A GENERAL NECESSARY CONDITION FOR EXACT OBSERVABILITY*

DAVID L. RUSSELL† AND GEORGE WEISS‡

Abstract. Suppose A generates an exponentially stable strongly continuous semigroup on the Hilbert space X, Y is another Hilbert space, and $C : D(A) \to Y$ is an admissible observation operator for this semigroup. (This means that to any initial state in X we can associate an output function in $L^2([0,\infty), Y)$.) This paper gives a necessary condition for the exact observability of the system defined by A and C. This condition, called **(E)**, is related to the Hautus Lemma from finite dimensional systems theory. It is an estimate in terms of the operators A and C alone (in particular, it makes no reference to the semigroup). This paper shows that **(E)** implies approximate observability and, if A is bounded, it implies exact observability. This paper conjectures that **(E)** is in fact equivalent to exact observability. The paper also shows that for diagonal semigroups, **(E)** takes on a very simple form, and applies the results to sequences of complex exponential functions.

Key words. exact observability, admissible observation operators, diagonal semi-groups, Riesz bases of complex exponentials

1. Introduction and statement of the main results.

Let X be a Hilbert space and suppose $\mathbb{T} = (\mathbb{T}_t)_{t\geq 0}$ is an exponentially stable, strongly continuous semigroup of operators on X, with generator $A : D(A) \to X$. Let Y be another Hilbert space and suppose $C : D(A) \to Y$ is a linear operator which is A-bounded, i.e.,

$$\|Cx\| \leq L \cdot \|Ax\| \tag{1.1}$$

holds for some $L \geq 0$ and any $x \in D(A)$.

This paper is concerned with the system described by the equations

$$\dot{z}(t) = Az(t), \quad z(0) = x, \tag{1.2a}$$

$$y(t) = Cz(t), \tag{1.2b}$$

where $t \geq 0$. The element $x \in X$ is called the *initial state*, $z(t)$ is called the *state* at time t, and y is the *output function*. By a solution of (1.2a) we mean of course $z(t) = \mathbb{T}_t x$ (this is a weak solution). Equation (1.2b) is more problematic: if $x \notin D(A)$ then it might happen that $z(t)$ is never in $D(A)$, so that $Cz(t)$ is not defined.

To ov rcome this difficulty, we assume that C is an *admissible observation operator* for $\mathbb{T}$, wh·ch means the following: there is a $K \geq 0$ such that

$$\int_0^\infty \|C\mathbb{T}_t x\|^2 dt \leq K \cdot \|x\|^2, \tag{1.3}$$

for any $x \in D(A)$. If C is admissible then the operator $\Psi_\infty : D(A) \to L^2([0,\infty), Y)$, defined by

$$(\Psi_\infty x)(t) = C\mathbb{T}_t x, \tag{1.4}$$

has a continuous extension to X. This extension, still denoted Ψ_∞, is called the *extended output map* of A and C. For more details on admissibility, see §2. Now by the solution of (1.2b) we mean the function $y = \Psi_\infty x$.

DEFINITION 1.1. The system described by (1.2) is *exactly observable* on $[0, \infty)$, if there is a $\kappa > 0$ such that for any $x \in D(A)$,

$$\int_0^\infty \|C\mathbb{T}_t x\|^2 dt \geq \kappa \cdot \|x\|^2. \tag{1.5}$$

Clearly, (1.5) means that the extended output map Ψ_∞ is bounded from below, i.e., Ψ_∞ has a bounded left inverse, i.e., the problem of computing x, given y in (1.2), is well posed. Note the analogy between (1.3) and (1.5) (admissibility and exact observability).

As is well known, the concept of admissible observation operator is dual to that of admissible control operator (see, e.g., Salamon [16]), and the concept of exact observability is dual to that of exact controllability (see, e.g., Dolecki and Russell [3]). It will be understood that all the definitions and results in this paper have a dual counterpart.

The concept of exact observability (and its dual) has received considerable attention in recent years, see, e.g., the treatise of Lions [11], the survey papers of Lagnese [9], Lions [12], and Russell [18], or the general exposition of Bensoussan [1]. Usually, the emphasis is on exact observability on a finite time interval $[0, \tau)$ (or its dual property), which means that the integral in (1.5) is over $[0, \tau)$ only. However, exact observability on $[0, \infty)$ is equivalent to exact observability on some finite time interval (this follows from admissibility and exponential stability; see Proposition 2.8).

Throughout this paper, $\mathbb{C}_-$ denotes the left open half-plane in $\mathbb{C}$, and $\mathbb{C}_+$ denotes the right open half-plane in $\mathbb{C}$. Our main result follows.

THEOREM 1.2. *Let $X, \mathbb{T}, A, Y$ and C be as in* (1.1) *and* (1.3). *If the system described by* (1.2) *is exactly observable on $[0, \infty)$, then the following estimate is true:*

(E) *There is an $m > 0$ such that for any $s \in \mathbb{C}_-$ and any $x \in D(A)$,*

$$\frac{1}{|\text{Re } s|^2}\|(sI - A)x\|^2 + \frac{1}{|\text{Re } s|}\|Cx\|^2 \geq m \cdot \|x\|^2. \tag{1.6}$$

The proof of this theorem is given in §3. We conjecture that its converse is also true.

CONJECTURE 1.3. *Let $X, \mathbb{T}, A, Y$ and C be as in* (1.1) *and* (1.3). *If* **(E)** *holds, then the system described by* (1.2) *is exactly observable on $[0, \infty)$.*

Theorem 1.2 and Conjecture 1.3 are an attempt to generalize the Hautus Lemma, due to Popov [15] and Hautus [5], which concerns finite-dimensional linear systems. The Hautus Lemma states that if $A \in \mathcal{L}(\mathbb{C}^n)$ and $C \in \mathcal{L}(\mathbb{C}^n, \mathbb{C}^p)$, then the system defined by (1.2) is observable if and only if

$$\text{rank} \begin{bmatrix} sI - A \\ C \end{bmatrix} = n \quad \forall s \in \mathbb{C}.$$

Observing that it is sufficient to verify this condition for $s \in \sigma(A)$ (the spectrum of A), we can restate the Hautus Lemma for the case of stable A (i.e., $\sigma(A) \subset \mathbb{C}_-$) in the following form, visibly related to Theorem 1.2.

PROPOSITION 1.4. *Suppose $A \in \mathcal{L}(\mathbb{C}^n), C \in \mathcal{L}(\mathbb{C}^n, \mathbb{C}^p)$ and $\sigma(A) \subset \mathbb{C}_-$. Then the system described by* (1.2) *is observable if and only if, for any $s \in \mathbb{C}_-$ and any nonzero $x \in \mathbb{C}^n$,*

$$\|(sI - A)x\|^2 + \|Cx\|^2 > 0.$$

For a short proof of the Hautus Lemma and related material see, e.g., Sontag [21]. It is not difficult to prove that, with A and C matrices and A stable, (**E**) is equivalent to the condition in Proposition 1.4.

We now return to infinite-dimensional systems.

DEFINITION 1.5. The system described by (1.2) is *approximately observable* on $[0,\infty)$ if for any nonzero $x \in D(A)$,

$$\int_0^\infty \|C\mathbb{T}_t x\|^2 dt > 0.$$

The above condition is equivalent with $\operatorname{Ker} \Psi_\infty = \{0\}$, where Ψ_∞ is the extended output map; see Remark 3.2. Obviously, exact observability implies approximate observability. The following theorem may be regarded as a partial result for Conjecture 1.3.

THEOREM 1.6. *Let $X, \mathbb{T}, A, Y$ and C be as in* (1.1) *and* (1.3). *If the estimate* (**E**) *holds, then the system described by* (1.2) *is approximately observable on* $[0,\infty)$.

The proof is in §3. The following theorem shows that Conjecture 1.3 is true at least in the case when A (and hence also C) is bounded.

THEOREM 1.7. *Let X and Y be Hilbert spaces and suppose $A \in \mathcal{L}(X), C \in \mathcal{L}(X,Y)$ and $\sigma(A) \subset \mathbb{C}_-$. If for every $s \in \mathbb{C}_-$ there is an $m_s > 0$ such that for each $x \in X$,*

$$\|(sI - A)x\|^2 + \|Cx\|^2 \geq m_s \cdot \|x\|^2, \tag{1.7}$$

then the system described by (1.2) *is exactly observable on* $[0,\infty)$.

Note that (1.6) implies (1.7). This theorem follows from results of Rodman [17]. A different proof is given in §3.

In §4 we consider a special class of systems described by (1.2) namely, we assume that A is a diagonal operator of l^2 and that its eigenvalues λ_k are *properly spaced*. That means that the eigenvalues are not too close to each other: $|\lambda_j - \lambda_k| \geq \delta \cdot |\text{Re } \lambda_k|$ for all $j,k \in \mathbb{N}$ with $j \neq k$, where $\delta > 0$. We show that for such systems, the estimate (**E**) is equivalent to a simple and easily verifiable condition on the operator C: if (e_k) is the standard basis of l^2 then $\|Ce_k\|/|\text{Re } \lambda_k|$ should be bounded away from 0.

In §5 we consider sequences of functions of the form

$$p_k(t) = e^{\lambda_k t} c_k,$$

where $\lambda_k \in \mathbb{C}_-$ and $c_k \in Y, Y$ being a Hilbert space. The problem is to find necessary as well as sufficient conditions for the sequence (p_k) to be a Riesz basis in its closed span in $L^2([0,\infty), Y)$. A clear necessary condition is $\|\sum x_k p_k\|^2 \leq \sum |x_k|^2$, for any finite sequence (x_k) of complex numbers. Another simple necessary condition is that the norms $\|p_k\|$ should be bounded from below. Surprisingly, these two necessary conditions combined are also sufficient for certain sequences (λ_k). If Conjecture 1.3 is true for diagonal semigroups, then they are sufficient whenever the sequence (λ_k) is properly spaced and bounded away from the imaginary axis. We display an interesting example of an analytic diagonal semigroup for which Conjecture 1.3 is true.

Note. The authors propose Conjecture 1.3 as a challenge, to prove or disprove. Contact one of the authors for details.

2. Some background on admissibility and observability. First we return to the definition of admissible observation operators. We work in a slightly more general context than in §1, since we do not assume that the semigroup is exponentially stable. The concept of admissible observation operator (as defined here) has its origin in Dolecki and Russell

[3]. Since then, many authors have addressed the subject. Our notation and terminology follows Weiss [23].

Let X by a Hilbert space and suppose $\mathbb{T} = (\mathbb{T}_t)_{t\geq 0}$ is a strongly continuous semigroup of operators on X, with generator $A : D(A) \to X$. We define the Hilbert space X_1 to be $D(A)$ with the norm

$$\|x\|_1 = \|(\beta I - A)x\|, \tag{2.1}$$

where $\beta \in \rho(A)$, the resolvent set of A, and $\|\cdot\|$ denotes the norm on X. It is easy to check that $\|\cdot\|_1$ is equivalent with the graph norm of A, in particular, the topology of X_1 is independent of the choice of β. We have

$$X_1 \subset X,$$

densely and with continuous embedding.

DEFINITION 2.1. Let $X, \mathbb{T}, A$, and X_1 be as above. Let Y be a Hilbert space and suppose $C \in \mathcal{L}(X_1, Y)$. Then C is an *admissible observation operator* for $\mathbb{T}$ if for some (and hence any) $\tau > 0$, the operator $\Psi_\tau : X_1 \to L^2([0,\infty), Y)$ defined by

$$(\Psi_\tau x)(t) = C\mathbb{T}_t x \quad \text{for } t \in [0,\tau), \tag{2.2}$$

and $(\Psi_\tau x)(t) = 0$ for $t \geq \tau$, has a continuous extension to X.

In other words, admissibility of C means that for some $\tau > 0, K_\tau \geq 0$ and any $x \in D(A)$,

$$\int_0^\tau \|C\mathbb{T}_t x\|^2 dt \leq K_\tau \cdot \|x\|^2. \tag{2.3}$$

It is not difficult to verify that if (2.3) holds for some $\tau > 0$, then it holds for any other $\tau > 0$. We denote the extension of Ψ_τ to X by the same symbol. If $\mathbb{T}$ is exponentially stable, then we may take also $\tau = \infty$ in Definition 2.1, obtaining the equivalent definition of admissibility given in §1. In this case, the extended output map Ψ_∞ (defined in §1) is the strong limit of the operators Ψ_τ, as $\tau \to \infty$. For any $x \in X$ and any $\tau \geq 0, \Psi_\tau x$ can be obtained from $\Psi_\infty x$ by truncation to $[0,\tau)$.

The operators Ψ_τ satisfy an interesting functional equation, which is used to define linear observation systems in an abstract way, as follows.

DEFINITION 2.2. Let X and Y be Hilbert spaces. An *abstract linear observation system* with state space X and output space Y is a pair $(\mathbb{T}, \Psi)$, where $\mathbb{T} = (\mathbb{T}_t)_{t\geq 0}$ is a strongly continuous semigroup on X and $\Psi = (\Psi_t)_{t\geq 0}$ is a family of bounded operators from X to $L^2([0,\infty), Y)$, such that $\Psi_0 = 0$ and

$$(\Psi_{\tau+t}x)(\sigma) = \begin{cases} (\Psi_\tau x)(\sigma) & \text{for } \sigma \in [0,\tau), \\ (\Psi_t \mathbb{T}_\tau x)(\sigma - \tau) & \text{for } \sigma \geq \tau, \end{cases}$$

for any $x \in X$, any τ, $t \geq 0$ and almost every $\sigma \geq 0$.

With the notation of Definition 2.1, let Ψ be the family of operators defined by (2.2) and continuous extension to X. Then it is easy to verify that $(\mathbb{T}, \Psi)$ is an abstract linear observation system. Conversely, every abstract linear observation system is obtained in this way. This is the content of a *representation theorem* proved in Salamon [20] and Weiss [23] (we refrain from its formal statement). One consequence is that we can restrict our attention to operators $C \in \mathcal{L}(X_1, Y)$; there is no need to consider operators C defined on other dense $\mathbb{T}$-invariant subspaces of X.

When, in §1, we wrote "the system described by (1.2)" then, strictly speaking, we meant the system $(\mathbb{T}, \Psi)$ determined by A and C. We will continue to use this terminology.

PROPOSITION 2.3. *Let $\mathbb{T}$ be an exponentially stable, strongly continuous semigroup on the Hilbert space X, with generator A. Let Y be a Hilbert space and suppose $C \in \mathcal{L}(X_1, Y)$ is an admissible observation operator for $\mathbb{T}$. Then there is a $K \geq 0$ such that for any $s \in \mathbb{C}_+$,*

$$\|C(sI - A)^{-1}\|_{\mathcal{L}(X,Y)} \leq \frac{K}{\sqrt{\operatorname{Re} s}}. \tag{2.4}$$

Proof. We have for any $x \in D(A)$, using (1.3),

$$\begin{aligned} \|C(sI - A)^{-1}x\|^2 &= \left\| \int_0^\infty e^{-st} C\mathbb{T}_t x \, dt \right\|^2 \\ &\leq \left(\int_0^\infty |e^{-st}|^2 dt \right) \cdot \left(\int_0^\infty \|C\mathbb{T}_t x\|^2 dt \right) \\ &\leq \frac{1}{2 \operatorname{Re} s} \cdot K \cdot \|x\|^2, \end{aligned}$$

which implies (2.4). □

We mention that if $\mathbb{T}$ is normal and Y is finite-dimensional, then (2.4) is not only necessary but also sufficient for the admissibility of C. For this and other, related results see Weiss [24].

DEFINITION 2.4. Let $X, \mathbb{T}, A, Y$, and C be as in Proposition 2.3 and let Ψ_∞ be the extended output map of A and C. The *observability Gramian* of A and C is the operator $P \in \mathcal{L}(X)$ defined by

$$P = \Psi_\infty^* \Psi_\infty.$$

PROPOSITION 2.5. *With the notation of Definition* 2.4, *we have for any $x \in D(A)$,*

$$\|Cx\|^2 = -2 \operatorname{Re} \langle Px, Ax \rangle. \tag{2.5}$$

Proof. Take $x \in D(A^2)$ and define $f(t) = \|C\mathbb{T}_t x\|^2$, for any $t \geq 0$. Then f is continuously differentiable and

$$\frac{d}{dt} f(t) = \langle C\mathbb{T}_t Ax, C\mathbb{T}_t x \rangle + \langle C\mathbb{T}_t x, C\mathbb{T}_t Ax \rangle.$$

Due to the exponential stability of $\mathbb{T}$, we can integrate over $[0, \infty)$ and obtain

$$-f(0) = \langle \Psi_\infty Ax, \Psi_\infty x \rangle + \langle \Psi_\infty x, \Psi_\infty Ax \rangle,$$

i.e.,

$$-\|Cx\|^2 = 2 \operatorname{Re} \langle \Psi_\infty x, \Psi_\infty Ax \rangle,$$

which is the same as (2.5). Since both sides of (2.5) are continuous functions of x on X_1 and $D(A^2)$ is dense in X_1, (2.5) must hold for any $x \in X_1$. □

Remark 2.6. If X_1^* denotes the antilinear dual of X_1 and we identify X with its antilinear dual, then we have the dense inclusions $X_1 \subset X \subset X_1^*$. If we regard A as a

bounded operator from X_1 to X, then $A^* \in \mathcal{L}(X, X_1^*)$ is an extension of A^* computed as the adjoint of an unbounded operator in X. Formula (2.5) can now be rewritten as

$$A^*P + PA = -C^*C$$

where both sides are in $\mathcal{L}(X_1, X_1^*)$. This can be thought of as an equation in P, called a *Lyapunov equation.*

DEFINITION 2.7. Let $\mathbb{T}$ be a strongly continuous semigroup on the Hilbert space X, with generator A. Let Y be a Hilbert space and suppose $C \in \mathcal{L}(X_1, Y)$ is an admissible observation operator for $\mathbb{T}$. The system described by (1.2) is *exactly observable* on $[0, \tau)$ (where $\tau > 0$) if the operator Ψ_τ (defined by (2.2) and continuous extension to X) is bounded from below.

In other words, exact observability on $[0, \tau)$ means that

$$\int_0^\infty \|C\mathbb{T}_t x\|^2 dt \geq \kappa_\tau \cdot \|x\|^2 \tag{2.6}$$

holds for some $\kappa_\tau > 0$ and any $x \in D(A)$. Whereas in Definition 2.1, the choice of τ did not matter, in Definition 2.7, the choice of τ is important: if (2.6) holds for some $\tau > 0$, then obviously it holds for any bigger number, but not necessarily for a smaller one.

If $\mathbb{T}$ is exponentially stable, then we may take also $\tau = \infty$ in Definition 2.7, reobtaining the definition of exact observability on $[0, \infty)$. At first glance, this concept appears to be weaker than exact observability on some finite time interval, so that the following proposition is slightly surprising.

PROPOSITION 2.8. *Let $X, \mathbb{T}, A, Y$, and C be as in Proposition* 2.3. *If the system described by* (1.2) *is exactly observable on $[0, \infty)$, then there is a $\tau > 0$ such that this system is exactly observable on $[0, \tau)$.*

Proof. For any $x \in D(A)$ and any $\tau > 0$, we have

$$\int_0^\tau \|C\mathbb{T}_t x\|^2 dt = \int_0^\infty \|C\mathbb{T}_t x\|^2 dt - \int_0^\infty \|C\mathbb{T}_t \mathbb{T}_\tau x\|^2 dt.$$

Using (1.3) and (1.5), we obtain

$$\begin{aligned}\int_0^\tau \|C\mathbb{T}_t x\|^2 dt &\geq \kappa \cdot \|x\|^2 - K \cdot \|\mathbb{T}_\tau x\|^2 \\ &\geq (\kappa - K \cdot \|\mathbb{T}_\tau\|^2) \cdot \|x\|^2.\end{aligned}$$

Since $\mathbb{T}$ is exponentially stable, the parenthesis above becomes positive for τ sufficiently big, so that we get (2.6). □

Remark 2.9. The definition of exact observability on $[0, \infty)$ can be extended also to systems whose semigroup is not exponentially stable (we might have to allow the value ∞ on the left-hand side of (1.5)). However, Proposition 2.8 cannot be generalized to such semigroups. A simple example is as follows: Consider $X = L^2[0, \infty)$ and for any $t \geq 0$, let $\mathbb{T}_t$ be the left shift by t on X. Define C on $D(A) = H^1[0, \infty)$ by $Cx = x(0)$. Then the system described by (1.2) is exactly observable on $[0, \infty)$, but it is not exactly observable on any finite interval. A physically more relevant example involves the linear water wave equation, as described, e.g., in Reid and Russell [16].

Remark 2.10. Admissibility and exact observability are invariant under translations of the generator. More precisely, with the notation of Definition 2.7, C is admissible also for the semigroup generated by $A + \lambda I$, for any $\lambda \in \mathbb{C}$. Similarly, if the system described by

(1.2) is exactly observable on $[0,\tau)$, $\tau<\infty$, then, replacing A by $A+\lambda I$, the new system is exactly observable on $[0,\tau)$. These statements are easy to verify.

Example 2.11. Let Ω be a bounded domain in $\mathbb{R}^n$, with boundary Γ of class C^2. We put

$$X=\begin{matrix}H_0^1(\Omega)\\ \times\\ L^2(\Omega)\end{matrix},\qquad D(A)=\begin{matrix}H^2(\Omega)\cap H_0^1(\Omega)\\ \times\\ H_0^1(\Omega)\end{matrix}$$

and define $A: D(A)\to X$ by

$$A=\begin{pmatrix}0 & I\\ \Delta & 0\end{pmatrix},$$

where Δ is the Laplacian. Then A is the generator of a strongly continuous group of unitary operators on X. Fix $\xi_0\in\mathbb{R}^n$ and put

$$\Gamma_0=\{\xi\in\Gamma|(\xi-\xi_0)\cdot\nu(\xi)>0\},$$

where $\nu(\xi)$ is the outward normal to Γ at ξ. Let $Y=L^2(\Gamma_0)$ and define $C: D(A)\to Y$ by

$$C\begin{pmatrix}x_1\\ x_2\end{pmatrix}(\xi)=\frac{\partial x_1(\xi)}{\partial\nu},$$

where $\partial/\partial\nu$ denotes outward normal derivative on Γ and $\xi\in\Gamma_0$. Then C is an admissible observation operator for the group generated by A. (This statement remains true if Γ_0 is replaced by Γ). For details and further references on this see Lasiecka, Lions, and Triggiani [10]. Moreover, the system described by (1.2) is exactly observable on $[0,\tau)$, where τ depends on Ω. This was proved by Ho in [6] (see also Lions [11, p. 55]).

If we replace A by $\tilde{A}=A-I$, then the semigroup becomes exponentially stable. By Remark 2.10, the system determined by $\tilde{A}$ and C is exactly observable on $[0,\infty)$, so that Theorem 1.2 applies. The important values of s for (1.6) are those on the vertical line with $\mathrm{Re}\,s=-1$ (because this line contains the spectrum of $\tilde{A}$). By writing down (**E**) for this system and $s=-1+i\omega$, where $\omega\in\mathbb{R}$, we get the following estimate.

There is an $m>0$ such that for any $x_1\in H^2(\Omega)\cap H_0^1(\Omega)$, any $x_2\in H_0^1(\Omega)$ and any $\omega\in\mathbb{R}$,

$$\|i\omega x_1-x_2\|^2_{H_0^1(\Omega)}+\|\Delta x_1-i\omega x_2\|^2_{L^2(\Omega)}+\left\|\frac{\partial x_1}{\partial\nu}\right\|^2_{L^2(\Gamma_0)}\geq m(\|x_1\|^2_{H_0^1(\Omega)}+\|x_2\|^2_{L^2(\Omega)}).$$

In particular, taking $x_1=u, x_2=i\omega u$ and $\omega^2=\lambda$, we get that for any $u\in H^2(\Omega)\cap H_0^1(\Omega)$ and any $\lambda\geq 0$,

$$\|(\Delta+\lambda)u\|^2_{L^2(\Omega)}+\left\|\frac{\partial u}{\partial\nu}\right\|^2_{L^2(\Gamma_0)}\geq m(\|u\|^2_{H_0^1(\Omega)}+\lambda\cdot\|u\|^2_{L^2(\Omega)}). \tag{2.7}$$

Remark 2.12. The estimate (2.7) can be obtained also by direct computations, without using Theorem 1.2, as sketched below. Introducing the "multiplier" function $h(\xi)=\xi-\xi_0$ we can show, integrating by parts twice, that for any real-valued $u\in H^2(\Omega)\cap H_0^1(\Omega)$,

$$\int_\Omega(\Delta u)(h\cdot\nabla u)d\xi=\frac{1}{2}\int_\Gamma\left(\frac{\partial u}{\partial\nu}\right)^2(h\cdot\nu)d\gamma+\frac{n-2}{2}\int_\Omega\|\nabla u\|^2d\xi$$

(see, e.g., Komornik [8, Lemma 2.2]). Performing some more integrations by parts, we can get the identity

$$-2\int_\Omega (\Delta u + \lambda u)\left(h\cdot\nabla u + \frac{n-1}{2}u\right)d\xi + \int_\Gamma \left(\frac{\partial u}{\partial \nu}\right)^2 (h\cdot\nu)d\gamma = \lambda\int_\Omega u^2 d\xi + \int_\Omega \|\nabla u\|^2 d\xi, \tag{2.8}$$

valid for any real λ. Using that for any $r > 0$,

$$-2\int_\Omega (\Delta u + \lambda u)\left(h\cdot\nabla u + \frac{n-1}{2}u\right)d\xi \leq r\int_\Omega (\Delta u + \lambda u)^2 d\xi + \frac{1}{r}\int_\Omega \left(h\cdot\nabla u + \frac{n-1}{2}u\right)^2 d\xi$$

and choosing r sufficiently large to make the last term above smaller than the last term in (2.8), we get an inequality which is equivalent to (2.7).

Remark 2.13. Let us do a little speculation in connection with Conjecture 1.3. With the notation of this conjecture, suppose that (**E**) holds. Using (2.5) and elementary manipulations, we get that for any $s \in \mathbb{C}_-$ and any $x \in D(A)$,

$$\frac{1}{|\text{Re } s|^2}\|(sI - A)x\|^2 + \frac{2}{|\text{Re } s|}\,\text{Re}\,\langle Px, (sI - A)x\rangle + 2\langle Px, x\rangle \geq m\cdot\|x\|^2.$$

Denoting

$$v(s,x) = \frac{1}{|\text{Re } s|}(sI - A)x,$$

the above estimate can be written in the form

$$\|v(s,x)\|^2 + 2\,\text{Re}\,\langle Px, v(s,x)\rangle + 2\langle Px, x\rangle \geq m\cdot\|x\|^2.$$

This reveals the following meaning of (**E**): for $s \in \mathbb{C}_-$ and $x \in D(A)$ with $\|x\| = 1$, the quantities $\|v(s,x)\|$ and $\|Px\|$ cannot simultaneously be very small. Verly loosely speaking, $\|Px\|$ being small means that x is close to being an unobservable state, while $\|v(s,x)\|$ being small means that x is close to being an eigenvector of A. Perhaps this could be a starting point for the proof of the conjecture.

3. The proof of the main results. In this section we prove the theorems stated in §1.

Proof of Theorem 1.2. We will prove the following estimate: For any $s \in \mathbb{C}_-$ and any $x \in D(A)$,

$$\frac{1}{|\text{Re } s|^2}\|(sI - A)x\|^2 + \frac{1}{|\text{Re } s|}\|Cx\|^2 \geq \mu\cdot\|\Psi_\infty x\|_{L^2}^2, \tag{3.1}$$

where

$$\frac{1}{\mu} = \frac{1}{2} + \|\Psi_\infty\|^2.$$

Clearly, this implies Theorem 1.2. We denote

$$z = (A - SI)x,$$

and we define $\xi : [0, \infty) \to X$ by $\xi(t) = \mathbb{T}_t x$. Then

$$\begin{aligned}\dot{\xi}(t) &= \mathbb{T}_t A x \\ &= \mathbb{T}_t(sx + z) \\ &= s\xi(t) + \mathbb{T}_t z,\end{aligned}$$

whence

$$\xi(t) = e^{st}x + \int_0^t e^{s(t-\sigma)}\mathbb{T}_\sigma z \, d\sigma.$$

Without loss of generality we may assume that $x \in D(A^2)$ (by density in X_1) so that $z \in D(A)$. Then, using (1.4),

$$\begin{aligned}(\Psi_\infty x)(t) &= C\xi(t) \\ &= e^{st}Cx + \int_0^t e^{s(t-\sigma)}C\mathbb{T}_\sigma z \, d\sigma \\ &= e^{st}Cx + (e_x * \Psi_\infty z)(t),\end{aligned}$$

where $*$ denotes convolution and e_s denotes the function

$$e_s(t) = e^{st}$$

If we use the following well-known property of convolutions:

$$\|u * v\|_{L^2} \le \|u\|_{L^1} \cdot \|v\|_{L^2},$$

we obtain

$$\begin{aligned}\|\Psi_\infty x\|_{L^2} &\le \|e_s\|_{L^2} \cdot \|Cx\| + \|e_s\|_{L^1} \cdot \|\Psi_\infty z\|_{L^2} \\ &\le \frac{1}{\sqrt{2|\operatorname{Re} s|}}\|Cx\| + \frac{1}{|\operatorname{Re} s|}\|\Psi_\infty\| \cdot \|z\|.\end{aligned}$$

Using that $(\alpha a + \beta b)^2 \le (\alpha^2 + \beta^2)(a^2 + b^2)$, we get

$$\|\Psi_\infty x\|_{L^2}^2 \le \left(\frac{1}{2} + \|\Psi_\infty\|^2\right)\left[\frac{1}{|\operatorname{Re} s|^2}\|z\|^2 + \frac{1}{|\operatorname{Re} s|}\|Cx\|^2\right],$$

which is the same as (3.1). □

For the proof of Theorem 1.6 we need the following lemma.

LEMMA 3.1. *Let $\tilde{A}$ be the generator of a strongly continuous semigroup of operators on a Banach space Z. If $\|(sI - \tilde{A})^{-1}\|$ is bounded on $\rho(\tilde{A})$, then $Z = \{0\}$ (the trivial space).*

Proof. For any $s \in \rho(\tilde{A})$ we have

$$\|(sI - \tilde{A})^{-1}\| \ge \frac{1}{d(s, \sigma(\tilde{A}))},$$

where d denotes distance, see, e.g., Nagel [13, p. 67]. If $\|(sI - \tilde{A})^{-1}\|$ is bounded then it follows that $\sigma(\tilde{A}) = \emptyset$, so that $(sI - \tilde{A})^{-1}$ is a bounded entire function. By Liouville's theorem, $(SI - \tilde{A})^{-1}$ is constant. We know that $\|(\lambda I - \tilde{A})^{-1}\|$ decays like $1/\lambda$ for big

positive λ (see, e.g., Pazy [14, p. 20]), so that we must have $(sI - \tilde{A})^{-1} = 0$, for any $s \in \mathbb{C}$. Since the range of $(sI - \tilde{A})^{-1}$ is dense in Z, it follows that $Z = \{0\}$. □

Proof of Theorem 1.6. For any $x \in D(A)$ and any $t, \tau \geq 0$ we have $(\Psi_\infty \mathbb{T}_\tau x)(t) = (\Psi_\infty x)(t + \tau)$ (see (1.4)), whence (by integration)

$$\|\Psi_\infty \mathbb{T}_\tau x\|_{L^2} \leq \|\Psi_\infty x\|_{L^2}. \tag{3.2}$$

Since $D(A)$ is dense in X and both sides of (3.2) are continuous functions of x on X, it follows that (3.2) holds for any $x \in X$ and any $\tau \geq 0$.

If we denote $Z = \text{Ker } \Psi_\infty$ (so that Z is a closed subspace of X), then (3.2) implies that Z is invariant under $\mathbb{T}$. Let $\tilde{\mathbb{T}}$ be the restriction of $\mathbb{T}$ to Z, so $\tilde{\mathbb{T}}$ is a strongly continuous semigroup on Z, and let $\tilde{A}$ be the generator of $\tilde{\mathbb{T}}$. It is easy to see that

$$D(\tilde{A}) = D(A) \cap Z, \qquad D(\tilde{A}) \subset \text{Ker } C,$$

and $\tilde{A}$ is the restriction of A to $D(\tilde{A})$.

Now suppose that (**E**) holds. Then for any $s \in \mathbb{C}_-$ and any $x \in D(\tilde{A})$,

$$\frac{1}{|\text{Re } s|^2} \|(sI - \tilde{A})x\|^2 \geq m \cdot \|x\|^2,$$

or, equivalently, for any $s \in \rho(\tilde{A}) \cap \mathbb{C}_-$,

$$\|(sI - \tilde{A})^{-1}\| \leq \frac{1}{\sqrt{m}\,|\text{Re } s|}. \tag{3.3}$$

Since $\tilde{\mathbb{T}}$ is exponentially stable, $\|(sI - \tilde{A})^{-1}\|$ is defined and bounded on some half-plane $\{s \in \mathbb{C} | \text{ Re } s > \alpha\}$, where $\alpha < 0$ (see, e.g., Pazy [14, p. 20]). Together with (3.3) we obtain that $\|(sI - \tilde{A})^{-1}\|$ is bounded on all of $\rho(\tilde{A})$. By Lemma 3.1, $Z = \{0\}$, so that $\Psi_\infty x \neq 0$ for any nonzero $x \in X$. This implies the condition in Definition 1.5. □

Remark 3.2. As mentioned in §1, approximate observability on $[0, \infty)$ is equivalent with Ker $\Psi_\infty = \{0\}$. Indeed, if Ker $\Psi_\infty \neq \{0\}$ then introducing $Z, \tilde{\mathbb{T}}$, and $\tilde{A}$ as in the proof of Theorem 1.6, we have $D(\tilde{A}) \neq \{0\}$ and $\Psi_\infty x = 0$ for any $x \in D(\tilde{A}) \subset D(A)$, so that the system is not approximately observable on $[0, \infty)$. The converse is obvious.

Remark 3.3. In Theorem 1.6 (and in its proof) the estimate (**E**) can be replaced by the following slightly less restrictive condition.

There are functions $p_1, p_2 : \mathbb{C}_- \to [0, \infty)$ such that: (1) p_1 is bounded on any half-plane $\{s \in \mathbb{C} | \text{ Re } s \leq \alpha\}$ with $\alpha < 0$, (2) for any $s \in \mathbb{C}_-$ and any $x \in D(A)$,

$$p_1(s) \cdot \|(sI - A)x\|^2 + p_2(s) \cdot \|Cx\|^2 \geq \|x\|^2.$$

We now turn to the proof of Theorem 1.7. As already mentioned in §1, this theorem is essentially due to Rodman; more precisely, its dual is a direct consequence of [17, Thm. 7.1.2 and Ex. 7.1]. (We have been made aware of [17] after working out our own proof.) In the hope that our proof might contain useful ideas for dealing with the case of unbounded A and C, we reproduce it below. We need three lemmas.

LEMMA 3.4. *Let X be a Hilbert space. We denote by $l^\infty(X)$ the space of bounded X-valued sequences with the supremum norm, and by $c_0(X)$ the subspace of $l^\infty(X)$ consisting of sequences convergent to zero. We introduce the factor space*

$$\mathcal{F}(X) = l^\infty(X)/c_0(X)$$

and we denote by π the canonical surjection from $l^\infty(X)$ onto $\mathcal{F}(X)$. We endow $\mathcal{F}(X)$ with the factor norm

$$\|\pi(z)\|_{\mathcal{F}(X)} = \inf_{c\in c_0(X)} \|z + c\|_{l^\infty(X)}.$$

Then the factor norm can be computed by

$$\|\pi(z)\|_{\mathcal{F}(X)} = \limsup_{n\to\infty} \|z_n\| \tag{3.4}$$

(z_n is the nth term of z) and $\mathcal{F}(X)$ is a Banach space with this norm.

The proof of (3.4) is easy and we leave it to the reader. For the fact that $\mathcal{F}(X)$ is a Banach space see, e.g., Brown and Pearcy [2, p. 222].

LEMMA 3.5. *With the notation of Lemma* 3.4, *suppose $T \in \mathcal{L}(X)$. We define $\tilde{T} \in \mathcal{L}(l^\infty(X))$ by termwise application of T, i.e., for any $z \in l^\infty(X)$,*

$$(\tilde{T}z)_n = Tz_n \quad \forall n \in \mathbb{N}.$$

Then there is a unique $\tilde{\tilde{T}} \in \mathcal{L}(\mathcal{F}(X))$ such that the diagram

$$\begin{array}{ccc} l^\infty(X) & \xrightarrow{\tilde{T}} & l^\infty(X) \\ \downarrow \pi & & \downarrow \pi \\ \mathcal{F}(X) & \xrightarrow{\tilde{\tilde{T}}} & \mathcal{F}(X) \end{array}$$

commutes. Moreover,

$$\begin{aligned} \|\tilde{\tilde{T}}\| = \|\tilde{T}\| = \|T\|, \\ \sigma(\tilde{\tilde{T}}) = \sigma(\tilde{T}) = \sigma(T). \end{aligned} \tag{3.5}$$

It is routine to verify all the statements in this lemma. In view of the fact that a similar construction, with a strongly continuous semigroup in place of T, appears in Nagel [13, pp. 21 and 78], we omit the details.

LEMMA 3.6. *With the notation of Lemma* 3.5, *if N is a closed $\tilde{T}$-invariant subspace of $l^\infty(X)$ that contains $c_0(X)$, i.e.,*

$$c_0(X) \subset N \subset l^\infty(X), \qquad \tilde{T}N \subset N,$$

then $\mathcal{N} = \pi(N)$ is a closed $\tilde{\tilde{T}}$-invariant subspace of $\mathcal{F}(X)$.

Proof. Let $\xi \in \mathcal{N}$, so $\xi = \pi(z)$, where $z \in N$. We have $\tilde{T}z \in N$, so $\pi(\tilde{T}z) \in \mathcal{N}$. By the commutativity of the diagram in Lemma 3.5, $\tilde{\tilde{T}}\xi = \pi(\tilde{T}z)$, so that $\mathcal{N}$ is $\tilde{\tilde{T}}$-invariant.

Put $N^c = l^\infty(X)\backslash N$ and $\mathcal{N}^c = \mathcal{F}(X)\backslash\mathcal{N}$. It follows from $c_0(X) \subset N$ that $\pi(N^c) = \mathcal{N}^c$. Since N^c is open, but the open mapping theorem $\mathcal{N}^c$ is open too, so that $\mathcal{N}$ is closed. □

Proof of Theorem 1.7. Let X, Y, A, and C be as in the statement of the theorem and let $\mathbb{T}_t = e^{At}$. Let the Banach spaces $l^\infty(X), c_0(X), \mathcal{F}(X)$, and the surjection π be as in Lemma 3.4. For any operator $T \in \mathcal{L}(X)$, we define $\tilde{T}$ and $\tilde{\tilde{T}}$ as in Lemma 3.5. Then it is easy to see that

$$\tilde{\mathbb{T}}_t = e^{\tilde{A}t}. \tag{3.6}$$

Let P be the observability Gramian of A and C and define

$$N = \{z \in l^\infty(X) | Pz_n \to 0\}.$$

Then N is a closed subspace of $l^\infty(X)$, because it is the kernel of $\pi\tilde{P}$. It is clear that N contains $c_0(X)$. We show that N is $\tilde{A}$-invariant. Let Ψ_∞ be the extended output map of A and C and let $z \in N$. From $\langle Pz_n, z_n\rangle = \|\Psi_\infty z_n\|^2$ we see that $\Psi_\infty z_n \to 0$. By (3.2) we get that for any $\tau \geq 0$, $\Psi_\infty \mathbb{T}_\tau z_n \to 0$, whence $P\mathbb{T}_\tau z_n \to 0$, i.e., $\tilde{\mathbb{T}}_\tau z \in N$. Thus, N is $\tilde{\mathbb{T}}_\tau$-invariant, for any $\tau \geq 0$. By (3.6) this implies that N is $\tilde{A}$-invariant. Now by Lemma 3.6 we conclude that $\mathcal{N} = \pi(N)$ is $\tilde{A}$-invariant.

Let $\mathcal{A}$ be the restriction of $\tilde{\tilde{A}}$ to $\mathcal{N}$. Since we have assumed that $\sigma(A) \subset \mathbb{C}_-$, (3.5) shows that we have $\sigma(\tilde{\tilde{A}}) \subset \mathbb{C}_-$, i.e., the (uniformly continuous) group generated by $\tilde{\tilde{A}}$ is exponentially stable. It follows that the restriction of this semigroup to $\mathcal{N}$ is also exponentially stable. Since the generator of this restriction is $\mathcal{A}$, it follows that

$$\sigma(\mathcal{A}) \subset \mathbb{C}_-. \tag{3.7}$$

Our goal is to show that $\mathcal{N} = \{0\}$. To achieve this, we assume the contrary, i.e., $\mathcal{N}$ is nonzero, and we show that this leads to a contradiction. The approximate point spectrum of a bounded operator on a nonzero Banach space is nonvoid (because it contains the boundary of the spectrum, see, e.g., [13, p. 64]). Applying this to $\mathcal{A}$ and taking (3.7) into account, we get that there exists $\lambda \in \mathbb{C}_-$ and a sequence (η_k) with values in $\mathcal{N}$ such that $\|\eta_k\| = 1$ for any $k \in \mathbb{N}$ and

$$\lim_{k\to\infty} (\lambda I - \mathcal{A})\eta_k = 0. \tag{3.8}$$

We have assumed in the theorem that for every $s \in \mathbb{C}_-$ there is an $m_s > 0$ such that (1.7) holds. In particular, taking $s = \lambda$ and using (2.5), we get that for any $x \in X$,

$$\|(\lambda I - A)x\|^2 - 2\,\mathrm{Re}\,\langle Px, Ax\rangle \geq m_\lambda \cdot \|x\|^2. \tag{3.9}$$

Let $k \in \mathbb{N}$ be such that

$$\|(\lambda I - \mathcal{A})\eta_k\|^2 \leq \tfrac{1}{2} m_\lambda \tag{3.10}$$

(such a k exists by (3.8)). Let $z \in N$ be such that $\eta_k = \pi(z)$. By the commutativity of the diagram in Lemma 3.5 we have

$$(\lambda I - \mathcal{A})\eta_k = \pi((\lambda I - \tilde{A})z),$$

whence by (3.4) and (3.10) we obtain

$$\limsup_{n\to\infty} \|(\lambda I - A)z_n\|^2 \leq \tfrac{1}{2} m_\lambda. \tag{3.11}$$

The fact that $z \in N$ means that the sequence (z_n) is bounded and $Pz_n \to 0$. Hence,

$$\lim_{n\to\infty} \langle Pz_n, Az_n\rangle = 0. \tag{3.12}$$

Now (3.9), (3.11), and (3.12) imply that

$$\limsup_{n\to\infty} \|z_n\|^2 \leq \tfrac{1}{2},$$

whence by (3.4) $\|\eta_k\|^2 \leq \frac{1}{2}$. But the sequence (η_k) was such that $\|\eta_k\| = 1$, which is a contradiction.

Thus we have shown that $\mathcal{N} = \{0\}$. This means that P is bounded from below, i.e., Ψ_∞ is bounded from below, i.e., the system described by (1.2) is exactly observable on $[0, \infty)$. □

Remark 3.7. With the notation of Conjecture 1.3, it is possible to show that if A and C satisfy the estimate (**E**), then the bounded operators $A_b \in \mathcal{L}(X)$ and $C_b \in \mathcal{L}(X, Y)$ defined by

$$A_b = A^{-1}, \qquad C_b = CA^{-1},$$

satisfy a similar estimate, with a possibly different number m_b instead of m. A_b is not stable in general, but it can be verified that C_b is an *infinite time admissible observation operator* for the semigroup generated by A_b, i.e., (1.3) holds with $e^{A_b t}$ instead of $\mathbb{T}_t$ and C_b instead of C. The pair (A_b, C_b) is interesting because the observability Gramian of the system determined by A_b and C_b is the same as for A and C (as is not difficult to verify). Now it almost seems that we could apply Theorem 1.7 to A_b and C_b and thus prove Conjecture 1.3. But a more careful look reveals that this is not the case, because Theorem 1.7 requires A to be stable.

4. Systems with diagonal semigroup on l^2. First we introduce some terminology. A bounded operator D on l^2 is called *diagonal* if it is of the form

$$(\mathrm{D}x)_k = d_k x_k \quad \forall k \in \mathbb{N},$$

where x_k denotes the kth component of x and (d_k) is a bounded sequence of complex numbers. Obviously,

$$\|\mathrm{D}\| = \sup_{k \in \mathbb{N}} |d_k|.$$

A strongly continuous semigroup $\mathbb{T}$ on l^2 is called *diagonal* if $\mathbb{T}_t$ is diagonal for each $t \geq 0$. Then $\mathbb{T}_t$ is given by

$$(\mathbb{T}_t x)_k = e^{\lambda_k t} x_k \quad \forall k \in \mathbb{N}, \tag{4.1}$$

where (λ_k) is a sequence of complex numbers with real parts bounded above. We assume that $\mathbb{T}$ is exponentially stable, which is equivalent to

$$\sup_{k \in \mathbb{N}} \operatorname{Re} \lambda_k < 0. \tag{4.2}$$

The generator A of $\mathbb{T}$ is given by

$$D(A) = \{x \in l^2 | (\lambda_k x_k) \in l^2\}, \tag{4.3a}$$

$$(Ax)_k = \lambda_k x_k \quad \forall k \in \mathbb{N}. \tag{4.3b}$$

Clearly, $\{\lambda_k | k \in \mathbb{N}\}$ is the set of eigenvalues of A. The space denoted in general by X_1 will now be denoted l_1^2. That is, l_1^2 is $D(A)$ with the norm $\|x\|_1 = \|Ax\|_{l^2}$ (we have chosen $\beta = 0$ in (2.1)).

If Y is a Hilbert space and $C \in \mathcal{L}(l_1^2, Y)$, then C is uniquely determined by the sequence (c_k) of vectors in Y defined by

$$c_k = Ce_k, \tag{4.4}$$

where (e_k) is the standard basis sequence of l^2, i.e., $x = x_1e_1 + x_2e_2 + \dots$. It is not trivial to give necessary and sufficient conditions for the admissibility of C, in terms of the sequence (c_k). For finite-dimensional Y, this problem has been solved in Ho and Russell [7] and Weiss [22], [23]. For infinite-dimensional Y, the problem has been almost solved in Hansen and Weiss [4]. Here we mention only the following simple necessary condition for admissibility.

PROPOSITION 4.1. *Let $\mathbb{T}$ be an exponentially stable, diagonal semigroup on l^2, with generator A. Let Y be a Hilbert space and assume that $C \in \mathcal{L}(l_1^2, Y)$ is an admissible observation operator for $\mathbb{T}$, i.e.,* (1.3) *holds. Let the sequences $(\lambda_k), (e_k)$, and (c_k) be as in* (4.1) *and* (4.4). *Then*

$$\frac{1}{|\operatorname{Re} \lambda_k|}\|c_k\|^2 \le 2K \quad \forall k \in \mathbb{N}. \tag{4.5}$$

Proof. Taking in (1.3) $x = e_k$, we get by (4.4)

$$\|c_k\|^2 \int_0^\infty |e^{\lambda_k t}|^2 dt \le K \quad \forall k \in \mathbb{N},$$

which is equivalent to (4.5). □

PROPOSITION 4.2. *With the notation of Proposition* 4.1, *assume that the system determined by A and C is exactly observable on $[0, \infty)$, i.e.,* (1.5) *holds. Then*

$$\frac{1}{|\operatorname{Re} \lambda_k|}\|c_k\|^2 \ge 2\kappa \quad \forall k \in \mathbb{N}. \tag{4.6}$$

Proof. Taking in (1.5) $x = e_k$, we get by (4.4)

$$\|c_k\|^2 \int_0^\infty |e^{\lambda_k t}|^2 dt \ge \kappa \quad \forall k \in \mathbb{N},$$

which is equivalent to (4.6). □

Note the analogy between (4.5) and (4.6).

DEFINITION 4.3. Let (λ_k) be a sequence in $\mathbb{C}_-$. We say that (λ_k) is *properly spaced* if it satisfies

$$\inf_{j,k \in \mathbb{N}, j \ne k} \left| \frac{\lambda_j - \lambda_k}{\operatorname{Re} \lambda_k} \right| = \delta > 0. \tag{4.7}$$

In particular, (4.7) implies that (λ_k) has no multiple values, and no accumulation points in $\mathbb{C}_-$.

The goal of this section is to prove the following theorem.

THEOREM 4.4. *With the notation of Proposition* 4.1, *if (λ_k) is properly spaced then* (4.6) *is equivalent to the estimate* (**E**) *in Theorem* 1.2.

For the proof we need two lemmas.

LEMMA 4.5. *Let (λ_k) be a sequence in $\mathbb{C}_-$ satisfying* (4.7). *Define the function $N : \mathbb{C}_- \to \mathbb{N}$ such that for any $s \in \mathbb{C}_-$, $\lambda_{N(s)}$ is among the closest elements of $\{\lambda_k | k \in \mathbb{N}\}$ to s:*

$$|s - \lambda_{N(s)}| = \min_{k \in \mathbb{N}} |s - \lambda_k|. \tag{4.8}$$

Then for any $s \in \mathbb{C}_-$ and any $k \in \mathbb{N}$ with $k \ne N(s)$, we have

$$\left| \frac{\operatorname{Re} s}{s - \lambda_k} \right| \le 1 + \frac{2}{\delta}. \tag{4.9}$$

Proof. Take $s \in \mathbb{C}_-$ and $k \in \mathbb{N}$ with $k \neq N(s)$. Then

$$|\lambda_{N(s)} - \lambda_k| \leq |s - \lambda_{N(s)}| + |s - \lambda_k|,$$

whence by (4.8)

$$|s - \lambda_k| \geq \tfrac{1}{2}|\lambda_{N(s)} - \lambda_k|.$$

This shows that s is an element of the set S defined by

$$S = \{z \in \mathbb{C}_- m || z - \lambda_k| \geq \tfrac{1}{2}|\lambda_{N(s)} - \lambda_k|\}$$

(S is the complement in $\mathbb{C}_-$ of a disk). Therefore, we have

$$\left| \frac{\text{Re } s}{s - \lambda_k} \right| \leq \sup_{z \in S} \left| \frac{\text{Re } z}{z - \lambda_k} \right|.$$

It is an exercise in elementary calculus to check that this supremum is attained at $z = \lambda_k - \frac{1}{2}|\lambda_{N(s)} - \lambda_k|$, which yields

$$\left| \frac{\text{Re } s}{s - \lambda_k} \right| \leq 1 + 2 \left| \frac{\text{Re } \lambda_k}{\lambda_{N(s)} - \lambda_k} \right|$$

Since, by (4.7), we have

$$\left| \frac{\text{Re } \lambda_k}{\lambda_{N(s)} - \lambda_k} \right| \leq \frac{1}{\delta},$$

we get (4.9). □

LEMMA 4.6. *With the notation of Proposition* 4.1, *assume that* (λ_k) *is properly spaced and let* $N : \mathbb{C}_- \to \mathbb{N}$ *be a function satisfying* (4.8). *For each* $s \in \mathbb{C}_-$, *we define the subspace* $V(s) \subset l^2$ *by*

$$V(s) = \{e_{N(s)}\}^{\perp} \tag{4.10}$$

(*i.e.*, $V(s)$ *is the space spanned by all vectors* e_k *with* $k \neq N(s)$). *We denote by* A_s *the part of* A *in* $V(s)$, *i.e.*,

$$A_s : D(A) \cap V(s) \to V(s)$$

and $A_s x = Ax$ *for any* $x \in D(A) \cap V(s)$.

Then there is a $\mathcal{G} \geq 0$ *such that for any* $s \in \mathbb{C}_-$

$$\|C(sI - A_s)^{-1}\|_{\mathcal{L}(V(s),Y)} \leq \frac{\mathcal{G}}{\sqrt{|\text{Re } s|}}. \tag{4.11}$$

Proof. We have from the resolvent identity

$$(sI - A_s)^{-1} = (-\bar{s}I - A_s)^{-1}[I - (\bar{s} + s)(sI - A_s)^{-1}],$$

whence

$$\begin{aligned} &\|C(sI - A_s)^{-1}\|_{\mathcal{L}(V(s),Y)} \\ &\quad \leq \|C(-\bar{s}I - A_s)^{-1}\|_{\mathcal{L}(V(s),Y)} \cdot [1 + 2|\text{Re } s| \cdot \|(sI - A_s)^{-1}\|_{\mathcal{L}(V(s))}]. \end{aligned} \tag{4.12}$$

If P_s denotes the orthogonal projection from l^2 onto $V(s)$, then $(-\bar{s}I - A_s)^{-1} = (-\bar{s}I - A)^{-1}P_s$. Using (2.4) and the fact that $\|P_s\| = 1$, we have

$$\|C(-\bar{s}I - A_s)^{-1}\|_{\mathcal{L}(V(s),Y)} \leq \frac{\mathcal{K}}{\sqrt{|\text{Re } s|}}. \tag{4.13}$$

The operator $|\text{Re } s| \cdot (sI - A_s)^{-1}$ on $V(s)$ is diagonal and its diagonal elements d_k are given by

$$d_k = \frac{|\text{Re } s|}{s - \lambda_k},$$

where $k \neq N(s)$. By (4.9) we have $|d_k| \leq 1 + \frac{2}{\delta}$, whence

$$|\text{Re } s| \cdot \|(sI - A_s)^{-1}\|_{\mathcal{L}(V(s))} \leq 1 + \frac{2}{\delta}. \tag{4.14}$$

Combining (4.12)–(4.14) we get

$$\|C(sI - A_s)^{-1}\|_{\mathcal{L}(V(s),Y)} \leq \frac{\mathcal{K}}{\sqrt{|\text{Re } s|}}\left(3 + \frac{4}{\delta}\right),$$

which is the same as (4.11). □

Note the resemblance between (2.4) and (4.11).

Proof of Theorem 4.4. The implication **(E)** $\Rightarrow$ (4.6) is very easy: Taking in (1.6) $s = \lambda_k$ and $x = e_k$, we get (4.6) with $2\kappa = m$.

Conversely, suppose (4.6) holds but **(E)** is false. This means that there are sequences (s_n) and (z^n) such that $s_n \in \mathbb{C}_-$, $z^n \in D(A)$, $\|z^n\| = 1$ and

$$\frac{1}{|\text{Re } s_n|^2}\|(s_nI - A)z^n\|^2 + \frac{1}{|\text{Re } s_n|}\|Cz^n\|^2 = \epsilon_n^2, \tag{4.15}$$

where $\epsilon_n \geq 0$ and $\epsilon_n \to 0$.

The main idea of the proof is to show that for large n, s_n is almost equal to some eigenvalue of A (which may depend on n), and z^n is almost equal to a corresponding normalized eigenvector. We need a lot of notation: Let the function N and the spaces $V(s)$ be as in (4.8) and (4.10). For any $s \in \mathbb{C}_-$, let P_s denote the orthogonal projection of l^2 onto $V(s)$ and let A_s denote the part of A in $V(s)$ (as in Lemma 4.6). Further, we introduce

$$q^n = \frac{1}{|\text{Re } s_n|}(s_nI - A_{s_n})P_{s_n}z^n, \qquad \alpha_n = z^n_{N(s_n)},$$

so that

$$\frac{1}{|\text{Re } s_n|}(s_nI - A)z^n = e_{N(s_n)}\frac{s_n - \lambda_{N(s_n)}}{|\text{Re } s_n|}\alpha_n + q^n. \tag{4.16}$$

From (4.15) it follows, using that the two terms on the right-hand side of (4.16) are orthogonal, that

$$\|q^n\| \leq \frac{1}{|\text{Re } s_n|}\|(s_nI - A)z^n\| \leq \epsilon_n \tag{4.17}$$

and, by a similar argument,

$$\left| \frac{s_n - \lambda_{N(s_n)}}{\text{Re } s_n} \right| \cdot |\alpha_n| \leq \epsilon_n. \tag{4.18}$$

We have

$$P_{s_n} z^n = |\text{Re } s_n| \cdot (s_n I - A_{s_n})^{-1} q^n.$$

Using (4.17) and the inequality (4.14), obtained in the proof of Lemma 4.6, we get

$$\|P_{s_n} z^n\| \leq \left(1 + \frac{2}{\delta}\right) \epsilon_n,$$

whence $P_{s_n} z^n \to 0$. Since $\|z^n\| = 1$, it follows that $\|(I - P_{s_n}) z^n\| \to 1$, i.e.,

$$\lim_{n\to\infty} |\alpha_n| = 1. \tag{4.19}$$

Together with (4.18), this implies

$$\lim_{n\to\infty} \left| \frac{s_n - \lambda_{N(s_n)}}{\text{Re } s_n} \right| = 0.$$

It is now easy to see that

$$\lim_{n\to\infty} \frac{\text{Re } \lambda_{N(s_n)}}{\text{Re } s_n} = 1. \tag{4.20}$$

Now we turn our attention to the second term in (4.15). We have

$$\begin{aligned} \|Cz^n\| &= \|c_{N(s_n)} \alpha_n + C P_{s_n} z^n\| \\ &\geq \|c_{N(s_n)}\| \cdot |\alpha_n| - \|C(s_n I - A_{s_n})^{-1} (s_n I - A_{s_n}) P_{s_n} z^n\| \\ &= \|c_{N(s_n)}\| \cdot |\alpha_n| - |\text{Re } s_n| \cdot \|C(s_n I - A_{s_n})^{-1} q^n\|, \end{aligned}$$

whence by (4.11)

$$\frac{1}{\sqrt{|\text{Re } s_n|}} \|Cz^n\| \geq \frac{1}{\sqrt{|\text{Re } \lambda_{N(s_n)}|}} \|c_{N(s_n)}\| \cdot \left| \frac{\text{Re } \lambda_{N(s_n)}}{\text{Re } s_n} \right|^{1/2} |\alpha_n| - \mathcal{G} \cdot \|q^n\|. \tag{4.21}$$

By (4.19) and (4.20), there is an $n_0 \in \mathbb{N}$ such that for $n \geq n_0$ we have

$$\left| \frac{\text{Re } \lambda_{N(s_n)}}{\text{Re } s_n} \right|^{1/2} |\alpha_n| \geq \frac{1}{2}.$$

This, together with (4.6), (4.17), and (4.21), implies that for any $n \geq n_0$,

$$\frac{1}{\sqrt{|\text{Re } s_n|}} \|Cz^n\| \geq \sqrt{2\kappa} \cdot \frac{1}{2} - \mathcal{G} \cdot \epsilon_n.$$

Since $\epsilon_n \to 0$, it follows that for n sufficiently large we have

$$\frac{1}{|\text{Re } s_n|} \|Cz^n\|^2 \geq \frac{\kappa}{3}.$$

On the other hand, (4.15) implies that for each $n \in \mathbb{N}$,

$$\frac{1}{|\text{Re } s_n|} \|Cz^n\|^2 \leq \epsilon_n^2,$$

which is a contradiction. Therefore, (**E**) must be true. □

5. Riesz bases of complex exponentials.

DEFINITION 5.1. Let H be a separable Hilbert space and let (p_k) be a sequence in H. Then (p_k) is a *Riesz basis* in H if for some (and hence any) orthonormal basis (e_k) in H there is an invertible operator $T \in \mathcal{L}(H)$ such that

$$p_k = Te_k \quad \forall k \in \mathbb{N}.$$

The following two propositions are taken (with minor modifications) from Young [25, pp. 32 and 157].

PROPOSITION 5.2. *Let Z be a Hilbert space and let (p_k) be a sequence in Z. Then the following statements are equivalent:*

(S1) *There is a positive constant K such that for any finite sequence $(x_1, x_2, \dots x_N)$ in $\mathbb{C}$,*

$$\left\| \sum_{k=1}^{N} x_k p_k \right\|^2 \leq K \sum_{k=1}^{N} |x_k|^2. \tag{5.1}$$

(S2) *The Gramian matrix of (p_k), defined by*

$$P_{j,k} = \langle p_k, p_j \rangle \quad \forall j, k \in \mathbb{N}, \tag{5.2}$$

determines a bounded operator on l^2.

We mention that sequences satisfying (S1) are called *Bessel sequences* (see [25, p. 155]). In the second proposition, the statements (S1) and (S2) are replaced by stronger statements.

PROPOSITION 5.3. *Let Z be a Hilbert space and let (p_k) be a sequence in Z. Then the following statements are equivalent:*

(S3) *(p_k) is a Riesz basis in its closed span in Z.*

(S4) *The Gramian matrix of (p_k), defined by* (5.2), *determines an invertible bounded operator on l^2.*

The following theorem explains the connection between sequences of complex exponential functions and linear systems with diagonal semigroup.

THEOREM 5.4. *Let (λ_k) be a sequence in $\mathbb{C}$ satisfying* (4.2) *and let (c_k) be a sequence in a Hilbert space Y. Let (p_k) be the sequence in $L^2([0,\infty), Y)$ defined by*

$$p_k(t) = e^{\lambda_k t} c_k. \tag{5.3}$$

Then the statement (S1) *is equivalent to the following:*

(S5) *Let $\mathbb{T}$ be the diagonal semigroup on l^2 defined by* (4.1) *and let A be its generator. Then the matrix $[c_1, c_2, \dots]$ determines an operator $C \in \mathcal{L}(l^2_1, Y)$ that is admissible for $\mathbb{T}$.*

Moreover, if the above statement is true then the observability Gramian P of A and C (as defined in §2) is given by the Gramian matrix of the sequence (p_k) (as defined in (5.2)).

Proof. First we introduce some notation. Let F be the vector space of sequences in $\mathbb{C}$ with only finitely many nonzero terms. The matrix $[c_1, c_2, \dots]$ defines an operator $C' : F \to Y$. Since F is $\mathbb{T}$-invariant, we can defined $\Psi_\infty : F \to L^2([0,\infty), Y)$ by

$$(\Psi_\infty x)(t) = C' \mathbb{T}_t x \quad \forall x \in F. \tag{5.4}$$

Note that if (e_k) denotes the standard orthonormal basis of l^2, then $c_k = C' e_k$, whence

$$p_k = \Psi_\infty e_k. \tag{5.5}$$

Now suppose that (S1) holds. Using (5.5) and denoting $x = \sum_{k=1}^{n} x_k e_k$, (5.1) becomes

$$\|\Psi_\infty x\|_{L^2}^2 \le K \cdot \|x\|^2 \quad \forall x \in F.$$

Since F is dense in l^2, it follows that Ψ_∞ has a unique continuous extension to l^2, which we denote the same way.

For any $t \ge 0$, define $\Psi_t = P_t \Psi_\infty$, where P_t is the orthogonal projection from $L^2([0,\infty), Y)$ onto $L^2([0,t), Y)$ (considered as a subspace) and put $\Psi = (\Psi_t)_{t\ge 0}$. Then it is easy to check that $(\mathbb{T}, \Psi)$ is an abstract linear observation system, as defined in §2. By the representation theorem mentioned in §2, there is a $C \in \mathcal{L}(l_1^2, Y)$ such that

$$(\Psi_\infty x)(t) = C\mathbb{T}_t x \quad \forall x \in l_1^2. \tag{5.6}$$

Comparing this to (5.4) and taking $t = 0$ (this is possible since $\Psi_\infty x$ is continuous for $x \in l_1^2$) we conclude that C is an extension of C'. It follows that C is determined by the same matrix $[c_1, c_2, \ldots]$. Obviously, C is admissible, so that (S5) holds.

Conversely, suppose that (S5) holds. Then, by assumption, the operator C' defined earlier has a continuous extension $C \in \mathcal{L}(l_1^2, Y)$ and the operator Ψ_∞ defined by (5.6) has a continuous extension to l^2. Let P be the observability Gramian of A and C, i.e., $P = \Psi_\infty^* \Psi_\infty$. The matrix of P is

$$P_{j,k} = \langle Pe_k, e_j \rangle = \langle \Psi_\infty e_k, \Psi_\infty e_j \rangle.$$

Using (5.5), we obtain $P_{j,k} = \langle p_k, p_j \rangle$, i.e., the Gramian matrix of (p_k). Thus, (S2) holds and, by Proposition 5.2, (S1) holds as well. □

The last theorem reduces a (difficult) problem, checking (S1), to another (difficult) problem, checking (S5). However, for verifying (S5), powerful methods are available, especially the Carleson measure criterion and other criteria derived from it, see [4], [7], and [24].

Remark 5.5. An elementary computation shows that if (p_k) is defined by (5.3) then the Gramian matrix of (p_k) (see (5.2)) is given by

$$P_{j,k} = -\frac{\langle c_k, c_j \rangle}{\lambda_k + \overline{\lambda_j}}.$$

COROLLARY 5.6. *With the notation of Theorem 5.4, the sequence* (p_k) *is a Riesz basis in its closed span if and only if the following holds:*

(S6) *The statement* (S5) *is true (i.e.,* C *is admissible for* $\mathbb{T}$*) and the system determined by* A *and* C *is exactly observable on* $[0,\infty)$.

Proof. Suppose that (p_k) is a Riesz basis in its closed span. Then by Proposition 5.3, (S4) holds, which implies (S2). By Proposition 5.2, (S1) holds whence, by Theorem 5.4, (S5) is true. By the "moreover" part of Theorem 5.4, P is given by the Gramian matrix of (p_k). Since (S4) holds, P is invertible, so that (S6) holds.

Conversely, suppose (S6) is true. By Theorem 5.4, P is given by the Gramian matrix of (p_k). Since P is invertible, (S4) holds whence, by Proposition 5.3, (p_k) is a Riesz basis in its closed span. □

Remark 5.7. Theorem 5.4 and Corollary 5.6 can be slightly generalized, as follows: If (λ_k) is not required to satisfy (4.2), only $\lambda_k \in \mathbb{C}_-$, and "admissible" is replaced by "infinite time admissible", then both results are still true, with the same proof. C being infinite time admissible simply means that (1.3) holds. Since $\mathbb{T}$ is not necessarily stable, infinite time admissibility is a stronger condition than admissibility (see also Remark 3.7).

Let (p_k) be a sequence of complex exponentials (as in (5.3)) and suppose that we wish to check whether it is a Riesz basis in its closed span. We have seen that one necessary condition is (S1). Another simple necessary condition is $\inf \|p_k\| > 0$. If Conjecture 1.3 would be true (at least for diagonal semigroups) then for a large class of such sequences, the above two conditions together would be sufficient for the sequence to be a Riesz basis in its closed span. More precisely, we have the following result.

THEOREM 5.8. *Let (λ_k) be a sequence in $\mathbb{C}_-$ satisfying* (4.2) *and properly spaced* (*see* (4.7)). *Let (c_k) be a sequence in a Hilbert space Y and let the sequence (p_k) in $L^2([0,\infty),Y)$ be defined by* (5.3). *We assume that* (S1) *holds and*

$$\|p_k\|^2 \geq \kappa > 0 \quad \forall k \in \mathbb{N}. \tag{5.7}$$

If Conjecture 1.3 *is true for the diagonal semigroup $\mathbb{T}$ defined by* (4.1), *then (p_k) is a Riesz basis in its closed span.*

Proof. By Theorem 5.4, (S5) holds. Let A and C be as in (S5). By an elementary computation, the condition on $\|p_k\|$ in the theorem is the same as (4.6). Since (λ_k) is properly spaced, by Theorem 4.4 the estimate (**E**) holds for A and C. If Conjecture 1.3 is true for $\mathbb{T}$ then the system determined by A and C is exactly observable on $[0,\infty)$. It follows that P, the observability Gramian of A and C, is invertible. By Theorem 5.4, P is given by the Gramian matrix of (p_k). By Proposition 5.3, (S3) holds. □

For certain classes of properly spaced sequences (λ_k), we can show that Conjecture 1.3 is true for the semigroup defined by (4.1). Then, if (c_k) is such that (5.7) holds, Theorem 5.8 can be used to show that (p_k) (defined by (5.3)) is a Riesz basis in its closed span. We will briefly discuss two such classes of sequences: one for which the numbers λ_k lie on a vertical line in $\mathbb{C}_-$, and one for which they lie on the real line. The following theorem (the vertical line case) is a consequence of Ingham's theorem.

THEOREM 5.9. *Let (λ_k) be a properly spaced sequence in $\mathbb{C}_-$ such that for some $\rho < 0$,*

$$\operatorname{Re} \lambda_k = \rho \quad \forall k \in \mathbb{N}. \tag{5.8}$$

Then Conjecture 1.3 *is true for the diagonal semigroup $\mathbb{T}$ defined by* (4.1).

Proof. Let Y be a Hilbert space and let $C : l_1^2 \to Y$ be an admissible observation operator for $\mathbb{T}$. Let (e_k) be the standard basis of l^2 and put $c_k = Ce_k$. Then, by Proposition 4.1 and by (5.8), (c_k) is bounded. Let A be the generator of $\mathbb{T}$ and suppose that A and C satisfy the estimate (**E**). Then, by Theorem 4.4, $\|c_k\|$ is bounded from below by a positive number. Thus, we have the factorization $C = C_0 D$, where C_0 is defined by

$$C_0 e_k = \frac{c_k}{\|c_k\|} \quad \forall k \in \mathbb{N},$$

and D is an invertible bounded diagonal operator on l^2.

There are several ways to show that C_0 is admissible for $\mathbb{T}$. One of them is to use the fact that D commutes with the semigroup and C is admissible:

$$\begin{aligned}\int_0^\infty \|C_0 \mathbb{T}_t x\|^2 dt &= \int_0^\infty \|C \mathbb{T}_t D^{-1} x\|^2 dt \\ &\leq K \cdot \|D^{-1}\|^2 \cdot \|x\|^2.\end{aligned}$$

By Remark 2.10, C_0 is admissible for the (unitary) semigroup generated by $A - \rho I$. Moreover, the system determined by $A - \rho I$ and C_0 is exactly observable on a certain finite

interval $[0, \tau)$. This follows from the vector-valued version of Ingham's theorem (see [25, p. 162]) together with another (much simpler) result appearing in [25, p. 157]. By Remark 2.10, the system determined by A and C_0 is also exactly observable on $[0, \tau)$, and hence on $[0, \infty)$: for some $k > 0$ and any $x \in l_1^2$,

$$\int_0^\infty \|C_0 \mathbb{T}_t x\|^2 dt \geq k \cdot \|x\|^2. \tag{5.9}$$

To show that the system determined by A and C is exactly observable on $[0, \infty)$, we will again use the fact that D commutes with the semigroup. For any $x \in l_1^2$ we have, using (5.9),

$$\begin{aligned} \int_0^\infty \|C\mathbb{T}_t x\|^2 dt &= \int_0^\infty \|C_0 \mathbb{T}_t D x\|^2 dt \\ &\geq k \cdot \|Dx\|^2 \\ &\geq \frac{k}{\|D^{-1}\|^2} \|x\|^2. \end{aligned}$$ □

Our result for real λ_k depends on a lemma from complex function theory.

LEMMA 5.10. *Let $a > 1$ and let the function f on the unit circle be defined by*

$$f(z) = \sum_{k=-\infty}^{\infty} \frac{z^k}{a^k + a^{-k}}. \tag{5.10}$$

Then f is real and

$$\min_{|z|=1} f(z) > 0.$$

Sketch of the proof. The Laurent series in (5.10) permits us to extend f to a holomorphic function in the annulus $\mathcal{D}$ defined by

$$\mathcal{D} = \{z \in \mathbb{C} | a^{-1} < |z| < a\}.$$

Put $g(z) = \text{Re } f(z)$, so g is harmonic in $\mathcal{D}$. We have, for $a^{-1} < r < a$ and $\theta \in \mathbb{R}$,

$$g(re^{i\theta}) = \frac{1}{2} + \sum_{k=1}^{\infty} \frac{r^k + r^{-k}}{a^k + a^{-k}} \cos k\theta.$$

Since $\frac{1}{2} + \sum_{k=1}^{\infty} \cos k\theta$ is the Fourier expansion of π times the Dirac measure at $\theta = 0$, we get that the boundary distribution of g on the circle with radius a is $a\pi\delta_a$, where δ_a is the Dirac measure at $z = a$. Similarly, on the circle with radius a^{-1}, g becomes $a^{-1}\pi\delta_{a^{-1}}$. Thus, the boundary distribution of g is a positive measure (supported at two points). It follows that $g(z) \geq 0$ in $\mathcal{D}$. Since g is not constant, by the minimum principle it cannot attain its infimum in $\mathcal{D}$, so that in fact $g(z) > 0$ in $\mathcal{D}$. Since for $|z| = 1$ we have $f(z) = g(z)$, f satisfies the desired estimate. □

It seems to us that it is difficult to give a purely computational proof for the above lemma. The following theorem considers a very restricted class of systems, where the eigenvalues of the generator are negative and grow exponentially and the output space is one-dimensional.

THEOREM 5.11. *Let* $\alpha > 1$ *and let* (λ_k) *be defined by*

$$\lambda_k = -\alpha^k \quad \forall k \in \mathbb{N}. \tag{5.11}$$

Then Conjecture 1.3 *is true for the diagonal semigroup* $\mathbb{T}$ *defined by* (4.1) *and for* $Y = \mathbb{C}$.

Proof. Let $C : l^2_1 \to \mathbb{C}$ be an admissible observation operator for $\mathbb{T}$. Let (e_k) be the standard basis of l^2 and put $c_k = Ce_k$. Then, by Proposition 4.1 and by (5.11), there is a $K > 0$ such that $|c_k|^2 \leq 2K\alpha^k$ holds for any $k \in \mathbb{N}$. Let A be the generator of $\mathbb{T}$ and suppose that A and C satisfy the estimate (**E**). Since (λ_k) is properly spaced, by Theorem 4.4 (the easy direction) there is a $\kappa > 0$ such that $|c_k|^2 \geq 2\kappa\alpha^k$ holds for any $k \in \mathbb{N}$. Thus, we have the factorization $C = C_0 D$, where C_0 is defined by

$$C_0 e_k = \alpha^{k/2}, \quad \forall k \in \mathbb{N},$$

and D is an invertible bounded diagonal operator on l^2.

To show that C_0 is admissible for $\mathbb{T}$, we can use either the Carleson measure criterion (see [7]) or the fact that D commutes with the semigroup and C is admissible (as in the proof of Theorem 5.9).

Let us show that the system determined by A and C_0 is exactly observable on $[0, \infty)$. If P_0 denotes the observability Gramian of A and C_0, we have to show that this (nonnegative) operator is bounded from below. By Theorem 5.4 (the "moreover" part) and by Remark 5.5, the matrix of P_0 is

$$P_{j,k} = \frac{\alpha^{k/2}\alpha^{j/2}}{\alpha^k + \alpha^j} = \frac{1}{\alpha^{(k-j)/2} + \alpha^{(j-k)/2}}.$$

Thus, P_0 is a Toeplitz (or convolution) operator, with generating bilateral sequence (τ_k) given by

$$\tau_k = \frac{1}{\alpha^{k/2} + \alpha^{-k/2}}.$$

We define a continuous function φ on the unit circle by

$$\varphi(z) = \sum_{k=-\infty}^{\infty} \tau_k z^k.$$

It is easy to show that for any $x = (x_k) \in l^2$, denoting $\hat{x}(z) = \sum_{k=1}^{\infty} x_k z^k$, we have

$$\langle P_0 x, x \rangle = \frac{1}{2\pi} \int_0^{2\pi} \varphi(e^{i\theta}) \cdot |\hat{x}(e^{i\theta})|^2 d\theta,$$

so that if φ is bounded from below (by a positive number) then P_0 is bounded from below. Denoting $a = \alpha^{1/2}$, we see that φ becomes f defined in (5.10), so that by Lemma 5.10, φ is bounded from below.

