The probability space is denoted $(\Omega, \mathcal{F}, P)$, where P is a probability measure that is induced from the cylindrical Wiener measure and $\mathcal{F}$ is the P-completion of the Borel σ-algebra on Ω. Let $(\mathcal{F}_t, t \geq 0)$ be an increasing P-complete family of sub-σ-algebras of $\mathcal{F}$ such that X_t is $\mathcal{F}_t$-measurable for $t \geq 0$ and $(\langle \ell, W(t)\rangle, \mathcal{F}_t, t \geq 0)$ is a martingale for each $\ell \in H$. $A(\alpha)$ is the infinitesimal generator of an analytic semigroup on H. For some $\beta \geq 0$, the operator $-A(\alpha) + \beta I$ is strictly positive, so that the fractional powers $(-A(\alpha) + \beta I)^\gamma$ and $(-A(\alpha)^* + \beta I)^\gamma$ and the spaces $D^\gamma_{A(\alpha)} = \mathcal{D}((-A(\alpha) + \beta I)^\gamma)$ and $D^\gamma_{A^*(\alpha)} = \mathcal{D}((-A^*(\alpha) + \beta I)^\gamma)$ with the graph norm topology for $\gamma \in \mathbb{R}$ can be defined. It is assumed that $B(\alpha) \in \mathcal{L}\big(H_1, D^{\varepsilon-1}_{A(\alpha)}\big)$, where H_1 is a real, separable Hilbert space and $\varepsilon \in (0,1)$ (cf. assumption (A4) below). For the solution of (2.1) on $[0,T]$, the control $(U(t), t \in [0,T])$ is an element of $M^p_W(0,T,H_1)$, where $M^p_W(0,T,H_1) = \big\{u : [0,T] \times \Omega \to H_1, u$ is $(\mathcal{F}_t)$-nonanticipative and $E\int_0^T |u(t)|^p\, dt < \infty\big\}$ and $p > \max(2, 1/\varepsilon)$ is fixed.

A selection of the following assumptions are used subsequently.

(A1) The family of unknown parameters are the elements of a compact set $\mathcal{K}$.

(A2) For $\alpha \in \mathcal{K}$, the operator $\Phi^*(-A^*(\alpha) + \beta I)^{-1/2+\delta}$ is Hilbert–Schmidt for some $\delta \in \big(0, \frac{1}{2}\big)$.

(A3) There are real numbers $M > 0$ and $\omega > 0$ such that, for $t > 0$ and $\alpha \in \mathcal{K}$,

$$|S(t;\alpha)|_{\mathcal{L}(H)} \leq Me^{-\omega t}$$

and

$$|A(\alpha)S(t;\alpha)|_{\mathcal{L}(H)} \leq Mt^{-1}e^{-\omega t},$$

where $(S(t;\alpha), t \geq 0)$ is the analytic semigroup generated by $A(\alpha)$.

(A4) For all $\alpha_1, \alpha_2 \in \mathcal{K}$, $\mathcal{D}(A(\alpha_1)) = \mathcal{D}(A(\alpha_2))$, $D^\delta_{A(\alpha_1)} = D^\delta_{A(\alpha_2)}$ and $D^\delta_{A^*(\alpha_1)} = D^\delta_{A^*(\alpha_2)}$ for $\delta \in \mathbb{R}$.

(A5) For each $\alpha \in \mathcal{K}$ and $x \in H$, there is a control $u_{\alpha,x} \in L^2(\mathbb{R}_+, H_1)$ such that

$$y(\cdot) = S(\cdot\,;\alpha)x + \int_0 S(\cdot - t;\alpha)B(\alpha)u_{\alpha,x}(t)\, dt \in L^2(\mathbb{R}_+, H).$$

(A6) The operator $A(\alpha)$ has the form

$$A(\alpha) = F_0 + \sum_{i=1}^{q} \alpha^i F_i,$$

where F_i is a linear, densely defined operator on H for $i = 0, 1, \ldots, q$ such that $\cap_{i=0}^q \mathcal{D}(F_i^*)$ is dense in H.

It is well known that the strong solution of (2.1) may not exist, so usually the mild solution of (2.1) is used, that is,

$$X(t;\alpha) = S(t;\alpha)X_0 + \int_0^t S(t-r;\alpha)B(\alpha)U(r)\,dr + \int_0^t S(t-r;\alpha)\Phi\,dW(r), \tag{2.2}$$

where $S(t;\alpha) = e^{tA(\alpha)}$. The mild solution is equivalent to the following inner product equation: For each $y \in \mathcal{D}(A^*(\alpha))$,

$$\begin{aligned}\langle y, X(t;\alpha)\rangle &= \langle y, X(0)\rangle + \int_0^t \langle A^*(\alpha)y, X(s;\alpha)\rangle\,ds \\ &\quad + \int_0^t \langle \Psi(\alpha)y, U(s)\rangle\,ds + \langle \Phi^* y, W(t)\rangle,\end{aligned} \tag{2.3}$$

where $\Psi(\alpha) = B^*(\alpha) \in \mathcal{L}\big(D^{1-\varepsilon}_{A^*(\alpha)}, H_1\big)$. The following lemma verifies that $(X(t;\alpha), t \in [0,T])$ is a well-defined process in $M^p_W(0,T,H)$.

LEMMA 2.1. *Assume that* (A2) *is satisfied. For* $T > 0$ *and* $\alpha \in \mathcal{K}$, *the processes* $(Z(t;\alpha), t \in [0,T])$ *and* $\hat{Z}(t;\alpha), t \in [0,T])$ *given by the equations*

$$Z(t;\alpha) = \int_0^t S(t-r;\alpha)\Phi\,dW(r), \tag{2.4}$$

$$\hat{Z}(t;\alpha) = \int_0^t S(t-r;\alpha)B(\alpha)U(r)\,dr \tag{2.5}$$

for $U \in M^p_W(0,T,H_1)$ *are elements of* $M^p_W(0,T,H)$, *with versions that have continuous sample paths.*

Proof. Let $|\cdot|_{HS}$ be the Hilbert–Schmidt norm on $\mathcal{L}(H)$. If (e_n) is an orthonormal basis of H, by (A2) we have that

$$\begin{aligned}\int_0^T |S(t;\alpha)\Phi|^2_{HS}\,dt &\le \int_0^T \frac{c}{t^{1-2\delta}} \sum_n |(-A(\alpha)+\beta I)^{-1/2+\delta}\Phi e_n|^2\,dt \\ &= |(-A(\alpha)+\beta I)^{-1/2+\delta}\Phi|^2_{HS} \int_0^T \frac{c}{t^{1-2\delta}}\,dt < \infty,\end{aligned}$$

where c is a constant. Thus $(Z(t;\alpha), t \in [0,T])$ is a well-defined H-valued process. To verify the existence of a continuous modification of $(Z(t;\alpha), t \in [0,T])$, the following processes are introduced:

$$\tilde{W}(t;\alpha) = W(t)[(-A(\alpha)+\beta I)^{-1/2+\delta}\Phi]^*$$

and

$$\tilde{Z}(t;\alpha) = \int_0^t S(t-r;\alpha)\,d\tilde{W}(r;\alpha) \quad \text{for } t \in [0,T].$$

There is a $D^{1/2-\delta}_A$-continuous modification of $(\tilde{Z}(t;\alpha), t \in [0,T])$ [7, Thm. 4]. Thus the process

$$Z(t;\alpha) = \int_0^t S(t-r;\alpha)(-A+\beta I)^{1/2-\delta} d\tilde{W}(t;\alpha)$$

has an H-continuous modification.

Since the inequality

$$|S(t-r;\alpha)B(\alpha)|_{\mathcal{L}(H_1,H)} \leq \frac{c}{(t-r)^{1-\varepsilon}}$$

is satisfied for $0 < r < t < T$, we can apply the Hölder inequality with the exponents p and $q = p/(p-1)$ to the integral (2.5) to verify that $(\hat{Z}(t;\alpha), t \in [0,T])$ is a well-defined H-valued process in $M_W^p(0,T,H)$ with a continuous modification. □

If $A(\alpha) = A^*(\alpha)$ and if $(A(\alpha) - \beta I)^{-1}$ is compact, then assumption (A2) is equivalent to the assumption that

$$\int_0^T t^{-2\delta}|S(t;\alpha)\Phi|_{HS}^2\,dt < \infty$$

for $T > 0$. For notational convenience, the dependence on α is suppressed. By the compactness of the resolvent of A, there is a sequence (λ_k), where $\lambda_k > \lambda_0 > 0$ and $\lambda_k \uparrow \infty$, and an orthonormal basis of (e_k) of H such that $(A - \beta I)e_k = \lambda_k e_k$ for $k \in \mathbb{N}$ and

$$S(t)\cdot = e^{\beta t}\sum_k e^{-\lambda_\kappa t} < \cdot, e_k > e_k.$$

If $\tilde{S}(t) = e^{-\beta t}S(t)$, then

$$\begin{aligned}\int_0^T t^{-2\delta}|\tilde{S}(t)\Phi|_{HS}^2\,dt &= \int_0^T t^{-2\delta}|\Phi^*\tilde{S}(t)|_{HS}^2\,dt \\ &= \sum_k |\Phi^* e_k|^2 \lambda_k^{2\delta-1}\int_0^{\lambda_k T} s^{-2\delta}e^{-2s}\,ds \\ &= \sum_k \left|\Phi^*\lambda_k^{-1/2+\delta}e_k\right|^2 b_k,\end{aligned}$$

where $0 < b_1 \leq b_k \leq b_{k+1}, b_k \to b_\infty < \infty$. Since

$$\sum_k \left|\Phi^*\lambda_k^{-1/2+\delta}e_k\right|^2 = |\Phi^*(-A+\beta I)^{-1/2+\delta}|_{HS}^2,$$

our assertion follows.

Consider the quadratic cost functional

$$J(X_0,U,\alpha,T) = \int_0^T [\langle QX(s),X(s)\rangle + \langle PU(s),U(s)\rangle]\,ds, \tag{2.6}$$

where $T \in (0,\infty], X(0) = X_0, Q \in \mathcal{L}(H), P \in \mathcal{L}(H_1)$ are selfadjoint operators satisfying

$$\langle Qx,x\rangle \geq r_1|x|^2, \tag{2.7}$$

$$\langle Py,y\rangle \geq r_2|y|^2 \tag{2.8}$$

for $x \in H, y \in H_1$ and constants $r_1 > 0$ and $r_2 > 0$. For the deterministic control problem for (2.1) with $\Phi \equiv 0$ and the cost functional (2.6) with $T = +\infty$ assuming (A5), the optimal cost is $\langle V(\alpha)X_0, X_0\rangle$ [8], [12], [18], where V satisfies the formal stationary Riccati equation

$$A^*(\alpha)V(\alpha) + V(\alpha)A(\alpha) - V(\alpha)B(\alpha)P^{-1}\Psi(\alpha)V(\alpha) + Q = 0 \tag{2.9}$$

and $\Psi(\alpha) = B^*(\alpha)$.

Equation (2.9) can be modified to a meaningful inner product equation as

$$\langle A(\alpha)x, Vy\rangle + \langle Vx, A(\alpha)y\rangle - \langle P^{-1}\Psi(\alpha)Vx, \Psi(\alpha)Vy\rangle + \langle Qx, y\rangle = 0 \tag{2.10}$$

for $x, y \in \mathcal{D}(A(\alpha))$. It has been shown [8], [12], [18] that, if (A5) is satisfied, then V is the unique, nonnegative, selfadjoint solution of (2.10) and $V \in \mathcal{L}(H, D_{A^*}^{1-\varepsilon})$. The solution of (2.9) is understood to be the solution of (2.10).

For adaptive control, the control policies $(U(t), t \geq 0)$ that are considered are linear feedback controls, that is,

$$U(t) = K(t)X(t), \tag{2.11}$$

where $(K(t), t \geq 0)$ is an $\mathcal{L}(H, H_1)$-valued process that is uniformly bounded almost surely by a constant $R > 0$. Let $\Delta > 0$ be fixed. It is assumed that the $\mathcal{L}(H, H_1)$-valued process $(K(t), t \geq 0)$ has the property that $K(t)$ is adapted to $\sigma(X(u), u \leq t - \Delta)$ for each $t \geq \Delta$. It is also assumed that $(K(t), t \in [0, \Delta])$ is a deterministic, operator-valued function. For such an admissible adaptive control, there is a unique solution of (2.1) with $K(t) = \tilde{K}(X(s), 0 \leq s \leq t - \Delta)$. If $\Delta = 0$, then (2.1) may not have a unique solution. Furthermore, the delay $\Delta > 0$ accounts for some time that is required to compute the adaptive feedback control law from the observation of the solution of (2.1).

Two more assumptions, (A7) and (A8), are now given that are used for the verification of the strong consistency of a family of least squares estimates of the unknown parameter vector α. Define $\mathbb{K} \subset \mathcal{L}(H, H_1)$ as

$$\mathbb{K} = \{K \in \mathcal{L}(H, H_1) : |K|_{\mathcal{L}(H,H_1)} \leq R\},$$

where R is given above.

Assume that $B(\alpha)$ is either independent of $\alpha \in \mathcal{K}$ or has the form

$$B(\alpha) = \Psi^*(\alpha), \tag{2.12}$$

where $\Psi(\alpha) = \hat{B}^* A^*(\alpha) \in \mathcal{L}\big(D_{A^*(\alpha)}^{1-\varepsilon}, H_1\big)$ and the operator $\hat{B} \in \mathcal{L}\big(H_1, D_{A(\alpha)}^{\varepsilon}\big)$ is given.

(A7) There is a finite-dimensional projection $\tilde{P}$ on H with range in $\cap_{i=1}^q \mathcal{D}(F_i^*)$ such that $i_{\tilde{P}}\Phi\Phi^* i_{\tilde{P}}^* > 0$, where $i_{\tilde{P}} : H \to \tilde{P}(H)$ is the projection map and $B(\alpha)$ is either independent of α or has the form (2.12). In the latter case, there is a finite-dimensional projection $\hat{P}$ on H and a constant $c > 0$ such that

$$|\hat{P}(I + K^*\hat{B}^*)F^*\tilde{P}|_{\mathcal{L}(H)} > c$$

is satisfied for all $F \in \{F_1, \ldots, F_q\}$ and $K \in \mathbb{K}$.

It is easy to verify that, if H is infinite-dimensional, if $\hat{B} \in \mathcal{L}(H_1, H)$ is compact, and if $(F_i^*)^{-1} \in \mathcal{L}(H)$ for $i = 1, 2, \ldots, q$, then (A7) is satisfied.

Let $(U(t), t \geq 0)$ be an admissible control, denoted generically as $U(t) = K(t)X(t)$, where $(X(t), t \geq 0)$ is the (unique) mild solution of (2.1) using the above admissible control. Let

$$\mathcal{A}(t) = (a_{ij}(t)) \tag{2.13}$$

and

$$\tilde{\mathcal{A}}(t) = (\tilde{a}_{ij}(t)), \tag{2.14}$$

where

$$a_{ij}(t) = \int_0^t \langle \tilde{P}F_iX(s), \tilde{P}F_jX(s)\rangle\, ds \tag{2.15a}$$

if B does not depend on α or

$$a_{ij}(t) = \int_0^t \langle \tilde{P}(F_i + F_i\hat{B}K(s))X(s), \tilde{P}(F_j + F_j\hat{B}K(s))X(s)\rangle\, ds \tag{2.15b}$$

if $B(\alpha)$ has the form (2.12) and

$$\tilde{a}_{ij}(t) = \frac{a_{ij}(t)}{a_{ii}(t)}. \tag{2.16}$$

It is easy to verify that the integrations in (2.15a) and (2.15b) are well defined.

For the verification of the strong consistency of a family of least squares estimates of the unknown parameter vector, the following assumption is used.

(A8) For each admissible adaptive control law, $(\tilde{\mathcal{A}}(t), t \geq 0)$ satisfies

$$\lim_{t\to\infty} \inf |\det \tilde{\mathcal{A}}(t)| > 0 \quad \text{a.s.}$$

3. An Itô formula. In this section, an Itô formula is verified for a smooth function of the solution of (2.1). While some Itô formulas are available for evolution equations (e.g., [6], [15]), apparently no result is available for an equation of the form (2.1).

Since the parameter vector α is fixed in this section, the dependence of (2.1) on α is suppressed throughout this section. The Itô equation obtained here is verified by an approximation of (2.1) using the resolvent. For $\lambda > \beta$, let $R(\lambda)$ be defined by

$$R(\lambda) = \lambda R(\lambda, A), \tag{3.1}$$

where $R(\lambda, A) = (\lambda I - A)^{-1}$ is the resolvent of A. By assumptions (A2), $R(\lambda)^{1/2-\delta}\Phi$ is Hilbert–Schmidt and $R(\lambda)\Phi$ is Hilbert–Schmidt, so there is an H-valued Wiener process $(W_\lambda(t), t \geq 0)$ defined by

$$W_\lambda(t) = W(t)\Phi^* R^*(\lambda), \tag{3.2}$$

where $W_\lambda(1)$ has the nuclear covariance $R(\lambda)\Phi\Phi^* R^*(\lambda)$. Consider the stochastic differential equation

$$\begin{aligned} dX_\lambda(t) &= AX_\lambda(t)\, dt + R(\lambda)BU(t)\, dt + R(\lambda)\, dW_\lambda(t), \\ X_\lambda(0) &= R(\lambda)X_0, \end{aligned} \tag{3.3}$$

where $\lambda > \beta$. It is shown that (3.3) has a strong solution.

LEMMA 3.1. *For $\lambda > \beta$, the stochastic equation* (3.3) *has a unique strong solution on* $[0, T]$, *that is,*

$$\int_0^T |AX_\lambda(t)|\, dt < \infty \quad \text{a.s.} \tag{3.4}$$

and

$$\begin{aligned} X_\lambda(t) = R(\lambda)X_0 &+ \int_0^t AX_\lambda(s)\, ds + \int_0^t R(\lambda)BU(s)\, ds \\ &+ R(\lambda)W_\lambda(t) \quad \text{a.s.} \end{aligned} \tag{3.5}$$

Proof. To verify that the mild solution of (3.3) satisfies (3.5), it is necessary to show that

$$\int_0^T \int_0^t |AS(t-s)R(\lambda)BU(s)|\,ds\,dt < \infty \quad \text{a.s.} \tag{3.6}$$

and

$$\int_0^T \int_0^t |AS(t-s)R(\lambda)|^2_{\mathcal{L}(H)}\,ds\,dt < \infty \quad \text{a.s.} \tag{3.7}$$

We have

$$\begin{aligned} &|AS(t-s)R(\lambda)B|_{\mathcal{L}(H_1,H)} \\ &\le |AS(t-s)|_{\mathcal{L}(D_A^{\varepsilon},H)}|R(\lambda)|_{\mathcal{L}(D_A^{\varepsilon-1},D_A^{\varepsilon})}|B|_{\mathcal{L}(H_1,D_A^{\varepsilon-1})} \\ &\le \frac{c}{(t-s)^{1-\varepsilon}}, \end{aligned}$$

so that

$$\begin{aligned} &\int_0^T \int_0^t |AS(t-s)R(\lambda)BU(s)|\,ds\,dt \\ &\le T\left(\int_0^T \frac{c}{t^{q(1-\varepsilon)}}\,dt\right)^{1/q}\left(\int_0^T |U(s)|^p\,ds\right)^{1/p}, \end{aligned}$$

which verifies (3.6). Since $|AS(t-s)R(\lambda)|_{\mathcal{L}(H)}$ is bounded for $0 \le s \le t \le T$, (3.7) is satisfied. Use the Fubini theorem to compute $\int_0^t AX_\lambda(s)\,ds$ as in [6], [14] to verify (3.5). □

Now it is shown that a sequence of processes can be obtained from solutions of (3.5) as $\lambda \to \infty$, which converges to (2.2).

LEMMA 3.2. *There is a sequence* (λ_n) *such that* $\lambda_n \uparrow +\infty$, *and, for* $t \in [0,T]$,

$$\lim_{n\to\infty} X_{\lambda_n}(t) = X(t) \quad \text{a.s.} \tag{3.8}$$

and

$$\sup\{|X_{\lambda_n}(t)| : \lambda_n > 0, t \in [0,T]\} < \infty \quad \text{a.s.}, \tag{3.9}$$

where $(X_{\lambda_n}(t), t \in [0,T])$ *satisfies* (3.5) *and* $(X(t), t \in [0,T])$ *satisfies* (2.1).

Proof. The Yosida approximation implies that $R(\lambda)X_0 \to X_0$ as $\lambda \to \infty$ for all $X_0 \in H$ and $|R(\lambda)|_{\mathcal{L}(H)} \le c$ for some $c > 0$. Since

$$|S(t-s)(R(\lambda)-I)BU(s)| \le \frac{K}{(t-s)^{1-\varepsilon}}|U(s)|, \tag{3.10}$$

where $K > 0$ is independent of $\lambda > \beta$, the Hölder inequality implies that

$$\sup_{t\in[0,T]}\left|\int_0^t S(t-s)R(\lambda)BU(s)\,ds\right| \le C_T\left(\int_0^T |U(s)|^p\,ds\right)^{1/p} \tag{3.11}$$

for some $C_T > 0$ and the dominated convergence theorem implies that

$$\lim_{\lambda\to\infty}\left|\int_0^t S(t-s)(R(\lambda)-I)BU(s)\,ds\right| = 0 \tag{3.12}$$

for $t \in [0,T]$. Let $\bar{W}_\lambda(t) = W(t)\Phi^*(I - R^2(\lambda))^*$, and, recalling (2.4), we have

$$\begin{aligned} &E \sup_{t\in[0,T]} \left| Z(t) - \int_0^t S(t-r)R(\lambda)\, dW_\lambda(r) \right|^2 \\ &= E \sup_{t\in[0,T]} \left| \int_0^t S(t-r)\, d\bar{W}_\lambda(r) \right|^2. \end{aligned} \tag{3.13}$$

By Theorem 2.1 of [16], the right-hand side of (3.13) tends to zero as $\lambda \to \infty$ if the trace of the covariance operator of $(-A+\beta I)^{-(1/2)+\delta}W_\lambda(1)$ tends to zero as $\lambda \to \infty$. If (e_n) is an orthonormal basis of H, then

$$\begin{aligned} &\mathrm{Tr}[(-A+\beta I)^{-(1/2)+\delta}(I - R^2(\lambda))\Phi\Phi^*(I - R^2(\lambda))^*(-A^* + \beta I)^{-(1/2)+\delta}] \\ &= |(I - R^2(\lambda))(-A+\beta I)^{-(1/2)+\delta}\Phi|_{HS}^2 \\ &= \sum_n |(I - R^2(\lambda))(-A+\beta I)^{-(1/2)+\delta}\Phi e_n|^2. \end{aligned} \tag{3.14}$$

This infinite series converges to zero as $\lambda \to \infty$ because

$$|(I - R^2(\lambda))(-A+\beta I)^{-(1/2)+\delta}\Phi e_n|^2 \to 0$$

for $n \in \mathbb{N}$, and the series is dominated by

$$\sum_n 2(c^4+1)|(-A+\beta I)^{-(1/2)+\delta}\Phi e_n| = 2(c^4+1)|(-A+\beta I)^{-(1/2)+\delta}\Phi|_{HS}^2 < \infty.$$

Thus the right-hand side of (3.13) converges to zero, and there is a sequence (λ_n) such that

$$\sup_{t\in[0,T]} \left| \int_0^t S(t-r)R(\lambda_n)\, dW_{\lambda_n}(t) - Z(t) \right|^2 \to 0 \quad \text{a.s.}$$

as $n \to \infty$. Therefore, for $t \in [0,T]$,

$$\lim_{n\to\infty} X_{\lambda_n}(t) = X(t) \quad \text{a.s.}$$

by (3.12) and (3.9) is satisfied because

$$\sup_{\lambda>\beta, t\in[0,T]} \left| \int_0^t S(t-s)R(\lambda)BU(s)\, ds \right| < \infty \quad \text{a.s.}$$

by (3.11). □

An Itô formula is now verified for smooth functions of a solution of (2.1).

LEMMA 3.3. *Let $V \in C^{1,2}([0,T]\times H, \mathbb{R})$ be such that $V_x(t,x) \in D_{A^*}^{1-\varepsilon}$ for all $t \in (0,T)$ and $V_x(t,\cdot) : H \to D_{A^*}^{1-\varepsilon}$ is continuous. Assume that the function $\langle Ax, V_x(t,x)\rangle$ for $x \in \mathcal{D}(A)$ can be extended to a continuous function $h : [0,T]\times H \to \mathbb{R}$, the following limit exists*:

$$\lim_{\lambda\to\infty} \mathrm{Tr}\, V_{xx}(t,x)R^2(\lambda)\Phi\Phi^*(R^*(\lambda))^2 = \pi(t,x) < \infty \tag{3.15}$$

and the map

$$x \mapsto \mathrm{Tr}\, V_{xx}(t,x)R^2(\lambda)\Phi\Phi^*(R^*(\lambda))^2 \tag{3.16}$$

is continuous on H uniformly with respect to $\lambda \geq \beta$ and

$$
\begin{aligned}
&|h(t,x)| + |\operatorname{Tr} V_{xx}(t,x)R^2(\lambda)\Phi\Phi^*(R^*(\lambda))^2| + |V(t,x)| \\
&\quad + |V_x(t,x)|_{D^{1-\varepsilon}_{A^*}} + |V_{xx}(t,x)|_{\mathcal{L}(H)} + |V_t(t,x)| \leq k(1+|x|^p)
\end{aligned} \tag{3.17}
$$

for $(t,x) \in (0,T) \times H, \lambda \geq \beta$ where $k > 0$ and $p > 0$. Then

$$
\begin{aligned}
&V(t,X(t)) - V(\tau, X(\tau)) \\
&\quad = \int_\tau^t \Big[h(s,X(s)) + V_s(s,X(s)) + \langle U(s), \Psi V_x(s,X(s))\rangle \\
&\qquad + \frac{1}{2}\pi(s,X(s))\Big]\, ds + \int_\tau^t \langle \Phi^* V_x(s,X(s)), dW(s)\rangle \quad \text{a.s.},
\end{aligned} \tag{3.18}
$$

where $0 \leq \tau \leq t \leq T$, $\Psi = B^*$ and $(X(t), t \in [0,T])$ satisfies (2.1).

Proof. The verification of (3.18) is accomplished by using a sequence of processes that satisfy (3.5). Since $(X_\lambda(t), t \in [0,T])$ is a strong solution of (3.5), the Itô formula [6] can be applied to $(V(X_\lambda(t)), t \in [0,T])$ to obtain

$$
\begin{aligned}
V(t,X_\lambda(t)) - V(\tau, X_\lambda(\tau)) = \int_\tau^t \Big[& h(s,X_\lambda(s)) + V_s(s,X_\lambda(s)) \\
& + \langle U(s), \Psi R^*(\lambda) V_x(s,X_\lambda(s))\rangle \\
& + \frac{1}{2} \operatorname{Tr} R^*(\lambda) V_{xx}(s,X_\lambda(s)) R^2(\lambda)\Phi\Phi^* R^*(\lambda)\Big]\, ds \\
& + \int_\tau^t \langle R^*(\lambda) V_x(s,X_\lambda(s)), dW_\lambda(s)\rangle \quad \text{a.s.}
\end{aligned} \tag{3.19}
$$

It suffices to assume that $(U(t), t \in [0,T])$ is uniformly bounded, almost surely. Lemma 3.2 verifies that

$$
\lim_{n\to\infty} V(t, X_{\lambda_n}(t)) = V(t,X(t)) \quad \text{a.s.}, \tag{3.20}
$$

$$
\lim_{n\to\infty} V_s(s, X_{\lambda_n}(s)) = V_s(s,X(s)) \quad \text{a.s.}, \tag{3.21}
$$

$$
\lim_{n\to\infty} V(\tau, X_{\lambda_n}(\tau)) = V(\tau,X(\tau)) \quad \text{a.s.}, \tag{3.22}
$$

$$
\lim_{n\to\infty} h(s, X_{\lambda_n}(s)) = h(s,X(s)) \quad \text{a.s.} \tag{3.23}
$$

for $0 \leq \tau \leq s \leq t \leq T$, where $\lambda_n \to \infty$. Let $\mathcal{L}_\lambda V$ and $\mathcal{L}V$ be defined as

$$
\begin{aligned}
\mathcal{L}_\lambda V(s,x) = & \langle U(s), \Psi R^*(\lambda) V_x(s,x)\rangle \\
& + \tfrac{1}{2} \operatorname{Tr} R^*(\lambda) V_{xx}(s,x) R^2(\lambda)\Phi\Phi^* R^*(\lambda)
\end{aligned}
$$

and

$$
\mathcal{L}V(s,x) = \langle U(s), \Psi V_x(s,x)\rangle + \tfrac{1}{2}\pi(s,x)
$$

for $(s,x) \in [0,T] \times H$. We have

$$
\begin{aligned}
&|\mathcal{L}_\lambda V(s,X_\lambda(s)) - \mathcal{L}V(s,X(s))| \\
&\leq |\mathcal{L}_\lambda V(s,X(s)) - \mathcal{L}V(s,X(s))| + |\mathcal{L}_\lambda V(s,X(s)) - \mathcal{L}_\lambda V(s,X_\lambda(s))|.
\end{aligned} \tag{3.24}
$$

From (3.15), we have that

$$\lim_{\lambda\to\infty} \mathcal{L}_\lambda V(s,X(s)) = \mathcal{L}V(s,X(s)) \quad \text{a.s.} \tag{3.25}$$

Furthermore,

$$\begin{aligned} &|\mathcal{L}_\lambda V(s,x) - \mathcal{L}_\lambda V(s,y)| \\ &\le |U(s)|\ |\Psi|_{\mathcal{L}(D^{1-\varepsilon}_{A^*},H_1)} |R^*(\lambda)|_{\mathcal{L}(H)} |V_x(s,x) - V_x(s,y)|_{D^{1-\varepsilon}_{A^*}} \\ &\quad + \tfrac{1}{2}|\operatorname{Tr} V_{xx}(s,x)R^2(\lambda)\Phi\Phi^*(R^*(\lambda))^2 \\ &\quad - \operatorname{Tr} V_{xx}(s,y)R^2(\lambda)\phi\phi^*(R^*(\lambda))^2|. \end{aligned} \tag{3.26}$$

The right-hand side of (3.26) tends to zero as $x \to y$ in H uniformly with respect to $\lambda \ge \beta$ by (3.15). Thus the second term on the right-hand side of (3.24) converges to zero almost surely. Choosing a sequence (λ_n) such that $\lambda_n \to \infty$, from Lemma 3.2 we obtain by (3.9), (3.17) and the dominated convergence theorem

$$\begin{aligned} &\lim_{n\to\infty} \int_\tau^t [h(s,X_{\lambda_n}(s)) + V_s(s,X_{\lambda_n}(s)) + \mathcal{L}_{\lambda_n} V(s,X_{\lambda_n}(s))\,ds \\ &= \int_\tau^t [h(s,X(s)) + V_s(s,X(s)) + \mathcal{L}V(s,X(s))]\,ds \quad \text{a.s.} \end{aligned} \tag{3.27}$$

Furthermore,

$$\begin{aligned} &E\left|\int_\tau^t \langle R^*(\lambda_n)V_x(s,X_{\lambda_n}(s)), dW_{\lambda_n}(s)\rangle - \int_\tau^t \langle \Phi^* V_x(s,X(s)), dW(s)\rangle\right|^2 \\ &= E\int_\tau^t |\Phi^*(R^*(\lambda_n))^2 V_x(s,X_{\lambda_n}(s)) - \Phi^* V_x(s,X(s))|^2\,ds \\ &\le 2E\int_\tau^t [|\Phi^*(R^*(\lambda_n))^2(V_x(s,X_{\lambda_n}(s)) - V_x(s,X(s))|^2 \\ &\quad + |[\Phi^*(R^*(\lambda))^2 - \Phi^*]V_x(s,X(s))|^2]\,ds. \end{aligned} \tag{3.28}$$

The right-hand side of (3.28) tends to zero as $n \to \infty$ by Lemma 3.2 and (3.17). Thus there is subsequence (λ_{n_j}) such that

$$\lim_{j\to\infty} \int_\tau^t \langle R^*(\lambda_{n_j})V_x(s,X_{\lambda_{n_j}}(s)), dW_{\lambda_{n_j}}(s)\rangle = \int_\tau^t \langle \Phi^* V_x(s,X(s)), dW(s)\rangle \quad \text{a.s.}$$

Thus (3.20)–(3.23), (3.27) verifies (3.18). □

Now some of the hypotheses of Lemma 3.3 are replaced by ones that are more easily verified while still obtaining the same conclusion.

PROPOSITION 3.4. *Assume that* (A2) *is satisfied. Let* $V \in C^{1,2}([0,T]\times H)$ *be such that* $V_x(t,x) \in D^{1-\varepsilon}_{A^*}$, $V_x(t,\cdot) : H \to D^{1-\varepsilon}_{A^*}$ *is continuous,* $\langle Ax, V_x(t,x)\rangle$ *for* $x \in \mathcal{D}(A)$ *can be extended to a continuous function* $h : [0,T]\times H \to \mathbb{R}$ *and*

$$|h(t,x)| + |V(t,x)| + |V_x(t,x)|_{D^{1-\varepsilon}_{A^*}} + |V_{xx}(t,x)|_{\mathcal{L}(H)} + |V_t(t,x)| \le k(1+|x|^p) \tag{3.29}$$

for $(t,x) \in [0,T)\times H$ *and* $p > 0, k > 0$. *Assume that one of the following three conditions is satisfied*:

(i) Φ *is Hilbert–Schmidt*;

(ii) $V_{xx}(t,x)$ *is nuclear,* $V_{xx}(t,\cdot)$ *is continuous in the norm* $|\cdot|_1$ *of nuclear operators and* $|V_{xx}(t,x)|_1 \le k(1+|x|^p)$ *for* $(t,x) \in (0,T) \times H$, *where* $k > 0$ *and* $p > 0$;

(iii) $V_{xx}(t,x) \in \mathcal{L}\big(D_A^{\delta-(1/2)}, D_{A^*}^{(1/2)-\delta}\big)$ *for* $(t,x) \in [0,T] \times H$, *the function*

$$L(\cdot) = (R^*(\beta))^{-(1/2)+\delta} V_{xx}(t,\cdot)(R(\beta))^{-(1/2)+\delta} : H \to \mathcal{L}(H)$$

is continuous and $|L(x)|_{\mathcal{L}(H)} \le k(1+|x|^p)$ *is satisfied for* $t > 0$ *and* $x \in H$.

Then (3.18) *is satisfied, where, for* (i) *and* (ii), $\pi(t,x) = \operatorname{Tr} V_{xx}(t,x)\Phi\Phi^*$ *and, for* (iii), $\pi(t,x) = \operatorname{Tr}(R^*(\beta))^{\delta-(1/2)} V_{xx}(t,x)\Phi\Phi^*(R^*(\beta))^{(1/2)-\delta}$.

Proof. By Lemma 2.3, it suffices to show that (i), (ii), or (iii) implies (3.15)–(3.17). Assume that (i) is satisfied. Then

$$\begin{aligned} &|\operatorname{Tr}[V_{xx}(s,x)R^2(\lambda)\Phi\Phi^*(R(\lambda))^2 - V_{xx}(s,x)\Phi\Phi^*]| \\ &= |\operatorname{Tr}[(R^*(\lambda))^2 V_{xx}(s,x)R^2(\lambda)\Phi\Phi^* - V_{xx}(s,x)\Phi\Phi^*]| \\ &\le \sum_j |(R^*(\lambda))^2 V_{xx}(s,x)R^2(\lambda) - V_{xx}(s,x))\Phi\Phi^* e_j|, \end{aligned} \tag{3.30}$$

where (e_j) is an orthonormal basis in H that includes the eigenvectors of $\Phi\Phi^*$. The series on the right-hand side of (3.30) is dominated by

$$\text{const} \sum_j |\Phi\Phi^* e_j| < \infty,$$

so the dominated convergence theorem implies that the series in (3.30) converges to zero as $\lambda \to \infty$. This verifies (3.15). Since

$$|\operatorname{Tr}(V_{xx}(s,x) - V_{xx}(s,y))R^2(\lambda)\Phi\Phi^*(R^*(\lambda))^2| \le c|V_{xx}(s,x) - V_{xx}(s,y)|_{\mathcal{L}(H)} \operatorname{Tr} \Phi\Phi^*,$$

where $c > 0$ does not depend on $\lambda \ge \beta$, (3.16) is verified. Equation (3.17) follows from (3.29).

Assume that (ii) is satisfied. Then

$$\begin{aligned} &|\operatorname{Tr} V_{xx}(s,x)R^2(\lambda)\Phi\Phi^*(R^*(\lambda))^2 - \operatorname{Tr} V_{xx}\Phi\Phi^*| \\ &= |\operatorname{Tr}[R^2(\lambda)\Phi\Phi^*(R^*(\lambda))^2 - \Phi\Phi^*]V_{xx}(s,x)| \\ &\le \sum_j |(R^2(\lambda)\Phi\Phi^*(R^*(\lambda))^2 - \Phi\Phi^*)V_{xx}(s,x)\hat{e}_j|, \end{aligned}$$

where $(\hat{e}_j)$ is an orthonormal basis in H including the eigenvectors of $V_{xx}(s,x)$. Proceeding as for (i), it follows that (3.15) is satisfied. Since

$$\begin{aligned} &|\operatorname{Tr}(V_{xx}(s,x) - V_{xx}(s,y))R^2(\lambda)\Phi\Phi^*(R^*(\lambda))^2| \\ &\le |R^2(\lambda)\Phi\Phi^*(R^*(\lambda))^2|_{\mathcal{L}(H)} |V_{xx}(s,x) - V_{xx}(s,y)|_1, \end{aligned}$$

$$\begin{aligned} &|\operatorname{Tr} V_{xx}(s,x)R^2(\lambda)\Phi\Phi^*(R^*(\lambda))^2| \\ &\le k|R^2(\lambda)\Phi\Phi^*(R^*(\lambda))^2|_{\mathcal{L}(H)}(1+|x|^p), \end{aligned}$$

so (3.16), (3.17) are satisfied.

Assume that (iii) is satisfied. Then

$$\begin{aligned} &|\operatorname{Tr} V_{xx}(s,x)R^2(\lambda)\Phi\Phi^*(R^*(\lambda))^2 - \pi(s,x)| \\ &= |\operatorname{Tr}[(R^*(\lambda))^2 L(x)R^2(\lambda)R^{(1/2)-\delta}(\beta)\Phi\Phi^*(R^*(\beta))^{(1/2)-\delta} \\ &\quad - L(x)R^{(1/2)-\delta}(\beta)\Phi\Phi^*(R(\beta))^{(1/2)-\delta}]|. \end{aligned}$$

Since the operator $R^{(1/2)-\delta}(\beta)\Phi\Phi^*(R^*(\beta))^{(1/2)-\delta}$ is nuclear by (A2), we can choose an orthonormal basis in H that includes the eigenvectors of this operator and proceed as in (i) to verify (3.15). Since

$$|\operatorname{Tr} V_{xx}(s,x)R^2(\lambda)\Phi\Phi^*(R^*(\lambda))^2 - \operatorname{Tr} V_{xx}(s,y)R^2(\lambda)\Phi\Phi^*(R^*(\lambda))^2|$$
$$\leq |(R^*(\lambda))^2(L(x)-L(y))R^2(\lambda)|_{\mathcal{L}(H)}|R^{(1/2)-\delta}(\beta)\Phi\Phi^*(R^*(\beta))^{(1/2)-\delta}|_1$$

and

$$|\operatorname{Tr} V_{xx}(s,x)R^2(\lambda)\Phi\Phi^*(R^*(\lambda))^2|$$
$$\leq |(R^*(\lambda))^2L(x)R^2(\lambda)|_{\mathcal{L}(H)} \cdot |R^{(1/2)-\delta}(\beta)\Phi\Phi^*(R^*(\beta))^{(1/2)-\delta}|_1$$
$$\leq \text{const}(1+|x|^p),$$

these inequalities verify (3.16), (3.17). □

For use of this Itô formula in the adaptive control problem, it is useful to state explicitly the case where $v(x) = \langle Vx, x\rangle$, where $V \in \mathcal{L}(H)$ is a selfadjoint operator.

COROLLARY 3.5. *Let $V \in \mathcal{L}(H)$ be selfadjoint such that $V \in \mathcal{L}(H, D_{A^*}^{1-\varepsilon})$ and $|\langle Vx, Ax\rangle| \leq k|x|^2$ for $x \in \mathcal{D}(A)$, where $k > 0$. Assume that one of the following conditions is satisfied:*

(i) *Φ is Hilbert–Schmidt,*

(ii) *V is nuclear,*

(iii) *$V \in \mathcal{L}(D_A^{\delta-(1/2)}, D_{A^*}^{(1/2)-\delta})$.*

Then, for all $0 \leq \tau \leq t \leq T$,

$$\begin{aligned}&\langle VX(t), X(t)\rangle - \langle VX(\tau), X(\tau)\rangle\\ &= \int_\tau^t [h(X(s)) + 2\langle U(s), \Psi VX(s)\rangle + \Pi(V)]\,ds\\ &\quad + 2\int_\tau^t \langle \Phi^*VX(s), dW(s)\rangle \quad \text{a.s.},\end{aligned} \tag{3.31}$$

where h is the continuous extension of $2\langle Vx, Ax\rangle$ on H, and, for (i) *and* (ii), $\Pi(V) = \operatorname{Tr} V\Phi\Phi^*$ *and, for* (iii), $\Pi(V) = \operatorname{Tr}(R^*(\beta))^{\delta-(1/2)}V\Phi\Phi^*(R^*(\beta))^{(1/2)-\delta}$.

4. Parameter identification. For the identification of the unknown parameters in the linear stochastic distributed parameter system (2.1), a family of least squares estimates are formed. In this section, it is assumed that $\beta = 0$, that is, $-A(\alpha)$ is strictly positive. Let $\tilde{P}$ be the projection given in (A7). The estimate of the unknown parameter vector at time t, $\hat{\alpha}(t)$ is the minimizer of the quadratic functional of α, $L(t;\alpha)$, given by

$$\begin{aligned}L(t;\alpha) = &-\int_0^t \langle \tilde{P}(A(\alpha)+B(\alpha)K(s))X(s), d\tilde{P}X(s)\rangle\\ &+\frac{1}{2}\int_0^t |\tilde{P}(A(\alpha)+B(\alpha)K(s))X(s)|^2\,ds,\end{aligned} \tag{4.1}$$

where $U(s) = K(s)X(s)$ is an admissible adaptive control.

THEOREM 4.1. *Let $(K(t), t \geq 0)$ be an admissible feedback control law. Assume that* (A2), (A6)–(A8) *are satisfied and $\alpha_0 \in \mathcal{K}^0$. Then the family of least squares estimates $(\hat{\alpha}(t), t > 0)$, where $\hat{\alpha}(t)$ is the minimizer of* (4.1), *is strongly consistent, that is,*

$$P_{\alpha_0}(\lim_{t\to\infty} \hat{\alpha}(t) = \alpha_0) = 1, \tag{4.2}$$

where α_0 is the true parameter vector.

Proof. If B does not depend on $\alpha \in \mathcal{K}$, then the proof of Theorem 4.1 follows from the proof of Theorem 1 in [10]. Therefore we may assume that $B(\alpha)$ has the form (2.12). Since the strong law of large numbers for Brownian motion is used to verify strong consistency, it is shown initially that

$$\lim_{t\to\infty} \int_0^t |\langle \ell, X(s)\rangle|^2 \, ds = +\infty \quad \text{a.s.} \tag{4.3}$$

for suitable $\ell \in H$.

If (P_n) is a sequence of increasing finite-dimensional projections with range in $\cap_{i=0}^p \mathcal{D}(F_i^*)$ that converges strongly to the identity I and $F \in \{F_1, \ldots, F_q\}$, then

$$\begin{aligned} &\lim_{n\to\infty} \int_0^t \langle \tilde{P}F(I + \hat{B}K(s))P_nX(s), \tilde{P}F(I + \hat{B}K(s))P_nX(s)\rangle \, ds \\ &= \int_0^t \langle \tilde{P}F(I + \hat{B}K(s))X(s), \tilde{P}F(I + \hat{B}K(s))X(s)\rangle \, ds \end{aligned} \tag{4.4}$$

in $L^1(P)$ almost surely because the sequence of integrals is monotone increasing.

Fix $n \in \mathbb{N}$. For the process $(P_nX(t), t \geq 0)$ with nonzero values in a finite-dimensional space, the verification of (4.3) is accomplished by using some of the methods in [9] for finite-dimensional systems. Since the expectation of the Lebesgue measure of the amount of time that a scalar Brownian motion is strictly away from zero is infinite, the 0–1 law for Brownian motion implies that, for almost all sample paths, the Lebesgue measure of the amount of time that a sample path is strictly away from zero is infinite.

If $\ell \in H$ and $\Phi^*\ell \neq 0$, then a well-known property of a scalar Brownian motion implies that

$$\liminf_{t\to\infty} \langle \Phi^*\ell, W(t)\rangle = -\infty \quad \text{a.s.} \tag{4.5}$$

and

$$\limsup_{t\to\infty} \langle \Phi^*\ell, W(t)\rangle = +\infty \quad \text{a.s.} \tag{4.6}$$

Fix $n \in \mathbb{N}$ and $\ell \in \cap_{i=0}^q \mathcal{D}(F_i^*)$ such that $\Phi^*\ell \neq 0$ and $P_n\ell \neq 0$. Assume that $P_n\tilde{P} = \tilde{P}$. Let (T_n) be a sequence of stopping times such that $\{\lim_{n\to\infty}\langle \Phi^*\ell, W(T_n)\rangle = +\infty\}$. Let $\Lambda_+ = \{\limsup_{n\to\infty} \int_0^{T_n} \langle M^*(s)\ell, X(s)\rangle \, ds = +\infty\}$, where $M^*(s) = (A^* + K^*(s)\hat{B}^*A^*)P_n$. For each $\omega \in \Lambda_+$, there is a subsequence $(T_{n_j}(\omega))$ such that

$$\lim_{j\to\infty} \int_0^{T_{n_j}(\omega)} \langle M^*(s,\omega)\ell, X(s,\omega)\rangle \, ds = +\infty. \tag{4.7}$$

Since

$$\begin{aligned} \langle \ell, X(t)\rangle^2 \geq &\left(\int_0^t \langle M^*(s)\ell, X(s)\rangle \, ds\right)^2 \\ &+ 2\int_0^t \langle M^*(s)\ell, X(s)\rangle \, ds \, \langle \Phi^*\ell, W(t)\rangle \\ &+ \langle \Phi^*\ell, W(t)\rangle^2, \end{aligned}$$

it follows directly that, for almost all $\omega \in \Lambda_+$,

$$\limsup_{t\to\infty} \langle \ell, X(t,\omega)\rangle^2 = +\infty.$$

Let $\Lambda_- = \{\limsup_{n\to\infty} \int_0^{T_n} \langle M^*(s)\ell, X(s)\rangle\, ds = -\infty\}$. For $\omega \in \Lambda_-$,

$$\lim_{n\to\infty} \int_0^{T_n} \langle M^*(s,\omega)\ell, X(s,\omega)\rangle\, ds = -\infty.$$

Since $-W$ has the same probability law as W, we have that, for almost $\omega \in \Lambda_-$,

$$\limsup_{t\to\infty} \langle \ell, X(t,\omega)\rangle^2 = +\infty.$$

Let $\Lambda_0 = \{\limsup_{n\to\infty} \mid \int_0^{T_n} \langle M^*(s)\ell, X(s)\rangle\, ds \mid < \infty\}$. It follows immediately that, for almost all $\omega \in \Lambda_0$,

$$\limsup_{t\to\infty} \langle \ell, X(t,\omega)\rangle^2 = +\infty.$$

Combining the results of the above three cases, we have

$$\limsup_{t\to\infty} \langle \ell, X(t)\rangle^2 = +\infty \quad \text{a.s.}$$

Since the Lebesgue measure of the amount of time that $(\langle \ell, P_n X(t)\rangle, t \geq 0)$ is strictly away from zero is infinite for almost all sample paths, it follows that

$$\lim_{t\to\infty} \int_0^t |\langle \ell, X(s)\rangle|^2\, ds = +\infty \quad \text{a.s.}$$

By (A7), it follows that there is a $\bar{c} > 0$ such that

$$\text{Tr}[(\hat{P}(I + K^*(s)\hat{B}^*)F^*\tilde{P})^*(\hat{P}(I + K^*(s)\hat{B}^*)F^*\tilde{P})] > c, \tag{4.8}$$

for all $s \in \mathbb{R}_+$, and $F \in \{F_1, \ldots, F_q\}$, which implies that

$$\lim_{t\to\infty} \int_0^t \langle \hat{P}(I + K^*(s)\hat{B}^*)F^*\tilde{P}X(s), \hat{P}(I + K^*(s)\hat{B}^*)F^*\tilde{P}X(s)\rangle\, ds = +\infty \quad \text{a.s.}$$

and, consequently,

$$\lim_{t\to\infty} \int_0^t \langle \tilde{P}F(I + \hat{B}K(s))X(s), \tilde{P}F(I + \hat{B}K(s))X(s)\rangle\, ds = +\infty \quad \text{a.s.}$$

To minimize (4.1) with respect to α, it is necessary and sufficient that $D_\alpha L(t;\alpha) = 0$. Computing the family of partial derivatives and using (2.1), we obtain the family of linear equations

$$\mathcal{A}(t)\hat{\alpha}(t) = \mathcal{A}(t)\alpha_0 + b(t) \tag{4.9}$$

or

$$\tilde{\mathcal{A}}(t)\hat{\alpha}(t) = \tilde{\mathcal{A}}(t)\alpha_0 + \tilde{b}(t), \tag{4.10}$$

where $\mathcal{A}(t)$ and $\tilde{\mathcal{A}}(t)$ are given by (2.13) and (2.14), respectively, and

$$b_j(t) = \int_0^t \langle \tilde{P}(F_j + \hat{B}K(s))X(s), d\tilde{P}\Phi W(s)\rangle,$$

$$\tilde{b}_j(t) = \frac{b_j(t)}{a_{jj}(t)},$$

$$b(t) = (b_1(t), \dots, b_q(t))',$$

$$\tilde{b}(t) = (\tilde{b}_1(t), \dots, \tilde{b}_q(t))'.$$

Let (c_n) be a sequence of positive, real numbers such that $c_n \downarrow 0$. Let $\Lambda_n = \{\liminf_{t\to\infty} |\det \tilde{\mathcal{A}}(t)| > c_n > 0\}$. The sequence (Λ_n) is increasing. By (A8), we have that $P(\Lambda_n) \uparrow 1$ as $n \to \infty$. Given $\varepsilon > 0$, there is an $N \in \mathbb{N}$ such that $P(\Lambda_N) > 1 - \varepsilon$. There is a random time such that $|\det \tilde{\mathcal{A}}(t,\omega)| > c_n$ for $\omega \in \Lambda_N$ and $t \geq T(\omega)$. Since $\tilde{b}(t) \to 0$ almost surely as $t \to \infty$ by the strong law of large numbers for Brownian motion, since $\tilde{\mathcal{A}}^*(t)\tilde{\mathcal{A}}(t)$ is uniformly bounded almost surely, and since $\varepsilon > 0$ is arbitrary, it follows that $\hat{\alpha}(t) \to \alpha_0$ almost surely as $t \to \infty$. □

For the applications of identification and adaptive control, it is important to have recursive estimators of the unknown parameters. Let $\langle \tilde{F}(s)x, y\rangle$ be the vector whose ith component is $\langle \tilde{P}F_i(I + \hat{B}K(s))x, y\rangle$. Using (2.1), (4.9), we have

$$\hat{\alpha}(t) = \mathcal{A}^{-1}(t) \int_0^t \langle \tilde{F}(s)X(s), d\tilde{P}X(s) - \tilde{P}F_0X(s)\,ds\rangle. \tag{4.11}$$

Since $\mathcal{A}^{-1}(t)$ satisfies the differential equation

$$d\mathcal{A}^{-1}(t) = -\mathcal{A}^{-1}(t)\,d\mathcal{A}(t)\,\mathcal{A}^{-1}(t),$$

the differential of (4.11) satisfies

$$d\hat{\alpha}(t) = \mathcal{A}^{-1}(t)\langle \tilde{F}(t)X(t), d\tilde{P}X(s) - \tilde{P}A(\hat{\alpha}(t))(I + \hat{B}K(t))X(t)\,dt\rangle. \tag{4.12}$$

5. Optimality for an adaptive control. In this section, the certainty equivalence, optimal ergodic control law is shown to be self-tuning and self-optimizing. The self-tuning property is obtained by using the continuity of the solution of a stationary Riccati equation with respect to parameters in the topology induced by a suitable operator norm. Since the unbounded operator $B(\alpha)$ appears in the linear transformation of the control in (2.1), this operator topology is more restrictive than for bounded linear transformations on the Hilbert space. This continuity property is also used to show that the certainty equivalence control stabilizes the unknown system in a suitable sense. The self-optimizing property is verified for this adaptive control.

The solution V of the stationary Riccati equation (2.9) satisfies the assumptions of Corollary 3.5 if one of the following three conditions is satisfied: (i) Φ is Hilbert–Schmidt, (ii) V is nuclear, or (iii) A is strictly negative. By (A5), $V \in \mathcal{L}(H, D_{A^*}^{1-\varepsilon})$ (see [12], [18]), and (2.10) implies that

$$|\langle Ax, Vx\rangle| = |\langle Rx, x\rangle| \leq k|x|^2$$

for some $R \in \mathcal{L}(H)$. If A is strictly negative, then it easily follows that

$$V \in \mathcal{L}\big(D_A^{\delta-(1/2)}, D_{A^*}^{(1/2)-\delta}\big).$$

Moreover, if (A2) is satisfied with $\Phi = I$, then V is nuclear because, from Theorems 1 and 2 of [12], it follows that $P_a = (-A^* + \beta I)^a V \in \mathcal{L}(H)$ for each $a \in (0,1)$. Thus

$V = P_a^*(-A + \beta I)^{-a}$ is nuclear because $(-A + \beta I)^{-a}$ is nuclear for $a = 1 - 2\delta$ by (A2), (A5).

If an adaptive control is self-tuning and some stability properties are satisfied for the solution of (2.1), then this adaptive control is self-optimizing.

PROPOSITION 5.1. *Assume that* (A2), (A5) *are satisfied, that the solution* V *of* (2.10) *satisfies the assumptions of Corollary* 3.5, *and that*

$$\lim_{t\to\infty} \frac{1}{t}\langle VX(t), X(t)\rangle = 0 \quad \text{a.s.}, \tag{5.1}$$

$$\limsup_{t\to\infty} \frac{1}{t}\int_0^t |X(s)|^2\, ds < \infty \quad \text{a.s.}, \tag{5.2}$$

where $(X(t), t \geq 0)$ *is the solution of* (2.1) *with* $\alpha_0 \in \mathcal{K}$ *and the control* $U \in \cap_{T>0} M_W^p(0, T, H_1)$. *Then*

$$\liminf_{T\to\infty} \frac{1}{T} J(X_0, U, \alpha_0, T) \geq \Pi(V) \quad \text{a.s.}, \tag{5.3}$$

where V *is the solution of* (2.10) *with* $\alpha = \alpha_0$. *Furthermore, if* U *is an admissible control* $U(t) = K(t)X(t)$ *such that*

$$\lim_{t\to\infty} K(t) = k_0 \quad \text{a.s.} \tag{5.4}$$

in the uniform $\mathcal{L}(H, H_1)$ *topology where* $k_0 = -P^{-1}\Psi V$, *then*

$$\lim_{T\to\infty} \frac{1}{T} J(X_0, U, \alpha_0, T) = \Pi(V) \quad \text{a.s.} \tag{5.5}$$

Proof. For $U \in M_W^p(0, T, H_1)$, we have

$$\begin{aligned}\langle VX(t), X(t)\rangle - \langle Vx, x\rangle = &\int_0^t h(X(s)) + 2\langle U(s), \Psi VX(s)\rangle\, ds \\ &+ t\Pi(V) + 2\int_0^t \langle \Phi^* VX(s), dW(s)\rangle \quad \text{a.s.},\end{aligned} \tag{5.6}$$

where $h(x)$ is the continuous extension of $2\langle Ax, Vx\rangle, x \in \mathcal{D}(A)$. Using the stationary Riccati equation (2.10), we obtain

$$\begin{aligned}&\langle VX(t), X(t)\rangle - \langle VX_0, X_0\rangle \\ &= \int_0^t [2\langle U(s), \Psi VX(s)\rangle + \langle P^{-1}\Psi VX(s), \Psi VX(s)\rangle - \langle QX(s), X(s)\rangle]\, ds \\ &\quad + 2\int_0^t \langle \Phi^* VX(s), dW(s)\rangle + t\Pi(V) \quad \text{a.s.}\end{aligned}$$

By a similar method as in Proposition 2 of [10], we obtain from (5.2) that

$$\lim_{t\to\infty} \frac{1}{t}\int_0^t \langle \Phi^* VX(s), dW(s)\rangle = 0 \quad \text{a.s.} \tag{5.7}$$

Thus

$$\lim_{T\to\infty}\left(\frac{1}{T} J(X_0, U, \alpha_0, T) - \frac{1}{T}\int_0^T |P^{1/2}U(s) + P^{-1}\Psi VX(s)|^2\, ds\right) = \Pi(V) \quad \text{a.s.},$$

and (5.3) is verified. If $U(t) = K(t)X(t)$ and if (5.4) is satisfied, then

$$\lim_{T\to\infty} \frac{1}{T} \int_0^T |P^{1/2}(U(s) + P^{-1}\Psi VX(s))|^2 \, ds = 0 \quad \text{a.s.}$$

by (5.3). Thus (5.5) is verified. □

Now it is shown that the stability conditions (5.1), (5.2) are satisfied for an admissible, self-tuning adaptive control.

PROPOSITION 5.2. *Assume that* (A2), (A5) *are satisfied. Let the solution* V *of* (2.10) *satisfy the assumptions of Corollary* 3.5. *If* $(X(t), t \geq 0)$ *is the solution of* (2.1) *with* $\alpha_0 \in \mathcal{K}$ *and an adaptive control law* $(K(t), t \geq 0)$ *that satisfies* (5.4), *then* (5.1), (5.2) *are satisfied.*

Proof. Apply the Itô formula (3.31) of Corollary 3.5 to $\langle VX(t), X(t)\rangle$ again to obtain (5.6). Let $(P(t), t \geq 0)$ satisfy

$$P(t) = \int_0^t \Big[h(X(s)) + 2\langle K(s)X(s), \Psi VX(s)\rangle + \frac{1}{2}\langle QX(s), X(s)\rangle \Big] \, ds + 2\int_0^t \langle \Phi^* VX(s), dW(s)\rangle$$

and use the stationary Riccati equation (2.10) to obtain

$$P(t) = \int_0^t \Big[2\langle K(s)X(s), \Psi VX(s)\rangle + 2\langle P^{-1}\Psi VX(s), \Psi VX(s)\rangle - \langle P^{-1}\Psi VX(s), \Psi VX(s)\rangle - \frac{1}{2}\langle QX(s), X(s)\rangle \Big] \, ds + 2\int_0^t \langle \Phi^* VX(s), dW(s)\rangle.$$

By (2.7), (2.8) and the boundedness of $\Phi^* V$, there are constants c_0, c_1, c_2, and c_3 such that

$$\begin{aligned} P(t) &\leq \int_0^t [2\langle (P^{-1}\Psi V + K(s))X(s), \Psi VX(s)\rangle - c_0|X(s)|^2] \, ds + 2\int_0^t \langle \Phi^* VX(s), dW(s)\rangle \\ &\leq \int_0^t (-c_1 + c_2|K(s) - k_0|_{\mathcal{L}(H,H_1)})|X(s)|^2 \, ds \\ &\quad + \int_0^t |\Phi^* VX(s)|^2 \, ds \left[-c_3 + \frac{2}{\int_0^t |\Phi^* VX(s)|^2 \, ds} \int_0^t \langle \Phi^* VX(s), dW(s)\rangle \right] \\ &= P_1(t) + P_2(t). \end{aligned}$$

Since $K(s) \to k_0$ almost surely as $s \to \infty$, $\limsup_{t\to\infty}(1/t)P_1(t) \leq 0$ almost surely, and by the strong law of large numbers for Brownian motion, we have $\limsup_{t\to\infty}(1/t)P_2(t) \leq 0$ almost surely. Thus

$$\Pi(V) \geq \limsup_{t\to\infty} \left[\frac{1}{t}\langle VX(t), X(t)\rangle + \frac{1}{2t}\int_0^t \langle QX(s), X(s)\rangle \, ds \right] \quad \text{a.s.,}$$

and (5.2) is verified.

To verify (5.1), again use the Itô formula (Corollary 3.5) for $\langle VX(t), X(t)\rangle$ as

$$\begin{aligned}
&\langle VX(t), X(t)\rangle - \langle VX(\tau), X(\tau)\rangle \\
&= \int_\tau^t [2\langle K(s)X(s), \Psi VX(s)\rangle - 2\langle k_0 X(s), \Psi VX(s)\rangle \\
&\quad - \langle QX(s), X(s)\rangle + \Pi(V)]\, ds + 2\int_\tau^t \langle \Phi^* VX(s), dW(s)\rangle \\
&\le \int_\tau^t (-c_1 + c_2|K(s) - k_0|)|X(s)|^2\, ds + (t-\tau)\Pi(V) \\
&\quad + 2\int_\tau^t \langle \Phi^* VX(s), dW(s)\rangle,
\end{aligned}$$

where $c_1 > 0, c_2 > 0$ and $\tau \in [0, t]$. Thus

$$\begin{aligned}
&\langle VX(t), X(t)\rangle - \langle VX(\tau), X(\tau)\rangle \\
&\le \int_\tau^t - c_3\langle VX(s), X(s)\rangle\, ds + c_4(t-\tau) + M(\tau, t)
\end{aligned} \tag{5.8}$$

for some $c_3 > 0, c_4 > 0$, and $t \ge \tau > T_0$, where T_0 is a random time and where

$$M(\tau, t) = 2\int_\tau^t \langle \Phi^* VX(s), dW(s)\rangle.$$

Let $\psi(t) = \langle VX(t), X(t)\rangle$ and let $(y(t), t \ge T_0)$ satisfy

$$y(t) = \psi(T_0) - c_3\int_{T_0}^t y(s)\, ds + c_4(t - T_0) + M(T_0, t) \tag{5.9}$$

for $t \ge T_0$. Taking the difference of (5.8) and (5.9), it is clear that $\psi(t) \le y(t)$ almost surely for $t \ge T_0$. Solving the integral equation (5.9), we have

$$\begin{aligned}
y(t) &= \psi(T_0)e^{-c_3(t-T_0)} + \frac{c_4}{c_3}\left(1 - e^{-c_3(t-T_0)}\right) \\
&\quad - c_3\int_{T_0}^t e^{-c_3(t-s)} M(T_0, s)\, ds + M(T_0, t) \quad \text{a.s.}
\end{aligned}$$

From (5.2), which has been verified above, and from the strong law of large numbers for Brownian motion, we have that

$$\lim_{t\to\infty} \frac{1}{t}\, y(t) = 0 \quad \text{a.s.},$$

which verifies (5.1). □

To verify the self-tuning property for the certainty equivalence adaptive control, $K(t) = -P^{-1}\Psi(\hat\alpha(t-\Delta))V(\hat\alpha(t-\Delta))$, where $(\hat\alpha(t), t \ge 0)$ is a family of strongly consistent estimators of the true parameter vector α_0. It is important to show a suitable continuous dependence of the solution $V(\alpha)$ of the stationary Riccati equation on $\alpha \in \mathcal{K}$. For B bounded, some results are given in [5], [10]. For B unbounded, as in (2.1), we can use a continuity result from [17, Thms. 1.1 and 5.3], which is reformulated below. It is assumed that $A(\alpha)$ is strictly negative for each $\alpha \in \mathcal{K}$. For notational convenience, let $A_0 = A(\alpha_0)$, where $\alpha_0 = \mathcal{K}$ is the true parameter value.

LEMMA 5.3. *Assume that* (A1), (A3), (A4) *are satisfied and that*

$$\lim_{\alpha\to\alpha_0} |\Psi(\alpha)-\Psi(\alpha_0)|_{\mathcal{L}(D^{1-\varepsilon}_{A_0^*},H_1)}=0, \tag{5.10}$$

$$\lim_{\alpha\to\alpha_0} |S(t;\alpha)-S(t;\alpha_0)|_{\mathcal{L}(D^{\varepsilon-1}_{A_0},H)}=0 \tag{5.11}$$

for each $t\geq 0$, *where* $\Psi(\alpha)=B^*(\alpha)$. *Then*

$$\lim_{\alpha\to\alpha_0} |V(\alpha)-V(\alpha_0)|_{\mathcal{L}(H,D^{1-\varepsilon}_{A_0^*})}=0. \tag{5.12}$$

Note that (A3) and (5.11) imply that

$$\lim_{\alpha\to\alpha_0} |A^{-1}(\alpha)-A^{-1}(\alpha_0)|_{\mathcal{L}(H)}=0,$$

and, from (A1), (5.10) and (5.11), we have that

$$\lim_{\alpha\to\alpha_0} |\Psi(\alpha)S^*(t;\alpha)-\Psi(\alpha_0)S^*(t;\alpha_0)|_{\mathcal{L}(H,H_1)}=0.$$

Thus we can follow the proof of Theorem 5.3 in [17] to obtain (5.12).

The self-optimizing property is now verified for a self-tuning adaptive control.

THEOREM 5.4. *Assume that* (A1)–(A4), (A6)–(A8) *are satisfied. Let* $(\hat{\alpha}(t),t\geq 0)$ *be the family of least squares estimates, where* $\hat{\alpha}(t)$ *is the minimizer of* (4.1). *Let* $(K(t),t\geq 0)$ *be an admissible adaptive control law such that*

$$K(t)=-P^{-1}\Psi(\hat{\alpha}(t-\Delta))V(\hat{\alpha}(t-\Delta)), \tag{5.13}$$

where $\Psi(\alpha)=B^*(\alpha)$ *and* $V(\alpha)$ *is the solution of* (2.10) *for* $\alpha\in\mathcal{K}$. *Then the family of estimates* $(\hat{\alpha}(t),t\geq 0)$ *is strongly consistent,*

$$\lim_{t\to\infty} K(t)=k_0 \quad \text{a.s.} \tag{5.14}$$

in $\mathcal{L}(H,H_1)$ *where* $k_0=-P^{-1}\Psi(\alpha_0)V(\alpha_0)$, *and*

$$\lim_{T\to\infty}\frac{1}{T}J(X_0,U,\alpha_0,T)=\operatorname{Tr}\Pi(V(\alpha_0)) \quad \text{a.s.}, \tag{5.15}$$

where $U(t)=K(t)X(t)$ *and* $\Pi(V)$ *is given in Corollary* 3.5.

The proof follows directly from Theorem 4.1, Lemma 5.3, and Propositions 5.1 and 5.2 with $A=A(\alpha_0)$. The solution $V=V(\alpha_0)$ of the Riccati equation satisfies the assumptions of Corollary 3.5 because $A(\alpha_0)$ is strictly negative.

6. Some examples.

Example 6.1. This is a family of examples from elliptic differential operators. Let G be a bounded, open domain in $\mathbb{R}^n$ with C^∞-boundary ∂G with G locally on one side of ∂G and let $L(x,D)$ be an elliptic differential operator of the form

$$L(x,D)f=\sum_{i,j=1}^{n} D_i a_{ij}(x)D_j f+\sum_{i=1}^{n}[b_i(x)D_i f+D_i(d_i(x)f)]+c(x)f, \tag{6.1}$$

where the coefficients a_{ij},b_i,d_i,c are elements of $C^\infty(\bar{G})$,

$$\sum_{i,j} a_{ij}(x)\xi_i\xi_j\geq\hat{\nu}|\xi|^2, \tag{6.2}$$

where $\xi = (\xi_1, \ldots, \xi_n) \in \mathbb{R}^n, x \in G, \hat{\nu} > 0$ is a constant, and $\{a_{ij}(x)\}$ is symmetric. Consider a stochastic parabolic control problem formally described by the equations

$$\frac{\partial y}{\partial t}(t,x) = L(x,D)y(t,x) + \eta(t,x) \tag{6.3}$$

for $(t,x) \in \mathbb{R}_+ \times G$ and

$$\frac{\partial y}{\partial \nu}(t,x) + h(x)y(t,x) = u(t,x) \tag{6.4}$$

for $(t,x) \in \mathbb{R}_+ \times \partial G$ and $y(0,x) = y_0(x)$, where $\partial/\partial\nu = \sum_{i,j=1}^n a_{ij}\nu_j D_i$ is the normal derivative, $\nu = (\nu_1, \ldots, \nu_n)$ is the outward normal to ∂G, the process $(\eta(t,x); (t,x) \in \mathbb{R}_+ \times G)$ formally denotes a space dependent white noise, $u \in L^2(0,T,L^2(\partial G))$ for any $T > 0, h \in C^\infty(\partial G)$, and $h \geq 0$.

To give a precise meaning to (6.3), (6.4), the semigroup approach is used. An intuitive justification of the semigroup model (2.1) is given. Let $H = L^2(G), H_1 = L^2(\partial G)$ and define $Af = L(x,D)f$. $A : H \to H$ is densely defined, and $\mathcal{D}(A) = \{f \in H^2(G) : \partial f/\partial\nu + hf = 0 \text{ on } \partial G\}$. It is well known that A generates an analytic semigroup, the linear operator $(A - \beta I)$ is strictly negative for some $\beta \geq 0$.

To introduce the control operator, consider the elliptic problem

$$(L(x,D) - \beta)z = 0 \quad \text{on } G, \tag{6.5}$$

$$\frac{\partial z}{\partial \nu} + hz = -g \quad \text{on } \partial G. \tag{6.6}$$

For $g \in L^2(\partial G)$, there is a unique solution $z \in H^{3/2}(G)$ [19]. Define $\hat{B} \in \mathcal{L}(H_1, H^{3/2}(G))$ by the equation $\hat{B}g = -z$. For $\varepsilon < 3/4$, we have $\hat{B} \in \mathcal{L}(H_1, D_A^\varepsilon)$ because $D_A^{(3/4)-\gamma} = H^{(3/2)-2\gamma}$ for any sufficiently small $\gamma > 0$ [13]. Let $y_\beta(t,x) = e^{-\beta t}y(t,x)$ and $\eta(t,x)\,dt = \Phi\,dW(t)$ for some $\Phi \in \mathcal{L}(H)$ and a cylindrical Wiener process $(W(t), t \geq 0)$ in H. From (6.5), (6.6), we have

$$dy_\beta = (L(x,D) - \beta)y_\beta\,dt + e^{-\beta t}\Phi\,dW(t), \tag{6.7}$$

$$\begin{aligned} \frac{\partial y_\beta}{\partial \nu} + hy_\beta &= e^{-\beta t}u = u_\beta(t) \quad \text{on } \partial G, \\ y_\beta(0) &= y(0). \end{aligned} \tag{6.8}$$

Formally performing the differentiation $(\partial/\partial t)\hat{B}u_\beta(t)$, we obtain

$$d\omega_\beta(t) = ((L(x,D) - \beta)y_\beta(t) - \hat{B}\dot{u}_\beta(t))\,dt + e^{-\beta t}\Phi\,dW(t),$$

$$\frac{\partial \omega_\beta}{\partial \nu} + h\omega_\beta = 0 \quad \text{on } \mathbb{R}_+ \times \partial G,$$

where $\omega_\beta(t) = y_\beta(t) - \hat{B}u_\beta(t)$. For (6.7), the formula for the mild solution is

$$\begin{aligned} \omega_\beta(t) = S_\beta(t)(y(0) + \hat{B}u(0)) &+ \int_0^t S_\beta(t-r)\Phi e^{\beta r}\,dW(r) \\ &- \int_0^t S_\beta(t-r)\hat{B}\dot{u}_\beta(r)\,dr, \end{aligned} \tag{6.9}$$

where $S_\beta(t) = e^{t(A-\beta I)}$. Formally integrating by parts the last integral in (6.9) yields

$$y_\beta(t) = \omega_\beta(t) - \hat{B}u_\beta(t) = S_\beta(t)y(0) + \int_0^t (A-\beta I)S_\beta(t-r)\hat{B}u_\beta(r)\,dr + \int_0^t e^{-\beta r}S_\beta(t-r)\Phi\,dW(r).$$

Thus, cancelling $e^{-\beta t}$, we have

$$y(t) = S(t)y(0) + \int_0^t S(t-r)Bu(r)\,dr + \int_0^t S(t-r)\Phi\,dW(r),$$

which is a mild solution of the form (2.3), where $B = \Psi^*$ and $\Psi \in \mathcal{L}(D_{A^*}^{1-\varepsilon}, H_1)$ extends the operator $\hat{B}^*(A^* - \beta I)$.

The assumptions that are used in this paper are now verified for this example. Assumption (A2) may not be satisfied so that it can be considered as a condition on the noise term (specifically on Φ). If Φ is Hilbert–Schmidt or if $\Phi W(t)$ evolves in H, then (A2) is satisfied. If $n = 1$ and $\Phi \in \mathcal{L}(H)$, then (A2) is satisfied. In this case,

$$Af = \frac{\partial}{\partial x}a(x)\frac{\partial}{\partial x}f + \left(b(x)\frac{\partial}{\partial x}f + \frac{\partial}{\partial x}d(x)f + c(x)f\right).$$

Let $A_1 = (\partial/\partial x)a(x)(\partial/\partial x)$. By Corollary 2.6.11 of [20],

$$|(-A_1^* + \beta I)^\gamma x|^2 \leq \text{ const}|(-A^* + \beta I)^\gamma x|^2$$

for $x \in \mathcal{D}((\beta I - A^*)^\gamma)$, where $\gamma \in \left(0, \frac{1}{2}\right)$. It follows that $(-A+\beta I)^{-\gamma}$ is Hilbert–Schmidt if $(-A_1 + \beta I)^{-\gamma}$ is Hilbert–Schmidt. Since $A_1 = A_1^*$ and $(A_1 - \beta I)^{-1}$ is compact, we can use the comments following Lemma 2.1 to conclude that $(-A_1 + \beta I)^{-(1/2)+\delta}$ is Hilbert–Schmidt if and only if

$$\int_0^T t^{-2\delta}|\tilde{S}(t)|_{HS}^2\,dt < \infty \tag{6.10}$$

for $T > 0$, where $(\tilde{S}(t), t \geq 0)$ is the semigroup generated by $A_1 - \beta I$. We have

$$|\tilde{S}(t)|_{HS}^2 = \int_G \int_G |G(t,\theta,r)|^2\,dr\,d\theta,$$

where $G(t,\theta,r)$ is the Green function for the problem

$$\frac{\partial \omega}{\partial t} = [a(x)\omega']' - \beta\omega, \qquad \frac{\partial \omega}{\partial \nu} + h\omega = 0,$$

since

$$|G(t,\theta,r)| \leq \frac{k_1}{\sqrt{t}}\exp\left[k_2\frac{|\theta - r|^2}{t}\right]$$

for $t > 0$ and $\theta, r \in G$, where k_1 and k_2 are positive constants [1], [2]. Condition (6.10) is satisfied for any $\delta \in \left(0, \frac{1}{4}\right)$. Thus (A2) is satisfied for any $\Phi \in \mathcal{L}(H)$. Assumption (A5) can be shown to be satisfied. For example, this is trivially satisfied if the operator A is strictly negative. In the above example, if $A(= A(\alpha_0))$ is strictly negative and (A2) is satisfied, then,

for the control system (2.1) with $\alpha = \alpha_0$ and the cost functional (2.6) where $Q \in \mathcal{L}(L^2(G))$ and $P \in \mathcal{L}(L^2(\partial G))$ are uniformly positive, the self-optimizing property (5.5) of Proposition 5.1 is satisfied.

Now consider a parameter dependent version of (6.3), (6.4)

$$\frac{\partial y}{\partial t}(t,x) = \alpha L(x,D)y(t;x) + \eta(t,x), \qquad (t,x) \in \mathbb{R}_+ \times G, \tag{6.11}$$

$$\begin{aligned} \frac{\partial y}{\partial \nu} &= u(t,x), \qquad (t,x) \in \mathbb{R}_+ \times \partial G, \\ y(0,x) &= y_0(x), \end{aligned} \tag{6.12}$$

where $\alpha \in \mathcal{K} = [\alpha_1, \alpha_2]$ is scalar parameter for $0 < \alpha_1 < \alpha_2$. Assume that the operator A corresponding to $L(x,D)$ is strictly negative and that (A2) is satisfied. Using the same semigroup model as above, we have that

$$\begin{aligned} y(t;\alpha) = S(t;\alpha)y_0 + \alpha \int_0^t S(t-r;\alpha)BU(r)\,dr \\ + \int_0^t S(t-r;\alpha)\Phi\,dW(r), \end{aligned} \tag{6.13}$$

where $S(t;\alpha) = e^{t\alpha A}$, $B = [\hat{B}^* A^*]^* \in \mathcal{L}(D_{A^*}^{1-\varepsilon}, H_1)$ and $\hat{B} \in \mathcal{L}(H_1, D_A^{\varepsilon})$ solves the elliptic problem

$$\begin{aligned} L(x,D)(\hat{B}g) &= 0 \quad \text{on } G, \\ \frac{\partial}{\partial \nu}(\hat{B}g) &= -g \quad \text{on } \partial G. \end{aligned}$$

Assumptions (A1), (A3)–(A6), and (5.10) are now trivially satisfied because $A(\alpha) = \alpha A, \alpha \in [\alpha_1, \alpha_2], \alpha_1 > 0$, and A is strictly negative. Condition (5.11) is satisfied because $S(\cdot) \in C((0,\infty), D_A^{1-\varepsilon})$. Furthermore, we have that $(A^*)^{-1} \in \mathcal{L}(H), \hat{B} \in \mathcal{L}(H_1, D_A^{\varepsilon})$ and that the embedding $D_A^{\varepsilon} \to H$ is compact, so (A7) is satisfied. Since the parameter is scalar, (A8) is trivially satisfied. Thus, by Theorem 4.1, the family of least squares estimates given in the statement there is strongly consistent for $\alpha_0 \in (\alpha_1, \alpha_2)$. For any strongly consistent family of estimators $(\hat{\alpha}(t), t \geq 0)$, the cost functional (2.6) with a uniformly positive $Q \in \mathcal{L}(L^2(G))$ and $P \in \mathcal{L}(L^2(\partial G))$, system (2.1) with $A(\alpha_0) = \alpha_0 A, B$ as above, $\beta = 0$, the adaptive control

$$U(t) = -P^{-1}\Psi(\hat{\alpha}(t-\Delta))V(\hat{\alpha}(t-\Delta))X(t)$$

has the self-optimizing property (5.15) by Theorem 5.4.

An elementary example of a boundary control problem with a vector parameter α is described that satisfies (A8). It is a specialization of (6.5). Let $H = L^2([0,1], \mathbb{R})$, let F_1 and F_2 be the linear operators

$$F_1 = \frac{d^2}{dx^2}, \qquad F_2 = \frac{d}{dx},$$

and let $A(\alpha)$ be

$$A(\alpha) = \alpha_1 F_1 + \alpha_2 F_2,$$

where $\alpha = (\alpha_1, \alpha_2), \alpha_i \in [\bar{a}_i, \bar{b}_i]$ and $\bar{a}_i > 0, \bar{b}_i < \infty$ for $i = 1, 2$. The domain of $A(\alpha)$ is $\mathcal{D}(A(\alpha)) = \{f \in H^2(0,1): \partial f/\partial \nu = 0 \text{ on } \{0,1\}\}$. Let $(k_n, \ell_n; n = 0, 1, \ldots)$ be the basis of H, defined as

$$k_n(x) = \sqrt{2} \sin 2n\pi x,$$

$$\ell_n(x) = \sqrt{2} \cos 2n\pi x.$$

Fix a positive integer N and let $\tilde{P}$ be the projection determined by the family $(k_n, \ell_n, n = 1, 2, \ldots, N)$. Since the adaptive control law $(BK(t), t \geq 0)$ is a family of compact operators, it is the limit of a family of finite rank operators. Thus, to evaluate $\mathcal{A}(t)$, it suffices to apply F_1 and F_2 to the finite sum $\sum_{j=1}^{\tilde{N}} (a_j k_j + b_j \ell_j)$. It is elementary to verify that

$$\langle F_1 k_n, F_2 k_m \rangle = \langle F_1 \ell_n, F_2 \ell_m \rangle = 0$$

for all m and n and that

$$\langle F_1 k_n, F_2 \ell_m \rangle = \langle F_1 \ell_n, F_2 k_m \rangle = 0$$

for $n \neq m$. Thus

$$\left\langle F_1 \sum_{j=1}^{\tilde{N}} (a_j k_j + b_j \ell_j), F_2 \sum_{j=1}^{\tilde{N}} (a_j k_j + b_j \ell_j) \right\rangle$$
$$= \sum_{j=1}^{\tilde{N}} a_j b_j (\langle F_1 k_j, F_2 \ell_j \rangle + \langle F_1 \ell_j, F_2 k_j \rangle) \quad \text{a.s.}$$

Since we have

$$\langle F_1 k_j, F_2 \ell_j \rangle = (2j\pi)^3, \qquad \langle F_1 \ell_j, F_2 k_j \rangle = -(2j\pi)^3,$$

by passage to the limit and integration, it follows that

$$a_{12}(t) = 0 \quad \text{a.s.}$$

for $t > 0$, and the matrix $\mathcal{A}(t)$ is diagonal. Thus, for $t > 0, \tilde{\mathcal{A}}(t) = I$ almost surely and $\det \tilde{\mathcal{A}}(t) = 1$ almost surely; so (A8) is trivially satisfied. This example can be generalized to many space dimensions. For example, consider the dimension-2 case. Let $H = L^2([0,1] \times [0,1], \mathbb{R})$ and let F_1, F_2, and F_3 be the linear operators

$$F_1 = \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2}, \quad F_2 = \frac{\partial}{\partial x}, \quad F_3 = \frac{\partial}{\partial y}.$$

Let $A(\alpha)$ be

$$A(\alpha) = \alpha_1 F_1 + \alpha_2 F_2 + \alpha_3 F_3,$$

where $\alpha = (\alpha_1, \alpha_2, \alpha_3), \alpha_i \in [\tilde{a}_i, \tilde{b}_i], \tilde{a}_i > 0$, and $\tilde{b}_i < \infty$ for $i = 1, 2, 3$. It easily follows by computations that are similar to the above that the matrix $\mathcal{A}(t)$ is diagonal, so that, for $t > 0, \tilde{\mathcal{A}}(t) = I$ almost surely and $\det \tilde{\mathcal{A}}(t) = 1$ almost surely. Thus (A8) is satisfied.

Example 6.2. This example is a structurally damped plate with random loading and point control. Consider the following model of a plate in the deflection w:

$$w_{tt}(t,x) + \Delta^2 w(t,x) - \alpha \Delta w(t,x) = \delta(x - x_0)u(t) + \eta(t,x) \tag{6.14}$$

for $(t,x) \in \mathbb{R}_+ \times G$,

$$w(0,\cdot) = w_0, \qquad w_t(0,\cdot) = w_1, \tag{6.15}$$

$$w|_{\mathbb{R}_+ \times \partial G} = \Delta w|_{\mathbb{R}_+ \times \partial G} = 0, \tag{6.16}$$

where $\alpha > 0$ is an unknown constant, $\eta(t,x)$ formally represents a space-dependent Gaussian white noise on the open, bounded, smooth domain $G \subset \mathbb{R}^n$ for $n \leq 3$, and $\delta(x - x_0)$ is the Dirac distribution at $x_0 \in G$. The cost functional is

$$J(w_0, w_1, u, \alpha, T) = \int_0^T (|w(t)|^2_{H^2(G)} + |w_t(t)|^2_{L^2(G)} + |u(t)|^2)\, dt. \tag{6.17}$$

For a mathematical treatment of the deterministic problem (6.14)–(6.17) where $\eta \equiv 0$, refer to [3], [4], [17] and references therein. Define the linear operator $\mathcal{A}$ by the equation $\mathcal{A}h = \Delta^2 h$, where $\mathcal{D}(\mathcal{A}) = \{h \in H^4(G) : h|_{\partial G} = \Delta h|_{\partial G} = 0\}$. Following [4], [17], (6.14)–(6.17) are rewritten in the form (2.1), (2.6), where $H = \mathcal{D}(\mathcal{A}^{1/2}) \times L^2(G) = (H^2(G) \cap H_0^1(G)) \times L^2(G), H_1 = \mathbb{R}$,

$$A(\alpha) = \begin{bmatrix} 0 & I \\ -\mathcal{A} & -\alpha \mathcal{A}^{1/2} \end{bmatrix},$$

$$Bu = \begin{bmatrix} 0 \\ \delta(x - x_0)u \end{bmatrix},$$

$$\Phi = \begin{bmatrix} 0 & 0 \\ 0 & \Phi_1 \end{bmatrix},$$

where $\Phi_1 \in \mathcal{L}(L^2(G))$ is a Hilbert–Schmidt operator and where $\Phi_1 \Phi_1^* > 0, Q = I, P = I$, and $(W(t), t \geq 0)$ in (2.1) is a cylindrical Wiener process on H. It is known [4] that $A(\alpha)$ generates a stable analytic semigroup, $(S(t;\alpha), t \geq 0)$, and that $B \in \mathcal{L}(H_1, D^{\varepsilon-1}_{A(\alpha)})$ for $\varepsilon \in (0, 1 - n/4)$, which is possible for $n \leq 3$ (cf. [17]). Suppose that the unknown parameter $\alpha \in \mathcal{K} = [a_0, a_1]$, where $0 < a_0 < a_1$. Assumptions (A1), (A2), (A4)–(A6) are clearly satisfied. Since B does not depend on $\alpha \in \mathcal{K}$, assumption (A7) is satisfied with a finite-dimensional projection $\tilde{P} : H \to \tilde{P}(H)$ of the form

$$\tilde{P} = \begin{bmatrix} 0 & 0 \\ 0 & \tilde{P}_1 \end{bmatrix},$$

where $\tilde{P}_1 : L^2(G) \to H^2(G)$ and $\tilde{P}_1 \neq 0$. Assumption (A8) is trivially satisfied because the parameter α is scalar. The assumptions of the uniform analyticity and the exponential stability of the semigroup $(S(t;\alpha), t \geq 0)$ and the continuous dependence of this semigroup on α, (5.11), can be verified by the explicit spectral expansions of $A(\alpha)$ and $(S(t;\alpha), t \geq 0)$ [4, Thm. A3]. Therefore, by Theorem 4.1, the family of least squares estimates given in the statement there is strongly consistent for $\alpha_0 \in (a_0, a_1)$. For any strongly consistent family of estimators $(\hat{\alpha}(t), t \geq 0)$, system (2.1) with $A(\alpha_0), B, \Phi$ as above, $\beta = 0$, and the adaptive control $(U(t), t \geq 0)$ given by

$$U(t) = -\Psi(\hat{\alpha}(t - \Delta))V(\hat{\alpha}(t - \Delta))X(t)$$

has the self-optimizing property (5.15) by Theorem 5.4.

Acknowledgments. We thank A. Bensoussan for suggesting the study of adaptive boundary control problems, and we dedicate this paper to him on his fiftieth birthday, when this work was initiated, following his suggestion. We also thank I. Vrkoc and J. Seidler for reading the manuscript and suggesting improvements, and I. Lasiecka for providing important information on deterministic, distributed parameter systems that broadened the scope of this paper.

SOLUTION OF SOME TRANSPORTATION PROBLEMS WITH RELAXED OR ADDITIONAL CONSTRAINTS*

S. T. RACHEV† AND L. RÜSCHENDORF‡

Abstract. The authors consider some modifications of the usual transportation problem by allowing bounds for the admissible supply—respectively, demand—distributions. In particular, the case that the marginal distribution function of the supply is bounded below by a *df* F_1, while the marginal *df* of the demand is bounded above by a *df* is considered. For the case that the difference of the marginals is fixed—this is an extension of the well-known Kantorovich–Rubinstein problem—the authors obtain new and general explicit results and bounds, even without the assumption that the cost function is of Monge type. The multivariate case is also treated. In the last section, the authors study Monge–Kantorovich problems with constraints of a local type, that is, on the densities of the marginals. In particular, the classical Dobrushin theorem on optimal couplings is extended with respect to total variation.

Key words. marginal problem, Monge function, marginal constraint, transportation problem

AMS subject classifications. 60E15, 49A36

1. Introduction.

For distribution functions F_1, F_2 let $\mathcal{F}(F_1, F_2)$ denote the set of all *df*'s on $\mathbb{R}^2$ with marginals F_1, F_2 (i.e., $F(x,\infty) = F_1(x), F(\infty, y) = F_2(y)$). Then the transportation problem with cost function $c \geq 0$ is to

$$\text{minimize} \int_{\mathbb{R}^2} c(x,y)dF(x,y) \quad \text{over all } F \in \mathcal{F}(F_1,F_2). \tag{1.1}$$

F_1 may be viewed as the supply distribution and F_2 as the demand distribution. Clearly, (1.1) is an infinite dimensional analogue of the discrete transportation problem: given $a_i \geq 0, b_j \geq 0, \sum_{i=1}^m a_i = \sum_{j=1}^n b_j$,

$$\text{minimize} \sum_{i=1}^m \sum_{j=1}^n c_{ij}x_{ij}, \quad \text{subject to the conditions:}$$
$$\sum_{j=1}^n x_{ij} = a_i, \quad 1 \leq i \leq m, \qquad \sum_{i=1}^m x_{ij} = b_j, \quad j = 1,\dots,n, \quad x_{ij} \geq 0, \quad \forall i,j. \tag{1.2}$$

If $c(x,y)$ (respectively (c_{ij})) satisfies the "Monge" conditions, i.e., c is right continuous and

$$c(x',y') - c(x,y') - c(x',y) + c(x,y) \leq 0 \quad \text{for all } x' \geq x, y' \geq y, \tag{1.3}$$

respectively

$$c_{ij} + c_{i+1,j+1} - c_{i,j+1} - c_{i+1,j} \leq 0, \quad \forall\, 1 \leq i < m, 1 \leq j < n, \tag{1.4}$$

then the solution of (1.1), (1.2) is well known and based on the "North-West corner rule," which leads to a greedy algorithm. For (1.1) the solution is given by the *df* F^*

$$F^*(x,y) = \min\{F_1(x), F_2(y)\}. \tag{1.5}$$

F^* is the upper Fréchet-bound. The Fréchet-bounds provide the following characterization of $\mathcal{F}(F_1, F_2)$:

(1.6)
$$F \in \mathcal{F}(F_1, F_2) \quad \text{if and only if}$$
$$F_*(x,y) := (F_1(x) + F_2(y) - 1)_+ \le F(x,y) \le F^*(x,y) \quad (\text{here } (\cdot)_+ = \max(0, \cdot)).$$

The lower Fréchet bound yields to a solution of the maximization problem corresponding to (1.1) (cf. [4], [5], [11]–[13]).

In terms of random variables an equivalent formulation of the transportation problem is the following:

(1.7) $$\text{minimize } Ec(X,Y), \quad \text{subject to } F_X = F_1, F_Y = F_2,$$

where X, Y are random variables on a rich enough (e.g., atomless) probability space $(\Omega, \mathcal{U}, \mathcal{P})$. The solutions (1.5) respectively (1.6) then can be represented as distributions of rv's X^*, Y^*:

(1.8) $$X^* = F_1^{-1}(U), \qquad Y^* = F_2^{-1}(U) \quad (\text{for } (1.1), (1.5)),$$

respectively

(1.9) $$X^* = F_1^{-1}(U), \qquad Y^* = F_2^{-1}(1-U) \quad (\text{for } F_*),$$

where U is uniformly distributed on (0,1), and $F_1^{-1}(u) = \inf\{y : F_1(y) \ge u\}$ is the generalized inverse of F_1 (cf. [4], [11]–[13]). (Throughout the paper we assume that *df*'s are right continuous.) For a general review on the Monge-Kantorovich transportation problem we refer to [8] and [1].

In this paper we study modifications of the transportation problem (1.1), where we relax or add new constraints. One type of additional side conditions has been studied by Barnes and Hoffman [2], in the discrete transportation problem (1.2); namely, additional capacity constraints $\sum_{r=1}^{i} \sum_{s=1}^{j} x_{rs} \le \gamma_{ij}, i \le m-1, j \le n-1$, and a solution was obtained by a greedy algorithm.

In the first part of this paper we make use of the assumption that the cost function is of Monge type. These conditions seem to be necessary, since already in the simpler discrete case there are no general explicit solutions without conditions of this type. In the second part, under the restrictions of given difference of the marginals, we obtain explicit results without the Monge condition. We study extensions to the multivariate case for cost functions of the type $c_p(x,y) = \|x-y\|_p$, $\| \quad \|_p$ the p-norm on $\mathbb{R}^n$ (c_p is not a Monge function for $n \ge 2$, and this problem is unsolved also in the discrete case). In the final section we consider local constraints on the marginals. In particular, we extend the classical Dobrushin result providing a construction of optimal couplings.

As for the proof of our results we use different methods from marginal problems, stochastic ordering, and duality theory. It seems that it is not possible to derive them all in a unified way; e.g., in §2, we construct in Theorems 1 and 2 solutions of the transportation problem with upper and lower bounds on the marginals under different assumptions on the cost functions. The proof of Theorem 1—for symmetric cost functions—is based on marginal problems, while the proof of Theorem 2—for unimodal cost functions—is based on stochastic ordering arguments.

2. Relaxation of the marginal constraints. Consider for *df*'s F_1, F_2 the set

(2.1) $$\mathcal{H}(F_1, F_2) = \{F : F \text{ is a } df \text{ on } \mathbb{R}^2 \text{ with marginal } df\text{'s } \tilde{F}_1 \le F_1, \tilde{F}_2 \ge F_2\}$$

of all df's F with $\tilde{F}_1(x) = F(x,\infty) \le F_1(x)$, always $x \in \mathbb{R}^1$, and $\tilde{F}_2(y) = F(\infty,y) \ge F_2(y), \forall\, y \in \mathbb{R}^1$. We study the transportation problem:

$$\text{(2.2)} \qquad \text{minimize} \int_{\mathbb{R}^2} c(x,y)dF(x,y), \quad \text{subject to } F \in \mathcal{H}(F_1,F_2)$$

or, equivalently,

$$\text{(2.3)} \qquad \text{minimize } Ec(X,Y), \quad \text{subject to } F_X \le F_1, F_Y \ge F_2.$$

In the discrete case the problem is to minimize $\sum c_{ij}x_{ij}$ where for some "supplies" $s_1,\dots,s_n$, $a_1 \le s_1, a_1 + a_2 \le s_1 + s_2, \dots$, and for some demands $d_1,\dots,d_n, b_1 \ge d_1, b_1 + b_2 \ge d_1 + d_2, \dots, (a_i, b_i$ as in (1.2)). This describes production and consumption processes based on priorities (e.g., by time) with capacities $s_1,\dots,s_n$, such that what is remained in stage i of the production (respectively consumption) process can be transferred to some of the next stages $i+1,\dots,n$.

THEOREM 1. *Suppose the cost function $c(x,y)$ is symmetric, $c(x,y)$ satisfies the Monge-condition* (1.3), *and let $c(x,x) = 0, \forall\, x$. Define*

$$\text{(2.3)} \qquad H^*(x,y) = \min\{F_1(x), \max\{F_1(y), F_2(y)\}\}, \qquad x,y \in \mathbb{R}.$$

Then

$$\text{(2.4)} \quad \begin{array}{ll} \text{(a)} & H^* \in \mathcal{H}(F_1,F_2), \\ \text{(b)} & H^* \textit{ solves the relaxed transportation problem } (2.2), \\ \text{(c)} & \displaystyle\int_{\mathbb{R}^2} c(x,y)dH^*(x,y) = \int_0^1 c(F_1^{-1}(u), \min(F_1^{-1}(u), F_2^{-1}(u)))du. \end{array}$$

Remark 1. Setting the df $G_1(y) = \max\{F_1(y), F_2(y)\}$, we see from Theorem 1 that the relaxed transportation problem (2.2) is equivalent to the transportation problem (1.1) with marginals F_1, G_1. In terms of random variables a solution is given by

$$\text{(2.5)} \quad X^* = F_1^{-1}(U), \qquad Y^* = G_1^{-1}(U) = \min(F_1^{-1}(U), F_2^{-1}(U)) \qquad \text{(cf. (1.8))}.$$

Proof. From the Monge condition the function $-c(x,y)$ may be viewed as a "distribution function" corresponding to a nonnegative measure μ_c on $\mathbb{R}^2$. Let X, Y be any real rv's and for $x,y \in \mathbb{R}^1$ denote $x \vee y = \max\{x,y\}, x \wedge y = \min\{x,y\}$. Theorem 1 is a consequence of the following two claims.

CLAIM 1 (Cambanis, Simons, and Stout [4], Dall'Aglio [5]). *For $c(x,y) = |x-y|^p$*

$$\text{(2.6)} \qquad \begin{aligned} 2Ec(X,Y) = \int_{\mathbb{R}^2} &(P(X < x \wedge y, Y \ge x \vee y) \\ &+ P(X \ge x \vee y, Y < x \wedge y))\mu_c(dx,dy). \end{aligned}$$

For the proof of Claim 1 define the function $f(x,y,w) : \mathbb{R}^2 \times \Omega \to \mathbb{R}$ by

$$f(x,y,w) = \begin{cases} 1 & \text{if } (X(w) < x, y \le Y(w)) \text{ or } (Y(w) < x, y \le X(w)) \\ 0 & \text{otherwise} \end{cases}$$

By Fubini's theorem,

$$\text{(2.7)} \qquad E_w \int_{\mathbb{R}^2} f(x,y,w)\mu_c(dx,dy) = \int_{\mathbb{R}^2} (E_w f(x,y,w))\mu_c(dx,dy).$$

Next the symmetry of $c(x,y)$ and $c(x,x)=0$ yields

$$\int_{\mathbb{R}^2} f(x,y,w)d\mu_c = -[c(Y(w),Y(w)) + c(X(w),X(w)) \\ -c(X(w),Y(w)) - c(Y(w),X(w))] = 2c(X(w),Y(w)). \tag{2.8}$$

Clearly,

$$E_w f(x,y,w) = P(X < x\wedge y, Y \geq x\vee y) + P(X \geq x\vee y, Y < x\wedge y). \tag{2.9}$$

Combining (2.7), (2.8), (2.9), we obtain (2.6).

CLAIM 2. *Define* $X^* = F_1^{-1}(U), Y^* = \min(F_1^{-1}(U), F_2^{-1}(U))$; *then*

$$Ec(X^*,Y^*) = \min\{Ec(X,Y); F_X \leq F_1, F_Y \geq F_2\} \tag{2.10}$$

and the value of the expectation in (2.10) *is given by*

$$\begin{aligned} Ec(X^*,Y^*) &= \frac{1}{2}\int_{\mathbb{R}^2} \max\{0, F_2((x\wedge y)-) - F_1((x\vee y)-)\}\mu_c(dx,dy) \\ &= \int_0^1 c(F_1^{-1}(t), \min\{F_1^{-1}(t), F_2^{-1}(t)\})dt. \end{aligned} \tag{2.11}$$

For the proof of Claim 2 let X, Y be any rv's with df's $F_X \leq F_1, F_Y \geq F_2$. Using Claim 1 we obtain

$$\begin{aligned} 2Ec(X,Y) &\geq \int_{\mathbb{R}^2} P(X \geq x\vee y, Y < x\wedge y)\mu_c(dx,dy) \\ &= \int_{\mathbb{R}^2} \{P(Y < x\wedge y) - P(X < x\vee y, Y < x\wedge y)\}\mu_c(dx,dy) \\ &\geq \int_{\mathbb{R}^2} \{P(Y < x\wedge y) - \min\{P(X < x\vee y), P(Y < x\wedge y)\}\mu_c(dx,dy) \\ &= \int_{\mathbb{R}^2} (P(Y < x\wedge y) - P(X < x\vee y))_+\mu_c(dx,dy) \\ &\geq \int_{\mathbb{R}^2} (F_2((x\wedge y)-) - F_1((x\vee y)-))_+\mu_c(dx,dy). \end{aligned} \tag{2.12}$$

Next we check that the lower bound we get in (2.12) is attained for $X^* = F_1^{-1}(U), Y^* = \min(F_1^{-1}(U), F_2^{-1}(U))$. In fact, by Claim 1 using $X^* \geq Y^*$ and $\{U < F_2(z)\} = \{F_2^{-1}(U) < z\}$ almost surely we obtain

$$\begin{aligned} &2Ec(X^*,Y^*) \\ &= \int_{\mathbb{R}^2} \{P(X^* \geq x\vee y, Y^* < x\wedge y) + P(X^* < x\wedge y, Y^* \geq x\vee y)\}\mu_c(dx,dy) \\ &= \int_{\mathbb{R}^2} P(X^* \geq x\vee y, Y^* < x\wedge y)\mu_c(dx,dy) \\ &= \int_{\mathbb{R}^2} P(F_1^{-1}(U) \geq x\vee y, \min(F_1^{-1}(U), F_2^{-1}(U)) < x\wedge y)\mu_c(dx,dy) \\ &= \int_{\mathbb{R}^2} P(F_1^{-1}(U) \geq x\vee y, F_2^{-1}(U) < x\wedge y)\mu_c(dx,dy) \\ &= \int_{\mathbb{R}^2} P(U \geq F_1(x\vee y), U < F_2(x\wedge y))_+\mu_c(dx,dy) \\ &= \int_{\mathbb{R}^2} (F_2((x\wedge y)-) - F_1((x\vee y)-))_+\mu_c(dx,dy). \end{aligned} \tag{2.13}$$

Obviously, $F_{(X^*,Y^*)} = H^* \in \mathcal{H}(F_1, F_2)$ and the proof of Theorem 1 is completed. □

Remark 2. Equation (2.5) suggests the following "greedy" algorithm for solving the finite discrete transportation problem with relaxed side conditions:

$$
\begin{aligned}
&\text{minimize} && \sum_{i=1}^{n}\sum_{j=1}^{n} c_{ij}x_{ij} \\
&\text{subject to:} && x_{ij} \geq 0 \\
&&& \sum_{s=1}^{j}\sum_{r=1}^{n} x_{rs} \geq \sum_{s=1}^{j} b_s =: G_j, \qquad 1 \leq j \leq n \\
&&& \sum_{r=1}^{i}\sum_{s=1}^{n} x_{rs} \leq \sum_{r=1}^{i} a_r =: F_i, \qquad 1 \leq i \leq n,
\end{aligned}
\tag{2.14}
$$

where the sum of the "demands" $\sum_{s=1}^{n} b_s$ equals the sum of the "supplies" $\sum_{r=1}^{n} a_r$, assuming that (c_{ij}) are symmetric, $c_{ii} = 0$ and c satisfying the Monge condition (1.4). Denote

$$
\begin{aligned}
&H_i = \max(F_i, G_i), \qquad 1 \leq i \leq n, \quad \text{and} \\
&\delta_1 = H_1, \delta_{i+1} = H_{i+1} - H_i, \qquad 1 \leq i \leq n-1;
\end{aligned}
\tag{2.15}
$$

(2.14) is equivalent to the standard transportation problem (1.2) with side conditions $(a_i), (\delta_i)$. In the following example we compare the solution of problem (2.14) with inequality constraints with the "greedy" solution of the standard transportation problem with equality constraints (1.2). For the problem with inequality constraints we first calculate the new artificial demands δ_j as in (2.15) and then apply the North-West corner rule.

Example.

							supply a_i	$F_i = \sum_{r=1}^{i} a_r$
$\boxed{y_{ij}}$ x_{ij}	$\boxed{20}$ 10	10					20	20
							0	20
		$\boxed{20}$ 20	$\boxed{20}$ 10	10			40	60
				$\boxed{20}$ 20			20	80
				$\boxed{10}$ 10			10	90
						$\boxed{10}$ 10	10	100
demand b_j	10	30	10	40	0	10		
$G_j = \sum_{s=1}^{j} b_s$	10	40	50	90	90	100		
$H_j = F_j \vee G_j$	20	40	60	90	90	100		
$\delta_1 = H_1, \delta_{j+1} = H_{j+1} - H_j$	20	20	20	30	0	10	"artificial" demands	

x_{ij} = solution of the standard transportation problem (1.2), using the classical North-West corner

y_{ij} = solution of the transportation problem with relaxed side conditions.

We next extend the solution to the non-symmetric case. We assume instead of symmetry the following unimodality condition, saying that for any x, y the functions $c(x,\cdot), c(\cdot,y)$ are unimodal; more precisely,

$$\begin{aligned} &c(x,y_1) \le c(x,y_2) \quad \text{if } x \le y_1 \le y_2 \text{ or } y_2 \le y_1 \le x, \quad \text{and} \\ &c(x_1,y) \le c(x_2,y) \quad \text{if } x_2 \le x_1 \le y \text{ or } y \le x_1 \le x_2. \end{aligned} \tag{2.16}$$

For the proof of this unimodal case we basically make use of stochastic ordering arguments.

THEOREM 2. *If $c(x,x) = 0$ for all x, and c satisfies the Monge condition* (1.3) *and the unimodality condition* (2.16), *then the relaxed transportation problem,*

$$\text{minimize } Ec(X,Y) \text{ subject to: } F_X \ge F_1, F_Y \le F_2, \tag{2.17}$$

has the solution

$$\begin{aligned} &X^* = F_1^{-1}(U), \qquad Y^* = \max\,(F_1^{-1}(U), F_2^{-1}(U)), \quad \text{so} \\ &F_{X^*,Y^*}(x,y) = \min\,(F_1(x), \min\,(F_1(y), F_2(y)) \quad \text{and} \\ &Ec(X^*,Y^*) = \int_0^1 c(F_1^{-1}(u), \max\,(F_1^{-1}(u), F_2^{-1}(u))du. \end{aligned} \tag{2.18}$$

Proof. Let X, Y be rv's with $F_X \ge F_1, F_Y \le F_2$; then by (1.8)

$$Ec(X,Y) \ge Ec(F_X^{-1}(U), F_Y^{-1}(U)). \tag{2.19}$$

Let $G(y) = \min\,(F_X(y), F_Y(y))$; then $F_X^{-1} \le F_1^{-1}, F_Y^{-1} \ge F_2^{-1}$ and $G^{-1} = \max\,(F_X^{-1}, F_Y^{-1})$. We now state the following.

CLAIM 1.

$$\int_0^1 c(F_X^{-1}(u), F_Y^{-1}(u))du \ge \int_0^1 c(F_X^{-1}(u), G^{-1}(u))du. \tag{2.20}$$

To show Claim 1 let for fixed $u \in (0,1), x = F_X^{-1}(u), y_1 = F_X^{-1}(u) \vee F_Y^{-1}(u) = G^{-1}(u)$, $y_2 = F_Y^{-1}(u)$.

Case 1. $x < y_2$. In this case, $x \le y_1 \le y_2$, and, therefore, the unimodality condition (2.18) implies $c(x,y_2) \ge c(x,y_1)$.

Case 2. $y_2 \le x$. In this case, $y_1 = x$ and therefore, $y_2 \le y_1 = x$. Again by the unimodality condition $c(x,y_2) \ge c(x,y_1)$. So Claim 1 holds.

CLAIM 2.

$$\int_0^1 c(F_X^{-1}(u), F_Y^{-1}(u) \vee F_X^{-1}(u))du \ge \int_0^1 c(F_1^{-1}(u), F_2^{-1}(u) \vee F_1^{-1}(u))du. \tag{2.21}$$

For the proof, define $\tilde{x}_1 = F_X^{-1}(u), \tilde{x}_2 = F_Y^{-1}(u), x_1 = F_1^{-1}(u), x_2 = F_2^{-1}(u)$ for fixed u. Then $\tilde{x}_1 \le x_1, x_2 \le \tilde{x}_2$.

$$\begin{aligned} &\text{If} \quad \tilde{x}_1 < \tilde{x}_2, \quad \text{then } \tilde{x}_1 \le \tilde{x}_2 \vee x_2 \le \tilde{x}_2, \\ &\text{if} \quad \tilde{x}_1 \ge \tilde{x}_2, \quad \text{then } \tilde{x}_1 = \tilde{x}_1 \vee x_2 \ge \tilde{x}_2. \end{aligned} \tag{2.22}$$

From (2.22) we obtain the following claim.

CLAIM 3.

$$c(\tilde{x}_1, \tilde{x}_1 \vee x_2) \ge c(x_1, x_1 \vee x_2). \tag{2.23}$$

For the proof of Claim 3 we use the relation $x_1 \geq \tilde{x}_1$. By (2.22) we have two cases.

Case 1. $x_2 > x_1 > \tilde{x}_1$. Then $c(\tilde{x}_1, x_2) = c(\tilde{x}_1, \tilde{x}_1 \vee x_2) \geq c(x_1, x_2) = c(x_1, x_1 \vee x_2)$ by the unimodality condition.

Case 2. (a) $x_1 \geq x_2 \geq \tilde{x}_1$. Then, trivially, $c(\tilde{x}_1, x_2) = c(\tilde{x}_1, x_2 \vee \tilde{x}_1) \geq c(x_1, x_1 \vee x_2) = c(x_1, x_1) = 0$.

(b) $x_1 \geq \tilde{x}_1 \geq x_2$. Then again $c(\tilde{x}_1, \tilde{x}_1) = c(\tilde{x}_1, \tilde{x}_1 \vee x_2) \geq c(x_1, x_1 \vee x_2) = c(x_1, x_1) = 0$, trivially.

Claims 1, 2, and 3 imply (2.18).

Remark 3.

(a) The unimodality assumption (2.16) is natural from the application point of view. Note that the transportation problem in Theorem 2 is the same as in Theorem 1 (where only the indices 1 and 2 have been changed). We used this change to demonstrate that the optimal solution F^* is not unique, but there is a large range of solutions. As a consequence observe that in order to achieve an optimal solution for the transportation problem with side conditions, either the demands can be adjusted by transports on or below the diagonal, or alternatively, the supplies can be adjusted in a similar way. Without the symmetry, respectively the unimodality condition, the solution may change extremely. Consider for any right continuous function $f = f(y) \geq 0$ the cost function $c(x, y) = f(y)$. Then c satisfies the Monge-condition, and so (2.17) is equivalent to the problem,

$$\text{minimize} \int f(y) dF_Y(y) \quad \text{subject to } F_Y \leq F_2, \tag{2.24}$$

i.e., we are looking for a $df \tilde{F}_2 \leq F_2$, such that the distribution of f with respect to $\tilde{F}_2$ has a minimal first moment. Obviously, the solution (2.20) of Theorem 2 is not a solution of (2.24).

(b) For the proof of Theorem 2 the assumption $c(x, x) = 0$ can be replaced by the weaker one,

$$c(x, x) \leq c(x, y) \wedge c(y, x), \quad \forall x, y. \tag{2.25}$$

3. Given sum of the marginals. Consider a flow in a network with n-nodes $i = 1, \ldots, n$, and let x_{ij} be the flow from node i to node j. Assume that for all nodes k the value of $\sum_i x_{ik} + \sum_j x_{kj}$ is fixed to be h_k. For a motivation of this problem let $a_i = \sum_{k=1}^n x_{ik}$, $b_i = \sum_{k=1}^n x_{ki}$ be the amount of labor corresponding to the outflow respectively to the inflow in node i. Assume that the total labor capacity in node i is given by h_i (in a certain time unit); then an admissible flow (x_{ij}) should satisfy the condition

$$h_i = a_i + b_i, \qquad 1 \leq i \leq n. \tag{3.1}$$

Let $F_1(k) = \sum_{i=1}^k a_i$, $F_2(k) = \sum_{i=1}^k b_i$, $H(k) = \sum_{i=1}^k h_k$; then $h_k = F_1(k) + F_2(k) - (F_1(k-1) + F_2(k-1))$ and (3.1) is equivalent to

$$H(k) = F_1(k) + F_2(k), \qquad 1 \leq k \leq n. \tag{3.2}$$

Let c_{ij} denote the cost of transporting a unit from node i to node j; then the problem is to minimize the total cost $\sum c_{ij} x_{ij}$ subject to condition (3.2) and $x_{ij} \geq 0$.

The general formulation of this problem is the following. For two df's F_1, F_2 define $G(x) := \frac{1}{2}(F_1(x) + F_2(x))$. For a cost function $c(x, y)$ consider the problem,

$$\text{minimize} \int_{\mathbb{R}^2} c(x, y) dF(x, y) \quad \text{subject to } F \in \mathcal{F}_G, \tag{3.3}$$

where $\mathcal{F}_G$ is the set of all df's $F(x,y)$ with marginal df's $\tilde{F}_1, \tilde{F}_2$ satisfying $\tilde{F}_1(x) + \tilde{F}_2(x) = 2G$.

In the special case $c(x,y) = |x-y|$, let X, Y be real rv's. Then by the triangle inequality

$$E|X-Y| \leq \inf_{a \in \mathbb{R}^1} (E|X-a| + E|Y-a|), \tag{3.4}$$

(3.4) is the optimal bound if one knows only $E|X-a|, a \in \mathbb{R}^1$. Note that $E|X-a| + E|Y-a| = \int |x-a| d(F_X + F_Y)(x)$ only depends on the sum of the marginals. Equation (3.3) is the best possible improvement of (3.4) provided $F_X + F_Y$ is known.

It was shown in [9] that

$$\sup\{E|X-Y|^p; F_X + F_Y = 2G\} = \int_0^1 |G^{-1}(t) - G^{-1}(1-t)|^p dt, \qquad p \geq 1. \tag{3.5}$$

PROPOSITION 3. *If $c \geq 0$ is symmetric and satisfies the Monge condition* (1.3), *then*

$$\inf\left\{\int c(x,y) dF(x,y); F \in \mathcal{F}_G\right\} = \int_0^1 c(G^{-1}(u), G^{-1}(u)) du, \tag{3.6}$$

$$\sup\left\{\int c(x,y) dF(x,y); F \in \mathcal{F}_G\right\} = \int_0^1 c(G^{-1}(u), G^{-1}(1-u) du. \tag{3.7}$$

Optimal pairs of rv's are given by $(G^{-1}(U), G^{-1}(U))$ respectively $(G^{-1}(U), G^{-1}(1-U))$.

Proof. Since c is symmetric, we obtain for any $F \in \mathcal{F}_G$, $\int c(x,y) dF(x,y) = \int \frac{1}{2}(c(x,y) + c(y,x)) dF(x,y) = \int c(x,y) d\{[F(x,y) + F(y,x)]/2\}$. But $F_s(x,y) = [F(x,y) + F(y,x)]/2 \in \mathcal{F}(G,G)$, so we obtain (3.6), (3.7) by application of (1.8), (1.9). □

For non-symmetric cost functions we have the following.

PROPOSITION 4. *If $c(x,y)$ satisfies the Monge condition and furthermore $x_1 \leq y \leq x_2$ implies that $c(x_1, x_2) \geq c(y,y)$, then*

$$\inf\left\{\int c(x,y) dF(x,y); F \in \mathcal{F}_G\right\} = \int_0^1 c(G^{-1}(u), G^{-1}(u)) du. \tag{3.8}$$

Proof. For rv's X, Y with $F_{X,Y} \in \mathcal{F}_{A+B}$, by the Monge condition $Ec(X,Y) \geq Ec(F_X^{-1}(U), F_Y^{-1}(U))$. Since $F_X(x) + F_Y(x) = 2G(x)$, it follows that $F_X \wedge F_Y \leq G \leq F_X \vee F_Y$, and therefore, $F_X^{-1} \wedge F_Y^{-1} \leq G^{-1} \leq F_X^{-1} \vee F_Y^{-1}$. It follows that $c(F_X^{-1}(U), F_Y^{-1}(U)) \geq c(G^{-1}(U), G^{-1}(U))$ implying (3.8). □

Remark 4. The set of marginals in the class $\mathcal{F}_G$ has a smallest and a largest element, namely

$$F_1^*(x) = \begin{cases} 2G(x), & x < x_0 \\ 1 & x \geq x_0 \end{cases} \quad \text{and} \quad F_2^*(x) = \begin{cases} 2G(x) - 1, & x \geq x_0 \\ 0 & x < x_0 \end{cases},$$

where $x_0 = \inf\{y; 2G(y) \geq 1\}$. There is no smallest df in $\mathcal{F}_G$. For the proof let $H_1(x), H_2(x)$ be the marginal df's of a smallest element $H \in \mathcal{F}_G$ and let G_1, G_2 be df's such that $G_1(x) + G_2(x) = 2G(x)$. If the lower Fréchet bounds satisfy $(H_1(x) + H_2(y) - 1)_+ \leq (G_1(x) + G_2(y) - 1)_+$, then $H_1 \leq G_1$ and $H_2 \leq G_2$, which amounts to $H_1 = G_1, H_2 = G_2$. In particular, this implies that $(G^{-1}(U), G^{-1}(1-U))$ is in the general non-symmetric case no longer a solution to the problem to maximize $\int c(x,y) dF(x,y)$ in the class $\mathcal{F}_G$. Let e.g., G be the df of $\frac{1}{4}\sum_{i=1}^4 \varepsilon_{\{i\}}$; then $P_1 = P^{(G^{-1}(U), G^{-1}(1-U))} = \frac{1}{4}(\varepsilon_{(1,4)} + \varepsilon_{(2,3)} + \varepsilon_{(3,2)} + \varepsilon_{(4,1)})$, while $P_2 = P^{((F_1^*)^{-1}(U), (F_2^*)^{-1}(1-U))} = \frac{1}{2}(\varepsilon_{(1,4)} + \varepsilon_{(2,3)})$. For $c_1(x,y) = 1_{(-\infty,(3,2)]}(x,y)$, we have $E_{P_1} c_1 = \frac{1}{4}, E_{P_2} c_1 = 0$, while for $c_2 = 1_{[(2,3),\infty)}, E_{P_1} c_2 = \frac{1}{4}, E_{P_2} c_2 = \frac{1}{2}$. Note that both functions, $-c_1, -c_2$, are Monge functions (but are not unimodal).

4. Given difference of the marginals. We next consider the case where in the network example we fix the total outflow minus the inflow of each node. This problem is known in the literature as minimal network flow problem (cf. e.g., [3, §9], or [1]). Similarly to §3 the outflow minus the inflow of each node is fixed; i.e., the following Kirchhoff equations hold: $\sum_k x_{ik} - \sum_k x_{ki} = a_i - b_i = h_i$ for all i, or, equivalently, with $F_1(k) = \sum_{j=1}^k a_j, F_2(k) = \sum_{j=1}^k b_j, H(k) = \sum_{j=1}^k h_j, H(k) = F_1(k) - F_2(k), 1 \le k \le n$. Let more generally F_1, F_2 be distribution functions and let $\mathcal{F}_H$ be the set of all "df's" of finite measures on $\mathbb{R}^2$ with marginals $\tilde{F}_1, \tilde{F}_2$ satisfying $\tilde{F}_1 - \tilde{F}_2 = F_1 - F_2 =: H$. We consider the following transportation problem:

$$\text{(4.1)} \qquad \text{minimize } \int c(x,y)dF(x,y) \quad \text{subject to } F \in \mathcal{F}_H.$$

$c(x,y)$ is symmetric, nonnegative and continuous, but does not need to satisfy the Monge conditions. For the solution we shall make use of the following dual representation (cf. Rachev and Shortt [10]):

$$\text{(4.2)} \qquad \begin{aligned} &\inf\left\{\int c(x,y)dF(x,y); F \in \mathcal{F}_H\right\} \\ &= \sup\left\{\int f dH(x); f(x) - f(y) \le c(x,y), \forall x, y\right\}. \end{aligned}$$

We first consider a special type of cost functions.

PROPOSITION 5. *Let* $c(x,y) = |x-y| \max(1, h(|x-a|), h(|y-a|))$, *where* h *is monotonically nondecreasing. Then*

$$\text{(4.3)} \qquad \inf\left\{\int c(x,y)dF(x,y); F \in \mathcal{F}_H\right\} = \int \max(1, h(|x-a|))|H|(x)dx,$$

provided $h(|x-a|)$ *is locally integrable.*

Proof. For the cost function c we observe that $f(x) - f(y) \le c(x,y)$, for all x, y, if and only if f is absolutely continuous with $|f'(x)| \le \max(1, h(|x-a|))$ almost surely. By the dual representation (4.2) and partial integration we obtain

$$\begin{aligned} &\inf\left\{\int c(x,y)dF(x,y); F \in \mathcal{F}_H\right\} \\ &= \sup\left\{\int f d(H)(x); |f'(x)| \le \max(1, h(|x-a|)), \forall x\right\} \\ &= \sup\left\{\int f'(x)(H)(x)dx; |f'(x)| \le \max(1, h(|x-a|)), \forall x\right\} \\ &= \int \max(1, h(|x-a|))|H|(x)dx. \qquad \square \end{aligned}$$

On the basis of the idea of this proof, we next consider more generally

$$\text{(4.4)} \qquad c(x,y) = |x-y|\zeta(x,y) \quad \left(\text{i.e. } \zeta(x,y) = \frac{c(x,y)}{|x-y|}\right).$$

THEOREM 6 (Generalized Kantorovich–Rubinstein problem). *Assume that for any* $x < t < y, \zeta(t,t) \le \zeta(x,y), \zeta(x,y)$ *symmetric and continuous on the diagonal and also that* $t \to \zeta(t,t)$ *is locally bounded; then*

$$\text{(4.5)} \qquad \inf\left\{\int c(x,y)dF(x,y); F \in \mathcal{F}_H\right\} = \int \zeta(t,t)|H|(t)dt.$$

Proof. Let $\mathcal{F} = \{f : f(x) - f(y) \le c(x,y), \text{ for all } x, y\}$ and let $\mathcal{F}^* = \{f \text{ absolutely continuous and } |f'(t)| \le \zeta(t,t), \text{ for all } t\}$; then $\mathcal{F} \subset \mathcal{F}^*$ as for $f \in \mathcal{F}$, we have $[f(x) - f(y)]/|x-y| \le \zeta(x,y)$ and, therefore, $\overline{\lim}_{y\to x}[f(x) - f(y)]/|x-y| \le \zeta(x,x)$. Also $\underline{\lim}_{y\to x}[f(x) - f(y)]/|x-y| = -\overline{\lim}[f(y) - f(x)]/|x-y| \ge -\overline{\lim}\,\zeta(y,x) = -\zeta(x,x)$. As $\zeta(t,t)$ is locally bounded, f is locally Lipschitz, absolutely continuous, and the inequalities above imply that $|f'(t)| \le \zeta(t,t)$ almost surely. If, conversely, $f \in \mathcal{F}^*$, then $f(x) - f(y) = \int_x^y f'(t)dt$, and therefore, $|f(x) - f(y)| \le \int_x^y |f'(t)|dt \le \int_x^y \zeta(t,t)dt \le |x-y|\zeta(x,y) = c(x,y)$. The dual representation (4.2) again implies (4.3) as in the proof of Proposition 5. □

It is very interesting to observe that restrictions on the difference of the marginals allow this general explicit result without "special" assumptions on c. Note that the solution only depends on the behavior of c at the diagonal, a property that is observed in the minimal network flow problems. Note that from Theorem 6 one obtains the remarkable consequence that

$$\inf\left\{\int |x-y|^p dF(x,y); F \in \mathcal{F}_H\right\} = 0 \tag{4.6}$$

for all $p > 1$, which confirms that cost functions as in Theorem 5 are of the right order.

We next consider an extension to the multivariate case $\mathbb{R}^n$ with the class of cost functions

$$c_p(x,y) = \|x-y\|_p = \left(\sum_{i=1}^n |x_i - y_i|^p\right)^{1/p}, \qquad 1 \le p < \infty.$$

Let F_1, F_2 be n-dimensional distribution functions and let for $H := F_1 - F_2$; $\mathcal{F}_H$ denotes the class of all $2n$-dimensional (joint) distribution functions F with n-dimensional marginals $\tilde{F}_1, \tilde{F}_2$ such that $\tilde{F}_1 - \tilde{F}_2 = H$. Denote

$$A_p(H) := \inf\left\{\int_{\mathbb{R}^{2n}} \|x-y\|_p dF(x,y); F \in \mathcal{F}_H\right\},$$

the value of the optimal multivariate transportation costs. Let $1/q + 1/p = 1$ and assume that F_1, F_2 have densities f_1, f_2 with respect to the Lebesgue measure $h := f_1 - f_2$.

THEOREM 7. (Multivariate transportation problem). (a) *For the value of the optimal transportation costs we have the upper bound*

$$A_p(H) \le B_p(H) := \int_{\mathbb{R}^n} \|y\|_p |J_H(y)|dy, \tag{4.8}$$

where $J_H(y) := \int_0^1 t^{-(n+1)} h(y/t)dt$.

(b) *If there exists a continuous function* $g : \mathbb{R}^n \to \mathbb{R}^1$, *almost everywhere differentiable and satisfying for* $p = 1$

$$\nabla g(y) = (\operatorname{sgn}(y_i J_H(y))) \quad \text{a.e.}, \tag{4.9}$$

respectively for $p > 1$,

$$\nabla g(y) = (\operatorname{sgn}(y_i J_H(y)))\left(\frac{|y_i|}{\|y\|_q}\right)^{q/p}, \tag{4.10}$$

then equality in (4.8) *holds.*

Proof. (a) From the duality theorem in Rachev and Shortt [10]

$$A_p(H) = \sup\left\{ \left| \int_{\mathbb{R}^n} f dH \right| ; |f(x) - f(y)| \le \|x - y\|_p \right\}.$$

From the Radermacher theorem we infer that any Lipschitz function f is almost everywhere differentiable, and as $\sup\{\langle \nabla f(y), a\rangle; \|a\|_p = 1\} = \|\nabla f(y)\|_q$, we obtain from the Lipschitz condition that $\|\nabla f(y)\|_q \le 1$ almost everywhere. Using a Taylor expansion

$$f(y) = f(0) + \int_0^1 \langle \nabla f(ty), y\rangle \, dt,$$

we conclude that

$$\begin{aligned} A_p(H) &\le \sup\left\{ \left| \int_{\mathbb{R}^n} \int_0^1 \langle \nabla f(ty), y\rangle \, dt \, h(y) \, dy \right| ; \|\nabla f(y)\|_q \le 1 \text{ a.e.} \right\} \\ &= \sup\left\{ \left| \int_{\mathbb{R}^n} \int_0^1 \langle \nabla f(y), y\rangle \frac{1}{t^{n+1}} h\left(\frac{y}{t}\right) dt \, dy \right| ; \|\nabla f(y)\|_q \le 1 \text{ a.e.} \right\} \\ &\le \sup\left\{ \int_{\mathbb{R}^n} \|y\|_p \, |J_H(y)| \, \|\nabla f(y)\|_q \, dy \, \|\nabla f(y)\|_q \le 1 \text{ a.e.} \right\} \\ &\le \int_{\mathbb{R}^n} \|y\|_p \, |J_H(y)| \, dy. \end{aligned} \tag{4.11}$$

(b) In the inequalities

$$|\langle x, y\rangle| \le \sum |x_i y_i| \le \|x\|_p \, \|y\|_q, \qquad \|x\|_p = 1,$$

equality is attained for $p > 1$ if and only if

$$x_i = \operatorname{sgn} y_i \frac{|y_i|^{q/p}}{\|y\|_q^{q/p}} = y_i \frac{|y_i|^{q/p-1}}{\|y\|_q^{q/p}},$$

while for $p = 1$ equality holds if and only if $\operatorname{sgn} x_i = \operatorname{sgn} y_i$. This implies part (b) of the Theorem. □

Remark 5. Conditions (4.9), (4.10) are fulfilled in dimension 1 so that the bound (4.8) is sharp and coincides with (4.3). A simple sufficient for $p = 1$ for (4.9) is given by

$$J_H \ge 0 \quad \text{a.e.}, \tag{4.12}$$

which is a stochastic ordering condition. More generally we can allow a "simple" structure of the set $\{J_H \ge 0\}$. We remark that the optimal multivariate transportation problem is a longstanding open problem also in the discrete case.

5. Upper bounds on the total transport mass. Let $\Gamma(x, y)$ be a "distribution function" of a finite measure and define for two fixed distribution functions F_1, F_2 on $\mathbb{R}^1$ the transportation problem:

$$H_\Gamma(x, y) := \sup\{F(x, y); F(x_i, y_i) \le \Gamma(x_i, y_i), i \in I, F \in \mathcal{F}(F_1, F_2)\}, \tag{5.1}$$

where $(x_i, y_i)_{i\in I} \subset \mathbb{R}^2$ may be finite or not. From the Fréchet-bounds in (1.6), we have the following conditions ensuring the nontriviality of the problem:

$$\Gamma(x_i, y_i) \ge (F_1(x_i) + F_2(y_i) - 1)_+, \quad \forall i \in I. \tag{5.2}$$

Problem (5.1) is an extension of a problem treated by Barnes and Hoffman [2] in the finite discrete case and by Olkin and Rachev [7] in the general case. In these papers it was assumed that $F(x,y) \le \Gamma(x,y)$ for all (x,y). Problem (5.2) is motivated by capacitated transportation problems with linearly ordered supply and demand nodes (cf. [2]). Several examples of this problem and extensions to further restrictions on the support of solutions ("staircase supports") are discussed in Hoffman and Veinott [6]. An application to a graph partitioning problem is given in Barnes and Hoffman [2].

THEOREM 8. *Let assumption* (5.2) *be fulfilled and define*

$$F^*(x,y) := \inf_{\substack{x_i \le x \\ y_i \le y}} \{\Gamma(x_i,y_i) + (F_1(x) - F_1(x_i)) + (F_2(y) - F_2(y_i))\} \wedge \min\{F_1(x), F_2(y)\} \tag{5.3}$$

(*with the convention that the infimum is zero, if there do not exist* $x_i \le x, y_i \le y$).

(a) $H_\Gamma(x,y) \le F^*(x,y), \forall\, x,y.$

(b) *If* F^* *is a df, then*

$$H_\Gamma(x,y) = F^*(x,y) \quad \textit{and} \quad F^* \textit{ is a solution of } (5.1). \tag{5.4}$$

(c) (cf. [2], [7]). *If* $\{(x_i,y_i), i \in I\} = \mathbb{R}^2$, *then* F^* *is a df.*

Proof. (a) For $x_i \le x, y_i \le y$, we have for any admissible F using rv's X, Y with $F_{X,Y} = F, F(x,y) = P(X \le x_i, Y \le y) + P(x_i < X \le x, Y \le y) = P(X \le x_i, Y \le y_i) + P(X \le x_i, y_i < Y \le y) + P(x_i < X \le x, Y \le y) \le \Gamma(x_i,y_i) + F_1(x) - F_1(x_i) + F_2(y) - F_2(y_i)$. Furthermore, by the Fréchet bounds (1.6), $F(x,y) \le \min\{F_1(x), F_2(y)\}$. Therefore, $F(x,y) \le F^*(x,y)$.

(b) If F^* is a *df*, then $F^* \in \mathcal{F}(F_1,F_2)$. For the proof observe that for $(x_i,y_i) \le (x,y)$ by (5.2), $\Gamma(x_i,y_i) + F_1(x) - F_1(x_i) + F_2(y) - F_2(y_i) \ge (F_1(x) + F_2(y) - 1)_+$ and so by definition of F^*, $(F_1(x) + F_2(y) - 1)_+ \le F^*(x,y) \le \min\{F_1(x), F_2(y)\}$, which implies by (1.6) that $F^* \in \mathcal{F}(F_1,F_2)$. Since $F^*(x_i,y_i) \le \Gamma(x_i,y_i)$, F^* is an admissible *df*, and, therefore, by (a) a solution of (5.1).

(c) For the proof of (c) we refer to [7]. □

Remark 6. (a) Parts (a) and (b) of Theorem 7 remain valid for any function $\Gamma(x,y) \ge 0$. The difficult part to verify is that F^* is a *df*. But it seems to be clear from the proof that, even in case when F^* is not a *df*, part (a) gives a good upper bound. An indication for this conclusion is part (c) of the theorem.

(b) From (5.4) one obtains for Monge functions c with the regularity condition

$$\int c(x,y_0)F_1(dx) + \int c(x_0,y)F_2(dy) < \infty$$

for some $x_0, y_0 \in \mathbb{R}$ that

$$\inf\left\{\int c(x,y)dF(x,y); F(x,y) \le \Gamma(x,y), \forall\, x,y, F \in \mathcal{F}(F_1,F_2)\right\} = \int c(x,y)dF^*(x,y). \tag{5.5}$$

(c) In the discrete case the solution F^* of (5.5) can be determined by the Barnes-Hoffman greedy algorithm (see [2], [6], [7]). In fact, if $a_i = F_1(x_i) - F_1(x_i-), i \in M =$

$\{1,\dots,m\}, j \in N = \{1,\dots,n\}, b_i = F_2(y_j) - F_2(y_j-), j \in N = \{1,\dots,n\}, \sum_{i\in M} a_i = \sum_{j\in N} b_j = 1, \sigma_{ij} = \Gamma(x_i, y_j)$, then

$$F^*(x_i, y_j) = \sum_{r=1}^{i}\sum_{s=1}^{j} p_{rs},$$

where p_{rs} are recursively defined:

$$p_{11} = \min(a_1, b_1, \sigma_{11});$$

$$p_{ij} = \min\left\{a_i - \sum_{s=1}^{j-1} p_{is}, b_j - \sum_{r=1}^{i-1} p_{rj}, \sigma_{ij} - \sum_{\substack{r\le i \\ (r,s)\neq(i,j)}}\sum_{s\le j} p_{rs}\right\}$$

if p_{rs} is determined for $r \le i < m$ and $s \le j < n$; and

$$p_{ij} = \min\left\{a_i - \sum_{s=1}^{j-1} p_{is}, b_j - \sum_{r=1}^{i-1} p_{rj}\right\}$$

if $i = m$ or $j = n$.

(d) $F(x, y)$ can be viewed as the analogue of the upper Fréchet bound in the set $\mathcal{F}(F_1, F_2)$ under the side constraint $F^*(x, y) \le \Gamma(x, y)$. To obtain a similar analogue for the lower Fréchet bound, consider

$$\max\{G(x, y) : G(x_i, y_i) \le \Delta(x_i, y_i), i \in I, G \in \mathcal{G}(F_1, F_2)\},$$

where $\mathcal{G}(F_1, F_2)$ is the set of all probabilities

$$G(x, y) = G_\mu(x, y) = \mu((-\infty, x] \times [y, \infty)),$$

$x, y \in \mathbb{R}$ of probability measures μ having marginal df's F_1 and F_2, and where Δ determines a positive measure δ by $G_\delta = \Delta$. Then the above maximum is attained at

$$\begin{aligned}\tilde{G}(x, y) = \inf_{\substack{x_i \le x \\ y_i \ge y}} &\{\Delta(x_i, y_i) + F_1(x) - F_1(x_i) + F_2(y_i-) \\ &- F_2(y-)\} \wedge F_1(x) \wedge (F_2(y_i-) - F_2(y-))\end{aligned} \tag{5.6}$$

if and only if $\Delta(x_i, y_i) \ge \max(0, F_1(x_i) - F_2(y_i-)), i \in I$ and $\tilde{G}$ generates a measure. If $\{(x_i, y_i), i \in I\} = \mathbb{R}^2$, then $\tilde{G}$ defines an optimal measure $\tilde{\mu}$ by $G_{\tilde{\mu}} = \tilde{G}$. Moreover under the same regularity conditions as in (b)

$$\begin{aligned}&\sup\left\{\int c(x, y)\mu(dx, dy); G_\mu \in \mathcal{G}, G_\mu(x, y) \le \Delta(x, y), x, y \in \mathbb{R}\right\} \\ &= \int c(x, y)\tilde{\mu}(dx, dy),\end{aligned}$$

(cf. [7] and Theorem 8).

(e) Consider the discrete version of the extremal problem in (d): Find

$$\max\left\{\sum_{i\in M}\cdot\sum_{j\in N} c_{ij}p_{ij}, \text{ subject to } \sum_{j\in N} p_{ij} = a_i \sum_{i\in M} p_{ij} = b_j \right.$$

$$\left. \text{and } \sum_{r\le i}\sum_{s\ge j} p_{rs} \le \Delta(x_i, y_j), i \in M, j \in N\right\},$$

where

$$\sum_{j\in N} b_j = \sum_{i\in M} a_i = 1.$$

Then the solution is determined by

$$\tilde{G}(x_i, y_j) = \sum_{r=1}^{i}\sum_{s=j}^{n} p_{rs}$$

$$= \min_{\substack{1\le r\le i\\ j\le s\le n}} \{\Delta(x_i, y_j) + (a_{r+1} + \cdots + a_i) + (b_j + \cdots + b_{s-1})\} \wedge \sum_{r=1}^{i} a_r \wedge \sum_{s=j}^{n} b_s,$$

or in other words by the following greedy algorithm:

$$p_{1n} = \min\{a_i, b_n, \Delta(x_1, y_n)\},$$

$$p_{ij} = \min\left\{a_i - \sum_{s=j+1}^{n} p_{is}, b_j - \sum_{r=1}^{i-1} p_{rj}, \Delta(x_i, y_j) - \sum_{\substack{r\le i\\ (r,s)\neq(i,j)}}\sum_{s\ge j} p_{rs}\right\},$$

if p_{rs} is determined for $r \le i \le m-1$ and $s \ge j > 1$; and

$$p_{ij} = \min\left\{a_i - \sum_{s=j+1}^{n} p_{is}, b_j - \sum_{r=1}^{i-1} p_{rj}\right\}$$

if $i = m$ or $j = 1$ (cf. [7]). □

Consider more generally a finite measure μ on $(\mathbb{R}^2, \mathcal{B}^2)$ and define for two probability measures P_1, P_2 on $(\mathbb{R}^1, \mathcal{B}^1)$ and $A_i \times B_i \in \mathcal{B}^1 \otimes \mathcal{B}^1, i \in I$,

$$M^{\mu}(P_1, P_2) = \{P \in M^1(P_1, P_2); P(A_i \times B_i) \le \mu(A_i \times B_i), i \in I\}, \tag{5.7}$$

where $M^1(P_1, P_2)$ denotes the set of all probability measures P on $\mathbb{R}^2$ with marginals P_1, P_2. As in (5.2), we assume

$$\mu(A_i \times B_i) \ge (P_1(A_i) + P_2(B_i) - 1)_+. \tag{5.8}$$

THEOREM 9. *Under assumption* (5.8) *define*

$$\begin{aligned} P^*(A \times B) = \inf_{\substack{A_i\subset A\\ B_i\subset B}} &\{\mu(A_i \times B_i) + (P_1(A) - P_1(A_i)) \\ &+ (P_2(B) - P_2(B_i))\} \wedge \min(P_1(A), P_2(B)), A, B \in \mathcal{B}^1. \end{aligned} \tag{5.9}$$

Then

$$h_{\mu}(A \times B) := \sup\{P(A \times B); P \in M^{\mu}(P_1, P_2)\} \le P^*(A \times B). \tag{5.10}$$

If P^* defines a measure, then

$$h_{\mu}(A \times B) = P^*(A \times B) \quad \textit{and } P^* \textit{ is a solution of } (5.9). \tag{5.11}$$

The proof of Theorem 9 is similar to that of Theorem 8. In contrast to Theorem 8 it allows us to consider "local" bounds in the transportation problem. Observe that in the finite discrete case bounds of the type

$$x_{ij} \le \mu_{ij} \quad \text{for some } (i, j) \tag{5.12}$$

are of this "local" type. So far in the literature there are no results concerning the solution of problem (5.6) respectively (5.12) with local bounds.

6. Local bounds for the transportation plans. While in the preceding sections the additional constraints were formulated mainly in terms of the *df*'s we now consider local constraints formulated for the densities. These restrictions of the local type of course are in some respect much stronger than those in §2 and generally they are much more difficult to handle.

Our first result deals with a transportation problem with the cost function

$$c(x,y) = I(x \neq y) = \begin{cases} 1 & \text{if } x \neq y \\ 0 & \text{if } x = y; \end{cases} \tag{6.1}$$

i.e., the cost of transportation is one for any unit that has to be moved and zero otherwise. c does not satisfy a Monge-type condition. We formulate this problem in a general measure space $(S,\mathcal{U})$ only assuming that

$$\{(x,y) : x \neq y\} \in \mathcal{U} \otimes \mathcal{U}. \tag{6.2}$$

Let $M_f(S), M_f(S \times S)$ denote the set of all finite measures on $(S,\mathcal{U})$ respectively. $(S \times S, \mathcal{U} \otimes \mathcal{U})$ and let for $\mu \in M_f(S \times S), \pi_i\mu, i = 1,2$, denote the marginals of μ. This transportation problem leads to an extension of Dobrushins result on optimal couplings.

THEOREM 10. (Optimal couplings with local restrictions). *Assume that* (6.2) *holds and let* $\mu_1, \mu_2 \in M_f(S)$ *with* $\mu_1(S) \leq \mu_2(S)$. *Then*

(a)

$$\begin{aligned} &\inf\{\mu((x,y); x \neq y); \mu \in M_f(S \times S), \pi_1\mu \geq \mu_1, \pi_2\mu \leq \mu_2\} \\ &= \lambda^-(S) := \sup_{C \in \mathcal{U}} (\mu_1(C) - \mu_2(C)). \end{aligned} \tag{6.3}$$

(b) *The infimum in* (6.3) *is attained for*

$$\mu^*(A \times B) = \gamma(A \cap B) + \frac{\lambda^-(A)\lambda^+(B)}{\lambda^+(S)}, \tag{6.4}$$

where $\lambda^+(A) = \sup_{C \subset A}(\mu_2 - \mu_1)(C), \lambda^-(A) = \sup_{C \subset A}(\mu_1 - \mu_2)(C)$ *and* $\gamma(A) = \mu_2(A) - \lambda^+(A) = \mu_1(A) - \lambda^-(A)$.

Proof. For any $\mu \in M_f(S \times S), \mu(x \neq y) \geq \sup_C \mu(C \times (S \backslash C)) = \sup_C \{\mu(C \times S) - \mu(C \times C)\} \geq \sup_C \{\mu(C \times S) - \mu(S \times C)\} \geq \sup_C \{\mu_1(C) - \mu_2(C)\} = \sup_C \{\lambda^-(C) - \lambda^+(C)\} = \lambda^-(\operatorname{supp} \lambda^-) = \lambda^-(S)$. On the other hand, $\mu^*(A \times S) = \gamma(A) + \lambda^-(A)\lambda^+(S)/\lambda^+(S) = \mu_1(A)$ and $\mu^*(S \times B) = \gamma(B) + \lambda^-(S)\lambda^+(B)/\lambda^+(S) \leq \gamma(B) + \lambda^+(B) = \mu_2(B)$ and $\mu^*(x \neq y) = \int I(x \neq y)(\gamma(dx,dy) + \lambda^-(dx)\lambda^+(dy)/\lambda^+(S)) = \int I(x \neq y) \lambda^-(dx)\lambda^+(dy)/\lambda^+(S) = \lambda^-(S)\lambda^+(S)/\lambda^+(S) = \lambda^-(S)$. □

Consider next finite measures μ_1, μ_2 on $\mathbb{R}$ with densities h_1, h_2 with respect to a dominating measure μ on $\mathbb{R}^1$. Define

$$\mathcal{P}_{\mu_1}^{\mu_2} := \{P \in M^1(\mathbb{R}^2, \mathcal{B}^2); \pi_1 P \geq \mu_1, \pi_2 P \leq \mu_2\}. \tag{6.5}$$

Any $P \in \mathcal{P}_{\mu_1}^{\mu_2}$ has marginals $P_1 = \pi_1 P, P_2 = \pi_2 P$ with densities $f_1 \geq h_1$ and $f_2 \leq h_2$ with respect to μ. We assume first that $1 = \mu_1(\mathbb{R}^1) \leq \mu_2(\mathbb{R}^1)$, i.e., μ_1 is a probability measure and so $f_1 = h_1$.

PROPOSITION 11. *Define* $z_0 = \inf\{y : \int_{(y,\infty)} h_2 d\mu \leq 1\}$,

$$f_2^*(y) = \begin{cases} h_2(y) & \text{if } y > z_0 \\ \dfrac{1 - \displaystyle\int_{(z_0,\infty)} h_2(u)du}{\mu(z_0)} & \text{if } y = z_0 \text{ and } \mu\{z_0\} > 0 \\ 0 & \text{otherwise} \end{cases} \tag{6.6}$$

and P^* the corresponding probability measure with μ-density f_2^*.

(a) $\sup\{\bar{F}_P(x,y); P \in \mathcal{P}_{\mu_1}^{\mu_2}\} = 1 - \max(F_{\mu_1}(x), F_{P^*}(y))$, *for all* x, y, *where* $\bar{F}_P(x,y) = P([x,\infty) \times [y,\infty))$ *is the survival function.*

(b) *The* sup *in* (a) *is attained for the distribution* $F^* = F_{X^*,Y^*}$, *where* $X^* = F_{\mu_1}^{-1}(U)$, $Y^* = F_{P^*}^{-1}(U)$.

(c) *If* c *is a cost function, which is componentwise antitone and satisfies the Monge condition, then*

$$\inf\left\{\int c(x,y)dF_P(x,y); P \in \mathcal{P}_{\mu_1}^{\mu_2}\right\} = \int c(x,y)dF^*(x,y). \tag{6.7}$$

Proof. (a), (b) For $P \in \mathcal{P}_{\mu_1}^{\mu_2}$ with marginals F_{μ_1}, G_2 we know that $\bar{F}_P(x,y) \le P(F_{\mu_1}^{-1}(U) \ge x, G_2^{-1}(U) \ge y) = P(U \ge \max(F_{\mu_1}(x), G_2(y))) = 1 - \max(F_{\mu_1}(x), G_2(y))$. By our construction of P^* we see that $F_{P^*}(y) \le G_2(y)$, for all y, and therefore, $\bar{F}_P(x,y) \le 1 - \max(F_{\mu_1}(x), F_{P^*}(y))$.

(c) The conditions on the cost function c were considered in [11]. In that terminology $-c$ is a Δ-monotone function. Therefore, (c) follows from (a), (b), and [11]. □

The "antitone" assumption in (c) of Proposition 11 does not have a good interpretation in terms of costs. Under some additional assumptions on the bounding measures we can construct solutions for more natural cost functions. Let again μ_1 have densities h_i with respect to μ, $1 = \mu_1(\mathbb{R}^1) \le \mu_2(\mathbb{R}^1)$.

THEOREM 12. *Assume that for some* $y_0 \in \mathbb{R}_1$ *we have*

$$h_1(u) \le h_2(u) \quad \text{for } u < y_0 \text{ and } h_1(u) \ge h_2(u) \text{ for } u \ge y_0. \tag{6.8}$$

Define $x_0 = \inf\{y : \int_{(y,\infty)} h_1(u)d\mu(u) \ge \int_{(y,\infty)} h_2(u)d\mu(u)\}$ *and define*

$$f_2(u) := \begin{cases} h_2(u) & \text{if } u > x_0 \\ \dfrac{\int_{[x,\infty)} h_1(u)d\mu(u) - \int_{(x_0,\infty)} h_2(u)d\mu(u)}{\mu(x_0)} & \text{if } u = x_0 \text{ and } \mu\{x_0\} > 0, \\ h_1(u) & \text{if } u < x_0. \end{cases} \tag{6.9}$$

Then for any cost function c *satisfying the Monge condition* (1.3) *and the unimodality condition* (2.16) *holds*:

$$\inf\left\{\int c(x,y)dF_P(x,y); P \in \mathcal{P}_{\mu_1}^{\mu_2}\right\} = \int_0^1 c(F_{\mu_1}^{-1}(u), F_2^{-1}(u))du, \tag{6.10}$$

where F_2 *is the df of the measure with density* f_2 *with respect to* μ. *The optimal distribution is induced by the rv's* $X^* = F_{\mu_1}^{-1}(U), Y^* = F_2^{-1}(U)$.

Proof. For any $P \in \mathcal{P}_{\mu_1}^{\mu_2}$ with marginals F_{μ_1}, G_2, we have by the Monge condition: $\int c(x,y)dF_P(x,y) \ge \int_0^1 c(F_{\mu_1}^{-1}(u), G_2^{-1}(u))du$. By our construction of F_2 we find that

$$\begin{aligned} &G_2(y) \ge F_2(y) \ge F_{\mu_1}(y) \quad \text{for all } y \ge x_0 \quad \text{and} \\ &F_2(y) = F_{\mu_1}(y) \quad \text{for all } y \le x_0; \end{aligned} \tag{6.11}$$

(6.11) implies that $F_{\mu_1}^{-1}(u) \ge F_2^{-1}(u) \ge G_2^{-1}(u)$ for $u > F_2(x_0)$ and $F_2^{-1}(u) = F_{\mu_1}^{-1}(u)$ for $u \le F_2(x_0)$. Our assumptions on c imply that $c(F_{\mu_1}^{-1}(u), G_2^{-1}(u)) \ge c(F_{\mu_1}^{-1}(u), F_2^{-1}(u))$ for all u. □

Remark 7. It is not difficult to extend the solution of Theorem 12 to the case $\mu_1(\mathbb{R}^1) < 1$ and the conditions $f_1 \geq h_1, f_2 \leq h_2$, for the densities of an admissible plan P, if we still have assumption (6.8). Again choose x_0 as in (6.9) and define

$$f_2(x) = \begin{cases} h_2(x), x > z_0, \\ \dfrac{1 - \int_{(z_0,\infty)} h_2(x)d\mu(x)}{\mu(z_0)} & \text{if } x = z_0 \text{ and } \mu(z_0) > 0, \\ 0 & \text{otherwise,} \end{cases} \tag{6.12}$$

where $z_0 = \inf\{y : \int_{(y,\infty)} h_2(x)d\mu(x) \leq 1\}$. Define $y_0 = \inf\{y : \int_{(y,\infty)} h_2(x)d\mu(x) \leq \int_{(y,\infty)} h_1(x)d\mu(x)\}$,

$$f_1(x) = \begin{cases} h_1(x) & \text{if } x > y_0, \\ f_2(x) & \text{if } x < y_0, \\ \dfrac{\int_{[y_0,\infty)} (h_2(x) - h_1(x))d\mu(x)}{\mu(y_0)} & \text{if } \mu(y_0) > 0. \end{cases} \tag{6.13}$$

Then we have for c as in Theorem 12

$$\inf\left\{\int c(x,y)dF_P(x,y); \pi_1 P \geq \mu_1, \pi_2 P \leq \mu_2\right\} = \int_0^1 c(F_1^{-1}(u), F_2^{-1}(u))du, \tag{6.14}$$

where F_i have densities f_i with respect to $\mu, i = 1, 2$. □

Acknowledgments. We are indebted to the referees for several valuable suggestions, among them the relevance of the transportation problem with fixed sum of marginals as considered in §3 for the "fractional b-matching problem" in the context of undirected graphs (cf. Neuhauser, G. L. and Wolsey, L. A. (1988), *Integer and Combinatorial Optimization*, Wiley). The authors are grateful to Michel Balinski for many helpful discussions.

THE FREE BOUNDARY OF THE MONOTONE FOLLOWER*

MARIA B. CHIAROLLA† AND ULRICH G. HAUSSMANN†

Abstract. This paper identifies the free boundary arising in the two-dimensional *monotone follower, cheap control problem.* It proves that if a region of inaction $\mathcal{A}$ is of locally finite perimeter (LFP), then $\mathcal{A}$ can be replaced by a new region of inaction $\tilde{\mathcal{A}}$ whose boundary is locally C^1 (up to sets of lower dimension). It then gives conditions under which the hypothesis (LFP) holds. Furthermore, under these conditions even higher regularity of the free boundary is obtained, namely $C^{2,\alpha}$, except perhaps at a single corner point.

Key words. monotone stochastic control, variational inequality, free boundary, locally finite perimeter, measure theoretic boundary

AMS subject classifications. 93E20, 49L99

1. Introduction.

The *monotone follower problem* is a stochastic control problem in which the state, a diffusion process, is controlled by a monotone, nondecreasing process. The one-dimensional case has been studied by several authors, e.g., [9] where the diffusion reduces to Brownian motion and [5] where the diffusion has affine drift and diffusion coefficient independent of the state of the motion. It has been shown that the optimal control is singular with respect to Lebesgue measure as a function of time and is characterized by a region of inaction $\mathcal{A}$ and its complement; in this case the "free" boundary $\partial\mathcal{A}$, i.e., the boundary of $\mathcal{A}$, reduces to a point. When the state is outside $\mathcal{A}$, an optimal control makes it jump to $\partial\mathcal{A}$; when the state is in $\mathcal{A}$, the control is inactive. At $\partial\mathcal{A}$ an optimal control acts like the "local time" of the state process at $\partial\mathcal{A}$, as it forces the process to stay inside $\mathcal{A}$ with an instantaneous action at the boundary.

In more than one dimension several problems arise; one of these is the question of smoothness of the free boundary. For example, in [13] the regularity of the boundary is crucial for the construction of the optimal control process that is obtained as the solution of a Skorokhod problem (see [10]). In [15] the regularity of $\partial\mathcal{A}$ is studied in the n-dimensional case, but strong hypotheses on the data are needed in order to differentiate the Bellman equation to obtain n obstacle problems, the union of whose coincidence sets is the region of action $\mathcal{A}^c$. Then C^1-regularity in a neighborhood of any point where the coincidence set has positive Lebesgue density follows from a result of Caffarelli [2].

In this paper we identify under mild conditions the free boundary $\partial\mathcal{A}$ of the two-dimensional *monotone follower problem* in the *cheap control* case (i.e., when the cost functional does not depend explicitly on the control). Then we study its regularity. In particular, we recover the result of [15] in the two-dimensional, cheap case. Our results are restricted to two dimensions for technical reasons, but work on the n-dimensional, non-cheap case is in progress. In a companion paper [4] we construct an optimal control that acts in the manner described above for the one-dimensional case.

In §2 we state the control problem and briefly recall some of the properties of the value function that will be used in the remaining sections. In §3 we identify a region of inaction $\mathcal{A}$ and the three regions into which the region of action $(\mathcal{A})^c$ splits. We also characterize $\partial\mathcal{A}$ as the union of the "graphs" of two functions. Then, in §4, we assume that $\mathcal{A}$ is of locally finite perimeter (LFP) and we show that $\mathcal{A}$ can be replaced by a new region of inaction $\tilde{\mathcal{A}}$ with boundary $\partial\tilde{\mathcal{A}}$ which is countably 1-rectifiable. In §5 we give conditions under which the local finiteness of the perimeter (i.e., (LFP)) of $\mathcal{A}$ holds. In §6 we upgrade the regularity of

* Received by the editors June 15, 1992; accepted for publication (in revised form) December 9, 1992.
† Mathematics Department, University of British Columbia, Vancouver, British Columbia, Canada V6T 1Z2.

the boundary as well as that of the value function under the conditions of §5. Finally in §7 we discuss the monotonicity of the boundary of $\mathcal{A}$. An Appendix concludes the paper.

It should be pointed out that when this work was in progress, only an earlier version of [15] was available to the authors; it did not include some of the results of the new version. The motivation for our §6 was to complete the results of that earlier version of [15].

These results form a portion of the Ph.D. dissertation of the first author.

2. Statement of the problem. Let the state X_t of a two-dimensional system be governed by the Itô equation

$$\begin{cases} dX_t = g\,dt + \sigma \cdot dW_t + dk_t, \\ X_0 = x + k_0, \end{cases} \tag{2.1}$$

where $x, g \in \mathbb{R}^2, \sigma$ is a constant 2×2 matrix, W_t is a standard two-dimensional Brownian motion on an underlying probability space $\{\Omega, \mathcal{F}, P\}$ endowed with a filtration $\{\mathcal{F}_t\}_{t\geq 0}$ satisfying the usual conditions, and the control $\{k_t\}_{t\geq 0}$ is a progressively measurable process with cadlag nondecreasing components k_t^1, k_t^2, such that $k_0^1 \geq 0, k_0^2 \geq 0$. The set of such processes is denoted by V_+. We write X_t^k for the state to denote the dependence on the control. The cost associated with each initial position $x \in \mathbb{R}^2$ and each control $k \in V_+$ is given by

$$J_x(k) = E\left\{\int_0^\infty f(X_t^k)e^{-\rho t}\,dt\right\}. \tag{2.2}$$

The value function is

$$\hat{u}(x) = \inf\{J_x(k) : k \in V_+\}. \tag{2.3}$$

Here $\rho > 0$ is a discount factor, and the cost rate f is strictly convex, non-negative and satisfies the following conditions:

$$f(x) \to +\infty \quad \text{as } |x| \to \infty; \tag{2.4}$$

there exist $p > 1$ and constants $0 < r \leq C_0, C_1, C_2$ such that for any $\lambda \in (0,1)$, any $x \in \mathbb{R}^2$ and any x' such that $|x'| \leq 1$:

$$r|x^+|^p - C_0 \leq f(x) \leq C_0(1 + |x|)^p; \tag{2.5}$$

$$|f(x) - f(x + x')| \leq C_1(1 + f(x) + f(x + x'))^{1-1/p}|x'|; \tag{2.6}$$

$$0 < f(x + \lambda x') + f(x - \lambda x') - 2f(x) \leq C_2\lambda^2(1 + f(x))^q; \tag{2.7}$$

where $q = (1 - 2/p)^+$ and $x^+ := (x_1^+, x_2^+)$ if $x = (x_1, x_2) \in \mathbb{R}^2$, with $x_i^+ := \max\{0, x_i\}$. An example is $f(x) = |x|^p$ with $p \in \mathbb{N}, p$ even. We set

- $B(x, r)$ is the open ball with center x and radius r.
- $\Lambda^* := \{(x_1, x_2) \in \mathbb{R}^2 : x_1 \geq 0, x_2 \geq 0\}$.
- $C^{m,\alpha}(\Omega)$ is the set of m times continuously differentiable functions : $\Omega \mapsto \mathbb{R}$ whose mth order partial derivatives are locally Hölder continuous of order α, where Ω is open, m is a non-negative integer, and $\alpha \in [0, 1]$.
- G_p is the set of locally Lipschitz continuous functions v on $\mathbb{R}^2$ such that $|v(x)| \leq C(1 + |x|)^p$, and $|\nabla v(x)| \leq C(1 + |x|)^{p-1}$ for almost every x, for some constant C, with $p > 1$.

- $Au(x) := -\frac{1}{2}\,\mathrm{trace}[\sigma\sigma^* D^2u(x)] - g\cdot\nabla u(x) + \rho u(x)$ with D^2u the Hessian matrix of u.

We recall the following main properties of the value function $\hat{u}$ (cf. [3, Thms. 2.1 and 2.11, Prop. 2.2]).

THEOREM 2.1. *There exist constants $\hat{r}, \hat{C}_0, \hat{C}_1, \hat{C}_2$ such that for each $\lambda \in (0,1)$ and each x' with $|x'| \le 1$, the function $\hat{u}(x)$ satisfies* (2.8)–(2.10) *below*

$$\hat{r}|x^+|^p - \hat{C}_0 \le \hat{u}(x) \le \hat{C}_0(1+|x|)^p, \tag{2.8}$$

$$|\hat{u}(x) - \hat{u}(x+x')| \le \hat{C}_1(1+|x|+|x+x'|)^{p-1}|x'|, \tag{2.9}$$

$$0 \le \hat{u}(x+\lambda x') + \hat{u}(x-\lambda x') - 2\hat{u}(x) \le \hat{C}_2\lambda^2(1+|x|)^{(p-2)^+}. \tag{2.10}$$

Hence the optimal cost $\hat{u}$ is in $W^{2,\infty}_{\mathrm{loc}}(\mathbb{R}^2)$. In particular, there exists a version of $\hat{u}$ in $C^{1,1}(\mathbb{R}^2)$.

THEOREM 2.2. *The optimal cost $\hat{u}$ is the maximal solution of*

$$\begin{cases} Au \le f \quad \text{a.e. in } \mathbb{R}^2; \\ \dfrac{\partial u}{\partial x_1} \ge 0, \qquad \dfrac{\partial u}{\partial x_2} \ge 0 \quad \text{a.e. in } \mathbb{R}^2; \\ (Au - f)\dfrac{\partial u}{\partial x_1}\dfrac{\partial u}{\partial x_2} = 0 \quad \text{a.e. in } \mathbb{R}^2; \\ u \in G_p, \qquad \| D^2u \| \in L^\infty_{\mathrm{loc}}. \end{cases}$$

3. Identification of the free boundary. Motivated by the above theorem we say that an open set $\mathcal{A}$ is *a set of inaction* for $\hat{u}$ if

$$\begin{aligned} A\hat{u}(x_1,x_2) &= f(x_1,x_2) \quad \text{a.e. } (x_1,x_2) \in \mathcal{A} \\ \hat{u}_{x_1}(x_1,x_2)\hat{u}_{x_2}(x_1,x_2) &= 0 \quad \text{a.e. } (x_1,x_2) \in \mathcal{A}^c. \end{aligned}$$

The obvious set of inaction is

$$\mathcal{A} = \{(x_1,x_2) : \hat{u}_{x_1}(x_1,x_2) > 0, \hat{u}_{x_2}(x_1,x_2) > 0\}.$$

In this section we study $\mathcal{A}$, its complement and its boundary.

The following theorem is proved in the Appendix. (Notice that this result was already implicit in [11, Thm. 4.1], although there the proof is quite confusing and seems to contain several gaps.)

THEOREM 3.1. *There exist two functions $\psi_2(x_1)$ and $\psi_1(x_2)$ such that*

$$\forall\, x_1 \in \mathbb{R}: \quad \begin{cases} \hat{u}_{x_2}(x_1,x_2) = 0 & \forall\, x_2 \le \psi_2(x_1), \\ \hat{u}_{x_2}(x_1,x_2) > 0 & \forall\, x_2 > \psi_2(x_1); \end{cases} \tag{3.1}$$

$$\forall\, x_2 \in \mathbb{R}: \quad \begin{cases} \hat{u}_{x_1}(x_1,x_2) = 0 & \forall\, x_1 \le \psi_1(x_2), \\ \hat{u}_{x_1}(x_1,x_2) > 0 & \forall\, x_1 > \psi_1(x_2); \end{cases} \tag{3.2}$$

i.e., the functions $\psi_2(x_1)$ and $\psi_1(x_2)$ are defined by

$$\begin{cases} \psi_2(x_1) = \inf\{x_2 : \hat{u}_{x_2}(x_1,x_2) > 0\}, \\ \psi_1(x_2) = \inf\{x_1 : \hat{u}_{x_1}(x_1,x_2) > 0\}. \end{cases} \tag{3.3}$$

We remark that Menaldi and Robin (cf. [11, Thm. 4.1]) claimed that the functions ψ_i are nonincreasing; however, their proof is incorrect. We study the monotonicity of ψ_i in §7 and give a counter-example to the Menaldi–Robin claim.

We now define

$$\begin{cases} R_0 := \{(x_1, x_2) : x_1 \le \psi_1(x_2), x_2 \le \psi_2(x_1)\}, \\ R_1 := \{(x_1, x_2) : x_1 \le \psi_1(x_2), \psi_2(x_1) < x_2\}, \\ R_2 := \{(x_1, x_2) : \psi_1(x_2) < x_1, x_2 \le \psi_2(x_1)\}; \end{cases} \tag{3.4}$$

$$\partial := \partial(R_0 \cup R_1 \cup R_2); \tag{3.5}$$

$$\begin{cases} \partial_0 := \partial R_0 \cap \partial, \\ \partial_1 := \partial R_1 \cap \partial, \\ \partial_2 := \partial R_2 \cap \partial; \end{cases} \tag{3.6}$$

$$\begin{aligned} \mathcal{A} := (R_0 \cup R_1 \cup R_2)^c &= \{(x_1, x_2) : \psi_1(x_2) < x_1, \psi_2(x_1) < x_2\} \\ &= \{(x_1, x_2) : \hat{u}_{x_1}(x_1, x_2) > 0, \hat{u}_{x_2}(x_1, x_2) > 0\}. \end{aligned} \tag{3.7}$$

Clearly $\mathcal{A}$ is open since $\hat{u}_{x_1}$ and $\hat{u}_{x_2}$ are continuous; $(R_0 \cup R_1 \cup R_2)^c$ is the region of inaction (i.e., the region where $A\hat{u} = f$ holds almost everywhere), and $\partial_0 = \partial R_0 \cap \partial\mathcal{A}$. Note that $\mathcal{A} \neq \emptyset$ as this follows from Theorem 3.1 and (2.8). Since $f, \hat{u}, \hat{u}_{x_i}$ are continuous and the "dynamic programming equation" $A\hat{u} = f$ holds almost everywhere in $\mathcal{A}$, this last equality can be interpreted to hold everywhere in $\mathcal{A}$ and tr $[\sigma\sigma^* D^2 u]$ can be taken to be defined everywhere in $\mathcal{A}$ by continuity.

Note that from the definition of ψ_i, the convexity of $\hat{u}$ and the fact that $\hat{u}_{x_i} \ge 0$ follows

$$\begin{aligned} &\forall\, (\bar{x}_1, \bar{x}_2) \in R_1 : (-\infty, \bar{x}_1] \times \{\bar{x}_2\} \subset R_1, \\ &\forall\, (\bar{x}_1, \bar{x}_2) \in R_2 : \{\bar{x}_1\} \times (-\infty, \bar{x}_2] \subset R_2. \end{aligned}$$

LEMMA 3.2. *Let* $\alpha_0 = \inf\{\hat{u}(x_1, x_2) : (x_1, x_2) \in \mathbb{R}^2\}$. *Then*

(i) $R_0 = \{(x_1, x_2) : \nabla\hat{u}(x_1, x_2) = 0\} = \{(x_1, x_2) : \hat{u}(x_1, x_2) = \alpha_0\}$;

(ii) *for every* $P \in R_0, (P - \Lambda^*) \subset R_0$;

(iii) *in* R_1 *one has* $\hat{u}_{x_2} =$ const *along horizontal line segments*;

(iv) *in* R_2 *one has* $\hat{u}_{x_1} =$ const *along vertical line segments*;

(v) *in* int(R_1) *one has* $\hat{u}_{x_2x_2} =$ const *along almost all horizontal line segments*;

(vi) *in* int(R_2) *one has* $\hat{u}_{x_1x_1} =$ const *along almost all vertical line segments*.

Proof. (i) From the definition of ψ_i follows $\hat{u}_{x_i} = 0$ in int(R_0). Now (i) follows by the continuity of $\hat{u}_{x_i}$ and the convexity of $\hat{u}$.

(ii) Let $P = (x_1, x_2) \in R_0$. Then $\hat{u}_{x_i} \ge 0\,(i = 1, 2)$ implies

$$\alpha_0 = \hat{u}(P) \ge \hat{u}(Q) \ge \alpha_0, \quad \forall\, Q \in P - \Lambda^*.$$

Hence $Q \in R_0$ by (i).

(iii) Let $\tilde{P} = (\tilde{x}_1, \tilde{x}_2) \in R_1$. Then $\hat{u} =$ const on $(-\infty, \tilde{x}_1] \times \{\tilde{x}_2\}$ (by the definition of ψ_1), so for every fixed $\delta > 0$, one has

$$\begin{cases} \hat{u}(\cdot\,, \tilde{x}_2 + \delta) - \hat{u}(\cdot\,, \tilde{x}_2) \uparrow & \text{in } (-\infty, \tilde{x}_1) \\ \hat{u}(\cdot\,, \tilde{x}_2) - \hat{u}(\cdot\,, \tilde{x}_2 - \delta) \downarrow & \text{in } (-\infty, \tilde{x}_1), \end{cases}$$

since $\hat{u}_{x_1} \ge 0$. It follows that $\hat{u}_{x_2}(\cdot\,, \tilde{x}_2)$ is constant on $(-\infty, \tilde{x}_1]$. Similarly (iv) follows.

The same arguments prove (v) and (vi) wherever $\hat{u}_{x_ix_i}$ exists. □

LEMMA 3.3. *The function ψ_i is upper semicontinuous* (u.s.c.), $i = 1, 2$.

Proof. Let us recall that $\psi_1(z) = \inf\{x_1 : \hat{u}_{x_1}(x_1, z) > 0\}$ is defined for every $z \in \mathbb{R}$ and is finite (cf. Theorem 3.1). Let $z \in \mathbb{R}, \varepsilon > 0$, then

$$\psi_1(z) - \psi_1(y) > \bar{x} - \varepsilon - \psi_1(y)$$

for some $\bar{x}$ such that $\hat{u}_{x_1}(\bar{x}, z) > 0$, and this holds for any $y \in \mathbb{R}$. Now from the continuity of $\hat{u}_{x_1}$ follows $\hat{u}_{x_1}(\bar{x}, y) > 0$ if $|y - z| < \delta$, for some $\delta > 0$. Therefore,

$$\psi_1(z) - \psi_1(y) > -\varepsilon \quad \text{if } |y - z| < \delta,$$

i.e., ψ_1 is u.s.c. □

Note that Lemma 3.3 implies that $R_0 \cup R_i$ is closed $(i = 1, 2)$.

For a function $h : \mathbb{R}^2 \to \mathbb{R}$ and a point $P_0 \in \mathbb{R}^2$, we set

$$h(P_0-) := \lim_{\substack{P \to P_0 \\ P \in R_0}} h(P), \qquad h(P_0+) := \lim_{\substack{P \to P_0 \\ P \in \mathcal{A}}} h(P), \tag{3.8}$$

if these limits exist. Then we have the following proposition.

PROPOSITION 3.4. (i) $\partial_0 \subset \{(x_1, x_2) : f(x_1, x_2) = \rho\alpha_0\} \cap \{(x_1, x_2) : \hat{u}(x_1, x_2) = \alpha_0\}$;

(ii) $\rho\alpha_0 = A\hat{u}(P_0-) = A\hat{u}(P_0+) = f(P_0)$ *for every* $P_0 \in \partial_0$;

(iii) $\emptyset \neq \partial(R_0 \cap R_1) \cap \partial(R_0 \cup R_2) \subset \partial_0$;

(iv) ∂_0 *is a singleton.*

Proof. Let $P_0 \in \partial_0$, then $P_0 \in R_0$ and so $\hat{u}(P_0) = \alpha_0$, according to Lemma 3.2. Moreover, since $\hat{u}$ is constant in R_0 and $\hat{u}_{x_1}, \hat{u}_{x_2}$ are continuous, we have

$$\rho\alpha_0 = \rho\hat{u}(P_0) = A\hat{u}(P_0-) \leq f(P_0).$$

On the other hand, since $\hat{u}$ is convex, $\operatorname{tr}[\sigma\sigma^* D^2\hat{u}(P_0+)] \geq 0$; therefore,

$$f(P_0) = A\hat{u}(P_0+) = -\frac{1}{2}\operatorname{tr}\left[\sigma\sigma^* D^2\hat{u}(P_0+)\right] + \rho\hat{u}(P_0) \leq \rho\hat{u}(P_0).$$

Thus,

$$A\hat{u}(P_0+) = f(P_0) = \rho\hat{u}(P_0) = \rho\alpha_0 = A\hat{u}(P_0-).$$

Now we show that $\partial(R_0 \cup R_1)$ and $\partial(R_0 \cup R_2)$ intersect. Suppose not, then (since ψ_i is a function of $x_j, i \neq j$) there are three cases (see Fig. 1):

(a) There exists $P_1 = (x_1, x_2) \in \operatorname{graph}(\psi_1)$ such that
  i) there exists $P_2 = (y_1, y_2) \in \partial(R_0 \cup R_2) \cap ((-\infty, x_1] \times \{x_2\})$,
  ii) there exists $z \leq x_1$ such that $\psi_2(z) < x_2$.

(b) There exists $Q_1 = (x_1, x_2) \in \operatorname{graph}(\psi_2)$ such that
  i) there exists $Q_2 = (y_1, y_2) \in \partial(R_0 \cup R_1) \cap (\{x_1\} \times (-\infty, x_2])$,
  ii) there exists $z \leq x_2$ such that $\psi_1(z) < x_1$.

(c) i) $\partial(R_0 \cup R_2) \cap \operatorname{subgraph}(\psi_1) = \emptyset$,
  ii) $\partial(R_0 \cup R_1) \cap \operatorname{subgraph}(\psi_2) = \emptyset$.

Let us assume that (a) holds. Then, $\nabla\hat{u}(P_2) = 0$ by (3.4) (recall that $R_0 \cup R_i$ are closed); so $P_2 \in R_0$. Also, $\hat{u}(P_2) = \hat{u}(P_1)$ (by the definition of ψ_1) since $y_1 < x_1 \leq \psi_1(x_2)$. Therefore, we have $\hat{u}(P_1) = \alpha_0$ (cf. Lemma 3.2), i.e., $P_1 \in R_0$. Hence $(z, x_2) \in R_0$ since $z \leq x_1$, and thus $\hat{u}(z, x_2) = \alpha_0$. But this is impossible because $\hat{u}$ is no longer constant above the graph of ψ_2, by the definition of ψ_2. So (a) cannot occur.

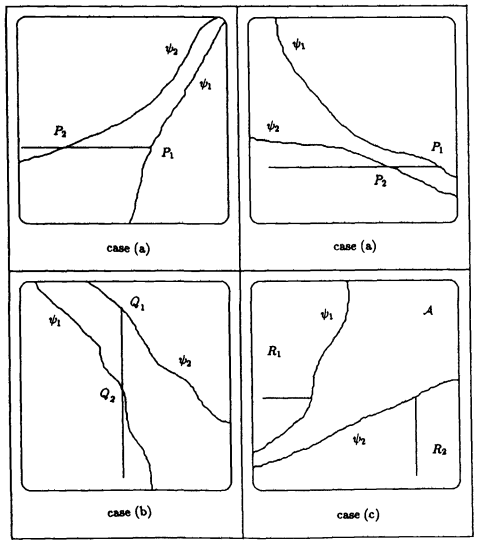

FIG. 1. *Possible cases* (a), (b), *and* (c) *occurring in the proof of Proposition* 3.4, *taking* ψ_1, ψ_2 *continuous.*

Similarly we can show that (b) cannot occur. Therefore $\partial(R_0 \cup R_1)$ must be to the left and above $\partial(R_0 \cup R_2)$, i.e., (c) must hold. So, since we are assuming $\partial(R_0 \cup R_1) \cap \partial(R_0 \cup R_2) = \emptyset$, there must exist a sequence $\{(x_n^1, x_n^2) : n \in \mathbb{N}\}$ of points of graph(ψ_1) such that $x_n^2 \to -\infty, x_n^1 \to -\infty$, and $x_n^2 > \psi_2(x_n^1)$; i.e., for each $n \in \mathbb{N}$,

$$\begin{cases} \hat{u}_{x_1}(x_n^1, x_n^2) & = 0, \\ \hat{u}_{x_2}(x_n^1, x_n^2) & > 0, \\ |(x_n^1, x_n^2)| \to +\infty & \text{as } n \to \infty. \end{cases}$$

From $A\hat{u} = f$ almost everywhere in $\mathcal{A}$ and tr $[\sigma\sigma^* D^2\hat{u}] \geq 0$ follows

$$-g \cdot \nabla\hat{u} + \rho\hat{u} \geq f \quad \text{in } \mathcal{A}$$

(recall that $\hat{u}, f, \hat{u}_{x_1}, \hat{u}_{x_2}$ are continuous). Hence, by continuity, the same is true on graph(ψ_1), and so we have

$$g_2^+ \hat{u}_{x_2}(x_n^1, x_n^2) + \rho\hat{u}(x_n^1, x_n^2) \geq f(x_n^1, x_n^2), \quad \text{for } n \in \mathbb{N}.$$

Now we recall that $f(x^1, x^2) \to +\infty$ as $|(x^1, x^2)| \to \infty$ and so we get

$$g_2^+ \hat{u}_{x_2}(x_n^1, x_n^2) + \rho\hat{u}(x_n^1, x_n^2) \to +\infty \quad \text{as } n \to +\infty. \tag{3.9}$$

However, $\hat{u}(x_n^1, x_n^2) \to +\infty$ as $n \to \infty$ would imply $\hat{u} \equiv +\infty$ since $\hat{u}$ is convex (and $\hat{u}_{x_1} \geq 0, \hat{u}_{x_2} \geq 0$) and since $x_n^2 \to -\infty$. Then $\hat{u}(x_n^1, x_n^2) \to +\infty$ is impossible. Similarly, $\hat{u}_{x_2}(x_n^1, x_n^2) \to +\infty$ as $n \to \infty$ cannot hold for that would imply $\hat{u}_{x_2} \equiv +\infty$ on graph(ψ_1); in fact, $\hat{u}_{x_2}(x_n^1, \cdot) \uparrow$ (by convexity) and $\hat{u}_{x_2} =$ const along horizontal line segments to the left of graph(ψ_1) (by Lemma 3.2(iii)) imply $\hat{u}_{x_2}(\psi_1(\cdot), \cdot) \uparrow$. Clearly $\hat{u}_{x_2} \equiv +\infty$ on graph(ψ_1) contradicts the polynomial growth of $\hat{u}_{x_2}$. Hence (3.9) is false and we must conclude that $\partial(R_0 \cup R_1) \cap \partial(R_0 \cup R_2) \neq \emptyset$.

Now let $P = (x_1, x_2) \in \partial(R_0 \cup R_1) \cap \partial(R_0 \cup R_2)$; thus $P \in \partial(R_0 \cup R_1 \cup R_2)$ and $P \in \partial(R_0)$. Hence $P \in \partial_0$ (cf. (3.6)).

Finally let $B = \{P : f(P) < \rho\alpha_0\}$. If $B = \emptyset$, then $\partial_0 = \operatorname{argmin} f$ and hence is a singleton. Otherwise B is a strictly convex set such that $\partial B = \{P : f(P) = \rho\alpha_0\}$; $R_0 = \{P : \hat{u}(P) = \alpha_0\}$ (cf. Lemma 3.2(i)) is a convex set and so is $\operatorname{int}(R_0)$. Also, in $\operatorname{int}(R_0)$ one has $\rho\alpha_0 = \rho\hat{u} = A\hat{u} \le f$, which implies $B \cap \operatorname{int}(R_0) = \emptyset$. Then, there exists a hyperplane separating B and $\operatorname{int}(R_0)$; hence $\partial B \cap R_0$ is at most a singleton (since B is strictly convex). Now (iv) follows from (i) and (iii). □

Remark 3.5. We only use the strict convexity of f to conclude that ∂_0 is a singleton. If we only assume f to be convex, then the above argument shows that ∂_0 is a line segment if $B \neq \emptyset$. If $B = \emptyset$, then ∂_0 is part of the boundary of the convex set $\operatorname{argmin} f \cap R_0$ and can be replaced by the line segment joining its end points. This gives a new R_0 and $\mathcal{A}$ but changes little else.

PROPOSITION 3.6. *If* $x_1^0 := \lim_{x_2 \to -\infty} \psi_1(x_2)$ *and* $x_2^0 := \lim_{x_1 \to -\infty} \psi_2(x_1)$, *then*

(i) x_1^0 *and* x_2^0 *exist and are finite*;

(ii) $\partial_0 = \{P_0\} := \{(x_1^0, x_2^0)\}$ *and* $R_0 = \partial_0 - \Lambda^*$;

(iii) ψ_i *is constant on* $(-\infty, x_j^0]$, $i \neq j, i, j = 1, 2$.

Proof. Let $\bar{x} \in \partial_1 \backslash \partial_0$; then $\bar{x}_1 = \psi_1(\bar{x}_2)$, $\bar{x}_2 > \psi_2(\bar{x}_1)$. Consider the line segment $S = \{(x_1, x_2) : x_1 \le \bar{x}_1, x_2 = \bar{x}_2\}$. Then $\hat{u}$ is constant on S (since $\hat{u}_{x_1} = 0$ on S by the definition of ψ_1). If $S \cap R_0 \neq \emptyset$, then $\hat{u} = \alpha_0$ on S (cf. Lemma 3.2) and hence $\hat{u} = \alpha_0$ on $(\bar{x}_1, \bar{x}_2) - \Lambda^*$ (since $\hat{u}_{x_i} \ge 0$). Hence $\hat{u} = \alpha_0$ on an open set in R_1, which is impossible by the definition of ψ_2. Therefore, $S \cap R_0 = \emptyset$, i.e., R_0 has to lie below any horizontal line through $\partial_1 \backslash \partial_0$. Similarly it must lie to the left of any vertical line through $\partial_2 \backslash \partial_0$. Since ∂_1 and ∂_2 meet at ∂_0, we have $R_0 \subset \partial_0 - \Lambda^*$. Now the assertions (i) and (ii) follow from the definition of R_0, Lemma 3.2, and Proposition 3.4 (iv).

To prove (iii), it suffices to observe that $\psi_i(x_j) = \psi_i(x_j^0)$ on $(-\infty, x_j^0]$, $i \neq j$, since $R_0 = \partial_0 - \Lambda^*$ by (ii). □

LEMMA 3.7. *The function* ψ_i *is locally bounded* $(i = 1, 2)$.

Proof. Fix $i = 1$. Recall that ψ_1 is u.s.c. (cf. Lemma 3.3), so ψ_1 is bounded above on compacta. Hence it suffices to show that ψ_1 is bounded below on any compact set $K \subset [x_2^0, +\infty)$ (cf. Proposition 3.6). Assume not, then there exists $z_1 \in K$ such that $\underline{\lim}_{\substack{y \to z_1 \\ y \in K}} \psi_1(y) = -\infty$; so there exists a sequence $y_n \to z_1$ such that $y_n \in K$ and $\psi_1(y_n) \to -\infty$ as $n \to \infty$. Also, since $K \subset [x_2^0, +\infty)$ we have

$$\{(\psi_1(y_n), y_n) : n \in \mathbb{N}\} \subset \partial_1.$$

By Theorem 2.2, $A\hat{u} = f$ almost everywhere in $\mathcal{A}$, but $\operatorname{tr}[\sigma\sigma^* D^2\hat{u}] \ge 0$ almost everywhere (since $\hat{u}$ is convex); hence

$$\rho\hat{u} \ge f + g \cdot \nabla\hat{u} \quad \text{a.e. in } \mathcal{A},$$

and by continuity this inequality can be interpreted to hold everywhere in $\operatorname{cl}(\mathcal{A})$. In particular, one has

$$\rho\hat{u} - g_2\hat{u}_{x_2} \ge f \quad \text{on } \partial_1.$$

Therefore,

$$f(\psi_1(y_n), y_n) \le \rho\hat{u}(\psi_1(y_n), y_n) - g_2\hat{u}_{x_2}(\psi_1(y_n), y_n),$$

but then, in the limit as $n \to \infty$, the left-hand side (LHS) will diverge to $+\infty$ since $f(x_1, x_2) \to +\infty$ as $|(x_1, x_2)| \to +\infty$, while the right-hand side (RHS) will remain bounded since

$$\begin{cases} \hat{u}(\psi_1(y_n), y_n) \le \hat{u}(\psi_1(z_1), y_n) \to \hat{u}(\psi_1(z_1), z_1), & \\ \hat{u}_{x_2}(\psi_1(y_n), y_n) \le \hat{u}_{x_2}(\psi_1(y_n), z_1) = \hat{u}_{x_2}(\psi_1(z_1), z_1) & \text{if } y_n \uparrow z_1, \\ \hat{u}_{x_2}(\psi_1(y_n), y_n) \text{ is nonincreasing with } n & \text{if } y_n \downarrow z_1, \end{cases}$$

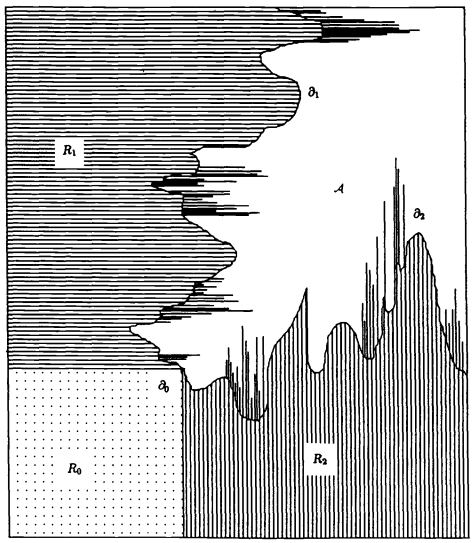

FIG. 2. *Sketch of the region of inaction $\mathcal{A}$ and its complement $R_0 \cup R_1 \cup R_2$.*

as follows from the fact that in R_1 both $\hat{u}$ and $\hat{u}_{x_2}$ are constant along horizontal line segments (cf. Lemma 3.2), and $\hat{u}_{x_1}, \hat{u}_{x_2} \geq 0$, a contradiction. (For ψ_2 the proof is the same.) □

LEMMA 3.8. *The function ψ_i is continuous at x_j^0, $i \neq j$ $(i, j = 1, 2)$. Hence, in particular,*

$$\emptyset \neq \text{graph}(\psi_1) \cap \text{graph}(\psi_2) = \partial_0 = \{P_0\}.$$

Proof. Let us fix $i = 1, j = 2$ for simplicity. By Lemma 3.3, ψ_1 is u.s.c.; therefore, if $\psi_1(x_2^0+) := \underline{\lim}_{z \downarrow x_2^0} \psi_1(z)$, we have $\psi_1(x_2^0+) \leq \psi_1(x_2^0)$. On the other hand, since $x_2^0 = \psi_2(x_1^0) = \psi_2(x_1)$ for any $x_1 \in (-\infty, x_1^0)$ (cf. Proposition 3.6), $\psi_1(x_2^0+) < \psi_1(x_2^0)$ would imply $[\psi_1(x_2^0+), \psi_1(x_2^0)] \times \{x_2^0\} \subset \partial_0$ (cf. (3.6) for the definition of ∂_0), but this is impossible since ∂_0 is a singleton (cf. Proposition 3.4). So $\psi_1(x_2^0+) = \psi_1(x_2^0)$; also, $\psi_1(x_2^0-) = \psi_1(x_2^0)$ by Proposition 3.6(iii). The last assertion of the lemma follows from Propositions 3.4 and 3.6. □

Hence we have established that the functions ψ_i cause the plane to split into the four regions R_0, R_1, R_2, and $\mathcal{A}$, as shown in Fig. 2.

Remark 3.9. We can show that $\nabla f(P_0)$ points into $-\Lambda^*$. This is the two-dimensional counterpart of the fact that in the one-dimensional case $f_x(x_0) \leq 0$ if $\{x_0\} = \partial\mathcal{A}$. To prove this remark observe that Theorem 2.2 and Lemma 3.2 imply $f(P) \geq A\hat{u}(P) = \rho\alpha_0$ for $P \in \text{int}(R_0)$. By continuity it follows that $f(P) \geq \rho\alpha_0$ for $P \in R_0$; but $f(P_0) = \rho\alpha_0$ by Proposition 3.4; hence P_0 minimizes f over R_0. It follows that $-\nabla f(P_0)$ (if it is not zero) is an outward normal to R_0 at P_0 and the result follows by Proposition 3.6(ii).

THEOREM 3.10. *For the free boundary $\partial\mathcal{A}$ one has*

(i) $\partial_0 = \{(x_1^0, x_2^0)\}; \nabla\hat{u}(x_1^0, x_2^0) = (0, 0)$.

(ii) $\partial_1 \cap \partial_2 = \partial_0$.

(iii) $\partial\mathcal{A} = \partial_1 \cup \partial_2$.

(iv) $\nabla\hat{u} = \begin{cases} (0, \hat{u}_{x_2}) & \text{on } \partial_1 \backslash \partial_0; \\ (\hat{u}_{x_1}, 0) & \text{on } \partial_2 \backslash \partial_0; \end{cases}$ *therefore* $\nabla\hat{u} \neq 0$ *on* $\partial\mathcal{A} \backslash \partial_0$.

Proof. Statements (i), (iii), and (iv) follow from the previous results.

(ii) Clearly $P \in \partial_1 \cap \partial_2$ implies $P \in R_0$, and so $P \in \partial_0$. On the other hand, it is obvious that $\partial_0 \subset \partial_1 \cap \partial_2$. □

Remark 3.11. Clearly we also have

$$\left.\begin{aligned} \hat{u}_{x_2x_1} &= 0 = \hat{u}_{x_1x_2} \\ \hat{u}_{x_1x_1} &= 0 \end{aligned}\right\} \quad \text{in int}(R_1),$$

and

$$\left.\begin{aligned} \hat{u}_{x_2x_1} &= 0 = \hat{u}_{x_1x_2} \\ \hat{u}_{x_2x_2} &= 0 \end{aligned}\right\} \quad \text{in int}(R_2).$$

Therefore for every x_i there exist functions $c_i(x_i), c_{ii}(x_i), i = 1, 2$, such that

$$A\hat{u}(x_1, x_2) = \begin{cases} -\frac{1}{2}a_{22}c_{22}(x_2) - g_2c_2(x_2) + \rho\hat{u}(x_1, x_2) & \text{a.e. in int}(R_1), \\ -\frac{1}{2}a_{11}c_{11}(x_1) - g_1c_1(x_1) + \rho\hat{u}(x_1, x_2) & \text{a.e. in int}(R_2), \end{cases}$$

and $\hat{u}(x_1, x_2)$ is constant in the variable x_1 in int(R_1) and in the variable x_2 in int(R_2).

4. Regularity of the free boundary. For the construction and approximation of the optimal control it is important to have some regularity of $\partial\mathcal{A}$. From the theory of sets of locally finite perimeter, it follows that the "measure theoretic boundary" of $\mathcal{A}$, a subset of $\partial\mathcal{A}$, is regular, cf. Theorem 4.8. Although we cannot determine what regularity, if any, the remaining part of $\partial\mathcal{A}$ possesses, we can modify $\mathcal{A}$ to a new set of inaction, $\tilde{\mathcal{A}}$, so that $\partial\tilde{\mathcal{A}}$ will have substantial regularity, cf. Theorem 4.32. We continue this discussion in Remark 4.9. We start with a few definitions (cf. [16, §5]).

DEFINITION 4.1. *For $\mathcal{O} \subset \mathbb{R}^2$ open, a function $u \in L^1(\mathcal{O})$ whose partial derivatives in the sense of distributions are measures with finite total variation in $\mathcal{O}$ is called a function of bounded variation, i.e., $u \in BV(\mathcal{O})$. If $u \in BV(\Omega)$ for every bounded open set Ω such that $cl(\Omega) \subset \mathcal{O}$, then we say that $u \in BV_{\text{loc}}(\mathcal{O})$.*

Thus, $u \in BV(\mathcal{O})$ if there exists a constant $C > 0$ such that

$$\left|\int_{\mathcal{O}} u(x)\frac{\partial\xi(x)}{\partial x_i}\,dx\right| \le C\,\|\xi\|_{L^\infty(\mathcal{O})} \quad \text{for } i = 1, 2 \text{ and all } \xi \in C_0^\infty(\mathcal{O}). \tag{4.1}$$

If $u \in BV(\mathcal{O})$, then its generalized gradient Du is a vector valued measure whose total variation is finite and given by

$$\|Du\|(\mathcal{O}) = \sup\left\{\sum_{i=1}^{2}\int_{\mathcal{O}} u(x)\frac{\partial\xi_i(x)}{\partial x_i}\,dx : \xi_i \in C_0^\infty(\mathcal{O}), \sum_{i=1}^{2}|\xi_i(x)|^2 \le 1, \text{ for } x \in \mathcal{O}\right\}. \tag{4.2}$$

Remark 4.2. Clearly, if $u \in C^1(\mathcal{O})$, then $\|Du\|(\mathcal{O}) = \int_{\mathcal{O}} |\nabla u|\,dx$ (this follows from (4.2) after an integration by parts). On the other hand, if $u \in W^{1,1}(\mathcal{O})$, then $\|Du\|(\mathcal{O}) = \int_{\mathcal{O}} |(u_{x_1}, u_{x_2})|\,dx$ where u_{x_i} is the weak derivative of u with respect to x_i. Therefore, $W^{1,1}(\mathcal{O}) \subset BV(\mathcal{O})$, but the two spaces are not equal (an example of a function in $BV(\mathcal{O})\setminus W^{1,1}(\mathcal{O})$ is given in Remark 4.5).

Finally, we point out that if $\mathcal{O} \subset \mathbb{R}$, then $u \in BV(\mathcal{O})$ (which is defined in a manner analogous to the two-dimensional case) has a more appealing characterization, namely (c) of the following remark.

Remark 4.3. If $\psi : \mathbb{R} \to \mathbb{R}$ is in $BV(\mathbb{R})$, there are other definitions equivalent to (the one-dimensional analogue of) Definition 4.1 (cf. [8, p. 26]), i.e., the following statements are equivalent:

(a) the derivative of ψ (in the distribution sense) is a finite measure;
(b) ψ can be approximated in L^1 by C^∞ functions with uniformly bounded variation;
(c) there exists a function $\tilde{\psi}$ such that $\tilde{\psi} = \psi$ almost everywhere and $\tilde{\psi}$ has bounded variation (in the usual sense) i.e., $V(\tilde{\psi}) = \sup\{V_a^b(\tilde{\psi}) : a < b, a, b \in \mathbb{R}\} < \infty$ where the variation of $\tilde{\psi}$ on $[a, b]$, $V_a^b(\tilde{\psi})$, is defined as

$$V_a^b(\tilde{\psi}) = \sup\left\{\sum_{i=1}^{m} |\tilde{\psi}(t_i) - \tilde{\psi}(t_{i-1})| : m \in \mathbb{N} \text{ and } a = t_0 < t_1 < \cdots < t_m = b\right\}. \tag{4.3}$$

Moreover, if ψ satisfies any of the conditions (a)–(c) above, then the total variation $\|D\psi\|(\mathbb{R})$ in the sense of (the one-dimensional analogue of) (4.2) is also given by

$$\|D\psi\|(\mathbb{R}) = \inf\{V(\tilde{\psi}) : \tilde{\psi} = \psi \text{ a.e.}\}. \tag{4.4}$$

DEFINITION 4.4. *A Borel set $E \subset \mathbb{R}^2$ is said to have* locally finite perimeter *if for every bounded open set $\Omega \subset \mathbb{R}^2$, the characteristic function of E, 1_E, is a function of bounded variation in Ω. Then the perimeter of E in Ω is defined as*

$$P(E, \Omega) = \|D1_E\|(\Omega) < \infty, \tag{4.5}$$

i.e.,

$$P(E, \Omega) := \sup\left\{\sum_{i=1}^{2} \int_E \frac{\partial \xi_i(x)}{\partial x_i}\, dx : \xi_i \in C_0^\infty(\Omega), \sum_{i=1}^{2} |\xi_i(x)|^2 \le 1, \text{ for } x \in \Omega\right\}. \tag{4.6}$$

Remark 4.5. If E is a bounded open set with C^2 boundary, then E is of finite perimeter and $P(E, \Omega)$ is the arc length of $\Omega \cap \partial E$ in the classical sense (cf. [16, Remark 5.4.2]) by an application of the Gauss–Green theorem. Hence $1_E \in BV(\Omega)$ but $1_E \notin W^{1,1}(\Omega)$!

We recall (cf. (3.4) and (3.7)) that

$$\mathcal{A} = \{\hat{u}_{x_1} > 0, \hat{u}_{x_2} > 0\}; \tag{4.7}$$

$$R_0 = \{\hat{u}_{x_1} = 0 = \hat{u}_{x_2}\}; \tag{4.8}$$

$$R_1 = \{\hat{u}_{x_1} = 0, \hat{u}_{x_2} > 0\}; \tag{4.9}$$

$$R_2 = \{\hat{u}_{x_1} > 0, \hat{u}_{x_2} = 0\}. \tag{4.10}$$

Then we make the following assumption.

(LFP). The sets $\{\hat{u}_{x_i} = 0\}, i = 1, 2$, are of locally finite perimeter.

Note that $\hat{u}_{x_i} \in BV_{\text{loc}}(\mathbb{R}^2)$ since

$$\hat{u}_{x_i} \in W^{1,1}_{\text{loc}}(\mathbb{R}^2); \tag{4.11}$$

hence almost all level sets of $\hat{u}_{x_i}$ are sets of locally finite perimeter (cf. [16, Thm. 5.4.4]).

DEFINITION 4.6. *If $E \subset \mathbb{R}^2$ is a Lebesgue measurable set, the* measure-theoretic boundary *of E is defined by*

$$\partial_M E = \{x : \bar{D}(E, x) > 0\} \cap \{x : \bar{D}(E^c, x) > 0\}, \tag{4.12}$$

where

$$\bar{D}(E, x) = \overline{\lim_{r \to 0}} \frac{|E \cap B(x, r)|}{|B(x, r)|}, \tag{4.13}$$

$|\cdot|$ being the Lebesgue measure in $\mathbb{R}^2$, and $B(x,r)$ being the open ball with center x and radius r. (If $\overline{\lim} = \underline{\lim}$ in (4.13), we denote their common value by $D(E,x)$.)

The $\partial_M E$ is a subset of the topological boundary ∂E and the points of ∂E where a tangent exists are in $\partial_M E$. If $E \subset \mathbb{R}^2$ is a set of locally finite perimeter, then its measure-theoretic boundary $\partial_M E$ is equal (up to a set of H^1 measure zero) to the reduced boundary of E, which is essentially the set of points of ∂E at which a measure-theoretic tangent exists. In this case a fundamental result of De Giorgi shows that the reduced boundary of E is a countably 1-rectifiable set (see the definition below), hence $\partial_M E$ is itself countably 1-rectifiable (cf. [16, Cor. 5.6.8, Lem. 5.9.5, and Thm. 5.7.3]).

DEFINITION 4.7. *A subset A of $\mathbb{R}^2$ is* countably 1-rectifiable *if*

$$A \subset \left(\bigcup_{i=1}^{\infty} f_j(A_j) \right) \cup A_0, \tag{4.14}$$

where $H^1(A_0) = 0$ and $f_j : A_j \to \mathbb{R}^2$, $A_j \subset \mathbb{R}$, is a countable collection of Lipschitz maps (H^1 being the one-dimensional Hausdorff measure on $\mathbb{R}^2$).

The following is an equivalent formulation of Definition 4.7 (cf. [16, Lem. 3.7.2]):

$$\begin{gathered} A \subset \mathbb{R}^2 \text{ is countably 1-rectifiable if} \\ A \subset \bigcup_{i=1}^{\infty} M_i \cup N, \end{gathered} \tag{4.15}$$

where $H^1(N) = 0$ and each M_i is a one-dimensional embedded C^1 submanifold of $\mathbb{R}^2$.

Since the union of two sets of locally finite perimeter is a set of locally finite perimeter ([8, Remark 1.7]) we obtain the following theorem.

THEOREM 4.8. *Assume* (LFP). *Then*

(i) *the region of inaction $\mathcal{A}$ is of locally finite perimeter;*

(ii) *$\partial_M \mathcal{A}$ is countably 1-rectifiable, i.e., $\partial_M \mathcal{A} \subset \bigcup_{i=1}^{\infty} M_i \cup N$ where*

- *$H^1(N) = 0$ (H^1 being the one-dimensional Hausdorff measure on $\mathbb{R}^2$),*
- *each M_i is a one-dimensional embedded C^1 submanifold of $\mathbb{R}^2$.*

Remark 4.9. We now know that $\partial_M \mathcal{A}$ is regular, so we turn to $\partial\mathcal{A} \backslash \partial_M \mathcal{A}$. As it is difficult to say much about this set, we show that it is possible to redefine $\mathcal{A}$ in order to obtain a new region of inaction $\tilde{\mathcal{A}}$ such that $\partial\tilde{\mathcal{A}}$ equals $\partial_M \tilde{\mathcal{A}}$ at least up to sets of lower dimension. More precisely, the difficulty lies in $\partial\mathcal{A}$ having possibly uncountably many "hairs" extending into $\mathcal{A}$ (there cannot be any extending into $\mathcal{A}^c$ because the ψ_i are u.s.c.), but we show that up to negligible sets the ψ_i have no discontinuities. We then "shave" these hairs off to obtain $\tilde{\mathcal{A}}$. In so doing we will not have lost any of $\partial_M \mathcal{A}$ and in fact $\partial\tilde{\mathcal{A}} \backslash \partial_M \mathcal{A}$ is negligible. Since all points of $\partial\mathcal{A}$ where a tangent vector exists are also points of the measure-theoretic boundary $\partial_M \mathcal{A}$, it is natural to start the study of $\partial\mathcal{A} \backslash \partial_M \mathcal{A}$ by examining those points of the boundary where the tangent fails to exist. Fortunately we have already obtained a parametric representation of $\mathcal{A}$ (cf. (4.7)) in terms of the functions ψ_1, ψ_2 so that the problem is now reduced to the study of the differentiability of ψ_1 and ψ_2. (LFP) and the local boundedness of ψ_i (cf. Lemma 3.7) will lead us to the existence of two functions, $\tilde{\psi}_1$ and $\tilde{\psi}_2$, differentiable almost everywhere and such that $\psi_i = \tilde{\psi}_i$ almost everywhere, $i = 1, 2$.

Throughout the remainder of this section we assume that (LFP) holds. Then, the set $R_0 \cup R_i$ $(i = 1, 2)$ is a set of locally finite perimeter (cf. (4.8)–(4.10)); hence the gradient of $1_{R_0 \cup R_i}$ is a vector valued measure whose total variation over any bounded open set $\mathcal{O} \subset \mathbb{R}^2$, $\|D1_{R_0 \cup R_i}\|(\mathcal{O})$, is finite (cf. (4.2) and (4.6)).

THEOREM 4.10. *Assume* (LFP), *then $\psi_i \in BV_{\text{loc}}(\mathbb{R})$ for $i = 1, 2$.*

Proof. Fix $i = 1$. Let Ω be a bounded open set in $\mathbb{R}$; then it follows from Lemma 3.7 that there exists $T > 0$ such that

$$(-\infty, -T) \times \Omega \subset ((R_0 \cup R_1) \cap (\mathbb{R} \times \Omega)) \subset (-\infty, T) \times \Omega;$$

therefore,

$$\|D1_{R_0 \cup R_1}\|(\mathbb{R} \times \Omega) = \|D1_{R_0 \cup R_1}\|((-T, T) \times \Omega),$$

and the RHS is finite since $R_0 \cup R_1$ is a set of locally finite perimeter. (Note that, in general, if E is a set of locally finite perimeter in $\mathbb{R}^2$, the total variation $\|D1_E\|(\mathbb{R} \times \Omega)$ need not be finite as $\mathbb{R} \times \Omega$ is not bounded.) Hence (LFP) together with $\|D1_{R_0 \cup R_1}\|(\mathbb{R} \times \Omega) < \infty$ allows us to apply Teorema 1.10 in [12, p. 525], and conclude $\psi_1 \in BV_{\text{loc}}(\mathbb{R})$. The proof for $i = 2$ is the same. □

The following result is crucial. Let Δ_ψ be the set of points of discontinuity of $\psi : \mathbb{R} \mapsto \mathbb{R}$, and denote by λ the Lebesgue measure on $\mathbb{R}$.

THEOREM 4.11. *If $\psi \in BV_{\text{loc}}(\mathbb{R})$ is upper semicontinuous, then $\lambda(\Delta_\psi) = 0$.*

Proof. It suffices to show that the set of points where $\psi|_{[a,b]}$ is discontinuous has measure zero for all finite intervals $[a, b]$. So let us fix $a < b$ and let $\psi \in BV([a, b])$; we again set

$$\Delta_\psi = \{x \in [a, b] : x \text{ is a point of discontinuity of } \psi\}. \tag{4.16}$$

Assume $\lambda(\Delta_\psi) > 0$. Also, $\psi \in BV([a, b])$ and Remark 4.3 (c) imply the existence of a function $\tilde{\psi}$ of bounded variation (i.e., $V_a^b(\tilde{\psi}) < \infty$) such that $\psi = \tilde{\psi}$ almost everywhere in $[a, b]$. Therefore, since $\tilde{\psi}$ may have at most countably many discontinuities,

$$\exists N \subset [a, b] \quad \text{such that} \begin{cases} \psi = \tilde{\psi} & \text{on } [a, b] \backslash N, \\ \tilde{\psi} \text{ is continuous} & \text{on } [a, b] \backslash N, \\ \lambda(N) = 0. \end{cases} \tag{4.17}$$

Thus, $\lambda(\Delta_\psi \backslash N) > 0$ and we set

$$\Delta'_\psi = \Delta_\psi \backslash N; \tag{4.18}$$

moreover, we may assume the elements of Δ'_ψ to be points of discontinuity of the second kind, since those of the first kind are at most countable (this is true for every real function) and hence may be assumed to be elements of N.

Let $y \in \Delta'_\psi$. Let $\varepsilon > 0$ be fixed and such that $\varepsilon < \psi(y) - \underline{\lim}_{z \to y} \psi(z)$. This is possible since ψ is u.s.c., and we are assuming that y is a point of discontinuity of the second kind, so $\psi(y) \geq \overline{\lim}_{z \to y} \psi(z) > \underline{\lim}_{z \to y} \psi(z)$. By continuity, since $y \in [a, b] \backslash N$, there exists $n_0 \in \mathbb{N}$ such that

$$|z - y| < 1/n_0, \qquad z \in [a, b] \backslash N \Rightarrow |\psi(z) - \psi(y)| < \varepsilon. \tag{4.19}$$

On the other hand, since $\psi(y) - \varepsilon > \underline{\lim}_{z \to y} \psi(z)$, it follows from (4.19) that

$$\exists x_0 \in N \cap B(y, 1/n_0) \quad \text{such that } \psi(x_0) < \psi(y) - \varepsilon. \tag{4.20}$$

Let $m_0 \in \mathbb{N}$ be such that $B(x_0, 1/m_0) \subset B(y, 1/n_0)$, then from $\lambda(N) = 0$ follows

$$\forall\, m \geq m_0 \quad \exists q_m \in ([a, b] \backslash N) \cap B(x_0, 1/m); \tag{4.21}$$

thus $\{q_m\} \subset [a, b] \backslash N$, $q_m \to x_0$ as $m \to \infty$, and we have

$$m \geq m_0 \Rightarrow q_m \in B(y, 1/n_0). \tag{4.22}$$

So (4.19) and (4.22) imply

$$m \geq m_0 \Rightarrow |\psi(q_m) - \psi(y)| < \varepsilon; \tag{4.23}$$

therefore,

$$\psi(y) - \varepsilon \leq \varliminf_{m\to\infty} \psi(q_m), \tag{4.24}$$

but $q_m \to x_0$ as $m \to \infty$ and ψ is u.s.c., so we must also have

$$\varliminf_{m\to\infty} \psi(q_m) \leq \overline{\lim_{z\to x_0}} \psi(z) \leq \psi(x_0). \tag{4.25}$$

Then (4.24) an (4.25) contradict (4.20) and the theorem is proved. □

Remark 4.12. The hypothesis that ψ is u.s.c. is absolutely crucial in Theorem 4.11, as shown by the simple example $\psi = 1_{\mathbb{Q}}$, where $\mathbb{Q}$ is the set of all rational numbers. In fact, $1_{\mathbb{Q}} \in BV(\mathbb{R})$ since $1_{\mathbb{Q}}$ is almost everywhere equal to the function of constant value zero, but $\Delta_{1_{\mathbb{Q}}} = \mathbb{R}$!

COROLLARY 4.13. *Assume* (LFP). *Then* $\lambda(\Delta_{\psi_i}) = 0, i = 1, 2$.

Proof. This follows trivially from Theorem 4.11, Theorem 4.10, and Lemma 3.3. □

COROLLARY 4.14. *Assume* (LFP). *Then the free boundary* $\partial\mathcal{A}$ *has two-dimensional Lebesgue measure zero, i.e.,*

$$|\partial\mathcal{A}| = |\partial_1 \cup \partial_2| = 0. \tag{4.26}$$

Proof. We have

$$\partial_1 \subset \{(x_1, x_2) \in \mathbb{R} \times [x_2^0, +\infty) : x_2 \in \Delta_{\psi_1}, x_1 \in [\varliminf_{z\to x_2} \psi_1(z), \psi_1(x_2)]\}$$
$$\cup \{(x_1, x_2) \in \mathbb{R} \times [x_2^0, +\infty) : x_2 \in (\Delta_{\psi_1})^c, x_1 = \psi_1(x_2)\};$$

therefore, Fubini's theorem implies $|\partial_1| = 0$ since $\lambda(\Delta_{\psi_1}) = 0$ by Corollary 4.13 and

$$\forall\, x_2 \in (\Delta_{\psi_1})^c \cap [x_2^0, +\infty) : \lambda(\{\psi_1(x_2)\}) = 0.$$

Similarly, $|\partial_2| = 0$ and (4.26) follows. □

Now we set

$$\tilde{\mathcal{A}} = \text{int}(\text{cl}(\mathcal{A})), \tag{4.27}$$

$$\tilde{\partial} = \partial\tilde{\mathcal{A}}, \tag{4.28}$$

$$\begin{cases} \tilde{\partial}_1 = \partial R_1 \cap \tilde{\partial}, \\ \tilde{\partial}_2 = \partial R_2 \cap \tilde{\partial}. \end{cases} \tag{4.29}$$

We need the following lemma whose proof is given in the Appendix.

LEMMA 4.15.

$$\begin{cases} \partial_i \backslash \tilde{\partial}_i = R_i \cap \tilde{\mathcal{A}}, & i = 1, 2, \\ \partial_0 \subset \tilde{\partial}. \end{cases}$$

COROLLARY 4.16. *Assume* (LFP). *Then the set* $\partial\mathcal{A}\backslash\partial\tilde{\mathcal{A}}$ *has empty intersection with* $\partial_M\mathcal{A}$, *the measure theoretic boundary of* $\mathcal{A}$, *i.e.,*

$$\partial_M\mathcal{A} \subset \partial\tilde{\mathcal{A}}. \tag{4.30}$$

Proof. If $P \in \partial_i \backslash \tilde{\partial}_i$, then $P \in \tilde{\mathcal{A}}$, an open set, so $B(P, r) \subset \tilde{\mathcal{A}}$ for r sufficiently small. Now the result follows immediately from (cf. Lemma 4.15)

$$|R_i \cap \tilde{\mathcal{A}}| = |\partial_i \backslash \tilde{\partial}_i| \leq |\partial_i| = 0$$

and the fact that all the elements of $\partial_M \mathcal{A}$ are points of positive Lebesgue density for both $\mathcal{A}$ and its complement (cf. Definition 4.6). □

We have shown that $\partial \backslash \tilde{\partial}$ is a subset of int(cl($\mathcal{A}$)) whose two-dimensional measure is zero. Moreover, it follows from Lemma 4.15 that

$$\tilde{\mathcal{A}} = \mathcal{A} \cup (\partial \backslash \tilde{\partial}); \tag{4.31}$$

hence $\tilde{\mathcal{A}}$ is also a region of inaction for $\hat{u}$.

Now we want to obtain a representation of $\tilde{\mathcal{A}}$ similar to the one provided by (3.7) for $\mathcal{A}$, i.e., we will show

$$\tilde{\mathcal{A}} = \{(x_1, x_2) \in \mathbb{R}^2 : x_1 > \tilde{\psi}_1(x_2), x_2 > \tilde{\psi}_2(x_1)\}, \tag{4.32}$$

where $\tilde{\psi}_1, \tilde{\psi}_2$ can be selected to be u.s.c. (just as ψ_1, ψ_2 were u.s.c.) and of locally bounded variation in the usual sense (instead, ψ_1, ψ_2 were only elements of $BV_{\text{loc}}(\mathbb{R})$).

We start by showing that $\tilde{\psi}_1, \tilde{\psi}_2$ can be uniquely chosen to be u.s.c. among all the functions provided by Remark 4.3, (c).

We set

$$\text{bv}(\psi_i) = \{\phi : \mathbb{R} \to \mathbb{R} \mid \phi = \psi_i \text{ a.e.}, V_a^b(\phi) < \infty \, \forall \, a, b \in \mathbb{R}, a < b\} \tag{4.33}$$

where the total variation $V_a^b(\phi)$ is defined by (4.3), and $i = 1, 2$. Let

$$\{\text{u.s.c.}\} = \{f : \mathbb{R} \to \mathbb{R} \mid f \text{ is upper semicontinuous}\}. \tag{4.34}$$

For any $\phi \in \text{bv}(\psi_i)$ we define $\bar{\phi} : \mathbb{R} \to \mathbb{R}$ by

$$\bar{\phi}(x) = \overline{\lim_{z \to x}} \, \phi(z), \qquad x \in \mathbb{R}. \tag{4.35}$$

LEMMA 4.17. *Assume* (LFP). *If* $\phi \in \text{bv}(\psi_i)$, *then* $\bar{\phi} \in \text{bv}(\psi_i) \cap \{\text{u.s.c.}\}$. *Moreover,*

$$\bar{\phi}(x) = \overline{\lim_{z \to x}} \, \bar{\phi}(z) \qquad x \in \mathbb{R}. \tag{4.36}$$

Proof. Surely $\text{bv}(\psi_i) \neq \emptyset$ as $\psi_i \in BV_{\text{loc}}(\mathbb{R})$ (cf. Remark 4.3). Let $\phi \in \text{bv}(\psi_i)$, then ϕ is continuous almost everywhere and so

$$\bar{\phi}(x) = \overline{\lim_{z \to x}} \, \phi(z) = \lim_{z \to x} \phi(z) = \phi(x) \quad \text{for a.e. } x \in \mathbb{R},$$

i.e.,

$$\bar{\phi}(x) = \phi(x) = \psi_i(x) \quad \text{for a.e. } x \in \mathbb{R}.$$

From (4.35) follows

$$\forall \varepsilon > 0 \quad \exists \delta_0 > 0 \quad \text{such that } 0 < |z - x| < \delta_0 \Rightarrow \phi(z) \leq \bar{\phi}(x) + \varepsilon;$$

then, if $z \in B(x, \delta_0)$ there exists δ_z such that $B(z, \delta_z) \subset B(x, \delta_0)$, and one has

$$0 < |y - z| < \delta_z \Rightarrow \phi(y) \leq \bar{\phi}(x) + \varepsilon;$$

i.e.,

$$\sup_{0<|y-z|<\delta_z} \phi(y) \le \bar{\phi}(x) + \varepsilon;$$

hence

$$\bar{\phi}(z) = \overline{\lim_{y\to z}}\, \phi(y) \le \bar{\phi}(x) + \varepsilon.$$

So we have

$$\forall\, \varepsilon > 0 \quad \exists \delta_0 > 0 \quad \text{such that } 0 < |z - x| < \delta_0 \Rightarrow \bar{\phi}(z) \le \bar{\phi}(x) + \varepsilon;$$

therefore

$$\overline{\lim_{z\to x}}\, \bar{\phi}(z) \le \bar{\phi}(x), \tag{4.37}$$

i.e., $\bar{\phi} \in \{\text{u.s.c.}\}$.

We now show that $\bar{\phi}$ is of locally bounded variation; in fact, if $a, b \in \mathbb{R}$ are points of continuity of ϕ such that $a < b$, then

$$V_a^b(\bar{\phi}) \le V_a^b(\phi). \tag{4.38}$$

Let $a, b \in \mathbb{R}$ be as above; let $a = x_0 < x_1 < \cdots < x_{n-1} < x_n = b$ such that $x_i - x_{i-1} = (b-a)/n$, $i = 1, 2, \ldots, n$. Also, let $\varepsilon > 0$, then from

$$\bar{\phi}(x_i) = \overline{\lim_{y\to x_i}}\, \phi(y)$$

follows

(i) there exists $\delta_i > 0$ such that $0 < |y - x_i| < \delta_i \Rightarrow \phi(y) \le \bar{\phi}(x_i) + \varepsilon/(2n)$, and with $\delta < \min\{\delta_1, \delta_2, \ldots, \delta_{n-1}, (b-a)/2n\}$,

(ii) there exist $z_1, z_2, \ldots, z_{n-1}$ such that $0 < |z_i - x_i| < \delta$ and $\phi(z_i) \ge \bar{\phi}(x_i) - \varepsilon/(2n)$.

So if we set $z_0 = a$, $z_n = b$ we obtain a new partition $a = z_0 < z_1 < \cdots < z_{n-1} < z_n = b$ of $[a, b]$ such that

$$|\bar{\phi}(x_i) - \phi(z_i)| \le \frac{\varepsilon}{2n} \quad \text{if } i = 1, 2, \ldots, n-1,$$

and

$$|\bar{\phi}(x_j) - \phi(x_j)| = |\phi(x_j) - \phi(x_j)| = 0 \quad \text{if } j = 0, n$$

since a, b are points of continuity of ϕ; hence $\bar{\phi}$ equals ϕ there. Then,

$$\begin{aligned}
&\sum_{i=1}^{n} |\bar{\phi}(x_i) - \bar{\phi}(x_{i-i})| \\
&\qquad \le \sum_{i=1}^{n} \{|\bar{\phi}(x_i) - \phi(z_i)| + |\phi(z_i) - \phi(z_{i-i})| + |\bar{\phi}(x_{i-1}) - \phi(z_{i-1})|\} \\
&\qquad \le \sum_{i=1}^{n} \left\{\frac{\varepsilon}{2n} + |\phi(z_i) - \phi(z_{i-1})| + \frac{\varepsilon}{2n}\right\} \\
&\qquad \le \varepsilon + \sum_{i=1}^{n} |\phi(z_i) - \phi(z_{i-1})| \\
&\qquad \le \varepsilon + V_a^b(\phi);
\end{aligned}$$

therefore, $V_a^b(\bar{\phi}) \le \varepsilon + V_a^b(\phi)$, and since $\varepsilon > 0$ is arbitrary (4.38) follows. Thus,

$$V_a^b(\bar{\phi}) < +\infty \quad \text{for every } a, b \in \mathbb{R}, a < b$$

(if a, b are points of discontinuity of ϕ, then we can always find $a' < a$ and $b' > b$ such that a', b' are points of continuity of ϕ, and we have $V_a^b(\bar{\phi}) \le V_{a'}^{b'}(\bar{\phi}) \le V_{a'}^{b'}(\phi) < \infty$).

It remains to show that the reverse inequality of (4.37) holds too so that (4.36) is verified. We observe that

$$\overline{\lim_{z\to y}}\, \phi(z) = \Big(\lim_{z\to y^+} \phi(z)\Big) \vee \Big(\lim_{z\to y^-} \phi(z)\Big)$$

as well as

$$\overline{\lim_{y\to x}}\, \bar{\phi}(z) = \Big(\lim_{y\to x^+} \bar{\phi}(y)\Big) \vee \Big(\lim_{y\to x^-} \bar{\phi}(y)\Big),$$

since ϕ and $\bar{\phi}$ are of locally bounded variation; hence they admit one-sided limits. Therefore,

$$\begin{aligned}
\overline{\lim_{y\to x}}\, \bar{\phi}(y) &= \Big(\lim_{y\to x^+} \bar{\phi}(y)\Big) \vee \Big(\lim_{y\to x^-} \bar{\phi}(y)\Big) \\
&\ge \Big(\lim_{y\to x^+} \Big(\lim_{z\to y^+} \phi(z)\Big)\Big) \vee \Big(\lim_{y\to x^-} \Big(\lim_{z\to y^-} \phi(z)\Big)\Big) \\
&= \Big(\lim_{z\to x^+} \phi(z)\Big) \vee \Big(\lim_{z\to x^-} \phi(z)\Big);
\end{aligned}$$

i.e.,

$$\overline{\lim_{y\to x}}\, \bar{\phi}(y) \ge \overline{\lim_{z\to x}}\, \phi(z) = \bar{\phi}(x). \tag{4.39}$$

Hence (4.37) and (4.39) imply (4.36), and the lemma is completely proved. □

PROPOSITION 4.18. *Assume* (LFP). *Then, the set*

$$\Big\{\phi \in \operatorname{bv}(\psi_i) \cap \{\text{u.s.c.}\} : \phi(x) = \overline{\lim_{z\to x}}\, \phi(z), x \in \mathbb{R}\Big\}$$

is a singleton $(i = 1, 2)$.

Proof. Assume not and let $\phi_1, \phi_2 \in \operatorname{bv}(\psi_i) \cap \{\text{u.s.c.}\}$ such that $\phi_j(x) = \overline{\lim}_{z\to x} \phi_j(z)$, $j = 1, 2$, and suppose there exists $y_0 \in \mathbb{R}$ such that $\phi_1(y_0) < \phi_2(y_0)$. Since $\phi_j \in \operatorname{bv}(\psi_i)$, ϕ_j admits one-sided limits and so one has

$$\phi_j(x) = \overline{\lim_{z\to x}}\, \phi_j(z) = \Big(\lim_{z\to x^+} \phi_j(z)\Big) \vee \Big(\lim_{z\to x^-} \phi_j(z)\Big). \tag{4.40}$$

Then, there are "essentially" two cases.

Case 1. $\phi_1(y_0) = \lim_{z\to y_0^+} \phi_1(z), \phi_2(y_0) = \lim_{z\to y_0^+} \phi_2(z)$.

Case 2. $\phi_1(y_0) = \lim_{z\to y_0^+} \phi_1(z), \phi_2(y_0) = \lim_{z\to y_0^-} \phi_2(z)$.

In Case 1, let $\varepsilon > 0$ be such that $\phi_1(y_0) + \varepsilon < \phi_2(y_0) - \varepsilon$; then

$$\exists \delta_1, \delta_2 > 0 \quad \text{such that } 0 < z - y_0 < \delta_1 \wedge \delta_2 \Rightarrow \begin{cases} |\phi_1(z) - \phi_1(y_0)| < \varepsilon, \\ |\phi_2(z) - \phi_2(y_0)| < \varepsilon; \end{cases}$$

i.e.,

$$0 < z - y_0 < \delta_1 \wedge \delta_2 \Rightarrow \phi_1(z) < \phi_1(y_0) + \varepsilon < \phi_2(y_0) - \varepsilon < \phi_2(z),$$

but this is impossible since $\phi_1 = \phi_2 = \psi_i$ almost everywhere.

In Case 2 one has

$$\lim_{z \to y_0^-} \phi_1(z) = \underline{\lim}_{z \to y_0} \phi_1(z) \leq \lim_{z \to y_0^+} \phi_1(z) = \phi_1(y_0) < \phi_2(y_0) = \lim_{z \to y_0^-} \phi_2(z);$$

i.e.,

$$\lim_{z \to y_0^-} \phi_1(z) < \lim_{z \to y_0^-} \phi_2(z).$$

Then, the same arguments as for Case 1 show that it is possible to find $\varepsilon > 0$ and $\delta_1, \delta_2 > 0$ such that

$$z < y_0, z \in B(y_0, \delta_1 \wedge \delta_2) \Rightarrow \phi_1(z) < \phi_1(y_0) + \varepsilon < \phi_2(y_0) - \varepsilon < \phi_2(z),$$

and again we end up contradicting $\phi_1 = \phi_2 = \psi_i$ almost everywhere. □

Proposition 4.18 justifies the following definition.

DEFINITION 4.19. *For $i = 1, 2$ we define $\tilde{\psi}_i$ as the unique element of the set*

$$\left\{\phi \in \text{bv}(\psi_i) \cap \{\text{u.s.c.}\} \mid \phi(x) = \overline{\lim_{z \to x}}\, \phi(z), x \in \mathbb{R}\right\}.$$

LEMMA 4.20. *Assume* (LFP). *For every $x \in \mathbb{R}$ one has $\tilde{\psi}_i(x) \leq \psi_i(x), i = 1, 2$.*

Proof. Clearly $\tilde{\psi}_i = \psi_i$ almost everywhere, so let $y_0 \in \mathbb{R}$ be a point where $\tilde{\psi}_i \neq \psi_i$ and let us assume that

$$\tilde{\psi}_i(y_0) > \psi_i(y_0). \tag{4.41}$$

Also, we may assume (for example) that

$$\tilde{\psi}_i(y_0) = \lim_{z \to y_0^-} \tilde{\psi}_i(z), \tag{4.42}$$

since $\tilde{\psi}_i$ satisfies (4.40). Now let $\gamma > 0$ be such that

$$\lim_{z \to y_0^-} \tilde{\psi}_i(z) > \gamma > \psi_i(y_0);$$

then

$$\exists \delta > 0 \quad \text{such that } z < y_0, |z - y_0| < \delta \Rightarrow \tilde{\psi}_i(z) > \gamma;$$

hence

$$\inf_{0 < y_0 - z < \delta} \tilde{\psi}_i(z) \geq \gamma > \psi_i(y_0). \tag{4.43}$$

On the other hand, from the upper semicontinuity of ψ_i follows

$$\gamma > \overline{\lim_{z \to y_0}}\, \psi_i(z),$$

and so

$$\exists \delta_0 > 0 \quad \text{such that} \quad \sup_{0 < |z - y_0| < \delta_0} \psi_i(z) < \gamma. \tag{4.44}$$

Thus, (4.43) and (4.44) imply

$$\sup_{0<y_0-z<\delta\wedge\delta_0} \psi_i(z) < \inf_{0<y_0-z<\delta\wedge\delta_0} \tilde{\psi}_i(z),$$

i.e.,

$$0 < y_0 - z < \delta \wedge \delta_0 \Rightarrow \psi_i(z) < \tilde{\psi}_i(z)$$

and this contradicts $\psi_i = \tilde{\psi}_i$ almost everywhere. Therefore, (4.41) must be false and the lemma is proved. □

LEMMA 4.21. *Assume* (LFP). *For every* $x \in \mathbb{R}$ *one has* $\underline{\lim}_{z\to x} \psi_i(z) \leq \tilde{\psi}_i(x)$, $i = 1, 2$.

Proof. Assume not; then there exists $\bar{x} \in \mathbb{R}$ such that

$$\underline{\lim}_{x\to\bar{x}} \psi_i(z) > \tilde{\psi}_i(\bar{x}); \tag{4.45}$$

but $\tilde{\psi}_i$ satisfies (4.40), so there is no loss of generality if we assume (for example)

$$\tilde{\psi}_i(\bar{x}) = \lim_{z\to\bar{x}^+} \tilde{\psi}_i(z). \tag{4.46}$$

Now let $\gamma > 0$ be such that $\underline{\lim}_{z\to\bar{x}} \psi_i(z) > \gamma > \tilde{\psi}_i(\bar{x})$; then from (4.46) follows

$$\exists \delta_1 > 0 \quad \text{such that } 0 < z - \bar{x} < \delta_1 \Rightarrow \tilde{\psi}_i(z) < \gamma;$$

hence

$$\sup_{0<z-\bar{x}<\delta_1} \tilde{\psi}_i(z) \leq \gamma. \tag{4.47}$$

On the other hand, since $\underline{\lim}_{z\to\bar{x}} \psi_i(z) > \gamma$, we have

$$\exists \delta_2 > 0 \quad \text{such that } \inf_{0<|z-\bar{x}|<\delta_2} \psi_i(z) > \gamma. \tag{4.48}$$

Therefore, if $\delta = \delta_1 \wedge \delta_2$, (4.47) and (4.48) imply

$$\sup_{0<z-\bar{x}<\delta} \tilde{\psi}_i(z) < \inf_{0<z-\bar{x}<\delta} \psi_i(z),$$

i.e.,

$$0 < z - \bar{x} < \delta \Rightarrow \tilde{\psi}_i(z) < \psi_i(z),$$

but this is impossible since $\tilde{\psi}_i = \psi_i$ almost everywhere. □

Remark 4.22. From Lemma 4.20 and Lemma 4.21 one has

$$\underline{\lim}_{z\to x} \psi_i(z) \leq \tilde{\psi}_i(x) = \overline{\lim}_{z\to x} \tilde{\psi}_i(z) \leq \overline{\lim}_{z\to x} \psi_i(z) \leq \psi_i(x), \tag{4.49}$$

for every $x \in \mathbb{R}, i = 1, 2$. In particular, Lemma 4.20 implies that

$$\text{graph}(\tilde{\psi}_1) \cap \text{graph}(\tilde{\psi}_2) = \{P_0\}, \tag{4.50}$$

since $\tilde{\psi}_i \equiv \psi_i$ on $(-\infty, x_j^0]$ (by Proposition 3.6, (iii), Lemma 3.8, and the definition of $\tilde{\psi}_i$).

PROPOSITION 4.23. *Assume* (LFP). *For the non-dense part of R_i in $\tilde{\mathcal{A}}$, $\partial_i\backslash\tilde{\partial}_i$, one has*

$$\text{(4.51)}\qquad \begin{cases} \partial_1\backslash\tilde{\partial}_1 \subset \left\{(x_1,x_2) : x_1 \in \left(\underline{\lim}_{z\to x_2} \psi_1(z), \psi_1(x_2)\right], x_2 > \psi_2(x_1)\right\}, \\ \partial_2\backslash\tilde{\partial}_2 \subset \left\{(x_1,x_2) : x_2 \in \left(\underline{\lim}_{z\to x_1} \psi_2(z), \psi_2(x_1)\right], x_1 > \psi_1(x_2)\right\}. \end{cases}$$

Proof. Let us recall that $\partial_1\backslash\tilde{\partial}_1 = R_1 \cap \tilde{\mathcal{A}}$ (cf. Lemma 4.15). Let $P = (x_1, x_2) \in \partial_1\backslash\tilde{\partial}_1$; then $P \in R_1$ and hence (cf. (4.9))

$$\text{(4.52)}\qquad x_1 \le \psi_1(x_2), \qquad x_2 > \psi_2(x_1).$$

Also, $P \in \tilde{\mathcal{A}}$ and $\tilde{\mathcal{A}}$ is open, so there is an open ball $B(P,r) \subset \tilde{\mathcal{A}}$, but then (cf. Corollary 4.14)

$$\text{(4.53)}\qquad |B(P,r) \cap R_1| \le |\tilde{\mathcal{A}} \cap R_1| = |\partial_1\backslash\tilde{\partial}_1| \le |\partial_1| = 0.$$

Claim. $x_1 > \underline{\lim}_{z\to x_2} \psi_1(z)$.
In fact, if not, then $x_1 \le \underline{\lim}_{z\to x_2} \psi_1(z)$. Thus,

$$\text{(4.54)}\qquad \forall \varepsilon > 0 \quad \exists \delta > 0 \quad \text{such that} \inf_{0<|z-x_2|<\delta} \psi_1(z) > x_1 - \varepsilon.$$

On the other hand, since ψ_2 is u.s.c., from $x_2 > \psi_2(x_1)$ follows

$$\text{(4.55)}\qquad \exists \varepsilon_0 < r/2 \quad \text{such that} \sup_{0<|t-x_1|<2\varepsilon_0} \psi_2(t) < x_2,$$

and from this we have

$$\text{(4.56)}\qquad \psi_2(x_1 - \varepsilon_0) < x_2 \quad \text{and} \quad (x_1 - \varepsilon_0, x_2) \in B(P,r).$$

Now (4.54) with $\varepsilon = \varepsilon_0$ implies

$$\text{(4.57)}\qquad \exists \delta_0 > 0 \quad \text{such that } 0 < |z - x_2| < \delta_0 \Rightarrow \psi_1(z) > x_1 - \varepsilon_0;$$

hence (4.56) and (4.57) imply

$$0 < z - x_2 < \delta_0 \Rightarrow \begin{cases} \psi_1(z) > x_1 - \varepsilon_0, \\ \psi_2(x_1 - \varepsilon_0) < z; \end{cases}$$

therefore (cf. (4.9))

$$0 < z - x_2 < \delta_0 \Rightarrow (x_1 - \varepsilon_0, z) \in R_1.$$

Also, since $(x_1 - \varepsilon_0, x_2) \in B(P,r)$,

$$\exists \delta_1 > 0 \quad \text{such that } 0 < z - x_2 < \delta_1 \Rightarrow (x_1 - \varepsilon_0, z) \in B(P,r);$$

so for $\delta = \delta_1 \wedge \delta_0$ we have

$$\text{(4.58)}\qquad 0 < z - x_2 < \delta \Rightarrow (x_1 - \varepsilon_0, z) \in R_1 \cap B(P,r),$$

but then, also,

$$\left\{(t,z) \in B(P,r) : x_1 - r < t \le x_1 - \varepsilon_0, x_2 < z < x_2 + \delta\right\} \subset R_1;$$

hence

$$|R_1 \cap B(P,r)| > \frac{(r-\varepsilon_0)\delta}{2} \neq 0, \tag{4.59}$$

and this is impossible because of (4.53). So the claim follows. The claim and (4.52) prove $(4.51)_1$. (The proof of $(4.51)_2$ is the same.) □

PROPOSITION 4.24. *Assume* (LFP). *If* $\bar{x}_j \in \pi_j(\partial_i \backslash \tilde{\partial}_i)$ *where* π_j *is the orthogonal projection on the* x_j*-axis, then*

$$(\partial_i \backslash \tilde{\partial}_i) \cap \left(\left(\varliminf_{z \to \bar{x}_j} \psi_i(z), \tilde{\psi}_i(\bar{x}_j) \right] \times \{\bar{x}_j\} \right) = \emptyset \quad \text{for } i \neq j, \quad i,j = 1,2.$$

Proof. Assume not and take $i = 1, j = 2$ for simplicity. Let $P = (\bar{x}_1, \bar{x}_2) \in \partial_1 \backslash \tilde{\partial}_1$ with

$$\bar{x}_1 \in \left(\varliminf_{z \to \bar{x}_2} \psi_1(z), \tilde{\psi}_1(\bar{x}_2) \right].$$

As in the proof of Proposition 4.23 (cf. (4.53)), from $P \in \partial_1 \backslash \tilde{\partial}_1$ and $\partial_1 \backslash \tilde{\partial}_1 = R_1 \cap \tilde{\mathcal{A}}$ follows that for some $r > 0$, $B(P,r) \subset \tilde{\mathcal{A}}$ and

$$|B(P,r) \cap R_1| = 0. \tag{4.60}$$

Thus, we can select $\gamma \in (\bar{x}_1 - r, \bar{x}_1 + r)$ such that

$$1_{R_1}(\gamma, \cdot) = 0 \qquad \text{a.e. in } B_\gamma(P,r). \tag{4.61}$$

where

$$B_\gamma(P,r) = \{z : (\gamma, z) \in B(P,r)\}.$$

In particular, we may fix

$$\gamma \in (\bar{x}_1 - r, \bar{x}_1 + r) \cap \left(\varliminf_{z \to \bar{x}_2} \psi_1(z), \tilde{\psi}_1(\bar{x}_2) \right),$$

and we may assume (for example)

$$\tilde{\psi}_1(\bar{x}_2) = \varliminf_{z \to x_{2-}} \tilde{\psi}_1(z), \tag{4.62}$$

since $\tilde{\psi}_1$ satisfies (4.40) and Proposition 4.18. Then, (4.62) and $\gamma < \tilde{\psi}_1(\bar{x}_2)$ imply

$$\exists \delta > 0 \quad \text{such that } 0 < \bar{x}_2 - z < \delta \Rightarrow \gamma < \tilde{\psi}_1(z). \tag{4.63}$$

On the other hand, (4.61) implies

$$(\gamma, z) \notin R_1 \quad \text{for a.e. } z \in B_\gamma(P,r); \tag{4.64}$$

therefore it must be

$$(\gamma, z) \in \mathcal{A} \quad \text{for a.e. } z \in B_\gamma(P,r), \tag{4.65}$$

since locally R_1 is the complement of $\mathcal{A}$. (In fact, since $R_1 \cap (R_2 \cup R_0) = \emptyset$, we can always assume $B(P,r) \cap (R_2 \cup R_0) = \emptyset$, with r smaller if necessary.) So from (4.65) we deduce

$$\gamma > \psi_1(z), \quad z > \psi_2(\gamma) \quad \text{for a.e. } z \in B_\gamma(P,r). \tag{4.66}$$

But $\tilde{\psi} \leq \psi_1$ by Lemma 4.20; hence (4.63) and (4.66) imply

$$\gamma > \psi_1(z) \geq \tilde{\psi}_1(z) > \gamma \quad \text{for a.e. } z \in (\bar{x}_2 - \eta, \bar{x}_2) \tag{4.67}$$

for $\eta = \min\{r, \delta\}$, and we have a contradiction. □

COROLLARY 4.25. *Assume* (LFP). *For the non-dense part of R_i in $\tilde{\mathcal{A}}, \partial_i \backslash \tilde{\partial}_i$, one has*

$$\begin{cases} \partial_1 \backslash \tilde{\partial}_1 \subset \{(x_1, x_2) : x_1 \in (\tilde{\psi}_1(x_2), \psi_1(x_2)], x_2 > \psi_2(x_1)\}, \\ \partial_2 \backslash \tilde{\partial}_2 \subset \{(x_1, x_2) : x_2 \in (\tilde{\psi}_2(x_1), \psi_2(x_1)], x_1 > \psi_1(x_2)\}. \end{cases} \tag{4.68}$$

Proof. This follows from Proposition 4.23 and Proposition 4.24. □

We can improve Corollary 4.25. In fact, we now show that the inclusions in (4.68) are equalities.

PROPOSITION 4.26. *Assume* (LFP). *The non-dense part of R_i in $\tilde{\mathcal{A}}, \partial_i \backslash \tilde{\partial}_i$, may be characterized as*

$$\begin{cases} \partial_1 \backslash \tilde{\partial}_1 = \{(x_1, x_2) : x_1 \in (\tilde{\psi}_1(x_2), \psi_1(x_2)], x_2 > \psi_2(x_1)\}, \\ \partial_2 \backslash \tilde{\partial}_2 = \{(x_1, x_2) : x_2 \in (\tilde{\psi}_2(x_1), \psi_2(x_1)], x_1 > \psi_1(x_2)\}. \end{cases} \tag{4.69}$$

Proof. Let $P = (\bar{x}_1, \bar{x}_2) \in \{(x_1, x_2) : x_1 \in (\tilde{\psi}_1(x_2), \psi_1(x_2)], x_2 > \psi_2(x_1)\}$; then $\bar{x}_1 > \tilde{\psi}_1(\bar{x}_2)$, and let us assume that $\psi_1(\bar{x}_2) = \lim_{z \to \bar{x}_2^+} \tilde{\psi}_1(z)$ (this is possible because of (4.40)). So we have

$$\bar{x}_1 > \tilde{\psi}_1(\bar{x}_2) = \lim_{z \to \bar{x}_2^+} \tilde{\psi}_1(z) = \overline{\lim_{z \to \bar{x}_2}} \tilde{\psi}_1(z) \geq \underline{\lim_{z \to \bar{x}_2}} \tilde{\psi}_1(z) = \lim_{z \to \bar{x}_2^-} \tilde{\psi}_1(z);$$

therefore, if $\gamma > 0$ is such that $\bar{x}_1 > \gamma > \tilde{\psi}_1(\bar{x}_2)$, then

$$\exists \delta > 0 \quad \text{such that } |z - \bar{x}_2| < \delta \Rightarrow \tilde{\psi}_1(z) < \gamma < \bar{x}_1.$$

So it is possible to find a ball $B(P, r)$ with $r < \bar{x}_1 - \gamma, r < \delta$, such that

(i) $\{(\tilde{\psi}_1(z), z) : z \in (\bar{x}_2 - \delta, \bar{x}_2 + \delta)\} \cap B(P, r) = \emptyset$,

(ii) $B(P, r) \cap (R_2 \cup \text{int}(R_0)) = \emptyset$

(note that (ii) follows from the fact that $P \in R_1$ and $R_1 \cap (R_2 \cup R_0) = \emptyset$ as in the proof of (4.65)). Now (i) and $\psi_1 > \tilde{\psi}_1$ only on a null set imply

$$\lambda(\{z \in (\bar{x}_2 - \delta, \bar{x}_2 + \delta) : \psi_1(z) > \gamma\}) = 0;$$

hence from Fubini's Theorem, (ii), and the definition of R_1 follows

$$|B(P, r) \cap R_1| = 0,$$

so that P is in the non-dense part of R_1 in $\tilde{\mathcal{A}}, \partial_1 \backslash \tilde{\partial}_1$. Hence $(4.69)_1$ follows from Corollary 4.25. (The proof of $(4.69)_2$ is the same.) □

Remark 4.27. We point out that there may be other points $P \in \partial_i$ such that $D(R_i, P) = 0$; these are points where ψ_i has a cusp pointing into $\mathcal{A}$, and they too have zero Lebesgue density with respect to R_i. The difference between such points and those in $\partial_i \backslash \tilde{\partial}_i$ is that the latter ones verify a condition even stronger than $D(R_i, P) = 0$, namely (4.53), i.e.,

$$\exists r > 0 \quad \text{s.t. } |R_i \cap B(P, r)| = 0. \tag{4.70}$$

We are now ready to characterize the boundary of the new region of inaction $\tilde{\mathcal{A}}$.

THEOREM 4.28. *Assume* (LFP). *The new region of inaction* $\tilde{\mathcal{A}} = \operatorname{int}(\operatorname{cl}(\mathcal{A}))$ *is given by*

$$\tilde{\mathcal{A}} = \{(x_1, x_2) \in \mathbb{R}^2 : x_1 > \tilde{\psi}_1(x_2), x_2 > \tilde{\psi}_2(x_1)\} \tag{4.71}$$

with $\tilde{\psi}_1$ *and* $\tilde{\psi}_2$ *as in Definition* 4.19.

Proof. It suffices to recall (cf. (4.31)) that

$$\tilde{\mathcal{A}} = \mathcal{A} \cup (\partial\mathcal{A} \backslash \partial\tilde{\mathcal{A}}) = \mathcal{A} \cup \bigcup_{i=1}^{2} \partial_i \backslash \tilde{\partial}_i,$$

so (4.71) follows from (4.7), $\tilde{\psi}_i \leq \psi_i, \tilde{\psi}_i = \psi_i$ almost everywhere, Proposition 4.26, and the fact that

$$\{(x_1, x_2) : \psi_1(x_2) \geq x_1 > \tilde{\psi}_1(x_2), \psi_2(x_1) \geq x_2 > \tilde{\psi}_2(x_1)\} = \emptyset \tag{4.72}$$

(in fact, $x_1 \leq \psi_1(x_2)$ and $x_2 \leq \psi_2(x_1)$ imply $(x_1, x_2) \in R_0 = \{(x_1^0, x_2^0)\} - \Lambda^*$, i.e., $x_i \in (-\infty, x_i^0], i = 1, 2$, but there $\psi_i = \tilde{\psi}_i$ (cf. Remark 4.22)). □

Hence $\partial\tilde{\mathcal{A}}$ is essentially obtained by adding all the finite line segments corresponding to the jumps of $\tilde{\psi}_i$ to the graph of $\tilde{\psi}_i|_{[x_j^0, \infty)}, i = 1, 2, j = 1, 2, j \neq i$.

DEFINITION 4.29. *Let* $\{\zeta_j\}_{j=1}^{\infty}$ *and* $\{\xi_j\}_{j=1}^{\infty}$ *be the points of discontinuity of* $\tilde{\psi}_1$ *and* $\tilde{\psi}_2$, *respectively. Then we set*

$$\begin{cases} \tilde{\psi}_1[\underline{j}] = \underline{\lim}_{z \to \zeta_j} \tilde{\psi}_1(z), \\ \tilde{\psi}_1[j] = \overline{\lim}_{z \to \zeta_j} \tilde{\psi}_1(z) = \tilde{\psi}_1(\zeta_j), \end{cases} \tag{4.73}$$

and similarly

$$\begin{cases} \tilde{\psi}_2[\underline{j}] = \underline{\lim}_{z \to \xi_j} \tilde{\psi}_2(z), \\ \tilde{\psi}_2[j] = \overline{\lim}_{z \to \xi_j} \tilde{\psi}_2(z) = \tilde{\psi}_2(\xi_j), \end{cases} \tag{4.74}$$

for every $j \in \mathbb{N}$.

PROPOSITION 4.30. *Assume* (LFP). *Then the new free boundary* $\partial\tilde{\mathcal{A}}$ *is given by*

$$\begin{aligned} \partial\tilde{\mathcal{A}} = \tilde{\partial}_1 \cup \tilde{\partial}_2 \; = & \left(\operatorname{graph}(\tilde{\psi}_1|_{[x_2^0, +\infty)}) \cup \bigcup_{j=1}^{\infty} [\tilde{\psi}_1[\underline{j}], \tilde{\psi}_1[j]) \times \{\zeta_j\} \right) \\ & \cup \left(\operatorname{graph}(\tilde{\psi}_2|_{[x_1^0, +\infty)}) \cup \bigcup_{j=1}^{\infty} \{\xi_j\} \times [\tilde{\psi}_2[\underline{j}], \tilde{\psi}_2[j]) \right). \end{aligned} \tag{4.75}$$

Proof. This is obvious from Theorem 4.28. □

As we observed at the beginning of this section, all points on the boundary $\partial\tilde{\mathcal{A}}$ where a tangent vector exists belong to the measure-theoretic boundary $\partial_M\tilde{\mathcal{A}}$. Here we show that this is in fact the case for almost every point of $\partial\tilde{\mathcal{A}}$. This result is an obvious consequence of the rectifiability of the boundaries $\tilde{\partial}_1$ and $\tilde{\partial}_2$. (Recall that $\tilde{\partial}_i$ is rectifiable since $\tilde{\psi}_i$ is a function of bounded variation.)

PROPOSITION 4.31. *Assume* (LFP). *Then the topological boundary $\partial\tilde{\mathcal{A}}$ and the measure-theoretic boundary $\partial_M\tilde{\mathcal{A}}$ are the same except for a set of one-dimensional Hausdorff measure zero, i.e.,*

$$H^1(\partial\tilde{\mathcal{A}}\backslash\partial_M\tilde{\mathcal{A}}) = 0. \tag{4.76}$$

Proof. It suffices to show that there exists a definite tangent to $\partial\tilde{\mathcal{A}}$ almost everywhere with respect to the one-dimensional Hausdorff measure H^1 in $\mathbb{R}^2$. But $\tilde{\psi}_1$ and $\tilde{\psi}_2$ are functions of locally bounded variation (in the usual sense); hence $\tilde{\partial}_1$ and $\tilde{\partial}_2$ are locally rectifiable curves, and the measure H^1 coincides with the arc-length s. Also, a result due to Tonelli (cf. [14]) guarantees that the classical formula

$$(s'(t))^2 = (x'(t))^2 + (y'(t))^2$$

is valid almost everywhere with respect to the parameter t for every rectifiable curve (if locally, $x = x(t)$, $y = y(t)$ is a parametric representation of the curve). In particular, if we choose the arc-length s as parameter, we obtain

$$(x'(s))^2 + (y'(s))^2 = 1 \qquad \text{a.e.}$$

and hence $x'(s), y'(s)$ exist almost everywhere (and are not both zero almost everywhere) assuring the existence of a definite tangent almost everywhere with respect to s. □

Finally, from Proposition 4.31 and Theorem 4.8 we obtain the regularity of the entire boundary of the new region of inaction.

THEOREM 4.32. *Assume* (LFP). *Then the new region of inaction $\tilde{\mathcal{A}}$ is of locally finite perimeter and its boundary $\partial\tilde{\mathcal{A}}$ is countably 1-rectifiable, i.e.,*

$$\partial\tilde{\mathcal{A}} \subset \bigcup_{i=1}^{\infty} M_i \cup N, \tag{4.77}$$

where $H^1(N) = 0$ and each M_i is a one-dimensional embedded C^1 submanifold of $\mathbb{R}^2$. □

5. Verification of (LFP). In the previous section we obtained the regularity of the free boundary arising in the control problem defined by (2.1) under the assumption (LFP); that is, we assumed the region of inaction $\mathcal{A}$ to be of locally finite perimeter. We aim to show that such an assumption is, after all, reasonable and verifiable. We restrict ourselves to the case where the diffusion matrix σ is nondegenerate. Such a condition naturally implies the coercivity (see below) of the bilinear form $a(u, v)$ associated with the operator Au, and this will allow us to show (LFP) by means of a localization of a result obtained by Brezis and Kinderlehrer [1] in the framework of variational inequalities with obstacles relative to locally coercive vector fields.

In addition to the assumptions stated in §2, we now assume the following:

$$\sigma\sigma^* \text{ is positive definite;} \tag{5.1}$$

$$f \in C^2(\mathbb{R}^2); \tag{5.2}$$

$$f_{x_i} \text{ and } \nabla(f_{x_i}) \text{ never vanish simultaneously } (i = 1, 2). \tag{5.3}$$

(It should be noticed that we already had $f \in C^{1,1}(\mathbb{R}^2)$ as this follows from the growth conditions (2.5)–(2.7) by using the same arguments as in Theorem 2.1.) Let $W_0^{1,2}(\Omega)$ be the closure of $C_0^\infty(\Omega)$ in $W^{1,2}(\Omega)$, for any open set $\Omega \subset \mathbb{R}^2$.

DEFINITION 5.1 ([6, p. 15]). *A bilinear form $a(u,v)$ is said to be coercive on $W_0^{1,2}(\Omega)$ if*

$$\exists \nu > 0 \quad \text{such that } a(u,u) \geq \nu \|u\|_{1,2}^2 \quad \text{for every } u \in W_0^{1,2}(\Omega), \tag{5.4}$$

where $\|\cdot\|_{1,2}$ is the norm in $W^{1,2}(\Omega)$.

In particular, we consider the bilinear form $a(u,v)$ associated with the operator Au, i.e.,

$$a(u,v) := \int_\Omega \left\{ \frac{1}{2} \sum_{i,j=1}^{2} (\sigma\sigma^*)_{ij} u_{x_i} v_{x_j} - \sum_{i=1}^{2} g_i u_{x_i} v + \rho uv \right\} dx \tag{5.5}$$

for $u, v \in W^{1,2}(\Omega)$, with Ω open in $\mathbb{R}^2$ (to be chosen later). Let us recall a few known results.

LEMMA 5.2 ([15, Lemma 4.3]). *Assume* (5.1). *Let $\Omega \subset \mathbb{R}^2$ be an open ball and let $a(u,v)$ be defined by* (5.5). *Then, $a(u,v)$ is coercive on $W_0^{1,2}(\Omega)$.*

Proof. This follows from $\rho > 0$, $\sigma\sigma^*$ positive definite and $\int_\Omega u u_{x_i} dx = 0$ for $u \in W_0^{1,2}(\Omega), i = 1,2$. □

DEFINITION 5.3. *Let a be as in* (5.5) *and let*

$$\mathbb{K}(\Omega) := \{v \in W^{1,2}(\Omega) : v \geq 0 \text{ a.e. in } \Omega\}. \tag{5.6}$$

We say that w is a local solution of the variational inequality

$$a(w, v-w) \geq (f_{x_i}, v-w) \qquad \forall v \in \mathbb{K}(\Omega), \tag{5.7}$$

if $w \in \mathbb{K}(\Omega)$ and we have

$$a(w, \eta(v-w)) \geq \int_\Omega f_{x_i} \eta (v-w)\, dx \quad \forall v \in \mathbb{K}(\Omega), \eta \in C_0^\infty(\Omega), \eta \geq 0. \tag{5.8}$$

THEOREM 5.4 ([15, Theorem 4.5]). *Assume* (5.1) *and* (5.2). *Let Ω be an open ball such that* $\mathrm{cl}(\Omega) \subset S_i$ *where*

$$S_i := \{x \in \mathbb{R}^2 : \hat{u}_{x_j}(x) > 0, j \neq i\}, \tag{5.9}$$

then $\hat{u}_{x_i}$ is a local solution of (5.7), $i = 1,2$.

THEOREM 5.5 ([6, problem 5, p. 30 and problem 1, p. 44]; [15, Thm. 4.6]). *Assume* (5.1) *and* (5.2). *Let Ω be an open ball such that* $\mathrm{cl}(\Omega) \subset S_i$, *then*

(i) $\hat{u}_{x_i} \in W^{2,\infty}(\Omega)$;

(ii) $A\hat{u}_{x_i} \geq f_{x_i}, \hat{u}_{x_i} \geq 0, (A\hat{u}_{x_i} - f_{x_i})\hat{u}_{x_i} = 0$ *almost everywhere in* Ω.

Clearly,

$$S_i = R_i \cup \mathcal{A}, \qquad i = 1,2;$$

hence Theorem 5.5(i) implies (for $i = 1,2$)

$$\hat{u}_{x_i} \in C^{1,1}(\Omega) \tag{5.10}$$

if Ω is an open ball such that $\mathrm{cl}(\Omega) \subset R_i \cup \mathcal{A}$.

The following lemma is proved in the Appendix.

LEMMA 5.6 ([6, problem 5, p. 30]). *Assume* (5.1) *and* (5.2). *If w is a local solution of* (5.7), *then*

$$
\begin{aligned}
a(\gamma w, v-\gamma w) \geq & \int_\Omega f_{x_i}\gamma(v-\gamma w)\,dx \\
& - \int_\Omega \left\{ \frac{1}{2}\sum_{i,j=1}^{2} (\sigma\sigma^*)_{ij} w\gamma_{x_i x_j} + \sum_{i,j=1}^{2} (\sigma\sigma^*)_{ij} w_{x_i}\gamma_{x_j} \right\} (v-\gamma w)\,dx \\
& - \int_\Omega \sum_{i=1}^{2} g_i \gamma_{x_i} w(v-\gamma w)\,dx
\end{aligned} \tag{5.11}
$$

for every $v \in \mathbb{K}_0(\Omega)$ and $\gamma \in C_0^\infty(\Omega), \gamma = 1$ on $\Omega', 0 \leq \gamma \leq 1$ in Ω ($\mathrm{cl}(\Omega') \subset \Omega$), where

$$
\mathbb{K}_0(\Omega) := \{v \in W_0^{1,2}(\Omega) : v \geq 0 \text{ a.e.}\}. \tag{5.12}
$$

Remark 5.7. We point out that, if w is a local solution of (5.7), then γw is the unique solution of (5.11) since $a(u,v)$ is coercive (cf. [6, Thm. 2.7, p. 15]).

Let us define the bilinear form

$$
\tilde{a}(u,v) := \int_\Omega \frac{1}{2}\sum_{i,j=1}^{2} (\sigma\sigma^*)_{ij} u_{x_i} v_{x_j}\,dx \tag{5.13}
$$

for $u, v \in W^{1,2}(\Omega)$, Ω open in $\mathbb{R}^2$; also, we set

$$
\begin{aligned}
\tilde{F}_r := & f_{x_r}\gamma - \frac{1}{2}\sum_{i,j=1}^{2} (\sigma\sigma^*)_{ij}\hat{u}_{x_r}\gamma_{x_i x_j} \\
& - \frac{1}{2}\sum_{i,j=1}^{2} (\sigma\sigma^*)_{ij}(\hat{u}_{x_r})_{x_i}\gamma_{x_j} + \sum_{i=1}^{2} g_i (\hat{u}_{x_r})_{x_i}\gamma \\
& - \rho\hat{u}_{x_r}\gamma, \qquad r = 1,2.
\end{aligned} \tag{5.14}
$$

Then, if Ω is an open ball such that $\mathrm{cl}(\Omega) \subset R_r \cup \mathcal{A}\,(r = 1,2)$ and $\gamma \in C_0^\infty(\Omega), \gamma = 1$ on $\Omega', 0 \leq \gamma \leq 1$ in Ω, $\mathrm{cl}(\Omega') \subset \Omega$, from Theorem 5.4 it follows that $w = \hat{u}_{x_r}$ satisfies (5.11), which can be restated as

$$
\tilde{a}(\gamma\hat{u}_{x_r}, v-\gamma\hat{u}_{x_r}) \geq \int_\Omega \tilde{F}_r(v-\gamma\hat{u}_{x_r})\,dx, \qquad \forall\, v \in \mathbb{K}_0(\Omega), \tag{5.15}
$$

where $\hat{u}_{x_r} \in W^{2,\infty}(\Omega)$ (by Theorem 5.5(i)), and hence $\tilde{F}_r \in W^{1,\infty}(\Omega)$ (by (5.14)). Clearly, the bilinear form $\tilde{a}(u,v)$ is coercive and $\gamma\hat{u}_{x_r} \in \mathbb{K}_0(\Omega)$; hence $\gamma\hat{u}_{x_r}$ is the unique solution of (5.15) (cf. Remark 5.7). Also, if we denote by

$$
\tilde{A}w = -\frac{1}{2}\sum_{i,j=1}^{2} (\sigma\sigma^*)_{ij} w_{x_i x_j} \tag{5.16}
$$

whenever the RHS makes sense (in the sense of distributions), then (5.15) may be formulated as

$$
(\tilde{A}(\gamma\hat{u}_{x_r}), v-\gamma\hat{u}_{x_r}) \geq \int_\Omega \tilde{F}_r(v-\gamma\hat{u}_{x_r})\,dx, \qquad \forall\, v \in \mathbb{K}_0(\Omega); \tag{5.17}
$$

now we observe that $\gamma\hat{u}_{x_r}$ is a Lipschitz function (in fact, $\gamma\hat{u}_{x_r} \in C^{1,1}(\Omega)$ by Sobolev embedding theorem); hence we can restrict (5.17) to $\mathcal{L}_0(\Omega)$, the convex set of Lipschitz functions v satisfying $v|_{\partial\Omega} = 0$ and $v \geq 0$ almost everywhere in Ω; i.e.,

$$(\tilde{A}(\gamma\hat{u}_{x_r}), v - \gamma\hat{u}_{x_r}) \geq \int_\Omega \tilde{F}_r(v - \gamma\hat{u}_{x_r})\,dx, \qquad \forall\, v \in \mathcal{L}_0(\Omega). \tag{5.18}$$

The variational inequality (5.18) is now in the setting of the problem studied by Brezis and Kinderlehrer [1], except for the fact that our $\tilde{F}_r \in W^{1,\infty}(\Omega)$, while theirs is in $C^1(\mathrm{cl}(\Omega))$. However, it is easy to see that all their estimates still hold in our case since they depend only on $\|\tilde{F}_r\|_{1,\infty}$ (where $\|\cdot\|_{1,\infty}$ is the norm in $W^{1,\infty}(\Omega)$); hence Brezis and Kinderlehrer's Theorem 4 applies and provides us with

$$\tilde{A}(\gamma\hat{u}_{x_r}) \in BV_{\mathrm{loc}}(\Omega), \qquad r = 1, 2. \tag{5.19}$$

Since $\tilde{A}(\gamma\hat{u}_{x_r}) = A(\gamma\hat{u}_{x_r}) + \sum_{i=1}^2 g_i(\gamma\hat{u}_{x_r})_{x_i} - \rho\gamma\hat{u}_{x_r}$ and $\gamma\hat{u}_{x_r} \in C^{1,1}(\Omega)$ (as we observed above), from (5.19) follows

$$A(\gamma\hat{u}_{x_r}) \in BV_{\mathrm{loc}}(\Omega), \qquad r = 1, 2; \tag{5.20}$$

but $\gamma \equiv 1$ on Ω', $\mathrm{cl}(\Omega') \subset \Omega$; hence we have

$$A\hat{u}_{x_r} \in BV_{\mathrm{loc}}(\Omega), \qquad r = 1, 2. \tag{5.21}$$

Now (5.21) and $f_{x_r} \in C^1(\mathbb{R}^2)$ (by 5.2)) imply $(f_{x_r} - A\hat{u}_{x_r}) \in BV_{\mathrm{loc}}(\Omega)$. Therefore, from Theorem 5.5(ii) will follow

$$1_{R_r \cap \Omega} = \frac{f_{x_r} - A\hat{u}_{x_r}}{f_{x_r}} \qquad \text{a.e. in } \Omega \tag{5.22}$$

if we establish the following two facts: $f_{x_r} \neq 0$ in Ω and $A\hat{u}_{x_r} = 0$ almost everywhere in $R_r \cap \Omega$. Then, (5.22) will imply $1_{R_r \cap \Omega} \in BV_{\mathrm{loc}}(\Omega)$, i.e. we will obtain the local finiteness of the perimeter of $R_r, r = 1, 2$, and hence that of $\mathcal{A}$. So we need to show that $f_{x_r} \neq 0$ in a neighborhood of the free boundary ∂_r. This follows from a generalization of Lemma 7.3, p. 195 of [6], which makes essential use of the hypotheses (5.1)–(5.3). With our notation such a result is stated as Theorem 5.8.

THEOREM 5.8 ([15, Thm. 4.8 and Cor. 4.9]). *Assume* (5.1), (5.2), *and* (5.3). *Then*

$$f_{x_r} < 0 \quad \textit{on the free boundary determined by Theorem } 5.5\text{(ii)}, r = 1, 2; \tag{5.23}$$

hence

$$f_{x_r} < 0 \quad \textit{on } \partial_r \backslash \partial_0, \qquad r = 1, 2. \tag{5.24}$$

Remark 5.9. Clearly $\partial_r \backslash \partial_0$ and the free boundary determined by (ii) of Theorem 5.5 coincide; in fact they both are characterized by the function ψ_r and the set S_r (cf. (5.9)).

We point out in [4, Remark 6.1] that the strict convexity of f makes (5.3) unnecessary in the above theorem.

LEMMA 5.10. *Assume* (5.1) *and* (5.2). *Then*

$$\hat{u}_{x_r} = 0 \quad \textit{and} \quad \nabla\hat{u}_{x_r} = 0 \quad \textit{on } R_r, \quad r = 1, 2; \tag{5.25}$$

$$A\hat{u}_{x_r} = 0 \quad \text{a.e. } \textit{in } R_r, \quad r = 1, 2. \tag{5.26}$$

Proof. Since $\hat{u}_{x_r} \in C^{1,1}(S_r)$ (cf. (5.10)) and $\hat{u}_{x_r}$ attains its minimum value in R_r, (5.25) follows. Now (5.26) is immediate if the boundary ∂_r has zero two-dimensional Lebesgue measure; otherwise from the fact that the $\hat{u}_{x_r x_i x_j}$'s exist almost everywhere and from the properties of R_r (for $j \neq r$, the x_j-sections of R_r are half-lines) it follows $\hat{u}_{x_r x_r x_r} = \hat{u}_{x_r x_r x_j} = \hat{u}_{x_r x_j x_r} = 0$ almost everywhere in $\partial_r \backslash \partial_0$; then $\hat{u}_{x_r x_j x_j}(P) = 0$ for almost every P in $\partial_r \backslash \partial_0$ follows by taking the limit of the Newton quotient along a sequence in $\{x_r = x_r(P)\} \cap (\partial_r \backslash \partial_0)$ and by recalling that there $\hat{u}_{x_r x_j} \equiv 0$ (such a sequence exists for almost every P if $|\partial_r| > 0$). □

Remark 5.11. As a matter of fact, it is possible to show that $|\partial_r| = 0$ under the conditions (5.1) and (5.2) (cf. [6, Thm. 3.4 and Thm. 3.5, p. 155]).

We are now ready to prove (LFP).

THEOREM 5.12. *Assume* (5.1) *and* (5.2). *Then the region of inaction $\mathcal{A}$ is of locally finite perimeter, i.e.,* (LFP) *is verified.*

Proof. Since $f_{x_r} \in C(\mathbb{R}^2)$ and $f_{x_r}|_{\partial_r \backslash \partial_0} < 0$, we can cover ∂_r with open balls Ω so that (5.22) holds there, i.e.,

$$1_{R_r \cap \Omega} = \frac{f_{x_r} - A\hat{u}_{x_r}}{f_{x_r}} \qquad \text{a.e. in } \Omega.$$

Then, $1_{R_r} \in BV_{\text{loc}}(\Omega), r = 1, 2$ (by Theorem 5.8, (5.2), and (5.21)); also $\partial\mathcal{A} = \partial_1 \cup \partial_2$; hence the assertion of the theorem follows. □

Clearly all the results of §4 hold in the present setting (since (LFP) holds for $\mathcal{A}$). However, under assumptions (5.1) and (5.2), Proposition 4.30 can be considerably improved thanks to the greater regularity of $\hat{u}_{x_r}$, as we show in the next section.

6. Higher regularity of the boundary. In this section we assume (5.1) and (5.2) and we show (with the notation of the previous sections) that the function ψ_i which defines the boundary ∂_i is Lipschitz continuous, and therefore $\psi_i = \tilde{\psi}_i$. The proof is a generalization of a result concerning the regularity of the free boundary of a filtration problem (cf. [6, Thm. 6.1, p. 177]). The arguments of the proof are based on PDE methods (and for these we need to assume (5.1) and (5.2)), and also on the geometry of the problem (that is, on the results of §3).

The results of this section parallel results in [15], but these results were not included in the earlier version of [15] available to the authors at the time of writing.

We need the following lemma that provides us with some basic properties of $\hat{u}_{x_r}$. Let us recall that $\hat{u}_{x_r} \in C^{1,1}(S_r)$ (cf. (5.10)).

LEMMA 6.1 ([6, Lem. 3.2 and Cor. 3.3, p. 155]). *Assume* (5.1) *and* (5.2). *Let Ω be an open ball in S_r that intersects $\partial_r \backslash \partial_0$, let $P \in \mathcal{A} \cap \Omega$ be such that* $\operatorname{dist}(P, \partial_r \backslash \partial_0) < \delta$, $\operatorname{dist}(P, \partial\Omega) \geq \varepsilon_0 > 0$, *and let $M > 0$ be such that*

$$|D_{ij}(\hat{u}_{x_r})| \leq M \quad \text{in } \Omega,$$

for all i, j. Then

$$\hat{u}_{x_r}(P) \leq M\delta^2 \leq C\delta^2, \tag{6.1}$$

$$|\nabla \hat{u}_{x_r}(P)| \leq C\delta, \tag{6.2}$$

where $C = C(\varepsilon_0, \|\hat{u}_{x_r}\|_{C^{1,1}(\Omega)}), r = 1, 2$.

THEOREM 6.2. *Assume* (5.1) *and $f \in C^3(\mathbb{R}^2)$. Then the functions ψ_1 and ψ_2 are continuous everywhere and locally Lipschitz away from the corner point ∂_0. In particular, the free*

boundary $\partial\mathcal{A}$ is given by

$$\partial\mathcal{A} = \partial_1 \cup \partial_2 = (\text{graph}(\psi_1|_{[x_2^0,+\infty)})) \cup (\text{graph}(\psi_2|_{[x_1^0,+\infty)})). \tag{6.3}$$

Proof (see also [6, Thm. 6.1, p. 177]). Fix $i = 1$ for simplicity and recall that

$$\hat{u}_{x_1} \in C^{1,1}(\Omega), \qquad i = 1, 2,$$

for every open ball $\Omega \subset \mathcal{A}$ (cf. (5.10)); hence

$$\hat{u} \in C^{2,1}(\Omega), \tag{6.4}$$

and so also

$$\hat{u} \in C^2(\mathcal{A}). \tag{6.5}$$

Then, from (6.4) and $f \in C^{2,\alpha}(\Omega)$ (by 5.1) follows

$$\hat{u} \in C^{4,\alpha}(\Omega) \quad \text{for every open ball } \Omega \subset \mathcal{A}, \tag{6.6}$$

by elliptic regularity (cf. [7, Prop. 6.17, p. 109]). This enables us to differentiate the Bellman equation once more; i.e., we get

$$A\hat{u}_{x_1x_1} = f_{x_1x_1} \quad \text{in } \mathcal{A},$$

and $f_{x_1x_1} \geq 0$ (by convexity) implies

$$A\hat{u}_{x_1x_1} \geq 0 \quad \text{in } \mathcal{A}. \tag{6.7}$$

Also, $\hat{u}_{x_1x_1} \geq 0$ (again by convexity) and $\hat{u}_{x_1x_1} = 0$ on $\partial_1\backslash\partial_0$ (by (5.25)). Now let Ω be an open ball in $S_1 = R_1 \cup \mathcal{A}$ such that $\Omega \cap \partial_1 \neq \emptyset$; then we apply the strong maximum principle (cf. [7, Thm. 3.5, p. 35]) to

$$\begin{cases} A\hat{u}_{x_1x_1} \geq 0 & \text{in } \Omega \cap \mathcal{A}, \\ \hat{u}_{x_1x_1} = 0 & \text{on } \Omega \cap \partial_1, \\ \hat{u}_{x_1x_1} \geq 0 & \text{in } \Omega, \\ \hat{u}_{x_1x_1} \in C^{2,\alpha}(\Omega \cap \mathcal{A}) \cap C^{0,1}(\Omega), \end{cases}$$

and we conclude ($\rho > 0$ is used here)

$$\hat{u}_{x_1x_1} > 0 \quad \text{in } \Omega \cap \mathcal{A}, \tag{6.8}$$

since if not, then the minimum (which is zero) would be achieved inside Ω and this contradicts the maximum principle unless $\hat{u}_{x_1x_1} = 0$ on $\Omega \cap \mathcal{A}$. In this case $\hat{u}_{x_1} = 0$ on horizontal line segments in $\Omega \cap \mathcal{A}$ contradicting the definition of $\mathcal{A}$.

We recall that $f_{x_1} < 0$ on $\partial_1\backslash\partial_0$ (by Theorem 5.8); hence, by continuity, $f_{x_1} < 0$ in a neighborhood of $\partial_1\backslash\partial_0$, and we assume

$$f_{x_1} < 0 \quad \text{in } \Omega. \tag{6.9}$$

Let $Q = (x_1^Q, x_2^Q) \in \partial_1 \cap \Omega$ and let $R > 0$ be such that there exists $b > 0$ for which

$$D_R := \{(x_1, x_2) \in \mathcal{A} : |x_2 - x_2^Q| < R,\ x_1 < b\} \subset \Omega,$$
$$\text{cl}(D_{2R}) := \text{cl}\{(x_1, x_2) \in \mathcal{A} : |x_2 - x_2^Q| < 2R,\ x_1 < b\} \subset \Omega.$$

Set

$$w := K\hat{u}_{x_1x_1} + H\hat{u}_{x_1x_2} - F\hat{u}_{x_1}$$

for $K > 0, F > 0$, and $|H| \leq 1$ (with the constants K and F to be chosen later). Then we have

$$Aw = Kf_{x_1x_1} + Hf_{x_1x_2} - Ff_{x_1},$$

and from this follows, for F sufficiently large (independently of K and H),

$$Aw > \varepsilon > 0 \quad \text{in } D_{2R}, \tag{6.10}$$

since $f_{x_1x_1}, f_{x_1x_2}$ are bounded in Ω and (6.9) holds. Also

$$w = 0 \quad \text{on } \partial D_R \cap \partial_1, \tag{6.11}$$

and (6.8) implies

$$w > 0 \quad \text{on } \partial D_{R'} \cap \{\text{dist}(\cdot, \partial_1) > \delta\}, \quad \text{for all } R \leq R' \leq 2R, \tag{6.12}$$

if $K \geq K(\delta)$ with $0 < \delta < 1$, a small number to be determined later. If we show

$$w > 0 \quad \text{on } \partial D_R \cap \{\text{dist}(\cdot, \partial_1) \leq \delta\} \cap \mathcal{A}, \tag{6.13}$$

then by applying the maximum principle to (6.10)–(6.13) we will conclude

$$w > 0 \quad \text{in } D_R. \tag{6.14}$$

We show (6.13) by contradiction. Assume (6.13) is false and let $\bar{P} \in \partial D_R \cap \mathcal{A}$ be such that

$$w(\bar{P}) \leq 0 \quad \text{and} \quad \text{dist}(\bar{P}, \partial_1) \leq \delta. \tag{6.15}$$

Now set

$$\tilde{w}(P) = w(P) + \nu|P - \bar{P}|^2, \qquad P \in \text{cl}(D_{2R}),$$

with $\nu > 0$ small enough to guarantee

$$A(\nu|P - \bar{P}|^2) > -\varepsilon$$

for ε as in (6.10) (this can be done because of (5.1), i.e., $\sum(\sigma\sigma^*)_{ij}\xi_i\xi_j \geq \alpha|\xi|^2$, for every $\xi \in \mathbb{R}^2$, with $\alpha > 0$). Thus,

$$A\tilde{w} > 0 \quad \text{in } D_{2R}, \tag{6.16}$$

$$\tilde{w} \geq 0 \quad \text{on } \partial D_{2R} \cap \partial_1, \tag{6.17}$$

and

$$\tilde{w} > 0 \quad \text{on } \partial D_{2R} \cap \{\text{dist}(\cdot, \partial_1) > \delta\} \tag{6.18}$$

as this follows from (6.12). Therefore, if we show

$$\tilde{w} > 0 \quad \text{on } \partial D_{2R} \cap \{\text{dist}(\cdot, \partial_1) \leq \delta\} \cap \mathcal{A}, \tag{6.19}$$

then by applying the strong maximum principle to (6.16)–(6.19) we will get

$$\tilde{w} > 0 \quad \text{in } D_{2R},$$

which contradicts

$$\tilde{w}(\bar{P}) = w(\bar{P}) \leq 0,$$

and hence we will have proved (6.13). So let us show that (6.19) holds. Let $P \in \partial D_{2R} \cap \{\text{dist}(\cdot, \partial_1) \leq \delta\} \cap \mathcal{A}$, and recall that

$$\hat{u}_{x_1} \in C^{1,1}(\Omega), \qquad \hat{u}_{x_1} = 0 \text{ on } \partial_1, \qquad \nabla \hat{u}_{x_1} = 0 \text{ on } \partial_1,$$

by (5.25) and (5.10); then, by Lemma 6.1 follows

$$\hat{u}_{x_1}(P) \leq C\delta^2 \quad \text{and} \quad |\nabla \hat{u}_{x_1}(P)| \leq C\delta.$$

Hence

$$\begin{aligned} \tilde{w}(P) &= K\hat{u}_{x_1x_1}(P) + H\hat{u}_{x_1x_2}(P) - F\hat{u}_{x_1}(P) + \nu|P - \bar{P}|^2 \\ &\geq K\hat{u}_{x_1x_1}(P) - HC\delta - FC\delta^2 + \nu|P - \bar{P}|^2 \\ &\geq K\hat{u}_{x_1x_1}(P) - C\delta(1 + F) + \nu R^2 \end{aligned}$$

since $\delta < 1$ and $|P - \bar{P}| \geq R$. Then, certainly $\tilde{w}(P) > 0$ if we choose $\delta < \nu R^2/[C(1 + F)]$; so (6.19) holds, and hence so does (6.13). Thus (6.14) holds true too, i.e.,

$$w > 0 \quad \text{in } D_R,$$

i.e.,

$$K\hat{u}_{x_1x_1} + H\hat{u}_{x_1x_2} - F\hat{u}_{x_1} > 0 \quad \text{in } D_R;$$

but $\hat{u}_{x_1} > 0$ in $\mathcal{A}$; hence we have

$$K\hat{u}_{x_1x_1} + H\hat{u}_{x_1x_2} > 0 \quad \text{in } D_R, \tag{6.20}$$

which means that $\hat{u}_{x_1}$ increases along lines of slope H/K in D_R, for any H such that $|H| \leq 1$. However, $\hat{u}_{x_1} = 0$ on ∂_1, therefore there exists a cone $\gamma^+(Q)$ with vertex Q, and angle $2\beta = 2\arctan(1/K)$, and with axis parallel to the x_1-axis such that

$$\gamma^+(Q) \cap D_R \subset \mathcal{A}.$$

The same holds for any $P \in \partial_1 \cap V_Q$, V_Q being a small neighborhood of Q, i.e.,

$$\gamma^+(P) \cap V_Q \subset \mathcal{A}, \qquad \forall\, P \in V_Q \cap \partial_1. \tag{6.21}$$

But we do know that R_1 is the subgraph of $\psi_1(x_2)$; hence it must also be

$$\gamma^-(P) \cap V_Q \subset R_1, \qquad \forall\, P \in V_Q \cap \partial_1, \tag{6.22}$$

if

$$\gamma^-(P) := \{(x_1, x_2) : (-x_1, x_2) \in \gamma^+(P)\}.$$

Thus ψ_1 is Lipschitz continuous in $\pi_2(V_Q)$ (with π_2 being the projection onto the x_2-axis); in fact,

$$\frac{|\psi_1(x_2)-\psi_1(y_2)|}{|x_2-y_2|} \le \max\left\{\tan\beta, \tan\left(\frac{\pi}{2}-\beta\right)\right\} = \max\{1/K, K\} \tag{6.23}$$

for every $x_2, y_2 \in \pi_2(V_Q)$. □

Finally, from the Lipschitz continuity follows even greater regularity by the application of classical regularity results (cf. [6, Thm. 6.2, p. 179]).

THEOREM 6.3. *Assume* (5.1) *and* $f \in C^3(\mathbb{R}^2)$. *Then, for* $i = 1,2, j \neq i$, *and with* $\{(x_1^0, x_2^0)\} = \partial_0$,

(i) $\psi_i \in C^1((x_j^0, +\infty))$ *and* $\hat{u}_{x_i} \in C^2(\mathcal{A} \cup (\partial_i \backslash \partial_0))$;

(ii) $f_{x_i} \in C^{m,\alpha}(\{f_{x_i} < 0\})\, (m \in \mathbb{N}, 0 < \alpha < 1) \Rightarrow \psi_i \in C^{m+1,\alpha}((x_j^0, +\infty))$;

(iii) f_{x_i} *is analytic in* $\{f_{x_i} < 0\} \Rightarrow \psi_i$ *is analytic in* $(x_j^0, +\infty)$.

Note that (i) is a consequence of a fundamental result of Caffarelli, which guarantees C^1-regularity of the boundary in a neighborhood of any point of positive Lebesgue density for the coincidence set (cf. [6, Thm. 3.10, p. 162]).

COROLLARY 6.4. *Assume* (5.1) *and* $f \in C^3(\mathbb{R}^2)$. *Then, for* $i = 1,2, j \neq i$, *and with* $\{(x_1^0, x_2^0)\} = \partial_0$,

(i) $\psi_i \in C^0((-\infty, +\infty)) \cap C^{2,\alpha}((x_j^0, +\infty))$;

(ii) $\hat{u} \in C^3(\mathcal{A} \cup (\partial\mathcal{A} \backslash \partial_0))$.

Proof. This follows from $f_{x_i} \in C^2$ and (i) and (ii) of Theorem 6.3, together with the established continuity of ψ_i at the corner point ∂_0 (cf. Lemma 3.8). □

The local finiteness of the perimeter of the region of inaction $\mathcal{A}$ provides us with a lot of information about its boundary. This is a property of geometric character and has never been used before to study the region of inaction, $\mathcal{A}$, of a singular control problem in the setting of the *monotone follower problem*. As §4 shows, this approach turns out to be extremely powerful in the two-dimensional case; in fact, the functions ψ_i being functions of a real variable and having obtained $\psi_i \in BV_{\text{loc}}(\mathbb{R})$, the useful characterization (c) of Remark 4.3 is available for ψ_i. This characterization allows the detailed analysis of the boundary that leads to its regularity. In more than two dimensions there are other characterizations of $BV_{\text{loc}}(\mathbb{R}^{n-1})$ which, however, are not as easy to apply and to work with; nevertheless they still are a useful tool to study the regularity of $\partial\tilde{\mathcal{A}}$ as we show in forthcoming work.

7. Monotonicity of ψ_i. We can examine the monotonicity properties of ψ_i under the strengthened conditions in [15], i.e.,

$$\sigma\sigma^* \text{ is positive definite;} \tag{7.1}$$

$$f \in C^3(\mathbb{R}^2). \tag{7.2}$$

Remark 7.1. Note that in Theorem 6.2 we showed that if (7.1) and (7.3) hold, then ψ_i is continuous everywhere and locally Lipschitz away from the corner point ∂_0 (and hence $\psi_i = \tilde{\psi}_i$).

Then we have the following proposition.

PROPOSITION 7.2. *Assume* (7.1) *and* (7.2). *If*

$$f_{x_1x_2} \ge 0 \quad \text{in } \mathbb{R}^2,$$

then ψ_i *is nonincreasing.*

Proof. We denote by v^ε the solution of the penalized problem (3.15) of [15], then $v^\varepsilon \to \hat{u}$, $v^\varepsilon_{x_i} \to \hat{u}_{x_i}$ uniformly on compacta. Moreover if $w = v^\varepsilon_{x_1 x_2}$, then

$$A_0 w = f_{x_1 x_2}, \tag{7.3}$$

where A_0 is a differential operator that differs from A only by first and 0th order terms. As $f_{x_1 x_2} \geq 0$, it follows from a version of the maximum principle for functions of $C^2(\mathbb{R}^2)$ bounded above by a polynomial that $w = v^\varepsilon_{x_1 x_2} \geq 0$.

This implies, for example, that $v^\varepsilon_{x_2}$ is nondecreasing along horizontal lines. Then, by using the fact that $v^\varepsilon_{x_2} \to \hat{u}_{x_2}$ uniformly on compacta as $\varepsilon \to 0$, we conclude that if $P \in \mathcal{A}$, then the horizontal ray to the right of P is also in $\mathcal{A}$. It follows that ψ_2 is nonincreasing. □

The following corollary is obtained by replacing w by $-w$ in the above proof.

COROLLARY 7.3. *Assume* (7.1) and (7.2), *and*

$$f_{x_1 x_2} \leq 0 \quad \text{in } \mathbb{R}^2. \tag{7.4}$$

Then ψ_i is nondecreasing $(i = 1, 2)$.

A particular example of interest is

$$J_x(k) = E\left\{\int_0^\infty f(X_t^k) e^{-t}\, dt\right\},$$

$$f(x_1, x_2) = x_1^2 + \alpha x_1 x_2 + x_2^2,$$

$$X_t = x + \sqrt{2} W_t + k_t$$

with $\alpha \in (-2, 0)$. We show that here ψ_i cannot be nonincreasing. Suppose to the contrary; then by the above corollary, $\psi_i = c_i$, a constant. Symmetry considerations allow us to conclude that $c_1 = c_2 = c$. We now attempt to solve

$$-\Delta u + u = f, \qquad x > c, y > c$$

$$u_x(c, y) = 0 = u_y(x, c), \qquad x > c, y > c.$$

Shifting the origin to (c, c), changing to polar coordinates, and applying Sturm–Liouville theory produces a solution of the form

$$u(x, y) = \sum_{k=0}^{\infty} a_k(r) \cos(4k\theta),$$

where (r, θ) is the polar form of $(x - c, y - c)$ and

$$a_k'' + \frac{a_k'}{r} - \left[\frac{(4k)^2}{r^2} + 1\right] a_k = g_k$$

$$g_0 = -\left(1 + \frac{\alpha}{\pi}\right) r^2 - \frac{4}{\pi}(2 + \alpha) cr - (2 + \alpha) c^2$$

$$g_k = \frac{2\alpha r^2}{\pi[(2k)^2 - 1]} + \frac{8(2 + \alpha) cr}{\pi[(4k)^2 - 1]}, \qquad k = 1, 2, \ldots.$$

Let us write this as $g_k = \alpha_0^k + \alpha_1^k r + \alpha_2^k r^2$. The solution a_k^h of the homogeneous equation is given in terms of modified Bessel functions and is not admissible if we insist that a_k be finite at $r = 0$ and that a_k'' be finite at $r = \infty$ (cf. (2.10)). A series solution of the nonhomogeneous equation turns out to have the form

$$a_k(r) = \sum_{n=2}^{\infty} b_{k,n} r^n$$

where

$$b_{k,2} = \frac{\alpha_0^k}{2^2 - (4k)^2}, \qquad b_{k,3} = \frac{\alpha_1^k}{3^2 - (4k)^2},$$

$$b_{k,4} = \frac{\alpha_2^k + \frac{\alpha_0^k}{2^2-(4k)^2}}{4^2 - (4k)^2},$$

$$b_{k,n} = \frac{b_{k,n-2}}{n^2 - (4k)^2} \qquad n = 5, 6, \ldots.$$

The difficulty now lies in that the denominators may be zero. This never occurs for $k = 0$, but when $k > 0$ and $n = 4k$, then the recurrence relationship cannot be solved unless the corresponding $b_{k,n}$ are zero, i.e., $b_{k,n} = 0$ for n even! But this only occurs if $\alpha_0^k = 0 = \alpha_2^k$, i.e., $\alpha = 0$ no matter what c is. In this case the variational inequality decomposes into two one-dimensional problems with solution

$$u(x, y) = x^2 + y^2 + 4 - 2(e^{1-x} + e^{1-y}), \qquad c = -1.$$

For non-zero α it follows that a solution of the variational inequality fails to exist no matter what c is if we assume that $\mathcal{A}$ is a quadrant. This shows that there are examples where the ψ_i are not nonincreasing.

A. Appendix.

Proof of Theorem 3.1. We recall that $\hat{u} \in C^1(\mathbb{R}^2)$ (cf. Theorem 2.3).

CLAIM 1. *For every x_2, there exists $\bar{x}_1$ such that for every $x_1 \geq \bar{x}_1$, $\hat{u}_{x_1}(x_1, x_2) > 0$.*

With $\bar{\bar{x}}_1 \in \mathbb{R}$ and $c > 0$ (both to be fixed later), we define the following function:

$$w(x_1, x_2) = \begin{cases} 0 & \text{if } x_1 \leq \bar{\bar{x}}_1, \\ c(x_1 - \bar{\bar{x}}_1) & \text{if } x_1 \geq \bar{\bar{x}}_1. \end{cases}$$

Since $Aw(x_1, x_2) = -g_1 c + \rho c(x_1 - \bar{\bar{x}}_1)$ for $x_1 \geq \bar{\bar{x}}_1$, we can choose $c > 0$ and $\bar{\bar{x}}_1 \in \mathbb{R}$ such that

$$Aw(x_1, x_2) \leq f(x_1, x_2) \quad \text{if } x_1 \geq \bar{\bar{x}}_1.$$

(This can be done because the assumed polynomial growth condition $(2.4)_1$ implies $r|(x_1, x_2)^+|^p - C_0 \leq f(x_1, x_2)$ with C_0 and r independent of x_2.) Since $f \geq 0$, then w is a solution of the quasi-variational inequality (2.42), whose maximal solution is $\hat{u}$ (cf. Theorem 2.9); so we conclude that $w \leq \hat{u}$. Therefore, since $\hat{u}_{x_1} \geq 0$, for every x_2 there exists some point $\bar{x}_1 \geq \bar{\bar{x}}_1$ such that $\hat{u}_{x_1}(\bar{x}_1, x_2) > 0$; from this we now deduce Claim 1 (since $\hat{u}$ is convex).

Similarly, we have that for every x_1 there exists $\bar{x}_2$ such that for every $x_2 \geq \bar{x}_2$, $\hat{u}_{x_2}(x_1, x_2) > 0$.

CLAIM 2. *For every $\tilde{x}_1$, $\hat{u}_{x_i}(\tilde{x}_1, x_2)$ remains bounded as $x_2 \to -\infty$, $(i = 1, 2)$.*

In fact, $\hat{u}_{x_2}(\tilde{x}_1, \cdot)$ is nondecreasing (by convexity) and ≥ 0 (by Theorem 2.11). So $\hat{u}_{x_2}(\tilde{x}_1, x_2) \to \infty$ as $x_2 \to -\infty$ would imply $\hat{u}_{x_2}(\tilde{x}_1, \cdot) \equiv +\infty$, which is impossible. On the other hand, since $\hat{u}$ is convex and non-negative, we have

$$\begin{aligned} \hat{u}(\tilde{x}_1 + h, x_2) &\geq \hat{u}(\tilde{x}_1, x_2) + h\hat{u}_{x_1}(\tilde{x}_1, x_2) \\ &\geq h\hat{u}_{x_1}(\tilde{x}_1, x_2) \quad \text{for every } x_2. \end{aligned}$$

Therefore, $\hat{u}_{x_1}(\tilde{x}_1, x_2) \to +\infty$ as $x_2 \to -\infty$ would imply (for $h > 0$) $\hat{u}(\tilde{x}_1 + h, x_2) \to +\infty$ as $x_2 \to -\infty$, so $\hat{u}(\tilde{x}_1 + h, \cdot) \equiv +\infty$ (since $\hat{u}_{x_2} \geq 0$). This is impossible because of the polynomial growth of $\hat{u}$.

CLAIM 3. *For every x_1 there exists $\tilde{x}_2$ such that $\hat{u}_{x_2}(x_1, \tilde{x}_2) = 0$.*

In fact, if not, then we have that there exists $\tilde{x}_1$ such that $\hat{u}_{x_2}(\tilde{x}_1, x_2) > 0$ for all x_2. So one of the following two cases occurs:

$$\text{Case (a):} \qquad \exists x_{2,n} \to -\infty \quad \text{such that } \hat{u}_{x_1}(\tilde{x}_1, x_{2,n}) > 0;$$

or

$$\text{Case (b):} \qquad \exists \tilde{x}_2 \quad \text{such that } \hat{u}_{x_1}(\tilde{x}_1, x_2) = 0 \quad \forall\, x_2 \leq \tilde{x}_2.$$

In Case (a), by continuity of $\hat{u}_{x_1}$ and $\hat{u}_{x_2}$, we have $\hat{u}_{x_1} > 0$ and $\hat{u}_{x_2} > 0$ on some open set U_n containing $(\tilde{x}_1, x_{2,n})$. Then, by Theorem 2.11, $A\hat{u} = f$ almost everywhere in U_n, i.e.,

$$-\frac{1}{2} \operatorname{tr}\left[\sigma\sigma^* D^2\hat{u}\right] - g \cdot \nabla\hat{u} + \rho\hat{u} = f \quad \text{a.e. in } U_n. \tag{A.1}$$

From (A.1) and $\operatorname{tr}\left[\sigma\sigma^* D^2\hat{u}\right] \geq 0$ almost everywhere (since $\hat{u}$ is convex) follows

$$\rho\hat{u} \geq f + g \cdot \nabla\hat{u} \quad \text{in } U_n, \tag{A.2}$$

so

$$\rho\hat{u}(\tilde{x}_1, x_2) \geq f(\tilde{x}_1, x_2) + g_1\hat{u}_{x_1}(\tilde{x}_1, x_2) + g_2\hat{u}_{x_2}(\tilde{x}_1, x_2) \quad \text{with } (\tilde{x}_1, x_2) \in U_n, \tag{A.3}$$

and in particular

$$\rho\hat{u}(\tilde{x}_1, x_{2,n}) \geq f(\tilde{x}_1, x_{2,n}) + g_1\hat{u}_{x_1}(\tilde{x}_1, x_{2,n}) + g_2\hat{u}_{x_2}(\tilde{x}_1, x_{2,n}). \tag{A.4}$$

Because we are assuming $f(x_1, x_2) \to +\infty$ as $|(x_1, x_2)| \to +\infty$, we have $f(\tilde{x}_1, x_{2,n}) \to +\infty$ as $n \to +\infty$, while $\hat{u}_{x_1}(\tilde{x}_1, x_{2,n})$ and $\hat{u}_{x_2}(\tilde{x}_1, x_{2,n})$ stay bounded as $n \to +\infty$ (by Claim 2). Then, from (A.4) we have

$$\rho\hat{u}(\tilde{x}_1, x_{2,n}) \to +\infty \quad \text{as } n \to +\infty,$$

but $\hat{u}(\tilde{x}_1, \cdot)$ is nondecreasing; therefore it must be $\hat{u}(\tilde{x}_1, \cdot) \equiv +\infty$, and this contradicts the polynomial growth of $\hat{u}$. So Case (a) cannot occur.

Let's now assume that Case (b) holds. Then, because of convexity and $\hat{u}_{x_1} \geq 0$, we have

$$\hat{u}_{x_1}(x_1, x_2) = 0 \quad \text{for every } (x_1, x_2) \in (\tilde{x}_1, \tilde{x}_2) - \Lambda^*. \tag{A.5}$$

Now Claim 1 allows us to define, for $x_2 \leq \tilde{x}_2$,

$$\psi_1(x_2) = \max\{x_1 : \hat{u}_{x_1}(x_1, x_2) = 0\} = \inf\{x_1 : \hat{u}_{x_1}(x_1, x_2) > 0\}.$$

Let's now define the region $\mathcal{T} = \operatorname{int}(\{(x_1, x_2) : x_1 \geq \psi_1(x_2), x_2 \leq \tilde{x}_2\})$. From the definition of ψ_1 follows that $\hat{u}_{x_1} \neq 0$ in $\mathcal{T}$. Moreover, by assumption $\hat{u}_{x_2} \neq 0$ on the line $x_1 = \tilde{x}_1$; also,

on the left of ψ_1, $\hat{u}$ is constant along horizontal line segments and therefore $\hat{u}_{x_2}$ is constant along horizontal line segments. In conclusion, $\hat{u}_{x_2}(\psi_1(x_2), x_2) = \hat{u}_{x_2}(\tilde{x}_1, x_2) > 0$ for $x_2 \leq \tilde{x}_2$. So by continuity of $\hat{u}_{x_2}$ we have $\hat{u}_{x_2} \neq 0$ in $U_{\psi_1} \cap \mathcal{T}$, U_{ψ_1} being a neighborhood of $\partial\mathcal{T}$. Then, $\hat{u}_{x_1} \neq 0$ and $\hat{u}_{x_2} \neq 0$ in $U_{\psi_1} \cap \mathcal{T}$. Now Theorem 2.11 implies that the dynamic programming equation holds in $U_{\psi_1} \cap \mathcal{T}$, i.e., $-\frac{1}{2}\text{tr}\,[\sigma\sigma^* D^2\hat{u}] - g \cdot \nabla\hat{u} + \rho\hat{u} = f$ almost everywhere in $U_{\psi_1} \cap \mathcal{T}$. We know tr $[\sigma\sigma^* D^2\hat{u}] \geq 0$ almost everywhere (since $\hat{u}$ is convex), so we have

$$\rho\hat{u}(\tilde{z}, x_2) \geq f(\tilde{z}, x_2) + g_1\hat{u}_{x_1}(\tilde{z}, x_2) + g_2\hat{u}_{x_2}(\tilde{z}, x_2) \quad \text{if } (\tilde{z}, x_2) \in U_{\psi_1} \cap \mathcal{T}.$$

It follows from the continuity of $\hat{u}_{x_1}$ and the definition of ψ_1 that $\overline{\lim}_{t \to x_2} \psi_1(t) \leq \psi_1(x_2)$; hence $(\psi_1(x_2), x_2) \in \partial\mathcal{T}$ for any $x_2 < \tilde{x}_2$. Therefore, we can take $\lim_{\substack{\tilde{z} \to \psi_1(x_2) \\ (\tilde{z}, x_2) \in \mathcal{T} \cap U_{\psi_1}}}$ and obtain (by continuity)

$$\rho\hat{u}(\psi_1(x_2), x_2) \geq f(\psi_1(x_2), x_2) + g_2\hat{u}_{x_2}(\psi_1(x_2), x_2), \quad \text{with } x_2 < \tilde{x}_2. \tag{A.6}$$

Also, $\hat{u}(\tilde{x}_1, x_2) = \hat{u}(\psi_1(x_2), x_2)$ (by the definition of ψ_1, since (A.5) implies $\tilde{x}_1 \leq \psi_1(x_2)$ for every $x_2 \leq \tilde{x}_2$); $\hat{u}_{x_2}(\tilde{x}_1, \tilde{x}_2) \geq \hat{u}_{x_2}(\tilde{x}_1, x_2)$ (by convexity and $x_2 \leq \tilde{x}_2$); finally, $\hat{u}_{x_2}(\psi_1(x_2), x_2) = \hat{u}_{x_2}(\hat{x}_1, x_2)$ (as we observed above). Then, from (A.6) follows

$$\begin{aligned} \rho\hat{u}(\tilde{x}_1, x_2) &\geq f(\psi_1(x_2), x_2) + g_2\hat{u}_{x_2}(\tilde{x}_1, x_2) \\ &\geq f(\psi_1(x_2), x_2) - |g_2|\hat{u}_{x_2}(\tilde{x}_1, \tilde{x}_2). \end{aligned}$$

Using the fact that

$$f(x_1, x_2) \to +\infty \quad \text{as } |(x_1, x_2)| \to +\infty,$$

we obtain

$$\hat{u}(\tilde{x}_1, x_2) \to +\infty \quad \text{as } x_2 \to -\infty,$$

which is impossible since $\hat{u}(\tilde{x}_1, x_2)$ decreases as $x_2 \to -\infty$ (as $\hat{u}_{x_2} > 0$). Therefore, Case (b) cannot occur and Claim 3 is finally proved.

Similarly we have that for every x_2 there exists $\tilde{x}_1$ such that $\hat{u}_{x_1}(\tilde{x}_1, x_2) = 0$. Then, the functions ψ_i in (3.3) are well defined. □

Proof of Lemma 4.15. Let us fix $i = 1$ for simplicity. Then,

$$\begin{aligned} \partial_1 \backslash \tilde{\partial}_1 &= (\partial R_1 \cap \partial\mathcal{A}) \backslash (\partial R_1 \cap \partial\tilde{\mathcal{A}}) \\ &= \partial R_1 \cap (\partial\mathcal{A} \backslash \partial\tilde{\mathcal{A}}) \\ &= \partial R_1 \cap ([\partial\mathcal{A} \cap (\text{cl}(\tilde{\mathcal{A}}))^c] \cup [\partial\mathcal{A} \cap (\text{cl}((\tilde{\mathcal{A}})^c))^c]), \end{aligned}$$

but $\tilde{\mathcal{A}}$ is open, so $(\text{cl}((\tilde{\mathcal{A}})^c))^c = ((\tilde{\mathcal{A}})^c)^c = \tilde{\mathcal{A}}$ and we have

$$\partial_1 \backslash \tilde{\partial}_1 = [\partial R_1 \cap \partial\mathcal{A} \cap (\text{cl}(\tilde{\mathcal{A}}))^c] \cup [\partial R_1 \cap \partial\mathcal{A} \cap \tilde{\mathcal{A}}].$$

Clearly, $\text{cl}(\tilde{\mathcal{A}}) \subset \text{cl}(\mathcal{A})$; on the other hand, since $\mathcal{A}$ is open, we have $\mathcal{A} = \text{int}(\mathcal{A}) \subset \text{int}(\text{cl}(\mathcal{A})) = \tilde{\mathcal{A}}$ and so also $\text{cl}(\mathcal{A}) \subset \text{cl}(\tilde{\mathcal{A}})$. Therefore,

$$\text{cl}(\mathcal{A}) = \text{cl}(\tilde{\mathcal{A}});$$

hence

$$\partial\mathcal{A} \cap (\text{cl}(\tilde{\mathcal{A}}))^c = \partial\mathcal{A} \cap (\text{cl}(\mathcal{A}))^c = \emptyset,$$

and we have

$$\partial_1 \backslash \tilde{\partial}_1 = \partial R_1 \cap \partial \mathcal{A} \cap \tilde{\mathcal{A}} = R_1 \cap \tilde{\mathcal{A}} \tag{A.7}$$

since R_1 is closed.

Finally we recall that $\partial_0 = \{P_0\}$ and $R_0 = P_0 - \Lambda^*$ (cf. Proposition 3.6, (ii)); hence

$$\forall r > 0: \quad |B(P_0, r) \cap R_0| = \frac{\pi r^2}{4};$$

that is,

$$P_0 \notin \text{int}(\text{cl}(\mathcal{A})) = \tilde{\mathcal{A}},$$

but $\{P_0\} = \partial_0 \subset \partial \mathcal{A}$, so it must be $P_0 \in \tilde{\partial}$. □

Proof of Lemma 5.6. Let $\Omega' \subset \text{cl}(\Omega') \subset \Omega$ be fixed; let $\gamma \in C_0^\infty(\Omega)$ be as in the statement of the lemma. Then, (5.8) implies

$$a(w, \gamma(\tilde{v} - \gamma w)) \geq \int_\Omega f_{x_i} \gamma(\tilde{v} - \gamma w)\, dx \tag{A.8}$$

with $\eta = \gamma^2$ and

$$\tilde{v} := \gamma v \quad \text{with } v \in \mathbb{K}(\Omega),$$

so that $\tilde{v} \in \mathbb{K}_0(\Omega)$. Now we calculate

$$\begin{aligned} a(\gamma w, \tilde{v} - \gamma w) =& \int_\Omega \frac{1}{2} \sum_{i,j=1}^{2} (\sigma\sigma^*)_{ij} (\gamma w)_{x_i} (\tilde{v} - \gamma w)_{x_j}\, dx \\ &- \int_\Omega \sum_{i=1}^{2} g_i (\gamma w)_{x_i} (\tilde{v} - \gamma w)\, dx \\ &+ \int_\Omega \rho \gamma w (\tilde{v} - \gamma w)\, dx \\ =& \int_\Omega \frac{1}{2} \sum_{i,j=1}^{2} (\sigma\sigma^*)_{ij} \gamma w_{x_i} (\tilde{v} - \gamma w)_{x_j}\, dx \\ &- \int_\Omega \sum_{i=1}^{2} g_i \gamma w_{x_i} (\tilde{v} - \gamma w)\, dx \\ &+ \int_\Omega \frac{1}{2} \sum_{i,j=1}^{2} (\sigma\sigma^*)_{ij} \gamma_{x_i} w (\tilde{v} - \gamma w)_{x_j}\, dx \\ &- \int_\Omega \sum_{i=1}^{2} g_i \gamma_{x_i} w (\tilde{v} - \gamma w)\, dx + \int_\Omega \rho \gamma w (\tilde{v} - \gamma w)\, dx. \end{aligned} \tag{A.9}$$

On the other hand,

$$\begin{aligned} a(w, \gamma(\tilde{v} - \gamma w)) =& \int_\Omega \frac{1}{2} \sum_{i,j=1}^{2} (\sigma\sigma^*)_{ij} w_{x_i} \{\gamma(\tilde{v} - \gamma w)_{x_j} + \gamma_{x_j} (\tilde{v} - \gamma w)\}\, dx \\ &- \int_\Omega \sum_{i=1}^{2} g_i w_{x_i} \gamma (\tilde{v} - \gamma w)\, dx + \int_\Omega \rho \gamma w (\tilde{v} - \gamma w)\, dx; \end{aligned} \tag{A.10}$$

hence (A.9) and (A.10) imply

$$
\begin{aligned}
a(\gamma w, \tilde{v} - \gamma w) =& a(w, \gamma(\tilde{v} - \gamma w)) - \int_\Omega \frac{1}{2} \sum_{i,j=1}^{2} (\sigma\sigma^*)_{ij} w_{x_i} \gamma_{x_j} (\tilde{v} - \gamma w)\, dx \\
& - \int_\Omega \rho w \gamma (\tilde{v} - \gamma w)\, dx + \int_\Omega \frac{1}{2} \sum_{i,j=1}^{2} (\sigma\sigma^*)_{ij} \gamma_{x_i} w (\tilde{v} - \gamma w)_{x_j}\, dx \\
& - \int_\Omega \sum_{i=1}^{2} g_i \gamma_{x_i} w (\tilde{v} - \gamma w)\, dx + \int_\Omega \rho \gamma w (\tilde{v} - \gamma w)\, dx,
\end{aligned}
$$

i.e.,

$$
\begin{aligned}
a(\gamma w, \tilde{v} - \gamma w) =& \, a(w, \gamma(\tilde{v} - \gamma w)) - \int_\Omega \frac{1}{2} \sum_{i,j=1}^{2} (\sigma\sigma^*)_{ij} w_{x_i} \gamma_{x_j} (\tilde{v} - \gamma w)\, dx \\
& - \int_\Omega \frac{1}{2} \sum_{i,j=1}^{2} (\sigma\sigma^*)_{ij} \{\gamma_{x_i x_j} w + \gamma_{x_i} w_{x_j}\} (\tilde{v} - \gamma w)\, dx \\
& - \int_\Omega \sum_{i=1}^{2} g_i \gamma_{x_i} w (\tilde{v} - \gamma w)\, dx \\
=& \, a(w, \gamma(\tilde{v} - \gamma w)) \\
& - \int_\Omega \left\{ \frac{1}{2} \sum_{i,j=1}^{2} (\sigma\sigma^*)_{ij} \gamma_{x_i x_j} w + \sum_{i,j=1}^{2} (\sigma\sigma^*)_{ij} \gamma_{x_i} w_{x_j} \right\} (\tilde{v} - \gamma w)\, dx \\
& - \int_\Omega \sum_{i=1}^{2} g_i \gamma_{x_i} w (\tilde{v} - \gamma w)\, dx.
\end{aligned}
\tag{A.11}
$$

Now from (A.8) and (A.11) we obtain (5.11) for $\tilde{v} \in \mathbb{K}_0(\Omega)$ of the form $\tilde{v} = \gamma v$ with $v \in \mathbb{K}(\Omega)$. Finally, let v be any element in $\mathbb{K}_0(\Omega)$, let $\Omega' = \operatorname{supp} v$, then (5.11) holds for v since $v = \gamma v$ and $\mathbb{K}_0(\Omega) \subset \mathbb{K}(\Omega)$. □

GENERALIZED SOLUTIONS OF THE HAMILTON–JACOBI EQUATION OF STOCHASTIC CONTROL*

ULRICH G. HAUSSMANN†

Abstract. A second-order generalized derivative based on Brownian motion is introduced. Using this derivative, an Itô-type formula is derived for functions $f(t,x)$, which are continuously differentiable in x with Lipschitz derivative and are Lipschitz continuous in t. It is then shown that the value function of a stochastic control problem is a "generalized" solution of a second-order Hamilton–Jacobi equation. Such solutions are analogous to the Clarke generalized solutions of first-order Hamilton–Jacobi equations. Finally, it is shown that any "generalized" solution is a viscosity subsolution and a viscosity solution is a "generalized" solution.