Thus we have shown that the system determined by A and C_0 is exactly observable on $[0, \infty)$. To show that the system determined by A and C has the same property, we can now apply the exact same argument as in the last part of the proof of Theorem 5.9. □

It seems that Theorems 5.9 and 5.11 can be generalized in many directions, for example, the eigenvalues λ_k can be moved by amounts not exceeding (in absolute value) a small factor times their real part.

Acknowledgments. The idea of Remark 2.12 is due to Prof. J. E. Lagnese. A conversation with D. Shea was very helpful in regard to Lemma 5.10 and Theorem 5.11.

EXACT CONTROLLABILITY FOR THE SCHRÖDINGER EQUATION*

ELAINE MACHTYNGIER†

Abstract. The exact controllability of Schrödinger equation in bounded domains with Dirichlet boundary condition is studied. Both the boundary controllability and the internal controllability problems are considered. Concerning the boundary controllability, the paper proves the exact controllability in $H^{-1}(\Omega)$ with L^2-boundary control. On the other hand, the exact controllability in $L^2(\Omega)$ is proved with L^2-controls supported in a neighborhood of the boundary. Both results hold for an arbitrarily small time. The method of proof combines both the HUM (Hilbert Uniqueness Method) and multiplier techniques.

Key words. Schrödinger equation, boundary controllability, interior controllability

AMS subject classifications. 35B45, 93B05

1. Introduction and main results. During the last few years, various authors have obtained exact controllability results for the wave and plate equations and for the elasticity system (see, e.g., Haraux [7]; Jaffard [9]; Lagnese [10]; Lagnese and Lions [11]; Lions [13], [14], [15]; Russell [20]; Zuazua [22], [23], and the bibliography therein).

As Rauch [19] pointed out, since every solution of Schrödinger equation

$$iy_t + \Delta y = 0$$

is also solution of the plate equation

$$y_{tt} + \Delta^2 y = 0,$$

we can get exact controllability results for the Schrödinger equation from those corresponding to plate equations.

The object of this work is to study directly the exact controllability problem for the Schrödinger equation by adapting the, by now well known, method (see for instance Lions [14]) which combines HUM (Hilbert Uniqueness Method) and multiplier techniques.

Let us formulate precisely the exact boundary controllability problem for the Schrödinger equation. Let Ω be an open bounded set of $\mathbf{R}^n$ with boundary $\Gamma = \partial\Omega$ of class C^3. We consider a partition (Γ_o, Γ_1) of Γ given by

$$\Gamma_o = \Gamma(x^o) = \{x \in \Gamma; m(x).\nu(x) > 0\}, \tag{1.1}$$

$$\Gamma_1 = \{x \in \Gamma; m(x).\nu(x) \leq 0\}, \tag{1.2}$$

where x^o is a fixed point of $\mathbf{R}^n$, $m(x) = x - x^o$, and $\nu(x)$ is the unit normal vector to Γ at $x \in \Gamma$ pointing towards the exterior of Ω, and "." denotes the scalar product in $\mathbf{R}^n$.

Let us consider the following Schrödinger equation with nonhomogeneous boundary conditions:

$$\begin{cases} iy_t + \Delta y = 0 & \text{in} \quad Q = \Omega \times (0,T) \\ y = \begin{cases} v \\ 0 \end{cases} & \begin{matrix} \text{on} \quad \Sigma_0 = \Gamma_o \times (0,T) \\ \text{on} \quad \Sigma_1 = \Gamma_1 \times (0,T) \end{matrix} \\ y(0) = y^o & \text{in} \quad \Omega. \end{cases} \tag{1.3}$$

For any initial data $y^o \in H^{-1}(\Omega)$ and $v \in L^2(\Sigma_o)$ there exists a unique weak solution of (1.3) in the class $y \in C([0,T];H^{-1}(\Omega))$. This solution is defined by transposition (see Lions and Magenes [16]).

Our main result is as follows.

THEOREM 1.1. *Let $T > 0$, Γ_o be defined by* (1.1) *and $\Sigma_o = \Gamma_o \times (0,T)$. Then, for any $y^o \in H^{-1}(\Omega)$, there exists $v \in L^2(\Sigma_o)$ such that the unique solution $y \in C([0,T];H^{-1}(\Omega))$ of* (1.3) *satisfies $y(T) = 0$.*

Let us now consider the exact controllability problem when the control acts in a subset of Ω.

We assume that the open subset $\omega \subset \Omega$ is a neighborhood of $\overline{\Gamma}_o$, that is, $\omega = \Omega \cap \mathcal{O}$ where $\mathcal{O}$ is an open set of $\mathbf{R}^n$ such that $\overline{\Gamma}_o \subset \mathcal{O}$, and let χ_ω be the characteristic function of ω.

Let us consider the following nonhomogeneous Schrödinger equation:

$$\text{(1.4)} \qquad \begin{cases} iy_t + \Delta y = h\chi_\omega & \text{in} \quad Q = \Omega \times (0,T) \\ y = 0 & \text{on} \quad \Sigma = \Gamma \times (0,T) \\ y(0) = y^o & \text{in} \quad \Omega. \end{cases}$$

It is well known (see Cazenave and Haraux [3], Cazenave [4]) that for any initial data $y^o \in L^2(\Omega)$ and $h \in L^2(\omega \times (0,T))$, there exists a unique weak solution of (1.4) in the class $y \in C([0,T];L^2(\Omega))$.

Concerning this problem our main exact controllability result is as follows.

THEOREM 1.2. *Let $T > 0$ and $\omega \subset \Omega$ be a neighborhood of $\overline{\Gamma}_o$. Then for any $y^o \in L^2(\Omega)$, there exists $h \in L^2(\omega \times (0,T))$ such that the solution of the problem* (1.4) *satisfies $y(T) = 0$.*

Recently some results connected to Theorems 1.1 and 1.2 have been obtained by Lebeau [12] and Fabre [5]. Lebeau, in [12], generalized the results about the exact controllability of hyperbolical problems of Bardos, Lebeau, and Rauch in [1] to the Schrödinger equation. He proved that when Ω is analytic and Γ_o (one open part of the boundary) controls geometrically Ω (cf. [1]); Theorem 1.1 holds. Our result is more restrictive in the sense that it only applies when $\Gamma_o = \Gamma(x^o)$, excluding many subsets Γ_o which geometrically control Ω and are not of the form (1.1). However, our technique presents several advantages:

(i) it applies provided Ω is of class C^3; and

(ii) it provides explicit estimates for the constants on the essential a priori estimations.

Fabre in [5] proved that the boundary control could be obtained as the limit of the internal controls with support in a neighborhood of the boundary of ε thickness by letting ε go to zero.

In the Hilbert spaces $L^2(\Omega)$ and $H_o^1(\Omega)$ we will consider the following inner products:

$$\langle u,v\rangle_{L^2(\Omega)} = \text{Re} \int_\Omega u(x)\overline{v(x)}dx, \quad \forall u,v \in L^2(\Omega)$$

and

$$\langle u,v\rangle_{H_o^1(\Omega)} = \text{Re} \int_\Omega \nabla u(x)\overline{\nabla v(x)}dx, \quad \forall u,v \in H_o^1(\Omega),$$

where $\bar{\bullet}$ denotes the conjugate of $\bullet$.

The rest of the paper is divided into two parts. In §2 we prove the Boundary Controllability Theorem 1.1. In §3 we prove the Internal Controllability Theorem 1.2.

Let us finally mention that the results of this paper were announced in Machtyngier [17].

2. Exact boundary controllability. To prove the Boundary Controllability Theorem 1.1 we need the following proposition.

PROPOSITION 2.1. *For every $T > 0$, there exist $c_i = c_i(T, \Omega) > 0$ $(i = 1, 2)$, such that*

$$\int_0^T \int_{\Gamma_o} \left| \frac{\partial \varphi}{\partial \nu} \right|^2 d\Sigma \le c_1 \|\varphi^o\|^2_{H_o^1(\Omega)} \tag{2.1}$$

and

$$\|\varphi^o\|^2_{H_o^1(\Omega)} \le c_2 \int_0^T \int_{\Gamma_o} \left\| \frac{\partial \varphi}{\partial \nu} \right|^2 d\Sigma \tag{2.2}$$

for every solution $\varphi = \varphi(x, t)$ of the problem

$$\begin{cases} i\varphi_t + \Delta\varphi = 0 & in \quad Q = \Omega \times (0, T) \\ \varphi = 0 & on \quad \Sigma = \Gamma \times (0, T) \\ \varphi(0) = \varphi^o & in \quad \Omega \end{cases} \tag{2.3}$$

with $\varphi^o \in H_o^1(\Omega)$.

(In (2.1) and (2.2) "$\partial\varphi/\partial\nu$" denotes the derivative on the direction ν, the normal unit vector to Γ oriented towards the exterior of Ω. We denote by $d\Sigma = d\Gamma\, dt$ the surface measure of Σ.)

Proof of Proposition 2.1. We proceed in several steps.

Step 1. First, we prove an identity for the solution of the problem

$$\begin{cases} i\varphi_t + \Delta\varphi = f & \text{in} \quad Q \\ \varphi = 0 & \text{on} \quad \Sigma \\ \varphi(0) = \varphi^o & \text{in} \quad \Omega. \end{cases} \tag{2.4}$$

LEMMA 2.2. *Let $q = q(x, t) \in C^2(\overline{Q}, \mathbf{R}^n)$. For every solution of* (2.4) *with $f \in \mathcal{D}(Q)$ and $\varphi^o \in \mathcal{D}(\Omega)$, the following identity holds:*

$$\begin{aligned} \frac{1}{2} \int_\Sigma (q.\nu) \left| \frac{\partial \varphi}{\partial \nu} \right|^2 d\Sigma &= \frac{1}{2} \operatorname{Im} \int_\Omega (\varphi q.\nabla\overline{\varphi}) dx \Big|_0^T \\ &+ \frac{1}{2} \operatorname{Im} \int_Q (q_t.\nabla\varphi\overline{\varphi}) dx dt \\ &+ \frac{1}{2} \operatorname{Re} \int_Q (\varphi \nabla(\operatorname{div}_x q).\nabla\overline{\varphi}) dx dt \\ &+ \operatorname{Re} \int_Q \sum_{j,k} \left(\frac{\partial q_k}{\partial x_j} \frac{\partial \overline{\varphi}}{\partial x_k} \frac{\partial \varphi}{\partial x_j} \right) dx dt + \operatorname{Re} \int_Q f\, q.\nabla\overline{\varphi}\, dx dt \\ &+ \frac{1}{2} \operatorname{Re} \int_Q f\overline{\varphi}(\operatorname{div}_x q) dx dt. \end{aligned} \tag{2.5}$$

In Lemma 2.2 we used the notation: $\operatorname{div}_x q = \sum_{j=1}^n (\partial q_j / \partial x_j)$ and

$$\begin{aligned} \frac{1}{2} \operatorname{Im} \int_\Omega (\varphi q.\nabla\overline{\varphi}) dx \Big|_0^T &= \frac{1}{2} \operatorname{Im} \int_\Omega (\varphi(x, T) q(x, T).\overline{\nabla\varphi(x, T)}) dx \\ &\quad - \frac{1}{2} \operatorname{Im} \int_\Omega (\varphi(x, 0) q(x, 0).\overline{\nabla\varphi(x, 0)}) dx. \end{aligned}$$

Proof of Lemma 2.2. We multiply (2.4) by $q.\nabla\overline{\varphi} + \frac{1}{2}\overline{\varphi}(\operatorname{div}_x q)$ and take the real part. Identity (2.5) holds by integration by parts. □

Step 2. For the proof of (2.1) we choose $q = q(x) \in C^2(\overline{Q}, \mathbf{R}^n)$ such that $q = \nu$ on Γ (see Lions [14] for the construction of this vector field) and $f \equiv 0$ in Q in the identity (2.5) and we obtain

$$\begin{aligned}\frac{1}{2}\int_\Sigma \left|\frac{\partial\varphi}{\partial\nu}\right|^2 d\Sigma \le k_1 \|q\|_{L^\infty(\Omega)}(\|\varphi(T)\|^2_{L^2(\Omega)} + \|\nabla\varphi(T)\|^2_{L^2(\Omega)} \\ +\|\varphi(0)\|^2_{L^2(\Omega)} + \|\nabla\varphi(0)\|^2_{L^2(\Omega)}) \\ +k_2\|q\|_{W^{2,\infty}(\Omega)}\int_0^T \|\varphi(t)\|_{L^2(\Omega)}\|\nabla\varphi(t)\|_{L^2(\Omega)}dt \\ +k_3\|q\|_{W^{1,\infty}(\Omega)}\int_0^T \|\nabla\varphi(t)\|^2_{L^2(\Omega)}dt.\end{aligned} \tag{2.6}$$

We know, by classic results of the Schrödinger equation (see Cazenave [4]), that

$$\|\varphi(t)\|_{L^2(\Omega)} = \|\varphi^o\|_{L^2(\Omega)} \quad \forall t \in [0,T] \tag{2.7}$$

and

$$\|\nabla\varphi(t)\|_{L^2(\Omega)} = \|\nabla\varphi^o\|_{L^2(\Omega)} \quad \forall t \in [0,T]. \tag{2.8}$$

Hence, we obtain

$$\frac{1}{2}\int_\Sigma \left|\frac{\partial\varphi}{\partial\nu}\right|^2 d\Sigma \le c_1\|\varphi^o\|^2_{H_o^1(\Omega)} \quad \forall\varphi^o \in \mathcal{D}(\Omega).$$

Since $\mathcal{D}(\Omega)$ is dense in $H_o^1(\Omega)$, the estimate (2.1) holds for every solution of the problem (2.3) with initial data $\varphi^o \in H_o^1(\Omega)$.

Remark 2.3. We remark that this estimate gives $(\partial\varphi/\partial\nu)|_\Sigma \in L^2(\Sigma)$. It is not a consequence of classic trace results.

Step 3. For the proof of (2.2) we choose $q(x,t) = m(x) = x - x^o$ and $f \equiv 0$ in Q in the identity (2.5) and, using (2.7), (2.8), we obtain

$$\frac{1}{2}\int_\Sigma (m.\nu)\left|\frac{\partial\varphi}{\partial\nu}\right|^2 d\Sigma = \frac{1}{2}\,\mathrm{Im}\int_\Omega (\varphi m.\nabla\overline{\varphi})dx\Big|_0^T + T\|\varphi^o\|^2_{H_o^1(\Omega)} \tag{2.9}$$

Furthermore, let $\varepsilon > 0$ such that $(T-\varepsilon) > 0$ and

$$\left|\mathrm{Im}\int_\Omega (\varphi m.\nabla\overline{\varphi})dx\right| \le c_\varepsilon\|\varphi^o\|^2_{L^2(\Omega)} + \varepsilon\|\varphi^o\|^2_{H_o^1(\Omega)}. \tag{2.10}$$

Thus

$$(T-\varepsilon)\|\varphi^o\|^2_{H_o^1(\Omega)} \le \frac{1}{2}\int_{\Sigma_o}(m.\nu)\left|\frac{\partial\varphi}{\partial\nu}\right|^2 d\Sigma + c_\varepsilon\|\varphi^o\|^2_{L^2(\Omega)}. \tag{2.11}$$

Step 4. To conclude the proof it is enough to prove the following estimate:

$$\|\varphi^o\|^2_{L^2(\Omega)} \le K\int_{\Sigma_o}\left|\frac{\partial\varphi}{\partial\nu}\right|^2 d\Sigma. \tag{2.12}$$

We argue by contradiction. If (2.12) is not satisfied for any $K > 0$, there exists a sequence $\{\varphi_n\}$ of solutions of (2.3) such that

$$\|\varphi_n(0)\|_{L^2(\Omega)} = 1 \quad \forall n \in \mathbf{N} \tag{2.13}$$

and

$$\int_{\Sigma_o} \left| \frac{\partial \varphi_n}{\partial \nu} \right|^2 d\Sigma \to 0 \quad \text{as} \quad n \to +\infty. \tag{2.14}$$

From (2.11) we deduce that $\{\varphi_n(0)\}$ is bounded in $H_o^1(\Omega)$ and then

$$\{\varphi_n\} \text{ is bounded in } L^\infty(0,T;H_o^1(\Omega)) \cap W^{1,\infty}(0,T;H^{-1}(\Omega)).$$

Thus, by extracting a subsequence (that we will still note by $\{\varphi_n\}$) we will have

$$\begin{cases} \varphi_n \to \varphi & \text{in } L^\infty(0,T;H_o^1(\Omega)) \quad \text{weak}^* \\ (\varphi_n)_t \to \varphi_t & \text{in } L^\infty(0,T;H^{-1}(\Omega)) \quad \text{weak}^*. \end{cases}$$

The function $\varphi \in L^\infty(0,T;H_0^1(\Omega)) \cap W^{1,\infty}(0,T;H^{-1}(\Omega))$ is clearly a solution of (2.3) and, from the compactness of the embedding (see Simon [21])

$$L^\infty(0,T;H_o^1(\Omega)) \cap W^{1,\infty}(0,T;H^{-1}(\Omega)) \to C([0,T];L^2(\Omega))$$

and (2.13), we deduce

$$\|\varphi(0)\|_{L^2(\Omega)} = 1. \tag{2.15}$$

On the other hand, (2.14) implies

$$\frac{\partial \varphi}{\partial \nu} = 0 \quad \text{on } \Sigma_o,$$

which, combined with (2.3), implies $\varphi \equiv 0$, from Holmgren's Uniqueness Theorem (see Hörmander [8, Chap. V, Thm. 5.3.3] and Lions [14, Chap. I, Thm. 8.2]). This is in contradiction with (2.15). This ends the proof of inequality (2.2). □

Proof of Theorem 1.1. Let us now apply HUM to deduce the exact boundary controllability result.

Let φ be the solution of the problem (2.3) with $\varphi^o \in H_o^1(\Omega)$. From step 2 of Proposition 2.1 we have $(\partial\varphi/\partial\nu)|_\Sigma \in L^2(\Sigma)$.

We consider the problem

$$\begin{cases} iy_t + \Delta y = 0 & \text{in} \quad Q \\ y = \begin{cases} \dfrac{\partial \varphi}{\partial \nu} & \text{on} \quad \Sigma_o \\ 0 & \text{on} \quad \Sigma_1 \end{cases} \\ y(T) = 0 & \text{in} \quad \Omega \end{cases} \tag{2.16}$$

from the following proposition.

PROPOSITION 2.4. *Let $v \in L^2(\Sigma)$. Then, there exists an unique solution*

$$y \in C([0,T];H^{-1}(\Omega)),$$

in the transposition sense, of the problem

$$\begin{cases} iy_t + \Delta y = 0 & in \quad Q \\ y = v & on \quad \Sigma \\ y(0) = 0 & in \quad \Omega. \end{cases} \tag{2.17}$$

Furthermore, the map $v \mapsto y$ is linear and continuous from $L^2(\Sigma)$ into $C([0,T];H^{-1}(\Omega))$.

Proof. We say that $y \in L^\infty(0,T;H^{-1}(\Omega))$ is a solution of (2.17) in the transposition sense if and only if

$$\text{Re} \int_0^T \langle y(t), \overline{f}(t)\rangle_{(H^{-1}(\Omega),H_o^1(\Omega))} dt = \text{Re} \int_\Sigma v \frac{\partial \overline{\theta}}{\partial \nu} d\Sigma \tag{2.18}$$

for every $f \in L^1(0,T;H_0^1(\Omega))$, where $\theta = \theta(x,t)$ is the solution of the problem

$$\begin{cases} i\theta_t + \Delta\theta = f & \text{in} \quad Q \\ \theta = 0 & \text{on} \quad \Sigma \\ \theta(T) = 0 & \text{in} \quad \Omega. \end{cases} \tag{2.19}$$

Applying the identity (2.5) with a vector field $q = \nu$ on Γ and using the following classic result (see Cazenave and Haraux [3, Chap. IV]):

$$\|\theta(t)\|_{H_o^1(\Omega)} \le \|f\|_{L^1(0,T;H_o^1(\Omega))}, \quad \forall t \in [0,T]$$

we obtain

$$\left\| \frac{\partial \theta}{\partial \nu} \right\|_{L^2(\Sigma)} \le c \|f\|_{L^1(0,T;H_o^1(\Omega))}.$$

Hence, we have

$$\begin{aligned} \left| \text{Re} \int_\Sigma v \frac{\partial \overline{\theta}}{\partial \nu} d\Sigma \right| &\le \|v\|_{L^2(\Sigma)} \left\| \frac{\partial \theta}{\partial \nu} \right\|_{L^2(\Sigma)} \\ &\le c \|v\|_{L^2(\Sigma)} \|f\|_{L^1(0,T;H_o^1(\Omega))}. \end{aligned} \tag{2.20}$$

From (2.20), we obtain that the map

$$f \mapsto \text{Re} \int_\Sigma v \frac{\partial \overline{\theta}}{\partial \nu} d\Sigma$$

is linear and continuous from $L^1(0,T;H_o^1(\Omega))$ into $\mathbf{R}$.

Hence, there exists a unique $y \in L^\infty(0,T;H^{-1}(\Omega))$ that satisfies (2.18) for every $f \in L^1(0,T;H_o^1(\Omega))$.

From (2.18) and (2.20) we have

$$\|y\|_{L^\infty(0,T;H^{-1}(\Omega))} \le c \|v\|_{L^2(\Sigma)}. \tag{2.21}$$

Thus, the map $v \mapsto y$ is continuous from $L^2(\Sigma)$ into $L^\infty(0,T;H^{-1}(\Omega))$.

Moreover, $y \in C([0,T];H^{-1}(\Omega))$. Indeed, we consider $\{v_n\}_{n \in N} \subset \mathcal{D}(0,T;C^2(\Gamma))$ such that

$$v_n \to v \text{ strong in } L^2(\Sigma). \tag{2.22}$$

Let y_n be the solution of (2.17) with boundary condition v_n. Since v_n is regular, in particular, we have $y_n \in C([0,T];H^{-1}(\Omega))$.

From (2.21) and (2.22), we have

$$y_n \to y \quad \text{in } L^\infty(0,T;H^{-1}(\Omega)).$$

Since $C([0,T];H^{-1}(\Omega))$ is a closed subspace of $L^\infty(0,T;H^{-1}(\Omega))$, we have

$$y \in C([0,T];H^{-1}(\Omega)).$$

We obtain that the solution of (2.16) is in the class $y \in C([0,T];H^{-1}(\Omega))$.

It is easy to see that, by multiplying (2.16) by $\overline{\varphi}$, taking the real part, and integrating it by parts, the following identity is satisfied:

$$\langle -iy(0), \varphi^o \rangle = \int_{\Sigma_o} \left| \frac{\partial \varphi}{\partial \nu} \right|^2 d\Sigma \quad \forall \varphi^o \in \mathcal{D}(\Omega).$$

Let Λ be a linear continuous operator from $H_o^1(\Omega)$ into $H^{-1}(\Omega)$ defined by

$$\Lambda \varphi^o = -iy(0),$$

where $y = y(x,t)$ is the solution of the problem (2.16).

From Proposition 2.1 we have

$$\langle \Lambda \varphi^o, \varphi^o \rangle \geq c \|\varphi^o\|^2_{H_o^1(\Omega)}.$$

Hence Λ is an isomorphism from $H_o^1(\Omega)$ to $H^{-1}(\Omega)$ and the theorem is proved. Indeed, given $y^o \in H^{-1}(\Omega)$, we choose the control $v = \partial\varphi/\partial\nu$ on Σ_o where φ is the solution of problem (2.3) with initial data $\varphi^o = \Lambda^{-1}(-iy^o)$. □

3. Exact interior controllability. In order to prove Theorem 1.2 we need to establish the following proposition.

PROPOSITION 3.1. *Let $\omega \subset \Omega$ be a neighborhood of $\overline{\Gamma}_o$. Then for every $T > 0$ there exists $c = c(T) > 0$ such that*

$$\|\varphi^o\|^2_{L^2(\Omega)} \leq c \int_0^T \int_\omega |\varphi|^2 dx\, dt \tag{3.1}$$

for every $\varphi = \varphi(x,t)$ solution of (2.3) *with initial data $\varphi^o \in L^2(\Omega)$.*

Proof. We proceed in several steps.

Step 1. First, we remark that the inequality

$$\|\varphi^o\|^2_{H_o^1(\Omega)} \leq c \int_0^T \int_{\hat{\omega}} |\nabla \varphi|^2 dx\, dt \tag{3.2}$$

holds for every solution $\varphi = \varphi(x,t)$ of the problem (2.3) with $\varphi^o \in H_o^1(\Omega)$, where $\hat{\omega} \subset \Omega$ is a neighborhood of $\overline{\Gamma}_o$.

Indeed, applying identity (2.5) with $f \equiv 0$ in Q and a vector field q satisfying

$$\begin{cases} q(x,t) = \nu(x) & \forall (x,t) \in \Gamma_o \times (\varepsilon, T-\varepsilon) \\ q(x,t).\nu(x) \geq 0 & \forall (x,t) \in \Gamma \times (0,T) \\ q(x,0) = q(x,T) = 0 & \forall x \in \Omega \\ q(x,t) = 0 & \forall (x,t) \in (\Omega \backslash \hat{\omega}) \times (0,T) \end{cases}$$

and using Proposition 2.1, we obtain (3.2).

Step 2. The inequality

$$\|\varphi^o\|^2_{H_o^1(\Omega)} \leq c \int_0^T (\|\varphi_t(t)\|^2_{H^{-1}(\omega)} + \|\varphi^o\|^2_{L^2(\Omega)})\, dt \tag{3.3}$$

is obtained in the following way.

From Step 1 we have

$$\|\varphi^o\|^2_{H^1_o(\Omega)} \leq c\int_0^T \|\varphi(t)\|^2_{H^1(\hat{\omega})}dt. \tag{3.4}$$

Moreover, we have the following result.

LEMMA 3.2. *Let $\Omega \subset \boldsymbol{R}^n$ be a regular domain, $f \in H^{-1}(\Omega)$ and let $u \in H^1_o(\Omega)$ be the solution of*

$$\begin{cases} -\Delta u = f & in \quad \Omega \\ u = 0 & on \quad \Gamma = \partial\Omega \end{cases} \tag{3.5}$$

Then, there exists $c > 0$ (which does not depend on f) such that

$$\|u\|^2_{H^1(\hat{\omega})} \leq c[\|f\|^2_{H^{-1}(\omega)} + \|u\|^2_{L^2(\Omega)}] \tag{3.6}$$

where ω and $\hat{\omega}$ are neighborhood of Γ such that $(\Omega \cap \overline{\hat{\omega}}) \subset \omega$.

Proof. Let us consider the function $\eta \in C^\infty(\mathbf{R}^n)$ such that

$$\eta(x) = \begin{cases} 1 & \text{in} \quad \hat{\omega} \\ 0 & \text{in} \quad \Omega/\omega. \end{cases}$$

Thus, the function $v = \eta u$, where u is the solution of (3.5), satisfies

$$\begin{cases} -\Delta v = -(\Delta\eta)u - 2\nabla\eta.\nabla u + \eta f \quad \text{in} \quad \omega \\ v \in H^1_o(\omega). \end{cases} \tag{3.7}$$

Since the operator $-\Delta$ is an isomorphism from $H^1_0(\omega)$ to $H^{-1}(\omega)$, we have

$$\|v\|_{H^1(\omega)} \leq c_1\|f\|_{H^{-1}(\omega)} + c_2\|u\|_{L^2(\Omega)} \tag{3.8}$$

Hence, we obtain (3.6) from (3.8) because

$$\|u\|_{H^1(\hat{\omega})} = \|v\|_{H^1(\hat{\omega})} \leq \|v\|_{H^1(\omega)}.$$

Remark 3.3. We also can use this lemma when ω and $\hat{\omega}$ are neighborhoods of $\overline{\Gamma}_o$ such that $(\Omega \cap \overline{\hat{\omega}}) \subset \omega$.

Thus, by combining (3.4), (3.6), and (2.3) we obtain

$$\|\varphi^o\|^2_{H^1_o(\Omega)} \leq c\int_0^T (\|\varphi_t(t)\|^2_{H^{-1}(\omega)} + \|\varphi(t)\|^2_{L^2(\Omega)})dt. \tag{3.9}$$

From (2.7), (3.9) we conclude the proof of (3.3).

Step 3. From (3.9), proceeding by contradiction and using compactness and Holmgren's Uniqueness Theorem, we obtain the following estimate:

$$\|\varphi^o\|^2_{H^1_0(\Omega)} \leq c\int_0^T \|\varphi_t(t)\|^2_{H^{-1}(\omega)}dt. \tag{3.10}$$

On the other hand, as the operator $-\Delta$ is an isomorphism from $H^1_o(\Omega)$ to $H^{-1}(\Omega)$, from (3.10) we have

$$\|\varphi_t(0)\|^2_{H^{-1}(\Omega)} \leq c\int_0^T \|\varphi_t(t)\|^2_{H^{-1}(\omega)}dt. \tag{3.11}$$

Step 4. Let $\varphi \in C([0,T];H^{-1}(\Omega))$ be the solution of (2.3) with $\varphi(0)=\varphi^o \in H^{-1}(\Omega)$ and define

$$\psi(t)=\int_0^t \varphi(s)ds + X,$$

where

$$\begin{cases} \Delta X = -i\varphi(0) \\ X \in H_o^1(\Omega). \end{cases}$$

Thus, ψ is a solution of problem (2.3) with $\psi(0)=X\in H_o^1(\Omega)$ and $\psi_t=\varphi$. Then, applying (3.11) to ψ we have

$$\|\varphi^o\|^2_{H^{-1}(\Omega)} \le c\int_0^T \|\varphi(t)\|^2_{H^{-1}(\omega)}dt. \tag{3.12}$$

Step 5. From (3.4) and (3.12) we have

$$\|\varphi^o\|^2_{H_o^1(\Omega)} \le c\int_0^T \|\varphi(t)\|^2_{H^1(\omega)}dt = c\|\varphi\|_{L^2(0,T;H^1(\omega))}, \tag{3.13}$$

$$\|\varphi^o\|^2_{H^{-1}(\Omega)} \le c\int_0^T \|\varphi(t)\|^2_{H^{-1}(\omega)}dt = c\|\varphi\|_{L^2(0,T;H^{-1}(\omega))}. \tag{3.14}$$

We are going to prove (3.1) by interpolation. Let us consider the linear operator

$$L: H^{-1}(\Omega) \to L^2(0,T;H^{-1}(\omega))$$

defined by

$$L\varphi(t)=(e^{it\Delta}\varphi)|_\omega.$$

It is clear that

$$\|L\varphi\|_{L^2(0,T;H^{-1}(\omega))} \le C\|\varphi\|_{H^{-1}(\Omega)}.$$

Furthermore, it follows from (3.12) that

$$\|L\varphi\|_{L^2(0,T;H^{-1}(\omega))} \ge c\|\varphi\|_{H^{-1}(\Omega)}.$$

Therefore, we can consider the closed subspace $X_o = L(H^{-1}(\Omega))$ of $L^2(0,T;H^{-1}(\omega))$, and the linear operator $\Pi = L^{-1}$ (since L is an isomorphism $H^{-1}(\Omega)\to X_o$).

Thus

$$\Pi \in \mathcal{L}(X_o, Y_o) \tag{3.15}$$

with $Y_o = H^{-1}(\Omega)$.

Next, we can set $X_1 = X_o \cap L^2(0,T;H^1(\omega))$, and it follows from (3.13) that

$$\Pi \in \mathcal{L}(X_1, Y_1) \tag{3.16}$$

with $Y_1 = H_o^1(\Omega)$.

From (3.15) and (3.16), cf. [16, Thm. 51, p. 27], we have

$$\Pi \in \mathcal{L}([X_o, X_1]_{1/2}, [Y_o, Y_1]_{1/2}).$$

From [16, Thm. 12.3, p. 27], we have

$$[Y_o, Y_1]_{1/2} = L^2(\Omega).$$

Furthermore, by [2, Thm. 5.1.2, p. 107], we have

$$[L^2(0,T;H^1(\omega)), L^2(0,T;H^{-1}(\omega))]_{1/2} = L^2(0,T;[H^1(\omega);H^{-1}(\omega)]_{1/2})$$

and from [16, Thm. 12.4], we obtain

$$[H^1(\omega);H^{-1}(\omega)]_{1/2} = L^2(\omega).$$

Hence, since X_o is a closed subspace of $L^2(0,T;H^{-1}(\omega))$ and X_1 a closed subspace of $L^2(0,T;H^1(\omega))$, using [16, Thm. 15.1, p. 107], we verify that the norm of the space $[X_o, X_1]_{1/2}$ is equivalent to the norm of $L^2(0,T;L^2(\omega))$, and since $\Pi \in \mathcal{L}([X_o, X_1]_{1/2}; L^2(\Omega))$, we have

$$\|\varphi^o\|^2_{L^2(\Omega)} \leq c \int_0^T \int_\omega |\varphi|^2 \, dxdt.$$

This ends the proof of the proposition. □

Proof of Theorem 1.2. We apply HUM to deduce the exact controllability as follows. We define the linear continuous operator from $L^2(\Omega)$ into $L^2(\Omega)$ by

$$\Lambda\varphi^o = -iy(0),$$

where $y = y(x,t)$ is the solution of the problem

$$\text{(3.17)} \qquad \begin{cases} iy_t + \Delta y = \varphi\chi_\omega & \text{in} \quad Q \\ y = 0 & \text{on} \quad \Sigma \\ y(T) = 0 & \text{in} \quad \Omega \end{cases}$$

and φ is the solution of (2.3) with initial data $\varphi^o \in L^2(\Omega)$.

It is easy to see that, by multiplying (3.17) by $\overline{\varphi}$, taking the real part and integrating it by parts, one following identity is satisfied:

$$\text{(3.18)} \qquad \langle \Lambda\varphi^o, \varphi^o \rangle = \int_o^T \int_\omega |\varphi|^2 \, dx \, dt, \quad \forall \varphi^o \in L^2(\Omega).$$

By combining estimate (3.1) and identity (3.18) we deduce that Λ is an isomorphism from $L^2(\Omega)$ to $L^2(\Omega)$. Hence, given $y^o \in L^2(\Omega)$, we choose the control $h = \varphi|_\omega$ where φ is the solution of (2.3) with initial data $\varphi^o = \Lambda^{-1}(-iy^o)$. Then the proof is finished. □

APPROXIMATE BOUNDARY CONTROLLABILITY FOR THE WAVE EQUATION IN PERFORATED DOMAINS*

DOINA CIORANESCU†, PATRIZIA DONATO‡, AND ENRIQUE ZUAZUA§

Abstract. This paper considers the wave equation in a perforated domain with holes of size $r(\epsilon)$ distributed with ϵ-periodicity, with the assumption that there exists a neighborhood of the exterior boundary without holes. The following question is asked: Is it possible to approximately control the wave equation in the perforated domain in such a way that when ϵ goes to zero the exact controllability of the limit system is obtained? Two main theorems give a positive answer to this question when $r(\epsilon)$ is the critical size that transforms at the limit the operator $(\partial^2/\partial t^2) - \Delta$ into $(\partial^2/\partial t^2) - \Delta + \mu$, where μ is a positive measure. In the first theorem, in a suitable sense, $L^2(\Omega) \times H^{-1}(\Omega)$ is approximated by the space of the admissible data for the exact controllability in the perforated domain. In the second, it is shown that the limit control, supported only by the exterior boundary of the perforated domain, is such that the related state in the perforated domain goes at the limit to the equilbrium state at the time T.

Key words. approximate controllability, wave equation, perforated domains, homogenization

1. Introduction and main results. We consider here some questions related to the approximate and exact Dirichlet boundary controllability of the wave equation in perforated domains.

Let Ω be a bounded domain in $\mathbb{R}^n, n \geq 2$ with boundary $\partial\Omega$ of class C^2. Let Ω_ϵ be the domain obtained by removing from Ω a set S_ϵ of closed smooth subsets (the "holes"), i.e., $\Omega_\epsilon = \Omega \backslash S_\epsilon$.

We assume that the measure of the set of holes goes to zero as the parameter ϵ tends to zero, and we are interested in describing the asymptotic behavior of the system under some geometrical assumptions on the domains Ω_ϵ.

Let us consider the wave equation in the perforated domain $\Omega_\epsilon \times (0,T)$ for a given $T > 0$

$$\begin{cases} y_\epsilon'' - \Delta y_\epsilon = 0 & \text{in } \Omega_\epsilon \times (0,T) \\ y_\epsilon(0) = y_\epsilon^0 & \text{in } \Omega_\epsilon \\ y_\epsilon'(0) = y_\epsilon^1 & \text{in } \Omega_\epsilon \end{cases} \tag{1.1}$$

with Dirichlet boundary conditions

$$y_\epsilon = v_\epsilon \quad \text{on } \Sigma_\epsilon = \partial\Omega_\epsilon \times (0,T), \tag{1.2}$$

where $\partial\Omega_\epsilon = \partial\Omega \cup \partial S_\epsilon$.

The exact controllability problem for system (1.1)–(1.2) consists of finding $T > 0$ large enough such that for every initial data $\{y_\epsilon^0, y_\epsilon^1\}$ in a given space there exists a control v_ϵ such that the solution of (1.2) satisfies

$$y_\epsilon(T) = y_\epsilon'(T) = 0.$$

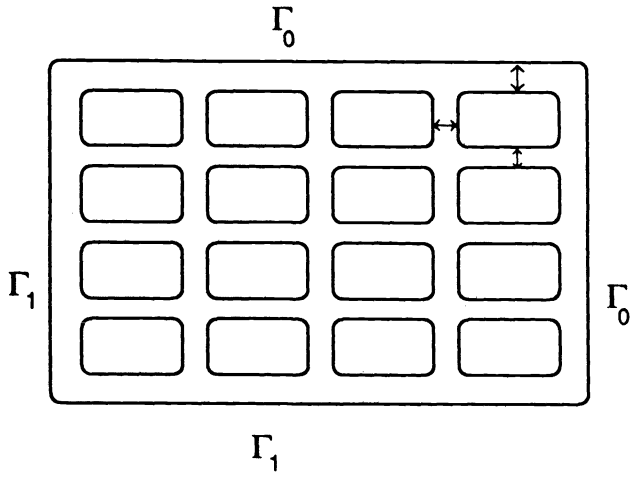

FIG. 1

The Hilbert Uniqueness Method (HUM) (see Lions [7]) furnishes such an exact control $v_\epsilon \in L^2(\Sigma_\epsilon)$ for T large enough ($T >$ diam Ω =diameter of Ω) and for every pair $\{y_\epsilon^0, y_\epsilon^1\} \in L^2(\Omega_\epsilon) \times H^{-1}(\Omega_\epsilon)$. This control minimizes the $L^2(\Sigma_\epsilon)$-norm among all the exact controls for (1.1)–(1.2). Moreover, in [3] we constructed special exact controls for which, under suitable geometric assumptions on S_ϵ (see (1.4)), the asymptotic behavior of the system as $\epsilon \to 0$ can be described.

Let us point out that these controls constructed in [3] are supported by the external boundary $\partial\Omega$ and also by the boundary of *all* the holes. Hence, they are not realistic from a practical point of view.

The support of the control can be restricted to a "large enough" subset Γ_o^ϵ of $\partial\Omega_\epsilon$. More precisely, as a consequence of the results proved by Bardos, Lebeau, and Rauch in [1], in order to have such an exact controllability property in $L^2(\Omega_\epsilon) \times H^{-1}(\Omega_\epsilon)$ with L^2-controls supported on Γ_0^ϵ and in time T_0, Γ_0^ϵ and T_0 must satisfy the following geometric property: Any generalized ray of geometric optics meets Γ_0^ϵ in a time $T \leq T_0$.

Therefore, if S_ϵ contains a sole "nontrapping" hole (for instance, a star-shaped hole), then exact controllability in $L^2(\Omega_\epsilon) \times H^{-1}(\Omega_\epsilon)$ can be achieved with L^2-controls by acting only on the exterior boundary. However, if S_ϵ contains more than one hole, in order to control the trapped generalized rays the exact control must also have a part supported on the boundary of the holes (see Fig. 1).

In practice, what is natural (and realistic) is to try to control system (1.1) by acting only on the external boundary $\Sigma = \partial\Omega \times (0,T)$. Thus, instead of (1.2) we must add to equations (1.1) the following boundary conditions:

$$(1.2)' \qquad \begin{cases} y_\epsilon = v_\epsilon & \text{on } \partial\Omega \times (0,T) \\ y_\epsilon = 0 & \text{on } \partial S_\epsilon \times (0,T). \end{cases}$$

System (1.1)–(1.2)′ is approximately controllable. More precisely, applying HUM again (see [7, Chap. 1]), it can be shown that if $T >$ diam Ω, there exists a Hilbert space F_ϵ such that, for every $\{y_\epsilon^0, y_\epsilon^1\}$ satisfying

$$\{y_\epsilon^1, -y_\epsilon^0\} \in F_\epsilon',$$

there exists an exact control $v_\epsilon \in L^2(\Sigma)$ so that the solution of (1.1)–(1.2)′ satisfies

$$y_\epsilon(T) = y'_\epsilon(T) = 0. \tag{1.3}$$

Moreover F'_ϵ is dense in $H^{-1}(\Omega_\epsilon) \times L^2(\Omega_\epsilon)$ and, as we saw above, F'_ϵ is strictly contained in $H^{-1}(\Omega_\epsilon) \times L^2(\Omega_\epsilon)$ as soon as S_ϵ contains more than one hole. On the other hand, F'_ϵ cannot be characterized in a usable way.

However, when letting ϵ go to zero, under suitable assumptions on the holes S_ϵ, the limit system of the wave equation is a second-order (in time) hyperbolic equation in the whole domain Ω. The exact controllability of this limit system can be achieved in $L^2(\Omega) \times H^{-1}(\Omega)$ with L^2-controls supported on the boundary of Ω. Therefore, the following general question arises: Is it possible to approximately control system (1.1) in such a way that when ϵ goes to zero we obtain the exact controllability of the limit system? This general question can be formulated more precisely in the following two ways.

The first question is: Given T large enough ($T >$ diam Ω) and $\{y^0, y^1\} \in L^2(\Omega) \times H^{-1}(\Omega)$, find approximate initial data $\{y^0_\epsilon, y^1_\epsilon\}$ such that $\{y^1_\epsilon, -y^0_\epsilon\} \in F'_\epsilon$ and

$$\{y^0_\epsilon, y^1_\epsilon\} \to \{y^0, y^1\}$$
$$y_\epsilon \to y$$
$$v_\epsilon \to v,$$

as $\epsilon \to 0$ (in a sense to be made precise), where v_ϵ is the exact control given by HUM for (1.1)–(1.2)′, y is the solution of the limit wave equation in the whole of Ω with initial data $\{y^0, y^1\}$, and v is the exact Dirichlet control for the limit state y so that $y(T) = y'(T) = 0$. Roughly, this question asks whether F'_ϵ converges to $L^2(\Omega) \times H^{-1}(\Omega)$ as ϵ goes to zero.

A second natural question, complementary to the first one, can also be posed. Suppose that we are given $\{y^0_\epsilon, y^1_\epsilon\} \in L^2(\Omega_\epsilon) \times H^{-1}(\Omega_\epsilon)$ so that $\{y^0_\epsilon, y^1_\epsilon\}$ converges in some sense to $\{y^0, y^1\} \in L^2(\Omega) \times H^{-1}(\Omega)$ (in a sense that will be made precise). As shown before, we cannot construct an exact L^2-control with support in $\partial\Omega \times (0,T)$ only. The question is as follows: Can we construct a Dirichlet boundary control v_ϵ supported only by $\partial\Omega \times (0,T)$ such that, if y_ϵ satisfies (1.1), (1.2)′, then

$$y_\epsilon(T) \to 0$$
$$y'_\epsilon(T) \to 0?$$

We give here a positive answer to these two questions under some assumptions on the geometry of the holes.

Our first assumption is as follows:

$$\left\{\begin{array}{l} \text{There exists a sequence of test functions } w_\epsilon \text{ such that} \\ \quad \text{(i) } w_\epsilon \in H^1(\Omega) \cap L^\infty(\Omega), \qquad \|w_\epsilon\|_{L^\infty(\Omega)} \le M_0 \\ \quad \text{(ii) } w_\epsilon = 0 \quad \text{on } S_\epsilon \\ \quad \text{(iii) } w_\epsilon \rightharpoonup 1 \quad \text{weakly in } H^1(\Omega) \text{ and almost everywhere in } \Omega \\ \quad \text{(iv) } -\Delta w_\epsilon = \mu_\epsilon - \gamma_\epsilon \quad \text{where} \quad \mu_\epsilon, \gamma_\epsilon \in H^{-1}(\Omega) \text{ with} \\ \qquad \mu_\epsilon \to \mu \quad \text{strongly in } H^{-1}(\Omega), \mu \in L^\infty(\Omega) \text{ and} \\ \qquad < \gamma_\epsilon, u_\epsilon >_\Omega = 0 \quad \text{for any } u_\epsilon \in H^1_0(\Omega) \text{ such that } u_\epsilon = 0 \text{ on } S_\epsilon. \end{array}\right. \tag{1.4}$$

This assumption implies that, at the limit, $-\Delta : H^1_0(\Omega_\epsilon) \to H^{-1}(\Omega_\epsilon)$ is transformed into $-\Delta + \mu I : H^1_0(\Omega) \to H^{-1}(\Omega)$ (for details see Cioranescu and Murat [6]).

The second assumption is the following:

$$\text{There exists } \alpha > 0 \text{ such that } d(S_\epsilon, \partial\Omega) \ge \alpha \quad \forall \epsilon > 0, \tag{1.5}$$

where $d(S_\epsilon, \partial\Omega)$ is the distance between S_ϵ and $\partial\Omega$.

Remark 1.1. This hypothesis signifies that we have a "safety zone"

$$D_\alpha = \{x \in \Omega : d(x, \partial\Omega) \leq \alpha\}$$

around $\partial\Omega$ where there are no holes. Moreover, it is easy to check that if Ω satisfies hypotheses (1.4) and (1.5) then the support of μ is contained in $\Omega \backslash D_\alpha$, the holes being located in $\Omega \backslash D_\alpha$ only.

We observe also that it is not restrictive to assume that $w_\epsilon \equiv 1$ in $D_{\alpha-\delta}$ for a fixed $\delta \in]0, \alpha[$. In fact, if not, we can define $\overline{w}_\epsilon = \psi + (1 - \psi) w_\epsilon$ where $\psi \in C^\infty(\Omega)$ satisfies

$$\psi \equiv 0 \quad \text{in } \Omega \backslash D_\alpha, \quad \psi \equiv 1 \quad \text{in } \Omega \backslash D_{\alpha-\delta}, \quad 0 \leq \psi \leq 1$$

and it is obvious that hypothesis (1.4) is still satisifed with $\overline{w}_\epsilon$ instead of w_ϵ. Consequently, in the following we will assume that $w_\epsilon \equiv 1$ in $D_{\alpha-\delta}$ for a fixed $\delta \in]0, \alpha[$.

Remark 1.2. Condition (1.4), without the assumption $\mu \in L^\infty(\Omega)$, was introduced by Cioranescu and Murat in [6] in the context of elliptic homogenization and ensures that the measure of the holes is asymptotically small enough. Note that if μ does not belong to $L^\infty(\Omega)$, at the limit we get the elliptic operator $-\Delta + \mu I : V \to V'$ with $V = H_0^1(\Omega) \cap L^2(\Omega; d\mu)$ (see [6] for the elliptic case and Cioranescu et al. [2] for the wave equation). The assumption $\mu \in L^\infty(\Omega)$ is necessary in the present paper to provide the exact controllability for the homogenized wave equation.

Let us now consider the wave equation related to the limit elliptic operator $-\Delta + \mu I$ in the domain $\Omega \times (0, T)$, with $T > 0$ and Dirichlet boundary condition

$$\begin{cases} y'' - \Delta y + \mu y = 0 \quad \text{in } \Omega \times (0, T) \\ y = v \quad \text{on } \partial\Omega \times (0, T) \\ y(0) = y^0 \quad \text{in } \Omega \\ y'(0) = y^1 \quad \text{in } \Omega \end{cases} \tag{1.6}$$

with $\{y^0, y^1\} \in L^2(\Omega) \times H^{-1}(\Omega)$.

If $T > \operatorname{diam} \Omega$, applying HUM to (1.6) we get the existence of a control $v \in L^2(\Sigma)$ such that the solution of (1.6) satisfies

$$y(T) = y'(T) = 0.$$

At this point, we use the fact that $\mu \in L^\infty(\Omega)$. Indeed, when μ is only a measure in $H^{-1}(\Omega)$, no exact boundary controllability result is known.

In order to state the main results of this paper we need to introduce the quasi-extension operator P_ϵ defined in [2]:

$$P_\epsilon \psi = w_\epsilon \tilde{\psi} \quad \forall \psi \in L^2(\Omega_\epsilon) \tag{1.7}$$

where $\tilde{\psi}$ is the extension of ψ by zero in the holes S_ϵ and w_ϵ are the test functions from hypothesis (1.4).

This operator extends as follows to an operator P_ϵ defined on $H^{-1}(\Omega_\epsilon)$:

$$\langle P_\epsilon \psi, \varphi \rangle_{W^{-1,q}(\Omega), W_0^{1,q/(q-1)}(\Omega)} = \langle \psi, w_\epsilon \varphi \rangle_{H^{-1}(\Omega_\epsilon), H_0^1(\Omega_\epsilon)}.$$

This operator satisfies

$$\begin{cases} P_\epsilon \in \mathcal{L}(H^{-1}(\Omega_\epsilon); W^{-1,q}(\Omega)) \\ \|P_\epsilon\|_{\mathcal{L}(H^{-1}(\Omega_\epsilon); W^{-1,q}(\Omega))} \leq C_q \end{cases}$$

for any $q \in (1, n/(n-1))$ (for details we refer the reader to [2]).

We are now able to formulate the main results. The following theorem answers the first question.

THEOREM 1.3. *Let y be the solution of system* (1.6) *with* $\{y^0, y^1\} \in L^2(\Omega) \times H^{-1}(\Omega)$ *and* $v \in L^2(\Sigma)$ *the exact control of* (1.6) *given by* HUM. *Let* y_ϵ *be the solution of*

$$\text{(1.8)} \qquad \begin{cases} y_\epsilon'' - \Delta y_\epsilon = 0 \quad \text{in } \Omega_\epsilon \times (0,T) \\ y_\epsilon = v \quad \text{on } \partial\Omega \times (0,T) \\ y_\epsilon = 0 \quad \text{on } \partial S_\epsilon \times (0,T) \\ y_\epsilon(T) = y_\epsilon'(T) = 0 \quad \text{in } \Omega_\epsilon. \end{cases}$$

Then, under hypotheses (1.4) *and* (1.5)

$$\{y_\epsilon'(0), -y_\epsilon(0)\} \in F_\epsilon'$$

and, moreover,

$$\text{(1.9)} \qquad \begin{cases} \text{(i)} & \widetilde{y_\epsilon} \to y \quad \text{strongly in } L^2(\Omega \times (0,T)) \\ \text{(ii)} & \widetilde{y_\epsilon(0)} \to y^0 \quad \text{strongly in } L^2(\Omega) \\ \text{(iii)} & P_\epsilon y_\epsilon'(0) \to y^1 \quad \text{strongly in } W^{-1,q}(\Omega) \end{cases}$$

for any $q \in (1, n/(n-1))$.

In the following, if $g \in H^{-1}(\Omega)$, we denote $g|_{\Omega_\epsilon}$ by $\in H^{-1}(\Omega_\epsilon)$ the functional defined by

$$\langle g|\Omega_\epsilon, \varphi\rangle_{H^{-1}(\Omega_\epsilon), H_0^1(\Omega_\epsilon)} = \langle g, \tilde{\varphi}\rangle_{H^{-1}(\Omega), H_0^1(\Omega)} \quad \forall \varphi \in H_0^1(\Omega_\epsilon).$$

Let us now answer the second question.

THEOREM 1.4. *Let* $\{y^0, y^1\} \in L^2(\Omega) \times H^{-1}(\Omega)$ *and* y *be the solution of* (1.6) *where* v *is an exact Dirichlet control. Let* y_ϵ *be the solution of system* (1.1) *with initial data* $\{y_\epsilon^0, y_\epsilon^1\} = \{y^0|_{\Omega_\epsilon}, y^1|_{\Omega_\epsilon}\}$ *and boundary data*

$$\begin{cases} y_\epsilon = v \quad \text{on } \partial\Omega \times (0,T) \\ y_\epsilon = 0 \quad \text{on } \partial S_\epsilon \times (0,T). \end{cases}$$

Then

$$\text{(1.10)} \qquad \begin{cases} \text{(i)} & \widetilde{y_\epsilon} \to y \quad \text{strongly in } L^2(\Omega \times (0,T)) \\ \text{(ii)} & P_\epsilon y_\epsilon' \to y' \quad \text{strongly in } L^2(0,T; W^{-1,q}(\Omega)) \end{cases}$$

and, moreover,

$$\text{(1.11)} \qquad \begin{cases} \text{(i)} & \widetilde{y_\epsilon}(T) \to 0 \quad \text{strongly in } L^2(\Omega) \\ \text{(ii)} & P_\epsilon y_\epsilon'(T) \to 0 \quad \text{strongly in } W^{-1,q}(\Omega) \end{cases}$$

for all $q \in (1, n/(n-1))$.

Remark 1.5. Regarding the sequence $\{\tilde{y}_\epsilon\}$, it would be interesting to have strong convergence in $C^0([0,T]; L^2(\Omega))$; this is still an open problem.

On the other hand, Theorems 1.3 and 1.4 are essentially homogenization results for the wave equation with nonhomogeneous Dirichlet boundary conditions in a perforated domain provided with a safety zone. We do not know if the theorems are true in domains without this property. A possible approach to this question is the following.

Suppose that (1.5) is not satisfied. Let Ω^1 be an open bounded set such that $\overline{\Omega} \subset \Omega^1$, and consider the new perforated domain $\Omega_\epsilon^1 = \Omega^1 \backslash S_\epsilon$. Clearly (1.4) and (1.5) hold.

Given $(y^0, y^1) \in L^2(\Omega) \times H^{-1}(\Omega)$ we may extend them to $(z^0, z^1) \in L^2(\Omega^1) \times H^{-1}(\Omega^1)$. Applying Theorem 1.4 to (z^0, z^1) in the cylinder $\Omega^1 \times (0,T)$, we find solutions z_ϵ of the wave equation in $\Omega_\epsilon^1 \times (0,T)$ with initial data (z^0, z^1) such that

$$(\tilde{z}_\epsilon(T), P_\epsilon z_\epsilon'(T)) \to (0,0) \quad \text{in } L^2(\Omega^1) \times W^{-1,q}(\Omega^1)$$

for every $1 < q < n/(n-1)$.

Now, clearly,

$$v_\epsilon = z_{\epsilon|_{\partial\Omega \times (0,T)}}$$

are approximate controls for the wave equation in $\Omega_\epsilon \times (0,T)$ such that $y_\epsilon = z_{\epsilon|_{\Omega_\epsilon \times (0,T)}}$ is a solution of (1.1)–(1.2)′ that satisfies

$$(\tilde{y}_\epsilon(T), P_\epsilon y_\epsilon'(T)) \to (0,0) \quad \text{in } L^2(\Omega) \times W^{-1,q}(\Omega).$$

However, we do not know the optimal regularity of v_ϵ and the smallest space in which they are uniformly bounded. This seems to be an interesting open problem.

Remark 1.6. As a consequence of the results by Bardos, Lebeau, and Rauch [1], system (1.6) is exactly controllable in $L^2(\Omega) \times H^{-1}(\Omega)$ with L^2-controls supported in a subset Γ_0 of $\partial\Omega$ in a time T if the geometric control property is satisfied. Theorems 1.3 and 1.4 can be easily adapted to this situation. The same convergence results hold for y_ϵ satisfying, instead of the boundary conditions of Theorems 1.3 and 1.4,

$$\begin{cases} y_\epsilon = v & \text{on } \Gamma_0 \times (0,T) \\ y_\epsilon = 0 & \text{on } (\partial\Omega \backslash \Gamma_0) \times (0,T) \\ y_\epsilon = 0 & \text{on } \partial S_\epsilon \times (0,T), \end{cases}$$

where $v \in L^2(\Gamma_0 \times (0,T))$ is the control of the limit system (1.6). In this case condition (1.5) may be relaxed to the following:

$$\text{There exists } \alpha > 0 \text{ such that } d(S_\epsilon, \Gamma_0) \geq \alpha \quad \forall \epsilon > 0.$$

Remark 1.7. In the case of the wave equation with oscillating coefficients, similar approximate controllability results are given in Cioranescu, Donato, and Zuazua [5] in the framework of the classical homogenization (the coefficients are ϵ-periodic). They are proved when assuming that the coefficients are constant in a neighborhood of $\partial\Omega$. This assumption is of the same type as (1.5): Around $\partial\Omega$ there is a safety zone where no oscillation occurs.

Remark 1.8. We mention also that a strong convergence result of solutions has been proved in [4] in the case of special controls introduced in [3].

The rest of the paper is organized as follows. The proofs of Theorems 1.3 and 1.4 lay on homogenization results for the wave equation with homogeneous Dirichlet boundary conditions in perforated domains given in Cioranescu, Donato, Murat, and Zuazua [2] and on some convergence results from Cioranescu, Donato, and Zuazua [3]. We recall them in §2 where we also give some complementary results. Section 3 is devoted to the proof of the main results. In §4 we give some examples.

2. Homogenization results for the wave equation. Consider the wave equation

$$\begin{cases} u_\epsilon'' - \Delta u_\epsilon = f_\epsilon & \text{in } \Omega_\epsilon \times (0,T) \\ u_\epsilon = 0 & \text{in } \partial\Omega_\epsilon \times (0,T) \\ u_\epsilon(0) = u_\epsilon^0 & \text{in } \Omega_\epsilon \\ u_\epsilon'(0) = u_\epsilon^1 & \text{in } \Omega_\epsilon \end{cases} \tag{2.1}$$

with data $\{u_\epsilon^0, u_\epsilon^1\} \in H_0^1(\Omega_\epsilon) \times L^2(\Omega_\epsilon)$, $f_\epsilon \in L^1(0,T; L^2(\Omega_\epsilon))$. We recall here some results concerning the asymptotic behaviour of u_ϵ as $\epsilon \to 0$. We refer to [2] for the proofs and for further details.

2.1. Convergence results in Ω. We have the following convergence results.

PROPOSITION 2.1 (see [2]). *Assume hypothesis* (1.4) *and suppose that the data* $\{u_\epsilon^0, u_\epsilon^1\}$ *and* f_ϵ *are such that*

$$\begin{cases} \{\tilde{u}_\epsilon^0, \tilde{u}_\epsilon^1\} \rightharpoonup \{u^0, u^1\} & \text{weakly in } H_0^1(\Omega) \times L^2(\Omega) \\ \tilde{f}_\epsilon \rightharpoonup f & \text{weakly in } L^1(0,T;L^2(\Omega)). \end{cases}$$

Then

$$\begin{cases} \tilde{u}_\epsilon \rightharpoonup u & \text{weakly } * \text{ in } L^\infty(0,T;H_0^1(\Omega)) \\ \tilde{u}_\epsilon' \rightharpoonup u' & \text{weakly } * \text{ in } L^\infty(0,T;L^2(\Omega)) \end{cases}$$

and

$$\begin{cases} \tilde{u}_\epsilon(t) \rightharpoonup u(t) & \text{weakly in } H_0^1(\Omega) \times L^2(\Omega) \\ \tilde{u}_\epsilon'(t) \rightharpoonup u'(t) & \text{weakly in } L^2(\Omega) \end{cases}$$

for all $t \in [0,T]$, *where* u *satisfies*

$$\begin{cases} u'' - \Delta u + \mu u = f & \text{in } \Omega \times (0,T) \\ u = 0 & \text{on } \partial\Omega \times (0,T) \\ u(0) = u^0 & \text{in } \Omega \\ u'(0) = u^1 & \text{in } \Omega. \end{cases} \tag{2.2}$$

Remark 2.2. Obviously, Proposition 2.1 holds for the backward wave equation.

Under stronger asssumptions on the convergence of the data, we can improve the convergence result for u_ϵ. Namely, we have the following proposition.

PROPOSITION 2.3 (see [2]). *Suppose that*

$$\begin{cases} \text{(i)} & \tilde{f}_\epsilon \to f \quad \text{strongly in } L^2(\Omega \times (0,T)) \\ \text{(ii)} & \tilde{u}_\epsilon^1 \to u^1 \quad \text{strongly in } L^2(\Omega) \\ \text{(iii)} & u_\epsilon^0 \in H_0^1(\Omega_\epsilon) \quad \text{and there exists } g_\epsilon \in H^{-1}(\Omega) \text{ such that} \\ & \qquad -\Delta u_\epsilon^0 = g_\epsilon \quad \text{in } \mathcal{D}'(\Omega_\epsilon) \text{ with } g_\epsilon \to g \text{ strongly in } H^{-1}(\Omega). \end{cases} \tag{2.3}$$

Then, under hypothesis (1.4),

$$\begin{cases} \tilde{u}_\epsilon' \to u' & \text{strongly in } C^0([0,T];L^2(\Omega)), \\ \int_\Omega |\nabla \tilde{u}_\epsilon|^2 dx \to \int_\Omega |\nabla u|^2 dx + < \mu, u^2 > & \text{in } C^0([0,T]), \end{cases} \tag{2.4}$$

where u *is a solution of* (2.2) *with* $u^0 \in H_0^1(\Omega)$ *and such that*

$$-\Delta u^0 + \mu u^0 = g \quad \text{in } H^{-1}(\Omega).$$

Moreover,

$$\tilde{\mu}_\epsilon(x,t) = w_\epsilon(x) u(x,t) + \rho_\epsilon(x,t) \tag{2.5}$$

with

$$\begin{cases} \text{(i)} & \rho_\epsilon' \to 0 \quad \text{strongly in } C^0([0,T];L^2(\Omega)) \\ \text{(ii)} & \nabla \rho_\epsilon \to 0 \quad \text{strongly in } C^0([0,T];L^1(\Omega)). \end{cases} \tag{2.6}$$

Remark 2.4. Let us point out that hypothesis (1.4) implies that

$$\chi_{\Omega_\epsilon} \to 1 \text{ strongly in } L^p(\Omega) \quad \text{for all } p \text{ with } 1 \leq p, < +\infty.$$

Indeed, since $w_\epsilon \chi_{S_\epsilon} \equiv 0$ in Ω, we have

$$\int_\Omega |1 - \chi_{\Omega_\epsilon}|^p dx = m(S_\epsilon) = \int_{S_\epsilon} (1 - w_\epsilon)^2 dx \leq \int_\Omega (1 - w_\epsilon)^2 dx,$$

and the last integral tends to zero since $w_\epsilon \to 1$ strongly in $L^2(\Omega)$. Consequently, if $\{h_\epsilon\} \subset L^2(\Omega)$ with

$$h_\epsilon \rightharpoonup h \quad \text{weakly in } L^2(\Omega),$$

and if $H_\epsilon = h_\epsilon|_{\Omega_\epsilon}$, then

$$\tilde{H}_\epsilon \rightharpoonup h \quad \text{weakly in } L^2(\Omega).$$

Remark 2.5. From (2.5) and Remark 1.1 it follows that

$$\widetilde{u_\epsilon}(x,t) = u(x,t) + \rho_\epsilon(x,t) \quad \text{in } D_{\alpha-\delta}$$

with δ sufficiently small. Then, from Proposition 2.3 we deduce that

$$\widetilde{u_\epsilon} \to u \quad \text{strongly in } C^0([0,T]; W^{1,1}(D_{\alpha-\delta})).$$

This convergence holds even in $C^0([0,T]; H^1(D_{\alpha-\delta}))$. This is a simple consequence of the fact that $w_\epsilon \equiv 1$ in $D_{\alpha-\delta}$ and follows easily from the proof of Theorem 4.1 in [2].

Similarly, also using hypothesis (2.3)(iii) we have

$$u_\epsilon^0|_{D_{\alpha-\delta}} \to u^0 \quad \text{strongly in } H^1(D_{\alpha-\delta}).$$

2.2. Convergence of the normal derivative on $\partial\Omega$. In [3] it is shown that if the convergence in hypothesis (1.4)(iii) is strong in $H^1(\Omega)$, and if

$$\{\widetilde{u_\epsilon^0}, \widetilde{u_\epsilon^1}, \tilde{f}_\epsilon\} \rightharpoonup \{u^0, u^1, f\} \quad \text{weakly in } H_0^1(\Omega) \times L^2(\Omega) \times L^2(\Omega \times (0,T)), \tag{2.7}$$

then

$$\left.\frac{\partial u_\epsilon}{\partial \nu}\right|_{\partial\Omega\times(0,T)} \rightharpoonup \left.\frac{\partial u}{\partial \nu}\right|_{\partial\Omega\times(0,T)} \quad \text{weakly in } L^2(\partial\Omega \times (0,T)). \tag{2.8}$$

Note that the strong convergence in (1.4)(iii) implies that $\mu \equiv 0$. Now, as pointed out in Remark 1.1, if Ω_ϵ satisfies (1.4) and (1.5), supp $\mu \subset \Omega \backslash D_\alpha$. This allows us to state the following result.

PROPOSITION 2.6. *Let u_ϵ be a solution of* (2.1) *and suppose that $\{u_\epsilon^0, u_\epsilon^1, f_\epsilon\}$ satisifes* (2.7). *Then if Ω_ϵ satisfies hypotheses* (1.4) *and* (1.5), *we have* (2.8). *Assume further that the data satisfy* (2.3). *Then the convergence* (2.8) *is strong.*

Sketch of proof. We follow along the lines of the proof of Lemma 4.6 in [3]. Essentially, the result is a consequence of the following inequality (see Lemma 4.5 in [3]):

$$\begin{cases} \left\| \frac{\partial u_\epsilon}{\partial \nu} \right\|_{L^2(\partial\Omega\times(0,T))} \leq C\{\|u_\epsilon\|_{H^1(D_{\alpha-\delta}\times(0,T))} + \|u_\epsilon^0\|_{H^1(D_{\alpha-\delta})} + \|u_\epsilon^1\|_{L^2(D_{\alpha-\delta})} \\ \qquad\qquad + \|u_\epsilon(T)\|_{H^1(D_{\alpha-\delta})} + \|u_\epsilon'(T)\|_{L^2(D_{\alpha-\delta})} \\ \qquad\qquad + \|f_\epsilon\|_{L^1(0,T;L^2(D_{\alpha-\delta}))}\}. \end{cases} \tag{2.9}$$

This inequality can easily be obtained by multiplying by $h \cdot \nabla u_\epsilon$ the equation defining u_ϵ, where $h \in (W^{1,\infty}(\Omega))^n$, $h = \nu$ on $\partial\Omega$, and supp $h \subset D_{\alpha-\delta}$. This implies, due to the hypotheses, that for a subsequence

$$\frac{\partial u_\epsilon}{\partial \nu} \rightharpoonup \xi \quad \text{weakly in } L^2(\partial\Omega \times (0,T)).$$

The same argument as in [3] shows that, in fact, $\xi = (\partial u/\partial \nu)$ and therefore the whole sequence converges.

To prove the last statement of the proposition, we again apply Lemma 4.5 from [3] to obtain the equivalent of (2.9) written for $u_\epsilon - u$:

$$\begin{cases} \left\| \frac{\partial(u_\epsilon - u)}{\partial \nu} \right\|_{L^2(\partial\Omega\times(0,T))} \le C\{\|u_\epsilon - u\|_{H^1(D_{\alpha-\delta}\times(0,T))} + \|u_\epsilon^0 - u^0\|_{H^1(D_{\alpha-\delta})} \\ \qquad + \|u_\epsilon^1 - u^1\|_{L^2(D_{\alpha-\delta})} \\ \qquad + \|u_\epsilon(T) - u(T)\|_{H^1(D_{\alpha-\delta})} \\ \qquad + \|u_\epsilon'(T) - u'(T)\|_{L^2(D_{\alpha-\delta})} \\ \qquad + \|f_\epsilon - f\|_{L^1(0,T;L^2(D_{\alpha-\delta}))}\}. \end{cases} \tag{2.10}$$

Let $\epsilon \to 0$. Then, as a consequence of hypothesis (2.3), Proposition 2.3, and Remark 2.5, each term in the right-hand side of the inequality converges to zero.

3. Proof of the main results.

3.1. Definition of F_ϵ. Before proving Theorems 1.3 and 1.4, let us briefly describe the construction of the space F_ϵ introduced in HUM.

Consider the wave equation

$$\begin{cases} \varphi_\epsilon'' - \Delta\varphi_\epsilon = 0 \quad \text{in } \Omega_\epsilon \times (0,T) \\ \varphi_\epsilon = 0 \quad \text{on } \partial\Omega_\epsilon \times (0,T) \\ \varphi_\epsilon(0) = \varphi_\epsilon^0 \quad \text{in } \Omega_\epsilon \\ \varphi_\epsilon'(0) = \varphi_\epsilon^1 \quad \text{in } \Omega_\epsilon \end{cases} \tag{3.1}$$

and define

$$\|\{\varphi_\epsilon^0, \varphi_\epsilon^1\}\|_{F_\epsilon} = \left(\int_0^T \int_{\Gamma_0} \left(\frac{\partial \varphi_\epsilon}{\partial \nu} \right)^2 d\sigma\, dt \right)^{1/2}, \tag{3.2}$$

where Γ_0 is a nonempty open subset of $\partial\Omega_\epsilon$ ($d\sigma$ denotes the surface measure on $\partial\Omega_\epsilon$). If T is large enough, by Holmgren's uniqueness theorem it follows that $\|\{\cdot,\cdot\}\|_{F_\epsilon}$ is a norm in $\mathcal{D}(\Omega_\epsilon) \times \mathcal{D}(\Omega_\epsilon)$. Then F_ϵ is defined as the Hilbert space obtained by completion of $\mathcal{D}(\Omega_\epsilon) \times \mathcal{D}(\Omega_\epsilon)$ for this norm. It is proved that there is exact controllability with controls in $L^2(\partial\Omega \times (0,T))$ if and only if the initial data $\{y_\epsilon^1, y_\epsilon^0\} \in F_\epsilon'$ (for details we refer the reader to Lions [7], [8]).

As mentioned above, when Ω_ϵ is smooth, $F_\epsilon = H_0^1(\Omega_\epsilon) \times L^2(\Omega_\epsilon)$ if and only if any generalized ray of geometric optics meets Γ_0 in a time less or equal to T (cf. [1]). On the other hand, if Ω_ϵ is C^2, by multiplier techniques, we can show that $F_\epsilon = H_0^1(\Omega_\epsilon) \times L^2(\Omega_\epsilon)$ if $T > 2\|x - x_0\|_{L^\infty(\Omega_\epsilon)}$ and $\Gamma_0^\epsilon = \{x \in \partial\Omega_\epsilon : (x - x_0) \cdot \nu_\epsilon(x) > 0\}$ for some $x_0 \in \mathbb{R}^n$, $\nu_\epsilon(x)$ being the outward unit vector to Ω_ϵ at point $x \in \partial\Omega_\epsilon$.

If we take $\Gamma_0^\epsilon = \Gamma_0 \subset \partial\Omega$, this condition is not satisified. Moreover, as $\epsilon \to 0$, there is an increasing number of generalized rays that never reach $\partial\Omega$ (see Fig. 1, where $\Gamma_1 = \partial\Omega \backslash \Gamma_0$), the space F_ϵ becomes larger and larger, and consequently F_ϵ' is smaller and smaller. It is quite impossible to characterize these spaces. Note, for example, that

F_ϵ may contain elements which are not distributions on Ω_ϵ. We know that F'_ϵ is strictly contained in $H^{-1}(\Omega_\epsilon)\times L^2(\Omega_\epsilon)$. What Theorem 1.3 shows is that, actually, each element of $H^{-1}(\Omega)\times L^2(\Omega)$ is a (strong) limit of appropriate elements of F'_ϵ, namely, $\{y'_\epsilon(0), -y_\epsilon(0)\}$, where y_ϵ is solution of (1.8).

3.2. Proof of Theorem 1.3. The function y_ϵ is a solution of (1.8) in the transposition sense, i.e., y_ϵ satisfies

$$\langle\{y'_\epsilon(0), -y_\epsilon(0)\}, \{\theta^0_\epsilon, \theta^1_\epsilon\}\rangle - \int_0^T \int_{\Omega_\epsilon} y_\epsilon f_\epsilon \, dx\, dt = \int_0^T \int_{\partial\Omega} v \frac{\partial\theta_\epsilon}{\partial\nu} d\sigma\, dt \tag{3.3}$$

for every $f_\epsilon \in L^1(0,T;L^2(\Omega_\epsilon)), \theta^0_\epsilon \in H^1_0(\Omega_\epsilon), \theta^1_\epsilon \in L^2(\Omega_\epsilon)$, where θ_ϵ is the unique solution of

$$\begin{cases} \theta''_\epsilon - \Delta\theta_\epsilon = f_\epsilon & \text{in } \Omega_\epsilon \times (0,T) \\ \theta_\epsilon = 0 & \text{on } \partial\Omega_\epsilon \times (0,T) \\ \theta_\epsilon(0) = \theta^0_\epsilon \\ \theta'_\epsilon(0) = \theta^1_\epsilon & \text{in } \Omega_\epsilon. \end{cases} \tag{3.4}$$

From [7] it is known that there exists a unique $y_\epsilon \in C([0,T];L^2(\Omega_\epsilon))\cap C^1([0,T];H^{-1}(\Omega_\epsilon))$ satisfying (3.3).

Let us first show that $\{y'_\epsilon(0), -y_\epsilon(0)\} \in F'_\epsilon$.

By the definition of F'_ϵ, we know that $\{y'_\epsilon(0), y_\epsilon(0)\} \in F'_\epsilon$ if and only if

$$|\langle\{y'_\epsilon(0), -y_\epsilon(0)\}, \{\varphi^0_\epsilon, \varphi^1_\epsilon\}\rangle| \le C\left(\int_0^T \int_{\Gamma_0} \left|\frac{\partial\varphi_\epsilon}{\partial\nu}\right|^2 d\sigma\, dt\right)^{1/2} \tag{3.5}$$

for all $\{\varphi^0_\epsilon, \varphi^1_\epsilon\} \in H^1_0(\Omega_\epsilon)\times L^2(\Omega_\epsilon)$ with φ_ϵ solution of (3.1).

By transposition we have the identity

$$\langle\{y'_\epsilon(0), -y_\epsilon(0)\}, \{\varphi^0_\epsilon, \varphi^1_\epsilon\}\rangle = \int_0^T \int_{\Gamma_0} v \frac{\partial\varphi_\epsilon}{\partial\nu} d\sigma\, dt,$$

from which (3.5) follows obviously since $v \in L^2(\Gamma_0 \times (0,T))$.