Key words. stochastic control, Hamilton–Jacobi equation (H–J), generalized solution, viscosity solution, Itô's formula

AMS subject classifications. 93E20, 49L25, 49J52

1. Introduction.

We consider the control problem:

$$X_s^{t,x,u} = x + \int_t^s b(r, X_r^{t,x,u}, u_r)\,dr + \int_t^s \sigma(r, X_r^{t,x,u}, u_r)\,dw_r \tag{1}$$

with cost

$$J^{t,x}(u) = \mathbb{E}\left\{\int_t^T f(r, X_r^{t,x,u}, u_r)\,dr + f_o(X_T^{t,x,u})\right\}. \tag{2}$$

Here $\{w_r : r \geq 0\}$ is a standard Brownian motion on a probability space $(\Omega, \mathcal{F}, P)$ with filtration $\{\mathcal{F}_t\}_{0\leq t\leq T}$ and $u \in \mathcal{U}$ is a control. The corresponding value function is

$$v(t,x) = \inf_{u\in\mathcal{U}} J^{t,x}(u), \tag{3}$$

where $\mathcal{U}$ is the set of U-valued progressively measurable stochastic process on $[0,T)$. If v is smooth, it is the unique (in the class of functions satisfying $v(T,x) = f_o(x)$) classical solution of the Hamilton–Jacobi equation (H–J), i.e.,

$$-v_t(t,x) + H(t,x,-v_x(t,x),-v_{x,x}(t,x)) = 0,$$

where the subscripts denote partial derivatives and where H is the Hamiltonian for the problem and is defined as

$$H(t,x,p,P) \stackrel{\text{def}}{=} \sup_{u\in U}\{\text{trace}[P\tfrac{1}{2}\sigma(t,x,u)\sigma^T(t,x,u)] + p\cdot b(t,x,u) - f(t,x,u)\}.$$

This situation occurs rarely, but it is true that v is always a weak (in the sense of distributions) solution, although the latter are not unique. On the other hand, if v is continuous, then it is the unique viscosity solution of H–J. In deterministic control theory (i.e., $\sigma = 0$) where H–J is a first order equation the same situation prevails, but another notion of solution has been found to be useful, i.e., the generalized solution of Clarke. The relationship between viscosity solutions and generalized solutions in the first order case has been analysed by Frankowska [3]. In this article we define a generalized solution of the second order H–J; we show that the

† Department of Mathematics, University of British Columbia, Vancouver, British Columbia, V6T 1Z2 Canada.

value function is such a solution and we look at the relationship between generalized solutions and viscosity solutions.

The standing assumptions are as follows:

1. b, σ are bounded, continuous on $[0,T] \times \mathbf{R}^d \times U$ and Lipschitz continuous in (t,x) uniformly in u, $\sigma(t,x,u)$ is a $d \times m$ dimensional matrix;

2. f is continuous, Lipschitz continuous in (t,x) uniformly in u and has at most polynomial growth in x;

3. f_o is continuous;

4. U is a compact metric space.

In §2 we introduce and discuss the second-order generalized derivative; in the following section we extend the Itô formula to functions with bounded generalized second derivatives for processes that are degenerate diffusions. This result is used in the sequel but may be of independent interest. In §4 we define the notion of a generalized solution of (H–J) and we show that the value function is a generalized solution. In the last section we discuss the relationship between the generalized solutions and viscosity solutions. An appendix containing some remarks about generalized second-order derivatives concludes the paper.

2. Generalized derivatives. The first-order generalized directional derivative of a function f at $x \in \mathbf{R}^d$ in the direction $v \in \mathbf{R}^d$, $f^o(x;v)$, is defined (at least if f is Lipschitz) by Clarke [1] as

$$f^o(x;v) \stackrel{\text{def}}{=} \limsup_{\substack{y \to x \\ t \to 0+}} \frac{f(y+tv) - f(y)}{t},$$

and the generalized gradient at $x, \partial f(x)$, is the closed convex set in the dual space $(\mathbf{R}^d)^*$ whose support functional is $v \to f^o(x;v)$. The set is nonempty, compact if f is Lipschitz continuous. The fact that $f^o(x;\cdot)$ is a support functional follows from the subadditivity and positive homogeneity of the map. The second-order generalized directional derivative at x has been defined by Cominetti and Correa [2] as a functional on $\mathbf{R}^d \times \mathbf{R}^d$, i.e.,

$$f^{oo}(x;u,v) \stackrel{\text{def}}{=} \limsup_{\substack{y \to x \\ s,t \to 0}} \frac{f(y+su+tv) - f(y+su) - f(y+tv) + f(y)}{st}, \tag{4}$$

which is positive homogeneous and subadditive in both u and v separately and is symmetric. One can then define a generalized Hessian as the set with support functional f^{oo}; in the Appendix we do this and we relate the result to other definitions appearing in the literature.

For stochastic control, however, where second-order H–J equations arise, it is more convenient to define a second-order derivative and a second-order differential somewhat differently. Let $\mathcal{S}^d$ be the symmetric $d \times d$ dimensional matrices and let $\mathcal{P}^d$ be the cone of nonnegative semi-definite elements of $\mathcal{S}^d$. Let $\mathcal{O} \subset \mathbf{R}^d$ be an open set and let $BM(\mathcal{O})$ be the set of locally bounded measurable real-valued functions defined on $\mathcal{O}$. Here we are considering actual functions, not equivalence classes as is the case with $L^\infty(\mathcal{O})$. For a function $f \in BM(\mathcal{O})$ we define a differential of f at x as a functional on $\mathcal{P}^d \times \mathbf{R}^d$ as follows.

DEFINITION 2.1. *For $a \in \mathcal{P}^d$ and $b \in \mathbf{R}^d$, the* upper generalized Gaussian derivative *of f at x in the direction b with covariance a is*

$$f^G(x;b,a) = \limsup_{\substack{y \to x \\ h \to 0+}} \frac{\mathbb{E}\{(\phi f)(y + bh + \theta w_h) - f(y)\}}{h},$$

where ϕ is any infinitely differentiable function of compact support that is equal to 1 in a neighbourhood of x, where θ is any $d \times m$ dimensional matrix such that $\theta\theta^T = 2a$ and where w is a standard m dimensional Brownian motion. $\mathbb{E}$ stands for expectation.

In [4] we defined a function called $f^G(x;a)$; it is in fact $2f^G(x;0,a)$. We use many of the results proved for f^G; the proofs for the case $b \neq 0$ are straightforward. It can be shown that $f^G(x;b,a)$ is independent of the choice of ϕ, θ, w, [4, Prop. 3.4]. Moreover as in [4, Prop. 4.2], $f^G(x;b,a)$ is positive homogeneous and subadditive on $\mathbf{R}^d \times \mathcal{P}^d$. Observing that $\mathcal{S}^d = \mathcal{P}^d - \mathcal{P}^d$, we can extend $f^G(x;b,a)$ to $\mathbf{R}^d \times \mathcal{S}^d$ as follows:

$$\bar{f}^G(x;b,a) \stackrel{\text{def}}{=} \inf\left\{ \sum_i f^G(x;b_i^+,a_i^+) + \sum_j (-f)^G(x;b_j^-,a_j^-) : a = \sum_i a_i^+ - \sum_j a_j^-, b = \sum_i b_i^+ - \sum_j b_j^-, a_i^+ \in \mathcal{P}^d, a_j^- \in \mathcal{P}^d \right\}. \tag{5}$$

We will show shortly that $\bar{f}^G(x;b,a) = f^G(x;b,a)$ for $a \in \mathcal{P}^d$. To this end, for $a \in \mathcal{P}^d$ and $b \in \mathbf{R}^d$, we define

$$\begin{aligned} f_G(x;b,a) &\stackrel{\text{def}}{=} \liminf_{\substack{y \to x \\ h \to 0+}} \frac{E\{(\phi f)(y + bh + \theta w_h) - f(y)\}}{h} \\ &= -(-f)^G(x;b,a), \end{aligned} \tag{6}$$

where ϕ, θ, w are as in Definition 2.1.

LEMMA 2.1. *For $a \in \mathcal{S}^d, b \in \mathbf{R}^d$,*

$$\bar{f}^G(x;b,a) = \inf\{f^G(x;b^+,a^+) - f_G(x;b^-,a^-) : a = a^+ - a^-, b = b^+ - b^-, a^{\pm} \in \mathcal{P}^d\}. \tag{7}$$

Proof. With $(a,b) = \sum_i (a_i^+, b_i^+) - \sum_j (a_j^-, b_j^-)$, $a^+ = \sum_i a_i^+$, $a^- = \sum_j a_j^-$, $b^+ = \sum_i b_i^+$, $b^- = \sum_j b_j^-$, the subadditivity of f^G implies

$$\begin{aligned} \sum_i f^G(x;b_i^+,a_i^+) + \sum_j (-f)^G(x;b_j^-,a_j^-) &\geq f^G(x;b^+,a^+) + (-f)^G(x;b^-,a^-) \\ &= f^G(x;b^+,a^+) - f_G(x;b^-,a^-) \\ &\geq \text{right-hand side of (7)}. \end{aligned}$$

It follows that the left side of (7) is at least as large as the right side.

The reverse inequality follows readily if we consider the sums in (5) to contain only one term and use (6). □

COROLLARY 2.1. *$\bar{f}^G(x;b,a) = f^G(x;b,a)$ for $(b,a) \in \mathbf{R}^d \times \mathcal{P}^d$.*

Proof. Corollary 4.3 of [4] implies that for $a, a^- \in \mathcal{P}^d$,

$$\begin{aligned} f^G(x;b+b^-,a+a^-) - f_G(x;b^-,a^-) &\geq [f^G(x;b,a) + f_G(x;b^-,a^-)] - f_G(x;b^-,a^-) \\ &= f^G(x;b,a). \end{aligned}$$

Hence with $a = a^+ - a^- \in \mathcal{P}^d$ and $b = b^+ - b^-$, it follows from the Lemma that $\bar{f}^G(x;b,a) \geq f^G(x;b,a)$. As the reverse inequality is obvious, we are done. □

From now on we shall suppress the overbar and take $f^G(x;\cdot,\cdot)$ to be defined on $\mathbf{R}^d \times \mathcal{S}^d$. We can similarly extend $f_G(x;\cdot,\cdot)$ to $\mathbf{R}^d \times \mathcal{S}^d$ by replacing inf by sup and $(\pm f)^G$ by $(\pm f)_G$ in (5). Now we obtain

$$f^G(x;-b,-a) = (-f)^G(x;b,a) = -f_G(x;b,a). \tag{8}$$

We write $\langle a, b\rangle$ for $a \cdot b$ if $a, b \in \mathbf{R}^d$ and for trace(ab) if $a, b \in \mathcal{S}^d$.

DEFINITION 2.2. *The* generalized second-order derivative *of f at x is*

$$\partial^2 f(x) = \{(\beta, \alpha) \in \mathbf{R}^d \times \mathcal{S}^d : \langle \alpha, a\rangle + \langle \beta, b\rangle \le f^G(x; b, a)\, \forall\, (b, a) \in \mathbf{R}^d \times \mathcal{S}^d\}.$$

LEMMA 2.2.

(9)
$$\begin{aligned}\partial^2 f(x) &= \{(\beta, \alpha) \in \mathbf{R}^d \times \mathcal{S}^d : \langle \alpha, a\rangle + \langle \beta, b\rangle \ge f_G(x; b, a)\, \forall\, (b, a) \in \mathbf{R}^d \times \mathcal{S}^d\} \\ &= \{(\beta, \alpha) \in \mathbf{R}^d \times \mathcal{S}^d : f_G(x; b, a) \le \langle \alpha, a\rangle + \langle \beta, b\rangle \le f^G(x; b, a)\, \forall\, (b, a) \in \mathbf{R}^d \times \mathcal{P}^d\}.\end{aligned}$$

Proof. The first equality is a simple application of (8). From this and the definition of $\partial^2 f(x)$ it follows that $\partial^2 f(x)$ is contained in the right side of (9).

Conversely, for (β, α) in the right side of (9), if we decompose $(b, a) \in \mathbf{R}^d \times \mathcal{S}^d$ into

$$(b, a) = (b^+, a^+) - (b^-, a^-), \qquad a^{\pm} \in \mathcal{P}^d,$$

then

$$\begin{aligned}&\langle \alpha, a\rangle + \langle \beta, b\rangle \\ &\quad = \langle \alpha, a^+ - a^-\rangle + \langle \beta, b^+ - b^-\rangle \\ &\quad = [\langle \alpha, a^+\rangle + \langle \beta, b^+\rangle] - [\langle \alpha, a^-\rangle + \langle \beta, b^-\rangle] \\ &\quad \le f^G(x; b^+, a^+) - f_G(x; b^-, a^-),\end{aligned}$$

so the result follows by Lemma 2.1. □

The following decomposition of $\partial^2 f$ is useful. Let us write $\partial^2_H f(x)$ for the Hessian defined by the author in [4], i.e., if we define $f_G(x; a) = 2f_G(x; 0, a)$, then

$$\partial^2_H f(x) = \{\alpha \in \mathcal{S}^d : f_G(x; a) \le \langle \alpha, a\rangle \le f^G(x; a)\, \forall\, a \in \mathcal{P}^d\}.$$

LEMMA 2.3. $\partial^2 f(x) \subset \partial f(x) \times \partial^2_H f(x)$ *with equality if f is strictly differentiable at x, i.e., if $\partial f(x)$ is a singleton.*

Proof. If $(\beta, \alpha) \in \partial^2 f(x)$, then for all $b \in \mathbf{R}^d$ (setting $a = 0$ in the definition)

$$\langle b, \beta\rangle \le f^G(x; b, 0) = f^o(x; b),$$

so that $\beta \in \partial f(x)$. Similarly $\alpha \in \partial^2_H f(x)$. Hence $\partial^2 f(x) \subset \partial f(x) \times \partial^2_H f(x)$.

On the other hand if $\partial f(x) = \{\beta\}$, then $f^G(x; b, a) = f^G(x; 0, a) + \langle b, \beta\rangle$. The result follows. □

Remark. The situation is a little simpler if we assume more regularity. For $\mathcal{O}$ an open set we say that $f \in C^{1,1}(\mathcal{O})$ if f is continuously differentiable on $\mathcal{O}$ with Lipschitz continuous derivatives. This is equivalent to saying that f is in the Sobolev space $W^{2,\infty}(\mathcal{O})$ and implies that the Hessian $f_{x,x}$ exists almost everywhere and is symmetric (since generalized derivatives are symmetric almost everywhere). In this case Lemma 2.3 tells us that $\partial^2 f(x) = \{\nabla f(x)\} \times \partial^2_H f(x)$. Define the Clarke Hessian as $\partial^2_C f(x) \overset{\text{def}}{=} \text{co}\{\lim_i f_{x,x}(x_i) : x_i \to x, x_i \in \text{dom } f_{x,x}\}$. Here co stands for the convex hull. In [4] we showed that for $f \in C^{1,1}(\mathcal{O})$, $\partial^2_H f(x)$ is the conic hull of $\partial^2_C f(x)$, i.e., for $\alpha \in \partial^2_H f(x)$ there exist $\alpha_+, \alpha_- \in \partial^2_C f(x)$ and $p_+, p_- \in \mathcal{P}^d$ such that $\alpha = \alpha_+ + p_+ = \alpha_- - p_-$.

Let us point out that the enlargement to the conic hull is of no importance in the theory of the H–J equation since we will always be concerned with inequalities of the form

$$c + \langle a, \alpha\rangle \le (\ge)\, 0,$$

where c is a scalar and $a \in \mathcal{P}^d$ (this is the ellipticity condition). If such an inequality holds for all $\alpha \in \mathcal{Q}$, then it also holds for all $\alpha \in \mathrm{cc}\mathcal{Q}$, the conic hull of $\mathcal{Q}$. Indeed if, for example, the inequality is $\leq$ and $\alpha \in \mathrm{cc}\mathcal{Q}$, then

$$c + \langle a, \alpha \rangle = c + \langle a, \alpha_- \rangle - \langle a, p_- \rangle \leq -\langle a, p_- \rangle \leq 0.$$

Conversely if the inequality holds for $\alpha \in \mathrm{cc}\mathcal{Q}$, it also holds for $\alpha \in \mathcal{Q}$ since $\mathcal{Q} \subset \mathrm{cc}\mathcal{Q}$.

Hence for $f \in C^{1,1}(\mathcal{O})$, we can take $\partial^2 f(x) = \{\nabla f(x)\} \times \partial^2_C f(x)$.

3. Itô's lemma. For the moment let us consider an uncontrolled Itô process X_t satisfying

$$dX_t = b_t\, dt + \sigma_t\, dw_t,$$

and a function $f : [0,T] \times \mathbf{R}^d \to \mathbf{R}$. We assume that a and b are progressively measurable and $\mathbb{E}\int_0^T |b_t|\, dt < \infty$ and $\mathbb{E}\int_0^T |\sigma_t|^2\, dt < \infty$. It is a well-known result of Itô's that if $f \in C^{1,2}((0,T) \times \mathbf{R}^d)$, then

$$df(t, X_t) = \mathcal{L}f(t, X_t)\, dt + f_x(t, X_t)^T \sigma_t\, dw_t, \quad \text{a.s.}, \tag{10}$$

with

$$\mathcal{L}f(t,x) = f_t(t,x) + \langle a_t, f_{x,x}(t,x) \rangle + b_t \cdot f_x(t,x).$$

Here $a_t = \frac{1}{2}\sigma_t \sigma_t^T$. If f is less regular, a similar result was established by Krylov [7]: Assume that X is as above with additionally $a_t - \lambda I \in \mathcal{P}^d$ for all t, almost all ω, and for some $\lambda > 0$. Suppose that $f \in W^{1,2,d+1}((0,T) \times \mathbf{R}^d)$, the Sobolev space of functions whose derivatives in the sense of distributions of order up to 1 in t and up to 2 in x are in $L^{d+1}((0,T) \times \mathbf{R}^d)$, and suppose also that f is continuous on $[0,T] \times \mathbf{R}^d$ and that the first-order distributional derivatives of f in x are in $L^{2(d+1)}((0,T) \times \mathbf{R}^d)$. Then (10) still holds. If a is degenerate, i.e., $\mathcal{L}$ is not uniformly elliptic, then (10) must, in general, be replaced by an inequality that holds in the mean, [7]. If however, $d = 1$, then the result is correct even in the degenerate case, [6, p. 219]. We shall show that (10) holds in arbitrary dimension for $f \in W^{1,2,\infty}((0,T) \times \mathbf{R}^d)$ if the equation is interpreted appropriately using the generalized Hessian.

We must first define the corresponding generalized second-order derivative. In principle we would use $\partial^2 f(y)$ with $y = (t,x)$, but we observe that in $\mathcal{L}f$ no second-order derivatives in t appear so that we can restrict our attention to a subspace of $\mathcal{S}^{d+1}$, i.e., matrices $a' \in \mathcal{S}^{d+1}$ such that

$$a' = \begin{pmatrix} 0 & 0 \\ 0 & a \end{pmatrix}.$$

If $f(t,x)$ is now a function on $\mathbf{R} \times \mathbf{R}^d = \mathbf{R}^{d+1}$, then for $a \in \mathcal{P}^d$, $b' = (b_o, b)^T \in \mathbf{R}^{d+1}$ we set

$$f^G(t,x;b',a) = \limsup_{\substack{(s,y)\to(t,x) \\ h \to 0+}} \frac{\mathbb{E}\{\phi f(s + b_o h, y + bh + \theta w_h) - f(s,y)\}}{h}$$

and $\partial^2 f(t,x)$ analogously. If $b_o \neq 0$, we can always normalize so that $b_o = 1$ without changing $\partial^2 f(t,x)$. Indeed let us write β' for (β_o, β) and take λ to be a scalar. If $\lambda > 0$, then

$$\langle \alpha, a \rangle + \langle \beta', \lambda b' \rangle \leq f^G(t,x;\lambda b', a)$$

if and only if

$$\langle \alpha, \lambda^{-1}a\rangle + \langle \beta', b'\rangle \le f^G(t,x;b',\lambda^{-1}a).$$

Now if $\lambda = -\mu < 0$, then the "if and only if" becomes (cf. (8))

$$\begin{aligned}\langle \alpha, -\mu^{-1}a\rangle + \langle \beta', b'\rangle &\ge -f^G(t,x;-b',\mu^{-1}a)\\ &= -(-f)^G(t,x;b',-\mu^{-1}a)\\ &= f_G(t,x;b',-\mu^{-1}a).\end{aligned}$$

According to (9), we will not change $\partial^2 f(t,x)$ if we take $\lambda = (b_o)^{-1}$. Hence we can always take $b' = (1,b)^T$. Let $\mathcal{O} \in \mathbf{R}\times\mathbf{R}^d$ be open. Let $f \in BM(\mathcal{O})$.

DEFINITION 3.1. *For* $(b,a) \in \mathbf{R}^d \times \mathcal{P}^d$,

$$\begin{aligned} f^G(t,x;b,a) &= \limsup_{\substack{(s,y)\to(t,x)\\ h\to 0+}} \frac{\mathbb{E}\{\phi f(s+h, y+bh+\theta w_h) - f(s,y)\}}{h},\\ f_G(t,x;a,b) &= \liminf_{\substack{(s,y)\to(t,x)\\ h\to 0+}} \frac{\mathbb{E}\{\phi f(s+h, y+bh+\theta w_h) - f(s,y)\}}{h}. \end{aligned} \tag{11}$$

We can extend these definitions to $a \in \mathcal{S}^d$ as usual. To emphasize the fact that we are only working with a first derivative in t, we now change notation from $\partial^2 f$.

DEFINITION 3.2.

$$\begin{aligned}\partial^{1,2} f(t,x) &= \{(\beta_o,\beta,\alpha) \in \mathbf{R}\times\mathbf{R}^d\times\mathcal{S}^d :\\ &\qquad \langle \alpha, a\rangle + \langle \beta, b\rangle + \beta_o \le f^G(t,x;b,a)\,\forall\,(b,a) \in \mathbf{R}^d\times\mathcal{S}^d\}\\ &= \{(\beta_o,\beta,\alpha) \in \mathbf{R}\times\mathbf{R}^d\times\mathcal{S}^d :\\ &\qquad f_G(t,x;a,b) \le \langle \alpha, a\rangle + \langle \beta, b\rangle + \beta_o \le f^G(t,x;b,a)\,\forall\,(b,a) \in \mathbf{R}^d\times\mathcal{P}^d\}.\end{aligned}$$

THEOREM 3.1. *Assume that* $f \in W^{1,2,\infty}((0,T)\times\mathbf{R}^d)$ *and that* σ, b *are bounded, predictable. Then there exists a predictable process* $(\beta_o(t,\omega),\beta(t,\omega),\alpha(t,\omega))$ *such that*

$$(\beta_o(t,\omega),\beta(t,\omega),\alpha(t,\omega)) \in \partial^{1,2} f(t, X_t(\omega))$$

and

$$\begin{aligned} f(t,X_t) = f(0,X_0) &+ \int_0^t [\beta_o(s,\omega) + \langle b_s, \beta(s,\omega)\rangle + \langle a_s, \alpha(s,\omega)\rangle]\,ds\\ &+ \int_0^t \beta(s,\omega)^T \sigma_s\,dw_s \qquad \text{a.s.}\end{aligned} \tag{12}$$

Moreover, there exists a set A *of full Lebesgue measure such that the usual derivatives* $(f_t(t,x), f_x(t,x), f_{x,x}(t,x))$ *exist for* $(t,x) \in A$ *and*

$$(\beta_o(t,\omega),\beta(t,\omega),\alpha(t,\omega)) = (f_t(t,X_t(\omega)), f_x(t,X_t(\omega)), f_{x,x}(t,X_t(\omega)))$$

whenever $(t,X_t(\omega)) \in A$.

Proof. The last part of the theorem is obvious since functions in $W^{1,2,\infty}$ are Lipschitz in t, and have Lipschitz continuous (in x) first-order partial derivatives with respect to x. So, in fact, $\beta(t,\omega) = f_x(t,X_t(\omega))$. Let X^ϵ satisfy

$$dX_t^\epsilon = b_t\,dt + \sigma_t\,dw_t + \sqrt{\epsilon}\,dw_t'$$

for an independent Brownian motion w'_t. Let

$$g_t^\epsilon = f(t, X_t^\epsilon) - f(0, X_0^\epsilon) - \int_0^t f_x(t, X_r^\epsilon)^T \sigma_r \, dw_r - \sqrt{\epsilon} \int_0^t f_x(t, X_r^\epsilon)^T \, dw'_r.$$

It is well known that $\lim_{\epsilon \to 0} \sup_{0 \le t \le T} |X_t^\epsilon - X_t| = 0$, and so

$$\begin{aligned} \lim_{\epsilon \to 0} g_t^\epsilon &= g_t \\ &\stackrel{\text{def}}{=} f(t, X_t) - f(0, X_0) - \int_0^t f_x(t, X_r)^T \sigma_r \, dw_r. \end{aligned}$$

Moreover, Krylov's result implies that

$$g_t^\epsilon - g_s^\epsilon = \int_s^t [\langle f_{x,x}(r, X_r^\epsilon), a_r \rangle + \langle f_x(r, X_r^\epsilon), b_r \rangle + f_t(r, X_r^\epsilon) + \tfrac{1}{2}\epsilon \langle f_{x,x}(r, X_r^\epsilon), I \rangle] \, dr \quad \text{a.s.},$$

and hence

$$|g_t - g_s| \le K \|f\|_{1,2,\infty} |t - s| \quad \text{a.s.}$$

for some constant K. Thus $dg_t(\omega)/dt \stackrel{\text{def}}{=} g'(t, \omega)$ exists almost everywhere, almost surely. If we set $g'_n(t, \omega) = n[g_t(\omega) - g_{t-1/n}(\omega)]$, then g'_n is adapted and continuous, hence predictable, and $g'_n \to g'$ almost everywhere, almost surely, so g' is predictable (we assume that the underlying filtration is complete). Define

$$F(t, \omega) = \{(\beta_o, \beta, \alpha) \in \partial^{1,2} f(t, X_t(\omega)) : g'(t, \omega) = \beta_o + \langle \beta, b_t(\omega) \rangle + \langle \alpha, a_t(\omega) \rangle\}.$$

We will show that there is a measurable (i.e., predictable) selection of F on $[0, T] \times \Omega$; this will establish the theorem.

We begin by showing that $F(t, \omega) \neq \emptyset$. Let

$$I(t, \omega) \stackrel{\text{def}}{=} \{\beta_o + \langle \beta, b_t(\omega) \rangle + \langle \alpha, a_t(\omega) \rangle : (\beta_o, \beta, \alpha) \in \partial^{1,2} f(t, X_t(\omega))\}.$$

Since $\partial^{1,2} f(t, X_t(\omega))$ is convex and compact, then so is $I(t, \omega)$, i.e., it is an interval $[A(t, \omega), B(t, \omega)]$. We define $A^\epsilon(t, \omega), B^\epsilon(t, \omega)$ similarly using X_t^ϵ. Since $(t, x) \to \partial^{1,2} f(t, x)$ is upper semi-continuous, then

$$\liminf_{\substack{t \to s \\ \epsilon \to 0+}} A^\epsilon(t, \omega) \ge A(s, \omega), \qquad \limsup_{\substack{t \to s \\ \epsilon \to 0+}} B^\epsilon(t, \omega) \le B(s, \omega).$$

Since

$$g_t^\epsilon(\omega) - g_s^\epsilon(\omega) \le \int_s^t B^\epsilon(r, \omega) \, dr + \tfrac{1}{2}\epsilon \|f\|_{1,2,\infty} |t - s|,$$

then for all $\delta > 0$, there exists ϵ_δ such that if $|t - s| < \epsilon_\delta$ and $\epsilon < \epsilon_\delta$, then

$$g_t^\epsilon(\omega) - g_s^\epsilon(\omega) \le [B(s, \omega) + \delta + k\epsilon] |t - s|$$

for some constant k. Now let $\epsilon \to 0$ to conclude that $g'(t, \omega) \le B(t, \omega) + \delta$. Let $\delta \to 0$ and do the corresponding estimate for $A(t, \omega)$ to conclude that $g'(t, \omega) \in I(t, \omega)$ and hence $F(t, \omega) \neq \emptyset$.

Next we observe that $F(t,\omega)$ is compact since $\partial^{1,2}f(t,X(\omega))$ is, since

$$\pi(t,\omega) \stackrel{\text{def}}{=} \{(\beta_o,\beta,\alpha) : g'(t,\omega) = \beta_o + \langle\beta, b_t(\omega)\rangle + \langle\alpha, a_t(\omega)\rangle\}$$

is closed and $F(t,\omega) = \pi(t,\omega) \cap \partial^{1,2}f(t,X_t(\omega))$.

It remains to show that the multifunction F is measurable. Observe that π is a plane so we have a formula for the distance ρ of an arbitrary but fixed point to the plane. As the mapping $(t,\omega) \to \rho$ is predictable, then π is measurable (see [8, Thm. 4.2]). Since $F(t,\omega) = \pi(t,\omega) \cap \partial^{1,2}f(t,X_t(\omega))$, then F is measurable provided $\partial^{1,2}f$ is (see [8, p. 863]). It is easy to see that upper semi-continuity of $\partial^{1,2}f$ as defined in [1] and established in [4] implies upper semi-continuity in the sense of [8], i.e., for any closed set K, $\{(t,x) : \partial^{1,2}f(t,x) \cap K \neq \emptyset\}$ is closed, which obviously implies measurability.

The existence of a measurable selection of F now follows from a standard theorem, [8, Thm. 4.1]. □

4. Generalized solutions. We consider the control problem

$$X_s^{t,x,u} = x + \int_0^s b(t+r, X_t^{t,x,u}, u_r)\,dr + \int_0^s \sigma(t+r, X_r^{t,x,u}, u_r)\,dw_r \tag{13}$$

with cost

$$J^{t,x}(u) = \mathbb{E}\left\{\int_0^{T-t} f(t+r, X_r^{t,x,u}, u_r)\,dr + f_o(X_{T-t}^{t,x,u})\right\}. \tag{14}$$

The corresponding value function is

$$v(t,x) = \inf_{u\in\mathcal{U}} J^{t,x}(u), \tag{15}$$

where $\mathcal{U}$ is the set of U-valued, progressively measurable stochastic process on $[0,T)$. It follows from a generalized dynamic programming argument, [5, Props. 5.9 and 5.11], that

$$\Gamma_s^{t,x,u} \stackrel{\text{def}}{=} \int_0^s f(t+r, X_r^{t,x,u}, u_r)\,dr + v(t+s, X_s^{t,x,u}) \tag{16}$$

is a submartingale for any $u \in \mathcal{U}$ and is a martingale if and only if u is optimal. If v is smooth, this implies that it is the unique classical solution of the H–J equation, i.e.,

$$-v_t(t,x) + H(t,x,-v_x(t,x),-v_{x,x}(t,x)) = 0,$$

where the subscripts denote partial derivatives and where H is the Hamiltonian for the problem and is defined on $[0,T] \times \mathbf{R}^d \times \mathbf{R}^d \times \mathcal{S}^d$ as

$$H(t,x,p,P) \stackrel{\text{def}}{=} \sup_{u\in U}\{\langle P, a(t,x,u)\rangle + \langle p, b(t,x,u)\rangle - f(t,x,u)\}.$$

Note that $a = \frac{1}{2}\sigma\sigma^T$. This situation occurs rarely, but it is true that v is always a weak (in the sense of distributions) solution, although the latter are not unique. We shall show that v satisfies the H–J equation in a generalized sense, at least if v possesses some regularity.

DEFINITION 4.1. *A function $v \in BM(\mathcal{O})$ is a* generalized solution *of* (H–J) *in $\mathcal{O}$ if, for each $(t,x) \in \mathcal{O}$,*

$$\inf_{(\beta_o,\beta,\alpha)\in\partial^{1,2}v(t,x)}\{\beta_o - H(t,x,-\beta,-\alpha)\} = 0. \tag{17}$$

Let us suppose that $v \in W^{1,2,\infty}_{\text{loc}}(\mathcal{O})$ so that v_t and $v_{x,x}$ exist almost everywhere. It follows from [4, Thm. 5.6] that

$$\begin{aligned}\partial^{1,2}v(t,x) = \text{ cc co}\{\lim_i (v_t(t_i,x_i), v_x(t,x), v_{x,x}(t_i,x_i)) : \\ (t_i,x_i) \to (t,x), (t_i,x_i) \in \text{dom}(v_t, v_{x,x})\},\end{aligned} \tag{18}$$

where the operation of taking the conic hull applies to the component in $\mathcal{S}^d$, i.e., for $M \subset \mathbf{R}^{d+1} \times \mathcal{S}^d$, $\text{cc}M = (M + \mathcal{P}^d_o) \cap (M - \mathcal{P}^d_o)$ where $\mathcal{P}^d_o = \{0\} \times \mathcal{P}^d$. Hence $\partial^{1,2}v(t,x) \neq \emptyset$. We now have the main result of this section.

THEOREM 4.1. *Assume that $v \in W^{1,2,\infty}_{\text{loc}}((0,T) \times \mathbf{R}^d)$ is the value function. Then v is a generalized solution of* (H–J) *on* $(0,T) \times \mathbf{R}^d$.

Proof. We shall first show that the left side of (17) is at least 0. Let us take u constant in (13); then

$$\begin{aligned}X^{s,y,u}_h &= y + \int_0^h b(s+r, X^{s,y,u}_r, u)\,dr + \int_0^h \sigma(s+r, X^{s,y,u}_r, u)\,dw_r \\ &= y + hb(t,x,u) + \sigma(t,x,u)w_h + \rho_1 + \rho_2,\end{aligned}$$

where

$$\rho_1 = \int_0^h [b(s+r, X^{s,y,u}_r, u) - b(t,x,u)]\,dr$$

and

$$\rho_2 = \int_0^h [\sigma(s+r, X^{s,y,u}_r, u) - \sigma(t,x,u)]\,dw_r.$$

Observe that the Lipschitz continuity in x of b and standard estimates show that

$$h^{-1}\rho_1 = o(1), \tag{19}$$

where $o(1)$ is a random function $g(s,y)$ such that

$$\lim_{\substack{(s,y)\to(t,x)\\ h\to 0+}} \mathbb{E}|g(s,y)|^2 = 0.$$

Similarly

$$h^{-1/2}\rho_2 = o(1). \tag{20}$$

Now

$$\begin{aligned}v(s+h, X^{s,y,u}_h) - v(s,y) &= [v(s+h, y + hb(t,x,u) + \sigma(t,x,u)w_h + \rho_1 + \rho_2) \\ &\quad - v(s+h, y + hb(t,x,u) + \sigma(t,x,u)w_h)] \\ &\quad + [v(s+h, y + hb(t,x,u) + \sigma(t,x,u)w_h) - v(s,y)] \\ &= \Delta v + [v(s+h, y + hb(t,x,u) + \sigma(t,x,u)w_h) - v(s,y)].\end{aligned} \tag{21}$$

But v_x is locally Lipschitz continuous, so

$$\begin{aligned}\Delta v &= [v_x(s+h, y + hb(t,x,u) + \sigma(t,x,u)w_h + \xi(\rho_1+\rho_2))](\rho_1+\rho_2) \\ &= v_x(s+h,y)(\rho_1+\rho_2) + [v_x(s+h, y + hb(t,x,u) + \sigma(t,x,u)w_h \\ &\qquad + \xi(\rho_1+\rho_2)) - v_x(s+h,y)](\rho_1+\rho_2),\end{aligned}$$

where ξ is a random variable assuming values in $(0, 1)$. Set

$$v_x(s+h, y+hb(t,x,u)+\sigma(t,x,u)w_h+\xi(\rho_1+\rho_2)) - v_x(s+h,y) = \Delta_1 v.$$

Then

$$\begin{aligned}\Delta_1 v &\le K|hb(t,x,u)+\sigma(t,x,u)w_h+\xi(\rho_1+\rho_2)| \\ &\le K_1\{|h|+|w_h|+|\rho_1|+|\rho_2|\}\end{aligned}$$

and hence

$$\lim_{\substack{(s,y)\to(t,x)\\ h\to 0+}} h^{-1}\mathbb{E}\Delta v = 0. \tag{22}$$

If now we set $b = b(t,x,u)$ and $a = \frac{1}{2}\sigma(t,x,u)\sigma(t,x,u)^T$, then it follows from (16), (11), (21), and (22) that

$$\begin{aligned}v_G(t,x;b,a) &= \liminf_{\substack{(s,y)\to(t,x)\\ h\to 0+}} h^{-1}\mathbb{E}\{\phi v(s+h, X_h^{s,y,u}) - v(s,y)\} \\ &= \liminf_{\substack{(s,y)\to(t,x)\\ h\to 0+}} h^{-1}\mathbb{E}\{v(s+h, X_h^{s,y,u}) - v(s,y)\} \\ &\ge \liminf_{\substack{(s,y)\to(t,x)\\ h\to 0+}} h^{-1}\mathbb{E}\int_0^h -f(s+r, X_r^{s,y,u})\,dr \\ &= -f(t,x,u)\end{aligned}$$

(the ϕ can be omitted since v has at most polynomial growth). Hence for $(\beta_o, \beta, \alpha) \in \partial^{1,2}v(t,x)$,

$$f(t,x,u) + \langle \alpha, a(t,x,u)\rangle + \langle \beta, b(t,x,u)\rangle + \beta_o \ge 0$$

so that

$$\beta_o - H(t,x,-\beta,-\alpha) \ge 0.$$

Let us now show that the left side of (4.1) is at most zero. Let (t,x) be a point such that $v_t(t,x), v_{x,x}(t,x)$ exist, i.e., $(t,x) \in \mathrm{dom}(v_t, v_{x,x})$.

Since we are not assuming convexity of U, we consider now the relaxed control problem, i.e., we take the controls to be probability measures on U, and if μ is such a control, we replace $f(t,x,u)$ by

$$f(t,x,u) = \int_U f(t,x,u)\,\mu(du)$$

and similarly for b. On the other hand, $\sigma(t,x,\mu)$ is a square root of

$$2a(t,x,\mu) = 2\int_U a(t,x,u)\,\mu(du).$$

If a is singular for some (t,x,u), then we may have to extend the probability space to carry an independent Brownian motion in addition to X. Neither the value function v nor the Hamiltonian H change under this enlargement. Let μ^* be an optimal Markov control. It exists by the results of [5]. We write $X^{t,x}_\cdot$ for the corresponding state, i.e.,

$$X_s^{t,x} = x + \int_0^s b(t+r, X_r^{t,x}, \mu^*(t+r, X_r^{t,x}))\,dr + \int_0^s \sigma(t+r, X_r^{t,x}, \mu^*(t+r, X_r^{t,x}))\,dw_r.$$

Then, cf. (16), Γ_s^{t,x,μ^*} is a martingale and so Theorem 3.1 implies there is a $\partial^{1,2}v(t+s, X_s^{t,x})$ valued process $(\beta_o(s), \beta(s), \alpha(s))$ such that

$$\int_0^s [f(t+r, X_r^{t,x}, \mu^*(t+r, X_r^{t,x})) + \beta_o(r) + \langle \beta(r), b(t+r, X_r^{t,x}, \mu^*(t+r, X_r^{t,x}))\rangle + \langle \alpha(r), a(t+r, X_r^{t,x}, \mu^*(t+r, X_r^{t,x}))\rangle]\, dr = 0 \qquad \text{a.s.}$$

We wish to differentiate the above with respect to s at $s = 0$ so we consider

(23)

$$h^{-1}\int_0^h [f(t+r, X_r^{t,x}, \mu^*(t+r, X_r^{t,x})) + \beta_o(r) + \langle \beta(r), b(t+r, X_r^{t,x}, \mu^*(t+r, X_r^{t,x}))\rangle + \langle \alpha(r), a(t+r, X_r^{t,x}, \mu^*(t+r, X_r^{t,x}))\rangle]\, dr = 0 \qquad \text{a.s.}$$

A typical term in (23) is

$$\begin{aligned} & h^{-1}\int_0^h \langle \alpha(r), a(t+r, X_r^{t,x}, \mu^*(t+r, X_r^{t,x}))\rangle\, dr \\ & = h^{-1}\int_0^h \langle v_{x,x}(t,x), a(t+r, X_r^{t,x}, \mu^*(t+r, X_r^{t,x}))\rangle\, dr + o(1) \\ & = h^{-1}\int_0^h \langle v_{x,x}(t,x), \int_U a(t,x,u)\mu^*(t+r, X_r^{t,x})(du)\rangle\, dr + o(1) \\ & = \langle v_{x,x}(t,x), a(t,x,\mu_h)\rangle + o(1) \end{aligned} \tag{24}$$

by the upper semi-continuity of $\partial^{1,2}v$ and the Lipschitz continuity of a. Here

$$\mu_h(A) = h^{-1}\int_0^h \mu^*(t+r, X_r^{t,x})(A)\, dr,$$

again a probability measure on U and $o(1) \to 0$ almost surely as $h \to 0$. Since U is compact, then there exists a sequence $h_n \to 0$ such that μ_{h_n} converges weakly to some probability measure μ_o on U. The terms involving f and b are treated similarly. Hence taking the limit $h \to 0$ along a suitable subsequence in (23) leads to

$$v_t(t,x) - \{\langle -v_{x,x}(t,x), a(t,x,\mu_o)\rangle - \langle -v_x(t,x), b(t,x,\mu_o)\rangle - f(t,x,\mu_o)\} = 0, \tag{25}$$

and hence

$$v_t(t,x) - H(t,x,-v_x,-v_{x,x}) \le 0.$$

This holds for $(t,x) \in \operatorname{dom}(v_t, v_{x,x})$. For arbitrary (t,x) let (t_i, x_i) be a sequence in $\operatorname{dom}(v_t, v_{x,x})$ converging to (t,x) such that $(v_t(t_i,x_i), v_x(t_i,x_i), v_{x,x}(t_i,x_i))$ converges; it will converge to an element of $\partial^{1,2}v(t,x)$ according to (18). It follows that

$$\inf_{(\beta_o,\beta,\alpha)\in\partial^{1,2}v(t,x)} \{\beta_o - H(t,x,-\beta,-\alpha)\} \le 0$$

and the proof is complete. □

5. Viscosity solutions. Let us now investigate the relation between generalized solutions and viscosity solutions of H–J. Recall that the viscosity solution is unique and is, in fact, the value function. It follows from Theorem 4.1 that the viscosity solution of H–J is a generalized solution. We would like, however, to investigate this relationship without recourse to the value function. We now call H–J any equation of the form

$$v_t(t,x) - H(t,x,-v_x(t,x),-v_{x,x}(t,x)) = 0,$$

with H continuous, convex in its last two arguments, and elliptic in the sense that $H(t,x,p,P) \leq H(t,x,p,Q)$ if $P \leq Q$. We begin with some definitions related to viscosity solutions. Let f be continuous in a neighbourhood of x.

DEFINITION 5.1. *The* superdifferential *of f at $x \in \boldsymbol{R}^d$ is the set*

$$D^2_+ f(x) = \left\{ (\beta,\alpha) \in \mathbf{R}^d \times \mathcal{S}^d : \limsup_{y \to x} \frac{f(y) - f(x) - \beta \cdot (y-x) - \frac{1}{2}(y-x)^T \alpha (y-x)}{\|y-x\|^2} \leq 0 \right\}.$$

The subdifferential *of f at $x \in \boldsymbol{R}^d$ is the set*

$$D^2_- f(x) = \left\{ (\beta,\alpha) \in \mathbf{R}^d \times \mathcal{S}^d : \liminf_{y \to x} \frac{f(y) - f(x) - \beta \cdot (y-x) - \frac{1}{2}(y-x)^T \alpha (y-x)}{\|y-x\|^2} \geq 0 \right\}.$$

It follows that these sets are closed, convex, and unbounded if not empty. In fact if $(\beta,\alpha) \in D^2_+ f(x)$, then $(\beta,\alpha) + \mathcal{P}^d_o \subset D^2_+ f(x)$. Recall that $\mathcal{P}^d_o = \{0\} \times \mathcal{P}^d$. Moreover

$$D^2_- f(x) = -D^2_+(-f)(x). \tag{26}$$

We point out that it is customary to let $\alpha \in \mathbf{R}^{d \times d}$ in the definition of the sub- and superdifferentials; however, since such α are only considered in inner products with symmetric matrices both in the definition and applications, it is no great loss to symmetrize them. To relate these derivatives to $\partial^2 f(t,x)$, we replace $\mathbf{R}^d$ by $\mathbf{R}^{d+1}$ and $\mathcal{S}^d$ by $\mathcal{S}^{d+1}$ in the above definitions. We write

$$\alpha' = \begin{pmatrix} \alpha_o & \alpha_1 \\ \alpha_1^T & \alpha \end{pmatrix}, \qquad \beta' = \begin{pmatrix} \beta_o \\ \beta \end{pmatrix},$$

with $\alpha \in \mathcal{S}^d, \beta \in \mathbf{R}^d$, and α_o, β_o scalars. Consider parabolic equations as degenerate elliptic equations; as these involve second-order derivatives only with respect to x, let us define $D^{1,2}_+ f$ and $D^{1,2}_- f$ by projecting out the unnecessary components in $D^2_+ f$ and $D^2_- f$, i.e.,

$$D^{1,2}_+ f(t,x) = \{(\beta_o,\beta,\alpha) \in \mathbf{R} \times \mathbf{R}^d \times \mathcal{S}^d : (\beta',\alpha') \in D^2_+ f(t,x)\},$$
$$D^{1,2}_- f(t,x) = \{(\beta_o,\beta,\alpha) \in \mathbf{R} \times \mathbf{R}^d \times \mathcal{S}^d : (\beta',\alpha') \in D^2_- f(t,x)\}.$$

We observe that these differentials are subsets of the corresponding differentials $D^{1,2,\pm}_{t+,x} f(t,x)$ defined by Zhou [9] as

$$D^{1,2,+}_{t+,x} f(t,x) = \Bigg\{ (\beta_o,\beta,\alpha) \in \mathbf{R} \times \mathbf{R}^d \times \mathcal{S}^d : \limsup_{\substack{y \to x \\ h \to 0+}} \frac{f(t+h,y) - f(t,x) - \beta_o h - \beta \cdot (y-x) - \frac{1}{2}(y-x)^T \alpha (y-x)}{h + \|y-x\|^2} \leq 0 \Bigg\},$$

and similarly $D^{1,2,-}_{t+,x} f(t,x)$. Note that if $(\beta_o^+, \beta^+, \alpha^+) \in D^{1,2}_+ f(t,x)$ and $(\beta_o^-, \beta^-, \alpha^-) \in D^{1,2}_- f(t,x)$, then $\beta_o^+ = \beta_o^-, \beta^+ = \beta^-$, and $\alpha^+ \geq \alpha^-$, whereas if $D^{1,2}_\pm f(t,x)$ is replaced by $D^{1,2,\pm}_{t+,x} f(t,x)$, then in the above we replace $\beta_o^+ = \beta_o^-$ by $\beta_o^+ \geq \beta_o^-$. Let $\mathcal{O} \subset \mathbf{R}^{d+1}$ be open.

THEOREM 5.1. *If f is continuous at $(t,x) \in \mathcal{O}$, then*

$$D^{1,2}_+ f(t,x) \subset \partial^{1,2} f(t,x) + \mathcal{P}^d_o,$$
$$D^{1,2}_- f(t,x) \subset \partial^{1,2} f(t,x) - \mathcal{P}^d_o.$$

Proof. We only prove the second inclusion as the first then follows from (26) and the fact that $-\partial^{1,2}(-f) = \partial^{1,2} f$. Consider $(\beta_o, \beta, \alpha) \in D^{1,2}_- f(t,x)$. Given $\epsilon > 0$, there exists $\delta > 0$ such that

$$\begin{aligned} f(s,y) - f(t,x) - \beta_o(s-t) - \beta \cdot (y-x) - \tfrac{1}{2}(y-x)^T \alpha (y-x) \\ \geq -\epsilon\{|s-t|^2 + \|y-x\|^2\} + (y-x)^T \alpha_1 (s-t) + \tfrac{1}{2}\alpha_o (s-t)^2 \end{aligned} \tag{27}$$

for $\|(s,y) - (t,x)\| < \delta$. For $a = \frac{1}{2}\theta\theta^T \in \mathcal{P}^d$, $b \in \mathbf{R}^d$ let $s = t + h$, $y = x + bh + \theta w_h$ for a suitable Brownian motion. If h is sufficiently small, then by Chebychev's inequality $\|(s,y) - (t,x)\| < \delta$ except on a set of probability measure less than Kh^2, where K is a constant that may depend on ϵ and a but not h. Let ϕ be a smooth function of compact support, equal to one on $\|(s,y) - (t,x)\| < \delta$. Since f is bounded near (t,x), then from (27) it follows that

$$\begin{aligned} &\mathbb{E}\phi f(t+h, x+bh+\theta w_h) - f(t,x) \\ &\quad \geq \beta_o h + \langle \beta, b \rangle h + \langle \alpha, a \rangle h - \epsilon\{(1 + \|b\|^2)h^2 + 2\|a\|h\} - O(h^2) \end{aligned}$$

and hence, after dividing by h, letting $h \to 0$ and then $\epsilon \to 0$,

$$f^G(t,x;b,a) \geq \beta_o + \langle \beta, b \rangle + \langle \alpha, a \rangle.$$

Since the support function at $(1,b,a)$ of $\partial^{1,2} f(t,x) - \mathcal{P}^d_o \stackrel{\text{def}}{=} \mathcal{A}$ is

$$\begin{aligned} \sup_{(\beta_o,\beta,\alpha)\in\mathcal{A}} \{\beta_o + \langle b, \beta \rangle + \langle a, \alpha \rangle\} &= f^G(t,x;b,a) - \inf\{\langle a, p \rangle : p \in \mathcal{P}^d\} \\ &= \begin{cases} f^G(t,x;b,a) & \text{if } a \in \mathcal{P}^d, \\ \infty & \text{otherwise,} \end{cases} \end{aligned}$$

we can conclude that $(\beta_o, \beta, \alpha) \in \partial^{1,2} f(t,x) - \mathcal{P}^d_o$. □

DEFINITION 5.2. *A continuous function v is a* viscosity subsolution *of* H–J *if, for every* (t,x),

$$\inf_{(\beta_o,\beta,\alpha)\in D^{1,2}_+ v(t,x)} \{\beta_o - H(t,x,-\beta,-\alpha)\} \geq 0;$$

it is a viscosity supersolution *if*

$$\sup_{(\beta_o,\beta,\alpha)\in D^{1,2}_- v(t,x)} \{\beta_o - H(t,x,-\beta,-\alpha)\} \leq 0;$$

and it is a viscosity solution *if it is both a viscosity sub- and supersolution.*

From Theorem 5.1 and the fact that for $p \in \mathcal{P}^d$,

$$H(t,x,-\beta,-\alpha) \geq H(t,x,-\beta,-\alpha-p),$$

it follows that *a generalized solution is a viscosity subsolution.* Unlike the deterministic case [3], it is not clear what additional hypothesis is required to ensure that it is a supersolution. We can, however, show that a viscosity solution is a generalized solution.

THEOREM 5.2. *If* $v \in W^{1,2,\infty}_{\text{loc}}(\mathcal{O})$ *is a viscosity solution of* H–J *on* $\mathcal{O}$, *then it is a generalized solution on* $\mathcal{O}$.

Proof. We follow Frankowska [3]. Let $(t_i, x_i) \to (t, x)$ with $(t_i, x_i) \in \operatorname{dom}(v_t, v_{x,x})$ and $(v_t(t_i, x_i), v_{x,x}(t_i, x_i)) \to (\beta_o, \alpha)$ for some (β_o, α). As a viscosity solution is an almost everywhere solution, then

$$v_t(t_i, x_i) - H(t_i, x_i, -v_x(t_i, x_i), -v_{x,x}(t_i, x_i)) = 0.$$

The continuity of H implies that

$$\beta_o - H(t, x, -v_x(t, x), -\alpha) = 0.$$

The convexity of H implies that the left-hand side above is concave. Then for $(\beta_o, \beta, \alpha) \in \operatorname{co}\{\lim_{(t_i,x_i)\to(t,x)}(v_t(t_i, x_i), v_x(t_i, x_i), v_{x,x}(t_i, x_i))\}$,

$$\beta_o - H(t, x, -\beta, -\alpha) \geq 0.$$

As pointed out previously, the same inequality now holds on the conic hull of the set and hence on $\partial^2 v(t, x)$ and v is a generalized solution. □

6. Appendix. To derive a generalized Hessian as a closed convex set with support functional f^{oo} (cf. (4) for the definition), it is easiest to use the setting of tensors. Recall that if $\mathcal{B}(\mathbf{R}^d)$ is the space of continuous bilinear functionals on $\mathbf{R}^d$ and if $(\mathbf{R}^d \otimes \mathbf{R}^d)^*$ is the dual of the tensor product $\mathbf{R}^d \otimes \mathbf{R}^d$, then $\mathcal{B}(\mathbf{R}^d)$ is isomorphic to $(\mathbf{R}^d \otimes \mathbf{R}^d)^*$. We shall identify these two isomorphic spaces. Now f^{oo} can be extended to a positive homogeneous subadditive functional defined on $\mathbf{R}^d \otimes \mathbf{R}^d$ by

$$f^{oo}_T(x; a) \stackrel{\text{def}}{=} \inf\left\{\sum_i f^{oo}(x; u_i, v_i) : a = \sum_i u_i \otimes v_i\right\}.$$

We can define the generalized Hessian of f at x as a set in $\mathcal{B}(\mathbf{R}^d)$ as follows:

$$\partial^2_T f(x) \stackrel{\text{def}}{=} \{\alpha \in \mathcal{B}(\mathbf{R}^d) : \langle \alpha, a\rangle \leq f^{oo}_T(x; a), a \in \mathbf{R}^d \otimes \mathbf{R}^d\},$$

where $\langle \cdot\,, \cdot \rangle$ denotes duality between $\mathbf{R}^d \otimes \mathbf{R}^d$ and $(\mathbf{R}^d \otimes \mathbf{R}^d)^*$ or $\mathcal{B}(\mathbf{R}^d)$. Cominetti and Correa [2] define a generalized Hessian, $\partial^2_{CC} f(x)$, somewhat differently using fans and prefans. It can be shown that, in their terminology, $\partial^2_T f(x)$ is the generator of the largest linearly generated prefan contained in $\partial^2_{CC} f(x)$.

Of course we may want the Hessian to contain only symmetric elements. In that case we simply work on a suitable subspace of $\mathbf{R}^d \otimes \mathbf{R}^d$. Let $\mathcal{S}^d$ denote the symmetric elements in $\mathcal{B}(\mathbf{R}^d)$, i.e.,

$$\mathcal{S}^d = \{f \in \mathcal{B}(\mathbf{R}^d) : f(x, y) = f(y, x)\}$$

(we identify it with the symmetric $d \times d$ matrices). The $\mathcal{S}^d$ is isomorphic to a subspace S^* of "symmetric" elements of $(\mathbf{R}^d \otimes \mathbf{R}^d)^*$. For $a = \sum_i x_i \otimes y_i$, we set $a^* = \sum_i y_i \otimes x_i$ and we set

$$\begin{aligned}\mathbf{R}^d \otimes_s \mathbf{R}^d &= \left\{\sum_i x_i \otimes x_i - \sum_j y_j \otimes y_j\right\} \\ &= \{a \in \mathbf{R}^d \otimes \mathbf{R}^d : a^* = a\}.\end{aligned}$$

Then polar decomposition and symmetry imply that the elements of S^* are determined by their action on $\mathbf{R}^d \otimes_s \mathbf{R}^d$ and we can take S^* to be $(\mathbf{R}^d \otimes_s \mathbf{R}^d)^*$. Ignoring the isomorphism from now on, we identify $\mathcal{S}^d$ with $(\mathbf{R}^d \otimes_s \mathbf{R}^d)^*$. Then for $a \in \mathbf{R}^d \otimes_s \mathbf{R}^d$ we define

$$f_S^{oo}(x;a) \stackrel{\text{def}}{=} \inf\left\{\sum_i f^{oo}(x;u_i,u_i) + \sum_j (-f)^{oo}(x;v_j,v_j) : a = \sum_i u_i \otimes u_i - \sum_j v_j \otimes v_j\right\}$$

and

$$\partial_S^2 f(x) \stackrel{\text{def}}{=} \{\alpha \in \mathcal{S}^d : \langle \alpha, a\rangle \le f_S^{oo}(x;a), a \in \mathbf{R}^d \otimes_s \mathbf{R}^d\}.$$

Observe that the definition of $f_S^{oo}(x;a)$ looks much like that of $\bar{f}^G(s;0,a)$, but we point out that in (5) $a_\cdot^\pm$ need not be rank one matrices!

LEMMA 6.1. (i) $\partial_S^2 f(x) \supset \partial_T^2 f(x) \cap \mathcal{S}^d$.

(ii) *If* $\partial_T^2(f)(x) \neq \emptyset$, *then* $\partial_S^2 f(x) \neq \emptyset$.

Proof. Since $(-f)^{oo}(x;u,v) = f^{oo}(x;-u,v)$, then $f_T^{oo}(x;a) \le f_S^{oo}(x;a)$ on $\mathbf{R}^d \otimes_s \mathbf{R}^d$. Now (i) follows. For $\alpha \in \mathcal{B}(\mathbf{R}^d) = (\mathbf{R}^d \otimes \mathbf{R}^d)^*$ we define α^* by $\alpha^*(u,v) \stackrel{\text{def}}{=} \alpha(v,u)$. Then $\langle \alpha^*, a\rangle = \langle \alpha, a^*\rangle$. The symmetry of f^{oo} implies that $f_T^{oo}(x;a^*) = f_T^{oo}(x;a)$ so that if $\alpha \in \partial_T^2 f(x)$, then $\alpha^* \in \partial_T^2 f(x)$ and hence $\frac{1}{2}(\alpha + \alpha^*) \in \partial_T^2 f(x) \cap \mathcal{S}^d$. The second result now follows by (i). □

We conjecture that equality holds in (i) above under reasonable hypotheses. The above definitions can of course all be given with $\mathbf{R}^d$ replaced by a topological vector space. At this point we can compare our Hessian, $\partial_H^2 f$, defined using a stochastic setting, and various other Hessians.

LEMMA 6.2. $f^G(x;0,a) \le f_S^{oo}(x;a)$ *and* $\partial_H^2 f(x) \subset \partial_S^2 f(x)$.

Proof. The second result follows trivially from the first so let us prove this result. Given $\theta \in \mathbf{R}^d$ and $\epsilon > 0$, there exists $\delta > 0$ such that if $|y-x| < \delta, |t| < \delta$, then

$$f(y+2\theta t) - 2f(y+\theta t) + f(y) \le t^2[f^{oo}(x;\theta,\theta) + \epsilon]. \tag{28}$$

For a scalar Brownian motion w and $h > 0$, let $t = w_h/2$ and choose ϕ smooth with compact support such that $\phi = 1$ on $\{y : |y-x| < \delta(|\theta|+1)\}$. Then for $|y-x| < \delta$, inequality (28) implies

$$\begin{aligned}\mathbf{1}_{\{|w_h|<\delta\}}[(\phi f)(y+\theta w_h) - f(y)] \le\ & 2\mathbf{1}_{\{|w_h|<\delta\}}[(\phi f)(y+\tfrac{1}{2}\theta w_h) - f(y)] \\ & + \tfrac{1}{4}\mathbf{1}_{\{|w_h|<\delta\}} w_h^2 (f^{oo}(x;\theta,\theta) + \epsilon).\end{aligned} \tag{29}$$

Since ϕf is bounded then, with $\rho = 1$ or $\frac{1}{2}$, $\mathbb{E}\mathbf{1}_{\{|w_h|\ge\delta\}}[(\phi f)(y+\rho\theta w_h) - f(y)] = O(h^2)$ by Chebychev's inequality, and $\mathbb{E}\mathbf{1}_{\{|w_h|\ge\delta\}} w_h^2 = O(h^{3/2})$. Now the inequality (29) implies

$$\begin{aligned}\mathbb{E}[(\phi f)(y+\theta w_h) - f(y)] \le\ & 2\mathbb{E}[(\phi f)(y+\tfrac{1}{2}\theta w_h) - f(y)] \\ & + \tfrac{1}{4}\mathbb{E} w_h^2 (f^{oo}(x;\theta,\theta) + \epsilon) + o(h).\end{aligned}$$

Hence $f^G(x;0,\frac{1}{2}\theta\theta^T) \le \frac{1}{2} f^{oo}(x;\theta,\theta)$ and so $f^G(x;0,a) \le f_S^{oo}(x;a)$ for $a \in \mathbf{R}^d \otimes_s \mathbf{R}^d$. □

Remark. We continue here the remark made at the end of §2. For $f \in C^{1,1}(\mathcal{O})$, $\partial_{CC}^2 f(x)$ is linearly generated by $\partial_C^2 f(x)$ [2]. Since it is also generated by $\partial_T^2 f(x)$, then $\partial_T^2 f(x) = \partial_C^2 f(x)$, and the conic hull of these sets is $\partial_H^2 f(x)$. It follows that in this setting

$$\partial_T^2 f(x) \subset \operatorname{cc}\partial_T^2 f(x) = \partial_H^2 f(x) \subset \partial_S^2 f(x),$$

and we do not have equality in Lemma 6.1(i).

ON THE NONLINEAR DYNAMICS OF FAST FILTERING ALGORITHMS*

CHRISTOPHER I. BYRNES†, ANDERS LINDQUIST‡, AND YISHAO ZHOU§

Abstract. The main purpose of this paper is to address a fundamental open problem in linear filtering and estimation, namely, what is the steady-state or asymptotic behavior of the Kalman filter, or the Kalman gain, when the observed stationary stochastic process is not generated by a finite-dimensional stochastic system, or when it is generated by a stochastic system having higher-dimensional unmodeled dynamics. For example, some time ago Kalman pointed out that the usual positivity conditions assumed in the classical situation are not in fact necessary for the Kalman filter to converge. Using a "fast filtering" algorithm, which incorporates the statistics of the observation process as initial conditions for a dynamical system, this question is analyzed in terms of the phase portrait of a "universal" nonlinear dynamical system. This point of view has additional advantages as well, since it enables one to use the theory of dynamical systems to study the sensitivity of the Kalman filter to (small) changes in initial conditions; e.g., to changes in the statistics of the underlying process. This is especially important since these statistics are often either approximated or estimated. In this paper, for a scalar observation process, necessary and sufficient conditions for the Kalman filter to converge are derived using methods from stochastic systems and from nonlinear dynamics—especially the use of stable, unstable, and center manifolds. It is also shown that, in nonconvergent cases, there exist periodic points of every period p, $p \geq 3$ that are arbitrarily close to initial conditions having unbounded orbits, rigorously demonstrating that the Kalman filter can also be "sensitive to initial conditions."

1. Introduction.

Given a scalar stationary stochastic process $\{y_0, y_1, y_2, \ldots\}$ that is the output of a linear, finite-dimensional stochastic system driven by white noise, it is well known that the minimum variance estimate $\hat{x}_t$ of the current state x_t of the system is generated by the Kalman filter. Indeed, the Kalman filter is a model of the unforced stochastic system driven by a term consisting of the current output estimation error amplified by the so-called "Kalman gain" k_t, which itself can be determined "off-line" by solving a matrix Riccati equation. In this case, the steady-state behavior of both the Riccati equation and the Kalman filter is well understood. The purpose of this paper is to address a fundamental open problem concerning filtering and estimation, namely, what is the steady-state or asymptotic behavior of the Kalman filter, or the Kalman gain, when the stochastic process $\{y_t\}$ is not generated by a stochastic system, or when it is generated by a stochastic system having higher-dimensional, unmodeled dynamics? This question has been raised, for example, by Kalman, who pointed out that the positivity constraints associated with the existence of a stochastic system realizing $\{y_t\}$ might not be necessary for the Kalman filter to converge, a fact rigorously established for first-order systems in [5]

and for two-dimensional systems in [6]. Indeed, in [5] a complete phase portrait of the Kalman gain and the Kalman filter, as a dynamical system, was derived for first-order systems.

The basis for this analysis of the Kalman filtering as a dynamical system was the formulation [25] of "fast filtering" algorithms two decades ago. Instead of determining the n-vector k_t by first solving a matrix Riccati equation for a symmetric matrix P_t involving $n(n+1)/2$ variables, the fast filtering algorithm involves solving only a system of $2n$ equations, which consist of a dynamical system propagating k_t and an "adjoint" vector k_t^*. Moreover, as first shown in [27] and crucial for our dynamical systems analysis of the Kalman filter, this dynamical system can be reformulated so that the statistics of the process $\{y_t\}$ enter into the fast filtering algorithm only as initial conditions. Thus, we can analyze the asymptotic behavior of the Kalman filter for different statistics in terms of the phase portrait of the fast filtering algorithm. This is in sharp contrast to analysis of the Riccati equation as a dynamical system, since different statistics lead to different Riccati equations and, in fact, not to different initial conditions.

This point of view has additional advantages as well, since it enables us to study the sensitivity of the Kalman filter to (small) changes in initial conditions; e.g., to changes in the underlying system $\{y_t\}$ or its statistics. This is especially important since the statistics of the underlying process are often either approximated or estimated. In this direction, for the first-order case, necessary and sufficient conditions for asymptotic convergence of k_t were discovered [5], verifying the expectation that the Kalman filter would indeed converge for a much larger set of initial conditions or "initial statistics" than the classical theory predicts. In the complement of this set of (convergent) initial conditions, it was shown that there existed infinitely many periodic points of each period p, $p \geq 3$. Moreover, arbitrarily close to each of these periodic initial conditions are initial conditions for trajectories that are unbounded. For this reason, in the complement of the set of convergent initial conditions the Kalman filter is sensitive to initial conditions.

In this paper, for nth-order filtering problems we derive a systems theoretic necessary and sufficient condition on the process $\{y_t\}$ for the sequence of Kalman gains, k_t, to converge to a classical limit. En route to this result, we must develop a good understanding of the phase portrait of the fast filtering algorithm as a nonlinear dynamical system, including the determination (via spectral factorization) of a complete set of analytic invariant integrals. This, in turn, requires the extension of the several classical and more recent results concerning positive real transfer functions, positive semidefinite Toeplitz forms, and spectral factorization to situations where the relevant positivity conditions are not necessarily satisfied. Indeed, one of the main themes of this paper is that several important results classically conceived in terms of certain positivity conditions actually hold in a more universal context. While our main interest in this phenomenon lies in characterizing when the Kalman filter converges to a classical limit, this theme is of course quite old. For example, Hurwitz's derivation [20] of the Routh–Hurwitz criterion actually computed the difference between left-half plane and right-half plane zeros (or poles) as the signature of a Hankel matrix, while the Routh–Hurwitz conditions are simply the inequalities reflecting the positivity of this Hankel matrix. A more recent, and more relevant, example is the relaxation of the positive real conditions in circuit synthesis in the development of modern realization theory, based on rationality of transfer functions, or on rank conditions on Hankel matrices.

The paper is organized as follows. In §2, we set notation and recall some preliminary results needed throughout the paper. We begin §3 by reviewing part of the important relationship between shaping filters and Toeplitz forms, both for positive real transfer functions and in general. This relationship then enables us to extend an elegant parameterization, discovered by Kimura [22] and by Georgiou [16], of positive real transfer functions in terms of Szegö polynomials to a parameterization of all rational transfer functions. Just as the Kimura–Georgiou parameterization plays an important role in the covariance extension problem, this generalized parameterization plays an essential role in analyzing the global asymptotic behavior of the Kalman filter. This generalized Kimura–Georgiou parameterization is in fact a bona fide (birational) change of coordinates, as we show in §4. We then express the fast filtering algorithm and (what turns out to be a complete set of) its analytic invariant integrals in this new coordinate system. We begin §5 with a brief introduction to stable, unstable, and center manifold theory and its application to local stability analysis. After calculating the dimensions of these invariant manifolds at an equilibrium of the fast filtering algorithm, we show that the level sets of the invariant integrals defined above locally define smooth submanifolds near the equilibria, and we identify the invariant manifolds in terms of these invariants.

In §§6 and 7 we turn to the problem of global convergence of the fast filtering algorithm. In terms of the basic invariant integrals, it is easy to determine a system theoretic necessary condition for an initial condition to generate a trajectory of the fast filtering algorithm, which converges to a classical limit. This condition, derived from a spectral factorization argument, is simply that a certain pseudopolynomial be sign-definite on the unit circle. Moreover, the local stability analysis carried out in §5 shows that, for initial conditions sufficiently near an equilibrium, this necessary condition is also sufficient locally. Our main result, Theorem 7.1, asserts that this is also true in the large: except for a thin set of points that escape in finite time (and that can be explicitly characterized), a necessary and sufficient condition for global convergence of the Kalman gain k_t to a limit k_∞ is sign definiteness of the corresponding pseudopolynomial. The proof is based on a well-known interpretation of fast filtering algorithms and an equivalent Riccati equation as a dynamical system evolving on a Lagrangian Grassmannian. We conclude the paper in §8 with a series of examples and simulations for first- and second-order systems.

2. Preliminaries. Let $v(z)$ be a proper rational function of degree n with a minimal realization

$$v(z) = \tfrac{1}{2} + h'(zI - F)^{-1}g \tag{2.1}$$

(where $F \in \mathbb{R}^{n\times n}, g, h \in \mathbb{R}^n$ and prime denotes transpose) and consider the corresponding matrix Riccati equation

$$P_{t+1} = FP_tF' + (g - FP_th)(1 - h'P_th)^{-1}(g - FP_th)' \tag{2.2}$$

having an orbit of symmetric matrices $\{P_1, P_2, P_3, \ldots\}$ for each symmetric $P_0 \in \mathbb{R}^{n\times n}$.

If $v(z)$ is *positive real*, i.e.,

$$v(z) \text{ analytic on } |z| \geq 1, \tag{2.3a}$$

$$v(z) + v(1/z) > 0 \quad \text{on } |z| = 1, \tag{2.3b}$$

then

$$\Phi(e^{i\omega}) = v(e^{i\omega}) + v(e^{-i\omega}) \tag{2.4}$$

is the spectral density of a stationary stochastic process $\{y_t; t \in \mathbb{Z}\}$ that can be represented (in uncountably many ways) by a minimal stochastic realization

$$\begin{aligned} x_{t+1} &= Fx_t + v_t, \\ y_t &= h'x_t + w_t \end{aligned} \tag{2.5}$$

of y, i.e., a stochastic system with $E\{x_{t+1}y_t\} = g$ obtained by passing white noise $\{v_t, w_t\}$ through a shaping filter, the transfer function of which

$$w(z) = h'(zI - F)^{-1}B + d' \tag{2.6}$$

(where B is a matrix and d a vector of appropriate dimensions) is a minimal stable spectral factor of Φ, i.e., $w(z)w(1/z)' = \Phi(z)$. In general $w(z)$ is a row vector valued rational function. If, in particular, $w(z)$ is a scalar and both its numerator and denominator polynomials are stable (all zeros in the open unit disc), we say that $w(z)$ is a *minimum phase spectral factor*. All such realizations (2.6) have the same *Kalman filter*

$$\hat{x}_{t+1} = F\hat{x}_t + k_t(y_t - h'\hat{x}_t); \qquad \hat{x}_0 = 0 \tag{2.7}$$

(where $\hat{x}_t$ is the linear minimum-variance estimate of x_t given $\{y_0, y_1, \dots, y_{t-1}\}$), and the gain

$$k_t = (1 - h'P_th)^{-1}(g - FP_th) \tag{2.8}$$

is determined by solving the corresponding matrix Riccati equation (2.2) with initial condition

$$P_0 = 0. \tag{2.9}$$

It is well known that, under these conditions, P_t tends monotonically to the stable equilibrium of (2.2) [13], [26]. The question addressed in this paper is what happens to the solution (2.2) when the parameters have been chosen such that $v(z)$ is no longer positive real.

Without loss of generality, we henceforth take (F, g, h) in the observer canonical form

$$F = \begin{bmatrix} -a_1 & 1 & 0 & \cdots & 0 \\ -a_2 & 0 & 1 & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ -a_{n-1} & 0 & 0 & \cdots & 1 \\ -a_n & 0 & 0 & \cdots & 0 \end{bmatrix}, \quad g = \begin{bmatrix} g_1 \\ g_2 \\ \vdots \\ g_n \end{bmatrix}, \quad h = \begin{bmatrix} 1 \\ 0 \\ \vdots \\ 0 \end{bmatrix}, \tag{2.10}$$

in terms of which we may write $F = J - ah'$, where a is the column vector $(a_1, a_2, \dots, a_n)'$ and J is the obvious shift matrix. Consequently, the Riccati equation is determined by the $2n$ parameters (a, g) and there are also the coefficients of the rational function $v(z)$, i.e.,

$$v(z) = \frac{1}{2} + \frac{g_1z^{n-1} + g_2z^{n-2} + \cdots + g_n}{z^n + a_1z^{n-1} + \cdots + a_n}. \tag{2.11}$$

For simplicity we write

$$v(z) = \frac{1}{2} + \frac{g(z)}{a(z)} = \frac{1}{2}\frac{b(z)}{a(z)}, \tag{2.12}$$

where $b(z) := a(z) + 2g(z)$ is a monic polynomial of degree n. It is easy to see that, if $v(z)$ is positive real, then

$$D(z, z^{-1}) = \tfrac{1}{2}[a(z)b(1/z) + a(1/z)b(z)] > 0 \quad \text{on } |z| = 1, \tag{2.13}$$

$$a(z) \text{ has all its zeros in } |z| < 1, \tag{2.14}$$

$$b(z) \text{ has all its zeros in } |z| < 1. \tag{2.15}$$

Conversely, if (2.13) plus either (2.14) or (2.15) hold, then $v(z)$ is positive real.

To determine the Kalman filter we can, instead of the Riccati equation (2.2), use the algorithm

$$a(t+1) = \frac{1}{1 - g_1(t)}[a(t) + (I - J)g(t)]; \qquad a(0) = a \tag{2.16a}$$

$$g(t+1) = \frac{1}{1 - g_1(t)^2}[-g_1(t)a(t) + (J - g_1(t)I)g(t)]; \quad g(0) = g \tag{2.16b}$$

consisting of $2n$ nonlinear first-order difference equations in terms of which

$$k_t = a(t) + g(t) - a. \tag{2.17}$$

This algorithm is a version, appearing in [27], of the fast Kalman filtering algorithm introduced in [25]. (Also see [5] where these matters are reviewed; in the notation of this paper $a(t) = q_t - q_t^*$.) Suppose $r_t := \prod_{k=0}^{t-1}[1 - g_1(k)^2]$ and the monic polynomials $a_t(z)$ and $b_t(z) := a_t(z) + 2g_t(z)$ are formed from $a(t)$ and $b(t) := a(t) + 2g(t)$ as above, then it is shown in [27] that the equality

$$r_t[a_t(z)b_t(1/z) + a_t(1/z)b_t(z)] = 2D(z, z^{-1}) \tag{2.18}$$

is preserved along the trajectory of (2.16). It is also shown in [27] that $a_t(z)$ and $b_t(z)$ have all their zeros in the unit disc $|z| < 1$. Consequently, if $v(z)$ is positive real, then so is

$$v_t(z) = \frac{1}{2}\frac{b_t(z)}{a_t(z)} = \frac{1}{2} + \frac{g_t(z)}{a_t(z)} \tag{2.19}$$

for each $t = 1, 2, 3, \ldots$, so that each $(a(t), g(t))$ is an admissible pair of parameters for the Kalman filtering problem, corresponding to stochastic systems.

3. Systems theoretic enhancements of some classical positivity results. One of the main results of this paper is to establish and analyze the fact that filtering algorithms do converge for parameter values that do not correspond to a bona fide stochastic system and, hence, that do not satisfy the relevant positivity conditions. These positivity conditions can be expressed in terms of a transfer function being positive real or a Toeplitz matrix being positive definite, as well as a number of other conditions involving familiar objects from classical analysis and systems theory. Our main result is just one manifestation of the fact that several classical and more recent results containing positivity and positive real functions have, of course, natural enhancements to statements concerning broader classes of nonsingular matrices and systems. In this section we develop this theme in the context of several particular results that we will find to be very useful in the remaining sections.

It is well known that a function $v(z)$ with the Laurent expansion

$$v(z) = \tfrac{1}{2} + c_1 z^{-1} + c_2 z^{-2} + c_3 z^{-3} + \cdots \tag{3.1}$$

around $z = \infty$ is positive real if and only if the Toeplitz matrices

$$T_t = \begin{bmatrix} 1 & c_1 & \cdots & c_t \\ c_1 & 1 & \cdots & c_{t-1} \\ \vdots & \vdots & \ddots & \vdots \\ c_t & c_{t-1} & \cdots & 1 \end{bmatrix} \tag{3.2}$$

are positive definite for all $t = 1, 2, 3, \ldots$.

A simpler test of positive realness due to Schur [32] can be described in terms of the Szegö polynomials $\{\varphi_0(z), \varphi_1(z), \varphi_2(z), \ldots\}$, a sequence of monic polynomials

$$\varphi_t(z) = z^t + \varphi_{t1} z^{t-1} + \cdots + \varphi_{tt} \tag{3.3}$$

that are orthogonal on the unit circle. Similarly, we define the reversed polynomial $\varphi_t^*(z)$ as

$$\varphi_t^*(z) = \varphi_{tt} z^t + \varphi_{t,t-1} z^{t-1} + \cdots + 1. \tag{3.4}$$

The Szegö polynomials are then determined from the sequence $\{c_1, c_2, c_3, \ldots\}$ through the polynomial recursions

$$\begin{aligned} \varphi_{t+1}(z) &= z\varphi_t(z) - \gamma_t \varphi_t^*(z); \qquad \varphi_0(z) = 1, \\ \varphi_{t+1}^*(z) &= \varphi_t^*(z) - \gamma_t z \varphi_t(z); \qquad \varphi_0^*(z) = 1, \end{aligned} \tag{3.5}$$

where $\{\gamma_0, \gamma_1, \gamma_2, \ldots\}$ are the *Schur parameters*

$$\gamma_t = \frac{1}{r_t} \sum_{k=0}^{t} \varphi_{t,t-k} c_{k+1} \tag{3.6}$$

and $\{r_0, r_1, r_2, \ldots\}$ are given by the recursion

$$r_{t+1} = (1 - \gamma_t^2) r_t; \qquad r_0 = 1, \tag{3.7}$$

the algorithm terminating if $|\gamma_t|$ becomes one. Indeed, it has been shown by Schur that

$$T_t > 0 \Leftrightarrow |\gamma_k| < 1 \quad \text{for } k = 0, 1, 2, \ldots, t-1. \tag{3.8}$$

It is also classical that the function (3.1) has an infinite *Schur parameter sequence* $\{\gamma_0, \gamma_1, \gamma_2, \ldots\}$ if and only if $|\gamma_t|$ never becomes one—otherwise, the Schur parameter sequence is finite, ending with a term of modulus one—and that for each $t = 1, 2, 3, \ldots$, there is a one-to-one correspondence between the set of all subsequences $\{c_1, c_2, \ldots, c_t\}$ such that T_k is nonsingular for $k = 1, 2, \ldots, t$ and the set of all subsequences $\{\gamma_0, \gamma_1, \ldots, \gamma_{t-1}\}$ such that $|\gamma_k| \neq 1$ for $k = 0, 1, 2, \ldots, t-2$.

That these claims also hold for nonpositive data follows from the following well-known enhancement of the positive result (3.8).

PROPOSITION 3.1. $\det T_t = \prod_{k=0}^{t} r_k$.

As a second illustration of this theme, Kimura [22] and Georgiou [16] have independently shown that to any positive real function (3.1) with the first n c-coefficients prescribed, or alternatively with $\gamma := (\gamma_0, \gamma_1, \ldots, \gamma_{n-1})'$ fixed, there is a unique vector $\alpha = (\alpha_1, \alpha_2, \ldots, \alpha_n)'$ of real numbers such that

$$v(z) = \frac{1}{2} \frac{\psi_n(z) + \alpha_1 \psi_{n-1}(z) + \cdots + \alpha_n \psi_0(z)}{\varphi_n(z) + \alpha_1 \varphi_{n-1}(z) + \cdots + \alpha_n \varphi_0(z)}, \tag{3.9}$$

where $\{\psi_0, \psi_1, \psi_2, \dots\}$ are the Szegö polynomials obtained by exchanging the Schur parameters $\{\gamma_t\}$ by $\{-\gamma_t\}$. This is a useful parameterization for the *rational covariance extension problem* [21], but, as we now demonstrate, (3.9) is actually a general interpolation formula that holds regardless of whether $v(z)$ is positive real, provided that the algorithm does not terminate for $t < n$. In fact, it follows that there is a one-to-one correspondence between the open dense set in $\mathbb{R}^{2n}$ of $2n$ parameters (α, γ) for which none of the elements of the vector $\gamma = (\gamma_0, \gamma_1, \dots, \gamma_{n-1})' \in \mathbb{R}^n$ has modulus one, and the corresponding open dense set of $(a, g) \in \mathbb{R}^{2n}$.

THEOREM 3.2. *Let $\gamma = (\gamma_0, \gamma_1, \dots, \gamma_{n-1})'$ be an arbitrary vector in $\mathbb{R}^n$ such that $\gamma_k^2 \neq 1$ for $k = 0, 1, \dots, n-2$, let $\{\varphi_k(z), \psi_k(z); k = 0, 1, \dots, n-1\}$ be the corresponding polynomials generated by* (3.5), *and set $c_1 := \gamma_0$ and*

$$c_{k+1} := r_k \gamma_k - \sum_{j=0}^{k-1} \varphi_{k,k-j}\, c_{j+1} \tag{3.10}$$

for $k = 1, 2, \dots, n-1$, where $r_1, r_2, \dots, r_n$ are defined by (3.7). *Let $a(z)$ and $b(z)$ be arbitrary monic polynomials of degree n such that*

$$\frac{b(z)}{2a(z)} = \frac{1}{2} + c_1 z^{-1} + c_2 z^{-2} + \cdots + c_n z^{-n} + \cdots. \tag{3.11}$$

Then there is a unique $\alpha = (\alpha_1, \alpha_2, \dots, \alpha_n)' \in \mathbb{R}^n$ such that

$$a(z) = \varphi_n(z) + \alpha_1 \varphi_{n-1}(z) + \cdots + \alpha_n, \tag{3.12a}$$

$$b(z) = \psi_n(z) + \alpha_1 \psi_{n-1}(z) + \cdots + \alpha_n. \tag{3.12b}$$

The proof of Theorem 3.2 is based on the following lemma.

LEMMA 3.3. *Let the polynomials $\{\varphi_k(z), \psi_k(z);\ k = 0, 1, \dots, n-1\}$ and the sequence $\{c_1, c_2, \dots, c_n\}$ be as defined in Theorem* 3.2. *Then*

$$\Psi_{n+1} = C_{n+1} \Phi_{n+1}, \tag{3.13}$$

where Φ, Ψ, and C are the nonsingular $(n+1) \times (n+1)$-matrices

$$\Phi_{n+1} = \begin{bmatrix} 1 & & & & \\ \varphi_{n1} & 1 & & & \\ \varphi_{n2} & \varphi_{n-1,1} & 1 & & \\ \vdots & \vdots & \vdots & \ddots & \\ \varphi_{nn} & \varphi_{n-1,n-1} & \varphi_{n-2,n-2} & \cdots & 1 \end{bmatrix}, \tag{3.14a}$$

$$\Psi_{n+1} = \begin{bmatrix} 1 & & & & \\ \psi_{n1} & 1 & & & \\ \psi_{n2} & \psi_{n-1,1} & 1 & & \\ \vdots & \vdots & \vdots & \ddots & \\ \psi_{nn} & \psi_{n-1,n-1} & \psi_{n-2,n-2} & \cdots & 1 \end{bmatrix}, \tag{3.14b}$$

$$C_{n+1} = \begin{bmatrix} 1 & & & & \\ 2c_1 & 1 & & & \\ 2c_2 & 2c_1 & 1 & & \\ \vdots & \vdots & \vdots & \ddots & \\ 2c_n & 2c_{n-1} & 2c_{n-2} & \cdots & 1 \end{bmatrix}. \tag{3.14c}$$

Proof. We want to prove that

$$\psi_{tk} = 2c_k + 2c_{k-1}\varphi_{t1} + 2c_{k-2}\varphi_{t2} + \cdots + 2c_1\varphi_{t,k-1} + \varphi_{tk}$$

for all $t \geq k$, or, equivalently,

$$\rho_{tk} = c_k + c_{k-1}\varphi_{t1} + c_{k-2}\varphi_{t2} + \cdots + c_1\varphi_{t,k-1} \tag{3.15}$$

for all $t = k, k+1, \ldots, n$, where $\{\rho_{tk}\}$ are the coefficients of the polynomials

$$\rho_t(z) = \tfrac{1}{2}[\psi_t(z) - \varphi_t(z)]. \tag{3.16}$$

Then, the recursions in φ_t and ψ_t imply that

$$\rho_{t+1}(z) = z\rho_t(z) + \gamma_t\pi_t^*(z), \tag{3.17}$$

where $\pi_t^*(z)$ is the reversed polynomial of

$$\pi_t(z) = \tfrac{1}{2}[\psi_t(z) + \varphi_t(z)], \tag{3.18}$$

i.e., $\pi_t^*(z) := z^n\pi_t(1/z)$. We also recall from the literature [24], [1], [17] that the coefficients of $\{\varphi_t\}$ satisfy the *normal equations*

$$\begin{bmatrix} 1 & c_1 & \cdots & c_{t-1} \\ c_1 & 1 & \cdots & c_{t-2} \\ \vdots & \vdots & \ddots & \vdots \\ c_{t-2} & c_{t-3} & \cdots & c_1 \\ c_{t-1} & c_{t-2} & \cdots & 1 \end{bmatrix} \begin{bmatrix} \varphi_{tt} \\ \varphi_{t,t-1} \\ \vdots \\ \varphi_{t1} \\ 1 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ \vdots \\ 0 \\ r_t \end{bmatrix} \tag{3.19}$$

having the Toeplitz matrix T_t as its coefficient matrix. As we have pointed out above, T_t is nonsingular if our basic assumption that $|\gamma_k| \neq 1$ for all $k = 0, 1, 2, \ldots, t-1$ holds [1]. It follows from (3.5) that $\varphi_{tt} = -\gamma_{t-1}$, and consequently $\psi_{tt} = \gamma_{t-1}$, and thus $\rho_{tt} = \varphi_{tt}$. Therefore, we see from the first equation (3.19) that (3.17) holds for $t = k$. We now proceed by induction. Suppose (3.15) holds for $t = s$, where $k \leq s \leq n-1$. We want to prove that it holds for $t = s+1$. To this end, note that for $t = s$ one of the normal equations reads

$$c_k + c_{k-1}\varphi_{s1} + c_{k-2}\varphi_{s2} + \cdots + c_1\varphi_{s,k-1} + \varphi_{sk} + c_1\varphi_{s,k+1} + \cdots + c_{s-k}\varphi_{ss} = 0.$$

However, in view of the induction hypothesis, this can be written

$$\rho_{sk} + \varphi_{sk} + c_1\varphi_{s,k+1} + \cdots + c_{s-k}\varphi_{ss} = 0$$

and therefore, since $\pi_{sk} = \rho_{sk} + \varphi_{sk}$,

$$\pi_{sk} = -c_1\varphi_{s,k+1} - \cdots - c_{s-k}\varphi_{ss}. \tag{3.20}$$

Now, identifying coefficients in the polynomial recursion (3.18), we obtain

$$\rho_{s+1,k} = \rho_{sk} + \gamma_s\pi_{s,s+1-k},$$

which, after inserting (3.20) and applying the induction hypothesis, takes the form

$$\rho_{s+1,k} = c_k + c_{k-1}(\varphi_{s1} - \gamma_s\varphi_{ss}) + \cdots + c_1(\varphi_{s,k-1} - \gamma_s\varphi_{s,s+2-k}).$$

However, it follows from (3.5) that $\varphi_{s+1,k} = \varphi_{sk} - \gamma_s \varphi_{s,s+1-k}$, and therefore (3.15) holds for $t = s+1$ as required. Hence the lemma follows by induction. □

Proof of Theorem 3.2. Since $\{\varphi_t\}$ and $\{\psi_t\}$ are families of monic polynomials of increasing degree t, there are $\alpha, \beta \in \mathbb{R}^n$ such that

$$a(z) = \varphi_n(z) + \alpha_1 \varphi_{n-1}(z) + \cdots + \alpha_n,$$
$$b(z) = \psi_n(z) + \beta_1 \psi_{n-1}(z) + \cdots + \beta_n.$$

Then (3.11) yields

$$\psi_n(z) + \beta_1 \psi_{n-1}(z) + \cdots + \beta_n$$
$$= [\varphi_n(z) + \alpha_1 \varphi_{n-1}(z) + \cdots + \alpha_n][1 + 2c_1 z^{-1} + 2c_2 z^{-2} + \cdots].$$

Therefore, identifying coefficients of nonnegative powers of z, we have

$$\Psi_{n+1} \begin{bmatrix} 1 \\ \beta \end{bmatrix} = C_{n+1} \Phi_{n+1} \begin{bmatrix} 1 \\ \alpha \end{bmatrix},$$

which, by Lemma 3.3, implies that $\beta = \alpha$. □

COROLLARY 3.4. *Consider the maps* $\gamma := (\gamma_0, \gamma_1, \ldots, \gamma_{n-1}) \to \Phi_{n+1}(\gamma)$ *and* $\gamma \to \Psi_{n+1}(\gamma)$ *defined through* (3.5), *the corresponding recursion for* $\{\psi_t\}$, (3.14a) *and* (3.14b). *Then* $\Psi_{n+1}(\gamma) = \Phi_{n+1}(-\gamma)$ *and* $\Phi_{n+1}(0) = \Psi_{n+1}(0) = I_{n+1}$. *Moreover,*

$$\begin{bmatrix} 1 \\ a \end{bmatrix} = \Phi_{n+1}(\gamma) \begin{bmatrix} 1 \\ \alpha \end{bmatrix} \qquad \begin{bmatrix} 1 \\ b \end{bmatrix} = \Psi_{n+1}(\gamma) \begin{bmatrix} 1 \\ \alpha \end{bmatrix}. \tag{3.21}$$

4. The fast filtering algorithm and its invariant integrals. One of the principal goals of this section is to express the fast filtering algorithm (2.16) in a more convenient way in terms of the parameters (α, γ) entering in the generalization, Theorem 3.2, of the Kimura–Georgiou parameterization of positive real systems. As a preliminary step, we first show that this parameterization constitutes in fact a bona fide change of coordinates. In the language of classical algebraic geometry, the map defined by (3.12) is a birational isomorphism [33]. More explicitly, consider the set

$$U_\gamma = \{(\alpha, \gamma) \in \mathbb{R}^{2n} \mid \gamma_i^2 \neq 1, i = 0, 1, \ldots, n-2\}.$$

Also, by virtue of (3.11), the generalized "correlation" coefficients $c_1, c_2, \ldots, c_n$ are functions of (a, b) so that we may define the open, dense set

$$V_c = \{(a, b) \in \mathbb{R}^{2n} \mid \det T_i \neq 0, i = 1, 2, \ldots, n-1\}.$$

We show that that the polynomial map $\mathcal{F}$ is a bijection of U_γ with V_c having a rational inverse so that $\mathcal{F}$ is indeed a birational isomorphism.

PROPOSITION 4.1. *The map* $\mathcal{F}$, *defined by* (3.12), *sending* $(\alpha, \gamma) \in \mathbb{R}^{2n}$ *to* $(a, b) \in \mathbb{R}^{2n}$ *is a polynomial map given by*

$$a = \varphi_n(\gamma) + \Phi_n(\gamma)\alpha,$$
$$b = \psi_n(\gamma) + \Psi_n(\gamma)\alpha, \tag{4.1}$$

where $\varphi_n := (\varphi_{n1}, \varphi_{n2}, \ldots, \varphi_{nn})'$ *and* $\psi_n := (\psi_{n1}, \psi_{n2}, \ldots, \psi_{nn})'$, *and* $\Phi_n(\gamma)$ *and* $\Psi_n(\gamma)$ *are given by* (3.14). *Moreover,* $\mathcal{F} : U_\gamma \to V_c$ *is a bijection with a rational inverse* $\mathcal{F}^{-1}$.

Proof. On V_c the map $\mathcal{F}$ has an inverse $\mathcal{F}^{-1}$ defined in the following way: (a,b) defines through (3.11) a sequence $\{c_1,c_2,\dots,c_n\}$ that, by (3.6), corresponds to a vector $\gamma=(\gamma_0,\gamma_1,\dots,\gamma_{n-1})'$, from which in turn the polynomials $\{\varphi_k(z);k=0,1,2,\dots,n-1\}$ can be defined. Then $\alpha\in\mathbb{R}^n$ is uniquely determined by (3.12a). Finally, (4.1) follows from (3.21). □

Recall from [27] or from [5] that if $\{\gamma_0,\gamma_1,\gamma_2,\dots\}$ is the (infinite or finite) Schur parameter sequence of (2.1), as defined in §3, then

$$\gamma_t=g_1(t)\qquad t=0,1,2,\dots, \tag{4.2}$$

where g_1 is generated by the fast filtering algorithm (2.16). A key observation now is that (2.16) is a time-invariant dynamical system in parameter space. In particular, let us stress the following simple but important observation.

LEMMA 4.2. *Let $v(z)$ be defined as in §2 and let $\{\gamma_0,\gamma_1,\gamma_2,\dots\}$ be its (infinite or finite) Schur parameter sequence. Then, for each $t=0,1,2,\dots$, as long as the algorithm (2.16) does not escape, $v_t(z)$ defined by (2.19) has the Schur parameter sequence $\{\gamma_t,\gamma_{t+1},\gamma_{t+2},\dots\}$.*

Proof. The fast filtering algorithm (2.16) is a time-invariant dynamical system, and unless it has escaped it will therefore trivially generate via (4.2) the sequence $\{\gamma_t,\gamma_{t+1},\gamma_{t+2},\dots\}$ if initialized at $(a(t),g(t))$ corresponding to $v_t(z)$. □

Corollary 3.4 allows us to change coordinates in the fast algorithm, expressing it instead in terms of (α,γ), where

$$\alpha=\begin{bmatrix}\alpha_1\\ \alpha_2\\ \vdots\\ \alpha_n\end{bmatrix},\qquad \gamma=\begin{bmatrix}\gamma_0\\ \gamma_1\\ \vdots\\ \gamma_{n-1}\end{bmatrix}, \tag{4.3}$$

as long as $(\alpha,\gamma)\in U_\gamma$, i.e., as long as $\{\gamma_0,\gamma_1,\dots,\gamma_{n-1}\}$ is the initial subsequence of a Schur parameter sequence.

THEOREM 4.3. *Let the rational function $v(z)$ defined by (2.1) have a Schur parameter sequence such that $\gamma_k^2\neq 1$ for $k=0,1,\dots,n-1$. Then the fast filtering algorithm takes the form*

$$\alpha(t+1)=A(\gamma(t))\alpha(t),\qquad \alpha(0)=\alpha \tag{4.4a}$$

$$\gamma(t+1)=G(\alpha(t+1))\gamma(t),\qquad \gamma(0)=\gamma \tag{4.4b}$$

in the coordinates of the generalized Kimura–Georgiou parameterization, where the maps $A,G:\mathbb{R}^n\to\mathbb{R}^{n\times n}$ are defined as

$$A(\gamma)=\begin{bmatrix}\frac{1}{1-\gamma_{n-1}^2} & \frac{\gamma_{n-1}\gamma_{n-2}}{(1-\gamma_{n-1}^2)(1-\gamma_{n-2}^2)} & \cdots & \frac{\gamma_{n-1}\gamma_0}{(1-\gamma_{n-1}^2)\cdots(1-\gamma_0^2)}\\ 0 & \frac{1}{1-\gamma_{n-2}^2} & \cdots & \frac{\gamma_{n-2}\gamma_0}{(1-\gamma_{n-2}^2)\cdots(1-\gamma_0^2)}\\ \vdots & \vdots & \ddots & \vdots\\ 0 & 0 & \cdots & \frac{1}{1-\gamma_0^2}\end{bmatrix} \tag{4.5}$$

and

$$G(\alpha)=\begin{bmatrix}0 & 1 & 0 & \cdots & 0\\ 0 & 0 & 1 & \cdots & 0\\ \vdots & \vdots & \vdots & \ddots & \vdots\\ 0 & 0 & 0 & \cdots & 1\\ -\alpha_n & -\alpha_{n-1} & -\alpha_{n-2} & \cdots & -\alpha_1\end{bmatrix}. \tag{4.6}$$

More precisely, if (α, γ) *are the parameters of* $v(z)$ *in the representation* (3.9), *then* $(\alpha(t), \gamma(t))$ *are the parameters of* $v_t(z)$, *as defined in* (2.19), *for each point in the finite or infinite orbit of* (α, γ). *Moreover, if* $\{\gamma_0, \gamma_1, \gamma_2, \dots\}$ *is the sequence of Schur parameters of* $v(z)$, *then the sequence* $\{\gamma_t, \gamma_{t+1}, \gamma_{t+2}, \dots\}$ *obtained by deleting the first* t *elements is the Schur parameters sequence of* $v_t(z)$. *In fact,*

$$\gamma_k(t) = \gamma_{t+k} \tag{4.7}$$

and therefore the Schur parameters are updated according to the recursion

$$\gamma_{t+n} = -\alpha_1(t+1)\gamma_{t+n-1} - \alpha_2(t+1)\gamma_{t+n-2} - \cdots - \alpha_n(t+1)\gamma_t. \tag{4.8}$$

Finally, the gain sequence $\{k_0, k_1, k_2, \dots, \}$ *of the Kalman filter is given by*

$$k_t = \Pi_n(\gamma(t))\alpha(t) + \pi_n(\gamma(t)) - \Phi_n(\gamma)\alpha - \varphi_n(\gamma), \tag{4.9}$$

where $\varphi_n(\gamma)$ *and* $\psi_n(\gamma)$ *are* n*-vectors of coefficients of* $\varphi(z)$ *and* $\psi(z)$, *and*

$$\Pi_n(\gamma) = \tfrac{1}{2}[\Phi_n(\gamma) + \Psi_n(\gamma)],$$
$$\pi_n(\gamma) = \tfrac{1}{2}[\varphi_n(\gamma) + \psi_n(\gamma)].$$

For a proof, we refer the reader to the Appendix.

In §5 we will show that the dynamical system (4.4) evolves on an invariant manifold X_D defined by the preserved pseudopolynomial (2.18), which we write in the form

$$D(z, z^{-1}) = d(z) + d(1/z), \tag{4.10a}$$

where

$$d(z) = \tfrac{1}{2}d_0 + d_1 z + d_2 z^2 + \cdots + d_n z^n. \tag{4.10b}$$

The symmetric pseudopolynomial D is determined by the initial condition (α, γ) in a manner described by the following lemma, the proof of which is given in the Appendix.

LEMMA 4.4. *Let* $D(z, z^{-1})$ *be the pseudopolynomial* (4.10) *corresponding to the initial condition* (α, γ). *Then*

$$d_0 = \alpha_n^2 + r_1\alpha_{n-1}^2 + \cdots + r_n, \tag{4.11}$$

where $r_1, r_2, \dots, r_n$ *are defined by* (3.7), *and* $d_i := d_i^{(n)}(\alpha, \gamma)$ *for* $i = 1, 2, \dots, n$, *where* $d_i^{(n)}$ *is determined recursively by*

$$\begin{aligned}
&d_1^{(1)}(\alpha_1, \gamma_0) = \alpha_1;\\
&d_i^{(k)}(\alpha_1, \dots, \alpha_k, \gamma_0, \dots, \gamma_{k-1}) = (1-\gamma_0^2)d_i^{(k-1)}(\alpha_1, \dots, \alpha_{k-1}, \gamma_1, \dots, \gamma_{k-1})\\
&\qquad +\alpha_k \textstyle\sum_{j=1}^{k} \alpha_{k-j}\pi_{j,j-i}, \quad \text{for } i = 1, 2, \dots, k-1;\\
&d_k^{(k)}(\alpha_1, \dots, \alpha_k, \gamma_0, \dots, \gamma_{k-1}) = \alpha_k,
\end{aligned}$$

where $\{\pi_{jl}\}$ *are the coefficients of the polynomials*

$$\pi_j(z) = z^j + \pi_{j1}z^{j-1} + \cdots + \pi_{jj}$$

generated by the polynomial recursion

$$\begin{aligned} &\pi_{t+1}(z) = (1+z)\pi_t(z) + (\gamma_t\gamma_{t-1} - 1)z\pi_{t-1}(z), \\ &\pi_0 = 1, \qquad \pi_1(z) = z, \end{aligned} \tag{4.12}$$

and $\pi_{ji} = 0$ *for* $i > j$. *Moreover, if* $\gamma_k^2 \neq 1$ *for* $k = 0, 1, \ldots, n-1$, *then at least one of the coefficients* $d_0, d_1, \ldots, d_n$ *of the pseudopolynomial* $D(z, z^{-1})$ *is nonzero.*

Comparing coefficients of $(z^i + z^{-i})$ in (2.18) we see that

$$r_t d_i(\alpha(t), \gamma(t)) = d_i(\alpha(0), \gamma(0)) \qquad i = 0, 1, 2, \ldots, n \tag{4.13}$$

for all $t \in \mathbb{Z}$ along the trajectory of the dynamical system (4.4). Hence the $n+1$ functions $d_i(\alpha, \gamma)$, $i = 0, 1, \ldots, n-1$ defined in Lemma 4.4 are invariant under the evolution of (4.4) up to a (common) scaling factor; i.e., these $(n+1)$ functions are projectively invariant. We can obtain n invariant quantities, either by viewing the pseudopolynomial, in terms of homogeneous coordinates, as a point in $\mathbb{P}^n$ (see [33]), or equivalently by dividing each of the $(n+1)$ equations in (4.13) by any one of the $(n+1)$ functions that is nonzero (by Lemma 4.4, there is always one), obtaining rational functions having values independent of r_t and hence depending only on (α, γ). That is, we can view the pseudopolynomial D either as determining $(n+1)$ projectively invariant functions $T_1, \ldots, T_{n+1}$ or as determining a map $\overline{T}$ to $\mathbb{P}^n$:

$$\begin{array}{ccc} \mathbb{R}^{2n} & \xrightarrow{T} & \mathbb{R}^{n+1} - \{0\} \\ & \overline{T} \searrow & \downarrow \Pi \\ & & \mathbb{P}^n, \end{array}$$

where $T = (T_1, \ldots, T_{n+1})$ and $\overline{T} = \Pi \circ T$ where

$$\Pi(x_1, \ldots, x_{n+1}) = [x_1, \ldots, x_{n+1}].$$

In this way we might expect (2.18) to define an n-fold X_D in $\mathbb{R}^{2n}$. Indeed, this analytic set will be a smooth n-manifold at a point (α, γ) provided $\operatorname{Jac} T\big|_{(\alpha,\gamma)}$ has an n-dimensional kernel. We return to this question in §§5 and 6 after having introduced some additional analytic tools.

From Theorem 4.3 and Lemma 4.4 it is clear that the fast filtering algorithm has a quasi-nested structure in the sense that whenever $\alpha_n = \alpha_{n-1} = \cdots = \alpha_{k+1} = 0$ but $\alpha_k \neq 0$, the dynamical system (4.4) and the invariant set X_D reduce to the k-dimensional case with the Schur parameter sequence shifted $n-k$ steps. (This is related to the occurrence of invariant directions [3] in the corresponding matrix Riccati equation (2.2) as pointed out in [27] and further elaborated on [31].) As explained in [25], [27], [26], [5], the fast algorithm is intimately connected to the Szegö orthogonal polynomial recursion (3.5), which in fact was the basic tool in the original derivation [25]. In view of this and the analysis above we would expect that it would also be connected to the Schur algorithm. Indeed, this has been shown in a recent paper [8].

5. Invariant manifolds and local convergence for the fast filtering algorithms. We now turn to a stability analysis of the equilibria of the fast filtering algorithms, expressed in the form (4.4), i.e.,

$$\begin{pmatrix} \alpha \\ \gamma \end{pmatrix}_{t+1} = f\begin{pmatrix} \alpha_t \\ \gamma_t \end{pmatrix}, \tag{5.1a}$$

where

$$f\begin{pmatrix} \alpha \\ \gamma \end{pmatrix} = \begin{bmatrix} A(\gamma)\alpha \\ G(A(\gamma)\alpha)\gamma \end{bmatrix}. \tag{5.1b}$$

For the stability analysis of the fast filtering algorithms, we need the geometric concepts of stable, unstable, and center manifolds, which play a role for nonlinear systems similar to the role played by generalized eigenspaces for the stability analysis of linear systems. Because this role is so important in determining stability, especially in the critical case, we precede our analysis of the local stability of the fast filtering algorithms with an introductory discussion of local invariant manifolds for nonlinear systems. As supplementary references we recommend, among other texts, Guckenheimer and Holmes [18], and Marsden and McCracken [28].

At an equilibrium $(\alpha_\infty, \gamma_\infty)$ of (5.1),

$$\begin{bmatrix} \alpha - \alpha_\infty \\ \gamma - \gamma_\infty \end{bmatrix}_{t+1} = C \begin{bmatrix} \alpha - \alpha_\infty \\ \gamma - \gamma_\infty \end{bmatrix}_t + O(\|\alpha - \alpha_\infty\|^2 + \|\gamma - \gamma_\infty\|^2)$$

determines to first order a linear system

$$\begin{bmatrix} \bar{\alpha} \\ \bar{\gamma} \end{bmatrix}_{t+1} = C \begin{bmatrix} \bar{\alpha} \\ \bar{\gamma} \end{bmatrix}_t,$$

where $\bar{\alpha} = \alpha - \alpha_\infty$, $\bar{\gamma} = \gamma - \gamma_\infty$. Denote by s the number of eigenvalues of the matrix C having modulus less than one, counting roots of the characteristic polynomial with their algebraic multiplicities. Similarly, denote by u the number of eigenvalues having modulus greater than one and by c the number of eigenvalues having modulus one. It is well known that if $u \geq 1$, then (5.1) is unstable, so we suppose for the moment that $u = 0$. In this case, if $c = 0$, then $(\alpha_\infty, \gamma_\infty)$ is an asymptotically stable equilibrium for the system (5.1), with all solutions converging geometrically to the equilibrium. The critical case $c \neq 0$ is more subtle, even for linear systems where Lyapunov stability is determined by the geometric multiplicities of the eigenvalues lying on the unit circle.

Remarkably, the linear case can in fact be analyzed geometrically in a manner that can be adapted to the critical nonlinear case, mutatis mutandis. Denote by V^s the sum of the generalized eigenspaces corresponding to eigenvalues inside the unit disk, by V^u the sum of the generalized eigenspaces corresponding to eigenvalues outside the unit disk, and by V^c the sum of the generalized eigenspaces corresponding to eigenvalues lying on the unit circle. Then, we have

$$\dim V^s = s, \quad \dim V^u = u, \quad \text{and} \dim V^c = c.$$

In particular, there is a direct sum decomposition of the state space consisting of three invariant subspaces

$$\mathbb{R}^{2n} = V^s \oplus V^u \oplus V^c.$$

Moreover, the evolution of the entire linear system is a superposition of the three motions on the constituent invariant subspaces: the asymptotically stable motion on V^s, the asymptotically expanding motion on V^u, and the motion on V^c, which is determined by the dimension of the Jordan blocks corresponding to the eigenvalues of unit modulus. For example, if $u = 0$ as assumed above, it can be easily verified that any trajectory of the full linear system converges geometrically to a trajectory

lying on V^c. Therefore, if $u = 0$, the (asymptotic) stability or instability of the full linear system is determined by the (asymptotic) stability or instability of the reduced dynamics on V^c.

In the nonlinear case, the geometric situation is similar. It is now classical that the nonlinear analogue of V^s can be locally defined as the set W^s of initial conditions that converge to the equilibrium at a geometric rate. The set W^s, referred to as the *stable manifold*, is known to be locally invariant and to be locally a smooth submanifold of the state space, having dimension s. A similar characterization of the set of geometrically expanding points can be given, leading to the unstable manifold W^u, which is locally defined as an invariant, smooth submanifold of dimension u. In this context, it is easy to see that if $u = 0$ and if $c = 0$, then W^s is a neighborhood of the equilibrium and therefore the equilibrium is locally asymptotically stable. An analysis of the critical case, $u = 0$ but $c \neq 0$, is facilitated by the existence of a center manifold W^c that plays a role analogous to the role played for linear systems by V^c. The existence of a center manifold has been established only relatively recently in part due to the absence of an explicit characterization of W^c as a set, a fact that also partially explains the fact that center manifolds need not be unique. This existence result is only part of the fundamental "center manifold theorem," which we now describe in more detail.

CENTER MANIFOLD THEOREM ([18], [28]).

(i) Existence. *Suppose* (5.1) *is a* C^{k+1} *system with an equilibrium* $(\alpha_\infty, \gamma_\infty)$ *for which* $\dim V^c = c$. *Then, in a sufficiently small neighborhood of the equilibrium there exists a* C^k*-submanifold* W^c *of dimension* c, *which is locally invariant and for which the tangent space to* W^c *at* $(\alpha_\infty, \gamma_\infty)$ *is* V^c.

(ii) Principle of asymptotic phase. *Suppose further that* $u = 0$ *for the equilibrium* $(\alpha_\infty, \gamma_\infty)$. *Then, for each initial condition sufficiently close to the equilibrium there is an initial condition on* W^c *for which the error between the corresponding trajectories asymptotically decreases geometrically.*

We will use this theorem for convergence analysis of the fast filtering algorithm (5.1).

LEMMA 5.1. *The point* (α, γ) *is an equilibrium of the fast filtering algorithm* (5.1) *if and only if* $\gamma = 0$. *The Jacobian of* f *at the equilibrium* $(\alpha, 0)$ *is given by*

$$\operatorname{Jac} f\Big|_{(\alpha,0)} = \begin{bmatrix} I & 0 \\ 0 & G(\alpha) \end{bmatrix},$$

where $G(\alpha)$ *is defined as in* (4.6).

Proof. Since $A(0) = I$, $(\alpha, 0)$ is clearly an equilibrium for each $\alpha \in \mathbb{R}^n$. It remains to show that each equilibrium is of this form. To this end, let (α, γ) satisfy

$$\alpha = A(\gamma)\alpha, \tag{5.2a}$$

$$\gamma = G(\alpha)\gamma. \tag{5.2b}$$

The last of equations (5.2a) reads

$$\alpha_n = \frac{\alpha_n}{1 - \gamma_0^2},$$

which requires that either α_n or γ_0 is zero, i.e., $\alpha_n \gamma_0 = 0$. In view of this, the second to last equation becomes

$$\alpha_{n-1} = \frac{\alpha_{n-1}}{1 - \gamma_1^2},$$

which implies that $\alpha_{n-1}\gamma_1 = 0$. Proceeding in this manner we see that

$$\alpha_{n-i}\gamma_i = 0; \quad i = 0, 1, 2, \ldots, n-1$$

and therefore the last of equations (5.2b) yields $\gamma_{n-1} = 0$. Then solving (5.2b) successively from the bottom yields $\gamma = 0$ as required. Since $A(0) = I$ and $\partial A/\partial\gamma(0) = 0$, the Jacobian of f is as stated in the lemma. □

In particular, this lemma shows that whenever α corresponds to a Schur polynomial,

$$\alpha(z) = z^n + \alpha_1 z^{n-1} + \cdots + \alpha_n, \tag{5.3}$$

the stable manifold of the fast filtering algorithm at $(\alpha, 0)$ is n-dimensional. The next result significantly refines this observation. In particular, we will characterize the stable manifold explicitly. As a preliminary, we denote by V_λ the generalized (complex) eigenspace of $G(\alpha)$ corresponding to an eigenvalue λ of $G(\alpha)$; i.e., a root of (5.3), and we define

$$\begin{aligned} s(\alpha) &= \dim_{\mathbf{C}} \textstyle\sum_{|\lambda|<1} V_\lambda, \\ u(\alpha) &= \dim_{\mathbf{C}} \textstyle\sum_{|\lambda|>1} V_\lambda, \\ c(\alpha) &= \dim_{\mathbf{C}} \textstyle\sum_{|\lambda|=1} V_\lambda. \end{aligned}$$

In particular, $(\alpha, 0)$ is hyperbolic if and only if $s(\alpha) + u(\alpha) = n$ or, equivalently, $c(\alpha) = 0$.

THEOREM 5.2. *The dimensions of the stable manifold and unstable manifold at* $(\alpha_\infty, 0)$ *are* $s(\alpha_\infty)$ *and* $u(\alpha_\infty)$, *respectively. The dimension of a center manifold is always* $n + c(\alpha_\infty)$. *In fact, any center manifold contains an open neighborhood of* $(\alpha_\infty, 0)$ *in the* n*-dimensional equilibrium manifold*

$$E = \{(\alpha, 0) : \alpha \in \mathbb{R}^n\}.$$

Moreover, if $c(\alpha_\infty) = 0$, *then the center manifold is unique and locally coincides with* E. *In this case, the equilibrium* $(\alpha_\infty, 0)$ *is Lyapunov stable if and only if* $u(\alpha_\infty) = 0$, *in which case the stable manifold is* n*-dimensional.*

Proof. Since any center manifold M must contain all local attractors in some neighborhood U of $(\alpha_\infty, 0)$, $M \cap U \supset E \cap U$. If $c(\alpha_\infty) = 0$, then by a dimension argument $M \cap U = E \cap U$ and hence $M \cap U$ is unique. In this case, by the center manifold theorem, the overall system will be Lyapunov stable when $u(\alpha_\infty) = 0$ and trajectories initialized at points (α, γ) sufficiently close to $E \cap A$, where $A = \{(\alpha, 0) :$ (5.3) is a Schur polynomial$\}$, will approach $(\alpha_\infty, 0)$ determined by (4.13) with a convergence rate

$$|\alpha_t| < C \cdot \mu^t \left\| \begin{pmatrix} \alpha \\ \gamma \end{pmatrix} \right\|,$$

where $\mu = \max_{|\lambda|<1} |\lambda|$, and λ is an eigenvalue of $G(\alpha_\infty)$. □

Finally, suppose $(\alpha_\infty, 0)$ is an equilibrium corresponding to a Schur polynomial (5.3) so that $(\alpha_\infty, 0)$ has an n-dimensional stable manifold, $W^s(\alpha_\infty, 0)$. Let (α, γ) be an initial condition lying on $W^s(\alpha_\infty, 0)$. We have noted that the equality (2.18) will hold on the orbit $\{(\alpha_t, \gamma_t); t = 0, 1, \ldots\}$ and hence must hold for $(\alpha_\infty, 0)$. From this observation we can obtain the n-invariants (4.13) in a simple form, by computing the

right-hand side of (2.18) in the limit as a solution of a spectral factorization problem, namely,

$$2r_\infty \alpha_\infty(z)\alpha_\infty(1/z) = 2D(z, z^{-1}), \tag{5.4}$$

where r_∞ is the limit of r_t as $t \to \infty$.

COROLLARY 5.3 (see [5]). *A necessary condition for an initial condition (α, γ) to generate a convergent trajectory is that the pseudo-polynomial $D(z, z^{-1})$ in (2.18) be sign definite.*

If the invariant set X_D introduced in §4 contains an equilibrium point, then $d_0 \neq 0$ in Lemma 4.4, and we may describe X_D in terms of the functions $\mathbb{R}^{2n} \to \mathbb{R}^n$ as

$$h_i(\alpha, \gamma) = 2\frac{d_i(\alpha, \gamma)}{d_0(\alpha, \gamma)}, \qquad i = 1, 2, \ldots, n, \tag{5.5}$$

where $d_i(\alpha, \gamma)$, $i = 0, 1, 2, \ldots, n$, are as defined in Lemma 4.4.

THEOREM 5.4. *Suppose that (α, γ) generates a convergent trajectory for the dynamical system (4.4), and let $D(z, z^{-1})$ be the corresponding pseudopolynomial (4.10). Then, at each point of the trajectory,*

$$h_i(\alpha(t), \gamma(t)) = \kappa_i, \qquad i = 1, 2, \ldots, n, \tag{5.6}$$

where $\kappa_1, \kappa_2, \ldots, \kappa_n$ are constants which can be determined from the initial condition (α, γ). In fact, if $\alpha_n \neq 0$, then $\kappa_n \neq 0$ and

$$d(z) = \alpha_n \left[z^n + \frac{\kappa_{n-1}}{\kappa_n} z^{n-1} + \cdots + \frac{1}{\kappa_n} \right], \tag{5.7}$$

and, if $\alpha_n = \cdots = \alpha_{k+1} = 0$ but $\alpha_k \neq 0$, then $\kappa_n = \cdots = \kappa_{k+1} = 0$, $\kappa_k \neq 0$ and

$$d(z) = r_{n-k}\alpha_k \left[z^k + \frac{\kappa_{k-1}}{\kappa_k} z^{k-1} + \cdots + \frac{1}{\kappa_k} \right]. \tag{5.8}$$

Conversely, any point (α, γ) such that

$$h_i(\alpha, \gamma) = \kappa_i \qquad i = 1, 2, \ldots, n \tag{5.9}$$

has a (finite or infinite) orbit satisfying (5.6) and the same pseudopolynomial (4.10) modulo multiplication by a nonzero constant.

Proof. According to Lemma 5.1, the equilibrium has the form $(\alpha_\infty, 0)$, and, since there is no finite escape, $r_t \neq 0$ for all $t \in \mathbb{Z}$. Consequently, in view of (A-16) and (4.11),

$$d_0(\alpha(t), \gamma(t)) = \frac{r_\infty}{r_t} d_0(\alpha_\infty, 0), \tag{5.10}$$

where, by (4.11),

$$d_0(\alpha, 0) = \alpha_n^2 + \alpha_{n-1}^2 + \cdots + \alpha_1^2 + 1$$

is nonzero. Moreover, $r_\infty \neq 0$. In fact, if $r_\infty = 0$, (5.4) implies that $D(z, z^{-1}) \equiv 0$, which contradicts Lemma 4.4. Hence (5.10) is nonzero and the rational functions (5.5) are finite on the whole trajectory. Moreover, for all $t \in \mathbb{Z}$,

$$h_i(\alpha(t), \gamma(t)) = h_i(\alpha(0), \gamma(0)) \qquad i = 0, 1, 2, \ldots, n.$$

Setting $\kappa_i := h_i(\alpha(0), \gamma(0))$, $i = 1, 2, \ldots, n$, we obtain (5.6). Next, note that $d_i = \frac{1}{2} d_0 \kappa_i$ and $d_n = \alpha_n$. Therefore, if $\alpha_n \neq 0$, then $\kappa_n \neq 0$ and $\frac{1}{2} d_0 = \alpha_n / \kappa_n$, and consequently (5.7) follows. If $\alpha_n = \cdots = \alpha_{k+1} = 0$ but $\alpha_k \neq 0$, then, by Lemma 4.4, $d_i = 0$ for $i = k+1, \ldots, n$ and $d_k = r_{n-k} \alpha_k \neq 0$. Hence, $\kappa_n = \cdots = \kappa_{k+1} = 0$, $\kappa_k \neq 0$ and $\frac{1}{2} d_0 = r_{n-k} \alpha_k / \kappa_k$, and therefore (5.8) follows. Consequently, any $(\alpha, \gamma) \in \mathbb{R}^{2n}$ satisfying (5.9) has a pseudopolynomial that differs from $D(z, z^{-1})$ by at most the nonzero constant, α_n or $r_{n-k} \alpha_k$, whichever case applies, and therefore the points on its orbit satisfy (5.6). □

In view of Theorem 5.4 it is reasonable to let the invariant set (5.9) be denoted X_D, with D interpreted as a point in projective space $\mathbb{P}^n$, as explained at the end of §4. We would like to determine at what points (α, γ) the invariant set X_D is an n-fold, i.e., for which (α, γ) the tangent space $T_{(\alpha,\gamma)} X_D$, or, which is the same, the kernel of the Jacobian of f at (α, γ), has dimension n.

To investigate this point, let us return to the pseudopolynomial relation (2.18) defining the integrals (5.6). To this end, let

$$S(a)v = a(z)v(1/z) + a(1/z)v(z) \tag{5.11}$$

define an operator $S(a) : V_n \to \mathcal{D}_n$ from the vector space V_n of polynomials having degree less than or equal to n into the vector space $\mathcal{D}_n$ of symmetric pseudopolynomials of degree at most n. Such an operator can be defined for each polynomial $a(z)$ of degree n. Relation (2.13) defining $D(z, z^{-1})$ in terms of $a(z)$ and $b(z)$ can then be written

$$S(a)b = 2D \tag{5.12}$$

and we may ask under what conditions this linear system may be solved for b in terms of D and a. It is well known that the answer to this question depends on the location of the zeros of $a(z)$. We say that $(\lambda, 1/\lambda)$ is a *pair of reciprocal roots* (of multiplicity μ) of a pseudo-polynomial $D(z, z^{-1})$ provided that both λ and $1/\lambda$ are roots (of multiplicity μ). According to this definition *each* root (of multiplicity μ) at $\lambda = 1$ or $\lambda = -1$ determines a pair, $(1, 1)$ or $(-1, -1)$, of reciprocal roots (of multiplicity μ).

LEMMA 5.5. *Let ρ be the number of reciprocal roots of $a(z)$ counted with multiplicity. Then*

$$\dim \ker S(a) = \rho. \tag{5.13}$$

Proof. This follows easily from the unit circle version of Orlando's formula [14]. Also see [10], noting that the Jury matrix of $a(z)$ is a matrix representation of $S(a)$. □

We may now write the invariance relation (2.18) in the form

$$r_t S(a_t) b_t = 2D. \tag{5.14}$$

The next lemma establishes notation for the subsequent analysis. Denote by H_n the hyperplane in V_n of monic polynomials. We note that for $\beta \in H_n$ the tangent space $T_\beta H_n$ to H_n at β is canonically isomorphic with V_{n-1}.

LEMMA 5.6. *Let (α, γ) be a point in the invariant algebraic set X_D, defined by* (5.9) *in Theorem* 5.4, *with the property that $\gamma_k^2 \neq 1$ for $k = 0, 1, \ldots, n-1$, and let*

(a, b) be given by (3.12). *Then the tangent space $T_{(\alpha,\gamma)}X_D$ of X_D at (α, γ) has the same dimension as the tangent space of*

$$\phi(a, b, r) = 2D \tag{5.15}$$

at $(a, b, 1)$, where $\phi : H_n \times H_n \times \mathbb{R} \to \mathcal{D}_n$ is defined by

$$\phi(a, b, r) = rS(a)b. \tag{5.16}$$

Proof. The lemma follows immediately from the fact that (5.9) is obtained from (5.15) by merely eliminating the variable r, which is nonzero since all $\gamma_k^2 \neq 1$, and changing coordinates under the bijection $\mathcal{F}$ of Corollary 3.4. □

It is not hard to characterize those tangent vectors that are annihilated by the Jacobian of ϕ at $(a, b, 1)$ and hence span the tangent space of (5.15) at $(a, b, 1)$.

LEMMA 5.7. *At any point $(a, b, 1)$, the kernel of the Jacobian of ϕ consists of those tangent vectors $(u, v, q_0) \in V_{n-1} \times V_{n-1} \times \mathbb{R}$ satisfying*

$$S(a)q + S(b)p = 0, \tag{5.17}$$

where

$$p(z) := u(z), \qquad q(z) := q_0 b(z) + v(z). \tag{5.18}$$

In other words, the kernel of the Jacobian of ϕ can be identified with pairs $(p, q) \in V_{n-1} \times V_n$, i.e., those polynomials of the form

$$\begin{aligned} p(z) &= p_1 z^{n-1} + \cdots + p_n, \\ q(z) &= q_0 z^n + q_1 z^{n-1} + \cdots + q_n, \end{aligned} \tag{5.19}$$

which satisfy the "variational equation"

$$a(z)q(1/z) + a(1/z)q(z) + b(z)p(1/z) + b(1/z)p(z) = 0. \tag{5.17}'$$

Proof. Consider the tangent vector $(a + \varepsilon u, b + \varepsilon v, 1 + \varepsilon q_0)$ at the point $(a, b, 1)$ where $u \in V_{n-1}, v \in V_{n-1}$ and $q_0 \in \mathbb{R}$. We compute the directional derivative of ϕ in the direction (u, v, q_0) as the limit of a Newton quotient

$$\frac{1}{\varepsilon}[\phi(a + \varepsilon u, b + \varepsilon v, 1 + \varepsilon q_0) - \phi(a, b)] \tag{5.20}$$

as $\varepsilon \to 0$, yielding (5.17)′. □

LEMMA 5.8. *Suppose α_∞ corresponds to a polynomial $\alpha(z)$, via* (5.3), *which has no pair of reciprocal roots. Then the invariant algebraic set X_D is a smooth submanifold of dimension n at the equilibrium $(\alpha_\infty, 0)$.*

Proof. When $\gamma = 0$ we have $a(z) = b(z) = \alpha(z)$, so that the variational equation reduces to

$$S(a)[p + q] = 0. \tag{5.21}$$

Since $a(z)$ has no pair of reciprocal roots, by Lemma 5.5, $\ker S(a) = 0$ and therefore we must have

$$p(z) = -q(z). \tag{5.22}$$

Note, in particular, that $q_0 = 0$, i.e., the tangent vectors belong to the $2n$-dimensional space with coordinates (a, b) or (α, γ) as in Corollary 3.4. Since (5.22) defines a subspace of tangent vectors having dimension n, by Lemma 5.6, (5.9) locally defines a smooth submanifold in a neighborhood of $(\alpha_\infty, 0)$ by the implicit function theorem. □

THEOREM 5.9. *Let $(\alpha_\infty, 0)$ be an equilibrium. If $c(\alpha_\infty) = u(\alpha_\infty) = 0$, then the stable manifold through $(\alpha_\infty, 0)$ coincides with an open subset of the invariant n-fold X_D determined from (5.9). Moreover, any point (α, γ) on X_D corresponding to a positive real function $v(z) := \frac{1}{2}(b(z)/a(z))$ will lie on this stable manifold and the minimum phase spectral factor of the spectral density $v(z) + v(1/z)$ will be*

$$w(z) = r_\infty^{1/2} \frac{\alpha_\infty(z)}{a(z)}. \tag{5.23}$$

Proof. Since $\alpha_\infty(z)$ is a Schur polynomial, (5.9) locally defines a smooth submanifold at $(\alpha_\infty, 0)$ by Lemma 5.8, with tangent space given by (5.22). We claim that (5.22) also characterizes, in the (a, b)-coordinates, those tangent vectors (p, q) that are vertical in the (α, γ)-coordinates at point $(\alpha_\infty, 0)$. In fact, the map $\mathcal{F}$ of Corollary 3.4 sends the "vertical vector" $(0, \gamma)$ to

$$(a, b) = (\varphi_n(\gamma), \psi_n(\gamma)), \tag{5.24}$$

where here φ_n and ψ_n are the n-vectors of coefficients in the Szegö polynomials $\varphi_n(z)$ and $\psi_n(z)$ as functions of γ. The vertical vectors $(0, \gamma)$ at the point $(\alpha_\infty, 0)$ corresponds to the tangent vectors (p, q) of (5.24), i.e., the vectors of the form

$$\left(\frac{\partial \varphi_n}{\partial \gamma_i}(0), \frac{\partial \psi_n}{\partial \gamma_i}(0) \right), \qquad i = 1, 2, \dots, n.$$

But, according to Corollary 3.4, $\varphi_n(\gamma) = \psi_n(-\gamma)$ so that

$$\frac{\partial \varphi_n}{\partial \gamma_i}(0) = -\frac{\partial \psi_n}{\partial \gamma_i}(0),$$

and hence $p = -q$ as claimed.

Now recall that the vertical vectors at $(\alpha_\infty, 0)$ are precisely the vectors lying in the sum of the generalized eigenspaces for the Jacobian, corresponding to asymptotically stable eigenvalues, i.e., in the tangent space to the stable manifold at $(\alpha_\infty, 0)$. In summary, the invariant set X_D is an n-dimensional smooth submanifold near the equilibrium $(\alpha_\infty, 0)$ that it contains, provided $(\alpha_\infty, 0)$ is an asymptotically stable equilibrium. In this case, the tangent space to this submanifold at the equilibrium coincides with the tangent space to the stable manifold $W^s(\alpha_\infty, 0)$. In particular, an initial condition lying on X_D corresponding to positive real functions (2.1) will converge geometrically to $(\alpha_\infty, 0)$, in harmony with classically known convergence properties of the Kalman filter. By uniqueness of $W^s(\alpha_\infty, 0)$ we see that it coincides, in a neighborhood of $(\alpha_\infty, 0)$, with the invariant set defined by (5.9). Finally, from (2.13) and (5.4), we see that the minimum phase spectral factor $w(z)$ corresponding to $v(z)$ is given by (5.23). □

Remark 1. As a consequence of Theorem 5.9, we can see that the set of rational integral invariants $\{h_1, h_2, \dots, h_n\}$, defined in (5.5), is complete. That is, there is no analytic (or meromorphic) invariant function h for which the differential dh is linearly

independent of the differentials dh_i, $i = 1, 2, \ldots, n$, at some point (α, γ). Indeed, if for some point $(\bar{\alpha}, \bar{\gamma})$

$$dh(\bar{\alpha}, \bar{\gamma}) \notin \text{span}\,\{dh_i(\bar{\alpha}, \bar{\gamma})\}_{i=1}^n,$$

then for all (α, γ) in some open dense set U we must have

$$dh(\alpha, \gamma) \notin \text{span}\,\{dh_i(\alpha, \gamma)\}_{i=1}^n \tag{5.25}$$

by a standard analyticity argument. Now consider the region $\mathcal{P}_n$ of all $(\alpha, \gamma) \in \mathbb{R}^{2n}$ satisfying the positive real conditions (2.13)–(2.15) with $a(z)$ and $b(z)$ given by (4.1). For any initial condition $(\alpha(0), \gamma(0)) \in \mathcal{P}_n$, we must have

$$h(\alpha(t), \gamma(t)) = h(\alpha_\infty, 0)$$

so that, on $\mathcal{P}_n$, h is determined by its restriction $\bar{h}$ to the equilibrium set

$$E_s = \{(\alpha_\infty, 0) \in \mathbb{R}^{2n} | \alpha_\infty(z) \text{ a Schur polynomial}\}.$$

On the other hand, α_∞ can be computed from $(\alpha(0), \gamma(0))$ as a rational function of the h_i. More explicitly, $h_i(\alpha(0), \gamma(0))$ determine, up to a scalar multiple, the pseudopolynomial $D(z, z^{-1})$ via (5.4) and (A-16). From $D(z, z^{-1})$, which is positive on the unit circle, we determine (independently of the scalar multiple) the stable polynomial $\alpha_\infty(z)$, and hence α_∞, via (5.4). Therefore, on all of $\mathcal{P}_n$ we have

$$h(\alpha(0), \gamma(0)) = \bar{h}(\alpha_\infty, 0) = \bar{h}(F(h_1(\alpha(0), \gamma(0)), \ldots, h_n(\alpha(0), \gamma(0)), 0), \tag{5.26}$$

where F is the rational function defined by (5.4), (4.10), and (5.4). In particular, on $\mathcal{P}_n$ we must have

$$dh \in \text{span}\,\{dh_i\},$$

contrary to the assertion that $U \cap \mathcal{P}_n$ be open and dense in $\mathcal{P}_n$.

So far, we have recovered (cf. Corollary 5.3) a necessary condition for an initial condition (α, γ) to generate an asymptotically convergent trajectory under the dynamics of the fast filtering algorithm; namely the pseudopolynomial $D(z, z^{-1})$ determined by (α, γ) must be sign-definite. In the case where $n = 1$, it has been demonstrated in [5] using somewhat specialized, detailed analysis that, apart from initial data that can escape in finite time, this condition is also sufficient for global convergence. In the case where $n = 2$, this has also been shown [6], although for $n \geq 2$ it is possible to have asymptotic convergence to equilibria that have a lower-dimensional stable manifold (see Theorem 5.2) as well as to the unique Lyapunov stable equilibrium, corresponding to a stable factor of the pseudopolynomial $D(z, z^{-1})$, as occurs in classical filtering. The final result in this section enables us to determine at what points (α, γ) the invariant n-fold X_D defined by (5.9) is a smooth manifold. As it turns out, the singular points correspond to certain systems having a lower-dimensional realization, which also are initial data converging to unstable equilibria.

THEOREM 5.10. *Consider the n-fold X_D defined by* (5.9) *with a corresponding pseudopolynomial $D(z, z^{-1})$. A point (α, γ) is a singular point of X_D if and only if $a(z)$ and $b(z)$, defined in terms of (α, γ) by* (3.12), *have a common pair of reciprocal roots.*

To prove this result, we derive a general formula for the dimension of the tangent space $T_{(\alpha,\gamma)}X_D$ from which our assertion will follow by the implicit function theorem.

LEMMA 5.11. $\dim T_{(\alpha,\gamma)}X_D = n + \sigma$, *where* σ *is the number of common pairs of reciprocal roots of the polynomials* $a(z)$ *and* $b(z)$ *given by* (3.12).

Proof of Theorem 5.10. According to Lemma 5.6 and Lemma 5.7, the tangent space $T_{(\alpha,\gamma)}X_D$ to X_D at (α,γ) has the same dimension as the vector space W of all solutions (p,q) to the variational equation (5.17), i.e., W is the subspace

$$W = \{(p,q) \mid S(a)q + S(b)p = 0\} \tag{5.27}$$

of $V_{n-1} \times V_n$, where $a(z)$ and $b(z)$ are given by (3.12). Now consider the map $\text{proj}_1 : W \to V_{n-1}$ defined via

$$\text{proj}_1(p,q) = p. \tag{5.28}$$

In particular,

$$\dim W = \dim \ker(\text{proj}_1) + \dim \text{range}(\text{proj}_1), \tag{5.29}$$

where

$$\ker(\text{proj}_1) = \{(0,q) \mid S(a)q = 0\} \simeq \ker S(a) \tag{5.30}$$

and

$$\text{range}(\text{proj}_1) = \{p \in V_{n-1} | S(b)p \in \text{range}\, S(a)\}. \tag{5.31}$$

Now recall from Lemma 5.5 that

$$\dim \ker S(a) = \rho_1, \quad \dim \ker S(b) = \rho_2, \tag{5.32}$$

where ρ_1 and ρ_2 are the number of pairs of reciprocal roots $(\lambda, 1/\lambda)$ of $a(z)$ and $b(z)$, respectively, counted with multiplicity. Matters being so, we can also characterize the range of $S(a)$ (and that of $S(b)$) in the vector space of symmetric pseudopolynomials $\mathcal{D}_n$.

Explicitly, if $(\lambda_1, 1/\lambda_1), \dots, (\lambda_{\rho_1}, 1/\lambda_{\rho_1})$ are the ρ_1 pairs of reciprocal roots (counted with multiplicity) of $a(z)$, then the range of $S(a)$ is the codimension ρ_1 subspace of symmetric pseudopolynomials that vanish at $\{\lambda_1, \dots, \lambda_{\rho_1}, 1/\lambda_1, \dots, 1/\lambda_{\rho_1}\}$. The notation

$$\dim \ker(\text{proj}_1) = \rho_1 \tag{5.33}$$

fixes the first term of (5.29). To determine the second, observe that the map $S(b)$ sends any $p \in \text{range}\, \text{proj}_1$ into the subspace

$$U := \text{range}\, S(a) \cap \text{range}\, S(b), \tag{5.34}$$

which consists of all pseudopolynomials in $\mathcal{D}_n$ with $\rho_1 + \rho_2 - \sigma$ pairs of reciprocal zeros fixed, where σ is the number of common such pairs of $a(z)$ and $b(z)$. The space U has codimension $\rho_1 + \rho_2 - \sigma$ in V_n, i.e.,

$$\dim U = n + 1 - \rho_1 - \rho_2 + \sigma. \tag{5.35}$$

Therefore, since $\dim \ker S(b) = \rho_2$, the dimensions of the subspace

$$Z := \{p \in V_n | S(b)p \in \text{range}\, S(a)\} \tag{5.36}$$

is $n+1-\rho_1+\sigma$, and, consequently,

$$\dim \text{range proj}_1 = n-\rho_1+\sigma, \tag{5.37}$$

i.e., one less than $\dim Z$, provided that there is a $p \in Z$ that does not belong to V_{n-1}. However, this is the case because

$$S(b)a = S(a)b \in \mathcal{D}_n, \tag{5.38}$$

i.e., $a(z) \in Z$. Combining (5.29), (5.33), and (5.37) we then see that $\dim W = n+\sigma$. □

6. Fast filtering algorithm, Riccati equations, and Lagrangian Grassmannians. Our goal is to prove a global convergence theorem for the fast filtering algorithm (4.4), or, equivalently, (2.16). As is to be expected, the convergence of (4.4) is intimately connected to the convergence of the matrix Riccati equation (2.2). It is no restriction to assume that $\alpha_n \neq 0$. In fact, as noted above, if $\alpha_n = 0$ we can reduce the dimension of the dynamical system (4.4), replacing n by $k < n$, so that $\alpha_k \neq 0$.

LEMMA 6.1. *Let $\alpha_n \neq 0$. Then, the fast filtering algorithm* (4.4) *tends to a limit* $(\alpha_\infty, 0)$ *if and only if the Riccati equation* (2.2) *with initial condition* $P_0 = 0$ *converges to some equilibrium* P_∞. *Here* P_∞ *satisfies the algebraic Riccati equation*

$$\Lambda(P) := FPF' - P + (g - FPh)(1 - h'Ph)^{-1}(g - FPh)' = 0, \tag{6.1}$$

where the parameters (F, g) *are those corresponding to the initial condition* (α, γ) *of* (4.4), *and*

$$\alpha_\infty = (1 - h'P_\infty h)^{-1}(g - FP_\infty h) + a. \tag{6.2}$$

Proof. The Riccati equation (2.2) can be written as

$$P_{t+1} - P_t = \Lambda(P_t). \tag{6.3}$$

As shown in [25] and pointed out in [5], the structure of the fast filtering algorithm is reflected in the fact that initial condition $P_0 = 0$ renders $\Lambda(P_0) = gg'$ nonnegative definite and rank one, a property that is preserved along the trajectory so that

$$\Lambda(P_t) = r_t g(t) g(t)', \tag{6.4}$$

where

$$r_t = 1 - h'P_t h. \tag{6.5}$$

If the fast filtering algorithm (4.4) converges, then by Lemma 5.1, $(\alpha(t), \gamma(t)) \to (\alpha_\infty, 0)$ for some $\alpha_\infty \in \mathbb{R}^n$, and r_t tends to a limit r_∞ as $t \to \infty$. Hence, according to Corollary 3.4, $a(t) \to \alpha_\infty$ and $b(t) \to \alpha_\infty$ and consequently $g(t) := \frac{1}{2}[b(t) - a(t)] \to 0$. In view of (6.3) and (6.4), this implies that P_t tends to a limit P_∞ as $t \to \infty$. Conversely, suppose that $P_t \to P_\infty$ as $t \to \infty$. Then $\Lambda(P_t) \to 0$, and, by (6.5), $r_t \to r_\infty$. The condition $\alpha_n = a_n + g_n \neq 0$ implies that $r_\infty \neq 0$. In fact, if $r_\infty = 0$, i.e., $h'P_\infty h = 1$, convergence would require that $g = FP_\infty h$ and consequently that $g_n = -a_n h'P_\infty h = -a_n$ (see (2.10)), contradicting the assumption that $\alpha_n \neq 0$. Therefore, by (6.4), $g(t)g(t)'$ and hence g(t) tends to zero, which, in turn, implies that $\gamma_t = g_1(t) \to 0$, i.e., $\gamma(t) \to 0$. Then it follows from (4.4a) that $\alpha(t)$ tends to

a limit α_∞ as $t \to \infty$. Finally, we see from (2.17) and (4.1) that the Kalman gain tends to $k_\infty := \alpha_\infty - a$ as $t \to \infty$. On the other hand, it follows from (2.8) that $k_\infty = r_\infty^{-1}(g - FP_\infty h)$ and hence (6.2) holds. □

LEMMA 6.2. *The statement of Lemma* 6.1 *remains true if* $F := J - ah'$, *defined by* (2.10), *is replaced by* $F := J - bh'$. *If* $\alpha_n \neq 0$, *then at least one of the matrices* $(J - ah')$ *and* $(J - bh')$ *is nonsingular.*

Proof. Exchanging the roles of a and b amounts to changing the initial condition (α, γ) of the dynamical system (4.4) for $(\alpha, -\gamma)$. If (α, γ) has the orbit $\{(\alpha(t), \gamma(t))\}$, then a simple inspection of (4.4) shows that $(\alpha, -\gamma)$ has the orbit $\{(\alpha(t), -\gamma(t))\}$ so that (α, γ) converges if and only if $(\alpha, -\gamma)$ does, both tending to the same limit $(\alpha_\infty, 0)$. This proves the first part of the lemma. To prove the second part, suppose that both $(J - ah')$ and $(J - bh')$ are singular, i.e., $a_n = b_n = 0$. Then $\alpha_n = \frac{1}{2}(a_n + b_n) = 0$, contradicting the assumption that $\alpha_n \neq 0$. □

LEMMA 6.3. *Suppose* F *is nonsingular. Then* $h'F^{-1}g = 1$ *if and only if* $\alpha_n = 0$.

Proof. Let $v(z)$ be as in (2.1). Then

$$v(0) = \tfrac{1}{2} - h'F^{-1}g.$$

On the other hand, since $\gamma_t = -\varphi_{t+1}(0) = \psi_{t+1}(0)$ for $t = 0, 1, 2, \ldots$, and $\varphi_0 = \psi_0 = 1$, (3.9) yields

$$v(0) = -\frac{1}{2}\frac{\gamma_{n-1} + \alpha_1\gamma_{n-2} + \cdots + \alpha_{n-1}\gamma_0 - \alpha_n}{\gamma_{n-1} + \alpha_1\gamma_{n-2} + \cdots + \alpha_{n-1}\gamma_0 + \alpha_n},$$

which equals $-\frac{1}{2}$ if and only if $\alpha_n = 0$. □

In considering the algebraic Riccati equation (6.1) it is important to remember that the situation here is more general than that usually considered in Kalman filtering (where $v(z)$ is positive real) since F may be unstable and $r_\infty := 1 - h'P_\infty h$ may be negative. Here the symmetric matrix P_∞ may have both negative and zero eigenvalues.

Recall now that there is an extensive literature, see, e.g., [2], [29], [30], [35], on the solution of a matrix Riccati equation as a power iteration on the *Lagrangian Grassmannian* manifold, $LG(n, 2n)$ consisting of n-dimensional subspaces $\mathcal{U} \subset \mathbb{R}^{2n}$ which are *Lagrangian* in the sense that

$$x' \begin{bmatrix} 0 & I \\ -I & 0 \end{bmatrix} y = 0 \quad \text{for all } x, y \in \mathcal{U}.$$

In regard to (2.2) this amounts to noting first the well-known fact that the dynamics of the matrix Riccati equation can be described via a linear fractional transformation. Note that, in view of Lemma 6.2 and Lemma 6.3, it is no restriction to assume that F is nonsingular and that the parameter σ, defined in Proposition 6.4, is nonzero in analyzing the convergence of (4.4).

PROPOSITION 6.4. *The matrix Riccati recursion* (2.2) *may be reformulated as*

$$P_{t+1} = (S_{21} + S_{22}P_t)(S_{11} + S_{12}P_t)^{-1}, \tag{6.6}$$

where the $2n \times 2n$ *matrix*

$$\begin{bmatrix} S_{11} & S_{12} \\ S_{21} & S_{22} \end{bmatrix} \tag{6.7}$$

is the symplectic matrix

$$S = \begin{bmatrix} F^{-1} + F^{-1}gh'F^{-1}\sigma^{-1} & F^{-1}gg'\sigma^{-1} \\ -hh'F^{-1}\sigma^{-1} & F' - hg'\sigma^{-1} \end{bmatrix}' \tag{6.8a}$$

with

$$\sigma = 1 - h'F^{-1}g. \tag{6.8b}$$

Proof. A straightforward calculation shows that $\Lambda(P)$, defined by (6.1), may be written

$$\Lambda(P) := APA' - P + APh(1 - h'Ph)^{-1}h'PA' + gg', \tag{6.9}$$

where $A := F - gh'$. Since F is invertible, so is A. In fact,

$$A^{-1} = F^{-1} + F^{-1}gh'F^{-1}\sigma^{-1}. \tag{6.10}$$

Consequently, (6.3) and the fact that

$$(I - hh'P)^{-1} = I + (1 - h'Ph)^{-1}hh'P \tag{6.11}$$

implies that

$$\begin{aligned} P_{t+1} &= gg' + AP_t(I - hh'P_t)^{-1}A' \\ &= [gg'(A')^{-1}(I - hh'P_t) + AP_t](I - hh'P_t)^{-1}A', \end{aligned}$$

which yields (6.6) with $S_{11} = (A')^{-1}$, $S_{12} = -(A')^{-1}hh'$, $S_{21} = gg'(A')^{-1}$, and $S_{22} = A + (1 - \sigma^{-1})gh'$. Inserting (6.10) then yields (6.8). A simple calculation shows that S is symplectic, i.e., that

$$S'\hat{J}S = \hat{J}, \tag{6.12a}$$

where

$$\hat{J} = \begin{bmatrix} 0 & I \\ -I & 0 \end{bmatrix}. \qquad \square \tag{6.12b}$$

COROLLARY 6.5. *The algebraic Riccati equation* (6.1) *may be written in the alternative form*

$$P = APA' + APh(1 - h'Ph)^{-1}h'PA' + gg', \tag{6.13}$$

where $A := F - gh'$ is invertible, and, in terms of A, the symplectic matrix S takes the form

$$S = \begin{bmatrix} (A')^{-1} & -(A')^{-1}hh' \\ gg'(A')^{-1} & A + (1 - \sigma^{-1})gh' \end{bmatrix}. \tag{6.14}$$

Next, setting

$$P_t = Y_tX_t^{-1} \tag{6.15}$$

and applying Proposition 6.4, we see that the matrix Riccati equation may be viewed as a linear symplectic system

$$Z_{t+1} = SZ_t \tag{6.16}$$

where

$$Z_t = \begin{bmatrix} X_t \\ Y_t \end{bmatrix} \quad \text{and} \quad Z_0 = \begin{bmatrix} I \\ P_0 \end{bmatrix}.$$

In particular, Lemma 6.1 states that the dynamics of the fast filtering algorithm correspond to the initial condition $P_0 = 0$, i.e.,

$$Z_0 = \begin{bmatrix} I \\ 0 \end{bmatrix}. \tag{6.17}$$

Studying the linear system (6.16) on the manifold $LG(n, 2n)$ of Lagrangian subspaces in $\mathbb{R}^{2n}$ instead of (2.2) or (4.4) amounts to a compactification of the phase space in the sense that P_t is also allowed to take infinite values, corresponding to X_t being singular. In particular, this compactification provides a model in which we can analyze high-gain limits, as well as finite escape, of the sequence of Kalman gains. The fact that P_t is symmetric insures that the subspace spanned by the columns of $\left[\begin{smallmatrix} X_t \\ Y_t \end{smallmatrix}\right]$ is Lagrangian.

In view of this, the dynamical behavior of the Riccati equation (2.2), as well as the fast algorithm (2.16) or (4.4), depends on the eigenvalue structure of S, which is connected to the zero structure of the pseudo-polynomial $D(z, z^{-1})$ through the following proposition.

PROPOSITION 6.6. *Let $\alpha_n \neq 0$. Then the eigenvalues of S are identical to the zeros of the pseudopolynomial $D(z, z^{-1})$.*

Proof. Since $\alpha_n \neq 0$, we have $\kappa_n \neq 0$. By a straightforward computation, we see that the characteristic polynomial of S is

$$\begin{aligned} \chi_S(z) = z^{2n} + \tfrac{\kappa_{n-1}}{\kappa_n} z^{2n-1} + \tfrac{\kappa_{n-2}}{\kappa_n} z^{2n-2} + \cdots + \tfrac{\kappa_1}{\kappa_n} z^{n+1} + \tfrac{2}{\kappa_n} z^n \\ + \tfrac{\kappa_1}{\kappa_n} z^{n-1} + \cdots + \tfrac{\kappa_{n-2}}{\kappa_n} z^2 + \tfrac{\kappa_{n-1}}{\kappa_n} z + 1, \end{aligned}$$

where $\kappa_1, \kappa_2, \ldots, \kappa_n$ are integral constants defined in Theorem 5.4. Comparing this with (4.10) and (5.7) we see that

$$D(z, z^{-1}) = \alpha_n z^{-n} \chi_S(z), \tag{6.18}$$

from which the proposition follows. □

This proposition allows us to analyze the dynamics of (2.2) and (4.4) not only for parameters (or, in the case of (4.4), initial conditions) that satisfy the positive real condition, but for general choices of parameters (initial conditions). If $\alpha_n = 0$, Proposition 6.6 should be applied to the dimension-reduced problem mentioned above. Hence, in this case the Riccati equation (2.2) can be replaced by one of smaller dimension, which is actually due to the occurrence of invariant directions [3], as was pointed out in [27] and further developed in [31].

The basic question now is to determine under what conditions (6.16) converges, i.e., under what conditions $S^t \mathcal{Z}_0$ tends to a limit as $t \to \infty$, where $\mathcal{Z}_0$ is the subspace spanned by the columns of Z_0, i.e., $\mathcal{Z}_0 = \operatorname{Im} \left[\begin{smallmatrix} I \\ 0 \end{smallmatrix}\right]$. Let us first study the set of equilibria of the power iteration $S^t \mathcal{Z}_0$, which must clearly consist of those n-dimensional

subspaces

$$\mathcal{U} = \operatorname{Im} \begin{bmatrix} X \\ Y \end{bmatrix}, \qquad X, Y \; n \times n, \tag{6.19}$$

which are S-invariant. In order that $\mathcal{U}$ should correspond to a (finite) solution of algebraic Riccati equation (6.1), as required by Lemma 6.1, $\mathcal{U}$ must be such that X is nonsingular so that

$$P = YX^{-1} \tag{6.20}$$

can be formed, and, for P to be the limit of the sequence $\{P_t\}$, $\mathcal{U}$ must be Lagrangian so that P is symmetric. The following is a consequence of (h, F) being observable.

LEMMA 6.7. *Let $\alpha_n \neq 0$ and let $\mathcal{U}$, defined by* (6.19), *be Lagrangian. Then X is nonsingular.*

For the proof, we need a result that is a discrete-time version of a result due the Kučera [23]; see [34, p. 379]. Since it is surprisingly more complicated than the continuous-time result, and we need it again below, we state it as a lemma, the proof of which is deferred to the Appendix.

LEMMA 6.8. *Let $\alpha_n \neq 0$ and let $\mathcal{U}$ be an n-dimensional S-invariant Lagrangian subspace. Then, the subspace*

$$\mathcal{W} := \mathcal{U} \cap \operatorname{Im} \begin{bmatrix} I \\ 0 \end{bmatrix}$$

satisfies the invariance condition

(i) $S\mathcal{W} \subset \mathcal{W}$

and, which is equivalent, the reversed invariance condition

(ii) $S^{-1}\mathcal{W} \subset \mathcal{W}$.

The same statements hold for

$$\tilde{\mathcal{W}} := \mathcal{U} \cap \operatorname{Im} \begin{bmatrix} 0 \\ I \end{bmatrix}.$$

Now the proof of Lemma 6.7 follows along the lines of the proof of Shayman's Proposition 1 in [34].

Proof of Lemma 6.7. Suppose $\tilde{\mathcal{W}}$, defined in Lemma 6.8, has dimension k, and that X is singular so that $k > 0$. Then

$$\tilde{\mathcal{W}} = \operatorname{Im} \begin{bmatrix} 0 \\ V \end{bmatrix}$$

for some $n \times k$ matrix V. Since $S\tilde{\mathcal{W}} \subset \tilde{\mathcal{W}}$ (Lemma 6.8) and S is nonsingular (Proposition 6.6), there is a nonsingular $k \times k$ matrix T such that

$$S \begin{bmatrix} 0 \\ V \end{bmatrix} = \begin{bmatrix} 0 \\ V \end{bmatrix} T,$$

i.e., $-(A')^{-1}hh'V = 0$ and $AV + (1 - \sigma^{-1})gh'V = VT$. The first of these equations yields

$$h'V = 0, \tag{6.21a}$$

whereupon the second becomes

$$AV = VT. \tag{6.21b}$$

However, since (h, F) is observable, so is (h, A), for $A = F - gh'$. Therefore (6.21) implies that $V = 0$, contradicting the assumption that X is singular. □

A partial answer to the question of whether the power iteration $S^t\mathcal{Z}_0$ converges can now be given by the following lemma, which generalizes some results due to Parlett and Poole [30]. This requires a few definitions. For any linear operator $A : \mathbb{R}^m \to \mathbb{R}^m$, an A-invariant subspace $\mathcal{U}$ is *dominant* (*codominant*) if the eigenvalues of the restriction $A|\mathcal{U}$ have moduli greater than or equal to (less than or equal to) those of all other eigenvalues of A.

LEMMA 6.9. *Let $A : \mathbb{R}^m \to \mathbb{R}^m$ be a linear operator. If there is a unique p-dimensional dominant A-invariant subspace $\mathcal{U}^-$ and a unique $(m-p)$-dimensional codominant A-invariant subspace $\mathcal{U}^+$, then $A^t\mathcal{X} \to \mathcal{U}^-$ as $t \to \infty$ for each p-dimensional subspace $\mathcal{X}$ such that $\mathcal{X} \cap \mathcal{U}^+ = 0$.*

Proof. If the eigenvalues of A (counted with multiplicity) satisfy

$$|\lambda_1| \geq |\lambda_2| \geq \cdots \geq |\lambda_p| > |\lambda_{p+1}| \geq \cdots \geq |\lambda_m|,$$

then the statement of the lemma follows directly from Theorem 4 in [30]. On the other hand, if

$$|\lambda_1| \geq \cdots \geq |\lambda_{p-q}| > |\lambda_{p-q+1}| = \cdots = |\lambda_{p+r}| > |\lambda_{p+r+1}| \geq \cdots \geq |\lambda_m|,$$

(or there is no eigenvalue larger (smaller) in modulus than λ_p, in which case we set $q = p$ $(r = m - p)$), we define $\hat{\mathcal{U}}^-$ and $\hat{\mathcal{U}}^+$ to be the subspaces spanned by the generalized eigenvectors corresponding to $\{\lambda_1, \ldots, \lambda_{p-q}\}$ and $\{\lambda_{p-q+1}, \ldots, \lambda_m\}$, respectively. Moreover, let $\tilde{\mathcal{U}}^-$ and $\tilde{\mathcal{U}}^+$ be the subspaces spanned by the generalized eigenvectors in $\mathcal{U}^-$, respectively, $\mathcal{U}^+$ corresponding to eigenvalues of modulus $|\lambda_p|$. Then $\tilde{\mathcal{U}}^-$ and $\tilde{\mathcal{U}}^+$ are A-invariant subspaces of $\mathcal{U}^-$ and $\mathcal{U}^+$ of dimensions q and r, respectively. In fact, $\dim(\tilde{\mathcal{U}}^- \cap \tilde{\mathcal{U}}^+) = \min(q, r)$. Now, since $\mathcal{X} \cap \mathcal{U}^+ = 0$, $\dim \mathcal{X} = p$ and $\dim \mathcal{U}^+ = m - p$, $\mathbb{R}^m = \mathcal{X} \oplus \mathcal{U}^+$, where $\oplus$ denotes direct sum. Therefore, since $\mathcal{U}^+ \subset \hat{\mathcal{U}}^+$, there is a subspace $\tilde{\mathcal{X}} \subset \mathcal{X}$ of dimension q such that $\hat{\mathcal{U}}^+ = \tilde{\mathcal{X}} \oplus \mathcal{U}^+$. Let $\hat{\mathcal{X}}$ be any $(p-q)$-dimensional subspace of $\mathcal{X}$ such that $\mathbb{R}^m = \hat{\mathcal{X}} \oplus \hat{\mathcal{U}}^+$. Now, since $\hat{\mathcal{U}}^-$ is the unique dominant $(p-q)$-dimensional A-invariant subspace, and $\hat{\mathcal{U}}^+$ is an invariant complement that, by construction, satisfies $\hat{\mathcal{X}} \cap \hat{\mathcal{U}}^+ = 0$, $A^t\hat{\mathcal{X}} \to \hat{\mathcal{U}}^-$ as $t \to \infty$ by [30, Thm. 4]. Moreover, $\mathcal{X} \cap \mathcal{U}^+ = 0$ implies that $\tilde{\mathcal{X}} \cap \tilde{\mathcal{U}}^+ = 0$. Then, following the argument in the proof of [30, Thm. 7], we see that $A^t\tilde{\mathcal{X}}$ becomes disjoint from the subspace corresponding to the eigenvalues $\{\lambda_{p+r+1}, \ldots, \lambda_m\}$ as $t \to \infty$ as these are smaller in modulus than $|\lambda_p|$. Therefore, since $\tilde{\mathcal{X}} \subset \hat{\mathcal{U}}^+$, the question of convergence of $A^t\tilde{\mathcal{X}}$ is reduced to that of [30, Thm. 6] dealing with the equimodular case. Hence, because $\tilde{\mathcal{U}}^-$ $(\tilde{\mathcal{U}}^+)$ is the unique q-dimensional (r-dimensional) dominant A-invariant subspace of $\hat{\mathcal{U}}^+$ and $\tilde{\mathcal{X}} \cap \tilde{\mathcal{U}}^+ = 0$, $A^t\tilde{\mathcal{X}} \to \tilde{\mathcal{U}}^-$ as $t \to \infty$. Consequently, since $\hat{\mathcal{X}} \oplus \tilde{\mathcal{X}} = \mathcal{X}$ and $\hat{\mathcal{U}}^- \oplus \tilde{\mathcal{U}}^- = \mathcal{U}^-$, $A^t\mathcal{X} \to \mathcal{U}^-$ as $t \to \infty$, as claimed. □

The following lemma shows that the basic assumptions of Lemma 6.9 are fulfilled for the power iteration $S^t\mathcal{Z}_0$, provided $D(z, z^{-1})$ is sign definite, i.e., has no zeros of odd multiplicity on the unit circle (Proposition 6.6). First, let us introduce some notation. Following Parlett and Poole [30] let us order the $2n$ generalized eigenvectors of S first by modulus of the associated eigenvalue with the largest first. Generalized

eigenvectors whose eigenvalues have the same modulus are ordered by exponent, where the *exponent* $e(v)$ of a generalized eigenvector v is defined as

$$e(v) = m - 2g + 1, \tag{6.22}$$

where m is the *multiplicity* of v, i.e., the dimension of the smallest invariant subspace containing it, and g is the *grade* of v, i.e., the dimension of the largest cyclic subspace containing v. Thus let

$$v_1, v_2, \ldots, v_{2n} \tag{6.23}$$

be the generalized eigenvectors ordered in this way, and let

$$\lambda_1, \lambda_2 \ldots, \lambda_{2n} \tag{6.24}$$

be the corresponding eigenvalues (which may be repeated). Then, for each $k = 1, 2, \ldots, 2n$, span $\{v_1, v_2, \ldots, v_k\}$ is a dominant S-invariant subspace.

LEMMA 6.10. *If S has no eigenvalues of odd multiplicity on the unit circle, there is a unique dominant n-dimensional S-invariant subspace $\mathcal{U}_D^-$ and a unique codominant n-dimensional subspace $\mathcal{U}_D^+$. Both are Lagrangian. In particular, $\mathcal{U}_D^-$ is spanned by $\{v_1, v_2, \ldots, v_n\}$ in* (6.23).

Proof. With the generalized eigenvectors of S and its corresponding eigenvalues ordered as in (6.23), (6.24), $\mathcal{U}_D^- := \text{span}\{v_1, v_2, \ldots, v_n\}$ is the *unique* dominant S-invariant n-subspace if either

(i) $|\lambda_n| > |\lambda_{n+1}|$

or

(ii) $|\lambda_n| = |\lambda_{n+1}|$ but $e(v_n) > e(v_{n+1})$;

see [30, p. 404]. Now, recall that S is symplectic so that if λ is an eigenvalue then so is $1/\lambda$. Therefore, if S has no eigenvalues on the unit circle, then case (i) holds, so there is a unique dominant S-invariant n-subspace. If there are eigenvalues on the unit circle, there must be an even number, say $2q$, where $q \leq n$, so that $\{v_1, v_2, \ldots, v_n\}$ contains $n - q$ generalized eigenvectors whose eigenvalues have moduli greater than 1 and q whose eigenvalues lie on the unit circle. If we can show that $e(v_n) > e(v_{n+1})$, case (ii) holds and there is a unique dominant S-invariant n-space, namely $\{v_1, v_2, \ldots, v_n\}$. To this end, let $\mu_1, \mu_2, \ldots, \mu_k$ be the eigenvalues of S on the unit circle (now *not* repeated), and let $m_1, m_2, \ldots, m_k$ be their multiplicities. Then, $\sum_{i=1}^{k} m_i = 2q$. For each $i = 1, \ldots, k$ let $v_i^{(j)}$, $j = 1, 2, \ldots, m_i$, be the (generalized) eigenvectors corresponding to μ_i. The exponent of $v_i^{(j)}$ is

$$e(v_i^{(j)}) = m_i - 2j + 1.$$

Since, by assumption, there are no eigenvalues of odd multiplicity on the unit circle, i.e., m_i is even, $e(v_i^{(j)}) \neq 0$. Therefore, $e(v_i^{(j)})$ is positive for $j = 1, 2, \ldots, m_i/2$ and negative for $j = m_i/2 + 1, \ldots, m_i$, and hence $\mathcal{U}_D^-$ is unique. In the same way, it is seen that $\mathcal{U}_D^+ := \text{span}\{v_{n-q+1}, \ldots, v_n, v_{n+q+1}, \ldots, v_{2n}\}$ is the unique codominant S-invariant n-subspace. The proof that $\mathcal{U}_D^-$ and $\mathcal{U}_D^+$ are Lagrangian can be found in the appendix of [7, Lem. 3.1x]. □

Returning to the fast filtering algorithm (4.4), the following lemma establishes the proper interpretation of the convergence of $S^t \mathcal{Z}_0$ to the dominant S-invariant subspace.

LEMMA 6.11. *Let* $\{\lambda_1, \lambda_2, \dots, \lambda_n\}$ *be the eigenvalues (counted with multiplicity) corresponding to the dominant* S*-invariant subspace* $\mathcal{U}_D^-$ *of Lemma* 6.10, *and let* $\mathcal{Z}_0$ *be the* n*-dimensional subspace spanned by the columns of* (6.17). *Then, if* $S^t\mathcal{Z}_0 \to \mathcal{U}_D^-$, *either the trajectory of* (4.4) *escapes to infinity in finite time or* $(\alpha(t), \gamma(t)) \to (\alpha_\infty, 0)$, *where the zeros of the corresponding polynomial*

$$\alpha_\infty(z) = z^n + \alpha_{\infty 1} z^{n-1} + \cdots + \alpha_{\infty n}$$

all lie in the closed unit disc. More precisely,

$$\alpha_\infty(z) = \left(z - \frac{1}{\lambda_1}\right)\left(z - \frac{1}{\lambda_2}\right)\cdots\left(z - \frac{1}{\lambda_n}\right). \tag{6.25}$$

Proof. To say that $S^t\mathcal{Z}_0 \to \mathcal{U}_D^-$ is equivalent to saying that

$$\begin{bmatrix} X_t \\ Y_t \end{bmatrix} \to \begin{bmatrix} X \\ Y \end{bmatrix} = (v_1, v_2, \dots, v_n)T \tag{6.26}$$

for some nonsingular $n \times n$ matrix T, where, as above,

$$\begin{bmatrix} X_t \\ Y_t \end{bmatrix} = S^t \begin{bmatrix} I \\ 0 \end{bmatrix}.$$

Since $\mathcal{U}_D^-$ is Lagrangian, X is nonsingular (Lemma 6.7). Therefore, if X_t is nonsingular for all $t \in \mathbb{Z}$, the solution $P_t = Y_t X_t^{-1}$ of the matrix Riccati equation (2.2) with initial condition $P_0 = 0$ tends to the limit $P = YX^{-1}$, which is thus a real symmetric solution of the algebraic Riccati equation (6.1). Then, by Lemma 6.1, $(\alpha(t), \gamma(t)) \to (\alpha_\infty, 0)$ where

$$\alpha_\infty = (1 - h'Ph)^{-1}(a + g - JPh). \tag{6.27}$$

If, on the other hand, X_t becomes singular in finite time τ, the Riccati trajectory $P_t = Y_t X_t^{-1}$ escapes to infinity at time τ. To analyze the convergent case, first note that T cancels out in forming $P_t = Y_t X_t^{-1}$ and $P = YX^{-1}$ and therefore we may without restriction assume that $T = I$. Hence

$$\begin{bmatrix} S_{11} & S_{12} \\ S_{21} & S_{22} \end{bmatrix} \begin{bmatrix} X \\ Y \end{bmatrix} = \begin{bmatrix} X \\ Y \end{bmatrix} \Lambda, \tag{6.28}$$

where Λ is the block diagonal matrix formed by the Jordan blocks corresponding to $\{\lambda_1, \lambda_2, \dots, \lambda_n\}$. From this it follows that

$$S_{11} + S_{12}P = X\Lambda X^{-1}. \tag{6.29}$$

Now, substituting S_{11} and S_{12} in (6.29) for their values as defined in (6.8), we have

$$(S_{11}' + PS_{12}')^{-1} = F[F + \sigma^{-1}(g - FPh)h']^{-1}F, \tag{6.30}$$

to which we apply the well-known "matrix inversion lemma"

$$(A + BD^{-1}C)^{-1} = A^{-1} - A^{-1}B(D + CA^{-1}B)^{-1}CA^{-1} \tag{6.31}$$

to obtain

$$(S_{11}' + PS_{12}')^{-1} = F - (1 - h'Ph)^{-1}(g - FPh)h' = J - \alpha_\infty h'. \tag{6.32}$$

Therefore, setting $\Gamma := J - \alpha_\infty h'$, (6.29) and (6.32) yield

$$(\Gamma')^{-1}X = X\Lambda, \tag{6.33}$$

i.e., $(\Gamma')^{-1}$ has eigenvalues $\{\lambda_1, \lambda_2, \dots, \lambda_n\}$. Then, $\alpha_\infty(z)$ being the characteristic polynomial of Γ must have the form (6.25), as claimed. Since $|\lambda_i| \geq 1$ for $i = 1, 2, \dots, n$, the zeros of $\alpha_\infty(z)$ are all in the closed unit disc. □

Finally, to establish a global convergence theorem for the fast filtering algorithm (4.4) based on Lemma 6.9, it therefore remains to interpret the condition $\mathcal{U}_D^+ \cap \mathcal{Z}_0 = 0$, where $\mathcal{Z}_0$ is the initial space corresponding to $Z_0 = \left[\begin{smallmatrix} I \\ 0 \end{smallmatrix}\right]$, in terms of the parameters (i.e., the initial conditions) of the algorithm.

LEMMA 6.12. *Let $\alpha_n \neq 0$ and let $\mathcal{U}$ be an n-dimensional Lagrangian S-invariant subspace, and set*

$$\mathcal{Z}_0 := \operatorname{Im} \begin{bmatrix} I \\ 0 \end{bmatrix}.$$

Then, if $a(z)$ and $b(z)$ are coprime, $\mathcal{U} \cap \mathcal{Z}_0 = 0$.

Proof. As above, set $\mathcal{W} := \mathcal{U} \cap \mathcal{Z}_0$ and let U be a full-rank matrix such that

$$\mathcal{W} = \operatorname{Im} \begin{bmatrix} U \\ 0 \end{bmatrix}.$$

Then, since $\mathcal{W}$ is S-invariant (Lemma 6.8), there is a square matrix T such that

$$S \begin{bmatrix} U \\ 0 \end{bmatrix} = \begin{bmatrix} U \\ 0 \end{bmatrix} T.$$

Therefore, in view of (6.14), $(A')^{-1}U = UT$ and $gg'(A')^{-1}U = 0$, from which we see that

$$U'A^{-n}[g, Ag, \dots, A^{n-1}g] = 0. \tag{6.34}$$

Consequently, $U = 0$, i.e., $\mathcal{W} = 0$, if and only if (A, g) is reachable. Since $A = F - gh'$, this is equivalent to (F, g) being reachable. However, since

$$\frac{1}{2}\frac{b(z)}{a(z)} = h'(zI - F)^{-1}g + \frac{1}{2}$$

and (h, F) is observable, (F, g) is reachable if and only if $a(z)$ and $b(z)$ are coprime. □

7. Global convergence of the fast filtering algorithm. We are now in a position to formulate the global convergence theorem. To this end, let $\mathcal{D}$ be the subset of all $(\alpha, \gamma) \in \mathbb{R}^{2n}$ such that $D(z, z^{-1})$ is sign definite on the unit circle, i.e., either nonnegative or nonpositive there. Finally, denote by Ω_e the subset of initial conditions $(\alpha, \gamma) \in \mathbb{R}^{2n}$, which generate trajectories that escape in finite time.

THEOREM 7.1. *For initial conditions $(\alpha, \gamma) \in \mathbb{R}^{2n} - \Omega_e$ there is convergence to an equilibrium under the dynamics of the fast filtering algorithm if and only if the corresponding pseudopolynomial $D(z, z^{-1})$ is sign definite. More precisely, the following statements hold:*

(i) *Ω_e and $\overline{\mathcal{D} \cap \Omega_e}$ have Lebesgue measure zero.*

(ii) $(\alpha,\gamma) \in \mathcal{D} - \mathcal{D} \cap \Omega_e$ *is a necessary and sufficient condition for convergence to an equilibrium.*

(iii) *If* $(\alpha,\gamma) \in \mathcal{D} - \mathcal{D} \cap \Omega_e$, *then* $(\alpha_t,\gamma_t) \to (\alpha_\infty, 0)$ *and the corresponding limit polynomial*

$$\alpha_\infty(z) = z^n + \alpha_{\infty 1} z^{n-1} + \cdots + \alpha_{\infty n}$$

satisfies

$$\alpha_\infty(z) = \tilde{\alpha}_\infty(z)\theta(z),$$

where $\tilde{\alpha}_\infty(z)$ *has all its zeros in the closed unit disc and where*

$$\theta(z) = (a, b),$$

i.e., $\theta(z)$ *is the greatest common divisor of* $a(z)$ *and* $b(z)$.

Moreover, $\tilde{\alpha}_\infty(z)$ *is determined up to a nonzero, scalar multiplicative factor* r_∞ *by the spectral factorization problem*

$$\tilde{a}(z)\tilde{b}(1/z) + \tilde{a}(1/z)\tilde{b}(z) = r_\infty \tilde{\alpha}_\infty(z)\tilde{\alpha}_\infty(1/z), \tag{7.1a}$$

where

$$a(z) = \tilde{a}(z)\theta(z), \qquad b(z) = \tilde{b}(z)\theta(z). \tag{7.1b}$$

Theorem 7.1 not only characterizes those initial conditions that generate a convergent trajectory, but also provides for an explicit determination of the equilibrium to which the corresponding trajectory will converge. Conversely, from this explicit recipe we can also determine which initial conditions will generate a trajectory that converges to a given equilibrium.

COROLLARY 7.2. *In the notation of Theorem* 7.1, *suppose* $\alpha_\infty(z) = \tilde{\alpha}_\infty(z)\theta(z)$ *where* $\tilde{\alpha}_\infty(z)$ *is a Schur polynomial and* $\theta(z)$ *has all of its zeros in* $|z| > 1$. *Then, the global stable "manifold"* $W^s(\alpha_\infty, 0)$ *is given by*

$$W^s(\alpha_\infty, 0) = \{(\alpha,\gamma) \notin \Omega_e\colon \text{(7.1) } \textit{holds with } (a,b) \textit{ given by } (4.1) \textit{ and } (\tilde{a},\tilde{b}) = 1\}.$$

Similarly, the global unstable "manifold" can be parameterized as all coprime pairs $(\bar{a},\bar{b})$ *satisfying*

$$a(z) = \bar{a}(z)\tilde{\alpha}_\infty(z), \qquad b(z) = \bar{b}(z)\tilde{\alpha}_\infty(z),$$

and

$$\bar{a}(z)\bar{b}(1/z) + \bar{a}(1/z)\bar{b}(z) = \bar{r}_\infty \theta(z)\theta(1/z).$$

Finally, a global center manifold $W^c(\alpha_\infty, 0)$ *is given by the equilibrium set* E.

Remark 2. The existence of stable and unstable manifolds as locally invariant immersed manifolds is of course a local result. In harmony with this, Lemma 5.8 gives a result characterizing $W^s(\alpha_\infty, 0)$ as a submanifold near $(\alpha_\infty, 0)$. In contrast, the description of $W^s(\alpha_\infty, 0)$ in the large as given in Corollary 7.2 does allow for singular points. These singular points are characterized in Theorem 5.10.

Proof of Theorem 7.1. We first assume that $\alpha_n \neq 0$ so that the pseudopolynomial $D(z, z^{-1})$ has degree n and the symplectic matrix S is well defined and nonsingular.

Finite escape occurs for precisely the initial conditions

$$Z_0 = S^{-t}\tilde{Z}, \qquad t = 0, 1, 2, \dots, \tag{7.2}$$

for which $\tilde{X}$ is singular. In (α, γ)-space, $\tilde{X}$ being singular corresponds to $(\tilde{\alpha}, \tilde{\gamma})$ belonging to the two hyperplanes $\gamma_{n-1} = \pm 1$. Forming the union of the countably many iterates via (7.2) of these hyperplanes forms a set Ω_e that has measure zero. Here $\mathcal{D} \cap \Omega_e$ also has measure zero. We defer the proof that $\overline{\mathcal{D} \cap \Omega_e}$ is a set of measure zero.

Concerning the second part of the theorem, we have already established that it is necessary that $D(z, z^{-1})$ is sign definite for (4.4) to converge (Corollary 5.3). We prove the converse statement by proving assertion (iii). Suppose that $D(z, z^{-1})$ is sign definite, i.e., it has no zeros of odd multiplicity on the unit circle. Then Proposition 6.6 implies that S has no eigenvalues of odd multiplicity on the unit circle. However, this implies that there are unique dominant and codominant S-invariant n-dimensional subspaces $\mathcal{U}_D^-$ and $\mathcal{U}_D^+$, respectively, which are Lagrangian (Lemma 6.10), so that we can apply Lemma 6.9.

First, suppose that $a(z)$ and $b(z)$ are relatively prime. Then, if $\mathcal{Z}_0$ is the subspace spanned by the columns of $Z_0 = \begin{bmatrix} I \\ 0 \end{bmatrix}$, we have $\mathcal{U}_D^+ \cap \mathcal{Z}_0 = 0$ (Lemma 6.12) so that $S^t\mathcal{Z}_0 \to \mathcal{U}_D^-$ as $t \to \infty$ (Lemma 6.9). But this implies that $(\alpha(t), \gamma(t)) \to (\alpha_\infty, 0)$ (Lemma 6.11) where $\alpha_\infty(z)$ has all its zeros in the closed unit disc, unless there is finite escape.

Next, suppose that $a(z) = \tilde{a}(z)\theta(z)$ and $b(z) = \tilde{b}(z)\theta(z)$, where $\theta(z)$ is a nontrivial monic polynomial and $\tilde{a}(z)$ and $\tilde{b}(z)$ are relatively prime. Then the factor $\theta(z)$ can be canceled in $v(z) = \frac{1}{2}(a(z)/b(z))$, so we may consider the dimension-reduced problem with (a, b) exchanged for $(\tilde{a}, \tilde{b})$. Since $D(z, z^{-1}) = \tilde{D}(z, z^{-1})|\theta(z)|^2$ is sign definite on the unit circle, then so is $\tilde{D}(z, z^{-1})$, and consequently, unless there is finite escape,

$$(\tilde{\alpha}(t), \tilde{\gamma}(t)) \to (\tilde{\alpha}_\infty, 0) \tag{7.3}$$

as $t \to \infty$, where $\tilde{\alpha}_\infty(z)$ has all its zeros in the closed unit disc (Lemma 6.11). On the other hand, it was shown in [27], and further elaborated on in [5], that the fast algorithm (2.16), which is equivalent to (4.4), can be written in the Szegö-like polynomial form

$$\begin{aligned} Q_{t+1}(z) &= Q_t(z) - \gamma_t z Q_t^*(z), \\ Q_{t+1}^*(z) &= z Q_t^*(z) - \gamma_t Q_t(z) \end{aligned} \tag{7.4}$$

(see [5, §2]), which, through the transformation

$$\begin{aligned} a_t(z) &= r_t^{-1}[Q_t(z) - Q_t^*(z)], \\ b_t(z) &= r_t^{-1}[Q_t(z) + Q_t^*(z)], \end{aligned} \tag{7.5}$$

and (3.7), provides us with a polynomial version in (a, b)-coordinates of the dynamical system (4.4). From this we see that, if $a_0(z) := a(z)$ and $b_0(z) := b(z)$ have a nontrivial common factor $\theta(z)$, then

$$\begin{aligned} a_t(z) &= \tilde{a}_t(z)\theta(z), \\ b_t(z) &= \tilde{b}_t(z)\theta(z) \end{aligned} \tag{7.6}$$

for *all* $t = 0, 1, 2, 3, \dots$. Since $\tilde{a}_0(z) = \tilde{a}(z)$ and $\tilde{b}_0(z) = \tilde{b}(z)$, it follows readily from (7.4) and (7.5) that $\{(\tilde{a}_t, \tilde{b}_t)\}$ is a trajectory in (a, b)-coordinates of the reduced system

obtained by cancellation of the factor $\theta(z)$. In view of (7.3) and (A-1), $\tilde{a}_t(z) \to \tilde{\alpha}_\infty(z)$ and $\tilde{b}_t(z) \to \tilde{\alpha}_\infty(z)$ as $t \to \infty$, where $\alpha_\infty(z)$ has all its zeros in the closed unit disc. Therefore, $a_t(z) \to \tilde{\alpha}_\infty(z)\theta(z)$ and $b_t(z) \to \tilde{\alpha}_\infty(z)\theta(z)$ so that $(\alpha_t, \gamma_t) \to (\alpha_\infty, 0)$ where

$$\alpha_\infty(z) = \tilde{\alpha}_\infty(z)\theta(z), \tag{7.7}$$

the zeros of which are located in the closed unit disc if and only if $\theta(z)$, the common factor of $a(z)$ and $b(z)$, has all its zeros in the closed unit disc.

To complete the proof of (i), we now demonstrate that

$$\overline{\mathcal{D} \cap \Omega_e} \subset \mathcal{D} \cap \Omega_e \cup \mathcal{F}_1 \cup \mathcal{F}_2,$$

where $\mathcal{F}_1$ and $\mathcal{F}_2$ are sets of measure zero. Indeed, $\mathcal{F}_1$ is the algebraic set consisting of those pairs (α, γ) for which the corresponding polynomials (a, b) have a nontrivial common factor and $\mathcal{F}_2$ is the algebraic set consisting of those pairs for which the corresponding pseudopolynomial $D(z, z^{-1})$ has a double root. Suppose then that $(\alpha^{(n)}, \gamma^{(n)})$ is a sequence in $\mathcal{D} \cap \Omega_e$ with limit

$$\lim_{n\to\infty} (\alpha^{(n)}, \gamma^{(n)}) = (\alpha, \gamma).$$

Of course, $(\alpha, \gamma) \in \mathcal{D}$ so our claim will follow if we show that $(\alpha, \gamma) \in \mathcal{D} - \mathcal{D} \cap \Omega_e$ implies $(\alpha, \gamma) \in \mathcal{F}_1 \cup \mathcal{F}_2$. From (iii) of Theorem 7.1, we know that if $(\alpha_0, \gamma_0) = (\alpha, \gamma)$, then

$$\lim_{t\to\infty} (\alpha_t, \gamma_t) = (\alpha_\infty, 0),$$

where $\alpha_\infty(z) = \tilde{\alpha}_\infty(z)\theta(z)$, where $\tilde{\alpha}_\infty(z)$ has all of its roots in the closed unit disc and $\theta = (a, b)$. If $\deg \theta \geq 1$, then $(\alpha, \gamma) \in \mathcal{F}_1$, so we suppose $\theta(z) \equiv 1$. In this case, to say $\alpha_\infty(z)$ has roots on the unit circle is to say $(\alpha, \gamma) \in \mathcal{F}_2$, so we may assume $\alpha_\infty(z)$ is a Schur polynomial, an assumption that we show is contrary to fact. If $\alpha_\infty(z)$ is a Schur polynomial, then $(\alpha_\infty, 0)$ belongs to the region $\mathcal{P}_n$ of all $(\alpha, \gamma) \in \mathbb{R}^{2n}$ satisfying the positive real conditions (2.13)–(2.15), and so $(\alpha_T, \gamma_T) \in \mathcal{P}_n$ for some finite $T > 0$. Since $\mathcal{P}_n$ is open and since the map on $\mathbb{R}^{2n}$

$$\Phi_T : (\alpha_0, \gamma_0) \mapsto (\alpha_T, \gamma_T),$$

defined by iterating the dynamical system (4.4) T times, is rational with no pole at (α, γ), there exists an $\varepsilon > 0$ such that

$$\Phi_T(B_\varepsilon(\alpha, \gamma)) \subset \mathcal{P}_n.$$

However, then no $(\alpha', \gamma') \in B_\varepsilon(\alpha, \gamma)$ can escape in finite time, contrary to the definition of (α, γ).

Finally, it is easy to modify the above argument to include the case $\alpha_n = 0$. Indeed, if for some $k < n$, $\alpha_n = \cdots = \alpha_{k+1} = 0$ and $\alpha_k \neq 0$, then $D(z, z^{-1})$ has degree k and the dynamical system (4.4) is reduced to a system of order $2k$ in $n - k$ steps. Therefore, $(\alpha(t), \gamma(t)) \to (\alpha_\infty, 0)$ if and only if $(\hat{\alpha}(t), \hat{\gamma}(t)) \to (\hat{\alpha}_\infty, 0)$, where the "hatted" quantities correspond to the reduced system. Then $\alpha_\infty(z) = z^{n-k}\hat{\alpha}_\infty(z)$ so that all statements concerning the reduced system also hold for the unreduced one. □

We remark that the initial conditions (α, γ) for which the pseudopolynomial $D(z, z^{-1})$ fails to be sign definite, and there consequently is no convergence, form an unbounded open set in $\mathbb{R}^{2n}$. As we illustrate in the next section, such points can be periodic or dense on some unbounded submanifold, depending on certain number theoretic considerations and leading to a remarkable sensitivity of the fast filtering algorithm to initial conditions in this region. We will return to this topic in a subsequent paper.

8. Examples and simulations. The purpose of this section is to illustrate our results for low-order problems, particularly the cases $n = 1$ and $n = 2$. Since these cases have been treated in [5] and [6], respectively, we quote only those results that best illustrate our main theorem.

In the first-order case the dynamical system (4.4) takes the form

$$\alpha_{t+1} = \frac{\alpha_t}{1 - \gamma_t^2}, \tag{8.1a}$$

$$\gamma_{t+1} = -\frac{\gamma_t \alpha_t}{1 - \gamma_t^2} \tag{8.1b}$$

corresponding to the rational function

$$v(z) = \frac{1}{2}\frac{b(z)}{a(z)}, \tag{8.2}$$

where

$$\begin{aligned} a(z) &= z + \alpha - \gamma, \\ b(z) &= z + \alpha + \gamma. \end{aligned} \tag{8.3}$$

This case was studied in detail in [5], where it was shown that points (α, γ) in the interior of the diamond I, with corners $(\pm 1, 0)$, $(0, \pm 1)$, depicted in Fig. 1 correspond to positive real $v(z)$, whereas the points (α, γ) in the shaded regions are precisely those for which $D(z, z^{-1})$ is sign definite on the unit circle, $v(1/z)$ being positive real in regions III and negative real in regions II. The dotted lines are the lines $\gamma = \pm 1$ of finite escape.

The invariant manifold X_D, defined by (5.9), becomes

$$1 + \alpha_t^2 - \gamma_t^2 = \frac{2}{\kappa}\alpha_t, \tag{8.4}$$

valid for all $\kappa \neq 0$ (including $\kappa = \infty$, corresponding to $d_0(\alpha, \gamma) = 0$); for $\kappa = 0$, the dynamical system (8.1) evolves along the axis $\alpha = 0$, converging in one step to the origin.

Fig. 2 depicts the invariant manifolds defined by (8.4) for certain values of κ. For $\kappa^2 < 1$ these manifolds are hyperbolas completely contained in the shaded, sign-definite region, and for $\kappa^2 = 1$ they degenerate into a pair of intersecting lines, in the boundary of the shaded region, intersecting in $(1, 0)$ or $(-1, 0)$. In fact, each point in the shaded region lies on such an invariant manifold and converges to the intersection of this hyperbola with the segment $\{(\alpha, 0) \mid -1 \leq \alpha \leq 1\}$.

Since $a(z)$ and $b(z)$, displayed in (8.3), can have a common pair of reciprocal roots only in $(1, 0)$ and $(-1, 0)$, Theorem 5.27 states that these are the only singular points, σ in Lemma 5.11 being zero everywhere else, a fact that is illustrated by the above analysis.

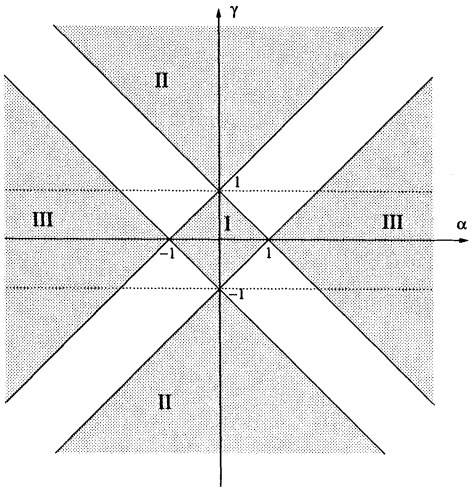

FIG. 1.

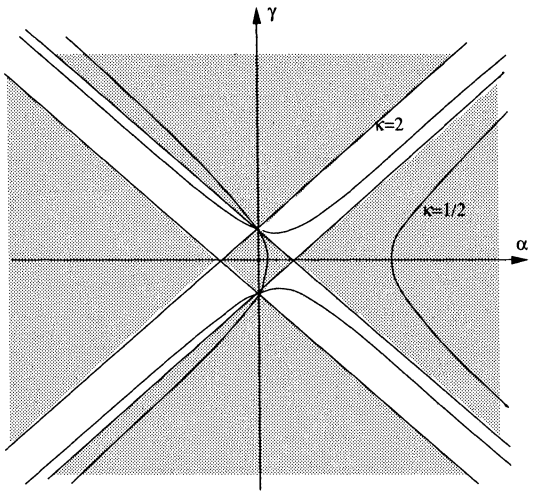

FIG. 2.

It is easy to check (see [5] for details) that hyperbolas for which $\kappa^2 < 1$ correspond to those symplectic matrices S that have two real eigenvalues, one inside the unit circle and the other outside, whereas the case $\kappa^2 = 1$ yields a symplectic matrix S that has an eigenvalue of multiplicity 2 either at 1 or at -1. Convergence in these cases is therefore in accordance with Theorem 7.1, since S has no eigenvalue of odd multiplicity on the unit circle. On the other hand, if $\kappa^2 > 1$, there is a complex pair of such eigenvalues, and the hyperbolas lie in the white region of Fig. 2, where the corresponding pseudopolynomials $D(z, z^{-1})$ are sign indefinite on the unit circle, implying nonconvergence by Theorem 7.1.

Those hyperbolas for which $\kappa^2 < 1$ intersect the α-axis in two points, one of which is a point α_∞ so that the polynomial $z + \alpha_\infty$ is Schur; i.e., so that $|\alpha_\infty| < 1$.

In [5] it has been shown that not only is the hyperbola (8.4) locally a stable manifold for $\kappa^2 < 1$, but rather it consists of a global stable manifold, excluding the unstable equilibrium and the measure zero set of points which escape in finite time. Also, $E = \{(\alpha_\infty, 0) : \alpha_\infty \in \mathbb{R}\}$ is a global center manifold through $(\alpha_\infty, 0)$. We note that the unstable equilibrium $(\alpha_\infty, 0)$, with $|\alpha_\infty| > 1$, has, by (5.2), a one-dimensional center manifold. In fact, these manifolds exist globally with the hyperbola being a global unstable manifold for the unstable equilibrium, on which trajectories either escape or evolve to the equilibrium, with the exception of the unstable equilibrium itself. E is again a global center manifold. The global convergence is completely understood in this case and described in [5].

If $\kappa^2 > 1$, then the hyperbolas do not intersect the α-axis, see Fig. 2, and indeed the dynamics are far more complex. In fact, in [5] it is shown that there are two alternatives that, taken together, prove that (8.1) is sensitive to initial conditions, in the technical sense (as in [11]). Explicitly, one knows that either (A) or (B) holds:

(A) $\arctan\sqrt{\kappa^2 - 1} \in \mathbb{Q}\pi$ and hence

$$\frac{1}{2}\arctan\sqrt{\kappa^2 - 1} = \frac{q}{p}\pi \quad \text{if } \kappa < -1$$

or

$$\frac{1}{2}\{\pi - \arctan\sqrt{\kappa^2 - 1}\} = \frac{q}{p}\pi \quad \text{if } \kappa > 1,$$

where p and q are coprime natural numbers. If p is odd, $2(p-1)$ points on the hyperbola escape in finite time and if p is even there are $(p-2)$ such points. All other points are periodic with period p and every period p, $p \geq 3$, is possible.

(B) $\arctan\sqrt{\kappa^2 - 1} \notin \mathbb{Q}\pi$ and a countably infinite set of points on the hyperbola escape in finite time. All other points generate a dense orbit.

Finally, consider the points $(\pm 1, 0)$, correspondingly to $\kappa^2 = 1$. According to Theorem 5.2, the center manifold is two-dimensional and consequently is global. In fact, hyperbolas of all types, containing periodic orbits and dense orbits or consisting of stable and unstable manifolds, intersect every neighborhood of either equilibrium $(\pm 1, 0)$ yielding a rather complicated mix of dynamics. However, points lying on the degenerate hyperbola for $\kappa = \pm 1$ do converge to the equilibrium $(\pm 1, 0)$, except for a countable set of points which escape in finite time.

In n dimensions, the n-folds (5.9) are defined for every value of $\kappa_1, \ldots, \kappa_n$. Moreover, setting $\kappa_n = \kappa_{n-1} = \cdots = \kappa_2 = 0$, we obtain an invariant subset of $\mathbb{R}^{2n}$ on which the n-dimensional algorithm restricts to the first-order algorithm on the hyperbola defined by $\kappa = \kappa_1$. Therefore, in addition to the equilibrium structure described in §5 and the convergence analysis in §6 yielding a parameterization of the global stable manifolds of these equilibria, we also know (see [5]) the following result.

PROPOSITION 8.1. *For any $p \geq 3$, there exist infinitely many periodic points of period p for the fast filtering algorithm. Arbitrarily close to any one of these initial conditions is an initial condition that generates an unbounded orbit. In particular, in the sign indefinite region (in which trajectories cannot converge to equilibria), the fast filtering algorithms can exhibit sensitivity to initial conditions.*

We refer the reader to [5] for further details of the various kinds of asymptotic behavior in the case where $n = 1$.

In the case where $n = 2$, the fast filtering algorithm (4.4) takes the form

$$\alpha_1(t+1) = \frac{1}{1-\gamma_{t+1}^2}\alpha_1(t) + \frac{\gamma_{t+1}}{1-\gamma_{t+1}^2}\frac{\gamma_t}{1-\gamma_t^2}\alpha_2(t), \tag{8.5a}$$

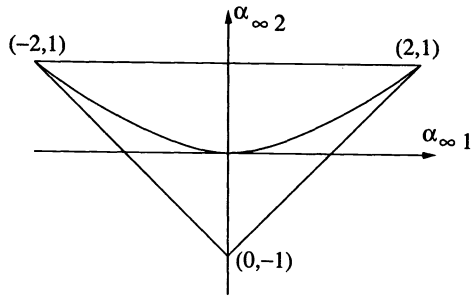

FIG. 3.

$$\alpha_2(t+1) = \frac{\alpha_2(t)}{1-\gamma_t^2}, \tag{8.5b}$$

$$\gamma_{t+1} = -\alpha_1(t)\gamma_t - \alpha_2(t)\gamma_{t-1}, \tag{8.5c}$$

and the invariant manifold X_D becomes

$$\begin{aligned} 2(r_1\alpha_1 + \alpha_1\alpha_2 + \gamma_0\gamma_1\alpha_2) &= \kappa_1(\alpha_2^2 + r_1\alpha_1^2 + r_2), \\ 2\alpha_2 &= \kappa_2(\alpha_2^2 + r_1\alpha_1^2 + r_2), \end{aligned} \tag{8.6}$$

where $r_1 = 1 - \gamma_0^2$ and $r_2 = (1-\gamma_0^2)(1-\gamma_1^2)$ are defined as in (3.7), as long as d_0, given by (4.11), is nonzero. The other cases are covered by dividing one or both of the equations in (8.6) by κ_1 and κ_2, respectively, and allowing these constants to take infinite values.

In the second-order case the invariant manifold X_D may have a singular point not only if $a(z)$ and $b(z)$ have a root $z = 1$ or $z = -1$ in common, which may occur outside of the equilibrium set, but also if

$$a(z) = b(z) = (z+\lambda)(z+1/\lambda),$$

which can only occur in an equilibrium point, because $\gamma_0 = \gamma_1 = 0$ in this case. By Lemma 5.1, equilibria are precisely the points of the form $(\alpha_\infty, 0)$. Inserting $(\alpha_\infty, 0)$ in (8.6) yields the constants κ_1, κ_2 defining the invariant manifold containing this point. In fact,

$$\begin{aligned} \kappa_1 &= \frac{2\alpha_{\infty 1}(1+\alpha_{\infty 2})}{\alpha_{\infty 2}^2 + \alpha_{\infty 1}^2 + 1}, \\ \kappa_2 &= \frac{2\alpha_{\infty 2}}{\alpha_{\infty 2}^2 + \alpha_{\infty 1}^2 + 1}. \end{aligned} \tag{8.7}$$

Conversely, it follows from Theorem 5.9 and Theorem 7.1 that to each point (κ_1, κ_2) such that $D(z, z^{-1})$ is sign definite, there corresponds a unique α_∞, such that $\alpha_\infty(z)$ is stable, i.e., all its zeros lie inside the unit circle. These α_∞ are precisely the points in the closed triangular stability region depicted in Fig. 3

Since the roots of

$$D(z, z^{-1}) = r_\infty \alpha_\infty(z)\alpha_\infty(1/z) \tag{8.8}$$

are the eigenvalues of the symplectic matrix S (Proposition 6.6), each point in the closed triangle depicted in Fig. 3 corresponds to a particular eigenvalue configuration

for which there is convergence. Excluding the segment $\alpha_{\infty 2} = 0$ that corresponds to the case where $n = 1$, the points in the interior of the triangle correspond to the situations when there are no eigenvalues on the unit circle. Below the parabola $\alpha_{\infty 2} = \alpha_{\infty 1}^2/4$, there are four real eigenvalues, while above there are two complex pairs. On the boundary of the triangle there are eigenvalues on the unit circle, but they are always of even multiplicity, as a simple application of (8.8) shows. The rest of the plane, outside of the triangle, corresponds to unstable solutions of the polynomial factorization problem (8.8) and hence to unstable equilibria $(\alpha_\infty, 0)$. To each point below the parabola in the interior of the triangle there corresponds one strictly unstable and two saddle equilibria outside the triangle. For an interior point above the parabola there is only one equilibrium outside the triangle and it is strictly unstable.

For all points in the interior of the triangle the invariant manifold X_D defined by (8.6) is a smooth surface. As shown in §6, not only is the invariant manifold through such a point locally a stable manifold, but it actually constitutes a global stable manifold, excluding the unstable equilibria, their stable manifolds, and the measure zero set of points that escape in finite time. Using the same argument as in the first-order case, $E = \{(\alpha_\infty, 0) : \alpha_\infty \in \mathbb{R}^2\}$ is a global center manifold through $(\alpha_\infty, 0)$ of dimension 2, for any α_∞ that does not lie on the lines through $(-2, 1)$, $(2, 1)$, and $(0, -1)$, i.e., on the boundary of the triangle.

The points on the boundary of the triangle are all singular. In fact, the invariant manifolds corresponding to the points on the line segment between $(-2, 1, 0, 0)$ and $(2, 1, 0, 0)$, as well as that of the point $(0, -1, 0, 0)$, have dimensions less than two. The center manifolds containing these points all have dimension four, while the center manifolds containing the points on the open boundary segments extending from the corner $(0, -1, 0, 0)$ have dimension three.

An initial condition $(\alpha, \gamma) \in \mathbb{R}^4$ for the fast filtering algorithm that does not belong to the plane $(\alpha_\infty, 0)$ of equilibria may or may not converge to an equilibrium. Figure 4 shows the plane $\alpha \mapsto (\alpha, \gamma)$ where γ is fixed so that, in this example, $\gamma_0 = 1/2$ and $\gamma_1 = \frac{1}{3}$. Each point in the bounded shaded region in Fig. 4 corresponds to a positive real function $v(z)$, and hence to a bona fide stochastic system, and converges, by classical results, to a stable equilibrium $(\alpha_\infty, 0)$ in the triangle of Fig. 3. This is precisely the solution set of the rational covariance extension problem for which the covariance data $\{c_1, c_2\}$ is prescribed so that the Schur parameters are $\gamma_0 = \frac{1}{2}$ and $\gamma_1 = \frac{1}{3}$. Initial conditions in the four unbounded shaded regions also correspond to orbits that converge to stable or unstable equilibria $(\alpha_\infty, 0)$ except for a zero measure set which escape in finite time.

As an example we may now choose the point $(0, 2, 1/2, 1/3)$, which lies in the topmost shaded unbounded region. We see from the simulation depicted in Fig. 5 that, using this point as an initial condition, the fast filtering algorithm (8.5) converges after having violated the positive real condition $|\gamma_t| < 1$ twice, showing that the corresponding $v(z)$ is not positive real. However, after six steps the iterate is inside the bounded positive real region and will remain there.

What happens if the initial condition (α, γ) lies in the white region of Fig. 4? These points correspond to sign indefinite $D(z, z^{-1})$ and according to Proposition 8.1 we have at least three kinds of behavior.

(i) (α, γ) is a periodic point;
(ii) the orbit of (α, γ) is dense on some manifold;
(iii) there is finite-time escape.

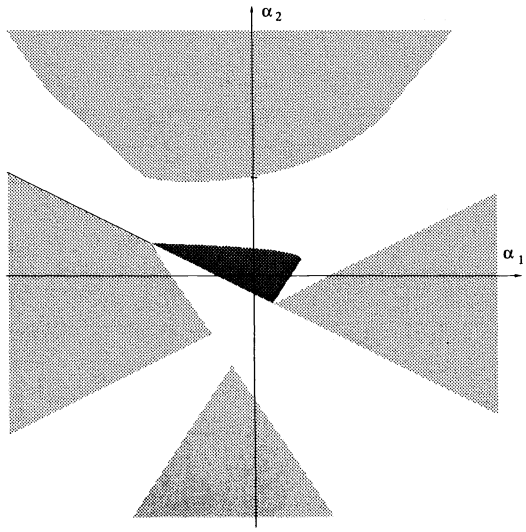

FIG. 4.

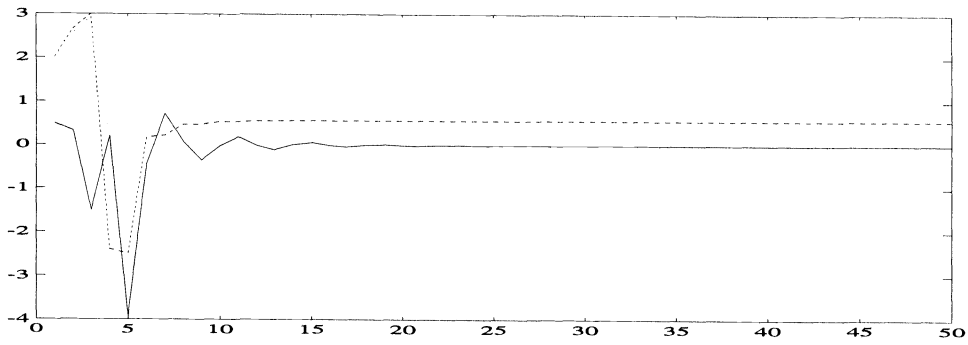

FIG. 5. *Plot of* α_1 (*dotted line*), α_2 (*dashed line*), γ (*solid line*).

These nonconvergent initial conditions and the invariant manifolds on which they lie correspond to the situations when S has eigenvalues of odd multiplicity on the unit circle. In the literature there has been a tendency to exclude the case with eigenvalues on the unit circle as being a rather complicated nongeneric case, but, as our analysis shows, this situation actually corresponds to an open unbounded set of initial conditions. Cases (i) and (iii), however, occur only for a measure zero subset of the white region. We refer the reader to [6] for simulations illustrating these types of dynamical behavior. Here we show only one simulation that illustrates that in the white region the fast filtering algorithm is extremely sensitive to the initial conditions. Consider the periodic point of period 144 corresponding to $\beta_1 = \sec \pi/8$

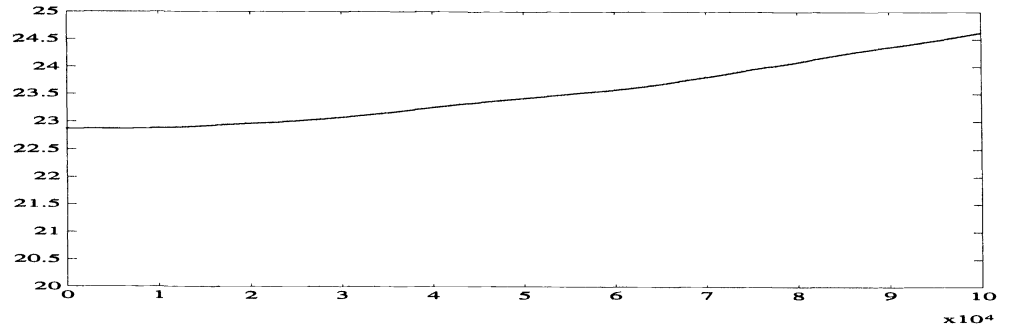

FIG. 6.

and $\beta_2 = \sec \pi/9$, where

$$\frac{2}{\beta_1} = \frac{-\kappa_1 + \sqrt{\kappa_1^2 - 8\kappa_2 + 8\kappa_2^2}}{2\kappa_2},$$
$$\frac{2}{\beta_2} = \frac{-\kappa_1 - \sqrt{\kappa_1^2 - 8\kappa_2 + 8\kappa_2^2}}{2\kappa_2}.$$

If we round off α_0 to the 15th digit, we obtain an orbit that is dense on the invariant manifold and part of whose γ-trajectory is depicted in Fig. 6. This dynamical behavior is apparently quite different to that of the periodic point which the new initial condition approximates.

If S has all its eigenvalues on the unit circle but at least two of them are real, then the dynamics degenerates to the first-order case. The interesting fact here is that $a(z)$ and $b(z)$ having a common pair of reciprocal roots which are not 1 corresponds to an equilibrium lying on the line $(\alpha_{\infty,1}, 1, 0, 0)$, where $|\alpha_{\infty,1}| > 2$, i.e., the part of the line that is not in the boundary of the triangle of Fig. 3. Moreover, this equilibrium is a saddle point.

A complete description of the positive real, sign definite and sign indefinite regions is available in the case $n = 2$, as reported in [19], where many simulation results are also given. Earlier graphical simulations of the positive real region, in the case $n = 2$, are contained in Georgiou's thesis [15]. Curiously, all graphical representations of the positive real region $\mathcal{A}_+(n)$ for γ fixed of which we are aware seem to be convex. Convexity of $\mathcal{A}_+(n)$ would in fact imply a Kharitonov-like property, namely, star-shapedness about the maximum-entropy filter, conjectured and established for the case $n = 1$ by Kimura. In this direction it is known that for reasons concerning the geometry of the spaces of real and of complex Schur polynomials, the convexity $\mathcal{A}_+(2)$ seems to be decidedly nontrivial. In general, although examples show [4] that $\mathcal{A}_+(n)$ can fail to be star-shaped for $n \geq 3$, $\mathcal{A}_+(n)$ is in fact always a Euclidian space [4].

Appendix. In this section, we provide the proofs deferred from §§4 and 6.

Proof of Theorem 4.3. Under the map $\mathcal{F}^{-1}$ of Corollary 3.4 the initial conditions (a, g) are transformed to (α, γ), where $\gamma_0, \gamma_1, \ldots, \gamma_{n-1}$ are the first n Schur parameters of $v(z)$ and $\alpha_1, \alpha_2, \ldots, \alpha_n$ are the parameters in the Kimura–Georgiou parameterization (3.9). Under the same map, $(a(t), g(t))$ goes into $(\alpha(t), \gamma(t))$ which, according to Corollary 3.4, satisfies

$$\text{(A-1a)} \qquad a(t) = \varphi_n(\gamma(t)) + \Phi_n(\gamma(t))\alpha(t),$$

(A-1b) $$b(t) = \psi_n(\gamma(t)) + \Psi_n(\gamma(t))\alpha(t),$$

(A-1c) $$g(t) = \tfrac{1}{2}[b(t) - a(t)].$$

Now, by Lemma 4.2, $\{\gamma_t, \gamma_{t+1}, \gamma_{t+2}, \ldots\}$ is the Schur parameter sequence of $v_t(z)$, and consequently (4.7) must hold. Therefore, if we can prove (4.8), then we have shown that (4.4b) holds. To this end note that, in view of (4.7), the last of equations (A-1a) reads

$$a_n(t+1) = -\gamma_{t+n-1} - \gamma_{t+n-2}\alpha_1(t+1) - \cdots - \gamma_{t+1}\alpha_{n-1}(t+1) + \alpha_n(t+1).$$

Hence if we can prove that

(A-2) $$a_n(t+1) = (1+\gamma_t)\alpha_n(t+1),$$

then (4.8) follows. However, from (A-1) we see that

(A-3) $$\alpha_n(t) = a_n(t) + g_n(t)$$

for all $t = 0, 1, 2, \ldots$, and then (A-2) follows from the bottom equations in each of (2.16a) and (2.16b). This establishes (4.4b).

To prove (4.4a) first note that since the dynamical system is time-invariant it is enough to show that $\alpha(1) = A(\gamma)\alpha$, i.e., that

(A-4) $$\alpha = A(\gamma)^{-1}\alpha(1),$$

where

(A-5) $$A(\gamma)^{-1} = \begin{bmatrix} 1-\gamma_{n-1}^2 & -\gamma_{n-1}\gamma_{n-2} & -\gamma_{n-1}\gamma_{n-3} & \cdots & -\gamma_{n-1}\gamma_0 \\ 0 & 1-\gamma_{n-2}^2 & -\gamma_{n-2}\gamma_{n-3} & \cdots & -\gamma_{n-2}\gamma_0 \\ 0 & 0 & 1-\gamma_{n-3}^2 & \cdots & -\gamma_{n-3}\gamma_0 \\ \vdots & \vdots & \vdots & & \vdots \\ 0 & 0 & 0 & \cdots & 1-\gamma_0^2 \end{bmatrix}.$$

In view of (4.8), proving (A-4) amounts to proving that

(A-6) $$\alpha_j = \gamma_{n-j}\gamma_n + \gamma_{n-j}\gamma_{n-1}\alpha_1(1) + \cdots + \gamma_{n-j}\gamma_{n-(j-1)}\alpha_{j-1}(1) + \alpha_j(1),$$

for $j = 1, 2, \ldots, n$. Now, after the change of coordinates (A-1), the kth equation of (2.16a) reads

$$\begin{aligned} &\varphi_{nk}^{(1)} + \varphi_{n-1,k-1}^{(1)}\alpha_1(1) + \cdots + \varphi_{n-k+1,1}^{(1)}\alpha_{k-1}(1) + \alpha_k(1) \\ &\quad = \frac{1}{1-\gamma_0}\{\pi_{nk} - \rho_{n,k+1} + (\pi_{n-1,k-1} - \rho_{n-1,k})\alpha_1 + \cdots \\ &\qquad + (\pi_{n-(k-1),1} - \rho_{n-(k-1),2})\alpha_{k-1}\} + \alpha_k, \end{aligned} \tag{A-7}$$

where $\varphi_{tk}^{(1)} := \varphi_{tk}(\gamma(1))$, and ρ_{tk} and π_{tk} are the coefficients of polynomials (3.16) and (3.18), respectively. Note that $\{\varphi_{tk}^{(1)}\}$ are the coefficients of the Szegö polynomials $\{\varphi_t^{(1)}(z)\}$ corresponding to the shifted Schur parameter sequence $\{\gamma_1, \gamma_2, \gamma_3, \ldots\}$ that are related to $\{\varphi_t(z)\}$ through the algebraic identity [16] (see also [12], [9])

$$\begin{bmatrix} \psi_{t+1}(z) \\ \varphi_{t+1}(z) \end{bmatrix} = \frac{1}{2}\begin{bmatrix} (1+\gamma_0)(z+1) & (1-\gamma_0)(z-1) \\ (1+\gamma_0)(z-1) & (1-\gamma_0)(z+1) \end{bmatrix}\begin{bmatrix} \psi_t^{(1)}(z) \\ \varphi_t^{(1)}(z) \end{bmatrix},$$

which can be inverted to yield

$$\begin{bmatrix} \psi_t^{(1)}(z) \\ \varphi_t^{(1)}(z) \end{bmatrix} = \frac{1}{2}\frac{1}{z(1-\gamma_0^2)} \begin{bmatrix} (1-\gamma_0)(1+z) & (1-\gamma_0)(1-z) \\ (1+\gamma_0)(1-z) & (1+\gamma_0)(1+z) \end{bmatrix} \begin{bmatrix} \psi_{t+1}(z) \\ \varphi_{t+1}(z) \end{bmatrix}.$$

Then

$$\varphi_t^{(1)}(z) = \frac{1}{2(1-\gamma_0)}[\pi_{t+1}(z) - z\rho_{t+1}(z)]. \tag{A-8}$$

Using recursion (3.5) it is easy to see that

$$\varphi_{t+1}(z) = z\varphi_t(z) + \gamma_t\gamma_{t-1}z\varphi_{t-1}(z) + \gamma_t\gamma_{t-2}z\varphi_{t-2}(z) + \cdots + \gamma_t\gamma_0 z - \gamma_t. \tag{A-9}$$

Similarly, changing the signs of the Schur parameters in (A-9), we also have

$$\psi_{t+1}(z) = z\psi_t(z) + \gamma_t\gamma_{t-1}z\psi_{t-1}(z) + \gamma_t\gamma_{t-2}z\psi_{t-2}(z) + \cdots + \gamma_t\gamma_0 z + \gamma_t. \tag{A-10}$$

Combining (A-9) with (A-10) yields the recursions

$$\pi_{t+1}(z) = z\{\pi_t(z) + \gamma_t\gamma_{t-1}\pi_{t-1}(z) + \cdots + \gamma_t\gamma_1\pi_1(z) + \gamma_t\gamma_0\}, \tag{A-11}$$

and

$$\rho_{t+1}(z) = z\rho_t(z) + \gamma_t\gamma_{t-1}z\rho_{t-1}(z) + \cdots + \gamma_t\gamma_1 z\rho_1(z) + \gamma_t. \tag{A-12}$$

Now, inserting (A-11) and (A-12) into (A-8), we obtain

$$\begin{aligned}\varphi_t^{(1)}(z) = \tfrac{1}{1-\gamma_0}\{&\pi_t(z) - z\rho_t(z) + \gamma_t\gamma_{t-1}[\pi_{t-1}(z) - z\rho_{t-1}(z)] \\ &+ \gamma_t\gamma_{t-2}[\pi_{t-2}(z) - z\rho_{t-2}(z)] + \cdots + \gamma_t\gamma_1[\pi_1(z) - z\rho_1(z)]\} - \gamma_t\end{aligned}$$

which, after identifying coefficients and observing that $\rho_{j1} = \gamma_0$ for $j = 1, 2, 3, \ldots,$ yields

$$\begin{aligned}\varphi_{tk}^{(1)} = \frac{1}{1-\gamma_0}&[\pi_{tk} - \rho_{t,k+1} + \gamma_t\gamma_{t-1}(\pi_{t-1,k-1} - \rho_{t-1,k}) + \cdots \\ &+\gamma_t\gamma_{t-k+1}(\pi_{t-k+1,1} - \rho_{t-k+1,2})] + \gamma_t\gamma_{t-k}, \qquad k = 1, \ldots, n.\end{aligned} \tag{A-13}$$

We now prove (A-6) by induction. For $j = 1$, (A-7) reads

$$\varphi_{n1}^{(1)} + \alpha_1(1) = \frac{1}{1-\gamma_0}[\pi_{n1} - \rho_{n2}] + \alpha_1. \tag{A-14}$$

On the other hand, (A-13) yields

$$\varphi_{n1}^{(1)} = \frac{1}{1-\gamma_0}[\pi_{n1} - \rho_{n2}] + \gamma_n\gamma_{n-1}$$

and therefore

$$\alpha_1 = \alpha_1(1) + \gamma_n\gamma_{n-1},$$

which shows that (A-6) is true for $j = 1$. Next, suppose that (A-6) holds for $j = 1, 2, \ldots, k-1$. We need to prove that (A-6) holds for $j = k$. To this end, use (A-6)

for $j = 1, 2, \dots, k-1$ to eliminate $\alpha_1, \alpha_2, \dots, \alpha_{k-1}$ from (A-7) and use (A-13) to eliminate $\varphi_{nk}^{(1)}, \varphi_{n-1,k-1}^{(1)}, \dots, \varphi_{n-k+1,1}^{(1)}$. This yields, after some simple calculations, (A-6) for $j = k$, as required.

Finally, formula (4.9) is obtained from (2.17) by merely inserting $a(t)$ and $g(t)$ as exhibited in (A-1). □

Proof of Lemma 4.4. It follows from (3.5) that $\{\pi_t\}$ as defined by (3.18) satisfies the recursion

$$\begin{aligned} \pi_{t+1}(z) &= z\pi_t(z) + \gamma_t \rho_t^*(z), \qquad \pi_0(z) = 1, \\ \rho_{t+1}^*(z) &= \rho_t^*(z) + \gamma_t z \pi_t(z), \qquad \rho_0^*(z) = 0, \end{aligned}$$

where $\rho_t^*(z) := z^n \rho_t(1/z)$, from which (4.12) is easily derived. Next, let $D(z, z^{-1})$ be defined by (2.13), and let $d(z)$ be the corresponding polynomial in (4.10). In view of (3.12),

$$D(z, z^{-1}) = \sum_{i=0}^{n} \sum_{j=0}^{n} \alpha_i \alpha_j \sigma_{ij}(z, z^{-1}), \tag{A-15}$$

where $\alpha_0 = 1$ and

$$\sigma_{ij}(z, z^{-1}) := \tfrac{1}{2}[\varphi_i(z)\psi_j(1/z) + \psi_i(z)\varphi_j(1/z)]. \tag{A-16}$$

Now, it is well-known and easy to check that

$$\sigma_{ii}(z, z^{-1}) = r_i, \tag{A-17a}$$

and hence by using (3.5) we see that

$$\sigma_{i,i-1}(z, z^{-1}) = r_{i-1} z. \tag{A-17b}$$

Then, for $j = 1, \dots, i$, we obtain, by induction and repeated use of (3.5)

$$\sigma_{i,i-j}(z, z^{-1}) = r_{i-j}(z^j + p_1 z^{j-1} + \cdots + p_{j-1} z), \tag{A-17c}$$

where $p_1, p_2, \dots, p_{j-1}$ are functions of $\gamma_{i-j}, \gamma_{i-j+1}, \dots, \gamma_{i-1}$ only. Consequently, it follows from (A-15) that

$$d_0 = \alpha_n^2 + r_1 \alpha_{n-1}^2 + \cdots + r_n, \tag{A-18}$$

and that

$$\begin{aligned} d(z) - \tfrac{1}{2} d_0 &= \textstyle\sum_{i=0}^{n-1} \sum_{j=i+1}^{n} \alpha_i \alpha_j \sigma_{n-i,n-j}(z, z^{-1}) \\ &= \textstyle\sum_{i=0}^{n-2} \sum_{j=i+1}^{n-1} \alpha_i \alpha_j \sigma_{n-i,n-j}(z, z^{-1}) + \alpha_n \sum_{j=1}^{n} \alpha_{n-j} \pi_j(z) \end{aligned} \tag{A-19}$$

because $\sigma_{j0} = \pi_j$. Now, writing $d^{(n)}$ instead of $d(z)$ to stress the fact that n is the dimension of α or γ (but *not* necessarily the degree of $d(z)$), we observe that the first term of (A-19) equals $d^{(n-1)}(z) - \frac{1}{2} d_0$ except that σ_{kl} has been replaced by $\sigma_{k+1,l+1}$, a replacement that, according to (A-17), amounts to exchanging $\{\gamma_0, \gamma_1, \dots, \gamma_{n-1}, \gamma_0, \gamma_1, \dots, \gamma_{n-1}\}$ by $\{\gamma_1, \gamma_2, \dots, \gamma_n, \gamma_1, \gamma_2, \dots, \gamma_n\}$. Consequently, since $d^{(1)}(z) = \frac{1}{2} d_0 + \alpha_1 z$, the coefficients of (4.10) are generated by the recursion in $d^{(k)}$ defined in the lemma.

Finally, suppose $d_i = 0$ for $i = 1, 2, \ldots, n$. Then, since $1 - \gamma_i^2 \neq 0$ for $i = 0, 1, 2, \ldots, n-1$, it follows from the recursion in $d^{(k)}$ that $\alpha_1 = \alpha_2 = \cdots = \alpha_n = 0$. But then, by (4.11), $d_0 = r_n := \prod_{i=0}^{n-1}(1 - \gamma_i^2) \neq 0$. Hence at least one of the coefficients must be nonzero as claimed. □

Proof of Lemma 6.8. Let $\begin{bmatrix} X \\ Y \end{bmatrix}$ be a matrix basis of $\mathcal{U}$ as in (6.19). Then

$$\mathcal{W} = \left\{ \begin{bmatrix} X \\ Y \end{bmatrix} z \mid z \in \ker Y \right\}. \tag{A-20}$$

The S-invariance of $\mathcal{U}$ implies that there is an $n \times n$ matrix R such that

$$S \begin{bmatrix} X \\ Y \end{bmatrix} = \begin{bmatrix} X \\ Y \end{bmatrix} R, \tag{A-21}$$

and therefore (i) holds if and only if $Rz \in \ker Y$ for all $z \in \ker Y$, i.e., $\ker Y$ is R-invariant. Set $z \in \ker Y$. Then, using (6.14), the second block of (A-21) yields

$$gg'(A')^{-1}Xz = YRz. \tag{A-22}$$

Since $\mathcal{U}$ is Lagrangian, $X'Y = Y'X$ so that $z'X'Y = 0$, and therefore

$$[z'X'g][g'(A')^{-1}Xz] = 0. \tag{A-23}$$

Let $\mathcal{V}_1$ and $\mathcal{V}_2$ be the largest subspaces of $\ker Y$ for which $g'(A')^{-1}Xz = 0$ and $g'Xz = 0$, respectively. Then for (A-23) to hold for all $z \in \ker Y$, either $\mathcal{V}_1$ or $\mathcal{V}_2$ must be all of $\ker Y$. In fact, if there are two one-dimensional subspaces $l_1 \in \mathcal{V}_1$ and $l_2 \in \mathcal{V}_2$, then an arbitrary point in the plane spanned by l_1 and l_2 must belong to $\ker Y$ and hence to either $\mathcal{V}_1$ or $\mathcal{V}_2$ for (A-23) to hold; say $\mathcal{V}_1$. But then the whole plane must belong to $\mathcal{V}_1$, and hence also l_2.

Now, first suppose that $g'(A')^{-1}Xz = 0$ for all $z \in \ker Y$. Then, it follows from (A-22) that $\ker Y$ is R-invariant, and hence (i) holds.

Next, suppose that $g'Xz = 0$ for all $z \in \ker Y$. Since $\alpha_n \neq 0$, $\kappa_n \neq 0$, and hence S is nonsingular, (Proposition 6.6). Therefore, in view of (A-21), R is also nonsingular, so that

$$S^{-1} \begin{bmatrix} X \\ Y \end{bmatrix} = \begin{bmatrix} X \\ Y \end{bmatrix} R^{-1} \tag{A-24}$$

and consequently

$$S^{-1}\mathcal{W} = \left\{ \begin{bmatrix} X \\ Y \end{bmatrix} R^{-1}z \mid z \in \ker Y \right\},$$

which belongs to $\mathcal{W}$ if and only if $R^{-1}z \in \ker Y$ for all $z \in \ker Y$. Now, by (6.12), $S^{-1} = \hat{J}^{-1}S'\hat{J}$ and hence (A-24) is equivalent to

$$S' \begin{bmatrix} -Y \\ X \end{bmatrix} = \begin{bmatrix} -Y \\ X \end{bmatrix} R^{-1}. \tag{A-25}$$

Taking $z \in \ker Y$ and remembering that $g'Xz = 0$, the top block of (A-25) yields $YR^{-1}z = 0$, which is what is required for condition (ii) to hold. Hence, we have proved that at least one of conditions (i) and (ii) holds.

Finally, we prove that these conditions are actually equivalent. Suppose $\dim \mathcal{W} = k$. If $k = 0$, the statement is trivial, so we assume that $k > 0$. Then

$$\mathcal{W} = \operatorname{Im} \begin{bmatrix} U \\ 0 \end{bmatrix} \tag{A-26}$$

for some full-rank $n \times k$ matrix U such that

$$S \begin{bmatrix} U \\ 0 \end{bmatrix} = \begin{bmatrix} U \\ 0 \end{bmatrix} T. \tag{A-27}$$

Since S is nonsingular, so is T, so (A-27) is equivalent to

$$S^{-1} \begin{bmatrix} U \\ 0 \end{bmatrix} = \begin{bmatrix} U \\ 0 \end{bmatrix} T^{-1}, \tag{A-28}$$

which holds if and only if $S^{-1}\mathcal{W} \subset \mathcal{W}$. This concludes the first part of the lemma. The proof of the second part concerning $\tilde{\mathcal{W}}$ is analogous. □

CONTROLLED INVARIANCE FOR SINGULAR DISTRIBUTIONS*

VISWANATH RAMAKRISHNA†

Abstract. For an analytic affine control system and an analytic locally controlled invariant distribution Δ with singularities, which is already invariant under the vector fields corresponding to the controls (in other words is input-insensitive), the problem of finding a feedback that will render Δ controlled invariant is studied. This can be done if one can solve a degenerate system of partial differential equations (PDEs). The latter can be achieved in the presence of scaling-like symmetries.

Key words. controlled invariance, distributions, Poincaré vector field, degenerate differential equations, overdetermined systems

AMS subject classifications. 93C10, 93C15, 93C25

1. Introduction.

Suppose we are given (i) an affine nonlinear control system

$$\dot{x} = f(x) + \sum_{i=1}^{m} g_i(x)u_i,$$

$x \in \mathbb{R}^n$, and f and g_i, smooth vector fields on $\mathbb{R}^n$; (ii) a smooth distribution Δ on $\mathbb{R}^n$. The controlled invariance problem then seeks feedback functions α_i and $\beta = (\beta_{ij})$ such that the resulting closed-loop system leaves Δ invariant; i.e., $[f + \sum_{i=1}^{m} g_i\alpha_i, \Delta] \subseteq \Delta$ and $[(g\beta)_i, \Delta] \subseteq \Delta$. This problem arises in a variety of applications, such as disturbance decoupling and noninteracting control [15], [23]. This problem is known to have a solution (under some assumptions) in a neighborhood of a point where Δ is nonsingular [15], [23]. The purpose of this paper is to provide some sufficient conditions under which the problem has a solution when Δ becomes singular. To clarify exactly the kind of distributions considered in this paper, we begin by reviewing some terminology from differential geometry.

A distribution Δ on U (U an open set of $\mathbb{R}^n$) is an assignment to each point x of U, a subspace $\Delta(x)$ of T_xU. A C^∞ vector field Y on U is said to belong to Δ if $Y(p) \in \Delta(p)$ for all $p \in U$. Δ is said to be smooth if, at each $p \in U, \Delta(p)$ is the linear hull of the vectors $\{X(p) | X \in D\}$, where D is the set of C^∞ vector fields on U that belong to Δ.

Given an open subset V of U, we denote by $\Delta|_V$ the restriction of the assignment Δ to V. Δ is said to be locally finitely generated if, about each $p \in U$, there is an open subset $V \subseteq U$ that contains p with the property that the set D of C^∞ vector fields on V that belong to $\Delta|_V$ is finitely generated over the ring of smooth (or analytic) functions on the open set V; i.e., there exist vector fields $X_1, \ldots, X_d \in D$ so that, if $Y \in D$, then we have

$$Y = \sum_{i=1}^{d} f_i X_i,$$

where the f_i are C^∞ (or analytic) functions on V.

The expression "Δ is generated by d smooth vector fields an open set V" means the same thing as the above equation. Note that, if Δ is generated on V by $X_1, \ldots, X_d$,

† Department of Systems Science and Mathematics, Washington University, St. Louis, Missouri 63130. Current Address, Frick Laboratories, Princeton University, Princeton, New Jersey 08544.

then $X_1(p), \ldots, X_d(p)$ span the vector space $\Delta(p)$ whenever $p \in V$. We say Δ is involutive if, whenever X and Y belong to Δ, so does $[X, Y]$. All distributions in this article are involutive and smooth. In the analytic case, all the above definitions remain valid with "analytic" replacing "C^∞." There is one important difference, however—an analytic distribution is always locally finitely generated.

In a neighborhood U of a reference point $p \in \mathbb{R}^n$, we make the following assumptions.

(A) Δ is involutive and finitely generated over $C^\infty(U)$ (respectievly, $C^\omega(U)$) by the vector fields $X_1, \ldots, X_d$.

(B) Δ is locally controlled invariant (also known as weakly (f, g) invariant), in the sense that

$$[f, X_i] = V_i + \sum_{j=1}^{m} c_j^i g_j, \qquad 1 = 1, \ldots, d$$

and

$$[g_j, X_i] = W_{ij} + \sum_{k=1}^{m} b_{jk}^i g_k, \qquad j = 1, \ldots, m, \quad i = 1, \ldots, d,$$

where V_i and W_{ij} are vector fields that belong to Δ; (c_j^i) and (b_{jk}^i) belong to $C^\infty(U)$ (respectively, $C^\omega(U)$).

It is known, then, that the required feedback functions may be found by solving the following partial differential equations (PDEs):

$$L_{X_i}(\alpha_k) - \sum_{j=1}^{m} b_{jk}^i \alpha_j = c_k^i, \qquad i = 1, \ldots, d, \quad k = 1, \ldots, m, \tag{1}$$

$$L_{X_i}(\beta_{jk}) - \sum_{r=1}^{m} b_{rk}^i \beta_{jr} = 0, \qquad i = 1, \ldots, d, \quad j, k = 1, \ldots, m. \tag{2}$$

(C) Δ is input-insensitive, i.e., $[g_j, \Delta] \subseteq \Delta$. We relax this condition in some cases. However, unless explicitly stated to the contrary, (C) is operative throughout this paper. If (C) holds, then only (1), which now takes the form

$$L_{X_i}(\alpha_k) = c_k^i, \qquad i = 1, \ldots, d, \quad k = 1, \ldots, b, \tag{3}$$

must be solved.

(D) The control vector fields $g_1, \ldots, g_m$, are linearly independent on a dense subset of U.

(E) $G \cap \Delta = \{0\}$ on a dense subset of U.

Then it is known (see [15]) that (B), (D), and (E) provide the integrability conditions for (2) and (3) on a dense subset of U and hence everywhere. The proof of this fact is a simple consequence of the Jacobi identity and the above hypotheses. If now, in addition, Δ is nonsingular, then (2) and (3) do indeed have smooth (respectively, analytic) solutions. In [15] the proof that (B), (D), and (E) yield the integrability conditions is given under the assumption that these conditions hold everywhere, not just on a dense subset. However, the same proof carries over, under our assumptions, to yield the conclusion on a dense subset (and hence everywhere). It must be emphasised

that we require "nice" behavior only on a dense subset and not everywhere, not out of a desire to be perversely general, but because this situation is forced upon us. Loosely speaking, the joint requirements that Δ be singular and that it be input-insensitive will, more often than not, force $G+\Delta/\Delta$ also to pick up singularities. Unless otherwise stated, therefore, we assume that all of the conditions (A)–(E) hold throughout this paper. We emphasize that this means that the integrability conditions for (2) and (3) are valid on all of U. Thus we tacitly assume that the integrability conditions, which are obviously necessary for the local solvability of these systems of partial differential equations, always hold.

Remark 1.1. (a) If Δ is nonsingular and so is G, then (B) and (E) are equivalent to $[f,\Delta] \subseteq \Delta + G$ and $[g_i,\Delta] \subseteq \Delta + G$. In fact, the smooth (respectively, analytic) implicit function theorem proves the smoothness of the functions (c_j^i) and (b_{jk}^i) and, once we have specified a basis for the distributions Δ and G, their uniqueness as well. We must assume (D) in the singular case. Note, however, that once this is assumed, the uniqueness follows from the denseness assumption in (D) and (E).

(b) Note that (A) and (D) hold automatically in the analytic case.

(c) Note that (D) and (E) imply that $G + \Delta/\Delta$ is nonsingular on a dense subset. The converse is not true however. We make the more restrictive assumptions because we cannot ensure, without additional assumptions, the possibility of an analytic extension of a separating feedback to all of U.

In §3 we obtain a "canonical" form for a basis for a locally finitely generated distribution with singularities. After the submission of this paper, it was brought to our attention by Dr. K. Grasse that our Theorem 3.1 could be deduced from [26, Thm. 1]. We wish to thank him for this. In [26] the author shows that involutive and locally finitely generated vector field systems give rise to a foliation with singularities. In particular, this means that at each point there is a "privileged chart." Using such a chart, we can produce a basis of fields of the type in Theorem 3.1. However, the proof presented here is more elementary and is constructive to the extent that the flowbox theorem is. We must also mention that singular distributions have been studed previously in other contexts [19], [12], [28], [26]. See [13] for a different study of a canonical form for involutive distributions in connection with control theory.

This canonical form clearly displays that solving (3) entails solving a degenerate system of PDEs (see §2 for a definition of a degenerate PDE). In §4 we show that solving this degenerate system suffices, in that we may construct a solution to all the equations in (3) from a solution to the degenerate system in (3).

Very little is known about even a single degenerate PDE, let alone a system. If we assume that all data are analytic, then, for a single analytic equation, there are conditions on the first-order eigenvalues of the vector field that guarantee a solution. These conditions are described in [3] and [4]. Since we use their results in more than one way, they have been summarized in §2.

Using these results, we are able to give one situation where a solution to (1.3) can be obtained (Theorem 5.3). To obtain Theorem 5.3, we must make a suitable basis change in Δ, for which we again must solve degenerate PDEs. It turns out that the scaling vector field plays an important role in this result.

For a different approach to the problem of controlled invariance of singular distributions, see [6] and [7]. For an example of a rigid body problem involving a distribution with singularities, see [22] and [24]. Consult the text [23] in connection with the problem of controlled invariance for general nonlinear systems, which has the merit of providing a way of studying controlled invariance for nonlinear discrete time sys-

tems [11]. The same text also formulates the integrability conditions for the PDEs under study in terms of the existence of flat connections. Finally, we refer to [8]–[10], [14]–[17], [20], [21], [23], [29] for more on the problem of controlled invariance.

2. Formal and convergent solutions to PDEs. In this section, we summarize results of Bengel and Gerard on the convergence of formal solutions to a degenerate PDE. We consider the following two kinds of equations:

$$L_X v = s(x) \tag{4}$$

and

$$L_X v = s(x, v). \tag{5}$$

In (4) and (5), both v and s can be r-vectors. If $v = (v_1, \ldots, v_r)$, then $L_X v$ is to be interpreted as the r-vector $(L_X v_1, \ldots, L_X v_r)$. s is taken to be an analytic r vector. The PDEs (4), (5) are said to be degenerate (at the origin) if the differential operator on the left-hand side vanishes at the origin. This happens if and only if the vector field X vanishes at the origin. In [3], [4], vector fields of the form

$$X = \sum_{j=1}^{n} (\gamma_j x_j + p_j(x_1, \ldots, x_n)) \frac{\partial}{\partial x_j}, \tag{6}$$

with $\gamma_j \in \mathbb{R}$ and the p_j analytic functions vanishing to the second-order at the origin, are studied.

For a multi-index $m = (m_1, \ldots, m_n)$ where the m_i are nonnegative integers, denote by $P_0(m)$ the quantity

$$P_0(m) = \left(\sum_{j=1}^{n} \gamma_j m_j \right) I_r$$

(where I_r is the rth-order identity matrix). Furthermore, let $\mid m \mid = \sum_{i=1}^{n} m_i$. We now have the following theorems.

THEOREM 2.1 (Bengel and Gérard). *If the operator X in* (6) *satisfies the estimate*

$$\mid P_0(m) \mid \geq C \mid m \mid, \qquad m \neq (0, \ldots, 0)$$

for some fixed positive constant C, and the obvious necessary condition $s(0) = 0$ holds, then, in a neighborhood of the origin, there exists an analytic solution to (4).

THEOREM 2.2 (Bengel and Gérard). *If the estimate of Theorem* 2.1 *holds and we have, in addition, that*

$$s(0,0) = 0, \qquad \mathrm{Jac}_v s(0,0) = 0,$$

where $\mathrm{Jac}_v s$ is the Jacobian matrix of s with respect to the v variables, then there exists, in a neighborhood of the origin in R^n, an analytic solution to (5).

Now consider the following equation:

$$L_X v = s(x, y, v) \tag{7}$$

with X as in (6), s analytic in all three variables x, y, and v, and where $y \in \mathbb{R}^p$ is a parameter.

Notation. If $x = (x_1, \ldots, x_n) \in \mathbb{R}^n$ and $m = (m_1, \ldots, m_n)$ is a multi-index, then x^m denotes $x_1^{m_1} x_2^{m_2} \cdots x_n^{m_n}$.

THEOREM 2.3 (Bengel and Gérard). *Let s in (7) satisfy $s(0,0,0) = 0$ and $(\partial s/\partial v)(0,0,0) = 0$. Assume (7) has a formal solution*

$$w = \sum_k w_k(y) x^k$$

(where k is a multi-index) with $w_k(0) = 0$. Then (7) has a solution

$$v = \sum_k v_k(y) x^k$$

that converges. Furthermore, given any ν, the v_k can be chosen so that w and v agree up to order ν.

The condition $P_0(m) \neq 0$ for all $m \neq 0$ allows us to set up formal solutions to the degenerate PDE (4) and to (5) when the latter is linear in v. For the more general case, we must linearize (5) and use a "Newton's method-" type argument. See [3] and [4] for more details. The estimate on $P_0(m)$ then allows us to establish convergence of the formal power series for the putative solution. Consult [2] for other situations that give rise to similar notions, especially in the study of *ordinary* differential equations (ODEs) with regular and irregular singularities.

Remark 2.1. (a) In both Theorems 2.1 and 2.2, the solution is unique up to the choice of an additive constant.

(b) We have not stated the results of [2] and [3] in full generality even for (4), (5), and (7). In this paper, we just want to give a flavor of the kind of estimates (usually called Poincaré or Siegel conditions) needed to obtain convergence of formal solutions. For a detailed description of Poincaré or Siegel conditions, consult [2].

(c) Theorem 2.2 would hold even if $(\partial f/\partial u)(0,0) \neq 0$. Denote by $\Lambda(m)$ the matrix $P_0(m) - (\partial f/\partial u)(0,0)$. If $\Lambda(m)$ satisfies the estimate $|\Lambda(m)| > C|m|$ for some positive constant C and all $m \neq 0$, then we can find an analytic solution to (5). Of course, now it may not be possible to prescribe the initial value of the solution.

We close this section with a definition that is required later.

DEFINITION 2.1. *A Poincaré vector field is an analytic vector field of the form in (6) satisfying the estimate in Theorem* 2.1.

3. Canonical basis for singular distributions. The goal of this section is to prove the following theorem, in which we work in a neighborhood V of the reference point, where Δ is locally finitely generated.

THEOREM 3.1. *Let Δ be an involutive, smooth distribution that is generated by d vector fields in a neighborhood V of $p \in \mathbb{R}^n$ (d can be greater than n). Suppose that $\dim\Delta(p) = d_0$, where $d_0 \leq d$. Then there exists a coordinate system $(U, (x_1, \ldots, x_n))$ centered at p such that Δ is spanned over $C^\infty(U)$ by*

$$X_l = \frac{\partial}{\partial x_l}, \qquad l = 1, \ldots, d_0, \tag{8}$$

$$X_l = \sum_{j=d_0+1}^{n} a_j^l(x_{d_0+1}, \ldots, x_n) \frac{\partial}{\partial x_j}, \qquad l = d_0 + 1, \ldots, d, \tag{9}$$

where the a_j^l are smooth functions that vanish at the origin in $\mathbb{R}^{n-d_0}$.

Proof. We induct on the triples $(\mathrm{n}, \mathrm{d}, d_0)$ ordered lexicographically. The result is vacuously true when the triplet takes the value (0,0,0). We assume the result is true for triplets $(\mathrm{m}, \mathrm{l}, l_0)$, which satisfy one of the following: (a) $m < n$, (b) $m = n, l < d$, (c) $m = n, l = d, l_0 < d_0$.

The inductive step. Before we resume the proof, we make two observations.

Observation A. We may assume that $0 < d_0 < d$. If $d_0 = 0$, the original coordinate system will suffice. If $d_0 = d$, the classical Frobenius theorem gives the result.

Observation B. Let Δ be an involutive distribution in R^n. Suppose that at some stage, we have found a basis for Δ, in some neighborhood, of the following form:

$$X_l = \frac{\partial}{\partial x_l}, \qquad l = 1, \ldots, q$$

and

$$X_l = \sum_{j=1}^{n} a_j^l(x) \frac{\partial}{\partial x_j}, \qquad l = q+1, \ldots, r.$$

Then Δ is spanned in that neighborhood by

$$X_l = \frac{\partial}{\partial x_l}, \qquad l = 1, \ldots, q$$

and

$$\tilde{X}_l = \sum_{j=q+1}^{n} a_j^l(x_1, \ldots, x_n) \frac{\partial}{\partial x_j}, \qquad l = q+1, \ldots, r.$$

In essence, we "chop off" from the expression displaying any element of Δ as a smooth linear combination of the X_l's, the $\partial/\partial x_j, j = 1, \ldots, q$ terms from the last $q+1$ to r terms and add them to the first q terms.

We now resume the proof of the theorem with the inductive step.

We can assume that Δ now has a basis of the form $X_1, \ldots, X_d$, where $X_1, \ldots, X_{d_0}$ are linearly independent and $X_l(0) = 0$ for $l = d_0 + 1, \ldots, d$. This is achieved by using the linear dependence relations at the origin among the basis elements of Δ, corresponding to the drop in rank of Δ there, to effect a linear basis change for the distribution Δ. In particular, since $X_1(0) \neq 0$, we can by the flowbox theorem (see [1], [5]) find a coordinate system in which $X_1 = \partial/\partial x_1$. In this coordinate system, Δ has a basis consisting of X_1 and

$$X_j = \sum_{i=1}^{n} a_i^j(x) \frac{\partial}{\partial x_i}, \qquad j = 2, \ldots, d. \tag{10}$$

Consequently, by Observation B, Δ is spanned in this neighborhood by

$$X_1 = \frac{\partial}{\partial x_1}, \quad \tilde{X}_j = \sum_{i=2}^{n} a_i^j(x) \frac{\partial}{\partial x_i}, \qquad j = 2, \ldots, d. \tag{11}$$

In particular, $\tilde{X}_2, \ldots, \tilde{X}_{d_0}$ are linearly independent; their span $\tilde{\Delta}$ is involutive (since Δ was, and none of the $\tilde{X}_j, j = 2, \ldots, d$ have a $\partial/\partial x_1$ component); and $\dim\tilde{\Delta}(0) = d_0 - 1$.

Note that Δ is spanned by any basis for $\tilde{\Delta}$ and X_1. We now seek a basis change for $\tilde{\Delta}$ with the property that all basis elements commute with X_1. To that end, let

$$[X_1, \tilde{X}_i] = \sum_{j=2}^{d} \alpha_j^i(x)\tilde{X}_j \tag{12}$$

be the equation expressing the involutivity of Δ. Note that on the right-hand side of (12) there is no component along X_1. We make a basis change of the form

$$X_i \doteq \left(\sum_{k=2}^{d} b_k^i \tilde{X}_k\right), \qquad i = 2, \ldots, d. \tag{13}$$

If $[X_1, X_i]$ is to be zero, we must have

$$\sum_{k=2}^{d} \left(\frac{\partial b_k^i}{\partial x_1}\tilde{X}_k + b_k^i \sum_{j=2}^{d} \alpha_j^k \tilde{X}_j\right) = 0. \tag{14}$$

This leads to $(d-1)$ separate systems of linear ODEs (with parameters $x_2, \ldots, x_n$), below:

$$\frac{db_j^i}{dx_1} + \sum_{k=2}^{n} b_k^i \alpha_j^k = 0, \qquad i, j = 2, \ldots, d. \tag{15}$$

These can be solved, and, by prescribing initial conditions $b_k^i(0)$ so that the matrix of initial conditions is invertible, we can ensure that the basis change thus found is invertible in a small neighborhood. Hence, $\tilde{\Delta}$ has a basis of the form

$$X_i \doteq \sum_{j=2}^{n} d_j^i(x_2, \ldots, x_n)\frac{\partial}{\partial x_j}, \qquad i = 2, \ldots, d. \tag{16}$$

The distribution $\hat{\Delta} \doteq \operatorname{span}_{C^\infty_{R^{n-1}}}\{X_2, \ldots, X_d\}$ is involutive, and it is spanned by $d-1$ vector fields; furthermore, its dimension at the origin is $d_0 - 1$. So, by the inductive hypothesis, we can find a coordinate system centered at the origin in R^{n-1}, $(V, (x_2, \ldots, x_n))$, so that $\tilde{\Delta}$ is spanned by the vector fields

$$X_l = \frac{\partial}{\partial x_l}, \qquad l = 2, \ldots, d_0 \tag{17}$$

and

$$X_l = \sum_{j=d_0+1}^{n} a_j^l(x_{d_0+1}, \ldots, x_n)\frac{\partial}{\partial x_j}, \qquad l = d_0 + 1, \ldots, d \tag{18}$$

with $a_j^l(0) = 0$. Now observe that Δ is spanned on $U = \mathbb{R} \times W$, where W is the neighborhood on which the basis in the penultimate two equations is valid, by X_1 and the basis in these two equations. Thus, finally we have found a coordinate system $(U, (x_1, \ldots, x_n))$ centered at the origin in R^n in which Δ is spanned over $C^\infty(R^n)$, in a neighborhood contained in U by the vector fields

$$X_l = \frac{\partial}{\partial x_l}, \qquad l = 1, \ldots, d_0, \tag{19}$$

$$X_l = \sum_{j=d_0+1}^{n} a_j^l(x_{d_0+1}, \ldots, x_n)\frac{\partial}{\partial x_j}, \qquad l = d_0+1, \ldots, d. \tag{20}$$

In the last equation, we have, of course, $a_j^l(0) = 0$. This finishes the proof of the theorem. □

Remark 3.1. If the distribution in question is analytic, then the construction of the theorem would produce a basis of analytic vector fields.

Remark 3.2. Note that the proof of the theorem is constructive to the extent that the proof technique of the flowbox theorem is constructive.

4. Solving a degenerate system suffices. According to Theorem 3.1, a locally finitely generated involutive C^∞ distribution has a basis consisting of coordinate vector fields and vector fields tangent to a lower-dimensional space and vanishing at the origin. Consequently, the PDEs (3) for rendering this distribution-controlled invariant contain in them a degenerate system of PDEs. We now show that, if we can find a solution to this degenerate system, then we can find a solution to the entire system of equations (3). More precisely, we have the following result.

PROPOSITION 4.1. *Let Δ be a distribution satisfying the hypothesis of Theorem* 3.1. *Let $X_i = \partial/\partial x_i$, $i = 1, \ldots, d_0$, and $X_{d_0+1}, \ldots, X_d$ be a basis for Δ in a neighborhood U of the reference point, as in Theorem* 3.1. *Let*

$$\frac{\partial}{\partial x_i}\alpha = c_i(x), \qquad i = 1, \ldots, d_0, \tag{21}$$

$$L_{X_j}\alpha = c_j(x), \qquad j = d_0+1, \ldots, d \tag{22}$$

be (3) *for Δ with respect to this basis. Assume that Δ satisfies hypotheses* (A)–(E) *of* §1, *so that the integrability conditions for the system of equations* (21), (22) *hold. Then, if there exists a solution $\alpha(x)$ to* (22), *we can find a function $\tilde{\alpha}(x)$ that solves the full system* (21) *and* (22).

Proof. Let $\alpha(x)$ be a solution to (22). Since Δ is weakly (f, g) invariant, we know from §1 that the integrability conditions for (21) and (22) hold on all of U. Since the X_j's for $j = 1, \ldots, d_0$ and the X_i's for $i = d_0+1, \ldots, d$ commute, these conditions contain equations of the form

$$\frac{\partial c_i}{\partial x_j}(x) = L_{X_i}c_j(x), \qquad i = d_0+1, \ldots, d, \quad j = 1, \ldots, d_0. \tag{23}$$

Now consider the following expression:

$$\begin{aligned} L_{X_i}&\left(\frac{\partial \alpha(x)}{\partial x_j} - c_j(x)\right) \\ &= \frac{\partial}{\partial x_j}(L_{X_i}\alpha) - L_{X_i}c_j \\ &= \frac{\partial c_i}{\partial x_j} - L_{X_i}c_j \\ &= 0, \end{aligned}$$

where the second equality results from the fact that the coordinate vector fields in the first d_0 coordinates commute with the X_i's, and the last equality is nothing other than the above integrability conditions. Now there is a second set of integrability

conditions arising by virtue of the commutativity of the coordinate vector fields among themselves. These read as

$$\frac{\partial c_k}{\partial x_l} = \frac{\partial c_l}{\partial x_k}, \qquad k,l = 1,\dots,d_0. \tag{24}$$

Let us now consider the expressions

$$\frac{\partial \alpha(x)}{\partial x_j} - c_j(x) = \gamma_j(x). \tag{25}$$

The γ_j are functions invariant under the X_l for $l > d_0$. The system

$$\frac{\partial \gamma}{\partial x_k} = \gamma_k, \qquad k = 1,\dots,d_0 \tag{26}$$

can be solved, provided the integrability conditions hold for it, namely,

$$\frac{\partial \gamma_q}{\partial x_k} = \frac{\partial \gamma_p}{\partial x_q} \tag{27}$$

(for $p,q = 1,\dots,d_0$). However, the last set of equations reads as

$$\frac{\partial}{\partial x_p}\left(\frac{\partial \alpha}{\partial x_q} - c_q\right) = \frac{\partial}{\partial x_q}\left(\frac{\partial \alpha}{\partial x_p} - c_p\right).$$

This holds since (24) holds. Thus (26) has a solution $\gamma(x)$. Observe that $L_{X_l}\gamma = 0$ whenever $l > d_0$. Consequently, the function $\tilde{\alpha} := \alpha - \gamma$ solves both (21) and (22).

5. Degenerate systems and scaling.

Blanket Assumption. For the remainder of the paper, unless otherwise specified, Δ, f, and g are all analytic. Note that analytic distributions are always locally finitely generated.

According to Proposition 4.1, it suffices to restrict our attention to involutive distributions with $d_0 = 0$. If $d_0 > 0$, we must solve a parameterized system of degenerate equations. If $d_0 = 0$, the parameters disappear. In this section, we consider the latter case.

THEOREM 5.1. *Let Δ be a distribution satisfying the hypotheses of Theorem* 3.1, *with $d_0 = 0$, and assume furthermore that Δ satisfies the hypotheses* (A)–(E) *of* §1. *Suppose that one of the basis vector fields for Δ, say X_1, is a Poincaré vector field. If the remaining basis elements commute with X_1, and $c_j^i(0) = 0$, then there exists an analytic feedback rendering Δ controlled invariant in a neighborhood of the origin.*

Proof. Since Δ satisfies (B), (D), and (E), the integrability conditions for (3) are satisfied. Since $[X_1, X_j] = 0$, these read as

$$L_{X_j} c_1 = L_{X_1} c_j. \tag{28}$$

Now, by Theorem 2.1, the equation

$$L_{X_1}\alpha = c_1 \tag{29}$$

has an analytic solution $\bar{\alpha}(x)$. Therefore $L_{X_1}(L_{X_i}\bar{\alpha} - c_i) = L_{X_i}L_{X_1}\bar{\alpha} - L_{X_1}c_i = L_{X_i}c_1 - L_{X_1}c_i = 0$ (by (28)). So $L_{X_i}\bar{\alpha} - c_i$ is an analytic function that satisfies the equation

$$L_{X_1}\gamma = 0. \tag{30}$$

However, the only analytic solution to (30) is γ =constant, as can be seen by setting up a formal power series solution to the PDE $L_{X_1}\gamma = 0$. Since $c_i(0) = 0$ and $X_i(0) = 0$ (for all $i = 2, \ldots, d$), it follows that $L_{X_i}\bar{\alpha} - c_i = 0$ identically for all $i = 2, \ldots, d$. Thus $\bar{\alpha}$ satisfies the remaining equations in (3), also.

We can see from the proof above that the condition $[X_1, X_i] = 0$ is required only to ensure that the solution to the equation $L_{X_1}\alpha = c_1$ satisfies the remaining equations, also. This condition can be weakened. However, doing so may violate the conditions necessary for solving the equation $L_{X_1}\alpha = c_1$.

DEFINITION 5.1. *For an analytic vector field* $X = \sum_{i=1}^{n} a_i(x)(\partial/\partial x_i)$ *on* $\mathbb{R}^n$, *vanishing at the origin, the linear part of* X *is the vector field* $Y := \sum_{i=1}^{n} b_i(x)(\partial/\partial x_i)$, *where* $b_i(x)$ *is the first-order term in the Taylor expansion of* a_i *about the origin.*

Remark 5.1. One common Poincaré vector field is described below.

A vector field X of the type (6) with $\gamma_j = 1$ for all j is said to be an LS vector field, because the flow of the linear part of such a vector field generates the scaling action on $\mathbb{R}^n$. More precisely, the scaling action is the action given in coordinates by

$$\phi[\lambda, (x_1, \ldots, x_n)] = (\lambda x_1, \ldots, \lambda x_n),$$

where λ is a nonzero real number. Here $\phi(,)$ denotes the action of the scaling group. More importantly, for our purposes, it is of great significance that to be an LS vector field is a property independent of the coordinate system. Indeed, if $X = \sum_{i=1}^{n} a_i(x)(\partial/\partial x_i)$, then its linear part is determined by its Jacobian matrix at 0, J. If $J = ((\partial a_i/\partial xj)(0)) = (\gamma_{ij})$, then $Y = \sum_{i=1}^{n}\sum_{j=1}^{n}(\gamma_{ij})x_j(\partial/\partial x_i)$. Now, for an LS vector field, $J = I_n$, the identity matrix, in every coordinate system. This is because the Jacobian matrix is transformed to a conjugate matrix under a coordinate change. However, I_n is the only matrix in its conjugacy class.

DEFINITION 5.2. *Let* Δ *be an analytic distribution on an open set* $U \subseteq \mathbb{R}^n$ *containing the origin. Let* Δ *satisfy the hypotheses of Theorem* 3.1 *with* $d_0 = 0$. *If* $\Delta = \mathrm{sp}\{X_i\}$, $i = 1, \ldots, d$ *for vector fields* X_i *analytic on* U, *then its first-order distribution is the distribution* $\tilde{\Delta}$, *defined on* U *as* $\tilde{\Delta} := \mathrm{sp}_{\mathbb{R}}\{Y_i\}$, *where the* Y_i *are as in Definition* 5.1. *Note that this definition does not depend on the choice of either a coordinate system or a basis for* Δ. Δ *is said to be nonsingular of the first order if* $\tilde{\Delta}$ *has maximal rank* d.

Remark 5.2. It is not necessary that, if Δ is nonsingular away from the origin, then the Y_i's are linearly independent away from the origin. As we see later, it is adequate for our purposes if they are linearly independent at any one point in U away from the origin.

DEFINITION 5.3. *With the notation of Definition* 5.2, Δ *is said to be abelian of first order if* $[Y_1, Y_j] = 0$ *for all* $j = 1, \ldots, d$, *where* Y_1 *is the linear part of the Poincaré vector field* X_1. *Once again, this is a property independent of the choice of either a coordinate system or any choice of basis for* Δ *containing* X_1.

Note that, if Δ contains in it an LS vector field, then Δ is automatically abelian of the first order. This is because, if X_1 is an LS vector field, then $Y_1 = \sum_{i=1}^{n} x_i(\partial/\partial x_i)$ and any linear vector field commutes with Y_1. Indeed, every matrix commutes with the identity matrix.

THEOREM 5.2. *Let* Δ *be a distribution satisfying the hypothesis of Theorem* 3.1 *with* $d_0 = 0$. *Suppose that* Δ *contains a vector field, say* $\tilde{X}_1$, *whose Jacobian at zero* J *is diagonalizable and has eigenvalues* γ_j *satisfying the estimate described in Theorem* 2.1. *Furthermore, assume that* Δ *is nonsingular of the first order and that* Δ *is abelian of the first order. Then we can find a basis for* Δ, $\{X_1, X_2, \ldots, X_d\}$ *with* X_1 *a Poincaré vector field, and* $[X_1, X_k] = 0$, $k = 1, \ldots, d$.

Proof. Since J is diagonalizable, we can, by linear change of coordinates, transform $\tilde{X}_1$ to X_1 with X_1 a Poincaré vector field. If the original basis of Δ was $\{\tilde{X}_1, \tilde{X}_2, \ldots, \tilde{X}_d\}$, then, under this coordinate change, $\tilde{X}_2, \ldots, \tilde{X}_d$ transform to some vector fields $\hat{X}_2, \ldots, \hat{X}_d$.

We now make a basis change of the form

$$T = (\beta_{ij}), \tag{31}$$

where the β_{ij}'s are analytic functions that satisfy $\beta_{ii}(0) = C_i$ for nonzero constants $C_i (i \geq 2)$ and $\beta_{ij}(0) = 0$ for $j > 1$, and $j \neq i$, $i = 2, \ldots, d$. The $\beta_{i1}(0)$ can be arbitrary. Note that T is invertible at 0 and hence in a neighborhood. We want the new basis $(X_1, X_2, \ldots, X_d) := T(X_1, \hat{X}_2, \ldots, \hat{X}_d)$ to satisfy $[X_1, X_i] = 0$, $i \geq 2$. Since Δ is involutive, we have

$$[X_1, \hat{X}_i] = \sum_{j=1}^{d} \alpha_{ij} \hat{X}_j, \quad \text{with } \hat{X}_1 = X_1, \tag{32}$$

and the α_{ij}'s are some analytic functions. If $[X_1, X_i]$ is to be zero, we must have

$$\sum_{j=1}^{d} (L_{x_1} \beta_{ij}) \hat{X}_j + \sum_{j=1}^{d} \beta_{ij} [X_1, \hat{X}_j] = 0. \tag{33}$$

Equation (33) shows that the PDEs for the rows of T form separate systems (i.e., we can solve each separately).

We illustrate the solvability of (33) by doing so for the second row of T. The argument for the other rows is exactly the same. The equations for the second row read as

$$\begin{aligned} L_{X_1} \beta_{21} &= -\beta_{22}\alpha_{21} - \cdots - \beta_{2d}\alpha_{d1}, \\ L_{X_1} \beta_{22} &= -\beta_{22}\alpha_{22} - \cdots - \beta_{2d}\alpha_{d2}, \\ &\vdots \\ L_{X_1} \beta_{2d} &= -\beta_{22}\alpha_{2d} - \cdots - \beta_{2d}\alpha_{dd}. \end{aligned} \tag{34}$$

We use Theorem 2.2 to prove that the last $(d-1)$ equations in (34) have analytic solutions. Then we plug these solutions into the first equation and use Theorem 2.1 to show that it has a solution. To that end, write the last $(d-1)$ equations as $L_X v = s(x, v)$, for a $(d-1)$ vector v. Clearly, $s(0,0) = 0$.

Futhermore, $(\partial s/\partial v)(0,0) = (-\alpha_{ij}(0))$. We must show that this is zero. To that end, let us proceed as follows: Since the $\hat{X}_i$ vanish at the origin and so does X_1, we have

$$\text{linear part of } [X_1, \hat{X}_i] = [Y_1, \hat{Y}_i] = 0 \quad \text{(for all x)}$$

(since Δ is abelian of the first order). Consequently, the linear part of $\sum_{j=1}^{d} \alpha_{ij} \hat{X}_j$ is also zero for all $x \in U$. Bearing in mind Remark 5.1, let us compute the Jacobian at zero of $\sum_{j=1}^{d} \alpha_{ij} \hat{X}_j$. This is equal to $\sum_{j=1}^{d} \alpha_{ij}(0) J_j$, where J_j is the Jacobian at zero of $\hat{X}_j$(as the $\hat{X}_j$ vanish at the origin). Since Δ is nonsingular of the the first order, this forces $\alpha_{ij}(0) = 0$ for all (i, j). Thus $(\partial s/\partial v)(0,0) = 0$. Consequently, Theorem

2.2 applies to provide analytic solutions whose values at zero may (by Remark 2.1(a)) be chosen as we please. If we plug these solutions into the first equation of (34), we get an equation of the type (5). Clearly, the right-hand side of this equation vanishes at $x^{\neg} = 0$. Consequently, Theorem 2.1 applies to yield a solution.

To give the reader a flavor of the kind of solutions that arise, we set up formal solutions to (34). For clarity of exposition, we limit ourselves to the case where $d = 3$ and the case where X_1 is an LS vector field. By Poincaré's linearization theorem [27], there exists a coordinate change preserving the origin so that X_1 transforms to the scaling vector field. Now the last two equations of (34) read as

$$L_{X_1}\beta_{22} = -\beta_{22}\alpha_{22} - \beta_{23}\alpha_{32}$$

and

$$L_{X_1}\beta_{23} = -\beta_{22}\alpha_{23} - \beta_{23}\alpha_{33}.$$

We seek solutions of the form

$$\beta_{22} = w = c_2 + \sum_{|m|\geq 1} w_m x^m,$$
$$\beta_{23} = v = \sum_{|m|\geq 1} v_m x^m,$$

where m stands for a multi-index. Clearly,

$$L_{X_1} w = \sum_{|m|\geq 1} |\, m \,|\, w_m x^m,$$
$$L_{X_1} v = \sum_{|m|\geq 1} |\, m \,|\, v_m x^m.$$

Let us also define

$$-\alpha_{22} = \alpha = \sum_{|m|\geq 1} \alpha_m x^m,$$
$$-\alpha_{32} = \beta = \sum_{|m|\geq 1} \beta_m x^m,$$
$$-\alpha_{23} = \gamma = \sum_{|m|\geq 1} \gamma_m x^m,$$
$$-\alpha_{33} = \delta = \sum_{|m|\geq 1} \delta_m x^m.$$

These functions are known analytic functions (since the distribution Δ is analytic). Consequently, the coefficients $\alpha_m, \beta_m, \gamma_m, \delta_m$ are predetermined. We know that the the nonsingularity and the abelianness in the first order of Δ entail that these functions vanish at the origin. Equating like powers of x, we have

$$w_m = c_2 \alpha_m, \tag{35}$$
$$v_m = c_2 \gamma_m, \tag{36}$$

for $\mid m \mid = 1$ and

$$w_m = \sum_l \sum_k \frac{\alpha_l w_k + \beta_l v_k}{\mid m \mid},$$
$$v_m = \sum_l \sum_k \frac{\gamma_l w_k + \delta_l v_k}{\mid m \mid} \tag{37}$$

for $\mid m \mid > 1$ and $l + k = m$.

We claim that (37) can be solved recursively for w_m, v_m. For $\mid m \mid = 1$, (35) shows that we can begin the induction. Let us assume the claim is true for $\mid m \mid = p$. Let $\mid m \mid = p + 1$ and let $m = (m_1, \ldots, m_n)$ be a multi-index with weight $p + 1$. Then

$$w_m = \sum_l \sum_k \frac{\alpha_l w_k + \beta_l v_k}{p+1}, \qquad l + k = m$$

and

$$v_m = \sum_l \sum_k \frac{\gamma_l w_k + \delta_l v_k}{p+1}, \qquad l + k = m.$$

Since $\alpha(0) = \beta(0) = \gamma(0) = \delta(0) = 0$, the u_k, v_k terms on the right-hand side of the last two equations all have weight $\leq p$ and hence have already been determined by the inductive hypothesis. Since the $\alpha_l, \beta_l, \gamma_l, \delta_l$ are known for all l, we are done. The procedure outlined above goes through verbatim when $d > 3$ (the only difference being an exponential increase in indices).

We now give sufficient conditions to ensure that $c_j^i(0) = 0$. Observe that, if Δ is a distribution with rank zero at the origin that contains even one vector field X_i whose Jacobian at the origin is a nonsingular matrix (if X_i has a hyperbolic equilibrium point at the origin, for instance) and is input-insensitive, then necessarily the control vector fields vanish at the origin. Indeed, we must have:

$$[g_j, X_i](0) \in \Delta(0) = 0.$$

Since each of the X_i vanish at the origin, we have that

$$[g_j, X_i](0) \ = \ -DX_i(0)g_j(0).$$

By hypothesis, the Jacobian of X_i at the origin, $DX_i(0)$, is nonsingular. This yields the conclusion and motivates the following definitions.

DEFINITION 5.4. *Assume the following:*

(i) $G(0) = 0$, *and denote by* $\tilde{g}$ *the linear parts of* g;

(ii) *The distribution* $\tilde{G} = \operatorname{span}_{\mathbf{R}}\{\tilde{g}\}$ *has maximal rank* m;

(iii) $\tilde{G} \cap \tilde{\Delta} = \{0\}$ *on a dense subset.*

We then say that the pair (G, Δ) *is nonsingular of the first order.*

Remark 5.3. If (G, Δ) is nonsingular of the first order $f(0) = 0$ and the linear part of f leaves $\tilde{\Delta}$ invariant, then $c_j^i(0) = 0$. Indeed, if in the equation $[f, X_i] = V_i + \Sigma c_j^i g_j$ we pass to linear parts, then we have that $\sum_{j=1}^m c_j^i(0)\tilde{g}_j = 0$ on a dense subset and so everywhere. Since $\tilde{G}$ has maximal rank m, there is at least some point where all the vectors obtained by evaluating the basis of $\tilde{G}$ are linearly independent (in fact, by analyticity most points are points where this rank condition is valid). So we have $c_j^i(0) = 0$.

Combining Theorems 5.1 and 5.2 and Remark 5.3, we have the following result.

THEOREM 5.3. *Assume the following*:

(a) Δ *satisfies assumptions* (A)–(E) *of* §1, *the hypotheses of Theorem* 3.1 *with* $d_0 = 0$, *and contains a Poincaré vector field*;

(b) Δ *is nonsingular of the first order*;

(c) Δ *is abelian of the first order*;

(d) *The pair* (G, Δ) *is nonsingular of the first order*;

(e) $f(0) = 0$, *and the linearization of* f *leaves* $\tilde{\Delta}$ *invariant.*

Then we can find an analytic feedback in a neighborhood of the origin that preserves the equilibrium of f *and renders* Δ *controlled invariant.*

Remark 5.4. (a) If the vector field in Δ is also an LS vector field, then (c) automatically holds.

(b) Results of a nature similar to Theorem 5.3 appear in [18], [25]. Their results are concerned with a finite-dimensional Lie algebra of analytic vector fields. However, the set of vector fields taking values in an involutive distribution, although a Lie algebra, is rarely finite-dimensional. This is, perhaps, why they could get by with coordinate changes alone.

Example. Consider in R^4 the involutive distribution $\operatorname{span}\{X_1, X_2\}$, where

$$X_1(x) = x_1 \frac{\partial}{\partial x_1} + x_2 \frac{\partial}{\partial x_2} + 2x_3 \frac{\partial}{\partial x_3} + x_4 \frac{\partial}{\partial x_4}$$

and

$$X_2(x) = x_2 \frac{\partial}{\partial x_1} - x_1 \frac{\partial}{\partial x_2} + x_3 \frac{\partial}{\partial x_3} + x_4 \frac{\partial}{\partial x_4}.$$

In fact, $[X_1, X_2] = 0$. Note, however, that Δ has singularities.

Let the control vector field g be given as

$$g(x) = x_3 \frac{\partial}{\partial x_3}.$$

Then Δ is input insensitive. In fact, $[g, X_i] = 0$, for $i = 1, 2$. In addition, $G \cap \Delta = 0$ on a dense subset $(x_1, x_2, x_4 \neq 0)$, but not on all of R^4. Also, $\tilde{\Delta}$ is nonsingular of the first order. Note also that the linear part of g spans a distribution of maximal rank 1 and that it intersects $\tilde{\Delta}$ in the zero section on a dense subset of R^4.

Finally, let the drift be given by

$$f(x) = (x_1 - x_2 + x_1^2 + x_2^2)\frac{\partial}{\partial x_1} + (x_1 + x_2)\frac{\partial}{\partial x_2} + (x_1^2 + x_2^2)x_3^2 \frac{\partial}{\partial x_3} + (x_1 x_4 + x_2 x_4 + x_4)\frac{\partial}{\partial x_4}.$$

We can also see that the linear part of f leaves $\tilde{\Delta}$ invariant. It is easy to calculate that

$$[f, X_1] = (x_1^2 + x_2^2)\frac{\partial}{\partial x_1} + 4(x_1^2 + x_2^2)x_3^2 \frac{\partial}{\partial x_3},$$

so that $c^1(x) = -2x_1 - x_2 + 4(x_1^2 + x_2^2)x_3$ and

$$[f, X_2] = (x_1^2 + x_2^2)x_3 \frac{\partial}{\partial x_2} + (x_1^2 + x_2^2)x_3 \frac{\partial}{\partial x_3},$$

and hence $c^2 = -2x_2 + x_1 + (x_1^2 + x_2^2)x_3$. It is easy to check that $X_2 c^1 = X_1 c^2$, so that the integrability conditions are satisfied, as they must be for theoretical reasons. To

find a solution to this system of PDEs, we first solve the equation corresponding to the Poincaré vector field X_1, this being easier of the two, since the solution is given by $\alpha_m = c_m^1/P_0(m)$, where, as usual, α_m and c_m^1 are the coefficients of the Taylor expansions of α and c^1. Thus the solution α is

$$\alpha(x) = (x_1^2 + x_2^2)x_3 - 2x_1 - x_2.$$

This α also solves $L_{X_2}\alpha = c^2$, as it should.

Remark 5.5. One might wonder whether one would ever encounter, in practice, a distribution that contains the scaling vector field. Let us consider the disturbance decoupling problem, for instance. If the output of the system (or the functions one has obtained at the instance of the first breakdown of the controlled invariant subdistribution algorithm [15], [23]) is an analytic function of the ratio of the states and if, furthermore, the disturbance vector field also vanishes at the origin, then we have precisely such a distribution. Such an output is discontinuous at the origin, but many practical measurement schemes, such as camera measurements, answer to such a description.

6. The "d_0 positive" case. Let us first suppose that $d_0 = d - 1$. Then, if the vector field X_d is a Poincaré vector field in $\mathbb{R}^{n-d_0}$, we can, by Theorem 2.3 and Proposition 4.1, find a solution to (3), so long as a formal solution to the equation

$$L_{X_d}\alpha = c_d(x) \tag{38}$$

exists. In general, (38) is an equation with parameters. Now it is easy to see that a formal solution to (38) exists if the Taylor expansion of c_d contains no first-order terms in the variables $x_1, x_2, \ldots, x_{d-1}$. While this condition can always be checked once c_d is known, there seems to be no clear-cut way to characterize this condition in terms of the vector fields f, g_i and the distribution Δ.

If $0 < d_0 < d - 1$, then we must, in general, solve a degenerate system with parameters. As of now, we do not know much about this situation, even if one of the degenerate vector fields is an LS vector field in $\mathbb{R}^{n-d_0}$. The argument presented in Theorem 5.1 would fail because now any analytic function depending only on $x_1, \ldots, x_{d_0}$ would be invariant under a Poincaré vector field. However, if it should turn out that the functions $c_{d_0+1}, \ldots, c_d$ do not depend on $x_1, \ldots, x_{d_0}$ (i.e., the parameters disappear) then we are back in the situation of Theorem 5.1, and we will be done. Put in a different way, we are demanding that the functions $c_{d_0+1}, \ldots, c_d$ be invariant under the group of translations in the variables $x_1, \ldots, x_{d_0}$. Sufficient conditions for these functions can be found in [24]. In our situation, it would suffice if, for instance, $[f, X_k]$ for $k = 1, \ldots, d_0$ were to lie in Δ already. We now discuss an example that illustrates this issue. This example is similar to the one in the previous section, except that the involutive distribution in question has nonzero dimension at the origin.

Example. Consider in R^5 the involutive distribution $\operatorname{span}\{X_1, X_2, X_3\}$, where

$$X_1(x) = \frac{\partial}{\partial x_1},$$

$$X_2(x) = x_1\frac{\partial}{\partial x_1} + x_2\frac{\partial}{\partial x_2} + x_3\frac{\partial}{\partial x_3} + 2x_4\frac{\partial}{\partial x_4} + x_5\frac{\partial}{\partial x_5},$$

and

$$X_3(x) = x_3\frac{\partial}{\partial x_2} - x_2\frac{\partial}{\partial x_3} + x_4\frac{\partial}{\partial x_4} + x_5\frac{\partial}{\partial x_5}.$$

To arrive at a basis of the form in Theorem 3.1, we just take X_1, X_3 as they are and modify X_2 to the field $x_2\partial/\partial x_2 + x_3\partial/\partial x_3 + 2x_4\partial/\partial x_5 + x_5\partial/\partial x_5$, which, for convenience, we label once more as X_2.

Note that $\dim\Delta(0) = 1$ and that its maximal rank is 3.

Let the control vector field g be given as

$$g(x) = \frac{\partial}{\partial x_1} + x_4\frac{\partial}{\partial x_4}.$$

Then Δ is input insensitive. In fact, $[g, X_i] = 0$, for $i = 1, 2$. In addition, $G \cap \Delta = 0$ on a dense subset but not on all of R^5. Note also that the linear part of g spans a distribution of maximal rank 1. Finally, let the drift be given by

$$f(x) = (x_2^2 + x_5^2 + x_1)\frac{\partial}{\partial x_1} + [x_1^2(x_2 - x_3) + x_2^2 + x_3^2]\frac{\partial}{\partial x_2} + [x_1^2(x_3 + x_2)]\frac{\partial}{\partial x_3}$$
$$+[x_1^2 + (x_2^2 + x_3^2)x_4]x_4\frac{\partial}{\partial x_4} + (x_2 + x_3)x_5\frac{\partial}{\partial x_5}.$$

It is easy to calculate that

$$[f, X_1] \in \Delta$$

so that $c^1(x) = 0$. We can also find $c^2(x) = -2x_2 - x_3 + 4(x_2^2 + x_2^3)x_4$ and $c^3(x) = -2x_3 + x_2 + (x_2^2 + x_2^3)x_4$. Note that neither c^2 nor c^3 depends on the variable x_1. This is a consequence of the translational symmetry in the variable x_1, which, in turn, follows because $[f, X_1] \in \Delta$. Once again, the integrability conditions for the PDEs are satisfied. Finally, a solution to the system is obtained by first solving the easier of the two equations, namely,

$$L_{X_2}\alpha(x) = c^2.$$

One solution is

$$\alpha(x) = (x_2^2 + x_3^2)x_4 - 2x_2 - x_3.$$

We can check easily that this solves the second equation $L_{X_3}\alpha(x) = c^3$, also. Since the solution does not involve x_1 at all, it also solves the equation $L_{X_1}\alpha = 0$.

7. The noninput insensitive case. If we are dealing with a single-input control system, then the theory for input-insensitivization parallels that of the PDEs (3). Indeed, in this case, (2) reads as

$$L_{X_i}(\beta) = b^i\beta, \tag{39}$$

where b^i is determined by $[g, X_i] = b^i g \ (\mathrm{mod}\Delta)$. Note that (39) can be written in a form analogous to (3), to wit,

$$L_{X_i}(\gamma) = b^i \tag{40}$$

with $\gamma = \ell n\beta$. The integrability conditions for (40) are $L_{X_i}b^j = L_{X_j}b^i$, which are (as they should be) the integrability conditions for (39). Consequently, Theorems 4.1, 5.1, and 5.3 with the obvious modifications carry over to this case.

If on the other hand there are many inputs, it seems difficult (at present, at least!) to generalize Theorems 4.1, 5.1, and so forth. The crux of the problem is that we do

not know what conditions, in addition to the integrability conditions, are needed for the local solvability of an overdetermined system of degenerate PDEs. At any rate, the proof technique of Theorems 4.1 and 5.1 would not carry over. If, on the other hand, we have $d = 1$ (and hence $d_0 = 0$) (thus the system is not overdetermined), then Theorem 2.2 would apply to produce an analytic feedback under suitable assumptions. If the pair (G, Δ) is nonsingular of the first order, then we can show, just as in Theorem 5.2, that (in the terminology of Theorem 2.2) $(\partial s/\partial v)(0,0) = 0$. Clearly, $s(0,0) = 0$. So Theorem 2.2 gives an analytic feedback, and by Remark (2.1(a)) we can arrange for this feedback to be invertible. On the other hand, if we assume that $G + \Delta/\Delta$ is of maximal rank at 0, then by calculating $[g, X_1](0)$ (where X_1 is the Poincaré vector field), we can see that $(\partial s/\partial v)(0,0) = -I_p$. In the terminology of Remark 2.5(c), $\Lambda(m) = (|m| + 1)I_p$. If we choose C to be 1, say, then Remark 2.5(c) would yield an analytic feedback that would render Δ input insensitive. Of course, we cannot make this feedback invertible—in fact, it will vanish at the origin. In related ongoing work, we are attempting to extend solutions to (1)–(3) past the singularities of Δ by finding group invariant solutions to these PDEs. This work suggests that, for Δ with $d_0 = 0$, it is very natural that $G + \Delta/\Delta$ also picks up singularities at 0.

8. Conclusion. In this paper, we have addressed the problem of rendering a locally controlled invariant analytic distribution with singularities controlled invariant. We showed that a solution to this problem involves solving a system of degenerate first-order PDEs. We have provided some instances of when this can be done. It would be interesting to see what bearing the results described in this paper have on the stabilization problem, since it is known [15] that the zero dynamics algorithm is closely related to the controlled invariance problem. Of course, we must first deal with input-insensitivization. In general, it seems that a delicate balance of techniques from symmetry groups, degenerate PDEs, and the blowing-up construction will be needed to address the problem of controlled invariance for singular distributions in general.

Acknowledgments. The author thanks Dr. K. Grasse for reading versions of the manuscript and offering innumerable suggestions to improve its quality; Dr. W. Dayawansa, Dr. K. Grasse, and Dr. H. Schättler for their comments, especially in streamlining the proof of Theorem 3.1; the anonymous referees for making several very important suggestions toward enhancing the readability of the paper; and Dr. C. Byrnes and Dr. D. Elliott for their remarks. I thank Ms. P. Johnson and Ms. C. Presswood for their clinical efficiency and infinite patience during their help in the typesetting process.

Note added in proof. Since the submission of this paper, we have been successful in obtaining further results on the subject matter of §§6 and 7. The details will be reported elsewhere.

DIFFERENTIAL GAMES WITH INFORMATION LAGS*

XIAOJUN QIAN†

Abstract. Differential games of generalized pursuit and evasion are studied. The definitions of strategy and payoff follow those of Berkovitz. It is shown under appropriate hypotheses on the data of the problem that if the Isaacs condition holds, then there exists a saddle point.

Then differential games with information lags are studied, in which Berkovitz's definitions of strategy and payoff are generalized to games with lags. It is first shown through an example that if a game has a lag, then value of the game does not exist in general. For games of fixed duration with information lags, it is demonstrated that if the Isaacs condition holds, then as the lags tend to zero, the upper and lower values as functions of the lags will tend to the value in the game with no lags. The same results hold also for differential games of generalized pursuit and evasion and for games of survival if certain reasonable conditions on the data and the structure of the terminal set hold.

Key words. differential games, saddle points, information lags, upper and lower values

AMS subject classifications. 90D25, 90D26

Formulated intuitively, a differential game has its state $x(t) \in \mathbb{R}^n$ at time t determined by a system of differential equations

$$\begin{aligned} &\frac{dx}{dt} = f(t, x, y(t), z(t)) \qquad \text{for } t_0 < t \le T \\ &x(t_0) = x_0, \end{aligned} \tag{1}$$

where $y(t)$ is chosen from some preassigned set $Y \subset \mathbb{R}^r$ by Player I at each instant of time t and $z(t)$ is chosen from some preassigned set $Z \subset \mathbb{R}^s$ by Player II at each instant of time t. The payoff is

$$g(t_f, x_f) + \int_{t_0}^{t_f} f^0(s, \phi(s), y(s), z(s))ds, \tag{2}$$

where ϕ is the solution of (1), the terminal time t_f is the first time that the trajectory $(t, \phi(t))$ reaches some preassigned terminal set $\mathcal{T}$, $x_f = \phi(t_f)$, g is a function defined on $[t_0, T] \times \mathbb{R}^n$, and f^0 is a function defined on $[t_0, T] \times \mathbb{R}^n \times Y \times Z$. Player I wishes to choose y so as to maximize the payoff while Player II wishes to choose z so as to minimize it. Such a game is called a game of survival. If $g \equiv 0$, we call the game a game of generalized pursuit and evasion. If the terminal set $\mathcal{T}$ is given by $[T, \infty) \times \mathbb{R}^n$, we call the game a game of fixed duration.

In his series of papers [1]–[3], Berkovitz studied the three types of differential games, using a definition of strategy that is an adaptation of that of Friedman [5] and Karlin [7] and a definition of payoff that is an adaptation of that of Krasovskii and Subbotin [8]. Berkovitz showed that if the Isaacs condition holds and the data satisfy reasonable hypotheses, then the three types of differential games have values that are continuous functions of the initial time and state. He showed in [1] that under these

† Department of Mathematics, Purdue University, West Lafayette, Indiana 47907.

hypotheses, games of fixed duration have saddle points, but he did not obtain the existence of a saddle point in the other games.

In §1 of our paper we present a result that is of interest in its own right and that we use in our study of problems with lags, namely, that if the Isaacs condition holds, then games of generalized pursuit and evasion have saddle points.

Friedman showed in [6] that, among other assumptions, if the compact sets Y and Z are convex, if $f^0 \geq 0$, and if f and f^0 are linear in y and z, that is,

$$f(t,x,y,z) = f_0(t,x) + F_1(t,x)y + F_2(t,x)z,$$
$$f^0(t,x,y,z) = f_0^0(t,x) + F_1^0(t,x)y + F_2^0(t,x)z,$$

where $F_1(t,x) \in \mathbb{R}^{n\times r}$, $F_2(t,x) \in \mathbb{R}^{n\times s}$, $F_1^0(t,x) \in \mathbb{R}^{1\times r}$, and $F_2^0(t,x) \in \mathbb{R}^{1\times s}$, then under his definitions, a saddle point exists for games of generalized pursuit and evasion. Friedman also showed that if $f^0(t,x,y,z) = f^0(t,x)$ and if the set $f(t,x,Y,Z) = \{f(t,x,y,z) | y \in Y, z \in Z\}$ is convex for any $(t,x) \in [t_0,T] \times \mathbb{R}^n$, then a generalized saddle point exists. In our result, we do not require the convexity of the sets Y and Z, the linearity of f and f^0 in y and z, nor the conditions that f^0 is independent of y and z and that the set $f(t,x,Y,Z)$ is convex.

In §2 of this paper, we extend Berkovitz's definition of differential games to games with information lags. First, we show through an example that if a differential game of fixed duration has a lag, then the value of the game does not exist in general. In [1]–[3], Berkovitz assumed that at each instant time t, each player has complete knowledge of his own action and that of his opponent from the initial time t_0 of the game up to but not including the current time t. A more realistic model of most conflict situations is that both players need a certain period of time to process information about their opponent's actions, i.e., at time t, Player I knows Player II's history between t_0 and $t-\lambda$ while Player II knows Player I's history between t_0 and $t-\mu$. The real numbers λ, μ, $0 \leq \lambda, \mu \leq t-t_0$, are called the lags of Player I and Player II, respectively. It will be shown that if the Isaacs condition holds, then as the lags tend to zero, the upper and lower values as functions of the lags will tend to the value in the game with no lags. Although such results are to be expected on intuitive grounds, and should hold if the model is realistic, the mathematical arguments needed to establish these results are delicate. Finally, we will show that if certain reasonable conditions on the data and the structure of the terminal set hold, then the results obtained for the fixed-time game with lags also hold for games of pursuit and evasion and games of survival with lags.

Friedman [5, p. 268] defined differential games with only one player having a lag. If Player I has the lag, Friedman defined the value of game as the limit of lower δ-values. In games without lag, he calls this limit the lower value of the game. If Player II has the lag, he defined the value as the limit of upper δ-values. In games without lag he calls this limit the upper value of the game. It is immediate from his definitions that the lower or upper δ-values of the game are monotonic in δ and so converge. Hence value for games with lags always exists in Friedman's sense. It is our belief that Friedman's definition is unsatisfactory in that his values are really upper or lower values, as the case may be. It was shown in [5] that if the opposing control variables appear "separated" in both the differential system and the payoff, then the values of the games with lag tend to the value of the game without lag. Recall, however, that Friedman's values for games with lag are really upper or lower values, so that our example and his results are not contradictory. We think that our definitions of

strategy and value are more natural than Friedman's; moreover, our result does not require a separation assumption on the dynamics of the game.

1. The existence of saddle point in games of generalized pursuit and evasion. The game that we study in this section is governed by (1) and has the following payoff:

$$\int_{t_0}^{t_f} f^0(s, \phi(s), u(s), v(s))\, ds, \tag{3}$$

where ϕ is the solution of (1) and t_f is the first time that $(t, \phi(t))$ reaches some preassigned terminal set $\mathcal{T}$. We use the notation of strategy and payoff introduced in [1] and [2] and establish the existence of saddle points in games of generalized pursuit and evasion.

We denote the game with initial point (t_0, x_0) by $G(t_0, x_0)$. Let $\hat{x} = (x^0, x)$ where $x^0 \in \mathbb{R}$ and let $\hat{f} = (f^0, f)$. We make the following assumptions concerning $\hat{f}$.

ASSUMPTION I. (i) *The function $\hat{f}$ is continuous on $D = [t_0, T] \times \mathbb{R}^{n+1} \times Y \times Z$.*

(ii) *There exists a function k that is integrable on $[t_0, T]$ such that $\langle \hat{x}, \hat{f}(t, x, y, z)\rangle \leq k(t)(1 + |\hat{x}|^2)$ for all $(t, \hat{x}, y, z)$ in D.*

(iii) *For any $R > 0$, there exists a constant $K_R > 0$ such that for all t in $[t_0, T]$, y in Y, z in Z, and $|x| \leq R$, $|\bar{x}| \leq R$, $|\hat{f}(t, x, y, z) - \hat{f}(t, \bar{x}, y, z)| \leq K_R|x - \bar{x}|$.*

ASSUMPTION II. *Let F_1 be a closed domain in $(t_0, \infty) \times \mathbb{R}^n$ with $C^{(2)}$ boundary ∂F_1. Let F denote the intersection of F_1 with the slab $t_0 \leq t \leq T$, and let F be bounded. Let the terminal set $\mathcal{T}$ be given by $\mathcal{T} = F \cup ([T, \infty) \times \mathbb{R}^n)$. Let $\hat{\partial} F = (\partial F) \cap (\partial F_1)$. At each point $(t, x) \in \hat{\partial} F$, let*

$$\nu^0 + \langle \nu, f(t, x, y, z)\rangle < 0 \tag{4}$$

for all $y \in Y$ and all $z \in Z$, where (ν^0, ν) is the normal to ∂F_1 at (t, x) pointing to the exterior of F_1.

ASSUMPTION II′. *Let F_1 be as in Assumption* II *and let F_1 further satisfy the condition $F_1 \supset ([T, \infty) \times \mathbb{R}^n)$. Let $F = F_1$ and let $\mathcal{T} = F$, and let* (4) *hold at each $(t, x) \in \partial F$.*

For $\tau_0 \in [t_0, T]$ and $\hat{\xi}_0 \in \mathbb{R}^{n+1}$, we consider game $\hat{G}(\tau_0, \hat{\xi}_0)$ governed by

$$\frac{dx}{dt} = f(t, x, u(t), v(t)), \qquad x(\tau_0) = \xi_0$$

with payoff $\xi_0^0 + \int_{\tau_0}^{t_f} f^0(s, \phi(s), u(s), v(s))\, ds$ and terminal set $\hat{\mathcal{T}} = \mathbb{R} \times \mathcal{T}$.

If we let $W^{\pm}(t_0, x_0)$ be the upper and lower values of $G(t_0, x_0)$ and $\hat{W}^{\pm}(t_0, \hat{x}_0)$ be the upper and lower values of $\hat{G}(t_0, \hat{x}_0)$, then $\hat{W}^{\pm}(t_0, \hat{x}_0) = W^{\pm}(t_0, x_0) + x_0^0$.

Let $\hat{F} = \mathbb{R} \times F$ and let (ν^0, ν) be the exterior unit normal to ∂F, then $(\nu^0, 0, \nu)$ is the exterior unit normal to $\partial \hat{F}$. Let $\hat{\nu} = (0, \nu)$. Since $\hat{f} = (f^0, f)$, Lemma 1 follows from (4).

LEMMA 1. *For every $(t, \hat{x}) \in \partial \hat{F}$, $\nu^0 + \langle \hat{\nu}, \hat{f}(t, \hat{x}, y, z)\rangle < 0$ for all $y \in Y$ and all $z \in Z$.*

For a point $(t, \hat{x})$ let $\hat{\rho}(t, \hat{x})$ denote the signed distance of $(t, \hat{x})$ to $\partial \hat{F}$ with negative values assigned to points interior to $\hat{F}$. Let $(\partial \hat{F})_\epsilon = \{(t, \hat{x}) : |\hat{\rho}(t, \hat{x})| < \epsilon\}$. Then for

each $R > 0$, there exists an $\epsilon_0 > 0$ such that $\hat{\rho}$ is C^1 in $(\partial\hat{F})_\epsilon \cap \{(t,\hat{x}) : |\hat{x}| < R\}$, and if $(\nu^0, \hat{\nu})$ is the unit normal to $\partial\hat{F}$ at $(\tau,\hat{\xi})$ pointing to the exterior of $\hat{F}$, then

$$\lim_{(t,\hat{x})\to(\tau,\hat{\xi})} (\hat{\rho}_t(t,\hat{x}), \hat{\rho}_{\hat{x}}(t,\hat{x})) = (\nu^0,\hat{\nu}) \quad \text{for all } (\tau,\hat{\xi}) \text{ in } (\partial\hat{F})_{\epsilon_0} \cap \{(t,\hat{x}) : |\hat{x}| < R\}.$$

Let $\hat{F}_\mu = \{(t,\hat{x}) : (t,\hat{x}) \in \hat{F},\ |\hat{\rho}(t,\hat{x})| < \mu\}$. Since either Assumption II or II′ holds for F, there exists a $\mu_0 > 0$ such that for all $0 < \mu < \mu_0$, $(\hat{F} - \hat{F}_\mu) \cap \{(t,\hat{x}) : |\hat{x}| < R\} \neq \emptyset$.

We now define as in [2] a family of games of fixed duration. Let $\gamma(r) = 1 - r$ if $0 \le r \le 1$ and let $\gamma(r) = 0$ if $r > 1$. For each $0 < \mu < \mu_0$ let

$$f^0_\mu(t,\hat{x},y,z) = \begin{cases} f^0(t,x,y,z)\gamma(|\hat{\rho}(t,\hat{x})|/\mu) & \text{if } (t,\hat{x}) \in \hat{F}, \\ f^0(t,x,y,z) & \text{if } (t,\hat{x}) \notin \hat{F}. \end{cases}$$

The function f^0_μ is continuous on $D \times (0,\mu_0)$, and $f^0_\mu(t,\hat{x},y,z) = 0$ if $(t,\hat{x}) \in \hat{F} - \hat{F}_\mu$. For each integer k such that $\epsilon_k = \frac{1}{k} < \mu_0$ we consider the game $\hat{G}_k(t_0,\hat{x}_0) = \hat{G}_{\epsilon_k}(t_0,\hat{x}_0)$ of fixed duration with terminal time T, with dynamics given by (1) and with payoff

$$x^0_0 + \int_{t_0}^{T} f^0_{\epsilon_k}(s,\hat{\phi}(s),y(s),z(s))ds.$$

From now on, we let $(t_0,x_0) \in \mathbb{R}^{n+1}$ be fixed and let $\hat{x}_0$ be $(0,x_0)$.

Let $\mathcal{X}$ be a compact subset of $\mathbb{R}^{n+2}$ containing $(t_0,\hat{x}_0)$ as an interior point. Berkovitz showed in [3, p. 496, (4.2); p. 497, (4.5)] that if k is sufficiently large, there exists a $c_0 > 0$ such that for all $(\tau,\hat{\xi}) \in \mathcal{X}$

$$\hat{W}^+(\tau,\hat{\xi}) \le \hat{W}^+(\tau,\hat{\xi},k) + \frac{c_0}{k}, \qquad \hat{W}^-(\tau,\hat{\xi}) \ge \hat{W}^-(\tau,\hat{\xi},k) - \frac{c_0}{k}, \tag{5}$$

where $\hat{W}^\pm(\tau,\hat{\xi},k)$ are the upper and lower values of $\hat{G}_k(\tau,\hat{\xi})$.

Since ∂F is $C^{(2)}$, $\partial\hat{F}$ is also $C^{(2)}$. It follows that if $\hat{\mathcal{B}}$ is a compact subset of $\partial\hat{F}$, then there exists an $\epsilon_0 > 0$ such that $\hat{\rho}$ is C^1 on $\mathcal{N}_{\epsilon_0}(\hat{\mathcal{B}})$, where $\mathcal{N}_{\epsilon_0}(\hat{\mathcal{B}})$ is the closed ϵ_0-neighborhood of $\hat{\mathcal{B}}$ in $\mathbb{R}^{n+2}$. Also, at points $(t_1,\hat{x}_1)$ of $\partial\hat{F}$, $(\hat{\rho}_t(t,\hat{x}), \hat{\rho}_{\hat{x}}(t,\hat{x})) \to (\nu^0,\hat{\nu})$ as $(t,\hat{x}) \notin \hat{F}$ tends to $(t_1,\hat{x}_1)$. Moreover, on compact subsets of $\partial\hat{F}$, the convergence is uniform. Therefore the following lemma follows from Lemma 1.

LEMMA 2. *If $\hat{\mathcal{B}}$ is a compact subset of $\partial\hat{F}$, there exist a $c > 0$ and an $\epsilon > 0$ such that for all $(t,\hat{x}) \in \mathcal{N}_\epsilon(\hat{\mathcal{B}})$, $\hat{\rho}_t(t,\hat{x}) + \langle \hat{\rho}_{\hat{x}}(t,\hat{x}), \hat{f}(t,\hat{x},y,z)\rangle \le -c$.*

LEMMA 3. *Let F_1 satisfy either Assumption* II *or* II′. *Let $(t_0,\hat{x}_{0n})$ be in $\mathcal{X}$ such that $\lim_{n\to\infty} \hat{x}_{0n} = \hat{x}_0$. Let $\{\hat{\phi}_n\}$ be a sequence of solutions of the differential equation*

$$\frac{d\hat{x}}{dt} = \hat{f}(t,\hat{x},u_n(t),v_n(t)), \qquad \hat{x}(t_0) = \hat{x}_{0n}, \quad t \in [t_0,T]$$

and let $\hat{\phi}[\cdot]$ be a motion resulting from $\{\hat{\phi}_n\}$. If t_{f_n}, t_f are the terminal times of $\hat{\phi}_n(\cdot)$ and $\hat{\phi}[\cdot]$, respectively, then $\lim_{n\to\infty} t_{f_n} = t_f$.

Proof. As in [2, Lem. 4.1], we have $t_f \le \liminf_{n\to\infty} t_{f_n}$.

We show by contradiction that any convergent subsequence of $\{t_{f_n}\}$ has limit t_f. Suppose there were a subsequence of $\{t_{f_n}\}$, still denoted as $\{t_{f_n}\}$, converging to a

limit greater than t_f, i.e., $\lim_n t_{f_n} > t_f$. Since each $t_{f_n} \le T$, $t_f < T$. Since $(t_0, \hat{x}_0)$ is in $\mathcal{X}$, there exists an $R > 0$ such that for any$\{\hat{\phi}_n(\cdot)\}$ and any motion $\hat{\phi}[\cdot]$ resulting from $\{\hat{\phi}_n\}$, $\{(t, \hat{\phi}_n(t))\}$, $(t, \hat{\phi}[t])$ will lie in $[t_0, T] \times \hat{B}_R$ for all $t \in [t_0, T]$, where $\hat{B}_R$ denotes the closed ball of radius R in $\mathbb{R}^{n+1}$. Hence $(t_f, \hat{\phi}[t_f])$, $\{(t_{f_n}, \hat{\phi}_n(t_{f_n}))\}$ will lie in $([t_0, T] \times \hat{B}_R) \cap \partial\hat{T}$. Let $\hat{\mathcal{B}}_R = ([t_0, T] \times \hat{B}_R) \cap \partial\hat{F}$. Then $\hat{\mathcal{B}}_R$ is a compact subset of $\partial\hat{F}$. The inequality $t_f < T$ implies that $(t_f, \hat{\phi}[t_f]) \in \hat{\mathcal{B}}_R$.

Let $\epsilon_0 = \epsilon_0(\hat{\mathcal{B}}_R)$, $c = c(\hat{\mathcal{B}}_R)$ be the constants in Lemma 2 associated with $\hat{\mathcal{B}}_R$. Since $\hat{\phi}_n(\cdot) \to \hat{\phi}[\cdot]$ uniformly on $[t_0, T]$, for any $\epsilon > 0$ with $\epsilon \le \epsilon_0$, there exists an integer $N_1 > 0$ such that if $n \ge N_1$

$$|\hat{\phi}_n(t) - \hat{\phi}[t]| < \epsilon \quad \text{for all } t \in [t_0, T]. \tag{6}$$

Therefore $(t_f, \hat{\phi}_n(t_f)) \in \mathcal{N}_\epsilon(\hat{\mathcal{B}}_R)$ if $n \ge N_1$.

Since $\lim t_{f_n} > t_f$, there exists $N_2 > 0$ such that if $n \ge N_2$, $t_{f_n} > t_f$. Let $N = \max(N_1, N_2)$. Let $\theta_n(t) = \hat{\rho}(t, \hat{\phi}_n(t))$, then

$$\frac{d\theta_n}{dt} = \hat{\rho}_t(t, \hat{\phi}_n(t)) + \langle \hat{\rho}_x(t, \hat{\phi}_n(t)), \hat{f}(t, \hat{\phi}_n(t), u_n(t), v_n(t)) \rangle. \tag{7}$$

If $(t, \hat{\phi}_n(t))$ stays in $\mathcal{N}_\epsilon(\hat{\mathcal{B}}_R)$, the right-hand side of the above equation is $\le -c$.

Since $(t_f, \hat{\phi}_n(t_f)) \in \mathcal{N}_\epsilon(\hat{\mathcal{B}}_R)$, it follows from the continuity of $\hat{\phi}_n$ that there exists a maximal interval $[t_f, t_f + \alpha_n)$ with $t_f + \alpha_n \le t_{f_n}$ such that if $t \in [t_f, t_f + \alpha_n)$, then $(t, \hat{\phi}_n(t)) \in \mathcal{N}_\epsilon(\hat{\mathcal{B}}_R)$ and $(t, \hat{\phi}_n(t)) \notin \hat{T}$. Note that $\alpha_n > 0$. For all $t \in [t_f, t_f + \alpha_n)$, (7) gives

$$\theta_n(t) - \theta_n(t_f) \le -c(t - t_f). \tag{8}$$

We claim that $t_f + \alpha_n = t_{f_n}$. Otherwise, we would have $\theta_n(t_f) < \epsilon$ and $\theta_n(t_f + \alpha_n) = \epsilon$. Then (8) would give that $0 < -c\alpha_n$, which is impossible. Therefore (8) holds for all $t \in [t_f, t_{f_n}]$.

If $t_{f_n} < T$, $\theta_n(t_{f_n}) = 0$. Then $(t_{f_n} - t_f) \le c^{-1}\theta_n(t_f) < \frac{\epsilon}{c}$ for $n \ge N$. If $t_{f_n} = T$, $\theta_n(T) \ge 0$. Then $(T - t_f) \le c^{-1}(\theta_n(t_f) - \theta_n(T)) \le c^{-1}\theta_n(t_f) < \frac{\epsilon}{c}$ for $n \ge N$.

In any case, we have $|t_{f_n} - t_f| < \frac{\epsilon}{c}$ if $n \ge N$. It follows that $\lim t_{f_n} = t_f$, which is a contradiction. Hence the lemma is proved. □

The proof of Lemma 3 gives the following result.

COROLLARY 4. *Suppose that F_1 satisfies either Assumption* II *or* II′. *Let ϵ_0 and c be determined by $\hat{\mathcal{B}}_R$ and let t_f be the terminal time of the trajectory $\hat{\phi}(t)$. Let $0 \le \epsilon \le \epsilon_0$ and let $\bar{t} < t_f$. If $(\bar{t}, \hat{\phi}(\bar{t})) \in \mathcal{N}_\epsilon(\hat{\mathcal{B}}_R)$, then $t_f - \bar{t} \le \frac{\epsilon}{c}$.*

COROLLARY 5. *Under either Assumption* II *or* II′, *once a trajectory or a motion gets into the terminal set, it can never get out.*

Proof. If the statement were false, then for some trajectory $\hat{\phi}(t, t_0, x_0, u, v)$ there would exist t_1 and t_2 with $t_1 < t_2$ such that

(1) $(t_1, \hat{\phi}(t_1)) \in \hat{T}$ and $(t_2, \hat{\phi}(t_2)) \notin \hat{T}$,

(2) $(t, \hat{\phi}(t)) \in \mathcal{N}_\epsilon(\hat{\mathcal{B}}_R)$ for $t_1 \le t \le t_2$.

Let $\theta(t) = \hat{\rho}(t, \hat{\phi}(t))$. From (8), we get that

$$\theta(t_2) - \theta(t_1) \le -c(t_2 - t_1)$$

or

$$\theta(t_2) \le -c(t_2 - t_1) + \theta(t_1).$$

Since $(t_1, \hat{\phi}(t_1)) \in \hat{T}$, $\theta(t_1) \leq 0$. So, $\theta(t_2) < 0$, which contradicts the assumption that $(t_2, \hat{\phi}(t_2)) \notin \hat{T}$. □

We assume that the following Isaacs condition holds. For all vectors $\hat{s} = (1, s)$ in $\mathbb{R}^{n+1}$ and any $(t, \hat{x}) \in [t_0, T] \times \mathbb{R}^{n+1}$

$$(\hat{I}) \qquad \max_y \min_z \langle \hat{s}, \hat{f}(t, x, y, z) \rangle = \min_z \max_y \langle \hat{s}, \hat{f}(t, x, y, z) \rangle,$$

where y ranges over the set Y and z ranges over the set Z.

Let v be any real number. Let

$$C^{(k)}(v) = \{(\tau, \hat{\xi}) : t_0 \leq \tau \leq T, \hat{\xi} \in \mathbb{R}^{n+1}, \hat{W}^-(\tau, \hat{\xi}, k) \leq v\}$$

and for any $\alpha > 0$, let

$$C_\alpha^{(k)}(v) = \{(\tau, \hat{\xi}) : t_0 \leq t \leq T, \hat{\xi} \in \mathbb{R}^{n+1}, \ \operatorname{dist}\big((\tau, \hat{\xi}), C^{(k)}(v)\big) \leq \alpha\}.$$

Let $\nu_k = \hat{W}^-(t_0, \hat{x}_0, k)$. Let V_k^ϵ be extremal to $C^{(k)}(\nu_k)$ and let $\Delta_k^\epsilon = \Delta_k^\epsilon(V_k^\epsilon)$ be the corresponding feedback strategy (see [1, p. 189]). Let Γ be any strategy for Player I and let $\hat{\phi}_k[\ , t_0, \hat{x}_0, \Gamma, \Delta_k^\epsilon]$ be any motion resulting from $(\Gamma, \Delta_k^\epsilon)$. Let $\{\hat{\phi}_{k,n}(\ , t_0, \hat{x}_0, u_{k,n}, v_{k,n})\}$ be a sequence of trajectories converging uniformly to $\hat{\phi}_k[\cdot]$ on $[t_0, T]$. Let t_f be the terminal time of $\hat{\phi}[\cdot]$ and let t_{f_n} be the terminal time of $\hat{\phi}_{k,n}(\cdot)$ (since the terminal time of $\hat{\phi}_{k,n}(\cdot)$ does not depend on k). Lemma 3 asserts that $t_{f_n} \to t_f$ as $n \to \infty$.

Since $\mathcal{X}$ is a compact subset of $\mathbb{R}^{n+2}$ containing $(t_0, \hat{x}_0)$ as its interior point, it follows from Assumption I that there exists $R > 0$ such that all of the trajectories $(t, \hat{\phi}(t))$ and motions $(t, \hat{\phi}[t])$ initiated from $\mathcal{X}$ will lie in $[t_0, T] \times \hat{\mathcal{B}}_R$ where $\hat{\mathcal{B}}_R = \{\hat{x} \in \mathbb{R}^{n+1} : \ |\hat{x}| \leq R\}$. Let $\mathcal{D} = \{(\tau, \hat{\xi}) : \ \tau \in [t_0, T], \ |\xi| \leq R\}$. Let

$$(9) \qquad M = \max_{\substack{(t,\hat{x}) \in \mathcal{D} \\ y \in Y, z \in Z}} |\hat{f}(t, x, y, z)|.$$

LEMMA 6. *Let Assumption* I *and either Assumption* II *or* II′ *hold and let the Isaacs condition* $(\hat{I})$ *hold for* $\hat{f}$. *Then there exist a nonnegative nondecreasing function* α *and a* k_0 *such that* $\alpha(\delta) \to 0$ *as* $\delta \to 0$ *and for* $n \geq k_0$

$$(10) \qquad (t, \hat{\phi}_{k,n}(t, t_0, \hat{x}_0, u_{k,n}, v_{k,n})) \in C^{(k)}_{(((M+1)/c)+1)^2\alpha(1/n)}(\nu_k)$$

for all $t_0 \leq t \leq t_{f_n}$ *and all* k.

Proof. Let $\hat{\mathcal{B}}_R$ be defined as in the proof of Lemma 3. Then $\hat{\mathcal{B}}_R$ is compact in $\partial \hat{F}$. Let $\epsilon = \epsilon(\hat{\mathcal{B}}_R) > 0$, $c = c(\hat{\mathcal{B}}_R) > 0$ be the constants determined as in Lemma 2.

If $\hat{\phi}_{k,n}(\cdot)$ never leaves $C^{(k)}(\nu_k)$, (10) certainly holds. Assume that $t_1 \in (t_0, T]$ is the first time at which $\hat{\phi}_{k,n}(\cdot)$ leaves $C^{(k)}(\nu_k)$. Let

$$\Pi(\Delta_{k,n}^\epsilon) : \ t_0 = \tau_0 < \tau_1 < \cdots < \tau_{j_0} \leq t_1 < \tau_{j_0+1} < \cdots < \tau_{p_{\Delta_{k,n}^\epsilon}} = T$$

be the nth partition of Δ_k^ϵ. Note that $t_1 \in [\tau_{j_0}, \tau_{j_0+1})$.

Consider $t \in [t_0, t_{f_n}]$ and suppose that $t \in [\tau_j, \tau_{j+1}]$ with $j \geq j_0 + 1$. Let $\hat{x}^* = \hat{\phi}_{k,n}(\tau_j)$, let $t^* = \tau_j$, and let $\hat{w}^*$ be the point in $C^{(k)}(\nu_k) \cap H(\tau_j)$ in the definition of

$V_k^e(t^*, \hat{x}^*) = V_k^e(\tau_j, \hat{\phi}_{k,n}(\tau_j))$. Let $\hat{s}^* = \hat{x}^* - \hat{w}^*$ and let y^* be any point in Y such that (y^*, z^*) is a saddle point for the local game $(t^*, \hat{x}^*, \hat{s}^*) = (\tau_j, \hat{\phi}_{k,n}(\tau_j), \hat{s}^*)$ with payoff $\langle \hat{s}^*, \hat{f}_k(t^*, \hat{x}^*, y, z)\rangle$.

Case 1. Assume $(t^*, \hat{w}^*) \notin \hat{\mathcal{T}}$. By [1, Lem. 8.3], for each $t > \tau_j$, there exists a relaxed control ζ_t such that the corresponding relaxed trajectory $\hat{\psi}_k(\cdot) = \hat{\psi}_k(\cdot, \tau_j, \hat{w}^*, u_{k,n}, \zeta_t)$ has the property that

$$(t, \hat{\psi}_k(t, \tau_j, \hat{w}^*, u_{k,n}, \zeta_t) \in C^{(k)}(\nu_k). \tag{11}$$

Let $e_{k,n}(t)$ denote the distance from $(t, \hat{\phi}_{k,n}(t, t_0, \hat{x}_0, u_{k,n}, v_{k,n})$ to $C^{(k)}(\nu_k)$. Since $\hat{\phi}_{k,n}(s, t_0, \hat{x}_0, u_{k,n}, v_{k,n}) = \hat{\phi}_{k,n}(s, \tau_j, \hat{\phi}_{k,n}(\tau_j), u_{k,n}, v_{k,n})$ for $s > \tau_j$, we have that

$$e_{k,n}(t) \le |\hat{\phi}_{k,n}(t, \tau_j, \hat{\phi}_{k,n}(\tau_j), u_{k,n}, v_{k,n}) - \hat{\psi}_k(t, \tau_j, \hat{w}^*, u_{k,n}, \zeta_t)|.$$

Case 1(a). If $(t, \hat{\psi}_k(t, \tau_j, \hat{w}^*, u_{k,n}, \zeta_t)) \notin \hat{\mathcal{T}}$, then by Corollary 5, for all $\tau_j \le s \le t$, $(s, \hat{\psi}_k(s, \tau_j, \hat{w}^*, u_{k,n}, \zeta_t)) \notin \hat{\mathcal{T}}$. Since $\hat{\psi}_k$ is the solution of $dx/ds = f(s, x, u_{k,n}, \zeta_t)$ for $\tau_j \le s \le t$, following the argument given in [1, p. 191] we get that for n sufficiently large

$$e_{k,n}^2(t) \le e_{k,n}^2(\tau_{j_0+1}) e^{\beta K} + E(\delta_n)(e^{\beta K} - 1)/\beta \quad \text{for } \tau_{j_0+1} \le t, \tag{12}$$

where K is the Lipschitz constant of $\hat{f}$, β is $2K$, L is a constant such that $\|\Pi_n\| = \delta_n \le L/n$, and $E(\cdot)$ is a nondecreasing function defined on $[0, \infty)$ such that $E(\delta) \to 0$ as $\delta \to 0$. Since $e_{k,n}(t_1) = 0$, we get that $e_{k,n}(\tau_{j_0+1}) \le ML/n$. Let $\alpha(\cdot)$ be a nondecreasing function defined on $[0, \infty)$ such that

$$\Big(\frac{ML}{n}\Big)^2 e^{\beta K} + E\Big(\frac{L}{n}\Big)(e^{\beta K} - 1)/\beta \le \alpha^2\Big(\frac{1}{n}\Big)$$

and such that $\alpha(\delta) \to 0$ as $\delta \to 0$. Then (12) gives that $e_{k,n}(t) \le \alpha(1/n)$, and hence

$$(t, \hat{\phi}_{k,n}(t, t_0, \hat{x}_0, u_{k.n}, v_{k,n})) \in C^{(k)}_{\alpha(1/n)}(\nu_k) \subset C^{(k)}_{(((M+1)/c)+1)^2\alpha(1/n)}(\nu_k).$$

Case 1(b). If for some $t \in [\tau_j, \tau_{j+1})$ every relaxed control ζ_t with the property (11) satisfies

$$(t, \hat{\psi}_k(t, \tau_j, \hat{w}^*, u_{k,n}, \zeta_t)) \in \hat{\mathcal{T}},$$

then let t_{f_ψ} be the infimum of such t. Hence for any $t \in [t_0, t_{f_\psi})$, the argument in Case 1(a) implies that

$$(t, \hat{\phi}_{k,n}(t)) \in C^{(k)}_{\alpha(1/n)}(\nu_k).$$

The continuity of $\hat{\phi}_{k,n}$ and the closedness of $C^{(k)}_{\alpha(1/n)}(\nu_k)$ imply that the preceding inclusion holds for all $t \in [t_0, t_{f_\psi}]$.

If $t_{f_n} \le t_{f_\psi}$, we are done with Case 1(b), and hence Case 1. If not, we claim that $(t_{f_\psi}, \hat{\phi}_{k,n}(t_{f_\psi})) \in \mathcal{N}_{\alpha(1/n)}(\hat{\mathcal{B}}_R)$. In fact, for any small $\delta > 0$, there exist t_δ^+ and t_δ^- such that $|t_{f_\psi} - t_\delta^\pm| \le \delta$ and a relaxed control $\zeta_{t_\delta^-}$ such that

$$(t_\delta^-, \hat{\psi}_k(t_\delta^-, \tau_j, \hat{w}^*, u_{k,n}, \zeta_{t_\delta^-})) \in C^{(k)}(\nu_k),$$

$$(t_\delta^-, \hat{\psi}_k(t_\delta^-, \tau_j, \hat{w}^*, u_{k,n}, \zeta_{t_\delta^-})) \notin \hat{T},$$

and

$$(t_\delta^+, \hat{\psi}_k(t_\delta^+, \tau_j, \hat{w}^*, u_{k,n}, \zeta_{t_\delta^-})) \in \hat{T}.$$

Therefore, we get

$$\begin{aligned}
&|(t_{f_\psi}, \hat{\phi}_{k,n}(t_{f_\psi}, \tau_j, \hat{\phi}_{k,n}(\tau_j), u_{k,n}, v_{k,n})) - (t_\delta^+, \hat{\psi}_k(t_\delta^+, \tau_j, \hat{w}^*, u_{k,n}, \zeta_{t_\delta^-}))| \\
&\le |t_{f_\psi} - t_\delta^+| + |\hat{\phi}_{k,n}(t_{f_\psi}) - \hat{\phi}_{k,n}(t_\delta^-)| + |\hat{\phi}_{k,n}(t_\delta^-) - \hat{\psi}_k(t_\delta^-)| \\
&\qquad + |\hat{\psi}_k(t_\delta^-) - \hat{\psi}_k(t_\delta^+)| \\
&\le \delta + M\delta + \alpha\Big(\frac{1}{n}\Big) + 2M\delta \\
&= (1 + 3M)\delta + \alpha\Big(\frac{1}{n}\Big).
\end{aligned}$$

The arbitrariness of δ implies the claim.

By Corollary 4, we get that $t_{f_n} - t_{f_\psi} \le \frac{1}{c}\alpha(1/n)$. This gives that for $t \in [t_{f_\psi}, t_{f_n}]$

$$\begin{aligned}
e_{k,n}(t) &\le |(t, \hat{\phi}_{k,n}(t)) - (t_{f_\psi}, \hat{\phi}_{k,n}(t_{f_\psi}))| + e_{k,n}(t_{f_\psi}) \\
&\le |t - t_{f_\psi}| + |\hat{\phi}_{k,n}(t) - \hat{\phi}_{k,n}(t_{f_\psi})| + e_{k,n}(t_{f_\psi}) \\
&\le \frac{1}{c}\alpha\Big(\frac{1}{n}\Big) + M\frac{1}{c}\alpha\Big(\frac{1}{n}\Big) + \alpha\Big(\frac{1}{n}\Big) \\
&= \Big(\frac{M+1}{c} + 1\Big)\alpha\Big(\frac{1}{n}\Big).
\end{aligned}$$

Hence (10) holds.

Case 2. Assume that $(t^*, \hat{w}^*) \in \hat{T}$ for some $j \ge j_0 + 1$. Let t^* be the first partition point such that $(t^*, \hat{w}^*) \in \hat{T}$. Then Case 1 says that for $t_0 \le t \le t^*$, $e_{k,n}(t) \le (((M+1)/c) + 1)\alpha(1/n)$. Hence $(t^*, \hat{\phi}_{k,n}(t^*)) \in \mathcal{N}_{(((M+1)/c)+1)\alpha(1/n)}(\hat{\mathcal{B}}_R)$. Corollary 4 says if n is large enough, $t_{f_n} - t^* \le \frac{1}{c}(((M+1)/c) + 1)\alpha(1/n)$. Therefore, for $t \in [t^*, t_{f_n}]$

$$\begin{aligned}
e_{k,n}(t) &\le |(t, \hat{\phi}_{k,n}(t)) - (t^*, \hat{\phi}_{k,n}(t^*))| + e_{k,n}(t^*) \\
&\le |t - t^*| + |\hat{\phi}_{k,n}(t) - \hat{\phi}_{k,n}(t^*)| + e_{k,n}(t^*) \\
&\le \frac{1}{c}\Big(\frac{M+1}{c} + 1\Big)\alpha\Big(\frac{1}{n}\Big) + \frac{M}{c}\Big(\frac{M+1}{c} + 1\Big)\alpha\Big(\frac{1}{n}\Big) + \Big(\frac{M+1}{c} + 1\Big)\alpha\Big(\frac{1}{n}\Big) \\
&= \Big(\frac{M+1}{c} + 1\Big)^2\alpha\Big(\frac{1}{n}\Big).
\end{aligned}$$

Hence, (10) holds. □

THEOREM 7. *If Assumption* I *and either Assumption* II *or* II′ *hold and if Isaacs condition* $(\hat{I})$ *holds for* $\hat{f}$, *then there exists a strategy* Δ^* *for Player* II *such that for any strategy* Γ *for Player* I

$$P(t_0, x_0, \Gamma, \Delta^*) \le W(t_0, x_0).$$

Proof. First, note that under the assumptions of the theorem, we have $\hat{W}(\tau, \hat{\xi}, k) = \hat{W}^{\pm}(\tau, \hat{\xi}, k)$, $W(t_0, x_0) = W^{\pm}(t_0, x_0)$, and $\hat{W}(\tau, \hat{\xi}) = \hat{W}^{\pm}(\tau, \hat{\xi})$. Therefore, the following is true from (5):

$$\hat{W}(\tau, \hat{\xi}, k) - \frac{c_0}{k} \le \hat{W}(\tau, \hat{\xi}) \le \hat{W}(\tau, \hat{\xi}, k) + \frac{c_0}{k}.$$

Note also that $\hat{W}(t_0, \hat{x}_0) = W(t_0, x_0)$ since $\hat{x}_0 = (0, x_0)$.

Let Γ be a strategy for Player I. If $\Delta_k^e = \{\Delta_{k,n}^e\}$, let $\Delta^* = \{\Delta_{k,k}^e\}$. Let $\hat{\phi}[\ , t_0, \hat{x}_0, \Gamma, \Delta^*]$ be a motion and assume that $\{\hat{\phi}_k(t, t_0, \hat{x}_0, u_k, v_k)\}$ is a sequence of kth stage trajectories converging uniformly to $\hat{\phi}[\cdot]$.

Let t_f be the terminal time of $\hat{\phi}[\cdot]$ and let t_{f_k} be the terminal time of $\hat{\phi}_k(\cdot)$. Then by Lemma 3, $t_f = \lim_{k\to\infty} t_{f_k}$.

It follows from Lemma 6 that $(t_{f_k}, \hat{\phi}_k(t_{f_k})) \in C_{(((M+1)/c)+1)^2\alpha(1/k)}(\nu_k)$ for k sufficiently large. Since

$$\hat{W}(t_0, \hat{x}_0, k) \le \hat{W}(t_0, \hat{x}_0) + \frac{c_0}{k} = W(t_0, x_0) + \frac{c_0}{k} \quad \text{and} \quad \nu_k = \hat{W}(t_0, \hat{x}_0, k),$$

$$(t_{f_k}, \hat{\phi}_k(t_{f_k})) \in C_{(((M+1)/c)+1)^2\alpha(1/k)}\left(W(t_0, x_0) + \frac{c_0}{k}\right). \tag{13}$$

If we let

$$C = \bigcap_{k=1}^{\infty} C_{\left(((M+1)/c)+1\right)^2\alpha(1/k)}\left(W(t_0, x_0) + \frac{c_0}{k}\right),$$

then C is closed. Since $\{C_{(((M+1)/c)+1)^2\alpha(1/k)}\ (W(t_0, x_0) + c_0/k)\}$ is a sequence of decreasing sets, it follows from (13) that $(t_f, \hat{\phi}[t_f]) \in C$.

Let $C' = \{(\tau, \hat{\xi}) :\ t_0 \le \tau \le T, \hat{\xi} \in \mathbb{R}^{n+1}, \hat{W}(\tau, \hat{\xi}) \le \hat{W}(t_0, \hat{x}_0)\}$. We claim that $C = C'$.

If the claim is true, then we have $(t_f, \hat{\phi}[t_f]) \in C'$, i.e., $\phi^0[t_f] = \phi^0[t_f, t_0, x_0, \Gamma, \Delta^*] \le W(t_0, x_0)$. Hence, we have $P(t_0, x_0, \Gamma, \Delta^*) \le W(t_0, x_0)$ for any Γ.

Now, let us prove the claim. Assume that $(\tau, \hat{\xi}) \in C'$, so $\hat{W}(\tau, \hat{\xi}) \le \hat{W}(t_0, \hat{x}_0) = W(t_0, x_0)$. Then $\hat{W}(\tau, \hat{\xi}, k) \le \hat{W}(\tau, \hat{\xi}) + c_0/k \le W(t_0, x_0) + c_0/k$ for any k. Hence $(\tau, \hat{\xi}) \in C$, and we get $C' \subset C$. If $(\tau, \hat{\xi}) \in C$, $(\tau, \hat{\xi}) \in C_{(((M+1)/c)+1)^2\alpha(1/k)}(W(t_0, x_0) + c_0/k)$ for any k. Therefore, there exists $(\tau_k, \hat{\xi}_k) \in C(W(t_0, x_0) + c_0/k)$ such that $|(\tau_k, \hat{\xi}_k) - (\tau, \hat{\xi})| \le \left(((M+1)/c) + 1\right)^2\alpha(1/k)$. Hence, we have that

$$\hat{W}(\tau_k, \hat{\xi}_k) \le \hat{W}(\tau_k, \hat{\xi}_k, k) + \frac{c_0}{k} \le W(t_0, x_0) + \frac{2c_0}{k}. \tag{14}$$

Since $\hat{W}(t, \hat{x})$ is continuous [2] and since $\lim_{k\to\infty}(\tau_k, \hat{\xi}_k) = (\tau, \hat{\xi})$, it follows from (14) that $\hat{W}(\tau, \hat{\xi}) \le W(t_0, x_0)$, i.e., $(\tau, \hat{\xi}) \in C'$ and hence $C \subset C'$. This completes the proof of Theorem 7. □

Similarly, we can show using (5) that if Assumption I and either Assumption II or II′ hold and if Isaacs condition $(\hat{I})$ holds for $\hat{f}$, there exists a strategy Γ^* for Player I such that $W(t_0, x_0) \le P(t_0, x_0, \Gamma^*, \Delta)$ for any Δ. Then, clearly, (Γ^*, Δ^*) constitutes a saddle point in the game.

2. Differential games with information lags. In this section, we first study games of fixed duration with lags and then study games of generalized pursuit and evasion with lags and games of survival with lags.

2.1. Differential games of fixed duration with lags. Our game is governed by (1) with payoff

$$P(t_0, x_0, \Gamma, \Delta) = g(\phi[T]) = g(\phi[T, t_0, x_0, \Gamma, \Delta]) \tag{15}$$

where Γ is a strategy selected by Player I prior to the start of play, Δ is a strategy selected by Player II prior to the start of play, and $\phi[\cdot, t_0, x_0, \Gamma, \Delta]$ is a motion corresponding to (Γ, Δ). The concepts of strategy and motion for games with lags will be given later.

Let Player I and Player II have lags $\lambda \geq 0$ and $\mu \geq 0$, respectively. Let Y be a compact subset of $\mathbb{R}^r$ and let Z be a compact subset of $\mathbb{R}^s$. Let $t_0 < T$ and let $D = [t_0, T] \times \mathbb{R}^n \times Y \times Z$.

ASSUMPTION I′. *Assumption* I *in* §1 *holds with* $\hat{f}$ *replaced by* f *and the function* g *is continuous on* $\mathbb{R}^n$.

If Assumption I′ holds and if the Isaacs condition holds for f on $[t_0, T] \times \mathbb{R}^n$, i.e., for all vector s in $\mathbb{R}^n$

$$\max_{y \in Y} \min_{z \in Z} \langle s, f(t, x, y, z) \rangle = \min_{z \in Z} \max_{y \in Y} \langle s, f(t, x, y, z) \rangle$$

then from [1] we know that a game of fixed duration with initial condition (t_0, x_0) and payoff (15) has a value. We will denote the value by $W(t_0, x_0)$. Moreover, there exists a pair of strategies (Γ^*, Δ^*) such that $W(t_0, x_0) = g(\Phi[T, t_0, x_0, \Gamma^*, \Delta^*])$.

For $\sigma > 0$, let $Y_{[t,t+\sigma)}$ denote the set of all measurable functions u defined on $[t, t+\sigma)$ and satisfying $u(t) \in Y$ almost everywhere, and let $Z_{[t,t+\sigma)}$ denote the set of all measurable functions v defined on $[t, t+\sigma)$ and satisfying $v(t) \in Z$ almost everywhere. Such functions will be called control functions or controls.

A strategy Γ^λ for Player I is a choice of a sequence $\Pi = \{\Pi_n\}$ of partitions of $[t_0, T]$ and a choice of a sequence of maps $\Gamma^\lambda_\Pi = \{\Gamma^\lambda_{\Pi,n}\}$, where the $\Gamma^\lambda_{\Pi,n}$ will be defined below. Thus $\Gamma^\lambda = (\Gamma^\lambda_\Pi, \Pi)$. For simplicity, we write Γ^λ forΓ^λ_Π and Γ^λ_n for $\Gamma^\lambda_{\Pi,n}$. We restrict the choice of sequences of partitions to those such that the norm of Π_n, denoted by $\|\Pi_n\|$, satisfies $\|\Pi_n\| \leq L/n$, where L is a constant independent of n. Let the partition points of Π_n be $t_0 < t_1 < \cdots < t_p = T$, where $p \leq L_1 n$ and L_1 is a constant independent of n and $LL_1 > 1$. Each map Γ^λ_n is a collection of maps $\Gamma^\lambda_{n,1}, \ldots, \Gamma^\lambda_{n,p}$ as follows. The map $\Gamma^\lambda_{n,1}$ selects an element in $Y_{[t_0,t_1)}$. For $2 \leq j \leq p$, the map $\Gamma^\lambda_{n,j}$ is a map from $Y_{[t_0,t_{j-1})} \times Z_{[t_0,t_{j-1}-\lambda)}$ to $Y_{[t_{j-1},t_j)}$. If $t_{j-1} - \lambda < t_0$, we replace $Y_{[t_0,t_{j-1})} \times Z_{[t_0,t_{j-1}-\lambda)}$ by $Y_{[t_0,t_{j-1})}$.

A strategy Δ^μ for Player II is a choice of sequence of partitions $\bar{\Pi} = \{\bar{\Pi}_n\}$ of $[t_0, T]$ such that $\|\bar{\Pi}_n\| \leq L/n$ and a choice of sequence of maps $\{\Delta^\mu_n\}$. Each Δ^μ_n is a collection of maps $\Delta^\mu_{n,1}, \ldots, \Delta^\mu_{n,q}$ with $q \leq nL_1$, as follows. If $\bar{\Pi}_n$ has partition points $t_0 = s_0 < s_1 < \cdots < s_q = T$, then $\Delta^\mu_{n,1}$ selects a function v in $Z_{[s_0,s_1)}$. For $2 \leq j \leq q$, $\Delta^\mu_{n,j}$ is a map from $Y_{[s_0,s_{j-1}-\mu)} \times Z_{[s_0,s_{j-1})}$ to $Z_{[s_{j-1},s_j)}$. If for some j, $s_{j-1} - \mu < s_0$, replace $Y_{[s_0,s_{j-1}-\mu)} \times Z_{[s_0,s_{j-1})}$ by $Z_{[s_0,s_{j-1})}$ in the definition of $\Delta^\mu_{n,j}$.

A pair of nth stage strategies $(\Gamma^\lambda_n, \Delta^\mu_n)$ determines control functions (u_n, v_n) on $[t_0, T]$, where

$$\begin{aligned}
u_n(t) &= (\Gamma^\lambda_{n,1})(t), && t \in [t_0, t_1), \\
v_n(t) &= (\Delta^\mu_{n,1})(t), && t \in [s_0, s_1), \\
u_n(t) &= (\Gamma^\lambda_{n,j})(u_{[t_0,t_{j-1})}, v_{[t_0,t_{j-1}-\lambda)})(t), && t \in [t_{j-1}, t_j), \quad j = 2, \ldots, p, \\
v_n(t) &= (\Delta^\mu_{n,j})(u_{[s_0,s_{j-1}-\mu)}, v_{[s_0,s_{j-1})})(t), && t \in [s_{j-1}, s_j), \quad j = 2, \ldots, q.
\end{aligned}$$

The control functions (u_n, v_n) determined this way are called the nth stage outcomes of $(\Gamma^\lambda, \Delta^\mu)$.

In differential equations (1), if we replace y by $u_n(t)$, z by $v_n(t)$, and x_0 by x_{0n}, we obtain the system of differential equations

$$\frac{dx}{dt} = f(t, x, u_n(t), v_n(t)),$$
$$x(t_0) = x_{0n}.$$

The unique solution $\phi_n(\ , t_0, x_{0n}, u_n, v_n)$ defined on $[t_0, T]$ is called an nth stage trajectory.

Any uniform limit of a convergent subsequence of $\{\phi_n(\ , t_0, x_{0n}, u_n, v_n)\}$ where $x_{0n} \to x_0$ and (u_n, v_n) is the outcome of $(\Gamma_n^\lambda, \Delta_n^\mu)$, will be called a motion or motion of the game corresponding to strategies $(\Gamma^\lambda, \Delta^\mu)$. We denote a motion corresponding to $(\Gamma^\lambda, \Delta^\mu)$ by $\phi[\ , t_0, x_0, \Gamma^\lambda, \Delta^\mu]$. Under Assumption I′, there do exist motions. We denote the set of all motions corresponding to $(\Gamma^\lambda, \Delta^\mu)$ by $\Phi[\ , t_0, x_0, \Gamma^\lambda, \Delta^\mu]$.

In a game of fixed duration with initial point (t_0, x_0), $P(t_0, x_0, \Gamma^\lambda, \Delta^\mu)$, the payoff corresponding to a pair of strategies $(\Gamma^\lambda, \Delta^\mu)$, is then set valued and is defined as follows:

$$P(t_0, x_0, \Gamma^\lambda, \Delta^\mu) = g(\Phi[T, t_0, x_0, \Gamma^\lambda, \Delta^\mu]).$$

We denote this game as $G_{\lambda,\mu}(t_0, x_0)$, and hence games with no lags will be written as $G_{0,0}(t_0, x_0) = G(t_0, x_0)$. Let $W^-_{\lambda,\mu}(t_0, x_0) = \sup \inf_{\Gamma^\lambda \Delta^\mu} P(t_0, x_0, \Gamma^\lambda, \Delta^\mu)$ and let $W^+_{\lambda,\mu}(t_0, x_0) = \inf \sup_{\Gamma^\lambda \Delta^\mu} P(t_0, x_0, \Gamma^\lambda, \Delta^\mu)$. Then $W^-_{\lambda,\mu}(t_0, x_0) \le W^+_{\lambda,\mu}(t_0, x_0)$.

Now we want to construct an example in which value does not exist. Consider the following problem

$$\frac{dx}{dt} = u + v \qquad 0 < t \le 1,$$
$$x(0) = 0$$

with $|u|, |v| \le 1$. The payoff function is $g(x(1)) = x^2(1)$. We assume that $0 \le \lambda \le 1$ and $0 < \mu \le 1$.

First, we shall show that $W^-_{\lambda,\mu}(0, 0) = 0$. Fix a strategy Γ^λ for Player I. We want to find a strategy $\Delta^\mu(\Gamma^\lambda)$ for Player II such that $g(\Phi[1, \Gamma^\lambda, \Delta^\mu(\Gamma^\lambda)]) = 0$. Let $\Gamma^\lambda = (\Gamma_n^\lambda)$, where $\Pi_n(\Gamma^\lambda)$ is given by $0 = \tau_0 < \tau_1 < \cdots < \tau_{p_n} = 1$. Let $\Pi_n(\Delta^\mu) = \Pi_n(\Gamma^\lambda)$. Let (u_n, v_n) be the nth outcome of $(\Gamma^\lambda, \Delta^\mu)$. If $\Gamma^\lambda_{n,1} = u_n|_{[\tau_0, \tau_1)}$, define

$$\Delta^\mu_{n,1} = -u_n|_{[\tau_0, \tau_1)} = v_n|_{[\tau_0, \tau_1)}.$$

If $\Gamma^\lambda_{n,2}(u_n|_{[\tau_0, \tau_1)}, v_n|_{[\tau_0, \tau_1 - \lambda)}) = u_n|_{[\tau_1, \tau_2)}$, define

$$\Delta^\mu_{n,2}(u|_{[\tau_0, \tau_1 - \mu)}, v|_{[\tau_0, \tau_1)}) = -u_n|_{[\tau_1, \tau_2)} = v_n|_{[\tau_1, \tau_2)}.$$

In general, if $\Gamma^\lambda_{n,i}(u_n|_{[\tau_0, \tau_{i-1})}, v_n|_{[\tau_0, \tau_{i-1} - \lambda)}) = u_n|_{[\tau_{i-1}, \tau_i)}$, then we define

$$\Delta^\mu_{n,i}(u|_{[\tau_0, \tau_{i-1} - \mu)}, v|_{[\tau_0, \tau_{i-1})}) = -u_n|_{[\tau_{i-1}, \tau_i)} = v_n|_{[\tau_{i-1}, \tau_i)}.$$

Therefore, we have $u_n(t) = -v_n(t)$. This gives us $\phi_n(1) = 0$. Hence, for every Γ^λ, $\Phi[1, \Gamma^\lambda, \Delta^\mu(\Gamma^\lambda)] = 0$, and this leads to $W^-_{\lambda,\mu}(0, 0) \le 0$. Since $g(x(1)) \ge 0$, we have $W^-_{\lambda,\mu}(0, 0) = 0$.

Now, we want to show that the upper value of the game $G_{\lambda,\mu}(0,0)$ is not less than $\frac{1}{4}\mu^2$. Fix any strategy Δ^μ for Player II. Let the partition points of Δ^μ be given by

$$\Pi_n(\Delta^\mu): \quad 0=\tau_0<\tau_1<\cdots<\tau_{n_0-1}\le\mu<\tau_{n_0}<\tau_{n_0+1}<\cdots<\tau_{p_n}=1.$$

Let $\Gamma^\lambda(\Delta^\mu)$ be a strategy for Player I depending on Δ^μ defined as follows. First $\Pi_n(\Gamma^\lambda(\Delta^\mu))=\Pi_n(\Delta^\mu)$. Let $v_n|_{[\tau_0,\tau_{n_0})}$ be the control function of Player II determined by Δ_n^μ.

Let $E(v_n|_{[\tau_0,\tau_{n_0})}\ge 0)$ denote the Lebesgue measure of the set $\{t\in[\tau_0,\tau_{n_0}): v_n|_{[\tau_0,\tau_{n_0})}(t)\ge 0\}$.

Case 1. If $E(v_n|_{[\tau_0,\tau_{n_0})}\ge 0)\ge\frac{1}{2}\tau_{n_0}$, then let $\Gamma_n^\lambda(\Delta^\mu)$ be the constant strategy corresponding to $u(t)\equiv 1$. Therefore, $\phi_n(1)=\int_0^1(u_n+v_n)\,d\tau\ge\int_{E(v_n|_{[\tau_0,\tau_{n_0})}\ge 0)}d\tau\ge\frac{1}{2}\tau_{n_0}\ge\mu/2$.

Case 2. If $E(v_n|_{[\tau_0,\tau_{n_0})}<0)\ge\frac{1}{2}\tau_{n_0}$, then let $\Gamma_n^\lambda(\Delta^\mu)$ be the constant strategy corresponding to $u(t)\equiv -1$. Therefore, $\phi_n(1)=\int_0^1(u_n+v_n)\,d\tau\le-\int_{E(v_n|_{[\tau_0,\tau_{n_0})}<0)}d\tau\le-\frac{1}{2}\tau_{n_0}\le-\mu/2$.

So in any case, we have for any n, $|\phi_n(1)|\ge\frac{1}{2}\tau_{n_0}$. By the definition of motion, we get $|\Phi(1)|\ge\frac{1}{2}\mu$. So we have $g(\Phi[1,\Gamma^\lambda(\Delta^\mu),\Delta^\mu])\ge\frac{1}{4}\mu^2$, for any Δ^μ. This gives us $W^+_{\lambda,\mu}(0,0)\ge\frac{1}{4}\mu^2$. Since $W^-_{\lambda,\mu}(0,0)=0<\frac{1}{4}\mu^2\le W^+_{\lambda,\mu}(0,0)$ if $\mu>0$, value does not exist.

Now, let us study the properties of upper and lower values as functions of the lags.

LEMMA 8. *Suppose that f and g satisfy Assumption* I′ *and that the Isaacs condition holds for f on $[t_0,T]\times\mathbb{R}^n$. Then*

$$W^-_{\lambda,0}(t_0,x_0)\le W^+_{\lambda,0}(t_0,x_0)\le W(t_0,x_0)\le W^-_{0,\mu}(t_0,x_0)\le W^+_{0,\mu}(t_0,x_0), \qquad \text{if } \lambda,\mu\ge 0,$$
$$W^-_{\lambda,0}(t_0,x_0)\le W^-_{\lambda,\mu}(t_0,x_0)\le W^+_{\lambda,\mu}(t_0,x_0)\le W^+_{0,\mu}(t_0,x_0), \qquad \text{if } \lambda,\mu\ge 0.$$

Proof. We only show that $W^+_{\lambda,0}(t_0,x_0)\le W(t_0,x_0)$. The others either are obvious or can be shown in the same way.

Let Γ^λ be a strategy for Player I for the game $G_{\lambda,0}(t_0,x_0)$. We will define a strategy Γ^0 of Player I for the game $G(t_0,x_0)$ corresponding to Γ^λ as follows. If

$$\Pi_n: \ t_0=\tau_0<\tau_1<\cdots<\tau_{p_n}=T$$

is the nth partition of $\Gamma^\lambda=\{\Gamma_n^\lambda\}$, let Π_n be the nth partition associated with Γ_n^0. Define

$$\Gamma^0_{n,1}(t)=\Gamma^\lambda_{n,1}(t) \qquad \text{for } t\in[\tau_0,\tau_1),$$
$$\Gamma^0_{n,2}(Y|_{[\tau_0,\tau_1)},Z|_{[\tau_0,\tau_1)})=\Gamma^\lambda_{n,2}(Y|_{[\tau_0,\tau_1)},Z|_{[\tau_0,\tau_1-\lambda)}) \qquad \text{for } t\in[\tau_1,\tau_2).$$

Note that if $\tau_1-\lambda<\tau_0$, then $\Gamma^\lambda_{n,2}(Y|_{[\tau_0,\tau_1)},Z|_{[\tau_0,\tau_1-\lambda)})=\Gamma^\lambda_{n,2}(Y|_{[\tau_0,\tau_1)})$. Similarly, we can define $\Gamma^0_{n,i}$ for $i\le 2\le p_n$. Let S denote the mapping just defined from the set of all possible Γ^λ into the set of all possible Γ^0, i.e., $S(\Gamma^\lambda)=\Gamma^0$. The mapping is one to one, but need not be onto. Notice that for any $(\Gamma^\lambda,\Delta^0)$, the nth stage outcome of $(\Gamma^\lambda,\Delta^0)$ equals the nth stage outcome of $(S(\Gamma^\lambda),\Delta^0)$. Therefore $\Phi[\,,t_0,x_0,\Gamma^\lambda,\Delta^0]=$

$\Phi[\,, t_0, x_0, S(\Gamma^\lambda), \Delta^0]$. Hence $g(\Phi[T, t_0, x_0, \Gamma^\lambda, \Delta^0]) = g(\Phi[T, t_0, x_0, S(\Gamma^\lambda), \Delta^0])$ for any $(\Gamma^\lambda, \Delta^0)$, which implies that for any fixed Δ^0,

$$\{g(\Phi[T, t_0, x_0, \Gamma^\lambda, \Delta^0]) : \text{ all possible } \Gamma^\lambda\} \subset \{g(\Phi[T, t_0, x_0, \Gamma^0, \Delta^0]) : \text{ all possible } \Gamma^0\}.$$

It follows that

$$\sup_{\Gamma^\lambda} g(\Phi[T, t_0, x_0, \Gamma^\lambda, \Delta^0]) \le \sup_{\Gamma^0} g(\Phi[T, t_0, x_0, \Gamma^0, \Delta^0])$$

for any Δ^0, and hence $W^+_{\lambda,0}(t_0, x_0) \le W(t_0, x_0)$. □

Let $v_0 = W^-(t_0, x_0)$ and let $C(v_0) = \{(\tau, \xi) : t_0 \le \tau \le T, \xi \in \mathbb{R}^n, W^-(\tau, \xi) \le v_0\}$. Let $\mathcal{X}$ be a compact set in $\mathbb{R}^{n+1}$ with (t_0, x_0) in its interior. By Gronwall's lemma and Assumption I(ii), there exists a constant K_0 such that any solution ϕ of

$$\frac{dx}{dt} = f(t, x, u(t), v(t)), \qquad x(t_1) = x_1 \tag{16}$$

with $(t_1, x_1) \in \mathcal{X}$ satisfies $|\phi(t)| \le K_0$ for $t_1 \le t \le T$, independent of the choice of controls u and v. Therefore, there exists a compact set $E \subset \mathbb{R}^{n+1}$ such that the set of solutions of (16) obtained as (t_1, x_1) ranges over $\mathcal{X}$ and u and v range over all possible controls is contained in E.

Since the game $G(t_0, x_0)$ has a saddle point, let us denote the saddle point by (Γ^*, Δ^*). Then we have $(t, \Phi[t, t_0, x_0, \Gamma^*, \Delta^*]) \in E$ and $(t, \Phi[t, t_0, x_0, \Gamma^*, \Delta^*]) \in C(v_0)$ for each $t_0 \le t \le T$. Hence $C(v_0) \cap E \cap H(t) \ne \emptyset$ where $t_0 \le t \le T$ and $H(t)$ is the hyperplane in $\mathbb{R}^{n+1}$ at t. Define $\tilde{C}(v_0) = C(v_0) \cap E$ and $S(t) = \tilde{C}(v_0) \cap H(t)$. We have $S(t) \ne \emptyset$ for each $t_0 \le t \le T$.

Now let us define an extremal strategy to the set $\tilde{C}(v_0)$ with Player II having a lag μ. Let $\phi(t, t_0, x_0, u, v) = x_0 + \int_{t_0}^t f(s, \phi(s), u(s), v(s))ds$ for $t_0 \le t \le T$. For $t_0 \le t \le t_0 + \mu$, let $V_e^\mu(\phi(t), t)$ be any fixed $z \in Z$. For $\mu + t_0 \le t$, define $t^* = t - \mu$, $x^* = \phi(t^*)$ and $x = \phi(t)$. If $(t^*, x^*) \in \tilde{C}(v_0)$, let $V_e^\mu(\phi(t), t)$ be any fixed $z \in Z$. If $(t^*, x^*) \notin \tilde{C}(v_0)$, let w^* be a point in $S(t^*)$ that is at minimal distance from $\phi(t^*)$. If w^* is not unique, we may select any such w^*. Let $s^* = x^* - w^*$. Define $V_e^\mu(\phi(t), t) = z^*$ where (y^*, z^*) is any saddle point of the local game at (t^*, x^*, s^*) with payoff $\langle s^*, f(t^*, x^*, y, z)\rangle$. We say that V_e^μ defined as above is extremal to $\tilde{C}(v_0)$. Let $\Delta_e^\mu = \Delta_e^\mu(V_e^\mu)$ be the corresponding feedback strategy (see [1] for definition of feedback strategy). Δ_e^μ so defined is indeed a strategy since at time t Player II bases his decision on the information available to him at time $t^* = t - \mu$.

LEMMA 9. *Let Assumption* I′ *and the Isaacs condition hold for* f. *Let* V_e^μ *be extremal to* $\tilde{C}(v_0)$ *and let* $\Delta_e^\mu = \Delta_e^\mu(V_e^\mu)$ *be the corresponding feedback strategy of Player II for the game* $G_{0,\mu}(t_0, x_0)$. *Then there exists a nonnegative function* η *defined for* $\mu \ge 0$ *such that* $\eta(\mu) \to 0$ *as* $\mu \to 0$ *and every motion* $\phi[\,, t_0, x_0, \Gamma^0, \Delta_e^\mu]$ *lies in* $C_{\eta(\mu)}(v_0) = \{(t, x) : t \in [t_0, T], x \in \mathbb{R}^n, \operatorname{dist}((t, x), C(v_0)) \le \eta(\mu)\}$.

Proof. We will actually show that every motion $\phi[\,, t_0, x_0, \Gamma^0, \Delta_e^\mu]$ lies in $\{(t, x) : \operatorname{dist}((t, x), S(t)) \le \eta(\mu)\}$. Let

$$M = \max\{|f(t, x, y, z)| : (t, x, y, z) \in E \times Y \times Z\}. \tag{17}$$

Let $\phi[\cdot] = \phi[\,, t_0, x_0, \Gamma^0, \Delta_e^\mu]$ be any motion in $\Phi[\,, t_0, x_0, \Gamma^0, \Delta_e^\mu]$ and let $\{\phi_n(\cdot)\} = \{\phi_n(\,, t_0, x_0, u_n, v_n)\}$ be a sequence of nth stage trajectories converging uniformly to

$\phi[\ , t_0, x_0, \Gamma^0, \Delta_e^\mu]$. If $\phi[\ , t_0, x_0, \Gamma^0, \Delta_e^\mu]$ lies entirely in $\tilde{C}(v_0)$, then we have nothing to prove. Assume that $\phi[\ , t_0, x_0, \Gamma^0, \Delta_e^\mu]$ does not lie entirely in $\tilde{C}(v_0)$. Let $t_n = \inf\{t \in [t_0, T] : (t, \phi_n(t)) \notin \tilde{C}(v_0)\}$. Since $\tilde{C}(v_0)$ is closed, $(t_n, \phi_n(t_n)) \in \tilde{C}(v_0)$.

Let $e(t)$ be the distance from $(t, \phi[t])$ to $S(t) = \tilde{C}(v_0) \cap H(t)$. Let $e_n(t)$ be the distance from $(t, \phi_n(t))$ to $S(t)$. Then $\lim_{n\to\infty} e_n(t) = e(t)$ for all $t \in [t_0, T]$.

Let $I_1, \ldots, I_{p_n}$, where $I_j = [\tau_{j-1}, \tau_j)$, $j = 1, 2, \ldots, p_n$, be the intervals of the nth partition Π_n. Let $\delta_n = \|\Pi_n\|$. Let $k_1 = k_1(n)$ denote the integer such that $t_n + \mu \in I_{k_1} = [\tau_{k_1 - 1}, \tau_{k_1})$.

We first show that for $t_n \le t \le \tau_{k_1}$, $e_n(t) \le 2M(\delta_n + \mu)$. Let $t \in [t_n, \tau_{k_1}]$. Since $(t_n, \phi_n(t_n)) \in C(v_0)$, it follows from [1, Lem. 8.3] that there exists a relaxed control ζ such that the relaxed trajectory $\psi(\ , t_n, \phi_n(t_n), u_n, \zeta)$ has the property that $(t, \psi(t)) \in C(v_0)$. Hence $e_n(t) \le |\psi(t) - \phi_n(t)| = |\int_{t_n}^t f(s, \psi(s), u_n(s), \eta(s))ds - \int_{t_n}^t f(s, \phi_n(s), u_n(s), v_n(s))ds| \le 2M(\delta_n + \mu)$, for $t_n \le t \le \tau_{k_1}$, where M is as in (17). Define

$$\alpha_0 = 2M(\delta_n + \mu). \tag{18}$$

Then $e_n(t) \le \alpha_0$, for $t_n \le t \le \tau_{k_1}$.

Now suppose $t \in [\tau_k, \tau_{k+1})$ with $k \ge k_1$. Let $t^* = \tau_k - \mu$, let $x^* = \phi_n(t^*)$, and suppose $(t^*, x^*) \notin \tilde{C}(v_0)$. Let w^* be the point in $S(t^*)$ selected as being at minimum distance from x^* in $S(t^*)$ in the definition of V_e^μ. Let $s^* = x^* - w^*$ and let y^* be any point in Y such that (y^*, z^*) is a saddle point for the local game (t^*, x^*, s^*) with payoff $\langle s^*, f(t^*, x^*, y, z)\rangle$.

By [1, Lemma 8.3], there exists a relaxed control ζ such that the corresponding relaxed trajectory $\psi(\ ) = \psi(\ , t^*, w^*, y^*, \zeta)$ has the property that $(t, \psi(t)) \in C(v_0)$. Therefore, we have that $e_n(t) \le |\phi_n(t, t^*, x^*, u_n, z^*) - \psi(t, t^*, w^*, y^*, \zeta)|$. Let $\rho_n(t) = |\phi_n(t) - \psi(t)|$, then

$$\begin{aligned}\frac{d\rho_n^2(t)}{dt} &= 2\langle f(t, \phi_n(t), u_n, z^*) - f(t, \psi(t), y^*, \zeta),\ \phi_n(t) - \psi(t)\rangle \\ &= 2\langle f(t^*, x^*, u_n, z^*) - f(t^*, x^*, y^*, \zeta) + \Delta^\phi f - \Delta^\psi f, \\ &\qquad (x^* - w^*) + \phi_n(t) - x^* - \psi(t) + w^*\rangle,\end{aligned} \tag{19}$$

where

$$\Delta^\phi f = f(t, \phi_n(t), u_n, z^*) - f(t^*, x^*, u_n, z^*)$$

and

$$\Delta^\psi f = f(t, \psi(t), y^*, \zeta) - f(t^*, x^*, y^*, \zeta).$$

Since $t - t^* \le \delta_n + \mu$, we have that $|\phi_n(t) - x^*| \le M(\delta_n + \mu)$ and $|\psi(t) - w^*| \le M(\delta_n + \mu)$. Since f is continuous, there exists a function $\epsilon : [0, \infty) \to [0, \infty)$ such that $\lim_{s\to 0}\epsilon(s) = 0$ and $|f(t_1, x, y, z) - f(t_2, x, y, z)| \le \epsilon(|t_1 - t_2|)$ for (t_1, x, y, z) and (t_2, x, y, z) in the compact set $E \times Y \times Z$. So, $|\Delta^\phi f| \le |f(t, \phi_n(t), u_n, z^*) - f(\tau_k, \phi_n(t), u_n, z^*)| + |f(\tau_k, \phi_n(t), u_n, z^*) - f(t^*, \phi_n(t), u_n, z^*)| + |f(t^*, \phi_n(t), u_n, z^*) - f(t^*, x^*, u_n, z^*)| \le \epsilon(\delta_n) + \epsilon(\mu) + KM(\delta_n + \mu)$. Similarly, $|\Delta^\psi f| \le \epsilon(\delta_n) + \epsilon(\mu) + KM(\delta_n + \mu) + K|x^* - w^*|$, where K is the Lipschitz constant in Assumption I′. Since $e_n(t)$ is uniformly bounded for $t \in [t_0, T]$, by applying these estimates to (19), we get $(d\rho_n^2(t)/dt) \le 2Ke_n^2(\tau_k - \mu) + O(\delta_n) + O(\mu)$. Integrating from $\tau_k - \mu = t^*$

to t on both sides of the above inequality and noting that $e_n(t) \le \rho_n(t)$ and that $e_n(\tau_k - \mu) = \rho_n(\tau_k - \mu)$, we get that for $\tau_k \le t \le \tau_{k+1}$,

$$e_n^2(t) \le e_n^2(\tau_k - \mu)\big(1 + 2K(\delta_n + \mu)\big) + \big(O(\delta_n) + O(\mu)\big)(\delta_n + \mu). \tag{20}$$

Since $t_n < \tau_{k_1} - \mu \le \tau_{k_1}$, $e_n^2(\tau_{k_1} - \mu) \le \alpha_0^2$. So, for $t_n \le t \le \tau_{k_1+1}$,

$$e_n^2(t) \le \alpha_0^2\big(1 + 2K(\delta_n + \mu)\big) + \big(O(\delta_n) + O(\mu)\big)(\delta_n + \mu) \triangleq \alpha_1^2. \tag{21}$$

If $(t^*, x^*) \in \tilde{C}(v_0)$, the argument used to show (18) will give that $e_n^2(t) \le \alpha_0^2$. Hence (21) holds.

Let $k_2 > k_1 + 1$ be such that $\tau_{k_2+1} - \mu > \tau_{k_1+1}$ and if $k \le k_2$, then $\tau_k - \mu \le \tau_{k_1+1}$, i.e., τ_{k_2} is the greatest partition point in Π_n that is less than or equal to $\tau_{k_1+1} + \mu$. Then for any $k_1 + 1 < k \le k_2$, it follows from (21) that $e_n^2(\tau_k - \mu) \le \alpha_1^2$. Therefore, (20) gives that for $\tau_{k_1+1} \le t \le \tau_{k_2+1}$, $e_n^2(t) \le \alpha_1^2\big(1 + 2K(\delta_n + \mu)\big) + \big(O(\delta_n) + O(\mu)\big)(\delta_n + \mu)$. Together with (21), we get that for $t_n \le t \le \tau_{k_2+1}$, $e_n^2(t) \le \alpha_0^2\big(1 + 2K(\delta_n + \mu)\big)^2 + \big(O(\delta_n) + O(\mu)\big)(\delta_n + \mu)\sum_{i=0}^{1}\big(1 + 2K(\delta_n + \mu)\big)^i \triangleq \alpha_2^2$.

Suppose we have defined k_j. Let $k_{j+1} > k_j + 1$ be such that $\tau_{k_{j+1}+1} - \mu > \tau_{k_j+1}$ and if $k \le k_{j+1}$, then $\tau_k - \mu \le \tau_{k_j+1}$, i.e., $\tau_{k_{j+1}}$ is the greatest partition point in Π_n that is less than or equal to $\tau_{k_j+1} + \mu$.

Suppose for $t_n \le t \le \tau_{k_j+1}$, we have $e_n^2(t) \le= \alpha_0^2\big(1 + 2K(\delta_n + \mu)\big)^j + \big(O(\delta_n) + O(\mu)\big)(\delta_n + \mu)\sum_{i=0}^{j_1}\big(1 + 2K(\delta_n + \mu)\big)^i \triangleq \alpha_j^2$. Then, it is clear that for $t_n \le t \le \tau_{k_{j+1}+1}$, $e_n^2(t) \le \alpha_j^2\big(1 + 2K(\delta_n + \mu)\big) + \big(O(\delta_n) + O(\mu)\big) \le \alpha_0^2\big(1 + 2K(\delta_n + \mu)\big)^{j+1} + \big(O(\delta_n) + O(\mu)\big)(\delta_n + \mu)\sum_{i=0}^{j}\big(1 + 2K(\delta_n + \mu)\big)^i$.

Note that $\tau_{k_{j+1}+1} - \tau_{k_j+1} > \mu$. So, we can only iterate for at most $[(T - t_0)/\mu]$ steps. Therefore, for $t_n \le t \le T$,

$$e_n^2(t) \le \alpha_0^2\big(1+2K(\delta_n+\mu)\big)^{[(T-t_0)/\mu]} + \big(O(\delta_n)+O(\mu)\big)(\delta_n+\mu)\sum_{i=0}^{[(T-t_0)/\mu]-1}\big(1+2K(\delta_n+\mu)\big)^i.$$

Letting $n \to \infty$ and using (18), we get

$$\begin{aligned} e^2(t) &\le 4M^2\mu^2(1 + 2K\mu)^{[(T-t_0)/\mu]} + O(\mu)\mu\sum_{i=0}^{[(T-t_0)/\mu]-1}(1 + 2K\mu)^i \\ &\le 4M^2\mu^2 e^{2K(T-t_0)} + O(\mu)\frac{e^{2K(T-t_0)} - 1}{2K} \triangleq \eta^2(\mu). \end{aligned}$$

□

LEMMA 10. *Let Assumption* I′ *hold. If* $\Phi[\,, t_0, x_0, \Gamma^0, \Delta_e^\mu] \subset C_{\eta(\mu)}(v_0)$ *for all* Γ^0, *there exists a nonnegative function* $\tilde{\eta}_0$ *of* μ *having the following properties:*

(1) $\tilde{\eta}_0(\mu) \downarrow 0$ *as* $\mu \downarrow 0$,

(2) $W_{0,\mu}^+(t_0, x_0) \le W(t_0, x_0) + \tilde{\eta}_0(\mu)$.

Proof. It follows from the continuity of g, from Assumption I′, and from the definition of motion that for any given $\epsilon > 0$, there exists $\delta > 0$ such that for any two pairs of strategies (Γ, Δ) and (Γ', Δ') and any motions $\phi[\,, t_1, x_1, \Gamma, \Delta]$, $\phi[\,, t_1, x_1, \Gamma', \Delta']$ the inequality

$$|g(\phi[T, t_1, x_1, \Gamma, \Delta]) - g(\phi[T, t_1, x_1, \Gamma', \Delta'])| < \epsilon$$

holds for any $(t_1, x_1) \in E$ whenever $|T - t_1| < \delta = \delta(\epsilon)$.

Let $\phi[\ , t_0, x_0, \Gamma^0, \Delta_\epsilon^\mu]$ be a motion $\subset C_{\eta(\mu)}(v_0)$. Let t_1 satisfy $|T - t_1| < \delta$ and let $x_1 = \phi[t_1, t_0, x_0, \Gamma^0, \Delta_\epsilon^\mu]$. By Lemma 8, there exists a w_1 such that $(t_1, w_1) \in C(v_0)$ and $|x_1 - w_1| \leq \eta(\mu)$. It is easy to see that for any Γ and any Δ

$$|\phi[T, t_1, x_1, \Gamma, \Delta] - \phi[T, t_1, w_1, \Gamma, \Delta]| \leq |x_1 - w_1| + 2M\delta \leq \eta(\mu) + 2M\delta. \tag{22}$$

From the continuity of g and (22), there exists a function $\sigma \geq 0$ satisfying $\sigma(s) \to 0$ as $s \to 0$ such that $|g(\phi[T, t_1, x_1, \Gamma, \Delta]) - g(\phi[T, t_1, w_1, \Gamma, \Delta])| \leq \sigma(\eta(\mu)) + \sigma(2M\delta)$. Note that the segment of the motion $\phi[t_0, x_0, \Gamma^0, \Delta_\epsilon^\mu]$ on the interval $[t_1, T]$ is again a motion, say $\phi[\ , t_1, x_1, \Gamma', \Delta']$. Therefore $g(\phi[T, t_0, x_0, \Gamma^0, \Delta_\epsilon^\mu]) = g(\phi[T, t_1, x_1, \Gamma', \Delta'])$.

Since $(t_1, w_1) \in C(v_0)$, it follows from [1, Lemma 8.2] that there exists a strategy $\Delta(\Gamma')$ in the game without lag and a motion $\phi[\ , t_1, w_1, \Gamma', \Delta(\Gamma')]$ such that

$$g(\phi[T, t_1, w_1, \Gamma', \Delta(\Gamma')]) < v_0 + \epsilon.$$

Hence

$$\begin{aligned}
&g(\phi[T, t_0, x_0, \Gamma^0, \Delta_\epsilon^\mu]) \\
&= g(\phi[T, t_1, x_1, \Gamma', \Delta']) - g(\phi[T, t_1, x_1, \Gamma', \Delta(\Gamma')]) + g(\phi[T, t_1, x_1, \Gamma', \Delta(\Gamma')]) \\
&\quad - g(\phi[T, t_1, w_1, \Gamma', \Delta(\Gamma')]) + g(\phi[T, t_1, w_1, \Gamma', \Delta(\Gamma')]) \\
&\leq \epsilon + \sigma(\eta(\mu)) + \sigma(2M\delta) + v_0 + \epsilon \\
&= 2\epsilon + v_0 + \sigma(\eta(\mu)) + \sigma(2M\delta),
\end{aligned}$$

From above inequality and the arbitrariness of ϵ and ϕ, we get $g(\Phi[T, t_0, x_0, \Gamma^0, \Delta_\epsilon^\mu]) \leq v_0 + \tilde{\eta}(\mu)$ with $\tilde{\eta}(\mu) = \sigma(\eta(\mu))$. The lemma follows from this inequality. □

Following the same ideas as used in the proofs of Lemmas 9 and 10, we can obtain the following result.

LEMMA 11. *If Assumption* I′ *and the Isaacs condition hold for* f, *there exists a nonnegative function* $\tilde{\eta}_1$ *of* λ *having the following properties:*

(1) $\tilde{\eta}_1(\lambda) \downarrow 0$ *as* $\lambda \downarrow 0$,

(2) $W^-_{\lambda,0}(t_0, x_0) \geq W(t_0, x_0) - \tilde{\eta}_1(\lambda)$.

THEOREM 12. *If Assumption* I′ *and the Isaacs condition hold for* f, *then*

$$0 \leq W^+_{\lambda,\mu}(t_0, x_0) - W^-_{\lambda,\mu}(t_0, x_0) \leq \tilde{\eta}_0(\lambda) + \tilde{\eta}_1(\mu),$$

where $\tilde{\eta}_i$, $i = 0, 1$, *are as in Lemmas* 10 *and* 11, *and hence*

$$\lim_{\substack{\lambda \to 0 \\ \mu \to 0}} W^\pm_{\lambda,\mu}(t_0, x_0) = W(t_0, x_0).$$

The proof is an immediate consequence of Lemmas 8, 10, and 11.

2.2. Differential games of generalized pursuit and evasion. The game is governed by (1) with payoff (3) and terminal set $\mathcal{T}$.

Let (t_0, x_0) with $(t_0, x_0) \notin \mathcal{T}$ be an initial point of the game. A strategy Γ^λ for Player I with lag $\lambda \geq 0$ on the interval $[t_0, T]$ and a strategy Δ^μ for Player II with lag $\mu \geq 0$ on the interval $[t_0, T]$ are defined as in §2.1, where games of fixed duration with information lags are defined.

Corresponding to $(\Gamma^\lambda, \Delta^\mu)$, we obtain a sequence of controls (u_n, v_n) and a sequence of nth stage trajectories $\hat{\phi}_n(\ ) \equiv (\phi_n^0, \phi_n)$ satisfying

$$\phi_n^{0\prime}(t) = f^0(t, \phi_n(t), u_n(t), v_n(t)), \qquad \phi_n^0(t_0) = x_{0n}^0,$$
$$\phi_n'(t) = f(t, \phi_n(t), u_n(t), v_n(t)), \qquad \phi_n(t_0) = x_{0n},$$

with $(x_{0n}^0, x_{0n}) \to (0, x_0)$. A motion $\hat{\phi}[\ , t_0, x_0, \Gamma^\lambda, \Delta^\mu]$ is a uniform limit of nth stage trajectories $\hat{\phi}_n(\ , t_0, x_0, u_n, v_n)$.

By the terminal time t_{f_n} of the nth stage trajectory $\hat{\phi}_n(\ )$ we mean the first time such that $(t, \phi(t)) \in \mathcal{T}$. The terminal time t_f of a motion $\hat{\phi}[\ , t_0, x_0, \Gamma^\lambda, \Delta^\mu]$ is defined similarly.

The payoff $P(t_0, x_0, \Gamma^\lambda, \Delta^\mu)$ resulting from a pair of strategies $(\Gamma^\lambda, \Delta^\mu)$ is defined as

$$P(t_0, x_0, \Gamma^\lambda, \Delta^\mu) \equiv \cup\{g(t_f, \phi[t_f, t_0, x_0, \Gamma^\lambda, \Delta^\mu]) + \phi^0[t_f, t_0, x_0, \Gamma^\lambda, \Delta^\mu]\}$$

where the union is taken over all motions $\hat{\phi}[\ , t_0, x_0, \Gamma^\lambda, \Delta^\mu]$ resulting from $(\Gamma^\lambda, \Delta^\mu)$. We designate the game just defined as $G_{\lambda,\mu}(t_0, x_0)$. We define the upper value of the game by $W_{\lambda,\mu}^+(t_0, x_0)$ and the lower value by $W_{\lambda,\mu}^-(t_0, x_0)$. Thus

$$W_{\lambda,\mu}^+(t_0, x_0) = \inf_{\Delta^\mu} \sup_{\Gamma^\lambda} P(t_0, x_0, \Gamma^\lambda, \Delta^\mu),$$
$$W_{\lambda,\mu}^-(t_0, x_0) = \sup_{\Gamma^\lambda} \inf_{\Delta^\mu} P(t_0, x_0, \Gamma^\lambda, \Delta^\mu).$$

An argument similar to that used to prove Lemma 8 gives the following lemma.

LEMMA 13. *Let Assumption* I *and either Assumption* II *or* II′ *hold. If the Isaacs condition holds, then*

$$W_{\lambda,0}^-(t_0, x_0) \le W_{\lambda,0}^+(t_0, x_0) \le W(t_0, x_0) \le W_{0,\mu}^-(t_0, x_0) \le W_{0,\mu}^+(t_0, x_0);$$

$$W_{\lambda,0}^-(t_0, x_0) \le W_{\lambda,\mu}^-(t_0, x_0) \le W_{\lambda,\mu}^+(t_0, x_0) \le W_{0,\mu}^+(t_0, x_0),$$

where $W(t_0, x_0)$ is the value of game of generalized pursuit and evasion without lags.

Let $\epsilon_k = 1/k$. We consider a fixed-duration game $G_{\lambda,\mu}(t_0, x_0, \epsilon_k)$ as in [2], which we henceforth will write as $G_{\lambda,\mu}(t_0, x_0, k)$, and we will let $W_{\lambda,\mu}^\pm(t_0, x_0, k)$ denote the upper and lower values of the game $G_{\lambda,\mu}(t_0, x_0, k)$.

LEMMA 14. *Let Assumption* I *and either Assumption* II *or* II′ *hold. If $\mathcal{C}$ is a compact set in $(([t_0, \infty) \times \mathbb{R}^n) - \mathcal{T}) \cup (\partial\mathcal{T})$, then there exists a constant $c > 0$ such that for all k sufficiently large and all (t_0, x_0) in $\mathcal{C}$, $W_{\lambda,0}^-(t_0, x_0) \ge W_{\lambda,0}^-(t_0, x_0, k) - c/k$.*

The proof of this lemma is identical to the proof of [2, Lem. 4.3], which does not involve the structure of the strategies Γ for Player I. The proof requires the construction of a strategy Δ^* for Player II. In the present lemma, Player II does not have an information lag, so that the strategy Δ^* constructed for Player II in the present case will be identical to the construction of the strategy Δ^* in [2]. The following lemma is similar.

LEMMA 15. *Let Assumption* I *and either Assumption* II *or* II′ *hold. If $\mathcal{C}$ is a compact set in $(([t_0, \infty) \times \mathbb{R}^n) - \mathcal{T}) \cup (\partial\mathcal{T})$, then there exists a constant $c > 0$ such that for all k sufficiently large and all (t_0, x_0) in $\mathcal{C}$, $W_{0,\mu}^+(t_0, x_0) \le W_{0,\mu}^+(t_0, x_0, k) + c/k$.*

For $\tau_0 \in [t_0, T]$ and $\hat{\xi}_0 \in \mathbb{R}^{n+1}$, as in [2], we define the game $\hat{G}_{\lambda,\mu}(\tau_0, \hat{\xi}_0)$, which is governed by

$$\frac{dx}{dt} = f(t, x, u(t), v(t)), \qquad x(\tau_0) = \xi_0$$

with payoff $\xi_0^0 + \int_{\tau_0}^{t_f} f^0(s, \phi(s), u(s), v(s))ds$ and terminal set $\hat{T} = \mathbb{R} \times T$. Let $\hat{W}^{\pm}_{\lambda,\mu}(\tau_0, \hat{\xi}_0)$ denote the upper and lower values of $\hat{G}_{\lambda,\mu}(\tau_0, \hat{\xi}_0)$. Then $\hat{W}^{\pm}_{\lambda,\mu}(\tau_0, \hat{\xi}_0) = \xi_0^0 + W^{\pm}_{\lambda,\mu}(\tau_0, \xi_0)$. Let $\hat{F}_1 = \mathbb{R} \times F_1$ and let $\hat{F} = \mathbb{R} \times F$.

For $\epsilon_k = 1/k$, consider the fixed duration game $\hat{G}_{\lambda,\mu}(\tau_0, \hat{\xi}_0, k)$ as defined in §1 of this paper. Let $\hat{W}^{\pm}_{\lambda,\mu}(\tau_0, \hat{\xi}_0, k)$ denote the upper and lower values of $\hat{G}_{\lambda,\mu}(\tau_0, \hat{\xi}_0, k)$.

Let $\nu_{0,k} = \hat{W}^{+}_{0,0}(t_0, \hat{x}_0, k)$ with $\hat{x}_0 = (0, x_0)$. Let $C(\nu_{0,k}) = \{(t, \hat{x}) : t_0 \le t \le T, \hat{x} \in \mathbb{R}^{n+1}, \hat{W}^{+}_{0,0}(t, \hat{x}, k) \le \nu_{0,k}\}$ and let $C_\alpha(\nu_{0,k}) = \{(t, \hat{x}) : t_0 \le t \le T, \hat{x} \in \mathbb{R}^{n+1}, \operatorname{dist}((t, \hat{x}), C(\nu_{0,k})) \le \alpha\}$.

Let $\mathcal{X}$ be a compact set in $\mathbb{R}^{n+2}$. By Gronwall's lemma and Assumption I(ii), there exists a compact set $E \subset \mathbb{R}^{n+2}$ such that the set of solutions of

$$\frac{d\hat{x}}{dt} = \hat{f}(t, \hat{x}, u(t), v(t)), \qquad \hat{x}(t_1) = \hat{x}_1$$

obtained as $(t_1, \hat{x}_1)$ ranges over $\mathcal{X}$ and u and v range over all possible controls is contained in E. Let $\tilde{C}(\nu_{0,k}) = C(\nu_{0,k}) \cap E$. Let $M = \max|\hat{f}(t, \hat{x}, y, z)|$ for all $(t, \hat{x}, y, z) \in E \times Y \times Z$.

Let $\mathcal{B} = E \cap \hat{\partial}\hat{F}$ where $\hat{\partial}\hat{F} = (\partial\hat{F}) \cap (\partial\hat{F}_1)$. Since E is compact, $\mathcal{B}$ is a compact subset of $\hat{\partial}\hat{F}$. Let $\epsilon_0 = \epsilon_0(\mathcal{B})$ and $c_0 = c_0(\mathcal{B})$ be determined as in Lemma 2. Let $\mathcal{N}_\alpha(\mathcal{B}) = \{(t, \hat{x}) : t_0 \le t \le T, \hat{x} \in \mathbb{R}^{n+1}, \operatorname{dist}\big((t, \hat{x}), \mathcal{B}\big) \le \alpha\}$.

LEMMA 16. *Let Assumption* I *and either Assumption* II *or* II′ *hold and let the Isaacs condition* $(\hat{I})$ *hold for* $\hat{f}$ *(as defined in* §1*). Let* V_e^μ *be extremal to* $\tilde{C}^{(k)}(\nu_{0,k})$ *and let* $\Delta_e^\mu = \Delta_e^\mu(V_e^\mu)$ *be the corresponding feedback strategy of Player* II *for game* $\hat{G}_{0,\mu}(t_0, \hat{x}_0, k)$ *with initial point* $(t_0, \hat{x}_0)$*. Then there exist a* $\mu_0 > 0$ *and a nonnegative function* η *defined for* $0 \le \mu \le \mu_0$ *such that* $\eta(\mu) \to 0$ *as* $\mu \to 0$ *and having the following property. For any* Γ^0 *and any* $0 \le \mu \le \mu_0$*, if* t_f *is the terminal time for* $\hat{\phi}[\ , t_0, \hat{x}_0, \Gamma^0, \Delta_e^\mu, k]$*, then there is a* t_{f_ψ}*,* $t_0 \le t_{f_\psi} \le t_f$ *such that* $t_f - t_{f_\psi} \le 1/c_0\eta(\mu)$ *and such that*

$$(t, \hat{\phi}[t, t_0, \hat{x}_0, \Gamma^0, \Delta_e^\mu, k]) \in C^{(k)}_{\eta(\mu)}(\nu_{0,k}) \cap H(t) \quad \text{for } t_0 \le t \le t_{f_\psi}.$$

Proof. Let Γ^0 be any strategy for Player I, let $\hat{\phi}[\ , t_0, \hat{x}_0, \Gamma^0, \Delta_e^\mu, k]$ be any motion resulting from strategies (Γ^0, Δ_e^μ) and let $\{\hat{\phi}_{k,n}(\ , t_0, \hat{x}_0, u_n, v_0)\}$ be a sequence of nth stage trajectories converging uniformly to $\hat{\phi}[\ , t_0, \hat{x}_0, \Gamma^0, \Delta_e^\mu, k]$. Let t_{f_n} be the terminal time of $\hat{\phi}_{k,n}(\ , t_0, \hat{x}_0, u_n, v_n)$. Note that the terminal time of $\hat{\phi}_{k,n}(\ , t_0, \hat{x}_0, u_n, v_n)$ does not depend on k. Let $\hat{e}_{k,n}(t)$ be the distance from

$$(t, \hat{\phi}_{k,n}(t, t_0, \hat{x}_0, u_n, v_n)) \quad \text{to } \tilde{C}^{(k)}(\nu_{0,k}) \cap H(t)$$

and let $\hat{e}_k(t)$ be the distance from

$$(t, \hat{\phi}[t, t_0, \hat{x}_0, \Gamma^0, \Delta_e^\mu, k]) \quad \text{to } \tilde{C}^{(k)}(\nu_{0,k}) \cap H(t).$$

Let $I_1, I_2, \ldots, I_{p_n}$ be the intervals of the nth partition Π_n. Let $\delta_n = \|\Pi_n\| \le L/n$. Let t_n be the first time at which $\hat{\phi}_{k,n}(t, t_0, \hat{x}_0, u_n, v_n)$ gets out of the set $C^{(k)}(\nu_{0,k})$. Let $j_1 = j_1(n)$ denote the integer such that $t_n + \mu \in I_{j_1} = [\tau_{j_1-1}, \tau_{j_1})$. Consider $t \in [t_n, t_{f_n}]$.

Case 1. Assume that $(t_n+\mu, \hat{\phi}_{k,n}(t_n+\mu, t_0, \hat{x}_0, u_n, v_n)) \in \hat{T}$. Then $t_{f_n} \le t_n+\mu$. Consider $t_n \le t \le T_{f_n}$. Since $(t_n, \hat{\phi}_{k,n}(t_n)) \in C^{(k)}(\nu_{0,k})$, according to [1, Lem. 8.3], there exists a relaxed control ζ_t such that the relaxed trajectory $\hat{\psi}_k(t, t_n, \hat{\phi}_{k,n}(t_n), u_n, \zeta_t)$ has the property that $(t, \hat{\psi}_k(t, t_n, \hat{\psi}_{k,n}(t_n), u_n, \zeta_t)) \in C^{(k)}(\nu_{0,k})$.

If for every $t \in [t_n, t_{f_n}]$, we have $(t, \hat{\psi}_k(t, t_n, \hat{\phi}_{k,n}(t_n), u_n, \zeta_t)) \notin \hat{T}$, then we get that for $t_n \le t \le t_{f_n}$

$$\begin{aligned}
\hat{e}_{k,n}(t) &\le |\hat{\phi}_{k,n}(t, t_n, \hat{\phi}_{k,n}(t_n), u_n, v_n) - \hat{\psi}_k(t, t_n, \hat{\phi}_{k,n}(t_n), u_n, \zeta_t)| \\
&\le |\hat{\phi}_{k,n}(t, t_n, \hat{\phi}_{k,n}(t_n), u_n, v_n) - \hat{\phi}_{k,n}(t_n)| + |\hat{\psi}_k(t, t_n, \hat{\phi}_{k,n}(t_n), u_n, \zeta_t) - \hat{\phi}_{k,n}(t_n)| \\
&\le 2M(t_{f_n} - t_n) \\
&\le 2M(t_n + \mu - t_n) \\
&= 2M\mu.
\end{aligned}$$

If for some $t \in [t_n, t_{f_n}]$ every relaxed control ζ_t having the property that

$$(t, \hat{\psi}_k(t, t_n, \hat{\phi}_{k,n}(t_n), u_n, \zeta_t)) \in C^{(k)}(\nu_{0,k})$$

satisfies $(t, \hat{\psi}_k(t, t_n, \hat{\phi}_{k,n}(t_n), u_n, \zeta_t)) \in \hat{T}$, let $t_{f_{\psi_n}}$ be the infimum of such t. Then we have that for $t_n \le t \le t_{f_{\psi_n}}$, $\hat{e}_{k,n}(t) \le 2M\mu$. An argument as in the proof of Lemma 16 gives that $(t_{f_{\psi_n}}, \hat{\phi}_{k,n}(t_{f_{\psi_n}})) \in \mathcal{N}_{2M\mu}(\mathcal{B})$. Since $2M\mu \le \epsilon_0$ for sufficiently small μ, we have $t_{f_n} - t_{f_{\psi_n}} \le (1/c_0)2M\mu$.

Case 2. Assume that $(t_n+\mu, \hat{\phi}_{k,n}(t_n+\mu)) \notin \hat{T}$. Hence $(t_n, \hat{\phi}_{k,n}(t_n)) \notin \hat{T}$ by Corollary 5. Consider $t_n \le t \le \tau_{j_1}$. Since $(t_n, \hat{\phi}_{k,n}(t_n)) \in C^{(k)}(\nu_{0,k})$, it follows from [1, Lem. 8.3] that there is a relaxed control ζ_t such that the relaxed trajectory $\hat{\psi}_k(\ , t_n, \hat{\phi}_{k,n}(t_n), u_n, \zeta_t)$ has the property that $(t, \hat{\psi}_k(t)) \in C^{(k)}(\nu_{0,k})$.

If for some $t \in [t_n, \tau_{j_1}]$, all the relaxed controls ζ_t satisfying the above property also satisfy $(t, \hat{\psi}_k(t, t_n, \hat{\phi}_{k,n}(t_n), u_n, \zeta_t)) \in \hat{T}$, then let $t_{f_{\psi_n}}$ be the infimum of such t. Then an argument similar to that in Case 1 gives that $\hat{e}_{k,n}(t) \le 2M(\delta_n+\mu)$ for $t_n \le t \le t_{f_{\psi_n}}$ and $(t_{f_{\psi_n}}, \hat{\phi}_{k,n}(t_{f_{\psi_n}})) \in \mathcal{N}_{2M(\delta_n+\mu)}(\mathcal{B})$. Hence for sufficiently small μ and sufficiently large n, $t_{f_n} - t_{f_{\psi_n}} \le (1/c_0)2M(\delta_n+\mu)$.

If for every $t \in [t_n, \tau_{j_1}]$ there is a relaxed control ζ_t that not only has the property that

$$(t, \hat{\psi}_k(t, t_n, \hat{\phi}_{k,n}(t_n), u_n, \zeta_t)) \in C^{(k)}(\nu_{0,k}),$$

but also has the property that $(t, \hat{\psi}_k(t, t_n, \hat{\phi}_{k,n}(t_n), u_n, \zeta_t)) \notin \hat{T}$, then we have $\hat{e}_{k,n}(t) \le 2M(\delta_n+\mu)$ for $t \in [t_n, \tau_{j_1}]$.

Consider $\tau_{j_1} \le t \le \tau_{j_1+1}$. Since $\tau_{j_1} - \mu \le \tau_{j_1}$, $\hat{e}_{k,n}(\tau_{j_1} - \mu) \le 2M(\delta_n+\mu)$. Let $t^* = \tau_{j_1} - \mu$, let $\hat{x}^* = \hat{\phi}_{k,n}(t^*)$ and let $\hat{w}^*$ be the point in $S(t^*) = C^{(k)}(\nu_{0,k}) \cap H(t^*)$ selected as being at minimum distance from $\hat{x}^*$ in the definition of V_e^{μ}. Then $(t^*, \hat{w}^*) \in C^{(k)}(\nu_{0,k})$. If $(t^*, \hat{w}^*) \in \hat{T}$, then since $\hat{e}_{k,n}(t^*) \le 2M(\delta_n+\mu)$, $(t^*, \hat{\phi}_{k,n}(t^*)) \in \mathcal{N}_{2M(\delta_n+\mu)}(\mathcal{B})$. Hence $0 \le t_{f_n} - t^* \le (1/c_0)2M(\delta_n+\mu)$ if $n \ge 2L/\epsilon_0$ and $\mu \le \epsilon_0/2M$, and $\hat{e}_{k,n}(t) \le 2M(\delta_n+\mu)$ for $t_0 \le t \le t^* = \tau_{j_1} - \mu$. If $(t^*, \hat{w}^*) \notin \hat{T}$, then the analysis in the proof of Lemma 9 gives that

$$\hat{e}_{k,n}^2(t) \le \hat{e}_{k,n}^2(\tau_{j_1} - \mu)(1 + 2K(\delta_n+\mu)) + (O(\delta_n) + O(\mu))(\delta_n+\mu).$$

If $(t, \hat{\psi}(t)) \in \hat{T}$ for some $t \in [\tau_{j_1}, \tau_{j_1+1}]$, then if we denote the terminal time of $\hat{\psi}(\ , t^*, \hat{w}^*, u_{k,n}, \zeta)$ as $t_{f_{\psi_n}}$, we have $t^* = \tau_{j_1} - \mu \le t_{f_{\psi_n}} \le \tau_{j_1+1}$. For $t_n \le t \le t_{f_{\psi_n}}$,

$$\begin{aligned}\hat{e}^2_{k,n}(t) &\le \hat{e}^2_{k,n}(\tau_{j_1} - \mu)(1 + 2K(\delta_n + \mu)) + (O(\delta_n) + O(\mu))(\delta_n + \mu) \\ &\le 4M^2(\delta_n + \mu)^2(1 + 2K(\delta_n + \mu)) + (O(\delta_n) + O(\mu))(\delta_n + \mu) \\ &= \alpha_1^2(\delta_n + \mu).\end{aligned}$$

Since $\hat{e}_{k,n}(t_{f_{\psi_n}}) \le \alpha_1(\delta_n + \mu)$ and $\alpha_1(\delta_n + \mu) \to 0$ as $\delta_n + \mu \to 0$, $(t_{f_{\psi_n}}, \hat{\phi}_{k,n}(t_{f_{\psi_n}})) \in \mathcal{N}_{\alpha_1(\delta_n+\mu)}(\mathcal{B})$ and hence $0 \le t_{f_n} - t_{f_{\psi_n}} \le (1/c_0)\alpha_1(\delta_n + \mu)$.

Let $j_2 > j_1 + 1$ be such that τ_{j_2} is the greatest partition point in Π_n that is less than or equal to $\tau_{j_1+1} + \mu$. Let $j_m > j_{m-1} + 1$ be such that τ_{j_m} is the greatest partition point in Π_n that is less than or equal to $\tau_{j_{m-1}} + \mu$, for $m = 1, 2, \ldots$. For $t_n \le t \le \tau_{j_m+1}$, an analysis similar to that used in the case when $\tau_{j_1} \le t \le \tau_{j_1+1}$ shows that there exists a $t_{f_{\psi_n}} \in [t_0, t_{f_n}]$ such that $0 \le t_{f_n} - t_{f_{\psi_n}} \le (1/c_0)\alpha(\delta_n + \mu)$ and such that for $t_0 \le t \le t_{f_{\psi_n}}$, $\hat{e}_{k,n}(t) \le \alpha(\delta_n + \mu)$ where $\alpha^2(\delta_n + \mu) = 4M^2(\delta_n + \mu)^2(1+2K(\delta_n+\mu))^{[(T-t_0)/\mu]} + (O(\delta_n)+O(\mu))(\delta_n+\mu)\sum_{i=0}^{[(T-t_0)/\mu]-1}(1+2K(\delta_n+\mu))^i$. Let $t_{f_\psi} = \inf \lim_{n\to\infty} t_{f_{\psi_n}}$. Since $\lim_{n\to\infty} t_{f_n} = t_f$, on letting $n \to \infty$, we get that $0 \le t_f - t_{f_\psi} \le (1/c_0)\alpha(\mu)$ and that for $t_0 \le t \le t_{f_\psi}$, $\hat{e}_{k,n}(t) \le \alpha(\mu)$ where

$$\begin{aligned}\alpha^2(\mu) &= 4M^2\mu^2(1 + 2K\mu)^{[(T-t_0)/\mu]} + O(\mu)\frac{(1 + 2K\mu)^{[(T-t_0)/\mu]} - 1}{2K} \\ &\le 4M^2\mu^2 e^{2K(T-t_0)} + O(\mu)\frac{e^{2K(T-t_0)} - 1}{2K} \\ &= \eta^2(\mu). \qquad \square\end{aligned}$$

LEMMA 17. *Let Assumption* I *and either Assumption* II *or* II′ *hold. Let u and v be any control functions in Y and Z, respectively. If t_f is the terminal time of a trajectory $\hat{\phi}(\ , \tau_0, \hat{\xi}_0, u, v, k)$ with $(\tau_0, \hat{\xi}_0) \in \mathcal{X}$, then for sufficiently large k,*

$$|\phi^0(T, \tau_0, \hat{\xi}_0, u, v, k) - \phi^0(t_f, \tau_0, \hat{\xi}_0, u, v, k)| \le \frac{M}{c_0 k}.$$

Proof. If $t_f = T$, then the inequality is clearly true. Assume $t_f < T$. Let $\hat{\theta}(t) = \hat{\rho}(t, \hat{\phi}(t))$, then $d\hat{\theta}/dt = \hat{\rho}_t(t, \hat{\phi}(t)) + \langle \hat{\rho}_{\hat{x}}(t, \hat{\phi}(t)), \hat{f}_k(t, \hat{\phi}(t), u(t), v(t))\rangle$. Let $k > 1/\epsilon_0$. If $(t, \hat{\phi}(t))$ stays in $\mathcal{N}_{1/k}(\mathcal{B})$, the right side of the preceding equation is $\le -c_0$. Let $t_f \le t \le T$ and let $(t, \hat{\phi}(t)) \in \mathcal{N}_{1/k}(\mathcal{B})$. We have that $\hat{\theta}(t) - \hat{\theta}(t_f) \le -c_0(t - t_f)$. Since $\hat{\theta}(t_f) = 0$, $(t - t_f) \le -\hat{\theta}(t)/c_0 \le 1/c_0 k$. Hence $|\phi^0(T, \tau_0, \hat{\xi}_0, u, v, k) - \phi^0(t_f, \tau_0, \hat{\xi}_0, u, v, k)| \le M/c_0 k$. $\square$

COROLLARY 18. *Let Assumption* I *and either Assumption* II *or* II′ *hold. If t_f is the terminal time of a motion $\hat{\phi}[\ , \tau_0, \hat{\xi}_0, \Gamma, \Delta, k]$ with $(\tau_0, \hat{\xi}_0) \in \mathcal{X}$, then for sufficiently large k, $|\phi^0[T, \tau_0, \hat{\xi}_0, \Gamma, \Delta, k] - \phi^0[t_f, \tau_0, \hat{\xi}_0, \Gamma, \Delta, k]| \le M/c_0 k$.*

LEMMA 19. *Let Assumption* I, *either Assumption* II *or* II′, *and the Isaacs condition (Î) hold for $\hat{f}$. Then*

$$W^+_{0,\mu}(t_0, x_0) \le W(t_0, x_0) + \left[\frac{2M}{c_0}\left(\frac{M+1}{c_0} + 1\right)\right]\eta(\mu).$$

Proof. From Lemma 16, there exists a $\bar{t} \in [t_0, t_f]$ such that

$$(\bar{t}, \hat{\phi}[\bar{t}, t_0, \hat{x}_0, \Gamma^0, \Delta^\mu_e, k]) \in C^{(k)}_{\eta(\mu)}(\nu_{0,k} \cap H(\bar{t})$$

and $0 \le t_f - \bar{t} \le (1/c_0)\eta(\mu)$ if μ is sufficiently small, where t_f is the terminal time of $\hat{\phi}[t, t_0, \hat{x}_0, \Gamma^0, \Delta_e^\mu, k]$.

Since $(\bar{t}, \hat{\phi}[\bar{t}, t_0, \hat{x}_0, \Gamma^0, \Delta_e^\mu, k]) \in C^{(k)}_{\eta(\mu)}(\nu_{0,k})$, there exists a $\hat{w} \in \mathbb{R}^{n+1}$ such that $(\bar{t}, \hat{w}) \in C^{(k)}(\nu_{0,k})$ and

$$|\hat{\phi}[\bar{t}, t_0, \hat{x}_0, \Gamma^0, \Delta_e^\mu, k] - \hat{w}| \le \eta(\mu). \tag{23}$$

Since $(\bar{t}, \hat{w}) \in C^{(k)}(\nu_{0,k})$, it follows from [1, Lem. 8.2] that for any $\epsilon > 0$ and any strategy Γ for Player I over $[\bar{t}, T]$ there exists a strategy $\Delta(\Gamma)$ for Player II over $[\bar{t}, T]$ such that

$$\phi^0[T, \bar{t}, \hat{w}, \Gamma, \Delta(\Gamma), k] \le \nu_{0,k} + \epsilon. \tag{24}$$

Note that if $\hat{\phi}[t] = \hat{\phi}[t, t_0, \hat{x}_0, \Gamma^0, \Delta_e^\mu, k]$, then

$$\begin{aligned}
|(\bar{t}, \hat{w}) - (t_f, \hat{\phi}[t_f])| &\le |\bar{t} - t_f| + |\hat{w} - \hat{\phi}[t_f]| \\
&\le |\bar{t} - t_f| + |\hat{w} - \hat{\phi}[\bar{t}]| + |\hat{\phi}[\bar{t}] - \hat{\phi}[t_f]| \\
&\le \frac{1}{c_0}\eta(\mu) + \eta(\mu) + \frac{M}{c_0}\eta(\mu) \\
&= \Big(\frac{M+1}{c_0} + 1\Big)\eta(\mu).
\end{aligned}$$

Since $(t_f, \hat{\phi}[t_f, t_0, \hat{x}_0, \Gamma^0, \Delta_e^\mu, k]) \in \mathcal{B}$, $(\bar{t}, \hat{w}) \in \mathcal{N}_{(((M+1)/c_0)+1)\eta(\mu)}(\mathcal{B})$.

If $(\bar{t}, \hat{w}) \notin \hat{T}$ and if $\bar{t}_f$ is the terminal time of $\hat{\phi}[\ , \bar{t}, \hat{w}, \Gamma, \Delta(\Gamma), k]$, then Corollary 4 asserts that for sufficiently small μ

$$\bar{t}_f - \bar{t} \le \frac{1}{c_0}\left(\frac{M+1}{c_0} + 1\right)\eta(\mu). \tag{25}$$

By Corollary 18 we have that there exists a k_0, independent of Γ and Δ, such that if $k \ge k_0$ and if t_f is the terminal time of $\hat{\phi}[t, \tau_0, \hat{\xi}_0, \Gamma, \Delta, k]$, then

$$|\phi^0[T, \tau_0, \hat{\xi}_0, \Gamma, \Delta, k] - \phi^0[t_f, \tau_0, \hat{\xi}_0, \Gamma, \Delta.k]| \le \frac{M}{c_0 k}. \tag{26}$$

Therefore

$$\begin{aligned}
&|w^0 - \phi^0[T, \bar{t}, \hat{w}, \Gamma, \Delta(\Gamma), k]| \\
\le &|w^0 - \phi^0[\bar{t}_f, \bar{t}, \hat{w}, \Gamma, \Delta(\Gamma), k]| \\
&\quad + |\phi^0[\bar{t}_f, \bar{t}, \hat{w}, \Gamma, \Delta(\Gamma), k] - \phi^0[T, \bar{t}, \hat{w}, \Gamma, \Delta(\Gamma), k]| \\
\le &M(\bar{t}_f - \bar{t}) + \frac{M}{c_0 k} \qquad \text{(by (26))} \\
\le &\frac{M}{c_0}\left(\frac{M+1}{c_0} + 1\right)\eta(\mu) + \frac{M}{c_0 k} \qquad \text{(by (25))}.
\end{aligned} \tag{27}$$

If $(\bar{t}, \hat{w}) \in \hat{T}$, Corollary 18 implies that

$$|w^0 - \phi^0[T, \bar{t}, \hat{w}, \Gamma, \Delta(\Gamma), k]| \le \frac{M}{c_0 k} \le \frac{M}{c_0}\left(\frac{M+1}{c_0} + 1\right)\eta(\mu) + \frac{M}{c_0 k}.$$

Hence, in any case, (27) holds.

Now, we have

$$\begin{aligned}
&\phi^0[T, t_0, \hat{x}_0, \Gamma^0, \Delta_e^\mu, k] \\
&= \phi^0[\bar{t}, t_0, \hat{x}_0, \Gamma^0, \Delta_e^\mu, k] + \phi^0[t_f, t_0, \hat{x}_0, \Gamma^0, \Delta_e^\mu, k] - \phi^0[\bar{t}, t_0, \hat{x}_0, \Gamma^0, \Delta_e^\mu, k] \\
&\quad + \phi^0[T, t_0, \hat{x}_0, \Gamma^0, \Delta_e^\mu, k] - \phi^0[\bar{t}, t_0, \hat{x}_0, \Gamma^0, \Delta_e^\mu, k] \\
&\le \phi^0[\bar{t}, t_0, \hat{x}_0, \Gamma^0, \Delta_e^\mu, k] + M(t_f - \bar{t}) + \frac{M}{c_0 k} \qquad \text{(by (26))} \\
&\le w^0 + \eta(\mu) + \frac{M}{c_0}\eta(\mu) + \frac{M}{c_0 k} \qquad \text{(by (23) and the definition of } \bar{t}) \\
&\le \phi^0[T, \bar{t}, \hat{w}, \Gamma, \Delta(\Gamma), k] + \frac{M}{c_0}\left(\frac{M+1}{c_0} + 1\right)\eta(\mu) + \frac{M}{c_0 k} \\
&\quad + \eta(\mu) + \frac{M}{c_0}\eta(\mu) + \frac{M}{c_0 k} \qquad \text{(by (27))} \\
&\le \nu_{0,k} + \epsilon + \left[\frac{M}{c_0}\left(\frac{M+1}{c_0} + 1\right)\right]\eta(\mu) + \frac{2M}{c_0 k} \qquad \text{(by (24))}.
\end{aligned}$$

By the arbitrariness of ϵ and the definition of $\hat{W}^+_{0,\mu}(t_0, \hat{x}_0, k)$, we get

$$\hat{W}^+_{0,\mu}(t_0, \hat{x}_0, k) \le \hat{W}^+_{0,0}(t_0, \hat{x}_0, k) + \left[\frac{2M}{c_0}\left(\frac{M+1}{c_0} + 1\right) + 1\right]\eta(\mu) + \frac{2M}{c_0 k}.$$

If k is sufficiently large, it follows from Lemma 15 that

$$W^+_{0,\mu}(t_0, x_0) \le W(t_0, x_0) + \frac{2c_0}{k} + \left[\frac{2M}{c_0}\left(\frac{M+1}{c_0} + 1\right) + 1\right]\eta(\mu) + \frac{2M}{c_0 k}.$$

The lemma is shown by letting $k \to \infty$. □

Under the same assumptions as in Lemma 19, we have $W^-_{\lambda,0}(t_0, x_0) \ge W(t_0, x_0) - ((M/c_0) + 1)\eta(\lambda)$. Hence, by Lemma 13, we have the following result.

THEOREM 20. *If Assumption* I *and either Assumption* II *or* II′ *hold and if the Isaacs condition (Î) holds, there exist a* $\delta > 0$ *and a nonnegative function* σ *such that* $\sigma(s) \to 0$ *as* $s \to 0$ *and*

$$0 \le W^+_{\lambda,\mu}(t_0, x_0) - W^-_{\lambda,\mu}(t_0, x_0) \le \sigma(\lambda) + \sigma(\mu)$$

for $0 \le \lambda, \mu \le \delta$, *and hence*

$$\lim_{\substack{\lambda \to 0 \\ \mu \to 0}} W^\pm_{\lambda,\mu}(t_0, x_0) = W(t_0, x_0).$$

2.3. Differential games of survival with lags. The game is governed by (1) with payoff (2). Applying the technique that has been used in [3], for differential games of survival with information lags, we have the following lemma.

LEMMA 21. *Assume that Assumption* I′ *and the Isaacs condition* ($\hat{I}$) *hold for* $\hat{f}$ *and that* F *satisfies either Assumption* II *or* II′. *If* g *is* $C^{(2)}$, *then there exist a* $\delta > 0$ *and a nonnegative function* σ *such that* $\sigma(s) \to 0$ *as* $s \to 0$ *and*

$$W^{-}_{\lambda,0}(t_0, x_0) + \sigma(\lambda) \geq W(t_0, x_0), \qquad \text{if } 0 \leq \lambda \leq \delta,$$
$$W^{+}_{0,\mu}(t_0, x_0) \leq W(t_0, x_0) + \sigma(\mu), \qquad \text{if } 0 \leq \mu \leq \delta.$$

Proof. We can assume without loss of generality that $g(t_0, x_0) = 0$. Then we can write

$$g(t_f, x_f) + \int_{t_0}^{t_f} f^0(s, \phi(s), u(s), v(s))\, ds$$
$$= \int_{t_0}^{t_f} [g_t(s, \phi(s)) + \langle Dg(s, \phi(s)), f(s, \phi(s), u(s), v(s))\rangle + f^0(s, \phi(s), u(s), v(s))]\, ds.$$

Thus the game G can be written as a game $\tilde{G}$ with $\tilde{g} \equiv 0$ and $\tilde{f}^0$ given by

$$\tilde{f}^0(t, x, y, z) = g_t(t, x) + \langle Dg(t, x), f(t, x, y, z)\rangle + f^0(t, x, y, z).$$

It is immediate to verify that if G satisfies the assumptions in Lemma 21, $\tilde{G}$ satisfies assumptions in Lemma 19. So, Lemma 21 holds. □

Remark. The condition on g in Lemma 21 can be weakened. If g is $C^{1,1}$, i.e., g is $C^{(1)}$ and g' is Lipschitz continuous, then the results of Lemma 21 hold.

Lemma 13 and Lemma 21 give us the following theorem.

THEOREM 22. *Under the same assumptions as in Lemma* 21, *the result of Theorem* 20 *holds.*

A DISSIPATIVE FEEDBACK CONTROL SYNTHESIS FOR SYSTEMS ARISING IN FLUID DYNAMICS*

KAZUFUMI ITO† AND SUNGKWON KANG‡

Abstract. A dissipative feedback control synthesis is constructed to regulate the systems arising in fluid dynamics. The feedback law is obtained by utilizing nonlinear dynamic programming techniques. The control law is designed for driving the system to a prescribed equilibrium state and enhancing the energy dissipation effects of the dynamical system. Two-dimensional Navier–Stokes equations and Burgers equation are used for numerical experiments to illustrate the effects of the feedback synthesis and the theoretical results.

Key words. feedback control, dynamic programming, Burgers' equation, Navier–Stokes equations

1. Introduction.

During the past years considerable attention has been given to the problem of active control of fluid flows. This interest is motivated by a number of potential applications such as control of flow separation, combustion, fluid-structure interaction, and super maneuverable aircraft. In this direction, Burns, Ito, and Kang ([BIK], [BK1], [BK2]) developed several computational algorithms for active control design for the Burgers equation, a simple model for convection-diffusion phenomena such as shock waves, traffic flows, supersonic flow around airfoils, etc. Using linearization techniques and linear quadratic regulator (LQR) theory, the feedback control laws were constructed to obtain a certain desired degree of stability for the closed-loop nonlinear system.

In this paper we construct and analyze a dissipative feedback control synthesis that regulates the systems arising in fluid dynamics. The control law is obtained by utilizing nonlinear dynamic programming techniques and designed for enhancing the energy dissipation effects of the dynamical systems and driving the systems to specific equilibrium states.

Let H, U, and V be separable Hilbert spaces. Assume that V is densely and continuously embedded into H and let V^* be the (strong) dual space of V. Consider a control problem governed by the following semilinear dynamics:

$$\frac{d}{dt}x(t) + \epsilon \mathcal{A}x(t) + \mathcal{F}(x(t)) = \mathcal{B}u(t) + f(t), \qquad x(0) = x_0, \tag{1.1}$$

where $\epsilon > 0$, $\mathcal{A}$ is a nonnegative selfadjoint operator defined on H with $\mathcal{D}(\mathcal{A}^{1/2}) = V$, $\mathcal{F}$ is a locally Lipschitz mapping from V into V^*, $\mathcal{B} \in \mathcal{L}(U, H)$ is a control input operator, and we assume $U = \mathbf{R}^m$. Thus, we have $\mathcal{B}u = \sum_{i=1}^m b_i u_i$ with $b_i \in H$. A class of problems described by (1.1) includes the Navier–Stokes equations, Burgers equation, and reaction-diffusion equations. Let x_e be an equilibrium state of the

system (1.1) with $u(t) \equiv 0$ and $f(t) \equiv 0$. In this paper, we consider a specific feedback control mechanism $u(t)$ of the form

$$
\begin{aligned}
u(t) &= (u_1(t), \dots, u_m(t)) \in \mathbf{R}^m, \\
u_i(t) &= -\gamma_i(t)\langle b_i, x(t) - x_e\rangle_H, \qquad i = 1, 2, \dots, m,
\end{aligned}
\tag{1.2}
$$

where b_i are control distribution functions in H and the feedback laws $\gamma_i(t) > 0$ will be determined by finding a suboptimal solution to the Hamilton–Jacobi–Bellman (HJB) equation. Note that the control law (1.2) is of the form $\mathcal{B}^* x(t)$ and this form of feedback is used commonly in control of flexible structure (e.g., in [B]) and is called the co-located rate sensors or the passive feedback form. This feedback law (1.2) is derived from the following considerations. First, the passive form (1.2) is an essential part of a linear optimal control law (see Lemma 2.2). Second, the closed-loop system (with $f \equiv 0$) is dissipative (see Theorem 2.6). Finally, it is easily implementable practically. In practice, the control distribution functions $b_i \in H$ are chosen as locally supported, and hence the feedback forms $\langle b_i, x(t) - x_e\rangle_H$ become local operations. As will be seen in §3, the control force generated through locally supported control distributions b_i's makes a significant change in global patterns of the flow.

The outline of the paper is as follows. In §2, detailed derivation of the feedback control law (1.2) is described. Also, properties of the feedback law, as well as well-posedness of the closed-loop system, are established. The feedback synthesis (1.2) is applied to the Burgers equation and the two-dimensional Navier–Stokes equations in §3. To see how this controller affects the global nature of the transient flow, such as achievement of the desired asymptotic behavior, energy dissipation effects, and time-dependent behavior of the solution, several numerical computations are performed.

Throughout this paper notation is very standard. We will use the notation $|\cdot|$ without any subindex for vector or operator norm. In all such cases the appropriate index for $|\cdot|$ will be understood from the context. A given Banach space X, X^* and $\langle\cdot,\cdot\rangle_{X^*,X}$ denote the strong dual space of X and the dual product, respectively. If X is a Hilbert space, $\langle\cdot,\cdot\rangle$ is the scalar inner product.

2. A dissipative feedback control law. In this section we consider a specific control law (1.2) and a "suboptimal" control law $\gamma_i(t)$ is derived. The control laws $\gamma_i(t)$ are determined based on the dynamic programming technique [FR]. Let H be a Hilbert space. Consider the following control problem

$$
\frac{d}{dt}x(t) + \epsilon\mathcal{A}x(t) + \mathcal{F}(x(t)) = \mathcal{B}u(t) + f(t), \qquad x(0) = x_0,
\tag{2.1}
$$

where $\epsilon > 0$, $\mathcal{A}$ is a nonnegative selfadjoint operator on H, and $\mathcal{B} \in \mathcal{L}(U, H)$ is the control input operator defined by

$$
\mathcal{B}u = \sum_{i=1}^{m} u_i b_i,
\tag{2.2}
$$

with $U = \mathbf{R}^m$ and $b_i \in H$. The function f is a source term and $\mathcal{F}$ is a locally Lipschitz nonlinear operator from $\mathcal{D}(\mathcal{A}^{1/2})$ into $\mathcal{D}(\mathcal{A}^{1/2})^*$.

We consider a regulation problem for the solution of (2.1) to an *equilibrium* $x_e \in \mathcal{D}(\mathcal{A}^{1/2})$ satisfying

$$
\epsilon\mathcal{A}x_e + \mathcal{F}(x_e) = 0 \quad \text{in } \mathcal{D}(\mathcal{A}^{1/2})^*.
$$

Assume the following:

(A1) $\langle \mathcal{F}(x) - \mathcal{F}(x_e),\, x - x_e \rangle = 0$ for all $x \in \mathcal{D}(\mathcal{A}^{1/2})$,

(A2) $\mathcal{F}(x)$ is Fréchet differentiable at x_e with derivative $\mathcal{F}'(x_e) \in \mathcal{L}(\mathcal{D}(\mathcal{A}^{1/2}), \mathcal{D}(\mathcal{A}^{1/2})^*)$.

Then the linearization of (2.1) about the equilibrium x_e becomes

$$\frac{d}{dt}y(t) + \epsilon \mathcal{A}y(t) + \mathcal{F}'(x_e)y(t) = \mathcal{B}v(t), \tag{2.3}$$

where $y(t)$ represents the variation of $x(t)$ from x_e.

Let $V = \mathcal{D}(\mathcal{A}^{1/2})$ with norm $\sqrt{|x|^2 + \langle \mathcal{A}x, x \rangle}$, and $\sigma_{x_e}(\cdot, \cdot)$ be a sesquilinear form on $V \times V$ defined by

$$\sigma_{x_e}(\phi, \psi) = \epsilon \langle \mathcal{A}\phi, \psi \rangle + \langle \mathcal{F}'(x_e)\phi, \psi \rangle.$$

Then it follows from (A1) and (A2) that σ_{x_e} is continuous and

$$\sigma_{x_e}(\phi, \phi) = \epsilon \langle \mathcal{A}\phi, \phi \rangle \quad \text{for all } \phi \in V.$$

In fact, $\mathcal{F}'(x_e)$ is skew-adjoint and

$$\langle \mathcal{F}'(x_e)\phi, \phi \rangle = 0 \quad \text{for all } \phi \in V.$$

Moreover, it follows from [P, p. 81] or [Ta] that the operator $\mathcal{A}_{x_e} = -\epsilon \mathcal{A} - \mathcal{F}'(x_e)$ generates an analytic semigroup on H.

2.1. Linear quadratic regulator problem. To give a mathematical motivation for considering the feedback law of form (1.2), we consider the following linear quadratic regulator (LQR) problem for the linearlized control systems (2.3): *Find the optimal control v that minimizes the quadratic cost functional*

$$J(v) = \int_0^\infty \left(|\mathcal{A}^{\frac{1}{2}} y(t)|^2 + |v(t)|^2 \right) dt, \tag{2.4}$$

subject to the control system (2.3).

Here, $|\mathcal{A}^{1/2}y|^2 = \langle y, \mathcal{A}y \rangle$ represents an energy stored in the system and the weight on control consumption is included in the definition of the operator $\mathcal{B}$. Assume that the pair $(\mathcal{A}_{x_e}, \mathcal{B})$ is *exponentially stabilizable*; i.e., there exists an operator $\mathcal{K} \in \mathcal{L}(V, U)$ such that $\mathcal{A}_{x_e} + \mathcal{B}\mathcal{K}$ generates an exponentially stable semigroup on H. It then follows from [PS], [BI] that the (LQR) problem has a unique optimal solution that is given by

$$v^{op}(t) = -\mathcal{B}^*\mathcal{P}y(t), \tag{2.5}$$

where the nonnegative selfadjoint operator $\mathcal{P} \in \mathcal{L}(H) \cap \mathcal{L}(V)$ satisfies the Riccati equation

$$\langle \mathcal{A}_{x_e}\phi, \mathcal{P}\psi \rangle + \langle \mathcal{P}\phi, \mathcal{A}_{x_e}\psi \rangle - \langle \mathcal{B}^*\mathcal{P}\phi,\, \mathcal{B}^*\mathcal{P}\psi \rangle + \langle \mathcal{A}\phi, \psi \rangle = 0 \tag{2.6}$$

for all $\phi, \psi \in V$. There are two difficulties associated with the feedback law (2.5); one is that the closed-loop operator $\mathcal{A}_{x_e} - \mathcal{B}\mathcal{B}^*\mathcal{P}$ may not generate an exponentially stable

semigroup, and the other is that $\mathcal{P}$ is not readily available and finding the solution $\mathcal{P}$ of (2.6) is nontrivial in general. Thus, we consider the following cost functional

$$J(v) = \int_0^\infty \left(|\mathcal{A}^{\frac{1}{2}} y(t)|^2 + \left| \frac{1}{2\epsilon} \mathcal{B}^* y(t) \right|^2 + |v(t)|^2 \right) dt. \tag{2.7}$$

Then we have the following result.

THEOREM 2.1. *Assume that $(\mathcal{A}_{x_e}, \mathcal{B})$ is exponentially stabilizable. Then there exists a unique optimal control that minimizes the cost* (2.7) *subject to the control system* (2.3) *and it is given by*

$$v^{op}(t) = -\frac{1}{2\epsilon} \mathcal{B}^* y(t). \tag{2.8}$$

Moreover, $\mathcal{A}_{x_e} - \frac{1}{2\epsilon}\mathcal{B}\mathcal{B}^*$ generates an exponentially stable (analytic) semigroup on H.

Proof. Note that $\bar{\mathcal{P}} = \frac{1}{2\epsilon} I \in \mathcal{L}(H) \cap \mathcal{L}(V)$ satisfies the Riccati equation

$$\begin{aligned} &\langle \mathcal{A}_{x_e}\phi, \bar{\mathcal{P}}\psi \rangle + \langle \bar{\mathcal{P}}\phi, \mathcal{A}_{x_e}\psi \rangle - \langle \mathcal{B}^*\bar{\mathcal{P}}\phi, *\mathcal{B}^*\bar{\mathcal{P}}\psi \rangle \\ &\qquad + \langle \mathcal{A}\phi, \psi \rangle + \tfrac{1}{4\epsilon^2} \langle \mathcal{B}^*\phi, \mathcal{B}^*\psi \rangle = 0 \end{aligned} \tag{2.9}$$

for all $\phi, \psi \in V$. Hence, the theorem follows from [BI, Thm. 3.5] and [PS, Thms. 3.4, 3.5 and Rem. 3.5], since $(\mathcal{A}_{x_e}, \mathcal{B}^*)$ is detectable. Therefore, the Riccati equation (2.9) has a unique nonnegative solution and the optimal control is given by (2.8). □

It follows from (2.2) that

$$(\mathcal{B}^*\phi)_i = \langle b_i, \phi \rangle \quad \text{for all } \phi \in H.$$

Thus the feedback law (2.8) is of form (2.1). Next, we show that the feedback law (2.8) is an essential part of linear feedback laws based on the Riccati equation in the following sense.

LEMMA 2.2. *Given a nonnegative selfadjoint operator $\mathcal{Q}$, assume that a nonnegative selfadjoint operator $\mathcal{P} \in \mathcal{L}(H) \cap \mathcal{L}(V)$ satisfies the Riccati equation*

$$\langle \mathcal{A}_{x_e}\phi, \mathcal{P}\psi \rangle + \langle \mathcal{P}\phi, \mathcal{A}_{x_e}\psi \rangle - \langle \mathcal{B}^*\mathcal{P}\phi, \mathcal{B}^*\mathcal{P}\psi \rangle + \langle \mathcal{A}\phi, \psi \rangle + \langle \mathcal{Q}\phi, \psi \rangle = 0 \tag{2.10}$$

for all $\phi, \psi \in V$. Then if V is compactly embedded in H, $\Sigma = \mathcal{P} - \frac{1}{2\epsilon} I$ is compact on H.

Proof. From (2.9) and (2.10) we have

$$\langle \mathcal{A}_{x_e}\phi, \Sigma\psi \rangle + \langle \Sigma\phi, \mathcal{A}_{x_e}\psi \rangle - \langle \mathcal{B}^*\mathcal{P}\phi, \mathcal{B}^*\mathcal{P}\psi \rangle + \langle \mathcal{Q}\phi, \psi \rangle = 0$$

for all $\phi, \psi \in V$. Thus we obtain

$$\Sigma = \int_0^t e^{s\mathcal{A}_{x_e}^*} (\mathcal{Q} - \mathcal{P}\mathcal{B}\mathcal{B}^*\mathcal{P}) e^{s\mathcal{A}_{x_e}} ds + e^{t\mathcal{A}_{x_e}^*} \Sigma e^{t\mathcal{A}_{x_e}},$$

where $e^{t\mathcal{A}_{x_e}}$, $t \geq 0$, denotes the analytic semigroup on H generated by $\mathcal{A}_{x_e}$. The lemma follows from the fact that $\Sigma x \in V$ for $x \in H$, since $|e^{t\mathcal{A}_{x_e}}|_{\mathcal{L}(H,V)} \leq M/t^{1/2}$, $t > 0$, for some constant $M > 0$ (see [Ta]). □

2.2. A nonlinear feedback law. Now, we seek a feedback control law of the form

$$u_i(t) = -\gamma_i(t)\langle b_i,\, x(t) - x_e\rangle, \tag{2.11}$$

where $\gamma_i(t) \geq 0$ is chosen so that the transition of the solution of the closed-loop system is accounted; i.e., the cost functional

$$\frac{1}{2}\int_0^\infty \left(\langle x(t) - x_e, \mathcal{A}(x(t) - x_e)\rangle + \langle \mathcal{Q}(x(t) - x_e), x(t) - x_e\rangle + |u(t)|^2\right) dt \tag{2.12}$$

is minimized subject to the control system

$$\begin{aligned} &\frac{d}{dt}x(t) + \epsilon\,\mathcal{A}x(t) + \mathcal{F}(x(t)) = \mathcal{B}u(t), \\ &u_i(t) = -\gamma_i(t)\langle b_i,\, x(t) - x_e\rangle, \qquad (1 \leq i \leq m). \end{aligned} \tag{2.13}$$

Before determining the feedback control law $\gamma(t) = (\gamma_1(t), \ldots, \gamma_m(t))$ we state the dissipative property of the closed-loop system (2.13).

LEMMA 2.3. *Given $\gamma(t) \in L^\infty(0,T;\mathbf{R}_+^m)$ and $x(0) = \phi \in H$, assume that* (2.13) *has a solution $x(t) \in L^2(0,T;V) \cap C(0,T;H) \cap H^1(0,T;V^*)$. Then we have*

$$\begin{aligned} &\frac{1}{2}|x(t) - x_e|_H^2 + \int_0^t \Big(\epsilon\langle x(s) - x_e, \mathcal{A}(x(s) - x_e)\rangle \\ &\qquad + \sum_{i=1}^m \gamma_i(s)|\langle b_i,\, x(t) - x_e\rangle|^2\Big)\, ds \\ &\qquad = \frac{1}{2}|x(0) - x_e|_H^2, \qquad t \in [0,T], \end{aligned} \tag{2.14}$$

where $\mathbf{R}_+^m = \{\,\eta = (\eta_1, \ldots, \eta_m) \in \mathbf{R}^m \,:\, \eta_i \geq 0,\ 1 \leq i \leq m\,\}$.

Proof. It follows from (2.13) that

$$\begin{aligned} &\frac{1}{2}\frac{d}{dt}|x(t) - x_e|_H^2 + \epsilon\,\langle \mathcal{A}(x(t) - x_e), x(t) - x_e\rangle + \langle \mathcal{F}(x(t)) - \mathcal{F}(x_e), x(t) - x_e\rangle \\ &\qquad + \sum_{i=1}^m \gamma_i(t)|\langle b_i,\, x(t) - x_e\rangle|^2 = 0. \end{aligned}$$

Integration of the above equation and assumption (A1) yield the estimate (2.14). □

Remark. In Lemma 2.8, we give a condition on $\mathcal{F}$ in which (2.13) has a unique global solution. Lemma 2.3 implies that the optimal feedback law provides additional energy dissipation.

We now construct the feedback laws $\gamma_i(t)$ in (2.11). Determination of the "optimal" control $\gamma_i(t)$ involves solving the HJB equation (see [FR]). It is not our interest here to establish a complete theory of feedback solutions based on the HJB equation. Rather we will use the HJB equation as a means of construction of feedback synthesis $\gamma_i(t)$. Thus, the following discussions are by no means rigorous. It is of our interest in future to verify the details. Also, we refer to a recent paper [Sr] and the references

therein for a mathematical treatment of the HJB equation in which the finite time horizon problem is treated.

Consider the HJB equation

(2.15)
$$\mathrm{Min}_{\gamma\geq 0}\left[\langle p, -\epsilon\mathcal{A}(x-x_e)-(\mathcal{F}(x)-\mathcal{F}(x_e))-\sum_{i=1}^{m}\gamma_i b_i\langle b_i, x-x_e\rangle\rangle\right.$$
$$\left.+\frac{1}{2}\left(\sum_{i=1}^{m}|\langle b_i, x-x_e\rangle|^2|\gamma_i|^2+\langle\mathcal{A}(x-x_e), x-x_e\rangle+\langle\mathcal{Q}(x-x_e), x-x_e\rangle\right)\right]=0,$$

where $p=\frac{\partial}{\partial x}W(x)$ and $W(x)$ is the value function defined below. The minimum of the problem (2.15) is attained when

(2.16)
$$\gamma_i=\begin{cases}\dfrac{(\langle b_i,p\rangle)(\langle b_i, x-x_e\rangle)}{|\langle b_i, x-x_e\rangle|^2}, & \text{if } (\langle b_i,p\rangle)(\langle b_i, x-x_e\rangle)\geq 0,\\ 0, & \text{otherwise.}\end{cases}$$

By Hamilton–Jacobi theory (e.g., see [FR], [L] for the finite-dimensional case and [CL], [BD] for the infinite-dimensional case), the value function

$$W(x)=\mathrm{Min}_{\gamma}J(\gamma)$$

satisfies the HJB equation (2.15), where $J(\gamma)$ is defined by (2.12). Conversely, assuming that (2.15), (2.16) has a solution $W(x)$ that is (at least) Lipschitz in V, then (2.16) with $p=\frac{\partial}{\partial x}W(x)$, $x\in V$, provides an optimal solution. To obtain the optimal feedback control γ^{op} we must solve the nonlinear partial differential equations (2.15), (2.16) for $W(x)$ in V. Instead of solving the equations, we look for p having the following form:

(2.17)
$$p(x)=c(x)(x-x_e),$$

where $c(x)$ is a scalar function in $x\in V$. Substitution of $p(x)$ into (2.15), (2.16) yields the equation

$$|\mathcal{B}^*(x-x_e)|^2c(x)^2+2\epsilon\langle x-x_e, \mathcal{A}(x-x_e)\rangle c(x)$$
$$-(\langle\mathcal{Q}(x-x_e), x-x_e\rangle+\langle x-x_e, \mathcal{A}(x-x_e)\rangle)=0.$$

The positive solution of the above equation is given by

(2.18)
$$c(x)=\frac{-\epsilon\langle x-x_e, \mathcal{A}(x-x_e)\rangle+\sqrt{g_1(x)+g_2(x)|\mathcal{B}^*(x-x_e)|^2}}{|\mathcal{B}^*(x-x_e)|^2},$$

where

$$g_1(x)=(\epsilon\langle x-x_e, \mathcal{A}(x-x_e)\rangle)^2,$$
$$g_2(x)=\langle x-x_e, \mathcal{A}(x-x_e)\rangle+\langle\mathcal{Q}(x-x_e), x-x_e\rangle.$$

Hence, letting $\gamma_i(t)\equiv c(x(t))$ for each i, we obtain the nonlinear feedback law

(2.19)
$$u(t)=-c(x)\mathcal{B}^*(x-x_e).$$

2.3. Properties of the proposed feedback law. Now we investigate properties of the feedback law (2.19).

THEOREM 2.4. *Suppose that* $\mathcal{Q} = \frac{1}{4\epsilon^2}\mathcal{B}\mathcal{B}^*$. *Then* $W(x) = \frac{1}{4\epsilon}|x - x_e|_H^2$ *satisfies the* HJB *equation* (2.15), (2.16).

Proof. Note that $\frac{\partial}{\partial x}W(x) = \frac{1}{2\epsilon}(x - x_e)$ and $\gamma_i(t) = \frac{1}{2\epsilon}$. Thus the left-hand side of (2.15) is equal to

$$\frac{1}{2\epsilon}\left\langle x - x_e, -\epsilon\mathcal{A}(x - x_e) - (\mathcal{F}(x) - \mathcal{F}(x_e)) - \sum_{i=1}^{m}\frac{1}{2\epsilon}b_i\langle b_i, x - x_e\rangle\right\rangle$$

$$+\frac{1}{2}\left(\sum_{i=1}^{m}\frac{1}{4\epsilon^2}|\langle b_i, x - x_e\rangle|^2 + \langle\mathcal{A}(x - x_e), x - x_e\rangle\right) = 0. \qquad \square$$

The next theorem is concerned with the bound of $c(x)$.

THEOREM 2.5. *Suppose that* $\mathcal{Q} = \alpha\mathcal{B}\mathcal{B}^*$ *with* $0 < \alpha \le 1/4\epsilon^2$. *Then* $0 \le c(x) \le \frac{1}{2\epsilon}$, *where* $c(x)$ *is given by* (2.18).

Proof. Note that

$$|\epsilon\langle x - x_e, \mathcal{A}(x - x_e)\rangle|^2 + |\mathcal{B}^*(x - x_e)|^2(\langle x - x_e, \mathcal{A}(x - x_e)\rangle + \alpha|\mathcal{B}^*(x - x_e)|^2)$$

$$= (\epsilon\langle x - x_e, \mathcal{A}(x - x_e)\rangle + \tfrac{1}{2\epsilon}|\mathcal{B}^*(x - x_e)|^2)^2 + (\alpha - \tfrac{1}{4\epsilon^2})|\mathcal{B}^*(x - x_e)|^4.$$

Thus, the theorem follows from (2.18). $\square$

In what follows we assume that $\mathcal{Q} = \alpha\mathcal{B}\mathcal{B}^*$ with $1 \le \alpha \le 1/4\epsilon^2$.

THEOREM 2.6. *Assume that the closed-loop system*

$$\frac{d}{dt}x(t) + \epsilon\mathcal{A}x(t) + \mathcal{F}(x(t)) = -c(x)\mathcal{B}\mathcal{B}^*(x(t) - x_e), \qquad x(0) = \phi \in H, \tag{2.20}$$

has a solution $x(t) \in L^2(0,T;V)\cap C(0,T;H)\cap H^1(0,T;V^*)$. *Then we have for* $\omega \ge 0$

$$\frac{1}{2}e^{\omega t}|x(t) - x_e|_H^2 + \int_0^t(\sqrt{h_1(x) + |\mathcal{B}^*(x - x_e)|^2h_2(x)} - \frac{\omega}{2}|x(s) - x_e|_H^2)e^{\omega s}\,ds \tag{2.21}$$

$$= \frac{1}{2}|x(0) - x_e|_H^2,$$

where

$$h_1(x) = (\epsilon\langle x - x_e, \mathcal{A}(x - x_e)\rangle)^2$$
$$h_2(x) = \langle x - x_e, \mathcal{A}(x - x_e)\rangle + \alpha|\mathcal{B}^*(x - x_e)|^2. \tag{2.22}$$

Proof. The proof follows from Lemma 2.3. $\square$

Next, we obtain the asymptotic stability property of the closed-loop system (2.20).

THEOREM 2.7. *Given* $x(0) = \phi \in H$, *assume that the system* (2.20) *has a global solution. Assume that there exists a positive constant* β *such that*

$$\epsilon\langle x - x_e, \mathcal{A}(x - x_e)\rangle + |\mathcal{B}^*(x - x_e)|^2 \ge \beta|x - x_e|_H^2 \quad \textit{for all } x \in V.$$

Then $|x(t) - x_e|_H \le e^{-\beta t}|x(0) - x_e|_H$ *and* $\lim_{t\uparrow\infty}c(x) = \frac{1}{2\epsilon}$.

Proof. It follows from the estimate (2.21) and the inequality

$$\sqrt{h_1(x) + |\mathcal{B}^*(x - x_e)|^2 h_2(x)} \geq \epsilon \langle x - x_e, \mathcal{A}(x - x_e)\rangle + |\mathcal{B}^*(x(t) - x_e)|^2,$$

that if we set $\omega = 2\beta$ we have

$$e^{2\beta t} |x(t) - x_e|_H^2 \leq |x(0) - x_e|_H^2.$$

The last assertion follows from the formula

$$c(x) = \frac{\langle x - x_e, \mathcal{A}(x - x_e)\rangle + \alpha |\mathcal{B}^*(x - x_e)|^2}{\sqrt{h_1(x)} + \sqrt{h_1(x) + |\mathcal{B}^*(x - x_e)|^2 h_2(x)}},$$

where $h_1(x)$ and $h_2(x)$ are defined in (2.22). □

Throughout the rest of this section, we consider the well-posedness property of the closed-loop control system (2.13) mentioned in the remark. Assume that $\mathcal{F}(x)$ appearing in (2.1) is given by

$$\langle \mathcal{F}(x), \psi\rangle = b(x; x, \psi) \quad \text{for } \psi \in V, \tag{2.23}$$

where b is a bounded trilinear form on $V \times V \times V$ satisfying

$$b(u; v, w) + b(u; w, v) = 0 \quad \text{for all } u, v, w \in V, \tag{2.24}$$

$$|b(u; w, u)| \leq C |u|_H |u|_V |w|_V \quad \text{for all } u, w \in V \tag{2.25}$$

for some constant $C \geq 0$. Suppose that $x_e \in V$ satisfies $\mathcal{A}x_e + \mathcal{F}(x_e) = 0$. Then, from (2.24), we have $\langle \mathcal{A}x_e, x_e\rangle = 0$ and hence $x_e \in \ker(\mathcal{A})$ and $\mathcal{F}(x_e) = 0$. Therefore, assumption (A1) is satisfied if and only if

$$b(\phi; x_e, \phi) = 0 \quad \text{for all } \phi \in V. \tag{2.26}$$

In fact, for any $\phi \in V$,

$$\begin{aligned} \langle \mathcal{F}(x) - \mathcal{F}(x_e),\, \phi\rangle &= b(x - x_e + x_e;\, x - x_e + x_e,\, \phi) \\ &= b(x - x_e;\, x - x_e,\, \phi) + b(x_e;\, x - x_e,\, \phi) + b(x - x_e;\, x_e,\, \phi). \end{aligned} \tag{2.27}$$

LEMMA 2.8. *Under assumptions* (2.23)–(2.26) *on the nonlinear operator* $\mathcal{F}$, *the control system* (2.13) *has a unique global weak solution* $x(\cdot) \in L^2(0, \infty; V) \cap C_{\text{loc}}(0, \infty; H) \cap H^1(0, \infty; V^*)$ *provided that* $\gamma \in L^\infty(0, \infty; \mathbf{R}_+^m)$, *i.e.,* $x(t)$ *satisfies*

$$\left\langle \frac{d}{dt} x(t), \phi \right\rangle + \epsilon \langle \mathcal{A}x(t), \phi\rangle + b(x(t); x(t), \phi) + \left\langle \sum_{i=1}^m \gamma_i(t) b_i \langle b_i,\, x(t) - x_e\rangle,\, \phi \right\rangle = 0 \tag{2.28}$$

for all $\phi \in V$.

Proof. Let $\xi(t) = x(t) - x_e$. Then (2.28) is equivalently written as

$$\left\langle \frac{d}{dt} \xi(t), \phi \right\rangle + \epsilon \langle \mathcal{A}\xi(t), \phi\rangle + \langle \mathcal{F}_e(\xi), \phi\rangle + \left\langle \sum_{i=1}^m \gamma_i b_i \langle b_i, \xi(t)\rangle,\, \phi \right\rangle = 0 \tag{2.29}$$

for all $\phi \in V$, where $\langle \mathcal{F}_e(\xi), \phi \rangle = b(\xi; \xi, \phi) + b(x_e; \xi, \phi)$ from (2.27). Note that the bilinear form on $V \times V$

$$a(t; \phi, \psi) = \epsilon \langle \mathcal{A}\phi, \psi \rangle + \sum_{i=1}^{m} \gamma_i(t)(\langle b_i, \phi \rangle)(\langle b_i, \psi \rangle) \tag{2.30}$$

satisfies, for almost all t,

$$|a(t; \phi, \psi)| \leq M_1 |\phi|_V |\psi|_V \quad \text{for some } M_1 > 0, \tag{2.31}$$

$$a(t; \phi, \phi) \geq \epsilon |\phi|_V^2 - \epsilon |\phi|_H^2 \tag{2.32}$$

and that from inequality (2.25)

$$|\mathcal{F}_e(\xi)|_{V^*} \leq (C |\xi|_H + M_2 |x_e|_V) |\xi|_V$$

for some constant $M_2 > 0$. Hence, it is not difficult to show that (2.29) has a unique solution $\xi \in L^2(0, T; V) \cap C(0, T; H) \cap H^1(0, T; V^*)$ for arbitrary $T \geq 0$ (e.g., see [CF, Lem. 8.4] or [Te, p. 282]). The uniqueness follows from the inequality (2.25). □

3. Application to Burgers equation and Navier–Stokes equations. In this section we apply the dissipative feedback control law (2.18) to the Burgers equation and the two-dimensional Navier–Stokes equations to demonstrate the theoretical results in §2. Several numerical computations are performed to see how this controller affects the global nature of the transient flow, which is not easily characterized analytically. These calculations support the validation of the proposed feedback law not only for achievement of the desired asymptotic behavior but also for time-dependent behavior of the solution. Specifically, throughout our numerical calculations, effects of the feedback control law (2.18) are shown by observing energy dissipation described in Theorem 2.6, convergence of the feedback control gains as in Theorem 2.7, and, most importantly, changes in flow patterns. The computations were carried out on an IBM 3090 and a SUN SPARC Station 2 at the University of Southern California and the Center for Applied Mathematical Sciences. Detailed explanation of the numerical schemes and their convergence results will be reported in a forthcoming paper.

In the first two examples, the Burgers equation with Dirichlet boundary conditions (Example 1) and periodic boundary conditions (Example 2) are considered. Before discussing the details, we derive abstract variational forms for both cases. The governing equation is given by

$$\begin{aligned} &\frac{\partial}{\partial t} y(t, x) - \epsilon \frac{\partial^2}{\partial x^2} y(t, x) + y(t, x) \frac{\partial}{\partial x} y(t, x) \\ &\qquad = -\sum_{i=1}^{m} \gamma_i(t) \cdot b_i(x) \int_\Omega b_i(s)(y(t, s) - y_e(s)) ds, \\ &y(0, x) = y_0(x), \end{aligned} \tag{3.1}$$

with appropriate boundary conditions, where $\epsilon = \frac{1}{\mathrm{Re}}$; Re is the Reynolds number; $b_i(x)$ are control distribution functions; $\gamma_i(t)$ are control laws to be determined; and $y_e(x)$ is a desired equilibrium state.

For simplicity, let the domain for (3.1) be (0,1) for Example 1 and the period in space for Example 2 be 1. Let $\Omega = (0,1)$ and let $H = L^2(\Omega)$, $U = \mathbf{R}^m$, and $V = H_0^1(\Omega)$ (or $H_p^1(\Omega)$=the completion of the set of all C^∞-periodic functions with period 1). To place the control system (3.1) into a variational form, let $y(t)(\cdot) = y(t,\cdot)$, $y_0(\cdot) = y(0,\cdot)$. Define the operator $\mathcal{A}$ and the control input operator $\mathcal{B}$ by

$$\mathcal{A}\phi = -\phi'' \quad \text{and} \quad \mathcal{B}u = \sum_{i=1}^{m} b_i u_i \tag{3.2}$$

for all $\phi \in \mathcal{D}(\mathcal{A}) \subset H$. Then $\mathcal{A}$ is a nonnegative selfadjoint operator on H and $\mathcal{B} \in \mathcal{L}(U,H)$. We now define the bilinear form a on $V \times V$ by

$$a(t;\phi,\psi) = \epsilon \langle \mathcal{A}\phi, \psi\rangle + \sum_{i=1}^{m} \gamma_i(t) \left(\int_\Omega b_i(s)(\phi(s) - y_e)\, ds\right) \cdot \left(\int_\Omega b_i(s)\psi(s)\, ds\right), \tag{3.3}$$

the trilinear form b on $V \times V \times V$ by

$$b(\phi;\psi,\eta) = \frac{1}{3}\int_\Omega \left((\phi\psi)' + \phi\psi'\right)\eta\, dx, \tag{3.4}$$

and the nonlinear operator $\mathcal{F}$ by

$$\langle \mathcal{F}\phi,\ \eta\rangle = b(\phi;\phi,\eta) \tag{3.5}$$

for all ϕ, ψ, $\eta \in V$. Then the variational form, in V^*, for the system (3.1) is given by

$$\begin{aligned} &\left\langle \frac{d}{dt}y(t), \psi \right\rangle + a(t;y(t),\psi) + b(y(t);y(t),\psi) = 0, \quad \text{or} \\ &\left\langle \frac{d}{dt}y(t), \psi \right\rangle + \epsilon\langle \mathcal{A}y(t),\psi\rangle + \langle \mathcal{F}y(t),\psi\rangle = -\langle \gamma(t)\mathcal{B}\mathcal{B}^*(y(t) - y_e),\ \psi\rangle \end{aligned} \tag{3.6}$$

for all $\psi \in V$. It is easy to see that the bilinear form a satisfies inequalities (2.31), (2.32) and the trilinear form b satisfies conditions (2.24), (2.25). Since $0 < \gamma(t) \le \frac{1}{2\epsilon}$ (Theorem 2.5), by Lemma 2.8, the variational form (3.6) has a unique global weak solution $y(t) \in L^2(0,\infty;V) \cap C_{loc}(0,\infty;H) \cap H^1(0,\infty;V^*)$.

Example 1 (Burgers equation with Dirichlet boundary conditions). In this example, two stabilization problems for the Burgers equation are considered. Smoothing effects will be enhanced by two different control laws $\gamma(t) = \frac{1}{2\epsilon}$ (case 1) and $\gamma(t)$ obtained by (2.18) (case 2). The desired equilibrium state $y_e = 0$, the Reynolds number Re=200, the initial condition $y_0(x) = \sin 2\pi x$, and the Dirichlet boundary conditions $y(t,0) = y(t,1) = 0$ are chosen. Two control distribution functions $b_1(x)$ and $b_2(x)$ are chosen as

$$b_1(x) = \begin{cases} 1, & |x - 0.3| \le 0.1, \\ 0, & \text{otherwise}, \end{cases} \qquad b_2(x) = \begin{cases} 1, & |x - 0.7| \le 0.1, \\ 0, & \text{otherwise}. \end{cases} \tag{3.7}$$

For case 2, the control laws $\gamma_i(t) \equiv c(y)$ are given by the formula (2.18) with $x = y$, $x_e = 0$, and $\mathcal{Q} = \mathcal{B}\mathcal{B}^*$, i.e.,

$$c(y) = \frac{-\epsilon\,|y'|^2 + \sqrt{\epsilon^2\,|y'|^4 + g(y)(|y'|^2 + g(y))}}{g(y)}, \tag{3.8}$$

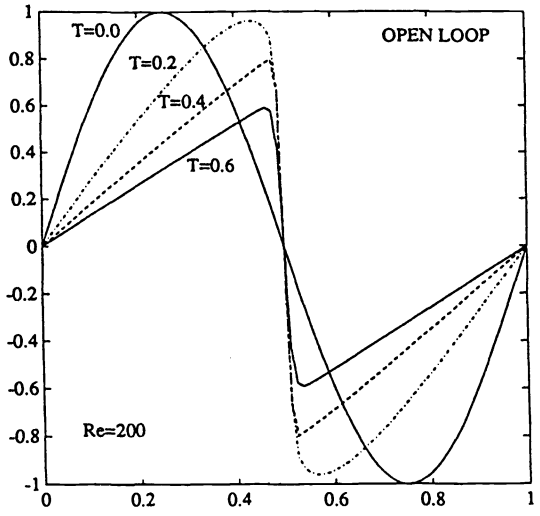

FIG. 1.1. *Open loop (Burgers equation). (Dirichlet B.C. Re* = 200.)

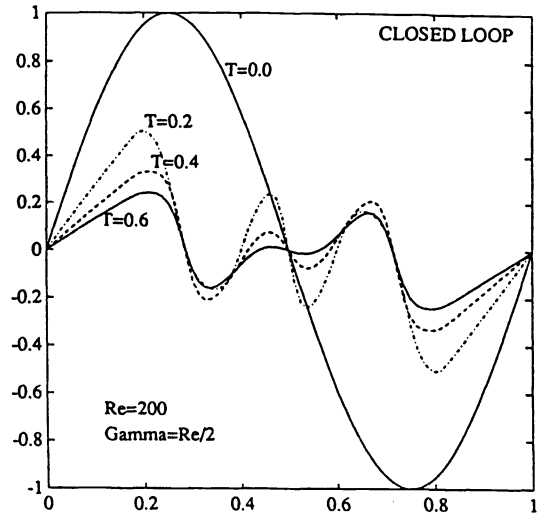

FIG. 1.2. *Closed loop* ($\gamma(t) \equiv 100$).

where $\epsilon = 0.005$ and

$$g(y) = \left(\int_0^1 b_1(x)y(t,x)\,dx\right)^2 + \left(\int_0^1 b_2(x)y(t,x)\,dx\right)^2.$$

In Fig. 1.1, it is easy to see that a steep gradient ("weak shock") of the open-loop solution ($\gamma_i(t) \equiv 0$) is forming in finite time around $x = 0.5$ due to the convective

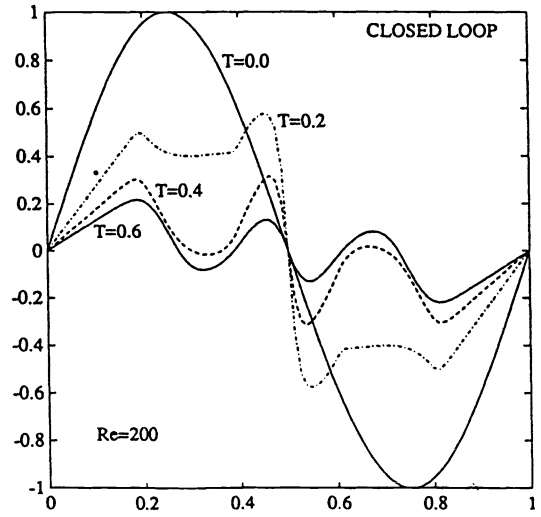

FIG. 1.3. *Closed loop* ($\gamma(t) \equiv 100$).

TABLE 1
Energy comparison (*Burgers equation*).

time	Open	Closed 1 ($\gamma(t) \equiv 100$)	Closed 2 ($\gamma(t) = c(y)$)	
	$\langle y, \mathcal{A}y \rangle$	$\langle y, \mathcal{A}y \rangle$	$\langle y, \mathcal{A}y \rangle$	$\gamma(t)$
$t = 0.0$	19.739	19.739	19.739	0.000
$t = 0.1$	26.346	25.075	18.139	19.736
$t = 0.2$	84.341	19.393	28.154	36.094
$t = 0.3$	108.429	14.639	23.589	59.208
$t = 0.4$	75.098	10.714	12.862	81.897
$t = 0.5$	49.646	7.421	6.901	93.517
$t = 0.6$	33.457	5.081	4.107	96.537

term $y(t,x)\frac{\partial}{\partial x}y(t,x)$. However, the solution is smoothed out eventually due to the diffusion effect $\epsilon(\partial^2/\partial x^2)y(t,x)$. Figures 1.2 and 1.3 show the closed-loop trajectories corresponding to two different feedback laws: $\gamma_i(t) \equiv \frac{1}{2\epsilon}$ (Fig. 1.2) and $\gamma_i(t) \equiv c(y)$ (Fig. 1.3). Recall that, from Theorem 2.7, $\lim_{t\uparrow\infty} \gamma_i(t) = \frac{1}{2\epsilon}$ (see Table 1). Comparing the trajectories (shown in Figs. 1.2 and 1.3) corresponding to the two controllers we observe that smoothing effects of the latter controller are better. For example, local weak shocks created by the latter controller in a neighborhood of control areas are less intensive than the other. Table 1 shows the energy dissipation effects by controllers and the convergence property of $\gamma_i(t)$ to $\frac{1}{2\epsilon}$. It is observed that the energy $\langle y, \mathcal{A}y \rangle$ of the closed-loop solution decay rapidly compared with those of the open-loop solution for both cases. Moreover, one can observe that the energy of the closed-loop in case 2 decays more gradually than the closed-loop in case 1. For numerical computation, we used the standard Galerkin approximation in [SB] with linear spline basis functions.

Example 2 ("Moving shock": Burgers equation with periodic boundary conditions). In this example, two tracking problems for the Burgers equation are considered. The initial condition $y_0(x) = \frac{1}{8} - \frac{1}{4}\sin 2\pi x$, the Reynolds number Re=1000, and

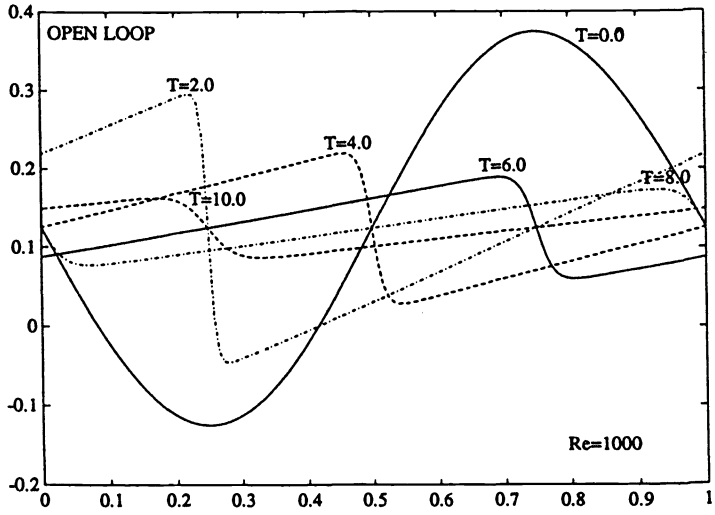

FIG. 2.1. *Open loop (Burgers equation). (Periodic B.C., Re = 1000).*

periodic boundary conditions are chosen. As time increases, a weak shock is formed and propagates with speed $\frac{1}{8}$. For this example, we will derive the solution to two desired equilibrium states $y_e = 0$ and $y_e = 0.5$ by injecting control signals. It is easy to see that the open-loop system (3.1) with $\gamma(t) \equiv 0$ has $\frac{1}{8}$ as the equilibrium state. A locally supported control distribution function $b(x)$ is chosen as

$$b(x) = \begin{cases} 1, & 0.8125 \le x \le 0.8672, \\ 0, & \text{otherwise}, \end{cases} \tag{3.9}$$

and the control law $\gamma(t)$ to achieve the desired state is obtained by formula (2.18) with $x = y$ and $Q = I$, i.e.,

$$\gamma(t) = \frac{-\epsilon\,|y'|^2 + \sqrt{\epsilon^2|y'|^4 + h(y, y_e)(|y'|^2 + |y - y_e|^2)}}{h(y, y_e)}, \tag{3.10}$$

where $\epsilon = 0.001$, $y_e = 0$ (Fig. 2.2) or $y_e = 0.5$ (Fig. 2.3), and

$$h(y, y_e) = \left(\int_0^1 b(x)(y(t, x) - y_e)\, dx \right)^2.$$

Figure 2.1 shows the formation of a weak shock (about time $t = 1.1$, which is not shown in the figure) and the propagation of the formed weak shock with speed $\frac{1}{8}$. Again, due to viscosity effects, the weak shock is smoothed out. The open-loop solution approaches the equilibrium state $y_e = \frac{1}{8} = 0.125$. The only control distribution function $b(x)$ is chosen which is locally supported with width 0.0547. In general, it is very difficult to regulate the flow because of high Reynolds number, 1000, and the very narrow control distribution region (compared with Example 1). As we see in Figs. 2.2 and 2.3, the desired equilibrium states $y_e = 0$ (Fig. 2.2) and $y_e = 0.5$

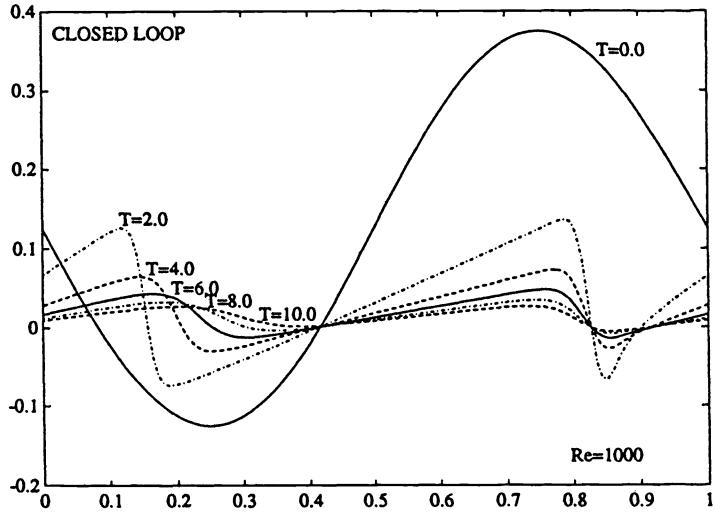

FIG. 2.2. *Closed loop* ($y_e = 0$).

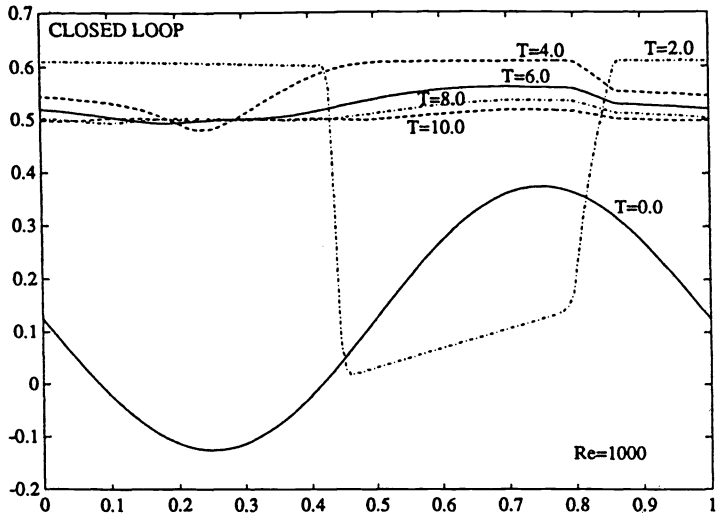

FIG. 2.3. *Closed loop* ($y_e = 0.5$).

(Fig. 2.3) are achieved by the control signals constructed from (2.18). Also, during the transition process, the weak shocks are smoothed out. However, a local weak shock is created by the controller. It is interesting to observe that, in Figure 2.3, huge control actions are needed in the beginning (e.g., up to time $t = 2.0$) to accelerate the flow to the high energy level $y_e = 0.5$ compared with the initial equilibrium state 0.125. Actually, the control signal $-\gamma(t)\mathcal{B}^*(y(t) - y_e)$ strongly depends on local property of

the solution.

For numerical computations, the Fourier-collocation method for space discretization and the two-step implicit method for time integration were used. To initialize the data, the Crank–Nicholson method was used (see [G]).

Example 3 (Navier–Stokes equations). In this example, we consider a velocity field control problem for the two-dimensional Navier–Stokes equations with periodic boundary conditions. For simplicity, the period in space is chosen to be 1. The governing equations are given by

$$
\begin{aligned}
&\frac{\partial u}{\partial t} - \nu \Delta u + (u \cdot \nabla) u + \nabla p = \begin{pmatrix} b_1(x) \\ b_2(x) \end{pmatrix} f(t), \\
&\nabla \cdot u = 0, \\
&u(t, x + e_i) = u(t, x), \quad x \in \mathbf{R}^2, \quad t > 0, \\
&u(x, 0) = u_0(x),
\end{aligned} \tag{3.11}
$$

where $x = (x_1, x_2) \in \mathbf{R}^2$, $u = u(t,x) = (u_1(t,x), u_2(t,x))$ is the velocity vector, $p = p(t,x)$ is the pressure, $f(t)$ is the control signal to be determined, $e_1 = (1,0)$ and $e_2 = (0,1)$ are the canonical basis elements of $\mathbf{R}^2$. For numerical test, the nondimensional viscosity ν and the control distribution vector $b(x) = (b_1(x_1, x_2), b_2(x_1, x_2))$ are chosen as $\nu = 0.01$ and

$$
b_1(x_1, x_2) = \begin{cases} 5, & \text{if } |x_1 - 0.5| \le 0.1, \text{ and} |x_2 - 0.4| \le 0.1, \\ 0, & \text{otherwise,} \end{cases} \qquad b_2(x_1, x_2) = 0. \tag{3.12}
$$

The initial velocity vector field $u_0(x)$ is induced by the following initial vorticity function $\omega_0(x_1, x_2)$

$$
= \begin{cases} 10(1 + \cos(\frac{\pi(x_1 - 0.5)}{0.2}))\,(1 + \cos(\frac{\pi(x_2 - 0.5)}{0.2})) + c, & |x_i - 0.5| \le 0.2,\ i = 1, 2, \\ c, & \text{otherwise,} \end{cases} \tag{3.13}
$$

where the constant c is chosen so that the discrete compatibility condition is satisfied. That is, the initial velocity field $u_0(x)$ is determined by

$$
u_0(x) = \left(\frac{\partial}{\partial x_2} \psi(x_1, x_2),\ -\frac{\partial}{\partial x_1} \psi(x_1, x_2) \right) + (0.5, 0),
$$

where the stream function $\psi(x)$ satisfies $-\Delta \psi = w_0(x)$ with periodic boundary conditions. This test example is motivated by the numerical study in [BP] in which $(0,0)$ is chosen as constant term in above. Note that the constant velocity field (0.5,0) is an equilibrium state of the Navier–Stokes equations (3.11) with $f(t) \equiv 0$. In this example, the solution will be driven to the zero equilibrium state $u_e = (0,0)$ by the control signal $f(t)$. Also, energy dissipation effects of the feedback law will be demonstrated.

Let $\Omega = (0,1) \times (0,1)$. Consider the following function spaces (see [Te]).

$$
\begin{aligned}
V &= \{ u \in H_p^1(\Omega) \times H_p^1(\Omega) \,:\, \nabla \cdot u = 0 \}, \\
H &= \{ u \in L^2(\Omega) \times L^2(\Omega) \,:\, \nabla \cdot u = 0 \},
\end{aligned} \tag{3.14}
$$

where H_p^1 is the completion of the set of all C^∞ periodic functions with period Ω with respect to the $H^1(\Omega)$ norm.

The Stokes operator $\mathcal{A}$ is defined by

$$
\langle \mathcal{A}u, v \rangle_H = a(u,v) = \sum_{i=1}^{2} \int_\Omega \nabla u_i \cdot \nabla v_i \, dx \tag{3.15}
$$

for $u, v \in V$ and it is given by

$$
\mathcal{A}u = -\Delta u \quad \text{for all } u \in \mathcal{D}(\mathcal{A}) = H^2(\Omega) \times H^2(\Omega) \cap V \tag{3.16}
$$

due to the periodic boundary conditions. For any u, v, $w \in V$, define the trilinear form

$$
b(u; v, w) = \sum_{i=1}^{2} \int_\Omega u_i D_i v_j w_j \, dx \tag{3.17}
$$

and the bilinear continuous operator B from $V \times V$ into V^* by

$$
\langle B(u,v), w \rangle_{V^*,V} = b(u; v, w), \tag{3.18}
$$

where V^* is the dual space of V.

With the bilinear form a and the trilinear form b, the variational form of the control system (3.11) becomes

$$
\begin{aligned}
\frac{d}{dt}\langle u, v \rangle + \nu a(u,v) + b(u,u,v) &= \langle b(x) f(t), v \rangle, \qquad v \in V, \\
u(0) &= u_0.
\end{aligned} \tag{3.19}
$$

It is easy to observe that the pressure term ∇p in (3.11) is dropped in the variational form (3.19) due to the divergence free condition. It is well known [Te] that the variational equation (3.19) with $b(x)f(t) \in V^*$ has a unique global weak solution $u \in L^2(0,T;V) \cap C(0,T;H) \cap H^1(0,T;V^*)$ for $T \geq 0$.

We now define the nonlinear operator $\mathcal{F} \in \mathcal{L}(V, V^*)$ and the control input operator $\mathcal{B} \in \mathcal{L}(\mathbf{R}, H)$ by

$$
\mathcal{F}(u) = \mathrm{P}B(u,u) \quad \text{and} \quad \mathcal{B}f = (\mathrm{P}b(x))f \tag{3.20}
$$

for all $u \in V$ and $f \in \mathbf{R}$, where P is the projection operator from $H_p^0(\Omega) \times H_p^0(\Omega)$ onto the state space H. Then it is easy to see that the operator $\mathcal{F}$ satisfies assumptions (A1) and (A2) in §2. Thus, we can construct the feedback control signal $f(t)$ from (2.18), (2.19), i.e.,

$$
f(t) = -\gamma(t) \int_\Omega b(x) \cdot (u(t,x) - u_e) \, dx, \tag{3.21}
$$

where

$$\gamma(t) = \frac{-\epsilon\,|\nabla(u-u_e)|_H^2 + \sqrt{\epsilon^2|\nabla(u-u_e)|_H^2 + g(u)(\int_\Omega b(x)\cdot(u(x)-u_e)dx)^2}}{|\int_\Omega b(x)\cdot(u(x)-u_e)dx|^2}$$

with $g(u) = |\nabla(u-u_e)|^2 + (\int_\Omega b(x)\cdot(u(x)-u_e)dx)^2$.

Figures 3.1–3.4 and 3.10–3.12 show vorticity plots of the open-loop ($f(t) \equiv 0$) and the closed-loop solutions from time t=0.0 to t=2.0. Figures 3.5–3.8 and 3.13–3.15 show the corresponding velocity vector fields. In all velocity field plots, vectors are scaled so that the longest vectors are of equal lengths. Recall that the constant term of the initial velocity field $u_0(x)$ was set to be $(0.5, 0)$ and the constant velocity $(.5, 0)$ is an equilibrium state of the open-loop system (3.11). From Figs. 3.1–3.8 and Table 2, it is easy to see the following observations for open-loop trajectories.

(i) The center ("eye") of the initial vortex blob moves along the x_1-axis.

(ii) Due to diffusion effects, the peak of vortex is smoothed out eventually. Here, the viscosity $\nu = 0.01$ is chosen.

(iii) The velocity vector field $u(t,x) = (u_1(x), u_2(x))$ approaches the uniform flow $(0.5, 0)$, the equilibrium state. In Table 2, we can see that $|u(t,\cdot)|_H^2 = \langle u, u\rangle$ converges to $0.25 = |(.5, 0)|_H^2$, as time t increases.

Remark 3.1. We observe from numerical experiments that the open-loop velocity field $u(x) = (u_1(x), u_2(x))$ becomes an "almost" uniform flow $u_e = (0.5, 0)$ after time $t = 5.0$.

Figure 3.9 shows the projected vector field of the control distribution vector $b(x)$

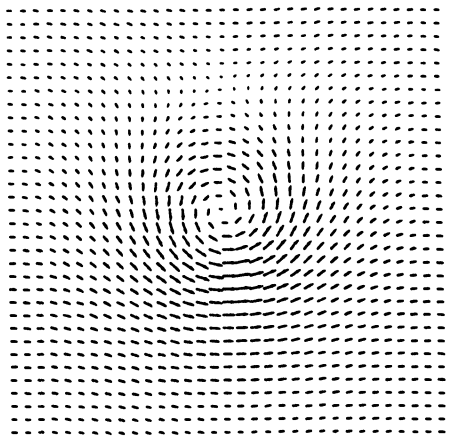

FIG. 3.5. *Velocity fields (open loop, $T = 0.0$).*

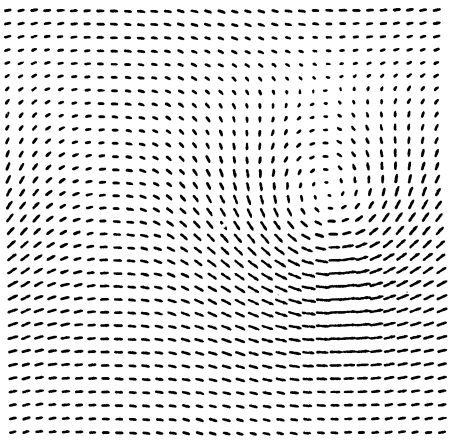

FIG. 3.6. *Velocity fields (open loop, $T = 0.5$).*

onto the divergence free space. The control input vector $b(x)$ is given by (3.12). The velocity vector fields and the corresponding vorticities of the closed-loop system with the control signal $f(t)$ are shown in Figs. 3.10–3.15. We can observe how this controller changes the global nature of the flow. The eye of vortex blob moves to the region $\{(x_1, x_2) \in \Omega : |x_1 - 0.5| \leq 0.1, |x_2 - 0.4| \leq 0.1\}$ where the control distribution vector $b(x)$ is located. Also, the flow changes its direction. "Sucking" actions of the controller for dropping the high energy level to the zero state (desired equilibrium state) are shown in Figs. 3.10–3.12. In the beginning, the energies $\langle u, \mathcal{A}u \rangle$ and $\langle u, u \rangle$ of the closed-loop system are reduced by the controller (Table 2). But, after time $t = 1.0$, the energy $\langle u, \mathcal{A}u \rangle$ goes to zero slowly compared with the open-loop system. This may be due to the fact that a continuing regulation effect of the controller produces a local vorticity in a neighborhood of the controller. The solution itself also approaches the zero state (desired state), i.e., $u(t, x) = (u_1(t, x), u_2(t, x)) \to (0, 0)$ as time t increases, since $\langle u, u \rangle = |u|_H^2 \to 0$ as $t \to \infty$. Note that the control input vector

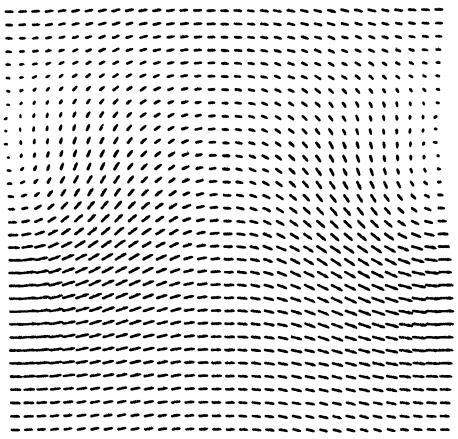

FIG. 3.7. *Velocity fields (open loop, $T = 1.0$).*

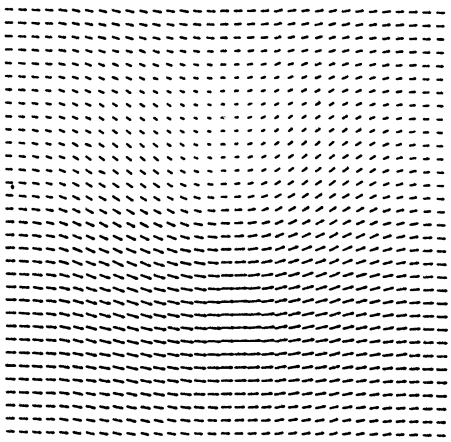

FIG. 3.8. *Velocity fields (open loop, $T = 2.0$).*

$b(x)$ satisfies the condition in Theorem 2.7 with $x_e \equiv 0$. Hence, the control signal $f(t)$ obtained from the formula (3.21) drives the given system (3.11) to the zero state $(0,0)$. On the other hand, as we mentioned before, the open-loop solution approaches the state $(0.5,0)$. Finally, as we expect, the feedback law $\gamma(t)$ converges to $50 = \frac{1}{2\nu}$, $\nu = 0.01$ (see Table 2 and Theorem 2.7). From numerical experiments, we observed that the control action continues "sucking" and "blowing" depending on the sign of $\int_\Omega b(x) \cdot (u(t,x) - u_e)dx$.

For this example, the Fourier–Galerkin scheme for space approximation and the Alternating Directional method for time integration were used [G].

DECENTRALIZED POLE ASSIGNMENT AND PRODUCT GRASSMANNIANS*

XIAOCHANG WANG†

Abstract. The pole assignment problems of linear systems by decentralized static output feedback are considered in this paper. A compactification of decentralized static feedback space, product Grassmannians, is introduced in this paper. Its degree under Plücker–Segre embedding is computed. Sufficient conditions for arbitrary and almost arbitrary pole assignability are given. It is also proved that the generic $m \times p$ system of McMillan degree n has arbitrary pole assignability by r-channel decentralized static output with m_i inputs and p_i outputs on the ith channel if $\sum_{i=1}^{r} m_i p_i \geq n$ when the degree of the product Grassmannians is odd, or if $\sum_{i=1}^{r} m_i p_i > n$ and the local channels have either the same numbers of inputs or the same numbers of outputs when the degree of the product Grassmannians is even.

Key words. linear systems, decentralized control, pole assignment, product Grassmannians, central projection, degree of variety

AMS subject classifications. 93B55, 93B27

1. Introduction.

In this paper, we investigate the pole assignment problem by decentralized static output feedback. The problem is formulated as follows: Let

$$\sigma: \quad \dot{x} = Ax + \sum_{i=1}^{r} B_i u_i, \quad y_i = C_i x, \qquad i = 1, 2, \ldots, r \tag{1}$$

be an r-channel linear system, where x, u_i, y_i are n, m_i, p_i vectors over $\mathbf{R}$, respectively, and u_i and y_i are the input and output of the ith channel. Under what conditions can the poles of σ be assigned to any self-conjugate set of n complex numbers by applying decentralized feedback

$$u_i = K_i y_i, \qquad i = 1, 2, \ldots, r \tag{2}$$

to the system?

Decentralized control is often applied to large-scale systems such as power systems, socioeconomic systems, large-scale space stations, and so forth. Centralized control of such systems is either uneconomical or unreliable due to long-distance information transfer between local control stations.

The decentralized pole assignment problem is fairly well understood if dynamic compensators are allowed in the feedback loop. Wang and Davison [16] proved that decentralized stabilization using local dynamic feedback is possible if and only if the fixed modes are stable. Corfmat and Morse [6] proved that a strongly connected system can be made controllable and observable through a single channel by local static feedback if and only if the set of fixed modes is empty. Thus the poles of such a system can be assigned freely by applying local dynamic feedback to one channel and local static feedback to all the other channels.

It is a standard technique to study the pole assignment problems through so-called "pole assignment map," i.e., the map that assigns each feedback compensator the closed-loop characteristic polynomial. A system has the arbitrary pole assignability if and only if the pole assignment map is onto. It is also a standard technique to extend the pole assignment map continuously to a compact set that contains the compensator space as a subset and study the extended pole assignment map. An example of using these techniques is the (centralized) static output feedback pole assignment problem. In 1981, Brockett and Byrnes [2] explained the problem as an intersection problem in a certain Grassmann variety $\mathrm{Grass}(p, m+p)$. This variety can be considered a compactification of the compensator space. In making the connection to the classical Schubert calculus, they were able to show that there are

$$\deg \mathrm{Grass}(p, m+p) = \frac{1!2!\cdots(p-1)!(mp)!}{m!(m+1)!\cdots(m+p-1)!} \tag{3}$$

complex static output feedback laws, which assign each set of poles for the generic m-input, p-output linear system of McMillan degree $n = mp$. In particular, if (3) is odd, real solutions always exist. It follows that the generic system has the arbitrary pole assignability if $mp \geq n$ and if $\deg \mathrm{Grass}(p, m+p)$ is odd. Using this model, we proved in [19] that the generic system has the arbitrary pole assignability if $mp > n$ and $\deg \mathrm{Grass}(p, m+p)$ is even.

Adopting these ideas to the decentralized pole assignment problems, we introduce a compactification of the decentralized feedback space, a product of Grassmannians in this paper. The degree of product Grassmannians under Plücker–Segre embedding is computed in §2. Sufficient conditions for arbitrary and almost arbitrary pole assignability are given in §3. Generic pole assignability is considered in §4. It is proved in §4 that, when the degree of a product of Grassmannians is odd and $n \leq \sum_{i=1}^{r} m_i p_i$, or when the degree is even and $n < \sum_{i=1}^{r} m_i p_i$, and either $m_1 = m_2 = \cdots = m_r$ or $p_1 = p_2 = \cdots = p_r$, then the generic system of McMillan degree n has arbitrary pole assignability by decentralized static output feedback.

This paper extends the results in [20]. In [20] we considered only pole assignment with local state feedback. The compactification in that case was a product of projective spaces, which was a special kind of product Grassmannian. We only studied the cases in which the degrees of the product projective spaces were odd in [20].

2. Decentralized pole assignment map and product Grassmannians. Let

$$m = \sum_{i=1}^{r} m_i, \qquad p = \sum_{i=1}^{r} p_i \tag{4}$$

and assume that

$$m \leq n, \qquad p \leq n. \tag{5}$$

If we apply the decentralized feedback (2) to (1), then the closed-loop system becomes

$$\dot{x} = \left(A + \sum_{i=1}^{r} B_i K_i C_i\right) x, \quad y_i = C_i x, \qquad i = 1, 2, \ldots, r. \tag{6}$$

Let

$$B = [B_1, B_2, \dots, B_r], \qquad C = \begin{bmatrix} C_1 \\ C_2 \\ \vdots \\ C_r \end{bmatrix} \tag{7}$$

and

$$K = \text{ block diag}(K_1, K_2, \dots, K_r). \tag{8}$$

We define the pole assignment map $\phi_\sigma : \mathbf{R}^{m_i p_i} \times \cdots \times \mathbf{R}^{m_r p_r} \to \mathbf{R}^n$ by

$$\phi_\sigma(K_1, \dots, K_r) = \det(sI - A - BKC), \tag{9}$$

where a characteristic polynomial $s^n + a_1 s^{n-1} + \cdots + a_n$ is identified with a point $(a_1, \dots, a_n)$ in $\mathbf{R}^n$. If σ is controllable and observable, then ϕ_σ can be expressed as

$$\phi_\sigma(K_1, \dots, K_r) = \det \begin{bmatrix} I_1 & & & \\ & \ddots & & N(s) \\ & & I_r & \\ K_1 & & & \\ & \ddots & & D(s) \\ & & K_r & \end{bmatrix}, \tag{10}$$

where I_i is the $p_i \times p_i$ identity matrix and $N(s)D^{-1}(s)$ is a right coprime fraction of the transfer function $C(sI - A)^{-1}B$ [2], [3], [17].

Let $\text{Grass}_K(p, m+p)$ be the Grassmannian of all p-dimensional subspaces of an $(m+p)$-dimensional vector space V_{m+p} over a field $\mathbf{K}$. Fix a basis of V_{m+p}; each point $z \in \text{Grass}_K(p, m+p)$ can be represented by an $(m+p) \times p$ full-rank matrix Z such that col sp $Z = z$. Two matrices Z_1 and Z_2 represent the same point if and only if there is a $Q \in GL(p)$ such that

$$Z_1 Q = Z_2. \tag{11}$$

$\text{Grass}_K(p, m+p)$ can be embedded in $\mathbf{P}^N$ by Plücker embedding [8], where

$$N = \binom{m+p}{m} - 1.$$

For each $z \in \text{Grass}_K(p, m+p)$, let Z be a matrix representation of z. The homogeneous Plücker coordinate of z in $\mathbf{P}^N$ is given by $z = (z_{\underline{i}})$, where $\underline{i} = (i_1, i_2, \dots, i_m), 1 \le i_1 < i_2 < \cdots < i_m \le m+p$ ranges over all multi-indices and where $z_{\underline{i}}$ is the p-minor of Z formed by the i_1th, i_2th, $\dots$, i_mth rows. The $\text{Grass}_K(p, m+p) \subset \mathbf{P}^N$ is defined by quadratic equations [8].

Let $\mathbf{P}^n$ and $\mathbf{P}^m$ be two projective spaces. For any $x = (x_0, x_1, \dots, x_n) \in \mathbf{P}^n$ and $y = (y_0, y_1, \dots, y_m) \in \mathbf{P}^m$, the map $S : \mathbf{P}^n \times \mathbf{P}^m \to \mathbf{P}^{mn+m+n}$ defined by $S(x, y) = x^t y$ induces an embedding $\mathbf{P}^n \times \mathbf{P}^m \subset \mathbf{P}^{mn+m+n}$, where the homogeneous Segre coordinate of (x, y) is given by the entries of the $(n+1) \times (m+1)$ matrix $x^t y$. This embedding is called the Segre embedding [12], [15]. If the homogeneous coordinates of $\mathbf{P}^{mn+m+n}$ are written as $(n+1) \times (m+1)$ matrices $\{W\}$, then $\mathbf{P}^n \times \mathbf{P}^m \subset \mathbf{P}^{mn+m+n}$

is defined by rank $(W) = 1$; i.e., all the 2×2 minors are zero. Similarly, for each $x_i = (x_{i0}, x_{i1}, \ldots, x_{in_i}) \in \mathbf{P}^{n_i}$, $i = 1, 2, \ldots, r$, $S(x_1, \ldots, x_r) = (x_{1i_1} x_{2i_2} \cdots x_{ri_r})_{i_j=0}^{n_j}$ defines the Segre embedding $\mathbf{P}^{n_1} \times \cdots \times \mathbf{P}^{n_r} \subset \mathbf{P}^N$, $N = \prod_{i=1}^r (n_i + 1) - 1$.

Let

$$\Pi_K^\alpha = \mathrm{Grass}_K(p_1, m_1 + p_1) \times \cdots \times \mathrm{Grass}_K(p_r, m_r + p_r), \tag{12}$$

where

$$\alpha = (p_1, \ldots, p_r, m_1, \ldots, m_r); \tag{13}$$

then Π_K^α is a projective variety. We can embed each $\mathrm{Grass}_K(p_i, m_i + p_i)$ into projective n_i-space $\mathbf{P}_K^{n_i}$,

$$n_i = \binom{m_i + p_i}{p_i} - 1,$$

using the Plücker embedding, and then embed $\mathbf{P}_K^{n_i} \times \cdots \times \mathbf{P}_K^{n_r}$ into the projective N-space $\mathbf{P}_K^N$, $N = \prod_{i=1}^r \binom{m_i + p_i}{p_i} - 1$, using the Segre embedding.

Following [17], it is possible to write (10) as

$$\phi_\sigma(K_1, \ldots, K_r) = \sum_{i=0}^{M} w_i g_i(s), \tag{14}$$

where $M = \binom{m+p}{p} - 1$ and $(w_0, \ldots, w_M)$ are the Plücker coordinates of

$$\begin{bmatrix} I_1 & & \\ & \ddots & \\ & & I_r \\ K_1 & & \\ & \ddots & \\ & & K_r \end{bmatrix} \in \mathrm{Grass}_R(p, m + p).$$

Note that some of the w_i's are identically zero. A w_i is not identically zero if and only if $w_i = \prod_{j=1}^r z_{ji_j}$, where z_{ji_j} is a $p_j \times p_j$ minor of

$$\begin{bmatrix} I_j \\ K_j \end{bmatrix};$$

namely, w_i is a component of Plücker–Segre coordinate of

$$\left(\begin{bmatrix} I_1 \\ K_1 \end{bmatrix}, \begin{bmatrix} I_2 \\ K_2 \end{bmatrix}, \ldots, \begin{bmatrix} I_r \\ K_r \end{bmatrix} \right) \in \Pi_R^\alpha.$$

Let $z = (z_0, \ldots, z_N)$ be the Plücker–Segre coordinate of

$$\left(\begin{bmatrix} I_1 \\ K_1 \end{bmatrix}, \begin{bmatrix} I_2 \\ K_2 \end{bmatrix}, \ldots, \begin{bmatrix} I_r \\ K_r \end{bmatrix} \right) \in \Pi_R^\alpha.$$

Then (14) becomes

$$\phi_\sigma(z) = \sum_{i=0}^{N} z_i g_i(s), \tag{15}$$

and (15) can be extended to a rational map on $\mathbf{P}_C^N$, where $\Pi_C^\alpha \subset \mathbf{P}_C^N$ by the Plücker–Segre embedding. The extended map is also denoted by ϕ_σ.

Let

$$E_\sigma = \{z \in \mathbf{P}_C^N | \phi_\sigma(z) \equiv 0\}. \tag{16}$$

Then (15) defines a central projection $\mathbf{P}_C^N - E_\sigma \to \mathbf{P}_C^n$ with center E_σ (see [17]), where a polynomial $a_0 s^n + a_1 s^{n-1} + \cdots + a_n$ is identified with a point $(a_0, a_1, \ldots, a_n) \in \mathbf{P}_C^n$. σ has arbitrary (almost arbitrary) pole assignability if

$$\phi_\sigma : \Pi_R^\alpha - E_\sigma \to \mathbf{P}_R^n$$

is onto (almost onto).

PROPOSITION 2.1. *Let X_i be a projective variety of dimension n_i and degree m_i, $i = 1, 2, \ldots, r$. Then the degree of $X_1 \times \cdots \times X_r$ under Segre embedding is*

$$\deg(X_1 \times \cdots \times X_r) = \frac{(n_1 + \cdots + n_r)!}{n_1! \cdots n_r!} \prod_{i=1}^{r} m_i.$$

Proof. We first prove that the Hilbert polynomial (see [9] for definition) of $X_1 \times \cdots \times X_r$ under Segre embedding is the product of the Hilbert polynomials of $\{X_i,\ i = 1, \ldots, r\}$. By induction, we only need to prove it for $r = 2$.

Assume that $X \subset \mathbf{P}^n$ and $Y \subset \mathbf{P}^m$. Let R_l be the $\mathbf{C}$-module consisting of all the homogeneous elements of degree l in the graded ring R. After the substitution $z_{ij} = x_i y_j$, any homogeneous polynomial of degree l in $\mathbf{C}[X \times Y]$ can be considered as a homogeneous polynomial both in $x_0, \ldots, x_n$ and $y_0, \ldots, y_m$ of the same degree of homogeneity l.

Take basis $\{f_1, \ldots, f_s\}$ of $\mathbf{C}[X]_l$ and $\{g_1, \ldots, g_s\}$ of $\mathbf{C}[Y]_l$. Then $\{h_{ij} = f_i g_j\}$ span the $\mathbf{C}[X \times Y]_l$. If

$$\sum_{i,j} a_{ij} f_i(x) g_j(y) \in I(X \times Y),$$

then

$$\sum_i a_{i1} f_i(x) g_1(y) + \cdots + \sum_i a_{im} f_i(x) g_m(y)$$

in $I(Y)$ for each fixed x in X. Since $\{g_j\}$ is a basis of $\mathbf{C}[Y]$, $\sum_i a_{ij} f_i(x) = 0$ for $x \in X$, i.e., $\sum_i a_{ij} f_i(x) \in I(X)$. So $a_{ij} = 0$. Therefore $\{h_{ij} = f_i g_j\}$ is a basis of $\mathbf{C}[X \times Y]_l$ and

$$\dim \mathbf{C}[X \times Y]_l = (\dim \mathbf{C}[X]_l)(\dim \mathbf{C}[Y]_l),$$

so the Hilbert polynomial of $X \times Y$ is the product of the Hilbert polynomials of X and Y.

Let $f_i(z)$ be the Hilbert polynomial of X_i, $i = 1, 2, \ldots, r$. Then

$$f_i(z) = \frac{m_i}{n_i!} z^{n_i} + \cdots.$$

The Hilbert polynomial of $X_1 \times \cdots \times X_r$ under Segre embedding is

$$f(z) = f_1(z) f_2(z) \cdots f_r(z) = \left(\prod_{i=1}^{r} \frac{m_i}{n_i!} \right) z^{n_1 + \cdots + n_r} + \cdots.$$

Therefore

$$\deg(X_1 \times \cdots \times X_r) = \frac{(n_1 + \cdots + n_r)!}{n_1! \cdots n_r!} \prod_{i=1}^{r} m_i. \qquad \square$$

PROPOSITION 2.2. *The* $\deg(X_1 \times \cdots \times X_r)$ *is odd if and only if the degree of all* X_i *are odd and the sets of exponents appearing in the binary representations of* $n_1, n_2, \ldots, n_r$ *are disjoint, where* $n_i = \dim X_i$, $i = 1, 2, \ldots, r$.

Proof. The second condition is equivalent to the fact that

$$\frac{(n_1 + \cdots + n_r)!}{n_1! n_2! \cdots n_r!}$$

is odd [20]. $\square$

COROLLARY 2.1. *It holds that*

$$\deg \Pi_C^{\alpha} = (m_1 p_1 + \cdots + m_r p_r)! \prod_{i=1}^{r} \frac{1!2! \cdots (p_i - 1)!}{m_i!(m_i + 1)! \cdots (m_i + p_i - 1)!}.$$

Proof. Simply note that

$$\deg \operatorname{Grass}_C(p_i, m_i + p_i) = \frac{1!2! \cdots (p_i - 1)!(m_i p_i)!}{m_i!(m_i + 1)! \cdots (m_i p_i - 1)!}$$

(see [10]). $\square$

COROLLARY 2.2. *The* $\deg \Pi_C^{\alpha}$ *is odd if and only if* Π_C^{α} *is in one of the following forms:*

(i) $\operatorname{Grass}_C(2, 2^m + 1) \times \mathbf{P}_C^{n_1} \times \cdots \times \mathbf{P}_C^{n_r}$, *where* $n_i = 2^{m_{i1}} + 2^{m_{i2}} + \cdots + 2^{m_{ir_i}}$, $m_{ij} \neq m_{kl}$ *if* $(i, j) \neq (k, l)$, *and either* $m_{ij} = 1$ *or* $m_{ij} > m$;

(ii) $\mathbf{P}_C^{n_1} \times \cdots \times \mathbf{P}_C^{n_r}$, *where* $n_i = 2^{m_{i1}} + 2^{m_{i2}} + \cdots + 2^{m_{ir_i}}$ *and* $m_{ij} \neq m_{kl}$ *if* $(i, j) \neq (k, l)$.

Here $\operatorname{Grass}(2^h - 1, 2^h + 1)$ *and* $\operatorname{Grass}(n_i - 1, n_i)$ *are identified with* $\operatorname{Grass}(2, 2^h + 1)$ *and* $\mathbf{P}^{n_i}$, *respectively.*

Proof. $\deg \operatorname{Grass}_C(p, m + p)$ is odd if and only if

$$\operatorname{Grass}_C(p, m + p) = \operatorname{Grass}_C(2, 2^h + 1)$$

or

$$\operatorname{Grass}_C(p, m + p) = \mathbf{P}_C^n$$

(see [1]). $\square$

EXAMPLE 2.1. We have that

$$\deg(\mathbf{P}_C^1 \times \mathbf{P}_C^2 \times \mathbf{P}_C^4) = 105 \quad \text{and} \quad \deg(\mathbf{P}_C^1 \times \operatorname{Grass}_C(2, 3)) = 35.$$

3. Sufficient conditions for arbitrary pole assignability. In what follows, d_α denotes the degree of Π_C^α, i.e.,

$$d_\alpha = (m_1p_1 + \cdots + m_rp_r)! \prod_{i=1}^{r} \frac{1!2! \cdots (p_i - 1)!}{m_i!(m_i + 1)! \cdots (m_i + p_i - 1)!}. \tag{17}$$

THEOREM 3.1. *An r-channel system σ of McMillan degree n with $n \leq \sum_{i=1}^{r} m_ip_i$ and d_α odd has arbitrary pole assignability by decentralized static feedback if*

$$\dim(E_\sigma \cap \Pi_C^\alpha) = \sum_{i=1}^{r} m_ip_i - n - 1.$$

In this formula, we assume that the empty set has dimension -1.

Proof. When $\sum_{i=1}^{r} m_ip_i = n$, $E_\sigma \cap \Pi_C^\alpha = \emptyset$ implies that $\phi_\sigma : \Pi_C^\alpha \to \mathbf{P}_C^n$ is a finite morphism and hence is onto and has degree d_α [12], [15]. Since d_α is odd,

$$\phi_\sigma : \Pi_R^\alpha \to \mathbf{P}_R^n$$

is also onto.

When $\sum_{i=1}^{r} m_ip_i > n$, there exists a subspace $H \subset \mathbf{P}_C^N, \bar{H} = H$ of codimension $\sum_{i=1}^{r} m_ip_i - n$ such that

$$E_\sigma \cap H \cap \Pi_C^\alpha = \emptyset.$$

Let $E_1 = E_\sigma \cap H$, ϕ_1 be the projection with center E_1, $E_2 = \phi_1(E_\sigma)$ and $\phi_2 : \mathbf{P}_R^a - E_2 \to \mathbf{P}_R^n$ be the projection with center E_2. Then

$$\phi_1 : \Pi_R^\alpha \to \mathbf{P}_R^a, \qquad a = \sum_{i=1}^{r} m_ip_i$$

is onto. Therefore

$$\begin{aligned} \phi_\sigma(\Pi_R^\alpha - E_\sigma) &= \phi_2(\phi_1(\Pi_R^\alpha - E_\sigma)) \\ &= \phi_2(\phi_1(\Pi_R^\alpha - E_1) - E_2) \\ &= \phi_2(\mathbf{P}_R^a - E_2) = \mathbf{P}_R^n. \end{aligned}$$

□

THEOREM 3.2. *An r-channel system σ of McMillan degree n with $n < \sum_{i=1}^{r} m_ip_i$ and d_α even has arbitrary pole assignability by decentralized static feedback if*

$$\dim E_\sigma \cap \Pi_C^\alpha = \sum_{i=1}^{r} m_ip_i - n - 1,$$

and there is a $z_0 \in E_\sigma \cap \Pi_R^\alpha$ such that

$$\dim E_\sigma \cap T_{z_0} = \sum_{i=1}^{r} m_ip_i - n - 1,$$

where T_{z_0} is the tangent space of Π_C^α at z_0.

Proof. Apply Proposition 3.2 of [19] to ϕ_σ directly. Note that Π_C^α is nonsingular. □

THEOREM 3.3. *An r-channel system σ of McMillan degree n with $n < \sum_{i=1}^{r} m_i p_i$ and d_α even has almost arbitrary pole assignability by decentralized static feedback if*

$$\dim E_\sigma \cap \Pi_C^\alpha = \sum_{i=1}^{r} m_i p_i - n - 1,$$

and there is a $z_0 \in E_\sigma \cap \Pi_R^\alpha$ such that

$$\dim E_\sigma \cap T_{z_0} \leq \sum_{i=1}^{r} m_i p_i - n.$$

Proof. The proof follows from Proposition 3.2 of [19]. □

4. Generic pole assignability. Let $\Sigma_{m,p}^n$ be the set of all m-input, p-output systems of McMillan degree n. Recall that $\Sigma_{m,p}^n$ is a quasi-affine variety of dimension $n(m+p)$. A subset U of $\Sigma_{m,p}^n$ is said to be generic if U is open and dense in $\Sigma_{m,p}^n$. In particular, U is generic if U contains a nonempty Zariski open subset of $\Sigma_{m,p}^n$. Any system in a generic set is called a generic system.

In this section, we consider the conditions under which a generic system has arbitrary pole assignability. Since

$$\dim \Pi_R^\alpha = \sum_{i=1}^{r} m_i p_i,$$

a necessary condition is

$$\sum_{i=1}^{r} m_i p_i \geq n. \tag{18}$$

It is also sufficient if d_α is odd (Theorem 4.1) and is not sufficient if d_α is even (Theorem 4.2). We also prove in this section that

$$\sum_{i=1}^{r} m_i p_i > n \tag{19}$$

is a sufficient condition if d_α is even and all local channels have either the same numbers of inputs or the same numbers of outputs.

In what follows, it will be convenient to switch rows of determinant in (10) and write

$$\phi_\sigma(M_1, M_2, \ldots, M_r) =$$

$$\det \left[\begin{array}{cccc|cccc} M_{11} & 0 & \cdots & 0 & N_{11} & N_{12} & \cdots & N_{1r} \\ M_{12} & 0 & \cdots & 0 & D_{11} & D_{12} & \cdots & D_{1r} \\ 0 & M_{21} & \cdots & 0 & N_{21} & N_{22} & \cdots & N_{2r} \\ 0 & M_{22} & \cdots & 0 & D_{21} & D_{22} & \cdots & D_{2r} \\ \vdots & \vdots & & \vdots & \vdots & \vdots & & \vdots \\ 0 & 0 & \cdots & M_{r1} & N_{r1} & N_{r2} & \cdots & N_{rr} \\ 0 & 0 & \cdots & M_{r2} & D_{r1} & D_{r2} & \cdots & D_{rr} \end{array}\right], \tag{20}$$

where

$$M_i = \begin{bmatrix} M_{i1} \\ M_{i2} \end{bmatrix} \in \mathrm{Grass}_C(p_i, m_i + p_i)$$

is an $(m_i + p_i) \times p_i$ full-rank matrix and where M_{i1} and M_{i2} are $p_i \times p_i$ and $m_i \times p_i$ submatrices, respectively.

PROPOSITION 4.1. *Let $n \leq \sum_{i=1}^{r} m_i p_i$. The set of systems in $\Sigma_{m,p}^n$ such that*

$$\dim(E_\sigma \cap \Pi_C^\alpha) = \sum_{i=1}^{4} m_i p_i - n - 1$$

is a nonempty Zariski open set, where dimension -1 means that the intersection is empty.

Proof. For a proof, see the Appendix. □

By Theorem 3.1 and Proposition 4.1, we obtain the following result.

THEOREM 4.1. *When d_α is odd, the generic system in $\Sigma_{m,p}^n$ has arbitrary pole assignability by decentralized static feedback if and only if*

$$\sum_{i=1}^{r} m_i p_i \geq n.$$

The same result is not true if d_α is even.

THEOREM 4.2. *For any $\sigma \in \Sigma_{2,2}^2$ with*

$$E_\sigma \cap \Pi_C^{(1,1,1,1)} = \emptyset,$$

the set of closed-loop characteristic polynomials that cannot be achieved by decentralized static feedback with $p_1 = p_2 = m_1 = m_2 = 1$ is a nonempty open subset of $\mathbf{R}^2$ (in the classical topology).

Proof. The condition implies that $\phi_\sigma : \Pi_C^{(1,1,1,1)} \to \mathbf{P}_C^2$ is onto, and $\phi_\sigma^{-1}(y)$ contains two points (counted with multiplicity) for any $y \in \mathbf{P}_C^2$. The set of $y \in \mathbf{R}^2$, such that $p_\sigma^{-1}(y)$ contains two complex conjugate points, is an open set of $\mathbf{R}^2$. We only need to show that it is nonempty.

$\Pi_C^{(1,1,1,1)}$ is defined in $\mathbf{P}_C^3$ by

$$Q(z) = z_0 z_3 - z_1 z_2 = 0,$$

where $z_0 = x_0 y_0$, $z_1 = x_0 y_1$, $z_2 = x_1 y_0$, $z_3 = x_1 y_1$, and $(x_0, x_1), (y_0, y_1)$ are the homogeneous coordinates of $\mathbf{P}_C^1$'s. We have

$$\phi_\sigma(z) = \det \begin{bmatrix} x_0 & 0 & \\ & & N(s) \\ 0 & y_0 & \\ x_1 & 0 & \\ & & D(s) \\ 0 & y_1 & \end{bmatrix}$$

or

$$\phi_\sigma(z) = \sum_{i=0}^{3} z_i g_i(s), \qquad Q(z) = 0.$$

By assumption, E_σ contains only one real point. Assume that $E_\sigma = \{e\}, e = (0, e_1, e_2, e_3)$, where $e_0 = 0$, because $g_0(s) = \det D(s)$ is the only polynomial of degree 2. Since $Q(e) \neq 0$, $e_1 e_2 \neq 0$, and it can be easily checked that the real polynomial

$$g_0(s) - \frac{1 + e_3^2}{4 e_1 e_2} g_3(s)$$

cannot be achieved by any real feedback. □

Remark 4.1. This theorem is an analogue of Corollary 6.4 of [2]. Note that $E_\sigma \cap \Pi_C^{(1,1,1,1)} = \emptyset$ for a generic system σ in $\Sigma_{2,2}^2$.

PROPOSITION 4.2. *Assume that d_α is even and that*

$$S = \{\sigma \in \Sigma_{m,p}^n \mid E_\sigma \cap \Pi_R^\alpha \neq \emptyset\}$$

is a generic set. Then the pole assignment map $\phi_\sigma : \Pi_R^\alpha - E_\sigma \to \mathbf{P}_R^n$ is onto for the generic system σ in $\Sigma_{m,p}^n$.

Remark 4.2. $E_\sigma \cap \Pi_C^\alpha = \emptyset$ for the generic system if $n \geq \sum_{i=1}^r m_i p_i$. So the second condition implies that $n < \sum_{i=1}^r m_i p_i$.

Proof. We must prove that

$$\dim E_\sigma \cap T_z = \sum_{i=1}^{r} m_i p_i - n - 1$$

for some $z \in E_\sigma \cap \Pi_R^\alpha$ for the generic system σ. The set of such systems is certainly open. Consider in $\Sigma_{m,p}^n \times \Pi_R^\alpha$ the incidence set

$$X_R = \{(\sigma, z) \mid z \in E_\sigma \cap \Pi_{\mathbf{R}}^\alpha\}.$$

Define

$$X_1 = \left\{(\sigma, z) \in X_R \mid \dim E_\sigma \cap T_z = \sum_{i=1}^{r} m_i p_i - n - 1\right\}.$$

X_1 is a nonempty Zariski open set of X_R by the Appendix. So $\pi_1(X_1)$ is dense in $\pi_1(X_R)$ and therefore is dense in $\Sigma_{m,p}^n$ by assumption, where π_1 is the projection defined by

$$\pi_1(\sigma, z) = \sigma. \qquad \square$$

PROPOSITION 4.3. *$E_\sigma \cap \Pi_R^\alpha \neq \emptyset$ for all systems if*

$$n > \sum_{i=1}^{r} m_i p_i$$

and either $m_1 = m_2 = \cdots = m_r$ or $p_1 = p_2 = \cdots = p_r$.

Proof. Without loss of generality, assume that $p_1 = \cdots = p_r$. Let $\{v_1, \ldots, v_m\}$ be the controllability indices of σ with

$$v_1 \leq v_2 \leq \cdots \leq v_m.$$

Then

$$p_1 m = \sum_{i=1}^{r} p_i m_i > n = v_1 + v_2 + \cdots + v_m \geq v_1 m,$$

which means that $p_1 > v_1$. Let

$$\begin{bmatrix} d_1 \\ n_1 \\ \vdots \\ d_r \\ n_r \end{bmatrix}$$

be the first column of

$$\begin{bmatrix} N_{11} & \cdots & N_{1r} \\ D_{11} & \cdots & D_{1r} \\ \vdots & & \vdots \\ N_{r1} & \cdots & N_{rr} \\ D_{r1} & \cdots & D_{rr} \end{bmatrix}$$

in (20) with column degree v_1 (Such a coprime fraction always exists by [7]). The column degree of

$$\begin{bmatrix} d_i \\ n_i \end{bmatrix}$$

is less than p_i, so there is an $(m_i + p_i) \times p_i$ full-rank matrix

$$M_i = \begin{bmatrix} M_{i1} \\ M_{i2} \end{bmatrix}$$

such that

$$\begin{bmatrix} d_i \\ n_i \end{bmatrix} \in \text{col sp} \begin{bmatrix} M_{i1} \\ M_{i2} \end{bmatrix}, \qquad i = 1, 2, \ldots, r,$$

which implies that

$$\phi_\sigma(M_1, M_2, \ldots, M_r) \equiv 0,$$

i.e.,

$$(M_1, M_2, \ldots, M_r) \in E_\sigma \cap \Pi_R^\alpha. \qquad \square$$

By Proposition 4.2 and 4.3, we obtain the next theorem.

THEOREM 4.3. *When d_α is even, the generic system in $\Sigma_{m,p}^n$ has arbitrary pole assignability by decentralized static feedback if*

$$\sum_{i=1}^{r} m_i p_i > n$$

and either $p_1 = p_2 = \cdots = p_r$ or $m_1 = m_2 = \cdots = m_r$.

Appendix. Let Z be an $(m+p)\times p$ full-rank matrix in $\mathrm{Grass}(p,m+p)$ and $z=(z_{\underline{i}})$ be its Plücker coordinate, where $\underline{i}=(i_1,\dots,i_p)$ and $z_{\underline{i}}$ is the $p\times p$ minor of M formed by the i_1th through i_pth rows.

NOTATION A.1. The following hold:

1. $\underline{i}\le\underline{j}\Leftrightarrow i_l\le j_l,\ l=1,\dots,p$;
2. $|\underline{i}|=i_1+i_2+\cdots+i_p-p(p+1)/2$.

DEFINITION A.1. *Define*

$$S(\underline{i})=\{z\in\mathrm{Grass}(p,m+p)|z_{\underline{j}}=0 \text{ if } \underline{j}\not\le\underline{i}\},$$

$$C(\underline{i})=\{z\in S(\underline{i})|z_{\underline{i}}\neq 0\},$$

and

$$S^*(\underline{i})=\{z\in\mathrm{Grass}(p,m+p)|z_{\underline{j}}=0 \text{ if } \underline{i}\not\le\underline{j}\}.$$

Then $S(\underline{i})$ and $S^*(\underline{i})$ are Schubert varieties of dimension $|\underline{i}|$ and $mp-|\underline{i}|$, respectively, $C(\underline{i})$ is a Schubert cell, and

$$S(\underline{i})=\bigcup_{\underline{j}\le\underline{i}}C(\underline{j}). \tag{21}$$

For any $z=(z_{\underline{j}})\in C(\underline{i})$,

$$z_{\underline{j}}=0 \quad \text{if} \quad |\underline{j}|\ge|\underline{i}| \text{ and } \underline{j}\neq\underline{i}. \tag{22}$$

Let $m=m_1+\cdots+m_r$ and $p=p_1+\cdots+p_r$. Then from (20) we have that

$$\Pi_C^{\alpha}=S^*(\underline{k})\cap S(\underline{l})\subset\mathrm{Grass}(p,m+p),$$

where

$$k_t=m_1+\cdots+m_{s-1}+t \quad \text{and} \quad l_t=k_t+m_s \tag{23}$$

$$\text{for } p_1+\cdots+p_{s-1}<t\le p_1+\cdots+p_s, \quad p_0=m_0=0.$$

LEMMA A.1. *Let*

$$H_t=\left\{z=(z_{\underline{j}})\in\mathbf{P}^M\,\middle|\,\sum_{|\underline{j}|=i}z_{\underline{j}}=0,\ i=t+1,\dots,mp\right\}.$$

Then

$$H_t\cap\mathrm{Grass}(p,m+p)=\bigcup_{|\underline{j}|=t}S(\underline{j}).$$

Proof. Note that

$$\bigcup_{|\underline{j}|=t}S(\underline{j})\subset H_t\cap\mathrm{Grass}(p,m+p).$$

Take any $z = (z_{\underline{i}}) \in H_t \cap \text{Grass}(p, m+p)$. Then $z \in C(\underline{i})$ for some $\underline{i}$ and

$$\sum_{|\underline{j}|=|\underline{i}|} z_{\underline{j}} = z_{\underline{i}} \neq 0$$

by (22). Therefore $|\underline{i}| \leq t$, and

$$x \in \bigcup_{|\underline{j}|\leq t} C(\underline{j}) = \bigcup_{|\underline{j}|=t} S(\underline{j}). \qquad \square$$

LEMMA A.2. *For any Schubert variety $S(\underline{i}) \subset \text{Grass}(p, m+p)$, the set*

$$\left\{ G(s) = N(s)D^{-1}(s) \in \Sigma_{m,p}^{|\underline{i}|} | \det \begin{bmatrix} Z_1 & N(s) \\ Z_2 & D(s) \end{bmatrix} \not\equiv 0 \text{ for all } \begin{bmatrix} Z_1 \\ Z_2 \end{bmatrix} \in S(\underline{i}) \right\}$$

is a nonempty Zariski open set of $\Sigma_{m,p}^{|\underline{i}|}$.

Remark A.1. Brockett and Byrnes [2] proved this for the special Schubert variety, $\text{Grass}(p, m+p)$ itself. The proof given here is similar to Rosenthal's proof [13] of the Brockett–Byrnes result.

Proof. We only need to prove that such a set is nonempty. Take an element $a = (a_{\underline{j}}) \in C(\underline{i})$ such that

$$a_{\underline{j}} \neq 0 \quad \text{for all } \underline{j} \leq \underline{i}$$

and define a curve $\sigma(s) = (\sigma_{\underline{j}}(s)) \subset \text{Grass}(m, m+p)$ by

$$\sigma_{\underline{j}}(s) = a_{\underline{j}} s^{|\underline{i}|-|\underline{j}|},$$

where $\sigma_{\underline{j}}(s)$ is the $m \times m$ minor of an $(m+p) \times m$ matrix $P(s)$ formed by eliminating the j_1th through $\ldots, j_p$th rows. The σ has the following properties:

1. $\sigma_{\underline{j}} = 0$ if $|\underline{j}| > |\underline{i}|$;
2. $\sigma_{\underline{i}} = a_{\underline{i}} \neq 0$;
3. $\sigma_{(1,2,\ldots,p)} = a_{(1,2,\ldots,p)} s^{|\underline{i}|}$ is the only $s^{|\underline{i}|}$ term.

Therefore $\sigma(s)$ can be realized as a polynomial matrix $\left[\begin{smallmatrix} N(s) \\ D(s) \end{smallmatrix}\right]$ such that $N(s)D^{-1}(s) \in \Sigma_{m,p}^{|\underline{i}|}$. For any

$$Z = \begin{bmatrix} Z_1 \\ Z_2 \end{bmatrix} \in S(\underline{i}),$$

$Z \in C(\underline{j})$ for some $\underline{j} \leq \underline{i}$, and

$$\begin{aligned} \det \begin{bmatrix} Z_1 & N(s) \\ Z_2 & D(s) \end{bmatrix} &= \sum_{\underline{t}} (-1)^{|\underline{t}|} z_{\underline{t}} \sigma_{\underline{t}}(s) \\ &= (-1)^{|\underline{j}|} z_{\underline{j}} a_{\underline{j}} s^{|\underline{i}|-|\underline{j}|} + \text{higher-power terms} \\ &\not\equiv 0 \end{aligned}$$

by (22). $\square$

Let Π^α be embedded in $\text{Grass}(p, m+p) \subset \mathbf{P}^M$, as in (20).

LEMMA A.3. *Define the subspace* $L_t \subset \mathbf{P}^M$ *for* $|\underline{k}| \le t < |\underline{l}|$ *by*

$$L_t = \left\{ z = (z_{\underline{j}}) \in \mathbf{P}^M \middle| \sum_{|\underline{j}|=i} z_{\underline{j}} = 0,\ i = t+1, \dots, |\underline{l}| \right\},$$

where $\underline{k}$ *and* $\underline{l}$ *are defined by* (23). *Then*

$$L_t \cap \Pi^\alpha = \bigcup_{|\gamma_1|+\cdots+|\gamma_r|=t-|\underline{k}|} S(\gamma_1) \times \cdots \times S(\gamma_r),$$

where $\gamma_j = (i_1, \dots, i_{p_j})$, $1 \le i_1 < \cdots < i_{p_j} \le m_j + p_j$, *and the Schubert variety* $S(\gamma_j)$ *is defined by Definition* A.1 *for*

$$\begin{bmatrix} M_{j1} \\ M_{j2} \end{bmatrix} \in \mathrm{Grass}(p_j, m_j + p_j).$$

Proof. It holds that

$$\begin{aligned} L_t \cap \Pi^\alpha &= L_t \cap S(\underline{k}) \cap S^*(\underline{l}) \\ &= H_t \cap S(\underline{k}) \cap S^*(\underline{l}) \\ &= \bigcup_{|\underline{j}|=t,\ \underline{j} \le \underline{l}} S(\underline{j}) \cap S^*(\underline{k}) \\ &= \bigcup_{|\underline{j}|=t,\ \underline{k} \le \underline{j} \le \underline{l}} C(\underline{j}) \cap S^*(\underline{k}) \\ &= \bigcup_{|\gamma_1|+\cdots+|\gamma_r| \le t-|\underline{k}|} C(\gamma_1) \times \cdots \times C(\gamma_r) \\ &= \bigcup_{|\gamma_1|+\cdots+|\gamma_r|=t-|\underline{k}|} S(\gamma_1) \times \cdots \times S(\gamma_r). \qquad \square \end{aligned}$$

LEMMA A.4. *For any* $S(\gamma_1) \times \cdots \times S(\gamma_r) \subset \Pi^\alpha$, *let* $n = |\gamma_1| + \cdots + |\gamma_r|$. *Then*

$$\{\sigma \in \Sigma^n_{m,p} | E_\sigma \cap S(\gamma_1) \times \cdots \times S(\gamma_r) = \emptyset\}$$

is a nonempty Zariski open set.

Proof. We only need to prove that it is nonempty. Take $N_j(s)D_j^{-1}(s) \in \Sigma^{|\gamma_j|}_{m_j,p_j}$ such that

$$\det \begin{bmatrix} M_{j1} & N_j(s) \\ M_{j2} & D_j(s) \end{bmatrix} \not\equiv 0$$

for all

$$\begin{bmatrix} M_{j1} \\ M_{j2} \end{bmatrix} \in S(\gamma_j)$$

and define $\sigma = N(s)D^{-1}(s) \in \Sigma^n_{m,p}$ with

$$N(s) = \text{block diag.}(N_1(s), \dots, N_r(s)),$$

$$D(s) = \text{block diag.}(D_1(s), \dots, D_r(s)).$$

Then

$$E_\sigma \cap S(\gamma_1) \times \cdots \times S(\gamma_r) = \emptyset. \qquad \square$$

PROPOSITION A.1. *Let $n \le \sum_{i=1}^r m_i p_i$. The set of systems in $\Sigma_{m,p}^n$ such that*

$$\dim(E_\sigma \cap \Pi_C^\alpha) = \sum_{i=1}^4 m_i p_i - n - 1$$

is a nonempty Zariski open set where dimension -1 means that the intersection is empty.

Proof. We only need to prove that the set is nonempty. When $\sum_{i=1}^r m_i p_i = n$, this follows from Lemma A.4. When $\sum_{i=1}^r m_i p_i > n$, take any σ in

$$\bigcap_{|\gamma_1|+\cdots+|\gamma_r|=n} \{\sigma \in \Sigma_{m,p}^n | E_\sigma \cap S(\gamma_1) \times \cdots \times S(\gamma_r) = \emptyset\}.$$

Then

$$\begin{aligned} E_\sigma \cap \Pi_C^\alpha \cap L(n + |\underline{k}|) &= E_\sigma \cap \bigcup_{|\gamma_1|+\cdots+|\gamma_r|=n} S(\gamma_1) \times \cdots \times S(\gamma_r) \\ &= \bigcup_{|\gamma_1|+\cdots+|\gamma_r|=n} E_\sigma \cap S(\gamma_1) \times \cdots \times S(\gamma_r) \\ &= \emptyset. \end{aligned}$$

Since

$$\text{codim } L(n + |\underline{k}|) = |\underline{l}| - |\underline{k}| - n = \sum_{i=1}^r m_i p_i - n,$$

we see that

$$\dim E_\sigma \cap \Pi_C^\alpha \le \sum_{i=1}^r m_i p_i - n - 1$$

by the projective dimension theorem [9]. On the other hand,

$$\dim E_\sigma \cap \Pi_C^\alpha \ge \sum_{i=1}^r m_i p_i - n - 1,$$

because $\dim \Pi_C^\alpha = \sum_{i=1}^r m_i p_i$ and $\text{codim } E_\sigma \le n + 1$. $\square$

PROPOSITION A.2. *Let*

$$X_R = \{(\sigma, z) \in \Sigma_{m,p}^n \times \Pi_{\mathbf{R}}^\alpha \mid z \in E_\sigma \cap \Pi_R^\alpha\}$$

and

$$X_1 = \left\{ (\sigma, z) \in X_R \mid \dim E_\sigma \cap T_z = \sum_{i=1}^r m_i p_i - n - 1 \right\}.$$

Then X_1 is a nonempty Zariski open subset of the X_R if $\sum_{i=1}^{r} m_i p_i > n$, $m \leq n$, and $p \leq n$.

Proof. We only need to prove that X_1 is nonempty. We switch rows of the determinant in (10) and write

$$\phi_\sigma(M_1, \ldots, M_r) = \det \left[\begin{array}{ccc|c} M_{12} & & & \\ & \ddots & & D(s) \\ & & M_{r2} & \\ \hline M_{11} & & & \\ & \ddots & & N(s) \\ & & M_{r1} & \end{array}\right],$$

where M_{i1} and M_{i2} are the same as in (20). For any

$$(\sigma, z) \in X_R, \qquad z = (M_1, \ldots, M_r),$$

$$\phi_\sigma(z) = \phi_\sigma(M_1, \ldots, M_r) \equiv 0,$$

and there exists a $Q_i \in GL(m_i + p_i, \mathbf{R})$ such that

$$Q_i \begin{bmatrix} M_{i2} \\ M_{i1} \end{bmatrix} = \begin{bmatrix} 0 \\ I_i \end{bmatrix}$$

for each

$$\begin{bmatrix} M_{i2} \\ M_{i1} \end{bmatrix},$$

where I_i is the $p_i \times p_i$ identity matrix. Let

$$L = Q_1 \times Q_2 \times \cdots \times Q_r.$$

Then $L(z) = z_0$, where

$$z_0 = \begin{bmatrix} 0 \\ I \end{bmatrix}.$$

If we write

$$L(\sigma) = L\left(\begin{bmatrix} D(s) \\ N(s) \end{bmatrix}\right) = \begin{bmatrix} P_1(s) \\ P_2(s) \end{bmatrix},$$

then $\det P_1(s) \equiv 0$, and $(\sigma, z) \in X_1$ if and only if

$$\dim E_{L(\sigma)} \cap T_{z_0} = \sum_{i=1}^{r} m_i p_i - n - 1. \tag{24}$$

Let $a_{ij}(s), 1 \leq i \leq m, j > m$ be the $m \times m$ minor of

$$\begin{bmatrix} P_1(s) \\ P_2(s) \end{bmatrix}$$

formed by the jth row and the first m rows, except the ith row. It is easy to check that (24) is true if and only if

$$\dim sp\{a_{ij}(s)\} = n+1, \tag{25}$$

where $i = 1, 2, \ldots, m$ and

$$m+p_1+\cdots+p_k < j \le m+p_1+\cdots+p_{k+1} \text{ if } m_1+\cdots+m_k < i \le m_1+\cdots+m_{k+1}.$$

Hence we need to construct an $(m+p)\times m$ polynomial matrix such that

(i) The minor formed by the first m rows is zero,

(ii) The matrix satisfies (25),

(iii) It can be changed into $\left[\begin{smallmatrix} D(s) \\ N(s) \end{smallmatrix}\right]$ by a row operation of the form $Q_1 \times Q_2 \times \cdots \times Q_r$.

By the assumptions, p_i and $m_i, i = 1, \ldots, r$ cannot all be 1. Without loss of generality, assume that $\max_i p_i > 1$. Let

$$n = p_1m_1 + \cdots + p_km_k + ap_{k+1} + b,$$

where $k < r$,

$$p_1 \le p_2 \le \cdots \le p_{k+1}, \qquad p_{k+1} > 1,$$

$$0 \le a < m_{k+1},$$

and

$$0 \le b < p_{k+1}.$$

Define

$$P(s) = \left[\begin{array}{ccccccccc}
A_1 & & & & & & & & \\
B_1 & A_2 & & & & & & & \\
 & B_2 & \ddots & & & & & & \\
 & & \ddots & A_k & & & & & \\
 & & & B_k & A_{k+1} & & & & \\
 & & & & 0 & I & & & \\
 & & & & & \ddots & \ddots & & \\
 & & & & & & 0 & I & \\
\hline
0 & \cdots & \cdots & \cdots & C_1 & \cdots & \cdots & 0 & \\
\vdots & & & & \vdots & & & \vdots & \\
\vdots & & & & C_{k+1} & \cdots & \cdots & 0 & \\
\vdots & & & & 0 & \cdots & \cdots & 0 & \\
\vdots & & & & \vdots & & & \vdots & \\
0 & \cdots & \cdots & \cdots & 0 & \cdots & \cdots & 0 &
\end{array}\right],$$

where A_i, B_i, and C_i are $m_i \times m_i, m_{i+1} \times m_i$, and $p_i \times m_i$ matrices defined by the following case.

Case 1. $a > 0$ and $b > 0$. It holds that

$$A_i = \begin{bmatrix} s^{p_i} & & & \\ 1 & \ddots & & \\ & \ddots & \ddots & \\ & & 1 & s^{p_i} \end{bmatrix}, \qquad B_i = \begin{bmatrix} 0 & \dots & 0 & 1 \\ 0 & \dots & 0 & 0 \\ \vdots & & \vdots & \vdots \\ 0 & \dots & 0 & 0 \end{bmatrix},$$

and

$$C_i = \begin{bmatrix} 0 & \dots & 0 & 1 \\ 0 & \dots & 0 & s \\ \vdots & & \vdots & \vdots \\ 0 & \dots & 0 & s^{p_i-1} \end{bmatrix}$$

for $i = 1, 2, \dots, k$,

$$A_{k+1} = \left[\begin{array}{cccc|ccc} \overbrace{\qquad\qquad\qquad}^{a} & & & & & & \\ s^{p_{k+1}} & & & & & & \\ 1 & \ddots & & & & & \\ & \ddots & s^{p_{k+1}} & & & & \\ & & 1 & s^b & & & \\ & & & 1 & 0 & & \\ & & & & \ddots & \ddots & \\ & & & & & 1 & 0 \end{array}\right]$$

and

$$C_{k+1} = \begin{bmatrix} 0 & \cdots & 1+s \\ 0 & \cdots & s+2s^2 \\ \vdots & & \vdots \\ 0 & \cdots & s^{p_{k+1}-1} + p_{k+1}s^{p_{k+1}} \end{bmatrix}.$$

Case 2. $b = 0$ and $a > 1$. Everything is the same as in Case 1, except that

$$A_{k+1} = \left[\begin{array}{ccccc|ccc} \overbrace{\qquad\qquad\qquad\qquad}^{a} & & & & & & & \\ s^{p_{k+1}} & & & & & & & \\ 1 & \ddots & & & & & & \\ & \ddots & s^{p_{k+1}} & & & & & \\ & & 1 & s^{p_{k+1}-1} & & & & \\ & & & 1 & s & & & \\ & & & & 1 & 0 & & \\ & & & & & \ddots & \ddots & \\ & & & & & & 1 & 0 \end{array}\right].$$

Case 3. $b = 0$, $a = 1$, and $k \neq 0$. Everything is the same as in Case 1, except that

$$A_k = \begin{bmatrix} s^{p_k} & & & \\ 1 & \ddots & & \\ & \ddots & s^{p_k} & \\ & & 1 & s^{p_k-1} \end{bmatrix}, \qquad A_{k+1} = \begin{bmatrix} s & & & \\ 1 & 0 & & \\ & \ddots & \ddots & \\ & & 1 & 0 \end{bmatrix}.$$

Case 4. $b = 0$, $a = 1$, and $k = 0$. Everything is the same as in Case 3, except that

$$C_1 = C_{k+1} = \begin{bmatrix} 0 & \dots & 1 \\ 0 & \dots & s \\ \vdots & & \vdots \\ 0 & \dots & s^{p_1-1} \end{bmatrix}.$$

Case 5. $a = 0$ and $b \geq p_k$. Everything is the same as in Case 1, except that

$$A_{k+1} = \begin{bmatrix} 0 & & & \\ 1 & \ddots & & \\ & \ddots & \ddots & \\ & & 1 & 0 \end{bmatrix}, \qquad C_{k+1} = \begin{bmatrix} 0 & \dots & 1 \\ 0 & \dots & s \\ \vdots & & \vdots \\ 0 & \dots & s^b \\ \vdots & & \vdots \\ 0 & \dots & 0 \end{bmatrix}.$$

Case 6. $a = 0$ and $0 < b < p_k$. Everything is the same as in Case 5, except that

$$A_k = \begin{bmatrix} s^{p_k} & & & \\ 1 & \ddots & & \\ & \ddots & s^{p_k} & \\ & & 1 & s^b \end{bmatrix}, \qquad C_{k+1} = \begin{bmatrix} 0 & \dots & s^{p_k-b} \\ 0 & \dots & s^{p_k-b+1} \\ \vdots & & \vdots \\ 0 & \dots & s^{k_k} \\ \vdots & & \vdots \\ 0 & \dots & 0 \end{bmatrix}.$$

Case 7. $a = 0$, $b = 0$, $m_k > 1$, and $p_k > 1$. Everything is the same as in Case 5, except that

$$A_k = \begin{bmatrix} s^{p_k} & & & & \\ 1 & \ddots & & & \\ & \ddots & s^{p_k} & & \\ & & 1 & s^{p_k-1} & \\ & & & 1 & s \end{bmatrix}, \qquad C_{k+1} = \begin{bmatrix} 0 & \dots & s \\ 0 & \dots & s^2 \\ \vdots & & \vdots \\ 0 & \dots & s^{p_k} \\ \vdots & & \vdots \\ 0 & \dots & 0 \end{bmatrix}.$$

Case 8. $a = 0$, $b = 0$, $p_k > 1$, $m_k = 1$, and $k > 1$. Everything is the same as in Case 5, except that $C_{k+1} = 0$,

$$A_{k-1} = \begin{bmatrix} s^{p_{k-1}} & & & \\ 1 & \ddots & & \\ & \ddots & s^{p_{k-1}} & \\ & & 1 & s^{p_{k-1}-1} \end{bmatrix}, \qquad A_k = \begin{bmatrix} s & & & \\ 1 & 0 & & \\ & \ddots & \ddots & \\ & & 1 & 0 \end{bmatrix},$$

and

$$C_k = \begin{bmatrix} 0 & \dots & s \\ 0 & \dots & s^2 \\ \vdots & & \vdots \\ 0 & \dots & s^{p_k} \end{bmatrix}.$$

Case 9. $a = 0$, $b = 0$, $p_k > 1$, $m_k = 1$, and $k = 1$,

$$B_1 = \begin{bmatrix} 0 & \dots & 1 \\ \vdots & & \vdots \\ 0 & \dots & 0 \end{bmatrix}, \quad A_1 = \begin{bmatrix} s & & & \\ 1 & 0 & & \\ & \ddots & \ddots & \\ & & 1 & 0 \end{bmatrix}, \quad A_2 = \begin{bmatrix} 0 & & & \\ 1 & \ddots & & \\ & \ddots & \ddots & \\ & & 1 & 0 \end{bmatrix},$$

$$C_1 = \begin{bmatrix} 0 & \dots & 1 \\ 0 & \dots & s \\ \vdots & & \vdots \\ 0 & \dots & s^{p_1-2} \\ 0 & \dots & 0 \end{bmatrix}, \qquad C_2 = \begin{bmatrix} 0 & \dots & 1 \\ 0 & \dots & s \\ \vdots & & \vdots \\ 0 & \dots & s^{p_1-1} \\ \vdots & & \vdots \\ 0 & \dots & 0 \end{bmatrix}.$$

Case 10. $a = 0$, $b = 0$, $p_k = 1$, and $m_1 + m_2 + \cdots + m_k > 1$. Everything is the same as in Case 5, except that

$$A_1 = \begin{bmatrix} 1 & & & \\ 1 & s & & \\ & \ddots & \ddots & \\ & & 1 & s \end{bmatrix}, \qquad C_{k+1} = \begin{bmatrix} 0 & \dots & 1 \\ 0 & \dots & s \\ \vdots & & \vdots \\ 0 & \dots & 0 \end{bmatrix}.$$

Case 11. $a = 0$, $b = 0$, $k = 1$, and $p_1 = m_1 = 1$,

$$A_1 = 0, \quad A_2 = \begin{bmatrix} 0 & & & \\ 1 & \ddots & & \\ & \ddots & \ddots & \\ & & 1 & 0 \end{bmatrix}, \qquad C_1 = 0, \quad C_2 = \begin{bmatrix} 0 & \dots & 1 \\ 0 & \dots & s \\ \vdots & & \vdots \\ 0 & & 0 \end{bmatrix}.$$

It is not difficult to check that $P(s)$ satisfies the requirements. □

Acknowledgments. The author thanks Professor K. A. Grasse and the referees for their help in identifying some errors and potentially confusing points in the original manuscript, and also Professor J. Rosenthal for his suggestions.

THE OUTPUT-NULLING SPACE, PROJECTED DYNAMICS, AND SYSTEM DECOMPOSITION FOR LINEAR TIME-VARYING SINGULAR SYSTEMS*

WILLIAM J. TERRELL†

Abstract. A decomposition of a given linear time-varying singular control system is developed by defining the output-nulling space with respect to a given output structure. Relevant subspaces and the dynamics on them are described by computable projection operators obtained from information in the system's derivative array. The relevant projectors are generated as solutions of a homogeneous linear matrix-differential equation. An algorithm for obtaining the system decomposition is outlined in a pointwise manner.

Key words. output-nulling/unobservable subspace, system decomposition, linear time-varying system, implicit, singular, descriptor, differential-algebraic

AMS subject classifications. 34A09, 34A30, 93B07, 93B10, 93B11, 34A46

1. Introduction.

Research in the last decade has established the wide applicability of implicit differential systems of the form

$$E(t)x' + F(t)x = B(t)u, \tag{1a}$$

where E, F are square matrices, E is identically singular on the interval $\mathcal{I}$, $x \in R^n$, and u is a smooth real-valued input function [17], [2], [1], [18]. Equation (1a) is often called a differential-algebraic equation (DAE). The fundamental existence and uniqueness theory for such linear time-varying equations is now fairly complete and is developed by Campbell [3], [5]. More recently, work has appeared on linear time-varying systems that include an output structure

$$y = C(t)x, \tag{1b}$$

where $C(t)$ is a smooth $l \times n$ matrix function. Observability and controllability concepts for system (1) are developed in [10], [8], respectively, and the fundamental duality statement relating these concepts is established in [8]. This recent work on linear time-varying systems is an important step in the development of a general theory of control for fully nonlinear implicit differential systems involving inputs and outputs. For the control theory of the linear time-invariant version of system (1) (see, for example, [16], [11], [12], [15], [22]). The earliest work on observability and controllability for time-varying nonsingular systems appears in [14], [23], [20].

In this paper we extend the work in [10] by developing a computable decomposition of (1) into unobservable subspace $\oplus$ observable complement. Section 2 surveys the solvability conditions (Theorem 2.1) and observability conditions (Theorem 2.2) used in [10]. The unobservable (or output-nulling) space is described in §3. In §4 we define observable complements and describe the dynamics on the unobservable subspace and an observable complement by means of smooth projection operators that are computable from information in the system's derivative array (§2). Section 5 provides a simple example of our results and illustrates an algorithm by which the system decomposition may be obtained in a pointwise manner.

2. Solvability and observability. We assume that (1a) is solvable on the closed and bounded interval $\mathcal{I}$. Solvability means that solutions exist on $\mathcal{I}$ for every sufficiently differentiable input u, and solutions depend uniquely on their value at any t_0 in $\mathcal{I}$ [5]. When the coefficient matrices E, F are constant, solvability corresponds to regularity of the matrix pencil, $E + \lambda F$.

To simplify notation, set $b(t) = B(t)u(t)$. Differentiating (1a) j times and (1b) k times gives the linear system of equations

$$\begin{bmatrix} \mathcal{F}_j & \mathcal{E}_j \end{bmatrix} \begin{bmatrix} x \\ \mathbf{x}_j \end{bmatrix} = \mathbf{b}_j, \tag{2}$$

$$\mathcal{C}_k \begin{bmatrix} x \\ \mathbf{x}_{k-1} \end{bmatrix} = \mathbf{y}_k, \tag{3}$$

where

$$\mathcal{F}_j = \begin{bmatrix} F \\ F' \\ \vdots \\ F^{(j)} \end{bmatrix}, \mathbf{y}_k = \begin{bmatrix} y \\ y' \\ \vdots \\ y^{(k)} \end{bmatrix}, \mathbf{b}_j = \begin{bmatrix} b \\ b' \\ \vdots \\ b^{(j)} \end{bmatrix}, \mathbf{x}_j = \begin{bmatrix} x' \\ x'' \\ \vdots \\ x^{(j+1)} \end{bmatrix}$$

and

$$\mathcal{E}_j = \begin{bmatrix} E & 0 & \cdot & \cdot & 0 \\ E' + F & E & 0 & \cdot & \cdot \\ E'' + 2F' & 2E' + F & E & \ddots & \cdot \\ \vdots & * & * & \ddots & 0 \\ E^{(j)} + jF^{(j-1)} & * & * & * & E \end{bmatrix}.$$

The matrix $\mathcal{C}_k$ is similarly generated by differentiation of the output equation. If (3) is written as $\tilde{C}_k x + \hat{C}_k \mathbf{x}_{k-1} = \mathbf{y}_k$ and $j + 1 \geq k$, the combined array is

$$\mathcal{O}_{j,k} = \left[\begin{array}{c|c} \mathcal{F}_j & \mathcal{E}_j \\ \tilde{C}_k & \begin{bmatrix} \hat{C}_k & 0_{(k+1)m \times (j+1-k)n} \end{bmatrix} \end{array}\right]. \tag{4}$$

The fundamental solvability conditions for (1a) and the results on observability for system (1) obtained in [10] are expressed in terms of the following definition.

DEFINITION 1. *The system of algebraic equations $Ax = b$, written as*

$$\begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} b_1 \\ b_2 \end{bmatrix}$$

is 1-full with respect to x_1, if x_1 is uniquely determined by any consistent vector b.

THEOREM 2.1 ([5]). *Suppose that* (1a) *is solvable on the interval $\mathcal{I}$ and that E, F are $2n$-times continuously differentiable. Then*

$$\mathcal{E}_j \text{ has constant rank on } \mathcal{I} \text{ for } j = n, \tag{5}$$

$$\mathcal{E}_j \text{ is 1-full with respect to } x' \text{ on } \mathcal{I} \text{ for } j = n, \tag{6}$$

$$[\mathcal{F}_j \ \mathcal{E}_j] \text{ has full row rank on } \mathcal{I} \text{ for } 1 \leq j \leq n. \tag{7}$$

Equation (1a) has *index* ν if ν is the smallest j for which conditions (5), (6), and (7) hold. Suppose then that (1a) is solvable and index ν. Since $\mathcal{E}_\nu$ has constant rank and is 1-full with respect to x' on $\mathcal{I}$, there exists a smooth nonsingular $R(t)$ such that [3]

$$R(t)\,\mathcal{E}_\nu(t) = \begin{bmatrix} I_{n\times n} & 0 \\ 0 & H(t) \\ 0_{\rho\times n} & 0 \end{bmatrix}.$$

It follows that the smooth row reduced form of $[\,\mathcal{E}_\nu\ \mathcal{F}_\nu\ \mathbf{b}_\nu\,]$ is

$$\left[\begin{array}{cc|c|c} I_{n\times n} & 0 & Q_1 & \bar{b}_1 \\ 0 & H & Q_2 & \bar{b}_2 \\ 0_{\rho\times n} & 0 & M & \bar{b}_3 \end{array}\right], \tag{8}$$

where H and M have full row rank by Theorem 2.1. From [4] and the rank properties of H and M just mentioned, the equation

$$M(t)x = \bar{b}_3 \tag{9}$$

determines the manifold of consistent initial conditions of (1a) at time t. For the unforced system (1a) with $u = 0$, we write $\mathcal{G}(t)$ for the solution space at time t.

System (1) is *weakly observable* if $u = 0$ and $y = 0$ imply $x = 0$. An important classical type of observability is total observability.

DEFINITION 2 ([10]). *System* (1) *is* totally observable *on $\mathcal{I}$ if knowledge of the output y and input u on any subinterval $\tilde{\mathcal{I}}$ of $\mathcal{I}$ uniquely determines* smooth *solutions x of* (1a) *on $\tilde{\mathcal{I}}$.*

A stronger type of observability is smooth observability.

DEFINITION 3 ([10]). *System* (1) *is* smoothly observable (*of order (k, j)*) *on $\mathcal{I}$ if there exists smooth $K_i(t)$, $L_i(t)$ on $\mathcal{I}$ such that*

$$x = \sum_{i=0}^{k} K_i(t)y^i(t) + \sum_{i=0}^{j} L_i(t)(Bu)^i(t).$$

If $C(t)$ in (1b) is not full column rank on a dense set, then the additional information required to determine x is obtained by differentiating (1b) and (1a).

THEOREM 2.2 ([10]). *System* (1) *is totally observable on $\mathcal{I}$ if and only if there exist j, k with $k \le j + 1$, such that the matrix $\mathcal{O}_{j,k}$ is 1-full with respect to x on a dense set in $\mathcal{I}$. If $\mathcal{O}_{j,k}$ is 1-full on a dense set in $\mathcal{I}$ and has constant rank, then* (1) *is smoothly observable of order (k, j).*

See [8] for a necessary and sufficient condition for smooth observability expressed in terms of matrix ranks. An analysis of observability for linear time-invariant singular systems is given in [22]. Here we merely note that if we are working with the linear time-invariant version of system (1), and we rewrite the system using the canonical form of [9] (or [22]), then the 1-full condition of Theorem 2.2 is equivalent to the matrix rank condition for observability given in [22, Cor. 2].

3. The output-nulling space. We work with the control system (1) with (1a) solvable on the interval $\mathcal{I}$.

DEFINITION 4. *The* output-nulling space $\mathcal{N}_{\mathcal{I}}(t)$ *for system* (1) *is the largest time-varying space invariant under the homogeneous equation* $E(t)x' + F(t)x = 0$ *and contained pointwise in* $\ker C(t)$.

The following lemma is easily established from Definition 4.

LEMMA 3.1. *For each* t_0, $\mathcal{N}(t_0)$ *consists of those consistent conditions* $x(t_0) \in \mathcal{G}(t_0)$ *whose corresponding solution to the homogeneous equation produces zero output on all of* $\mathcal{I}$.

Since our interval $\mathcal{I}$ is fixed, we drop the subscript $\mathcal{I}$ on $\mathcal{N}$. We always have $\{0\} \subset \mathcal{N}(t)$. Solvability implies that $\mathcal{N}(t_0) = \{0\}$ for *some* t_0 if and only if $\mathcal{N}(t) = \{0\}$ for all t in $\mathcal{I}$, because a solution of the homogeneous equation is either identically zero or never zero on $\mathcal{I}$. If t_0, t_1 are in $\mathcal{I}$, it follows that linearly independent vectors in $\mathcal{N}(t_0)$ are taken to linearly independent vectors in $\mathcal{N}(t_1)$ under the flow of the differential equation. Thus, we arrive at the following lemma.

LEMMA 3.2. $\mathcal{N}(t)$ *has constant dimension on* $\mathcal{I}$.

Total observability or smooth observability as defined in [10] implies $\mathcal{N} = \{0\}$, but simple examples in [21] show that the converse does not hold.

We now show that for systems with analytic coefficients, the output-nulling space $\mathcal{N}$ can be characterized using information in the derivative array $\mathcal{O}_{j,k}$. We need the following lemma.

LEMMA 3.3. *Suppose that* $H(t)$ *is an* $m \times n$ *real analytic matrix function defined on an open interval containing the closed bounded interval* $\mathcal{I}$. *Let*

$$H[k] = \begin{bmatrix} H \\ H' \\ \vdots \\ H^{(k)} \end{bmatrix}$$

and suppose $q = \max\{\operatorname{rank} H[k](t) : k \geq 0, t \in \mathcal{I}\}$. *Then there exists* k^* *such that* $H[k^*]$ *has rank* q *everywhere on* $\mathcal{I}$. *Consequently,*

$$\bigcap_{k \geq 0} \ker H[k] = \ker H[k^*]$$

has constant dimension $n-q$ *on* $\mathcal{I}$. *Moreover,* v *is a constant vector such that* $H(t)v = 0$ *on* $\mathcal{I}$ *if and only if* $v \in \ker H[k^*](t))$ *for all* t *in* $\mathcal{I}$, *or equivalently,* $v \in \ker(H[k^*](t))$ *for some* t *in* $\mathcal{I}$.

Proof. For every t and k we have $\ker H[k+1](t) \subset \ker H[k](t)$, so that the space

$$Z(t) = \bigcap_{k \geq 0} \ker H[k](t)$$

is well defined. Let $\bar{k}$ and t_0 be such that $\operatorname{rank} H[\bar{k}](t_0) = q$. By real analyticity, $H[\bar{k}]$ has rank q at all but a finite number of points $t_1, \ldots, t_r$ in $\mathcal{I}$. Let $v_1, \ldots, v_{n-q}$ be independent vectors in $\ker H[\bar{k}](t_0)$. By choice of q we have $\ker H[k](t_0) = \ker H[\bar{k}](t_0)$ for all $k \geq \bar{k}$. Then $\frac{d^k}{dt^k} H(t)v_i|_{t_0} = 0$ for all $k \geq 0$, and real analyticity implies $H(t)v_i = 0$ for all t in $\mathcal{I}$. But then $v_1, \ldots, v_{n-q}$ are all in $Z(t)$ for every t. Thus, $Z(t)$ has dimension at least $n-q$ for all t. However, by choice of q we cannot have more than $n-q$ independent vectors in any $Z(t)$; hence, $Z(t)$ has constant dimension $n-q$.

Now, by finite dimensionality there exist integers $k_1, \ldots, k_r \geq \bar{k}$ such that

$$\bigcap_{k \geq 0} \ker H[k](t_p) = \ker H[k_p](t_p)$$

for $p = 1, \ldots, r$. Let $k^* = \max\{\bar{k}, k_1, \ldots, k_r\}$. Then we have

$$Z(t) = \ker H[k^*](t)$$

for every t in $\mathcal{I}$.

Finally, note that since H is analytic, the vector v satisfies $H(t)v = 0$ on $\mathcal{I}$ if and only if $v \in Z(t)$ for every t. □

THEOREM 3.4. *Let ν be the index of the* DAE (1a). *Suppose the coefficients E, F, B, C of system* (1) *are real analytic. Then there exists a positive integer k^* such that the following statement is true. For any t_0 in $\mathcal{I}$, $x_0 \in \mathcal{N}(t_0)$ if and only if the equation*

$$\mathcal{O}_{j,k}(t_0) \begin{bmatrix} x_0 \\ \mathbf{x}_j \end{bmatrix} = 0 \tag{10}$$

is consistent for one (and hence any) pair j, k satisfying $k \geq k^*$ and $j \geq \nu + k - 1$.

Proof. The consistency condition (10) is clearly a necessary condition for x_0 to be in $\mathcal{N}(t_0)$. The way in which the derivative array $\mathcal{O}_{j,k}$ transforms under coordinate change [3] allows us to prove sufficiency for the decoupled canonical form for analytic systems [9]

$$\begin{aligned} z_1' &= B_1(t)u, \\ N(t)z_2' + z_2 &= B_2(t)u, \\ y &= C_1(t)z_1 + C_2(t)z_2. \end{aligned}$$

Note that the top $n \times n$ block of the $\mathcal{F}_j$ matrix is

$$\begin{bmatrix} 0 & 0 \\ 0 & I \end{bmatrix},$$

the lower blocks being zero. Using the notation of Lemma 3.3, the consistency condition expressed with the new derivative array has the form

$$\tilde{\mathcal{O}}_{j,k} \begin{bmatrix} z_0 \\ \mathbf{z}_j \end{bmatrix} = \begin{bmatrix} \mathcal{F}_j & \mathcal{E}_j \\ [C_1[k](t)\ C_2[k](t)] & [*\ 0] \end{bmatrix} \begin{bmatrix} z_{10} \\ z_{20} \\ \mathbf{z}_j \end{bmatrix} = 0 \tag{11}$$

for $j \geq \nu + k - 1$. Note that the starred entry in (11) has kn columns. By Lemma 3.3 there exists k^* such that $C_1[k](t)$ has constant rank on $\mathcal{I}$ for $k \geq k^*$. Let $k \geq k^*$ and let $j \geq \nu + k - 1$. Since the array $[\mathcal{F}_j\ \mathcal{E}_j]$ determines the solution manifold of the DAE, consistency of (11) implies that z_{20} must be zero, since $N(t)z_2' + z_2 = g$ is totally singular [9]. Thus we have

$$\mathcal{F}_j \begin{bmatrix} z_{10} \\ z_{20} \end{bmatrix} = 0.$$

Equation (11) now implies that $\mathbf{z}_{k-1} = 0$, because $\mathcal{E}_j$ uniquely determines $z', \ldots, z^{(k)}$ [10]. Therefore, consistency of (11) at t_0 and the form of * in (11) implies

$$C_1[k](t_0)z_{10} = 0. \tag{12}$$

The initial condition z_{10} is a constant solution of the canonical homogeneous equation $z_1' = 0$. Thus, from Lemma 3.3, if z_0 is consistent, then $C_1^{(k)}(t_0)z_{10} = 0$ for all k, and by analyticity $C_1(t)z_{10} = 0$ for all t in $\mathcal{I}$. So $z_0 = [z_{10}^T, 0^T]^T \in \mathcal{N}(t_0)$. □

Remark. Careful consideration of $\tilde{\mathcal{O}}_{j,k}$ in (11) shows that the nullspace of $\tilde{\mathcal{O}}_{j,k}$ has constant dimension. Therefore, $\mathcal{O}_{j,k}$ has constant rank on $\mathcal{I}$ and we have the next corollary.

COROLLARY 3.5. *For systems with analytic coefficients, $\mathcal{N} = \{0\}$ on $\mathcal{I}$ implies smooth observability on $\mathcal{I}$. Thus, $\mathcal{N} = \{0\}$ on $\mathcal{I}$ is equivalent to smooth observability on $\mathcal{I}$ for these systems.*

Proof. From Theorem 3.4 we see that $\mathcal{N} = \{0\}$ implies $\mathcal{O}_{j,k}$ is 1-full on $\mathcal{I}$ for a pair j, k, and by the Remark above, $\mathcal{O}_{j,k}$ has constant rank on $\mathcal{I}$. By Theorem 2.2, the system is smoothly observable on $\mathcal{I}$. □

While Theorem 3.4 assumes analyticity, the subspace $\mathcal{N}$ is characterized by the derivative array for many nonanalytic systems as well. However, it appears difficult to make a general statement that improves on Theorem 3.4. The following example shows that the derivative array may not characterize the output-nulling space for nonsingular systems with C^∞ coefficients.

Example 1. Consider the following nonsingular system which has a zero $F(t)$ coefficient:

$$x_1' = u_1, \qquad x_2' = u_2$$

with output

$$y_1 = \phi(t)x_1, \qquad y_2 = \phi(-t)x_2,$$

where ϕ is defined on an interval around zero and $\phi^{(i)}(t) \neq 0$ for $t < 0$ and all $i \geq 0$, while $\phi(t) = 0$ for $t \geq 0$. Using the notation of Lemma 3.3, the output matrix $C(t)$ has the property that $\operatorname{rank} C[k](t)$ is one for all t except $t = 0$, where $C[k](0) \equiv 0$. But for nonzero v, if v is in $\ker C[k](t_1)$ for $t_1 > 0$, then v cannot be in $\ker C[k](t_2)$ for $t_2 < 0$. □

By considering further the rank and nullity structure of $\tilde{\mathcal{O}}_{j,k}$ in (11), it is possible to state a condition on $\mathcal{O}_{j,k}$ that is necessary if the array is to characterize $\mathcal{N}$ by the consistency of (10).

DEFINITION 5. *The* nullity *of a sequence of matrices $H_k(t)$ defined on $\mathcal{I}$* stabilizes on $\mathcal{I}$ at k^* *if* $\dim \ker H_k(t) = \dim \ker H_{k^*}(t)$ *for all $k \geq k^*$ and* $\dim \ker H_{k^*}(t)$ *is constant on $\mathcal{I}$.*

If we maintain the relation $j = \nu + k - 1$, and define $\mathcal{O}_k \equiv \mathcal{O}_{j,k}$, then it is not difficult to prove the following corollary.

COROLLARY 3.6 ([21]). *If $\mathcal{N}(t_0)$ is characterized for every t_0 in $\mathcal{I}$ by the consistency equation*

$$\mathcal{O}_{k^*}(t_0) \begin{bmatrix} x_0 \\ \mathbf{x}_{\nu+k^*} \end{bmatrix} = 0 \tag{13}$$

for some k^*, then the nullity of $\mathcal{O}_k$ necessarily stabilizes on $\mathcal{I}$ at k^*.

4. System decomposition and dynamics. One difficulty in obtaining decompositions of a singular system with respect to observability is that the solution manifold $\mathcal{M}_b(t)$ of $E(t)x' + F(t)x = b$ depends on b as well as t. However, the space $\mathcal{M}_b(t)$ is a translate of $\mathcal{G}(t)$, the solution manifold at t for the unforced equation $E(t)x' + F(t)x = 0$. From the analysis of observability in [10], $\mathcal{G}(t)$ is the main object of interest with regard to control-theoretic structure of the system (cf. also [8] on

controllability). Moreover, $\mathcal{G}(t)$ is computable. From the smooth row reduced form (8) of

$$\mathcal{E}_j \mathbf{x}_j + \mathcal{F}_j x = \mathbf{b}_j, \tag{14}$$

$\mathcal{G}(t)$ is determined as the solution space of the equation $M(t)x = 0$, where $M(t)$ is $\rho \times n$ and rank $M(t) = \rho =$ nullity $\mathcal{E}_j(t)$ for all t. We seek descriptions of the dynamics on $\mathcal{G}(t)$ and on a complement of $\mathcal{G}(t)$ in R^n.

4.1. Natural projections associated with a natural completion. As motivation for the following discussion, we note that the natural way to solve for x' at t_0 (when it is uniquely determined) is to apply a row-reduction procedure to (14), and the row-reduction procedure is equivalent to premultiplication by a matrix R. A *completion* of a differential-algebraic equation is an ordinary differential equation whose solution set includes the solutions of the DAE. We discuss the existence of completions after stating the next definition.

DEFINITION 6 ([6]). *Let j have a value such that the conditions* (5), (6), *and* (7) *hold with the "for j" phrase omitted. Let $R(t)$ be smooth and nonsingular with*

$$R(t)\,[\mathcal{E}_j(t)\ \mathcal{F}_j(t)] = \left[\begin{array}{cc|c} I_n & 0 & G \\ 0 & H(t) & K \\ 0 & 0 & M \end{array}\right]. \tag{15}$$

Let the $n \times (j+1)n$ matrix $[R_0(t), \ldots, R_j(t)]$ be the first n rows of $R(t)$, with each $R_i(t)$ an $n \times n$ matrix function. Then the algebraic system (14) *implies that*

$$(D + G)x = \sum_{i=0}^{j} R_i(t)(D^i b)(t) \qquad \left(D = \frac{d}{dt}\right). \tag{16}$$

The ordinary differential equation (16) *is called a* natural completion *of $E(t)x' + F(t)x = b$.*

There are natural completions corresponding to any value of j for which the solvability conditions (5), (6), and (7) hold. One such natural completion is given by

$$x' = -\pi_1(\mathcal{E}_j^{\dagger})\mathcal{F}_j x + \pi_1(\mathcal{E}_j^{\dagger})\mathbf{b}_j, \tag{17}$$

where $A^{\dagger}$ is the Moore–Penrose generalized inverse of A [7] and $\pi_1 : R^{(j+1)n} \mapsto R^n$ denotes projection onto the first n components. The completion (17) is called a *least squares completion* [6]. In many cases it may be possible to use a smaller set of equations than that provided by a given sufficient j [6].

Given a natural completion (16), suppose there exists a projection-valued operator $\overline{P}(t)$ such that

(P1) $\mathcal{R}(\overline{P}(t)) = \mathcal{G}(t)$ for all t, and

(P2) $\overline{P}(D + G) = (D + G)\overline{P}$, i.e., the operator $\overline{P}$ commutes with the operator $D + G$ of the natural completion (16).

Consider the differential equation

$$(D + G(t))x = \overline{P}(t) \sum_{i=0}^{j} R_i(t) D^i b(t). \tag{18}$$

If $x(t)$ is a solution of (18) with $x(t_0) \in \mathcal{G}(t_0)$, then $\overline{P}(t)x(t)$ is also a solution of (18) with the same initial condition at t_0. Thus, $\overline{P}(t)x(t) = x(t)$ and $x(t) \in \mathcal{G}(t)$. The time-varying manifold $\mathcal{G}(t)$ is therefore invariant under (18). In particular, if $x(t)$ is any solution of $E(t)x' + F(t)x = b$, then $\overline{x} \equiv \overline{P}x$ satisfies (18). Equation (18) therefore provides a description of the dynamics of the DAE on $\mathcal{G}(t)$. Our previous arguments show that if the commutativity property (P2) holds and $\mathcal{R}(\overline{P}(t_0)) = \mathcal{G}(t_0)$ for some t_0, then $\mathcal{R}(\overline{P}(t)) \supset \mathcal{G}(t)$ for all t. But if $\overline{P}(t)$ is a smooth projector on the connected interval $\mathcal{I}$, then $\dim \mathcal{R}(\overline{P}(t))$ is constant [13, p. 35], hence $\mathcal{R}(\overline{P}(t)) = \mathcal{G}(t)$.

The next proposition shows that projectors $\overline{P}$ are generated as solutions of the linear matrix differential equation

$$\frac{d}{dt}X(t) = [X(t), G(t)], \tag{19}$$

where $[A(t), B(t)] = A(t)B(t) - B(t)A(t)$.

PROPOSITION 4.1. *Let $D \equiv d/dt$ be the operator of differentiation with respect to t operating on C^∞ functions. Let $G(t)$ be a continuous square matrix function, and let $P(t)$ be a differentiable square matrix function. Then*

1. *$P(t)$ commutes with $D + G(t)$ if and only if $P(t)$ is a solution of* (19).
2. *If P_1, P_2 are solutions of* (19), *then so are P_1P_2 and $P_1 + P_2$.*
3. *If $P(t)$ is a solution of* (19) *and $P^2(t_0) = P(t_0)$ for some t_0, then $P^2(t) = P(t)$ for all t.*

Proof. As operators on C^∞ functions, we have

$$P(D+G) - (D+G)P = (-P' + PG - GP) = (-P' + [P, G]),$$

from which 1 follows. A direct calculation shows that 2 holds, and 3 follows from 2 and uniqueness of solutions of linear differential equations. □

From 2, the set of solutions of (19) is also closed under the bracket [,]. We apply Proposition 4.1 as follows. Choose an initial condition $P_0 = P(t_0)$ for the differential equation (19) that is a projection with range $\mathcal{G}(t_0)$. The solution of (19) will then be a smooth projection-valued operator, having range $\mathcal{G}(t)$ for all t, and satisfying properties (P1), (P2).

DEFINITION 7. *A projection-valued operator $\overline{P}(t)$ satisfying* (P1), (P2) *is called a* natural projection *associated with the given natural completion* (16).

4.2. Decomposition with respect to observability. A system decomposition with respect to observability should include these features:

(1) an identification of the output-nulling space, and a consequent splitting of the state space into "unobservable part ⊕ a complement";

(2) the splitting should satisfy an "invariance" property under the system dynamics, so that the unobservable part (the output-nulling part) may be suitably divided out; and the system modulo the unobservable part should be (at least weakly) observable.

In this section we show that the decomposition described in the next definition meets these requirements.

DEFINITION 8. *Given a natural completion*

$$(D+G)x = \sum_{i=0}^{j} R_i D^i b \tag{20}$$

of a solvable DAE, $E(t)x' + F(t)x = b$, *and given a natural projection* $\overline{P}$ *for* (20), *an* observability resolution *for* (20) *with respect to the output* $y = C(t)x$ *is a set of projections* $\{P_1(t), P_2(t), P_3(t)\}$ *such that*

1. $P_iP_j = 0$ *for* $i \neq j$.
2. $P_i(D + G) = (D + G)P_i$ *for* $i = 1, 2, 3$.
3. $P_1 + P_2 + P_3 = I$.
4. $P_1 + P_2 = \overline{P}$, *the given natural projection.*
5. $\mathcal{R}(P_1(t)) = \mathcal{N}(t)$, *the output-nulling space.*

The existence of such P_i is established in the proof of Theorem 4.2. Since the P_i are computable from a linear matrix ordinary differential equation (ODE), an observability resolution is a type of canonical form that is expressed more closely in terms of the original coefficients and identifies a smooth observable complement of $\mathcal{N}(t)$ in $\mathcal{G}(t)$. If $\{P_1(t), P_2(t), P_3(t)\}$ is an observability resolution for (20) relative to the output matrix $C(t)$, then $\{Q^{-1}P_1Q, Q^{-1}P_2Q, Q^{-1}P_3Q\}$ is an observability resolution for the transformed completion

$$Q^{-1}(D + G)Qx = Q^{-1}\sum_{i=0}^{j} R_iD^ib,$$

relative to the output matrix $C(t)Q(t)$.

Given the output-nulling space $\mathcal{N}(t)$, there is no "distinguished" observable complement in $\mathcal{G}(t)$, but there is a unique observability resolution for given initial data as described in the next theorem.

THEOREM 4.2. *Choose* t_0 *in* $\mathcal{I}$ *and choose a complement* $\mathcal{D}(t_0)$ *of* $\mathcal{N}(t_0)$ *in* $\mathcal{G}(t_0)$. *Let* $\overline{P}$ *be a natural projection for* (20). *Then there is a unique observability resolution for* (20) *with*

$$\ker(P_1(t_0)) = \mathcal{D}(t_0) \oplus \mathcal{R}(I - \overline{P}(t_0)).$$

Proof. Let P_0 be the unique projection such that

$$\mathcal{R}(P_0) = \mathcal{N}(t_0), \qquad \ker(P_0) = \mathcal{D}(t_0) \oplus \mathcal{R}(I - \overline{P}(t_0)). \tag{21}$$

Let $P_1(t)$ be the unique solution of

$$X' = [X, G], \qquad X(t_0) = P_0. \tag{22}$$

Then property 2 holds for $i = 1$ and $P_1(t)$ is a projection for all t. To get an observability resolution, we necessarily define

$$P_2(t) = \overline{P}(t) - P_1(t),$$
$$P_3(t) = I - \overline{P}(t).$$

$P_3(t)$ is a projection because $\overline{P}(t)$ is. Once we establish that $P_2(t)$ is indeed a projection and that $\{P_1, P_2, P_3\}$ is an observability resolution, the uniqueness statement follows.

Since P_1 and $\overline{P}$ satisfy the differential equation in (22), so do P_2 and P_3, and P_1, P_2, P_3 are as smooth as G. We have thus established properties 2, 3, and 4 of Definition 8 for these P_i.

We prove next that P_2 is a projection and that property 1 holds. Since P_1 and $\overline{P}$ satisfy (19), Proposition 4.1 implies that

$$(P_1\overline{P})' = [P_1\overline{P}, G],$$
$$(\overline{P}P_1)' = [\overline{P}P_1, G].$$

Consider the initial condition for these equations at time t_0. From (21) and the fact that $\overline{P}(t_0)$ projects onto $\mathcal{G}(t_0)$ and $\ker(\overline{P}(t_0)) \subset \ker(P_1(t_0))$, we get $P_1(t)\overline{P}(t) = P_1(t)$ for all t and $\overline{P}(t)P_1(t) = P_1(t)$ for all t. It follows that $P_2(t)$ is a projection for all t. Also, $P_1P_3 = P_3P_1 = 0$ because $P_1P_3 = P_1(I - \overline{P})$ and $P_3P_1 = (I - \overline{P})P_1$. And $P_1P_2 = P_2P_1 = 0$ because $P_1P_2 = P_1(\overline{P} - P_1)$ and $P_2P_1 = (\overline{P} - P_1)P_1$. Using $\overline{P} = P_1 + P_2$, we have $P_2\overline{P} = \overline{P}P_2 = P_2$ since P_2 is a projection. Thus, $P_3P_2 = (I - \overline{P})P_2 = P_2 - P_2 = 0$ and $P_2P_3 = P_2(I - \overline{P}) = 0$. This completes the proof of property 1.

To prove property 5, note that we have $\mathcal{R}(P_1(t_0)) = \mathcal{N}(t_0)$. By properties 1 and 2, $\mathcal{R}(P_i)$ is a reducing subspace for $D + G$ for $i = 1, 2, 3$. Therefore, by property 3, $D + G$ has a representation of the form

$$\begin{bmatrix} D+G_1 & 0 & 0 \\ 0 & D+G_2 & 0 \\ 0 & 0 & D+G_3 \end{bmatrix}$$

in the coordinates $z_i \in \mathcal{R}(P_i)$ on C^∞ functions. We now show that $\mathcal{N}(t) \subset \mathcal{R}(P_1(t))$ for all t. Suppose $z(t) \in \mathcal{N}(t)$ is an output-nulling solution. By (21) and property 1, we know that $z_2(t_0) = P_2(t_0)z(t_0) = 0$ and $z_3(t_0) = P_3(t_0)z(t_0) = 0$, so $z(t_0) = P_1(t_0)z(t_0) = z_1(t_0)$. Any solution of the homogeneous equation must satisfy the differential equations

$$\begin{aligned} (D+G_1)z_1(t) &= 0, \\ (D+G_2)z_2(t) &= 0, \\ (D+G_3)z_3(t) &= 0. \end{aligned} \tag{23}$$

Since $z_2(t_0) = 0$ and $z_3(t_0) = 0$, we must have $z_2(t) = 0$, $z_3(t) = 0$ for all t. Therefore, $z(t) = z_1(t) \in \mathcal{R}(P_1(t))$ for all t. Since $z(t)$ was an arbitrary output-nulling solution, we have $\mathcal{N}(t) \subset \mathcal{R}(P_1(t))$ for all t. Since $\operatorname{rank} P_1(t)$ is constant, $\mathcal{R}(P_1(t)) = \mathcal{N}(t)$ for all t. This proves property 5 of the definition. □

We now use the resolution $\{P_1, P_2, P_3\}$ to *generate* a coordinate transformation to a system form whose new coordinates explicitly exhibit a decoupling of the three system components. It is possible to do this *locally*, in a neighborhood of each t_0 in $\mathcal{I}$, by the following procedure:

Let $n_j = \dim \mathcal{R}(P_j)$ for $j = 1, 2, 3$. Let t_0 be in $\mathcal{I}$.

1. Choose n_j independent columns of $P_j(t_0)$ for $j = 1, 2, 3$. These columns remain independent on some interval $(t_0 - \epsilon, t_0 + \epsilon)$.

2. Form the matrix $Q(t) = [\hat{P}_1(t)\, \hat{P}_2(t)\, \hat{P}_3(t)]$, where $\hat{P}_j(t)$ is an $n \times n_j$ matrix whose columns are the columns of $P_j(t)$ chosen in 1. By construction, $Q(t)$ is smooth and nonsingular on $(t_0 - \epsilon, t_0 + \epsilon)$.

3. Define new coordinates w by

$$x = Q(t)w = [\hat{P}_1(t)\, \hat{P}_2(t)\, \hat{P}_3(t)] \begin{bmatrix} w_1 \\ w_2 \\ w_3 \end{bmatrix}. \tag{24}$$

In the w coordinates, the resolution $\{P_j\}$ becomes $\{\tilde{P}_j\}$, where, for $j = 1, 2, 3$, $\tilde{P}_j = Q^{-1}P_jQ = \operatorname{diag}[\delta_{1j}I_{n_1}\ \delta_{2j}I_{n_2}\ \delta_{3j}I_{n_3}]$, where δ_{ij} is the Kronecker delta.

COROLLARY 4.3. *Given a natural completion*

$$(D+G)x = \sum_{i=0}^{j} R_i D^i(Bu)$$

and given an observability resolution $\{P_1, P_2, P_3\}$ *relative to a given* $\overline{P}$ *and output matrix* $C(t)$*, the transformation* $x = Q(t)w$ *defined in* (24) *produces a new completion, defined on* $(t_0 - \epsilon, t_0 + \epsilon)$*, which has the form*

$$w_1' + \tilde{G}_1(t)w_1 = \tilde{P}_1 Q^{-1} \sum_{i=0}^{j} R_i D^i(Bu), \tag{25}$$

$$w_2' + \tilde{G}_2(t)w_2 = \tilde{P}_2 Q^{-1} \sum_{i=0}^{j} R_i D^i(Bu), \tag{26}$$

$$w_3' + \tilde{G}_3(t)w_3 = \tilde{P}_3 Q^{-1} \sum_{i=0}^{j} R_i D^i(Bu). \tag{27}$$

Given an input $u(t)$*, let* x_0 *be consistent for the original* DAE *at* t_0*, and let* $w_0 = Q^{-1}(t_0)x_0$*. Then, with this restriction on initial conditions* w_{30} *in* (27)*, the system for* w_2 *and* w_3*, with output*

$$y = C(t)Q(t)w = C(t)\hat{P}_2(t)w_2 + C(t)\hat{P}_3(t)w_3$$

is (at least weakly) observable on any closed subinterval of $(t_0 - \epsilon, t_0 + \epsilon)$*.*

Proof. The only part of the statement that requires proof is the fact that the coefficient of w, namely, $\tilde{G} \equiv Q^{-1}Q' + Q^{-1}GQ$, has a block diagonal form as stated. The $\tilde{P}_j$ are constant, as shown above, and satisfy $\tilde{P}_j' = [\tilde{P}_j, \tilde{G}]$, since they commute with $(D + \tilde{G})$. Thus, $[\tilde{P}_j, \tilde{G}] = 0$, so $\tilde{P}_j$ commutes with $\tilde{G}$ for $j = 1, 2, 3$. Since the $\tilde{P}_j$ themselves commute, $\tilde{G}$ is block diagonal. □

The original derivation of the general form for solvable systems [5] uses a matrix of independent solutions of the homogeneous equation as part of a globally defined coordinate transformation to the new form. The approach of Corollary 4.3 is local, but does not require explicit knowledge of system solutions. By this approach, finding the desired transformation requires computation of P_1, P_2, and P_3 from a linear ODE (equivalent to a vector system of size n^2), once $G(t)$ is itself known. If a splitting of $\mathcal{G} = \mathcal{N} \oplus \mathcal{D}$ according to observability is not needed, then a computation of $n_1 + n_2 = \dim \mathcal{G}$ independent columns of $\overline{P}$, plus a complementary set of columns from P_3, is required. We note that the decomposition of Corollary 4.3 is similar to one given in [19] but does not follow from the results of that paper, since we do not assume constant rank of our coefficient matrices and we do not require coordinate changes to reach the decomposition.

For linear time-varying nonsingular systems, the paper [24] establishes structural forms with respect to observability (and controllability) by proving the existence of appropriate coordinate transformations. The new features in Corollary 4.3 are (i) the *generation* of an appropriate transformation, using computable projections onto relevant subspaces, and (ii) applicability to singular as well as nonsingular systems. We now outline an algorithm for the pointwise computation of the system decomposition.

(1) The solution manifold $\mathcal{G}(t)$ is pointwise computable from array $[\mathcal{F}_j\ \mathcal{E}_j]$.

(2) The matrix $G(t)$ of the natural completion is computable from $[\mathcal{F}_j\ \mathcal{E}_j]$.

(3) The projections P_i are computable from a linear ODE involving $G(t)$ and knowledge of the solution space $\mathcal{G}(t)$ and output-nulling space $\mathcal{N}(t)$.

(4) The transformation $Q(t)$ may be computed pointwise from the P_i by choosing independent columns.

(5) The remaining element required to compute the matrix $\tilde{G}(t)$ of the transformed completion is the derivative Q'. But $P_i' = [P_i, G]$, so Q' is pointwise computable by choosing the appropriate columns of $[P_i, G]$.

5. An example. We end the paper with a simple example to illustrate the algorithm just outlined for the calculation of the projections, and the decoupled completion of Corollary 4.3.

Example 2. Consider the system with $B(t) = I$ and

$$E(t) = \begin{bmatrix} 1 & -t & 0 & 0 \\ 0 & 1 & t & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix}, \qquad F(t) = \begin{bmatrix} 0 & -1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}.$$

The output is given by $y = x_2 + x_3 + x_4$. This system is index one. It is possible to backsolve from the array $[\mathcal{E}_1 \ \mathcal{F}_1 \ \mathbf{u}_1]$ to get x' for a natural completion. One may take the matrices R_0 and R_1 to be

$$R_0 = \begin{bmatrix} 1 & t & -t^2 & 0 \\ 0 & 1 & -t & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix}, \qquad R_1 = \begin{bmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix},$$

and $G(t)$ is given by

$$G(t) = \begin{bmatrix} 0 & -1 & t & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix}.$$

The manifold $\mathcal{G}$ is defined by $x_4 = 0$. We take $\overline{P} = \operatorname{diag}[1\ 1\ 1\ 0]$, since this projection has range $\mathcal{G}$ and commutes with $D+G(t)$. If the output is identically zero for a solution of the homogeneous equation, then necessarily we have $x_2 = -x_3 = -c_3$, c_3 constant. But the second system equation (or the second equation of the completion) implies that $x_2' = -c_3$, hence $c_3 = 0$. The remaining equation $x_1' = 0$ is satisfied for any $x_1 = c_1$, c_1 constant. Thus, the space $\mathcal{N}$ is given as $\mathcal{N}(t) = \{[c_1\ 0\ 0\ 0]^T : c_1 \textit{ arbitrary}\}$. As the initial condition for a projection P_1 onto $\mathcal{N}$ we take $P_1(0) = \operatorname{diag}[1\ 0\ 0\ 0]$. Integration of the equation $P_1' = [P_1, G]$ yields

$$P_1(t) = \begin{bmatrix} 1 & -t & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix}.$$

Then $P_1(t)x \in \ker[0\ 1\ 1\ 1] = \ker C(t)$. The projection $P_2(t)$ is calculated as

$$P_2 = \overline{P} - P_1 = \begin{bmatrix} 0 & t & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix},$$

while P_3 is then

$$P_3 = I - \overline{P} = \begin{bmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}.$$

We may define a coordinate transformation using the given resolution $\{P_1, P_2, P_3\}$ by setting

$$Q(t) = \begin{bmatrix} 1 & t & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}, \qquad x = Q(t)w,$$

which, in this case, is a global transformation. The new transformed completion in w coordinates is given by

$$\tilde{G} = \begin{bmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix}$$

together with

$$\tilde{R}_0 = Q^{-1}R_0 = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & -t & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix}, \qquad \tilde{R}_1 = Q^{-1}R_1 = \begin{bmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}.$$

The output is $y = [0\ 1\ 1\ 1]Q(t)w = [0\ 1\ 1\ 1]w$. The observable dynamics and output equation are given by

$$w_2' + w_3 = u_2 - tu_3, \tag{28a}$$

$$w_3' = u_3, \tag{28b}$$

$$y = w_2 + w_3 + u_4. \tag{28c}$$

The dynamics for w_1 and w_4 may also be obtained from Corollary 4.3; in this case, $w_1' = u_1$, and $w_4' = u_4'$.

As a final remark, we note that system (28) in Example 2 is smoothly observable. In fact, two differentiations of the output equation (28c) and substitution for w_1', w_2' from (28a), (28b) is sufficient to solve for the observable state in terms of input, output, and their derivatives.

6. Conclusion. In this paper we defined the output-nulling space of a linear time-varying singular control system. We showed how to decompose the system, by means of projection operators, into (unobservable subspace) $\oplus$ (observable complement) relative to a given output structure. The relevant subspaces and projectors were shown to be computable for a large class of control systems by pointwise linear algebra from information in the system's derivative array. We described the dynamics on these spaces by the projection operators. Finally, we illustrated the dynamic system decomposition by applying our algorithm to a simple example.

Acknowledgment. I thank my thesis advisor, Dr. Stephen L. Campbell, for helpful comments in the preparation of this paper. In addition, I thank the two referees for thorough comments and suggestions that resulted in an improved exposition.

NEW EXISTENCE RESULTS FOR OPTIMAL CONTROLS IN THE ABSENCE OF CONVEXITY: THE IMPORTANCE OF EXTREMALITY*

ERIK J. BALDER†

Abstract. A new approach to "existence without convexity" is presented. Instead of applying a Weierstrass–Tonelli-type existence result to a convexified (i.e., relaxed) form of the control problem, which is standard, it uses a new extremum principle. This principle guarantees the existence of an optimal relaxed control function that is a convex combination of relaxations of ordinary control functions. The same linear relationship is maintained for the corresponding trajectories, and this is of much benefit in the final phase, which consists of a deconvexification by a global subgradient argument and Lyapunov's theorem. The extremum principle is based on extreme point features of the relaxed control problem. It can be stated in an abstract form and extends the classical extremum principle of Bauer. The new approach applies both to optimal control problems of suitable type (dynamics linear in the state variable) and to abstract variational problems without dynamics, well-known in economics. With a different interpretation, it can also give bang-bang existence results. Several new applications serve to illustrate the power of the approach.

Key words. optimal control, existence without convexity, Bauer extremum principle, extreme points, Young measures, relaxed controls

AMS subject classifications. 49J15, 49J27, 49J45, 46A55

1. Introduction.

This paper introduces a new, quite general approach to the subject of "existence without convexity" for optimal control. It may be recalled that control problems without the usual convexity conditions for the orientor field do not lend themselves directly to the traditional approach in the spirit of Tonelli, because the corresponding integral functionals fail to have suitable lower semicontinuity properties. Yet such problems may have optimal solutions, as was first demonstrated by Neustadt [27]; see [15, Chap. 16] for an extensive account. In recent years, existence problems of this kind have gained increasing prominence in mechanics (e.g., see [11]).

The approach presented here differs notably from the usual ones by the use of a new extremum principle, which can be stated in an abstract form and generalizes the well-known extremum principle of Bauer [19, 13.A-B]. As particular cases, the main existence result of this paper contains the traditional existence results of this kind (e.g., [27], [28], [15], [24]), the recent nontraditional results of Raymond [29], [31], Cellina and Colombo [14], and Mariconda [25], as well as the abstract existence results for variational problems without dynamics, as given by Aumann and Perles [3], Berliocchi and Lasry [12], Artstein [2], and Balder [5], [6]. In addition to these connections with the existing literature, several new applications are produced, even within classical contexts.

To illustrate some of the key ideas, let us tackle in this section the existence question for the following special optimal control problem (B_0):

$$\text{minimize } I(u) := \int_0^1 [(u^2(t)-1)^2 - y_u^2(t)]dt - \exp\left(-\sup_{t\in[0,1]} |y_u(t)|\right)$$

* Received by the editors December 31, 1990; accepted for publication (in revised form) January 26, 1993.

over all integrable functions $u : [0,1] \to \boldsymbol{R}$. Here y_u, the absolutely continuous trajectory corresponding to u, is given by

$$y_u(t) = \int_0^t u(\tau)\, d\tau.$$

We can easily show that, if the term $-y_u^2(t)$ were to be changed to $+y_u^2(t)$, the resulting optimal control problem does not have an optimal solution. In fact, if also—next to this change of sign—the exponential term in $I(u)$ is omitted, the resulting problem constitutes a classical counterexample to existence, which is due to Bolza (see [21, pp. 304–305]). Nevertheless, (B_0) has an optimal solution, and much of this section is devoted to proving this. Even though (B_0) is a very special problem, this constitutes a new existence result. It cannot be obtained from the current literature, either directly or indirectly. However, without the exponential term, the existence result would be of the recent nontraditional type found in [14], [29], [31]; this type is characterized by the presence of a trajectory cost integrand that is *concave* in the state variable. (The same kind of of concavity was also studied in the unpublished paper [4], but only for control problems having a compact space of control points: In fact, under the additional constraint $|u(t)| \leq 1$ almost everywhere, the above existence result for (B_0)—with the exponential term as stated—would also follow from [4].)

The existence result for (B_0) follows from Theorem 2.2, which contains an existence result "without convexity" for a control problem (B) that is much more general than (B_0). The proof of Theorem 2.2 is based on the three phases of the *convexification-deconvexification scheme* given below:

(i) *Phase* 1 (*convexification*). Determine the relaxed form (B_{rel}) of (B).

(ii) *Phase* 2 (*extremum principle*). Apply the abstract extremum principle (Theorem 3.1) to (B_{rel}); this guarantees the existence of a special optimal relaxed solution of (B_{rel}) (having the so-called *Minkowski form*).

(iii) *Phase* 3 (*deconvexification*). Use the special optimal relaxed solution of Phase 2 to obtain an optimal solution for (B).

Standard approaches to existence without convexity use a theorem of the Weierstrass–Tonelli type in Phase 2 and therefore fail to take advantage of the geometric—in particular extremal—features of the relaxed problem (B_{rel}).

A short-cut to the key ideas of this paper is obtained when we first work out the convexification-deconvexification scheme for the simple problem (B_0), instead of (B).

Phase 1. *Convexification via relaxation.* The motivation for relaxation comes from the extremum principle: It only applies to minimization problems with a (partly) concave (or quasi-concave) objective function. Since the integrand $v \mapsto (v^2-1)^2$ of I is neither convex nor concave, relaxation provides the necessary concavity for the objective function. Incidentally, it should be observed that practically all approaches to "existence without convexity" initially convexify toward existence anyway; in essence, this is done to create a setting in which the lower semicontinuity and compactness needs of the Tonelli–Weierstrass approach can be met.

The relaxed version $(B_{0,\text{rel}})$ of the simple problem (B_0) has the following objective function:

$$J(x) := \int_0^1 \left[\int_{\boldsymbol{R}} (v^2-1)^2\, x(t)(dv)\right] dt - \int_0^1 y_x^2(t)dt - \exp\left(-\sup_{0\leq t\leq 1} |y_x(t)|\right).$$

Here x is a transition probability (alias Young measure) from [0,1] into $M_1^+(\boldsymbol{R})$, with $M_1^+(\boldsymbol{R})$ denoting the set of all Borel probability measures on $\boldsymbol{R}$; see §4 for more

details about Young measures. Let us denote the set of all Young measures from $[0,1]$ into $M_1^+(\boldsymbol{R})$ by C. Above, the relaxed trajectory corresponding to $x \in C$ is denoted by y_x. It is given by

$$y_x(t) := \int_0^t \left[\int_{\boldsymbol{R}} \upsilon \, x(\tau)(d\upsilon) \right] d\tau,$$

provided that these integrals exist. Formally, for trajectories corresponding to an "original" control function u, we should now write y_{ϵ_u} instead of y_u, but this distinction will be neglected, as it is obvious what is meant. Clearly, $x \mapsto y_x(t)$ is affine for every fixed t. Hence J is concave.

By itself, concavity of the objective is not enough to bring the extremum principle of Phase 2 to bear. Also essential is the presence of a constraint $b_0(x) \leq 0$, with $b_0 : C \to (-\infty, +\infty]$ an affine *inf-compact* function (that is, the level sets $\{x \in C : b_0(x) \leq \gamma\}$ must be compact for every $\gamma \in \boldsymbol{R}$). It is not immediately obvious how such a constraint could be found for (B_0). Consider, however, the following reasoning ad hoc. For the constant function $u \equiv 0$, we evidently have $I(0) = 0$. Using the Cauchy–Schwarz inequality, it is easy to see that $I(u) \leq 0$ implies that $\int_0^1 (u^4(t) - 3u^2(t))dt \leq 0$. In turn, this gives $\int_0^1 u^4(t)\, dt \leq 9$. We conclude that this constraint can be added to (B_0) without altering the optimization problem in any essential way, i.e.,

$$\inf\{I(u) : u \in L_1([0,1])\} \;=\; \inf\left\{ I(u) : u \in L_1([0,1]), \int_0^1 u^4(t)\, dt \leq 9 \right\}.$$

To the relaxed problem $(B_{0,\mathrm{rel}})$ we now simply add the relaxation of this constraint: Let $(B_{0,\mathrm{rel}})$, the relaxed version of (B_0), be given by

$$\text{minimize } J(x) := \int_0^1 \left[\int_{\boldsymbol{R}} (\upsilon^2 - 1)^2 \, x(t)(d\upsilon) \right] dt - \int_0^1 y_x^2(t) dt - \exp\left(- \sup_{0 \leq t \leq 1} |y_x(t)| \right)$$

over all relaxed control functions $x : [0,1] \to M_1^+(\boldsymbol{R})$ satisfying

$$b_0(x) := \int_0^1 \left[\int_{\boldsymbol{R}} (\upsilon^4 - 9) \, x(t)(d\upsilon) \right] dt \;\leq\; 0.$$

From well-known facts about Young measures, it follows that b_0 is inf-compact (see §4). A beneficial side-effect of introducing the constraint is that the integral in the definition of $y_x(t)$ certainly exists when $x \in C$ satisfies $b_0(x) \leq 0$.

Phase 2. Application of the extremum principle. After the aforegoing relaxation, the new extremum principle (see §3) can be applied to the problem $(B_{0,\mathrm{rel}})$. In this phase, the approach of this paper deviates from the standard in an essential way. While the latter merely apply some result of the Weierstrass–Tonelli variety to the relaxed problem, the extremum principle guarantees the existence of an optimal solution $x_* \in C$ for $(B_{0,\mathrm{rel}})$ that has the following special *Minkowski form*:

$$x_*(t) \;=\; \lambda \epsilon_{u_1}(t) + (1 - \lambda)\epsilon_{u_2}(t) \quad \text{a.e.}$$

Here $\lambda \in [0,1]$ is a constant, and u_1, u_2 are two measurable—in fact, integrable—functions from [0,1] into $\boldsymbol{R}$. (Recall the notation involved: $\epsilon_u(t)$ denotes the Dirac (probability) measure concentrated at the point $u(t)$, $t \in [0,1]$.) Optimal solutions

in Minkowski form were also investigated in [4]. For the remainder of the paper, it is very important that the trajectories inherit an equally simple linear relationship,

$$y_{x_*} = \lambda y_{u_1} + (1-\lambda) y_{u_2}. \tag{1}$$

This differs completely from what the standard approaches can deliver; e.g., see [15], [14], [31]. At best, they prove the existence of an optimal relaxed control function $\tilde{x} \in C$ of the form

$$\tilde{x}(t) = \sum_k \lambda_k(t) \epsilon_{u_k}(t),$$

with *t-dependent* convex coefficients $\lambda_k(t)$. However, it is obvious that any linear relationship like (1) between the corresponding trajectories is lost in the process.

Phase 3. *Deconvexification.* First, let us check that $\inf(B_{0,\mathrm{rel}}) \leq \inf(B_0)$. For any ordinary control function $u : [0,1] \to \boldsymbol{R}$ with $\int_0^1 u^4 \leq 9$, the relaxation $x := \epsilon_u$ satisfies $b_0(x) \leq 0$, and, evidently, $y_x = y_u$ and $J(x) = I(u)$. So $\inf(B_{0,\mathrm{rel}}) \leq \inf_{u \in L_1([0,1])}\{I(u) : \int_0^1 u^4 \leq 9\} = \inf(B_0)$, by what we concluded in Phase 1. By optimality of x_*, found in Phase 2, it follows that a sufficient condition for a measurable control function $u : [0,1] \to \boldsymbol{R}$ to be optimal for (B_0) is that (a) $b_0(\epsilon_u) \leq 0$ and (b) $I(u) \leq J(x_*)$; let us see how (a) and (b) can be ensured for u. Define the trajectory cost functional $\bar{r} : C([0,1]) \to \boldsymbol{R}$ by

$$\bar{r}(y) := -\int_0^1 y^2(t)\, dt - \exp(-\|y\|),$$

where the supremum norm $\|y\| := \sup_{t \in [0,1]} |y(t)|$ is used. We already saw that $\bar{r}$ is concave on $C([0,1])$. Clearly, $\bar{r}$ is also continuous in the supremum norm on $C([0,1])$. Hence, there exists a subgradient $y^* \in (C([0,1]))^*$ to the convex function $-\bar{r}$ in the point y_{x_*}, i.e.,

$$\bar{r}(y_{x_*}) - \bar{r}(y) \geq \langle y - y_{x_*}, y^* \rangle \quad \text{for all } y \in C([0,1]).$$

Let the control cost functional r be given by

$$r(x) := \int_0^1 \left[\int_{\boldsymbol{R}} (v^2 - 1)^2 \, x(t)(dv) \right] dt.$$

An obvious sufficient condition to guarantee that (a) and (b), above, hold, hence to guarantee u's optimality for (B_0), is given by the following system (A_0) of three equations:

$$\begin{aligned} b_0(\epsilon_u) &= b_0(x_*), \\ r(\epsilon_u) &= r(x_*), \\ \langle y_u, y^* \rangle &= \langle y_{x_*}, y^* \rangle. \end{aligned}$$

Indeed, the first equation implies that $b_0(\epsilon_u) = b_0(x_*) \leq 0$, and the third one causes $\bar{r}(y_u) \leq \bar{r}(y_{x_*})$ by the subgradient property. Together with the second equality, this gives $I(u) = J(\epsilon_u) \leq J(x_*)$, establishing (a) and (b).

Now $y^* \in (C([0,1]))^*$ has a Riesz representation [37, I.5.8]. That is, there exists a bounded signed Borel measure θ on $[0,1]$ such that $\langle y, y^* \rangle = \int_{[0,1]} y(t)\, \theta(dt)$ for all $y \in C([0,1])$. By the Minkowski form of x_* and Fubini's theorem, we can rewrite

$$\langle y_u - y_{x_*}, y^* \rangle = \int_0^1 [u(t) - \lambda u_1(t) - (1-\lambda) u_2(t)] \theta((t,1])\, dt,$$

thanks to the linear relationship in (1). Similar substitutions can also be performed directly in the two other equalities. This leads to the following equivalent form of (A_0):

$$\int_0^1 u^4(t)\, dt = \lambda \int_0^1 u_1^4(t)\, dt + (1-\lambda) \int_0^1 u_2^4(t)\, dt,$$

$$\int_0^1 (u^2(t) - 1)^2\, dt = \lambda \int_0^1 (u_1^2(t) - 1)^2\, dt + (1-\lambda) \int_0^1 (u_2^2(t) - 1)^2\, dt,$$

$$\int_0^1 u(t) \theta((t,1])\, dt = \lambda \int_0^1 u_1(t) \theta((t,1])\, dt + (1-\lambda) \int_0^1 u_2(t) \theta((t,1])\, dt.$$

Clearly, by Lyapunov's theorem, this system can be solved for some measurable u, which is then the optimal control for (B_0), by the properties exhibited for (A_0).

As was already observed, the linear relationship (1) between the trajectories is lost in the approaches that have appeared in the literature. Fortunately, in the traditional existence results without convexity [15], the trajectory cost integrand is *linear* in the state variable. Therefore, the entire trajectory cost can be integrated away, so that essentially one is left with only a control cost and—possibly—a final cost term. However, the recent nontraditional existence results mentioned above have the trajectory cost integrand concave in the state variable, just like problem (B_0). Then such an integration device can no longer be used, and the resulting nonlinear relationship between the trajectories of $\tilde{x}$ and of the u_i's leads to quite involved applications of Lyapunov's theorem; see [14, pp. 101–105] and [31, pp. 122–125]. These involve not only integrable selections of subgradients [14], but also an infinite sequence of iterates of an integral operator in the more general—but still quite modest—context of [31] (optimal control of a linear differential equation). The ad hoc character of these arguments is evident; moreover, they display a worrisome tendency to grow more complex as the dynamical system becomes more general. The inclusion of the extremum principle in Phase 2 of the convexification-deconvexification scheme avoids such complications altogether and reaches much further.

The organization of this paper is as follows. Section 2 presents the general optimal control problem (B) and contains in Theorem 2.2 the principal existence result "without convexity" of this paper. A version of this existence result, for variational problems without dynamics, is given in Theorem 2.3. Section 3 can also be read independently from the other sections. It contains the new extremum principle (Theorem 3.1), formulated for an abstract optimization problem in a topological vector space setting. This principle provides sufficient conditions for the existence of an optimal solution that is a (finite) convex combination of extreme points of the optimization domain (this is the natural abstraction of the Minkowski form introduced before). Theorem 3.1 contains the well-known Bauer extremum principle. In §4 Theorems 2.2 and 2.3 are proved by working out the convexification-deconvexification scheme. First, the relaxed version (B_{rel}) of (B) is formulated; it is based on an extra hypothesis that makes it possible to apply Theorem 3.1 directly to (B_{rel}). Phase 3

(deconvexification) then proceeds by solving a system (A) of linear equations, much like we did above with (A_0). Finally, by means of deparametrization, it is shown that, for the existence result to hold, the extra hypothesis is not really needed. In §5 several new applications show the power of Theorems 2.2 and 2.3.

The approach followed in this paper can also be used to obtain new *bang-bang*-type existence results for problems with suitably concave cost functions. These applications are of a different nature, however; refer to [10] for the details.

2. Existence without convexity. Two new, general existence results without convexity are presented in this section. The first and most important one is a quite general existence result for optimal control problems. The second one is actually a special version, formulated for certain variational problems that lack a dynamical system altogether.

Let T be a compact metric space, the *abstract time domain*, equipped with its Borel σ-algebra $\mathcal{B}(T)$ and a *nonatomic* finite measure μ. Let $\mathcal{T}$ denote either $\mathcal{B}(T)$ or its μ-completion. Let U be a metric Lusin or Suslin space of *control points*, equipped with the Borel σ-algebra $\mathcal{B}(U)$. To simplify matters, we may think of U as a Euclidean or a complete separable metric space. Let $t \mapsto U(t)$ be a multifunction from T into U, having a $\mathcal{T} \times \mathcal{B}(U)$-measurable graph M. A *control pair* is a pair (π, u), where π, the *control parameter*, belongs to a compact metric space Π, where $\Gamma(\pi)$ is the abstract *time domain* determined by π, and where $u : \Gamma(\pi) \to U$ is a measurable *control function* such that $u(t) \in U(t)$ for almost every t in $\Gamma(\pi)$. Let $\mathcal{G}$ denote the set of all such control pairs (π, u). As shown in Example 5.1, control parameters can be used not only to specify the control time domain, but also the initial and/or final positions of the dynamical systems, hitting times, and/or positions with a specified target, and so forth (see also [37]). The following continuity condition is supposed to hold for the μ-measure of the symmetric differences of the time domains:

$$\lim_{k\to\infty} \mu(\Gamma(\pi_k)\Delta\Gamma(\pi_0)) = 0 \quad \text{whenever } \pi_k \to \pi_0 \text{ in } \Pi.$$

For instance, in the control problem (B_0) of §1, we had $M := [0,1] \times \boldsymbol{R}$, and the space Π is trivial (say $\Pi := \{0\}$). Thus, we can set there $\Gamma(0) := T := [0,1]$. Of course, T is then equipped with the Lebesgue measure μ.

Let us start the description of the trajectories of the control problem. Let $b : M \to \boldsymbol{R}^\nu$ be a measurable function and let $\kappa : T \times T \to \boldsymbol{R}^{n\times\nu}$ be bounded in absolute value by a constant c_κ, measurable in its second variable, and *continuously hereditary* in the following way [37, II.5]: There exists a continuous functional $\sigma : T \to [0,1]$ such that $\alpha \mapsto \mu(T_\alpha)$ is also continuous, for $T_\alpha := \{t \in T : \sigma(t) \le \alpha\})$, and such that

$$\kappa(t,\tau) = 0 \quad \text{if } \sigma(t) < \sigma(\tau).$$

The following expression defines the *control action integral operator*:

$$\mathcal{A}(\pi,u)(t) := \int_{\Gamma(\pi)} \kappa(t,\tau) b(\tau, u(\tau)) \mu(d\tau).$$

A control pair $(\pi, u) \in \mathcal{G}$ is called *admissible* if it satisfies

$$\int_{\Gamma(\pi)} |b(t,u(t))| \mu(dt) \; < \; +\infty.$$

In §4 it is demonstrated that $\mathcal{A}(\pi, u)$ belongs to $C(T; \boldsymbol{R}^n)$ whenever $(\pi, u) \in \mathcal{G}$ is admissible. The *trajectory* $y_{\pi,u}$ in $C(T; \boldsymbol{R}^n)$, corresponding to an admissible pair $(\pi, u) \in \mathcal{G}$, is defined by

$$y_{\pi,u} := \Phi(\pi, \mathcal{A}(\pi, u)).$$

Here the *representation operator* $\Phi : \Pi \times C(T; \boldsymbol{R}^n) \to C(T; \mathbf{R}^n)$ is supposed to be such that $\Phi(\pi, y)$ is continuous in (π, y) and affine in y. Moreover, constants $c_{\Phi,1}, c_{\Phi,2}$ are supposed to exist such that

$$\|\Phi(\pi, y)\| \leq c_{\Phi,1}\|y\| + c_{\Phi,2} \quad \text{on } \Pi \times C(T; \boldsymbol{R}^n).$$

Similar to the previous section, $\|\cdot\|$ denotes the supremum norm here. For motivation for these concepts, skip to Example 5.1. As is shown in §5, linear ordinary differential equations, linear Volterra equations, and linear functional-integral equations can be covered in this way. For instance, for (B_0) in §1, we had $b(t, v) = v$, $\kappa(t, \tau) = 1$ if $\tau \leq t$ and $\kappa(t, \tau) = 0$ otherwise; σ and Φ were the respective identity functions, and $\mu(T_\alpha) = \alpha$.

Let $g_0, g_1, \ldots, g_m : M \to (-\infty, +\infty]$ be measurable functions. Carrying a notion due to Cesari to its logical extreme, we define the *orientor field* $Q : T \times \boldsymbol{R}^\nu \to 2^{\boldsymbol{R} \times [-\infty, +\infty]^m}$, corresponding to $g_0, \ldots, g_m$ and b, by letting $Q(t, v)$ be the set of all $(w^0, w) \in \boldsymbol{R} \times [-\infty, +\infty]^m$ such that

$$w^0 \geq g_0(t, v), \ldots, w^m \geq g_m(t, v) \quad \text{and} \quad v = b(t, v)$$

for some $v \in U(t)$; here $w := (w^1, \ldots, w^m)$. This orientor field is supposed to have the upper semicontinuity property (K) [15] on $T \times \boldsymbol{R}^\nu$, i.e.,

$$Q(t, v) \;=\; \cap_{\epsilon > 0} cl \cup_{|v' - v| < \epsilon} Q(t, v') \quad \text{for every } (t, v) \in T \times \boldsymbol{R}^\nu.$$

Here "cl" denotes closure in $\boldsymbol{R} \times [-\infty, +\infty]^m$. Also, we suppose that there exists $\chi' : \boldsymbol{R}_+ \to [0, +\infty]$, nondecreasing, lower semicontinuous, and convex, such that $\chi'(0) = 0$,

$$\lim_{\xi \to \infty} \chi'(\xi)/\xi \;=\; +\infty,$$

and such that, for a certain integrable function $\phi_0 \in L_1^+(T)$,

$$g_0(t, v) \geq \chi'(|b(t, v)|) - \phi_0(t) \quad \text{on } M.$$

Furthermore, it is suppposed that, for every $\epsilon > 0$, there exists an integrable $\phi_\epsilon \in L_1^+(T)$ such that

$$g_i(t, v) + \epsilon\chi'(|b(t, v)|) \geq -\phi_\epsilon(t) \quad \text{on } M$$

for $i = 1, \ldots, m$. The *control cost integral functional* (for $i = 0$) and the ith constraint integral functional (for $i = 1, \ldots, m$) are defined by

$$I_{g_i}(\pi, u) := \int_{\Gamma(\pi)} g_i(t, u(t))\mu(dt).$$

Let $\alpha_1, \ldots, \alpha_m : \Pi \to \boldsymbol{R}$ be lower semicontinuous functionals. A control pair $(\pi, u) \in \mathcal{G}$ is called *feasible* if

$$I_{g_1}(\pi, u) + \alpha_1(\pi) \leq 0, \ldots, I_{g_m}(\pi, u) + \alpha_m(\pi) \leq 0.$$

For instance, in the original problem (B_0), we had $g_0(t,v) = (v^2-1)^2$, and there were no constraints of the above kind. Also, in that problem, we can choose $\chi'(\xi) := (\max(\xi^2-1,0))^2$, causing $g_0(t,v) \geq \chi'(|v|) = \chi'(|b(t,v)|)$.

Remark 2.1. A sufficient condition for the above property (K) of Q is as follows. Suppose that, for every t, the following hold:

(i) $\chi'(|b(t,\cdot)|)$ is inf-compact on $U(t)$,
(ii) $g_1(t,\cdot),\dots,g_m(t,\cdot)$ are lower semicontinuous on $U(t)$,
(iii) $b(t,\cdot)$ is continuous on $U(t)$,
(iv) $U(t)$ is closed in U.

Then Q has property (K). To demonstrate this, it is enough to show the following: If, for a sequence $(v_k) \in U(t)$ the limits $\bar{v} := \lim_k b(t,v_k)$ and $(\bar{w}^0,\bar{w}) := \lim_k (g_0(t,v_k),\dots,g_m(t,v_k))$ exist, respectively, in $\boldsymbol{R}^\nu$ and $\boldsymbol{R}\times[-\infty,+\infty]^m$, then there exists $\bar{v}\in U(t)$ with $\bar{v} = b(t,\bar{v})$ and $\bar{w}^j \geq g_j(t,\bar{v})$, $j=1,\dots,m$. Since $\bar{w}^0 < +\infty$ and $\chi'(|b(t,v_k)|) \leq g_0(t,v_k)+\phi_0(t)$, condition (i) implies that a subsequence of (v_k) converges to some $\bar{v}\in U(t)$; by (ii)–(iv), this limit easily solves the above. In view of the properties χ' already has, a particular case of the above situation is obtained when U is Euclidean and when $\lim_{|v|\to+\infty, v\in U(t)} |b(t,v)| = +\infty$ for every $t\in T$.

Let $\bar{g}: T\times\boldsymbol{R}^n \to (-\infty,+\infty]$ be $\mathcal{T}\times\mathcal{B}(\boldsymbol{R}^n)$-measurable such that, for every $t\in T$,

$$\bar{g}(t,\cdot) \text{ is lower semicontinuous and concave on } \boldsymbol{R}^n.$$

We suppose that there exist integrable $\bar{\phi}_1,\dots,\bar{\phi}_{\bar{d}},\bar{\psi}\in L_1^+(T)$ and nondecreasing functions $\bar{m}_1,\dots,\bar{m}_{\bar{d}}:\boldsymbol{R}_+\to\boldsymbol{R}_+$, such that $\bar{\chi}:\xi\mapsto\sum_{i=1}^{\bar{d}}\bar{m}_i(\xi)\int_T\bar{\phi}_i\,d\mu$ satisfies

$$\bar{g}(t,\eta)+\bar{\chi}(|\eta|) \;\geq\; -\bar{\psi}(t) \quad \text{on } T\times\boldsymbol{R}^n.$$

The following growth relationship between ξ' and $\bar{\chi}$, lower bounds of, respectively, g_0 and $\bar{g}$, is supposed to hold:

$$\lim_{\xi\to\infty}[\mu(T)\chi'(\xi)-\bar{\chi}(c_{\Phi,1}c_\kappa\mu(T)\xi+c_{\Phi,2})] \;=\; +\infty.$$

The *trajectory cost integral functional* is defined by

$$I_{\bar{g}}(\pi,y) := \int_{\Gamma(\pi)}\bar{g}(t,y(t))\mu(dt).$$

In (B_0) we encountered $\bar{g}(t,\eta) := -\eta^2$. So if we set there $\bar{m}_1(\eta) := \eta^2$ and $\bar{\phi}_1\equiv 1$, then the above conditions hold.

Let $s_1,\dots,s_d:\Pi\times\mathcal{C}(T;\boldsymbol{R}^n)\to\boldsymbol{R}$ be d *evaluation functionals*, which intervene in the final cost expression, as does the *indirect final cost functional* $e:\Pi\times\boldsymbol{R}^d\to(-\infty,+\infty]$. We suppose that

$$\begin{gathered} s_i(\pi,y) \text{ is continuous in } (\pi,y) \text{ and linear in } y,\\ e \text{ is lower semicontinuous on } \Pi\times\boldsymbol{R}^d,\\ e(\pi,\zeta)\geq -c_e \quad \text{on } \Pi\times\boldsymbol{R}^d \end{gathered}$$

for some constant c_e. With $s := (s_1,\dots,s_d)$, the *indirect final cost* of $(\pi,u)\in\mathcal{G}$ is given by $e(\pi,s(y_{\pi,u}))$.

In addition, we allow for a more direct evaluation of final costs: Let $\bar{e}:\Pi\times\mathcal{C}(T;\boldsymbol{R}^n)\to(-\infty,+\infty]$ be the *direct final cost functional*. It is supposed that

$$\bar{e}(\pi,y) \text{ is lower semicontinuous in } (\pi,y) \text{ and concave in } y$$

(in comparison with e above, concavity is additional) and that

$$\bar{e}(\pi, y) \geq -c_{\bar{e}} \quad \text{on } \Pi \times \mathcal{C}(T; \boldsymbol{R}^n)$$

for some constant $c_{\bar{e}}$. The *direct final cost* of $(\pi, u) \in \mathcal{G}$ is given by $\bar{e}(\pi, y_{\pi,u})$. In problem (B_0), we had $e \equiv 0$ and $\bar{e}(y) = -\exp(-\|y\|)$; it was already observed that this functional is concave.

The main existence result without convexity of this paper can now be stated; several applications can be found in §5.

THEOREM 2.2 (optimal control). *Consider the following problem* (B):

$$\text{minimize } I(\pi, u) := I_{g_0}(\pi, u) + I_{\bar{g}}(\pi, y_{\pi,u}) + e(\pi, s(y_{\pi,u})) + \bar{e}(\pi, y_{\pi,u})$$

over all admissible and feasible control pairs $(\pi, u) \in \mathcal{G}$. *Assume, next to the conditions stated in this section, that* $\inf(B) < +\infty$. *Then there exists an optimal control pair for* (B).

When the dynamical system is absent/trivial (i.e., $b \equiv 0$, $\bar{g} \equiv 0$, $e, \bar{e} \equiv 0$, and so on), the condition that T is compact and metric can be dispensed with. It then suffices to have an abstract nonatomic finite measure space $(T, \mathcal{T}, \mu)$. Observe how, for $b \equiv 0$, the property (K) for Q becomes equivalent to

$$Q(t, 0) \text{ is closed for every } t \in T,$$

and the lower bound for g_0 reads

$$g_0(t, v) \geq -\phi_0'(t) \quad \text{on } M$$

for some integrable $\phi_0' \in L_1(T)$ (indeed $\phi_0' := \phi_0 - \chi'(0)$).

THEOREM 2.3 (variational problem). *Consider the following problem* (B'):

$$\text{minimize } I_{g_m}(\pi, u) + \alpha_m(\pi)$$

over all pairs $(\pi, u) \in \mathcal{G}$ *such that* $I_{g_0}(\pi, u) \leq 0$ *and* $I_{g_i}(\pi, u) + \alpha_i(\pi) \leq 0$, $i = 1, \ldots, m-1$. (*The reversal in the roles of* g_0 *and* g_m, *while not necessary, increases the options for applications.*) *Assume, next to the conditions stated in this section* (*when specialized to the trivial dynamics case* $b \equiv 0$, $\bar{g} \equiv 0$, $e, \bar{e} \equiv 0$) *and the already-announced abstract nature of the nonatomic measure space* $(T, \mathcal{T}, \mu)$, *that* $\inf(B) < +\infty$. *Then there exists an optimal pair for* (B').

This result generalizes a well-known existence result for a variational problem in economics, first stated by Aumann and Perles [3], and later generalized by Berliocchi and Lasry [12], Artstein [2], and Balder [5]; cf. Corollary 5.4, below.

3. Fundamental extremum principle. This section, abstract in nature, can be read independently from the rest of this paper. Let E be a Hausdorff locally convex topological vector space and let C be a subset of E. A new, abstract extremum principle is now stated for an optimization problem, where a partly quasi-concave objective function is minimized over C under *finitely many* affine constraints. It guarantees the existence of a special optimal solution, viz., one that is a *convex combination of extreme points of* C.

THEOREM 3.1 (extremum principle). *Consider the following abstract optimization problem* (P):

$$\text{minimize } J(x) := f(x) + g(L(x))$$

over all $x \in C$ satisfying the constraints

$$b_0(x) \leq 0, b_1(x) \leq 0, \ldots, b_m(x) \leq 0.$$

Here, $b_0, b_1, \ldots, b_m : C \to (-\infty, +\infty]$ are functions such that

$$b_0 \text{ is inf-compact}^1 \text{ and affine,}$$
$$b_1, \ldots, b_m \text{ are lower semicontinuous and affine on } C_0,$$

where $C_0 := \{x \in C : b_0(x) \leq 0\}$. Also, C is supposed to be such that

$$C \text{ is a convex extremal subset of some compact convex subset of } E$$

(i.e., $\frac{1}{2}(x + x') \in C$ implies that $x, x' \in C$ for all x, x' in the compact convex subset), and $f : C \to (-\infty, +\infty]$ and $g : L(C) \to (-\infty, +\infty]$ are objective functions such that

$$f \text{ is lower semicontinuous and quasiconcave on } C_0,$$
$$g \text{ is lower semicontinuous on } L(C_0),$$

where $L : C \to \boldsymbol{R}^d$ is an operator such that

$$L \text{ is continuous and affine on } C_0.$$

Then (P) has an optimal solution that is a convex combination of at most $2m+4d+2$ extreme points of C, provided that it has at least one feasible solution. Moreover, if C_0 happens to be extremal in C, then $m + 2d + 1$ extreme points already suffice.

Remarkably, no compactness or even closedness (in E) is required for C itself. It should be stressed already that the extremality condition for C is *automatically* satisfied when C is the set of all probability measures on a suitable (but noncompact) topological space or, more generally, when C is the set of all Young measures on such a space. Indeed, the extremality condition reflects the extremal position that the set of Young measures holds with respect to its compactification; cf. §4. Similar results for probability measures are classical [17, III].

The classical extremum principle of Bauer (see [16, 25.9] for concave f and [19, 13.A-B] for quasi-concave f) is contained in Theorem 3.1.

COROLLARY 3.2 (Bauer extremum principle). *Consider the optimization problem*

$$\text{minimize } f(x)$$

over all $x \in K$. Here K and $f : K \to (-\infty, +\infty]$ are such that

$$K \text{ is a nonempty compact convex subset of } E,$$
$$f \text{ is lower semicontinuous and quasi-concave.}$$

Then the above optimization problem has an optimal solution that is an extreme point of K.

Proof. Apply Theorem 3.1 to the case where $C := K$ by setting g, $b_0 \equiv 0$ and m, $d := 0$. Then $C = C_0 = K$, so the additional clause of Theorem 3.1 applies. □

We now work in the converse direction and prove Theorem 3.1 by a combination of Corollary 3.2 and the following new characterization of the extreme points of an

[1] i.e., $\{x \in C : b_0(x) \leq \gamma\}$ is compact for every $\gamma \in R$.

affinely constrained subset of E, which extends certain well-known results of this type (e.g. [12, p. 145]). Such characterizations, with applications in the theory of moments, seem to have started with Rosenbloom [33]; cf. [34], [35] for linear-programming-oriented applications to optimal control. A very nice, general exposition can be found in [38].

PROPOSITION 3.3. *Under the conditions of Theorem* 3.1, *every extreme point of the feasible set for* (P) *is a convex combination of at most* $2m+2$ *extreme points of* C. *Moreover, if* C_0 *happens to be extremal in* C, *then* $m+1$ *extreme points of* C *already suffice.*

Proof. By the properties of b_0, the set C_0 is compact and convex. So by [38, Thm. 2.1, Ex. 2.1] every extreme point of the feasible set for (P) is a convex combination of at most $m+1$ extreme points of C_0 (here we use the fact that the feasible set is precisely the set of all $x \in C_0$ with $b_i(x) \leq 0$, $i = 1, \ldots, m$). Let $\hat{C}$ denote the compact convex set in which C is supposed to be a convex extremal subset. Now observe that the extension $\hat{b}_0 : \hat{C} \to (-\infty, +\infty]$ of b_0, obtained by setting $\hat{b}_0 \equiv +\infty$ on the convex set $\hat{C} \backslash C$, is affine. It is also inf-compact (hence lower semicontinuous) on $\hat{C}$, by the inf-compactness of b_0 on C (indeed, for every $\gamma \in \boldsymbol{R}$, the set $\{x \in \hat{C} : \hat{b}_0(x) \leq \gamma\}$, which coincides with $\{x \in C : b_0(x) \leq \gamma\}$, is compact). Since $C_0 = \{x \in \hat{C} : \hat{b}_0(x) \leq 0\}$, the result from [38] can be applied once more, giving that every extreme point of C_0 is a convex combination of at most two extreme points of $\hat{C}$. However, $C_0 \subset C$, and extremality of C in $\hat{C}$ cause the two extreme points in the latter combination to be extreme points of C itself. Under the additional clause, this last step can be omitted. □

Proof of Theorem 3.1. By compactness of C_0 and lower semicontinuity of the b_i's on C_0, it follows that the feasible set of (P) is compact. Also, the objective function J is easily seen to be lower semicontinuous on the feasible set. So, by the Weierstrass theorem, there exists a feasible $\bar{x}$ such that $J(x) \geq J(\bar{x})$ for all other feasible x. Consider the auxiliary optimization problem $(\bar{P})$, which runs as follows:

$$\text{minimize } f(x)$$

over the set K of all $x \in C$ satisfying both $b_0(x) \leq 0, b_1(x) \leq 0, \ldots, b_m(x) \leq 0$ and $L(x) = L(\bar{x})$. Define $b_{m+j}(x) := L_j(x) - L_j(\bar{x})$ and $b_{m+d+j} := -b_{m+j}$ for $j = 1, \ldots, d$. Here L_j denotes the jth component function of L. Then K is precisely the set of all $x \in C_0$ satisfying $b_i(x) \leq 0$, $i = 1, \ldots, m+2d$. All of the b_i's are lower semicontinuous and affine on C_0. In particular, K is a compact convex subset of C_0. By Corollary 3.2 [19, 13.A-B], there exists an optimal solution x_* for $(\bar{P})$ that is an extreme point of K. By the above, it is clear that the characterization of Proposition 3.3 applies to x_*. This gives x_*, precisely as stated. Finally, note that x_* is also an optimal solution of (P), since optimality of $\bar{x}$ for (P) and optimality of x_* for $(\bar{P})$ give, when combined,

$$J(x) \;\geq\; J(\bar{x}) = f(\bar{x}) + g(L(x_*)) \;\geq\; J(x_*)$$

for every x that is feasible for (P).

The following example illustrates the role of the unusual extremality condition for C. Here we see in essence what was already announced immediately following Theorem 3.1: The extremality condition always holds when we take for C the set of all probability measures on a suitable topological space. See [17, III] for topological background material.

Example 3.4. Consider $C := M_1^+((0,1])$, the set of all Borel probability measures on the interval $(0,1]$. Canonically, a probability measure on $(0,1]$ can also be regarded

as a probability measure on the larger set $[0,1]$. Hence, C is a convex subset of $\hat{C} := M_1^+([0,1])$, and it is easy to see that C is extremal in $\hat{C}$. In turn, $\hat{C}$ is a convex subset of the set $E := M([0,1])$ of all bounded signed measures on $[0,1]$. Equip E with the usual narrow topology (this coincides with the weak star—alias vague—topology $\sigma(E, C([0,1]))$. This topology makes E Hausdorff [17, III] and locally convex. By [17, III.60], the set $\hat{C}$ is compact in E. Let $b_0 : C \to (-\infty, +\infty]$ be given by $b_0(x) := \int_{(0,1]} v^{-1}\, x(dv) - 2$. By [17, III.55], b_0 is certainly lower semicontinuous for the narrow topology on C (which is indeed the relative topology induced by the narrow topology on E [17, III]). Furthermore, for any $x \in C$, we see that $b_0(x) \leq \gamma < +\infty$ implies that $x([\epsilon, 1]) \geq 1 - \epsilon(2+\gamma)$ for any $\epsilon > 0$. Therefore, it follows by Prohorov's theorem [17, III.59] that b_0 is inf-compact on C. Define $\bar{x} := \frac{1}{2}\epsilon_{1/3} + \frac{1}{2}\epsilon_1$, where ϵ_ξ denotes the Dirac (probability) measure concentrated in the point ξ, $\xi \in (0,1]$. It is easy to verify that $\bar{x}$ is an extreme point of $C_0 = \{x \in M_1^+((0,1]) : \int_{(0,1]} v^{-1}\, x(dv) \leq 2\}$. The form of $\bar{x}$ is as predicted by Proposition 3.3 (with $m = 0$), for it is well known [16, Prob. 25.1] that the Dirac measures on $(0,1]$ form precisely the extreme points of C. Finally, note that, for the artifical problem of minimizing $-b_0$ over C_0, $\bar{x}$ is also of the form predicted by Theorem 3.1.

We can now somewhat explain what went on in Phase 2 in §1 (more details are forthcoming): In (B_0), we had $m = 0$, the only constraint being $b_0(x) \leq 0$. Also, $f := J$, $g \equiv 0$, and $d = 0$. This would give an optimal solution x_*, which is a convex combination of at most two extreme points of the set C of all transition probabilities from $[0,1]$ into $M_1^+(\boldsymbol{R})$. By analogy with the previous example, it would seem obvious that the extreme points of C are formed by the Dirac transition probabilities, i.e., the transition probabilities of the form ϵ_u, hence the expression for x_* given in §1.

4. Proof of the results in §2. We follow the lines of the convexification-deconvexification scheme. These were explained in §1, but they were only worked out there for the simple problem (B_0). An additional feature of our present march toward the optimal control pair is as follows: Phase 1 is concluded by applying the Weierstrass theorem for the purpose of establishing the optimal control *parameter*. The optimal control *function* is then determined through Phases 2 and 3. Another complication is formed by the great degree of generality incorporated in property (K) for the orientor field Q. For this reason, if we are prepared to accept the only marginally more stringent conditions (i)–(iv) of Remark 2.1, we will find Proposition 4.9 a useful substitute for Theorem 2.2. Actually, the convexification-deconvexification scheme leads straight to that proposition; thereafter, deparametrization and measurable regularization ideas are used to deduce Theorem 2.2 from Proposition 4.9.

4.1. Phase 1: Convexification via relaxation. Let us formulate a relaxed version (B_{rel}) of problem (B). The present choice of relaxation only makes sense under a working hypothesis, which we make from here until Proposition 4.9.

WORKING HYPOTHESIS. *The sufficient conditions* (i)–(iv) *for property* (K), *as stated in Remark* 2.1, *hold.*

Let G be the set of all relaxed control pairs (π, x), with $\pi \in \Pi$ and $x : \Gamma(\pi) \to M_1^+(U)$ a transition probability such that $x(t)(U(t)) = 1$ almost everywhere. Let $r : G \to (-\infty, +\infty]$ be defined by

$$r(\pi, x) := \int_{\Gamma(\pi)} \left[\int_{U(t)} g_0(t, v)\, x(t)(dv) \right] \mu(dt).$$

The relaxed trajectory can easily be stated; it is given by

$$y_{\pi,x} := \Phi(\pi, A(\pi, x)),$$

where

$$A(\pi,x)(t) := \int_{\Gamma(\pi)} \kappa(t,\tau) \left[\int_{U(t)} b(\tau,v)\, x(\tau)(dv) \right] \mu(d\tau).$$

Of course, this presupposes that (π, x) is *admissible*, i.e.,

$$a_{m+1}(\pi,x) := \int_{\Gamma(\pi)} \left[\int_{U(t)} |b(t,v)|\, x(t)(dv) \right] \mu(dt) < +\infty.$$

Just as for the original control functions, such admissibility implies that the trajectory $y_{\pi,x}$ belongs to $C(T; \boldsymbol{R}^n)$ (see Lemma 4.3, below). The constraints are relaxed as follows: Define $a_i : G \to (-\infty, +\infty]$ by

$$a_i(\pi,x) := \int_{\Gamma(\pi)} \left[\int_{U(t)} g_i(t,v)\, x(t)(dv) \right] \mu(dt);$$

then $(\pi, x) \in G$ is called *feasible* if $a_i(\pi, x) + \alpha_i(\pi) \leq 0$ for $i = 1, \ldots, m$. Let $\bar{r} : \Pi \times C(T; \boldsymbol{R}^n) \to (-\infty, +\infty]$ be defined by

$$\bar{r}(\pi,y) := \int_{\Gamma(\pi)} \bar{g}(t, y(t)) \mu(dt) + \bar{e}(\pi, y).$$

Clearly, this functional is well defined (see also §4) and concave in the y-variable. The relaxed version (B_{rel}) of (B) is defined as follows:

$$\text{minimize } J(\pi,x) := r(\pi,x) + \bar{r}(\pi, y_{\pi,x}) + e(\pi, s(y_{\pi,x}))$$

over all admissible and feasible pairs $(\pi, x) \in G$.