In order to prove convergence (1.9)(i) let us choose in (3.3) $\theta^0_\epsilon = \theta^1_\epsilon = 0$ and f_ϵ such that

$$\begin{cases} f_\epsilon \in L^2(\Omega\times(0,T)) \\ f_\epsilon \rightharpoonup f \quad \text{weakly in } L^2(\Omega\times(0,T)). \end{cases} \tag{3.6}$$

We claim that

$$\int_0^T \int_\Omega \widetilde{y}_\epsilon f_\epsilon \, dx\, dt \to \int_0^T \int_\Omega y\, f \, dx\, dt, \tag{3.7}$$

which is precisely convergence (1.9)(i).

To begin with the proof of this claim, we remark that Proposition 2.1 can be applied to θ_ϵ, a solution of system (3.4), all its assumptions being fulfilled. It follows that

$$\tilde{\theta}_\epsilon \rightharpoonup \theta \quad \text{weakly * in } L^\infty(0,T;H^1_0(\Omega)),$$

where θ satisfies the limit system

$$\begin{cases} \theta'' - \Delta\theta + \mu\theta = f & \text{in } \Omega\times(0,T) \\ \theta = 0 & \text{on } \partial\Omega\times(0,T) \\ \theta(0) = \theta'(0) = 0 & \text{in } \Omega. \end{cases}$$

Moreover, Proposition 2.6 asserts that

$$\left.\frac{\partial\theta_\epsilon}{\partial\nu}\right|_{\partial\Omega\times(0,T)} \rightharpoonup \left.\frac{\partial\theta}{\partial\nu}\right|_{\partial\Omega\times(0,T)} \quad \text{weakly in } L^2(\partial\Omega\times(0,T)),$$

the domain Ω_ϵ satisfying hypothesis (1.5). This convergence shows that

$$\lim_{\epsilon\to 0}\int_0^T\int_{\Omega_\epsilon} y_\epsilon f_\epsilon dx\,dt = \lim_{\epsilon\to 0}\int_0^T\int_\Omega \widetilde{y}_\epsilon f_\epsilon\,dx\,dt = -\int_0^T\int_{\partial\Omega} v\frac{\partial\theta}{\partial\nu}d\sigma\,dt.$$

Let us now consider the solution y of system (1.6) introduced in Theorem 1.3. Since v is the exact control, we have $y(T) = y'(T) = 0$. Thus y, which is also defined by transposition, satisfies

$$\langle\{y'(0), -y(0)\},\{\eta^0,\eta^1\}\rangle - \int_0^T\int_\Omega y\,g\,dx\,dt = \int_0^T\int_{\partial\Omega} v\frac{\partial\eta}{\partial\nu}d\sigma\,dt \tag{3.8}$$

for all $g \in L^1(0,T;L^2(\Omega)), \eta^0 \in H_0^1(\Omega), \eta^1 \in L^2(\Omega)$ with η the unique solution of

$$\begin{cases} \eta'' - \Delta\eta + \mu\eta = g & \text{in } \Omega\times(0,T)\\ \eta = 0 & \text{on } \partial\Omega\times(0,T)\\ \eta(0) = \eta^0 & \\ \eta'(0) = \eta^1 & \text{in } \Omega. \end{cases}$$

In particular, (3.8) holds for $g = f$ and $\eta^0 = \eta^1 = 0$, in which case, by uniqueness, $\eta = \theta$, and thus (3.7) holds.

It remains to prove the convergences (1.9)(ii) and (1.9)(iii). To do that, we will make use several times of the formulation by transposition of the system defining y_ϵ, with particular choices of the test function. First let ρ_ϵ satisfy the following system:

$$\begin{cases} \rho_\epsilon'' - \Delta\rho_\epsilon = 0 & \text{in } \Omega_\epsilon\times(0,T)\\ \rho_\epsilon = 0 & \text{on } \partial\Omega_\epsilon\times(0,T)\\ \rho_\epsilon(0) = 0 & \text{in } \Omega_\epsilon\\ \rho_\epsilon'(0) = \rho_\epsilon^1 & \text{in } \Omega_\epsilon. \end{cases}$$

With this ρ_ϵ as test function in the definition by transposition of y_ϵ, we have

$$0 = \int_{\Omega_\epsilon} y_\epsilon(0)\rho_\epsilon^1 dx + \int_0^T\int_{\partial\Omega} v\frac{\partial\rho_\epsilon}{\partial\nu}d\sigma\,dt.$$

Suppose that $\rho_\epsilon^1 = \overline{\rho_\epsilon^1}|_{\Omega_\epsilon}$ with

$$\overline{\rho_\epsilon^1} \rightharpoonup \rho^1 \quad \text{weakly in} L^2(\Omega).$$

Propositions 2.3 and 2.6 show that

$$\begin{cases} \left.\frac{\partial\rho_\epsilon}{\partial\nu}\right|_{\partial\Omega\times(0,T)} \rightharpoonup \left.\frac{\partial\rho}{\partial\nu}\right|_{\partial\Omega\times(0,T)} & \text{weakly in } L^2(\partial\Omega\times(0,T))\\ \widetilde{\rho}_\epsilon \rightharpoonup \rho \quad \text{weakly * in } L^\infty(0,T;H_0^1(\Omega)) \end{cases}$$

with the ρ solution of

$$\begin{cases} \rho'' - \Delta\rho + \mu\rho = 0 & \text{in } \Omega\times(0,T)\\ \rho = 0 & \text{on } \partial\Omega\times(0,T)\\ \rho(0) = 0 & \text{in } \Omega\\ \rho'(0) = \rho^1 & \text{in } \Omega \end{cases} \tag{3.9}$$

and, arguing as before, we have

$$\lim_{\epsilon\to 0}\int_{\Omega_\epsilon} y_\epsilon(0)\rho_\epsilon^1\,dx = \lim_{\epsilon\to 0}\int_\Omega \widetilde{y_\epsilon(0)}\overline{\rho_\epsilon^1}dx = -\int_0^T\int_{\partial\Omega} v\frac{\partial\rho}{\partial\nu}\,d\sigma\,dt. \tag{3.10}$$

From the definition, by transposition of y written with the ρ solution of (3.9) as a test function, we have immediately that

$$0 = \int_\Omega y^0\rho^1\,dx + \int_{\partial\Omega} v\frac{\partial\rho}{\partial\nu}d\sigma\,dt,$$

which, combined with (3.10), gives

$$\lim_{\epsilon\to 0}\int_\Omega \widetilde{y_\epsilon(0)}\overline{\rho_\epsilon^1}dx = \int_\Omega y^0\rho^1 dx;$$

thus convergence (1.9)(ii) is established.

To prove (1.9)(iii), let $\psi_\epsilon^0 \in W_0^{1,q'}(\Omega)$ be a sequence such that

$$\psi_\epsilon^0 \rightharpoonup \psi^0 \quad \text{weakly in} W_0^{1,q'}(\Omega), \tag{3.11}$$

where $1/q' + 1/q = 1$, with $q \in (1, n/(n-1))$.

Now let ξ_ϵ be a solution of

$$\begin{cases} \xi_\epsilon'' - \Delta\xi_\epsilon = 0 \quad \text{in } \Omega_\epsilon \times (0,T) \\ \xi_\epsilon = 0 \quad \text{on } \partial\Omega_\epsilon \times (0,T) \\ \xi_\epsilon(0) = \psi_\epsilon^0 w_\epsilon \quad \text{in } \Omega_\epsilon \\ \xi_\epsilon'(0) = 0 \quad \text{in } \Omega, \end{cases}$$

where w_ϵ are the functions introduced in hypothesis (1.4).

With this ξ_ϵ as a test function, y_ϵ satisfies

$$0 = \langle y_\epsilon'(0), \psi_\epsilon^0 w_\epsilon\rangle_{H^{-1}(\Omega_\epsilon),H_0^1(\Omega_\epsilon)} - \int_0^T\int_{\partial\Omega} v\frac{\partial\xi_\epsilon}{\partial\nu}d\sigma\,dt. \tag{3.12}$$

By the definition (1.7) of the extension operator P_ϵ given in §1, we have

$$\begin{aligned} \langle P_\epsilon y_\epsilon'(0), \psi_\epsilon^0\rangle_{W^{-1,q}(\Omega),W_0^{1,q'}(\Omega)} &= \langle w_\epsilon\widetilde{y_\epsilon'(0)}, \psi_\epsilon^0\rangle_{W^{-1,q}(\Omega),W_0^{1,q'}(\Omega)} \\ &= \langle y_\epsilon'(0), w_\epsilon\psi_\epsilon^0|_{\Omega_\epsilon}\rangle_{H^{-1}(\Omega_\epsilon),H_0^1(\Omega_\epsilon)}. \end{aligned} \tag{3.13}$$

The second duality makes sense because the definitions of w_ϵ and ψ_ϵ^0 imply that $w_\epsilon\psi_\epsilon^0 \in H_0^1(\Omega_\epsilon)$. Moreover, by hypothesis (1.4), $w_\epsilon\psi_\epsilon^0 \rightharpoonup \psi^0$ weakly in $H_0^1(\Omega)$.

Once again, by Propositions 2.1 and 2.6, we have, from (3.12) and (3.13), that

$$\lim_{\epsilon\to 0}\langle P_\epsilon y_\epsilon'(0), \psi_\epsilon^0\rangle_{W^{-1,q}(\Omega),W_0^{1,q'}(\Omega)} = \int_0^T\int_{\partial\Omega} v\frac{\partial\xi}{\partial\nu}d\sigma\,dt, \tag{3.14}$$

where ξ is a solution of

$$\begin{cases} \xi'' - \Delta\xi + \mu\xi = 0 \quad \text{in } \Omega \times (0,T) \\ \xi = 0 \quad \text{on } \partial\Omega \times (0,T) \\ \xi(0) = \psi^0 \quad \text{in } \Omega \\ \xi'(0) = 0 \quad \text{in } \Omega. \end{cases}$$

Now, as before, take ξ as a test function for the definition by transposition of y. It comes about that

$$\langle y^1, \psi^0\rangle_{H^{-1}(\Omega),H_0^1(\Omega)} = \int_0^T\int_{\partial\Omega} v\frac{\partial\xi}{\partial\nu}d\sigma\,dt \tag{3.15}$$

which, with (3.14), gives the claimed result and completes the proof of Theorem 1.3. □

3.3. Proof of Theorem 1.4. The tool for proving Theorem 1.4 is exactly the same as in the previous proof, i.e., the choice of particular test functions in the formulation by transposition of the solution y_ϵ. We give here only the main steps. We have, by definition,

$$\left\{\begin{array}{l} \displaystyle\int_0^T\int_{\Omega_\epsilon} y_\epsilon f_\epsilon\,dx\,dt = -\int_{\Omega_\epsilon} y_\epsilon^0\theta_\epsilon'(0)dx \\ \qquad\qquad + \langle y_\epsilon^1, \theta_\epsilon(0)\rangle_{H^{-1}(\Omega_\epsilon),H_0^1(\Omega_\epsilon)} - \displaystyle\int_0^T\int_{\partial\Omega} v\frac{\partial\theta_\epsilon}{\partial\nu}d\sigma\,dt, \\ \qquad\qquad \forall f_\epsilon \in L^1(0,T;L^2(\Omega_\epsilon)) \end{array}\right. \tag{3.16}$$

with θ_ϵ solution of

$$\left\{\begin{array}{l} \theta_\epsilon'' - \Delta\theta_\epsilon = f_\epsilon \quad \text{in } \Omega_\epsilon\times(0,T) \\ \theta_\epsilon = 0 \quad \text{on } \partial\Omega_\epsilon\times(0,T) \\ \theta_\epsilon(T) = \theta_\epsilon'(T) = 0 \quad \text{in } \Omega_\epsilon. \end{array}\right. \tag{3.17}$$

Take in (3.17) f_ϵ satisfying (3.6). We will pass to the limit in identity (3.16). To do that, apply Proposition 2.1 (see also Remark 2.2) to θ_ϵ. We have

$$\widetilde{\theta_\epsilon} \rightharpoonup \theta \quad \text{weakly * in } L^\infty(0,T;H_0^1(\Omega))$$

with θ the unique solution of

$$\left\{\begin{array}{l} \theta'' - \Delta\theta + \mu\theta = f \quad \text{in } \Omega\times(0,T) \\ \theta = 0 \quad \text{on } \partial\Omega\times(0,T) \\ \theta(T) = \theta'(T) = 0 \quad \text{in } \Omega \end{array}\right.$$

and, by Proposition 2.6,

$$\left.\frac{\partial\theta_\epsilon}{\partial\nu}\right|_{\partial\Omega\times(0,T)} \rightharpoonup \left.\frac{\partial\theta}{\partial\nu}\right|_{\partial\Omega\times(0,T)} \quad \text{weakly in } L^2(\partial\Omega\times(0,T)).$$

Moreover, from Proposition 2.1 we also have the following pointwise convergences:

$$\begin{array}{l} \widetilde{\theta_\epsilon}(t) \rightharpoonup \theta(t) \quad \text{weakly in } H_0^1(\Omega) \\ \widetilde{\theta_\epsilon'}(t) \rightharpoonup \theta'(t) \quad \text{weakly in } L^2(\Omega) \end{array}$$

for all $t\in[0,T]$. These convergences enable us to pass to the limit in the right-hand side term of identity (3.16). Recalling the definitions of y_ϵ^0 and y_ϵ^1, we have, successively,

$$\begin{array}{l} \langle y_\epsilon^0, \theta_\epsilon'(0)\rangle_{L^2(\Omega_\epsilon),L^2(\Omega_\epsilon)} = \displaystyle\int_\Omega y^0\widetilde{\theta_\epsilon'(0)}dx \to \int_\Omega y^0\theta'(0)dx \\ \langle y_\epsilon^1, \theta_\epsilon(0)\rangle_{H^{-1}(\Omega_\epsilon),H_0^1(\Omega_\epsilon)} = \langle y^1, \widetilde{\theta_\epsilon(0)}\rangle_{H^{-1}(\Omega),H_0^1(\Omega)} \to \langle y^1,\theta(0)\rangle_{H^{-1}(\Omega),H_0^1(\Omega)}, \end{array}$$

hence

$$\left\{\begin{array}{l} \displaystyle\lim_{\epsilon\to0}\int_0^T\int_{\Omega_\epsilon}\widetilde{y_\epsilon}f_\epsilon dx\,dt = -\int_\Omega y^0\theta'(0)dx \\ \qquad\qquad +\langle y^1,\theta(0)\rangle_{H^{-1}(\Omega),H_0^1(\Omega)} - \displaystyle\int v\frac{\partial\theta}{\partial\nu}d\sigma\,dt. \end{array}\right. \tag{3.18}$$

Consider the formulation by transposition of system (1.6) with θ as a test function:

$$\int_0^T \int_\Omega yf\,dx\,dt = -\int_\Omega y^0\theta'(0)dx + \langle y^1, \theta(0)\rangle_{H^{-1}(\Omega),H_0^1(\Omega)} - \int_0^T \int_{\partial\Omega} v\frac{\partial\theta}{\partial\nu}d\sigma\,dt.$$

This identity combined with (3.18) gives the strong convergence in $L^2(\Omega)$ of $\widetilde{y_\epsilon}$ and thus (1.10) is proved.

To prove convergence (1.11), first let ρ_ϵ be the solution of

$$\text{(3.19)}\qquad \begin{cases} \rho_\epsilon'' - \Delta\rho_\epsilon = 0 \quad \text{in } \Omega_\epsilon \times (0,T) \\ \rho_\epsilon = 0 \quad \text{on } \partial\Omega_\epsilon \times (0,T) \\ \rho_\epsilon(T) = 0 \quad \text{in } \Omega_\epsilon \\ \rho_\epsilon'(T) = \rho_\epsilon^1|_{\Omega_\epsilon} \quad \text{in } \Omega_\epsilon \end{cases}$$

where

$$\rho_\epsilon^1 \rightharpoonup \rho^1 \quad \text{weakly in } L^2(\Omega).$$

By transposition, y_ϵ satisfies, in particular,

$$0 = \int_{\Omega_\epsilon} y_\epsilon(T)\rho_\epsilon^1\,dx - \int_{\Omega_\epsilon} y_\epsilon^0\rho_\epsilon'(0)\,dx + \langle y_\epsilon^1, \rho_\epsilon(0)\rangle_{H^{-1}(\Omega_\epsilon),H_0^1(\Omega_\epsilon)} - \int_0^T \int_{\partial\Omega} v\frac{\partial\rho_\epsilon}{\partial\nu}d\sigma\,dt.$$

Passing to the limit as before, we have that

$$\text{(3.20)}\qquad \begin{cases} \lim_{\epsilon\to 0}\int_{\Omega_\epsilon} y_\epsilon(T)\rho_\epsilon^1\,dx = \lim_{\epsilon\to 0}\int_\Omega \widetilde{y_\epsilon(T)}\rho_\epsilon^1\,dx \\ \qquad = \int_\Omega y^0\rho'(0)dx - \langle y^1, \rho(0)\rangle_{H^{-1}(\Omega),H_0^1(\Omega)} + \int_0^T \int_{\partial\Omega} v\frac{\partial\rho}{\partial\nu}d\sigma\,dt, \end{cases}$$

where ρ is the solution of the limit system for (3.19) given by Proposition 2.1, i.e., ρ satisfies

$$\begin{cases} \rho'' - \Delta\rho + \mu\rho = 0 \quad \text{in } \Omega \times (0,T) \\ \rho = 0 \quad \text{on } \partial\Omega \times (0,T) \\ \rho(T) = 0 \quad \text{in } \Omega \\ \rho'(T) = \rho^1 \quad \text{in } \Omega. \end{cases}$$

On the other hand, with this ρ as a test function in the definition of y we obtain

$$-\int_\Omega y^0\rho'(0)dx + \langle y^1, \rho(0)\rangle_{H^{-1}(\Omega),H_0^1(\Omega)} - \int v\frac{\partial\rho}{\partial\nu}d\sigma\,dt = 0,$$

which, combined with (3.20), leads to

$$\lim_{\epsilon\to 0}\int_\Omega \widetilde{y_\epsilon(T)}\rho_\epsilon^1\,dx = 0,$$

hence (1.11)(i) is proved.

Finally, to prove (1.11)(ii), take, as in the last step of the proof of Theorem 1.3, $\psi_\epsilon^0 \in W_0^{1,q'}(\Omega)$ satisfying (3.11) and choose as a test function in (3.16) the solution ξ_ϵ of the system

$$\begin{cases} \xi_\epsilon'' - \Delta\xi_\epsilon = 0 \quad \text{in } \Omega_\epsilon \times (0,T) \\ \xi_\epsilon = 0 \quad \text{on } \partial\Omega_\epsilon \times (0,T) \\ \xi_\epsilon(T) = \psi_\epsilon^0 w_\epsilon \quad \text{in } \Omega_\epsilon \\ \xi_\epsilon'(T) = 0 \quad \text{in } \Omega_\epsilon. \end{cases}$$

Arguing for the proof of (3.15), we obtain

$$\lim_{\epsilon\to 0} \langle P_\epsilon y_\epsilon'(T), \psi_\epsilon^0 \rangle_{W^{-1,q}(\Omega), W_0^{1,q'}(\Omega)} = 0,$$

which ends the proof of Theorem 1.5. □

4. Examples and Related Problems. Here we give some examples where hypothesis (1.4) is satisfied. For instance, that is the case when S_ϵ is the union of periodically distributed holes (the period is 2ϵ) of critical size

$$S_\epsilon = \cup_{i=1}^{N_\epsilon} T_i^\epsilon,$$

where T_i^ϵ are balls of radius $\gamma^\epsilon = a^\epsilon$ with

$$a_\epsilon = \begin{cases} \delta_\epsilon \exp\left(-\frac{c_0}{\epsilon^2}\right) & \text{if } n = 2 \\ c_0 \epsilon^{n/n-2} & \text{if } n > 2, \end{cases}$$

where c_0 is a positive constant and δ_ϵ is such that $\epsilon^2 \log \delta_\epsilon \to 0$. Hypothesis (1.4) holds with

$$\begin{cases} \mu = \frac{\pi}{2}\frac{1}{c_0} & \text{if } n = 2 \\ \mu = \frac{s_n(n-2)}{2n} c_0^{n-2} & \text{if } n \geq 3, \end{cases}$$

where s_n is the surface of the unit sphere in $\mathbb{R}^n$. It is this size a_ϵ which, in the elliptic case, transforms $-\Delta$ in $-\Delta + \mu$, as it was proved in [6] where more examples can be found as well as explicit computations of w_ϵ. Of course, in this example when ϵ goes to zero the number of holes tends to ∞.

When $a_\epsilon \ll \gamma_\epsilon$, hypothesis (1.4) holds with $\mu = 0$. For this situation, with Ω satisfying hypothesis (1.5), the equivalent of Theorems 1.3 and 1.4 were partially proved in [4].

DENSITY RESULTS FOR PROPER EFFICIENCIES*

DEMING ZHUANG†

Abstract. Several density results are established for different notions of proper efficiency in vector optimization without the requirement of ordering cones being boundedly based. For a compact set, the set of Henig proper efficient points is shown to be dense in the set of all efficient points. Density theorems for Borwein's proper efficiency and for positive scalarizable efficiency follow immediately with appropriate assumptions.

Key words. vector optimization, proper efficiency, density results, bases of ordering convex cones

AMS subject classifications. 49A27, 46A40, 90C31

1. Introduction and preliminaries. Vector optimization problems originated from decision-making problems appearing in economics, management science, and social science, where it is often required that decision making be based on optimizing several criteria. A vector optimization problem therefore involves finding all efficient points in some vector partial order. However, some efficient points (see Example 2.1) exhibit certain abnormal properties: They may cause arbitrarily large marginal trade off or may not be expressed as a solution of an appropriate linear scalar optimization problem. Therefore, various concepts of proper efficiency have been introduced to eliminate such anomalous efficient points. Any reasonable concept of proper efficiency should retain most of the efficient points and exclude only anomalous ones. Thus, when a new proper efficiency is introduced, it is important to study density results—sufficient conditions to guarantee that the closure of the set of proper efficient points contains all efficient points. Density results for various proper efficiencies have been considered by many authors (e.g., see [1]–[4], [11]–[15], [17], [21], [24]). Most previous results required compactness, or at least boundedness, of the base of the ordering cones. While those results have proved to be important in applications, one notable limitation is that many natural ordering cones in infinite-dimensional normed linear spaces do not have bases that are bounded, let alone compact. Recently, Dauer and Gallagher [12] established some interesting density results without the requirement of ordering cones being boundedly based. In this note, we show density results for several kinds of proper efficiencies without such a requirement. The machinery developed here also enables us to derive much stronger results when the boundedness of the base of the ordering cone is present. This is demonstrated in [9]; see also [25].

For the sake of simplicity, we make the following assumptions (unless specifically stated otherwise). Throughout the note, X will always be a partially ordered real normed linear space and a subset C of X is always assumed to be nonempty. The partial ordering cone S of X is always assumed to be closed, convex ($S+S \subset S$), and pointed ($S \cap -S\{0\}$). We associate a *dual cone* with S, denoted by S^+, in X^* (the norm dual of X)

$$S^+ := \{\phi \in X^* | \phi(s) \geq 0 \quad \forall s \in S\}.$$

Then S^+ is a convex cone and is closed in $\sigma(X^*, X)$, the weak-star topology.

Recall that a *base* of a cone S is a convex subset Θ of S such that

$$S = \{\lambda\theta | \lambda \geq 0 \text{ and } \theta \in \Theta\} \quad \text{and} \quad 0 \notin \text{cl}(\Theta).$$

Of course, S is pointed if S has a base. We also use the following notation:

(1) cone(A) denotes the cone generated by the set A, i.e.,

$$\text{cone}(A) := \cup\{tA | t \geq 0\};$$

while cl[cone(A)] denotes the closure of cone(A);

(2) S^{+i} denotes the set of all strictly positive linear functionals in S^+, that is,

$$S^{+i} := \{f \in X^* | f(s) > 0 \text{ for all } s \text{ in } S \text{ and } s \neq 0\}.$$

It follows directly from the Hahn–Banach theorem that S^{+i} is nonempty exactly when S has a base.

2. Proper efficiencies. Efficiency (Pareto minimality) is a fundamental concept in vector optimization.

DEFINITION 2.0. A point x_0 in C is said to be an *efficient point* of C with respect to S, written as $x_0 \in E(C, S)$, if

$$(C - \{x_0\}) \cap -S = \{0\}. \tag{2.1}$$

For simplicity, we often write (2.1) as

$$(C - x_0) \cap -S = 0.$$

Note that, as S is assumed to be convex and pointed, we have

$$E(C, S) = E(C + S, S). \tag{2.2}$$

Some efficient points exhibit abnormal behavior.

Example 2.1. Consider

$$\min_S \{(x, y) \in \mathbb{R}^2 | x^2 + y^2 = 1, y \leq 0\},$$

where S is the nonnegative orthant in $\mathbb{R}^2$. Then $(-1, 0)$ is an efficient point with respect to S. However, when x is near -1, y increases as x decreases; moreover,

$$\frac{y - 0}{-1 - x} \to \infty \quad \text{as } x \to -1,$$

i.e., the *marginal trade off* is arbitrarily large. This is an undesirable property [13]. We may also note that the point $(-1, 0)$ is not scalarizable by a strictly positive linear functional.

To eliminate such anomalous types of efficient points, Geoffrion [13] introduced the notion of proper efficiency in $\mathbb{R}^n$ with respect to the usual ordering cone, the nonnegative orthant $\mathbb{R}^n_+$, which extends Kuhn and Tucker's definition of proper efficiency [22].

DEFINITION 2.2. Let C be a subset of $\mathbb{R}^n$. A point $x_0 = (x_0(1), x_0(2), \ldots x_0(n))$ in C is said to be a *Geoffrion proper efficient point* of C, written as $x_0 \in GE(C, \mathbb{R}^n_+)$, if x_0 is efficient and if there is $M > 0$ with the property that whenever $x \in C$ with $x_0(i) > x(i)$ for some $i \in \{1, 2, \ldots, n\}$, we can find some $j \in \{1, 2, \ldots n\} \backslash \{i\}$ such that $x_0(j) < x(j)$ and

$$\frac{x(i) - x_0(i)}{x_0(j) - x(j)} \leq M.$$

According to this definition, the point $(-1, 0)$ in Example 2.1 is not proper efficient.

Geoffrion's notion of proper efficiency was extended to the setting of a locally convex topological linear space with partial ordering induced by a closed convex cone by Borwein in [3].

DEFINITION 2.3. Let X be a normed space and let C be a subset of X. A point x_0 in C is said to be a *Borwein proper efficient* point of C with respect to S, written as $x_0 \in BE(C, S)$, if

$$\text{cl}[\text{cone}(C - x_0)] \cap -S = 0. \tag{2.3}$$

It is clear from these definitions that $BE(C, S) \subset E(C, S)$. The containment can be strict as is demonstrated by an example of the closed Euclidean unit ball in $\mathbb{R}^2$ with respect to $\mathbb{R}^2_+$. In this case $(0, -1)$ and $(-1, 0)$ are efficient but not proper efficient.

Borwein's proper efficiency coincides with Geoffrion's proper efficiency in finite-dimensional settings [3]. Existence results and various scalarization properties of Borwein's proper efficiency can be found in [3], [4], [6], [11], and are surveyed in [8], [10], [19], [20], and elsewhere.

When the ordering cone S has a base Θ, Henig defined another kind of proper efficiency which refines Borwein's proper efficiency in this setting [15].

DEFINITION 2.4. Let X be a normed space and let C be a subset of X. A point x_0 in C is said to be a *Henig proper efficient point* (or Henig point) of C with respect to S (more properly, with respect to Θ), denoted by

$$x_0 \in HE(C, S) \quad \text{or} \quad x_0 \in HE(C, \Theta),$$

if there exists some $\varepsilon > 0$ such that

$$\text{cl}[\text{cone}(C - x_0)] \cap -S_\varepsilon(\Theta) = 0, \tag{2.4}$$

where $S_\varepsilon(\Theta) := \text{cl}[\text{cone}(\Theta + \varepsilon B)]$ and B is the closed unit ball of X. We call $S_\varepsilon(\Theta)$ the *Henig dilating cone*. Note that (2.4) says $x_0 \in BE(C, S_\varepsilon(\Theta))$. In other words, $x_0 \in HE(C, \Theta)$ if and only if, for some $\varepsilon > 0, x_0 \in BE(C, S_\varepsilon(\Theta))$. It is clear that if the ordering cone S has a base Θ, then $HE(C, \Theta) \subset BE(C, S)$, since $S \subset S_\varepsilon(\Theta)$ for all $\varepsilon > 0$. The following example shows that, in general, the containment is strict.

Example 2.5. Let X be $l_1(\mathbb{N})$ and S be the natural ordering cone $l_1+ (\mathbb{N})$ that has a bounded base:

$$\Theta = \{x \in X / \Sigma x(n) = 1 \text{ and } x(n) \geq 0, n = 0, 1, 2, \ldots\}.$$

Let

$$C := \{-e_n + 2^{-(n-1)} e_1 | n = 2, 3, 4, \ldots\} \cup \{0\},$$

where e_i is the ith basis element in $l_1(\mathbb{N})$, that is, $e_i = \{0, \ldots, 1, 0 \ldots)$ with 1 on the ith coordinate.

Then because $\text{cl}[\text{cone}(C)] = \text{cone}(C)$ and $\text{cone}(C) \cap -S = 0$, we have $0 \in BE(C, S)$. However, for $n = 2, 3, \ldots$

$$x_n := -e_n + 2^{-(n-1)} e_1 \in C \cap (2^{-(n-1)} B - \Theta).$$

Hence $0 \notin HE(C, \Theta)$.

3. Density theorem for Henig proper efficiency. We have seen that, in general, the set of Henig proper efficient points is strictly contained in the set of efficient points. In this section, we show that with (weak) compactness of the set C, the set of Henig proper efficient points of C is (weakly dense) norm dense in the set of efficient points.

The following lemma and proposition on properties of Henig dilating cones are keys to the proof of the main theorem. They are partial results in [9]. For the reader's convenience, we present the proof here again.

LEMMA 3.1. *Let X be a normed linear space, $S \subset X$ a closed and convex cone with a closed base Θ. Let $\delta := \inf\{\|\theta\| \,|\theta \in \Theta\} > 0$. Define, for $0 < \varepsilon < \delta$, the Henig dilating cone*

$$S_\varepsilon(\Theta) := \mathrm{cl}[\mathrm{cone}(\Theta + \varepsilon B)].$$

Then $S_\varepsilon(\Theta) = \mathrm{cone}[\mathrm{cl}(\Theta + \varepsilon B)]$ and $S_\varepsilon(\Theta)$ is pointed.

Proof. Let

$$\Theta_\varepsilon := \mathrm{cl}(\Theta + \varepsilon B).$$

Since $S_\varepsilon(\Theta)$ is closed, $\mathrm{cl}[\mathrm{cone}(\Theta_\varepsilon] = S_\varepsilon(\Theta)$. Then since $0 \notin \Theta_\varepsilon$ for $0 < \varepsilon < \delta$,

$$\mathrm{cl}[\mathrm{cone}(\Theta_\varepsilon)] = \mathrm{cone}(\Theta_\varepsilon) \cup R(\Theta_\varepsilon), \tag{3.1}$$

where $R(\Theta_\varepsilon) := \{\lim t_\alpha \theta_\alpha^\varepsilon | t_\alpha \to 0, t_\alpha \geq 0, \theta_\alpha^\varepsilon \in \Theta_\varepsilon\}$.

Indeed, x in $\mathrm{cl}[\mathrm{cone}(\Theta_\varepsilon)]$ implies that x is either in $\mathrm{cone}(\Theta_\varepsilon)$ or

$$x = \lim t_\alpha \theta_\alpha^\varepsilon \quad \text{for } t_\alpha \geq 0 \quad \text{and} \quad \theta_\alpha^\varepsilon \in \Theta_\varepsilon.$$

Without loss of generality (taking subnets if necessary), we may assume that t_α converges. If t_α tends to infinity, then t_α^{-1} tends to zero, which implies that $\theta_\alpha^\varepsilon$ tends to zero. This is impossible as 0 is not in the closure of Θ_ε. Hence, t_α converges to t for some $t < \infty$. If $t = 0$, then x is in $R(\Theta_\varepsilon)$ by the definition. If $t \neq 0$, then as $\Theta_\varepsilon := \mathrm{cl}(\Theta + \varepsilon B)$,

$$\theta_\alpha^\varepsilon \to t^{-1} x \in \Theta_\varepsilon.$$

Hence, $x \in \mathrm{cone}(\Theta_\varepsilon)$. Therefore, (3.1) is verified.

Note that it is easy to check that

$$R(\Theta_\varepsilon) = R(\Theta) \subset S \subset \mathrm{cone}(\Theta_\varepsilon)$$

because Θ is a base for S and S is closed. Whence $\mathrm{cone}(\Theta_\varepsilon) = S_\varepsilon(\Theta)$.

Now, $S_\varepsilon(\Theta) = \mathrm{cone}(\Theta_\varepsilon)$ and has a closed base Θ_ε; hence $S_\varepsilon(\Theta)$ is pointed. □

PROPOSITION 3.2. *Let X be a normed space and suppose the ordering cone S has a closed base Θ. Let*

$$\delta := \inf\{\|\theta\| \,|\theta \in \Theta\}.$$

Then for any set C in X the following are equivalent:

(1) $x_0 \in E(C, S_\varepsilon(\Theta))$ *for some* $0 < \varepsilon < \delta$;

(2) $x_0 \in HE(C, \Theta)$.

Proof. From the definitions,

$$HE(C, \Theta) \subset E(C, S_\varepsilon(\Theta))$$

is clear for any sufficiently small $\varepsilon > 0$. On the other hand, x_0 is in $E(C, S_\varepsilon(\Theta))$ if and only if

$$\operatorname{cone}(C - x_0) \cap -S_\varepsilon(\Theta) = 0.$$

By Lemma 3.1, for $0 < \varepsilon < \delta$, $\operatorname{cl}(\varepsilon B - \Theta)$ is a closed base and

$$-S_\varepsilon(\Theta) = \operatorname{cone}[\operatorname{cl}(\varepsilon B - \Theta)].$$

Thus, for any $0 < \varepsilon' < \varepsilon$, $\operatorname{cone}(C - x_0) \cap (\varepsilon' B - \Theta) = \emptyset$. This implies that

$$\operatorname{cone}(C - x_0) \cap [(2^{-1}\varepsilon' B - \Theta) + 2^{-1}\varepsilon' \operatorname{int}(B)] = \emptyset.$$

Noting that the second set is open, we have

$$\operatorname{cl}[\operatorname{cone}(C - x_0)] \cap \operatorname{cl}(2^{-1}\varepsilon' B - \Theta) = \emptyset.$$

Therefore, by Lemma 3.1 again,

$$\operatorname{cl}[\operatorname{cone}(C - x_0)] \cap \operatorname{cone}[\operatorname{cl}(2^{-1}\varepsilon' B - \Theta)] = \operatorname{cl}[\operatorname{cone}(C - x_0)] \cap -S_{\varepsilon''}(\Theta) = \{0\}$$

for $\varepsilon'' := 2^{-1}\varepsilon'$. This proves that x_0 is in $BE(C, S_{\varepsilon''}(\Theta))$, i.e., $x_0 \in HE(C, \Theta)$. Hence (1) implies (2). □

Now we present our main density theorem. Note that for a fixed closed base Θ, we always have

$$HE(C + S, \Theta) \subset HE(C, \Theta).$$

THEOREM 3.3. *Let X be a normed linear space, let S be a closed ordering cone with a closed base Θ, and let C be a nonempty subset of X.*

(1) *If C is weakly compact, then $HE(C + S, \Theta)$ is weakly dense in $E(C, S)$.*

(2) *If C is norm compact, then $HE(C + S, \Theta)$ is norm dense in $E(C, S)$.*

Proof. (1) Let x_0 be in $E(C, S)$. Without loss of generality, we may assume that $x_0 = 0$. Let

$$\delta := \inf\{\|\theta\| \mid \theta \in \Theta\}.$$

We claim that for any given weak neighbourhood W of 0, we can find $0 < \varepsilon < \delta$ so that

$$C_\varepsilon := C \cap -S_\varepsilon(\Theta) \subset W. \tag{3.2}$$

Indeed, suppose (3.2) were not true; then there would be a continuous linear functional $f \neq 0$ such that for n so large that $1/n < \delta$, we could find c_n in C with the property

$$c_n \in -S_{1/n}(\Theta), \qquad |f(c_n)| \geq 1.$$

Since, by Lemma 3.1,

$$-S_{1/n}(\Theta) = -\operatorname{cone}[\operatorname{cl}(\Theta + n^{-1}B)] \subset -\operatorname{cone}[\Theta + (n-1)^{-1}B],$$

there would be b_n in B, θ_n in Θ, and $t_n > 0$ such that

$$-c_n = t_n[\theta_n + (n-1)^{-1}b_n].$$

Since C is weakly compact we may (on extracting a subnet if necessary) assume that c_n tends to c_0 weakly and t_n tends to $\mu \in [0, \infty]$.

(i) If $\mu = \infty$, then, as $-c_n$ is bounded, $t_n^{-1}(-c_n) = \theta_n + (n-1)^{-1}b_n$ tends to zero. This contradicts the fact $0 \notin \Theta$.

(ii) If $\mu > 0$, we have

$$w - \lim(-c_n) = \mu\theta$$

for some $\theta \in \Theta$. This violates the fact that $0 \in E(C, S)$.

(iii) If $\mu = 0$, then because for all n,

$$-c_n = t_n[\theta_n + (n-1)^{-1}b_n] \geq_S t_n b_n/(n-1),$$

we have $0 \geq_S c_0$, which implies that $0 = c_0$ as $0 \in E(C, S)$. Then for large n,

$$\inf|f(c_n)| \geq 1$$

is clearly impossible. Therefore (3.2) is verified.

Now C_ε is weakly compact, so by Theorem 2.1 in [6], $E(C_\varepsilon, K)$ is not empty for every closed ordering cone K. In particular,

$$E(C_\varepsilon, S_\varepsilon(\Theta)) \neq \emptyset.$$

Let $e \in E(C_\varepsilon, S_\varepsilon(\Theta))$, and we check that $e \in E(C, S_\varepsilon(\Theta))$ and e is in W. Therefore, by Proposition 3.2,

$$E(C, S_\varepsilon(\Theta)) = E(C + S, S_\varepsilon(\Theta)) \subset HE(C + S, \Theta).$$

The first equality holds because $S_\varepsilon(\Theta)$ is convex and pointed. Since both x_0 and W are arbitrarily chosen, we see that $HE(C + S, \Theta)$ is weakly dense in $E(C, S)$.

(2) When C is norm compact then by (1), given x_0 in $E(C, S)$ we can find a net c_α in $HE(C + S, \Theta)$ converging weakly to x_0 and, from the proof, each c_α is in C. Since C is compact in this case, c_α may be assumed to be norm convergent. Therefore $HE(C+S, \Theta)$ is norm dense in $E(C, S)$. □

4. Density results for other proper efficiencies. In this section we derive density results for various other proper efficiencies. These results are established by exploring the relationship between Henig proper efficiency and other proper efficiencies and then applying Theorem 3.3. First, as an easy consequence of Theorem 3.3 we prove a density theorem for Borwein's proper efficiency.

COROLLARY 4.1. *Let X be a normed linear space, let S be a closed ordering cone with a closed base Θ, and let C be a nonempty subset of X.*

(1) *If C is weakly compact, then $BE(C + S, S)$ is weakly dense in $E(C, S)$.*

(2) *If C is norm compact, then $BE(C + S, S)$ is norm dense in $E(C, S)$.*

Proof. When S has a base, $HE(C + S, \Theta) \subset BE(C + S, S)$. □

Let us recall another class of proper efficient points.

DEFINITION 4.2. If S is based and C is closed, x is said to be *positive scalarizable*, denoted by $x \in \text{Pos}(C, S)$ if there is some $f \in S^{+i}$ such that $f(C - x) \geq 0$.

Scalarization is a fundamental principle in vector optimization theory. Thus positive scalarizable points form an important class of proper efficient points. It is easy to see that every positive scalarizable point is Borwein proper efficient. But any Borwein proper efficient point in $l_2(\mathbb{R})$ with ordering cone $l_2^+(\mathbb{R})$ is not positive scalarizable, as there is

no strict positive linear functional on the space. Example 2.5 shows also that positive scalarizable points may not be Henig proper efficient.

Example 4.3. Let X, S, Θ, and C be as in Example 2.5. We have seen that $0 \notin HE(C, \Theta)$. To see 0 is in $\text{Pos}(C, S)$, we observe that

$$\phi = (2^{-1}, 2^{-2}, \ldots, 2^{-n}, \ldots) \in S^{+i} := \{y \in l_\infty(\mathbb{N}) | y(n) > 0, n = 1, 2, \ldots\}$$

and $\phi(x_n) = 0$ for $x_n := -e_n + 2^{-(n-1)}e_1 \in C$.

When the set C is convex and the ordering cone S is based, however, a positive scalarizable point is Henig proper efficient. Moreover, any Henig point is also positive scalarizable, as the following proposition shows.

PROPOSITION 4.4. *Let X be a normed linear space, let S be a closed ordering cone with a closed base Θ, and let*

$$\delta := \inf\{\|\theta\| \,|\theta \in \Theta\}.$$

Suppose that C is convex. Then x in $BE(C, S_\varepsilon(\Theta))$ for some $0 < \varepsilon < \delta$ implies that x is in $\text{Pos}(C, S)$. *On the other hand, x in* $\text{Pos}(C, S)$ *implies that there is a closed base Θ' of S such that x is in $HE(C, \Theta')$.*

Proof. If x is in $BE(C, S_\varepsilon(\Theta))$ for some $0 < \varepsilon < \delta$, then

$$\text{cl}[\text{cone}(C - x_0)] \cap \text{cl}[\text{cone}(\varepsilon B - \Theta)] = 0.$$

By Lemma 3.1, this implies

$$\text{cone}(C - x_0) \cap \text{int}[\text{cone}(\varepsilon B - \Theta)] = \emptyset.$$

As $\text{cone}(C - x_0)$ and $\text{cone}(\varepsilon B - \Theta)$ are convex and the latter has nonempty interior, the Hahn–Banach theorem [16, p. 15] provides a nonzero linear functional ϕ in X^* and b in $\mathbb{R}$ such that

$$\phi[\text{cone}(C - x_0)] \geq b \geq \phi[\text{cone}(\varepsilon B - \Theta)].$$

Note that 0 in $\text{cone}(C - x_0)$ implies that $b \leq 0$. Moreover,

$$0 \geq b \geq \phi[\text{cone}(\varepsilon B - \Theta)]$$

implies that $b = 0$. Hence for all $\|x\| \leq 1$, and each θ in Θ,

$$\phi(\theta) \geq \phi(\varepsilon 2^{-1} x).$$

Thus $\phi(\theta) \geq \varepsilon 2^{-1}\|\phi\| > 0$. Thus, $\phi \in S^{+i}$, and $\phi(C - x) \geq 0$. This proves that x_0 is in $\text{Pos}(C, S)$.

Conversely, suppose that x_0 is in $\text{Pos}(C, S)$. Let ϕ be in S^{+i} such that $\|\phi\| = 1$ and $\phi(C - x_0) \geq 0$. Let $\Theta' = \phi^{-1}(1) \cap S$. Then Θ' is a closed base for S and for $0 < \varepsilon < 1$,

$$\phi(\Theta' + \varepsilon B) > 0.$$

So, $\phi(x) < 0$ for all x in $-S_\varepsilon(\Theta') \backslash \{0\}$. Hence,

$$\text{cl}[\text{cone}(C - x_0)] \cap -S_\varepsilon(\Theta') = 0.$$

Therefore, x_0 is in $BE(C, S_\varepsilon(\Theta'))$. □

COROLLARY 4.5. *Let X be a normed linear space, let S be a closed ordering cone with a closed base Θ, and let C be a nonempty convex subset of X.*

(1) *If C is weakly compact, then $\text{Pos}(C + S, S)$ is weakly dense in $E(C, S)$.*

(2) *If C is norm compact, then $\text{Pos}(C + S, S)$ is norm dense in $E(C, S)$.*

Proof. The corollary follows because in this case,

$$HE(C + S, \Theta) \subset \text{Pos}(C + S, S). \qquad \square$$

CONSUMPTION-INVESTMENT MODELS WITH CONSTRAINTS*

THALEIA ZARIPHOPOULOU†

Abstract. The paper examines a general investment and consumption problem for a single agent who consumes and invests in a riskless asset and a risky one. The objective is to maximize the total expected discounted utility of consumption. Trading constraints, limited borrowing, and no bankruptcy are binding, and the optimization problem is formulated as a stochastic control problem with state and control constraints. It is shown that the value function is the unique smooth the associated Hamilton–Jacobi–Bellman equation and the optimal consumption and portfolios are provided in feedback form.

Key words. dynamic programming, Bellman equation, viscosity solutions, state constraints, mathematical finance, investment and consumption models

AMS subject classifications. 49L20, 49L25, 90A09, 60H10

Introduction. This paper treats a general consumption and investment problem for a single agent. The investor consumes wealth X_t at a nonnegative rate C_t and distributes it between two assets continuously in time. One asset is a *bond*, i.e., a riskless security with instantaneous rate of return r. The other asset is a *stock* whose value is driven by a Wiener process.

The objective is to maximize the *total expected (discounted) utility from consumption* over an infinite trading horizon and the *total expected utility both from consumption and terminal wealth* in the case of finite horizon. The investor faces the following *trading constraints:* Wealth must stay nonnegative, i.e., bankruptcy never occurs, moreover, the amount π_t invested in stock must not exceed an exogenous function $f(X_t)$ of the wealth at any time t. The function f represents general borrowing constraints, which are frequently binding in practice, such as in portfolio insurance models with prespecified liability flow, models with nontraded assets, stochastic income and/or uninsurable risks, etc. The possibility of imposing short-selling constraints, which amounts to requiring $g(x_t) \leq \pi_t$ for some exogenous function g, is addressed in detail in §1. Finally, the agent is a "small investor," in that his or her decisions do not affect the asset prices and he or she does not pay transaction fees when trading.

This financial model gives rise to a stochastic control problem with control variables *consumption rate* C_t and *portfolio vector* (π_t^0, π_t), where π_t^0 and π_t are the amount of wealth invested in bond and stock, respectively. The state variable X_t is the total wealth at time t. Finally, the value function is the maximum total expected discounted utility.

The goal of this paper is to determine the value functions of these control problems, to examine how smooth they are, and to characterize the optimal policies. The basic tools come from the theory of partial differential equations, in particular the theory of viscosity solutions for second-order partial differential equations and elliptic regularity. We first show that the value functions are the unique constrained viscosity solutions of the associated Hamilton–Jacobi–Bellman (HJB) equation. Then we prove that viscosity solutions of these equations are smooth. Finally, we obtain an explicit feedback form for the optimal policies (C^*, π^*).

The paper is organized as follows: In §1 we describe the model and we give a summary of the history of consumption—investment models in continuous-time finance. Sections 2–5 deal with the infinite horizon model. More precisely, in §2 we describe basic properties of the value function, and in §3 we characterize the value function as a constrained viscosity

solution of the HJB equation. Moreover, in §4 we prove that the value function is the unique constrained solution of the HJB equation. In §5, we show that the value function is also a smooth solution of this equation and we provide the optimal policies. Finally, in §6 we state results for the finite horizon model.

1. We consider a market with two assets: A *bond* and a *stock*. The price P_t^0 of the bond is given by

$$\begin{aligned} dP_t^0 &= rP_t^0\,dt \qquad (t \geq 0) \\ P_0^0 &= p_0, \qquad (p_0 > 0), \end{aligned} \tag{1.1}$$

where $r > 0$ is the *interest rate*. The price P_t of the stock satisfies

$$\begin{aligned} dP_t &= bP_t\,dt + \sigma P_t\,dW_t \qquad (t \geq 0) \\ P_0 &= p, \qquad (p > 0), \end{aligned} \tag{1.2}$$

where b is the *mean rate of return*, σ is the *dispersion coefficient* and the process $W_\cdot$, which represents the source of uncertainty in the market, is a standard Brownian motion defined on the underlying probability space (Ω, F, P). We will denote by F_t the augmentation under P of $F_t^W = \sigma(W_s : 0 \leq s \leq t)$ for $0 < t < +\infty$. The interest rate r, the mean rate of return b, and the dispersion coefficient σ are assumed to be constant with $\sigma \neq 0$ and $b > r > 0$.

The total current *wealth* $X_t = \pi_t^0 + \pi_t$ is the state variable and π_t^0 and π_t are the amount of wealth invested in bond and stock, respectively; X_t evolves (see [40]) according to the equation

$$\begin{aligned} dX_t &= rX_t\,dt + (b-r)\pi_r\,dt - C_t\,dt + \sigma\pi_t\,dW_t \qquad (t \geq 0) \\ X_0 &= x, \qquad (x \in [0, +\infty)) \end{aligned} \tag{1.3}$$

where x is the *initial endowment* of the investor.

The *control process* are the consumption rate C_t and the portfolio π_t. To state their properties we introduce the following sets:

$$\begin{aligned} \mathcal{L}_+ = \Bigg\{ & z_t : z_t \text{ is } F_t\text{-progressively measurable process, } z_t \geq 0 \text{ a.s. } \forall t \geq 0 \\ & \text{and } \int_o^t z_s\,ds < +\infty \text{ a.s. } \forall t \geq 0 \Bigg\} \\ \mathcal{M} = \Bigg\{ & z_t : z_t \text{ is } F_t\text{-progressively measurable process} \\ & \text{and } \int_0^t z_s^2\,ds < +\infty \text{ a.s. } \forall t \geq 0 \Bigg\}. \end{aligned}$$

The set $\mathcal{A}_x$ of *admissible controls* for $x \in [0, +\infty)$ consists of all pairs (C, π) such that:

(i) $C \in \mathcal{L}_+$,

(ii) $\pi \in \mathcal{M}$.

Moreover, $\pi_t \leq f(X_t)$ almost surely for all $t \geq 0$, where the function $f : [0, +\infty) \to [0, +\infty)$ has the following properties:

$$\begin{aligned} & f \text{ is increasing, concave, } \quad f(0) \geq 0 \quad \text{and} \\ & |f(x) - f(y)| \leq K|x - y| \quad \forall x, y \geq 0 \end{aligned} \tag{1.4}$$

(iii) $X_t \geq 0$ almost surely for all $t \geq 0$, where X_t is the trajectory given by the state equation (1.3) using the controls (C, π).

The function f represents the borrowing constraints that the investor must meet; these constraints are present in models with prespecified liabilities such as problems of management of funds as well as in models with uninsurable risks. The possibility of short-selling constraints, i.e., $g(x) \leq \pi$, is not examined in this paper for the following reasons: First, if $g \leq 0$, the short-selling constraints can be removed because the model is of constant coefficients with $b > r$ (see, for example, [40] and [8]). Second, if $0 < g(x) \leq \pi$ this only facilitates the analysis presented here and therefore this case is not discussed.

All the results in this paper hold for the case $f \equiv \infty$, which was studied in [18], provided that some of the arguments in what follows are slightly modified. We will not pursue this any further in this paper unless it is necessary for the study of the $f \equiv \infty$ case. On the other hand, we will occasionally use some results of [18] only to facilitate the presentation and avoid lengthy arguments.

The *total expected discounted utility* J coming from consumption is given by

$$J(x, C, \pi) = E \int_0^{+\infty} e^{-\beta t} U(C_t)\, dt$$

with $(C, \pi) \in \mathcal{A}_x$, where Eg denotes the expectation of g with respect to the probability measure P, $\beta > 0$ is a *discount factor* such that

$$\beta > r, \tag{1.5}$$

and U is the *utility function,* which is assumed to have the following properties:

$$\begin{aligned} &U \text{ is a strictly increasing, concave } C^2(0, +\infty) \text{ function such that} \\ &U(c) \leq M(1 + c)^\gamma \quad \text{with } 0 < \gamma < 1 \quad \text{and} \quad M > 0, \\ &U(0) \geq 0, \quad \lim_{c \to 0} U'(c) = +\infty, \quad \lim_{c \to \infty} U'(c) = 0. \end{aligned} \tag{1.6}$$

The *value function* is given by

$$v(x) = \sup_{\mathcal{A}_x} E \int_0^{+\infty} e^{-\beta t} U(C_t)\, dt. \tag{1.7}$$

To guarantee that the value function is well defined when U is unbounded, we assume that

$$\beta > r\gamma + \gamma(b - r)/\sigma^2(1 - \gamma).$$

The above condition yields that the value function which corresponds to $f \equiv +\infty$ and $U(c) = M(1 + c)^\gamma$, and thereby all value functions, are finite (see [18]).

The goal is to characterize v as a classical solution of the HJB equation, associated with the control problem, and use the regularity of v to provide the optimal policies.

We now state the main results.

THEOREM 1.1. *The value function v is the unique $C^2((0, +\infty)) \cap C([0, +\infty))$ solution of*

$$\beta v = \max_{\pi \leq f(x)} \left[\tfrac{1}{2}\sigma^2\pi^2 v_{xx} + (b - r)\pi v_x\right] + \max_{c \geq 0}[-cv_x + U(c)] + rxv_x \tag{1.8}$$

in the class of concave functions.

THEOREM 1.2. *The optimal policies C_t^* and π_t^* are given in the feedback form $C_t^* = c^*(X_t), \pi_t^* = \pi^*(X_t)$ where*

$$c^*(x) = (U')^{-1}(v_x(x)) \quad \textit{and} \quad \pi^*(x) = \min\left\{f(x), -\frac{b - r}{\sigma^2}\frac{v_x(x)}{v_{xx}(x)}\right\}.$$

We continue with a brief discussion of the history of the model.

The single agent consumption-portfolio problem was first investigated by Merton in 1969 and 1971 ([28], [29]). He assumed that the returns of asset prices in perfect markets satisfy the "geometric Brownian motion" hypothesis and he considered utility functions belonging to the hyperbolic absolute risk aversion (HARA) family, i.e., $U(c) = 1 - \gamma/\gamma[\beta c/1 - \gamma + \eta]^{\gamma}$. Under these assumptions, he found explicit formulae for the optimal consumption and portfolio in both the finite and infinite horizon case. Moreover, he showed that the optimal policies are linear functions of the current wealth if and only if the utility function belongs to the HARA family.

In Merton's work, the portfolio is unconstrained, which means that unlimited borrowing and short selling are allowed. Moreover, the consumption process has to stay nonnegative and bankruptcy should never occur. Extra restrictions on the parameters β, γ, and η were later imposed by Merton [30] and Sethi and Taksar [34] to meet the above feasibility conditions.

Another important contribution is the work of Karatzas et al. [18], which is a continuation of work initiated by Lehoczky, Sethi, and Shreve [25]. Reference [18] examines a model with constant coefficients when borrowing and short selling are allowed (i.e., $f \equiv \infty$) and provides solutions of the Bellman equation in closed form. The possibility of bankruptcy is treated in this paper as well as in Sethi and Taksar [33]. The special case of a finite horizon model with constant market coefficients is examined by the same authors in [19]. The fact that borrowing and short selling are allowed is used strongly in [19] (see also [4]) to "linearize" the fully nonlinear Bellman equation to get a system of two linear parabolic equations. Solving these linear equations, they obtain a closed-form solution of the HJB equation.

The Bellman equation can be also linearized when only short-selling constraints are imposed; such a model was studied by Shreve and Xu [35], [36] and Xu [39] in a finite horizon setting in incomplete markets. Such linearization cannot be done if general borrowing constraints are imposed, which is the case we treat in this paper.

A different approach to studying investment-consumption problems with constraints in continuous-time finance was introduced by the author in [40], which studies an investment consumption model with borrowing and short-selling constraints, i.e., $0 \leq \pi_t \leq X_t$. This new approach is based on the theory of viscosity solutions of nonlinear first- and second-order partial differential equations and appears to be flexible enough to handle a wide variety of problems with constraints and related asymptotic problems, e.g., convergence of numerical schemes, asymptotic behavior, etc.

The asymptotic behavior of the value function and the optimal policies for the model with constraints and different interest rates were examined by Fleming and Zariphopoulou in [13]. Moreover, numerical results for the optimal policies and the value function were obtained by Fitzpatrick and Fleming in [10]. A consumption-investment model with leverage constraints (i.e., $f(x) = x + L, L > 0$) was examined by Vila and Zariphopoulou in [38].

Finally, a martingale representation technology has been used by Pliska [32], Cox and Huang [4], Pages [31], and Karatzas, Lehoczky, and Shreve [19] to study optimal portfolio and consumption policies in models with general market coefficients. Moreover, the case of incomplete markets with short-selling constraints in the finite horizon setting has been examined by He and Pearson [15], Xu [39], Shreve and Xu [35], [36], and in the absence of constraints by Karatzas et al. [20].

After this paper was submitted, the author received a paper by Cvitanic and Karatzas

[7]. This paper uses martingale and convex duality methods to study a finite horizon model with nonconstant coefficients and constrained portfolio policies but with utility functions which are more restrictive than the ones used in this paper; in particular, they only consider the case of utility functions with Arrow–Pratt index less than one.

2. In this section we derive some basic properties of the value function.

PROPOSITION 2.1. *The value function v is concave and strictly increasing.*

Proof. The concavity of v is an immediate consequence of the concavity of the utility function U and the fact that if $(C^1, \pi^1) \in \mathcal{A}_{x_1}$, $(C^2, \pi^2) \in \mathcal{A}_{x_2}$, and $\lambda \in (0,1)$, then $(\lambda C^1 + (1-\lambda)C^2, \lambda\pi^1 + (1-\lambda)\pi^2) \in \mathcal{A}_{\lambda x_1 + (1-\lambda)x_2}$; the latter follows from the linear dependence of the dynamics (1.3) with respect to the controls and the state variable.

That v is increasing follows from the observation that $\mathcal{A}_{x_1} \subset \mathcal{A}_{x_2}$ if $x_1 \leqq x_2$. If v is not strictly increasing, then it must be constant on an interval, which, by concavity, has to be of the form $[x_0, \infty)$ for some $x_0 \geqq 0$, i.e., there must exist $x_0 \in [0, +\infty)$ such that $v(x) = v(x_0)$, for all $x \geqq x_0$. In this case, fix $\epsilon > 0$ and choose $(C^\epsilon, \pi^\epsilon) \in \mathcal{A}_{x_0}$ such that

$$v(x_0) \leqq E \int_0^{+\infty} e^{-\beta t} U(C_t^\epsilon)\, dt + \epsilon.$$

If

$$x_1 > \max\left(x_0, \frac{U^{-1}\left[\beta\left(E\int_0^{+\infty} e^{-\beta t}U(C_t^\epsilon)\,dt + \epsilon\right)\right]}{r} \right),$$

the policy $(\overline{C}, \overline{\pi}) = (rx_1, 0)$ is in $\mathcal{A}_{x_1}$. Therefore

$$v(x_0) < \frac{1}{\beta}U(rx_1) = E\int_0^{+\infty} e^{-\beta t}U(rx_1)\,dt \leqq v(x_1),$$

which contradicts our assumption. □

PROPOSITION 2.2. *The value function v is uniformly continuous on $\overline{\Omega} = [0, \infty)$ and $v(0) = U(0)/\beta$.*

Proof. Since $(0,0) \in \mathcal{A}_0$, $v(0) \geqq U(0)/\beta$. On the other hand, $v \leqq u$ in $[0, +\infty)$, where u is the value function with $f \equiv +\infty$ studied in [16]. Since (cf. [18]) $u(0) = U(0)/\beta$ and $u \in C([0, +\infty))$, it follows that $v(0) = U(0)/\beta$ and v is continuous at $x = 0$. The continuity of v in $(0, +\infty)$ follows from concavity.

Finally, since v is uniformly continuous on compact subsets of $\overline{\Omega}$, we remark that its uniform continuity on $\overline{\Omega}$ follows from the fact that, by concavity, v is Lipschitz continuous in $[a, +\infty)$ with Lipschitz constant of order $1/a$ for every $a > 0$. □

PROPOSITION 2.3. *The value function satisfies $v(x) \leq 0(x^\gamma)$ as $x \to +\infty$.*

Proof. Since $v \leq u$ on $\overline{\Omega}$, where u is the value function with $f \equiv +\infty$ and $U(c) = M(1+x)^\gamma$, we only need to check this upper bound for u.

On the other hand, a direct modification of the proof of Theorem 4.5 in [13] yields that if $U \sim c^\gamma$ (as $c \to \infty$), then $u \sim x^\gamma$ (as $x \to \infty$). □

We conclude this section by stating (for a proof see [1], [26]) a fundamental property of the value function known as the *Dynamic Programming Principle.*

PROPOSITION 2.4. *If θ is a stopping time (i.e., a nonnegative $\mathcal{F}$-measurable random variable) then*

$$v(x) = \sup_{\mathcal{A}_x} E\left[\int_0^\theta e^{-\beta t}U(C_t)\,dt + e^{-\beta\theta}v(X_\theta)\right] (x \in \overline{\Omega}). \tag{2.1}$$

3. In this section we show that the value function v is a constrained viscosity solution of the HJB equation associated with the underlying stochastic control problem. The characterization of v as a constrained viscosity solution is natural because of the presence of the state $(X_t \geq 0)$ and control $(\pi_t \leq f(X_t))$ constraints.

The notion of viscosity solution was introduced by Crandall and Lions [6] for first-order and by Lions [27] for second-order equations. For a general overview of the theory we refer to the *User's Guide* by Crandall, Ishii, and Lions [5].

Next we recall the notion of contrained viscosity solutions, which was introduced by Soner [37] and Capuzzo-Dolcetta and Lions [3] for first-order equations (see also Ishii and Lions [16] and Katsoulakis [21]). To this end, consider a nonlinear second-order partial differential equation of the form

$$F(x, u, u_x, u_{xx}) = 0 \quad \text{in } \Omega, \tag{3.1}$$

where Ω is an open subset of $\mathbb{R}$ and $F : \Omega \times \mathbb{R} \times \mathbb{R} \times \mathbb{R} \to \mathbb{R}$ is continuous and (degenerate) elliptic, i.e.,

$$F(x, t, p, X + Y) \leq F(x, t, p, X) \quad \text{if } Y \geqq 0.$$

DEFINITION 3.1. A continuous function $u : \overline{\Omega} \to \mathbb{R}$ is a *constrained viscosity solution* of (3.1) if and only if

(i) u is a *viscosity subsolution* of (3.1) on $\overline{\Omega}$, i.e., if for any $\varphi \in C^2(\overline{\Omega})$ and any maximum point $x_0 \in \Omega$ of $u - \varphi$,

$$F(x_0, u(x_0), \varphi_x(x_0), \varphi_{xx}(x_0)) \leq 0;$$

and

(ii) u is a *viscosity supersolution* of (3.1) in Ω, i.e., if for any $\varphi \in C^2(\overline{\Omega})$ and any minimum point $x_0 \in \Omega$ of $u - \varphi$,

$$F(x_0, u(x_0), \varphi_x(x_0), \varphi_{xx}(x_0)) \geq 0.$$

Remark 1. We say that $u \in C(\overline{\Omega})$ is a viscosity solution of (3.1) in Ω if and only if it is both sub- and supersolution in Ω.

Remark 2. As a matter of fact, we can extend the definition of viscosity subsolutions (respectively, supersolutions) for upper-semicontinuous (respectively, lower-semicontinuous) functions.

THEOREM 3.1. *The value function v is a constrained viscosity solution of* (1.8) *on* $\overline{\Omega}$.

The fact that, in general, value functions of control problems and differential games turn out to be viscosity solutions of the associated partial differential equations is a direct consequence of the principle of dynamic programming and the definition of viscosity solutions (see, for example, Lions [26], Evans and Souganidis [9], Fleming and Souganidis [12], etc.). The main difficulty, however, in the problem at hand is that the consumption rates and the portfolios are not uniformly bounded. This gives rise to some serious complications in the proofs of the results of the aforementioned papers. To overcome these difficulties we need to introduce a number of approximations of the original problem and make use repeatedly of the *stability* properties of viscosity solutions.

Proof of Theorem 3.1. We first show that v is a viscosity supersolution of (1.8) in Ω.

Let $\varphi \in C^2(\overline{\Omega})$ and $x_0 \in \Omega$ be a minimum of $v - \varphi$; without any loss of generality, we may assume that

$$v(x_0) = \varphi(x_0) \quad \text{and} \quad v \geq \varphi \quad \text{in } \Omega. \tag{3.2}$$

We need to show that

$$\beta v(x_0) \geq \max_{\pi \leq f(x_0)} \left[\tfrac{1}{2}\sigma^2\pi^2\varphi_{xx}(x_0) + (b-r)\pi\varphi_x(x_0)\right] + \max_{c \geq o}[-c\varphi_x(x_0) + U(c)] + rx_0\varphi_x(x_0). \tag{3.3}$$

To this end, at $(C, \pi) \in \mathcal{A}_{x_0}$ such that $C_t = C_0, \pi_t = \pi_0 \leq f(x_0)$, for all $t \geq 0$. The dynamic programming principle, together with (3.2), yields

$$v(x_0) \geq E\left[\int_0^\theta e^{-\beta t}U(C_0)\,dt + e^{-\beta\theta}\varphi(X_\theta)\right] \tag{3.4}$$

where $X_\cdot$ is the trajectory given by (1.3) using the controls (C_0, π_0) and starting at x_0 and $\theta = \min(\tau, \frac{1}{n})$, with $n > 0$ and $\tau_\cdot = \inf\{t \geq 0 : X_t = 0\}$.

On the other hand, applying Itô's lemma to $g(t, X_t) = e^{-\beta t}\varphi(X_t)$, we get

$$E[e^{-\beta\theta}\varphi(X_\theta)] = v(x_0) + E\int_0^\theta e^{-\beta t}\left[-\beta\varphi(X_t) + \frac{1}{2}\sigma^2\pi_0^2\varphi_{xx}(X_t) + (b-r)\pi_0\varphi_x(X_t) - C_0\varphi_x(X_t) + rX_t\varphi_x(X_t)\right]dt.$$

Combining the above equality with (3.4) and using standard estimates from the theory of stochastic differential equations (see [14]), we get

$$E\int_0^\theta \left[-\beta v(x_0) + \frac{1}{2}\sigma^2\pi_0^2\varphi_{xx}(x_0) + (b-r)\pi_0\varphi_x(x_0) - C_0\varphi_x(x_0) + U(C_0) + rx_0\varphi_x(x_0)\right]ds + E\int_0^\theta h(s)\,ds \leq 0,$$

where $h(s) = 0(s)$. Dividing both sides by $E(\theta)$ and passing to the limit as $n \to \infty$ yields

$$\beta v(x_0) \geq \left[\tfrac{1}{2}\sigma^2\pi_0^2\varphi_{xx}(x_0) + (b-r)\pi_0\varphi_x(x_0)\right] + [-C_0\varphi_x(x_0) + U(C_0)] + rx_0\varphi_x(x_0),$$

for every pair of constant controls $(C_0, \pi_0), C_0 \geq 0$, and $\pi_0 \leq f(x_0)$; inequality (3.3) then follows easily.

We next show that v is a viscosity subsolution of (1.8) on $\overline{\Omega}$.

We first approximate v by a sequence of functions $(v_\epsilon^{N,n})$ defined by

$$v_\epsilon^{N,n}(x) = \sup_{\mathcal{A}_{N,n}} E\int_0^{+\infty} e^{-\beta t}\left[U(C_t) - \frac{1}{\epsilon}p(X_t)\right]dt, \qquad (x \in \mathbb{R})$$

for $\epsilon > \imath, N > 0, n > 0$, and $p(x) = \max(0, -x)$. The set of admissible policies $\mathcal{A}_{N,n}$ consists of all pairs (C, π) such that

(i) $C \in \mathcal{L}_+$ and $C_t \leq N$ almost surely for all $t \geq 0$,

(ii) $\pi \in \mathcal{M}$ and $-n \leq \pi_t \leq \hat{f}(X_t)$ almost surely for all $t \geq 0, n > 0$ where the function $\hat{f} : \mathbb{R} \to \mathbb{R}$ (denoted for convenience in the sequel by f) satisfies (1.4) and coincides with f on $[0, +\infty)$;

(iii) X_t is the trajectory given by the state equation (1.3) using the controls (C, π) and starting at $x \in \mathbb{R}$.

It follows from the dynamic programming principle and the definition of viscosity solution (see [27]), that $v_\epsilon^{N,n}$ is a viscosity solution of

$$\beta v_\epsilon^{N,n} = \max_{-n \leq \pi \leq f(x)}\left[\tfrac{1}{2}\sigma^2\pi^2 v_{\epsilon,xx}^{N,n} + (b-r)\pi v_{\epsilon,x}^{N,n}\right] + \max_{0 \leq c \leq N}[-cv_{\epsilon,x}^{N,n} + U(c)] + rxv_{\epsilon,x}^{N,n} - \frac{1}{\epsilon}p(x) \qquad (x \in \mathbb{R}).$$

We next observe that as $n \to \infty$,

$$v_\epsilon^{N,n} \to v_\epsilon^N, \text{ locally uniformly in } \mathbb{R},$$

(see [22, Chap. 6]) where

$$v_\epsilon^{N(x)} = \sup_{\mathcal{A}_N} E \int_0^{+\infty} e^{-\beta t}\left[U(C_t) - \frac{1}{\epsilon}p(X_t)\right] dt \qquad (x \in \mathbb{R})$$

and the set $\mathcal{A}_N$ of admissible policies is defined in the same way as $\mathcal{A}_{N,n}$, but without a lower bound on π.

It is immediate that

$$v_\epsilon^N \leq \frac{U(N)}{\beta} \quad \text{in } \mathbb{R} \tag{3.5}$$

and

$$v^N \leq v_\epsilon^N \quad \text{on } [0, +\infty), \tag{3.6}$$

where, for $x \in [0, +\infty)$,

$$v^N(X) = \sup_{\mathcal{A}_{x,N}} E \int_0^{+\infty} e^{-\beta t} U(C_t)\, dt \tag{3.7}$$

and

$$\mathcal{A}_{x,N} = \{(C, \pi) \in \mathcal{A}_x : C_t \leq N \text{ a.s. } \forall t \geq 0\}.$$

Moreover, the v_ϵ^N's are increasing and concave with respect to x. Both properties follow as in Proposition 2.1.

Finally, the stability property of viscosity solutions (see [27, Prop. I.3]) yields that v_ϵ^N is a viscosity solution of

$$\begin{aligned} \beta v_\epsilon^N = \max_{\pi \leq f(x)} \left[\tfrac{1}{2}\sigma^2\pi^2 v_{\epsilon,xx}^N + (b-r)\pi v_{\epsilon,x}^N\right] + \max_{0 \leq c \leq N}[-c v_{\epsilon,x}^N + U(c)] \\ + rx v_{\epsilon,x}^N - \tfrac{1}{\epsilon}p(x) \qquad (x \in \mathbb{R}). \end{aligned} \tag{3.8}$$

In the sequel we look at the behavior of the v_ϵ^N's on $[0, +\infty)$ as $\epsilon \to 0$. Since the only available bounds on the v_ϵ^N's are the ones stated above, we employ the limsup operation introduced by Barles and Perthame [2]. To this end, we define

$$v^{N,*}(x) = \limsup_{y \to x, \epsilon \to 0} v_\epsilon^N(y) \qquad (x \in [0, +\infty))$$

and we claim that

(i) $v^{N,*}$ is an upper semicontinuous viscosity subsolution on $\overline{\Omega}$ of

$$\begin{aligned} \beta v^{N,*} = \max_{\pi \leq f(x)} \left[\tfrac{1}{2}\sigma^2\pi^2 v_{xx}^{N,*} + (b-r)\pi v_x^{N,*}\right] \\ + \max_{0 \leq c \leq N}[-c v_x^{N,*} + U(c)] + rx v_x^{N,*} \qquad (x \in [0, +\infty)); \end{aligned} \tag{3.9}$$

and

(ii) $v^{N,*} = v^N$ on $\overline{\Omega}$.

We first observe that $v^{N,*}$ is increasing and concave on $\overline{\Omega}$. The first property is an immediate consequence of the definition. For the concavity we argue as follows: The concavity of $v^{N,*}$ in Ω follows from the fact that, since the v_ϵ^N's are concave in Ω and uniformly bounded on $\overline{\Omega}$, they converge, as $\epsilon \to 0$, locally uniformly to a concave function which actually coincides with $v^{N,*}$. It remains to show that

$$v^{N,*}((1-\lambda)x) \geq \lambda v^{N,*}(0) + (1-\lambda)v^{N,*}(x) \tag{3.10}$$

for $\lambda \in (0,1)$ and $x > 0$.

Let (ϵ_n) and $(y_n) \in \mathbb{R}$ be sequences such that, as $n \to \infty, \epsilon_n \to 0, y_n \to 0$, and $v^{N,*}(0) = \limsup_{y_n \to 0, \epsilon \to 0} v_\epsilon^N(y_n)$. The concavity of v_ϵ^N yields

$$v_{\epsilon_n}^N(\lambda y_n + (1-\lambda)x) \geq \lambda v_{\epsilon_n}^N(y_n) + (1-\lambda)v_{\epsilon_n}^N(x). \tag{3.11}$$

On the other hand,

$$v^{N,*}(x) = \lim_{\epsilon \to 0} v_\epsilon^N(x) \qquad (x \in (0, +\infty)). \tag{3.12}$$

Indeed, let $x \in [x_1, x_2]$ with $x_1 > 0$. The concavity of v_ϵ^N's and (3.5) yields that the v_ϵ^N are locally Lipschitz on $[x_1, x_2]$ with Lipschitz constant L independent of ϵ, i.e.,

$$v_\epsilon^N(y) \leq v_\epsilon^N(x) + L|y - x| \qquad (x, y \in [x_1, x_2]);$$

therefore

$$\limsup_{\epsilon \to 0, y \to x} v_\epsilon^N(y) \leq \limsup_{\epsilon \to 0} v_\epsilon^N(x).$$

Moreover,

$$\limsup_{\epsilon \to 0} v_\epsilon^N(x) = \lim_{\epsilon \to 0} v_\epsilon^N(x)$$

since the v_ϵ^N's are increasing in ϵ. Combining the last inequalities we get

$$v^{N,*}(x) \leq \lim_{\epsilon \to 0} v_\epsilon^N(x)$$

which, together with the definition of $v^{N,*}$ yields (3.12).

We now observe that, for n large enough, $\lambda y_n + (1-\lambda)x > a$, for some $a > 0$. Sending $n \to \infty$ in (3.11) and using the properties of $(\epsilon_n), (y_n)$, and (3.12) we conclude.

We continue with the proof of (3.9). We need to examine the following cases.

Case 1. $f \equiv \infty$.

Let $\varphi \in C^2(\overline{\Omega})$ and assume that $v^{N,*} - \varphi$ has a maximum at 0, which can be assumed to be strict. We need to show

$$\beta v^{N,*}(0) \leq \max_{\pi} \left[\tfrac{1}{2}\sigma^2\pi^2\varphi_{xx}(0) + (b-r)\pi\varphi_x(0)\right] + \max_{0 \leq c \leq N}[-c\varphi_x(0) + U(c)]. \tag{3.13}$$

First observe that the concavity and monotonicity of $v^{N,*}$ imply $\varphi_x(0) > 0$. Inequality (3.5), along with the fact that the max with respect to π in (3.13) is unconstrained, implies

that (3.13) holds if $\varphi_{xx}(0) \geqq 0$. It remains to prove (3.13) if $\varphi_{xx}(0) < 0$. To this end, we first extend φ to $\mathbb{R}^-$ in $C^2(\mathbb{R})$ so that for some $\alpha > 0$,

$$\varphi_{xx}(x) < 0 \qquad (-\alpha \leq x \leq 0)$$

and

$$v_\epsilon^N(-\alpha) \leq v_\epsilon^N(0) - \varphi(0) + \varphi(-\alpha) - \alpha.$$

Let x_ϵ be a maximum point of $v_\epsilon^N - \varphi$ over $[-\alpha, \alpha]$. If $x_\epsilon = -\alpha$, the choice of φ together with (3.6) yields

$$v_\epsilon^N(-\alpha) - \varphi(-\alpha) \leq v_\epsilon^N(0) - \varphi(0) - \alpha$$

which is a contradiction. Moreover, 0 being a strict maximum of $v^{N,*} - \varphi$ yields $x_\epsilon \neq \alpha$ for ϵ small enough. Since v_ϵ^N is viscosity solution of (3.8) we have

$$\begin{aligned} \frac{1}{\epsilon} p(x_\epsilon) \leq & \max_{\pi} \left[\tfrac{1}{2}\sigma^2\pi^2\varphi_{xx}(x_\epsilon) + (b-r)\pi\varphi_x(x_\epsilon) \right] \\ & + \max_{0\leq c\leq N} [-c\varphi_x(x_\epsilon) + U(c)] + rx_\epsilon\varphi_x(x_\epsilon) - \beta v_\epsilon^N(x_\epsilon). \end{aligned} \tag{3.14}$$

We next observe that the right-hand side of the above inequality is finite since $\varphi_{xx}(x_\epsilon) < 0, \varphi_x(x_\epsilon) > 0$ and $-v_\epsilon^N(x_\epsilon) < +\infty$, where the latter follows from

$$v_\epsilon^N(x_\epsilon) - \varphi(x_\epsilon) \geq v_\epsilon^N(0) - \varphi(0) \geq v^N(0) - \varphi(0).$$

Let $\overline{x}$ be a limit (along subsequence) of the x_ϵ's. The definitions of p and (3.14) yield $\overline{x} \geq 0$. Actually, $\overline{x} = 0$.

Indeed,

$$v_\epsilon^N(x_\epsilon) - \varphi(x_\epsilon) \geq v_\epsilon^N(0) - \varphi(0)$$

and therefore

$$v^{N,*}(\overline{x}) - \varphi(\overline{x}) \geq v^{N,*}(0) - \varphi(0)$$

which yields $\overline{x} = 0$, since 0 is a strict maximum.

Moreover,

$$\lim_{\epsilon\to 0} v_\epsilon^N(x_\epsilon) = v^{N,*}(0).$$

Indeed, $\limsup_{\epsilon\to 0} v_\epsilon^N(x_\epsilon) \leq v^{N,*}(0)$. On the other hand, if $\limsup_{\epsilon\to 0} v_\epsilon^N(x_\epsilon) < v^{N,*}(0)$, then $v^{N,*}(0) - \varphi(0) > \limsup_{\epsilon\to 0}[v_\epsilon^N(x_\epsilon) - \varphi(x_\epsilon)]$, which is a contradiction. Finally, passing to the limit in (3.14) as $\epsilon \to 0$, we get (3.13).

Working similarly, we show that $v^{N,*}$ is a viscosity subsolution of (1.8) in $(0, +\infty)$.

It remains to show that

$$v^{N,*} = v^N \quad \text{on } [0, +\infty). \tag{3.15}$$

Since $v^{N,*}$ and v^N are, respectively, viscosity subsolution of (1.8) on $[0, +\infty)$ and supersolution in $(0, +\infty)$, a comparison result similar to Theorem 4.1 (easily modified for the case the consumption rates are uniformly bounded) implies

$$v^{N,*} \leqq v^N \quad \text{on } [0, +\infty) \tag{3.16}$$

which together with (3.6) yields (3.15) in $(0, +\infty)$.

Finally, the upper semicontinuity of $v^{N,*}$ implies $v^{N,*}(0) = v^N(0)$.

Case 2. $f < +\infty$.

In view of the analysis above, we only have to examine the case $\varphi_{xx}(0) = 0$, i.e., we need to show

$$\beta v^{N,*}(0) \leq (b-r)f(0)\varphi_x(0) + \max_{0 \leq c \leq N} [-c\varphi_x(0) + U(c)]$$

where we used that $\varphi_x(0) > 0$. We first observe

$$v^{N,*}(0) = \frac{U(0)}{\beta}.$$

This follows from the fact that $U(0)/\beta \leq v^{N,*}(0) \leq v^N_\infty(0)$ and $v^N_\infty(0) \leq u(0) = U(0)/\beta$, where v^N_∞ is given by (3.7) for $f \equiv \infty$.

Using that $\max_{0 \leq c \leq N}[-c\varphi_x(0) + U(c)] \geq U(0)$, (3.17), and $\varphi_x(0) > 0$, we conclude.

We now conclude the proof of the theorem.

In view of the stability properties of viscosity solutions, to conclude the proof of the theorem we only need to establish that as $N \to \infty$,

$$v^N \to v, \text{ locally uniformly on } \overline{\Omega}.$$

To this end, fix $x \in \overline{\Omega}, \epsilon > 0$, and choose $(C^\epsilon, \pi^\epsilon) \in \mathcal{A}_x$ such that

$$v(x) \leq E \int_0^{+\infty} e^{-\beta t} U(C^\epsilon_t)\, dt + \epsilon. \tag{3.17}$$

From the definitions of $\mathcal{A}_{x,N}$ and $\mathcal{A}_x$ we have that $(C^\epsilon \wedge N, \pi) \in \mathcal{A}_{x,N}$. Moreover, since U is increasing and nonnegative, the monotone convergence theorem yields

$$\lim_{N \to \infty} E \int_0^{+\infty} e^{-\beta t} U(C^\epsilon_t \wedge N)\, dt = E \int_0^{+\infty} e^{-\beta t} U(C^\epsilon_t)\, dt$$

which, combined with (3.17) and the definitions of v^N and v, gives

$$v^N(x) \leq v(x) \leq E \int_0^{+\infty} e^{-\beta t} U(C^\epsilon_t \wedge N)\, dt + 2\epsilon \leq v^N(x) + 2\epsilon \quad \text{for } N \geq N(\epsilon).$$

Therefore, $v^N \to v$ as $N \to \infty$, for each $x \in \overline{\Omega}$. On the other hand, since v^N increases with respect to N and v is continuous, Dini's theorem implies that $v^N \to v$ locally uniformly on $\overline{\Omega}$. □

4. In this section we present a comparison result for constrained viscosity solutions of (1.8). Comparison results for a large class of boundary problems were given by Ishii and Lions [16]. The equation on hand, however, does not satisfy some of the assumptions in [16], in view of the fact that the controls are not uniformly bounded. It is therefore necessary to modify some of the arguments of Theorem II.2 of [16] to take care of these difficulties. For completeness we present the whole proof; we rely, however, on some basic facts which are analyzed in [14].

THEOREM 4.1. *If u is an upper-semicontinuous concave viscosity subsolution of* (1.8) *on $\overline{\Omega}$ and v is a bounded from below, sublinearly growing, uniformly continuous on $\overline{\Omega}$, and locally Lipschitz in Ω supersolution of* (1.8) *on Ω, then $u \leq v$ on $\overline{\Omega}$.*

Before we begin with the proof of the theorem, we observe that (1.8) can be written as

$$\beta u = G(x, u_x, u_{xx}) \tag{4.1}$$

where $G : \overline{\Omega} \times \mathbb{R} \times \mathbb{R} \to \mathbb{R}$ is given by

$$G(x,p,A) = \max_{\pi \le f(x)} \left[\tfrac{1}{2}\sigma^2\pi^2 A + (b-r)\pi p\right] + \max_{c \ge 0}[-cp + U(c)] + rxp.$$

An important ingredient of the proof of Theorem 4.1 is the sup- and inf-*convolution* approximation of u and v, respectively. Next we recall their definitions and summarize their main properties. For a general discussion about sup- and inf-convolution as well as their use in proving comparison results for second-order PDEs we refer to Lasry and Lions [24], Jensen, Lions, and Souganidis [17], and Ishii and Lions [16].

For $\epsilon > 0$ the ϵ sup-convolution of u is defined by

$$u^\epsilon(x) = \sup_{y \in \Omega}\left\{u(y) - \frac{1}{\epsilon}|x-y|^2\right\} \quad \forall x \in \overline{\Omega}, \tag{4.2}$$

and, similarly, the ϵ inf-convolution of v by

$$v_\epsilon(x) = \inf_{z \in \Omega}\left\{v(z) + \frac{1}{\epsilon}|x-z|^2\right\} \quad \forall x \in \overline{\Omega}. \tag{4.3}$$

It follows that the sup and inf in the definitions of u^ϵ and v_ϵ are actually taken for

$$|x-y| \le C\sqrt{\epsilon} \quad \text{and} \quad |x-z| \le C\sqrt{\epsilon}, \tag{4.4}$$

where $C = C(x)$ depends on the coefficients of the sublinear growth of u and v.

Moreover

(i) u^ϵ is a viscosity subsolution of

$$F'_\epsilon(x, u^\epsilon, u^\epsilon_x, u^\epsilon_{xx}) = 0 \quad \text{in } \Omega_\epsilon,$$

where $F^\epsilon(x,t,p,A) = \min\{\beta t - G(y,p,A) : |y-x| \le C\sqrt{\epsilon}\}$ and $\overline{\Omega}_\epsilon = \{x \in \Omega : x \ge C\sqrt{\epsilon}\}$; and

(ii) v_ϵ is a viscosity supersolution of

$$F^\epsilon(x, v_\epsilon, v_{\epsilon,x}, v_{\epsilon,xx}) = 0 \quad \text{in } \Omega_\epsilon,$$

where

$$F^\epsilon(x,t,p,A) = \max\{\beta t - G(y,p,A) : |y-x| \le C\sqrt{\epsilon}\}.$$

Proof of Theorem 4.1. We present the proof of the theorem for the case $f < +\infty$. The case $f \equiv \infty$ is discussed at the end of the section.

We argue by contradiction, i.e., we assume that

$$\sup_{x \in \overline{\Omega}}[u(x) - v(x)] > 0. \tag{4.5}$$

Then for sufficiently small $\theta > 0$

$$\sup_{x\in\overline{\Omega}}[u(x) - v(x) - \theta x] > 0. \tag{4.6}$$

Indeed, if not, there would be a sequence $\theta_n \downarrow 0$ such that $\sup_{x\in\overline{\Omega}}[u(x) - v(x) - \theta_n x] \leq 0$, which in turn would yield $\sup_{x\in\overline{\Omega}}[u(x) - v(x)] \leq 0$, contradicting (4.5).

Since u has, by concavity, sublinear growth and v is bounded from below, there exists $\overline{x} \in \overline{\Omega}$ such that

$$\sup_{x\in\overline{\Omega}}[u(x) - v(x) - \theta x] = u(\overline{x}) - v(\overline{x}) - \theta\overline{x}. \tag{4.7}$$

Next, for $\delta > 0$ and $\eta > 0$ we define $\varphi : \overline{\Omega} \times \overline{\Omega} \to \mathbb{R}$ by

$$\varphi(x, y) = u(x) - v(y) - \left|\frac{y - x}{\delta} - 4\eta\right|^4 - \theta x$$

and observe that for each fixed η, φ attains its maximum at a point (x_0, y_0) such that for δ small and some $l = l(\theta) > 0$,

$$|y_0 - x_0| \leq l\delta. \tag{4.8}$$

Indeed, φ is bounded and

$$\sup_{\overline{\Omega}\times\overline{\Omega}} \varphi(x, y) \geq \varphi(x, x + 4\eta\delta) \geq u(\overline{x}) - v(\overline{x}) - \theta\overline{x} - \omega_v(k\eta\delta) \tag{4.9}$$

where ω_v is the modulus of continuity of v and $k > 0$. Using (4.6) and (4.7) we get

$$\sup_{\overline{\Omega}\times\overline{\Omega}} \varphi(x, y) > 0 \tag{4.10}$$

for δ and η sufficiently small.

Next, let (x_n, y_n) be a maximizing sequence for φ and observe that

$$u(x_n) - v(y_n) - \theta x_n \geq \left|\frac{y_n - x_n}{\delta} - 4\eta\right|^4 \quad \text{as } n \to \infty.$$

The last inequality, combined with the fact that u has sublinear growth, implies (4.8).

On the other hand, the choice of (x_n, y_n) and (4.10) yields that the sequence (x_n) and, in view of the above observation, (y_n) are bounded as $n \to \infty$. Hence, along subsequences, (x_n, y_n) converges to a maximum point of φ, which we denote by (x_0, y_0).

We next fix δ small enough and we consider for $\epsilon \in (0, 1)$ the function

$$\varphi^\epsilon(x, y) = u^\epsilon(x) - v_\epsilon(y) - \left|\frac{y - x}{\delta} - 4\eta\right|^4 - \theta x$$

where u^ϵ and v_ϵ are, respectively, the ϵ sup- and inf-convolutions of u and v given by (4.3) and (4.4).

In the sequel we need to study separately the cases $\overline{x} > 0$ and $\overline{x} = 0$.

Case A. $\overline{x} > 0$.

If δ is small enough it follows that the point (x_0, y_0) lies in a fixed compact subset of $\Omega \times \Omega$. Moreover, the function φ^ϵ achieves its maximum at a point that we denote by

$(\overline{x}_\epsilon, \overline{y}_\epsilon)$, which lies in $\Omega_\epsilon \times \Omega_\epsilon$ (see [16]). Since $\beta > 0$ we can apply Proposition II.3 of [14], according to which there exist $X_\epsilon, Y_\epsilon \in \mathbb{R}$ such that

$$F_\epsilon(\overline{x}_\epsilon, u^\epsilon(\overline{x}_\epsilon), w_x(\overline{x}_\epsilon), \overline{y}_\epsilon) + \theta, X_\epsilon) \leq 0, \qquad F^\epsilon(\overline{y}_\epsilon, v_\epsilon(\overline{y}_\epsilon), -w_y(\overline{x}_\epsilon, \overline{y}_\epsilon), -Y_\epsilon) \geq 0$$

and

$$\begin{pmatrix} X_\epsilon & 0 \\ 0 & Y_\epsilon \end{pmatrix} \leq \begin{pmatrix} w_{xx}(\overline{x}_\epsilon, \overline{y}_\epsilon) & w_{xy}(\overline{x}_\epsilon, \overline{y}_\epsilon) \\ w_{yx}(\overline{x}_\epsilon, \overline{y}_\epsilon) & w_{yy}(\overline{x}_\epsilon, \overline{y}_\epsilon) \end{pmatrix}$$

where $w(x, y) = |(y - x)/\delta - 4\eta|^4$. Therefore

$$F_\epsilon\left(\overline{x}_\epsilon, u^\epsilon(\overline{x}_\epsilon), -\frac{4}{\delta}\left(\frac{\overline{y}_\epsilon - \overline{x}_\epsilon}{\delta} - 4\eta\right)^3 + \theta, X_\epsilon\right) \leq 0, \tag{4.11}$$

$$F^\epsilon\left(\overline{y}_\epsilon, v_\epsilon(\overline{y}_\epsilon), -\frac{4}{\delta}\left(\frac{\overline{y}_\epsilon - \overline{x}_\epsilon}{\delta} - 4\eta\right)^3, -Y_\epsilon\right) \geq 0. \tag{4.12}$$

Also,

$$\begin{pmatrix} X_\epsilon & 0 \\ 0 & Y_\epsilon \end{pmatrix} \leq \frac{12}{\delta^2}\left(\frac{\overline{y}_\epsilon - \overline{x}_\epsilon}{\delta} - 4\eta\right)^2 \begin{pmatrix} 1 & -1 \\ -1 & 1 \end{pmatrix},$$

and therefore

$$X_\epsilon + Y_\epsilon \leq 0. \tag{4.13}$$

We next observe that there exists a constant $c \geq 0$ such that

$$Y_\epsilon \geq c. \tag{4.14}$$

We argue by contradiction. Let us assume that there exists a subsequence (Y_{ϵ_n}) such that $\lim_{\epsilon_n \to 0} Y\epsilon_n = Y < 0$. From the definition of F_ϵ we have

$$\begin{aligned} \beta v_\epsilon(\overline{y}\epsilon) \geq \max_{\pi \leq f(\widehat{y}_\epsilon)} \left[-\tfrac{1}{2}\sigma^2\pi^2 Y_{\epsilon_n} - (b - r)\pi w_y(\overline{x}_\epsilon, \overline{y}_\epsilon)\right] \\ + \max_{c \geq 0}[cw_y(\overline{x}_\epsilon, \overline{y}_\epsilon) + U(c)] - r\,\widehat{y}_\epsilon w_y(\overline{x}_\epsilon, \overline{y}_\epsilon), \end{aligned}$$

for some $\widehat{y}_\epsilon \in \Omega$ such that $|\overline{y}_\epsilon - \widehat{y}_\epsilon| \leq C\sqrt{\epsilon}$. Sending $\epsilon_n \downarrow 0$ and using that $v_\epsilon(\overline{y}_\epsilon) \leq U(N)/\beta$, we get a contradiction.

Therefore, there exists $Y \in \mathbb{R}_0^+$ or $Y = +\infty$ such that $\lim_{\epsilon \to 0} Y_\epsilon = Y$ (along a subsequence). Moreover, (4.13) and (4.14) imply that there exists $X \in \mathbb{R}_0^-$ or $X = -\infty$ such that $\lim_{\epsilon \to 0} X_\epsilon = X$ (along a subsequence).

Sending $\epsilon \to 0$, inequalities (4.11) and (4.12) yield (see [16])

$$\begin{aligned} \beta u(x_0) \leq \max_{\pi \leq f(x_0)} \left[\tfrac{1}{2}\sigma^2\pi^2 X + (b - r)\pi(w_x(x_0, y_0) + \theta)\right] \\ + g(w_x(x_0, y_0) + \theta) + rx_0(w_x(x_0, y_0) + \theta) \end{aligned} \tag{4.15}$$

and

$$\begin{aligned} \beta v(y_0) \geq \max_{\pi \leq f(y_0)} \left[-\tfrac{1}{2}\sigma^2\pi^2 Y + (b - r)\pi w_x(x_0, y_0)\right] \\ + g(w_x(x_0, y_0)) + ry_0 w_x(x_0, y_0) \end{aligned} \tag{4.16}$$

where we used that $w_x(x_0, y_0) = -w_y(x_0, y_0)$ and $g(p) = \max_{c \geq 0}[-cp + U(c)]$.

We now look at the following cases.

Case (i). $X = -\infty$. Inequalities (4.15) and (4.16) yield

$$\beta u(x_0) \leq g(w_x(x_0, y_0) + \theta) + rx_0(w_x(x_0, y_0) + \theta)$$

and

$$\beta v(y_0) \geq g(w_x(x_0, y_0)) + ry_0 w_x(x_0, y_0).$$

Therefore,

$$\beta(u(x_0) - v(y_0) - \theta x_0) \leq r(x_0 - y_o)w_x(x_0, y_0) \tag{4.17}$$

where we used that g is a decreasing function and (1.5).

Case (ii). $X \leq 0$. From (1.4), (4.8), and (4.15) we get

$$\begin{aligned}\beta u(x_0) \leq \max_{\pi \leq f(y_0)+Kl(\theta)\delta} \left[\tfrac{1}{2}\sigma^2\pi^2 X + (b-r)\pi w_x(x_0, y_0)\right] + g(w_x(x_0, y_0) + \theta) \\ + rx_0(w_x(x_0, y_0) + \theta) + (b-r)\theta f(x_0)\end{aligned}$$

which, combined with (4.16), gives

$$\begin{aligned}\beta[u(x_0) - v(y_0) - \theta_{x_0}] \leq & \max_{\pi \leq f(y_0)+Kl(\theta)\delta} \left[\tfrac{1}{2}\sigma^2\pi^2 X + (b-r)\pi w_x(x_0, y_0)\right] \\ & - \max_{\pi \leq f(y_0)} \left[\tfrac{1}{2}\sigma^2\pi^2 y + \pi w_x(x_0, y_0)\right] \\ & + r(x_0 - y_0)w_x(x_0, y_0) + (b-r)\theta f(x_0).\end{aligned} \tag{4.18}$$

In the sequel we will need the following two lemmas.

LEMMA 4.1. *Let $p > 0$ and $X \leq 0, Y \geq 0$ be such that*

$$\begin{pmatrix} X & 0 \\ 0 & Y \end{pmatrix} \leq A \begin{pmatrix} 1 & -1 \\ -1 & 1 \end{pmatrix} \tag{4.19}$$

with $A > 0$. Then

$$\begin{aligned}\max_{\pi \leq a_1} \left[\tfrac{1}{2}\sigma^2\pi^2 X + (b-r)\pi p\right] - \max_{\pi \leq a_2} \left[-\tfrac{1}{2}\sigma^2\pi^2 Y + (b-r)\pi p\right] \\ \leq \omega((a_1 - a_2)^2 A + (a_1 - a_2)p)\end{aligned} \tag{4.20}$$

where $a_1 > a_2$ and $\omega : [0, +\infty) \to [0, +\infty)$ is uniformly continuous with $\omega(0) = 0$.

LEMMA 4.2. *For fixed $\eta > 0$ and $\theta > 0$, the following holds:*

$$\lim_{\delta \downarrow 0} \left| \frac{y_0 - x_0}{\delta} - 4\eta \right| = 0. \tag{4.21}$$

Moreover,

$$\lim_{\theta \downarrow 0} \lim_{\delta \downarrow 0} \theta f(x_0(\theta, \delta)) = 0. \tag{4.22}$$

We now conclude the proof of the theorem and next give the proof of the lemmas. First observe that (4.17) gives

$$\beta(u(\overline{x}) - v(\overline{x}) - \theta\overline{x}) \leq \left[-4r\left(\frac{y_0 - x_0}{\delta}\right)\left(\frac{y_0 - x_0}{\delta} - 4\eta\right)^3 + \omega_v(k\eta\delta) + \left(\frac{y_0 - x_0}{\delta} - 4\eta\right)\right]^4.$$

Sending $\delta \to 0$ and using (4.21) we contradict (4.6).

Next, we use (4.18) and Lemma 4.2 with

$$A = \frac{12}{\delta^2}\left(\frac{y_0 - x_0}{\delta} - 4\eta\right)^2, \quad a_1 = f(y_0) + Kl(\theta)\delta, \quad a_2 = f(y_0)$$

and

$$p = -\frac{4}{\delta}\left(\frac{y_0 - x_0}{\delta} - 4\eta\right)^3.$$

Note that from the definition of g and (4.16) we must have $p = w_x(x_0, y_0) > 0$. We get

$$\begin{aligned}\beta[u(\overline{x}) - v(\overline{x}) - \theta\overline{x}] \leq \omega\left(12K^2l^2(\theta)\left(\frac{y_0 - x_0}{\delta} - 4\eta\right)^2 + 4Kl(\theta)\left|\frac{y_0 - x_0}{\delta} - 4\eta\right|^3\right) \\ + 4r\left|\frac{y_0 - x_0}{\delta}\right|\left|\frac{y_0 - x_0}{\delta} - 4\eta\right|^3 + (b - r)\theta f(x_0) + \omega_v(k\eta\delta) + \left(\frac{y_0 - x_0}{\delta} - 4\eta\right)^4.\end{aligned} \tag{4.23}$$

We now use (4.21) and (4.22) and we send first $\delta \downarrow 0$, then $\theta \downarrow 0$, and last $\eta \downarrow 0$ to contradict (4.3).

Case B. $\overline{x} = 0$.

Since the proof follows along the lines of Theorem VI.5 in [16], modified with arguments similar to the ones in Case A, we only present the main steps.

First, we work as in Theorem VI.5 in [16], with $h \equiv -\infty$ and w as before, to get the existence of $X_\epsilon, Y_\epsilon \in \mathbb{R}$ such that

$$\beta u^\epsilon(\overline{x}_\epsilon) \leq G(\widehat{x}_\epsilon, w_x(\overline{x}_\epsilon, \overline{y}_\epsilon) + \theta, X_\epsilon),$$

$$\beta v_\epsilon(\overline{y}_\epsilon) \geq G(\widehat{y}_\epsilon, -w_y(\overline{x}_\epsilon, \overline{y}_\epsilon), -y_\epsilon),$$

and

$$\begin{bmatrix} X_\epsilon & 0 \\ 0 & Y_\epsilon \end{bmatrix} \leq \begin{bmatrix} w_{xx}(\overline{x}_\epsilon, \overline{y}_\epsilon) & w_{xy}(\overline{x}_\epsilon, \overline{y}_\epsilon) \\ w_{yx}(\overline{x}_\epsilon, \overline{y}_\epsilon) & w_{yy}(\overline{x}_\epsilon, \overline{y}_\epsilon) \end{bmatrix}$$

for some $\widehat{x}_\epsilon, \widehat{y}_\epsilon \in \mathbb{R}$, where $|\widehat{x}_\epsilon - \overline{x}_\epsilon| \leq C\sqrt{\epsilon}$ and $|\widehat{y}_\epsilon - y_\epsilon| \leq C\sqrt{\epsilon}$ for some positive constant C independent of ϵ, δ, and η.

Next, working as in Case A we pass to the limit as $\epsilon \downarrow 0$ and using Lemma 3.2 we derive (4.23) for $\overline{x} = 0$. Finally, we use (4.21) and (4.22) and we send first $\theta \downarrow 0$, then $\delta \downarrow 0$ and last $\eta \downarrow 0$ to conclude.

Proof of Lemma 4.1. We first observe that (4.18) yields

$$X + Y \leq 0. \tag{4.24}$$

Let π_1^* and π_2^*, satisfying $\pi_1^* \leq a_1$ and $\pi_2^* \leq a_2$, be the points where the constrained maxima of $[\frac{1}{2}\sigma^2\pi^2 X + (b - r)\pi p]$ and $[-\frac{1}{2}\sigma^2\pi^2 Y + (b - r)\pi p]$ are, respectively, achieved. We look at the following cases.

Case 1. $\pi_1^* = a_1$ and $\pi_2^* = a_2$. Then

$$\begin{aligned}&\max_{\pi \leq a_1}\left[\tfrac{1}{2}\sigma^2\pi^2 X + (b - r)\pi p\right] - \max_{\pi \leq a_2}\left[-\tfrac{1}{2}\sigma^2\pi^2 Y + (b - r)\pi p\right] \\ &\quad = \tfrac{1}{2}\sigma^2(a_1^2 X + a_2^2 Y) + (b - r)p(a_1 - a_2).\end{aligned} \tag{4.25}$$

Multiplying both sides of (4.19) by the positive definite matrix

$$\Sigma = \begin{bmatrix} a_1^2 & a_1 a_2 \\ a_1 a_2 & a_2^2 \end{bmatrix},$$

and taking the trace, yields

$$\tfrac{1}{2}(a_1^2 X + a_2^2 Y) \leq \tfrac{1}{2}(a_1 - a_2)^2 A$$

which, combined with (4.25), gives (4.20).

Case 2.

$$\pi_1^* = -\frac{(b-r)p}{\sigma^2 X} \qquad \text{and} \qquad \pi_2^* = \frac{(b-r)p}{\sigma^2 Y}.$$

Then, the maxima are unconstrained and we easily get

$$\max_{\pi}\left[\tfrac{1}{2}\sigma^2\pi^2 X + (b-r)\pi p\right] - \max_{\pi}\left[-\tfrac{1}{2}\sigma^2\pi^2 Y + (b-r)\pi p\right] \leq \max_{\pi}\left[\tfrac{1}{2}\sigma^2\pi^2(X+Y)\right] = 0$$

where we used (4.24).

Case 3. $\pi_1^* = -(b-r)p/\sigma^2 X < a_1$ and $\pi_2^* = a_2$. Then

$$\max_{\pi \leq a_1}\left[\frac{1}{2}\sigma^2\pi^2 X + (b-r)\pi p\right] = -\frac{(b-r)^2 p^2}{2\sigma^2 X} < \frac{(b-r)a_1}{2}p$$

and

$$\max_{\pi \leq a_2}\left[-\frac{1}{2}\sigma^2\pi^2 Y + (b-r)\pi p\right] = -\frac{1}{2}\sigma^2 a_2^2 Y + (b-r)a_2 p.$$

If $Y = 0$, (4.20) follows immediately. If $Y > 0$, then by assumption, $(b-r)p/\sigma^2 Y > a_2$. Therefore,

$$\begin{aligned} \frac{(b-r)}{2}a_1 p - \left[-\frac{1}{2}\sigma^2 a_2^2 Y + (b-r)a_2 p\right] &= \frac{(b-r)}{2}p(a_1 - a_2) + \frac{1}{2}\sigma^2 a_2^2 Y - \frac{(b-r)}{2}a_2 p \\ &= \frac{(b-r)}{2}p(a_1 - a_2) + \frac{1}{2}a_2[\sigma^2 a_2 Y - (b-r)p] \\ &< \frac{(b-r)}{2}p(a_1 - a_2). \end{aligned}$$

Case 4. $\pi_1^* = a_1$ and $\pi_2^* = (b-r)p/\sigma^2 Y$. This case is easily reduced to Case 2. □

Proof of Lemma 4.2. Relation (4.21) follows directly from (4.7) and (4.8). To show (4.22), since f is Lipschitz, it suffices to show $\lim_{\theta \downarrow 0} \lim_{\delta \downarrow 0} \theta x_0(\theta, \delta) = 0$. Indeed, from (4.7) we have

$$u(x_0) - v(x_0) - \theta x_0(\theta, \delta) \geq [u(\overline{x}) - v(\overline{x}) - \theta\overline{x}] - \omega_v(kl(\theta)\delta) - \omega_v(k\eta\delta) \tag{4.26}$$

which in turn implies (for fixed θ) $\sup_{\delta > 0} x_0(\theta, \delta) < +\infty$.

Therefore, there exists $\hat{x}_0(\theta)$ such that $\lim_{\delta \to 0} x_0(\theta, \delta) = \hat{x}_0(\theta)$. The limit here is taken along subsequences which, to simplify notation, we denote the same way as the whole family. By sending $\delta \to 0$, (4.26) combined with (4.5) implies

$$u(\overline{x}_0) - v(\overline{x}_0) - \theta\overline{x}_0 \geq [u(x) - v(x) - \theta x] \quad \forall x \in \overline{\Omega}. \tag{4.27}$$

We now send $\theta \to 0$. If $\lim_{\theta \downarrow 0} \theta \hat{x}_0 = \alpha \neq 0$, again along subsequences, (4.27) yields $\sup_{\overline{\Omega}}[u - v] - \alpha \geq \sup_{\overline{\Omega}}[u - v]$ which implies $\sup_{\overline{\Omega}}[u - v] \leq 0$, which contradicts (4.5). □

Remark. In the case $f \equiv \infty$, we assume

$$\sup[u(x) - v(x) - \theta x^{\delta}] > 0$$

for some $\delta \in (\gamma, 1)$, and we argue as before.

5. In this section we show that the value function is a smooth solution of the Hamilton–Jacobi–Bellman equation and we characterize the optimal policies.

THEOREM 5.1. *The value function v is the unique continuous on $[0, +\infty)$ and twice continuously differentiable in $(0, +\infty)$ solution of* (1.8) *in the class of concave functions.*

Before we go into the details of the proof of the theorem we describe the main ideas. We will work in intervals $(x_1, x_2) \subset [0, +\infty)$ and show that v solves a uniformly elliptic HJB equation in (x_1, x_2) with boundary conditions $v(x_1)$ and $v(x_2)$. Standard elliptic regularity theory (cf. Krylov [23]) and the uniqueness result about viscosity solutions will yield that v is smooth in (x_1, x_2).

We next explain how we come up with the uniformly elliptic HJB equation. Formally, according to the constraints, the optimal π^* is either $f(x)$, if

$$-\frac{b-r}{\sigma^2}\frac{v_x(x)}{v_{xx}(x)} \geq f(x) \quad \text{or} \quad -\frac{b-r}{\sigma^2}\frac{v_x(x)}{v_{xx}(x)}, \quad \text{if} \quad -\frac{b-r}{\sigma^2}\frac{v_x(x)}{v_{xx}(x)} \leq f(x).$$

In the second case, we want to get a positive lower bound of π^* in $[x_1, x_2]$. Since v_x is nonincreasing and strictly positive, it is bounded from below away from zero. Therefore, it suffices to find a lower bound for v_{xx}.

An important feature of the proof is the approximation of v by a family of smooth functions (v^{ϵ}) which are solutions of a suitably regularized equation. Next, we define the v^{ϵ}'s and discuss their main properties.

Let W_t^1 be a Wiener process which is independent of W_t and is defined on some probability space (Ω^1, F^1, P^1). We consider the process $\overline{W}_t = (W_t, W_t^1)$, which is a Wiener process, on $(\Omega \times \Omega^1, \overline{F}, P \times P^1)$ and $\overline{F} = \sigma(F \times F^1)$ where $\sigma(F \times F^1)$ is the smallest σ-algebra which contains $F \times F^1$. Let ϵ be a positive number. A real process $(C^{\epsilon}, \pi^{\epsilon})$ which is F_t-progressively measurable is called an *admissible* policy if:

(i) $C_t^{\epsilon} \geq 0$ a.s. $\forall t \geq 0$ and $\int_0^{+\infty} C_s^{\epsilon} ds < +\infty$ a.s.;

(ii) $\int_0^{+\infty} (\pi_s^{\epsilon})^2 ds < +\infty$ a.s. and $\pi_t^{\epsilon} \leq f(X_t^{\epsilon})$ a.s. $\forall t \geq 0$ where f satisfies (1.4);

(iii) $X_t^{\epsilon} \geq 0$ a.s. $\forall t \geq 0$, where X_t^{ϵ} is the trajectory given by the state equation

$$\begin{cases} dX_t^{\epsilon} = [rX_t^{\epsilon} + (b-r)\pi_t^{\epsilon} - C_t^{\epsilon}]dt + \sigma\pi_t^{\epsilon} dW_t + \sigma\epsilon X_t^{\epsilon} dW_t^1 \ (t > 0) \\ X_0^{\epsilon} = x \qquad (x \epsilon [0, +\infty)) \end{cases}$$

using the controls $(C^{\epsilon}, \pi^{\epsilon})$.

We denote by $\mathcal{A}_x^{\epsilon}$ the set of admissible policies. We define the value function v^{ϵ} by

$$v^{\epsilon}(x) = \sup_{\mathcal{A}_x^{\epsilon}} E \int_0^{+\infty} e^{-\beta t} U(C_t^{\epsilon}) dt,$$

where U is the usual utility function. Using arguments similar to those in Propositions 2.1 and 2.2 we can prove that v^ϵ is concave, strictly increasing in x, and uniformly continuous on $\overline{\Omega}$.

Using a variation of Theorems 3.1 and 4.1, we have that the value function v^ϵ is the unique constrained viscosity solution on $\overline{\Omega}$ of the equation

$$\beta v^\epsilon = \max_{\pi \le f(x)} \left[\frac{1}{2}\sigma^2(\pi^2 + \epsilon^2 x^2)v^\epsilon_{xx} + (b-r)\pi v^\epsilon_x\right] + \max_{c\ge 0}[-cv^\epsilon_x + U(c)] + rxv^\epsilon_x. \tag{5.1}$$

We next consider a sequence (v^ϵ_L) with

$$v^\epsilon_L(x) = \sup_{\mathcal{A}^{\epsilon,L}} E\int_0^{+\infty} e^{-\beta t}U(C_t)dt \qquad (x \in \mathbb{P}).$$

The set $\mathcal{A}^{\epsilon,L}$ of admissible policies consists of pairs $(C^{\epsilon,L}, \pi^{\epsilon,L})$ such that $C^{\epsilon,L}, \pi^{\epsilon,L}$ are F_t-progressively measurable satisfying (i), (ii), and also $-L \le \pi^{\epsilon,L}_t$ almost surely for all $t \ge 0$.

Working as in Theorems 3.1 and 4.1, we get that v^ϵ_L is the unique constrained viscosity solution of $\overline{\Omega}$ of

$$\begin{aligned}\beta v^\epsilon_L = &\max_{-L\le\pi\le f(x)}\left[\tfrac{1}{2}\sigma^2\pi^2 v^\epsilon_{L,xx} + (b-r)\pi v^\epsilon_{L,x}\right]\\ &+\max_{c\ge 0}[-cv^\epsilon_{L,x} + U(c)] + rxv^\epsilon_{L,x}\end{aligned} \tag{5.2}$$

and, also, the unique viscosity solution (see [16]) of

$$\begin{aligned}\beta u = &\max_{-L\le\pi\le f(x)}\left[\tfrac{1}{2}\sigma^2\pi^2 u_{xx} + (b-r)\pi u_x\right]\\ &+\max_{c\ge 0}[-cu_x + U(c)] + rxu_x(x\epsilon[x_1, x_2])\\ u(x_1) = v^\epsilon_L(x_1), &\qquad u(x_2) = v^\epsilon_L(x_2).\end{aligned} \tag{5.3}$$

On the other hand, (5.3) admits a unique smooth solution u which is also the unique viscosity solution; therefore, v^ϵ_L is smooth which, together with the fact that v^ϵ_L is increasing and concave, yields that v^ϵ_L is also smooth solution of

$$\begin{aligned}\beta u = &\max_{0\le\pi\le f(x)}\left[\tfrac{1}{2}\sigma^2\pi^2 u_{xx} + (b-r)\pi u_x\right]\\ &+\max_{c\ge 0}[-cu_x + U(c)] + rxu_x\\ u(x_1) = v^\epsilon_L(x_1), &\qquad u(x_2) = v^\epsilon_L(x_2).\end{aligned}$$

We next observe that there exists w concave such that $v^\epsilon_L \to w$, as $L \to \infty$, locally uniformly in $\overline{\Omega}$. Therefore, w is a constrained viscosity solution of (5.1) and, by uniqueness of viscosity solution, it coincides with v^ϵ. This also implies that v^ϵ is a viscosity solution of

$$\begin{aligned}\beta u = &\max_{0\le\pi\le f(x)}\left[\tfrac{1}{2}\sigma^2\pi^2 u_{xx} + (b-r)\pi u_x\right]\\ &+\max_{c\ge 0}[-cu_x + U(c)] + rxu_x\\ u(x_1) = v^\epsilon(x_1), &\quad u(x_2) = v^\epsilon(x_2).\end{aligned} \tag{5.4}$$

Equation (5.4) admits a unique smooth solution which is the unique viscosity solution. Therefore v^ϵ is smooth.

Proof. Consider an interval $[x_1, x_2] \subset [0, +\infty)$ and let $[\overline{x}_1, \overline{x}_2]$ and $[X_1, X_2]$ with $X_1 > 0$ be such that $[x_1, x_2] \subset [\overline{x}_1, \overline{x}_2] \subset [X_1, X_2]$. Since v is concave and increasing, its first and second derivatives exist almost everywhere. Without any loss of generality, we can assume that $v_x(X_1)$ and $v_x(X_2)$ exist. The reason for this will become apparent in the sequel.

We are now going to prove that the optimal portfolio π^ϵ of the approximating problem is bounded from below by a positive number which is independent of ϵ (of course it may depend on (x_1, x_2)). To this end, it suffices to show that

$$-\frac{b-r}{\sigma^2}\frac{v^\epsilon_x}{v^\epsilon_{xx}} \geq c > 0 \quad \text{on } [x_1, x_2].$$

We first show that $v^\epsilon \to v$ locally uniformly on $\overline{\Omega}$. Indeed, v^ϵ and v^ϵ_x are bounded locally by u and u/x where u is the value function with $f(x) = +\infty$ and $\epsilon = 0$. This follows from the fact that $v^\epsilon \leq u^\epsilon \leq u$ (where u^ϵ is the value function with $f(x) = +\infty$ and $\epsilon > 0$), which can be proved by using a similar comparison result as in Theorem 4.1. Therefore, there exists a subsequence $\{v^{\epsilon_n}\}$ and a function w such that $v^{\epsilon_n} \to w$ locally uniformly in $\overline{\Omega}$. Moreover, an argument similar to the proof of Proposition 2.2 yields that $\lim_{x\to 0} v^\epsilon(x) = U(0)/\beta$ uniformly in ϵ, therefore $w(0) = U(0)/\beta$.

Using a variation of Proposition I.3 in [27] we get that w is a constrained viscosity of (1.8). Moreover, since w is concave, using Theorem 4.1 we get that it is the unique constrained viscosity solution of (1.8). Therefore, we conclude that all subsequences have the same limit which coincides with v. Using that $v^\epsilon \to v$ locally uniformly and the fact that v^ϵ and v are concave, we get that $\lim_{\epsilon\to 0} v^\epsilon_x(x_0) = v_x(x_0)$ at any point x_0 where $v_x(x_0)$ exists. Taking into account that v^ϵ_x is nondecreasing in $[X_1, X_2]$, we conclude that there exist positive constants $R_1 = R_1([X_1, X_2])$ and $R_2 = R_2([X_1, X_2])$ such that

$$R_1 \leq v^\epsilon_x(x) \leq R_2 \quad \text{on } [x_1, x_2]. \tag{5.5}$$

We next show that there exists a constant $R = R([X_1, X_2])$ such that

$$|v^\epsilon_{xx}(x)| \geq R \quad \text{on } [x_1, x_2]. \tag{5.6}$$

To this end, let $\zeta : \mathbb{R}^+ \to \mathbb{R}^+$ be as follows:

(i) $\zeta \in C^\infty_0$ (i.e., ζ is a smooth function with compact support);

(ii) $\zeta \equiv 1$ on $[x_1, x_2]$, $\zeta \equiv 0$ on $\mathbb{R}\backslash[\overline{x}_1, \overline{x}_2]$, and $0 \leq \zeta \leq 1$ otherwise;

(iii) $|\zeta_x| \leq M\zeta^p$, $|\zeta_{xx}| \leq M\zeta^p$ with $0 < p < 1$ and $M > 0$.

From now on, for simplicity we suppress the ϵ-notation. We next consider a function $Z : [X_1, X_2] \to \mathbb{R}$ given by $Z(x) = \zeta^2 v^2_{xx} + \lambda v^2_x - \mu v$, where λ and μ are positive constants to be chosen later. We are interested in looking at the maximum of Z on $[X_1, X_2]$. The following cases can happen.

Case 1. The function Z attains its maximum at a point $x_0 \notin \text{supp } \zeta$. Then using (ii) and that $v > 0, v_x > 0$, we get

$$v^2_{xx}(x) \leq \lambda v^2_x(x_0) + \mu v(x) \quad \forall x \in [x_1, x_2]$$

which implies (5.6).

Case 2. The function Z attains its maximum at the point $x_0 \in \text{supp } \zeta$. In this case we have

$$Z_x(x_0) = 0 \quad \text{and} \quad Z_{xx}(x_0) \leq 0 \tag{5.7}$$

where

$$Z_x = 2\zeta\zeta_x v_{xx}^2 + 2\zeta^2 v_{xx}v_{xxx} + 2\lambda v_x v_{xx} - \mu v_x \tag{5.8}$$

and

$$\begin{aligned} Z_{xx} = {} & 2\zeta_x^2 v_{xx}^2 + 2\zeta\zeta_{xx}v_{xx}^2 + 8\zeta\zeta_x v_{xx}v_{xxx} + 2\zeta^2 v_{xxx}^2 \\ & + 2\zeta^2 v_{xx}v_{xxxx} + 2\lambda v_{xx}^2 + 2\lambda v_x v_{xxx} - \mu v_{xx}. \end{aligned} \tag{5.9}$$

We examine each of the following cases separately.

Case 2(a).

$$x_0 \in A_1 = \left\{ x \in [x_1, x_2] : -\frac{b-r}{\sigma^2}\frac{v_x^\epsilon(x)}{v_{xx}^\epsilon(x)} < f(x) \right\}.$$

In this case the Bellman equation has the form

$$\beta v = -\gamma\frac{v_x^2}{v_{xx}} + \frac{1}{2}\epsilon^2\sigma^2 x^2 v_{xx} - v_x I(v_x) + U(I(v_x)) + rxv_x \tag{5.10}$$

with $\gamma = (b-r)^2/2\sigma^2$. Here we used that $\max_{c\geq 0}[-cp + U(c)] = -pI(p) + U(I(p))$ with $I = (U')^{-1}$. After differentiating (5.10) twice and rearranging the terms we get:

$$\begin{aligned} -\gamma\frac{v_x^2 v_{xxxx}}{v_{xx}^2} - \frac{1}{2}\epsilon^2\sigma^2 x^2 v_{xxx} - \gamma\frac{v_x^2 v_{xxx}^2}{v_{xx}^3} = {} & -\beta v_{xx} \\ & + v_{xx}[2r - 2\gamma + \epsilon^2\sigma^2] + 2\gamma\frac{v_x v_{xxx}}{v_{xx}} - 3\gamma\frac{v_x^2 v_{xxx}^2}{v_{xx}^3} \\ & + v_{xxx}[rx - I(v_x) + 2\epsilon^2\sigma^2 x] - v_{xx}^2 I'(v_x). \end{aligned} \tag{5.11}$$

On the other hand, (5.7) yields

$$-\left[\gamma\frac{v_x^2(x_0)}{v_{xx}^2(x_0)} + \frac{1}{2}\epsilon^2\sigma^2 x_0^2\right] Z_{xx}(x_0) \geq 0$$

which, combined with (5.9), yields

$$\begin{aligned} -\left[\gamma\frac{v_x^2}{v_{xx}} + \frac{1}{2}\epsilon^2\sigma^2 x^2\right] Z_{xx} = {} & 2\zeta^2 v_{xx}\left[-\gamma\frac{v_x^2 v_{xxxx}}{v_{xx}^2} - \frac{1}{2}\epsilon^2\sigma^2 x^2 v_{xxxx} - \gamma\frac{v_x^2 v_{xxx}^2}{v_{xx}^3}\right] \\ & + 2\lambda v_x\left[-\gamma v_x - \frac{1}{2}\epsilon^2\sigma^2 x^2 v_{xx} - \gamma\frac{v_x^2 v_{xxx}}{v_{xx}^2}\right] + \mu\left[\gamma\frac{v_x^2}{v_{xx}} + \frac{1}{2}\epsilon^2\sigma^2 x^2 v_{xx}\right] \\ & - 2\gamma\zeta_x^2 v_x^2 - \epsilon^2\sigma^2 x^2\zeta_x^2 v_{xx}^2 - 2\gamma v_x^2\zeta\zeta_{xx} - x^2\epsilon^2\sigma^2\zeta\zeta_{xx}v_{xx}^2 - 8\gamma\zeta\zeta_x\frac{v_x^2 v_{xxx}}{v_{xx}} \\ & - 4x^2\epsilon^2\sigma^2\zeta\zeta_x v_{xx}v_{xxx} - \epsilon^2\sigma^2 x^2\zeta^2 v_{xxx}^2 - \lambda x^2\epsilon^2\sigma^2 v_{xx}^2 \geq 0, \end{aligned} \tag{5.12}$$

where all the expressions are evaluated at x_0.

Using (5.10), (5.11), and

$$\begin{aligned} -\gamma v_x - \frac{1}{2}\epsilon^2\sigma^2 x^2 v_{xxx} - \gamma\frac{v_x^2 v_{xxx}}{v_{xx}^2} = {} & v_{xx}[rx - I(v_x) + \epsilon^2\sigma^2 x] \\ & + v_x(r - 3\gamma) - \beta v_x \end{aligned} \tag{5.13}$$

which follows from differentiating (5.10) once and rearranging terms, we obtain from (5.12):

$$
\begin{aligned}
&-2\beta\zeta^2 v_{xx}^2 + 2\zeta^2(2r - 2\gamma + \epsilon^2\sigma^2)v_{xx}^2 + 4\gamma\zeta^2 v_x v_{xxx} - 6\gamma\zeta^2\frac{v_x^2 v_{xxx}^2}{v_{xx}^2} \\
&\quad + 2\zeta^2 v_{xx} v_{xxx}[rx - I(v_x) + 2\epsilon^2\sigma^2 x] - 2\zeta^2 v_{xx}^3 I'(v_x) \\
&\quad + 2\lambda v_x v_{xx}[rx - I(v_x) + \epsilon^2\sigma^2 x] + 2\lambda(r - 3\gamma)v_x^2 - 2\lambda\beta v_x^2 + 2\gamma\mu\frac{v_x^2}{v_{xx}} \\
&\quad + \mu v_x[-rx + I(v_x)] - \mu U(I(v_x)) \\
&\quad + \beta\mu v - 2\gamma\zeta_x^2 v_x^2 - \epsilon^2\sigma^2 x^2\zeta_x^2 v_{xx}^2 - 2\gamma v_x^2\zeta\zeta_{xx} - \epsilon^2\sigma^2 x^2\zeta\zeta_{xx}v_{xx}^2 - 8\gamma\zeta\zeta_x\frac{v_x^2 v_{xxx}}{v_{xx}} \\
&\quad - 4x^2\epsilon^2\sigma^2\zeta\zeta_x v_{xx}v_{xxx} - \epsilon^2\sigma^2 x^2\zeta_x^2 v_{xxx}^2 - \lambda x^2\epsilon^2\sigma^2 v_{xx}^2 \geq 0.
\end{aligned}
$$

A further calculation yields that at x_0,

$$
\begin{aligned}
&(rx - I(v_x) + \epsilon^2\sigma^2 x)(2\zeta^2 v_{xx}v_{xxx} + 2\lambda v_x v_{xx} - \mu v_x) + 2\zeta^2\epsilon^2\sigma^2 x v_{xx}v_{xxx} \\
&\quad + \epsilon^2\sigma^2\mu x v_x - 2\beta\zeta^2 v_{xx}^2 - 4\left(\gamma - r - \frac{\epsilon^2\sigma^2}{2}\right)\zeta^2 v_{xx}^2 + 4\gamma\zeta^2 v_x v_{xxx} \\
&\quad - 6K\zeta^2\frac{v_x^2 v_{xxx}^2}{v_{xx}^2} - 2\lambda\beta v_x^2 - 2\lambda(3\gamma - r)v_x^2 + \mu\beta v + 2\gamma\mu\frac{v_x^2}{v_{xx}} - \mu U(I(v_x)) \\
&\quad - 2\gamma\zeta_x^2 v_x^2 - 2\gamma\zeta\zeta_{xx}v_x^2 - 8\gamma\zeta\zeta_x\frac{v_x^2 v_{xxx}}{v_{xx}} + \epsilon^2\sigma^2 x^2[4\zeta\zeta_x|v_{xx}|v_{xxx} - \zeta^2 v_{xxx}^2 \\
&\quad - \lambda v_{xx}^2] - \epsilon^2\sigma^2 x^2\zeta_x^2 v_{xx}^2 - \epsilon^2\sigma^2 x^2\zeta\zeta_{xx}v_{xx}^2 \geq 2\zeta^2 v_{xx}^3 I'(v_x).
\end{aligned}
$$

(5.14)

If $A(x) = 2\zeta^2 v_{xx}v_{xxx} + 2\lambda v_x v_{xx} - \mu v_{x'}$ (5.7) and (5.8) imply

$$A(x_0) = -2\zeta(x_0)\zeta_x(x_0)v_{xx}^2(x_0).$$

Then (5.14) becomes

$$
\begin{aligned}
&-2\zeta\zeta_x v_{xx}^2(rx - I(v_x) + \epsilon^2\sigma^2 x) - 2\beta\zeta^2 v_{xx}^2 - 2\lambda\beta v_x^2 + \mu\beta v - 2\lambda(3\gamma - r)v_x^2 \\
&\quad -2\gamma\mu\frac{v_x^2}{|v_{xx}|} - \mu U(I(v_x)) - 2\gamma\zeta_x^2 v_x^2 - \epsilon^2\sigma^2 x^2\zeta_x^2 v_{xx}^2 - \epsilon^2\sigma^2 x^2\zeta\zeta_{xx}v_{xx}^2 - 2\gamma\zeta\zeta_{xx}v_x^2 \\
&\quad + \left[-4\left(\gamma - r - \frac{\epsilon^2\sigma^2}{2}\right)\zeta^2 v_{xx}^2 + 4\gamma\zeta^2 v_x v_{xxx} - 6\gamma\zeta^2\frac{v_x^2 v_{xxx}^2}{v_{xx}^2} + 8\gamma\zeta\zeta_x\frac{v_x^2 v_{xxx}}{|v_{xx}|}\right] \\
&\quad +\epsilon^2\sigma^2 x^2\left[\left(4\zeta\zeta_x - \frac{2\zeta^2}{x}\right)|v_{xx}|v_{xxx} - \zeta^2 v_{xxx}^2 - \lambda v_{xx}^2\right] + \epsilon^2\sigma^2\mu x v_x \\
&\quad \geq 2\zeta^2 v_{xx}^3 I'(v_x).
\end{aligned}
$$

(5.15)

Let

$$B(x) = -4\left(\gamma - r - \frac{\epsilon^2\sigma^2}{2}\right)\zeta^2 v_{xx}^2 + 4\gamma\zeta^2 v_x v_{xxx} - 6\gamma\zeta^2\frac{v_x^2 v_{xxx}^2}{v_{xx}^2} + 8\gamma\zeta\zeta_x\frac{v_x^2 v_{xxx}}{|v_{xx}|}$$

and

$$C(x) = \left(4\zeta\zeta_x - \frac{2\zeta^2}{x}\right)|v_{xx}|v_{xxx} - \zeta^2 v_{xxx}^2 - \lambda v_{xx}^2.$$

Let ϵ sufficiently small and $\theta \in (0, \frac{3}{4})$. Using the Cauchy–Schwartz inequality we get

$$B(x_0) \leq C\left(\frac{\zeta_x^2(x_0)}{\theta}v_x^2(x_0) + \zeta^2(x_0)v_{xx}^2(x_0)\right) \tag{5.16}$$

for some positive constant C.

A similar argument yields

$$C(x_0) \leq v_{xx}^2(x_0)\left[\left(2\zeta_x(x_0) - \frac{\zeta(x_0)}{x_0}\right)^2 - \lambda\right]. \tag{5.17}$$

We next choose λ so that $\lambda > 4\zeta_x^2 + (2/x_1^2)$ on $[\overline{x}_1, \overline{x}_2]$. Then $C(x_0) \leq 0$. If we leave out all the negative terms in (5.15) and use (5.16) and (5.17) we get

$$\begin{aligned} & v_{xx}^2(x_0)[-2\zeta(x_0)\zeta_x(x_0)[rx_0 - I(v_x(x_0))) + 2\epsilon^2\sigma^2 x_0] \\ & \quad -\epsilon^2 x_0^2\sigma^2\zeta(x_0)\zeta_{xx}(x_0) + C\zeta^2(x_0)] \\ & \quad +v_x^2(x_0)\left[C\frac{\zeta_x^2(x_0)}{\theta} - 2\gamma\zeta(x_0)\zeta_{xx}(x_0)\right] \\ & \quad +\mu[\beta v(x_0) + 2\epsilon\sigma^2 x_0 v_x(x_0))] \\ & \quad \geq 2\zeta(x_0)^2 v_{xx}^3(x_0) I'(v_x(x_0)). \end{aligned} \tag{5.18}$$

We now return to the ϵ-notation. From (5.5) we have

$$I(v_x^\epsilon(x_0)) \leq I(R_1) \tag{5.19}$$

and

$$|I'(v_x^\epsilon(x_0))| \leq |I'(R_2)|. \tag{5.20}$$

From (5.18), (5.19), and (5.20) we get that for some constants k_1, k_2, k_3, and k_4,

$$v_{xx}^\epsilon(x_0)^2[k_1\zeta(x_0)|\zeta_x(x_0)| + k_2\zeta(x_0)|\zeta_{xx}(x_0)| + C\zeta^2(x_0)] + k_4 \geq k_3\zeta(x_0)^2|v_{xx}^\epsilon(x_0)|^3.$$

Using property (iii) of ζ with $p = \frac{1}{3}$ we obtain

$$C_1 v_{xx}^\epsilon(x_0)^2[\zeta(x_0)^2 + \zeta(x_0)^{1+1/3}] + k \geq k_3\zeta(x_0)^2|v_{xx}^\epsilon(x_0)|^3 \tag{5.21}$$

for some $C_1 > 0$. Now if $w(x_0) = \zeta^2(x_0)|v_{xx}^\epsilon(x_0)|^3$, then $w(x_0)^{2/3} = \zeta(x_0)^{4/3}|v_{xx}^\epsilon(x_0)|^2$. In view of property (ii) of ζ, (5.21) yields

$$2C_1 w(x_0)^{2/3} + \overline{k} \geq k_3 w(x_0),$$

for some $\overline{k} > 0$ and, therefore,

$$w(x_0) \leq N$$

where $N = N(C_1, \overline{K}, K_3)$ is independent of ϵ.

Thus

$$(v_{xx}^\epsilon)^2 + \lambda(v_x^\epsilon)^2 - \mu v^\epsilon \leq N^{2/3} + \lambda(v_x^\epsilon(x_0))^2 - \mu v^\epsilon(x_0) \text{ on } [x_1, x_2],$$

i.e., there exists a constant L_1, independent of ϵ, such that

$$|v_{xx}^\epsilon| \leq L_1 \text{ on } [x_1, x_2].$$

Case 2b.

$$x_0 \epsilon A_2 = \left\{x \epsilon [x_1, x_2] : -\frac{b-r}{\sigma^2}\frac{v_x^\epsilon(x)}{v_{xx}^\epsilon(x)} \geq f(x)\right\}.$$

In this case,

$$|v^\epsilon_{xx}(x_0)| \leq L_2 \quad \text{on } [x_1, x_2] \quad \text{where } L_2 = \frac{b-r}{\sigma^2}\frac{R_2}{f(x_1)}.$$

Therefore,

$$|v^\epsilon_{xx}| \leq R \quad \text{on } [x_1, x_2]. \tag{5.22}$$

where $R = \max(L_1, L_2)$, independent of ϵ.

Combining (5.5) and (5.22) we see that

$$-\frac{b-r}{\sigma^2}\frac{v^\epsilon_x}{v^\epsilon_{xx}} \geq B > 0 \quad \text{on } [x_1, x_2] \quad \text{with } B = \frac{b-r}{\sigma^2}\frac{R_1}{R}.$$

Let us now consider the equation

$$\begin{aligned} \beta u = &\max_{B\leq\pi\leq f(x)}\left[\tfrac{1}{2}\sigma^2(\pi^2+\epsilon^2x^2)u_{xx} + (b-r)\pi u_x\right] \\ &+ \max_{c\geq 0}[-cu_x + U(c)] + rxu_x \\ u(x_1) = v^\epsilon(x_1), &\quad u(x_2) = v^\epsilon(x_2) \quad (x\epsilon[x_1, x_2]). \end{aligned} \tag{5.23}$$

In view of the above analysis, we know that v^ϵ solves (5.23). Let $\epsilon \to 0$. Since $v^\epsilon \to v$, locally uniformly, v is a viscosity solution of

$$\begin{aligned} \beta u = &\max_{B\leq\pi\leq f(x)}\left[\tfrac{1}{2}\sigma^2\pi^2u_{xx} + (b-r)\pi u_x\right] \\ &+ \max_{c\geq 0}[-cu_x + U(c)] + rxu_x (x\epsilon[x_1, x_2]) \\ u(x_1) = v(x_1), &\quad u(x_2) = v(x_2). \end{aligned} \tag{5.24}$$

On the other hand, (4.21) admits a unique smooth solution u (see [23]) which is the unique viscosity solution (see [16, Thm. II.2]); therefore v is smooth. □

THEOREM 5.2. *The feedback optimal controls C^* and π^* are given by*

$$c^*(x) = I(v_x(x)) \quad \textit{and} \quad \pi^*(x) = \min\left\{-\frac{b-r}{\sigma^2}\frac{v_x(x)}{v_{xx}(x)}, f(x)\right\} \quad \textit{for } x > 0.$$

The state equation (1.3) *has a strong unique solution X^*_t, corresponding to $C^*_t = c^*(X^*_t)$ and $\pi^*_t = \pi^*(X^*_t)$ and starting at $x > 0$ at $t = 0$, which is unique in probability law up to the first time τ such that $X^*_\tau = 0$.*

Proof. The formulae for π^* and C^* follow from a standard verification theorem (see [11]) and the equation. We now show that π^* and C^* are locally Lipschitz functions of x. It is clear that v_x is locally Lipschitz because in any compact set K there exists a constant $C = C(K)$ such that $|v_{xx}| \leq C(K), (x\epsilon K)$. Therefore C^* is locally Lipschitz. Moreover, from the Bellman equation we have that

$$v_{xx} = H(x, v, v_x)$$

where

$$H(x, v, v_x) = \frac{2[\beta v - (b-r)f(x)v_x + v_x I(v_x) - U(I(v_x)) + rxv_x]}{\sigma^2 f(x)^2}$$

$$\text{if} \quad -\frac{b-r}{\sigma^2}\frac{v_x}{v_{xx}} \geq f(x)$$

and

$$H(x,v,v_x) = -\frac{b-r}{2\sigma^2}\frac{v_x^2}{\beta v - rxv_x + v_x I(v_x) - U(I(v_x))} \quad \text{if} \quad -\frac{b-r}{\sigma^2}\frac{v_x}{v_{xx}} < f(x).$$

Since v_x is locally Lipschitz we get that v_{xx} is also locally Lipschitz. Therefore (see Gikhman and Skorohod [14]) equation (1.3) has a unique strong solution X_t^* in probability law up to the first time τ such that $X_\tau^* = 0$. □

6. In this section we discuss the finite horizon model and we state results about the value function and the optimal policies.

The investor starts at time $t \in [0,T)$ with an initial endowment x, consumes at rate C_s and invests π_s^0 (respectively, π_s) amount of money in bond (respectively, in stock) for $t \le s \le T$. The prices of the bond and the stock satisfy the same equations as in the infinite horizon case. The wealth of the investor $X_s = \pi_s^0 + \pi_s (t \le s \le T)$ satisfies the state equation

$$\begin{aligned} &dX_s = rX_s ds + (b-r)\pi_s ds - C_s ds + \sigma\pi_s dW_s \qquad (t \le s \le T) \\ &X_t = x \qquad (x > 0). \end{aligned} \tag{6.1}$$

The agent faces the same constraints as in the infinite horizon case. In other words, the wealth must stay nonnegative; the agent cannot consume at a negative rate and must meet borrowing constraints ($\pi_s \le f(X_s)$ for $t \le s \le T$).

The *total utility* coming both from consumption and terminal wealth is

$$J(x,t,C,\pi) = E\left[\int_t^T U(C_s)ds + \Phi(X_T)\right]$$

where U is the usual utility function and Φ is the *bequest* function which is typically concave, increasing, and smooth.

The *value function* is

$$\mathcal{A}(x,t) = \sup_{\mathcal{A}_{(x,t)}} J(x,t,C,\pi)$$

where $\mathcal{A}_{(x,t)}$ is the set of admissible controls.

In the sequel we state the main theorems. Since the proofs are modifications of the ones given in the previous sections they are not presented here.

THEOREM 6.1. *The value function is the unique continuous on* $\Omega \times [t,T]$ *and* $C^{2,1}(\Omega \times (t,T))$ *solution of*

$$\begin{aligned} &v_t + \max_{\pi \le f(x)}\left[\tfrac{1}{2}\sigma^2\pi^2 v_{xx} + (b-r)\pi v_x\right] + \max_{c \ge 0}[-cv_x + U(c)] + rxv_x = 0 \\ &v(x,T) = \Phi((x) \end{aligned} \tag{6.2}$$

in the class of concave (with respect to the space variable x) functions.

THEOREM 6.2. *The feedback optimal controls* C^* *and* π^* *are given by* $C_t^* = c^*(X_t^*,t)$ *and* $\pi_t^* = \pi^*(X_t^*,t)$ *where* $C^*(x,t) = (U')^{-1}(v_x(x,t))$ *and*

$$\pi^*(x,t) = \min\left\{-\frac{b-r}{\sigma^2}\frac{v_x(x,t)}{v_{xx}(x,t)}, f(x)\right\} \quad \textit{for } x > 0.$$

A SUPER-OPTIMIZATION METHOD FOR FOUR-BLOCK PROBLEMS*

P.-O. NYMAN†

Abstract. This paper deals with a discrete time frequency domain approach to super-optimization of four-block problems via a dimension reduction and diagonalization technique based on the so-called equalizer principle, an optimality criterion associated with the polynomial approach to $\mathcal{H}^\infty$-optimization by Kwakernaak. The reduction technique provides a hierarchical decomposition of the super-optimization problem into successive ordinary $\mathcal{H}^\infty$-optimization problems, one for each singular value to be minimized. The procedure allows computation of super-optimal solutions for a large class of four-block problems.

Key words. super-optimization, $\mathcal{H}^\infty$-optimal control, equalizer principle

AMS subject classifications. 93B36, 93B50, 93B35

1. Introduction. In ordinary $\mathcal{H}^\infty$-optimization of a multivariable control system, the compensator is chosen to minimize the largest singular value of the transfer function. Such a controller is, in general, far from unique, and a substantial amount of freedom is left which could be used to optimize some additional performance criterion. Among many possible choices a most natural and appealing one is to pursue a compensator minimizing not only the largest singular value, but also the second largest, the third largest, etc., with respect to lexicographic ordering. This strengthened $\mathcal{H}^\infty$-optimality criterion was proposed by Young in [27] where, in the context of an one-block problem, an algorithm was given and the existence and uniqueness of the optimal solution was proved. Strengthened $\mathcal{H}^\infty$-optimization has also received attention in the control theoretic community (see, e.g., [3], [8], [9], [11], [15], [16], [18], [21], [24], [26]) and has been called *super optimization*. Similar to ordinary $\mathcal{H}^\infty$-optimization, super-optimization is motivated by robustness requirements. In fact, simple examples suggest that a super-optimal compensator may improve the robustness properties achieved by an arbitrary $\mathcal{H}^\infty$-optimal compensator. Algorithms appearing in the literature mostly restrict themselves to one- and two-block problems. The two-block method in [9], based on a state-space descriptor representation of all $\mathcal{H}^\infty$-optimal solutions is, however, reported to have an extension to the four-block problem.

In this paper we propose a frequency domain approach to super-optimization of the four-block problem. The setting will be discrete time, but with appropriate modifications the method may be used for continuous time as well. As in [27], a dimension reducing and diagonalizing technique is used to decompose the problem into $\mathcal{H}^\infty$-minimizations of individual singular values in a hierarchical fashion. The diagonalization transformations are derived via the so-called equalizer principle, an optimality criterion associated with the polynomial $\mathcal{H}^\infty$-optimization approach by Kwakernaak (cf., e.g., [13]). Previous use of the equalizer principle in the context of super-optimization may be found in [11], [15], and [18]. By using a polynomial matrix fraction representation of data, the computational steps may be adapted for numerical calculations based on polynomial routines of the type considered in [14]. This certainly holds for the minimizations of individual singular values, where the polynomial $\mathcal{H}^\infty$-optimization approach by Kwakernaak is available.

The paper is organized as follows. Section 2 collects a few preliminaries. Section 3 gives some useful characterizations of the conditions of equalizer principle. In §4 these are used to establish the dimension reduction and diagonalization technique. The spectral density associated with the equalizer principle plays an essential role here. In §5 the

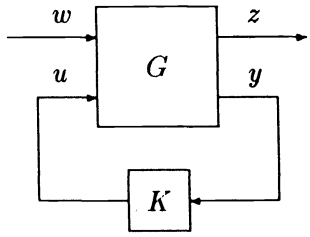

FIG. 1. *The standard configuration.*

reduction technique and the polynomial $\mathcal{H}^\infty$-optimizations approach are conjoined into a super-optimization procedure. Section 6, which logically may precede §4, gives a method for computing the spectral density needed for the dimension reduction. In §7 conditions for the existence of the spectral density are given in terms of a four-block operator. Finally, in §8 the super-optimization procedure is illustrated with a numerical four-block example.

2. Preliminaries. We first recall some well-known facts about the rich class of interesting control theoretic $\mathcal{H}^\infty$-optimization problems described by the so-called standard problem formulation, illustrated by the block diagram in Fig. 1. The block G is a generalized plant which, in addition to the actual plant, also includes weighting functions. The block K is a feedback compensator. Both G and K are supposed to be representable by rational transfer matrices, also denoted G and K. The signal w contains all external inputs to the system. The output z to be controlled may be thought of as a control error. The signals u and y are the control input and the measured output, respectively. Let

$$G = \begin{matrix} \\ m \\ q \end{matrix} \overset{\begin{matrix} n & p \end{matrix}}{\begin{bmatrix} G_{11} & G_{12} \\ G_{21} & G_{22} \end{bmatrix}}$$

be a partition of the plant done conformly with its input $(w^{\mathrm{T}}, u^{\mathrm{T}})^{\mathrm{T}}$ and output $(z^{\mathrm{T}}, y^{\mathrm{T}})^{\mathrm{T}}$. The transfer matrix from the input w to the output z may then be written

$$H_K = G_{11} + G_{12}K(I - G_{22}K)^{-1}G_{21}. \tag{1}$$

The standard problem of $\mathcal{H}^\infty$ control consists of finding a compensator K stabilizing the plant G, and making the $\mathcal{H}^\infty$ norm of H_K as small as possible. For a precise definition of what is meant by a stabilizing compensator we refer to [6]. Assuming G to be stabilizable (i.e., that G admits a stabilizing compensator), we have at our disposal the so-called Youla parametrization, which states that a compensator K stabilizes G if and only if

$$K = -(U_l + D_r Q)(V_l - N_r Q)^{-1} = -(V_r - QN_l)^{-1}(U_r + QD_l), \tag{2}$$

where the rational matrices $U_l, V_l, N_l, D_l U_r, V_r, N_r, D_r$ are obtained from a doubly coprime factorization

$$G_{22} = N_r D_r^{-1} = D_l^{-1} N_l, \qquad \begin{bmatrix} V_r & U_r \\ -N_l & D_l \end{bmatrix} \begin{bmatrix} D_r & -U_l \\ N_r & V_l \end{bmatrix} = \begin{bmatrix} I_p & 0 \\ 0 & I_q \end{bmatrix}. \tag{3}$$

For a proof see [6] and [25]. Using (2) and (3) we may write $K(I - G_{22}K)^{-1} = -(U_l + D_r Q)D_l$ which, substituted into (1), gives

$$H_K = F + BQC,$$

where $F = G_{11} - G_{12}U_l D_l G_{21} \in \mathcal{RH}^\infty_{m\times n}$, $B = -G_{12}D_r \in \mathcal{RH}^\infty_{m\times p}$, and $C = D_l G_{21} \in \mathcal{RH}^\infty_{q\times n}$. The standard problem therefore is equivalent to the model-matching problem of finding a $Q \in \mathcal{RH}^\infty_{p\times q}$ such that $\|F + BQC\|_\infty$ is minimized. Conversely, any model-matching problem is easily expressed as a standard problem. As the basic structure for $\mathcal{H}^\infty$-optimization problems we therefore take, instead of the standard configuration, the model-matching configuration; that is, a coset in $\mathcal{H}^\infty_{m\times n}$ defined by

$$\Sigma = F + B\mathcal{H}^\infty_{p\times q}C = \{F + BQC | Q \in \mathcal{H}^\infty_{p\times q}\}, \tag{4}$$

where $F \in \mathcal{H}^\infty_{m\times n}$, $B \in \mathcal{H}^\infty_{m\times p}$, $C \in \mathcal{H}^\infty_{q\times n}$ are rational matrices, with B tall and of full column rank, and C wide and of full row rank. To guarantee that $\mathcal{H}^\infty$-optimal solutions exist we assume that $B(e^{i\theta})$ and $C(e^{i\theta})$ have full rank for each $e^{i\theta}$ on the unit circle (cf. [6]).

$\mathcal{H}^\infty$-optimization over the coset Σ is also known as the *four-block problem.* More precisely, it may be shown to be equivalent to $\mathcal{H}^\infty$-optimization over

$$\begin{bmatrix} A_{11} + M\mathcal{H}^\infty_{p\times q} & A_{12} \\ A_{21} & A_{22} \end{bmatrix}, \tag{5}$$

where M is a rational square inner matrix which, together with the four rational matrix blocks $A_{ij}, i, j \in \{1, 2\}$, is obtained from the data F, B, and C. If one of B and C is square we call Σ a *two-block problem.* This corresponds in (5) to disappearance of A_{22} together with one of the blocks A_{12}, A_{21}. If both B and C are square Σ is called a *one-block problem.* This corresponds to disappearance of all three blocks A_{22}, A_{12}, and A_{21}.

When desired, we may, via an inner-outer factorization of B and a co-inner/co-outer factorization of C, together with subsequent absorption of the outer and co-outer factors in the parameter $Q \in \mathcal{H}^\infty_{p\times q}$, take B inner and C co-inner; that is, $B^*B = I$ and $CC^* = I$ on the unit circle.

2.1. The polynomial $\mathcal{H}^\infty$-optimization approach. Polynomial methods have come to play a significant role in frequency domain design of optimal control. One reason for this is their capability of providing numerically reliable techniques. A manifestation of this is the so-called *polynomial approach* to $\mathcal{H}^\infty$-optimization by Kwakernaak [13]. The method allows us to compute not only suboptimal, but also strictly optimal solutions to the standard problem. Of central interest in the polynomial approach is a parametrization of all stabilizing compensators K such that $\|H_K\|_\infty \leq \lambda$, where λ is greater or equal to the minimal $\mathcal{H}^\infty$ norm λ_o. For $\lambda > \lambda_o$ the parametrization is obtained via two polynomial J-spectral factorizations, one for the denominator and one for the numerator of a certain para-Hermitian rational matrix Π_λ that depends only on the plant G and the performance level λ. This results in a rational J-spectral factor Z_λ of Π_λ such that K stabilizes G and achieves $\|H_K\|_\infty \leq \lambda$ if and only if for some stable U with $\|U\|_\infty \leq 1$ we have

$$K = YX^{-1}, \qquad \begin{bmatrix} X \\ Y \end{bmatrix} = Z_\lambda^{-1} \begin{bmatrix} I \\ U \end{bmatrix}. \tag{6}$$

By decreasing λ, compensators with performance arbitrarily close to λ_o may be computed. Moreover, the numerical value of λ_o may be delimited to desired accuracy.

As λ reaches the optimal value λ_o, the numerator and denominator of the compensator acquire a common factor that may be canceled. This results in a so-called *reduced degree solution* K_o that is $\mathcal{H}^\infty$-optimal, that is, $\|H_{K_o}\|_\infty = \lambda_o$. A second phenomenon that takes place as λ reaches λ_o is that some of the coefficients of Z_λ approach infinity. Due to this fact, (6) is not suitable for parametrization of strictly optimal solutions. However, if the

numerator of Π_{λ_o} is only partially J-spectral factorized (i.e., with the signature matrix J replaced by a certain para-Hermitian polynomial matrix), then a partial rational J-spectral factor $\hat{Z}_{\lambda_o}$ of Π_{λ_o} is obtained which gives rise to a parametrization of all strictly optimal compensators. In the simplest case, where the problem has a solution with largest singular value of multiplicity one, the parametrization may be expressed in the following way.