Next, we prepare (B_{rel}) for a treatment by means of Theorem 3.1. In the course of this, we present a brief summary of Young measure theory. By the presence of the variable time domains, this expands slightly on the more standard expositions [6], [36]. Let R stand for the set of all (equivalence classes of) transition *sub*probabilities $x : T \to M^+_{\leq 1}(U)$. Here $M^+_{\leq 1}(U)$ denotes the set of all Borel subprobabilities (i.e., measures with mass at most 1) on U. For every $(\pi, x) \in G$, the control part x is by definition a transition probability from $\Gamma(\pi)$ into $M^+_1(U)$. Note that x can be extended so as to belong to R, simply by setting $x(t)$ equal to the null measure on U for almost every t in $T \backslash \Gamma(\pi)$. We call this *extension by nullity* of Young measures. This device, to make the relaxed control functions—in particular, the relaxations of the original control functions—"null and void" outside the time domain over which control is exercised, can already be found in McShane's work [26], but seems not to have received the attention that it deserves (for instance, the brief description in [37, VI.5.2] diverges, and is considerably less general). The fact that R consists of (equivalence classes of) transition *sub*probabilities causes no essential differences with the usual treatment of Young measure topology: It is well known [7], [6] that R can be identified with a subset in the closed unit ball $\hat{R}$ of the space $E := L_\infty(T, \mathcal{T}, \mu; M(\hat{U}))$ of (equivalence classes of) essentially bounded, scalarly (i.e., with respect to $C(\hat{U})$, the set of all continuous

functions on $\hat{U}$) measurable functions from T into $M(\hat{U})$. Here $\hat{U}$ denotes the Hilbert cube compactification of U (for U a Suslin (Lusin) space, this makes U a universally measurable [Borel measurable] subset of $\hat{U}$; cf. [17]). Also, $M(\hat{U})$ denotes the set of all bounded signed Borel measures on $\hat{U}$. By the Alaoglu–Bourbaki theorem, $\hat{R}$ is compact for the weak star topology on E. Define the functional $a_0 : G \to [0, +\infty]$ by

$$a_0(\pi, x) := \int_{\Gamma(\pi)} \left[\int_{U(t)} \chi'(|b(t,v)|)\, x(t)(dv) \right] \mu(dt).$$

LEMMA 4.1. (i) a_0 *is* inf-*compact on* $G \subset \Pi \times R$.

(ii) r *and* a_{m+1} *are lower semicontinuous on* G.

(iii) *For every* $\gamma \in \boldsymbol{R}$, $a_1, \ldots, a_m$ *are lower semicontinuous on* $\{(\pi, x) \in G : a_0(\pi, x) \leq \gamma\}$.

Proof. (i) Observe that, by L_1-norm separability of E's predual $L_1(T, \mathcal{T}, \mu; C(\hat{U}))$, the weak star topology on $\hat{R}$ is metrizable [19, 12.F]. So let us now prove for an arbitrary $\gamma \in \boldsymbol{R}$ that the set G', consisting of all $(\pi, x) \in G$ for which $a_0(\pi, x) \leq \gamma$, is sequentially compact. Given any sequence $((\pi_k, x_k))$ in G', we may suppose without loss of generality that $(\pi_0, x_0) := \lim_k (\pi_k, x_k)$ exists in the englobing compact set $\Pi \times \hat{R}$. Then $\mu(\Gamma(\pi_k) \Delta \Gamma(\pi_0)) \to 0$, by the continuity property of Γ. Define $g \in L_1 := L_1(T, \mathcal{T}, \mu; C(\hat{U}))$ by $g(t,v) := 1$ if $t \in \Gamma(\pi_0)$ and $g(t,v) := 0$, otherwise. Then the weak star convergence $x_k \to x_0$ implies that $\langle g, x_k \rangle \to \langle g, x_0 \rangle$, i.e., $\mu(\Gamma(\pi_0)) = \lim_k \mu(\Gamma(\pi_0) \cap \Gamma(\pi_k)) = \int_{\Gamma(\pi_0)} x_0(t)(\hat{U})\, \mu(dt)$. Since $x_0(t)(\hat{U}) \leq 1$ for almost every t in T, this implies that $x_0(t) \in M_1^+(\hat{U})$ for almost every t in $\Gamma(\pi_0)$. Similar reasoning for the function $1 - g$ leads to $x_0(t) =$ null measure for almost every t in $T \backslash \Gamma(\pi_0)$. Thus, it follows that $\int_{\Gamma(\pi_k)} [\int_{\hat{U}} g(t,v)\, x_k(t)(dv)] \mu(dt) \to \int_{\Gamma(\pi_0)} [\int_{\hat{U}} g(t,v)\, x_0(t)(dv)] \mu(dt)$ for every $g \in L_1$. By well-known arguments, this implies $\liminf_k \int_{\Gamma(\pi_k)} [\int_{\hat{U}} g(t,v)\, x_k(t)(dv)] \mu(dt) \geq \int_{\Gamma(\pi_0)} [\int_{\hat{U}} g(t,v)\, x_0(t)(dv)] \mu(dt)$ for every measurable $g : T \times \hat{U} \to [0, +\infty]$ such that $g(t, \cdot)$ is lower semicontinuous (i.e., inf-compact) on the compact set $\hat{U}$ (e.g., see [6, Lemma A.2]). In particular, the function g has those properties, where g is defined by $g(t,v) := \chi'(|b(t,v)|)$ if $v \in U(t)$ and by $g(t,v) := +\infty$ if $v \in \hat{U} \backslash U(t)$ (note the role played by our working hypothesis in connection with Remark 2.1(i)). This gives $\gamma \geq \liminf_k a_0(\pi_k, x_k) \geq \int_{\Gamma(\pi_0)} [\int_{\hat{U}} g(t,v)\, x_0(t)(dv)] \mu(dt)$. It follows that $\int_{\hat{U}} g(t,v)\, x_0(t)(dv) < +\infty$ for almost every t in $\Gamma(\pi_0)$, which in turn forces $x_0(t)(U(t)) = 1$ for almost every t in $\Gamma(\pi_0)$. We conclude that (π_0, x_0) belongs to G'.

(ii) Since $g_0(t,v) \geq -\phi_0(t)$ and $|b(t,v)| \geq 0$ on M, lower semicontinuity of the two integral functionals follows by [6, Lemma A.2, Thm. 3.3], in view of the fact that both integrands are measurable in (t,v) and lower semicontinuous in v (for g_0, this holds by the working hypothesis).

(iii) By standard arguments [6, Lemma A.2, Thm. 3.3], the hypotheses give that $a_i + \epsilon a_0$ is lower semicontinuous on G for every $\epsilon > 0$ (note the role played by the working hypothesis in connection with Remark 2.1(ii)). For $a_0(\pi, x) \leq \gamma$, we obviously have

$$a_i(\pi, x) \;=\; \sup_{\epsilon > 0} [a_i(\pi, x) + \epsilon a_0(\pi, x) - \epsilon \gamma],$$

so the result follows from the fact that the pointwise supremum of lower semicontinuous functionals is also lower semicontinuous. □

LEMMA 4.2. (i) $a_0(\pi,x) \geq \chi(a_{m+1}(\pi,x))$ *on* G, *with* $\chi(\xi) := \mu(T)\chi'(\xi/\mu(T))$.
(ii) $\bar{r}(\pi,y) \geq -c_{\bar{e}} - \bar{\chi}(\|y\|) - \int_T \bar{\psi} d\mu$ *on* $\Pi \times \mathcal{C}(T;\boldsymbol{R}^n)$.
(iii) $\bar{r}$ *is lower semicontinuous on* $\Pi \times \mathcal{C}(T;\boldsymbol{R}^n)$.

Proof. (i) By Jensen's inequality, we obtain, for every $t \in \Gamma(\pi)$,

$$\int_{U(t)} \chi'(|b(t,v)|)\, x(t)(dv) \;\geq\; \chi'\left(\int_{U(t)} |b(t,v)|\, x(t)(dv)\right),$$

thanks to convexity of χ'. By $\chi'(0) = 0$ and $x(t) =$ null measure for $t \notin \Gamma(\pi)$ (extension by nullity), one more application of Jensen's inequality gives the desired inequality.

(ii) By monotonicity of the $\bar{m}_i$, the definition of the supremum norm entails $\bar{m}_i(y(t)) \leq \bar{m}_i(\|y\|)$ for every t, $i = 1,\ldots,\bar{d}$. The desired inequality then follows with ease.

(iii) By Fatou's lemma (applicable by the lower bound for $\bar{r}$ indicated in the above proof of (ii)), the result follows easily from the lower semicontinuity of $\bar{g}(t,\eta)$ in η, the continuity property of $\Gamma(\pi)$ in π, and the lower semicontinuity of $\bar{e}$. □

LEMMA 4.3. (i) *For every admissible pair* $(\pi,x) \in G$, $A(\pi,x)$ *belongs to* $\mathcal{C}(T;\boldsymbol{R}^n)$.
(ii) *For every* $\gamma \in \boldsymbol{R}$, *the function* A *is continuous on* $\{(\pi,x) \in G : a_0(\pi,x) \leq \gamma\}$.

Proof. (i) The proof is contained in the equicontinuity part of the next proof.

(ii) Denote the subset $\{a_0 \leq \gamma\}$ of G by G'. First, let us check that, for every fixed $t \in T$, the mapping $(\pi,x) \mapsto A(\pi,x)(t)$ is continuous from G' into $\boldsymbol{R}^n$. Observe that, for the jth component,

$$[A(\pi,x)(t)]^j \;=\; \int_{\Gamma(\pi)} \left[\int_{U(t)} g_{t,j}(t,v)\, x(t)(dv)\right] \mu(dt),$$

where $g_{t,j} : T \times U \to \boldsymbol{R}$ is defined by $g_{t,j}(\tau,v) := [\kappa(t,\tau)b(\tau,v)]^j$, $j = 1,\ldots,n$. This integrand is measurable in (τ,v) and continuous in v, so both $g_{t,j,\epsilon}(\tau,v) := g_{t,j}(\tau,v) + \epsilon\chi'(|b(\tau,v)|)$ and $g'_{t,j,\epsilon}(\tau,v) := -g_{t,j}(\tau,v) + \epsilon\chi'(|b(\tau,v)|)$ are measurable in (τ,v), lower semicontinuous in v, and bounded from below by an integrable function (in fact, by a constant). The latter follows directly from the inequality $|g_{t,j}(\tau,v)| \leq c_\kappa |b(\tau,v)|$ and the property $\lim_{\xi\to\infty} \chi'(\xi)/\xi = +\infty$. Reasoning similarly to that in the proof of Lemma 4.1(ii), it follows that the integral functional appearing in the right-hand side of the above expression for $[A(\pi,x)(t)]^j$ is continuous in (π,x) on G'.

The argument is now finished by showing that $\{A(\pi,x) : (\pi,x) \in G'\}$ forms an equicontinuous collection on the compact set T. (In particular, taking for G' the singleton consisting of (π,x), with $\gamma := a_{m+1}(\pi,x)$, settles the proof of part (i).) For t, $t' \in T$, it follows by σ-hereditarity of κ that

$$|A(\pi,x)(t) - A(\pi,x)(t')| \;\leq\; \int_{T_{\sigma(t)}\Delta T_{\sigma(t')}} |\kappa(t,\tau) - \kappa(t',\tau)||b(t,v)|x(\tau)(dv)\mu(d\tau).$$

Let $\epsilon > 0$ be arbitrary; then $-|b(\tau,v)| + \epsilon\chi'(|b(\tau,v)|)$ is bounded from below by some nonpositive constant $-c_\epsilon$. So

$$|A(\pi,x)(t) - A(\pi,x)(t')| \;\leq\; 2c_\kappa[c_\epsilon \mu(T_{\sigma(t)}\Delta T_{\sigma(t')}) + \epsilon\gamma],$$

uniformly in $(\pi,x) \in G'$. The measure of the symmetric difference converges to zero as $t' \to t$ (by the continuity of both σ and $\alpha \mapsto \mu(T_\alpha)$), so equicontinuity has

been proved. By the Arzela–Ascoli theorem [37, I.5.4], it follows that the mapping $(\pi, x) \mapsto A(\pi, x)$ is also continuous. □

Phase 1 concludes with an application of the Weierstrass theorem, which is essentially only used to determine an optimal control parameter (this explains why it was not needed for (B_0) in §1).

LEMMA 4.4. *There exists an optimal solution for the relaxed optimal control problem* (B_{rel}).

Proof. Clearly, $\inf(B_{\mathrm{rel}}) > -\infty$ and $\inf(B_{\mathrm{rel}}) \leq \inf(B) < +\infty$ (the latter by hypothesis). Let F be the nonempty set of all feasible and admissible relaxed control pairs $(\pi, x) \in G$ satisfying $J(\pi, x) \leq \inf(B_{\mathrm{rel}}) + 1$. Clearly, $\inf(B_{\mathrm{rel}}) = \inf_{(\pi,x)\in F} J(\pi, x)$. By Lemma 4.2, every pair $(\pi, x) \in F$ satisfies

$$\mu(T)\chi'(a_{m+1}(\pi, x)/\mu(T))\bar{\chi}(c_{\Phi,1}c_\kappa a_{m+1}(\pi, x) + c_{\Phi,2}) \leq \beta' + \int_T \phi_0 \, d\mu,$$

for $\beta' := \inf(B_{\mathrm{rel}}) + 1 + \int_T \bar{\psi} \, d\mu + c_e + c_{\bar{e}}$. By the limit relationship between χ' and $\bar{\chi}$, it follows that there exists a constant $\alpha \in \boldsymbol{R}$ such that $a_{m+1}(\pi, x) \leq \alpha$ for all $(\pi, x) \in F$. In turn, this implies that

$$r(\pi, x) - \bar{\chi}(c_{\Phi,1}c_\kappa\alpha + c_{\Phi,2}) \leq \beta',$$

by monotonicity of $\bar{\chi}$. Hence, it follows that $r(\pi, x) \leq \beta' + \bar{\chi}(c_{\Phi,1}c_\kappa\alpha + c_{\Phi,2})$ for all $(\pi, x) \in F$. Evidently, this implies that $a_0(\pi, x) \leq \beta := \beta' + \bar{\chi}(c_{\Phi,1}c_\kappa\alpha + c_{\Phi,2}) + \int_T \phi_0 \, d\mu$. Therefore, the constraints

$$a_0(\pi, x) \leq \beta, \qquad a_{m+1}(\pi, x) \leq \alpha$$

hold *implicitly* and can be added to the definition of F without altering (B_{rel}). Thus, $\inf(B_{\mathrm{rel}}) = \inf(Q)$, where (Q) is the problem of minimizing $J(\pi, x)$ over the set F' of all pairs $(\pi, x) \in G$ for which $a_0(\pi, x) \leq \alpha$, $a_i(\pi, x) \leq 0$, $i = 1, \ldots, m$, and $a_{m+1}(\pi, x) \leq \beta$. By Lemmas 4.1–4.3 (with β now taking the place of the γ used there), the feasible set F' of this problem is compact, and its objective functional J is lower semicontinuous. So there exists an optimal relaxed pair for (Q) by the Weierstrass theorem; by the above, this is also optimal for (B_{rel}). □

Remark 4.5. From the proof of Lemma 4.4, it is evident that the coercivity conditions (i.e., the lower bounds for g_0, $\bar{g}$ and the limit property involving χ, $\bar{\chi}$) *only* serve to guarantee the existence of $\alpha, \beta \in \boldsymbol{R}$ such that

$$a_0(\pi, x) \leq \beta, \quad a_{m+1}(\pi, x) \leq \alpha \quad \text{for all } (\pi, x) \in F.$$

In other words, a simpler and more limited alternative would have been to introduce from the beginning a nontrivial constraint $a_0'(\pi, x) \leq 0$ for (B), with a_0' such that (i) a_0' is inf-compact on G (this takes care of Lemma 4.1(i) by hypothesis) and (ii) $a_0'(\pi, \cdot)$ is affine for every $\pi \in \Pi$. The coercivity conditions could then have been omitted.

4.2. Phase 2: Application of the extremum principle. This phase consists simply of an application of Theorem 3.1.

PROPOSITION 4.6. *There exists an optimal solution* $(\pi_*, x_*) \in G$ *for* (B_{rel}) *such that* x_* *is a convex combination of at most* $N = 2m + 4d + 4$ *relaxations of functions* u_k *with* $(\pi_*, u_k) \in \mathcal{G}$, *i.e.,*

$$x_*(t) = \sum_{k=1}^{N} \lambda_k \epsilon_{u_k}(t) \quad \textit{for a.e. } t \textit{ in } \Gamma(\pi_*),$$

for certain $\lambda_1, \ldots, \lambda_N \in [0,1]$, *satisfying* $\sum_{k=1}^N \lambda_k = 1$ (*that is,* x_* *has Minkowski form*).

Proof. In the proof of Lemma 4.4, it was demonstrated that $\inf(Q) = \inf(B_{\mathrm{rel}})$ and that (Q) has an optimal solution, say $(\pi_*, \bar{x}) \in F' \subset G$. Consider the auxiliary optimization problem (Q_{π_*}): Minimize $J(\pi_*, x)$ over all transition probabilities $x : \Gamma(\pi_*) \to M_1^+(U)$ such that $(\pi_*, x) \in F'$. Clearly, $\inf(Q_{\pi_*}) = J(\pi_*, \bar{x}) = \inf(B_{\mathrm{rel}})$. Writing F', we see that (Q_{π_*}) is precisely of the form addressed by Theorem 3.1. For this, we take C to be the set of all transition probabilities $x : \Gamma(\pi_*) \to M_1^+(U)$ such that $(\pi_*, x) \in G$ and we set $f(x) := r(\pi_*, x) + \bar{r}(\pi_*, y_{\pi_*, x})$, $L(x) := s(\pi_*, y_{\pi_*, x})$, and $g(\zeta) := e(\pi_*, \zeta)$). The required concavity and affinity are seen to hold by elementary considerations—cf. §1. The required extremality property of C is seen to hold by observing that the set $\hat{C}$ of all transition probabilities $x : \Gamma(\pi_*) \to M_1^+(\hat{U})$ is compact (this follows from the compactness of $\hat{R}$ observed in the proof of Lemma 4.1) and convex and contains C as an extremal subset. Therefore, the extremum principle applies. Since $J(\pi_*, x_*)$ attains $\inf(Q_{\pi_*})$, the above gives also $J(\pi_*, x_*) = \inf(B_{\mathrm{rel}})$. Finally, it remains to observe that, by [13, IV.15] (see also [23]), the extreme points of C are precisely those (equivalence classes of) transition probabilities $x : \Gamma(\pi_*) \to M_1^+(U)$ that are of the form $x = \epsilon_u$ for some measurable $u : \Gamma(\pi_*) \to U$ with $u(t) \in U(t)$ almost everywhere □

4.3. Phase 3: Deconvexification. The following proposition provides the key to this phase.

LEMMA 4.7. *Let* (π_*, x_*) *be as in Proposition* 4.6. *There exist* $d+1$ *dual elements* $y_1^*, \ldots, y_{d+1}^*$ *in* $(\mathcal{C}(T; \boldsymbol{R}^n))^*$ *such that the following holds true: For any measurable function* $u : \Gamma(\pi_*) \to U$, *with* $u(t) \in U(t)$ *almost everywhere, the system* (A) *of* $m + d + 3$ *equations*

$$I_{g_i}(\pi_*, u) = \sum_k \lambda_k I_{g_i}(\pi_*, u_k), \qquad i = 0, \ldots, m+1,$$

$$\langle \mathcal{A}(\pi_*, u), y_j^* \rangle = \sum_k \lambda_k \langle \mathcal{A}(\pi_*, u_k), y_j^* \rangle, \qquad j = 1, \ldots, d+1$$

implies that (π_*, u) *is an optimal pair for* (B).

Proof. We already observed that $\bar{r}(\pi_*, \cdot)$ is concave. By Lemma 4.2(ii), the convex functional $-\bar{r}(\pi_*, \cdot)$ is locally bounded from above at every point of $\mathcal{C}(T; \boldsymbol{R}^n)$, including the point y_{x_*, π_*} (here the nature of the supremum norm and the monotonicity of $\bar{\chi}$ are used). By [18, I.2.4, I.5.2], this implies that there exists a subgradient $y^* \in (\mathcal{C}(T; \boldsymbol{R}^n))^*$ for $-\bar{r}(\pi_*, \cdot)$ in the point y_{x_*, π_*}, i.e.,

$$\bar{r}(\pi_*, y_{x_*, \pi_*}) - \bar{r}(\pi_*, y) \geq \langle y - y_{x_*, \pi_*}, y^* \rangle \quad \text{for all } y \in \mathcal{C}(T; \boldsymbol{R}^n).$$

Define y_{d+1}^* to be the image of y^* under the adjoint $\Lambda^* : (\mathcal{C}(T; \boldsymbol{R}^n))^* \to (\mathcal{C}(T; \boldsymbol{R}^n))^*$ of the continuous linear mapping $\Lambda : y \mapsto \Phi(\pi_*, y) - \Phi(\pi_*, 0)$. Also, our assumptions for (B) imply that each evaluation map s_i belongs to the dual space $(\mathcal{C}(T; \boldsymbol{R}^n))^*$; let $y_j^* := \Lambda^*(s_j)$, $j = 1, \ldots, d$.

Now take any u as stated, satisfying (A). The first equation $(i = 0)$ implies that (π_*, u) and (π_*, x_*) have the same control cost (i.e., $r(\pi_*, \epsilon_u) = r(\pi_*, x_*)$). The equations for $i = 1$ to $i = m+1$ imply that $a_i(\pi_*, \epsilon_u) = a_i(\pi_*, x_*)$. Hence, by the fact that (π_*, x_*) is admissible and feasible for (B_{rel}), (π_*, u) is admissible and feasible for (B). The final equation $(j = d+1)$ implies that $\bar{r}(\pi_*, y_{\pi_*, x_*}) - \bar{r}(\pi_*, y_{\pi_*, u}) \geq \langle y_{d+1}^*, A(\pi_*, x_*) - A(\pi_*, \epsilon_u) \rangle = 0$, by the above subgradient property of y^*. The

remaining equations (for $j = 1$ to $j = d$) imply that $s(\pi_*, y_{\pi_*,x_*}) = s(\pi_*, y_{\pi_*,u})$. Adding all four cost terms shows that $I(\pi_*, u) \le J(\pi_*, x_*) = \inf(B_{\text{rel}}) \le \inf(B)$. So (π_*, u) is optimal for (B). □

LEMMA 4.8. *There exists a measurable function $u_* : \Gamma(\pi_*) \to U$, with $u_*(t) \in U(t)$ almost everywhere, which solves the system (A) of Lemma 4.7.*

Proof. Each of the $y_j^* \in (C(T; \boldsymbol{R}^n))^*$ has a Riesz representation [37, I.5.8]; that is, there exists a bounded signed Borel vector measure $\theta_j := (\theta_j^1, \dots, \theta_j^n)$ on T such that $\langle y, y_j^* \rangle = \sum_{p=1}^n \int_T y^p(t)\, \theta_j^p(dt)$ for all $y := (y^1, \dots, y^n) \in C(T; \boldsymbol{R}^n)$. By Fubini's theorem

$$\sum_k \lambda_k \langle \mathcal{A}(\pi_*, u_k), y_j^* \rangle \;=\; \sum_k \lambda_k \int_{\Gamma(\pi_*)} \tilde{b}_{j,k}(\tau)\mu(d\tau),$$

where $\tilde{b}_{j,k}(\tau) := \sum_{p,p'} \int_T \kappa_{p,p'}(t,\tau) b_j^{p'}(\tau, u_k(\tau)) \theta_j^p(dt)$ defines an integrable function, $j = 1, \dots, d+1$, $k = 1, \dots, N$. More directly, the remaining right-hand sides in (A) can be written as

$$\sum_k \lambda_k I_{g_i}(\pi_*, u_k) \;=\; \sum_k \lambda_k \int_{\Gamma(\pi_*)} g_{i,k}(\tau)\mu(d\tau),$$

with integrable functions $g_{i,k}(\tau) := g_i(\tau, u_k(\tau))$, $i = 0, 1, \dots, m+1$, $k = 1, \dots, N$. Since μ is nonatomic, it follows by Lyapunov's theorem that there exists a measurable partition $C_1, \dots, C_N$ of $\Gamma(\pi_*)$ such that $\nu(C_k) = \lambda_k \nu(\Gamma_{\pi_*})$ for all k. Here ν denotes the vector measure with component measures having, respectively, densities $\tilde{b}_{j,k}$ and $g_{i,k}$ with respect to μ. Then, however, a solution u_* of (A) is obtained by defining $u_* : \Gamma(\pi_*) \to U$ as follows: For $t \in C_k$, define $u_*(t) := u_k(t)$, $k = 1, \dots, N$. □

PROPOSITION 4.9. *Under the working hypothesis in connection with Remark 2.1, there exists an optimal solution for (B).*

Proof. By Lemmas 4.7 and 4.8, the pair (π_*, u_*) of Lemma 4.8 is an optimal solution for (B). □

This finishes the application of the convexification-deconvexification scheme to problem (B). The proof of Theorem 2.2 would now be finished if it were not for the fact that we used the conditions of Remark 2.1, instead of our original property (K) required for the orientor field (this is where Theorem 2.2 differs from Proposition 4.9, just proved). So it remains to see how the original situation can be reduced to the one that we considered until now. We do so by relying on the device of *deparametrization* via measurable regularization, as introduced in [6].

To begin, let us reformulate (B) in the case where the integrands $g_0, g_1, \dots, g_m$ would have happened to be nonmeasurable. In that case,

$$I_{g_i}^*(\pi, u) := \inf \left\{ \int_{\Gamma(\pi)} \phi \, d\mu : \phi \in L_1(T), \phi(t) \ge g_i(t, u(t)) \quad \text{a.e.} \right\}$$

defines an *outer integral functional* (which coincides with $I_{g_i}(\pi, u)$ if g_i is measurable); e.g., see [8, App. A]. In that imaginary nonmeasurability case, we could define the following optimal control problem (B^*):

$$\text{minimize } I^*(\pi, u) := I_{g_0}^*(\pi, u) + I_{\bar{g}}(\pi, y_{\pi,u}) + e(\pi, s(y_{\pi,u})) + \bar{e}(\pi, y_{\pi,u})$$

over all admissible pairs $(\pi, u) \in \mathcal{G}$ satisfying the revised feasibility constraints $I_{g_i}^*(\pi, u) + \alpha_i(\pi) \le 0$, $i = 1, \dots, m$. The trajectories $y_{\pi,u}$ are exactly defined as in §2,

with no alterations needed, since *only* the integrands g_i are subjected to our present (imaginary) nonmeasurability investigation. The following result extends Proposition 4.9 to the nonmeasurable extension (B^*) of (B).

PROPOSITION 4.10. *Under the conditions of Theorem 2.2 and the working hypothesis, but possibly without the measurability conditions for the integrands $g_0, g_1, \ldots, g_m$, there exists an optimal control pair for (B^*).*

Proof. By the measurable regularization ideas introduced in [6, A.5], the following is true: For each i, there exists a $\mathcal{T} \times \mathcal{B}(U)$-measurable function $\tilde{g}_i : M \to (-\infty, +\infty]$ such that $\tilde{g}_i(t, \cdot)$ is lower semicontinuous on $U(t)$ for almost every t, and the following properties hold: (i) $\tilde{g}_i(t, \cdot) \geq g_i(t, \cdot)$ for almost every t, (ii) $I_{\tilde{g}_i}(\pi, u) = I^*_{g_i}(\pi, u)$ for all $\pi \in \Pi$ and all measurable $u : \Gamma(\pi) \to U$ with $u(t) \in U(t)$ almost everywhere (to see that this follows by [6, A.5], extend each g_i by setting $g_i \equiv +\infty$ on $(T \times U) \backslash M$). Define the auxiliary control problem $(\tilde{B})$ just as (B) in §2, but with the integrands g_i replaced by $\tilde{g}_i$. By property (i) of the measurable regularizations, it can be seen that all conditions used until now for the g_i are transferred to the $\tilde{g}_i$ (the essential inequalities all point in the right way), including those of the working hypothesis. Proposition 4.9 therefore applies to the auxiliary problem $(\tilde{B})$, which must have an optimal control pair (π_*, u_*). By property (ii) of the measurable regularizations, however, it follows that problems $(\tilde{B})$ and (B^*) are the same (the objective and constraint integral functionals coincide). Hence, (π_*, u_*) is also an optimal solution for (B^*). □

Let us now introduce an optimal control problem (B_{red}), which is an equivalent *reduction* [32] of the original problem (B), but which has the nonmeasurability characteristics of (B^*). We do this using the device of deparametrization, following ideas of Cesari and Rockafellar [15], [32], respectively, to which the measurable regularization idea has been added [6].

Let $\ell_0 : T \times \boldsymbol{R}^\nu \times [-\infty, +\infty]^m \to (-\infty, +\infty]$ be defined by

$$\ell_0(t, v, w) := \inf_{v \in U(t)} \{g_0(t, v) : g_1(t, v) \leq w^1, \ldots, g_m(t, v) \leq w^m, b(t, v) = v\}$$

(by convention, $\ell_0(t, v, w) := +\infty$ if the set over which the infimum is taken is empty). Observe that

$$\ell_0(t, v, w) \;=\; \inf\{w^0 : (w^0, w) \in Q(t, v)\}.$$

Therefore, by closedness of $Q(t, v)$ (a direct consequence of Q having property (K)), each of the above two infima on the right side is *attained* as soon as it is merely finite (i.e., if $\ell_0(t, v, w) < +\infty$). From the latter expression, it also follows easily that $\ell_0(t, \cdot, \cdot)$ is lower semicontinuous on $\boldsymbol{R}^\nu \times [-\infty, +\infty]^m$ for every $t \in T$, thanks again to property (K); cf. [15], [6]. Although the graph of the orientor field Q is measurable, this does not imply that ℓ_0 should be measurable (the reason being that projections of measurable sets need not be measurable). Furthermore, for $i = 1, \ldots, m$ we define

$$\ell_i(t, v, w) := \begin{cases} w^i & \text{if } (w^0, w) \in Q(t, v) \text{ for some } w^0 \in \boldsymbol{R}, \\ +\infty & \text{otherwise.} \end{cases}$$

Observe that $\ell_i(t, v, w) \geq w^i$ and that $\ell_i(t, \cdot, \cdot)$ is lower semicontinuous for every $t \in T$, by property (K). We define the optimal control problem (B_{red}) as follows:

$$\text{minimize } I_{\text{red}}(\pi, z) := I^*_{\ell_0}(\pi, z) + I_{\bar{g}}(\pi, y_{\pi,z}) + e(\pi, s(y_{\pi,z})) + \bar{e}(\pi, y_{\pi,z})$$

over all pairs (π, z), where $z : \Gamma(\pi) \to U_{\text{red}}$ is measurable and satisfies

$$\int_{\Gamma(\pi)} |b_{\text{red}}(t, z(t))| \mu(dt) < +\infty \qquad \text{(admissibility)},$$

$$I^*_{\ell_1}(\pi, z) + \alpha_1(\pi) \le 0, \dots, I^*_{\ell_m}(\pi, z) + \alpha_m(\pi) \le 0 \qquad \text{(feasibility)}.$$

Here $U_{\text{red}} := \boldsymbol{R}^\nu \times [-\infty, +\infty]^m$, $b_{\text{red}}(t, v, w) := |v|$, and $y_{\pi,z}$ is given by

$$y_{\pi,z} := \Phi(\pi, \mathcal{A}_{\text{red}}(\pi, z)),$$

with

$$\mathcal{A}_{\text{red}}(\pi, z)(t) := \int_{\Gamma(\pi)} \kappa(t, \tau) b_{\text{red}}(\tau, z(\tau)) \mu(d\tau).$$

Again outer integration is used, as follows:

$$I^*_{\ell_i}(\pi, z) := \inf \left\{ \int_{\Gamma(\pi)} \phi \, d\mu : \phi \in L_1(T), \phi(t) \ge \ell_i(t, z(t)) \quad \text{a.e.} \right\}.$$

PROPOSITION 4.11. *Under the conditions of* §2, *there exists an optimal solution* (π_*, z_*) *for* (B_{red}).

Proof. Let us apply Proposition 4.10. By definition of ℓ_0, the original lower bound for g_0 implies that

$$\ell_0(t, v, w) \ge \chi'(|v|) - \phi_0(t) \ge -\phi_0(t) \quad \text{on } T \times U_{\text{red}}.$$

Likewise, the original inequality $g_i + \epsilon\chi'(|b|) \ge -\phi_\epsilon$ now implies that

$$\ell_i(t, v, w) + \epsilon\chi'(|v|) \ge -\phi_\epsilon(t) \quad \text{on } T \times U_{\text{red}}.$$

Note further that $b_{\text{red}}(t, v, w) := |v|$, defined above, is automatically inf-compact in (v, w) (note the role played by the intrinsic compactness of $[-\infty, +\infty]^m$). Thus condition (i) of Remark 2.1 is valid. Also, above the $\ell_i(t, v, w)$ were seen to be lower semicontinuous in the variable (v, w); thus, condition (ii) of that remark is met. Lastly, we work here with $U_{\text{red}}(t) \equiv U_{\text{red}}$, so condition (iii) of that remark holds, too. The remaining conditions of Proposition 4.10 are easily seen to hold as well for (B_{red}), so we conclude from Proposition 4.10 that (B_{red}) has an optimal solution (π_*, z_*). □

LEMMA 4.12. $\inf(B_{\text{red}}) \le \inf(B)$.

Proof. For any pair $(\pi, u) \in \mathcal{G}$, feasible and admissible for (B), we obtain an admissible pair (π, z) for (B_{red}) by setting $z(t) := (b(t, u(t)), g_1(t, u(t)), \dots, g_m(t, u(t)))$ (recall that for (B) itself the g_i were—and still are—measurable). Clearly, $\ell_i(t, z(t)) = g_i(t, u(t))$ on $\Gamma(\pi)$ for all $i = 1, \dots, m$, so (π, z) is also feasible. Furthermore, $\ell_0(t, z(t)) \le g_0(t, u(t))$ and $y_{\pi,u}(t) = y_{\pi,z}(t)$, so it follows that $I_{\text{red}}(\pi, z) \le I(\pi, u)$. □

We now finish the proof of Theorem 2.2. By Lemma 4.12, Proposition 4.11, and $\inf(B) < +\infty$, it follows that $I_{\text{red}}(\pi_*, z_*)$; hence $I^*_{\ell_0}(\pi_*, z_*)$ is finite. The latter implies that there exists $\phi_* \in L_1(\Gamma(\pi_*))$ with $\ell_0(t, z_*(t)) \le \phi_*(t)$ and $\int_{\Gamma(\pi)} \phi_* d\mu = I^*_{\ell_0}(\pi_*, z_*)$; cf. [8, Prop. A.1]. In particular, this implies that $\ell_0(t, z_*(t)) < +\infty$ almost everywhere. By what was observed about attainment of the infimum in connection with finiteness of the expression defining ℓ_0, it follows that, for almost every t in $\Gamma(\pi_*)$, there exists

$u_t \in U(t)$ such that $\ell_0(t, z_*(t)) = g_0(t, u_t)$, $b(t, u_t) = v_*(t)$, and $g_i(t, u_t) \leq w_*^i(t)$ almost everywhere for all i. Here we write $z_*(t) =: (v_*(t), w_*^1(t), \ldots, w_*^m(t))$. By a standard measurable selection argument, this implies that there exists a measurable function $u_* : \Gamma(\pi_*) \to U$ such that $u_*(t) \in U(t)$, $g_0(t, u_*(t)) \leq \phi_*(t)$, $b(t, u_*(t)) = v_*(t)$, and $g_i(t, u_*(t)) \leq w_*^i(t)$ almost everwhere for all i. By the properties of z_*, it is now easy to see that $(\pi_*, u_*) \in \mathcal{G}$ is feasible and admissible for (B) and satisfies $I(\pi_*, u_*) \leq I_{\text{red}}(\pi_*, z_*) = \inf(B_{\text{red}}) \leq \inf(B)$. This proves that (π_*, u_*) is the desired optimal control pair for (B). The proof of Theorem 2.2 has thus been finished.

Taking Remark 4.5 into account, it is easy to see that all conditions of Theorem 2.2 are fulfilled in Theorem 2.3, except for that concerning the underlying measure space (now T does not have to be compact and metric). Compactness and metrizability of T were only used in the proof of Lemma 4.8, to ensure the existence of a Riesz representation. In all other steps of the proof of Theorem 2.2, an abstract measure space could be used, except for the proof of Lemma 4.1. There the fact was used that the σ-algebra $\mathcal{T}$ (T being there a separable metric space) was countably generated (indeed, this implies separability of $L_1 := L_1(T, \mathcal{T}, \mu; C(\hat{U}))$ and, by [19, 12.F], metrizability of the weak star topology on $\hat{R}$). Yet we need not even retain the condition that $\mathcal{T}$ is countably generated, by concentrating on a minimizing sequence for (B'), and using a conditional expectation argument; see the proof of [6, A.3, p. 592].

5. Applications and discussion. In this section, applications are presented to show that Theorems 2.2 and 2.3 are very flexible and general. We start with an example that describes an important dynamical system used in this section.

Example 5.1. Consider on $T = [0, 1]$ the following differential equation in n dimensions:

$$\dot{y}(t) = B(t)y(t) + b(t, u(t)) \quad \text{a.e. in } [t_0, t_1],$$

with variable initial/final time $t_0, t_1 \in T$, $t_0 \leq t_1$. Here the matrix-valued function $B : [0, 1] \to \boldsymbol{R}^{n \times n}$ is supposed to be Lebesgue-integrable. Also, $b : [0, 1] \times U \to \boldsymbol{R}^n$ is supposed to be product measurable, where U is a Borel-measurable subset of $\boldsymbol{R}^q$.

Suppose that the trajectories y must "hit" a compact space-time target set $H \subset [0, 1] \times \boldsymbol{R}^n$, i.e., must satisfy

$$(t', y(t')) \in H \quad \text{for some } t' \in [t_0, t_1].$$

We choose for the space Π of control parameters the set of all $\pi := (t_0, t_1, t', p')$ with $(t_0, t_1) \in [0, 1]^2$, $t_0 \leq t' \leq t_1$, and $(t', p') \in H$. We set $\Gamma(\pi) := [t_0, t_1]$ and

$$\mathcal{A}(\pi, u)(t) := \int_{[t_0, t_1]} \kappa(t, \tau) b(\tau, u(\tau)) d\tau,$$

where $\kappa(t, \tau) := 1$ for $t \geq \tau$ and $\kappa(t, \tau) = 0$, otherwise. Note that this gives $\mathcal{A}(\pi, u)(t) = \mathcal{A}(\pi, u)(t_1)$ for $t \geq t_1$ and $\mathcal{A}(\pi, u)(t) = 0$ for $t \leq t_0$ (recall that we write $\pi := (t_0, t_1, t', p')$). With $\sigma(\alpha) := \alpha$, continuous hereditarity is obvious. The well-known variation of constants formula for the "real" solution $\tilde{y}_{\pi, u}$, corresponding to an admissible pair $(\pi, u) \in \mathcal{G}$, is as follows [37, II.4.8]:

$$\tilde{y}_{\pi, u}(t) := E(t, t')p' + \int_{t'}^{t} E(t, \tau) b(\tau, u(\tau)) d\tau,$$

for $t_0 \leq t \leq t_1$; this formula remains valid for $t < t'$ by the usual change of sign convention. Here $E(t, \tau) := E(t)E^{-1}(\tau)$, where E and $F := E^{-1}$ are fundamental

matrix solutions of the homogeneous differential equation: $\dot{E} = BE$, $E(0) = I_n$, and $\dot{F} = -FB$, $F(1) = I_n$ (identity matrix). The solutions E and F are absolutely continuous, hence bounded in matrix-norm on $[0,1]$. By partial integration in the above formula, we obtain

$$\tilde{y}_{\pi,u}(t) = E(t,t')p' + \mathcal{A}(\pi,u)(t) - E(t,t')\mathcal{A}(\pi,u)(t') + \int_{t'}^{t} E(t,\tau)B(\tau)\mathcal{A}(\pi,u)(\tau)d\tau$$

for $t \in [t_0,t_1]$ (also this expression is valid for $t < t'$ by the change of sign convention). Therefore, $\Phi : \Pi \times C([0,1];\boldsymbol{R}^n) \to C([0,1];\boldsymbol{R}^n)$ can be chosen as follows:

$$\Phi((t_0,t_1,t',p'),y)(t) := E(t,t')p' + y(t) - E(t,t')y(t') + \int_{t'}^{t} E(t,\tau)B(\tau)y(\tau)d\tau.$$

Observe that $\Phi(\pi,y)$ is continuous in (π,y) and affine in y, as it should be. Note that the constant $c_{\Phi,1} := 1 + \sup_{(t,\tau)\in[0,1]^2, t\geq\tau} |E(t,\tau)|(1 + \int_0^1 |B(t)|\,dt)$ is finite; existence of a suitable finite $c_{\Phi,2}$ follows by compactness of H. It is easy to verify the following facts for the formal solution $y_{\pi,u} := \Phi(\pi,\mathcal{A}(\pi,u))$: On $[t_0,t_1]$, the formal solution $y_{\pi,u}$ coincides with the real solution $\tilde{y}_{\pi,u}$; on $[0,t_0]$ and $[t_1,1]$, the formal solution $y_{\pi,u}$ is the solution of the homogeneous equation $\dot{y} = By$, respectively, with the final condition $y(t_0) = y_{\pi,u}(t_0)$ and the initial condition $y(t_1) = y_{\pi,u}(t_1)$. Thus, we see that the trajectory cost integral functional for (π,u) (defined by integration over $\Gamma(\pi) = [t_0,t_1]$) reflects the costs along the real solution $\tilde{y}_{\pi,u}$. Likewise, for the indirect and direct final cost terms $e(\pi,s(y))$ and $\bar{e}(\pi,y)$ to be meaningful, it is necessary that they, too, are only based on the restriction of y to the time interval $\Gamma(\pi) = [t_0,t_1]$. For instance, to take $s_1(\pi,y) := y(t_0)$ makes sense (by $s_1(\pi,y_{\pi,u}) = s_1(\pi,\tilde{y}_{\pi,u})$), but to set $s_1(\pi,y) := y(0)$ (when $t_0 > 0$) makes only formal sense.

COROLLARY 5.2. *Using the notation of Example* 5.1, *consider the following problem* (B_1):

$$\textit{minimize} \int_{t_0}^{t_1} g_0(t,u(t))dt + \int_{t_0}^{t_1} \bar{g}(t,y(t))dt + c(t_0,t_1,y(t_0),y(t_1)) + \bar{c}(t_0,t_1,y)$$

over all $(t_0,t_1,t',p') \in \Pi$, *all absolutely continuous* $y : [t_0,t_1] \to \boldsymbol{R}^n$ *and all measurable* $u : [t_0,t_1] \to U$, *satisfying*

$$\begin{gathered} \dot{y}(t) = B(t)y(t) + b(t,u(t)) \quad \textit{a.e. in } [t_0,t_1], \\ u(t) \in U(t) \quad \textit{a.e. in } [t_0,t_1], \\ y(t') = p', \\ (t_0,t_1,t',p',y(t_0),y(t_1)) \in D. \end{gathered}$$

Here D *is a closed subset of* $[0,1]^2 \times H \times \boldsymbol{R}^{2n}$; $c : [0,1]^2 \times \boldsymbol{R}^{2n} \to (-\infty,+\infty]$ *and* $\bar{c} : [0,1]^2 \times C([0,1]) \to (-\infty,+\infty]$ *are lower semicontinuous and bounded from below. Suppose also that* $\bar{c}(t_0,t_1,\cdot)$ *is concave on* $C([0,1])$ *for every* t_0,t_1. *Let the assumptions of Example* 5.1 *hold for the dynamical system; let* $g_0 : [0,1] \times U \to (-\infty,+\infty]$ *and* $\bar{g} : [0,1] \times \boldsymbol{R}^n \to (-\infty,+\infty]$ *satisfy the measurability, lower semicontinuity, concavity, growth, and orientor field conditions of Theorem* 2.2 (*the constants* $c_{\Phi,i}$ *were discussed in Example* 5.1). *Assume that* $\inf(B_1) < +\infty$. *Then there exists an optimal control pair for* (B_1).

Proof. In Example 5.1, we already found the representation and integral operators Φ and $\mathcal{A}$ for the dynamical system of (B_1). For control and trajectory integral cost

terms, the conditions of Theorem 2.2 obviously hold. As for the indirect final costs, we define a lower semicontinuous function $e : \Pi \times \boldsymbol{R}^2 \to (-\infty, +\infty]$ by setting

$$e(t_0, t_1, t', p', \zeta_1, \zeta_2) := \begin{cases} c(t_0, t_1, \zeta_1, \zeta_2) & \text{if } (t_0, t_1, t', p', \zeta_1, \zeta_2) \in D, \\ +\infty & \text{otherwise.} \end{cases}$$

Together with this, we set $s_1(t_0, t_1, t', p', y) := y(t_0)$ and $s_2(t_0, t_1, t', p', y) := y(t_1)$; these evaluations are continuous in all variables jointly, and linear in y, as required in Theorem 2.2. The treatment of the direct final cost term is obvious. Therefore, we conclude that all conditions of Theorem 2.2 have been met. The result follows immediately. □

The main results of Raymond [31, Thm. 4.2], Cellina and Colombo [14], and the main existence result without convexity of Cesari [15, 16.5.i] are special cases of Corollary 5.2. This is now demonstrated.

In the notation of the present paper, Raymond works with the dynamical system

$$\begin{gathered} \dot{y}(t) = B(t)y(t) + u'(t) \quad \text{a.e. in } [t_0, t_1], \\ (u(t), u'(t)) \in U'(t) \quad \text{a.e. in } [t_0, t_1], \\ y(t_0) = p \in P. \end{gathered}$$

To understand this, note that he works with a *multifunction* $b : M \to 2^{\boldsymbol{R}^n}$, having measurable graph [31, (H1)]. Although in appearance it would seem more general to work with the differential inclusion

$$\dot{y}(t) - B(t)y(t) \in b(t, u(t)), \qquad u(t) \in U(t) \quad \text{a.e. in } [t_0, t_1],$$

as he does, we observe that this relation is, after all, only equivalent to

$$\dot{y}(t) - B(t)y(t) = u'(t), \quad u'(t) \in b(t, u(t)), \quad u(t) \in U(t) \quad \text{a.e. in } [t_0, t_1],$$

by an implicit measurable function theorem [13, III.38]. Taking for $U'(t)$ the set of all pairs $(v, v') \in \boldsymbol{R}^{q+n}$ with $v' \in b(t, v)$ shows the point (it is no coincidence that in his hypothesis [31, (H2)] precisely the present $U'(t)$ is required to be closed for every t). As for the hypotheses of the above corollary, these hold in Raymond's paper by the following substitutions : If his parameter q equals 1, then take $\chi'(\xi) := c_1\Phi_1$ (c_1, Φ_1 is as in his condition (H12) on p. 125) and $\bar{m}_1(\xi) := \xi^q = \xi, \bar{\phi}_1 \equiv c_2$ (here c_2 is as in his condition (H6) on p. 112). By superlinear growth of his Φ_1, the required limit property follows. If Raymond's parameter q is strictly larger than 1, then use $\chi'(\xi) := c_1\xi^q, \bar{m}_1 := \xi^q, \bar{m}_2 := |\xi|^s$ (his s then satisfies $1 \leq s < q$) and $\bar{\phi}_1 \equiv c_2, \bar{\phi}_2 :=$ his a_2. Actually, Raymond's (H6) has $c_1 > c_2 c_{\Phi,1}^2$, with $c_{\Phi,1} := \sup_{t \geq \tau} |E(t, \tau)|$ (cf. Example 5.1), but let us observe that this can be relaxed into the slightly weaker $c_1 > c_2 c_{\Phi,1}$ (it is weaker since $c_{\Phi,1} \geq 1$, as follows from the semigroup property). When this is substituted, we obtain precisely the desired limit property of Theorem 2.2. Furthermore, in the notation developed above, the orientor field corresponding to [31] is given by

$$Q(t, v) := \{w \in \boldsymbol{R} : w \geq g_0(t, v), (v, v) \in U'(t)\}.$$

By Raymond's (H12), there exist a nonnegative $\Phi(t, |v|)$ (his notation), inf-compact in $|v|$, and an integrable function ϕ such that $g_0(t, v) \geq \Phi(t, |v|) + c_1|v'|^q - \phi(t)$ whenever $v' \in c(t, v)$. Thus, property (K) holds by Remark 2.1, since his conditions

cause $U'(t)$ to be closed, as noted above. All remaining assumptions are easily seen to hold in Raymond's paper (see also Example 5.1). In passing, in the above derivation, an improvement of the growth condition was indicated: $c^2_{\Phi,1}$ can be replaced by $c_{\Phi,1}$ in his (H6). More significant generalizations are that, unlike [31], Corollary 5.2 does not ask for an explicit (inf-)compactness condition for the function g_0 and that the "hitting" condition improves upon the initial condition used in [31]. Also, there is a minor technical improvement in terms of the conditions imposed on the function B (Raymond supposes continuity of B).

Next, we observe that the result of Cellina and Colombo [14] also follows from Corollary 5.2, since their result already follows from Raymond's [31, Thm. 4.2] (they work with a calculus of variations model, which translates into the optimal control model of the corollary by taking $B = 0$ and $b(t, v) := v$).

Corollary 5.2 also generalizes [15, 16.5.i], the principal existence result "without convexity" of Cesari [15]; this result has been formulated in its strongest form by Cesari in his comments on p. 464 of [15] ("alternate hypotheses"), which serve to strengthen the actual statement of 16.5.i in [15]. Of course, the most important difference in Cesari's result lies in fact that he supposes $\bar{g}(t, \cdot)$ to be *linear*, instead of concave (in that case, we can set $\bar{m}_1(|\eta|) := |\eta|$, so the required limit property holds automatically by superlinear growth of χ'). It should be noted that the property (K) condition used in [15], which might seem to be more demanding at first, is equivalent to the one used in this paper. A more minor point is that Cesari assumes—unneccessarily—that B be bounded. His measurability and (semi)continuity conditions are stated in an equivalent "Scorza–Dragoni form."

An even more general version of the above result, which deals with the optimal control of a linear Volterra equation, could now be stated. It considerably generalizes the main existence result of Angell in [1]. However, in [10, Cor. 3.2] such a Volterra equation has already been shown to fit into the model (there this fact was used to derive from Theorem 2.2 a generalization of the *bang-bang* existence result of Angell [1]); with the above corollary in mind, we can easily obtain the intended extension. (Incidentally, as mentioned in the Introduction, applications of the present paper to the subject of optimal bang-bang control can be found in [10].)

Furthermore, the recent existence result of Mariconda [25, Thm. 2], stated first for a parametric problem in the calculus of variations, also follows from Corollary 5.2 above. More precisely, we improve one of Mariconda's conditions in passing. Indeed, as was already observed in [25, p. 296], by a classical argument, his variational problem can be restated in the following optimal control form: Minimize $\int_0^{t_1} g_0(u(t))dt$ over all t_1 in some bounded closed interval $\boldsymbol{R}_+$ (we can suppose this to be [0,1] without any loss of generality) and over all measurable $u : [0, 1] \to U$, where U is the unit sphere in $\boldsymbol{R}^n$ (actually, any compact subset of $\boldsymbol{R}^n$ would do for the present proof). The dynamical system is then $\dot{y}(t) = u(t)$ almost everywhere. Also, the following constraints are imposed in Mariconda's problem: $y(0) \in H'$, $y(t_1) \in D'$, where $H' \subset \boldsymbol{R}^n$ is compact and $D' \subset \boldsymbol{R}^n$ closed. Thus, in terms of Corollary 5.2, we have $H = [0, 1] \times H'$, $B \equiv 0$, $b(t, v) = v$, $U(t) \equiv U$, and the corresponding D is the set of all $(0, t_1, t', p', y_0, y_1)$ with $t_1 = t' \in [0, 1]$, $p' \in H'$, $y_0 \in H'$ and $y_1 \in D'$ (for instance). Note that, in his setup, the conditions of Remark 2.1 are satisified (if we take $g_0 : U \to \boldsymbol{R}$ to be lower semicontinuous on the compact U, it is inf-compact; this is less than what Mariconda needs). As for coercivity, we can, of course, set $\chi'(\xi) = 0$ for $\xi \leq 1$ and $\chi'(\xi) = +\infty$ for $\xi > 1$ (trivially, we set $\bar{g} \equiv 0$, $\phi_i \equiv 0$, and so forth).

Another existence result to which Corollary 5.2 applies can be found in [20],

[21]. Although the main existence result of Ioffe in [20] (in [21], this is Theorem 2 of §9.2.1) addresses existence under convexity conditions, the special problem: Minimize $\int_{t_0}^{t_1}[|u(t)|^{\nu_1} - |y(t)|^{\nu_2}]dt$, $\dot{y}(t) = u(t)$, $y(t_0) = \eta_0$, $y(t_1) = \eta_2$, which is considered in §3 of [20] (and in §9.2.1 of [21]) can be approached by means of Corollary 5.2. For $\nu_1 > \nu_2 \geq 1$, this is straightforward (set $g_0(t,v) := |v|^{\nu_1}$, $\bar{g}(t,\eta) := |\eta|^{\nu_2}$). For $\nu_1 = \nu_2$, the limit property of the corollary (i.e., the one of Theorem 2.2) certainly holds if $t_1 - t_0 < 1$. Ioffe goes further by showing that, in this case, $t_1 - t_0 < 2$ is actually enough. (Incidentally, for $t_1 - t_0 \geq 2$, the infimum of the control problem is $-\infty$, and no optimal solutions exist.)

Let us also recognize that the simple problem (B_0) is out of reach of all the results mentioned above. Yet it follows directly from Corollary 5.2: Set $\Gamma(t_0,t_1,t',p') \equiv [0,1]$ for all (t_0,t_1,t',p') in Π, $g_0(t,u) := (v^2-1)^2$, $\bar{g}(t,\eta) := -\eta^2$, $e'(t_0,t_1,t',p',y) := -\exp(-\|y\|)$, and $D := [0,1]^2 \times H \times \boldsymbol{R}^2$. We also set $b(t,v) := v$ and $B \equiv 0$, $c \equiv 0$, and $\bar{c}(t_0,t_1,y) := -\exp(-\|y\|)$. Then it is easy to see that the assumptions and conditions of Corollary 5.2 hold, with $\chi'(\xi) := [\max(\xi^2-1,0)]^2$ and $\bar{m}_1(\eta) := \eta^2$.

These applications of Theorem 2.2 are finished by stating another existence result that is out of the reach of the current literature; it concerns the optimal control of a functional-integral equation over a fixed compact metric time domain T.

COROLLARY 5.3. *In the notation of Theorem 2.2, but with a trivial control parameter space* $\Pi := \{0\}$, *consider the following optimal control problem* (B_2):

$$\text{minimize } \int_T g_0(t,u(t))\mu(dt) + \int_T \bar{g}(t,y_u(t))\mu(dt)$$

over all continuous $y : T \to \boldsymbol{R}^n$ *and all measurable* $u : T \to U$, *satisfying*

$$y(t) = Sy(t) + \mathcal{A}(0,u)(t) \quad \text{on } T,$$
$$u(t) \in U(t) \quad \text{a.e. in } T.$$

Here S *is the functional-integral operator given by*

$$Sy(t) := \int_T \kappa'(t,\tau)\theta(y)(\tau)\mu(d\tau),$$

where θ *is a bounded linear operator from* $\mathcal{C}(T;\boldsymbol{R}^n)$ *into* $L_\infty(T,\mathcal{T},\mu;\boldsymbol{R}^\nu)$. *It is supposed that* $I - S$ *is an injection (under suitable hereditarity conditions, this is known to be the case* [37, II.5.6]). *Also,* $\kappa' : T \times T \to \boldsymbol{R}^{\nu\times n}$ *is such that* $t \mapsto \kappa'(t,\cdot)$ *can be considered as a continuous mapping from* T *into* $L_1(T,\mathcal{T},\mu;\boldsymbol{R}^{\nu\times n})$. *Let* $g_0 : [0,1]\times U \to (-\infty,+\infty]$ *and* $\bar{g} : [0,1]\times\boldsymbol{R}^n \to (-\infty,+\infty]$ *satisfy the measurability, lower semicontinuity, concavity, growth, and orientor field conditions of Theorem* 2.2, *taking* $c_{\Phi,1} := \|(I-S)^{-1}1\|$ *and* $c_{\Phi,2} := 0$. *Assume that* $\inf(B_2) < +\infty$. *Then there exists an optimal control function for* (B_2).

Proof. Since S is a compact linear operator [37, II.5.5], it follows by [37, I.3.13] that the inverse $(I-S)^{-1}$ is well defined and continuous (Fredholm alternative); cf. [37, II.5.5]. So if we set $\Pi := \{0\}$ and $\Phi(y,0) := (I-S)^{-1}y$, the representation structure for the trajectories, as required in Theorem 2.2, holds. All other conditions are easily seen to hold, so the result follows from Theorem 2.2. □

Let us finish with an application of Theorem 2.3. It coincides with the existence result of Artstein [2], [5].

COROLLARY 5.4. *Consider the problem* (B_3)

$$\text{minimize } \int_T g_0(t,u(t))\mu(dt)$$

over all measurable functions $u : T \to U$ *satisfying*

$$u(t) \in U(t) \quad \text{a.e. in } T$$

and

$$\int_T g_j(t, u(t))\mu(dt) \leq \beta_j, \qquad j = 1, \ldots, m,$$

where $(T, \mathcal{T}, \mu)$ *is a* σ*-finite nonatomic measure space, and* U, M *are as in* §2. *Suppose that* $g_0, \ldots, g_m : M \to (-\infty, +\infty]$ *are all measurable and lower semicontinuous in their second variable and suppose that*

$$g_m(t, \cdot) \text{ is inf-compact for every } t \in T$$

and that $U(t)$ *is closed for all* t. *Finally, suppose that*

$$g_m \text{ is integrably bounded from below}$$

and that, for every $\epsilon > 0$, *there exists an integrable* $\phi_\epsilon \in L_1^+(T)$ *such that*

$$g_i(t, v) + \epsilon g_m(t, v) \geq -\phi_\epsilon(t) \quad \text{on } M$$

for $i = 0, 1, \ldots, m-1$. *Assume that* $\inf(B_3) < +\infty$. *Then there exists an optimal solution for* (B_3).

Proof. By Remark 2.1, we can simply apply Theorem 2.3. □

Acknowledgments. I thank the referees for their helpful comments and criticism. The evolution of this paper was greatly influenced by invited lectures in Italy, France, Canada, and the Netherlands. To all hosts and genii loci involved, I extend my special thanks.

AN ADAPTIVE SERVOMECHANISM FOR A CLASS OF INFINITE-DIMENSIONAL SYSTEMS*

HARTMUT LOGEMANN† AND ACHIM ILCHMANN‡

Abstract. A universal adaptive controller is constructed that achieves asymptotic tracking of a given class of reference signals and asymptotic rejection of a prescribed set of disturbance signals for a class of multivariable infinite-dimensional systems that are stabilizable by high-gain output feedback. The controller does not require an explicit identification of the system parameters or the injection of a probing signal. In contrast to most of the work in universal adaptive control, this paper is based on an input-output approach and the results do not require a state-space representation of the plant. The abstract input-output results are applied to retarded systems and integrodifferential systems.

Key words. servomechanisms, adaptive control, high-gain feedback, infinite-dimensional systems, functional differential equations, input-output methods

1. Introduction.

One of the most important applications of feedback is to achieve servoaction, that is, to obtain a closed-loop system that tracks a given class of reference signals and rejects a given class of external disturbances with zero asymptotic error. This problem has been well understood for many years provided that the plant is linear and time-invariant and the plant uncertainty is sufficiently small (see Wonham [30, p. 203] and Vidyasagar [27, p. 294] for finite-dimensional systems and Francis [4], Callier and Desoer [2], and Curtain [3] for infinite-dimensional systems). The basic design principle in the theory of linear servomechanisms, which is also referred to as the *internal model principle*, says (roughly speaking) that a controller that achieves robust servoaction necessarily contains a duplicate of the dynamics of the reference and disturbance signals.

If the plant uncertainty is large, which is the case if only certain structural information on the plant is available to the designer, it is desirable to construct a universal adaptive servomechanism, that is, a fixed nonlinear controller that achieves servoaction for a whole prescribed class of linear time-invariant systems and all possible initial conditions without explicit identification of the system parameters. Although the problem of universal adaptive stabilization of finite and infinite-dimensional systems has received considerable attention in recent years (cf. e.g., Mårtensson [17], [18], Logemann and Owens [14], Logemann and Mårtensson [13], and the references therein), there are only few papers on universal adaptive servomechanisms, which in addition deal exclusively with finite-dimensional systems. Mårtensson [19] pointed out that adaptive tracking of constant reference signals can be easily achieved for a given class of multivariable systems if a universal adaptive stabilizer is known and the class is invariant under precompensation by an integrator. Helmke, Prätzel-Wolters, and Schmid [8] proved a similar result for single-input single-output systems allowing for a more general class of reference signals including ramps, linear combinations of sinusoidal signals, etc. If the plant is known to lie in a given finite set of (multivariable) systems, if the reference and disturbance signals belong to the solution space of a given linear autonomous differential equation, and if an L^∞-bound on the disturbances is known, Miller and Davison [21] constructed a switching controller that solves the servoproblem for any plant in this finite set. In [20] Miller and Davi-

son presented a low-gain controller that carries out asymptotic error regulation for constant reference and disturbance signals for any multivariable plant, provided it is asymptotically stable and has no transmission zeros at zero. For the class of all single-input single-output, relative degree one or two, minimum-phase systems of McMillan degree less than or equal to n, Morse [22] constructed a $4(n+1)$-dimensional model reference adaptive controller that achieves asymptotic tracking of any signal generated by a two-dimensional reference system. On the basis of high-gain concepts, Mareels [16] introduced a control law that solves the tracking problem for any single-input single-output minimum-phase system of known relative degree, provided the sign of the high-frequency gain and an upper bound on its magnitude is known. Finally, for the class of all single-input single-output minimum-phase systems having relative degree one, Helmke, Prätzel-Wolters, and Schmid [9] constructed a high-gain controller that has the property that the resulting closed-loop system tracks any reference signal annihilated by a given linear ordinary differential operator with constant coefficients.

The purpose of this paper is to construct a universal adaptive servomechanism for the class of multivariable infinite-dimensional systems that are minimum-phase and have an invertible high-frequency-gain. We show that the series interconnection of the controller presented in Byrnes and Willems [1] and a suitable precompensator solves the adaptive servoproblem for the class of systems under consideration. This result is also new for the finite-dimensional case. It generalizes the result in [9], where an adaptive tracking problem was solved for finite-dimensional single-input single-output systems. The disturbance rejection problem is not addressed in [9]. Moreover, the proof in [9] does not extend to multivariable systems; neither does it carry over to infinite-dimensional plants, and so the generalization is far from being trivial. We mention that in [9] a state-space approach is used, while our treatment is based on the input-output set-up for high-gain adaptive stabilization as developed by Logemann and Owens [14]. So, in contrast to almost all papers in the area, our approach does not require a state-space model of the plant. Non-zero initial conditions are taken into account by using "initial-condition terms." The input-output results are applied to retarded systems and integrodifferential convolution systems.

The paper is organized as follows. In §2 we introduce a class of infinite-dimensional systems that are stabilizable by high-gain feedback and will be dealt with in the rest of the paper. Moreover, we collect a number of results on a functional differential equation of Volterra type that will be useful in what follows. Section 3 shows that the high-gain based switching algorithm, introduced by Byrnes and Willems [1] in a finite-dimensional state-space set-up, stabilizes any infinite-dimensional plant belonging to the class of systems introduced in §2. Section 4 contains the main result of the paper. We prove that the series connection of the adaptive stabilizer presented in §3, followed by a suitable precompensator containing an internal model of the dynamics of the reference and disturbance signals, achieves servoaction for the class of systems under consideration. Section 5 is devoted to the application of the input-output results of §4 to retarded systems and integrodifferential convolution systems. In particular it is shown that the adaptive servomechanism presented in §4 achieves "internal stability" in the sense that the internal variables of the plant and the precompensator remain bounded provided that the reference signal is bounded. The proof of a technical result is relegated to the Appendix.

Nomenclature.

$\mathbb{C}_+ :=$ open right-half plane.

$\mathbb{C}_- :=$ open left-half plane.

$LL^p(\mathbb{R}_+, \mathbb{R}^n) :=$ vector space of locally p-integrable functions defined on $\mathbb{R}_+$ with values in $\mathbb{R}^n$.

$H^\infty(\mathbb{C}^{n\times n}) :=$ algebra of bounded holomorphic functions defined on $\mathbb{C}_+$ with values in $\mathbb{C}^{n\times n}$.

$H^2(\mathbb{C}^n) :=$ the usual Hardy–Lebesgue space of order 2 of holomorphic functions defined on $\mathbb{C}_+$ with values in $\mathbb{C}^n$.

$BV([a,b],\mathbb{R}^{n\times n}) :=$ vector space of $\mathbb{R}^{n\times n}$-valued functions of bounded variation defined on $[a,b]$.

$M(\mathbb{R}_+,\mathbb{R}^{n\times n}) :=$ vector space of bounded Borel measures on $\mathbb{R}_+$ with values in $\mathbb{R}^{n\times n}$.

Let f be a function defined on $[0,a)$, where $0 < a \le \infty$. Then for all $\tau \in [0,a)$,

$$(\pi_\tau f)(t) := \begin{cases} f(t), & 0 \le t \le \tau, \\ 0, & t > \tau. \end{cases}$$

$\mathcal{L}$ denotes the Laplace transform.

The superscript "$\hat{}$" is used to denote Laplace transformed or Laplace–Stieltjes transformed functions.

2. Preliminaries and system description. We shall assume that externally our plant is described by a transfer-function matrix G of size $m \times m$ which is meromorphic on $\mathbb{C}_+$ and satisfies

$$\text{(2.1)} \qquad \begin{cases} G^{-1}(s) = sD^{-1} + H(s), \\ \text{where} \quad D \in \mathbb{R}^{m\times m},\ \det(D) \neq 0 \quad \text{and} \quad H \in H^\infty(\mathbb{C}^{m\times m}). \end{cases}$$

Of course (2.1) is equivalent to

$$\text{(2.2)} \qquad G(s) = \left(I + \frac{1}{s}DH(s)\right)^{-1} \frac{1}{s}D,$$

i.e., G is the feedback interconnection of the integrator $(1/s)D$ and the transfer-function matrix H.

In order to characterize condition (2.1) in terms of the zeros and the high-frequency behavior of G, we have to make precise what we mean by a zero of a meromorphic transfer-function matrix.

DEFINITION 2.1. *Suppose that R is a matrix of size $m \times m$ whose entries are meromorphic functions defined on a region $\Omega \subset \mathbb{C}$. Let (U,V) be a holomorphic right-coprime factorization of R over Ω, i.e., U and V are holomorphic matrices of size $m \times m$ defined on Ω such that $\det(V(s)) \not\equiv 0$, $R(s) = U(s)V^{-1}(s)$, and there exist holomorphic matrices X and Y of size $m \times m$ defined on Ω satisfying $X(s)U(s)+Y(s)V(s) \equiv I_m$.*[†] *The zeros of $R(s)$ are defined to be the zeros of* $\det(U(s))$.

PROPOSITION 2.2. *Let $G(s)$ be a meromorphic transfer-function matrix of size $m \times m$ defined on a region $\Omega \supset \overline{\mathbb{C}}_+$. Then $G^{-1}(s)$ admits a decomposition of the form* (2.1) *if and only if*

(i) $sG(s) - D = O(1/s)$ *as* $|s| \to \infty$ *in* $\mathbb{C}_+$,

[†] Since the ring of holomorphic functions defined on a region has the property that finitely generated ideals are principal (see Rudin [23, p. 328]) and since the field of meromorphic functions defined on a region is the quotient field of the ring of holomorphic functions defined on that region (see Rudin [23, p. 327]), it follows from Vidyasagar, Schneider, and Francis [28] that such a factorization exists and is unique up to multiplication from the right by unimodular holomorphic matrices.

and

(ii) $G(s)$ *has no zeros in* $\overline{\mathbb{C}}_+$.

Proof. See Logemann and Zwart [15]. □

Note that condition (i) in Proposition 2.2 is a generalization of the relative-degree one condition for finite-dimensional single-input single-output systems.

Remark 2.3. The transfer-function matrix G of a stabilizable and detectable finite-dimensional system $\dot{x} = Ax + Bu$, $y = Cx$ satisfies (2.1) if and only if the system is minimum-phase, i.e.,

$$\det \begin{pmatrix} sI - A & -B \\ C & 0 \end{pmatrix} \neq 0 \quad \text{for all } s \in \overline{\mathbb{C}}_+,$$

and has invertible high-frequency gain, i.e., $\det(CB) \neq 0$. Moreover the matrix D in (2.1) is given by CB.

In the following we shall assign an operator $\mathcal{H} : L^2(\mathbb{R}_+, \mathbb{C}^m) \to L^2(\mathbb{R}_+, \mathbb{C}^m)$ to the transfer-function matrix H by defining $\mathcal{H} := \mathcal{L}^{-1}\mathcal{M}_H\mathcal{L}$, where $\mathcal{L}$ denotes the Laplace transform and $\mathcal{M}_H$ denotes the multiplication by H on the Hardy space $H^2(\mathbb{C}^m)$. The operator $\mathcal{H}$ is linear, bounded, and shift-invariant (in the sense of Vidyasagar [26]). As a consequence $\mathcal{H}$ is causal (see [26]) and therefore has a unique causal extension to $LL^2(\mathbb{R}_+, \mathbb{C}^m)$. This extension will also be denoted by $\mathcal{H}$. The converse is also true, i.e., given a linear, bounded, shift-invariant operator $\mathcal{H} : L^2(\mathbb{R}_+, \mathbb{C}^m) \to L^2(\mathbb{R}_+, \mathbb{C}^m)$, there exists $H \in H^\infty(\mathbb{C}^{m\times m})$ such that $\mathcal{H} = \mathcal{L}^{-1}\mathcal{M}_H\mathcal{L}$ (see Harris and Valenca [7], Logemann [12], and Weiss [29]). Finally we mention that $LL^2(\mathbb{R}_+, \mathbb{R}^m)$ is an $\mathcal{H}$-invariant subspace of $LL^2(\mathbb{R}_+, \mathbb{C}^m)$[‡] if and only if $H(s) = \bar{H}(\bar{s})$ for all $s \in \mathbb{C}_+$. In control applications the latter condition will always be satisfied and it is assumed to hold in the following.

The function G satisfying (2.1) can be thought of as being the transfer-function matrix of

$$\dot{y} = D(u - (\mathcal{H}y + w)), \qquad y(0) = y_0 \in \mathbb{R}^m, \tag{2.3}$$

where $u \in LL^1(\mathbb{R}_+, \mathbb{R}^m)$ and $w \in L^2(\mathbb{R}_+, \mathbb{R}^m)$ takes account of non-zero initial conditions in the system with transfer-function matrix H. The initial value problem (2.3) is a special case of the following initial value problem, which will play an important role in this paper. Consider

$$\begin{aligned} \dot{x}(t) &= (Sx)(t) + f(t, x(t)) + g(t), \qquad t \geq \alpha, \\ x_{|[0,\alpha]} &= x_0 \in C([0, \alpha], \mathbb{R}^n), \qquad \alpha \geq 0, \end{aligned} \tag{2.4}$$

where the following hold.

(i) $S : LL^2(\mathbb{R}_+, \mathbb{R}^n) \to LL^2(\mathbb{R}_+, \mathbb{R}^n)$. We assume that $S(0) = 0$ and that there exists $\kappa > 0$ such that $\|\pi_t(Sx - Sx')\| \leq \kappa\|\pi_t(x - x')\|$ for all $x, x' \in LL^2(\mathbb{R}_+, \mathbb{R}^n)$ and for all $t \geq 0$, i.e., S is unbiased, causal, and of finite incremental gain.

(ii) $f : \mathbb{R}_+ \times \mathbb{R}^n \to \mathbb{R}^n$ is a function. We assume that $f(t, x)$ is continuous in t and locally Lipschitz continuous in x, uniformly in t on bounded intervals.

(iii) g is in $LL^1(\mathbb{R}_+, \mathbb{R}^n)$.

Of course, if $\alpha = 0$ in (2.4), then $C([0, \alpha], \mathbb{R}^n) = \mathbb{R}^n$. In order to define what we mean by a solution of the initial value problem (2.4) on $[0, \beta)(\alpha < \beta \leq \infty)$, we have to give a meaning to Sx if $x \in C([0, \beta), \mathbb{R}^n)$ (remember that S operates on functions whose domain of definition is $\mathbb{R}_+$). We set $(Sx)(t) = (S\pi_\tau x)(t)$ for $0 \leq t \leq \tau < \beta$. Since S is causal, this definition does not depend on the choice of τ.

[‡] Notice that here $LL^2(\mathbb{R}_+, \mathbb{C}^m)$ is considered as a *real* vector space.

DEFINITION 2.4. *A solution of* (2.4) *on* $[0,\beta)(\alpha < \beta \leq \infty)$ *is an absolutely continuous function* x *on* $[0,\beta)$ *such that* $x_{|[0,\alpha]} = x_0$ *and the differential equation in* (2.4) *is satisfied by* x *almost everywhere on* $[0,\beta)$.

THEOREM 2.5. *The initial-value problem* (2.4) *has a unique solution on some interval* $[0,\beta)$, *where* $\alpha < \beta \leq \infty$. *If* $\beta < \infty$ *and* β *cannot be increased, then there exists a strictly increasing sequence* $t_i \in (0,\beta)$, *satisfying* $\lim_{i\to\infty} t_i = \beta$, *such that* $\lim_{i\to\infty} \|x(t_i)\| = \infty$.

The above theorem has been proved in Logemann and Owens [14]. Similar results can be found in Gripenberg, Londen, and Staffans [5, p. 359], and Hinrichsen and Pritchard [10]. Theorem 2.5 implies in particular that the initial value problem (2.3) has a unique solution for all $w \in L^2(\mathbb{R}_+,\mathbb{R}^m)$, $u \in LL^1(\mathbb{R}_+,\mathbb{R}^m)$, and $y_0 \in \mathbb{R}^m$.

3. Adaptive stabilization. The aim of this section is to construct a universal adaptive control law that stabilizes any system of the form (2.3), i.e., the control law does not depend on D and $\mathcal{H}$, and the closed-loop system satisfies $\lim_{t\to\infty} y(t) = 0$ for all $y_0 \in \mathbb{R}^m$ and $w \in L^2(\mathbb{R}_+,\mathbb{R}^m)$.

In the following, we need a result from linear algebra which has been proved by Mårtensson [17], [18]. For $m \geq 1$ we call a set $\mathcal{U} \subset GL(m,\mathbb{R})$ *unmixing*, if for any $A \in GL(m,\mathbb{R})$ there is a $U \in \mathcal{U}$ such that $\operatorname{spec}(AU) \subset \mathbb{C}_-$.

PROPOSITION 3.1 ([17], [18]). *For all* $m \geq 1$, *there exist unmixing sets of finite cardinality.*

Unfortunately the cardinality of the unmixing sets constructed in [17], [18] is far too large than would be convenient for applications. Hardly anything is known on the minimum cardinality of unmixing sets. However, for $m = 1$ the set $\{1,-1\}$ is obviously unmixing, while for $m = 2$ there exists an unmixing set of cardinality 6 (see [17], [18]). It has been shown by Zhu [31] that $GL(3,\mathbb{R})$ can be unmixed by a set having cardinality 32.

In the following, let $\{K_1,\dots,K_N\}$ be an unmixing set for $GL(m,\mathbb{R})$. Since (2.3) can be stabilized by high-gain feedback of the form $u(t) = ky(t)$, provided that $\operatorname{spec}(D) \subset \mathbb{C}_-$ and k is a sufficiently large positive number, it seems reasonable to consider the following adaptive control law:

$$\begin{aligned} u(t) &= k(t)K_{\sigma(k(t))}y(t), \\ \dot{k}(t) &= \|y(t)\|^2, \qquad k(0) = k_0 \in \mathbb{R}. \end{aligned} \tag{3.1}$$

In (3.1) the function $\sigma : \mathbb{R} \to \{1,\dots,N\}$ is given by

$$\sigma(k) = \begin{cases} 1, & k \in [-\tau_1,\tau_1), \\ i, & k \in [\tau_{lN+i},\tau_{lN+i+1}) \cup [-\tau_{lN+i+1},-\tau_{lN+i}) \quad \text{for some } l \in \mathbb{N}_0, \end{cases} \tag{3.2}$$

where the sequence $(\tau_j)_{j\in\mathbb{N}_0}$ is defined as

$$\tau_{j+1} = \tau_j^2, \qquad \tau_1 > 1. \tag{3.3}$$

Note that the gain $k(t)$ is monotonically increasing and thus the function σ ensures that $K_{\sigma(k(t))}$ will hit some stabilizing gain matrix K_i if $k(t)$ diverges. The growth condition (3.3) captures the intuitive idea that the length of the intervals $[\tau_j,\tau_{j+1})$ should increase rapidly, in order to enable the closed-loop system to settle down. Although the closed-loop system given by (2.3) and (3.1) is of the form (2.4), we cannot apply Theorem 2.5 straight away in order to establish well posedness of the closed loop, since the map $\mathbb{R} \to \{K_1,\dots,K_N\}, k \mapsto K_{\sigma(k)}$ is not continuous. However, Theorem 2.5 can be used to prove the following.

LEMMA 3.2. *For each pair of initial conditions* $(y_0,k_0) \in \mathbb{R}^m \times \mathbb{R}$ *and for each* $w \in L^2(\mathbb{R}_+,\mathbb{R}^m)$, *the closed-loop system given by* (2.3) *and* (3.1) *has a unique absolutely continuous solution* (y,k) *that can be extended to the right as long as it remains bounded.*

Proof. See Appendix.

Now we are in the position to prove the main result of this section. It says that the control law (3.1) stabilizes any system of the form (2.3), or in other words (3.1) is a universal adaptive control law for this class.

THEOREM 3.3. *The solution* (y, k) *of the closed-loop system given by* (2.3) *and* (3.1) *exists on* $\mathbb{R}_+$ *and has the following properties*:

(i) $\lim_{t\to\infty} k(t)$ *exists and is finite*;

(ii) $y \in L^2(\mathbb{R}_+, \mathbb{R}^m) \cap L^\infty(\mathbb{R}_+, \mathbb{R}^m)$;

(iii) $\lim_{t\to\infty} y(t) = 0$.

We shall prove Theorem 3.3 by combining ideas of Byrnes and Willems [1] with the following lemma, which can be found in Ilchmann and Logemann [11].

LEMMA 3.4. *Suppose that* σ *and* τ_j *are given by* (3.2) *and* (3.3), *respectively, and for* $\alpha > 0$ *and* $i \in \{1, \dots, N\}$ *define* $F_i^\alpha : \mathbb{R} \to \{1, -\alpha\}$ *by*

$$F_i^\alpha(x) = \begin{cases} 1, & \text{if } \sigma(x) = i, \\ -\alpha, & \text{if } \sigma(x) \neq i. \end{cases} \tag{3.4}$$

Then we have

$$\sup_{k>k_0} \frac{1}{k - k_0} \int_{k_0}^{k} x F_i^\alpha(x) dx = +\infty \tag{3.5}$$

for all $k_0 \in \mathbb{R}, \alpha > 0, i \in \{1, \dots, N\}$.

Proof of Theorem 3.3. By assumption there exists $i \in \{1, \dots, N\}$ such that $\operatorname{spec}(DK_i) \subset \mathbb{C}_-$. Hence there is a positive definite matrix $Q = Q^T \in GL(m, \mathbb{R})$ satisfying

$$K_i^T D^T Q + QDK_i = -I. \tag{3.6}$$

Furthermore, choose $\alpha > 0$ such that

$$K_j^T D^T Q + QDK_j \leq \alpha I \quad \text{for all } j \in \{1, \dots, N\}. \tag{3.7}$$

By Lemma 3.2, the closed-loop system given by (2.3) and (3.1) has a unique solution (y, k). Let $[0, t^*)$ denote its maximal interval of existence. Setting $\|x\|_Q := (\langle x, Qx\rangle)^{1/2}$ for $x \in \mathbb{R}^m$ and using (2.3), (3.4), (3.6), and (3.7) we obtain

$$\begin{aligned} \frac{d}{dt}\|y(t)\|_Q^2 &= \dot{y}(t)^T Q y(t) + y(t)^T Q \dot{y}(t) \\ &= k(t) y(t)^T (K_{\sigma(k(t))}^T D^T Q + QDK_{\sigma(k(t))}) y(t) - (\mathcal{H}y)(t)^T D^T Q y(t) \\ &\quad - w(t)^T D^T Q y(t) - y(t)^T Q D(\mathcal{H}y)(t) - y(t)^T Q D w(t) \\ &\leq -F_i^\alpha(k(t)) k(t) \dot{k}(t) - 2y(t)^T Q D(\mathcal{H}y)(t) - 2y(t)^T Q D w(t). \end{aligned} \tag{3.8}$$

Using Hölder's inequality and the causality and boundedness of $\mathcal{H}$, it is easy to show that for all $f \in LL^2(\mathbb{R}_+, \mathbb{C}^m)$ and $t \geq 0$,

$$\left| \int_0^t f(\tau)^T Q D(\mathcal{H}f)(\tau) d\tau \right| \leq \|Q\| \|D\| \|\mathcal{H}\| \int_0^t \|f(\tau)\|^2 d\tau. \tag{3.9}$$

Integrating (3.8) from 0 to t, $t < t^*$, changing variables, and applying (3.9) yields

$$\begin{aligned}\|y(t)\|_Q^2 - \|y_0\|_Q^2 &\leq -\int_{k_0}^{k(t)} xF_i^\alpha(x)dx + \lambda_1 \int_0^t \|y(\tau)\|^2 d\tau \\ &\quad + \lambda_2 \|w\|_2 \left(\int_0^t \|y(\tau)\|^2 d\tau\right)^{1/2} \\ &= (k(t) - k_0)\left\{\lambda_1 + \frac{\lambda_2\|w\|_2}{\sqrt{k(t)-k_0}} - \frac{1}{k(t)-k_0}\int_{k_0}^{k(t)} xF_i^\alpha(x)dx\right\},\end{aligned} \tag{3.10}$$

where λ_1 and λ_2 are suitable positive constants depending on $\mathcal{H}$, D, and Q.

In order to show global existence of the solution (y, k) on $\mathbb{R}_+$ it is (by Lemma 3.2) sufficient to show that (y, k) is bounded on $[0, t^*)$. In order to prove that $k(t)$ is bounded on $[0, t^*)$, assume the contrary. It then follows from Lemma 3.4 that the limes inferior of the right-hand side of (3.10) is $-\infty$, contradicting the fact that the left-hand side of (3.10) is bounded from below by $-\|y_0\|_Q^2$. Hence $k(t)$ is bounded on $[0, t^*)$ and from (3.1) and (3.10) we obtain that $y \in L^2(0, t^*; \mathbb{R}^m) \cap L^\infty(0, t^*; \mathbb{R}^m)$. In particular we have $t^* = \infty$, which implies (i) and (ii). In order to prove (iii), notice that by (2.3), (i), and (ii) $\dot{y} \in L^2(\mathbb{R}_+; \mathbb{R}^m)$. As a consequence (iii) holds true. □

Remark 3.5. (i) It is not difficult to see that the sequence given by (3.3) can be replaced by any strictly increasing sequence $(\tau_j)_{j\in\mathbb{N}}$ satisfying $\lim_{j\to\infty} \tau_j/\tau_{j-1} = +\infty$ (cf. Ilchmann and Logemann [11] and Ryan [24]).

(ii) Let $u \in LL^2(\mathbb{R}_+, \mathbb{R}^m), w \in L^2(\mathbb{R}_+, \mathbb{R}^m)$ and suppose that y satisfies (2.3). If $Q \in \mathbb{R}^{m\times m}$ is positive definite, then the inequality

$$\|y(t)\|_Q^2 \leq \|y_0\|_Q^2 + \mu\left(1 + \int_0^t \|y(\tau)\|^2 d\tau\right) + 2\int_0^t y(\tau)^T QDu(\tau)d\tau \tag{3.11}$$

holds for all $t \geq 0$, where μ is a suitable positive constant depending on $\mathcal{H}, D, Q$, and w. Inequality (3.11) has been derived implicitly in the proof of Theorem 3.3 and may be of some independent interest.

Remark 3.6. The controller (3.1) was introduced by Byrnes and Willems [1] in a finite-dimensional state-space set-up. The main result in [1] says that any finite-dimensional state-space system with m inputs and m outputs can be stabilized by the control law (3.1), provided it is minimum-phase and has invertible high-frequency gain. However, the proof is not convincing, since the inequality (3.4) in [1] is in general wrong. A result similar to that in [1] can be found in Mårtensson [17], [18]. The proof in [17], [18] is not convincing either, since it is based on the claim that for the adaptive control system

$$\begin{aligned}\dot{x}(t) &= Ax(t) + Bu(t), \qquad x(0) = x_0 \in \mathbb{R}^n, \\ y(t) &= Cx(t), \\ u(t) &= k(t)Qy(t), \\ \dot{k}(t) &= \|u(t)\|^2 + \|y(t)\|^2, \qquad k(0) = k_0 \in \mathbb{R},\end{aligned}$$

there exist constants $c > 0$ and $T \geq 0$ such that

$$\int_t^\infty (\|u(\tau)\|^2 + \|y(\tau)\|^2)d\tau \leq c\|x(t)\|^2$$

for all $x_0 \in \mathbb{R}^n$, $k_0 \in \mathbb{R}$, $t \geq T$, provided that (A, B, C) is minimum-phase and $\sigma(CBQ) \subset \mathbb{C}_-$.

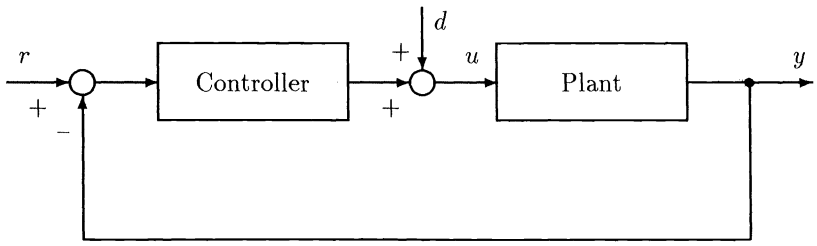

FIG. 1. *Closed-loop system.*

This is not proved in [17], [18] and it seems to the authors that it is unlikely to hold true.

We close this section with a conjecture on the limiting closed-loop system. If the assumptions of Theorem 3.3 are satisfied, then $\lim_{t\to\infty} k(t) =: k_\infty(w, y_0, k_0)$ exists and is finite. The linear system

$$\begin{cases} \dot{\tilde{y}} = D[k_\infty(w, y_0, k_0)K_{\sigma(k_\infty(w,y_0,k_0))}\tilde{y} - \mathcal{H}\tilde{y} - \tilde{w}], \\ \tilde{y}(0) = \tilde{y}_0 \in \mathbb{R}^m, \tilde{w} \in L^2(\mathbb{R}_+, \mathbb{R}^m) \end{cases} \tag{3.12}$$

is called the terminal system of the nonlinear closed-loop system given by (2.3) and (3.1). It is easy to see that (3.12) does not satisfy $\lim_{t\to\infty} \tilde{y}(t) = 0$ for arbitrary $(\tilde{w}, \tilde{y}_0) \in L^2(\mathbb{R}_+, \mathbb{R}^m) \times \mathbb{R}^m$. Indeed, consider the special case that $\mathcal{H} = 0$ and choose $w = 0, y_0 = 0$, and $k_0 = 0$ in (2.3) and (3.1). Since $k_\infty(0,0,0) = 0$, it follows that the solution $\tilde{y}$ of (3.12) is given by $\tilde{y}(t) = \tilde{y}_0 - D\int_0^t \tilde{w}(\tau)d\tau$, and hence $\tilde{y}(t)$ in general does not converge to 0 as $t \to \infty$. However, recent work of Townley [25] on adaptive stabilization of finite-dimensional systems leads us to the following conjecture.

Conjecture. For given $k_0 \in \mathbb{R}$ there exists an open and dense set $\mathcal{I}(k_0) \subset L^2(\mathbb{R}_+, \mathbb{R}^m) \times \mathbb{R}^m$ such that the terminal system (3.12) is stable in the sense that

$$\tilde{y} \in L^2 \cap L^\infty(\mathbb{R}_+, \mathbb{R}^m) \quad \text{and} \quad \lim_{t\to\infty} \tilde{y}(t) = 0 \quad \text{for all } (\tilde{w}, \tilde{y}_0) \in L^2(\mathbb{R}_+, \mathbb{R}^m) \times \mathbb{R}^m,$$

provided that $(w, y_0) \in \mathcal{I}(k_0)$.

4. Adaptive tracking and disturbance rejection. Consider the control scheme in Fig. 1, where the plant is described by (2.1) or, equivalently, by (2.3). The aim of this section is to construct a single controller, such that the closed-loop system asymptotically tracks a given reference trajectory r and asymptotically rejects a given disturbance signal d for all plants of the form (2.1). The signals r and d belong to prespecified vector spaces of functions that are defined as follows. Let $\rho_i, \delta_i \in \mathbb{R}[s]$ be monic polynomials, $1 \le i \le m$, and set $\rho := (\rho_1, \ldots, \rho_m)^T$ and $\delta := (\delta_1, \ldots, \delta_m)^T$. The admissible reference signals are given by

$$\mathcal{S}_\rho := \left\{ r : \mathbb{R}_+ \to \mathbb{R}^m \mid \rho_i\left(\frac{d}{dt}\right) r_i \equiv 0, i = 1, \ldots, m \right\},$$

while the disturbances d are supposed to belong to $\mathcal{S}_\delta + L^2(\mathbb{R}_+, \mathbb{R}^m)$, where $\mathcal{S}_\delta$ is defined as $\mathcal{S}_\rho$ with ρ_i replaced by δ_i. The well-known internal model principle from linear control theory (see e.g., Wonham [30, p. 203], and Vidyasagar [27, p. 294], for the finite-dimensional case and Francis [4], Callier and Desoer [2], and Curtain [3] for the infinite-dimensional case) suggests that the dynamics of the reference and disturbance signals should be replicated in the

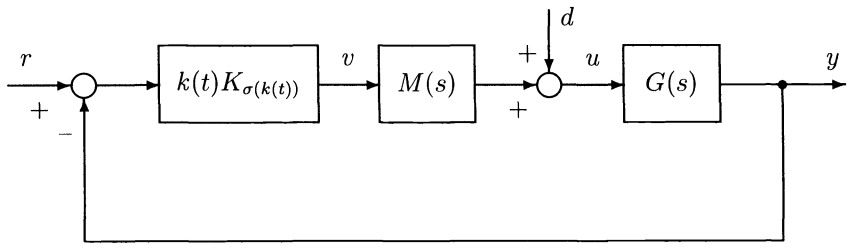

FIG. 2. *High-gain adaptive servomechanism.*

loop via a precompensator. To this end set

$$p(s) = \operatorname{lcm}(s, \rho_1(s), \dots, \rho_m(s), \delta_1(s), \dots, \delta_m(s)),$$

where we choose p to be monic. Moreover, let q be a monic polynomial that is Hurwitz and satisfies $\deg(q) = \deg(p)$. We define the precompensator $M(s)$ containing the internal model to be

$$M(s) = \frac{q(s)}{p(s)} I_m.$$

Note that by construction $M(s)$ contains an integrator. This is required for a purely technical reason: Without $M(s)$ having a pole in 0 we were not able to prove Theorem 4.1 below. Let G_M denote the precompensated plant, i.e., $G_M(s) = G(s)M(s)$. Now realize that, by (2.1),

$$G_M^{-1}(s) = \frac{p(s)}{q(s)}(sD^{-1} + H(s)) = sD^{-1} + H_M(s),$$

where

$$H_M(s) := s\left(\frac{p(s)}{q(s)} - 1\right) D^{-1} + \frac{p(s)}{q(s)} H(s) \tag{4.1}$$

belongs to $H^\infty(\mathbb{C}^{m\times m})$. The important point here is that the structural property (2.1) of the plant G remains invariant under precompensation by $M(s)$. The overall adaptive controller we shall investigate in the following is given by

$$\begin{cases} \hat{u}(s) = M(s)\hat{v}(s) + \hat{d}(s), \\ v(t) = k(t)K_{\sigma(k(t))}(r(t) - y(t)), \\ \dot{k}(t) = \|r(t) - y(t)\|^2, \qquad k(0) = k_0, \end{cases} \tag{4.2}$$

where σ and $K_1, \dots, K_N$ are defined as in §3 (cf. Fig. 2). Using the fact that the first equation of (4.2) can be written as

$$\hat{u}(s) = M(s)(\hat{v}(s) + M^{-1}(s)\hat{d}(s)),$$

setting $d_M(t) := \mathcal{L}^{-1}(M^{-1}\hat{d})(t)$ and $\mathcal{H}_M := \mathcal{L}^{-1}\mathcal{M}_{H_M}\mathcal{L}$,† we obtain the following time-domain description of the closed-loop system given by (2.3) and (4.2):

† As before, the unique causal extension of $\mathcal{H}_M$ to $LL^2(\mathbb{R}_+, \mathbb{R}^m)$ will be denoted by the same symbol $\mathcal{H}_M$.

(4.3)

$$\begin{cases} \dot{y}(t) &= D(v(t) + d_M(t) - (\mathcal{H}_M y)(t) - w_M(t)), \quad y(0) = y_0, \quad w_M \in L^2(\mathbb{R}_+, \mathbb{R}^m) \\ v(t) &= k(t) K_{\sigma(k(t))}(r(t) - y(t)) \\ \dot{k}(t) &= \|r(t) - y(t)\|^2, \qquad k(0) = k_0, \end{cases}$$

where as in §2 the term w_M takes account of non-zero initial conditions (cf. also §5).

We are now in the position to prove the main result of this paper, which shows that the controller (4.2) solves the servoproblem for all systems of the form (2.3).

THEOREM 4.1. *The solution (y, k) of the closed-loop system* (4.3) *exists on $\mathbb{R}_+$ and has the following properties*:

(i) $\lim_{t\to\infty} k(t)$ *exists and is finite*,
(ii) $y - r \in L^2(\mathbb{R}_+, \mathbb{R}^m) \cap L^\infty(\mathbb{R}_+, \mathbb{R}^m)$,
(iii) $\lim_{t\to\infty}(y(t) - r(t)) = 0$.

Proof. Rewriting the first equation of (4.3) as

$$\frac{d}{dt}(r - y) = -D(v + \mathcal{H}_M(r - y) + d_M - \mathcal{H}_M r - D^{-1}\dot{r} - w_M),$$

we see that (i)–(iii) will follow from Theorem 3.3, provided that the term $d_M - \mathcal{H}_M r - D^{-1}\dot{r}$ belongs to $L^2(\mathbb{R}_+, \mathbb{R}^m)$. It is easy to show that $d_M \in L^2(\mathbb{R}_+, \mathbb{R}^m)$. Indeed, by definition we have

$$\hat{d}_M(s) = M^{-1}(s)\hat{d}(s) = M^{-1}(s)\hat{d}_1(s) + M^{-1}(s)\hat{d}_2(s), \tag{4.4}$$

where $d_1 \in L^2(\mathbb{R}_+, \mathbb{R}^m)$ and $d_2 \in \mathcal{S}_\delta$. Now, clearly we have

$$M^{-1}(s)\hat{d}_1(s) \in H^2(\mathbb{C}^m). \tag{4.5}$$

Moreover, since $p(d/dt)d_{2i} \equiv 0, 1 \le i \le m$ (where d_{2i} denotes the ith component of d_2), it follows that there exist polynomials $\beta_i \in \mathbb{R}[s]$ such that

$$\hat{d}_{2i}(s) = \frac{\beta_i(s)}{p(s)} \quad \text{and} \quad \deg(\beta_i) \le \deg(p) - 1 = \deg(q) - 1.$$

Therefore

$$M^{-1}(s)\hat{d}_2(s) = \left(\frac{\beta_1(s)}{q(s)}, \ldots, \frac{\beta_m(s)}{q(s)}\right)^T \in H^2(\mathbb{C}^m). \tag{4.6}$$

Combining (4.4)–(4.6) shows that $\hat{d}_M \in H^2(\mathbb{C}^m)$ and hence $d_M \in L^2(\mathbb{R}_+, \mathbb{R}^m)$. It remains to show that $\mathcal{H}_M r + D^{-1}\dot{r} \in L^2(\mathbb{R}_+, \mathbb{R}^m)$. This will be done in two steps.

Step 1. Suppose that $r(0) = 0$. Then we have

$$\mathcal{L}(\mathcal{H}_M r + D^{-1}\dot{r})(s) = H_M(s)\hat{r}(s) + sD^{-1}\hat{r}(s), \tag{4.7}$$

and moreover $\hat{r}(s) = [1/p(s)]\gamma(s)$, where $\gamma(s) := (\gamma_1(s), \ldots, \gamma_m(s))^T, \gamma_i \in \mathbb{R}[s]$, and $\deg(\gamma_i) \le \deg(p) - 2 = \deg(q) - 2$. Using (4.1) it follows from (4.7) that

$$\begin{aligned} \mathcal{L}(\mathcal{H}_M r + D^{-1}\dot{r})(s) &= s\left(\frac{p(s)}{q(s)} - 1\right) D^{-1}\frac{1}{p(s)}\gamma(s) \\ &\quad + \frac{p(s)}{q(s)} H(s)\frac{1}{p(s)}\gamma(s) + sD^{-1}\frac{1}{p(s)}\gamma(s) \\ &= D^{-1}\frac{s}{q(s)}\gamma(s) + H(s)\frac{1}{q(s)}\gamma(s) \in H^2(\mathbb{C}^m), \end{aligned}$$

since $H \in H^\infty(\mathbb{C}^{m\times m})$, $\deg(\gamma_i) \le \deg(q) - 2$ and q is Hurwitz. Hence we have shown that

$$\mathcal{H}_M r + D^{-1}\dot{r} \in L^2(\mathbb{R}_+, \mathbb{R}^m),$$

provided that $p(d/dt)r \equiv 0$ and $r(0) = 0$.

Step 2. Now suppose that $r(0) = r_0 \neq 0$. Define $z(t) := r(t) - \Theta(t)r_0$, where

$$\Theta(t) := \begin{cases} 0, & t < 0, \\ 1, & t \ge 0; \end{cases}$$

notice that

$$\mathcal{H}_M r + D^{-1}\dot{r} = \mathcal{H}_M z + D^{-1}\dot{z} + \mathcal{H}_M(\Theta r_0). \tag{4.8}$$

Since $p(0) = 0$, it follows that $p(d/dt)z \equiv 0$. Moreover $z(0) = 0$ and hence we obtain from Step 1 that $\mathcal{H}_M z + D^{-1}\dot{z} \in L^2(\mathbb{R}_+, \mathbb{R}^m)$. Therefore, by (4.8) it remains to show that $\mathcal{H}_M(\Theta r_0) \in L^2(\mathbb{R}_+, \mathbb{R}^m)$. To this end write $p(s) = s\tilde{p}(s), \tilde{p} \in \mathbb{R}[s]$, which is possible by assumption. Using (4.1) it follows that

$$\mathcal{L}(\mathcal{H}_M(\Theta r_0))(s) = H_M(s)\frac{1}{s}r_0 = \left(\frac{p(s)}{q(s)} - 1\right) D^{-1}r_0 + \frac{\tilde{p}(s)}{q(s)}H(s)r_0 \in H^2(\mathbb{C}^m)$$

and hence $\mathcal{H}_M(\Theta r_0) \in L^2(\mathbb{R}_+, \mathbb{R}^m)$. □

5. Applications to retarded systems and integrodifferential convolution systems. In this section we show how retarded and integrodifferential convolution systems fit into the input-output set-up developed in §§3 and 4. We solve the adaptive servoproblem for these classes of systems under the assumption that the plant is minimum-phase and has invertible high-frequency gain. Moreover, it turns out that the internal variables of the plant and the precompensator remain bounded, provided that the reference signal is bounded.

5.1. Retarded systems. In the following we extend any function $F \in BV([a, b], \mathbb{R}^{n\times n})$ to the whole real axis by setting $F(t) = F(a)$ for $t < a$ and $F(t) = F(b)$ for $t > b$. Any measurable function $f : \Omega \to \mathbb{R}^n, \Omega \subset \mathbb{R}$, will be extended to the whole real axis by defining $f(t) = 0$ for $t \notin \Omega$. For $F = (F_{ij}) \in BV([0, h], \mathbb{R}^{n\times n})$ and $f = (f_1, \dots, f_n)^T, f_i \in LL^1(\mathbb{R}, \mathbb{R}), 1 \le i \le n$, we define

$$dF * f := \begin{pmatrix} \sum_{j=1}^n dF_{1j} * f_j \\ \vdots \\ \sum_{j=1}^n dF_{nj} * f_j \end{pmatrix},$$

where dF_{ij} denote the measure on $\mathbb{R}$ induced by F_{ij} and $dF_{ij} * f_j$ denotes the convolution of the measure dF_{ij} and the function f_j. If f is continuous on $[-h, \infty)$, then of course

$$(dF * f)(t) = \int_0^h dF(\tau)f(t - \tau) \quad \text{for } t \ge 0.$$

Consider the retarded system

$$\begin{aligned} \dot{x} &= dA * x + Bu, \\ y &= Cx, \\ x_{|_{[-h,0]}} &= x_0 \in C([-h, 0], \mathbb{R}^n), \end{aligned} \tag{5.1}$$

where $A \in BV([0,h],\mathbb{R}^{n\times n})$, $B \in \mathbb{R}^{n\times m}$, and $C \in \mathbb{R}^{m\times n}$. We assume that

$$\det(CB) \neq 0 \tag{5.2}$$

and

$$\det \begin{pmatrix} sI - \hat{A}(s) & -B \\ C & 0 \end{pmatrix} \neq 0 \text{ for all } s \in \overline{\mathbb{C}}_+, \tag{5.3}$$

where $\hat{A}(s) := \int_0^h \exp(-s\tau)dA(\tau)$ denotes the Laplace–Stieltjes transform of A. The transfer function matrix $G(s)$ of (5.1) is given by

$$G(s) = C(sI - \hat{A}(s))^{-1}B.$$

Remark 5.1. As in the finite-dimensional case, we shall call (5.3) the minimum-phase condition. It can be shown that (5.3) holds if and only if the following three conditions hold:

(i) The transfer function matrix $G(s)$ has no zeros in $\overline{\mathbb{C}}_+$;

(ii) $rk(sI - \hat{A}(s), B) = n \quad$ for all $s \in \overline{\mathbb{C}}_+$;

(iii) $rk \begin{pmatrix} sI - \hat{A}(s) \\ C \end{pmatrix} = n \quad$ for all $s \in \overline{\mathbb{C}}_+$.

Let $\rho_i, \delta_i (i = 1,\dots,m), \rho, \delta, p$, and q be as in §4 and let

$$\begin{aligned} \dot{\xi} &= A_M\xi + B_M v, \quad \xi(0) = \xi_0 \in \mathbb{R}^l \\ z &= C_M\xi + I_m v \end{aligned} \tag{5.4}$$

be a stabilizable and detectable realization of $M(s) = [q(s)/p(s)]I_m$. We shall consider the closed-loop system given by (5.1), (5.4),

$$\begin{aligned} v(t) &= k(t)K_{\sigma(k(t))}(y(t) - r(t)), \\ \dot{k}(t) &= \|y(t) - r(t)\|^2, \quad k(0) = k_0 \in \mathbb{R}, \end{aligned} \tag{5.5}$$

and

$$u(t) = z(t) + d(t), \tag{5.6}$$

where $r \in \mathcal{S}_\rho, d \in \mathcal{S}_\delta + L^2(\mathbb{R}_+,\mathbb{R}^m)$ and $K_1,\dots,K_N$ and $\sigma : \mathbb{R} \to \{1,\dots,N\}$ are defined as in §3.

The following result shows that the universal adaptive controller presented in §4 achieves asymptotic tracking and disturbance rejection for the class of retarded systems satisfying (5.2) and (5.3).

THEOREM 5.2. *If* (5.2) *and* (5.3) *are satisfied, then for any* $x_0 \in C([-h,0],\mathbb{R}^n), \xi_0 \in \mathbb{R}^l, k_0 \in \mathbb{R}, r \in \mathcal{S}_\rho$, *and* $d \in \mathcal{S}_\delta + L^2(\mathbb{R}_+,\mathbb{R}^m)$, *the closed-loop system given by* (5.1) *and* (5.4)–(5.6) *has the following properties*:

(i) $\lim_{t\to\infty} k(t)$ *exists and is finite*;

(ii) $y - r \in L^2(\mathbb{R}_+,\mathbb{R}^m) \cap L^\infty(\mathbb{R}_+,\mathbb{R}^m)$;

(iii) $\lim_{t\to\infty}(y(t) - r(t)) = 0$;

(iv) $(x,\xi)^T \in L^\infty(\mathbb{R}_+,\mathbb{R}^{n+l})$ *provided* r *is bounded.*

Proof. First of all it follows from (5.2) and (5.3) that

$$G^{-1}(s) = s(CB)^{-1} + H(s), \tag{5.7}$$

where $H \in H^\infty(\mathbb{C}^{m\times m})$ (see Logemann and Mårtensson [13]), i.e., $G^{-1}(s)$ admits a decomposition of the form (2.1). We proceed in four steps.

Step 1. Recall from the proof of Theorem 4.1 that

$$d_M(t) = \mathcal{L}^{-1}(M^{-1}\hat{d})(t) \in L^2(\mathbb{R}_+, \mathbb{R}^m). \tag{5.8}$$

Defining

$$\chi(t) := \begin{cases} 0, & t = 0, \\ 1, & t \in (0, h], \end{cases}$$

and setting

$$A_{se}(\cdot) := \begin{pmatrix} A(\cdot) & \chi(\cdot)BC_M \\ 0 & \chi(\cdot)A_M \end{pmatrix}, \quad B_{se} := \begin{pmatrix} B \\ B_M \end{pmatrix},$$
$$C_{se} := (C, 0) \quad \text{and} \quad x_{se} := \begin{pmatrix} x \\ \xi \end{pmatrix},$$

the series connection of (5.4) followed by (5.1) in the presence of the disturbance d can be reformulated as follows:

$$\begin{aligned} \dot{x}_{se} &= dA_{se} * x_{se} + B_{se}(v + d_M), \\ y &= C_{se}x_{se} \\ x_{se}(t) &= \begin{pmatrix} x_0(t) \\ \xi_0 \end{pmatrix} \quad \text{for all } t \in [-h, 0]. \end{aligned} \tag{5.9}$$

It follows trivially from (5.2) that

$$\det(C_{se}B_{se}) \neq 0. \tag{5.10}$$

Moreover, since $q(s)$ is Hurwitz, it follows from the stabilizability and detectability of (5.4) that

$$\det \begin{pmatrix} sI - A_M & -B_M \\ C_M & I_m \end{pmatrix} \neq 0 \quad \text{for all } s \in \overline{\mathbb{C}}_+. \tag{5.11}$$

Realizing that

$$\begin{aligned} &\det \begin{pmatrix} sI - \hat{A}_{se}(s) & -B_{se} \\ C_{se} & 0 \end{pmatrix} \\ &\quad = \det(sI - \hat{A}(s)) \det(G(s)) \det(sI - A_M) \det(M(s)) \\ &\quad = \det \begin{pmatrix} sI - \hat{A}(s) & -B \\ C & 0 \end{pmatrix} \det \begin{pmatrix} sI - A_M & -B_M \\ C_M & I_m \end{pmatrix}, \end{aligned}$$

we obtain from (5.3) and (5.11)

$$\det \begin{pmatrix} sI - \hat{A}_{se}(s) & -B_{se} \\ C_{se} & 0 \end{pmatrix} \neq 0 \quad \text{for all } s \in \overline{\mathbb{C}}_+, \tag{5.12}$$

i.e., the series connection of (5.4) followed by (5.1) is minimum-phase.

Step 2. It follows from (5.10) that $\mathbb{R}^{n+l} = \ker C_{se} \oplus \operatorname{im} B_{se}$. Hence there exists a non-singular real transformation $P \in \mathbb{R}^{(n+l)\times(n+l)}$ such that

$$P^{-1}B_{se} = \begin{pmatrix} CB \\ 0 \end{pmatrix}, \quad C_{se}P = (I_m \quad 0).$$

It is useful to partition the matrix $P^{-1}A_{se}(\cdot)P$ as follows:

$$P^{-1}A_{se}(\cdot)P = \begin{pmatrix} A_{11}(\cdot) & A_{12}(\cdot) \\ A_{21}(\cdot) & A_{22}(\cdot) \end{pmatrix},$$

where $A_{11}(\cdot), A_{12}(\cdot), A_{21}(\cdot)$, and $A_{22}(\cdot)$ are matrices with entries in $BV([0,h],\mathbb{R})$ of size $m \times m, m \times (n+l-m), (n+l-m) \times m$ and $(n+l-m) \times (n+l-m)$, respectively. Setting $\eta_{se}(t) = P^{-1}x_{se}(t)$, it follows from (5.9) that

$$\begin{aligned} \dot{\eta}_{se} &= d(P^{-1}A_{se}P) * \eta_{se} + P^{-1}B_{se}(v + d_M), \\ y &= C_{se}P\eta_{se}, \\ \eta_{se}|_{[-h,0]} &= P^{-1}x_{se}|_{[-h,0]}. \end{aligned} \tag{5.13}$$

Since η_{se} can be written as $\eta_{se} = (y,\eta)^T$, it is clear that (5.13) can be decomposed as

$$\dot{y} = CBv_1, \tag{5.14}$$

$$\begin{aligned} \dot{\eta} &= dA_{22} * \eta + dA_{21} * v_2, \\ \gamma &= -(CB)^{-1}(dA_{12} * \eta + dA_{11} * v_2), \end{aligned} \tag{5.15}$$

$$v_1 = v + d_M - \gamma, \qquad v_2 = y \tag{5.16}$$

$$y|_{[-h,0]} = \eta_1, \qquad \eta|_{[-h,0]} = \eta_2, \tag{5.17}$$

where $(\eta_1,\eta_2) = \eta_{se}|_{[-h,0]}$ and in particular $\eta_1 = Cx_0$. Let $\eta(\eta_2,\eta_1,\omega)$ denote the solution of the retarded system (5.15) driven by the initial conditions $\eta|_{[-h,0]} = \eta_2, v_2|_{[-h,0]} = \eta_1$ and the input $v_2|_{[0,\infty)} = \omega \in LL^2(\mathbb{R}_+,\mathbb{R}^m)$. The corresponding output $\gamma(\eta_2,\eta_1,\omega)$ can be written in the form

$$\gamma(\eta_2,\eta_1,\omega) = \mathcal{K}\omega + \tilde{w}, \tag{5.18}$$

where

$$\mathcal{K}w = -(CB)^{-1}(dA_{12} * \eta(0,0,\omega) + dA_{11} * \omega) \tag{5.19}$$

and

$$\tilde{w} = -(CB)^{-1}(dA_{12} * \eta(\eta_2,\eta_1,0) + dA_{11} * \eta_1). \tag{5.20}$$

Step 3. We claim that the retarded system (5.15) is exponentially stable, which is equivalent to saying that $\det(sI - \hat{A}_{22}(s)) \neq 0$ for all $s \in \overline{\mathbb{C}}_+$, where $\hat{A}_{22}(s) = \int_0^h \exp(-s\tau)dA_{22}(\tau)$ (cf. Hale [6, p. 165]). It follows from the properties of P that

$$\det\begin{pmatrix} sI - \hat{A}_{se}(s) & -B_{se} \\ C_{se} & 0 \end{pmatrix} = \det\begin{pmatrix} sI - \hat{A}_{11}(s) & -\hat{A}_{12}(s) & -CB \\ -\hat{A}_{21}(s) & sI - \hat{A}_{22}(s) & 0 \\ I & 0 & 0 \end{pmatrix}.$$

Defining

$$T_1(s) := \begin{pmatrix} I & 0 & -(sI - \hat{A}_{11}(s)) \\ 0 & I & \hat{A}_{21}(s) \\ 0 & 0 & I \end{pmatrix}, \qquad T_2(s) := \begin{pmatrix} I & 0 & 0 \\ 0 & I & 0 \\ 0 & -(CB)^{-1}\hat{A}_{12}(s) & I \end{pmatrix},$$

we obtain

$$\begin{aligned}
&\det\begin{pmatrix} sI-\hat{A}_{se}(s) & -B_{se} \\ C_{se} & 0 \end{pmatrix} \\
&= \det\left\{ T_1(s)\begin{pmatrix} sI-\hat{A}_{11}(s) & -\hat{A}_{12}(s) & -CB \\ -\hat{A}_{21}(s) & sI-\hat{A}_{22}(s) & 0 \\ I & 0 & 0 \end{pmatrix} T_2(s) \right\} \\
&= \det\begin{pmatrix} 0 & 0 & -CB \\ 0 & sI-\hat{A}_{22}(s) & 0 \\ I & 0 & 0 \end{pmatrix} \\
&= (-1)^m \det(CB)\det(sI-\hat{A}_{22}(s)).
\end{aligned}$$

Hence $\det(sI-\hat{A}_{22}(s)) \neq 0$ for all $s \in \overline{\mathbb{C}}_+$ by the minimum-phase property (5.12).

Step 4. As a consequence of the exponential stability of the retarded system (5.15), the linear mapping $\mathcal{K}$ defined by (5.19) is bounded from $L^2(\mathbb{R}_+,\mathbb{R}^m)$ into itself and the function $\tilde{w}$ is in $L^2(\mathbb{R}_+,\mathbb{R}^m)$. Moreover, it is clear that the operator $\mathcal{K}$ is shift-invariant. The system given by (5.14)–(5.17) can be written as

$$\dot{y} = CB(v-\mathcal{K}y-w), \qquad y(0) = Cx_0(0), \tag{5.21}$$

where $w := \tilde{w} - d_M \in L^2(\mathbb{R}_+,\mathbb{R}^m)$. Let $\mathcal{K}$ be the unique element in $H^\infty(\mathbb{C}^{m\times m})$ such that $\mathcal{K} = \mathcal{L}^{-1}\mathcal{M}_K\mathcal{L}$. It is easy to see that K is of the form required for the application of Theorem 4.1, i.e.,

$$K(s) = s\left(\frac{p(s)}{q(s)} - 1\right)(CB)^{-1} + \frac{p(s)}{q(s)}H(s),$$

where $H(s)$ is given by (5.7). Statements (i)–(iii) follow now from Theorem 4.1. Finally, suppose that r is bounded. By statement (ii) this implies that y is bounded, and hence using the exponential stability of (5.15), we see that η is bounded. As a consequence $\eta_{se} = (\eta, y)^T$ is bounded, which in turn implies the boundedness of $x_{se} = (x,\xi)^T$. □

5.2. Integrodifferential convolution systems. Another interesting class of systems covered by Theorem 4.1 is the class of integrodifferential convolution systems. Consider the system

$$\begin{aligned}
\dot{x} &= A * x + Bu, \\
y &= Cx, \\
x(0) &= x_0 \in \mathbb{R}^n,
\end{aligned} \tag{5.22}$$

where $A \in M(\mathbb{R}_+,\mathbb{R}^{n\times n}), B \in \mathbb{R}^{n\times m}$, and $C \in \mathbb{R}^{m\times n}$. The Volterra integrodifferential system

$$\begin{aligned}
\dot{x}(t) &= A_0x(t) + \int_0^t A_1(t-\tau)x(\tau)d\tau + Bu(t), \\
y(t) &= Cx(t), \\
x(0) &= x_0 \in \mathbb{R}^n,
\end{aligned}$$

where $A_0 \in \mathbb{R}^{n\times n}$ and $A_1 \in L^1(\mathbb{R}_+,\mathbb{R}^{n\times n})$ is obviously a special case of (5.22). We assume that

$$\det(CB) \neq 0 \tag{5.23}$$

and

$$\det \begin{pmatrix} sI - \hat{A}(s) & -B \\ C & 0 \end{pmatrix} \neq 0 \quad \text{for all } s \in \overline{\mathbb{C}}_+, \tag{5.24}$$

where $\hat{A}(s) := \int_0^\infty \exp(-s\tau) dA(\tau)$.

THEOREM 5.3. *If* (5.23) *and* (5.24) *are satisfied, then for any* $x_0 \in \mathbb{R}^n, \xi_0 \in \mathbb{R}^l, k_0 \in \mathbb{R}$, $r \in \mathcal{S}_\rho$, *and* $d \in \mathcal{S}_\delta + L^2(\mathbb{R}_+, \mathbb{R}^m)$, *the closed-loop system given by* (5.22) *and* (5.4)–(5.6) *has the following properties*:

(i) $\lim_{t\to\infty} k(t)$ *exists and is finite*;
(ii) $y - r \in L^2(\mathbb{R}_+, \mathbb{R}^m) \cap L^\infty(\mathbb{R}_+, \mathbb{R}^m)$;
(iii) $\lim_{t\to\infty}(y(t)) - r(t)) = 0$;
(iv) $(x, \xi)^T \in L^\infty(\mathbb{R}_+, \mathbb{R}^{n+l})$, *provided* r *is bounded.*

Proof. Defining

$$A_{se} := \begin{pmatrix} A & \delta_0 B C_M \\ 0 & \delta_0 A_M \end{pmatrix}, \qquad B_{se} := \begin{pmatrix} B \\ B_M \end{pmatrix},$$
$$C_{se} := (C, 0) \quad \text{and} \quad x_{se} := \begin{pmatrix} x \\ \xi \end{pmatrix},$$

where δ_0 denotes the unit point mass at 0, the series connection of (5.4) followed by (5.22) in the presence of the disturbance d can be formulated as follows:

$$\begin{aligned} \dot{x}_{se} &= A_{se} * x_{se} + B_{se}(v + d_M), \\ y &= C_{se} x_{se}, \\ x_{se}(0) &= \begin{pmatrix} x_0 \\ \xi_0 \end{pmatrix}, \end{aligned} \tag{5.25}$$

where d_M is given by (5.8).

Using the same coordinate transformation P as in §5.1, it is clear that (5.25) can be written in the form

$$\dot{y} = CBv_1, \tag{5.26}$$

$$\begin{aligned} \dot{\eta} &= A_{22} * \eta + A_{21} * v_2, \\ \gamma &= -(CB)^{-1}(A_{12} * \eta + A_{11} * v_2); \end{aligned} \tag{5.27}$$

$$v_1 = v + d_M - \gamma, \qquad v_2 = y, \tag{5.28}$$

$$(y(0), \eta(0))^T = P^{-1} x_{se}(0), \tag{5.29}$$

where $(y, \eta)^T = P^{-1} x_{se}$ and the A_{ij} are bounded matrix-valued measures on $\mathbb{R}_+$. Let R denote the differential resolvent of the integrodifferential system (5.27), i.e., R is the unique solution of

$$\dot{R} = A_{22} * R, \qquad R(0) = I.$$

The solution η is then given by

$$\eta(t) = R(t)\eta(0) + (R * A_{21} * v_2)(t)$$

(see Gripenberg, Londen, and Staffans [5, p. 76]) and the output γ can be written in the form

$$\gamma = \mathcal{K}v_2 + \tilde{w},$$

where

$$\mathcal{K}v_2 = -(CB)^{-1}(A_{12} * R * A_{21} + A_{11}) * v_2 \tag{5.30}$$

and

$$\tilde{w} = -(CB)^{-1}(A_{12} * R)\eta(0). \tag{5.31}$$

Now we can show, as in §5.1, that

$$\det(sI - \hat{A}_{22}(s)) \neq 0 \quad \text{for all } s \in \overline{\mathbb{C}}_+, \tag{5.32}$$

where $\hat{A}_{22}(s) = \int_0^\infty \exp(-s\tau)dA_{22}(\tau)$, and hence R is integrable (see Gripenberg, Londen, and Staffans [5, p. 83]). It follows that the linear operator $\mathcal{K}$ defined by (5.30) is bounded from $L^2(\mathbb{R}_+, \mathbb{R}^m)$ into itself. Moreover it is trivial to show that $\mathcal{K}$ is shift-invariant. Since R is integrable we obtain from Gripenberg, Londen, and Staffans [5, p. 83], that the entries of R are square-integrable as well. Therefore the function $\tilde{w}$ defined by (5.31) is in $L^2(\mathbb{R}_+, \mathbb{R}^m)$. Finally it follows that the system (5.25) can be written as

$$\dot{y} = CB(v - \mathcal{K}y - w), \qquad y(0) = Cx_0,$$

where $w := \tilde{w} - d_M$ is in $L^2(\mathbb{R}_+, \mathbb{R}^m)$ (by (5.8)) and $\mathcal{K} : L^2(\mathbb{R}_+, \mathbb{R}^m) \to L^2(\mathbb{R}_+, \mathbb{R}^m)$ is linear bounded and shift-invariant. The claim now follows in exactly the same way as in the proof of Theorem 5.2. □

6. Conclusions. In this paper we have presented an input-output approach to the adaptive servoproblem for multivariable infinite-dimensional minimum-phase systems with invertible high-frequency gains. In particular, we have shown the following:

- The switching algorithm, introduced by Byrnes and Willems [1] in a finite-dimensional state-space set-up, stabilizes any infinite-dimensional plant belonging to the class of systems given by (2.1).
- The series interconnection of the Byrnes–Willems controller with a suitable precompensator solves the adaptive servoproblem for the class of systems satisfying (2.1).
- The input-output results obtained in §§3 and 4 apply to retarded systems and integro-differential convolution systems.

The adaptive control laws presented in §§3 and 4 give positive answers to feasibility and existence questions. They do not provide satisfying adaptive controllers from an engineer's point of view. However, the following comments show that the results of this paper might also be of some practical importance.

- It seems plausible that the technique in §4 (or variations thereof) can be used in order to obtain adaptive servomechanisms from various adaptive stabilization algorithms available in the literature.
- If the conjecture formulated in §3 turns out to be true, the high-gain switching algorithm can be used in order to identify a stabilizing linear controller or a linear servocompensator for the class of infinite-dimensional systems under consideration by a single simulation.

7. Appendix.

Proof of Lemma 3.2. The closed-loop system is given by

$$\begin{aligned} \dot{y}(t) &= D(k(t)K_{\sigma(k(t))}y(t) - (\mathcal{H}y)(t) - w(t)), \\ \dot{k}(t) &= \|y(t)\|^2, \qquad t \geq 0, \\ y(0) &= y_0, \qquad k(0) = k_0. \end{aligned} \tag{7.1}$$

Without loss of generality we may assume that $k_0 \geq 0$. The proof is divided into three steps.

Step 1. Existence and uniqueness on a "small" interval.

Consider equation (7.1) with $\sigma(k(t))$ replaced by $\sigma(k_0)$, i.e.,

$$\begin{aligned} \dot{y}(t) &= D(k(t)K_{\sigma(k_0)}y(t) - (\mathcal{H}y)(t) - w(t)), \\ \dot{k}(t) &= \|y(t)\|^2, \qquad t \geq 0, \\ y(0) &= y_0, \qquad k(0) = k_0 \end{aligned} \tag{7.2}$$

By Theorem 2.5, (7.2) has a unique absolutely continuous solution $(\tilde{y}, \tilde{k})$ on some interval $[0, T)$. Set $\tau(k_0) = \min\{\tau_i \mid \tau_i > k_0\}$ and let $T' \in (0, T)$ be such that $\tilde{k}(T') < \tau(k_0)$. Since $\sigma(\tilde{k}(t)) = \sigma(k_0)$ for all $t \in [0, T']$, it follows that $(\tilde{y}, \tilde{k})$ is the unique solution of (7.1) on $[0, T')$.

Step 2. Extended uniqueness.

Let (y_i, k_i) be solutions of (7.1) on $[0, T_j), i = 1, 2$. We claim that $(y_1, k_1) \equiv (y_2, k_2)$ on $[0, T)$, where $T := \min(T_1, T_2)$. Let us assume the contrary, i.e. there exists $t \in (0, T)$ for which $(y_1(t), k_1(t)) \neq (y_2(t), k_2(t))$. Defining

$$t^* := \inf\{t \in (0, T) \mid (y_1(t), k_1(t)) \neq (y_2(t), k_2(t))\},$$

it follows that $t^* > 0$ (by Step 1) and $(y_1(t^*), k_1(t^*)) = (y_2(t^*), k_2(t^*))$ (by continuity). Now set $k^* := k_1(t^*) = k_2(t^*)$ and realize that the initial-value problem

$$\begin{aligned} \dot{y}(t) &= D(k(t)K_{\sigma(k^*)}y(t) - (\mathcal{H}y)(t) - w(t)), \\ \dot{k}(t) &= \|y(t)\|^2, \qquad t \geq t^*, \\ y|_{[0,t^*]} &= y_1|_{[0,t^*]}, \qquad k|_{[0,t^*]} = k_1|_{[0,t^*]} \end{aligned} \tag{7.3}$$

is solved by (y_1, k_1) and (y_2, k_2) on $[0, t^* + \epsilon)$ for some sufficiently small $\epsilon > 0$. It follows from Theorem 2.5 that $(y_1(t), k_1(t)) = (y_2(t), k_2(t))$ for all $t \in [0, t^* + \epsilon)$, which contradicts the definition of t^*.

Step 3. Continuation of solutions.

Let $(\tilde{y}, \tilde{k})$ be a solution of (7.1) on $[0, T), 0 < T < \infty$. Assume that $(\tilde{y}, \tilde{k})$ is bounded. We claim that under these conditions the solution $(\tilde{y}, \tilde{k})$ can be continued to the right (beyond T). Since $\tilde{k}$ is bounded, continuous, and nondecreasing, it is clear that $\lim_{t \to T} \tilde{k}(t) =: \tilde{k}_T$ exists and is finite. As a consequence we have $\tilde{y} \in L^2(0, T; \mathbb{R}^m)$ and hence, by (7.1), $\dot{\tilde{y}} \in L^2(0, T; \mathbb{R}^m) \subset L^1(0, T; \mathbb{R}^m)$. Using the fact that

$$\tilde{y}(t) = y_0 + \int_0^t \dot{\tilde{y}}(\tau) d\tau,$$

it follows that $\lim_{t \to T} \tilde{y}(t) =: \tilde{y}_T$ exists and is finite. By Theorem 2.5 the initial-value problem

$$\begin{aligned} \dot{y}(t) &= D(k(t)K_{\sigma(\tilde{k}_T)}y(t) - (\mathcal{H}y(t) - w(t)), \\ \dot{k}(t) &= \|y(t)\|^2, \qquad t \geq T, \\ y(t) &= \begin{cases} \tilde{y}(t), & t \in [0, T), \\ \tilde{y}_T, & t = T, \end{cases} \qquad k(t) = \begin{cases} \tilde{k}(t), & t \in [0, T), \\ \tilde{k}_T, & t = T, \end{cases} \end{aligned}$$

has a unique absolutely continuous solution $(\bar{y}, \bar{k})$ on $[0, T+\epsilon)$ for some $\epsilon > 0$. Finally let $\delta \in (0, \epsilon)$ be such that

$$\bar{k}(T+\delta) < \min\{\tau_i \mid \tau_i > \tilde{k}_T\}.$$

Then $(\bar{y}, \bar{k})$ is a solution of (7.1) on $[0, T+\delta)$ extending the solution $(\tilde{y}, \tilde{k})$. □

MINIMAX-OPTIMAL STRATEGIES FOR THE BEST-CHOICE PROBLEM WHEN A BOUND IS KNOWN FOR THE EXPECTED NUMBER OF OBJECTS*

T. P. HILL† AND D. P. KENNEDY‡

Abstract. For the best-choice (or secretary) problem with an unknown number N of objects, minimax-optimal strategies for the observer and minimax distributions for N are derived under the assumption that N is a random variable with expected value at most M, where M is known. The solution is derived as a special case of the situation where N is constrained by $Ef(N) \leq M$, where f is increasing with $f(i) - f(i-1)$ convex.

Key words. best-choice problem; secretary problem; minimax strategies; optimal stopping; convexity; Lagrangian; Lagrange multiplier

AMS subject classification. 60G40

1. Introduction.

In the classical best-choice (or secretary) problem a known fixed number, n, of rankable objects is presented one by one in random order (all $n!$ possible orderings being equally likely). As each object is presented, the observer must either select it and stop observing or reject it and continue observing. He may never return to a previously rejected object, and his decision to stop must be based solely on the relative ranks of the objects he has observed so far. The goal is to maximize the probability that the best object is selected. For a history and review of the literature of this problem and its numerous variants the reader is referred to Freeman (1983) and Ferguson (1989). In the best-choice setting, the optimal strategy for the observer is to view k_n objects without selecting and subsequently to take the first object, if any, better than all its predecessors, where $k_1 = 0$ and for $n > 1$, k_n is the unique positive integer satisfying

$$\sum_{i=k_n}^{n-1} \frac{1}{i} \geq 1 > \sum_{i=k_n+1}^{n-1} \frac{1}{i}.$$

If the number of objects is not known, but is a random variable taking values in the positive integers, then minimax-optimal strategies for selecting the best object are known for several situations (cf. Freeman (1983), Ferguson (1989)). For example, Presman and Sonin (1972) derived the optimal stop rules when the distribution of N is known, and Hill and Krengel (1991) found minimax-optimal stop rules (and distributions) when N has unknown distribution but known upper bound n. It is the purpose of this paper to derive the analogous minimax-optimal strategies when N again has unknown distribution, but has expectation at most M, where M is known. Since the arguments in this case generalize easily to the constraint $Ef(N) \leq M$, where f is a known positive function for which $f(i) - f(i-1)$ is nondecreasing and convex, the proofs will be given in the more general setting. The reader may want to keep in mind the natural case $f(i) \equiv i$, which corresponds to the expected-value constraint.

In the (zero-sum, two-person) game-theoretic interpretation of this problem there are two players, a controller P and an observer Q. Given $M > 0$ and a constraint function f, player P first picks a distribution for the number of objects, subject to the constraint $E(f(N)) \leq M$, and then the actual number N of objects to be presented to Q is chosen randomly according to this distribution. Then, knowing only the constraint (and not N itself), player Q begins

‡ Statistical Laboratory, Department of Pure Mathematics and Mathematical Statistics, University of Cambridge, 16 Mill Lane, Cambridge CB2 1SB, United Kingdom.

his observation-selection of the objects and receives one dollar from player P if the object he selects is the best of the N objects and pays player Q one dollar if it is not the best.

Formally, the strategies available to the two players are given as follows. For $M \geq f(1)$, the set of allowable strategies for player P is

$$\mathcal{P}_M = \left\{ \mathbf{p} = (p_1, p_2, \cdots) : p_j \geq 0, \sum_{j=1}^{\infty} p_j = 1, \sum_{j=1}^{\infty} f(j) p_j \leq M \right\}$$

(the set of distributions for N for which $Ef(N) \leq M$), and

$$\mathcal{Q} = \{ \mathbf{q} = (q_1, q_2, \cdots) : 0 \leq q_j \leq 1 \}$$

is the set of allowable strategies for player Q, where if strategy $\mathbf{q}$ is used player Q stops at object j with probability q_j (independently of the rest of the process) if object j is the best so far. If the strategies $\mathbf{p}$, $\mathbf{q}$ are used by the respective players, the pay-off function $V(\mathbf{p}, \mathbf{q})$, which is the probability that player Q selects the best object, is given (cf. Hill and Krengel (1991)) by

$$V(\mathbf{p}, \mathbf{q}) = \sum_{j=1}^{\infty} \frac{p_j}{j} \sum_{i=1}^{j} q_i \prod_{m=1}^{i-1} \left(1 - \frac{q_m}{m}\right). \tag{1}$$

For each value of $M \geq f(1)$, the aim is to derive minimax-optimal strategies $\mathbf{p}_M \in \mathcal{P}_M$, $\mathbf{q}_M \in \mathcal{Q}$ satisfying

$$V(\mathbf{p}_M, \mathbf{q}) \leq V(\mathbf{p}_M, \mathbf{q}_M) \leq V(\mathbf{p}, \mathbf{q}_M) \quad \text{for all } \mathbf{p} \in \mathcal{P}_M, \mathbf{q} \in \mathcal{Q}. \tag{2}$$

Example 1.1. As will follow from the main results below, for the optimal strategies when N is a random variable with expected value at most 3, the optimal strategy for the observer is $(\frac{7}{13}, 1, 1, \cdots)$, i.e., stop with the first object with probability $\frac{7}{13}$, and otherwise stop with the first object thereafter, if any, that is better than any previously seen. Using this strategy, the best object will be selected with probability at least $\frac{16}{39}$ no matter what the distribution of N is, provided its expectation is at most 3. Conversely, the optimal P-strategy (worst-case distribution) for this case is $(\frac{2}{13}, 0, \frac{7}{13}, \frac{4}{13}, 0, 0, \cdots)$, i.e., there is only the one object with probability $\frac{2}{13}$, exactly three objects with probability $\frac{7}{13}$, and exactly four objects with probability $\frac{4}{13}$; and against this distribution no stop rule will select the best object with probability exceeding $\frac{16}{39}$.

That the optimal Q-strategy is monotonic is intuitive (since if it is good to stop at time j with the best object seen so far, it is even better to stop at later times if that object is the best yet seen), but that the optimal P-strategy typically (as in Example 1.1) places mass on *two* large numbers seems surprising, and it is never the case for the uniformly bounded problem. In general, the optimal value is a complicated piecewise linear function of the form $\lambda + \mu M$ for appropriate λ and μ. It will be seen that there are real numbers $a_1 < a_2 < \cdots$, such that the minimax-optimal $\mathbf{q}_M$ is constant over each interval $a_i \leq M \leq a_{i+1}$, while the minimax-optimal $\mathbf{p}_M$ is linear in M in the interval and is thus a convex combination of the distributions that are optimal at the end points $M = a_i$ and $M = a_{i+1}$. The next example, which identifies values and optimal strategies for an interval of values of M (including the special case $M = 3$ of Example 1.1), shows typical behavior of the optimal strategies and value as M varies.

Example 1.2. As will follow from the main results below, for the expected-value constraint $f(i) \equiv i$, the optimal strategies and value for $19/7 \leq M \leq 317/75$ are as follows.

If $19/7 \le M < 101/29$:

$$\mathbf{q}_M = \left(\frac{7}{13}, 1, 1, \cdots\right);$$
$$\mathbf{p}_M = a_M \left(\frac{1}{7}, 0, \frac{6}{7}, 0, 0, \cdots\right) + (1 - a_M) \left(\frac{5}{29}, 0, 0, \frac{24}{29}, 0, 0, \cdots\right),$$

where $a_M = 7(101 - 29M)/156$;

$$V(\mathbf{p}_M, \mathbf{q}_M) = (47 - 5M)/78.$$

If $101/29 \le M < 69/17$:

$$\mathbf{q}_M = \left(\frac{105}{213}, 1, 1, \cdots\right);$$
$$\mathbf{p}_M = b_M \left(\frac{5}{29}, 0, 0, \frac{24}{29}, 0, \cdots\right) + (1 - b_M) \left(\frac{3}{17}, 0, 0, \frac{4}{17}, \frac{10}{17}, 0, \cdots\right),$$

where $b_M = 29(69 - 17M)/284$;

$$V(\mathbf{p}_M, \mathbf{q}_M) = (459 - 39M)/852.$$

If $69/17 \le M < 317/75$:

$$\mathbf{q}_M = \left(\frac{50}{107}, \frac{14}{19}, 1, 1, \cdots\right);$$
$$\mathbf{p}_M = c_M \left(\frac{3}{17}, 0, 0, \frac{4}{17}, \frac{10}{17}, 0, 0, \cdots\right) + (1 - c_M) \left(\frac{13}{75}, \frac{2}{75}, 0, 0, \frac{60}{75}, 0, \cdots\right),$$

where $c_M = 17(317 - 75M)/214$;

$$V(\mathbf{p}_M, \mathbf{q}_M) = (54 - 4M)/107.$$

Although the statements of the main results in this article are probabilistic in nature, the proofs are primarily optimization-theoretic. Since general optimization theory saddle-point theorems do not seem to yield a direct solution to the problem formulated here, optimization arguments using a Lagrangian, but heavily based on ad hoc convexity tools, have been developed. In principle, one could use the same techniques to handle a larger class of constraint functions such as those reflecting known bounds on means *and* variances (or several other moments), but this would involve examination of the many cases corresponding to criticality of the various constraints and is not done here.

The organization of the paper is as follows. Section 2 introduces notation, important parameters, and the value of the game and establishes a number of useful identities and inequalities, the proofs of which may be skipped at first reading. Section 3 identifies the minimax-optimal strategy for the observer player Q, which is obtained by solving for the coefficient of p_j/j in a Lagrangian, and §4 builds on these results to establish the optimal (worst-case) distribution for N (i.e., the minimax-optimal strategy for the controller player P), and summarizes all the results in the main theorem, Theorem 4.3.

2. Notation, preliminaries and the value of the game. The first lemma records some easy convexity results; the proof is left to the reader.

LEMMA 2.1. *Suppose* $g : \mathbb{N} \to (0, \infty)$. *Then*

(i) g *is convex (respectively, strictly convex) if and only if* $g(i) - g(i-1)$ *is nondecreasing (increasing) in* i;

(ii) *if* g *is convex (respectively, strictly convex), then* $\sum_{j=k+1}^{i} g(j)/(i-k)$ *is convex (strictly convex) in* $i > k$ *for each* $k \geq 0$.

Basic assumption. Throughout this paper, $f(0) = 0$ and $f : \mathbb{N} \to (0, \infty)$ and

$$f(i) - f(i-1) \quad \text{is nondecreasing and convex,} \tag{3}$$

the canonical example being $f(i) \equiv i$.

Let $s_0 = 0$, $s_k = \sum_{j=1}^{k} 1/j$ for $k \geq 1$ and for $1 \leq k < n$, set $s_k^n = s_n - s_k$ and $F_k^n = nf(n) - kf(k)$.

LEMMA 2.2. *For all such* f,

(i) $f(i)$ *is increasing and convex on* $i \in \mathbb{N}$;

(ii) $if(i)$ *is increasing and strictly convex on* $i \in \mathbb{N}$;

(iii) $if(i) - (i-1)f(i-1)$ *is increasing and convex on* $i \in \mathbb{N}$;

(iv) $s_k^n/(n-k)$ *is decreasing and strictly convex in* $n > k$;

(v) $F_k^n/(n-k)$ *is increasing and convex in* $n > k$;

(vi) F_k^n/s_{k-1}^{n-1} *is increasing in* $n > k$,

(vii) $\frac{F_k^{n+1}}{n-k+1} > \frac{F_k^n}{n-k} \geq F_k^{k+1} > f(k) > (\sum_{j=1}^{k-1} \frac{f(j)}{j+1} + f(k))/s_k$.

Proof. The proof is routine, using (3), Lemma 2.1 and the definitions of s_k^n and F_k^n. □

The next objective will be to define some basic parameters that play a central role in the main results of this paper and to establish some useful inequalities and equalities interrelating these parameters.

For $1 \leq k < n$, define $\alpha_{n,k} > 0$, $\overline{\alpha}_{n,k} > 0$, $m_{n,k} > 0$, $\overline{m}_{n,k} > 0$, $\lambda_{n,k} > 0$, and $\mu_{n,k} < 0$, as follows:

$$\frac{1}{\alpha_{n,k}} = s_k + \frac{n-k}{ks_{k-1}^{n-1}}, \qquad \frac{1}{\overline{\alpha}_{n,k}} = s_k + \frac{n-k+n(1-s_k^{n-1})}{k+1}, \tag{4}$$

$$\begin{aligned} \frac{m_{n,k}}{\alpha_{n,k}} &= \sum_{j=1}^{k-1} \frac{f(j)}{j+1} + f(k) + \frac{F_k^n}{ks_{k-1}^{n-1}}, \\ \frac{\overline{m}_{n,k}}{\overline{\alpha}_{n,k}} &= \sum_{j=1}^{k-1} \frac{f(j)}{j+1} + f(k) + \frac{F_k^n + nF_n^{n+1}(1-s_k^{n-1})}{k+1}, \end{aligned} \tag{5}$$

$$\lambda_{n,k} = \frac{\alpha_{n,k}m_{n+1,k} - \alpha_{n+1,k}m_{n,k}}{m_{n+1,k} - m_{n,k}}, \qquad \mu_{n,k} = \frac{\alpha_{n+1,k} - \alpha_{n,k}}{m_{n+1,k} - m_{n,k}}. \tag{6}$$

Note that $\alpha_{n,k}$ and $\overline{\alpha}_{n,k}$ do not depend on f. Using these parameters, the value of the game $\mathbf{v}_M = V(\mathbf{p}_M, \mathbf{q}_M)$ appearing in (2) can now be stated (although proof that it is indeed the value is the subject of the subsequent sections).

Recall that k_n is the optimal cutoff value for the classical secretary problem with n objects and so $s_{k_n-1}^{n-1} \geq 1 > s_{k_n}^{n-1}$ and $k_n \leq k_{n+1} \leq k_n + 1$. Set $m_n = m_{n,k_n}$, $\overline{m}_n = \overline{m}_{n,k_n}$, $\alpha_n = \alpha_{n,k_n}$, and $\overline{\alpha}_n = \overline{\alpha}_{n,k_n}$.

DEFINITION. *For all* $M > f(1)$,

$$v_M = \begin{cases} \lambda_{n,k_n} + \mu_{n,k_n} M & \text{if } m_n \le M < m_{n+1} \text{ and } k_{n+1} = k_n, \text{ or} \\ & \text{if } m_n \le M < \overline{m}_n \text{ and } k_{n+1} = k_n + 1, \\ \lambda_{n,k_{n+1}} + \mu_{n,k_{n+1}} M & \text{if } \overline{m}_n \le M < m_{n+1} \text{ and } k_{n+1} = k_n + 1. \end{cases} \tag{7}$$

Notice that $v_{m_n} = \alpha_n$, *and* $v_{\overline{m}_n} = \overline{\alpha}_n$ *when* $k_{n+1} = k_n + 1$.

Example 2.3. For the canonical expected-value case $f(i) \equiv i$,

$$(m_3, m_4, \overline{m}_4, m_5) = \left(\frac{19}{7}, \frac{101}{29}, \frac{69}{17}, \frac{317}{75}\right),$$

$$(\alpha_{3,1}, \alpha_{4,1}, \alpha_{5,1}, \alpha_{4,2}, \alpha_{5,2}) = \left(\frac{3}{7}, \frac{11}{29}, \frac{25}{73}, \frac{10}{27}, \frac{26}{75}\right),$$

$$(m_{3,1}, m_{4,1}, m_{5,1}, m_{4,2}, m_{5,2}) = \left(\frac{19}{7}, \frac{101}{29}, \frac{313}{73}, \frac{97}{27}, \frac{317}{75}\right),$$

$$(\lambda_{3,1}, \lambda_{4,1}, \lambda_{4,2}) = \left(\frac{47}{78}, \frac{459}{852}, \frac{54}{107}\right), \quad \text{and}$$

$$(\mu_{3,1}, \mu_{4,1}, \mu_{4,2}) = \left(\frac{-5}{78}, \frac{-39}{852}, \frac{-4}{107}\right),$$

and together with (7) these yield the value $v_M = V(\mathbf{p}_M, \mathbf{q}_M)$ in Example 1.2. □

The next lemma establishes some useful inequalities.

LEMMA 2.4. *For* $n > 1$,

(i) *for fixed* k, $\alpha_{n,k}$ *is decreasing in* $n > k$;

(ii) *for fixed* k, $m_{n,k}/\alpha_{n,k}$ *and* $m_{n,k}$ *are increasing in* $n > k$;

(iii) *for fixed* n, $\alpha_{n,k}$ *is maximized at* $k = k_n$; $\alpha_{n,k}$ *is increasing in* k, $1 \le k \le k_n$, *and decreasing in* k, $k_n \le k \le n$;

(iv) *for fixed* n, $m_{n,k}/\alpha_{n,k}$ *and* $m_{n,k}$ *are minimized at* $k = k_n$; *they are decreasing in* k, $1 \le k \le k_n$ *and increasing in* k, $k_n \le k \le n$;

(v) $\overline{\alpha}_n < \alpha_n < \alpha_{n-1}$;

(vi) $\overline{m}_n > m_n > m_{n-1}$;

(vii) $\overline{\alpha}_n \ge \alpha_{n+1}$ *when* $k_{n+1} = k_n + 1$;

(viii) $m_{n,k_{n+1}} \le \overline{m}_n \le m_{n+1} < m_{n+1,k_n}$ *when* $k_{n+1} = k_n + 1$; *and*

(ix) $\lambda_{n,k} > 0$ *and* $\mu_{n,k} < 0$.

Proof. (i) By Lemma 2.2 (iv),

$$1/\alpha_{n,k} = s_k + (n-k)/(ks_{k-1}^{n-1}) < s_k + (n-k+1)/(ks_{k-1}^{n}) = 1/\alpha_{n+1,k}.$$

(ii) By Lemma 2.2 (vi),

$$\frac{m_{n+1,k}}{\alpha_{n+1,k}} - \frac{m_{n,k}}{\alpha_{n,k}} = \frac{F_k^{n+1}}{ks_{k-1}^{n}} - \frac{F_k^{n}}{ks_{k-1}^{n-1}} > 0.$$

Also, (i), (4), and Lemma 2.2 (vii) give

$$m_{n+1,k} - m_{n,k} = (\alpha_{n,k} - \alpha_{n+1,k}) \left(\frac{s_k F_k^n}{n-k} - \sum_{j=1}^{k-1} \frac{f(j)}{j+1} - f(k) \right) + \left(\frac{F_k^{n+1}}{n-k+1} - \frac{F_k^n}{n-k} \right) (1 - s_k \alpha_{n+1,k}) > 0.$$

(iii) Observing that $n-k-1 > ks_k^{n-1}$, it may be seen that the difference

$$\frac{1}{\alpha_{n,k+1}} - \frac{1}{\alpha_{n,k}} = \frac{(s_k^{n-1}-1)(1-(n-k-1)/(ks_k^{n-1}))}{(k+1)s_{k-1}^{n-1}}$$

is ≤ 0 or > 0 according as $k < k_n$ or $k \geq k_n$.

(iv) By Lemma 2.2 (ii), $F_{k+1}^n > (n-k-1)F_k^{k+1}$ and since $n-k-1 > ks_k^{n-1}$,

$$\frac{F_{k+1}^n}{ks_k^{n-1}} = \left(\frac{F_{k+1}^n}{n-k-1}\right)\left(\frac{n-k-1}{ks_k^{n-1}}\right) > F_k^{k+1}.$$

It follows that

$$\frac{m_{n,k+1}}{\alpha_{n,k+1}} - \frac{m_{n,k}}{\alpha_{n,k}} = \frac{(s_k^{n-1}-1)}{(k+1)s_{k-1}^{n-1}}\left(F_k^{k+1} - \frac{F_{k+1}^n}{ks_k^{n-1}}\right)$$

is ≤ 0 or > 0 according as $k < k_n$ or $k \geq k_n$. This last equality implies

$$\begin{aligned} m_{n,k+1} - m_{n,k} &= \alpha_{n,k+1}\left[\frac{m_{n,k+1}}{\alpha_{n,k+1}} - \frac{m_{n,k}}{\alpha_{n,k}} + m_{n,k}\left(\frac{1}{\alpha_{n,k}} - \frac{1}{\alpha_{n,k+1}}\right)\right] \\ &= \frac{\alpha_{n,k+1}(s_k^{n-1}-1)}{(k+1)s_{k-1}^{n-1}}\left[F_k^{k+1} - m_{n,k} + \left(\frac{(n-k-1)m_{n,k} - F_{k+1}^n}{ks_k^{n-1}}\right)\right]. \end{aligned}$$

From (4), (5), and Lemma 2.2 (vii) note that

$$\frac{m_{n,k}}{\alpha_{n,k}} < s_k f(k) + \frac{F_k^n}{ks_{k-1}^{n-1}} = s_k\left(f(k) - \frac{F_k^n}{n-k}\right) + \frac{F_k^n}{(n-k)\alpha_{n,k}} < \frac{F_k^n}{(n-k)\alpha_{n,k}};$$

hence

$$m_{n,k} < \frac{F_k^n}{n-k} < \frac{F_{k+1}^n}{n-k-1} < F_{n-1}^n. \tag{8}$$

Since $n-k-1 > ks_k^{n-1}$, it follows that

$$F_k^{k+1} - m_{n,k} + \left(\frac{(n-k-1)m_{n,k} - F_{k+1}^n}{ks_k^{n-1}}\right) < F_k^{k+1} - \frac{F_{k+1}^n}{n-k-1} < 0,$$

which implies that $m_{n,k+1} \leq m_{n,k}$ or $m_{n,k+1} > m_{n,k}$ according as $k < k_n$ or $k \geq k_n$.

(v) Note that $ns_{k-1}^{n-1} > n-k$. Since from (4),

$$\frac{1}{\overline{\alpha}_{n,k}} - \frac{1}{\alpha_{n,k}} = \frac{(1-s_k^{n-1})(ns_{k-1}^{n-1} - (n-k))}{(k+1)s_{k-1}^{n-1}},$$

putting $k = k_n$ and recalling the fact that $1 > s_{k_n}^{n-1}$ gives the result.

(vi) From (5),

$$\frac{\overline{m}_{n,k}}{\overline{\alpha}_{n,k}} - \frac{m_{n,k}}{\alpha_{n,k}} = \frac{(1-s_k^{n-1})}{k+1}\left(nF_n^{n+1} - \frac{F_k^n}{s_{k-1}^{n-1}}\right).$$

Hence

$$\overline{m}_{n,k} - m_{n,k} = \overline{\alpha}_{n,k}\left[\frac{\overline{m}_{n,k}}{\overline{\alpha}_{n,k}} - \frac{m_{n,k}}{\alpha_{n,k}} + m_{n,k}\left(\frac{1}{\alpha_{n,k}} - \frac{1}{\overline{\alpha}_{n,k}}\right)\right]$$
$$= \frac{\overline{\alpha}_{n,k}(1-s_k^{n-1})}{k+1}\left[n(F_n^{n+1} - m_{n,k}) - \frac{F_k^n - (n-k)m_{n,k}}{s_{k-1}^{n-1}}\right].$$

Again using the inequality $s_{k-1}^{n-1} > (n-k)/n$ and (8),

$$n(F_n^{n+1} - m_{n,k}) - \frac{F_k^n - (n-k)m_{n,k}}{s_{k-1}^{n-1}} > n\left(F_n^{n+1} - \frac{F_k^n}{n-k}\right) > 0,$$

whence $\overline{m}_{n,k} - m_{n,k}$ is >0 or ≤ 0 according as $1 > s_k^{n-1}$ or $1 \leq s_k^{n-1}$. From (ii) and (iv) above, $m_n = m_{n,k_n} \leq m_{n,k_{n+1}} < m_{n+1,k_{n+1}} = m_{n+1}$.

(vii) Similarly,

$$\frac{1}{\overline{\alpha}_{n,k}} - \frac{1}{\alpha_{n+1,k+1}} = \frac{(1-s_k^n)(ns_k^n - (n-k))}{(k+1)s_k^n},$$

which is ≤ 0 or >0 according as $k < k_{n+1}$ or $k \geq k_{n+1}$; taking $k = k_n < k_{n+1}$ gives the result.

(viii) Note that

$$\frac{m_{n+1,k+1}}{\alpha_{n+1,k+1}} - \frac{\overline{m}_{n,k}}{\overline{\alpha}_{n,k}} = \frac{(1-s_k^n)(F_{k+1}^{n+1} - nF_n^{n+1}s_k^n)}{(k+1)s_k^n},$$

and it follows using the expression in the proof of (vii) above that

$$m_{n+1,k+1} - \overline{m}_{n,k} = \overline{\alpha}_{n,k}\left[\frac{m_{n+1,k+1}}{\alpha_{n+1,k+1}} - \frac{\overline{m}_{n,k}}{\overline{\alpha}_{n,k}} + m_{n+1,k+1}\left(\frac{1}{\overline{\alpha}_{n,k}} - \frac{1}{\alpha_{n+1,k+1}}\right)\right]$$
$$= \frac{\overline{\alpha}_{n,k}(1-s_k^n)}{(k+1)s_k^n}[F_{k+1}^{n+1} - (n-k)m_{n+1,k+1} - ns_k^n(F_n^{n+1} - m_{n+1,k+1})].$$

Observe from (8) that $m_{n+1,k+1} < F_n^{n+1}$ and using $ns_k^n > n-k$ gives

$$F_{k+1}^{n+1} - (n-k)m_{n+1,k+1} - ns_k^n(F_n^{n+1} - m_{n+1,k+1}) < 0,$$

from which it may be seen that $\overline{m}_n \leq m_{n+1} < m_{n+1,k_n}$ by setting $k = k_n < k_{n+1}$ and using (iv) above. That $m_{n,k_{n+1}} \leq \overline{m}_n$ in this case follows in a similar fashion.

(ix) The conclusion follows easily from (6) and (i)–(viii) above. □

The next lemma records some useful identities relating the parameters.

LEMMA 2.5. *For* $1 \leq k < n$, *the following equations* (9)–(17) *hold*:

$$\frac{\overline{\alpha}_{n,k} - \alpha_{n,k}}{\overline{m}_{n,k} - m_{n,k}} = \mu_{n,k} = \frac{\alpha_{n+1,k} - \overline{\alpha}_{n,k}}{m_{n+1,k} - \overline{m}_{n,k}}; \tag{9}$$

$$\frac{\alpha_{n,k}\overline{m}_{n,k} - \overline{\alpha}_{n,k}m_{n,k}}{\overline{m}_{n,k} - m_{n,k}} = \lambda_{n,k} = \frac{\overline{\alpha}_{n,k}m_{n+1,k} - \alpha_{n+1,k}\overline{m}_{n,k}}{m_{n+1,k} - \overline{m}_{n,k}}; \tag{10}$$

$$\frac{\overline{\alpha}_{n,k} - \alpha_{n,k+1}}{\overline{m}_{n,k} - m_{n,k+1}} = \mu_{n,k+1} = \frac{\alpha_{n+1,k+1} - \overline{\alpha}_{n,k}}{m_{n+1,k+1} - \overline{m}_{n,k}}; \tag{11}$$

$$\frac{\alpha_{n,k+1}\overline{m}_{n,k} - \overline{\alpha}_{n,k}m_{n,k+1}}{\overline{m}_{n,k} - m_{n,k+1}} = \lambda_{n,k+1} = \frac{\overline{\alpha}_{n,k}m_{n+1,k+1} - \alpha_{n+1,k+1}\overline{m}_{n,k}}{m_{n+1,k+1} - \overline{m}_{n,k}}. \tag{12}$$

$$\left(\frac{1 - s_k^{n-1}}{s_{k-1}^{n-1}}\right)\frac{1}{\alpha_{n+1,k}} - \left(\frac{1 - s_k^n}{s_{k-1}^n}\right)\frac{1}{\alpha_{n,k}} = \left(\frac{k+1}{nks_{k-1}^{n-1}s_{k-1}^n}\right)\frac{1}{\overline{\alpha}_{n,k}}; \tag{13}$$

$$\left(\frac{1 - s_k^{n-1}}{s_{k-1}^{n-1}}\right)\frac{m_{n+1,k}}{\alpha_{n+1,k}} - \left(\frac{1 - s_k^n}{s_{k-1}^n}\right)\frac{m_{n,k}}{\alpha_{n,k}} = \left(\frac{k+1}{nks_{k-1}^{n-1}s_{k-1}^n}\right)\frac{\overline{m}_{n,k}}{\overline{\alpha}_{n,k}}; \tag{14}$$

$$\frac{m_{n+1,k} - \overline{m}_{n,k}}{m_{n+1,k} - m_{n,k}} = \frac{\alpha_{n+1,k} - \overline{\alpha}_{n,k}}{\alpha_{n+1,k} - \alpha_{n,k}} = \frac{nk\overline{\alpha}_{n,k}s_{k-1}^{n-1}(s_k^n - 1)}{\alpha_{n,k}(k+1)}; \tag{15}$$

$$\frac{\overline{m}_{n,k} - m_{n,k}}{m_{n+1,k} - m_{n,k}} = 1 - \frac{m_{n+1,k} - \overline{m}_{n,k}}{m_{n+1,k} - m_{n,k}} = \frac{nk\overline{\alpha}_{n,k}s_{k-1}^n(1 - s_k^{n-1})}{\alpha_{n+1,k}(k+1)}; \tag{16}$$

$$-\frac{\lambda_{n,k}}{\mu_{n,k}} = \frac{ns_{k-1}^{n-1}F_n^{n+1} - F_k^n}{ns_{k-1}^{n-1} - (n-k)}. \tag{17}$$

Proof. It is sufficient to prove just one side of the relations (9)–(12) in each case. For example, for (9) think of the slopes of the lines joining the points $(m_{n,k}, \alpha_{n,k})$, $(\overline{m}_{n,k}, \overline{\alpha}_{n,k})$ and $(m_{n+1,k}, \alpha_{n+1,k})$. To prove (9) and (10), first note that

$$-\frac{\lambda_{n,k}}{\mu_{n,k}} = \frac{(m_{n+1,k}/\alpha_{n+1,k}) - (m_{n,k}/\alpha_{n,k})}{(1/\alpha_{n+1,k}) - (1/\alpha_{n,k})} = \frac{(\overline{m}_{n,k}/\overline{\alpha}_{n,k}) - (m_{n,k}/\alpha_{n,k})}{(1/\overline{\alpha}_{n,k}) - (1/\alpha_{n,k})}, \tag{18}$$

which follows by observing that

$$\frac{1}{\overline{\alpha}_{n,k}} - \frac{1}{\alpha_{n,k}} = \frac{(1 - s_k^{n-1})(ns_{k-1}^{n-1} - (n-k))}{(k+1)s_{k-1}^{n-1}} = \frac{nks_{k-1}^n(1 - s_k^{n-1})}{k+1}\left[\frac{1}{\alpha_{n+1,k}} - \frac{1}{\alpha_{n,k}}\right]$$

and

$$\begin{aligned}\frac{\overline{m}_{n,k}}{\overline{\alpha}_{n,k}} - \frac{m_{n,k}}{\alpha_{n,k}} &= \frac{(1 - s_k^{n-1})}{k+1}\left(nF_n^{n+1} - \frac{F_k^n}{s_{k-1}^{n-1}}\right) \\ &= \frac{nks_{k-1}^n(1 - s_k^{n-1})}{k+1}\left[\frac{m_{n+1,k}}{\alpha_{n+1,k}} - \frac{m_{n,k}}{\alpha_{n,k}}\right].\end{aligned}$$

To see (9) (and hence (10)), notice that (18) implies that

$$\begin{aligned}\frac{1}{\mu_{n,k}} &= \frac{1}{\alpha_{n,k}}\left[\frac{(m_{n+1,k}/\alpha_{n+1,k}) - (m_{n,k}/\alpha_{n,k})}{(1/\alpha_{n,k}) - (1/\alpha_{n+1,k})}\right] + \frac{m_{n,k}}{\alpha_{n,k}} \\ &= \frac{1}{\alpha_{n,k}}\left[\frac{(\overline{m}_{n,k}/\overline{\alpha}_{n,k}) - (m_{n,k}/\alpha_{n,k})}{(1/\alpha_{n,k}) - (1/\overline{\alpha}_{n,k})}\right] + \frac{m_{n,k}}{\alpha_{n,k}} \\ &= \frac{\overline{m}_{n,k} - m_{n,k}}{\overline{\alpha}_{n,k} - \alpha_{n,k}}.\end{aligned}$$

The relations (11) and (12) are derived in an identical manner after proving that

$$-\frac{\lambda_{n,k+1}}{\mu_{n,k+1}} = \frac{(m_{n+1,k+1}/\alpha_{n+1,k+1}) - (m_{n,k+1}/\alpha_{n,k+1})}{(1/\alpha_{n+1,k+1}) - (1/\alpha_{n,k+1})} = \frac{(\overline{m}_{n,k}/\overline{\alpha}_{n,k}) - (m_{n,k+1}/\alpha_{n,k+1})}{(1/\overline{\alpha}_{n,k}) - (1/\alpha_{n,k+1})},$$

which comes from the calculations

$$\frac{1}{\overline{\alpha}_{n,k}} - \frac{1}{\alpha_{n,k+1}} = \frac{(s_k^{n-1}-1)(n-k-ns_k^n)}{(k+1)s_k^{n-1}} = ns_k^n(1-s_k^{n-1})\left[\frac{1}{\alpha_{n+1,k+1}} - \frac{1}{\alpha_{n,k+1}}\right]$$

and

$$\frac{\overline{m}_{n,k}}{\overline{\alpha}_{n,k}} - \frac{m_{n,k+1}}{\alpha_{n,k+1}} = \frac{(1-s_k^{n-1})}{k+1}\left(nF_n^{n+1} - \frac{F_{k+1}^n}{s_k^{n-1}}\right) = ns_k^n(1-s_k^{n-1})\left[\frac{m_{n+1,k+1}}{\alpha_{n+1,k+1}} - \frac{m_{n,k+1}}{\alpha_{n,k+1}}\right].$$

The identities (13)–(16) may be obtained from direct calculation from the definitions (4) and (5). □

3. The optimal *Q*-strategy. For each pair n, k, $1 \le k < n$ and $1 \le j \le k+1$, define

$$q_j^{n,k} = \frac{\lambda_{n,k} + \mu_{n,k}F_{j-1}^j}{1 - s_{j-1}\lambda_{n,k} - \mu_{n,k}\left(\sum_{i=1}^{j-2}(f(i)/(i+1)) + f(j-1)\right)}, \tag{19}$$

where an empty sum is zero, and define the strategy $\mathbf{q}^{n,k} = (q_1^{n,k}, q_2^{n,k}, \ldots, q_k^{n,k}, 1, 1, \cdots)$.

Using these strategies, the minimax-optimal *Q-strategies* $\mathbf{q}_M$ appearing in (2) can now be given.

DEFINITIONS. *For all* $M > f(1)$,

$$\begin{aligned} n(M) &= n \quad \textit{when } m_n \le M < m_{n+1}; \\ k(M) &= \begin{cases} k_n & \textit{if } m_n \le M < m_{n+1} \textit{ and } k_{n+1} = k_n, \textit{ or} \\ & \textit{if } m_n \le M < \overline{m}_n \textit{ and } k_{n+1} = k_n + 1, \\ k_{n+1} & \textit{if } \overline{m}_n \le M < m_{n+1} \textit{ and } k_{n+1} = k_n + 1; \end{cases} \quad \textit{and} \\ \mathbf{q}_M &= \mathbf{q}^{n(M),k(M)}. \end{aligned} \tag{20}$$

Example 3.1. For the expected-value case $f(i) \equiv i$, it follows from the calculations in Example 2.3 that

$$\mathbf{q}^{3,1} = \left(\frac{7}{13}, 1, 1, \cdots\right),$$

$$\mathbf{q}^{4,1} = \left(\frac{105}{213}, 1, 1, \cdots\right), \quad \text{and}$$

$$\mathbf{q}^{4,2} = \left(\frac{50}{107}, \frac{14}{19}, 1, 1, \cdots\right),$$

and together these yield the minimax-optimal $\mathbf{q}_M$ in Example 1.2. □

First it must be shown that $\mathbf{q}^{n,k} \in \mathbf{Q}$ for all $1 \le k < n$; that is, each coordinate must be shown to be a probability.

LEMMA 3.2. *For* $1 \le j \le k+1 \le n$, $0 \le q_j^{n,k} \le 1$.

Proof. First, the numerator of $q_j^{n,k}$ is > 0. This is because $\lambda_{n,k} + \mu_{n,k} F_{j-1}^j =$

$$\begin{aligned}
&\frac{\alpha_{n,k}\alpha_{n+1,k}}{m_{n+1,k} - m_{n,k}} \left[\frac{m_{n+1,k}}{\alpha_{n+1,k}} - \frac{m_{n,k}}{\alpha_{n,k}} + \left(\frac{1}{\alpha_{n,k}} - \frac{1}{\alpha_{n+1,k}} \right) F_{j-1}^j \right] \\
&= \frac{\alpha_{n,k}\alpha_{n+1,k}}{m_{n+1,k} - m_{n,k}} \left[\frac{n-k+1}{k s_{k-1}^n} \left(\frac{F_k^{n+1}}{n-k+1} - F_{j-1}^j \right) - \frac{n-k}{k s_{k-1}^{n-1}} \left(\frac{F_k^n}{n-k} - F_{j-1}^j \right) \right] > 0,
\end{aligned} \tag{21}$$

by Lemma 2.2 (iv) and (v) and the fact that $F_k^n/(n-k)$ exceeds F_{j-1}^j for $j \le k+1$. Denote the denominator of $q_j^{n,k}$ in (19) by β_j. Then to show $\beta_j > 0$, note that

$$\beta_j - \beta_{j+1} = (\lambda_{n,k} + \mu_{n,k} F_{j-1}^j)/j > 0,$$

by (21) for $j \le k+1$, so it is sufficient to show that $\beta_{k+1} > 0$. But now, from (4) and (5) calculate that

$$\begin{aligned}
\beta_{k+1} &= \frac{(1 - s_k \alpha_{n,k})\alpha_{n+1,k}}{m_{n+1,k} - m_{n,k}} \left[\frac{m_{n+1,k}}{\alpha_{n+1,k}} - \frac{m_{n,k}}{\alpha_{n,k}} + \left(\frac{1}{\alpha_{n,k}} - \frac{1}{\alpha_{n+1,k}} \right) \frac{F_k^n}{n-k} \right] \\
&= \frac{(1 - s_k \alpha_{n,k})(1 - s_k \alpha_{n+1,k})}{m_{n+1,k} - m_{n,k}} \left[\frac{F_k^{n+1}}{n-k+1} - \frac{F_k^n}{n-k} \right] > 0.
\end{aligned} \tag{22}$$

To show that $q_j^{n,k} \le 1$ for $j \le k+1$, note that the statement that $q_j^{n,k} \le 1$ is equivalent to

$$\gamma_j = \lambda_{n,k}(1 + s_{j-1}) + \mu_{n,k} \left(F_{j-1}^j + f(j-1) + \sum_{i=1}^{j-2} \frac{f(i)}{i+1} \right) \le 1.$$

Thus it is sufficient to show that $\gamma_{j+1} - \gamma_j \ge 0$ for $j \le k$ and $q_{k+1}^{n,k} \le 1$. First, using (4) and the expressions for the numerator and denominator from above, showing that

$$q_{k+1}^{n,k} = \frac{k s_{k-1}^{n-1}(F_k^{n+1} - (n-k+1)F_k^{k+1}) - k s_{k-1}^n (F_k^n - (n-k)F_k^{k+1})}{(n-k)F_k^{n+1} - (n-k+1)F_k^n} \le 1$$

is equivalent after rearrangement to showing that

$$\frac{1 - [(k s_{k-1}^n)/(n-k+1)]}{1 - [(k s_{k-1}^{n-1})/(n-k)]} \le \frac{(F_k^{n+1}/(n-k+1)) - F_k^{k+1}}{(F_k^n/(n-k)) - F_k^{k+1}}. \tag{23}$$

But by the convexity of $1/i$ in i, the left-hand side of (23) is dominated by $(n-k)/(n-k-1)$, which in turn is dominated by the right-hand side of (23) using Lemma 2.2 (iii). Furthermore,

$$\gamma_{j+1} - \gamma_j = [\lambda_{n,k} + \mu_{n,k}(j F_j^{j+1} - (j-1)F_{j-1}^j)]/j,$$

and since F_{j-1}^j is increasing in j and $\mu_{n,k} < 0$, to prove that $\gamma_{j+1} \ge \gamma_j$ for $j \le k$, it is sufficient to show that

$$-\frac{\lambda_{n,k}}{\mu_{n,k}} \ge k F_k^{k+1} - (k-1)F_{k-1}^k. \tag{24}$$

From (17),

$$-\frac{\lambda_{n,k}}{\mu_{n,k}} = \frac{ns_{k-1}^{n-1}F_n^{n+1} - F_k^n}{ns_{k-1}^{n-1} - (n-k)} \geq \frac{(n+k-1)F_n^{n+1} - 2(k-1)(F_k^n/(n-k))}{n-k+1}, \tag{25}$$

the last inequality because, by the convexity of $1/i$,

$$s_{k-1}^{n-1} \leq \frac{1}{2}(n-k)\left(\frac{1}{n} + \frac{1}{k-1}\right) = \frac{(n-k)(n+k-1)}{2n(k-1)}.$$

Finally, it may be seen that the right-hand side of (25) exceeds that of (24) using Lemma 2.2 (iii) again. □

It is now possible to prove an inequality that will imply that if the Q-player uses strategy $\mathbf{q}_M$, then it forces the P-player to put positive probability mass only on the points $1, 2, \ldots, k(M), n(M), n(M)+1$. Recall the definitions of $\mathbf{q}_M$ and $\mathbf{v}_M$.

PROPOSITION 3.3. *For all* $M > f(1)$,

$$V(\mathbf{p}, \mathbf{q}_M) \geq v_M \quad \textit{for all } \mathbf{p} = (p_1, p_2, \cdots) \in \mathcal{P}_M, \tag{26}$$

with equality in (26) *if and only if* $\sum_{j=1}^{\infty} p_j f(j) = M$ *and* $\mathbf{p}$ *assigns positive mass only to points in* $\{1, \ldots, k(M), n(M), n(M)+1\}$.

Proof. By the definitions of $\mathbf{q}_M$ and v_M, it is enough to show

$$V(\mathbf{p}, \mathbf{q}^{n,k}) \geq \lambda_{n,k} + \mu_{n,k}M, \quad \text{for all } \mathbf{p} = (p_1, p_2, \cdots) \in \mathcal{P}_M, \tag{27}$$

with equality if and only if $\sum_{j=1}^{\infty} p_j f(j) = M$ and $\mathbf{p}$ assigns positive mass only to points $\{1, \ldots, k, n, n+1\}$. First observe that

$$\prod_{m=1}^{j}\left(1 - \frac{q_m^{n,k}}{m}\right) = 1 - s_j\lambda_{n,k} - \mu_{n,k}\left(\sum_{m=1}^{j-1}\frac{f(m)}{m+1} + f(j)\right) \tag{28}$$

and

$$\sum_{i=1}^{j} q_i^{n,k} \prod_{m=1}^{i-1}\left(1 - \frac{q_m^{n,k}}{m}\right) = j\lambda_{n,k} + jf(j)\mu_{n,k}. \tag{29}$$

For strategies $\mathbf{p} = (p_1, p_2, \cdots)$ and $\mathbf{q} = (q_1, q_2, \cdots)$, recall (1) and define the Lagrangian

$$\begin{aligned} L(\mathbf{p}, \mathbf{q}) &= V(\mathbf{p}, \mathbf{q}) + \lambda_{n,k}\left(1 - \sum_{j=1}^{\infty} p_j\right) + \mu_{n,k}\left(M - \sum_{j=1}^{\infty} p_j f(j)\right) \\ &= \lambda_{n,k} + \mu_{n,k}M + \sum_{j=1}^{\infty}\frac{p_j}{j}\left[\sum_{i=1}^{j} q_i \prod_{m=1}^{i-1}\left(1 - \frac{q_m}{m}\right) - \lambda_{n,k}j - \mu_{n,k}jf(j)\right]. \end{aligned} \tag{30}$$

The dependence of L on n and k will be suppressed in the notation. For $\mathbf{p} \in \mathcal{P}_M$, since $\mu_{n,k} < 0$, it is immediate that $V(\mathbf{p}, \mathbf{q}) \geq L(\mathbf{p}, \mathbf{q})$, with equality if and only if $\sum_{j=1}^{\infty} p_j f(j) = M$. When $\mathbf{q} = \mathbf{q}^{n,k}$ it is now sufficient to show that the coefficient of p_j/j in (30) is ≥ 0 for all j and is $= 0$ if and only if $j = 1, 2, \ldots, k, n, n+1$. But for $1 \leq j \leq k$ this is true from (29).

For $j > k$ the coefficient of p_j/j is

$$\sum_{i=1}^{k} q_i^{n,k} \prod_{m=1}^{i-1} \left(1 - \frac{q_m^{n,k}}{m}\right) + \prod_{m=1}^{k} \left(1 - \frac{q_m^{n,k}}{m}\right) \sum_{i=k+1}^{j} \prod_{r=k+1}^{i-1} \left(\frac{r-1}{r}\right)$$

$$- \lambda_{n,k} j - \mu_{n,k} j f(j) = \lambda_{n,k}(k-j) - \mu_{n,k} F_k^j + k s_{k-1}^{j-1} \tag{31}$$

$$\cdot \left[1 - s_k \lambda_{n,k} - \mu_{n,k} \left(\sum_{i=1}^{k-1} \frac{f(i)}{i+1} + f(k)\right)\right],$$

from (29), with the convention that an empty product is 1. Using (4)–(6) and (22) and putting $G_s^r = F_s^r/(r-s)$ for $r > s$, (31) reduces to

$$\frac{(1 - s_k \alpha_{n,k})(1 - s_k \alpha_{n+1,k})(j-k) k \delta_j}{m_{n+1,k} - m_{n,k}},$$

where

$$\delta_j = \frac{s_{k-1}^{j-1}}{j-k}(G_k^{n+1} - G_k^n) - \frac{s_{k-1}^{n-1}}{n-k}(G_k^{n+1} - G_k^j) + \frac{s_{k-1}^n}{n-k+1}(G_k^n - G_k^j).$$

Note that $\delta_n = \delta_{n+1} = 0$, and

$$\delta_{j+1} - \delta_j = \left(\frac{s_{k-1}^j}{j-k+1} - \frac{s_{k-1}^{j-1}}{j-k}\right)(G_k^{n+1} - G_k^n) - \left(\frac{s_{k-1}^n}{n-k+1} - \frac{s_{k-1}^{n-1}}{n-k}\right)(G_k^{j+1} - G_k^j).$$

But, using Lemma 2.1 (ii), $G_k^{j+1} - G_k^j$ is positive and nondecreasing and the expression $(s_{k-1}^j/(j-k+1)) - (s_{k-1}^{j-1}/(j-k))$ is negative and increasing in $j > k$; hence $\delta_{j+1} < \delta_j$ for $j < n$ and $\delta_{j+1} > \delta_j$ for $j > n$, which shows that (31) is > 0 when $j > k$, $j \neq n$, $n+1$, which completes the proof. □

Once the analogue of Proposition 3.3 is proved for the P-strategy (Proposition 4.2 below), this will establish the minimax-optimality of both $\mathbf{q}_M$ and $\mathbf{p}_M$ and that v_M is the value of the game.

4. The optimal P-strategy and main theorem. For $1 \leq k \leq k_n < n$, define distributions $\mathbf{p}^{n,k} = (p_1^{n,k}, p_2^{n,k}, \cdots)$ concentrated on the points $\{1, 2, \ldots, k, n\}$ by

$$p_j^{n,k} = \begin{cases} \alpha_{n,k}/(j+1) & \text{for } 1 \leq j < k, \\ \alpha_{n,k}(s_{k-1}^{n-1} - 1)/s_{k-1}^{n-1} & \text{for } j = k, \\ n\alpha_{n,k}/(k s_{k-1}^{n-1}) & \text{for } j = n, \end{cases}$$

with $p_j^{n,k} \equiv 0$ otherwise. Note that $\mathbf{p}^{n,k}$ is a distribution only for $k \leq k_n$ and that $m_{n,k} = \sum_{j=1}^{\infty} f(j) p_j^{n,k}$. Set $\mathbf{p}^n = \mathbf{p}^{n,k_n}$ for $n \geq 2$, and $\mathbf{p}^1 = (1, 0, 0, \cdots)$. Also, when $k_{n+1} = k_n + 1$, define the distribution $\overline{\mathbf{p}}^n = (\overline{p}_1^n, \overline{p}_2^n, \cdots)$ concentrated on $\{1, 2, \ldots, k_n, n, n+1\}$ by

$$\overline{p}_j^n = \begin{cases} \overline{\alpha}_n/(j+1) & \text{for } 1 \leq j \leq k_n, \\ \overline{\alpha}_n n^2 (s_{k_n}^n - 1)/(k_n + 1) & \text{for } j = n, \\ \overline{\alpha}_n n(n+1)(1 - s_{k_n}^{n-1})/(k_n + 1) & \text{for } j = n+1, \end{cases}$$

with $\overline{p}_j^n \equiv 0$ otherwise. Note that $\overline{m}_n = \sum_{j=1}^{\infty} f(j) \overline{p}_j^n$.

Remark. The distributions $\mathbf{p}^n$, $n = 1, 2, \cdots$ are exactly the minimax-optimal P-player strategies for the $N \leq n$ problem studied in Hill and Krengel (1991).

The minimax-optimal (worst-case distribution) strategy $\mathbf{p}_M$ in (2) for player P can now be shown to be convex combinations of these base strategies $\mathbf{p}^n$ and $\overline{\mathbf{p}}^n$.

DEFINITION. *For all* $M > f(1)$, *define* $\mathbf{p}_M \in \mathcal{P}_M$ *by*

$$(32)\quad \mathbf{p}_M = \begin{cases} \left(\dfrac{m_{n+1}-M}{m_{n+1}-m_n}\right)\mathbf{p}^n + \left(\dfrac{M-m_n}{m_{n+1}-m_n}\right)\mathbf{p}^{n+1} \in \mathcal{P}_M \\ \qquad\qquad \text{if } k_{n+1} = k_n \text{ and } m_n \le M < m_{n+1}; \\ \left(\dfrac{\overline{m}_n-M}{\overline{m}_n-m_n}\right)\mathbf{p}^n + \left(\dfrac{M-m_n}{\overline{m}_n-m_n}\right)\overline{\mathbf{p}}^n \in \mathcal{P}_M \\ \qquad\qquad \text{if } k_{n+1} = k_n + 1 \text{ and } m_n \le M < \overline{m}_n; \\ \left(\dfrac{m_{n+1}-M}{m_{n+1}-\overline{m}_n}\right)\overline{\mathbf{p}}^n + \left(\dfrac{M-\overline{m}_n}{m_{n+1}-\overline{m}_n}\right)\mathbf{p}^{n+1} \in \mathcal{P}_M \\ \qquad\qquad \text{if } k_{n+1} = k_n + 1 \text{ and } \overline{m}_n \le M < m_{n+1}. \end{cases}$$

Notice that the strategy $\mathbf{p}_M$ *places positive probability mass only on the points in the set* $\{1, \ldots, k(M), n(M), n(M)+1\}$ *and that, when* $k_{n+1} = k_n$, $\overline{m}_n$ *is a changeover point in that when* M *increases through the value* $M = \overline{m}_n$, $\mathbf{p}_M$ *increases the number of points in its support by* 1.

Example 4.1. For the expected-value case $f(i) \equiv i$, it follows from the calculations in Example 2.3 that

$$\mathbf{p}^3 = \mathbf{p}^{3,1} = \left(\frac{1}{7}, 0, \frac{6}{7}, 0, 0, \cdots\right),$$

$$\mathbf{p}^4 = \mathbf{p}^{4,1} = \left(\frac{5}{29}, 0, 0, \frac{24}{29}, 0, 0, \cdots\right),$$

$$\overline{\mathbf{p}}^4 = \left(\frac{3}{17}, 0, 0, \frac{4}{17}, \frac{10}{17}, 0, 0, \cdots\right), \quad \text{and}$$

$$\mathbf{p}^5 = \mathbf{p}^{5,2} = \left(\frac{13}{75}, \frac{2}{75}, 0, 0, \frac{60}{75}, 0, 0, \cdots\right),$$

and together these yield the minimax-optimal strategies $\mathbf{p}_M$ in Example 1.2. □

Now the analogue of Proposition 3.3 will be proved, which, together with Proposition 3.3, will establish the minimax-optimality of $\mathbf{q}_M$ and $\mathbf{p}_M$ simultaneously.

PROPOSITION 4.2. *For all* $M > f(1)$,

$$(33)\qquad V(\mathbf{p}_M, \mathbf{q}) \le v_M \quad \text{for all } \mathbf{q} = (q_1, q_2, \cdots) \in Q.$$

Proof. The argument of Theorem C of Hill and Krengel (1991) demonstrates that

$$V(\mathbf{p}^{n,k}, (q_1, q_2, \ldots, q_k, 1, 1, \cdots)) \equiv \alpha_{n,k}, \quad \text{for } 0 \le q_i \le 1,\ i = 1, \ldots, k,$$

and a similar argument shows that, when $k_{n+1} = k_n + 1$,

$$V(\overline{\mathbf{p}}^n, (q_1, q_2, \ldots, q_{k_{n+1}}, 1, 1, \cdots)) \equiv \overline{\alpha}_n, \quad \text{for } 0 \le q_i \le 1,\ i = 1, \ldots, k_{n+1}.$$

Furthermore, Hill and Krengel (1991) established that for any $\mathbf{q} = (q_1, q_2, \cdots) \in \mathcal{Q}$ and $k \ge k_n$,

$$(34)\quad V(\mathbf{p}^n, \mathbf{q}) \le V(\mathbf{p}^n, (q_1, \ldots, q_k, 1, 1, \cdots)) \le V(\mathbf{p}^n, (q_1, \ldots, q_{k_n}, 1, 1, \cdots)) = \alpha_n,$$

and again it is straightforward to prove that when $k_{n+1} = k_n + 1$ and $k \geq k_{n+1}$,

$$(35)\quad V(\overline{\mathbf{p}}^n, \mathbf{q}) \leq V(\overline{\mathbf{p}}^n, (q_1, \ldots, q_k, 1, 1, \cdots)) \leq V(\overline{\mathbf{p}}^n, (q_1, \ldots, q_{k_{n+1}}, 1, 1, \cdots)) = \overline{\alpha}_n.$$

Three cases corresponding to the three possibilities in (32) must be considered.

Case 1. $k_{n+1} = k_n$ and $m_n \leq M < m_{n+1}$.

$$V(\mathbf{p}_M, \mathbf{q}) = \left(\frac{m_{n+1} - M}{m_{n+1} - m_n}\right) V(\mathbf{p}^n, \mathbf{q}) + \left(\frac{M - m_n}{m_{n+1} - m_n}\right) V(\mathbf{p}^{n+1}, \mathbf{q})$$
$$\leq \left(\frac{m_{n+1} - M}{m_{n+1} - m_n}\right) \alpha_n + \left(\frac{M - m_n}{m_{n+1} - m_n}\right) \alpha_{n+1} = \lambda_{n,k_n} + \mu_{n,k_n} M,$$

for all $\mathbf{q} \in \mathcal{Q}$, using (34).

Case 2. $k_{n+1} = k_n + 1$ and $m_n \leq M < \overline{m}_n$. Using the relations in (9)–(16) and setting $M = \overline{m}_n$ it may be seen that $\mathbf{p}_{\overline{m}_n} = \overline{\mathbf{p}}_n$, whence

$$\mathbf{p}_M \equiv \left(\frac{m_{n+1,k_n} - M}{m_{n+1,k_n} - m_n}\right) \mathbf{p}^n + \left(\frac{M - m_n}{m_{n+1,k_n} - m_n}\right) \mathbf{p}^{n+1,k_n}.$$

Note from Lemma 2.4 (viii) that for M in this range, $M \leq m_{n+1,k_n}$. For any $\mathbf{q} \in \mathcal{Q}$,

$$V(\mathbf{p}_M, \mathbf{q}) = \left(\frac{m_{n+1,k_n} - M}{m_{n+1,k_n} - m_n}\right) V(\mathbf{p}^n, \mathbf{q}) + \left(\frac{M - m_n}{m_{n+1,k_n} - m_n}\right) V(\mathbf{p}^{n+1,k_n}, \mathbf{q}),$$

which, by (34), is dominated by

$$(36)\quad \left(\frac{m_{n+1,k_n} - M}{m_{n+1,k_n} - m_n}\right) V(\mathbf{p}^n, (q_1, \ldots, q_{k_n+1}, 1, 1, \cdots)) + \left(\frac{M - m_n}{m_{n+1,k_n} - m_n}\right) V(\mathbf{p}^{n+1,k_n}, (q_1, \ldots, q_{k_n+1}, 1, 1, \cdots)).$$

Now consider the coefficient of $q_{k_n+1} \prod_{m=1}^{k_n} (1 - q_m/m)$ in (36) which equals

$$\frac{p_n^{n,k_n}}{n} \left(\frac{m_{n+1,k_n} - M}{m_{n+1,k_n} - m_n}\right) (1 - s_{k_n}^{n-1}) + \frac{p_{n+1}^{n+1,k_n}}{n+1} \left(\frac{M - m_n}{m_{n+1,k_n} - m_n}\right) (1 - s_{k_n}^n)$$
$$= \frac{\alpha_n}{k_n} \left(\frac{m_{n+1,k_n} - M}{m_{n+1,k_n} - m_n}\right) \left(\frac{1 - s_{k_n}^{n-1}}{s_{k_n-1}^{n-1}}\right) + \frac{\alpha_{n+1,k_n}}{k_n} \left(\frac{M - m_n}{m_{n+1,k_n} - m_n}\right) \left(\frac{1 - s_{k_n}^n}{s_{k_n-1}^n}\right).$$

Rearranging this expression as

$$\frac{\alpha_n \alpha_{n+1,k_n}}{k_n (m_{n+1,k_n} - m_n)} \left[\left(\frac{1 - s_{k_n}^{n-1}}{s_{k_n-1}^{n-1}}\right) \left(\frac{m_{n+1,k_n} - M}{\alpha_{n+1,k_n}}\right) + \left(\frac{1 - s_{k_n}^n}{s_{k_n-1}^n}\right) \left(\frac{M - m_n}{\alpha_n}\right)\right],$$

and using (13) and (14) (with $k = k_n$) this equals

$$\frac{\alpha_n \alpha_{n+1,k_n} (k_n + 1)}{n k_n s_{k_n-1}^{n-1} s_{k_n-1}^n (m_{n+1,k_n} - m_n)} \left(\frac{\overline{m}_n - M}{\overline{\alpha}_n}\right) \geq 0,$$

for $M \leq \overline{m}_n$. It follows that (36) is not decreased by taking $q_{k_n+1} = 1$, so it may be seen that

$$V(\mathbf{p}_M, \mathbf{q}) \leq \left(\frac{m_{n+1,k_n} - M}{m_{n+1,k_n} - m_n}\right) V(\mathbf{p}^n, (q_1, \ldots, q_{k_n}, 1, 1, \cdots)) + \left(\frac{M - m_n}{m_{n+1,k_n} - m_n}\right) V(\mathbf{p}^{n+1,k_n}, (q_1, \ldots, q_{k_n}, 1, 1, \cdots)),$$

which in turn implies that

$$V(\mathbf{p}_M, \mathbf{q}) \le \left(\frac{m_{n+1,k_n} - M}{m_{n+1,k_n} - m_n}\right) \alpha_n + \left(\frac{M - m_n}{m_{n+1,k_n} - m_n}\right) \alpha_{n+1,k_n} = \lambda_{n,k_n} + \mu_{n,k_n} M.$$

Case 3. $k_{n+1} = k_n + 1$ and $\overline{m}_n \le M < m_{n+1}$. It follows from (34) and (35) as in Case 1 that

$$\begin{aligned} V(\mathbf{p}_M, \mathbf{q}) &= \left(\frac{m_{n+1} - M}{m_{n+1} - \overline{m}_n}\right) V(\overline{\mathbf{p}}^n, \mathbf{q}) + \left(\frac{M - \overline{m}_n}{m_{n+1} - \overline{m}_n}\right) V(\mathbf{p}^{n+1}, \mathbf{q}) \\ &\le \left(\frac{m_{n+1} - M}{m_{n+1} - \overline{m}_n}\right) \overline{\alpha}_n + \left(\frac{M - \overline{m}_n}{m_{n+1} - \overline{m}_n}\right) \alpha_{n+1} \\ &= \lambda_{n,k_{n+1}} + \mu_{n,k_{n+1}} M, \end{aligned}$$

using (11) and (12). □

The main results in this paper can now be summarized in the following theorem.

THEOREM 4.3. *With* $\mathbf{p}_M, \mathbf{q}_M$, *and* v_M *as in* (32), (20), *and* (7), *respectively*,

$$V(\mathbf{p}_M, \mathbf{q}) \le V(\mathbf{p}_M, \mathbf{q}_M) = v_M \le V(\mathbf{p}, \mathbf{q}_M), \quad \text{for all } \mathbf{p} \in \mathcal{P}_M, \mathbf{q} \in \mathcal{Q}.$$

Proof. The proof is immediate from Propositions 3.3 and 4.2 and the definitions. □

Acknowledgment. The main question addressed in this paper was raised by Shmuel Gal in the AMS-IMS-SIAM Conference on Sequential Search Strategies in Amherst (1990), and the authors are grateful to the organizers Tom Ferguson and Steve Samuels for invitations to speak at that conference.

THE H_∞-PROBLEM WITH CONTROL CONSTRAINTS*

VIOREL BARBU†

Abstract. Necessary and sufficient conditions for the existence of a solution to the suboptimal H_∞-problem for input-output linear systems with control constraints are established.

Key words. stabilizing feedback, Hamilton–Jacobi equations, analytic semigroup, convex function, subdifferential

AMS subject classifications. 93B50, 93C35, 49A40

1. Problem formulation.

Consider the input-output system

$$\begin{aligned} &x'(t) = Ax(t) + B_2u(t) + B_1w(t), && t \in R = [0,\infty),\\ &x(0) = x_0,\\ &z(t) = C_1x(t) + D_{12}u(t) && \text{a.e. } t \in R^+,\\ &u(t) \in U_0 && \text{a.e. } t > 0, \end{aligned} \tag{1.1}$$

where A is the infinitesimal generator of a C_0-semigroup e^{At} on $X, B_2 \in L(U,X), B_1 \in L(W,X), C_1 \in L(X,Z), D_{12} \in L(U,Z)$ and $z' = dx/dt$. Here X, Z, U, W are separable real Hilbert spaces and U_0 is a closed convex subset of U such that $0 \in U_0$.

The system (1.1) will be studied under the following standard hypotheses:

$$D_{12}^*D_{12} = I, \qquad D_{12}^*C_1 = 0, \tag{1.2}$$

$$\text{The pair } (A, C_1) \text{ is exponentially detectable.} \tag{1.3}$$

Here and throughout in the sequel we shall use the asterisk symbol to denote the dual operators. Also we shall denote by $|\cdot|, |\cdot|_Z, |\cdot|_U, |\cdot|_W$ the norm in X, Z, U, and W, respectively, and by $(\cdot,\cdot), (\cdot,\cdot)_Z, (\cdot,\cdot)_U, (\cdot,\cdot)_W$ the corresponding scalar products.

In system (1.1) $x \in X, u \in U$, and $z \in Z$ are the state, the control variable, and the disturbance (exogeneous variable), respectively.

By definition an *admissible feedback control* is a multivalued mapping $F : X \to U_0$ having the property that for every $x_0 \in X$ and $f \in L^2_{\text{loc}}(R^+;X)$ the Cauchy problem

$$x' \in Ax + B_2Fx + f \quad \text{in } R^+; \qquad x(0) = x_0 \tag{1.4}$$

has at least one mild solution x, i.e., there is $u(t) \in Fx(t)$ almost everywhere $t > 0$, $u \in L^2_{\text{loc}}(R^+;U)$ such that

$$x(t) = e^{At}x_0 + \int_0^t e^{A(t-s)}(B_2u(s) + f(s))\,ds, \qquad t > 0. \tag{1.4$'$}$$

An admissible feedback control $F$is said to be stabilizing if for all $x_0 \in X$ and $f \in L^2(R^+;X)$ the Cauchy problem (1.4) has at least one mild solution $x \in C(R^+;X) \cap L^2(R^+;X)$, i.e., there exists $u \in L^2(R^+;X)$ such that $u(t) \in Fx(t)$ almost everywhere $t > 0$ and (1.4)$'$ holds.

† Department of Mathematics, University of Iasi, 6600 Iasi, Romania.

We shall denote by $\mathcal{F}$ the set of all stabilizing feedback controls F. For every $f \in \mathcal{F}$ and $w \in L^2(R^+; X), x_0 \in X$ we set

$$S_F(x_0, w) = z = C_1 x + D_{12} u, \tag{1.5}$$

where $(x, u) \in L^2(R^+; X) \times L^2(R^+; U), u(t) \in Fx(t)$ almost everywhere $t > 0$ satisfy system (1.1), i.e.,

$$x(t) = e^{At} x_0 + \int_0^t e^{A(t-s)} (B_2 u(s) + B_1 w(s))\, ds, \qquad t \geq 0. \tag{1.6}$$

The operator $S_F : X \times L^2(R^+; W) \to L^2(R^+; Z)$ is in general multivalued but everywhere defined on $X \times L^2(R^+; W)$.

According to the theory of standard H_∞-problem [2], we shall define the H_∞-suboptimal control problem for system (1.1) as follows: given $\delta > 0$ and $\alpha > 0$ finds $F \in \mathcal{F}$ such that

$$|S_F(x_0, w)|^2 \leq \rho^2 \|w\|^2_{L^2(R^+;W)} + \alpha |x_0|^2, \qquad \forall (x_0, w) \in X \times L^2(R^+; W), \tag{1.7}$$

where $0 < \rho < \delta$.

Here

$$|S_F(x_0, w)| = \sup\{\|\theta\|_{L^2(R^+;Z)}; \theta \in S_F(x_0, w)\}.$$

The main result of this work, Theorem 1 below, solves the above problem in terms of a stationary Hamilton–Jacobi equation and is a generalization of known results [2]–[4], [5], [6] to the unconstrained case. This result seems to be new even in the finite-dimensional framework. Although the approach borrows an idea already used in the study of standard H_∞-problem, namely to reduce the problem to a differential game associated with system (1.1), the proof is quite different and there are significant differences between our treatment and the standard one.

2. The main result. Throughout in the sequel we shall assume that system (1.1) satisfies hypotheses (1.2) and (1.3) and also that (i) e^{At} are compacts for all $t > 0$; and (ii) e^{At} is a C_0-analytic semigroup.

THEOREM 1. *If the H_∞-suboptimal control problem has a solution $F \in \mathcal{F}$, then there is a continuous, convex function $\varphi : X \to R$ such that $\partial\varphi : X \to X$ is compact,*

$$0 \leq 2\varphi(x) \leq \alpha |x|^2, \qquad \forall x \in X, \tag{2.1}$$

$$\begin{aligned} 2(Ax, \eta) &+ |P_{U_0}(-B_2^* \eta)|^2_U + \delta^{-2} |B_1^* \eta|^2_W + 2(B_2^* \eta, P_{U_0}(-B_2^* \eta))_U + |C_1 x|^2 \\ &= 0, \quad \forall x \in D(A), \quad \forall \eta \in \partial\varphi(x). \end{aligned} \tag{2.2}$$

Moreover, the Cauchy problem

$$\begin{aligned} x' &= Ax + B_2 P_{U_0}(-B_2^* \partial\varphi(x)) + \delta^{-2} B_1 B_1^* \partial\varphi(x), \\ x(0) &= x_0 \end{aligned} \tag{2.3}$$

has for every $x_0 \in X$ at least one mild solution

$$x^* \in C(R^+; X) \cap L^2(R^+; X); \qquad \lim_{t \to \infty} x^*(t) = 0. \tag{2.4}$$

Conversely, if (2.2) *has a solution φ with the above properties then the feedback $F = P_{U_0}(-B_2^* \partial\varphi)$ is stabilizing and guarantees inequality* (1.7) *with $\rho = \delta$.*

Here $P_{U_0} : U \to U_0$ is the projection operator on U_0 and $\partial\varphi$ is the subdifferential of φ, i.e.,

$$\partial\varphi(x_0) = \{\eta \in X; \varphi(x_0) \leq \varphi(x) + (\eta, x_0 - x), \forall x \in X\}.$$

The multivalued mapping $\partial\varphi$ is said to be compact if it maps bounded subsets into compact sets.

We note that in the case of unconstrained H_∞-control problem, i.e., $U_0 = U$, (2.2) reduces to the Riccati equation corresponding to the regular H_∞-problem [3], [4], [8], while the closed-loop inequality (1.7) becomes

$$\|S_F(0, w)\|_{L^2(R^+;Z)} \leq \rho\|w\|_{L^2(R^+;W)}, \qquad \forall w \in L^2(R^+; W).$$

However, in our case a gap arises between the necessary and sufficient conditions for existence of solution to H_∞-problem. Perhaps in most significant cases, the existence of a solution φ to (2.2) is necessary and sufficient for existence of a solution to H_∞-suboptimal control problem.

Now, we shall illustrate Theorem 1 with a few examples.

Example 1. Consider the system

$$x' = -x + u + w \quad \text{in } R^+; \qquad z = \{x, u\}, \quad u(t) \geq 0, \quad t \geq 0. \tag{2.5}$$

Here $X = U = W = R$, $Z = R \times R$ and $U_0 = \{u \in R; u \geq 0\}$. Equation (2.2) has therefore in this case the following form:

$$2x\varphi'(x) - |(\varphi'(x))^-|^2 - (\delta^2)^{-1}|\varphi'(x)|^2 - x^2 = 0. \tag{2.6}$$

By a little calculation we see that for $\delta > 1$ this equation has a unique convex solution φ satisfying (2.1) and which is given by

$$\varphi(x) = \begin{cases} 2^{-1}(\delta^2 + \delta(\delta^2 - 1)^{1/2})x^2 & \text{for } x \geq 0, \\ 2^{-1}(\delta^2 - 1)^{-1/2}((2\delta^2 - 1)^{1/2} - \delta)x^2 & \text{for } x < 0, \end{cases}$$

and the suboptimal H_∞ feedback control F is given by

$$u = Fx = \begin{cases} 0 & \text{for } x \geq 0, \\ -(\delta^2 - 1)^{-1/2}((2\delta^2 - 1)^{1/2} - \delta)x & \text{for } x < 0. \end{cases} \tag{2.7}$$

Example 2. Consider the input-output system

$$y_t - \Delta y + ay = u + w \quad \text{in } \Omega \times R^+,$$

$$y = 0 \quad \text{in } \partial\Omega \times R^+,$$

$$z = (y, u) \in L^2(\Omega) \times L^2(\Omega); \qquad u \geq 0 \text{ a.e. in } \Omega \times R^+,$$

where $a \in R, w \in W = L^2(\Omega)$ and Ω is a bounded open subset of R^N.

In this case $A = -\Delta, D(A) = H_0^1(\Omega) \cap H^2(\Omega), U = L^2(\Omega), U_0 = \{u \in L^2(\Omega); u \geq 0\}$ almost everywhere in Ω and equation (2.2) has the following form:

$$2\int_\Omega \nabla y(x) \cdot \nabla_x \varphi_y(y(x))\, dx - \int_\Omega ((\varphi_y(y(x)))^-)^2\, dx + \delta^{-2}\int_\Omega (\varphi_y(y(x)))^2\, dx$$
$$+ \int_\Omega |y(x)|^2\, dx = 0, \qquad \forall y \in H_0^1(\Omega),$$

while the H_∞-suboptimal control is given by

$$u = F(y) = (\varphi_y(y(x)))^- \qquad \text{a.e. } x \in \Omega.$$

3. Proof of Theorem 1. We shall assume first that there is $F \in \mathcal{F}$ such that (1.7) is satisfied. Define on the space $L^2(R^+;U) \times L^2(R^+;W)$ the function

$$\begin{aligned} K(u,w) &= 2^{-1}\int_0^\infty (|z(t)|_Z^2 + h(u(t)) - \delta^2|w(t)|_W^2)\,dt \\ &= 2^{-1}\int_0^\infty (|C_1x(t)|_Z^2 + h(u(t)) - \delta^2|w(t)|_W^2)\,dt, \end{aligned} \tag{3.1}$$

where x is the mild solution to (1.1), $h(u) = |u|_U^2 + I_{U_0}(u)$ and $I_{U_0} : U \to (-\infty, +\infty]$ is the indicator function of U_0, i.e., $I_{U_0}(u) = 0$ for $u \in U_0$, $I_{U_0}(u) = +\infty$ for $u \bar{\in} U_0$.

Denote $\mathcal{U} = L^2(R^+;U), \mathcal{W} = L^2(R^+;W)$ and consider the problem

$$\sup_{w\in\mathcal{W}} \inf_{u\in\mathcal{U}} K(u,w). \tag{3.2}$$

We shall denote by $\varphi(x_0)$ the value of (3.2), i.e.,

$$\varphi(x_0) = \sup_{w\in\mathcal{W}} \inf_{u\in\mathcal{U}} K(u,w), \qquad x_0 \in X. \tag{3.3}$$

Clearly we have

$$2\varphi(x_0) \geq \sup\left\{\int_0^\infty (|C_1x(t)|_Z^2 - \delta^2|w(t)|_W^2)\,dt; w \in \mathcal{W}\right\} \geq 0,$$

while by closed-loop inequality (1.7) we see that

$$0 \leq 2\varphi(x_0) \leq \alpha|x_0|^2, \qquad \forall\, x_0 \in X. \tag{3.4}$$

We will prove that the function is a solution to Hamilton–Jacobi equation (2.1) in the sense precised in Theorem 1. To this aim we shall consider a family of approximately sup inf problems on the finite intervals $[0,n]$. Namely,

$$\sup_{w\in\mathcal{W}_n} \inf_{u\in\mathcal{U}_n} K_n(u,w), \qquad n = 1,2,\ldots, \tag{3.5}$$

where

$$K_n(u,w) = 2^{-1}\int_0^n (|C_1x(t)|_Z^2 + h(u(t)) - \delta^2|w(t)|_W^2)\,dt.$$

x is the corresponding solution to (1.1) on $[0,n]$ and $\mathcal{U}_n = L^2(0,n;U), \mathcal{W}_n = L^2(0,n;W)$. We denote by φ_n the corresponding value of problem (3.5), i.e.,

$$\varphi_n(x_0) = \sup_{w\in\mathcal{W}_n} \inf_{u\in\mathcal{U}_n} K_n(u,w). \tag{3.6}$$

As a supremum of the family of convex lower-semicontinuous functions

$$x_0 \to \inf\left\{2^{-1}\int_0^\infty (|C_1x(t)|_Z^2 + h(u(t)) - \delta^2|w(t)|_W^2)\,dt; u \in \mathcal{U}\right\},$$

the function φ is itself convex and lower semicontinuous. Since it is everywhere defined it is continuous on X. Similarly, the functions φ_n are convex and continuous. Moreover, we have

$$0 \leq 2\varphi_n(x_0) \leq \alpha|x_0|^2, \qquad \forall\, x_0 \in X. \qquad \square$$

LEMMA 1. *Problem* (3.5) *has at least one solution* (u_n, w_n), *which is expressed as*

$$u_n(t) = P_{U_0}(B_2^* p_n(t)); \qquad w_n(t) = -\delta^{-2} B_1^* p_n(t) \quad \text{a.e. } t \in (0,n), \tag{3.7}$$

where

$$p_n' = -A^* p_n + C_1^* C_1 x_n \quad \text{in } [0,n]; \qquad p_n(n) = 0. \tag{3.8}$$

Moreover, we have

$$\lim_{n\to\infty} \varphi_n(x_0) = \varphi(x_0), \qquad \forall\, x_0 \in X. \tag{3.9}$$

Proof. It is readily seen that for every n there exists $F \in \mathcal{F}$ such that

$$\|S_F(x_0,w)\|^2_{L^2(0,n;Z)} \le \rho^2 \|w\|^2_{\mathcal{W}_n} + \alpha |x_0|^2, \qquad \forall\, (x_0,w) \in X \times \mathcal{W}_n, \tag{3.10}$$

where $0 < \rho < \delta$ (it suffices to take in (1.7), $w = w_0$ on $(0,n)$ and $w = 0$ on (n,∞)). Then for every $w \in \mathcal{W}_n$ the minimization problem

$$\inf\{K_n(u,w); u \in \mathcal{U}_n\}$$

has a unique solution $\bar{u} = \Gamma w$, because $K(\cdot\,, w)$ is strictly convex, lower semicontinuous, coercive, and $\not\equiv +\infty$ (by (1.7)). In fact this is an optimal control problem governed by state system (1.1) and in virtue of standard results, u satisfies the Euler–Lagrange system (see e.g., [1], p. 258)

$$p' = -A^* p + C_1^* C_1 \bar{x} \quad \text{on } (0,n); \quad p(n) = 0, \tag{3.11}$$

$$B_2^* p(t) - \bar{u}(t) \in N_{U_0}(\bar{u}(t)) \quad \text{a.e. } t \in (0,n), \tag{3.12}$$

where $N_{U_0}(u)$ is the normal cone to U_0 at u and $\bar{x}$ is the corresponding solution to (1.1) with $u = \bar{u}$. Recall that (3.12) can be rewritten as

$$\bar{u}(t) = P_{U_0}(B_2^* p(t)) \quad \text{a.e. } t \in (0,n). \tag{3.13}$$

For $\bar{u} = u_n, \bar{x} = x_n$, (3.11) and (3.13) reduce to (3.8) and the first equation in (3.7), respectively. Now problem (3.5) reduces to

$$\inf\{-K(\Gamma w, w); w \in \mathcal{W}_n\}. \tag{3.14}$$

We note $\Gamma : \mathcal{W}_n \to \mathcal{U}_n$ is weakly-strongly continuous and $\Phi : \mathcal{W}_n \to R$,

$$\Phi(w) = 2^{-1} \int_0^n (|C_1 x^w(t)|_Z^2 + h(\Gamma w(t)))\, dt$$

is weakly continuous. (Here x^w is the solution to (1.1) where $u = \Gamma w$.) Indeed, if $w_k \to w$ weakly in $\mathcal{W}_n$, then we have

$$2\Phi(w_k) \le \int_0^n (|C_1 y_k(t)|_Z^2 + h(\Gamma w(t)))\, dt,$$

where y_k is the solution to (1.1) with $u = \Gamma w$ and $w = w_k$. Since by the assumption (i) $w \to x^w$ is compact from $L^2(0,n;W) = \mathcal{W}_n$ to $C([0,n];X)$, on a subsequence, again denoted k, we have

$$C_1 y_k \to C_1 x^w \quad \text{in } C([0,n];X), \quad u_k = \Gamma w_k \to \bar{u}$$

weakly in $\mathcal{U}_n$ and $C_1 x^{w_k} \to C_1 x$ in $C([0,n];X)$ where (x,u,w) satisfies system (1.1). We have

$$2^{-1}\int_0^n (|C_1x(t)|_Z^2 + h(\bar{u}(t)))\,dt \le \Phi(w) = \inf\{K_n(u,w); u \in \mathcal{U}_n\} + 2^{-1}\delta^2\|w\|_{\mathcal{W}_n}^2.$$

Hence $\bar{u} = \Gamma w, x = x^w$, and $\Gamma w_k \to \Gamma w$ strongly in $\mathcal{U}_n$ as claimed. Hence the function $w \to K(\Gamma w, w)$ is weakly lower semicontinuous on $\mathcal{W}_n$ while by (3.10) we see that

$$-2K_n(\Gamma w, w) \ge -\alpha|x_0|^2 + (\delta - \rho)\|w\|_{\mathcal{W}_n}^2, \qquad \forall\, w \in \mathcal{W}_n. \tag{3.14}'$$

This implies that problem (3.14) has at least one solution w_n. Then clearly $(u_n = \Gamma w_n, w_n)$ is a solution to problem (3.5). We shall prove now that the second equation in (3.7) holds. To this end we note that the function Φ defined above is convex and its subdifferential $\partial\Phi$ is given by

$$\partial\Phi(w) = -B_1^* p^w,$$

where p^w is the solution to system (3.11) where $\bar{x} = x^w$. Since $\partial\Phi$ is single valued we conclude that Φ is Gâteaux differentiable and so the solution w_n to (3.14) satisfies the equation

$$\partial\Phi(w_n) = -B_1^* p_n = \delta^2 w_n, \qquad \text{a.e. in } (0,n),$$

where p_n is the solution to (3.7).

To prove (3.9) we note first that

$$\varphi_n(x_0) \le \sup_{w\in\mathcal{W}} \inf_{u\in\mathcal{U}} K(u,w) = \varphi(x_0). \tag{3.15}$$

Now let $\varepsilon > 0$ and $\bar{w} \in \mathcal{W}$ be such that $\inf\{K(u,\bar{w}); u \in \mathcal{U}\} \ge \varphi(x_0) - \varepsilon$. We have

$$\begin{aligned} 2\varphi_n(x_0) &= \int_0^n (|C_1x_n(t)|_Z^2 + h(u_n(t)) - \delta^2|w_n(t)|_W^2)\,dt \\ &\ge \int_0^n (|C_1y_n(t)|_Z^2 + h(v_n(t)) - \delta^2|\bar{w}(t)|_W^2)\,dt, \end{aligned}$$

where $v_n = \arg\inf\{K_n(u,\bar{w}); u \in \mathcal{U}_n\}$ and y_n is the corresponding solution to (1.1). We have therefore

$$\int_0^n (|C_1y_n(t)|_Z^2 + h(v_n(t)))\,dt \le \int_0^n (|C_1x^{\bar{w}}(t)|_Z^2 + h(\Gamma_0\bar{w}(t)))\,dt,$$

where $\Gamma_0\bar{w} = \arg\inf\{K(u,\bar{w}); u \in \mathcal{U}\}$. On the other hand, on a subsequence, we have

$$v_n \to v \quad \text{weakly in } L^2(R^+;U),$$

$$C_1y_n \to C_1y \quad \text{weakly in } L^2(R^+;Z),$$

$$y_n \to y \quad \text{uniformly on compacta,}$$

where (y,v,w) satisfy system (1.1). This yields

$$2^{-1}\int_0^\infty (|C_1y|_Z^2 + h(v))\,dt = \inf\{K(u,\bar{w}); u \in \mathcal{U}\} + 2^{-1}\delta^2\|\bar{w}\|_{\mathcal{W}}^2.$$

Hence $v = \Gamma_0 \bar{w}$ and for $n \to \infty$,

$$2^{-1} \int_0^n (|C_1 y_n(t)|_Z^2 + h(v_n(t)))\, dt \to \inf\{K(u, \bar{w}); u \in \mathcal{U}\} + 2^{-1}\delta^2 \|\bar{w}\|_{\mathcal{W}}^2 \geq \varphi(x_0) - \varepsilon.$$

Then by (3.15) we see that

$$\varphi(x_0) - \varepsilon \leq \varphi_n(x_0) \leq \varphi(x_0)$$

for $n \geq N(\varepsilon, x_0)$, thereby completing the proof. □

Incidentally, we have also proved that (see (3.14)′)

$$\int_0^n (|C_1 x_n(t)|_Z^2 + |u_n(t)|_U^2 + |w_n(t)|_W^2)\, dt \leq C, \qquad \forall n,$$

and so on a subsequence we have

$$\begin{array}{ll} u_n \to u^* & \text{weakly in } L^2(R^+; U), \\ w_n \to w^* & \text{weakly in } L^2(R^+; W), \\ x_n(t) \to x^*(t) & \text{strongly in } X \text{ and uniformly on compacta}, \\ C_1 x_n \to C_1 x^* & \text{weakly in } L^2(R^+; Z), \end{array} \tag{3.16}$$

where (x^*, u^*, w^*) satisfy system (1.1).

For every $x_0 \in X$ we shall denote by $P_n x_0$ the set

$$P_n x_0 = \{-p_n(0)\},$$

where p_n is any solution to system (3.8) arising from a solution (x_n, u_n, w_n) to problem (3.5).

LEMMA 2. *We have*

$$P_n = \partial \varphi_n. \tag{3.17}$$

Proof. It is readily seen that $P_n x_0 \subset \partial \varphi_n(x_0)$, for all $x_0 \in X$. Indeed we have

$$\begin{aligned} 2(\varphi_n(x_0) - \varphi_n(y_0)) &\leq \int_0^n (|C_1 x_n(t)|_Z^2 + h(u_n(t)))\, dt - \int_0^n (|C_1 y_n(t)|_Z^2 + h(v_n(t)))\, dt \\ &\leq 2 \int_0^n ((C_1 x_n(t), (C_1(x_n(t) - y_n(t))_Z \\ &\quad + (\partial h(u_n(t), u_n(t) - v_n(t))_U)\, dt, \end{aligned}$$

where $v_n = \arg\inf_{u \in \mathcal{U}_n} K_n(u, w_n) = \Gamma_{w_n}$ and y_n is the solution to (1.1) where $w = w_n$ and $u = v_n$. Now if p_n is a solution to (3.8) we have

$$\begin{aligned} \varphi_n(x_0) - \varphi_n(y_0) &\leq \int_0^n ((p_n' + A^* p_n, x_n - y_n) + (B_2^* p_n, u_n - v_n)_U)\, dt \\ &= -(p_n(0), x_0 - y_0), \qquad \forall x_0, y_0 \in X, \end{aligned}$$

as claimed. To prove that $P_n = \partial \varphi_n$, it suffices to show that P_n is maximal monotone, i.e., the range $R(\lambda I + P_n)$ is all of X for some $\lambda > 0$ (see e.g., [1]). To this end let $y_0 \in X$ be arbitrary but fixed. To solve the equation

$$x_0 + P_n x_0 = y_0 \tag{3.18}$$

consider the sup inf problem

$$\sup_{w\in\mathcal{W}_n}\inf_{u\in U_n, x(0)\in X}\left\{\int_0^n (|C_1x(t)|_Z^2 + h(u(t)) - \delta^2|w(t)|_W^2)\,dt + \lambda|x(0)|^2 - 2(x(0),y_0) \text{ subject to (1.1)}\right\}. \tag{3.19}$$

Clearly the inf problem has for every $w\in\mathcal{W}_n$ a unique solution $\bar{u}=\Gamma_n w$ given by (see [1], p. 258)

$$\begin{aligned} \bar{u}(t) &= P_{U_0}(B_2^*p(t)) \quad \text{a.e. } t\in(0,n),\\ p' &= -A^*p + C_1^*C_1\bar{x} \quad \text{in } (0,n),\\ p(0) &= \lambda\bar{x}(0) - y_0; \qquad p(n) = 0. \end{aligned} \tag{3.20}$$

Now in virtue of inequality (1.7) we have for all λ sufficiently large

$$\begin{aligned} &\int_0^n (|C_1\bar{x}(t)|_Z^2 + h(\bar{x}(t)) - \delta^2|w(t)|_W^2)\,dt + \lambda|\bar{x}(0)|^2 - 2(\bar{x}(0),y_0)\\ &\le -(\delta^2-\rho^2)\int_0^n |w(t)|_W^2\,dt + \lambda|\bar{x}(0)|^2 - 2(\bar{x}(0),y_0) + \alpha|\bar{x}(0)|^2\\ &\le -\alpha_0^2\int_0^n |w(t)|_W^2\,dt, \qquad \forall w\in\mathcal{W}_n, \end{aligned} \tag{3.21}$$

because

$$\begin{aligned} &\int_0^n (|C_1\bar{x}(t)|_Z^2 + h(\bar{u}(t)))\,dt + \lambda|\bar{x}(0)|^2 - 2(\bar{x}(0),y_0)\\ &\quad\le \int_0^n |C_1\tilde{x}(t)|_Z^2\,dt \le M\int_0^n |w(t)|_W^2\,dt, \qquad \forall w\in\mathcal{W}_n, \end{aligned} \tag{3.22}$$

where $\tilde{x}' = A\tilde{x} + B_1w$; $\tilde{x}(0)=0$. Then by (3.20) and (3.22) we see that $\lambda^2|\bar{x}(0)|^2 \le M_1\int_0^n |w(t)|_W^2\,dt$, which implies (3.21) for λ sufficiently large.

This implies as in the proof of Lemma 1 that problem (3.19) has at least one solution $(\bar{u}_n,\bar{w}_n)\in\mathcal{U}_n\times\mathcal{W}_n$ given by

$$\bar{u}_n(t) = P_{U_0}(B_2^*\bar{p}_n(t)), \qquad w_n(t) = -\delta^{-2}B_1^*\bar{p}_n(t), \tag{3.23}$$

where $\bar{p}_n$ is the solution to (3.20) with $\bar{x}=\bar{x}_n$.

On the other hand, it is readily seen that $(\bar{u}_n,\bar{w}_n)$ is also the solution to problem (3.5) where $x_0=\bar{x}_n(0)$, i.e.,

$$(\bar{u}_n,\bar{w}_n) = \arg\sup_w\inf_u\{K_n(u,w);\ x(0)=\bar{x}_n(0)\}.$$

Then by (3.20) we conclude that $x_0=\bar{x}_n(0)$ is the solution to (3.18). Hence $\partial\varphi_n = P_n$ thereby completing the proof of Lemma 2. □

Consider the function $\psi_n : [0,n]\times X \to R$ defined by

$$\psi_n(t,x_0) = \sup_w\inf_u 2^{-1}\int_t^n (|C_1x|_Z^2 + h(u) - \delta^2|w|_W^2)\,dt \tag{3.24}$$

subject to $u\in L^2(t,n;U)$, $w\in L^2(t,n;W)$, and

$$x' = Ax + B_2u + B_1w \quad \text{in } [t,n]; \qquad x(t)=x_0.$$

LEMMA 3. *Let p_n be a solution to system* (3.8). *Then*

$$p_n(t) \in -\partial\psi_n(t, x_n(t)), \qquad \forall\, t \in [0, n], \tag{3.25}$$

and there is C independent of n such that

$$|p_n(t)| \leq C, \qquad \forall\, t \in [0, n]. \tag{3.26}$$

Proof. For every $t \in [0, n]$, the function $\psi_n(t, \cdot)$ is convex, continuous, and as seen in Lemma 3, $-p_n^t(t) \in \partial\psi_n(t, x_0)$, where $\partial\psi_n$ is the subdifferential of $\psi_n(t, \cdot)$ and p_n^t is the solution to

$$(p_n^t)' = -A^* p_n^t + C_1^* C_1 x_n^t \quad \text{in } [t, n]; \qquad p_n^t(n) = 0,$$

and u_n^t, w_n^t, x_n^t are optimal in (3.24). Moreover, it is readily seen (the dynamic programming principle) that if $x_0 = x_n(t)$, then $u_n^t = u_n, w_n^t = w_n, x_n^t = x_n$ on $[t, n]$ where (u_n, w_n) is the solution to problem (3.5). We may therefore infer that in this case $p^n(s) = p_n(s)$, for all $s \in [t, n]$ and

$$p_n(t) = -\partial\psi_n(t, x_n(t)), \qquad \forall\, t \in [0, n],$$

where p_n is the solution to system (3.8).

On the other hand

$$\psi_n(t, x_n(t)) \leq \psi_n(t, x_n(t) + \beta\theta) - \beta(\partial\psi_n(t, x_n(t)), \theta)$$

for all $\theta \in X$ and $\beta > 0$. This yields for $\theta = p_n(t)|p_n(t)|^{-1}$,

$$\begin{aligned} |p_n(t)| &\leq \beta^{-1}\psi_n(t, x_n(t) + \beta\theta) \leq \beta^{-1}\varphi(x_n(t) + \beta\theta) \\ &\leq \alpha\beta^{-1}|x_n(t) + \beta\theta|^2/2. \end{aligned}$$

Let $K \in L(Z, X)$ be such that $e^{(A+KC_1)t}$ is exponentially stable (1.3). Then we have, respectively,

$$x_n' = (A + KC_1)x_n + B_1 w_n + B_2 u_n - KC_1 x_n$$

and

$$(x^*)' = (A + KC_1)x^* + B_1 w^* + B_2 u^* - KC_1 x^*,$$

where (x^*, u^*, w^*) are defined by (3.16).

We have therefore

$$x^* \in L^2(R^+; X) \cap C(R^+; X), \qquad \lim_{t\to\infty} x^*(t) = 0, \tag{3.27}$$

and

$$x_n(t) \to x^*(t) \qquad \text{uniformly on } R^+. \tag{3.28}$$

Hence

$$\limsup_{n\to\infty} |p_n(t)| \leq \alpha\beta^{-1}(|x^*(t)|^2 + 2\beta|x^*(t)| + \beta^2)/2, \tag{3.29}$$

and this completes the proof of Lemma 3. □

Selecting further sequence if necessary we may assume that

$$\begin{aligned} &p_n \to p \quad \text{weak star in } L^\infty(R^+;X), \\ &p_n(t) \to p(t) \quad \text{uniformly on compact intervals,} \end{aligned} \tag{3.30}$$

where p is a mild solution to equation

$$p' = -A^*p + C_1^*C_1x^* \quad \text{in } R^+, \tag{3.31}$$

i.e.,

$$p(t) = e^{A^*(s-t)}p(s) - \int_t^s e^{A^*(\varsigma-t)}C_1^*C_1x^*(\varsigma)\,d\varsigma, \tag{3.31}'$$

for all $0 \le t < s < \infty$.

Now by (3.29) we see that

$$2|p(t)| \le \alpha\beta^{-1}(|x^*(t)|^2 + 2\beta|x^*(t)| + \beta^2), \qquad \forall\, t \ge 0, \beta > 0,$$

and by (3.27) we infer that $\lim_{t\to\infty} |p(t)| \le \alpha\beta/2$ for all $\beta > 0$. Hence

$$\lim_{t\to\infty} p(t) = p(\infty) = 0. \tag{3.32}$$

Note also that by Lemma 1 and (3.16), (3.30) we have

$$u^*(t) = P_{U_0}(-B_2^*p(t)), \qquad w^*(t) = -\delta^{-2}B_1^*p(t), \qquad \text{a.e. } t > 0. \tag{3.33}$$

We shall denote by $P : X \to X$ the mapping defined by

$$Px_0 = \{-p(0)\}, \qquad \forall\, x_0 \in X,$$

where $p \in C(R^+;X)$ is any solution to (3.31), (3.32).

LEMMA 4. *We have* $\partial\varphi = P$.

Proof. Letting n tend to $+\infty$ in $p_n(0) \in -\partial\varphi_n(x_0)$, i.e.,

$$-(p_n(0), x_0 - y_0) \ge \varphi_n(x_0) - \varphi_n(y_0), \qquad \forall\, y_0 \in X,$$

it follows by Lemmas 1 and 2 that $-p(0) \in \partial\varphi(x_0)$, i.e., $P \subset \partial\varphi$. To prove that $P = \partial\varphi$, it suffices to show that $R(I + P) = X$, i.e., for every $y_0 \in X$ the equation

$$x_0 + Px_0 \ni y_0 \tag{3.34}$$

has at least one solution. Since by Lemma 2, $R(I + P_n) = X$ for all n, the equation $x + P_nx \ni y_0$ has a unique solution: x_0^n, i.e.,

$$x_0^n - p_n(0) = y_0,$$

where p_n is a solution to system (3.8) with $x(0) = x_0^n$. Since $(I + P_n)^{-1}$ is nonexpansive on X, $\{x_0^n\}$ is bounded and so on a subsequence, $x_0^n \to x_0$ weakly in X. Then clearly the corresponding sequence of solutions (u_n, w_n) to problem (3.5) is bounded in $L^2(R^+;U) \times L^2(R^+;W)$, and so we may assume (3.16) holds and this implies as above that

$$p_n(t) \to p(t) \quad \text{uniformly on every } [0,T],$$

where p is a solution to (3.31), (3.32). Hence $x_0 - p(0) = y_0$ and so x_0 is the solution to (3.34) as desired.

Now by (3.31)$'$ and by assumption (i) we see that $\partial\varphi = P$ is compact, i.e., maps bounded sets in compacta.

Let $x_0 \in D(A)$ be arbitrary but fixed and let η be any element of $\partial\varphi(x_0)$. According to Lemma 4 there are $(x^*, u^*, w^*) \in L^2(R^+; X) \times L^2(R^+; U) \times L^2(R^+; W)$ and $p \in C(R^+; X)$ such that

$$(x^*)' = Ax^* + B_2 P_{U_0}(-B_2^* p) - \delta^{-2} B_1 B_1^* p \quad \text{in } R^+,$$

$$p' = -A^* p + C_1^* C_1 x^* \quad \text{in } R^+;$$

$$x^*(0) = x_0, \qquad p(\infty) = 0,$$

$$p(0) = \eta.$$

By assumption (ii) we see that x^* and p are strong solutions to these equations. Then multiplying the first equation by p' the second by $(x^*)'$ and subtracting the results we get

$$2(Ax^*(t), p(t)) - \delta^{-2}|B_1^* p(t)|^2 - h^*(-B_2^* p(t)) - |C_1 x^*(t)|^2 = 0, \qquad \forall\, t \geq 0,$$

where

$$h^*(v) = \sup\{(v, x) - h(x); x \in X\} = 2^{-1}(|v|_U^2 - |v - P_{U_0}(v)|_U^2).$$

Now letting t tend to zero, we get (2.2). On the other hand, by (3.25) we have

$$(p(t), x^*(t) - y_0) \geq \varphi(x^*(t) - \varphi(y_0)), \qquad \forall\, t \geq 0, y_0 \in X,$$

because by Lemma 1 we know that

$$\lim_{n\to\infty} \psi_n(t, x) = \sup_w \inf_u \left\{ \frac{1}{2} \int_t^\infty (|C_1 x|_Z^2 + h(u) - \delta^2 |w|_W^2)\, dt, u \in L^2(t, \infty; U), \right.$$

$$\left. w \in L^2(t, \infty; W); x' = Ax + B_2 u + B_1 w \text{ in } (t, \infty), x(t) = x_0 \right\}$$

$$= \varphi(x_0).$$

Hence $-p(t) \in \partial\varphi(x^*(t))$, for all $t \geq 0$ and so by (3.27) we conclude that x^* is a mild solution to multivalued equation (2.3) satisfying (2.4).

Let us assume now that (2.2) has a solution φ which is convex, continuous with $\partial\varphi$, compact, and which satisfies (2.2). We must prove that the feedback control $F = P_{U_0}(-B_2^* \partial\varphi)$ belongs to $\mathcal{F}$ and

$$|S_F(x_0, w)|^2 \leq \delta^2 \|w\|_{L^2(R^+;W)}^2 + \alpha |x_0|^2 \tag{3.35}$$

for all $(x_0, w) \in X \times L^2(R^+; W)$.

Consider the Cauchy problem

$$x' = Ax + B_2 P_{U_0}(-B_2^* \partial\varphi(x)) + B_1 w; \qquad x(0) = x_0 \tag{3.36}$$

for $x_0 \in X$ and $w \in L^2(R^+; W)$. We shall prove first that (3.36) has a mild solution x on R^+.

Since the mapping $x \to B_2 P_{U_0}(-B_2^* \partial\varphi)$ is not convex-valued, the standard existence theory does not apply in this case. However we consider the approximating equation

$$x'_\lambda = Ax_\lambda + B_2 P_{U_0}(-B_2^* \nabla\varphi_\lambda(x_\lambda)) + B_1 w; \qquad x_\lambda(0) = x_0,$$

where $\nabla\varphi_\lambda = \lambda^{-1}(I - (I + \lambda\partial\varphi)^{-1})$ (see [1]). Since $\nabla\varphi_\lambda$ is Lipschitzian, this equation has a unique mild solution x_λ. Moreover, by (2.2) it is readily seen that

$$\sup\{|\eta|; \eta \in \partial\varphi(x)\} \leq C(|x| + 1) \qquad \forall x \in X$$

and therefore

$$|\nabla\varphi_\lambda(x_\lambda)| \leq C_1(x_\lambda| + 1), \qquad \forall \lambda > 0.$$

This implies that $\{x_\lambda\}$ is uniformly bounded on every interval $[0, T]$, and by standard compacity arguments (see e.g., [7]) we infer that $\{x_\lambda\}$ is uniformly convergent on every interval to a continuous function $x = x(t)$. Since $\nabla\varphi_\lambda(x_\lambda) \in \partial\varphi((I + \lambda\partial\varphi)^{-1}x_\lambda)$ and $\partial\varphi$ is compact, we have on a subsequence

$$P_{U_0}(-B_2^* \nabla\varphi_\lambda(x_\lambda)) \to P_{U_0}(-B_2^*\eta(t)), \qquad \text{a.e. } t > 0,$$

where $\eta(t) \in \partial\varphi(x(t)), t \geq 0$. This implies that x is a mild solution to (3.36). Since e^{At} is analytic, the function x is a strong solution to (3.36) (i.e., is absolutely continuous and satisfies almost everywhere this equation).

Now multiplying (3.36) by $\eta(t) \in \partial\varphi(x(t))$ and using (2.2), we get

$$\begin{aligned} \frac{d}{dt}\varphi(x(t)) &= (Ax(t) + B_2 P_{U_0}(-B_2^*\eta(t)), \eta(t)) + (w(t), B_1^*\eta(t))_W \\ &= -2^{-1}|C_1 x(t)|_Z^2 + \delta^{-2}|B_1^*\eta(t)|_W^2 - |P_{U_0}(-B_2^*\eta(t))|_U^2 \\ &\quad + (w(t), B_1^*\eta(t))_W, \qquad \forall t \geq 0. \end{aligned} \tag{3.37}$$

Integrating (3.37) on $(0, t)$ we get

$$\begin{aligned} &\varphi(x(t)) + 2^{-1}\int_0^t (|C_1 x(s)|_Z^2 + |u(s)|_U^2 - \delta^{-2}|B_1^*\eta(s)|_W^2)\, ds \\ &\quad = \varphi(x_0) + \int_0^t (w(s), B_1^*\eta(s))W\, ds, \qquad \forall t \geq 0, \end{aligned} \tag{3.38}$$

and therefore

$$\int_0^t (|C_1 x(s)|_Z^2 + |u(s)|_U^2)\, ds \leq C, \qquad \forall t \geq 0. \tag{3.39}$$

On the other hand, we may write (3.36) as

$$x' = (A + KC_1)x - KC_1 x + B_2 u + B_1 w, \qquad x(0) = x_0,$$

where $e^{(A+KC_1)t}$ is exponentially stable. Then by estimate (3.39) we see that

$$x \in L^2(R^+; W) \quad \text{and} \quad \lim_{t\to\infty} x(t) = 0.$$

Since in the previous argument $B_1 w$ can be replaced by any L^2 function f, we conclude that $F \in \mathcal{F}$. We note that (3.38) holds for any mild solution x to system (1.1) where $u(t) \in P_{U_0}(-B_2^*\partial\varphi(x(t)))$ almost everywhere $t > 0$. This yields

$$\frac{1}{2}\int_0^\infty (|C_1 x(t)|_Z^2 + h(u(t)))\, dt \leq \varphi(x_0) + \frac{\delta^2}{2}\int_0^\infty |w(t)|_W^2\, dt, \qquad \forall w \in L^2(R^+; W)$$

as claimed. The proof of Theorem 1 is complete. □

POSITIVE DEPENDENCE OF A CLASS OF MULTIVARIATE EXPONENTIAL DISTRIBUTIONS*

INGRAM OLKIN† AND Y. L. TONG‡

Abstract. The positive dependence of a subclass of multivariate exponential distributions is examined. This class is characterized by an index vector $\mathbf{k}$ and a parameter vector $\boldsymbol{\lambda}$, which are used as an ordering to yield degrees of positive dependence. The results presented have a direct implication on the reliability function of a system and the survival probability function of a shock model, and consequently on the optimal assembly of systems.

Key words. system reliability, component systems, shock models, majorization, Schur-convex functions

1. Introduction.

There is a large literature dealing with the role of multivariate exponential distributions in reliability theory. (Here we use the term multivariate exponential distribution to mean any joint distribution with univariate exponential marginal distributions.) Early attention was focused on probabilistic models for generating bivariate exponential distributions. These arise from shock models, physical applications, statistical considerations, and so on (see, e.g., [Freund (1961)], [Marshall and Olkin (1967a), (1967b)], [Downton (1970)], [Block and Basu (1974)], [Friday (1976)], [Friday and Patil (1977)]). Some of these bivariate exponential distributions extend naturally to the multivariate case [Marshall and Olkin (1967a)], [Arnold (1968)], [Proschan and Sullo (1974)], [Basu and Block (1975)]. A key feature of these distributions is that the number of parameters is large, thereby creating difficulties in statistical inference. For small dimensionality some headway has been made. Statistical estimation of the parameters was studied in [Proschan and Sullo (1976)], and a test for independence was proposed in [Al-Saadi and Young (1982)]. For a comprehensive general review of the literature on multivariate exponential distributions, see [Johnson and Kotz (1972), Chap. 41], [Friday (1976)], [Friday and Patil (1977)], [Block (1985)], and [Marshall and Olkin (1985)].

For two nonnegative random vectors $\mathbf{X} = (X_1, \ldots, X_n)$ and $\mathbf{X}' = (X_1', \ldots, X_n')$ with the same marginal distributions, we say that $\mathbf{X}$ is more positively dependent than $\mathbf{X}'$ if

$$P\left(\bigcap_{i=1}^{n} \{X_i \in \mathcal{B}\}\right) \geq P\left(\bigcap_{i=1}^{n} \{X_i' \in \mathcal{B}\}\right) \quad \text{for all Borel sets } \mathcal{B} \tag{1.1}$$

(see [Tong (1989)]). In effect, by taking $\mathcal{B}$ to be an interval in $\mathcal{R}$ whose indicator function is monotonic, more positive dependence concentrates probabilities more heavily in the permutation symmetric lower and upper orthants.

Positive dependence is an important characteristic of random variables, and multivariate exponential distributions have been a source of considerable study. In particular, we determine configurations of the parameters for which comparisons of positive dependence can be made.

In this paper we study a subclass of multivariate exponential distributions of [Marshall and Olkin (1967a)], characterized by an index vector $\mathbf{k}$ and a parameter vector $\boldsymbol{\lambda}$, for which we obtain results on positive dependence. Examples of parallel-series systems and shock models are shown to fit in this subclass when $\mathcal{B}$ is the set $\mathcal{B} = \{x : x \leq t\}$ or $\mathcal{B} = \{x : x > t\}$ for

arbitrary but fixed t (§2). In §3 we obtain results concerning positive dependence via a partial ordering of the index vectors and a partial ordering of the parameter vectors. These results have a direct implication on the reliability function of a system and the survival probability function of a shock model.

To fix notation we say that a random variable X is exponentially distributed with parameter λ if $\overline{G}(x) = P\{X > x\} = e^{-\lambda x}$. For a multivariate distribution of $(X_1, \ldots, X_n)$ we write $F(x_1, \ldots, x_n) = P(\cap_{i=1}^n \{X_i \le x_i\})$ and for simplicity $F(t, \ldots, t) \equiv P(\cap_{i=1}^n \{X_i \le t\})$; the survival function is denoted $\overline{F}(x_1, \ldots, x_n) = P(\cap_{i=1}^n \{X_i > x_i\})$ or $\overline{F}(t, \ldots, t) = P(\cap_{i=1}^n \{X_i > t\})$.

2. A class of multivariate exponential distributions with a common univariate marginal distribution. To motivate the subclass considered, we briefly review the Marshall–Olkin (M–O) multivariate exponential for the trivariate case [Marshall and Olkin (1967a), §4]. Let U_1, U_2, U_3, V_{12}, V_{13}, V_{23}, W_{123} denote independent exponential random variables and let

$$\begin{aligned} X_1 &= \min(U_1, V_{12}, V_{13}, W_{123}), \\ X_2 &= \min(U_2, V_{12}, V_{23}, W_{123}), \\ X_3 &= \min(U_3, V_{13}, V_{23}, W_{123}). \end{aligned} \tag{2.1}$$

Then (X_1, X_2, X_3) has the M–O trivariate exponential distribution. The key point to note is that this formulation requires $2^n - 1$ independent random variables to generate an n-variate exponential distribution. However, not all component systems require the full range of variables. For example,

$$\begin{aligned} X_1' &= \min(U_1, V_{12}, W_{123}), \\ X_2' &= \min(U_2, V_{12}, W_{123}), \\ X_3' &= \min(U_3, W_{123}) \end{aligned} \tag{2.2}$$

is a subclass of (2.1) and requires only five instead of seven variables to generate the trivariate model.

Thus, the motivation for the subclass being considered is exactly to define a subclass of models that might be useful in some applications. One subclass is the following: Let $U_1, \ldots, U_n$, $V_1, \ldots, V_n$, and W be independent univariate exponential random variables with $EU_i = \lambda_1^{-1}$, $EV_i = \lambda_2^{-1}$ $(i = 1, \ldots, n)$, and $EW = \lambda_0^{-1}$. Let $\mathbf{k} = (k_1, \ldots, k_n)$ be a vector of nonnegative integers with

$$\sum_{s=1}^{n} k_s = n, \qquad k_1 \ge \cdots \ge k_r \ge 1, \qquad k_{r+1} = \cdots = k_n = 0, \tag{2.3}$$

for some $r \le n$. In the results given below, the monotonicity of the k_i's in (2.3) is not essential, as we shall see; this condition is made primarily for notational convenience. For given $\mathbf{k}$ let $\mathbf{X} \equiv \mathbf{X}(\mathbf{k}) = (X_1, \ldots, X_n)$ be an n-dimensional multivariate exponential random vector defined by

$$X_j = \begin{cases} \min(U_j, V_1, W), & j = 1, \ldots, K_1, \\ \min(U_j, V_2, W), & j = k_1 + 1, \ldots, K_2, \\ \quad \vdots \qquad \vdots & \\ \min(U_j, V_r, W), & j = K_{r-1} + 1, \ldots, n, \end{cases} \tag{2.4}$$

where $K_0 = 0$, $K_1 = k_1$, $K_2 = k_1 + k_2, \ldots, K_{r-1} = k_1 + \cdots + k_{r-1}$. That is, each of the X_j's depends on a different U_j and a common W, the first k_1 depend on V_1, the next k_2

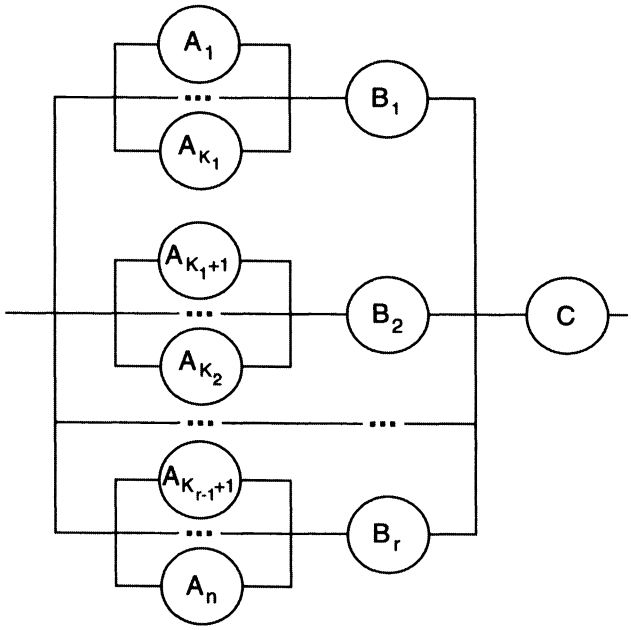

FIG. 1. *A parallel-series system.*

depend on V_2, and so on. From the construction the univariate marginal distributions of the X_j's are exponential with a mean $\lambda^{-1} \equiv (\lambda_1 + \lambda_2 + \lambda_0)^{-1}$.

The joint distribution of the X_i's is exchangeable only when $\mathbf{k} = (n, 0, \ldots, 0)$ or $\mathbf{k} = (1, 1, \ldots, 1)$. Furthermore, the construction suggests that the components $X_j = \min(U_j, V_1, W)$, $j = 1, \ldots, n$ of $\mathbf{X}(n, 0, \ldots, 0)$, are more positively dependent (in the sense of (1.1)) than the components $X_j = \min(U_j, V_j, W)$, $j = 1, \ldots, n$ of $\mathbf{X}(1, 1, \ldots, 1)$ because the former depends on the same variable V_1, whereas the latter permits the V_j's to differ. (An analytical proof is provided in [Shaked and Tong (1985)].)

We now compare the positive dependence for intermediate cases of the components of $\mathbf{X}(\mathbf{k})$. Let

$$F_{\mathbf{k},\boldsymbol{\lambda}}(t, \ldots, t) \equiv P_{\mathbf{k},\boldsymbol{\lambda}}\left[\bigcap_{i=1}^{n} \{X_i \leq t\}\right], \qquad \overline{F}_{\mathbf{k},\boldsymbol{\lambda}}(t, \ldots, t) = P_{\mathbf{k},\boldsymbol{\lambda}}\left[\bigcap_{i=1}^{n} \{X_i > t\}\right], \tag{2.5}$$

where $\boldsymbol{\lambda} = (\lambda_1, \lambda_2, \lambda_0)$. We first examine how these probability functions depend on λ_1, λ_2, and λ_0 when both $\mathbf{k}$ and the sum $\lambda = \lambda_0 + \lambda_1 + \lambda_2$ are kept fixed.

Example 2.1. *System reliability.* Suppose that three types of components labeled A, B, and C are connected in a parallel-series fashion such that subsets of size k_s of the type A components comprise a subsystem connected in parallel, the s-th subsystem connected in series to a component $B_s (s = 1, \ldots, r)$; all of the type B components are connected to a type C component in parallel as shown in Fig. 1. If the lifelength distributions of the components A, B, and C are exponential with means λ_1^{-1}, λ_2^{-1}, and λ_0^{-1}, respectively, then the system reliability is simply

$$R_{\mathbf{k},\boldsymbol{\lambda}}(t) \equiv P_{\mathbf{k},\boldsymbol{\lambda}}\{\text{lifelength of system } > t\} = 1 - F_{\mathbf{k},\boldsymbol{\lambda}}(t, \ldots, t). \tag{2.6}$$

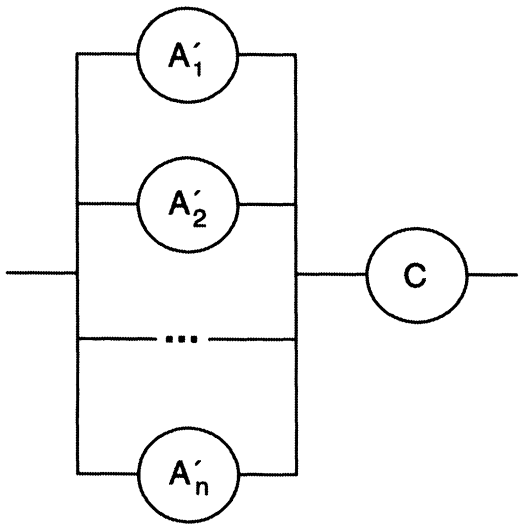

FIG. 2. *The case* $k_1 = \cdots = k_n = 1$.

When $k_1 = \cdots = k_n = 1$ so that $\mathbf{k} = (1, 1, \ldots, 1)$, then the system in Fig. 1. reduces to that in Fig. 2, where the lifelengths of components $A_1', \ldots, A_n'$ have independent exponential distributions with a common mean $(\lambda_1 + \lambda_2)^{-1}$.

Example 2.2. *Shock models.* In a fatal shock model suppose that the components of an n-component system die after receiving a fatal shock from one of several sources and that independent Poisson processes govern the occurrence of shocks. If (i) the failure times for components of type A, B, C, governed by shocks, are independent exponential variables with means λ_1^{-1}, λ_2^{-1}, λ_0^{-1}, respectively; (ii) a separate type A shock applies to each of the n components; (iii) shocks of type B affect groups of $k_1, k_2, \ldots, k_r$ components; and (iv) a shock to type C applies to all the n components, then the survival probability function of concern is

$$\begin{aligned}\overline{F}_{\mathbf{k},\boldsymbol{\lambda}}(x_1, \ldots, x_n) &= P_{\mathbf{k},\boldsymbol{\lambda}}\left[\bigcap_{i=1}^{n}\{X_i > x_i\}\right] \\ &= \exp\left[-\lambda_1 \sum_{i=1}^{n} x_i - \lambda_2 \sum_{s=1}^{r} \max(x_{K_{s-1}+1}, \ldots, x_{K_s}) - \lambda_0 \max_{1\le i\le n} x_i\right],\end{aligned} \tag{2.7}$$

where $K_0 \equiv 0$. When $x_1 = \cdots = x_n = t$, (2.7) reduces to

$$\overline{F}_{\mathbf{k},\boldsymbol{\lambda}}(t, \ldots, t) = \exp[-n\lambda_1 t - r\lambda_2 t - \lambda_0 t]. \tag{2.8}$$

It should be noted that in general we need not restrict our attention to just three types of components A, B, and C. Although our model given in (2.4) can be modified for any number of types of components, we have not obtained manageable analytical results for the general case. (In the general case there are several W variables, and a corresponding conditioning argument, given their values, becomes complicated.) Thus, throughout this paper we consider only three types of components as modeled in (2.4).

3. Positive dependence properties. In this section we present analytic results concerning how the positive dependence of the random variables $X_1(\mathbf{k}), \ldots, X_n(\mathbf{k})$ depends on $\mathbf{k}$ and

$\boldsymbol{\lambda}$. In particular, we show that when the random variables are more positively dependent in a fashion to be defined, then they are more concentrated in the sense that both $F_{\mathbf{k},\boldsymbol{\lambda}}(t,\dots,t)$ and $\overline{F}_{\mathbf{k},\boldsymbol{\lambda}}(t,\dots,t)$ defined in (2.5) become larger.

Positive dependence of the components $\mathbf{X}(\mathbf{k})$ depend on $\mathbf{k}$ and $\boldsymbol{\lambda}$, and in particular on the number of variables r used in the generation (2.4) of the joint distribution. We first show that if the parameters remain fixed, then we obtain more positive dependence if $\mathbf{k}$ is ordered by majorization. (For details of majorization, see [Marshall and Olkin, (1979)].)

THEOREM 3.1. *Let n, $\boldsymbol{\lambda}$, and t be arbitrary but fixed, and let $\mathbf{k}, \mathbf{k}'$ be two vectors satisfying* (2.3). *If $\mathbf{k} \succ \mathbf{k}'$, where $\succ$ denotes the majorization ordering, then*

$$\overline{F}_{\mathbf{k},\boldsymbol{\lambda}}(t,\dots,t) \geq \overline{F}_{\mathbf{k}',\boldsymbol{\lambda}}(t,\dots,t). \tag{3.1}$$

Proof. The result follows from (2.8) and the fact that if

$$\mathbf{k} = (k_1,\dots,k_r,k_{r+1},\dots,k_n) \succ (k_1',\dots,k_{r'}',k_{r'+1}',\dots,k_n') = \mathbf{k}',$$

where $k_1 \geq \cdots \geq k_r \geq 1$, $k_{r+1} = \cdots = k_n = 0$, $k_1' \geq \cdots \geq k_{r'}' \geq 1$, $k_{r'+1}' = \cdots = k_n' = 0$, then $r \leq r'$. □

We next compare two distributions for which $\mathbf{k}$ remains fixed but the parameters $\boldsymbol{\lambda}$ change. To do this we require the definition of a "decreasing transformation."

DEFINITION 3.2. *Let $\boldsymbol{\lambda} = (\lambda_1,\lambda_2,\lambda_0)$ and $\boldsymbol{\lambda}^* = (\lambda_1^*,\lambda_2^*,\lambda_0^*)$ denote two vectors of parameters. The vector $\boldsymbol{\lambda}^*$ is said to be a* decreasing transformation *of $\boldsymbol{\lambda}$ (denoted $\boldsymbol{\lambda} \overset{t}{>} \boldsymbol{\lambda}^*$) if $\boldsymbol{\lambda} \neq \boldsymbol{\lambda}^*$ and*

$$\lambda_1 \leq \lambda_1^*, \quad \lambda_1+\lambda_2 \leq \lambda_1^*+\lambda_2^*, \quad \textit{and} \quad \lambda_1+\lambda_2+\lambda_0 = \lambda_1^*+\lambda_2^*+\lambda_0^*.$$

Note that the distinction between decreasing transformation and majorization is that the former does not require an ordering of the elements. An important aspect of a decreasing transformation is that the marginal distributions remain unchanged. We show in Theorem 3.4 that the random variables are more positively orthant dependent (for definition see, e.g., [Tong (1990), p. 102]) under $\boldsymbol{\lambda}^*$. The following example may serve to illustrate the structure.

Example 3.3. Suppose $n = 4$, $\mathbf{k} = (2,2,0,0)$, and $\boldsymbol{\lambda} = (2,5,6) \overset{t}{>} (4,3,6) = \boldsymbol{\lambda}^*$. Then the distribution of the lifelength of the system under $\boldsymbol{\lambda}$ and under $\boldsymbol{\lambda}^*$ is as in Figs. 3 and 4, respectively. Here the lifelengths of the A, B, and C components are independent exponential variables with means $\frac{1}{2}$, $\frac{1}{3}$, and $\frac{1}{6}$, respectively. In Fig. 3, X_1 and X_2 involve the same component A_{12} and X_3 and X_4 involve the same component A_{32}, so that it is intuitively clear that the system of Fig. 3 is more positively dependent than that of Fig. 4.

THEOREM 3.4. *Let n, $\mathbf{k}$, and t be arbitrary but fixed, and let*

$$\boldsymbol{\lambda} = (\lambda_1,\lambda_2,\lambda_0) \quad \textit{and} \quad \boldsymbol{\lambda}^* = (\lambda_1^*,\lambda_2^*,\lambda_0^*) \tag{3.2}$$

be two parameter vectors. If $\lambda \overset{t}{>} \lambda^*$, then

$$\overline{F}_{\mathbf{k},\boldsymbol{\lambda}}(x_1,\dots,x_n) \geq \overline{F}_{\mathbf{k},\boldsymbol{\lambda}^*}(x_1,\dots,x_n) \quad \textit{for all } (x_1,\dots,x_n) \in \mathbb{R}_+^n. \tag{3.3}$$

Proof. The proof follows from (2.7) and the fact that

$$\sum_{i=1}^{n} x_i \geq \sum_{s=1}^{r} \max(x_{K_{s-1}+1},\dots,x_{K_s}) \geq \max_{1\leq i\leq n} x_i. \qquad \square$$

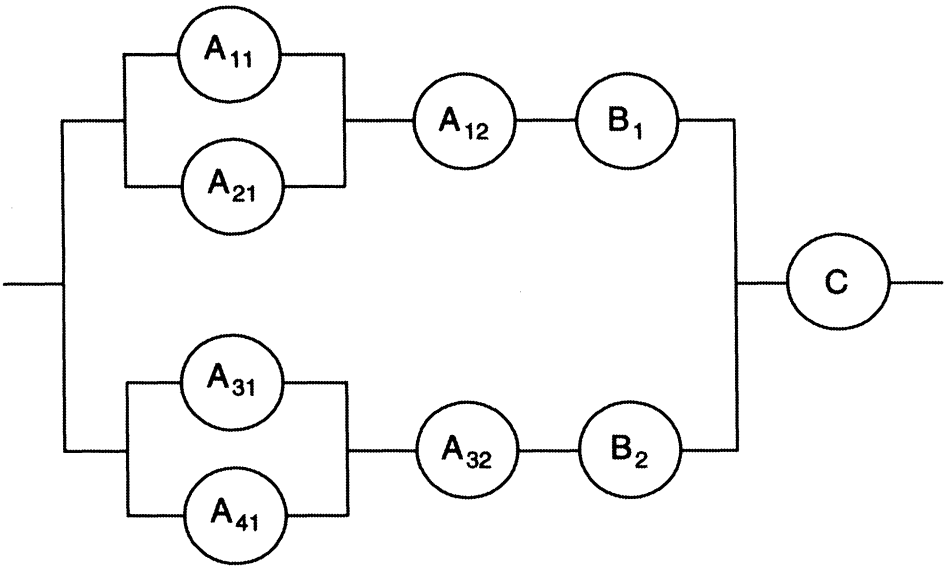

FIG. 3. *A parallel-series system.*

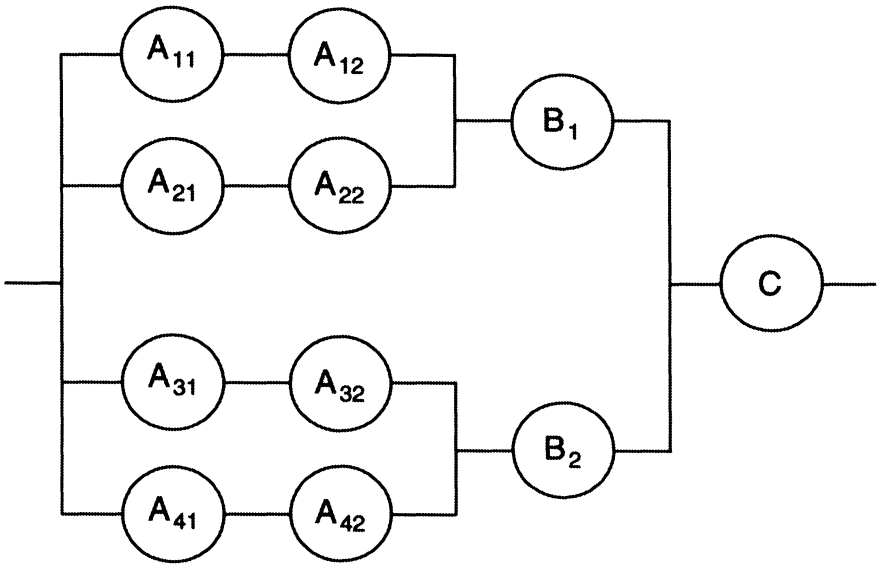

FIG. 4. *A parallel-series system.*

It follows from Theorem 3.4 that

$$\overline{F}_{\mathbf{k},\boldsymbol{\lambda}}(t,\ldots,t) \geq \overline{F}_{\mathbf{k},\boldsymbol{\lambda}^*}(t,\ldots,t) \quad \text{for all } t \in (0,\infty). \tag{3.4}$$

We now examine in more detail the function $F_{\mathbf{k},\boldsymbol{\lambda}}(t,\ldots,t)$ and its reliability function $R_{\mathbf{k},\boldsymbol{\lambda}}(t) =$

$1 - F_{\mathbf{k},\boldsymbol{\lambda}}(t,\ldots,t)$. In particular, if (2.5) prevails, then

$$R_{\mathbf{k},\boldsymbol{\lambda}}(t) = \overline{G}_0(t)\left[1 - \prod_{s=1}^{r}\{1 - \overline{G}_2(t)[1 - G_1^{k_s}(t)]\}\right], \tag{3.5}$$
$$\overline{G}_j(t) = e^{-\lambda_j t}, \quad G_j(t) = 1 - \overline{G}_j(t) \quad \text{for } j = 0, 1, 2.$$

THEOREM 3.5. *Let n, $\boldsymbol{\lambda}$, and t be arbitrary but fixed, and let $\mathbf{k}, \mathbf{k}'$ satisfy* (2.3). *If $\mathbf{k} \succ \mathbf{k}'$, then*

$$R_{\mathbf{k},\boldsymbol{\lambda}}(t) \le R_{\mathbf{k}',\boldsymbol{\lambda}}(t). \tag{3.6}$$

Proof. Although this theorem can be derived by applying a more general result in [Tong (1989)], here we give an independent proof that more clearly illustrates the structure using the specific expression in (3.5). Consider the function

$$h(\mathbf{k}) \equiv \log \prod_{s=1}^{r}\{1 - c_2(1 - c_2^{k_s})\}$$
$$= \sum_{s=1}^{r} \log\{\bar{c}_2 + c_2 e^{k_s \log c_1}\} \equiv \sum_{s=1}^{r} \phi(k_s),$$

where $c_1 = G_1(t)$, $c_2 = 1 - \bar{c}_2 = \overline{G}_2(t)$ are in $(0,1)$, $\phi(u) = \log\{\bar{c}_2 + c_2 e^{\rho u}\}$. Because

$$\phi''(u) = c_2\rho^2\bar{c}_2 e^{\rho u}(\bar{c}_2 + c_2 e^{\rho u})^{-2} > 0$$

for all $\rho = \log c_1 < 0$ and $u \ge 0$, the function $h(\mathbf{k})$, and hence $\prod_{s=1}^{r}\{1 - \overline{G}_2(t)(1 - G_1^{k_s}(t))\}$, is a Schur-convex function of $\mathbf{k}$. (See [Marshall and Olkin (1979), p. 11].) Thus, $R_{\mathbf{k},\boldsymbol{\lambda}}(t)$ is a Schur-concave function of $\mathbf{k}$. □

Note that $F_{\mathbf{k},\boldsymbol{\lambda}}(t,\ldots,t) = 1 - R_{\mathbf{k},\boldsymbol{\lambda}}(t)$ is a Schur-convex function of $\mathbf{k}$.

The practical implication of Theorem 3.5 is that the reliability increases as $\mathbf{k}$ moves toward the uniform distribution in the sense of majorization. This has a direct application in the optimal assembly of systems, as is illustrate further in §4.

The next result is an analog to Theorem 3.5.

THEOREM 3.6. *Let n, $\mathbf{k}$, and t be arbitrary but fixed. If $\boldsymbol{\lambda} \overset{t}{>} \boldsymbol{\lambda}^*$, then*

$$R_{\mathbf{k},\boldsymbol{\lambda}}(t) \le R_{\mathbf{k},\boldsymbol{\lambda}^*}(t). \tag{3.7}$$

Proof. Define a parameter vector $\boldsymbol{\lambda}'$ of positive elements given by

$$\boldsymbol{\lambda}' = (\lambda_1', \lambda_2', \lambda_0') \equiv (\lambda_1, \lambda_1^* + \lambda_2^* - \lambda_1, \lambda_0^*).$$

We show that

$$R_{\mathbf{k},\boldsymbol{\lambda}}(t) \le R_{\mathbf{k},\boldsymbol{\lambda}'}(t) \le R_{\mathbf{k},\boldsymbol{\lambda}^*}(t).$$

The second inequality follows as a special case from the discussion in [Tong (1989), Ex. 3.1] with $B = \{x : x \le t\}$ and $g(u,v,w) = \min(u,v,w)$. To prove the first inequality, let $\delta = \lambda_2' - \lambda_2 \ge 0$. Then

$$R_{\mathbf{k},\boldsymbol{\lambda}}(t) = e^{-\lambda_0 t}\left[1 - \prod_{s=1}^{r}(1 - z_s e^{-\lambda_2 t})\right] \tag{3.8}$$
$$= e^{-\delta t}e^{-\lambda_0' t}\left[1 - \prod_{s=1}^{r}(1 - z_s e^{\delta t}e^{-\lambda_2' t})\right],$$

where $z_s \equiv z_s(t) = 1 - G_1^{k_s}(t)\,(s = 1, \ldots, r)$ are arbitrary but fixed, $z_s \in [0, 1]$. For notational convenience, let $c \equiv e^{\delta t} \geq 1$, $\omega \equiv e^{-\lambda_2' t} < 1$, so that

$$R_{\mathbf{k},\boldsymbol{\lambda}}(t) = \frac{1}{c}\, e^{-\lambda_0' t} \left[1 - \prod_{s=1}^{r} (1 - c\omega z_s)\right]. \tag{3.9}$$

In (3.9) let $y_s \equiv \omega z_s \leq 1$, $s = 1, \ldots, r$, so that inequality (3.7) becomes

$$\frac{1}{c}\left[1 - \prod_{j=1}^{r} (1 - cy_j)\right] \leq \left[1 - \prod_{j=1}^{r} (1 - y_j)\right]. \tag{3.10}$$

That (3.10) holds follows by an inductive argument: it holds for $r = 1$ and 2 (for $r = 1$ it becomes an equality). Suppose that it holds for $r - 1$. Then

$$\begin{aligned}
\frac{1}{c}\left[1 - \prod_{j=1}^{r} (1 - cy_j)\right] &= \frac{1}{c}\left[1 - \prod_{j=1}^{r-1} (1 - cy_j)\right](1 - cy_r) + y_r \\
&\leq \left[1 - \prod_{j=1}^{r-1} (1 - y_j)\right](1 - cy_r) + y_r \\
&\leq \left[1 - \prod_{j=1}^{r-1} (1 - y_j)\right](1 - y_r) + y_r \\
&= 1 - \prod_{j=1}^{r} (1 - y_j),
\end{aligned}$$

where the first inequality is based on the induction hypothesis and the second inequality holds from the reliability context in that $1 - e^{\lambda_2 t} z_r > 0$. □

To illustrate an application of Theorems 3.5 and 3.6, consider the following specific example.

Example 3.7. For fixed n and $\mathbf{k}$ let $\boldsymbol{\lambda} = (3, 2, 8)$, $\boldsymbol{\lambda}^* = (5, 2, 6)$. From

$$\boldsymbol{\lambda} \overset{t}{>} \boldsymbol{\lambda}' = (3, 4, 6) \overset{t}{>} \boldsymbol{\lambda}^*,$$

it follows that

$$R_{\mathbf{k},\boldsymbol{\lambda}}(t) \leq R_{\mathbf{k},\boldsymbol{\lambda}'}(t) \leq R_{\mathbf{k},\boldsymbol{\lambda}^*}(t).$$

In the special case that $\mathbf{k}$ is equal to $\mathbf{k}^{(1)} \equiv (n, 0, \ldots, 0)$ or $\mathbf{k}^{(2)} \equiv (1, 1, \ldots, 1)$, it is clear from Figs. 1 and 2 that

$$R_{\mathbf{k}^{(1)},\boldsymbol{\lambda}}(t) \leq R_{\mathbf{k}^{(2)},\boldsymbol{\lambda}}(t) = R_{\mathbf{k}^{(1)},\boldsymbol{\lambda}^*}(t).$$

Thus, in this special case, the effect on the reliability function when $\mathbf{k}$ is changed from $(n, 0, \ldots, 0)$ to $(1, 1, \ldots, 1)$ for fixed $\boldsymbol{\lambda} = (3, 2, 8)$ is identical to that when $\boldsymbol{\lambda}$ is changed from $(3, 2, 8)$ to $(5, 2, 6)$ when $\mathbf{k}$ is fixed to be $(n, 0, \ldots, 0)$.

4. Applications in reliability and shock models. The results of §3 can be used to study a variety of applications, as in the case of optimal allocation of components in a system or network as shown in Fig. 1. In particular, Theorem 3.5 provides a solution for the optimal assembly of systems by choosing an optimal design vector $\mathbf{k}$, and Theorem 3.6 illustrates how a configuration of $\boldsymbol{\lambda}$ (for fixed $\lambda_0 + \lambda_1 + \lambda_2$) affects the performance of a system when $\mathbf{k}$ is given.

The optimal assembly of systems, as shown in the earlier work such as [Derman, Lieberman, and Ross (1974)], extensively involves applications of stochastic inequalities. (For references on recent developments in this area, see [Boland, Proschan, and Tong (1993)].) In the present application we note that if the lifelengths of the components are exponentially distributed, then for a fixed number r of type-B components, the system reliability is maximized when the $\mathbf{k}$ vector is such that $|k_i - k_{i'}| \leq 1$ for all $1 \leq i, i' \leq r$. Furthermore, if r increases and the majorization ordering $\mathbf{k} \succ \mathbf{k}'$ holds, then the system becomes more reliable.

A similar application can be found in the shock model described in Example 2.2. In that application the probability function $\overline{F}_{\mathbf{k},\boldsymbol{\lambda}}(t)$ is maximized when the vector $\mathbf{k} = (n - r + 1, 1, \ldots, 1, 0, \ldots, 0)$ for all fixed $\boldsymbol{\lambda}$, r, and t.

OBSERVABILITY AND OBSERVERS FOR NONLINEAR SYSTEMS*

J. P. GAUTHIER† AND I. A. K. KUPKA‡

Abstract. This paper deals with observability and observers for general nonlinear systems. In the non-control-affine case, we characterize systems that are observable independently of the inputs. An exponential observer for these systems is also exhibited.

Key words. nonlinear systems, observability

AMS subject classifications. 93A99, 93B07, 93B10

1. Introduction.

In this paper, we deal with general, single-output, nonlinear systems:

$$\Sigma \begin{cases} \dot{x} = f_u(x), \\ y = h_u(x), \end{cases}$$

where x belongs to an analytic connected manifold X and the vector fields $f_u(x)$ and the map $h_u(x)$ are analytic with respect to x.

It will be assumed that Σ is smooth with respect to $u \in U$ (an analytic manifold) in a sense that will be made precise in §3.

Our purpose is the following.

(1) We want to characterize those systems Σ that are observable independently of the input ("uniform" observability).

(2) For these systems, we want to construct an exponential observer.

These results have been obtained previously in the case of *control-affine systems*. In this latter case the following facts hold:

(3) There is a local necessary and sufficient condition of "uniform" observability. This local condition leads to a local canonical form for uniform observability.

(4) Assuming that this canonical form is global and assuming some global regularity conditions (some functions have to be globally Lipschitz), an exponential observer is exhibited with arbitrary exponential decay of the error.

Point (3) was dealt with first by Williamson [W] in the case of bilinear systems. It was considered for general control-affine nonlinear systems in [GB], [NI], and [GHO]. Observers for these systems were exhibited in [GHO] and, as stated previously, our aim is to generalize these results to the non-control-affine case, which seems to be much more complicated, as we will see.

Observable nonlinear systems generically have bad inputs [S] (inputs that make them unobservable). However, it seems that in a number of practical cases, systems are observable whatever the input is. These systems are designed to satisfy this property of uniform observability, which is nongeneric.

In other cases where there are sufficiently few bad inputs, our method can be adapted. See [DG] for a very interesting practical case treated in detail.

The observers that we construct have a shortcoming: they are "high-gain" observers (in a sense that will be made clear later). Therefore, they can be very sensitive to noise, though in

a number of cases it appears that they are not. On the other hand, it was recently proved (see [D]) that, for these systems, a version of the extended Kalman filter in a special coordinate system converges. The proof of this last fact is more or less a reformulation of our basic proof [GHO].

The type of methodology we use was also applied in [NTT] and [T] for a class of mechanical systems (rigid robots, namely), leading to different results.

Finally, let us point out that our method, although nongeneric (because of the nongenericity of uniform observability), is more general than other classical approaches, such as linearization or bilinearization by output injection. Basic papers on linearization by output injection are [KI] and [KR]; for bilinearization, see [HG1] and [HG2]. Notice, however, that in this last case, observers can also be obtained for systems with bad inputs.

This paper is organized as follows. In §2, we introduce a new concept of observability called infinitesimal observability, which is slightly different from standard observability and more tractable for our purposes. We study these two concepts and prove some of their properties.

In §3, we give the characterization of those systems that are observable independently of the inputs: It turns out that a certain flag of distributions (related to the system considered for every fixed value of the input) has to be independent of the value of this input on the complement of some subanalytic set of codimension 1.

This generalizes the control-affine case, but is much more difficult to prove. In particular, in the control-affine case, standard observability can be dealt with. In the non-control-affine case, the infinitesimal observability assumption is needed.

A canonical form follows from these considerations, generalizing that of the control-affine case, which appears somewhat special. We use this canonical form to construct a "high-gain" observer in §4. Under some mild additional regularity assumptions, the error can be made to decay at an arbitrary exponential rate. This observer generalizes the observer of the control-affine case, but, again, it is more difficult to prove the arbitrary exponential convergence.

2. Infinitesimal observability. We consider the input-output system of the Introduction:

$$\Sigma \begin{cases} \dfrac{dx}{dt} = f_u(x) = f(u,x), \\ y = h_u(x) = h(u,x), \end{cases} \qquad y \in R,$$

and we assume that f and h are analytic in x and jointly continuous in both u and x.

The output depends directly on the input, which is not very relevant in practice. However, the sake of mathematical generalization is not our primary motive: the reason for assuming this dependence is to make the first step of the proof of our main theorems, Theorems 3.0 and 3.1, similar to that of the following steps. Moreover, the canonical form is much more symmetric. Finally, a very special property appears in the two-dimensional case (see Remark 3.3) if the output does not depend on the input.

Let us recall the concept of input-output mapping of the system Σ. Our space of inputs will be the space $L^\infty[U]$ of all measurable and bounded functions $u : [O, T_u[\to U$ defined on a semi-open interval $[O, T_u[$ (depending on u). Usually the inputs are defined on closed intervals $[O, T_u]$, but this is totally unimportant. We take the domains of our inputs to be semi-open, mainly for the sake of symmetry in our definitions.

The space of our output functions will be the space $L[R]$ of all measurable functions $y : [O, T_y[\to R$ defined on the semi-open intervals $[O, T_y[$.

For any input $\hat{u} \in L^\infty[U]$, $\hat{u} : [0, T\hat{u}[\to U$, and any initial state x_0, the maximal solution

(for positive times) $\hat{x}$ of the Cauchy problem

$$\frac{d\hat{x}}{dt}(t) = f(u(t), \hat{x}(t)), \qquad \hat{x}(0) = x_0$$

is defined on a semi-open interval $[0, e(\hat{u}, x_0)[$, where $0 < e(\hat{u}, x_0) \leq T_{\hat{u}}$. That $e(\hat{u}, x_0)$ can be at most equal to $T_{\hat{u}}$ is obvious. If $e(\hat{u}, x_0) < T_{\hat{u}}$, then $e(\hat{u}, x_0)$ is the positive escape time of x_0. It is characterized by the fact that the function $t \to \hat{x}(t) \in X$ has no accumulation point as t tends to $e(\hat{u}, x_0)$; i.e., no sequence

$$\{\hat{x}(t_n) \mid t_n \in [0, e(\hat{u}, x_0)[,\ n \in N,\ t_n \to e(\hat{u}, x_0) \text{ as } n \to +\infty\}$$

has a limit in X.

Let us now recall the main property of $e(\hat{u}, x_0)$.

LEMMA 2.0. *For any input $\hat{u} \in L^\infty[U]$ the function $x_0 \in X \to e(\hat{u}, x_0) \in \overline{R}_+^*$ is lower semicontinuous ($\overline{R}_+^* = \{a \mid 0 < a \leq \infty\}$).*

Now we can define the input-output mapping of Σ.

DEFINITION 2.0. *The input-output mapping P_Σ is defined by the following*:

$$L^\infty[U] \times X \to L[R], \qquad (\hat{u}, x_0) \to P_\Sigma(\hat{u}, x_0),$$

where $P_\Sigma(\hat{u}, x_0)$ is the function $\hat{y} : [0, e(\hat{u}, x_0)[\to L[R]$ defined by $\hat{y}(t) = h(\hat{u}(t), \hat{x}(t))$, $\hat{x}(t)$ as above.

Remark 2.0. For any $\hat{u} \in L^\infty[U]$, $P_{\Sigma,\hat{u}} : X \to L[R]$ will denote the mapping $x_0 \to P_\Sigma(\hat{u}, x_0)$.

DEFINITION 2.1. *A system is called observable if for any triple*

$$(\hat{u}, x_s, x_r) \in L^\infty[U] \times X \times X, \qquad x_s \neq x_r,$$

the set of all $t \in [0, \min(e(\hat{u}, x_s), e(\hat{u}, x_r))[$ such that $P_\Sigma(\hat{u}, x_s)(t) \neq P_\Sigma(\hat{u}, x_r)(t)$ is not of measure zero.

This means that any input separates any two distinct states. But what we need in this study is an apparently weaker condition: we require that for any input $\hat{u}$, the associated input-output mapping does not map any infinitesimal point (i.e., tangent vector) of X into 0, or in other words, that it distinguishes between any infinitesimal point of X and the associated point of X. To make this precise, we need the concept of the lifting of a system Σ to the tangent-space TX (the infinitesimal point space) of X.

Lifting of a system Σ to TX. The mapping $f : U \times X \to TX$ associated with the parametrized vector field f on X induces the tangent mapping $T_X f : U \times TX \to TTX$ (tangent bundle of TX). This mapping defines a parametrized vector field (also denoted by $T_X f$) on TX, since for any $(u, \xi) \in U \times TX$, $T_X f(u, \xi)$ belongs to $T_\xi TX$. Similarly, the function $h : U \times X \to R$ induces a differential $d_X h : U \times TX \to R$. Now we can define the lifting of Σ to TX.

DEFINITION 2.2. *The lifting $T\Sigma$ of Σ to TX is the input-output system*

$$T\Sigma \begin{cases} \dfrac{d\xi}{dt} = T_X f(u, \xi) = T_X f_u(\xi), \\ \eta = d_X h(u, \xi) = d_X h_u(\xi). \end{cases}$$

The trajectories of Σ and $T\Sigma$ are related as follows: let $\pi : TX \to X$ be the canonical projection of the tangent bundle TX. If

$$\xi : [0, t_\xi[\to TX$$

is a trajectory of $T\Sigma$ associated with the input $\hat{u}$, its projection

$$\pi\xi : [0, t_\xi] \to X$$

is a trajectory of Σ associated with the same input $\hat{u}$. But if we know the trajectories of Σ, we can find those of $T\Sigma$. More precisely, let us, for any $x \in X$ and any input $\hat{u} \in L^\infty[U]$, denote by

$$t \in [0, e(\hat{u}, x)[\to \varphi_t(\hat{u}, x) \in X$$

the maximal trajectory of the system Σ corresponding to the input $\hat{u}$ and starting at x (denoted by $\hat{x}$ before). By Lemma 2.0, for any input $\hat{u} \in L[U]$, any $x \in X$, and any time $\tau, 0 \leq \tau < e(\hat{u}, x)$, there exists an open neighborhood $V_{x,\tau}$ of x in X such that $e(\hat{u}, x') > \tau$ for all $x' \in V_{x,\tau}$, and the mapping

$$x' \in V_{x,\tau} \to \varphi_\tau(\hat{u}, x')$$

is a diffeomorphism.

Let $T_X\varphi_\tau : T_{x'}X \to T_Z X$, $z = \varphi_\tau(\hat{u}, x')$, be the induced tangent mapping. For any input $\hat{u} \in L^\infty[U]$, any $\xi_0 \in TX$, $e(\hat{u}, \xi_0) = e(\hat{u}, \pi(\xi_0))$, and the maximal solution $\hat{\xi} : [0, e(\hat{u}, \xi_0)[\to TX$ of $T\Sigma$ corresponding to the input $\hat{u}$ and starting at ξ_0 is given by

$$\hat{\xi}(t) = T_X\varphi_t(\hat{u}, \xi_0), \qquad 0 \leq t < e(\hat{u}, \pi(\xi_0)). \tag{1}$$

Let $x \in X$ and let $t \in [0, e(\hat{u}, x)[$; then $P_\Sigma(\hat{u}, x)(t) = h(\hat{u}(t), \varphi_t(\hat{u}, x))$.
Let $\xi \in TX$ and $t \in [0, e(\hat{u}, \xi)[$; then

$$P_{T\Sigma}(\hat{u}, \xi)(t) = d_X h(\hat{u}(t), T_X\varphi_t(\hat{u}, \xi)).$$

We also introduce the mappings $\Phi_{\Sigma,\hat{u}} : B(\hat{u}) \to X$ and $\Phi_{T\Sigma,\hat{u}} : BT(\hat{u}) \to TX$ defined by

$$\Phi_{\Sigma,\hat{u}}(x, t) = \varphi_t(\hat{u}, x),$$
$$\Phi_{T\Sigma,\hat{u}}(\xi, t) = T_X\varphi_t(\hat{u}, \pi\xi)\xi,$$

where $B(\hat{u})$ and $BT(\hat{u})$ are the subdomains of $X \times R_+$, $TX \times R_+$, respectively, such that

$$B(\hat{u}) = \{(x, t) \mid x \in X,\ t \in R_+,\ 0 \leq t < e(\hat{u}, x)\},$$
$$BT(\hat{u}) = \{(\xi, t) \mid \xi \in TX,\ t \in R_+,\ 0 \leq t < e(\hat{u}, \xi)\}.$$

Then $\Phi_{\Sigma,\hat{u}}$ is differentiable in the X variables and its tangent mapping $T_X\Phi_{\Sigma,\hat{u}} : BT(\hat{u}) \to TX$ is given by

$$T_X\Phi_{\Sigma,\hat{u}} = \Phi_{T\Sigma,\hat{u}}.$$

Remark 2.1. The considerations above show that for any input $\hat{u} \in L^\infty_{[U]}$ and any state $x \in X$, the restriction of $P_{T\Sigma}$ to $\{\hat{u}\} \times T_x X$ defines a linear mapping

$$P_{T\Sigma,\hat{u},x} : T_x X \to L^\infty_c([0, e(\hat{u}, x)[; R)$$
$$\text{given by } P_{T\Sigma,\hat{u},x}(\xi) = P_{T\Sigma}(\hat{u}, \xi)(t),$$

where $L^\infty_c([0, e(\hat{u}, x)[; R)$ is the space of all equivalence classes of measurable functions $g : [0, e(\hat{u}, x)[\to R$ such that for any $T, 0 < T < e(\hat{u}, x)$, $g_{|[0,T]}$ belongs to L^∞.

Now we can introduce the concept of infinitesimal observability.

DEFINITION 2.3. *A system Σ is called infinitesimally observable at $(\hat{u}, x) \in L^\infty_{[U]} \times X$ if the linear mapping*

$$P_{T\Sigma,\hat{u},x} : T_xX \to L^\infty_c([0, e(\hat{u}, x)[; R), \qquad \xi \in T_xX \to P_{T\Sigma}(\hat{u}, \xi)$$

is injective.

DEFINITION 2.4. *A system Σ is called* infinitesimally observable at $\hat{u} \in L^\infty_{[U]}$ *if it is infinitesimally observable at all pairs $(\hat{u}, x)$, $x \in X$. It is called* uniformly infinitesimally observable *if it is infinitesimally observable at all inputs $\hat{u} \in L^\infty_{[U]}$.*

Remark 2.2. One has for any $\xi \in TX$ and almost any $t \in [0, e(\hat{u}, \xi)[$,

$$P_{T\Sigma}(\hat{u}, \xi)(t) = d_x P^t_{\Sigma,\hat{u}}(\xi), \tag{2}$$

where the right-hand side is the differential $TX \to R$ induced by the function $P^t_{\Sigma,\hat{u}} : V \to R$, and V is the open set

$$\{x \in X \mid 0 < t < e(\hat{u}, x)\} \quad \text{and} \quad P^t_{\Sigma,\hat{u}}(x) = P_\Sigma(\hat{u}, x)(t).$$

In view of the relation (2) above, the fact that a system is *infinitesimally observable* at $\hat{u} \in L^\infty[U]$ means that the mapping $P_{\Sigma,\hat{u}} : X \to L_{[R]}$ is an *immersion* of X into $L_{[R]}$. (As was stated above, $P_{\Sigma,\hat{u}}$ is differentiable in the following sense: we know that $e(\hat{u}, x) \geq e(\hat{u}, x_0) - \varepsilon$ in a neighborhood $U\varepsilon$ of x_0. Then $P_{\Sigma,\hat{u}}$ is differentiable in the classical sense from $U\varepsilon$ into $L^\infty([0, e(\hat{u}, x_0) - \varepsilon[; R)$. $P_{\Sigma,\hat{u}}$ is an immersion in the sense that these differential maps are injective.)

Example 2.0. Consider the (uncontrolled) system on R^2:

$$\begin{aligned} \dot{X}_1 &= X_2, \\ \dot{X}_2 &= 0, \\ Y &= X_1^3. \end{aligned}$$

This system is not infinitesimally observable at $x_0 = 0$, but clearly it is observable on R^2.

Next we shall study the relations between observability and infinitesimal observability.

THEOREM 2.0. (i) *For any system Σ and any input $\hat{u}$, the set $\theta(\hat{u})$ of all states $x \in X$ such that Σ is infinitesimally observable at $(\hat{u}, x)$ is open in X (could be empty, of course).*

(ii) *If Σ is observable for an input $\hat{u}$, then $\theta(\hat{u})$ is everywhere dense in X.*

(iii) *If Σ is infinitesimally observable at $(\hat{u}, x)$, then there exists an open neighborhood V of X such that the restriction $P_{\Sigma,\hat{u}|V}$ is injective.*

Proof. Since the output function h of Σ depends on the inputs, the outputs are measurable functions only and hence are not uniquely defined pointwise. To palliate this difficulty, we define "regularized" outputs. For any input $\hat{u} \in L^\infty_{[U]}$ and any $x \in X$, the restriction of $P_\Sigma(\hat{u}, x)$ to any interval $[0, T]$ is bounded for any T, $0 \leq T < e(\hat{u}, x)$, and hence integrable. So we can define the regularized output by:

$$\overline{P_\Sigma}(\hat{u}, x)(t) = \int_0^t P\Sigma(\hat{u}, x)(s)\, ds \quad \text{for all } t \in [0, e(\hat{u}, x)[.$$

$\overline{P_\Sigma}(\hat{u}, x)(t)$ is an absolutely continuous function. Obviously, we can do the same for the output $P_{T\Sigma}$ of $T\Sigma$ and define for $\hat{u} \in L^\infty_{[U]}$ and $\xi \in TX$:

$$\overline{P}_{T\Sigma}(\hat{u}, \xi)(t) = \int_0^t P_{T\Sigma}(\hat{u}, \xi)(s)\, ds.$$

If we introduce the mappings

$$\overline{P}_{\Sigma,\hat{u}} : \Omega(\hat{u}) = \{(x,t) \in X \times R \,|\, 0 \leq t < e(\hat{u},x)\} \to X,$$
$$\overline{P}_{T\Sigma,\hat{u}} : T\Omega(\hat{u}) = \{(\xi,t) \in TX \times R \,|\, 0 \leq t < e(\hat{u},\xi)\} \to TX,$$

then $\overline{P}_{\Sigma,\hat{u}}$, $\overline{P}_{T\Sigma,\hat{u}}$ are both continuous in x and t, analytic in x, and

$$T_X \overline{P}_{\Sigma,\hat{u}} = \overline{P}_{T\Sigma,\hat{u}}.$$

Let us introduce for every input $\hat{u} \in L^\infty_{[U]}$ the following distribution $D(\hat{u})$: $D(\hat{u})_x = \operatorname{Ker} P_{T\Sigma,\hat{u},x}$, $x \in X$ (for the notation, see Definition 2.3). Then Σ is infinitesimally observable at $(\hat{u},x)$ if and only if $D(\hat{u})_x = 0$.

To be able to handle $D(\hat{u})$ conveniently, we shall give a new definition of $D(\hat{u})$. It is obvious, from the definition of $\overline{P}$, that

$$D(\hat{u})_x = \bigcap_{0 \leq t < e(\hat{u},x)} \operatorname{Ker} \omega(x,t) \quad \text{where } \omega(x,t) : T_xX \to R$$

is the linear form $\xi \in T_xX \to \omega(x,t)\,(\xi) = \overline{P}_{T\Sigma}(\hat{u},\xi)\,(t)$.

Since $\overline{P}_{T\Sigma,\hat{u}}$ is continuous in x and t, so is the form ω. If $D(\hat{u})_x = 0$ at some x, then there exists $d = \dim X$ times $0 < t_1 < t_r < \cdots < t_d < e(\hat{u},x)$ such that the forms $\omega(x,t_i)$, $1 \leq i \leq d$, are linearly independent in T_xX.

Using Lemma 2.0 we can find an open neighborhood W_x of x in X such that for any $z \in W_x$, $e(\hat{u},z) > t_d$ and the forms $\omega(z,t_i)$, $1 \leq i \leq d$, are linearly independent on T_zX. Hence $D(\hat{u})_z \subset \cap_{i=1}^d \operatorname{Ker} \omega(z,t_i) = 0$. This proves (i). To prove (ii) we have to show that if Σ is observable for $\hat{u}$, then any open subset Y of X contains a point such that $D(\hat{u})_x = 0$.

Let $c = \sup\{\operatorname{codim} D(\hat{u})_x \,|\, x \in Y\}$. We have to prove that $c = d = \dim X$. But first we shall prove that the set of all $x \in Y$, such that $\operatorname{codim} D(\hat{u})_x = c$, is open.

In fact, for any such $\overline{x} \in Y$, we can find c times $0 < t_1 < \cdots < t_c < e(\hat{u},\overline{x})$ such that the forms $\omega(\overline{x},t_1),\ldots,\omega(\overline{x},t_c)$ are linearly independent. Then, using Lemma 2.0 and the continuity of $\omega(x,t)$ in x, we can find an open neighborhood W of $\overline{x}$ in Y such that for all $x \in W$, $e(\hat{u},x) > t_c$ and the forms $\omega(x,t_1),\ldots,\omega(x,t_c)$ are linearly independent.

Since for any $x \in W$, $D(\hat{u})_x \subset \cap_{i=1}^c \operatorname{Ker} \omega(z,t_i)$, $\operatorname{codim} D(\hat{u})_x \geq c$, but by the definition of c, $\operatorname{codim} D(\hat{u})_x \leq c$. Hence, $\operatorname{codim} D(\hat{u})_x = c$ for all $x \in W$ and $D(\hat{u}) = \cap_{i=1}^c \operatorname{Ker} \omega(.,t_i)$.

For any $\xi \in TW$, we have that

$$\omega(z_i,t_i)\,(\xi) = \int_0^{t_i} d_X h(\hat{u}(s), T_X\varphi_s(\hat{u},\xi))\,ds;$$

hence $\omega(.,t_i) = d_X F_i$, where $F_i : W \to R$ is the function

$$F_i(x) = \int_0^{t_i} h(\hat{u}(s),\, \varphi_s(\hat{u},x))\,ds = \overline{P}_\Sigma(\hat{u},x)(t_i).$$

This shows that $D(\hat{u})_{|W}$ is an integrable distribution whose leaves are the connected components of the level manifold of the function $(F_1,\ldots,F_c)$.

Now we show that $c = d$. Assume that $c < d$ and take any compact connected set K containing more than one point and contained in a leaf L of $D(\hat{u})_{|W}$. This is possible since $\dim L = d - c > 0$. The infimum of the function $x \in K \to e(\hat{u},x)$ is attained at some point $x_0 \in K$.

For any time T, $0 \leq T < e(\hat{u}, x_0)$, there exists an open connected neighborhood V_T of K in W such that $e(\hat{u}, x) > T$ for all $x \in V_T$.

Since $\omega(.,T)_{|V_T} = d_X F_T$ where $F_T : V_T \to R$ is the function

$$F_T(x) = \int_0^T h(\hat{u}(s), \varphi_s(\hat{u}, x))\, ds$$
$$= \overline{P}_\Sigma(\hat{u}, x)(T),$$

and Ker $\omega(.,T) \supset D(\hat{u})_{|W}$, F_T is constant on any connected component of the intersection $L \cap V_T$, in particular, on the one containing K. Hence F_T is constant on K for all T, $0 \leq T < e(\hat{u}, x_0)$.

Since $F_T(x) = \overline{P}_\Sigma(\hat{u}, x)(T)$, we have that $\overline{P}_\Sigma(\hat{u}, x)(t) = \overline{P}_\Sigma(\hat{u}, x_0)(t)$ for all $x \in K$ and all $t \in [0, e(\hat{u}, x_0)[$.

Differentiating with respect to t, we get $P_\Sigma(\hat{u}, x)(t) = P_\Sigma(\hat{u}, x_0)(t)$ for all $x \in K$ and almost all $t \in [0, e(\hat{u}, x_0)[$. This shows that $\hat{u}$ does not distinguish x_0 and x for any $x \in K$—a contradiction. Hence $c = 0$ and this proves (ii).

(iii) is easy to prove and is left to the reader. □

3. Analytic systems that are observable for any input. In this section, we need additional assumptions about the system. We shall assume that one of the following holds.

Assumption H1. U is a compact connected analytic manifold, possibly with a boundary, and f and h are analytic in x and u.

Assumption H2. U is a vector-space R^p and f and h are analytic in x and u and *polynomial* in u.

We now introduce a flag of distributions.

DEFINITION 3.0. *For each integer* n, $0 \leq n < \dim X = d$, *and for any* $u \in U$, *let us denote by* $D_n(u)$ *the analytic distribution on* X *defined as follows*:

$$D_n(u) = \bigcap_{i=0}^{n} \text{Ker } dh_u^i,$$

where $h_u^i : X \to R$ *is the function* $= \theta(f_u)^i(h_u)$ *and* θ *denotes the Lie derivative.*

It is clear that $D_0(u) \supset D_1(u) \supset \cdots \supset D_{d-1}(u)$. Let M denote the projection on X of the subset

$$\tilde{M} = \{(u, x) \mid dh_u^0(x) \wedge dh_u^1 \wedge \cdots \wedge dh_u^{d-1}(x) = 0\}$$

of $U \times X$. We can now state our main theorem.

THEOREM 3.0. *Assume that* Σ *is uniformly infinitesimally observable and that it satisfies Assumption* H1 (*respectively*, H2). *Then we have the following.*

(i) *The set* M *is a subanalytic* (*respectively, semi-analytic in the case of* H2) *set of codimension at least* 1. *In the case* H1, M *is closed. In any case, denote by* $\overline{M}$ *its closure.*

(ii) *On* $X - \overline{M}$, $D_n(u)$ *has constant rank equal to* $d - n - 1$ *for all* $n, 0 \leq n \leq d - 1$.

(iii) *On* $X - \overline{M}$, $D_n(u)$ *is independent of* $u \in U$ *for* $0 \leq n \leq d - 1$.

First let us make some remarks.

Remark 3.0. Since $\tilde{M}$ is an analytic subset of $U \times X$, it is clear that under Assumption H1 (respectively, H2) its projection M is subanalytic (respectively, semi-analytic). What is not so obvious is that its codimension is at least 1.

Remark 3.1. The points $(u, x) \in U \times X \backslash \tilde{M}$ can be characterized as those $x \in X$ having a neighborhood V_0 in X such that the restriction to V_0 of the functions $h_u^0, h_u^1, \ldots, h_u^{d-1}$ form a system of analytic coordinates on V_0.

It is easy to see that Theorem 3.0 is equivalent to the apparently stronger Theorem 3.1, stated now.

THEOREM 3.1. *Let Σ be uniformly infinitesimally observable and let it satisfy either Assumption* H1 *or* H2. *Then*

(i) *M is a subanalytic (respectively, semi-analytic in the case of* H2) *subset of codimension* 1 *in X;*

(ii) *For any $a \in X - \overline{M}$ and any $v \in U$, there exists an open neighborhood V_a of a, $V_a \subset X - \overline{M}$, such that the functions $x^0 = h_v^0|_{V_a}$, $x^1 = h_v^1|_{V_a}, \dots, x^{d-1} = h_v^{d-1}|_{V_a}$, form a coordinate system on V_a, and on $U \times V_a$, each h^i is a function of u, $x^0, \dots, x^i$ only, $0 \le i \le d-1$:*

$$h^i = H^i(u, x^0, \dots, x^i).$$

COROLLARY. *With the assumptions and notations of Theorem* 3.1, *in the coordinates $(x^0, \dots, x^{d-1})$, the system Σ has the following expression:*

$$\text{(C)} \qquad \begin{aligned} \frac{dx^0}{dt} &= F^0(u, x^0, x^1), \\ &\vdots \\ \frac{dx^i}{dt} &= F^i(u, x^0, x^1, \dots, x^{i+1}), \\ &\vdots \\ \frac{dx^{d-1}}{dt} &= F^{d-1}(u, x^0, x^1, \dots, x^{d-1}), \\ y &= H^0(u, x^0), \end{aligned}$$

and the functions

$$\frac{\partial H^0}{\partial x^0}, \frac{\partial F^i}{\partial x^{i+1}}, \qquad 0 \le i \le d-2$$

are nowhere zero on $U \times Va$.

Proof of Theorem 3.1. We shall prove, by induction on n, the following assertion:

(A_n). Let M_n be the projection on X of the semi-analytic (respectively, analytic, partially algebraic) subset $\tilde{M}_n = \{(u, x) \mid dh_u^0(x) \wedge \cdots \wedge dh_u^n(x) = 0\}$.

Then M_n is a subanalytic (respectively, semi-analytic) subset of X of codimension ≥ 1, and for any $a \in X \backslash \overline{M}_n$ and any $v \in U$, there exists an open neighborhood V of a such that the restriction of h^i to $U \times V$ is a function of u and of the restrictions $h_v^0|_V, \dots, h_v^i|_V$ of $h_v^0, \dots, h_v^i$ to V only, for all i, $0 \le i \le n$ (this last property we shall denote by (P_n)).

It is clear that A_{d-1} implies Theorem 3.1, in fact, since the functions $h_v^0, \dots, h_v^{d-1}$ are independent on V, there exists a, perhaps smaller, neighborhood of a such that $h_v^0, \dots, h_v^{d-1}$ form a system of analytic coordinates on V_a. Also, $M_{d-1} = M$ and $M_{d-1} \supset \cdots \supset M_1 \supset M_0$.

Assume we have proved $A_0, \dots, A_{n-1}$, and let us prove A_n. This will be done in four steps. In order to prove Steps 1, 2, and 4, we construct feedback laws contradicting infinitesimal observability. In Step 1, this feedback is a constant control. In Step 2, it is a general feedback depending on ξ. In Step 4, it only depends on x.

Let Z_n be the set of all $x \in X$ such that $dh_u^0(x) \wedge \cdots \wedge dh_u^n(x) = 0$ for all $u \in U$. Since $Z_n = \cap_{u \in U} Z_n(u)$, where $Z_n(u) = \{x \in X \mid dh_u^0(x) \wedge \cdots \wedge dh_u^n(x) = 0\}$ is an analytic subset of X, it follows that Z_n is also analytic ([NA, Corollary 2, p. 100]).

Step 1. We claim that the codimension of Z_n is at least 1.

Were it otherwise, Z_n would contain an open set ω. Then $\omega - \overline{M_{n-1}}$ is also open and nonempty. Since for any $u \in U$, $dh_u^0(x) \wedge \cdots \wedge dh_u^n(x) = 0$ on $\omega - \overline{M_{n-1}}$, any point $a \in \omega - \overline{M_{n-1}}$ has, for any given $v \in U$, an open neighborhood W in $\omega - \overline{M_{n-1}}$ such that h_v^n is a function of $h_v^0, \ldots, h_v^{n-1}$ in W.

If $\xi : [0, e[\to TW$ is any trajectory of $T\Sigma$ corresponding to the constant control $u(t) = v$, and such that

$$\xi(0) \in T_a X, \quad \xi(0) \neq 0, \quad dh_v^0(\xi(0)) = \cdots = dh_v^{n-1}(\xi(0)) = 0,$$

then $dh_v^0(\xi) = \cdots = dh_v^{n-1}(\xi) = 0$. In fact, $\left(\frac{d}{dt}\right)(dh_v^i(\xi)) = d(\theta(f_v)h_v^i)(\xi) = dh_v^{i+1}(\xi)$ for all i, $0 \leq i \leq n-1$.

Since $dh_v^n(\xi)$ is a linear combination of the $dh_v^0(\xi)$, $dh_v^{n-1}(\xi)$ it follows from the uniqueness part of Cauchy's theorem for linear differential equations that $dh_v^0(\xi) = \cdots = dh_v^{n-1}(\xi) = 0$. Thus Σ is not uniformly infinitesimally observable—a contradiction.

Step 2. On $TU \times T(X - \overline{M_{n-1}})$, $d_x h^0 \wedge \cdots \wedge d_x h^n \wedge d_u d_x h^n = 0$.

Here d_u (respectively, d_x) denotes the differential with respect to u variables (respectively, x variables) only. If $x_1, \ldots, x_d$ is some coordinate system on some open set X' of X, and $u^1, \ldots, u^c$ is a system of coordinates on some open set U' of U, then

$$d_X h^i = \sum_{j=1}^{d} \frac{\partial h^i}{\partial x^j}(u, x)\, dx^j, \qquad d_u d_x h^n = \sum_{k=1}^{c}\sum_{j=1}^{d} \frac{\partial^2}{\partial u^k \partial x^j} h^n\, du^k \wedge dx^j.$$

Assume the assertion of Step 2 is not true. Then there exists a pair $(u_0, \xi_0) \in \operatorname{int}(U) \times T(X - \overline{M_{n-1}})$ such that $d_x h_{u_0}^i(\xi_0) = 0$ for $1 \leq i \leq n$, but $d_u d_x h^n(., \xi_0)$ is not identically zero on $T_{u_0}U$. By the implicit function theorem, there exists an open neighborhood N of ξ_0 in $T(X - \overline{M_{n-1}})$ and an analytic mapping $\overline{u} : N \to U$ such that $d_x h_{\overline{u}(\xi)}^n(\xi) = 0$ for all ξ in N and $\overline{u}(\xi_0) = u_0$. Let $a = \pi(\xi_0)$ be the base of ξ_0. Since $a \in X - \overline{M}_{n-1}$, we can apply assertion A_{n-1} to a and u_0. Call V_a the corresponding neighborhood; restrict both N and V_a so that $\pi(N) \subset V_a$, and so that for any $v \in \overline{u}(N)$ the statement of A_{n-1} applies to $h_v^0, \ldots, h_v^{n-1}$, i.e., h^{n-1} is a function of u and $h_v^0, \ldots, h_v^{n-1}$ only in $U \times V_a$.

Let $\hat{\xi} : [0, e[\to N$ be the solution of the feedback system $\frac{d\xi}{dt} = T_x f(\overline{u}(\xi), \xi)$ such that $\xi(0) = \xi_0$. We claim that $d_x h_{\hat{u}(t)}^i(\hat{\xi}(t)) = 0$ for all $t \in [0, e[$ and all $0 \leq i \leq n-1$, where $\hat{u}(t) = \overline{u}(\hat{\xi}(t))$. In fact,

$$1 \leq i \leq n-2 \begin{cases} \dfrac{d}{dt}\left(d_x h_{\hat{u}(t)}^0(\hat{\xi}(t))\right) = d_x h_{\hat{u}(t)}^1(\hat{\xi}(t)) + d_u d_x h^0\left(\dfrac{d\hat{u}(t)}{dt}, \hat{\xi}(t)\right), \\ \dfrac{d}{dt}\left(d_x h_{\hat{u}(t)}^i(\hat{\xi}(t))\right) = d_x h_{\hat{u}(t)}^{i+1}(\hat{\xi}(t)) + d_u d_x h^i\left(\dfrac{d\hat{u}(t)}{dt}\hat{\xi}(t)\right), \\ \dfrac{d}{dt}\left(d_x h_{\hat{u}(t)}^{n-1}(\hat{\xi}(t))\right) = d_u d_x h^{n-1}\left(\dfrac{d\hat{u}(t)}{dt}, \hat{\xi}(t)\right), \end{cases}$$

since by construction,

$$d_x h_{\overline{u}(\hat{\xi}(t))}^n(\hat{\xi}(t)) = d_x h_{\hat{u}(t)}^n(\hat{\xi}(t)) = 0.$$

By the choice of V_a, each h^i is a function of u and$h_{\hat{u}(t)}^0, \ldots, h_{\hat{u}(t)}^i$ only in $U \times V_a$, and this is true for all t in $[0, e[$. Hence

$$d_u d_x h^i\left(\frac{d\hat{u}(t)}{dt}, \hat{\xi}(t)\right)$$

is a linear combination, for all $1 \leq i \leq n$ and all t, of $d_x h^0_{\hat{u}(t)}(\hat{\xi}(t)), \ldots, d_x h^i_{\hat{u}(t)}(\hat{\xi}(t))$.

By Cauchy's uniqueness theorem applied to the linear system above, we get that $d_x h^i_{\hat{u}(t)}(\hat{\xi}(t)) = 0$ for all t. This violates the fact that Σ is uniformly infinitesimally observable.

Step 3. *Proof of* (P_n). Take any point a in $X\backslash(Zn \cup \overline{M_{n-1}})$. There exists a $v \in \mathrm{Int}(U)$ such that (v, a) is not in $\tilde{M}_n$. We know that $d_x h^0 \wedge \cdots \wedge d_x h^n \wedge d_u d_x h^n = 0$ everywhere on $X\backslash\overline{M_{n-1}}$. Now apply A_{n-1} to a and v. Since (v, a) is not in $\tilde{M}_n$, $d_x h^0_v(a) \wedge \cdots \wedge d_x h^n_v(a) \neq 0$. Restricting the neighborhood V_a given by A_{n-1}, we can assume that the set $\{h^0_v, \ldots, h^n_v\}$ can be extended to a coordinate system in V_a.

Applying Lemma 3.0 below to $Y = U$, $Z = V_a$, $F^i = h^i$, we get that h^n is a function of u and $h^0_v, \ldots, h^n_v$ only in $U \times V_a$.

Step 4. *Proof of the fact that* M_n *has codimension* 1. A and V_a are chosen as in Step 3.

For simplicity let us denote the restrictions $h^0_v|V_a, \ldots, h^n_v|V_a$ by $x^0, \ldots, X^n$. Then $h^i = H^i(u, x^0, \ldots, x^i)$ for $0 \leq i \leq n$ in $U \times V_a$. Then,

$$d_x h^0 \wedge \cdots \wedge d_x h^n = \frac{\partial H^0}{\partial x^0}\frac{\partial H^1}{\partial x^1} \cdots \frac{\partial H^n}{\partial x^n}\, dx^0 \wedge \cdots \wedge dx^n,$$

$$d_x h^0 \wedge \cdots \wedge d_x h^{n-1} = \frac{\partial H^0}{\partial x^0}\frac{\partial H^1}{\partial x^1} \cdots \frac{\partial H^{n-1}}{\partial x^{n-1}}\, dx^0 \wedge \cdots \wedge dx^{n-1}.$$

Since

$$V_a \cap \overline{M_{n-1}} = \emptyset, \qquad \frac{\partial H^0}{\partial x^0}, \ldots, \frac{\partial H^{n-1}}{\partial x^{n-1}}$$

are all everywhere nonzero in $U \times V_a$. Since $\tilde{M}_n = \{(u, x) \in U \times X | dh^0_u(x) \wedge \cdots \wedge dh^n_u(x) = 0\}$, we see that

$$\tilde{M}_n \cap (U \times V_a) = \left\{ (u, x) \in U \times V_a \;\middle|\; \frac{\partial H^n}{\partial x^n}(u, x) = 0 \right\}.$$

What remains to be proved is that M_n has empty interior. If not, M_n would contain an open set θ, and $\theta\backslash(Z_n \cup \overline{M_{n-1}})$ would be a nonempty open set. Take a point $a \in \theta\backslash(Z_n \cup \overline{M_{n-1}})$. Apply the considerations just developed to a and restrict the neighborhood V_a we have constructed to $V_a \cap (\theta\backslash(Z_n \cup \overline{M}_{n-1}))$.

Denote by $P : \tilde{M}_n \cap (U \times V_a) \to V_a$ the restriction of the projection $U \times V_a \to V_a$ to $\tilde{M}_n$. Since P is surjective, Sard's theorem and the implicit function theorem show that there is an open subset W of V_a and an analytic mapping $\overline{u} : W \to U$ such that

$$\frac{\partial H^n}{\partial x^n}(\overline{u}(x), x) = 0 \quad \text{for all } x \in W.$$

The same reasoning as before shows that Σ is not uniformly infinitesimally observable: let $\hat{\xi} : [0, e[\to TW$ be any maximal (for positive times) solution of the feedback system

$$\frac{d\hat{\xi}}{dt} = T_x f(\overline{u}(\pi(\hat{\xi})), \hat{\xi}) \quad \text{in } TW \text{ such that } \hat{\xi}(0) \neq 0$$

but

$$d_x h^i_{\overline{u}(x_0)}(\hat{\xi}(0)) = 0 \quad \text{for } 0 \leq i \leq n-1, \quad x_0 = \pi(\hat{\xi}(0)).$$

As before, we have

$$\frac{d}{dt} d_x h^i_{\hat{u}}(\hat{\xi}) = d_x h^{i+1}_{\hat{u}}(\hat{\xi}) + d_u d_x h^i \left(\frac{d\hat{u}}{dt}, \hat{\xi}\right), \qquad 0 \le i \le n-1,$$

where $\hat{u}(t) = \overline{u}(\pi(\hat{\xi}(t)))$, $\hat{u} : [0, e[\to U$.

Since

$$\frac{\partial H^i}{\partial x^i} \not\equiv 0 \quad \text{in } U \times V_a, \quad 0 \le i \le n-1,$$

$$d_u d_x h^i \left(\frac{d\hat{u}}{dt}, \hat{\xi}\right)$$

is a linear combination of $d_x h^0_{\hat{u}}(\hat{\xi}), \dots, d_x h^i_{\hat{u}}(\hat{\xi})$. Also,

$$d_x h^n_{\hat{u}}(\hat{\xi}) = \sum_{j=0}^{n} \frac{\partial H^n}{\partial x^j}(\hat{u}, \pi(\hat{\xi}))\, dx^j(\hat{\xi}).$$

But

$$\frac{\partial H^n}{\partial x^n}(\hat{u}, \pi(\hat{\xi})) = \frac{\partial H^n}{\partial x^n}(\overline{u}(\pi(\hat{\xi})), \hat{\xi}) = 0.$$

So $d_x h^n_{\hat{u}}(\hat{\xi})$ is again a linear combination of $d_x h^0_{\hat{u}}(\hat{\xi}), \dots, d_x h^{n-1}_{\hat{u}}(\hat{\xi})$. Again, we can apply Cauchy's uniqueness theorem and get a contradiction. Thus M_n and hence $\overline{M_n}$ are of codimension 1, since the interior of M_n is empty. □

Proof of the corollary to Theorem 3.1. Since $V_a \subset X \backslash \overline{M}$, $d_x h^0 \wedge \cdots \wedge d_x h^{d-1} \not\equiv 0$ everywhere on $U \times V_a$, this is equivalent to the derivatives

$$\frac{\partial H^0}{\partial x^0}, \dots, \frac{\partial H^{d-1}}{\partial x^{d-1}}$$

being everywhere nonzero in $U \times V_a$.

But we can compute the components $F^0, \dots, F^{d-2}$ by induction using the formula

$$F^i = \frac{1}{\dfrac{\partial H^i}{\partial x^i}} \left[H^{i+1} - \sum_{j=0}^{i+1} \frac{\partial H^i}{\partial x^j} F^j \right], \qquad 0 \le i \le d-2. \qquad \square$$

Example 3.0. We give an example of an analytic case, with $u \in R$, where the condition

$$\frac{\partial H^0}{\partial x^i} \text{ never vanishes}$$

is false:

$$\Sigma \begin{cases} \dot{x} = 1, & x \in R, \\ y = \dfrac{1}{2}\left(x - \dfrac{\sin(2x(1+u^2)^{\frac{1}{2}})}{2(1+u^2)^{\frac{1}{2}}}\right) + x \sin^2 u = h(u,x), \end{cases}$$

$$\frac{\partial h}{\partial x} = \sin^2 u + \sin^2(x(1+u^2)^{\frac{1}{2}}).$$

Therefore,

$$\frac{\partial h}{\partial x} = 0 \quad \text{iff } u = k\pi \quad \text{and} \quad x(1+u^2)^{\frac{1}{2}} = m\pi.$$

For the set M, we get

$$x = \frac{m\pi}{(1+(k\pi)^2)^{\frac{1}{2}}},$$

which provides a dense set on R. Now, Σ is uniformly infinitesimally observable. $T\Sigma$ takes the form

$$T\Sigma \begin{cases} \dot{x} = 1, \\ \dot{\xi} = 0, \end{cases}$$
$$\eta = [\sin^2 u + \sin^2(x(1+u^2)^{\frac{1}{2}})]\xi.$$

For $\xi(0) \neq 0$, $\eta = 0$ implies

$$u = k\pi, \qquad x(t) = \frac{m\pi}{(1+(k\pi)^2)^{\frac{1}{2}}},$$

which does not define a set invariant by the dynamics $\dot{x} = 1$.

Remark 3.2. The "usual" control-affine case is the following:

$$\Sigma \begin{cases} \dot{x} = f(x) + u\,g(x), \\ y = h(x). \end{cases}$$

This case is linear with respect to u; therefore, it satisfies Assumption H2. The canonical form (C) reduces to

$$\begin{aligned} \dot{x}_1 &= \varphi_1(x_1, x_2) + u\psi_1(x_1, x_2), \\ &\vdots \\ \dot{x}_{n-1} &= \varphi_{n-1}(x) + u\psi_{n-1}(x), \\ \dot{x}_n &= \varphi_n(x) + u\psi_n(x), \\ y &= h(x_1). \end{aligned}$$

$\partial h/\partial x_1$ nonzero means that we can replace the coordinate x_1 by $h(x_1)$. $\partial F^i/\partial x^{i+1}$ nonzero implies

$$\frac{\partial \varphi_i}{\partial x_{i+1}} + u\frac{\partial \psi_i}{\partial x_{i+1}}$$

are nonzero and hence

$$\frac{\partial \psi_i}{\partial x_{i+1}} = 0, \qquad \frac{\partial \varphi_i}{\partial x_{i+1}} \neq 0.$$

Now, by taking the appropriate coordinate change, we get the usual canonical form of [GB], [GHO] in this case:

$$\begin{aligned} \dot{x}_1 &= x_2 + u\widetilde{\psi_1}(x_1), \\ \dot{x}_{d-1} &= x_d + u\widetilde{\psi_{d-1}}(x_1, \ldots, x_{d-1}), \\ \dot{x}_d &= \tilde{\varphi}_d(x) + u\widetilde{\psi_d}(x), \\ y &= x_1. \end{aligned}$$

Remark 3.3. In the "usual" general case, engineers assume that the output function h does not depend on u.

$$\Sigma \begin{cases} \dot{x} = f(u,x), \\ y = h(x), \end{cases}$$

or, near a generic point for h,

$$\Sigma' \begin{cases} \dot{x} = f(u,x), \\ y = x_1. \end{cases}$$

In the two-dimensional case, the canonical form (C) reduces to

$$C' \begin{cases} \dot{x}_1 = f_1(u,x_1,x_2), \\ \dot{x}_2 = f_2(u,x_1,x_2), \\ y = x_1, \end{cases}$$

which implies no additional restriction on Σ'.

The condition $\partial f_1/\partial x_2$ nonzero is open (at least locally). Therefore (at least locally), in the two-dimensional case, there is an *open set* of systems that are observable independently of the input. This is rather unexpected (and it is not the case in the control-affine situation).

Now our theorems (3.0, 3.1) have an obvious converse in the following.

THEOREM 3.2 (converse of Theorems 3.0, 3.1). *Assume that, around some point x_0 of X, the equivalent conditions of Theorems* 3.0 *and* 3.1 *are met. Then there is a neighborhood V_{x_0} of x_0 such that $\Sigma_{|V_{x_0}}$ (Σ restricted to V_{x_0}) is* uniformly infinitesimally observable (*and then also observable in the usual sense, independently of the input*).

Proof. Choose a V_{x_0} such that $\Sigma_{|V_{x_0}}$ has the canonical form (C), with

$$\frac{\partial H^0}{\partial x^0}, \qquad \frac{\partial F^i}{\partial x^{i+1}} \neq 0.$$

Using the expression $T\Sigma_1$ of $T\Sigma$ in local coordinates, we get

$$\left\{ \begin{array}{c} \begin{bmatrix} \dot{\xi}_1 \\ \dot{\xi}_2 \\ \vdots \\ \dot{\xi}_{d-1} \\ \dot{\xi}_d \end{bmatrix} = \begin{bmatrix} d_x\varphi_1(u,x_1,x_2) \\ d_x\varphi_2(u,x_1,x_2,x_3) \\ \vdots \\ d_x\varphi_{d-1}(u,x) \\ d_x\varphi_d(u,x) \end{bmatrix} \begin{bmatrix} \xi_1 \\ \vdots \\ \xi_d \end{bmatrix}, \\ \eta = d_x\varphi_0(u,x_1)\xi_1. \end{array} \right\}$$

Since

$$\frac{\partial \varphi_0}{\partial x_1} \neq 0,$$

$\eta(t) = 0$ implies $\xi_1(t) = 0$, $\dot{\xi}_1(t) = 0$, which implies

$$0 = \frac{\partial \varphi_1}{\partial x_2}\,\xi_2(t),$$

and $\xi_2(t)$ is zero because

$$\frac{\partial \varphi_1}{\partial x_2} \neq 0.$$

By induction, $\xi(t) = 0$ and $\Sigma_{|V_{x_0}}$ is uniformly infinitesimally observable. □

LEMMA 3.0. *Let Y, Z be two connected analytic manifolds and let $f^0, \dots, f^n : Y \times Z \to R$ be $n+1$ analytic functions such that*

(i) $d_Z f^0 \wedge \cdots \wedge d_Z f^n \wedge d_Y d_Z f^n = 0$ *on* $Y \times Z$.

(ii) *There exists $y_0 \in Y$ such that : $f^0_{y_0}, \dots, f^n_{y_0} : Z \to R$ can be extended to a global coordinate system on Z.*

(iii) *There exists an analytic function $h_i : Y \times \theta_i \to R$, θ_i open in R^n, $0 \le i \le n-1$, such that*

$$f^i(y,z) = h^i(y, f^0_{y_0}, \dots, f^{n-1}_{y_0}(z)) \quad \textit{for all } (y,z) \in Y \times Z.$$

Then there exists a function $h^n : Y \times \theta_n \to R, \theta_n \subset R^{n+1}$ such that for all $(y,z) \in Y \times Z$,

$$f^n(y,z) = h^n(y, f^0_{y_0}(z), \dots, f^n_{y_0}(z)).$$

Proof. Let $x^0, \dots, x^d : Z \to R$ be a global analytic coordinate system on Z such that $x^i = f^i_{y_0}$, $0 \le i \le n$.

Then for any relatively compact $Z' \subset Z$, there exists an open neighborhood Y_0 of y_0 in Y such that for any $y \in Y_0$, $f^0_y, \dots, f^n_y, x^{n+1}, \dots, x^d : Z' \to R$ form a global coordinate system on Z'. By restricting Y_0, we can assume that it carries a coordinate system $\tilde{y} = y^1, \dots, y^m : Y_0 \to R$ such that $\tilde{y}(Y_0) \subset R^m$ is convex and $\tilde{y}(y_0) = 0$.

Then $d_Z f^0 \wedge \cdots \wedge d_Z f^n \wedge d_Y d_Z f^n = 0$ on $Y \times Z$ implies that

$$d_Z f^0 \wedge \cdots \wedge d_Z f^n \wedge d_Z \left(\frac{\partial f^n}{\partial y^i} \right) = 0 \quad \text{on } Y_0 \times Z \quad \text{for all } 1 \le i \le m.$$

This in turn implies that

$$d_Z \left(\frac{\partial f^n}{\partial y^i} \right) = \sum_{j=0}^{n} A^n_{i,j}\, d_Z f^j_y \quad \text{on } Z' \quad \text{for all } y \in Y_0,$$

where $A^n_{i,j}$ are analytic functions on $Y_0 \times Z'$.

So, there are analytic functions

$$\tilde{h}^n_k : Y_0 \times \tilde{\theta} \to R, \quad \tilde{\theta} \subset R^{n+1} \quad \text{open}, \ 1 \le k \le m,$$

such that for all $(y,z) \in Y_0 \times Z'$ and all k, $1 \le k \le m$,

$$\frac{\partial f^n}{\partial y^k}(y,z) = \tilde{h}^n_k(y, f^0_y(z), \dots, f^{n-1}_y(z),\ f^n_y(z)).$$

Using assumption (iii) there are analytic functions $h^n_k : Y_0 \times \theta \to R$, $1 \le k \le m$, θ open $\subset R^{n+1}$ such that

$$\frac{\partial f^n}{\partial y^k}(y,z) = h^n_k(y, f^0_{y0}(z), \dots, f^{n-1}_{y0}(z),\ f^n_y(z))$$

or

$$\frac{\partial f^n}{\partial y^k}(y,z) = h^n_k(y, x^0(z), \dots, x^{n-1}(z),\ f^n_y(z))$$

for all $(y,z) \in Y_0 \times Z'$ and all k, $1 \le k \le m$.

But for all $t \in [0, 1]$ and all $(y, z) \in Y_0 \times Z'$ we have

$$f^n(ty, z) = \int_0^t \sum_{k=1}^{m} \frac{\partial f^n}{\partial y^k}(sy, z) y^k \, ds + f^n(y_0, z),$$

where ty is the point with coordinates $ty^1(y), \ldots, ty^m(y)$, which yields

$$\text{(E)} \qquad \begin{aligned} f^n(ty, z) \; &= \int_0^t \sum_{k=1}^{m} h_k^n(sy, x^0(z), \ldots, x^{n-1}(z),\ f^n(sy, z)) y^k \, ds \\ &\quad + f^n(y_0, z). \end{aligned}$$

Now there exists a neighborhood $Y_0' \subset Y_0$ of y_0 such that the equation (E) has a unique solution (given $f^n(y^0, z)$) defined on $Y_0' \times Z'$ and for all $t \in [0, 1]$. This solution is an analytic function of t, $x_0, \ldots, x_{n-1}, f^n_{Y_0'}$. Hence, if we take $t = 1$, we obtain

$$f^n(y, z) = H^n(y, x^0(z), \ldots, x^{n-1}(z), f^n_{y_0}) \quad \text{on } Y_0' \times Z'$$

or

$$f^n_y = H^n(y, x^0, \ldots, x^n) \quad \text{on } Y_0' \times Z'.$$

But since $x^0, \ldots, x^d : Z \to R$ is a global coordinate system on Z, we have $f^n = G(y, x^0, \ldots, x^d)$ on $Y \times Z$. But on the open subset $Y_0' \times Z'$,

$$\frac{\partial G}{\partial x^j} = \frac{\partial H^n}{\partial x^j} = 0 \quad \text{if } n + 1 \le j \le d.$$

Hence, $\partial G / \partial x^j = 0$ everywhere and $f^n = G(y, x^0, \ldots, x^n)$. □

4. An observer with arbitrary exponential decay for systems that are uniformly infinitesimally observable. As was stated in the Introduction, the observer will be a generalization of the "high-gain" observer that we used in the control-affine case ([GHO]; see also [D], [DG], and [GHK]).

To prove our theorem, we need a technical lemma, which is based upon the same idea as a result in [DA] for stabilization purposes.

LEMMA 4.0. *Consider the time-dependent real matrices $A(t)$ and $C(t)$:*

$$A(t) = \begin{bmatrix} 0 & \varphi_2(t) & 0 & \cdots & \cdots & 0 \\ 0 & 0 & \varphi_3(t) & 0 & \cdots & 0 \\ 0 & \cdots & \cdots & \cdots & 0 & \varphi_d(t) \\ 0 & \cdots & \cdots & \cdots & \cdots & 0 \end{bmatrix},$$

$$C(t) = [\varphi_1(t), 0, \ldots, 0],$$

with $\varphi_1(t)$ such that $0 < \alpha \le \varphi_1(t) \le \beta < \infty$; $i = 1, \ldots, d$.

Then there is a $\lambda > 0$ and there is a vector $\overline{K} \in R^d$ and a symmetric, positive definite $d \times d$ matrix S, depending on α, β only such that

$$(A(t) - \overline{K}\, C)' S + S(A(t) - \overline{K} C) \le -\lambda Id$$

(in which $(A(t) - \overline{K}C)'$ means the transpose of $(A(t) - \overline{K}C)$).

Proof. The proof is an induction on the dimension. For $d = 1$, we consider the quadratic form $S(x_1, x_2)$,

$$S(x, x) = \frac{x^2}{2}.$$

Then $S(x, (A - \overline{K}C)x) = -k\,\varphi_1(t)(x^2/2)$ with a sufficiently large k does the job.

Step d. We look for $\overline{K} = (k, K)$, $k \in R$, $K \in R^{d-1}$ in

$$\left[A(t) - \begin{pmatrix} k \\ K \end{pmatrix} C(t)\right] x = \begin{bmatrix} -k\varphi_1 & C_1(t) \\ -K\varphi_1 & A_1(t) \end{bmatrix} \begin{pmatrix} x_1 \\ x_2 \end{pmatrix}, \qquad \begin{matrix} x_1 \in R, \\ x_2 \in R^{d-1}, \end{matrix} \tag{3}$$

with $C_1(t) = (\varphi_2(t), 0, \ldots, 0)$ and

$$A_1 = \begin{bmatrix} 0 & \varphi_3 & 0 \cdots & 0 \\ \cdot & \cdot & \cdot & \cdot \\ 0 & \cdots & 0 & \varphi_d \\ 0 & \cdots & \cdots & 0 \end{bmatrix}.$$

First we make the following coordinates change:

$$Z_1 = x_{1'}, \qquad Z_2 = x_2 + \Omega x_1.$$

The matrix in (3) becomes

$$\begin{bmatrix} -k\varphi_1 - C_1\Omega & C_1 \\ (-K - \Omega k)\varphi_1 - (A_1 + \Omega C_1)\Omega & (A_1 + \Omega C_1) \end{bmatrix} = B(t). \tag{4}$$

By the induction hypothesis relative to α, β, there is a λ, an Ω, and a quadratic Lyapunov function $Z_2' S_{n-1} Z_2$ such that

$$-(A_1 + \Omega C_1)\, S_{n-1} - S_{n-1}\,(A_1 + \Omega C_1) \leq -\lambda Id.$$

We will look for S_n of the form

$$\begin{bmatrix} \frac{1}{2} & 0 \\ 0 & S_{n-1} \end{bmatrix}.$$

Setting $V(Z, Y) = Z' S_n Y$, we get

$$\begin{aligned} 2V(z, B(t)z) &= (-k\varphi_1 - C_1\Omega)z_1^2 + C_1 z_2 z_1 + 2z_2' S_{n-1}(A_1 + \Omega C_1)z_2 \\ &\quad + 2z_2' S_{n-1}[(-K - \Omega k)\,\varphi_1 - (\Omega C_1 + A_1)\Omega]z_1, \\ 2V(z, B(t)z) &\leq (-k\varphi_1 - C_1\Omega)z_1^2 - \lambda\|z_2\|^2 \\ &\quad + (\varphi_2 + 2\|S_{n-1}\|\|(K + \Omega k)\varphi_1 + (A_1 + \Omega C_1)\Omega\|)|z_1|\|z_2\|. \end{aligned}$$

Ω and k being given, K is chosen such that $(K + \Omega k) = 0$. On the other hand,

$$|z_1|\|z_2\| = |z_1/\varepsilon|\|\varepsilon z_2\| \leq \frac{1}{2}\left(\varepsilon^2\|z_2\|^2 + \frac{1}{\varepsilon^2}|z_1|^2\right).$$

Hence

$$2V(z, B(t)z) \leq \left((-k\varphi_1 - C_1\Omega) + \delta(t)\frac{1}{2\varepsilon^2}\right)|z_1|^2 + \left(-\lambda + \delta(t)\frac{\varepsilon^2}{2}\right)\|z_2\|^2,$$

where $\delta(t) = \varphi_2 + 2\|S_{n-1}\|\|(A_1 + \Omega C_1)\Omega\|$.

Since $\delta(t)$ is bounded from above, ε can be chosen small enough for $(-\lambda + \delta(t)(\varepsilon^2/2)) < -\frac{\lambda}{2}$.

Since φ_1 is bounded from below, k can be chosen large enough for

$$-k\varphi_1 - C_1\Omega + \delta(t)\frac{1}{2\varepsilon^2} < -\frac{\lambda}{2}.$$

Hence, $2V(z, B(t)z) \leq -\frac{\lambda}{2}\|z\|^2$.

Setting

$$\theta = \begin{bmatrix} 1 & 0 \\ \Omega & I \end{bmatrix},$$

we have $z = \theta x$, $2x'\theta' S_n B(t)\theta x \leq -\frac{\lambda}{2}x'\theta'\theta x$. Hence with $\tilde{s}_n = \theta' Sn\theta$, $2x'\tilde{s}_n[A - \binom{k}{K}C]x \leq -\frac{\lambda}{2}x'\theta'\theta x$, we obtain

$$2\,x'\tilde{s}_n\left[A(t) - \binom{k}{K}C(t)\right]x \leq -\frac{\lambda}{2}\gamma\|x\|^2$$

for some $\gamma > 0$, which gives the result. □

Now, to exhibit the observer, we need a number of additional technical assumptions.

We will assume

—A1. $X = R^d$ and the canonical form (C) given by Theorems 3.0 and 3.1 is global, i.e., Σ can be globally written on R^d in the form (C).

—A2. Each of the maps

$$\frac{\partial F^i}{\partial x^{i+1}}, \qquad 0 \leq i \leq d-2,$$

is globally Lipschitz with respect to $\underline{x^i}$ uniformly with respect to u and x^{i+1} (denoting $\underline{x^i} = (x^0, \ldots, x^i)$) in (C).

—A3. There exists α, β real, $0 < \alpha < \beta$, such that

$$\alpha \leq \left|\frac{\partial H^0}{\partial x^0}\right|, \quad \left|\frac{\partial F^i}{\partial x^{i+1}}\right| \leq \beta, \quad 0 \leq i \leq d-2 \quad \text{everywhere.}$$

We can assume, in fact, after making an obvious change of coordinates (if necessary), that

$$\alpha \leq \frac{\partial H^0}{\partial x^0}, \frac{\partial F^i}{\partial x^{i+1}} \leq \beta, \qquad 0 \leq i \leq d-2.$$

These assumptions are very strong. However,

—If Σ is uniformly infinitesimally observable, then it can be put locally under the form (C) (by Theorems 3.0 and 3.1). Assume that it is under the form (C) on some sufficiently regular bounded subset B of R^d (a ball, for instance). Then the functions H^0, F^i can be C^k extended to all of R^d in such a way that these assumptions are met.

—In a number of practical cases, they are satisfied. (See [DG] for a nice case and [GHO] for another one. Potential applications to mechanical systems can be obtained from [T] and [NTT].)

Under these assumptions, with the system being rewritten as

$$(\Sigma) \qquad \left.\begin{aligned} \dot{x}_1 &= \varphi_1(u, x_1, x_2) \\ &\vdots \\ \dot{x}_d &= \varphi_d(u, x) \\ y &= \varphi_0(u, x_1) \end{aligned}\right\} = F(u, x),$$

a candidate observer system is (as in [GHO]) just the "high-gain extended Luenberger observer":

$$(\mathrm{O}) \qquad \dot{\hat{x}} = F(u, \hat{x}) - K_\theta(\varphi_0(u, \hat{x}) - y(t)),$$

in which $K_\theta = \Delta_\theta K$, $\Delta_\theta = \mathrm{diag}(\theta, \theta^2, \ldots, \theta^d)$ for some $\theta > 0$ and K, together with S, come from Lemma 4.0, relative to α, β in Assumption A3 above.

We have the following theorem.

THEOREM 4.0. *Assume A_1, A_2, and A_3. Then* (O) *is an exponential observer for* (Σ) *in the sense that*

$$\|\hat{x}(t) - x(t)\| \leq ke^{-at}\|\hat{x}(0) - x(0)\|, \qquad t \geq 0,$$

for every initial condition $\hat{x}(0)$, $x(0)$. Moreover, θ can be chosen large enough for a to be arbitrary.

Proof. Setting $\varepsilon = \hat{x} - x$, we get

$$(5) \qquad \dot{\varepsilon} = F(u, \hat{x}) - F(u, x) - K_\theta(\varphi_0(u, \hat{x}) - y(t)).$$

Consider a trajectory solution of the equations (Σ), (O): $x(t)$, $\hat{x}(t)$, $\varepsilon(t)$, $u(t)$. We have, for $1 \leq i \leq d$ and at each time t, denoting $(x_1, \ldots, x_i, 0, \ldots, 0)$ by $\underline{x^i}$:

$$\begin{aligned} \varphi_i(u, \hat{x}) - \varphi_i(u, x) &= \varphi_i(u, \underline{\hat{x}^i}, \hat{x}_{i+1}) - \varphi_i(u, \underline{x^i}, x_{i+1}) \\ &= \varphi_i(u(t), \underline{\hat{x}^i}(t), \hat{x}_{i+1}(t)) - \varphi_i(u, \underline{x^i}(t), \hat{x}_{i+1}(t)) \\ &\quad + \varphi_i(u, \underline{x^i}(t), \hat{x}_{i+1}(t)) - \varphi_i(u, \underline{x^i}(t), x_{i+1}(t)) \\ &= \varphi_i(u, \underline{\hat{x}^i}, \hat{x}_{i+1}) - \varphi_i(u, \underline{x^i}, \hat{x}_{i+1}) \\ &\quad + \frac{\partial \varphi_i}{\partial x_{i+1}}(u(t), \underline{x^i}(t), \delta_i(t))\varepsilon_{i+1}(t) \end{aligned}$$

for some $\delta_i(t)$.

We set

$$g_{i+1}(t) = \frac{\partial \varphi_i}{\partial x_{i+1}}(u(t), \underline{x^i}(t), \delta_i(t))$$

to obtain

$$\dot{\varepsilon}_i = \varphi_i(u, \underline{\hat{x}^i}, \hat{x}_{i+1}) - \varphi_i(u, \underline{x^i}, \hat{x}_{i+1}) + g_{i+1}(t)\varepsilon_{i+1}(t) - (K_\theta)_i \quad g_1(t)\varepsilon_1,$$

where

$$g_1(t) = \frac{\partial \varphi_0}{\partial x_1}(u(t), \delta_0(t)).$$

This yields

$$\dot{\varepsilon} = (A(t) - K_\theta C(t))\varepsilon + \overline{F}. \tag{6}$$

With $C(t) = (g_1(t), 0, \ldots, 0)$,

$$A(t) = \begin{bmatrix} 0 & g_2(t) & 0, \ldots, & 0 \\ 0 & 0 & g_3(t) & 0, \ldots, 0 \\ \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot \\ 0 & \cdot & \cdot & g_d(t) \\ 0 & \cdot & \cdot & 0 \end{bmatrix}$$

and

$$\overline{F} = \begin{pmatrix} \vdots \\ \varphi_i(u, \underline{\hat{x}}^i, \hat{x}_{i+1}) - \varphi_i(u, \underline{x}^i, \hat{x}_{i+1}) \\ \vdots \end{pmatrix}.$$

Because the φ_i are Lipschitz with respect to $\underline{x_i}$, by Assumption A2, the end of the proof is as in [GHO] for the control-affine case: Set

$$x^0 = \Delta_\theta^{-1} x, \quad \hat{x}^0 = \Delta_\theta^{-1}\hat{x}, \quad \varepsilon^0 = \Delta_\theta^{-1}\varepsilon,$$
$$\dot{\varepsilon}^0 = \Delta_\theta^{-1}\dot{\varepsilon} = \Delta_\theta^{-1}(A(t) - K_\theta C(t))\Delta_\theta \varepsilon^0 + \Delta_\theta^{-1}\overline{F}.$$

Otherwise,

$$\Delta_\theta^{-1}\overline{F} = \Delta_\theta^{-1} \begin{pmatrix} \vdots \\ \varphi_i(u, \Delta_\theta \underline{\hat{x}^{i,0}}, \hat{x}_{i+1}) - \varphi_i(u, \Delta_\theta \underline{x^{i,0}}, \hat{x}_{i+1}) \\ \vdots \end{pmatrix}.$$

The main fact is that $\|\Delta_\theta^{-1}\overline{F}\| \le L\|\varepsilon^0\|$, where $L/\sqrt{d}$ is the Lipschitz constant of the φ_i' s with respect to $\underline{x_i}$, as is easily verified. Hence

$$\begin{aligned} \frac{1}{2}\frac{d}{dt}(\varepsilon^{0\prime} S \varepsilon^0) = \varepsilon^{0\prime} S \dot{\varepsilon}^0 &= \varepsilon^{0\prime} S \Delta_\theta^{-1}(A(t) - K_\theta C(t))\Delta_\theta \varepsilon^0 + \varepsilon^{0\prime} S \Delta_\theta^{-1}\overline{F} \\ &\le \theta\, \varepsilon^{0\prime} S(A(t) - KC(t))\varepsilon^0 + L\|S\|\|\varepsilon^0\|^2 \\ &\le \left(-\theta\frac{\lambda}{2} + L\|S\|\right)\|\varepsilon^0\|^2. \end{aligned}$$

Hence, for θ sufficiently large, $\gamma > 0$ being arbitrary, we get

$$\frac{d}{dt}(\varepsilon^{0\prime} S \varepsilon^0) \le -\|S\|\|\varepsilon^0\|^2 \le -\gamma\, \varepsilon^{0\prime} S \varepsilon^0,$$

which yields $\varepsilon^{0\prime} S \varepsilon^0 \le \varepsilon^{0\prime} S \varepsilon^0 e^{-\gamma t}$. □

Acknowledgment. We thank Prof. W. Respondek for several very interesting discussions on the subject. We especially thank him for pointing out an unpublished result by W. Dayawansa that gave the idea for the proof of Lemma 4.0. We thank Prof. Dayawansa for allowing us to communicate this result.

DECOMPOSITION AND PARAMETRIZATION OF SEMIDEFINITE SOLUTIONS OF THE CONTINUOUS-TIME ALGEBRAIC RICCATI EQUATION*

HARALD K. WIMMER†

Abstract. Negative-semidefinite solutions of the ARE $\mathcal{R}(X) = A^*X + XA + XBB^*X - C^*C = 0$ are studied. With respect to an appropriate basis the ARE breaks up into a Lyapunov equation $A_0^*X_0 + X_0A_0 = 0$, where A_0 has only purely imaginary eigenvalues, and an indecomposable Riccati equation $\mathcal{R}_r(X_r) = A_r^*X_r + X_rA_r + X_rB_rB_r^*X_r - C_r^*C_r = 0$ such that each solution $X \leq 0$ is of the form $X = \operatorname{diag}(X_0, X_r)$. The focus is on the solutions $\mathcal{S} = \{X \mid X = \operatorname{diag}(0, X_r), \mathcal{R}_r(X_r) = 0, X_r \leq 0\}$. The set $\mathcal{S}$ has as an order-isomorphic image a well-defined set $\mathcal{N}$ of A-invariant subspaces. The characterization of $\mathcal{N}$ involves the stabilizable and the uncontrollable subspace of (A, B, C).

Key words. algebraic Riccati equation, semidefinite solutions, parametrization by invariant subspaces

AMS subject classifications. 15A24, 93C45

1. Introduction.

We consider the algebraic Riccati equation (ARE)

$$\mathcal{R}(X) = A^*X + XA + XBB^*X - C^*C = 0, \tag{1.1}$$

where A, B, C are complex matrices of sizes $n \times n, n \times p, q \times n$, respectively. It is the purpose of this paper to give a complete description of the set

$$\mathcal{T} = \{X \mid \mathcal{R}(X) = 0, X \leq 0\}$$

of negative-semidefinite solutions of (1.1).

The following notation will be used. In the partitions

$$\mathbb{C} = \mathbb{C}_{\leq} \cup \mathbb{C}_{>} = C_{<} \cup \mathbb{C}_{=} \cup \mathbb{C}_{>}, \tag{1.2}$$

the subscripts refer to real parts such that $\mathbb{C}_{\leq} = \{\lambda \mid \lambda \in \mathbb{C}, \operatorname{Re} \lambda \leq 0\}$, etc. Put

$$E_\lambda(A) = \operatorname{Ker}(A - \lambda I)^n.$$

To (1.2) correspond the decompositions $\mathbb{C}^n = E_{\leq}(A) \oplus E_{>}(A)$ and

$$\mathbb{C}^n = E_{<}(A) \oplus E_{=}(A) \oplus E_{>}(A), \tag{1.3}$$

where $E_{\leq}(A) = \oplus\{E_\lambda(A), \lambda \in \mathbb{C}_{\leq}\}$, etc. With our choice of notation we also have in mind its use for the discrete-time algebraic Riccati equation [14] where the subscripts refer to $|\lambda| \leq 1$, etc. Let $\operatorname{Inv} A$ denote the lattice of A-invariant subspaces of $\mathbb{C}^n$. To the triple (A, B, C) we associate the controllable subspace

$$R(A, B) = \operatorname{Im}(B, AB, \ldots, A^{n-1}B)$$

and the unobservable subspace

$$V(A, C) = \operatorname{Ker} \begin{pmatrix} C \\ CA \\ \vdots \\ CA^{n-1} \end{pmatrix}.$$

† Mathematisches Institut, Universität Würzburg, D-8700 Würzburg, Germany.

It will be convenient to define

$$V_{\leq}(A,C) = V(A,C) \cap E_{\leq}(A),$$

and similarly $V_{=}(A,C), V_{<}(A,C)$, etc. Let

$$\sigma(A - sI, B) = \{\lambda \mid \lambda \in \mathbb{C},\ \operatorname{rank}(A - \lambda I, B) < n\}$$

denote the set of uncontrollable eigenvalues of A, and similarly define

$$\sigma\begin{pmatrix} A - sI \\ C \end{pmatrix} = \left\{\lambda \mid \lambda \in \mathbb{C},\ \operatorname{rank}\begin{pmatrix} A - sI \\ C \end{pmatrix} < n\right\}.$$

Then $V_{=}(A,C) = 0$ if and only if

$$\sigma\begin{pmatrix} A - sI \\ C \end{pmatrix} \cap \mathbb{C}_{=} = \emptyset.$$

Note that $R(A,B) + E_{<}(A) = \mathbb{C}^n$ or equivalently $\sigma(A - sI, B) \cap \mathbb{C}_{\geq} = \emptyset$ means that (A,B) is stabilizable.

We know from [5], [7] that $\mathcal{T} \neq \emptyset$ is equivalent to

$$V(A,C) + R(A,B) + E_{<}(A) = \mathbb{C}^n. \tag{1.4}$$

If we write (1.4) as

$$V_{=}(A,C) + V_{>}(A,C) + R(A,B) + E_{<}(A) = \mathbb{C}^n$$

and put

$$U_r = V_{>}(A,C) + R(A,B) + E_{<}(A), \tag{1.5}$$

then (1.4) holds if and only if there exists a subspace U_0 such that $\mathbb{C}^n = U_0 \oplus U_r$ and $U_0 \subseteq V_{=}(A,C)$.

DEFINITION 1.1. *We call* $\mathbb{C}^n = U_0 \oplus U_r$ *an LR*-decomposition *of* $\mathbb{C}^n$ *if* $U_0 \subseteq V_{=}(A,C)$. *The subspace* U_r *is the* Riccati component *and* U_0 *is a* Lyapunov complement.

The following decomposition theorem is the main tool for our investigation. It will be proved in §3.

THEOREM 1.2. *Let* $\mathbb{C}^n = U_0 \oplus U_r$ *be an LR-decomposition. Assume*

$$U_0 = \left\{\begin{pmatrix} x_0 \\ 0 \end{pmatrix}\right\} \quad \textit{and} \quad U_r = \left\{\begin{pmatrix} 0 \\ x_r \end{pmatrix}, x_r \in \mathbb{C}^{n_r}\right\}. \tag{1.6}$$

Then

$$A = \begin{pmatrix} A_0 & 0 \\ A_{r0} & A_r \end{pmatrix}, \qquad B = \begin{pmatrix} 0 \\ B_r \end{pmatrix}, \qquad C = (0, C_r), \tag{1.7}$$

and

$$\sigma(A_0) \subseteq \mathbb{C}_{=}, \tag{1.8}$$

and

$$V_{>}(A_r, C_r) + R(A_r, B_r) + E_{<}(A_r) = \mathbb{C}^{n_r}. \tag{1.9}$$

We have $X \in \mathcal{T}$ if and only if

$$X = \operatorname{diag}(X_0, X_r) \tag{1.10}$$

and X_0 and X_r satisfy

$$\mathcal{L}_0(X_0) = A_0^* X_0 + X_0 A_0 = 0, \qquad X_0 \leq 0 \tag{1.11}$$

and

$$\mathcal{R}_r(X_r) = A_r^* X_r + X_r A_r + X_r B_r B_r^* X_r - C_r^* C_r = 0, \qquad X_r \leq 0. \tag{1.12}$$

Since (1.11) has the trivial solution $X_0 = 0$, we can associate to each $X = \operatorname{diag}(X_0, X_r) \in \mathcal{T}$ a solution $\rho X \in \mathcal{T}$ given by $\rho X = \operatorname{diag}(0, X_r)$. The basis-free definition of ρ in the theorem below will be proved in §3.

THEOREM 1.3. *Let $\mathbb{C}^n = U_0 \oplus U_r$ be an LR-decomposition and let Π be the projection on U_r along U_0. Then we have*

$$(I - \Pi)^* X \Pi = 0 \tag{1.13}$$

for $X \in \mathcal{T}$. The map $\rho : \mathcal{T} \to \mathcal{T}$ defined by $\rho X = X\Pi$ is independent of the Lyapunov complement U_0.

Put $\mathcal{S} = \rho\mathcal{T}$. The partially ordered set $\mathcal{S}$—or rather an order-isomorphic image $\mathcal{N}$ of $\mathcal{S}$—will become the main object of our study. Define

$$\mathcal{N} = \{N \mid N \in \operatorname{Inv} A, V_{\leq}(A, C) \subseteq N \subseteq V(A, C), N + R(A, B) + E_{<}(A) = \mathbb{C}^n\}.$$

In §4 we adopt a point of view of [3] and [12] and focus on the kernels of solutions to obtain a parametrization of $\mathcal{S}$. The following result will be proved.

THEOREM 1.4. *The map $\gamma : \mathcal{S} \to \mathcal{N}$ given by $\gamma X = \operatorname{Ker} X$ is a bijection, and γ and γ^{-1} are order preserving.*

The remaining part of the paper contains applications of the preceding theorems. Section 5 deals with the existence of negative-definite solutions and §6 with solutions X where the spectrum of the associated closed-loop matrix $A + BB^*$ lies in a prescribed set Λ such that $\mathbb{C}_{\leq} \subseteq \Lambda$. Most of what has been known about semidefinite solutions of (1.1) can be found in the survey article [9] of Kučera and in Ando's monograph [1]. In addition we refer to [6], [7], and [12].

2. Auxiliary results. Put $A_X = A + BB^* X$. Then (1.1) can be written as

$$\mathcal{R}(X) = A_X^* X + X A_X - X B B^* X - C^* C = 0. \tag{2.1}$$

In many instances it will be of advantage to regard (2.1) as a Lyapunov matrix equation

$$A_X^* X + X A_X = X B B^* X + C^* C$$

with semidefinite right-hand side. The following facts are well known.

LEMMA 2.1. *Suppose X satisfies $A^* X + X A = R^* R$ and $X \leq 0$.*

(1) *If $\sigma(A) \subseteq \mathbb{C}_=$, then $R = 0$.*

(2) *If*

$$\sigma \begin{pmatrix} A - sI \\ R \end{pmatrix} \cap \mathbb{C}_= = \emptyset, \tag{2.2}$$

then $\sigma(A) \subseteq \mathbb{C}_<$.

(3) *If* $A^*X + XA = 0$ *and* $X < 0$, *then* $\sigma(A) \subseteq \mathbb{C}_=$ *and* A *is diagonalizable.*

For matrices A_i, B_i, C_i that will appear in partitions of A, B, C we define Riccati operators

$$\mathcal{R}_i(X) = A_i^*X + XA_i + XB_iB_i^*X - C_i^*C_i$$

and Lyapunov operators

$$\mathcal{L}_i(X) = A_i^*X + XA_i.$$

In what follows we encounter more than once a subspace $N \in \mathrm{Inv}A$ such that $N \subseteq \mathrm{Ker}\, C$. Therefore we fix the following set-up. It is understood that in a given context matrices and vectors shall be partitioned in a conforming manner. Let a basis of $\mathbb{C}^n$ be given such that

$$N = \left\{ \begin{pmatrix} x_1 \\ 0 \end{pmatrix}, x_1 \in \mathbb{C}^{n-n_2} \right\}. \tag{2.3}$$

Then

$$A = \begin{pmatrix} A_1 & A_{12} \\ 0 & A_2 \end{pmatrix} \quad \text{and} \quad C = (0, C_2). \tag{2.4}$$

Assume

$$B = \begin{pmatrix} B_1 \\ B_2 \end{pmatrix}. \tag{2.5}$$

If

$$X = \begin{pmatrix} X_1 & X_{12} \\ X_{12}^* & X_2 \end{pmatrix}$$

is a solution of (1.1), then we have

$$A_1^*X_1 + X_1A_1 = -(X_1 \quad X_{12})BB^*(X_1 \quad X_{12})^*. \tag{2.6}$$

In the case where X is of the form $X = \mathrm{diag}(X_1, X_2)$, the block X_2 satisfies $\mathcal{R}_2(X_2) = 0$. The following observations are well known and easy to prove.

LEMMA 2.2. *Let* N *and* A, B, C *be as in* (2.3)–(2.5). *Then*

$$V_\leq(A, C) \subseteq N \tag{2.7}$$

is equivalent to

$$\sigma \begin{pmatrix} A_2 - sI \\ C_2 \end{pmatrix} \cap \mathbb{C}_\leq = \emptyset, \tag{2.8}$$

and

$$N + R(A, B) + E_<(A) = \mathbb{C}^n \tag{2.9}$$

is equivalent to

$$\sigma(A_2 - sI, B_2) \cap \mathbb{C}_\geq = \emptyset, \tag{2.10}$$

i.e., to stabilizability of (A_2, B_2).

The conditions (2.8) and (2.10) have implications for definiteness of solutions.

THEOREM 2.3 (see, e.g., [8]). *There exists a unique solution $W_2 < 0$ of $\mathcal{R}_2(X_2) = 0$ if and only if both* (2.8) *and* (2.10) *are satisfied. The matrix W_2 is the least solution, i.e., $\mathcal{R}_2(X_2) = 0$ implies $W_2 \leq X_2$.*

Apart from the use of Theorem 2.3 we want the proof of the parametrization theorem in §4 to be self-contained. For that purpose we include already at this stage an existence result that appears in much more general form in Theorem 1.4.

COROLLARY 2.4 [5], [7]. *If $V(A,C) + R(A,B) + E_<(A) = \mathbb{C}^n$ holds, then $\mathcal{T} \neq \emptyset$.*

Proof. Take $N = V(A,C)$ in (2.3). Then according to Lemma 2.2, the matrices A_2, B_2, C_2 in (2.4) and (2.5) satisfy (2.8) and (2.10). Hence there exists a solution $X_2 < 0$ of $\mathcal{R}_2(X_2) = 0$, and $X = \operatorname{diag}(0, X_2) \leq 0$ satisfies $\mathcal{R}(X) = 0$. □

Let

$$H = \begin{pmatrix} A & BB^* \\ C^*C & -A^* \end{pmatrix}$$

be the Hamiltonian matrix associated to (1.1). There is a link between $V_=(A,C)$ and the space $E_=(H)$.

LEMMA 2.5. *We have*

$$\dim E_=(H) = 2 \dim V_=(A,C)$$

if and only if

$$E_=(A) \subseteq V(A,C) + R(A,B). \tag{2.11}$$

Proof. Note that (2.11) is equivalent to

$$E_=(A) \subseteq V_=(A,C) + R(A,B). \tag{2.12}$$

Assume

$$V_=(A,C) = \operatorname{Im} \begin{pmatrix} I_{n_1} \\ 0 \end{pmatrix}$$

or equivalently (2.4) with $\sigma(A_1) \subseteq \mathbb{C}_=$ and

$$\sigma \begin{pmatrix} A_2 - sI \\ C_2 \end{pmatrix} \cap \mathbb{C}_= = \emptyset. \tag{2.13}$$

If B is given by (2.5), then (2.12) means $E_=(A_2) \subseteq R(A_2, B_2)$, i.e.,

$$\sigma(A_2 - sI, B_2) \cap \mathbb{C}_= = \emptyset. \tag{2.14}$$

On the other hand (2.4) yields

$$H = \begin{pmatrix} A_1 & A_{12} & * & * \\ 0 & A_2 & * & B_2B_2^* \\ 0 & 0 & -A_1^* & 0 \\ 0 & C_2^*C_2 & -A_{12}^* & -A_2^* \end{pmatrix}.$$

Hence we have $\dim E_=(H) = 2n_1$ if and only if

$$\sigma(H_2) \cap \mathbb{C}_= = \emptyset, \tag{2.15}$$

where

$$H_2 = \begin{pmatrix} A_2 & B_2B_2^* \\ C_2^*C_2 & -A_2^* \end{pmatrix}.$$

It is well known that

$$\sigma(H) \cap \mathbb{C}_= = [\sigma(A - sI, B) \cap \mathbb{C}_=] \cup \left[\sigma \begin{pmatrix} A - sI \\ C \end{pmatrix} \cap \mathbb{C}_=\right].$$

Because of (2.13) the property (2.15) is equivalent to (2.14), which completes the proof. □

3. The decomposition theorem. Recall U_r in (1.5). The space

$$U_1 = V_=(A, C) \cap U_r = V(A, C) \cap R(A, B) \cap E_=(A)$$

is crucial for the proof of Theorem 1.2. We shall see that

$$U_1 \subseteq \text{Ker } X \quad \text{if } X \in \mathcal{T}. \tag{3.1}$$

The following statement is equivalent to (3.1).

LEMMA 3.1. *Assume*

$$U_r = V_>(A, C) + R(A, B) + E_<(A) = \mathbb{C}^n. \tag{3.2}$$

Then we have

$$V_=(A, C) \subseteq \text{Ker } X \tag{3.3}$$

for all $X \in \mathcal{T}$.

Proof. Because of (1.3), condition (3.2) implies $E_=(A) \subseteq R(A, B)$. Hence we have $V_=(A, C) \subseteq R(A, B)$, or equivalently

$$R(A, B)^\perp = V(A^*, B^*) \subseteq V_=(A, C)^\perp. \tag{3.4}$$

Now assume $N = V_=(A, C)$ in (2.3) such that $\sigma(A_1) \subseteq \mathbb{C}_=$. From (2.6) and Lemma 2.1 we obtain

$$B^* \begin{pmatrix} X_1 \\ X_{12}^* \end{pmatrix} = 0, \tag{3.5}$$

which implies

$$A^* \begin{pmatrix} X_1 \\ X_{12}^* \end{pmatrix} + \begin{pmatrix} X_1 \\ X_{12}^* \end{pmatrix} A_1 = 0. \tag{3.6}$$

Hence (3.5) and (3.6) yield

$$B^*(A^*)^i \begin{pmatrix} X_1 \\ X_{12}^* \end{pmatrix} = 0, \quad i = 0, 1, \ldots, n-1,$$

or equivalently

$$\text{Im} \begin{pmatrix} X_1 \\ X_{12}^* \end{pmatrix} \subseteq V(A^*, B^*).$$

From (3.4) and $V_=(A,C)^\perp = \operatorname{Im}\binom{0}{I}$ follows $X_1 = 0$. And because of $X \le 0$ we have $X = \operatorname{diag}(0, X_2)$, which proves (3.3). □

Proof of Theorem 1.2. Let $\mathbb{C}^n = U_0 \oplus U_r$ be a given *LR*-decomposition and assume (1.6). Then it is obvious that (1.7)–(1.9) hold. If

$$X = \begin{pmatrix} X_0 & X_{0r} \\ X_{0r}^* & X_r \end{pmatrix} \in \mathcal{T}$$

is partitioned accordingly, then the block X_r satisfies (1.12). From Lemma 3.1 we obtain

$$V_=(A_r, C_r) \subseteq \operatorname{Ker} X_r. \tag{3.7}$$

Note that

$$V_=(A,C) = U_0 \oplus [V_=(A,C) \cap U_r] = U_0 \oplus U_1.$$

Let U_2 be such that $U_r = U_1 \oplus U_2$. If we choose an appropriate basis and take $U_0 \oplus U_1 \in \operatorname{Inv} A$ into account then we have

$$A = \begin{pmatrix} A_0 & 0 & 0 \\ A_{10} & A_1 & A_{12} \\ 0 & 0 & A_2 \end{pmatrix}, \qquad B = \begin{pmatrix} 0 \\ B_1 \\ B_2 \end{pmatrix}, \qquad C = (0, 0, C_2),$$

where

$$\sigma(A_0) \cup \sigma(A_1) \subseteq \mathbb{C}_= \tag{3.8}$$

and

$$\sigma \begin{pmatrix} A_2 - sI \\ C_2 \end{pmatrix} \cap \mathbb{C}_= = \emptyset. \tag{3.9}$$

From

$$U_1 = \{(0, x_1^T, 0)^T, (x_1^T, 0)^T \in V_=(A_r, C_r)\} \tag{3.10}$$

and (3.7) follows (3.1), i.e., $U_1 \subseteq \operatorname{Ker} X$. Hence

$$X = \begin{pmatrix} X_0 & 0 & X_{02} \\ 0 & 0 & 0 \\ X_{02}^* & 0 & X_2 \end{pmatrix}, \tag{3.11}$$

and (1.1) is equivalent to the following set of three equations: $\mathcal{L}_0(X_0) = A_0^* X_0 + X_0 A_0 = 0$,

$$A_0^* X_{02} + X_{02}(A_2 + B_2 B_2^* X_2) = 0, \tag{3.12}$$

and

$$\mathcal{R}_2(X_2) = A_2^* X_2 + X_2 A_2 + X_2 B_2 B_2^* X_2 - C_2^* C_2 = 0. \tag{3.13}$$

Put $\hat{A}_2 = A_2 + B_2 B_2^* X_2$ such that (3.13) can be written as $\hat{A}_2^* X_2 + X_2 \hat{A}_2 = R_2^* R_2$ with $R_2^* = (X_2 B_2, C_2^*)$. Since (3.9) implies

$$\sigma \begin{pmatrix} \hat{A}_2 - sI \\ R_2 \end{pmatrix} \cap \mathbb{C}_= = \emptyset,$$

Lemma 2.1 yields $\sigma(\hat{A}_2) \cap \mathbb{C}_= = \emptyset$. Because of (3.8), (3.12) has only the trivial solution $X_{02} = 0$. Hence the matrix (3.11) is further reduced to $X = \operatorname{diag}(X_0, 0, X_2)$, which is a decomposition of the form (1.10).

Conversely if $X = \operatorname{diag}(X_0, X_r)$ is such that (1.11) and (1.12) hold, then Lemma 3.1 yields $X_r = \operatorname{diag}(0, X_2)$ and X is a solution of $\mathcal{R}(X) = 0$. □

Proof of Theorem 1.3. Fix U_2 such that $U_r = U_1 \oplus U_2$. Let a basis of $\mathbb{C}^n$ be given such that (1.6), (3.10), and $U_2 = \{(0, 0, x_2^T)^T\}$ hold. Then we have

$$X = \operatorname{diag}(X_0, X_r) \tag{3.14}$$

and

$$X_r = \operatorname{diag}(0, X_2) \tag{3.15}$$

for $X \in \mathcal{T}$. Therefore $\Pi = \operatorname{diag}(0, I)$; hence (3.14) an equivalent to (1.13). Let Ψ be the projection onto U_2 along $V_=(A, C) = U_0 \oplus U_1$. Obviously (3.15) implies $X\Psi = X\Pi$, which shows that $\rho X = X\Pi$ is independent of the choice of the Lyapunov component U_0. □

The map ρ has the properties of a closure operator [2] on the partially ordered set $\mathcal{T}$, namely: (1) $X \leq \rho X$, (2) $X \leq Y \Rightarrow \rho X \leq \rho Y$, (3) $\rho^2 X = \rho X$ for all $X, Y \in \mathcal{T}$.

In the next section we are concerned with the set $\mathcal{S} = \rho\mathcal{T}$. It is obvious that $X \in \mathcal{T}$ is in $\mathcal{S}$ if and only if $V_=(A, C) \subseteq \operatorname{Ker} X$. Similarly, we have $\mathcal{T} \neq \emptyset$ together with $\mathcal{T} = \mathcal{S}$ if and only if

$$V_>(A, C) + R(A, B) + E_<(A) = \mathbb{C}^n. \tag{3.16}$$

LEMMA 3.2. *Assume $\mathcal{T} \neq \emptyset$. Then $\mathcal{T} = \mathcal{S}$ is equivalent to*

$$E_=(A) \subseteq R(A, B) \tag{3.17}$$

and also to

$$V_=(A, C) \subseteq R(A, B). \tag{3.18}$$

Proof. If we intersect both sides of (3.18) with $E_=(A)$ we obtain (3.17) in the form $R(A, B) \cap E_=(A) = E_=(A)$. Assume now (3.18). Then $\mathcal{T} \neq \emptyset$, i.e., $\mathbb{C}^n = V(A, C) + R(A, B) + E_<(A) = V_>(A, C) + [V_=(A, C) + R(A, B)] + [V_<(A, C) + E_<(A)]$ implies (3.16). □

4. Kernels of solutions. Scherer's approach in [12], which is based on the map $\gamma : X \mapsto \operatorname{Ker} X$, can be adapted to our analysis and leads to a description of the solution set $\mathcal{S}$.

LEMMA 4.1. (1) *If X is a solution of* (1.1) *then* Ker X *is A-invariant and satisfies*

$$\operatorname{Ker} X \subseteq V(A, C) \tag{4.1}$$

(2) *For $X \in \mathcal{T}$ we have*

$$V_<(A, C) \subseteq \operatorname{Ker} X. \tag{4.2}$$

(3) *A solution $X \in \mathcal{S}$ satisfies*

$$V_\leq(A, C) \subseteq \operatorname{Ker} X \tag{4.3}$$

and

$$\operatorname{Ker} X + R(A, B) + E_<(A) = \mathbb{C}^n. \tag{4.4}$$

Proof. (1) If $Xy = 0$, then $y^*\mathcal{R}(X)y = -y^*C^*Cy = 0$ yields Ker $X \subseteq$ Ker C. From $Cy = 0$ and $\mathcal{R}(X)y = 0$ we obtain $XAy = 0$. Now (4.1) follows from the fact that $V(A, C)$ is the largest A-invariant subspace in Ker C.

(2) Take $N =$ Ker X in (2.3) such that $X = \text{diag}(0, X_2)$, $X_2 < 0$. Put $Y = X_2^{-1}$ and $\tilde{A}_2 = A_2 - YC_2^*C_2$. Then $\mathcal{R}_2(X_2) = 0$ can be written as

$$Y\tilde{A}_2^* + \tilde{A}_2 Y = -(B_2B_2^* + YC_2^*C_2Y).$$

Obviously $Y < 0$ implies $\sigma(\tilde{A}_2) \cap \mathbb{C}_< = \emptyset$, which is equivalent to

$$\sigma\begin{pmatrix} A_2 - sI \\ C_2 \end{pmatrix} \cap \mathbb{C}_< = \emptyset$$

or to (4.2).

(3) For $X \in \mathcal{S}$ we have $V_=(A, C) \subseteq$ Ker X, which establishes (4.3). If we take $N =$ Ker X as above then we conclude that

$$V_=(A_2, C_2) = 0. \tag{4.5}$$

Now put $\hat{A}_2 = A_2 + B_2B_2^*X_2$. Again write $\mathcal{R}_2(X_2) = 0$ as

$$\hat{A}_2^*X_2 + X_2\hat{A}_2 = X_2B_2B_2^*X_2 + C_2^*C_2.$$

Then $X_2 < 0$ implies $\sigma(\hat{A}_2) \subseteq \mathbb{C}_\leq$. Suppose $\hat{A}_2 y = \lambda y$ and $\lambda \in \mathbb{C}_=$. Then the preceding Lyapunov equation yields $B_2^*X_2y = 0$ and $C_2y = 0$. Hence $A_2y = \lambda y$, and $y \in V_=(A_2, C_2)$. From (4.5) follows $y = 0$. Hence

$$\sigma(\hat{A}_2) \subseteq \mathbb{C}_<, \tag{4.6}$$

which means (A_2, B_2) is stabilizable, i.e., we have $R(A_2, B_2) + E_<(A_2) = \mathbb{C}^{n_2}$, which in turn proves (4.4). □

COROLLARY 4.2. *For $X \in \mathcal{S}$ we have*

$$\text{Ker } X = V_\leq(A, C) \oplus E_>(A_X). \tag{4.7}$$

Furthermore $E_>(A_X) \in$ Inv A and $A = A_X$ on $E_>(A_X)$.

Proof. As before assume $X = \text{diag}(0, X_2)$, $X_2 < 0$. Then

$$A_X = \begin{pmatrix} A_1 & \hat{A}_{12} \\ 0 & \hat{A}_2 \end{pmatrix} \quad \text{and} \quad C = (0, C_2).$$

Hence (4.6) and (4.3) imply

$$\text{Ker } X = \{(x_1^T, 0)^T, x_1 \in E_\leq(A_1) \oplus E_>(A_1)\} = V_\leq(A, C) \oplus E_>(A_X).$$

The remaining statements are easy to verify. □

With (4.1), (4.3), and (4.4) we have the properties which characterize the set $\{\text{Ker } X \mid X \in \mathcal{S}\}$. Recall the definition

$$\mathcal{N} = \{N \mid N \in \text{Inv } A, V_\leq(A, C) \subseteq N \subseteq V(A, C), N + R(A, B) + E_<(A) = \mathbb{C}^n\}.$$

Proof of Theorem 1.4. From Lemma 4.1 it is clear that $X \in \mathcal{S}$ implies $\gamma X =$ Ker $X \in \mathcal{N}$. To show that $\gamma : \mathcal{S} \to \mathcal{N}$ is bijection, we fix a subspace $N \in \mathcal{N}$. We want to show

that there exists a unique $Y \in \mathcal{T}$ with $\operatorname{Ker} Y = N$. Because of $V_=(A,C) \subseteq N$ such a Y is necessarily in $\mathcal{S}$. As usual we work in the set-up (2.3)–(2.5). Note that $\operatorname{Ker} X = N$ together with $X \leq 0$ is equivalent to $X = \operatorname{diag}(0, X_2), X_2 < 0$. Furthermore X is a solution of $\mathcal{R}(X) = 0$ if and only if X_2 satisfies $\mathcal{R}_2(X_2) = 0$. According to Lemma 2.2 the properties (2.7) and (2.9) of N can be expressed by (2.8) and (2.10). Hence Theorem 2.3 yields a unique solution $Y_2 < 0$ of $\mathcal{R}_2(X_2) = 0$. Then $Y = \operatorname{diag}(0, Y_2)$ is the uniquely determined solution in $\mathcal{T}$ with $\operatorname{Ker} Y = N$. It is obvious that γ is order preserving, since $X \leq Y \leq 0$ implies $\operatorname{Ker} X \subseteq \operatorname{Ker} Y$. Now assume that $N, M \in \mathcal{N}$ satisfy $N \subseteq M$. Let N be given as in (2.3). Put $W = \gamma^{-1}(N), Y = \gamma^{-1}(M)$. Then $\operatorname{Ker} W = N \subseteq \operatorname{Ker} Y$ implies $W = \operatorname{diag}(0, W_2), W_2 < 0$, and $Y = \operatorname{diag}(0, Y_2), Y_2 \leq 0$. Both W_2 and Y_2 are solutions of $\mathcal{R}_2(X_2) = 0$. According to Theorem 2.3 the definite matrix W_2 is the least solution of $\mathcal{R}_2(X_2) = 0$. Hence $W_2 \leq Y_2$ and $W \leq Y$, which shows that also γ^{-1} is order preserving. □

Remark 4.3. The following statements are equivalent:

(4.8)
(1) $\mathcal{N} \neq \emptyset$,
(2) $V(A,C) + R(A,B) + E_<(A) = \mathbb{C}^n$,

(4.9)
(3) $V(A,C) \in \mathcal{N}$,
(4) $E_>(A) \subseteq V(A,C) + R(A,B)$,

and

$$\dim E_=(H) = 2 \dim V_=(A,C). \tag{4.10}$$

Proof. It is easy to see that the definition of $\mathcal{N}$ implies the equivalence of (1), (2), and (3). Because of (1.3) we can state (4.8) as

$$E_>(A) + E_=(A) \subseteq V(A,C) + R(A,B) \tag{4.11}$$

or equivalently as a pair of two inclusions, namely (4.9) together with

$$E_=(A) \subseteq V(A,C) + R(A,B). \tag{4.12}$$

According to Lemma 2.5 the conditions (4.12) and (4.10) are equivalent, which implies the equivalence of (2) and (4). □

Since $\mathcal{T} \neq \emptyset$ if and only if $\mathcal{S} \neq \emptyset$ (i.e., $\mathcal{N} \neq \emptyset$) the preceding remark yields the known necessary and sufficient conditions for the existence of a solution $X \leq 0$ of (1.1). Condition (2) is contained in [5], [7] whereas (4) can be found in [10]. The fact $\mathcal{T}$ has a greatest element [5], [7] is another immediate consequence of Theorem 1.4. Since $X \leq \rho X$ and $V = V(A,C) = \sup \mathcal{N}$, we see that $\gamma^{-1}(V)$ is greatest negative-semidefinite solution of (1.1).

In [13], [8], [4], [1] solutions of (1.1) are parametrized under more restrictive hypotheses such as controllability or stabilizability, and the parametrization is based on the subspaces $E_>(A_X)$. The subsequent observation makes a connection to those results. From (4.7) follows that a solution $X \in \mathcal{S}$ is uniquely determined by $E_>(A_X)$. Define

$$\mathcal{G} = \{G \mid G \in \operatorname{Inv} A, G \subseteq V_>(A,C), G + V_\leq(A,C) + R(A,B) + E_<(A) = \mathbb{C}^n\}.$$

Then the map $\mu : \mathcal{S} \to \mathcal{G}$ given by $\mu X = E_>(A_X)$ is a bijection, and μ and μ^{-1} are order preserving. □

5. Negative-definite solutions. From Theorem 1.2 we obtain a condition for the existence of negative-definite solutions of (1.1). The following result is attributed to Richardson and Kwong.

THEOREM 5.1 [11]. *The* ARE (1.1) *has a solution* $W < 0$ *if and only if with respect to an appropriate basis the matrices* A, B, C *take the form*

$$A = \begin{pmatrix} A_0 & 0 \\ 0 & A_r \end{pmatrix}, \qquad B = \begin{pmatrix} 0 \\ B_r \end{pmatrix}, \qquad C = (0, C_r), \tag{5.1}$$

where

$$\sigma(A_0) \subseteq \mathbb{C}_= \quad \text{and } A_0 \text{ is diagonalizable}, \tag{5.2}$$

and

$$\sigma(A_r - sI, B_r) \cap \mathbb{C}_{\geq} = \emptyset, \qquad \sigma \begin{pmatrix} A_r - sI \\ C_r \end{pmatrix} \cap \mathbb{C}_{\leq} = \emptyset. \tag{5.3}$$

Assume (5.1)–(5.3). *Then* $W < 0$ *is a solution of* (1.1) *if and only if*

$$W = \operatorname{diag}(W_0, W_r), \tag{5.4}$$

and $W_0 < 0$, $\mathcal{L}_0(W_0) = 0$, *and* W_r *is the unique negative-definite solution of* $\mathcal{R}_r(X_r) = 0$.

The concept of LR-decomposition yields a more specific existence condition.

THEOREM 5.2. *The* ARE (1.1) *has a negative-definite solution if and only if the following conditions are satisfied*:

(5.5) (1) $\mathbb{C}^n = V_=(A, C) \oplus U_r$,

(5.6) (2) $V_<(A, C) = 0$,

(3) $A_{|V_=(A,C)}$ *is diagonalizable.*

If

$$V_=(A, C) = \left\{ \begin{pmatrix} x_0 \\ 0 \end{pmatrix} \right\} \quad \text{and} \quad U_r = \left\{ \begin{pmatrix} 0 \\ x_r \end{pmatrix} \right\}, \tag{5.7}$$

then the matrices A, B, C *take the form* (5.1) *and have the properties* (5.2) *and* (5.3).

Proof. Suppose (1.1) has a solution $W < 0$. Let $\mathbb{C}^n = U_0 \oplus U_r$ be an LR-decomposition such that $U_0 \subseteq V_=(A, C)$ and $U_r = V_>(A, C) + R(A, B) + E_<(A)$. We know that $U_1 = V_=(A, C) \cap U_r \subseteq \operatorname{Ker} W$. Therefore $V_=(A, C) \cap U_r = 0$, and from $V_=(A, C) + U_r = \mathbb{C}^n$ follows (5.5). From (4.2) we obtain (5.6). Let a basis of $\mathbb{C}^n$ be chosen such that (5.7) holds. Then (5.1) is obvious, and (5.4) follows from Theorem 1.2. Since $W_0 < 0$ satisfies $A_0^* W_0 + W_0 A_0 = 0$, we obtain (5.2) from Lemma 2.1. The matrix $W_r < 0$ is a solution of $\mathcal{R}_r(X_r) = 0$ and because of $V_=(A_r, C_r) = 0$, it is the only negative-definite solution. Hence Theorem 2.3 yields (5.3). The sufficiency part of the theorem is obvious. □

6. Location of $\sigma(A_X)$. In addition to definiteness or semidefiniteness of solutions, the location of $\sigma(A_X)$ is of interest. For a subset $\Lambda \subseteq \mathbb{C}$ put $E_\Lambda(A) = \oplus\{E_\lambda(A), \lambda \in \Lambda\}$ and $V_\Lambda(A) = V(A, C) \cap E_\Lambda(A)$. In the important case where $\Lambda = \mathbb{C}_{\leq}$, the equivalence of (1) and (2) of the subsequent theorem can be found in [4].

THEOREM 6.1. *Let* $\Lambda \subseteq \mathbb{C}$, *be given, and assume* $\mathbb{C}_{\leq} \subseteq \Lambda$. *Then the following statements are equivalent*:

(1) *There exists an* $X \in \mathcal{T}$ *such that*

$$\sigma(A_X) \subseteq \Lambda. \tag{6.1}$$

(2) *Both*

$$V(A,C) + R(A,B) + E_<(A) = \mathbb{C}^n \tag{6.2}$$

and

$$R(A,B) + E_\Lambda(A) = \mathbb{C}^n \tag{6.3}$$

hold.

$$\text{(3) } V_\Lambda(A,C) + R(A,B) + E_<(A) = \mathbb{C}^n. \tag{6.4}$$

Proof. (1) $\Rightarrow$ (2). Because of $\sigma(A - sI, B) = \sigma(A_X - sI, B)$, the inclusion (6.1) implies $\sigma(A - sI, B) \subseteq \Lambda$, which is equivalent to (6.3).

(2) $\Rightarrow$ (3). Put $K = \mathbb{C}\backslash\Lambda$. Because of

$$\begin{aligned} R(A,B) + E_\Lambda(A) &= [R(A,B) \cap E_\Lambda(A)] + [R(A,B) \cap E_K(A)] + E_\Lambda(A) \\ &= [R(A,B) \cap E_K(A)] + E_\Lambda(A), \end{aligned}$$

condition (6.3) is equivalent to $R(A,B) \cap E_K(A) = E_K(A)$, i.e., to $E_K(A) \subseteq R(A,B)$. If we write (6.2) as

$$V_\Lambda(A,C) + [V_K(A,C) + R(A,B)] + E_<(A) = \mathbb{C}^n,$$

then $V_K(A,C) \subseteq E_K(A) \subseteq R(A,B)$ yields (6.4).

(3) $\Rightarrow$ (1). Clearly (6.1) is equivalent to $E_\Lambda(A_X) = \mathbb{C}^n$. Put $M = \Lambda\backslash\mathbb{C}_\leq$ such that $E_\Lambda(A_X) = E_\leq(A_X) \oplus E_M(A_X)$. Then (6.1) takes the equivalent form

$$E_>(A_X) = E_M(A_X). \tag{6.5}$$

Note that $\mathbb{C}_\leq \subseteq \Lambda$ yields $V_\leq(A,C) \subseteq V_\Lambda(A,C)$. Hence (6.4) implies $V_\Lambda(A,C) \in \mathcal{N}$, and there exists a solution $X \in \mathcal{S}$ such that $\operatorname{Ker} X = V_\Lambda(A,C) = V_\leq(A,C) \oplus V_M(A,C)$. From (4.7), i.e., $\operatorname{Ker} X = V_\leq(A,C) \oplus E_>(A_X)$, we obtain $E_>(A_X) = V_M(A,C)$. Therefore we have $\sigma(A_X) \cap \mathbb{C}_> \subseteq M$ or $E_>(A_X) \subseteq E_M(A_X)$, which yields (6.5). □

A STRONG SEPARATION PRINCIPLE FOR STOCHASTIC CONTROL SYSTEMS DRIVEN BY A HIDDEN MARKOV MODEL*

RAYMOND RISHEL†

Abstract. For a linear quadratic system driven by the output of a hidden Markov model, it is shown that the optimal control is obtained by computing the optimal control as if this output was a known deterministic function, and then substituting the best current estimates of the future values of this output for the known function in this control.

Key words. separation principle, hidden Markov model, non-Gaussian noise, linear quadratic, partially observed, optimal stochastic control

AMS subject classification. 93E20

1. Introduction. Consider a linear quadratic control problem in which it is desired to choose the control u_t for the system

$$dx_t = (Ax_t + Bu_t)\,dt + dz_t \tag{1}$$

with given initial state $x_0 = a$, to minimize the quadratic criteria

$$E\left[\int_0^T (x_t' M x_t + u_t' N u_t)\,dt + x_T' Q x_T\right], \tag{2}$$

where the driving noise z_t has the form

$$z_t = \int_0^t H(y_s)\,ds + W_t, \tag{3}$$

in which y is a Markov process and W is a Wiener process independent of y. That is, the driving noise z is the sum of the nonlinear output

$$\int_0^t H(y_s)\,ds \tag{4}$$

of the Markov process y and the Wiener process W. The state x_t of the system is observed and the control u_t is to be chosen based on the past observations of x to minimize the criteria (2).

This problem is a linear quadratic control problem driven by a type of non-Gaussian noise. It can also be thought of as a partially observed stochastic control problem with observed component x and unobserved component y. It is a system driven by a hidden Markov model in that the Markov process y is hidden from the controller, but x is observed.

If in (3), $H(y_s)$ is replaced by a known deterministic function H_s, standard linear quadratic arguments show that the optimal control has the form

$$u_t = -N^{-1}B'[K_t x_t + J_t]. \tag{5}$$

In (5), K_t is the solution of the matrix Ricatti equation

$$\dot{K}_t = -A'K_t - K_t A + K_t B N^{-1} B' K_t - M \tag{6}$$

† Department of Mathematics, University of Kentucky, Lexington, Kentucky 40506.

with terminal condition

$$K_T = Q, \tag{7}$$

and J_t is given by

$$J_t = \int_t^T \phi(t,s) K_s H_s \, ds \tag{8}$$

where $\phi(t,s)$ is the solution of the matrix differential equation

$$\frac{d}{dt}\phi(t,s) = (-A' + K_t B N^{-1} B')\phi(t,s) \tag{9}$$

with boundary condition

$$\phi(s,s) = I \tag{10}$$

where I is the identity matrix.

We wish to show that a strong separation principle holds in that for the original stochastic problem the same control (5) is optimal, if in (8), H_s is replaced by the best current estimate of the future values of $H(y_s)$ given the observations of the process x up to the current time t. That is, the optimal control for the stochastic problem is obtained by replacing H_s in (8) by the conditional expectation

$$E[H(y_s)|x_r;\ 0 \le r \le t]. \tag{11}$$

Special cases of the problem stated in (1)–(3) have been discussed by Helmes and Rishel in [3] and [4] and by Beneš in [1]. In these papers there is no quadratic term involving the state in the performance criteria and in [3] and [4] the Markov process y_t is either a jump Markov process or a diffusion process. When there is no quadratic term involving the state in the performance criteria, the optimal control is linear in a quantity called the *predicted miss*. In the present case, with a quadratic state term in the performance, this is no longer true. A type of separation was mentioned in [3], but the current type of strong separation principle was not pointed out in [1], [3], or [4].

Separation principles for discrete time linear quadratic non-Gaussian systems are well known. Root in [9] shows that the separation principle holds for partially observed linear quadratic discrete time systems driven by independently and identically distributed (i.i.d.) zero mean non-Gaussian random variables. However, the discrete time version of the current problem would be more general than that of [9].

2. Preliminary considerations. Let us begin our discussion by defining the quantities in the problem and the class of controls more precisely. In (1) x_t is the n-dimensional state; u_t is the m-dimensional control; and A, B, M, N, Q are, respectively, $(n \times n)$-, $(n \times m)$-, $(n \times n)$-, $(m \times m)$-, and $(n \times n)$-dimensional matrices. The matrix N is positive definite symmetric and M and Q are nonnegative definite symmetric matrices.

The Markov process y has values in a measurable space $\mathcal{S}$ with σ-field Σ. It will be assumed to have stationary transition probabilities

$$P(t,y,E) \tag{12}$$

and an initial probability distribution $P_0(E)$. Let B denote the space of bounded measurable functions f on $\mathcal{S}$. The transition probability (12) defines a semigroup P_t of operators on B by

$$P_t[f](y) \triangleq \int_{\mathcal{S}} P(t,y,dz) f(z). \tag{13}$$

The function $H(y)$ is a bounded m-dimensional vector-valued measurable function defined on $\mathcal{S}$.

Let

$$\mathcal{F}_t^x \triangleq \sigma[x_r;\ 0 \le r \le t] \tag{14}$$

and

$$\mathcal{F}_t^z \triangleq \sigma[z_r;\ 0 \le r \le t] \tag{15}$$

be, respectively, the σ-fields generated by the past of x and the past of z up to time t. Let β denote the Borel field on $[0, T]$.

The class of admissible controls must satisfy the following two properties:

(i) For each control u there is a corresponding strong solution of (1). By a strong solution of (1) we mean a solution that is a nonanticipative functional on the driving noise z, that is, a solution x, so that x_t can be represented as

$$x_t = F(t, (z_r;\ 0 \le r \le t)), \tag{16}$$

where F is a $(B \times \mathcal{F}_T^z)$-measurable function so that for each t, $F(t, (z_t;\ 0 \le r \le t))$ is $\mathcal{F}_t^z$-measurable.

(ii) Each control u is a measurable stochastic process and for each t, u_t is $\mathcal{F}_t^x$-measurable, where x is the solution of (1) corresponding to u. That is, the control u_t used at time t depends only on measurements of its corresponding process x made up to time t.

Remark. Our assumptions on the class of admissible controls imply that for each t

$$\mathcal{F}_t^x = \mathcal{F}_t^z. \tag{17}$$

To see this, notice that property (i) implies

$$\mathcal{F}_t^x \subset \mathcal{F}_t^z. \tag{18}$$

Equation (1) implies

$$x_t - a - \int_0^t (Ax_s + Bu_s)\, ds = \int_0^t H(y_s)\, ds + W_t = z_t. \tag{19}$$

This and property (ii) imply

$$\mathcal{F}_t^z \subset \mathcal{F}_t^x. \tag{20}$$

Thus the two inequalities (18) and (20) imply (17).

3. Estimation and extrapolation. First we will need some results on nonlinear filtering and nonlinear extrapolation. These follow rather directly from results of Kunita [5] and are summarized in Lemma 1.

LEMMA 1. *The conditional probability distribution π_t of y_t given $\mathcal{F}_t^x$ exists as a probability measure-valued random process such that for each f in B,*

$$\int_{\mathcal{S}} f(y)\pi_t(dy) = E[f(y_t)|\mathcal{F}_t^x]. \tag{21}$$

It is independent of the control used. If we use the notation

$$\pi_t(f) = \int_{\mathcal{S}} f(y)\pi_t(dy), \tag{22}$$

then π_t is the unique solution of the equations

$$\pi_t(f) = P_0(P_t f) + \int_0^t [\pi_r((P_{t-r}f)H') - \pi_r(P_{t-r}f)\pi_r(H')]\, d\nu_r, \tag{23}$$

which hold for each $f \in B$. In (23), *ν is the innovations Wiener process defined by*

$$\nu_t \triangleq \int_0^t [H(y_r) - \pi_r(H)]\, dr + W_t. \tag{24}$$

For $s > t$ the extrapolated value

$$E[H(y_s)|\mathcal{F}_t^x] \tag{25}$$

of $H(y(s))$, given the past observations of x up to time t, can be expressed in terms of π_t by either

$$E[H(y_s)|\mathcal{F}_t^x] = \pi_t(P_{s-t}H) \tag{26}$$

or

$$E[H(y_s)|\mathcal{F}_t^x] = P_0(P_s(H)) + \int_0^t [\pi_r((P_{s-r}H)H') - \pi_r(P_{s-r}H)\pi_r(H')]\, d\nu_r. \tag{27}$$

Proof of Lemma 1. Since the σ-field equality (17) holds,

$$E[f(y_t)|\mathcal{F}_t^x] = E[f(y_t)|\mathcal{F}_t^z]. \tag{28}$$

Thus, since both y and z do not depend on the control, (28) is independent of the control. It now follows from Kunita [5][1] that a unique probability measure-valued process π_t exists, so

$$\int_{\mathcal{S}} f(y)\pi_t(dy) = E[f(y_t)|\mathcal{F}_t^z], \tag{29}$$

π_t is the unique solution of (23) and (24), and (24) is a Wiener process.

To obtain the formula (26) for the extrapolated value (25) of $H(y_s)$, notice that

$$\mathcal{F}_t^{yW} \supset \mathcal{F}_t^z; \tag{30}$$

thus the law of iterated conditional expectations gives

$$E[H(y_s)|\mathcal{F}_t^z] = E[E[H(y_s)|\mathcal{F}_t^{yW}]|\mathcal{F}_t^z]. \tag{31}$$

Since y and W are mutually independent,

$$E[H(y_s)|\mathcal{F}_t^{yW}] = E[H(y_s)|\mathcal{F}_t^y] = P_{s-t}(H). \tag{32}$$

Thus (26) follows from (31) and (32). Formula (27) now follows from (26) and (23) by substituting $P_{s-t}(H)$ for f in (23) and using the semigroup property of P_t.

[1] Actually the results of Kunita [5] are stated with $\mathcal{S}$ a compact space, and f and H continuous functions, but these results of [5] hold under the current assumptions.

4. The linear quadratic optimality argument. Let us show that if J_t^π is defined by

$$J_t^\pi \triangleq \int_t^T \phi(t,s) K_s \pi_t(P_{s-t}H)\, ds, \tag{33}$$

then

$$u_t = -N^{-1}B'[K_t x_t + J_t^\pi] \tag{34}$$

is an optimal control. We show in Appendix I that (34) satisfies the conditions (i) and (ii) for admissibility.

We shall need to take the stochastic differential of J_t^π. In Appendix II we show that

$$dJ_t^\pi = -[(A - BN^{-1}B'K_t)'J_t^\pi + K_t\pi_t(H)]\, dt + \Gamma_t\, d\nu_t, \tag{35}$$

where Γ_t is defined by

$$\Gamma_t \triangleq \int_t^T \phi(t,s) K_s[\pi_t((P_{s-t}H)H') - \pi_t(P_{s-t}H)\pi_t(H')]\, ds. \tag{36}$$

THEOREM 1. *If x is the solution of* (1) *with initial state a corresponding to any admissible control u, then*

$$E\left[\int_0^T (x_t'Mx_t + u_t'Nu_t)\, dt + x_T'Qx_T\right] \geq a'K_0a + J_0^{\pi'}a + R_0 \tag{37}$$

where

$$R_t = \int_t^T [2J_s^{\pi'}\pi_s(H) - J_s^{\pi'}BN^{-1}B'J_s^\pi + \text{ trace } K_s + \text{ trace } \Gamma_s]\, ds. \tag{38}$$

If x is the solution of (1) *with initial state a corresponding to the control given by* (34) *and* (33), *then equality holds in* (37). *Thus* (34) *and* (33) *define the optimal control.*

Proof of Theorem 1. Let u be any admissible control and x be the corresponding solution of (1) with initial state a. Apply Ito's stochastic differential rule and (35) to obtain

$$\begin{aligned} d[x_t'K_tx_t + 2J_t^{\pi'}x_t] &= x_t'\dot{K}_tx_t\, dt + 2(x_t'K_t + J_t^{\pi'})\, dx_t \\ &\quad + 2x_t'dJ_t^\pi + (\text{trace } K_t + \text{ trace } \Gamma_t)\, dt. \end{aligned} \tag{39}$$

From (1) and (24),

$$dx_t = (Ax_t + Bu_t + \pi_t(H))\, dt + d\nu_t. \tag{40}$$

Adding $(x_tMx_t + u_tNu_t)\, dt$ to both sides of (39) and using (40) gives

$$\begin{aligned} &d[x_t'K_tx_t + 2J_t^{\pi'}x_t] + (x_t'Mx_t + u_t'Nu_t)\, dt \\ &\quad = x_t'(\dot{K}_t + M)x_t + 2(x_t'K_t + J_t^{\pi'})[(Ax_t + \pi_t(H))\, dt + d\nu_t] \\ &\qquad + 2(x_t'K_t + J_t^{\pi'})Bu_t\, dt + u_t'Nu_t\, dt \\ &\qquad + 2x_t'dJ_t^\pi + (\text{trace } K_t + \text{ trace } \Gamma(t))\, dt. \end{aligned} \tag{41}$$

Now the minimum over u_t of

$$2(x_t'K_t + J_t^{\pi'})Bu_t + u_t'Nu_t \tag{42}$$

is attained by $u_t = -N^{-1}B'(K_t x_t + J_t^\pi)$ and is given by

$$
\begin{aligned}
&-(x_t'K_t + J_t^{\pi'})BN^{-1}B'(K_t x + J_t^\pi) \\
&\quad = -(x_t'K_tBN^{-1}B'K_t x_t + 2x_t'K_tBN^{-1}B'J_t^\pi + J_t^{\pi'}BN^{-1}B'J_t^\pi).
\end{aligned} \tag{43}
$$

Thus, for any control u,

$$
\begin{aligned}
&d[x_t'K_t x_t + 2J_t^{\pi'}x_t] + (x_t'Mx_t + u_t'Nu_t)\,dt \\
&\quad \geq x_t'(\dot{K}_t + K_tA + A'K_t + M - K_tBN^{-1}B'K_t)x_t \\
&\qquad + 2x_t'[(A'J_t^\pi + K_t\pi_t(H))\,dt - K_tBN^{-1}B'J_t^\pi\,dt + dJ_t^\pi + K_t\,d\nu_t] \\
&\qquad + [2J_t^{\pi'}\pi_t(H) - J_t^{\pi'}BN^{-1}B'J_t^\pi + \text{ trace } K_t + \text{ trace } \Gamma(t)]\,dt + J_t^{\pi'}\,d\nu_t.
\end{aligned} \tag{44}
$$

Now (44), (6), (35), and (38) imply

$$
d[x_t'K_t x_t + 2J_t^{\pi'}x_t] + (x_t'Mx_t + u_t'Nu_t)\,dt \geq 2x_t'(\Gamma_t + K_t)\,d\nu_t + J_t^{\pi'}\,d\nu_t - dR_t. \tag{45}
$$

Integrating both sides of (45) from 0 to T and taking expected values using the fact that $K_T = Q$, $J_T^\pi = 0$, $R_T = 0$, and the expected value of the stochastic integral is zero, gives

$$
E\left[x_T'Qx_T - (a'K_0a + J_0^{\pi'}a) + \int_0^T (x_t'Mx_t + u_t'Nu_t)\,dt\right] \geq R_0. \tag{46}
$$

Thus, on rearranging (90) and using the fact that a and J_0^π are not random,

$$
E\left[x_T'Qx_T + \int_0^T (x_t'Mx_t + u_t'Nu_t)\,dt\right] \geq a'K_0a + J_0^{\pi'}a + R_0 \tag{47}
$$

holds for any control.

If we repeat the argument above for the control (34), then equality will hold in (44). Thus the same steps will show that (47) holds with equality for this control. Thus (34) is the optimal control.

5. An application. Let us illustrate a typical type of application of Theorem 1. Consider the following model for a production planning problem. Suppose that a factory produces goods and will operate most efficiently at a given level of production. Suppose it also wishes to maintain a given level of inventory on hand. The company from time to time replaces their product with a new model and their sales are also dependent on economic conditions. Because of this, the manager chooses a model for his total sales z_t which satisfies

$$
dz_t = y_t\,dt + \sigma dW_t, \tag{48}
$$

in which y_t is a finite state jump Markov process, and W_t is a Wiener process. The term σdW_t represents the short time variations of sales about their "mean rate" y_t. The mean rate y_t depends on the customers' reactions to new models and the economic conditions. Because these change at random times, the manager feels the choice of a jump Markov process, which takes on different constants over different random intervals, is an appropriate model for this mean rate.

Let x_t denote the deviation of the inventory from its desired level, and u_t the deviation of the production rate from its desired level. The inventory equation is

$$
dx_t = u_t\,dt - dz_t. \tag{49}
$$

Consider the problem in which the manager wishes to penalize deviation from his desired inventory and production levels by choosing u_t to minimize

$$E\left[\int_0^T x_s^2 + \lambda u_s^2 \, ds\right], \tag{50}$$

subject to (49) holding. In (50), T is a fixed final time.

When y_t is not random but a known function of time, the optimal control is

$$u_t = \lambda^{-1}(K_t x_t + J_t), \tag{51}$$

where K_t is the solution of

$$\dot{K}_t = \lambda^{-1} K_t^2 - 1; \qquad K_T = 0, \tag{52}$$

and

$$J_t = \int_t^T e^{-\int_t^s \lambda^{-1} K_u \, du} K_s y_s \, ds. \tag{53}$$

Theorem 1 implies, when y_t is modeled as a jump Markov process, that the optimum control is given by (51) where y_s in (53) is replaced by

$$\hat{y}_{ts} = \pi_t P_{s-t}(y). \tag{54}$$

In this case equation (23), defining π_t, is equivalent to the Wonham filter [11] for the vector of conditional probabilities of the states of the jump Markov process, and P_{s-t} is the transition probability matrix of the jump Markov process.

6. Conclusions. For a linear quadratic system driven by the known function of time plus a Wiener process, the optimal control is a linear feedback plus a functional on the future values of this known function. For a linear quadratic system driven by an unknown Markov process plus a Wiener process it was shown that the same linear feedback plus the same functional of the extrapolated future values of the Markov process gives the optimal control. Nonlinear filtering formulas give these extrapolated future values of the Markov process in terms of the conditional distribution of the state of the Markov process given the past measurements and the transition probabilities of the Markov process.

This control problem could be considered as a control problem with state given by (x_t, π_t), where π_t is the conditional probability distribution of the unobserved Markov process. Control problems with a probability distribution as their state were discussed early in the history of stochastic control by Kusher [6] and Mortensen [8]. More recently, Lions [7] has discussed optimal control of Zakai's equation. The current problem gives an example of a control problem whose state involves a probability distribution for which the control law is explicitly computed.

Appendix I. We shall show in this appendix that the control (34) satisfies the conditions (i) and (ii) for admissibility. Let us investigate (i), that is, show that there is a strong solution of (1) corresponding to (34).

To define a solution of (1) corresponding to the control (34) we must have simultaneous solutions of the system of equations

$$dx_t = [Ax_t - BN^{-1}B'(K_t x_t + J_t^{\pi})]\, dt + dz_t, \tag{55}$$

$$J_t^\pi = \int_t^T \phi(t,s) K_s \pi_t(P_{s-t}H)\, ds, \tag{56}$$

$$\pi_t(f) = P_0(P_t f) + \int_0^t [\pi_r((P_{t-r}f)H') - \pi(P_{t-r}f)\pi_r(H')]\, d\nu_r, \tag{57}$$

$$\nu_t = z_t - \int_0^t \pi_r(H)\, dr, \tag{58}$$

where K_t is the solution of (6) and (7). It follows from Kunita [5, Thms. 2.1, 2.2], that there is a unique strong solution of (57) and (58), i.e., a solution π_t, which can be expressed by a $\beta \times \mathcal{F}_t^z$ measure-valued measurable function ψ which is $\mathcal{F}_t^z$-measurable for each t as

$$\pi_t = \psi(t, z_r;\ 0 \le r \le t). \tag{59}$$

Let $\chi(s,t)$ denote the transition matrix of the linear system

$$dx_t = (A - BN^{-1}B'K_t)x_t\, dt. \tag{60}$$

Then the solution of (55) can be expressed as

$$\begin{aligned} x_t &= \chi(0,t)a \\ &\quad + \int_0^t \chi(s,t)BN^{-1}B' \int_s^T \phi(s,v)K_v \psi(v, z_r;\ 0 \le r \le v) P_{v-t}(H)\, dv ds \\ &\quad + \int_0^t \chi(s,t)\, dz_s. \end{aligned} \tag{61}$$

Thus the strong solution of (1) is explicitly exhibited by (61), showing that property (i) is satisfied.

Remark. One might think that property (ii) for the control (34) follows from our previous remark about the equivalence of the σ-fields $\mathcal{F}_t^z$ and $\mathcal{F}_t^x$. However, the remark is valid for controls which are admissible. The fact that property (ii) held was used to show that (19) implied (20) in the proof of that remark. At this point we do not know that property (ii) holds for (34) and must prove it.

To show that (ii) holds, notice that if we solve (55) for dz and substitute this into (58) and (57), we obtain the equation

$$\begin{aligned} \pi_t(f) &= P_0(P_t f) \\ &\quad - \int_0^t [\pi_r(P_{t-r}f)H') - \pi_r(P_{t-r}f)\pi_r(H')][BN^{-1}B'J_r^\pi - \pi_r(H)]\, dr \\ &\quad + \int_0^t [\pi_r((P_{t-r}f)H') - \pi_r(P_{t-r}(f))\pi_r(H')] \\ &\quad \times (dx_r - (Ax_r - BN^{-1}B'K_r x_r)\, dr), \end{aligned} \tag{62}$$

driven by x_t for $\pi_t(f)$. Now, from (33) and (34), it will follow that (ii) holds if we can show for each t that $\pi_t(f)$ is $\mathcal{F}_t^x$-measurable. Let us show that this holds by solving (62) by successive approximations where each of the approximating solutions has this property.

THEOREM 2. *Define*

$$\pi_t^0(f) \triangleq P_0(P_t f), \tag{63}$$

and for $n > 0$,

$$\begin{aligned}\pi_t^n(f) \triangleq\ & P_0(P_t f) \\ & + \int_0^t [\pi^{n-1}((P_{t-r}f)H') - \pi_r^{n-1}(P_{t-r}f)\pi_r^{n-1}(H')] \\ & \quad \times [BN^{-1}B'J_r^{\pi^{n-1}} - \pi_r^{n-1}(H)]\,dr \\ & + \int_0^t [\pi^{n-1}((P_{t-r}f)H') - \pi_r^{n-1}(P_{t-r}f)\pi_r^{n-1}(H')] \\ & \quad \times [dx_r - (Ax_r - BN^{-1}B'K_r x_r)\,dr].\end{aligned} \tag{64}$$

Then for each $n \geq 0$, $\pi_t^n(f)$ *is* $\mathcal{F}_t^x$*-measurable for each* t *and*

$$\lim_{n\to\infty} E[(\pi_t^n(f) - \pi_t(f))^2] = 0, \tag{65}$$

where $\pi_t(f)$ *is the unique solution of* (23) *and* (24).

Proof. First notice that $\pi_t^0(f)$ is a deterministic function of t and hence is $(\mathcal{F}_0^x \subset \mathcal{F}_t^x)$-measurable for each t. Now this and an induction using (64) show $\pi_t^n(f)$ is $\mathcal{F}_t^x$-measurable for each fixed t.

Let us next prove by induction that there is a constant K such that

$$E[(\pi_t(f) - \pi_t^n(f))^2] \leq \frac{K^{n+1}t^{n+1}}{(n+1)!}. \tag{66}$$

If $|f|$ is defined by

$$|f| = \sup_{s\in\mathcal{S}} |f(s)|, \tag{67}$$

notice that

$$|\pi_t(f)| \leq |f| \quad \text{and} \quad |P_{t-r}(f)| \leq |f|. \tag{68}$$

For brevity, define

$$C_{rt}^{\pi} \triangleq \pi_r((P_{t-r}f)H') - \pi_r(P_{t-r}f)\pi_r(H'). \tag{69}$$

Using the inequalities

$$\left(\sum_{i=1}^n a_i\right)^2 \leq n\sum_{i=1}^n a_i^2 \tag{70}$$

and (68), we see that

$$|C_{rt}^{\pi}|^2 \leq 4|f|^2|H|^2. \tag{71}$$

Now using (57), (63), (69), and (71),

$$E[(\pi_t(f) - \pi_t^0(f))^2] = E\left(\int_0^t C_{rt}^{\pi}\,d\nu\right)^2 = \int_0^t E|C_{rt}^{\pi}|^2\,dt \leq 4|f|^2|H|^2 t. \tag{72}$$

Thus (66) will hold for $n = 0$ if

$$K \geq 4|f|^2|H|^2. \tag{73}$$

For $n > 1$, rewriting $\pi_t^n(f)$ in terms of $d\nu$ rather than dx, and using (58) and (55), we have

$$\pi_t^n(f) = P_0(P_t f) + \int_0^t C_{rt}^{\pi^{n-1}}[D_r^{\pi^{n-1}} - D_r^{\pi}]\,dt + \int_0^t C_{rt}^{\pi^{n-1}}\,d\nu, \tag{74}$$

where we have used the abbreviated notation

$$D_r^{\pi} \triangleq BN^{-1}B'J_r^{\pi} - \pi_r(H). \tag{75}$$

Note that we may also write

$$\begin{aligned} D_r^{\pi} &= BN^{-1}B' \int_r^T \phi(r,s)K_s\pi_r(P_{s-r}H)\,ds - \pi_r(H) \\ &= \pi_r BN^{-1}B' \int_r^T \phi(r,s)K_s(P_{s-r}H) - H) \triangleq \pi_r(\gamma_r). \end{aligned} \tag{76}$$

Thus (68), (70), and (76) imply

$$|D_r^{\pi}|^2 \le |\gamma_r|^2 \le 2|B|^4|N^{-1}|^2T^2|\phi|^2|K|^2|H|^2 + 2|H|^2. \tag{77}$$

Subtracting (74) from (23), squaring, taking expected values, and using (70), we have

$$\begin{aligned} E[(\pi_t(f) - \pi_t^n(f))^2] \le\ & 2E\left[\left(\int_0^t C_{rt}^{\pi^{n-1}}[D_r^{\pi} - D_r^{\pi^{n-1}}]\,dt\right)^2\right] \\ & + 2E\left[\left(\int_0^t (C_{rt}^{\pi} - C_{rt}^{\pi^{n-1}})\,d\nu\right)^2\right]. \end{aligned} \tag{78}$$

Using Jensen's inequality on the first integral and properties of stochastic integrals on the second gives

$$\begin{aligned} E[(\pi_t(t) - \pi_t^n(f))^2] \le\ & 2E\int_0^t (C_{rt}^{\pi^{n-1}})^2[D_r^{\pi} - D_r^{\pi^{n-1}}]^2\,dt \\ & + 2E\left(\int_0^t (C_{rt}^{\pi} - C_{rt}^{\pi^{n-1}})^2\,dt\right). \end{aligned} \tag{79}$$

Now

$$\begin{aligned} C_{rt}^{\pi} - C_{rt}^{\pi_n} =\ & \pi_r((P_{t-r}f)H') - \pi_r^n((P_{t-r}f)H') \\ & + \pi_r(P_{t-r}f)(\pi_r(H') - \pi_r^n(H')) \\ & + [\pi_r(P_{t-r}f) - \pi_r^n(P_{t-r}f)]\pi_r^n(H'). \end{aligned} \tag{80}$$

So, using (70) and (68),

$$\begin{aligned} |C_{rt}^{\pi} - C_{rt}^{\pi_n}|^2 \le\ & 3|\pi_r((P_{t-r}f)H') - \pi_r^n(P_{t-r}f)H'|^2 \\ & + 3|f|^2|(\pi_r(H') - \pi_r^n(H'))^2 + 3|H'|^2|\pi_r(P_{t-r}f) - \pi_r^n(P_{t-r}f)|^2. \end{aligned} \tag{81}$$

Thus, from (79), and using (71), (76), (81), and (70),

$$
\begin{aligned}
&E[(\pi_t(f)-\pi_t^n(f))^2] \\
&\quad\le 6\int_0^t E|\pi_t((P_{t-r}f)H')-\pi^{n-1}((P_{t-r}f)H')|^2\,dr \\
&\quad\quad + 6|f|^2\int_0^t E|\pi_r(H')-\pi_r^{n-1}(H')|^2\,dr \\
&\quad\quad + 6|H'|^2\int_0^t |\pi_r(P_{t-r}f)-\pi^{n-1}(P_{t-r}f)|^2\,dr \\
&\quad\quad + 8|f|^2H'|^2\int_0^t |\pi_r(\gamma_r)-\pi_r^{n-1}(\gamma_r)|^2\,dr.
\end{aligned} \tag{82}
$$

Now using our induction hypothesis that (66) holds for $n-1$ and using (68),

$$
E[(\pi_r(f)-\pi_t^n(f))^2] \le (18|f|^2|H'|^2+8|f|^2|H'|^2|\gamma|^2)K^n\int_0^t \frac{r^n}{n!}\,dr. \tag{83}
$$

Thus (83) will imply (66) if

$$
K \ge 18|f|^2|H'|+8|f|^2|H'|^2|\gamma|^2. \tag{84}
$$

Choosing K in this way we see that induction implies that (66) must hold for all n. Now (66) implies (65).

The mean square convergence of $\pi_t^n(f)$ in the sense of (65) implies that there is a subsequence n_j so that $\pi_t^{n_j}(f)$ converges almost surely for Lebesgue measure almost every t to $\pi_t(f)$. This implies that $\pi_t(f)$ is $\mathcal{F}_t$-measurable for almost every t. Since $\pi_t(f)$ is a solution of (23) it is almost surely continuous in t. Thus $\pi_t(f)$ is $\mathcal{F}_t^x$-measurable for each t. Thus property (ii) is satisfied by the control (34).

Appendix II. In this appendix we shall establish a lemma that implies (35) and (36).

LEMMA 2. *Let $\mathcal{F}_t$ be an increasing family of σ-fields and ν an m-dimensional vector-valued $\mathcal{F}_t$-Wiener process. For $0\le t<s\le T$ let γ_{ts} be an $n\times m$-matrix-valued bounded measurable random process, such that γ_{ts} is $\mathcal{F}_t$-measurable for each fixed t, and such that α_s is an n-dimensional vector-valued, and A_t and K_t are $(n\times n)$-dimensional matrix-valued bounded measurable functions defined on $[0,T]$. Let H_{ts}, ϕ_{ts}, J_t satisfy*

$$
H_{ts} = \alpha_s + \int_0^t \gamma_{rs}\,d\nu_r, \tag{85}
$$

$$
\phi_{ts} = I + \int_t^s A_r\phi_{rs}\,dr, \tag{86}
$$

$$
J_t = \int_t^T \phi_{ts}K_sH_{ts}\,ds; \tag{87}
$$

then

$$
dJ_t = -(A_tJ_t - K_tH_{tt})\,dt + \left[\int_t^T \phi_{ts}K_s\gamma_{ts}\,ds\right]d\nu_t. \tag{88}
$$

The proof of Lemma 2 will consist mainly of a succession of interchanges of order of integration. Interchange of order of ordinary integration and stochastic integration is valid. For a proof, see Szpirglass [10]. Actually, Szpirglass's proof is stated for a rectangle but interchanges over more general regions follow by multiplying the integrand by the characteristic function of the region. We shall need the interchange over a triangle. Limits of integration change exactly as in ordinary integration when stochastic and ordinary integration are interchanged over a triangle.

Proof of Lemma 2. Using (86) in (87),

$$J_t = \int_t^T K_s H_{ts}\, ds + \int_t^T \int_t^s A_r \phi_{rs} K_s H_{ts}\, dr ds. \tag{89}$$

Interchanging the order of integration in the second integral of (89), and using that from (85) for $t < r < s$,

$$H_{ts} = H_{rs} - \int_t^r \gamma_{\tau s}\, d\nu_\tau \tag{90}$$

gives

$$\begin{aligned} J_t &= \int_t^T K_s H_{ts}\, ds + \int_t^T \int_r^T A_r \phi_{rs} K_s H_{rs}\, ds dr \\ &\quad - \int_t^T \int_r^T \left[A_r \phi_{rs} K_s \int_t^r \gamma_{\tau s}\, d\nu_\tau \right] ds dr. \end{aligned} \tag{91}$$

Interchanging the outer two orders of integration and then the inner two orders of integration in the third integral of (91) gives

$$J_t = \int_t^T K_s H_{ts}\, ds + \int_t^T A_r J_r\, dr - \int_t^T \int_t^s \left[\int_\tau^s A_r \phi_{rs}\, dr \right] K_s \gamma_{\tau s}\, d\nu_\tau\, ds. \tag{92}$$

Using (86),

$$\begin{aligned} J_t &= \int_t^T K_s H_{ts}\, ds + \int_t^T A_r J_r\, dr \\ &\quad + \int_t^T \int_t^s K_s \gamma_{\tau s}\, d\nu_\tau\, ds - \int_t^T \int_t^s \phi_{\tau s} K_s \gamma_{\tau s}\, d\nu_\tau\, ds. \end{aligned} \tag{93}$$

Using from (85) that

$$\int_t^s \gamma_{\tau s}\, d\nu_\tau = H_{ss} - H_{ts} \tag{94}$$

in the third integral of (93), and interchanging ordinary and stochastic integration in the last integral of (93), gives

$$J_t = \int_t^T K_s H_{ss}\, ds + \int_t^T A_r J_r\, dr - \int_t^T \int_\tau^T \phi_{\tau s} K_s \gamma_{\tau s}\, ds d\nu_\tau. \tag{95}$$

Now (88) follows from (95) by taking the differential.

Remark. It now follows from (33), (23), (9), (10), and Lemma 2 that (34) and (36) hold.

OPTIMAL SWITCHING IN AN ECONOMIC ACTIVITY UNDER UNCERTAINTY*

KJELL ARNE BREKKE† AND BERNT ØKSENDAL‡

Abstract. This paper considers the problem of finding the optimal sequence of opening (starting) and closing (stopping) times of a multi-activity production process, given the costs of opening, running, and closing the activities and assuming that the state of the economic system is a stochastic process. The problem is formulated as an extended impulse control problem and solved using stochastic calculus. As an application, the optimal starting and stopping strategy are explicitly found for a resource extraction when the price of the resource is following a geometric Brownian motion.

Key words. impulse control, optimal switching, options

AMS subject classifications. 60G40, 60H30

1. Introduction. The theory of optimal stopping has a wide variety of applications in economics. These applications range over real and financial options, entry to a market, or optimal start of a production process under uncertainty. In other applications it will be natural to consider the possibility of the reverse action, like exiting from a market or shutting down a production. However, optimal stopping theory does not cover situations involving both these actions, such as sequential starting and stopping. For example, there are industries where part of the production process is temporarily shut down when electricity prices are too high; at high prices all workers are relocated to other tasks and when the prices fall below a certain limit, production is restarted. When is the optimal time to shut down, then to restart, then to shut down again, etc.? Problems of this type could be called *starting and stopping problems* or *optimal switching problems*. They may be regarded as special cases of sequential optimal stopping problems.

The starting and stopping problem has been considered in various contexts. It was discussed in connection with taxes and convenience yield by Brennan and Schwartz [BS]. A similar entry and exit model (but without resource extraction) has been studied by Dixit [D]. Neither of these papers gives a rigorous mathematical proof that an optimal starting and stopping strategy exists and that it has the form stated. The more general problem of starting and stopping several activities simultaneously is considered in [MZ], in the context of oil exploration. Optimal switching for alternating processes is studied in [M], which also contains references to other related works.

The purpose of this paper is to formulate problems of this type as *generalized impulse control problems* and to solve them using stochastic calculus. Impulse control problems have been thoroughly studied in [BL]. However, their results do not seem to apply to the situations we are interested in, because the cost function, $-f$, will not be positive in our case (see §2). Nevertheless, our method is inspired by their approach. For concreteness our results are applied to the following sequential stopping problem involving resource depletion with a stochastic price development, studied in [BØ]:

Suppose it costs the amount L to open a field for resource extraction, that the running/rental cost is K per time unit and that the cost of closing down a field is C. If the price of the resource under consideration is varying as a stochastic process (to be specified below), when is the optimal time to open the field and to close it? It seems reasonable that if the field is open, it may be a good strategy to continue the extraction for a while even if the price has gone below the running costs, because there may be a chance that prices could go up again

and closing and re-opening the field is costly. On the other hand, even with such an optimistic point of view there is clearly a limit as to how low the prices can go before closing is the optimal strategy. Similarly, if the field is closed one would wait for a resource price that is higher than the running costs before opening again. But how high?

In [BØ] a candidate ϕ_0 for the solution of the resource extraction problem is found explicitly, as an application of a high contact principle for optimal stopping. But it is not proved there that this candidate actually is the solution. This will be established in this paper. More generally, we consider the problem of optimal starting and stopping of a multi-activity system under uncertainty. We prove that a given function satisfying certain quasivariational inequalities necessarily is the solution of the problem.

This paper is organized as follows: In §2 we formulate a general starting and stopping problem as an impulse control problem. In §3 we give sufficient conditions that a given function and its associated starting and stopping strategy solves the general problem in §2. Then in §4 we apply this to the specific problem of optimal resource extraction mentioned above.

2. A mathematical formulation of the problem. The problems mentioned in the introduction are special cases of the following general problem:

Suppose there are m possible "indicator vectors" $z_1, \dots, z_m$ of the state of the system. Let Z_t denote the indicator vector at time t, so that for all t

$$Z_t \in \{z_1, \dots, z_m\} =: \mathcal{Z} \tag{2.1}$$

We will assume that Z_t is right-continuous with left limits (cadlag).

Remark. If, for example, we consider a firm with k production activities which can be either "on/open" or "off/closed," then each indicator vector $z \in \mathcal{Z}$ can be represented as a k-tuple

$$z = (a_1, a_2, \dots, a_k)$$

where each a_i is either 0 (meaning activity i is closed) or 1 (meaning activity i is open). So in this case there are $m = 2^k$ possible indicator vectors. The components of an indicator vector z are called *indicator values*. In particular, in the resource extraction example there are just 2 indicator values, which we denote by 0 or 1 depending on whether the field is closed or open.

The firm's environment at time t, e.g., prices of output or input goods, is denoted by U_t. We assume that U_t is a stochastic process in $\mathbf{R}^n$ satisfying the following stochastic differential equation

$$dU_t = b(t, U_t, Z_t)dt + \sigma(t, U_t, Z_t)dB_t \tag{2.2}$$

where $b : \mathbf{R}^{n+1} \times \mathcal{Z} \to \mathbf{R}^n, \sigma : \mathbf{R}^{n+1} \times \mathcal{Z} \to \mathbf{R}^{n \times m}$ are Lipschitz functions with at most linear growth in the variables number $2, \dots, n+1$ and B_t denotes m-dimensional Brownian motion. (See e.g., [Ø] for basic information on stochastic differential equations and see [BL] regarding the solution of equations of type (2.2).)

The state of the whole economic system at time t is represented by the stochastic process

$$X_t = \begin{bmatrix} t \\ U_t \\ Z_t \end{bmatrix}. \tag{2.3}$$

The probability law of X_t given that $X_0 = x = (s, u, z)$ is denoted by P^x and expectation with respect to P^x is denoted by E^x.

An *impulse control* w for this system consists of a double (possibly finite) sequence

$$w = (\theta_1, \theta_2, \dots, \theta_k, \dots; \zeta_1, \zeta_2, \dots, \zeta_k, \cdots)_{k \le N} \qquad (N \le \infty) \tag{2.4}$$

where each $\theta_k \le \infty$ is a stopping time (with respect to the filtration $\{\mathcal{F}_t\}$ for the Brownian motion $\{B_t\}$), $\theta_k \le \theta_{k+1}$ and $\theta_k \to \infty$ almost surely (so if N is finite then $\theta_N \equiv \infty$). Associated to the impulse time θ_k is the impulse $\zeta_k \in \mathcal{Z}$, which is the new value of Z_t at time $t = \theta_k$.

We may regard $\theta_1, \theta_2, \cdots$ as the times when we decide to interfere with the system and the corresponding $\zeta_1, \zeta_2 \cdots$ are the new indicator values that we give the system at these times. We often simplify the notation and write $w = (\theta_1, \theta_2, \cdots)$. Let W denote the set of all impulse controls.

If $w \in W$ is applied to the system, it takes the form

$$X_t = X_t^{(w)} = \begin{bmatrix} t \\ U_t \\ \zeta_k \end{bmatrix} \quad \text{if } \theta_k \le t < \theta_{k+1}. \tag{2.5}$$

Note that $X_t^{(w)}$ is right-continuous for all $w \in W$. Let E^x denote the expected value when $X_0 = x = (s, u, z)$.

Let $f(x)$ denote the profit per time unit when the system is in the state x. For $x = (s, u, z) \in \mathbf{R}^{n+1} \times \mathcal{Z}$ and $\zeta \in \mathcal{Z}$ let $H(x, \zeta) \in \mathbf{R}$ be the cost of switching the indicator value from z to ζ when the state is $x = (s, u, z)$. Assume from now on that

$$E^x \left[\int_s^\infty |f(X_t^{(w)})| dt \right] < \infty \tag{2.6}$$

for all x and all $w \in W$. Then the expected total profit of running the system with the impulse control $w = (\theta_1, \theta_2, \cdots; \zeta_1, \zeta_2, \cdots) \in W$ is given by

$$J^w(x) = E^x \left[\int_s^\infty f(X_t^{(w)}) dt - \sum_{j=1}^\infty H(X_{\theta_j -}, \zeta_j) \right], \tag{2.7}$$

where $X_{\theta_j -} = \lim_{t \uparrow \theta_j} X_t$.

We assume that the switching cost function $H : \mathbf{R}^{n+1} \times \mathcal{Z} \times \mathcal{Z} \to \mathbf{R}^+$ satisfies

$$H(x, \zeta) > 0 \quad \text{for all} \quad x \in \mathbf{R}^{n+1} \times \mathcal{Z} \quad \text{and all} \quad \zeta \ne z \tag{2.8}$$

and, if $\mathcal{Z}$ consists of more than 2 elements:

$$H(s, u, z, \zeta_2) \le H(s, u, z, \zeta_1) + H(s, u, \zeta_1, \zeta_2) \quad \text{if } z \ne \zeta_1 \ne \zeta_2 \ne z. \tag{2.9}$$

We also assume that

$$(s, u) \to H(s, u, z, \zeta) \quad \text{is continuous for all } z, \zeta. \tag{2.10}$$

(The values of H when $z = \zeta$ are not used, so we only need to define $H(s, u, z, \zeta)$ for $z \ne \zeta$.)

Remarks. (1) Condition (2.9) states that if we want to switch from indicator state z to indicator state ζ_2, then it is not more expensive to do this directly (in one step) than in two steps, via an intermediate indicator value ζ_1. For example, if

$$H(s, u, z, \zeta) = e^{-\rho s} H_0(z, \zeta) \qquad (\rho \text{ constant}),$$

then (2.9) becomes the "triangle inequality"

$$H_0(z,\zeta_2) \le H_0(z,\zeta_1) + H_0(\zeta_1,\zeta_2) \qquad z \ne \zeta_1 \ne \zeta_2 \ne z.$$

If we are given a function H satisfying (2.8) and (2.10) we can always modify it to satisfy (2.9) as well, by putting

$$\tilde{H}(s,u,z,\zeta) = H(s,u,z,\zeta) \wedge \min_{z\ne\zeta_1\ne\zeta} \{H(s,u,z,\zeta_1) + H(s,u,\zeta_1,\zeta)\}.$$

If H fails to satisfy (2.9) this means that the switching cost of going from z to ζ may be reduced by first jumping to an indicator vector ζ_1 and then immediately jumping to ζ. In this case Z_t cannot be right-continuous. By introducing $\tilde{H}$ we are simply saying that we regard this kind of immediate switch from z to ζ_1 to ζ as a direct switch from z to ζ, neglecting the intermediate indicator vector ζ_1. This makes the problem essentially unchanged and now the corresponding processes Z_t will be cadlag.

(2) In the resource extraction example the switching cost function has the values

$$\begin{aligned} H(s,u,0,1) &= Le^{-\rho s} \qquad \text{(discounted opening cost)} \\ H(s,u,1,0) &= Ce^{-\rho s} \qquad \text{(discounted closing cost),} \end{aligned} \tag{2.11}$$

where $\rho > 0$ is a (constant) discount factor.

We can now formulate the switching problem as follows:

PROBLEM 2.1. Find for all $x = (s,u,z)$

$$\tilde{\phi}(x) := \sup_{w\in W} J^w(x)$$

and find, if possible, an *optimal* impulse control $\tilde{w}$, i.e., find $\tilde{w} \in W$ such that

$$\tilde{\phi}(x) = J^{\tilde{w}}(x).$$

Remark. This is essentially an impulse control problem of the type considered in [BL]. However, in [BL] it is assumed that $-f$ is positive (or lower bounded), and this is not a reasonable assumption in our economic application. Therefore it is not possible to apply their results directly to our situation.

In [BØ] a candidate $\phi_0(x)$ for the solution of Problem 2.1 in the specific application of starting and stopping a resource extraction (see §4) was found by adopting the following dynamic programming argument: Suppose the system initially is in state $x = (t,u,z)$. Then if at a stopping time τ we interfere and start/stop the system, the system gets the impulse $\zeta = 1 - z$ and then the new state becomes $X_\tau = (\tau, U_\tau, Z_\tau)$, where $Z_\tau = \zeta$. The cost of this operation is

$$H(X_{\tau^-},\zeta) = H(\tau, U_\tau, z, 1-z)$$

where H is given by (2.11) above. From then on the maximal profit is $\tilde{\phi}(X_\tau)$. This procedure can of course at most be optimal. We conclude that, for all stopping times τ,

$$\tilde{\phi}(x) \ge E^x\left[\int_s^\tau f(X_t)dt - H(X_{\tau^-}, 1 - Z_{\tau^-}) + \tilde{\phi}(X_\tau)\right]. \tag{2.12}$$

If an optimal impulse control $\tilde{w} = (\tilde{\theta}_1, \tilde{\theta}_2, \cdots)$ exists, then by choosing $\tau = \tilde{\theta}_1$ we get equality in (2.12). Hence $\tilde{\phi}$ must satisfy the equation

$$\tilde{\phi}(x) = \sup_\tau E^x\left[\int_s^\tau f(X_t)dt - H(X_{\tau^-}, 1 - Z_{\tau^-}) + \tilde{\phi}(X_\tau)\right]. \tag{2.13}$$

Using the "high contact principle" or "smooth pasting" a solution $\phi_0(x)$ of equation (2.13) for the resource extraction problem was found in [BØ]. For more information on smooth pasting see e.g., [S]. However, this does not prove that $\phi_0 = \tilde{\phi}$, because there may (a priori) be several solutions of equation (2.13). We will in §4 prove that we indeed have $\phi_0 = \tilde{\phi}$ (under certain conditions). This will be obtained as an application of the more general results we develop in §3.

3. Solution of the optimal switching problem. From now on we put, for fixed $z \in \mathcal{Z}$,

$$Y_t = (t, U_t, z) \qquad (= (t, U_t) \text{ if we suppress } z) \tag{3.1}$$

so that Y_t represents the state of the system corresponding to the "non-interference" impulse control $w_\infty = (\theta_1)$ where $\theta_1 = \infty$. Then Y is a diffusion with generator A given by

$$A = \frac{\partial}{\partial s} + \sum_{i=1}^{n} b_i \frac{\partial}{\partial u_i} + \frac{1}{2} \sum_{i,j=1}^{n} (\sigma\sigma^T)_{ij} \frac{\partial^2}{\partial u_i \partial u_j}. \tag{3.2}$$

In the following we suppress the constant z and regard Y_t as the $(n+1)$-dimensional process (t, U_t).

The following concept is useful:

DEFINITION 3.1. We say that a continuous function $g(x)$ is *stochastically* C^2 in a domain $D \subset \mathbf{R}^{n+1}$ (with respect to Y_t) if all the first partial derivatives of g with respect to t and u and all the second partial derivatives of g with respect to u exist almost everywhere in D with respect to the *Green measures* $G(y, \cdot)$ of Y_t and the following *generalized Dynkin formula* holds:

$$E^y[g(Y_{\theta'})|\mathcal{F}_\theta] = g(Y_\theta) + E^y\left[\int_\theta^{\theta'} Ag(Y_t)dt|\mathcal{F}_\theta\right] \tag{3.3}$$

for all $y \in D$ and for all stopping times $\theta \le \theta' \le \tau_D$, where $\mathcal{F}_\theta$ is the filtration generated by $\{B_{t\wedge\theta}(\cdot)\}_{t\ge 0}$,

$$\tau_D = \inf\{t > 0; Y_t \notin D\} \tag{3.4}$$

and we assume $E^y[\tau_D] < \infty$.

Remark. The *Green measure* $G(y, \cdot)$ is defined by

$$G(y, F) = E^y\left[\int_0^{\tau_D} \chi_F(Y_t)dt\right]; \qquad y \in D, F \quad \text{Borel set in } D.$$

In (3.3) Ag is the operator A applied to g, which makes sense almost everywhere $G(y, \cdot)$ and therefore makes sense in (3.3).

By the classical Dynkin formula all C^2 functions g that satisfy $E^y[\int_0^{\tau_D} |Ag(Y_t)|dt] < \infty$ for all y are stochastically C^2. In [BØ, Lem. 1] conditions are given which imply that a C^1 function that is C^2 outside a "thin" (in a measure sense) regular set is stochastically C^2. This turns out to be sufficient for the application in §4.

Recall that we have assumed that

$$E^x\left[\int_0^\infty |f(X_t^{(w)})|dt\right] < \infty \tag{3.5}$$

for all x and all $w \in W$.

LEMMA 3.2. *Suppose $\phi(s,u,z)$ is a stochastically C^2 function in $D = \mathbf{R}^{n+1}$ with respect to Y_t satisfying the three conditions*

$$\phi(t, U_t, z) \to 0 \quad \text{as } t \to \infty \quad \text{a.s. } P^y \quad \text{for all } z \in \mathcal{Z}; y = (s,u,z), \tag{3.6}$$

the family

$$\{\phi(\tau, U_\tau, z)\}_{\tau \in \mathcal{T}} \tag{3.7}$$

is uniformly integrable with respect to P^y for all $z \in \mathcal{Z}$, where $\mathcal{T}$ is the set of all $\mathcal{F}_t$-stopping times and

$$A\phi + f \leq 0 \quad \text{a.e. with respect to } G(y,\cdot). \tag{3.8}$$

Let $s \leq \theta \leq \theta' \leq \infty$ be two stopping times. Then for all $y = (s,u,z)$ and all z_0 we have

$$\phi(\theta, U_\theta, z_0) \geq E^y\left[\int_\theta^{\theta'} f(Y_t)dt + \phi(\theta', U_{\theta'}, z_0)|\mathcal{F}_\theta\right]. \tag{3.9}$$

(We interpret $\phi(\tau, U_\tau, z_0)$ as 0 if $\tau = \infty$ ($\tau = \theta$ or θ')).

Remark. The requirement that ϕ be stochastically C^2 corresponds to the "high contact" condition in optimal stopping. See [BØ].

Proof. Choose a constant $T < \infty$ and apply the generalized Dynkin formula (3.3) to $g(s,u,z) = \phi(s,u,z)$:

$$E^y[\phi(\theta' \wedge T, U_{\theta' \wedge T}, z)|\mathcal{F}_\theta] = \phi(\theta \wedge T, U_{\theta \wedge T}, z) + E^y\left[\int_{\theta \wedge T}^{\theta' \wedge T} A\phi(t, U_t, z)dt|\mathcal{F}_\theta\right].$$

By (3.8) this gives

$$\phi(\theta \wedge T, U_{\theta \wedge T}, z) \geq E^y\left[\int_{\theta \wedge T}^{\theta' \wedge T} f(Y_t)dt + \phi(\theta' \wedge T, U_{\theta' \wedge T}, z)|\mathcal{F}_\theta\right].$$

Now let $T \to \infty$. Then by continuity

$$\phi(\theta \wedge T, U_{\theta \wedge T}, z) \to \phi(\theta, U_\theta, z)$$

and by (3.5)

$$E^y\left[\int_{\theta \wedge T}^{\theta' \wedge T} f(Y_t)dt\right] \to E^y\left[\int_\theta^{\theta'} f(Y_t)dt\right].$$

Finally, by (3.6) and (3.7)

$$E^y[\phi(\theta' \wedge T, U_{\theta' \wedge T}, z)|\mathcal{F}_\theta] \to E^y[\phi(\theta', U_{\theta'}, z)|\mathcal{F}_\theta].$$

This gives (3.9).

Define the *switching operator* M on the family $\mathcal{H}$ of Borel measurable functions on $\mathbf{R}^{n+1} \times \mathcal{Z}$ by

$$Mh(s,u,z) = \max_{\zeta \in \mathcal{Z} \setminus \{z\}} \{h(s,u,\zeta) - H(x,\zeta)\}; \qquad h \in \mathcal{H}, \qquad x = (s,u,z) \tag{3.10}$$

where H is the switching cost function (see (2.8)–(2.10)).

Note that

$$h(s,u,z) \geq Mh(s,u,z) \Leftrightarrow h(s,u,z) \geq h(s,u,\zeta) - H(x,\zeta) \quad \text{for all } \zeta \neq z. \quad \square \tag{3.11}$$

We are now ready for the first main result of this paper.

THEOREM 3.3. *Let ϕ be a stochastically C^2 function (with respect to Y_t) satisfying* (3.6), (3.7), (3.8), *as well as the condition*

$$\phi \geq M\phi \quad \text{everywhere} \tag{3.12}$$

Then

$$\phi(x) \geq J^w(x) \quad \text{for all} \quad w \in W \quad \text{and all } x = (s,u,z). \tag{3.13}$$

Proof. Let $w = (\theta_1, \theta_2, \cdots)$ with $\theta_1 \geq s$, let $X_t = X_t^{(w)} = (t, U_t, Z_t)$ and put $\theta_0 = s$. Since $\phi \geq M\phi$ we get by (3.11) and Lemma 3.2 applied to $\theta = \theta_k, \theta' = \theta_{k+1}$, and $z_0 = Z_{\theta_k}; k = 0,1,2,\ldots$:

$$\begin{aligned}\phi(\theta_k, U_{\theta_k}, Z_{\theta_k}) &\geq E^y\left[\int_{\theta_k}^{\theta_{k+1}} f(X_t)dt + \phi(\theta_{k+1}, U_{\theta_{k+1}}, Z_{\theta_k})|\mathcal{F}_{\theta_k}\right] \\ &\geq E^y\left[\int_{\theta_k}^{\theta_{k+1}} f(X_t)dt + \phi(\theta_{k+1}, U_{\theta_{k+1}}, \zeta_{k+1}) - H(X_{\theta_{k+1}^-}, \zeta_{k+1})|\mathcal{F}_{\theta_k}\right].\end{aligned} \tag{3.14}$$

Now $\zeta_{k+1} = Z_{\theta_{k+1}}$ by (2.5); so if we take expectation and sum from $k = 0$ to $k = n-1$, we get, with $y = (s,u,z)$,

$$\begin{aligned}&\phi(s,u,z) + \sum_{k=1}^{n-1} E^y[\phi(\theta_k, U_{\theta_k}, Z_{\theta_k})] \\ &\geq E^y\left[\int_s^{\theta_n} f(X_t)dt - \sum_{k=1}^{n} H(X_{\theta_k^-}, Z_{\theta_k}) + \sum_{k=1}^{n} \phi(\theta_k, U_{\theta_k}, Z_{\theta_k})\right].\end{aligned} \tag{3.15}$$

Hence

$$\phi(s,u,z) \geq E^y\left[\int_s^{\theta_n} f(X_t)dt - \sum_{k=1}^{n} H(X_{\theta_k^-}, Z_{\theta_k}) + \phi(\theta_n, U_{\theta_n}, Z_{\theta_n})\right]. \tag{3.16}$$

Now let $n \to \infty$. Then $\theta_n \to \infty$ and by (3.6) and (3.7) we get

$$\phi(s,u,z) \geq E^y\left[\int_s^{\infty} f(X_t)dt + \sum_{k=1}^{\infty} H(X_{\theta_k^-}, Z_{\theta_k})\right],$$

which is (3.13). $\square$

Next we find an optimal impulse control and the corresponding minimal expected cost.

THEOREM 3.4. *Suppose $\hat{\phi} = \hat{\phi}(t,u,z)$ is a stochastically C^2 function (with respect to Y_t) satisfying* (3.6), (3.7), (3.8), (3.12) *and in addition that*

$$A\hat{\phi} + f = 0 \quad \text{on } \{(s,u,z); \hat{\phi}(s,u,z) > M\hat{\phi}(s,u,z)\}. \tag{3.17}$$

Define the impulse control $\hat{w} = (\hat{\theta}_1, \hat{\theta}_2, \ldots; \hat{\zeta}_1, \hat{\zeta}_2, \cdots)$ *as follows: Put*

$$\hat{\theta}_1 = \inf\{t > 0; \hat{\phi}(X_t^{(0)}) = M\hat{\phi}(X_t^{(0)})\}, \quad \text{where } X_t^0 = Y_t, \tag{3.18}$$

and choose $\hat{\zeta}_1$ *such that*

$$M\hat{\phi}(X_{\hat{\theta}_1}^{(0)}) = \hat{\phi}(\hat{\theta}_1, U_{\hat{\theta}_1}, \hat{\zeta}_1) - H(X_{\hat{\theta}_1}^{(0)}, \hat{\zeta}_1). \tag{3.19}$$

Define

$$Z_t^{(1)} = \begin{cases} z & \text{if } 0 \le t < \hat{\theta}_1 \\ \hat{\zeta}_1 & \text{if } \hat{\theta}_1 \le t, \end{cases}$$

and put

$$dX_t^{(1)} = \begin{bmatrix} dt \\ dU_t \\ dZ_t^{(1)} \end{bmatrix},$$

i.e., $X_t^{(1)}$ *is the result of applying the impulse control* $\hat{w}_1 = (\hat{\theta}_1, \infty; \hat{\zeta}_1)$ *to* Y_t.

Inductively, if stopping times $0 \le \hat{\theta}_1 \le \hat{\theta}_2 \le \cdots \le \hat{\theta}_k$ *with corresponding impulses* $\hat{\zeta}_1, \ldots, \hat{\zeta}_k$ *have been constructed, define*

$$\hat{\theta}_{k+1} = \inf\{t > \hat{\theta}_k; \hat{\phi}(X_t^{(k)}) = M\hat{\phi}(X_t^{(k)})\}, \qquad k \ge 0, \tag{3.20}$$

where for $k \ge 1$, $X_t^{(k)}$ *is the result of applying the impulse control* $\hat{w}_k = (\hat{\theta}_1, \cdots, \hat{\theta}_k, \infty)$ *to* Y_t. *Next choose* $\hat{\zeta}_{k+1}$ *such that*

$$M\hat{\phi}(\hat{\theta}_{k+1}, U_{\hat{\theta}_{k+1}}, \hat{\zeta}_k) = \hat{\phi}(\hat{\theta}_{k+1}, U_{\hat{\theta}_{k+1}}, \hat{\zeta}_{k+1}) - H(X_{\hat{\theta}_{k+1}}^{(k)}, \hat{\zeta}_{k+1}). \tag{3.21}$$

Then $\hat{w} \in W$ *and*

$$\hat{\phi}(x) = J^{\hat{w}}(x); \tag{3.22}$$

$$\hat{w} \text{ is optimal for Problem } 2.1, \tag{3.23}$$

and

$$\hat{\phi} = \tilde{\phi}. \tag{3.24}$$

Proof. We repeat the arguments of the proofs of Lemma 3.2 and Theorem 3.3. First note that between $\hat{\theta}_k$ and $\hat{\theta}_{k+1}$ we have $A\hat{\phi} = -f$ so we get equality if we apply Lemma 3.2 to $\theta_k = \hat{\theta}_k, \theta_{k+1} = \hat{\theta}_{k+1}$, and $\phi = \hat{\phi}$. Therefore we get equality in (3.15) so that for all n we have

$$\hat{\phi}(s,u,z) = E^y\left[\int_s^{\hat{\theta}_n} f(X_t)dt - \sum_{k=1}^{n} H(X_{\hat{\theta}_k^-}, Z_{\hat{\theta}_k}) + \hat{\phi}(\hat{\theta}_n, U_{\hat{\theta}_n}, Z_{\hat{\theta}_n})\right]. \tag{3.25}$$

Put $F = \{\omega; \lim_{n\to\infty} \hat{\theta}_n(\omega) < \infty\}$ and $\hat{\theta} = \lim_{n\to\infty} \hat{\theta}_n$. Then letting $n \to \infty$ in (3.25) we get

$$\hat{\phi}(s,u,z) = E^y\left[\int_s^{\hat{\theta}} f(X_t)dt - \sum_{k=1}^{\infty} H(X_{\hat{\theta}_k^-}, Z_{\hat{\theta}_k}) + \hat{\phi}(\hat{\theta}, U_{\hat{\theta}}, Z_{\hat{\theta}}) \cdot \chi_F\right]. \tag{3.26}$$

But if $\omega \in F$, we have that $(\hat{\theta}_k, U_{\hat{\theta}_k}) \to (\hat{\theta}, U_{\hat{\theta}})$ and therefore by (2.9) there exists $a(\omega) > 0$ such that

$$H(X_{\hat{\theta}_k^-}, Z_{\hat{\theta}_k}) \geq a(\omega) \quad \text{for } w \in F \quad \text{for all } k,$$

which gives

$$\sum_{k=1}^{\infty} H(X_{\hat{\theta}_k^-}, Z_{\hat{\theta}_k}) = \infty \quad \text{for } \omega \in F.$$

From (3.26) and (3.5) we can conclude that $P^x(F) = 0$, which shows that $\hat{\theta}_n \to \infty$ almost surely. Therefore $\hat{w} \in W$.

Now we can apply Theorem 3.3 to $\phi = \hat{\phi}, w = \hat{w}$, and by condition (3.17) we get equality in (3.13). So

$$\hat{\phi}(x) = J^{\hat{w}}(x),$$

while from Theorem 3.3

$$\hat{\phi}(x) \geq J^{w}(x) \quad \text{for all } w \in W.$$

It follows that $\hat{w}$ is optimal and that

$$\hat{\phi}(x) = \sup_{w \in W} J^{w}(x) = \tilde{\phi}(x), \text{ as claimed.} \qquad \square$$

Remark. Note that $\hat{\theta}_k$ is the first exit time after $\hat{\theta}_{k-1}$ for $X_t^{(\hat{w})}$ from the set

$$D = \{x; \hat{\phi}(x) > M\hat{\phi}(x)\}. \tag{3.27}$$

Therefore, writing $X_t = X_t^{(\hat{w})}$, we have

$$\begin{aligned} \hat{\phi}(X_{\hat{\theta}_k}) &= M\hat{\phi}(X_{\hat{\theta}_k^-}) + H(X_{\hat{\theta}_k^-}, \hat{\zeta}_k) \\ &= \hat{\phi}(X_{\hat{\theta}_k^-}) + H(X^{(k)}_{\hat{\theta}_k^-}, \hat{\zeta}_k). \end{aligned} \tag{3.28}$$

Suppose we have strict inequality in (2.9), i.e.,

$$H(s,u,z,\zeta_2) < H(s,u,z,\zeta_1) + H(s,u,\zeta_1,\zeta_2) \quad \text{if } z \neq \zeta_1 \neq \zeta_2 \neq z. \tag{3.29}$$

Then if $\hat{\zeta}_{k-1} \neq \zeta \neq \hat{\zeta}_k$, we have

$$\begin{aligned} \hat{\phi}(X_{\hat{\theta}_k}) &\geq \hat{\phi}(\hat{\theta}_k, U_{\hat{\theta}_k}, \zeta) - H(X_{\hat{\theta}_k^-}, \zeta) + H(X_{\hat{\theta}_k^-}, \hat{\zeta}_k) \\ &= \hat{\phi}(\hat{\theta}_k, U_{\hat{\theta}_k}, \zeta) - H(X_{\hat{\theta}_k}, \zeta) \\ &\quad + [H(\hat{\theta}_k, U_{\hat{\theta}_k}, \hat{\zeta}_{k-1}, \hat{\zeta}_k) + H(\hat{\theta}_k, U_{\hat{\theta}_k}, \hat{\zeta}_k, \zeta) - H(\hat{\theta}_k, U_{\hat{\theta}_k}, \hat{\zeta}_{k-1}, \zeta)] \\ &> \hat{\phi}(\hat{\theta}_k, U_{\hat{\theta}_k}, \zeta) - H(X_{\hat{\theta}_k}, \zeta), \quad \text{by (3.29).} \end{aligned} \tag{3.30}$$

Moreover, by (3.28) we have

$$\begin{aligned} \hat{\phi}(\hat{\theta}_k, U_{\hat{\theta}_k}, \hat{\zeta}_k) &= \hat{\phi}(\hat{\theta}_k, U_{\hat{\theta}_k}, \hat{\zeta}_{k-1}) + H(\hat{\theta}_k, U_{\hat{\theta}_k}, \hat{\zeta}_{k-1}, \hat{\zeta}_k) \\ &> \hat{\phi}(\hat{\theta}_k, U_{\hat{\theta}_k}, \hat{\zeta}_{k-1}) - H(\hat{\theta}_k, U_{\hat{\theta}_k}, \hat{\zeta}_k, \hat{\zeta}_{k-1}). \end{aligned} \tag{3.31}$$

Combining (3.30) and (3.31) we get

$$\hat{\phi}(X_{\hat{\theta}_k}) > M\hat{\phi}(X_{\hat{\theta}_k}). \tag{3.32}$$

So we see that if (3.29) holds, then the new impulse $\hat{\zeta}_k$ brings the state X_t back into D at the instant $\hat{\theta}_k$ when X_t first hits ∂D (the boundary of D) after $\hat{\theta}_{k-1}$. Thus the optimal strategy can be illustrated as in Fig. 1.

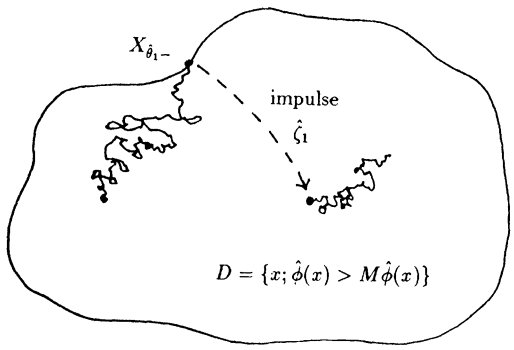

FIG. 1

4. Application to resource extraction. We assume that the price P_t at time t per unit of the resource follows a geometric Brownian motion. This means that P_t is the solution of a stochastic differential equation of the form

$$dP_t = \alpha P_t dt + \beta P_t dB_t, \tag{4.1}$$

where α, β are constants and B_t is a one-dimensional Brownian motion. The solution P_t of (4.1) is

$$P_t = P_0 \exp\left(\left(\alpha - \frac{1}{2}\beta^2\right)t + \beta B_t\right) \quad \text{for } t \geq 0. \tag{4.2}$$

Let Q_t denote the stock of remaining resources in the field. We assume that when the field is open, extraction rate is proportional to the amount of remaining reserves. In other words,

$$dQ_t = -\lambda Z_t Q_t dt, \tag{4.3}$$

where $\lambda > 0$ is a constant and

$$Z_t = \begin{cases} 1 & \text{if the field is open at time } t \\ 0 & \text{if the field is closed at time } t. \end{cases} \tag{4.4}$$

The state X_t of the system at time t is characterized by the four quantities t, P_t, Q_t, Z_t:

$$X_t = \begin{bmatrix} t \\ P_t \\ Q_t \\ Z_t \end{bmatrix}. \tag{4.5}$$

If there is a constant running cost $K > 0$ per time unit, the net discounted profit rate f is given by

$$f(x) = f(s, p, q, z) = (\lambda pq - K)ze^{-\rho s}. \tag{4.6}$$

So in this case Problem 2.1 becomes

$$\tilde{\phi}(x) = \sup_{w \in W}\left\{E^x\left[\int_s^\infty (\lambda P_t Q_t - K)Z_t e^{-\rho t}dt - \sum_j H(X_{\theta_j^-}, 1 - Z_{\theta_j^-})\right]\right\}, \tag{4.7}$$

where H is given by (2.11).

Remark. (1) Note that if we define

$$\Gamma_t = P_t Q_t,$$

then Γ_t satisfies the stochastic differential equation

$$d\Gamma_t = (\alpha - \lambda Z_t)\Gamma_t dt + \beta \Gamma_t dB_t.$$

Furthermore, P_t and Q_t only enter the objective function as $P_t Q_t = \Gamma_t$. Hence the problem could have been reformulated using only Γ_t, and consequently p and q will enter the solution in the form of the product pq.

(2) It is natural to ask if a better performance could be obtained if, instead of either having the field open at full production or entirely closed, we allow the field to be partially open at all times. If we assume that we can avoid opening and closing costs this way, but have the same running cost K, the problem can be formulated as a stochastic control problem as follows:

$$\Phi(x) = \sup_{\mu_t} E^x \left[\int_s^\infty (\lambda \mu_t P_t Q_t - K) e^{-\rho t} dt \right],$$

where $\mu_t = \mu(X_t) \in (0,1)$ represents the degree of production (fraction of full production) we choose at state X_t and where

$$dQ_t = -\lambda \mu_t Q_t dt,$$

while P_t is as before. The Hamilton-Jacobi-Bellman equation for this problem states that (see e.g., [Ø, Ch. 11]):

$$\sup_{m \in (0,1)} \left\{ (\lambda m p q - K) e^{-\rho t} + \frac{\partial \Phi}{\partial t} + \alpha p \frac{\partial \Phi}{\partial p} + \frac{1}{2} \beta^2 p^2 \frac{\partial^2 \Phi}{\partial p^2} - \lambda m q \frac{\partial \Phi}{\partial q} \right\} = 0$$

and that an optimal choice of μ (if it exists) is a value of m for which the supremum is attained. However, in this case the expression is affine in m, so it is clear that no such $m \in (0,1)$ exists. This indicates that the optimal production is "bang-bang": either full production or no production at all. Therefore it is plausible that it suffices to consider the sequential stopping problem (4.7).

Using the high contact principle it is proved in [BØ] that a solution $\phi_0(x) = \phi_0(s,p,q,z)$ of the dynamic programming equation (2.12) corresponding to (4.7) is given by

$$\phi_0(s,p,q,z) = e^{-\rho s} \psi_0(p,q,z), \tag{4.8}$$

where

$$\psi_0(p,q,z) = \begin{cases} u(p,q) - L & \text{if } z = 0 \,\&\, p \geq \xi/q \\ zu(p,q) + (1-z)v(p,q) & \text{if } z = 0 \,\&\, p < \xi/q \\ & \text{or } z = 1 \,\&\, p > \eta/q \\ v(p,q) - C & \text{if } z = 1 \,\&\, p \leq \eta/q. \end{cases} \tag{4.9}$$

Here $u(p,q)$ refers to the open field, and $v(p,q)$ refers to the closed field.

It is proved in [BØ] that $u(p,q)$ and $v(p,q)$ satisfy the following partial differential equations:

$$-ru - \lambda q \frac{\partial u}{\partial q} + \alpha p \frac{\partial u}{\partial p} + \frac{1}{2} \beta^2 p^2 \frac{\partial^2 u}{\partial p^2} = -\lambda p q + K$$

and

$$-rv + \alpha p \frac{\partial v}{\partial p} + \frac{1}{2}\beta^2 p^2 \frac{\partial^2 v}{\partial p^2} = 0.$$

Combined with the boundary values deduced from the high contact principle, this gives the following expressions for u and v:

$$u(p,q) = \frac{pq}{\rho + \lambda - \alpha} - \frac{K}{\rho} + k_1 (pq)^{\nu} \tag{4.10}$$

and

$$v(p,q) = k_2 (pq)^{\gamma} \tag{4.11}$$

with

$$\gamma = \beta^{-2}\left[-\alpha + \frac{1}{2}\beta^2 + \sqrt{\left(\alpha - \frac{1}{2}\beta^2\right)^2 + 2\rho\beta^2}\right] > 1 \quad \text{if } \rho > \alpha, \tag{4.12}$$

$$\nu = \beta^{-2}\left[-\alpha + \lambda + \frac{1}{2}\beta^2 - \sqrt{\left(\alpha - \lambda - \frac{1}{2}\beta^2\right)^2 + 2\rho\beta^2}\right] < 0, \tag{4.13}$$

and $k_1, k_2, \xi > \eta > 0$ are constants that solve the following system of equations:

$$\frac{\xi}{\rho + \lambda - \alpha} + k_1 \xi^{\nu} = k_2 \xi^{\gamma} + \frac{K}{\rho} + L, \tag{4.14}$$

$$\frac{\xi}{\rho + \lambda - \alpha} + \nu k_1 \xi^{\nu} = \gamma k_2 \xi^{\gamma}, \tag{4.15}$$

$$\frac{\eta}{\rho + \lambda - \alpha} + k_1 \eta^{\nu} = k_2 \eta^{\gamma} + \frac{K}{\rho} - C, \tag{4.16}$$

$$\frac{\eta}{\rho + \lambda - \alpha} + \nu k_1 \eta^{\nu} = \gamma k_2 \eta^{\gamma}. \tag{4.17}$$

(Note that (4.14)–(4.17) are the "high contact" equations; (4.14) and (4.15) imply that ψ_0 is C^1 across ξ, and (4.16) and (4.17) imply that ψ_0 is C^1 across η.)

It is proved in [BØ] that if we assume that

$$\rho > \alpha \tag{4.18}$$

and that

$$\text{the system (4.14)–(4.17) has a solution} \quad k_1, k_2, \xi > \eta > 0, \tag{4.19}$$

then (2.13) holds for ϕ_0, i.e.,

$$\phi_0(x) = \sup_{\tau} E^x \left[\int_s^{\tau} (\lambda P_t Q_t - K) Z_t e^{-\rho t} dt - H(X_{\tau^-}, 1 - Z_{\tau^-}) + \phi_0(X_{\tau})\right]. \tag{4.20}$$

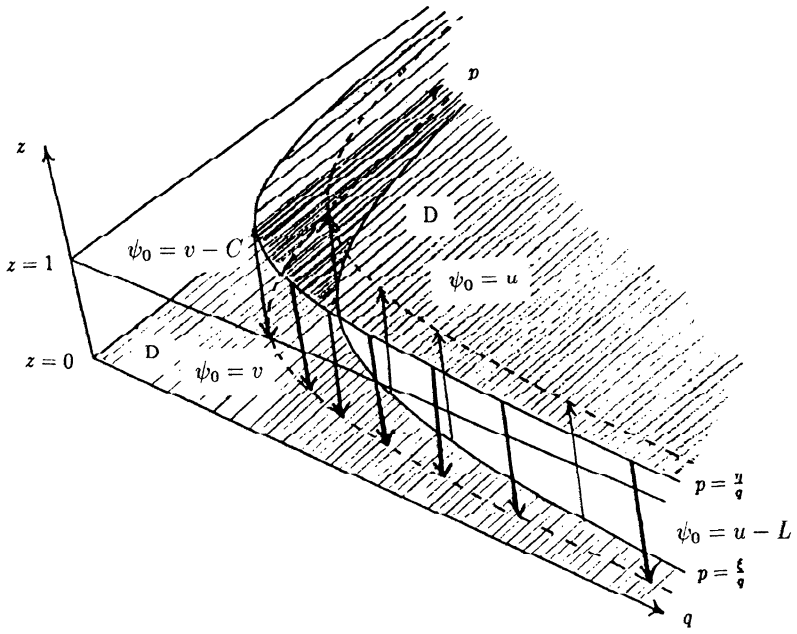

FIG. 2

However, as pointed out earlier this does not imply that $\phi_0 = \tilde{\phi}$, because it is not clear whether the solution of (2.13) is unique.

Remark. We have not been able to derive tractable general conditions for the existence of a solution of the system (4.14)–(4.17). Note, however, that there clearly exist parameter values such that the solution set is not empty. For example, if we choose $\xi > \eta > 0$ and solve (4.15) and (4.17) for k_1, k_2 (a linear system) and substitute these values in (4.14) and (4.16), then we can solve the other equations for, say, L and C if the remaining parameter values are given.

The strategy $w \in W$ corresponding to the candidate ϕ_0 is illustrated in Fig. 2, and can be described as follows (see §3):

(4.21) $$\begin{cases} \text{Jump from the } z = 0 \text{ level (closed field) to the } z = 1 \text{ level} \\ \text{(open field) as soon as } P_tQ_t \geq \xi \text{ and jump from } z = 1 \text{ to } z = 0 \\ \text{as soon as } P_tQ_t \leq \eta. \end{cases}$$

Put

$$H_0(z, \zeta) = \begin{cases} L & \text{if } z = 0, \zeta = 1 \\ C & \text{if } z = 1, \zeta = 0. \end{cases}$$

Then

$$H(s, u, z, \zeta) = e^{-\rho s} H_0(z, \zeta).$$

From (4.9) we see that

$$\psi_0(p, q, 0) = \psi_0(p, q, 1) - H_0(0, 1) \quad \text{if } p \geq \xi/q (\Rightarrow p \geq \eta/q)$$
$$\psi_0(p, q, 1) = \psi_0(p, q, 0) - H_0(1, 0) \quad \text{if } p \leq \eta/q (\Rightarrow p \leq \xi/q)$$

and for other values of (p, q, z) we have

$$\psi_0(p, q, z) > \psi_0(p, q, 1 - z) - H_0(z, 1 - z).$$

We conclude that with M defined as in (3.10),

$$\psi_0(p, q, z) \geq M\psi_0(p, q, z) \quad \text{for all } (p, q, z) \tag{4.22}$$

and if we define *the continuation region*

$$D = \{(p, q, z); \qquad z = 0 \text{ and } p < \xi/q \text{ or } z = 1 \text{ and } p > \eta/q\}, \tag{4.23}$$

then

$$(p, q, z) \in D \Leftrightarrow \psi_0(p, q, z) > M\psi_0(p, q, z). \tag{4.24}$$

It follows from [BØ, Lem. 1] that

$$\phi_0 \text{ is stochastically } C^2 \text{ with respect to } Y_t. \tag{4.25}$$

In this case the generator A of Y_t in (3.2) takes the form

$$Ag(t, p, q) = \frac{\partial g}{\partial t} + \alpha p \frac{\partial g}{\partial p} - \lambda q \frac{\partial g}{\partial q} + \frac{1}{2}\beta^2 p^2 \frac{\partial^2 g}{\partial p^2}. \tag{4.26}$$

In particular, if $g(s, p, q) = e^{-\rho s}h(p, q)$, then

$$Ag = e^{-\rho s}A_0 h, \tag{4.27}$$

where

$$A_0 h(p, q) = -\rho h + \alpha p \frac{\partial h}{\partial p} - \lambda q \frac{\partial h}{\partial q} + \frac{1}{2}\beta^2 p^2 \frac{\partial^2 h}{\partial p^2}. \tag{4.28}$$

We now claim that

$$A_0\psi_0 + f_0 = 0 \quad \text{in } D, \tag{4.29}$$

and interpreting A_0 in the almost everywhere $G(y, \cdot)$ sense (as with A above),

$$A_0\psi_0 + f_0 \leq 0 \quad \text{a.e. in } \mathbf{R}^+ \times \mathbf{R}^+ \times \{0, 1\}, \tag{4.30}$$

where $f_0 = (\lambda pq - K)z$, i.e., $f_0 = e^{\rho t}f$.

Remark. Let $D_1 = \{(p, q); (p, q, 1) \in D\}$ and $D_0 = \{(p, q); (p, q, 0) \in D\}$. Then by (4.24) we have $D_1 \cup D_0 = \mathbf{R}^+ \times \mathbf{R}^+$. So for all (p, q) we have from (4.29) that $A_0\psi_0(p, q) + f_0(p, q, z) = 0$ for some $z \in \{0, 1\}$. The requirement (4.30) can thus be written

$$f_0(p, q, z) \leq f_0(p, q, 1 - z) \quad \text{outside } D,$$

i.e., *if we are switching from state z, we must switch to a state with greater profit rate.*

Proof of (4.29). Recall that in [BØ] (formulas (75) and (76)) it is proved (and it is easily checked) that

$$A_0 v = 0 \quad \text{when } z = 0 \tag{4.31}$$

and

$$A_0 u = -f_0 \quad \text{when } z = 1. \tag{4.32}$$

From (4.31) and (4.9) we conclude that

$$A_0\psi_0 = A_0 v = 0(= -f_0) \quad \text{when } z = 0 \text{ and } p < \frac{\xi}{q}. \tag{4.33}$$

Similarly, from (4.32) and (4.9) we get

$$A_0\psi_0 = A_0 u = -f_0 \quad \text{when } z = 1 \text{ and } p > \frac{\eta}{q}. \tag{4.34}$$

Equation (4.29) follows from (4.33) and (4.34). □

Proof of (4.30). Equation (4.30) is a consequence of (4.20).

The general theory of optimal stopping (see e.g., [Ø]) gives that the right hand side of (4.20)—and hence ϕ_0 itself—is superharmonic with respect to the opertor $g \to A_0 g + f_0$. This implies that $A\phi_0 + f_0 \leq 0$ outside ∂D and hence almost everywhere with respect to $G(y, \cdot)$. □

Next we give a condition which ensures that f satisfies (3.5).

LEMMA 4.1. *Assume that*

$$\rho > \alpha. \tag{4.35}$$

Then

$$E^x\left[\int_0^\infty |f(X_t^{(w)})|dt\right] < \infty \quad \textit{for all } w \in W.$$

Proof. Since $Z_t \leq 1$ and $Q_t \leq Q_0$ for all t and all w it suffices to prove that

$$E^y\left[\int_0^\infty P_t e^{-\rho t} dt\right] < \infty \quad \text{for } y = (0, p, q, 1).$$

Now

$$P_t = p \cdot \exp\left(\left(\alpha - \frac{1}{2}\beta^2\right)t + \beta B_t\right).$$

Hence

$$E^y\left[\int_0^\infty P_t e^{-\rho t} dt\right] = \int_0^\infty \exp((\alpha - \rho)t)dt < \infty$$

since $\alpha - \rho < 0$. □

Finally we observe from (4.9) that the function $\phi_0 = e^{-\rho t}\psi_0$ satisfies (3.6). To verify (3.7) choose $\varepsilon > 0$ and consider

$$R_t = P_t^{1+\varepsilon} e^{-\rho(1+\varepsilon)t} = p^{1+\varepsilon} \cdot \exp\left(\left(\alpha - \frac{1}{2}\beta^2 - \rho\right)(1+\varepsilon)t + \beta(1+\varepsilon)B_t\right).$$

Note that

$$R_t = R_0 + \int_0^t \gamma R_s ds + \int_0^t \sigma R_s dB_s,$$

where

$$\sigma = \beta(1+\varepsilon)$$

and

$$\gamma = \left(\alpha - \frac{1}{2}\beta^2 - \rho\right)(1+\varepsilon) + \frac{1}{2}\beta^2(1+\varepsilon)^2 = (\alpha-\rho) + \varepsilon\left(\alpha + \frac{1}{2}\beta^2 - \rho + \frac{1}{2}\beta^2\varepsilon\right).$$

Choose $\varepsilon > 0$ so small that $\gamma < 0$ and let τ be a stopping time. For all natural numbers N we have

$$E^x[|\phi_0(\tau \wedge N, U_{\tau\wedge N}, z)|^{1+\varepsilon}] \leq q^{1+\varepsilon} E^x[R_{\tau\wedge N}]$$
$$= (pq)^{1+\varepsilon} + E^x\left[\int_0^{\tau\wedge N} \gamma R_s ds\right] \leq (pq)^{1+\varepsilon}.$$

Letting $N \to \infty$ we get

$$E^x[|\phi_0(\tau, U_\tau, z)|^{1+\varepsilon}] \leq (pq)^{1+\varepsilon}$$

for all stopping times τ. This implies (3.7).

Summing up we conclude the following.

THEOREM 4.2. *Assume that* (4.19) *and* (4.35) *hold. Then the function* $\phi_0 = e^{-\rho t}\psi_0$ *given by* (4.9) *solves the starting and stopping problem* (4.7).

The corresponding optimal impulse control $\hat{w}$ is given by (4.21).

Proof. By (4.35) f satisfies condition (3.5). The function $\phi = \phi_0$ satisfies conditions (3.6), (3.7), as well as (3.8), (3.12), and (3.17) in virtue of (4.30), (4.22), and (4.29), respectively. Therefore Theorem 3.4 applies to ϕ_0 and the proof is complete. □

L^∞-EXACT OBSERVABILITY OF THE HEAT EQUATION WITH SCANNING POINTWISE SENSOR*

ALEXANDER KHAPALOV†

Abstract. The problem of exact observability of the heat equation in an arbitrary space dimension with scanning pointwise sensor is considered in the case when the space for outputs is $L^\infty(\varepsilon,\theta)$, $\varepsilon > 0$. A new method for the construction of observation curves for sensors that are able to ensure $L^\infty(\varepsilon,\theta)$-exact observability at final time is given, based on the maximum principle for the heat equation. An application of the method to the observability problem with discrete-time scanning observations and related approximate controllability results are also discussed.

Key words. observability, controllability, the heat equation, scanning pointwise sensors

1. Introduction, statement of problem. Let Ω be a bounded domain of an n-dimensional Euclidean space R^n with a boundary $\partial\Omega$ of the class C^{2s_0+1}, where $2s_0+1 \geq [n/2]+3$. In Ω we consider the following homogeneous boundary problem:

$$\begin{gathered}\frac{\partial u(x,t)}{\partial t} = \Delta u(x,t),\\ t \in T = (0,\theta), \quad x \in \Omega \subset R^n, \quad Q = \Omega \times T, \quad \Sigma = \partial\Omega \times T,\\ u(x,t)|_\Sigma = 0, \qquad u(x,0) = u_0(x),\end{gathered} \tag{1.1}$$

with an unknown initial condition $u_0(\cdot) \in L^2(\Omega)$.

The main aim of the present paper is to study exact observability of (1.1) in the case when available observations are provided by a scanning pointwise sensor, namely,

$$y(t) = u(\hat{x}(t),t), \qquad t \in T, \tag{1.2}$$

where $y(\cdot)$ is a scalar output and $\hat{x}(t)$, $t \in T$ is an observation curve (measurable, in general) for the sensor, so that

$$\hat{x}(t) \in \bar{\Omega} \quad \text{a.e. in } T,$$

where $\bar{\Omega}$ denotes the closure of Ω. This type of observations requires a corresponding regularity of the solutions of (1.1), which is provided by the above assumption on $\partial\Omega$. Indeed, this assumption implies [16] (see §2 below for details) that all the solutions of system (1.1) are classical for $t > 0$, $x \in \bar{\Omega}$, and, in particular, the following enclosure is verified:

$$u(\hat{x}(\cdot),\cdot) \in L^\infty(T_\varepsilon), \qquad T_\varepsilon = (\varepsilon,\theta)$$

for any $\varepsilon \in (0,\theta)$ and for any solution of (1.1).

System (1.1), (1.2) is said to be *observable* if its initial state can be uniquely determined from the observation $y(\cdot)$ over the time interval $(0,\theta)$. System (1.1), (1.2) is said to be *B-exactly (or continuously) observable at final time* if

$$\exists \gamma > 0 \text{ such that } \| u(\hat{x}(\cdot),\cdot) \|_B \geq \gamma \| u(\cdot,\theta) \|_{L^2(\Omega)} \tag{1.3}$$

for any solution $u(x,t)$ of system (1.1), where B denotes the space for outputs.

Observability of the parabolic systems with stationary pointwise sensors (when $\hat{x}(t) \equiv \bar{x},\ t \in T$) was previously studied in a large number of publications on the basis of harmonic analysis (see [17], [3], [21], [22], [2], [5], and the literature therein). In [17] Mizel and Seidman established exact observability at time $t = t^*$ of the one-dimensional heat equation with boundary pointwise sensor, assuming that $\Omega = (0,1)$, $u_x(0,t) = u_x(1,t) = 0$ and that t^* is big enough. Dolecki [3] and Sakawa [21] obtained sufficient conditions for exact observability at final (again "big enough") time for the case of internal pointwise sensors. Employing the analytical continuation techniques, Sakawa also derived necessary and sufficient conditions for observability. It is well known now that, in the stationary setting, observability of the system in question depends crucially upon the growth and the multiplicities of the associated eigenvalues. In particular, from Müntz–Szász type theorems [23], [13], [6], it follows that, if $n > 1$, then the stationary scalar sensor is not able to ensure exact observability of system (1.1), (1.2) at final time for $B = C[0,\theta]$, $L^p(T)$, $p \geq 1$. Furthermore, in the known examples [3], [21], [2], [5] of *observable* parabolic systems with stationary observations, the dimension of x does not exceed 2. On the other hand, in physical situations, available outputs (measurement data) are generally finite-dimensional at every moment of time. In the present paper, we show how this difficulty can be overcome by the introduction of moving pointwise sensors.

Remark 1.1. The problem of the choice of trajectories for moving sensors and actuators (as the optimal sensor and actuator allocation problem) arises in a natural way in the context of state estimation and control of distributed parameter systems (see [15], [10], [1], [9], and the literature therein). To our knowledge, observability of distributed-parameter systems with scanning pointwise sensors was previously studied in [3], [14]. In [3], for the sensor moving along the line $\hat{x}(t) = at+b$, Dolecki established (making use of the explicit representation of eigenfunctions) exact observability of the one-dimensional heat equation. In [14] Martin showed how the results of [21] can be reformulated in the form of moving sensors. Both papers reduced, in fact, the problem in question to the traditional stationary setting and did not employ the advantages of the motion itself.

The main result of this paper is a new method for the construction of observation curves for sensors that are able to provide the system with $L^\infty(\varepsilon,\theta)$-exact observability at final time for any $\varepsilon \in (0,\theta)$, given in advance (it is clear that if system (1.1), (1.2) is (exactly) observable at final time on (ε,θ), it is (exactly) observable on any interval (t^*,θ), $t^* \in (0,\varepsilon)$). (The approach developed in this paper was announced in the paper presented by the author at the IV International Conference on Control of Distributed Parameter Systems, held at Vorau, Austria, 1988.) In [11] it was used to analyse the observability problem arising in the framework of the theory of guaranteed estimation of parabolic systems under uncertainty. A more general abstract scheme of the proof of existence results, given in the above-mentioned conference paper and in [11], employed the separability of the space $C(\bar{\Omega} \times [\varepsilon,\theta])$ containing all the solutions of (1.1) taken on the interval $[\varepsilon,\theta]$.

The method proposed in this paper is constructive and makes use of the general representation of the solutions of (1.1) in the form of the generalized Fourier expansion along the eigenfunctions as well as of the separability of the space $C(\bar{\Omega})$. To some extent, it can be treated as an analogue of Galerkin's method coupled with the general a priori estimates techniques when being applied in the framework of the observability theory. From this point of view, the proposed method is rather general. Indeed,

it employes *a priori estimates* of instantaneous type for solutions (in the present paper, we use the maximum principle for the heat equation). The latter allows us to extend the results of the paper to a number of systems (including time-varying), admitting similar a priori estimates, when, instead of the eigenfunctions, an arbitrary appropriate basis—as in Galerkin's scheme—can be used. We state the proposed method in the form of an abstract algorithm. Each iteration of the algorithm can be associated with some part of the observation time-interval and provides $L^\infty(T_\varepsilon)$-exact observability at final time in the corresponding finite-dimensional subspace of $L^2(\Omega)$, spanned by the eigenfunctions of (1.1). Note that we deal with the case when the space for outputs $(L^\infty(T_\varepsilon))$ is not Hilbert. Therefore, we construct a countable net (which can be specified in infinitely many ways) in the pair of the sets of solutions and of outputs. We then establish the linkage between this net and appropriate countable sets of pairs $\{x^k, t_k\}_{k=1}^\infty$ that are to form the "skeletons" for required observation curves. Although a countable number of points in $\bar{\Omega} \times T$ is involved, we recall that this is to recover $u(\cdot, \theta)$, which is an element of the Hilbert space (see also Remarks 4.1 and 4.2(ii) in §4).

The main *existence* result of the paper, associated with the proposed method, can be formulated as follows.

THEOREM 1.1. *Given $\varepsilon \in T$, an arbitrary curve $\hat{x}(\cdot)$ constructed along Procedure* 3.1 (*described in* §3) *ensures $L^\infty(\varepsilon, \theta)$-exact observability of system* (1.1), (1.2) *at final time.*

The paper is organized as follows. Section 2 deals with some preliminary results. In §3 we introduce a scheme for the construction of *continuous* observation curves that are able to ensure required observability at final time in any finite-dimensional subspace (specified in advance), spanned by the eigenfunctions of (1.1). Then Procedure 3.1, describing the general algorithm for the construction of observation curves, is given. Theorem 1.1 is proved in §4. In the same section, we discuss a number of important corollaries and consider the specific case of the one-dimensional heat equation. Section 5 deals with an application of the method to the discrete-time observability problem with scanning sensor that is of practical importance (see also Remark 1.2). For the stationary sensors and infinite time horizon, a similar problem was studied in [8], where the authors used the results of Sakawa [21]. Section 6 deals with approximate controllability results related by duality with the main results of the paper. We restrict ourselves here by the case when $n \leq 3$ and establish approximate controllability of the heat equation with scanning pointwise control in $H^{-1}(\Omega)$.

Remark 1.2. The present stage of technology provides a growing number of examples of observations, where the modelling, based on a scanning sensor approach, might be of practical interest: the sensor (and actuator) allocation problem and an associated estimation (and control) policy for advanced composite materials (so-called "smart or intelligent" structures; see, for example, [19] and the bibliography therein); measurements of surface temperature by optical pyrometers and measurements of vibration and strain in materials using optical registrations; remote sensing of atmospheric species from a ground-, aircraft-, or satellite-based platform [18].

2. Preliminaries. This section deals with several auxiliary results that are employed below. It is well known that the general solution of problem (1.1) may be represented in the form

$$u(x,t) = \sum_{i=1}^{\infty} e^{-\lambda_i t} \langle u_0(\cdot),\, \omega_i(\cdot) \rangle \omega_i(x), \tag{2.1}$$

where

$$\langle u_0(\cdot),\, \omega_i(\cdot)\rangle \;=\; \int_\Omega u_0(x)\omega_i(x)dx$$

and $\lambda_i,\ \omega_i(\cdot)\ (i=1,2,\ldots)$ denote the eigenvalues and the eigenfunctions, orthonormalized in $L_2(\Omega)$, of the spectral problem

$$\Delta\omega_i(x) = -\lambda_i\omega_i(x),$$

so that

$$\lambda_{i+1} \geq \lambda_i > 0, \quad \lambda_i \to +\infty, \quad i \to +\infty.$$

In [16] it was shown that, if $\partial\Omega \in C^{2s}$ and $u_0(\cdot) \in H_D^{2s-1}(\Omega)$, then the generalized solution of (1.1) belongs to $H^{2s,s}(Q)$ and the following estimate is verified:

$$\| u(\cdot,\cdot) \|_{H^{2s,s}(Q)} \leq \text{const}\ \| u_0(\cdot) \|_{H^{2s-1}(\Omega)}, \tag{2.2}$$

where

$$H_D^r(\Omega) = \{\phi \mid \phi \in H^r(\Omega),\ \phi\,|_{\partial\Omega} = \cdots = \Delta^{[(r-1)/2]}\phi\,|_{\partial\Omega} = 0\}.$$

Recall further that the norm

$$\{v,v\}^{1/2} \;=\; \left(\sum_{k=1}^{\infty}\lambda_k^r v_k^2\right)^{1/2}, \quad v_k = \int_\Omega v(x)\,\omega_k(x)\,dx$$

is equivalent to the standard one in $H_D^r(\Omega)$. Due to the smoothing effect, this implies, in particular (as was mentioned in §1), that all the solutions of (1.1) are classical on $\bar\Omega \times [\varepsilon,\theta]$ (see [16] for details).

It is well known [7], [16] that any solution of system (1.1) satisfies the *maximum principle*

$$\max_{x\in\bar\Omega} \mid u(x,t') \mid \geq \max_{x\in\bar\Omega} \mid u(x,t'') \mid, \qquad 0 < t' \leq t'', \tag{2.3}$$

which lies in the basis of the method presented in the next section.

3. $C[\varepsilon,\theta]$-exact observability in finite dimensions. Denote by $L^2_{(k)}(\Omega)$ the finite-dimensional subspace of $L^2(\Omega)$ spanned by the functions

$$\omega_i(\cdot), \qquad i = 1,2,\ldots,k.$$

It is clear that, if $u(x,0)$ belongs to $L^2_{(k)}(\Omega)$, then $u(\cdot,t) \in L^2_{(k)}(\Omega)$, for all $t > 0$.

In this section, we discuss the problem of exact observability with respect to the sequence of the above subspaces. We show that required observation curves can be found among the continuous ones.

Let $\{x^j\}_{j=1}^\infty$ be a sequence of spatial points in $\bar\Omega$ and let $\{t_j\}_{j=1}^\infty$ be a sequence of instants of time in T. We say that an observation curve $\hat x(\cdot)$ has a *skeleton* $\{x^j,t_j\}_{j=1}^J$, where J can be both finite and infinite if it is continuous at all the instants $\{t_j\}_{j=1}^J$ and satisfies the following condition:

$$\hat x(t_j) = x^j, \qquad j = 1,\ldots,J.$$

LEMMA 3.1. *Given $\varepsilon \in (0,\theta)$ and a positive integer k, there exist continuous observation curves that ensure $C[\varepsilon,\theta]$-exact observability of* (1.1), (1.2) *at final time in $L^2_{(k)}(\Omega)$. To specify a required curve, it suffices to determine an appropriate* finite *skeleton.*

Proof of Lemma 3.1. Denote by $Y_{\varepsilon k}$ the set of all the possible outputs (1.2), generated by the initial conditions from $L^2_{(k)}(\Omega)$ and taken on T_ε. Observe that (1.1), (1.2) is $C[\varepsilon,\theta]$-exactly observable in $L^2_{(k)}(\Omega)$ if and only if the mapping

$$\mathbf{P}:\ C[\varepsilon,\theta] \supset Y_{\varepsilon k} \ \to\ L^2_{(k)}(\Omega), \qquad \mathbf{P}u(\hat{x}(\cdot),\cdot) = u(\cdot,\theta)$$

exists and is bounded, so that $Y_{\varepsilon k}$ is a subspace of $C[\varepsilon,\theta]$ and

$$\| \mathbf{P} \| = \sup\{\| \mathbf{P}u(\hat{x}(\cdot),\cdot) \| \mid u(\hat{x}(\cdot),\cdot) \in Y_{\varepsilon k},\ \| u(\hat{x}(\cdot),\cdot) \|_{C([\varepsilon,\theta]} \le 1\} < \infty.$$

Thus, to prove that $\hat{x}(\cdot)$ satisfies Lemma 3.1, it suffices to show that the preimage of the set

$$\{u(\hat{x}(\cdot),\cdot) \mid u(\hat{x}(\cdot),\cdot) \in Y_{\varepsilon k},\ \| u(\hat{x}(\cdot),\cdot) \|_{C[\varepsilon,\theta]} \le 1\}$$

for the mapping $u(\cdot,\theta) \to u(\hat{x}(\cdot),\cdot)$ is bounded in $L^2(\Omega)$.

Select in the interval T_ε an arbitrary monotone sequence of instants

$$\varepsilon = t_0 < t_1 < t_2 < \cdots < t_k < t_{k+1} < \cdots < \theta$$

and denote $\tau_k = (t_{k-1}, t_k)$, $k = 1, \ldots$.

Step 1. Consider first the case when $u(x,t)$ is generated by $u(\cdot,0) \in L^2_{(1)}(\Omega)$. Then, due to (2.1),

$$u(x,t) = e^{-\lambda_1 t} u_{01} \omega_1(x),$$

where

$$u_{01} = \int_\Omega u(x,0)\, \omega_1(x)\, dx.$$

Let $x^1_{(1)}$ be an arbitrary solution of the following optimization problem:

$$| \omega_1(x) | \to \max, \qquad x \in \bar{\Omega},$$

so that

$$| \omega_1(x^1_{(1)}) | = \max_{x \in \bar{\Omega}} | \omega_1(x) | . \tag{3.1}$$

This problem may admit, in general, several solutions. We take any of them.

Select any instant t^1_1 from τ_1 and consider an arbitrary continuous curve $\hat{x}(t)$, $t \in [0,\theta]$ that passes through the point $x^1_{(1)}$ at $t = t^1_1$, so that $\hat{x}(t^1_1) = x^1_{(1)}$. Then, if $u(x,t)$ is such that

$$\| u(\hat{x}(\cdot),\cdot) \|_{C[\varepsilon,\theta]} = \max\{| u(\hat{x}(t),t) | \mid t \in [\varepsilon,\theta]\} \le 1,$$

we obtain the following estimate:

$$| u_{01} | \le e^{+\lambda_1 t^1_1} | \omega_1^{-1}(x^1_{(1)}) | .$$

It is not hard to see that $\mid \omega_1^{-1}(x_{(1)}^1) \mid \neq 0$; otherwise, due to (3.1), $\omega_1(x) \equiv 0$. The last estimate yields

$$\| u(\cdot,\theta) \|_{L^2(\Omega)} \leq e^{+\lambda_1(t_1^1-\theta)}(\text{meas}\,\{\Omega\})^{1/2},$$

since

$$1 = \| \omega_1(\cdot) \|^2_{L^2(\Omega)} \leq \max\{\mid \omega_1(x) \mid^2 \mid x \in \bar{\Omega}\}\ \text{meas}\,\{\Omega\}.$$

Thus, we obtain the conclusion of Lemma 3.1 for system (1.1), (1.2) in the subspace $L^2_{(1)}(\Omega)$ with $\gamma = e^{-\lambda_1(t_1^1-\theta)}(\text{meas}\,\{\Omega\})^{-1/2}$.

Step 2. Let us proceed now with the general case. Denote by Φ_k the set

$$\Phi_k = \{v(\cdot) \mid \| v(\cdot) \|_{L^2(\Omega)} = 1, \quad v(\cdot) \in L^2_{(k)}(\Omega)\}.$$

We note next that Φ_k is also a bounded finite-dimensional subset of $C(\bar{\Omega})$. Therefore, for any positive δ, we can specify in it a finite δ-net

$$\Phi_k^\delta = \{v_k^j(\cdot)\}_{j=1}^{J_k}, \qquad v_k^j(\cdot) \in \Phi_k,$$

where J_k depends upon δ, so that, for any element $v(\cdot) \in \Phi_k$, there exists a positive integer $j = j_* \leq J_k$ such that $\| v(\cdot) - v_k^{j_*}(\cdot) \|_{C(\bar{\Omega})} \leq \delta$. The maximum principle (2.3) (applied for the set Φ_k) allows us to transform Φ_k^δ (due to finite dimension of Φ_k, (2.3) can be extended to $[0,\theta]$) into the δ-net $\Phi_k^\delta(\cdot)$ in the space $C(\bar{\Omega} \times [0,\theta])$,

$$\Phi_k^\delta(\cdot) = \{u_k^j(x,t),\ u_k^j(x,0) = v_k^j(x)\}_{j=1}^{J_k}, \qquad x \in \bar{\Omega}, \quad t \in [0,\theta]$$

for the set of all those solutions $u(x,t)$ that are generated at instant $t = 0$ by initial conditions from Φ_k.

Take any β in the interval $(0,1)$ and select

$$\delta = \delta_k(\beta) = \beta\, \tfrac{1}{2}(\text{meas}\{\Omega\})^{-1/2} e^{-\lambda_k t_k}, \tag{3.2}$$

denoting accordingly $J_k = J_k(\beta)$.

Selecting in τ_k an arbitrary sequence of instants of time t_k^j, $j = 1,2,\ldots,J_k(\beta)$, so that

$$t_{k-1} < t_k^1 < t_k^2 < \cdots < t_k^{J_k(\beta)} < t_k,$$

we introduce the following series of optimization problems for $j = 1,\ldots,J_k(\beta)$.

Problem (k,j). Find $x_{(k)}^j$ in such a way that

$$\max_{x \in \bar{\Omega}} \mid u_k^j(x,t_k^j) \mid = \mid u_k^j(x_{(k)}^j, t_k^j) \mid . \tag{3.3}$$

In general, Problem (k,j) admits nonunique solutions, but, if so, we may take any of them.

Let $\hat{x}(t)$, $t \in [0,\theta]$, be an arbitrary continuous curve in $\bar{\Omega}$ that has the skeleton $\{x_{(k)}^j, t_k^j\}_{j=1}^{J_k(\beta)}$. We show that it satisfies the necessary requirements.

Take any solution of (1.1) such that $u(\cdot,t) \in L^2_{(k)}(\Omega)$, for all $t \in T$,

$$u(x,t) = \sum_{i=1}^{k} e^{-\lambda_i t} < u(\cdot,0),\ \omega_i(\cdot) > \omega_i(x) \tag{3.4}$$

and assume that

$$\| u(\hat{x}(\cdot),\cdot) \|_{C[\varepsilon,\theta]} = \max\{| u(\hat{x}(t),t) | \mid t \in [\varepsilon,\theta]\} \leq 1. \tag{3.5}$$

This yields, in particular,

$$| u(\hat{x}(t_k^j), t_k^j) | \leq 1, \qquad j = 1,\dots,J_k(\beta). \tag{3.6}$$

Denote by α the value of $L^2(\Omega)$-norm of the function $u(\cdot,\cdot)$ taken at $t = 0$,

$$\alpha = \| u(\cdot,0) \|_{L^2(\Omega)}. \tag{3.7}$$

Without loss of generality, we may assume that $\alpha \neq 0$.

Select an element $u_k^{j*}(\cdot,\cdot) \in \Phi_k^{\delta_k(\beta)}(\cdot)$, such that

$$| \alpha^{-1}u(x,t) - u_k^{j*}(x,t) | \leq \delta_k(\beta) \quad \text{for all } x \in \bar{\Omega},\ t \in [0,\theta]. \tag{3.8}$$

Hence, in particular,

$$\| u(\cdot,t_k^{j*}) \|_{C(\bar{\Omega})} \leq \alpha \| u_k^{j*}(\cdot,t_k^{j*}) \|_{C(\bar{\Omega})} + \alpha\delta_k(\beta). \tag{3.9}$$

On the other hand, making use of (3.3) and again (3.8), we obtain

$$\alpha \| u_k^{j*}(\cdot,t_k^{j*}) \|_{C(\bar{\Omega})} = | \alpha u_k^{j*}(x_{(k)}^{j*}, t_k^{j*}) | \leq | u(\hat{x}(t_k^{j*}), t_k^{j*}) | + \alpha\delta_k(\beta). \tag{3.10}$$

Combining (3.5), (3.9), and (3.10) yields

$$\| u(\cdot,t_k^{j*}) \|_{C(\bar{\Omega})} \leq 1 + 2\alpha\delta_k(\beta). \tag{3.11}$$

Observe that, due to (3.4), (3.7),

$$\begin{aligned} \alpha^2 e^{-2\lambda_k t_k^{j*}} &= e^{-2\lambda_k t_k^{j*}} \textstyle\sum_{i=1}^k \langle u(\cdot,0),\, \omega_i(\cdot)\rangle^2 \\ &\leq \sum_{i=1}^k e^{-2\lambda_i t_k^{j*}} \langle u(\cdot,0),\, \omega_i(\cdot)\rangle^2 \\ &= \int_\Omega u^2(x,t_k^{j*})dx \leq \operatorname{meas}\{\Omega\} \| u(\cdot,t_k^{j*}) \|^2_{C(\bar{\Omega})}. \end{aligned} \tag{3.12}$$

Combining (3.11) and (3.12), we arrive at

$$\begin{aligned} &(\operatorname{meas}\{\Omega\})^{-1/2} \left(\sum_{i=1}^k e^{-2\lambda_i t_k^{j*}} \langle u(\cdot,0),\, \omega_i(\cdot)\rangle^2 \right)^{1/2} \\ &- 2\delta_k(\beta) \left(\sum_{i=1}^k \langle u(\cdot,0),\, \omega_i(\cdot)\rangle^2 \right)^{1/2} \leq 1. \end{aligned} \tag{3.13}$$

Taking into account the inequality

$$e^{-\lambda_k t_k} \left(\sum_{i=1}^k \langle u(\cdot,0),\, \omega_i(\cdot)\rangle^2 \right)^{1/2} \leq \left(\sum_{i=1}^k e^{-2\lambda_i t_k^{j*}} \langle u(\cdot,0),\, \omega_i(\cdot)\rangle^2 \right)^{1/2}$$

and (3.13), (3.2), we finally obtain

$$\begin{aligned} \| u(\cdot,\theta) \|_{L^2(\Omega)} &\le \| u(\cdot,t_k) \|_{L^2(\Omega)} \\ &\le \left(\sum_{i=1}^{k} e^{-2\lambda_i t_k^{j*}} \langle u(\cdot,0),\, \omega_i(\cdot) \rangle^2 \right)^{1/2} \\ &\le (\text{meas } \{\Omega\})^{1/2} \frac{1}{1-\beta}. \end{aligned} \tag{3.14}$$

Estimate (3.14), coupled with (3.5), implies the existence and boundedness of $\mathbf{P}$ on $Y_{\varepsilon k} \subset C[\varepsilon,\theta]$. In turn, this provides $C[\varepsilon,\theta]$-exact observability of system (1.1), (1.2) at final time in $L^2_{(k)}(\Omega)$ with the constant

$$\gamma = (\text{meas } \{\Omega\})^{-1/2}(1-\beta) \;\le\; \| \mathbf{P} \|^{-1}, \tag{3.15}$$

so that

$$(\text{meas } \{\Omega\})^{-1/2}(1-\beta) \| u(\cdot,\theta) \|_{L^2(\Omega)} \le \max_{t\in[\varepsilon,\theta]} | u(\hat{x}(t),t) | .$$

This completes the proof of Lemma 3.1.

The following procedure describes the algorithm for the construction of the skeletons for the observation curves ensuring $C[\varepsilon,\theta]$-exact observability of (1.1), (1.2) at final time in all $L^2_{(k)}(\Omega)$.

Procedure 3.1. Let $\varepsilon \in (0,\theta)$ and $\beta \in (0,1)$ be given.

1. Select an arbitrary monotone sequence of instants of time $\{t_k\}_{k=1}^{\infty} \subset T_\varepsilon$. It is clear that there exists a limit $\lim_{k\to\infty} t_k = \hat{t} \le \theta$.

2. Determine the values $\delta_k = \delta_k(\beta)$, $k = 1, 2 \ldots$, from (3.2).

3. Given k (we can start from any positive integer k), find a $\delta_k(\beta)$-net $\Phi_k^{\delta_k(\beta)}(\cdot)$. The latter provides the value $J_k = J_k(\beta)$.

4. Selecting an arbitrary monotone sequence $\{t_k^j\}_{j=1}^{J_k(\beta)}$ in the interval $\tau_k = (t_{k-1}, t_k)$, $t_0 = \varepsilon$, find from (3.3) a respective sequence of spatial points $\{x_{(k)}^j\}_{j=1}^{J_k(\beta)}$.

5. Repeat steps 3 and 4 with $k+1$ instead of k.

Let $\varepsilon \in T$ and $\beta \in (0,1)$ be given. We say that an observation curve $\hat{x}(t)$, $t \in [0,\theta]$ is constructed along Procedure 3.1 if it has a skeleton

$$\{x_{(k)}^j, t_k^j\}, \quad k = 1, 2, \ldots, \quad j = 1, \ldots, J_k(\beta),$$

specified according to Procedure 3.1, and $\hat{x}(\cdot)$ is continuous on $[\varepsilon, \hat{t})$ (see step 1 of Procedure 3.1).

From Lemma 3.1, we immediately obtain the following assertion.

COROLLARY 3.1. *Given $\varepsilon \in (0,\theta)$ and $\beta \in (0,1)$, let $\hat{x}(\cdot)$ be an arbitrary observation curve constructed along Procedure* 3.1. *Then, for any $k = 1, \ldots,$ to ensure the estimate*

$$(\text{meas } \{\Omega\})^{-1/2}(1-\beta) \| u(\cdot,\theta) \|_{L^2(\Omega)} \le \| u(\hat{x}(\cdot),\cdot) \|_{L^\infty(T_\varepsilon)}$$

for the solutions of (1.1) *with initial data from $L^2_{(k)}(\Omega)$, it suffices to take into account the observations* (1.2) *only over the time interval $\tau_k = (t_{k-1}, t_k)$.*

4. Proof of Theorem 1.1 and discussion of main results. For any given $\varepsilon \in (0,\theta)$ and $\beta \in (0,1)$, we show that an arbitrary curve $\hat{x}(\cdot)$ constructed along Procedure 3.1 satisfies the necessary requirements.

We recall first that estimate (3.14) is uniform over $k = 1, \ldots$. Denote by Y_ε the set of all the possible outputs (1.2) taken on T_ε. Observe that (1.1), (1.2) is $L^\infty(T_\varepsilon)$-exact observable if and only if the mapping

$$\mathbf{P}: \; L^\infty(T_\varepsilon) \supset Y_\varepsilon \; \to \; L^2(\Omega), \qquad \mathbf{P}u(\hat{x}(\cdot),\cdot) = u(\cdot,\theta)$$

exists and is bounded (so that the domain of $\mathbf{P}$ may be extended to $\bar{Y}_\varepsilon$),

$$\| \mathbf{P} \| = \sup\{\| \mathbf{P}u(\hat{x}(\cdot),\cdot) \| \mid \; u(\hat{x}(\cdot),\cdot) \in Y_\varepsilon, \; \| u(\hat{x}(\cdot),\cdot) \|_{L^\infty(T_\varepsilon)} \le 1\} \; < \; \infty.$$

To prove Theorem 1.1, it suffices to show that the preimage of the set

$$\{u(\hat{x}(\cdot),\cdot) \mid u(\hat{x}(\cdot),\cdot) \in Y_\varepsilon, \; \| u(\hat{x}(\cdot),\cdot) \|_{L^\infty(T_\varepsilon)} \le 1\}$$

for the mapping $u(\cdot,\theta) \to u(\hat{x}(\cdot),\cdot)$ is bounded in $L^2(\Omega)$.

Take any positive μ. Let $u(x,t)$ be an arbitrary solution of system (1.1) (e.g., (2.1) is fulfilled) such that

$$\| u(\hat{x}(\cdot),\cdot) \|_{L^\infty(T_\varepsilon)} \le 1. \tag{4.1}$$

Split then the sum on the right-hand side of (2.1) into two parts,

$$u(x,t) = u_N(x,t) + v_N(x,t),$$

where

$$u_N(x,t) = \sum_{i=1}^{N} e^{-\lambda_i t} < u(\cdot,0), \, \omega_i(\cdot) > \omega_i(x),$$

$$v_N(x,t) = \sum_{i=N+1}^{\infty} e^{-\lambda_i t} < u(\cdot,0), \, \omega_i(\cdot) > \omega_i(x),$$

in such a way that

$$\| v_N(\cdot,\theta) \|_{L^2(\Omega)} \le \mu, \tag{4.2}$$

and, in addition,

$$\| v_N(\cdot,\cdot) \|_{C(\bar{\Omega}\times[\varepsilon,\theta])} \le \mu.$$

The latter and (4.1) imply that

$$| u_N(\hat{x}(t),t) | \le 1 + \mu \quad \forall t \in \tau_N,$$

where τ_N is defined in step 4 of Procedure 3.1. Applying estimate (3.14) with $k = N$ and with $1 + \mu$ instead of 1 yields

$$\| u_N(\cdot,\theta) \|_{L^2(\Omega)} \le (\text{meas}\,\{\Omega\})^{1/2} \frac{1+\mu}{1-\beta}.$$

Finally, combining (4.2) and the last estimate, we arrive at

$$\| u(\cdot,\theta) \|_{L^2(\Omega)} \leq (\text{meas}\,\{\Omega\})^{1/2}\frac{1+\mu}{1-\beta} + \mu. \tag{4.3}$$

This justifies the existence and boundedness of $\mathbf{P}$ on $Y_\varepsilon \subset L^\infty(T_\varepsilon)$. Recalling that $\mu(>0)$ was selected in arbitrary way, we obtain

$$\| \mathbf{P} \| \leq (\text{meas}\,\{\Omega\})^{1/2}\frac{1+\mu}{1-\beta} + \mu \quad \forall \mu > 0.$$

This allows us to conclude that the needed inequality (1.3) holds with the same γ as in Lemma 3.1.

COROLLARY 4.1. *Given $\varepsilon \in (0,\theta)$ and $\beta \in (0,1)$, an arbitrary observation curve $\hat{x}(\cdot)$ constructed along Procedure* 3.1 *makes system* (1.1), (1.2) *be $L^\infty(T_\varepsilon)$-exactly observable at final time with the constant γ from* (3.15).

COROLLARY 4.2. *Given $\varepsilon \in (0,\theta)$ and $\beta \in (0,1)$, let $\hat{x}(\cdot)$ be constructed along Procedure* 3.1. *Then*

$$\begin{aligned} &\| u(\hat{x}(\cdot),\cdot) \|_{L^\infty(T_\varepsilon)} \\ &\geq (\text{meas}\,\{\Omega\})^{-1/2}(1-\beta)\,|< u(\cdot,0),\, \omega_i(\cdot) >|\; e^{-\lambda_i\theta}, \qquad i = 1,\dots, \end{aligned} \tag{4.4}$$

for any solution $u(x,t)$ of system (1.1).

Proof of this assertion follows from representation (2.1) and estimate (4.3) (or (1.3)).

Corollary 4.2 implies a "weaker" observability property.

COROLLARY 4.3. *Given $\varepsilon \in (0,\theta)$ and $\beta \in (0,1)$, an arbitrary curve $\hat{x}(\cdot)$ constructed along Procedure* 3.1 *provides system* (1.1), (1.2) *with observability.*

Remark 4.1. To construct a curve according to Procedure 3.1, we must determine a countable number of pairs forming its skeleton, although, for its approximation (in the sense of Lemma 3.1), we may restrict ourselves by a finite skeleton. The situation here, to some extent, is similar to the well-known example [3], [21], [2], [5] of the one-dimensional heat equation with stationary pointwise observations when, to obtain observability, we must locate a single sensor at *irrational point* (if $\Omega = (0,1)$). In fact, Procedure 3.1 requires the same *countable* "amount of information" as an irrational point (see also Remark 4.2(ii)), but an appropriate distribution of this information in time and space allows us to solve the problem of $L^\infty(T_\varepsilon)$-exact observability at final time for any space dimension.

Consider a sequence of functions

$$\psi_i(t) = e^{-\lambda_i t}\omega_i(\hat{x}(t)), \qquad t \in T, \quad i = 1,2,\dots,$$

and denote by $L^\infty_{(i)}(T_\varepsilon)$ the subspace of $L^\infty(T_\varepsilon)$ spanned by the functions

$$\psi_j(\cdot), \qquad j = 1,\dots; \quad j \neq i.$$

Set

$$d_i = \inf_{\psi(\cdot)\in L^\infty_{(i)}(T_\varepsilon)} \| \psi_i(\cdot) - \psi(\cdot) \|_{L^\infty(T_\varepsilon)}, \qquad i = 1,2,\dots.$$

Properties of exponentials $\{e^{-\lambda_i t}\}_{i=1}^\infty$ play a crucial role in the study of observability and controllability of the parabolic systems [17], [3], [6], [20]–[22], [2], [5] in the

stationary setting of problem. It is well known [23], [13], [6] that, if the dimension of x is higher than 1 and $\hat{x}(\cdot) \equiv \bar{x}$, then

$$d_i = 0, \qquad i = 1, \dots,$$

not only with respect to $L^\infty(T_\varepsilon)$-norm but also in $C[0,\theta]$, $L^p(T)$, $p \geq 1$. From estimate (4.4), we obtain the following assertion.

COROLLARY 4.4 (minimality in $L^\infty(T_\varepsilon)$). *If $\hat{x}(\cdot)$ is constructed along Procedure 3.1, then*

$$d_i = \inf_{\psi(\cdot) \in L^\infty_{(i)}(T_\varepsilon)} \| \psi_i(\cdot) - \psi(\cdot) \|_{L^\infty(T_\varepsilon)} \geq (\operatorname{meas} \Omega)^{-1/2}(1-\beta)e^{-\lambda_i \theta}, \quad i = 1, 2, \dots, \tag{4.5}$$

regardless of the system's space dimension.

At first, estimates (4.5) appear unexpected but, to explain them, we recall that Corollary 4.2 has been derived on the basis of the maximum principle for the heat equation, which is not affected by the multiplicity of eigenvalues and their growth. From this point of view, the proposed techniques rather employ the eigenfunctions that are always distinct.

Remark 4.2. Procedure 3.1 leaves unanswered the question of the geometry of observation curves providing exact observability. However, a few comments can be made here.

(i) If in Procedure 3.1 we set $\hat{t} = \theta$ (see step 1 of the algorithm), we may construct required curves to be continuous in $[0,\theta)$.

(ii) After a slight modification of Procedure 3.1, namely, if instead of precise solutions in (3.3) we take their approximations (this may affect the value of γ in (3.15)), then all the spatial points forming skeletons may be selected to be with *rational* coordinates.

At the end of this section, we consider the one-dimensional heat equation and give a specific example of observation curves that can solve the observability problem.

Example. Consider the following initial-boundary value problem:

$$\frac{\partial u(x,t)}{\partial t} = \frac{\partial^2 u(x,t)}{\partial x^2}, \quad 0 < x < 1, \quad t \in T, \tag{4.6}$$

$$u(t,0) = u(t,1) = 0, \qquad u(x,0) = u_0(x),$$

with stationary pointwise observations

$$y(t) = u(\bar{x}, t), \quad t \in T. \tag{4.7}$$

It is well known [3], [21], [2], [5] that (4.6), (4.7) is observable if and only if the point $\bar{x}$ is irrational, and it is $L^2(T)$-exactly observable if $\bar{x}$ is an irrational number of special type.

Let $\hat{x}(t)$, $t \in [0,\theta]$ be an arbitrary continuous curve connecting the ends of the interval [0,1] in the following way:

$$\exists\, t_1,\ t_2 \in [\varepsilon, \theta] \text{ such that } \hat{x}(t_1) = 0,\ \hat{x}(t_2) = 1. \tag{4.8}$$

Then, applying the maximum principle for the solutions of system (4.6) in the domain

$$D = \{(x,t) \mid 0 \leq x \leq \hat{x}(t),\ t \in [t_1, t_2]\}$$

yields the estimate

$$\| u(\cdot,\theta) \|_{C[0,1]} \leq \| u(\hat{x}(\cdot),\cdot) \|_{C[t_1,t_2]}, \tag{4.9}$$

which ensures exact observability at final time of system (4.6), (4.7) with $B = C[\varepsilon,\theta]$.

The attractive property of scanning sensor in this example (in contrast to stationary one) is that estimate (4.9) is the same for any continuous curve $\hat{x}(\cdot)$ satisfying (4.8). This makes such a class of curves be stable with respect to those perturbations that leave the perturbed curves in the mentioned class.

5. Observability with discrete-time scanning sensors. Consider system (1.1) with the discrete-time observations

$$y_i = u(x^i, t_i), \quad i = 1, 2, \ldots . \tag{5.1}$$

Here $\{y_i)\}_{i=1}^{\infty}$ is measurement data, $\{t_i\}_{i=1}^{\infty} \subset T$ is a monotone sequence of measurement instants; the spatial points $\{x^i\}_{i=1}^{\infty} \subset \bar{\Omega}$ specify the location of scanning sensor at the instants t_i, $i = 1, \ldots$.

We assume that the space for outputs $\mathbf{y} = \{y_1, \ldots, y_i, \ldots\}$ in this section is l^{∞} with the norm

$$\| \mathbf{y} \|_{l^{\infty}} = \sup_{i=1,\ldots} | y_i | .$$

Inequality (1.3) in the definition of B-exact observability at final time, adjusted for system (1.1), (5.1), may be represented as follows:

$$\sup_{i=1,\ldots} | u(x^i, t_i) | \geq \gamma \| u(\cdot,\theta) \|_{L^2(\Omega)} . \tag{5.2}$$

LEMMA 5.1. *Given $\varepsilon \in T$ and $\beta \in (0,1)$, let the sequence of pairs $\{x^i, t_i\}_{i=1}^{\infty}$ in* (5.1) *be selected according to Procedure* 3.1. *Then system* (1.1), (5.1) *is l^{∞}-exactly observable at final time, and estimate* (5.2) *holds with the constant γ from* (3.15).

The proof of Lemma 5.1 immediately follows from the proof of Theorem 1.1.

The following assertion illustrates principal possibilities of the scheme developed in §3, although it may be not of direct practical interest.

THEOREM 5.1. *Let $\varepsilon \in T$ and $\beta \in (0,1)$ be given. There exists a class of skeletons for* (5.1) *such that, for any of its elements, not only the skeleton itself but also any of its restrictions on arbitrary time intervals $(a,b) \subset T_{\varepsilon}$, regardless of the duration, make system* (1.1), (5.1) *l^{∞}-exact observable at final time $t = \theta$ with the same constant γ in* (5.2).

Proof. The idea of the proof is based on the fact that the results of §§3 and 4 employ the observations taken only at a countable set of instants of time: along the skeleton of the observation curve. Furthermore, these instants can be located in an arbitrary way in the interval T_{ε}.

Fix an arbitrary pair $\varepsilon \in T$ and $\beta \in (0,1)$. Let $\{t_i\}_{i=1}^{\infty}$ be an arbitrary set that is dense in T_{ε} and let $\{\delta_j\}_{j=1}^{\infty}$ be an arbitrary sequence of positive numbers such that $\lim_{j\to\infty} \delta_j = 0$. For each interval $(t_i - \delta_j, t_i) \bigcap T_{\varepsilon}$, select next a sequence of pairs according to Procedure 3.1 (with the same given ε and β),

$$\{x_{ij}^k, t_{ij}^k\}_{k=1}^{\infty}, \qquad i,j = 1, \ldots . \tag{5.3}$$

Observe that countability of the set of indices $i,j,k = 1,2 \ldots$ allows us to select all the instants t_{ij}^k to be distinct. Hence, we can renumber the pairs in (5.3) to obtain the sequence of pairs, forming the skeleton satisfying the requirements of Theorem 5.1.

6. From $L^\infty(T_\varepsilon)$-exact observability to approximate controllability. Consider in the domain Ω (satisfying the assumptions of §1) the following mixed problem:

$$\frac{\partial z(x,t)}{\partial t} = \Delta z(x,t) + v(t)\delta(x - x^*(t)), \quad t \in T, \quad x \in \Omega, \tag{6.1}$$
$$z(x,t)|_\Sigma = 0, \qquad z(x,0) = 0,$$

where $v(\cdot) \in L^2(T)$ is control and $x^*(\cdot)$ is a measurable function, $x^*(t) \in \bar{\Omega}$ almost everywhere in T.

System (6.1) is said to be approximately controllable in the Hilbert space H if its attainable set at time $t = \theta$ is dense in H.

To our knowledge, the problem of approximate controllability with internal pointwise controls for the parabolic systems is not well understood. The case of the moving spatially-averaged controls was considered by Martin, who reformulated the results of [20] (dual to [21]) in the form of moving controls. In this section, we apply the observability results, obtained in §§3 and 4, to the study of approximate controllability of (6.1). We restrict ourself by the case when $n \leq 3$, although Corollary 4.3 allows us to consider (in an appropriate space) an arbitrary space dimension.

We define the generalized solution of (6.1) by transposition (see [12, p. 186]) as a unique element of $L^2(Q)$ such that

$$\int_Q z(x,t)(-\frac{\partial \psi}{\partial t} - \Delta\psi)dxdt = \int_0^T \psi(x^*(t),t)v(t)dt \tag{6.2}$$
$$\forall \psi \in H^{2,1}(Q), \quad \psi\,|_\Sigma = 0, \quad \psi\,|_{t=\theta} = 0.$$

Indeed, for $n \leq 3$, any element ψ of $H^{2,1}(Q)$ is of Carathéodory type, and hence $\psi(x^*(\cdot),\cdot) \in L^2(T)$. Furthermore, the argument similar to that in [12, p. 202] gives

$$t \to z(\cdot,t) \text{ is a continuous function of } [0,\theta] \to H^{-1}(\Omega). \tag{6.3}$$

THEOREM 6.1. *Let $\varepsilon \in (0,\theta)$ and $\beta \in (0,1)$ be given and $n \leq 3$. Let $x^*(\cdot)$ be an arbitrary measurable curve such that $x^*(t) \equiv \hat{x}(\theta - t)$ for all $t \in (0, \theta - \varepsilon)$, where $\hat{x}(t)$, $t \in T_\varepsilon$ is constructed along Procedure* 3.1. *Then system* (6.1) *is approximately controllable in $H^{-1}(\Omega)$.*

Proof. Take any $\varepsilon \in (0,\theta)$ and $\beta \in (0,1)$. Introduce next the system dual to (6.1) as follows:

$$\frac{\partial u(x,t)}{\partial t} = -\Delta u(x,t), \quad t \in T, \quad x \in \Omega, \tag{6.4}$$
$$u(x,t)|_\Sigma = 0, \quad u(x,\theta) = u_\theta(x), \quad u_\theta(\cdot) \in H_0^1(\Omega),$$

$$y(t) = u(x^*(t),t), \qquad t \in T. \tag{6.5}$$

Observe that system (6.4) is well-posed in backward time and that its solutions belong to $H^{2,1}(Q)$ (see (2.2)). The conclusion of Theorem 6.1 now follows from the duality relations (see, for example, [4]) and Corollary 4.3 (deduced from $L^\infty(T_\varepsilon)$-exact observability), applied to system (6.4), (6.5). Moreover, to prove this, we can consider only controls of the following type:

$$v(\cdot) = \begin{cases} v^*(t) \in L^2(0,\theta-\varepsilon), & t \in (0,\theta-\varepsilon), \\ 0, & t \in (\theta-\varepsilon,\theta). \end{cases}$$

Indeed, in this case, from (6.1) and (6.4), (6.5), we obtain the identity

$$[z(\cdot,\theta),u_\theta(\cdot)] = \int_0^{\theta-\varepsilon} u(x^*(t),t)v^*(t)dt, \tag{6.6}$$

which is valid for $v^*(\cdot) \in L^2(0,\theta-\varepsilon)$, $u_\theta(\cdot) \in H_0^1(\Omega)$, where the symbol $[\cdot,\cdot]$ denotes the duality relation between $H_0^1(\Omega)$ and $(H_0^1(\Omega))' = H^{-1}(\Omega)$. Identity (6.6) implies the conclusion of Theorem 6.1.

7. Concluding remarks. In this paper, the problem of $L^\infty(T_\varepsilon)$-exact observability has been studied for the heat equation with internal scanning pointwise sensor. A new method for the construction of observation curves for sensors providing required observability has been given in the form of an abstract algorithm (Procedure 3.1), based on the classical maximum principle for the heat equation. Each iteration of the algorithm can be associated with some part of the interval (ε,θ) and provides exact observability in the corresponding finite-dimensional subspace of $L^2(\Omega)$, spanned by the eigenfunctions of (1.1). Procedure 3.1 is not affected by the multiplicities and the growth of the eigenvalues of the system in question and can be applied regardless of the system's space dimension. Approximate controllability of the heat equation in the space dimension $n \leq 3$ with scanning pointwise control has been established in $H^{-1}(\Omega)$ for the control curves, provided by the proposed method.

BOUNDARY CONTROL OF A ONE-DIMENSIONAL LINEAR THERMOELASTIC ROD*

SCOTT W. HANSEN†

Abstract. Boundary control of a linear partial differential equation that describes the temperature distribution and displacement within a one-dimensional thermoelastic rod is examined. In particular, it is shown that temperature or heat flux control at an endpoint is sufficient to obtain exact null-controllability. This improves earlier results for similar systems in which only partial null-controllability is obtained. Sharp regularity results for the controlled system are also obtained.

Key words. linear thermoelasticity, moment problem, boundary control, regularity

AMS subject classifications. 93B05, 80A20, 70J99

1. Introduction.

Although there is extensive literature on the topic of control and stabilization of elastic systems, relatively little has been published that includes the thermoelastic coupling. This is probably due, in part, to the relatively small effect thermoelastic damping has upon most systems of interest. However, for certain applications such as stabilization of satellite antennas, where large temperature variations are common (e.g., due to moving in and out of shadows), the need to model this coupling becomes critical. Furthermore, the recent work of Gibson, Rosen, and Tao [5] illustrates the importance of modelling even light thermoelastic damping in the design of finite-dimensional compensators.

Some notable literature on stabilization of thermoelastic systems include [13], [14], [16]–[18], and references therein. Very little, however, is known about the controllability structure of thermoelastic systems. In Lagnese and Lions [14], boundary control (e.g., velocity or position control on the boundary) is used to exactly control the mechanical portion of the state space. This type of controllability is called *partial exact controllability.* When this type of control is used, the thermal component of the state is ignored, and, consequently, if the mechanical portion is driven to rest, it will not generally remain there due to the thermal stresses that remain. The main purpose of this paper is to show that, at least for the case of a one-dimensional thermoelastic rod, exact controllability (to zero) of both mechanical and thermal components of the state space is possible by only controlling the thermal (or mechanical) component on the boundary.

A derivation of the equations of one-dimensional nonlinear thermoelasticity can be found in [21]. In the case of a homogeneous rod with uniform cross sections (see [2], [6] for the precise assumptions), the linearization of these equations can be written as

$$\begin{aligned} \frac{\partial\theta}{\partial t}(t,x) &= \frac{\partial^2\theta}{\partial x^2}(t,x) - \frac{\gamma\partial^2 w}{\partial x\partial t}(t,x), \\ \frac{\partial^2 w}{\partial t^2}(t,x) &= c^2\frac{\partial^2 w}{\partial x^2}(t,x) - c^2\gamma\frac{\partial\theta}{\partial x}(t,x), \end{aligned} \tag{1.1}$$

which holds on $(t,x) \in (0,\infty) \times \Omega$ ($\Omega = (0,1)$). Here θ represents a relative temperature about the stress-free reference state $\theta = 0$, and w is proportional to the displacement. The constants $\gamma > 0$ and $c > 0$ represent, respectively, the amount of thermal-mechanical coupling and the small-amplitude wave speed about a constant temperature state. (See [6] for a precise definition of γ and c.) In most materials of interest, γ is several orders of magnitude smaller than 1.

The physical quantities relevant to the formulation of boundary conditions for (1.1) are the velocity v, heat flux q, stress σ, and temperature θ, where the first three of these are

$$v(t,x) = \frac{\partial w}{\partial t}(t,x),$$
$$q(t,x) = -\frac{\partial \theta}{\partial x}(t,x),$$
$$\sigma(t,x) = \frac{\partial w}{\partial x}(t,x) - \gamma\theta(t,x).$$

In [6] it was shown that, under any of the boundary conditions,

$$v(t,i) = 0, \quad q(t,i) = 0, \quad i = 0,1; \tag{1.2}$$

$$\sigma(t,i) = 0, \quad \theta(t,i) = 0, \quad i = 0,1; \tag{1.3}$$

$$\sigma(t,0) = \theta(t,0) = v(t,1) = q(t,1) = 0, \tag{1.4}$$

the eigenfunctions associated with (1.1) form a Riesz basis for the space of finite energy states and the corresponding eigenvalues are uniformly shifted into the left half-plane, except for possibly one or two eigenvalues located at the origin. This result is partially restated in Theorem 2.1 and is our starting point in our examination of associated control problems.

In the case of boundary conditions (1.4), there are no eigenvalues at the origin. For this reason, it is notationally convenient to restrict our presentation to control of boundary conditions of the type (1.4), although similar results apply for control of boundary conditions of the type (1.2) or type (1.3).

Let $y(t) = (y_1(t), y_2(t), y_3(t))' = (w_x(t,\cdot), w_t(t,\cdot), \theta(t,\cdot))'$ represent the state of system (1.1) at time t and let $(v_y(x), q_y(x), \sigma_y(x), \theta_y(x))$ represent the velocity, heat flux, and so forth, in terms of the state y. We are mainly concerned with the following boundary control problem associated with (1.1):

$$\frac{dy}{dt} = \tau y \equiv \begin{bmatrix} 0 & D & 0 \\ c^2 D & 0 & -\gamma c^2 D \\ 0 & -\gamma D & D^2 \end{bmatrix} y, \qquad (t,x) \in (0,\infty) \times \Omega, \tag{1.5}$$

$$y(0) = y^0 \quad \text{in } \Omega, \tag{1.6}$$

$$\begin{aligned} \sigma_{y(t)}(0) = 0, \quad \theta_{y(t)}(0) = g(t), \quad t \geq 0, \\ v_{y(t)}(1) = 0, \quad q_{y(t)}(1) = f(t), \quad t \geq 0, \end{aligned} \tag{1.7}$$

where $D = d/dx$, $\gamma > 0$, $c > 0$. Thus, at the left end, the temperature is controlled, and the stress vanishes. At the right end, the heat flux is controlled while the position is fixed.

We must define some function spaces to describe our main results. Let $\mathcal{H} = (L^2(\Omega))^3$ with the energy inner product

$$\langle y, z \rangle = \int_0^1 y_1 \bar{z}_1 + \frac{1}{c^2} y_2 \bar{z}_2 + y_3 \bar{z}_3 \, dx$$

and let

$$\mathcal{D}(A) = \{y \in H^1[0,1] \times H^1[0,1] \times H^2[0,1] \mid \sigma_y(0) = \theta_y(0) = v_y(1) = q_y(1) = 0\}.$$

Now define $A : \mathcal{D}(A) \to \mathcal{H}$ by

$$Ay = \tau y \quad \forall\, y \in \mathcal{D}(A). \tag{1.8}$$

We denote $l^2 = \{(c_k)_{k\in\mathbb{I}} \mid \sum_{k\in\mathbb{I}} |c_k|^2 < \infty\}$, where $\mathbb{I}$ is a countable index set (usually either the integers $\mathbb{Z}$ or positive integers $\mathbb{N}$). For $\alpha \in \mathbb{R}$, define

$$S_\alpha = \left\{ \sum_{k=1}^{\infty} a_k \sin\left(k\pi - \frac{\pi}{2}\right) x \mid (a_k k^\alpha) \in l^2 \right\}, \tag{1.9}$$

$$C_\alpha = \left\{ \sum_{k=1}^{\infty} a_k \cos\left(k\pi - \frac{\pi}{2}\right) x \mid (a_k k^\alpha) \in l^2 \right\}. \tag{1.10}$$

S_α and C_α become Hilbert spaces with, e.g., $\|y\|_{S_\alpha} = \|(a_k k^\alpha)\|_{l^2}$. (When $\alpha < 0$, S_α and C_α are the dual spaces to $S_{-\alpha}$ and $C_{-\alpha}$, respectively.) $C((a,b), M)$ denotes the set of functions that are continuous on the interval (a,b) with values in the space M.

Our main results are the following, together with related results given in §§3–5.

THEOREM 1.1. *Let $y^0 = 0$, $f \in L^2(0,\infty)$, and $g \in L^2(0,\infty)$. Then the solution to (1.5)–(1.7) belongs to $C([0,\infty), S_0 \times C_0 \times S_{-1/2})$. If, additionally, $g \equiv 0$, then the solution belongs to $C([0,\infty), S_1 \times C_1 \times S_{1/2})$. These solution spaces are optimal in the sense that none of the indices $\{0, 1, 1/2, -1/2\}$ may be increased.*

THEOREM 1.2. *Assume that $0 < \gamma \le 1$ in (1.5) and $T > 2/c$.*

(i) *For the boundary control problem (1.5)–(1.7), with $f \equiv 0$, given any $y^0 \in \mathcal{H}$, there exists $g \in L^2[0,T]$ such that $y \in C([0,T], S_0 \times C_0 \times S_{-1/2})$ and $y(T) = 0$.*

(ii) *For the boundary control problem (1.5)–(1.7), with $g \equiv 0$, given any $y^0 \in \mathcal{D}(A)$, there exists $f \in L^2[0,T]$ such that $y \in C([0,T], S_1 \times C_1 \times S_{1/2})$ and $y(T) = 0$. In either case, T cannot in general be reduced to $2/c$.*

Remark 1.3. The following identifications hold:

$$\begin{gathered} S_0 = C_0 = L^2(\Omega), \\ S_1 = \{f \in H^1(\Omega) \mid f(0) = 0\}, \\ C_1 = \{f \in H^1(\Omega) \mid f(1) = 0\}, \\ S_{1/2} = [S_1, S_0]_{1/2} = \{f \in H^{1/2}(\Omega) \mid x^{-1/2} f(x) \in L^2(\Omega)\}, \\ S_{-1/2} = S_{1/2}', \\ \mathcal{H} = S_0 \times C_0 \times S_0, \\ \mathcal{D}(A) = S_1 \times C_1 \times S_2, \end{gathered}$$

with equivalent norms; see [15] and §2. (In the above, H^α denotes the usual Sobolev space of order α, $[F,G]_{1/2}$ denotes the usual interpolation space between spaces F and G, as defined in [15], and $'$ denotes duality with respect to $L^2(\Omega)$.)

In the above theorems, solutions are uniquely defined by continuous extension of the variation of constants formula; see §3 for details.

Proposition 5.1 gives a more general statement of Theorem 1.2, and Remark 5.2 shows that the spaces used in Theorem 1.2 are optimal in a certain sense.

The proof of Theorem 1.1 is given in §3 and involves an application of the Carleson measure criterion of Ho and Russell [10] and Weiss [22], which gives a sharp criterion for wellposedness of control systems. The proof of Theorem 1.2 involves reducing the control problem to a pair of coupled moment problems that are coupled through the control. A general class of such coupled moment problems is examined in §4, where it is shown that there are projections that decouple such moment problems into simpler ones for which known results are applicable. This leads to various controllability results, including Theorem 1.2, which are given in §5.

Results similar to Theorems 1.1 and 1.2 follow in the same way for boundary control systems based on the boundary condition (1.2) or (1.3). Likewise, we could also consider the case where the stress and/or velocity at an end is controlled, and similar results would follow. We mention some of these results in §5.

A short appendix is included which contains the proof of several technical details used throughout the rest of the paper.

2. Preliminaries. Throughout this paper, an *isomorphism* is understood to denote a bounded, invertible operator from one Hilbert space onto another. If X is a separable Hilbert space, a sequence $(\varphi_k)_{k\in\mathbb{N}}$ in X forms a *Riesz basis* for X if $\varphi_k = Be_k$ $(k \in \mathbb{N})$, where (e_k) is an orthonormal basis for X and B is an isomorphism. The following theorem and its corollary were proved in Hansen [6].

THEOREM 2.1. *Let A be defined by* (1.8). *The spectrum of A (and also of A^*) consists of isolated eigenvalues $(\lambda_{kj})_{k\in\mathbb{N},j\in\{1,2,3\}}$ with $\lambda_{kj} = (k\pi - \pi/2)s_{kj}$, where*

$$(s_{kj}^2 + c^2)(s_{kj} + k\pi - \pi/2) + \gamma^2 c^2 s_{kj} = 0. \tag{2.1}$$

The eigenfunctions of A (and also A^*), properly normalized, form a Riesz basis for $\mathcal{H}$.

An analysis of (2.1) in [6] shows that (λ_{kj}) can be decomposed into a real branch $(\mu_k)_{k\in\mathbb{N}}$ and a nonreal branch $(\sigma_k)_{k\in\mathbb{Z}}$ with

$$\begin{aligned} \mu_k &= -\left(k\pi - \frac{\pi}{2}\right)^2 + O(1), \quad k \in \mathbb{N}, \\ \sigma_k &= -\frac{\gamma^2}{2} + ic\left(k\pi - \frac{\pi}{2}\right) + O(k^{-1}), \quad k \in \mathbb{Z}. \end{aligned} \tag{2.2}$$

We let $(\psi_\lambda)_{\lambda\in\sigma(A)}$ denote the normalized eigenvectors of A^* and $(\varphi_\lambda)_{\lambda\in\sigma(A)}$ denote the biorthonormalized eigenvectors of A (each eigenvalue is counted up to its multiplicity), so that $\langle \varphi_{\lambda_k}, \psi_{\lambda_j} \rangle = \delta_{kj}$, where δ_{kj} is the Kronecker delta. There are at most a finite number of eigenvalues of multiplicity greater than 1, and all eigenvalues are simple if $\gamma \leq 1$ (see Lemma A.1) or if $|k|$ is sufficiently large (see [6]). The form of the eigenvectors of A^* is given in the Appendix.

COROLLARY 2.2. *A is the generator of a strongly continuous contraction semigroup $(\mathbb{T}_t)_{t\geq 0}$ on $\mathcal{H}$ for which there exist $M > 1$ and $\beta > 0$ such that*

$$\|\mathbb{T}_t\| \leq Me^{-\beta t} \quad \forall\, t \geq 0.$$

Theorem 2.1 and Corollary 2.2 also hold in the case of boundary condition (1.2) or (1.3), although the energy decay occurs in the orthogonal complement of the nullspace of the generator [6]. In addition, several recent papers [1], [12], [17] have shown

exponential stability to hold for other sets of natural boundary conditions. These exponential stability results are important in that we can infer the existence of optimizing feedbacks for stabilization problems with quadratic cost criteria; see [5].

For any set $S \subset \mathbb{C}$, we can define an associated spectral projection $P(S) \in \mathcal{L}(\mathcal{H})$ by

$$(P(S))\,x = \frac{1}{2\pi i}\int_{\Gamma} R(\lambda; A)x\,d\lambda \quad \forall\, x \in \mathcal{H},$$

where $R(\lambda, A)$ is the resolvent operator of A and where Γ is an appropriate contour that encloses the eigenvalues in S. There is no difficulty in defining Γ, since the spectrum is discrete. In cases where Γ contains infinitely many eigenvalues, convergence for all $x \in \mathcal{H}$ is guaranteed by Theorem 2.1. Let us denote

$$P = P(\mathbb{R}) \quad \text{and} \quad Q = I - P(\mathbb{R}),$$

where I denotes the identity operator on $\mathcal{H}$. Let

$$\Lambda = P\mathcal{H} \quad \text{and} \quad \Sigma = Q\mathcal{H}.$$

Since the projections are continuous, it follows that $\mathcal{H} = \Lambda \oplus \Sigma$.

PROPOSITION 2.3. *Let $\mathbb{T}$ denote the semigroup defined in Corollary 2.2. Then, for $t \geq 0$,*

$$\mathbb{T}_t = \mathbb{S}_t P + \mathbb{G}_t Q, \tag{2.3}$$

where $\mathbb{G}$ extends to a strongly continuous group $(\mathbb{G}_t)_{t\in\mathbb{R}}$ and $\mathbb{S}$ extends to an analytic semigroup $(\mathbb{S}_t)_{\mathrm{Re}\ t>0}$. The infinitesimal generators of $\mathbb{S}$ and $\mathbb{G}$ are given by the restrictions of A, $A|_\Lambda$, and $A|_\Sigma$, respectively.

Proof. The spaces Λ and Σ are closed $\mathbb{T}$-invariant spaces, and hence the restriction of $\mathbb{T}$ to either of these spaces is a C_0 semigroup with respect to the inherited topology. For $t \geq 0$, let $\mathbb{S}_t = \mathbb{T}_t|_\Lambda$ and $\mathbb{G}_t = \mathbb{T}_t|_\Sigma$. It follows that, for $t \geq 0$, $\mathbb{T}_t = \mathbb{T}_t(P+Q) = \mathbb{S}_t P + \mathbb{G}_t Q$; hence (2.3) is valid. For any $x \in \Lambda \cap \mathcal{D}(A)$,

$$Ax = \lim_{t\downarrow 0} \frac{\mathbb{T}_t x - x}{t} = \lim_{t\downarrow 0} \frac{\mathbb{S}_t x - x}{t}.$$

Thus $\mathbb{S}$ is generated by (the densely defined operator) $A|_\Lambda$, and likewise $\mathbb{G}$ is generated by $A|_\Sigma$.

It remains to show that $\mathbb{G}$ extends to a group (by $\mathbb{G}_{-t} = \mathbb{G}_t^{-1}$) and that $\mathbb{S}$ has an analytic extension to $\mathrm{Re}\, t > 0$. Define $F : \mathcal{H} \to l^2$ by

$$\sum_{\lambda_k \in \sigma(A)} c_{\lambda_k}\phi_{\lambda_k} \to (c_{\lambda_k}).$$

Since (ϕ_{λ_k}) forms a Riesz basis for $\mathcal{H}$, F is an isomorphism. Define $\tilde{\mathbb{T}} = (\tilde{\mathbb{T}}_t)_{t\geq 0}$ by $\tilde{\mathbb{T}}_t = F\mathbb{T}_t F^{-1}$, and for $x \in \mathcal{H}$ define $\tilde{x}$ by $\tilde{x} = Fx$. Through this mapping, the pair $(\mathbb{T}, \mathcal{H})$ is isomorphic to $(\tilde{\mathbb{T}}, l^2)$ in the sense that $F\mathbb{T}_t x = \tilde{\mathbb{T}}_t \tilde{x}$ for any $t \geq 0$ and any $x \in \mathcal{H}$. Since any Riesz basis becomes an orthonormal basis under some equivalent inner product (see [25]), it follows that the induced topology $\|\tilde{x}\|_i = \|x\|$ is equivalent to the topology generated by the standard l^2 inner product. Thus, to show that $\mathbb{S}$

extends to an analytic semigroup $(\mathbb{S}_t)_{\mathrm{Re}\, t>0}$, it suffices to show that $\tilde{\mathbb{T}}|_{F\Lambda}$ extends analytically to $\mathrm{Re}\, t > 0$ with respect to the standard l^2 topology. It is easily seen that $\tilde{\mathbb{T}}|_{F\Lambda}$ is a diagonal semigroup on l^2 $(= F\Lambda)$ with (diagonal) generator $(FAF^{-1})|_{F\Lambda}$. If $\mathcal{A}$ is any diagonal generator, it is easy to show that $\|R(\lambda, \mathcal{A})\|$ is inversely proportional to the distance λ is from $\sigma(\mathcal{A})$. Since $\sigma(A|_\Lambda) = \sigma((FAF^{-1})|_{F\Lambda})$ is entirely on the negative real axis, the appropriate resolvent bound [19, p. 62] holds, which shows that $\tilde{\mathbb{T}}|_{F\Lambda}$, and hence also $\mathbb{S}$, extends to an analytic semigroup in $\mathrm{Re}\, t > 0$. Likewise, since $\sigma(FAF^{-1}|_{F\Sigma})$ is contained in a vertical strip of $\mathbb{C}$, it follows from, e.g., Pazy [19, p. 23] that $\tilde{\mathbb{T}}|_{F\Sigma}$ extends to a group. Hence $\mathbb{G}$ also extends to a group. □

It will be useful to introduce notation for certain interpolation spaces. Since $0 \in \rho(A)$ (the resolvent set of A) and $\sigma(-A)$ is in $\{\lambda \in \mathbb{C} \mid \mathrm{Re}\ \lambda > 0\}$, for any $\alpha \in \mathbb{R}$, $(-A)^\alpha$ may be defined as in, e.g., Pazy [19, p. 69]. For $\alpha > 0$, $(-A)^\alpha$ is an isomorphism from $\mathcal{D}((-A)^\alpha)$ (with graph-norm topology) to $\mathcal{H}$. For $\alpha \geq 0$, we define $\mathcal{H}_\alpha$ to be the restriction of $\mathcal{H}$ to $\mathcal{D}((-A)^\alpha)$ with

$$\|x\|_\alpha = \|(-A)^\alpha x\|. \tag{2.4}$$

For $\alpha < 0$, we let $\mathcal{H}_\alpha$ denote the completion of $\mathcal{H}$ with respect to the norm also given by (2.4). The above spaces are explained in more detail in, e.g., [8], [23]. For our problem, we have that $\mathcal{D}(A) = \mathcal{D}(A^*)$. Thus it follows that $\mathcal{H}_1^* = \mathcal{H}_{-1}$ (where the duality pairing is with respect to the completion of $\langle \cdot, \cdot \rangle$). Furthermore, since the eigenfunctions of A form a Riesz basis, it can be shown that, for $\alpha \in [0, 1]$, $\mathcal{H}_\alpha = [\mathcal{H}_1, \mathcal{H}_0]_{1-\alpha}$, where $[\mathcal{H}_1, \mathcal{H}_0]_{1-\alpha}$ is the interpolation space defined in [15]. Using standard properties of interpolation spaces, we can show $\mathcal{H}_\alpha^* = \mathcal{H}_{-\alpha}$ for all $\alpha \in \mathbb{R}$.

We recall a result from Weiss [23], as it applies to our problem.

PROPOSITION 2.4. *For any $\alpha < 0$, A has a unique continuous extension to an operator on $\mathcal{H}_\alpha$, also denoted by A, which is an isomorphism from $\mathcal{H}_{\alpha+1}$ to $\mathcal{H}_\alpha$. Furthermore, if L commutes with A, i.e., if*

$$LAx = ALx \quad \forall x \in \mathcal{H}_1 = \mathcal{D}(A),$$

then the restriction of L to $\mathcal{H}_\alpha$ $(\alpha > 0)$ belongs to $\mathcal{L}(\mathcal{H}_\alpha)$. Furthermore, L has a unique continuous extension to an operator in $\mathcal{L}(\mathcal{H}_\alpha)$ for any $\alpha < 0$.

In particular, the projections P and Q, and semigroups $\mathbb{T}$, $\mathbb{S}$, and $\mathbb{G}$ each have unique continuous extensions to $\mathcal{H}_\alpha$ (for any $\alpha < 0$). Throughout this paper, we make no notational distinction between an operator and its possible extensions. We thus define the spaces Λ_α and Σ_α by

$$\Lambda_\alpha = P\mathcal{H}_\alpha \quad \text{and} \quad \Sigma_\alpha = Q\mathcal{H}_\alpha \quad \forall \alpha \in \mathbb{R}.$$

As a consequence of Proposition 2.4,

$$\mathcal{H}_\alpha = \Lambda_\alpha \oplus \Sigma_\alpha \quad \forall\, \alpha \in \mathbb{R}. \tag{2.5}$$

The spaces Λ_α and Σ_α become Hilbert spaces with the norms $\|\cdot\|_{\Lambda_\alpha}$ and $\|\cdot\|_{\Sigma_\alpha}$ inherited from (2.4).

3. Regularity. In this section, we obtain via the Carleson measure criterion of Ho and Russell [10] and Weiss [22] the spaces of maximal regularity of system (1.5)–(1.7). We begin with a discussion of the Carleson measure criterion.

Consider the control system

$$\dot{x} = \mathcal{A}x + bu(t), \tag{3.1}$$

where $x(t) \in l^2$ is the state, $u \in L^2[0,\infty)$ is the control function, $\mathcal{A}$ is assumed to be diagonal with diagonal elements ν_k, which satisfy

$$\sup_{k\in\mathbb{N}} \operatorname{Re} \nu_k = \omega_0 < 0, \tag{3.2}$$

and $b \in l^2_{-1}$, i.e., is a column vector with components b_k, which satisfy

$$\sum_{k=1}^{\infty} \left| \frac{b_k}{\nu_k} \right|^2 < \infty.$$

Thus $\mathcal{A}$ generates a strongly continuous diagonal semigroup $(T_t)_{t\geq 0}$ on l^2.

For any $h > 0$ and any $\omega \in \mathbb{R}$, let

$$R(h,\omega) = \{z \in \mathbb{C} \mid 0 \leq \operatorname{Re} z \leq h,\ |\operatorname{Im} z - \omega| \leq h\}.$$

DEFINITION 3.1. With $\mathcal{A}$, b, and T as above, b satisfies the *Carleson measure criterion* for the semigroup T if there is some $M \geq 0$ such that, for any $h > 0$ and any $\omega \in \mathbb{R}$,

$$\sum_{-\nu_k \in R(h,\omega)} |b_k|^2 \leq M \cdot h. \tag{3.3}$$

The Carleson measure criterion is used to determine the *admissibility* of the *input element* b in (3.1). The input element b is *admissible* for T if, for some $t > 0$, the sequence $\left(\int_0^t e^{\nu_k(t-s)} b_k v(s) ds\right)_{k\in\mathbb{N}}$ lies in l^2 for all $v \in L^2[0,\infty)$. When b is admissible, for any $\tau > 0$, the operator $\Phi_\tau \colon L^2[0,\infty) \to l^2_{-1}$ defined by

$$\Phi_\tau u = \int_0^\tau T_{\tau-s} b u(s) ds \quad \forall\, u \in L^2[0,\infty) \tag{3.4}$$

maps continuously into l^2. In this case, for any initial condition $x_0 \in l^2$ and any $u \in L^2(0,\infty)$, a unique solution of (3.1) is given by

$$x(t) = T_t x_0 + \Phi_t u, \tag{3.5}$$

with $x \in C([0,\infty), l^2)$. If b is not admissible, then there exists $u \in L^2[0,\infty)$ for which the solution of (3.1) (if it can be defined at all) is not continuous in time.

Remark 3.2. It should be pointed out that the stability restriction (3.2) is unessential; we have defined the Carleson measure criterion as it applies to stable systems. See [10] for the general definition.

Remark 3.3. In Definition 3.1, it is not necessary to verify (3.3) for every possible value of (h,ω). It is enough to consider the pairs (h_n,ω_n) for which $\nu_n = h_n + i\omega_n$. (This follows by a simple geometrical argument.)

THEOREM 3.4 (Ho and Russell, Weiss). *With b, $\mathcal{A}$, and T as above, b is admissible for T if and only if b satisfies the Carleson measure criterion for T.*

The above asserts that the control system (3.1) is well-posed on l^2 (in the above discussed sense) if and only if the sequence (b_k) satisfies (3.3).

For $\alpha \in \mathbb{R}$, we denote $l^2_\alpha = \{(c_k) \mid (|\nu_k|^\alpha c_k) \in l^2\}$.

DEFINITION 3.5. Let $\alpha \in \mathbb{R}$. With b, $\mathcal{A}$, and T as above, the pair (b,T) is *well-posed on l^2_α* if, for some $\tau > 0$, the operator Φ_τ defined in (3.4) maps continuously into l^2_α.

If (b,T) is well-posed on l^2_α, then we may define solutions of (3.1) by (3.5), and these solutions are continuous in time with values in l^2_α. We have the following corollary.

COROLLARY 3.6. *Let $\alpha \in \mathbb{R}$. The pair (b,T) in (3.1) is well-posed on l^2_α if and only if $(b_k|\nu_k|^\alpha)_{k\in\mathbb{N}}$ satisfies the Carleson measure criterion for T.*

Proof. Let $\tau > 0$ and $u \in L^2(0,\infty)$. Let $(\zeta_k) = \Phi_\tau u$ as given by (3.4). If $(b_k|\nu_k|^\alpha)_{k\in\mathbb{N}}$ satisfies the Carleson measure criterion, then $(\zeta_k|\nu_k|^\alpha) \in l^2$ or, equivalently, $(\zeta_k) \in l^2_\alpha$. □

We now return to the control problem (1.5)–(1.7). To apply Theorem 3.4 to our system, the input elements associated with (1.5)–(1.7) must be identified.

Let $G : \mathbb{R}^2 \to \mathcal{H}$ denote the *Green's map* associated with (1.5)–(1.7):

$$\begin{aligned} G(u_1,u_2)' = w; \qquad \tau w = 0 \quad \text{in } \Omega, \\ \sigma_w(0) = 0, \quad v_w(1) = 0, \quad \theta_w(0) = u_1, \quad q_w(1) = u_2. \end{aligned}$$

We obtain $G(u_1,u_2)' = (\gamma(-u_2 x + u_1), 0, -u_2 x + u_1)'$. If $y^0 = 0$ and $f, g \in C_0^\infty(0,\infty)$, then the (classical) solution y to (1.5)–(1.7) at time t coincides with an element of $\mathcal{H}_{-1}$ $(= \mathcal{D}(A^*)^*)$, also denoted by $y(t)$, which is given by (e.g., [3], [24])

$$y(t) = -\int_0^t A\mathbb{T}_{t-\tau} G(g,f)'(\tau)\, d\tau. \tag{3.6}$$

Since the appropriate extensions of A and $\mathbb{T}$ commute on $\mathcal{H}$,

$$\begin{aligned} y(t) &= \int_0^t \mathbb{T}_{t-s}(-AG)(g,f)'(s)\, ds \\ &\equiv \int_0^t \mathbb{T}_{t-s} B(g,f)'(s)\, ds. \end{aligned}$$

The boundary control operator B maps $\mathbb{R}^2$ into $\mathcal{H}_{-1}$ continuously and hence is a sum of two continuous functionals on $\mathcal{H}_1$. From integration by parts,

$$\begin{aligned} \langle B(u_1,u_2)', w\rangle &= \langle -G(u_1,u_2)', A^* w\rangle \\ &= -u_1 \bar{q}_w(0) - u_2 \bar{\theta}_w(1) \quad \forall\, w \in \mathcal{H}_1. \end{aligned}$$

Thus we define b_0, b_1 as elements of $\mathcal{H}_{-1}$ by

$$\begin{aligned} \langle b_0, \bar{w}\rangle &= -q_w(0) \quad \forall\, w \in \mathcal{H}_1, \\ \langle b_1, \bar{w}\rangle &= -\theta_w(1) \quad \forall\, w \in \mathcal{H}_1, \end{aligned} \tag{3.7}$$

so that (3.6) becomes

$$y(t) = \int_0^t \mathbb{T}_{t-s}(b_0 g(s) + b_1 f(s))\, ds \quad \text{on } \mathcal{H}_{-1}. \tag{3.8}$$

The map $(g,f)' \to y$ as given by (3.6) (or (3.8)) is bounded when considered as a map

$$(L^2(0,T))^2 \to C([0,T],\mathcal{H}_{-1}), \qquad (T>0)$$

and thus defines a generalized solution for $(g,f) \in (L^2(0,T))^2$. It follows that

$$\dot{y} = Ay + b_0 g(t) + b_1 f(t), \qquad y(0) = y^0 \in \mathcal{H} \tag{3.9}$$

has a unique continuous solution in $\mathcal{H}_{-1}$ (given by (3.8) if $y^0 = 0$), which satisfies (3.9) on $\mathcal{H}_{-2}$.

By Propositions 2.3 and 2.4, the projections P and Q continuously decompose the solutions in (3.8) by $y(t) = x(t) + z(t)$, where

$$x(t) = \int_0^t \mathbb{S}_{t-s}(Pb_0 g(s) + Pb_1 f(s))\, ds \quad \text{on } \Lambda_{-1}, \tag{3.10}$$

$$z(t) = \int_0^t \mathbb{G}_{t-s}(Qb_0 g(s) + Qb_1 f(s))\, ds \quad \text{on } \Sigma_{-1}. \tag{3.11}$$

Note that all of the results in this section that pertain to diagonal systems apply to system (3.9), since (as in the proof of Proposition 2.3) A, $\mathbb{T}$, $\mathbb{G}$, $\mathbb{S}$, and so forth can be viewed as diagonal operators on l^2 relative to the Riesz basis of eigenfunctions. Likewise, an input element b may be identified with a vector in l^2_{-1} whose components are its respective Fourier coefficients. As such, the Carleson measure criterion can be used to check wellposedness of the pairs $(b,\mathbb{T})$ on $\mathcal{H}_\alpha$.

An analysis of the admissibility of the input elements Pb_0, Pb_1, Qb_0, and Qb_1 provides the smoothest spaces Λ_α and Σ_β in which $x(t)$ and $z(t)$ are time-continuous for all L^2 controls. This then determines the maximal regularity of the solutions $y(t)$ to system (1.5)–(1.7). We have the following result.

PROPOSITION 3.7. *In the above notation,*

(i) $(Pb_0, \mathbb{S})$ *is well-posed on* Λ_α *for all* $\alpha \le -1/4$,
(ii) $(Pb_1, \mathbb{S})$ *is well-posed on* Λ_α *for all* $\alpha \le 1/4$,
(iii) $(Qb_0, \mathbb{G})$ *is well-posed on* Σ_α *for all* $\alpha \le 0$,
(iv) $(Qb_1, \mathbb{G})$ *is well-posed on* Σ_α *for all* $\alpha \le 1$.

Furthermore, the bounds given for α *are sharp.*

Proof. We first prove (i). By (3.7), $b_0 \in \mathcal{H}_{-1}$, and hence $Pb_0 \in \Lambda_{-1}$. Therefore its series

$$\begin{aligned} Pb_0 &= \sum_{k\in\mathbb{N}} \langle Pb_0, \psi_{\mu_k}\rangle \varphi_{\mu_k} \\ &= \sum_{k\in\mathbb{N}} \langle b_0, \psi_{\mu_k}\rangle \varphi_{\mu_k} \equiv \sum_{k\in\mathbb{N}} c_k \varphi_{\mu_k} \end{aligned}$$

converges in Λ_{-1}. The coefficients (c_k) are easily computed from (3.7) and (A.5) (of the Appendix). It follows that there exist positive constants m and M such that

$$mk < |c_k| < Mk \quad \forall\, k \in \mathbb{N}. \tag{3.12}$$

For $k \in \mathbb{N}$, let $b_k = c_k/|\mu_k|^{1/4}$. The semigroup $\mathbb{S}$ can be identified with the diagonal semigroup $\tilde{\mathbb{S}} \equiv \operatorname{diag}(e^{\mu_1 t}, e^{\mu_2 t}, \dots)$ relative to the Riesz basis of eigenfunctions. Thus, by Corollary 3.6, (i) holds if the sequence (b_k) satisfies the Carleson measure criterion for $\tilde{\mathbb{S}}$. Since the eigenvalues (μ_k) grow quadratically (see (2.2)), (3.12) implies that there are constants $m_1 > 0$ and $M_1 > 0$ for which

$$m_1 k < |b_k|^2 < M_1 k \quad \forall k \in \mathbb{N}.$$

It follows that there are positive numbers m_2, m_3, M_2, M_3 for which

$$m_3|\mu_n| < m_2 n^2 < \sum_{k=1}^{n} |b_k|^2 < M_2 n^2 < M_3|\mu_n| \quad \forall n \in \mathbb{N}.$$

Thus, if $N \in \mathbb{N}$ and $h = |\mu_N|$, we have

$$m_3 h \leq \sum_{-\mu_k \in R(h,0)} |b_k|^2 \leq M_3 h. \tag{3.13}$$

Thus (3.3) holds by Remark 3.3, and hence (i) holds. The first inequality in (3.13) shows that $\alpha = -1/4$ cannot be increased.

The proof of (ii) is essentially the same. For (iii) and (iv), the eigenvalues lie in a vertical strip, and their imaginary parts possess a uniform asymptotic separation. From this, it is easy to show that (3.3) holds if and only if the sequence (b_k) in (3.3) is bounded. Estimates (A.5) of the Appendix show that Qb_0 corresponds to a sequence that is bounded and bounded away from zero. Hence (iv) follows, and $\alpha = 0$ is optimal. (A.5) also shows that AQb_1 corresponds to a sequence that is bounded and bounded away from zero. Hence $(AQb_1, \mathbb{G})$ is well-posed on Σ_0. From this, it follows that $(Qb_1, \mathbb{G})$ is well-posed on Σ_1 and that $\alpha = 1$ is optimal. □

The next two lemmas relate the spaces Λ_α and Σ_α to the spaces S_α and C_α.

LEMMA 3.8. *Let S_α and C_α be defined by* (1.9), (1.10) *and assume that $-1 \leq \alpha \leq 1$. Then*

$$\mathcal{H}_\alpha = \Lambda_\alpha \oplus \Sigma_\alpha = S_\alpha \times C_\alpha \times S_{2\alpha} \tag{3.14}$$

with equivalent norms. Furthermore,

$$\Lambda_\alpha \subset S_{2+2\alpha} \times C_{1+2\alpha} \times S_{2\alpha}, \tag{3.15}$$

$$\Sigma_\alpha \subset S_\alpha \times C_\alpha \times S_{1+\alpha}. \tag{3.16}$$

Finally, the mapping $P_{12} : \Sigma_\alpha \to S_\alpha \times C_\alpha$ given by $P_{12}x = (x_1, x_2)$ and the mapping $P_3 : \Lambda_\alpha \to S_{2\alpha}$ defined by $P_3 x = x_3$ are isomorphisms.

The proof relies upon asymptotic properties of the eigenvectors and is given in the Appendix.

LEMMA 3.9. *Let $|\alpha| \leq 1$, $|\beta| \leq 1$, and $|\beta - 2\alpha| < 1$. The following set-equivalences hold:*

$$\Lambda_\alpha + \Sigma_\beta = S_\beta \times C_\beta \times S_{2\alpha}. \tag{3.17}$$

In particular,

$$\Lambda_{-1/4} + \Sigma_0 = S_0 \times C_0 \times S_{-1/2}, \tag{3.18}$$

$$\Lambda_{1/4} + \Sigma_1 = S_1 \times C_1 \times S_{1/2}. \tag{3.19}$$

Proof. It suffices to prove (3.18). The proof of the general case is done in the same way. If $y = x+z$ with $x \in \Lambda_{-1/4}$ and $z \in \Sigma_0$, then, by Lemma 3.8, $y \in S_0 \times C_0 \times S_{-1/2}$. Thus $\Lambda_{-1/4}+\Sigma_0 \subset S_0 \times C_0 \times S_{-1/2}$. Now let $y \equiv (y_1, y_2, y_3)' \in S_0 \times C_0 \times S_{-1/2}$. Let P_3 denote the operator defined in Lemma 3.8 and assume that $\tilde{y} \equiv (\tilde{y}_1, \tilde{y}_2, \tilde{y}_3)' = P_3^{-1} y_3$. Then $P_3 \tilde{y} = \tilde{y}_3 = y_3$, and, by (3.15), $\tilde{y}_1 \in S_{3/2}$ and $\tilde{y}_2 \in C_{1/2}$. Let $x = (y_1 - \tilde{y}_1, y_2 - \tilde{y}_2, 0)'$. Then $y = x + \tilde{y}$ and $x \in S_0 \times C_0 \times S_0 = \mathcal{H}_0 = \Lambda_0 + \Sigma_0$. Also, however, $\tilde{y} \in \Lambda_{-1/4}$; hence $y \in \Lambda_{-1/4} + \Sigma_0$. This proves (3.18). □

Proof of Theorem 1.1. We first examine the case where $f \equiv 0$ in (3.10), (3.11). Let $t \geq 0$. By Proposition 3.7, $x(t) \in \Lambda_{-1/4}$, $z(t) \in \Sigma_0$, and the indices $-1/4$ and 0 are optimal in that they may not be increased. Thus, by Lemma 3.9, $y(t) = x(t) + z(t) \in S_0 \times C_0 \times S_{-1/2}$. Furthermore, (3.17) implies that the index $-1/2$ is optimal, and *not both* of the first two indices (0 and 0) may be increased. A sufficient condition that both the first two indices cannot be increased beyond 0 is that the operator $\mathcal{G}_T : L^2(0,\infty) \to \Sigma_0$ given by

$$\mathcal{G}_T u = \int_0^T \mathbb{G}_{T-s} Q b_0 u(s)\, ds$$

map onto a subspace of finite codimension for sufficiently large T. (Indeed, if this is so and if P_{12} represents the projection operator defined in Lemma 3.8, then, by Lemma 3.8, $P_{12}\mathcal{G}_T$ cannot map into any of the spaces $S_\alpha \times C_\beta$ with $\alpha > 0$ or $\beta > 0$.) In the case where $\gamma \leq 1$, it is shown in the proof of Proposition 5.1 that $\mathcal{G}_T$ is surjective (for large enough T). If $\gamma > 1$, the possibility of multiple eigenvalues arises; however, the same proof shows that $\mathcal{G}_T$ maps onto a subspace of finite codimension. Hence the trajectories $y(t)$ are time-continuous (see §3) with values in $S_0 \times C_0 \times S_{-1/2}$, and (pending the proof of Proposition 5.1) each of the indices are optimal in that none may be increased.

For the case with $g \equiv 0$ in (3.10), (3.11), we have $x(t) \in \Lambda_{1/4}$ and $z(t) \in \Sigma_1$. Thus, by (3.19), $y(t) \in S_1 \times C_1 \times S_{1/2}$, and, as in the previous case, the indices can be shown to be optimal. □

4. A moment problem of mixed parabolic-hyperbolic type. As we see in §5, the problem of controlling (3.9) from an initial state to a terminal state is equivalent to solving an associated moment problem of the following form:

$$c_k = \int_0^T e^{\mu_k s} u(s) ds, \qquad k \in \mathbb{N}, \tag{4.1}$$

$$d_k = \int_0^T e^{\sigma_k s} u(s) ds, \qquad k \in \mathbb{Z}. \tag{4.2}$$

The space of all sequences $(c_k) \cup (d_k)$ for which there exists some $u \in L^2[0,T]$ such that (4.1), (4.2) holds is called the *moment space* of (4.1), (4.2). While the individual

moment spaces of (4.1) and (4.2) are rather well understood, one cannot directly use these results to infer properties of the (joint) moment space of (4.1), (4.2). The main purpose of this section is to show that the moment space of (4.1), (4.2) is the union of of the individual moment spaces for (4.1) and (4.2), provided that T is greater than some nominal value t_c that depends upon the sequence (σ_k).

Because the results of this section pertain to a variety of sequences (σ_k), (μ_k) more general than those defined by (2.1), (2.2), throughout this section, we consider (4.1), (4.2) with the following general assumptions on the exponents (σ_k), (μ_k).

Assumption H0. $\{(\sigma_k)\}_{k\in\mathbb{Z}} \cap \{(\mu_k)\}_{k\in\mathbb{N}} = \emptyset$.

Assumption H1. There exists $\beta \in \mathbb{C}$, $c > 0$, and $(\nu_k)_{k\in\mathbb{Z}} \in l^2$ for which (σ_k) satisfies

(i) $\sigma_k = \beta + ck\pi i + \nu_k$ for all $k \in \mathbb{Z}$,
(ii) $\sigma_k \neq \sigma_j$ unless $j = k$.

Assumption H2. There exist positive ρ, B, δ, ε, and $0 \leq \theta < \pi/2$ for which (μ_k) satisfies

(i) $|\arg(-\mu_k)| \leq \theta$ for all $k \in \mathbb{N}$,
(ii) $|\mu_k - \mu_j| \geq \delta|k^2 - j^2|$ for all $k, j \in \mathbb{N}$,
(iii) $\varepsilon(\rho + Bk^2) \leq |\mu_k| \leq \rho + Bk^2$ for all $k \in \mathbb{N}$.

Assumptions H0, H1, and H2 are considered standing assumptions for all the results of this section.

Eigenvalues associated with one-dimensional hyperbolic systems often satisfy Assumption H1, while those of one-dimensional parabolic (or "abstract parabolic") systems often satisfy Assumption H2. The quadratic growth and separation assumptions in Assumption H2, parts (ii) and (iii), can be replaced by more general growth rates (see [7, Thm. 1.1]); however, we avoid this additional complication here.

It is convenient to introduce a notation for some spaces that we need to use. For $0 \leq a < b$, let

$$W_{[a,b]} = \text{closed span } (e^{\sigma_k t}) \quad \text{in } L^2[a,b],$$
$$E_{[a,b]} = \text{closed span } (e^{-\mu_k t}) \quad \text{in } L^2[a,b].$$

With $\|\cdot\|_{[a,b]} := \|\cdot\|_{L^2[a,b]}$, $W_{[a,b]}$ and $E_{[a,b]}$ are Hilbert spaces.

DEFINITION 4.1. Let H be a Hilbert space with closed subspaces M and N. We say that M and N are *uniformly separated in* H if $M \cap N = \{0\}$ and their sum $M + N$ is H-closed.

Equivalently, the subspaces M and N are uniformly separated in H if and only if there exists $\delta > 0$ (called the minimum gap in Kato [11]) such that, for any $f \in M$ and $g \in N$, each of norm 1, that $\|f - g\| \geq \delta$. See [11] for details.

The following result is the main one of this section and allows us to decouple the moment problem (4.1), (4.2).

THEOREM 4.2. *Assume the standing hypothesis (Assumptions* H0, H1, *and* H2). *For each $T > 2/c$, the spaces $W_{[0,T]}$ and $E_{[0,T]}$ are uniformly separated. This does not hold for $T \leq 2/c$.*

The proof relies upon the several results that follow, and is given later in this section.

Throughout the following, we denote $t_c = 2/c$.

LEMMA 4.3. *For any $a \in \mathbb{R}$, $W_{[a,a+t_c]} = L^2[a, a + t_c]$. Furthermore, for $T \geq t_c$, $(e^{\sigma_k t})_{k\in\mathbb{Z}}$ forms a Riesz basis for each of the spaces $W_{[a,a+T]}$.*

Proof. The sequence $(\sigma_k)_{k\in\mathbb{Z}}$ lies in a vertical strip of $\mathbb{C}$, and $|\operatorname{Im}\sigma_k - ck\pi| \to 0$ as $|k| \to \infty$. This implies (see [21, p.196]) that there exists N such that $(e^{s_k t})_{k\in\mathbb{Z}}$ forms a Riesz basis for $L^2(a, a+t_c)$ for any $a \in \mathbb{R}$, where $s_k = \sigma_k$ if $|k| > N$ and $s_k = \beta + ck\pi i$ if $|k| \le N$. By [21, p.40] and [21, p. 129], a Riesz basis of exponentials for $L^2(a, a+t_c)$ is stable with respect to a change of finitely many exponentials (i.e., for $|k| \le N$, $e^{s_k t} \to e^{\sigma_k t}$). Therefore the first statement of the lemma holds, and the second is true for $T = t_c$. For any $N \in \mathbb{N}$, we can choose a sequence $(e^{\tilde{s}_k t})_{k\in\mathbb{Z}}$ for which $|\operatorname{Im}\tilde{s}_k - ck\pi/N| \to 0$ as $|k \to \infty|$ and (σ_k) is a subsequence of $(\tilde{s}_k)$. As in the proof of the first statement, it follows that $(e^{\tilde{s}_k t})$ forms a Riesz basis for $L^2(a, a+Nt_c)$, for any $a \in \mathbb{R}$. Since a subset of a Riesz basis is necessarily a Riesz basis for the subspace given by its closed span, it follows that $(e^{\sigma_k t})$ forms a Riesz basis for $W_{[a,a+Nt_c]}$, for any $a \in \mathbb{R}$. Thus the second statement of the lemma is true for $T = Nt_c$ for any $N \in \mathbb{N}$. Let $t_c \le T \le Nt_c$. By [21, p.32], $(e^{\sigma_k t})$ forms a Riesz basis for $W_{[a,a+T]}$ if and only if there exist positive numbers m_T and M_T such that, for any $n \in \mathbb{N}$ and arbitrary scalars $c_1, c_2, \ldots, c_n$, we have

$$m_T\|(c_i)\|_{l^2}^2 \le \left\|\sum_{i=1}^{n} c_i e^{\sigma_i t}\right\|_{[a,a+T]}^2 \le M_T\|(c_i)\|_{l^2}^2. \tag{4.3}$$

Let $p_n(t) = \sum_{i=1}^{n} c_i e^{\sigma_i t}$. Since $[a, a+t_c] \subset [a, a+T] \subset [a, a+Nt_c]$, it follows that

$$\|p_n\|_{[a,a+t_c]}^2 \le \|p_n\|_{[a,a+T]}^2 \le \|p_n\|_{[a,a+Nt_c]}^2.$$

Furthermore, (4.3) holds if $T = t_c$ or if $T = Nt_c$. It thus follows that, for arbitrary $T \in (t_c, Nt_c)$, the inequalities in (4.3) hold with $m_T = m_{t_c}$ and $M_T = M_{Nt_c}$. □

The previous lemma implies that, for each $f \in W_{[a,a+T]}$, with $a \in \mathbb{R}$ and $T \ge t_c$, there is a uniquely defined sequence $(c_k) \in l^2$ for which

$$f = \sum_{k\in\mathbb{Z}} c_k e^{\sigma_k t}, \qquad t \in [a, a+T]. \tag{4.4}$$

Thus given any $f \in W_{[a,a+T]}$, we may define an extension $\tilde{f} \in L^2_{\mathrm{loc}}(\mathbb{R})$ by

$$\tilde{f} = \sum_{k\in\mathbb{Z}} c_k e^{\sigma_k t}, \qquad t \in \mathbb{R}. \tag{4.5}$$

LEMMA 4.4. *Let $a, b \in \mathbb{R}$ and assume that $T \ge t_c$. Then the mapping F: $W_{[a,a+t_c]} \to W_{[b,b+T]}$ defined by*

$$Ff = \tilde{f}\Big|_{[b,b+T]}$$

is an isomorphism.

Proof. For $\alpha, \beta \in \mathbb{R}$, with $\beta \ge \alpha + t_c$, let $J_{[\alpha,\beta]}: W_{[\alpha,\beta]} \to l^2$ by

$$J_{[\alpha,\beta]} f = (c_k)_{k\in\mathbb{Z}},$$

where (c_k) is determined by (4.4). Lemma 4.3 implies that $J_{[\alpha,\beta]}$ is an isomorphism. Therefore $F = J_{[b,b+T]}^{-1} J_{[a,a+t_c]}$ is an isomorphism as well. □

For $a, s \in \mathbb{R}$ define $J_a(s) \in \mathcal{L}(L^2[a, a+t_c])$ by

$$(J_a(s)f)(t) = \tilde{f}(t+s)\,\big|_{t\in[a,a+t_c]}, \tag{4.6}$$

where f and $\tilde{f}$ are given by (4.4) and (4.5). (Lemmas 4.3 and 4.4 show that J_a is well-defined.) By Lemma 4.4, for any $a, s \in \mathbb{R}$, $J_a(s)$ is an isomorphism. In fact, it can be seen that $J_a = (J_a(s))_{s\in\mathbb{R}}$ forms a group. The generator of this group was characterized in Russell [20].

PROPOSITION 4.5. *For any $a \in \mathbb{R}$, $J_a = (J_a(s))_{s\in\mathbb{R}}$ is a strongly continuous group of operators on $L^2[a, a+t_c]$. J_a is generated by the derivative operator d/dt on the domain*

$$\mathcal{D}\left(\frac{d}{dt}\right) = \left\{ f \in H^1[a, a+t_c] \,|\, f(a+t_c) - e^{\beta t_c} f(a) = \int_a^{a+t_c} q(\tau) f(\tau) d\tau \right\}, \tag{4.7}$$

where $q \in L^2(a, a+t_c)$ is uniquely determined by a and (σ_k) and satisfies $\|q\| \leq M_a \|(\nu_k)\|_{l^2}$ for some $M_a > 0$.

An explicit formula for q can be found in [20]. This, however, does not concern us.

The next result concerns properties of the spaces $E_{[0,T]}$.

PROPOSITION 4.6. *Let $0 < \alpha < \pi/2 - \theta$ (θ is defined in Assumption* H2*) and assume that T and ν are positive. Each $f \in E_{[0,T]}$ has an analytic extension $\hat{f}$ to the the region $\Delta_\nu = \{\lambda \in \mathbb{C} \,|\, |\arg\lambda| < \alpha, |\lambda| > \nu\}$. Furthermore, there exist positive constants M, ω such that, for any $\lambda \in \Delta_\nu$,*

$$|\hat{f}(\lambda)| \leq M e^{-\omega\rho|\lambda|} \|f\|_{[0,T]} \quad \forall f \in E_{[0,T]}, \tag{4.8}$$

where M and ω depend only upon B, δ, ε, and θ (of (H2)).

This result was proved in more generality in [7].

A key point in the above proposition is that M and ω are independent of ρ (in Assumption H2) and the particular sequence $(\mu_k)_{k\in\mathbb{N}}$. Thus, by selectively removing a finite number of μ_k (those with the biggest real parts) from (μ_k), we can increase the ρ defined in Assumption H2 without affecting the constants M and ω and hence obtain any desired decay rate in (4.8) for the functions generated by such a subsequence of exponentials.

We restate this key point as follows.

COROLLARY 4.7. *Let r and T be positive numbers. The space $E_{[0,T]}$ can be decomposed into the direct sum $F \oplus R$, where F is finite-dimensional and all functions $f \in R$ have an analytic continuation $\hat{f}(z)$, which satisfies*

$$|\hat{f}(z)| < M e^{-r|z|} \|f\|_{[0,T]} \quad \forall z \in \Delta_\nu,\ f \in R. \tag{4.9}$$

Proof of Theorem 4.2. Let $\epsilon > 0$. We wish to show that the spaces $W_{[0,t_c+\varepsilon]}$ and $E_{[0,t_c+\varepsilon]}$ are uniformly separated. Let $J_{\varepsilon/2} = \left(J_{\varepsilon/2}(s)\right)_{s\in\mathbb{R}}$ denote the group defined by (4.6) and Proposition 4.5. Since groups are obviously invertible, there exist $m > 0$ and $r_0 > 0$ for which

$$\|J_{\varepsilon/2}(s) f\| > m e^{-r_0 s} \|f\| \quad \forall\, s > 0,\ f \in L^2(\varepsilon/2, t_c + \varepsilon/2).$$

It follows from the above and Lemma 4.4 that there exists $\tilde{m} > 0$ for which

$$\|\tilde{f}\|_{[s,s+t_c]} > \tilde{m} e^{-r_0 s} \|f\| \quad \forall\, s > 0,\ f \in W_{[\varepsilon/2, t_c+\varepsilon]}, \tag{4.10}$$

where $\tilde{f}$ is defined by (4.5).

Let $r > r_0$. We may without loss of generality assume that all functions in $E_{[0,t_c+\varepsilon]}$ have analytic continuations that satisfy (4.9). (This follows, since $E_{[0,t_c+\varepsilon]}$ could be decomposed as in Corollary 4.7, and, since $(\mu_k) \cup (\sigma_k)$ are distinct, F is necessarily uniformly separated from $W_{[0,t_c+\varepsilon]}$.)

Now assume, to the contrary, that the two spaces are not uniformly separated. Then there exists $(f_n)_{n\in\mathbb{N}} \in E_{[0,t_c+\varepsilon]}$ and $(g_n)_{n\in\mathbb{N}} \in W_{[0,t_c+\varepsilon]}$, each of norm 1 for which

$$\|f_n - g_n\|_{[0,t_c+\varepsilon]} \to 0 \quad \text{as } n \to \infty.$$

Since each f_n has an analytic continuation $\hat{f}_n$ that satisfies the bound (4.9) (use $T = t_c + \varepsilon$ and the M determined by $\nu = \varepsilon/2$), it follows that $(\hat{f}_n)$ forms a normal family on compact subsets of $\Delta_0 = \{z \in \mathbb{C} \,|\, z \neq 0,\ |\arg z| < \alpha\}$. It follows that there exists a subsequence, still denoted $(\hat{f}_n)$, which converges uniformly on the interval $I = [\varepsilon/2,\, t_c + \varepsilon]$ to $f(t)$. Since obviously $f \in L^2(I)$, we know that $\|g_n - f\|_I \to 0$ as $n \to \infty$. Thus $f \in W_I$, and, by Vitali's convergence theorem [9], f has an analytic continuation $\hat{f}$ to Δ_0 for which

$$|\hat{f}(t)| \leq Me^{-rt} \quad \forall t \geq \epsilon/2. \tag{4.11}$$

Assume for the moment that $\|f\|_I = 0$. It then follows that $\|g_n\|_I \to 0$, and consequently $\|g_n\|_{[0,\varepsilon/2]} \to 1$ as $n \to \infty$. This, however, is impossible by Lemma 4.4. Thus $\|f\|_I > 0$.

Let $F(s,t) = \hat{f}(s+t)$. Since $\hat{f}$ is differentiable, it follows that $\partial F/\partial s = \partial F/\partial t$ for $s + t > \varepsilon/2$. Furthermore, $\hat{f}\,|_I = \tilde{f}\,|_I \in W_I$. Thus, for all $s \in (0, \varepsilon/2)$,

$$F(s, t_c + \varepsilon/2) - e^{\beta t_c} F(s, \varepsilon/2) = \int_{\varepsilon/2}^{t_c+\varepsilon/2} q(\tau) F(s,\tau)\, d\tau. \tag{4.12}$$

Morera's theorem can be used to show that the the right-hand side of (4.12) is analytic in Δ_0. Since the left-hand side of (4.12) is also analytic in this region, we conclude that (4.12) holds for all $s \in (\varepsilon/2, \infty)$. Hence right-translations of $\hat{f}$ are given by $J_{\varepsilon/2}$ (in Proposition 4.5) acting upon f, as are those of $\tilde{f}$; i.e., for $s > 0$,

$$\hat{f}\,|_{[s+\varepsilon/2,\, s+t_c+\varepsilon/2]} = J_{\varepsilon/2}(s)\left(f\,|_{[\varepsilon/2,\, \varepsilon/2+t_c]}\right) = \tilde{f}\,|_{[s+\varepsilon/2,\, s+t_c+\varepsilon/2]}.$$

It thus follows that $\tilde{f}(t) = \hat{f}(t)$ for $t > \varepsilon/2$, but this is in conflict with (4.10) and (4.11). □

The following results relate Theorem 4.2 to the moment problem (4.1), (4.2).

PROPOSITION 4.8. *Let $(d_k)_{k\in\mathbb{Z}} \in l^2$. Then, for any $T \geq t_c$, there is a unique $u \in W_{[0,T]}$, which solves the moment problem* (4.2). *Any $f \in L^2[0,T]$ given by $f = u + v$ with $v \in W^{\perp}_{[0,T]}$ also solves* (4.2).

Proof. This follows easily from Lemma 4.3. □

PROPOSITION 4.9. *Assume that, for any $p > 0$, $(c_k)_{k\in\mathbb{N}}$ satisfies*

$$|c_k| e^{pk} \to 0 \quad \text{as } k \to \infty. \tag{4.13}$$

Then, given any $\tau > 0$, there exists a unique $u \in E_{[0,\tau]}$, which solves the moment problem (4.1). *Any $f \in L^2[0,\tau]$ given by $f = u + v$ with $v \in E_{[0,\tau]}^{\perp}$ also solves* (4.1).

Proof. From [7, Thm. 1.1], there is a $p_0 > 0$ for which the biorthonormal functions $(q_k(t))$ to $(e^{\mu_k t})$ in $E_{[0,\tau]}$ satisfy

$$\|q_k\|_{[0,\tau]} \leq M e^{p_0 k},$$

for some $M > 0$. We define $u = \sum_{k=1}^{\infty} c_k q_k$. It is easily checked that $u \in E_{[0,\tau]}$, and both u and f solve (4.1). □

Remark 4.10. Condition (4.13) can be weakened to

$$|c_k| \cdot e^{p_0 k} \to 0 \quad \text{as } k \to \infty,$$

where a suitable p_0 can be found from [7, Thm. 1.1].

THEOREM 4.11. *Under the standing hypothesis* (*Assumptions* H0, H1, H2), *given any sequence $(c_k)_{k\in\mathbb{N}}$ that satisfies* (4.13) *and any $(d_k)_{k\in\mathbb{Z}} \in l^2$, for any time $T > t_c$, there exists $u \in L^2(0,T)$, which simultaneously solves the moment problems* (4.1) *and* (4.2). *This does not hold for $T \leq t_c$.*

Proof. If $T = t_c$, the solution to (4.2) is unique (this follows from Lemma 4.3), and hence it is not in general possible to simultaneously solve (4.1) and (4.2). If $T < t_c$, then (4.2) does not necessarily have a solution, and hence it is necessary that $T \geq t_c$. Thus assume that $T > t_c$. By Theorem 4.2, the spaces $E \equiv E_{[0,T]}$ and $W \equiv W_{[0,T]}$ are uniformly separated. Thus $V := E + W$ is closed, and hence a Hilbert space with $\|\cdot\|_V = \|\cdot\|_{[0,T]}$. (So $V = E \oplus W$.) Let $E^{\perp}$, $W^{\perp}$ denote the orthogonal complements of E, W in V. Let P_E denote the orthogonal projection from V onto E. By a theorem in Kato [11, Chap. 4, §4], $E^{\perp}$ and $W^{\perp}$ are also uniformly separated, and hence $V = E^{\perp} \oplus W^{\perp}$. From this, it is easy to show that (the restriction) $P_E|_{W^{\perp}}$ is an isomorphism. Likewise, we may define an orthogonal projection P_W for which $P_W|_{E^{\perp}}$ is an isomorphism. By Propositions 4.8 and 4.9, there exist $g \in W_{[0,T]}$, which solves (4.2), and $f \in E_{[0,T]}$, which solves (4.1). Let

$$u = (P_E|_{W^{\perp}})^{-1} f + (P_W|_{E^{\perp}})^{-1} g.$$

We easily see that u solves both (4.1) and (4.2), and, since $P_E|_{W^{\perp}}$ and $P_W|_{E^{\perp}}$ are isomorphisms, $u \in L^2[0,T]$. □

Remark 4.12. If, in addition to the hypothesis of Theorem 4.11, it is known that $(d_k\sigma_k)_{k\in\mathbb{Z}} \in l^2$, then the solution u of (4.1), (4.2) may be assumed to satisfy $u(0) = 0$ and have a (distributional) derivative in L^2. This can be proved by a modification of a result in [4]. However, without any preconditions on (d_k), it can be shown that there do not in general exist smooth solutions to (4.1), (4.2) regardless of how large T is.

5. Controllability.

Consider

$$\dot{y}(t) = Ay(t) + bu(T-t), \quad 0 < t < T; \qquad y(0) = y^0, \tag{5.1}$$

where A is defined in (1.8), $u \in L^2[0,T]$, b represents b_0 or b_1 in (3.7), and y^0 belongs to an appropriate space that we specify later. If we wish to control the state to some

terminal state y^T in time T, the variation of parameters formula must hold (on an appropriate space) as follows:

$$y^T - \mathbb{T}_T y^0 = \int_0^T \mathbb{T}_s b v(s) ds.$$

Using the same decomposition as in (3.10), (3.11), we must have

$$x^T - \mathbb{S}_T x^0 = \int_0^T \mathbb{S}_\tau P b u(\tau) d\tau, \tag{5.2}$$

$$z^T - \mathbb{G}_T z^0 = \int_0^T \mathbb{G}_\tau Q b u(\tau) d\tau, \tag{5.3}$$

where $x = Py$, $z = Qy$, and likewise for x^T and z^T. So that the solution to (5.1) exists pointwise in time, we require that (5.2) and (5.3) hold on the respective spaces in which $(\mathbb{S}, Pb)$ and $(\mathbb{G}, Qb)$ are well-posed. Thus, if b represents b_0 (respectively, b_1), then (5.2) should hold on $\Lambda_{-1/4}$ (respectively, $\Lambda_{1/4}$), and (5.3) should hold on Σ_0 (respectively, Σ_1).

When (5.2) and (5.3) are integrated against the eigenfunctions of A^*, we arrive at the pair of coupled moment problems (4.1), (4.2), where (σ_k) and (μ_k) are defined by (2.1) and

$$c_k = \frac{\langle x^T, \psi_{\mu_k}\rangle - e^{\mu_k T}\langle x^0, \psi_{\mu_k}\rangle}{\langle b, \psi_{\mu_k}\rangle}, \qquad d_k = \frac{\langle z^T, \psi_{\sigma_k}\rangle - e^{\sigma_k T}\langle z^0, \psi_{\sigma_k}\rangle}{\langle b, \psi_{\sigma_k}\rangle}. \tag{5.4}$$

The sequences $(\langle b, \psi_{\mu_k}\rangle)_{k\in\mathbb{N}}$ and $(\langle b, \psi_{\sigma_k}\rangle)_{k\in\mathbb{Z}}$ each consist of only nonzero terms, and their asymptotic properties are given in (A.5) in the Appendix.

We easily see from (2.2) that Assumptions H0, H1, and H2 of the previous section are satisfied, provided that there are no multiple eigenvalues.

To describe the controllability of (5.1), we consider separately the problems of null-controllability and reachability. We say that a $\mathbb{T}$-invariant space M_0 is *b-null-controllable in time T* if, given any $y^0 \in M_0$, there exists $u \in L^2(0,T)$ for which (5.2), (5.3) hold (on the proper spaces) with $x^T = z^T = 0$. Likewise, we say that a $\mathbb{T}$-invariant space M_T is *b-reachable in time T* if, given any $y^T \in M_T$, (5.2) and (5.3) hold with $x^0 = z^0 = 0$.

We have the following result.

PROPOSITION 5.1. *Let $T > 2/c$, $\alpha \in \mathbb{R}$, and $0 < \gamma \le 1$.*

(i) *The space $\Sigma_0 + \Lambda_\alpha$ is b_0-null-controllable in time T, and $\Sigma_1 + \Lambda_\alpha$ is b_1-null-controllable in time T.*

(ii) *Let $V = \{\sum_{k\in\mathbb{N}} c_k \phi_{\mu_k} \mid (c_k)$ satisfies (4.13)$\}$. The space $\Sigma_0 + V$ is b_0-reachable in time T, and $\Sigma_1 + V$ is b_1-reachable in time T.*

In either case, the result does not remain true for $T \le 2/c$ or if Σ_0 or Σ_1 are replaced by larger $\mathbb{G}$-invariant spaces.

Proof. Let us first prove that $\Sigma_0 + \Lambda_\alpha$ is b_0-null-controllable in time T. (This is the case where the temperature is controlled at the left end of the rod.) Let $y^0 = x^0 + z^0$ with $x^0 \in \Lambda_\alpha$ and $z^0 \in \Sigma_0$. Since

$$z^0 = -\mathbb{G}_T^{-1} \int_0^T \mathbb{G}_\tau Q b v(\tau)\, d\tau,$$

it is necessary (since $\mathbb{G}_T$ is an isomorphism on Σ_0) that $z^0 \in \Sigma_0$ for (5.3) to hold on Σ_0. Thus Σ_0 cannot be replaced by a larger $\mathbb{G}$-invariant space. With $x^0 \in \Lambda_\alpha$, it follows from the analyticity of $\mathbb{S}$ that $\mathbb{S}_T x^0 \in \Lambda_0$. Hence, if the moment problem determined by (5.2), (5.3) has a solution, then (5.2) and (5.3) hold on the appropriate spaces $\Lambda_{-1/4}$ and Σ_0, respectively. From Lemma A.1 (in the Appendix) and (2.2), we can easily see that the eigenvalues (σ_k), (μ_k) satisfy Assumptions (H0), (H1), and (H2) of §4. To compute (c_k) and (d_k) in (4.1), (4.2), we use (5.4) and (A.5) (in the Appendix) and find that there are positive numbers m and M for which

$$m|\langle z^0, \psi_{\sigma_k}\rangle| \le |d_k| \le M|\langle z^0, \psi_{\sigma_k}\rangle| \quad \forall k \in \mathbb{Z}, \tag{5.5}$$

$$|c_k| \le Mk^{2\alpha} e^{\mu_k T} \|x^0\|_{\Lambda_\alpha}. \tag{5.6}$$

Thus $(d_k) \in l^2$ and (c_k) satisfies (4.13). Hence, by Theorem 4.11, the moment problem has a solution for $T > 2/c$ (but not in general for $T \le 2/c$). The proof that $\Lambda_\alpha + \Sigma_1$ is b_1-null-controllable is essentially the same. Thus (i) holds.

For the problem of reachability, first note that, if $y^T = x^T + z^T$ with x^T and z^T as in the hypothesis, then (5.2) and (5.3) hold on the proper spaces, provided that the moment problem has a solution. The moment problem that corresponds to (5.3) is easily seen to satisfy (5.5) and hence is solvable for any $(d_k) \in l^2$. Similarily, with $x^T \in V$, it is easily seen that the coefficients (c_k) satisfy (4.13). Thus (ii) holds by Theorem 4.11. □

More general statements can be made about the reachable space for the parabolic component (see [4]).

The proof of Theorem 1.2 now easily follows.

Proof of Theorem 1.2. Let $T > 2/c$. First, consider (1.5), (1.6) with $f(t) \equiv 0$. (This is equivalent to (5.1) with $b = b_0$.) Since $y^0 \in \mathcal{H}$, certainly we have that $y^0 \in \Sigma_0 + \Lambda_{-1/4}$. By Proposition 5.1, there exists $u \in L^2(0, 2/c + \epsilon)$ for which (5.2) and (5.3) hold with $x^T = z^T = 0$. Since $x \in C([0,T], \Lambda_{-1/4})$ and $z \in C([0,T], \Sigma_0)$, it follows from Lemma 3.9 that $y = x + z \in C([0,T], S_0 \times C_0 \times S_{-1/2})$. Part (ii) of Theorem 1.2 is proved likewise.

Remark 5.2. Theorem 1.2 is optimal in a couple of respects. In part (i), by Proposition 5.1 and Lemma 3.9, the space $\mathcal{H} = S_0 \times C_0 \times S_0$ is the largest null-controllable space of the form $S_\alpha \times C_\alpha \times S_0$. Likewise, in part (ii), the space $\mathcal{D}(A) = S_1 \times C_1 \times S_2$ is the largest null-controllable space of the form $S_\alpha \times C_\alpha \times S_2$. Similar statements can be made regarding reachability. Furthermore, by Theorem 1.1, the spatial regularity of the solutions given in Theorem 1.2 is optimal in the sense described in Theorem 1.1. (This means that, for general L^2-controls, no improvement in spatial regularity is possible. Of course, the spatial regularity can be improved if the controls are known to be smooth. However, by Remark 4.12, there does not in general exist smooth controls unless the initial/terminal spaces are restricted.)

Remark 5.3. Proposition 5.1 implies a certain *partial exact controllability* result. Namely, for the case of temperature control ($b = b_0$), given any $y^0 \in \mathcal{H}$ and any $z^T \in L^2(\Omega) \times L^2(\Omega)$, for any $\varepsilon > 0$, it is possible to find a control $g \in L^2(0, 2/c + \varepsilon)$ that transfers y^0 to a state y^T, which has z^T for its first two components. (The third component is not controlled.) More loosely stated, the mechanical components are exactly controllable on $(L^2(\Omega))^2$ in time $T = 2/c + \varepsilon$. Likewise for the case of heat flux control, the mechanical components are exactly controllable on $S_1 \times C_1$ in time T.

The above asserts that it is possible to exactly control the mechanics (position, velocity) of the rod with temperature (or heat flux) control alone. Furthermore, Theorem 1.2 shows that null-controllability of the whole state space (position, velocity, temperature) is possible. We could ask whether it is possible to drive an initial state y^0 to a terminal state of the form $y^T = (y_1^T, y_2^T, 0)'$. As the following shows, this is not generally possible without some severe restrictions.

NEGATIVE RESULT 5.4. *Let b denote b_0 or b_1. For any $n > 0$, there exists $y_n \in S_n \times C_n$ for which the state $y^T = (y_n, 0)$ is not b-reachable in any time $T > 0$.*

Sketch of proof. For $n > 0$, let $P_{12} : \mathcal{H}_n \to S_n \times C_n$ by $(y_1, y_2, y_3) \to (y_1, y_2)$ and define $M_n = P_{12}\Lambda_n$. If the space $M_n \times \{0\}$ were b_1-reachable, then the corresponding moment problems must necessarily have solutions. Hence the set $\mathcal{C}$ of sequences (c_k) corresponding to PM_n should be in the moment space of (4.1). (P is the projection in (5.2).) From (5.4) and estimates in the Appendix, it follows that there exists N (which depends upon n) such that, if

$$\sum_{k\in\mathbb{N}} |c_k| k^N < \infty, \tag{5.7}$$

then $(c_k) \in \mathcal{C}$. Let $(q_k)_{k\in\mathbb{N}}$ denote the biorthonormal sequence to $(\exp(\mu_j t))_{k\in\mathbb{N}}$ in $E_{[0,T]}$. ($E_{[0,T]}$ was defined in §4.) It is known [7] that $\|q_k\| \geq m_1 e^{m_0 k}$ for some $m_0 > 0$, $m_1 > 0$. The solution to (4.1) is given by

$$u = \sum_{k\in\mathbb{N}} c_k q_k$$

and must converge for all (c_k) in the moment space. However, there are clearly many sequences (c_k) satisfying (5.7) for which $\|c_k q_k\| \to \infty$ as $k \to \infty$. □

As mentioned in the Introduction, results similar to Theorems 1.1 and 1.2 apply if the stress or velocity are controlled instead of the temperature or heat flux at an endpoint. For example, consider the boundary control problem (1.5), (1.6), with the boundary conditions

$$\begin{aligned} \sigma_{y(t)}(0) &= g(t), \quad \theta_{y(t)}(0) = 0, \quad t \geq 0, \\ v_{y(t)}(1) &= f(t), \quad q_{y(t)}(1) = 0, \quad t \geq 0. \end{aligned} \tag{5.8}$$

This system can be shown to be equivalent to

$$\frac{dy}{dt} = Ay(t) + b_\sigma f(t) + b_v g(t), \qquad y(0) = y^0, \tag{5.9}$$

where A is defined by (1.8) and where the input elements b_σ and b_v are defined by

$$\begin{aligned} \langle b_\sigma, \bar{z}\rangle &= -v_z(0) = -z_2(0) \quad \forall\, z = (z_1, z_2, z_3)' \in \mathcal{H}_1, \\ \langle b_v, \bar{z}\rangle &= \sigma_z(1) = z_1(1) - \gamma z_3(1) \quad \forall\, z = (z_1, z_2, z_3)' \in \mathcal{H}_1. \end{aligned}$$

Hence (5.8), (5.9) can be analyzed in the same manner as (3.7), (3.9). In this way, we can obtain the following results, which we state without proof.

PROPOSITION 5.5. *Let $y^0 = 0$, $f \in L^2(0,\infty)$, and $g \in L^2(0,\infty)$. Then the solution to* (1.5), (1.6), (5.8) *belongs to $C([0,\infty), S_0 \times C_0 \times S_{1/2})$. If, additionally, $g \equiv 0$, then the solution belongs to $C([0,\infty), S_0 \times C_0 \times S_1)$. These solution spaces are optimal in the sense that none of the indices $\{0, 1/2, 1\}$ may be increased.*

PROPOSITION 5.6. *Assume that* $0 < \gamma \leq 1$ *in* (1.5) *and* $T > 2/c$.

(i) *For the boundary control problem* (1.5), (1.6), (5.8), *with* $f \equiv 0$, *any* $y^0 \in \mathcal{H}$ *can be controlled to zero by some* $g \in L^2[0,T]$. *The resulting solution is in* $C((0,T], S_0 \times C_0 \times S_{1/2}) \cap C([0,T], \mathcal{H})$.

(ii) *For the boundary control problem* (1.5), (1.6), (5.8), *with* $g \equiv 0$, *any* $y^0 \in \mathcal{H}$ *can be controlled to zero by some* $f \in L^2[0,T]$. *The resulting solution is in* $C((0,T], S_0 \times C_0 \times S_1) \cap C([0,T], \mathcal{H})$.

In Propositions 5.5 and 5.6, the control time and all the spaces involved can be shown to be optimal in the same sense as those of Theorems 1.1 and 1.2.

Appendix. As described in §2, the eigenfunctions of A^* consist of a real branch $(\mu_k)_{k\in\mathbb{N}}$ and a nonreal branch $(\sigma_k)_{k\in\mathbb{Z}}$, which are determined by the characteristic equations (2.1) and satisfy the asymptotic estimates (2.2). The nonreal branch consists of complex conjugate pairs for which

$$\bar{\sigma}_k = \sigma_{-k+1} \quad \forall k \in \mathbb{N}. \tag{A.1}$$

Let $r_k = k\pi - \pi/2$ for $k \in \mathbb{N}$. For $k \in \mathbb{N}$, the associated eigenfunctions are given by (see [6])

$$\psi_{\sigma_k} = \begin{pmatrix} \sin r_k x \\ \dfrac{\sigma_k}{r_k} \cos r_k x \\ \dfrac{-\gamma\sigma_k}{\sigma_k + r_k^2} \sin r_k x \end{pmatrix}, \qquad \psi_{\mu_k} = \begin{pmatrix} \dfrac{c^2\gamma}{(\mu_k/r_k)^2 + c^2} \sin r_k x \\ \dfrac{(\mu_k/r_k)c^2\gamma}{(\mu_k/r_k)^2 + c^2} \cos r_k x \\ \sin r_k x \end{pmatrix}. \tag{A.2}$$

For $k \leq 0$, ψ_{σ_k} are given by conjugation, as in (A.1). The above eigenfunctions are not normalized (as was assumed in §2), but they are *almost normalized*; that is, their norms are bounded and bounded away from zero. Since all the estimates we derive here concern only the asymptotic order, the estimates that we obtain here remain valid for the normalized eigenfunctions of §2.

For a sequence $(c_k)_{k\in\mathbb{N}}$, let us say that $c_k = \mathcal{O}(k^\alpha)$ if there are positive numbers m and M for which $mk^\alpha \leq |c_k| \leq Mk^\alpha$. It can be seen from (2.1) and (2.2) that

$$\psi_{\sigma_k} = \begin{pmatrix} \mathcal{O}(1) \cdot \sin r_k x \\ \mathcal{O}(1) \cdot \cos r_k x \\ \mathcal{O}(k^{-1}) \cdot \sin r_k x \end{pmatrix}, \qquad \psi_{\mu_k} = \begin{pmatrix} \mathcal{O}(k^{-2}) \cdot \sin r_k x \\ \mathcal{O}(k^{-1}) \cdot \cos r_k x \\ \mathcal{O}(1) \cdot \sin r_k x \end{pmatrix}. \tag{A.3}$$

By [6, Rem. 3.3], the eigenfunctions of A likewise satisfy

$$\phi_{\sigma_k} = \begin{pmatrix} \mathcal{O}(1) \cdot \sin r_k x \\ \mathcal{O}(1) \cdot \cos r_k x \\ \mathcal{O}(k^{-1}) \cdot \sin r_k x \end{pmatrix}, \qquad \phi_{\mu_k} = \begin{pmatrix} \mathcal{O}(k^{-2}) \cdot \sin r_k x \\ \mathcal{O}(k^{-1}) \cdot \cos r_k x \\ \mathcal{O}(1) \cdot \sin r_k x \end{pmatrix}. \tag{A.4}$$

Let b_0 and b_1 denote the input elements defined by (3.7). From (A.2) and (A.3), we have

$$\begin{aligned} \langle b_0, \psi_{\sigma_k} \rangle &= \mathcal{O}(1), & \langle b_0, \psi_{\mu_k} \rangle &= \mathcal{O}(k), \\ \langle b_1, \psi_{\sigma_k} \rangle &= \mathcal{O}(k^{-1}), & \langle b_1, \psi_{\mu_k} \rangle &= \mathcal{O}(1). \end{aligned} \tag{A.5}$$

Proof of Lemma 3.8. The first equality in (3.14) is just (2.5). For the second, note that $\mathcal{H} = S_0 \times C_0 \times S_0$ and $\mathcal{H}_1 = S_1 \times C_1 \times S_2$. It follows from standard properties of interpolation spaces (e.g., [15]) that, for $\alpha \in [0,1]$,

$$\begin{aligned}\mathcal{H}_\alpha &= [\mathcal{H}_1, \mathcal{H}]_{1-\alpha} \\ &= [S_1 \times C_1 \times S_2, S_0 \times C_0 \times S_0]_{1-\alpha} \\ &= S_\alpha \times C_\alpha \times S_{2\alpha}.\end{aligned}$$

The above also holds for $\alpha \in [-1,0]$ by duality.

To prove (3.15), we first note from the eigenvalue estimates (2.1), for any $\alpha \in \mathbb{R}$,

$$\Lambda_\alpha = \left\{ \sum_{k=1}^{\infty} c_k \varphi_{\mu_k} \mid (c_k k^{2\alpha}) \in l^2 \right\}. \tag{A.6}$$

Thus, if $x = (x_1, x_2, x_3)' = \sum_{k=1}^{\infty} c_k \varphi_{\mu_k} \in \Lambda_\alpha$, then by (A.4) and (A.6)

$$\begin{aligned} x_1 &= \sum_{k=1}^{\infty} c_k \cdot \mathcal{O}(k^{-2}) \cdot \sin r_k x \ \in S_{2+2\alpha}, \\ x_2 &= \sum_{k=1}^{\infty} c_k \cdot \mathcal{O}(k^{-1}) \cdot \cos r_k x \ \in C_{1+2\alpha}, \\ x_3 &= \sum_{k=1}^{\infty} c_k \cdot \mathcal{O}(1) \cdot \sin r_k x \ \in S_{2\alpha}. \end{aligned}$$

Hence $\Lambda_\alpha \subset S_{2+2\alpha} \times C_{1+2\alpha} \times S_{2\alpha}$. Theorem 2.1 and (A.6) imply that $(k^{-2\alpha}\phi_{\mu_k})$ forms a Riesz basis for Λ_α. Hence an equivalent norm $|\cdot|$ on Λ_α is given by $|x| = \|(c_k k^{2\alpha})\|_{l^2} = \|P_3 x\|_{S_\alpha}$. Thus P_3 is an isomorphism from Λ_α to S_α. Similar arguments show that (3.16) holds and that $P_{12}\big|_{\Sigma_\alpha}$ is an isomorphism. □

LEMMA A.1. *Let A be defined by* (1.8). *For $0 \le \gamma \le 1$, the spectrum of A consists entirely of simple eigenvalues.*

Proof. For $k \in \mathbb{N}$, let $r_k = k\pi - \pi/2$. First, assume that for some $k \in \mathbb{N}$, the characteristic equation (2.1) has a double root; i.e., $p_k(x) \equiv (x^2 + c^2)(x + r_k) + \gamma^2 c^2 x$ can be written as

$$p_k(x) = (x + a)(x + b)^2,$$

where a and b are positive. (Any double root is clearly real, and the roots must be negative since A is dissipative.) Equating coefficients of the two polynomials leads to

$$1 + \gamma^2 = \frac{(a + 2b)(2a + b)}{ab},$$

which is impossible with $\gamma^2 \le 8$. Thus, if λ is a double eigenvalue, there exists distinct positive integers j, k such that $p_k(\lambda/r_k) = 0$ and $p_j(\lambda/r_j) = 0$. This can be written as

$$\lambda^3 + \lambda^2 r_k^2 + \lambda c^2(1 + \gamma^2) r_k^2 + c^2 r_k^4 = 0, \tag{A.7}$$

$$\lambda^3 + \lambda^2 r_j^2 + \lambda c^2(1 + \gamma^2) r_j^2 + c^2 r_j^4 = 0. \tag{A.8}$$

Let $G = 1 + \gamma^2$, $S = r_k^2 + r_j^2$, and $P = r_k^2 r_j^2$. By eliminating the λ^3 term and, respectively, the constant term in (A.7), (A.8), we find (using $\lambda \neq 0$) that

$$\lambda^2 + \lambda c^2 G + c^2 S = 0, \qquad \lambda^2 S + \lambda P + c^2 G P = 0.$$

All the coefficients are positive. We again eliminate the highest-order terms and, respectively, the constant terms to obtain

$$\lambda(c^2 GS - P) + c^2(S^2 - GP) = 0, \tag{A.9}$$

$$\lambda(GP - S^2) + P(c^2 G^2 - S) = 0. \tag{A.10}$$

It is easy to show that, if any of the coefficients in (A.9) or (A.10) are zero, then they all are. In this case, we have $GP = S^2$, but this is impossible for $\gamma^2 < 3$, since

$$S^2 = (r_k^2 + r_j^2)^2 \geq 4(r_k^2 r_j^2) = 4P. \tag{A.11}$$

We may thus assume that none of the coefficients in (A.9) or (A.10) are zero. Next, we eliminate λ from (A.9), (A.10) and find that

$$c^4 G^2 + c^2 S(S^2/PG - 3) + P/G = 0.$$

Since c^2 is positive, the coefficient of c^2 must be negative, and the discriminant (of the quadratic polynomial in c^2) must be positive. This leads to

$$\left(\frac{S^2}{PG} - 3\right)^2 > 4/3,$$

which is impossible by (A.11) for $\gamma^2 \leq 1$. □

Remark A.2. It is worth noting that double eigenvalues are possible if γ is larger: if $c^2 = 81\pi^2/4000$ and $\gamma^2 = 91/9$, then $\lambda = (9/40)\pi^2 \exp(i2\pi/3)$ is a double eigenvalue (corresponding to $k = 1$ and $j = 2$ in the notation of (A.7), (A.8)). This shows that null-controllability does not hold for all $\gamma > 0$. Our restriction: $0 < \gamma \leq 1$ is only sufficient to ensure that no double eigenvalues occur.

CONTROL OF INFINITE BEHAVIOR OF FINITE AUTOMATA*

J. G. THISTLE† AND W. M. WONHAM‡

Abstract. A problem in the control of automata on infinite strings is defined and analyzed. The key to the investigation is the development of a fixpoint characterization of the "controllability subset" of a deterministic Rabin automaton, the set of states from which the automaton can be controlled to the satisfaction of its own acceptance condition. The fixpoint representation allows straightforward computation of the controllability subset and the construction of a suitable state-feedback control for the automaton. The results have applications to control synthesis, automaton synthesis, and decision procedures for logical satisfiability; in particular, they represent a direct, efficient and natural solution to Church's problem, the construction of winning strategies for two-player zero-sum ω-regular games of perfect information, and the emptiness problem for automata on infinite trees.

Key words. discrete-event systems, synthesis problems, Church's problem, tree automaton emptiness, ω-languages, ω-automata, ω-regular games

1. Introduction.

This paper and the companion article [42] outline a theory of the control of infinite behavior of discrete-event systems. Based on [43], the articles extend some of the fundamental results of the finitary *supervisory control theory* of Ramadge and Wonham (see [35]). The present paper focuses on a key computational problem that arises not only in connection with control but also in several other contexts within the study of infinite behavior of discrete-event systems. As formulated here, the problem concerns the control of finite automata on infinite strings, commonly termed finite *ω-automata*.

A survey of the theory of ω-automata is given in [44]. Like their more familiar counterparts on finite strings, ω-automata consist of transition structures and accompanying acceptance conditions. However, whereas acceptance conditions for finite strings depend on the state *last* entered by the automaton upon reading a symbol string, the criterion for infinite strings instead involves the set of states entered *infinitely often* during the processing of the string. This article is specifically concerned with *Rabin* acceptance conditions (see §3).

Though relatively new to control theory, ω-automata are well-established tools in the theory of discrete-event systems. First introduced by Büchi as a means of deciding satisfiability of certain logical formulas [3] and by Muller as a natural means of describing infinite behavior of asynchronous switching circuits [27], they have since been applied to numerous studies of digital hardware, computer software and the associated logics (see, for example, [44], [12], [22], [23], [48], [46], [29], [1]), and, to a more limited extent, discrete-event control systems (see [2], [17], [36], [18], [40]).

Automata are traditionally interpreted as information-processing devices, "reading" strings of symbols (or inputs of other forms), executing a state transition in response to each symbol, and either accepting or rejecting strings according to their acceptance conditions. From the perspective of control, however, they are more naturally viewed as dynamic systems that spontaneously execute sequences of state transitions, "generating" strings of symbols as they do so, the acceptance condition distinguishing those strings that in some sense represent desirable behavior [34]. This is the view that we adopt here. Moreover, it is assumed here that, at any point in the system's operation, it is possible to restrict the set of symbols that may be generated to any one of a given family of subsets of the complete alphabet; this represents a means of control over the state transitions of the automaton. The article examines the computation of the "controllability subset" of a deterministic Rabin automaton (the set of states from which the automaton can be controlled to the satisfaction of its own acceptance condition) and the construction of corresponding control strategies.

This problem arises naturally in the study of the supervisory control of infinite behavior of discrete-event systems; indeed, the results of the current article are applied to effective supervisor synthesis in [42]. The same problem, however, also occurs in several other branches of the theory of discrete-event systems. In its earliest formulation, it represents a basic paradigm for program synthesis: *Church's problem* is that of constructing an automaton whose infinite input-output behavior satisfies a given logical formula [6], [7]. As many of the relevant logical languages are equivalent in expressiveness to finite ω-automata, Church's problem is often formulated in purely automata-theoretic terms, which make it formally equivalent to the problem studied here [24], [4], [33], [29], [28]. The first comprehensive solution to Church's problem exploited its equivalence to the problem of constructing winning strategies for two-person, zero-sum, and ω-regular games of perfect information [24], [4]. Simpler solutions have since been obtained through reduction to a further equivalent problem, the so-called *emptiness problem for automata on infinite trees* [44], [33], [29], [1], [49], which represents an important means of deciding satisfiability for a variety of logics, including many propositional logics of programs [12], [31], [32], [38], [47].

The present control-theoretic formulation admits a particularly direct and natural solution. First, the controllability subset is defined "operationally" in terms of the infinite strings generated by the automaton under suitable control. It is then shown that this operational definition can be replaced by a "denotational" one, a more direct characterization of the controllability subset as a certain fixpoint of an "inverse dynamics operator," which depends only on the one-step dynamics of the controlled automaton. The computation of this fixpoint is straightforward, and intermediate results of the calculation can be used to compute a suitable control in the form of a state feedback map. This approach is essentially optimal in computational complexity.

Section 2 presents some preliminaries concerning extremal fixpoints of monotone operators. In §3 the controllability subset is formally defined. Section 4 discusses some operations on automata that allow for structural induction in later definitions and proofs. The "inverse dynamics" and "p-reachability" operators of a deterministic Rabin automaton are then defined in §5. In §6 the controllability subset is characterized as a certain fixpoint of these operators. The computational complexity of deciding membership of a state in the controllability subset is examined in §7, and it is shown that straightforward computation of the fixpoint is essentially optimal in this respect. The results of the article are illustrated with an example in §8 and compared with earlier work in §9.

One of the advantages of the methods of the article is its extensibility to control under liveness assumptions. The case of liveness assumptions represented by Büchi acceptance conditions is outlined in [41], where the results of the present article are also summarized. More general forms of liveness assumptions will be treated in future reports.

2. Preliminaries: Fixpoints of monotone operators. The methods of this paper require special notation for extremal fixpoints of monotone operators. This section presents a suitable calculus based on the use of "fixpoint quantifiers." Originally applied to the denotational semantics of recursion (see [8]), such quantifiers have also been used to extend the power of various logics of programs [10], [30], [21], [45].

Our definitions of monotonicity and continuity and our presentation of the fundamental results of Tarski and Knaster (Theorem 2.1) are adapted from those of [16].

2.1. Monotone and continuous operators. A k-ary *operator* on a power set 2^X is a map $f : (2^X)^k \to 2^X$.

An operator is *monotone* if it preserves inclusion, that is,

$$X_i \subseteq X_i' \Longrightarrow f(X_1, \ldots, X_i, \ldots X_k) \subseteq f(X_1, \ldots, X_i', \ldots X_k), \qquad 1 \leq i \leq k.$$

An operator is $\cup$-*continuous* if, for any i, $1 \leq i \leq k$, and any nondecreasing sequence $X_i^0 \subseteq X_i^1 \subseteq X_i^2 \cdots$,

$$\bigcup_{j=0}^{\infty} f(X_1, \ldots, X_i^j, \ldots, X_k) = f\left(X_1, \ldots, \bigcup_{j=0}^{\infty} X_i^j, \ldots, X_k\right).$$

An operator is $\cap$-*continuous* if, for any i, $1 \leq i \leq k$ and any nonincreasing sequence $X_i^0 \supseteq X_i^1 \supseteq X_i^2 \cdots$,

$$\bigcap_{j=0}^{\infty} f(X_1, \ldots, X_i^j, \ldots, X_k) = f\left(X_1, \ldots, \bigcap_{j=0}^{\infty} X_i^j, \ldots, X_k\right).$$

Both $\cup$-continuity and $\cap$-continuity imply monotonicity; for operators on finite power sets, the reverse implications hold.

Monotonicity is important for our purposes because it implies the existence of extremal fixpoints (in the sense of set inclusion). The continuity properties provide a convenient means of computing such fixpoints (see Theorem 2.1 below).

2.2. A fixpoint calculus. The expressions of our fixpoint notation consist of monotone operators applied to subsets and the "fixpoint quantifiers" μ and ν that quantify over subsets. Expressions of the form

$$\mu Y.\ \phi(Y) \qquad \text{(respectively, } \nu Y.\ \phi(Y)\text{)}$$

represent the least (respectively, greatest) $Y \subseteq X$ such that $Y = \phi(Y)$, in other words, the least (respectively, greatest) fixpoints of the operator that maps every $Y \subseteq X$ to $\phi(Y)$. The question of the existence of such fixpoints is dealt with below.

- For any $Y' \subseteq X$,

$$\mu Y.\ (Y' \cup Y) = Y'.$$

The dual result is

$$\nu Y.\ (Y' \cap Y) = Y'.$$

• Adding fixpoint quantifiers to the expressions in the previous example, we find that

$$\nu Y'.\ \mu Y.\ (Y' \cup Y) = \nu Y'.\ Y' = X$$

and, dually,

$$\mu Y'.\ \nu Y.\ (Y' \cap Y) = \mu Y'.\ Y' = \emptyset.$$

2.3. Fixpoint lemmata. The basic results on extremal fixpoints of monotone operators follow from more general theorems of Tarski and Knaster.[1]

THEOREM 2.1 (Tarski–Knaster). *Let $f : 2^X \to 2^X$ be a monotone operator on X. Then f has least and greatest fixpoints; in fact,*

(i) $\mu Y.\ f(Y) = \bigcap\{Y' \subseteq X :\ Y' = f(Y')\} = \bigcap\{Y' \subseteq X :\ Y' \supseteq f(Y')\}$,

(i′) $\nu Y.\ f(Y) = \bigcup\{Y' \subseteq X :\ Y' = f(Y')\} = \bigcup\{Y' \subseteq X :\ Y' \subseteq f(Y')\}$,

(ii) *If f is $\cup$-continuous then* $\mu Y.\ f(Y) = \bigcup_{i=0}^{\infty} f^i(\emptyset)$,

(ii′) *If f is $\cap$-continuous then* $\nu Y.\ f(Y) = \bigcap_{i=0}^{\infty} f^i(X)$

(*where f^i denotes the i-fold composition of f with itself*).

LEMMA 2.2. *Let $f_1,\ f_2 : 2^X \to 2^X$ be monotone operators on X. If*

$$f_1(Y) \subseteq f_2(Y) \quad \forall Y \subseteq X,$$

then (a) $\mu Y.\ f_1(Y) \subseteq \mu Y.\ f_2(Y)$ *and* (b) $\nu Y.\ f_1(Y) \subseteq \nu Y.\ f_2(Y)$.

Theorem 2.1 guarantees that operators have extremal fixpoints, provided that they are monotone. Monotonicity is clearly preserved under composition of operators, and Lemma 2.2 shows that it is preserved under fixpoint quantification.[2] Together, these results imply that the semantics of our calculus are well defined.

3. Controllability subsets of Rabin automata. Before defining Rabin automata and their controllability subsets, we establish some notation for formal languages.

Σ^* denotes the set of all finite strings (including the *empty string*, denoted by 1, having length 0) over some finite symbol alphabet Σ; Σ^ω denotes the set of (countably) infinite strings over Σ; Σ^∞ denotes $\Sigma^* \cup \Sigma^\omega$. A *language* is any set of strings over Σ; in particular, an *ω-language* is a subset of Σ^ω.

A finite string $k \in \Sigma^*$ is a *prefix* of $v \in \Sigma^\infty$ if k is an initial substring of v; in this case, we write $k \leq v$; if k is not identical to v (i.e., if k is a *proper* prefix), we may write $k < v$. For any string $v \in \Sigma^\infty$, we let $\mathrm{pre}(v)$ denote its set of (finite) prefixes, that is, $\mathrm{pre}(v) := \{k \in \Sigma^* : k \leq v\}$.

A *Rabin automaton* [26], [33] is a 5-tuple

$$\mathcal{A} = (\Sigma, X, \delta, x_0, \{(R_p, I_p) : p \in P\})$$

[1] See [39]. For more information on the history of these results, see [25]. The authors are grateful to Karen Rudie for pointing out this second reference.

[2] That is, if $f : (2^X)^k \longrightarrow 2^X$ is monotone, then so is the operator $f_1^\mu : (2^X)^{k-1} \longrightarrow 2^X$ defined by

$$f_1^\mu : (Y_2, \ldots, Y_k) \mapsto \mu Y_1.\ f(Y_1, Y_2, \ldots, Y_k),$$

and similarly for greatest fixpoints.

consisting of: an *alphabet* Σ, a finite *state set* X, a *transition function* $\delta : \Sigma \times X \longrightarrow 2^X$, an *initial state* x_0, and a *family of accepting pairs* $(R_p, I_p) \in 2^X \times 2^X$ with index set P.

It is convenient to extend δ to a map $\delta : \Sigma^* \longrightarrow 2^X$ according to

$$(1, x) \overset{\delta}{\mapsto} x,$$

$$(k\sigma, x) \overset{\delta}{\mapsto} \bigcup\{\delta(\sigma, x_k) : x_k \in \delta(k, x)\} \quad \forall\, k \in \Sigma^*,\ \sigma \in \Sigma.$$

A *path* on $\mathcal{A}$ of a string $v \in \Sigma^\infty$ is a total function $\pi : \mathrm{pre}(v) \longrightarrow X$ such that

$$\pi(1) = x_0 \quad \forall\, k \in \mathrm{pre}(v),\ \sigma \in \Sigma\ :\ k\sigma \in \mathrm{pre}(v) \Rightarrow \pi(k\sigma) \in \delta(\sigma, \pi(k)).$$

Thus a path determines a state sequence consistent with the form of the string and the transition structure of the automaton.

Often, we wish to discuss "paths" that do not begin with the initial state (i.e., for which $\pi(1) \neq x_0$). For this, we define $\mathcal{A}_x$ to be the automaton obtained from $\mathcal{A}$ by designating $x \in X$ the initial state.

In keeping with our interpretation of automata as generators, we say that a string $v \in \Sigma^\infty$ is *generated* by $\mathcal{A}$ if v has a path on $\mathcal{A}$.

The *recurrence set* of a path $\pi : \mathrm{pre}(s) \longrightarrow X$ is

$$\Omega_\pi := \{x \in X : |\pi^{-1}(x)| = \omega\}.$$

In other words, the recurrence set is the set of states entered infinitely often on a given path. The recurrence set Ω_π is nonempty if and only if the string s is infinite.

For our purposes, it is convenient to adopt a slight modification of the standard definition of acceptance. A path π is *accepted* if

$$\exists p \in P : \Omega_\pi \cap R_p \neq \emptyset,\ \Omega_\pi \subseteq I_p.$$

Such paths represent infinite state sequences along which, for some $p \in P$, R_p is "continually recurrent" (is occupied infinitely often) and I_p is "eventually invariant" (is occupied almost always). (It is more customary to specify in place of I_p its complement, say $\overline{I_p}$, and require the equivalent condition that $\Omega_\pi \cap \overline{I_p} = \emptyset$, in other words, that $\overline{I_p}$ be "finitely recurrent" (occupied almost never).)

The ω-language *accepted* by $\mathcal{A}$ is the set of all (infinite) strings over Σ that have accepted paths on $\mathcal{A}$.

We say that $\mathcal{A}$ is *deterministic* if $|\delta(\sigma, x)| \leq 1$ for all $\sigma \in \Sigma, x \in X$. In this case, we represent the transition function as a partial function $\delta : \Sigma^* \times X \longrightarrow X$, writing $\delta(k, x)!$ to signify that the function is defined for the particular argument (k, x). If $\mathcal{A}$ is deterministic, then every string has at most one path π on $\mathcal{A}$.

According to our definition, a string is accepted by $\mathcal{A}$ if it has a path on $\mathcal{A}$ along which, for some $p \in P$, R_p is continually recurrent and I_p is eventually invariant. While this notion of acceptance may appear arbitrary, it is quite general in the sense that all of the languages that are accepted by finite ω-automata, the so-called ω-regular languages, are accepted by deterministic Rabin automata [26], [5], [9]. Indeed, the Rabin acceptance condition arises naturally in the "determinization" of nondeterministic ω-automata [26], [37], [14].

To introduce a control feature, we assume that a family $\mathbf{C} \subseteq 2^\Sigma$ of *control patterns* is given, representing subsets of the alphabet to which we can restrict, at any point

in the operation of the automaton, the set of symbols that it may generate. Control strategies can be represented as "feedback maps" $f : \Sigma^* \longrightarrow \mathbf{C}$ (pfn), which can be interpreted as associating with the sequence of all past symbols generated by the automaton a corresponding control action. Consistent with this interpretation, we say that $v \in \Sigma^\infty$ is generated by $\mathcal{A}$ *under* f if v is generated by $\mathcal{A}$, and, for all $k\sigma \in \text{pre}(v)$, $f(k)$ is defined and $\sigma \in f(k)$. We say that f is complete with respect to $\mathcal{A}$ if for all $k \in \Sigma^*$ generated by $\mathcal{A}$ under f, $f(k)$ is defined [34], [42].