A compensator K stabilizes G if and only if for some stable rational matrix U with $\|U\|_\infty \leq 1$ we have

$$K = YX^{-1}, \qquad \begin{bmatrix} X \\ Y \end{bmatrix} = \hat{Z}_\lambda^{-1} \begin{bmatrix} I & 0 \\ 0 & \alpha \\ 0 & \beta \\ U & 0 \end{bmatrix}, \tag{7}$$

where α and β are some fixed constants.

Comparing (7) and (6) we see that when passing from suboptimality to optimality there is a reduction in the dimension of the free parameter U. We also see that the optimal compensators contain a common part that is given by the column $[0 \quad \alpha \quad \beta \quad 0]^{\mathrm{T}}$ of (7). In the scalar case only, this part is present and determines the unique optimal compensator.

We point out that the technique for computing $\hat{Z}_\lambda$ is numerically feasible and leads to compensators having the correct reduced degree structure. For a detailed description of the algorithm we refer to [13]. For a MATLAB implementation the reader may consult [14].

A reduced degree solution admits a spectral density Φ such that the following sufficient condition for optimality holds.

Equalizer principle. Suppose that the compensator K_o is *equalizing*, that is,

$$H_{K_o}^* H_{K_o} = \lambda_o^2 I - L_o^* L_o \tag{8}$$

for some nonnegative constant λ_o and some rational rank deficient matrix L_o, and that K_o and L_o minimize

$$\frac{1}{2\pi} \int_0^{2\pi} tr\{[H_K^*(e^{i\theta}) H_K(e^{i\theta}) + L^*(e^{i\theta}) L(e^{i\theta})] \Phi(e^{i\theta})\} d\theta \tag{9}$$

with respect to all stabilizing compensators K and all rank deficient matrices L. Then K_o minimizes $\|H_K\|_\infty$ with respect to all stabilizing compensators, and $\|H_{K_o}\|_\infty = \lambda_o$.

The equalizer principle is closely associated with the polynomial approach. For an account of the use of this criterion in proving optimality of reduced solutions we refer to [10], [11], [1], [12], and [13].

Besides its usefulness as an optimality criterion for ordinary $\mathcal{H}^\infty$-optimization, the equalizer principle provides a bridge to super-optimization. Via the spectral density of the equalizer principle, the $\mathcal{H}^\infty$-optimal solutions, that is, those optimal with respect to the largest singular value, may be diagonalized, and a similar but smaller super-optimization problem for the remaining singular values may be derived. The super-optimization algorithm considered in this paper is based on this fact. It is much inspired by that given in [27], but is applicable to the four-block problem. For the one-block problem a similar method was studied in [18]. The equalizer principle also plays a central role in [15] and [11], where super-optimization of a mixed sensitivity problem is studied.

2.2. Notation. The notation we use is fairly standard. By the jth *singular value* of a complex matrix A, denoted $s_j(A)$, we mean the jth largest eigenvalue of $(A^*A)^{1/2}$, where A^* is the conjugate transpose of A. A corresponding eigenvector of $(AA^*)^{1/2}$ is called a (*right*) *singular vector* of A associated with $s_j(A)$. For a matrix valued function F on the

unit circle $\mathbb{T}$ we mean by F^* the function on $\mathbb{T}$ defined by $F^*(e^{i\theta}) = F(e^{i\theta})^*$. Consider on $\mathbb{C}^{m\times n}$ the Schatten p-norms $|\cdot|_p$, that is,

$$|A|_p = \begin{cases} [\sum_{j=1}^n s_j(A)^p]^{1/p}, & 1 \le p < \infty, \\ |A|_\infty = s_1(A), & p = \infty. \end{cases}$$

Note that $p = \infty, p = 2$, and $p = 1$ yield the spectral norm, the Frobenius norm, and trace norm, respectively. By $\mathcal{L}^p_{m\times n}$ we mean the space of (equivalence classes of) $\mathbb{C}^{m\times n}$ valued Lebesgue measurable functions F on $\mathbb{T}$ for which $\|F\|_p < \infty$, where the norm $\|\cdot\|_p$ is defined by

$$\|F\|_p = \begin{cases} [\frac{1}{2\pi}\int_0^{2\pi} |F(e^{i\theta})|_p^p d\theta]^{1/p}, & 1 \le p < \infty, \\ \|F\|_\infty = \operatorname{ess\,sup}\{|F(e^{i\theta})|_\infty : \theta \in [0, 2\pi)\}, & p = \infty. \end{cases}$$

The inner product in the Hilbert space $\mathcal{L}^2_{m\times n}$ is given by

$$(F, G) = \frac{1}{2\pi}\int_0^{2\pi} \operatorname{tr}\{G(e^{i\theta})^* F(e^{i\theta})\} d\theta.$$

By the Hardy space $\mathcal{H}^p_{m\times n}$, $1 \le p \le \infty$ we mean the closed subspace of $\mathcal{L}^p_{m\times n}$ of functions F whose Poisson integral $\tilde{F}$ is analytic in the open unit disk $\mathbb{D}$, or equivalently, whose Fourier coefficients $(2\pi)^{-1}\int_0^{2\pi} F(e^{i\theta})e^{-ik\theta}d\theta$ vanish for $k < 0$. As in the scalar valued case, the correspondence between F and $\tilde{F}$ is an isomorphism. When so desired we identify F and $\tilde{F}$. By $\mathcal{RL}^p_{m\times n}$ and $\mathcal{RH}^p_{m\times n}$ we mean the subspaces of rational functions in $\mathcal{L}^p_{m\times n}$ and $\mathcal{H}^p_{m\times n}$, respectively. Note that regarded as sets is $\mathcal{RL}^p_{m\times n}$ equal to $\mathcal{RL}^q_{m\times n}$ for all $1 \le p, q \le \infty$. The same holds for $\mathcal{RH}^p_{m\times n}$.

A function $F \in \mathcal{H}^2_{m\times n}$ is *inner* if $F^*F = I$ almost everywhere on $\mathbb{T}$. It is *outer* if there exists a scalar valued outer function $g \in \mathcal{H}^\infty$ such that $gF \in \mathcal{H}^\infty_{m\times n}$ and $gF\mathcal{H}^2_n$ is dense in $\mathcal{H}^2_m$ (cf. [22]). F is said to be *co-inner* (*co-outer*) if the transpose of F is inner (outer). For any $F \in \mathcal{H}^2_{m\times n}$ there exists an integer $k \le m, n$, an inner function $F_i \in \mathcal{H}^\infty_{m\times k}$, and an outer function $F_o \in \mathcal{H}^2_{k\times n}$ such that F has the *inner-outer factorization* $F = F_iF_o$ (cf. [5], [22]).

Define for any $F \in \mathcal{L}^\infty_{m\times n}$ a bounded linear functional $\langle\cdot, F\rangle$ on $\mathcal{L}^1_{n\times m}$ by

$$\langle G, F\rangle = \frac{1}{2\pi}\int_0^{2\pi} \operatorname{tr}\{F(e^{i\theta})G(e^{i\theta})\} d\theta = \frac{1}{2\pi}\int_0^{2\pi} \operatorname{tr}\{G(e^{i\theta})F(e^{i\theta})\} d\theta. \tag{10}$$

The mapping $F \to \langle\cdot, F\rangle$ is an isometric isomorphism from $\mathcal{L}^\infty_{m\times n}$ onto $(\mathcal{L}^1_{n\times m})^*$ (cf. [23], [27]). As a convenient abbreviation for the right-hand side of (10) we take the liberty of using the notation $\langle G, F\rangle$ even when the arguments do not belong to the aforementioned spaces, the only requirement being that $\operatorname{tr}\{F(e^{i\theta})G(e^{i\theta})\}$ is integrable.

A function $\Phi \in \mathcal{L}^1_{n\times n}$ is called a *spectral density* if $\Phi \ne 0$ and $\Phi(e^{i\theta}) \ge 0$ for every $\theta \in [0, 2\pi)$. Note that $\|\Phi\|_1 = (2\pi)^{-1}\int_0^{2\pi} \operatorname{tr}\{\Phi(e^{i\theta})\} d\theta$.

Similarly to $\|F\|_\infty$, we introduce bounds for each singular value $s_j\{F(e^{i\theta})\}, 1 \le j \le n$, by defining

$$s_j^\infty(F) = \operatorname{ess\,sup}\{s_j\{F(e^{i\theta})\} : \theta \in [0, 2\pi)\}.$$

Let $\le_k$ be the partial ordering on $\mathbb{R}^n$ which is lexicographic with respect to the first k positions and ignores the remaining ones. More precisely,

$$(a_1, \ldots, a_k, a_{k+1}, \ldots, a_n) \le_k (b_1, \ldots, b_k, b_{k+1}, \ldots, b_n)$$

if and only either $a_i = b_i$ for all $i = 1, 2, \ldots, k$, or else $a_i < b_i$ at the smallest $1 \le i \le k$ where $a_i \ne b_i$. Let $\mathcal{F}$ be any subset of $\mathcal{L}^\infty_{m\times n}$. We then say that $F_o \in \mathcal{F}$ is *class k optimal* if

$$(s_1^\infty(F_o), s_2^\infty(F_o), \ldots, s_n^\infty(F_o)) \le_k (s_1^\infty(F), s_2^\infty(F), \ldots, s_n^\infty(F))$$

for all $F \in \mathcal{F}$. When $k = 1$ we also say that F_o is $\mathcal{L}^\infty$*-optimal*, or $\mathcal{H}^\infty$*-optimal* in case $\mathcal{F} \subseteq \mathcal{H}^\infty_{n\times n}$. When $k = n$ we call F_o *super-optimal.*

3. Conditions for $\mathcal{H}^\infty$-optimality. In this section, we collect some basic results concerning the spectral density associated with the equalizer principle and the $\mathcal{H}^\infty$-optimal solutions satisfying this criterion. By taking $\mathcal{Z}$ equal to the set of all functions $Z_{K,L} = H_K^* H_K + L^* L$ appearing in the integrand of (9), the equalizer principle may be regarded as a case of the following lemma (see [18]).

LEMMA 1. *Suppose we are given a nonempty subset $\mathcal{Z}$ of $\mathcal{L}^\infty_{m\times n}$ and a $\Phi \in \mathcal{L}^1_{n\times m}$ with $\Phi \ne 0$. Let $\mathcal{Z}_o$ be the set of all $Z_o \in \mathcal{Z}$ such that*

$$|\langle \Phi, Z_o\rangle| \le |\langle \Phi, Z\rangle| \quad \textit{for all } Z \in \mathcal{Z}, \tag{11}$$

$$|\langle \Phi, Z_o\rangle| = \|Z_o\|_\infty \|\Phi\|_1. \tag{12}$$

Then $\mathcal{Z}_o$ either is empty or equals the set of $\mathcal{L}^\infty$-optimal functions in $\mathcal{Z}$.

Proof. Owing to isometry we have $\|Z\|_\infty = \|\langle \cdot, Z\rangle\|$. Thus $\|Z_o\|_\infty \|\Phi\|_1 = |\langle \Phi, Z_o\rangle| \le |\langle \Phi, Z\rangle| \le \|Z\|_\infty \|\Phi\|_1$. Since $\|\Phi\|_1 > 0$, the conclusions follow. □

If the set $\mathcal{Z}_o$ is nonempty, that is, if Φ allows a Z_o such that (11) and (12) are satisfied, then Φ is said to *distinguish* the $\mathcal{L}^\infty$-optimal functions in $\mathcal{Z}$, or to be *distinguishing* for $\mathcal{Z}$. The reason behind this terminology is that either Φ allows no Z_o to satisfy conditions (11) and (12), or else they are satisfied precisely by the $\mathcal{L}^\infty$-optimal functions in $\mathcal{Z}$. We remark, however, that a set $\mathcal{Z}$ may very well have $\mathcal{L}^\infty$-optimal elements without admitting any distinguishing Φ.

Note that if all $Z \in \mathcal{Z}$, together with Φ, take only nonnegative semidefinite values on $\mathbb{T}$, then the absolute value signs in (11) and (12) may be omitted. This certainly holds in the setting of the equalizer principle, and more generally if, for some subset Σ of $\mathcal{L}^\infty_{m\times n}$, we have $\mathcal{Z} = \mathcal{S}(\Sigma)$, where $\mathcal{S}(\Sigma)$ denotes the set $\{H^* H : H \in \Sigma\}$. All our applications of Lemma 1 will be special cases of this, where we in fact will take $\Sigma = F + \mathcal{U}$ for some given function $F \in \mathcal{H}^\infty_{m\times n}$ and some subspace $\mathcal{U}$ of $\mathcal{H}^\infty_{m\times n}$, that is, Σ is a coset of $\mathcal{U}$ in $\mathcal{H}^\infty_{m\times n}$. The following lemma applies to this situation and characterizes the second condition of Lemma 1.

LEMMA 2. *Suppose that $Z \in \mathcal{L}^\infty_{m\times n}$ with $Z(e^{i\theta}) \ge 0$ for each $\theta \in [0, 2\pi)$. Let $\Phi \in \mathcal{L}^1_{n\times m}$ be a spectral density. Then*

$$\langle \Phi, Z\rangle = \|Z\|_\infty \|\Phi\|_1 \tag{13}$$

if and only if

$$Z(e^{i\theta})\Phi(e^{i\theta}) = \|Z\|_\infty \Phi(e^{i\theta}) \quad \textit{for almost all } \theta \in [0, 2\pi). \tag{14}$$

Note that condition (14) means that for almost all $\theta \in [0, 2\pi)$, each nonzero vector in the range of $\Phi(e^{i\theta})$ is an eigenvector of $Z(e^{i\theta})$ with the corresponding eigenvalue equal to $s_1^\infty(Z) = \|Z\|_\infty$. A similar result holds even if Z and Φ are not required to have positive

semidefinite values. For a proof of this and of Lemma 2 see [18]. Note also that if Z and Φ are continuous, then (14) must hold, not only almost everywhere, but for all $\theta \in [0, 2\pi)$.

For a given spectral density $\Phi \in \mathcal{L}^{\infty}_{n\times n}$, we denote by $\mathcal{A}(\Sigma; \Phi)$ the set of $H \in \Sigma$ such that

$$\langle \Phi, H^*H\rangle \leq \langle \Phi, G^*G\rangle \quad \text{for all} \quad G \in \Sigma;$$

that is, such that the first condition of Lemma 1 holds for H^*H. The following lemma gives a useful characterization of this set.

LEMMA 3. *Let $H_o \in F + \mathcal{U}$. Suppose $\Phi \in \mathcal{L}^1_{n\times n}$ is a spectral density. Then:*

(i) *The function H_o belongs to $\mathcal{A}(F+\mathcal{U}; \Phi)$ if and only if*

$$\langle \Phi H_o^*, U\rangle = 0 \quad \textit{for all} \quad U \in \mathcal{U}. \tag{15}$$

(ii) *Suppose that $H_o \in \mathcal{A}(F+\mathcal{U}; \Phi)$ and that Φ has a factorization $\Phi = \phi\phi^*$, where ϕ belongs to some $\mathcal{L}^2_{n\times k}$. Then $H \in \mathcal{A}(F+\mathcal{U}; \Phi)$, if and only if $H\phi = H_o\phi$.*

Proof. (i) Suppose that $H_o = F + U_o \in \mathcal{A}(F+\mathcal{U}; \Phi)$. Let $Z_o = H_o^*H_o$ and consider an arbitrary $Z = (F+U)^*(F+U) \in \mathcal{S}(F+\mathcal{U})$. With $\Delta = U - U_o$ we then have $Z = Z_o + H_o^*\Delta + \Delta^*H_o + \Delta^*\Delta$. Hence

$$\begin{aligned}\frac{1}{2\pi}\int_0^{2\pi} \operatorname{tr}(Z\Phi)d\theta = \frac{1}{2\pi}\int_0^{2\pi} \operatorname{tr}(Z_o\Phi)d\theta + 2\operatorname{Re}\left\{\frac{1}{2\pi}\int_0^{2\pi} \operatorname{tr}(H_o^*\Delta\Phi)d\theta\right\} \\ + \frac{1}{2\pi}\int_0^{2\pi} \operatorname{tr}(\Delta^*\Delta\Phi)d\theta.\end{aligned} \tag{16}$$

In the middle term the expression within braces is precisely $\langle \Phi H_o^*, \Delta\rangle$, which we wish to prove equal to zero for all $\Delta \in \mathcal{U}$. Suppose $(2\pi)^{-1}\int_0^{2\pi} \operatorname{tr}(H_o^*\Delta\Phi)d\theta$ would differ from zero for some Δ. Replacing Δ by $\epsilon\,\Delta$, where ϵ is a suitable complex constant of sufficiently small modulus, we may then assume that

$$\frac{1}{2\pi}\int_0^{2\pi} \operatorname{tr}(\Delta^*\Delta\Phi)d\theta < -2\operatorname{Re}\left\{\frac{1}{2\pi}\int_0^{2\pi} \operatorname{tr}(H_0^*\Delta\Phi)d\theta\right\}.$$

But this would mean that $(2\pi)^{-1}\int_0^{2\pi} \operatorname{tr}(Z\Phi)d\theta < (2\pi)^{-1}\int_0^{2\pi} \operatorname{tr}(Z_o\Phi)d\theta$, which contradicts our assumptions about H_o. Thus (15) must hold. The converse is immediate from (15) and (16).

(ii) Suppose that $H_o = F + U_o$ and $H = F + U$ are in $\mathcal{A}(F+\mathcal{U}; \Phi)$. From (15) we then have $\langle \Phi(U_o - U)^*, W\rangle = 0$ for each $W \in \mathcal{U}$. Taking $W = U_o - U$ and using the factorization of Φ we get

$$\langle \phi^*(U_o - U)^*, (U_o - U)\phi\rangle = ((U_o - U)\phi, (U_o - U)\phi) = 0.$$

Hence $(U_o - U)\phi = 0$ and thus also $H_o\phi = H\phi$. The converse is obvious. □

3.1. Rational data. The preceding two lemmas are concerned with a structure that is somewhat more general than what we need. Consider therefore a coset of the form (4). Thus $\Sigma = F + B\mathcal{H}^{\infty}_{p\times q}C$, where the "data" $F \in \mathcal{H}^{\infty}_{m\times n}$, $B \in \mathcal{H}^{\infty}_{m\times p}$, and $C \in \mathcal{H}^{\infty}_{q\times n}$ are rational matrices, with $B(e^{i\theta})$ having full column rank and $C(e^{i\theta})$ having full row rank for each $e^{i\theta}$ on the unit circle. For such a Σ it is plausible that there are, among the $\mathcal{H}^{\infty}$-optimal functions, also rational ones. Moreover, it is then reasonable to believe that a distinguishing spectral density for $\mathcal{S}(\Sigma)$, if it exists, also may be taken rational.

We will assume something slightly weaker, however, namely, that the spectral density has a particular kind of factorization. For distinguishing spectral densities, this leads to the existence of rational densities in §6, something of indispensable value in practical computations. To arrive at the required factorization we first study the rational case.

Suppose B and C have been taken inner and co-inner, respectively. Let $\tilde{B} = [B \quad \hat{B}]$ be a completion of B to a square inner matrix in $\mathcal{H}^\infty_{m\times m}$, that is, $\hat{B} \in \mathcal{RH}^\infty_{m\times(m-p)}$ is an inner complement of B. Similarly, let C be completed to a square inner matrix

$$\tilde{C} = \begin{bmatrix} C \\ \tilde{C} \end{bmatrix} \in \mathcal{RH}^\infty_{n\times n},$$

where $\tilde{C} \in \mathcal{RH}^\infty_{(n-q)\times n}$ is a co-inner complement of C. Suppose $\mathcal{S}(\Sigma)$ has a rational distinguishing spectral density Φ of rank r. Using spectral factorization we may write $\tilde{C}\Phi\tilde{C}^* = \vartheta\vartheta^*$ for some $\vartheta \in \mathcal{RH}^2_{n\times r}$ of full column rank (in fact, ϑ belongs to $\mathcal{H}^\infty_{n\times r}$). Partition ϑ as

$$\vartheta = \begin{bmatrix} \vartheta_1 \\ \vartheta_2 \end{bmatrix},$$

where $\vartheta_1 \in \mathcal{RH}^2_{q\times r}$ and $\vartheta_2 \in \mathcal{RH}^2_{(n-q)\times r}$. Suppose $\vartheta_1 \neq 0$. We may then write $\vartheta_1 = \varphi\zeta$, where $\varphi \in \mathcal{RH}^2_{q\times k}$, $k \leq r$ is co-outer, and $\zeta \in \mathcal{RH}^2_{k\times r}$ co-inner. Complete ζ to an inner matrix

$$\tilde{\zeta} = \begin{bmatrix} \zeta \\ \hat{\zeta} \end{bmatrix} \in \mathcal{RH}^\infty_{r\times r}.$$

Then

$$\vartheta\tilde{\zeta}^* = \begin{bmatrix} \varphi & 0 \\ \vartheta_2\zeta^* & \vartheta_2\hat{\zeta}^* \end{bmatrix}.$$

Define

$$\phi_1 = \tilde{C}^* \begin{bmatrix} \varphi \\ \vartheta_2\zeta^* \end{bmatrix}, \quad \phi_2 = \tilde{C}^* \begin{bmatrix} 0 \\ \vartheta_2\hat{\zeta}^* \end{bmatrix}, \quad \Phi_1 = \phi_1\phi_1^*, \quad \Phi_2 = \phi_2\phi_2^*.$$

Note that when $k = r$, Φ_2 disappears. Suppose therefore that $k < r$. Then ϕ_1 and ϕ_2 both have full column rank, and

$$\Phi = [\phi_1 \quad \phi_2] \begin{bmatrix} \phi_1^* \\ \phi_2^* \end{bmatrix} = \phi_1\phi_1^* + \phi_2\phi_2^* = \Phi_1 + \Phi_2.$$

We claim that both Φ_1 and Φ_2 are distinguishing special densities. We first check condition (12). Since Φ is distinguishing, Lemma 2 gives $H_o^*H_o\tilde{C}^*\vartheta = \lambda^2\tilde{C}^*\vartheta$, where H_o is $\mathcal{H}^\infty$-optimal, and $\lambda = \|H_o\|_\infty$. From this it follows that $H_o^*H_o\phi_1 = \lambda^2\phi_1$, and hence also $H_o^*H_o\Phi_1 = \lambda^2\Phi_1$. Thus Φ_1 satisfies condition (12). Similarly Φ_2 satisfies this condition. To check condition (11), we observe that $C\phi_2 = C\hat{C}^*\vartheta_2\hat{\zeta}^* = 0$. It follows that $\langle\Phi_2H_o^*, BQC\rangle = 0$ for each $Q \in \mathcal{H}^\infty_{p\times q}$. By Lemma 3 this means that condition (11) holds for Φ_2. Moreover, since

$$\langle\Phi_1H_o^*, BQC\rangle = \langle\Phi H_0^*, BQC\rangle - \langle\Phi_2H_0^*, BQC\rangle = 0,$$

we see that (11) holds for Φ_1, also. This shows that both Φ_1 and Φ_2 are distinguishing spectral densities for $\mathcal{S}(\Sigma)$. By considering Φ_1 we may therefore assume, without loss of generality, that a rational spectral density has a factorization

$$\Phi = \phi\phi^*, \qquad \phi = \tilde{C}^* \begin{bmatrix} \varphi \\ \chi \end{bmatrix}, \tag{17}$$

where $\chi \in \mathcal{L}^2_{(n-q)\times k}$ and either (1): $\varphi \in \mathcal{H}^2_{q\times k}$ is nonzero and co-outer; or (2): $\varphi = 0$. Of these two alternatives, the second takes care of the case $\vartheta_1 = 0$. Note that if C is square, then (17) reduces to $\phi = C^*\varphi$, with $\varphi \neq 0$ co-outer.

In the rest of this section we only consider spectral densities having a factorization of the form (17). We do not require them to be rational, however; that is, we allow φ and χ to be nonrational functions. The following lemma and its corollary show that in particular a distinguishing spectral density of this type may be assumed to have at most rank one almost everywhere on the unit circle.

LEMMA 4. *Let $\Sigma = F + B\mathcal{H}^\infty_{p\times q}C$ be a coset of the form* (4) *in which B is taken inner and C co-inner. Suppose $\Phi \in \mathcal{L}^\infty_{m\times n}$ is a spectral density having a factorization $\Phi = \phi\phi^*$, where*

$$\phi = \tilde{C}^* \begin{bmatrix} \varphi \\ \chi \end{bmatrix}, \quad \varphi \in \mathcal{H}^2_{q\times k}, \quad \chi \in \mathcal{L}^2_{(n-q)\times k},$$

and one of the following cases apply:

1. *$\varphi \neq 0$ and co-outer; or*
2. *$\varphi = 0$.*

Let ϕ_j be the jth column of ϕ, and $\hat{\Phi} = \phi_j\phi_j^*$. Then

(i) $\mathcal{A}(\Sigma;\Phi) = \mathcal{A}(\Sigma;\hat{\Phi})$.

(ii) *In case* 1 *the following statements are equivalent:*

$$H \in \mathcal{A}(\Sigma;\Phi), \tag{18}$$

$$H\phi \perp B\mathcal{H}^2_{p\times k}, \tag{19}$$

$$H\phi_j \perp B\mathcal{H}^2_p, \quad \textit{for each } 1 \leq j \leq k. \tag{20}$$

Proof. Statement (i) is proven separately for cases 1 and 2.

Case 1. Suppose $\varphi \neq 0$ is co-outer. The equivalence of (19) and (20) is a direct consequence of the definition of the inner product. We therefore prove that (18) holds if and only if (19) holds. Note first that for every $Q \in \mathcal{H}^\infty_{p\times q}$ we have

$$\langle \Phi H^*, BQC\rangle = \langle \Phi H^*, B[Q \quad 0]\tilde{C}\rangle = \langle \phi^* H^*, BQ\varphi\rangle. \tag{21}$$

From this and Lemma 3 it follows that $H \in \mathcal{A}(\Sigma;\Phi)$ if and only if

$$(H\phi, BQ\varphi) = 0 \tag{22}$$

for each $Q \in \mathcal{H}^\infty_{p\times q}$. If (19) holds then clearly (22) holds and hence, $H \in \mathcal{A}(\Sigma;\Phi)$. Conversely, suppose $H \in \mathcal{A}(\Sigma;\Phi)$. Since φ is co-outer there exists a scalar valued outer function g in $\mathcal{H}^\infty$ such that $g\varphi \in \mathcal{H}^\infty_{q\times k}$ and $\mathcal{H}^2_{p\times q}g\varphi$ is dense in $\mathcal{H}^2_{p\times k}$. Moreover, since

$B\mathcal{H}^\infty_{p\times q}$ is dense in $B\mathcal{H}^2_{p\times q}$, the functions $BQg\varphi$ must be dense in $B\mathcal{H}^2_{p\times k}$. But since (22) holds for all $BQg\varphi$, the denseness implies (19). This proves (ii).

Note that each column ϕ_j of ϕ is itself co-outer. In exactly the same way it therefore may be shown that $H \in \mathcal{A}(\Sigma;\hat{\Phi})$ if and only if (20) holds. Since (19) is equivalent to (20) it follows that $\mathcal{A}(\Sigma;\Phi) = \mathcal{A}(\Sigma;\hat{\Phi})$. This proves (i) in case 1.

Case 2. Similarly to (21) we have

$$\langle \hat{\Phi}H^*, BQC\rangle = \langle \phi_j^* H^*, BQ\varphi_j\rangle, \tag{23}$$

where φ_j is the jth column of φ. But since $\varphi = 0$, the expressions (21) and (23) both vanish. Hence by Lemma 3 (i), $\mathcal{A}(\Sigma;\Phi) = \Sigma$ and $\mathcal{A}(\Sigma;\hat{\Phi}) = \Sigma$. This proves (i) in Case 2. □

COROLLARY 1. *Suppose Φ is a distinguishing spectral density for $\mathcal{S}(\Sigma)$. Then $\hat{\Phi}$ is also a distinguishing spectral density for $\mathcal{S}(\Sigma)$.*

Proof. Let H be $\mathcal{H}^\infty$-optimal in Σ. By the lemma it suffices to prove that $\hat{\Phi}$ satisfies Lemma 2. But since Lemma 2 holds for Φ, and ϕ has full column rank, we have $H^*H\phi = \|H\|^2_\infty\phi$. Hence also $H^*H\phi_j = \|H\|^2_\infty\phi_j$, which implies $H^*H\hat{\Phi} = \|H\|^2_\infty\hat{\Phi}$. □

We have shown that a distinguishing spectral density admitting a factorization (17) may be replaced by one having the "rank one" form

$$\Phi = \phi\phi^*, \qquad \phi = \tilde{C}^* \begin{bmatrix} \varphi \\ \chi \end{bmatrix}, \tag{24}$$

where $\chi \in \mathcal{L}^2_{n-q}$, and either:

1. $0 \neq \varphi \in \mathcal{H}^2_q$ is co-outer; or
2. $\varphi = 0$.

When C is square, that is, $q = n$, this reduces to $\phi = C^*\varphi$, with $\varphi \in \mathcal{H}^2_n$ co-outer. Note again that $\varphi = 0$ if and only if $C\phi = 0$. Since we are only interested in $\mathcal{H}^\infty$-optimization over cosets with rational "data," in the sequel we assume Φ to be of the form (24). In §6 it will be shown that whenever a distinguishing Φ of this type exists, then it may in fact be taken rational. In the following two sections we may therefore assume that Φ is taken rational.

4. Dimension reduction and diagonalization. Consider a coset $\Sigma = F + B\mathcal{H}^\infty_{p\times q}C$ in $\mathcal{L}^\infty_{m\times n}$ of the form (4). We do not require B anc C to be inner and co-inner, respectively, only that B has full column rank and C full row rank on the unit circle. The purpose of this section is to determine a coset structure similar to that of Σ for a certain subset of $\mathcal{A}(\Sigma;\Phi)$. Moreover, when Φ is distinguishing, the functions in this subset have a convenient diagonalizable form and comprise all $\mathcal{H}^\infty$-optimal functions in Σ. This will play a central role in reducing class k optimization problems to class $k-1$ optimization problems.

The following lemma and its corollary state some basic facts used in the derivation of the reduction.

LEMMA 5. *Let A be a rational $m \times n$ matrix of column rank $k < n$. Then there exists a (tall) $P \in \mathcal{RH}^\infty_{n\times(n-k)}$ of full column rank on the unit circle such that:*

1. $AP = 0$.
2. *If $AX = 0$ for some $X \in \mathcal{H}^2_{n\times p}$, $(X \in \mathcal{L}^2_{n\times p})$, then $X = PM$ for some $M \in \mathcal{H}^2_{(n-k)\times p}$, $(M \in \mathcal{L}^2_{(n-k)\times p})$. Moreover, if X is rational, then M may be taken rational.*

Proof. In the trivial case $k = 0$, that is, $A = 0$, simply take P equal to the $n \times n$ identity matrix. Suppose therefore that $k > 0$. Use polynomial coprime factorization to write $A = D^{-1}N$, where D and N are polynomial matrices of dimensions $m \times m$ and

$m \times n$, respectively. By reduction to Hermite form we find an $n \times n$ unimodular polynomial matrix U such that

$$NU = [R \quad 0], \tag{25}$$

where R is an $m \times k$ polynomial matrix of full column rank. Partition $U = [\hat{U} \quad P]$, where $\hat{U}$ is $n \times k$ and P is $n \times (n-k)$. Then (25) implies $NP = 0$, and hence also $AP = 0$. Moreover, since U is unimodular P must have full column rank everywhere on the unit circle. This proves the first part of the lemma.

Suppose for $X \in \mathcal{H}^2_{n\times p}$ we have $AX = 0$, that is, $NX = 0$. Let $Y = U^{-1}X$. Since U is unimodular, Y also belongs to $\mathcal{H}^2_{n\times p}$. Partition Y as

$$Y = \begin{bmatrix} \hat{Y} \\ M \end{bmatrix},$$

where $\hat{Y} \in \mathcal{H}^2_{k\times p}$ and $M \in \mathcal{H}^2_{(n-k)\times p}$. By multiplying (25) from the right by Y and using the assumption $NX = 0$ we see that $R\hat{Y} = 0$. Moreover, since R has full column rank this yields $\hat{Y} = 0$. Hence

$$X = UY = [\hat{U} \quad P] \begin{bmatrix} 0 \\ M \end{bmatrix} = PM.$$

The last statement of the lemma follows immediately from the construction of M. The proof for the case $X \in \mathcal{L}^2_{n\times p}$ is completely analogous. □

A corresponding result holds for equations $XA = 0$.

COROLLARY 2. *Let A be a rational $m \times n$ matrix of row rank $k < m$. Then there exists a (wide) $P \in \mathcal{RH}^\infty_{(m-k)\times m}$ of full row rank on the unit circle such that:*

1. $PA = 0$.

2. *If $XA = 0$ for some $X \in \mathcal{H}^2_{p\times m}$, $(X \in \mathcal{L}^2_{p\times m})$, then $X = MP$ for some $M \in \mathcal{H}^2_{p\times(m-k)}$, $(M \in \mathcal{L}^2_{p\times(m-k)})$. Moreover, if X is rational, then M may be taken rational.*

Proof. For the proof, apply the lemma to the transpose of A. □

The matrix $P \in \mathcal{RH}^\infty_{n\times(n-k)}$ in Lemma 5 is far from unique and does not need to be chosen polynomial as in the proof. It can in fact be chosen inner, and in this form it is essentially unique. An analogous statement holds for P in Corollary 2.

Suppose $\Phi \in \mathcal{RL}^\infty_{n\times n}$ is a rational spectral density with $\Phi = \phi\phi^*$ for some $\phi \in \mathcal{L}^2_n$. In the context of a coset of the form (4) we obtain, as an immediate consequence of the previous lemma and its corollary, the following result.

LEMMA 6. *Suppose $\Sigma = F + B\mathcal{H}^\infty_{p\times q}C$ is a coset of the form* (4), *and $\Phi \in \mathcal{RL}^\infty_{n\times n}$ a rational spectral density of rank* 1. *Let $\Phi = \phi\phi^*$ be any factorization of Φ with $\phi \in \mathcal{RL}^2_n$.*

(i) *If $C\phi \neq 0$ and $q > 1$ then there exists a $P \in \mathcal{RH}^\infty_{(q-1)\times q}$ of full row rank on the unit circle such that:*

(a) $PC\phi = 0$; *and*

(b) $QC\phi = 0$ *if and only if* $Q = Q_1P$ *for some* $Q_1 \in \mathcal{H}^\infty_{p\times(q-1)}$.

(ii) *Suppose that $H_o = F + BQ_oC \in \mathcal{A}(\Sigma;\Phi)$. If $\phi^*H_o^*B \neq 0$ and $p > 1$, then there exists an $R \in \mathcal{RH}^\infty_{p\times p-1}$ of full column rank on the unit circle, not depending on the particular choice of H_o, such that*

(a) $\phi^*H_o^*BR = 0$; *and*

(b) $\phi^*H_o^*BQ = 0$ *if and only if* $Q = RQ_2$ *for some* $Q_2 \in \mathcal{H}^\infty_{(p-1)\times q}$.

Proof. By applying Corollary 2 to $C\phi$ we obtain P such that (a) and (b) hold. This proves (i). For (ii) we obtain R by applying Lemma 5 to $\phi^*H_o^*B$. By Lemma 3 (ii),

$H_o\phi = H_o'\phi$ for each $H_o' \in \mathcal{A}(\Sigma;\Phi)$. Hence R does not depend on the particular H_o we choose. □

For an arbitrary $H_o \in \Sigma$ define a set

$$\mathcal{D}(\Sigma;\Phi,H_o) = \{H \in \Sigma | H^*H\Phi = H_o^*H_o\Phi\}.$$

For $H_o \in \mathcal{A}(\Sigma;\Phi)$ the following theorem gives a useful parametrization of $\mathcal{D}(\Sigma;\Phi,H_o)$.

THEOREM 1. *Suppose* $\Sigma = F + \mathcal{B}\mathcal{H}_{p\times q}^{\infty}C \subseteq \mathcal{L}_{m\times n}^{\infty}$ *is a coset of the form* (4), *and* Φ *a rational spectral density of rank* 1. *Let* $\Phi = \phi\phi^*$ *be any factorization of* Φ *with* $\phi \in \mathcal{R}\mathcal{L}_n^2$. *Suppose* $H_o \in \mathcal{A}(\Sigma;\Phi)$. *Then* $\mathcal{D}(\Sigma;\Phi,H_o) \subseteq \mathcal{A}(\Sigma;\Phi)$ *and has one of the following forms:*

(i) *If* $C\phi = 0$ *and* $\phi^*H_o^*B = 0$, *then* $\mathcal{D}(\Sigma;\Phi,H_o) = \Sigma$.

(ii) *If* $C\phi = 0$, $\phi^*H_o^*B \neq 0$, *and* $p > 1$, *then*

$$\mathcal{D}(\Sigma;\Phi,H_o) = H_o + BR\mathcal{H}_{(p-1)\times q}^{\infty}C,$$

where $BR \in \mathcal{R}\mathcal{H}_{m\times(p-1)}^{\infty}$ *has full column rank on the unit circle*; R *chosen as in Lemma 6.*

(iii) *If* $C\phi \neq 0, q > 1$, *and* $\phi^*H_o^*B = 0$, *then*

$$\mathcal{D}(\Sigma;\Phi,H_o) = H_o + B\mathcal{H}_{p\times(q-1)}^{\infty}PC,$$

where $PC \in \mathcal{R}\mathcal{H}_{(q-1)\times n}^{\infty}$ *has full row rank on the unit circle*; P *chosen as in Lemma 6.*

(iv) *If* $C\phi \neq 0, q > 1, \phi^*H_o^*B \neq 0$, *and* $p > 1$, *then*

$$\mathcal{D}(\Sigma;\Phi,H_o) = H_o + BR\mathcal{H}_{(p-1)\times(q-1)}^{\infty}PC,$$

where $BR \in \mathcal{R}\mathcal{H}_{m\times(p-1)}^{\infty}$ *and* $PC \in \mathcal{R}\mathcal{H}_{(q-1)\times n}^{\infty}$ *have full column rank, respectively, full row rank, on the unit circle*; R *and* P *chosen as in Lemma* 6.

(v) *If either* (a): $C\phi \neq 0$ *and* $q = 1$, *or* (b): $\phi^*H_o^*B \neq 0$, *and* $p = 1$, *then*

$$D(\Sigma;\Phi,H_o) = \{H_o\}.$$

Proof. Since $H_o \in \mathcal{A}(\Sigma;\Phi)$ it is clear that $\mathcal{D}(\Sigma;\Phi,H_o) \subseteq \mathcal{A}(\Sigma;\Phi)$. To prove (i)–(v) we first note that each $H \in \Sigma$ may be written $H = H_o + BQC$ for some $Q \in \mathcal{H}_{p\times q}^{\infty}$. Moreover, the following identity then holds.

$$H^*H = H_o^*H_o + H_o^*BQC + C^*Q^*B^*H_o + C^*Q^*QC. \tag{26}$$

(i) Clearly each $H \in \mathcal{D}(\Sigma;\Phi,H_o)$ has the form $H = H_o + BQC$ for some $Q \in \mathcal{H}_{p\times q}^{\infty}$. Conversely, suppose $H = H_o + BQC$, where Q is an arbitrary function in $\mathcal{H}_{p\times q}^{\infty}$. Since $C\phi = 0$ and $\phi^*H_o^*B = 0$, identity (26) implies $H^*H\Phi = H_o^*H_o\Phi$. Thus $H \in \mathcal{D}(\Sigma;\Phi,H_o)$.

(ii) Suppose $H = H_o + BQC \in \mathcal{D}(\Sigma;\Phi,H_o)$. Then $H^*H\Phi = H_o^*H_o\Phi$, which by the full row rank property of ϕ gives $H^*H\phi = H_o^*H_o\phi$. Assumption $C\phi = 0$ together with identity (26) then implies $\phi^*H_o^*BQC = 0$, which immediately results in $\phi^*H_o^*BQ = 0$. Lemma 6(ii) therefore gives $Q = RQ_3$ for some $Q_3 \in \mathcal{H}_{(p-1)\times q}^{\infty}$, that is, $H = H_o + BRQ_3C$. Conversely, suppose $H = H_o + BQC$, with $Q = RQ_3$ for some $Q_3 \in \mathcal{H}_{(p-1)\times q}^{\infty}$. Then by Lemma 6(ii), $\phi^*H_o^*BQ = 0$. Hence identity (26) implies $H^*H\Phi = H_o^*H_o\Phi$, that is, $H \in \mathcal{D}(\Sigma;\Phi,H_o)$.

(iii) Suppose $H = H_o + BQC \in \mathcal{D}(\Sigma;\Phi,H_o)$. By Lemma 3(ii) we then have $BQC\phi = 0$, and hence $QC\phi = 0$. By Lemma 6(i) this gives $Q = Q_1P$ for some

$Q_1 \in \mathcal{H}^\infty_{p\times(q-1)}$, that is, $H = H_o + BQ_1PC$. Conversely, suppose $H = H_o + BQC$ is of this form, that is, $Q = Q_1P$ for some $Q_1 \in \mathcal{H}^\infty_{p\times(q-1)}$. Then by Lemma 6(i), $QC\phi = 0$. This, together with the assumption $\phi^* H_o^* B = 0$ and identity (26), gives $H^*H\Phi = H_o^* H_o \Phi$. Hence $H \in \mathcal{D}(\Sigma; \Phi, H_o)$.

(iv) Suppose $H = H_o + BQC \in \mathcal{D}(\Sigma; \Phi, H_o)$. As in (iii) we then have $QC\phi = 0$, and $Q = Q_1P$ for some $Q_1 \in \mathcal{H}^\infty_{p\times(q-1)}$. Hence identity (26), together with the fact that PC has full row rank, implies $\phi^* H_o^* BQ_1 = 0$. By Lemma 6(ii), we therefore have $Q_1 = RQ_2$ for some $Q_2 \in \mathcal{H}^\infty_{(p-1)\times(q-1)}$, that is, $H = H_o + BRQ_2PC$. Conversely, suppose $H = H_o + BQC$, with $Q = RQ_2P$ for some $Q_2 \in \mathcal{H}^\infty_{(p-1)\times(q-1)}$. Then $\phi^* H_o^* BQ = 0$ and $QC\phi = 0$. Hence identity (26) implies $H^*H\Phi = H_o^* H_o \Phi$, that is, $H \in \mathcal{D}(\Sigma; \Phi, H_o)$.

(v) Case a: Suppose $H = H_o + BQC \in \mathcal{D}(\Sigma; \Phi, H_o)$. By Lemma 3(ii), $BQC\phi = 0$, and hence also $QC\phi = 0$. Since $C\phi \neq 0$ is scalar valued, this gives $Q = 0$, that is, $H = H_o$.

Case b: Suppose $H = H_o + BQC \in \mathcal{D}(\Sigma; \Phi, H_o)$. Then $H^*H\phi = H_o^* H_o \phi$. Either $C\phi = 0$ or else by Lemma 3(ii), $BQC\phi = 0$, that is, $QC\phi = 0$. In either case, identity (26) implies $\phi^* H_o^* BQ = 0$. But since $\phi^* H_o^* B$ is scalar valued, this in turn implies $Q = 0$, that is, $H = H_o$. □

By Theorem 1, $\mathcal{D}(\Sigma; \Phi, H_o)$ is for each $H_o \in \mathcal{A}(\Sigma; \Phi)$ a coset, which, except for case (v), is of type (4). Since the matrices R and P do not depend on H_o, this also holds for the subspace associated with the coset, for instance, in case (iv) the subspace $BR\mathcal{H}^\infty_{p\times q}PC$.

We will identify $\mathcal{D}(\Sigma; \Phi, H_o)$ with a subset $\hat{\Sigma}(\Phi, H_o)$ of $\mathcal{H}^\infty_{m\times(n-1)}$ having a parametrization similar to that of Theorem 1. Consider therefore the rational spectral density $\Phi = \phi\phi^*, \phi \in \mathcal{L}^2_n$ in Theorem 1. Clearly

$$\phi = fg \tag{27}$$

for some inner $f \in \mathcal{RH}^2_n$ and some scalar valued function $g \in \mathcal{RL}^2$. To see this we choose a rational scalar valued inner function θ such that $\theta^*\phi \in \mathcal{H}^2_n$. By an inner-outer factorization we have $\theta\phi = fh$, where $f \in \mathcal{RH}^2_n$ is inner and $h \in \mathcal{RH}^2$ is outer. Thus we may take $g = \theta^{-1}h$. The inner vector f clearly depends on the choice of the factor ϕ and the function θ. However, by a co-inner/co-outer factorization of f and a subsequent absorption of the co-inner part in g, we could choose f to be co-outer, also. This inner/co-outer f would then be uniquely determined by Φ. Since we make no use of this fact we will only require f to be inner. Hence f is unique only up to multiplication by some scalar valued inner function. Via f we may relate Φ to a square inner matrix

$$V := [V_a \quad V_b] \in \mathcal{RH}^\infty_{n\times n}, \tag{28}$$

where $V_a = f$, and $V_b \in \mathcal{RH}^\infty_{n\times(n-1)}$ is an inner complement of V_a. If $n = 1$, this reduces to $V = V_a$. Define a mapping $\gamma : \mathcal{H}^\infty_{m\times n} \to \mathcal{H}^\infty_{m\times(n-1)}$ by $\gamma(H) = HV_b$. For $H_o \in \Sigma$ let

$$\hat{\Sigma}(\Phi, H_o) = \gamma(\mathcal{D}(\Sigma; \Phi, H_o)). \tag{29}$$

COROLLARY 3. *Suppose $H_o \in \mathcal{A}(\Sigma; \Phi)$. Then corresponding to* (i)–(v) *of Theorem* 1, *the following cases occur:*

(i) $\hat{\Sigma}(\Phi, H_o) = H_oV_b + B\mathcal{H}^\infty_{p\times q}CV_b$, *where* CV_b *has full row rank on the unit circle.*

(ii) $\hat{\Sigma}(\Phi, H_o) = H_oV_b + B\mathcal{H}^\infty_{p\times(q-1)}PCV_b$, *where* PCV_b *has full row rank on the unit circle.*

(iii) $\hat{\Sigma}(\Phi, H_o) = H_oV_b + BR\mathcal{H}^\infty_{(p-1)\times q}CV_b$, *where* BR *has full column rank, and* CV_b *has full row rank, on the unit circle.*

(iv) $\hat{\Sigma}(\Phi, H_o) = H_oV_b + BR\mathcal{H}^\infty_{(p-1)\times(q-1)}PCV_b$, *where* BR *has full column rank, and* PCV_b *has full row rank, on the unit circle.*

(v) $\hat{\Sigma}(\Phi, H_o) = \{H_oV_b\}$.

Moreover γ *determines a one-to-one correspondence between the coset* $\mathcal{D}(\Sigma; \Phi, H_o)$ *and the coset* $\hat{\Sigma}(\Phi, H_o)$.

Proof. For each case the corresponding case of Theorem 1 shows that $\hat{\Sigma}(\Phi, H_o)$ is of the required form, except possibly for the rank conditions on CV_b and PCV_b. To check these we note in cases (i) and (ii) that $CV_a = 0$, which implies that CV_b has full row rank on the unit circle. In cases (iii) and (iv), $PCV_a = 0$, which implies that PCV_b has full row rank on the unit circle. To prove the last statement we only need to show that γ restricted to $\mathcal{D}(\Sigma; \Phi, H_o)$ is injective. But in each case (i)–(iv) this follows from the full rank properties of BR, CV_b, and PCV_b. □

If so desired we could use a co-inner factor U_a of the row vector $\phi^* H_o^*$ to construct a rational square inner matrix $U = [U_a^{\mathrm{T}} \quad U_b^{\mathrm{T}}]^{\mathrm{T}}$. By redefining γ such that $\gamma(H) = U_bHV_b$ the set $\hat{\Sigma}(\Phi, H_o)$ would then take a more symmetric form. For instance, case (iv) of Corollary 3 would read

$$\hat{\Sigma}(\Phi, H_o) = U_bH_oV_b + U_bBR\mathcal{H}^\infty_{(p-1)\times(q-1)}PCV_b,$$

where U_bBR has full column rank and PCV_b has full row rank, on the unit circle. This corresponds closely to the form used in [27].

COROLLARY 4. *For any* $H \in \mathcal{D}(\Sigma; \Phi, H_o)$ *we have*

$$\mathcal{D}(\Sigma; \Phi, H) = \mathcal{D}(\Sigma; \Phi, H_o),$$
$$\hat{\Sigma}(\Phi, H) = \hat{\Sigma}(\Phi, H_o).$$

Proof. This follows directly from the coset property of $\mathcal{D}(\Sigma; \Phi, H_o)$ in Theorem 1. □

According to Corollary 3, $\hat{\Sigma}(\Phi, H_o)$ is a coset which, except for the case (v), is of type (4). Furthermore, via the mapping $\gamma, \hat{\Sigma}$ may be identified with $\mathcal{D}(\Sigma; \Phi, H_o)$. The inverse image $\gamma^{-1}(G), G \in \hat{\Sigma}(\Phi, H_o)$ is easily computed. For instance, in case (iv) of Corollary 3 we have $\gamma^{-1}(G) = H_o + BR^{-1}B^{-1}(G - H_oV_b)(PCV_b)^{-1}C$, where R^{-1} and B^{-1} are left inverses of R and B, respectively, and $(PCV_b)^{-1}$ is a right inverse of PCV_b. This becomes even easier if we know the $Q \in \mathcal{H}^\infty_{p\times q}$ determining G. Just take $\gamma^{-1}(G) = H_o + BRQPC$. This is, for instance, the case when G is an H^∞-optimal function computed via the polynomial approach.

The following theorem and its corollary accentuate the usefulness of $\hat{\Sigma}(\Phi, H_o)$.

THEOREM 2. *Suppose* $\Sigma = F + \mathcal{B}\mathcal{H}^\infty_{p\times q}C \in \mathcal{L}^\infty_{m\times n}$, $n > 1$, *is a coset of the form* (4), *and* Φ *a rational spectral density for* $\mathcal{S}(\Sigma)$ *of rank* 1. *Let* $\Phi = \phi\phi^*$ *be any factorization of* Φ *with* $\phi \in \mathcal{RL}^2_n$. *Let* $V = [V_a \quad V_b]$ *be as in* (28), *where* V_a *is the inner factor of* ϕ *given by* (27), *and* V_b *an inner complement of* V_a. *Suppose* $H_o \in \Sigma$ *satisfies* $H_o^* H_o \Phi = \lambda^2 \Phi$. *Then* $H \in \Sigma$ *belongs to* $\mathcal{D}(\Sigma; \Phi, H_o)$ *if and only if*

$$V^*H^*HV = \begin{bmatrix} \lambda^2 & 0 \\ 0 & V_b^*H^*HV_b \end{bmatrix}. \tag{30}$$

Proof. Suppose $H = F + BQC \in \mathcal{D}(\Sigma; \Phi, H_o)$. Since $\phi = gV_a$ for some scalar valued rational function g, it follows that $H^*HV_a = H_o^*H_oV_a = \lambda^2 V_a$. Thus

$$V^*H^*HV = \begin{bmatrix} V_a^*H^*HV_a & V_a^*H^*HV_b \\ V_b^*H^*HV_a & V_b^*H^*HV_b \end{bmatrix} = \begin{bmatrix} \lambda^2 & 0 \\ 0 & V_b^*H^*HV_b \end{bmatrix}. \tag{31}$$

Conversely, suppose (30) holds for some $H \in \Sigma$. Since $\Phi = gg^*V_aV_a^*$ we have

$$V^*\Phi V = \begin{bmatrix} gg^* & 0 \\ 0 & 0 \end{bmatrix}. \tag{32}$$

Hence using (30)

$$V^*H^*H\Phi V = V^*H^*HV \cdot V^*\Phi V = \lambda^2 \begin{bmatrix} gg^* & 0 \\ 0 & 0 \end{bmatrix}, \tag{33}$$

which by (32) is the same as $H^*H\Phi = \lambda^2\Phi$. □

COROLLARY 5. *Suppose H_o is $\mathcal{H}^\infty$-optimal in Σ, that is, $\|H_o\|_\infty = \lambda$, and that Φ is distinguishing for $\mathcal{S}(\Sigma)$. Then*

(i) *A function $H \in \Sigma$ is $\mathcal{H}^\infty$-optimal in Σ if and only if $H \in \mathcal{D}(\Sigma; \Phi, H_o)$ and $\|HV_b\|_\infty \le \lambda$.*

(ii) *For $k > 1$, a function $H \in \Sigma$ is class k optimal (super-optimal) in Σ if and only if $H \in \mathcal{D}(\Sigma; \Phi, H_o)$ and HV_b is class $k-1$ optimal (super-optimal) in $\hat{\Sigma}(\Phi, H_o)$.*

Proof. (i) Suppose H is $\mathcal{H}^\infty$-optimal in Σ. Then, since H_o is also $\mathcal{H}^\infty$-optimal and Φ distinguishing, it follows from Lemmas 1 and 2 that $H \in \mathcal{D}(\Sigma; \Phi, H_o)$. Moreover, by Theorem 2, H has a diagonalization (30). Since V is square and inner this means that the singular values of H are λ^2 together with those of HV_b. By the $\mathcal{H}^\infty$-optimality of H this means that $\|HV_b\|_\infty \le \lambda$. Conversely, suppose that $H \in \mathcal{D}(\Sigma; \Phi, H_o)$ and that $\|HV_b\|_\infty \le \lambda$. Then by Theorem 2, H has a diagonalization (30). Thus $\|H\|_\infty = \lambda$, that is, H is $\mathcal{H}^\infty$-optimal in Σ.

(ii) The proof is similar to the proof of (i). □

We finally consider the case where the functions in Σ are column vectors.

THEOREM 3. *Suppose $\Sigma \subseteq \mathcal{L}^\infty_{m\times n}$ is a coset of the form* (4) *with either $m = 1$ or $n = 1$. Then any $\mathcal{H}^\infty$-optimal function in Σ is necessarily super-optimal. Moreover:*

(i) *If $\mathcal{S}(\Sigma)$ admits a distingiushing spectral density, then the $\mathcal{H}^\infty$-optimal function is unique.*

(ii) *If $\mathcal{S}(\Sigma)$ does not admit a distingiushing spectral density, then an $\mathcal{H}^\infty$-optimal function may be nonunique.*

Proof. (i) Suppose $H_o \neq 0$ is $\mathcal{H}^\infty$-optimal in $\Sigma = F + B\mathcal{H}^\infty_{p\times q}C \subseteq \mathcal{H}^\infty_{m\times n}$. Consider first the case $m = 1$. Since B is tall, $m = 1$ implies $p = 1$, that is, B is scalar valued. Since $\lambda = \|H_o\|_\infty > 0$, we have, by Lemma 2, $H_o\phi \neq 0$ and hence $\phi^*H_o^*B \neq 0$. Theorem 1 (v) therefore shows that $\mathcal{D}(\Sigma; \Phi, H_o) = \{H_o\}$. Thus H_o is the only $\mathcal{H}^\infty$-optimal function in Σ. Suppose now that $n = 1$. Then $q = 1$ and C is scalar valued. Consequently, $C\phi \neq 0$. By Theorem 1(v) we therefore have $\mathcal{D}(\Sigma; \Phi, H_o) = \{H_o\}$. Hence again H_o is the only $\mathcal{H}^\infty$-optimal function in Σ.

(ii) This may be shown by constructing simple counter examples (also, cf. [10]). □

5. Super-optimization. The results of the previous section, in particular Theorem 1 and Corollaries 3 and 5, provide us with the following procedure for computing class k optimal functions in a coset

$$\Sigma_1 := F + B\mathcal{H}^\infty_{p\times q}C \subseteq \mathcal{H}^\infty_{m\times n}$$

of the type (4).

Step 1. Apply the polynomial approach, or any other approach, to obtain an $\mathcal{H}^\infty$-optimal function $H_1 = F + BQ_1C$ in Σ_1, where $Q_1 \in \mathcal{Q}_1 := \mathcal{H}^\infty_{p\times q}$. This determines a class 1 optimal function in Σ.

Step 2. If a distinguishing spectral density Φ_1 exists for $\mathcal{S}(\Sigma_1)$, then construct as in (28) the inner matrix $V_1 = [V_{1a} \quad V_{1b}]$ associated with Φ_1. In cases (i)–(vi) of Theorem 1, $\mathcal{D}(\Sigma_1; \Phi_1, H_1)$ has the form $H_1 + B\mathcal{Q}_2C$, where $\mathcal{Q}_2$ is a subspace of $\mathcal{Q}_1$. In case (iv) for instance, $\mathcal{Q}_2 = R_1\mathcal{H}^\infty_{(p-1)\times(q-1)}P_1$, where R_1 and P_1, respectively, denote the matrices R and P of Theorem 1. Define the coset

$$\Sigma_2 := H_1V_{1b} + B\mathcal{Q}_2CV_{1b}, \in \mathcal{H}^\infty_{m\times(n-1)}. \tag{34}$$

By Corollary 3 this is of the type (4).

Apply the polynomial approach, or any other approach, to Σ_2 to obtain an $\mathcal{H}^\infty$-optimal function $H_2 = H_1V_{1b} + BQ_2CV_{1b}$ in Σ_2, where $Q_2 \in \mathcal{Q}_2$. By Corollary 5,

$$H_1 + BQ_2C = F + B(Q_1 + Q_2)C$$

is then class 2 optimal in Σ_1.

Step 3. If a distinguishing spectral density Φ_2 exists for $\mathcal{S}(\Sigma_2)$, we may as before construct the inner matrix $V_2 = [V_{2a} \quad V_{2b}]$ associated with Φ_2. In cases (i)–(iv) of Theorem 1 $\mathcal{D}(\Sigma_2; \Phi_2, H_2)$ is a coset $H_2 + B\mathcal{Q}_3CV_{1b}$, where $\mathcal{Q}_3$ is a subspace of $\mathcal{Q}_2$. In case (iv) for instance, we may have $\mathcal{Q}_3 = R_1R_2\mathcal{H}^\infty_{(p-2)\times(q-2)}P_2P_1$. Define the coset

$$\Sigma_3 := H_2V_{2b} + B\mathcal{Q}_3CV_{1b}V_{2b} \in \mathcal{H}^\infty_{m\times(n-2)}. \tag{35}$$

By Corollary 3 this is of the type (4).

Apply the polynomial approach, or any other approach, to Σ_3 to obtain an $\mathcal{H}^\infty$-optimal function $H_3 = H_2V_{2b} + BQ_3CV_{1b}V_{2b}$ in Σ_3, where $Q_3 \in \mathcal{Q}_3$. By Corollary 5, $H_2 + BQ_3CV_{1b} = H_1V_{1b} + B(Q_2 + Q_3)CV_{1b}$ is then class 2 optimal in Σ_2, and

$$H_2 + B(Q_2 + Q_3)C = F + B(Q_1 + Q_2 + Q_3)C$$

is class 3 optimal in Σ_1.

Step k. In the general kth step we obtain a coset

$$\Sigma_k = H_{k-1}V_{(k-1),b} + B\mathcal{Q}_kCV_{1b}\cdots V_{(k-1),b} \in \mathcal{H}^\infty_{m\times(n-k+1)} \tag{36}$$

which, in cases (i)–(iv) of Theorem 1, is of type (4). In case (iv) for instance, we may have $\mathcal{Q}_k = R_1R_2\cdots R_{k-1}\mathcal{H}^\infty_{(p-k+1)\times(q-k+1)}P_{k-1}\cdots P_1$. Use the polynomial approach, or any other approach, to find an $\mathcal{H}^\infty$-optimal function

$$H_k = H_{k-1}V_{(k-1),b} + BQ_kCV_{1b}\cdots V_{(k-1),b}$$

in Σ_k. By Corollary 5, the function $H_{k-1} + BQ_kCV_{1b}\cdots V_{(k-2),b}$ is then class 2 optimal in Σ_{k-1}. By repeated use of this argument we find that the function

$$F + B(Q_1 + \cdots + Q_k)C$$

is class k optimal in Σ_1.

The process stops when one of the following situations occurs:

1. A distinguishing spectral density Φ_k exists for $\mathcal{S}(\Sigma_k)$ but $\mathcal{D}(\Sigma_k; \Phi_k, H_k) = \{H_k\}$; that is, we are in situation (v) of Theorem 1. The class k optimal function in Σ corresponding to H_k is then unique and hence also super-optimal.

2. No distinguishing spectral density exists, and either $m-k+1=1$ or $n-k+1=1$. The functions in Σ_k then have only one nonzero singular value, and this is clearly minimized by H_k. Consequently, the class k optimal function in Σ corresponding to H_k is super-optimal. It need not be unique, however (cf. Theorem 3).

3. No distinguishing spectral density exists for $\mathcal{S}(\Sigma_k)$ and $m-k+1>1$ and $n-k+1>1$. The class k optimal function in Σ corresponding to H_k is then, in general, neither unique nor super-optimal.

We remark that cases (2) and (3) never occur for one-block problems (cf. [18]). Moreover, as clearly demonstrated by, for instance, [10], [11], [1], [12], and [13], two- and four-block problems commonly admit a distinguishing spectral density. It is therefore believed that situation (3) occurs less frequently in practice. If the process terminates in state (3), in principle we could proceed by searching for a super-optimal function in Σ_k instead of for only an $\mathcal{H}^\infty$-optimal function. The corresponding function in Σ would then be super-optimal. This, however, seems to be a problem of totally different character, and its treatment is outside the scope of this paper.

In any case, the present method allows computation of super-optimal solutions for a large class of model-matching problems, including all one-block problems and a substantial number of genuine two- and four-block problems. For the remaining problems we only obtain a class k optimal solution, which does not need to be super-optimal.

6. Construction of the spectral density. In this section we consider the problem of constructing the distinguishing spectral density needed to carry out the dimension reduction step of the super-optimization algorithm. Since we do not make use of the spectral density itself, but rather its spectral factor, we may confine our study to spectral densities of the form $\Phi=\phi\phi^*\in\mathcal{L}^1_{n\times n}$, where ϕ is an arbitrary vector in $\mathcal{L}^2_n$, not necessarily rational. Exactly as for the rational case, Φ then has a representation (24). Unfortunately, for some four-block problems a distinguishing spectral density does not need to exist. However, we show that if one with the prescribed form exists, then there also exists a rational one. Explicit formulas for computing it are given. These in fact provide a necessary and sufficient condition for the existence of a distinguishing spectral density of the given form.

The equalizer principle binds a distinguishing spectral density Φ rather tightly to the $\mathcal{H}^\infty$-optimal functions H_o. This strongly suggests that in computing H_o some of the intermediate results may assist in finding Φ (cf., e.g., [10], [11], [12], and [13]). We take another approach, however, and consider a method of determining Φ that relies only on the knowledge of a rational $\mathcal{H}^\infty$-optimal function H_o and its norm $\|H_o\|_\infty$. With this we run the risk of repeating some of the effort taken in determining H_o. On the other hand, it has the attractive property of being independent of the $\mathcal{H}^\infty$-optimization method used to obtain H_o. In order of computational complexity we separate the one-, two-, and four-block cases. To simplify the exposition, without loss of generality, we assume that the matrices B and C of the coset $\Sigma=F+B\mathcal{H}^\infty_{p\times q}C$ have been chosen inner and co-inner, respectively.

6.1. The one-block case. We begin with the simplest case, the one-block problem. Consequently, we take $\Sigma=F+B\mathcal{H}^\infty_{p\times q}C$ and B and C square and inner. It is shown in [18] that in the one-block case a distinguishing spectral density of type (24) always exists for $\mathcal{S}(\Sigma)$. Suppose therefore that ϕ is such a distinguishing spectral density. Since C is square this means that for some co-outer $\varphi\in\mathcal{H}^2_n$ we have $\Phi=\phi\phi^*$, where $\phi=C^*\varphi$. Let H_o be an arbitrary rational $\mathcal{H}^\infty$-optimal function in Σ, and let $\lambda=\|H_o\|_\infty$. From Lemma 2

$$(H_o^*H_o-\lambda^2 I)C^*\varphi=0. \tag{37}$$

Suppose $H_o^* H_o - \lambda^2 I$ has column rank $n-k$. Apply Corollary 2 to equation (37) to get a full column rank matrix $P \in \mathcal{RH}^\infty_{n\times k}$ such that $\varphi = Pu$ for some $u \in \mathcal{H}^2_k, u \neq 0$. Moreover, from (37) it is easily seen that $H_o C^* P$ has full column rank k. Using Lemma 4(ii) we also find that $H_o C^* P u$ is perpendicular to $B\mathcal{H}^2_m$. Thus,

$$\Psi H_o C^* P u \in \mathcal{H}^2_m \ominus \Psi B\mathcal{H}^2_m, \tag{38}$$

where Ψ is any $n\times n$ rational square inner matrix such that $\Psi H_o C^* P \in \mathcal{H}^\infty_{m\times k}$. One way to obtain Ψ is to start with a polynomial coprime factorization $H_o C^* P = D^{-1}N$ and consider a polynomial spectral factorization $DD^* = \hat{D}\hat{D}^*$, where $\det(\hat{D})$ has no roots in the closed unit disk. Then $\Psi = \hat{D}^{-1}D$ has the required properties. Recall that $\mathcal{H}^2_m \ominus \Psi B\mathcal{H}^2_m$ is a finite-dimensional space, which (up to equivalence) contains only rational functions. Since $\Psi H_o C^* P$ has full column rank, this means that u in fact must be rational (modulo some null function). Choose a basis for $\mathcal{H}^2_m \ominus \Psi B\mathcal{H}^2_m$ consisting of rational vectors $E_1, \dots, E_p$. A suitable choice of $E_1, \dots, E_p$ is given in Appendix A. Let $E = [E_1, E_2, \dots, E_p]$ be the matrix having E_i as its ith column. Then for some $\xi \in C^p$,

$$\Psi H_o C^* P u = E\xi. \tag{39}$$

Conversely, suppose that $u \in \mathcal{H}^2_k$ satisfies (39). We may then assume u to be rational as well. Clearly (38) holds, also. Write $\varphi\theta = Pu$, where $\varphi \in \mathcal{RH}^2_n$ is co-outer and $\theta \in \mathcal{RH}^2$ is co-inner. Then taking $\phi = C^*\varphi$ it is easily seen from (38) that $H_o\phi \perp \theta^* B\mathcal{H}^2_m$. But since $B\mathcal{H}^2_m \subseteq \theta^* B\mathcal{H}^2_m$, this implies that $H_o\phi \perp B\mathcal{H}^2_m$. Let

$$\Phi = C^* P u u^* P^* C = \phi\phi^*, \tag{40}$$

where $\phi = C^*\varphi$. By Lemma 4(ii) we then have $H_o \in \mathcal{A}(\Sigma;\Phi)$, that is, the first condition (12) of Lemma 1 holds. On the other hand, the choice of P guarantees that $(H_o^* H_o - \lambda^2 I)\phi = 0$. By Lemma 2 this shows that Φ satisfies the second condition (12) of Lemma 1. Consequently, this Φ is distinguishing and rational.

To summarize, we have shown that the problem of finding a distinguishing spectral density Φ is equivalent to solving equation (39) for a nonzero $u \in \mathcal{RH}^2_k$ and a nonzero $\xi \in C^p$. Moreover, via (40) such a solution gives rise to rational Φ. A way to solve (39) will be considered in Appendix B.

It is worthwhile to note the following special case of equation (39). Suppose that the $\mathcal{H}^\infty$-optimal solution H_o satisfies $H_o^* H_o = \lambda^2 I$. This can always be arranged for when the polynomial approach is used to obtain H_o. We may then take $P = I$ and $\varphi = u$. Moreover, $\Psi H_o C^*$ is then invertible. In fact, $(\Psi H_o C^*)^{-1} = \lambda^{-2} C H_o^* \Psi^*$. Hence, equation (39) is equivalent to the somewhat simpler equation

$$u = \lambda^{-2} C H_o^* \Psi^* E\xi. \tag{41}$$

6.2. The two-block case. For the two-block case we may assume that the coset is of the form $\Sigma = F + B\mathcal{H}^\infty_{p\times n} C$, where B is tall and C is square. Otherwise consider transpositions. Suppose that $\mathcal{S}(\Sigma)$ has a distinguishing spectral density Φ of type (24). Since C is square we may, as for the one-block case, assume that

$$\Phi = C^*\varphi\varphi^* C,$$

where $\varphi \neq 0$ is a co-outer vector in $\mathcal{H}^2_n$. Suppose that $H_o \in \Sigma$ is $\mathcal{H}^\infty$-optimal, and let $\lambda = \|H_o\|_\infty$. By Lemma 2, $(H_o^* H_o - \lambda^2 I)C^*\varphi = 0$. Suppose $H_o^* H_o - \lambda^2 I$ has column rank $n-k$. Then by Corollary 2 there exists a rational $P \in \mathcal{RH}^\infty_{n\times k}$ such that

$$\varphi = Pu \tag{42}$$

for some $u \in \mathcal{H}_k^2, u \neq 0$. Moreover, by Lemma 4(ii)

$$H_o C^* P u \perp B\mathcal{H}_p^2. \tag{43}$$

Choose an inner matrix $\Psi \in \mathcal{RH}_{p\times p}^\infty$ such that $\Psi B^* H_o C^* P \in \mathcal{RH}_{p\times k}^\infty$. Then (43) implies

$$\Psi B^* H_o C^* P u \in \mathcal{H}_p^2 \ominus \Psi \mathcal{H}_p^2. \tag{44}$$

Note that this condition is similar to (39) except that $\Psi B^* H_o C^* P$ does not need to have full column rank. By applying the Hermite form to the numerator of a polynomial left coprime factorization of $\Psi B^* H_o C^* P$, we may write $\Psi B^* H_o C^* P = [R \quad 0]V$, where R is a rational matrix of full column rank, say r, and V is a unimodular polynomial matrix. Define $v \in \mathcal{H}_r^2$ and $w \in \mathcal{H}_{k-r}^2$ by

$$\begin{bmatrix} v \\ w \end{bmatrix} = Vu. \tag{45}$$

Then (44) implies

$$Rv \in \mathcal{H}_p^2 \ominus \Psi \mathcal{H}_p^2. \tag{46}$$

We have shown that the existence of Φ implies the existence of a $v \in \mathcal{H}_r^2$ such that (46) holds. But since the space $\mathcal{H}_p^2 \ominus \Psi \mathcal{H}_p^2$ consists of only rational functions (up to equivalence), and R has full column rank, this means that v must in fact be rational (up to equivalence).

Conversely, suppose that the matrix R can be formed in the way described, and that (46) holds for some $v \in \mathcal{H}_r^2$. We may as well assume v to be rational. Take an arbitrary $w \in \mathcal{H}_{k-r}^2$ and let

$$u := V^{-1} \begin{bmatrix} v \\ w \end{bmatrix}. \tag{47}$$

Then u satisfies (44). Write $Pu = \varphi\theta$, where $\varphi \in \mathcal{H}_n^2$ is co-outer and $\theta \in \mathcal{H}^2$ is co-inner. Take $\phi = C^*\varphi$, and

$$\Phi = C^* P u u^* P^* C = \phi\phi^*. \tag{48}$$

As in the one-block case we then find that $H_o \phi \perp B\mathcal{H}_p^2$. Consequently, $H_o \in \mathcal{A}(\Sigma; \Phi)$. Moreover, the choice of P guarantees that $(H_o^* H_o - \lambda^2 I)\phi = 0$. Thus by Lemma 2 and Lemma 1, Φ must be distinguishing. Note that if w also is taken rational, then Φ will be rational.

To summarize, we have shown that a distinguishing spectral density Φ exists if and only if the matrix R can be constructed and there exists a solution $v \neq 0$ of (46). Moreover, via (47) and (48), a solution of (46) gives rise to a distinguishing spectral density which may be chosen rational.

It remains to solve (46). Note that this is a relation exactly of type (38). We may therefore proceed as in the one-block case.

6.3. The four-block case. In the most general situation, the four-block case, we have B tall and C wide in the coset $\Sigma = F + B\mathcal{H}_{p\times p}^\infty C$. Suppose that $\mathcal{S}(\Sigma)$ has a distinguishing spectral density Φ of the form (24), that is,

$$\Phi = \phi\phi^*, \qquad \phi = \tilde{C}^* \begin{bmatrix} \varphi \\ \chi \end{bmatrix} \neq 0, \tag{49}$$

for some $\varphi \in \mathcal{H}_q^2$ and $\chi \in \mathcal{L}_{n-q}^2$, where one of the following two cases occurs:

1. $0 \neq \varphi \in \mathcal{H}_q^2$ is co-outer; or
2. $\varphi = 0$.

Here $\tilde{C} = [C^T \quad \tilde{C}^T]^T$ is a completion of C to a square $n \times n$ inner matrix, with $\hat{C}$ being a co-inner complement of C. By Lemma 2 we then have

$$(H_o^* H_o - \lambda^2 I)\tilde{C}^* \begin{bmatrix} \varphi \\ \chi \end{bmatrix} = 0. \tag{50}$$

Consequently, by Corollary 2 there exists a full column rank $n \times k$ polynomial matrix

$$P = \begin{bmatrix} P_1 \\ P_2 \end{bmatrix} \tag{51}$$

partitioned with P_1 having q rows, such that $\varphi \in \mathcal{L}_q^2$ and $\chi \in \mathcal{L}_{n-q}^2$ satisfy (50) if and only if

$$\begin{bmatrix} \varphi \\ \chi \end{bmatrix} = \begin{bmatrix} P_1 \\ P_2 \end{bmatrix} w \tag{52}$$

for some $w \in \mathcal{L}_k^2$.