We can now define the set from which the infinite behavior of an automaton can be controlled to the satisfaction of its acceptance condition. For any Rabin automaton $\mathcal{A} = (\Sigma, X, \delta, x_0, \{(R_p, I_p) : p \in P\})$, define $P^{\mathcal{A}} \subseteq X$ as the set of all $x \in X$ for which there exists a complete feedback map $f : \Sigma^* \longrightarrow \mathbf{C}$ such that

1) Every $s \in \Sigma^\omega$ generated by $\mathcal{A}_x$ under f is accepted by $\mathcal{A}_x$, and

2) For any $k \in \Sigma^*$ generated by $\mathcal{A}_x$ under f, there exists $\sigma \in \Sigma$ such that $k\sigma$ is generated by $\mathcal{A}_x$ under f.

Clause 1) captures the notion that f should control $\mathcal{A}$ to the satisfaction of its acceptance condition. Clause 2) eliminates trivial solutions by requiring that every finite string generated by $\mathcal{A}_x$ under f have proper extensions that are also generated by $\mathcal{A}_x$ under f; for deterministic $\mathcal{A}$, this means that the control strategy represented by f must avoid system deadlocks.

We call $P^{\mathcal{A}}$ the *controllability subset* of $\mathcal{A}$. The above definition can be considered "operational" in the sense that it is stated in terms of the infinite strings generated by $\mathcal{A}$ under suitable control. While straightforward and intelligible from an intuitive standpoint, this description is of limited mathematical usefulness. The main results of the article establish an alternative representation that can be described as "denotational," in the sense that it is mathematically much more direct; it characterizes the controllability subset as a certain fixpoint of an operator that depends in a simple manner on the transition structure of the automaton and the family of control patterns. The new definition allows both efficient computation of the controllability subset and effective synthesis of appropriate controls.

4. Automaton structure. The recursive form of our fixpoint characterization of the controllability subset and the inductive nature of some of our proofs necessitate a precise notion of the structural complexity of automata and methods of converting complex automata to simpler ones. One useful measure of structural complexity is the number of pairs in the acceptance condition; another is the number of "live" states as defined by Rabin [33].

Let $\mathcal{A} = (\Sigma, X, \delta, x_0, \{(R_p, I_p) : p \in P\})$ be a Rabin automaton. The set of *live* states of $\mathcal{A}$ is given by[3]

$$L(\mathcal{A}) := \{x \in X : (\exists \sigma \in \Sigma)\ \delta(\sigma, x) \neq x\}.$$

In other words, a state is live if other states can be reached from it. An approximate opposite to liveness is "degeneracy." A state $x \in X$ is *degenerate* if there are transitions leaving x, but all of them simply lead back to x; more precisely, $x \in X$ is degenerate if

$$\exists \sigma \in \Sigma :\ \delta(\sigma, x)! \quad \forall \sigma \in \Sigma : \delta(\sigma, x) = x.$$

The set of degenerate states of $\mathcal{A}$ is denoted by $D(\mathcal{A})$. The subsets $L(\mathcal{A})$ and $D(\mathcal{A})$ are, of course, disjoint, but $L(\mathcal{A}) \cup D(\mathcal{A})$ may be a proper subset of X; indeed, $L(\mathcal{A}) \cup D(\mathcal{A}) = \{x \in X : (\text{there exists } \sigma \in \Sigma)\delta(\sigma, x)!\}$.

[3] Rabin excludes the initial state from the set of live states.

For any $x \in X$, $X' \subseteq X$, and $p \in P$, the following operations[4] on the Rabin automaton $\mathcal{A} = (\Sigma, X, \delta, x_0, \{(R_p, I_p) : p \in P\})$ potentially reduce its structural complexity as measured by $|L(\mathcal{A})|$ and $|P|$:

self-looping of a subset: $\mathcal{A}(\hookrightarrow X') := (\Sigma, X, \delta', x_0, \{(R'_p, I'_p) : p \in P\})$, where

$$\delta'(\sigma, x') = \begin{cases} x' & \text{if } x' \in X', \\ \delta(\sigma, x') & \text{otherwise,} \end{cases}$$
$$R'_p = R_p \cup X', \quad I'_p = I_p \cup X' \quad \forall p \in P;$$

restriction to a subset: $\mathcal{A} \restriction X' := (\Sigma, X, \delta', x_0, \{(R'_p, I'_p) : p \in P\})$, where

$$\delta'(\sigma, x') = \begin{cases} \delta(\sigma, x') & \text{if } x' \in X', \\ x' & \text{otherwise,} \end{cases}$$
$$R'_p = R_p \cap X', \quad I'_p = I_p \cap X' \quad \forall p \in P;$$

exclusion of a pair: Let $\mathcal{A} \restriction (I_p \cup D(\mathcal{A})) = (\Sigma, X, \delta', x_0, \{(R'_q, I'_q) : q \in P\})$. Then

$$\mathcal{A} \downarrow p := \begin{cases} (\Sigma, X, \delta', x_0, \{(R'_q, I'_q) : q \in P\}) & \text{if } |P| = 1, \\ (\Sigma, X, \delta', x_0, \{(R'_q, I'_q) : q \in P \setminus \{p\}\}) & \text{if } |P| > 1. \end{cases}$$

Self-looping of a subset $X' \subseteq X$ turns every $x \in X'$ into a degenerate state and ensures that the singleton $\{x\}$ satisfies the acceptance criterion. On the other hand, restriction to a subset $X' \subseteq X$ turns all other states into degenerate states that do *not* satisfy the acceptance condition. Finally, exclusion of a pair indexed by $p \in P$ restricts the automaton to the subset $I_p \cup D(\mathcal{A})$ and, provided that $|P| > 1$, eliminates the pair (R_p, I_p). All three of these operations potentially reduce the number of live states, while the third potentially reduces the number of pairs in the acceptance condition.

The effects of the operations on the subset $P^{\mathcal{A}}$ can be described as follows.

PROPOSITION 4.1. *Let $\mathcal{A} = (\Sigma, X, \delta, x_0, \{(R_p, I_p) : p \in P\})$ be a deterministic Rabin automaton and suppose that $x \in X$, $X' \subseteq X$ and $p \in P$. Then*

(a) $P^{\mathcal{A}} \cap D(\mathcal{A}) = \bigcup_{p \in P} (R_p \cap I_p) \cap D(\mathcal{A})$,

(b) $P^{\mathcal{A}} \cup X' \subseteq P^{\mathcal{A}(\hookrightarrow X')}$,

(c) $P^{\mathcal{A} \restriction X'} \subseteq P^{\mathcal{A}} \cap X'$,

(d) $P^{\mathcal{A} \downarrow p} \subseteq P^{\mathcal{A}} \cap (I_p \cup D(\mathcal{A}))$.

Proof. The proof follows by definition. □

Part (a) means intuitively that an automaton can be controlled to satisfy its acceptance condition from a degenerate state if and only if that degenerate state itself satisfies the acceptance criterion (since no other states can be reached from it). Part (b) states that self-looping makes it easier to force the automaton to satisfy its acceptance criterion by creating degenerate states that satisfy the criterion, while (c) and (d) state, respectively, that restriction and exclusion make it harder by creating degenerate states that do not satisfy the acceptance condition and by strengthening the acceptance condition.

5. The inverse dynamics operator and p-reachability operators. We characterize $P^{\mathcal{A}} \subseteq X$ as a certain fixpoint of the following monotone operator. Let

[4] The operations of "self-looping" and "restriction" are based on similar operations defined in [33].

$\mathcal{A} = (\Sigma, X, \delta, x_0, \{(R_p, I_p) : p \in P\})$ be a deterministic Rabin automaton. Its *inverse dynamics operator* is given by

$$\theta^{\mathcal{A}} : 2^X \longrightarrow 2^X,$$
$$X' \mapsto \{x \in X : (\exists \Gamma \in \mathbf{C})[(\forall \sigma \in \Gamma)\delta(\sigma, x) \in X',\ (\exists \sigma \in \Gamma)\delta(\sigma, x)!]\}.$$

For any $X' \subseteq X$, $\theta^{\mathcal{A}}(X')$ is the set of all states in which the automaton can be controlled so that its next state belongs to X'.

The subset $P^{\mathcal{A}}$ is indeed one of the fixpoints of $\theta^{\mathcal{A}}$, as shown in the following result.

PROPOSITION 5.1. *Let $\mathcal{A}$ be a deterministic Rabin automaton. Then*

$$P^{\mathcal{A}} = \theta^{\mathcal{A}}(P^{\mathcal{A}}).$$

Proof. The proof follows by definition. □

This result does not determine $P^{\mathcal{A}}$ uniquely, since $\theta^{\mathcal{A}}$ may have many fixpoints, but we show that, with the use of the inverse dynamics operator, $P^{\mathcal{A}}$ can be uniquely represented by an expression in our fixpoint calculus. Other significant state subsets can be represented in similar fashion; for example, if $X_1 \subseteq X$, then

$$\nu X_2.\ [\theta^{\mathcal{A}}(X_2) \cap X_1]$$

denotes the supremal "control-invariant" subset of X_1 (see Theorem 2.1 (i′)); the fixpoint

$$\mu X_2.\ \theta^{\mathcal{A}}(X_1 \cup X_2)$$

is the "reachability subset" of X_1, the set of states from which the automaton can be controlled to reach X_1 (see Theorem 2.1(ii)); for $I_p \subseteq X$, the subset

$$\mu X_2.\ [\theta^{\mathcal{A}}(X_1 \cup X_2) \cap I_p]$$

is the set of states from which $\mathcal{A}$ can be controlled to reach $X_1 \subseteq X$ by way of a path that lies within[5] I_p.

To write a succinct expression for $P^{\mathcal{A}}$, it is convenient to generalize this second notion of reachability. Let $\mathcal{A} = (\Sigma, X, \delta, x_0, \{(R_p, I_p) : p \in P\})$ be a Rabin automaton. For any $p \in P$, the *p-reachability operator* of $\mathcal{A}$ is given by

$$\rho_p^{\mathcal{A}} : (2^X)^2 \longrightarrow 2^X,$$
$$(X_1, X_2) \mapsto \mu X_3.\ [\theta^{\mathcal{A}}(X_1) \cup [\theta^{\mathcal{A}}(X_1 \cup X_2 \cup X_3) \cap I_p]].$$

Thus $\rho_p^{\mathcal{A}}(\emptyset, X_2) \subseteq X$ is simply the set of states from which $\mathcal{A}$ can be controlled to reach X_2 by way of a path that lies within I_p. In general, $\rho_p^{\mathcal{A}}(X_1, X_2)$ is the set of states from which $\mathcal{A}$ can be controlled to reach X_2 by way of a path that lies within $I_p \subseteq X$ or, failing that, to reach X_1 (and to do so in at most one state transition after leaving I_p).

It is shown in the next section that the subset $P^{\mathcal{A}}$ can be described in terms of extremal fixpoints of the p-reachability operators. As preliminaries, we present the following two results, which respectively relate the inverse dynamics operator and the p-reachability operators to the structure of automata.

[5] With the possible exception of the final state in the path, which may belong to $X_1 \setminus I_p$.

PROPOSITION 5.2. *Let $\mathcal{A} = (X, \Sigma, \delta, x_0, \{(R_p, I_p) : p \in P\})$ be a Rabin automaton and suppose $x \in X$, $p \in P$ and $X', X'' \subseteq X$. Then*

(a) $\theta^{\mathcal{A}}(X') \cap D(\mathcal{A}) = X' \cap D(\mathcal{A})$,

(b) $\theta^{\mathcal{A}(\hookrightarrow X'')}(X') \setminus X'' = \theta^{\mathcal{A}}(X') \setminus X''$,

(c) $\theta^{\mathcal{A}\restriction X''}(X') \cap X'' = \theta^{\mathcal{A}}(X') \cap X''$,

(d) $\theta^{\mathcal{A}\restriction p}(X') \cap [I_p \cup D(A)] = \theta^{\mathcal{A}}(X') \cap [I_p \cup D(A)]$.

Part (a) simply means that all transitions leaving a degenerate state lead back to that state. Part (b) says that the self-looping of a subset X'' affects only transitions from states belonging to X''. On the other hand, part (c) says that restriction to $X'' \subseteq X$ affects only transitions from states *not* belonging to X''; part (d) is similar.

PROPOSITION 5.3. *Let $\mathcal{A} = (X, \Sigma, \delta, x_0, \{(R_p, I_p) : p \in P\})$ be a Rabin automaton and suppose that $x \in X$, $X_1, X_2 \subseteq X$, and $p \in P$. Then*

(a) $\rho_p^{\mathcal{A}}(X_1, X_2) \cap D(\mathcal{A}) = [X_1 \cup (X_2 \cap I_p)] \cap D(\mathcal{A})$,

(b) *If $X' \subseteq X_1 \subseteq X$, $\rho_p^{\mathcal{A}(\hookrightarrow X')}(X_1, X_2) \setminus X' = \rho_p^{\mathcal{A}}(X_1, X_2) \setminus X'$,*

(c) *If $X_1 \subseteq X' \subseteq X$, $\rho_p^{\mathcal{A}\restriction X'}(X_1, X_2) \subseteq \rho_p^{\mathcal{A}}(X_1, X_2) \cap X'$,*

(d) *If $X_1, \rho_p^{\mathcal{A}}(X_1, X_2) \subseteq X'$ and $\rho_p^{\mathcal{A}\restriction X'}(X_1, X_2) = \rho_p^{\mathcal{A}}(X_1, X_2)$.*

Proof. See [43]. □

Part (a) reflects the nature of degeneracy: degenerate states lead only to themselves. Part (b) states that the self-looping of a subset $X' \subseteq X_1$ does not affect the p-reachability of (X_1, X_2) from other states: intuitively, if the automaton ever reaches the subset X', then it will also have reached X_1, so further transitions (namely, those affected by the self-looping operation) will be irrelevant. Part (c) means that restriction to a subset $X' \supseteq X_1$ limits p-reachability of a pair (X_1, X_2) (by eliminating paths to X_1 that lie partly outside X' and by shrinking the set I_p). On the other hand, if the pair (X_1, X_2) is not p-reachable from X', then the restriction makes no difference; this is reflected in part (d).

6. Fixpoint characterization of the controllability subset. The p-reachability operators admit a concise representation of the controllability subset. Let $\mathcal{A} = (\Sigma, X, \delta, x_0, \{(R_p, I_p) : p \in P\})$ be a deterministic Rabin automaton. Then $C^{\mathcal{A}} \subseteq X$ is given by[6]

$$C^{\mathcal{A}} := \begin{cases} \mu X_1.\ \nu X_2.\ \rho_p^{\mathcal{A}}(X_1, X_2 \cap R_p), & \text{if } |P| = 1, \\ \mu X_1.\ [\bigcup\limits_{p \in P} \nu X_2.\ \rho_p^{\mathcal{A}}(X_1, C^{\mathcal{A}(\hookrightarrow X_1 \cup (X_2 \cap R_p))\restriction p})] & \text{if } |P| > 1. \end{cases}$$

Consider the case where $|P| = 1$. By Theorem 2.1(ii), $C^{\mathcal{A}}$ is the least upper bound of the nondecreasing sequence of subsets $C_0 \subseteq C_1 \subseteq C_2 \subseteq \cdots$, given by

$$C_0 := \emptyset,$$
$$C_{i+1} := \nu X_2.\ \rho_p^{\mathcal{A}}(C_i, X_2 \cap R).$$

Intuitively, $C_1 \subseteq X$ is the largest $X_2 \subseteq X$ from which the automaton can be controlled to reach $X_2 \cap R_p$ by way of a path that lies within I_p (see Theorem 2.1(i′)); in other words, C_1 is the set of states from which the automaton can be controlled to remain forever within I_p and to enter R_p infinitely often. By induction, C_i represents the subset from which the automaton can be controlled so that it enters R_p infinitely often and enters $X \setminus I_p$ fewer than i times. Thus $C^{\mathcal{A}}$ is indeed the set of states from

[6] Existence of $C^{\mathcal{A}}$ follows by induction on $|P|$ from Proposition 6.2(b).

which $\mathcal{A}$ can be controlled to enter R_p infinitely often and eventually to enter I_p and remain there.

If $|P| > 1$, $C^{\mathcal{A}}$ is the least upper bound of the nondecreasing sequence $C_0 \subseteq C_1 \subseteq C_2 \subseteq \cdots$, given by

$$C_0 := \emptyset,$$
$$C_{i+1} := \bigcup_{p \in P} \nu X_2.\ \rho_p^{\mathcal{A}}(C_i, C^{\mathcal{A}(\hookrightarrow C_i \cup (X_2 \cap R_p))|p}).$$

Thus $C_1 \subseteq X$ is the set of states from which, for some $p \in P$, $\mathcal{A}$ can be controlled to remain forever within I_p and either enter R_p infinitely often or satisfy the acceptance condition obtained by excluding the pair (R_p, I_p), in other words, to remain forever within I_p and satisfy the original acceptance condition. By induction, C_i is the subset in which a sequence $p_i, p_{i-1}, p_{i-2}, \ldots, p_1$ of i elements of P can be inductively chosen in such a way that, if p is the latest element to have been selected, then $\mathcal{A}$ can be controlled so that it either remains within I_p forever and satisfies its acceptance condition or eventually reaches a state in which a new element in the sequence can be chosen. (When the last element p_1 is chosen, $\mathcal{A}$ is in a state from which it can be controlled to remain forever within I_{p_1} and satisfy its acceptance condition, that is, $\mathcal{A}$ is in C_1.) It follows that $C^{\mathcal{A}}$ is the subset from which $\mathcal{A}$ can be controlled to satisfy its acceptance condition.

As this interpretation suggests, $C^{\mathcal{A}}$ coincides with $P^{\mathcal{A}}$, as is shown in the next result.

PROPOSITION 6.1. *For any deterministic Rabin automaton $\mathcal{A}$, $P^{\mathcal{A}} = C^{\mathcal{A}}$.*

Proof. The proof follows by Proposition 6.3 and Theorem 6.4, below. □

Before proving the results that lead to Proposition 6.1, we establish some basic properties of $C^{\mathcal{A}}$ in Proposition 6.2.

PROPOSITION 6.2. *Let $\mathcal{A} = (\Sigma, X, \delta, x_0, \{(R_p, I_p) : p \in P\})$ be a deterministic Rabin automaton. Suppose that $x \in X$, $X' \subseteq X$, and $p \in P$. Then*

(a) $C^{\mathcal{A}} \cap D(\mathcal{A}) = \bigcup_{p \in P}(R_p \cap I_p) \cap D(\mathcal{A})$,

(b) $C^{\mathcal{A}(\hookrightarrow X')} \supseteq C^{\mathcal{A}} \cup X'$,

(c) $C^{\mathcal{A}(\hookrightarrow X')} = C^{\mathcal{A}} \iff X' \subseteq C^{\mathcal{A}}$,

(d) $C^{\mathcal{A}|X'} \subseteq C^{\mathcal{A}} \cap X'$,

(e) $C^{\mathcal{A}|p} \subseteq C^{\mathcal{A}} \cap [I_p \cup D(\mathcal{A})]$,

(f) $C^{\mathcal{A}} = \theta^{\mathcal{A}}(C^{\mathcal{A}})$,

(g) *if $L(\mathcal{A}) \subseteq I_p$ and $X' \supseteq C^{\mathcal{A}(\hookrightarrow X' \cap R_p \cap I_p)} \cap R_p \cap I_p$ then $C^{\mathcal{A}(\hookrightarrow X' \cap R_p \cap I_p)|p} = C^{\mathcal{A}(\hookrightarrow X' \cap R_p \cap I_p)}$,*

(h) *if $L(\mathcal{A}) \subseteq I_p$ then $C^{\mathcal{A}} = \nu X_2.\ \theta^{\mathcal{A}}(C^{\mathcal{A}(\hookrightarrow X_2 \cap R_p \cap I_p)})$.*

Proof. See [43]. □

Part (a) means that the automaton can be controlled to satisfy its acceptance condition from a degenerate state if and only if that degenerate state itself satisfies the acceptance criterion. This is natural, since degenerate states lead only to themselves.

Part (b) describes the way the controllability subset generally expands when a subset is self-looped, owing to the creation of degenerate states that satisfy the acceptance criterion. Part (c) states that the controllability subset is unaffected by this operation if and only if the states that are self-looped already belong to the controllability subset.

Parts (d) and (e) reflect the fact that restriction to a subset and exclusion of a pair shrink the controllability subset by creating degenerate states that do not satisfy the acceptance criterion and by strengthening the acceptance criterion.

Part (f) means simply that the controllability subset is a fixpoint of the inverse dynamics operator.

Part (g) describes a situation in which exclusion of a pair (R_p, I_p) does not affect the controllability subset, namely, that in which all live states belong to I_p (so that the restriction to $I_p \cup D(\mathcal{A})$ is of no consequence) and a sufficiently large subset of R_p has been self-looped (so that the elimination of the pair (R_p, I_p) does not strengthen the acceptance condition).

Finally, part (h) states that, when all live states belong to some I_p, the controllability subset is the set of all states from which the automaton can be controlled to satisfy its acceptance condition or simply to enter $R_p \cap I_p$ infinitely often (the invariance of I_p following automatically).

These preliminary results allow us to prove that $P^{\mathcal{A}}$ and $C^{\mathcal{A}}$ coincide (Proposition 6.1). We first establish that $P^{\mathcal{A}} \subseteq C^{\mathcal{A}}$; in other words, if $\mathcal{A}$ can be controlled to satisfy its acceptance condition from state x, then $x \in C^{\mathcal{A}}$:

PROPOSITION 6.3. *For any deterministic Rabin automaton $\mathcal{A}$, $P^{\mathcal{A}} \subseteq C^{\mathcal{A}}$.*

Proof. We proceed by induction on the number of live states of $\mathcal{A} = (\Sigma, X, \delta, x_0, \{(R_p, I_p) : p \in P\})$, in the manner of [33]. Note that

$$\begin{aligned} & P^{\mathcal{A}} \cap D(\mathcal{A}) \\ &= \bigcup_{p \in P} (R_p \cap I_p) \cap D(\mathcal{A}) \qquad \text{(Prop. 4.1(a))} \\ &= C^{\mathcal{A}} \cap D(\mathcal{A}) \qquad \text{(Prop. 6.2(a))}. \end{aligned}$$

By Proposition 5.1, it thus suffices to show that $P^{\mathcal{A}} \cap L(\mathcal{A}) \subseteq C^{\mathcal{A}}$.

If $\mathcal{A}$ contains no live states, then the result holds vacuously. For the induction step, suppose that $x \in P^{\mathcal{A}} \cap L(\mathcal{A})$ and assume that the result holds for all Rabin automata with fewer live states than $\mathcal{A}$. We prove that $x \in C^{\mathcal{A}}$.

By assumption, there exists some complete feedback map $f : \Sigma^* \longrightarrow \mathbf{C}$ satisfying both clauses of the definition of $P^{\mathcal{A}}$. The central issue in the proof is the nature of the relationship between the strings generated by $\mathcal{A}_x$ under f and the live states of $\mathcal{A} =: (\Sigma, X, \delta, x_0, \{(R_p, I_p) : p \in P\})$. The following three cases exhaust the possibilities:

(a) There exists a live state $x' \in X$ such that, for all $k' \in \Sigma^*$ generated by $\mathcal{A}_x$ under f, $\delta(k', x) \neq x'$;

(b) For some pair of live states $x', x'' \in X$, there exists $k' \in \Sigma^*$ generated by $\mathcal{A}_x$ under f such that $\delta(k', x) = x'$ and for all $k'' \in \Sigma^*$ generated by $\mathcal{A}_x$ under f such that $k' < k''$, $\delta(k'', x) \neq x''$;

(c) For all pairs of live states $x', x'' \in X$, and every $k' \in \Sigma^*$ generated by $\mathcal{A}_x$ under f such that $\delta(k', x) = x'$, there exists $k'' \in \Sigma^*$ generated by $\mathcal{A}_x$ under f such that $k' < k''$ and $\delta(k'', x) = x''$.

In case (a), we have

$$\begin{aligned} x &\in P^{\mathcal{A}\restriction(X \setminus \{x'\})} \\ &\subseteq C^{\mathcal{A}\restriction(X \setminus \{x'\})} \qquad \text{(by inductive hypothesis)} \\ &\subseteq C^{\mathcal{A}} \quad \text{(Prop. 6.2(d))}. \end{aligned}$$

Similarly, for case (b), we have

$$\begin{aligned} x' = \delta(k', x) &\in P^{\mathcal{A}\restriction(X \setminus \{x''\})} \\ &\subseteq C^{\mathcal{A}\restriction(X \setminus \{x''\})} \qquad \text{(by inductive hypothesis)} \\ &\subseteq C^{\mathcal{A}} \qquad \text{(Prop. 6.2(d))}. \end{aligned}$$

Thus

$$\begin{aligned} x &\in P^{\mathcal{A}} \\ &\subseteq P^{\mathcal{A}(\hookrightarrow x')} \qquad \text{(Prop. 4.1(b))} \\ &\subseteq C^{\mathcal{A}(\hookrightarrow x')} \qquad \text{(by inductive hypothesis)} \\ &= C^{\mathcal{A}} \qquad \text{(Prop. 6.2(c)).} \end{aligned}$$

In case (c), there exists a string s generated by $\mathcal{A}_x$ under f having a path π on $\mathcal{A}$ such that $\Omega_\pi = L(\mathcal{A})$. It follows that, for some $p \in P$,

$$L(\mathcal{A}) \subseteq I_p \quad \text{and} \quad L(\mathcal{A}) \cap R_p \neq \emptyset.$$

Furthermore, for any $x''' \in L(\mathcal{A})$, we have

$$\begin{aligned} x''' &\in P^{\mathcal{A}} \\ &= \theta^{\mathcal{A}}(P^{\mathcal{A}}) \qquad \text{(Prop. 5.1)} \\ &\subseteq \theta^{\mathcal{A}}(P^{\mathcal{A}(\hookrightarrow L(\mathcal{A})\cap R_p)}) \qquad \text{(Prop. 4.1 (b))} \\ &= \theta^{\mathcal{A}}(C^{\mathcal{A}(\hookrightarrow L(\mathcal{A})\cap R_p)}) \qquad \text{(by inductive hypothesis).} \end{aligned}$$

Thus

$$\begin{aligned} L(\mathcal{A}) &\subseteq \nu X_2.\ \theta^{\mathcal{A}}(C^{\mathcal{A}(\hookrightarrow X_2 \cap R_p \cap I_p)}) \qquad \text{(Thm. 2.1(i'))} \\ &= C^{\mathcal{A}} \qquad \text{(Prop. 6.2(h))} \end{aligned}$$

This completes the induction. □

The next result establishes the converse of Proposition 6.3, namely, it shows that, if the deterministic Rabin automaton $\mathcal{A}$ is in state $x \in C^{\mathcal{A}}$, then it can be controlled to satisfy its acceptance condition. Moreover, it states that "state feedback" is sufficient. Together, Proposition 6.3 and Theorem 6.4 thus imply that a Rabin automaton can be controlled to satisfy its acceptance condition if and only if it can be so controlled by means of state feedback.

THEOREM 6.4 (state feedback). *Let $\mathcal{A} = (\Sigma, X, \delta, x_0, \{(R_p, I_p) : p \in P\})$ be a deterministic Rabin automaton. Then there exists a total map $\phi^{\mathcal{A}} : C^{\mathcal{A}} \longrightarrow \mathbf{C}$ such that*

1) *For any $s \in \Sigma^\omega$ and any path $\pi : \mathrm{pre}(s) \longrightarrow X$ of s on $\mathcal{A}$, the condition*

$$\pi(1) \in C^{\mathcal{A}} \quad \text{and} \quad \forall k\sigma \in \mathrm{pre}(s) \ :\ \sigma \in \phi^{\mathcal{A}}(\pi(k))$$

implies that

$$\exists p \in P \ :\ \Omega_\pi \cap R_p \neq \emptyset \quad \text{and} \quad \Omega_\pi \subseteq I_p;$$

2) *For any $x \in C^{\mathcal{A}}$,*

$$\begin{gathered} \exists \sigma \in \phi^{\mathcal{A}}(x) \ :\ \delta(\sigma, x)!, \\ \forall \sigma \in \phi^{\mathcal{A}}(x) \ :\ \delta(\sigma, x)! \implies \delta(\sigma, x) \in C^{\mathcal{A}}. \end{gathered}$$

Proof. The details of the proof are intricate, but the methods are simple. We consider every least fixpoint as the limit of a nondecreasing sequence of state subsets, by Theorem 2.1. Membership in these subsets is used to define a well-founded partial ordering or "ranking" of states: the earlier a state occurs in the sequence of subsets, the lower its rank. The theorem is then proved through arguments concerning

the effect of a suitable state feedback control on various ranks of the system state; these typically show that, under appropriate conditions, a particular rank is either nonincreasing or strictly decreasing.

We construct a suitable map by induction on $|P|$. We give only the induction step; the base of the induction (dealing with the case where $|P| = 1$) is similar; see [43] for details.

Suppose then that $|P| > 1$ and assume that the result holds for all automata having fewer pairs. Then

$$C^{\mathcal{A}} = \mu X_1.\ \left[\bigcup_{p \in P} \nu X_2.\ \rho_p^{\mathcal{A}}(X_1, C^{\mathcal{A}(\hookrightarrow X_1 \cup (X_2 \cap R_p))\downarrow p}) \right].$$

By Theorem 2.1, this fixpoint is the least upper bound of the nondecreasing sequence $C_0^{\mathcal{A}} \subseteq C_1^{\mathcal{A}} \subseteq C_2^{\mathcal{A}} \subseteq \cdots$, given by

$$\begin{aligned} C_0^{\mathcal{A}} &:= \emptyset, \\ C_{i+1}^{\mathcal{A}} &:= \bigcup_{p \in P} \nu X_2.\ \rho_p^{\mathcal{A}}(C_i^{\mathcal{A}}, C^{\mathcal{A}(\hookrightarrow C_i^{\mathcal{A}} \cup (X_2 \cap R_p))\downarrow p}) \\ &= \bigcup_{p \in P} C_{i+1,p}^{\mathcal{A}}, \end{aligned}$$

where

$$\begin{aligned} C_{i+1,p}^{\mathcal{A}} &:= \nu X_2.\ \rho_p^{\mathcal{A}}(C_i^{\mathcal{A}}, C^{\mathcal{A}(\hookrightarrow C_i^{\mathcal{A}} \cup (X_2 \cap R_p))\downarrow p}) \\ &= \rho_p^{\mathcal{A}}(C_i^{\mathcal{A}}, C^{\mathcal{A}(\hookrightarrow C_i^{\mathcal{A}} \cup (C_{i+1,p}^{\mathcal{A}} \cap R_p))\downarrow p}) \\ &= \mu X_3.\ \ [\theta^{\mathcal{A}}(C_i^{\mathcal{A}}) \\ &\qquad \cup [\theta^{\mathcal{A}}(C_i^{\mathcal{A}} \cup C^{\mathcal{A}(\hookrightarrow C_i^{\mathcal{A}} \cup (C_{i+1,p}^{\mathcal{A}} \cap R_p))\downarrow p} \cup X_3) \cap I_p]]. \end{aligned}$$

Each $C_{i+1,p}^{\mathcal{A}}$ is the least upper bound of the nondecreasing sequence, given by

$$\begin{aligned} C_{i+1,p,0}^{\mathcal{A}} &:= \emptyset, \\ C_{i+1,p,j+1}^{\mathcal{A}} &:= [\theta^{\mathcal{A}}(C_i^{\mathcal{A}}) \\ &\qquad \cup [\theta^{\mathcal{A}}(C_i^{\mathcal{A}} \cup C^{\mathcal{A}(\hookrightarrow C_i^{\mathcal{A}} \cup (C_{i+1,p}^{\mathcal{A}} \cap R_p))\downarrow p} \cup C_{i+1,p,j}^{\mathcal{A}}) \cap I_p]] \\ &= C_{i+1,p,j+1,0}^{\mathcal{A}} \cup C_{i+1,p,j+1,1}^{\mathcal{A}}, \end{aligned}$$

where

$$\begin{aligned} C_{i+1,p,j+1,0}^{\mathcal{A}} &:= \theta^{\mathcal{A}}(C_i^{\mathcal{A}}), \\ C_{i+1,p,j+1,1}^{\mathcal{A}} &:= \theta^{\mathcal{A}}(C_i^{\mathcal{A}} \cup C^{\mathcal{A}(\hookrightarrow C_i^{\mathcal{A}} \cup (C_{i+1,p}^{\mathcal{A}} \cap R_p))\downarrow p} \cup C_{i+1,p,j}^{\mathcal{A}}) \cap I_p. \end{aligned}$$

Thus

$$C^{\mathcal{A}} = \bigcup_{i=1}^{|X|} \bigcup_{p \in P} \bigcup_{j=1}^{|X|} \bigcup_{k=0,1} C_{i,p,j,k}^{\mathcal{A}}.$$

Define total feedback maps $\phi_{i,p,j,k}^{\mathcal{A}} : C_{i,p,j,k}^{\mathcal{A}} \longrightarrow \mathbf{C}$ for each of the components $C_{i,p,j,k}^{\mathcal{A}}$ as follows:

- If $k = 0$, define $\phi_{i+1,p,j+1,k}^{\mathcal{A}} : C_{i+1,p,j+1,k}^{\mathcal{A}} \longrightarrow \mathbf{C}$ so that, for all $x \in C_{i+1,p,j+1,0}^{\mathcal{A}}$,

$$\forall \sigma \in \phi_{i+1,p,j+1,k}^{\mathcal{A}}(x)\ :\ \delta(\sigma, x) \in C_i^{\mathcal{A}};$$

• If $k = 1$, define $\phi^{\mathcal{A}}_{i+1,p,j+1,k} : C^{\mathcal{A}}_{i+1,p,j+1,k} \longrightarrow \mathbf{C}$ so that, for all $x \in C^{\mathcal{A}}_{i+1,p,j+1,1} \subseteq I_p$,

$$\forall \sigma \in \phi^{\mathcal{A}}_{i+1,p,j+1,k}(x) : \\ \delta(\sigma, x) \in C^{\mathcal{A}}_i \cup C^{\mathcal{A}(\hookrightarrow C^{\mathcal{A}}_i \cup (C^{\mathcal{A}}_{i+1,p} \cap R_p))\downarrow p} \cup C^{\mathcal{A}}_{i+1,p,j} \ .$$

Choose a total ordering of P and order the 4-tuples (i,p,j,k) lexicographically. Define a total map $\phi^{\mathcal{A}} : C^{\mathcal{A}} \longrightarrow \mathbf{C}$ so that

$$\phi^{\mathcal{A}} : x \mapsto \begin{cases} \phi^{\mathcal{A}(\hookrightarrow C^{\mathcal{A}}_i \cup (C^{\mathcal{A}}_{i+1,p} \cap R_p))\downarrow p}(x) & \text{if } x \in C^{\mathcal{A}(\hookrightarrow C^{\mathcal{A}}_i \cup (C^{\mathcal{A}}_{i+1,p} \cap R_p))\downarrow p} \setminus C^{\mathcal{A}}_i \cup R_p, \\ \phi^{\mathcal{A}}_{i+1,p,j+1,k}(x) & \text{otherwise,} \end{cases}$$

where (i,p,j,k) is the least 4-tuple in the lexicographic ordering such that $x \in C^{\mathcal{A}}_{i+1,p,j+1,k}$.

Clause 2) of the theorem follows from the definition of $\phi^{\mathcal{A}}$ (by the inductive hypothesis). For clause 1), suppose that $s \in \Sigma^\omega$ and there exists a path $\pi : \mathrm{pre}(s) \longrightarrow X$ of s on $\mathcal{A}$ such that

$$\pi(1) = x \quad \text{and} \quad (\forall k\sigma \in \mathrm{pre}(s))[\sigma \in \phi^{\mathcal{A}}(\pi(k))].$$

We must show that there exists $p \in P \ : \ \Omega_\pi \cap R_p \neq \emptyset$ and $\Omega_\pi \subseteq I_p$.

Define

$$I\text{−rank} : C^{\mathcal{A}} \longrightarrow \mathbb{N} \times P, \\ x \mapsto (i,p),$$

where (i,p) is the least pair (in the lexicographic ordering) such that $x \in C^{\mathcal{A}}_{i,p}$.

Note that

$$\begin{aligned} & C^{\mathcal{A}(\hookrightarrow C^{\mathcal{A}}_i \cup (C^{\mathcal{A}}_{i+1,p} \cap R_p))\downarrow p} \setminus (C^{\mathcal{A}}_i \cup (C^{\mathcal{A}}_{i+1,p} \cap R_p) \cup D(\mathcal{A})) \\ & = \theta^{\mathcal{A}(\hookrightarrow C^{\mathcal{A}}_i \cup (C^{\mathcal{A}}_{i+1,p} \cap R_p))\downarrow p}(C^{\mathcal{A}(\hookrightarrow C^{\mathcal{A}}_i \cup (C^{\mathcal{A}}_{i+1,p} \cap R_p))\downarrow p}) \setminus (C^{\mathcal{A}}_i \cup (C^{\mathcal{A}}_{i+1,p} \cap R_p) \cup D(\mathcal{A})) \\ & \qquad \text{(Prop. 6.2 (f))} \\ & = [\theta^{\mathcal{A}(\hookrightarrow C^{\mathcal{A}}_i \cup (C^{\mathcal{A}}_{i+1,p} \cap R_p))\downarrow p}(C^{\mathcal{A}(\hookrightarrow C^{\mathcal{A}}_i \cup (C^{\mathcal{A}}_{i+1,p} \cap R_p))\downarrow p}) \cap I_p] \setminus (C^{\mathcal{A}}_i \cup (C^{\mathcal{A}}_{i+1,p} \cap R_p) \\ & \qquad \cup D(\mathcal{A})) \text{ (Prop. 6.2 (e))} \\ & = [\theta^{\mathcal{A}(\hookrightarrow C^{\mathcal{A}}_i \cup (C^{\mathcal{A}}_{i+1,p} \cap R_p))}(C^{\mathcal{A}(\hookrightarrow C^{\mathcal{A}}_i \cup (C^{\mathcal{A}}_{i+1,p} \cap R_p))\downarrow p}) \cap I_p] \setminus (C^{\mathcal{A}}_i \cup (C^{\mathcal{A}}_{i+1,p} \cap R_p) \\ & \qquad \cup D(\mathcal{A})) \text{ (Prop. 5.2 (d))} \\ & = [\theta^{\mathcal{A}}(C^{\mathcal{A}(\hookrightarrow C^{\mathcal{A}}_i \cup (C^{\mathcal{A}}_{i+1,p} \cap R_p))\downarrow p}) \cap I_p] \setminus (C^{\mathcal{A}}_i \cup (C^{\mathcal{A}}_{i+1,p} \cap R_p) \cup D(\mathcal{A})) \\ & \qquad \text{(Prop. 5.2 (b))} \\ & \subseteq C^{\mathcal{A}}_{i+1,p}. \end{aligned}$$

It follows, by the definition of $\phi^{\mathcal{A}}$ and the inductive hypothesis, that, for all $x \in C^{\mathcal{A}}, \sigma \in \phi^{\mathcal{A}}(x)$, if $\delta(\sigma,x) \notin D(\mathcal{A})$, then

$$I\text{−rank}(\delta(\sigma,x)) \leq I\text{−rank}(x),$$

and, if I−rank$(x) = (i,p)$ and $x \notin I_p \cup D(\mathcal{A})$, then, by Proposition 6.2(e),

$$I\text{−rank}(\delta(\sigma,x)) < I\text{−rank}(x) \quad \forall \sigma \in \phi^{\mathcal{A}}(x).$$

If (i,p) is the least pair for which $\Omega_\pi \cap C^{\mathcal{A}}_{i+1,p} \neq \emptyset$, then it follows that $\Omega_\pi \subseteq C^{\mathcal{A}}_{i+1,p} \cap (I_p \cup D(\mathcal{A}))$. Note that, if $\Omega_\pi \cap C^{\mathcal{A}}_{i+1,p} \cap D(\mathcal{A}) \neq \emptyset$, then there exists $q \in P \ : \ \Omega_\pi \cap R_q \neq \emptyset$

and $\Omega_\pi \subseteq I_q$ holds (by Proposition 6.2(a)). We may therefore assume instead that $\Omega_\pi \subseteq I_p$.

Define

$$R\text{-rank} : C^{\mathcal{A}} \longrightarrow \mathbb{N} \times P \times \mathbb{N},$$
$$x \mapsto (i, p, j)$$

where (i, p, j) is the least triple such that $x \in C^{\mathcal{A}}_{i,p,j}$.

By definition of $\phi^{\mathcal{A}}$, if $x \in C^{\mathcal{A}}$, $\sigma \in \phi^{\mathcal{A}}(x)$, $I\text{-rank}(x) = (i+1, p)$, and $\delta(\sigma, x) \notin C^{\mathcal{A}(\hookrightarrow C_i^{\mathcal{A}} \cup (C^{\mathcal{A}}_{i+1,p} \cap R_p))\downarrow p}$, then

$$R\text{-rank}(\delta(\sigma, x)) < R\text{-rank}(x).$$

If (i, p) is the least pair such that $\Omega_\pi \cap C^{\mathcal{A}}_{i+1,p} \neq \emptyset$, then it follows that $\Omega_\pi \cap C^{\mathcal{A}(\hookrightarrow C_i^{\mathcal{A}} \cup (C^{\mathcal{A}}_{i+1,p} \cap R_p))\downarrow p} \neq \emptyset$. Then, however, by the inductive assumption, we have either $\Omega_\pi \cap R_p \neq \emptyset$ or $\Omega_\pi \subseteq C^{\mathcal{A}(\hookrightarrow C_i^{\mathcal{A}} \cup (C^{\mathcal{A}}_{i+1,p} \cap R_p))\downarrow p} \setminus (C_i^{\mathcal{A}} \cup R_p)$. The result follows by another application of the inductive assumption. □

7. The complexity of computing controllability subsets. In this section, we demonstrate that the computation of controllability subsets by straightforward calculation of the appropriate fixpoint is essentially optimal. We first establish that the problem is NP-complete and then show that calculation of the fixpoint is singly exponential in the number of accepting pairs and polynomial in the size of the state set. These results match the strongest known results for the polynomially equivalent emptiness problem for Rabin automata on infinite trees [13], [29].

THEOREM 7.1. *The problem of deciding membership in the controllability subset of a deterministic Rabin automaton is* NP*-complete.*

Proof. NP*-hardness.* The proof follows by reduction from the emptiness problem for Rabin automata on infinite trees over a one-symbol alphabet. This was shown to be NP-hard in [13].

Membership in NP. If a Rabin automaton $\mathcal{A} = (\Sigma, X, \delta, x_0, \{(R_p, I_p) : p \in P\})$ is deterministic, then it follows from Proposition 6.3 and Theorem 6.4 that $x \in C^{\mathcal{A}}$ if and only if there exists a "state feedback" map $\phi : X \longrightarrow \mathbf{C}$ (pfn) such that $x \in \text{dom}(\phi)$ and if the following conditions hold:

1) For any $s \in \Sigma^\omega$ and any path $\pi : \text{pre}(s) \longrightarrow X$ of s on $\mathcal{A}$, the condition

$$\pi(1) \in \text{dom}(\phi) \quad \text{and} \quad \forall k\sigma \in \text{pre}(s) \ : \ \sigma \in \phi^{\mathcal{A}}(\pi(k))$$

implies that

$$\exists p \in P \ : \ \Omega_\pi \cap R_p \neq \emptyset \quad \text{and} \quad \Omega_\pi \subseteq I_p;$$

2) For any $x' \in \text{dom}(\phi)$,

$$\exists \sigma \in \phi(x') \ : \ \delta(\sigma, x')! \text{ and}$$
$$\forall \sigma \in \phi(x') \ : \ \delta(\sigma, x')! \implies \delta(\sigma, x') \in \text{dom}(\phi).$$

However, any map $\phi : X \longrightarrow \mathbf{C}$ can be constructed in polynomial time, and the conditions 1) and 2) can be checked in polynomial time, using the results of [15]. NP-hardness follows. See [43] for details. □

THEOREM 7.2. *The controllability subset of a deterministic Rabin automaton $\mathcal{A}$ can be computed in time $\bigcirc(kl(mn)^{3m})$, where k is the number of control patterns,*

l is the size of the alphabet, m is the number of state subset pairs in the acceptance condition, and n is the number of states.

Proof. The proof follows by straightforward analysis of the fixpoint computation. See [43] for details. □

8. Example. Consider the Rabin automaton $\mathcal{A} = (\Sigma, X, \delta, x_0, \{(R_p, I_p) : p \in P\})$ pictured in Fig. 8.1; the index set P is $\{\alpha, \beta\}$ and the pairs $(R_\alpha, I_\alpha) = (\{4\}, \{1, 2, 3, 4\})$ and $(R_\beta, I_\beta) = (\{-4\}, \{-1, -2, -3, -4\})$ are represented by the pairs of dotted and dashed boxes.

For simplicity, we take the alphabet Σ to be X^2; the transition function is represented by the arcs of the diagram, the symbol associated with a transition from state i to j being (i, j). The automaton is thus deterministic.

The family $\mathbf{C}$ of control patterns is the set of all subsets of Σ that contain the following symbols:

$$(0, \pm 1),\ (\pm 1, \mp 1),\ (\pm 3, \pm 4),\ (\pm 4, \pm 3),\ (\pm 2, \pm 3),\ (\pm 2, \pm 4).$$

This means that the state transitions corresponding to these symbols cannot be prevented, while all others can.

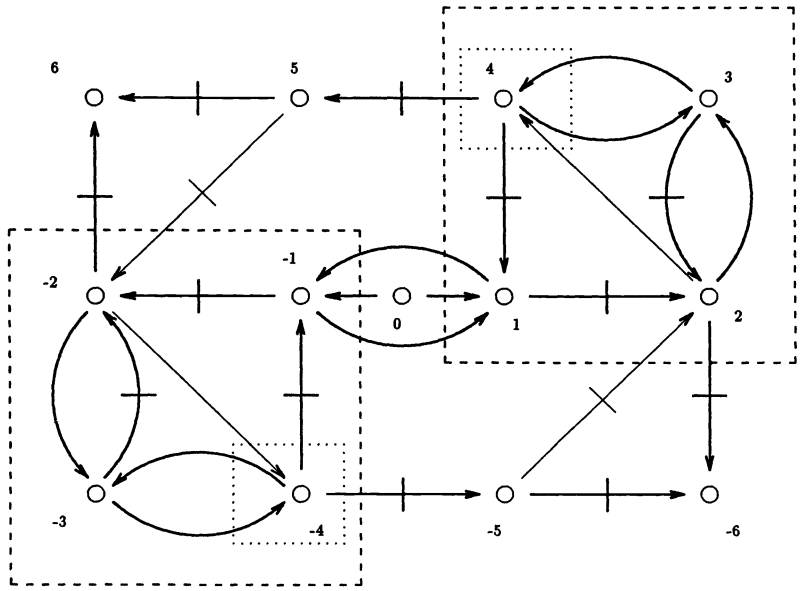

FIG. 8.1. *Rabin automaton $\mathcal{A}$.*

The controllability subset is computed by recursive application of (ii) and (ii′) of Theorem 2.1. The calculation is displayed in Table 8.1 using the notation of [43].

At the beginning of the procedure and after completing the first column of the table, it is necessary to construct an automaton of the form $\mathcal{A}(\hookrightarrow X_1 \cup (X_2 \cap R_p)) \downarrow p$ for every $p \in P$ and to compute its controllability subset. In our example, we begin the computation by constructing the automaton

$$\mathcal{A}(\hookrightarrow \emptyset \cup (X \cap R_\alpha)) \downarrow \alpha = \mathcal{A}(\hookrightarrow R_\alpha) \downarrow \alpha,$$

shown in Fig. 8.2, and calculating $C^{\mathcal{A}(\hookrightarrow R_\alpha)\downarrow\alpha}$, as shown in Table 8.2. (The corresponding results for $\beta \in P$ are obtained by replacing the states with their negatives.)

TABLE 8.1
Computation of $C^{\mathcal{A}}$.

	$C^{\mathcal{A}}_{1,\alpha,1,1}$	$C^{\mathcal{A}}_{2,\alpha,1,0}$	$\phi^{\mathcal{A}}(x)$
6			
5		α, β	$\Sigma \setminus \{(5,6)\}$
4	α	α, β	$\Sigma \setminus \{(4,1),(4,5)\}$
3	α	α, β	$[\Sigma \setminus \{(3,2)\}]$
2	α	α, β	$[\Sigma \setminus \{(2,-6)\}]$
1			
0			
-1			
-2	β	α, β	$[\Sigma \setminus \{(-2,6)\}]$
-3	β	α, β	$[\Sigma \setminus \{(-3,-2)\}]$
-4	β	α, β	$\Sigma \setminus \{(-4,-1),(-4,-5)\}$
-5		α, β	$\Sigma \setminus \{(-5,-6)\}$
-6			

$C^{\mathcal{A}}_{1,\beta,1,1} = C^{\mathcal{A}}_{2,\beta,1,0}$

Once the first column of Table 8.1 is computed, we construct

$$\mathcal{A}(\hookrightarrow X_1 \cup (X \cap R_\alpha)) \downarrow \alpha = \mathcal{A}(\hookrightarrow X_1) \downarrow \alpha$$

(where X_1 is the set of states marked by either α or β in the first column of Table 8.1) and calculate its controllability subset. The results are displayed in Fig. 8.3 and Table 8.3. (The corresponding results for β are again obtained by symmetry.)

Note that the states ± 6 are excluded from $C^{\mathcal{A}}$; they are "dead ends" from which no other state can be reached. The states $-1, 0, 1$ are excluded because of the cycle formed by 1 and -1.

A state feedback controller is given by the last column of Table 8.1. It is computed by identifying the subsets defined in the proof of Theorem 6.4 with the appropriate entries in the table and assigning control patterns that satisfy the rules set out in the proof. Those control patterns that appear in square brackets are taken from the feedback maps for $\mathcal{A}(\hookrightarrow R_\alpha) \downarrow \alpha$ and $\mathcal{A}(\hookrightarrow R_\beta) \downarrow \beta$, in accordance with the rules. The transition structure of Fig. 8.4 represents the set of strings generated by the automaton under the state feedback map. It can be plainly seen that every infinite string generated is accepted by $\mathcal{A}$ and that every finite string generated has an extension that is also generated under the state feedback control.

9. Discussion. We have presented a procedure for the computation of the *controllability subset* of a deterministic Rabin automaton, namely, the set of states from which the automaton can be controlled to the satisfaction of its acceptance condition. The key to the method is the representation of the controllability subset as a fixpoint of an *inverse dynamics operator*, which depends only on the one-step dynamics of the controlled system. Straightforward computation of this fixpoint matches tight upper bounds on the complexity of the problem. Moreover, intermediate results of the calculation allow the construction of a state feedback map that provides suitable control action.

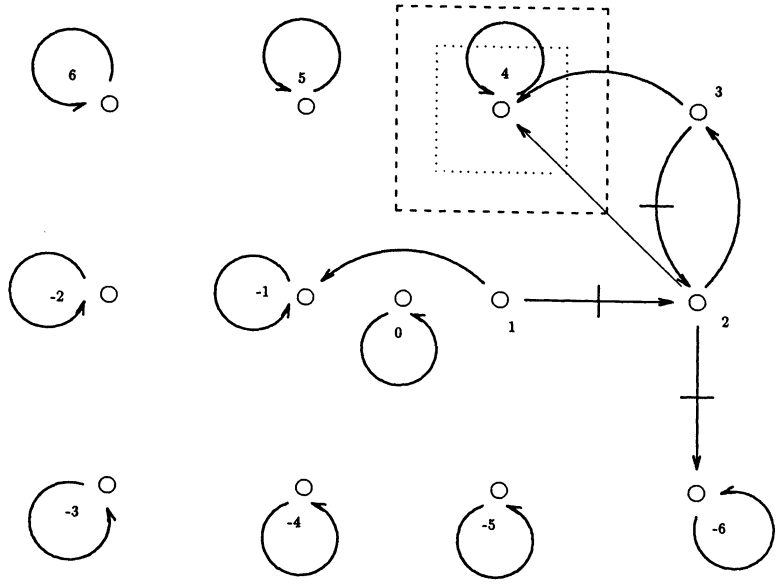

FIG. 8.2. *Simplified automaton* $\mathcal{A}(\hookrightarrow R_\alpha) \downharpoonright \alpha$.

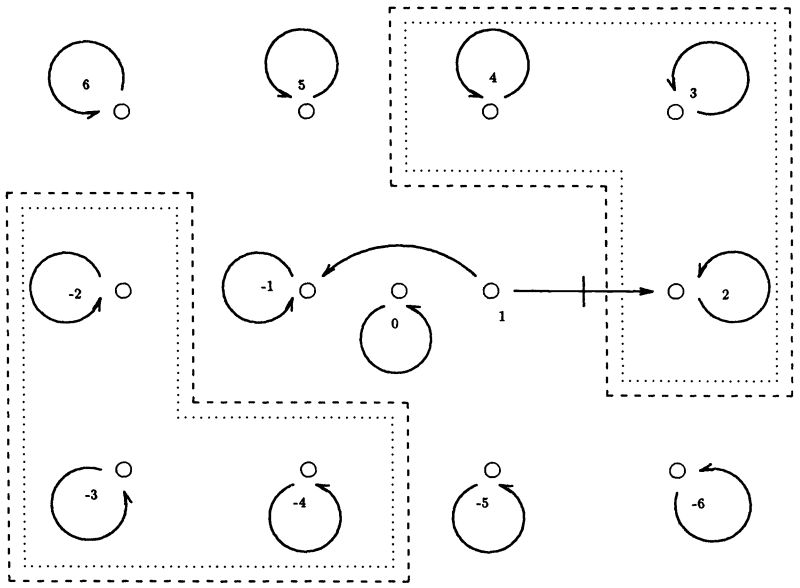

FIG. 8.3. *Simplified automaton* $\mathcal{A}(\hookrightarrow X_1) \downharpoonright \alpha$, *where* $X_1 = \{-4, -3, -2, 2, 3, 4\}$. (*The dotted and dashed boxes represent a single accepting pair.*)

The problem studied in the article was, in effect, first solved by Büchi and Landweber [24], [4], who applied game-theoretic techniques to the study of Church's problem [7]. Simpler solutions were later obtained through the equivalent emptiness problem for automata on infinite trees [33], [29]. The earliest approaches to the emptiness problem were developed by Rabin [33] and Hossley and Rackoff [20], employing, respectively, the structural induction method used in the present article and a reduction to the emptiness problem for automata on finite trees.

TABLE 8.2
Computation of $C^{\mathcal{A}(\hookrightarrow R_\alpha)\restriction\alpha}$.

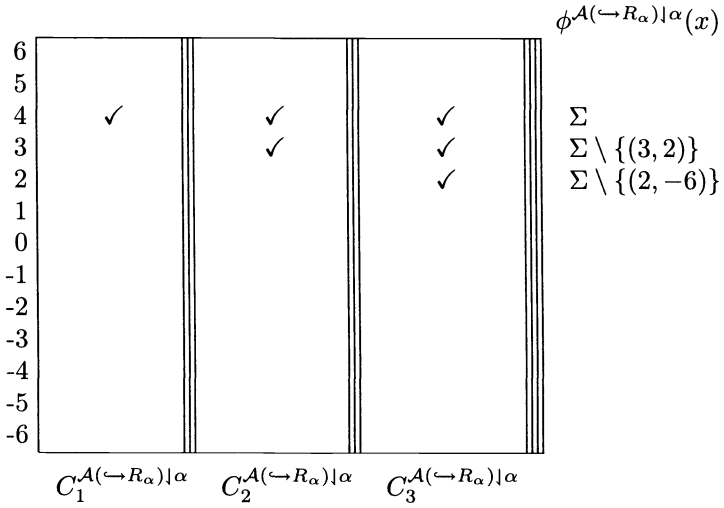

TABLE 8.3
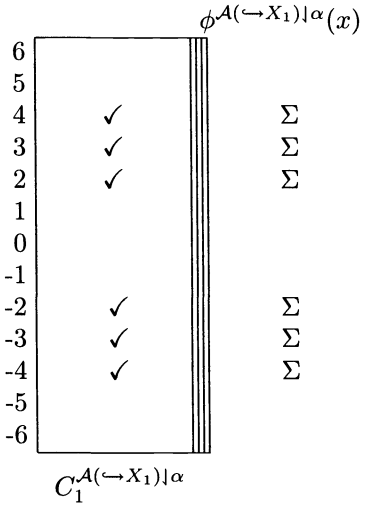
Computation of $C^{\mathcal{A}(\hookrightarrow X_1)\restriction\alpha}$, *where* $X_1 = \{-4, -3, -2, 2, 3, 4\}$.



A key result of both of these approaches is the so-called "finite model theorem," which states roughly that a given tree automaton accepts some infinite tree if and only if it accepts an infinite tree that has a finite description; moreover, such a tree can be effectively constructed. This result was strengthened by Emerson to a "small model theorem," which states that an automaton accepts some infinite tree if and only if it accepts an infinite tree obtained by "unwinding" some finite graph embedded in its own transition structure [11]. Emerson's proof is not directly constructive.[7] The state

[7] The small model theorem does not hold for more general *Muller* automata, but Gurevich and Harrington have established a positive result stating roughly that a Muller automaton can be controlled to satisfy its own acceptance condition if and only if it can be so controlled by means of

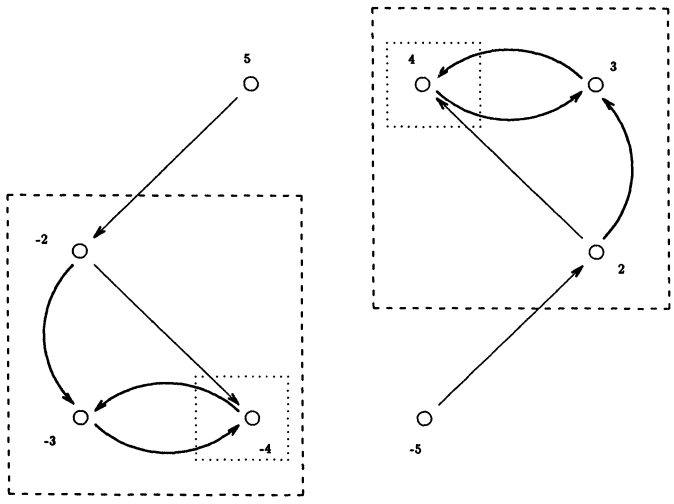


FIG. 8.4. *Transition structure representing strings generated by $\mathcal{A}$ under state feedback.*

feedback result of the current article (Theorem 6.4) is a new, constructive version of the small model theorem.

Two recent approaches to the emptiness problem are those of Pnueli and Rosner [29] and Emerson and Jutla [13]. These have established the tight upper bound on the computational complexity of the problem given in §7. Pnueli and Rosner's method was to refine the technique of Hossley and Rackoff, while Emerson and Jutla applied results on logical model-checking, expressing the acceptance condition in temporal logic, translating the resulting formula into a logical fixpoint calculus, and then checking for the existence of a model of the resulting formula embedded in the automaton's transition structure. The efficacy of this approach follows from the small model theorem.

In technical terms, the method of this paper is essentially a synthesis of those of Rabin and Emerson and Jutla, employing Rabin's method of induction on the number of "live" states and Emerson and Jutla's use of a fixpoint calculus and induction on the number of accepting pairs. The new solution is computationally simpler than Rabin's and mathematically more direct than Emerson and Jutla's: unlike those of [13], the results of this article do not depend on the small model theorem; in fact, the small model theorem is essentially a corollary of the main results of this report.

In addition to these technical advantages, the current approach has a system-theoretic flavor, which, in our opinion, renders it more transparent than the combinatorial, automata-theoretic techniques of [33], [20], [29] or the model-theoretic methods of [13]. This, together with its mathematical directness, suggests that the new technique more readily admits useful extensions. Indeed, in [41] the authors outline a generalization of the present results that allows for liveness assumptions represented by Büchi acceptance conditions. This solves an instance of a problem posed, but not constructively solved, in [1]. The methods of [20], [29] do not appear to admit such an extension.[8]

---

feedback of its own state and that of a buffer that stores the sequence of the most recent visits to the respective accepting subsets [19], [50].

[8] The treatment of liveness in Wong-Toi and Dill [49] (i.e., as a qualification of the specification) is inappropriate for our setting.

To conclude, this paper presents a direct, efficient, and natural solution to a basic problem in discrete-event system theory having applications to control synthesis, program synthesis, and logical decidability. The results illustrate fruitful interchange between control and computer science.

Acknowledgments. The reading of a preliminary version of these results by the first author's thesis examiners, particularly Professors Eric Hehner, Raymond Kwong, and Amir Pnueli, is gratefully acknowledged.

SUPERVISION OF INFINITE BEHAVIOR OF DISCRETE-EVENT SYSTEMS*

J. G. THISTLE† AND W. M. WONHAM‡

Abstract. Some basic results of supervisory control theory are extended to the setting of ω-languages, formal languages consisting of infinite strings. The extension permits the investigation of both liveness and safety issues in the control of discrete-event systems. A new controllability property appropriate to the infinitary setting (*ω-controllability*) is defined; this language property captures in a natural way the limitations of available control actions. It is shown that every specification language contains a unique maximal ω-controllable sublanguage, representing the least upper bound of the set of achievable closed-loop sublanguages. This supremal ω-controllable sublanguage allows a simple formulation of necessary and sufficient conditions for the solvability of an infinitary supervisory control problem.

The problems of effectively deciding solvability of the control problem and of effectively synthesizing appropriate supervisors are solved for the case where the plant is represented by a deterministic Büchi automaton and the specification of legal behavior by a deterministic Rabin automaton.

Key words. discrete-event systems, supervisory control, controllable languages, synthesis, ω-languages, ω-automata

1. Introduction.

This paper extends basic results of the supervisory control theory of Ramadge and Wonham [17] and others to infinite-string languages and the corresponding finite automata on infinite strings; in particular, it generalizes results of [20] to the case in which specification languages need not be topologically closed relative to plant behavior.

Infinite-string languages, or ω-languages, provide richer models and specifications of DES than do their finite-string counterparts [3], [5], [19], [20]. Moreover, automata on infinite inputs, or ω-automata, form the basis of an extensive theory of automaton synthesis [26] having applications to control [24].

The use of ω-languages and ω-automata in modeling and specifying dynamic systems is well established. First proposed by Muller [15] as a means of describing the infinite behavior of asynchronous switching circuits, they have since been applied to studies of digital hardware and computer software (see, for example, [8]) and, to a smaller extent, discrete-event control systems [27], [13], [20], [11], [22], [2]. Such languages provide a natural means of modeling nonterminating systems and perhaps more importantly, they offer greater expressive power than $*$-languages [15], [3], [5].

This difference in expressive power is best described in the terminology of software verification, whereby a "safety" property is one that states that some condition(s) will *not* occur (ever), and a "liveness" property states that some condition(s) *must* occur (eventually) [14]. (In control-theoretic terms, safety corresponds roughly to invariance or stability; liveness is comparable to reachability or asymptotic stability.)

Whereas safety properties can be specified in terms of $*$-languages, the expression of liveness properties requires the use of ω-languages. Indeed, according to Alpern and Schneider's formal definitions, a safety property is one that can be expressed as a condition on the set of finite event sequences, while a liveness property is one that restricts only the set of infinite event sequences [1].

This paper does not represent the first use of ω-languages and ω-automata within the context of the control theory of Ramadge and Wonham. Ramadge and Golaszewski have already employed ω-language models in this setting [17]–[20], [11], but their main application of ω-languages is in the modeling of the uncontrolled system (namely, in the expression of fairness assumptions); their specifications of controlled behavior are all safety properties. The same applies to the study of Kumar, Garg, and Marcus [12], [13]. Young, Spanjol, and Garg consider systems modeled and specified by deterministic Büchi automata [28], [29]; the results of this paper are more general [22], [25].

Section 2 discusses the necessary preliminaries from the theory of formal languages. Section 3 describes a model of a discrete-event system (DES) as a controlled language generator and defines the property of *deadlock-freedom* [19], [20]. Section 4 defines the key language property of *ω-controllability*, which serves to characterize the limitations of available control actions. This infinitary controllability property is stronger than the essentially finitary notion defined elsewhere and is particularly useful in studying the supervision of infinite behavior, as in §5. Here, a natural ω-language analogue of the original supervisory control problem of [16] is considered, allowing the specification of liveness as well as safety properties.

The effective solution of the synthesis problem is considered in §6, where it is assumed that specifications of legal behavior are represented by deterministic Rabin automata and DESs are modeled as deterministic Büchi automata [20]. More general classes of system models will be considered in future reports.

The results of the article are summarized and compared with related work in §7.

2. Language preliminaries. This section establishes notation and terminology for formal languages. For further background material, refer to [26], [4], [6].

Let Σ be a finite alphabet. Then Σ^* denotes the set of all finite strings over Σ, including the empty string 1. The expression Σ^ω represents the set of infinite strings over Σ. The union of Σ^* and Σ^ω is denoted by Σ^∞.

Any $L \subseteq \Sigma^*$ is called a *$*$-language* over Σ, and any $S \subseteq \Sigma^\omega$ is an *ω-language* over Σ. When dealing with singleton languages, we generally omit braces if such omission is unlikely to lead to confusion; thus $\{v\} \subset \Sigma^\infty$ is typically represented by v.

For any $k \in \Sigma^*$ and $v \in \Sigma^\infty$, kv denotes the catenation of the two strings. If K is a $*$-language and V is a $*$- or ω-language, then $KV := \{kv \in \Sigma^\infty : k \in K \text{ and } v \in V\}$ is called the *product* of K and V. The *quotient*[1] V/K is defined by $V/K := \{w \in \Sigma^\infty : (\text{there exists } k \in K)(kw \in V)\}$.

The *Kleene closure* K^* of a $*$-language $K \subseteq \Sigma^*$ is given by $K^* := \bigcup_{i=0}^{\infty} K^i$, where K^i denotes the i-fold product of K with itself. (K^0 denotes $\{1\}$.) Thus K^* is the set of all catenations of strings in K. The *ω-Kleene closure* K^ω of a $*$-language $K \subseteq \Sigma^*$ is the "infinite product" of K with itself, that is, the set of all strings $s = k_1 k_2 k_3, \ldots, k_i \in K \setminus \{1\}$.

[1] The notation V/K for the quotient is not to be confused with other usage whereby $V/K = \{w \in \Sigma^* : (\exists k \in K)(wk \in V)\}$, that is, where the order of k and w in the concatenation is reversed.

For any $k \in \Sigma^*$, $v \in \Sigma^\infty$, we write $k \leq v$ if k is a *prefix* of v, i.e., if there exists $t \in \Sigma^\infty$ such that kt is identical to v. Define the map pre: $2^{\Sigma^\infty} \longrightarrow 2^{\Sigma^*}$ by pre: $V \mapsto \{k \in \Sigma^* : (\text{there exists } v \in V)(k \leq v)\}$. Thus pre(V) is the set of all finite prefixes of strings in V. For any $R \subseteq \Sigma^\omega$, we call pre$(R) \subseteq \Sigma^*$ the *prefix* of R. For any $K \subseteq \Sigma^*$, we call pre(K) the $*$-*closure* of K. If $K = \text{pre}(K)$, we say that K is $*$-*closed.*

The *limit* [7] of a $*$-language is given by[2] $\lim(K) := \text{pre}^{-1}(K) \cap \Sigma^\omega$, where pre^{-1}: $2^{\Sigma^*} \to 2^{\Sigma^\infty}$ is the inverse of pre: $2^{\Sigma^\infty} \to 2^{\Sigma^*}$, i.e., $\text{pre}^{-1}(K) := \{v \in \Sigma^\infty : \text{pre}(v) \subseteq K\}$. Thus the limit of $K \subseteq \Sigma^*$ is the set of all infinite strings whose prefixes are all contained in K. For example, if K is $\alpha^*[1 \cup \beta]$, then $\lim(K) = \alpha^\omega$.

The operator clo : $2^{\Sigma^\omega} \longrightarrow 2^{\Sigma^\omega}$ is defined by

$$\text{clo}: \ R \mapsto \lim(\text{pre}(R)) = \text{pre}^{-1}(\text{pre}(R)) \cap \Sigma^\omega.$$

In other words, clo(R) is the set of all infinite strings, all of whose prefixes are contained in pre(R). Thus, if $R = \alpha^*\beta^\omega$, then clo$(R) = \alpha^\omega \cup \alpha^*\beta^\omega$. We call clo$(R)$ the ω-*closure* of R. If $R = \text{clo}(R)$, we say that R is ω-*closed*; if $R = \text{clo}(R) \cap S$ (where $S \subseteq \Sigma^\omega$), we say that R is closed *relative to* or *with respect to* S.[3] It can be seen from the definition of clo : $2^{\Sigma^\omega} \longrightarrow 2^{\Sigma^\omega}$ that ω-closed languages are completely determined by their prefixes.

3. Discrete-event systems and supervisors. The following sections describe a basic model (essentially due to Ramadge [20]) of DESs as controlled generators of finite and infinite event sequences.

3.1. Discrete-event systems. We model a DES as a pair $\mathbf{G} = (L, S) \in 2^{\Sigma^*} \times 2^{\Sigma^\omega}$ consisting of a $*$-language L called the $*$-*behavior* of $\mathbf{G}$ and an ω-language S called the ω-*behavior* of $\mathbf{G}$ [19], [20].[4]

The $*$-behavior L is assumed to be $*$-closed, i.e., pre$(L) = L$. We also assume that pre$(S) \subseteq L$. If the reverse inclusion holds (that is, if pre$(S) = L$), then we say that the DES (L, S) is *deadlock-free*.[5]

3.2. Supervisors. We adjoin to the DES model the control feature proposed in [10]; namely, we associate with the alphabet Σ a nonempty family $\mathbf{C} \subseteq 2^\Sigma$ of *control patterns*. A *supervisor* is a partial function $f : \Sigma^* \to \mathbf{C}$.

We assume that $\mathbf{C}$ is closed under union, that is, if $\Gamma, \Gamma' \in \mathbf{C}$, then $\Gamma \cup \Gamma' \in \mathbf{C}$. This property ensures the existence of supremal controllable sublanguages but entails no loss of generality, in the sense that control schemes devised under the assumption can always be implemented nondeterministically [10].

---

[2] This definition, due to Elgot, should not be confused with similar ones appearing in the literature. Elgot's *limit* [7] of a $*$-language is a subset of Eilenberg's *closure* [6], which in turn is contained in Boasson and Nivat's *adherence* [4]. (The three definitions coincide when applied to $*$-closed languages.)

[3] Our definition of ω-closure is equivalent to that of Ramadge [20], which involves a metric; see [4].

[4] We use the symbol L, for "language," to represent $*$-behavior in a manner consistent with the usual notation of the Ramadge–Wonham theory; we follow Ramadge in letting S, for "sequences," represent ω-behavior. These symbols should not be misconstrued as standing, respectively, for liveness and safety. On the contrary, the $*$-behavior L is the more closely connected with safety properties and S with liveness. The authors are grateful to Professor Amir Pnueli for pointing out this potential source of confusion.

[5] Ramadge [20] uses the term "nonblocking."

For any DES $\mathbf{G} = (L, S)$ and any supervisor f, the *controlled discrete-event system* $\mathbf{G}^f$, representing the action of the supervisor $f : L \to \mathbf{C}$ on the DES $\mathbf{G} = (L, S)$, is given by $\mathbf{G}^f = (L^f, S^f)$, where

(i) L^f, the $*$-language *synthesized by* f, is defined by the following recursion:[6]

(a) $1 \in L^f$,

(b) For all $k \in \Sigma^*, \sigma \in \Sigma$

$$k\sigma \in L^f \iff k \in L^f \cap \mathrm{dom}(f) \quad \text{and} \quad k\sigma \in L \quad \text{and} \quad \sigma \in f(k);$$

(ii) S^f, the ω-language *synthesized by* f, is given by $S^f := \lim(L^f) \cap S$.

The definition of L^f means that a sequence of events $k\sigma$ can occur under supervision if and only if the sequence k can occur under supervision, and, once it has, the event σ can take place without violating either the "physical" constraints embodied by L or the control pattern imposed by the supervisor. This interpretation of L^f is valid only if the map f is defined for all strings in L^f. We therefore say that a map $f : L \to \mathbf{C}$ is a *complete*[7] supervisor for the DES (L, S) if and only if $L^f \subseteq \mathrm{dom}(f)$. In the following, we deal exclusively with complete supervisors.

PROPOSITION 3.1. *For any* DES $\mathbf{G}$ *and any supervisor* $f : L \to \mathbf{C}$, $\mathbf{G}^f = (L^f, S^f)$ *is indeed a* DES, *i.e.,* $\mathrm{pre}(L^f) = L^f$ *and* $\mathrm{pre}(S^f) \subseteq L^f$. *Furthermore, the* $*$- *and* ω*-behaviors of* $\mathbf{G}^f$ *are sublanguages of those of* $\mathbf{G}$; *that is,* $L^f \subseteq L$ *and* $S^f \subseteq S$; S^f *is* ω*-closed relative to* S.

We say that $f : L \to \mathbf{C}$ is a *deadlock-free* supervisor for $\mathbf{G} = (L, S)$ if $\mathbf{G}^f$ is a deadlock-free DES.

4. Closed-loop behavior and controllability. The following sections characterize achievable closed-loop system behavior by identifying the $*$- and ω-languages that can be synthesized by supervisors.

4.1. Closed-loop $*$-behaviors and $*$-controllability. We begin with a review of Golaszewski and Ramadge's results on the synthesis of $*$-languages [10].

For any $*$-language $V \subseteq \Sigma^\infty$ and any $s \in \mathrm{pre}(V)$, the *active set of* V *after* s, $\Sigma_V(s) \subseteq \Sigma$, is given by

$$\Sigma_V(s) := \Sigma \cap (\mathrm{pre}(V)/s).$$

Thus $\Sigma_V(s)$ is the set of all $\sigma \in \Sigma$ such that $s\sigma \in \mathrm{pre}(V)$.

Given languages $V \subseteq \Sigma^\infty$, $L \subseteq \Sigma^*$ with $\mathrm{pre}(V) \subseteq L$, V is $*$-*controllable* with respect to L if and only if

$$\forall s \in \mathrm{pre}(V)\ \exists \Gamma \in \mathbf{C} : \Gamma \cap \Sigma_L(s) = \Sigma_V(s).$$

In other words, V is $*$-controllable with respect to L if and only if the extensions $s\sigma \in s\Sigma \cap \mathrm{pre}(L)$ of any $s \in \mathrm{pre}(V)$ can be restricted through control to exactly those $s\sigma$ that belong to $\mathrm{pre}(V)$.

PROPOSITION 4.1 (Golaszewski–Ramadge–Wonham). *For any* DES $\mathbf{G} = (L, S)$ *and any nonempty* $*$*-language* $M \subseteq L$, *there exists a complete supervisor for* $\mathbf{G}$ *that synthesizes* M *if and only if* M *is* $*$*-controllable with respect to* L *and* $*$*-closed.*

[6] This definition differs slightly from that of [20].

[7] This is not an exact analogue of the automaton-based definition of [16], but it has a similar interpretation.

4.2. Closed-loop ω-behaviors: $*$- and ω-controllability. The $*$-controllability property also characterizes the class of ω-languages that are synthesized by deadlock-free supervisors.

PROPOSITION 4.2 (Ramadge [20]). *For any* DES $\mathbf{G} = (L, S)$ *and any nonempty* $T \subseteq S$, *there exists a complete, deadlock-free supervisor* f *for* $\mathbf{G}$ *that synthesizes* T *if and only if* T *is* $*$*-controllable with respect to* L *and* ω*-closed with respect to* S.

The $*$-controllability of an ω-language $T \subseteq S$ means that all infinite extensions of strings in $\mathrm{pre}(T)$ can be controlled to belong to the ω-closure of T relative to S. A more intuitively satisfying notion of controllability would imply that all such infinite extensions could be controlled to belong to T itself, regardless of whether T were ω-closed relative to S. In this section, we define such a property, called *ω-controllability*. The new property is useful in characterizing the solvability of supervisor synthesis problems, mainly because it separates the issue of controllability from that of closure (see §5).

We first define the *controllability prefix* $\mathrm{pre}_{\mathbf{G}}(T)$ of an ω-language T. For any DES $\mathbf{G} = (L, S)$, define

$$\begin{aligned} \mathrm{pre}_{\mathbf{G}} : \quad & 2^S \to 2^{\mathrm{pre}(S)} \\ & T \mapsto \{t \in \mathrm{pre}(T) \ : \ (\exists T' \subseteq T/t) \\ & \qquad [T' \neq \emptyset \text{ is } * \text{-controllable w.r.t. } L/t \\ & \qquad\qquad \text{and } \omega\text{-closed w.r.t. } S/t] \ \}. \end{aligned}$$

By Proposition 4.2, $\mathrm{pre}_{\mathbf{G}}(T)$ represents the set of all $*$-strings in $\mathrm{pre}(T)$ whose infinite extensions can be controlled to belong to T.

In an alternative interpretation of $\mathrm{pre}_{\mathbf{G}}(T)$, the operation of a controlled system is viewed as an infinite game between supervisor and DES (where the supervisor wins just in case the ω-string generated belongs to T). Then $\mathrm{pre}_{\mathbf{G}}(T)$ is the set of "winning positions" for the supervisor.

PROPOSITION 4.3. *For any* DES (L, S) *and any* $T, T' \subseteq S$ *and* $t \in \mathrm{pre}(T)$,

(a) $\quad T \subseteq T' \Longrightarrow \mathrm{pre}_{\mathbf{G}}(T) \subseteq \mathrm{pre}_{\mathbf{G}}(T')$;

(b) $\quad \mathrm{pre}_{(L/t, S/t)}(T/t) = (\mathrm{pre}_{(L,S)}(T))/t$;

(c) *If* T *is* $*$*-controllable w.r.t.* L *and* ω*-closed w.r.t.* S,
$$\mathrm{pre}_{\mathbf{G}}(T) = \mathrm{pre}(T);$$

(d) $\quad \forall k \in \mathrm{pre}_G(T) : \exists \Gamma \in \mathbf{C} : \Gamma \cap \Sigma_L(k) \subseteq \Sigma_{\mathrm{pre}_G(T)}(k)$.

Proof. (a) The proof follows by definition.
(b) It holds that

$$\begin{aligned} & t' \in (\mathrm{pre}_{(L,S)}(T))/t \\ \Longleftrightarrow \ & tt' \in \mathrm{pre}_{(L,S)}(T) \\ \Longleftrightarrow \ & tt' \in \mathrm{pre}(T) \quad \text{and} \quad \exists T' \subseteq T/tt' \ : \ T' \neq \emptyset \text{ is} \\ & *\text{-controllable w.r.t. } L/tt', \omega\text{-closed w.r.t. } S/tt' \\ \Longleftrightarrow \ & t' \in \mathrm{pre}(T/t) \quad \text{and} \quad \exists T' \subseteq (T/t)/t' \ : \ T' \neq \emptyset \text{ is} \\ & *\text{-controllable w.r.t. } (L/t)/t', \omega\text{-closed w.r.t. } (S/t)/t' \\ \Longleftrightarrow \ & t' \in \mathrm{pre}_{(L/t, S/t)}(T/t). \end{aligned}$$

(c) It is easily shown that $*$-controllability and ω-closure are "preserved under quotients" in the following sense:

$$\begin{aligned} T \ *\text{-controllable w.r.t. } L &\implies T/t \ *\text{-controllable w.r.t. } L/t, \\ T \ \omega\text{-closed w.r.t. } S &\implies T/t \ \omega\text{-closed w.r.t. } S/t, \end{aligned}$$

where $T \subseteq \Sigma^\omega$. The result follows.

(d) Suppose that $t \in \mathrm{pre}_{\mathbf{G}}(T)$. Then there exists a nonempty $T' \subseteq T/t$ that is $*$-controllable with respect to L/t and ω-closed with respect to S/t. By $*$-controllability, there exists $\Gamma \in \mathbf{C}$ such that

$$\begin{aligned} & \Gamma \cap \Sigma_{L/t}(1) = \Sigma_{\mathrm{pre}(T')}(1) \\ \iff \quad & \Gamma \cap L/t = \Sigma \cap \mathrm{pre}(T') \\ \iff \quad & \Gamma \cap L/t = \Sigma \cap \mathrm{pre}_{(L/t,S/t)}(T') && \text{(part (c))} \\ \implies \quad & \Gamma \cap L/t \subseteq \Sigma \cap (\mathrm{pre}_{(L/t,S/t)}(T/t)) && \text{(part (a))} \\ \iff \quad & \Gamma \cap L/t \subseteq \Sigma \cap (\mathrm{pre}_{(L,S)}(T))/t && \text{(part (b))} \\ \iff \quad & \Gamma \cap \Sigma_L(t) \subseteq \Sigma_{\mathrm{pre}_{\mathbf{G}}(T)}(t). && \square \end{aligned}$$

A natural controllability property would require the supervisor to be always in a winning position. For any DES $\mathbf{G} = (L, S)$ and any $T \subseteq S$, T is *ω-controllable* with respect to $\mathbf{G}$ if T is $*$-controllable with respect to L and $\mathrm{pre}(T) = \mathrm{pre}_{\mathbf{G}}(T)$. (In the case where $\mathbf{C}$ is closed under containment (i.e., $\Gamma \in \mathbf{C}$ and $\Gamma \subseteq \Gamma' \implies \Gamma' \in \mathbf{C}$), as in the original Ramadge–Wonham theory, $\mathrm{pre}(T) = \mathrm{pre}_{\mathbf{G}}(T)$ implies $*$-controllability of T, by Proposition 4.3(d).)

Let $\Sigma = \{\alpha, \beta\}$, $L = \alpha^*\beta^*$, $S = \lim(L) = \{\alpha^\omega\} \cup \alpha^*\beta^\omega$, and $E = \alpha^*\beta^\omega$. If $\mathbf{C} = \{\Gamma \subseteq \Sigma : \alpha \in \Gamma\}$, then E is $*$-controllable with respect to L, but not ω-controllable with respect to (L, S) (as $\mathrm{pre}_{(L,S)}(E) = \emptyset$).

By Proposition 4.3(c), the two properties coincide for languages that are ω-closed relative to S.

PROPOSITION 4.4. *For any* DES (L, S) *and any* $T \subseteq S$, *if* T *is* ω*-closed with respect to* S,

$$T \text{ is } \omega\text{-controllable w.r.t. } (L, S) \iff T \text{ is } *\text{-controllable w.r.t. } L.$$

By Proposition 4.4, we may replace $*$-controllability with ω-controllability in Proposition 4.2.

PROPOSITION 4.5. *For any* DES (L, S) *and any* $T \subseteq S$, *there exists a complete, deadlock-free supervisor for* (L, S) *that synthesizes* T *if and only if* T *is* ω*-controllable with respect to* (L, S) *and* ω*-closed with resepct to* S.

This new characterization of achievable closed-loop behavior provides the key to explaining solvability of the supervisor synthesis problems of the next section.

5. Supervisor synthesis. We next discuss an ω-language analogue of the supervisory control problem of [16]. The original $*$-language problem is of basic importance in supervisor synthesis and has provided a foundation for numerous extensions.

5.1. The supervisory control problem for ω-languages (SCP$^\omega$).

PROBLEM 5.1 (SCP$^\omega$). *Given a* DES (L, S) *and* ω*-languages* $A, E \subseteq \Sigma^\omega$ *such that* $A \subseteq E \subseteq S$, *construct a complete, deadlock-free supervisor* f *for* (L, S) *such that* $A \subseteq S^f \subseteq E$.

The requirement that the supervisor be deadlock-free does not limit the generality of the problem. It is used to eliminate solutions in which containment in the maximal

legal sublanguage is satisfied vacuously; in cases where deadlocks are to be allowed, problems can be suitably recast; see [25] for an example.

By Proposition 4.5, solvability of SCP$^\omega$ is equivalent to the existence of a nonempty sublanguage $T \subseteq S$, ω-controllable with respect to (L, S) and ω-closed with respect to S, such that $A \subseteq T \subseteq E$. The ω-controllable and the ω-closed languages have different closure properties under union and intersection. Specifically, ω-controllability is preserved under arbitrary unions but not intersections, and ω-closure is preserved under arbitrary intersections but not arbitrary unions. It is therefore convenient to define, below, the following separate language classes.

For any DES $\mathbf{G} = (L, S)$ and any ω-languages $A \subseteq E \subseteq S$,

$$\mathcal{C}^\omega(E) := \{T \subseteq S : T \subseteq E \subseteq S \text{ and } T \text{ is } \omega\text{-controllable w.r.t. } \mathbf{G}\},$$
$$\mathcal{F}^\omega(A) := \{T \subseteq S : A \subseteq T \subseteq S \text{ and } T \text{ is } \omega\text{-closed w.r.t. } S\}.$$

With respect to the DES $\mathbf{G}$, $\mathcal{C}^\omega(E)$ is the class of ω-controllable sublanguages of E, and $\mathcal{F}^\omega(A)$ is the class of ω-closed superlanguages of A. We call an ω-language a *solution* to SCP$^\omega$ if it is a nonempty element of $\mathcal{C}^\omega(E) \cap \mathcal{F}^\omega(A)$.

We also bring in the $*$-language class of [16]. For any $*$-language L and any $L' \subseteq L$,

$$\mathcal{CF}^*(L') := \{K \subseteq L' : K \text{ is } *\text{-controllable w.r.t. } L \text{ and } *\text{-closed}\}.$$

The class $\mathcal{CF}^*(L')$ contains a supremal element $\sup \mathcal{CF}^*(L')$ [16]. For the ω-language classes, we have the following result.

PROPOSITION 5.2. *For any* DES $\mathbf{G} = (L, S)$ *and any* ω*-languages* $A \subseteq E \subseteq S$,

(a) $\sup \mathcal{C}^\omega(E)$ *exists in* $\mathcal{C}^\omega(E)$, *namely,*

$$\sup \mathcal{C}^\omega(E) = \lim(\sup \mathcal{CF}^*(\mathrm{pre}_{\mathbf{G}}(E))) \cap E;$$

(b) $\inf \mathcal{F}^\omega(A)$ *exists in* $\mathcal{F}^\omega(A)$, *namely,*

$$\inf \mathcal{F}^\omega(A) = \mathrm{clo}(A) \cap S.$$

Proof. Part (b) is clear, since clo is a Kuratowski closure operator. For part (a), let

$$E' := \lim(\sup \mathcal{CF}^*(\mathrm{pre}_{\mathbf{G}}(E))) \cap E.$$

We show that E' is the supremal element of $\mathcal{C}^\omega(E)$. To establish ω-controllability we apply the following claim.

CLAIM 1. *It holds that*

$$\sup \mathcal{CF}^*(\mathrm{pre}_{\mathbf{G}}(E)) \subseteq \mathrm{pre}_{\mathbf{G}}(E').$$

Suppose that $k \in \sup \mathcal{CF}^*(\mathrm{pre}_{\mathbf{G}}(E)) \subseteq \mathrm{pre}_{\mathbf{G}}(E)$. Then there exists a nonempty $E_k \subseteq E/k$, $*$-controllable with respect to L/k and ω-closed with respect to S/k. Since k is arbitrary, it suffices to show that $E_k \subseteq E'/k$.

Let $k' \in \mathrm{pre}(E_k)$. Then $E_k/k' \subseteq E/kk'$ is nonempty, $*$-controllable with respect to L/kk', and ω-closed with respect to S/kk'. We therefore have $kk' \in \mathrm{pre}_{\mathbf{G}}(E)$. Because k' is arbitrary, this means that

$$k\mathrm{pre}(E_k) \subseteq \mathrm{pre}_{\mathbf{G}}(E).$$

Now

$$\begin{aligned}
& E_k \subseteq E/k \text{ is } *\text{-controllable w.r.t. } L/k \\
\Longrightarrow\ & \sup\mathcal{CF}^*(\mathrm{pre}_{\mathbf{G}}(E)) \cup k\mathrm{pre}(E_k) \text{ is } *\text{-controllable w.r.t. } L \text{ and } *\text{-closed} \\
& \qquad (\mathbf{C} \text{ is closed under union; } k \in \sup\mathcal{CF}^*(\mathrm{pre}_{\mathbf{G}}(E))) \\
\Longleftrightarrow\ & k\mathrm{pre}(E_k) \subseteq \sup\mathcal{CF}^*(\mathrm{pre}_{\mathbf{G}}(E)) \qquad (k\mathrm{pre}(E_k) \subseteq \mathrm{pre}_{\mathbf{G}}(E)) \\
\Longleftrightarrow\ & kE_k \subseteq \lim(\sup\mathcal{CF}^*(\mathrm{pre}_{\mathbf{G}}(E))) \cap E \qquad (k \in \sup\mathcal{CF}^*(\mathrm{pre}_{\mathbf{G}}(E))).
\end{aligned}$$

Thus $E_k \subseteq E'/k$. This completes the proof of the claim.

We now have

$$\begin{aligned}
\mathrm{pre}(E') &\subseteq \sup\mathcal{CF}^*(\mathrm{pre}_{\mathbf{G}}(E)) \qquad \text{(by definition)} \\
&\subseteq \mathrm{pre}_{\mathbf{G}}(E') \qquad \text{(Claim 1)} \\
&\subseteq \mathrm{pre}(E') \qquad \text{(by definition)}.
\end{aligned}$$

Thus

$$\mathrm{pre}(E') = \sup\mathcal{CF}^*(\mathrm{pre}_{\mathbf{G}}(E)) = \mathrm{pre}_{\mathbf{G}}(E'),$$

so E' is ω-controllable with respect to $\mathbf{G}$.

Now suppose that $E'' \in \mathcal{C}^\omega(E)$. Then

$$\begin{aligned}
E'' &\subseteq \mathrm{clo}(E'') \cap E \\
&= \lim(\mathrm{pre}(E'')) \cap E \\
&= \lim(\sup\mathcal{CF}^*(\mathrm{pre}(E''))) \cap E \qquad (*\text{-controllability}) \\
&= \lim(\sup\mathcal{CF}^*(\mathrm{pre}_{\mathbf{G}}(E''))) \cap E \qquad (\omega\text{-controllability}) \\
&\subseteq E'.
\end{aligned}$$

This establishes that E' is indeed the unique maximal element of $\mathcal{C}^\omega(E)$. □

In the special case where $\mathbf{C}$ is closed under containment, $\sup\mathcal{C}^\omega(E) = \lim(\mathrm{pre}_{\mathbf{G}}(E)) \cap E$ (by Proposition 4.3 (d)) [25]. The solvability of SCP$^\omega$ can be characterized in terms of the extremal elements of $\mathcal{C}^\omega(E)$ and $\mathcal{F}^\omega(A)$.

THEOREM 5.3. SCP$^\omega$ *is solvable if and only if* $\sup\mathcal{C}^\omega(E) \neq \emptyset$ *and*

$$\inf\mathcal{F}^\omega(A) \subseteq \sup\mathcal{C}^\omega(E)\ .$$

Proof. Necessity follows from Proposition 4.5. For sufficiency, let

$$A' := \inf\mathcal{F}^\omega(A) \subseteq \sup\mathcal{C}^\omega(E) =: E'$$

and suppose that $E' \neq \emptyset$.

Because E' is $*$-controllable and nonempty, there exists a complete, deadlock-free supervisor $f_0 : \Sigma^* \to \Gamma$ that synthesizes $\mathrm{clo}(E') \cap S$, by Proposition 4.2.

Because E' is ω-controllable, there exists for every $m \in \mathrm{pre}(E')$ a nonempty ω-language $E'_m \subseteq E'/m$, $*$-controllable with respect to L/m and ω-closed with respect to S/m; let $f_m : \Sigma^* \to \Gamma$ be a corresponding complete, deadlock-free supervisor.

Let M be the set of all elements of $\mathrm{pre}(E') \setminus \mathrm{pre}(A')$ of minimal length. Define the following supervisor $f : \Sigma^* \to \Gamma$:

$$f(s) := \begin{cases} f_0(s) & \text{if } s \in \mathrm{pre}(A'), \\ f_m(s/m) & \text{if } s \in m\ \mathrm{pre}(E'_m), \text{ where } m \in M, \\ \text{undefined} & \text{otherwise.} \end{cases}$$

Note that f is thus well defined, since the sets $m\ \mathrm{pre}(E'_m)$, $m \in M$ are pairwise disjoint.

We claim that f is a complete, deadlock-free supervisor for (L, S) and that $A' \subseteq S^f \subseteq E'$. The result is a consequence of the following claim.

CLAIM 2. *It holds that*

$$\text{(a)} \qquad L^f = \mathrm{pre}(A') \cup \bigcup_{m\in M} m\mathrm{pre}(E'_m),$$
$$\text{(b)} \qquad S^f = A' \cup \bigcup_{m\in M} mE'_m.$$

(a) We show by induction on the length of strings that

$$k \in L^f \iff k \in \mathrm{pre}(A') \cup \bigcup_{m\in M} m\mathrm{pre}(E'_m).$$

The result holds by definition when k is the empty string. For the induction step, suppose that the result holds for k. Then

$$\begin{aligned}
& k\sigma \in L^f \\
\iff\ & k\sigma \in L, k \in L^f \text{ and } \sigma \in f(k) \\
\iff\ & k\sigma \in L, k \in \mathrm{pre}(A') \cup \textstyle\bigcup_{m\in M} m\mathrm{pre}(E'_m) \text{ and } \sigma \in f(k) \quad \text{(induction hypothesis)} \\
\iff\ & k\sigma \in L, [(k \in \mathrm{pre}(A') \text{ and } \sigma \in f_0(k)) \\
& \qquad \text{or } (\exists m \in M)(k \in m\mathrm{pre}(E'_m) \text{ and } \sigma \in f_m(k/m))] \\
\iff\ & k\sigma \in L, [(k \in L^{f_0} \cap \mathrm{pre}(A') \text{ and } \sigma \in f_0(k)) \\
& \qquad \text{or } (\exists m \in M)(k \in m(L/m)^{f_m} \text{ and } \sigma \in f_m(k/m))] \\
& \qquad\qquad \text{(deadlock-freedom of } f_m) \\
\iff\ & k\sigma \in L^{f_0} \cap \mathrm{pre}(A')\Sigma \text{ or } (\exists m \in M)(k\sigma/m \in (L/m)^{f_m}) \\
\iff\ & k\sigma \in \mathrm{pre}(A') \text{ or } (\exists m \in M)(k\sigma/m \in \mathrm{pre}(E'_m)) \\
& \qquad\qquad \text{(deadlock-freedom of } f_0 \text{ and } f_m) \\
\iff\ & k\sigma \in \mathrm{pre}(A') \cup \textstyle\bigcup_{m\in M} m\mathrm{pre}(E'_m).
\end{aligned}$$

(b) First, note that

$$\lim(L^f) = \mathrm{clo}(A') \cup \bigcup_{m\in M} m\mathrm{clo}(E'_m)\ .$$

The inclusion ($\supseteq$) is easily proved. For the reverse, suppose that $s \in \lim(L^f)$. Then

$$\mathrm{pre}(s) \subseteq L^f = \mathrm{pre}(A') \cup \bigcup_{m\in M} m\mathrm{pre}(E'_m).$$

Now, if $\mathrm{pre}(s) \subseteq \mathrm{pre}(A')$, then $s \in \mathrm{clo}(A')$, and the inclusion holds; otherwise, $\mathrm{pre}(s) \subseteq \mathrm{pre}(m) \cup m\mathrm{pre}(E'_m)$, where $m \in M$ is the shortest element of $\mathrm{pre}(s)\backslash\mathrm{pre}(A')$. In that case, $s \in m\mathrm{clo}(E'_m)$.

Thus,

$$\begin{aligned}
S^f &= \lim(L^f) \cap S \\
&= (\mathrm{clo}(A') \cup \textstyle\bigcup_{m\in M} m\mathrm{clo}(E'_m)) \cap S \\
&= (\mathrm{clo}(A') \cap S) \cup \textstyle\bigcup_{m\in M} (m\mathrm{clo}(E'_m) \cap S) \\
&= (\mathrm{clo}(A') \cap S) \cup \textstyle\bigcup_{m\in M} m(\mathrm{clo}(E'_m) \cap S/m) \\
&= A' \cup \textstyle\bigcup_{m\in M} mE'_m.
\end{aligned}$$

This completes the proof of the claim. Completeness of f follows from part (a).

The containments $A' \subseteq S^f \subseteq E'$ follow from part (b).
For deadlock-freedom,

$$\begin{aligned} \mathrm{pre}(S^f) &= \mathrm{pre}(A' \cup \bigcup_{m\in M} mE'_m) \qquad \text{(part (b))} \\ &= \mathrm{pre}(A') \cup \bigcup_{m\in M} m\mathrm{pre}(E'_m) \\ &= L^f \qquad \text{(part (a))}. \quad \square \end{aligned}$$

COROLLARY 5.4. *For any* DES (L, S) *and any* $E \subseteq S$, *the* ω*-language* $\sup \mathcal{C}^\omega(E)$ *is the least upper bound of the achievable closed-loop behaviors contained in* E, *that is,*

$$\sup \mathcal{C}^\omega(E) = \bigcup \{R \subseteq E : R \text{ is } *\text{-controllable w.r.t. } L \text{ and } \omega\text{-closed w.r.t. } S\}.$$

Proof. ($\supseteq$) The proof follows by Proposition 4.4. ($\subseteq$) Let $s \in \sup \mathcal{C}^\omega(E)$ and define $A := \{s\}$. Then, by Theorem 5.3, there exists $R \subseteq \sup \mathcal{C}^\omega(E)$, $*$-controllable with respect to L and ω-closed with respect to S, such that $A \subseteq R \subseteq E$. $\square$

Let an ω-language $R \subseteq \Sigma^\omega$ be a *maximal solution* to SCP$^\omega$ if it is a nonempty maximal element (in the sense of set inclusion) of the language class $\mathcal{C}^\omega(E) \cap \mathcal{F}^\omega(A)$.

COROLLARY 5.5. *When* SCP$^\omega$ *is solvable, it has maximal solutions if and only if* $\sup \mathcal{C}^\omega(E)$ *is* ω*-closed with respect to* S, *i.e., if and only if* $\sup \mathcal{C}^\omega(E) \in \mathcal{F}^\omega(A)$. *In this case,* $\sup \mathcal{C}^\omega(E)$ *is the unique maximal solution.*

Proof. The proof follows by Corollary 5.4, since $\mathcal{C}^\omega(E) \cap \mathcal{F}^\omega(A)$ is closed under finite unions. $\square$

COROLLARY 5.6. $\sup \mathcal{C}^\omega(E)$ *is* ω*-closed with respect to* S *whenever* E *is* ω*-closed.*

Proof. The proof follows by Proposition 5.2. $\square$

Intuitively, an ω-language $E \subseteq \Sigma^\omega$ that is ω-closed relative to S is completely determined by its finite prefixes; it represents no restriction on infinite strings beyond that implied by the restriction on finite strings to $\mathrm{pre}(E)$. Hence it is not surprising that, when E is ω-closed relative to S, the existence of maximal solutions carries over to the infinite string case (as Corollaries 5.5 and 5.6 imply). On the other hand, maximal legal sublanguages that are not ω-closed relative to S embody an additional restriction on infinite trajectories beyond that implied by the restriction on finite trajectories; in other words, such languages incorporate liveness specifications. The nonexistence of maximal solutions reflects the open-ended nature of the liveness component of the specification [22], [28], [29].

6. Effective solution of SCP$^\omega$. To study effective supervisor synthesis, we assume that both DES and specification languages are represented by finite automata. We suppose the DES to be modeled as a deterministic Büchi automaton [20]. The Büchi acceptance criterion is chosen for technical simplicity; more general models will be considered in future reports. The maximal legal sublanguage $E \subseteq S$ is assumed to be given by a deterministic Rabin automaton (see [24]). For the minimal acceptable sublanguage $A \subseteq E$, we need only a representation of the prefix $\mathrm{pre}(E)$, by Proposition 5.2; we assume $\mathrm{pre}(A)$ to be given by a finite automaton.

Computation of controllability prefixes. A central aspect of the effective solution of SCP$^\omega$ is the computation of the controllability prefix $\mathrm{pre}_{(L,S)}(E) \subseteq \mathrm{pre}(E)$ of the maximal legal sublanguage $E \subseteq S$. For this, it is convenient to assume that the languages $L \subseteq \Sigma^*$, $S \subseteq \Sigma^\omega$, and $E \subseteq \Sigma^\omega$ are represented by different acceptance criteria based on the same transition structure. We therefore define a *Rabin–Büchi*

automaton to be a 6-tuple

$$(\Sigma, X, \delta, x_0, \{(R_p, I_p) : p \in P\}, R),$$

where the first four components determine a deterministic transition structure in the usual way, the fifth is a set of pairs of state subsets as appears in a Rabin acceptance criterion (as defined in [24]), and the sixth is a state subset as employed in a Büchi acceptance criterion [26].

In particular, we assume that a deterministic Rabin–Büchi automaton $\mathcal{A} = (\Sigma, X, \delta, x_0, \{(R_p, I_p) : p \in P\}, R)$ is given, such that the Rabin automaton $(\Sigma, X, \delta, x_0, \{(R_p, I_p) : p \in P\})$ accepts $E \subseteq S \subseteq \Sigma^\omega$, the $*$-automaton $(\Sigma, X, \delta, x_0, X)$ accepts $L \subseteq \Sigma^*$, and the Büchi automaton $(\Sigma, X, \delta, x_0, R)$ accepts $S \subseteq \Sigma^\omega$.[8] The language $\mathrm{pre}_{(L,S)}(E) \subseteq \mathrm{pre}(E)$ then corresponds to the following subset $C^{\mathcal{A}} \subseteq X$ of the state set of $\mathcal{A}$. Let $\mathcal{A} = (\Sigma, X, \delta, x_0, \{(R_p, I_p) : p \in P\}, R)$ be a Rabin–Büchi automaton. Then

$$C^{\mathcal{A}} := \{x \in X : E_x \subseteq S_x, (\exists E'_x \subseteq E_x)\ [E'_x \neq \emptyset \text{ is } *\text{-controllable w.r.t. } L_x \text{ and } \omega\text{-closed w.r.t. } S_x]\},$$

where, for any $x \in X$, $E_x \subseteq \Sigma^\omega$ is the ω-language accepted by the Rabin automaton $(\Sigma, X, \delta, x, \{(R_p, I_p) : p \in P\})$, $L_x \subseteq \Sigma^*$ is the $*$-language accepted by the $*$-automaton $(\Sigma, X, \delta, x, X)$, and $S_x \subseteq \Sigma^\omega$ is the ω-language accepted by the Büchi automaton $(\Sigma, X, \delta, x, R)$.

Because $\mathcal{A}$ is deterministic we have, for any $k \in \mathrm{pre}(E)$,

$$k \in \mathrm{pre}_{(L,S)}(E) \iff \delta(k, x_0) \in C^{\mathcal{A}}.$$

Just as $\mathrm{pre}_{(L,S)}(E)$ represents the set of prefixes of E whose infinite extensions "can be controlled to belong to E," under the assumption that all ω-strings generated belong to S, so $C^{\mathcal{A}}$ intuitively represents the set of states of $\mathcal{A}$ from which the automaton "can be controlled to satisfy its Rabin acceptance criterion" under the assumption that all infinite trajectories followed by $\mathcal{A}$ satisfy the Büchi acceptance criterion.

In cases where this liveness assumption is vacuous (for example, where $R = X$), the subset $C^{\mathcal{A}}$ reduces to the "controllability subset" [24] of the Rabin automaton $(\Sigma, X, \delta, x_0, \{(R_p, I_p) : p \in P\})$. It was shown in [24] that, with the use of a suitable fixpoint calculus, this subset could be represented as a certain fixpoint of an "inverse dynamics operator" based on the one-step dynamics of the controlled automaton and that this characterization allowed for efficient computation and effective control synthesis. This result can be easily extended to the present setting by means of a suitable generalization of the definition of the "inverse dynamics operator" of [24]; see [23].

Computation of supremal ω-controllable sublanguages. Once $\mathrm{pre}_{\mathbf{G}}(E)$ has been computed, it remains to find $\sup \mathcal{C}\mathcal{F}^*(\mathrm{pre}_{\mathbf{G}}(E))$, or alternatively $\sup \mathcal{C}^*(\mathrm{pre}_{\mathbf{G}}(E))$, and take the intersection of its limit with E to yield the supremal ω-controllable sublanguage $\sup \mathcal{C}^\omega(E)$ (by Proposition 5.2).

[8] Such an automaton can, of course, be constructed from separate automata accepting E, L, and S. Actually, we need only assume that the $*$-automaton accepts some $*$-language $L' \subseteq \Sigma^*$ such that $L' \cap \mathrm{pre}(E)\Sigma = L \cap \mathrm{pre}(E)\Sigma$, and the Büchi automaton accepts some ω-language $S' \subseteq \Sigma^\omega$ such that $S' \cap \mathrm{clo}(E) = S \cap \mathrm{clo}(E)$; for any such languages, $\mathrm{pre}_{(L',S')}(E) = \mathrm{pre}_{(L,S)}(E)$.

Owing to the structure of the controllability subset $C^{\mathcal{A}}$, the computation of $\sup\mathcal{CF}^*(\mathrm{pre}_{\mathbf{G}}(E))$ requires only a one-step deletion of state transitions. We first define the following "state feedback" map. Let $\mathcal{A} = (\Sigma, X, \delta, x_0, \{(R_p, I_p) : p \in P\}, R)$ be a deterministic Rabin–Büchi automaton. Define

$$\Gamma^{\mathcal{A}} : C^{\mathcal{A}} \longrightarrow \mathbf{C},$$
$$x \mapsto \bigcup\{\Gamma \in \mathbf{C} : (\forall \sigma \in \Gamma)[\delta(\sigma, x)! \Longrightarrow \delta(\sigma, x) \in C^{\mathcal{A}}]\}.$$

The map $\Gamma^{\mathcal{A}}$ can be interpreted as the most liberal state feedback control that ensures the invariance of the subset $C^{\mathcal{A}}$.

Now define a transition function corresponding to $\Gamma^{\mathcal{A}}(x)$. Let $\mathcal{A} = (\Sigma, X, \delta, x_0, \{(R_p, I_p) : p \in P\}, R)$ be a deterministic Rabin–Büchi automaton. Define

$$\delta^{\mathcal{A}} : \Sigma \times X \to X,$$
$$(\sigma, x) \mapsto \begin{cases} \delta(\sigma, x) & \text{if } x \in C^{\mathcal{A}} \text{ and } \sigma \in \Gamma^{\mathcal{A}}(x), \\ \text{undefined} & \text{otherwise.} \end{cases}$$

We also let $\delta^{\mathcal{A}}$ denote the following natural extension of the above function:

$$\delta^{\mathcal{A}} : \Sigma^* \times X \longrightarrow X,$$
$$(1, x) \mapsto x,$$
$$(k\sigma, x) \mapsto \delta^{\mathcal{A}}(\sigma, \delta^{\mathcal{A}}(k, x)).$$

The transition function $\delta^{\mathcal{A}}$ produces the freest achievable closed-loop $*$-behavior contained in $\mathrm{pre}_{\mathbf{G}}(E)$, namely, $\sup\mathcal{CF}^*(\mathrm{pre}_{\mathbf{G}}(E))$.

PROPOSITION 6.1. *Let $\mathcal{A} = (\Sigma, X, \delta, x_0, \{(R_p, I_p) : p \in P\}, R)$ be a deterministic Rabin–Büchi automaton. Let E be the ω-language accepted by $\mathcal{A}$, and L the $*$-language accepted by $(\Sigma, X, \delta, x_0, X)$. Then the $*$-automaton*

$$(\Sigma, X, \delta^{\mathcal{A}}, x_0, C^{\mathcal{A}})$$

accepts the $*$-language $\sup\mathcal{CF}^*(\mathrm{pre}_{(L,S)}(E))$.

Proof. Let the $*$-language accepted by the $*$-automaton be L'. We must show that

$$L' = \sup\mathcal{CF}^*(\mathrm{pre}_{(L,S)}(E)).$$

Since $\delta^{\mathcal{A}}$ is a restriction of δ, we have $L' \subseteq \mathrm{pre}_{(L,S)}(E)$.

The $*$-controllability and $*$-closure of L' follow from the definition of $\delta^{\mathcal{A}}$. This proves that $L' \in \mathcal{CF}^*(\mathrm{pre}_{(L,S)}(E))$. We now show that, for any $L'' \in \mathcal{CF}^*(\mathrm{pre}_{(L,S)}(E))$, $L'' \subseteq L'$. Specifically, we show by induction on the length of strings that, for all $k \in \Sigma^*$,

$$k \in L'' \Longrightarrow k \in L'.$$

For the base, $1 \in L'' \Longrightarrow 1 \in \mathrm{pre}_{(L,S)}(E) \iff x_0 \in C^{\mathcal{A}} \iff 1 \in L'$. For the induction step, it suffices to show that, for all $k \in L' \cap L''$,

$$\Sigma_{L'}(k) \supseteq \Sigma_{L''}(k).$$

Suppose not. Let $\sigma \in \Sigma_{L''}(k) \setminus \Sigma_{L'}(k)$. Then

$$\begin{aligned} & \sigma \notin \Gamma^{\mathcal{A}}(\delta^{\mathcal{A}}(k, x_0)) \\ \iff & \sigma \notin \Gamma^{\mathcal{A}}(\delta(k, x_0)) \\ \iff & (\forall \Gamma \in \mathbf{C})[\sigma \in \Gamma \Longrightarrow (\exists \sigma' \in \Gamma)[\delta(\sigma', \delta(k, x_0)) \notin C^{\mathcal{A}}]] \\ \iff & (\forall \Gamma \in \mathbf{C})[\sigma \in \Gamma \Longrightarrow \Gamma \cap \Sigma_L(k) \not\subseteq \Sigma_{\mathrm{pre}_{(L,S)}(E)}(k)] \\ \Longrightarrow & (\forall \Gamma \in \mathbf{C})[\Gamma \cap \Sigma_L(k) \neq \Sigma_{L''}(k)]. \end{aligned}$$

This contradicts $*$-controllability of L''. □

THEOREM 6.2. *Let $\mathcal{A} = (\Sigma, X, \delta, x_0, \{(R_p, I_p) : p \in P\}, R)$ be a deterministic Rabin–Büchi automaton. Let E be the ω-language accepted by the Rabin automaton $(\Sigma, X, \delta, x_0, \{(R_p, I_p) : p \in P\})$, L the $*$-language accepted by the $*$-automaton $(\Sigma, X, \delta, x_0, X)$, and $S \subseteq \lim(L)$ the ω-language accepted by the Büchi automaton $(\Sigma, X, \delta, x_0, R)$. Suppose that $E \subseteq S$. Then the deterministic Rabin automaton*

$$(\Sigma, X, \delta^{\mathcal{A}}, x_0, \{(R_p, I_p) : p \in P\})$$

accepts the ω-language $\sup \mathcal{C}^{\omega}(E)$ relative to the DES (L, S).

Proof. The proof follows by Propositions 5.2 and 6.1. □

Testing solvability. Once $\sup \mathcal{C}^{\omega}(E)$ has been computed, the existence of solutions to SCP$^{\omega}$ can be checked by testing the containment

$$\inf \mathcal{F}^{\omega}(A) \subseteq \sup \mathcal{C}^{\omega}(E).$$

Let $\mathcal{A}_{\inf} = (\Sigma, X, \delta, x_0, F)$ be a $*$-automaton accepting $\mathrm{pre}(A)$,[9] $\mathcal{A}_S = (\Sigma, X', \delta', x_0', R')$ a deterministic Büchi automaton accepting S, and $\mathcal{A}_{\sup} = (\Sigma, X''\delta'', x_0'', \{(R_p, I_p) : p \in P\})$ a total, deterministic Rabin automaton accepting $\sup \mathcal{C}^{\omega}(E)$. Then $\inf \mathcal{F}^{\omega}(A) \setminus \sup \mathcal{C}^{\omega}(E)$ is accepted by the Streett automaton[10]

$$\mathcal{A}_{\mathrm{diff}} = (\Sigma, X''', \delta''', x_0''', \{(\emptyset, X \times R \times X''), (\emptyset, F \times X' \times X'')\} \cup \{(I_p''', R_p''') : p \in P\}),$$

where

$$X''' = X \times X' \times X'',$$

$$\delta''' : (\sigma, (x, x', x'')) \mapsto \begin{cases} (\delta(\sigma, x), \delta'(\sigma, x'), \delta''(\sigma, x'')) & \text{if } \mathcal{A}_{\inf} \text{ is deterministic,} \\ \delta(\sigma, x) \times \{\delta'(\sigma, x')\} \times \{\delta''(\sigma, x'')\} & \text{otherwise;} \end{cases}$$

$$x_0''' = (x_0, x_0', x_0''),$$

$$I_p''' = X \times X' \times R_p,$$

$$R_p''' = X \times X' \times I_p.$$

(Streett automata are specified in the same way as Rabin automata, but employ the negation of the Rabin acceptance condition [21], [26]; hence this automaton accepts

[9] Such an automaton can be computed in polynomial time, given an ω-automaton accepting $A \subseteq \Sigma^{\omega}$.

[10] Because $\mathrm{pre}(A)$ is $*$-closed, we may have $F = X$. In this case, the subset pair $(F \times X' \times X'', \emptyset)$ may be omitted from $\mathcal{A}_{\mathrm{diff}}$.

$\inf\mathcal{F}^\omega(A) \cap [\Sigma^\omega \setminus \sup\mathcal{C}^\omega(E)] = \inf\mathcal{F}^\omega(A) \setminus \sup\mathcal{C}^\omega(E)$.) To check the containment, it suffices to test this automaton for emptiness [9]. The complexity of testing solvability is polynomial in the numbers of states of $\mathcal{A}_{\inf}$, $\mathcal{A}_S$, and $\mathcal{A}_{\sup}$ and linear in the number of state subset pairs of $\mathcal{A}_{\sup}$.

Supervisor synthesis. If SCP$^\omega$ is solvable, then the method outlined in the proof of Theorem 5.3 can be used to synthesize a supervisor that solves SCP$^\omega$.

Let $\mathcal{A}_{\sup} = (\Sigma, X'', \delta'', x_0'', \{(R_p, I_p) : p \in P\})$ be the deterministic Rabin automaton of the previous section. A subset $F'' \subseteq X''$ can be computed[11] in polynomial time such that the $*$-automaton $(\Sigma, X'', \delta'', x_0'', F'')$ accepts $\mathrm{pre}(\sup\mathcal{C}^\omega(E))$. Because $\mathrm{pre}(\sup\mathcal{C}^\omega(E))$ is $*$-controllable with respect to L, we may define the feedback map

$$\begin{aligned} \phi_0 &: F'' \longrightarrow \mathbf{C}, \\ x' &\mapsto \{\sigma \in \Sigma : \delta''(\sigma, x') \in F''\}. \end{aligned}$$

The map

$$\begin{aligned} f_0 &: \Sigma^* \longrightarrow \mathbf{C}, \\ k &\mapsto \phi_0(\delta''(k, x_0)) \end{aligned}$$

is a complete supervisor for (L, S) that synthesizes the $*$-language $\mathrm{pre}(\sup\mathcal{C}^\omega(E))$. It follows that f_0 synthesizes the ω-language $\lim(\mathrm{pre}(\sup\mathcal{C}^\omega(E))) \cap S = \mathrm{clo}(\sup\mathcal{C}^\omega(E)) \cap S$. Moreover, because $\mathrm{pre}(\sup\mathcal{C}^\omega(E)) = \mathrm{pre}(\mathrm{clo}(\sup\mathcal{C}^\omega(E)) \cap S)$, f_0 is deadlock-free.

By the results of [23], there exists a feedback map $\phi : X'' \longrightarrow \mathbf{C}$ such that, for any $k \in \mathrm{pre}(\sup\mathcal{C}(E))$, the supervisor

$$\begin{aligned} f_k &: \Sigma^* \longrightarrow \mathbf{C}, \\ l &\mapsto \phi(\delta''(kl, x)) \end{aligned}$$

is a complete, deadlock-free supervisor for $(L/k, S/k)$ that synthesizes some nonempty sublanguage of E/k.

It follows by the proof of Theorem 5.3 that the supervisor

$$\begin{aligned} f &: \Sigma^* \longrightarrow \mathbf{C}, \\ l &\mapsto \begin{cases} f_0(l) & \text{if } l \in \mathrm{pre}(A), \\ f_k(l/k) & \text{if } k \text{ is the shortest element of } \mathrm{pre}(l) \setminus \mathrm{pre}(A) \end{cases} \end{aligned}$$

solves SCP$^\omega$. If the $*$-automaton $\mathcal{A}_{\inf}$ of the previous section is deterministic and total, then f can be defined in terms of a state feedback map based on the transition structure of the automaton

$$\mathcal{A}_{\mathrm{diff}} = (\Sigma, X''', \delta''', x_0''', \{(\emptyset, X \times R \times X''), (\emptyset, F \times X' \times X'')\} \cup \{(I_p''', R_p''') : p \in P\})$$

constructed in the previous section, namely, $f : k \mapsto \psi(\delta'''(k, x_0'''))$, where

$$\begin{aligned} \psi &: X''' \longrightarrow \mathbf{C}, \\ (x, x', x'') &\mapsto \begin{cases} \phi_0(x'') & \text{if } x \in F, \\ \phi(x'') & \text{otherwise.} \end{cases} \end{aligned}$$

[11] Using algorithms for testing emptiness of automata on infinite strings [9].

7. Conclusion. This report extends some of the basic results of the Ramadge–Wonham supervisory control theory to an infinite-string framework. The generalization allows the consideration of liveness as well as safety properties in the formulation of control problems for discrete-event systems. The article introduces the language property of *ω-controllability*, which provides a more precise characterization of the limitations of available control actions than does the earlier, finitary notion of controllability upon which it is based. A central result is that every sublanguage of the language generated by a given DES contains a unique maximal ω-controllable sublanguage (provided that the family of *control patterns* is closed under union). Within the present framework, this supremal ω-controllable sublanguage provides the key to solvability of problems of DES supervision.

Effective supervisor synthesis is studied under the assumption that the DES is modeled as a deterministic Büchi automaton and legal behavior specified by a deterministic Rabin automaton. The computation of the supremal ω-controllable sublanguage is exponential in the size of the Rabin acceptance condition but polynomial in the size of the automaton state sets; the further step of testing for the existence of solutions is polynomial-time.

The ω-language formulation of the article is essentially due to Ramadge. However, Ramadge [19], [20] and Golaszewski and Ramadge [11] consider only specifications that are ω-closed relative to DES behavior, and therefore represent pure safety properties; thus the infinitary setting serves only to provide a model of nonterminating behavior rather than to allow liveness specifications and does not necessitate the infinitary controllability property employed here [22]. The study of Kumar, Garg, and Marcus is similar in this respect [12], [13]. Young, Spanjol, and Garg [28], [29] consider liveness specifications represented by deterministic Büchi automata and introduce the language property of *finite stabilizability*; the conjunction of finite stabilizability and $*$-controllability is within this context equivalent to ω-controllability [22].

The main contribution of the present article is the extension of supervisory control theory to allow the use of liveness properties in the specification of DESs. While the importance of such properties is widely recognized in computer science, it has yet to be thoroughly evaluated from the perspective of control. Liveness properties can be expected to lead to simpler, more modular specifications, owing to their relatively weak, open-ended nature. For the same reason, they allow qualitatively acceptable behavior to be specified as liberally as possible, permitting the existence and form of solutions to be studied before quantitative performance criteria are introduced [14]. This article provides a framework for the study of such potential benefits.

Acknowledgments. The reading of a preliminary version of these results by the first author's thesis examiners, particularly Professors Eric Hehner, Raymond Kwong, and Amir Pnueli, is gratefully acknowledged. Thanks are due also to the referees for helpful comments on the presentation of the material.

A VERSION OF OLECH'S LEMMA IN A PROBLEM OF THE CALCULUS OF VARIATIONS*

ARRIGO CELLINA† AND SANDRO ZAGATTI‡

Abstract. This paper studies the solutions of the minimum problem for a functional of the gradient under linear boundary conditions. A necessary and sufficient condition, based on the facial structure of the epigraph of the integrand, is provided for the continuous dependence of the solutions on boundary data.

Key words. calculus of variations, extremality, strong convergence, weak convergence

AMS subject classification. 49A50

1. Introduction. A well-known result in the framework of integrals of multifunctions, Olech's lemma, gives a condition implying strong convergence out of a very weak form of convergence to extreme points [O1]. Namely, if e is an extreme point of the closure of the integral of a multifunction, there is a unique integrand in the multifunction that gives e; moreover, if u and v are arbitrary selections and $\int u$ and $\int v$ are sufficiently close to e, then u and v are close to each other in L^1. Hence this result exhibits a condition (extremality) that implies both uniqueness and continuous dependence that has been investigated, in the context of n-dimensional integration, by various authors (see [A], [AR], [Re], [Ba], [V] and the references quoted there); the purpose of this note is to investigate a similar property in the context of the calculus of variations. More precisely, we consider the problem (studied in the context of crystallography) of minimizing a functional of the gradient under linear boundary conditions:

$$\mathcal{P}_a: \qquad \text{Minimize } \int_\Omega g(\nabla u(x))dx; \qquad u \in \langle a, \cdot \rangle + W_0^{1,1}(\Omega); \quad (\Omega \subset \mathbb{R}^n)$$

and study the dependence on $a \in \mathbb{R}^n$ of the solutions to $\mathcal{P}_a$.

Analogously to the case of Olech's lemma, which infers strong convergence of the selections from the convergence of their integrals to the extreme points of the integral of the multifunction, here we have a vector parameter a playing the role of the integral, in the sense that the location of $(a, g^{**}(a))$ with respect to the facial structure of the epigraph of g^{**} (the bipolar of g) determines whether continuous dependence of the solutions of $\mathcal{P}_a$ with respect to boundary data holds.

As shown in [C1] and in [C2], uniqueness for problem $\mathcal{P}_a$ holds if and only if the dimension d of the face of the epigraph of g^{**} to whose relative interior $(a, g^{**}(a))$ belongs is strictly less than n, the dimension of the space, and in this case the solution is $u_a = \langle a, \cdot \rangle$. Hence we might ask the following question: given a point a such that the previous uniqueness condition holds, is it true that whenever a point a' is sufficiently close to a, solutions of $\mathcal{P}_{a'}$ are close to u_a in $W^{1,1}$? This is certainly true in a special

case: assume indeed that, given a, there exists a neighbourhood U of a such that for any point a' in U, $\mathcal{P}_{a'}$ has the unique solution $u_{a'}$; in this case continuous dependence follows from the explicit form of the solutions.

Hence the problem arises whenever the point a is such that $\mathcal{P}_a$ admits the unique solution u_a and there are points a_k, arbitrarily close to a, for which the corresponding problem $\mathcal{P}_{a_k}$ has infinitely many solutions. This happens when $(a_k, g^{**}(a_k))$ belongs to an n-dimensional face F of $\mathrm{epi}(g^{**})$ and $(a, g^{**}(a))$ belongs to a face F_1 of dimension less than n contained in the relative boundary of F. It is to this case we will refer in our main result, according to which the following conditions are equivalent.

(i) All the solutions u^k of $\mathcal{P}_{a_k}$ are close to u_a in $W^{1,1}$ whenever a_k is close to a;

(ii) $(a, g^{**}(a))$ is an extreme point of the epigraph of g^{**}.

As such, our result is the exact *replica* to Olech's lemma, but it is not true, in general, that uniqueness always implies continuous dependence. Indeed uniqueness holds whenever the dimension d of the face F_1 is in $\{0, 1, \dots, n-1\}$ while for $d = 1, \dots, n-1$, continuous dependence does not hold. Hence our result provides a characterization of extreme points in the sense that whenever $\mathcal{P}_{a_k}$ admits solutions different from the affine one (i.e., when $(a_k, g^{**}(a_k))$ belongs to an n-dimensional face) and $a_k \to a$, then a sequence $\{u^k\}_{k\in\mathbb{N}}$ of solutions of $\mathcal{P}_{a_k}$ converges strongly to u_a if and only if $(a, g^{**}(a))$ is extremal. Moreover, our result provides a precise definition of the type of convergence (partially weak, partially strong) that occurs for $1 \le d \le n-1$.

The previous analysis applies in particular to the special case of a rotationally symmetric function g. In Remark 4.2 we present a detailed description of this case.

2. Preliminaries and notation. In this paper we study the solutions of the following problems:

$$\mathcal{P}_a: \qquad \text{Minimize } \int_\Omega g(\nabla u(x))dx; \qquad u \in u_a + W_0^{1,1}(\Omega);$$

$$\mathcal{P}_a^{**}: \qquad \text{Minimize } \int_\Omega g^{**}(\nabla u(x))dx; \qquad u \in u_a + W_0^{1,1}(\Omega),$$

where g is a lower semicontinuous (l.s.c.), not necessarily convex, function defined on $\mathbb{R}^n$ with values in $\mathbb{R}$ bounded from below and g^{**} is its bipolar (see [ET] for a definition). Ω is an open, bounded subset of $\mathbb{R}^n$ with piecewise C^1 boundary and $u_a \equiv \langle a, x\rangle$ ($a \in \mathbb{R}^n$). By $u_a + W_0^{1,1}(\Omega)$ we mean the set of functions u that can be written as $u = u_a + v$, where $v \in W_0^{1,1}(\Omega)$. Here and in the following, $\langle\cdot,\cdot\rangle$ denotes the scalar product in $\mathbb{R}^n$ and $|\cdot|$ the associated norm. A point in $\mathbb{R}^n \times \mathbb{R}$ is denoted as a pair (x, z) with $x \in \mathbb{R}^n$ and $z \in \mathbb{R}$. We use the spaces $L^1(\Omega)$ and $W_0^{1,1}(\Omega)$ endowed with the usual norm $\|\cdot\|_{L^1(\Omega)}$, $\|u\|_{W_0^{1,1}(\Omega)} = \|\nabla u\|_{L^1(\Omega)}$. The weak convergence in such spaces is denoted with the half arrow $\rightharpoonup$.

For S subset of $\mathbb{R}^n$ and $x \in \mathbb{R}^n$, $\mathrm{dist}(x, S)$ is the distance of x from S, S^c is the complement, $\mathrm{co}(S)$ is the convex hull and $\mu(\cdot)$ is the Lebesgue measure. When zero belongs to S, the smallest linear manifold containing S is denoted by $\mathrm{span}(S)$; the dimension of an affine set is the dimension of the subspace parallel to it, and we say that a subset S of $\mathbb{R}^n$ has dimension p if the dimension of the affine hull of S is p, and write $\dim(S) = p$. For a scalar function f we define the negative and the positive parts $f^- \equiv \max(-f, 0)$ and $f^+ \equiv \max(f, 0)$.

We make use in this paper of basic elements of convex analysis such as the notions of face, extreme point of a convex set, relative boundary (r.b.), relative interior (r.i.) and polytope, following the notations contained in [R]; we call $\mathrm{extr}(C)$ the set of extreme points of a convex set C.

Given a subset S of $\mathbb{R}^n \times \mathbb{R}$ we denote by $\hat{S}$ the projection of S on $\mathbb{R}^n$, i.e.,

$$\hat{S} = \{x \in \mathbb{R}^n : \exists z \in \mathbb{R} : \quad (x,z) \in S\}.$$

The study of problems $\mathcal{P}_a$ and $\mathcal{P}_a^{**}$ involves the properties of the epigraph of g^{**}, $\mathrm{epi}(g^{**})$, which is a convex subset of $\mathbb{R}^n \times \mathbb{R}$; we recall now some properties of the epigraph of a convex function (see [C1], [C2]).

PROPOSITION 2.1. *Let $h : \mathbb{R}^n \to \mathbb{R}$ be a convex l.s.c. function. Then we have the following*:

(i) *The collection of the relative interior of the faces of* $\mathrm{epi}(h)$ *is a partition of* $\mathrm{epi}(h)$.

(ii) *If F is a face of* $\mathrm{epi}(h)$ *containing a point $(x, h(x))$ in its relative interior, F is a proper face and* $\dim(F) \leq n$; *moreover* $\dim(F) = \dim(\hat{F})$.

(iii) *If F_1 is a proper face of a proper face F of* $\mathrm{epi}(h)$ *and* r.i. (F_1) *contains a point $(x, h(x))$, then $\hat{F}_1$ is a proper face of $\hat{F}$. Moreover a point $(x, h(x))$ is an extreme point of* $\mathrm{epi}(h)$ *if and only if x is an extreme point of all the projections of the faces that contain $(x, h(x))$.*

Proof. Statement (i) is a particular case of [R, Thm. 18.2]. To prove (ii) we simply note that $(x, h(x))$ cannot belong to the relative interior of $\mathrm{epi}(h)$; then $\dim(F) \leq n$. Moreover F cannot contain a point (x, z) with $z > h(x)$; hence $\dim(F) = \dim(\hat{F})$. Statement (iii) is trivial. □

We will need the following characterization of faces of a convex set (see [O2]).

LEMMA 2.1. *Let F be a convex subset of $\mathbb{R}^n$ and F_d a d-dimensional face of F such that zero belongs to* r.i.(F_d). *Then there exist $n - d$ orthonormal vectors $h_1, \ldots, h_{n-d}$ such that F is contained in the cone*

$$\begin{aligned} C := &\{x : \langle h_1, x\rangle > 0\} \bigcup \{x : \langle h_1, x\rangle = 0,\ \langle h_2, x\rangle > 0\} \\ &\bigcup \{x : \langle h_1, x\rangle = \langle h_2, x\rangle = \cdots = \langle h_{n-d-1}, x\rangle = 0,\ \langle h_{n-d}, x\rangle > 0\} \bigcup \\ &\bigcup \{x : \langle h_1, x\rangle = \langle h_2, x\rangle = \cdots = \langle h_{n-d}, x\rangle = 0\} \end{aligned}$$

and

$$F_d = F \bigcap \{x : \langle h_1, x\rangle = \langle h_2, x\rangle = \cdots = \langle h_{n-d}, x\rangle = 0\}.$$

We remind the reader now of the well-known criteria of weak convergence in $L^1(\Omega)$ and $W_0^{1,1}(\Omega)$ (see [D, p. 19]).

THEOREM 2.1. *Let Ω be a bounded open subset of $\mathbb{R}^n$, and $\{f_k\}_{k\in\mathbb{N}}$ be a sequence in $L^1(\Omega)$; then*

$$f_k \rightharpoonup f \quad \text{in } L^1(\Omega)$$

if and only if

(i) $\|f_k\|_{L^1(\Omega)} \leq M$,

(ii) f_k *is absolutely equiintegrable,*

(iii) $\lim_{k\to\infty} \int_D [f_k(x) - f(x)]dx = 0$ *for any cube $D \subset \Omega$.*

THEOREM 2.2. *Let Ω be a bounded open subset of $\mathbb{R}^n$, and $\{f_k\}_{k\in\mathbb{N}}$ be a sequence in $W_0^{1,1}(\Omega)$; then*

$$f_k \rightharpoonup f \quad \text{in } W_0^{1,1}(\Omega)$$

if and only if

$$D_i f_k \rightharpoonup D_i f \quad \text{in } L^1(\Omega)$$

for $i = 1, \ldots, n$.

(See [B, p. 175].) We end this section with the following definition.

DEFINITION 2.1. *We say that a function* $g : \mathbb{R}^n \to \mathbb{R}$ *satisfies the growth condition* (C) *if there exists a function* $\phi : \mathbb{R} \to \mathbb{R}$ *such that* $\lim_{t\to+\infty} \frac{\phi(t)}{t} = +\infty$ *and* $g(y) \geq \phi(|y|)$ *for any* $y \in \mathbb{R}^n$.

3. Existence and uniqueness. In [C1] and [C2] Cellina gives sufficient and necessary conditions on the affine boundary datum u_a for the existence and the uniqueness of solutions of $\mathcal{P}_a$ and $\mathcal{P}_a^{**}$ investigating the facial structure of the epigraph of g^{**}. The main results stated in the quoted papers can be summarized as follows. We emphasize that a solution of $\mathcal{P}_a$ is a solution of $\mathcal{P}_a^{**}$ as well.

THEOREM 3.1. *Let* $g : \mathbb{R}^n \to \mathbb{R}$ *be l.s.c. (not necessarily convex), bounded from below, satisfying growth condition* (C); *let* Ω *be a bounded open subset of* $\mathbb{R}^n$ *with piecewise* C^1 *boundary.*

(i) *If* $\mathcal{P}_a$ *admits a solution, then*

(1) *either* $g(a) = g^{**}(a)$ *or the face of* $\mathrm{epi}(g^{**})$ *to whose relative interior* $(a, g^{**}(a))$ *belongs has dimension* n.

(ii) *Conversely, if condition* (1) *holds then* $\mathcal{P}_a$ *admits at least one solution.*

THEOREM 3.2. *Assume the hypotheses of Theorem* 3.1. *Then*

(i) $\mathcal{P}_a^{**}$ *admits the unique solution* u_a *if and only if* $(a, g^{**}(a))$ *belongs to the relative interior of a face of* $\mathrm{epi}(g^{**})$ *of dimension strictly less than* n.

(ii) $\mathcal{P}_a$ *admits the unique solution* u_a *if and only if* $g^{**}(a) = g(a)$ *and* $(a, g^{**}(a))$ *belongs to the relative interior of a face of* $\mathrm{epi}(g^{**})$ *of dimension strictly less than* n.

The proof of the second part of Theorem 3.1 consists essentially of the explicit construction of the solution of $\mathcal{P}_a$ in the case in which $(a, g^{**}(a))$ belongs to the relative interior of an n-dimensional face of $\mathrm{epi}(g^{**})$. Since we need this construction in the proof of our main result, we recall it in its main steps and refer to [C2] for details.

We begin with a lemma.

LEMMA 3.1. *Let* $\{y_i,\ i = 1, \ldots, m\}$ *be a set of vectors in* $\mathbb{R}^n$, *and consider* $S = \mathrm{co}\{y_i,\ i = 1, \ldots, m\}$. *Suppose* $\dim(S) = n$, $0 \in \mathrm{int}(S)$ *and call* S^* *the polar set of* S. *Then there exists a finite partition* $\{S_i^*,\ i = 1, \ldots, m\}$ *of* S^* *and a Lipschitz continuous function* w, *defined on* $\mathbb{R}^n$, *such that*

(i) $w{=}0$ *on* $(S^*)^c$;

(ii) $\nabla w = y_i$ *almost everywhere in* S_i^*, $i = 1, \ldots, m$;

(iii) *there exists an index set* I *contained in* $\{1, \ldots, m\}$ *such that the set* $\{y_i, i \in I\}$ *contains a system of* n *linearly independent vectors and* $\mu(S_i^*) > 0$ *for* $i \in I$.

Proof. The proof of (i) and of (ii) can be found in [C2]. To prove statement (iii) we recall that since zero belongs to the interior of S, $m > n$, the polar S^* is bounded and it can be written as

$$S^* = \bigcap_{i=1}^{m} \{x : \langle y,x\rangle \leq 1\}.$$

We also recall that the sets S_i^* are defined by

$$S_i^* := co\{F_i^*, 0\},$$

where $F_i^* = S^* \cap \{x : \langle y_i, x\rangle = 1\}$. Since $\mathrm{dist}(0, F_i^*) > 0$ for any index i, $\mu(S_i^*) > 0$ if and only if $\dim(F_i^*) = n - 1$. S^* has at least $n + 1$ faces of dimension $n - 1$; hence we may assume, renaming the indices, that there exists $p \geq n + 1$ such that $\dim(F_i^*) = n - 1$ for $i = 1, \ldots, p$ and $\dim(F_i^*) < n - 1$ for $i = p + 1, \ldots, m$. A face F_j^*

with $j > p$ is a proper face of a face F_i^* with $i < p$, hence $S_j^* \subset S_i^*$, and we can write

$$S^* = \bigcap_{i=1}^{p} \{x : \langle y,x\rangle \leq 1\}.$$

Then the set $\{y_i, i = 1, ..., p\}$ contains a system of n linearly independent vectors since otherwise S^* would be unbounded. □

Proof of Theorem 3.1 (ii). Assume that $(a, g^{**}(a))$ belongs to r.i.(F), the relative interior of F, where F is an n-dimensional face of epi(g^{**}). Our goal is to construct a solution of $\mathcal{P}_a$ (different from u_a). Since g satisfies the growth condition (C), F is bounded and is contained in a hyperplane H separating it from epi(g^{**}). According to Proposition 2.1, H cannot be vertical, i.e.,

$$H = \{(x,z) \in \mathbb{R}^n \times \mathbb{R} : z = \langle h, x\rangle + k\} \qquad (h \in \mathbb{R}^n, k \in \mathbb{R})$$

and, since the extreme points of F are of the form $(y, g(y))$,

$$\operatorname{extr}(\hat{F}) = \{y \in \mathbb{R}^n : \ (y, g(y)) \in \operatorname{extr}(F)\}.$$

Consider a subset $\{y_i,\ i = 1, \ldots, m\}$ of extr$(\hat{F})$ such that $\dim(\operatorname{co}\{y_i,\ i = 1, \ldots, m\}) = n$ and $a \in$ r.i.$(\operatorname{co}\{y_i,\ i = 1, \ldots, m\})$; we remark that whenever

$$a = \sum_{i=1}^{m} \lambda_i y_i, \quad 0 < \lambda_i < 1, \quad \sum_{i=1}^{m} \lambda_i = 1, \tag{3.1}$$

it is

$$g^{**}(a) = \langle h, a\rangle + k = \sum_{i=1}^{m} \lambda_i(\langle h, y_i\rangle + k) = \sum_{i=1}^{m} \lambda_i g^{**}(y_i) = \sum_{i=1}^{m} \lambda_i g(y_i); \tag{3.2}$$

we define the polytope $S(a) := \operatorname{co}\{y_i - a,\ i = 1, ..., m\}$. We can apply Lemma 3.1, defining a partition $\{S_i^*(a),\ i = 1, ..., m\}$ of $S^*(a)$ and a Lipschitz function w^a such that $w^a = 0$ on $(S^*(a))^c$ and $\nabla w^a = y_i - a$ almost everywhere on $S_i^*(a)$.

We now consider the collection of subsets of Ω

$$\mathcal{U} = \{z + rS^*(a),\ z \in \Omega,\ r \in \mathbb{R},\ r < \operatorname{dist}(z, \Omega^c)\}.$$

$\mathcal{U}$ is a Vitali covering of Ω, and we can select a countable subcovering $\{\Omega_j(a),\ j \in \mathbb{N}\}$ such that

(1) $\Omega_j(a) = z_j + r_j S^*(a) \subset \Omega$ for all $j \in \mathbb{N}$;
(2) $\Omega_j(a) \bigcap \Omega_k(a) = \emptyset$, if $j \neq k$;
(3) $\Omega = N \bigcup (\bigcup_{j=1}^{\infty} \Omega_j(a))$ where $\mu(N) = 0$;
(4) $\Omega_j(a) = \bigcup_{i=1}^{m} \Omega_j^i(a)$ (disjoint union); where $\Omega_j^i(a) = z_j + r_j S_i^*(a)$. We set also $\Omega^i(a) = \bigcup_{j=1}^{\infty} \Omega_j^i(a)$, obtaining $\Omega = \bigcup_{i=1}^{m} \Omega^i(a)$, and define

$$w_j^a(x) = r_j w^a\left(\frac{x - z_j}{r_j}\right) \qquad \text{a.e. } x \in \Omega_j(a), \qquad j \in \mathbb{N}$$

and

$$v^a(x) = \sum_{j=1}^{\infty} w_j^a(x), \quad \text{a.e. } x \in \Omega.$$

v^a belongs to $W_0^{1,1}(\Omega)$ and it is

$$\nabla v^a = y_i - a \quad \text{a.e. on } \Omega^i(a), \qquad i = 1, \dots, m. \tag{3.3}$$

Then

$$0 = \int_\Omega \nabla v^a = \sum_{i=1}^m \int_{\Omega^i(a)} (y_i - a),$$

i.e.,

$$a = \sum_{i=1}^m \frac{\mu(\Omega^i(a))}{\mu(\Omega)} y_i. \tag{3.4}$$

We set $u(x) := v^a(x) + \langle a, x\rangle = v^a(x) + u_a(x)$; first, (3.3) implies

$$\nabla u = y_i \quad \text{a.e. on } \Omega^i(a), \tag{3.5}$$

and by virtue of (3.1), (3.2), and (3.4), u is a solution of $\mathcal{P}_a$. □

We are interested in the following question. Consider a sequence $\{a_k\}_{k\in\mathbb{N}}$ converging to a point a such that $\mathcal{P}_a$ admits the unique solution u_a, and a sequence $\{u^k\}_{k\in\mathbb{N}}$ of solutions of $\mathcal{P}_{a_k}$ $(\mathcal{P}_{a_k}^{**})$ (in the sense that for any $k \in \mathbb{N}$, u^k is a solution of $\mathcal{P}_{a_k}$ $(\mathcal{P}_{a_k}^{**})$). We ask whether $\{u^k\}_{k\in\mathbb{N}}$ converges (in some topology) to u_a as $k \to \infty$. When it happens that, for any $k \in \mathbb{N}$, $(a_k, g^{**}(a_k))$ belongs to the relative interior of a face of dimension strictly less than n, the question is trivial because $u^k \equiv u_{a_k}$ and converges to u_a strongly in $W_0^{1,1}(\Omega)$. The interesting case is when $(a, g^{**}(a))$ belongs to the relative interior of a face F_1 of $\operatorname{epi}(g^{**})$ of dimension strictly less than n, and, for an infinite number of indices $k \in \mathbb{N}$, $(a_k, g^{**}(a_k))$ belongs to the relative interior of at least one n-dimensional face of $\operatorname{epi}(g^{**})$ containing $(a, g^{**}(a))$ (and also F_1) in its relative boundary. According to our main result $(a, g^{**}(a))$ is an extreme point of $\operatorname{epi}(g^{**})$ if and only if any sequence $\{u^k\}_{k\in\mathbb{N}}$ converges strongly to u_a in $W_0^{1,1}(\Omega)$.

4. Main result. We will need the following technical lemmas.

LEMMA 4.1. *Let Ω be an open bounded subset of $\mathbb{R}^n$ and $\{v^k\}_{k\in\mathbb{N}}$ be a sequence in $W_0^{1,1}(\Omega)$. Suppose that $v^k \to 0$ in $L^1(\Omega)$ and that, for some $i \in \{1, \dots, n\}$, $|D_i v^k| \le M$ almost everywhere in Ω, where M is a positive constant. Then*

$$D_i v^k \rightharpoonup 0 \quad \text{in } L^1(\Omega).$$

Proof. We can suppose $i = 1$ and $\Omega = I \times S$, where I is an open bounded interval of $\mathbb{R}$ and S is an open bounded subset of $\mathbf{R}^{n-1}$, since v^k can be extended as zero out of Ω. Let us write $v^k = v^k(x_1, x')$ with $x_1 \in I$ and $x' \in S$; the uniform boundedness of $|D_1 v^k|$ implies that the sequence $\{D_1 v^k\}_{k\in\mathbb{N}}$ is bounded in L^1-norm and is absolutely equi-integrable. According to Theorem 2.1 it is sufficient to prove that for any cube $D \subset \Omega$,

$$\lim_{k\to\infty} \int_D D_1 v^k \to 0.$$

(1) Suppose first $v^k \in C_0^1(\Omega)$ and define

$$\varphi^k(x_1) = \int_S |v^k(x_1, x')| dx', \qquad k \in \mathbb{N}, \quad x_1 \in I.$$

$\{\varphi^k\}_{k\in\mathbb{N}}$ is a sequence of nonnegative continuous functions on I differentiable almost everywhere for any k and the sequence of derivatives is uniformly bounded; hence they are equicontinuous and equibounded.

Moreover $\lim_{k\to\infty}\|\varphi^k\|_{L^1(I)} = \lim_{k\to\infty}\|v^k\|_{L^1(\Omega)} = 0$, then $\varphi^k \to 0$ uniformly on I.

Consider a cube $D \subset \Omega$, $D = (\xi,\eta)\times Q$ where $\xi,\eta \in I$ and Q is an $(n-1)$-dimensional cube contained in S. It is

$$\left|\int_D D_1 v^k(x_1,x')dx_1dx'\right| = \left|\int_Q\left(\int_\xi^\eta D_1 v^k(x_1,x')dx_1\right)dx'\right| \le 2\sup_{x_1\in I}\left(\int_S |v^k(x_1,x')|dx'\right).$$

Hence $D_1 v^k \to 0$ in $L^1(\Omega)$.

(2) Consider now the general case $v^k \in W_0^{1,1}(\Omega)$.

By density there exists a sequence $w^k \in C_0^1(\Omega)$ such that $|D_1 w^k|$ is uniformly bounded in Ω and

$$\|v^k - w^k\|_{W_0^{1,1}} \le \frac{1}{k} \quad \forall k \in \mathbb{N}.$$

Obviously $w^k \to 0$ in $L^1(\Omega)$ and the previous arguments show that $D_1 w^k \to 0$ in $L^1(\Omega)$; hence $D_1 v^k \to 0$ in $W_0^{1,1}(\Omega)$. □

LEMMA 4.2. *Let P be a polytope in $\mathbb{R}^n$ and F be a proper face of P. Then F is exposed, i.e., there exists a supporting hyperplane π of P such that $F = P\cap\pi$.*

Proof. We can assume $0 \in F$ as well.

Set $P = \mathrm{co}\{v_1,\dots,v_m\}$ and $V = \max\{|v_1|,\dots,|v_m|\}$. Consider the collection of all nontrivial hyperplanes H_α separating F from P. Let ν_α be the number of vectors $v_1,\dots,v_m$ contained in H_α but not belonging to F and call ν_0 the minimum, attained for some hyperplane H_0 defined by $H_0 = \{x : \langle h_0, x\rangle = 0\}$. We wish to show that $\nu_0 = 0$. Assume, by contradiction, that it is positive. Set P_0 to be $P\cap H_0$. Note that there is $\eta > 0$ such that for every v_i in P but not in P_0, $\langle h_0, v_i\rangle \ge \eta$. Also, $F\cap H_0$ is a proper face of $P\cap H_0$, so that there is a unit vector k in H_0 separating $F\cap H_0$ from $P\cap H_0$, i.e., $\langle k,x\rangle = 0$ for $x \in F\cap H_0$ and for some y in $P\cap H_0$, $\langle k,y\rangle > 0$. Since $y \in \mathrm{co}\{v_1,\dots,v_m\}$, there is a v_j in $P\cap H_0$ such that $\langle k, v_j\rangle > 0$. Consider $h_1 = h_0 + (\eta/2V)k$. We have that $\langle h_1, x\rangle = 0$ for $x \in F$, that for v_i in P but not in $P\cap H_0$, $\langle h_1, v_i\rangle \ge \eta - (\eta/2V)|v_i| \ge \eta/2$. and that $\langle h_1, v_j\rangle > 0$, contradicting the definition of ν_0. □

The following is our main result; it is convenient to introduce the following definition.

DEFINITION 4.1. *Let $\{v^k\}_{k\in\mathbb{N}}$ be a sequence in $W^{1,1}(\Omega)$ and $v \in W^{1,1}(\Omega)$, where Ω is an open bounded subset of $\mathbb{R}^n$. Let d be the largest integer such that there exists a d-dimensional subspace L of $\mathbb{R}^n$ such that, given any vector e in L, it is*

$$\langle \nabla v^k - \nabla v, e\rangle \overset{k\to\infty}{\longrightarrow} 0 \quad \text{in } L^1(\Omega).$$

We say that $\{v^k\}_{k\in\mathbb{N}}$ converges *d-strongly to v in $W^{1,1}(\Omega)$.*

Remark 4.1. To prove that a sequence converges d-strongly, it is sufficient to find a system E of d independent vectors such that the condition expressed in Definition 4.1 holds and that for any vector e in the orthogonal complement of E, $\langle \nabla v^k - \nabla v, e\rangle$ does not converge to zero in $L^1(\Omega)$. We should also note that $\{v^k\}_{k\in\mathbb{N}}$ is a d-strongly converging sequence in $W^{1,1}(\Omega)$ if and only if there exists a nonsingular change of

coordinates U such that, setting $w^k(x) = v^k(Ux)$, $D_j w^k$ converges strongly in $L^1(U\Omega)$ for $j = 1, \dots, d$ and does not converge in $L^1(U\Omega)$ for $j = d+1, \dots, n$. Obviously d-strong convergence in $W_0^{1,1}(\Omega)$ implies strong convergence in $L^1(\Omega)$ for any $d \geq 1$ (Poincaré inequality, see [B, p. 174]) and it is equivalent to strong convergence in $W_0^{1,1}(\Omega)$ when $d = n$.

THEOREM 4.1. *Let g be l.s.c. satisfying the growth condition* (C), *and let Ω be a bounded open subset of $\mathbb{R}^n$ with piecewise C^1 boundary. Suppose that $g(a) = g^{**}(a)$ and that $(a, g^{**}(a))$ belongs to the relative interior of a proper face F_1 of an n-dimensional face F of* $\operatorname{epi}(g^{**})$, *and let $\{a_k\}_{k\in\mathbb{N}}$ be any sequence such that $(a_k, g^{**}(a_k))$ belongs to the relative interior of F for any $k \in \mathbb{N}$ and $\lim_{k\to\infty} a_k = a$.*

(i) *If any sequence $\{u^k\}_{k\in\mathbb{N}}$ of solutions of $\mathcal{P}_{a_k}$ converges $(n-r)$-strongly to u_a in $W_0^{1,1}(\Omega)$, then $\dim(F_1) = r$. In particular, if any sequence $\{u^k\}_{k\in\mathbb{N}}$ of solutions of $\mathcal{P}_{a_k}$ converges strongly to u_a in $W_0^{1,1}(\Omega)$, then $(a, g^{**}(a))$ is an extreme point of* $\operatorname{epi}(g^{**})$.

(ii) *If $\dim(F_1) = r$ then any sequence $\{u^k\}_{k\in\mathbb{N}}$ of solutions of $\mathcal{P}^{**}_{a_k}$ converges $(n-r)$-strongly to u_a in $W_0^{1,1}(\Omega)$. In particular, if $(a, g^{**}(a))$ is an extreme point of* $\operatorname{epi}(g^{**})$, *then any sequence $\{u^k\}_{k\in\mathbb{N}}$ of solutions of $\mathcal{P}^{**}_{a_k}$ converges strongly to u_a in $W_0^{1,1}(\Omega)$.*

Proof. First, since $\dim(F_1) < n$ and $g(a) = g^{**}(a)$, $\mathcal{P}_a$, as well as $\mathcal{P}^{**}_a$, admits the unique solution u_a; moreover, growth condition (C) implies that $\hat{F}$ is bounded and we set

$$L = \sup_{y\in\hat{F}} |y|.$$

In the proof we assume, without losing generality, $a = 0$.

(i) Suppose that any sequence $\{u^k\}_{k\in\mathbb{N}}$ of solutions of $\mathcal{P}_{a_k}$ converges $(n-r)$-strongly to zero. We proceed by contradiction: we assume that $\dim(\hat{F}_1)$ is greater than r and show that there exists a sequence $\{u^k\}_{k\in\mathbb{N}}$ of solutions of $\mathcal{P}_{a_k}$ that does not converge $(n-r)$-strongly to zero in $W_0^{1,1}(\Omega)$.

(1) Set $d = r+1$ and consider $y_1, \dots, y_p \in \operatorname{extr}(\hat{F}_1)$ $(p \geq d+1)$ such that $a = 0 \in \text{r.i.}(\operatorname{co}\{y_1, \dots, y_p\})$ and $\dim(\operatorname{span}\{y_1, \dots, y_p\}) = d$. Since $a_k \in \text{r.i.}(\hat{F})$, for any k there are $n+1$ extreme points of $\hat{F}$, $v^k_{p+1}, \dots, v^k_{p+n+1}$ such that, setting $m = p+n+1$, the polytope $P_k := \operatorname{co}\{y_1, \dots, y_p, v^k_{p+1}, \dots, v^k_m\}$ has dimension n and $a_k \in \operatorname{int}(P_k)$. Setting $y^k_i = y_i - a_k$ for $i = 1, \dots, p$ and $y^k_i = v^k_i - a_k$ for $i = p+1, \dots, m$, and considering the polytope $P_k - a_k := \operatorname{co}\{y^k_i, i = 1, \dots, m\}$, we can define the (bounded) polar $S^*(a_k)$ of $P_k - a_k$ and a solution u^k of $\mathcal{P}_{a_k}$, defined as in §3, whose gradient, recalling (3.5), takes the values y_i or v^k_i on the sets $\Omega^i(a_k)$.

(2) Extracting subsequences if necessary, we may assume that y^k_i converges to a vector $y_i \in \partial\hat{F}$ for $i = p+1, \dots, m$ and $y_i \in \hat{F}_1$ for $i = p+1, \dots, s$, $y_i \in \partial\hat{F} \setminus \hat{F}_1$ for $i = s+1, \dots, m$, where $p \leq s \leq m$. We define the limit polytope $P := \operatorname{co}\{y_i, i = 1, \dots, m\}$ and its polar S^* written as

$$S^* = \bigcap_{i=1}^{m} \{x : \langle y_i, x\rangle \leq 1\}.$$

We also define

$$C^* = \bigcap_{i=1}^{s} \{x : \langle y_i, x\rangle \leq 1\}, \qquad T^* = \bigcap_{i=s+1}^{m} \{x : \langle y_i, x\rangle \leq 1\},$$

so that $S^* = C^* \bigcap T^*$, and remark that when $s = m$, $T^* = \mathbb{R}^n$ and $S^* = C^*$; in the following we consider $s < m$ since otherwise the proof proceeds in a similar and simpler way. Recalling the definition of the partition of a polar set (Lemma 3.1), we can apply the same definition to C^*, obtaining $C^* = \bigcup_{i=1}^{s} C_i^*$ and $S_i^* \subseteq C_i^*$.

Set L_d to be $\operatorname{span}\{y_i, i = 1, \dots, s\}$ and write $\mathbb{R}^n = L_d \oplus L_d^{\perp}$; the cylinder C^* can be written $C^* = S^{d*} \oplus L_d^{\perp}$, and, analogously, $C_i^* = S_i^{d*} \oplus L_d^{\perp}$; where we have set $S^{d*} := C^* \bigcap L_d$ and $S_i^{d*} := C_i^* \bigcap L_d$. We remark that S^{d*} is the polar of the d-dimensional set $\operatorname{co}\{y_1, \dots, y_s\} \cap L_d$ and $\{S_i^{d*}, i = 1, \dots, s\}$ is the relative partition; since $0 \in \text{r.i.}(\operatorname{co}\{y_i, i = 1, \dots, s\})$, S^{d*} is bounded and by point (iii) of Lemma 3.1 there exists a set I of d indices such that $\{y_i, i \in I\}$ are linearly independent and, calling μ_d the d-dimensional measure in L_d,

$$\frac{\mu_d(S_i^{d*})}{\mu_d(S^{d*})} \geq \lambda > 0 \quad \text{for } i \in I. \tag{4.1}$$

Moreover, boundedness of S^{d*} implies that there exists M ($M \geq -1$) such that

$$C^* = \bigcap_{i=1}^{s} \left[\bigcup_{\alpha_i \in [-M,1]} \{x : \langle y_i, x \rangle = \alpha_i\} \right]. \tag{4.2}$$

(3) Consider now $P_d := \operatorname{co}\{y_i, i = 1, \dots, s\}$: P_d is a face of P and, by Lemma 4.2, it is exposed. Let w be a unit vector in $L_d^{\perp}$ such that $P_d = P \bigcap \{x : \langle w, x \rangle = 0\}$ and $\langle w, x \rangle > 0$ for all $x \in P$. Let $z_{d+1}, \dots, z_n$ be orthonormal vectors in $L_d^{\perp}$ such that $w = (n-d)^{-1/2} \sum_{j=d+1}^{n} z_j$. For every $y \in \{y_{s+1}, \dots, y_m\}$, $\sum_{j=d+1}^{n} \langle z_j, y \rangle = (n-d)^{1/2} \langle w, y \rangle > 0$.

(4) Let us define the family of sets

$$Q_{[R_1,R_2]} := \bigcap_{j=d+1}^{m} \{x : \langle z_j, x \rangle \in [R_1, R_2]\} \qquad R_1, R_2 \in \mathbb{R};$$

it is our purpose to show that there exist $R_0 > 0$ and $\alpha > 1$ such that for any $R > R_0$,

$$S^* \bigcap Q_{[-\alpha R, -R]} = C^* \bigcap Q_{[-\alpha R, -R]}. \tag{4.3}$$

Since $S^* = C^* \bigcap T^*$ it is enough to prove that the right-hand side is contained in the left-hand side (when $s = m$, i.e., $S^* = C^*$, this is obvious). We show that in general $C^* \bigcap Q_{[-\alpha R, -R]}$ is contained in T^*: it follows that a point in $C^* \bigcap Q_{[-\alpha R, -R]}$ is in $C^* \bigcap T^* = S^*$, hence in $S^* \bigcap Q_{[-\alpha R, -R]}$. So, let x be any point in $C^* \bigcap Q_{[-\alpha R, -R]}$; recalling (4.2), we have

$$\langle y_i, x \rangle \in [-M, 1], \qquad i = 1, \dots, s,$$

$$\langle z_j, x \rangle \in [-\alpha R, -R], \qquad j = s+1, \dots, m.$$

Take $y \in \{y_i, i = s+1, \dots, m\}$; since $\{y_1, \dots, y_s, z_{d+1}, \dots, z_n\}$ contains a system of n independent vectors, y can be written as $y = \sum_{i=1}^{s} \nu_i y_i + \sum_{j=d+1}^{n} \mu_j z_j$, where, by point (3), $\sum_{j=d+1}^{n} \mu_j > 0$. Writing $\mu_j^+ = \max(\mu_j, 0)$ and $\mu_j^- = \max(-\mu_j, 0)$ we have, recalling (4.2),

$$\langle y, x \rangle = \sum_{i=1}^{s} \nu_i \langle y_i, x \rangle + \sum_{j=d+1}^{n} \mu_j \langle z_j, x \rangle$$

$$\leq (|M|+1)\sum_{i=1}^{s}|\nu_i| + \left(-\sum_{j=d+1}^{n}\mu_j^+ + \alpha\sum_{j=d+1}^{n}\mu_j^-\right)R.$$

By choosing α satisfying $1 < \alpha < (\sum_{j=d+1}^{n}\mu_j^+)(\sum_{j=d+1}^{n}\mu_j^-)^{-1}$, the term in parenthesis becomes negative; hence, if R is greater than some R_0 sufficiently large, it turns out that $\langle y, x\rangle \leq 1$. Repeat this choice for every $y \in \{y_i, i = s+1, \ldots, m\}$; take R_0 as the largest value and α as the smallest value so obtained, and have $x \in T^*$. By an analogous procedure we also have

$$S_i^* \bigcap Q_{[-\alpha R,-R]} = C_i^* \bigcap Q_{[-\alpha R,-R]}. \tag{4.4}$$

(5) We now take $R \geq R_0$ and consider the sets $S^* \bigcap Q_{[-\alpha R,R]}$ and $S_i^* \bigcap Q_{[-\alpha R,R]}$ for $i = 1, \ldots, s$. Such sets are bounded; by (4.3) and (4.4), we have

$$\mu\left(S^* \bigcap Q_{[-\alpha R,R]}\right) \leq \mu\left(C^* \bigcap Q_{[-\alpha R,R]}\right) = \mu_d(S^{d*})((\alpha+1)R)^{n-d},$$

and

$$\begin{aligned}\mu\left(S_i^* \bigcap Q_{[-\alpha R,R]}\right) &= \mu\left(S_i^* \bigcap Q_{[-\alpha R,-R]}\right) + \mu\left(S_i^* \bigcap Q_{[-R,R]}\right)\\ &= \mu\left(C_i^* \bigcap Q_{[-\alpha R,-R]}\right) + \mu\left(S_i^* \bigcap Q_{[-R,R]}\right)\\ &\geq \mu_d(S_i^{d*})((\alpha-1)R)^{n-d}.\end{aligned}$$

Hence, recalling (4.1),

$$\frac{\mu\left(S_i^* \bigcap Q_{[-\alpha R,R]}\right)}{\mu\left(S^* \bigcap Q_{[-\alpha R,R]}\right)} \geq \frac{\mu_d(S_i^{d*})}{\mu_d(S^{d*})}\left(\frac{\alpha-1}{\alpha+1}\right)^{n-d} \geq \gamma > 0, \qquad i \in I, \tag{4.5}$$

for some positive γ.

(6) Now consider the sets $S^*(a_k) = \bigcup_{i=1}^{m} S_i^*(a_k)$, polar of $P_k - a_k$ and their decompositions. Given $Q = Q_{[R_1,R_2]}$ the sets $S^*(a_k) \cap Q$ and $S_i^*(a_k) \cap Q$ are bounded polytopes whose vertices converge to the vertices of $S^* \cap Q$ and $S_i^* \cap Q$, respectively, since the vertices of P_k converges to the vertices of P. In particular the measures of $S^*(a_k) \cap Q$ and $S_i^*(a_k) \cap Q$ converge to the measures of $S^* \cap Q$ and $S_i^* \cap Q$. Setting

$$\gamma_i^k(R) := \frac{\mu\left(S_i^*(a_k) \bigcap Q_{[-\alpha R,R]}\right)}{\mu\left(S^*(a_k) \bigcap Q_{[-\alpha R,R]}\right)},$$

we have, by (4.5),

$$\lim_{k\to\infty} \gamma_i^k(R) = \frac{\mu\left(S_i^* \bigcap Q_{[-\alpha R,R]}\right)}{\mu\left(S^* \bigcap Q_{[-\alpha R,R]}\right)}, \qquad i \in I, \quad R \geq R_0. \tag{4.6}$$

The sets $S^*(a_k)$ are bounded for any k; hence there exists a sequence R_k in $\mathbb{R}^+$ such that $R_k \nearrow +\infty$ as $k \to \infty$ and

$$\gamma_i^k(R_k) = \frac{\mu\left(S_i^*(a_k)\right)}{\mu\left(S^*(a_k)\right)};$$

this last equality and (4.6) imply that

$$\liminf_{k\to\infty} \frac{\mu\left(S_i^*(a_k)\right)}{\mu\left(S^*(a_k)\right)} \geq \gamma, \qquad i \in I. \tag{4.7}$$

(7) Take $i \in I$. When $i \leq p$, $y_i^k = y_i - a_k$ and $\nabla u^k = y_i$ almost everywhere on $\Omega^i(a_k)$, then (4.7) implies that, for k sufficiently large,

$$\begin{aligned}\int_\Omega |\langle \nabla u^k(x), y_i\rangle|\, dx &\geq \int_{\Omega^i(a_k)} |y_i|^2\, dx = \mu(\Omega^i(a_k))\, |y_i|^2 \\ &\geq \mu(\Omega)\frac{\mu(S_i^*(a_k))}{\mu(S^*(a_k))}\, |y_i|^2 \geq \mu(\Omega)\frac{\gamma}{2}\, |y_i|^2 .\end{aligned}$$

When $i > p$, $y_i^k = v_i^k - a_k$ and $\nabla u^k = v_i^k$ almost everywhere on $\Omega^i(a_k)$; remarking that $v_i^k \to y_i$ and that $|v_i^k| \leq L$, we have, through similar computations, for k sufficiently large,

$$\int_{\Omega^i(a_k)} \left\langle \nabla u^k(x), v_i^k \right\rangle dx = \int_{\Omega^i(a_k)} |v_i^k|^2 dx \geq \frac{\gamma}{4}\mu(\Omega)|y_i|^2;$$

hence

$$\begin{aligned}\int_{\Omega^i(a_k)} \langle \nabla u^k(x), y_i\rangle\, dx &= \int_{\Omega^i(a_k)} \left\langle \nabla u^k(x), v_i^k \right\rangle dx + \int_{\Omega^i(a_k)} \left\langle \nabla u^k(x), y_i - v_i^k \right\rangle dx \\ &\geq \frac{\gamma}{4}\mu(\Omega)|y_i|^2 - L\mu(\Omega)|y_i - v_i^k| \geq \frac{\gamma}{8}\mu(\Omega)|y_i|^2.\end{aligned}$$

We have shown that

$$\int_\Omega |\langle \nabla u^k(x), y_i\rangle|\, dx \geq \int_{\Omega^i(a_k)} \langle \nabla u^k(x), y_i\rangle\, dx \geq \frac{\gamma}{8}\mu(\Omega)|y_i|^2;$$

hence for any y_i, $i \in I$, $\langle \nabla u^k, y_i\rangle$ does not converge in $L^1(\Omega)$. Since $\{y_i, i \in I\}$ is a system of d linearly independent vectors, u^k cannot converge $n-d+1 = n-r$ strongly to zero in $W_0^{1,1}(\Omega)$ and part (i) of the theorem is proved.

(ii) Suppose now $\dim(F_1) = r$ and consider a sequence $\{u^k\}_{k\in\mathbb{N}}$ of solutions of $\mathcal{P}_{a_k}^{**}$. We wish to show that there exist $n-r$ orthonormal vectors h_i in $\mathbb{R}^n$ such that $\langle h_i, \nabla u^k\rangle$ goes to zero in $L^1(\Omega)$ as k goes to infinity.

(1) We begin by remarking that $a = 0 \in \text{r.i.}(\hat{F}_1)$ and $a_k \in \text{r.i.}(\hat{F})$; by [C1, Thm. 1], $(\nabla u^k(x), g^{**}(\nabla u^k(x))) \in F$ and by $\nabla u^k(x) \in \hat{F}$ almost everywhere on Ω; hence $|\nabla u^k(x)| \leq M$ almost everywhere on Ω. Recalling Lemma 2.1, let $h_1, \ldots, h_{n-r}$ be the vectors defining the cone C such that $\hat{F} \subset C$. We have $\langle h_1, \nabla u^k\rangle \geq 0$ almost everywhere in Ω; writing $\nabla u^k = a_k + \nabla v^k$ with $v^k \in W_0^{1,1}(\Omega)$ it turns out that almost everywhere in Ω,

$$\langle h_1, \nabla v^k\rangle \geq -\langle h_1, a_k\rangle . \tag{4.8}$$

We extend v^k by setting $\tilde{v}^k = v^k$ on Ω and $\tilde{v}^k = 0$ on Ω^c; $\tilde{v}^k$ is in $W^{1,1}(\mathbb{R}^n)$ with compact support. Take a basis $\{e_1, \ldots, e_n\}$ in $\mathbb{R}^n$ such that $e_i = h_i$, $i = 1, \ldots, n-r$, and write a point ξ of $\mathbb{R}^n$ as $\xi = (\xi_1, \ldots, \xi_n) = (\xi_1, \xi')$, where ξ_i is the component with respect to e_i. Define the functions

$$\varphi_{\xi'}(\xi_1) = \tilde{v}^k(\xi_1, \xi');$$

$\varphi_{\xi'}(\cdot)$ is a function of $W^{1,1}(\mathbb{R})$ with compact support for almost every ξ' (see [Z, p. 44]) and this implies that the integral of its derivative is equal to zero. Since

$$\frac{d}{d\xi_1}\varphi_{\xi'}(\xi_1) = \langle h_1, \nabla\tilde{v}^k(\xi_1,\xi')\rangle\,,$$

this means that

$$\int_{\mathbb{R}} (\langle h_1, \nabla\tilde{v}^k(\xi_1,\xi')\rangle)^-\, d\xi_1 = \int_{\mathbb{R}} (\langle h_1, \nabla\tilde{v}^k(\xi_1,\xi')\rangle)^+\, d\xi_1.$$

By repeated integration and by a unitary change of variables, we obtain

$$\int_{\Omega} (\langle h_1, \nabla v^k(x)\rangle)^-\, dx = \int_{\Omega} (\langle h_1, \nabla v^k(x)\rangle)^+\, dx.$$

Remarking that the right-hand side of (4.8) is negative, we then have

$$\int_{\Omega} |\langle h_1, \nabla v^k(x)\rangle|\, dx = 2\int_{\Omega} (\langle h_1, \nabla v^k(x)\rangle)^-\, dx \le 2|a_k|\mu(\Omega),$$

and

$$\int_{\Omega} |\langle h_1, \nabla u^k(x)\rangle|\, dx \le 3|a_k|\mu(\Omega).$$

Hence $\langle h_1, \nabla u^k\rangle \overset{k\to\infty}{\to} 0$ in $L^1(\Omega)$.

(2) Now let $\epsilon > 0$. By Egorov's theorem there exists a compact subset Ω_ϵ of Ω such that $\mu(\Omega\backslash\Omega_\epsilon) \le \epsilon$ and $\langle h_1, \nabla u^k\rangle \overset{k\to\infty}{\longrightarrow} 0$ uniformly on Ω_ϵ. Let $k_\epsilon \in \mathbb{N}$ such that $|a_k| \le \epsilon$ and $\sup_{\Omega_\epsilon} |\langle h_1, \nabla u^k\rangle| \le \epsilon$ for any $k \ge k_\epsilon$. For $x \in \Omega_\epsilon$ and $k \ge k_\epsilon$, $\nabla u^k(x)$ belongs to an ϵ-neighbourhood of $\hat{F} \cap H_1$, where $H_1 = \{x : \langle h_1, x\rangle = 0\}$. A point y in an ϵ-neighbourhood of $\hat{F} \cap H_1$ can be written as $y = y_1 + y_\epsilon$, where $y_1 \in \hat{F} \cap H_1$ and $|y_\epsilon| \le \epsilon$; we have $\langle h_2, y_1\rangle \ge 0$ and $\langle h_2, y\rangle = \langle h_2, y_1\rangle + \langle h_2, y_\epsilon\rangle \ge \langle h_2, y_\epsilon\rangle \ge -\epsilon$. Hence $\langle h_2, \nabla u^k(x)\rangle \ge -\epsilon$ and $\langle h_2, \nabla v^k(x)\rangle \ge -\epsilon - |a_k| \ge -2\epsilon$ for any $x \in \Omega_\epsilon$. By computations analogous to those of point (1), we obtain, for any $k \ge k_\epsilon$,

$$\int_{\Omega_\epsilon} |\langle h_2, \nabla v^k(x)\rangle|\, dx \le 4\epsilon\mu(\Omega);$$

then,

$$\int_{\Omega} |\langle h_2, \nabla u^k(x)\rangle|\, dx = \int_{\Omega\backslash\Omega_\epsilon} |\langle h_2, \nabla u^k(x)\rangle|\, dx + \int_{\Omega_\epsilon} |\langle h_2, \nabla u^k(x)\rangle|\, dx \le \epsilon M + 5\epsilon\mu(\Omega).$$

Hence $\langle h_2, \nabla u^k\rangle \overset{k\to\infty}{\longrightarrow} 0$ in $L^1(\Omega)$.

This process can be iterated to show that $\langle h_i, \nabla u^k\rangle \overset{k\to\infty}{\longrightarrow} 0$ in $L^1(\Omega)$ for $i = 1, \dots, n-r$ and this proves that $\{u^k\}_{k\in\mathbb{N}}$ converges d-strongly to u_a in $W_0^{1,1}(\Omega)$ for some $d \ge n-r$. By point (i), if $d > n-r$, we would have $\dim(F_1) < r$, a contradiction. Hence $\{u^k\}_{k\in\mathbb{N}}$ converges $(n-r)$-strongly in $W_0^{1,1}(\Omega)$. □

COROLLARY 4.1. *Assume the hypotheses of Theorem* 4.1. *Then any sequence* $\{u^k\}_{k\in\mathbb{N}}$ *of solutions of* $\mathcal{P}_{a_k}^{**}$ *converges weakly to* u_a.

Proof. Take any sequence $\{u^k\}_{k\in\mathbb{N}}$ of solutions of $\mathcal{P}^{**}_{a_k}$. The derivatives of u^k are uniformly bounded almost everywhere, and by point (ii) of Theorem 4.1, $u^k \to 0$ in $L^1(\Omega)$. Then the proof is a straightforward application of Lemma 4.1. □

Remark 4.2 (Rotational symmetry). Theorem 4.2 states that in general continuous dependence of the solutions from boundary data does not hold if the point $(a, g^{**}(a))$ is not extremal. However, in one special case continuous dependence holds whenever the solution is unique: assume indeed that the function g is rotationally symmetric, i.e., there exists $h : \mathbb{R}^+ \to \mathbb{R}^+$ such that $g(\nabla u) = h(|\nabla u|)$. Two cases are possible: either (a) $h(0) < h(r)$ for all $r > 0$ or (b) there exists $R > 0$ such that $h(R) = h(0)$ (assume that R is the largest such point). In case (a) there are no extremal faces of $\mathrm{epi}(g^{**})$ having dimension n; hence, by the previous results, uniqueness and continuous dependence hold for every boundary datum. In case (b) there is a unique n-dimensional face, the ball of radius R, whose relative boundary consists of its extreme points; hence both uniqueness and continuous dependence hold if and only if $|a| \geq R$.

For a more general g we have the following result.

COROLLARY 4.2. *Assume the hypotheses of Theorem* 3.2.

(i) *If the point* $\{a\}$ *is such that* $\mathcal{P}_a$ $(\mathcal{P}^{**}_a)$ *admits the unique solution* u_a *and there exists a neighbourhood* U *of* $\{a\}$ *such that for any* $b \in U$ $(b, g^{**}(b))$ *belongs to a face of* $\mathrm{epi}(g^{**})$ *of dimension strictly less than* n, *then continuous dependence holds in* U.

(ii) *If the point* $\{a\}$ *is such that* $\mathcal{P}_a$ $(\mathcal{P}^{**}_a)$ *admits the unique solution* u_a *and* $(a, g^{**}(a))$ *belongs to the relative boundary of an* n*-dimensional face of* $\mathrm{epi}(g^{**})$, *then continuous dependence holds if and only if* $(a, g^{**}(a))$ *is an extreme point of* $\mathrm{epi}(g^{**})$.

Remark 4.3 (example). Consider the (convex) integrand $g = g^{**} : \mathbb{R}^2 \to \bar{\mathbb{R}}$, defined as

$$g(y_1, y_2) = \begin{cases} |y_1| + |y_2| & \text{if } (y_1, y_2) \in D, \\ +\infty & \text{otherwise,} \end{cases}$$

where $D = \{(y_1, y_2) \in \mathbb{R}^2 : |y_1| + |y_2| \leq 1\}$. Consider the corresponding minimum problem $\mathcal{P}_a$, where a is a point of $\mathbb{R}^2$ and Ω is any open bounded subset of $\mathbb{R}^2$.

By the above results $\mathcal{P}_a$ admits infinite solutions for any $a = (a_1, a_2) \in \mathrm{int}(D)$ such that $a_1 a_2 \neq 0$, while existence and uniqueness hold for $a \in \partial D \bigcup \{a = (a_1, a_2) \in \mathbb{R}^2 : a_1 a_2 = 0\} = E$. Set $b_0 = (0,0)$, $b_1 = (1,0)$, $b_2 = (0,1)$, $b_3 = (-1,0)$, $b_4 = (0,-1)$; the points $(b_i, g(b_i))$ $(i = 0, \ldots, 4)$ are the only extreme points of the epigraph of g, while the line segments joining $(b_0, g(b_0))$ to $(b_i, g(b_i))$ $(i = 1, \ldots, 4)$ are one-dimensional faces of the epigraph of g.

According to our main result, for $a \in E \setminus \bigcup_{i=0}^{4} b_i$ the solution of $\mathcal{P}_a$ is unique but (strong) continuous dependence does not hold, while both uniqueness and continuous dependence hold for $a = b_i$ $(i = 0, \ldots, 4)$.

Remark 4.4. In Theorem 4.1 we assume that the sequence $\{(a_k, g^{**}(a_k))\}_{k\in\mathbb{N}}$ is entirely contained in a *fixed* n-dimensional face F. We can suppose otherwise that, as k goes to infinity, the sequence touches different faces of the epigraph of g^{**}. In this case the proof of statement (i) of Theorem 4.1 does not need any modification since to prove that $\dim(F_1) = r$ it is sufficient to consider a subsequence of $\{(a_k, g^{**}(a_k))\}_{k\in\mathbb{N}}$ entirely contained in the relative interior of one n-dimensional face.

Conversely we may assume $\dim(F_1) = r$ and study the behaviour of a sequence of solutions $\{u^k\}_{k\in\mathbb{N}}$ of $\mathcal{P}^{**}_{a_k}$ when $a^k \to a$ and $(a_k, g^{**}(a_k))$ belongs to more than one face. In general we may assume that there exists a finite collection $\{F_1, \ldots, F_q\}$ of n-dimensional faces that contain $(a, g^{**}(a))$ in their respective relative boundaries

and such that $(a_k, g^{**}(a_k))$ belongs to to the relative interior of each of the F_i for an infinite number of indices k. The sequence $\{u^k\}_{k\in\mathbb{N}}$ can be decomposed in the disjoint union of $q+1$ subsequences $\{u^{k_i}\}_{k_i\in\mathbb{N}}$, $i=1,\dots,q+1$, where the indices $k_1,\dots,k_q$ are those ones for which $(a_{k_i}, g^{**}(a_{k_i}) \in \text{r.i.}(F_i)$ while the values $(a_{k_{q+1}}, g^{**}(a_{k_{q+1}}))$ belong to faces of dimension strictly less than n. Since $u^{k_{q+1}} \equiv \langle a_{k_{q+1}}, \cdot\rangle$ it converges strongly to u_a in $W_0^{1,1}(\Omega)$, while the sequences $\{u^{k_i}\}_{k_i\in\mathbb{N}}$, $i=1,\dots,q$ converge $(n-r)$-strongly to u_a in $W_0^{1,1}(\Omega)$ in the sense that $\langle \nabla u^{k_i}, e_j^i\rangle \overset{k_i\to\infty}{\longrightarrow} \langle \nabla u_a, e_j^i\rangle$ in $L^1(\Omega)$, where $E^i = \{e_1^i,\dots,e_{(n-r)}^i\}$ is an orthonormal system in $(\text{span}(\hat{F}_1 - a))^\perp$ for any $i=1,\dots,q$. Hence the whole sequence $\{u^k\}_{k\in\mathbb{N}}$ converges $(n-r)$-strongly (and also weakly) to u_a in $W_0^{1,1}(\Omega)$. Hence statement (ii) of Theorem 4.1 and Corollary 4.1 remain true.

CHARACTERIZATION OF THE $\mathcal{L}_2$-INDUCED NORM FOR LINEAR SYSTEMS WITH JUMPS WITH APPLICATIONS TO SAMPLED-DATA SYSTEMS*

N. SIVASHANKAR† AND PRAMOD P. KHARGONEKAR‡

Abstract. This paper considers a continuous-time linear system with finite jumps at discrete instants of time. An iterative method to compute the $\mathcal{L}_2$-induced norm of a linear system with jumps is presented. Each iteration requires solving an algebraic Riccati equation. It is also shown that a linear feedback interconnection of a continuous-time finite-dimensional linear time-invariant (FDLTI) plant and a discrete-time finite-dimensional linear shift-invariant (FDLSI) controller can be represented as a linear system with jumps. This leads to an iterative method to compute the $\mathcal{L}_2$-induced norm of a sampled-data system.

1. Introduction.

Consider a sampled-data system consisting of a continuous-time linear plant and a discrete-time linear controller. This system contains signals that evolve in continuous time as well as signals that evolve in discrete time. It is rather difficult to apply the standard analysis results for linear continuous-time systems and linear discrete-time systems to the analysis of sampled-data systems. This fact has motivated much of the recent research on the analysis and the synthesis of sampled-data control systems. In a recent paper, Sun, Nagpal, and Khargonekar, [32] have shown that *linear systems with jumps* are useful in the synthesis of $\mathcal{H}_\infty$ controllers for sampled-data systems. Roughly speaking, a linear continuous-time system with jumps is a standard linear continuous-time system whose state undergoes finite jump discontinuities at discrete instants of time. It turns out that the class of linear systems with jumps contains standard linear continuous-time systems, linear discrete-time systems, and sampled-data systems. The interested reader is referred to the book by Lakshmikantham, Bainov, and Simeonov [24] for a general introduction to systems with jump discontinuities.

The main problem considered in this paper is the analysis and computation of the $\mathcal{L}_2$-induced norm of linear systems with jumps. The $\mathcal{L}_2$-induced norm is very closely related to the $\mathcal{H}_\infty$ norm; recall that the $\mathcal{L}_2$-induced norm of a linear time-invariant system is the $\mathcal{H}_\infty$ norm of its transfer function. The main results of this paper show that the $\mathcal{L}_2$-induced norm of a linear system with jumps can be computed by solving matrix Riccati equations. Based on comparing our results and Riccati equations with the well-known results on the characterization and computation of the $\mathcal{H}_\infty$ norm of standard linear time-invariant systems [1], [8], [36], we believe that these results are the most natural and direct generalizations of these classical results. Both the finite-

and infinite-horizon cases are treated. The finite-horizon result, Theorem 5.2, is given in terms of existence of solution to a matrix Riccati differential equation with jumps over the finite horizon. The infinite-horizon case is treated by analyzing the limiting behavior of the finite-horizon Riccati equation. This leads to a characterization in Theorem 5.3 of the $\mathcal{L}_2$-induced norm in terms of existence of a stabilizing solution to a Riccati differential equation with jumps on the infinite horizon. This result is intuitivly appealing in that the Riccati equation is given directly in terms of the system parameters and contains the standard continuous and discrete-time Riccati equations as special cases in a very natural manner. However, this characterization is not convenient for computations. For this purpose, we give an equivalent characterization in Theorem 5.1, where we show that in the infinite-horizon case, the $\mathcal{L}_2$-induced norm can be characterized in terms of *existence of a stabilizing solution to one discrete-time algebraic Riccati equation and invertibility of a matrix function.* This theorem immediately leads to an algorithm for computing the $\mathcal{L}_2$-induced norm of a linear system with jumps. As should be expected, the standard analysis results on the $\mathcal{H}_\infty$ norm of linear time-invariant continuous-time and discrete-time systems are simple corollaries of these results.

The $\mathcal{L}_2$-induced norm can be used to provide necessary and sufficient conditions for robust stability of sampled-data systems (see [29] and the references therein for details). Thus, the results in the paper have immediate applications to the robust stability analysis of sampled-data feedback systems.

In addition to being of independent interest, in our view, the framework of linear systems with jumps gives the most natural setting for extending the well-known results on $\mathcal{H}_\infty$ control of standard linear time-invariant systems to the case of hybrid systems containing both discrete-time and continuous-time signals. As will be seen, the framework of systems with jumps contain the standard continuous-time, discrete-time, and sampled-data systems, and in this sense it is a unifying framework. Also, as far as controller synthesis is concerned, Sun, Nagpal, and Khargonekar [32] have used linear systems with jumps in deriving results on $\mathcal{H}_\infty$ controller synthesis for sampled-data systems. It should be noted that our results cannot be obtained as a special case of the $\mathcal{H}_\infty$ synthesis results. This is because our analysis condition, naturally, involves both the continuous-time plant and the discrete-time controller parameters while the synthesis solution depends only on the continuous-time plant parameters.

The last few years have seen a surge in research activity in the analysis and the synthesis of sampled-data control systems. Some basic issues regarding stability of sampled-data systems have been addressed in [15], [10]. Analysis and synthesis of sampled-data systems using various system norms has been studied in [6], [7], [2]–[5], [11], [12], [14], [18], [20], [23], [28], [32]–[34], [37]. Many of these papers use the "lifting technique" (see, for example, [22]) to convert the sampled-data system to an equivalent discrete-time system with infinite-dimensional input and output spaces (see [5], [2], [34], [37] and the references therein for details). More recently, direct state-space solutions to the $\mathcal{H}_\infty$ control problem for sampled-data systems without resorting to the lifting technique have been given in [32], [33].

Our results are most closely related to the results on the computation of the $\mathcal{L}_2$-induced norm of a sampled-data system that has been investigated in [2], [5], [17], [18]. In [18], it has been shown that the $\mathcal{L}_2$-induced norm of a sampled-data system is less than a prespecified number if and only if an associated discrete-time descriptor system has no eigenvalues on the unit circle and the norm of a certain

infinite-dimensional operator is less than one. The approach taken in [17], [18] is based on a representation of the sampled-data system with a state vector that contains continuous- as well as discrete-time signals. In [2], [5], it has been shown that the $\mathcal{L}_2$-induced norm of a sampled-data system is less than a prespecified number if and only if the $\mathcal{H}_\infty$ norm of an associated discrete-time system is less than one and the norm of a related infinite-dimensional operator is less than one. The approach taken in [2], [5] is based on lifting the sampled-data system to a discrete-time system with infinite-dimensional input and output spaces. Our paper provides an alternative solution to the problem treated in [2], [5], [17], [18]. The main difference between our work and these papers lies in the use of linear systems with jumps and the recent state-space time-domain approach to the $\mathcal{H}_\infty$ control theory (see the recent books [7], [31] and the references cited there). As stated above, the resulting characterizations appear to be the most natural generalizations of the classical results on the characterization of the $\mathcal{H}_\infty$ norm of standard continuous- and discrete-time systems using Riccati equations. Since we use a time-domain approach, we get results for the finite- and infinite-horizon cases, which is one distinction between our approach and [2], [5], [17], [18]. Since we do not use the lifting approach, our Riccati equations are given quite directly in terms of the problem data. When our results are specialized to the case of sampled-data systems, they are *mathematically equivalent* to the results of [2], [5], [18], although the form of the results is so different that this equivalence is not easy to see. In this context, our condition on the invertibility of a matrix function is related to the norm condition on a certain infinite-dimensional linear operator in [5], [2], [18]. (See the remarks following Theorem 5.1 for further details.) From a computational point of view, our conditions are as easy to check as those in [5], [2], [18].

The paper is organized as follows. The class of linear systems with jumps is introduced in the next section. We show in §3 that sampled-data systems are a special case of linear systems with jumps. In §4 we introduce the worst case performance measure and give the problem formulation. The main results of this paper are contained in §5. We present the proofs of the main results in §6 and give some concluding remarks in §7.

We end this section with some remarks on the notation used in this paper. Let $\mathcal{C}^n$ denote the space of continuous functions from the time set $[0,\infty)$ to $\Re^n$ and let $\mathcal{PC}^n$ denote the space of piecewise-continuous functions from the time set $[0,\infty)$ to $\Re^n$ that are bounded on compact sets of $[0,\infty)$ and are continuous from the left at every point except the origin. We will denote by $\mathcal{L}_2^n\,[a,b]$ the standard Lebesgue space of square integrable functions over the time interval $[a,b]$ with values in $\Re^n$, and the $\mathcal{L}_2$ norm is defined as

$$\|f\|_{[a,b]} := \left\{\int_a^b f'(t)f(t)dt\right\}^{1/2}.$$

If $f \in \mathcal{L}_2^n\,[0,\infty)$, then its $\mathcal{L}_2$ norm is defined as

$$\|f\|_2 := \left\{\int_0^\infty f'(t)f(t)dt\right\}^{1/2}.$$

Similarly, in discrete-time $\mathcal{S}^n$ denotes the space of $\Re^n$-valued sequences defined on the time set {0,1,2,...}, $\ell_2^n\,[0,k]$ denotes the space of all $(k+1)$ length sequences with

values in $\Re^n$, and the ℓ_2 norm of a $(k+1)$ length sequence $\{\xi_i\}_{i=0}^k$ is defined as

$$\|\xi\|_{[0,k]} := \left[\sum_{i=0}^{k} \xi_i' \xi_i\right]^{1/2}.$$

Again, if $\{\xi_i\}_{i=0}^{\infty} \in \ell_2^n$, then its ℓ_2 norm is defined as

$$\|\xi\|_2 := \left[\sum_{i=0}^{\infty} \xi_i' \xi_i\right]^{1/2}.$$

We will drop the superscript n in the subsequent sections because the dimension of the signal space will be clear from the context.

Finally, for a matrix function M,

$$M : \Re \to \Re^{n \times n},$$

the *left limit of* M *at* $\alpha \in \Re$ is defined as

$$M(\alpha^-) := \lim_{\epsilon \downarrow 0} M(\alpha - \epsilon)$$

if the limit exists, and the *right limit of* M *at* $\alpha \in \Re$ is defined as

$$M(\alpha^+) := \lim_{\epsilon \downarrow 0} M(\alpha + \epsilon)$$

if the limit exists.

2. Linear systems with jumps. Consider the system of equations

$$\Sigma : \begin{cases} \dot{x}(t) = Ax(t) + Bw(t); \quad x(0) = 0; \quad t \neq iT, \\ x(iT^+) = A_d x(iT) + B_d w_d(iT), \\ z(t) = Cx(t), \\ z_d(iT) = C_d x(iT), \end{cases} \tag{1}$$

where i is a nonnegative integer and T is a real number. Here x is the state vector, w and z are the *continuous-time* input and output, and w_d and z_d are the *discrete-time* input and output. It is clear from (1) that the state x of the system jumps at discrete instants of time iT. The state $x(t)$ is left continuous but may be right discontinuous with finite jumps at $t = iT$. The following properties are of significance:

- By setting $A_d = I$, $B_d = 0$, and $C_d = 0$ in (1), we recover standard finite-dimensional linear time-invariant (FDLTI) continuous-time systems.
- By setting $A = 0$, $B = 0$, and $C = 0$ in (1), we recover standard finite-dimension linear shift-invariant (FDLSI) discrete-time systems.
- It will be seen in §3 that a linear feedback interconnection of a FDLTI continuous-time system and a FDLSI discrete-time controller by sample and (zero-order) hold devices leads to a linear system with jumps.

Suitable generalizations of the class of linear systems with jumps also have potential applications in the analysis and synthesis of multirate systems and systems with nonuniform sampling period. This topic will not be pursued in this paper and is left for future research.

Now consider the system Σ with $w = w_d = 0$. The solution $x(t)$ of the unforced system is given by

$$x(t) = \Phi(t, s)x(s); \qquad t \geq s,$$

where the matrix function $\Phi(t, s)$ is the *state transition matrix* of the system Σ. It is piecewise continuous with possible discontinuities at $t, s = iT$, and is characterized by

$$\begin{aligned} \frac{\partial}{\partial t}\Phi(t, s) &= A\Phi(t, s); \qquad t \geq s; \quad t \neq iT, \\ \Phi(iT^+, s) &= A_d\Phi(iT, s); \qquad iT \geq s, \\ \Phi(s, s) &= I. \end{aligned}$$

DEFINITION 2.1 ([32]). *The system Σ in (1) is said to be internally exponentially stable if there exist positive constants c_1, c_2 such that*

$$\|\Phi(t, s)\| \leq c_1 e^{-c_2(t-s)}, \quad \textit{for all } t \geq s.$$

We will abbreviate *internally exponentially stable* as *stable.*

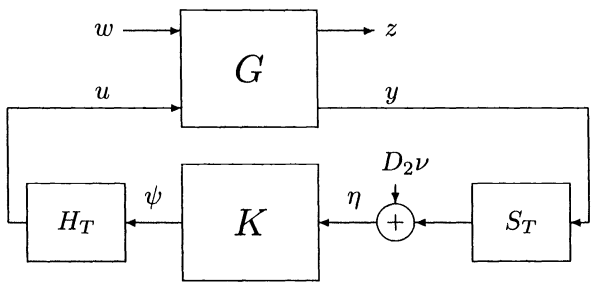

FIG. 1.

3. Sampled-data systems. In this section we consider a general linear interconnection of a FDLTI continuous-time plant and a FDLSI discrete-time controller by sample and hold devices. We show that such an interconnection is a special case of linear system with jumps. In particular, we show that such an interconnection has a state-space representation similar to (1).

Consider the sampled-data feedback system in Fig. 1. Here G is a FDLTI causal continuous-time plant, K is a FDLSI causal discrete-time controller, w is the exogenous input, u is the control input, z is the controlled output, and y is the measurement output. The block labeled S_T represents the sampling operator with time period T defined as follows:

$$S_T : \mathcal{C} \to \mathcal{S} : y \mapsto S_T y : (S_T y)(k) = y(kT).$$

The system block denoted by H_T represents the (zero-order) hold operator with time period T:

$$H_T : \mathcal{S} \to \mathcal{PC} : \psi \mapsto H_T\psi : (H_T\psi)(t) = \psi(k), \qquad kT < t \leq (k+1)T.$$

Consider the transfer function representation of G:

$$z = G_{11}w + G_{12}u, \qquad y = G_{21}w + G_{22}u.$$

We will assume throughout this paper that G_{22} is strictly proper. This ensures the well-posedness of the feedback system. In Fig. 1, note that S_T acts on the measurement output y. For this to make sense, y must be continuous. To ensure this, it is sufficient to assume that G_{21} is strictly proper. For the sake of simplicity in notation, we will assume that G_{11} is also strictly proper. However, this technical assumption can be easily removed.

Let

$$G: \quad \begin{aligned} \dot{x} &= Fx + E_1 w + E_2 u; \qquad x(0) = 0, \\ z &= H_1 x + D_{12} u, \\ y &= H_2 x; \end{aligned} \tag{2}$$

$$K: \quad \begin{aligned} \xi(k+1) &= \Phi\xi(k) + \Gamma\eta(k); \qquad \xi(0) = 0, \\ \psi(k) &= \Theta\xi(k) + \Upsilon\eta(k) \end{aligned} \tag{3}$$

be the state-space representations of the systems in Fig. 1. The input to the controller is corrupted by discrete-time noise and is given by

$$\eta(k) = y(kT) + D_2 w_d(k) = H_2 x(kT) + D_2 w_d(k).$$

The control input to the plant is constant between two sampling instants and is given by

$$u(t) = (H_T\psi)(t) = \psi(k), \qquad kT < t \leq (k+1)T.$$

The sampled-data feedback system in Fig. 1 is called internally asymptotically stable if the associated unforced shift-invariant discrete-time system with the state

$$\begin{pmatrix} x(k) \\ \xi(k) \end{pmatrix} := \begin{pmatrix} x(kT) \\ \xi(k) \end{pmatrix}$$

is asymptotically stable [11].

It has been shown in [15] that

$$x_{sd}(t) := \begin{pmatrix} x_1(t) \\ x_2(t) \\ x_3(t) \end{pmatrix}$$

represents the state of the closed loop hybrid sampled-data system where

$$\begin{aligned} x_1(t) &:= x(t) \quad \forall t, \\ x_2(t) &:= \psi(k), \qquad kT < t \leq (k+1)T, \\ x_3(t) &:= \xi(k+1), \qquad kT < t \leq (k+1)T. \end{aligned}$$

With this representation of the state of the closed-loop system in Fig. 1, we can obtain the state space representation of the hybrid system as

$$\Sigma_{sd}: \begin{cases} \dot{x}_{sd}(t) = Ax_{sd}(t) + Bw(t); \qquad x_{sd}(0) = 0, \quad t \neq kT, \\ x_{sd}(kT^+) = A_d x_{sd}(kT) + B_d w_d(k), \\ z(t) = Cx_{sd}(t), \end{cases} \tag{4}$$

where A, B, A_d, B_d, and H have the following representation:

$$A := \begin{pmatrix} F & E_2 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \qquad B := \begin{pmatrix} E_1 \\ 0 \\ 0 \end{pmatrix},$$

$$A_d := \begin{pmatrix} I & 0 & 0 \\ \Upsilon H_2 & 0 & \Theta \\ \Gamma H_2 & 0 & \Phi \end{pmatrix}, \qquad B_d := \begin{pmatrix} 0 \\ \Upsilon D_2 \\ \Gamma D_2 \end{pmatrix},$$

$$C := (H_1 \;\; D_{12} \;\; 0).$$

Thus, the sampled-data system can be expressed (in state space form) as a linear system with finite jumps Σ_{sd}. Note that we do not have any discrete-time output in (4). However, if we want to include some function of the state x_{sd} or the input at the sampling instants in the cost function, then we will have a discrete-time output, z_d. It can be shown that the sampled-data feedback system in Fig. 1 is internally asymptotically stable if and only if the linear system with jumps Σ_{sd} described by (4) is stable.

4. Problem formulation. Consider the linear system with jumps Σ in (1). It is easy to see that Σ generates an input/output map $\mathcal{T}$ which is a causal linear operator

$$\mathcal{T} : \mathcal{L}_2[0,\tau] \oplus \ell_2[0,k] \to \mathcal{L}_2[0,\tau] \oplus \ell_2[0,k] : w \oplus w_d \mapsto z \oplus z_d, \tag{5}$$

where k is the largest integer such that $kT \leq \tau$. If Σ is stable, then

$$\mathcal{T} : \mathcal{L}_2[0,\infty) \oplus \ell_2 \to \mathcal{L}_2[0,\infty) \oplus \ell_2 : w \oplus w_d \mapsto z \oplus z_d \tag{6}$$

can be shown to be a causal bounded linear operator.

For the system Σ in (1), define the worst case performance measure $J(\tau)$ as

$$J(\tau) := \sup \left\{ \left[\frac{\|z\|^2_{[0,\tau]} + \|z_d\|^2_{[0,k]}}{\|w\|^2_{[0,\tau]} + \|w_d\|^2_{[0,k]}} \right]^{1/2} \right\}, \tag{7}$$

where the supremum is taken over all $w \in \mathcal{L}_2[0,\tau], w_d \in \ell_2[0,k]$ such that $\|w\|^2_{[0,\tau]} + \|w_d\|^2_{[0,k]} \neq 0$. Here, k is the largest integer such that $kT \leq \tau$.

The numerator and the denominator in the performance measure (7) should be thought of as "mixed" $\mathcal{L}_2/\ell_2$ norms on the inputs and the outputs of the system. Essentially, the performance measure $J(\tau)$ is the worst case ratio of the output energy to the input energy. Thus, $J(\tau)$ can be viewed as a worst case gain of the system Σ. In the infinite-horizon case, when the system Σ is stable, we will denote the performance measure as $J(\infty)$. This performance measure has been motivated by the $\mathcal{H}_\infty$ norm for standard linear systems [13], [21], [32]. Recall that the $\mathcal{H}_\infty$ norm of a stable FDLTI system is equal to its $\mathcal{L}_2$-induced norm. Thus, the performance measure defined above is a generalization of the usual $\mathcal{H}_\infty$ norm. Indeed, $J(\infty)$ reduces to the $\mathcal{H}_\infty$ norm if we specialize Σ to standard continuous-time or discrete-time systems. Let $\mathcal{T}$ (as described in (5)) be the linear operator associated with the system Σ. Then it can be easily verified that the induced operator norm of $\mathcal{T}$ is given by $J(\tau)$. Similarly, $J(\infty)$ is the induced operator norm of $\mathcal{T}$ in (6).

PROBLEM STATEMENT. *Given a real number $\gamma > 0$, give necessary and sufficient conditions such that $J(\infty) < \gamma$.*

5. Characterization of the $\mathcal{L}_2$-induced norm. We will first present the main result of this paper and then give some auxiliary results and corollaries that go along with this main result. We will present our analysis results for linear systems with jumps. Since sampled-data systems are a special case of linear systems with jumps, it follows that the results in this section can be easily specialized to the case of sampled-data systems.

5.1. Main result. Consider the system Σ in (1) over the time interval $t \in [0, \infty)$ and the associated performance measure $J(\infty)$. In this section we will assume that the system Σ is stable.

For $t \in [0, T]$, let

$$\Pi(t) := \begin{pmatrix} \Pi_{11}(t) & \Pi_{12}(t) \\ \Pi_{21}(t) & \Pi_{22}(t) \end{pmatrix} := \exp\left[\begin{pmatrix} A & \gamma^{-2}BB' \\ -C'C & -A' \end{pmatrix} t\right] \tag{8}$$

and

$$\Lambda(t) := \begin{pmatrix} \Lambda_{11}(t) & \Lambda_{12}(t) \\ \Lambda_{21}(t) & \Lambda_{22}(t) \end{pmatrix} := \exp\left[-\begin{pmatrix} -A' & -\gamma^{-2}C'C \\ BB' & A \end{pmatrix} t\right]. \tag{9}$$

We now give the main result for the infinite horizon case.

THEOREM 5.1. *Consider the linear system with jumps in* (1) *over the time interval* $t \in [0, \infty)$. *Let the system given in* (1) *be stable. Let* $\gamma > 0$ *be a real number. Then the following statements are equivalent.*

(i) $J(\infty) < \gamma$.

(ii) *There exists a symmetric matrix* $\tilde{P}$ *such that* $\left(I - \gamma^{-2}B_d'\tilde{P}B_d\right) > 0$ *and*

$$H_1\begin{pmatrix} I \\ \tilde{P} \end{pmatrix} = H_2\begin{pmatrix} I \\ \tilde{P} \end{pmatrix} F_P, \tag{10}$$

where

$$H_1 := \begin{pmatrix} A_d & 0 \\ -C_d'C_d & I \end{pmatrix}\begin{pmatrix} \Pi_{11}(T) & \Pi_{12}(T) \\ \Pi_{21}(T) & \Pi_{22}(T) \end{pmatrix}, \qquad H_2 := \begin{pmatrix} I & -\gamma^{-2}B_dB_d' \\ 0 & A_d' \end{pmatrix} \tag{11}$$

and

$$F_P := \left[I - \gamma^{-2}B_dB_d'\tilde{P}\right]^{-1} A_d\left(\Pi_{11}(T) + \Pi_{12}(T)\tilde{P}\right)$$

has all its eigenvalues within the open unit disk (discrete-time stable matrix). Moreover, $\left(\Pi_{11}(t) + \Pi_{12}(t)\tilde{P}\right)$ *is invertible for all* $t \in [0, T]$.

(iii) *There exists a symmetric matrix* $\tilde{Q}$ *such that* $\left(I - \gamma^{-2}C_d\tilde{Q}C_d'\right) > 0$ *and*

$$G_1\begin{pmatrix} I \\ \tilde{Q} \end{pmatrix} = G_2\begin{pmatrix} I \\ \tilde{Q} \end{pmatrix} F_Q, \tag{12}$$

where

$$G_1 := \begin{pmatrix} A_d' & 0 \\ -B_dB_d' & I \end{pmatrix}\begin{pmatrix} \Lambda_{11}(T) & \Lambda_{12}(T) \\ \Lambda_{21}(T) & \Lambda_{22}(T) \end{pmatrix}, \qquad G_2 := \begin{pmatrix} I & -\gamma^{-2}C_d'C_d \\ 0 & A_d \end{pmatrix} \tag{13}$$

and

$$F_Q := \left[I - \gamma^{-2} C_d' C_d \tilde{Q}\right]^{-1} A_d' \left(\Lambda_{11}(T) + \Lambda_{12}(T)\tilde{Q}\right)$$

has all its eigenvalues within the open unit disk (discrete-time stable matrix). Moreover, $\left(\Lambda_{11}(t) + \Lambda_{12}(t)\tilde{Q}\right)$ *is invertible for all* $t \in [0, T]$.

Note that there are two parts in the statement of (ii). In the first part of statement (ii), we claim that $\tilde{P}$ must satisfy the following properties:

1. $\left(I - \gamma^{-2} B_d' \tilde{P} B_d\right) > 0$;
2. $H_1 \begin{pmatrix} I \\ \tilde{P} \end{pmatrix} = H_2 \begin{pmatrix} I \\ \tilde{P} \end{pmatrix} F_P$;
3. F_P is stable.

In the context of sampled-data systems, there is an intutive explanation for item 1 given above. Sampled-data systems can be viewed as linear finite-dimensional discrete-time systems with infinite-dimensional inputs and outputs [2], [5], [23]. It is well known that such a positive definite condition appears in the standard $\mathcal{H}_\infty$ analysis problem for discrete-time systems [16], [31]. So it is only natural that such a condition also appear in the $\mathcal{H}_\infty$ analysis problem for sampled-data systems.

Regarding item 2 above, with some tedious algebra it can be shown that the matrices H_1 and H_2 form a symplectic pair, i.e., $H_1 J H_1' = H_2 J H_2'$ where

$$J := \begin{pmatrix} 0 & I \\ -I & 0 \end{pmatrix}.$$

Thus, along with item 3 above, it is clear that $\tilde{P}$ is the unique stabilizing solution to the discrete-time algebraic Riccati equation (10) [26], [35], [16].

In the second part of statement (ii) we claim that $\tilde{P}$ should be such that $(\Pi_{11}(t) + \Pi_{12}(t)\tilde{P})$ is invertible for all $t \in [0, T]$. This condition is equivalent to a certain $\mathcal{L}_2$-induced norm of the system Σ being less than γ over one period [21]. Again, in the context of sampled-data systems, this condition has an intuitive explanation. Note that the sampled-data feedback system runs open loop (without the controller) in between sampling instants. For the induced norm of the feedback system to be less than γ over $[0, \infty)$, it is obvious that the induced norm should necessarily be less than γ within a sampling period. Now observe that the matrix function $\Pi(t)$ in (8) depends only on the parameters of the open-loop plant G and this explains the invertibility condition in (ii). This invertibility condition is related to the invertibility of a certain infinite-dimensional linear operator that appears in other works on sampled-data systems [5], [2], [18]. Numerically, this invertibility condition can be checked either by doing a search over one period or by checking the existence and boundedness of the solution to a standard Riccati differential equation (14) over one period.

A systematic way of checking if $J(\infty) < \gamma$ could be as follows. We can first check the existence of a solution $\tilde{P}$ to items 1–3 in the first part of statement (ii). If such a (stabilizing) solution exists, then it is unique. Now we can check if the solution $\tilde{P}$ satisfies the invertibility condition in the second part of statement (ii). *Thus, the invertibility condition needs to be checked only after the computation of* $\tilde{P}$.

Remarks similar to the ones made above can also be made regarding statement (iii) in the theorem. So (10) and (12) represent generalized eigenvalue problems, and one can solve for $\tilde{P}$ and $\tilde{Q}$ using numerical linear algebra methods.

Computation of $J(\infty)$.

Assume that a tolerance level $\epsilon > 0$ is given.

Step 1. Set $\gamma_h = L$, where L is a sufficiently large real number and $\gamma_l = 0$.

Step 2. Set $\gamma = (\gamma_h + \gamma_l)/2$.

Step 3. Check if (10) has a symmetric solution satisfying the conditions stated in (ii) of Theorem 5.1.

Step 4a. If a solution exists and

If $(\gamma_h - \gamma_l) < \epsilon$, then STOP.

Else, set $\gamma_h = \gamma$ and go to Step 2.

Step 4b. If a solution does not exist, then set $\gamma_l = \gamma$ and go to Step 2.

The above iterative procedure gives a simple way of calculating the induced norm of system Σ in (1) to a desired accuracy.

5.2. Finite- and infinite-horizon results. In the previous section we gave a characterization of the $\mathcal{L}_2$-induced norm of the system Σ in the infinite-horizon case. As stated in the Introduction, this result is obtained by analyzing the finite- and infinite-horizon cases. Therefore, we will next give the corresponding result in the finite-horizon case. As we can see, this result is a natural generalization of the known results on the finite-horizon $\mathcal{L}_2$-induced norm of standard linear systems (see, for example, [7], [21], [31]).

THEOREM 5.2. *Consider the linear system with jumps in* (1) *over a finite-time interval* $[0, \tau]$. *Let* k *be the largest integer such that* $0 \leq kT \leq \tau$. *Let* $\gamma > 0$ *be a real number. Then the following statements are equivalent.*

(i) $J(\tau) < \gamma$.

(ii) *There exists a symmetric piecewise differentiable matrix function* $P(t)$, $t \in [0, \tau]$ *such that* $(I - \gamma^{-2} B_d' P(iT^+) B_d) > 0$ *for all* $i \in \{0, 1, \ldots, k\}$ *and*

$$-\dot{P}(t) = A' P(t) + P(t)A + \gamma^{-2} P(t) B B' P(t) + C' C; \qquad t \neq iT, \tag{14}$$

$$\begin{aligned} P(iT) = {} & A_d' P(iT^+) A_d + C_d' C_d \\ & + A_d' P(iT^+) B_d \left(\gamma^2 I - B_d' P(iT^+) B_d\right)^{-1} B_d' P(iT^+) A_d, \end{aligned} \tag{15}$$

$$P(\tau^+) = 0. \tag{16}$$

(iii) *There exists a symmetric piecewise differentiable matrix function* $Q(t)$, $t \in [0, \tau]$ *such that* $(I - \gamma^{-2} C_d Q(iT^-) C_d') > 0$ *for all* $i \in \{0, 1, \ldots k\}$ *and*

$$\dot{Q}(t) = AQ(t) + Q(t)A' + \gamma^{-2} Q(t) C' C Q(t) + BB'; \qquad t \neq iT, \tag{17}$$

$$\begin{aligned} Q(iT) = {} & A_d Q(iT^-) A_d' + B_d B_d' \\ & + A_d Q(iT^-) C_d' \left(\gamma^2 I - C_d Q(iT^-) C_d'\right)^{-1} C_d Q(iT^-) A_d', \end{aligned} \tag{18}$$

$$Q(0^-) = 0. \tag{19}$$

Thus, to check if the performance measure $J(\tau)$ is less than the prespecified level γ, we must check the existence of a symmetric solution to a matrix Riccati differential equation with finite jumps. This solution reflects the hybrid nature of our system and the performance measure. The Riccati differential equation for P (14)–(16) is solved backwards in time. For the sake of simplicity, assume that the terminal time instant $\tau \in (kT, (k+1)T)$ for some positive integer k. We first integrate the differential equation (14) with the terminal condition $P(\tau^+) = 0$ up to the time instant $(kT + \epsilon)$,

where $\epsilon > 0$ is a sufficiently small real number. At the jump point kT, we use the difference equation (15) with the value of $P(kT+\epsilon)$ to obtain the initial value to the Riccati differential equation in the next interval. This procedure is repeated up to $t = 0$. If the solution $P(t)$ blows up for some $t \in [0, \tau]$, then clearly the solution to (14)–(16) does not exist and therefore $J(\tau) \geq \gamma$. Similarly, (17)–(18) is solved forward in time with initial condition $Q(0^-) = 0$ to obtain $Q(t), t \in [0, \tau]$. If $Q(t)$ blows up for some $t \in [0, \tau]$, then it again indicates that $J(\tau) \geq \gamma$. This leads to an obvious bisection method as in the previous subsection for computing $J(\tau)$ to any desired accuracy.

We will now present a result that is analogous to Theorem 5.2 in the infinite-horizon case. This result, along with Theorem 5.2, will be useful in establishing Theorem 5.1. Again, this result is a natural generalization of the corresponding results for standard continuous- and discrete-time linear systems.

Given a piecewise-continuous matrix function $P(t), t \in [0, \infty)$, define the linear system with jumps:

$$\Sigma_P : \begin{cases} \dot{x}(t) = (A + \gamma^{-2} B B' P(t)) x(t); & x(0) = 0; \qquad t \neq iT, \\ x(iT^+) = (I - \gamma^{-2} B_d B_d' P(iT^+))^{-1} A_d x(iT). \end{cases} \tag{20}$$

Similarly, given a piecewise-continuous matrix function $Q(t), t \in [0, \infty)$, define

$$\Sigma_Q : \begin{cases} \dot{x}(t) = (A + \gamma^{-2} Q(t) C' C) x(t); & x(0) = 0; \qquad t \neq iT, \\ x(iT) = A_d (I - \gamma^{-2} Q(iT^-) C_d' C_d)^{-1} x(iT^-). \end{cases} \tag{21}$$

Now we state the extension of Theorem 5.2 for the infinite-horizon case.

THEOREM 5.3. *Consider the linear system with jumps in* (1) *over the time interval* $t \in [0, \infty)$. *Let the system given in* (1) *be stable. Let* $\gamma > 0$ *be a real number. Then the following statements are equivalent.*

(i) $J(\infty) < \gamma$.

(ii) *There exists a bounded symmetric piecewise differentiable matrix function* $P(t)$, $t \in [0, \infty)$ *such that* $(I - \gamma^{-2} B_d' P(iT^+) B_d) > 0$ *for all* $i \in \{1, 2, \ldots\}$, $(I - \gamma^{-2} B_d' P(iT^+) B_d)^{-1}$ *is a bounded sequence,* $P(t)$ *satisfies* (14), (15) *for all* $t \in [0, \infty)$, *and the system* Σ_P *is stable.*

(iii) *There exists a bounded symmetric piecewise differentiable matrix function* $Q(t)$, $t \in [0, \infty)$ *such that* $(I - \gamma^{-2} C_d Q(iT^-) C_d') > 0$ *for all* $i \in \{1, 2, \ldots\}$, $(I - \gamma^{-2} C_d Q(iT^-) C_d')^{-1}$ *is a bounded sequence,* $Q(t)$ *satisfies* (17), (18) *for all* $t \in [0, \infty)$ *with* $Q(0^-) = 0$, *and the system* Σ_Q *is stable.*

Note that both $P(t)$ and $Q(t)$ in Theorem 5.3 are given by a differential Riccati equation in the interval between consecutive jumps, and at the beginning of every interval the initial condition to the Riccati differential equation is evaluated using a difference Riccati equation. The equation for $P(t)$ has no terminal condition and is obtained by taking limit of the finite-horizon solution (14), (15) as $\tau \to \infty$.

Since we are dealing with linear time-invariant systems with finite discrete jumps at periodic intervals, we should expect some sort of stationarity property in the Riccati equations in the infinite horizon case. *Intuitively, this stationarity property leads to the results in Theorem* 5.1 *from Theorem* 5.3. As we show in §6, $P(t)$ (respectively, $Q(t)$) in Theorem 5.3 is intrinsically related to $\tilde{P}$ (respectively, $\tilde{Q}$) in Theorem 5.1. In particular, due to the periodic nature of the underlying system, $P(t)$ is periodic (with a period T) and $\tilde{P} = P(iT^+)$ for $i \in \{0, 1, 2, \ldots\}$. The invertibility condition on

$\left(\Pi_{11}(t) + \Pi_{12}(t)\tilde{P}\right)$ in Theorem 5.1 guarantees the existence of $P(t)$ in between sampling instants. (Note that an analogous invertibility condition is absent in Theorem 5.3 since the existence of $P(t)$ is required for all t.)

Since continuous-time and discrete-time FDLTI systems are special cases of a linear system with jumps, it should come as no surprise that the standard analysis conditions for continuous-time and discrete-time FDLTI systems [13], [31] fall out naturally from Theorems 5.3 and 5.1.

COROLLARY 5.4. *Consider the linear time-invariant continuous-time asymptotically stable system*

$$\Sigma_c : \begin{cases} \dot{x}(t) = Ax(t) + Bw(t); & x(0) = 0, \\ z(t) = Cx(t). \end{cases} \tag{22}$$

Then,

$$J(\infty) = \sup_{0=w\in\mathcal{L}_2[0,\infty)} \frac{\|z\|_2}{\|w\|_2} =: \|T_{zw}\|_\infty.$$

Let $\gamma > 0$. Then, the following statements are equivalent.

(i) $\|T_{zw}\|_\infty < \gamma$.

(ii) *There exists a unique symmetric matrix P such that*

$$A'P + PA + C'C + \gamma^{-2}PBB'P = 0, \tag{23}$$

$(A + \gamma^{-2}BB'P)$ is asymptotically stable.

(iii) *There exists a unique symmetric matrix Q such that*

$$AQ + QA' + BB' + \gamma^{-2}PC'CP = 0, \tag{24}$$

$(A + \gamma^{-2}QC'C)$ is asymptotically stable.

COROLLARY 5.5. *Consider the linear shift-invariant discrete-time asymptotically stable system*

$$\Sigma_d : \begin{cases} x(k+1) = A_d x(k) + B_d w_d(k); & x(0) = 0, \\ z_d(k) = C_d x(k). \end{cases} \tag{25}$$

Then,

$$J(\infty) = \sup_{0=w_d\in\ell_2} \frac{\|z_d\|_2}{\|w_d\|_2} =: \|T_{z_d w_d}\|_\infty.$$

Let $\gamma > 0$. Then, the following statements are equivalent.

(i) $\|T_{z_d w_d}\|_\infty < \gamma$.

(ii) *There exists a unique symmetric matrix P such that $(I - \gamma^{-2}B_d'PB_d) > 0$,*

$$A_d'PA_d - P + C_d'C_d + A_d'PB_d(\gamma^2 I - B_d'PB_d)^{-1}B_d'PA_d = 0, \tag{26}$$

and $(A_d + B_d(\gamma^2 I - B_d'PB_d)^{-1}B_d'PA_d)$ is asymptotically stable.

(iii) *There exists a unique symmetric matrix Q such that $(I - \gamma^{-2}C_dQC_d') > 0$,*

$$A_dQA_d' - Q + B_dB_d' + A_dQC_d'(\gamma^2 I - C_dQC_d')^{-1}C_dQA_d' = 0, \tag{27}$$

and $(A_d + A_dQC_d'(\gamma^2 I - C_dQC_d')^{-1}C_d)$ is asymptotically stable.

6. Proofs. This section is divided into two parts. In the first part, we will give a proof for the finite-horizon result, and in the second part we will give a proof for the infinite-horizon result.

Consider the system (1) over the time interval $t \in [0, \tau]$. Suppose $\tau = kT$ for some positive integer k and there exists a piecewise differentiable matrix function $P(t)$ satisfying (14)–(16). Applying the terminal condition $P(\tau^+) = P(kT^+) = 0$ to (15) we get

$$P(kT) = P(\tau) = C_d' C_d.$$

Then, it is clear that condition (ii) in Theorem 5.2 is equivalent to the following condition.

There exists a symmetric piecewise differentiable matrix function $P(t)$, $t \in [0, \tau]$ such that $(I - \gamma^{-2} B_d' P(iT^+) B_d) > 0$ for all $i \in \{0, 1, \ldots, k\}$ and

$$-\dot{P}(t) = A' P(t) + P(t) A + \gamma^{-2} P(t) B B' P(t) + C' C; \qquad t \neq iT, \tag{28}$$

$$\begin{aligned} P(iT) = {} & A_d' P(iT^+) A_d + C_d' C_d \\ & + A_d' P(iT^+) B_d \left(\gamma^2 I - B_d' P(iT^+) B_d\right)^{-1} B_d' P(iT^+) A_d, \end{aligned} \tag{29}$$

$$P(\tau) = C_d' C_d. \tag{30}$$

Also note that if $\tau = kT$, it follows that

$$x'(\tau) P(\tau) x(\tau) = x'(\tau) C_d' C_d x(\tau) = z_d'(kT) z_d(kT). \tag{31}$$

If the terminal time instant lies between two consecutive jump instants, i.e., $\tau \in (kT, (k+1)T)$ for some nonnegative integer k (k depends on τ), then it is clear that $P(\tau) = P(\tau^+) = 0$.

We state a lemma next that will be used repeatedly in the proofs. This lemma can be established using routine "completion of squares" and "dynamic programming" arguments [36], [21]. For the sake of brevity, we do not give the proof of the lemma here; the details of this proof can be found in [30].

LEMMA 6.1. *Consider the system given in* (1). *Let* $J(\tau) < \gamma$. *Suppose there exists a symmetric piecewise differentiable matrix function* $P(t)$ *satisfying* (14)–(16) *in the interval* $[\sigma, \tau]$ *for some* $\sigma \geq 0$.

(i) *Then for* $t_0 \in [\sigma, \tau]$,

$$\begin{aligned} V(t_0, x_0) &:= \inf_{w, w_d} \left[\gamma^2 \|w\|^2_{[t_0,\tau]} - \|z\|^2_{[t_0,\tau]} + \gamma^2 \|w_d\|^2_{[m,l]} - \|z_d\|^2_{[m,l]} \,|x(t_0) = x_0\right] \\ &= -x_0' P(t_0) x_0, \end{aligned} \tag{32}$$

where m *is the smallest integer satisfying* $0 \leq \sigma \leq t_0 \leq mT$ *and*

$$l = \begin{cases} k & \text{if } \tau \in (kT, (k+1)T), \\ k+1 & \text{if } \tau = (k+1)T \end{cases}$$

for some nonnegative integer k. *The infimum in* (32) *is achieved by*

$$w(t) = \gamma^{-2} B' P(t) x(t) \quad \forall\, t \neq iT, \qquad t \in [t_0, \tau], \tag{33}$$

$$w_d(iT) = (\gamma^2 I - B_d' P(iT^+) B_d)^{-1} B_d' P(iT^+) A_d x(iT) \quad \forall\, i \in \{m, m+1, \ldots, l\}. \tag{34}$$

(ii) *Furthermore,*

$$V(t_0,0) := \inf_{w,w_d} \left[\gamma^2\|w\|^2_{[t_0,\tau]} - \|z\|^2_{[t_0,\tau]} + \gamma^2\|w_d\|^2_{[m,l]} - \|z_d\|^2_{[m,l]} \,|x(t_0) = 0\right] = 0 \tag{35}$$

and the infimum in (35) *is obtained with* $w(t) = 0, t \in [t_0,\tau]$ *and* $w_d(iT) = 0, i \in \{m,\dots,l\}$.

6.1. Finite-horizon case.

Proof of Theorem 5.2. We will first show (i) $\Leftrightarrow$ (ii) and then show (i) $\Leftrightarrow$ (iii) by duality.

Proof of (i) $\Leftarrow$ (ii) *in Theorem* 5.2. Let $P(t), t \in [0,\tau]$ be a piecewise differentiable matrix function satisfying (14)–(16). Let k be the largest integer such that $kT < \tau$. (To avoid triviality, assume $\tau > 0$.) Differentiating the function $x(t)P(t)x(t)$ and then integrating it from iT^+ to s (where $s := \min((i+1)T,\tau)$) we obtain

$$x'(t)P(t)x(t)|^s_{iT^+} = -\|z\|^2_{(iT,s]} + \gamma^2\|w\|^2_{(iT,s]} - \left\|\left(\gamma w - \frac{1}{\gamma}B'Px\right)\right\|^2_{(iT,s]}. \tag{36}$$

Similarly, at $t = iT$, we have

$$\begin{aligned} &x'(iT^+)P(iT^+)x(iT^+) - x'(iT)P(iT)x(iT) \\ &\quad = -z_d'(iT)z_d(iT) + \gamma^2 w_d'(iT)w_d(iT) - v'(iT)M_i v(iT), \end{aligned} \tag{37}$$

where $M_i := (\gamma^2 I - B_d'P(iT^+)B_d)$, and $v(iT) := w_d(iT) - M_i^{-1}B_d'P(iT^+)A_d x(iT)$.

Set

$$\hat{w}(t) := \gamma w(t) - \frac{1}{\gamma}B'P(t)x(t) \quad \forall\, t \in [0,\tau] \tag{38}$$

and

$$\hat{w}_d(iT) := M_i^{1/2}\left(w_d(iT) - M_i^{-1}B_d'P(iT^+)A_d x(iT)\right) \quad \forall i \in \{0,1,\dots,k\}. \tag{39}$$

Consider the system Σ_w :

$$\begin{aligned} \dot{x}(t) &= \left[A + \gamma^{-2}BB'P(t)\right]x(t) + \frac{1}{\gamma}B\hat{w}(t); \qquad x(0) = 0; \qquad t \neq iT, \\ x(iT^+) &= \left[A_d + B_d M_i^{-1}B_d'P(iT^+)A_d\right]x(iT) + B_d M_i^{-1/2}\hat{w}_d, \\ w(t) &= \frac{1}{\gamma}\hat{w}(t) + \gamma^{-2}B'P(t)x(t), \\ w_d(iT) &= M_i^{-1/2}\hat{w}_d(iT) + M_i^{-1}B_d'P(iT^+)A_d x(iT). \end{aligned} \tag{40}$$

Let $\mathcal{T}_w$ be the input/output operator generated by Σ_w, which can be described as

$$\mathcal{T}_w : \mathcal{L}_2[0,\tau] \oplus \ell_2[0,k] \to \mathcal{L}_2[0,\tau] \oplus \ell_2[0,k] : \hat{w} \oplus \hat{w}_d \mapsto w \oplus w_d. \tag{41}$$

As τ is finite, it is easy to see that the operator $\mathcal{T}_w$ is bounded, and there exists a real number $c > 0$ such that

$$\|w\|^2_{[0,\tau]} + \|w_d\|^2_{[0,k]} \le c\left(\|\hat{w}\|^2_{[0,\tau]} + \|\hat{w}_d\|^2_{[0,k]}\right). \tag{42}$$

If $\tau \neq (k+1)T$, then adding (36) and (37) from $i=0$ to $i=k$, we obtain

$$x'(\tau)P(\tau)x(\tau) - x'(0)P(0)x(0) = -\|z\|^2_{[0,\tau]} + \gamma^2\|w\|^2_{[0,\tau]} - \|\hat{w}\|^2_{[0,\tau]} - \|z_d\|^2_{[0,k]} + \gamma^2\|w_d\|^2_{[0,k]} - \|\hat{w}_d\|^2_{[0,k]}.$$

With $x(0)=0, P(\tau)=0$ and (42), it follows from the above equation that

$$0 \leq -\|z\|^2_{[0,\tau]} - \|z_d\|^2_{[0,k]} + (\gamma^2 - 1/c)\left(\|w\|^2_{[0,\tau]} + \|w_d\|^2_{[0,k]}\right).$$

This is true for all inputs $w, w_d \in \mathcal{L}_2[0,\tau] \oplus \ell_2[0,k]$ and the corresponding outputs $z, z_d \in \mathcal{L}_2[0,\tau] \oplus \ell_2[0,k]$, which proves that $J(\tau) \leq \sqrt{\gamma^2 - 1/c} < \gamma$ for the case $\tau \neq (k+1)T$.

If $\tau = (k+1)T$, then with $x(0)=0$, it follows that

$$\begin{aligned} 0 &\leq -\|z\|^2_{[0,\tau]} - \|z_d\|^2_{[0,k]} + (\gamma^2 - 1/c)\left(\|w\|^2_{[0,\tau]} + \|w_d\|^2_{[0,k]}\right) - x'(\tau)P(\tau)x(\tau) \\ &= -\|z\|^2_{[0,\tau]} - \|z_d\|^2_{[0,k+1]} + (\gamma^2 - 1/c)\left(\|w\|^2_{[0,\tau]} + \|w_d\|^2_{[0,k]}\right). \end{aligned}$$

Here, the last equality follows from (31). This establishes $J(\tau) < \gamma$ for the case $\tau = (k+1)T$.

Proof of (i) $\Rightarrow$ (ii) *in Theorem* 5.2. Now given that $J(\tau) < \gamma$, we must show that there exists a symmetric, piecewise-differentiable matrix function $P(t)$ satisfying (14)–(16). A brief outline of this proof is as follows. Let $\tau \in (kT, (k+1)T]$, where k is some integer. Note that $P(t)$ is a solution to a differential equation with jumps moving backward in time with a boundary condition at τ. So we first establish the existence of $P(t)$ in the interval $(kT, \tau]$, i.e., the last interval. Then, using the jump equation of the state in (1) we show the existence of $P(kT)$ satisfying the jump equation (15). Next, we show the existence of $P(t)$ in the interval $((k-1)T, kT)$. The existence of $P(t)$ for all $t \in [0,\tau]$ is established by repeating these arguments.

Step 1. For the case $\tau \neq (k+1)T$, the existence of $P(t)$ satisfying (14) in the interval $(kT,\tau]$ follows from [25, Thm. 2.3]. For the case $\tau = (k+1)T$, the numerator of $J(\tau)$ includes a term $z_d'((k+1)T)z_d((k+1)T)$. Clearly,

$$z_d'((k+1)T)z_d((k+1)T) = x_d'((k+1)T)C_d'C_dx_d((k+1)T).$$

Since $\tau = (k+1)T$, this term can be viewed as a penalty on the final state in the cost function $J(\tau)$. Such a cost function has been previously considered in [21]. Indeed, the existence of $P(t)$ satisfying (28) in the interval $(kT,\tau]$ follows from [21, Thm. 2.2] in this case. We will assume hereafter in this proof that $\tau \neq (k+1)T$. It is very easy to extend the proof to the case $\tau = (k+1)T$.

Since the solution to (14) exists in $(kT,\tau]$, it follows from Lemma 6.1 that

$$\inf_w \left[\gamma^2\|w\|^2_{(kT,\tau]} - \|z\|^2_{(kT,\tau]} \,\middle|\, x(kT^+) = x_0\right] = -x_0'P(kT^+)x_0. \tag{43}$$

It is easy to verify that

$$\begin{aligned} &\gamma^2 w_d'(kT)w_d(kT) - z_d'(kT)z_d(kT) - x'(kT^+)P(kT^+)x(kT^+) \\ &= \begin{pmatrix} w_d'(kT) & x'(kT) \end{pmatrix} \begin{pmatrix} M_k & -B_d'P(kT^+)A_d \\ -A_d'P(kT^+)B_d & -C_d'C_d - A_d'P(kT^+)A_d \end{pmatrix} \begin{pmatrix} w_d(kT) \\ x(kT) \end{pmatrix}, \end{aligned}$$

where $M_k := \gamma^2 I - B_d' P(kT^+) B_d$.

Now assume that $w(t) = 0$ for all $t \in [0, kT]$, $w_d(iT) = 0$ for all $i \in \{0, 1, \ldots, (k-1)\}$, and $w_d(kT) \neq 0$. Choose $w(t), t \in (kT, \tau]$ to be the input that achieves the infimum in the first part of Lemma 6.1. Since $x(0) = 0$, it follows that $x(kT) = 0$ and $z_d(kT) = 0$. Using the definition of M_k and the system equations, we obtain

$$\gamma^2 w_d'(kT) w_d(kT) - z_d'(kT) z_d(kT) - x'(kT^+) P(kT^+) x(kT^+) = w_d'(kT) M_k w_d(kT).$$

Using (43), Lemma 6.1, and the fact that $J(\tau) < \gamma$, it follows that there exists an $\epsilon > 0$ such that

$$\begin{aligned} w_d'(kT) M_k w_d(kT) &= \gamma^2 w_d'(kT) w_d(kT) - z_d'(kT) z_d(kT) - x'(kT^+) P(kT^+) x(kT^+) \\ &= \left[\gamma^2 w_d'(kT) w_d(kT) - z_d'(kT) z_d(kT) + \gamma^2 \|w\|^2_{(kT,\tau]} - \|z\|^2_{(kT,\tau]} \,|\, x(kT) = x(t_0) = 0\right] \\ &\geq \epsilon \|w_d(kT)\|^2. \end{aligned}$$

Therefore

$$M_k = (\gamma^2 I - B_d' P(kT^+) B_d) \geq \epsilon I. \tag{44}$$

Now set $P(kT)$ to be

$$P(kT) := A_d' P(kT^+) A_d + C_d' C_d + A_d' P(kT^+) B_d \left(\gamma^2 I - B_d' P(kT^+) B_d\right)^{-1} B_d P(kT^+) A_d.$$

Thus, we have shown the existence of solution $P(t)$ to (14), (15) in the interval $t \in [kT, \tau]$.

Step 2. We now show the existence of solution to (14), (15) on the interval $((k-1)T, kT)$. Since the solution to (14), (15) exists on the interval $[kT, \tau]$, using Lemma 6.1 it follows that

$$\begin{aligned} &\inf_{w, w_d} \left[\gamma^2 \|w\|^2_{(kT,\tau]} - \|z\|^2_{(kT,\tau]} + \left[\gamma^2 w_d'(kT) w_d(kT) - z_d'(kT) z_d(kT)\right] \,|\, x(kT) = x_0\right] \\ &\quad = -x_0' P(kT) x_0. \end{aligned}$$

Let $w(t) = 0$, for all $t \in (0, (k-1)T]$ and $w_d(iT) = 0$ for all $i \in \{1, \ldots, (k-1)\}$. Since $x(0) = 0$, it follows that $x((k-1)T^+) = 0$. Then, using dynamic programming arguments,

$$\begin{aligned} &\inf_{w, w_d} \left[\gamma^2 \|w\|^2_{((k-1)T,\tau]} - \|z\|^2_{((k-1)T,\tau]} \right. \\ &\qquad \left. + \left[\gamma^2 w_d'(kT) w_d(kT) - z_d'(kT) z_d(kT)\right] \,|\, x((k-1)T^+) = 0\right] \\ &\quad = \inf_{w} \left[\gamma^2 \|w\|^2_{((k-1)T,kT]} - \|z\|^2_{((k-1)T,kT]} - x'(kT) P(kT) x(kT) \,|\, x((k-1)T^+) = 0\right]. \end{aligned}$$

Since $J(\tau) < \gamma$, it follows that there exists an $\epsilon > 0$ such that

$$\begin{aligned} &\inf_{w} \left[\gamma^2 \|w\|^2_{((k-1)T,kT]} - \|z\|^2_{((k-1)T,kT]} - x'(kT) P(kT) x(kT) \,|\, x((k-1)T^+) = 0\right] \\ &\qquad \geq \epsilon \|w\|^2_{((k-1)T,kT]}. \end{aligned}$$

Then,

$$\sup_{w} \left\{ \frac{\|z\|^2_{((k-1)T,kT]} + x'(kT) P(kT) x(kT)}{\|w\|^2_{((k-1)T,kT]}} : \|w\|_{((k-1)T,kT]} \neq 0 \right\} < \gamma^2.$$

This is a finite-horizon $\mathcal{H}_\infty$ norm analysis problem with a penalty on the final state. Using [21, Thm. 2.2] it follows that there exists a symmetric matrix function $P(t), t \in ((k-1)T, kT)$ that satisfies (14).

By repeating the above arguments, we can show the existence of $P(t)$ satisfying (14) and (15) in the interval $t \in [0, (k-1)T]$. This completes the proof of (i) $\Leftrightarrow$ (ii) in Theorem 5.2.

Proof of (i) $\Leftrightarrow$ (iii) *in Theorem* 5.2.

This follows using standard arguments using adjoints and is omitted. See [30] for details. □

6.2. Infinite-horizon case.

Proof of Theorems 5.1 *and* 5.3.

We will prove (i) $\Leftrightarrow$ (ii) in Theorems 5.1 and 5.3 next. To maintain clarity and flow in the proofs, we will first prove (i) $\Rightarrow$ (ii) in Theorem 5.3 and then the same implication will be proved for Theorem 5.1. We will then follow this up with the proof of (i) $\Leftarrow$ (ii) in Theorems 5.3 and 5.1.

Proof of (i) $\Rightarrow$ (ii) *in Theorem* 5.3. Let the solution to (14)–(15) at time t with the final time τ and final time condition $P(\tau^+) = 0$ be denoted by $P(t, \tau)$. Consider the system in (1). From the finite-horizon results we know that if $J(\tau) < \gamma$, then the solution to (14)–(16) $P(t, \tau)$ exists for all $t \leq \tau < \infty$. In the infinite-horizon case, it can be shown that if $J(\infty) < \gamma$, then [27], [30]

1. There exists a $\beta > 0$, such that $P(t, \tau) \leq \beta I$ for all $t \in [0, \tau]$ and all $\tau \in [0, \infty)$,
2. $P(t, \tau)$ is nondecreasing as a function of the final time $\tau \in [0, \infty)$.

From items (1) and (2) above, it follows that $P(t, \tau)$ is a bounded function of t and τ and is nondecreasing with respect to τ. Hence,

$$\lim_{\tau \to \infty} P(t, \tau) =: \bar{P}(t)$$

exists and is bounded on $[0, \infty)$. Since ϵ is independent of τ and k in (44), it follows that for all $i \in \{0, 1, 2, \ldots\}$,

$$(\gamma^2 I - B_d' \bar{P}(iT^+) B_d) \geq \epsilon I > 0.$$

Therefore, $(I - \gamma^{-2} B_d' \bar{P}(iT^+) B_d)^{-1}$ is a bounded sequence. It now follows that (using arguments as in [19]) $\bar{P}(t)$ satisfies (14), (15) for all $t \in [0, \infty)$. We now show that Σ_P is stable.

Stability of Σ_P. Consider the system in (1). Since $J(\infty) < \gamma$, there exists an $\epsilon > 0$, such that $J(\infty) \leq \gamma - \epsilon$. Therefore, $J(\tau) \leq \gamma - \epsilon$ for all $\tau \in [0, \infty)$. Then, for any $t_0 \leq \tau$, with $x_0 := x(t_0) = 0$, it follows that

$$(45) \left[\|z\|^2_{[t_0,\tau]} + \|z_d\|^2_{[m,k]} - \gamma^2 (\|w\|^2_{[t_0,\tau]} + \|w_d\|^2_{[m,k]}) \right] \leq -\epsilon \left[\|w\|^2_{[t_0,\tau]} + \|w_d\|^2_{[m,k]} \right],$$

where m is the smallest integer such that $t_0 \leq mT$ and k is the largest integer such that $kT \leq \tau$. Given any inputs $w(t), w_d(iT)$ for $t, iT \in [t_0, \tau]$, and initial condition $x_0 \neq 0$, we can decompose the outputs $z(t)$ and $z_d(iT)$ as

$$z(t) = z_0(t) + z_i(t), \qquad z_d(iT) = z_{d0}(iT) + z_{di}(iT),$$

where z_0, z_{d0} are the homogeneous parts of the solution (depending only on x_0) and z_i, z_{di} are the forced parts (depending only on w, w_d.) Now, since the system (1) is

stable, it follows that there exists a constant $\alpha > 0$ (independent of t_0 and τ) such that

$$\sqrt{\left[\|z_0\|^2_{[t_0,\tau]} + \|z_{d0}\|^2_{[m,k]}\right]} < \alpha\|x_0\|. \tag{46}$$

Using arguments as in [27], it can be established that

(47)

$$\left[\|z\|^2_{[t_0,\tau]} + \|z_d\|^2_{[m,k]} - \gamma^2\|w\|^2_{[t_0,\tau]} - \gamma^2\|w_d\|^2_{[m,k]}\right]$$
$$\leq 2\alpha^2\|x_0\|^2 - \sqrt{\left[\|w\|^2_{[t_0,\tau]} + \|w_d\|^2_{[m,k]}\right]}\left[\epsilon\sqrt{\left[\|w\|^2_{[t_0,\tau]} + \|w_d\|^2_{[m,k]}\right]} - 4\alpha\gamma\|x_0\|\right].$$

Now consider the system Σ_P given in (20) where $P(t)$ is the solution $\bar{P}(t)$ to (14), (15). This system can be viewed as

$$\Sigma_{aux} : \begin{cases} \dot{x}(t) &= Ax(t) + Bw(t); \quad x(0) = 0; \quad t \neq iT, \\ x(iT^+) &= A_d x(iT) + B_d w_d(iT), \end{cases} \tag{48}$$

where the inputs are given by

$$w(t) = \gamma^{-2}B'\bar{P}(t)x(t)\ w_d(iT) = (\gamma^2 I - B_d'\bar{P}(iT^+)B_d)^{-1}B_d'\bar{P}(iT^+)A_d x(iT). \tag{49}$$

Observe that these inputs have the same form as the inputs that achieve the infimum in Lemma 6.1.

We first claim that there exists $\xi > 0$ such that given any initial time t_0 and initial condition x_0, we have

$$\left[\|w\|^2_{[t_0,\infty)} + \|w_d\|^2_2\right] \leq \xi\|x_0\|^2. \tag{50}$$

If not, given any $\eta > 0$ there exist x_0, t_0, τ such that

$$\left[\|w\|^2_{[t_0,\tau]} + \|w_d\|^2_{[m,k]}\right] > \eta^2\|x_0\|^2, \tag{51}$$

where m is the smallest integer such that $t_0 \leq mT$ and k is the largest integer such that $kT \leq \tau$. In particular, let

$$\eta \geq \frac{2\alpha\gamma}{\epsilon}\left[1 + \sqrt{\left(1 + \frac{\epsilon}{2\gamma^2}\right)}\right], \tag{52}$$

where $\epsilon, \alpha > 0$ are as defined before in (45) and (46).

From (48), (51), and (52) it follows that

$$\left[\|z\|^2_{[t_0,\tau]} + \|z_d\|^2_{[m,k]} - \gamma^2\|w\|^2_{[t_0,\tau]} - \gamma^2\|w_d\|^2_{[m,k]}\right] < \left[2\alpha^2 - \eta^2\left(\epsilon - \frac{4\alpha\gamma}{\eta}\right)\right]\|x_0\|^2$$
$$< 0.$$

However, the inputs to the system Σ_{aux} in (48) achieve the infimum in Lemma 6.1. It then follows that

$$x_0'P(t_0,\tau)x_0 = \left[\|z\|^2_{[t_0,\tau]} + \|z_d\|^2_{[m,k]} - \gamma^2\|w\|^2_{[t_0,\tau]} - \gamma^2\|w_d\|^2_{[m,k]}\right] < 0,$$

which contradicts the fact that $P(t_0, \tau) \geq 0$ for all $\tau \in [0, \infty)$ and all $t_0 \in [0, \tau]$. Thus, given any initial time t_0 and initial condition x_0, there exists $\xi > 0$ (independent of t_0) such that (50) is satisfied. Since the system Σ in (1) is stable, it follows for the system (48) there exists $\delta_1, \delta_2 > 0$ such that

$$\|x\|_{[t_0,\infty)} \leq \left[\delta_1 \|w\|_{[t_0,\infty)} + \delta_2 \|w_d\|_2\right]. \tag{53}$$

Since the inputs w and w_d are chosen as given by (49), it follows from (50) that

$$\|x\|_{[t_0,\infty)} \leq (\delta_1 + \delta_2)\sqrt{\xi}\|x_0\|$$

and the constants are independent of the initial time instant t_0. By [9, Thm. 3, p. 190] it follows that Σ_P is stable. This proves (i) $\Rightarrow$ (ii) in Theorem 5.3.

Proof of (i) $\Rightarrow$ (ii) *in Theorem* 5.1. Since the coefficients of the differential and difference equations (14)–(15) are constant, it follows that

$$P(t + T, \tau + T) = P(t, \tau).$$

Now, letting $\tau \to \infty$, it follows that $\bar{P}(t)$ is periodic with a period T. We can write $\bar{P}((i+1)T)$ in terms of $\bar{P}(iT^+)$ by solving (14) over one period with initial condition $\bar{P}(iT^+)$ as

$$\bar{P}((i+1)T) = (\Pi_{21}(T) + \Pi_{22}(T)\bar{P}(iT^+))(\Pi_{11}(T) + \Pi_{12}(T)\bar{P}(iT^+))^{-1}, \tag{54}$$

where $\Pi(t), t \in [0, T]$ is as defined in (8). Also, using (15) we can write $\bar{P}((i+1)T)$ in terms of $\bar{P}((i+1)T^+)$ as

$$\bar{P}((i+1)T) = A_d' \bar{P}((i+1)T^+)\left(I - \gamma^{-2} B_d B_d' \bar{P}((i+1)T^+)\right)^{-1} A_d + C_d' C_d. \tag{55}$$

Since $\bar{P}(t)$ is periodic, it follows that $\bar{P}(iT^+) = \bar{P}((i+1)T^+) =: \tilde{P}$. Then, using (54) and (55) it follows that

$$\begin{aligned}(\Pi_{21}(T) + \Pi_{22}(T)\tilde{P}) = A_d' \tilde{P}\left(I - \gamma^{-2} B_d B_d' \tilde{P}\right)^{-1} A_d(\Pi_{11}(T) + \Pi_{12}(T)\tilde{P}) \\ + C_d' C_d(\Pi_{11}(T) + \Pi_{12}(T)\tilde{P}).\end{aligned} \tag{56}$$

Thus, $\tilde{P}$ defined by (56) is the solution to (14), (15) at $t = iT^+$ for all $i \in \{0, 1, 2, \ldots\}$. Using the fact that $\Pi(T)$ defined in (8) is a symplectic matrix, after some tedious algebra, it can be verified that we can write (56) as

$$H_1 \begin{pmatrix} I \\ \tilde{P} \end{pmatrix} = H_2 \begin{pmatrix} I \\ \tilde{P} \end{pmatrix} F_P, \tag{57}$$

where H_1, H_2, and F_P are as defined in Theorem 5.1.

Consider the system Σ_P given in (20) where $P(t)$ is the solution $\bar{P}(t)$ to (14), (15). Since $\bar{P}(t)$ is periodic, it follows that Σ_P is a stable periodic system. The key observation is that F_P is the state transition matrix of Σ_P from time instant 0^+ to T^+. To verify this, we first need to compute the state transition matrix of

$$\dot{x}(t) = (A + \gamma^{-2} B B' \bar{P}(t))x(t) \tag{58}$$

from $t = 0^+$ to $t = T$. Consider the system of equations

$$\begin{pmatrix} \dot{x}(t) \\ \dot{p}(t) \end{pmatrix} = \begin{pmatrix} A & \gamma^{-2}BB' \\ -C'C & -A' \end{pmatrix} \begin{pmatrix} x(t) \\ p(t) \end{pmatrix}.$$

Then $\Pi(\hat{t})$ as defined in (8) is the state transition matrix of this system of equations from 0 to $\hat{t}$ for $\hat{t} \in [0, T]$. Define the change of variables

$$\begin{pmatrix} r(t) \\ s(t) \end{pmatrix} = \begin{pmatrix} I & 0 \\ -\bar{P}(t) & I \end{pmatrix} \begin{pmatrix} x(t) \\ p(t) \end{pmatrix}.$$

Then it is easy to verify that in the new variables

$$\begin{pmatrix} \dot{r}(t) \\ \dot{s}(t) \end{pmatrix} = \begin{pmatrix} A + \gamma^{-2}BB'\bar{P}(t) & \gamma^{-2}BB' \\ 0 & -\left(A + \gamma^{-2}BB'\bar{P}(t)\right)' \end{pmatrix} \begin{pmatrix} r(t) \\ s(t) \end{pmatrix}. \tag{59}$$

Let the state transition matrix of this system of differential equations be $\Pi_P(t, \tau)$. Then simple algebra shows that

$$\begin{aligned} \Pi_P(\hat{t}, 0) &= \begin{pmatrix} I & 0 \\ -\bar{P}(\hat{t}) & I \end{pmatrix} \Pi(\hat{t}) \begin{pmatrix} I & 0 \\ \bar{P}(0^+) & I \end{pmatrix} \\ &= \begin{pmatrix} \Pi_{11}(\hat{t}) + \Pi_{12}(\hat{t})\bar{P}(0^+) & * \\ 0 & * \end{pmatrix}, \end{aligned} \tag{60}$$

where $*$ represent quantities of no interest. Since (59) is upper triangular, it follows that the state transition matrix of the system in (58) from $t = 0^+$ to $t = \hat{t}$ is given by

$$\Phi_{A+\gamma^{-2}BB'\bar{P}(t)}(\hat{t}, 0^+) := \Pi_{11}(\hat{t}) + \Pi_{12}(\hat{t})\bar{P}(0^+) = \Pi_{11}(\hat{t}) + \Pi_{12}(\hat{t})\tilde{P}, \tag{61}$$

where the last equality follows from the fact that $\bar{P}(0^+) = \tilde{P}$. Moreover, since $(\Pi_{11}(\hat{t}) + \Pi_{12}(\hat{t})\tilde{P})$ is the transition matrix of the system in (58), it is invertible for all $\hat{t} \in [0, T]$. Now the state transition matrix of the system Σ_P from the time instant 0^+ to T^+ is given by

$$\begin{aligned} \Phi_P(T^+, 0^+) &:= (I - \gamma^{-2}B_dB_d'\tilde{P})^{-1}A_d\Phi_{A+\gamma^{-2}BB'\bar{P}(t)}(T, 0^+) \\ &= (I - \gamma^{-2}B_dB_d'\tilde{P})^{-1}A_d\left(\Pi_{11}(T) + \Pi_{12}(T)\tilde{P}\right) = F_P. \end{aligned}$$

Since the system Σ_P is exponentially stable and periodic, it follows that F_P is a stable matrix and hence all its eigenvalues are within the open unit disk. This concludes the proof of (i) $\Rightarrow$ (ii) in Theorem 5.1.

Proof of (ii) $\Rightarrow$ (i) *in Theorem* 5.3. The proof of this part is along the same lines as that of the proof of (ii) $\Rightarrow$ (i) in Theorem 5.2. Observe that since the system Σ given by (1) is stable, it follows that for all $w, w_d \in \mathcal{L}_2[0, \infty) \oplus \ell_2$,

$$\lim_{t \to \infty} x(t) = 0, \tag{62}$$

where $x(t)$ is the state of Σ at time $t \in [0, \infty)$. Also, since P is bounded, Σ_P is stable, and $(I - \gamma^{-2}B_d'P(iT^+)B_d)^{-1}$ is a bounded sequence, it follows that there exists a $c > 0$ such that for the system Σ_w in (40),

$$\|w\|_2^2 + \|w_d\|_2^2 \leq c\left[\|\hat{w}\|_2^2 + \|\hat{w}_d\|_2^2\right]. \tag{63}$$

Then, proceeding as in the proof of Theorem 5.2, we obtain

$$\left[\lim_{\tau\to\infty} x'(\tau)P(\tau)x(\tau)\right] - x'(0)P(0)x(0) = -\|z\|_2^2 + \gamma^2\|w\|_2^2 - \|\hat{w}\|_2^2 - \|z_d\|_2^2 + \gamma^2\|w_d\|_2^2 - \|\hat{w}_d\|_2^2.$$

Now using (62), (63), and $x(0) = 0$, it follows that

$$0 \le -\|z\|_2^2 - \|z_d\|_2^2 + (\gamma^2 - 1/c)\left(\|w\|_2^2 + \|w_d\|_2^2\right)$$

for all inputs $w, w_d \in \mathcal{L}_2[0,\infty] \oplus \ell_2$ and the corresponding outputs $z, z_d \in \mathcal{L}_2[0,\infty] \oplus \ell_2$, which proves that $J(\infty) < \gamma$.

Proof of (ii) $\Rightarrow$ (i) *in Theorem* 5.1. We first show that if a solution to (10) exists with $\left(\Pi_{11}(t) + \Pi_{12}(t)\tilde{P}\right)$ invertible for all $t \in [0,T]$, then a solution $P(t)$ to (14), (15) for $t \in [0,\infty)$ also exists and is bounded. Set $P(0^+) = \tilde{P}$. Define

$$P(0) := A_d'\tilde{P}A_d + C_d'C_d + A_d'\tilde{P}B_d\left(\gamma^2 I - B_d'\tilde{P}B_d\right)^{-1}B_d'\tilde{P}A_d.$$

Since $\left(\Pi_{11}(t) + \Pi_{12}(t)\tilde{P}\right)$ is invertible, we can define $P(t), t \in (0,T]$ as

$$P(t) := \left(\Pi_{21}(t) + \Pi_{22}(t)\tilde{P}\right)\left(\Pi_{11}(t) + \Pi_{12}(t)\tilde{P}\right)^{-1}.$$

It is easily verified that $P(t)$ satisfies (14) for $t \in (0,T]$. Moreover, extend $P(t)$ to $t \in [0,\infty)$ as a periodic function:

$$P(t + kT) = P(t), \quad t \in [0,T] \quad k \in \{0,1,2,\ldots\}.$$

It follows that $P(iT^+) = \tilde{P}$ for all $i \in \{0,1,\ldots\}$. This $P(t)$ satisfies (14), (15) and is bounded for all $t \in [0,\infty)$. Also, since $\left(I - \gamma^{-2}B_d'\tilde{P}B_d\right) > 0$, it follows that $\left(I - \gamma^{-2}B_d'P(iT^+)B_d\right) > 0$ for all $i \in \{0,1,\ldots\}$ and $\left(I - \gamma^{-2}B_d'P(iT^+)B_d\right)^{-1}$ is a bounded sequence. As shown above, F_P is the state transition matrix from kT^+ to $(k+1)T^+$ of the system Σ_P. If F_P is a stable matrix, then it follows that Σ_P is stable. So (14), (15) has a bounded solution over the time interval $[0,\infty)$ and the system Σ_P is stable. From the proof of (ii) $\Rightarrow$ (i) in Theorem 5.3, it follows that $J(\infty) < \gamma$.

The proof of (i) $\Leftrightarrow$ (iii) in Theorems 5.3 and 5.1 can be obtained by duality and arguments similar to those used in the proof of (i) $\Leftrightarrow$ (ii) in Theorems 5.3 and 5.1. For the sake of brevity, this proof and the proofs of the corollaries are omitted in this paper. The interested reader can find the details of this proof in [30]. □

7. Conclusion. We have defined an $\mathcal{H}_\infty$-like worst case performance measure for linear systems with finite jumps. We have given necessary and sufficient conditions for the performance measure to be less than a prespecified level. Applying these results to sampled-data systems, we have given an iterative method to compute the $\mathcal{L}_2$-induced norm of a sampled-data system. The results of this paper can be easily extended to the case of a sampled-data system with a generalized hold function.

Acknowledgments. The authors gratefully acknowledge Dr. Anton Stoorvogel for noticing an error in a preliminary draft of this paper.

THE EQUIVALENCE OF EXTREMALS IN DIFFERENT REPRESENTATIONS OF UNBOUNDED CONTROL PROBLEMS*

J. WARGA† AND Q. J. ZHU†

Abstract. Control problems defined by ordinary differential equations with right-hand sides that are unbounded functions of the control variables are considered. These problems can be reformulated in terms of bounded (relaxed or unrelaxed) differential inclusions by introducing a new independent variable (which is a function of the old state and control functions). These differential inclusions can have different "compact control" representations depending on both the choice of the new independent variable and on the different parametrizations of the set-valued right-hand sides.

The extremals of different (relaxed or unrelaxed) "compact control" representations of such unbounded problems are compared. It is proved that, for a representation that is Lipschitzian in the state variables, the extremals corresponding to different choices of the independent variable are in a one-to-one correspondence, with the corresponding state functions having the same images. If different representations that correspond to different choices of the independent variable and parametrization are compared, then the one-to-one correspondence applies to the sets of "Lojasiewicz extremals" (that is, state functions that remain extremal for every control that generates them) provided the representations are, except for a scalar factor, continuously differentiable in the state variables and satisfy certain "nondegeneracy" conditions. The latter results rely heavily on a theorem of S. Lojasiewicz, Jr., on the equivalence of extremals, which we generalize in certain respects.

Key words. controlled ordinary differential equations, unbounded controls, control representations of differential inclusions, rescaled independent variables, equivalent extremals

AMS subject classification. 49B10

1. Introduction.

A classical problem of the optimal control of autonomous differential equations is the search for the infimum of $h_0(y(1))$ subject to $h_1(y(1)) = 0$ and

$$y(t) = \int_0^t f(y(s), u(s))ds \quad \forall\, t \in [0,1], \tag{1.1}$$

where u is a measurable mapping of [0,1] into a topological space U and $f : \mathbf{R}^n \times U \mapsto \mathbf{R}^n$. We refer to a set $\mathcal{A}$ of solutions (y,u) of (1.1), or to the corresponding set of functions y, as *nearly optimal* if there exist positive numbers c' and c'' such that $\mathcal{A}$ contains all the solutions of (1.1) for which $h_0(y(1)) \leq c'$ and $\mid h_1(y(1)) \mid \leq c''$. If f is continuous, $f(\cdot, r)$ locally Lipschitzian uniformly for $r \in U$, U a compact metric space, (1.1) admits at least one solution for which $h_1(y(1)) = 0$, and some set of nearly optimal solutions y is bounded, then the corresponding relaxed differential inclusion

$$y'(t) \in \overline{co} f(y(t), U) \quad \text{a.e. in } [0,1], \qquad y(0) = 0$$

admits an optimal solution $\bar{y}$ and a *minimizing sequence* $((y_j, u_j))$ such that (y_j, u_j) satisfies (1.1) and

$$\lim_j (h_0, h_1)(y_j(1)) = (h_0, h_1)(\bar{y}(1)) = (h_0(\bar{y}(1)), 0).$$

*Received by the editors July 6, 1992; accepted for publication (in revised form) January 26, 1993.

†Department of Mathematics, Northeastern University, Boston, Massachusetts 02115.

If U is not compact and f is unbounded, as is usually the case in problems of the calculus of variations, then the existence of a relaxed solution can sometimes be assured if f satisfies certain "growth conditions." However, in the absence of such growth conditions, it may happen that a minimizing sequence $((y_j, u_j))$ yields functions y_j that converge, in some special sense, to a discontinuous function. Such cases were investigated by Neustadt [N], Rishel [R], and Schmaedeke [S] for certain impulsive controls u, and specifically when f is linear in certain unbounded scalar components of u with uniformly bounded L^1 norms while the other components of u have values confined to a compact set. A more general situation is one when there exists a number L such that, for all (y, u) in some nearly optimal set of solutions, we have

$$\int_0^1 \mid y'(t) \mid dt \leq L$$

and, as a consequence, $y([0,1]) \subset \text{int } V$, where V is the closed ball of center 0 and radius $L + 1$ in $\mathbf{R}^n$. If this is the case, the problem can be approached [W2], [W3, §VI.4] by treating (t, y) as a state function of a new independent variable θ. Using this approach, we select a continuous function $\varphi : V \times U \mapsto (0, \infty)$ such that, for some positive numbers c_1 and c_2,

$$c_1 \leq \varphi(v, r)^{-1}(\mid f(v, r) \mid +1) \leq c_2 \quad \forall\, v \in V, \quad r \in U.$$

We then choose $\theta = \int_0^t \varphi(y(s), u(s))ds$ as the new independent variable, and thus consider the system

$$d\tau/d\theta = \varphi(\eta(\theta), \tilde{u}(\theta))^{-1}, \qquad d\eta/d\theta = \varphi(\eta(\theta), \tilde{u}(\theta))^{-1} f(\eta(\theta), \tilde{u}(\theta)), \tag{1.2}$$

with the initial conditions $\tau(0) = 0, \eta(0) = 0$, on some "free" interval $[0, \alpha]$, where (τ, η) represents (t, y) as a function of $\theta, \tilde{u}(\theta) \in U$, and the condition $t \in [0, 1]$ is equivalent to $\tau(\alpha) = 1$. In system (1.2), the right-hand sides are bounded and the arguments of [W3, §VI.4] provide a way of constructing a minimizing sequence $((y_j, u_j))$ for (1.1) once an optimal relaxed solution of system (1.2) is available. The existence of such an optimal relaxed solution of system (1.2), with α in the interior of some compact interval I depending on L, c_1 and c_2, is assured so long as (1.1) admits at least one solution (y, u) with $h_1(y(1)) = 0$.

Thus system (1.2) and its relaxed version, with endpoint restrictions

$$\tau(\alpha) = 1, \qquad h_1(\eta(\alpha)) = 0, \tag{1.3}$$

become the object of our study. To simplify notation, we reformulate the corresponding control problem (with n, h_0, h_1, f, and V redefined accordingly) as one of searching for the infimum of $h_0(y(\alpha))$ subject to $h_1(y(\alpha)) = 0$ and

$$y(t) = \int_0^t \varphi(y(s), u(s))^{-1} f(y(s), u(s))ds \quad \forall\, t \in [0, \alpha]. \tag{1.4}$$

This formulation encompasses the "fixed time" problem defined by (1.1), in which case the redefined function f has one component equal to 1 (and corresponding to the equation $dt/dt = 1$). However, we may also consider a corresponding "free time" problem, in which the interval of integration is subject to choice (so that we no longer

require $\tau(\alpha) = 1$), and thus we make no assumption about a component of f being equal to 1 except in Theorem 3.1.

To search for a relaxed solution, it is natural to seek a representation of

$$F_\varphi(v) = \text{ closure } \{\varphi(v,r)^{-1} f(v,r) \mid r \in U\} \quad \forall\, v \in V$$

in the "control" form

$$F_\varphi(v) = f^\#(v, \Omega),$$

where Ω is a compact metric space, $f^\#$ is continuous, and $f^\#(\cdot, \omega)$ has a Lipschitz constant independent of ω. If we can find such a representation, then we are dealing with a conventional (possibly nonsmooth) optimal control problem in which the candidates for optimal solutions are found among the relaxed extremals of the problem.

Different choices of functions φ and $f^\#$ may yield different sets of extremals (each of which contains the optimal solutions). It is our purpose to discuss conditions under which extremals corresponding to such different choices are equivalent in the sense that the corresponding state functions transform into one another by a (nonlinear) rescaling of the independent variable. In §2, we consider the (smooth or nonsmooth) equation obtained from (1.4) by a mapping of a dense subset of a compact metric space onto the topological space U. We then show, in Theorem 2.5, that the sets of extremals corresponding to different choices of the function φ are in a one-to-one correspondence as described above. In Theorems 3.1 and 3.3 we consider not only different choices of φ but also different representations of $F_\varphi(v)$ in the control form $f^\#(v, \Omega)$. Our important tool in this endeavor is a (modified form of a) theorem of Lojasiewicz [L2] on the equivalence of "extremals(L)" corresponding to different C^1 representations of the same "nondegenerate" and bounded differential inclusion. This limits us, however, to representations $f^\#(v, \omega)$ that are (except for a scalar factor) C^1 in the first argument, a counterexample of Lojasiewicz [L1, Ex. 2, p. 8] showing that his result is invalid in the general nonsmooth case. Since another counterexample of Lojasiewicz [L2, Ex. 6, p. 251] demonstrates that his theorem is not valid in general for unbounded controls, we can also consider our Theorems 3.1 and 3.3 as variants of Lojasiewicz'es theorem applicable to a class of unbounded control problems that fall outside the scope of his theorem. We also derive Theorem 3.2, a variant of Lojasiewicz's "bounded control" theorem, and in certain respects a generalization of it. In §4, we present some comments and illustrative examples. Finally, in the Appendix, we adapt Lojasiewicz's arguments to prove the modified form of his theorem that is needed for our purposes.

2. A compactification of the parametrized problem. We henceforth make the following assumption.

Assumption 2.1. U is a topological space, $V \subset \mathbf{R}^n$, and $f : V \times U \mapsto \mathbf{R}^n$ continuous.

We first consider a representation of the set $F(v)$ introduced in [W3, p. 375–376]. We denote by $|\cdot|$ the euclidean norm.

DEFINITION 2.2.

2.2.1. *The set* Φ. We denote by Φ the set of all continuous functions $\varphi : V \times U \mapsto (0, \infty)$ such that

(a) the function $v \mapsto \varphi(v,r)^{-1}$ has a Lipschitz constant independent of r, and

(b) there exist positive constants c_φ and d_φ for which

$$c_\varphi \le \varphi(v,r)^{-1}(|\, f(v,r) \mid +1) \le d_\varphi \quad \forall\ v \in V, \quad r \in U.$$

2.2.2. *The set* $\mathcal{F}(\Omega, P, \varphi_0)$. Let $\varphi_0 \in \Phi$, Ω be a compact metric space, Ω', a dense subset of Ω, and $P : \Omega' \mapsto U$ a continuous surjection. We set, for all $v \in V$, $\omega \in \Omega'$ and $\varphi \in \Phi$,

$$f_\varphi(v,\omega) = \varphi(v, P(\omega))^{-1} f(v, P(\omega)), \qquad K_\varphi(v,\omega) = \varphi(v, P(\omega))/\varphi_0(v, P(\omega)).$$

We denote by $\mathcal{F}(\Omega, P, \varphi_0)$ the set of all $\varphi \in \Phi$ such that the function

$$(v,\omega) \mapsto (f_\varphi(v,\omega), K_\varphi(v,\omega)) : V \times \Omega' \mapsto \mathbf{R}^n \times \mathbf{R}$$

has a continuous extension to $V \times \Omega$ that is locally Lipschitzian as a function of v uniformly for $\omega \in \Omega$. It follows that, for every choice of $\varphi, \psi \in \mathcal{F}(\Omega, P, \varphi_0)$, the function

$$(v,\omega) \mapsto K_{\varphi,\psi}(v,\omega) := \varphi(v, P(\omega))/\psi(v, P(\omega)) : V \times \Omega' \mapsto (0,\infty)$$

has a continuous extension to $V \times \Omega$ that is bounded between two positive constants.

DEFINITION 2.3. *Derivate containers and generalized Jacobians.* Let $W \subset \mathbf{R}^p$, $w_0 \in \operatorname{int} W$ and $h : W \mapsto \mathbf{R}^k$ be locally Lipschitzian. We refer to a set $\Lambda h(w_0)$ as *a derivate container* of h at w_0 if there exists a sequence (h_j) of C^1 functions from a neighborhood $\mathcal{N}$ of w_0 to $\mathbf{R}^k$ converging uniformly to h on $\mathcal{N}$ and such that

$$\Lambda h(w_0) = \cap_{\epsilon>0} \text{ closure } \{h_j'(w) \mid \mid w - w_0 \mid < \epsilon,\ j > 1/\epsilon\}.$$

We denote by $\partial h(w_0)$ Clarke's *generalized Jacobian of* h at w_0 [C, p. 69] defined by

$$\partial h(w_0) := \cap_{\epsilon>0} \overline{co}\ \{h'(w) \mid h'(w) \text{ exists}, \mid w - w_0 \mid < \epsilon\}.$$

(It is well known [W6, Thm. 4, p. 549] that $\partial h(w_0)$ is the smallest convex derivate container of h at w_0 but examples can be given [W5, pp. 17–18], [W7, pp. 594–595] of nonconvex derivate containers $\Lambda h(w_0)$ that are proper subsets of $\partial h(w_0)$.) If h depends on an additional variable z, we denote by $\Lambda_1 h(w_0, z)$ or $\Lambda_v h(v, z) \mid_{v=w_0}$ ($\partial_1 h(w_0, z)$ or $\partial_v h(v, z) \mid_{v=w_0}$) a ("partial") derivate container (generalized Jacobian) of $h(\cdot, z)$ at w_0.

DEFINITION 2.4. *Extremals.* Let $W \subset \mathbf{R}^k$, Ω be a compact metric space, $g : W \times \Omega \mapsto \mathbf{R}^k$ continuous, $h_0 : W \mapsto \mathbf{R}$ and $h_1 : W \mapsto \mathbf{R}^m$ locally Lipschitzian, and the function $w \mapsto g(w,\omega)$ locally Lipschitzian uniformly for $\omega \in \Omega$. Let $\operatorname{rpm}(\Omega)$ be the set of Radon probability measures on Ω with the weak star topology of $C(\Omega)^*$, and let $\mathcal{S}(\Omega)$ (the set of relaxed controls corresponding to Ω) be the set of all measurable functions $\sigma : \mathbf{R} \mapsto \operatorname{rpm}(\Omega)$. For $\sigma \in \mathcal{S}(\Omega)$, we write

$$g(w, \sigma(t)) := \int g(w,\omega)\sigma(t)(d\omega),$$

and denote by the superscript ^{T} the transpose of a matrix or a column vector. As is well known, it suffices for control problems defined by (i) below to restrict ourselves to relaxed controls $\sigma \in \mathcal{S}'(\Omega)$, denoted by $[\rho, \theta, k]$, such that, for each t, $\sigma(t)$ is concentrated at k points $\rho_1(t), \ldots, \rho_k(t)$ with masses $\theta_1(t), \ldots, \theta_k(t)$. We henceforth use the term "relaxed control" to mean an element of $\mathcal{S}'(\Omega)$.

With the functions h_0 and h_1 fixed, we refer to a triplet

$$(y, \sigma, \alpha) \in C([0,\alpha], \mathbf{R}^n) \times \mathcal{S}'(\Omega) \times (0,\infty)$$

as a *g-extremal* if (y, σ, α) satisfies

(i) $$y(t) = \int_0^t g(y(s), \sigma(s))ds \quad \forall\, t \in [0, \alpha]$$

and there exist a nonzero vector $(\lambda_0, \lambda_1) \in [0, \infty) \times \mathbf{R}^m$, a derivate container

$$\Lambda(h_0, h_1)(y(\alpha))$$

of (h_0, h_1) at $y(\alpha)$, and an absolutely continuous function $p : [0, \alpha] \mapsto \mathbf{R}^k$ such that

(ii) $$p(\alpha)^T \in (\lambda_0, \lambda_1)^T \Lambda(h_0, h_1)(y(\alpha));$$

(iii) $$p'(t)^T \in -p(t)^T \partial_1 g(y(t), \sigma(t)) \text{ a.e. in } [0, \alpha];$$

(iv) $$H(t) := p(t)^T g(y(t), \sigma(t)) = \min_{\omega \in \Omega} p(t)^T g(y(t), \omega) \text{ a.e. in } [0, \alpha];$$

(v) $$H(t) = 0 \text{ a.e. in } [0, \alpha].$$

(If $v \mapsto g(v, \omega)$ is C^1 and g_v continuous then the constancy of $H(t)$ follows from relations (iii) and (iv) [W1, Thm. 5.1, p. 138] while the vanishing of $H(t)$ then follows from support conditions—a slightly generalized form of relation (ii)—for a problem with variable initial and end conditions (taking account of the fact that the time interval is "free"). In the more general case, however, relation (v) appears to be an independent consequence of optimality [W4, (2.2.4), p. 46], [C, p. 152].)

We refer to a homeomorphism $s : A \mapsto B$ as bi-Lipschitzian if both s and s^{-1} are Lipschitzian.

THEOREM 2.5. *Let $\Phi, \Omega, P,$ and $\mathcal{F}(\Omega, P, \varphi_0)$ be as in Definition 2.2, $\varphi, \psi \in \mathcal{F}(\Omega, P, \varphi_0)$, $\sigma = [\rho, \theta, k]$, and (y, σ, α) an f_φ-extremal corresponding to a choice of $\lambda_0, \lambda_1, \Lambda(h_0, h_1)(y(\alpha))$ and p. Then there exist a strictly increasing bi-Lipschitzian homeomorphism*

$$\tau \mapsto s(\varphi, \psi, y, \sigma, \alpha)(\tau) = s(\tau)$$

of $[0, s^{-1}(\alpha)]$ onto $[0, \alpha]$ and $\kappa = (\kappa_1, \ldots, \kappa_k)$ such that, for

$$\tilde{y} = y \circ s, \ \tilde{\sigma} = [\rho \circ s, \kappa, k], \ \tilde{\alpha} = s^{-1}(\alpha),$$

$(\tilde{y}, \tilde{\sigma}, \tilde{\alpha})$ is an f_ψ-extremal corresponding to the choice of

$$\lambda_0, \lambda_1, \Lambda(h_0, h_1)(\tilde{y}(\tilde{\alpha}))(= \Lambda(h_0, h_1)(y(\alpha))) \text{ and } \tilde{p} = p \circ s.$$

Furthermore, $s(\psi, \varphi, \tilde{y}, \tilde{\sigma}, \tilde{\alpha})$ is the inverse of $s(\varphi, \psi, y, \sigma, \alpha)$ and the inverse correspondence yields (y, σ, α) as corresponding to $(\tilde{y}, \tilde{\sigma}, \tilde{\alpha})$. Thus there exists a one-to-one correspondence between f_φ-extremals and f_ψ-extremals defined by a rescaling of the independent variable in y and ρ_j and a modification of the weights associated with ρ_j.

Proof. We observe that the functions f_φ, f_ψ and $K = K_{\psi,\varphi}$ satisfy the relation

$$f_\varphi(v, \omega) = K(v, \omega) f_\psi(v, \omega) \quad \forall\, v \in V, \quad \omega \in \Omega.$$

Now let

$$\nu(t) = 1/K(y(t), \sigma(t)) = 1/\Sigma_{j=1}^{k} \theta_j(t) K(y(t), \rho_j(t)) \quad \forall\, t \in [0, \alpha],$$

and let $\gamma(t) = \int_0^t \nu(\tau) d\tau$. Then γ is a strictly increasing Lipschitzian function on $[0, \alpha]$ and has a Lipschitzian inverse $s = \gamma^{-1}$. We observe that

$$s'(\gamma(t))\gamma'(t) = s'(\gamma(t))\nu(t) = 1 \text{ a.e. in } [0, \alpha];$$

hence $s'(\beta) = 1/\nu(s(\beta))$ almost everywhere in $[0, \gamma(\alpha)]$. Let

$$\kappa_j(\beta) = \nu(s(\beta))^{-1} \theta_j(s(\beta)) K(y(s(\beta)), \rho_j(s(\beta))) \quad \forall\, j = 1, \ldots, k.$$

Then

$$\begin{aligned}
\tilde{y}'(\beta) &= y'(s(\beta))/\nu(s(\beta)) = \nu(s(\beta))^{-1} \Sigma_{j=1}^{k} \theta_j(s(\beta)) f_\varphi(y(s(\beta)), \rho_j(s(\beta))) \\
&= \nu(s(\beta))^{-1} \Sigma_{j=1}^{k} \theta_j(s(\beta)) K(y(s(\beta)), \rho_j(s(\beta))) f_\psi(y(s(\beta)), \rho_j(s(\beta))) \\
&= \Sigma_{j=1}^{k} \kappa_j(\beta) f_\psi(y(s(\beta)), \rho_j(s(\beta))) = f_\psi(\tilde{y}(\beta), \tilde{\sigma}(\beta)) \text{ a.e. in } [0, \tilde{\alpha}].
\end{aligned}$$

Thus $(\tilde{y}, \tilde{\sigma}, \tilde{\alpha})$ satisfies (i) of Definition 2.4 for $g = f_\psi$.

Now let

$$\tilde{p}(\beta) = p(s(\beta)), \ \tilde{\rho}(\beta) = \rho(s(\beta)) \quad \forall\, \beta \in [0, \tilde{\alpha}].$$

Then

$$\tilde{p}(\tilde{\alpha})^T = p(\alpha)^T \in (\lambda_0, \lambda_1)^T \partial(h_0, h_1)(y(\alpha)) = (\lambda_0, \lambda_1)^T \partial(h_0, h_1)(\tilde{y}(\tilde{\alpha}))$$

and, for almost all $\beta \in [0, \tilde{\alpha}]$ and all $j = 1, \ldots, k$, we have

$$H(s(\beta)) = \tilde{p}(\beta)^T f_\varphi(\tilde{y}(\beta), \tilde{\rho}_j(\beta)) = \min_{\omega \in \Omega} \tilde{p}(\beta)^T f_\varphi(\tilde{y}(\beta), \omega) = 0;$$

hence

$$\tilde{H}(\beta) := \tilde{p}(\beta)^T f_\psi(\tilde{y}(\beta), \tilde{\rho}_j(\beta)) = \min_{\omega \in \Omega} \tilde{p}(\beta)^T f_\psi(\tilde{y}(\beta), \omega) = 0.$$

Finally, we observe that if, for $i = 1, \ldots, k$, M_i and N_i are real-valued and Lipschitzian near w and $M_i(w) = 0$ then

$$\partial(\Sigma_{i=1}^{k} M_i N_i)(w) = \partial_v [\Sigma_{i=1}^{k} N_i(w) M_i(v)]_{v=w}.$$

It follows, using the relations

$$f_\varphi = K f_\psi \text{ and } H(t) = p(t)^T (K f_\psi)(y(t), \rho_j(t)) = 0 \text{ a.e. in } [0, \alpha],$$

that

$$\begin{aligned}
&p(t)^T \partial_1 [\Sigma_{j=1}^{k} \theta_j(t) (K f_\psi)(y(t), \rho_j(t))] \\
&\quad = \partial_1 [\Sigma_{j=1}^{k} \theta_j(t) (K p(t)^T f_\psi)(y(t), \rho_j(t))] \\
&\quad = \partial_v [\Sigma_{j=1}^{k} \theta_j(t) K(y(t), \rho_j(t)) p(t)^T f_\psi(v, \rho_j(t))]_{v=y(t)} \\
&\quad = \partial_1 [\Sigma_{j=1}^{k} \nu(t) \kappa_j(s^{-1}(t)) p(t)^T f_\psi(v, \rho_j(t))]_{v=y(t)} \text{ a.e. in } [0, \alpha];
\end{aligned}$$

hence

$$\begin{aligned}\tilde{p}'(\beta)^T &= p'(s(\beta))^T s'(\beta) = \nu \circ s(\beta)^{-1} p'(s(\beta))^T \\ &\in -\nu \circ s(\beta)^{-1} p(s(\beta))^T \partial_1 (K f_\psi)(y \circ s(\beta), \sigma \circ s(\beta)) \\ &= -\nu \circ s(\beta)^{-1} p(s(\beta))^T \partial_1 [\Sigma_{j=1}^k \theta_j(s(\beta))(K f_\psi)(y(s(\beta)), \rho_j(s(\beta)))] \\ &= -\partial_1 [\Sigma_{j=1}^k \kappa_j(\beta) p(s(\beta))^T f_\psi(y(s(\beta)), \rho_j(s(\beta)))] \\ &= -\tilde{p}(\beta)^T \partial_1 f_\psi(\tilde{y}(\beta), \tilde{\sigma}(\beta)) \text{ a.e. in } [0, \tilde{\alpha}].\end{aligned}$$

This completes the proof that $(\tilde{y}, \tilde{\sigma}, \tilde{\alpha})$ is an f_ψ-extremal.

Now let us apply the same argument, with $\varphi, y, \sigma, \alpha, K_{\psi,\varphi}$ and $\psi, \tilde{y}, \tilde{\sigma}, \tilde{\alpha}, K_{\varphi,\psi}$ interchanged. Then $K_{\varphi,\psi} = 1/K$ and, setting

$$\tilde{\gamma}(\beta) = \int_0^\beta K(\tilde{y}(b), \tilde{\sigma}(b)) db, \ \beta = \gamma(t) = s^{-1}(t),$$

we obtain

$$\tilde{\gamma}'(\gamma(t)) = K(y(t), \sigma(t)) = 1/\gamma(t) \ \text{ a.e.;}$$

hence $\tilde{\gamma}'(\gamma(t)) = t$ almost everywhere and $\tilde{\gamma} = s$. We can also verify that the control corresponding to $\tilde{\sigma}$ is σ. This shows that the correspondence of the f_φ-extremals and the f_ψ-extremals is one-to-one, with $s(\psi, \varphi, \tilde{y}, \tilde{\sigma}, \tilde{\alpha})$ the inverse of $s(\varphi, \psi, y, \sigma, \alpha)$. □

3. Equivalence of Lojasiewicz extremals of different representations. For the sake of simplicity, we refer to a function $f\# : V \times \Omega \mapsto \mathbf{R}^k$ as C^1 in v if Ω is a compact metric space, $f\#$ continuous, $f\#(\cdot, \omega)$ a C^1 function for all $\omega \in \Omega$, and $D_1 f\#$ (the partial derivative with respect to the first argument of $f\#$) continuous. We say that $f\#$ is a C^1 representation of sets $G(v)$ for $v \in V$ if $f\#$ is C^1 in v and $f\#(v, \Omega) = G(v)$ for $v \in V$. We denote by $\mathrm{Arc}_{\mathrm{rel}}(g, \Omega)$ (respectively, $\mathrm{Arc}_{\mathrm{unrel}}(g, \Omega)$) the collection of all (y, α) such that, for some relaxed (respectively, unrelaxed) control σ,

$$y(t) = \int_0^t g(y(s), \sigma(s)) ds \ \ \forall\, t \in [0, \alpha]$$

g-extremal(L). Let $W \subset \mathbf{R}^k$, Ω be a compact metric space, $g : W \times \Omega \mapsto \mathbf{R}^k$ continuous and the function $w \mapsto g(w, \omega)$ locally Lipschitzian uniformly for $\omega \in \Omega$. We refer to a couple (y, α) as a relaxed (respectively, unrelaxed) *g-extremal* (L) (for a *Lojasiewicz extremal of g*) if $y \in \mathrm{Arc}_{\mathrm{rel}}(g, \Omega)$ (respectively, $\mathrm{Arc}_{\mathrm{unrel}}(g, \Omega)$) and, for every relaxed (respectively, unrelaxed) control σ that satisfies the equation

$$y(t) = \int_0^t g(y(s), \sigma(s)) ds \quad \forall\, t \in [0, \alpha],$$

there exists a nonzero absolutely continuous function $p : [0, \alpha] \mapsto \mathbf{R}^n$ such that

$$p'(t)^T \in -p(t)^T \partial_1 g(y(t), \sigma(t)) \text{ a.e. in } [0, \alpha];$$

$$H(t) := p(t)^T g(y(t), \sigma(t)) = \min_{\omega \in \Omega} p(t)^T g(y(t), \omega) \text{ a.e. in } [0, \alpha];$$

$$H(t) = 0 \text{ a.e. in } [0, \alpha].$$

(This is a necessary condition for $y(\alpha)$ to belong to the boundary of the attainable set $\{y(t) \mid (y,\alpha) \in Arc(g,\Omega), t \leq \alpha\}$, where Arc = Arc_{rel}, respectively, Arc = $\text{Arc}_{\text{unrel}}$.)

We apply the following modified form of a result of Lojasiewicz [L2, Thm. 3, p. 253].[1]

LOJASIEWICZ'S THEOREM. *Let g_1 and g_2 be C^1 representations of sets $G(v)$ such that, for all $v \in V$, the convex hulls of $G(v)$ have nonempty interiors. Then the (relaxed respectively unrelaxed) g_1-extremals(L) and g_2-extremals(L) coincide.*

DEFINITION. *The set X.* Let B be the open (euclidean) unit ball in $\mathbf{R}^n$ and $Z = \mathbf{R}^n \backslash \mathrm{B}$. We denote by X' the set of all C^1 functions $\chi : V \times Z \mapsto (0,\infty)$ such that each is bounded between two positive constants and $\lim_{|z|\to\infty} \chi(v,z)$ exists uniformly for all $v \in$ V. We denote by $[Z]$ the one-point compactification of Z (i.e., $Z \cup \{\infty\}$) and extend χ to $V \times [Z]$ as a continuous function by setting $\chi(v,\infty) = \lim_{|z|\to\infty} \chi(v,z)$. We denote by X the set of all such extensions of $\chi \in X'$.

THEOREM 3.1. *Let f have one component equal to* 1, $\varphi_\chi(v,r) = \chi(v, f(v,r)) \mid f(v,r) \mid$, *and Ξ be the set of all $\xi = (\chi, g, \Gamma)$ such that $\chi \in X$, Γ is a compact metric space, $g : V \times \Gamma \mapsto \mathbf{R}^n$ continuous, $g(\cdot,\gamma)$ locally Lipschitzian uniformly for $\gamma \in \Gamma$, the function $(v,\gamma) \mapsto \mid g(v,\gamma) \mid^{-1} g(v,\gamma)$ C^1 in v, and*

$$g(v,\Gamma) = \text{closure}\{\varphi_\chi(v,r)^{-1} f(v,r) \mid r \in U\} \quad \forall\, v \in V.$$

Assume that either

(a) *there exists some $\chi_0 \in X$ such that*

$$\text{int co}\, \{\varphi_{\chi_0}(v,r)^{-1} f(v,r) \mid r \in U\} \neq \emptyset \quad \forall\, v \in V,$$

or

(b) *V is compact, $f(v,U)$ is infinite, and $f(v,U)$ spans $\mathbf{R}^n$ for all $v \in V$.*

Then, for every choice of $\xi' = (\chi, g, \Gamma)$ and $\xi'' = (\psi, h, \Delta)$ in Ξ and of a relaxed (respectively, unrelaxed) g-extremal(L) (y,α), there exists a strictly increasing bi-Lipschitzian homeomorphism $s := s(\xi', \xi'', y, \alpha) : [0, s^{-1}(\alpha)] \mapsto [0,\alpha]$ such that $(\tilde{y}, \tilde{\alpha}) = (y \circ s, s^{-1}(\alpha))$ is a relaxed (respectively, unrelaxed) h-extremal(L), and this correspondence is one-to-one. If $\chi = \psi$ then every g-extremal(L) is also an h-extremal(L).

Theorem 3.2 below applies to bounded problems only and represents a variant of Lojasiewicz's Theorem. For the sake of greater simplicity, we have replaced the pertinent (and somewhat complicated) assumptions of Lojasiewicz's Theorem by the stronger assumption that the control variables have compact ranges. However, our arguments are independent of these assumptions except when they refer to a modified form of Lojasiewicz's Theorem. Thus Theorem 3.2 remains valid when the compactness assumption is replaced by the pertinent assumptions of Lojasiewicz's Theorem. On the other hand, Theorem 3.2 applies to some nonsmooth problems and somewhat weakens the assumption that int co $f(v,U) \neq \emptyset$.

THEOREM 3.2. *Let $V \subset \mathbf{R}^n$, U and U_1 be compact metric spaces, $f : V \times U \mapsto \mathbf{R}^n$ and $g : V \times U_1 \mapsto \mathbf{R}^n$ bounded and continuous, $f(v,U) = g(v,U_1)$ for all $v \in V$, and $f(\cdot,r)$, respectively, $g(\cdot,r_1)$ locally Lipschitzian uniformly for $r \in U$, respectively, $r_1 \in U_1$. Assume that either*

---

[1] Lojasiewicz has pointed out to us the following correction due to a typographical mistake in the proof of Theorem 3 of [L2]: on p. 254, line 6*, on the right-hand side of the equality sign, y should be replaced by $M(t)y$.

(a) *there exist* $c_2 > c_1 > 0$ *and a locally Lipschitzian function* $\chi : V \times \mathbf{R}^n \mapsto [c_1, c_2]$ *such that the functions*

$$f^{\#}(v,r) = \chi(v, f(v,r))^{-1} f(v,r), \qquad g^{\#}(v,r_1) = \chi(v, g(v,r_1))^{-1} g(v,r_1),$$

are C^1 *in* v *and* int co $f^{\#}(v,U) \neq \emptyset$ *for all* $v \in V$, *or*

(b) f *and* g *are* C^1 *in* v, V *is compact and, for all* $v \in V$, $f(v,U)$ *is infinite and* $f(v,U)$ *spans* $\mathbf{R}^n$.

Then every relaxed (respectively, unrelaxed) f*-extremal*(L) (y,α) *is also a relaxed (respectively, unrelaxed)* g*-extremal*(L).

Theorem 3.1 applies to functions f with one component equal to 1 and the functions $\varphi(v,r)$ must be chosen as functions of v and $f(v,r)$. We can dispense with these conditions if, for some fixed $\varphi_0(v,r)$, both $\varphi(v,r)^{-1} f(v,r)$ and $\varphi_0(v,r)^{-1} f(v,r)$ can be expressed in terms of the new control. The price that we must pay for this somewhat greater freedom is a weakening of our conclusions. The new Theorem 3.3 applies to the more restricted class of *extremals*$(L+)$ ("*strengthened Lojasiewicz extremals*").

g-extremal$(L+)$. We refer to a couple (y,α) as a relaxed (respectively, unrelaxed) g-extremal$(L+)$ if $(y \circ s, \tilde{\alpha})$ is a relaxed (respectively, unrelaxed) g-extremal(L) for every bi-Lipschitzian homeomorphism $s : [0,\tilde{\alpha}] \mapsto [0,\alpha]$ for which $(y \circ s, \tilde{\alpha}) \in \mathrm{Arc}_{\mathrm{rel}}(g,\Omega)$ (respectively, $(y \circ s, \tilde{\alpha}) \in \mathrm{Arc}_{\mathrm{unrel}}(g,\Omega)$). This definition describes a property that clearly characterizes every solution with its endpoint on the boundary of the relaxed (respectively, unrelaxed) attainable set.

THEOREM 3.3. *Let* Φ *be as in Definition* 2.2.1 *and* $\varphi_0 \in \Phi$ *such that*

$$\text{int co}\{\varphi_0(v,r)^{-1} f(v,r) \mid r \in U\} \neq \emptyset \quad \forall\, v \in V.$$

Let Ξ *be the set of all* $\xi = (\varphi, g, K, \Gamma)$ *such that* $\varphi \in \Phi$, Γ *is a compact metric space, the functions* $g : V \times \Gamma \mapsto \mathbf{R}^n$ *and* $K : V \times \Gamma \mapsto (0,\infty)$ *are* C^1 *in* v, *and*

$$g(v,\Gamma) = \text{closure}\{\varphi(v,r)^{-1} f(v,r) \mid r \in U\},$$

$$\{K(v,\gamma) g(v,\gamma) \mid \gamma \in \Gamma\} = \text{closure}\{\varphi_0(v,r)^{-1} f(v,r) \mid r \in U\}.$$

Then, for every choice of $\xi' = (\varphi, g, K, \Gamma)$ *and* $\xi'' = (\psi, h, L, \Delta)$ *in* Ξ *and of a relaxed (respectively, unrelaxed)* g*-extremal*$(L+)$ (y,α), *there exists a strictly increasing bi-Lipschitzian homeomorphism* $s := s(\xi', \xi'', y, \alpha) : [0, s^{-1}(\alpha)] \mapsto [0,\alpha]$ *such that* $(\tilde{y}, \tilde{\alpha}) = (y \circ s, s^{-1}(\alpha))$ *is a relaxed (respectively, unrelaxed)* h*-extremal*$(L+)$, *and this correspondence is one-to-one.*

In the proofs of Theorems 3.1–3.3 we use the term "g-extremal" as in Definition 2.4 but with the relation (ii) replaced by $p(\alpha) \neq 0$.

Proof of Theorem 3.1.

Step 1. First assume that condition (a) is satisfied. Since, by assumption, f has one component equal to 1, we can write it in the form $f = (1, f_2)$. Thus, if we set $f(v,U) = F(v)$ then $z = (1, z_2) \in Z = \mathbf{R}^n \backslash B$ for every $z \in F(v)$. Similarly, we write $g = (g_1, g_2)$. For $z = (z_1, z_2) \in Z$, let

$$p(z) = (1, z_2/z_1) \; if \; z_1 \neq 0, \quad p(z) = \infty \; if \; z_1 = 0,$$

and, for all $v \in V$ and $\gamma \in \Gamma$, let

$$K(v,\gamma) = \chi_0(v, p(g(v,\gamma)))/\chi(v, p(g(v,\gamma))), \qquad g^{\#}(v,\gamma) = K(v,\gamma)^{-1} g(v,\gamma).$$

We observe that

$$F_\chi(v) := \{\chi(v, f(v,r))^{-1} \mid f(v,r) \mid^{-1} f(v,r) \mid r \in U\}$$
$$= \{\chi(v,z)^{-1} \mid z \mid^{-1} z \mid z \in F(v)\}$$

and $g(v,\Gamma) = \overline{F_\chi(v)}$.

To each $\zeta \in F_\chi(v)$ there correspond some $z = (1, z_2) \in F(v)$, r in U and γ in some subset $\Gamma'(v)$ of Γ such that

$$\zeta = \chi(v,z)^{-1} \mid z \mid^{-1} z = g(v,\gamma) = (g_1, g_2)(v,\gamma), \qquad z = f(v,r),$$

and similarly for each element of $\{z, r, \zeta, \gamma\}$ there are other elements of this quadruplet satisfying the above relations. Thus $g_1(v,\gamma) \neq 0$ and $z_2 = g_2(v,\gamma)/g_1(v,\gamma)$. It follows that

$$g^\#(v,\gamma) = \frac{\chi(v,z)}{\chi_0(v,z)} \frac{1}{\chi(v,z) \mid z \mid} z = \varphi_{\chi_0}(v,r)^{-1} f(v,r)$$

and

$$\text{closure } g^\#(v,\Gamma'(v)) = \text{closure}\{\varphi_{\chi_0}(v,r)^{-1} f(v,r) \mid r \in U\} = \overline{F_{\chi_0}(v)}.$$

Now let $v \in V$ and $\gamma \in \Gamma$. Then there exist a sequence (r_i) in U and corresponding sequences (γ_i) and (z_i) such that

$$g(v,\gamma) = \lim_i g(v,\gamma_i) = \lim_i \chi(v, f(v,r_i))^{-1} \mid f(v,r_i) \mid^{-1} f(v,r_i).$$

Since $[Z]$ is metrizable and compact and both χ and χ_0 are continuous on $V \times [Z]$ and bounded away from 0, we may replace (r_i) by an appropriate subsequence so that the points $z_i = f(v,r_i)$ converge to a limit in $[Z]$ and

$$g^\#(v,\gamma) = K(v,\gamma)^{-1} g(v,\gamma) = \lim_i \chi_0(v, p(f(v,r_i)))^{-1} \mid f(v,r_i) \mid^{-1} f(v,r_i)$$
$$= \lim_i \chi_0(v,z_i)^{-1} \mid z_i \mid^{-1} z_i \in \text{closure } g^\#(v,\Gamma'(v)) = \overline{F_{\chi_0}(v)};$$

hence $g^\#(v,\Gamma) = \overline{F_{\chi_0}(v)}$.

The proof of Theorem 2.5, with f_φ, f_ψ replaced by $g, g^\#$, applies without change and we conclude that for every g-extremal (y,α) there exists a bi-Lipschitzian homeomorphism $s(\xi', y, \alpha) = s_1$ such that the couple $(y^\#, \alpha^\#) := (y \circ s_1, s_1^{-1}(\alpha))$ is a $g^\#$-extremal and conversely, with s_1 replaced by its inverse. We observe, furthermore, that the homeomorphism s_1, as defined in the proof of Theorem 2.5, is uniquely determined by χ and y. Indeed, s_1 is defined by $\int_0^t \nu(\tau)d\tau$, where $\nu(t) = 1/K(y(t), \sigma(t))$, and we have

$$K(y(t),\sigma(t)) = \chi_0(y(t), g(y(t),\sigma(t)))/\chi(y(t), g(y(t),\sigma(t)))$$
$$= \chi_0(y(t), y'(t))/\chi(y(t), y'(t)) \text{ a.e. in } [0,\alpha].$$

The same argument, applied to ξ'', yields $h^\# : V \times \Delta \mapsto \mathbf{R}^n$ such that

$$g^\#(v,\Gamma) = h^\#(v,\Delta) = \text{closure}\{\chi_0(v,z)^{-1} \mid z \mid^{-1} z \mid z \in F(v)\} = \overline{F_{\chi_0}(v)}.$$

Thus, by assumption (a), int co $g^\#(v,\Gamma) \neq \emptyset$ for all $v \in$ V. Now let $\xi''' = (1/\psi, h^\#, \Delta)$. Since the homeomorphisms $s(\cdot)$ are uniquely determined by the state functions and the functions χ, it follows, by Lojasiewicz's Theorem, that to every relaxed (respectively,

unrelaxed) g-extremal(L) (y, α) there corresponds a unique function $z = y \circ s$, with $s = s(\xi', y, \alpha) \circ s(\xi''', y^{\#}, \alpha^{\#})$, such that $(z, s^{-1}(\alpha))$ is a relaxed (respectively, unrelaxed) h-extremal(L). Furthermore, if $\chi = \psi$ then

$$s(\xi''', y^{\#}, \alpha^{\#}) = s(\xi', y, \alpha)^{-1},$$

and therefore $z = y$ and (y, α) is also an h-extremal(L).

Step 2. Now assume that condition (b) is satisfied. We show that condition (a) follows, thus completing the proof of the theorem.

Let $f^*(v, r) = \mid f(v, r) \mid^{-1} f(v, r)$. Then, for each $v \in V$, there exist $r_v^0, \ldots, r_v^n \in U$ such that the set $H(v) = \{f^*(v, r_v^0), \ldots, f^*(v, r_v^n)\}$ spans $\mathbf{R}^n$ and, if int co $f^*(v, U) \neq \emptyset$, then also int co $H(v) \neq \emptyset$. It follows that each $v \in V$ has a neighborhood $\mathcal{N}(v)$ in V such that, for all $w \in \mathcal{N}(v), \mathcal{H}(w, v) = \{f^*(w, r_v^0), \ldots, f^*(w, r_v^n)\}$ spans $\mathbf{R}^n$ and, if int co $f^*(w, U) \neq \emptyset$, then also int co $\mathcal{H}(w, v) \neq \emptyset$. The compact set V can be covered by a finite collection of such neighborhoods, say by $\mathcal{N}(v_1), \ldots, \mathcal{N}(v_k)$. Let the set

$$\{r_{v_j}^i \mid i = 0, \ldots, n; j = 1, \ldots, k\}$$

be enumerated as $\{\rho_1, \ldots, \rho_s\}$. Then, for every choice of $v \in V$, the set

$$\mathcal{K}(v) = \{f^*(v, \rho_1), \ldots, f^*(v, \rho_s)\}$$

spans $\mathbf{R}^n$ and, if int co $f^*(v, U) \neq \emptyset$, then also int co $\mathcal{K}(v) \neq \emptyset$.

Let $B(z, a) (\bar{B}(z, a))$ denote the open (closed) ball of center z and radius a in $\mathbf{R}^n$. For all $v \in V$ and $i = 1, \ldots, s$, let $z_i(v) = f(v, \rho_i)$. We first show that there exists $\beta_0 \in (0, 1]$ such that

$$f(v, U) \setminus \bigcup_{i=1}^{s} B(z_i(v), \beta_0) \neq \emptyset \quad \forall\, v \in V.$$

Indeed, otherwise there exists a sequence (v_n) in the compact set V converging to some w and such that

$$(*) \qquad f(v_n, U) \subset \bigcup_{i=1}^{s} B(z_i(v_n), 1/n).$$

Since $f(w, U)$ is infinite, there exist $r_w \in U$ and $\alpha > 0$ such that

$$\mid f(w, r_w) - z_i(w) \mid > \alpha \quad \forall\, i = 1, \ldots, s.$$

It follows, by the continuity of f and z_i, that

$$\mid f(v_n, r_w) - z_i(v_n) \mid > \alpha/2 \quad \forall\, i = 1, \ldots, s$$

for sufficiently large n, thus contradicting (*).

Now let

$$A(v) = \bigcup_{i=1}^{s} \bar{B}(z_i(v), \beta_0/2), \qquad B(v) = \mathbf{R}^n \setminus \bigcup_{i=1}^{s} B(z_i(v), \beta_0).$$

Then $A(v)$ and $B(v)$ are closed, the set-valued mappings $v \mapsto A(v)$ and $v \mapsto B(v)$ continuous (in the Hausdorff metric), and

$$A(v) \cap B(v) = \emptyset, \quad F(v) \cap A(v) \neq \emptyset, \quad F(v) \cap B(v) \neq \emptyset.$$

Therefore the graphs of $A(\cdot)$ and $B(\cdot)$ are closed and disjoint in $V \times \mathbf{R}^n$ and there exists a continuous function $\chi^{\#} : V \times \mathbf{R}^n \mapsto [1,2]$ such that $\chi^{\#}(v, A(v)) = 1$ and $\chi^{\#}(v, B(v)) = 2$ for all $v \in \mathrm{V}$.

If int co $f^*(v,U) = \emptyset$ then there exist $\lambda(v) \in \mathbf{R}^n \backslash \{0\}$ and $c(v) \in \mathbf{R} \backslash \{0\}$ such that $\lambda(v)^T f^*(v,U) = \{c(v)\}$ and $\lambda(v)$ is unique up to a constant nonzero multiplier (because $f^*(v,U)$ spans $\mathbf{R}^n$). Thus $2\lambda(v)^T f^*(v,r) = 2c(v) \neq c(v)$ for all $r \in \mathrm{U}$. It follows that

$$(**) \qquad \text{int co}\{\chi^{\#}(v,z)^{-1} \mid z \mid^{-1} z \mid z \in F(v)\} \neq \emptyset\} \quad \forall\, v \in V.$$

Since the set $\bigcup_{v \in V} \bigcup_{i=1}^{s} B(z_i(v), \beta_0)$ is bounded and $\chi^{\#}(v,z) = 2$ outside that set, we can approximate $\chi^{\#}$ uniformly and arbitrarily closely with a C^1 function converging to 2 as $\mid z \mid \to \infty$, and therefore relation (**) will remain valid if $\chi^{\#}$ is replaced by an appropriate function $\chi_0 \in \mathrm{X}$. □

Proof of Theorem 3.2. First assume that condition (a) is satisfied. Let

$$\varphi(v,r) = \chi(v, f(v,r)), L(v,\gamma) = \chi(v, g(v,\gamma)), \qquad g^{\#}(v,\gamma) = L(v,\gamma)^{-1} g(v,\gamma).$$

Then

$$g^{\#}(v, U_1) = \{\varphi(v,r)^{-1} f(v,r) \mid r \in U\}.$$

The proof of Theorem 2.5, with f_φ, f_ψ, K replaced by $g, g^{\#}, L$ applies without change and we conclude that, for every g-extremal (y, σ, α), there exists a bi-Lipschitzian homeomorphism $s(y,\sigma,\alpha) = s$ such that the triplet $(\tilde{y}, \tilde{\sigma}, \tilde{\alpha}) := (y \circ s, \sigma \circ s, s^{-1}(\alpha))$ is a $g^{\#}$-extremal and conversely, with s replaced by its inverse. We observe, furthermore, that the homeomorphism s, as defined in the proof of Theorem 2.5, is uniquely determined by χ and y. Indeed, s is defined by $\int_0^t \nu(\tau) d\tau$, where $\nu(t) = 1/L(y(t), \sigma(t))$, and we have

$$L(y(t), \sigma(t)) = \chi(y(t), g(y(t), \sigma(t))) = \chi(y(t), y'(t)) \quad \text{a.e. in } [0, \alpha].$$

This shows that if (y, α) is a g-extremal(L) then $(\tilde{y}, \tilde{\alpha})$ is a $g^{\#}$-extremal(L), and conversely.

The same argument, applied to f, yields $f^{\#} : V \times U \mapsto \mathbf{R}^n$ such that

$$g^{\#}(v, U_1) = f^{\#}(v, U) = \{\varphi(v,r)^{-1} f(v,r) \mid r \in U\}$$

and

$$f^{\#}(v,r) = \chi(v, f(v,r))^{-1} f(v,r) \quad \forall\, r \in U, v \in V.$$

Thus, by assumption (a), int co $g^{\#}(v, U_1) \neq \emptyset$ for all $v \in \mathrm{V}$. It follows, by Lojasiewicz's Theorem, that every relaxed (respectively, unrelaxed) $g^{\#}$-extremal(L) $(\tilde{y}, \tilde{\alpha})$ is also an $f^{\#}$-extremal(L). Now let $\tilde{\sigma}_1$ be a control such that

$$\tilde{y}'(\beta) = \int_0^{\beta} f^{\#}(\tilde{y}(b), \tilde{\sigma}_1(b)) db \quad \forall\, \beta \in [0, \tilde{\alpha}].$$

Then our previous argument shows that the $f^{\#}$-extremal $(\tilde{y}, \tilde{\sigma}_1, \tilde{\alpha})$ corresponds to an f-extremal (y, σ_1, α), where (y, α) is the same g-extremal(L) that corresponds to the $g^{\#}$-extremal(L) $(\tilde{y}, \tilde{\alpha})$. This shows that every g-extremal(L) is also an f-extremal(L).

Since we have shown in Step 2 of the proof of Theorem 3.1 that assumption (b) implies assumption (a), our proof is complete. □

Proof of Theorem 3.3. By the definition of Φ (Definition 2.2.1), the function K is bounded between two positive constants. Let

$$g^{\#}(v, \gamma) = K(v, \gamma) g(v, \gamma) \quad \forall\, v \in V, \gamma \in \Gamma.$$

The proof then proceeds essentially as in the last two paragraphs of Step 1 of the proof of Theorem 3.1. However, since the homeomorphism $s(\cdot)$ may now depend on both y and the control σ, we must restrict ourselves to extremals($L+$). □

4. Comments and examples. In the modified version of Lojasiewicz's Theorem in §3, we assert that if the (relaxed or unrelaxed) g_1-extremal(L) is a "free time" extremal, i.e., the corresponding Hamiltonian $H(t) = 0$ almost everywhere then the same is the case for the g_2-extremal(L). The proof of this assertion, in the Appendix, is an adaptation of Lojasiewicz's original proof.

Another pertinent theorem of Lojasiewicz [L2, Thm. 2, p. 246] asserts that the assumption about co $G(v)$ can be replaced by the assumption that the function

$$(v, p) \mapsto \mathcal{H}(v, p) := \min_{r \in U} p^T f(v, r) : V \times \mathbf{R}^n \mapsto \mathbf{R}$$

is differentiable at $(y(t), q)$ for almost all $t \in [0, \alpha]$ and for all q such that $\mathcal{H}(y(t), q) = q^T y'(t)$, where (y, α) is the g_1-extremal(L).

We should mention that there are several counterexamples showing that Lojasiewicz's Theorem is not valid for ordinary extremals as distinct from extremals(L) (e.g., if the control problem admits a state function $y(\cdot)$ that is generated by two controls, one of which is extremal and the other nonextremal). However, we know of no counterexamples showing that both of the above conditions (about co $G(v)$ or the differentiability of $\mathcal{H}$) cannot be dispensed with. While our Theorem 3.2 shows that these "nondegeneracy" assumptions as well as the C^1 requirement may be somewhat weakened, it is still an open question whether Lojasiewicz's Theorem remains valid for C^1 problems without any assumptions concerning the convex hull of $G(v)$.

Our Theorem 3.3 applies to extremals($L+$), a more restricted class than the extremals(L) that appear in Lojasiewicz's Theorem and in Theorems 3.1 and 3.2. The following example of Lojasiewicz [L3] shows that, even for simple problems, an extremal(L) need not be an extremal($L+$). Consider the control problem defined by

$$y_1' = y_2, \quad y_2' = -y_1 + u, \quad \text{with } u(t) \in [0, 1].$$

Then $(y, \alpha) = (0, \alpha)$ is an extremal(L) for $\alpha \leq \pi$ but it is not extremal (in the Pontryagin sense) for $\alpha > \pi$. However, while our proof only enables us to draw conclusions concerning extremals($L+$), we are unable at present to answer the question whether Theorem 3.3 is valid for extremals(L).

Our first example describes a class of simple problems to which Theorem 2.5 applies.

Example 4.1. Consider the following control problem with linear controls:

$$y'(t) = g(y(t))u(t), \qquad u(t) \in U,$$

where $g(v) = (g_{ij}(v))$ is a $n \times m$ matrix with locally Lipschitz continuous elements g_{ij} and U is an arbitrary subset of $\mathbf{R}^m$. Let S^m be the boundary of the unit ball in $\mathbf{R}^{m+1}$, and let $Q : R^m \mapsto S^m$ be defined by

$$Q(r) = (1+ \mid r \mid^2)^{-1/2}(r, 1).$$

Then, for $s = (s_1, \ldots, s_{m+1})$, $Q^{-1}(s) := P(s) = (s_1, \ldots, s_m)s_{m+1}^{-1}$. Let $\Omega' = Q(U)$ and $\Omega = \text{closure}(\Omega')$. Then (Ω, Ω', P) is a metric compactification of U. For any $j = 1, 2, \ldots$, set $\varphi_j(r) = (1+ \mid r \mid^j)^{1/j}$, and observe that

$$\varphi_j(P(s))^{-1}g(y(t))P(s) = g(y(t))(s_1, \ldots, s_m)/\left(s_{m+1}^j + \left(\sum_{i=1}^m s_i^2\right)^{j/2}\right)^{1/j}$$

is continuous on Ω. Let $k \in \{1, 2, \ldots\}$ and $\varphi_0 = \varphi_k$. Then $\varphi_j \in \mathcal{F}(\Omega, P, \varphi_0)$ for all $j = 1, 2, \ldots$ and Theorem 2.5 is applicable for every choice of locally Lipschitzian h_0 and h_1. Thus the (relaxed or unrelaxed) extremals of the bounded control problems corresponding to different choices of $\varphi = \varphi_j$ are equivalent modulo a rescaling of the independent variable.

The next example illustrates the use of Theorem 3.1.

Example 4.2. For all $v = (v_1, v_2) \in \mathbf{R}^2$, let

$$f(v, r) = (1, r) \quad \forall\, r \in U = (0, \infty),$$

$$\chi_1(v, z) = 1,\ \chi_2(v, z) = (1, 1)^T z/ \mid z \mid \quad \forall\, z \in \mathbf{R}^2, \mid z \mid \geq 1.$$

Consider the systems

$$y' = g(y, \gamma) = (\mid \cos(\gamma) \mid, \mid \sin(\gamma) \mid), \qquad \gamma(t) \in \Gamma = [-\pi, \pi] \tag{4.2.1}$$

and

$$y' = h(y, \delta) = (\cos^2(y_2 + \delta), \sin^2(y_2 + \delta)), \qquad \delta(t) \in \Delta = [-\pi, \pi]. \tag{4.2.2}$$

Then, in the notation of Theorem 3.1,

$$g(v, \Gamma) = \text{closure}\{\varphi_{\chi_1}(v, r)^{-1} f(v, r) \mid r \in U\},$$

$$h(v, \Delta) = \text{closure}\{\varphi_{\chi_2}(v, r)^{-1} f(v, r) \mid r \in U\}.$$

We observe that int co $g(v, \Gamma) \neq \emptyset$. Thus Theorem 3.1 implies that systems (4.2.1) and (4.2.2) have sets of extremals(L) that are equivalent modulo a rescaling of the independent variable.

While the conditions of Theorems 2.5 and 3.1 are often easier to check than those of Theorem 3.3, the latter (with its weaker conclusions) can apply in some problems where the former theorems fail. The following is an example.

Example 4.3. Consider the system

$$y_1' = 1, \qquad y_2' = u, \qquad u(t) \in (0, \infty). \tag{4.3.1}$$

Let

$$\varphi(r) = (1 + r^2)^{1/2}(2 + \sin r^{-1}), \qquad \psi(r) = (1 + r^2)^{1/2}(2 + \sin r).$$

Theorem 2.5 does not apply here because, no matter what the choice of φ_0 is, this theorem requires that the function

$$\varphi(r)/\psi(r) = (2 + \sin r^{-1})/(2 + \sin r),$$

with $r = P(\omega)$, can be extended continuously from Ω' to Ω, which is impossible.

Now consider the following two different bounded reparametrizations of system (4.3.1):

$$y' = \omega = g_\varphi(\omega), \qquad \omega(t) \in \Omega_\varphi = \text{ closure } \{\varphi(r)^{-1}(1, r) \mid r \in (0, +\infty)\} \tag{4.3.2}$$

and

$$y' = \omega = g_\psi(\omega), \qquad \omega(t) \in \Omega_\psi = \text{closure}\{\psi(r)^{-1}(1, r) \mid r \in (0, +\infty)\}. \tag{4.3.3}$$

Theorem 3.1 does not apply in this case either because, in the setting of Theorem 3.1, the functions φ and ψ above correspond to

$$\chi_\varphi = 2 + \sin z_2^{-1}, \qquad \chi_\psi = 2 + \sin z_2,$$

and neither χ_φ nor χ_ψ has a continuous extension to $[Z]$. However, by choosing

$$\varphi_0(v, r) = (1 + r^2)^{1/2}, \quad K_\varphi(v, \omega) = \mid g_\varphi(\omega) \mid^{-1}, \quad K_\psi(v, \omega) = \mid g_\psi(\omega) \mid^{-1},$$

we can apply Theorem 3.3 to conclude that the sets of extremals$(L+)$ of (4.3.2) and (4.3.3) are equivalent up to a rescaling. We observe that the set Ω_φ is the union of the image of the function

$$r \mapsto (1 + r^2)^{-1/2}(2 + \sin r^{-1})^{-1}(r, 1) : (0, \infty) \mapsto \mathbf{R}^2,$$

of the singleton $\{(\frac{1}{2}, 0)\}$ and of the straight line segment $\{0\} \times [\frac{1}{3}, 1]$ while the set

$$\{K(v, \omega)g(v, \omega) \mid \omega \in \Omega_\varphi\}$$

is the unit quarter-circle in the first quadrant. A similar description applies to Ω_ψ.

Our last example illustrates an application of Theorem 3.2.

Example 4.4. Let $V \subset \mathbf{R}^2, w : V \mapsto [1, 2]$ be locally Lipschitzian but not differentiable, and $g_1, g_2 : V \mapsto \mathbf{R}^2$ be C^1 and such that the set $\{g_1(v), g_2(v)\}$ is linearly independent for all $v \in$ V. Let

$$f(v, r) = w(v)(g_1(v) + r[g_2(v) - g_1(v)]) \quad \forall r \in U = [0, 1].$$

Consider the control problems defined by

$$y'(t) = f(y(t), u(t)), \qquad u(t) \in U, \tag{4.4.1}$$

and

$$y'(t) = (y_1, y_2)'(t) = f(y(t), \sin^2(y_1(t) + \gamma(t))), \qquad \gamma(t) \in \Gamma = [0, \pi]. \tag{4.4.2}$$

These two control problems are both representations of the same differential inclusion $y'(t) \in G(y(t))$ almost everywhere. As an immediate consequence of Theorem 3.2 (e.g.,

with $\chi(v,z) =\mid z \mid$), they have the same set of extremals(L). However, Lojasiewicz's theorems do not apply here because systems (4.4.1) and (4.4.2) are not C^1 in the state variables, int co $G(v) = \emptyset$ for all v, and the function

$$(v,p) \mapsto \mathcal{H}(v,p) = \min_{r\in U} p^T f(v,r) = w(v)\min\{p^T g_1(v),\ p^T g_2(v)\}$$

is not differentiable for (p,v) such that $p^T g_1(v) - p^T g_2(v) = 0$ and wherever $w(\cdot)$ is not differentiable.

5. Appendix. The proofs of Lojasiewicz's Theorem and of our version of it require a specialized separation lemma. For the sake of completeness, we include a proof of this lemma.

LEMMA 5.1 (Lojasiewicz's separation lemma). *Let $X_1,\dots,X_k$ be compact and convex subsets of $\mathbf{R}^n$. Then $\cap_{i=1}^k X_i = \emptyset$ if and only if there exist half-spaces $H_1,\dots, H_{k-1}$ such that*

$$X_1 \subset H_1,\ H_i \cap X_{i+1} \subset H_{i+1} \quad \forall i = 1,2,\dots,k-2, \quad H_{k-1}\cap X_k = \emptyset.$$

Proof. The "if" part is obvious. We now assume that $\cap_{i=1}^k X_i = \emptyset$ and prove the "only if" part. Let

$$M = \max\{\mid x \mid \mid x \in \cup_{i=1}^k X_i\},\ K = \{(x,x,\dots,x) \in \mathbf{R}^{kn} \mid \mid x \mid \leq M\}$$

$$X = X_1 \times X_2 \times \cdots \times X_k.$$

Then K and X are convex and compact subsets of $\mathbf{R}^{kn}$ and $\cap_{i=1}^k X_i = \emptyset$ if and only if $X \cap K = \emptyset$. By the classical convex separation theorem, there exist n_i, α and a half-space

$$H = \left\{(x_1,x_2,\dots,x_k) \in \mathbf{R}^{kn} \mid \sum_{i=1}^k n_i \cdot x_i \leq \alpha\right\}$$

containing X and disjoint from K. Set $\beta_i = \max\{n_i \cdot x_i \mid x_i \in X_i\}$. Let

$$H_j = \left\{x \in \mathbf{R}^n \mid (n_1 + \ldots + n_j)\cdot x \leq \alpha - \sum_{i=j+1}^k \beta_i\right\}.$$

We claim that $H_1,\dots,H_{k-1}$ satisfy the statement of the lemma. Indeed, $x \in X_1$ implies $n_1 \cdot x \leq \beta_1$; hence $x \in H_1$. Furthermore, $x \in H_i \cap X_{i+1}$ for $i \in \{1,\cdots,k-2\}$ implies that $(n_1 + \cdots + n_i)\cdot x \leq \alpha - \sum_{j=i+1}^k \beta_j$ and $n_{i+1}\cdot x \leq \beta_{i+1}$. Therefore $(n_1 + \cdots + n_{i+1})\cdot x \leq \alpha - \sum_{j=i+2}^k \beta_j$, i.e., $x \in H_{i+1}$.

It remains to show that $H_{k-1} \cap X_k = \emptyset$. Assume that this is not the case and let $x \in H_{k-1}\cap X_k$. Then we have $(n_1 + \cdots + n_{k-1})\cdot x \leq \alpha - \beta_k$ and $n_k \cdot x \leq \beta_k$, i.e., $(n_1 + \cdots + n_k)\cdot x \leq \alpha$, which implies $(x,x,\dots,x) \in K \cap H$, a contradiction. □

Proof of the modified form of Lojasiewicz's Theorem. Let $g : V \times \Omega \mapsto \mathbf{R}^n$ be C^1 in v. Then we can extend g to $V \times$ rpm(Ω) by setting $g(v,\nu) := \int g(v,\omega)\nu(d\omega)$ for all $\nu \in$ rpm(Ω) and, as extended, g remains C^1 in v, with

$$g(v, \text{rpm}(\Omega)) = co \quad g(v,\Omega).$$

Thus it suffices to prove the theorem for original (i.e., unrelaxed) g-extremals(L) (the relaxed g-extremals(L) becoming the unrelaxed g-extremals(L) when U is replaced by rpm(U)).

Let $g_1 : V \times U \mapsto \mathbf{R}^n$ and $g_2 : V \times \Omega \mapsto \mathbf{R}^n$, and let (y, α) be a g_1-extremal(L) and σ an unrelaxed control such that

$$y(t) = \int_0^t g_2(y(s), \sigma(s))ds \quad \forall\, t \in [0, \alpha].$$

Define $M(t)$ to be the solution of the Cauchy problem

$$M'(t) = D_1 g_2(y(t), \sigma(t))M(t) \text{ a.e. in } [0, \alpha], \qquad M(\alpha) = I.$$

We can verify that, if $p_0 \in \mathbf{R}^n$ and $p(t)^T = p_0^T M(t)^{-1}$, then

$$p'(t)^T = -p(t)^T D_1 g_2(y(t), \sigma(t)).$$

Therefore it suffices to show that there exists $p_0 \in \mathbf{R}^n \backslash \{0\}$ such that

$$p_0 M(t)^{-1}(z - y'(t)) \geq 0 \quad \forall\, z \in G(y(t)), \qquad p_0 M(t)^{-1} y'(t) = 0.$$

Let $e : [0, \alpha] \mapsto \mathbf{R}^n$ be a measurable function and, for $t \in [0, \alpha]$, set

$$E(t) = \{(s, u) \in [0, \alpha] \times U \mid g_1(y(t) + s \cdot e(t), u) = g_2(y(t) + s \cdot e(t), \sigma(t))\}$$

and

$$E_0(t) = \{0\} \times U \cap \text{closure}\{E(t) \backslash (\{0\} \times U)\}.$$

Since g_1 and g_2 are representations of the sets $G(v)$ for all v, it follows that, for every choice of $t, s \in (0, \alpha]$, there exists $u \in U$ such that $(s, u) \in E(t)$. Thus $E_0(t) \neq \emptyset$ and, by well-known measurability theorems (see, e.g., [W3, I.7.6 and I.7.7, pp. 150–151]), $E(\cdot)$ and $E_0(\cdot)$ are measurable set-valued mappings with closed values and there exists a measurable selection $\tau(\cdot)$ of $E_0(\cdot)$. Denote by u_e the second coordinate of τ. Then u_e is measurable and $u_e(t) \in U$ almost everywhere in $[0, \alpha]$. Moreover, for almost all $t \in [0, \alpha]$ and all $k = 1, 2, \ldots$, we can find $s_k > 0$ and $u_k \in U$ satisfying

$$g_1(y(t) + s_k \cdot e(t), u_k) = g_2(y(t) + s_k \cdot e(t), \sigma(t)), \tag{5.1}$$

$$\lim_{k \to \infty} (s_k, u_k) = (0, u_e(t)).$$

Fix $t \in [0, \alpha]$ such that $y'(t) = g_2(y(t), \sigma(t))$ and (5.1) holds. Then

$$\begin{aligned} g_1(y(t) + s_k \cdot e(t), u_k) &= g_1(y(t), u_k) + s_k D_1 g_1(y(t), u_k)e(t) + o(s_k) \\ &= g_2(y(t), \sigma(t)) + s_k D_1 g_2(y(t), \sigma(t))e(t) + o(s_k) \\ &= g_2(y(t) + s_k \cdot e(t), \sigma(t)). \end{aligned}$$

Therefore

$$\lim_{k \to \infty} s_k^{-1}(g_1(y(t), u_k) - g_2(y(t), \sigma(t))) \tag{5.2}$$

$$= -[D_1 g_1(y(t), u_e(t)) - D_1 g_2(y(t), \sigma(t))]e(t).$$

Relation (5.1) implies that $g_1(y(t), u_e(t)) = g_2(y(t), \sigma(t))) = y'(t)$ for almost all $t \in [0, \alpha]$; hence u_e is a control corresponding to our g_1-extremal(L) (y, α) and therefore there exists a corresponding arc p_e such that

$$p_e(t)^T y'(t) = p_e(t)^T g_2(y(t), \sigma(t)) \leq p_e(t)^T g_1(y(t), u_k);$$

hence, by (5.2),

$$0 \leq -p_e(t)^T[D_1 g_1(y(t), u_e(t)) - D_1 g_2(y(t), \sigma(t))]e(t) \\ = [p_e'(t)^T + p_e(t)^T D_1 g_2(y(t), \sigma(t))]e(t). \tag{5.3}$$

Let $q_e(t)^T = p_e(t)^T M(t)$. Then (5.3) yields

$$q_e'(t)^T M(t)^{-1} e(t) \geq 0. \tag{5.4}$$

Next consider, for each t, the nonempty cone

$$P(t) = \{p \in \mathbf{R}^n \mid p^T M(t)^{-1}(z - y'(t)) \geq 0 \quad \forall z \in G(y(t)), \qquad p^T M(t)^{-1} y'(t) = 0\}.$$

Let B be the closed unit ball in $\mathbf{R}^n$ and ∂B its boundary. It follows from Lusin's theorem that the measurable compact-valued mapping $t \mapsto Q(t) := P(t) \cap \partial B$ admits a subset I of $[0, \alpha]$ of full measure such that $y'(t) \in G(y(t))$ for all $t \in I$ and $Q(\cdot)$ is approximately continuous at each $t \in I$. Therefore any continuous function $p : [0, \alpha] \mapsto \mathbf{R}^n$ such that $p(t) \in P(t)$ almost everywhere also satisfies $p(t) \in P(t)$ for all $t \in I$.

We next prove that

$$\bigcap_{t \in [0,\alpha]} P(t) \neq \{0\}. \tag{5.5}$$

First observe that $D_1 g_1(y(t), U)$ is bounded and there exists, therefore, a constant r such that every adjoint vector function $p(\cdot)$ of the g_1-extremal (y, α), with $\mid p(\alpha) \mid = 1$, satisfies $r < \mid p(t)^T M(t) \mid < 1/r$. Assume that (5.5) does not hold, i.e., $\cap_{t \in [0,\alpha]} P(t) = \{0\}$. Then $\cap_{t \in [0,\alpha]} P(t) \cap \partial B = \emptyset$ and, since $P(t) \cap \partial B$ are compact, it follows that there exist $k \geq 2$ and $t_1, \ldots, t_k \in I$ with $0 = t_1 < t_2 < \cdots < t_k \leq \alpha$ such that $\cap_{1 \leq i \leq k} P(t_i) \cap \partial B = \emptyset$; hence $\cap_{1 \leq i \leq k} P(t_i) = \{0\}$. Let X_i be the convex hull of the set of all $x \in P(t_i)$ satisfying

$$r \leq \mid x \mid \leq 1/r.$$

Observe that each $P(t_i)$ is a proper cone (i.e., $P(t_i)$ does not contain a straight line) because co $G(y(t))$ has a nonempty interior. Therefore $0 \notin X_i$ and $\cap_{1 \leq i \leq k} X_i = \emptyset$. By Lemma 5.1, this last relation implies that there exist closed half-spaces $H_1, \ldots H_{k-1}$ such that

$$X_1 \subset H_1, \ H_i \cap X_{i+1} \subset H_{i+1} \quad \forall\, i = 1, 2, \ldots, k-2, \qquad H_{k-1} \cap X_k = \emptyset. \tag{5.6}$$

Let n_i be the outward unit normal to H_i, i.e., $\mid n_i \mid = 1$ and, for some c_i, $H_i = \{p \in \mathbf{R}^n \mid p \cdot n_i \geq c_i\}$. Define $e : [0, \alpha] \mapsto \mathbf{R}^n$ as follows: $e(t) = M(t) n_i$ when $t \in [t_i, t_{i+1})$ and $i = 1, 2, \cdots k-1$. Consider corresponding p_e and q_e as defined in the previous paragraph. Then

$$q_e(t_i) \in X_i \text{ for } i = 1, 2, \ldots, k. \tag{5.7}$$

By (5.4), we have $q_e'(t) \cdot n_i \geq 0$ almost everywhere in $[t_i, t_{i+1}]$. Therefore $q_e(t_{i+1}) \cdot n_i \geq q_e(t_i) \cdot n_i$. Thus we have the following implication:

$$q_e(t_i) \in H_i \ \text{ implies } \ q_e(t_{i+1}) \in H_i. \tag{5.8}$$

Relations (5.6)–(5.8) yield $q_e(t_k) \in H_{k-1} \cap X_k = \emptyset$, which is absurd. Thus there exists a nonzero $p_0 \in P(t)$ such that

$$p_0 M(t)^{-1}(z - y'(t)) \geq 0 \quad \forall z \in G(y(t)), \quad p_0 M(t)^{-1} y'(t) = 0.$$

This completes the proof. □

CONTROLLABILITY OF A SYSTEM OF TWO SYMMETRIC RIGID BODIES IN THREE SPACE*

MICHAEL J. ENOS†

Abstract. Consider a mechanical system consisting of two completely symmetric, three-dimensional rigid bodies, each with inertia tensor the identity matrix and mass center at $0 \in \boldsymbol{R}^3$. Imposing the constraint that this system have zero total angular momentum, the angular velocities of these bodies are negatives of one another, and the transfer of this system from one position to another is nonholonomic. While Chow's theorem establishes the fixed-endpoint controllability of this system, this result does not explicitly exhibit any motions between a given set of endpoints. This paper shows how to explicitly construct simple motions of this system on $[0, 1]$ with arbitrary endpoints in $SO(3)^2$. In particular, using normalized quaternions to describe rotations in terms of elementary functions, a continuous motion with the given endpoints is constructed; it consists of at most three successive motions during each of which the bodies rotate on fixed axes.

Key words. controllability, system of rigid bodies, nonholonomic mechanics, rotation group

AMS subject classifications. 49, 70, 93

1. Introduction.

Recent papers ([5], [8]) have studied the free motion of a mechanical system consisting of two identical, three-dimensional rigid bodies attached at an ideal spherical joint. Here we consider a simple realization of this system; in particular, we assume that the mass centers of the bodies are coincident and that each body has a completely symmetric mass distribution about its mass center. With this latter assumption we may assume that the inertia tensor of each body is the identity matrix E.

This system will be denoted $(\mathcal{B}_1, \mathcal{B}_2)$ and positions of the $\mathcal{B}_i$ will be identified with matrices $A_i \in SO(3)$ in the standard way.

As a physical example of this system, we might consider a satellite with spherical, concentric inner and outer shells connected by a Cardan suspension of negligible mass, the inner shell being more dense than the outer one (see Fig. 1). This example differs from the "classical" dual-spin satellite in the nature of the coupling of the bodies; in classical models (see [3],[6]), the inner body is constrained to rotate about an axis fixed in the outer one, while here the bodies have full $SO(3)$ freedom in their relative orientations as α, β and γ are varied.

As in the papers mentioned above, we will consider motions of this system in the absence of external forces, and we will focus on those with zero angular momentum; our assumptions then guarantee that

$$\omega_1 + \omega_2 = 0, \tag{1.1}$$

where ω_i is the angular velocity of $\mathcal{B}_i$, $i = 1, 2$, so the bodies instantaneously rotate with opposite angular velocities. On the other hand, we will consider a larger class of motions than the free motions and the construction of paths between given endpoints. We can study these motions by considering the control system with state (A_1, A_2) and

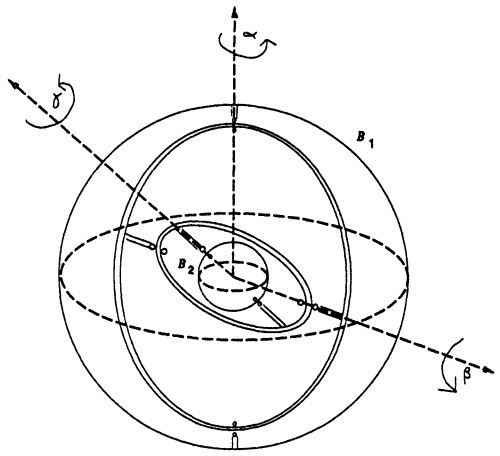

FIG. 1

control $\omega \stackrel{\text{def}}{=} \omega_1$, for which the state satisfies the differential equation

$$\left(\dot{A}_1, \dot{A}_2\right) = (\hat{\omega} A_1, -\hat{\omega} A_2), \tag{1.2}$$

where $\hat{\omega} \in so(3)$ is the skew-symmetric matrix of the cross product operator $v \mapsto \omega \times v$ on $\mathbb{R}^3$.

The free motions of this system are trivial to obtain; indeed, during a free, zero-angular-momentum motion the bodies rotate about a fixed axis in opposite directions at constant angular rates. The collection of all zero angular momentum motions is much larger; for instance, for any motion A' of the first body and initial condition $(A_1, A_2)(0)$ of the whole system, there is a corresponding zero angular momentum motion (A_1, A_2) with this initial condition for which $A_1 = A'_1$.

From a mechanical standpoint, we can view those motions for which ω is non-constant as arising from internal torques exerted by the $\mathcal{B}_i$ on each other (indeed, by Euler's equations, a torque of $2\dot{\omega}_1$ exerted by $\mathcal{B}_2$ on $\mathcal{B}_1$ produces such a motion). In the example in Fig. 1, these torques could be affected by motors of negligible mass that control the angles α, β, and γ.

Let $\mathcal{S}$ denote the collection of continuous solutions of (1.2) on $[0, 1]$ with piecewise constant controls ω that are right continuous and have only finitely many discontinuities. This paper concerns the controllability of this system for given endpoints $(A_1, A_2)(0) = (A_1^{(0)}, A_2^{(0)})$ and $(A_1, A_2)(1) = (A_1^{(1)}, A_2^{(1)})$ with motions in $\mathcal{S}$. Physically speaking, such motions are impossible since they require impulsive, Dirac-type torques at the discontinuities; on the other hand, we can always reparametrize a motion in $\mathcal{S}$ (in such a way that the controls vanish at the discontinuities) to obtain a smooth, physically possible motion.

Although zero-total-angular-momentum motions of the bodies are highly constrained, the constraint is on the velocities and the system is nonholonomic. For instance, if the first body rotates through an angle of $\pi/2$ about the fixed vector $\mathbf{i}$, the net rotation of the second body is through $\pi/2$ on $-\mathbf{i}$; on the other hand, if the system undergoes a series of free motions during which the first body rotates through an angle of $\pi/2$ on the vectors $\mathbf{j}$, $\mathbf{i}$, then $-\mathbf{k}$, its net rotation is again through $\pi/2$ on $\mathbf{i}$ but we obtain a different net rotation of the second body.

In fact, it is not hard to see that this system is controllable. Let $M = SO(3)^2$; using the right invariance of the system (2), we can identify each tangent space T_pM with $so(3)^2$, or, equivalently, the set of all pairs (ω_1, ω_2) of angular velocity vectors given in space coordinates. Using the Riemannian metric $\langle(\omega_1,\omega_2),(\omega_1',\omega_2')\rangle = 1/2(\langle\omega_1,\omega_1'\rangle + \langle\omega_2,\omega_2'\rangle)$ on TM, let H denote the distribution on TM spanned by vector fields of the form $(\omega, -\omega)$ and V the distribution spanned by those of the form (ω,ω). The velocity along any zero angular momentum motion must lie in H and the Lie bracket $[(\omega,-\omega),(\omega',-\omega')]$ of any two such vector fields is $(\omega\times\omega', \omega\times\omega') \in V$. Since it is easily seen that $TM = H \oplus V$ and any vector field in V can be obtained as a bracket of vector fields in H, it follows that the brackets of vector fields in H generate the entire tangent bundle TM, so the system is controllable by Chow's theorem. Since the results of Chow's theorem also imply controllability with piecewise-constant controls, the system is controllable with motions in $\mathcal{S}$.

While Chow's theorem establishes controllability, it gives no immediate information about those motions in S that have a given set of endpoints. Our main objective in this paper is the explicit construction of a simple class of motions in $\mathcal{S}$ with given endpoints. In particular, we will show that for any choice of endpoints in M, there is a motion in $\mathcal{S}$ with these endpoints and for which the control has at most two discontinuities, and further produce this motion explicitly in terms of elementary functions.

It is surprising that beyond the use of Chow's theorem to establish controllability, very little work has been done on the explicit construction of motions of nonholonomic systems with given endpoints. A notable exception is [7], where the controllability with certain constrained motions of a two-body, freely rotating system (generally referred to as "the falling cat") is considered. While that example involves a system with less material symmetry, the constraints on the coupling of the bodies are so restrictive that the motions of this system are essentially those of a single rigid body. The anholonomy in our present example is much more pronounced.

In §2 we show that any motion in $\mathcal{S}$ is completely determined by a finite collection of rotations and that the construction of a motion in $\mathcal{S}$ with given endpoints is equivalent to obtaining suitable factorizations for each of a pair of rotations.

For general choices of endpoints, the construction of a motion in $\mathcal{S}$ with those endpoints involves eight different rotations, and the use of matrix coordinates for rotations becomes cumbersome. On the other hand, when we instead use normalized quaternions to parametrize $SO(3)$, the computations become simpler; moreover, with this approach, many features of the underlying geometry in this problem become apparent. In §3 we recall the algebraic properties of the group of normalized quaternions and describe a useful geometric interpretation of quaternions due to Rodrigues. We restate the factorization of the preceding section in these new coordinates.

In §4, we describe those endpoints that can be joined with a motion with constant control and show that in general a control with at least two discontinuities is required for a given set of endpoints. We also state our main result here, that at most two discontinuities in the controls are required for a given set of endpoints.

Section 5 gives a factorization that implies controllability with one discontinuity on the control when certain conditions are present on the endpoints. In §6, we show that for any set of endpoints, we can, by making a slight adjustment (which amounts to adding a discontinuity in the control), reduce the situation to that in §5.

Hence, combining these results, we obtain our main result in §7. At each step we provide explicit formulas for constructing these motions.

2. Controllability with motions in $\mathcal{S}$. As described in the Introduction, we will consider the control system $((A_1, A_2), \omega)$ with state (A_1, A_2) and control ω taking values in $SO(3)^2$ and $\mathbb{R}^3$, respectively, and satisfying the differential equation

$$\left(\dot{A}_1, \dot{A}_2\right) = (\hat{\omega} A_1, -\hat{\omega} A_2)\,. \tag{2.1}$$

We will study the collection $\mathcal{S}$, those continuous motions (A_1, A_2) on $[0, 1]$ with right continuous, piecewise constant controls ω having only finitely many discontinuities.

If $(A_1, A_2) \in \mathcal{S}$, it is clear that we can write the control ω corresponding to this motion as

$$\omega = \sum_{j=1}^{N-1} \omega^j \chi_{[t_{j-1}, t_j)} + \omega^N \chi_{[t_{N-1}, t_N]}, \tag{2.2}$$

where $N < \infty$,

$$0 = t_0 < t_1 < \cdots < t_N = 1$$

is some partition of $[0, 1]$, and the ω^j are vectors in $\mathbb{R}^3$.

When $(A_1, A_2) \in \mathcal{S}$, it is easy to solve (1) on any interval of continuity $[t_{j-1}, t_j)$ of ω by exponentiating $\hat{\omega}$; in particular, we have

$$(A_1, A_2)(t) = \left(D_j(t) A_1(t_{j-1}), D_j^t(t) A_2(t_{j-1})\right), \qquad t \in [t_{j-1}, t_j],$$

where

$$D_j(t) = \exp\left((t - t_{j-1})\hat{\omega}^j\right). \tag{2.3}$$

It is easy to see that $D_j(t)$ is the matrix of the rotation through the angle $(t - t_{j-1})|\omega^j|$ about the constant vector $\omega^j/|\omega^j|$ when $|\omega^j| \neq 0$ and $D_j(t)$ is the identity rotation when $\omega^j = 0$.

Applying this fact successively on the intervals $[t_{j-1}, t_j)$ and defining the A_i so as to be continuous on $[0, 1]$, we have the following lemma.

LEMMA 2.1. *Any motion in $\mathcal{S}$ is of the form*

$$\left(A_1, A_2\right)(t) = \left(D_j(t) D_{j-1}(t_{j-1}) \cdots D_1(t_1)\, A_1(0), D_j^t(t) D_{j-1}^t(t_{j-1}) \cdots D_1^t(t_1)\, A_2(0)\right), \qquad t \in [t_{j-1}, t_j)$$

for some partition $\{t_j\}_{j=1}^N$ of $[0, 1]$ and set of vectors $\{\omega^j\}_{j=1}^N$, where the D_j are as in (2.3).

Setting $t = 1$ in this formula and letting $G_j \overset{\text{def}}{=} D_j(t_j), 1 \leq j \leq N$, we have the following characterization of those motions in $\mathcal{S}$ with a given set of endpoints.

COROLLARY 2.2. *Let $A_i^{(k)} \in SO(3)$, $i = 1, 2$ and $k = 0, 1$. Any motion $(A_1, A_2)_* \in \mathcal{S}$ which satisfies the endpoint conditions*

$$(A_1, A_2)_*(0) = \left(A_1^{(0)}, A_2^{(0)}\right) \quad \text{and} \quad (A_1, A_2)_*(1) = \left(A_1^{(1)}, A_2^{(1)}\right)$$

has the form in Lemma 2.1, *and the G_j satisfy*

$$\left(A_1^{(1)} A_1^{(0)t}, A_2^{(1)} A_2^{(0)t}\right) = \left(G_N \cdots G_1, G_N^t \cdots G_1^t\right). \tag{2.4}$$

□

This reduces the problem of constructing a motion in $\mathcal{S}$ with given endpoints to that of obtaining a suitable factorization of a given pair of rotations. In particular, we want to factor the *net rotations* $A_i^{(1)} A_i^{(0)t}$ that the bodies undergo during the desired fixed-endpoint motion.

Remark 2.3. Given rotations G_j with the properties in Corollary 2.2, it is easy to construct a motion in $\mathcal{S}$: Let ϕ^j and $\mathbf{n}^j$ denote the angle and axis of the rotation G_j, let $t_j = j/N$, and define

$$\omega^j \stackrel{\text{def}}{=} \frac{\phi^j}{t_j - t_{j-1}} \mathbf{n}^j,$$

$1 \leq j \leq N$. Then the formula in Lemma 2.1, with $D_j(t)$ as in (2.3), is a motion in $\mathcal{S}$ with the correct endpoints.

3. Quaternions. Let $C \in SO(3)$. The action of C on $\mathbb{R}^3$ is that of rotation through an angle ϕ about a unit vector $\mathbf{n}$. Assuming that a positive angle ϕ rotates vectors in a counterclockwise direction when viewed from the tip of $\mathbf{n}$, we will write $R(\phi\mathbf{n})$ for this rotation. It is clear that any rotation can be represented as $R(\phi\mathbf{n})$ for some $\mathbf{n}$ and some unique $\phi \in [0, \pi]$. Formulas for ϕ and $\mathbf{n}$ in terms of the matrix entries of C can be found in the Appendix.

For any rotation $R(\phi\mathbf{n})$, put

$$(\lambda, \Lambda) \stackrel{\text{def}}{=} \left(\cos\frac{\phi}{2}, \sin\frac{\phi}{2}\mathbf{n}\right). \tag{3.1}$$

We say that λ and Λ are *Euler–Rodrigues parameters* (ERPs) for $R(\phi\mathbf{n})$. It is clear that any (λ, Λ) so defined satisfies

$$\lambda^2 + |\Lambda|^2 = 1, \tag{3.2}$$

and so may be naturally identified with a point on the three sphere S^3.

Algebraically, those (λ, Λ) that satisfy (3.2) form the group of normalized quaternions, using quaternion multiplication:

$$(\lambda_1, \Lambda_1)(\lambda_2, \Lambda_2) = (\lambda_1\lambda_2 - \langle \Lambda_1, \Lambda_2 \rangle, \lambda_1\Lambda_2 + \lambda_2\Lambda_1 + \Lambda_1 \times \Lambda_2); \tag{3.3}$$

the group identity is $(1, 0)$, and group elements are inverted using the formula

$$(\lambda, \Lambda)(\lambda, -\Lambda) = (\lambda, -\Lambda)(\lambda, \Lambda) = (1, 0). \tag{3.4}$$

Let $\hat{R} : S^3 \mapsto SO(3)$ be the map taking a quaternion to the rotation it represents, i.e., $\hat{R}(\cos\frac{\phi}{2}, \sin\frac{\phi}{2}\mathbf{n}) = R(\phi\mathbf{n})$. $\hat{R}$ is a covering map and group homomorphism; moreover it is a two-to-one map, since

$$\hat{R}(\lambda_1, \Lambda_1) = \hat{R}(\lambda_2, \Lambda_2) \Longleftrightarrow (\lambda_1, \Lambda_1) = \pm(\lambda_2, \Lambda_2) \tag{3.5}$$

(this is a nice illustration of the fact that $SO(3)$ is the quotient of S^3 by the antipodal map).

Finally, if $(\lambda, \Lambda) \in S^3$ and $u \in \mathbb{R}^3$, we have

$$(0, \hat{R}(\lambda, \Lambda)u) = (\lambda, \Lambda)(0, u)(\lambda, -\Lambda);$$

using this formula, we can recover the matrix $\hat{R}(\lambda, \Lambda)$ from (λ, Λ) by conjugating $\mathbf{i}$, $\mathbf{j}$, and $\mathbf{k}$ with (λ, Λ) to obtain the column vectors of this matrix.

Remark 3.1. Using the fact that $\hat{R}$ is a group homomorphism and (3.5), it is clear that the factorization (2.4) of Corollary 2.2 is equivalent to

$$(\gamma_N, \Gamma_N) \cdots (\gamma_1, \Gamma_1) = \pm (\lambda_1, \Lambda_1)$$

and

$$(\gamma_N, -\Gamma_N) \cdots (\gamma_1, -\Gamma_1) = \pm (\lambda_2, \Lambda_2), \tag{3.6}$$

where the (λ_i, Λ_i) are ERPs for the $A_i^{(1)} A_i^{(0)t}$ and the (γ_j, Γ_j) are ERPs for the G_j.

We will find quaternions more convenient for the computations that follow and study the factorization (3.6) in what follows.

By (3.5), it is clear that any rotation has ERPs (λ, Λ) with $\lambda \geq 0$; with this choice we have $\lambda = \cos \frac{\phi}{2}$, where ϕ is the "standard" angle of the rotation, i.e., that in $[0, \pi]$. In what follows we will assume the λ_i in Remark 3.1 are nonegative.

4. Controllability with constant and single-switch controls and statement of Theorem 4.2. In constructing motions in $\mathcal{S}$ with a given set of endpoints, an obvious first question to ask is how many discontinuities in the controls (equivalently, how many factors in the products in (2.4) and (3.6)) are required for a motion with a given set of endpoints. It should come as no surprise that only very special choices of endpoints may be connected with a path with constant control. In fact, this is only possible when the net rotations of the bodies between the endpoints are inverses of each other.

LEMMA 4.1. *Let* $A_i^{(k)} \in SO(3)$ *and let* (λ_i, Λ_i) *be as in Remark* 3.1, $i = 1, 2$ *and* $k = 0, 1$. *There is a path with these endpoints and constant control if and only if*

$$(\lambda_1, -\Lambda_1) = (\lambda_2, \Lambda_2) \quad \text{if } \lambda_1 \neq 0$$

or

$$\lambda_2 = 0 \quad \text{and} \quad \Lambda_2 = \pm \Lambda_1 \quad \text{if } \lambda_1 = 0.$$

In either case we can take $N = 1$ *and* $(\gamma_1, \Gamma_1) = (\lambda_1, -\Lambda_1)$ *in Remark* 3.1.

Proof. Controllability with a constant control means we can take $N = 1$ in Corollary 2.2, i.e., using Remark 3.1, there exists (γ, Γ) such that

$$\pm (\lambda_1, \Lambda_1) = (\gamma, \Gamma) = \pm (\lambda_2, -\Lambda_2).$$

If $\lambda_1 \neq 0$, our assumption that each λ_i is positive implies $\Lambda_2 = -\Lambda_1$, and if $\lambda_1 = 0$, this only requires $\Lambda_1 = \pm \Lambda_2$. □

As a second try, we can consider those motions in $\mathcal{S}$ with controls having one discontinuity. Taking $N = 2$ in (3.6), we require (γ_i, Γ_i), $i = 1, 2$, such that

$$(\gamma_2, \Gamma_2)(\gamma_1, \Gamma_1) = \pm (\lambda_1, \Lambda_1) \quad \text{and} \quad (\gamma_2, -\Gamma_2)(\gamma_1, -\Gamma_1) = \pm (\lambda_2, \Lambda_2).$$

Making use of (3.3), this shows that we must have

$$\pm \lambda_1 = \gamma_2 \gamma_1 - \langle \Gamma_2, \Gamma_1 \rangle = \pm \lambda_2,$$

and since the λ_i have the same sign by assumption, this means $\lambda_1 = \lambda_2$. In other words, by (3.1), the net rotations of the bodies must have the same angle of rotation.

Since this is not generally true, we must consider those controls with at least two switches.

As it turns out, two is always enough; in what follows, we will establish the following theorem.

THEOREM 4.2. *For any choice of the* (λ_i, Λ_i), *there exist* (γ_j, Γ_j), $1 \leq j \leq 3$, *such that* $\gamma_j \geq 0$,

$$(\gamma_3, \Gamma_3)(\gamma_2, \Gamma_2)(\gamma_1, \Gamma_1) = (\lambda_1, \Lambda_1), \quad \textit{and} \quad (\gamma_3, -\Gamma_3)(\gamma_2, -\Gamma_2)(\gamma_1, -\Gamma_1) = (\lambda_2, \Lambda_2).$$

In the process of proving this result, we will explicitly construct and geometrically describe the (γ_j, Γ_j). We will also derive formulas for the (γ_j, Γ_j) in terms of elementary functions of the (λ_i, Λ_i).

Remark 4.3. Note, by the discussion at the beginning of §3, that the angles ϕ^j and axes $\mathbf{n}^j$ of the rotations $\hat{R}(\gamma_j, \Gamma_j)$ are immediately available from the (γ_j, Γ_j); in particular, we have $\phi^j = 2\cos^{-1}\gamma_j \in [0, \pi]$ and $\mathbf{n}^j = \Gamma_j/|\Gamma_j|$ $(\Gamma_j \neq 0)$. We can then obtain the desired motion as in Remark 2.3.

5. A result on motions with a single switch. As noted above, the factorization in Remark 3.1 with $N = 2$ requires $\lambda_1 = \lambda_2$. Here we describe a condition that is also sufficient for the factorization, and derive formulas for the (γ_j, Γ_j) in this case.

We will combine this result with one from the next section to prove Theorem 4.2.

PROPOSITION 5.1. *Suppose* (δ_i, Δ_i) $(i = 1, 2)$ *are such that* $\delta_1 = \delta_2 \in [0, 1)$ *and the* Δ_i *are linearly independent. Then there exist* (γ_j, Γ_j), $j = 2, 3$, *such that each* γ_j *is nonnegative,*

$$(\gamma_3, \Gamma_3)\,(\gamma_2, \Gamma_2) = (\delta_1, -\Delta_1) \quad \textit{and} \quad (\gamma_3, -\Gamma_3)\,(\gamma_2, -\Gamma_2) = (\delta_2, -\Delta_2)\,.$$

Explicitly,

$$(\gamma_2, \Gamma_2) = \left(\frac{|\Delta_2 - \Delta_1|}{2\,|\Delta_1|} \cos\theta_2, \sin\theta_2 \, \frac{\Delta_2 - \Delta_1}{|\Delta_2 - \Delta_1|} + \cos\theta_2 \, \frac{|\Delta_1 + \Delta_2|}{2\,|\Delta_1|\,|\Delta_2 \times \Delta_1|} \Delta_2 \times \Delta_1 \right)$$

and

$$(\gamma_3, \Gamma_3) = \left(\frac{|\Delta_2 - \Delta_1|}{2\,|\Delta_1|} \cos\theta_3, \sin\theta_3 \, \frac{\Delta_2 - \Delta_1}{|\Delta_2 - \Delta_1|} - \cos\theta_3 \, \frac{|\Delta_1 + \Delta_2|}{2\,|\Delta_1|\,|\Delta_2 \times \Delta_1|} \Delta_2 \times \Delta_1 \right),$$

where $\theta_2, \theta_3 \in \left[0, \frac{\pi}{2}\right]$ *is any pair of angles satisfying* $\theta_2 + \theta_3 = \frac{\phi}{2}$ *and* ϕ *is the unique angle in* $(0, \pi]$ *such that* $\delta_1 = \cos\frac{\phi}{2}$.

Proof. Let $\phi \stackrel{\text{def}}{=} 2\cos^{-1}\delta_1 \in (0, \pi]$, and note that by assumption, $|\Delta_i| = \sin\frac{\phi}{2} \in (0, 1]$ for each i. Since the Δ_i are linearly independent,

$$u \stackrel{\text{def}}{=} -\frac{\Delta_1 + \Delta_2}{2} \quad \text{and} \quad v \stackrel{\text{def}}{=} \frac{\Delta_2 - \Delta_1}{2} \tag{5.1}$$

are nonzero; moreover, it is easily seen that

$$\langle u, v \rangle = 0 \quad \text{and} \quad |u|^2 + |v|^2 = |\Delta_1|^2 = \sin^2\frac{\phi}{2}. \tag{5.2}$$

The construction will be more transparent under a rotation of axes. Recall that if $D \in SO(3)$ and $q \in \mathbb{R}^3$, then the coordinates of the vector q observed from the

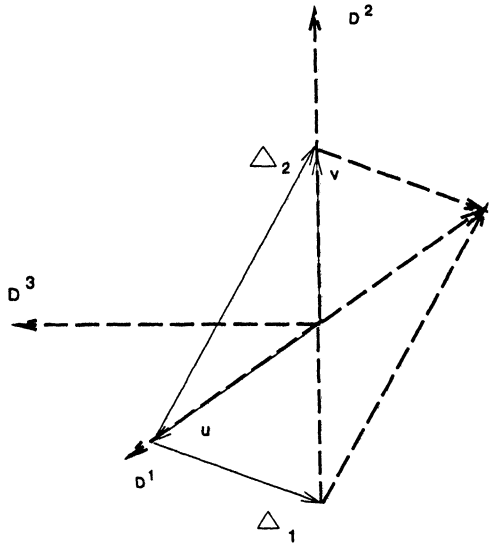

FIG. 2

coordinate axes $\{D^k\}_{k=1}^3$ are given by $D^t q$. Now, if we define the matrix D by

$$D \stackrel{\text{def}}{=} \left(\frac{u}{|u|} \;\vdots\; \frac{v}{|v|} \;\vdots\; \frac{u}{|u|} \times \frac{v}{|v|} \right), \tag{5.3}$$

then $D \in SO(3)$, $D^t u = |u|\,\mathbf{i}$, and $D^t v = |v|\,\mathbf{j}$ (see Fig. 2).

Pick $\theta_j \in \left[0, \frac{\pi}{2}\right]$, $j = 2, 3$, to satisfy $\theta_2 + \theta_3 = \frac{\phi}{2}$ and define

(5.4)

$$\gamma_j \stackrel{\text{def}}{=} \frac{|v| \cos \theta_j}{\sin \frac{\phi}{2}}, \quad j = 2, 3, \quad \overline{\Gamma}_2 \stackrel{\text{def}}{=} \begin{pmatrix} 0 \\ \sin \theta_2 \\ \frac{|u| \cos \theta_2}{\sin \frac{\phi}{2}} \end{pmatrix}, \quad \text{and} \quad \overline{\Gamma}_3 \stackrel{\text{def}}{=} \begin{pmatrix} 0 \\ \sin \theta_3 \\ \frac{-|u| \cos \theta_3}{\sin \frac{\phi}{2}} \end{pmatrix}.$$

Then

$$\left|\overline{\Gamma}_j\right|^2 + \gamma_j^2 = \frac{(|u|^2 + |v|^2) \cos^2 \theta_j}{\sin^2 \frac{\phi}{2}} + \sin^2 \theta_j = \cos^2 \theta_j + \sin^2 \theta_j = 1 \quad (j = 2, 3),$$

$$\gamma_2 \gamma_3 - \left\langle \overline{\Gamma}_2, \overline{\Gamma}_3 \right\rangle = \frac{|v|^2 + |u|^2}{\sin^2 \frac{\phi}{2}} \cos \theta_2 \cos \theta_3 - \sin \theta_2 \sin \theta_3 = \cos(\theta_2 + \theta_3) = \delta_1 = \delta_2,$$

$$\begin{aligned} \gamma_2 \overline{\Gamma}_3 + \gamma_3 \overline{\Gamma}_2 &= \frac{|v| \cos \theta_2}{\sin \frac{\phi}{2}} \begin{pmatrix} 0 \\ \sin \theta_3 \\ \frac{-|u| \cos \theta_3}{\sin \frac{\phi}{2}} \end{pmatrix} + \frac{|v| \cos \theta_3}{\sin \frac{\phi}{2}} \begin{pmatrix} 0 \\ \sin \theta_2 \\ \frac{|u| \cos \theta_2}{\sin \frac{\phi}{2}} \end{pmatrix} \\ &= \frac{|v| \sin(\theta_2 + \theta_3)}{\sin \frac{\phi}{2}} \mathbf{j} = |v|\,\mathbf{j} = D^t v, \end{aligned}$$

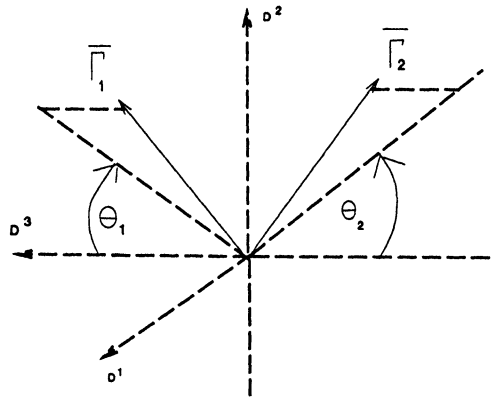

FIG. 3

and

$$\overline{\Gamma}_3 \times \overline{\Gamma}_2 = \begin{pmatrix} 0 \\ \sin\theta_3 \\ \frac{-|u|\cos\theta_3}{\sin\frac{\phi}{2}} \end{pmatrix} \times \begin{pmatrix} 0 \\ \sin\theta_2 \\ \frac{|u|\cos\theta_2}{\sin\frac{\phi}{2}} \end{pmatrix}$$

$$= \frac{|u|}{\sin\frac{\phi}{2}}(\sin\theta_2\cos\theta_3 + \sin\theta_3\cos\theta_2)\mathbf{i} = \frac{|u|\sin(\theta_2+\theta_3)}{\sin\frac{\phi}{2}}\mathbf{i} = D^t u.$$

Now let $\Gamma_j \overset{\text{def}}{=} D\overline{\Gamma}_j$, $j = 2, 3$. It is clear that the first two equations above hold when the $\overline{\Gamma}_j$ are replaced by the Γ_j, since D is orthonormal. It follows that the (γ_j, Γ_j) satisfy the normalization condition (3.2) and by (3.3) the scalar components of the products $(\gamma_3, \Gamma_3)(\gamma_2, \Gamma_2)$ and $(\gamma_3, -\Gamma_3)(\gamma_2, -\Gamma_2)$ are both $\delta_1 = \delta_2$.

Moreover, since $DD^t = E$ and $D(q \times r) = (Dq) \times (Dr)$ for any $q, r \in \mathbb{R}^3$, multiplying the second two equations above by D gives $\gamma_2\Gamma_3 + \gamma_3\Gamma_2 = v$ and $\Gamma_3 \times \Gamma_2 = u$. Adding and subtracting these equations and using (5.1) and (3.3) the vector components of $(\gamma_3, \Gamma_3)(\gamma_2, \Gamma_2)$ and $(\gamma_3, -\Gamma_3)(\gamma_2, -\Gamma_2)$ are $-\Delta_1$ and $-\Delta_2$, respectively.

By the definitions of D and the Γ_j, the formulas for the $\overline{\Gamma}_j$ in (5.4) express the Γ_j as linear combinations of unit vectors in the directions of u and $v \times u$; by (5.1), it is clear that we can obtain these vectors by normalizing $\Delta_2 - \Delta_1$ and $\Delta_2 \times \Delta_1$. The coefficients of these vectors in the formulas for the Γ_j, as well as the formulas for the γ_j, are clear from (5.4), (5.1), and the fact that $|\Delta_1| = \sin\frac{\phi}{2}$. □

Notice that the (γ_j, Γ_j) obtained above are not unique; rather, the set of pairs with the desired properties is a one-parameter family for which the vector components all lie in a given plane (see Fig. 3).

COROLLARY 5.2. *If, for a given choice of endpoints, the* (λ_i, Λ_i) *satisfy the hypotheses on the* Δ_i *in Proposition* 5.1, *then there is a motion in* $\mathcal{S}$ *with these endpoints and one discontinuity in its control.*

Proof. Take $(\delta_i, \Delta_i) = (\lambda_i, -\Lambda_i)$, $i = 1, 2$ in Proposition 5.1. The motion can then be constructed as outlined in Remark 4.3. □

When these hypotheses do not hold, we can apply Proposition 5.1 after some adjustments; we deal with the logistics of this in the next section.

6. The first rotation. We will devote this section to proving the following proposition.

PROPOSITION 6.1. *For any* (λ_i, Λ_i), $i = 1, 2$, *there exists* (γ_1, Γ_1) *such that* $(\delta_1, \Delta_1) \stackrel{\text{def}}{=} (\gamma_1, \Gamma_1)(\lambda_1, -\Lambda_1)$ *and* $(\delta_2, \Delta_2) \stackrel{\text{def}}{=} (\gamma_1, -\Gamma_1)(\lambda_2, -\Lambda_2)$ *are each the identity* $(1, 0)$ *or satisfy the hypotheses of Proposition* 5.1, *i.e.,* $\delta_1 = \delta_2 \in [0, 1)$ *and the* Δ_i *are linearly independent. Moreover,* $\gamma_1 \geq 0$.

For the remainder of this section, we will assume that some fixed choice of the (λ_i, Λ_i) has been made. First note that the condition $\delta_1 = \delta_2$ is not particularly restrictive.

LEMMA 6.2. *Let* $\mathbf{n}$ *be any unit vector in* $\mathbb{R}^3$. *There exists* $\phi \in [0, 2\pi]$ *such that* $\delta_1 = \delta_2$ *when* $(\gamma_1, \Gamma_1) = (\cos \frac{\phi}{2}, \sin \frac{\phi}{2}\mathbf{n})$. *In particular,*

$$\tan \frac{\phi}{2} = \frac{\lambda_2 - \lambda_1}{\langle \Lambda_1, \mathbf{n} \rangle + \langle \Lambda_2, \mathbf{n} \rangle}. \tag{6.1}$$

Proof. Note that for any $\mathbf{n}$ we have $\delta_1 = \cos \frac{\phi}{2}\lambda_1 + \sin \frac{\phi}{2}\langle \Lambda_1, \mathbf{n} \rangle$ and $\delta_2 = \cos \frac{\phi}{2}\lambda_2 - \sin \frac{\phi}{2}\langle \Lambda_2, \mathbf{n} \rangle$. Equating these expressions, dividing the resulting equation by $\cos \frac{\phi}{2}$, and solving for $\tan \frac{\phi}{2}$ gives the result. □

This result tells us that we can obtain (γ_1, Γ_1) explicitly in Proposition 5.1; however, we must choose $\mathbf{n}$ in such a way that $\phi \in [0, \pi]$, the δ_i are nonnegative, and the Δ_i are linearly independent when nonzero. The choice of $\mathbf{n}$ required for these conditions varies, depending on the endpoints.

As it turns out, there is always an appropriate choice of $\mathbf{n}$ for which $\mathbf{n}, \Lambda_1$, and Λ_2 are coplanar. For such $\mathbf{n}$, it is easiest to address these issues under an appropriate rotation of axes. In particular, the action of those quaternions with vector part parallel to $\mathbf{n}$ becomes quite transparent when we rotate axes so that $\mathbf{n}$ lies on a coordinate axis and $\mathbf{n}, \Lambda_1$, and Λ_2 lie in a coordinate plane: Let J be any $SO(3)$ matrix with first column vector parallel to $\mathbf{n}$ and third column vector orthogonal to each Λ_i; then $\mathbf{n}$ and the $\overline{\Lambda}_i \stackrel{\text{def}}{=} J^t\Lambda_i$ have these features.

Let $\overline{\Gamma}_1 \stackrel{\text{def}}{=} J^t\Gamma_1$ and $\overline{\Delta}_i \stackrel{\text{def}}{=} J^t\Delta_i$, $i = 1, 2$. It is easily checked using (3.3) that $(\delta_1, \overline{\Delta}_1) = (\gamma_1, \overline{\Gamma}_1)(\lambda_1, -\overline{\Lambda}_1)$ and similarly $(\delta_2, \overline{\Delta}_2) = (\gamma_1, -\overline{\Gamma}_1)(\lambda_2, -\overline{\Lambda}_2)$. Moreover, since $(\gamma_1, J^t\overline{\Gamma}_1) = (\cos \frac{\phi}{2}, \sin \frac{\phi}{2}\mathbf{i})$, another application of (3.3) shows that

$$\begin{pmatrix} \delta_1 \\ \overline{\Delta}_1 \end{pmatrix} = \begin{pmatrix} \left\langle \frac{\phi}{2} \right\rangle & 0 \\ 0 & \left\langle \frac{\phi}{2} \right\rangle \end{pmatrix} \begin{pmatrix} \lambda_1 \\ -\overline{\Lambda}_1 \end{pmatrix} \quad \text{and} \quad \begin{pmatrix} \delta_2 \\ \overline{\Delta}_2 \end{pmatrix} = \begin{pmatrix} \left\langle -\frac{\phi}{2} \right\rangle & 0 \\ 0 & \left\langle -\frac{\phi}{2} \right\rangle \end{pmatrix} \begin{pmatrix} \lambda_2 \\ -\overline{\Lambda}_2 \end{pmatrix},$$

where $\langle (\cdot) \rangle \in SO(2)$ is the matrix of the rotation by $(\cdot)$.

On the other hand, by the definition of J, for each i we have

$$\begin{pmatrix} \lambda_i \\ -\overline{\Lambda}_i \end{pmatrix} = \begin{pmatrix} \lambda_i \\ -\langle \Lambda_i, \mathbf{n} \rangle \\ \pm \left| \Lambda_i |_{\mathbf{n}^\perp} \right| \\ 0 \end{pmatrix} = \begin{pmatrix} \ell_i \begin{pmatrix} \cos k_i \\ \sin k_i \end{pmatrix} \\ \pm\sqrt{1 - \ell_i^2} \\ 0 \end{pmatrix} \tag{6.2}$$

for suitable $\ell_i \in [0, 1]$ and $k_i \in \left[-\frac{\pi}{2}, \frac{\pi}{2}\right]$ (in particular, $\ell_i = \left(\lambda_i^2 + \langle \Lambda_i, \mathbf{n} \rangle^2\right)^{1/2}$ and $k_i = -\tan^{-1}\left[\frac{\langle \Lambda_i, \mathbf{n} \rangle}{\lambda_i}\right]$). This is illustrated in Fig. 4.

It follows that

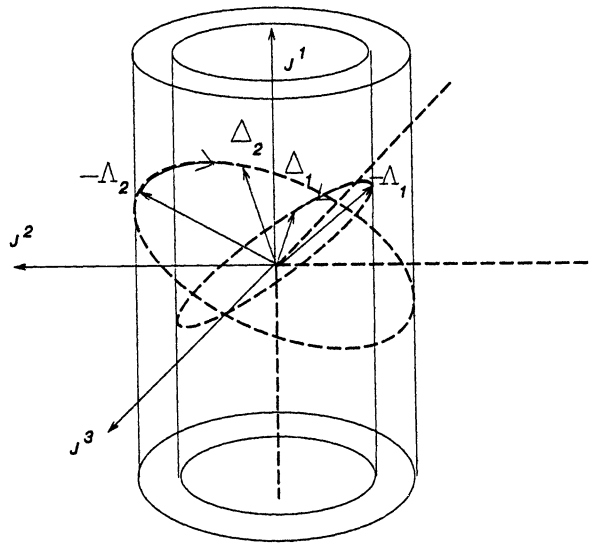

FIG. 4

(6.3)

$$\begin{pmatrix}\delta_1\\ \overline{\Delta}_1\end{pmatrix} = \begin{pmatrix} \ell_1 \begin{pmatrix} \cos\left(k_1+\frac{\phi}{2}\right)\\ \sin\left(k_1+\frac{\phi}{2}\right)\end{pmatrix} \\ \pm\sqrt{1-\ell_1^2}\begin{pmatrix}\cos\frac{\phi}{2}\\ \sin\frac{\phi}{2}\end{pmatrix}\end{pmatrix} \quad \text{and} \quad \begin{pmatrix}\delta_2\\ \overline{\Delta}_2\end{pmatrix} = \begin{pmatrix} \ell_2 \begin{pmatrix} \cos\left(k_2-\frac{\phi}{2}\right)\\ \sin\left(k_2-\frac{\phi}{2}\right)\end{pmatrix} \\ \pm\sqrt{1-\ell_2^2}\begin{pmatrix}\cos\frac{\phi}{2}\\ -\sin\frac{\phi}{2}\end{pmatrix}\end{pmatrix}.$$

This shows that the rotation of axes defined by J "straightens out" the action of $(\gamma_1,\Gamma_1) = (\cos\frac{\phi}{2}, \sin\frac{\phi}{2}\mathbf{n})$ for a given choice of $\mathbf{n}$. Varying ϕ, we obtain the following geometric description of the $(\delta_i,\overline{\Delta}_i)$: The $\overline{\Delta}_i$ rotate about $\mathbf{i}$ on the surfaces of cylinders, their projections on $\mathbf{i}$ varying sinusoidally; correspondingly, the δ_i also vary sinusoidally (this is also a nice geometric interpretation of the exponential map on S^3).

This construction makes it straightforward to prove Proposition 6.1; before doing this we make one more observation.

LEMMA 6.3. *If for some choice of* $\mathbf{n}$ *and some* $\phi' \in [0,\pi]$ *we have* $\operatorname{sgn}(\ell_1\cos(k_1+\frac{\phi'}{2}) - \ell_2\cos(k_2-\frac{\phi'}{2})) = \operatorname{sgn}(\lambda_2-\lambda_1)$, *and if each* $\ell_i \in [0,1)$, *then there is a solution* ϕ *of* (6.1) *for which the conclusions of Proposition* 6.1 *hold with* $(\gamma_1,\Gamma_1) = (\cos\frac{\phi}{2}, \sin\frac{\phi}{2}\mathbf{n})$.

Proof. Since $\lambda_i = \ell_i\cos k_i$ for each i and $\ell_1\cos(k_1+\frac{\phi}{2}) - \ell_2\cos(k_2-\frac{\phi}{2})$ is continuous in ϕ, the first assumption, (6.3), and the intermediate value theorem guarantee that there is a solution ϕ of (6.1) in $(0,\phi')$; by Lemma 6.2, this means that $\delta_1 = \delta_2$ for this choice of ϕ. Moreover, since neither ℓ_i is 1, (6.3) shows that the projections of the $\overline{\Delta}_i$ in $\mathbf{i}^\perp$ are nonzero, and since $\phi \in (0,\pi)$, these vectors are linearly independent, i.e., the $\overline{\Delta}_i$ are linearly independent. It is clear that $\delta_1 > 0$. □

The proof of Proposition 6.1 proceeds in five steps. We begin with the "generic" case.

LEMMA 6.4. *If* $\lambda_1 \neq \lambda_2$, $\lambda_i \in [0,1)$, $i = 1,2$, *and* Λ_1 *is a positive scalar multiple of* Λ_2 *when these vectors are linearly dependent, choose* $\mathbf{n}$ *to satisfy*

$$-\langle \Lambda_i, \mathbf{n}\rangle \quad \text{and} \quad \left|\Lambda_i|_{\mathbf{n}^\perp}\right| > 0, \qquad i = 1,2 \quad \text{if} \quad \lambda_1 > \lambda_2;$$

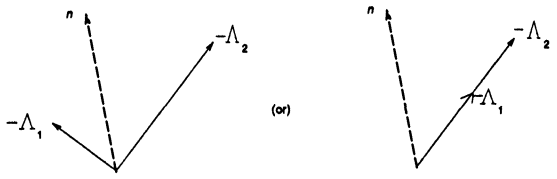

FIG. 5

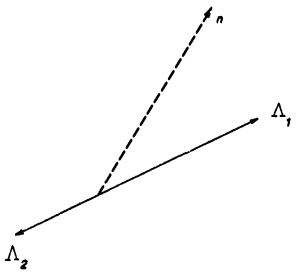

FIG. 6

$$\left\langle \Lambda_i, \mathbf{n} \right\rangle \quad \text{and} \quad \left| \Lambda_i|_{\mathbf{n}^\perp} \right| > 0, \qquad i = 1, 2 \quad \text{if} \quad \lambda_1 < \lambda_2.$$

Then the conclusions of Lemma 6.3 *hold.*

Proof. Suppose $\lambda_1 > \lambda_2$ and choose $\mathbf{n}$ as above (see Fig. 5).

By (6.2), $\ell_i \geq 0$ and $-\langle \Lambda_i, \mathbf{n} \rangle = -\langle \overline{\Lambda}_i, \mathbf{i} \rangle = \ell_i \sin k_i$ and $\left| \Lambda_i|_{\mathbf{n}^\perp} \right| = \left| \overline{\Lambda}_i|_{\mathbf{i}^\perp} \right| = \sqrt{1 - \ell_i^2}$ are both strictly positive. It follows that each $\ell_i \in (0, 1)$ and each $k_i \in (0, \frac{\pi}{2})$.

Let $\phi' \stackrel{\text{def}}{=} \pi - 2k_1$. Then $\ell_1 \cos(\frac{\phi'}{2} + k_1) = 0$ and $\ell_2 \cos(k_2 - \frac{\phi'}{2}) = \ell_2 \cos(k_1 + k_2 - \frac{\pi}{2}) > 0$, so that $\operatorname{sgn}(\lambda_2 - \lambda_1) = \operatorname{sgn}(\ell_1 \cos(k_1 + \frac{\phi}{2}) - \ell_2 \cos(k_2 - \frac{\phi}{2}))$.

The result follows from Lemma 6.3.

The proof is similar when $\lambda_2 > \lambda_1$; with the second choice above of $\mathbf{n}$, the k_i are negative and one takes $\phi' = \pi + 2k_2$. □

The next lemma treats a less generic case.

LEMMA 6.5. *When $\lambda_1 \neq \lambda_2$, each $\lambda_i < 1$, and the Λ_i are negative scalar multiples, let $\mathbf{n}$ be any vector satisfying*

$$\left\langle \Lambda_1, \mathbf{n} \right\rangle \quad \text{and} \quad \left| \Lambda_1|_{\mathbf{n}^\perp} \right| > 0.$$

Then the conclusions of Lemma 6.3 *hold.*

Proof. Choose $\mathbf{n}$ as stated (see Fig. 6).

Since the projection in $\mathbf{n}^\perp$ of Λ_1 is nonzero, $\ell_1 < 1$, and since $\langle \Lambda_1, \mathbf{n} \rangle$ is nonzero, $\ell_1 > 0$, by (6.2). Since the Λ_i are parallel, ℓ_2 is also in $(0, 1)$.

Equation (6.2) also shows that $\langle \Lambda_i, \mathbf{n} \rangle = -\ell_i \sin k_i$ for each i, so that $k_1 \in [-\frac{\pi}{2}, 0)$ and $k_2 \in (0, \frac{\pi}{2}]$ and consequently

$$\ell_1 \cos\left(\frac{\pi}{2} + k_1\right) = -\ell_1 \sin k_1 = \langle \Lambda_1, \mathbf{n} \rangle = \sqrt{1 - \lambda_1^2}\, \langle \mathbf{n}_1, \mathbf{n} \rangle$$

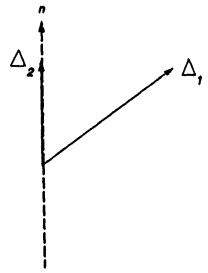

FIG. 7

and

$$\ell_2 \cos\left(k_2 - \frac{\pi}{2}\right) = \ell_2 \sin k_2 = -\langle \Lambda_2, \mathbf{n}\rangle = -\sqrt{1-\lambda_2^2}\,\langle \mathbf{n}_2, \mathbf{n}\rangle\,,$$

where $\mathbf{n}_i \overset{\text{def}}{=} \Lambda_i/|\Lambda_i|$, $i = 1, 2$. It follows that

$$\ell_1 \cos\left(k_1 + \frac{\pi}{2}\right) - \ell_2 \cos\left(k_2 - \frac{\pi}{2}\right) = \langle \mathbf{n}_1, \mathbf{n}\rangle \left(\sqrt{1-\lambda_1^2} - \sqrt{1-\lambda_2^2}\right),$$

since $\langle \mathbf{n}_1, \mathbf{n}\rangle = -\langle \mathbf{n}_2, \mathbf{n}\rangle$. Moreover, it is easy to see that $\operatorname{sgn}\sqrt{1-\lambda_1^2} - \sqrt{1-\lambda_2^2} = \operatorname{sgn}(\lambda_2 - \lambda_1)$, since by assumption each $\lambda_i \in [0, 1]$.

Since the hypotheses of Lemma 6.3 hold, the result now follows. □

The next result deals with another special case.

LEMMA 6.6. *If $\lambda_1 \neq \lambda_2$ and one of the λ_i is 1, choose $\mathbf{n}$ so that*

$$\left\langle \Lambda_1, \mathbf{n}\right\rangle \quad \textit{and} \quad \left|\Lambda_1|_{\mathbf{n}^\perp}\right| > 0 \quad \textit{if} \quad \lambda_2 = 1;$$

and

$$-\left\langle \Lambda_2, \mathbf{n}\right\rangle \quad \textit{and} \quad \left|\Lambda_2|_{\mathbf{n}^\perp}\right| > 0 \quad \textit{if} \quad \lambda_1 = 1.$$

Then there is a solution ϕ of (6.1) in $[0, \pi]$ for which Proposition 6.1 holds with $(\gamma_1, \Gamma_1) = (\cos\frac{\phi}{2}, \sin\frac{\phi}{2}\mathbf{n})$.

Proof. If $\lambda_2 = 1$, make the first choice above of $\mathbf{n}$.

Since $\lambda_2 = 1$, $\ell_2 = 1$ and $k_2 = 0$ by (6.2). Moreover, since $\left|\Lambda_1|_{\mathbf{n}^\perp}\right| > 0$, $\ell_1 \in (0, 1)$, and since $\ell_1 \sin k_1 = -\langle \Lambda_1, \mathbf{n}\rangle < 0$, $k_1 \in [-\frac{\pi}{2}, 0]$. Since $\ell_1 \cos(k_1 + \frac{\pi}{2}) > 0$ and $\ell_2 \cos(k_2 - \frac{\pi}{2}) = 0$, we have $\operatorname{sgn}(\lambda_2 - \lambda_1) = \operatorname{sgn}(\ell_1 \cos(k_1 + \frac{\pi}{2}) - \ell_2 \cos(k_2 - \frac{\pi}{2}))$, so, as in Lemma 6.3, there is a solution $\phi \in (0, \pi)$ of (6.1).

Moreover, by (6.3), we have $\overline{\Delta}_2 = \sin\frac{\phi}{2}\mathbf{i}$ since $\ell_2 = 1$, and the projection of $\overline{\Delta}_1$ in $\mathbf{i}^\perp$ has magnitude $\sqrt{1-\ell_1^2} > 0$, so the $\overline{\Delta}_i$ are linearly independent (see Fig. 7).

The proof is similar for the case $\lambda_1 = 1$. □

The last special case we deal with is the one in which the bodies have the same net rotations and the angles of net rotation are smaller than π.

LEMMA 6.7. *If $\Lambda_1 = \Lambda_2$ and $\lambda_1 = \lambda_2 \in (0, 1)$, let $\mathbf{n}$ be any unit vector in $\Lambda_1^\perp$, ϕ any angle in $(0, \pi)$. Then the conclusions of Lemma 6.3 hold for this choice of ϕ.*

Proof. With the stated choice of $\mathbf{n}$, we have $\langle \Lambda_i, \mathbf{n}\rangle = -\ell_i \sin k_i = 0$ and $\cos k_i = \lambda_i > 0$, by (6.2); therefore, $k_i = 0$ and $\ell_i \in (0, 1)$, $i = 1, 2$ (see Fig. 8). It follows that $\delta_1 = \ell_1 \cos(k_1 + \frac{\phi}{2}) = \ell_2 \cos(k_2 - \frac{\phi}{2}) = \delta_2$ for *any* ϕ. Using (6.3), it is clear that for any $\phi \in (0, \pi)$ the Δ_i are linearly independent. □

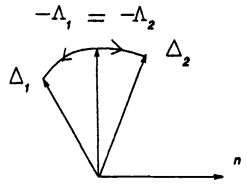

FIG. 8

Proof of Proposition 6.1. Suppose first that the Λ_i are linearly independent. Since $|\Lambda_i|^2 + {\lambda_i}^2 = 1$, we have $\lambda_i < 1$, $i = 1, 2$. If $\lambda_1 \neq \lambda_2$, the hypotheses of Lemma 6.4 hold, and if $\lambda_1 = \lambda_2$, it is clear that Proposition 6.1 holds with $(\gamma_1, \Gamma_1) = (1, 0)$.

Suppose next that the Λ_i are linearly dependent and $\lambda_1 \neq \lambda_2$. If one of the λ_i is 1, we are in the situation of Lemma 6.6. If neither of the λ_i is 1, the Λ_i are either positive scalar multiples, in which case we have the hypotheses of Lemma 6.4, or negative scalar multiples, in which case we are in the situation of Lemma 6.5, so in any case Proposition 6.1 is true.

Finally, suppose the Λ_i are linearly dependent and the λ_i are equal. If the Λ_i are equal with $\lambda_1 \in (0, 1)$, we have the hypotheses of Lemma 6.7. If the Λ_i are equal and $\lambda_1 = 0$, or if the Λ_i are nonzero and negatives of one another, we have the hypotheses of Lemma 4.1. The only remaining case is that when $\lambda_1 = \lambda_2 = 1$, in which case Proposition 6.1 is immediate.

7. Proof of Theorem 4.2. Theorem 4.2 is now easy to prove based on Lemma 4.1, and Propositions 5.1 and 6.1. Given a choice of the net rotations of the bodies, with quaternion representations (λ_i, Λ_i) as in Remark 3.1, it is clear by Lemma 4.1 that we can take $(\gamma_2, \Gamma_2) = (\gamma_3, \Gamma_3) = (1, 0)$ in Theorem 4.2 when the (λ_i, Λ_i) are inverses of each other, and if the (λ_i, Λ_i) satisfy the hypotheses of Proposition 6.1, we can take $(\gamma_1, \Gamma_1) = (1, 0)$ in Theorem 4.2. If neither of these conditions holds, Proposition 6.1 implies that for some (γ_1, Γ_1), $(\delta_1, \Delta_1) = (\gamma_1, \Gamma_1)(\lambda_1, -\Lambda_1)$ and $(\delta_2, \Delta_2) = (\gamma_1, -\Gamma_1)(\lambda_2, -\Lambda_2)$ satisfy the hypotheses of Proposition 5.1. Applying Proposition 5.1, we have (γ_j, Γ_j), $j = 2, 3$, such that

$$(\gamma_3, \Gamma_3)(\gamma_2, \Gamma_2)(\gamma_1, \Gamma_1)(\lambda_1, -\Lambda_1) = (1, 0) \Longleftrightarrow (\gamma_3, \Gamma_3)(\gamma_2, \Gamma_2)(\gamma_1, \Gamma_1) = (\lambda_1, \Lambda_1)$$

and

$$\begin{aligned}(\gamma_3, -\Gamma_3)(\gamma_2, -\Gamma_2)(\gamma_1, -\Gamma_1)(\lambda_2, -\Lambda_2) = (1, 0)\\ \Longleftrightarrow (\gamma_3, -\Gamma_3)(\gamma_2, -\Gamma_2)(\gamma_1, -\Gamma_1) = (\lambda_2, \Lambda_2)\end{aligned}$$

by (3.4). □

In proving this result, we have shown how to construct motions in $\mathcal{S}$ for a given set of endpoints and have given explicit formulas at each step; following the proof of Proposition 6.1, we can always identify which of the zero-, two-, or one-switch situations we are in, and Lemma 4.1, Proposition 5.1, and Lemmas 6.4–6.6 give the formulas for the rotations involved. Once the quaternions are obtained, the actual construction of motions proceeds as in Remarks 4.3 and 2.3.

8. Concluding remarks. The motions obtained here provide simple and intuitive ways of moving between points in $SO(3)^2$ with the imposed constraints. Indeed, a rotation at constant angular velocity is the most fundamental and easily understood motion of a rigid body. By the results of §§5 and 6, the triples of rotations involved are far from being uniquely determined.

In our development we relied on the fact that these motions could be determined algebraically, working on S^3. We can regard the continuous behavior of such a trajectory as being determined by a "shell" of rotations.

Papers treating optimal control problems with this same two body system and other, more complicated, multibody systems have been completed by the author and others since the original submission of this paper. They describe alternative motions of nonholonomic systems like the one described here.

Finally, we mention here that the author has noted generalizations of the results presented here to two body systems with less material symmetry using piecewise constant controls given by the angular momentum of one of the bodies. We hope to report on this at a later date.

9. Appendix: Angle and axis of a rotation. Any $M \in SO(3)$ is the matrix of a rotation through an angle $\phi \in [0, \pi]$ about a unit vector $\mathbf{n} \in \mathbb{R}^3$. The following standard formulas express ϕ and $\mathbf{n}$ in terms of the entries M^{ij} of M when $\sin\phi \neq 0$:

$$\cos\phi = \frac{\mathrm{Tr}(M) - 1}{2},$$

$$\mathbf{n} = \frac{1}{2\sin\phi} \begin{pmatrix} M^{23} - M^{32} \\ M^{31} - M^{13} \\ M^{12} - M^{21} \end{pmatrix}.$$

Derivations of these formulas can be found in, for instance, [1]. As noted in this and other references, the axis $\mathbf{n}$ of the rotation with angle of rotation 0 can be selected arbitrarily. On the other hand, the formula above for $\mathbf{n}$ also becomes undefined when $\phi = \pi$, and the axis of rotation is certainly not indeterminate in this case.

We know of no reference that gives a formula for $\mathbf{n}$ when $\phi = \pi$. We provide one here; for details consult [4]. If $\phi = \pi$, it can be shown that either there is a standard unit vector E^i which is fixed by this rotation, or there are standard unit vectors E^j and E^k that are linearly independent from M^j and M^k, respectively. In the first case, we have

$$\mathbf{n} = E^i,$$

and in the second case we have

$$\mathbf{n} = \pm \frac{(E^j - M^j) \times (E^k - M^k)}{|(E^j - M^j) \times (E^k - M^k)|}.$$

OPTIMAL ANGULAR VELOCITY TRACKING WITH FIXED-ENDPOINT RIGID BODY MOTIONS*

MICHAEL J. ENOS†

Abstract. The problem of finding a fixed-endpoint motion of a rigid body in three space with angular velocity close to a given, arbitrary vector function ω is considered. In particular, if u is the angular velocity of the body in space coordinates, minimizers of $\left\| |u-\omega| \right\|_p$ on an admissible class consisting of smooth rigid body motions on $[0,1]$ with prescribed endpoints are sought for $1 \leq p \leq \infty$. It is shown that, when working in an appropriate moving frame, each of these problems can be formulated as an autonomous problem that can be solved completely in closed form. While this moving frame must in general be obtained numerically, it can be obtained in advance, independently of the solutions; hence all of the extremals for this problem are identified and existence and uniqueness results are obtained.

Key words. rigid body dynamics, nonautonomous optimal control problems, rotation group

AMS subject classifications. 49, 70, 93

1. Introduction.

There has been a renewed interest in recent years in the study of rigid body dynamics from a control point of view. In fact, there are many natural optimal control problems with rigid body motions that have, surprisingly, remained untouched. In spite of much recent development of theoretical machinery for control problems on manifolds, there is (in our opinion) a shortage of examples of nontrivial, specific problems of this type that can be solved completely. Here we describe one such problem that may be regarded as a natural generalization of the classical geodesic problem on $SO(3)$. It is a special case of a more general problem studied in [5].

Consider the motions of any rigid body; ignoring the motion of its center of mass, the configuration space of the body is the rotation group $SO(3)$. Along any smooth motion $A(t)$, we have $\dot{A} = \hat{u}A$ for some unique, skew-symmetric operator $\hat{u}$ (in particular, $\hat{u} = \dot{A}A^t$). Using $SO(3)$ matrices to describe the orientation of the body in space coordinates, $A(t)$ is an $SO(3)$-valued matrix function and $\hat{u}(t)$ is the matrix of the cross product operator on $\mathbb{R}^3$, $(\cdot) \mapsto u \times (\cdot)$. Consequently, the column vectors of A, and the points in the rigid body, instantaneously rotate about u at the angular rate $|u|$, i.e., the vector u is the *angular velocity* of the body in space coordinates.

The transfer to a given state or stabilization about some position of the angular velocity or angular momentum of a rigid body, *without regard to the initial and terminal orientations of the body*, has been studied in several papers (for instance [4], [6], and [3]). In this paper we are concerned with finding a *fixed-endpoint motion* of a rigid body on $[0,1]$ with angular velocity $u(t)$ that is as close as possible, on the average, to a given, *arbitrary* vector $\omega(t)$. Note that imposing the fixed-endpoint condition on A makes it impossible, in general, to exactly match u with ω (indeed, if $u \equiv \omega$ and a left endpoint $A(0)$ is given, then the right endpoint of $A(1)$ is uniquely determined), so this problem generally has a nonzero cost.

A natural measure of "u and ω being close on the average" is given by $\left\| |u-\omega| \right\|_p$,

$1 \leq p \leq \infty$, and we will consider the following optimal control problem.

PROBLEM 1.1.

$$\left\| |u - \omega| \right\|_p \mapsto \inf;$$

$$\dot{A} = \hat{u}A;$$

$$A(0) = A_0 \quad \textit{and} \quad A(1) = A_1,$$

where $A(t)$ is a path in $SO(3)$, ω is a given path in $\mathbb{R}^3$, and A_0, $A_1 \in SO(3)$ are given.

We will construct and geometrically describe all the extremals for this problem and obtain what amounts to a closed-form solution; in particular, we will obtain an explicit solution in terms of quantities that can be computed independently of the variables A and u. Our main result is Theorem 3.3, which appears at the end of §3. The basic tool we will use is a change of variables that makes this nonautonomous problem equivalent to the classical, autonomous geodesic problem on $SO(3)$. We give a solved example in §4. Also, in the Appendix, we sketch an intuitive, elementary proof of the fact that length minimizing geodesics on $SO(3)$ are continuous rotations with constant angular velocity (i.e., exponentials of constant vectors) that rotate through angles in $[0, \pi]$. In the concluding remarks, we describe a generalization of this problem and mention some other, seemingly fundamental, fixed-endpoint optimal control problems on the rotation group that have not to our knowlege received much attention.

2. Equivalence to an autonomous problem. Here we establish some elementary facts about paths in $SO(3)$ and show that Problem 1.1 is equivalent to an autonomous problem under a suitable rotation of axes.

Throughout, we will assume all quantities are C^∞ smooth for simplicity. All statements may be specialized in an obvious way to the C^r category.

Remark 2.1. We will use the following notation: If $B(t)$ is a path in $SO(3)$, $\omega_B(t)$ denotes the "angular velocity" of B in space coordinates, i.e., the unique vector $\widehat{\omega_B} = \dot{B}B^t$.

The following lemma gives some basic properties of angular velocities.

LEMMA 2.2. *Let B, C, and F be paths in $SO(3)$ and $v(t)$ a path in $\mathbb{R}^3$. Then*

$$F = BC \Longrightarrow \omega_F = \omega_B + B\omega_C, \tag{2.1}$$

$$\omega_{B^t} = -B^t\omega_B. \tag{2.2}$$

Proof. To prove the "product rule" (2.1), note that $B(u \times v) = (Bu) \times (Bv)$ for any $u, v \in \mathbb{R}^3$, so that

$$\dot{F} = \dot{B}C + B\dot{C} = (\hat{\omega}_B B)\, C + B\,(\hat{\omega}_C C) = (\omega_B \widehat{+} B\omega_C)BC = (\omega_B \widehat{+} B\omega_C)F.$$

This implies (2.2):

$$0 = \frac{d}{dt}(B^tB) = (\omega_{B^t} \widehat{+} B^t\omega_B). \qquad \square$$

Now pick any $C_0 \in SO(3)$ and consider the differential equation

$$\dot{C} = \hat{\omega} C, \qquad C(0) = C_0, \tag{2.3}$$

where ω is as in Problem 1.1. The solution $C(t)$ is, clearly, a path in $SO(3)$.

PROPOSITION 2.3. *In Problem* 1.1, *let* $B \stackrel{\text{def}}{=} C^t A$, $v \stackrel{\text{def}}{=} C^t(u-\omega)$, $B_0 \stackrel{\text{def}}{=} C^t(0)A_0$, *and* $B_1 \stackrel{\text{def}}{=} C^t(1)A_1$. *Then Problem* 1.1 *is equivalent to the following problem.*

PROBLEM 2.4.

$$\left\| |v| \right\|_p \mapsto \inf;$$

$$\dot{B} = \hat{v} B;$$

$$B(0) = B_0 \quad \textit{and} \quad B(1) = B_1,$$

over paths B *in* $SO(3)$.

Proof. First note that

$$B(0) = B_0 \iff (C^t A)(0) = C^t(0)A(0) = C^t(0)A_0 \iff A(0) = A_0.$$

Similarly, $B(1) = B_1 \iff A(1) = A_1$.

It is clear that $v = \omega_B$; also, the definition of B, (2.1), and (2.2) show that

$$v = \omega_{C^t A} = \omega_{C^t} + C^t \omega_A = -C^t \omega + C^t u = C^t(u - \omega),$$

so that

$$\left\| |u - \omega| \right\|_p = \left\| |C^t(u - \omega)| \right\|_p = \left\| |v| \right\|_p. \qquad \square$$

Note that $C^t v$ and $C^t A$ are the coordinates of the vector v and the rigid body motion A observed from a coordinate system rotating with angular velocity ω. Also, Problem 2.4 is *autonomous*, so that this rotation of axes significantly simplifies the problem. Moreover, while C generally involves the numerical solution of a nonautonomous differential equation, we can compute C *in advance*, i.e., before formulating the problem. Finally, note that when $p = 2$, Problem 2.4 is just a control formulation of the classical problem of finding the free motions of a completely symmetric rigid body, since the kinetic energy of a symmetric body is a constant multiple of the square of the magnitude of its angular velocity.

3. Solutions of Problem 1.1. Assume until further notice that $p < \infty$. Since $\left\| |v| \right\|_p = \left(\int_0^1 |v|^p dt \right)^{1/p}$, we want to minimize $\int_0^1 |v|^p dt$ in Problem 2.4. Note that $|v|^p = \langle v, v \rangle^{p/2}$ defines a Riemannian metric on $TSO(3)$, so the fact that $SO(3)$ is a Lie group implies there is a path of minimal length in this metric between any two of its points, i.e., we are assured of the existence of a solution.

By standard methods, for instance, the method of symplectic reduction [2] or an elementary application of the Pontryagin Maximum Principle, the extremals for Problem 2.4 when $p > 1$ are paths of the form $B(t) = \exp(t\hat{v})$ with v constant, i.e., continuous rotations with constant angular velocity. The extremals for $p = 1$ are the same up to a time reparametrization, i.e., with the rotation angle $t|v|$ replaced by a

nondecreasing function $g(t)$ satisfying $g(0) = 0$. This follows from the case $p > 1$ and the familiar fact that the integral $2\int_0^1 |v|dt = \int_0^1 |\hat{v}|dt = \int_0^1 |\dot{A}|dt$ is invariant under time reparametrizations of $A(t)$.

LEMMA 3.1. *Let $R(\phi\mathbf{n}) \in SO(3)$ denote the rotation through the positive angle ϕ about the unit vector $\mathbf{n}$. When $p > 1$, the extremals of Problem 2.4 are of the following form:*

$$B(t) = R(t\phi\mathbf{n})B_0, \quad \text{where } \phi\mathbf{n} = v = \text{constant}. \tag{3.1}$$

When $p = 1$, the extremals are of the following form:

$$B(t) = R(g(t)\mathbf{n})B_0, \quad \text{where } g' \geq 0,\ g(0) = 0 \text{ and } v = g'(t)\mathbf{n}\ (\mathbf{n} \text{ const.}). \tag{3.2}$$

It is straightforward to classify the extremals for Problem 2.4 for given endpoints B_0, B_1. Setting $t = 1$ in $B(t)$, we require

$$R(\phi\mathbf{n}) = B_1 B_0^t \stackrel{\text{def}}{=} D, \tag{3.3}$$

where we define ϕ to be $g(1)$ in the case $p = 1$.

In the general case, i.e., when $B_1 \neq B_0$, the set of pairs $(\phi, \mathbf{n})$ with this property is countable, i.e., we have countably many extremals for Problem 2.4 (regarded as continuous rotations) with the endpoints B_0, B_1. More specifically, note that the rotation D can be expressed as $R(\phi_*\mathbf{n}_*)$ for an appropriate unit vector $\mathbf{n}_*$ and angle $\phi_* \in [0, \pi]$. The angle ϕ_* is uniquely determined. $\mathbf{n}_*$ is uniquely determined when $\phi_* \in (0, \pi)$; can be selected arbitrarily when $\phi_* = 0$ (any rotation through the angle 0 is the identity); and is determined up to multiplication by ± 1 when $\phi_* = \pi$ (the rotations in either direction about a given vector through the angle π are identical). While explicit formulas for ϕ_* and $\mathbf{n}_*$ in terms of the matrix entries of D are "standard," the formulas found in many references do not work when $\phi_* = \pi$; see [5] for a formula that works in this case.

The set of *all* angle/axis pairs satisfying (3.3) can be obtained by adding nonnegative multiples of 2π to ϕ_* and rotating about $\mathbf{n}_*$, or by adding nonnegative multiples of 2π to $2\pi - \phi_*$ and rotating about $-\mathbf{n}_*$. In other words, *the extremals for Problem 2.4 are all continuous rotations of B_0 about the line containing $\mathbf{n}_*$, and are distinguished by the number of times and direction in which they rotate.* See Fig. 1.

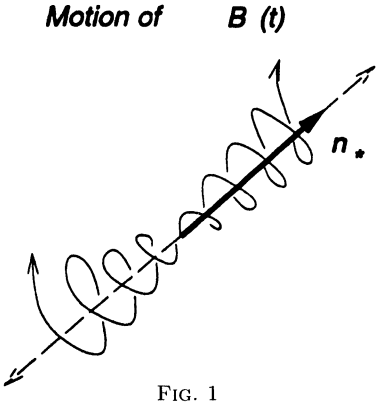

FIG. 1

It is easy to determine the minimizers for Problem 2.4. If $B = R(t\phi\mathbf{n})B_0$ is an extremal and $p > 1$, we have

$$\left\| |v| \right\|_p = \left(\int_0^1 |v|^p dt \right)^{1/p} = \left(\int_0^1 |\phi\mathbf{n}|^p dt \right)^{1/p} = \phi,$$

and it follows that the extremals with lowest cost are the ones with $(\phi, \mathbf{n}) = (\phi_*, \mathbf{n}_*)$. Similarly, when $p = 1$, we take $\mathbf{n} = \mathbf{n}_*$ and $g(t)$ to satisfy $g(1) = \phi_*$.

Finally, since $\left\| |v| \right\|_\infty = \lim_{p\to\infty} \left\| |v| \right\|_p$, it is clear that the minimizers for the case $1 < p < \infty$ are also minimizers for the case $p = \infty$. An elementary argument shows that the same uniqueness results are true here. If v is the angular velocity of another admissible path and $\left\| |v| \right\|_\infty = \phi_*$, then $\left\| |v| \right\|_2 \leq \phi_*$ (otherwise, $|v| > \phi_*$ on an interval, so that $\left\| |v| \right\|_\infty > \phi_*$). Since $|v|(t) \leq \phi_*$ and $\left\| |v| \right\|_2 = \phi_*$, we infer that $|v| \equiv \phi_*$, i.e., the motion corresponding to v is a solution of Problem 2.4 for $p = 2$.

Summarizing the results of this section, we obtain the following solutions of Problem 2.4.

PROPOSITION 3.2. *If $p > 1$, the solutions of Problem 2.4 are the extremals of the form $B_*(t) = R(t\phi_*\mathbf{n}_*)B_0$, where $R(\phi_*\mathbf{n}_*) = B_1 B_0^t$ and $\phi_* \in [0, \pi]$; there is a unique solution when $\phi_* \in [0, \pi)$ and there are two solutions when $\phi_* = \pi$.*

When $p = 1$, the solutions of Problem 2.4 are of the form $R(g(t)\mathbf{n}_*)B_0$ with $g' \geq 0$, $g(0) = 0$, $g(1) = \phi_*$, and $\mathbf{n} = \mathbf{n}_*$.

Combining this with the results of §2, we have the following solutions of Problem 1.1.

THEOREM 3.3. *The solutions of Problem 1.1 are those motions A of the form $A = CB$, where B is a solution of Problem 2.4 as given in Proposition 3.2, C is any path in $SO(3)$ satisfying $\dot{C}C^t = \hat{\omega}$, $B_0 = C^t(0)A_0$, and $B_1 = C^t(1)A_1$.*

4. An example. Consider Problem 1.1 in the situation where the vector ω is of constant magnitude and rotating about a fixed axis at a fixed rate, i.e.,

$$\omega = \rho \begin{pmatrix} \cos\beta \\ \sin\beta\cos t\gamma \\ \sin\beta\sin t\gamma \end{pmatrix}.$$

To obtain solutions of Problem 1.1, Theorem 3.3 tells us to construct a rotating frame C with angular velocity ω and, working in this frame, find the solutions of Problem 2.4.

To construct C, note that the frame $F \overset{\text{def}}{=} R(t\gamma\mathbf{i})$ has angular velocity $\gamma\mathbf{i}$ and that

$$F^t\omega = \rho \begin{pmatrix} \cos\beta \\ \sin\beta \\ 0 \end{pmatrix},$$

so that by (2.1), any frame C with angular velocity ω satisfies

$$\omega_{F^tC} = -F^t\omega_F + F^t\omega = \begin{pmatrix} \rho\cos\beta - \gamma \\ \rho\sin\beta \\ 0 \end{pmatrix} \overset{\text{def}}{=} \Omega.$$

Ω being constant, we can take $F^tC = R(t\Omega)$, so that $C = FR(t\Omega) = R(t\gamma\mathbf{i})R(t\Omega)$. It is easily seen that $B_0 = C^t(0)A_0 = A_0$ and $B_1 = C^t(1)A_1 = R(-\Omega)R(-\gamma\mathbf{i})A_1$. If

$B_0 \neq B_1$, the solutions $B(t)$ of Problem 2.4 rotate about a fixed axis between these positions as in Proposition 3.2, i.e.,

$$B(t) = \begin{cases} R(t\phi_*\mathbf{n}_*)A_0, & p > 1; \\ R(g(t)\mathbf{n}_*)A_0, & p = 1, \end{cases}$$

where $R(\phi_*\mathbf{n}_*) = B_1B_0^t = R(-\gamma\mathbf{i})R(-\Omega)A_1A_0^t$ and $\phi_* \in [0, \pi]$, and $g(t)$ is as in Proposition 3.2. By Theorem 3.3, the solutions $A(t)$ of Problem 1.1 are given by products of exponentials

$$A(t) = \begin{cases} R(t\Omega)R(t\gamma\mathbf{i})R(t\phi_*\mathbf{n}_*)A_0, & p > 1; \\ R(t\Omega)R(t\gamma\mathbf{i})R(g(t)\mathbf{n}_*)A_0, & p = 1, \end{cases}$$

where $g(t), \phi_*$, and $\mathbf{n}_*$ are as described in the last section. Intuitively, the optimal motions rotate about $\mathbf{n}_*$, as $\mathbf{n}_*$ rotates about the vector Ω, as Ω rotates about $\mathbf{i}$; see Fig. 2.

The solutions of Problem 1.1 are qualitatively of this form unless the endpoint conditions A_0, A_1 are completely adapted to the path C, i.e., the net rotation $A_1A_0^t$ is identical to $C(1)C^t(0)$, in which case C^tA is constant, the cost is identically zero, and $A(t)$ is a product of only two exponentials.

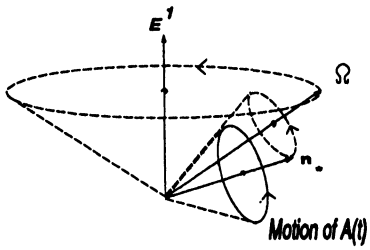

FIG. 2

It is interesting to note that, when $p = 1$ and $B(t)$ is not constant, the solutions of Problem 2.4 (distinguished by the choice of $g(t)$) are all reparametrizations of the same geometric path (the usual situation with geodesics), while this is definitely *not* the case in the context of Problem 1.1: *Different choices of $g(t)$ lead to very different-looking solutions relative to a fixed space frame*, due to the nonautonomous nature of the problem. For instance, the solutions with $g(t) \equiv t\phi_*$ and $g(t) = 0$ on $[0, \frac{1}{2}]$, $g(t) = 2(t - \frac{1}{2}\phi_*)$ on $[\frac{1}{2}, 1]$ follow quite different geometric paths in space coordinates.

5. Concluding remarks. The basic idea we used in solving Problem 1.1 is that of changing variables to autonomize the problem, essentially working around the time-dependent quantities involved. Here we were able to accomplish this by simply changing our point of view with a time-dependent rotation of axes. This philosophy can be of use in other nonautonomous problems.

The actual computation of minimizers in §3 illustrates some of the difficulties involved in obtaining complete solutions of optimal control problems on manifolds, namely, we generally need to use information about the geometry of state space. For more complicated rigid body problems, the use of quaternion geometry can frequently be helpful in this context.

A more general problem of this type is that of optimal, fixed-endpoint tracking of angular *momentum* with a fixed-endpoint motion in $SO(3)$, i.e., of minimizing $\left\| |Iu - h| \right\|_p$, where $I = ADA^t$, with D a constant, positive, and diagonal matrix, is the inertia tensor of a general rigid body. Problem 1.1 is the specialization of this problem to the case of a spherically symmetric body. This problem is treated in [5]. For this new problem, the moving frame construction we used above is not applicable; however, it can be shown that the extremals satisfy the equation

$$\frac{d}{dt}\Big(I(Iu - h)\Big) = h \times (Iu).$$

The system consisting of this equation and $\dot{A} = \hat{u}A$ is integrable by quadratures when h is constant and the body is axisymmetric (i.e., when the inertia tensor I has two equal eigenvalues) and the solution can be expressed in terms of elliptic integrals. The solutions in this case are not unlike the motions of a Lagrange top.

Another problem related to Problem 1.1 is that of minimizing the integral of a function which is small when $A(t)$ is close to a given path $C(t)$ in $SO(3)$, for instance, minimizing $\int_0^1 \Big\langle A - C, A - C \Big\rangle dt$ or, equivalently, $\int_0^1 -\Big\langle A, C \Big\rangle dt$. In some sense, when we solve Problem 1.1 are also trying to make the motions A and C close, if we choose C to satisfy $\omega_C = \omega$ and $C(0) = A_0$, since it is clear that $A \longrightarrow C$ as $u \longrightarrow \omega$. Yet the solutions are different (for instance the solutions of this new problem are generally nonsmooth), and the relationship between these problems might be interesting to investigate.

Other problems with single rigid bodies that to our knowledge have not been treated include the problem of time-optimal transfer of a general rigid body between two orientations with bounded torques, and the torque-optimal transfer of a general rigid body between two orientations on a fixed-time interval.

Other interesting problems can be obtained by adapting some of these ideas to nonholonomic mechanical systems which have recently appeared in the literature, for instance freely rotating systems of coupled rigid bodies.

6. Appendix: Direct derivation of length minimizers on $SO(3)$. We can alternatively give a proof that the minimizers of Problem 2.4 are given by Proposition 3.2 using only some basic geometric observations about $SO(3)$ and the fact that any smooth path in $SO(3)$ looks locally like the exponential of a constant vector. We briefly sketch this proof here for $p = 1$, the case $p > 1$ being similar.

As noted in §3, any rotation in $SO(3)$ can be represented as $R(\phi\mathbf{n})$ with $\phi \in [0, \pi]$. We will assume in this section that any such representation of a rotation is a standard one, with $\phi \in [0, \pi]$.

The product of two rotations $R(\phi_1\mathbf{n}_1)R(\phi_2\mathbf{n}_2)$ is a third rotation $R(\phi_3\mathbf{n}_3)$. Given $\phi_i, \mathbf{n}_i$, $i = 1, 2$, we can use formulas due to Rodrigues (see [1]) to write an expression for ϕ_3 and $\mathbf{n}_3$. Here we are only interested in the formula for ϕ_3, which is

$$\cos\frac{\phi_3}{2} = \cos\frac{\phi_1}{2}\cos\frac{\phi_2}{2} - \sin\frac{\phi_1}{2}\sin\frac{\phi_2}{2}\Big\langle \mathbf{n}_1, \mathbf{n}_2 \Big\rangle.$$

It is evident from this equation that

$$\phi_1 + \phi_2 \geq \phi_3, \tag{6.1}$$

with equality if and only if $\mathbf{n}_1 = \mathbf{n}_2$.

Let $B_*(t) = R(t\phi\mathbf{n})B_0$, where $R(\phi\mathbf{n}) = B^1B_0^t$. The statement that $B_*(t)$ is a solution of Problem 2.4 ($p = 1$) is that

$$\phi \leq \int_0^1 |v|dt \tag{6.2}$$

for any path $B(t)$ in $SO(3)$ satisfying $\dot{B} = \hat{v}B$, $B(0) = B_0$, and $B(1) = B_1$.

The idea of our proof is to approximate the path $B(t)$ with "polygonal lines," where we regard a "line" as a continuous rotation at constant angular velocity; in particular, define a sequence of paths $\{D_i\}_{i=1}^{\infty}$ as follows: Let $D_0 = B_*$, let D_1 be the path consisting of a rotation at constant angular velocity from $B(0)$ to $B(\frac{1}{2})$ on $[0, \frac{1}{2}]$ followed by a constant angular velocity path from $B(\frac{1}{2})$ to $B(1)$ on $[\frac{1}{2}, 1]$, and so on, on successive partitions of $[0, 1]$; see Fig. 3. Using matrix coordinates, it can be shown that the sequence (D_i) converges uniformly to B and that the sequence of derivatives $(\dot{D}_i)$ converges uniformly to $\dot{B}$. Consequently, since $\hat{v} = \dot{B}B^t$, the sequence (ω_{D_i}) of angular velocities converges uniformly to v, so that $\left\| |\omega_{D_i}| \right\|_1$ converges to $\left\| |v| \right\|_1$.

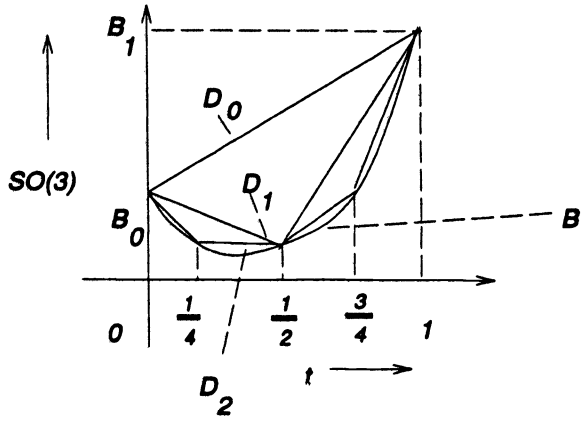

FIG. 3

Now, it is easy to show that the cost on each interval on which D_i rotates about a fixed axis is the angle rotated through, so the cost along D_i is the sum of the angles rotated through on the intervals of smoothness of D_i. Hence, by the inequality (6.1), the cost along D_1 exceeds that along D_0; a similar argument shows that the cost of D_i exceeds the cost of D_{i-1} for all i, i.e., the cost must increase in i, so that (6.2) holds.

The idea of "polygonal approximation" with geodesics that we used here can also be of use in direct sufficiency proofs for other problems.

ERRATUM: ON THE OPTIMAL TRACKING PROBLEM*

OFER ZEITOUNI† AND MOSHE ZAKAI†

The proof of Lemma 3.2 in [1] contains an error. In contrast to what is written, (3.17) does not seem to follow from [2], and is probably incorrect.

The Lemma itself does hold. In the proof, we must replace the upper bound in (3.17) by the claim that there exists a constant C such that

$$\frac{P(||\tilde{\mu}||_T > c)}{\exp -(hx^2/2\epsilon)} \leq C/\epsilon^2, \tag{1}$$

which is more than enough to conclude.

To see (1), observe that we may represent $\tilde{\mu}_t$ as $\tilde{\mu}_t = e^{-\alpha t}(\nu_{e^{2\alpha t}} - \nu_1)/\sqrt{\alpha}$, where $\alpha = h/\epsilon$, ν_t is a standard Brownian motion and the equality is in law. Therefore, letting $\Delta = 1/\alpha^2$,

$$\begin{aligned}
P(||\tilde{\mu}||_T > c) &\leq 2P\left(\sup_{0\leq t\leq T} \frac{e^{-\alpha t}(\nu_{e^{2\alpha t}} - \nu_1)}{\sqrt{\alpha}} > c\right) \\
&\leq 2\sum_{i=1}^{\lceil 1/\Delta\rceil} P\left(\sup_{(i-1)\Delta T\leq t\leq i\Delta T} \frac{e^{-\alpha t}(\nu_{e^{2\alpha t}} - \nu_1)}{\sqrt{\alpha}} > c\right) \\
&\leq 2\sum_{i=1}^{\lceil 1/\Delta\rceil} P\left(\sup_{0\leq t\leq i\Delta T} \frac{(\nu_{e^{2\alpha t}} - \nu_1)}{\sqrt{\alpha}} > ce^{\alpha(i-1)\Delta T}\right) \\
&\leq 4\sum_{i=1}^{\lceil 1/\Delta\rceil} P(\nu_{e^{2\alpha i\Delta T}} \geq c\sqrt{\alpha}e^{\alpha(i-1)\Delta T}) \\
&\leq \frac{C_1}{\Delta}\exp(-\alpha c^2 e^{-2\alpha\Delta T}/2).
\end{aligned}$$

Inequality (1) follows by noting that by our choice, $\alpha\Delta \to_{\epsilon\to 0} 0$, while $\alpha^2\Delta = 1$.

Acknowledgment. We thank Ehud Barak for pointing out the mistake in the proof of (3.17).

STABILITY OF RECURSIVE STOCHASTIC TRACKING ALGORITHMS*

LEI GUO†

Abstract. First, the paper gives a stability study for the random linear equation $x_{n+1} = (I - A_n)x_n$. It is shown that for a quite general class of random matrices $\{A_n\}$ of interest, the stability of such a vector equation can be guaranteed by that of a corresponding scalar linear equation, for which various results are given without requiring stationary or mixing conditions. Then, these results are applied to the main topic of the paper, i.e., to the estimation of time varying parameters in linear stochastic systems, giving a unified stability condition for various tracking algorithms including the standard Kalman filter, least mean squares, and least squares with forgetting factor.

1. Introduction.

An important issue in system identification, signal processing, adaptive control and many other fields is whether the algorithms designed possess some tracking capabilities when the system parameters (or signals) to be estimated are changing with time. The basic time-varying model is that of a linear regression:

$$y_k = \varphi_k^\tau \theta_k + v_k, \qquad k \geq 0 \tag{1.1}$$

where y_k and v_k are the scalar observation and noise, respectively, and φ_k and θ_k are, respectively, the d-dimensional stochastic regressor and the unknown time-varying parameter. It is usually convenient to denote the parameter variation at instant k by Δ_k:

$$\Delta_k \triangleq \theta_k - \theta_{k-1}, \qquad k \geq 1. \tag{1.2}$$

It is well known that many problems from different application areas can be cast in the form (1.1) (see e.g., [1], [2]), and a variety of recursive algorithms have been derived for tracking the unknown parameters θ_k. These algorithms are basically of the following form:

$$\hat{\theta}_{k+1} = \hat{\theta}_k + L_k(y_k - \varphi_k^\tau \hat{\theta}_k) \tag{1.3}$$

where L_k is the adaptation gain that can be chosen in a number of ways (see e.g., [1]–[3]). In the present time-varying case, a common feature of the gain L_k is that it does not tend to zero as the time k goes to infinity. This is very natural from an intuitive point of view. When the system parameters are time-varying, the algorithm must be persistently alert to follow the parameter variations. Here we illustrate three choices of L_k that correspond to three standard algorithms.

Kalman filtering (KF) algorithm.

$$L_k = \frac{P_k \varphi_k}{R + \varphi_k^\tau P_k \varphi_k} \tag{1.4}$$

$$P_{k+1} = P_k - \frac{P_k \varphi_k \varphi_k^\tau P_k}{R + \varphi_k^\tau P_k \varphi_k} + Q, \tag{1.5}$$

† Institute of Systems Science, Chinese Academy of Sciences, Beijing 100080, People's Republic of China.

where $P_0 \geq 0, R > 0, Q > 0$ and $\hat{\theta}_0$ are deterministic and can be arbitrarily chosen. Here R and Q may be regarded as the a priori estimates for the variances of v_k and Δ_k, respectively. Taking R and Q as constants is just for simplicity of discussion, and generalizations to time-varying cases are straightforward.

It is well known that (see e.g., [4, Chap. 13] and [5, Chap. 3]) if φ_k is $\mathcal{F}_{k-1}$ measurable, where $\mathcal{F}_k \triangleq \sigma\{y_i, i \leq k\}$, and if $\{\Delta_k, v_k\}$ is a Gaussian white noise process, then θ_k generated by (1.3)–(1.5) is the minimum variance estimate for θ_k, and P_k is the estimation error covariance, i.e.,

$$\hat{\theta}_k = E[\theta_k|\mathcal{F}_{k-1}], \qquad P_k = E[\tilde{\theta}_k\tilde{\theta}_k^\tau|\mathcal{F}_{k-1}] \tag{1.6}$$

provided that $Q = E\Delta_k\Delta_k^\tau$, $R = Ev_k^2$, $\hat{\theta}_0 = E\theta_0$ and $P_0 = E[\tilde{\theta}_0\tilde{\theta}_0^\tau]$, where $\tilde{\theta}_k$ is the estimation error

$$\tilde{\theta}_k = \theta_k - \hat{\theta}_k, \tag{1.7}$$

which is of prime interest to us.

Least mean squares (LMS) algorithm.

$$L_k = \mu\frac{\varphi_k}{1 + \|\varphi_k\|^2}, \tag{1.8}$$

where $\mu \in (0, 1]$ is called the step size or adaptation rate. Such an algorithm is also referred to as a gradient algorithm because the increment of the algorithm (1.3) and (1.8) is opposite to the (stochastic) gradient of the mean square error

$$e_k(\theta) = E(y_k - \varphi_k^\tau\theta)^2.$$

Thus, it is a type of steepest descent algorithm that aims at minimizing $e_k(\theta)$ recursively.

Recursive least squares (RLS) algorithm.

$$L_k = \frac{P_k\varphi_k}{\alpha + \varphi_k^\tau P_k\varphi_k} \tag{1.9}$$

$$P_{k+1} = \frac{1}{\alpha}\left[P_k - \frac{P_k\varphi_k\varphi_k^\tau P_k}{\alpha + \varphi_k^\tau P_k\varphi_k}\right], \tag{1.10}$$

where $P_0 > 0$, and $\alpha \in (0, 1)$ is a forgetting factor. This algorithm is derived by minimizing the following criterion over $\theta \in \mathbb{R}^d$:

$$V_k(\theta) = \frac{1}{k}\sum_{i=0}^{k}\alpha^{k-i}(y_i - \theta^\tau\varphi_i)^2 \tag{1.11}$$

(see e.g., [1], pp. 57–58). Note that in (1.11) old measurements are exponentially discounted, and so the estimate is expected to be representative for the current properties of the system.

All of the above-mentioned algorithms are well known and widely used in applications. The KF algorithm is attractive due to the fact that it generates the conditional expectation of the unknown parameter given the past measurements in the ideal case (see (1.6)). The LMS has been used in many applications, mainly because of its simplicity for implementation. The advantage of the RLS algorithm over LMS is that it generates more accurate estimates in the

transient phase (see e.g., [6]). In many cases, the RLS algorithm is optimal in the sense that it minimizes the criterion (1.11), while for the KF algorithm, it is not known if it is still optimal in some sense when the Gaussian assumption fails and the covariances of v_k and Δ_k are not available.

There is a vast literature on the analysis of algorithms of type (1.3). In the area of adaptive signal processing, the LMS algorithm has received a great deal of attention (see e.g., [7]–[12]). Most of the existing analysis require that the signals $\{y_k, \theta_k, \varphi_k\}$ possess some sort of stationarity, independence, or mixing properties. The KF algorithm has also attracted much research attention (e.g., [11], [13]–[15]). The first rigorous stability analysis for KF that allows $\{\varphi_k\}$ to be a large class of stochastic regressors seems to be that in [14]. Finally, for the RLS algorithm, we mention the preliminary works in [6], [16], [17], among many others.

In the related area of stochastic adaptive control, the Kalman filter was used by Meyn and Caines [31] to design the adaptive control law for a first-order stochastic system. By applying the Markov chain ergodic theory, they obtained the first concrete adaptive control result for systems with nontrivial (random) parameter variations. For high-order systems with randomly varying parameters, stability of an LMS-based adaptive minimum variance controller was demonstrated in [30]. Similar results were recently established in [32] for a KF-based model reference adaptive controller. However, the parameter tracking properties of the estimation algorithms are not studied in these papers.

In this paper, we first present a series of stability results on the vector random linear equation $x_{n+1} = (I - A_n)x_n$, where $\{A_n\}$ is a sequence of random matrices of the same dimension, which may not satisfy the usual stationary or mixing conditions. The key observation is that for a variety of $\{A_n\}$ of interest, the stability study of the vector linear equation may be reduced to that of a relatively simple scalar equation. Then we present a stability/excitation condition for recursive stochastic tracking algorithms and establish upper bounds for the tracking error.

The main contributions of the paper are as follows:

(i) The new stability condition is the weakest known and a unified one for the three standard algorithms mentioned above. This is important since establishing stability is known to be a crucial step for any further studies (see e.g., [18]).

(ii) For a large class of random models of interest in applications including time-varying autoregressive models, we can verify the present condition, whereas conditions introduced previously (see e.g., [14], [28]) cannot be verified;

(iii) For the commonly used ϕ-mixing process, we can prove that our stability condition is also a necessary one in some sense.

2. Stability of random equation $x_{n+1} = (I - A_n)x_n$.

2.1. Preliminaries. To begin, by substituting (1.1) into (1.3) and using the notations (1.2) and (1.7), we get the following error equation:

$$\tilde{\theta}_{k+1} = (I - L_k\varphi_k^\tau)\tilde{\theta}_k - L_k v_k + \Delta_{k+1}, \qquad k \geq 0. \tag{2.1}$$

Clearly, this equation falls into the following general form of linear equations:

$$x_{k+1} = (I - A_k)x_k + \xi_{k+1}, \qquad k \geq 0 \tag{2.2}$$

where $\{A_k\}$ is a sequence of $d \times d$ random matrices, and $\{\xi_{k+1}\}$ represents the disturbance. Usually, we are primarily interested in the following problem: does $\{x_k\}$ remain bounded in some sense when $\{\xi_k\}$ belongs to a certain class of random processes? To rigorously study this problem, we need to introduce some notations and definitions.

For any matrix X, its norm is defined as its maximum singular value, i.e. $\|X\| = \{\lambda_{\max}(XX^\tau)\}^{1/2}$.

DEFINITION 2.1. A random matrix (or vector) sequence $\{A_k, k \geq 0\}$ defined on the basic probability space $(\Omega, \mathcal{F}, P)$ is called L_p-stable $(p > 0)$ if $\sup_{k\geq 0} E\|A_k\|^p < \infty$.

In the sequel, we will refer to $\|A_k\|_{L_p}$ defined by

$$\|A_k\|_{L_p} \triangleq \{E\|A_k\|^p\}^{1/p} \tag{2.3}$$

as the L_p-norm of A_k.

To motivate further discussions, let us consider the following propositions.

PROPOSITION 2.1. *Consider the random equation* (2.2) *with* $x_0 = 0$. *Suppose that* $\{A_k, k \geq 0\}$ *is an independent sequence and* $\det[E(I - A_k)(I - A_k)^\tau] \neq 0$. *Then for any* $\{\xi_k\} \in \mathcal{B}$, $\{x_k\}$ *is* L_2*-stable if and only if there exist two constants* $M > 0$ *and* $\lambda \in [0, 1)$ *such that*

$$\left\| \prod_{j=i+1}^{k} (I - A_j) \right\|_{L_2} \leq M\lambda^{k-i}, \qquad \forall k \geq i, \qquad \forall i \geq 0 \tag{2.4}$$

where $\mathcal{B}$ *is a set of random processes defined by*

$$\mathcal{B} = \{\xi = (\xi_k) : \xi \text{ is } L_2\text{-stable and independent of } \{A_k\}\} \tag{2.5}$$

and where by definition

$$\prod_{j=i+1}^{k} (I - A_j) = \begin{cases} (I - A_k) \cdots (I - A_{i+1}), & k > i; \\ I, & k \leq i. \end{cases} \tag{2.6}$$

The proof is in Appendix A. Obviously, the only nontrivial conclusion in this proposition is that (2.4) is a necessary condition for L_2-stability of $\{x_k\}$. Related results in the deterministic framework may be found in [19]. We remark that when the independence assumptions are removed, similar necessity results are also true. This is the content of Proposition 2.2.

PROPOSITION 2.2. *Consider the random equation* (2.2) *with* $x_0 = 0$. *Assume that* $(I - A_k)^{-1}$ *exists for any* $k \geq 0$. *Denote*

$$\mathcal{B}^0 = \{\xi : \sup_k \|\xi_k\|_{L_2} \leq 1\}; \tag{2.7}$$

then the following property also implies (2.4):

$$\sup_{\xi\in\mathcal{B}^0} \sup_k \|x_k\|_{L_2} < \infty. \tag{2.8}$$

The proof is also given in Appendix A. These two propositions indicate that (2.4) is in some sense the necessary (and also sufficient) condition for the stability of $\{x_k\}$ generated by (2.2). This prompts us to introduce the following definition.

DEFINITION 2.2. A sequence of $d \times d$ random matrices $A = \{A_k\}$ is called stably exciting of order p, $(p \geq 1)$ with parameter $\lambda \in [0, 1)$, if it belongs to the following set

$$\mathcal{S}_p(\lambda) = \left\{ A : \left\| \prod_{j=i+1}^{k} (I - A_j) \right\|_{L_p} \leq M\lambda^{k-i}, \forall k \geq i, \forall i \geq 0, \text{ for some } M > 0 \right\}. \tag{2.9}$$

The investigation of products of random matrices has a long history (see e.g., [20]–[26] and the references therein), and almost all of the existing results rely on some stationary or mixing assumptions on the random coefficients. In particular, in [21] and [22] a time-invariant quadratic Lyapunov function was used to analyze the stability of a random linear differential equation under stationary and ergodic assumptions on the coefficients, while in [24] and [26] it was shown that under some mixing conditions, the stability of a random linear differential equation may be guaranteed by that of a corresponding "averaged" deterministic equation.

However, in general, stationary or mixing conditions cannot be directly imposed on the random coefficients in the study of tracking algorithms. Our treatment here is based on the observation that for a quite large class of matrix sequence $\{A_k\}$ of interest in applications, the study of its stably exciting property may be reduced to that of a certain class of scalar sequences. For convenience of discussion, we introduce the following subclass of $\mathcal{S}_1(\lambda)$ for scalar sequence $a = (a_k, k \geq 0)$:

$$\mathcal{S}^0(\lambda) = \left\{ a : a_k \in [0,1], E \prod_{j=i+1}^{k} (1 - a_j) \leq M\lambda^{k-i}, \forall\, k \geq i, \forall\, i \geq 0, \text{ for some } M > 0 \right\} \tag{2.10}$$

where $\lambda \in [0,1)$ is a parameter reflecting the stability margin. Note that for λ given above, $\log \lambda$ is related to the familiar concept of Lyapunov exponent (cf. [25]), and its absolute value is proportional to the exciting extent of $\{a_k\}$.

Clearly, for any constant $c \in (0,1]$, $\{c\} \in \mathcal{S}^0(1-c)$, and if $0 \leq \alpha_k \leq \beta_k \leq 1$ and $\{\alpha_k\} \in \mathcal{S}^0(\lambda)$, then $\{\beta_k\} \in \mathcal{S}^0(\lambda)$.

LEMMA 2.1. *Let $\alpha = \{\alpha_k, \mathcal{F}_k\}$ and $a = \{a_k, \mathcal{F}_k\}$ be adapted processes, such that*

$$a_k \in [0,1], \qquad E[a_{k+1}|\mathcal{F}_k] \geq \alpha_k, \qquad k \geq 0.$$

Then $\alpha \in \mathcal{S}^0(\lambda)$ implies that $a \in \mathcal{S}^0(\sqrt{\lambda})$.

Proof. We first assume that $0 \leq \alpha_k < 1$. For any $n > m, k \in [m,n]$, set

$$A_k = \left\{ \prod_{i=m}^{k} (1 - \alpha_i) \right\}^{-1}, \qquad A_{m-1} = 1$$
$$x_{k+1} = (1 - a_{k+1})x_k, \qquad x_m = 1.$$

Then

$$x_{n+1} = \prod_{i=m}^{n} (1 - a_{i+1}).$$

Note that

$$\begin{aligned} EA_k x_{k+1} &= EA_k[1 - E(a_{k+1}|\mathcal{F}_k)]x_k \\ &\leq EA_k(1 - \alpha_k)x_k = EA_{k-1}x_k. \end{aligned}$$

Hence

$$EA_n x_{n+1} \leq EA_{n-1}x_n \leq \cdots \leq EA_{m-1}x_m = 1.$$

Consequently,

$$E\prod_{i=m}^{n}(1-a_{i+1}) = Ex_{n+1} \le E\sqrt{x_{n+1}}$$
$$= E\sqrt{x_{n+1}A_n}\sqrt{A_n^{-1}} \le \sqrt{E(x_{n+1}A_n)EA_n^{-1}} \le \sqrt{EA_n^{-1}}$$
$$\le \left\{E\prod_{i=m}^{n}(1-\alpha_i)\right\}^{1/2} \le \sqrt{M}(\sqrt{\lambda})^{n-m+1}.$$

Hence $a \in \mathcal{S}^0(\sqrt{\lambda})$.

Next, we consider the general case $\alpha_k \in [0,1]$. By the monotonic convergence theorem, it is known that

$$\lim_{\varepsilon\to 1^-} E\prod_{k=m}^{n}(1-\varepsilon\alpha_k) \le M\lambda^{n-m+1}.$$

Hence there exists $0 < \varepsilon^* < 1$ such that for any $\varepsilon \in (\varepsilon^*, 1)$,

$$E\prod_{k=m}^{n}(1-\varepsilon\alpha_k) \le 2M\lambda^{n-m+1}.$$

Hence by $\varepsilon\alpha_k \in (0,1)$ and the fact proved above we have

$$E\prod_{k=m}^{n}(1-\varepsilon a_{k+1}) \le \sqrt{2M}(\sqrt{\lambda})^{n-m+1}.$$

Thus, by noticing that $\varepsilon a_{k+1} \le a_{k+1}$, we have $a \in \mathcal{S}^0(\sqrt{\lambda})$. This completes the proof. □

LEMMA 2.2. *Let* $\{\alpha_k, \mathcal{F}_k\}$ *be an adapted process,* $\alpha_k \in [0,1]$. *If for some integer* $h > 0$, $\{E[\alpha_{k+h}|\mathcal{F}_k]\} \in \mathcal{S}^0(\lambda)$, *then* $\{\alpha_k\} \in \mathcal{S}^0(\lambda^{2^{-h}})$.

Proof. Set $a_k = E[\alpha_{k+h-1}|\mathcal{F}_k]$. Then since

$$E[a_{k+1}|\mathcal{F}_k] = E\{E[\alpha_{k+h}|\mathcal{F}_{k+1}]|\mathcal{F}_k\} = E\{\alpha_{k+h}|\mathcal{F}_k\},$$

we know by Lemma 2.1 that $a_k \in \mathcal{S}^0(\sqrt{\lambda})$ or

$$\{E[\alpha_{k+h-1}|\mathcal{F}_k]\} \in \mathcal{S}^0(\sqrt{\lambda}).$$

Continuing this procedure h times, we finally get $\{\alpha_k\} \in \mathcal{S}^0(\lambda^{2^{-h}})$. □

LEMMA 2.3. *Let* $\{\alpha_k\} \in \mathcal{S}^0(\lambda)$, *and* $\alpha_k \le \alpha^* < 1$, *where* α^* *is a constant. Then for any* $0 < \varepsilon < 1$, $\{\varepsilon\alpha_k\} \in \mathcal{S}^0(\lambda^{(1-\alpha^*)\varepsilon})$.

Proof. We will need the following inequality ([14, p. 145])

$$1 - x \le (1-tx)^{\frac{(1-\alpha)}{t}}, \qquad t > 1, \qquad 0 \le tx \le \alpha < 1, \tag{2.11}$$

which can be proven by using standard differentiation methods.

Let M and $\lambda \in (0,1)$ be such that

$$E\prod_{k=m+1}^{n}(1-\alpha_k) \le M\lambda^{n-m}.$$

Then using the inequality (2.11) we have by taking $x = \varepsilon\alpha_k, t = 1/\varepsilon$,

$$E\prod_{k=m+1}^{n}(1-\varepsilon\alpha_k) \le E\left[\prod_{k=m+1}^{n}(1-\alpha_k)^{(1-\alpha^*)\varepsilon}\right]$$
$$\le \left\{E\prod_{k=m+1}^{n}(1-\alpha_k)\right\}^{(1-\alpha^*)\varepsilon} \le M^{(1-\alpha^*)\varepsilon}[\lambda^{(1-\alpha^*)\varepsilon}]^{n-m},$$

which implies the desired result. □

We now give some examples to illustrate the class $\mathcal{S}^0(\lambda)$.

Example 2.1. Nonzero strictly stationary processes do not necessarily belong to $\mathcal{S}^0(\lambda)$. Consider the process $\alpha_k \equiv \alpha$, with α being uniformly distributed on $[0, 1]$. Obviously, $\{\alpha_k\}$ is a stationary process. For any $n > 0$, we have

$$E\prod_{k=1}^{n}(1-\alpha_k) = E(1-\alpha)^n = \int_0^1 (1-x)^n\,dx = \frac{1}{n+1}.$$

This implies that $\{\alpha_k\} \notin \mathcal{S}^0(\lambda)$ for any $\lambda \in [0, 1)$, since the convergence rate of $E\prod_{k=1}^{n}(1-\alpha_k)$ is not exponentially fast.

Example 2.2. Let $\{\alpha_k, \mathcal{F}_k\}$ be any adapted process, $\alpha_k \in [0, 1]$. If there exists some constant $\alpha > 0$ and an integer $h > 0$, such that $E[\alpha_{k+h}|\mathcal{F}_k] \ge \alpha$, then $\{\alpha_k\} \in \mathcal{S}^0((1-\alpha)^{2^{-h}})$.

This fact can be easily proved by using Lemma 2.2. Example 2.2 contains many standard signals, for example, ϕ-mixing processes. To be precise, let ξ_k be a ϕ-mixing process, i.e., there exists a sequence $\phi(n) \xrightarrow[n\to\infty]{} 0$, such that

$$\sup_{A\in\mathcal{F}_{t+s}^{\infty}, B\in\mathcal{F}_0^t} |P(A|B) - P(A)| \le \phi(s), \quad \forall\, t, s,$$

where $\mathcal{F}_t^s \triangleq \sigma\{\xi(u), t \le u \le s\}$. Then for any $\mathcal{F}_t^{\infty}$-measurable f_t, with $|f_t| \le 1$, the following inequality holds (cf. [10], p. 82)

$$|E[f_{t+h}|\mathcal{F}_0^t] - Ef_{t+h}| \le 2\phi(h), \quad \forall\, t, h. \tag{2.12}$$

Hence if we take $f_t = f(\xi(t))$ and assume that $Ef_t \ge \alpha > 0$, for all t, where $f(\cdot) \in [0, 1]$ is a measurable function, then there exists an integer $h > 0$, such that $E[f_{t+h}|\mathcal{F}_0^t] \ge \alpha/2 > 0$, for all t. This verifies the conditions of Example 2.2 for ϕ-mixing processes.

2.2. A_k **nonnegative definite.** We are now in a position to study the more general class $\mathcal{S}_p(\lambda)$ defined by (2.9). We first study the stably exciting properties of nonnegative matrices $A_k, k \ge 1$, and see how the verification of $\{A_k\} \in \mathcal{S}_p(\lambda)$ can be transferred to that of a certain scalar sequence in $\mathcal{S}^0(\lambda)$.

THEOREM 2.1. *Let $\{A_i, \mathcal{F}_i\}$ be an adapted sequence of random matrices, $0 \le A_i \le I$. If there exists an integer $h > 0$, such that $\{\lambda_k\} \in \mathcal{S}^0(\lambda)$, where λ_k is defined by*

$$\lambda_k \triangleq \lambda_{\min}\left\{E\left[\frac{1}{1+h}\sum_{i=kh+1}^{(k+1)h} A_i|\mathcal{F}_{kh}\right]\right\},$$

then $\{A_k\} \in \mathcal{S}_2(\lambda^{\alpha})$, with $\alpha = 1/[8h(1+h)^2]$.

Proof. Recursively define

$$\Phi(n+1, m) = (I - A_n)\Phi(n, m), \quad \Phi(m, m) = I, \quad n \ge m \ge 0. \tag{2.13}$$

Then it can be shown that (see Appendix B) for any $m \geq 1$,

$$\begin{aligned}&\lambda_{\max}\{E[\Phi^\tau((m+1)h+1, mh+1)\Phi((m+1)h+1, mh+1)|\mathcal{F}_{mh}]\}\\ &\quad\leq 1 - \frac{\lambda_m}{(1+h)}.\end{aligned} \tag{2.14}$$

Now, for any $n > m + h$, let us define

$$k_0 = \min\{k : m \leq kh + 1 \leq n\}, \qquad k_1 = \max\{k : m \leq kh + 1 \leq n\}.$$

Then it is clear that

$$E\|\Phi(n, m)\|^2 \leq E\|\Phi(k_1 h + 1, k_0 h + 1)\|^2 \tag{2.15}$$

and

$$(k_1 + 1)h + 1 > n, \qquad (k_0 - 1)h + 1 < m. \tag{2.16}$$

Hence for $\{A_i\} \in \mathcal{S}_2(\lambda^\alpha)$, it suffices to find a constant c which is free of k_1 and k_0 such that, for all $k_1 \geq k_0$,

$$E\|\Phi(k_1 h + 1, k_0 h + 1)\|^2 \leq c\lambda^{2\alpha h(k_1 - k_0 + 1)}. \tag{2.17}$$

To prove this, we consider the following equation:

$$x_k = \Phi(kh + 1, (k - 1)h + 1)x_{k-1}, \qquad k \geq k_0 + 1 \tag{2.18}$$

where x_{k_0} is deterministic and $\|x_{k_0}\| = 1$. It is easily seen that $x_k \in \mathcal{F}_{kh}$, and $x_{k_1} = \Phi(k_1 h+1, k_0 h+1)x_{k_0}$. Therefore, for (2.17), we need only to prove that for any deterministic x_{k_0} with $\|x_{k_0}\| = 1$,

$$E\|x_{k_1}\|^2 \leq c\lambda^{2\alpha h(k_1 - k_0)} \tag{2.19}$$

where c is independent of k_0, k_1 and x_{k_0}.

Let us set for any $k \geq k_0 + 1$,

$$\alpha_k = \begin{cases} 1 - \dfrac{\|\Phi(kh + 1, (k - 1)h + 1)x_{k-1}\|}{\|x_{k-1}\|}, & \text{if } \|x_{k-1}\| \neq 0; \\ 1, & \text{otherwise.} \end{cases} \tag{2.20}$$

Since $0 \leq A_i \leq I$, $i \geq 0$, implies $\|\Phi(n, m)\| \leq 1$, for all $n \geq m$, $m \geq 0$, it is clear that $\alpha_k \in [0, 1]$, $\alpha_k \in \mathcal{F}_{kh}$, and by (2.18) and (2.20),

$$\|x_k\| \leq (1 - \alpha_k)\|x_{k-1}\|$$

and

$$\|x_{k_1}\| \leq \prod_{k=k_0+1}^{k_1} (1 - \alpha_k). \tag{2.21}$$

We now show that

$$E[\alpha_{k+1}|\mathcal{F}_{kh}] \geq \frac{\lambda_k}{2(1+h)}. \tag{2.22}$$

Set $\Omega_k = \{\omega : \|x_k\| = 0\}$. Then $\Omega_k \in \mathcal{F}_{kh}$, and by (2.20)

$$I_{\Omega_k} E[\alpha_{k+1}|\mathcal{F}_{kh}] = E[I_{\Omega_k}\alpha_{k+1}|\mathcal{F}_{kh}] = I_{\Omega_k}.$$

Hence by noting $\lambda_k < 1$ we see that (2.22) is true on the set Ω_k.

To prove that (2.21) is also true on the set Ω_k^c, we first note that by (2.14), we have

$$\begin{aligned}
&E[\|\Phi((k+1)h+1, kh+1)x_k\||\mathcal{F}_{kh}] \\
&\le \{E[\|\Phi((k+1)h+1, kh+1)x_k\|^2|\mathcal{F}_{kh}]\}^{1/2} \\
&\le \{x_k^\tau E[\Phi^\tau((k+1)h+1, kh+1)\Phi((k+1)h+1, kh+1)|\mathcal{F}_{kh}]x_k\}^{1/2} \\
&\le \left\{x_k^\tau\left(1 - \frac{\lambda_k}{1+h}\right)x_k\right\}^{1/2} \le \left(1 - \frac{\lambda_k}{2(1+h)}\right)\|x_k\|.
\end{aligned}$$

Consequently, by (2.20) we have

$$\begin{aligned}
I_{\Omega_k^c} E[\alpha_{k+1}|\mathcal{F}_{kh}] &\ge I_{\Omega_k^c}\left(1 - \left(1 - \frac{\lambda_k}{2(1+h)}\right)\right) \\
&= \frac{\lambda_k}{2(1+h)} I_{\Omega_k^c}.
\end{aligned} \tag{2.23}$$

Hence (2.22) is also true on Ω_k^c.

Since $\{\lambda_k\} \in \mathcal{S}^0(\lambda)$ and $\lambda_k \le h/(1+h)$, then by Lemma 2.3 we know that $\{\lambda_k/[2(1+h)]\} \in \mathcal{S}^0(\lambda^{4h\alpha})$. From this, (2.22) and Lemma 2.1 (together with its proof), we know that

$$\prod_{k=k_0+1}^{k_1}(1-\alpha_k) \le c\lambda^{2h\alpha(k_1-k_0)},$$

for some constant c independent of k_1, k_0, and x_{k_0}. Consequently, by (2.21) we see that (2.19) is true. Hence the proof of Theorem 2.1 is complete. □

COROLLARY 2.1. *Under the same conditions and notations as in Theorem* 2.1, *the following property holds*:

$$\{A_k\} \in \begin{cases} \mathcal{S}_p(\lambda^\alpha), & 1 \le p \le 2; \\ \mathcal{S}_p(\lambda^{2\alpha/p}), & p > 2. \end{cases} \tag{2.24}$$

Proof. For $1 \le p \le 2$, we use the monotonicity of the norm $\|\cdot\|_{L_p}$, while for $p > 2$ we apply the simple inequality $\|I - A_j\| \le 1$, and then derive

$$\left\|\prod_{j=i+1}^{k}(I - A_j)\right\|_{L_p} \le \begin{cases} \|\prod_{j=i+1}^{k}(I - A_j)\|_{L_2}, & 1 \le p \le 2; \\ \|\prod_{j=i+1}^{k}(I - A_j)\|_{L_2}^{2/p}, & p > 2. \end{cases}$$

Consequently (2.24) follows from this and Theorem 2.1. □

THEOREM 2.2. *Let* $\{A_i, \mathcal{F}_i\}$ *be an adapted sequence of random matrices,* $0 \le A_i \le I$. *If* $\{A_i\} \in \mathcal{S}_1(\lambda)$ *for some* $\lambda \in [0, 1)$, *then there exists an integer* $h > 0$ *such that*

$$\inf_m \lambda_{\min}\left\{\sum_{i=mh+1}^{(m+1)h} EA_i\right\} > 0.$$

Proof. By the assumption we know that there exists a suitably large integer $h > 0$ such that

$$E\left\|\prod_{i=mh+1}^{(m+1)h}(I - A_i)\right\| \leq M\lambda^h < \frac{1}{2}, \qquad \forall m. \tag{2.25}$$

Let ρ_m be the smallest eigenvalue of the matrix $E[\sum_{i=mh+1}^{(m+1)h} A_i]$, and x_m be its corresponding unit eigenvector. Then we have

$$\rho_m = E\left[\sum_{i=mh+1}^{(m+1)h} x_m^\tau A_i x_m\right].$$

Hence for any integers $i_j \in [mh+1, (m+1)h], j = 1, \ldots, k, k \leq h$,

$$\begin{aligned}
&Ex_m^\tau A_{i_1}\cdots A_{i_k}x_m \leq E\|x_m^\tau A_{i_1}^{1/2}\|\|A_{i_1}^{1/2}A_{i_2}\cdots A_{i_k}^{1/2}\|\|A_{i_k}^{1/2}x_m\| \\
&\leq E\|x_m^\tau A_{i_1}^{1/2}\|\cdot\|A_{i_k}^{1/2}x_m\| \leq \{E\|x_m^\tau A_{i_1}^{1/2}\|^2\cdot E\|A_{i_k}^{1/2}x_m\|^2\}^{1/2} \\
&= \{E(x_m^\tau A_{i_1}x_m)E(x_m^\tau A_{i_k}x_m)\}^{1/2} \leq \max_{mh+1\leq i\leq (m+1)h} E(x_m^\tau A_i x_m) \leq \rho_m.
\end{aligned}$$

Consequently, by (2.25) we have

$$\begin{aligned}
\frac{1}{2} &> E\left\|\prod_{i=mh+1}^{(m+1)h}(I - A_i)\right\| \geq Ex_m^\tau \prod_{i=mh+1}^{(m+1)h}(I - A_i)x_m \\
&= 1 - \sum_{k=1}^{h}\sum_{mh+1\leq i_1<\ldots<i_k\leq(m+1)h} E(x_m^\tau A_{i_1}\cdots A_{i_k}x_m) \\
&\geq 1 - \sum_{k=1}^{h}\sum_{mh+1\leq i_1<\ldots<i_k\leq(m+1)h} \rho_m = 1 - \sum_{k=1}^{h}\binom{h}{k}\rho_m,
\end{aligned}$$

which implies that

$$\rho_m \geq \frac{1}{2\sum_{k=1}^{h}\binom{h}{k}}.$$

Hence Theorem 2.2 is true. □

We remark that the converse assertion of Theorem 2.2 is not true in general. This fact can be seen from Example 2.1. However, it will be true if we impose additional assumptions on $\{A_k\}$, for example, the ϕ-mixing properties. The following theorem provides necessary and sufficient conditions for such a matrix process to be in $\mathcal{S}_1(\lambda)$.

THEOREM 2.3. *If $\{A_k, k \geq 0\}$ is a ϕ-mixing matrix sequence with dimension $d \times d$, and $0 \leq A_k \leq I$, then the following three properties are equivalent*:

(i) $\{A_k\} \in \mathcal{S}_1(\lambda)$ *for some* $\lambda \in [0, 1)$;

(ii) *There is an integer* $h_0 > 0$ *such that*

$$\delta \triangleq \inf_m \lambda_{\min}\left\{\sum_{i=mh_0+1}^{(m+1)h_0} EA_i\right\} > 0;$$

(iii) *There exist some* $h > 0, \lambda \in (0,1)$, *such that* $\{\lambda_k\} \in \mathcal{S}^0(\lambda)$ *where* λ_k *is defined as in Theorem* 2.1 *with* $\mathcal{F}_k \triangleq \sigma\{A_i, i \le k\}$.

Proof. By Theorems 2.1 and 2.2 we need only to prove that (ii) implies (iii).

Let the mixing rate of $\{A_k, k \ge 0\}$ be $\phi(k)$. Then applying the inequality (2.12), we are easily convinced of the following property:

$$\|E[A_{t+k}|\mathcal{F}_t] - EA_{t+k}\| \le 2d\phi(k), \quad \forall t, k. \tag{2.26}$$

Since $\phi(n) \xrightarrow[n\to\infty]{} 0$, we can find a constant (integer) M such that

$$\phi(k) \le \frac{\delta}{4(2h_0+1)d}, \quad \forall k \ge M, \tag{2.27}$$

where δ is defined in (ii).

Set $h = M + 2h_0 + 1$. Then by (ii) and the assumption $A_i \ge 0$, it is easy to convince oneself that

$$\lambda_{\min}\left\{\sum_{k=mh+1+M}^{(m+1)h} EA_k\right\} \ge \delta, \quad \forall m \ge 0. \tag{2.28}$$

Finally, combining (2.26)–(2.28) we conclude that for any $m \ge 0$,

$$\begin{aligned}
(1+h)\lambda_m &= \lambda_{\min}\left\{E\left[\sum_{k=mh+1}^{(m+1)h} A_k|\mathcal{F}_{mh}\right]\right\} \\
&\ge \lambda_{\min}\left\{E\left[\sum_{k=mh+1+M}^{(m+1)h} A_k|\mathcal{F}_{mh}\right]\right\} \\
&\ge \lambda_{\min}\left\{E\left[\sum_{k=mh+1+M}^{(m+1)h} A_k\right]\right\} - \left\|E\left[\sum_{k=mh+1+M}^{(m+1)h} A_k|\mathcal{F}_{mh}\right] - E\left[\sum_{k=mh+1+M}^{(m+1)h} A_k\right]\right\| \\
&\ge \delta - (h-M)\frac{2d\delta}{4(2h_0+1)d} = \delta - \frac{\delta}{2} = \frac{\delta}{2} > 0.
\end{aligned}$$

Hence for the h defined above, we have proved that $\{\lambda_k\} \in \mathcal{S}^0\{1 - \delta/[2(1+h)]\}$, i.e., (iii) holds. This completes the proof. □

2.3. A_k **nonsymmetric.** We now turn to the case where A_k is possibly nonsymmetrical and see how to transfer the study of $\{A_k\} \in \mathcal{S}_p(\lambda)$ to that of a scalar random sequence in $\mathcal{S}^0(\lambda)$.

Before pursuing this further, it is worth mentioning that in the continuous-time case, if $\{A(t)\}$ is a stationary ergodic matrix process and satisfies

$$E\lambda_{\max}\{A(0)^\tau + PA(0)P^{-1}\} < 0$$

for some positive definite matrix P, then the results of [21] and [22] state that the random differential equation $\dot{x}(t) = A(t)x(t)$ is almost surely asymptotically stable. This result may be generalized to the discrete-time case. However, this kind of results have the following limitations: (i) ergodicity is required; (ii) exponential stability can not be guaranteed, and (iii) applications to stochastic tracking algorithms are difficult.

Here, we will present a result that does not have the above-mentioned limitations. For this, we introduce the following recursive random Lyapunov equation:

$$P_{k+1} = (I - A_k)P_k(I - A_k)^\tau + Q_k, \qquad P_0 > 0, \quad k \geq 0, \tag{2.29}$$

where $\{Q_k\}$ is a sequence of nonnegative random matrices.

THEOREM 2.4. *Let $\{A_k\}$ be a sequence of $d \times d$ random matrices, and $\{Q_k\}$ be a sequence of positive definite random matrices. Then for $\{P_k\}$ recursively defined by* (2.29) *we have, for all $n > m$,*

$$\left\| \prod_{k=m}^{n-1} (I - A_k) \right\|^2 \leq \prod_{k=m}^{n-1} \left(1 - \frac{1}{1 + \|Q_k^{-1} P_{k+1}\|} \right) \|P_n\| \cdot \|P_m^{-1}\|. \tag{2.30}$$

Hence if $\{P_k\}$ satisfies the following two conditions,

$$\text{(i)} \quad \left\{ \frac{1}{1 + \|Q_k^{-1} P_{k+1}\|} \right\} \in \mathcal{S}^0(\lambda), \quad \textit{for some } \lambda \in [0, 1);$$

$$\text{(ii)} \quad \sup_{n \geq m \geq 0} \|(\|P_n\| \cdot \|P_m^{-1}\|)\|_{L_p} < \infty, \quad \textit{for some } p \geq 1,$$

then $\{A_k\} \in \mathcal{S}_p(\lambda^{1/2p})$.

Proof. Let us consider the following equation for $n > m$,

$$x_{k+1} = (I - A_k)x_k, \qquad k \in [m, n-1]$$

where x_m is taken to be deterministic and $\|x_m\| = 1$. Then

$$x_n = \prod_{i=m}^{n-1} (I - A_i)x_m. \tag{2.31}$$

Next we consider the following Lyapunov function $V_k = x_k^\tau P_k^{-1} x_k$. Then by denoting $B_k = I - A_k$, we have

$$V_{k+1} = x_{k+1}^\tau P_{k+1}^{-1} x_{k+1} = x_k^\tau B_k^\tau P_{k+1}^{-1} B_k x_k. \tag{2.32}$$

But, by (2.29) and the matrix inversion formula (see e.g., [27, p. 824]) we have

$$\begin{aligned} B_k^\tau P_{k+1}^{-1} B_k &= B_k^\tau [B_k P_k B_k^\tau + Q_k]^{-1} B_k \\ &= P_k^{-1} - [P_k + P_k B_k^\tau Q_k^{-1} B_k P_k]^{-1} \\ &= P_k^{-1/2} \{ I - [I + P_k^{1/2} B_k^\tau Q_k^{-1} B_k P_k^{1/2}]^{-1} \} P_k^{-1/2} \\ &\leq \{ 1 - [1 + \|Q_k^{-1} B_k P_k B_k^\tau\|]^{-1} \} P_k^{-1} \leq \left(1 - \frac{1}{1 + \|Q_k^{-1} P_{k+1}\|} \right) P_k^{-1}, \end{aligned}$$

which in conjunction with (2.32) yields

$$V_{k+1} \leq \left(1 - \frac{1}{1 + \|Q_k^{-1} P_{k+1}\|} \right) V_k$$

and so

$$V_n \le \prod_{k=m}^{n-1} \left(1 - \frac{1}{1 + \|Q_k^{-1} P_{k+1}\|}\right) V_m.$$

Hence by this, (2.31) and the dependence of V_k on x_m we have

$$\begin{aligned}
\left\| \prod_{k=m}^{n-1} (I - A_i) \right\|^2 &= \max_{\|x_m\|=1} \|x_n\|^2 = \max_{\|x_m\|=1} \|x_n^\tau P_n^{-1/2} P_n^{1/2}\|^2 \\
&\le \max_{\|x_m\|=1} \|x_n^\tau P_n^{-1/2}\|^2 \|P_n^{1/2}\|^2 = \max_{\|x_m\|=1} (V_n \|P_n\|) \\
&\le \left\{ \prod_{k=m}^{n-1} \left(1 - \frac{1}{1 + \|Q_k^{-1} P_{k+1}\|}\right) \right\} \left\{ \|P_n\| \max_{\|x_m\|=1} V_m \right\} \\
&\le \left\{ \prod_{k=m}^{n-1} \left(1 - \frac{1}{1 + \|Q_k^{-1} P_{k+1}\|}\right) \right\} \{\|P_n\| \cdot \|P_m^{-1}\|\}.
\end{aligned}$$

Hence (2.30) holds. The second assertion $\{A_k\} \in \mathcal{S}_p(\lambda^{1/2p})$ follows directly from (2.30) and the Hölder inequality.

This theorem does not require that $A_i's$ are nonnegative definite matrices and means that the verification of $\{A_k\} \in \mathcal{S}_p(\lambda^{1/2p})$ can be reduced to two relatively simple tasks: (i) to verify that a certain scalar sequence is in $\mathcal{S}^0(\lambda)$, and (ii) to prove that a certain process is "L_p-stable." We remark that suitably choosing the sequence $\{Q_k\}$ is crucial in simplifying the tasks (i) and (ii). In §4, we will see that for the analysis of KF or RLS algorithms, the sequence $\{P_k\}$ may simply be taken as that defined by (1.5) or (1.10). □

3. Stability/excitation condition. For the basic time-varying model (1.1), we will need the following excitation condition for estimating $\{\theta_k\}$.

CONDITION 3.1 (Excitation condition). *The regressor $\{\varphi_k, \mathcal{F}_k\}$ is an adapted sequence of random vectors (i.e., φ_k is $\mathcal{F}_k$-measurable, for all k, where $\{\mathcal{F}_k\}$ is a sequence of nondecreasing σ-algebras), and there exists an integer $h > 0$ such that $\{\lambda_k\} \in \mathcal{S}^0(\lambda)$ for some $\lambda \in (0, 1)$, where λ_k is defined by*

$$\lambda_k \triangleq \lambda_{\min} \left\{ E \left[\frac{1}{1+h} \sum_{i=kh+1}^{(k+1)h} \frac{\varphi_i \varphi_i^\tau}{1 + \|\varphi_i\|^2} \,\middle|\, \mathcal{F}_{kh} \right] \right\}. \tag{3.1}$$

In the next section, we will show that this condition guarantees the L_p-stability of all three standard algorithms described in §1. The main purpose of this section is to illustrate this condition by several propositions and examples of interest in application.

PROPOSITION 3.1. *Let $\{\varphi_k\}$ be a ϕ-mixing process; then the necessary and sufficient condition for Condition* 3.1 *to be satisfied is that there exists an integer $h > 0$ such that*

$$\inf_{k \ge 0} \lambda_{\min} \left\{ \sum_{i=kh+1}^{(k+1)h} E \left[\frac{\varphi_i \varphi_i^\tau}{1 + \|\varphi_i\|^2} \right] \right\} > 0. \tag{3.2}$$

This fact directly follows from the equivalence of the assertions (ii) and (iii) in Theorem 2.3, since $\{\varphi_i \varphi_i^\tau / (1 + \|\varphi_i\|^2)\}$ is also a ϕ-mixing process. The ϕ-mixing process is commonly used in the literature (e.g., [8], [9], [17], [18]). It includes a large class of important processes,

for instance, deterministic processes, M-dependent processes and processes generated from bounded white noise filtered through a stable finite-dimensional linear filter. However, as is well known, ϕ-mixing is not perfect as a model in many applications, so next we show that Condition 3.1 is still satisfied by another important class of regressors that does not verify the ϕ-mixing condition.

In the sequel, for convenience of discussion we set $\mathcal{G}_k = \mathcal{F}_{kh}$ where h is defined in Condition 3.1. Note that λ_k is $\mathcal{G}_k$-measurable for any $k \geq 1$.

PROPOSITION 3.2. *If for some $h > 0$, $\{\lambda_k\}$ defined by* (3.1) *has the following time-varying lower bound*:

$$\lambda_k \geq \frac{1}{a_k}, \qquad \forall\, k \geq 1,$$

where $\{a_k, \mathcal{G}_k\}$ is an adapted sequence, $a_k \geq 1, Ea_0 < \infty$, and

$$E[a_k|\mathcal{G}_{k-1}] \leq \alpha a_{k-1} + \beta, \qquad 0 \leq \alpha < 1, 0 < \beta < \infty, \qquad \forall\, k \geq 1. \tag{3.3}$$

Then $\{\lambda_k\} \in \mathcal{S}^0(\lambda)$ for some $\lambda \in (0, 1)$, i.e., Condition 3.1 *holds.*

Proof. By Lemma 4 in [14], we know that there exists a constant $\lambda \in (0, 1)$ such that $\{1/a_k\} \in \mathcal{S}^0(\lambda)$. Hence Condition 3.1 follows immediately. □

Remark 3.1. Intuitively speaking, in order to guarantee $\{\lambda_k\} \in \mathcal{S}^0(\lambda)$, the lower bound $\{1/a_k\}$ should not "diminish" or equivalently, $\{a_k\}$ should not "grow unboundedly." Condition (3.3) effectively is a growth constraint on the random process $\{a_k\}$. If in (3.3) we take $\alpha = 0$ and $a_k = \beta$, then we get the excitation condition used in [14]. Moreover, if we assume that $\{a_k\}$ satisfies $a_k \in \mathcal{G}_k, a_k \geq 1$ and

$$a_k \leq \alpha a_{k-1} + \eta_k, \qquad \alpha \in [0, 1), \qquad E[|\eta_k|^{1+\delta}|\mathcal{G}_{k-1}] \leq M, \quad \forall\, k \geq 1 \tag{3.4}$$

for some constants $\delta > 0$, and $M < \infty$, then we get the excitation condition proposed in [28], which obviously satisfies (3.3). Therefore, the condition of Proposition 3.2 (and hence Condition 3.1) is weaker than those proposed in [14] and [28]. Consequently, all examples presented in [14] and [28] satisfy the condition of Proposition 3.2. In particular, we have Example 3.1.

Example 3.1. Let the regressor $\{\varphi_k\}$ be generated by the following state space model:

$$\begin{aligned} x_k &= Ax_{k-1} + B\xi_k, & E\|x_0\|^4 < \infty \\ \varphi_k &= Cx_k + \zeta_k, & k \geq 0, \end{aligned}$$

where $A \in \mathbb{R}^{n\times n}$, $B \in \mathbb{R}^{n\times q}$ and $C \in \mathbb{R}^{d\times n}$ are deterministic matrices, A is stable, (A, B, C) is output controllable and $\{\xi_k, \zeta_k\}$ is an independent process with zero mean, and

$$E\xi_k\xi_k^\tau \geq \varepsilon I > 0, \qquad E[\|\xi_k\|^4 + \|\zeta_k\|^4] \leq M, \qquad \forall\, k \geq 0,$$

where ε and M are constants. Then the condition of Proposition 3.2 is satisfied.

The proof of this example is essentially the same as that for Example 2 in [28], but here the moment condition imposed on the driving signal $\{\xi_k, \zeta_k\}$ is weaker. It is also worth noting that to verify the condition in [14] we have to assume that $\{\xi_k, \zeta_k\}$ is uniformly bounded in the sample path (see [14, p. 142]).

We now turn to the main task of this section, i.e., to study the case where $\{\varphi_k\}$ is generated by a time-varying $AR(p)$ model. This model not only is a natural extension of the standard time-invariant $AR(p)$ models extensively studied in a variety of areas, but also is closely related to the closed-loop systems resulting from adaptive control (cf. [30]). We remark

that in this case, the existing excitation conditions (e.g., in [14] and [28]) do not seem to be satisfied. The basic reason is that the "contraction" factor α in (3.4) is a random process rather than a constant.

Let the time-varying $AR(p)$ model be described by

$$\begin{aligned} y_k &= a_1(k)y_{k-1} + \cdots + a_p(k)y_{k-p} + v_k \\ &\triangleq \theta_k^\tau \varphi_k + v_k, \qquad k \geq 0 \end{aligned} \tag{3.5}$$

where θ_k and φ_k are p-dimensional vectors defined in a standard way, and where $\{v_k\}$ is an independent sequence that is independent of φ_0 and satisfies

$$Ev_k = 0, \qquad Ev_k^2 \geq \sigma_v^2 > 0, \qquad \sup_k E|v_k|^9 < \infty. \tag{3.6}$$

Obviously, the regressor satisfies the following state space equation:

$$\varphi_{k+1} = A_k \varphi_k + bv_k \tag{3.7}$$

where

$$A_k = \begin{bmatrix} a_1(k) & \cdots & \cdots & a_p(k) \\ 1 & \cdots & \cdots & 0 \\ \vdots & \ddots & & \\ 0 & \cdots & 1 & 0 \end{bmatrix}, \qquad b = [1, 0 \cdots 0]^\tau. \tag{3.8}$$

Example 3.2. Consider the $AR(p)$ model (3.5)–(3.6). Let $\{A_k\}$ defined by (3.8) be an independent sequence that is independent of $\{v_k\}$. If

$$\sup_k \|A_k\|_{L_q} < \infty, \qquad \left\| \prod_{i=kp}^{(k+1)p-1} A_i \right\|_{L_4} \leq \delta, \quad \forall k \geq 0, \tag{3.9}$$

where $q = \max\{4, 2(p-1)\}$ and $\delta \in (0, 1)$, then the condition of Proposition 3.2 is satisfied.

The proof is given in Appendix C.

When the coefficient sequence $\{A_k\}$ is (strongly) dependent, the analysis becomes more complicated. We now consider a standard situation.

PROPOSITION 3.3. Consider the $AR(p)$ model (3.5)–(3.6). Let $\{A_k, \mathcal{F}_k'\}$ be an adapted sequence that can be decomposed as

$$A_k = A + \bar{A}_k \tag{3.10}$$

where A is a stable matrix and $\{\bar{A}_k, \mathcal{F}_k'\}$ is dominated by a nonnegative linear process:

$$\|\bar{A}_k\| \leq \beta_k, \qquad \beta_k = \beta\beta_{k-1} + e_k, \qquad 0 \leq \beta < 1, \tag{3.11}$$

where $e_k \geq 0$, $e_k \in \mathcal{F}_k'$ and e_{k+1} is independent of $\mathcal{F}_k'$. Assume that $\mathcal{F}_\infty' \triangleq \sigma\{\cup_i \mathcal{F}_i'\}$ is independent of $\{v_k\}$ and that for some constants $\varepsilon > 0$ and $b > 0$

$$\log\{E[\exp(be_k)]\} \leq \varepsilon, \qquad \forall k \geq 0. \tag{3.12}$$

Then Condition 3.1 is satisfied provided that ε and b are suitably small and large respectively.

The proof of this proposition is given in Appendix C.

Example 3.3. Let the parameter θ_k in (3.5) be the superposition of a "nominal" parameter θ and a "fluctuation" $\bar{\theta}_k$, i.e., $\theta_k = \theta + \bar{\theta}_k$. Moreover, let the time-invariant $AR(p)$ model obtained by replacing θ_k by θ in (3.5) be stable. If either $\|\bar{\theta}_k\|$ is small or $\bar{\theta}_k$ is generated by a stable *ARMA* model:

$$\bar{\theta}_k + F_1\bar{\theta}_{k-1} + \cdots + F_q\bar{\theta}_{k-q} = w_k + G_1 w_{k-1} + \cdots + G_r w_{k-r}$$

where $\{w_k\}$ is a Gaussian white noise sequence which is independent of $\{v_k\}$ with small variance. Then conditions (3.10)–(3.12) of Proposition 3.3 hold.

The proof of this example is straightforward and the details are omitted.

Remark 3.2. Conditions in Example 3.2, Proposition 3.3, and Example 3.3 are stronger than necessary as can be easily seen from the proof; they are used for simplicity of discussion. Certainly, various generalizations are possible, for example, a more general state space model (3.7) may be considered without requiring that A_k and b have the canonical form (3.8); in Example 3.2, the independence assumption of $\{A_k\}$ can be replaced by some weakly dependent conditions; and in Example 3.3, the Gaussian assumption on $\{w_k\}$ can be weakened by assuming that the distribution of $\{w_k\}$ has exponentially decaying tail (a condition similar to (3.12)).

The following result plays an essential role in the proof of Proposition 3.3 and will also be used in the next section.

LEMMA 3.1. *Let* $\{x_k, \mathcal{F}_k\}$ *be an adapted process,* $x_k \geq 1$, *and*

$$x_{k+1} \leq \alpha_{k+1}x_k + \xi_{k+1}, \qquad k \geq 0, \qquad Ex_0^2 < \infty \tag{3.13}$$

where $\{\alpha_k, \mathcal{F}_k\}$ *and* $\{\xi_k, \mathcal{F}_k\}$ *are adapted nonnegative processes with properties*:

$$\alpha_k \geq \varepsilon_0 > 0, \quad \forall k, \quad \left\| \prod_{k=m}^{n} E[\alpha_{k+1}^4 | \mathcal{F}_k] \right\|_{L_1} \leq M\gamma^{n-m+1}, \quad \forall n \geq m, \quad \forall m \tag{3.14}$$

and

$$E[\xi_{k+1}^2 | \mathcal{F}_k] \leq N < \infty, \qquad \forall k \tag{3.15}$$

where $\varepsilon_0, M, N,$ *and* $\gamma \in (0,1)$ *are constants. Then*

(i) $\left\| \prod_{k=m}^{n} \alpha_k \right\|_{L_2} \leq M^{1/4}\gamma^{(1/4)(n-m+1)}, \qquad \forall n \geq m, \quad \forall m;$

(ii) $\sup_k E\|x_k\| < \infty;$

(iii) $\{1/x_k\} \in S^0(\lambda)$ *for some* $\lambda \in (0,1)$.

Proof. Denote $\beta_k = E[\alpha_{k+1}^4 | \mathcal{F}_k]$, and set $z_{k+1} = \left(\prod_{i=m}^{k} \beta_i\right)^{-1} \prod_{i=m}^{k} \alpha_{i+1}^4$. Then we have $z_{k+1} = z_k\beta_k^{-1}\alpha_{k+1}^4$, and so

$$Ez_{k+1} = E\{E[z_{k+1}|\mathcal{F}_k]\} = Ez_k = \cdots = Ez_{m+1} = 1, \qquad \forall k \geq m.$$

Consequently, for all $n \geq m$,

$$E\prod_{i=m}^{n} \alpha_{i+1}^2 = E\sqrt{z_{n+1}}\sqrt{\prod_{m}^{n} \beta_i}$$

$$\leq \sqrt{Ez_{n+1}}\sqrt{E\prod_{m}^{n} \beta_i} \leq \sqrt{M}\sqrt{\gamma^{n-m+1}}$$

so (i) holds, while (ii) follows immediately from (i), (3.15), and (3.13). We now proceed to prove the last assertion (iii).

We first consider the case where N defined by (3.15) is less than one. In this case, by (3.15) we have $E[\xi_{k+1}|\mathcal{F}_k] \le 1$.

For any $n > m$, set for $k \in [m, n]$

$$y_k = \left(1 - \frac{1}{x_k}\right) y_{k-1}, \qquad y_{m-1} = 1. \tag{3.16}$$

Then $y_k \in \mathcal{F}_k$ and by (3.13) we have

$$x_k y_k = (x_k - 1)y_{k-1} \le (\alpha_k x_{k-1} + \xi_k - 1)y_{k-1}$$

so with $\gamma_k \triangleq E[\alpha_{k+1}|\mathcal{F}_k]$ by noticing that $E[\xi_k|\mathcal{F}_{k-1}] \le 1$ we get

$$E[x_k y_k|\mathcal{F}_{k-1}] \le \gamma_{k-1}(x_{k-1}y_{k-1}), \qquad k \ge m. \tag{3.17}$$

Denote $z_k = \left(\prod_{i=m-1}^{k-1} \gamma_i\right)^{-1} x_k y_k, k \ge m-1$. Then by (3.17) we have for $k \ge m$,

$$E[z_k|\mathcal{F}_{k-1}] \le \left(\prod_{i=m-1}^{k-2} \gamma_i\right)^{-1} x_{k-1}y_{k-1} = z_{k-1}.$$

Consequently,

$$Ez_k \le Ez_{k-1} \le \cdots \le Ez_{m-1} = Ex_{m-1}. \tag{3.18}$$

Hence by (ii) we have for some constant $M_0 < \infty$, $\sup_{m\ge 0} \sup_{k\ge m} Ez_k \le M_0$. Thus by the Schwarz inequality and (3.14) we have

$$\begin{aligned} E\prod_{k=m}^{n}\left(1 - \frac{1}{x_k}\right) = Ey_n \le E\sqrt{x_n y_n} &= E\sqrt{z_n \prod_{i=m-1}^{n-1} \beta_i} \\ &\le \sqrt{Ez_n} \cdot \sqrt{E\prod_{i=m-1}^{n-1} \beta_i} \le \sqrt{M_0} M^{1/8} \gamma^{1/8(n-m+1)} \end{aligned}$$

where for the last inequality (3.14) has been used. Hence (iii) holds.

Next, we consider the general case where N in (3.15) is an arbitrary constant. By (3.15) we may take a constant c large enough such that

$$E[\xi_{k+1} I(\xi_{k+1} \ge c)|\mathcal{F}_k] \le 1, \quad \text{and} \quad \delta \triangleq (1 + \varepsilon_0)\frac{c}{1+c} > 1.$$

Then we have by (3.13),

$$x_{k+1} \le \alpha_{k+1} x_k + c + \xi_{k+1} I(\xi_{k+1} > c), \qquad k \ge 0. \tag{3.19}$$

Without loss of generality, we may assume that the equality in (3.19) holds for all k. Hence by setting $\bar{x}_k = x_k/(1+c)$ we get

$$\bar{x}_{k+1} = \alpha_{k+1}\bar{x}_k + \eta_{k+1} \tag{3.20}$$

where $\eta_{k+1} = [c + \xi_{k+1} I(\xi_{k+1} > c)]/(1+c)$. It is clear that $E[\eta_{k+1}|\mathcal{F}_k] \le 1$. Then by the fact we have just proved we know that $\{1/\bar{x}_k\} \in S^0(\gamma^{1/8})$, where γ is given in (3.14).

Note that by (3.14) and (3.20)

$$\bar{x}_{k+1} \ge \alpha_{k+1}\left(\frac{c}{1+c}\right) + \frac{c}{1+c} \ge \frac{c}{1+c}(1+\varepsilon_0) > 1, \qquad k \ge 1.$$

Hence applying Lemma 2.3 with $\varepsilon = 1/(1+c)$ we know that $\{1/x_k\} \in S^0(\lambda)$, for some $\lambda \in (0,1)$. This completes the proof of Lemma 3.1. □

We remark that the condition $x_k \ge 1$ in Lemma 3.1 is by no means a restrictive condition in applications since if $x_k \ge 0$ satisfies (3.13), then the shifted process $x'_k \triangleq x_k + 1$ satisfies both $x'_k \ge 1$ and $x'_{k+1} \le \alpha_{k+1} x'_k + \xi'_{k+1}$ where $\xi'_{k+1} = \xi_{k+1} + 1$.

COROLLARY 3.1. *Let $\{x_k\}$ satisfy conditions in Lemma* 3.1. *If $\{y_n, \mathcal{F}_n\}$ is a nonnegative adapted process and satisfies*:

$$y_{k+1} \le \beta y_k + \eta_{k+1}, \qquad 0 \le \beta < 1, \qquad \forall\, k \tag{3.21}$$

where $E[\eta_k^{2q}|\mathcal{F}_{k-1}] \le M_1 < \infty$, M_1 is a positive constant and $q > \log \varepsilon_0 / \log \beta$ is a positive integer and ε_0 is defined in (3.14), *then $\{1/(x_k + y_k)\} \in S^0(\lambda)$ for some $\lambda \in (0,1)$.*

Proof. Take ε so small such that $(1+\varepsilon)\beta^q \le \varepsilon_0$, and define $T_k = (1/q) y_k^q + (1/s)$, where $s = (1 - 1/q)^{-1}$. Note that for any $\varepsilon > 0$ and $q > 0$ there is a constant $M > 0$ depending on ε and q such that

$$(x+y)^q \le (1+\varepsilon)x^q + My^q, \qquad \forall\, x \ge 0, \quad \forall\, y \ge 0. \tag{3.22}$$

Then we have

$$\begin{aligned} T_k &\le \frac{1}{q}[\beta y_{k-1} + \eta_k]^q + \frac{1}{s} \\ &\le \frac{1}{q}[(1+\varepsilon)(\beta y_{k-1})^q + M\eta_k^q] + \frac{1}{s} \\ &\le \varepsilon_0 \left[\frac{1}{q} y_{k-1}^q + \frac{1}{s}\right] + \frac{M}{q}\eta_k^q + \frac{1}{s} \le \varepsilon_0 T_{k-1} + \frac{M}{q}\eta_k^q + \frac{1}{s}. \end{aligned}$$

Hence

$$\begin{aligned} x_k + T_k &\le \alpha_k x_{k-1} + \xi_k + \varepsilon_0 T_{k-1} + \frac{M}{q}\eta_k^q + \frac{1}{s} \\ &\le \alpha_k (x_{k-1} + T_{k-1}) + \xi_k + \frac{M}{q}\eta_k^q + \frac{1}{s}. \end{aligned}$$

Applying Lemma 3.1 we know that $\{1/(x_k + T_k)\} \in S^0(\lambda)$, for some $\lambda \in (0,1)$. Finally note that $y_k \le T_k$; we conclude that $\{1/(x_k + y_k)\} \in S^0(\lambda)$. □

4. Tracking error bounds. In this section we establish tracking error bounds for the standard algorithms introduced in §1. We first present a lemma.

LEMMA 4.1. *Let $\{c_{nk}, n \ge k \ge 0\}, \{d_{nk}, n \ge k \ge 0\}$, and $\{\xi_k, k \ge 0\}$ be three nonnegative random processes satisfying*:

(i) $c_{nk} \in [0,1], Ec_{nk} \le M\lambda^{n-k}$, *for all $n \ge k \ge 0$, for some $M > 0$ and $\lambda \in [0,1)$;*

(ii) *There exist some constants $\varepsilon > 0$ and $\alpha > 0$ such that*

$$\sup_{n \ge k \ge 0} E[\exp(\varepsilon d_{nk}^{1/\alpha})] < \infty;$$

(iii) $\sigma_p \triangleq \sup_k \|\xi_k \log^\beta(e+\xi_k)\|_{L_p} < \infty$, *for some* $p \geq 1, \beta > 0$.

Then

$$\sum_{k=0}^{n} \|c_{nk} d_{nk} \xi_k\|_{L_p} \leq c\sigma_p f(\sigma_p^{-1}), \qquad \forall n \geq 0, \tag{4.1}$$

where c *is a constant independent of* σ_p, *and*

$$f(\sigma_p^{-1}) = \begin{cases} \log^{1+(\beta/2)}(e+\sigma_p^{-1}), & \text{if } \beta > 2\max(1,\alpha); \\ \log^{\beta}(e+\sigma_p^{-1}), & \text{if } \{c_{nk}\} \text{ is deterministic and } \beta = \alpha; \\ \log(e+\sigma_p^{-1}), & \text{if } \{d_{nk}\} \text{ is deterministic and } \beta > 1. \end{cases} \tag{4.2}$$

The proof is given in Appendix D.

We now proceed to analyze the Kalman filter algorithm. To apply Theorem 2.4 we need to prove some boundedness properties of $\{P_k\}$ first.

LEMMA 4.2. *For* $\{P_k\}$ *generated by* (1.5), *if Condition* 3.1 *holds, then there exists a constant* $\varepsilon^* > 0$ *such that for any* $\varepsilon \in [0, \varepsilon^*)$,

$$\sup_{k \geq 0} E \exp(\varepsilon \|P_k\|) < \infty.$$

Proof. Denote

$$T_m = \sum_{k=(m-1)h+1}^{mh} tr(P_{k+1}), \qquad T_0 = 0. \tag{4.3}$$

Then $T_m \in \mathcal{G}_m \triangleq \mathcal{F}_{mh}$, and similar to Lemma 3 in [28] we have

$$T_{m+1} \leq (1 - a_{m+1}) T_m + b \tag{4.4}$$

where

$$a_{m+1} = \frac{tr\left[(P_{mh+1} + hQ)^2 \sum_{k=mh+1}^{(m+1)h} \dfrac{\varphi_k \varphi_k^\tau}{1+\|\varphi_k\|^2}\right]}{h(R+1)[1+\lambda_{\max}(P_{mh+1}+hQ)]tr(P_{mh+1}+hQ)}, \qquad b = \frac{3}{2}h(h+1)trQ.$$

Similar to (39) and (40) in [28] we have $a_{m+1} \in [0, 1/(1+R)]$ and

$$E[a_{m+1} | \mathcal{G}_m] \geq \frac{(1+h)\|Q\|\lambda_m}{d(R+1)(1+h\|Q\|)} \tag{4.5}$$

where λ_m is defined by (3.1). By using Condition 3.1 and applying Lemmas 2.1 and 2.3, it is easy to see that $\{a_{k+1}\} \in S^0(\lambda)$ for some $\lambda \in [0, 1)$. Hence, the rest of the proof is completely the same as that for Lemma 4 in [28], because the key property (43) in [28] is still true. □

LEMMA 4.3. *Let* $\{P_k\}$ *be generated by* (1.5). *Then under Condition* 3.1, *for any* $\mu \in (0, 1]$ *there is a constant* $\lambda \in (0, 1)$ *such that* $\{\mu/(1 + \|Q^{-1}\| \cdot \|P_k\|)\} \in S^0(\lambda)$.

Proof. Denote $x_k = \mu^{-1}(h + \|Q^{-1}\| T_k)$, where T_k is defined by (4.3). Then it follows from (4.4) that

$$x_{k+1} \leq (1 - a_{k+1}) x_k + \mu^{-1}(h + b\|Q^{-1}\|). \tag{4.6}$$

It is easy to see from (4.5), Condition 3.1, and Lemma 2.3 that Lemma 3.1 is applicable to (4.6); hence, we have $\{1/x_k\} \in S^0(\gamma)$, for some $\gamma \in (0,1)$. Note that $x_k = \sum_{i=(k-1)h+1}^{kh} \mu^{-1} \cdot [1 + \|Q^{-1}\| tr(P_{i+1})]$; hence, it is easy to conclude that $\{\mu/[1 + \|Q^{-1}\| tr(P_k)]\} \in S^0(\lambda)$ for some $\lambda \in (0,1)$ (see the proof of Lemma 5 in [14]), which ensures the desired result. □

THEOREM 4.1. *Consider the time-varying model* (1.1) *and the Kalman filter algorithm* (1.3)–(1.5). *Suppose that Condition* 3.1 *is satisfied and that for some* $p \geq 1$ *and* $\beta > 2$,

$$\sigma_p \triangleq \sup_k \|\xi_k \log^{\beta}(e + \xi_k)\|_{L_p} < \infty \tag{4.7}$$

and

$$\|\tilde{\theta}_0\|_{L_{2p}} < \infty \tag{4.8}$$

where $\xi_k = |v_k| + \|\Delta_{k+1}\|, \tilde{\theta}_0 = \theta_0 - \hat{\theta}_0$, *and* v_k *and* Δ_{k+1} *are given by* (1.1) *and* (1.2), *respectively. Then the tracking error* $\{\theta_k - \hat{\theta}_k, k \geq 0\}$ *is* L_p*-stable and*

$$\limsup_{k\to\infty} \|\theta_k - \hat{\theta}_k\|_{L_p} \leq c[\sigma_p \log^{1+\beta/2}(e + \sigma_p^{-1})], \tag{4.9}$$

where c *is a finite constant depending on* $\{\varphi_k\}, R, Q$ *and* p *only; its precise value may be found from the proof.*

Proof. By (1.4) we may rewrite (1.5) as

$$P_{k+1} = (I - L_k\varphi_k^{\tau})P_k(I - L_k\varphi_k^{\tau})^{\tau} + Q_k$$

where $Q_k = RL_kL_k^{\tau} + Q$. It is easy to see that $Q_k \geq Q$ and $P_{k+1} \geq Q$. Hence by applying Theorem 2.4 we have for all $n > m$,

$$\left\| \prod_{k=m}^{n-1} (I - L_k\varphi_k^{\tau}) \right\| \leq \prod_{k=m}^{n-1} \left(1 - \frac{1}{1 + \|Q^{-1}\| \cdot \|P_{k+1}\|}\right)^{1/2} \cdot \|P_n\|^{1/2}\|Q^{-1}\|^{1/2}. \tag{4.10}$$

Note also that $\|L_k\| \leq \|P_k\|^{1/2}/(2\sqrt{R})$, so by (2.1) we get

$$\begin{aligned} \|\tilde{\theta}_{k+1}\|_{L_p} \leq{}& \left\| \prod_{i=0}^{k} (I - L_i\varphi_i^{\tau})\tilde{\theta}_0 \right\|_{L_p} + \|Q^{-1}\|^{1/2} \sum_{i=0}^{k} \\ & \cdot \left\| \prod_{j=i+1}^{k} \left(1 - \frac{1}{2(1 + \|Q^{-1}\| \cdot \|P_{j+1}\|)}\right) \|P_{k+1}\|^{1/2} \left(1 + \frac{\|P_i\|^{1/2}}{2\sqrt{R}}\right) \xi_i \right\|_{L_p}. \end{aligned} \tag{4.11}$$

Note that by the Schwarz inequality and Lemma 4.2,

$$\sup_{k\geq i} E \exp(\varepsilon \|P_{k+1}\|^{1/2}\|P_i\|^{1/2}) \leq \sup_{k\geq i} [E \exp(\varepsilon \|P_{k+1}\|)]^{1/2} [E \exp(\varepsilon \|P_i\|)]^{1/2} < \infty.$$

So by noting Lemma 4.3 and applying Lemma 4.1 to the second term on the right-hand side of (4.11), we get the desired result. □

Next, we consider the LMS algorithm.

THEOREM 4.2. *Consider the time-varying model* (1.1) *and the LMS algorithm* (1.3) *and* (1.8). *Suppose that Condition* 3.1 *holds and that for some* $p \geq 1$ *and* $\beta > 1$, (4.7) *and* (4.8) *hold. Then* $\{\theta_k - \hat{\theta}_k, k \geq 0\}$ *is* L_p*-stable, and*

$$\limsup_{k\to\infty} \|\theta_k - \hat{\theta}_k\|_{L_p} \leq c[\sigma_p \log(e + \sigma_p^{-1})], \tag{4.12}$$

where σ_p is defined by (4.7) *and c is a constant.*

Proof. Let $c_{ki} = \left\| \prod_{j=i+1}^{k} \left(I - \mu \frac{\varphi_j \varphi_j^\tau}{1+\|\varphi_j\|^2} \right) \right\|$. Then by Condition 3.1, Lemma 2.3, and Theorem 2.1 we know that $\{c_{ki}\}$ satisfies conditions in Lemma 4.1. Note that $\|L_k\| \le \mu$, so by (2.1) we have

$$\|\tilde{\theta}_{k+1}\|_{L_p} \le \|c_{k,-1}\tilde{\theta}_0\|_{L_p} + \sum_{i=0}^{k} \|c_{ki}\xi_i\|_{L_p}$$

and the desired result (4.12) follows by applying Lemma 4.1. □

Remark 4.1. Combining Propositions 2.1 and 2.2 with Theorem 2.3, we see that Condition 3.1 is also a necessary one for the stability of the LMS algorithm *in some sense.*

Finally, we study the recursive least squares algorithm.

LEMMA 4.4. *Let $\{P_k\}$ be generated by* (1.10) *with forgetting factor $\alpha \in (0,1)$. If Condition* 3.1 *holds, then for any $p \ge 1$*

$$\sup_{k\ge 0} E\|P_k\|^p < \infty,$$

provided that α satisfies $\lambda^{[16hd(2h-1)p]^{-1}} < \alpha < 1$, where λ and h are given by Condition 3.1, *and d is the dimension of $\{\varphi_k\}$.*

Proof. The proof ideas are similar to those for Lemmas 1 and 2 in [14] for the Kalman filter algorithm. For any $m \ge 0$ by (1.10) we have

$$P_k \le \frac{1}{\alpha} P_{k-1} \le \cdots \le \left(\frac{1}{\alpha}\right)^{h-1} P_{mh+1}, \qquad k \in [mh+1, (m+1)h].$$

Then by the matrix inverse formula from (1.10) again we have for $k \in [mh+1, (m+1)h]$,

$$\begin{aligned} P_{k+1} &= [\alpha P_k^{-1} + \varphi_k \varphi_k^\tau]^{-1} \le [\alpha \alpha^{h-1} P_{mh+1}^{-1} + \varphi_k \varphi_k^\tau]^{-1} \\ &= \left(\frac{1}{\alpha}\right)^h \left[P_{mh+1} - \frac{P_{mh+1}\varphi_k \varphi_k^\tau P_{mh+1}}{\alpha^h + \varphi_k^\tau P_{mh+1} \varphi_k} \right] \\ &\le \left(\frac{1}{\alpha}\right)^h \left[P_{mh+1} - \frac{P_{mh+1}\varphi_k \varphi_k^\tau P_{mh+1}}{[\alpha^h + \lambda_{\max}(P_{mh+1})][1+\|\varphi_k\|^2]} \right]. \end{aligned} \tag{4.13}$$

Denote

$$T_m = \sum_{k=(m-1)h+1}^{mh} tr(P_{k+1}), \qquad a_{m+1} = \frac{tr\left[P_{mh+1}^2 \sum_{k=mh+1}^{(m+1)h} \frac{\varphi_k \varphi_k^\tau}{1+\|\varphi_k\|^2} \right]}{[\alpha^h + \lambda_{\max}(P_{mh+1})] h tr(P_{mh+1})}. \tag{4.14}$$

Then summing up both sides of (4.13) we get

$$T_{m+1} \le \alpha^{-h}[1 - a_{m+1}] h tr(P_{mh+1}). \tag{4.15}$$

But by the inequality $P_{k+1} \le \alpha^{-1} P_k$ it follows that

$$\begin{aligned} h tr(P_{mh+1}) &= \sum_{k=(m-1)h+1}^{mh} tr(P_{mh+1}) \\ &\le \sum_{k=(m-1)h+1}^{mh} \alpha^{k-mh} tr(P_{k+1}) = \alpha^{1-h} T_m. \end{aligned}$$

Hence by (4.15)

$$T_{m+1} \le \alpha^{1-2h}[1 - a_{m+1}]T_m. \tag{4.16}$$

For any $p \ge 1$, denote

$$b_{m+1} = \alpha^{(1-2h)p}\left[1 - \frac{a_{m+1}}{2}\right] I(tr(P_{mh+1}) \ge 1).$$

Then by (4.15) and (4.16),

$$\begin{aligned} T_{m+1}^p &\le T_{m+1}^p[I(tr(P_{mh+1}) \ge 1) + I(tr(P_{mh+1} \le 1))] \\ &\le b_{m+1}T_m^p + (h\alpha^{-h})^p. \end{aligned} \tag{4.17}$$

By the definition of a_{m+1} in (4.14) and the fact that $tr(P_k^2) \ge d^{-1}(trP_k)^2$,

$$\begin{aligned} E[a_{m+1}|\mathcal{F}_{mh}] &\ge \frac{(h+1)\lambda_m tr(P_{mh+1}^2)}{h(1 + tr(P_{mh+1}))tr(P_{mh+1})} \\ &\ge \frac{(h+1)\lambda_m}{2hd}, \quad \text{on } \{tr(P_{mh+1}) \ge 1\}. \end{aligned}$$

Hence by the definition of b_{m+1},

$$E[b_{m+1}|\mathcal{F}_{mh}] \le \alpha^{(1-2h)p}\left(1 - \frac{(h+1)\lambda_m}{4hd}\right) I(tr(P_{mh+1}) \ge 1). \tag{4.18}$$

Denote

$$\alpha_{m+1} = \begin{cases} b_{m+1}, & \text{if } tr(P_{mh+1}) \ge 1; \\ \alpha^{(1-2h)p}\left(1 - \dfrac{(1+h)\lambda_m}{4hd}\right), & \text{otherwise.} \end{cases} \tag{4.19}$$

Then we have by (4.17)

$$T_{m+1}^p \le \alpha_{m+1}T_m^p + (h\alpha^{-h})^p. \tag{4.20}$$

By Condition 3.1, $\lambda_m \in S^0(\lambda)$ for some $\lambda \in (0,1)$. Since $\lambda_m \le h/(1+h)$, by Lemma 2.3 we know that $\{[(1+h)/(4hd)]\lambda_m\} \in S^0(\lambda^{(4hd)^{-1}})$. Hence by (4.18) and (4.19) and the assumption that $\lambda^{[16hd(2h-1)p]^{-1}} < \alpha$, it is easy to see that Lemma 3.1 is applicable to (4.20) and thus we get $\sup_m ET_m^p < \infty$. So Lemma 4.4 holds. □

THEOREM 4.3. *Consider the time-varying model* (1.1) *together with the forgetting factor algorithm* (1.3), (1.9), *and* (1.10). *Suppose that the following conditions are satisfied*:

(i) *Conditions* 3.1 *holds, i.e.*, $\lambda_m \in S^0(\lambda)$ *for some* $\lambda \in (0,1)$ *and some integer* $h > 0$, *where* λ_m *is defined by* (3.1);

(ii) *For some* $p \ge 1$

$$\sup_k(\|v_k\|_{L_{3p}} + \|\Delta_k\|_{L_{3p}}) \le \sigma_{3p};$$

(iii) $\sup_k \|\varphi_k\|_{L_{6p}} < \infty$;

(iv) *The forgetting factor* α *satisfies* $\lambda^{[48hd(2h-1)p]^{-1}} < \alpha < 1$, *where* d *is the dimension of* $\{\varphi_k\}$.

Then there exists a constant c such that

$$\limsup_{k\to\infty} \|\theta_k - \hat{\theta}_k\|_{L_p} \le c\sigma_{3p}.$$

Proof. We may complete the proof by using Theorem 2.4 just as it has been used for Theorem 4.1. However, in the present case the following analysis appears to be more straightforward.

By the matrix inverse formula, it follows from (1.10) that

$$P_{k+1}^{-1} = \alpha P_k^{-1} + \varphi_k \varphi_k^\tau. \tag{4.21}$$

Multiplying P_k^{-1} from both sides of (1.10) and using (1.9) we get $[I - L_k\varphi_k^\tau] = \alpha P_{k+1}P_k^{-1}$, and so

$$\prod_{j=i+1}^{k} (I - L_j\varphi_j^\tau) = \alpha^{k-i} P_{k+1} P_{i+1}^{-1}. \tag{4.22}$$

On the other hand, multiplying φ_k from both sides of (1.10) we have $P_{k+1}^{-1}L_k = \varphi_k$. Hence by (2.1) and (4.22),

$$\begin{aligned}\|\theta_{k+1} - \hat{\theta}_{k+1}\|_{L_p} &\le \alpha^k \|P_{k+1}P_0^{-1}\tilde{\theta}_0\|_{L_p} \\ &\quad + \sum_{i=0}^{k} \alpha^{k-i} (\|P_{k+1}\varphi_i v_i\|_{L_p} + \|P_{k+1}P_{i+1}^{-1}\Delta_{i+1}\|_{L_p}).\end{aligned}$$

By the Hölder inequality, Assumptions (i)–(iv), and Lemma 4.4 we know that the proof will be complete if we can show that $\sup_i \|P_{i+1}^{-1}\|_{L_{3p}} < \infty$. But, this can be easily seen from (4.21) and Assumption (iii), since

$$\|P_{k+1}^{-1}\|_{L_{3p}} \le \alpha \|P_k^{-1}\|_{L_{3p}} + \|\varphi_k\|_{L_{6p}}^2, \qquad \forall\, k \ge 0. \qquad \square$$

Remark 4.2. Under additional statistical assumptions on the processes $\{\varphi_k, v_k, \Delta_k\}$, a refined upper bound for the tracking error of the forgetting factor RLS can be derived (see [33]).

Conclusions. In this paper, stability and tracking error bounds are established for several standard estimation algorithms under a very general excitation condition. The various stability results presented in the paper are believed to be necessary preliminaries for further study of tracking properties, e.g., approximate expressions of the variance of the tracking errors (see e.g., [18]). Also, applications of the results to adaptive control systems as studied in e.g., [30] are possible. These issues will be discussed in detail elsewhere.

Appendix A.

Proof of Proposition 2.1. The solution of (2.2) may be expressed by

$$x_{n+1} = \sum_{i=0}^{n} \left[\prod_{j=i+1}^{n} (I - A_j) \right] \xi_{i+1}. \tag{A.1}$$

From this and the independence of $\{A_k\}$ and $\{\xi_k\}$ we know that the sufficiency of (2.4) is obvious.

To prove the necessity, we take $\{\xi_k\}$ to be an independently and identically distributed (i.i.d.) sequence with zero mean and unit variance. Then by denoting $B_k = I - A_k$, we have for some $c > 0$ and for any $n \geq k > 0$,

$$\begin{aligned} c &\geq E\|x_{n+1}\|^2 = tr \sum_{i=0}^{n} E\left[\prod_{j=i+1}^{n} B_j\right]\left[\prod_{j=i+1}^{n} B_j\right]^\tau \\ &\geq \sum_{i=k}^{n} tr\left\{E\left[\prod_{j=i+1}^{n} B_j\right]\left[\prod_{j=i+1}^{n} B_j\right]^\tau\right\}. \end{aligned} \tag{A.2}$$

Denote

$$a(n,i) = tr\left\{E\left[\prod_{j=i+1}^{n} B_j\right]\left[\prod_{j=i+1}^{n} B_j\right]^\tau\right\}.$$

It is easy to verify that $a(n,i) > 0$, for all $n \geq i$. Then by the independency of $\{A_j\}$ we have for any $n \geq i \geq k$,

$$\begin{aligned} a(n,k) &= trE[B_n \cdots B_{k+1} B_{k+1}^\tau \cdots B_n^\tau] \\ &= trE\{B_n \cdots B_{i+1} E[B_i \cdots B_{k+1} B_{k+1}^\tau \cdots B_i^\tau] B_{i+1}^\tau \cdots B_n^\tau\} \\ &\leq trE[B_n \cdots B_{i+1} B_{i+1}^\tau \cdots B_n^\tau] trE[B_i \cdots B_{k+1} B_{k+1}^\tau \cdots B_i^\tau] \\ &= a(n,i)a(i,k). \end{aligned}$$

Hence by (A.2) we have

$$c \geq a(n,k) \sum_{i=k}^{n} a^{-1}(i,k)$$

or

$$\sum_{i=k}^{n} a^{-1}(i,k) \leq c a^{-1}(n,k), \quad \forall n \geq k \geq 0. \tag{A.3}$$

From this we have

$$\begin{aligned} \sum_{i=k}^{n} a^{-1}(i,k) &= a^{-1}(n,k) + \sum_{i=k}^{n-1} a^{-1}(i,k) \\ &\geq \left(1 + \frac{1}{c}\right) \sum_{i=k}^{n-1} a^{-1}(i,k) \geq \cdots \\ &\geq \left(1 + \frac{1}{c}\right)^{n-k} a^{-1}(k,k) = \left(1 + \frac{1}{c}\right)^{n-k} d. \end{aligned}$$

Therefore, by (A.3)

$$c a^{-1}(n,k) \geq \left(1 + \frac{1}{c}\right)^{n-k} d$$

or

$$a(n,k) \le \frac{c}{d}\left(\frac{c}{1+c}\right)^{n-k}, \qquad \forall n \ge k, \quad \forall k \ge 0.$$

So (2.4) holds with $\lambda = [c/(1+c)]^{1/2} < 1$. □

Proof of Proposition 2.2. Denote $\psi(i,k) = \prod_{j=k+1}^{i}(I - A_j)$, and set for any fixed $k \ge 0$,

$$\xi_{i+1} = \psi(i,k)[E\psi(i,k)^\tau \psi(i,k)]^{-1/2}\eta_{i+1}, \tag{A.4}$$

where $\{\eta_{i+1}\}$ is a d-dimensional i.i.d. sequence independent of $\{A_i\}$ with $E\eta_{i+1} = 0$, $E\eta_i\eta_i^\tau = (1/d)I$. It is easy to see that

$$\begin{aligned} E\|\xi_{i+1}\|^2 &= tr[E\xi_{i+1}\xi_{i+1}^\tau] \\ &= \frac{1}{d}\, trE\{\psi(i,k)[E\psi(i,k)^\tau\psi(i,k)]^{-1}\psi(i,k)^\tau\} = 1. \end{aligned}$$

Hence for any $k \ge 0, \xi \in \mathcal{B}^0$. Substituting (A.4) into (A.1) and calculating the covariance, we get

$$Ex_{n+1}x_{n+1}^\tau = \frac{1}{d}E\sum_{i=0}^{n}\psi(n,k)[E\psi(i,k)^\tau\psi(i,k)]^{-1}\psi(n,k)^\tau, \qquad \forall k \ge 0,$$

and so

$$\begin{aligned} &[E\psi(n,k)^\tau\psi(n,k)]^{1/2}\sum_{i=0}^{n}[E\psi(i,k)^\tau\psi(i,k)]^{-1}[E\psi(n,k)^\tau\psi(n,k)]^{1/2} \\ &\le tr\, E\left\{\sum_{i=0}^{n}\psi(n,k)[E\psi(i,k)^\tau\psi(i,k)]^{-1}\psi(n,k)^\tau\right\} I \\ &= dE\|x_{n+1}\|^2 I \le cI, \quad \forall n \ge k, \quad \forall k, \end{aligned}$$

where for the last inequality we have used the assumption (2.8) and where c is a finite constant. This inequality implies that

$$\sum_{i=0}^{n}[E\psi(i,k)^\tau\psi(i,k)]^{-1} \le c[E\psi(n,k)^\tau\psi(n,k)]^{-1}.$$

Hence by denoting $a^{-1}(i,k) \triangleq \lambda_{\min}\{[E\psi(i,k)^\tau\psi(i,k)]^{-1}\}$, we obtain

$$\sum_{i=k}^{n}a^{-1}(i,k) \le \sum_{i=0}^{n}a^{-1}(i,k) \le ca^{-1}(n,k), \qquad \forall n \ge k \ge 0.$$

This inequality is exactly the same as (A.3). Hence by the same arguments as those in the proof of Proposition 2.1, we get

$$a(n,k) \le \frac{c}{d}\left(\frac{c}{1+c}\right)^{n-k}, \quad \forall n \ge k, \qquad \forall k \ge 0.$$

Finally, observing that $a(n,k) = \lambda_{\max}\{E[\psi(n,k)^\tau\psi(n,k)]\}$, we get the desired result (2.4). □

Appendix B.

Proof of (2.14). For simplicity of notations, set $k = mh + 1$. Following the ideas in the proofs of Theorem 4.5 and Lemma 10.7 in [5], we denote z_{k-1} as the unit eigenvector corresponding to the largest eigenvalue ρ_{k-1} of the matrix $E[\Phi^\tau(k+h,k)\Phi(k+h,k)|\mathcal{F}_{k-1}]$, and recursively define z_j by

$$z_j = (I - A_j)z_{j-1}, \qquad j \geq k. \tag{B.1}$$

It follows from (2.13) that $z_{k+h-1} = \Phi(k+h,k)z_{k-1}$. Hence we have

$$\begin{aligned} E(\|z_{k+h-1}\|^2|\mathcal{F}_{k-1}) &= z_{k-1}^\tau E[\Phi^\tau(k+h,k)\Phi(k+h,k)|\mathcal{F}_{k-1}]z_{k-1} \\ &= \rho_{k-1}\|z_{k-1}\|^2 = \rho_{k-1}. \end{aligned} \tag{B.2}$$

By (B.1) we have

$$z_j = z_{k-1} - \sum_{i=k}^{j} A_i z_{i-1}, \quad \forall\, j \in [k, k+h-1].$$

Hence by the Schwarz inequality

$$\begin{aligned} E[\|z_{j-1} - z_{k-1}\|^2|\mathcal{F}_{k-1}] &= E\left[\left\|\sum_{i=k}^{j-1} A_i z_{i-1}\right\|^2 |\mathcal{F}_{k-1}\right] \\ &\leq E\left[\left(\sum_{i=k}^{j-1}\|A_i^{1/2}z_{i-1}\|^2\right)\sum_{i=k}^{j-1}\|A_i^{1/2}\|^2|\mathcal{F}_{k-1}\right] \\ &\leq hE\left[\sum_{i=k}^{j-1} z_{i-1}^\tau A_i z_{i-1}|\mathcal{F}_{k-1}\right], \qquad j \in [k, k+h]. \end{aligned} \tag{B.3}$$

By the definition of λ_m and the Minkowski inequality we have

$$\begin{aligned} &\sqrt{(1+h)}\lambda_m^{1/2} \\ &\leq \left\{ z_{k-1}^\tau E\left[\sum_{i=mh+1}^{(m+1)h} A_i|\mathcal{F}_{mh}\right] z_{k-1}\right\}^{1/2} = \left\{E\left[\sum_{i=k}^{k+h-1}\|A_i^{1/2}z_{k-1}\|^2|\mathcal{F}_{k-1}\right]\right\}^{1/2} \\ &\leq \left\{E\left[\sum_{i=k}^{k+h-1}\|A_i^{1/2}z_{i-1}\|^2|\mathcal{F}_{k-1}\right]\right\}^{1/2} + \left\{E\left[\sum_{i=k}^{k+h-1}\|z_{i-1}-z_{k-1}\|^2|\mathcal{F}_{k-1}\right]\right\}^{1/2}. \end{aligned}$$

From this and (B.3) it follows that

$$\sqrt{(1+h)}\lambda_m^{1/2} \leq (1+h)\left\{E\left[\sum_{i=k}^{k+h-1}\|A_i^{1/2}z_{i-1}\|^2|\mathcal{F}_{k-1}\right]\right\}^{1/2}$$

or

$$E\left[\sum_{i=k}^{k+h-1}\|A_i^{1/2}z_{i-1}\|^2|\mathcal{F}_{k-1}\right] \geq \frac{\lambda_m}{1+h}. \tag{B.4}$$

By (B.1) and the fact that $0 \le A_i \le I$ it is easily derived that

$$z_j^\tau z_j \le z_{j-1}^\tau z_{j-1} - z_{j-1}^\tau A_j z_{j-1},$$

from which we have

$$\begin{aligned}\|z_{k+h-1}\|^2 &\le \|z_{k-1}\| - \sum_{i=k}^{k+h-1} z_{i-1}^\tau A_i z_{i-1} \\ &= 1 - \sum_{i=k}^{k+h-1} z_{i-1}^\tau A_i z_{i-1}.\end{aligned}$$

Combining this with (B.2) and (B.4) we get

$$\begin{aligned}\rho_{k-1} &= E[\|z_{k+h-1}\|^2 | \mathcal{F}_{k-1}] \\ &\le 1 - E\left[\sum_{i=k}^{k+h-1} z_{i-1}^\tau A_i z_{i-1} | \mathcal{F}_{k-1}\right] \le 1 - \frac{\lambda_m}{1+h},\end{aligned}$$

which is tantamount to (2.14). □

Appendix C. We first prove Proposition 3.3. The proof is divided into two steps.

Step 1. We first prove that

$$\lambda_k \ge \frac{1}{P(\beta_{kp-1})[1 + \|\varphi_{kp}\|^4]}, \quad \forall k \ge 1 \tag{C.1}$$

where λ_k is defined by (3.1) with $h = p$ and $\mathcal{F}_k = \sigma\{\mathcal{F}_i', v_i, i \le k-1\}$ and where $P(x)$ is a polynomial of x with nonnegative coefficients.

By (3.7) we have

$$\varphi_{k+1} = \left(\prod_{j=s}^{k} A_j\right)\varphi_s + \sum_{i=s}^{k}\left(\prod_{j=i+1}^{k} A_j\right) b v_i, \quad \forall k \ge s, \quad \forall s \ge 0. \tag{C.2}$$

By (3.1) with $h = p$ and the Schwarz inequality it is easy to show that (cf. [14] or [28], p. 168)

$$\begin{aligned}\lambda_k &\ge \frac{1}{p+1}\lambda_{\min}\left\{E\left[\frac{\varphi_{(k+1)p}\varphi_{(k+1)p}^\tau}{1 + \|\varphi_{(k+1)p}\|^2} \,\middle|\, \mathcal{F}_{kp}\right]\right\} \\ &\ge \frac{1}{1+p}\frac{\{\lambda_{\min}(E[\varphi_{(k+1)p}\varphi_{(k+1)p}^\tau | \mathcal{F}_{kp}])\}^2}{E[(\|\varphi_{(k+1)p}\|^4 + \|\varphi_{(k+1)p}\|^2) | \mathcal{F}_{kp}]}.\end{aligned} \tag{C.3}$$

We first analyze the numerator. Denote the controllability Gramian by H_{kp+1}:

$$H_{kp+1} \triangleq \sum_{i=kp}^{(k+1)p-1}\left(\prod_{j=i+1}^{(k+1)p-1} A_j\right) bb^\tau \left(\prod_{j=i+1}^{(k+1)p-1} A_j\right)^\tau. \tag{C.4}$$

Then by (C.2), (3.6), and the independence assumptions we have

$$E[\varphi_{(k+1)p}\varphi_{(k+1)p}^\tau | \mathcal{F}_{kp}] \ge \sigma_v^2 E[H_{kp+1} | \mathcal{F}_{kp}]. \tag{C.5}$$

By (3.8) and (C.4) it is easy to verify that $det[H_{kp+1}] = 1$, and hence by (C.5)

$$\begin{aligned}\lambda_{\min}\{E[\varphi_{(k+1)p}\varphi_{(k+1)p}^{\tau}|\mathcal{F}_{kp}]\} &\geq \sigma_v^2 E[\lambda_{\min}(H_{kp+1})|\mathcal{F}_{kp}] \\ &\geq \sigma_v^2 E\left[\frac{det(H_{kp+1})}{\{\lambda_{\max}(H_{kp+1})\}^{p-1}}\,\middle|\,\mathcal{F}_{kp}\right] \\ &\geq \frac{\sigma_v^2}{E\{\|H_{kp+1}\|^{p-1}|\mathcal{F}_{kp}\}}.\end{aligned} \tag{C.6}$$

Concerning the denominator in (C.3), we first note that

$$E[\|\varphi_{(k+1)p}\|^2|\mathcal{F}_{kp}] \leq \frac{1}{2} + \frac{1}{2}E[\|\varphi_{(k+1)p}\|^4|\mathcal{F}_{kp}] \tag{C.7}$$

and that by (C.2)

$$\begin{aligned}E[\|\varphi_{(k+1)p}\|^4|\mathcal{F}_{kp}] \leq\ & 8E\left[\left\|\prod_{i=kp}^{(k+1)p-1} A_i\right\|^4 \,\middle|\, \mathcal{F}_{kp}\right]\|\varphi_{kp}\|^4 \\ &+ 8p^3\|b\|^4 \sup_k Ev_k^4 \sum_{i=kp}^{(k+1)p-1} E\left[\left\|\prod_{j=i+1}^{(k+1)p-1} A_j\right\|^4 \,\middle|\, \mathcal{F}_{kp}\right].\end{aligned}$$

Then, substituting this, (C.6), and (C.7) into (C.3) and using (3.10)–(3.11) together with the Markovian properties of β_k, it is not difficult to conclude (C.1). □

Step 2. We prove that

$$\left\{\frac{1}{P(\beta_{kp-1})[1 + \|\varphi_{kp}\|^4]}\right\} \in S^0(\lambda), \quad \text{for some } \lambda \in (0,1). \tag{C.8}$$

Since A is a stable matrix, there is a norm $\|\cdot\|_\delta$ on $\mathbb{R}^p$ such that its induced norm on $\mathbb{R}^{p\times p}$ (also denoted by $\|\cdot\|_\delta$) satisfies $\|A\|_\delta \triangleq \delta < 1$. Clearly, there is a constant $c > 1$ such that, for all $x \in \mathbb{R}^p$, $\|x\| \leq c\|x\|_\delta$. In order to apply Corollary 3.1 we denote

$$\begin{aligned}x_k &= \|\varphi_{kp}\|_\delta^8 + \beta_{kp-1}^L + 1 \\ y_k &= \frac{c^8}{2}P^2(\beta_{kp-1}), \qquad \mathcal{G}_k = \sigma\{\mathcal{F}_i', v_i, i \leq kp-1\}\end{aligned}$$

where L is a suitably large number defined later on. Then both$\{x_k, \mathcal{G}_k\}$ and $\{y_k, \mathcal{G}_k\}$ are adapted processes. Clearly, $P(\beta_{kp-1})[1 + \|\varphi_{kp}\|^4] \leq x_k + y_k$. Hence, (C.8) will be proved if conditions in Corollary 3.1 can be verified.

By (3.11) and the convexity of the function $P^2(x), x \geq 0$, we have

$$\begin{aligned}y_{k+1} &\leq \frac{c^8}{2}P^2\left(\beta^p\beta_{kp-1} + \sum_{i=kp}^{(k+1)p-1} e_i\right) \\ &\leq \frac{c^8}{2}P^2\left(\beta\beta_{kp-1} + (1-\beta)\frac{1}{1-\beta}\sum_{i=kp}^{(k+1)p-1} e_i\right) \\ &\leq \beta y_k + \frac{c^8}{2}(1-\beta)P^2\left(\frac{1}{1-\beta}\sum_{i=kp}^{(k+1)p-1} e_i\right).\end{aligned}$$

Hence $\{y_k\}$ satisfies the required properties.

Now, it only remains to prove that $\{x_k\}$ satisfies conditions in Lemma 3.1. By (3.10)–(3.11) we have

$$\|A_k\|_\delta \le \delta + \|\bar{A}_k\|_\delta \le \delta + c_\delta \beta_k,$$

where $c_\delta > 0$ is a constant. This motivates us to set $\alpha_{k+1} \triangleq \prod_{i=kp}^{(k+1)p-1}(\delta + c_\delta \beta_i)$. Clearly, $\alpha_k \in \mathcal{G}_k$, and by a completely similar argument as that used in [29] we know that under condition (3.12) (with small ε and large b) there are constants $M > 0, \gamma \in (0,1)$ such that

$$\left\| \prod_{k=m}^{n} E[\alpha_{k+1}^4 | \mathcal{G}_k] \right\| \le M\gamma^{n-m+1}, \quad \forall n \ge m, \quad \forall m \ge 0.$$

Let α be a positive number such that $(1+\alpha)^4\gamma < 1$, where γ is defined above. It is easy to see from (C.2) and the definition of α_{k+1} that there is a constant $M_\alpha > 0$ such that for any $\varepsilon_0 > 0$,

$$\text{(C.9)} \quad \|\varphi_{(k+1)p}\|_\delta^8 \le (1+\alpha)\alpha_{k+1}\|\varphi_{kp}\|_\delta^8 + M_\alpha \left\| \sum_{i=kp}^{(k+1)p-1} \left(\prod_{j=i+1}^{(k+1)p-1} A_j \right) b v_i \right\|_\delta^8$$

$$\le (1+\alpha)\alpha_{k+1}\|\varphi_{kp}\|_\delta^8 + \frac{\varepsilon_0}{2}\beta_{kp-1}^L$$

$$\text{(C.10)} \quad + c_1 \left(\sum_{i=kp}^{(k+1)p-1} e_i + 1 \right)^L + c_2 \left(\sum_{i=kp}^{(k+1)p-1} |v_i| + 1 \right)^9$$

for some constants L, c_1, and c_2, where for the last inequality we have used the fact that $\|A_j\|_\delta \le \delta + c_\delta \beta_j$ together with the Markovian property of $\{\beta_j\}$.

Without loss of generality we may assume that L in (C.10) is so large that

$$\text{(C.11)} \quad 4\beta^{pL} \le (1+\alpha)\delta^{8p} \triangleq \varepsilon_0.$$

By (C.11) and (3.11) it is easy to see that there is a constant $c_3 > 0$ such that

$$\text{(C.12)} \quad \beta_{kp-1}^L \le \frac{\varepsilon_0}{2}\beta_{(k-1)p-1}^L + c_3 \left(\sum_{i=(k-1)p}^{kp-1} e_i \right)^L.$$

Combining (C.11) and (C.12), using the definition of x_k and the fact that $(1+\alpha)\alpha_{k+1} \ge \varepsilon_0$, we get for some constant $c_4 > 0$,

$$x_{k+1} \le (1+\alpha)\alpha_{k+1}x_k + c_4 \left[1 + \left(\sum_{i=kp}^{(k+1)p-1} e_i + 1 \right)^L + \left(\sum_{i=kp}^{(k+1)p-1} |v_i| + 1 \right)^9 \right].$$

Hence both $\{x_k\}$ and $\{y_k\}$ satisfy conditions of Corollary 3.1, and so $\{1/(x_k + y_k)\} \in S^0(\lambda)$ for some $\lambda \in (0,1)$. This proves (C.8). Finally, combining (C.1) and (C.8) we know that Proposition 3.3 is true. □

Proof of Example 3.2. Set $\mathcal{F}_k = \sigma\{A_i, v_i, i \le k-1\}$. Since $\{A_i\}$ is an independent sequence, similar to the proof of (C.1) we have for some constant $c_5 \ge 1$,

$$\lambda_k \ge \frac{1}{a_k}, \qquad a_k = c_5(1 + \|\varphi_{kp}\|^4), \qquad k \ge 0. \tag{C.13}$$

So we need only to prove that $\{a_k\}$ verifies (3.3). Let $\alpha > 0$ be such that $(1+\alpha)\delta^4 < 1$ where δ is given by (3.9). By (C.2), (3.9) and the independence assumptions we know that

$$E[\|\varphi_{(k+1)p}\|^4 | \mathcal{F}_{kp}] \le (1+\alpha)\delta^4 \|\varphi_{kp}\|^4 + c_6$$

for some constant $c_6 > 0$. Consequently, we have

$$E[a_{k+1} | \mathcal{F}_{kp}] \le (1+\alpha)\delta^4 \alpha_k + c_5(1+c_6).$$

Hence (3.3) is true. □

Appendix D.

Proof of Lemma 4.1. We first consider the case where $\beta > 2\max(1, \alpha)$. Let $\delta_p > 0$ be such that

$$\sup_{n \ge k \ge 0} \|(d_{nk}\xi_k)\log^{\beta/2}(e + d_{nk}\xi_k)\|_{L_p} \le \delta_p.$$

Then exactly the same argument as that used for Lemma 8 in [28] yields

$$\sum_{k=0}^{n} \|c_{nk} d_{nk} \xi_k\|_{L_p} \le c[\delta_p \log(e + \delta_p^{-1})]. \tag{D.1}$$

So we need only to find a relationship between δ and σ. By inequality (52) in [28] we know that

$$xy \le \sigma \exp(\varepsilon x^{1/\alpha}) + c_1 y[\log^{\alpha}(e + \sigma^{-1}) + \log^{\alpha}(e + y)] \tag{D.2}$$

holds for all $\sigma > 0, \varepsilon > 0$, and $\alpha > 0$, where c_1 is a constant depending only on ε and α. Applying (D.2) with $x = d_{nk}^p \log^{p\beta/2}(e + d_{nk}), y = \xi_k^p \log^{p\beta/2}(e + \xi_k), \sigma = \sigma_p^p, \alpha = p\beta/2$ we have

$$\begin{aligned} & Ed_{nk}^p \xi_k^p \log^{p\beta/2}(e + d_{nk}\xi_k) \le 2^{p\beta/2} Exy \\ & \le 2^{p\beta/2} E\{\sigma_p^p \exp(\varepsilon x^{2/(p\beta)}) + c_1 y[\log^{p\beta/2}(e + \sigma_p^{-p}) + \log^{p\beta/2}(e+y)]\} \\ & \le c\sigma_p^p \log^{p\beta/2}(e + \sigma_p^{-1}), \quad \text{for some constant } c. \end{aligned} \tag{D.3}$$

Hence we may take $\delta_p = c\sigma_p \log^{\beta/2}(e + \sigma_p^{-1})$. Substituting this into (D.1) we know that the first case in (4.2) is true, while the second case can be proved in a similar way. Finally, the last case can be derived from (D.1) by noting $\delta_p \le c_1 \sigma_p$ for some $c_1 > 0$. □

UNIFORM EXPONENTIAL STABILITY AND APPROXIMATION IN CONTROL OF A THERMOELASTIC SYSTEM*

ZHUANGYI LIU† AND SONGMU ZHENG‡

Abstract. This paper has two objectives. First, necessary and sufficient conditions are given to characterize the uniform exponential stability of a sequence of c_0-semigroups $T_n(t)$ on Hilbert space H_n. Secondly, approximation in control of a one-dimensional thermoelastic system, subject to Dirichlet–Dirichlet as well as Dirichlet–Neumann boundary conditions, is considered. The uniform exponential stability and strong convergence of corresponding semigroups associated with approximate scheme are proved. Numerical experimental results are also presented.

Key words. linear thermoelastic system, uniform exponential stability, semigroup, approximation in control

AMS subject classifications. 93C20, 93D20, 73C25

1. Introduction. For a homogeneous rod with uniform cross section, in general, the equation of one-dimensional linear thermoelasticity can be written as (see [D])

$$u_{tt} - c^2 u_{xx} + c^2 \gamma \theta_x = 0, \qquad (0,\pi) \times (0,+\infty), \tag{1.1}$$

$$\theta_t + \gamma u_{xt} - \theta_{xx} = 0, \qquad (0,\pi) \times (0,+\infty), \tag{1.2}$$

where u is proportional to the displacement and θ is the relative temperature about the stress-free reference temperature. The constants $\gamma > 0$ and $c > 0$ represent, respectively, the amount of thermal-mechanical coupling and the small-amplitude wave speed about a constant temperature state. (See [D] for a precise definition of γ and c.) In most materials of interest, γ is several orders of magnitude smaller than 1.

By introducing new variable (velocity)

$$v = u_t, \tag{1.3}$$

(1.1), (1.2) is reduced to the following abstract first-order evolution equation:

$$\frac{dz}{dt} = \mathcal{A}z \tag{1.4}$$

with

$$z = \begin{pmatrix} z_1 \\ z_2 \\ z_3 \end{pmatrix} \equiv \begin{pmatrix} u \\ v \\ \theta \end{pmatrix}, \tag{1.5}$$

and

$$\mathcal{A} = \begin{pmatrix} 0 & I & 0 \\ c^2 D^2 & 0 & -c^2 \gamma D \\ 0 & -\gamma D & D^2 \end{pmatrix}. \tag{1.6}$$

Here we have used the notation $D = \partial/\partial x$, $D^2 = \partial^2/\partial x^2$.

If both ends of the rod are clamped and kept at the reference temperature, then we have the Dirichlet–Dirichlet boundary conditions

$$u|_{x=0,\pi} = \theta|_{x=0,\pi} = 0, \quad \text{for } t > 0. \tag{1.7}$$

Let the state space be

$$H = H_0^1(\Omega) \times L^2(\Omega) \times L^2(\Omega) \tag{1.8}$$

equipped with the norm

$$\|z\|_H = \left(\|Dz_1\|_{L^2}^2 + \frac{1}{c^2} \|z_2\|_{L^2}^2 + \|z_3\|_{L^2}^2 \right)^{1/2}. \tag{1.9}$$

It is shown in [BLM] that the operator $\mathcal{A}$ with $\mathcal{D}(\mathcal{A}) = H^2 \cap H_0^1 \times H_0^1 \times H^2 \cap H_0^1$ generates a c_0-semigroup $T(t)$ on the Hilbert space H. Our study is motivated by the linear quadratic Gaussian (LQG) optimal control problem of the thermoelastic system and its approximation; we refer to [GRT] for the detailed description. Recall that a c_0-semigroup $T(t)$ on a Hilbert space H is said to be exponentially stable if there exist positive constants M and α such that

$$\|T(t)\|_{\mathcal{L}(H,H)} \leq Me^{-\alpha t} \quad \forall t > 0. \tag{1.10}$$

Accordingly, a sequence of C_0-semigroups $T_n(t)$ on the Hilbert spaces H_n are said to be uniformly exponentially stable if

$$\|T_n(t)\|_{\mathcal{L}(H_n,H_n)} \leq Me^{-\alpha t} \quad \forall t > 0, \quad \forall n. \tag{1.11}$$

As shown in [GRT], the exponential stability of semigroup $T(t)$ associated with the open-loop system (1.4) and the uniformly exponential stability of approximating semigroups $T_n(t)$, if such results are available, will play a very important role in the study of the corresponding LQG optimal control problem and the convergence of the approximating optimal controls. The exponential stability of the semigroup associated with the thermoelastic system (1.4) subject to Dirichlet–Neumann boundary condition was proved by Hansen [Ha] in 1990. Another approach of the proof was given by Gibson, Rosen, and Tao (see [GRT]). But the problem for the Dirichlet–Dirichlet boundary conditions had remained open until Kim [K] and Liu and Zheng [LZ] independently suceeded in proving exponential energy decay rate for this case.

The purpose of this paper is to study the uniform exponentially stable approximation and its application to the thermoelastic system (1.4) with Dirichlet–Dirichlet boundary conditions. As mentioned before, it is crucial to show that (1.11) holds. Let us explain the difficulties in proving (1.11). For the wave equation with internal or boundary friction damping, the dissipation is relatively strong so that the energy method can be applied to obtain the exponential stability (1.10) (see [C], [L1], [L2]) as well as the uniformly exponential stability (1.11) for the approximation (see [BIW]). However, the dissipation in the thermoelastic system, due to heat conduction, is much weaker. To our knowledge, the energy method has been used to obtain the exponential stability in more regular Sobolev's space $\mathcal{D}(\mathcal{A})$ as Slemrod [S] and Rivera [R] did, but not in the primary Hilbert space H, at least for the case of Dirichlet–Dirichlet boundary conditions. As far as (1.11) is concerned, the existence of a positive constant M independent of n is also a difficult part of the proof. As the counterexample in [Hu] shows, even for semigroups $T_n(t) = e^{\mathcal{A}_n t}$ with $\mathcal{A}_n$ being an $n \times n$ matrix, uniform negative boundedness away from zero of the spectrum $\sigma(\mathcal{A}_n)$ of $\mathcal{A}_n$ does not guarantee the existence of such an M. As can be seen in [GRT], the existence of a uniform constant M is somehow related

to the independence of eigenvectors of $\mathcal{A}_n$. In the Dirichlet–Neumann boundary conditions case, we could indeed use such information coming from decoupling to prove (1.11). But in the case of Dirichlet–Dirichlet boundary conditions a new approach must be adopted.

The paper is organized as follows. In §2 we give necessary and sufficient conditions to characterize the uniform exponential stability of a sequence of semigroups $T_n(t)$. In §3, as an application of the results in §2, the uniform exponential stability (1.11) and convergence are proved for the so-called modal approximation of the thermoelastic system subject to Dirichlet–Dirichlet or Dirichlet–Neumann boundary conditions. In §4 numerical experimental results are presented.

2. Uniform exponential stability of C_0-semigroups. In this section we give necessary and sufficient conditions to characterize the uniform exponential stability of $T_n(t)$, a sequence of c_0-semigroups on Hilbert spaces H_n.

For a single semigroup $T(t)$, the characteristic condition of exponential stability was given by Huang [Hu]. In what follows we extend his results to a sequence of semigroups $T_n(t)$.

THEOREM 2.1. *Let $T_n(t)$ $(n = 1, \ldots)$ be a sequence of c_0-semigroups of operators on the Hilbert spaces H_n and let $\mathcal{A}_n$ be the corresponding infinitesimal generators. Then $T_n(t)$ are uniformly exponentially stable if and only if the following three conditions hold*:

$$\sup_{n\in N}\{\operatorname{Re}\lambda;\ \lambda\in\sigma(\mathcal{A}_n)\}=\sigma_0<0; \tag{2.1}$$

there exist $\sigma \in (\sigma_0, 0)$ such that

$$\sup_{\operatorname{Re}\lambda\geq\sigma,n\in N}\{\|(\lambda I-\mathcal{A}_n)^{-1}\|\}=M_0<\infty; \tag{2.2}$$

and there exist $M_1 > 0$ such that

$$\|T_n(t)\|_{\mathcal{L}(H_n,H_n)}\leq M_1<\infty\quad\forall t>0,\qquad n\in N. \tag{2.3}$$

We postpone the proof until the end of this section.

THEOREM 2.2. *Let $T_n(t)$ $(n = 1, \ldots)$ be a sequence of semigroups of operators on the Hilbert spaces H_n and let $\mathcal{A}_n$ be the corresponding infinitesimal generators. Then $T_n(t)$ are uniformly exponentially stable if and only if* (2.1), (2.3), *and*

$$\sup_{\operatorname{Re}\lambda\geq 0,n\in N}\{\|(\lambda I-\mathcal{A}_n)^{-1}\|\}<\infty \tag{2.4}$$

hold.

Proof. We only need to prove that (2.1), (2.3), and (2.4) imply (2.1)–(2.3). Let

$$M=\sup_{\operatorname{Re}\lambda\geq 0,n\in N}\{\|\lambda I-\mathcal{A}_n)^{-1}\|\}<\infty, \tag{2.5}$$

and $\lambda = (\tau + \boldsymbol{i}\omega)$, $\tau \in [-1/2M, 0]$. Then

$$\begin{aligned}\|(I+\tau(\boldsymbol{i}\omega I-\mathcal{A}_n)^{-1})x\| &\geq \|x\|-\frac{1}{2M}\|(\boldsymbol{i}\omega I-\mathcal{A}_n)^{-1}x\|\\ &\geq \|x\|-\frac{1}{2}\|x\|=\frac{1}{2}\|x\|.\end{aligned} \tag{2.6}$$

This implies that

$$\|(I+\tau(\boldsymbol{i}\omega I-\mathcal{A}_n)^{-1})^{-1}\|\leq 2. \tag{2.7}$$

By

$$\lambda I - \mathcal{A}_n = (I + \tau(\boldsymbol{i}\omega I - \mathcal{A}_n)^{-1})(\boldsymbol{i}\omega I - \mathcal{A}_n), \tag{2.8}$$

we conclude that $\lambda I - \mathcal{A}_n$ is invertible and

$$\begin{aligned} \|(\lambda I - \mathcal{A}_n)^{-1}\| &= \|(\boldsymbol{i}\omega I - \mathcal{A}_n)^{-1}(I + \tau(\boldsymbol{i}\omega I - \mathcal{A}_n)^{-1})^{-1}\| \\ &\le 2\|(\boldsymbol{i}\omega I - \mathcal{A}_n)^{-1}\| \le 2M. \end{aligned} \tag{2.9}$$

Let

$$\sigma = \max\left(-\frac{1}{2M}, \frac{\sigma_0}{2}\right). \tag{2.10}$$

Then

$$\sigma_0 < \sigma < 0, \quad \sigma \in \left[-\frac{1}{2M}, 0\right). \tag{2.11}$$

It turns out from (2.9) that (2.2) is satisfied. □

In particular, (2.3) holds if $T_n(t)$ is a sequence of semigroups of contraction. Thus we have the following result.

COROLLARY 2.3. *Let $T_n(t)$ be a sequence of semigroups of contraction on the Hilbert spaces H_n and $\mathcal{A}_n$ be the corresponding infinitesimal generators. Then $T_n(t)$ are uniformly exponentially stable if and only if* (2.1) *and* (2.4) *hold.*

In what follows we give the proof of Theorem 2.1.

Proof of Theorem 2.1. If $T_n(t)$ are uniformly exponentially stable, i.e., there exist M, $\alpha > 0$ such that

$$\|T_n(t)\|_{\mathcal{L}(H_n, H_n)} \le Me^{-\alpha t} \quad \forall t > 0, \qquad n \in N, \tag{2.12}$$

then

$$\omega_0(\mathcal{A}_n) \overset{\text{def}}{=} \lim_{t \to +\infty} \frac{\ln \|T_n(t)\|}{t} \le -\alpha. \tag{2.13}$$

Thus (2.1) follows from the following property:

$$\sigma_0(\mathcal{A}_n) \overset{\text{def}}{=} \sup_{n \in N} \{\text{Re } \lambda; \lambda \in \sigma(\mathcal{A}_n)\} \le \omega_0(\mathcal{A}_n) \le -\alpha. \tag{2.14}$$

Let $\sigma = -\alpha/2$. Then $\sigma_0 < \sigma < 0$. For Re $\lambda \ge \sigma$, we have

$$\begin{aligned} \|(\lambda I - \mathcal{A}_n)^{-1}x\| &= \left\| \int_0^{+\infty} e^{-\lambda t} T_n(t)x \, dt \right\| \\ &\le M\|x\| \int_0^{+\infty} e^{-\text{Re}\lambda t} e^{-\alpha t} \, dt = \frac{M\|x\|}{\alpha + \text{Re } \lambda} \le 2\frac{M\|x\|}{\alpha}. \end{aligned} \tag{2.15}$$

This implies that (2.2) holds. Furthermore, (2.3) immediately follows from (2.12). Thus the proof of the "only if" part is complete.

On the other hand, suppose (2.1)–(2.3) hold. Let

$$\tilde{\mathcal{A}}_n = \mathcal{A}_n - \frac{\sigma}{2} I. \tag{2.16}$$

Then

$$\sup_{n\in N}\{\operatorname{Re}\lambda;\lambda\in\sigma(\tilde{\mathcal{A}}_n)\}\le-\frac{\sigma}{2}+\sigma_0<\frac{\sigma}{2}<0, \tag{2.17}$$

and

$$\sup_{\operatorname{Re}\lambda\ge(\sigma/2),n\in N}\{\|(\lambda I-\tilde{\mathcal{A}}_n)^{-1}\|\}=M_0<\infty. \tag{2.18}$$

In what follows we prove that (2.17), (2.18), and (2.3) imply that there exists a positive constant $M>0$ independent of n such that the corresponding semigroups $\tilde{T}_n(t)=T_n(t)e^{-(\sigma/2)t}$ with infinitesimal generators $\tilde{\mathcal{A}}_n$ satisfy

$$\|\tilde{T}_n(t)\|\le M, \tag{2.19}$$

which results in (2.12) with $\alpha=-\frac{\sigma}{2}>0$.

To prove (2.19), we use the same technique as Huang did in [Hu]. First, by (2.3) we have

$$\|\tilde{T}_n(t)\|\le M_1e^{-(\sigma/2)t}. \tag{2.20}$$

Therefore

$$\omega_0(\tilde{\mathcal{A}}_n)\le-\frac{\sigma}{2}. \tag{2.21}$$

Our next step is to prove the following estimate:

$$|(\tilde{T}_n(t)x,y)|\le\frac{cM_1^2}{2\pi}\|x\|\,\|y\|\quad\text{for } t\ge1,\qquad x,y\in H_n\quad\forall n \tag{2.22}$$

with constant $c>0$. For this purpose we first prove the following two lemmas.

LEMMA 2.4. *For any $x\in H_n$, $\tau>-\sigma/2$, as a function of $\omega\in R$,*

$$\|((\tau+\boldsymbol{i}\omega)I-\tilde{\mathcal{A}}_n)^{-1}x\|\in L^2(R),\qquad\|((\tau+\boldsymbol{i}\omega)I-\tilde{\mathcal{A}}_n)^{-1}x\|\to0\quad\text{as }|\omega|\to\infty.$$

Moreover,

$$\int_{-\infty}^{+\infty}\|((\tau+\boldsymbol{i}\omega)I-\tilde{\mathcal{A}}_n)^{-1}x\|^2\,d\omega\le\frac{\pi M_1^2\|x\|^2}{\tau+\frac{\sigma}{2}}, \tag{2.23}$$

$$\int_{-\infty}^{+\infty}\|((\tau-\boldsymbol{i}\omega)I-\tilde{\mathcal{A}}_n^*)^{-1}x\|^2\,d\omega\le\frac{\pi M_1^2\|x\|^2}{\tau+\frac{\sigma}{2}}. \tag{2.24}$$

Proof. By Hille–Yosida's theorem we have

(2.25)

$$\begin{aligned}\|((\tau+\boldsymbol{i}\omega)I-\tilde{\mathcal{A}}_n)^{-1}x\|^2&=\left(\int_0^\infty e^{-((\tau+\boldsymbol{i}\omega)I)t}\tilde{T}_n(t)x\,dt,\int_0^\infty e^{-((\tau+\boldsymbol{i}\omega)I)s}\tilde{T}_n(s)x\,ds\right)\\&=\int_0^\infty\int_0^\infty e^{-\tau(t+s)}e^{-\boldsymbol{i}\omega(t-s)}(\tilde{T}_n(t)x,\tilde{T}_n(s)x)\,dt\,ds\\&=\int_0^\infty\int_{-s}^\infty e^{-\tau(u+2s)}e^{-\boldsymbol{i}\omega u}(\tilde{T}_n(u+s)x,\tilde{T}_n(s)x)\,du\,ds\\&=\int_0^\infty e^{-\boldsymbol{i}\omega u}\left(\int_0^\infty e^{-\tau(u+2s)}(\tilde{T}_n(u+s)x,\tilde{T}_n(s)x)\,ds\right)du\\&\quad+\int_{-\infty}^0 e^{-\boldsymbol{i}\omega u}\left(\int_{-u}^\infty e^{-\tau(u+2s)}(\tilde{T}_n(u+s)x,\tilde{T}_n(s)x)\,ds\right)du\\&\overset{\text{def}}{=}\int_{-\infty}^{+\infty}f(u)e^{-\boldsymbol{i}\omega u}\,du\end{aligned}$$

with

$$f(u) = \begin{cases} \displaystyle\int_0^\infty e^{-\tau(u+2s)}(\tilde{T}_n(u+s)x, \tilde{T}_n(s)x)\,ds, & u > 0, \\ \displaystyle\int_{-u}^\infty e^{-\tau(u+2s)}(\tilde{T}_n(u+s)x, \tilde{T}_n(s)x)\,ds, & u < 0. \end{cases} \tag{2.26}$$

Therefore, we have for $u > 0$

$$\begin{aligned} |f(u)| &\le \int_0^\infty e^{-\tau(u+2s)}\|\tilde{T}_n(u+s)x\| \cdot \|\tilde{T}_n(s)x\|\,ds \\ &\le M_1^2\|x\|^2 \int_0^\infty e^{-\tau(u+2s)}e^{-(\sigma/2)(u+s)}e^{-(\sigma/2)s}\,ds \\ &= \frac{M_1^2\|x\|^2}{2\left(\tau+\frac{\sigma}{2}\right)}\,e^{-(\tau+(\sigma/2))u}, \end{aligned} \tag{2.27}$$

and for $u < 0$,

$$\begin{aligned} |f(u)| &\le M_1^2\|x\|^2 \int_{-u}^\infty e^{-\tau(u+2s)}e^{-(\sigma/2)(u+s)}e^{-(\sigma/2)s}\,ds \\ &= \frac{M_1^2\|x\|^2}{2\left(\tau+\frac{\sigma}{2}\right)}\,e^{(\tau+(\sigma/2))u}. \end{aligned} \tag{2.28}$$

It turns out that $f \in L^1(R) \cap L^\infty(R)$,

$$\|f\|_{L^\infty} \le \frac{M_1^2\|x\|^2}{2\left(\tau+\frac{\sigma}{2}\right)}. \tag{2.29}$$

By [HS, p. 401b] we conclude that $\|((\tau+i\omega)I - \tilde{\mathcal{A}}_n)^{-1}x\|^2 \in L^1(R)$ and

$$\int_{-\infty}^{+\infty} \|((\tau+i\omega)I - \tilde{\mathcal{A}}_n)^{-1}x\|^2\,d\omega \le 2\pi\|f\|_{L^\infty}. \tag{2.30}$$

In addition, from the Riemann–Lebesgue theorem, $\|((\tau+i\omega)I - \tilde{\mathcal{A}}_n)^{-1}x\| \to 0$. Combining (2.30) with (2.29) yields (2.23). Inequality (2.24) can be proved in the same way. □

LEMMA 2.5. *For any $x \in H_n$, $\omega \in R$ we have*

$$\|(i\omega I - \tilde{\mathcal{A}}_n)^{-1}x\| \le 2^m\|((-\sigma+i\omega)I - \tilde{\mathcal{A}}_n)^{-1}x\| \tag{2.31}$$

with m being an integer such that

$$m - 1 < -2M_0\sigma \le m. \tag{2.32}$$

Proof. Let

$$\tau_m = -\sigma, \quad \Delta\tau = \frac{1}{2M_0}, \quad \tau_i = \tau_m - (m-i)\,\Delta\tau, \qquad (i = m-1, \ldots, 0). \tag{2.33}$$

Then $\tau_0 \le 0$. Since

(2.34)
$$\|[I-(\tau_i-\tau)((\tau_i+\boldsymbol{i}\omega)I-\tilde{\mathcal{A}}_n)^{-1}]x\| \geq \|x\|-(\tau_i-\tau)\|((\tau_i+\boldsymbol{i}\omega)I-\tilde{\mathcal{A}}_n)^{-1}x\| \geq \|x\|-\Delta\tau\cdot M_0\cdot\|x\| \geq \tfrac{1}{2}\|x\| \quad \text{for } \tau\in[\tau_{i-1},\tau_i],$$

we have

$$\|[I-(\tau_i-\tau)((\tau_i+\boldsymbol{i}\omega)I-\tilde{\mathcal{A}}_n)^{-1}]^{-1}\| \leq 2. \tag{2.35}$$

For any fixed i, $(i=m,\dots,1)$ and any $\tau\in[\tau_{i-1},\tau_i]$, we obtain

(2.36)
$$\begin{aligned}\|((\tau+\boldsymbol{i}\omega)I-\tilde{\mathcal{A}}_n)^{-1}x\| &= \|[I-(\tau_i-\tau)((\tau_i+\boldsymbol{i}\omega)I-\tilde{\mathcal{A}}_n)^{-1}]^{-1}((\tau_i+\boldsymbol{i}\omega)I-\tilde{\mathcal{A}}_n)^{-1}x\|\\ &\leq \|[I-(\tau_i-\tau)((\tau_i+\boldsymbol{i}\omega)I-\tilde{\mathcal{A}}_n)^{-1}]^{-1}\|\\ &\quad\cdot\|((\tau_i+\boldsymbol{i}\omega)I-\tilde{\mathcal{A}}_n)^{-1}x\|\\ &\leq 2\|((\tau_i+\boldsymbol{i}\omega)I-\tilde{\mathcal{A}}_n)^{-1}x\|,\end{aligned}$$

which results in (2.31). □

COROLLARY 2.6. *We have*

$$\int_{-\infty}^{+\infty}\|(\boldsymbol{i}\omega I-\tilde{\mathcal{A}}_n)^{-1}x\|^2\,d\omega \leq cM_1^2\|x\|^2 \tag{2.37}$$

and

$$\int_{-\infty}^{+\infty}\|(-\boldsymbol{i}\omega I-\tilde{\mathcal{A}}_n^*)^{-1}x\|^2\,d\omega \leq cM_1^2\|x\|^2 \tag{2.38}$$

with a positive constant c depending only on σ.

We are now in position to prove (2.22). Let $\tau_0>\tau_1>-(\sigma/2)>0$. Then for $x\in\mathcal{D}(\tilde{\mathcal{A}}_n^2)$, $y\in H_n$, by the inverse formula [Pa, Cor. 7.5, p. 29] we have

$$\begin{aligned}(\tilde{T}_n(t)x,y) &= \frac{1}{2\pi\boldsymbol{i}}\lim_{\omega\to+\infty}\int_{\tau_1-\boldsymbol{i}\omega}^{\tau_1+\boldsymbol{i}\omega}e^{\lambda t}((\lambda I-\tilde{\mathcal{A}}_n)^{-1}x,y)\,d\lambda\\ &= \frac{1}{2\pi\boldsymbol{i}}\lim_{\omega\to+\infty}\left[\frac{e^{\lambda t}}{t}((\lambda I-\tilde{\mathcal{A}}_n)^{-1}x,y)\Big|_{\tau_1-\boldsymbol{i}\omega}^{\tau_1+\boldsymbol{i}\omega}\right.\\ &\quad\left.+\int_{\tau_1-\boldsymbol{i}\omega}^{\tau_1+\boldsymbol{i}\omega}\frac{e^{\lambda t}}{t}((\lambda I-\tilde{\mathcal{A}}_n)^{-2}x,y)\,d\lambda\right].\end{aligned} \tag{2.39}$$

From Lemma 2.4 we have that

$$(\tilde{T}_n(t)x,y) = \lim_{\omega\to+\infty}\frac{1}{2\pi\boldsymbol{i}}\int_{\tau_1-\boldsymbol{i}\omega}^{\tau_1+\boldsymbol{i}\omega}\frac{e^{\lambda t}}{t}((\lambda I-\tilde{\mathcal{A}}_n)^{-2}x,y)\,d\lambda. \tag{2.40}$$

Since $\sup_{n\in N}\{\text{Re }\lambda;\lambda\in\sigma(\tilde{\mathcal{A}}_n)\}<(\sigma/2)<0$, for $t>0$, $e^{\lambda t}/t((\lambda I-\tilde{\mathcal{A}}_n)^{-2}x,y)$ is analytic in the domain $\{\lambda;\text{Re }\lambda\in(\sigma/2,\tau_0)\}$. Let Γ_ω be the curve composed of $\Gamma_0=\{\text{Re }\lambda=\tau_1,-\omega\leq\text{ Im }\lambda\leq\omega\}$, $\Gamma_{1,2}=\{0\leq\text{ Re }\lambda\leq\tau_1,\text{ Im }\lambda=\pm\omega\}$, and $\Gamma_3=\{\text{Re }\lambda=0,-\omega\leq\text{ Im }\lambda\leq\omega\}$. From

$$\int_{\Gamma_\omega}\frac{e^{\lambda t}}{t}((\lambda I-\tilde{\mathcal{A}}_n)^{-2}x,y)\,d\lambda=0 \tag{2.41}$$

and, due to Lemma 2.4,

$$\lim_{\omega\to+\infty}\int_{\Gamma_{1,2}}\frac{e^{\lambda t}}{t}((\lambda I-\tilde{\mathcal{A}}_n)^{-2}x,y)\,d\lambda=0, \tag{2.42}$$

it follows that

$$\begin{aligned}(\tilde{T}_n(t)x,y) &= \frac{1}{2\pi i}\lim_{\omega\to+\infty}\int_{-i\omega}^{i\omega}\frac{e^{\lambda t}}{t}((\lambda I-\tilde{\mathcal{A}}_n)^{-2}x,y)\,d\lambda\\ &= \frac{1}{2\pi}\int_{-\infty}^{+\infty}\frac{e^{i\omega t}}{t}((i\omega I-\tilde{\mathcal{A}}_n)^{-2}x,y)\,d\omega.\end{aligned} \tag{2.43}$$

Therefore,

$$\begin{aligned}|(\tilde{T}_n(t)x,y)| &\le \frac{1}{2\pi}\int_{-\infty}^{+\infty}\frac{1}{t}\,\|(i\omega I-\tilde{\mathcal{A}}_n)^{-1}x\|\cdot\|(-i\omega I-\tilde{\mathcal{A}}_n^*)^{-1}y\|\,d\omega\\ &\le \frac{1}{2\pi t}\left(\int_{-\infty}^{+\infty}\|(i\omega I-\tilde{\mathcal{A}}_n)^{-1}x\|^2\,d\omega\right)^{1/2}\left(\int_{-\infty}^{+\infty}\|(-i\omega I-\tilde{\mathcal{A}}_n^*)^{-1}y\|^2\,d\omega\right)^{1/2}.\end{aligned} \tag{2.44}$$

Combining it with (2.37), (2.38) yields (2.22) for $x\in\mathcal{D}(\tilde{\mathcal{A}}_n^2)$, $y\in H_n$. Since $\mathcal{D}(\tilde{\mathcal{A}}_n^2)$ is dense in H_n, (2.22) also holds for any $x,y\in H_n$. By taking $y=\tilde{T}_n(t)x$, we conclude that for $t\ge 1$

$$\|\tilde{T}_n(t)\|\le\frac{cM_1^2}{2\pi}. \tag{2.45}$$

For $0\le t\le 1$, by (2.3) we have

$$\|\tilde{T}_n(t)\|=\|T_n(t)e^{-\frac{\sigma}{2}t}\|\le M_1e^{-\sigma/2}. \tag{2.46}$$

Therefore,

$$\|\tilde{T}_n(t)\|\le\max\left(\frac{cM_1^2}{2\pi},M_1e^{-\sigma/2}\right)\stackrel{\text{def}}{=}M\quad\forall t>0 \tag{2.47}$$

which results in

$$\|T_n(t)\|=\|\tilde{T}_n(t)e^{\frac{\sigma}{2}t}\|\le Me^{\frac{\sigma}{2}t},\qquad\sigma<0\quad\forall t>0. \tag{2.48}$$

Thus the proof of Theorem 2.1 is complete.

3. Approximations of the thermoelastic system. In this section we first present a general approximate scheme for thermoelastic system (1.4). Then we will use Corollary 2.3 to show the uniform exponential stability of a particular approximate scheme that is often referred to as the modal method. We also provide a convergence proof of this scheme.

Let

$$E_j=\begin{pmatrix}\phi_j\\0\\0\end{pmatrix},\quad E_{n+j}=\begin{pmatrix}0\\\psi_j\\0\end{pmatrix},\quad E_{2n+j}=\begin{pmatrix}0\\0\\\xi_j\end{pmatrix},\qquad j=1,\dots,n \tag{3.1}$$

be a basis for the finite-dimensional space $H_n=H_1^n(\Omega)\times H_2^n(\Omega)\times H_3^n(\Omega)\subset H_0^1(\Omega)\times H_0^1(\Omega)\times H_0^1(\Omega)\subset H=H_0^1(\Omega)\times L^2(\Omega)\times L^2(\Omega)$. The inner product on H_n is the one

induced by the H-product. For simplicity, we take $c^2 = 1$ in H-norm (1.9) without affecting the proof of our results. We consider the approximation to the solution of (1.4) of the form

$$z_n = \sum_{j=1}^{3n} \tilde{z}_j(t) E_j(x), \tag{3.2}$$

which is required to satisfy the following variational system:

$$(\dot{z}_n, E_j)_H = (\mathcal{A} z_n, E_j)_H, \qquad j = 1, \dots, 3n. \tag{3.3}$$

Then we have

$$\begin{aligned} M_n \dot{\tilde{z}}_n &= \begin{bmatrix} M_n^{(1)} & & \\ & M_n^{(2)} & \\ & & M_n^{(3)} \end{bmatrix} \begin{bmatrix} \dot{\tilde{z}}_n^{(1)} \\ \dot{\tilde{z}}_n^{(2)} \\ \dot{\tilde{z}}_n^{(3)} \end{bmatrix} \\ &= \begin{bmatrix} 0 & \tilde{D}_n^T & 0 \\ -\tilde{D}_n & 0 & -\gamma \tilde{F}_n \\ 0 & \gamma \tilde{F}_n^T & -G_n \end{bmatrix} \begin{bmatrix} \tilde{z}_n^{(1)} \\ \tilde{z}_n^{(2)} \\ \tilde{z}_n^{(3)} \end{bmatrix} = \tilde{A}_n \tilde{z}_n \end{aligned} \tag{3.4}$$

with

$$\begin{aligned} &\left(M_n^{(1)}\right)_{ij} = (D\phi_i, D\phi_j)_{L^2}, \quad \left(M_n^{(2)}\right)_{ij} = (\psi_i, \psi_j)_{L^2}, \quad \left(M_n^{(3)}\right)_{ij} = (\xi_i, \xi_j)_{L^2}, \\ &(\tilde{D}_n)_{ij} = (D\phi_i, D\psi_j)_{L^2}, \quad (\tilde{F}_n)_{ij} = (D\xi_i, \psi_j)_{L^2}, \quad (G_n)_{ij} = (D\xi_i, D\xi_j)_{L^2} \end{aligned} \tag{3.5}$$

and

$$\tilde{z}_n^{(i)} = (\tilde{z}_{(i-1)n+1}, \dots, \tilde{z}_{in})^T, \qquad i = 1, 2, 3. \tag{3.6}$$

By construction, the matrix $M_n^{(i)}$ is symmetric and positive definite. Therefore, there exists a lower triangle matrix $L_n^{(i)}$ such that $M_n^{(i)} = (L_n^{(i)})^T (L_n^{(i)})$. Let $L_n = \operatorname{diag}(L_n^{(1)}, L_n^{(2)}, L_n^{(3)})$ and denote $L_n \tilde{z}_n$ by $\bar{z}_n$. Then to obtain approximate solution z_n we are led to solving ordinary differential equations

$$\dot{\bar{z}}_n = A_n \bar{z}_n \tag{3.7}$$

with

$$A_n = \begin{bmatrix} 0 & (L_1^T)^{-1} \tilde{D}_n^T L_2^{-1} & 0 \\ -(L_2^T)^{-1} \tilde{D}_n L_1^{-1} & 0 & -\gamma (L_2^T)^{-1} \tilde{F}_n L_3^{-1} \\ 0 & \gamma (L_3^T)^{-1} \tilde{F}_n^T L_2^{-1} & -(L_3^T)^{-1} G_n L_3^{-1} \end{bmatrix}. \tag{3.8}$$

It is easy to see that

$$(A_n \bar{z}_n, \bar{z}_n)_{C^{3n}} = -\left(G_n L_3^{-1} \bar{z}_n^{(3)}, L_3^{-1} \bar{z}_n^{(3)}\right)_{C^n} \le 0 \tag{3.9}$$

provided that G_n is semipositive definite. In that case, A_n generates a C_0-semigroup $T_n(t)$ of contraction on H.

The modal approximation scheme is to choose the eigenvectors of the system as the basis vectors. Here, we will use the eigenvectors of the uncoupled thermoelastic system, i.e., $\gamma = 0$ in (1.4). Thus we still call it modal approximation. Let

$$\phi_j = \sqrt{\frac{2}{\pi}} \frac{1}{j} \sin jx, \quad \psi_j = \sqrt{\frac{2}{\pi}} \sin jx, \quad \xi_j = \sqrt{\frac{2}{\pi}} \sin jx, \qquad j = 1, \dots, n. \tag{3.10}$$

A straightforward calculation following (3.5) and (3.8) yields

$$A_n = \begin{bmatrix} 0 & D_n & 0 \\ -D_n & 0 & -\gamma F_n \\ 0 & \gamma F_n^T, & -D_n^2 \end{bmatrix} \tag{3.11}$$

with

$$D_n = \begin{bmatrix} 1 & & \\ & \ddots & \\ & & n \end{bmatrix}, \qquad F_{ij} = \begin{cases} -\dfrac{4}{\pi}\dfrac{ij}{i^2 - j^2}, & |i-j| = \text{odd}, \\ 0, & \text{otherwise}. \end{cases} \tag{3.12}$$

THEOREM 3.1. *The semigroups generated by A_n defined in* (3.11) *are uniformly exponentially stable, i.e., there exist positive constants M and α, independent of n, such that*

$$\|T_n(t)\|_{\mathcal{L}(H_n, H_n)} \leq Me^{-\alpha t}. \tag{3.13}$$

Proof. By Corollary 2.3 we need only to prove that (2.1) and (2.4) hold. This will be done by contradiction. We first point out that the real parts of the eigenvalues of the matrix A_n are strictly negative for every n.

(i) If (2.4) is not true, then there must exist a sequence of $\lambda_n \in C$ with $\mathrm{Re}\lambda_n \geq 0$, $\mathrm{Re}\lambda_n \to 0$ (as $n \to +\infty$), a sequence of $h_n \in C^{3n}$ with $\|h_n\|_{C^{3n}} = 1$, and a subsequence of A_n, still denoting by A_n such that

$$\|(\lambda_n I - A_n)h_n\|_{C^{3n}} \to 0. \tag{3.14}$$

The matrix

$$A_0^n = \begin{bmatrix} 0 & D_n \\ -D_n & 0 \end{bmatrix} \tag{3.15}$$

has eigenvalues

$$\pm \boldsymbol{i}j, \qquad j = 1, \ldots, n, \tag{3.16}$$

and corresponding eigenvectors

$$\mathcal{E}_j = \frac{1}{\sqrt{2}} \begin{pmatrix} e_j \\ \boldsymbol{i}e_j \end{pmatrix}, \quad \mathcal{E}_{-j} = \frac{1}{\sqrt{2}} \begin{pmatrix} e_j \\ -\boldsymbol{i}e_j \end{pmatrix}, \qquad j = 1, \ldots, n, \tag{3.17}$$

with e_j being the jth unit vector.

It follows from

$$\mathrm{Re}((\lambda_n I - A_n)h_n, h_n)_{C^{3n}} \to 0 \tag{3.18}$$

that

$$\mathrm{Re}\lambda_n + \|D_n h_n^{(3)}\|^2 \to 0. \tag{3.19}$$

Hereafter we denote by $\|\cdot\|$ the l^2 norm in C^n. Therefore, we have

$$\|h_n^{(3)}\| \leq \|D_n h_n^{(3)}\| \to 0. \tag{3.20}$$

Taking the first $2n$ rows of (3.14) into consideration gives

$$\left\| (\lambda_n I - A_0^n) \begin{pmatrix} h_n^{(1)} \\ h_n^{(2)} \end{pmatrix} + \begin{pmatrix} 0 \\ \gamma F_n h_n^{(3)} \end{pmatrix} \right\|_{C^{2n}} \to 0. \tag{3.21}$$

We now claim that

$$\|F_n h_n^{(3)}\| \to 0. \tag{3.22}$$

In fact,

$$\begin{aligned} \left(F_n h_n^{(3)}\right)_i &= \frac{2}{\pi} \left(D \sin ix, \sum_{j=1}^{n} (h_n^{(3)})_j \sin jx \right)_{L^2} \\ &= -\frac{2}{\pi} \left(\sin ix, \sum_{j=1}^{n} j \cos jx (h_n^{(3)})_j \right)_{L^2}. \end{aligned} \tag{3.23}$$

By Parsaval's inequality,

$$\|F_n h_n^{(3)}\|^2 \le \frac{2}{\pi} \left\| \sum_{j=1}^{n} j \cos jx (h_n^{(3)})_j \right\|_{L^2}^2 \le \sum_{j=1}^{n} j^2 |(h_n^{(3)})_j|^2 = \|D_n h_n^{(3)}\|^2. \tag{3.24}$$

Thus, (3.22) follows from (3.20). Moreover, we deduce from (3.21) that

$$\left\| (\lambda_n I - A_0^n) \begin{pmatrix} h_n^{(1)} \\ h_n^{(2)} \end{pmatrix} \right\|_{C^{2n}} \to 0. \tag{3.25}$$

Since the eigenvectors $\{\mathcal{E}_{\pm j}\}$ form a basis in C^{2n}, we have

$$\begin{pmatrix} h_n^{(1)} \\ h_n^{(2)} \end{pmatrix} = \sum_{j=-n, j\neq 0}^{n} \alpha_{nj} \mathcal{E}_j. \tag{3.26}$$

It follows from $\|h_n\|_{C^{3n}} = 1$ and $\|h_n^{(3)}\| \to 0$ that

$$\left\| \begin{pmatrix} h_n^{(1)} \\ h_n^{(2)} \end{pmatrix} \right\|_{C^{2n}}^2 = \sum_{j=-n, j\neq 0}^{n} |\alpha_{nj}|^2 \to 1. \tag{3.27}$$

Substituting (3.26) into (3.25), we obtain

$$\begin{aligned} \left\| (\lambda_n I - A_0^n) \begin{pmatrix} h_n^{(1)} \\ h_n^{(2)} \end{pmatrix} \right\|_{C^{2n}}^2 &= \left\| \sum_{j=-n, j\neq 0}^{n} (\lambda_n - \boldsymbol{i} j) \alpha_{nj} \mathcal{E}_j \right\|_{C^{2n}}^2 \\ &= \sum_{j=-n, j\neq 0}^{n} |\lambda_n - \boldsymbol{i} j|^2 |\alpha_{nj}|^2 \to 0, \quad \text{as } n \to +\infty. \end{aligned} \tag{3.28}$$

If for n large enough, $|\lambda_n - \boldsymbol{i} j| \ge \delta > 0$ for all j, then $\sum_{j=-n, j\neq 0}^{n} |\alpha_{n,j}|^2 \to 0$, a contradiction with (3.27). Thus we derive from (3.27) and (3.28) that there exists $j(n) \in \{\pm 1, \pm 2, \ldots, \pm n\}$

such that as $n \to +\infty$

$$\begin{aligned} \lambda_n - \boldsymbol{i}j(n) &\to 0, \\ \sum_{j=-n, j\neq 0, j(n)}^{n} |\alpha_{n,j}|^2 &\to 0, \\ |\alpha_{n,j(n)}| &\to 1, \end{aligned} \tag{3.29}$$

and

$$\left\| \begin{pmatrix} h_n^{(1)} \\ h_n^{(2)} \end{pmatrix} - \alpha_{n,j(n)} \mathcal{E}_{j(n)} \right\|_{C^{2n}} \to 0. \tag{3.30}$$

Taking the last n rows of (3.14) into consideration, we obtain

$$\|\lambda_n h_n^{(3)} + D_n^2 h_n^{(3)} - \gamma F_n^T h_n^{(2)}\| \to 0. \tag{3.31}$$

By (3.29), (3.31) and $j(n) \neq 0$, if we denote $h_n^{(3)}/j(n)$ by y_n, then

$$\|g_n\| \overset{\text{def}}{=} \left\| \boldsymbol{i}j(n)y_n + D_n^2 y_n - \boldsymbol{i}\frac{\gamma\alpha_{n,j(n)}}{\sqrt{2}|j(n)|} F_n^T e_{|j(n)|} \right\| \to 0. \tag{3.32}$$

Taking real part of the inner product of g_n with $D_n^2 y_n$ yields

$$\operatorname{Re}(g_n, D_n^2 y_n) = \|D_n^2 y_n\|^2 - \operatorname{Re}\left(\boldsymbol{i}\frac{\gamma\alpha_{n,j(n)}}{\sqrt{2}|j(n)|} F_n^T e_{|j(n)|}, D_n^2 y_n \right). \tag{3.33}$$

We now estimate the last term on the right hand side of (3.33). Indeed,

(3.34)

$$\begin{aligned} \operatorname{Re}\left(\frac{1}{|j(n)|} F_n^T e_{|j(n)|}, D_n^2 y_n \right) &= \frac{2}{\pi j(n)} \operatorname{Re} \sum_{i=1}^{n} \int_0^\pi -(D \sin ix) \sin j(n)x dx \cdot \overline{i^2 (y_n)_i} \\ &= \frac{2}{\pi} \operatorname{Re} \sum_{i=1}^{n} i \int_0^\pi \sin ix \cos j(n)x dx \cdot \overline{i(y_n)_i} \\ &= -\frac{2}{\pi} \operatorname{Re} \sum_{i=1}^{n} \int_0^\pi \cos ix \sin j(n)x dx \cdot \overline{i(h_n^{(3)})_i} \\ &\quad + \frac{2}{\pi} \operatorname{Re} \sum_{i=1}^{n} (\cos ix \cos j(n)x) \Big|_0^\pi \cdot \frac{1}{j(n)} \overline{i(h_n^{(3)})_i}. \end{aligned}$$

Therefore,

$$\begin{aligned} I &\equiv \left| \operatorname{Re}\left(\boldsymbol{i}\frac{\gamma\alpha_{n,j(n)}}{\sqrt{2}|j(n)|} F_n^T e_{|j(n)|}, D_n^2 y_n \right) \right| \\ &\leq \frac{\gamma|\alpha_{n,j(n)}|}{\sqrt{\pi}} (\|\sin j(n)x\|_{L^2} \|D_n h_n^{(3)}\| + 2\|Dz_n\|_{L^\infty}) \\ &= \frac{\gamma|\alpha_{n,j(n)}|}{\sqrt{\pi}} \left(\frac{\pi}{2} \|D_n h_n^{(3)}\| + 2\|Dz_n\|_{L^\infty} \right), \end{aligned} \tag{3.35}$$

where

$$z_n = \sqrt{\frac{2}{\pi}} \sum_{i=1}^{n} (y_n)_i \sin ix. \tag{3.36}$$

By the well-known Nirenberg inequality, we have

$$\begin{aligned} \|Dz_n\|_{L^\infty} &\le c_1 \|D^2 z_n\|_{L^2}^{1/2} \|Dz_n\|_{L^2}^{1/2} + c_2 \|Dz_n\|_{L^2} \\ &= c_1 \|D_n^2 z_n\|^{1/2} \|D_n z_n\|^{1/2} + c_2 \|D_n z_n\| \end{aligned} \tag{3.37}$$

with c_1, c_2 being positive constants independent of z_n.

Combining (3.35) with (3.37) and applying Young's inequality yields

$$I \le \frac{\gamma |\alpha_{n,j(n)}|}{\sqrt{\pi}} \left(\frac{\pi}{2} \|D_n h_n^{(3)}\| + 2c_2 \|D_n y_n\| \right) + \frac{1}{4} \|D_n^2 y_n\| + c_3 \|D_n y_n\|^{2/3}. \tag{3.38}$$

On the other hand,

$$|\mathrm{Re}(g_n, D_n^2 y_n)| \le \frac{1}{2} \|g_n\|^2 + \frac{1}{2} \|D_n^2 y_n\|^2. \tag{3.39}$$

Thus combining (3.38), (3.39) with (3.33), we obtain

$$\|D_n^2 y_n\| \to 0. \tag{3.40}$$

Let w_n be the unique solution to the equation

$$\boldsymbol{i} j(n) w_n + D_n^2 w_n - \boldsymbol{i} \frac{\gamma \alpha_{n,j(n)}}{\sqrt{2}|j(n)|} F_n^T e_{|j(n)|} = 0. \tag{3.41}$$

Then

$$(w_n)_i = \begin{cases} \dfrac{-\mathrm{sign}(j(n)) \boldsymbol{i} 2\sqrt{2} \gamma \alpha_{n,j(n)} i}{\pi(\boldsymbol{i} j(n) + i^2)(i^2 - j^2(n))}, & |i - j(n)| = \text{odd}, \\ 0, & \text{otherwise}. \end{cases} \tag{3.42}$$

From (3.32) and (3.41), we obtain

$$\|\boldsymbol{i} j(n)(y_n - w_n) + D_n^2 (y_n - w_n)\| \to 0, \tag{3.43}$$

which results in, in a similar way as before,

$$\|D_n^2 (y_n - w_n)\| \to 0. \tag{3.44}$$

It follows immediately from (3.40), (3.44) that

$$\|D_n^2 w_n\| \to 0. \tag{3.45}$$

On the other hand, since $|\alpha_{n,j(n)}| \to 1$, as $n \to \infty$, we obtain for n large enough

$$\begin{aligned} \|D_n^2 w_n\|^2 &= \sum_{i=1, |i-j(n)|=\text{odd}}^{n} \frac{8\gamma^2 |\alpha_{n,j(n)}|^2 i^6}{\pi^2 (j^2(n) + i^4)(i^2 - j^2(n))^2} \\ &\ge \begin{cases} \dfrac{2\gamma^2 |\alpha_{n,j(n)}|^2 (|j(n)| + 1)^6}{\pi^2 ((|j(n)| + 1)^4 + j^2(n))(2|j(n)| + 1)^2}, & |j(n)| < n \\ \dfrac{2\gamma^2 |\alpha_{n,j(n)}|^2 (n-1)^6}{\pi^2 ((n-1)^4 + n^2)(2n-1)^2}, & |j(n)| = n \end{cases} \\ &\ge \delta > 0 \end{aligned} \tag{3.46}$$

with δ being a constant independent of $n, j(n)$. Thus, we have a contradiction.

(ii) If (2.1) is not true, then there must exist a sequence of $\lambda_n \in C$ with $\lambda_n \in \sigma(A_n)$, $\operatorname{Re} \lambda_n \to 0$, a sequence of $h_n \in \mathcal{D}(A_n)$ with $\|h_n\|_{C^{3n}} = 1$ and a subsequence of A_n, still denoting by A_n, such that

$$(\lambda_n I - A_n)h_n = 0. \tag{3.47}$$

Taking real part of the inner product of (3.47) with h_n, we obtain

$$\operatorname{Re} \lambda_n + \|D_n h_n^{(3)}\|^2 = 0, \tag{3.48}$$

which also results in (3.20). Taking the first $2n$ rows of (3.47) into consideration, we again obtain (3.25). Repeating the same argument as before leads to a contradiction again. Thus the proof of Theorem 3.1 is complete. □

Remark 3.1. For the cases of Dirichlet–Neumann and Neumann–Dirichlet boundary conditions, we can show that the approximate semigroups by the modal method are also uniformly exponentially stable. For example, if u satisfies the Dirichlet boundary condition and θ satisfies the Neumann boundary condition, then $\int_0^\pi \theta(x,t)\,dx = \int_0^\pi \theta_0(x)\,dx$, which is derived by integrating (1.2) with respect to x and t, where $\theta_0(t)$ is the initial temperature distribution of the rod.

After changing to the new dependent variable

$$\bar{\theta} = \theta - \frac{1}{\pi}\int_0^\pi \theta_0(x)\,dx, \tag{3.49}$$

we can choose the state space $H = \{(y_1, y_2, y_3) \in H_0 \times L^2 \times L^2 | \int_0^\pi y_3\,dx = 0\}$, choose ϕ_j, ψ_j as before and ξ_j to be $\sqrt{2/\pi}\cos jx$. In this case, the matrix D_n is the same as (3.12). Moreover, the matrix $F_n = -D_n$. Therefore, the proof of $\|D_n^2 y_n\| \to 0$ and $\|D_n^2 w_n\| \to 0$ can be even more easily carried out. Accordingly, we have

$$(w_n)_i = \frac{-\operatorname{sign}(j(n))\gamma\alpha_{n,j(n)}}{\sqrt{2}(i^2 + ij(n))} \tag{3.50}$$

and

$$\begin{aligned} \|D_n^2 w_n\|^2 &= \sum_{i=1}^{n} \frac{\gamma^2 |\alpha_{n,j(n)}|^2 i^4}{2(i^4 + j^2(n))} \\ &\geq \frac{\gamma^2 |\alpha_{n,j(n)}|^2 j^4(n)}{2(j^4(n) + j^2(n))} \geq \delta > 0. \end{aligned} \tag{3.51}$$

The strong convergence of the approximating semigroups $T_n(t)$ to $T(t)$ and $T_n^*(t)$ to $T^*(t)$ is another important issue for the approximation of LQG problems (see [GRT, Hypoths. 4.3, 4.4]). Let P_n be the orthogonal projection from H to H_n. Then the matrix A_n in (3.11) is the matrix representation of the operator $\mathcal{A}_n = P_n \mathcal{A} P_n$. Let

$$\mathcal{D} = \mathcal{D}(\mathcal{A}) \cap (H^4 \times H^3 \times H^4). \tag{3.52}$$

It is easy to see that $\mathcal{D}$ is dense in H. Since $(I - \mathcal{A})\mathcal{D}(\mathcal{A}) = H$, we also know that $(I - \mathcal{A})\mathcal{D}$ is dense in H. With the dissipativeness of $\mathcal{A}$ and $\mathcal{A}_n$, by the Trotter–Kato theorem (see [P, Thm. 4.5]), we only need to show $\mathcal{A}_n z \to \mathcal{A} z$ in H for all $z \in \mathcal{D}$ for the strong convergence of the approximation semigroups $T_n(t)$ to $T(t)$.

THEOREM 3.2. *$T_n(t), T_n^*(t) \xrightarrow{s} T(t), T^*(t)$ in H, respectively. Moreover, the convergence is uniform in bounded t-intervals.*

Proof. Let $z \in \mathcal{D}$. Then

$$z = \sum_{j=1}^{\infty} \left[a_j \begin{pmatrix} \frac{1}{j} \sin jx \\ 0 \\ 0 \end{pmatrix} + b_j \begin{pmatrix} 0 \\ \sin jx \\ 0 \end{pmatrix} + c_j \begin{pmatrix} 0 \\ 0 \\ \sin jx \end{pmatrix} \right] \tag{3.53}$$

with $\{a_j j^3, b_j j^3, c_j j^4\}_1^{\infty}$ being l^2 sequences. Furthermore, we have

$$\mathcal{A}z = \begin{pmatrix} \sum_{i=1}^{\infty} b_i \sin ix \\ \sum_{i=1}^{\infty} \left(-a_i i - \gamma \sum_{j=1}^{\infty} c_j j f_{ij} \right) \sin ix \\ \sum_{i=1}^{\infty} \left(-\gamma \sum_{j=1}^{\infty} b_j j f_{ij} - c_i i^2 \right) \sin ix \end{pmatrix}, \tag{3.54}$$

and

$$\mathcal{A}_n z = \begin{pmatrix} \sum_{i=1}^{n} b_i \sin ix \\ \sum_{i=1}^{n} \left(-a_i i - \gamma \sum_{j=1}^{n} c_j j f_{ij} \right) \sin ix \\ \sum_{i=1}^{n} \left(-\gamma \sum_{j=1}^{n} b_j j f_{ij} - c_i i^2 \right) \sin ix \end{pmatrix}, \tag{3.55}$$

where $f_{ij} = 2/\pi \langle \cos jx, \sin ix \rangle_{L^2}$. Now $\mathcal{A}z - \mathcal{A}_n z$ can be written as

$$\begin{pmatrix} \sum_{i=n+1}^{\infty} b_i \sin ix \\ \sum_{i=n+1}^{\infty} \left(-a_i i - \gamma \sum_{j=1}^{\infty} c_j j f_{ij} \right) \sin ix \\ \sum_{i=n+1}^{\infty} \left(-\gamma \sum_{j=1}^{\infty} b_j j f_{ij} - c_i i^2 \right) \sin ix \end{pmatrix} - \begin{pmatrix} 0 \\ \gamma \sum_{i=1}^{n} \left(\sum_{j=n+1}^{\infty} c_j j f_{ij} \right) \sin ix \\ \gamma \sum_{i=1}^{n} \left(\sum_{j=n+1}^{\infty} b_j j f_{ij} \right) \sin ix \end{pmatrix} = I + II. \tag{3.56}$$

It follows from $\mathcal{A}z \in H$ that $\|I\|_H \to 0$ as $n \to 0$. The second entry of II can be estimated as follows:

(3.57)

$$\begin{aligned}\left\| \sum_{i=1}^{n} \left(\sum_{j=n+1}^{\infty} c_j j f_{ij} \right) \sin ix \right\|^2 &= \sum_{i=1}^{n} \left(\sum_{j=n+1}^{\infty} c_j j f_{ij} \right)^2 \\ &\le \sum_{i=1}^{n} \left(\sum_{j=n+1}^{\infty} |c_j|^{2\alpha} j^2 \sum_{j=n+1}^{\infty} |c_j|^{2-2\alpha} |f_{ij}|^2 \right) \\ &\le \left(\sum_{j=n+1}^{\infty} |c_j|^{2\alpha} j^2 \right) \left(\sum_{j=n+1}^{\infty} |c_j|^{2-2\alpha} \sum_{i=1}^{\infty} |f_{ij}|^2 \right) \\ &= \frac{\pi}{2} \left(\sum_{j=n+1}^{\infty} |c_j|^{2\alpha} j^2 \right) \left(\sum_{j=n+1}^{\infty} |c_j|^{2-2\alpha} \right).\end{aligned}$$

Since $\sum_{j=n+1}^{\infty} |c_j|^2 j^6$ is a convergent series, then $\sum_{j=1}^{\infty} |c_j|^{2\alpha} j^2$ and $\sum_{j=n+1}^{\infty} |c_j|^{2-2\alpha}$ are also convergent as long as $\frac{5}{6} > \alpha > \frac{1}{2}$. Therefore, by (3.57), we obtain

$$\left\| \sum_{i=1}^{n} \left(\sum_{j=n+1}^{\infty} c_j j f_{ij} \right) \sin ix \right\|^2 \to 0. \tag{3.58}$$

Similarly, we can obtain

$$\left\| \sum_{i=1}^{n} \left(\sum_{j=n+1}^{\infty} b_j j f_{ij} \right) \sin ix \right\| \to 0. \tag{3.59}$$

Thus, we have proved

$$\lim_{n\to\infty} \|\mathcal{A}z - \mathcal{A}_n z\|_H = 0, \qquad \forall\, z \in \mathcal{D}. \tag{3.60}$$

The convergence of approximate adjoint semigroups can be verified in a similar way since $\mathcal{A}$ and $\mathcal{A}^*$ only differ by the sign in front of the coupling coefficient γ (see [H]). □

Remark 3.2. For the cases of Dirichlet–Neumann and Neumann–Dirichlet boundary conditions, the convergence of $T_n(t)$ and $T_n^*(t)$ is obvious from the above analysis since there is no need to expand cos jx in terms of sin ix in (3.54) and (3.55).

4. Numerical studies. As has been demonstrated in §§2 and 3, preserving uniform exponential stability for the general approximation scheme of thermoelastic system (1.4) can be a complicated problem, due to the structure of the matrix A_n defined in (3.8). On the other hand, for any given approximation scheme, we can compute the eigenvalues of A_n to observe the trends in their location. If the eigenvalues are approaching the imaginary axis, then the uniform exponential stability is unlikely to be preserved. In other words, condition (2.1) will be violated.

In this section, we present three approximation schemes to system (1.4). For each of them, the matrix A_n is constructed and its eigenvalues are computed. In all the following examples, we take $\gamma = 0.1$. Since the real eigenvalues of the matrix A_n are much smaller than the real part of the complex eigenvalues, it is enough to observe the complex one only.

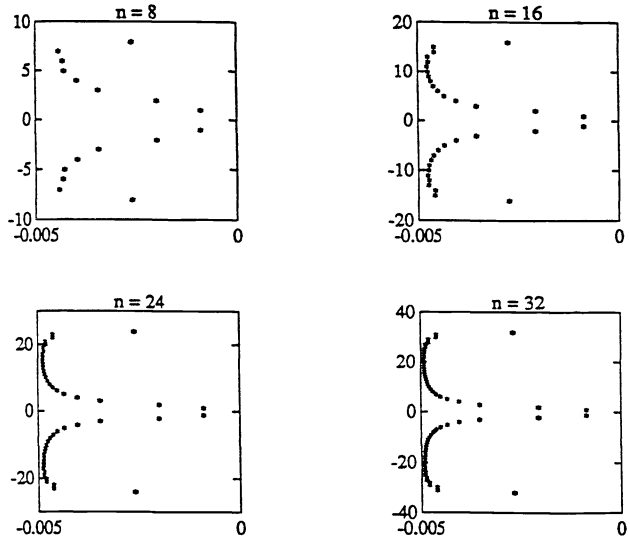

FIG. 4.1. *Location of the complex eigenvalues of the matrix A_n for the modal method in the case of Dirichlet–Dirichlet boundary conditions.*

TABLE 4.1

Distance between $\sigma(A_n)$ and the imaginary axis for the modal method in the case of Dirichlet–Dirichlet boundary conditions.

n	$\min\{-\mathrm{Re}\,\lambda,\ \lambda \in \sigma(A_n)\}$
8	8.9227×10^{-4}
16	8.9383×10^{-4}
24	8.9402×10^{-4}
32	8.9407×10^{-4}

4.1. Modal method. The modal method presented in §3 is implemented. The location of the eigenvalues is shown in Fig. 4.1. We can see that a uniform distance between the eigenvalues and the imaginary axis is preserved, which is consistent with (2.1). In Table 4.1, these distances for $n = 8, 16, 24, 32$ are reported. Comparing the results for the wave equation with boundary damping [BIW], we know that the damping due to heat conduction is much weaker. Another observation is that for fixed n, the eigenvalues of higher frequency modes, in particular, the one of the nth mode, are closer to the imaginary axis. However, as the number of modes increases, these eigenvalues bend back towards the vertical line $\lambda = -\gamma^2/2$. Hansen [H] has proved that, in the cases of Dirichlet–Neumann and Neumann–Dirichlet boundary conditions, the real part of the eigenvalues tend to $-\gamma^2/2$ asymptotically. The corresponding modal approximation scheme mentioned in Remark 3.1 preserves this property as shown in Fig. 4.2. It seems from Fig. 4.1 that in the case of Dirichlet–Dirichlet boundary conditions, the eigenvalues have the same asymptotic behavior. We list them in Table 4.2 for certain modes with $n = 24, 32, 64$, which clearly suggests a fast convergence.

4.2. Finite element method. The classical finite element method is to divide the domain $\Omega = [0, \pi]$ into subintervals, usually in equal length, and use spline functions for the approximation. Here, we choose ϕ_j, ψ_j, and ξ_j to be the normalization of the linear spline functions

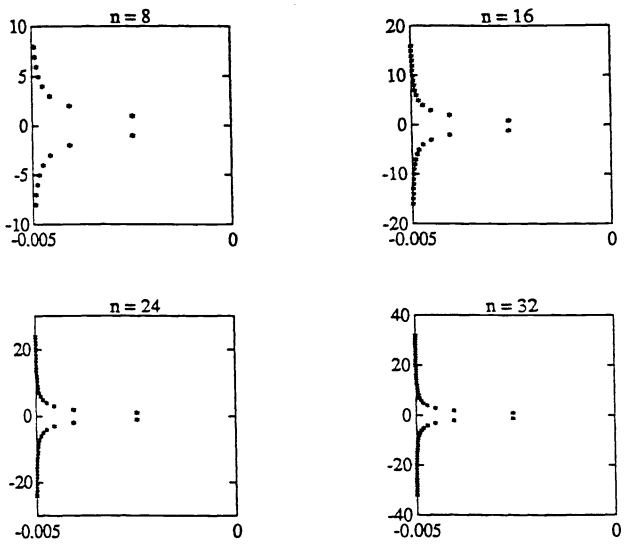

FIG. 4.2. *Location of the complex eigenvalues of the matrix A_n for the modal method in the case of Dirichlet–Neumann boundary conditions.*

22	$-4.5899 \times 10^{-3} + i22.000$	$-4.9003 \times 10^{-3} + i22.000$	$-4.9396 \times 10^{-3} + i22.000$
23	$-4.5960 \times 10^{-3} + i23.000$	$-4.9033 \times 10^{-3} + i23.000$	$-4.9435 \times 10^{-3} + i23.000$
24	$-2.6492 \times 10^{-3} + i24.000$	$-4.8881 \times 10^{-3} + i24.000$	$-4.9466 \times 10^{-3} + i24.000$

$$(4.1)\quad h_j(x) = \begin{cases} 1 - \dfrac{1}{\Delta}|x - j\Delta|, & x \in [(j-1)\Delta, (j+1)\Delta], \\ 0, & \text{otherwise}, \end{cases} \qquad j = 1, \ldots, n-1,$$

with $\Delta = \frac{\pi}{n}$.

It was pointed out in [BLM] that the eigenvalues of the matrix A_n derived from this approximation scheme approach the imaginary axis as n increases. Thus the uniform exponential stability is unlikely to be preserved. The location of the eigenvalues are shown in Fig. 4.3. The difference between Figs. 4.1 and 4.3 is due to the slow convergence of the linear spline approximation. For large n, the eigenvalues of the lower frequency modes do move toward the corresponding locations in Fig. 4.1. We also tested for the cubic spline approximation. For $n = 32$, the eigenvalues of the lower frequency modes are virtually the same as in Fig. 4.1, but the higher frequency one again approaches the imaginary axis. We include this method here to compare with the mixed finite element method, which will be presented in what follows.

4.3. Mixed finite element method. In the most common implementation of the finite element method for thermoelastic system (1.4), the approximation spaces H_1^n and H_2^n are

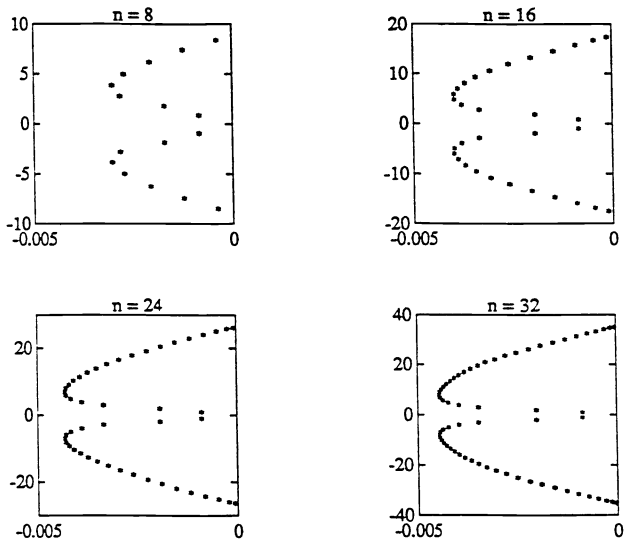

FIG. 4.3. *Location of the complex eigenvalues of the matrix A_n for the finite element method in the case of Dirichlet–Dirichlet boundary conditions.*

often chosen to be identical. However, this neglects the fact that u and v have different smoothness in spacial variable x. A general approximation scheme, called the mixed finite element method, was proposed by Ito and Kappel [IK] using different approximation spaces H_1^n and H_2^n. It was applied to the weakly damped wave equation [BIW], and was proved to be able to preserve the uniform exponential stability for the one-dimensional case. To apply this method here, we choose ψ_j to be the normalization of the piecewise constant function

$$f_j(x) = \begin{cases} 1, & x \in [(j-1)\Delta, (j+1)\Delta], \\ 0, & \text{otherwise}, \end{cases} \qquad j = 1, \dots, n-1 \tag{4.2}$$

with $\Delta = \pi/n$, and choose ϕ_j and ξ_j the same as in the above finite element method.

From (3.2), the three components of the approximate solution z_n are

$$z_n^{(1)} = \sum_{j=1}^{n-1} \tilde{z}_j \phi_j, \quad z_n^{(2)} = \sum_{j=1}^{n-1} \tilde{z}_{n-1+j} \psi_j, \quad z_n^{(3)} = \sum_{j=1}^{n-1} \tilde{z}_{2n-2+j} \xi_j. \tag{4.3}$$

They are required to satisfy the following variational system, which is analogous to (3.4):

$$(\dot{z}_n^{(1)}, \phi_j)_{H_0^1} = (q_n(z_n^{(2)}), \phi_j)_{H_0^1}, \tag{4.4}$$

$$(\dot{z}_n^{(2)}, \psi_j)_{L^2} = -(z_n^{(1)}, q_n(\psi_j))_{H_0^1} - \gamma(D_x z_n^{(3)}, p_n(\psi_j))_{L^2}, \tag{4.5}$$

$$(\dot{z}_n^{(3)}, \xi_j)_{L^2} = -\gamma(D_x p_n(z_n^{(2)}), \xi_j)_{L^2} - (z_n^{(3)}, \xi_j)_{H_0^1}, \tag{4.6}$$

where the mapping $q_n : H_2^n \to H_1^n$ is given by $q_n(\psi_j) = \phi_j$, and $p_n : H_2^n \to H_3^n$ is given by $p_n(\psi_j) = \xi_i$ for $j = 1, \dots, n-1$.

Then we have system (3.4), (3.5) again except that at this time

$$(D_n)_{ij} = (D_x \phi_i, D_x \phi_j)_{L^2}, \qquad (F_n)_{ij} = (D_x \xi_i, \xi_j)_{L^2}. \tag{4.7}$$

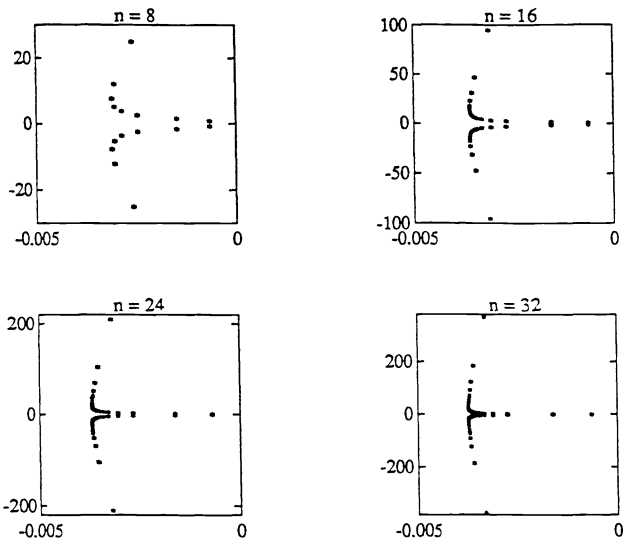

FIG. 4.4. *Location of the complex eigenvalues of the matrix A_n for the mixed finite element method in the case of Dirichlet–Dirichlet boundary conditions.*

We point out here that the only difference between the approximate system (3.4) for the finite element method and the mixed finite element method used in this section is the minor diagonal elements of matrix $M_n^{(2)}$. More precisely,

$$M^{(2)}_{n(\text{finite element})} = \begin{bmatrix} 1 & \frac{1}{4} & & & \\ \frac{1}{4} & 1 & \ddots & & \\ & \ddots & \ddots & & \\ & & \ddots & 1 & \frac{1}{4} \\ & & & \frac{1}{4} & 1 \end{bmatrix}, \tag{4.8}$$

and

$$M^{(2)}_{n(\text{mixed finite element})} = \begin{bmatrix} 1 & \frac{1}{2} & & & \\ \frac{1}{2} & 1 & \ddots & & \\ & \ddots & \ddots & & \\ & & \ddots & 1 & \frac{1}{2} \\ & & & \frac{1}{2} & 1 \end{bmatrix}. \tag{4.9}$$

However, this difference dramatically changes the location of the eigenvalues that are shown in Fig. 4.4. We can see that a uniform distance between the eigenvalues and imaginary axis is maintained. Thus this approximation scheme might be uniform exponentially stable. We tried to use the same contradiction argument as we did in §3 to prove it, but this question still remains open. The obvious disadvantage of this approximation scheme is the slow convergence.

Comparing Figs. 4.1, 4.3, and 4.4, we observe a common phenomenon. The eigenvalues of A_n converge to the eigenvalues of $\mathcal{A}$ in such a fashion that the lower frequency ones are

always more accurate than the higher frequency ones for each n. Among the three approximation schemes, the modal method is most favorable since it not only preserves the exponential stability uniformly, but also provides a rather fast convergence.

THE ASYMPTOTIC BEHAVIOR OF SIMULATED ANNEALING PROCESSES WITH ABSORPTION*

TZUU-SHUH CHIANG† AND YUNSHYONG CHOW†

Abstract. For a large class (satisfying a Perron–Frobenius property) of simulated annealing processes with an absorbing state a and arbitrary cost function, it is shown that there exist constants $h(i) \geq 0$, $\beta_{ij} > 0$ and $\delta > 0$, $N \geq 0$, independent of the starting points such that, for nonabsorbing states i and j,

$$\lim_{t\to\infty} \{P(X_t = i)\lambda^{h(j)}(t)\}/\{P(X_t = j)\lambda^{h(i)}(t)\} = \beta_{ij} \quad \text{and}$$

$$P(X_t \neq a) = \exp\left[-\int_0^t \delta\lambda^N(s) + O(\lambda^{N+1}(s))ds\right] \quad \text{for } t \text{ large.}$$

Here, $\lambda(t) = \exp(-1/T(t))$, $T(t) \to 0$, is the temperature function. As an application, the asymptotic behavior of the expected time of hitting a state (in particular, a global minimum) of a simulated annealing process without absorbing states can be determined.

0. Introduction.

For a finite set $S = \{1, 2, \ldots, n\}$, consider an inhomogeneous Markov process X_t on S with transition rates of the following type:

$$q_{ij}(t) = \begin{cases} p_{ij}\lambda(t)^{U(i,j)} & \text{for } j \neq i, \\ -\sum_{k\neq i} q_{ik}(t) & \text{for } j = i, \end{cases} \tag{0.0}$$

where $\lambda(t) = \exp(-1/T(t))$, $T(t) \to 0$, is a suitable temperature function, $P = (p_{ij})_{i,j\in S}$ is the neighborhood choosing-matrix with nonnegative entries, and $U : S \times S \to [0, \infty]$ is a cost function. We assume that $p_{ij} = 0$ if and only if $U(i, j) = \infty$. Processes of this type arise naturally in combinatorial optimization problems and are generally referred to as simulated annealing processes with cost U. Readers are referred to [3], [7], [8] for more details regarding the motivations, their physical meanings, and applications. If there is no absorbing state and (p_{ij}) forms an irreducible matrix, we call it a *regular simulated annealing process*. If there is a nontrivial absorbing state $a \in S$, that is, $p_{aj} = 0$ for all $j \neq a$ and $p_{ja} > 0$ for some $j \neq a$, and $(p_{jk})_{j,k\neq a}$ is irreducible, we call it a *singular simulated annealing process*. For the special case where $U(i, j) = (U(j) - U(i))^+$, a regular simulated annealing process has been used in practice to find the global minima of U [3], [7], [8]. Under some mild conditions on $\lambda(t)$ (sometimes necessary), it is proved in [1] that there exist constants $\beta_i > 0$ such that, with $d(i) = U(i) - \min U$,

$$\lim_{t\to\infty} P(X_t = i)/\lambda(t)^{d(i)} = \beta_i, \quad \forall i \in S, \tag{0.1}$$

independent of the starting points. The method used in [1] was to consider the following forward equation associated with X_t:

$$\vec{F}'(t) = Q^T(t) \cdot \vec{F}(t), \tag{0.2}$$

* Received by the editors May 31, 1989; accepted for publication (in revised form) April 1, 1993. This research was partially supported by the National Science Council of the Republic of China.

† Institute of Mathematics, Academia Sinica, Taipei, Taiwan 11529.

where $Q(t) = (q_{ij}(t))$ is as in (0.0), $\vec{F}(t) = (F_i(t);\ i \in S)^T$, and $F_i(t) = P(X_t = i)$. Thus with probability close to 1, the process will concentrate on the global minima set for large time [4], [5] and (0.1) gives the exact convergence rate. Similar results hold for regular simulated annealing processes with general cost functions ([2], [6], [10]), and a complicated cycle method was used to describe its "global minima" set, which is denoted as $\underline{S}$. Thus one of the important questions that remains to be answered is the expected time of hitting a global minimum. Let τ be the first hitting time of $\underline{S}$ and $F_i(t) = P(X_t = i,\ \tau > t)$. Then

$$E\tau = \int_0^\infty P(\tau > t)dt = \int_0^\infty \sum_{i \notin \underline{S}} F_i(t)dt, \tag{0.3}$$

and an easy calculation shows that $\{F_i(t)\}$ satisfies the following differential equations:

$$F_i'(t) = \sum_{j \notin \underline{S}} q_{ji}(t)F_j(t), \quad \forall\, i \notin \underline{S}. \tag{0.4}$$

Note that (0.4) is the forward equation associated with the singular-simulated annealing process Y_t, where X_t and Y_t have the same transitions except on $\underline{S}$, which is taken to be the absorbing state for Y_t. This motivates us to study the asymptotic behavior of singular cases. The cycle method mentioned above for treating regular processes cannot be directly applied here for (0.4) because there will eventually be no cycle in a singular system. A new condition (0.12) will be developed later to suit our purposes. To precisely describe the results, we first introduce some notations and definitions.

Let S, U be, as above, the state space and the nonnegative cost function on $S \times S$, respectively. We assume that U is *integer-valued*. It should be apparent from the discussion that this is only for technical reasons. In the singular case, which is the main concern in this paper, there is a (unique) absorbing state $a \in S$ such that $U(a, i) = \infty$ for any $i \neq a$ and $U(i, a) < \infty$ for some $i \neq a$. For any two states $i,\ j \in S$, a path connecting i to j is a sequence $i = i_0, i_1, \ldots, i_{k+1} = j$ such that $U(i_r, i_{r+1}) < \infty$ for $0 \leq r \leq k$. We say that $i \geq j$ (relative to U) if there exists a path $i = i_0, i_1, \ldots, i_{k+1} = j$ connecting i to j such that $U(i_r, i_{r+1}) = \min_{i_r \neq z \in S} U(i_r, z) < \infty$ for each $0 \leq r \leq k$. Thus $i \geq j$ if and only if there is a path connecting i to j such that all the costs in the intermediate steps are minimal. We say that $i \geq j$ at level h if, in addition to the above, $U(i_r, i_{r+1}) \leq h$ for all $0 \leq r \leq k$. A state i is said to be minimal if no state j can satisfy $i \geq j$ unless $j \geq i$. Two states i and j are equivalent (at level h), in notation $i \sim j (i \overset{h}{\sim} j)$, if $i \geq j$ (at level h) and $j \geq i$ (at level h). An hth order cycle is defined to be an equivalence class of minimal states under the relation "$\overset{h}{\sim}$." (We assume $i \overset{h}{\sim} i$ for any $i \in S$.) We remark that the absorbing state is only equivalent to itself for any equivalence relation described above. We define a hierarchy of states in S. First, let $(S^0, U^0) = (S, U)$ and $V^0(i) = V(i) = \min_{i \neq j \in S} U(i, j)$ for $i \in S$. Having defined (S^{n-1}, U^{n-1}) and V^{n-1}, let $S^n = \{c^n : c^n$ is an $(n-1)$th order cycle of $(S^{n-1}, U^{n-1})\}$ and define

$$d_{n-1}(c^n) = \max_{c^{n-1} \in c^n} V^{n-1}(c^{n-1}) \quad \text{as the "depth" of } c^n, \tag{0.5}$$

$$U^n(c^n, \tilde{c}^n) = d_{n-1}(c^n) + \min_{\substack{c^{n-1} \in c^n \\ \tilde{c}^{n-1} \in \tilde{c}^n}} \{U^{n-1}(c^{n-1}, \tilde{c}^{n-1}) - V^{n-1}(c^{n-1})\}, \tag{0.6}$$

$$V^n(c^n) = \min_{\tilde{c}^n \neq c^n} U^n(c^n, \tilde{c}^n), \tag{0.7}$$

$$h^n(c^n) = d_n(c^{n+1}) - V^n(c^n). \tag{0.8}$$

The new cost functions U^n appeared in combinatories in solving the minimal spanning tree problem, and the quantity $V^n(c^n)$ is simply the minimal cost coming out of c^n. The symbols c^n, $\tilde{c}^n$ are usually reserved for cycles in S^n. A cycle $c^n \in S^n$ is called nontrivial if c^n consists of more than one state in S^{n-1}. In that case $d_{n-1}(c^n) = n - 1$ and $V^n(c^n) \geq n$ by (0.5) and (0.7). A pair (S^n, U^n) is called indecomposable if no more nontrivial nth order cycle can be formed in S^{n+1} and $V^n(c^n) \leq n$ for every $c^n \in S^n$. If there is no absorbing state, then the sequence (S^0, U^0), $(S^1, U^1), \ldots, (S^n U^n) \cdots$ will eventually become trivial in the sense that S^{N+1} is a singleton from some N on. This case has been studied extensively in many papers ([1]–[8]). Because we are particularly interested in singular simulated annealing processes, the procedure of forming new pairs (S^n, U^n) generally becomes impossible at certain point N and we end up with an indecomposable pair (S^N, U^N), where S^N has more than one state and no more cycles can be formed.

For the first N such that (S^N, U^N) is indecomposable, we impose the following conditions on $\lambda(t)$:

$$\lambda(t) \to 0 \quad \text{and} \quad \lambda'(t)/\lambda(t) = o(\lambda^N(t)) \quad \text{as } t \to \infty. \tag{0.9}$$

It follows from (0.9) that

$$\int^{\infty} \lambda^N(t)dt = \infty. \tag{0.10}$$

Condition (0.9) requires the annealing rate $\lambda(t)$ decrease to 0 slowly, and (0.10) guarantees that the process is not trapped at any particular state forever. For the commonly used $\lambda(t) = t^{-1/c}$, (0.9) holds if and only if $c > N$. If $c < N$, it is well known that the process will be trapped at local minima and therefore no general statements can be made regarding its limiting behavior. See [5, Thm. 1].

The following notion of a transition rate matrix is used repeatedly.

DEFINITION 0.1. *An $m \times m$ matrix $A = (a_{ij})$ is called a transition rate matrix if* (i) *the column sums of A are nonpositive, that is, $\sum_{i=1}^{m} a_{ij} \leq 0$ for each j,* (ii) *$a_{ij} \geq 0$ for all $i \neq j$ and $a_{ii} \leq 0$ for each i.*

Note that the transpose of the matrix $Q(t) = (q_{ij}(t))$ in (0.0) is a transition rate matrix. However, we sometimes call $Q(t)$ a transition rate matrix for the sake of brevity.

We next define a Perron–Frobenius property and some quantities associated with (S^N, U^N) to describe the results. Let $S^N(N)$ denote the set of all states in S^N of which the minimal cost coming out is N, that is, $S^N(N) = \{c^N \in S^N : V^N(c^N) = N\}$. For each $c^N \in S^N(N)$, let $E(c^N)$ be the equivalence class containing c^N in $S^N(N)$. Note that S^N has no cycles by the assumption that (S^N, U^N) is indecomposable, but equivalence classes can still be defined. The forward equation of states in $E(c^N)$ again takes the form (0.2) and can be written as the following:

$$(F'_{\tilde{c}^N};\ \tilde{c}^N \in E(c^N))^T = Q^T_{E(c^N)} \cdot (\lambda^N F_{\tilde{c}^N};\ \tilde{c}^N \in E(c^N))^T + \text{higher order terms}, \tag{0.11}$$

where $Q^T_{E(c^N)}$ is a transition rate matrix with strictly negative eigenvalues. Let $\sigma(E(c^N))$ be the largest eigenvalue of $Q_{E(c^N)}$. The following condition is called Perron–Frobenius property.

(0.12)

There exists a unique $E(c^N) \subseteq S^N(N)$ such that $\sigma(E(c^N)) = \max_{\tilde{c}^N \in S^N(N)} \sigma(E(\tilde{c}^N))$.

Condition (0.12) holds automatically if $S^N(N)$ forms a single equivalence class. In any case it is a mild condition because for a fixed energy landscape U, $\sigma(E(c^N))$ depends only on the neighborhood choosing matrix $(p_{ij})_{i,j\in S}$. Because $(p_{ij})_{i,j\in S}$ is chosen arbitrarily, it happens with Lebesgue measure 0 that two matrices $Q_{E(c^N)}$ and $Q_{E(\tilde{c}^N)}$ can have the same largest eigenvalue.

Let $c^N_{\max}$ be any state in the unique solution of (0.12). The height of a state in S^N is defined as follows

$$h^N(c^N) = \min \sum_j U^N(c^N_j, c^N_{j+1}) - V^N(c^N_{j+1}), \tag{0.13}$$

where the minimum is taken over all paths $c^N_1, c^N_2, \cdots$ connecting $c^N_{\max}$ to c^N in S^N.

The following quantities are crucial to describing our results:

$$-\delta = \sigma(E(c^N_{\max})), \tag{0.14}$$

$$\text{For each } i \in S, \quad h(i) = \sum_{j=0}^{N} h^j(c^j), \tag{0.15}$$

where $i = c^0 \in c^1 \in \cdots \in c^N$ is the unique sequence of cycles containing i successively formed in (0.5)–(0.6), $h^j(c^j)$, $j = 1, \ldots, N-1$, are defined in (0.8) and $h^N(c^N)$ in (0.13). Some examples of δ and h^N are in Examples 2 and 3 in §4. We remark that unlike the regular case that S^N forms a cycle in S^{N+1}, in which case there is only one equivalence class in $S^N(N)$ and (0.12) is always satisfied with $\delta = 0$ in (0.14), there might be several different equivalence classes with the same (maximal, nonzero) largest eigenvalue. In this completely general case with no assumption made regarding $S^N(N)$, our analysis fails and there seems no natural way to generalize (0.8) as an appropriate height function. We therefore impose a mild condition (0.12) so that the natural generalization (0.13) can be defined to replace (0.8). Indeed, for any cycle C and states $c_1, c_2 \in C$, we always have $\lim_{t\to\infty} P(X_t \in c_1)\lambda(t)^{V(c_1)}/\{P(X_t \in c_2)\lambda^{V(c_2)}(t)\}$ exists ([2], Thm. 1.1). Hence the function V characterizes the relative weights among all the states in a cycle. The usual height function (0.8) thus describes the "inverse weight" of c with respect to C. ("c has height k with respect to C" means that $\lim_{t\to\infty} P(X_t \in c)/\{P(X_t \in C)\lambda^k(t)\}$ exists and is positive.) It is therefore clear that states $c \in C$ with maximal V, that is,

$$V(c) = \max_{\tilde{c}\in C} V(\tilde{c}), \tag{0.16}$$

have the largest probability in C and the probability of the process being at a different state $\tilde{c}$ is a factor $\lambda^{h(\tilde{c})}$ of it. In case that (S^N, U^N) does not form a cycle, which is crucial for the above argument to work, we must select a state in S^N that plays the same role in S^N as c does in (0.16). The proper choice we found in our analysis is a state satisfying the Perron–Frobenius property (0.12). The new function (0.13) is then tailor made as a height function relative to such a choice. Details are in §3. In the interesting case where $U(i,j) = [U(j) - U(i)]^+$, if i and j are neighbors and the absorbing state a is taken to be the global minima set of U, the forward equation of X_t will eventually have the form

$$dP(\tau > t)/dt = \left(\sum_{i\neq a} F_i(t)\right)' = (-\delta\lambda^N(t) + O(\lambda^{N+1}(t))) \cdot \sum_{i\neq a} F_i(t), \tag{0.17}$$

where τ is the hitting time of a. Here N has the geometric meaning as the greatest depth of all local minima as was first defined in [5]. The quantity $\delta \cdot \lambda^N$ can be interpreted as the

rate at which the whole system is attracted to a. The constant δ depends on the neighborhood choosing matrix (p_{ij}) and is not directly related to the geometric structure of U. Actually, for a finite set S with a given potential function U and fixed neighborhood system, the constant δ can take any (positive) value by manipulating p_{ij}'s. Examples 2 and 3 in §4 illustrate this point.

The main result in this paper can now be stated as follows.

THEOREM 0.2. *Let $\{X_t;\ t \geq 0\}$ be a singular-simulated annealing process satisfying* (0.9) *and the Perron–Frobenius property* (0.12). *Then there exist constants $\beta_{ij} > 0$ independent of the starting points such that for nonabsorbing states i and j,*

$$\begin{aligned} &\lim P(X_t = i)\lambda^{h(j)}(t)/\{P(X_t = j)\lambda^{h(i)}(t)\} = \beta_{ij} \quad \textit{and} \\ &P(X_t \neq \textit{ absorbing state}) = \exp\left[-\int_0^t \delta\lambda^N(s) + O(\lambda^{N+1}(s))ds\right] \quad \textit{for } t \textit{ large}, \end{aligned} \tag{0.18}$$

where $h(i)$ and δ are given in (0.15), (0.14), *respectively.*

Remark. For the case where $(p_{ij})_{i,j\neq a}$ is not irreducible, we need to break up the state space into irreducible classes. Relations (0.18) still hold in each class.

Remark. The Perron–Frobenius property is used to define the height function $h(i)$, $i \in S$ in (0.18). If it fails to hold, that is, there are more than one equivalence classes in $S^N(N)$ with the same maximal eigenvalues, we can conclude that (Corollary 2.4)

$$P(X_t = i)/\lambda^{h(i)}(t) = O\left(\exp\left[-\delta\int_0^t \lambda^N + O(\lambda^{N+1})ds\right]\right), \tag{0.19}$$

where $h(i) = \sum_{j=0}^N h^j(c^j)$ as in (0.15), but now h^N is the smallest height function computed relative to all the equivalence classes with the same maximal largest eigenvalue. This result is slightly weaker than (0.18), and the height function $h(i)$ can fail to represent the exact convergence rate of $P(X_t = i)$ for some i. See Example 4.2. From some examples that we have computed, it seems that (0.18) should hold even without the Perron–Frobenius property, but the correct height function h is very difficult to describe. We hope to address this point further in the future.

Next we mention a simple consequence of the Perron–Frobenius theorem [9] and list all the notations that are used throughout the paper.

LEMMA 0.3 [1], [2]. *Let $A = (a_{ij})$ be a transition rate matrix of order m. If $A^{-1} = (b_{ij})$ exists, then we have the following:*

(i) *All the eigenvalues of A have negative real parts.*

(ii) $b_{ii} \leq (\min_i a_{ii})^{-1}$ *and* $b_{ii} \leq b_{ij} \leq 0$ *for all i, j.*

(iii) $b_{ij} < 0$ *if and only if i is reachable from j, that is, there exist $i_0 = i, i_1, \ldots, i_k = j$ such that $a_{i_n,i_{n+1}} > 0$ for each $0 \leq n < k$. On the other hand, if A is noninvertible but irreducible, then we have the following:*

(iv) *Zero is an eigenvalue with multiplicity one and all other eigenvalues of A have negative real parts.*

(v) $\sum_{i=1}^m a_{ij} = 0$ *for each $1 \leq j \leq m$.*

(vi) *For any proper subset B of $\{1, 2, \ldots, m\}$, the principal minor $A_B = (a_{ij};\ i, j \in B)$ is an invertible transition rate matrix.*

$F_i(t) = P(X_t = i)$ for $i \in S$. $Q(t) = (q_{ij}(t))$ always denotes a transition rate matrix as in (0.0) for some forward equation. $A_{A,B}(k) = (r_{ij};\ i \in A,\ j \in B)$, where $r_{ij} = p_{ij}$ if $U(i, j) = k$ and 0 otherwise. Note that $Q_{A,B}(k)$ is a constant matrix. It is selected from $Q(t)$ for obvious reasons. $Q_A(k) = Q_{A,A}(k)$. $\vec{e} = (1, 1, \ldots, 1)$ of any dimension. A vector $\vec{v} = (v_1, \ldots, v_m)$ is said nonnegative (positive) if all $v_i \geq 0$ ($v_i > 0$). For the

pair (S^n, U^n), $S^n(k) = \{c^n \in S^n : V^n(c^n) = k\}$, $S^n(i, i+1, \ldots, j) = \cup_{k=i}^{j} S^n(k)$ and $S^n(i, \infty) = \cup_{k \geq i} S^n(k)$. For $c^n \in S^n$, $F_{c^n}(t) = \sum_{c^{n-1} \in c^n} F_{c^{n-1}}(t)$. Note that $F_{c^n}(t) = P(X_t \in c^n)$. For $A \subseteq S^n$, $\vec{F}_A(t) = (F_{c^n}(t);\ c^n \in A)^T$ and $\vec{F}'_A(t) = (F'_{c^n}(t);\ c^n \in A)^T$ are column vectors. The superscript T always means "transpose". For $A \subseteq S^n$, $F_A(t) = \vec{e} \cdot \vec{F}_A(t) = \sum_{c^n \in A} F_{c^n}(t)$. Note that $F_A(t) = P(X_t \in A)$.