Case A. Consider the situation where $P_1 \neq 0$ with column rank r. Suppose again that Φ is a distinguishing spectral density given by $\varphi \in \mathcal{H}_q^2$ and $\chi \in \mathcal{L}_{n-q}^2$ as in (49), and that w in $\mathcal{L}_k^2$ satisfies (52). Let

$$P_1 = U \begin{bmatrix} D & 0 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} V_1 \\ V_2 \end{bmatrix}, \qquad V := \begin{bmatrix} V_1 \\ V_2 \end{bmatrix}$$

be, for instance, a Smith decomposition of P_1, where U and V are unimodular polynomial matrices, and D a polynomial diagonal matrix of say type $r \times r$. In the partition of V, V_1 is assumed to have r rows. Factorize $D = D_2 D_1$, with the diagonal elements of D_1 having all roots inside the open unit disk and the diagonal elements of D_2 having no roots in the open unit disk. Then $\varphi = P_1 w \in \mathcal{H}_q^2$ implies that $D_2 D_1 V_1 w \in \mathcal{H}_r^2$. Since $u := D_1 V_1 w \in \mathcal{L}_r^2$ and the elements of D_2 are outer, this means that u in fact belongs to $\mathcal{H}_r^2$ (cf. [17, Cor. 3, p. 12]). Clearly $v := V_2 w \in \mathcal{L}_{k-r}^2$. Note that $\varphi = 0$ implies $u = 0$. Moreover, let

$$M = PV^{-1} \begin{bmatrix} D_1^{-1} & 0 \\ 0 & I_{k-r} \end{bmatrix},$$

where I_{k-r} is the $(k-r) \times (k-r)$ identity matrix. Then M has full column rank and

$$\begin{bmatrix} \varphi \\ \chi \end{bmatrix} = M \begin{bmatrix} u \\ v \end{bmatrix}. \tag{53}$$

On the other hand, suppose $u \in \mathcal{H}_r^2$ and $v \in \mathcal{L}_{k-r}^2$. Let φ and χ be given by (53). Then clearly $\chi \in \mathcal{L}_{n-q}^2$, and from the definition of M it follows that

$$\varphi = U \begin{bmatrix} D_2 D_1 & 0 \\ 0 & 0 \end{bmatrix} V \cdot V^{-1} \begin{bmatrix} D_1^{-1} & 0 \\ 0 & I_{k-r} \end{bmatrix} \begin{bmatrix} u \\ v \end{bmatrix} = U \begin{bmatrix} D_2 u \\ 0 \end{bmatrix} \in \mathcal{H}_q^2.$$

Note that $u = 0$ implies $\varphi = 0$. We claim that $H_o \tilde{C}^* M$ has full column rank. To see this we take $u \in \mathcal{L}_r^2$ and $v \in \mathcal{L}_{k-r}^2$ such that

$$H_o \tilde{C}^* M \begin{bmatrix} u \\ v \end{bmatrix} = 0.$$

Then by (50) we have

$$\tilde{C}^* M \begin{bmatrix} u \\ v \end{bmatrix} = \lambda^{-2} H_o^* H_o \tilde{C}^* M \begin{bmatrix} u \\ v \end{bmatrix} = 0.$$

But since $\tilde{C}^* M$ has full column rank, this implies $u = 0$, and $v = 0$. Hence $H_o \tilde{C}^* M$ also has full column rank. We summarize these results as a lemma.

LEMMA 7. *Suppose that the matrix P_1 in (51) has column rank $0 < r \leq k$.*

(i) *There exists an $M \in \mathcal{RL}^{\infty}_{n \times k}$ of full column rank, such that $\varphi \in \mathcal{L}^2_q$ and $\chi \in \mathcal{L}^2_{n-q}$ satisfy equation (50), together with the additional requirement $\varphi \in \mathcal{H}^2_q$, if and only if*

$$\begin{bmatrix} \varphi \\ \chi \end{bmatrix} = M \begin{bmatrix} u \\ v \end{bmatrix} \tag{54}$$

for some $u \in \mathcal{H}^2_r$ and $v \in \mathcal{L}^2_{k-r}$.

(ii) *$\varphi = 0$ if and only if $u = 0$.*

(iii) *$H_o \tilde{C}^* M$ has full column rank k.*

We have shown that for the distinguishing spectral density Φ with $\varphi \in \mathcal{H}^2_q$ we can find $u \in \mathcal{H}^2_r$, and $v \in \mathcal{L}^2_{k-r}$, such that (54) holds. Note that the v part disappears when P_1 has full column rank $r = k$. To continue our construction we consider as separate subcases the two types of φ we introduced earlier.

Subcase A1. Suppose first that $\varphi \neq 0$ and is co-outer. Since Φ is distinguishing we have by Lemma 4 that $H_o \phi \perp \mathcal{B}\mathcal{H}^2_p$, or equivalently

$$\Psi B^* H_o \tilde{C}^* M \begin{bmatrix} u \\ v \end{bmatrix} \perp \Psi \mathcal{H}^2_p, \tag{55}$$

where $\Psi \in \mathcal{H}^{\infty}_{p \times p}$ is a rational square inner matrix such that $\Psi B^* H_o \tilde{C}^* M \in \mathcal{R}\mathcal{H}^{\infty}_{p \times k}$. In conformance with u and v we introduce a partition $\Psi B^* H_o \tilde{C}^* M = [K \quad A]$, where K has r columns and A has $k - r$ columns. By applying, for instance, the Hermite form to the numerator of a polynomial left coprime factorization of A, we may write $A = [R \quad 0]V$, where R is a rational matrix of full column rank, say s, and V is a unimodular polynomial matrix. Devine $v_1 \in \mathcal{L}^2_s$ and $v_2 \in \mathcal{L}^2_{k-r-s}$ by

$$\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = Vv. \tag{56}$$

Consequently, (55) implies

$$Ku + Rv_1 \perp \Psi \mathcal{H}^2_p. \tag{57}$$

Let $R = LD^{-1}$ be a polynomial coprime factorization of R. Then $\mathcal{R}\mathcal{L}^2_s = L\mathcal{L}^2_s$, with L also having rank s. Thus (57) implies

$$Ku + L\hat{v}_1 \perp \Psi \mathcal{H}^2_p, \tag{58}$$

where

$$\hat{v}_1 = D^{-1} v_1. \tag{59}$$

Denote by P_{H^2} the orthogonal projection of $\mathcal{L}^2_p$ onto $\mathcal{H}^2_p$, and let $w = P_{H^2} z^d \hat{v}_1$. Suppose that the degree of L is d. By considering the Fourier series of $\hat{v}_1$, it is easy to see that

$L\hat{v}_1 - Lz^{-d}w$ has nonvanishing Fourier coefficients only for negative indices. Thus $L\hat{v}_1 - Lz^{-d}w$ is orthogonal to the space $\mathcal{H}_p^2$ and hence also to its subspace $\Psi\mathcal{H}_p^2$. Consequently, (58) implies

$$Ku + Lz^{-d}w \perp \Psi\mathcal{H}_p^2. \tag{60}$$

Written in a slightly different form this gives

$$[z^d K \quad L] \begin{bmatrix} u \\ w \end{bmatrix} \in \mathcal{H}_p^2 \ominus z^d \Psi \mathcal{H}_p^2. \tag{61}$$

Thus the existence of a distinguishing Φ with $\varphi \neq 0$ co-outer in $\mathcal{H}_q^2$ implies that we can construct the matrices K and L as just described, and find a $u \in \mathcal{H}_r^2$ not equal to zero, and a $w \in \mathcal{H}_s^2$, such that (61) holds.

Conversely, suppose that we can form the matrices K and L, and that (61) holds for some $u \in \mathcal{H}_r^2$, not equal to zero, and some $w \in \mathcal{H}_s^2$. Define $\hat{v}_1 = z^{-1}w \in \mathcal{L}_s^2$. Then it is easily seen that (58) holds, also. Furthermore, with $v_1 = D\hat{v}_1$ we obtain (57). Finally with

$$v = V^{-1} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = V^{-1} \begin{bmatrix} z^{-1}Dw \\ v_2 \end{bmatrix}, \tag{62}$$

where $v_2 \in \mathcal{L}_{k-r-s}^2$ is arbitrary, we find that (55) holds. Write

$$\psi = M \begin{bmatrix} u \\ v \end{bmatrix}. \tag{63}$$

By inner-outer factorization we have

$$\psi = \begin{bmatrix} \varphi \\ \chi \end{bmatrix} \theta,$$

where φ is co-outer and θ is co-inner. Hence, with

$$\phi = \tilde{C}^* \begin{bmatrix} \varphi \\ \chi \end{bmatrix}$$

condition (55) implies that $H_o\phi \perp B\mathcal{H}_p^2$. Consequently, with

$$\Phi = \tilde{C}^* \psi\psi^* \tilde{C} = \phi\phi^* \tag{64}$$

Lemma 4 shows that $H_o \in \mathcal{A}(\Sigma; \Phi)$. Hence, the first condition (11) of Lemma 1 is satisfied. Clearly the choice of M also guarantees that the second condition (12) of Lemma 1 holds. Thus Φ is a distinguishing spectral density.

To summarize subcase A1: We have shown that a distinguishing spectral density Φ with $\varphi \in \mathcal{H}_q^2$ co-outer exists if and only if the matrices K and L can be formed and there exist a nonzero $u \in \mathcal{H}_r^2$ and a $w \in \mathcal{H}_s^2$ such that (61) holds. Moreover, via (62), (63), and (64), a Φ may be computed from u and w. Thus it only remains to find u and w. Note, however, that (61) is a relation of the type occurring in (44). We may therefore proceed exactly as in the two-block case to solve (61). As in the two-lock case it then follows that a solution u, w may be taken rational. Consequently, the corresponding spectral density may also be chosen rational.

Subcase A2. Consider now the case $\varphi = 0$. We still assume that $P_1 \neq 0$. Since $\varphi = P_1 w = 0$ for $w \neq 0$, P_1 must have less than full column rank. We can still find $M, u,$

and v as in Lemma 7. However, we must have $u = 0$. Conversely, suppose P_1 has less than full column rank. Take $u = 0$ and an arbitrary v, and define φ and χ by equation (54), and Φ by (49). Then $\varphi = 0$, and hence $C\phi = 0$. But this implies $\langle \Phi H_o^* BQC \rangle = 0$ for all $Q \in \mathcal{H}^\infty_{p\times q}$. By Lemma 3 this means that condition (11) of Lemma 1 holds for Φ. On the other hand, condition (12) holds trivially by the choice of M. Consequently, Φ is distinguishing.

To summarize subcase A2: When $P_1 \neq 0$, a distinguishing spectral density with $\varphi = 0$, exists if and only if P_1 has less than full column rank. Moreover, a distinguishing Φ may be computed via (54) and (49) by taking $u = 0$ and v arbitrary. In particular, when v is chosen rational then Φ will also be rational.

Case B. Suppose $P_1 = 0$. Take an arbitrary $w \in \mathcal{L}^2_k$. Define φ and χ by (52), and ϕ and Φ by (49). Clearly $\varphi = 0$, and hence $C\phi = 0$. But this implies that $\langle \Phi H_o^* BQC \rangle = 0$ for all $Q \in \mathcal{H}^\infty_{p\times q}$. By Lemma 3 this means that condition (11) of Lemma 1 holds for Φ. On the other hand, condition (12) holds trivially by the choice of P. Consequently, Φ is distinguishing. It will be rational if w is chosen rational.

This completes the construction of a distinguishing spectral density for the four-block case. We remark that subcases A1 and A2 do not completely exclude each other. It is easy to construct "diagonal" examples with two distinguishing spectral densities, one having $\varphi \neq 0$ and the other have $\varphi = 0$.

7. Existence of the distinguishing spectral density in terms of a four-block operator. In [18] it is shown that a spectral density Φ of rank one is distinguishing for the one-block problem if and only if $\Phi = \phi\phi^*$ with ϕ a maximizing vector of a Sarason type operator associated with the one-block problem. In this section we give a similar condition for the four-block problem. Without loss of generality, we may consider the following special case of (4). Let the set of functions over which $\mathcal{H}^\infty$ optimization takes place be given by

$$\Sigma = \begin{bmatrix} F_{11} + M\mathcal{H}^\infty_{p\times q} & F_{12} \\ F_{21} & F_{22} \end{bmatrix}, \tag{65}$$

where $F_{11} \in \mathcal{RH}^\infty_{p\times q}$, $F_{12} \in \mathcal{RH}^\infty_{p\times n-q}$, $F_{21} \in \mathcal{RH}^\infty_{m-p\times q}$, $F_{22} \in \mathcal{RH}^\infty_{m-p\times n-q}$, and M is an inner matrix in $\mathcal{RH}^\infty_{p\times p}$. Let $\mathcal{H}(M) = \mathcal{H}^2_p \ominus M\mathcal{H}^2_p$ and $\mathcal{L}(M) = \mathcal{L}^2_p \ominus M\mathcal{H}^2_p$. Denote by $P_{\mathcal{H}(M)}$ the orthogonal projection from $\mathcal{L}^2_p$ unto $\mathcal{H}(M)$, and by $P_{\mathcal{L}(M)}$ the orthogonal projection from $\mathcal{L}^2_p$ unto $\mathcal{L}(M)$. Moreover, for any matrix $V \in \mathcal{H}^\infty_{m\times n}$ we denote by $V(S)$ the operator $V(S) : \mathcal{H}^2_n \to \mathcal{H}^2_m$ of multiplying by V. Similarly, for any $W \in \mathcal{L}^\infty_{m\times n}$ we denote by $W(U)$ the operator $W(U) : \mathcal{L}^2_n \to \mathcal{L}^2_m$ of multiplying by W. Following [2], [4], and [20], we associate with (65) the four-block operator

$$A = \begin{bmatrix} P_{\mathcal{H}(M)}F_{11}(S) & P_{\mathcal{L}(M)}F_{12}(U) \\ F_{21}(S) & F_{22}(U) \end{bmatrix} \tag{66}$$

from $\mathcal{H}^2_q \oplus \mathcal{L}^2_{n-q}$ to $\mathcal{L}(M) \oplus \mathcal{L}^2_{m-p}$, the norm of which is given by

$$\|A\| = \lambda_o := \inf\{\|H\|_\infty : H \in \Sigma\}.$$

A vector $\phi \in \mathcal{H}^2_q \oplus \mathcal{L}^2_{n-q}$ is said to be *maximizing* for A if $\|A\phi\| = \|A\|\|\phi\|$.

The following theorem provides a necessary and sufficient condition for the existence of a distinguishing spectral density.

THEOREM 4. *Consider the four-block problem* Σ *in* (65) *and a spectral density* $\Phi = \phi\phi^*$ *with* $\phi \in \mathcal{L}^2_n$ *taken as in* (24). *Then* Φ *is distinguishing for* $\mathcal{S}(\Sigma)$ *if and only if* ϕ *is a maximizing vector of the four-block operator* A.

Proof. For a proof see [19].

A sufficient, but not necessary, condition for the existence of a maximizing vector is that the so-called *essential norm* of A is strictly less than $\|A\|$[4], [20]. Moreover, in [20] it is shown that the essential norm of A is given by

$$\max\left\{\|[F_{21} \quad F_{22}]\|_\infty, \left\|\begin{bmatrix} F_{12} \\ F_{22} \end{bmatrix}\right\|_\infty\right\}. \tag{67}$$

Hence, if (67) is strictly less than λ_o then the four-block problem admits a distinguishing spectral density.

8. Example. We illustrate the super-optimization method in §5 with a numerical four-block example given by the coset

$$\Sigma_1 = F + B\mathcal{H}^\infty_{2\times 2}C, \tag{68}$$

where

$$F(z) = \begin{bmatrix} \frac{(4(\sqrt{2}+1)z^2-12(\sqrt{2}+1)z-9}{3\sqrt{6}(z-3)} & -\frac{8(\sqrt{2}+1)z^2-24(\sqrt{2}+1)z+9}{6\sqrt{3}(z-3)} & \frac{\sqrt{3}z(3\sqrt{2}+16-8z)}{3\sqrt{6}(z-2)} \\ \frac{(2(4\sqrt{2}z^2-12\sqrt{2}z+9}{6\sqrt{3}(z-3)} & -\frac{8\sqrt{2}z^2-24\sqrt{2}z-9}{3\sqrt{6}(z-3)} & \frac{2z}{\sqrt{2}(z-2)} \\ \frac{(4(\sqrt{2}-1)z^2-12(\sqrt{2}z-1)-9}{3\sqrt{6}(z-3)} & -\frac{8(\sqrt{2}-1)z^2-24(\sqrt{2}-1)z+9}{6\sqrt{3}(z-3)} & \frac{\sqrt{3}z(3\sqrt{2}-16+8z)}{3\sqrt{6}(z-2)} \end{bmatrix},$$

$$B(z) = \begin{bmatrix} -\frac{5z^2-14z+5}{2\sqrt{2}(z^2-5z+6)} & \frac{z^2-1}{2\sqrt{2}(z^2-5z+6)} \\ \frac{z^2-1}{2(z^2-5z+6)} & -\frac{5z^2-14z+5}{2(z^2-5z+6)} \\ -\frac{5z^2-14z+5}{2\sqrt{2}(z^2-5z+6)} & \frac{z^2-1}{2(z^2-5z+6)} \end{bmatrix},$$

$$C(z) = \begin{bmatrix} \frac{1}{\sqrt{3}} & \frac{1}{\sqrt{6}} & -\frac{z}{\sqrt{2}} \\ -\frac{1}{\sqrt{3}} & -\frac{1}{\sqrt{6}} & -\frac{z}{\sqrt{2}} \end{bmatrix}.$$

B and C are both inner matrices.

Consider first the problem of finding a $F + BQC$ of minimal $\mathcal{H}^\infty$-norm in the coset (68). Invoke the polynomial approach of §1 to determine a Q_{o1} such that $H_{o1} = F + BQ_{o1}C$ is $\mathcal{H}^\infty$-optimal in Σ_1. One solution is given by

$$Q_{o1}(z) = \begin{bmatrix} -\frac{5(38z+21)}{6(49z+69)} & -\frac{2z+57}{2(49z+69)} \\ -\frac{2z+57}{2(49z+69)} & -\frac{5(38z+21)}{6(49z+69)} \end{bmatrix}.$$

The minimal norm is $\lambda_1 = \|H_{o1}\|_\infty = 4$.

To obtain the model-matching problem for the second largest singular value we first need a ϕ_1 such that $\Phi_1 = \phi_1\phi_1^*$ is a distinguishing spectral density for $\mathcal{S}(\Sigma_1)$. Using the method of §6 we obtain

$$\phi_1(z) = \begin{bmatrix} \frac{1}{\sqrt{3}(2z-1)} \\ -\frac{2}{\sqrt{6}(2z-1)} \\ -\frac{1}{2z-1} \end{bmatrix}.$$

The inner factor V_{1a} of ϕ_1 and a corresponding inner complement V_{1b} are given by

$$V_{1a}(z) = \begin{bmatrix} \frac{1}{\sqrt{6}} \\ -\frac{1}{\sqrt{2}} \\ -\frac{1}{\sqrt{2}} \end{bmatrix}, \qquad V_{1b}(z) = \begin{bmatrix} \frac{1}{\sqrt{6}} & \frac{2}{\sqrt{6}} \\ -\frac{1}{\sqrt{3}} & \frac{1}{\sqrt{3}} \\ \frac{1}{\sqrt{2}} & 0 \end{bmatrix}.$$

As a result, $C\phi \neq 0$ and $\phi^* H_{o1}^* B = 0$. Thus we are in situation (iii) of Theorem 1. The matrix P_1 required to reduce the parameter space from $\mathcal{H}_{2\times 2}^\infty$ to $\mathcal{H}_{2\times 1}^\infty$ is, as in Lemma 6, obtained by parametrizing the set of all solutions $Q \in \mathcal{H}_{2\times 2}^\infty$ of the equation $QC\phi = 0$. This gives $P_1 = [1 \quad -1]$. The model-matching problem for the second largest singular value then becomes

$$\Sigma_2 = F_2 + B\mathcal{H}_{2\times 1}^\infty C_2,$$

where

$$F_2(z) = H_{o1}(z)V_{1b}(z) = \begin{bmatrix} -\frac{2(\sqrt{2}-1)z}{3\sqrt{2}} & \frac{2(69z+49)}{3(49z+69)} \\ \frac{2z}{3} & -\frac{4(69z+49)}{3\sqrt{2}(49z+69)} \\ \frac{2(\sqrt{2}+1)z}{3\sqrt{2}} & \frac{2(69z+49)}{3(49z+69)} \end{bmatrix},$$

$$C_2(z) = P_1(z)C(z)V_{1b}(z) = [0 \quad 1].$$

Invoking the polynomial approach once more we obtain the $\mathcal{H}^\infty$-optimal solution $H_{o2} = F_2 + B_2 Q_{o2} C_2$ determined by

$$Q_{o2}(z) = \begin{bmatrix} 0 \\ 0 \end{bmatrix}.$$

The minimal norm is $\lambda_2 = \|H_{o2}\|_\infty = 4/3$.

To obtain the model-matching problem for the smallest singular value, we construct a ϕ_2 such that $\Phi_2 = \phi_2 \phi_2^*$ is distinguishing spectral density for $\mathcal{S}(\Sigma_2)$. We may choose

$$\phi_2(z) = \begin{bmatrix} 1 \\ 0 \end{bmatrix},$$

which is inner already; that is, $V_{2a} = \phi_2$. An inner complement is given by

$$V_{2b}(z) = \begin{bmatrix} 0 \\ 1 \end{bmatrix}.$$

Since $C_2\phi = 0$, we are in situation (i) of Theorem 1. Thus, no reduction of the parameter space $\mathcal{H}_{2\times 1}^\infty$ of Σ_2 takes place. Consequently, the third problem is

$$\Sigma_3 = F_3 + B\mathcal{H}_{2\times 1}^\infty C_3,$$

where

$$F_3(z) = H_{o2}(z)V_{2b}(z) = \begin{bmatrix} \frac{2(69z+49)}{3(49z+69)} \\ -\frac{4(69z+49)}{3\sqrt{2}(49z+69)} \\ \frac{2(69z+49)}{3(49z+69)} \end{bmatrix}, \qquad C_3(z) = C_2(z)V_{2b}(z) = 1.$$

Using the polynomial approach we obtain an $\mathcal{H}^\infty$-optimal solution $H_{o3} = F_3 + BQ_{o3}C_3$ determined by

$$Q_{o3}(z) = \begin{bmatrix} \dfrac{295(z-3)}{24\sqrt{2}(49z+69)} \\ -\dfrac{295(z-3)}{24\sqrt{2}(49z+69)} \end{bmatrix}.$$

The minimal norm is $\lambda_3 = \|H_{o3}\|_\infty = 9/8$. A corresponding distinguishing spectral density $\Phi_3 = \phi_3\phi_3^*$ is given by $\phi_3(z) = 1/(3z-1)$. Since Σ_3 consists of 3×1 matrix valued functions and admits a distinguishing spectral density, the solution H_{o3} is, in fact, by Theorem 3, unique.

By recovering the corresponding solution, first in Σ_2 and then in Σ_1, we obtain a unique super-optimal solution $H_{\text{sup}} = F + BQ_{\text{sup}}C$ of the original problem Σ_1, where

$$Q_{\text{sup}}(z) = -\begin{bmatrix} 25/48 & 7/48 \\ 7/48 & 25/48 \end{bmatrix},$$

and

$$H_{\text{sup}}(z) = \begin{bmatrix} \dfrac{32(\sqrt{2}+1)z+27}{24\sqrt{6}} & -\dfrac{64(\sqrt{2}+1)z-27}{48\sqrt{3}} & -\dfrac{4\sqrt{3}(2\sqrt{2}+1)z}{6\sqrt{3}} \\ \dfrac{32\sqrt{2}z-27}{24\sqrt{3}} & -\dfrac{64\sqrt{2}z+27}{24\sqrt{6}} & -\dfrac{4\sqrt{3}z}{3\sqrt{6}} \\ \dfrac{32(\sqrt{2}-1)z+27}{24\sqrt{6}} & -\dfrac{64(\sqrt{2}-1)z-27}{48\sqrt{3}} & \dfrac{4\sqrt{3}(2\sqrt{2}-1)z}{6\sqrt{3}} \end{bmatrix},$$

with singular values

$$\begin{aligned}(s_1^\infty(H_{\text{sup}}), s_2^\infty(H_{\text{sup}}), s_3^\infty(H_{\text{sup}})) &= (s_1\{H_{\text{sup}}(e^{i\theta})\}, s_2\{H_{\text{sup}}(e^{i\theta})\}, s_3(H_{\text{sup}}(e^{i\theta})\}) \\ &= (4, 4/3, 9/8)\end{aligned}$$

for all points $e^{i\theta}$ on the unit circle. This completes the construction of the super-optimal solution.

9. Conclusions. A super-optimization algorithm for the general four-block (standard problem) in $\mathcal{H}^\infty$-optimal control has been presented. It successively reduces the original problem to smaller super-optimizations problems. Each step amounts to an ordinary $\mathcal{H}^\infty$-optimization of the largest remaining singular value, and a subsequent removal of the optimized part. The central part of the paper concerns the derivation of a removal technique based on the spectral density of the equalizer principle. The $\mathcal{H}^\infty$-optimizations may be done with any method producing strictly optimal solutions. A method that readily applies, and motivated much of this work, is the polynomial approach by Kwakernaak.

The representation of the kth $\mathcal{H}^\infty$-optimization problem Σ_k in the super-optimization algorithm is not unique. Although any solution H_k of the kth optimization problem of the super-optimization algorithm, and any inner complement V_{kb} of the inner part of a corresponding distinguishing spectral density, may be used to generate data for the following optimization problem, from a numerical point of view it is desirable to obtain data of reasonably low McMillan degree. Further investigation is needed, however, in order to find H_k and V_{kb} meeting such degree constraints.

Appendix A. Let K be a rational inner matrix in $\mathcal{H}^\infty_{m\times m}$. We wish to obtain a basis for the finite-dimensional space $\mathcal{H}^2_m \ominus K\mathcal{H}^2_m$. An easily computable basis is described in [7]. For completeness we include the construction.

Write $K = PQ^{-1}$, where P and Q are coprime polynomial matrices. Then $h \in \mathcal{H}^2_m$ implies $Q^{-1}h \in \mathcal{H}^2_m$, which in turn gives $K\mathcal{H}^2_m \subseteq P\mathcal{H}^2_m$. Conversely, we have $P\mathcal{H}^2_m \subseteq K\mathcal{H}^2_m$. Thus, $\mathcal{H}^2_m \ominus K\mathcal{H}^2_m = \mathcal{H}^2_m \ominus P\mathcal{H}^2_m$. To find a basis for $\mathcal{H}^2_m \ominus P\mathcal{H}^2_m$, we will, without loss of generality, assume that P is column reduced. This can always be achieved by multiplying P (and Q) from the right by a suitable unimodular matrix. Since K is inner, this also holds for $\det(K)$. Thus, the zeros of $\det(K)$ must be in the open unit disk $\mathbb{D}$. This, in turn, implies that the zeros of $\det(P)$ are in $\mathbb{D}$, also. Let d_j be the highest power of z that occurs in the jth column of $P(z)$. Write

$$P(z) = (P_0 + P_1 z^{-1} + \cdots + P_q z^{-q})D(z) \tag{69}$$

where

$$D(z) = \operatorname{diag}(z^{d_1}, z^{d_2}, \ldots, z^{d_m}),$$

and $P_0, \ldots, P_q$ are constant $m \times m$ matrices with q the highest power of z in $P(z)$. Since P is column reduced, P_0 must be nonsingular. Define

$$\hat{P}(z) = P_0^* + P_1^* z + \cdots + P_q^* z^q.$$

Clearly $\hat{P} \in \mathcal{H}^\infty_{m\times m}$. To see also that $\hat{P}^{-1} \in H^\infty_{m\times m}$ we note, using (69), that

$$\det(\hat{P}(z)) = z^{d_1+d_2+\cdots+d_m}\det(P(z)^*) = z^{d_1+d_2+\cdots+d_m}\overline{\det(P(z))}.$$

This means that $\det(\hat{P}(z))$ cannot have any zero in the closed unit disk with a possible exception at $z = 0$. But owing to the column reduceness $\det(\hat{P}(0)) = \det(P_0^*) \neq 0$. Consequently, $\hat{P}^{-1} \in \mathcal{H}^\infty_{m\times m}$, as required. Moreover, $\hat{P}^{-1}$ determines a linear bijection on $\mathcal{H}^\infty_{m\times m}$. From (69) we also get

$$P(e^{i\theta}) = (P_o + P_1 e^{-i\theta} + \cdots + P_q e^{-iq\theta})Q(e^{-i\theta}) = \hat{P}(e^{i\theta})^* Q(e^{-i\theta}),$$

which implies that $f \in \mathcal{H}^2_m$ is perpendicular to $P\mathcal{H}^2_m$ if and only if $\hat{P}f$ is perpendicular to $Q\mathcal{H}^2_m$. Moreover, using the fact that $\hat{P}^{-1} \in H^\infty_{m\times m}$, this yields

$$\mathcal{H}^2_m \ominus P\mathcal{H}^2_m = \hat{P}^{-1}(\mathcal{H}^2_m \ominus D\mathcal{H}^2_m).$$

Since $\hat{P}^{-1}$ is a linear bijection on $\mathcal{H}^2_m$, any basis $\{b_1, b_2, \ldots\}$ of $\mathcal{H}^2_m \ominus D\mathcal{H}^2_m$ gives rise to a basis $\{\hat{P}^{-1}b_1, \hat{P}^{-1}b_2, \ldots\}$ of $\hat{P}^{-1}(\mathcal{H}^2_m \ominus D\mathcal{H}^2_m)$. However, $\mathcal{H}^2_m \ominus D\mathcal{H}^2_m$ consists of all polynomial vectors

$$v = (v^1, v^2, \ldots, v^m)^T,$$

where v^j is a polynomial of degree strictly less than d_j. A natural basis in $\mathcal{H}^2_m \ominus D\mathcal{H}^2_m$ is therefore given by the vectors

$$e_i^j(z) = (0, \ldots, 0, z^j, 0, \ldots, 0)^T, \quad i = 1, 2, \ldots, m, \quad j = 0, 1, \ldots, \deg d_i - 1,$$

where z^j occurs in the ith component. Consequently,

$$\{\hat{P}^{-1}e_i^j | i = 1, 2, \ldots, m, j = 0, 1, \ldots, \deg d_i\}$$

is a basis for $\mathcal{H}^2_m \ominus P\mathcal{H}^2_m$. In [7] this is called the *expedient basis*.

Appendix B. We show how to solve an equation of the type (39) occurring in computation of a distinguishing spectral density. We do this in the form of a lemma.

LEMMA 8. *Let A and B be rational matrices of dimensions $m \times k$ and $m \times p$, respectively, where A has full column rank. Suppose the equation*

$$Au - B\xi \tag{70}$$

has a nontrivial solution $u \in \mathcal{H}_k^2$, $(u \in \mathcal{L}_k^2), \xi \in \mathbb{C}^p$. Then there exists a complex matrix L of, say, dimensions $p \times r$, having full column rank, and a matrix $K \in \mathcal{RH}_{k\times r}^\infty, (K \in \mathcal{RL}_{k\times r}^\infty)$ such that $u \in \mathcal{RH}_k^2 (u \in \mathcal{RL}_k^2)$ and $\xi \in \mathbb{C}^p$ solves (70) *if and only if*

$$\begin{bmatrix} u \\ \xi \end{bmatrix} = \begin{bmatrix} K \\ L \end{bmatrix} \zeta \tag{71}$$

for some $\zeta \in \mathbb{C}^r$. Moreover, the linear mapping $\zeta \to (u^T, \xi^T)^T$ determined by (71) *is injective.*

Proof. Consider first the case where $u \in \mathcal{H}_k^2$. Apply, for instance, the Hermite form to the numerator of a polynomial right coprime factorization of A to write

$$A = U \begin{bmatrix} D \\ 0 \end{bmatrix}, \tag{72}$$

where U is a unimodular polynomial matrix, and D is a square rational matrix of, say, dimensions $k \times k$ having full rank. Let

$$U^{-1} = \begin{bmatrix} W_1 \\ W_2 \end{bmatrix},$$

where W_1 has k rows and W_2 has $m - k$ rows. With this, (70) takes the equivalent form

$$u = D^{-1} W_1 B\xi, \tag{73}$$

$$0 = W_2 B\xi. \tag{74}$$

We treat equation (73) first. Use polynomial coprime factorization to write $D^{-1}W_1B = \Gamma^{-1}\Delta$. Factorize $\det(\Gamma) = d_1 d_2$, where d_1 has all its roots in closed unit disk $\overline{\mathbb{D}}$ and d_2 has all its roots outside $\overline{\mathbb{D}}$. Then $\Gamma^{-1} = d_1^{-1} d_2^{-1} T$ for some polynomial matrix T. Clearly, a necessary and sufficient condition for $D^{-1}W_1B\xi \in \mathcal{H}_t^2$ is, therefore, that each component of the polynomial vector

$$T\Delta\xi = \det(\Gamma) D^{-1} W_1 B\xi,$$

cancels all the roots of d_1 (counting multiplicities). Let $M = \det(\Gamma) D^{-1} W_1 B$, and let $z_1, \ldots, z_r$ be the roots of d_1, with multiplicities $m_1, \ldots, m_r$, respectively. Thus, solving (73) is equivalent to finding a $\xi \in \mathbb{C}^p$ satisfying the following homogeneous system of linear equations:

$$M^{(j)}(z_i)\xi = 0, \qquad 1 \le i \le r,\ 0 \le j < m_i, \tag{75}$$

where $M^{(j)}$ means the jth derivative of M (with $M^{(0)} = M$).

To include the second equation (74) we take a left polynomial coprime factorization $F^{-1}N$ of W_2B, and let d be the highest degree of any element in the numerator N. Then

$$N(z) = N_0 + N_1 z + \cdots + N_d z^d,$$

where $N_k, 0 \leq k \leq d$ are ordinary complex matrices. Consequently, (74) holds if and only if

$$N_k \xi = 0, \qquad k = 0, 1, \ldots, d. \tag{76}$$

Thus the problem of solving the original equation (70) has been reduced to solving simultaneously the set of linear numerical equations in (75) and (76). If a solution ξ exists, then $u = D^{-1} W_1 B \xi$, together with ξ, constitutes a solution of the original equation.

Suppose the null space of the system of equations given by (75) and (76) has dimension k. Let L be a $p \times r$ complex matrix whose columns form a basis of this null space. Then ξ solves (75) and (76) if and only if

$$\xi = L\zeta$$

for some $\zeta \in \mathbb{C}^r$. Consequently, with $K = D^{-1} W_1 B L$, we find that u belongs to $\mathcal{H}_k^2$ and satisfies (70) for some $\xi \in \mathbb{C}^p$ if and only if

$$u = K\zeta \quad and \quad \xi = L\zeta$$

for some $\zeta \in \mathbb{C}^r$.

In the case where $u \in \mathcal{RL}_k^2$, the proof is completely analogous, except that we only need to solve (74) and then define u by (73). The last statement follows directly from the fact that L has full column rank. In fact, even the mapping $\zeta \to \xi$ is injective.

Acknowledgments. I would like to thank Professor Huibert Kwakernaak for many valuable discussions concerning this work. I am indebted to him for the idea of using the conditions of Lemma 6 to generate the matrices R and P reducing the dimension of the parameter. (An efficient MATLAB macro for computing them is available in [14].) I am also grateful to the referees for suggestions that improved the final version of the manuscript.

RATES OF CONVERGENCE FOR AN ADAPTIVE FILTERING ALGORITHM DRIVEN BY STATIONARY DEPENDENT DATA*

ANDREW HEUNIS†

Abstract. Eweda and Macchi [IEEE *Trans. Automat. Control*, 29 (1984), pp. 119–127] and Watanabe [IEEE *Trans. Inform. Theory*, 30 (1984), pp. 134–140] show that the sequence of random vectors generated by a stochastic gradient adaptive filtering algorithm converges almost surely and in L_p (for p an even integer) to the solution of the associated Wiener–Hopf equation when the driving data process is stationary and weakly dependent. Under strong (i.e., Rosenblatt or α) and ψ-mixing conditions, together with various moment bounds on the driving data process, an almost sure functional invariance principle is obtained that approximates the sample paths of the random process generated by the stochastic gradient algorithm with the sample paths of a particular Gauss–Markov process. Almost sure rates of convergence in the form of laws of the iterated logarithm follow from the functional invariance principle. As a byproduct a functional central limit theorem is also obtained for a sequence of processes derived by suitably scaling the sequence of iterations generated by the algorithm.

Key words. adaptive filtering, strong invariance principle, law of the iterated logarithm, Lyapunov equation, strong and ψ-mixing processes, almost sure rates of convergence

AMS subject classifications. 60F15, 60F17, 93E10

1. Introduction.

Assume that $\{X_j, j \geq 1\}$ and $\{a_j, j \geq 1\}$ are given jointly stationary random processes defined on a common probability space, X_j being R^N-valued and a_j being real-valued, realizations of which can be observed but whose statistics are unknown. A basic problem in adaptive filtering is to use the single realizations $\{X_j(\omega), j \geq 1\}$ and $\{a_j(\omega), j \geq 1\}$ to compute a vector h_* in R^N that minimizes the function

$$h \to E(\langle h, X_j \rangle - a_j)^2$$

(where $\langle x, y \rangle$ denotes the inner product of vectors x and y in R^N), or, equivalently, solves the Wiener–Hopf equation

$$(*) \qquad E(X_j X_j^T)h = E(a_j X_j),$$

where X_j is regarded as a column vector. Problems of this kind arise in many contexts such as linear classification, adaptive equalization, and ARMA modeling (see Eweda and Macchi [1, Exs. 1 and 2, p. 120], and Widrow and Stearns [2, Chap. 6]), and one of the main characteristics of such problems is that successive elements of the vector-valued process $\{X_j\}$ are usually strongly correlated.

One of the most successful and widely used algorithms for computing h_* on the basis of single realizations is a recursion of the form

$$(**) \qquad h_{j+1} = h_j + \mu_j(a_j - h_j^T X_j)X_j \qquad j \geq 1,$$

in which h_j is a column vector and $\{\mu_j\}$ is a sequence of nonrandom positive scalars satisfying the two conditions

$$\sum_{j=1}^{\infty} \mu_j = \infty \quad \text{and} \quad \sum_{j=1}^{\infty} \mu_j^2 < \infty.$$

In a very significant advance, Eweda and Macchi [1, §III] show that the sequence of random vector $\{h_j\}$ resulting from this algorithm converges almost surely to h_* when the

* Received by the editors July 30, 1991; accepted for publication (in revised form) September 29, 1992.
† Department of Electrical Engineering, University of Waterloo, Waterloo, Ontario N2L 3G1, Canada.

data process $\{(a_j, X_j^T)\}$ that "drives" the algorithm satisfies rather unrestrictive moment bounds, as well as a very general condition of decaying dependence between the random vectors (a_j, X_j^T) and (a_k, X_k^T), when the indices j and k are widely separated. In a related development, Watanabe [3, Thms. 1–4] proves 2 rth mean convergence of $\{h_j\}$ to h_* for all natural numbers r under moment bounds and mixing conditions that are significantly, but seemingly unavoidably, stronger than the conditions postulated in [1]. The remarkable aspect of these results is that both establish convergence without resorting to projection onto a compact neighbourhood of h_*, as is often necessary when using the established theory of stochastic algorithms (a comprehensive account of which can be found in Benveniste, Metivier, and Priouret [4]).

In probability theory we find a most celebrated result, namely, the strong invariance principle of Strassen [5, Thm. 2], which asserts that the running sum of a given sequence of independent and identically distributed zero-mean second-order random variables (of any underlying distribution) can be approximated *almost surely* by the sample paths of a suitable Brownian motion. This has many ramifications, because it allows us to use our very detailed understanding of the sample properties of Brownian motion to obtain a precise characterization of the asymptotic behaviour of the given sum of random variables. Motivated by the invariance principle of Strassen [5], our goal in this note is to obtain an almost surely approximation of the "difference" process $\{h_j - h_*\}$ by some "standard" process whose sample-path properties are well understood. We show that the difference process can in fact be approximated almost surely by a Gauss–Markov process, which is itself a linear function of a suitable Brownian motion. To illustrate the applicability of this result, we use it to prove a law of the iterated logarithm (which in turn implies a precise and unimprovable almost sure rate of convergence of h_j to h_*) and a functional central limit theorem for $\{h_j - h_*\}$. Our proof of the invariance principle relies intrinsically on (a slight variant of) the 2 rth mean convergence results of Watanabe [3] mentioned above, and hence we work under conditions on the driving data $\{(a_j, X_j^T)\}$ that are very similar to those postulated in [3].

In §2 we state the main result, which is a strong invariance principle (Proposition 2.1), as well as the consequent law of the iterated logarithm (Proposition 2.2) and functional central limit theorem (Proposition 2.3); we also give the regularity conditions that will always be assumed. In §3 these propositions are established. Section 4 is an appendix in which various subsidiary results, needed for the proofs in §3, are stated and proved (these results can be referenced at will once the reader is familiar with the basic regularity conditions and notation specified in §2). Section 5 is another appendix in which several useful results from probability theory, perhaps not well known to readers, have been gathered for convenience.

2. Main results. Let $\{a_j, j \geq 1\}$ and $\{X_j, j \geq 1\}$ be random processes, real and R^N-valued, respectively, that are defined on a common probability space $(\Omega, \mathbf{A}, P)$. We study the asymptotic properties of R^N-valued random vectors h_j generated by the stochastic gradient algorithm

$$h_{j+1} = h_j + \frac{\mu}{j}(a_j - h_j^T X_j)X_j, \qquad j \geq 1, \tag{1}$$

where h_1 is an arbitrary fixed nonrandom R^N-vector, μ is a positive constant, and X_j and h_j are column vectors. Certain regularity conditions will be needed for this problem, but before stating these we recall the notion of a strong mixing process: Suppose that $\{\xi_n, n \geq 1\}$ is a process assuming values in R^D, and for each integer $m \geq 1$ define

$$\alpha_\xi(m) \triangleq \sup |P(AB) - P(A)P(B)|,$$

where the supremum is taken over all $n \geq 1$, all $A \in \sigma\{\xi_j, 1 \leq j \leq n\}$, and all $B \in \sigma\{\xi_j, j \geq n+m\}$. Then $\{\xi_n\}$ is *strong mixing* when $\alpha_\xi(m) \to 0$ as $m \to \infty$.

Returning to the regularity conditions, it will henceforth be assumed that the following hold:

(A) The R^{N+1}-valued process $\{(a_j, X_j^T), j \geq 1\}$ is strong mixing with $\alpha_{(a,X)}(m) = O(m^{-\beta})$ for some $\beta > 3$, and strictly stationary (i.e., the finite-dimensional distribution functions of $\{(a_j, X_j^T)\}$ are invariant under translation through the positive integers);

(B) The symmetric matrix $R \stackrel{\Delta}{=} E(X_j X_j^T)$ is positive definite and the constant μ in (1) is sufficiently large to ensure that $(2\mu R - I)$ is positive definite;

(C) There are positive constants C and ε such that $E|X_j|^{4k} = O(C^k k!)$ and $E|a_j|^{37+\varepsilon} < \infty$ for all integers $j, k \geq 1$.

Define $h_* \stackrel{\Delta}{=} R^{-1}E(a_j X_j)$ (the unique solution of the Wiener–Hopf equation (*)) and let $z_j \stackrel{\Delta}{=} a_j X_j - X_j X_j^T h_*$. Clearly, $\{z_j\}$ is strictly stationary and strong mixing with $\alpha_z(m) = O(m^{-\beta})$ for some $\beta > 3$, and it is easily seen from Holder's inequality and the moment bounds in (C) that z_j has finite third order moments. It then follows from Theorem 5.2(i) in §5 that the series in

$$\Gamma \stackrel{\Delta}{=} E(z_1 z_1^T) + \sum_{j=2}^{\infty} E(z_1 z_j^T) + \sum_{j=2}^{\infty} E(z_j z_1^T)$$

converge absolutely and, clearly, that Γ is symmetric positive semidefinite. The final regularity condition is:

(D) The matrix Γ is positive definite.

The moment conditions in (C) are essentially those required by Watanabe [3, Thm. 3] (restated as Theorem 5.4 in §5), which will play an essential role in later developments. These moment conditions can be substantially weakened if the sense in which $\{(a_j, X_j^T)\}$ is mixing is strengthened. Accordingly, we state alternatives to conditions (A) and (C), but first the notion of ψ-mixing is introduced: Suppose that $\{\xi_n, n \geq 1\}$ is some R^D-valued process, and for each integer $m \geq 1$ define

$$\psi_\xi(m) \stackrel{\Delta}{=} \sup \frac{|P(AB) - P(A)P(B)|}{P(A)P(B)},$$

where the supremum is taken over all $n \geq 1$, all $A \in \sigma\{\xi_j, 1 \leq j \leq n\}$, and all $B \in \sigma\{\xi_j, j \geq n+m\}$. Then $\{\xi_n\}$ is *ψ-mixing* when $\psi_\xi(m) \to 0$ as $m \to \infty$. Note that it is possible to have $\psi_\xi(m) = +\infty$ for a given m. ψ-mixing is obviously a much more restrictive mixing condition than strong mixing. Indeed, a Gaussian ψ-mixing process is always s-dependent for some finite integer s, thus in general a Gaussian ARMA process driven by white noise cannot be ψ-mixing (the more general ϕ-mixing condition, often used to model dependent signals in adaptive filtering, is equivalent to ψ-mixing in the Gaussian case and is thus similarly restrictive in this respect (see Bradley [6, Thm. 5.1]). Nevertheless, there are several interesting examples of (non-Gaussian) ψ-mixing processes, for which we refer the reader to Bradley [6]. ψ-mixing has been used to model dependence in the driving data in several analyses of stochastic gradient algorithms quite similar to (1) (see, e.g., Bitmead [7]). The alternatives to conditions (A) and (C) are as follows:

(A*) The R^{N+1}-valued process $\{(a_j, X_j^T), j \geq 1\}$ is ψ-mixing and strictly stationary. Moreover, there is some integer M and constants $K > 0, \beta > 3$ such that $\psi_{(a,X)}(m) \leq K\, m^{-\beta}$ for all $m \geq M$ (it is possible that $\psi_{(a,X)}(m) = \infty$ when $1 \leq m < M$);

(C*) For all $j \geq 1$ we have $E|X_j|^{96M} < \infty$ and $E|a_j|^{(24+24/(4M-1))} < \infty$, where M is the constant in condition (A*). Note the trade-off between moment bounds and mixing

rates that occurs here: large M implies slower ψ-mixing, and this in turn requires more restrictive moment bounds on X_j.

The main result of this note is the following invariance principle.

PROPOSITION 2.1. (i) *Assume conditions* (A), (B), *and* (C). *Then there exists a probability space* $(\tilde{\Omega}, \tilde{\mathbf{A}}, \tilde{P})$ *on which is defined a real-valued process* $\{\tilde{a}_j, j \geq 1\}$, *and* R^N*-valued processes* $\{\tilde{X}_j, j \geq 1\}$, *and* $\{\tilde{W}(t), t \geq 0\}$ *such that*

(a) $\{(\tilde{a}_j, \tilde{X}_j^T), j \geq 1\} \stackrel{D}{=} \{(a_j, X_j^T), j \geq 1\}$, *where* $\stackrel{D}{=}$ *indicates that the left- and right-hand processes have identical finite-dimensional joint distributions*;

(b) $\{\tilde{W}(t), t \geq 0\}$ *is a Brownian motion with covariance matrix* $\mu^2\Gamma$;

(c) *There exists some constant where* $\gamma, 1/2 > \gamma > 0$, *such that, for almost all* $\tilde{\omega}[\tilde{P}]$,

$$t^{1/2}(\tilde{h}_{[t]+1}(\tilde{\omega}) - h_*) = t^{-1/2}\tilde{Y}(t, \tilde{\omega}) + O(t^{-\gamma}) \quad \text{for all } t > 0, \tag{2}$$

where $[a]$ *denotes the integer part of a real number* $a > 0$, *the* $\tilde{h}_j$ *are defined by*

$$\tilde{h}_1 \stackrel{\Delta}{=} h_1 \quad \text{and} \quad \tilde{h}_{j+1} = \tilde{h}_j + \frac{\mu}{j}(\tilde{a}_j - \tilde{h}_j^T \tilde{X}_j)\tilde{X}_j, \qquad j \geq 1, \tag{3}$$

and $\tilde{Y}(t)$ *is a process defined on* $(\tilde{\Omega}, \tilde{\mathbf{A}}, \tilde{P})$ *by*

$$\tilde{Y}(t) \stackrel{\Delta}{=} \tilde{W}(t) - (\mu R - I)\int_0^1 \tau^{(\mu R - 2I)}\tilde{W}(\tau t)d\tau, \qquad t > 0. \tag{4}$$

(ii) *Assume conditions* (A*), (B), *and* (C*). *Then all assertions in* (i) *continue to hold.*

Remark 2.1. The constant implicit in the notation $O(t^{-\gamma})$ used in (2) will, of course, depend on $\tilde{w}$. It is easily seen that the process $\tilde{Y}(t)$ in (4) is also the Gauss–Markov process that solves the following linear SDE:

$$d\tilde{Y}(t) = (I - \mu R)t^{-1}\tilde{Y}(t)dt + d\tilde{W}(t) \quad \text{subject to } \tilde{Y}(0) = 0.$$

Remark 2.2. One can consider the algorithm in (1) to be "driven" by a data process $\{(a_j, X_j^T)\}$ that is defined on $(\Omega, \mathbf{A}, P)$ and to be "generating" $\{h_j\}$ on the same probability space in accordance with (1). Proposition 2.1 introduces, in place of $\{(a_j, X_j^T)\}$, a surrogate process $\{(\tilde{a}_j, \tilde{X}_j^T)\}$ of identical distribution but defined on a different probability space $(\tilde{\Omega}, \tilde{\mathbf{A}}, \tilde{P})$ along with a Brownian motion $\{\tilde{W}(t), t \geq 0\}$ such that (2) holds. In general it is *not* possible to assert the existence of a Brownian motion $\{W(t), t \geq 0\}$ on the original space $(\Omega, \mathbf{A}, P)$ such that for some constant $\gamma > 0$ and almost all $\omega[P]$, we have

$$t^{1/2}(h_{[t]+1}(\omega) - h_*) = t^{-1/2}(W(t) - (\mu R - I)\int_0^1 \tau^{(\mu R - 2I)}W(\tau t)d\tau) + O(t^{-\gamma}),$$

because $(\Omega, \mathbf{A})$ may not even have enough "measure-theoretic" structure to carry a Brownian motion. It is therefore necessary, when establishing Proposition 2.1, to construct an "enriched" space $(\tilde{\Omega}, \tilde{\mathbf{A}}, \tilde{P})$ supporting a Brownian motion as well as a driving data process $\{(\tilde{a}_j, \tilde{X}_j^T)\}$ that is identical in distribution to $\{(a_j, X_j^T)\}$, and then to show that (2) holds. In view of (1), (3), and Proposition 2.1(a), it follows that $\{(a_j, X_j^T, h_j^T), j \geq 1\} \stackrel{D}{=} \{(\tilde{a}_j, \tilde{X}_j^T, \tilde{h}_j^T), j \geq 1\}$, and since the physical manifestation of the stochastic gradient algorithm is solely a consequence of the joint distribution of the "input-output" process $\{(a_j, X_j^T, h_j^T), j \geq 1\}$, there is no loss of generality in switching to the enriched probability space $(\tilde{\Omega}, \tilde{\mathbf{A}}, \tilde{P})$ and regarding the algorithm as being implemented by (3) instead. It

should be noted that strong approximation ideas are also considered, from a significantly different point of view, in Gerencser [8].

For the law of the iterated logarithm that follows from Proposition 2.1 we need the following notation due to Kuelbs [9]: If $\{x_j, j \geq 1\}$ is a sequence in a metric space $(\mathbf{X}, \rho)$, then $C(\{x_j\})$ denotes the set of *all* accumulation points (if any) of the sequence, and, if K is a compact subset of $(\mathbf{X}, \rho)$ and $\rho(x, K) \triangleq \inf\{\rho(x, y); y \in K\}$ is the distance from a point x to K, then $\{x_j, j \geq 1\} \to\to K$ indicates (i) that $\rho(x_j, K) \to 0$ as $j \to \infty$, and (ii) that $C(\{x_j\}) = K$. Let J denote a *fixed* integer such that $\log\log(j) \geq 1$ for all $j \geq J$.

PROPOSITION 2.2 (law of the iterated logarithm). (i) *Assume conditions* (A)–(D). *Then for almost all* $\omega[P]$,

$$\left\{ \frac{j^{1/2}(h_j(\omega) - h_*)}{(2\log\log(j))^{1/2}}, j \geq J \right\} \to\to K, \tag{5}$$

where $K \triangleq \{x \in R^N | \langle x, M^{-1}x\rangle \leq \mu^2\}$, *and* M *is the unique positive definite solution of the Lyapunov equation* $(2\mu R - I)M + M(2\mu R - I) = 2\Gamma$.

(ii) *Assume conditions* (A*), (B), (C*), *and* (D). *Then* (5) *holds for almost all* $\omega[P]$.

Proposition 2.2 immediately implies the following almost sure rate of convergence of $\{h_j\}$ to h_*:

$$|h_j(\omega) - h_*| = O\left(\left(\frac{\log\log(j)}{j}\right)^{1/2}\right).$$

Observe that this rate of convergence cannot be improved. Indeed, if there is a better rate for some ω, then there exists a sequence of real numbers $\{\psi_j(\omega)\}$ such that

$$|h_j(\omega) - h_*| = O(\psi_j(\omega)) \quad \text{where } \psi_j(\omega) = o\left(\left(\frac{\log\log(j)}{j}\right)^{1/2}\right).$$

However, this implies that $\lim_{j\to\infty}(j^{1/2}(h_j(\omega) - h_*))/(2\log\log(j))^{1/2}) = 0$ which, in view of (5), can take place on a set of P-measure zero only.

PROPOSITION 2.3 (functional central limit theorem). *Assume either conditions* (A), (B), (C), *or conditions* (A*), (B), (C*). *Then the sequence* $\{\xi_n(t), 0 \leq t \leq 1\}$ *of processes defined by*

$$\xi_n(t) \triangleq tn^{1/2}(h_{[nt]+1} - h_*)$$

for all $0 \leq t \leq 1$ *and integers* $n \geq 1$ *converges weakly to the process* $\{\tilde{Y}(t), 0 \leq t \leq 1\}$, *defined by* (4) *as* $n \to \infty$.

3. Proofs of propositions 2.1–2.3. We establish Proposition 2.1 by making use of the following fairly special consequence of Berger [10, Cor. 2.24, p. 541] (which is itself a significant extension of similar approximation theorems obtained in a one-dimensional setting by Ruppert [11] and in the important dissertation of Mark [12]).

THEOREM 3.1. *Assume that a sequence* $\{\nu_j, j \geq 1\}$ *of* R^N*-vectors is generated from a given sequence of* R^N*-vectors* $\{w_j, j \geq 1\}$ *by the recursion*

$$\nu_{j+1} = (I - j^{-1}\Lambda)\nu_j + j^{-1}w_j, \qquad j \geq 1, \tag{6}$$

where Λ is a symmetric N by N matrix such that $(2\Lambda - I)$ is positive definite. If $\{w_j\}$ is a random sequence defined on a probability space $(\Xi, \boldsymbol{F}, Q)$ along with an R^N-Brownian motion $\{B(t), t \geq 0\}$ such that, for some constant $\eta > 0$,

$$B(t) - \sum_{1 \leq j \leq t} w_j = O(t^{1/2-\eta}) \quad \textit{for all } t \geq 1, \textit{ a.s. } [Q], \tag{7}$$

then there exists a constant γ, where $\frac{1}{2} > \gamma > 0$, such that almost surely [Q],

$$[t]\nu_{[t]+1} - \left(B(t) - (\Lambda - I)\int_0^1 \tau^{(\Lambda - 2I)} B(\tau t)\, d\tau\right) = O(t^{1/2-\gamma}) \quad \textit{for all } t > 0. \tag{8}$$

Note the similarity between the approximating processes in (8) and (4). In using this theorem, one is usually given the sequence $\{w_j\}$ and the main task is to show existence of some $B(t)$ for which (7) holds. We see that the main technical difficulty in carrying out this step arises from the fact that w_j depends on ν_j in our application (see (9) and (10)).

Proof of Proposition 2.1(i). Define

$$\nu_j \triangleq h_j - h_*, z_j \triangleq a_j X_j - X_j X_j^T h_* \quad \text{and} \quad w_j \triangleq \mu z_j - \mu(X_j X_j^T - R)\nu_j \tag{9}$$

for $j \geq 1$. Then $E(z_j) = 0$ and, from (1) and (9),

$$\nu_1 \triangleq h_1 - h_* \quad \text{and} \quad \nu_{j+1} = (I - j^{-1}\mu R)\nu_j + j^{-1} w_j \quad \text{for } j \geq 1. \tag{10}$$

According to Lemma 4.1(i), there exists a probability space $(\tilde{\Omega}, \tilde{\mathbf{A}}, \tilde{P})$ carrying real and R^N-valued processes $\{\tilde{a}_j, j \geq 1\}$ and $\{\tilde{X}_j, j \geq 1\}$, respectively, along with an R^N-valued Brownian motion $\{\tilde{W}(t), t \geq 0\}$ with covariance matrix $\mu^2\Gamma$, such that:

$$\{(\tilde{a}_j, \tilde{X}_j^T), j \geq 1\} \stackrel{D}{=} \{(a_j, X_j^T), j \geq 1\}, \tag{11}$$

and

$$\sum_{1 \leq j \leq t} \mu \tilde{z}_j - \tilde{W}(t) = O(t^{1/2-\eta}) \quad \text{for all } t \geq 1, \quad \text{a.s. } [\tilde{P}], \tag{12}$$

for some constant $\eta > 0$, where

$$\tilde{z}_j \triangleq \tilde{a}_j \tilde{X}_j - \tilde{X}_j \tilde{X}_j^T h_*. \tag{13}$$

Define $\{\tilde{\nu}_j, j \geq 1\}$ and $\{\tilde{w}_j, j \geq 1\}$ by the following recursions:

$$\tilde{\nu}_1 \triangleq \nu_1 \quad \text{and} \quad \tilde{\nu}_{j+1} = (I - j^{-1}\mu R)\tilde{\nu}_j + j^{-1}\tilde{w}_j \quad \text{for } j \geq 1, \tag{14}$$

$$\tilde{w}_j \triangleq \mu \tilde{z}_j - \mu(\tilde{X}_j \tilde{X}_j^T - R)\tilde{\nu}_j. \tag{15}$$

From (10), (11), and (14) it follows that $\{(a_j, X_j^T, \nu_j^T), j \geq 1\} \stackrel{D}{=} \{(\tilde{a}_j, \tilde{X}_j^T, \tilde{\nu}_j^T), j \geq 1\}$, and by (12), (15), and Lemma 4.2, there is some constant $\eta > 0$ such that

$$\sum_{1 \leq j \leq t} \tilde{w}_j - \tilde{W}(t) = O(t^{1/2-\eta}) \quad \text{for all } t \geq 1, \quad \text{a.s. } [\tilde{P}]. \tag{16}$$

By (14), (16), and Theorem 3.1, there exists some constant $1/2 > \gamma > 0$ such that

$$t^{1/2}\tilde{\nu}_{[t]+1} = t^{-1/2}\tilde{Y}(t) + O(t^{-\gamma}) \quad \text{for all } t > 0, \quad \text{a.s. } [P], \tag{17}$$

where $\tilde{Y}(t)$ is given by (4). Let $\tilde{h}_j \stackrel{\Delta}{=} \tilde{\nu}_j + h_*$ for $j \geq 1$. From (13), (14), and (15), it is seen that the process $\{\tilde{h}_j, j \geq 1\}$ is generated by the recursion in (3), and by (17) it also satisfies the invariance principle (2), as required. □

Proof of Proposition 2.1(ii). This is identical to the proof of Proposition 2.1(i) except that Lemma 4.1(ii) is used in place of Lemma 4.1(i), and Lemma 4.3 is used instead of Lemma 4.2. □

Before establishing Proposition 2.2 let us introduce the following notation: $C_0^N[0,1]$ denotes the set of continuous functions $\phi : [0,1] \to R^N$ such that $\phi(0) = 0$, with the usual metric of uniform convergence over the interval [0,1], and $L_2^N[0,1]$ denotes the set of functions $\phi : [0,1] \to R^N$ whose components are square integrable over [0,1]. Let S denote the space of absolutely continuous functions in $C_0^N[0,1]$ defined by

$$S \stackrel{\Delta}{=} \left\{ \phi(\cdot) \in C_0^N[0,1] | \dot{\phi}(\cdot) \in L_2^N[0,1], \int_0^1 \langle \dot{\phi}(\tau), \Gamma^{-1}\dot{\phi}(\tau) \rangle d\tau \leq \mu^2 \right\}. \tag{18}$$

Proof of Proposition 2.2. The proofs of parts (i) and (ii) are identical. By Proposition 2.1 there exists some probability space $(\tilde{\Omega}, \tilde{\mathbf{A}}, \tilde{P})$ carrying a Brownian motion $\tilde{W}(t)$ with covariance matrix $\mu^2\Gamma$, and processes $\{\tilde{a}_j\}, \{\tilde{X}_j\}$, and $\{\tilde{h}_j\}$ such that $\{(a_j, X_j^T, h_j^T), j \geq 1\} \stackrel{D}{=} \{(\tilde{a}_j, \tilde{X}_j^T, \tilde{h}_j^T), j \geq 1\}$. The process $\{\tilde{h}_j\}$ is generated by the recursion in (3), and, for some constant $\frac{1}{2} > \gamma > 0$,

$$j^{1/2}(\tilde{h}_{j+1} - h_*) = j^{-1/2}\tilde{Y}(j) + O(j^{-\gamma}) \quad \text{for all } j \geq 1, \quad \text{a.s. } [\tilde{P}], \tag{19}$$

where $\tilde{Y}(j)$ is defined by (4). Let Δ be the set of all functions ϕ in $C_0^N[0,1]$ such that each component of the R^N-valued function $t \to t^{(\mu R - 2I)}\phi(t)$ is integrable over $0 < t \leq 1$ (Δ will be a strict subset of $C_0^N[0,1]$ when $\mu R - 2I$ has one or more negative eigenvalues). Define the function $F : \Delta \to R^N$ by

$$F(\phi) \stackrel{\Delta}{=} \phi(1) - (\mu R - I) \int_0^1 \tau^{(\mu R - 2I)}\phi(\tau) d\tau. \tag{20}$$

By Lemma 4.4(a), $S \subset \Delta$ whence $F[S]$, the image of S under F, is well defined. Thus, by Lemma 4.5 along with (19),

$$\left\{ j^{1/2} \frac{(\tilde{h}_{j+1}(\tilde{\omega}) - h_*)}{(2\,\text{loglog}(j))^{1/2}}, j \geq J \right\} \to\to F[S] \tag{21}$$

for almost all $\tilde{\omega}[\tilde{P}]$. It remains to show that $F[S]$ is equal to the set K in the statement of Proposition 2.2. Define an inner product $[\cdot, \cdot]$ in $L_2^N[0,1]$ as follows:

$$[\eta_1, \eta_2] \stackrel{\Delta}{=} \int_0^1 \langle \eta_1(\tau), \Gamma^{-1}\eta_2(\tau) \rangle d\tau \tag{22}$$

for $\eta_1, \eta_2 \in L_2^N[0,1]$. Define linear subspaces V_1 and V_2 by

$$V_1 \triangleq \{\psi(\cdot) \in L_2^N[0,1] | \psi(t) \triangleq \Gamma t^{(\mu R - I)} Dx \text{ for some } x \in R^N\}, \tag{23a}$$

$$V_2 \triangleq \{\eta(\cdot) \in L_2^N[0,1] | [\eta, \psi] = 0 \text{ for all } \psi \in V_1\}, \tag{23b}$$

where condition (B) in §2 ensures square integrability of the functions $\psi(\cdot)$ in V_1, and D denotes a non-singular $N \times N$ matrix such that $D^T D = (2\mu R - I)$. Clearly, $L_2^N[0,1]$ is a Hilbert space when the inner product is defined by (22), and this inner product will henceforth always be assumed. Let

$$\psi(t) \triangleq \Gamma t^{\mu R - I)} Dx, \tag{24}$$

where $x \in R^N$, be a typical element in V_1. Then we see that

$$[\psi, \psi] = \langle Dx, MDx \rangle, \tag{25}$$

where

$$M \triangleq \int_0^1 \tau^{(\mu R - I)} \Gamma \tau^{(\mu R - I)} d\tau, \tag{26}$$

which is clearly positive definite. In view of (25), V_1 is complete and therefore closed in the norm generated by the inner product in (22). Furthermore, because V_2 is the orthogonal complement of V_1 (in $L_2^N[0,1]$), from the projection theorem in Hilbert space it follows that each element in $L_2^N[0,1]$ can be uniquely expressed as the sum of a vector in V_1 and a vector in V_2:

$$L_2^N[0,1] = V_1 + V_2 \tag{27}$$

(see Friedman [13, p. 209]). Using the integration by parts justified by Lemma 4.4(b), the function F in (20) can be written as

$$F(\phi) = \int_0^1 \tau^{(\mu R - I)} \dot{\phi}(\tau) d\tau \tag{28}$$

for all $\phi \in S$, and because (by (22), the nonsingularity of Γ and D, and the definition of V_2)

$$\int_0^1 \tau^{(\mu R - I)} \eta(\tau) d\tau = 0 \tag{29}$$

for all $\eta \in V_2$, it follows from (18) and (27)–(29) that

$$F[S] = \left\{ \int_0^1 \tau^{(\mu R - I)} \psi(\tau) d\tau | \psi(\cdot) \in V_1, [\psi, \psi] \leq \mu^2 \right\}. \tag{30}$$

For $\psi(\cdot) \in V_1$ defined by (24), clearly

$$\int_0^1 \tau^{(\mu R - I)} \psi(\tau) d\tau = MDx, \tag{31}$$

where M is given by (26), and therefore (25), (30), and (31) imply that

$$F[S] = \{x \in R^N | \langle x, M^{-1}x\rangle \leq \mu^2\}. \tag{32}$$

Finally, substituting $\sigma = -\log\tau$ into (26) gives

$$M = \int_0^\infty e^{-\sigma(\mu R - I/2)}\Gamma e^{-\sigma(\mu R - I/2)}d\sigma, \tag{33}$$

whence M is the positive-definite and unique solution of the Lyapunov equation in Proposition 2.2 (see, e.g., Vidyasagar [14, Thm. 55 and (56), p. 175]). Proposition 2.2 follows from (21), (32), and the equality in distribution of $\{h_j, j \geq 1\}$ and $\{\tilde{h}_j, j \geq 1\}$. □

We now establish Proposition 2.3, the functional central limit theorem. It is in fact a very easy corollary of Proposition 2.1.

Proof of Proposition 2.3. Replacing t in (2) and (4) with nt, where $0 < t \leq 1$ and $n \geq 1$ is an integer, we see that for almost all $\tilde{\omega}[\tilde{P}]$,

$$\begin{aligned} &n^{1/2}t^{1/2}(\tilde{h}_{[nt]+1}(\tilde{\omega}) - h_*) \\ &= n^{-1/2}t^{-1/2}\left[\tilde{W}(nt,\tilde{\omega}) - (\mu R - I)\int_0^1 \tau^{(\mu R - 2I)}\tilde{W}(nt\tau,\tilde{\omega})d\tau\right] + t^{-\gamma}O(n^{-\gamma}) \end{aligned} \tag{34}$$

for $0 < t \leq 1$ and $n \geq 1$. Now define $\tilde{W}_n(t) \triangleq n^{-1/2}\tilde{W}(nt)$ and

$$\tilde{Y}_n(t) \triangleq \tilde{W}_n(t) - (\mu R - I)\int_0^1 \tau^{(\mu R - 2I)}\tilde{W}_n(\tau t)d\tau \tag{35}$$

for $0 < t \leq 1$ and $n \geq 1$. Multiplying each side of (34) by $t^{1/2}$ and using the fact that we can choose γ in (34) such that $0 < \gamma < \frac{1}{2}$, for almost all $\tilde{\omega}[\tilde{P}]$ it follows that

$$\tilde{\xi}_n(t,\tilde{\omega}) = \tilde{Y}_n(t,\tilde{\omega}) + O(n^{-\gamma}) \tag{36}$$

for $0 \leq t \leq 1$, and $n \geq 1$, where $\tilde{\xi}_n(t) \triangleq tn^{1/2}(\tilde{h}_{[nt]+1} - h_*)$, and the constant of proportionality implied by $O(n^{-\gamma})$ does not depend on t. Since the Brownian motions $\tilde{W}(\cdot)$ and $\tilde{W}_n(\cdot)$ have identical distributions, so also do the processes $\tilde{Y}(t)$ and $\tilde{Y}_n(t), 0 \leq t \leq 1$, defined in (4) and (35), respectively. Moreover, in view of (36),

$$\lim_{n\to\infty} \rho(\tilde{\xi}_n(\cdot,\tilde{\omega}), \tilde{Y}_n(\cdot,\tilde{\omega})) = 0 \tag{37}$$

for almost all $\tilde{\omega}[\tilde{P}]$, where $\rho(\cdot,\cdot)$ denotes the Skorohod metric in $D[0,1;R^N]$. Thus, by [15, Thm. 4.1, p. 25] of Billingsley, the sequence $\{\tilde{\xi}_n(t), 0 \leq t \leq 1\}$ converges weakly to $\{\tilde{Y}(t), 0 \leq t \leq 1\}$. □

4. Appendix I. Various technical results needed for the proofs in §3 are established in this appendix. Lemma 4.1 is used in the proof of Proposition 2.1 (see (11) and (12)).

LEMMA 4.1. (i) *Assume conditions* (A), (B), *and* (C). *Then there exists a probability space* $(\tilde{\Omega}, \tilde{\mathbf{A}}, \tilde{P})$ *carrying real and* R^N*-valued processes* $\{\tilde{a}_j, j \geq 1\}$ *and* $\{\tilde{X}_j, j \geq 1\}$, *respectively, along with an* R^N*-valued Brownian motion* $\{\tilde{W}(t), t \geq 0\}$, *whose covariance matrix is* $\mu^2\Gamma$, *such that*

(a) $$\{(\tilde{a}_j, \tilde{X}_j^T), j \geq 1\} \stackrel{D}{=} \{(a_j, X_j^T), j \geq 1\}.$$

Furthermore, there exists a constant $\eta > 0$ *such that*

(b) $$\sum_{1 \le j \le t} \mu(\tilde{a}_j \tilde{X}_j - \tilde{X}_j \tilde{X}_j^T h_*) = \tilde{W}(t) + O(t^{1/2-\eta}) \quad \textit{for all } t \ge 1, \quad \textit{a.s. } [\tilde{P}].$$

(ii) *Assume conditions* (A*), (B), *and* (C*). *Then the assertions in* (i) *hold.*

Proof. (i) Define the R^{2N+1}-valued process $\{\xi_n, n \ge 1\}$ by

(38) $$\xi_n^T \triangleq (a_n - E(a_n), X_n^T - E(X_n^T), (a_n X_n - X_n X_n^T h_*)^T).$$

By condition (A), this is a zero-mean process that is strong mixing with $\alpha_{\xi_n}(m) = O(n^{-\beta})$ for some $\beta > 3$. Moreover, the moment bounds in condition (C) are ample to ensure that the ξ_n have third order moments. By Theorem 5.2 the matrix

$$T \triangleq E(\xi_1 \xi_1^T) + \sum_{j=2}^{\infty} E(\xi_1 \xi_j^T) + \sum_{j=2}^{\infty} E(\xi_j \xi_1^T)$$

exists, and there is some probability space $(\tilde{\Omega}, \tilde{\mathbf{A}}, \tilde{P})$ carrying an R^{2N+1}-valued process $\{\tilde{\xi}_n, n \ge 1\}$ along with an R^{2N+1}-valued Brownian motion $\{\tilde{B}(t), t \ge 0\}$ whose covariance matrix is T, such that for some number $\eta > 0$

(39) $$\{\xi_n, n \ge 1\} \stackrel{D}{=} \{\tilde{\xi}_n, n \ge 1\}$$

and

(40) $$\sum_{1 \le n \le t} \tilde{\xi}_n = \tilde{B}(t) + O(t^{1/2-\eta}), \qquad t \ge 1, \quad \text{a.s. } [\tilde{P}].$$

Now partition the vector $\tilde{\xi}_n$ as follows:

(41) $$\tilde{\xi}_n^T \triangleq (\tilde{a}_n - E(a_n), \tilde{X}_n^T - E(X_n^T), \tilde{\zeta}_n^T),$$

where $\{\tilde{a}_n\}$ is a real-valued process and $\{\tilde{X}_n\}, \{\tilde{\zeta}_n\}$ are R^N-valued processes, all defined on $(\tilde{\Omega}, \tilde{\mathbf{A}}, \tilde{P})$. It is clear from (38)–(40) that

(42) $$\{(a_n, X_n^T), n \ge 1\} \stackrel{D}{=} \{(\tilde{a}_n, \tilde{X}_n^T), n \ge 1\}$$

and

(43) $$\tilde{\zeta}_n = \tilde{a}_n \tilde{X}_n - \tilde{X}_n \tilde{X}_n^T h_* \quad \text{a.s. } [\tilde{P}].$$

Now condition (D) implies that the lower $N \times N$ submatrix of T is Γ while the process $\{\tilde{V}(t), t \ge 1\}$ is an R^N-valued Brownian motion with covariance matrix Γ when $\tilde{V}(t)$ is the vector that consists of the last N elements of $\tilde{B}(t)$. From (40), (41), and (43) we see that

$$\sum_{1 \le n \le t} (\tilde{a}_n \tilde{X}_n - \tilde{X}_n \tilde{X}_n^T h_*) = \tilde{V}(t) + O(t^{1/2-\eta}) \quad \text{for all } t \ge 1.$$

The lemma follows upon defining $\tilde{W}(t) \triangleq \mu \tilde{V}(t)$.

(ii) Condition (A*) implies (A), and clearly (C*) ensures that ξ_n in (38) has third order moments. The proof goes through as in (i) with no changes. □

Lemma 4.2 is used in the proof of Proposition 2.1 (see (16)).

LEMMA 4.2. *Assume conditions* (A), (B), *and* (C). *Then there exists some constant* $\eta > 0$ *such that, almost surely* $[P]$,

$$\sum_{1\le j\le t}(X_jX_j^T - R)\nu_j = O(t^{1/2-\eta}) \quad \textit{for all } t \ge 1, \tag{45}$$

where $\nu_j \triangleq h_j - h_*$.

Proof. Fix $0 < b < 1$ and define $s(j) \triangleq [j^b], U_j \triangleq X_jX_j^T$, and $\mu_j \triangleq \mu/j$ for integers $j \ge 1$. From (1) and (9),

$$\nu_j = \nu_{j-s(j)} + \eta_j\nu_{j-s(j)} + \xi_j \quad \text{for } j \ge 2, \tag{46}$$

where

$$\eta_j \triangleq \left\{\prod_{i=1}^{s(j)}(I - \mu_{j-i}U_{j-i})\right\} - I, \tag{47}$$

$$\xi_j \triangleq \sum_{k=1}^{s(j)}\left\{\prod_{i=1}^{k-1}(I - \mu_{j-i}U_{j-i})\right\}\mu_{j-k}z_{j-k}. \tag{48}$$

(The matrix products in (47) and (48) are from left to right with increasing i.) The proof is given in three steps.

Step I. We show that there are constants $0 < b < \frac{1}{2}$ and $\eta > 0$ such that almost surely $[P]$,

$$\sum_{1\le j\le t}(U_j - R)\nu_{j-s(j)} = O(t^{1/2-\eta}), \tag{49}$$

where, for convenience, $\nu_0 \triangleq 0$. Without loss of generality, suppose $N = 1$, since the argument used in this step generalises trivially to the vector-valued case. Fix any $\eta > 0$ and define

$$u_j \triangleq j^{-(1/2-\eta)}(U_j - R)\nu_{j-s(j)} \quad \text{for all } j \ge 1. \tag{50}$$

It remains to show that

$$\sum_{j=1}^{\infty} u_j < \infty \quad \text{a.s. } [P], \tag{51}$$

for then (49) follows by the Kronecker lemma. Clearly,

$$E\left[\sum_{j=a+1}^{a+n} u_j\right]^2 = E\left[\sum_{j=a+1}^{a+n} u_j^2\right] + 2E\left[\sum_{\substack{i,j=a+1\\ a+1\le i\le j-s(j)}}^{a+n} u_iu_j\right] + 2E\left[\sum_{\substack{i,j=a+1\\ j-s(j)<i<j}}^{a+n} u_iu_j\right]. \tag{52}$$

Each of the terms on the right of (52) is now bounded. By (50) and Cauchy–Schwarz,

$$E(u_j^2) \le j^{-(1-2\eta)}\|(U_j - R)^2\|_2\|\nu_{j-s(j)}^2\|_2. \tag{53}$$

Now, clearly, $\sup_j \|(U_j - R)^2\|_2 \leq K_1 < \infty$, and taking $r = 2$ in Theorem 5.4 gives

$$E|\nu_{j-s(j)}|^4 \leq K_2(j - s(j))^{-1} \qquad j \geq 2, \tag{54}$$

for some constant K_2. Moreover, obviously there is a constant K_3 such that $(j-s(j))^{-1} \leq K_3 j^{-1}$ for each $j \geq 2$. Hence, by (53) and (54) there is a constant K_4, where

$$E\left[\sum_{j=a+1}^{a+n} u_j^2\right] \leq K_4 \left[\sum_{j=a+1}^{a+n} j^{-(3/2-2\eta)}\right] \tag{55}$$

for all integers $a \geq 0, n \geq 1$. Next we bound the second term on the right of (52). Because $a + 1 \leq i \leq j - s(j)$, the function $(U_i - R)\nu_{i-s(i)}\nu_{j-s(j)}$ is measurable with respect to $\sigma\{(a_k, X_k^T), k \leq j - s(j)\}$ and $(U_j - R)$ is clearly $\sigma\{(a_k X_k^T), k \geq j\}$-measurable. Writing $\alpha(m)$ for $\alpha_{(a,X)}(m)$ and using Theorem 5.1(i), below, along with $E(U_j - R) = 0$ and condition (A),

$$\begin{aligned} E(u_i u_j) &\leq 10(ij)^{-(1/2-\eta)}\alpha^{1/p}(s(j))\|U_j - R\|_q \|(U_i - R)\nu_{i-s(i)}\nu_{j-s(j)}\|_p \\ &\leq 10(ij)^{-(1/2-\eta)}\alpha^{1/p}(s(j))\|U_j - R\|_q \{\|U_i - R\|_{pq}\|\nu_{i-s(i)}\|_{p^2}\|\nu_{j-s(j)}\|_{p^2}\}, \end{aligned} \tag{56}$$

where $p \triangleq (4m + 1)/2m, q \triangleq (4m + 1)$, for any positive integer m, and the second line in (56) follows by Holder's inequality (the dependence of p and q on m will not be indicated). By condition (C) there is some constant $K_5(m)$, depending only on m, such that $\|U_j - R\|_q \|U_i - R\|_{pq} \leq K_5(m)$ for all $i, j \geq 1$. Also

$$|\nu_{j-s(j)}|^{p^2} \leq |\nu_{j-s(j)}|^4 + |\nu_{j-s(j)}|^8 \tag{57}$$

for all integers $m \geq 1, j \geq 2$, since $4 \leq p^2(m) \leq 8$ for all $m \geq 1$. Taking first $r = 2$, then $r = 4$ in Theorem 5.4 and using condition (B) shows that $\|\nu_{j-s(j)}\|_{p^2} \leq K_6 j^{-(1/p^2)}$. Defining $\gamma(m) \triangleq ((1/2) + (1/p^2(m)) - \eta)$, we then obtain from (56) that

$$\begin{aligned} E\left[\sum_{\substack{i,j=a+1 \\ a+1\leq i\leq j-s(j)}}^{a+n} u_i u_j\right] &\leq K_7(m) \sum_{j=a+2}^{a+n} \alpha^{1/p}(s(j)) j^{-\gamma} \sum_{i=a+1}^{j-s(j)} i^{-\gamma} \\ &\leq K_8(m) \sum_{j=a+2}^{a+n} \alpha^{1/p}(s(j)) j^{-\gamma} j^{1-\gamma} \\ &\leq K_9(m) \sum_{j=a+1}^{a+n} j^{(1-2\gamma-b\beta/p)}. \end{aligned} \tag{58}$$

Choose $0 < b < \frac{1}{2}$ such that $b\beta > 1$. Then, since $p(m) \to 2$ as $m \to \infty$, we can fix m large enough to obtain $(1 - 2\gamma - b\beta/p) = -\theta + 2\eta$ for some $\theta > 1$; thus

$$E\left[\sum_{\substack{i,j=a+1 \\ a+1\leq i\leq j-s(j)}}^{a+n} u_i u_j\right] \leq K_{10} \sum_{j=a+1}^{a+n} j^{-(\theta-2\eta)} \tag{59}$$

for all $a \geq 0, n \geq 1$, and a constant $\theta > 1$. Now we bound the third term on the right of (52). Since $j - s(j) < i < j$ and $E(U_j - R) = 0$, from Theorem 5.1(i) and an argument similar to that which gave (56),

$$\begin{aligned} E(u_i u_j) &\leq 10(ij)^{-(1/2-\eta)}\alpha^{1/p}(j - i))\|U_j - R\|_q \|(U_i - R)\nu_{i-s(i)}\nu_{j-s(j)}\|_p \\ &\leq K_{11}(m)\alpha^{1/p}(j - i) i^{-\gamma} j^{-\gamma} \leq K_{11}(m)\alpha^{1/p}(j - i) i^{-2\gamma}, \end{aligned} \tag{60}$$

where, as before, $p \triangleq (4m+1)/2m, q \triangleq (4m+1)$, and $\gamma \triangleq ((1/2)+(1/p^2)-\eta)$. For some positive integer m and with no loss of generality we can take $\gamma > 0$. Thus, from (60),

$$E\left[\sum_{\substack{i,j=a+1\\ j-s(j)<i<j}}^{a+n} u_i u_j\right] \leq K_{11}(m)\sum_{k=1}^{n-1}\sum_{i=a+1}^{a+n-k}\alpha^{1/p}(k) i^{-2\gamma}. \tag{61}$$

Choosing m large enough to ensure $(1/p)\beta > 1$ and $2\gamma = \psi - 2\eta$ for some $\psi > 1$ gives $\sum \alpha^{1/p}(k) < \infty$, and hence from (61),

$$E\left[\sum_{\substack{i,j=a+1\\ j-s(j)<i<j}}^{a+n} u_i u_j\right] \leq K_{12}\sum_{j=a+1}^{a+n} j^{-(\psi-2\eta)} \tag{62}$$

for some constant $\psi > 1$ and all $a \geq 0$ and $n \geq 1$. Putting (52), (55), (59), and (62) together shows that for some constant $\zeta > 1$,

$$E\left[\sum_{j=a+1}^{a+n} u_j\right]^2 \leq K\sum_{j=a+1}^{a+n} j^{-(\zeta-2\eta)} \tag{63}$$

for all $a \geq 0, n \geq 1$. Now choose $\eta > 0$ such that

$$\sum_{j=1}^{\infty} \log^2(j) j^{-(\zeta-2\eta)} < \infty, \tag{64}$$

and, for integers $a \geq 0, n \geq 1$, define

$$g(a,n) \triangleq K\sum_{j=a+1}^{a+n} j^{-(\zeta-2\eta)}, \qquad h(a,n) \triangleq K\sum_{j=a+1}^{a+n} \log^2(j) j^{-(\zeta-2\eta)}. \tag{65}$$

Clearly Theorem 5.3 applies and (51) follows.

Step II. We show that for each constant $0 < b < 1$ there is some $\eta > 0$ such that almost surely $[P]$,

$$\sum_{1\leq j\leq t} (U_j - R)\eta_j \nu_{j-s(j)} = O(t^{1/2-\eta}), \tag{66}$$

where η_j is given by (47) and $s(j) \triangleq [j^b]$. It is enough to show that

$$\sum_{j=1}^{\infty} j^{-(1/2-\eta)} E|(U_j - R)\eta_j \nu_{j-s(j)}| < \infty, \tag{67}$$

for this implies

$$\sum_{j=1}^{\infty} j^{-(1/2-\eta)} |(U_j - R)\eta_j \nu_{j-s(j)}| < \infty \quad \text{a.s.}, \tag{68}$$

from which (66) follows by Kronecker's lemma. Thus fix any $0 < b < 1$ and define

$$M_j \triangleq (U_j - R)\eta_j. \tag{69}$$

If $|A|$ denotes a matrix norm on the set of N by N matrices such that $|AB| \leq |A||B|$ for matrices A and B, then by the Cauchy–Schwarz inequality and an application of Theorem 4.4 with $r = 1$, there is a constant K_0 such that

$$E|(U_j - R)\eta_j \nu_{j-s(j)}| \leq E^{1/2}(|M_j|^2)E^{1/2}(|\nu_{j-s(j)}|^2) \leq K_0 E^{1/2}(|M_j|^2) j^{-1/2} \tag{70}$$

for all $j \geq 2$. To bound $E^{1/2}|M_j|^2$ note from (47) that

$$\eta_j = \sum_{k=1}^{s(j)} (-1)^k \left\{ \sum_{1 \leq i_1 < \cdots < i_k \leq s(j)} (\mu_{j-i_1} \cdots \mu_{j-i_k})(U_{j-i_1} \cdots U_{j-i_k}) \right\}. \tag{71}$$

Also, for all $1 \leq k \leq s(j)$,

$$\begin{aligned} \left\{ \sum_{i=1}^{s(j)} \mu_{j-i}|U_{j-i}| \right\}^k &= \prod_{r=1}^{k} \left\{ \sum_{i_r=1}^{s(j)} \mu_{j-i_r}|U_{j-i_r}| \right\} \\ &\geq k! \left\{ \sum_{1 \leq i_1 < \cdots < i_k \leq s(j)} (\mu_{j-i_1} \cdots \mu_{j-i_k})(|U_{j-i_1}| \cdots |U_{j-i_k}| \right\}. \end{aligned} \tag{72}$$

Taking matrix norms in (71) and using (72) gives

$$|\eta_j| \leq \sum_{k=1}^{s(j)} (1/k!) \left\{ \sum_{i=1}^{s(j)} \mu_{j-i}|U_{j-i}| \right\}^k. \tag{73}$$

Now for any $k \geq 2$, clearly $\{\mu_{j-i}|U_{j-i}|\} \leq (\mu_{j-i})^{(k-1)/k}\{(\mu_{j-i})^{1/k}|U_{j-i}|\}$; thus, by Holder's inequality,

$$\left\{ \sum_{i=1}^{s(j)} \mu_{j-i}|U_{j-i}| \right\}^k \leq \left\{ \sum_{i=1}^{s(j)} \mu_{j-i} \right\}^{(k-1)} \left\{ \sum_{i=1}^{s(j)} \mu_{j-i}|U_{j-i}|^k \right\} \tag{74}$$

for all $k \geq 1$. Hence, from (69), (73), and (74),

$$E(|M_j|^2) \leq \sum_{k_1=1}^{s(j)} \sum_{k_2=1}^{s(j)} \left\{ \sum_{i_1=1}^{s(j)} \mu_{j-i_1} \right\}^{(k_1-1)} \left\{ \sum_{i_2=1}^{s(j)} \mu_{j-i_2} \right\}^{(k_2-1)} \left\{ \sum_{i_1=1}^{s(j)} \sum_{i_2=1}^{s(j)} \mu_{j-i_1}\mu_{j-i_2} B \right\}, \tag{75}$$

where

$$\begin{aligned} B &\triangleq (1/k_1!)(1/k_2!)E[|U_j - R|^2 \cdot |U_{j-i_1}|^{k_1} \cdot |U_{j-i_2}|^{k_2}] \\ &\leq K_1\{(1/k_1!)E^{1/4}(|U_{j-i_1}|^{4k_1})\}\{(1/k_2!)E^{1/4}(|U_{j-i_2}|^{4k_2})\} \end{aligned} \tag{76}$$

for some constant K_1, where the last line follows from Holder's inequality. Now by condition (C) there is a constant K_2 such that

$$(1/k!)E^{1/4}(|U_j|^{4k}) \leq (C^{2k} \cdot (2k)!)^{1/4}/(k!) \leq K_2(2eC)^{k/2} \equiv K_2 C_1^k \tag{77}$$

where $(2k)!$ has been upper-bounded and $k!$ lower-bounded using the following extended version of Stirling's formula:

$$(2\pi)^{1/2}n^{n+1/2}e^{-n}e^{1/(1+12n)} < n! < (2\pi)^{1/2}n^{n+1/2}e^{-n}e^{1/12n}$$

(see Feller [16, (9.15), p. 54]). From (75) and (77)

$$E(|M_j|^2) \le K_3 \left\{ \sum_{k=1}^{s(j)} \left(C_1 \sum_{i=1}^{s(j)} \mu_{j-i} \right)^k \right\}^2. \tag{78}$$

Since $0 < b < 1$, there is some integer J_1 such that

$$C_1 \sum_{i=1}^{s(j)} \mu_{j-i} \le 2C_1 \mu j^{b-1} < \frac{1}{2} \tag{79}$$

for all $j \ge J_1$; hence by (78) there is a constant K_4 such that

$$E(|M_j|^2) \le K_3 \left\{ \sum_{k=1}^{\infty} (2C_1 j^{b-1})^k \right\}^2 \le K_4 j^{2b-2} \tag{80}$$

for all $j \ge J_1$. By (70) and (80), for each $0 < b < 1$ there is some $\eta > 0$ such that (67) holds, as required.

Step III. We show that for each constant $0 < b < \frac{1}{2}$ there is some $\eta > 0$ such that almost surely $[P]$,

$$\sum_{1 \le j \le t} (U_j - R)\xi_j = O(t^{1/2-\eta}), \tag{81}$$

where ξ_j is given by (48) and $s(j) \triangleq [j^b]$. Define

$$x_j \triangleq |(U_j - R)\xi_j| \le \sum_{k=1}^{s(j)} \mu_{j-k}\beta_{j,k}|C_{j,k}|, \tag{82}$$

where, from (48),

$$C_{j,k} \triangleq \prod_{i=1}^{k-1} (I - \mu_{j-i}U_{j-i}), \tag{83}$$

$$\beta_{j,k} \triangleq |U_j - R| \cdot |z_{j-k}|. \tag{84}$$

Here, for an $N \times N$ matrix A, $|A|$ denotes the norm $|A| \triangleq \sup_{|x|=1} |Ax|$, where $|x|$ is the Euclidean norm of any R^N-vector x. By Holder's inequality and condition (C) it is easily confirmed that $E^{1/2}(\beta_{j,k}) \le K_1 < \infty$ for all $j \ge 1$ and $1 \le k \le s(j)$. Thus, by (82) and Holder's inequality,

$$E(x_j) \le K_2 \sum_{k=1}^{s(j)} \mu_{j-k} E^{1/2}\{|C_{j,k}|^2\}. \tag{85}$$

Now for any $\mu > 0$ and symmetric positive semidefinite matrix U, it follows from standard properties of the above matrix norm that $|I - \mu U| \leq 1 + \mu^2 |U|^2$, so from (83),

$$|C_{j,k}| \leq \prod_{i=1}^{k-1} (1 + \mu_{j-i}^2 |U_{j-i}|^2). \tag{86}$$

Thus, by (86) and an argument identical to that used to obtain line (24) in Watanabe [3], we can show that there is some constant K_3 such that

$$E(|C_{j,k}|^2) \leq K_3 \tag{87}$$

for all $j \geq 1$ and $1 \leq k \leq j$. From (87) and (85) there is a constant K_4 such that

$$E(x_j) \leq K_4 j^{b-1} \tag{88}$$

for all $j \geq 1$. Exactly as in Step II it follows that for each $0 < b < \frac{1}{2}$ there is some $\eta > 0$ such that $\sum j^{-(1/2-\eta)} x_j < \infty$ almost surely; hence (81) follows from Kronecker's lemma.

Finally, putting together (81), (66), (49), and (46) we obtain (45). □

LEMMA 4.3. *Assume conditions* (A*), (B), *and* (C*). *Then there exists some constant* $\eta > 0$ *such that* (45) *holds almost surely* $[P]$.

Proof. The proof is similar to that of Lemma 4.2; hence we indicate only the changes in that proof. Fix $0 < b < 1$ and define $s(j) \triangleq [j^b], U_j \triangleq X_j X_j^T$, and $\mu_j \triangleq \mu/j$.

Step I. Here is it shown that for each $b > \frac{1}{6}$ there is some $\eta > 0$ such that (49) holds almost surely $[P]$. It is enough to prove (51) where μ_j is defined by (50). Clearly,

$$\begin{aligned} E\left[\sum_{j=a+1}^{a+n} u_j\right]^2 \leq\ & 2E\left[\sum_{\substack{i,j=a+1 \\ j-M \leq i \leq j}}^{a+n} u_i u_j\right] + 2E\left[\sum_{\substack{i,j=a+1 \\ a+1 \leq i \leq j-s(j)}}^{a+n} u_i u_j\right] \\ & + 2E\left[\sum_{\substack{i,j=a+1 \\ j-s(j) < i < j-M}}^{a+n} u_i u_j\right] \end{aligned} \tag{89}$$

for all $a \geq 1 + M^{1/b}$ and $n \geq 1$, since $j > a$ implies that $s(j) > M$. Consider the first term on the right of (89). Clearly,

$$\{r_1 M - (2r)(2M+1)\}(r_2 - 4(2r)) = 4(2r)^2(2M+1) \tag{90}$$

for $r = 2$, where $r_1 \triangleq 24$ and $r_2 \triangleq 24(1 + 1/(4M-1))$, thus Theorem 5.5 gives

$$E|\nu_{j-s(j)}|^4 \leq K_1 (j - s(j))^{-1} \leq K_2 j^{-1} \quad \text{for all } j \geq 2. \tag{91}$$

By Holder's inequality and condition (C*),

$$E(u_i u_j) \leq K_3 (ij)^{-(1/2-\eta)} \|\nu_{i-s(i)}\|_4 \|\nu_{j-s(j)}\|_4 \tag{92}$$

and hence, from (91),

$$E\left[\sum_{\substack{i,j=a+1 \\ j-M \leq i \leq j}}^{a+n} u_i u_j\right] \leq K_4 \left[\sum_{j=a+1}^{a+n} j^{-(3/2-2\eta)}\right] \tag{93}$$

for all $a \geq 1 + M^{1/b}, n \geq 1$. Next bound the second term on the right of (89). To lighten the notation we write $\psi(m)$ for $\psi_{(a,X)}(m)$. Since $a+1 \leq i \leq j - s(j)$ and $E(U_j - R) = 0$, it follows from Theorem 5.1(ii), (A*), and (91) that

$$\begin{aligned} E(u_i u_j) &\leq (ij)^{-(1/2-\eta)}\psi(s(j))E|U_j - R|E|(U_i - R)\nu_{i-s(i)}\nu_{j-s(j)}| \\ &\leq K_5(ij)^{-(1/2-\eta)}\psi(s(j))\|\nu_{i-s(i)}\|_4\|\nu_{j-s(j)}\|_4 \leq K_6\psi(s(j))(ij)^{-(3/4-\eta)}, \end{aligned} \tag{94}$$

and so

$$E\left[\sum_{\substack{i,j=a+1 \\ a+1\leq i\leq j-s(j)}}^{a+n} u_i u_j\right] \leq K_6 \sum_{j=a+1}^{a+n} j^{(2\eta - b\beta - 1/2)} \leq K_6 \sum_{j=a+1}^{a+n} j^{-(\theta-2\eta)} \tag{95}$$

for all $a \geq 1 + M^{1/b}, n \geq 1$, and some constant $\theta > 1$, where the second inequality follows since $b > \frac{1}{6}$ implies that $b\beta > \frac{1}{2}$ (to get the first inequality in (95), note that $j > a \geq 1 + M^{1/b}$ implies $s(j) > M$; hence by (A*) we obtain $\psi(s(j)) \leq K_7 j^{-b\beta}$). Now bound the third term on the right of (89). Since $j - s(j) < i < j - M$ and $E(U_j - R) = 0$ from Theorem 5.1(ii) it follows that

$$E(u_i u_j) \leq K_8(ij)^{-(1/2-\eta)}\psi(j-i)\|\nu_{i-s(i)}\|_4\|\nu_{j-s(j)}\|_4 \leq K_8 i^{-((3/2)-2\eta)}\psi(j-i), \tag{96}$$

and hence

$$E\left[\sum_{\substack{i,j=a+1 \\ j-s(j)<i<j-M}}^{a+n} u_i u_j\right] \leq K_9 \sum_{k=M+1}^{n-1} \sum_{i=a+1}^{a+n-k} \psi(k) i^{-(3/2-2\eta)} \leq K_{10} \sum_{j=a+1}^{a+n} j^{-(3/2-2\eta)} \tag{97}$$

since $j - i > M$. From (97), (95), (93), (89), and Theorem 4.3 we obtain (49).

Step II. In this step it is shown that for each $0 < b < \frac{1}{2}$ there is a constant $\eta > 0$ such that (66) holds almost surely $[P]$, where η_j is given by (47). As in the proof of Lemma 4.2, it is enough to prove (67). Defining M_j as in (69) we see that (70) continues to hold (but using Theorem 4.5 instead of Theorem 4.4), and hence the proof reduces to finding an upper bound similar to (80) but based on the use of (A*) and (C*). Fix any $0 < b < \frac{1}{2}$. By Lemma 5.7 and conditions (A*) and (C*) there is some constant $\gamma > 0$ such that

$$E\left[\prod_{l=1}^{k} |U_j - R|^2 |U_{j-i_l}|^2\right] \leq \gamma^{1+k} \tag{98}$$

for all $j \geq 2, k \geq 1$, and indices $1 \leq i_1 < i_2 < \cdots < i_k \leq s(j)$. By (98), (71), (69), the Cauchy–Schwarz inequality, and some simple manipulations,

$$E(|M_j|^2) \leq \gamma \left[\sum_{k=1}^{s(j)} \left\{ \sum_{1\leq i_1<\cdots i_k\leq s(j)} (\mu_{j-i_1}\cdots\mu_{j-i_k})\gamma^{k/2} \right\}\right]^2. \tag{99}$$

Clearly, there is a constant K_1 (depending only on b) such that $\mu_{j-i} \leq K_1 j^{-1}$ for all $1 \leq i \leq s(j)$ and $j \geq 2$, so

$$\left\{ \sum_{1\leq i_1<\cdots i_k\leq s(j)} (\mu_{j-i_1}\cdots\mu_{j-i_k})\gamma^{k/2} \right\} \leq \binom{s(j)}{k} \frac{C^k}{j^k} \tag{100}$$

for $j \geq 2$, where $C \triangleq K_1\gamma^{1/2}$. To bound $(C/j)^k$, fix a constant $1 > \delta > 2b$, define $p(j) \triangleq j^{-\delta/2}$, and put

$$\lambda_j \triangleq -\frac{1}{p(j)}\log(1-p(j)). \tag{101}$$

Clearly, $\lim_{j\to\infty}\lambda_j = 1$, and since $b < \delta/2$, there exists some J_1 such that

$$\frac{1}{s(j)}\log(C^{-1}j^{\delta/2}) \geq \lambda_j p(j) \quad \text{for all } j \geq J_1. \tag{102}$$

Thus, from (101) and (102), $(Cp(j))^k \leq (1-p(j))^{s(j)-k}$ for all $1 \leq k \leq s(j)$ and $j \geq J_1$, and, therefore,

$$\frac{C^k}{j^k} \leq j^{\delta-1}(p(j))^k(Cp(j))^k \leq j^{\delta-1}(p(j))^k(1-p(j))^{s(j)-k} \tag{103}$$

for all $1 \leq k \leq s(j)$ and $j \geq J_1$. In view of (100), (103), and the binomial theorem,

$$\sum_{k=1}^{s(j)}\left\{\sum_{1\leq i_1<\cdots i_k\leq s(j)}(\mu_{j-i_1}\cdots\mu_{j-i_k})\gamma^{k/2}\right\} \leq j^{\delta-1} \tag{104}$$

for all $j \geq J_1$. Thus, by (99),

$$E(|M_j|^2) \leq \gamma j^{2\delta-2} \tag{105}$$

for all $j \geq J_1$. Since $0 < \delta < 1$ we can choose $\eta > 0$ such that $2-\delta-\eta > 1$ and (67) follows by (105) and (70).

Step III. Here it is shown that for each $0 < b < \frac{1}{2}$ there is some $\eta > 0$ such that (81) holds almost surely $[P]$. The argument is identical to that used in Step III in the proof of Lemma 4.2 except that to get (87) under conditions (A*) and (C*) we follow an argument exactly like that used to obtain line (43) in Watanabe [3]. □

Lemmas 4.4 and 4.5 establish properties of the function F (defined in (20)) that are needed for the proof of Proposition 2.2. Because (B) in §2 does not ensure that $(\mu R - 2I)$ is positive definite (it may have some strictly negative eigenvalues) it is necessary to check that the integrals in (20) and (28) are well defined for $\phi \in S$, and to justify the integration by parts in going from (20) to (28).

LEMMA 4.4. *Assume condition* (B) *in* §2. *Then the following hold.*

(a) *For each* $\phi \in S, S$ *being defined by* (18), *the functions* $t \to t^{(\mu R-I)}\dot{\phi}(t)$ *and* $t \to t^{(\mu R-2I)}\phi(t)$ *are integrable over* $0 < t \leq 1$; *in particular,* $F(\phi)$ *is well defined, where* F *is given by* (20).

(b) *For each* $\phi \in S$, *the following integration-by-parts formula holds*:

$$\int_0^1 \tau^{(\mu R-I)}\dot{\phi}(\tau)d\tau = \phi(1) - (\mu R - I)\int_0^1 \tau^{(\mu R-2I)}\phi(\tau)d\tau. \tag{107}$$

Proof. It is sufficient to carry out the proof in the special case where $N = 1$; in the general case we simply diagonalize the symmetric matrix μR and carry out the same argument for each element along the main diagonal. For the proof we need the following simple consequence of the Cauchy–Schwarz inequality (see Natanson [17, Thm. 7, p. 257]): If $\phi \in C_0^N[0,1]$ is such that $\phi \in L_2^N[0,1]$, then

$$\sum_{i=0}^{n-1}\frac{|\phi(t_{i+1})-\phi(t_i)|^2}{|t_{i+1}-t_i|} \leq \int_0^1 |\dot{\phi}(\tau)|^2 d\tau \tag{108}$$

for each partition $0 = t_0 < t_1 < \cdots < t_n = 1$.

(a) Since $2\mu R - 1 > 0$, the function $t \to t^{(\mu R - 1)}$ is square integrable over the interval $0 < t \leq 1$, whence integrability of the first function in (a) follows from the Cauchy–Schwarz inequality. For integrability of the second function in (a), observe that

$$\int_0^1 \tau^{(\mu R-2)}\phi(\tau)d\tau = \int_0^1 \tau^{(\mu R-3/2)}\tau^{-1/2}\phi(\tau)d\tau. \tag{109}$$

Moreover, by (108) and the fact that $\phi(0) = 0$,

$$t^{-1/2}|\phi(t)| \leq \left(\int_0^1 |\dot{\phi}(\tau)|^2 d\tau\right)^{1/2} < \infty, \tag{110}$$

for all $0 < t \leq 1$, and (109) and (110) along with the integrability of $t \to t^{(\mu R-3/2)}$ over $0 < t \leq 1$ (which follows from the fact that $2\mu R - 1 > 0$) imply that the second function in (a) is integrable.

(b) It is enough to show that $\varepsilon^{(\mu R-1)}\phi(\varepsilon) \to 0$ as $\varepsilon \to 0$, for (107) follows upon integration by parts over the interval $(\varepsilon, 1], \varepsilon > 0$, and then taking $\epsilon \to 0$. However, the required limit follows from (110) and the fact that $\mu R - \frac{1}{2} > 0$. □

Lemma 4.5 is used to prove Proposition 2.2 (see (21)).

LEMMA 4.5. *Assume conditions* (B) *and* (D) *in* §2, *let* $\{\tilde{W}(t)\}$ *be a Brownian motion with covariance matrix* $\mu^2\Gamma$ *defined on a probability space* $(\tilde{\Omega}, \tilde{\mathbf{A}}, \tilde{P})$, *and let* $\tilde{Y}(t)$ *be defined in terms of* $\tilde{W}(t)$ *by* (4). *Then for almost all* $\tilde{\omega}[\tilde{P}]$,

$$\{(2j\,\mathrm{loglog}(j))^{-1/2}\tilde{Y}(j,\tilde{\omega}), j \geq J\} \to\to F[S].$$

Proof. For $0 \leq t \leq 1, \tilde{\omega} \in \tilde{\Omega}$, and integer $j \geq J$, define

$$\tilde{\phi}_j(t,\tilde{\omega}) \triangleq (2j\,\mathrm{loglog}(j))^{-1/2}\tilde{W}(jt,\tilde{\omega}).$$

According to Theorem 5.6, the set S defined in (18) is a compact subset of $C_0^N[0,1]$ and, for almost all $\tilde{\omega}[\tilde{P}]$,

$$\{\tilde{\phi}_j(\cdot,\tilde{\omega}), j \geq J\} \to\to S. \tag{111}$$

Fix some $\tilde{\omega}$ in the set of $\tilde{P}$-unit measure such that (111) holds and the set of functions

$$t \to t^{(\mu R-2I)}\tilde{\phi}_j(t,\tilde{\omega}), \qquad j \geq J$$

has equi-absolutely continuous integrals over $0 < t \leq 1$ (see Lemma 4.6), and fix an arbitrary ϕ in S. If $\{j_r\}$ is a subsequence such that $\{\tilde{\phi}_{j_r}(\cdot,\tilde{\omega})\}$ converges in $C_0^N[0,1]$ to ϕ then the Vitali convergence theorem (Natanson [17, Thm. 2, p. 152]) along with the definition of F in (20) and the above equi-absolute integrability shows that $\{F(\tilde{\phi}_{j_r}(\cdot,\tilde{\omega}))\}$ converges to $F(\phi)$ as $r \to \infty$. From (111) it is thus clear that $F(\phi)$ is an accumulation point of the sequence $\{F(\tilde{\phi}_j(\cdot,\tilde{\omega})), j \geq 1\}$, whence, by the arbitrary choice of $\phi \in S$, it follows that $F[S] \subset C(\{F(\tilde{\phi}_j(\cdot,\tilde{\omega}))\})$. To establish the opposite inclusion, observe that compactness of S along with the fact (see (111)) that $\rho(\tilde{\phi}_j(\cdot,\tilde{\omega}), S) \to 0$ (where $\rho(\tilde{\phi}_j(\cdot,\tilde{\omega}), S)$ denotes the distance from $\tilde{\phi}_j(\cdot,\tilde{\omega})$ to S in the metric $\rho(\cdot,\cdot)$ of uniform convergence in $C_0^N[0,1]$) implies that $\{\tilde{\phi}_j(\cdot,\tilde{\omega})\}$ is a totally bounded subset of $C_0^N[0,1]$. If $z \in C(\{F(\tilde{\phi}_j(\cdot,\tilde{\omega}))\})$, then there is a subsequence $\{F(\tilde{\phi}_{j_r}(\cdot,\tilde{\omega}))\}$ of $\{F(\tilde{\phi}_j(\cdot,\tilde{\omega}))\}$ that converges to z, and by the total boundedness of $\{\tilde{\phi}_j(\cdot,\tilde{\omega})\}$, there is a further subsequence

$\{\tilde{\phi}_{j_l}(\cdot,\tilde{\omega})\}$ of $\{\tilde{\phi}_{j_r}(\cdot,\tilde{\omega})\}$ that converges uniformly to some $\phi \in S$. Thus the sequence of functions $t \to t^{(\mu R-2)}\tilde{\phi}_{j_l}(t,\tilde{\omega}), 0 < t \leq 1$, has equi-absolutely continuous integrals and converges pointwise in t to the limiting function $t \to t^{(\mu R-2)}\phi(t)$. By Vitali's theorem, $F(\phi_{j_l}(\cdot,\tilde{\omega})) \to F(\phi)$, whence $z = F(\phi) \in F[S]$ and therefore $C(\{F(\tilde{\phi}_j(\cdot,\tilde{\omega}))\}) \subset F[S]$. Thus $\{F(\tilde{\phi}_j(\cdot,\tilde{\omega})), j \geq J\} \to\to F[S]$; since $F(\tilde{\phi}_j(\cdot,\tilde{\omega})) = (2j\,\mathrm{loglog}(j))^{-1/2}\tilde{Y}(j,\tilde{\omega})$ (see (4) and (20)), this establishes Lemma 4.5. □

The next result has substance when matrix $\mu R - 2I$ has negative eigenvalues. It relies on the fact that $2\mu R - I$ is positive definite and is used to prove Lemma 4.5.

LEMMA 4.6. *Assume conditions* (B) and (D) *in* §2 *and let* $\{\tilde{W}(t)\}$ *be a Brownian motion with covariance matrix* $\mu^2\Gamma$ *defined on a probability space* $(\tilde{\Omega}, \tilde{\mathbf{A}}, \tilde{P})$. *Then for almost all* $\tilde{\omega}[\tilde{P}]$, *the set of functions*

$$t \to t^{(\mu R-2I)}(2j\,\mathrm{loglog}(j))^{-1/2}\tilde{W}(jt,\tilde{\omega}), \qquad j \geq J,$$

has equi-absolutely continuous integrals over $0 < t \leq 1$ (see Natanson [17, pp. 151–152]).

Proof. As in Lemma 4.4, it is sufficient to carry out the proof in the special case where $N = 1$. For ease of notation, let $\sigma^2 \triangleq E(\tilde{W}^2(1))$ and fix a constant $c > \sigma^2$. By the local law of the iterated logarithm for Brownian motion (Loeve [18, §41.3B, p. 249]) there exists, for almost all $\tilde{\omega}[\tilde{P}]$, some (small) $\delta(c,\tilde{\omega})$ such that $1 > \delta(c,\tilde{\omega}) > 0$ and

$$|(2jt\,\mathrm{loglog}(1/jt))^{-1/2}\tilde{W}(jt,\tilde{\omega})| < c \tag{112}$$

for $0 < jt < \delta(c,\tilde{\omega})$. Likewise, by the asymptotic law of the iterated logarithm for Brownian motion (Loeve [18, p. 249]) there exists, for almost all $\tilde{\omega}[\tilde{P}]$, some (large) $\Delta(c,\tilde{\omega}) > 1$ such that

$$|(2jt\,\mathrm{loglog}(jt))^{-1/2}\tilde{W}(jt,\tilde{\omega})| < c \tag{113}$$

for $jt > \Delta(c,\tilde{\omega})$. Fix some arbitrary Borel subset $E \subset (0,1]$, and define the sets

$$\begin{aligned} I_1(c,\tilde{\omega},j) &\triangleq E \cap \{\tau; 0 < j\tau < \delta(c,\tilde{\omega})\}, \\ I_2(c,\tilde{\omega},j) &\triangleq E \cap \{\tau; j\tau > \Delta(c,\tilde{\omega})\}, \\ I_3(c,\tilde{\omega},j) &\triangleq E \cap \{\tau; \delta(c,\tilde{\omega}) \leq j\tau \leq \Delta(c,\tilde{\omega})\}. \end{aligned}$$

For fixed $j \geq J$,

$$\begin{aligned} &\int_{I_1(c,\tilde{\omega},j)} \tau^{(\mu R-2)}(2j\,\mathrm{loglog}(j))^{-1/2}|\tilde{W}(j\tau,\tilde{\omega})|d\tau \\ &\quad \leq \int_{I_1(c,\tilde{\omega},j)} \tau^{(\mu R-3/2)}(j\tau)^{-1/2}|\tilde{W}(j\tau,\tilde{\omega})|d\tau \qquad (\mathrm{loglog}(j) \geq 1 \text{ for } j \geq J) \\ &\quad \leq c\int_{I_1(c,\tilde{\omega},j)} \tau^{(\mu R-3/2)}(2\,\mathrm{loglog}(1/j\tau))^{1/2}d\tau \qquad (\text{by (112)}) \\ &\quad \leq c\int_{I_1(c,\tilde{\omega},j)} \tau^{\alpha-1}\tau^{\gamma}(2\,\mathrm{loglog}(1/j\tau))^{1/2}d\tau \end{aligned} \tag{114}$$

(for constants $\alpha, \gamma > 0$, since $\mu R > \frac{1}{2}$),

$$\leq c_1 j^{-\gamma}\int_E \tau^{\alpha-1}d\tau \quad \text{a.s. } [\tilde{P}]$$

for some constant $c_1 > 0$ that depends only on c and $\tilde{\omega}$. The last inequality follows from the fact that

$$\sup_{\tau \in I_1(c,\tilde{\omega},j)} \tau^{\gamma}(2\operatorname{loglog}(1/j\tau))^{1/2} \leq \sup_{x \geq \delta^{-1}(c,\tilde{\omega})} (jx)^{-\gamma}(2\operatorname{loglog} x)^{1/2} = O(j^{-\gamma}),$$

where the constant implied by O depends only on c and $\tilde{\omega}$. Since $\tau \leq 1$ for all τ in E,

$$\begin{aligned} &\int_{I_2(c,\tilde{\omega},j)} \tau^{(\mu R-2)}(2j\operatorname{loglog}(j))^{-1/2}|\tilde{W}(j\tau,\tilde{\omega})|d\tau \\ &\quad \leq \int_{I_2(c,\tilde{\omega},j)} \tau^{(\mu R-2)}(2j\operatorname{loglog}(j\tau))^{-1/2}|\tilde{W}(j\tau,\tilde{\omega})|d\tau \\ &\quad = \int_{I_2(c,\tilde{\omega},j)} \tau^{(\mu R-3/2)}(2j\tau\operatorname{loglog}(j\tau))^{-1/2}|\tilde{W}(j\tau,\tilde{\omega})|d\tau \\ &\quad \leq c\int_E \tau^{(\mu R-3/2)}d\tau \quad \text{a.s. } [\tilde{P}] \end{aligned} \tag{115}$$

(by (113)). Finally, there exists some finite bound $B(c,\tilde{\omega})$ such that $(2jt)^{-1/2}|\tilde{W}(jt,\tilde{\omega})| < B(c,\tilde{\omega})$ for $\delta(c,\tilde{w}) \leq jt \leq \Delta(c,\tilde{\omega})$, whence, for $j \geq J$, it is easily seen that, almost surely $[P]$,

$$\int_{I_3(c,\tilde{\omega},j)} \tau^{(\mu R-2)}(2j\operatorname{loglog}(j))^{-1/2}|\tilde{W}(j\tau,\tilde{\omega})|d\tau \leq B(c,\tilde{\omega})\int_E \tau^{(\mu R-3/2)}d\tau. \tag{116}$$

By (114)–(116), for almost all $\tilde{\omega}[\tilde{P}]$,

$$\begin{aligned} &\int_E \tau^{(\mu R-2)}(2j\operatorname{loglog}(j))^{-1/2}|\tilde{W}(j\tau,\tilde{\omega})|d\tau \\ &\quad \leq c_1\int_E \tau^{\alpha-1}d\tau + (B(c,\tilde{\omega})+c)\int_E \tau^{(\mu R-3/2)}d\tau \end{aligned} \tag{117}$$

for all $j \geq J$ and all Borel sets $E \subset (0,1]$. Since $\alpha > 0$ and $\mu R > \frac{1}{2}$, Lemma 4.6 follows from (117). □

5. Appendix 2. In this appendix, we collect for convenience several results from probability theory that are used in the proofs of §§3 and 4.

A useful property of random variables needed to prove Lemmas 4.2 and 4.3 (see lines (56), (60), (94), and (96)) is given by Theorem 5.1.

THEOREM 5.1. *Suppose that* **G** *and* **H** *are two sub* σ*-algebras in a probability space* $(\Omega, \mathbf{A}, P)$, *and* X *and* Y *are random variables defined on* Ω *that are measurable with respect to* **G** *and* **H**, *respectively.*

(i) *If* $r, s, t > 1$ *are constants such that* $(1/r) + (1/s) + (1/t) = 1$, *and if* $\|X\|_s < \infty$ *and* $\|Y\|_t < \infty$, *then*

$$|E(XY) - (EX)(EY)| \leq 10\{\alpha(\mathbf{G}, \mathbf{H})\}^{1/r}\|X\|_s\|Y\|_t,$$

where $\alpha(\mathbf{G}, \mathbf{H}) \triangleq \sup|P(AB) - P(A)P(B)|$ *and the supremum is taken over all* $A \in \mathbf{G}$, $B \in \mathbf{H}$;

(ii) *If* $E|X| < \infty$, *and* $E|Y| < \infty$, *then*

$$|E(XY) - (EX)(EY)| \leq \{\psi(\mathbf{G}, \mathbf{H})\}E|X|E|Y|,$$

where $\psi(\mathbf{G}, \mathbf{H}) \triangleq \sup|P(AB) - P(A)P(B)|/P(A)P(B)$ *and the supremum is taken over all* $A \in \mathbf{G}, B \in \mathbf{H}$.

Part (i) of Theorem 5.1 is due to Davydov [19] and a full proof is given in Lemma 1 of Deo [20]. The proof of part (ii) is almost trivial (see, e.g., Watanabe [3, Lem. 2]).

The next result is used in the proof of Lemma 4.1 (see (39), (40)).

THEOREM 5.2. *Suppose that* $\{\xi_n, n \geq 1\}$ *is a strictly stationary sequence of* R^D*-valued zero-mean random vectors defined on a common probability space and having finite third-order moments. If* $\{\xi_n\}$ *is strong mixing with* $\alpha_\xi(m) = O(m^{-\beta})$ *for some* $\beta > 3$, *then* (i) *the series*

$$T \triangleq E(\xi_1 \xi_1^T) + \sum_{j=2}^{\infty} E(\xi_1 \xi_j^T) + \sum_{j=2}^{\infty} E(\xi_j \xi_1^T)$$

converge absolutely, and (ii) *there exists some constant* $\eta > 0$ *along with a probability space* $(\Omega^{(1)}, \mathbf{A}^{(1)}, P^{(1)})$ *on which is defined an* R^D*-valued Brownian motion* $\{B^{(1)}(t)\}$ *with covariance matrix T and a sequence* $\{\xi_n^{(1)}, n \geq 1\}$ *of* R^D*-valued random vectors such that*

(i) $\{\xi_n, n \geq 1\} \stackrel{D}{=} \{\xi_n^{(1)}, n \geq 1\}$ *and*

(ii) $\sum_{1 \leq n \leq t} \xi_n^{(1)} = B^{(1)}(t) + O(t^{1/2-\eta})$ *for all* $t \geq 1$ *a.s.* $[P^{(1)}]$.

Theorem 5.2 is a special case of [21, Thm. 4] in Kuelbs and Philipp, and is a generalization to dependent random vectors of the strong invariance principle for independent and identically distributed random variables first established by Strassen [5, Thm. 2].

The next theorem is a criterion for almost sure convergence of partial sums of random variables (see Stout [22, Thm. 2.4.2]). It is used to prove Lemmas 4.2 and 4.3 (see (65)).

THEOREM 5.3. *Suppose that* $\{\xi_k, k \geq 1\}$ *is a sequence of random variables defined on* $(\Omega, \mathbf{A}, P)$, *and let* $g(i,j)$ *and* $h(i,j)$ *be nonnegative functions whose arguments* i *and* j *are nonnegative integers, such that for all integers* $a \geq 0$ *and* $k, n > 1$:

(i) $g(a,k) + g(a+k,n) \leq g(a,k+n)$;

(ii) $h(a,k) + h(a+k,n) \leq h(a,k+n)$;

(iii) $h(a,n) \leq K < \infty$ *and* $Kh(a,n) \geq g(a,n)\log^2(a+1)$ *for some constant* K;

(iv) $$E\left[\sum_{k=a+1}^{a+n} \xi_k\right]^2 \leq g(a,n).$$

Then $\sum_{k=1}^{\infty} \xi_k < \infty$ *almost surely.*

The next theorem is a variant of a result of Watanabe [3] concerning $2r$th mean convergence of the recursion (1). It is used to prove Lemma 4.2 (see (54), (58), and (70)). (Recently Gerencser [23] has established L_q convergence for algorithms more general than (1). These entail use of a projection onto a neighbourhood of the limit, and [23] gives the first rigorous proofs of this commonly used mechanism.)

THEOREM 5.4. *Consider the recursion* (1), *where* (i) $\{(a_j, X_j^T), j \geq 1\}$ *is a strictly stationary strong mixing process with* $\alpha_{(a,X)}(m) = O(m^{-\beta_1})$ *for some* $\beta_1 > 0$; (ii) *there is a constant C such that, for each* $j, E|X_j|^{4k} = O(C^k k!)$ *for all integers* $k \geq 1$; (iii) *the matrix* $E(X_j X_j^T)$ *is positive definite, and* (iv) *for some* $\varepsilon > 0$ *and positive integer r we have* $E|a_j|^{8r+5+\varepsilon} \leq K_1 < \infty$ *for all j. If* λ *denotes the least eigenvalue of* $E(X_j X_j^T)$ *and* $\min\{2\mu\lambda, 2r\beta_1/(4r+1)\} > 1$, *then* $E|h_j - h_*|^{2r} = O(j^{-1})$.

Watanabe [3, Thm. 3] obtains the above result in the case where the driving process $\{(a_j, X_j^T)\}$ is uniform (or ϕ-) mixing. However, the proof given there adapts fairly easily to the case for which $\{(a_j, X_j^T)\}$ is strong mixing where, in place of the classical Ibragimov bound for uniform mixing processes (see [3, Lem. 1]), we use Theorem 5.1(i).

In the case of ψ-mixing driving data we have the following result on $2r$th mean convergence, which is Theorem 4 in Watanabe [3]. We must prove Lemma 4.3 (see (91)).

THEOREM 5.5. *Consider the recursion* (1), *where* (i) $E|X_j|^{4r_1M} < \infty$ and $E|a_j|^{r_2} < \infty$ *for positive integers* r_1, M, *and a positive constant* r_2; (ii) $\{(a_j, X_j^T)\}$ *is* ψ*-mixing and, for positive constants* $\beta_2, K, \psi_{(a,X)}(m) \leq Km^{-\beta_2}$ *for all* $m \geq M$; *and* (iii) *for some positive integer* r, *we have* $r_1M \geq 12r, r_2 > 8r$, *and*

$$\{r_1M - (2r)(2M+1)\}(r_2 - 8r) \geq 16r^2(2M+1).$$

If λ *is the least eigenvalue of* $E(X_jX_j^T)$ *and* $\min\{2\mu\lambda, \beta_2\} > 1$, *then* $E|h_j - h_*|^{2r} = O(j^{-1})$.

For the proof of Lemma 4.5, we need the functional law of the iterated logarithm for Brownian motion due to Strassen [5; Thm. 1].

THEOREM 5.6. *Suppose that* $\{W(t)\}$ *is an* R^N*-valued Brownian motion defined on* $(\Omega, \boldsymbol{A}, P)$, *with covariance matrix* $\mu^2\Gamma$ (*where* μ *is a scalar*). *Then the set* S *defined in* (18) *is a compact subset of* $C_0^N[0,1]$, *and for almost all* $\omega[P]$,

$$\{\phi_j(\cdot,\omega), j \geq J\} \longrightarrow\!\!\!\!\!\rightarrow S,$$

where $\phi_j(t,\omega) \stackrel{\Delta}{=} (2j\,\mathrm{loglog}(j))^{-1/2}W(jt,\omega)$ *for* $0 \leq t \leq 1$.

Lemma 5.7, which is implicit in the developments of Watanabe [3, p. 138], gives a useful property of ψ-mixing, and is needed to prove Lemma 4.3 (see (98)).

LEMMA 5.7. *Suppose that* $\{\xi_n\}$ *is a real-valued random process such that* $\psi_\xi(M) < \infty$ *and* $B \stackrel{\Delta}{=} \sup_n E|\xi_n|^M < \infty$ *for some positive integer* M. *Then there is a constant* $\gamma > 0$ *depending only on* $\psi_\xi(M)$ *and* B *such that*

$$E\left[\prod_{l=1}^{n}|\xi_l|\right] \leq \gamma^l \quad \textit{for all } n \geq 1.$$

Acknowledgment. The author thanks a reviewer for the proof of Lemma 4.1, which is simpler than the original.

SHARP LIPSCHITZ CONSTANTS FOR BASIC OPTIMAL SOLUTIONS AND BASIC FEASIBLE SOLUTIONS OF LINEAR PROGRAMS*

WU LI†

Abstract. The main purpose of this paper is to give Lipschitz constants for basic optimal solutions (or vertices of solution sets) and basic feasible solutions (or vertices of feasible sets) of linear programs with respect to right-hand side perturbations. The Lipschitz constants are given in terms of norms of pseudoinverses of submatrices of the matrices involved, and are sharp under very general assumptions. There are two mathematical principles involved in deriving the Lipschitz constants: (1) the local upper Lipschitz constant of a Hausdorff lower semicontinuous mapping is equal to the Lipschitz constant of the mapping and (2) the Lipschitz constant of a finite-set-valued mapping can be inherited by its continuous submappings. Moreover, it is proved that any Lipschitz constant for basic feasible solutions can be used as an Lipschitz constant for basic optimal solutions, feasible solutions, and optimal solutions.

Key words. sharp Lipschitz constant, linear program, (basic) optimal solution, (basic) feasible solution, lower semicontinuous mapping, locally upper Lipschitz continuous mapping, pseudoinverse

1. Introduction.

Consider the following linear programming problem:

$$c_{\min}(b,d) := \min\{c^T x : Ax \le b, Cx = d\}, \tag{1.1}$$

where A is an $m \times n$ matrix, C a $k \times n$ matrix, $c \in \mathbb{R}^n, b \in \mathbb{R}^m$, and $d \in \mathbb{R}^k$. Let $F\binom{b}{d} := \{x \in \mathbb{R}^n : Ax \le b, Cx = d\}$ denote the feasible set of (1.1) and $S\binom{b}{d} := \{x \in \mathbb{R}^n : Ax \le b, Cx = d, c^T x = c_{\min}(b,d)\}$ the solution set of (1.1). If an optimal solution is primal degenerate, then $S\binom{b}{d}$ contains more than one solution and is a convex polyhedral set [8]. In general, F and S are set-valued mappings (or multifunctions). It was first shown by Hoffman [11] that F is Lipschitz continuous. That is, there exists a scalar $\gamma > 0$, such that

$$H\left(F\binom{b}{d}, F\binom{b'}{d'}\right)_\nu \le \gamma \cdot \left\|\binom{b}{d} - \binom{b'}{d'}\right\|_\mu \quad \text{for } b, b' \in \mathbb{R}^m, d, d' \in \mathbb{R}^k, \tag{1.2}$$

where $\|\cdot\|_\mu$, $\|\cdot\|_\nu$ denote two arbitrary norms and $H(\cdot,\cdot)_\nu$ denotes the Hausdorff metric induced by $\|\cdot\|_\nu$:

$$H(K,G)_\nu := \max\{\max_{x\in K}\min_{y\in G}\|x-y\|_\nu, \max_{y\in G}\min_{x\in K}\|y-x\|_\nu\} \quad \text{for } K, G \subset \mathbb{R}^n.$$

The scalar γ in (1.2) is also known as a Lipschitz constant (or a condition constant (cf. [21])) for the solutions of the linear system $Ax \le b, Cx = d$ with respect to right-hand side perturbations. Sixteen years later, in characterizing convex polyhedra, Walkup and Wets [32] proved that any convex polyhedral set-valued mapping is Lipschitz continuous. Even though this statement is an easy consequence of the Lipschitz continuity of F (cf. [14]), the proofs are completely different. Actually, the proof given by Walkup and Wets implies that ext F is also Lipschitz continuous, where ext $F\binom{b}{d}$ denotes the set of all basic feasible solutions (i.e., extreme points or vertices) of $F\binom{b}{d}$. That is, there exists a scalar $\beta > 0$ such that

$$H\left(\text{ext } F\binom{b}{d}, \text{ext } F\binom{b'}{d'}\right)_\nu \le \beta \cdot \left\|\binom{b}{d} - \binom{b'}{d'}\right\|_\mu \quad \text{for } b, b' \in \mathbb{R}^m, d, d' \in \mathbb{R}^k. \tag{1.3}$$

There are quite a few papers on estimation of γ in (1.2). Robinson's estimate [28] involves the minimum norm of points in certain polyhedral sets. Cook et al. [4] had an estimate of γ by the determinants of square submatrices of $\binom{A}{C}$ when $\|\cdot\|_\mu, \|\cdot\|_\nu$ are $\|\cdot\|_\infty$-norm and $\binom{A}{C}$ is an integer matrix. By using the norm of the inverse of $\binom{A}{C}$ on a polyhedral set, Mangasarian [21], and Mangasarian and Shiau [23] gave an estimate of γ in the case that $\|\cdot\|_\nu$ is the $\|\cdot\|_\infty$-norm. Bergthaller and Singer [2] used the norms of nonsingular submatrices of $\binom{A}{C}$ to estimate γ when $\|\cdot\|_\mu$ is the $\|\cdot\|_\infty$-norm. (In private correspondence, I. Singer showed the author that their approach actually yields estimates of γ for arbitrary norms $\|\cdot\|_\mu$ and $\|\cdot\|_\nu$.) Mangasarian and Shiau, and Bergthaller and Singer showed that their estimates are better than the one given by Cook, Gerards, Schrijver, and Tardos in the case that $\|\cdot\|_\mu$ and $\|\cdot\|_\nu$ are $\|\cdot\|_\infty$-norm. With the exception of Bergthaller and Singer's paper, all authors had similar estimates for S. It is worth mentioning that Mangasarian and Shiau's estimate of Lipschitz constant for S is independent of c. For applications of such Lipschitz constants in convergence analysis of descent methods for solving linearly constrained minimization problems, see [9], [12], and [19].

However, there is no paper on estimation of β in (1.3). Walkup and Wets proved the existence of β in (1.3) by using lifting projections of convex polyhedra [32].

The main purpose of this paper is to give the sharp Lipschitz constants for ext F and ext S. In §2, we first show that the local upper Lipschitz constant of a Hausdorff lower semicontinuous mapping is equal to the Lipschitz constant of the mapping. Then we prove that the Lipschitz constant of a finite-set-valued mapping can be inherited by its continuous submappings. The first result enables us to use a local estimate of β as a global one, and the second result is used to prove that any Lipschitz constant for ext F can be used as a Lipschitz constant for ext S when rank $\binom{A}{C} = n$. In general, ext $F\binom{b}{d}$ and ext $S\binom{b}{d}$ might be empty, so we consider the submappings F_0 (of F) and S_0 (of S) in §3. Lipschitz constants for ext F_0 and ext S_0 are given in various norms, which reduce to Lipschitz constants of ext F and ext S when rank $\binom{A}{C} = n$. The Lipschitz constants given in p-norms are extremely simple and most likely to be useful. The main objective of §4 is to show that Lipschitz constants for ext F_0 can be used as Lipschitz constants for F and S. Therefore, we obtain various Lipschitz constants for F and S. It becomes clear from the analysis given in §3 that the Lipschitz constants given for ext F when rank $\binom{A}{C} = n$ are sharp under very general assumptions. The detailed proof is given in §5. Also, we compare our Lipschitz constants for F and S with some known, better Lipschitz constants for F and S in §5. Comments and remarks are given in §6.

To conclude this section, we introduce some common notation used in the following sections. For any vector x (or matrix B) and an index set I, x_I (or B_I), denote the vector (or matrix) consisting of components (or rows) of x (or B) whose indices are in I. Let $B_{I,0}$ be the matrix obtained by replacing rows of B whose indices are not in I by 0. x^T (or B^T) is the transpose of x (or B). rank(B) denotes the rank of the matrix B. B^+ denotes the pseudoinverse of B [10]. $\mathcal{R}(B)$ is the range of B (i.e., $\mathcal{R}(B) := \{Bx : x \in \mathbb{R}^s\}$ if B is an $r \times s$ matrix). B is said to be row independent if row vectors of B are linearly independent. Let diag$(\alpha_1, \cdots, \alpha_n)$ be the $n \times n$ diagonal matrix with diagonal elements $\alpha_1, \cdots, \alpha_n$. For any set $K \subset \mathbb{R}^n$, conv(K) stands for the convex hull of K. For $x \in \mathbb{R}^n$, the p-norm of x is defined as $\|x\|_p := (\sum_{i=1}^n |x_i|^p)^{1/p}$ for $1 \le p < \infty$ and $\|x\|_\infty := \max_{1\le i\le n}|x_i|$. Let $\|\cdot\|_\nu$ and $\|\cdot\|_\mu$ be two arbitrary norms on $\mathbb{R}^n$ and $\mathbb{R}^{m+k}$, respectively. $\|\cdot\|_\mu$ is said to be a monotone norm if $\|x\|_\mu \le \|y\|_\mu$, whenever $|x_i| \le |y_i|$ for $1 \le i \le m+k$. For $x \in \mathbb{R}^n$ and $K \subset \mathbb{R}^n, d(x, K)_\nu := \min\{\|x - y\|_\nu : y \in K\}$. The upper Hausdorff metric $d(G, K)_\nu := \sup_{x\in G} d(x, K)_\nu$ for $G, K \subset \mathbb{R}^n$, and the Hausdorff metric $H(\cdot,\cdot)_\nu$ on subsets of $\mathbb{R}^n$ with respect to $\|\cdot\|_\nu$ is defined as

$$H(K,G)_\nu := \max\{d(K,G)_\nu, d(G,K)_\nu\} \quad \text{for } G,K \subset \mathbb{R}^n.$$

To avoid the case when $K = \emptyset$ or $G = \emptyset$, we assume that $d(K,\emptyset)_\nu = d(\emptyset,K)_\nu = -\infty$. $K + G := \{x + y : x \in K, y \in G\}$. For an index set I, $|I|$ denotes the number of indices in I. Define

$$\mathcal{M}(A,C) := \left\{ I \subset \{i\}_1^m : |I| = \operatorname{rank}\begin{pmatrix} A \\ C \end{pmatrix} - \operatorname{rank}(C),\ \operatorname{rank}\begin{pmatrix} A_I \\ C \end{pmatrix} = \operatorname{rank}\begin{pmatrix} A \\ C \end{pmatrix} \right\}. \tag{1.4}$$

For an $n \times (m+k)$ matrix B, the norm of B as a linear mapping from $(\mathbb{R}^{m+k}, \|\cdot\|_\mu)$ to $(\mathbb{R}^n, \|\cdot\|_\nu)$ is defined as

$$\|B\|_{\mu,\nu} := \max\{\|By\|_\nu : y \in \mathbb{R}^{m+k}, \|y\|_\mu = 1\}.$$

Then the Lipschitz constant for F, ext F, S, ext S is given by the following formula:

$$\beta_{\mu,\nu}(A,C) := \max_{I \in \mathcal{M}(A,C)} \left\| \begin{pmatrix} A_{I,0} \\ C \end{pmatrix}^+ \right\|_{\mu,\nu}. \tag{1.5}$$

In general, ext $F\binom{b}{d}$ and ext $S\binom{b}{d}$ might be empty sets. Therefore, we consider the following submappings of F and S:

$$\begin{aligned} F_0\begin{pmatrix} b \\ d \end{pmatrix} &:= \{x \in \mathbb{R}^n : Ax \le b, Cx = d, Qx = 0\}, \\ S_0\begin{pmatrix} b \\ d \end{pmatrix} &= \{x \in \mathbb{R}^n : c^T x = c_{\min}(b,d), Ax \le b, Cx = d, Qx = 0\}, \end{aligned} \tag{1.6}$$

where Q is any matrix such that $QA^T = 0, QC^T = 0$, and rank $\begin{pmatrix} A \\ C \\ Q \end{pmatrix} = n$. Note that $x \in \text{ext } F_0\binom{b}{d}$ (i.e., x is a vertex of $F_0\binom{b}{d}$) if and only if $x \in F_0\binom{b}{d}$ and there exists $J \in \mathcal{M}(A,C)$ such that $A_J x = b_J$. When rank $\binom{A}{C} = n, x \in \text{ext } F\binom{b}{d}$ is called a basic feasible solution and $x \in \text{ext } S\binom{b}{d}$ is called a basic optimal solution.

A set-valued mapping (or multifunction) T from $(\mathbb{R}^{m+k}, \|\cdot\|_\mu)$ to the subsets of $(\mathbb{R}^n, \|\cdot\|_\nu)$ (i.e., $T(x) \subset \mathbb{R}^n$ for $x \in \mathbb{R}^{k+m}$) is said to be λ-Lipschitz continuous, denoted by $T \in \text{Lip}(\lambda)_{\mu,\nu}$, if

$$H(T(x),T(y))_\nu \le \lambda \cdot \|x - y\|_\mu \quad \text{for } x,y \in \mathbb{R}^{k+m}.$$

T is said to be locally upper Lipschitz continuous with modulo λ, denoted by $UL(\lambda)_{\mu,\nu}$ [30], if, for any $x \in \mathbb{R}^{k+m}$, there exists a neighborhood U of x such that

$$d(T(y),T(x))_\nu \le \lambda \cdot \|x - y\|_\mu \quad \text{for } y \in U.$$

T is Hausdorff lower semicontinuous if $\lim_{z \to x} d(T(x),T(z))_\nu = 0$. T is Hausdorff upper semicontinuous if $\lim_{z \to x} d(T(z),T(x))_\nu = 0$. T is Hausdorff continuous if T is both Hausdorff upper semicontinuous and Hausdorff lower semicontinuous (i.e., $\lim_{z \to x} H(T(z), T(x))_\nu = 0$). T_0 is said to a submapping of T if $T_0(x) \subset T(x)$ for all x.

2. Lipschitz constant and local upper Lipschitz constant. In this section, we first show that the local upper Lipschitz constant of a Hausdorff lower semicontinuous mapping is equal to the Lipschitz constant of the mapping. This property of set-valued mappings

allows us to use local Lipschitz constants for ext F_0 and ext F as global Lipschitz constants (cf. the proof of Lemma 3.3). Then we prove that the Lipschitz constant of a finite-set-valued mapping can be inherited by its continuous submappings. So it becomes clear that the Lipschitz constants for ext F_0 and ext F can be used as Lipschitz constants for ext S_0 and ext S (cf. Lemmas 3.7 and 3.8).

THEOREM 2.1. *If T is Hausdorff lower semicontinuous and $T \in UL(\lambda)_{\mu,\nu}$, then $T \in Lip(\lambda)_{\mu,\nu}$.*

Proof. Let $x, y \in \mathbb{R}^{k+m}$. Let $y_\theta = \theta y + (1-\theta)x$. Define

$$\theta^* = \sup\{\theta : d(T(y_\theta), T(x))_\nu \le \lambda \cdot \|y_\theta - x\|_\mu \text{ and } 0 \le \theta \le 1\}.$$

First we claim that

$$d(T(y_{\theta^*}), T(x))_\nu \le \lambda \cdot \|y_{\theta^*} - x\|_\mu. \tag{2.1}$$

In fact, there exists a sequence of scalars $\theta_1, \theta_2, \theta_3, \ldots$, such that

$$d(T(y_{\theta_\tau}), T(x))_\nu \le \lambda \cdot \|y_{\theta_\tau} - x\|_\mu \quad \text{and} \quad \lim_\tau \theta_\tau = \theta^*.$$

For any θ_τ, we have

$$\begin{aligned} d(T(y_{\theta^*}), T(x))_\nu &\le d(T(y_{\theta^*}), T(y_{\theta_\tau}))_\nu + d(T(y_{\theta_\tau}), T(x))_\nu \\ &\le d(T(y_{\theta^*}), T(y_{\theta_\tau}))_\nu + \lambda \cdot \|y_{\theta_\tau} - x\|_\mu, \end{aligned}$$

where the first inequality follows from the triangle inequality for upper Hausdorff metric. Since $y_{\theta_\tau} \to y_{\theta^*}$ as $\tau \to \infty$, by the Hausdorff lower semicontinuity of $T, d(T(y_{\theta^*}), T(y_{\theta_\tau}))_\nu \to 0$ as $\tau \to \infty$. Therefore,

$$\begin{aligned} d(T(y_{\theta^*}), T(x))_\nu &\le \lim_\tau [d(T(y_{\theta^*}), T(y_{\theta_\tau}))_\nu + \lambda \cdot \|y_{\theta_\tau} - x\|_\mu] \\ &= \lim_\tau \lambda \cdot \|y_{\theta_\tau} - x\|_\mu = \lambda \cdot \|y_{\theta^*} - x\|_\mu. \end{aligned}$$

This proves (2.1).

Now we claim that $\theta^* = 1$. In fact, since $T \in UL(\lambda)_{\mu,\nu}$, if $\theta^* < 1$, then there exists $\theta^* < \theta < 1$ such that

$$d(T(y_\theta), T(y_{\theta^*}))_\nu \le \lambda \cdot \|y_\theta - y_{\theta^*}\|_\mu. \tag{2.2}$$

It follows from (2.1) and (2.2) that

$$\begin{aligned} d(T(y_\theta), T(x))_\nu &\le d(T(y_\theta), T(y_{\theta^*}))_\nu + d(T(y_{\theta^*}), T(x))_\nu \\ &\le \lambda \cdot \|y_\theta - y_{\theta^*}\|_\mu + \lambda \cdot \|y_{\theta^*} - x\|_\mu \\ &= \lambda \cdot \|y_\theta - x\|_\mu, \end{aligned}$$

which contradicts the definition of θ^*. Since $\theta^* = 1$, (2.1) implies that $T \in Lip(\lambda)_{\mu,\nu}$. □

Remark. It follows from the proof of Theorem 2.1 that T is λ-Lipschitz continuous on any convex subset where T is Hausdorff lower semicontinuous. An immediate consequence of this observation is that the solutions of linear complementarity problem $(M, q(t))$, with $q(t) := (1-t)q^1 + tq^2$, are Lipschitz continuous for $0 \le t \le 1$ if they are Hausdorff lower semicontinuous for $0 \le t \le 1$. This is an improvement of Theorem 3.2 in [23]. Furthermore, it is known that polyhedral set-valued mappings are in $UL(\lambda)$ [30]. Thus, the Lipschitz continuity of such mappings is equivalent to their Hausdorff lower semicontinuity. Theorem 2.1 might also be useful to study general parametric programs with polyhedral structures [14].

Similarly, the following "dual form" of Theorem 2.1 also holds. We say that T is locally lower Lipschitz continuous with modulo λ, if, for any x, there exists a neighborhood U of x such that

$$d(T(x), T(y))_\nu \le \lambda \cdot \|x - y\|_\mu \quad \text{for } y \in U.$$

THEOREM 2.2. *If T is Hausdorff upper semicontinuous and T is locally lower Lipschitz continuous with modulo λ, then $T \in Lip(\lambda)_{\mu,\nu}$.*

Note that ext $S\binom{b}{d} \subset$ ext $F\binom{b}{d}$, and ext $F\binom{b}{d}$ is a finite set. In this case, the Lipschitz constant of ext F can be inherited by ext S. This is actually true for general set-valued mappings.

THEOREM 2.3. *Suppose that $T \in \mathrm{Lip}(\lambda)_{\mu,\nu}$ and $T(x)$ is a finite set for any x. If T_0 is a Hausdorff continuous submapping of T, then $T_0 \in \mathrm{Lip}(\lambda)_{\mu,\nu}$.*

Proof. Since $T \in Lip(\lambda)_{\mu,\nu}$ and $T_0(x) \subset T(x)$, we have

$$d(T_0(y), T(x))_\nu \le d(T(y), T(x))_\nu \le \lambda \cdot \|x - y\|_\mu \quad \text{for all } x, y. \tag{2.3}$$

Since T_0 is Hausdorff upper semicontinuous and $T(x)$ is a finite set, there exists a neighborhood U of x such that

$$d(T_0(y), T(x))_\nu = d(T_0(y), T_0(x))_\nu \quad \text{for } y \in U. \tag{2.4}$$

It follows from (2.3) and (2.4) that $T_0 \in UL(\lambda)_{\mu,\nu}$. Since T_0 is also Hausdorff lower semicontinuous, by Theorem 2.1, $T_0 \in \mathrm{Lip}(\lambda)_{\mu,\nu}$. □

Remark. The above theorem says that the Lipschitz constant of a finite-set-valued mapping can be inherited by its continuous submappings.

3. Lipschitz constants for basic feasible solutions and basic optimal solutions. The main results in this section are Theorems 3.4, 3.6, 3.9, and 3.10, which give the Lipschitz constants for ext F and ext S in terms of pseudoinverses. The Lipschitz constant for ext F and ext S in p-norms is extremely simple and most likely to be useful. The key technical result is Lemma 3.3, which gives a Lipschitz constant for ext F_0. All Lipschitz constants for ext F, ext S, F, and S are based on Lemma 3.3. As an application of Theorem 2.3, we prove that any Lipschitz constant for ext F_0 (or ext F) can be used as a Lipschitz constant for ext S_0 (or ext S) (cf. Lemmas 3.7 and 3.8). Lemma 3.5 is stated for deriving the Lipschitz constant for F and S in p-norms.

Before proving the key technical lemma, we need two auxiliary results. The first is the Lipschitz continuity of ext F_0 implicitly proved by Walkup and Wets [32], which is stated here for easy reference, and the second is an identity about pseudoinverses, which enables us to handle nonmonotone norm $\|\cdot\|_\mu$.

LEMMA 3.1. *If T is a convex polyhedral set-valued mapping (i.e., $\{(x, y) : y \in T(x)\}$ is a convex polyhedral set), then* ext T *is Lipschitz continuous. Specifically,* ext F_0 *is Lipschitz continuous.*

LEMMA 3.2. *Suppose that matrices B and E satisfy $BE = E$ and $B^T = B$. Then $E^+B = E^+$.*

Proof. By the Moore–Penrose conditions [10], we have $EE^+E = E, E^+EE^+ = E^+, (EE^+)^T = EE^+$, and $(E^+E)^T = E^+E$. Therefore,

$$\begin{aligned}
E(E^+B)E &= EE^+(BE) = EE^+E = E,\\
(E^+B)E(E^+B) &= E^+(BE)E^+B = (E^+EE^+)B = E^+B,\\
(E(E^+B))^T &= (BEE^+B)^T = B^T(EE^+)^TB^T = B(EE^+)B = E(E^+B),\\
((E^+B)E)^T &= (E^+E)^T = E^+E = (E^+B)E.
\end{aligned}$$

Thus, E^+B is also a pseudoinverse of E. Since the pseudoinverse is unique,

$$E^+ = E^+B. \qquad \square$$

LEMMA 3.3. *For any* $b, b' \in \mathbb{R}^m$ *and* $d, d' \in \mathbb{R}^k$,

$$H\left(\text{ext } F_0\begin{pmatrix} b' \\ d' \end{pmatrix}, \text{ext } F_0\begin{pmatrix} b \\ d \end{pmatrix}\right)_\nu \leq \beta_{\mu,\nu}(A, C) \left\| \begin{pmatrix} b' - b \\ d' - d \end{pmatrix} \right\|_\mu .$$

Proof. Let w be an extreme point of $F_0\binom{b}{d}$. Let I be the index set such that

$$A_I w = b_I \quad \text{and} \quad A_i w < b_i \quad \text{for } i \notin I. \tag{3.1}$$

It follows from (3.1) that there exists $\delta_w > 0$ such that if $\|x - w\|_\nu \leq \delta_w$ and $\|\binom{b-b'}{d-d'}\|_\mu \leq \delta_w$, then

$$A_i x < b'_i \quad \text{for } i \notin I. \tag{3.2}$$

Now let $U_w = \{\binom{b'}{d'} : \|\binom{b-b'}{d-d'}\|_\mu \leq \delta_w\}, V_w = \{x : \|x - w\|_\nu < \delta_w\}, \binom{b'}{d'} \in U_w$, and $z \in \text{ext } F_0\binom{b'}{d'} \cap V_w$. Since z is a vertex, there exists an index set $J \in \mathcal{M}(A, C)$ such that $A_J z = b'_J$. By (3.2), we know that $J \subset I$. Let $\mathcal{I}_0 = \text{diag}(\lambda_1, \ldots, \lambda_{k+m})$, where $\lambda_i = 0$ for $1 \leq i \leq m$ and $i \notin J$, and $\lambda_i = 1$, otherwise. Then, $z - w$ satisfies the following system of linear equations:

$$\begin{pmatrix} A_{J,0} \\ C \end{pmatrix}(w - z) = \mathcal{I}_0 \begin{pmatrix} b - b' \\ d - d' \end{pmatrix}. \tag{3.3}$$

Since $\text{rank} \begin{pmatrix} A_{J,0} \\ C \\ Q \end{pmatrix} = n$ and $AQ^T = 0, CQ^T = 0$, we know that $\mathcal{R}(Q^T)$ is the orthogonal complement of $\mathcal{R}\left(\binom{A_{J,0}}{C}^T\right)$ [10]. It follows from $Q(w - z) = 0$ that $w - z \in \mathcal{R}\left(\binom{A_{J,0}}{C}^T\right)$. Since $\binom{A_{J,0}}{C}^T\binom{A_{J,0}}{C}$ is the orthogonal projection to $\mathcal{R}\left(\binom{A_{J,0}}{C}^T\right)$ [10], we obtain

$$\begin{pmatrix} A_{J,0} \\ C \end{pmatrix}^+ \begin{pmatrix} A_{J,0} \\ C \end{pmatrix}(w - z) = (w - z). \tag{3.4}$$

By (3.3) and (3.4), we have

$$w - z = \begin{pmatrix} A_{J,0} \\ C \end{pmatrix}^+ \mathcal{I}_0 \begin{pmatrix} b - b' \\ d - d' \end{pmatrix}.$$

By $\mathcal{I}_0\binom{A_{J,0}}{C} = \binom{A_{J,0}}{C}, \mathcal{I}_0^T = \mathcal{I}_0$, and Lemma 3.2, we obtain

$$\begin{pmatrix} A_{J,0} \\ C \end{pmatrix}^+ \mathcal{I}_0 = \begin{pmatrix} A_{J,0} \\ C \end{pmatrix}^+. \tag{3.5}$$

Thus,

$$w - z = \begin{pmatrix} A_{J,0} \\ C \end{pmatrix}^+ \begin{pmatrix} b - b' \\ d - d' \end{pmatrix}, \tag{3.6}$$

which implies that

$$\|w - z\|_\nu \le \beta_{\mu,\nu}(A, C) \left\| \begin{pmatrix} b - b' \\ d - d' \end{pmatrix} \right\|_\mu . \tag{3.7}$$

Since ext F_0 is Hausdorff upper semicontinuous (cf. Lemma 3.1) and ext $F_0\binom{b}{d}$ is a finite set, by (3.7) there exists a neighborhood U of $\binom{b}{d}$ such that

$$d\left(\text{ext } F_0\begin{pmatrix} b' \\ d' \end{pmatrix}, \text{ext } F_0\begin{pmatrix} b \\ d \end{pmatrix}\right)_\nu \le \beta_{\mu,\nu}(A, C) \left\| \begin{pmatrix} b - b' \\ d - d' \end{pmatrix} \right\|_\mu \quad \text{for } \begin{pmatrix} b' \\ d' \end{pmatrix} \in U.$$

Thus, ext $F_0 \in UL(\beta_{\mu,\nu}(A, C))_{\mu,\nu}$. Since ext F_0 is Hausdorff lower semicontinuous (cf. Lemma 3.1), it follows from Theorem 2.1 that

$$H\left(\text{ext } F_0\begin{pmatrix} b' \\ d' \end{pmatrix}, \text{ext } F_0\begin{pmatrix} b \\ d \end{pmatrix}\right)_\nu \le \beta_{\mu,\nu}(A, C) \left\| \begin{pmatrix} b - b' \\ d - d' \end{pmatrix} \right\|_\mu . \qquad \square$$

Remark. If rank $\binom{A}{C} = n$, then ext $F_0\binom{b}{d} = \text{ext } F\binom{b}{d}$. Thus, an immediate consequence of Lemma 3.3 is the following estimate of the Lipschitz constant for ext F.