We outline our proof and discuss the details in §§1–3.

Step 1. Beginning with (0.2), we establish (by a "boosting and merging" technique) that for each $n = 1, 2, \ldots, N$, the forward equation of states in (S^n, U^n) always preserve a form similar to (0.2) (Lems. 1.1 and 1.2),

$$F'_{c^n}(t) = \sum_{\tilde{c}^n} q_{\tilde{c}^n, c^n}(t) \cdot F_{\tilde{c}^n}(t) + \text{ higher order terms.} \tag{0.20}$$

The exact form of "higher order terms" can be found later. They are neglected for the time being.

Step 2. From (0.20), we show that states in a single cycle have comparable probabilities and their relation can be given as follows (Theorem 1.3). For $c^n \in c^{n+1}$,

$$F_{c^n} = \theta \lambda^{h^n(c^n)}(t) \cdot F_{c^{n+1}}(t) + \text{ higher order terms.}$$

Step 3. Let $S^N(k) = \{c^n \in S^N;\ V^N(c^N) = k\}$. We show that the states in $S^N(k)$, $k \leq N-1$, can be replaced by states in $S^N(N)$ and that the forward equation in $S^N(N)$ takes a form similar to (0.20).

Step 4. Suppose the Perron–Frobenius property (0.12) is satisfied. Then we establish the following comparison of F_{c^N} with $F_{c^N_{\max}}$:

$$F_{c^N} = \theta \cdot \lambda^{h^N(c^N)} \cdot F_{c^N_{\max}} + \text{ higher order terms} \quad \text{and}$$
$$F'_{c^N_{\max}}(t) = \left[-\delta \lambda^N(t) + O(\lambda^{N+1}(t))\right] \cdot F_{c^N_{\max}} \quad \text{(Lems. 3.1 and 3.2).}$$

In §1 we rederive all the estimates used in [1], [2], but omit unnecessary repetition of some technical details. Section 2 treats the indecomposable pair (S^N, U^N) and determines $h(i)$ and β_i for some states in S. Section 3 continues to work in §2 and determines $h(i)$ and β_i for all nonabsorbing states in S. Some representive examples are given in §4 to demonstrate the techniques we use and the application for the expected hitting time of regular simulated annealing processes.

1. Preliminary estimates. Let $\{X_t\}$ be a singular-simulated annealing process satisfying (0.9). The forward equation of nonabsorbing states associated with such a process assumes the following form:

$$\vec{F}'_{S\setminus\{a\}}(t) = Q^T(t) \cdot \vec{F}_{S\setminus\{a\}}(t),$$

where $Q(t) = (q_{ij}(t))_{i,j \neq a}$ is the transition rate matrix in (0.0). Because the absorbing state does not play a role in the analysis, we *abuse* the notation S for $S\setminus\{a\}$. In this section, two techniques called "boosting" and "merging" are used repeatedly to establish some preliminary estimates of $F_i(t)$ and single-out a unique class of states with maximal probability under a "Perron–Frobenius property" assumption. These estimates would be of correct order and yield the desired result if we had a regular simulated annealing process. Conceptually this section is equivalent to [1] or [2]. However, the notation and techniques are more complicated because the error terms are handled more delicately. This complication is of course expected because we have a more complicated process and its necessity becomes clear in the next section.

We begin with a "boosting" lemma that prepares the way for a "merging" in (S^0, U^0). The word "boosting" refers to the power of λ.

LEMMA 1.1 (Boosting). *Let (S^0, U^0) be a decomposable pair. Then for any $c^1 \in S^1(0)$, we have $F_{c^1} = O(\lambda F_{S^1(1,\infty)})$.*

Proof. Let $A = \{i \in S^0 : V(i) = 0$ and i is not contained in any nontrivial zeroth-order cycle in $S^1\}$. Note that $A = S^1(0)$. Then the forward equation of states in A assumes the following form:

$$\vec{F}'_A = Q_A^T(0) \cdot \vec{F}_A + O(\lambda F_S). \tag{1.1}$$

The fact that $Q_A^T(0)$ is a transition rate matrix implies that $\vec{e} \cdot Q_A(0) \leq 0$. Because the states in A cannot form any cycle in S^1, $Q_A^T(0)$ is invertible. Thus we can find a vector $\vec{v} > 0$ in the neighborhood of $\vec{e}$ such that $\vec{v} \cdot Q_A^T(0) < 0$ by the open mapping theorem. Therefore,

$$\vec{v} \cdot \vec{F}'_A = \vec{v} \cdot Q_A^T(0) \cdot \vec{F}_A + O(\lambda F_S) \leq -\alpha \vec{v} \cdot \vec{F}_A + O(\lambda F_{S \setminus A})$$

for some positive α when t is large. Note that the change of error term is justified by combining λF_A with $\vec{v} \cdot \vec{F}_A$. Let $f = \vec{v} \cdot \vec{F}_A$. Then $f' \leq -\alpha f + O(\lambda F_{S \setminus A})$. As in [1, Lem. 1.1], for some $M > 0$

$$\begin{aligned} \limsup_{t \to \infty} f(t)/(\lambda F_{S \setminus A}) &\leq \limsup_{t \to \infty} \int_0^t [(\exp(\alpha s)) \cdot M \lambda F_{S \setminus A}] ds / [(\exp(\alpha t)) \cdot \lambda F_{S \setminus A}] \\ &\leq \limsup_{t \to \infty} (M \lambda F_{S \setminus A})/(\alpha \lambda F_{S \setminus A} + O(\lambda^2 F_{S \setminus A})) \leq M/\alpha. \end{aligned}$$

Because $\vec{v} > 0$ and $F_{S \setminus A} = F_{S^1(1,\infty)}$, we therefore have $F_i = O(\lambda F_{S \setminus A}) = O(\lambda F_{S^1(1,\infty)})$ for each $i \in A$.

We remark that the l'Hôpital's rule was used in the above derivations. This is justified because of condition (0.10). Also, the term λ' did not appear when taking the derivative of the denominator because of (0.9). □

The following lemma indicates that the states forming a nontrivial cycle in S^1 can be merged into a "single" state and thus simplifies the forward equations in S^1. This explains its name.

LEMMA 1.2 (Merging). *Let $c^1 \in S^1$ be a nontrivial zeroth-order cycle. Then for any state $i \in c^1$, there exists a positive constant θ_i such that $F_i = \theta_i F_{c^1} + O(\lambda F_{S^1(1,\infty)})$. Thus the forward equation of any $c^1 \in S^1$ has the form*

$$F'_{c^1} = -p_{c^1} \lambda^{V^1(c^1)} + \sum_{\tilde{c}^1 \neq c^1} p_{\tilde{c}^1, c^1} \lambda^{U^1(\tilde{c}^1, c^1)} F_{\tilde{c}^1} + O(\lambda^2 F_{S^1(1,\infty)}),$$

where $p_{c^1} > 0$ and $p_{\tilde{c}^1, c^1} \geq 0$ are constants.

Proof. Because the states in c^1 form a cycle, their forward equations assume the following form because of Lemma 1.1:

$$\vec{F}'_{c^1} = Q_{c^1}^T(0) \cdot \vec{F}_{c^1} + O(\lambda F_{S^1(1,\infty)}),$$

where $Q_{c^1}^T(0)$ is a singular, irreducible transition rate matrix. Let $-\alpha$ be an eigenvalue of $Q_{c^1}^T(0)$ and $\vec{v}$ a corresponding eigenvector. By Lemma 2.2(iv), $\alpha = 0$ or Re $\alpha > 0$. Let $f = \vec{v} \cdot \vec{F}_{c^1}$. Then $f' = -\alpha f + O(\lambda F_{S^1(1,\infty)})$. If $\alpha = 0$, then $f' = O(\lambda F_{S^1(1,\infty)})$, trivially. If Re $\alpha > 0$, then

$$\begin{aligned}&\limsup_{t\to\infty}|f(t)|/(\lambda F_{S^1(1,\infty)})\\&\quad\le \limsup_{t\to\infty}\left\{\int_0^t(\exp[(\operatorname{Re}\alpha)s])\cdot M\lambda F_{S^1(1,\infty)}\right\}/\{(\exp[(\operatorname{Re}\alpha)t])\cdot\lambda F_{S^1(1,\infty)}\}\\&\quad\le \limsup_{t\to\infty} M\lambda F_{S^1(1,\infty)}/[(\operatorname{Re}\alpha)\lambda F_{S^1(1,\infty)}+O(\lambda^2F_{S^1(1,\infty)})]=M/(\operatorname{Re}\alpha).\end{aligned}$$

Thus $\vec{v}\cdot\vec{F}_{c^1}=O(\lambda F_{S^1(1,\infty)})$ and therefore $\vec{v}\cdot\vec{F}'_{c^1}=O(\lambda F_{S^1(1,\infty)})$. By Jordan's decomposition (see the proof of Lemma 2.2 in [2] for details), we can then find a basis $(\vec{v}_1,\vec{v}_2,\ldots)$ of $\mathbb{C}^{|c^1|}$ such that $\vec{v}_k\cdot\vec{F}'_{c^1}=O(\lambda F_{S^1(1,\infty)})$ for each k. Thus $\vec{F}'_{c^1}=O(\lambda F_{S^1(1,\infty)})$, and then so does $Q^T_{c^1}(0)\cdot\vec{F}_{c^1}$. The assertions in the lemma now follow by first noting $Q^T_{c^1}(0)$ is a singular irreducible transition rate matrix with rank $|c^1|-1$ and then solving linear equations. □

We remark that the forward equation in Lemma 1.2 makes sense only for the cycles c^1 and $\tilde{c}^1$ where $U^1(\tilde{c}^1,c^1)$ equals 0 or 1. For cycles $c^1\in S^1$ with $V^1(c^1)>1$, their forward equations are neglected for now and will be resumed one by one through the following induction.

Lemmas 1.1 and 1.2 are the induction foundation of the following theorem.

THEOREM 1.3 (Boosting and merging). *If (S^n,U^n) is decomposable, then for any $c^{n+1}\in S^{n+1}(0,1,\ldots,n)$, we have $\lambda^{V^{n+1}(c^{n+1})}F_{c^{n+1}}=O(\lambda^{n+1}F_{S^{n+1}(n+1,\infty)})$. Moreover, for a nontrivial nth-order cycle $c^{n+1}\in S^{n+1}$ and $c^n\in c^{n+1}$, there exists a positive constant θ_{c^n} such that*

$$\lambda^{V^n(c^n)}F_{c^n}=\theta_{c^n}\lambda^nF_{c^{n+1}}+O(\lambda^{n+1}F_{S^{n+1}(n+1,\infty)}). \tag{1.2}$$

The forward equation of any $c^{n+1}\in S^{n+1}$ has the following form:

$$\begin{aligned}F'_{c^{n+1}}=&-p_{c^{n+1}}\lambda^{V^{n+1}(c^{n+1})}F_{c^{n+1}}+\sum_{\tilde{c}^{n+1}\neq c^{n+1}}p_{\tilde{c}^{n+1},c^{n+1}}\lambda^{U^{n+1}(\tilde{c}^{n+1},c^{n+1})}F_{\tilde{c}^{n+1}}\\&+O(\lambda^{n+2}F_{S^{n+1}(n+1,\infty)}).\end{aligned} \tag{1.3}$$

Proof. We proceed by induction. When $n=0$, the theorem reduces to Lemmas 1.1 and 1.2. Suppose the theorem holds for (S^{n-1},U^{n-1}). Consider the forward equation of states in $S^n(T,k)=\{c^n\in S^n: V^n(c^n)=k,\ c^n$ is not contained in a nontrivial nth-order cycle in $S^{n+1}\}$. (Note that $S^n(T,k)=S^{n+1}(k),\ k=0,\ldots,n$.) By induction hypothesis,

$$\vec{F}'_{S^n(T,k)}=\sum_{r=0}^{n}Q^T_{S^n(T,r),S^n(T,k)}(r)\cdot(\lambda^r\vec{F}_{S^n(T,r)})+O(\lambda^{n+1}F_{S^n(n,\infty)}). \tag{1.4;k}$$

The following boosting and merging techniques play an essential role in this paper and will be used repeatedly in the sequel.

First, consider (1.4;k), $k=0$. Because $Q^T_{S^n(T,0)}(0)$ is an invertible transition rate matrix, we can find a basis $\vec{v}_1,\ldots,\vec{v}_{|S^n(T,0)|}$ so that $\vec{v}_k\cdot\vec{F}'_{S^n(T,0)}=O(\lambda^{n+1}F_{S^n(n,\infty)})$ by Jordan's decomposition. (See [2, Lems. 2.2 and 2.3] for details.) We thus can express $\vec{F}_{S^n(T,0)}$ in terms of $\{F_{c^n};\ c^n\in\cup_{i=1}^n S^n(T,i)\}$,

$$\begin{aligned}\vec{F}_{S^n(T,0)}=&-(Q^T_{S^n(T,0)}(0))^{-1}\cdot\left(\sum_{r=1}^{n}Q^T_{S^n(T,r),S^n(T,0)}(r)\right)\cdot(\lambda^r\vec{F}_{S^n(T,r)})\\&+O(\lambda^{n+1}F_{S^n(n,\infty)}).\end{aligned} \tag{1.5;0}$$

Substituting (1.5;0) into (1.4;k), $k = 1, 2, \ldots, n$, we obtain

$$
\begin{aligned}
\vec{F}'_{S^n(T,k)} = \sum_{r=1}^{n} \Big[& Q^T_{S^n(T,r),S^n(T,k)}(r) - Q^T_{S^n(T,0),S^n(T,k)}(0) \cdot \\
& (Q^T_{S^n(T,0)}(0))^{-1} \cdot Q^T_{S^n(T,r),S^n(T,0)}(r) \Big] \\
& \cdot (\lambda^r \vec{F}_{S^n(T,r)}) + O(\lambda^{n+1} F_{S^n(n,\infty)}) \\
= \sum_{r=1}^{n} & Q(1)^T_{S^n(T,r),S^n(T,k)}(r) \cdot (\lambda^r \vec{F}_{S^n(T,r)}) + O(\lambda^{n+1} F_{S^n(n,\infty)}).
\end{aligned} \tag{1.5;k}
$$

Having eliminated $S^n(T,0)$ from $S^n(T,k)$, $k = 1, \ldots, n$, the following lemma asserts that (1.5;k), $k = 1, \ldots, n$, again constitute a forward equation and thus enable us to eliminate $S^n(T,1), \ldots, S^n(T,n-1)$, successively.

LEMMA 1.4. *The system $Q(1)^T$, viewed as a transition among states in $\cup_{i=1}^n S^n(T,i)$, forms a forward equation, that is, for each $k = 1, \ldots, n$,*

$$
\begin{aligned}
\vec{e} \cdot \sum_{r=1}^{n} Q(1)^T_{S^n(T,k),S^n(T,r)}(k) = \vec{e} \cdot \Big[& Q^T_{S^n(T,k)}(k) - Q^T_{S^n(T,0)S^n(T,k)}(0) \\
& \cdot (Q^T_{S^n(T,0)}(0))^{-1} \cdot Q^T_{S^n(T,k),S^n(T,0)}(k) \Big] \\
+ \vec{e} \cdot \Bigg[& \sum_{\substack{r=1 \\ r \neq k}}^{n} Q^T_{S^n(T,k),S^n(T,r)}(k) - Q^T_{S^n(T,0),S^n(T,r)}(0) \\
& \cdot (Q^T_{S^n(T,0)}(0))^{-1} \cdot Q^T_{S^n(T,k),S^n(T,0)}(k) \Bigg] \\
\leq 0. &
\end{aligned}
$$

Proof. We only prove $k = 1$; the proof for the other k is the same. Consider the following identity:

$$
\left[\begin{array}{c|c}
 & \begin{matrix} 0 \\ \vdots \\ 0 \end{matrix} \\
\hline
Q^T_{S^n(T,0)}(0) & \\
\hline
\sum_{r=1}^{n} \vec{e} \cdot Q^T_{S^n(T,0),S^n(T,r)}(0) & -1
\end{array}\right]
$$

$$
\cdot \left[\begin{array}{c|c}
 & \begin{matrix} 0 \\ \vdots \\ 0 \end{matrix} \\
\hline
(Q^T_{S^n(T,0)}(0))^{-1} & \\
\hline
\sum_{r=1}^{n} \vec{e} \cdot Q^T_{S^n(T,0),S^n(T,r)} \cdot (Q^T_{S^n(T,0)}(0))^{-1} & -1
\end{array}\right] = I,
$$

where I is the identity matrix. Because the first term in the product is a transition rate matrix, all the entries of $\sum_{r=1}^{n} [\vec{e} \cdot Q^T_{S^n(T,0),S^n(T,r)}(0) \cdot (Q^T_{S^n(T,0)}(0))^{-1}]$ are nonpositive with absolute value less than or equal to one, by Lemma 0.2. Thus

$$\begin{aligned}
&\vec{e}\cdot\left[Q^T_{S^n(T,1)}(1)-Q^T_{S^n(T,0),S^n(T,1)}(0)\cdot\left(Q^T_{S^n(T,0)}(0)\right)^{-1}\cdot Q^T_{S^n(T,1),S^n(T,0)}(1)\right]\\
&\quad+\vec{e}\cdot\left(\sum_{r=2}^{n}Q^T_{S^n(T,1),S^n(T,r)}(1)-Q^T_{S^n(T,0),S^n(T,r)}(0)\right.\\
&\qquad\left.\cdot\left(Q^T_{S^n(T,0)}(0)\right)^{-1}\cdot Q^T_{S^n(T,1),S^n(T,0)}(1)\right)\\
&=\vec{e}\cdot Q^T_{S^n(T,1)}(1)+\vec{e}\cdot\sum_{r=2}^{n}Q^T_{S^n(T,1),S^n(T,r)}(1)\\
&\quad-\sum_{r=1}^{n}\vec{e}\cdot Q^T_{S^n(T,0),S^n(T,r)}(0)\cdot\left(Q^T_{S^n(T,0)}(0)\right)^{-1}\cdot Q^T_{S^n(T,1),S^n(T,0)}(1)\\
&\le\vec{e}\cdot Q^T_{S^n(T,1)}(1)+\vec{e}\cdot\sum_{r=2}^{n}Q^T_{S^n(T,1),S^n(T,r)}(1)+\vec{e}\cdot Q^T_{S^n(T,1),S^n(T,0)}(1)\le 0,
\end{aligned}$$

because

$$Q^T_{\cup_{i=1}^{n}S^n(T,i)}(1)$$

is a transition rate matrix. This proves the lemma. □

Having eliminated $S^k(T,k)$, $k=0,\dots,n-1$, we have

$$\vec{F}'_{S^n(T,n)}=Q(n)^T_{S^n(T,n)}(n)\cdot(\lambda^n\vec{F}_{S^n(T,n)})+O(\lambda^{n+1}F_{S^n(n,\infty)}),\tag{1.6}$$

where $Q(n)^T_{S^n(T,n)}(n)$ is an invertible transition rate matrix. We are thus in the same situation as that of Lemma 1.1. Therefore, $\vec{F}_{S^n(T,n)}=O(\lambda F_{S^{n+1}(n+1,\infty)})$. (Note the change in the error term from that in (1.6).) Having boosted the power of λ by one, we then substitute this back to obtain $\lambda^k\vec{F}_{S^n(T,n)}=O(\lambda^{n+1}F_{S^{n+1}(n+1,\infty)})$. This completes the boosting part of the lemma. Let $c^{n+1}\in S^{n+1}$ be a nontrivial nth-order cycle. We next consider the merging of states in c^{n+1}. The forward equation of states in $c^{n+1}(k)=\{c^n\in c^{n+1}: V^n(c^n)=k\}$ assumes the following form:

$$\vec{F}'_{c^{n+1}(k)}=\sum_{i=0}^{n}Q^T_{c^{n+1}(i),c^{n+1}(k)}(i)\cdot(\lambda^i\vec{F}_{c^{n+1}(i)})+O(\lambda^{n+1}F_{S^{n+1}(n+1,\infty)}),$$

for $k=0,1,\dots,n$. Note that the error term has the present form because of the order estimates just obtained in the proof. Applying the boosting technique $(n-1)$ times, we obtain (similar to (1.6)) the following:

$$\vec{F}'_{c^{n+1}(n)}=Q(n)^T_{c^{n+1}(n)}(n)\cdot(\lambda^n\vec{F}_{c^{n+1}(n)})+O(\lambda^{n+1}F_{S^{n+1}(n+1,\infty)}),$$

where Q is a singular transition rate matrix. Thus we are back to the situation in Lemma 1.2, and (1.2) thus follows. We are now ready to prove (1.3). To boost the order of the error term from λ^{n+1} to λ^{n+2}, we have to boost the order of all error terms in previous steps. First, let $c^1\in S^{n+1}(1)\subseteq S^1(1)$. If c^1 is a nontrivial zeroth-order cycle in $S^1(1)$, then the forward equation of states in c^1 assumes the following form:

$$\vec{F}'_{c^1}=Q^T_c(0)\cdot\vec{F}_{c^1}+O(\lambda^{n+1}F_{S^{n+1}(n+1,\infty)}).\tag{1.7}$$

The error term in (1.7) differs from that in (1.1) by an nth power of λ. This is because we have now updated the error estimates. The method in Lemma 1.2 then implies that $F_i = \theta_i F_{c^1} + O(\lambda^{n+1} F_{S^{n+1}(n+1,\infty)})$ for each $i \in c^1$. Suppose $c^2 \in S^{n+1}(2) \subseteq S^2(2)$ and c^2 is a nontrivial first-order cycle. Then the forward equation of states in $c^2(k) = \{c^1 \in c^2 : V^1(c^1) = k\}$ assumes the following form:

$$(1.8;k) \quad \vec{F}'_{c^2(k)} = \sum_{i=0}^{1} Q^T_{c^2(i),c^2(k)}(i) \cdot (\lambda^i \vec{F}_{c^2(i)}) + O(\lambda^{n+1} F_{S^{n+1}(n+1,\infty)}), \qquad k = 0, 1.$$

The boosting and merging techniques thus imply that for $c^1 \in c^2$,

$$\lambda^{V^1(c^1)} F_{c^1} = \theta_{c^1} \cdot \lambda F_{c^2} + O(\lambda^{n+1} F_{S^{n+1}(n+1,\infty)}).$$

We inductively obtain that for nontrivial $(k-1)$th-order cycle $c^k \in S^{n+1}(k) \subseteq S^k(k)$, $k = 1, 2, \ldots, n$,

$$\lambda^{V^{k-1}(c^{k-1})} F_{c^{k-1}} = \theta_{c^{k-1}} \cdot \lambda^{k-1} F_{c^k} + O(\lambda^{n+1} F_{S^{n+1}(n+1,\infty)})$$

holds for $c^{k-1} \in c^k$. Thus the forward equation of a state $c^{n+1} \in S^{n+1}$ has the following form:

$$F'_{c^{n+1}} = -p_{c^{n+1}} \lambda^{V^{n+1}(c^{n+1})} F_{c^{n+1}} + \sum_{k=0}^{n+1} \sum_{\substack{V^{n+1}(\tilde{c}^{n+1})=k \\ \tilde{c}^{n+1} \neq c^{n+1}}} p_{\tilde{c}^{n+1},c^{n+1}} \lambda^k F_{\tilde{c}^{n+1}}$$

$$+ O(\lambda^{n+2} F_{S^{n+1}(n+1,\infty)}).$$

This completes the proof. □

Remark. From the above proof, it is clear that for a cycle C with forward equation $(F'_i;\ i \in C) = Q \cdot (\lambda^{V(i)} F_i;\ i \in C)+$ higher order terms, (1.2) can be obtained by solving $Q \cdot (\lambda^{V(i)} F_i;\ i \in C) = 0$. Indeed, because the rank of Q is one less than its dimension, we have $\lambda^{V(i)} F_i = \beta_{ij} \lambda^{V(j)} F_j$ for some $\beta_{ij} > 0$.

2. Indecomposable pair and Perron–Frobenius property. In this section we define a Perron–Frobenius property of a singular-simulated annealing process, which guarantees the existence of a class of dominant (but equivalent) states and then establish an intermediate theorem.

Let $\{X_t\}$ be a singular-simulated annealing process on S with cost function U, and N the smallest number such that (S^N, U^N) is indecomposable. By Theorem 1.3, the forward equation of states in $S^N(k)$, $0 \leq k \leq N$, assumes the following form:

$$(2.0;k) \qquad \vec{F}'_{S^N(k)} = \sum_{i=0}^{N} Q^T_{S^N(i),S^N(k)}(i) \cdot (\lambda^i \vec{F}_{S^N(i)}) + O(\lambda^{N+1} F_{S^N(N)}),$$

where Q is the transition rate matrix on S^N.

Following the boosting and merging technique once, we can eliminate the term $\vec{F}_{S^N(0)}$ from $\{\vec{F}_{S^N(k)};\ k > 0\}$ and obtain for $k = 1, \ldots, N$,

$$\vec{F}'_{S^N(k)} = \sum_{i=1}^{N} \Big[Q^T_{S^N(i),S^N(k)}(i) - Q^T_{S^N(0),S^N(k)}(0) \cdot (Q^T_{S^N(0)}(0))^{-1} \cdot$$

$$(2.1;k) \qquad Q^T_{S^N(i),S^N(0)}(i) \Big] \cdot (\lambda^i \vec{F}_{S^N(i)}) + O(\lambda^{N+1} F_{S^N(N)})$$

$$= \sum_{i=1}^{N} Q(1)^T_{S^N(i),S^N(k)}(i) \cdot (\lambda^i \vec{F}_{S^N(i)}) + O(\lambda^{N+1} F_{S^N(N)}).$$

After applying the techniques of boosting and merging N times, we obtain the following:

$$(2.2;N) \qquad \vec{F}'_{S^N(N)} = Q(N)^T_{S^N(N)}(N) \cdot (\lambda^N \vec{F}_{S^N(N)}) + O(\lambda^{N+1} F_{S^N(N)}),$$

where $Q(N)^T_{S^N(N)}(N)$ is an invertible transition rate matrix. Recall that two states c_1^N and c_2^N in $S^N(N)$ are said to be equivalent if $c_1^N \geq c_2^N$ and $c_2^N \geq c_1^N$ (see the Introduction). Denote the set of all the equivalence classes of $S^N(N)$ by $E(S^N(N)) = \{S^N(N,i) : S^N(N,i)$ is an equivalence class of $(S^N(N), \geq)\}$. We remark that the equivalence classes can also be defined from $(S^N(N), Q(N)^T_{S^N(N)}(N))$, where $Q(N)^T_{S^N(N)}(N)$ is viewed as an ordinary transition rate matrix. Indeed, the following identity and Lemma 0.3 show that an element $[-Q^T_{S^N(0),S^N(k)}(0) \cdot (Q^T_{S^N(0)}(0))^{-1}](c_1^N, c_2^N) > 0$, where $c_1^N \in S^N(k)$ and $c_2^N \in S^N(0)$ if and only if $c_2^N \geq c_1^N$:

$$\left[\begin{array}{c|ccc} Q^T_{S^N(0)}(0) & 0 & & \\ \hline Q^T_{S^N(0),S^N(k)}(0) & \begin{matrix}-1\\ \cdot\\ 0\end{matrix} & \begin{matrix}0\\ \cdot\\ -1\end{matrix} & \end{array}\right] \cdot$$

$$\left[\begin{array}{c|ccc} (Q^T_{S^N(0)}(0))^{-1} & 0 & & \\ \hline Q^T_{S^N(0),S^N(k)}(0) \cdot (Q^T_{S^N(0)}(0))^{-1} & \begin{matrix}-1\\ \cdot\\ 0\end{matrix} & \begin{matrix}0\\ \cdot\\ -1\end{matrix} & \end{array}\right] = I,$$

where I is the identity matrix. From this fact, it follows that $[Q(1)^T_{S^N(i),S^N(k)}(i)]\,(c_1^N, c_3^N) > 0$ where $c_1^N \in S^N(k)$ and $c_3^N \in S^N(i)$ if and only if $U^N(c_3^N, c_1^N) = N$ or $c_3^N \geq c_2^N \geq c_1^N$ for some $c_2^N \in S^N(0)$. In either case $c_3^N \geq c_1^N$. We thus conclude inductively that in (2.2;N), $[Q(N)^T_{S^N(N)}(N)]\,(c_1^N, c_2^N) > 0$ for $c_1^N, c_2^N \in S^N(N)$ if and only if $c_2^N \geq c_1^N$ in (S^N, U^N). Let $\sigma(S^N(N,i)) < 0$ be the largest eigenvalue of the transition rate matrix among states of $Q(N)^T_{S^N(N,i)}(N)$. The Perron–Frobenius property (0.12) that we need guarantees the existence of a unique equivalence class $S^N(N, \max)$ in $E(S^N(N))$ such that $\sigma(S^N(N, \max)) = -\delta$, the maximum of $\sigma(S^N(N,i))$ over $E(S^N(N))$.

We remark that $-\delta$ can be obtained as follows. We first equate the right-hand side of (2.0;k) to 0 for $k = 0, 1, \ldots, N-1$. Because this is a linear system with more unknowns than equations, we can solve $\lambda^k F_{S^N(k)}$ in terms of $\lambda^N F_{S^N(N)}$ for $k = 0, 1, \ldots, N-1$. Substituting $\lambda^k F_{S^N(k)}$ into the forward equation of $S^N(N)$, we obtain (2.2;N) and $-\delta$ is the largest eigenvalue of the coefficient matrix $Q(N)_{S^N(N)}$.

The next lemma shows that $S^N(N, \max)$ is the dominant term among all equivalence classes in $S^N(N)$. First, we say that $S^N(N,i) \leq S^N(N,j)$ if there are states $c_1^N \in S^N(N,i)$ and $c_2^N \in S^N(N,j)$ such that $c_1^N \leq c_2^N$.

LEMMA 2.1. *Let $S^N(N,i)$ be an equivalence class in $E(S^N(N))$. Then $F_{S^N(N,i)} = O(F_{S^N(N,\max)})$. To be more precise, if $S^N(N,i) \not\leq S^N(N, \max)$, then $F_{S^N(N,i)} =$*

$O(\lambda F_{S^N(N,\max)})$, *and if* $c^N \in S^N(N,i) \leq S^N(N,\max)$, *then there exists a constant* θ_{c^N} *such that* $F_{c^N} = \theta_{c^N} \cdot F_{S^N(N,\max)} + O(\lambda F_{S^N(N,\max)})$.

Proof. Let $A = \cup_{S^N(N,i) \not\leq S^N(N,\max)} S^N(N,i)$, $B = \cup_{S^N(N,i) \leq S^N(N,\max)} S^N(N,i)$, and $D = S^N(N) \backslash S^N(N,\max)$. The forward equation of states in D assumes the following form by (2.2;N):

(2.3)

$$\vec{F}'_D = Q(N)^T_D(N) \cdot (\lambda^N \vec{F}_D) + Q(N)^T_{S^N(N,\max),D}(N) \cdot (\lambda^N \vec{F}_{S^N(N,\max)}) + O(\lambda^{N+1} F_{S^N(N)}).$$

Let $\vec{v} > 0$ be a vector such that $\vec{v} \cdot Q(N)^T_D(N) < 0$ and let $f = \vec{v} \cdot \vec{F}_D$. Then

$$f' \leq -\alpha\lambda^N f + \vec{v} \cdot Q(N)^T_{S^N(N,\max),D}(N) \cdot (\lambda^N \vec{F}_{S^N(N,\max)}) + O(\lambda^{N+1} F_{S^N(N,\max)}),$$

where the constant $-\alpha$ can be chosen so that $-\alpha < -\alpha_1 = -\delta = \sigma(S^N(N,\max))$ by the Perron–Frobenius theorem. Let $\vec{v}_1 > 0$ be an eigenvector corresponding to $(-\delta)$ of the matrix $Q(N)^T_{S^N(N,\max)}(N)$. Then

$$\begin{aligned}
&\limsup_{t\to\infty} f(t)/(\vec{v}_1 \cdot \vec{F}_{S^N(N,\max)}) \\
&\quad \leq \limsup_{t\to\infty} \left[\int_0^t \left(\exp \int_0^s \alpha\lambda^N\right) \cdot (\vec{v}_1 \cdot \vec{F}_{S^N(N,\max)})\right] \Big/ \left[\left(\exp \int_0^t \alpha\lambda^N\right) \cdot (\vec{v}_1 \cdot \vec{F}_{S^N(N,\max)})\right] \\
&\quad \leq \limsup_{t\to\infty} (\vec{v}_1 \cdot \vec{F}_{S^N(N,\max)})/[(\alpha - \delta) \cdot (\vec{v}_1 \cdot \vec{F}_{S^N(N,\max)})] = 1/(\alpha - \delta).
\end{aligned}$$

(The last inequality holds because of l'Hôpital's rule and is the main reason why we need the P–F property.) Thus we have $F_{S^N(N,i)} = O(F_{S^N(N,\max)})$ for any $S^N(N,i) \in E(S^N(N))$. Then consider the forward equation of states in A,

$$\vec{F}'_A = Q(N)^T_A(N) \cdot (\lambda^N \vec{F}_A) + O(\lambda^{N+1} F_{S^N(N,\max)}).$$

The same technique applied to (2.3) can now be applied again to yield $F_{S^N(N,i)} = O(\lambda F_{S^N(N,\max)})$ for $S^N(N,i) \not\leq S^N(N,\max)$. Having obtained this estimate, the forward equation of states in B can be written as follows:

$$\begin{aligned}
\vec{F}'_B &= Q(N)^T_B(N) \cdot (\lambda^N \vec{F}_B) + Q(N)^T_{A,B}(N) \cdot (\lambda^N \vec{F}_A) + O(\lambda^{N+1} F_{S^N(N,\max)}) \\
&= Q(N)^T_B(N) \cdot (\lambda^N \vec{F}_B) + O(\lambda^{N+1} F_{S^N(N,\max)}).
\end{aligned}$$

Let $\vec{v}_k$ be an eigenvector of $Q(N)^T_B(N)$ corresponding to the eigenvalue $(-\alpha_k)$. If $-(\operatorname{Re}\ \alpha_k) < -\delta$, then, similar to the above, we obtain $\vec{v}_k \cdot \vec{F}_B = O(\lambda F_{S^N(N,\max)})$, and therefore

(2.4)
$$\begin{bmatrix} \vec{v}_1 \\ \vec{v}_2 \\ \vdots \\ \vec{v}_{|B|} \end{bmatrix} \cdot \vec{F}_B = \begin{bmatrix} \vec{v}_1 \cdot \vec{F}_{S^N(N,\max)} \\ O(\lambda F_{S^N(N,\max)}) \\ \vdots \\ O(\lambda F_{S^N(N,\max)}) \end{bmatrix}.$$

Note that $\vec{v}_1$ is the eigenvector corresponding to the largest eigenvalue $-\delta = \sigma(S^N(N,\max))$ and $\vec{v}_1 \cdot \vec{F}_B = \vec{v}_1 \cdot \vec{F}_{S^N(N,\max)}$. Let L be the matrix on the left side of (2.4). Multiplying both

sides of (2.4) by L^{-1} and observing that the first column of L^{-1} is strictly positive by Lemma 0.3(iii), we then conclude the proof of the lemma. □

We can rephrase Lemma 2.1 by saying that for a state $c^N \in S^N(N)$, if $h^N(c^N)$ (relative to any state in $S^N(N, \max)$) is zero, then $F_{c^N} = \theta_{c^N} \cdot F_{S^N(N,\max)} + O(\lambda F_{S^N(N,\max)})$ and $F_{c^N} = O(\lambda F_{S^N(N,\max)})$ if $h^N(c^N) \geq 1$. Now consider states in $S^N(N-1)$. The forward equation of states in $S^N(N-1)$ assumes the following form:

$$\begin{aligned}\vec{F}'_{S^N(N-1)} &= Q(N-1)^T_{S^N(N-1)}(N-1) \cdot (\lambda^{N-1}\vec{F}_{S^N(N-1)}) \\ &\quad + Q(N-1)^T_{S^N(N),S^N(N-1)}(N) \cdot (\lambda^N \vec{F}_{S^N(N)}) + O(\lambda^{N+1}F_{S^N(N,\max)}).\end{aligned}$$

Let $A = \{c^N : c^N \in S^N(N-1) \text{ and } h^N(c^N) \geq 2\}$. Then the forward equation of states in A has the following simpler expression

$$\begin{aligned}\vec{F}'_A &= Q(N-1)^T_A(N-1) \cdot (\lambda^{N-1}\vec{F}_A) \\ &\quad + Q(N-1)^T_{S^N(N),A}(N) \cdot (\lambda^N \vec{F}_{S^N(N)}) + O(\lambda^{N+1}F_{S^N(N,\max)}) \\ &= Q(N-1)^T_A(N-1) \cdot (\lambda^{N-1}\vec{F}_A) + O(\lambda^{N+1}F_{S^N(N,\max)}).\end{aligned}$$

Thus $\vec{F}_A = O(\lambda^2 F_{S^N(N,\max)})$. On the other hand, for states in $B = \{c^N : c^N \in S^N(N-1)$ and $h^N(c^N) = 1\}$, we have

$$\begin{aligned}\vec{F}'_B &= Q(N-1)^T_B(N-1) \cdot (\lambda^{N-1}\vec{F}_B) \\ &\quad + Q(N-1)^T_{S^N(N),B}(N) \cdot (\lambda^N \vec{F}_{S^N(N)}) + O(\lambda^{N+1}F_{S^N(N,\max)}).\end{aligned}$$

We thus obtain

$$\vec{F}_B = [Q(N-1)^T_B(N-1)]^{-1} \cdot Q(N-1)^T_{S^N(N),B}(N) \cdot (\lambda \vec{F}_{S^N(N)}) + O(\lambda^2 F_{S^N(N,\max)})$$

and $F_{c^N} = \theta_{c^N} \cdot \lambda F_{S^N(N,\max)} + O(\lambda^2 F_{S^N(N,\max)})$ for $c^N \in B$. Inductively, we conclude that the following lemma holds.

LEMMA 2.2. *Let $c^N \in S^N(k)$ with $h^N(c^N) = N - k$. Then there exists a constant $\theta_{c^N} > 0$ such that $F_{c^N} = \theta_{c^N} \cdot \lambda^k F_{S^N(N,\max)} + O(\lambda^{k+1}F_{S^N(N,\max)})$. If $c^N \in S^N(k)$ but $h^N(c^N) > N - k$, then $F_{c^N} = O(\lambda^{k+1}F_{S^N(N,\max)})$.*

By using Lemma 2.1 and (2.4), we have $F'_{S^N(N,\max)} = -\delta\lambda^N F_{S^N(N,\max)} + O(\lambda^{N+1}F_{S^N(N,\max)})$. It is trivial to solve this differential equation, which yields

$$F_{S^N(N,\max)}(t) = c_0 \exp\left[-\delta \int_{t_0}^{t} (\lambda^N(s) + O(\lambda^{N+1}))ds\right]$$

for t large. We now state an intermediate theorem regarding the order estimates of some states in S.

THEOREM 2.3. *Let $\{X_t\}$ be a singular-simulated annealing process satisfying* (0.9) *and* (0.12). *Let N be the smallest integer such that (S^N, U^N) is indecomposable. Then there exist constants $\beta_{ij} > 0$ and a function $\beta(t) = O(\lambda^{N+1}(t))$ such that* (0.18) *holds for any $i, j \in \cup c^N$, where $c^N \in S^N(k)$ with $h^N(c^N) = N - k$ for some k. If $i \in c^N \in S^N(k)$ with $h^N(c^N) > N - k$, then*

$$P(X_t = i) = O\left(\lambda^{d(i)+N-k+1} \cdot \exp\left[-\delta \int_0^t (\lambda^N(s) + \beta(s))ds\right]\right),$$

where $d(i) = \sum_{j=0}^{N-1} h^j(c^j)$.

Proof. The proof is a combination of Lemmas 2.1, 2.2, and Theorem 1.3. □

From the proof above, we can conclude, without assuming the Perron–Frobenius property (0.12), the following weaker form of (0.18).

COROLLARY 2.4. *Let* $\{X_t\}$ *be a singular-simulated annealing process satisfying* (0.9). *Let* N *be the smallest integer such that* (S^N, U^N) *is indecomposable. Then for some function* $\beta(t) = O(\lambda^{N+1}(t))$,

$$P(X_t = i) = O\left(\lambda^{h(i)} \exp\left[-\delta \int_0^t \lambda^N(s) + \beta(s)ds\right]\right) \quad \textit{for } t \textit{ large.}$$

Note that in (0.19), $h(i)$ is defined to be $\sum_{j=0}^{N} h^j(c^j)$ as in (0.15). Only $h^N(c^N)$ now needs an explanation because of lack of the Perron–Frobenius property. In (0.13), the defining equation of $h^N(c^N)$, we now take the minimum over all paths connecting $\tilde{c}^N$ to c^N, where $\tilde{c}^N$ is in any equivalence class of $S^N(N)$ with the maximal largest eigenvalue.

3. Exact asymptotic behavior. We continue to seek the exact asymptotic behavior of each state in S. Again, we have to rederive all our previous estimates with the updated information contained in Theorem 2.3.

LEMMA 3.1. *Let* $c^N \in S^N(k) \subseteq S^k(k)$ *be such that* $h^N(c^N) \geq N - k + 1$. *Then for any* $c^{k-1} \in c^N$, *there exists a positive constant* $\theta_{c^{k-1}}$ *such that*

$$\lambda^{V^{k-1}(c^{k-1})} F_{c^{k-1}} = \theta_{c^{k-1}} \cdot \lambda^{k-1} F_{c^N} + O(\lambda^{N+1} F_{S^N(N,\max)}).$$

Proof. Let c^N be a nontrivial zeroth-order cycle in $S^1(1)$. If $h^N(c^N) \geq N$, its forward equation has the following form:

$$\vec{F}'_{c^N} = Q^T_{c^N}(0) \cdot \vec{F}_{c^N} + O(\lambda^{N+1} F_{S^N(N,\max)}).$$

The error term is of order $O(\lambda^{N+1} F_{S^N(N,\max)})$ because $h^N(c^N) \geq N$ and the contribution from states other than c^N is of order $O(\lambda^{N+1} F_{S^N(N,\max)})$ by Lemma 2.2. Thus, by the same technique as in Lemma 1.2, we obtain $F_i = \theta_i \cdot F_{c^N} + O(\lambda^{N+1} F_{S^N(N,\max)})$ for $i \in c^N$. Suppose Lemma 3.1 is true for $n \leq r$ and let $c^N \in S^N(r+1)$ be such that $h^N(c^N) \geq N - r$. The forward equation of states in $c^N(j) = \{c^r \in c^N : V^r(c^r) = j\}$ has the following form:

$$(3.1;j) \qquad \vec{F}'_{c^N(j)} = \sum_{k=0}^{r} Q^T_{c^N(k), c^N(j)}(k) \cdot (\lambda^k \vec{F}_{c^N(k)}) + O(\lambda^{N+1} F_{S^N(N,\max)}).$$

The boosting and merging technique can now be applied to (3.1;j), $j = 1, \ldots, r$, to obtain $\lambda^{V^r(c^r)} F_{c^r} = \theta_{c^r} \lambda^r F_{c^N} + O(\lambda^{N+1} F_{S^N(N,\max)})$ for any $c^r \in c^N$. This completes the proof. □

Lemma 3.1 implies that the forward equation of any state c^N in $A = \{c^N \in S^N : h^N(c^N) \geq N - V^N(c^N) + 1\}$ assumes the following form:

$$F'_{c^N} = -p_{c^N} \lambda^{V^N(c^N)} F_{c^N} + \sum_{c^N \neq \tilde{c}^N \in A} p_{\tilde{c}^N, c^N} \lambda^{V^N(\tilde{c}^N)} F_{\tilde{c}^N} + \sum_{\tilde{c}^N \in S^N \setminus A} p_{\tilde{c}^N, c^N} \lambda^{V^N(\tilde{c}^N)+1} F_{\tilde{c}^N} + O(\lambda^{N+2} F_{S^N(N,\max)}).$$

Let $B = S^N \backslash A$, $B(k) = \{c^N \in B : V^N(c^N) = k\}$, and $A(k) = \{c^N \in A : V^N(c^N) = k\}$, $0 \le k \le N$. Then in matrix form,

$$\begin{aligned}\vec{F}'_{A(k)} &= \sum_{j=0}^{N} Q^T_{A(j),A(k)}(j) \cdot (\lambda^j \vec{F}_{A(j)}) \\ &\quad + \sum_{j=0}^{N} Q^T_{B(j),A(k)}(j+1) \cdot (\lambda^{j+1} \vec{F}_{B(j)}) + O(\lambda^{N+2} F_{S^N(N,\max)}).\end{aligned} \tag{3.2;k}$$

The purpose of Lemma 3.1 is to generate the second term on the right-hand side of (3.2;k), which has not played any role in previous sections but is of vital importance now.

LEMMA 3.2. *Let $c^N \in S^N(N)$ with $h^N(c^N) \ge 2$. Then $F_{c^N} = O(\lambda^2 F_{S^N(N,\max)})$. Moreover, for any $c^N \in S^N(k)$ with $h^N(c^N) \ge N-k+2$, we have $F_{c^N} = O(\lambda^{n-k+2} F_{S^N(N,\max)})$.*

Proof. The proof is basically a repetition of that of Theorem 2.3. Having successively applied the boosting and merging techniques n times, we have

$$\begin{aligned}\vec{F}'_{A(N)} &= Q(N)^T_{A(N)}(N) \cdot (\lambda^N \vec{F}_{A(N)}) \\ &\quad + \sum_{j=0}^{N} Q(N)^T_{B(j),A(N)}(j+1) \cdot (\lambda^{j+1} \vec{F}_{B(j)}) + O(\lambda^{N+2} F_{S^N(N,\max)}).\end{aligned} \tag{3.3}$$

Let $D = \{c^N \in A(N) : h^N(c^N) \ge 2\}$. Because $Q(N)^T_{A(N)\backslash D,D}(N) = 0$ and $Q(N)^T_{B(N),D}(N+1) = 0$,

$$\vec{F}'_D = Q(N)^T_D(N) \cdot (\lambda^N \vec{F}_D) + O(\lambda^{N+2} F_{S^N(N,\max)}).$$

This implies that $\vec{F}_D = O(\lambda^2 F_{S^N(N,\max)})$ as in Lemma 1.1. Similarly, we consider

$$\begin{aligned}\vec{F}'_{A(N-1)} &= Q(N-1)^T_{A(N-1)}(N-1) \cdot (\lambda^{N-1} \vec{F}_{A(N-1)}) \\ &\quad + \sum_{j=0}^{N} Q(N-1)^T_{B(j),A(N)}(j+1) \cdot (\lambda^{j+1} \vec{F}_{B(j)}) + O(\lambda^{N+2} F_{S^N(N,\max)})\end{aligned}$$

and obtain, with $G = A(N-1) \cap \{c^N : h^n(c^N) \ge 3\}$,

$$\vec{F}'_G = Q(N-1)^T_G(N-1) \cdot (\lambda^{N-1} \vec{F}_G) + O(\lambda^{N+2} F_{S^N(N,\max)}).$$

Thus $\vec{F}_G = O(\lambda^3 F_{S^N(N,\max)})$. The lemma follows now by an obvious induction. □

We are now ready to prove the main theorem of this paper.

Proof of Theorem 0.2. Let $i \in c^N \in S^N(k) \subseteq S^k(k)$ with $h^N(c^N) = N-k+1$. From (3.3), the forward equation of states in $A(N) \cap \{c^N : h^N(c^N) = 1\} = A(N,1)$ assumes the following form:

$$\begin{aligned}\vec{F}'_{A(N,1)} &= Q(N)^T_{A(N,1)}(N) \cdot (\lambda^N \vec{F}_{A(N,1)}) \\ &\quad + \sum_{j=0}^{N} Q(N)^T_{B(j),A(N,1)}(j+1) \cdot (\lambda^{j+1} \vec{F}_{B(j)}) + O(\lambda^{N+2} F_{S^N(N,\max)}).\end{aligned}$$

Note that all terms of the form $\{\lambda^N F_{c^N} : c^N \in A(N), h^N(c^N) \ge 2\}$ have been absorbed into the error term by Lemma 3.2 and therefore do not appear in (3.3). The same proof

of Lemma 2.2 can now be applied to yield $F_{c^N} = \theta_{c^N} \cdot \lambda F_{S^N(N,\max)} + O(\lambda^2 F_{S^N(N,\max)})$ for each $c^N \in A(N,1)$ and θ_{c^N} is a positive constant. The forward equation of states in $A(N-1) \cap \{c^N : h^N(c^N) = 2\} = A(N-1,2)$ can be written as

$$\begin{aligned}\vec{F}'_{A(N-1,2)} &= Q(N-1)^T_{A(N-1,2)}(N-1) \cdot (\lambda^{N-1}\vec{F}_{A(N-1,2)}) \\ &\quad + Q(N-1)^T_{A(N,1),A(N-1,2)}(N) \cdot (\lambda^N \vec{F}_{A(N,1)}) \\ &\quad + \sum_{j=0}^{N} Q(N-1)^T_{B(j),A(N-1,2)}(j+1) \cdot (\lambda^{j+1}\vec{F}_{B(j)}) + O(\lambda^{N+2}F_{S^N(N,\max)}).\end{aligned}$$

This, again, will yield that $F_{c^N} = \theta_{c^N} \cdot \lambda^2 F_{S^N(N,\max)} + O(\lambda^3 F_{S^N(N,\max)})$ for each $c^N \in A(N-1,2)$. The theorem is now completed for any state $i \in H_r = \{i : i \in c^N \in S^N(k)$ with $h^N(c^N) = N - k + r$ for some $k\}$, where $r = 0$ or 1. A similar induction on r can obviously complete the proof of the theorem. □

4. Examples.

Example 1. $S = \{1,2,3,4,a\}$ and has a linear neighborhood structure. The cost function $U(i,j) = (U(j) - U(i))^+$ is determined by a potential function $U(\cdot)$ with $U(1) = U(3) = 1$ and $U(2) = U(4) = 3$. It is easy to compute that $U(1,2) = U(3,2) = U(3,4) = 2$ and $U(2,1) = U(2,3) = U(4,3) = U(4,a) = 0$. The forward equation of $\{1,2,3,4\}$ is as follows:

$$\begin{aligned}F_1' &= -p_1\lambda^2 F_1 + p_{21}F_2, \\ F_2' &= -p_2 F_2 + p_1\lambda^2 F_1 + p_{32}\lambda^2 F_3, \\ F_3' &= -p_3\lambda^2 F_3 + p_{23}F_2 + p_{43}F_4, \\ F_4' &= -p_4 F_4 + p_{34}\lambda^2 F_3,\end{aligned} \tag{4.1}$$

where $p_1 = p_{12}$, $p_2 = p_{21} + p_{23}$, $p_3 = p_{32} + p_{34}$, and $p_4 = p_{43} + p_{4a}$. In matrix form, the forward equation of $\{2, 4\}$ is as follows:

$$\begin{pmatrix}F_2\\F_4\end{pmatrix}' = \begin{pmatrix}-p_2 & 0\\0 & -p_4\end{pmatrix}\begin{pmatrix}F_2\\F_4\end{pmatrix} + \begin{pmatrix}p_1 & p_{32}\\0 & p_{34}\end{pmatrix}\begin{pmatrix}\lambda^2 F_1\\\lambda^2 F_3\end{pmatrix}.$$

The boosting and merging technique (Theorem 1.3) implies that (see (1.5;0))

$$\begin{pmatrix}F_2\\F_4\end{pmatrix} = \begin{pmatrix}p_2 & 0\\0 & p_4\end{pmatrix}^{-1}\begin{pmatrix}p_1 & p_{32}\\0 & p_{34}\end{pmatrix}\begin{pmatrix}\lambda^2 F_1\\\lambda^2 F_3\end{pmatrix} + O(\lambda^3 F_1 + \lambda^3 F_3). \tag{4.2}$$

By eliminating F_2, F_4 from the forward equation of $\{1,3\}$,

$$\begin{aligned}\begin{pmatrix}F_1\\F_3\end{pmatrix}' &= \left\{\begin{pmatrix}-p_1 & 0\\0 & -p_3\end{pmatrix} + \begin{pmatrix}p_{21} & 0\\p_{23} & p_{43}\end{pmatrix}\begin{pmatrix}p_1 p_2^{-1} & p_{32}p_2^{-1}\\0 & p_{34}p_4^{-1}\end{pmatrix}\right\}\begin{pmatrix}\lambda^2 F_1\\\lambda^2 F_3\end{pmatrix} \\ &\quad + O(\lambda^3 F_1 + \lambda^3 F_3) \\ &= Q(2)^T_{S^2(2)}(2)\begin{pmatrix}\lambda^2 F_1\\\lambda^2 F_3\end{pmatrix} + O(\lambda^3 F_1 + \lambda^3 F_3).\end{aligned} \tag{4.3}$$

(See (2.2;N).) Because $Q(2)^T_{S^2(2)}(2)$ is irreducible, the Perron–Frobenius property is thus satisfied. Lemma 2.1 then implies the existence of positive constants θ_1 and θ_3 such that

$$F_i = \theta_i(F_1 + F_3) + O(\lambda(F_1 + F_3)), \qquad i = 1,3. \tag{4.4}$$

The relative orders among all F_i's are specified by (4.2) and (4.4). To find their asymptotic behaviors we multiply (4.3) by an eigenvector $\vec{v} = (v_1, v_3)$ corresponding to the largest eigenvalue, say $-\delta$, of $Q(2)^T_{S^2(2)}(2)$. By the Perron–Frobenius theorem, $\delta > 0$ and v_1, v_3 can be assumed positive. This leads to

$$g' = -\delta(\lambda^2 + O(\lambda^3)) \cdot g, \quad \text{where } g = v_1 F_1 + v_3 F_3.$$

An integration shows

$$g(t) \approx \exp\left[-\delta \int_0^t (\lambda^2(s) + O(\lambda^3))ds\right].$$

The asymptotic behaviors of F_i's then follow immediately. Because $h^2(2) = h^2(4) = 2$, this result is in accordance with Theorem 0.2.

Example 2. $S = \{1, 2, a\}$. Let $U(1) = 1$, $U(2) = 2$, $U(i, j) = [U(j) - U(i)]^+$, and $U(i, a) = 0$ for $i, j = 1, 2$. The forward equation of $\{1, 2\}$ is as follows:

$$F_1' = -(p_1 + p_{12}\lambda)F_1 + p_{21}F_2,$$
$$F_2' = -p_2 F_2 + p_{12}\lambda F_1.$$

In this case, $N = 0$ and the Perron–Frobenius property is satisfied if and only if $p_1 \neq p_2$. Let $-\delta = \max(-p_1, -p_2)$. If $-\delta = -p_1 > -p_2$, then

$$F_1 = \exp\left(-\delta t + \int_0^t O(\lambda)ds\right)$$

and $F_2 = O(\lambda) \cdot F_1$. If $-\delta = -p_2 > -p_1$, then

$$F_1 = \exp\left(-\delta t + \int_0^t O(\lambda)ds\right)$$

and $F_2 = O(1) \cdot F_1$.

On the other hand, suppose $p_1 = p_2 (= 1$ for brevity). Then $(F_2 - \lambda^{1/2}F_1)' = -(F_2 - \lambda^{1/2}F_1) + O(\lambda^{1/2}(F_2 + \lambda^{1/2}F_1))$. Hence

$$F_2 - \lambda^{1/2}F_1 = e^{-t}\left(c + \int_0^t e^s\, O(\lambda^{1/2}(F_2 + \lambda^{1/2}F_1))ds\right)$$

and by l'Hôpital's rule,

$$F_2 - \lambda^{1/2}F_1 = o(F_2 + \lambda^{1/2}F_1) \quad \text{if } \int^\infty \lambda^{1/2} = \infty.$$

Thus $\lim P(X_t = 1) \cdot \lambda^{1/2}(t)/P(X_t = 2) = \beta > 0$. Note that the height function h defined in the second remark after Theorem 0.2 is 0 and does not reflect the exact convergence rate for state 2.

Example 3. $S = \{1, 2, a\}$ and $U(2, 1) = U(2, a) = 0$, $U(1, 2) = 1$. This example intends to show that the expected time of hitting a global minimum can be infinity for a regular-simulated annealing process. The forward equation of $\{1, 2\}$ is as follows:

$$F_1' = -p_1\lambda F_1 + p_{21}F_2,$$
$$F_2' = -p_2 F_2 + p_1\lambda F_1,$$

where $p_1 = p_{12}$ and $p_2 = p_{21} + p_{2a}$. Take $T(t) = c/(\log t)$. Then $\lambda(t) = \exp(-1/T(t)) = t^{-1/c}$ and $\int^{\infty} \lambda(t)dt = \infty$ if and only if $c \geq 1$. If $0 < c < 1$, then

$$F_1(t) \geq F_1(t_0) \exp\left(-p_1 \int_{t_0}^{\infty} \lambda(s)ds\right) > 0$$

and thus $P(\tau = \infty) > 0$, where τ is the hitting time of state a for a regular-simulated annealing process with $\{a\} = \{\text{global minimum}\}$. If $c \geq 1$, then [1, Cor. 0.3] and Theorem 0.2 are applicable. In particular, $P(\tau < \infty) = 1$. From Theorem 1.3, we have $F_2 = p_1 p_2^{-1} \lambda F_1 + O(\lambda^2 F_1)$. Thus $F_1' = -p_1(1 - p_{21}p_2^{-1})\lambda F_1 + O(\lambda^2 F_1)$. Obviously,

$$F_1(t) \approx \exp\left[(-p_1(1 - p_{21}p_2^{-1})) \int_0^t (\lambda(s) + O(\lambda^2))ds\right]$$

asymptotically. By (0.3), $E\tau \approx \int_0^{\infty} F_1(t)dt$. It is thus easy to see that $E\tau < \infty$ if and only if (i) $c > 1$ or (ii) $c = 1$ and $p_1(1 - p_{21}p_2^{-1}) > 1$.

Acknowledgment. We thank the referee for his suggestions for improving the presentation of this paper.

ASYMPTOTIC FIRST HITTING-TIME DISTRIBUTION OF ANNEALING PROCESSES*

CHRISTIAN MAZZA†

Abstract. This paper presents asymptotics for the distribution of the first hitting time τ of $E_{\min}$ for the continuous-time version of simulated annealing processes. The method considers the backward equation associated with the process. It is shown that under certain assumptions, it is possible to characterize the eigenvectors of the transition matrix with the help of polynomials that are related to some families of graphs.

Key words. simulated annealing, continuous time, first hitting time, digraph, eigenvector

AMS subject classifications. primary 60J27, 60J99; secondary 15A51, 15A18, 90B40

1. Introduction.

Let S be a finite set and let $E : S \to \mathbb{R}$ be an arbitrary real-valued function. Simulated annealing is a Monte Carlo method for locating the minima of $E(\cdot)$ on S, i.e., $E_{\min} := \{i \in S;\ E(i) = \min_{j\in S} E(j)\}$. This probabilistic algorithm is defined to be a time nonhomogeneous Markov chain $X(t)$, $t \in \mathbb{N}$, on S with transition matrix

$$P_{ij}(T(t)) = q_{ij} \exp(-[E(j) - E(i)]^+ T(t)^{-1}), \qquad i \neq j, \tag{1}$$

where $[\cdot]^+$ denotes the positive part, and $T(t)$ is a positive function converging to 0 as $t \to \infty$, called temperature function. (q_{ij}) is the transition matrix of an irreducible Markov chain on S. The question of convergence for this kind of processes has been studied by many authors [Hajek (1988)], [Chiang and Chow (1988b)], [Holley and Stroock (1988)]. It has been proved [Hajek (1988)] that there exists a constant $D \geq 0$ such that $\lim_{t\to\infty} P(X(t) \in E_{\min}) = 1$ if and only if $\sum_{t=1}^{\infty} \exp(-DT(t)^{-1}) = +\infty$. Define τ to be the first hitting time of $E_{\min}$. This article presents asymptotics for the distribution of τ for the continuous-time version of the Markov chain $X(t)$. The process runs as follows (see, e.g., [Feller (1950)]). Let $q_i(t) := \sum_{j\neq i} P_{ij}(T(t))$ and $\Gamma(i,j,t) := P_{ij}(T(t))q_i(t)^{-1}$, for $i \neq j$; $\Gamma(i,i,t) := 0$ for all t, for all i. If at epoch t the process is in state i, the probability that, between t and $t+h$, a move occurs is $q_i(t)h + o(h)$. $\Gamma(i,j,t)$ is interpreted as the conditional probability that, if a move from i occurs between t and $t+h$, the process jumps to j. Intuitively the process can be described as follows: The process being at time t at location x waits for an exponential time Δ with mean 1 before it selects at random a neighbor y with probability q_{xy}. When $E(y) \leq E(x)$, the process moves to y. However, when $E(y) > E(x)$, it moves to y with probability $\exp(-T(t+\Delta)^{-1}(E(y)-E(x)))$, and with probability $1-\exp(-T(t+\Delta)^{-1}(E(y)-E(x)))$ it stays at x. The sample functions of $X(\cdot)$ are S-valued right-continuous step functions. Mathematically, the process is described via its transition semigroup, which is expressed by a system of differential equations.

1.1. The Fokker–Planck equation.

Let $P_{ij}(t',t)$ be the transition function associated with the annealing process. Consider the operator

$$L_T\Phi(i) := \sum_{j\in S} (\Phi(j) - \Phi(i))P_{ij}(T), \qquad i \in S, \tag{2}$$

for $\Phi : S \to \mathbb{R}$. Transition probabilities are determined by the Fokker–Planck, or forward equation,

$$\frac{\partial}{\partial t} P_{ij}(t',t) = [L^*_{T(t)} P_{i,\cdot}(t',t)](j), \qquad t \geq t', \tag{3}$$

* Received by the editors March 20, 1991; accepted for publication (in revised form) March 5, 1993. This work was partially supported by the Swiss National Science Foundation.

† Institut de Mathématiques, Université de Fribourg, CH-1700 Fribourg, Switzerland.

$$P_{ij}(t',t') = \delta_{ij}, \tag{4}$$

where (3) means

$$\frac{\partial}{\partial t}[P(t',t)\Phi](i) = [P(t',t)L_{T(t)}\Phi](i), \qquad t \geq t',$$

for $\Phi : S \to \mathbb{R}$, and where

$$[P(t',t)\Phi](i) := \sum_{j\in S} \Phi(j)P_{ij}(t',t). \tag{5}$$

$P_{ij}(t',t)$ satisfies the Chapman–Kolmogorov equation

$$P_{ij}(t',t) = \sum_{k\in S} P_{ik}(t',t'')P_{kj}(t'',t), \qquad 0 \leq t' < t'' < t,$$

which, in addition to the Fokker–Planck equation, yields the backward equation

$$\frac{\partial}{\partial t'}[P(t',t)\Phi](i) = -[L_{T(t')}P(t',t)\Phi](i), \qquad 0 \leq t' \leq t. \tag{6}$$

Once the initial distribution ν has been specified, the transition kernel $P(t',t)$ completely determines the annealing process.

1.2. First hitting-time distribution and backward equation. Let $\tau := \inf\{t \geq 0;\ X(t) \in E_{\min}\}$ be the first hitting time of $E_{\min}$. Consider the process $\tilde{X}(\cdot)$ on S with

$$\tilde{P}_{ij}(T(t)) := \begin{cases} P_{ij}(T(t)) & \text{if } i \in S - E_{\min}, \\ 0 & \text{if } i \in E_{\min} \text{ and } i \neq j, \\ 1 & \text{if } i = j \text{ and } i \in E_{\min}, \end{cases}$$

as infinitesimal generator. Start $X(\cdot)$ and $\tilde{X}(\cdot)$ at time t_0 at location $i \in S - E_{\min}$. Up to τ, the distribution of $\tilde{X}(\cdot)$ is then the same as the distribution $X(\cdot)$. Let $\Phi : S \to \mathbb{R}$. The backward equation for the absorbing chain $\tilde{X}(\cdot)$,

$$\frac{\partial}{\partial t'}[\tilde{P}(t',t)\Phi](i) = -[\tilde{L}_{T(t')}\tilde{P}(t',t)\Phi](i), \qquad 0 \leq t' \leq t, \tag{7}$$

permits a characterization of the distribution of the first hitting time τ. Indeed, choose the indicator function of $S - E_{\min}$ for Φ. Then, for $i \in E_{\min}^c$,

$$[\tilde{P}(t',t)\Phi](i) = \sum_{j\in S-E_{\min}} P(\tilde{X}(t) = j|\tilde{X}(t') = i) \tag{8}$$

$$= P(\tilde{X}(t) \in E_{\min}^c|\tilde{X}(t') = i) = P(\tau > t|\tilde{X}(t') = i). \tag{9}$$

Let $y(i,t',t) := P(\tau > t|\tilde{X}(t') = i)$. As $[\tilde{P}(t',t)\Phi](i) = y(i,t',t)$, we obtain, by (7),

$$\begin{aligned} \frac{\partial}{\partial t'}y(i,t',t) &= -\sum_{k\in S}[\tilde{P}(t',t)\Phi](k)\tilde{P}_{ik}(T(t')) + [\tilde{P}(t',t)\Phi](i) \\ &= y(i,t',t) - \sum_{k\in S-E_{\min}} y(k,t',t)\tilde{P}_{ik}(T(t')). \end{aligned}$$

In matrix form, if $Y(t',t) := (y(i,t',t))_{i\in S-E_{\min}}$, we have

$$\frac{\partial Y(t',t)}{\partial t'} \equiv A(t')Y(t',t), \qquad 0 \le t' \le t, \tag{10}$$

$$Y(t,t) = (1,\dots,1)^{\mathrm{Tr}}, \tag{11}$$

where Tr denotes the matrix transpose, $A(t') = Id - B(T(t'))$, and $B(T(t'))$ is the matrix obtained from $P(T(t'))$ by deleting the rows and the columns corresponding to states of $E_{\min}$. An alternative approach could be to consider the forward equation for the absorbing chain $\tilde{X}(\cdot)$ (as in [Lawler and Sokal (1988)]) to obtain asymptotics for the probabilities $P(\tilde{X}(t) = j|\tilde{X}(t') = i)$, $i, j \in E_{\min}^c$, and therefore for (8). More precisely, set $\Phi := 1_{\{j\}}$, $j \in E_{\min}^c$ in the forward equation for $\tilde{X}(\cdot)$; using the fact that $\tilde{X}(\cdot)$ is absorbed on $E_{\min}$, we obtain

$$\frac{\partial}{\partial t}\bar{Y}(t',t) \equiv -\bar{Y}(t',t)A(t), \qquad t' \le t, \tag{12}$$

where $\bar{Y}(t',t)$ is the row vector

$$\bar{Y}(t',t) \equiv (\tilde{P}_{ij}(t',t))_{j\in E_{\min}^c}$$

and the matrices $A(t)$, $t \in \mathbb{R}$ are as above. In both approaches we are confronted with linear differential systems related to the matrices $A(t)$. In the special case of time-homogeneous Markov chains, i.e., $A(t) \equiv A$, the matrices A and $\exp(\int_{t'}^{t} A(u)du) \equiv \exp((t-t')A)$ commute, and the relations $y(i,t',t) \equiv \bar{Y}(t',t)(1,\dots,1)^{\mathrm{Tr}}$, and (12) yield

$$\frac{\partial}{\partial t}Y(t',t) \equiv -AY(t',t), \qquad t \ge t',$$

$$Y(t',t') = (1,\dots,1)^{\mathrm{Tr}}.$$

A powerful result of [Levinson (1948)] (see, e.g., [Eastham (1989)]) yields explicit formulas for the solutions of (10) in terms of the eigenvalues and eigenvectors of the generator. A study of the spectrum can be done along ideas of [Freidlin and Wentzell (1984)] on large deviations. We characterize the eigenvectors with the help of polynomials related to some families of digraphs. Under certain assumptions it is then possible to obtain asymptotics of the form

$$P(\tau \ge t|X(t_0) = k) = (p_k + o(1))\exp\left(-b_k\int_{t_0}^{t}\exp(-D(k)T(v)^{-1})dv\right), \tag{13}$$

as $t \to \infty$, for $k \in S - E_{\min}$, where $p_k \ge 0$, $b_k > 0$, and $D(k) \ge 0$. Although the results are obtained under certain hypotheses, the method has the advantage of not being limited to the simulated annealing case, and could be useful for studying Markov chains with transition probabilities of order $\varepsilon(t)^{V_{ij}}$, where $\varepsilon(t) \to 0$ as $t \to \infty$, and $V_{ij} \le +\infty$ are nonnegative constants (see, e.g., [Connors and Kumar (1989)]). As stated above, the first ingredient of the approach is a theorem of Levinson on systems of differential equations.

THEOREM 1.2.1 [Levinson (1948)]. *Let $\Lambda(t)$ be a diagonal matrix*

$$\Lambda(t) = \mathrm{Diag}(\lambda_1(t),\dots,\lambda_N(t)),$$

which verifies condition L. For all integer pairs (i,j) in $[1,N]$, $i \ne j$ and for all t', t such that $t_0 \le t' \le t$, either

$$\int_{t'}^{t}\Re(\lambda_i(v) - \lambda_j(v))dv \le K_1 \tag{14}$$

or

$$\int_{t'}^{t} \Re(\lambda_i(v) - \lambda_j(v))dv \geq K_2, \tag{15}$$

where K_1 and K_2 are two real constants. Let $R(t)$ be an $N \times N$ matrix satisfying

$$\int_0^{\infty} |R(t)|dt < \infty, \tag{16}$$

where $|R(t)|$ is the matrix maximum norm. Then, when $t \to \infty$, the differential system

$$\frac{dx}{dt} = \{\Lambda(t) + R(t)\}x(t) \tag{17}$$

has solutions $x_u(t)$, $1 \leq u \leq N$, such that

$$x_u(t) = (e_u + o(1)) \exp\left(\int_{t_0}^{t} \lambda_u(v)dv\right), \tag{18}$$

where e_u is the uth unit vector.

2. Spectral analysis. To obtain information on solutions of (10), we use Levinson's theorem, which applies to differential systems in the so called "Levinson form" (17); knowledge about the spectrum and about the eigenvectors of $B(T)$ is then necessary to put the system in Levinson form by diagonalization.

2.1. Wentzell approximations. Wentzell approximations concerning large deviations for Markov processes can be used in our situation [Wentzell (1972)]. Let $P(T) = (P_{ij}(T))$ be a family of stochastic matrices of the form

$$P_{ij}(T) = l_{ij} \exp(-V_{ij}T^{-1}), \qquad i \neq j, \tag{19}$$

where l_{ij}, $V_{ij} \leq \infty$ are nonnegative constants.

DEFINITION 2.1.1. *Let $W \subset S$. We associate with each $W \subset S$ a set of digraphs $G(W)$, called Wentzell graphs, as follows. By definition, a digraph $g \in G(W)$ with node set S is a family of arrows $(i \to j)$, $i, j \in S$, $i \neq j$, satisfying the following conditions*: (1) *g does not contain any cycle*, (2) *for each $i \in S - W$, g contains a unique arrow starting at i*; (3) *for all $i \in W$, g contains no arrow starting at i. ($G(S)$ consists of just the empty graph). $G^{(u)}$, $1 \leq u \leq |S|$, is the set of the W-graphs for all $W \subset S$, $|W| = u$. Let $g \in G(W)$, $W \subset S$, and $G := \cup_{W \subset S} G(W)$. Consider the function*

$$E(\cdot) : G \to \mathbb{R} \tag{20}$$

defined by

$$E(i \to j) := V_{ij}, \qquad E(g) := \sum_{(i \to j) \in g} V_{ij}. \tag{21}$$

Set

$$V^{(u)} := \min_{g \in G^{(u)}} E(g) \tag{22}$$

for $u = 1, \ldots, |S|$ ($V^{(|S|)} := 0$).

LEMMA 2.1.2 [Wentzell (1972)]. *Let* $A := \mathrm{Diag}(1-a_1, 1-a_2, \ldots, 1-a_N)$; *let* $(P_{ij}) = P \in \mathbb{R}^{N\times N}$ *be a stochastic matrix. Then* $\det(A-P)$ *is a multinomial in the indeterminates* a_i; *the coefficient of* $(-a_{i_1})\cdots(-a_{i_n})$ *is the sum of products* $\pi(g) := \prod_{(i\to j)\in g} P_{ij}$, *where the sum is taken over all the graphs of* $G\{i_1,\ldots,i_n\}$. *Let* $a = 1-\lambda$, *where* λ *is an eigenvalue of* P. *Then*

$$A^1(-a) + A^2(-a)^2 + \cdots + A^N(-a)^N = 0, \tag{23}$$

where

$$A^u := \sum_{g\in G^u} \pi(g). \tag{24}$$

THEOREM 2.1.3 [Wentzell (1972)]. *Let* $\lambda_1(T) = 1$, *and let* $\lambda_2(T),\ldots,\lambda_N(T)$ *denote the eigenvalues of the matrix* $P(T)$, *arranged in order of decreasing real part. Then, for* $u = 2,\ldots,N$,

$$\Re(1-\lambda_u(T)) \asymp \exp(-(V^{(u-1)} - V^{(u)})T^{-1}), \tag{25}$$

where $\Re(\cdot)$ *denotes the real part and* $\asymp$ *indicates that* $\lim_{T\to 0} T\log(1-\Re(\lambda_u(T))) = -(V^{(u-1)} - V^{(u)})$, *for all* u. *Moreover, the broken line through the points* $(u, V^{(u)})$ *is convex downward,*

$$V^{(1)} - V^{(2)} \geq V^{(2)} - V^{(3)} \geq \cdots \geq V^{(N-1)} - V^{(N)}. \tag{26}$$

Originally, (25) yields for stochastic matrices with entries satisfying

$$\lim_{T\to 0} T\log(P_{ij}(T)) = -V_{ij}.$$

2.2. Spectral analysis of $B(T)$. Let $E_{\min} = \{s+1, s+2, \ldots, s+m\}$, where $s := |S - E_{\min}|$ and $N = s+m$. Define $B(T)$ to be the substochastic matrix obtained from $P(T)$ by deleting the rows and columns corresponding to the states of $E_{\min}$. Complete $B(T)$ to a stochastic matrix by defining the states of $E_{\min}$ as absorbing

$$B'_{ij}(T) := 0, \quad \forall\, i \in E_{\min}, \quad j \neq i,$$
$$B'_{ij}(T) := P_{ij}(T(t)), \quad \forall\, i \in S - E_{\min}, \quad j \neq i.$$

All the coefficients of $B'(T)$ have exponential order. In particular, $B'_{ij}(T) = \exp(-\infty T)$ for all $i \in E_{\min}$, for all $T > 0$. Define the constants

$$V_{ij} := \begin{cases} [E(j) - E(i)]^+ & \text{if } q_{ij} > 0 \text{ and } i \notin E_{\min}, \\ +\infty & \text{if } i \in E_{\min} \text{ or if } q_{ij} = 0. \end{cases} \tag{27}$$

Let $-\lambda(T)$ be a nonzero eigenvalue of $B'(T) - Id$. By (25), there exist constants $V^{(u)}$ for $m \leq u \leq s+m$ such that

$$\lambda(T) \asymp \exp(-(V^{(u)} - V^{(u+1)})T^{-1}) \tag{28}$$

as $T \to 0$. States of $E_{\min}$ are absorbing. Assume $W \subset S$ is such that $|W| < m = |E_{\min}|$. Each $g \in G(W)$ then has one arrow $(i \to j)$ with $i \in E_{\min}$; as $E(i\to j) = \infty$, $E(g) = \infty$ for all $g \in G(W)$. Thus

$$V^{(u)} = \infty, \quad A^u = 0, \quad \text{for } 0 \leq u < m \tag{29}$$

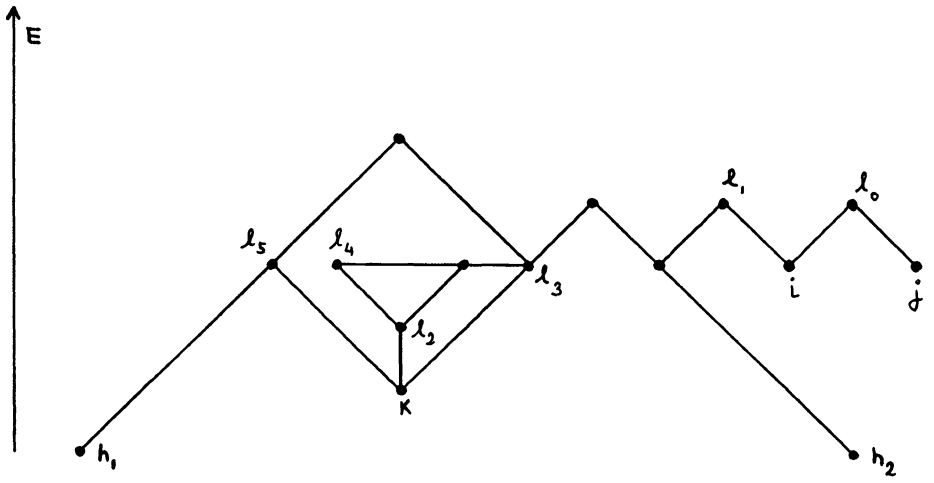

FIG. 1. $E_{\min} = \{h_1, h_2\}$, $E_{\text{locmin}} = \{k, i\}$, $d(k) = E(l_5) - E(k)$, $d(i) = E(l_1) - E(i)$, $d(j) = E(l_0) - E(j)$, $[k] = \{k, l_2, l_3, l_4\}$ *and* $[i] = \{i\}$, $[j] = \{j\}$, $[j] \subset [i]$.

(the m zero eigenvalues corresponding to states of $E_{\min}$).

DEFINITION 2.2.1. *Assume that* $q_{ij} > 0$ *if and only if* $q_{ji} > 0$. *Two states* i *and* j *are neighbors if and only if* $q_{ij} > 0$. *We denote by* E_{locmin} *the set of nodes* $i \in S - E_{\min}$ *for which* $E(j) \geq E(i)$ *for all* j *in the neighborhood of* i. *Two states* i *and* j *are said to communicate at height* h *if either* $i = j$ *and* $E(i) \leq h$, *or if there is a path*

$$i = x_0 \to x_1 \to \cdots \to x_n = j,$$

such that $E(x_u) \leq h$ *for* $0 \leq u \leq n$ *and* $q_{x_{u-1}x_u} > 0$ *for* $1 \leq u \leq n$. *We then have an equivalence relation* $\cong_h$ *on the set* $S_h := \{p \in S;\ E(p) \leq h\}$. *For* $i \in S - E_{\min}$, *let* $d(i)$ *be the depth of* i *defined by the relation*

$$E(i) + d(i) := \inf\{h > 0;\ \exists j \in S_h \text{ with } i \underset{h}{\cong} j \text{ and } E(j) < E(i)\} \tag{30}$$

($d(i) = 0$ *if* $i \notin E_{\text{locmin}}$), *and define the set*

$$[i] := \{p \in S;\ \exists h < E(i) + d(i) \text{ with } i \underset{h}{\cong} p\} \tag{31}$$

(see Fig. 1).

DEFINITION 2.2.2. *We say we are in the generic case if the following conditions are satisfied*: (1) $V^{(u)} - V^{(u+1)} > V^{(u+1)} - V^{(u+2)}$ *if* $V^{(u)} - V^{(u+1)} \neq 0$, *for* $m \leq u$; (2) *if* $i, j \in S - E_{\min}$ *are neighbors, then* $E(i) \neq E(j)$; (3) *for all* $(i, j) \in (S - E_{\min} - E_{\text{locmin}})^2$, $i \neq j$, $\lim_{T \to 0} P_{ii}(T) \neq \lim_{T \to 0} P_{jj}(T)$.

Remark 2.2.3. By (25), Definition 2.2.2(1) implies that there exists $t_0 \geq 0$ such that the eigenvalues $\lambda(t)$ of $B(T(t))$, which converge to 1, are all different for $t \geq t_0$. Definition 2.2.2(1) is hard to check without knowledge about the constants $V^{(u)}$; we will see in §2.3 that they are strongly related to the depths associated with the local minima, and therefore Definition 2.2.2(1) will be much easier to check. Assume the states are arranged in order of increasing values of $E(\cdot)$ and that we are in the generic case. Let $\alpha := |E_{\text{locmin}}|$. Considering the form of the transition matrix (1) and the hypothesis of Definition 2.2.2(2), we see that the limiting matrix $B(0^+)$ is triangular, and has α eigenvalues equal to 1 and $s - \alpha$ different

eigenvalues $1-\lambda<1$ (by Definition 2.2.2(3)). Let k be a node of $S-E_{\min}-E_{\text{locmin}}$; we associate with k the simple eigenvalue $-\lambda_{\sigma(k)}(T)$ of $B(T)-Id$, which converges to $-\lambda_{\sigma(k)}(0^+):=P_{kk}(0^+)-1\neq 0$. Define $\mathcal{N}(k)^-:=\{j\neq k;\ E(j)\leq E(k) \text{ and } q_{jk}>0\}$. As $1-P_{kk}(0^+)=\sum_{i\neq k}P_{ki}(0^+)$, Definition 2.2.2(3) becomes

$$\sum_{i\in\mathcal{N}(k)^-} q_{ki}\neq \sum_{i\in\mathcal{N}(j)^-} q_{ji}$$

for all $k\neq j$, $k,\ j\in S-E_{\min}-E_{\text{locmin}}$.

Hypothesis 2.2.4. Assume that Definition 2.2.2 holds and that

$$[k]\cap E_{\text{locmin}}=\{k\},\qquad \forall\, k\in E_{\text{locmin}}. \tag{32}$$

Note that the depths of the local minima are arranged in order of increasing value,

$$0\leq d_1\leq d_2\leq\cdots\leq d_{\sigma(k)-1}\leq d_{\sigma(k)}\leq d_{\sigma(k)+1}\leq\cdots\leq d_\alpha, \tag{33}$$

where $\alpha=|E_{\text{locmin}}|$, $d_{\sigma(k)}$ is the depth of the local minimum k ($d_{\sigma(k)}=d(k)$), and σ is a permutation of $\{1,\dots,s\}$. We set $d_{\sigma(j)}:=0$ for $j\notin E_{\text{locmin}}$.

2.3. Construction of optimal graphs. The constants $V^{(u)}$ appearing in (22) have been computed in [Chiang and Chow (1988a)]. For our purpose, we construct digraphs $g\in G^u$ for which $E(g)=V^{(u)}$. This constructive method will be useful in the remaining argument. Assume that (32) is satisfied. Let (S,Γ) be the graph with node set S and edge set Γ defined as follows: $(i,j)\in\Gamma$ if and only if $q_{ij}>0$. We identify, for each $i\in E_{\text{locmin}}$, all nodes $p\in[i]$ in a class $\langle i\rangle$. If $k\in S-\cup_{j\in E_{\text{locmin}}}[j]$, define $\langle k\rangle:=\{k\}$. Let $\langle k\rangle$ and $\langle k'\rangle$ be two classes of this quotient set $\tilde{S}$. Now define a new graph $(\tilde{S},\tilde{\Gamma})$ with node set $\tilde{S}$ and edge set $\tilde{\Gamma}$: if $k,\ k'\in S-\cup_{j\in E_{\text{locmin}}}[j]$ and $(k,k')\in\Gamma$, then $(k,k')=(\langle k\rangle,\langle k'\rangle)\in\tilde{\Gamma}$. If $k\in S-\cup_{j\in E_{\text{locmin}}}[j]$, $k'\in[i]$ for $i\in E_{\text{locmin}}$, and $(k,k')\in\Gamma$, then $(k,\langle i\rangle)\in\tilde{\Gamma}$. This quotient graph $(\tilde{S},\tilde{\Gamma})$ is in fact a multigraph. Consider the function $\tilde{E}$, which is defined on $\tilde{S}$,

$$\tilde{E}(\langle k\rangle):=\begin{cases} E(i)+d(i) & \text{if } k\in[i] \text{ for some } i\in E_{\text{locmin}},\\ E(k) & \text{otherwise,}\end{cases}$$

and extend $\tilde{E}(\cdot)$ to families of Wentzell graphs on $\tilde{S}$, as in Definition 2.1.1 (see Fig. 2).

Let $\tilde{\gamma}$ be a path in $(\tilde{S},\tilde{\Gamma})$. We say that $\tilde{\gamma}$ is monotonically decreasing (respectively, increasing) if $\tilde{E}$ is decreasing (respectively, increasing) along $\tilde{\gamma}$. The quotient graph $(\tilde{S},\tilde{\Gamma})$ contains no strict local minimum for $\tilde{E}$. Let $\langle j_1\rangle$ be an arbitrary node of $\tilde{S}$. Choose any neighbor $\langle l\rangle$ of $\langle j_1\rangle$, with $(\langle j_1\rangle,\langle l\rangle)\in\tilde{\Gamma}$ and $\tilde{E}(\langle l\rangle)\leq\tilde{E}(\langle j_1\rangle)$. Proceeding in this way, we obtain a nonincreasing path $\tilde{\gamma}_1$ that starts at $\langle j_1\rangle$ and ends in $E_{\min}$. Then choose an arbitrary element j_2 in the complement of $\tilde{S}-\tilde{\gamma}_1$. Working in the same way, we obtain a nonincreasing path $\tilde{\gamma}_2$ that starts at j_2 and stops the first time $\tilde{\gamma}_2$ meets $\tilde{\gamma}_1\cup E_{\min}$. We then obtain a directed forest $\tilde{g}\in\tilde{G}(E_{\min})$, with roots in $E_{\min}$, which is the union of directed trees, each of them being pointed in $E_{\min}$ (cf. Fig. 3).

Each path $\tilde{\gamma}\in\tilde{g}$ is monotonically decreasing; therefore $\tilde{E}(\tilde{g})=0$. Let $i\in E_{\text{locmin}}$. There exists a node p_2 in $\tilde{g}$ such that $(\langle i\rangle\to p_2)\in\tilde{g}$ with $\tilde{E}(\langle i\rangle)=\tilde{E}(p_2)$, and possibly a node p_1 with $(p_1\to\langle i\rangle)\in\tilde{g}$ with $\tilde{E}(p_1)\geq\tilde{E}(\langle i\rangle)$ (see Fig. 4).

Let q_1 and q_2 be two nodes of $[i]$, neighbors of p_1 and p_2, respectively. Choose any node j_1 of $[i]$. If $j_1\neq i$, (32) implies that there exists a node j_2 in the neighborhood of j_1 such that $E(j_2)<E(j_1)$. Then there exists a decreasing path γ_1 that starts at j_1 and ends at i, since by hypothesis, $[i]\cap E_{\text{locmin}}=\{i\}$. Then choose any node k_1 in $[i]\cap\gamma_1^c$. Working in the same

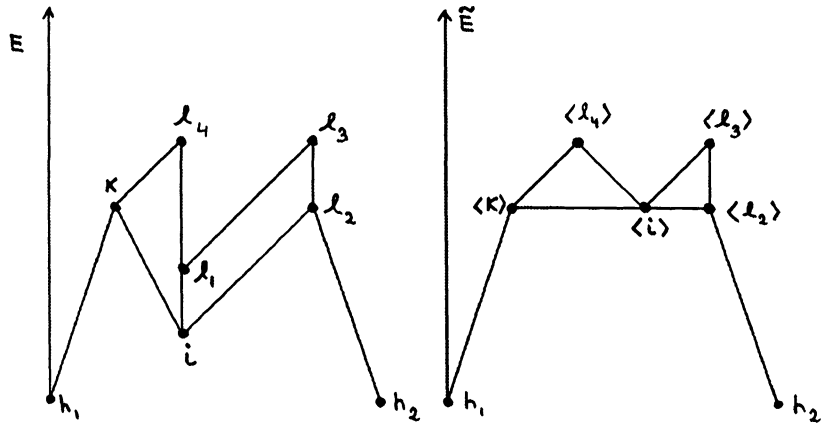

FIG. 2. *Graphical representation of* (S, Γ) *and* $(\tilde{S}, \tilde{\Gamma})$. $E_{\min} = \{h_1, h_2\}$. *The line between two nodes indicates they are neighbors; for example,* $(i, k) \in \Gamma$. $E_{\text{locmin}} = \{i\}$, $d(i) = E(k) - E(i)$, $[i] = \{i, l_5, l_1\}$, $\langle i \rangle = [i]$, $\langle l_1 \rangle = [i]$, $(\langle l_3 \rangle, \langle i \rangle) \in \tilde{\Gamma}$.

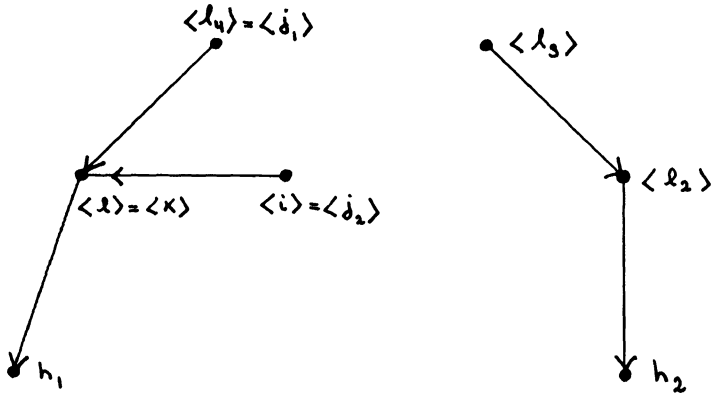

FIG. 3. *Decreasing paths in the quotient graph.*

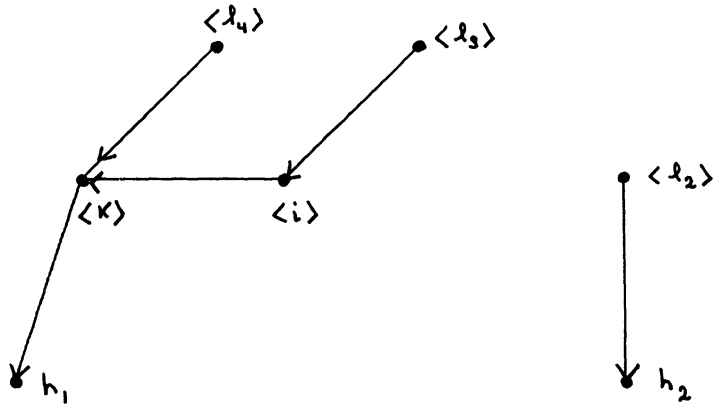

FIG. 4. $p_2 = \langle k \rangle, p_1 = \langle l_3 \rangle$.

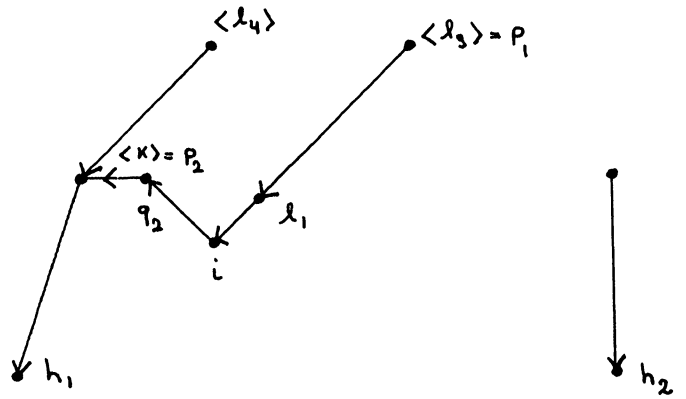

FIG. 5. *Example of a graph g of* $G(E_{\min})$ *for which* $E(g) = \sum_{i \in E_{\text{locmin}}} d(i)$. $q_1 = l_1$, $q_2 = l_5$.

way, we obtain a decreasing path γ_2 that starts at k_1 and ends the first time γ_2 meets γ_1. In this way, we obtain a maximal directed tree h_i in $[i]$. Let $p \in [i]$. The unique geodesic of h_i that starts at p and ends at i is then monotonically decreasing. We add to $\tilde{g}$: the monotonically increasing geodesic of h_i from i to q_2, all the other decreasing geodesics of h_i with terminal nodes i, and the arrow $(q_2 \to p_2)$, $(p_1 \to q_1)$. Then we obtain a graph $g \in G(E_{\min})$ with $E(g) = \sum_{i \in E_{\text{locmin}}} d(i)$ (see Fig. 5).

Let h be an arbitrary graph of $G(E_{\min})$ and let $i \in E_{\text{locmin}}$. Let γ be the path of h that starts at i and ends in $E_{\min}$. For each step $(k \to l) \in \gamma$, $E(k \to l) = [E(l) - E(k)]^+$ and the contribution of $E(\cdot)$ on this path in $[i]$ is at least equal to the depth of the local minimum, since γ comes out of $[i]$. Thus $E(h) \geq \sum_{i \in E_{\text{locmin}}} d(i)$ since, by (32), $[i] \cap E_{\text{locmin}} = \{i\}$ for all $i \in E_{\text{locmin}}$. It follows then that $E(g) = \min_{h \in G(E_{\min})} E(h)$ and $V^{(m)} = \sum_{i \in E_{\text{locmin}}} d(i)$, $m = |E_{\min}|$. To compute $V^{(m+1)}$, we must choose a node $p \in S - E_{\min}$ and evaluate E on $G(E_{\min} \cup \{p\})$. If $p \in S - \cup_{i \in E_{\text{locmin}}}[i]$, E is at least equal to $V^{(m)}$; otherwise it is easy to see that we must choose $p \in E_{\text{locmin}}$ with $d_{\sigma(p)} = d_\alpha$. We have $V^{(m+1)} = V^{(m)} - d_\alpha$. Proceeding in the same way, we obtain $V^{(u)} = +\infty$ for $1 \leq u < m$, $V^{(m)} - V^{(m+1)} = d_\alpha$, $V^{(m+1)} - V^{(m+2)} = d_{\alpha-1}, \ldots, V^{(\alpha+m-1)} - V^{(\alpha+m)} = d_1$, $V^{(u)} = 0$ for $u \geq m + \alpha$.

Remark 2.3.1. The constructions of this section can be generalized for matrices with entries of the form (19) where $V_{ij} = [E(j) - E(i)]^+$ for arbitrary graphs (S, Γ) [Mazza (1990)].

If (32) holds we have seen that

$$\{V^{(u)} - V^{(u+1)}\}_{m \leq u \leq |S|-1} \equiv \{d(k)\}_{k \in S - E_{\min}}.$$

Therefore, under (32), Definition 2.2.2(1) becomes $d_1 < d_2 < \cdots < d_\alpha$, i.e., all the local minima have different depths. It is not difficult to see that under Hypothesis 2.2.4,

$$\Re(1 - \lambda_u(T)) = (c_u + o(1))\exp(-(V^{(u-1)} - V^{(u)})T^{-1}), \qquad u = 2, \ldots, N, \tag{34}$$

for positive constants c_u.

2.4. Eigenvectors of $B(T)$. Let $-\lambda(T)$ be a nonzero eigenvalue of $B'(T) - Id$, which is solution of the equation (see (23) and (29))

$$A^m + A^{m+1}(-\lambda)^1 + \cdots + A^{m+s}(-\lambda)^s = 0. \tag{35}$$

Consider the *cofactor matrix* $\mathrm{Cof}(B(T) - (1 - \lambda(T))Id)$ associated with the matrix $B(T) - (1 - \lambda(T))Id$. We have

$$(B(T) - (1 - \lambda(T))Id) \circ \mathrm{Cof}(B(T) - (1 - \lambda(T))Id)^{\mathrm{Tr}} = 0, \tag{36}$$

where $\circ$ denotes the matrix product. Any row $C(T)$ of the cofactor matrix could be a candidate for eigenvector, but $C(T)$ might vanish. Note that even if $C(T) \neq 0$ for all $T > 0$, it might happen that $C(T) \to 0$ as $T \to 0$. Nevertheless, we establish a lemma that permits the computation of the cofactor matrix associated with the transition matrix of an arbitrary Markov chain.

DEFINITION 2.4.1. *Let $X(t)$ be a Markov chain on a finite set S with transition matrix P. $|S| := N$. Let Λ be a subset of S. Define the restricted chain on $S - \Lambda$ as the chain obtained by making the states of Λ absorbing. Define the family of digraphs for the restricted chain on $S - \Lambda$ and G_Λ, and set*

$$G_\Lambda^u := \{g \in G_\Lambda(U);\ U \subset S,\ |U| = u + |\Lambda|\}, \tag{37}$$

$$A_\Lambda^u := \sum_{g \in G_\Lambda^u} \pi(g), \qquad 0 \leq u \leq |S - \Lambda|. \tag{38}$$

LEMMA 2.4.2. *Consider a Markov chain on a finite set S with transition matrix $P \in \mathbb{R}^{N \times N}$ ($N := |S|$). Let $\hat{P}(\lambda) := P - (1 - \lambda)Id$. Let $C_{ij}(\lambda)$, $j \neq i$, be the term of* $\mathrm{Cof}(\hat{P}(\lambda))$ *associated with the* ith *row and the* jth *column. Then*

$$C_{ij}(\lambda) = (-1)^{N+1} \sum_{\gamma : j \to i} P(\gamma) P_\gamma(\lambda), \tag{39}$$

where the sum is taken over all simple paths γ (no-cycle) from j to i, $P(\gamma)$ is the probability associated with γ, $P_\gamma(\lambda)$ is the polynomial

$$A^0_{\mathcal{N}(\gamma)} + A^1_{\mathcal{N}(\gamma)}(-\lambda) + \cdots + A^{N-r}_{\mathcal{N}(\gamma)}(-\lambda)^{N-r}, \tag{40}$$

$r := |\mathcal{N}(\gamma)|$, and $\mathcal{N}(\gamma)$ is the "trace" of γ (nodes situated on γ).

Remark 2.4.3. If we set $\lambda = 0$ in (39), we obtain a lemma in [Freidlin and Wentzell (1984), p. 177] on the invariant measure of irreducible Markov chains. For the matrix B, $C_{ij}(\lambda)$ becomes

$$(-1)^{|S - E_{\min}|+1} \sum_{\substack{\gamma : j \to i \\ \mathcal{N}(\gamma) \subset S - E_{\min}}} P(\gamma)[A^0_{\mathcal{N}(\gamma) \cup E_{\min}} + A^1_{\mathcal{N}(\gamma) \cup E_{\min}}(-\lambda) + \cdots + A^{s-r}_{\mathcal{N}(\gamma) \cup E_{\min}}(-\lambda)^{s-r}],$$

where $r := |\mathcal{N}(\gamma)|$, $s = |S - E_{\min}|$. See §3.1 for the proof.

2.5. First hit of $E_{\min}$. Let γ be a simple path of (S, Γ) from j to k, for $k \in E_{\mathrm{locmin}}$ and $j \in S - E_{\min}$. Consider the quotient graph: $\hat{\gamma}$ is now a path of $(\tilde{S}, \tilde{\Gamma})$ from $\langle j \rangle$ to $\langle k \rangle$ (from $\langle k \rangle$ to $\langle k \rangle$ if $j \in [k]$).

DEFINITION 2.5.1. *If k is a node of E_{locmin}, define by k^- the set of elements $j \in S - E_{\min}$ such that each path $\hat{\gamma}$ from j to $\langle k \rangle$ has a strictly increasing arrow, and set $k^+ := (k^-)^c$. If k is a node of $S - E_{\min} - E_{\mathrm{locmin}}$, then k^- is defined as the set of nodes such that each path γ from j to k has a strictly increasing arrow and k^+ is defined as $(k^-)^c$. We say that the elements of $S - E_{\min}$ are well ordered if*

$$j \in k^+ \Rightarrow k \in j^-, \quad \forall k, \quad j \in S - E_{\min}. \tag{41}$$

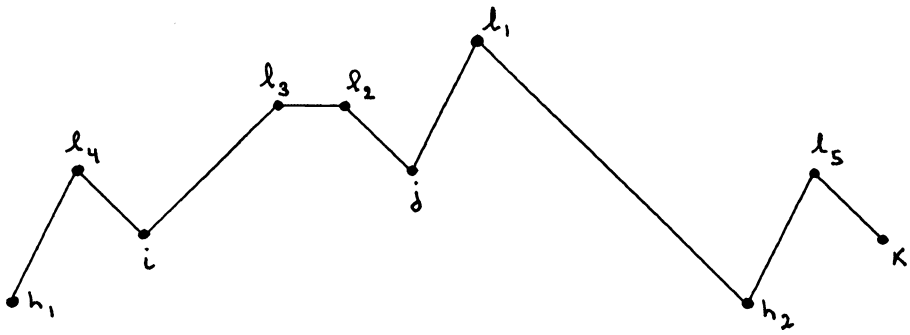

FIG. 6. *In this example,* $d(i) = E(l_4) - E(i)$, $d(j) = E(l_2) - E(j)$, *and* $d(k) = E(l_5) - E(k)$; $i \in j^-$, $j \in i^+$, $j \in k^-$, *and* $k \in j^-$.

Example 1. In Fig. 2, $i \in l_3^-$, $l_3 \in l_2^+$, $l_2 \in l_3^-$, and $l_3 \in i^+$.

Example 2. See Fig. 6.

The elements of $S - E_{\min}$ are not well ordered since $l_3 \in l_2^+$ and $l_2 \in l_3^+$. Roughly speaking, the concept of "well orderedness" permits us to avoid horizontal paths between nodes. If, for example, i and j are two nodes of $S - E_{\min} - E_{\text{locmin}}$, the assumption that the elements are well ordered implies that there is no path γ from i to j such that $E(\gamma) = 0$. As this notion is directly related to (S, Γ) and $E(\cdot)$, it is difficult to check in general. The elements are well ordered when no situation like $j \in k^+$, $k \in j^+$ occurs. If $j \in S - E_{\min} - E_{\text{locmin}}$ and $k \in E_{\text{locmin}}$, then obviously $k \in j^-$; if Definition 2.2.2(2) holds, and this will be the case in the next theorem, it is easy to see that we have only to concentrate on pairs of local minima. Suppose that Definition 2.2.2(2) holds and that $k \in j^+$, $j \in k^+$ for two nodes k and j of $S - E_{\min} - E_{\text{locmin}}$. Then there exists a monotonically decreasing path γ from j to k, and one from k to j; thus $E(j) \geq E(k)$ and $E(k) \geq E(j)$, so that $E(j) = E(k)$. If γ is given by the sequence $x_0 = j \to x_1 \to \cdots \to x_n = k$, then x_0 and x_1 are two neighbors such that $E(x_0) = E(x_1)$, which contradicts Definition 2.2.2(2). This shows that we must check the notion only for pairs of local minima.

Let $k \in S - E_{\min}$. Define $\Lambda(k)$ as the subset of $S - E_{\min}$ consisting of those j for which there exists a path γ from j to k for which $\mathcal{N}(\gamma) \cap E_{\min} = \emptyset$. Let

$$D(k) := \max_{j \in \Lambda(k)} d(j). \tag{42}$$

THEOREM 2.5.2. *Assume that Hypothesis* 2.2.4 *is satisfied and the elements of* $S - E_{\min}$ *are well ordered. Let* $T : \mathbb{R}^+ \to \mathbb{R}^+$ *be a differentiable function such that* $T(t) \to 0$ *as* $t \to \infty$ *and*

$$\int_0^\infty \left| \frac{d}{dt} \exp(-KT^{-1}(t)) \right| dt < +\infty \tag{43}$$

for every nonnegative constant $K \in \mathbb{R}$. *Then, if* t_0 *is large enough,*

$$P(\tau \geq t | X(t_0) = k) = (p_k + o(1)) \exp\left(-b_k \int_{t_0}^t \exp(-D(k)T(v)^{-1}) dv \right), \tag{44}$$

as $t \to \infty$, *for constants* $p_k \geq 0$ *and* $b_k > 0$. *Thus, the first hitting time* τ *is almost surely finite if*

$$\int_0^\infty \exp(-D(k)T(v)^{-1}) dv = +\infty. \tag{45}$$

Remark 2.5.3. Theorem 2.5.2 generalizes to the case where condition $[k] \cap E_{\text{locmin}} = \{k\}$ of (32) is replaced by $\{x \in E_{\text{locmin}};\ x \in [k] \text{ and } E(x) = E(k)\} = \{k\}$ for all $k \in E_{\text{locmin}}$, so that a given set $[k]$ might contain other elements of E_{locmin} [Mazza (1990)].

Let us specify the role of the hypotheses. The main idea consists of using the cofactor expansion (39) to put the differential system (10) in Levinson form (17). It can be proved (see, e.g., [Groebner (1956)]) that $\operatorname{rank}(\operatorname{Cof}(B - (1-\lambda)Id)) \leq 1$ for all $\lambda \in \operatorname{spec}(Id - B)$, and that $\operatorname{Cof}(B - (1-\lambda)Id) \equiv 0$ if λ has multiplicity greater than one. As explained in Remarks 2.2.3 and 2.3.1, Hypothesis 2.2.4 implies that the spectrum of $B(T(t))$ is simple for all $t \geq t_0$. This permits a direct use of the cofactor expansion for diagonalization of system (10). As $\lambda_{\sigma(k)}(T(t)) \to 0$ as $t \to \infty$ for all $k \in E_{\text{locmin}}$, the spectrum is asymptotically degenerate. As we will see in the proof of Theorem 2.5.2, the assumption that the elements of $S - E_{\min}$ are well ordered permits keeping the rank of the eigenvector matrix $W(T(t)) = (w_\lambda(T(t)))_{\lambda \in \operatorname{spec}(B(t))}$ unaltered in the limit $t \to \infty$. This is quite restrictive, but as we mentioned in §1, the method could be applied to various situations. Concerning the problem of relaxing the hypotheses, it might be possible to use the cofactor expansion for the blocks in the Jordan decomposition of $B(T)$, and to relax them in this way.

3. Proofs.

3.1. Proof of Lemma 2.4.2. Let $A(i) := \{1, 2, \ldots, i-1, i+1, \ldots N\}$. Define $B(i,j)$ to be the set of all bijective maps from $A(i)$ to $A(j)$. Assume $i < j$. Let ψ be the map of $B(i,j)$ given by

$$\psi(k) = \begin{cases} k, & \text{if } 1 \leq k \leq i-1, \\ i, & \text{if } k = i+1, \\ k-1, & \text{if } i+2 \leq k \leq j, \\ k, & \text{if } j < k < N. \end{cases}$$

$C_{ij}(\lambda)$ in (39) then becomes

$$(-1)^{i+j} \sum_{\pi \in B(i,i)} \operatorname{sign}(\pi) \hat{P}_{1\psi(\pi(1))} \hat{P}_{2\psi(\pi(2))} \cdots \hat{P}_{(i-1)\psi(\pi(i-1))} \cdot \hat{P}_{(i+1)\psi(\pi(i+1))} \cdots \hat{P}_{j\psi(\pi(j))} \cdots \hat{P}_{N\psi(\pi(N))}.$$

Let ψ' be the map of $B(j,j)$ given by

$$\psi'(k) = \begin{cases} k, & \text{if } 1 \leq k \leq i-1, \\ k+1, & \text{if } i \leq k \leq j-2, \\ i, & \text{if } k = j-1, \\ k, & \text{if } j < k \leq N. \end{cases}$$

Note that

$$\psi' \circ \psi(k) = \begin{cases} k, & \text{if } k \neq j, \\ i, & \text{if } k = j. \end{cases} \tag{46}$$

Then

$$-C_{ij} = \sum_{\pi \in B(i,i)} \operatorname{sign}(\pi) \prod_{k \in A_i} \hat{P}_{k,\psi' \circ \psi \circ \pi(k)}.$$

Consider, for π the cycle in j,

$$j \to \pi(j) \to \pi^2(j) \to \cdots \to \pi^{l-1}(j) \to \pi^l(j) = j,$$

which becomes, by (46),

$$j \to (\psi' \circ \psi \circ \psi)(j) = \pi(j), \quad \text{since } \pi(j) \neq j,$$

$$\pi(j) \to (\psi' \circ \psi \circ \pi)(\pi(j)) = \pi^2(j), \quad \text{since } \pi^2(j) \neq j,$$

$$\cdots$$

$$\pi^{l-1} \to (\psi' \circ \psi \circ \pi)(\pi^{l-1}) = i.$$

The cycle is interpreted as a path from j to i in S, denoted by γ_π, with trace $\mathcal{N}(\gamma_\pi)$. If $P(\gamma_\pi)$ is the probability associated with γ_π, then

$$-C_{ij} = \sum_{\pi \in B(i,i)} \operatorname{sign}(\pi) P(\gamma_\pi) \prod_{k \in A(i), k \notin \mathcal{N}(\gamma_\pi)} \hat{P}_{k,\psi' \circ \psi \circ \pi(k)}.$$

Next factorize the sum over all bijective maps $\pi \in B(i,i)$ so that the associated path corresponds to a given path γ,

$$\sum_{\gamma: j \to i} P(\gamma) \sum_{\pi: \gamma_\pi = \gamma} \operatorname{sign}(\pi) \prod_{k \in A(i), k \notin \mathcal{N}(\gamma_\pi)} \hat{P}_{k,\psi' \circ \psi \circ \pi(k)}.$$

Let π be a permutation such that $\gamma_\pi = \gamma$. The size of the associated cycle $\hat{\gamma}$ is $|\mathcal{N}(\gamma)| - 1$. π is then the composition of a cyclic permutation $\hat{\gamma}$ and of a permutation ν of $B(i,i)$, which leaves the nodes of $\mathcal{N}(\hat{\gamma})$ ($\mathcal{N}(\hat{\gamma})$ = orbit of $\hat{\gamma}$ in j) invariant. $-C_{ij}$ becomes

$$\sum_{\gamma: j \to i} P(\gamma) \operatorname{sign}(\hat{\gamma}) \sum_{\pi: \gamma_\pi = \gamma} \operatorname{sign}(\nu) \prod_{k \in A(i), k \notin \mathcal{N}(\gamma_\pi)} \hat{P}_{k,\nu(k)}.$$

As $\hat{\gamma}$ is cyclic, $\operatorname{sign}(\hat{\gamma}) = (-1)^{|\mathcal{N}(\gamma)|}$. Then

$$\delta(\gamma) := \sum_{\pi: \gamma_\pi = \gamma} \operatorname{sign}(\nu) \prod_{k \in A(i), k \notin \mathcal{N}(\gamma_\pi)} \hat{P}_{k,\nu(k)}$$

is the determinant of the matrix obtained by deleting the rows and the columns of $\hat{P}$ corresponding to states of $\mathcal{N}(\gamma)$. To apply Lemma 23 of [Wentzell (1972)], complete this matrix to a new matrix $\hat{P}'$ by defining the states of $\mathcal{N}(\gamma)$ as absorbing. If $k \in \mathcal{N}(\gamma)$, then $\hat{P}'_{kl} = 0$ if $l \neq k$ and $\hat{P}'_{kk} = 1 - (1 - \lambda) = \lambda$. If $k \notin \mathcal{N}(\gamma)$, then $\hat{P}'_{kl} = \hat{P}_{kl}$. This matrix is in fact the transition matrix of the restricted chain on $S - \mathcal{N}(\gamma)$ from which we subtract $(1 - \lambda)Id$. Then

$$(+\lambda)^{|\mathcal{N}(\gamma)|} \delta(\gamma) = (-1)^N [A^1(-\lambda) + \cdots + A^N(-\lambda)^N].$$

Since the states of $\mathcal{N}(\gamma)$ are absorbing, we have, by (29),

$$A^1 = \cdots = A^{|\mathcal{N}(\gamma)|-1} = 0.$$

Then

$$\delta(\gamma) = (-1)^{\mathcal{N}(\gamma)+N} P_\gamma(\lambda),$$

where $P_\gamma(\lambda)$ is the polynomial $A^0_{\mathcal{N}(\gamma)} + \cdots + A_{\mathcal{N}(\gamma)}(-\lambda)^{N-|\mathcal{N}(\gamma)|}$. $-C_{ij}$ therefore becomes

$$\sum_{\gamma: j \to i} P(\gamma)(-1)^{|\mathcal{N}(\gamma)|}(-1)^{|\mathcal{N}(\gamma)|+N} P_{\mathcal{N}(\gamma)}(\lambda). \qquad \square$$

Proof of Remark 2.4.3. For $B(T)$, consider $B'(T)$ and apply Lemma 2.4.2. We have

$$P'_\gamma(\lambda) = A^0_{\mathcal{N}(\gamma)} + \cdots + A^{s+m-r}_{\mathcal{N}(\gamma)}(-\lambda)^{s+m-r},$$

where $s = |S - E_{\min}|$, $m = |E_{\min}|$, $r = |\mathcal{N}(\gamma)|$. If $\mathcal{N}(\gamma) \cap E_{\min} \neq \emptyset$, then $P'(\gamma) = 0$. It is then sufficient to consider paths γ with $\mathcal{N}(\gamma) \subset S - E_{\min}$. As $E_{\min}$ is absorbing, we have, by (29), $A^0_{\mathcal{N}(\gamma)} = \cdots = A^{m-1}_{\mathcal{N}(\gamma)} = 0$; then the terms of the sum become

$$P(\gamma)(-\lambda)^m [A^m_{\mathcal{N}(\gamma)} + \cdots + A^{s-r}_{\mathcal{N}(\gamma)}(-\lambda)^{s-r}],$$

and the result follows from the equality $A^{m+u}_{\mathcal{N}(\gamma)} = A^u_{\mathcal{N}(\gamma) \cup E_{\min}}$. $\square$

3.2. Proof of Theorem 2.5.2. In the remaining argument, we assume that Hypothesis 2.2.4 is satisfied. Let γ be a simple path from j to k. All nodes of $\mathcal{N}(\gamma)$ are absorbing. Let g be a graph for the restricted chain on $S - E_{\min} - \mathcal{N}(\gamma)$ such that $g \in G_{\mathcal{N}(\gamma) \cup E_{\min}}(\mathcal{N}(\gamma) \cup E_{\min})$. Let g be a graph with node set $\mathcal{N}(g) \subset S$ and arrow set $\mathcal{A}(g)$. For any couple of graphs g_1 and g_2 such that $\mathcal{A}(g_1) \cap \mathcal{A}(g_2) = \emptyset$, consider the graph sum $g_1 \cup g_2$, which is defined as follows: $\mathcal{N}(g_1 \cup g_2) := \mathcal{N}(g_1) \cup \mathcal{N}(g_2)$ and $\mathcal{A}(g_1 \cup g_2) := \mathcal{A}(g_1) \cup \mathcal{A}(g_2)$ (note that g_1 and g_2 may have common nodes). Then $g \cup \gamma \in G_{E_{\min}}(\{k\} \cup E_{\min})$, and

$$E(g \cup \gamma) = E(g) + E(\gamma). \tag{47}$$

For any graph g define $c(g) := \prod_{(i \to j) \in g} q_{ij}$, where the probabilities q_{ij} are those defined in (1). In exponential form,

$$P(\gamma) = c(\gamma)\exp(-E(\gamma)T^{-1})$$

and

$$A^0_{\mathcal{N}(\gamma) \cup E_{\min}} = \sum_{g \in G_{\mathcal{N}(\gamma) \cup E_{\min}}(\mathcal{N}(\gamma) \cup E_{\min})} c(g)\exp(-E(g)T^{-1}). \tag{48}$$

LEMMA 3.2.1. *Let γ be a simple path from j to k. Then*

$$P(\gamma)A^n_{\mathcal{N}(\gamma) \cup E_{\min}} = \sum_U \sum_g c(g)\exp(-E(g)T^{-1}), \tag{49}$$

where the first sum is taken over all subsets U of $S - E_{\min} - \mathcal{N}(\gamma)$ with $|U| = n$, and the second over all graphs g of the family $G(U \cup \{k\} \cup E_{\min})$ containing γ.

Proof. As $\mathcal{N}(\gamma)$ is absorbing, we must consider only graph g of $G_{\mathcal{N}(\gamma) \cup E_{\min}}(U \cup \mathcal{N}(\gamma) \cup E_{\min})$ for $U \subset S - \mathcal{N}(\gamma) - E_{\min}$, $|U| = n$. The result is then a consequence of the relation

$$g \cup \gamma \in G_{E_{\min}}(\{k\} \cup U \cup E_{\min}). \tag{50}$$ $\square$

DEFINITION 3.2.2. *Define $G(k, j)$ to be the unique nonnegative real number such that*

$$C_{kj}(\lambda_{\sigma(k)})(T) \sim \exp(-G(k, j)T^{-1}) \quad \text{as } T \to 0.$$

$G(k,j)$ is well defined since all the terms (49) *appearing in the development* (39) *of* $C_{kj}(\lambda_{\sigma(k)})$ *have exponential form and since, by* (34),

$$\lambda_{\sigma(k)}(T) \sim \exp(-d_{\sigma(k)}T^{-1}) \quad \text{as } T \to 0.$$

LEMMA 3.2.3. *Let k be a local minimum and let $-\lambda_{\sigma(k)}(T)$ be the associated eigenvalue. Then*

$$C_{kk}(\lambda_{\sigma(k)}(T)) \neq 0 \qquad \forall T > 0,$$

$$G(k,k) = d_1 + d_2 + \cdots + d_{\sigma(k)-1} + d_{\sigma(k)}(\alpha - \sigma(k)),$$

$$G(k,j) \geq G(k,k) \qquad \forall j,$$

$$|C_{kj}(\lambda_{\sigma(k)}(T))| < c_{kj}|C_{kk}(\lambda_{\sigma(k)}(T))| \quad \forall j \in S - E_{\min}, \quad c_{kj} > 0,$$

$w_k^j(T) := C_{kj}(\lambda_{\sigma(k)})(C_{kk}(\lambda_{\sigma(k)}))^{-1}$ *converges as* $T \to 0\ \forall j \in S - E_{\min}, \forall k \in E_{\text{locmin}}$.

Proof. Consider the restricted chain on $S - E_{\min} - \{k\}$; $(-1)^s C_{kk}(\lambda_{\sigma(k)})$ becomes, by (39),

$$A^0_{\{k\}\cup E_{\min}} + A^1_{\{k\}\cup E_{\min}}(-\lambda_{\sigma(k)})^1 + \cdots + A^{s-1}_{\{k\}\cup E_{\min}}(-\lambda_{\sigma(k)})^{s-1},$$

where $s := |S - E_{\min}|$. By (34), the eigenvalues $1 - \lambda$ satisfy

$$\lambda(T) \sim \exp(-(V^{(u)} - V^{(u+1)})T^{-1}), \qquad 1 \leq u \leq s-1,$$

where the constants $V^{(u)}$, $1 \leq u \leq s-1$ are the constants associated with the restricted chain on $S - E_{\min} - \{k\}$ (see Definition 2.4.1). In the generic case, $d_{\sigma(k)} \neq V^{(u)} - V^{(u+1)}$ for all u since k is absorbing. $\lambda_{\sigma(k)}$ is then not solution of the equation $C_{kk}(\lambda) = 0$.

Under Hypothesis 2.2.4, it is easy to evaluate the coefficient $A^n_{\{k\}\cup E_{\min}}$. We must consider the depths of all local minima contained in $E_{\text{locmin}} - \{k\}$. ($\alpha := |E_{\text{locmin}}|$). Proceeding as in §2.3, we obtain

(51)

$$\begin{gathered}
A^0_{\{k\}\cup E_{\min}}|(\lambda_{\sigma(k)})|^0 \sim \exp(-(d_1 + \cdots + d_{\sigma(k)-1} + d_{\sigma(k)+1} + \cdots + d_\alpha)T^{-1}),\\
A^1_{\{k\}\cup E_{\min}}|(\lambda_{\sigma(k)})|^1 \sim \exp(-(d_1 + \cdots + d_{\sigma(k)-1} + d_{\sigma(k)+1} + \cdots + d_{\alpha-1} + d_{\sigma(k)})T^{-1})\\
\cdots\\
A^{\alpha-\sigma(k)}_{\{k\}\cup E_{\min}}|(\lambda_{\sigma(k)})|^{\alpha-\sigma(k)} \sim \exp(-(d_1 + \cdots + d_{\sigma(k)-1} + d_{\sigma(k)}(\alpha - \sigma(k)))T^{-1})\\
A^{\alpha-\sigma(k)+1}_{\{k\}\cup E_{\min}}|(\lambda_{\sigma(k)})|^{\alpha-\sigma(k)+1} \sim \exp(-(d_1 + \cdots + d_{\sigma(k)-2} + d_{\sigma(k)}(\alpha - \sigma(k) + 1))T^{-1})\\
\cdots\\
A^{s-1}_{\{k\}\cup E_{\min}}|(\lambda_{\sigma(k)})|^{s-1} \sim \exp(-(d_{\sigma(k)}(s-1))T^{-1}).
\end{gathered}$$

Thus

(52)

$$\max_{0\leq n\leq s-1} A^n_{\{k\}\cup E_{\min}}|(-\lambda_{\sigma(k)})^n| = \exp(-(d_1 + \cdots + d_{\sigma(k)-1} + d_{\sigma(k)}(\alpha - \sigma(k)))T^{-1}).$$

Consider the cofactor $C_{kj}(\lambda_{\sigma(k)})$. By Lemma 2.4.2 we must consider all simple paths γ from j to k. By Lemma 3.2.1 we also have

$$P(\gamma)A^n_{\mathcal{N}(\gamma)\cup E_{\min}} = \sum_U \sum_{g\in G} c(g)\exp(-E(g)T^{-1}),$$

where the first sum to be taken over all subsets $U \subset S - E_{\min} - \mathcal{N}(\gamma)$, $|U| = n$, and the second over all graphs $g \in G(U \cup \{k\} \cup E_{\min})$ containing γ. $P(\gamma)A^n_{\mathcal{N}(\gamma)\cup E_{\min}}$ is then dominated by $A^n_{\{k\}\cup E_{\min}}$. The order of $C_{kk}(\lambda_{\sigma(k)})$ has been obtained by considering each term $A^n_{\{k\}\cup E_{\min}}|(-\lambda_{\sigma(k)})^n|$. We have

$$(53)\quad (A^n_{\{k\}\cup E_{\min}}|(-\lambda_{\sigma(k)})^n|)(A^{\alpha-\sigma(k)}_{\{k\}\cup E_{\min}}|(-\lambda_{\sigma(k)})^{\alpha-\sigma(k)}|)^{-1} \underset{T\to 0}{\longrightarrow} 0, \quad \text{for } n \neq \alpha - \sigma(k).$$

Then we conclude that the order of $C_{kj}(\lambda_{\sigma(k)})$ is greater than the order of $C_{kk}(\lambda_{\sigma(k)})$. The required result follows from the form of the cofactors. □

LEMMA 3.2.4. *Let $k \in E_{\text{locmin}}$ and $j \in S - E_{\min}$. If $j \in k^-$, then*

$$G(k,j) > G(k,k), \qquad w^j_k(T) \underset{T\to 0}{\longrightarrow} 0.$$

DEFINITION 3.2.5. *Let Λ be a subset of S and $\Lambda \supset E_{\min}$. Suppose that the states of Λ are the only absorbing states. If $n < |\Lambda|$, $E(g) = +\infty$ for all g of $G(U)$ and each $U \subset S$ with $|U| = n$. Define the subset*

$$\tilde{\Lambda} := \{i \in E_{\text{locmin}};\ [i] \cap \Lambda \neq \emptyset\},$$

the new depths

$$d^1_{\sigma(i)} := \begin{cases} 0, & \text{if } i \notin \tilde{\Lambda}, \\ d_{\sigma(i)} + E(i) - \min\limits_{p\in\Lambda\cap[i]} E(p), & \text{otherwise}, \end{cases}$$

so that $0 \le d^1_{\sigma(i)} \le d_{\sigma(i)}$ and

$$d^2_{\sigma(i)} := d_{\sigma(i)} - d^1_{\sigma(i)}.$$

Working as in §2.3, we obtain

$$A^0_\Lambda \sim \exp\left(-\sum_{i\in E_{\text{locmin}}} d^2_{\sigma(i)}T^{-1}\right),$$

$$A^1_\Lambda \sim \exp\left(-\left(\sum_{i\in E_{\text{locmin}}} d^2_{\sigma(i)} - \max_i d^2_{\sigma(i)}\right)T^{-1}\right),$$

....

Proof of Lemma 3.2.4. Let γ be a simple path from j to k with $c(\gamma) > 0$. $F > 0$ is defined to be the total contribution of $\tilde{E}$ on $\hat{\gamma}$ (γ in the quotient). Consider Definition 3.2.5 with $\Lambda := \mathcal{N}(\gamma) \cup E_{\min}$ (see Fig. 7). We have

$$P(\gamma) \sim c(\gamma)\exp\left(-\left(F + H + \sum_{\tilde{\Lambda}-\{k\}} d^1_{\sigma(i)}\right)T^{-1}\right),$$

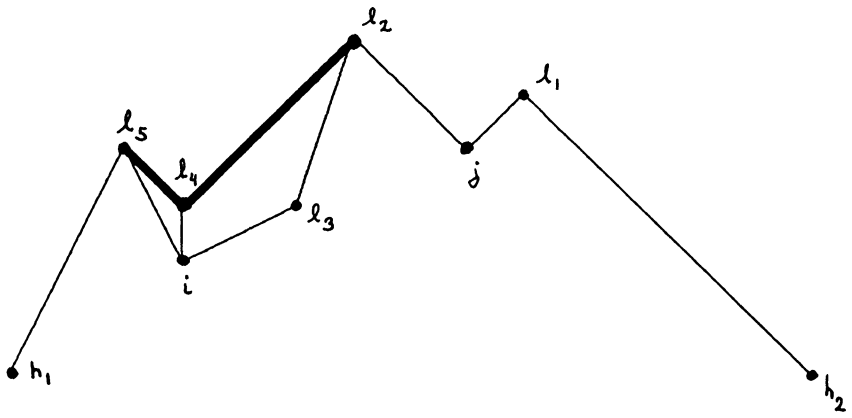

FIG. 7. $\Lambda = \{l_2, l_4, l_5\}$, $[i] = \{i, l_4, l_3\}$, $\tilde{\Lambda} = \{i\}$. $d(i) = E(l_5) - E(i)$, $d(j) = E(l_1) - E(j)$, $d^1_{\sigma(i)} = E(l_5) - E(l_4)$, $d^2_{\sigma(i)} = E(l_4) - E(i)$, $d^1_{\sigma(j)} = 0$, $d^2_{\sigma(j)} = d_{\sigma(j)} = d(j)$.

where H is a nonnegative constant. Consider the polynomial

$$A^0_{\mathcal{N}(\gamma)\cup E_{\min}} + A^1_{\mathcal{N}(\gamma)\cup E_{\min}}(-\lambda_{\sigma(k)})^1 + \cdots + A^{s-r}_{\mathcal{N}(\gamma)\cup E_{\min}}(-\lambda_{\sigma(k)})^{s-r} \tag{54}$$

with $r = |\mathcal{N}(\gamma)|$, and the products

$$P(\gamma)A^p_{\mathcal{N}(\gamma)\cup E_{\min}}|\lambda_{\sigma(k)}|^p, \quad 0 \le p \le s - r.$$

Let $p = 0$. Then

$$A^0_{\mathcal{N}(\gamma)\cup E_{\min}} \sim \exp\left(-\sum_{i\in E_{\text{locmin}}} d^2_{\sigma(i)}T^{-1}\right).$$

To evaluate

$$\max_p A^p_{\mathcal{N}(\gamma)\cup E_{\min}}|\lambda_{\sigma(k)}|^p,$$

arrange the terms of the sum $\sum d^2_{\sigma(i)}$ in order of increasing value and compare them to $d_{\sigma(k)}$. If $d^2_{\sigma(i)} \le d_{\sigma(k)}$ for all $i \in E_{\text{locmin}}$, then $\max A^p_{\mathcal{N}(\gamma)\cup E_{\min}}|\lambda_{\sigma(k)}|^p = A^0_{\mathcal{N}(\gamma)\cup E_{\min}}$ and the term associated with γ in the development of C_{kj} has order

$$\exp\left(-\left(F + H + \sum_{\tilde{\Lambda}-\{k\}} d^1_{\sigma(i)} + \sum_{i\in E_{\text{locmin}}} d^2_{\sigma(i)}\right)T^{-1}\right),$$

$$= \exp\left(-\left(F + H + \sum_{i\in E_{\text{locmin}}-\{k\}} d_{\sigma(i)}\right)T^{-1}\right).$$

Otherwise, let p_1 be element of E_{locmin} such that

$$d^2_{\sigma(p_1)} = \max_{E_{\text{locmin}}-\{k\}} d^2_{\sigma(i)} > d_{\sigma(k)}.$$

We have then

$$A^0_{\mathcal{N}(\gamma)\cup E_{\min}} < A^1_{\mathcal{N}(\gamma)\cup E_{\min}}|\lambda_{\sigma(k)}|^1 \sim \exp\left(-\left(\sum_{E_{\text{locmin}}-\{k\}-\{p_1\}} d^2_{\sigma(i)} + d_{\sigma(k)}\right)T^{-1}\right).$$

Working in the same way, we obtain a sequence $\{p_1,\dots,p_v\}$ such that

$$d^2_{\sigma(p_1)} \geq d^2_{\sigma(p_2)} \geq \cdots \geq d^2_{\sigma(P_{v-1})} > d^2_{\sigma(p_v)},$$

v being the first index for which $d^2_{\sigma(p_v)} \leq d_{\sigma(k)}$. $P(\gamma)\max_p A^p_{\mathcal{N}(\gamma)\cup E_{\min}}|\lambda_{\sigma(k)}|^p$ has order

$$\exp\Bigg(-\Bigg(F+H+\sum_{E_{\text{locmin}}-\{k\}} d^1_{\sigma(i)} + \sum_{E_{\text{locmin}}-\{k\}-\{p_1,\dots,p_{v-1}\}} d^2_{\sigma(i)} + (v-1)d_{\sigma(k)}\Bigg)T^{-1}\Bigg),$$

which is equal to

$$\exp\Bigg(-\Bigg(F+H+\sum_{\{p_1,\dots,p_{v-1}\}}(d^1_{\sigma(i)}+d_{\sigma(k)}) + \sum_{E_{\text{locmin}}-\{k\}-\{p_1,\dots,p_{v-1}\}}(d^2_{\sigma(i)}+d^1_{\sigma(i)})\Bigg)T^{-1}\Bigg).$$

As $d^2_{\sigma(i)} + d^1_{\sigma(i)} = d_{\sigma(i)}$, we obtain

$$\exp\Bigg(-\Bigg(F+H+(v-1)d_{\sigma(k)}+\sum_{i\in E_{\text{locmin}}-\{k\}-I} d_{\sigma(i)}\Bigg)T^{-1}\Bigg) \cdot \exp\Bigg(-\Bigg(\sum_{p_1,\dots,p_{v-1}} d^1_{\sigma(i)}\Bigg)T^{-1}\Bigg),$$

where I is a subset of $E_{\text{locmin}} - \{k\}$ that contains $v-1$ elements. The term associated with γ then has order

$$\exp\Bigg(-\Bigg(F+H+(v-1)d_{\sigma(k)}+\sum_{i\in E_{\text{locmin}}-\{k\}-I} d_{\sigma(i)}\Bigg)T^{-1}\Bigg) \cdot \exp\Bigg(-\Bigg(\sum_{p_1,\dots,p_{v-1}} d^1_{\sigma(i)}\Bigg)T^{-1}\Bigg),$$

and $G_{kj}(\gamma,\lambda_{\sigma(k)}) = F+H+(v-1)d_{\sigma(k)} + \sum_{i\in E_{\text{locmin}}-\{k\}-I} d_{\sigma(i)} + \sum_{p_1,\dots,p_{v-1}} d_{\sigma(i)}$. Since $G(k,k) = d_1+\cdots+d_{\sigma(k)-1}+d_{\sigma(k)}(\alpha-\sigma(k))$, the term associated with γ has order at least equal to $F+G(k,k) > G(k,k)$. This conclusion holds for all paths γ since $j \in k^-$. We conclude therefore that $G(k,j) > G(k,k)$. □

LEMMA 3.2.6. *Let $-\lambda_{\sigma(k)}(T)$ be the eigenvalue of $B(T)-Id$ converging to $P_{kk}(0^+)-1$, $k \in S - E_{\min} - E_{\text{locmin}}$. Then $C_{kk}(\lambda_{\sigma(k)}) \neq 0$ and $C_{kk}(\lambda_{\sigma(k)})$ converges to a nonzero limit. Moreover, if $j \in k^-$, then*

$$G(k,j) - G(k,k) > 0, \qquad w^j_k(T) := C_{kj}(\lambda_{\sigma(k)}(T))C_{kk}(\lambda_{\sigma(k)}(T))^{-1} \underset{T\to 0}{\longrightarrow} 0.$$

Consider the matrix $W := (w_k)_{k \in S - E_{\min}}$.

COROLLARY 3.2.7. *Suppose that the elements of E_{locmin} are well ordered. Then there exists $T_0 > 0$ such that*

$$W(T) \quad \text{is regular} \quad \forall\, T \leq T_0,$$
$$W(T) \to W(0^+), \quad \text{where the latter is regular.}$$

Proof of Lemma 3.2.6. If T is small enough, $-\lambda_{\sigma(k)}$ is simple. $C_{kk}(\lambda)(-\lambda)^{|E_{\min}|+1}$ is the characteristic polynomial associated with the restricted chain on $S - E_{\min} - \{k\}$, which has $|E_{\min}| + 1$ zero eigenvalues and $|S - E_{\min}| - 1$ nonzero eigenvalues, each asymptotically different from $-\lambda_{\sigma(k)}$ (by (34), and Definitions 2.2.3 and 2.3.1). It follows that $C_{kk}(\lambda_{\sigma(k)}) \neq 0$. Let $j \in S - E_{\min}$. We have $C_{kj}(\lambda_{\sigma(k)}) = \sum_{\gamma : j \to k} P(\gamma) P_\gamma(\lambda_{\sigma(k)})$. If $j \in k^-$, then $P(\gamma) \to 0$ as $T \to 0$ for all γ, and it follows that $G(k, j) > 0$. Moreover, as $C_{kk}(\lambda_{\sigma(k)})$ does not converge to 0, $G(k, k) = 0$ and $G(k, j) - G(k, k) > 0$. □

Proof of Corollary 3.2.7. By Definition 2.2.3, the vectors $w_k, k \in S - E_{\min} - E_{\text{locmin}}$ are independent for $T > 0$. In the limit $T \to 0$, the vectors $w_k(0^+)$ are the eigenvectors associated with the eigenvalues $-\lambda_{\sigma(k)}(0^+)$ of the matrix $B(0^+)$, which are all different. Thus they are independent. For $k \in E_{\text{locmin}}$, $\lambda_{\sigma(k)}(T) \to 0$. By Hypothesis 2.2.4, the elements of E_{locmin} are well ordered. Let $k, l \in E_{\text{locmin}}$ such that $l \in k^-$; then $w_k^k(T) \to 1$ and $w_l^k(T) \to 0$ by Lemma 3.2.4. It follows that the vectors $w_k(0^+)$ and $w_l(0^+)$ are independent. Corollary 3.2.7 follows by iterating this argument for all vectors w_k, $k \in E_{\text{locmin}}$. □

LEMMA 3.2.8. *Assume Hypothesis* 2.2.4 *is satisfied. Let $T : \mathbb{R}^+ \to \mathbb{R}^+$ be a differentiable function such that $T(t) \to 0$ as $t \to \infty$ and which verifies* (43),

$$\int_0^\infty \left| \frac{d}{dt} \exp(-KT^{-1}(t)) \right| dt < +\infty,$$

for every nonnegative constant $K \in \mathbb{R}$. Then

(a) $$\frac{d}{dt} \lambda_{\sigma(k)}(T(t)) \sim \lambda_{\sigma(k)}(T(t)) \frac{d}{dt} \left(\frac{-1}{T(t)} \right), \quad \forall\, k \in E_{\text{locmin}},$$

(b) $$\int_0^\infty \left| \frac{d}{dt} w_k^j \right| (t) dt < \infty, \qquad \forall\, k, j \in S - E_{\min}.$$

Proof. Assume first that $k \in S - E_{\min} - E_{\text{locmin}}$. We follow the method given in [Levinson (1948)]. Differentiating the cofactor $C_{kj}(\lambda_{\sigma(k)})$ as a function of t, we obtain an expression that is linear homogeneous in the entries of $(d/dt)B$ and $(d/dt)\lambda_{\sigma(k)}$. We must check the integrability of the terms involving the coefficients $|(d/dt)B_{il}|$. By definition, $B_{il}(T(t)) = q_{il} \exp(-E_{il} T(t)^{-1})$, where we assume that $q_{il} > 0$ (otherwise the result is obvious), and $E_{il} := [E(l) - E(i)]^+$. Thus

$$\left| \frac{d}{dt} B_{il}(T(t)) \right| = q_{il} E_{il} \left| \frac{d}{dt} (T(t)^{-1}) \right| \exp(-E_{il} T(t)^{-1}), \tag{55}$$

which is integrable by (43).

To see (b), we check the integrability of $|(d/dt)\lambda_{\sigma(k)}(T(t))|$. Let $M(\lambda) := B - (1 - \lambda) Id$. As $-\lambda_{\sigma(k)}$ is a characteristic root of $B - Id$, $\det(M(\lambda_{\sigma(k)})) \equiv 0$. As a function of t, $M(\lambda)(t)$ is a function of two functions of t, namely $M(T(t), \lambda(T(t)))$. Define $Q(T(t), \lambda(T(t))) := \det(M(T(t), \lambda(T(t))))$. Then we obtain

$$\frac{\partial Q}{\partial \lambda} \frac{d\lambda(T(t))}{dt} + \frac{\partial Q}{\partial T} \frac{dT}{dt} \equiv 0. \tag{56}$$

As $Q(T(t), \lambda(T(t))) = \det(B(T(t)) - Id + \lambda(T(t)))$, we have

$$\frac{\partial Q}{\partial \lambda} = \frac{\partial}{\partial \lambda}\left(\prod_{u=1}^{s}(\lambda_u - \lambda)\right), \tag{57}$$

where $\{\lambda_u\}_{u=1,\dots,s} = \operatorname{spec}(Id - B)$. Thus

$$\frac{\partial Q}{\partial \lambda} = \sum_{u=1}^{s}\prod_{v\neq u}(\lambda_v - \lambda). \tag{58}$$

As $\lambda = \lambda_{\sigma(k)} \in \operatorname{spec}(Id - B)$,

$$\frac{\partial Q}{\partial \lambda}\bigg|_{\lambda=\lambda_{\sigma(k)}} = \prod_{v\neq\sigma(k)}(\lambda_v - \lambda_{\sigma(k)}). \tag{59}$$

As $\lambda_{\sigma(k)}(T(t))$ is simple for all t (see Remark 2.2.3), $\partial Q/\partial\lambda \neq 0$ for all t. Moreover, Remark 2.2.3 implies that $\lambda_{\sigma(k)}(0^+) \neq 0$ and $\lambda_{\sigma(k)}(0^+) \neq \lambda_{\sigma(k')}(0^+)$ for all $k \neq k'$. We conclude therefore that $(\partial/\partial\lambda)\det(M(\lambda_{\sigma(k)}))$ converges to a nonzero limit as $t \to \infty$. By (56) and (57) we can write

$$\frac{d}{dt}\lambda_{\sigma(k)} = -\frac{\partial}{\partial t}\det(M(\lambda_{\sigma(k)}))\left(\prod_{u\neq\sigma(k)}(\lambda_u - \lambda_{\sigma(k)})\right)^{-1}. \tag{60}$$

The integrability of $|(d/dt)\lambda_{\sigma(k)}(T(t))|$ follows then from the integrability of $|(\partial/\partial t)\det(M(\lambda_{\sigma(k)}))|$.

Let

$$\prod_{i:\pi(i)\neq i}\exp(-E_{i\pi(i)}T^{-1})\prod_{i:\pi(i)=i}(P_{ii}(T(t)) - \lambda(T(t))) \tag{61}$$

be a typical term of Q, where π is a permutation. Its partial derivative with respect to T has the form

$$\lambda(T(t))^n \exp(-KT^{-1}(t)), \tag{62}$$

where $n \in \mathbb{N}$ and $K > 0$. The integrability of $|(\partial Q/\partial T)(\partial T/\partial t)|$ then follows from the integrability of the terms (62), which are integrable (recall the integrability of $|(d/dt)B_{il}(T(t))|$). Let $k \in E_{\text{locmin}}$. We first prove assertion (a). Consider the denominator of (60). By hypothesis, $\lambda_{\sigma(k)}$ is simple for all t, so that the product is different from 0 for all t. Let $\lambda_{\sigma(j)}$ be the eigenvalue associated with the local minimum j, which verifies $\lambda_{\sigma(j)} \sim \exp(-d_{\sigma(j)}T(t)^{-1})$. Let $\hat{\lambda}_{\sigma(j)}$ be the eigenvalue associated with j for the restricted chain on $S - E_{\min} - \{k\}$. Proceeding as in §2.3, we obtain $\lambda_{\sigma(j)} \sim \hat{\lambda}_{\sigma(j)}$. If $j \notin E_{\text{locmin}}$, the equivalence $\lambda_{\sigma(j)} \sim \hat{\lambda}_{\sigma(j)}$ follows from the triangular form of the limiting transition matrix and by hypothesis. Thus

$$\prod_{u\neq\sigma(k)}(\lambda_{\sigma(k)} - \lambda_u) \sim C_{kk}(\lambda_{\sigma(k)}).$$

Consider now the numerator of (60), which is equal to

$$\sum_{n=0}^{s}\frac{\partial A^n_{E_{\min}}}{\partial t}(-\lambda_{\sigma(k)})^n, \tag{63}$$

with

$$A^n_{E_{\min}} = \sum_{g \in G^n_{E_{\min}}} c(g)\exp(-E(g)T(t)^{-1}).$$

Then we have

$$\frac{d}{dt}A^n_{E_{\min}} = \frac{d}{dt}(-T(t)^{-1}) \sum_{g \in G^n_{E_{\min}}} c(g)E(g)\exp(-E(g)T(t)^{-1}).$$

Let us show that the last sum is equivalent to $C_{kk}(\lambda_{\sigma(k)})\lambda_{\sigma(k)}(d/dt)(-T(t)^{-1})$. For that purpose, let $D_n := \sum_{g \in G^n_{E_{\min}}} c(g)E(g)\exp(-E(g)T(t)^{-1})$. Assume first that $n \leq \alpha$. Working as in the proof of Lemma 3.2.3, we obtain

$$D_n \sim \exp(-(d_1 + \cdots + d_{\alpha-n})T^{-1}).$$

If $n > \alpha$, we have $D_n \sim$ const. Then

$$D_n\lambda^n_{\sigma(k)} \sim \exp(-(d_1 + \cdots + d_{\alpha-n} + nd_{\sigma(k)})T^{-1}).$$

In any case, the dominating term of (63) is

$$\exp(-(d_1 + \cdots + d_{\sigma(k)-1} + (\alpha - \sigma(k) + 1)d_{\sigma(k)})T^{-1}),$$

so that Lemma 3.2.3 implies (a).

We now check the integrability of $(d/dt)w^j_k$ for $k \in E_{\text{locmin}}$. We have

$$C_{kk}(\lambda_{\sigma(k)}) = \sum_{n=0}^{s-1} A^n_{E_{\min}\cup\{k\}}(-\lambda_{\sigma(k)})^n$$

and

$$A^n_{E_{\min}\cup\{k\}}(\lambda_{\sigma(k)})^n \sim \exp(-C_nT^{-1}),$$

where C_n is a positive constant. We have seen in the proof of Lemma 3.2.3 that if γ is a simple path from j to k, then

$$P(\gamma)A^n_{E_{\min}\cup\mathcal{N}(\gamma)}(\lambda_{\sigma(k)})^n \sim \exp(-B_nT^{-1}), \qquad B_n > 0,$$

with $\min_n C_n \geq \min_n B_n$. Now normalize w^j_k:

$$w^j_k := (C_{kj}(\lambda_{\sigma(k)})\exp(C_*T^{-1}))(C_{kk}(\lambda_{\sigma(k)})\exp(C_*T^{-1}))^{-1} =: \tilde{C}_{kj}\tilde{C}^{-1}_{kk},$$

where $C_* := \min_n C_n$. $\tilde{C}_{kk}$ converges to a nonzero limit, so that

$$\frac{d}{dt}w^j_k \sim \left(\frac{d}{dt}\tilde{C}_{kj}\right)\tilde{C}_{kk} - \tilde{C}_{kj}\left(\frac{d}{dt}\tilde{C}_{kk}\right).$$

It remains to see that $|(d/dt)\tilde{C}_{kj}|$ and $|(d/dt)\tilde{C}_{kk}|$ are integrable. We have

$$\tilde{C}_{kk} = \sum_{n:C_n>C_*} \exp(C_*T^{-1})A^n_{E_{\min}\cup\{k\}}(-\lambda_{\sigma(k)})^n + \text{ const},$$

$$A^n_{E_{\min}\cup\{k\}} = \sum_{g\in G^n_{E_{\min}}} c(g)\exp(-E(g)T^{-1}).$$

However, by (a),

$$\frac{d}{dt}(\exp(-(E(g)-C_*)T^{-1})\lambda^n_{\sigma(k)}) \sim \frac{d}{dt}(-T^{-1})\exp(-(E(g)-C_*)T^{-1})\lambda^n_{\sigma(k)},$$

so that

$$\left|\frac{d}{dt}\tilde{C}_{kk}\right| \sim \frac{d}{dt}(-T^{-1})\exp(C_*T^{-1})\sum_{n:C_n>C_*}\exp(-C_nT^{-1}),$$

which is integrable (recall the integrability of $|(d/dt)B_{il}(T(t))|$). The integrability of $|(d/dt)\tilde{C}_{kj}|$ is obtained in the same way. □

Proof of Theorem 2.5.2. Assume, without loss of generality, that $\Lambda(k) = S - E_{\min}$. Let $Y(t',t)$ be the solution of the system

$$\frac{\partial Y}{\partial t'} = (-B(t') + Id)Y, \qquad 0 \le t' \le t, \tag{64}$$
$$Y(t,t) = (1,\dots,1)^{\mathrm{Tr}}.$$

Let $W(T(t'))$ be the regular matrix given in Corollary 3.2.7, where we assume $t_0 = 0$. Define $x(t') := W(T(t'))^{-1}Y(t')$. Then we have the new system

$$\frac{\partial x}{\partial t'} = R(t')x(t') + \mathrm{Diag}(\lambda_{\sigma(k)}(t'))Y(t'),$$

where $R(t') = -W^{-1}(d/dt')W(T(t'))$ and $\lambda_{\sigma(k)}(t')$ are the eigenvalues of $B - Id$ associated with the elements k of $S - E_{\min}$. System (64) therefore becomes

$$x(t,t) = W^{-1}(T(t))(1,\dots,1)^{\mathrm{Tr}}.$$

This system has the Levinson form (17). $|R(t)|$ is integrable by Corollary 3.2.7 and Lemma 3.2.8; it is not difficult to see that conditions (14) and (15) of Levinson's theorem are satisfied, so that we know the system has $s := |S - E_{\min}|$ solutions $x_u(t')$ with

$$x_u(t') = (e_u + o(1))\exp\left(\int_0^{t'}\lambda_u(v)dv\right).$$

Let x be an arbitrary solution; then there exist constants $f_1,\dots,f_s \in \mathbb{R}$ such that

$$x(t') = \sum_u f_u(e_u + o(1))\exp\left(\int_0^{t'}\lambda_u(v)dv\right).$$

Set $t' = t$; then we have the equation

$$x(t) = W^{-1}(T(t))(1,\dots,1)^{\mathrm{Tr}},$$

which has a solution since $W(T(t))$ is inversible for all t. The matrix $Z(t) := (e_1 + o(1), \dots, e_s + o(1))$ is regular for all t, so that

$$\left(f_u\exp\left(\int_0^t\lambda_u(v)dv\right)\right)_u = Z^{-1}(t)W^{-1}(T(t))(1,\dots,1)^{\mathrm{Tr}},$$

and then

$$f_u(t) = \exp\left(-\int_0^t \lambda_u(v)dv\right) \langle Z^{-1}(t)W^{-1}(T(t))(1,\ldots,1)^{\mathrm{Tr}},\, e_u\rangle,$$

where $\langle\cdot,\cdot\rangle$ is the scalar product. Then, if $t' = 0$,

$$Y(0,t) = \sum_u W(T(0))Z_u(0) \exp\left(-\int_0^t \lambda_u(v)dv\right) \langle Z^{-1}(t)W^{-1}(T(t))(1,\ldots,1)^{\mathrm{Tr}},\, e_u\rangle.$$

As $t \to \infty$, $Z^{-1}(t)$ converges to the identity matrix and $W^{-1}(T(t))$ to $W^{-1}(0^+)$, so that $Y(0,t)$ follows the behavior of its dominating term

$$\exp\left(-\min_u \int_0^t \lambda_u(v)dv\right) \sim \exp\left(-b_k \int_0^t \exp(-D(k)T^{-1}(v))dv\right),$$

where b_k is one of the constants c_u appearing in (34), and is associated with a node realizing $D(k)$. □

ON THE SOLUTIONS OF A CLASS OF CONTINUOUS LINEAR PROGRAMS*

EDWARD J. ANDERSON† AND ANDREW B. PHILPOTT‡

Abstract. This paper discusses the form of solutions for a class of continuous linear programs called separated continuous linear programs. It is shown that under certain assumptions on the problem data the optimal solutions can be taken to be piecewise analytic functions. This yields a strong duality result as a corollary.

Key words. continuous linear program, duality, discrete approximation

AMS subject classifications. 49A55, 49B36, 49D99, 90C48

1. Introduction.

In 1953 Bellman [7] introduced a class of optimization problems which he called *bottleneck problems.* These problems are generally referred to in the literature as continuous linear programs since they can be formulated as linear programs having variables which are functions of time as follows:

$$\begin{aligned} \text{CLP} \qquad & \text{maximize} \int_0^T c(t)^T x(t)dt \\ & \text{subject to } B(t)x(t) + \int_0^t K(t,s)x(s)ds \leq b(t), \\ & \qquad x(t) \geq 0, \qquad t \in [0,T]. \end{aligned}$$

The usual approach to solving CLP is to form an approximation by discretizing the time interval $[0,T]$ (see, e.g., Buie and Abrham [9]). A number of authors (see Lehman [12], Drews [10], Hartberger [11], Segers [17], Perold [13], and Anstreicher [6]) have attempted to generalize the simplex method to solve instances of CLP without discretizing. Such a generalization requires the analogues of basic feasible solutions and a pivot operation to be defined. The most comprehensive treatment of these issues is represented by the work of Perold [13] who derives a characterization of the extreme points of the feasible region of CLP in the case where the matrices $B(\cdot)$ and $K(\cdot,\cdot)$ are constant and the components of $x(\cdot)$ are so-called right analytic functions. (A function $g : [0,T] \to R$ is called *right analytic* if for each $t \in [0,T)$ there is some $\epsilon > 0$ and an analytic function $h_t(\cdot) : (t-\epsilon, t+\epsilon) \to R$ such that $g(s) = h_t(s), s \in [t, t+\epsilon)$.) In general, however, there is no guarantee that there will be an extreme-point optimal solution to CLP that is right analytic, even when the matrices B and K are constant and the functions appearing in the problem formulation are all analytic. Observe that a right analytic function may have an infinite number of discontinuities.

We are tempted to conjecture (see [13, p. 111]) that in many instances of CLP there will be optimal solutions that are analytic with a finite number of jump discontinuities. We call such functions *piecewise analytic* and define them formally as follows. First a set $\{t_0, t_1, \ldots, t_m\}$ is said to be a *partition* of $[0,T]$ if

$$0 = t_0 < t_1 < \cdots < t_m = T.$$

‡ Department of Engineering Science, University of Auckland, Auckland, New Zealand.

Now, we call a function $g(\cdot)$ *piecewise analytic* (*piecewise constant*) on $[0,T]$ if there is a partition $\{t_0, t_1, \ldots, t_m\}$, $\epsilon > 0$, and analytic (constant) functions $h_i(\cdot) : (t_{i-1} - \epsilon, t_i + \epsilon) \to R$ such that $g(s) = h_i(s)$, $s \in [t_{i-1}, t_i)$ for $i = 1, 2, \ldots, m$.

The purpose of this paper is to show that for a substantial class of continuous linear programs there is a piecewise analytic optimal solution. The class of problems we consider are called *separated continuous linear programs*, which have the following form:

$$\text{SCLP} \qquad \text{minimize} \int_0^T c(t)^T x(t)dt$$

$$\text{subject to} \int_0^t Gx(s)ds + y(t) = a(t), \tag{1}$$

$$Hx(t) + z(t) = b(t), \tag{2}$$

$$x(t), y(t), z(t) \geq 0, \qquad t \in [0,T]. \tag{3}$$

Here $x(\cdot)$, $z(\cdot)$, $b(\cdot)$ and $c(\cdot)$ are bounded measurable functions; $y(\cdot)$ and $a(\cdot)$ are continuous functions. The dimensions of $x(\cdot)$, $y(\cdot)$, and $z(\cdot)$ are n_1, n_2, and n_3, respectively. We let $\hat{x}^T(\cdot) = (x^T(\cdot), y^T(\cdot), z^T(\cdot))$.

This problem was first studied by Anderson [1] in the context of job-shop scheduling, and is discussed in detail in [2] and [3]. By differentiating the constraints (1), SCLP can be shown to be equivalent to a special type of linear optimal control problem with state variable inequality constraints. These constraints pose difficulties when applying classical optimal control techniques, since in many cases the control ceases to be of bang-bang type. However, with an assumption that the feasible region of SCLP is bounded, the optimal solution can be shown to be an extreme point of this set. The reader is referred to [3] for this result and a characterization of the extreme points of SCLP as appropriately defined basic feasible solutions.

The assumption that the feasible region of SCLP is bounded also allows the derivation of some results defining the form of optimal solutions of SCLP. In this respect, it is shown in [3] that if the components of $b(\cdot)$ are constant and the components of $a(\cdot)$ and $c(\cdot)$ are affine functions then SCLP has an optimal solution $\hat{x}(\cdot)$ that is piecewise affine. In recent work, Pullan [16] has shown under the same boundedness assumption that if the components of $b(\cdot)$ are constant, the components of $a(\cdot)$ are affine, and the components of $c(\cdot)$ are concave analytic functions on a neighbourhood of $[0,T]$, then SCLP has an optimal solution $\hat{x}(\cdot)$ that is piecewise affine. In this paper we demonstrate, under the (stronger) assumption that the set $D(t) = \{\xi : H\xi \leq b(t), \xi \geq 0\}$ is bounded for each t, that SCLP has an optimal solution $\hat{x}(\cdot)$ that is piecewise analytic if the components of $a(\cdot)$ and $b(\cdot)$ are analytic on a neighbourhood of $[0,T]$ and the components of $c(\cdot)$ are constant functions.

2. Solutions for separated continuous linear programs. The proof of our result proceeds according to the following plan. First, by using a dual problem, we construct a lower bound on the value of SCLP. Following the approach of Pullan [15] this lower bound is shown to be the same as the value of a discrete approximation to SCLP. We then define a certain partition and corresponding discrete program DP that has the property that the lower bound is tight. With this partition we may construct from the optimal solution $(\bar{x}, \bar{y}, \bar{z})$ to DP a piecewise analytic feasible solution to SCLP with the same objective function value as $(\bar{x}, \bar{y}, \bar{z})$, thus making it optimal.

Dual problems for SCLP can be defined in various ways. We choose to define the

dual SCLP* as follows:

$$\begin{aligned}\text{SCLP}^* \qquad &\text{maximize } -\int_0^T d\pi(t)^T a(t) - \int_0^T \eta(t)^T b(t)dt \\ &\text{subject to } c(t) - G^T\pi(t) + H^T\eta(t) \geq 0, \\ &\qquad \eta(t) \geq 0, \text{ a.e. on } [0,T], \\ &\qquad \pi(t) \text{ monotonic increasing and right continuous} \\ &\qquad \text{on } [0,T] \text{ with } \pi(T) = 0.\end{aligned}$$

Here the components of $\eta(\cdot)$ are in $L_1[0,T]$. It is straightforward (see [15]) to establish the following result.

LEMMA 2.1 (weak duality). $V(\text{SCLP}^*) \leq V(\text{SCLP})$.

(Here, and in what follows, we write $V(\text{P})$ for the optimal value of program P.)

We now restrict our attention to the case where the components of a and b are analytic on a neighbourhood of $[0,T]$ and the components of c are constant functions. In this case we can obtain a bound on $V(\text{SCLP})$ by considering the solution to a discretized problem. Formally, given a partition $\{t_0, t_1, \ldots, t_m\}$ of $[0,T]$, if we define $\bar{a}_i = a(t_i) - a(t_{i-1})$ and $\bar{b}_i = \int_{t_{i-1}}^{t_i} b(t)dt$, then we are led to the following discrete version of SCLP:

$$\begin{aligned}\text{DP} \qquad &\text{minimize} \quad \sum_{i=1}^m c^T\bar{x}_i \\ &\text{subject to} \quad G\bar{x}_1 + \bar{y}_1 = a(t_0) + \bar{a}_1, \\ &\qquad G\bar{x}_i + \bar{y}_i - \bar{y}_{i-1} = \bar{a}_i, \qquad i = 2,3,\ldots,m, \\ &\qquad H\bar{x}_i + \bar{z}_i = \bar{b}_i, \qquad i = 1,2,\ldots,m, \\ &\qquad \bar{x}_i, \bar{y}_i, \bar{z}_i \geq 0, \qquad i = 1,2,\ldots,m.\end{aligned}$$

The problem DP has a linear programming dual given by

$$\begin{aligned}\text{DP}^* \qquad &\text{maximize} \quad a^T(t_0)\bar{\pi}_1 + \sum_{i=1}^m \bar{a}_i^T\bar{\pi}_i - \sum_{i=1}^m \bar{\eta}_i^T\bar{b}_i \\ &\text{subject to} \quad c - G^T\bar{\pi}_i + H^T\bar{\eta}_i \geq 0, \quad i = 1,2,\ldots,m, \\ &\qquad \bar{\pi}_i - \bar{\pi}_{i-1} \geq 0, \qquad i = 2,3,\ldots,m, \\ &\qquad \bar{\eta}_i \geq 0, \qquad i = 1,2,\ldots,m, \\ &\qquad \bar{\pi}_m \leq 0.\end{aligned}$$

The following result gives a bound on $V(\text{SCLP})$.

LEMMA 2.2. $V(\text{DP}) \leq V(\text{SCLP})$.

Proof. Suppose that $(\bar{x}_i, \bar{y}_i, \bar{z}_i)$, $i = 1,2,\ldots,m$, is an optimal solution to DP. Then by the duality theorem of linear programming there is some $(\bar{\pi}, \bar{\eta})$ that solves DP* with $V(\text{DP}^*) = V(\text{DP})$. It is easy to see that any feasible solution to DP* can be used to construct a piecewise constant feasible solution to SCLP*. Formally we set $\pi(T) = \eta(T) = 0$ and define $\pi(t) = \bar{\pi}_i$, $\eta(t) = \bar{\eta}_i$, for $t \in [t_{i-1}, t_i)$. Furthermore, since

$$a^T(t_0)\bar{\pi}_1 + \sum_{i=1}^m \bar{a}_i^T\bar{\pi}_i - \sum_{i=1}^m \bar{\eta}_i^T\bar{b}_i = -\int_0^T d\pi(t)^T a(t) - \int_0^T \eta(t)^T b(t)dt,$$

it follows that $V(\text{DP}^*) \leq V(\text{SCLP}^*)$, whence the result follows from Lemma 2.1. □

In what follows, we show how to define a partition so that the optimal solution $\bar{x}$ to DP with this partition has the same value as $V(\text{SCLP})$. This can be achieved by constructing from $\bar{x}$ a feasible solution x to SCLP, which is analytic in each interval of the partition and satisfies $\int_0^T x(t)dt = \sum_{i=1}^m \bar{x}_i$. Since c is constant this solution x will have the same value as $V(\text{DP})$, and is thus a piecewise analytic optimal solution for SCLP by virtue of Lemma 2.2.

For each interval of the partition, the solution $x(t)$ at time t is defined to be a convex combination of certain extreme points of a subset of $D(t) = \{\xi : H\xi \leq b(t), \xi \geq 0\}$, with the property that its integral over the interval matches $\bar{x}_i$. To ensure that this is possible we need to assume that $D(t)$ is bounded for each t. Furthermore, to show that the $x(\cdot)$ constructed is feasible for SCLP we must ensure that it generates variables $y(\cdot)$ that are nonnegative. This is achieved by working with a very large partition with the property that each component of $y(\cdot)$ generated by each of the possible extreme points is monotonic on each interval of the partition, thus guaranteeing that $y(\cdot)$ is nonnegative between the endpoints of each such interval.

To define the extreme-point solutions alluded to above, we make use of the matrix

$$K = \begin{bmatrix} G & I & -I & 0 \\ H & 0 & 0 & I \end{bmatrix},$$

obtained by differentiating (1) and writing these constraints with (2) in matrix form, where the columns correspond to variables $x(\cdot)$, $\dot{y}^+(\cdot)$, $\dot{y}^-(\cdot)$, $z(\cdot)$, and the right-hand side is $[\dot{a}(\cdot)\ b(\cdot)]^T$. Clearly K has full rank, and so any $n_2 + n_3$ linearly independent columns of K form a basis matrix K_B, say. Let

$$Q = \left\{ K_B^{-1} \begin{bmatrix} \dot{a}(\cdot) \\ b(\cdot) \end{bmatrix} : K_B \quad \text{is a basis matrix of} \quad K \right\},$$

where $\dot{a}$ denotes da/dt, and let

$$R = \{\rho_j(\cdot) : \quad \rho \in Q, \quad 1 \leq j \leq n_2 + n_3\}.$$

Since each component of $\dot{a}(\cdot)$ and $b(\cdot)$ is analytic on a neighbourhood of $[0, T]$, R consists of a finite set of analytic functions. By a standard result on analytic functions, each of these is either identically zero or has a finite number of zeros on $[0, T]$. Let $\{t_0, t_1, \ldots, t_m\}$ be the smallest partition of $[0, T]$ that contains all the zeros of each function in R that is not identically zero. We call this the *canonical partition* of $[0, T]$. It follows for any subinterval (t_{i-1}, t_i) of the canonical partition that for all $\rho_j(\cdot) \in R$, either $\rho_j(t) > 0$, $t \in (t_{i-1}, t_i)$, or $\rho_j(t) = 0$, $t \in (t_{i-1}, t_i)$, or $\rho_j(t) < 0$, $t \in (t_{i-1}, t_i)$.

Henceforth we concentrate our attention on a typical subinterval (t_{i-1}, t_i) of the canonical partition as defined above. For such an interval we make the following definitions. Given any vector $u^{(i)} \in \{-1, 0, 1\}^{n_2}$, we let $U^{(i)} = \text{diag}(u^{(i)})$, and define

$$K^{(i)} = \begin{bmatrix} G & U^{(i)} & 0 \\ H & 0 & I \end{bmatrix},$$

$$\bar{E}_i = \left\{ \bar{\psi} : K^{(i)}\bar{\psi} = \begin{bmatrix} \bar{a}_i \\ \bar{b}_i \end{bmatrix}, \quad \bar{\psi} \geq 0 \right\},$$

and for $t \in (t_{i-1}, t_i)$, let

$$E_i(t) = \left\{ \psi : K^{(i)}\psi = \begin{bmatrix} \dot{a}(t) \\ b(t) \end{bmatrix}, \quad \psi \geq 0 \right\}.$$

Here $\bar{a}_i$ and $\bar{b}_i$ are defined as above for the canonical partition. Thus $\bar{E}_i$ consists of vectors $\bar{\psi} = (\bar{\xi}^T, \bar{\eta}^T, \bar{\zeta}^T)^T$ that, upon identifying $\bar{x}_i$ with $\bar{\xi}$ and $\bar{z}_i$ with $\bar{\zeta}$, are feasible for DP in the ith interval of the partition without the constraint $\bar{y}_i \geq 0$ but with the restriction that over the interval the jth component of the y variables must not decrease when $u_j^{(i)} = 1$, must not increase when $u_j^{(i)} = -1$, and must remain constant when $u_j^{(i)} = 0$. Similarly $E_i(t)$ consists of vectors that satisfy the differentiated constraints of SCLP in the ith interval of the partition, as well as having y components decreasing, held constant, or increasing, depending on the value of $u^{(i)}$. (To simplify the notation we choose to suppress the dependence of $\bar{E}_i$ and $E_i(t)$ on $u^{(i)}$.) Observe that both $\bar{E}_i$ and $E_i(t)$ are convex, polyhedral sets. The following lemmas show that each extreme point of $\bar{E}_i$ is the integral over (t_{i-1}, t_i) of the corresponding extreme point of $E_i(t)$.

LEMMA 2.3. *If $\bar{\psi}$ is a basic feasible solution for $\bar{E}_i$ with basis matrix K_B, then*

$$\bar{\psi} = \int_{t_{i-1}}^{t_i} K_B^{-1} \begin{bmatrix} \dot{a}(t) \\ b(t) \end{bmatrix} dt.$$

Proof. The proof is immediate from the definition of $\bar{a}_i$ and $\bar{b}_i$. □

LEMMA 2.4. *If $\bar{\psi}$ is a basic feasible solution for $\bar{E}_i$ with basis matrix K_B, then for all $t \in (t_{i-1}, t_i)$,*

$$K_B^{-1} \begin{bmatrix} \dot{a}(t) \\ b(t) \end{bmatrix} \geq 0.$$

Proof. Let

$$\psi(t) = K_B^{-1} \begin{bmatrix} \dot{a}(t) \\ b(t) \end{bmatrix},$$

and suppose for some j that $e_j^T \psi(t) < 0$ for some $t \in (t_{i-1}, t_i)$. Since the columns of $K^{(i)}$ that appear in K_B also appear in K, K_B is a basis matrix of K. Thus $e_j^T \psi(t) \in R$ and by virtue of the definition of the canonical partition, $e_j^T \psi(t) < 0$ for every $t \in (t_{i-1}, t_i)$. By Lemma 2.3 it follows that

$$e_j^T K_B^{-1} \begin{bmatrix} \bar{a}_i \\ \bar{b}_i \end{bmatrix} < 0,$$

which contradicts the assumption that $\bar{\psi}$ is a basic feasible solution for $\bar{E}_i$. □

The following result is now immediate.

LEMMA 2.5. *For each extreme point $\bar{\psi}$ of $\bar{E}_i$ there exists a function $\psi(\cdot)$, analytic on a neighbourhood of $[0, T]$, with $\psi(t)$ an extreme point of $E_i(t)$, and $\int_{t_{i-1}}^{t_i} \psi(t)dt = \bar{\psi}$.*

We are now ready to prove the main result of the paper. This shows how a piecewise analytic optimal solution to SCLP may be constructed from an optimal solution to DP with the canonical partition. Since the cost coefficients are all constant, we need only ensure that the piecewise analytic solution is feasible for SCLP and has

$\int_{t_{i-1}}^{t_i} x(s)ds$ matching $\bar{x}_i$ on the partition. The feasibility of the piecewise analytic solution is guaranteed by constructing it from the extreme points of sets $E_i(t)$, which have been defined so that the y variables are monotonic within each interval of the partition.

THEOREM 2.6. *Suppose that in* SCLP *the components of* $a(\cdot)$ *and* $b(\cdot)$ *are analytic on a neighbourhood of* $[0,T]$ *and the components of* $c(\cdot)$ *are constant functions. If* $D(t) = \{\xi : H\xi \leq b(t), \xi \geq 0\}$ *is bounded for all* t *then* SCLP *has an optimal solution for which* $x(\cdot)$ *is piecewise analytic.*

Proof. Since $D(t)$ is bounded, SCLP has an optimal solution, say $x^*(\cdot)$. Let $P = \{t_0, t_1, \ldots, t_m\}$ be the canonical partition for SCLP, and for each i define $\bar{x}_i = \int_{t_{i-1}}^{t_i} x^*(s)ds$. It is clear that we may define $\bar{y}_i$ and $\bar{z}_i$ similarly so that $(\bar{x}_i, \bar{y}_i, \bar{z}_i)$, $i = 1, 2, \ldots, m$, is feasible for DP with the partition P. For each $i = 1, 2, \ldots, m$ we define $u^{(i)}$ by

$$e_j^T u^{(i)} = \begin{cases} -1, & e_j^T(\bar{a}_i - G\bar{x}_i) < 0, \\ 0, & e_j^T(\bar{a}_i - G\bar{x}_i) = 0, \\ 1, & e_j^T(\bar{a}_i - G\bar{x}_i) > 0, \end{cases}$$

and define $\bar{E}_i$ and $E_i(t)$ as above.

For the moment let us consider $\bar{E}_i$ for some i. Let $\{\bar{\psi}^{(k)} : k = 1, 2, \ldots, N\}$ be the set of extreme points of $\bar{E}_i$, and denote the vector $(\bar{x}_i^T, (\bar{a}_i - G\bar{x}_i)^T U^{(i)}, \bar{z}_i^T)^T$ by $\hat{x}_i$. It is clear from the definition of $u^{(i)}$, that $\hat{x}_i \in \bar{E}_i$, whence since $\bar{E}_i$ is bounded (because $D(t)$ is) $\hat{x}_i$ is a convex combination of the extreme points of $\bar{E}_i$, i.e., there exists $\theta^{(k)} \geq 0$, $k = 1, 2, \ldots, N$, with $\sum_{k=1}^N \theta^{(k)} = 1$, and $\hat{x}_i = \sum_{k=1}^N \theta^{(k)} \bar{\psi}^{(k)}$. By Lemma 2.5 we can find functions $\psi^{(k)}(\cdot)$, analytic on a neighbourhood of $[0,T]$, such that $\psi^{(k)}(t)$ is an extreme point for $E_i(t)$, $t \in (t_{i-1}, t_i)$, and $\int_{t_{i-1}}^{t_i} \psi^{(k)}(t) = \bar{\psi}^{(k)}$.

Let

$$\psi_i(t) = \sum_{k=1}^N \theta^{(k)} \psi^{(k)}(t), \qquad t \in [t_{i-1}, t_i).$$

It follows that

$$\int_{t_{i-1}}^{t_i} \psi_i(t)dt = \sum_{k=1}^N \theta^{(k)} \int_{t_{i-1}}^{t_i} \psi^{(k)}(t)dt = \sum_{k=1}^N \theta^{(k)} \bar{\psi}^{(k)} = \hat{x}_i, \tag{4}$$

Now, letting $\psi_i(\cdot) = (\xi_i(\cdot)^T, \eta_i(\cdot)^T, \zeta_i(\cdot)^T)^T$, define $\hat{x}(t) = (x(t)^T, y(t)^T, z(t)^T)^T$ for $t \in [t_{i-1}, t_i)$, $i = 1, 2, \ldots, m$ by

$$\begin{aligned} x(t) &= \xi_i(t), \\ y(t) &= a(t_0) + \sum_{j=1}^{i-1} \int_{t_{j-1}}^{t_j} U^{(j)} \eta_j(t_j) + \int_{t_{i-1}}^{t} U^{(i)} \eta_i(s)ds, \\ z(t) &= \zeta_i(t), \end{aligned}$$

and define $\hat{x}(T) = \lim_{t \uparrow T} \hat{x}(t)$. Then $\hat{x}(\cdot)$ is piecewise analytic, and by virtue of the definition of $E_i(t)$, it follows that $x(\cdot) \geq 0$ and $z(\cdot) \geq 0$.

To show that $y(\cdot) \geq 0$ observe that for each i

$$y(t_i) - y(t_{i-1}) = \int_{t_{i-1}}^{t_i} U^{(i)} \eta_i(t)dt = U^{(i)} \int_{t_{i-1}}^{t_i} \eta_i(t)dt = U^{(i)} U^{(i)} (\bar{a}_i - G\bar{x}_i),$$

by virtue of (4) and the definition of $\hat{x}_i$. It follows from the definition of $U^{(i)}$ that $y(t_i) - y(t_{i-1}) = \bar{a}_i - G\bar{x}_i$. Since $y(t_0) = a(t_0)$, we have for $i = 1, 2, \ldots, m$, that $y(t_i) = \bar{y}_i \geq 0$. Since for $t \in [t_{i-1}, t_i)$, $\dot{y}(t) = U^{(i)}\eta_i(t)$ and $\eta_i(t) \geq 0$, it is easy to see for each such interval that $y(t)$ lies between $y(t_{i-1}) = \bar{y}_{i-1}$ and $y(t_i) = \bar{y}_i$, and hence is nonnegative.

Finally it remains to show that $\hat{x}(\cdot)$ is optimal for SCLP, which we do by observing that

$$\int_0^T c^T x^*(t)dt = \sum_{i=1}^m c^T \bar{x}_i = \sum_{i=1}^m c^T \int_{t_{i-1}}^{t_i} x(t)dt = \int_0^T c^T x(t)dt,$$

from which the result follows. □

COROLLARY 2.7. *Under the conditions of Theorem* 2.6 *the optimal value of* SCLP *equals the optimal value of* DP *with the canonical partition.*

Proof. Given any feasible solution to DP with the canonical partition, the proof of Theorem 2.6 shows how to construct a feasible solution to SCLP with the same value. If DP is unbounded then we may apply the construction to show that SCLP is unbounded, which contradicts an assumption of the theorem. Thus DP has an optimal solution, which corresponds to a feasible solution to SCLP with the same value, yielding the result by virtue of Lemma 2.2. □

COROLLARY 2.8 (strong duality). *Under the conditions of Theorem* 2.6 *the optimal value of* SCLP *equals the optimal value of* SCLP* *with attainment in both primal and dual.*

Proof. With the canonical partition, $V(\text{SCLP}) = V(\text{DP}) = V(\text{DP}^*) = V(\text{SCLP}^*)$ and the solutions of DP and DP* can be used to construct optimal solutions to SCLP and SCLP*, respectively. □

3. Concluding remarks. Under suitable assumptions on the problem data we have shown above that SCLP has a piecewise analytic optimal solution. However, the piecewise analytic optimal solution we construct in Theorem 2.6 is not necessarily a basic feasible solution, and although our boundedness assumption ensures that an optimal basic feasible solution to SCLP must exist, there is, as Perold [13, p. 14] has observed, no guarantee that any such solution will be piecewise analytic.

Theorem 2.6 may be applied to a number of examples of SCLP with constant costs. In particular we may show that the continuous-time minimum-cost network flow problem CNP of [5] has a piecewise analytic optimal solution when the arc costs are constant with time, and the arc and node capacities are analytic. A further special case of this problem is the continuous-time maximum flow problem (MFP) dealt with in [4] and [14]. If the arc and node capacities in MFP are analytic then MFP has a piecewise analytic solution. Indeed we can also show in this case that the corresponding generalized cut for this problem has a finite number of switches, and thus corresponds to an optimal solution to the dual of MFP.

It is interesting to speculate on whether a stronger result than Theorem 2.6 is true. By taking canonical partitions between breakpoints of the functions $a(\cdot)$, $b(\cdot)$, and $c(\cdot)$ it is certainly possible to extend Theorem 2.6 to the case where $c(\cdot)$ is required to be piecewise constant and $a(\cdot)$ and $b(\cdot)$ are piecewise analytic, respectively. In view of Pullan's result for concave analytic $c(\cdot)$ cited above, it is natural to seek an extension of Theorem 2.6 to the case where $c(\cdot)$, as well as $a(\cdot)$ and $b(\cdot)$, is an analytic function. Unfortunately, although this result may well be true, it is certainly much harder to establish.

We might also conjecture that some result similar to Theorem 2.6 is true when $b(\cdot)$ is a (not necessarily analytic) continuous function. In the absence of integral constraints (1), SCLP with constant cost coefficients becomes a linear program with a time varying right-hand side vector. Böhm [8] has shown, using a continuous selection theorem, that such a parametric linear program has an optimal solution that varies continuously with time. However, it is not known whether SCLP has a continuous optimal solution when the integral constraints are included, even if $a(\cdot)$ is required to be constant.

THE RICCATI EQUATION FOR OPTIMAL CONTROL PROBLEMS WITH MIXED STATE-CONTROL CONSTRAINTS: NECESSITY AND SUFFICIENCY*

VERA ZEIDAN†

Abstract. The goal of this paper is to conduct a complete study of second-order conditions for the optimal control problem with mixed state-control constraints. The conjugate point theory is presented and a necessary condition in terms of the corresponding Riccati equation is obtained. Sufficiency criteria are developed in terms of strengthened necessary conditions, including the Riccati equation. The results generalize the known ones for pure control constraints as well as for the mixed state-control constraints.

Key words. optimal control, mixed state-control constraints, Riccati equation, conjugate points, strong normality, necessary conditions, sufficient conditions, weak and strong local minima

AMS subject classification. 49B10

1. Introduction.

Second-order conditions for the optimal control problem with equality or inequality constraints on the control, state, or on both variables have been the focus of several papers in the literature starting about two decades ago; see, for instance, [12], [6], [11], [20], [14], [15], and [13]. For the case of pure control equality and inequality constraints, the accessory problem is given in [20], where necessary conditions involving conjugate points and the Riccati equation also were developed for optimality of continuous controls. For the same problem, sufficiency criteria for weak and strong local minima were obtained in [11]. They consist of strengthened necessary conditions and in particular, the Riccati equation presented in [20]. For pure state constraints, sufficient conditions in terms of a certain Riccati inequality are given in [14]. Concerning the problem with mixed control-state equality and inequality constraints, we can find the accessory problem in [12] and [6]. For the equality constraints case, see also [15]. The accessory problem can be also obtained by applying results known for the abstract nonlinear programming setting [8] and [16] to the optimal control problem. A study of the case when the accessory problem, corresponding to the one with equality mixed constraints, is abnormal can be found in [3]. In a recent work [9], a set of sufficient conditions in terms of a Riccati-type equation were established by applying a generalization of [8] to the problem. However, between these conditions and the necessary conditions there is a gap larger than expected. Recently a sufficiency criterion for weak local minimality of a continuous control was given in [13].

In this paper two objectives are accomplished for the optimal control problem with mixed state-control constraints and L^∞-control functions. First, the notion of conjugate points is introduced and necessary conditions in terms of this notion, and then in terms of a Riccati-type equation, were established. Hence, the results of [20] are generalized to the case of L^∞-controls and mixed state-control constraints. As we will see, our results invoke the concept of strong normality, which also extends the one given in [20]. The second objective is to complete the study of problems with mixed state-control constraints by developing second-order sufficient conditions (Theorem 6.1) for weak and strong local optimality that are natural strengthening

of the necessary conditions obtained in the first part of the paper. Thus, the gap between the two sets of conditions is as small as possible, and hence the results in [9] and [11] are included in Theorem 6.1. In Corollary 6.1 we show that if the ideas in [14] were adopted to our setting, the resulting sufficiency criterion would be a special case of Theorem 6.1. Finally we show that the recent sufficiency theorem obtained in [13] for continuous control candidates is included in this paper (see Remarks 6.4 and 6.5).

The paper is divided as follows. Section 2 contains the statement of the problem. Known results needed for the rest of the paper are given in §3. A thorough study of the normality and the controllability of the accessory problem is presented in §4. The second-order necessary and sufficient conditions are given, respectively, in §§5 and 6. An example illustrating the results is given in §7.

2. Statement of the problem. Consider the following optimal control problem:

$$\text{(C)} \qquad \text{minimize } J(x,u) := \ell(x(b)) + \int_a^b g(t,x(t),u(t))dt$$

$$\text{subject to } \dot{x}(t) = f(t,x(t),u(t)) \qquad \text{a.e.} \tag{2.1}$$

$$x(a) = A\,, \qquad \psi(x(b)) = 0 \tag{2.2}$$

and

$$G(t,x(t),u(t)) \leq 0 \qquad \text{a.e.,} \tag{2.3}$$

where $x(\cdot) : [a,b] \longrightarrow \mathbb{R}^n$ is absolutely continuous (AC), $u(\cdot) : [a,b] \longrightarrow \mathbb{R}^m$ is in $L^\infty[a,b]$, and

$$\begin{aligned} &g : [a,b] \times \mathbb{R}^n \times \mathbb{R}^m \longrightarrow \mathbb{R}, \quad && f : [a,b] \times \mathbb{R}^n \times \mathbb{R}^m \longrightarrow \mathbb{R}^n \\ &\psi : \mathbb{R}^n \longrightarrow \mathbb{R}^r, && G : [a,b] \times \mathbb{R}^n \times \mathbb{R}^m \longrightarrow \mathbb{R}^k \\ &\ell : \mathbb{R}^n \longrightarrow \mathbb{R}\,, \end{aligned}$$

and $r \leq n$, $k \leq m$.

DEFINITION 2.1. *A pair* (x,u) *is* admissible *for* (C) *if* x *is* AC, u *is in* $L^\infty[a,b]$ *and the constraints* (2.1)–(2.3) *are satisfied by* (x,u).

DEFINITION 2.2. *An admissible pair* $(\hat{x},\hat{u})$ *is a* weak *local minimum for* (C) *if for some* $\epsilon > 0$, $(\hat{x},\hat{u})$ *minimizes* $J(x,u)$ *over all admissible pairs* (x,u) *satisfying*

$$\| x - \hat{x} \|_\infty < \epsilon \text{ and } \| u - \hat{u} \|_\infty < \epsilon.$$

The pair $(\hat{x},\hat{u})$ *is a* strong *local minimum if only the first inequality holds.*

3. Preliminary results. Given a pair $(\hat{x},\hat{u}) \in AC \times L^\infty[a,b]$. We define

$$T(\hat{x},\hat{u};\epsilon) := \{(t,x,u) \in [a,b] \times \mathbb{R}^n \times \mathbb{R}^m : |x - \hat{x}(t)| < \epsilon \text{ and } |u - \hat{u}(t)| < \epsilon\}\,,$$

$((x(\cdot),u(\cdot)) \in T(\hat{x},\hat{u};\epsilon)$ means that $(t,x(t),u(t)) \in T(\hat{x},\hat{u};\epsilon)$ almost everywhere),

$$I(t) := \{i \in \{1,\dots k\} : G^i(t,\hat{x}(t),\hat{u}(t)) = 0\}$$

(the elements of $I(t)$ are arranged in an increasing order), and

$$G^{I(t)} := \left\{G^i : i \in I(t)\right\}, \qquad G^\emptyset := 0.$$

For $\mathcal{F} := (f, g, G)$, the following regularity conditions will be recalled.

(R1) There exist $\epsilon > 0$ and $\alpha > 0$ such that for $t \in [a, b]$ almost everywhere, $\mathcal{F}(t, \cdot, \cdot)$ and its first derivatives in (x, u) are continuous on $\{(x, u) : (t, x, u) \in T(\hat{x}, \hat{u}; \epsilon)\}$ uniformly in t and essentially bounded at $(t, \hat{x}(t), \hat{u}(t)), \psi$ and ℓ are C^1 on $\{x : |x - \hat{x}(b)| < \epsilon\}$, $\nabla\hat{\psi}(b) := \nabla\psi(\hat{x}(b))$ is of full rank, and if $I(t) \neq \emptyset$

$$G_u^{I(t)}(t, \hat{x}(t), \hat{u}(t)) \left(G_u^{I(t)}(t, \hat{x}(t), \hat{u}(t))\right)^* \geq \alpha I_{\mathrm{Card} I(t)} \quad \text{a.e.},$$

where A^* is the transpose of the matrix A and $I_{\mathrm{Card} I(t)}$ is the identity matrix with a number of rows and columns equal to the number of elements in $I(t)$, i.e., Card $I(t)$.

(R2) There exists $\epsilon > 0$ such that $\mathcal{F}(t, \cdot, \cdot)$ and its derivatives in (x, u) up to second order are continuous on $\{(x, u) : (t, x, u) \in T(\hat{x}, \hat{u}; \epsilon)\}$ uniformly in t and essentially bounded at $(t, \hat{x}(t), \hat{u}(t)), \psi$ and ℓ are C^2 on $\{x : |x - \hat{x}(b)| < \epsilon\}$.

(R3) For every subset $A \subset \{1, \ldots, k\}$ and for every bounded set $M \subset [a, b] \times \mathbb{R}^n \times \mathbb{R}^m$, there exists $\epsilon > 0$ such that, either $M_\epsilon^A := \{(t, x, u) \in M : -\epsilon \leq G^i(t, x, u) \leq 0, \forall i \in A\}$ is empty or $G_u^A(t, x, u)(G_u^A(t, x, u))^* \geq \epsilon$ on M_ϵ^A.

(R4) The multivalued map $t \rightsquigarrow I(t)$ is piecewise constant.

The next result is a weak version of the minimum principle applied to (C) [10, VI. 3]. Any admissible pair $(\hat{x}, \hat{u})$ satisfying conditions (a)–(e) below is an *extremal*. An extremal $(\hat{x}, \hat{u})$ is *normal* if the corresponding l_0 is not zero.

THEOREM 3.1 (see [10]). *Let $(\hat{x}, \hat{u})$ be a weak local minimum for* (C). *Assume* (R1) *holds; then there exist $\hat{p} : [a, b] \to \mathbb{R}^n$ in AC, $\hat{q} : [a, b] \to \mathbb{R}^k$ in $L^\infty[a, b]$, $\nu \in \mathbb{R}^r$ and $\lambda_0 \in \mathbb{R}$ such that*

(a) $\lambda_0 \geq 0$, *for all i, $\hat{q}^i(t) \geq 0$ almost everywhere, and $\lambda_0 + |\nu| + \| \hat{q} \|_\infty \neq 0$;*

(b) $-\dot{\hat{p}}^*(t) = \hat{H}_x(t)$ *almost everywhere;*

(c) $\hat{H}_u(t) = 0$ *almost everywhere;*

(d) $\hat{q}^i(t)\hat{G}^i(t) = 0$ *almost everywhere, for all $i = 1, \ldots, k$;*

(e) $\hat{p}(b) = [\nabla\hat{\psi}(b)]^*\nu + \lambda_0[\nabla\ell(\hat{x}(b))]^*$,

where

$$H(t, x, u, p, q, \lambda_0) = \lambda_0 g(t, x, u) + p^* f(t, x, u) + q^* G(t, x, u). \tag{3.1}$$

$\hat{H}(t)$ is the evaluation of H at $(t, \hat{x}(t), \hat{u}(t), \hat{p}(t), \hat{q}(t), \lambda_0)$, and $\hat{G}(t)$ is $G(t, \hat{x}(t), \hat{u}(t))$.

Remark 3.1. If λ_0 and $\hat{p}$ are given, then (R1) and conditions (c) and (d) yield the uniqueness of $\hat{q}$ (see the proof of Proposition 4.1).

The following result is a necessary condition of second order. It is in terms of the accessory problem associated to (C). It is given with more generality in [12]. It can also be deduced by applying the second-order necessary conditions developed in [8] or [16] for the abstract optimization problem. For the case where only equality mixed state-control constraints are present, the accessory problem can be found in [15].

Set $\Lambda_0 := \{(\lambda_0, \nu, p, q)$ satisfying Theorem 3.1 with $\lambda_0 + |\nu| + \| q \|_\infty = 1\}$.

THEOREM 3.2 (see [12]). *Assume* (R1)–(R3) *and that $(\hat{x}, \hat{u})$ is a weak local minimum for* (C). *Then Λ_0 is nonempty. If Λ_0 is a singleton then*

$$J_2(\eta, v) := \frac{1}{2}\eta^*(b)\Gamma\eta(b) + \frac{1}{2}\int_a^b (\eta^*(t), v^*(t)) \nabla^2_{(x,u)} \hat{H}(t) \begin{pmatrix} \eta(t) \\ v(t) \end{pmatrix} dt \geq 0$$

for all $(\eta, v) \in AC \times L^\infty[a, b]$ such that

$$\dot{\eta}(t) = \hat{f}_x(t)\eta(t) + \hat{f}_u(t)v(t) \quad \text{a.e.}, \tag{3.2}$$

$$\eta(a) = 0, \ \nabla\hat{\psi}(b)\eta(b) = 0, \tag{3.3}$$

$$\hat{G}_x^{I(t)}(t)\eta(t) + \hat{G}_u^{I(t)}(t)v(t) = 0 \quad a.e., \tag{3.4}$$

where

$$\Gamma = \sum_{i=1}^{r} \nu_i \nabla^2 \psi_i(\hat{x}(b)) + \lambda_0 \nabla^2 \ell(\hat{x}(b)), \tag{3.5}$$

$\hat{f}(t)$ *is* $f(t, \hat{x}(t), \hat{u}(t))$ *and* $\hat{\psi}(b) = \psi(\hat{x}(b))$.

Remark 3.2. Theorem 3.2 gives rise to the accessory problem; that is,

(AP) minimize $J_2(\eta, v)$ over $(\eta, v) \in AC \times L^\infty[a, b]$ and satisfying (3.2)–(3.4).

Thus, Theorem 3.2 states that when Λ_0 contains a single element, a necessary condition for optimality is that the minimum value of (AP) is zero.

4. Normality and controllability. In this section we derive a condition namely, the strong normality, that insures the normality of both problem (C) and the accessory problem (AP) and the uniqueness of the multipliers, as required in Theorem 3.2. It will turn out that strong normality is equivalent to the M-controllability of the linearized system, where M is $\nabla\hat{\psi}(b)$.

DEFINITION 4.1. *A pair* $(\hat{x}, \hat{u})$ *satisfying Theorem* 3.1 *is* normal *if* $\lambda_0 \neq 0$.

DEFINITION 4.2. *An admissible pair* $(\hat{x}, \hat{u})$ *is* strongly *normal on an interval* $[c, b] \subseteq [a, b]$ *if* (R1) *is satisfied on* $[c, b]$ *and the only solution to the system*

$$-\dot{p}(t) = \hat{f}_x^*(t)p(t) + \hat{G}_x^*(t)q(t) \qquad t \in [c, b] \quad a.e., \tag{4.1}$$

$$\hat{f}_u^*(t)p(t) + \hat{G}_u^*(t)q(t) = 0 \qquad t \in [c, b] \quad a.e., \tag{4.2}$$

$$p(b) = [\nabla\hat{\psi}(b)]^*\nu, \quad \text{and} \quad q^i(t)\hat{G}^i(t) = 0 \qquad \forall i = 1, \ldots, k, t \in [c, b] \quad a.e., \tag{4.3}$$

is $p \equiv 0$, *where* $q(\cdot)$ *in* $L^\infty[c, b]$ *and* $\nu \in \mathbb{R}^r$.

Remark 4.1. If $p \equiv 0$ solves the above system, then from (R1) it results that also $q \equiv 0$ on $[c, b]$ and $\nu = 0$.

Remark 4.2. Assume that the extremal $(\hat{x}, \hat{u})$ is strongly normal on $[a, b]$. Then we can easily show that any solution to (AP) is normal, $(\hat{x}, \hat{u})$ is normal for (C), and when $\lambda_0 = 1$, the multipliers $\hat{p}$, $\hat{q}$, and ν in Theorem 3.1 are unique.

Note that when no final state constraint is present; that is, when $\psi : \mathbb{R}^n \longrightarrow \{0\}$, then any admissible pair is automatically strongly normal on any subinterval $[c, b]$ of $[a, b]$.

Now we define the tangent subspace to the active constraints

$$T^{I(t)}(t) := \left\{ u \in \mathbb{R}^m : \hat{G}_u^{I(t)}(t)u = 0 \right\}.$$

Let $Y^I(\cdot)$ be uniformly bounded on $[a, b]$ with $Y^{I(t)}(t)$ a matrix whose columns form an orthonormal basis for $T^{I(t)}(t)$, and $Y^{I(t)}(t) = 0$ if $T^{I(t)}(t) = \{0\}$. Thus

$$\hat{G}_u^{I(t)}(t)Y^{I(t)}(t) = 0 \qquad \text{a.e.} \tag{4.4}$$

Set

$$\beta^{I(t)}(t) := \begin{cases} \left[\hat{G}_u^{I(t)}(t)\right]^* \left[\hat{G}_u^{I(t)}(t)\left(\hat{G}_u^{I(t)}(t)\right)^*\right]^{-1} & \text{if } I(t) \neq \emptyset \\ 0 & \text{if } I(t) = \emptyset. \end{cases} \tag{4.5}$$

Condition (R1) implies that the multivalued map $t \hookrightarrow I(t)$ from $[a,b]$ to the subsets of $\{1,\dots,k\}$ is measurable. Hence $\beta^I(\cdot)\,\hat{G}_x^I(\cdot)$ is in $L^\infty[a,b]$ and $Y^I(\cdot)$ can be chosen in $L^\infty[a,b]$.

The following result rephrases the strong normality definition in terms of a system that does not contain q.

PROPOSITION 4.1. *Assume* (R1) *on* $[c,b] \subseteq [a,b]$. *Then* $(\hat{x},\hat{u})$ *is strongly normal on* $[c,b]$ *if and only if the only solution on* $[c,b]$ *of the system*

$$-\dot{p}(t) = \left[\hat{f}_x^*(t) - \left(\hat{G}_x^{I(t)}(t)\right)^* \left(\beta^{I(t)}(t)\right)^* \hat{f}_u^*(t)\right] p(t), \qquad a.e., \tag{4.6}$$

$$\left(Y^{I(t)}(t)\right)^* (t)\hat{f}_u^*(t)p(t) = 0 \qquad a.e., \tag{4.7}$$

$$p(b) = [\nabla\hat{\psi}(b)]^*\nu \tag{4.8}$$

is $p \equiv 0$ *and* $\nu = 0$.

Proof of Proposition 4.1. Assume $(\hat{x},\hat{u})$ is strongly normal on $[c,b]$. If the system (4.6)–(4.8) has a nonzero solution (p,ν) then, by (R1), $p\not\equiv 0$. Define

$$q = \begin{pmatrix} q^1 \\ \vdots \\ q^k \end{pmatrix}$$

as follows:

$$q^i(t) := \begin{cases} -e_{\alpha_i}^* \left(\beta^{I(t)}(t)\right)^* \hat{f}_u^*(t)p(t) & \text{if } i \in I(t) \\ 0 & \text{if } i \notin I(t), \end{cases}$$

where α_i is the position of i in $I(t)$, and $e_{\alpha_i}^* = (0,0,\dots,0,1,0,\dots 0)$ has "1" in the α_ith position. First, it is clear that for all i, $q^i(t)\hat{G}^i(t) = 0$, for $t \in [c,b]$ almost everywhere, and $q(\cdot)$ is in $L^\infty[c,b]$. Thus, (4.8) yields that (4.3) satisfied. Now using q in (4.6) and (4.7) we obtain

$$-\dot{p}(t) = \hat{f}_x^*(t)p(t) + \left(\hat{G}_x^{I(t)}(t)\right)^* q^{I(t)}(t) \tag{4.9}$$

$$\hat{f}_u^*(t)p(t) + \left(\hat{G}_u^{I(t)}(t)\right)^* q^{I(t)}(t) = 0, \tag{4.10}$$

where $q^{I(t)} = \left(q^i\right)_{i\in I(t)}$.

This is equivalent to saying that p and q solve (4.1) and (4.2). Therefore, (p,q,ν) solve (4.1)–(4.3) with $p\not\equiv 0$. Thus, we obtain a contradiction and whence (4.6)–(4.8) has zero as the only solution.

Conversely, assume that zero is the only solution to (4.6)–(4.8). Let us show that $(\hat{x}, \hat{u})$ is strongly normal on $[c, b]$. If not, there exist $p \not\equiv 0$, $\nu \in \mathbb{R}^r$, and q in $L^\infty[c, b]$ solving (4.1)–(4.3). This is equivalent to (4.9), (4.10), and (4.8) being satisfied by $p \not\equiv 0$, ν, and q. Using (R1) we solve (4.10) for $q^{I(t)}$ to obtain

$$q^{I(t)}(t) = -\left(\beta^{I(t)}(t)\right)^* \hat{f}_u^*(t)p(t)\,,$$

which, if used in (4.9), produces (4.6). Equations (4.4) and (4.10) yield (4.7). From the hypothesis we must have $p \equiv 0$ and $\nu = 0$, which is a contradiction. Therefore $(\hat{x}, \hat{u})$ must be strongly normal. □

Now consider the linearized system of (2.1) and (2.3); that is,

$$\dot{\eta}(t) = \hat{f}_x(t)\eta(t) + \hat{f}_u(t)v(t) \qquad \text{a.e.}, \tag{4.11}$$

$$\hat{G}_x^{I(t)}\eta(t) + \hat{G}_u^{I(t)}v(t) = 0 \qquad \text{a.e.}, \tag{4.12}$$

where η is absolutely continuous and v is in $L^\infty[c, b]$. This system coincides with (3.2) and (3.4). If (R1) holds on $[c, b]$ then (4.12) yields that

$$v(t) = Y^{I(t)}(t)\alpha(t) - \beta^{I(t)}(t)\hat{G}_x^{I(t)}(t)\eta(t) \qquad \text{a.e.}, \tag{4.13}$$

where $\alpha(\cdot)$ is in $L^\infty[c, b]$.

Set $\Phi(t, c)$ as the fundamental matrix of the linear system

$$\dot{\eta}(t) = \left(\hat{f}_x(t) - \hat{f}_u(t)\beta^{I(t)}(t)\hat{G}_x^{I(t)}(t)\right)\eta(t). \tag{4.14}$$

Then the *reachable* set at b from $\eta(c) = 0$ of the system (4.11) and (4.12) is

$$\mathcal{R}_c(b) = \left\{ \int_c^b \Phi(b, c)\Phi^{-1}(s, c)\hat{f}_u(s)Y^{I(t)}(s)\alpha(s)ds : \alpha(\cdot) \in L^\infty[c, b] \right\}. \tag{4.15}$$

DEFINITION 4.3. *Let M be an $r \times n$-matrix of full rank $(r \leq n)$. We say that the system* (4.11), (4.12) *is* M-controllable *on* $[c, b]$ *if*

$$M\mathcal{R}_c(b) = \mathbb{R}^r.$$

When $M = \bigtriangledown\psi(\hat{x}(b))$, the M-controllability is shown below to be equivalent to the strong normality.

PROPOSITION 4.2. *Assume* (R1), *then $(\hat{x}, \hat{u})$ is strongly normal on $[c, b]$ if and only if the system* (4.11) *and* (4.12) *is $\bigtriangledown\hat{\psi}(b)$-controllable.*

Proof. It suffices to show that the nonstrong normality of $(\hat{x}, \hat{u})$ is equivalent to

$$0 \notin \operatorname{int} \bigtriangledown \hat{\psi}(b)\mathcal{R}_c(b).$$

By the separation theorem, this latter condition is equivalent to the existence of $\nu \in \mathbb{R}^r \backslash \{0\}$ with $\nu^* \bigtriangledown \hat{\psi}(b)\mathcal{R}_c(b) \geq 0$. This is equivalent to

$$\left(Y^{I(t)}(t)\right)^*(t)\hat{f}_u^*(t)p(t) = 0 \qquad \text{a.e.},$$

where

$$p(t) = [\Phi^{-1}]^*(t, c)\Phi^*(b, c) \bigtriangledown \hat{\psi}(b)\nu\,.$$

Thus p satisfies (4.6)–(4.8) with $p(b) \neq 0$. This is equivalent, by Proposition 4.1, to $(\hat{x}, \hat{u})$ is not strongly normal on $[c, b]$. □

5. Necessary conditions: Conjugate points–Riccati equation. In this section we introduce the notion of a conjugate point at an extremal $(\hat{x}, \hat{u})$. This definition is shown to be expressed in terms of a linear system of differential equations. The nonexistence of conjugate points to b in (a, b) turns out to be necessary for the optimality of an extremal that is strongly normal on each subinterval $[c, b]$ of $[a, b]$. Finally, another necessary condition in terms of a certain Riccati-type equation is derived.

Throughout this section (R1)–(R4) are assumed to hold on $[a, b]$ at a given extremal $(\hat{x}, \hat{u})$ that is strongly normal on $[a, b]$. By Remark 4.2, we can take λ_0 in Theorem 3.1 to be 1 and in this case the corresponding multipliers $\hat{p}$, $\hat{q}$ and ν are unique. The Hamiltonian of the problem is then

$$H(t, x, u, p, q) = g(t, x, u) + p^* f(t, x, u) + q^* G(t, x, u)$$

and $\hat{H}(t) = H(t, \hat{x}(t), \hat{u}(t), \hat{p}(t), \hat{q}(t))$.

DEFINITION 5.1. *A point $c \in [a, b)$ is* conjugate *to b along $(\hat{x}, \hat{u})$ if there exists a nonzero $(\eta, \lambda, \mu, v) \in AC \times AC \times L^\infty[a, b] \times L^\infty[a, b]$ with $\eta \not\equiv 0$ on $[a, c]$ and satisfying*

$$\dot{\eta}(t) = \hat{f}_x(t)\eta(t) + \hat{f}_u(t)v(t) \quad a.e., \tag{5.1}$$

$$-\dot{\lambda}(t) = \hat{f}_x^*(t)\lambda(t) + \hat{H}_{xx}(t)\eta(t) + \hat{H}_{xu}(t)v(t) + \hat{G}_x^*(t)\mu(t) \quad a.e., \tag{5.2}$$

$$\hat{f}_u^*(t)\lambda(t) + \hat{H}_{ux}(t)\eta(t) + \hat{H}_{uu}(t)v(t) + \hat{G}_u^*(t)\mu(t) = 0 \quad a.e., \tag{5.3}$$

$$\hat{G}_x^{I(t)}(t)\eta(t) + \hat{G}_u^{I(t)}(t)v(t) = 0 \quad a.e., \qquad \mu^i(t) = 0 \text{ for } i \notin I(t), \tag{5.4}$$

$$\lambda(b) = (\nabla\hat{\psi}(b))^*\delta + \Gamma\eta(b) \text{ for some } \delta \in \mathbb{R}^r, \tag{5.5}$$

$$\nabla\hat{\psi}(b)\eta(b) = 0, \quad \text{and} \quad \eta(c) = 0, \tag{5.6}$$

where Γ is defined by (3.5) *with $\lambda_0 = 1$ and $\mathbb{R}^0 = \{0\}$.*

Remark 5.1. Since $(\hat{x}, \hat{u})$ is strongly normal, the accessory problem (AP) is normal at any extremal (η, v). Thus, if (η, v) is an extremal for (AP), (5.1)–(5.6) hold for $c = a$ and for some (λ, μ, δ).

In the following proposition the conjugate point definition is rephrased in terms of a linear system in η and λ.

DEFINITION 5.2. *We say that the* strengthened Legendre–Clebsch *condition is satisfied at $(\hat{x}, \hat{u})$ if for some $\bar{\alpha} > 0$ we have*

$$\left(Y^{I(t)}(t)\right)^* \hat{H}_{uu}(t)Y^{I(t)}(t) \geq \bar{\alpha} I_{m-\mathrm{Card}I(t)} \quad t \in [a, b] \quad a.e. \tag{5.7}$$

whenever $Y^{I(t)}(t) \neq 0$, where $Y^{I(t)}(t)$ is defined in (4.4).

This condition is a strengthening of the Legendre–Clebsch condition

$$\left(Y^{I(t)}(t)\right)^* \hat{H}_{uu}(t)Y^{I(t)}(t) \geq 0 \text{ a.e.}$$

PROPOSITION 5.1. *Assume that* (5.7) *holds at $(\hat{x}, \hat{u})$. Then, $c \in [a, b)$ is conjugate to b if and only if there exists a nonzero $(\eta, \lambda) \in AC \times AC$ with $\eta \not\equiv 0$ on $[a, c]$, satisfying the following linear system:*

$$\dot{\eta} = \left[\hat{f}_x + \hat{f}_u(Z^I\hat{H}_{uu} - I_m)\beta^I\hat{G}_x^I - \hat{f}_u Z^I \hat{H}_{ux}\right]\eta - \hat{f}_u Z^I \hat{f}_u^*\lambda \quad a.e., \tag{5.8}$$

$$-\dot{\lambda} = \left[\hat{f}_x^* + \left(\hat{G}_x^I\right)^* (\beta^I)^* \left(\hat{H}_{uu} Z^I - I_m\right) \hat{f}_u^* - \hat{H}_{xu} Z^I \hat{f}_u^*\right] \lambda$$

$$+ \left[\hat{H}_{xx} - \left(\hat{H}_{uu}\beta^I \hat{G}_x^I - \hat{H}_{ux}\right)^* Z^I \left(\hat{H}_{uu}\beta^I \hat{G}_x^I - \hat{H}_{ux}\right) - \hat{H}_{xu}\beta^I \hat{G}_x^I \right. \tag{5.9}$$

$$\left. - \left(\hat{H}_{xu}\beta^I \hat{G}_x^I\right)^* + \left(\beta^I \hat{G}_x^I\right)^* \hat{H}_{uu}\beta^I \hat{G}_x^I\right] \eta \quad a.e.,$$

$$\lambda(b) = [\nabla\hat{\psi}(b)]^*\delta + \Gamma\eta(b) \quad \textit{for some } \delta \in \mathbb{R}^r \tag{5.10}$$

$$\nabla\hat{\psi}(b)\eta(b) = 0, \quad \textit{and} \quad \eta(c) = 0, \tag{5.11}$$

where the functions in (5.8) *and* (5.9) *are evaluated at* t, *the functions* Y^I *and* β^I *are given by* (4.4) *and* (4.5), *and*

(5.12)

$$Z^{I(t)}(t) = \begin{cases} Y^{I(t)}(t)\left[\left(Y^{I(t)}(t)\right)^* \hat{H}_{uu}(t) Y^{I(t)}(t)\right]^{-1} \left(Y^{I(t)}(t)\right)^*(t) & \textit{if } Y^{I(t)}(t) \neq 0 \\ 0 & \textit{otherwise.} \end{cases}$$

Proof. First let us show that the existence of $(\eta, \lambda, \mu, v) \neq 0$ that solves (5.1)–(5.4) is equivalent to saying that $(\eta, \lambda) \neq 0$ and (η, λ, μ, v) satisfies (5.1)–(5.4). In fact, if $(\eta, \lambda, \mu, v) \neq 0$ and solves (5.1)–(5.4) with $(\eta, \lambda) \equiv 0$, it follows that

$$\hat{G}_u^I v = 0 \quad \text{a.e.}, \qquad \mu^i(t) = 0 \ \text{ for } \ i \notin I(t)$$

and

$$\hat{H}_{uu} v + \left(\hat{G}_u\right)^* \mu = 0 \quad \text{a.e.}$$

If $Y^{I(t)}(t) = 0$ for almost all t in an interval $\mathcal{J}_i \subset [a, b]$, then $\hat{G}_u^I$ is invertible almost everywhere there, and thus the above implies that $(\mu, v) \equiv 0$ on $\mathcal{J}_i$. If $Y^{I(t)}(t) \neq 0$ on an interval $\mathcal{J}_i$, then for $\mu^{I(t)}(t) = \left(\mu^i(t)\right)_{i \in I(t)}$ the above equations yield that for some $\alpha(\cdot)$,

$$v(t) = Y^{I(t)}(t)\alpha(t) \qquad \text{a.e.} \in \mathcal{J}_i,$$

and

$$\hat{H}_{uu}(t) Y^{I(t)}(t)\alpha(t) + \left(\hat{G}_u^{I(t)}(t)\right)^* \mu^{I(t)}(t) = 0 \quad \text{a.e.} \in \mathcal{J}_i.$$

Now, using (5.7) and (4.4), the last equation yields $\alpha(t) \equiv 0$ and $\mu^{I(t)}(t) \equiv 0$. Whence $(\mu, v) \equiv 0$, yielding a contradiction. Therefore, $(\eta, \lambda) \neq 0$.

To complete the proof we show that (η, λ, μ, v) solve (5.1)–(5.4) is equivalent to (η, λ) solve (5.8) and (5.9). Note that the first of (5.4) is equivalent to (4.13); that is,

$$v(t) = Y^{I(t)}(t)\alpha(t) - \beta^{I(t)}(t)\hat{G}_x^{I(t)}(t)\eta(t) \quad \text{a.e.} \tag{5.13}$$

for some $\alpha(\cdot) \in L^\infty[a, b]$, and (5.3) is equivalent to

$$(Y^I)^* \left[\hat{f}_u^* \lambda + \hat{H}_{ux}\eta + \hat{H}_{uu} v\right] = 0 \quad \text{a.e.} \tag{5.14}$$

with

$$\mu^I = \left(\beta^I\right)^* \left[-\hat{f}_u^* \lambda - \hat{H}_{ux}\eta - \hat{H}_{uu}v\right] \quad \text{a.e.} \tag{5.15}$$

Using (5.13) in (5.14), (5.15), (5.1), and (5.2), it results that (5.1)–(5.4) are equivalent to

$$v = \left[\left(Z^I \hat{H}_{uu} - I_m\right)\beta^I \hat{G}_x^I - Z^I \hat{H}_{ux}\right]\eta - Z^I f_u^* \lambda \quad \text{a.e.} \tag{5.16}$$

$$\mu^I = \left(\beta^I\right)^* \left(\hat{H}_{uu} Z^I - I_m\right)\left[\hat{f}_u^* \lambda + \left(\hat{H}_{ux} - \hat{H}_{uu}\beta^I \hat{G}_x^I\right)\eta\right] \quad \text{a.e.} \tag{5.17}$$

and (5.8) and (5.9) hold. □

Now we are ready to state the necessary condition involving the conjugate point theory.

THEOREM 5.1. *Let $(\hat{x}, \hat{u})$ be a weak local minimum for* (C). *Assume that $(\hat{x}, \hat{u})$ is strongly normal on each interval $[c, b] \subset [a, b]$, then there exists no point in (a, b) conjugate to b.*

Proof. We will argue by contradiction. If there exists $c \in (a, b)$ conjugate to b, by Proposition 5.1 we have a nonzero $(\eta, \lambda) \in AC \times AC$ with $\eta \not\equiv 0$ on $[a, c]$ satisfying (5.8)–(5.11).

Define v through (5.16) and set

$$(\bar{\eta}, \bar{\lambda}, \bar{v})(t) = (\eta, \lambda, v)(t)\chi_{[c,b]}(t),$$

where $\chi_{[c,b]}(\cdot)$ is the characteristic function of $[c, b]$. Thus, using Proposition 5.1 and the fact that (5.8), (5.9), (5.16), and (5.17) are equivalent to (5.1)–(5.4), it follows that $(\bar{\eta}, \bar{v})$ is admissible for the accessory problem (AP) and $J_2(\bar{\eta}, \bar{v}) = 0$. Hence, $(\bar{\eta}, \bar{v})$ solves (AP). Then, applying Theorem 3.1 to (AP), taking into account Remark 5.1, we obtain $(\tilde{\lambda}, \tilde{\mu}, \tilde{\delta})$ satisfying, with $(\bar{\eta}, \bar{v})$, (5.1)–(5.6) with $c = a$. The strong normality on $[c, b]$ yields that $\lambda \equiv \bar{\lambda} \equiv \tilde{\lambda}$ on $[c, b]$, and $\delta = \tilde{\delta}$. Since (η, λ) and $(\bar{\eta}, \tilde{\lambda})$ satisfy (5.8) and (5.9) and coincide on $[c, b]$, there they are equal on $[a, b]$. Thus, $\eta \equiv 0$ on $[a, c]$, which leads a contradiction. Therefore no $c \in (a, b)$ is conjugate to b. □

Now we define what would have been the extension to the mixed state-control constraints of the classical notion of conjugate points.

DEFINITION 5.3. *A point $c \in (a, b)$ is* classically conjugate *to b along $(\hat{x}, \hat{u})$ if there exists a nonzero $(\eta, \lambda, \mu, v) \in AC \times AC \times L^\infty[a, b] \times L^\infty[a, b]$ satisfying* (5.1)–(5.6).

Remark 5.2. By Proposition 5.1, the above definition is equivalent to saying that there exists $(\eta, \lambda) \neq 0$ satisfying (5.8)–(5.11). Thus, when G depends only on u, the notion of classically conjugate point reduces to one given in [20, Def. 6.1]. As we will soon see, whenever $(\hat{x}, \hat{u})$ is strongly normal on any interval of the form $[a, c]$, Definitions 5.1 and 5.3 are equivalent. However, in the literature (see, e.g., [20]) the nonexistence of conjugate points is proven necessary for optimality of a piecewise continuous control $\hat{u}$, under the two-sided strong normality at $(\hat{x}, \hat{u})$. Therefore Theorem 5.1 is a generalization of those results, not only to the case where $\hat{u}$ in $L^\infty[a, b]$ and the constraints are in terms of both the control and the state variables, but also to the case when only strong normality on intervals of the form $[c, b]$ holds, that is, only one-sided strong normality is required.

DEFINITION 5.4. *A pair $(\hat{x}, \hat{u})$ is* strongly normal *on $[a, c] \subseteq [a, b]$ if on $[a, c]$ the system* (4.1), (4.2) *and*

$$q^i(t)\hat{G}^i(t) = 0 \quad \forall i = 1, \ldots, k$$

has only $p \equiv 0$ as a solution.

Remark 5.3. Since (R1) holds, Proposition 4.1 yields that Definition 5.4 is equivalent to saying that on $[a, c]$ the system (4.6), (4.7) has only $(p, \nu) = 0$ as a solution.

PROPOSITION 5.2. *Assume that $(\hat{x}, \hat{u})$ is strongly normal on any interval $[a, c] \subseteq [a, b]$. Then, Definitions* 5.1 *and* 5.3 *are equivalent.*

Proof. One direction of the equivalence is trivial. Now, assume c is classically conjugate to b but not conjugate to b. Then, by Proposition 5.1, there exists $(\eta, \lambda) \neq 0$ satisfying (5.8)–(5.11) with $\eta \equiv 0$ on $[a, c]$. Using this last property in (5.8) and (5.9) we obtain that λ satisfies on $[a, c]$ the system (4.6), (4.7). Using the strong normality on $[a, c]$, it results that $\lambda \equiv 0$ on $[a, c]$. Thus, (η, λ) must be zero on $[a, b]$. This is a contradiction. Therefore, the two definitions are equivalent. □

Consider the matrix system associated with the system (5.8)–(5.11):

$$\dot{X} = AX - \hat{f}_u Z^I \hat{f}_u^* \Lambda, \tag{5.18}$$

$$-\dot{\Lambda} = A^*\Lambda + \Big[\hat{H}_{xx} - \Big(\hat{H}_{uu}\beta^I \hat{G}_x^I - \hat{H}_{ux}\Big)^* Z^I \Big(\hat{H}_{uu}\beta^I \hat{G}_x^I - \hat{H}_{ux}\Big) - \hat{H}_{xu}\beta^I \hat{G}_x^I - \Big(\hat{H}_{xu}\beta^I \hat{G}_x^I\Big)^* + \Big(\beta^I \hat{G}_x^I\Big)^* \hat{H}_{uu}\beta^I \hat{G}_x^I\Big] X, \tag{5.19}$$

$$NX(b) = 0, \quad (I_n - N)(\Gamma X(b) - \Lambda(b)) = 0, \tag{5.20}$$

where

$$A = \hat{f}_x + \hat{f}_u(Z^I \hat{H}_{uu} - I_m)\beta^I \hat{G}_x^I - \hat{f}_u Z^I \hat{H}_{ux},$$

and

$$N = (\nabla\hat{\psi}(b))^*[\nabla\hat{\psi}(b)(\nabla\hat{\psi}(b))^*]^{-1} \nabla\hat{\psi}(b) \tag{5.21}$$

is a projection.

Theorem 5.1 and Propositions 5.1 and 5.2 lead to the following corollary.

COROLLARY 5.1. *Let $(\hat{x}, \hat{u})$ satisfy the conditions of Theorem* 5.1. *Assume in addition that $(\hat{x}, \hat{u})$ is strongly normal on each interval of the form $[a, c] \subseteq [a, b]$. Then there exists (X, Λ) solving* (5.18)–(5.20) *with*

$$X^*\Lambda = \Lambda^* X \quad \textit{and} \quad \det X(t) \neq 0 \textit{ on } (a, b).$$

Proof. Let (X, Λ) be the solution of (5.18), (5.19) with the following boundary conditions:

$$X(b) = I_n - N \quad \text{and} \quad \Lambda(b) = \Gamma(I_n - N) - N; \tag{5.22}$$

then (X, Λ) satisfies (5.18)–(5.20) and $d/dt[X^*\Lambda - \Lambda^* X] = 0$. Using (5.22) we deduce that (X, Λ) satisfies $X^*\Lambda = \Lambda^* X$.

Now, if for some $c \in (a, b)$ and $\alpha (\neq 0) \in \mathbb{R}^n$ we have $X(c)\alpha = 0$, then $(\eta(t), \lambda(t)) := (X(t)\alpha, \Lambda(t)\alpha)$ satisfies (5.8)–(5.11) with $\delta = -[\nabla\hat{\psi}(b)(\nabla\hat{\psi}(b))^*]^{-1} \nabla\hat{\psi}(b)\alpha$. Moreover, $(\eta, \lambda) \neq 0$ since $(\eta(b), \lambda(b)) \neq 0$. Thus, from Proposition 5.1 and Definition 5.3, c is classically conjugate to b, and hence c is conjugate to b (see Proposition 5.2). However, this contradicts Theorem 5.1. Therefore the result is true. □

The next result is the final one in this section. It basically states that the existence of a solution to a certain Riccati equation is necessary for optimality. A natural strengthening of this condition will be shown in this paper to be sufficient.

COROLLARY 5.2. *Assume the conditions of Corollary* 5.1. *Then there exists a Lipschitz continuous symmetric matrix function* $W(\cdot)$ *satisfying on* (a,b) *the equation*

$$
\begin{aligned}
L^I(W) := {} & \dot{W} + \hat{f}_x^* W + W\hat{f}_x \\
& - \left(\hat{f}_u^* W + \hat{H}_{ux} - \hat{H}_{uu}\beta^I \hat{G}_x^I\right)^* Z^I \left(\hat{f}_u^* W + \hat{H}_{ux} - \hat{H}_{uu}\beta^I \hat{G}_x^I\right) \\
& - \left(\beta^I \hat{G}_x^I\right)^* \left(\hat{f}_u^* W + \hat{H}_{ux}\right) - \left(W\hat{f}_u + \hat{H}_{xu}\right)\beta^I \hat{G}_x^I \\
& + \left(\beta^I \hat{G}_x^I\right)^* \hat{H}_{uu}\beta^I \hat{G}_x^I + \hat{H}_{xx} = 0
\end{aligned} \tag{5.23}
$$

with

$$
\lim_{t\to b}(I_n - N)(\Gamma - W(t)X(t))(I_n - N) = 0\,, \tag{5.24}
$$

where $X(\cdot)$ *is continuous and* $X(b) = I_n - N$.

Proof. Define on (a,b)

$$
W := \Lambda X^{-1},
$$

where (X,Λ) is the pair in Corollary 5.1. We can easily check that W is Lipschitz symmetric and satisfies (5.23). Moreover

$$
W(t)X(t) = \Lambda(t) \text{ on } (a,b)\,,
$$

$X(\cdot)$ is continuous on $[a,b]$ with $X(b) = I_n - N$, and

$$
\Lambda(b) = \Gamma(I_n - N) - N\,.
$$

Therefore, (5.24) follows. □

Remark 5.3. If $W(\cdot)$ is continuous at b then (5.24) becomes

$$
\Gamma - W(b) = 0 \quad \text{on } \{y : \nabla\hat{\psi}(b)y = 0\}\,.
$$

6. Sufficient conditions: Riccati equation. Consider the problem (C) of §2. The goal of this section is to provide a sufficiency criterion for weak and strong local optimality in (C) of a pair $(\hat{x},\hat{u}) \in AC \times L^\infty[a,b]$. The conditions involved here are basically strengthening of the necessary conditions of §5 and of the Pontryagin minimum principle in §3.

Let $(\hat{x},\hat{u})$ be an extremal for (C) with corresponding multipliers $\lambda_0 = 1$, $\hat{q}(\cdot)$, $\hat{p}(\cdot)$ and ν. Define

$$
J(t) := \{i \in \{1,\dots,k\} : \hat{q}^i(t) > 0\}
$$

and, for $\gamma > 0$, (6.1)

$$J_\gamma(t) := \{i \in \{1, \dots, k\} : \hat{q}^i(t) > \gamma\}.$$

In this section we adopt the notation used in §§3 and 4 with $I(t)$ replaced by $J(t)$ or $J_\gamma(t)$, e.g., G^J, T^J, β^J, Z^J, etc, or $G^{J_\gamma}, T^{J_\gamma}, \beta^{J_\gamma}, Z^{J_\gamma}$, etc.

The following theorem consists of sufficiency results for weak and strong local minimality in (C).

THEOREM 6.1. *Let $(\hat{x}, \hat{u})$ be an admissible pair. Assume that there exist $(\hat{p}, \hat{q}) \in AC \times L^\infty[a,b]$, and $\nu \in \mathbb{R}^r$ such that $\lambda_0 = 1$, $(\hat{p}, \hat{q})$, and ν satisfy Theorem* 3.1, *and that* (R1), (R2) *hold, where $J(\cdot)$, defined in* (6.1), *replaces $I(\cdot)$. Suppose in addition that*

(1) *there exists $\gamma > 0$ such that $J(t) = J_\gamma(t)$ almost everywhere;*

(2) $\left(Y^{J(t)}(t)\right)^* (t)\hat{H}_{uu}(t)Y^{J(t)}(t) \geq \bar{\alpha} I_{m-\mathrm{Card}J(t)}$ $t \in [a,b]$ *almost everywhere, whenever $Y^{J(t)}(t) \neq 0$, where Y^J is defined by* (4.4) *with $J(t)$ instead of $I(t)$;*

(3) *there exist a Lipschitz symmetric matrix function W on $[a,b]$ and $\bar{\delta} > 0$ satisfying*

$$L^J(W) \geq \bar{\delta} I_n \qquad t \in [a,b] \quad a.e. \tag{6.2}$$

and

$$\Gamma - W(b) > 0 \quad \text{on } \{y : \nabla\hat{\psi}(b)y = 0\}$$

where $L^J(W)$ is defined by (5.23), *in which $J(t)$ replaces $I(t)$, and Γ and N are given by* (3.5) *and* (5.21), *respectively.*

Then $(\hat{x}, \hat{u})$ is a weak local minimum for (C).

Moreover, if condition (c) *of Theorem* 3.1 *is replaced by the following:*

$$\begin{aligned} &\text{There exists } \delta > 0 \text{ and a mapping } u : T(\hat{x}, \hat{p}; \delta) \to \mathbb{R}^m \text{ such that} \\ &u(t, \cdot, \cdot) \text{ is continuous uniformly in } t,\ u(t, \hat{x}(t), \hat{p}(t)) = \hat{u}(t) \text{ a.e., and} \\ &u(t,x,p) \in \arg\min_u \{p^* f(t,x,u) + g(t,x,u) : G(t,x,u) \leq 0\}, \end{aligned} \tag{6.3}$$

then $(\hat{x}, \hat{u})$ is a strong local minimum for (C).

Remark 6.1. When the Lagrange multipliers associated with the active constraints are all nonzero (no degenerate inequalities) $J(t)$ coincides with $I(t)$. Thus, all the conditions of Theorem 6.1 are natural strengthenings of the necessary conditions presented in §§3 and 5. Hence, the above theorem provides sufficient conditions as close as possible to the necessary ones. An attempt was made in [9] to obtain similar results for this problem using the abstract nonlinear programming approach. However, the conditions imposed there are strong and hence too far from the necessary ones. Furthermore, Theorem 6.1 generalizes Theorems 2.1 and 2.2 in [11] to the case where $\hat{u}$ is in $L^\infty[a,b]$ and mixed state-control constraints are present.

A second-order sufficiency criterion was given in [14, Thm. 4.2] for the problem (C) where G depends only on x. The technique used there is the one employed earlier in [17] for the case where $u \in U$. However, condition (d) of Theorem 4.2 in [14] does not take *fully* into account the presence of the inequality state constraints. In fact, if we were to extend Sorger's condition (d) to our case, that is, where G depends on (x,u), we obtain condition (b) of the next corollary, which is clearly stronger than conditions (2) and (3) of Theorem 6.1. As explained at the end of this section, in Remarks 6.5 and 6.6, the results of this section include those developed recently in [13] for the case when $\hat{u}$ and the data as a function of t are continuous on $[a,b]$, the

end points of $\hat{x}$ are fixed and condition (R1) is strengthened. In that case condition 1 of Theorem 6.1 is not needed.

COROLLARY 6.1. *In Theorem* 6.1 *conditions* 2 *and* 3 *can be replaced by the following stronger conditions*:

(a) $\hat{H}_{uu}(t) \geq \bar{\alpha} I_m$ *a.e.t.*,

(b) *there exists a Lipschitz symmetric matrix function* W_0 *satisfying on* $[a, b]$

$$D(W) := \dot{W} + \hat{f}_x^* W + W\hat{f}_x + \hat{H}_{xx} - [W\hat{f}_u + \hat{H}_{xu}]\hat{H}_{uu}^{-1}[\hat{f}_u^* W + \hat{H}_{ux}] \geq 0 \text{ a.e.},$$

and

$$\Gamma - W(b) \geq 0 \quad \text{on } \{y : \nabla\hat{\psi}(b)y = 0\}.$$

Proof. Condition (a) yields that $\hat{H}_{uu}^{-1}$ has essentially bounded entries. Hence, (R1) and (R2) imply the conditions of the embedding theorem for ordinary differential equations (see, e.g., Theorem 4.1 in the Appendix of [4]). This theorem leads to the existence of $\lambda > 0$ and a Lipschitz symmetric matrix function W on $[a, b]$ satisfying

$$D(W) \geq \lambda I_n \quad \text{a.e.}$$

and

$$\Gamma - W(b) \geq \lambda I_n \quad \text{on } \{y : \nabla\hat{\psi}(b)y = 0\}.$$

Since $\hat{H}_{uu}(t) \geq Z^J(t)$ almost everywhere, it follows from the inequalities above that $L^J(W) \geq D(W) \geq \lambda I_n$. □

Remark 6.2. Conditions (a) and (b) above are too strong, since they imply that condition (c) of Proposition 6.2, given below, holds for all $(x, u) \in \mathbb{R}^{n+m}$.

The following result sheds light on how to obtain a function W satisfying condition 3 of Theorem 6.1 without imposing strong conditions, but reasonable and verifiable ones.

COROLLARY 6.2. *Condition* 3 *of Theorem* 6.1 *can be replaced by the following*: *there exists on* $[a, b]$ *a Lipschitz symmetric solution* W_0 *of*

$$L^J(W) \geq 0 \quad \text{a.e.}$$

and

$$\Gamma - W(b) \geq 0 \quad \text{on } \{y : \nabla\hat{\psi}(b)y = 0\}.$$

Proof. We have $Y^J(\cdot)$ and $\beta^J(\cdot)\hat{G}_x^J(\cdot)$ in $L^\infty[a, b]$. Hence, condition 2 of Theorem 6.1 implies that $Z^J(\cdot)$ is also in $L^\infty[a, b]$ and hence the embedding theorem for ordinary differential equations [4] yields the result. □

The proof of Theorem 6.1 is based on the following result involving the Hamilton–Jacobi inequality. This technique was used earlier in [17], [11], [18] and recently in [13].

PROPOSITION 6.1. *Suppose there exists a function* $V : [a, b] \times \mathbb{R}^n \to \mathbb{R}$ *such that for almost all* t, $V(\cdot, \cdot)$ *is differentiable on* $T(\hat{x}; \epsilon_0)$, *and* $V(\cdot, x(\cdot))$ *is absolutely continuous whenever* $x(\cdot)$ *is. Assume that, for* $\bar{F}(t, x, u) := V_t(t, x) + V_x(t, x)f(t, x, u) + g(t, x, u)$

(i) $\min_{(x,u)} \{\bar{F}(t, x, u) : (t, x, u) \in T(\hat{x}, \hat{u}; \epsilon_0)$ *and* $G(t, x, u) \leq 0\} = \bar{F}(t, \hat{x}(t), \hat{u}(t))$ *a.e.*,

and

(ii) $\min_x \{\ell(x)_- V(b,x) : \psi(x) = 0 \text{ and } |x - \hat{x}(b)| < \epsilon_0\} = \ell(\hat{x}(b))_- V(b, \hat{x}(b))$.

Then $(\hat{x}, \hat{u})$ *is a weak local minimum for* (P).

If condition (i) is true for $(t,x,u) : (t,x) \in T(\hat{x}; \epsilon_0)$ and $G(t,x,u) \leq 0$, then $(\hat{x}, \hat{u})$ is a strong local minimum.

Proof. If (x,u) is admissible for (C) and in $T(\hat{x}, \hat{u}; \epsilon_0)$ then by (i) and (ii)

$$J(x,u) - J(\hat{x}, \hat{u}) = \int_a^b \{\bar{F}(t, x(t), u(t)) - \hat{\bar{F}}(t)\} dt + \ell(x(b)) - \ell(\hat{x}(b))$$

$$+ \int_a^b \frac{d}{dt}[V(t, \hat{x}(t)) - V(t, x(t))] dt$$

$$\geq 0.$$

If (i) holds for $(t,x) \in T(\hat{x}; \epsilon_0)$ and $G(t,x,u) \leq 0$, take (x,u) admissible with $x(\cdot) \in T(\hat{x}; \epsilon)$. The same arguments as before yield $J(x,u) \geq J(\hat{x}, \hat{u})$. □

The next result represents a sufficiency criterion for condition (i) of Proposition 6.1 to hold. This is a generalization of [1, Thm. 3.4.3] to the case where a parameter t is present. The following condition will be used:

(R5) $$\exists \alpha > 0 : \nabla_{(x,u)} \hat{G}^{J(t)}(t)(\nabla_{(x,u)} \hat{G}^{J(t)}(t))^* \geq \alpha I_{\mathrm{Card} J(t)} \quad \text{a.e.}$$

PROPOSITION 6.2. *Let* $F(t,x,u)$ *be a real valued map such that* (F,G) *satisfies for some* $\epsilon > 0$ *condition* (R2). *Assume* (R5) *holds and that there exists* $\hat{q} : [a,b] \to \mathbb{R}^k$ *in* $L^\infty[a,b]$ *such that*

(a) *for all* i *and for* $t \in [a,b]$ *almost everywhere,* $\hat{q}^i(t) \geq 0$ *and* $(\hat{q}^i(t))^* \hat{G}^i(t) = 0$;

$$\nabla_{(x,u)} \hat{F}(t) + \hat{q}^*(t) \nabla_{(x,u)} \hat{G}(t) = 0 \quad a.e.,$$

(b) *condition* (1) *of Theorem* 6.1 *holds for some* γ,

(c) *for almost all* t, $\nabla^2_{(x,u)} \hat{F}(t) + \sum_{i=1}^k \hat{q}^i(t) \nabla^2_{(x,u)} \hat{G}^i(t) \geq 2\bar{\gamma} I_{n+m}$ *on*

$$\mathcal{L}^J(t) := \left\{ (x,u) \in \mathbb{R}^{n+m} : \hat{q}^i(t) \nabla_{(x,u)} \hat{G}^i(t) \begin{pmatrix} x \\ u \end{pmatrix} = 0 \ \forall i \right\}. \tag{6.4}$$

Then there exists $0 < \epsilon_0 \leq \epsilon$ *such that condition* (i) *of Proposition* 6.1 *is satisfied for* $\bar{F} = F$.

Remark 6.3. Proposition 6.2 is a key result for proving Theorem 6.1. Consider the special case when $\hat{u}$ and (F,G) and its derivatives in (x,u) up to second order are continuous in t. Then $\hat{q}$ is also continuous and condition (b) of Proposition 6.2 is not needed. In this case the proof is much simpler. It is analogous to the proof of the corresponding result in [11], where the constraints $d = G$ and $h = 0$ depend only on u. However, if we wish to assume that $F(t,\cdot,\cdot)$ and $G(t,\cdot,\cdot)$ are only C^{1+} (have Lipschitz gradients [19]), then the Hessian matrices in condition (c) are replaced by Clarke's generalized Jacobians $\partial_{(x,u)} \nabla_{(x,u)} F$ and $\partial_{(x,u)} \nabla_{(x,u)} G$ (see [2]), which are assumed to be upper semicontinuous in (t,x,u), where

$$\partial \nabla S(s) := \text{Convex hull} \left\{ M = \lim_{i \to \infty} \nabla^2 S(s_i) : s_i \underset{i \to \infty}{\longrightarrow} s \text{ and } \nabla^2 S(s_i) \text{exists} \right\}.$$

Thus, by using [5, Lem. 1], the proof also follows from that in [11].

Since the dependence on t is only $L^\infty[a,b]$, the proof of Proposition 6.2 will require the next result, which is a generalization of Hoffman's Lemma [1, §3.3.4] to our setting, where the cone $\mathcal{K}$, the elements $x_i^*(t) := \nabla \hat{G}^i(t)$ and the index set J depend on a parameter t.

LEMMA 6.1. *Let $G(t,\cdot,\cdot)$ be differentiable uniformly in t on $T(\hat{x},\hat{u};\epsilon)$, $(\hat{x},\hat{u})$ and $\nabla_{(x,u)}\hat{G}(t)$ be in $L^\infty[a,b]$, and* (R4) *hold. Define, for $t \in [a,b]$ almost everwhere,*

$$\mathcal{K}^J(t) := \left\{ h \in \mathbb{R}^{n+m} : \nabla_{(x,u)}\hat{G}^i(t)h \le 0 \text{ for } i \in J(t) \right\}$$

and

$$\rho(h, \mathcal{K}^J(t)) := \inf_{k \in \mathcal{K}(t)} |h-k|.$$

Then there exists a constant C independent of h and t such that

$$\rho(h, \mathcal{K}^J(t)) \le C \left\{ \sum_{i \in J(t)} \left[\nabla_{(x,u)}\hat{G}^i(t)h \right]_+ \right\},$$

where

$$\left[\nabla_{(x,u)}\hat{G}^i(t)h \right]_+ = \begin{cases} 0 & \text{if} \quad \nabla_{(x,u)}\hat{G}^i(t)h < 0 \\ \nabla_{(x,u)}\hat{G}^i(t)h & \text{if} \quad \nabla_{(x,u)}\hat{G}^i(t)h \ge 0. \end{cases}$$

Hence, for

$$\mathcal{L}^J(t) := \left\{ h \in \mathbb{R}^{n+m} : \nabla_{(x,u)}\hat{G}^i(t)h = 0 \, \forall i \in J(t) \right\},$$

$$\rho(h, \mathcal{L}^J(t)) \le C \sum_{i \in J(t)} |\nabla_{(x,u)} \hat{G}^i(t)h|.$$

Proof of Lemma 6.1. The proof follows the steps of Hoffman's Lemma in [1] with some modifications. As in (6) of that proof,

$$\rho(h, \mathcal{K}^J(t)) = \sup \left\{ \sum_{i \in J(t)} \lambda_i \nabla_{(x,u)} \hat{G}^i(t)h : \left| \sum_{i \in J(t)} \lambda_i \nabla_{(x,u)} \hat{G}^i(t) \right| \le 1, \ \lambda_i \ge 0 \ \forall i \right\}.$$

Define the finite-dimensional space

$$L_t := \left\{ z = \sum_{i \in J(t)} \lambda_i \nabla_{(x,u)} \hat{G}^i(t) : \lambda_i \in \mathbb{R} \quad \forall i \right\}$$

and the linear continuous operator

$$\Lambda_t : \mathbb{R}^{\operatorname{Card} J(t)} \longrightarrow L_t$$

$$\lambda = \left(\lambda_1, \ldots \lambda_{\operatorname{Card} J(t)}\right)^* \longrightarrow \Lambda_t(\lambda) = \sum_{i \in J(t)} \lambda_i \nabla_{(x,u)} \hat{G}^i(t).$$

Thus, from (R4) it results that Λ_t is a bijection and

$$\Lambda_t(\lambda) = X := \left(\lambda^* \hat{G}_x^{J(t)}(t),\, \lambda^* \hat{G}_u^{J(t)}(t)\right)$$

implies that

$$\lambda^* = X \left(\nabla_{(x,u)} \hat{G}^{J(t)}(t)\right)^* \left[\nabla_{(x,u)} \hat{G}^{J(t)}(t) \left(\nabla_{(x,u)} \hat{G}^{J(t)}(t)\right)^*\right]^{-1},$$

and hence, for some constant C independent of h and t,

$$|\lambda| \leq C|X| \leq C \left| \sum_{i \in J(t)} \lambda_i \nabla_{(x,u)} \hat{G}^i(t) \right|.$$

Therefore, the above equation for ρ yields the result. □

Proof of Proposition 6.2. If $\hat{q} \equiv 0$ almost everywhere, then (c) and the continuity of $\nabla^2_{(x,u)} F(t,\cdot,\cdot)$ uniformly in t yield that for some $\epsilon_0 > 0 (\epsilon_0 \leq \epsilon)$, $F(t,\cdot,\cdot)$ is strictly convex and hence, by (a) the result follows. If $\hat{q} \not\equiv 0$, define

$$L(t,x,u,q) := F(t,x,u) + q^* G(t,x,u)$$

and $\mathcal{K}^J(t)$ and $\mathcal{L}^J(t)$ as in Lemma 6.1. By this same lemma, there exists a positive constant C_1 (independent of t) such that

$$\forall h \in \mathbb{R}^{n+m}, h = h_1 + h_2 \text{ with } h_1 \in \mathcal{K}^J(t) \text{ and}$$

$$|h_2| \leq C_1 \sum_{i \in J(t)} [\nabla \hat{G}^i(t) h]_+,$$

where

$$[\nabla \hat{G}^i(t) h]_+ = \begin{cases} 0 & \text{if } \nabla \hat{G}^i(t) h < 0 \\ \nabla \hat{G}^i(t) h & \text{if } \nabla \hat{G}^i(t) h \geq 0, \end{cases} \tag{6.5}$$

and ∇G stands for $\nabla_{(x,u)} G$. Furthermore, we can represent h_1 as

$$\begin{aligned} &h_1 = h_1' + h_1'', \text{ with } h_1' \in \mathcal{L}^J(t) \text{ and} \\ &|h_1''| \leq C_2 \sum_{i \in J(t)} |\nabla \hat{G}^i(t) h_1| = C_2 \left\{ - \sum_{i \in J(t)} \nabla \hat{G}^i(t) h_1'' \right\}, \end{aligned} \tag{6.6}$$

where $C_2 > 0$.

Choose $A > 0$ such that

$$A C_2^{-1} \gamma - C_1 \max_{i=1}^{i=k} \| \hat{q}^i \|_\infty \| \nabla \hat{G}^i \|_\infty - 1 > 0, \tag{6.7}$$

where γ is the constant in condition (b). Let $\delta_1 \in (0,1]$ be such that $\delta := (C_1 + A)\delta_1$ satisfy $\delta < 1$, and

$$\bar{\gamma}(1-\delta)^2 - 2 \| B \|_\infty \delta(1+\delta) - \| B \|_\infty \| \delta^2 - \frac{\bar{\gamma}}{2} \geq 0 \tag{6.8}$$

where $B(t) := \frac{1}{2} \nabla^2_{(x,u)} \hat{L}(t)$, and $\bar{\gamma}$ the constant in condition (c).

The regularity hypotheses on F, G, and $\hat{q}$ yield that $L(t, \cdot, \cdot, \hat{q}(t))$ satisfies the same regularity conditions as F does. Thus, for any $(x(\cdot), u(\cdot)) : G(t, x(t), u(t)) \leq 0$ almost everywhere, and for

$$h(t) := \begin{pmatrix} x(t) - \hat{x}(t) \\ u(t) - \hat{u}(t) \end{pmatrix},$$

Taylor's expansion and condition (a) yield

(6.9)

$$\begin{aligned} F(t, x(t), u(t)) &= L(t, x(t), u(t), \hat{q}(t)) - \hat{q}^*(t) G(t, x(t), u(t)) \\ &= \hat{L}(t) - \hat{q}^*(t) \hat{G}(t) + \left[\nabla \hat{L}(t) - \hat{q}^*(t) \nabla \hat{G}(t) \right] h(t) + r_1(h(t)) \\ &= \hat{F}(t) - \hat{q}^*(t) \nabla \hat{G}(t) h(t) + r_1(h(t)) \qquad \text{a.e.}, \end{aligned}$$

where as

$$|h(t)| \to 0, \frac{r_1(h(t))}{|h(t)|} \longrightarrow 0$$

uniformly in t. Moreover,

$$F(t, x(t), u(t)) \geq L(t, x(t), u(t), \hat{q}(t)) = \hat{L}(t) + h^*(t) B(t) h(t) + r_2(h(t)) \quad \text{a.e.} \tag{6.10}$$

where as

$$|h(t)| \to 0, \frac{r_2(h(t))}{|h(t)|^2} \longrightarrow 0$$

uniformly in t, and for all $i = 1, \ldots, k$,

$$0 \geq G^i(t, x(t), u(t)) = \hat{G}^i(t) + \nabla \hat{G}^i(t) h(t) + \rho_i(h(t)) \tag{6.11}$$

where as

$$|h(t)| \to 0, \frac{\rho_i(h(t))}{|h(t)|} \longrightarrow 0$$

uniformly in t.

Choose $\epsilon_0 \in (0, \|B\|_\infty^{-1})$ such that for all $h(\cdot)$ with $|h(t)| < \epsilon_0$ almost everywhere, we have

$$\sum_{i=1}^{k} |\rho_i(h(t))| + |r_1(h(t))| \leq \delta_1 |h(t)| \quad \text{a.e.} \tag{6.12}$$

and

$$|r_2(h(t))| \leq \frac{\bar{\gamma}}{2} |h(t)|^2 \quad \text{a.e.} \tag{6.13}$$

Now, let $(x(\cdot), u(\cdot))$ such that $G(t, x(t), u(t)) \leq 0$ almost everwhere, with

$$h(t) := \begin{pmatrix} x(t) - \hat{x}(t) \\ u(t) - \hat{u}(t) \end{pmatrix}$$

satisfying $|h(t)| < \epsilon_0$ almost everywhere. Let us show that $F(t, x(t), u(t)) \leq \hat{F}(t)$ almost everywhere.

From (6.5), (6.6), (6.11), and (6.12) we have

$$h(t) = h_1(t) + h_2(t) \text{ with } h_1(t) \in \mathcal{K}^J(t) \quad \text{a.e.},$$

$$|h_2(t)| \leq C_1 \sum_{i \in J(t)} |\rho_i(h(t))| \leq C_1 \delta_1 |h(t)| \quad \text{a.e.}, \tag{6.14}$$

$$h_1(t) = h_1'(t) + h_1''(t) \text{ with } h_1'(t) \in \mathcal{L}^J(t) \quad \text{a.e.},$$

and

$$|h_1''(t)| \leq C_2 \left[\sum_{i \in J(t)} - \nabla \hat{G}^i(t) h_1''(t) \right] \quad \text{a.e.} \tag{6.15}$$

Case 1. $|h_1''(t)| > A\delta_1 |h(t)|$ for $t \in M$ almost everwhere, where $M \subseteq [a, b]$ has a positive measure. Then, (6.15) yields that, on M,

$$A\delta_1 |h(t)| < |h_1''(t)| \leq C_2 \left\{ \sum_{i \in J(t)} - \nabla \hat{G}^i(t) h_1'' \right\}. \tag{6.16}$$

Thus, from (6.9), (6.14), (6.15), and the above inequality we have, for $t \in M$,

$$F(t, x(t), u(t)) - \hat{F}(t) = - \sum_{i \in J(t)} \langle \hat{q}_i(t) \nabla \hat{G}^i(t), h_2(t) + h_1''(t) \rangle + r_1(h(t)).$$

By (b), (6.16), (6.14), and (6.12),

$$F(t, x(t), u(t)) - \hat{F}(t) \geq \delta_1 |h(t)| \left\{ AC_2^{-1} \gamma - C_1 \max_{i=1}^{k} \| q_i \|_\infty \| \nabla \hat{G}_i \|_\infty - 1 \right\}.$$

Thus, using (6.7),

$$F(t, x(t), u(t)) - \hat{F}(t) \geq 0 \quad \text{for } t \in M \quad \text{a.e.}$$

Case 2. $|h_1''(t) \leq A\delta_1 |h(t)|$ on a subset $S \subseteq [a, b]$ of positive measure. Then, from (6.14) we have

$$|h_1''(t) + h_2(t)| \leq \delta |h(t)| \quad \text{a.e. on } S,$$

and hence, $h(t) = h_1'(t) + h_2'(t)$ with $h_1'(t) \in \mathcal{L}^J(t)$, $h_2'(t) := h_1''(t) + h_2(t)$. The above inequality implies

$$(1 - \delta)|h(t)| \leq |h_1'(t)| \leq (1 + \delta)|h(t)|.$$

Now, use these inequalities with (6.10), conditions (a) and (c), and (6.12) we obtain

$$\begin{aligned} F(t, x(t), u(t)) - \hat{F}(t) &\geq (h_1'(t) + h_2'(t))^* B(t)(h_1'(t) + h_2'(t)) + r_2(h(t)) \\ &\geq \bar{\gamma} |h_1'(t)|^2 - 2 \| B \|_\infty |h_1'(t)| |h_2'(t)| \\ &\quad - \| B \|_\infty |h_2'(t)|^2 - \frac{\bar{\gamma}}{2} |h(t)|^2 \\ &\geq \left[\bar{\gamma}(1 - \delta)^2 - 2 \| B \|_\infty (1 + \delta)\delta - \| B \|_\infty \delta^2 - \frac{\bar{\gamma}}{2} \right] |h(t)|^2 \\ &\geq 0 \qquad \text{for } t \in S \text{ a.e.} \end{aligned}$$

from (6.8). Therefore the result is proved. □

Remark 6.4. If condition (1) of Theorem 6.1 is not satisfied, Proposition 6.2 remains valid whenever there exists $\gamma > 0$ such that J in (R5) and $\mathcal{L}^J$ is replaced by J_γ, where

$$\mathcal{L}^{J_\gamma}(t) := \left\{ (x,u) \in \mathbb{R}^{n+m} : \nabla_{(x,u)} \hat{G}^i(t) \begin{pmatrix} x \\ u \end{pmatrix} = 0 \ \ \forall\, i \in J_\gamma(t) \right\}.$$

In fact, in this case Lemma 6.1 and the proof of Proposition 6.2 remain valid when we replace J by J_γ, the constant γ in (6.7) by the above γ, and (6.9) by

$$\begin{aligned} F(t,x(t),u(t)) &\geq L(t,x(t),u(t),\hat{q}(t)) - \sum_{i \in J_\gamma(t)} \hat{q}^i(t) G^i(t,x(t),u(t)) \\ &= \hat{L}(t) - \sum_{i \in J_\gamma(t)} \hat{q}^i(t) \hat{G}^i(t) + [\nabla \hat{L}(t) - \sum_{i \in J_\gamma(t)} \hat{q}^i(t) \nabla \hat{G}^i(t)] h(t) \\ &\quad + r_1(h(t)) \\ &= \hat{F}(t) - \sum_{i \in J_\gamma(t)} \hat{q}^i(t) \nabla \hat{G}^i(t) h(t) + r_1(h(t)) \qquad \text{a.e.} \end{aligned}$$

Proof of Theorem 6.1. The idea of the proof is to construct in terms of the given functions $\hat{p}, \hat{q}, W$, and $(\hat{x}, \hat{u})$ a function V that satisfies the conditions of Proposition 6.1.

Define

$$V(t,x) := \langle \hat{p}(t), x - \hat{x}(t) \rangle + \tfrac{1}{2} \langle x - \hat{x}(t),\, W(t)(x - \hat{x}(t)) \rangle \tag{6.17}$$

then the function $\bar{F}(t,x,u)$ in Proposition 6.1 becomes

$$\begin{aligned} \bar{F}(t,x,u) \quad &= \langle \dot{\hat{p}}(t), x - \hat{x}(t) \rangle - \langle \hat{p}(t), \dot{\hat{x}}(t) \rangle + \tfrac{1}{2} \langle x - \hat{x}(t),\, \dot{W}(t)(x - \hat{x}(t)) \rangle \\ &\quad + \langle x - \hat{x}(t),\, W(t) \dot{\hat{x}}(t) \rangle + \langle \hat{p}(t) + W(t)(x - \hat{x}(t)), f(t,x,u) \rangle + g(t,x,u). \end{aligned} \tag{6.18}$$

To prove condition (i) of Proposition 6.1, we shall use Proposition 6.2. From (6.18), it is clear that $\bar{F}$ satisfies the regularity conditions required there. From Theorem 3.1, it follows that

$$\nabla \hat{\bar{F}}(t) + \hat{q}^*(t) \nabla \hat{G}(t) = \left(\dot{\hat{p}}^*(t) + \hat{H}_x(t), \hat{H}_u(t) \right) = 0 \quad \text{a.e.},$$

and hence condition (a) of Proposition 6.2 holds. Moreover

$$\nabla^2 \hat{\bar{F}}(t) + \sum_{i=1}^{k} \hat{q}^i(t) \nabla^2 \hat{G}^i(t) = \begin{bmatrix} \dot{W} + \hat{f}_x^* W + W \hat{f}_x + \hat{H}_{xx} & W \hat{f}_u + \hat{H}_{xu} \\ \hat{f}_u^* W + \hat{H}_{ux} & \hat{H}_{uu} \end{bmatrix}(t). \tag{6.19}$$

Note that (6.4) and (6.1) yield that

$$\mathcal{L}^J(t) = \left\{ (x,u) \in \mathbb{R}^n \times \mathbb{R}^m : u = Y^J(t) d - \beta^{J(t)}(t) \hat{G}_x^{J(t)}(t) x \quad \text{for some } d \right\},$$

where $d \in \mathbb{R}^{m - \mathrm{Card} J(t)}$ and β^J and Y^J are defined in (4.4), (4.5) with $I(t)$ replaced by $J(t)$. Thus, condition (c) of Proposition 6.2 is equivalent to the following:

$$\begin{aligned} C(t) := &\begin{bmatrix} I_n & -\left(\beta^J \hat{G}_x^J\right)^* \\ O^* & \left(Y^J\right)^* \end{bmatrix} \begin{bmatrix} \dot{W} + \hat{f}_x^* W + W \hat{f}_x + \hat{H}_{xx} & W \hat{f}_u + \hat{H}_{xu} \\ \hat{f}_u^* W + \hat{H}_{ux} & \hat{H}_{uu} \end{bmatrix} \\ &\cdot \begin{bmatrix} I_n & 0 \\ -\beta^J \hat{G}_x^J & Y^J \end{bmatrix}(t) \geq 2\bar{\gamma} I_t \text{ a.e.}, \end{aligned}$$

where I_t is the $(n+m-\mathrm{Card}J(t)) \times (n+m-\mathrm{Card}J(t))$-identity matrix, and $0 = 0_{n\times(m-\mathrm{Card}J(t))}$. After straightforward calculation we can show that this condition is

$$C(t) = N^*(t) \begin{bmatrix} L^J(W) & 0 \\ 0^* & \left(Y^J\right)^* \hat{H}_{uu} Y^J \end{bmatrix} (t) N(t) \geq 2\bar{\gamma} I_t \quad \text{a.e.},$$

where

$$N(t) := \begin{bmatrix} I_n & 0 \\ E(t) & I_{m-\mathrm{Card}J(t)} \end{bmatrix},$$

$$E := \left(\left(Y^J\right)^* \hat{H}_{uu} Y^J\right)^{-1} \left(Y^J\right)^* [\hat{f}_u^* W + \hat{H}_{ux} - \hat{H}_{uu} \beta^J \hat{G}_x^J].$$

Condition (2) of Theorem 6.1 and condition (R1) yield that $\left(\left(Y^J\right)^* \hat{H}_{uu} Y^J\right)^{-1}$ and $\left[\hat{G}_u^J \left(\hat{G}_u^J\right)^*\right]^{-1}$ are bounded for almost all t in $[a,b]$. Thus, (R1) and (R2) imply that E is bounded for almost all t in $[a,b]$. Since

$$N^{-1}(t) = \begin{bmatrix} I_n & 0 \\ -E(t) & I_{m-\mathrm{Card}J(t)} \end{bmatrix}$$

then, for some $\gamma_0 > 0$,

$$\left|N^{-1}(t)\right| \leq \gamma_0 \text{ for } t \in [a,b] \quad \text{a.e.}$$

Whence, for almost all t and for any

$$v = \begin{pmatrix} v_1 \\ v_2 \end{pmatrix} \in \mathbb{R}^n \times \mathbb{R}^{m-\mathrm{Card}J(t)},$$

$$|v|^2 = \left|N^{-1}(t)N(t)v\right|^2 \leq \left|N^{-1}(t)\right|^2 |N(t)v|^2 \leq \gamma_0^2 |N(t)v|^2 .$$

Therefore, using conditions (2) and (3)(a) of Theorem 6.1 we get for $t \in [a,b]$ almost everhwere and for $\bar{\lambda} := \min\{\bar{\delta}, \bar{\alpha}\}$

$$\begin{aligned} v^* C(t) v &= v_1^* L^J(W)(t) v_1 + (v_1^* E^*(t) + v_2^*) \left(\left(Y^J\right)^* \hat{H}_{uu} Y^J\right)(t)(E(t)v_1 + v_2) \\ &\geq \bar{\delta}|v_1|^2 + \bar{\alpha}|E(t)v_1 + v_2|^2 \\ &\geq \bar{\lambda}|N(t)v|^2 \\ &\geq 2\bar{\gamma}|v|^2 , \end{aligned}$$

where $\bar{\gamma} = \bar{\lambda}/2\gamma_0^2$, proving that condition (c) of Proposition 6.2 holds. Thus, by the latter, there exists $\epsilon_1 > 0 (\epsilon_1 \leq \epsilon)$ such that

$$\bar{F}(t,x,u) \leq \hat{\bar{F}}(t) \quad \text{a.e.}$$

and for $(t,x,u) \in T(\hat{x},\hat{u};\epsilon_0)$ with $G(t,x,u) \leq 0$, that is, condition (i) of Proposition 6.1 is satisfied. On the other hand, consider the problem

$$\begin{array}{ll} \text{minimize} & \mathcal{F}(x) := \ell(x) - V(b,x) \\ \text{over} & \psi(x) = 0 \end{array}$$

where V is defined by (6.17).

From condition (e) of Theorem 3.1 we have

$$\nabla \mathcal{F}(\hat{x}(b)) + \nu^* \nabla \psi(\hat{x}(b)) = 0,$$

and from (3.5) and Condition (3)(b) of the Theorem, it follows

$$\nabla^2 \mathcal{F}(\hat{x}(b)) + \sum_{i=1}^{r} \nu_i \nabla^2 \psi_i(\hat{x}(b)) > 0$$

on $\{y : \nabla\psi(\hat{x}(b))y = 0\}$. Thus, from the finite-dimensional version of Proposition 6.2 (e.g., see [7]), it results that for some $\epsilon_0 > 0 (\epsilon_0 \leq \epsilon_1)$ condition (ii) of Proposition 6.1 holds. Therefore, by this proposition the first part of Theorem 6.1 is proved.

Now, to prove the rest of Theorem 6.1 we will use the second part of Proposition 6.1. Let δ be the constant in (6.3). Define

$$p(t,x) = \hat{p}(t) + W(t)(x - \hat{x}(t)).$$

Then, the continuity uniformly in t of $p(t,\cdot)$ and of $u(t,\cdot,\cdot)$ in (6.3) implies that there exists $\tilde{\epsilon} > 0$ $(\tilde{\epsilon} \leq \epsilon_0)$ such that, for almost all t and for $x : |x - \hat{x}(t)| < \tilde{\epsilon}$, we have

$$|u(t,x,p(t,x)) - \hat{u}(t)| < \epsilon_0. \tag{6.20}$$

Thus, for $(t,x) \in T(\hat{x};\tilde{\epsilon})$ and all $u : G(t,x,u) \leq 0$,

$$\bar{F}(t,x,u) \leq \bar{F}(t,x,u(t,x,p(t,x))).$$

Since $G(t,x,u(t,x,p(t,x))) \leq 0$, from (6.20) and the proof of the first part of Theorem 6.1 we obtain

$$\bar{F}(t,x,u) \leq \hat{\bar{F}}(t) \quad \text{for } (t,x) \in T(\hat{x};\tilde{\epsilon}) \text{ and } G(t,x,u) \leq 0.$$

From Proposition 6.1 we obtain that $(\hat{x},\hat{u})$ is a strong local minimum. □

Remark 6.5. If $\hat{G}_u^{J(t)}(t)$ is not of full rank uniformly in t, i.e., does not satisfy (R1), but instead (R5) is satisfied, then the above proof with Proposition 6.2 show that condition 2 and inequality (6.2) in Theorem 6.1 can be replaced by a more primitive condition involving (6.19), namely, for $t \in [a,b]$ almost everywhere,

$$\begin{bmatrix} \dot{W} + \hat{f}_x^* W + W\hat{f}_x + \hat{H}_{xx} & W\hat{f}_u + \hat{H}_{xu} \\ \hat{f}_u^* W + \hat{H}_{ux} & \hat{H}_{uu} \end{bmatrix}(t) \geq \bar{\gamma} I_{n+m} \tag{6.21}$$

on $\mathcal{L}^J(t)$, where $\mathcal{L}^J(t)$ is defined by (6.4) and $\bar{\gamma} > 0$. Hence, in the special setting where $\hat{u}$ and the t-dependence of the data are continuous, W is C^1 and both end points of x are fixed, the first part of Theorem 6.1 was recently proved in [13]. There, the condition used is (6.21) instead of inequality (6.2) and condition 2. If in this special setting the data g and f were only C^{1+} in (x,u) (as opposed to C^2), Remark 6.3 and the proof of Theorem 6.1 imply that Theorem 6.1 remains valid when inequality (6.2) and condition 2 are replaced by the following condition: for all $t \in [a,b]$,

$$\begin{bmatrix} \dot{W} + \hat{f}_x^* W + W\hat{f}_x + \sum_{i=1}^{k} \hat{q}^i \hat{G}^i_{xx} + \alpha & W\hat{f}_u + \sum_{i=1}^{k} \hat{q}^i \hat{G}^i_{xu} + \beta \\ \hat{f}_u^* W + \sum_{i=1}^{k} \hat{q}^i \hat{G}^i_{ux} + \gamma & \sum_{i=1}^{k} \hat{q}^i \hat{G}^i_{uu} + \delta \end{bmatrix}(t) \geq \bar{\gamma} I_{n+m}$$

on $\mathcal{L}^J(t)$, for all

$$\begin{bmatrix} \alpha & \beta \\ \gamma & \delta \end{bmatrix} \in \partial_{(x,u)} \nabla_{(x,u)} \hat{\mathcal{H}}(t),$$

where $\mathcal{H}(t,x,u) = g(t,x,u) + \langle \hat{p}(t), f(t,x,u) \rangle$. Thus, the results in [13] for the problem (C) are included in this section.

Remark 6.6. All the results of this paper can be extended to the multidimensional control problem, that is, when $t \in \Omega \subseteq \mathbb{R}^s$. Therefore, from the previous remark it follows that this section generalizes [13, Thm. 2] to the case where the control $\hat{u}$ at the t-dependence of the data are merely essentially bounded, the function W is only Lipschitz and one end point of x is varying. Moreover, we provide strong as well as weak local minimality criteria.

As indicated in Remark 6.1, the lack of the t-continuity of the data is compensated for in Theorem 6.1 with condition 1. However, as we shall see below, if this condition is violated, we can still obtain a sufficiency criterion when conditions 2 and 3 of Theorem 6.1 are strengthened by using J_γ instead of J, where γ is some positive number.

THEOREM 6.2. *Suppose all the conditions, except condition* 1, *in Theorem* 6.1 *are satisfied where* J *is replaced by* J_γ, *for some* $\gamma > 0$. *Then the results of Theorem* 6.1 *remain valid.*

Proof. The proof is identical to that of Theorem 6.1, where J is replaced by J_γ and Remark 6.4 is used instead of Proposition 6.2. □

Remark 6.7. Corollaries 6.1 and 6.2, where J is replaced by γ, hold for Theorem 6.2.

7. Numerical example. For

$$\tilde{x}(t) := \begin{cases} t^2 |\sin \frac{\pi}{t}| & \text{for } t \neq 0 \\ 0 & \text{for } t = 0 \end{cases}$$

and

$$\tilde{u}(t) := 2t \left| \sin \frac{\pi}{t} \right| - \pi \cos \frac{\pi}{t} \operatorname{sgn}\left(\sin \frac{\pi}{t} \right) \quad \text{a.e.},$$

define the optimal control problem

$$(\tilde{\mathrm{C}}) \qquad \text{minimize} \int_0^1 \left[(u_1 - \tilde{u})^3 - \frac{1}{2} u_2^2 - \frac{1}{8}(x - \tilde{x} + 64)(u_1 - \tilde{u}) \right] dt$$

$$\text{subject to } \dot{x} = u_1 - \frac{1}{8}(x - \tilde{x}) \quad \text{a.e.},$$

$$x(0) = x(1) = 0,$$

$$(u_1 - \tilde{u})^2 + u_2^2 + 2x - 2\tilde{x} \leq 4 \quad \text{a.e.}$$

Set $\hat{x} = \tilde{x}, \hat{u} = (\tilde{u}, 2), \hat{p} \equiv 8$ and $\hat{q} \equiv \frac{1}{2}$. We will soon show the $(\hat{x}, \hat{u}, \hat{p}, \hat{q})$ satisfies the conditions of Theorem 6.1 and hence $(\hat{x}, \hat{u})$ is a *strong local minimum* for $(\tilde{\mathrm{C}})$.

Here we have $u \in \mathbb{R}^2, x \in \mathbb{R}$,

$$g(t,x,u) = (u_1 - \tilde{u}(t))^3 - \tfrac{1}{2} u_2^2 - \tfrac{1}{8}(x - \tilde{x}(t) + 64)(u_1 - \tilde{u}(t)),$$

$$f(t,x,u) = u_1 - \tfrac{1}{8}(x - \tilde{x}(t)),$$

$$G(t,x,u) = (u_1 - \tilde{u}(t))^2 + u_2^2 + 2x - 2\tilde{x}(t),$$

and

$$H(t,x,u,p,q) = pf(t,x,u) + g(t,x,u) + qG(t,x,u).$$

We can easily check that $l_0 = 1, \hat{x}, \hat{u}, \hat{p}$ and $\hat{q}$ satisfy the conditions of Theorem 3.1. Moreover, since $\tilde{x}$ is Lipschitz and $\tilde{u}$ is in $L^\infty[0,1]$, the data of the problem satisfies the regularity assumptions in (R1) and (R2). Furthermore, $J(t) \equiv 1$, and

$$\hat{G}_u(t)\hat{G}_u^*(t) = 16 \quad \text{a.e.}$$

Take

$$Y(t) = \begin{bmatrix} 1 \\ 0 \end{bmatrix}.$$

Then $Y^*(t)\hat{H}_{uu}(t)Y(t) = 1$. For this problem we have

$$\beta^1 = \begin{bmatrix} 0 \\ \frac{1}{4} \end{bmatrix},$$

$$Z^1 = \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix},$$

and hence

$$L^1(W) = \dot{W} - \tfrac{1}{4}W - (W - \tfrac{1}{8})^2.$$

Take $W_0(t) = \frac{t}{2}$. It results that

$$L^1(W_0(t)) = \frac{-t^2}{4} + \frac{31}{64} \geq \frac{15}{64} \quad \text{a.e.}$$

Therefore, by the first part of Theorem 6.1, it follows that $(\hat{x}, \hat{u})$ is a weak local minimum for $(\tilde{C})$.

Note that the strong local normality on any subinterval of $[0,1]$ of the form $[0,c]$ or $[c,1]$ holds true at $(\hat{x}, \hat{u})$ and hence, $W_0(t) = \frac{t}{2}$ satisfies the necessary condition of Corollary 5.2.

Now we shall show that condition (6.3) of Theorem 6.1 holds.

Take $q \equiv \frac{1}{2}$. Then $H_{u_2} \equiv 0$. Consider the equations

$$\begin{cases} H_{u_1}(t,x,u,p,\frac{1}{2}) = 0 \\ G(t,x,u) = 0. \end{cases}$$

Since

$$\nabla_u(H_{u_1}, G) = \begin{bmatrix} 1 + 6(u_1 - \tilde{u}) & 0 \\ 2(u_1 - \tilde{u}) & 2u_2 \end{bmatrix},$$

by the implicit function theorem on Banach spaces we obtain that for some $\bar{\delta} > 0$ there exists a mapping $u : T(\hat{x}, \hat{p}; \bar{\delta}) \to \mathbb{R}^2$ such that $u(t, \hat{x}(t), \hat{p}(t)) = \hat{u}(t) = (\tilde{u}(t), 2)$ and $u(t, ., .)$ is continuous uniformly in t. Hence $u_2(t, x, p) > 0$ and

$$\left\{(u_1, u_2) : \nabla_u G(t, x, u(t, x, p)) \begin{pmatrix} u_1 \\ u_2 \end{pmatrix} = 0\right\}$$

is of the form $c\bar{u}$, where c is in $\mathbb{R}$ and

$$\bar{u} := \begin{pmatrix} 1 \\ \frac{\tilde{u}(t) - u_1(t,x,p)}{u_2(t,x,p)} \end{pmatrix}.$$

Moreover

$$\bar{u}^* \nabla_u^2 H\left(t, x, u, p, \frac{1}{2}\right) \bar{u} = 1 + 6(u_1 - \tilde{u}(t)) > \frac{1}{2}$$

for $\|u_1 - \tilde{u}\|_\infty < \frac{1}{12}$. Thus, for some $\delta < \bar{\delta}$, $u(t, x, p)$ provides a minimum for H over u whenever $(t, x, p) \in T(\hat{x}, \hat{p}; \delta)$. Therefore, from Theorem 6.1 it results that $(\hat{x}, \hat{u})$ is a strong local minimum.

Acknowledgment. The author thanks Professor H. Maurer for bringing to her attention the recent work [13].

A MULTISTATE, MULTICONTROL PROBLEM WITH UNBOUNDED CONTROLS *

J. R. DORROH† AND GUILLERMO FERREYRA†

Abstract. This paper gives the optimal synthesis for a two-dimensional singular control problem of the Vidale–Wolfe type. The controls take values in an unbounded set. Moreover, the optimal feedback control turns out to be impulsive on certain regions, and the order in which these impulses occur is important. A parameterization of time is introduced into the problem. This helps to elucidate the optimal synthesis, to prove its optimality by the verification method, and to design suboptimal physical approximations to the optimal impulsive control.

Key words. unbounded multidimensional control, optimal advertising, dynamic programming

1. Introduction.

In this paper, we consider the singular control problem ($\mathcal{P}$): Maximize

$$J = J(x_0, y_0, u, v, \tau) = \int_0^\infty [Ax\tau + By\tau - u - v]e^{-\rho t}\, ds \tag{1.1}$$

over the set $\mathcal{U}$ of ordered triples (u, v, τ) of nonnegative locally integrable functions on $[0, \infty)$ subject to

$$\begin{aligned} \dot{x} &= \alpha(1-x)u - \beta x\tau, \quad x(0) = x_0, \qquad 0 < x_0 < 1, \\ \dot{y} &= \gamma(1 - y/x)v - \eta y\tau, \quad y(0) = y_0, \qquad 0 < y_0 < x_0, \\ \dot{t} &= \tau, \quad t(0) = 0, \quad t(\infty) = \infty, \end{aligned} \tag{1.2}$$

where $\dot{} = d/ds$, $\beta, \eta \geq 0$, and $A, B, \rho, \alpha, \gamma > 0$. In §2, we discuss necessary conditions for the problem ($\mathcal{P}$) in this generality. In §3, we give the optimal synthesis in the special case $\beta = 0$, $\eta = 0$. These restrictions will be imposed at that point.

The problem ($\mathcal{P}$) is motivated by the singular control problem ($\mathcal{P}_0$): Maximize

$$J_0 = J_0(x_0, y_0, u, v) = \int_0^\infty [Ax + By - u - v]e^{-\rho t}\, dt$$

over the set $\mathcal{U}_0$ of ordered pairs (u, v) of nonnegative locally integrable functions on $[0, \infty)$ subject to

$$\begin{aligned} x' &= \alpha(1-x)u - \beta x, \quad x(0) = x_0, \qquad 0 < x_0 < 1, \\ y' &= \gamma(1 - y/x)v - \eta y, \quad y(0) = y_0, \qquad 0 < y_0 < x_0, \end{aligned} \tag{1.3}$$

where $' = d/dt$.

As stated, ($\mathcal{P}_0$) has no solution, for it leads to impulsive controls. There is a vast literature on impulsive control problems; see, for example, [1], [2]. However,

the methods described in these references require that the cost of a jump be given in the model. This would be highly artificial in our situation; moreover it is not clear how these costs would be arrived at without introducing the parameter s. See the discussion in [6, p. 365]. The problem $(\mathcal{P})$ is obtained from $(\mathcal{P}_0)$ by introducing the parameter s and treating t as a state variable. It is well known [3], [11] that since the vector fields $(1-x,0)$ and $(0,1-y/x)$ do not commute, serious difficulties occur in the attempt to define, by means of the parameterization introduced in (1.2), an extension of the notion of the solution of (1.3) to the case where u and v have simultaneous impulses. However, in an optimal control problem such as ours, there is a functional to be optimized, and in fact, an optimal parameterization of t can be determined along with optimal u and v. Obviously, because of the parameterization, the optimal synthesis will not be unique. However, given an initial state, the image in (x,y,t)-space of the optimal trajectory is unique, as are the optimal profit and the feedback controls. In the optimal synthesis, the control τ is equal to zero on some nondegenerate s-intervals. On these intervals, the time t is constant, the control u or v is nonzero, and the corresponding state variable x or y increases to a well-defined value. This would correspond to an impulsive control and a jump in x or y for the problem $(\mathcal{P}_0)$. Even though x and y are continuous functions of the parameter s in the problem $(\mathcal{P})$ that we treat, we refer to increases in x or y that occur on an s-interval on which t is constant as *jumps*. Remarkably, in some of these s-intervals, both x and y increase, but not simultaneously, and the order is important. To our knowledge, this is the first example that exhibits this phenomenon. The complex jumps have interesting implications for continuous approximations of the optimal synthesis. This is discussed in §4.

The problem $(\mathcal{P}_0)$ is the Vidale–Wolfe advertising model for two products of a company in which the saturation level for the rate of sales $x(t)$ of the first product is taken to be 1, and the saturation level for the rate of sales $y(t)$ of the second product is equal to the rate of sales of the first product. The controls u and v are the rates of investment in advertising each product. The quantities $1-x$ and $1-y/x$ are the portions of the potential sales rates of the two products upon which advertising has an effect. The terms $-\beta x$ and $-\eta y$ represent the "forgetting effect." That is, if no advertising of a product is done ($u=0$ or $v=0$), then its rate of sales decays exponentially. Note that it follows from the state equations that $0<x(t)<1$ and that $0<y(t)<x(t)$. The functional describing the profit contains two positive terms due to the rates of sales $x(t)$ and $y(t)$ and two negative terms due to the expenditure on advertising. The discount factor $e^{-\rho t}$ reflects the time value of money. Several variations of the Vidale–Wolfe model for a single product [12] have been considered in [4]–[6], [9], and [10].

We assume throughout the paper that

$$A\alpha > \rho+\beta, \qquad B\gamma > \rho+\eta. \tag{1.4}$$

From an economic viewpoint, these assumptions are quite natural for a profitable enterprise, and mathematically they lead to the richest case in which all features occur.

2. Necessary conditions. The Hamiltonian for the system (1.1), (1.2) is given by

$$\begin{aligned} H(x,y,t,u,v,\tau,p_1,p_2,p_3,p_4) =& [p_3-\beta x p_1-\eta y p_2-(Ax+By)e^{-\rho t}p_4]\tau \\ &+[\alpha(1-x)p_1+e^{-\rho t}p_4]u+[\gamma(1-y/x)p_2+e^{-\rho t}p_4]v, \end{aligned} \tag{2.1}$$

where p_1, p_2, p_3, p_4 satisfy the adjoint equations

$$\begin{aligned} \dot{p}_1 &= \alpha u p_1 + \beta\tau p_1 - \gamma\frac{y}{x^2}vp_2 + A\tau e^{-\rho t}p_4, \\ \dot{p}_2 &= \gamma\frac{v}{x}p_2 + \eta\tau p_2 + B\tau e^{-\rho t}p_4, \\ \dot{p}_3 &= \rho(-Ax\tau - By\tau + u + v)e^{-\rho t}p_4, \\ \dot{p}_4 &= 0. \end{aligned} \tag{2.2}$$

Assuming $p_4 = -1$, Pontryagin's maximum principle implies the following necessary conditions.

If $\tau = 0$ and $v > 0$, then $p_2 = e^{-\rho t}/\gamma(1 - y/x)$. Differentiating this expression with respect to s, substituting for $\dot{x}$ and $\dot{y}$ from (1.2), and substituting into the adjoint equation yields $(y/x^2)\alpha(1 - x)u = 0$, or $u = 0$. This implies that jumps are either horizontal or vertical, since $\tau = 0$, $u > 0$, $v > 0$ is not optimal. In the next section, we will show that if both x and y undergo jumps while t remains fixed, then it is optimal to jump first in x and then in y.

If $\tau > 0$, $u = 0$, $v > 0$, then $p_2 = e^{-\rho t}/\gamma(1 - y/x)$. Proceeding as before, we deduce the necessary condition

$$B\gamma(1 - y/x)^2 - (\rho + \beta)(1 - y/x) - (\eta - \beta) = 0.$$

Let $z = \tilde{z}$ be the smaller root of

$$B\gamma(1 - z)^2 - (\rho + \beta)(1 - z) - (\eta - \beta) = 0. \tag{2.3}$$

Then $0 < \tilde{z} < 1$.

If $\tau > 0$, $u > 0$, $v = 0$, then $p_1 = e^{-\rho t}/\alpha(1 - x)$. As before, we deduce the condition

$$A\alpha(1 - x)^2 - \rho(1 - x) - \beta = 0.$$

If $\tau > 0$, $u > 0$, $v > 0$, then $p_1 = e^{-\rho t}/\alpha(1 - x)$, and $p_2 = e^{-\rho t}/\gamma(1 - y/x)$. These lead to

$$A\alpha(1 - x)^2 - \rho(1 - x) - \beta = -\frac{y}{x^2}\frac{v}{\tau}\frac{\alpha(1 - x)^2}{1 - y/x},$$

and

$$B\gamma(1 - y/x)^2 - (\rho + \beta)(1 - y/x) - (\eta - \beta) = \alpha(1 - x)\frac{u}{\tau}.$$

These two equations, together with (1.2), define a spiral around the point $(\tilde{x}, \tilde{z}\tilde{x})$, where $\tilde{x}$ is the smaller root of

$$\left[A + \frac{\eta\tilde{z}^2}{\gamma(1 - \tilde{z})^2}\right]\alpha(1 - x)^2 - \rho(1 - x) - \beta = 0$$

(thus, $0 < \tilde{x} < 1$). These spirals are trajectories of our system only on the region $\{(x, y) : x \geq \tilde{x}, \quad y/x \leq \tilde{z}\}$ since we must have $u, v \geq 0$.

Moreover, higher-order conditions [8] imply that no portion of any one of these spirals is optimal. In fact, considering the system (1.2) with the added state variables s and w defined by

$$\begin{aligned} \dot{s} &= 1, \qquad s(0) = 0, \\ \dot{w} &= (-Ax\tau - By\tau + u + v)e^{-\rho t}, \qquad w(0) = 0, \end{aligned}$$

we have, for $\bar{x} = (s, x, y, t, w)$,

$$\dot{\bar{x}} = a_0(\bar{x}) + a_1(\bar{x})u + a_2(\bar{x})v + a_3(\bar{x})\tau,$$

where

$$a_0 = (1,0,0,0,0), \qquad a_1 = (0, \alpha(1-x), 0, 0, e^{-\rho t}),$$
$$a_2 = (0,0,\gamma(1-y/x), 0, e^{-\rho t}), \qquad a_3 = (0, -\beta x, -\eta y, 1, -(Ax+By)e^{-\rho t}).$$

Let

$$\bar{H}(\bar{x}, \bar{u}, \bar{p}) = H(x, y, t, u, v, \tau, p_1, p_2, p_3, p_4) + p_0,$$

where $\dot{p}_0 = 0$, $\bar{p} = (p_0, p_1, p_2, p_3, p_4)$, and $\bar{u} = (u, v, \tau)$. Following the notation of [8, p. 286], the controls are of degree h, with $1 \le h \le \infty$, since

$$\frac{\partial}{\partial \bar{u}_i} \frac{d}{ds} \frac{\partial \bar{H}}{\partial \bar{u}_i} = 0.$$

Then [8, Thm. 6.2, p. 286] implies that for $\tau, u, v, > 0$, we must have

$$\frac{\partial}{\partial \bar{u}_i} \frac{d}{ds} \frac{\partial}{\partial \bar{u}_j} \bar{H}(\bar{x}, \bar{u}, \bar{p}) = 0, \tag{2.4}$$

for $i, j = 1, 2, 3$. Now (2.4) implies

$$\frac{\partial}{\partial v} \frac{d}{ds} \frac{\partial H}{\partial u} = -\gamma \frac{y}{x^2} \alpha(1-x) p_2 = 0, \tag{2.5}$$

$$\frac{\partial}{\partial \tau} \frac{d}{ds} \frac{\partial H}{\partial u} = \beta \alpha p_1 + (A\alpha(1-x) - \rho) e^{-\rho t} p_4 = 0. \tag{2.6}$$

Thus $p_2 = 0$ by (2.5), and $p_4 = 0$ by (2.2), so that (2.6) implies that $p_1 = 0$. Since $\tau > 0$, its coefficient in (2.1) must be zero, and thus $p_3 = 0$. This contradicts the nontriviality of the adjoint variable. Therefore, no piece of a spiral is optimal.

3. The optimal synthesis. For the remainder of this paper we assume

$$\beta = \eta = 0.$$

Thus $\tilde{z}$ and $\tilde{x}$ are given by

$$B\gamma(1-\tilde{z}) - \rho = 0, \qquad A\alpha(1-\tilde{x}) - \rho = 0.$$

Since we are assuming that $B\gamma, A\alpha > \rho$, this implies $0 < \tilde{x}, \tilde{z} < 1$. We also define $\tilde{y} = \tilde{x}\tilde{z}$. We need one more technical assumption; it is

$$\left(B - \frac{\rho}{\gamma}\right)(B\gamma - \rho) \le A(A\alpha - \rho). \tag{3.1}$$

This assumption is made so that one of the switching curves will have geometry that enables us to obtain the optimal synthesis. The assumption that $\eta = 0$ eliminates a switching curve whose presence was very perplexing.

We resolve the nonuniqueness due to parameterization by taking τ to be 1 whenever $\tau \neq 0$, and by taking $u = 1$ whenever $u \neq 0$ and $\tau = 0$, and likewise for v. We have

already demonstrated that u and v simultaneously nonzero is not optimal. In fact, when $\beta = \eta = 0$, it is not optimal for any two controls to be simultaneously nonzero. To obtain our last switching curve, consider a trajectory starting at a state (x_0, y_0, t_0), moving horizontally to (x_1, y_0, t_0), then vertically to $(x_1, \tilde{z}x_1, t_0)$, and finally $x = x_1$, $y = \tilde{z}x_1$ for $t \geq t_0$. This is achieved by taking controls $u = 1$, $v = 0$, $\tau = 0$ first, then $u = 0$, $v = 1$, $\tau = 0$, and finally $u = 0$, $v = 0$, $\tau = 1$. Solving the adjoint equations with $p_i(\infty) = 0$ for $i = 1, 2, 3$ leads to $E(x_1, y_0) = 0$, where E is the function defined in Lemma 3.1.

LEMMA 3.1. *Let the function E be defined on the set*

$$\mathcal{E} = \{(x, y) : \tilde{x} < x < 1,\ 0 \leq y < x\tilde{z}\}$$

by

$$E(x, y) = \frac{1}{\gamma} \log\left(\frac{1 - \tilde{z}}{1 - y/x}\right) - \frac{y/x}{\gamma(1 - y/x)} + \frac{\tilde{z}}{\gamma(1 - \tilde{z})} - \frac{1}{\alpha(1 - x)} + \frac{A}{\rho}.$$

Then there is a unique function φ on the interval $[0, \tilde{y}]$ such that $x = \varphi(y)$ satisfies the equation $E(x, y) = 0$ for $0 \leq y \leq \tilde{y}$. Furthermore, $\varphi(\tilde{y}) = \tilde{x}$, φ is strictly decreasing, $\tilde{x} < \varphi(0) < 1$, and $E(x, y) < 0$ for $(x, y) \in \mathcal{E}$ and $y \geq \tilde{y}$ or $0 \leq y \leq \tilde{y}$, $x > \varphi(y)$.

Proof. It is easy to see that $E(\tilde{x}, \tilde{y}) = 0$, and that $E(x, y) < 0$ for $\tilde{x} < x < 1$, $\tilde{y} \leq y \leq x\tilde{z}$. We also see that

$$E_y(x, y) = -\frac{z}{\gamma x(1 - z)^2}$$

and that

$$E_x(x, y) = \frac{z^2}{\gamma x(1 - z)^2} - \frac{1}{\alpha(1 - x)^2},$$

where $z = y/x$. Thus $E_y(x, y) \leq 0$ for all $(x, y) \in \mathcal{E}$, and $E_y(x, y) < 0$ for $y > 0$. It is also clear that E_x has a strong maximum at $(\tilde{x}, \tilde{y})$. But the assumption (3.1) is exactly the assumption that $\tilde{x}E_x(\tilde{x}, \tilde{y}) \leq 0$. We also see that $E(\tilde{x}, y) > 0$ and $E(1^-, y) = -\infty$ for $0 \leq y < \tilde{y}$. The lemma now follows from the implicit function theorem and the intermediate value property for continuous functions.

DEFINITION 3.1. *We denote by w the function on $[0, \tilde{y}]$ defined implicitly by the requirement that $x = w(y)$ be a solution of $E(x, y) = 0$, where E is the function defined in Lemma* 3.1. *That is, w denotes the function φ defined in Lemma* 3.1.

The Hamilton–Jacobi–Bellman equation for the value function V is

$$0 = \max\{Pu + Qv + R\tau : u, v, \tau \geq 0\},$$

where

$$P = \alpha(1 - x)V_x - e^{-\rho t},$$
$$Q = \gamma(1 - y/x)V_y - e^{-\rho t},$$
$$R = V_t + (Ax + By)e^{-\rho t}.$$

We will give controls and prove that they are optimal. We will do this by computing the corresponding payoff function and proving that this function satisfies the Hamilton–Jacobi–Bellman equation and is thus the value function. Let the regions Ω_1, Ω_2, Ω_3, and Ω_4 be defined by

$$\Omega_1 = \{(x, y) : \tilde{x} < x < 1,\ x\tilde{z} < y < x\},$$
$$\Omega_2 = \{(x, y) : 0 < y \leq \tilde{y},\ w(y) < x < 1\} \cup \{(x, y) : \tilde{x} < x < 1,\ \tilde{y} \leq y < x\tilde{z}\},$$
$$\Omega_3 = \{(x, y) : 0 < y < \tilde{y},\ y < x < w(y)\},$$
$$\Omega_4 = \{(x, y) : \tilde{y} < y < \tilde{x},\ y < x < \tilde{x}\}.$$

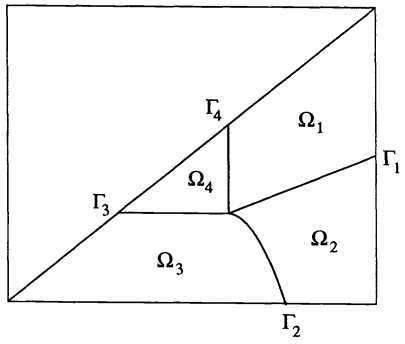

FIG. 1

Let the curves Γ_1, Γ_2, Γ_3, and Γ_4 be defined by

$$\begin{aligned}\Gamma_1 &= \{(x,y) : \tilde{x} < x < 1,\ y = x\tilde{z}\},\\ \Gamma_2 &= \{(x,y) : 0 < y < \tilde{y},\ x = w(y)\},\\ \Gamma_3 &= \{(x,y) : \tilde{y} < x < \tilde{x},\ y = \tilde{y}\},\\ \Gamma_4 &= \{(x,y) : x = \tilde{x},\ \tilde{y} < y < \tilde{x}\}.\end{aligned}$$

The regions Ω_k and the curves Γ_k are illustrated in Fig. 1. Let $\tilde{\Omega}_k = \Omega_k \times [0,\infty)$ and $\tilde{\Gamma}_k = \Gamma_k \times [0,\infty)$ for $k = 1,2,3,4$. The surfaces $\tilde{\Gamma}_1$, $\tilde{\Gamma}_2$, and $\tilde{\Gamma}_4$ are switching surfaces, but $\tilde{\Gamma}_3$ is not.

THEOREM 3.1. *Under the assumption* (3.1) (*and* $\beta = \eta = 0$, $A\alpha, B\gamma > \rho$), *optimal controls for the problem* ($\mathcal{P}$) *are given by*

$$u = \begin{cases} 0 & \text{on } \tilde{\Omega}_1 \cup \tilde{\Omega}_2 \cup \tilde{\Gamma}_1 \cup \tilde{\Gamma}_2 \cup \tilde{\Gamma}_4 \cup \{(\tilde{x},\tilde{y})\} \times [0,\infty),\\ 1 & \text{on } \tilde{\Omega}_3 \cup \tilde{\Omega}_4 \cup \tilde{\Gamma}_3,\end{cases}$$

$$v = \begin{cases} 0 & \text{on } \tilde{\Omega}_1 \cup \tilde{\Omega}_3 \cup \tilde{\Omega}_4 \cup \tilde{\Gamma}_1 \cup \tilde{\Gamma}_3 \cup \tilde{\Gamma}_4 \cup \{(\tilde{x},\tilde{y})\} \times [0,\infty),\\ 1 & \text{on } \tilde{\Omega}_2 \cup \tilde{\Gamma}_2,\end{cases}$$

$$\tau = \begin{cases} 0 & \text{on } \tilde{\Omega}_2 \cup \tilde{\Omega}_3 \cup \tilde{\Omega}_4 \cup \tilde{\Gamma}_2 \cup \tilde{\Gamma}_3,\\ 1 & \text{on } \tilde{\Omega}_1 \cup \tilde{\Gamma}_1 \cup \tilde{\Gamma}_4 \cup \{(\tilde{x},\tilde{y})\} \times [0,\infty).\end{cases}$$

Proof. The payoff function V is given below by giving its restrictions to the regions $\tilde{\Omega}_1$ through $\tilde{\Omega}_4$. V^k is the restriction of V to $\tilde{\Omega}_k$. Each of the functions V^k extends continuously to the boundary of $\tilde{\Omega}_k$, and the extensions agree on the common boundaries of the regions $\tilde{\Omega}_k$. The payoff function is obtained by solving (1.2) (with $t(0) = t$, $x(0) = x$, $y(0) = y$) with the given controls and evaluating (1.1). Let

$$V^1 = \frac{Ax}{\rho}e^{-\rho t} + \frac{By}{\rho}e^{-\rho t},$$

$$V^2 = \frac{x}{\gamma}\log\left(\frac{1-\tilde{z}}{1-y/x}\right)e^{-\rho t} + \frac{1}{\rho}[Ax + Bx\tilde{z}]e^{-\rho t},$$

$$V^3 = \frac{1}{\alpha}\log\left(\frac{1-w(y)}{1-x}\right)e^{-\rho t} + V^2(t, w(y), y),$$

$$V^4 = \frac{1}{\alpha}\log\left(\frac{1-\tilde{x}}{1-x}\right)e^{-\rho t} + \frac{A\tilde{x}}{\rho}e^{-\rho t} + \frac{By}{\rho}e^{-\rho t}.$$

The payoff function is $C^{(1)}$ (but not $C^{(2)}$). The classical verification theorem [7, Thm. 4.4, p. 87] can be easily modified to apply to this infinite horizon problem. Two observations are relevant for this. The payoff function V approaches zero along any trajectory as s approaches ∞. Also, if u, v, τ are admissible controls, (x, y, t) is the corresponding trajectory, and $S > 0$, then

$$\int_S^\infty (Ax\tau + By\tau - u - v)\, e^{-\rho t} ds \leq \int_S^\infty (A+B)\,\tau e^{-\rho t} ds = \frac{A+B}{\rho} e^{-\rho t(S)}.$$

All we need is to verify the Hamilton–Jacobi–Bellman equation on $\tilde{\Omega}_1 \cup \tilde{\Omega}_2 \cup \tilde{\Omega}_3 \cup \tilde{\Omega}_4$, which means that we need to show that

$$P = 0 \quad \text{on } \tilde{\Omega}_3 \cup \tilde{\Omega}_4, \tag{3.2}$$

$$P \leq 0 \quad \text{on } \tilde{\Omega}_1 \cup \tilde{\Omega}_2, \tag{3.3}$$

$$Q = 0 \quad \text{on } \tilde{\Omega}_2, \tag{3.4}$$

$$Q \leq 0 \quad \text{on } \tilde{\Omega}_1 \cup \tilde{\Omega}_3 \cup \tilde{\Omega}_4, \tag{3.5}$$

$$R = 0 \quad \text{on } \tilde{\Omega}_1, \tag{3.6}$$

$$R \leq 0 \quad \text{on } \tilde{\Omega}_2 \cup \tilde{\Omega}_3 \cup \tilde{\Omega}_4. \tag{3.7}$$

We give P, Q, and R by giving their restrictions to each set $\tilde{\Omega}_k$; with P^k denoting the restriction of P to $\tilde{\Omega}_k$, etc.,

$$e^{\rho t}P^1 = \alpha(1-x)\frac{A}{\rho} - 1,$$

$$e^{\rho t}P^2 = \alpha(1-x)\left[\frac{1}{\gamma}\log\left(\frac{1-\tilde{z}}{1-y/x}\right) - \frac{y/x}{\gamma(1-y/x)} + \frac{1}{\rho}[A + B\tilde{z}]\right] - 1,$$

$$e^{\rho t}P^3 = 0,$$

$$e^{\rho t}P^4 = 0,$$

$$e^{\rho t}Q^1 = \frac{B\gamma}{\rho}(1-y/x) - 1,$$

$$e^{\rho t}Q^2 = 0,$$

$$e^{\rho t}Q^3 = \frac{1-y/x}{1-y/w(y)} - 1,$$

$$e^{\rho t}Q^4 = \frac{B\gamma}{\rho}(1-y/x) - 1,$$

$$e^{\rho t}R^1 = 0,$$

$$e^{\rho t}R^2 = -\frac{\rho x}{\gamma}\log\left(\frac{1-\tilde{z}}{1-y/x}\right) + B(y - x\tilde{z}),$$

$$e^{\rho t}R^3 = e^{\rho t}R^2(t, w(y), y) + \frac{\rho}{\alpha}\log\left(\frac{1-x}{1-w(y)}\right) + A(x - w(y)),$$

$$e^{\rho t}R^4 = \frac{\rho}{\alpha}\log\left(\frac{1-x}{1-\tilde{x}}\right) + A(x - \tilde{x}).$$

The derivation of most of these formulas is straightforward. The formula for Q^3 uses the fact that $e^{\rho t}V_x^2(t, w(y), y) = 1/\alpha(1 - w(y))$, which follows from the definition of w and the definition of $\tilde{z}$.

Conditions (3.2), (3.4), and (3.6) are immediate from the above formulas, and (3.5) is easily seen, as well as the fact that $P < 0$ on $\tilde{\Omega}_1$. We can use the definition of $\tilde{z}$ to see that $e^{\rho t}P^2 = \alpha(1 - x)E(x, y)$, and thus the fact that $P < 0$ on $\tilde{\Omega}_2$ follows from Lemma 3.1. To establish (3.7), consider the functions G and H defined on (0,1) by

$$H(z) = \frac{\rho}{\gamma}\log(1 - z) + Bz,$$
$$G(x) = \frac{\rho}{\alpha}\log(1 - x) - A(1 - x).$$

It is easy to see that G is increasing on $(0, \tilde{x}]$ and decreasing on $[\tilde{x}, 1)$ and that H is increasing on $(0, \tilde{z}]$ and decreasing on $[\tilde{z}, 1)$. Since

$$e^{\rho t}R^2(t, x, y) = x[H(y/x) - H(\tilde{z})],$$

it is clear that $R < 0$ on $\tilde{\Omega}_2$. Since

$$e^{\rho t}R^3(t, x, y) = e^{\rho t}R^2(t, w(y), y) + G(x) - G(w(y)),$$

it is clear that $R < 0$ on $\tilde{\Omega}_3$. Since

$$e^{\rho t}R^4(t, x, y) = G(x) - G(\tilde{x}),$$

it is clear that $R < 0$ on $\tilde{\Omega}_4$. This establishes (3.7).

4. Suboptimal controls for $(\mathcal{P}_0)$. It is clear from the solution of $(\mathcal{P})$ that $(\mathcal{P}_0)$ has no solution in the class of locally integrable control functions, unless $(x_0, y_0) \in \Omega_1 \cup \Gamma_1 \cup \Gamma_4$. In other words, J_0 has no maximum for u, v nonnegative and locally integrable unless $(x_0, y_0) \in \Omega_1 \cup \Gamma_1 \cup \Gamma_4$. What we show in this section is that the supremum of J_0 over the class of nonnegative locally integrable controls is equal to the maximum of J. We do this for an initial state in Ω_3, which is the most interesting case. Since the suboptimal controls are for the problem $(\mathcal{P}_0)$, they do not involve the parameter s. However, the parameterization $s \to t(s)$ introduced in the problem $(\mathcal{P})$ permits a visualization of the optimal synthesis that is crucial for the design of suboptimal locally integrable controls u_ε and v_ε for the problem $(\mathcal{P}_0)$. To design suboptimal controls for the problem $(\mathcal{P}_0)$, we approximate first the jump from (x_0, y_0) to $(w(y_0), y_0)$ and then the jump from $(w(y_0), y_0)$ to $(w(y_0), \tilde{z}w(y_0))$.

Let $(x_0, y_0) \in \Omega_3$, and let

$$u_\varepsilon^1(t) = \begin{cases} \dfrac{1}{\varepsilon\alpha}\log\left(\dfrac{1 - x_0}{1 - w(y_0)}\right) & \text{for } 0 < t < \varepsilon, \\ 0 & \text{for } \varepsilon < t, \end{cases}$$

$$v_\varepsilon^1(t) = \begin{cases} 0 & \text{for } 0 < t < \varepsilon, \\ \dfrac{w(y_0)}{\varepsilon\gamma}\log\left(\dfrac{1 - y_0/w(y_0)}{1 - \tilde{z}}\right) & \text{for } \varepsilon < t < 2\varepsilon, \\ 0 & \text{for } 2\varepsilon < t. \end{cases}$$

Then solving

$$\frac{d}{dt}x_\varepsilon^1 = \alpha(1-x_\varepsilon^1)u_\varepsilon^1, \qquad x_\varepsilon^1(0) = x_0$$
$$\frac{d}{dt}y_\varepsilon^1 = \gamma(1-y_\varepsilon^1/x_\varepsilon^1)v_\varepsilon^1, \qquad y_\varepsilon^1(0) = y_0,$$

we find that

$$x_\varepsilon^1(t) = \begin{cases} 1-(1-x_0)^{1-t/\varepsilon}(1-w(y_0))^{t/\varepsilon} & \text{for } 0 \le t \le \varepsilon, \\ w(y_0) & \text{for } \varepsilon \le t, \end{cases}$$

$$y_\varepsilon^1(t) = \begin{cases} y_0 & \text{for } 0 \le t \le \varepsilon, \\ w(y_0) - w(y_0)(1-y_0/w(y_0))^{(2\varepsilon-t)/\varepsilon}(1-\tilde{z})^{(t-\varepsilon)/\varepsilon} & \text{for } \varepsilon \le t \le 2\varepsilon, \\ w(y_0)\tilde{z} & \text{for } 2\varepsilon \le t. \end{cases}$$

Letting $x^1(t) = \lim_{\varepsilon\to 0} x_\varepsilon^1(t)$, $y^1(t) = \lim_{\varepsilon\to 0} y_\varepsilon^1(t)$, it is clear that

$$x^1(t) = \begin{cases} x_0 & \text{for } t = 0, \\ w(y_0) & \text{for } t > 0, \end{cases}$$

$$y^1(t) = \begin{cases} y_0 & \text{for } t = 0, \\ w(y_0)\tilde{z} & \text{for } t > 0. \end{cases}$$

The Lebesgue dominated convergence theorem implies that

$$\lim_{\varepsilon\to 0}\int_0^\infty [Ax_\varepsilon^1(t) + By_\varepsilon^1(t)]e^{-\rho t}dt = [Aw(y_0) + Bw(y_0)\tilde{z}]/\rho,$$

and direct calculation implies that

$$\lim_{\varepsilon\to 0}\int_0^\infty [-u_\varepsilon^1(t) - v_\varepsilon^1(t)]e^{-\rho t}dt = \frac{1}{\alpha}\log\left(\frac{1-w(y_0)}{1-x_0}\right) + \frac{w(y_0)}{\gamma}\log\left(\frac{1-\tilde{z}}{1-y_0/w(y_0)}\right).$$

Thus

$$J_\varepsilon^1 = \int_0^\infty [Ax_\varepsilon^1(t) + By_\varepsilon^1(t) - u_\varepsilon^1(t) - v_\varepsilon^1(t)]e^{-\rho t}dt$$

converges to $V(0, x_0, y_0)$ as $\varepsilon \to 0$.

On the other hand, the controls given below, which look equivalent if one only considers the problem $(\mathcal{P}_0)$, are not suboptimal. Let

$$u_\varepsilon^2(t) = \begin{cases} 0 & \text{for } 0 < t < \varepsilon, \\ \dfrac{1}{\varepsilon\alpha}\log\left(\dfrac{1-x_0}{1-w(y_0)}\right) & \text{for } \varepsilon < t < 2\varepsilon, \\ 0 & \text{for } 2\varepsilon < t, \end{cases}$$

$$v_\varepsilon^2(t) = \begin{cases} \dfrac{x_0}{\varepsilon\gamma}\log\left(\dfrac{1-y_0/x_0}{1-\tilde{z}}\right) & \text{for } 0 < t < \varepsilon, \\ 0 & \text{for } \varepsilon < t. \end{cases}$$

These controls also produce trajectories $x_\varepsilon^2(t)$, $y_\varepsilon^2(t)$ that converge to $x^1(t)$, $y^1(t)$, respectively, as $\varepsilon \to 0$. However,

$$\lim_{\varepsilon\to 0}\int_0^\infty [-u_\varepsilon^2(t) - v_\varepsilon^2(t)]e^{-\rho t}dt = \frac{1}{\alpha}\log\left(\frac{1-w(y_0)}{1-x_0}\right) + \frac{x_0}{\gamma}\log\left(\frac{1-\tilde{z}}{1-y_0/x_0}\right).$$

Therefore,

$$J_\varepsilon^2 = \int_0^\infty [Ax_\varepsilon^2(t) + By_\varepsilon^2(t) - u_\varepsilon^2(t) - v_\varepsilon^2(t)]e^{-\rho t}dt$$

does not converge to $V(0, x_0, y_0)$ as $\varepsilon \to 0$.

Remark. There is an economic explanation why, for an initial state in Ω_3, we should increase x before y to approach the supremum of J_0. The reason is that the advertising of the second product is more effective when the market share of the first product is greater. This is intuitively correct, and it is reflected in the model.

NUMERICAL APPROXIMATIONS FOR HEREDITARY SYSTEMS WITH INPUT AND OUTPUT DELAYS: CONVERGENCE RESULTS AND CONVERGENCE RATES*

A. MANITIUS† AND H. T. TRAN‡

Abstract. In this paper, the averaging approximation scheme for linear retarded functional differential equations with delays in control and observation is considered in the context of the state space theory developed by Pritchard and Salamon [*SIAM J. Control Optim.*, 25 (1987), pp. 121–144]. Using known results from linear semigroup theory, convergence and estimate of convergence rate of the approximating semigroups are established. These extend results due to Banks and Burns [*SIAM J. Control Optim.*, 16 (1978), pp. 169–208] and Lasiecka and Manitius [*SIAM J. Numer. Anal.*, 25 (1988), pp. 883–907] on hereditary systems with delays in state, to the case when delays in control and observation are included. The main difference from the case when delays in input and output are excluded is that unbounded input and output operators must be dealt with in the abstract formulation. Moreover, in the presence of the unboundedness of the input and output operators, new convergence results of the state solutions and the output are also obtained.

1. Introduction.

The object of this paper is to extend previous results on the averaging approximation scheme for linear retarded functional differential equations (RFDE) to the case when general delays in control and observation are included.

The averaging approximation scheme has been invented (in a different context) by Soviet authors Repin [R1] and Krasovskii [K2] in the early sixties. A detailed historical review can be found in Banks and Burns [B1]. In this paper by Banks and Burns, precise statements of convergence results and applications to open-loop control problems on finite time intervals were given for the first time. Later, Gibson [G1] showed that for the finite time interval, convergence result of the feedback control laws can be obtained using the averaging scheme. In the case of infinite time horizon, it is important to know whether the approximation scheme preserves, uniformly with respect to the discretization mesh, the asymptotic stability of the original systems. This stability preservation property of the averaging scheme was later proved by Salamon [S1]. Later, Lasiecka and Manitius [L1] established a stronger version of Salamon's result. They showed that in the case of RFDE and averaging approximations one obtains uniform differentiability of the approximating semigroups. As is shown in [L1], this fact has far reaching consequences. First, when the original semigroup is