THEOREM 3.4. *If* rank $\binom{A}{C} = n$, *then*

$$H\left(\text{ext } F\begin{pmatrix} b \\ d \end{pmatrix}, \text{ext } F\begin{pmatrix} b' \\ d' \end{pmatrix}\right)_\nu \le \beta_{\mu,\nu}(A, C) \cdot \left\| \begin{pmatrix} b - b' \\ d - d' \end{pmatrix} \right\|_\mu , \tag{3.8}$$

i.e., ext $F \in Lip(\beta_{\mu,\nu}(A, C))_{\mu,\nu}$.

Remark. Note that, by ignoring the zero components, we can replace (3.6) by

$$w - z = \begin{pmatrix} A_J \\ C \end{pmatrix}^+ \begin{pmatrix} b_J - b'_J \\ d - d' \end{pmatrix}.$$

Therefore, for $1 \le p, q \le \infty$,

$$\|w - z\|_p \le \left\| \begin{pmatrix} A_J \\ C \end{pmatrix}^+ \right\|_{q,p} \left\| \begin{pmatrix} b_J - b'_J \\ d - d' \end{pmatrix} \right\|_q \le \beta^*_{q,p}(A, C) \cdot \left\| \begin{pmatrix} b - b' \\ d - d' \end{pmatrix} \right\|_q ,$$

where

$$\beta^*_{q,p}(A, C) := \max_{J \in \mathcal{M}(A,C)} \left\| \begin{pmatrix} A_J \\ C \end{pmatrix}^+ \right\|_{q,p} . \tag{3.9}$$

If C is row independent, then $\binom{A_J}{C}$ is also row independent, and

$$\begin{pmatrix} A_J \\ C \end{pmatrix}^+ = \begin{pmatrix} A_J \\ C \end{pmatrix}^T \left(\begin{pmatrix} A_J \\ C \end{pmatrix} \begin{pmatrix} A_J \\ C \end{pmatrix}^T \right)^{-1} .$$

Thus, the proof of Lemma 3.3 yields the following estimates of Lipschitz constants for ext F_0 in p-norm and q-norm.

LEMMA 3.5. *Let* $1 \le p, q \le \infty$. *If C is row independent, then*

$$H\left(\text{ext } F_0\begin{pmatrix} b' \\ d' \end{pmatrix}, \text{ext } F_0\begin{pmatrix} b \\ d \end{pmatrix}\right)_p \le \max_{J \in \mathcal{M}(A,C)} \left\| \begin{pmatrix} A_J \\ C \end{pmatrix}^T \left(\begin{pmatrix} A_J \\ C \end{pmatrix} \begin{pmatrix} A_J \\ C \end{pmatrix}^T \right)^{-1} \right\|_{q,p} \left\| \begin{pmatrix} b' - b \\ d' - d \end{pmatrix} \right\|_q .$$

Remark. We could verify that $\beta^*_{q,p}(A,C)$ defined in (3.9) is actually equal to $\beta_{q,p}(A,C)$ defined in (1.4) for $1 \le p,q \le \infty$ (cf. [18, Lem. 3.6]). When rank $\binom{A}{C} = n$ and C is row independent, then the pseudoinverse in (3.9) is the inverse.

THEOREM 3.6. *If* $1 \le p,q \le \infty$, *rank* $\binom{A}{C} = n$, *and* C *is row independent, then*

$$H\left(\text{ext } F\binom{b'}{d'}, \text{ext } F\binom{b}{d}\right)_p \le \max_{J\in\mathcal{M}(A,C)} \left\| \binom{A_J}{C}^{-1} \right\|_{q,p} \cdot \left\| \binom{b'-b}{d'-d} \right\|_q .$$

Note that, if $c = 0$, then $S = F$ and $S_0 = F_0$. Therefore, it seems that Lipschitz constants for ext S_0 and ext S with $c = 0$ yield Lipschitz constants for ext F_0 and ext F. However, it becomes apparent that Lipschitz constants for ext F_0 and ext F are also valid for ext S_0 and ext S.

LEMMA 3.7. *If* ext $F_0 \in Lip(\beta)_{\mu,\nu}$, *then* ext $S_0 \in Lip(\beta)_{\mu,\nu}$.

Proof. It is well known that ext $S_0\binom{b}{d} \subset$ ext $F_0\binom{b}{d}$ for all b,d (i.e., basic optimal solutions are basic feasible solutions). Since $c_{\min}(b,d)$ is a continuous function of b,d, by Lemma 3.1, ext S_0 is a continuous mapping. Note that ext $F_0\binom{b}{d}$ is a finite set for any b,d. Therefore, the above lemma is a consequence of Theorem 2.3. □

LEMMA 3.8. *If* rank $\binom{A}{C} = n$ *and* ext $F \in Lip(\beta)_{\mu,\nu}$, *then* ext $S \in Lip(\beta)_{\mu,\nu}$.

Remark. The above lemma shows that any Lipschitz constant for ext F works for ext S. Thus, the following two theorems are consequences of Lemma 3.8, and Theorems 3.4 and 3.6.

THEOREM 3.9. *If* rank $\binom{A}{C} = n$, *then*

$$H\left(\text{ext } S\binom{b}{d}, \text{ext } S\binom{b'}{d'}\right)_\nu \le \beta_{\mu,\nu}(A,C) \cdot \left\| \binom{b-b'}{d-d'} \right\|_\mu .$$

THEOREM 3.10. *If* $1 \le p,q \le \infty$, rank $\binom{A}{C} = n$, *and* C *is row independent, then*

$$H\left(\text{ext } S\binom{b'}{d'}, \text{ext } S\binom{b}{d}\right)_p \le \max_{J\in\mathcal{M}(A,C)} \left\| \binom{A_J}{C}^{-1} \right\|_{q,p} \cdot \left\| \binom{b'-b}{d'-d} \right\|_q .$$

4. Lipschitz constants for feasible and optimal solutions. It is well known that any convex polyhedral set can be represented as a convex hull of a finite set and a convex recession cone [15], [31]. The first two lemmas in this section give representations of $F\binom{b}{d}$ and $S\binom{b}{d}$ as a convex hull of a finite set and a convex recession cone in algebraic form. Then we show that the Hausdorff distance of two sets $\text{conv}(X) + K$ and $\text{conv}(Y) + K$ is bounded by the Hausdorff distance of X and Y. This result, together with Lemmas 4.1 and 4.2, implies that the Lipschitz constant for ext F_0 and ext S_0 are also valid for F and S. Therefore, we obtain various Lipschitz constants for F and S from the Lipschitz constants for ext F_0 given in §3.

LEMMA 4.1. *Let* $K := \{x : Ax \le 0, Cx = 0\}$. *Then*

$$F\binom{b}{d} = \text{conv}\left(\text{ext } F_0\binom{b}{d}\right) + K. \tag{4.1}$$

Proof. In fact, it is easy to see that $F\binom{b}{d} \supset \text{conv}\left(\text{ext } F_0\binom{b}{d}\right) + K$. Since $F\binom{b}{d} \subset F_0\binom{b}{d} + K$, it suffices to show that

$$F_0\binom{b}{d} \subset \text{conv}\left(\text{ext } F_0\binom{b}{d}\right) + K.$$

Since $F_0\binom{b}{d}$ contains no line, it can be generated by its extreme points and extreme rays [15]. Therefore, it suffices to show that any extreme ray $\ell := \{z + \lambda p : \lambda \geq 0\}$ is a subset of ext $F_0\binom{b}{d} + K$. In fact, $z \in$ ext $F_0\binom{b}{d}$. $A(z + \lambda p) \leq b$ and $C(z + \lambda p) = d$, for $\lambda \geq 0$, imply $Ap \leq 0$ and $Cp = 0$ (i.e., $p \in K$). Thus, $\ell \subset$ ext $F_0\binom{b}{d} + K$. □

Replacing C by $\binom{C}{c^T}$ in the above lemma, we obtain the following relation between ext S_0 and S.

LEMMA 4.2. *Let* $K := \{x : Ax \leq 0, Cx = 0, c^T x = 0\}$. *Then*

$$S\binom{b}{d} = \text{conv}\left(\text{ext } S_0\binom{b}{d}\right) + K. \tag{4.2}$$

LEMMA 4.3. *Let X,Y,K be closed subsets of* $\mathbb{R}^n$. *Then* $H(\text{conv}(X) + K, \text{conv}(Y) + K)_\nu \leq H(X, Y)_\nu$.

Proof. Let $u \in \text{conv}(X) + K$. Then there exist $\{x^i\}_1^t \subset X, z \in K$, and $\theta_i > 0$ for $1 \leq i \leq t$, such that $\sum_{i=1}^t \theta_i = 1$ and $u = z + \sum_{i=1}^t \theta_i x^i$. Let $\{y^i\}_1^t \subset Y$ be such that $d(x^i, Y)_\nu = \|x^i - y^i\|_\nu$ for $1 \leq i \leq t$. Then $v := z + \sum_{i=1}^t \theta_i x^i \in \text{conv}(Y) + K$ and

$$d(u, \text{conv}(Y) + K)_\nu \leq \|u - v\|_\nu \leq \sum_{i=1}^t \theta_i \cdot \|x^i - y^i\|_\nu \leq d(X, Y)_\nu.$$

Therefore, d(conv$(X) + K$, conv$(Y) + K)_\nu \leq d(X, Y)_\nu$. Similarly, d(conv$(Y) + K$, conv$(X) + K)_\nu \leq d(Y, X)_\nu$. □

Remark. The above three lemmas are algebraic versions of well-known results about convex sets. We include the proofs here for the convenience of readers. Particularly, Lemma 4.3 can be found in the proof of the main result in [32].

Now, by Lemmas 4.1–4.3, and 3.7, it is easy to see that the Lipschitz constant for ext F_0 can be used as a Lipschitz constant for F and S.

THEOREM 4.4. *If* ext $F_0 \in Lip(\beta)_{\mu,\nu}$, *then* $F, S \in Lip(\beta)_{\mu,\nu}$.

Therefore, we have the following error estimates for F and S, which are consequences of Theorem 4.4 and Lemmas 3.3, 3.5, and 3.6.

COROLLARY 4.5. *For any* $b, b' \in \mathbb{R}^m$ *and* $d, d' \in \mathbb{R}^k$,

$$H\left(F\binom{b}{d}, F\binom{b'}{d'}\right)_\nu \leq \beta_{\mu,\nu}(A, C) \cdot \left\| \binom{b - b'}{d - d'} \right\|_\mu.$$

COROLLARY 4.6. *If* $1 \leq p, q \leq \infty$ *and C is row independent, then*

$$H\left(F\binom{b'}{d'}, F\binom{b}{d}\right)_p \leq \max_{J \in \mathcal{M}(A,C)} \left\| \binom{A_J}{C}^T \left(\binom{A_J}{C} \binom{A_J}{C}^T \right)^{-1} \right\|_{q,p} \cdot \left\| \binom{b' - b}{d' - d} \right\|_q.$$

COROLLARY 4.7. *If* $1 \leq p, q \leq \infty$, rank $\binom{A}{C} = n$, *and C is row independent, then*

$$H\left(F\binom{b'}{d'}, F\binom{b}{d}\right)_p \leq \max_{J \in \mathcal{M}(A,C)} \left\| \binom{A_J}{C}^{-1} \right\|_{q,p} \cdot \left\| \binom{b' - b}{d' - d} \right\|_q.$$

COROLLARY 4.8. *For any* $b, b' \in \mathbb{R}^m$ *and* $d, d' \in \mathbb{R}^k$,

$$H\left(S\binom{b}{d}, S\binom{b'}{d'}\right)_\nu \leq \beta_{\mu,\nu}(A, C) \cdot \left\| \binom{b - b'}{d - d'} \right\|_\mu.$$

COROLLARY 4.9. *If* $1 \le p, q \le \infty$ *and* C *is row independent, then*

$$H\left(S\begin{pmatrix}b'\\d'\end{pmatrix}, S\begin{pmatrix}b\\d\end{pmatrix}\right)_p \le \max_{J\in\mathcal{M}(A,C)} \left\| \begin{pmatrix}A_J\\C\end{pmatrix}^T \left(\begin{pmatrix}A_J\\C\end{pmatrix}\begin{pmatrix}A_J\\C\end{pmatrix}^T\right)^{-1} \right\|_{q,p} \cdot \left\| \begin{pmatrix}b'-b\\d'-d\end{pmatrix} \right\|_q.$$

COROLLARY 4.10. *If* $1 \le p, q \le \infty$, rank $\begin{pmatrix}A\\C\end{pmatrix} = n$, *and* C *is row independent, then*

$$H\left(S\begin{pmatrix}b'\\d'\end{pmatrix}, S\begin{pmatrix}b\\d\end{pmatrix}\right)_p \le \max_{J\in\mathcal{M}(A,C)} \left\| \begin{pmatrix}A_J\\C\end{pmatrix}^{-1} \right\|_{q,p} \cdot \left\| \begin{pmatrix}b'-b\\d'-d\end{pmatrix} \right\|_q.$$

5. Sharpness of Lipschitz constants and comparison with known results. In this section, we first show that the Lipschitz constant for ext F and ext S is sharp under very general assumptions. Then we point out that the Lipschitz constants for F and S given in §4 can be improved.

THEOREM 5.1. *If* rank $\begin{pmatrix}A\\C\end{pmatrix} = n$, C *is row independent, and* $\|\cdot\|_\mu$ *is a monotone norm, then there exist* $\begin{pmatrix}b\\d\end{pmatrix}$ *and* $\begin{pmatrix}b'\\d'\end{pmatrix}$ *such that*

$$H\left(\text{ext } F\begin{pmatrix}b\\d\end{pmatrix}, \text{ext } F\begin{pmatrix}b'\\d'\end{pmatrix}\right)_\nu = \beta_{\mu,\nu}(A,C)\cdot \left\| \begin{pmatrix}b-b'\\d-d'\end{pmatrix} \right\|_\mu > 0, \tag{5.1}$$

i.e., $\beta_{\mu,\nu}(A,C)$ *is the sharp Lipschitz constant for* ext F.

Proof. Let $A_{J,0}$ be such that rank $\begin{pmatrix}A_{J,0}\\C\end{pmatrix} = n$ and

$$\beta_{\mu,\nu}(A,C) = \left\| \begin{pmatrix}A_{J,0}\\C\end{pmatrix}^+ \right\|_{\mu,\nu}.$$

Let $\bar{b} \in \mathbb{R}^m$ and $\bar{d} \in \mathbb{R}^k$ be such that

$$\left\| \begin{pmatrix}A_{J,0}\\C\end{pmatrix}^+ \begin{pmatrix}\bar{b}\\\bar{d}\end{pmatrix} \right\|_\nu = \left\| \begin{pmatrix}A_{J,0}\\C\end{pmatrix}^+ \right\|_{\mu,\nu} \cdot \left\| \begin{pmatrix}\bar{b}\\\bar{d}\end{pmatrix} \right\|_\mu = \beta_{\mu,\nu}(A,C)\cdot \left\| \begin{pmatrix}\bar{b}\\\bar{d}\end{pmatrix} \right\|_\mu > 0. \tag{5.2}$$

Since $\begin{pmatrix}A_{J,0}\\C\end{pmatrix}$ has full column rank,

$$\begin{pmatrix}A_{J,0}\\C\end{pmatrix}^+ = \left(\begin{pmatrix}A_{J,0}\\C\end{pmatrix}^T \begin{pmatrix}A_{J,0}\\C\end{pmatrix}\right)^{-1} \begin{pmatrix}A_{J,0}\\C\end{pmatrix}^T.$$

Let $\mathcal{I}_0 := \text{diag}(\lambda_1, \ldots, \lambda_{m+k})$, where $\lambda_i = 0$ for $1 \le i \le m, i \notin J$, and $\lambda_i = 1$, otherwise. Then

$$\mathcal{R}\left(\left(\begin{pmatrix}A_{J,0}\\C\end{pmatrix}^+\right)^T\right) = \mathcal{R}\left(\begin{pmatrix}A_{J,0}\\C\end{pmatrix}\left(\begin{pmatrix}A_{J,0}\\C\end{pmatrix}^T \begin{pmatrix}A_{J,0}\\C\end{pmatrix}\right)^{-1}\right) = \mathcal{R}\begin{pmatrix}A_{J,0}\\C\end{pmatrix} = \mathcal{R}(\mathcal{I}_0),$$

where the last equality follows from the fact that the rank of $\begin{pmatrix}A_{J,0}\\C\end{pmatrix}$ is equal to the number of nonzero rows of $\begin{pmatrix}A_{J,0}\\C\end{pmatrix}$. Since $\begin{pmatrix}A_{J,0}\\C\end{pmatrix}\begin{pmatrix}A_{J,0}\\C\end{pmatrix}^+$ is the orthogonal projection onto

$$\mathcal{R}\left(\left(\begin{pmatrix}A_{J,0}\\C\end{pmatrix}^+\right)^T\right) = \mathcal{R}(\mathcal{I}_0)$$

[10], we have

$$\begin{pmatrix}A_{J,0}\\C\end{pmatrix}\begin{pmatrix}A_{J,0}\\C\end{pmatrix}^+ \mathcal{I}_0 = \mathcal{I}_0.$$

However, $\binom{A_{J,0}}{C}^+ \mathcal{I}_0 = \binom{A_{J,0}}{C}^+$ (cf. (3.5)). Therefore,

$$\begin{pmatrix} A_{J,0} \\ C \end{pmatrix} \begin{pmatrix} A_{J,0} \\ C \end{pmatrix}^+ = \mathcal{I}_0,$$

which implies that

$$\left\| \begin{pmatrix} A_{J,0} \\ C \end{pmatrix} \begin{pmatrix} A_{J,0} \\ C \end{pmatrix}^+ \begin{pmatrix} \bar{b} \\ \bar{d} \end{pmatrix} \right\|_\mu = \left\| \mathcal{I}_0 \begin{pmatrix} \bar{b} \\ \bar{d} \end{pmatrix} \right\|_\mu \le \left\| \begin{pmatrix} \bar{b} \\ \bar{d} \end{pmatrix} \right\|_\mu, \tag{5.3}$$

where the last inequality follows from the monotonicity of $\|\cdot\|_\mu$.

Let $b_i^* := 0$ for $i \in J$ and $b_i^* := |(A\binom{A_{J,0}}{C}^+ \binom{\bar{b}}{\bar{d}})_i| + 1$ for $i \notin J$. Let

$$b_\theta := \theta \cdot A_{J,0} \begin{pmatrix} A_{J,0} \\ C \end{pmatrix}^+ \begin{pmatrix} \bar{b} \\ \bar{d} \end{pmatrix} + b^*, \quad d_\theta := \theta \cdot C \begin{pmatrix} A_{J,0} \\ C \end{pmatrix}^+ \begin{pmatrix} \bar{b} \\ \bar{d} \end{pmatrix},$$
$$x_\theta := \theta \cdot \begin{pmatrix} A_{J,0} \\ C \end{pmatrix}^+ \begin{pmatrix} \bar{b} \\ \bar{d} \end{pmatrix}.$$

Consider the following system:

$$Ax \le b_\theta, \qquad Cx = d_\theta. \tag{5.4}$$

Note that x_θ is a vertex of the solution set of the above system, and $(Ax_\theta)_i < (b_\theta)_i$ for $i \notin J$ and $0 \le \theta \le 1$. If $\theta > 0$ is small enough, then x_0 is the vertex of the solution set of (5.4) for $\theta = 0$ that is closest to x_θ. Therefore, for $\theta > 0$ small enough,

$$\begin{aligned} H\left(\text{ext } F\begin{pmatrix} b_\theta \\ d_\theta \end{pmatrix}, \text{ext } F\begin{pmatrix} b_0 \\ d_0 \end{pmatrix}\right)_\nu &\ge d\left(x_\theta, \text{ext } F\begin{pmatrix} b_0 \\ d_0 \end{pmatrix}\right)_\nu = \|x_\theta - x_0\|_\nu \\ &= \theta \cdot \left\| \begin{pmatrix} A_{J,0} \\ C \end{pmatrix}^+ \begin{pmatrix} \bar{b} \\ \bar{d} \end{pmatrix} \right\|_\nu = \theta \cdot \beta_{\mu,\nu}(A,C) \cdot \left\| \begin{pmatrix} \bar{b} \\ \bar{d} \end{pmatrix} \right\|_\mu \\ &\ge \beta_{\mu,\nu}(A,C) \cdot \theta \cdot \left\| \begin{pmatrix} A_{J,0} \\ C \end{pmatrix} \begin{pmatrix} A_{J,0} \\ C \end{pmatrix}^+ \begin{pmatrix} \bar{b} \\ \bar{d} \end{pmatrix} \right\|_\mu \\ &= \beta_{\mu,\nu}(A,C) \cdot \left\| \begin{pmatrix} b_\theta - b_0 \\ d_\theta - d_0 \end{pmatrix} \right\|_\mu > 0, \end{aligned}$$

where the second inequality follows from (5.3) and the first equality follows from (5.2). Therefore, $\beta_{\mu,\nu}(A,C)$ is the sharp Lipschitz constant for ext F. □

Similarly, the Lipschitz constant for ext F given in Theorem 3.6 is also sharp. We leave the details for interested readers (cf. the remarks after Lemma 3.5).

THEOREM 5.2. *If* rank $\binom{A}{C} = n$, *C is row independent, and* $1 \le p, q \le \infty$, *then there exist* $\binom{b}{d}$ *and* $\binom{b'}{d'}$ *such that*

$$H\left(\text{ext } F\begin{pmatrix} b \\ d \end{pmatrix}, \text{ext } F\begin{pmatrix} b' \\ d' \end{pmatrix}\right)_p = \max_{J \in \mathcal{M}(A,C)} \left\| \begin{pmatrix} A_J \\ C \end{pmatrix}^{-1} \right\|_{q,p} \cdot \left\| \begin{pmatrix} b - b' \\ d - d' \end{pmatrix} \right\|_q > 0.$$

However, the Lipschitz constants for F and S given in §4 can be improved. In fact, we have the following sharp Lipschitz constants for F and S [18].

LEMMA 5.3. *For any* $b, b' \in \mathbb{R}^m, d, d' \in \mathbb{R}^k$,

$$H\left(F\begin{pmatrix} b \\ d \end{pmatrix}, F\begin{pmatrix} b' \\ d' \end{pmatrix}\right)_\nu \le \alpha_{\mu,\nu}(A,C)\cdot \left\| \begin{pmatrix} b-b' \\ d-d' \end{pmatrix} \right\|_\mu,$$

where $K_J := \{x \in \mathbb{R}^n : A_{J,0}x \le 0, Cx = 0\}$ *and*

$$\alpha_{\mu,\nu}(A,C) := \max_{J\in\mathcal{M}(A,C)} \sup\left\{ d\left(\begin{pmatrix} A_{J,0} \\ C \end{pmatrix}^+ \begin{pmatrix} u \\ v \end{pmatrix}, K_J\right)_\nu : \left\| \begin{pmatrix} u \\ v \end{pmatrix} \right\|_\mu = 1 \right\}. \tag{5.5}$$

LEMMA 5.4. *For any* $b, b' \in \mathbb{R}^m, d, d' \in \mathbb{R}^k$,

$$H\left(S\begin{pmatrix} b \\ d \end{pmatrix}, S\begin{pmatrix} b' \\ d' \end{pmatrix}\right)_\nu \le \gamma_{\mu,\nu}(A,C)\cdot \left\| \begin{pmatrix} b-b' \\ d-d' \end{pmatrix} \right\|_\mu,$$

where $G := \{x \in \mathbb{R}^n : Ax = 0, Cx = 0\}$ *and*

$$\gamma_{\mu,\nu}(A,C) := \max_{J\in\mathcal{M}(A,C)} \sup\left\{ d\left(\begin{pmatrix} A_{J,0} \\ C \end{pmatrix}^+ \begin{pmatrix} u \\ v \end{pmatrix}, G\right)_\nu : \left\| \begin{pmatrix} u \\ v \end{pmatrix} \right\|_\mu = 1 \right\}. \tag{5.6}$$

Since $\{0\} \subset G \subset K_J$ and $G = \{0\}$ when $\dim \begin{pmatrix} A \\ C \end{pmatrix} = n$, it is easy to see that the following relation holds among $\gamma_{\mu,\nu}(A,C), \beta_{\mu,\nu}(A,C)$, and $\alpha_{\mu,\nu}(A,C)$.

LEMMA 5.5. $\alpha_{\mu,\nu}(A,C) \le \gamma_{\mu,\nu}(A,C) \le \beta_{\mu,\nu}(A,C)$. *Moreover,* $\gamma_{\mu,\nu}(A,C) = \beta_{\mu,\nu}(A,C)$, *if* $\dim \begin{pmatrix} A \\ C \end{pmatrix} = n$.

Let $\|x\|_{\nu^*} := \sup\{x^T y : y \in \mathbb{R}^n, \|y\|_\nu = 1\}$ denote the dual norm of $\|\cdot\|_\nu$. Then we have the following dual representations of $\alpha_{\mu,\nu}(A,C)$ and $\gamma_{\mu,\nu}(A,C)$ [18].

LEMMA 5.6. *If C is row independent, then*

$$\alpha_{\mu,\nu}(A,C) = \sup\left\{ \left\| \begin{pmatrix} u \\ v \end{pmatrix} \right\|_{\mu^*} : \begin{array}{l} \|A^T u + C^T v\|_{\nu^*} = 1, u \ge 0, \textit{ the rows of } A \\ \textit{corresponding to nonzero components of } u \\ \textit{and the rows of } C \textit{ are linearly independent} \end{array} \right\}, \tag{5.7}$$

$$\gamma_{\mu,\nu}(A,C) = \sup\left\{ \left\| \begin{pmatrix} u \\ v \end{pmatrix} \right\|_{\mu^*} : \begin{array}{l} \|A^T u + C^T v\|_{\nu^*} = 1, \textit{ the rows of } A \\ \textit{corresponding to nonzero components of } u \\ \textit{and the rows of } C \textit{ are linearly independent} \end{array} \right\}. \tag{5.8}$$

Remark. Similar Lipschitz constants, such as those given on the right-hand sides of (5.7) and (5.8), were first given by Mangasarian and Shiau [23]. When C is row independent and $\|\cdot\|_\nu \equiv \|\cdot\|_\infty$, they proved that $F \in Lip(\alpha^*_{\mu,\nu}(A,C))_{\mu,\nu}$, where

$$\alpha^*_{\mu,\nu}(A,C) := \sup\left\{ \left\| \begin{pmatrix} u \\ v \end{pmatrix} \right\|_{\mu^*} : \begin{array}{l} \|A^T u + C^T v\|_{\nu^*} = 1, u \ge 0, \text{ the rows of} \\ \begin{pmatrix} A \\ C \end{pmatrix} \text{ corresponding to nonzero components} \\ \text{of } \begin{pmatrix} u \\ v \end{pmatrix} \text{ are linearly independent} \end{array} \right\}.$$

When C is row independent, $\|\cdot\|_\nu \equiv \|\cdot\|_\infty$, and $\|\cdot\|_\mu$ is a monotone norm, they proved that $S \in Lip(\gamma^*_{\mu,\nu}(A,C))_{\mu,\nu}$, where

$$\gamma^*_{\mu,\nu}(A,C) := \sup\left\{ \left\| \begin{pmatrix} u \\ v \end{pmatrix} \right\|_{\mu^*} : \begin{array}{l} \|A^T u + C^T v\|_{\nu^*} = 1, \text{ the rows of} \\ \begin{pmatrix} A \\ C \end{pmatrix} \text{ corresponding to nonzero components} \\ \text{of } \begin{pmatrix} u \\ v \end{pmatrix} \text{ are linearly independent} \end{array} \right\}.$$

It is easy to see that $\gamma_{\mu,\nu}(A,C) \le \gamma^*_{\mu,\nu}(A,C)$ and $\alpha_{\mu,\nu}(A,C) \le \alpha^*_{\mu,\nu}(A,C)$. Also, it was shown in [18] that

$$\lim_{\epsilon\to 0+} \frac{\gamma^*_{\mu,\nu}(A_\epsilon,C)}{\gamma_{\mu,\nu}(A_\epsilon,C)} = +\infty \quad \text{and} \quad \lim_{\epsilon\to 0+} \frac{\alpha^*_{\mu,\nu}(A_\epsilon,C)}{\alpha_{\mu,\nu}(A_\epsilon,C)} = +\infty,$$

where $A_\epsilon = \begin{pmatrix} 1 & 0 \\ -1 & \epsilon \end{pmatrix}$ and $C = (0\ \ 1)$. Therefore, Lemmas 5.3 and 5.4 are improvements of Mangasarian and Shiau's results.

6. Conclusion and remarks. In this paper, the sharp Lipschitz constant for ext F is given in terms of norms of pseudoinverses of submatrices of $\binom{A}{C}$. In particular, the sharp Lipschitz constant for ext F in p-norms is given as the maximum norm of $n\times n$ nonsingular matrices of the form $\binom{A_J}{C}$. If rank $\binom{A}{C} = n$, then any Lipschitz constant for ext F can be used as Lipschitz constants for ext S, F, and S. In general, the local upper Lipschitz constant of a Hausdorff lower semicontinuous mapping is equal to the Lipschitz constant of the mapping, and the Lipschitz constant of a finite-set-valued mapping can be inherited by its continuous submappings.

There is an interesting application of Lipschitz constants for F. Consider $Q(t) := \{x \in \mathbb{R}^n : c^T x = t, Ax \le b, Cx = d\}$. Then $Q(c_{\min}(b,d)) = S\binom{b}{d}$ and $x \in Q(t)$, if $t = c^T x$ and $x \in F\binom{b}{d}$. Therefore, by applying Corollary 4.5 to Q, we establish that there exists a constant $\beta > 0$, depending on A, C, c, such that

$$d\left(x, S\begin{pmatrix} b \\ d \end{pmatrix}\right)_2 \le \beta \cdot (c^T x - c_{\min}(b,d)) \quad \text{for } x \in F\begin{pmatrix} b \\ d \end{pmatrix}, \tag{6.1}$$

which is Mangasarian and Meyer's result on the weak sharp minimum of linear programs [22]. Also it is easy to verify that

$$c^T x - c_{\min}(b,d) \le \|c\|_2 \cdot d\left(x, S\begin{pmatrix} b \\ d \end{pmatrix}\right)_2 \quad \text{for } x \in F\begin{pmatrix} b \\ d \end{pmatrix}.$$

Therefore,

$$d\left(x, S\begin{pmatrix} b \\ d \end{pmatrix}\right)_2 \le \beta \cdot (c^T x - c_{\min}(b,c)) \le \beta \cdot \|c\|_2 \cdot d\left(x, S\begin{pmatrix} b \\ d \end{pmatrix}\right)_2 \quad \text{for } x \in F\begin{pmatrix} b \\ d \end{pmatrix}.$$

If $\beta\|c\|_2$ is close to 1, then $c^T x - c_{\min}(b,d)$ is a fair measurement of the distance of a feasible point x to the solution set. Jittorntrum and Osborne proved in [13] and [25] that (6.1) holds if $S\binom{b}{d}$ is a singleton. Equation (6.1) is due to Mangasarian and Meyer [22], and is referred to as strong uniqueness in [13], [25], [26], and [17], as well as (weak) sharp minima in [27], [6], and [7]. Equation (6.1) is closely related to the strong uniqueness concept in approximation theory. For references on strong uniqueness in approximation theory, see [3], [5], [24], and [16].

Another related problem concerns Lipschitz constants for solutions of a system of nonlinear inequalities and equalities. See [29], [20], and [1] for relevant results and references. It would be interesting to know whether or not one could obtain Lipschitz constants for extreme points of solution sets of nonlinear systems.

A RELAXATION APPROACH APPLIED TO DOMAIN OPTIMIZATION*

R. B. GONZÁLEZ DE PAZ†

Abstract. A domain optimization problem related to potential theory is studied by means of a relaxation approach where a concave functional on a given convex set is defined. The functional has a minimizing point that is the characteristic function of an optimal domain. As a consequence of the necessary conditions of optimality, the domain is the solution of a free boundary value problem.

Key words. optimal design, optimal control, free boundary value problems, distributed parameter systems

AMS subject classifications. 49A22, 49B22, 35R35

1. Introduction. The mathematical aspects of the optimal design theory have been the subject of intensive research during the last decade. In its general setting, a functional which depends on a variable domain is given, and we consider its minimization on a certain class of feasible domains. To date, two main theoretical aspects have been studied. One problem concerns the existence of optimal domains. Here the main approach lies in the variational calculus framework, where a topology is defined so that the set of feasible domains is compact and the domain functional is lower semicontinuous. Some particular cases have been solved (cf. Chenais [11], Gonzalez de Paz [16], [17]), but others have been treated using some classes of "generalized domains" (cf. Murat and Tartar [22]).

The other main problem has been how to adapt differential calculus techniques in order to obtain some kind of gradient of the domain functional (cf. Cea [9], Pironneau [25], Simon [26], Zolesio [30]). However, to date, results achieved in both directions do not have a unified perspective. This work presents an approach that unifies the solution for both problems in a special case by means of a relaxation technique. We consider the problem in which we denote by Ω a domain in $\mathbb{R}^2$ that we assume to be doubly connected. We denote by Γ_0 and Γ the interior and exterior boundary of the domain Ω and by Ω_0 the domain bounded by Γ_0.

It is well known that for this case, the classical capacity problem is reduced to finding a potential function u_Ω such that:

$$\Delta u_\Omega = 0 \quad \text{in } \Omega, \tag{1.1}$$

$$u_\Omega = 0 \quad \text{on } \Gamma, \tag{1.2}$$

$$u_\Omega = 1 \quad \text{on } \Gamma_0. \tag{1.3}$$

The capacity of the domain Ω_0 related to Ω, noted $\mathrm{Cap}_\Omega(\Omega_0)$, is given by

$$\mathrm{Cap}_\Omega(\Omega_0) = \int_\Omega |\nabla u_\Omega|^2 \, d\omega.$$

Let us assume that the boundary Γ_0 and the following isoperimetric condition are given:

$$\text{meas } \Omega = A, \tag{1.4}$$

where A is a positive constant. We look for the shape of Ω such that $\mathrm{Cap}_\Omega(\Omega_0)$, the capacity of Ω_0 related to Ω, is minimized. Among others, this problem has been studied by Acker [1] and Aguilera, Alt, and Cafarelli [2].

We remark that by minimizing the functional

$$v \to J(v) = \int_{\Omega} |\nabla v|^2 \, d\omega$$

on a suitable function space, we obtain a solution for the problem (1.1)–(1.3). For the corresponding solution u_Ω we have

$$J(u_\Omega) = \int_{\Omega} |\nabla u_\Omega|^2 \, d\omega = \operatorname{Cap}_\Omega(\Omega_0).$$

Using this property, we define a new "relaxed" problem so that, by applying some convex analysis techniques, we prove the existence of the optimal domain Ω. In fact, the relaxed problem leads to the minimization of a concave function on a convex set of functions. The concavity structure will allow us to prove that there exists a characteristic function where the minimum is attained. This approach is similar to the one used by Gonzalez de Paz [17] for the study of the existence of a domain with minimal capacity when the interior boundary is unknown. The results presented were announced in [15]. In [16] a similar approach is applied to study the optimal design of elastic shafts.

Furthermore, we are able to calculate the derivative of the relaxed functional and, under certain regularity properties, we show that it is equivalent to the derivative given by other authors (cf. Simon [26], Pironneau [25], Zolesio [30]). It is worth remarking that the optimal domain solves a free boundary value problem treated by several authors (cf. Alt and Cafarelli [3], Acker [1]).

2. The relaxed problem. Let Ω_0 be a connected, bounded domain in $\mathbb{R}^2$, star-shaped related to the origin, with Lebesgue measure A_0 and boundary Γ_0 that is Lipschitz continuous. Let B_R be an open disc with center at some point in the interior of Ω_0. To allow for the feasible domains to be contained in the disc, we choose the radius R large enough so that for $d = \operatorname{dist}(\partial B_R, \Gamma_0)$, the annulus with outer boundary ∂B_R and width d has an area greater than the given constant A, and we put $D_R = B_R \backslash \overline{\Omega}_0$ and denote by $\|\|$ the usual L^2-norm in B_R. Furthermore, let μ be a nonegative function such that

$$0 \le \mu \le 1 \quad \text{almost everywhere in } B_R, \tag{2.1}$$

$$\int_{B_R} \mu \, d\omega = A_0 + A, \tag{2.2}$$

$$\int_{\Omega_0} \mu \, d\omega = A_0. \tag{2.3}$$

Here, $d\omega$ denotes the usual Lebesgue measure in $\mathbb{R}^2$. We remark also that the constraints (2.2) and (2.3) are equivalent to

$$\mu = 1 \quad \text{almost everywhere on } \Omega_0 \tag{2.2a}$$

and

$$\int_{D_R} \mu \, d\omega = A. \tag{2.3a}$$

Let $L^\infty(B_R)^+$ be the set of the nonnegative, bounded functions on B_R. We denote by C the convex subset of $L^\infty(B_R)^+$ defined by the constraints (2.1), (2.2), and (2.3).

Following the definitions introduced by Kinderlehrer and Stampacchia [20], we put

$$K_R = (v | v \in H_0^1(B_R), v \geq 1 \text{ on } \Omega_0);$$

here $H_0^1(B_R)$ denotes the usual Sobolev space, i.e., the completion of $C_0^\infty(B_R)$ related to the H^1-norm, which is defined by the application $u \to \|u\|^2 + \|\nabla u\|^2$ (cf. Neças [24]). Furthermore, the inequality $v \geq 1$ on Ω_0 must be understood in the sense of H^1, i.e., there exists a sequence of Lipschitz functions $(u_n) \subset \text{Lip}(B_R)$ such that

$$u_n \geq 1 \quad \text{on } \Omega_0$$

and

$$u_n \to v \quad \text{strongly in } H^1$$

(cf., for example, Kinderlehrer and Stampacchia [20]).

For a fixed $\mu \in L^\infty(B_R)^+$ and a fixed constant $\epsilon > 0$, we now define on the Sobolev space $H_0^1(B_R)$ the functional

$$v \to J_\mu(v) = \frac{1}{2} \int_{B_R} |\nabla v|^2 \, d\omega - \epsilon \int_{B_R} \mu \, v \, d\omega. \tag{2.4}$$

The minimization of $v \to J_\mu(v)$ on K_R was treated by Kinderlehrer and Stampacchia [20]. This functional is convex and weakly lower semicontinuous so that for a fixed $\mu \in L^\infty(B_R)^+$ there exists an element $u_\mu \in K_R$ such that the functional is minimized (cf. Ekeland and Temam [12], Moreau [23]).

The problem $P(\mu)$. As a consequence of classical arguments, the minimizer $u_\mu \in K_R$ is the weak solution of the following boundary value problem, which we denote herein as the problem $P(\mu)$:

$$-\Delta u_\mu = \mu\epsilon \quad \text{in } D_R = B_R \backslash \overline{\Omega}_0 \quad \text{in the weak sense} \tag{2.5}$$

$$u_\mu = 1 \quad \text{on } \Omega_0 \quad \text{in the } H^1 \text{sense} \tag{2.6}$$

$$u_\mu = 0 \quad \text{on } \partial B_R \quad \text{in the sense of traces.} \tag{2.7}$$

Remark 2.1. Recall that the functional $v \to J_\mu(v)$ is strictly convex, so that the solution $u_\mu \in K_R$ is unique.

Remark 2.2. The element u_μ is a nonnegative function. To prove this, define

$$u_\mu^+ = \max(u_\mu, 0).$$

This is an element of $H_0^1(B_R)$ (cf. Kinderlehrer and Stampacchia [20]). Moreover, because of the extremality property of u_μ we have $u_\mu^+ \in K_R$ and

$$\int_{B_R} \mu u_\mu^+ \, d\omega = \int_{B_R} \mu u_\mu \, d\omega.$$

If u_μ were strictly negative on a set of positive measure, then

$$\|\nabla u_\mu^+\| < \|\nabla u_\mu\|,$$

which implies

$$J_\mu(u_\mu^+) < J_\mu(u_\mu).$$

This is a contradiction, therefore $u_\mu^+ = u_\mu$.

Remark 2.3. The function u_μ is an element of $C^{1,1}_{\text{loc}}(\overline{D}_R)$. First we recall that $u_\mu \in C^{1,\alpha}(\overline{D}_R)$ for $0 \leq \alpha < 1$ (see Kinderlehrer and Stampacchia [20]).

It follows that u_μ is a Lipschitz function. Furthermore, $\Delta u_\mu \in L^\infty(D_R)$. From these results and the boundary conditions (2.6) and (2.7) it follows that

$$u_\mu \in W^{2,\infty}_{\text{loc}}(D_R)$$

(cf. Gebhardt [14] and Jensen [18]). This implies that ∇u_μ is a locally Lipschitz function (for the definition of $W^{2,\infty}(D_R)$, cf. Neças [24]). In the case where we have more regularity on the boundary $\partial\Omega_0$, for instance, $C^{2,\alpha}$-regularity, then $u_\mu \in W^{2,\alpha}(D_R)$ (cf. Frehse [13]).

The optimization problem related to μ. We now define the functional Φ on $L^\infty(B_R)^+$ as follows:

$$\Phi(\mu) = J_\mu(u_\mu) = \min_{u \in K} J_\mu(u).$$

We study the problem of minimization of Φ in $C \subset L^\infty(B_R)^+$ where C denotes the convex set defined by the constraints (2.1), (2.2), and (2.3). The convex set C is compact for the topology $\sigma(L^\infty, L^1)$. We prove that the functional Φ is continuous for the same topology in order to show the existence of a minimizing element.

THEOREM 2.1. *The functional Φ is $\sigma(L^\infty, L^1)$-continuous on C.*

Proof. First we establish the following assertion: There exists a ball B_ϱ in $H_0^1(B_R)$ of radius ϱ such that, for every $\mu \in C$,

$$\min_{u \in K_R} J_\mu(u) = \min_{u \in K_R \cap B_\varrho} J_\mu(u).$$

Let μ be given, and let u_μ be the corresponding minimizing element of J_μ in K_R. Then for every $v \in K_R$ we have

$$(\nabla u_\mu, \nabla v) = \epsilon(\mu, v).$$

Here the parentheses denote the usual scalar product in $L^2(B_R)$. For the special case $v = u_\mu$,

$$\|\nabla u_\mu\|^2 = \epsilon(\mu, u_\mu) \leq \epsilon \|\mu\|_{L^\infty} \|u_\mu\|_{L^1},$$

and by using the Cauchy–Schwarz and Poincaré inequalities,

$$\|u_\mu\|_{L^1} \leq \alpha \|u_\mu\| \leq \alpha' \|\nabla u_\mu\|,$$

where α and α' are constants depending on the ball B_R. Then we obtain, for every $\mu \in C$,

$$\epsilon \|\mu\|_{L^\infty} \leq \epsilon,$$

and finally,

$$\|\nabla u_\mu\| \leq \alpha' \epsilon,$$

so the expected ball has radius $\varrho = \alpha' \epsilon$.

Because of the Rellich–Kondrasov injection theorem, the set $K' = K_R \cap B_\varrho$ is compact in $L^1(B_R)$ (cf. Neças [24]).

Note that applying integration by parts we have

$$\Phi(\mu) = -\frac{\epsilon}{2}\int_{B_R} \mu u_\mu \, d\omega.$$

Let us give a sequence $(\mu_n)_n \subset C$ converging to an element $\mu\tilde{}$ in C in the $\sigma(L^\infty, L^1)$-topology. For the corresponding sequence $(u_n)_n$ and $u\tilde{}$ solutions of the problems $P(\mu_n)$ and $P(\mu\tilde{})$, we have for every test function $\varphi \in C_0^\infty(D_R)$,

$$(\nabla(u_n - u\tilde{}), \nabla\varphi) = \epsilon(\mu_n - \mu\tilde{}, \varphi).$$

This implies that $u_n \to u\tilde{}$ weakly in $H_0^1(B_R)$. Due to the Rellich–Kondrasov theorem, the sequence also converges strongly in $L^1(B_R)$. We now write,

$$\langle \mu_n, u_n\rangle - \langle \mu\tilde{}, u\tilde{}\rangle = \langle \mu_n - \mu\tilde{}, u_n\rangle + \langle \mu\tilde{}, u_n - u\tilde{}\rangle.$$

The brackets describe the (L^∞, L^1)-duality. The second term on the right-hand side of the equation converges to zero due to the strong convergence in $L^1(B_R)$. For the first term we recall that on the unit ball of L^∞ the $\sigma(L^\infty; L^1)$ convergence is equivalent to the uniform convergence on the compact subsets of $L^1(B_R)$ (cf. Bourbaki [6, Chap. 4]). As every u_n is in the L^1-compact set K', this term also converges to zero and it follows that the functional Φ is continuous on C.

We remark that the result of Theorem 2.1 may be restated the following way.

COROLLARY 2.2. *Let $B \subset L^\infty(B_R)$ be the unit ball. For the boundary value problem $P(\mu)$ described above, the corresponding Green operator $(\Delta)^{-1} : B \to H_0^1(B_R)$ is continuous related to the $\sigma(L^\infty, L^1)$-topology and the norm topology in $H_0^1(B_R)$, respectively.*

Furthermore, as $C \subset L^\infty(B_R)^+$ is $\sigma(L^\infty, L^1)$-compact, we have as a consequence the following corollary.

COROLLARY 2.3. *There exists an element $\mu_R \in C$ such that*

$$\Phi(\mu_R) = \min_{\mu \in C} \Phi(\mu).$$

THEOREM 2.4. *There exists a set $\Omega_R \subset D_R$ such that μ_R is the characteristic function of the set $\tilde{\Omega}_R = \Omega_0 \cup \Omega_R$.*

Proof. The functional Φ is the lower envelope of affine linear functions so that it is concave. This implies that among the minimizing elements there are extremal points of C, and these are characteristic functions of sets with measure $A + A_0$ (cf. Castaing and Valadier [7]). So there exists $\mu_R = \chi_{\tilde{\Omega}_R}$ with $\tilde{\Omega}_R = \Omega_0 \cup \Omega_R$.

We denote Ω_R as an optimal set, as its characteristic function describes a minimizing element for the relaxed problem. The necessary conditions of optimality are studied in order to obtain a description of the optimal domain as the solution of a free boundary value problem.

3. Necessary conditions of optimality and their consequences. In order to study the optimality conditions we must calculate the Gateaux directional derivative $\Phi'(\mu; \alpha)$. Classically, for every direction $\alpha \in L^\infty(B_R)$ it is defined as follows:

$$\Phi'(\mu; \alpha) = \lim_{t \to 0_+} 1/t(\Phi(\mu + t\alpha) - \Phi(\mu)).$$

THEOREM 3.1. *The functional Φ has a weak derivative in the sense of Gateaux for every $\mu \in L^\infty(B_R)^+$ and every direction $\alpha \in L^\infty(B_R)$. It has the following form:*

$$\Phi'(\mu; \alpha) = -\epsilon\langle u_\mu, \alpha\rangle_{L^1, L^\infty}.$$

Proof. We recall that

$$\Phi(\mu) = \inf_{u \in K} \frac{1}{2}\|\nabla u\|^2 - \epsilon\langle u, \mu\rangle = \frac{1}{2}\|\nabla u_\mu\|^2 - \epsilon\langle u_\mu, \mu\rangle.$$

With Φ being the lower envelope of a family of affine functions related to μ and K' a compact set, it follows from a theorem of Valadier [28] that

$$\Phi'(\mu; \alpha) = -\epsilon\langle u_\mu, \alpha\rangle_{L^1, L^\infty} \tag{3.1}$$

for every $\alpha = \gamma - \mu$ with $\gamma \in L^\infty(B_R)^+$.

Remark 3.1. Φ is concave and $\sigma(L^\infty, L^1)$-continuous, so it follows that its derivative is Fréchet (cf. Valadier [28]).

Remark 3.2. Herein let us denote $u_R = u_{\mu_R}$ as the corresponding solution for the boundary value problem $P(\mu_R)$ described by conditions (2.5)–(2.7).

The first-order necessary conditions of optimality give, for every $\alpha = \mu - \mu_R, \mu \in C$, (cf. Cea [8])

$$-\langle u_R, \alpha\rangle_{L^1, L^\infty} \geq 0. \tag{3.2}$$

If we restrict ourselves to characteristic functions of sets $\mu = \chi_{\tilde{\Omega}}$ such that $\tilde{\Omega} = \Omega_0 \cup \Omega$, we obtain, for every domain Ω in D_R with measure equal to A and such that Γ_0 is contained in $\partial\Omega$,

$$-\langle u_R, \chi_{\tilde{\Omega}} - \chi_{\tilde{\Omega}_R}\rangle \geq 0, \tag{3.3}$$

which is equivalent to

$$\int_{\Omega_R} u_R \, d\omega \geq \int_{\Omega} u_R \, d\omega. \tag{3.4}$$

Inequality (3.4) states that the integrand u_R must be "placed" in D_R so that the integral has a maximal value. We denote by $\Gamma = \partial\Omega_R \cap D_R$ the boundary of Ω_R related to D_R. The set Γ can be interpreted as a free boundary as a consequence of the following theorem.

THEOREM 3.2. *For the optimal set Ω_R there exists a positive number p_R such that*

$$\Omega_R = \{x \in D_R | u_R(x) > p_R\},$$

where the equality is understood to hold up to a null measure set, and

$$\Gamma = \{x \in D_R | u_R(x) = p_R\}.$$

Proof. The existence of a Lagrange multiplier related to the constraint (2.2) for the functional $\mu \to \int_{B_R} u_R \mu \, d\omega$ is a classical fact (cf. Cea and Malanowski [10]). This means that there exists a constant p_R such that, for all elements γ in $L^\infty(B_R)^+$ such that $0 \leq \gamma \leq 1$,

$$\int_{B_R} \mu u_R \, d\omega - p_R \int_{B_R} \mu \, d\omega \geq \int_{B_R} \gamma u_R \, d\omega - p_R \int_{B_R} \gamma \, d\omega.$$

Then we have, for almost every $x \in B_R$,

$$\begin{aligned} u_R(x) > p_R \quad &\text{implies } \mu(x) = 1, \\ u_R(x) < p_R \quad &\text{implies } \mu(x) = 0. \end{aligned}$$

Setting $\gamma = \chi_{\tilde{\Omega}_R}$ with $\tilde{\Omega}_R = \Omega_0 \cup \Omega_R$, and recalling that μ fulfills constraint (2.2), we have $\mu = \chi_{\tilde{\Omega}_R}$.

We define $G = B_R \backslash \tilde{\Omega}_R$ and it follows that

$$\{x \in B_R | u_R(x) > p_R\} \subset \tilde{\Omega}_R,$$
$$\{x \in B_R | u_R(x) < p_R\} \subset G.$$

Both inclusions must be understood up to a null measure set. Furthermore, we have the following inclusions up to a null measure set:

$$\tilde{\Omega}_R \subset \{x \in B_R | u_R(x) \geq p_R\},$$

which implies that

$$\Omega_R \subset \{x \in D_R | u_R(x) \geq p_R\}.$$

From the definition of Ω_R it follows that

$$\{x \in D_R | u_R(x) > p_R\} \subset \Omega_R.$$

A result due to Stampacchia [20] states that if $u_R \in H^1(D_R)$ is constant on a measurable set E, then $\nabla u_R = 0$ almost everywhere on E. Furthermore, if $u_R \in H^2(D_R)$ it follows that $\Delta u_R = 0$ almost everywhere on E. As equation (2.5) is verified in the sense almost everywhere on D_R, this implies that meas $(\{x \in D_R | u_R(x) = p_R\} \cap \Omega_R) = 0$ and the first assertion of the theorem is proved.

The characterization of Γ follows from the fact that the function u_R is continuous and superharmonic in D_R (cf. Gonzalez de Paz [17]).

COROLLARY 3.3. *The support of the measure $\mu_R d\omega$ is the compact set*

$$\tilde{\Omega}_R = \{x \in B_R | u_R(x) \geq p_R\}.$$

Remark 3.3. From the boundary condition (2.6) we have

$$u_R \geq p_R \quad \text{on } \Omega_0.$$

Remark 3.4. The function $u_R \in H_0^1(B_R) \cap C_{\text{loc}}^{1,1}(\overline{B}_R)$ is a solution of the following free boundary value problem:

$$-\Delta u = \epsilon \quad \text{in } \Omega_R \quad \text{in the weak sense,} \tag{3.5}$$
$$\Delta u = 0 \quad \text{in } D_R \backslash \overline{\Omega}_R, \tag{3.6}$$
$$u = p \quad \text{on } \Gamma, \tag{3.7}$$
$$u = 1 \quad \text{on } \Gamma_0. \tag{3.8}$$

Remark 3.5. We should point out that in the case where Ω_0 is not star shaped, $D_R \backslash \overline{\Omega}_R$ might have more than one connected component, which would indicate the existence of more "holes" in the domain. On the other hand, because of the maximum principle, the domain Ω_R is connected.

Remark 3.6. The gradient of u_R is continuous so that

$$(\nabla u_R)^+ = (\nabla u_R)^- \quad \text{on } \Gamma, \tag{3.9}$$

where the plus sign denotes the limit at the boundary taken in the inward direction to Ω_R and the minus sign denotes the limit in the outward direction.

Because of the regularity of u_R, it is known that free boundaries of this type are locally Lipschitz (cf. Kinderlehrer and Stampacchia [20]). If we recall the fact that the free boundary Γ is a level set of u_R, then we have in the neighborhoods of points where $|\nabla u_R| > 0$ on Γ,

$$\partial u_R/\partial n^+ = \partial u_R/\partial n^- \quad \text{on } \Gamma. \tag{3.10}$$

The condition (3.10) can be interpreted as a "transmission" condition on the free boundary.

Calculation of the regular domain functional derivative. Some analog-free boundary value problems such as the one considered above have been studied by Zolesio [29] using other optimal design techniques. Under suitable regularity assumptions, we show that our approach is related to this one.

Let $\varphi_t : B_R \to B_R$ be a C^k-diffeomorphism (k a fixed integer) that is continuously dependent on a positive parameter t, and let φ_0 be the identity application, so that for any given domain $\Omega \subset B_R$, defined as before, we have $\varphi_0(\Omega) = \Omega$. Furthermore, let us denote $\varphi_t(\Omega) = \Omega_t$, so that the application $t \to \varphi_t$ describes continuous deformations of Ω. Using a certain topology, and assuming that the application is differentiable, Zolesio in [30] calculates the derivative $D_t\varphi_t = \theta$; here θ is the vector field describing the "deformation speed." For the domain functionals $\Omega_t \to J(\Omega_t)$, the shape derivative of $J(\Omega_t)$ at Ω in the direction of the field θ is defined:

$$dJ(\Omega;\theta) = \limsup_{t\to 0^+} \{J(\Omega_t) - J(\Omega)\}/t.$$

A similar case was treated by Simon [26]: Given a regular vector field $\theta \in C^k(B_R)$, for small parameter $t > 0$ the diffeomorphism stated above is given by the application $\varphi_t = Id + t\theta$, and the derivative of domain functionals is calculated. In the case of the Dirichlet integral $\Omega \to \int_\Omega |\nabla u_\Omega|^2 \, d\omega$ where u_Ω is the corresponding capacitary potential function, the result is already classic and it is known as the Hadamard formula. We have, as the shape derivative,

$$dJ(\Omega;\theta) = -\frac{1}{2}\int_\Gamma |\partial u_\Omega/\partial n|^2 \langle n, \theta\rangle \, ds.$$

Here the term $\langle n, \theta\rangle$ describes the normal component of the vector field θ to Γ.

THEOREM 3.4. *Let $\varphi_t : B_R \to B_R$ be as above, and let Γ be a smooth curve. Then for $\alpha_t = \chi_{\Omega_t} - \chi_\Omega$ we have*

$$\lim_{t\to 0^+} \frac{1}{t}\Phi'(\chi_\Omega, \alpha_t) = \frac{1}{2}\int_\Gamma (|\partial u_e/\partial n|^2 - |\partial u_i/\partial n|^2)\langle \theta, n\rangle \, ds. \tag{3.11}$$

Here the restrictions of u_R on Ω_R and $D_R\backslash\overline{\Omega}_R$ are denoted by u_i and u_e, respectively.

Proof. We put $\mu_t = \chi_{\Omega_t}$ and $\mu_0 = x_\Omega$, and let u_t and u_0 elements of $H_0^1(B_R)$ be the solutions of the boundary value problems $P(\mu_t)$ and $P(\mu_0)$, respectively; then $\delta u = u_t - u_0$ is the weak solution of $-\Delta v = \epsilon\alpha_t$, where $\alpha_t = \mu_t - \mu_0$.

Recall that

$$\Phi(\mu) = \min_{u\in K} J_\mu(u) = -\frac{1}{2}\epsilon\int_{B_R} \mu u_\mu \, d\omega.$$

Moreover, integrating by parts we obtain

$$\int_{B_R} \mu_t u_0 \, d\omega = \int_{B_R} \mu_0 u_t \, d\omega$$

so that, if we calculate,

$$-\epsilon\int_{B_R} u_0\alpha_t\,d\omega - \frac{1}{2}\epsilon\int_{B_R}\alpha_t\delta u\,d\omega = -\frac{1}{2}\epsilon\int_{B_R}\mu_t u_t\,d\omega + \frac{1}{2}\epsilon\int_{B_R}\mu_0 u_0\,d\omega$$
$$= \Phi(\mu_t) - \Phi(\mu_0).$$

This implies that

$$\lim_{t\to 0^+}\frac{1}{t}[\Phi(\mu_t) - \Phi(\mu_0)] = \lim_{t\to 0^+}\frac{1}{t}[-\langle\epsilon u_0, \mu_t - \mu_0\rangle - -\frac{1}{2}\langle\epsilon(u_t - u_0), \mu_t - \mu_0\rangle].$$

If $t \to 0^+$, then $\mu_t \to \mu_0$ in the $\sigma(L^\infty, L^1)$-topology and $u_t \to u_0$ strongly in $L^2(B_R)$, so that the second term on the right-hand side vanishes. If we assume that the boundary Γ is smooth enough, we can apply Zolesio's techniques (cf. [30]). Thus we can write, in the case where $\mu = \chi_{\tilde{\Omega}_R}$,

$$\Phi(\mu) = \frac{1}{2}\int_{B_R}|\nabla u_\mu|^2\,d\omega - \epsilon\int_{B_R}\mu u_\mu\,d\omega = J_1(\Omega_R) + J_2(D_R\backslash\overline{\Omega}_R),$$

where

$$J_1(\Omega_R) = \frac{1}{2}\int_{\Omega_R}|\nabla u_\mu|^2\,d\omega - \epsilon\int_{\tilde{\Omega}_R} u_\mu\,d\omega$$
$$J_2(D_R\backslash\overline{\Omega}_R) = \frac{1}{2}\int_{D_R\backslash\Omega_R}|\nabla u_\mu|^2\,d\omega.$$

We have then, as shape derivatives,

$$dJ_1(\Omega_R;\theta) = -\frac{1}{2}\int_\Gamma |\partial u_i/\partial n|^2\,\langle\theta, n\rangle\,ds$$
$$dJ_2(D_R\backslash\overline{\Omega}_R;\theta) = \frac{1}{2}\int_\Gamma |\partial u_e/\partial n|^2\,\langle\theta, n\rangle\,ds,$$

where n describes the normal vector to the curve Γ. This gives, as a result,

$$\lim_{t\to 0^+}\frac{1}{t}[\Phi(\mu_t) - \Phi(\mu_0)] = \lim_{t\to 0^+}\frac{1}{t}\Phi'(\mu_0, \alpha_t)$$
$$= \frac{1}{2}\int_\Gamma(|\partial u_e/\partial n|^2 - |\partial u_i/\partial n|^2)\langle\theta, n\rangle\,ds.$$

4. The limit case for an unbounded domain. Our aim in this section is to prove that, when the ball radius increases to infinity, the corresponding solutions of our "relaxed problems" converge to the solution of the original problem.

For Ω_0 as defined in the Introduction, we note by W the set of all doubly connected domains Ω with a given measure A and Γ_0 as an inner boundary and a Lipschitz-continuous outer boundary Γ. Let us recall that for a given domain $\Omega \in W$, we have the corresponding weak solution $u_\Omega \in H_0^1(\Omega)$ of the following boundary value problem:

(4.1) $\quad -\Delta u = \mu\epsilon \quad$ in Ω $\quad$ in the weak sense

(4.2) $\quad u = 1 \quad$ on Ω_0 $\quad$ in the H^1 – sense

(4.3) $\quad u = 0 \quad$ on Γ $\quad$ in the sense of traces.

For the case of a ball B_R with radius R such that $\Omega \subset B_R$, if the boundary $\Gamma = \partial\Omega \cap D_R$ is smooth enough, the function u_Ω can be extended to a function $\tilde{u} \in H_0^1(B_R)$ such that this extension is zero on $B_R \backslash (\Omega \cup \Omega_0)$. It is clear that if μ is the characteristic function of $\tilde{\Omega} = \Omega_0 \cup \Omega$, for any feasible R we can calculate for $\tilde{u}$ as defined above:

$$J_\mu(\tilde{u}) = \frac{1}{2}\int_{B_R} |\nabla \tilde{u}|^2 \, d\omega - \epsilon \int_{B_R} \mu \tilde{u} \, d\omega = \frac{1}{2}\int_{\tilde{\Omega}} |\nabla u_\Omega|^2 \, d\omega - \epsilon \int_{\tilde{\Omega}} u_\Omega \, d\omega.$$

So formally, we write $J_\mu(\tilde{u}) = J_\mu(u_\Omega)$. This gives the motivation to define for each $\Omega \in W$ the energy functional $\Omega \to En(\Omega) = J_\mu(u_\Omega)$ with $\mu = \chi_{\tilde{\Omega}}$, which is independent of the radius R. For every $\chi_{\tilde{\Omega}} \in C$ as above, with $\Omega \in W$, there exists a ball B_R and a $\mu_R \in C$ such that

$$\Phi(\mu_R) \leq \Phi(\mu) \leq J_\mu(u_\Omega) = En(\Omega).$$

Let us take an increasing sequence of R_n such that its limit is infinity. By taking extensions of $H_0^1(B_R)$ into $H^1(\mathbb{R}^2)$, we have for $R_{n'} > R_n$ the inclusions $K_{R_n} \subset K_{R_{n'}}$, and for the corresponding minimizers μ_R as defined in Corollary 2.3 this implies that

$$\Phi(\mu_{R_{n'}}) \leq \Phi(\mu_{R_n}).$$

The sequence $(\Phi(\mu_{R_n}))_n$ is monotone decreasing; we prove that a limit does exist. We denote as Y the completion of the space of test functions in $\mathbb{R}^2$ with the L^2-norm of the gradient. Among others, this space has been used by Temam [27] to study partial differential equations in unbounded domains.

Remark 4.1. The following injections are continuous:

$$H_0^1(\mathbb{R}^2) = H^1(\mathbb{R}^2) \subset Y,$$

$$Y \subset L^\alpha_{\text{loc}}(\mathbb{R}^2)$$

for every $\alpha \geq 1$. Moreover, the injection

$$H^1_{\text{loc}}(\mathbb{R}^2) \subset L^\alpha_{\text{loc}}(\mathbb{R}^2)$$

is compact for every $1 \leq \alpha < \infty$. These injections remain valid for the unbounded domain $D = \mathbb{R}^2 \backslash \overline{\Omega}_0$.

LEMMA 4.1. *There exists a ball B_0 with radius R_0 such that for every element of a subsequence $(R_{nk})_k \subset (R_n)_n$ the optimal domains $\Omega_{R_{nk}}$ are included in B_0.*

Proof. Let C be the convex set of functions as defined before but extended to $\mathbb{R}^2$. As for every $R_n : \|\mu_{R_n}\|_{L^2}^2 = A + A_0$, there exists a subsequence also noted $\{\mu_{R_n}\}_n$ that converges weakly to a $\mu^* \in L^2(\mathbb{R}^2)$. We remark that, because the μ_{R_n} are characteristic functions of finite measure sets, it follows for every $R_n : \mu_{R_n} \in L^1(\mathbb{R}^2)$ with $\|\mu_{R_n}\|_{L^1} = A + A_0$. Following the proof of the concentration-compactness lemma given by Lions [21] we consider the function $Q_n(R) = \sup_{x \in \mathbb{R}^2} \int_{x+B_R} \mu_{R_n} \, d\omega$ and we have that $\lim_{R\to\infty} Q_n(R) = A + A_0$. The sequence $(Q_n)_n$ is nondecreasing, nonnegative, and uniformly bounded, so that classically there exists a subsequence $(n_k)_k$ and a nondecreasing, nonnegative function Q such that $Q_{nk} \to Q$ pointwise. Because of the $\sigma(L^\infty, L^1)$-convergence of the original sequence $(\mu_{R_n})_n$, it follows that $Q(R) = \sup_{x \in \mathbb{R}^2} \int_{x+B_R} \mu^* \, d\omega$; and because of the integral constraint (2.2), $\lim_{R\to\infty} Q(R) = A + A_0$. In this case, there exists a ball B_0 with radius R_0

such that for every k, $\int_{B_0} \mu_{nk}\, d\omega = A + A_0$ and our assertion follows. Without loss of generality, we let R_0 be large enough so that $x = 0$.

THEOREM 4.2. *Let the assumptions on the sequence $(R_n)_n$ be as above. Then there exist elements $u^* \in Y$ and $\mu^* \in C$ such that*

$$\frac{1}{2}\int_{\mathbb{R}^2} |\nabla u^*|^2\, d\omega - \epsilon \int_{\mathbb{R}^2} \mu^* u^*\, d\omega = \inf_{R_n} \Phi(\mu_{R_n}).$$

Proof. We note that $\tilde{u}_{R_n}$ is the natural extension of u_{R_n} in $H^1(\mathbb{R}^2)$. Recall that, for every $\varphi \in K_R$ and for every R,

$$(\nabla u_R, \nabla \varphi) = \epsilon(\mu_R, \varphi). \tag{4.4}$$

Let us define the set $K = \{\varphi \in Y | \varphi \geq 1 \text{ on } \Omega_0\}$. Due to the $\sigma - L^2$-convergence of the sequence $(\mu_{R_n})_{R_n}$, we may assume the existence of a distribution u^* such that, if $R_n \to \infty$, we have for every $\varphi \in K$

$$(\nabla \tilde{u}_{R_n}, \nabla \varphi) \to (\nabla u^*, \nabla \varphi) = \epsilon(\mu^*, \varphi) \tag{4.5}$$

so that, for the weak topology of $L^2(\mathbb{R}^2)$,

$$\nabla \tilde{u}_{R_n} \to \nabla u^* \in L^2(\mathbb{R}^2)$$

and $u^* \in Y$ is a weak solution for the Poisson equation (cf. related results in Bottaro and Marina [5])

$$-\Delta u^* = \epsilon \mu^* \quad \text{in } D. \tag{4.6}$$

The sequence $(\tilde{u}_{R_n})_n$ converges weakly in Y; because of the inclusions quoted in Remark 4.1, $u^* \in L^2_{\text{loc}}(\mathbb{R}^2)$. This means that the functions $\tilde{u}_{R_n}$ and u^* are elements of $H^1_{\text{loc}}(\mathbb{R}^2)$. Recalling again Remark 4.1 it follows that if $R_n \to \infty$, for $n \to \infty$ then

$$\tilde{u}_{R_n} \to u^* \quad \text{strongly in } L^2_{\text{loc}}(\mathbb{R}^2).$$

As for every R_n:

$$\int_{\mathbb{R}^2} \mu_{R_n} \tilde{u}_{R_n}\, d\omega = \int_{B_o} \mu_{R_n} \tilde{u}_{R_n}\, d\omega. \tag{4.7}$$

The strong $L^2_{\text{loc}}(\mathbb{R}^2)$-convergence implies that

$$\int_{\mathbb{R}^2} \mu_{R_n} \tilde{u}_{R_n}\, d\omega \to \int_{\mathbb{R}^2} \mu^* u^*\, d\omega. \tag{4.8}$$

We deduce from (4.5), (4.7), and (4.8) that

$$\|\nabla \tilde{u}_{R_n}\| \to \|\nabla u^*\|.$$

The sequence $(\nabla u_{R_n})_n$ converges strongly in $L^2(\mathbb{R}^2)$ and consequently,

$$\Phi(\mu_{R_n}) \to \Phi(\mu^*) = \inf_{R_n} \Phi(\mu_{R_n}).$$

Existence of the optimal domain. We now define $\tilde{\Omega}^* = (x \in \mathbb{R}^2 | \mu^* > 0)$ in the sense of measures, and we put $\Omega^* = \tilde{\Omega}^* \backslash \overline{\Omega}_0$.

Remark 4.2. $D\backslash\overline{\Omega}^*$ is an open set of D, and as a consequence of the differential equation (4.6) the function u^* is harmonic in $D\backslash\overline{\Omega}^*$.

LEMMA 4.3. *Let $(\tilde{u}_{R_n})_n \subset H^1(\mathbb{R}^2)$ be the same sequence as before. Then if $R_n \to \infty$, it follows that*

$$\int_D |\nabla \tilde{u}_{R_n}|^2 \, d\omega \to \int_{\Omega^*} |\nabla u^*|^2 \, d\omega.$$

Proof. Recall that the function u^* is harmonic in $D\backslash\overline{\Omega}^*$; secondly, for every R_n we have, for $\tilde{\Omega}_{R_n} = \Omega_0 \cup \Omega_{R_n}$,

$$\int_{D_{R_n}} |\nabla u_{R_n}|^2 \, d\omega = \int_{D_{R_n}\backslash\Omega_{R_n}} |\nabla u_{R_n}|^2 \, d\omega + \int_{\Omega_{R_n}} |\nabla u_{R_n}|^2 \, d\omega$$

and

$$\int_{D_{R_n}\backslash\Omega_{R_n}} |\nabla u_R|^2 \, d\omega \leq \gamma \mathrm{Cap}_{B_{R_n}}(\tilde{\Omega}_{R_n}), \tag{4.9}$$

where γ is a constant depending only on the boundary condition on Γ_0 and $\mathrm{Cap}_{B_R}(\tilde{\Omega}_R)$ is the capacity of the set $\tilde{\Omega}_R$ related to the ball B_R. Let us recall that for the ball B_0 as in Lemma 4.1, and for every $R_{nk} \geq R_0$,

$$\Omega_{R_{nk}} \subset B_0 \subset B_{R_{nk}}.$$

Then, it follows that $\mathrm{Cap}_{B_{R_{nk}}}(\tilde{\Omega}_{R_{nk}}) \leq \mathrm{Cap}_{B_{R_{nk}}}(B_0)$.

It is known that for the two-dimensional case, $\mathrm{Cap}_{B_R}(B_0) = 0(1/\log(1/R))$, so that if $R_{nk} \to \infty$ the capacity tends to zero. Consequently, from inequality (4.9) we have that

$$\int_{D\backslash\Omega^*} |\nabla u^*|^2 \, d\omega = 0.$$

COROLLARY 4.4. *The function u^* is equal to zero in the unbounded component of $D\backslash\overline{\Omega}^*$.*

Proof. As a consequence of Lemma 4.3, u^* is constant almost everywhere in $D\backslash\overline{\Omega}^*$. We note this constant on the unbounded component as p^*. If we define $v_{R_n} = u^* - \tilde{u}_{R_n} \in C(D)$, it is clear that each function is uniformly bounded at infinity and, for every R,

$$\lim_{|x|\to\infty} v_R(x) = p^*.$$

The sequence $(v_{R_n})_n$ has a limit v^* for the norm topology in Y and each v_{R_n} is a harmonic function in the complement of B_{R_n}. Moreover, v^* is bounded at infinity.

Let R_0 be as in Lemma 4.1, and let $B_{R'}$ be another ball such that $R' > R_0$, so that all the elements of the sequence $(\tilde{u}_{R_n})_{R_n \geq R'}$ are harmonic in the interior of the set $S = B_{R'}\backslash B_{R_o}$.

Because of Remark 4.1, we have that

$$\tilde{u}_{R_n} \to u^* \quad \text{strongly in } L^2(S).$$

It is known that, for every closed set $S' \subset S$, the sequence of harmonic functions converges uniformly (cf. Kellog [19]). Consequently $v^* = 0$ pointwise in S'. Let $\Sigma \subset S'$ be a regular continuous curve and let D_Σ be an unbounded, open domain contained in the complement

of B_{R_o} with Σ as boundary. Then v^* is a harmonic function equal to zero on Σ and bounded at infinity; it is a classical fact that v^* must be equal to zero everywhere in D_Σ. The function v^* is continuous and the limit of a sequence in $C(D_\Sigma)$, so it follows that, for every $x \in D_\Sigma$,

$$v^*(x) = \lim_{R_n \to \infty} v_{R_n}(x) = \lim_{R_n \to \infty} u^*(x) - \tilde{u}_{R_n}(x) = 0,$$

but the second term $\tilde{u}_{R_n}$ vanishes when $|x| \to \infty$, and this implies that

$$\lim_{|x| \to \infty} v^*(x) = \lim_{|x| \to \infty} \lim_{R_n \to \infty} v_{R_n}(x) = \lim_{|x| \to \infty} u^*(x) = p^*.$$

Thus p^* must be the null constant.

We further define the set $\Omega^+ = \{x \in D | u^*(x) > 0$ in the sense of $H^1\}$. We recall that $u(x) > 0$ at a point x in the sense of H^1 if there exists a ball centered in x with radius ϱ noted $B(x, \varrho)$ and $\varphi \in$ Lip $(B(x, \varrho)); \varphi(x) > 0$ such that $u - \varphi \geq 0$ in the sense of H^1. As a consequence of the definition the set Ω^+ is open. It is clear that up to a null measure set $\Omega^* \subset \Omega^+$.

Remark 4.3. The function u^* is an element of $C^{1,\alpha}(\Omega^+)$. This follows because $-\Delta u^* = \epsilon \mu^*$ almost everywhere in Ω^+. The right-hand term is a bounded function. Recalling regularity properties quoted in Remark 2.2, we obtain $u^* \in C^{1,\alpha}(\Omega^+)$.

THEOREM 4.5. *The element $\mu^* \in C$ has the property $\mu^* = \chi_{\Omega^*}$, and for all domains $\Omega \in W$,*

$$En(\Omega^*) \leq En(\Omega).$$

Proof. We put $K = \{u \in Y | u \geq 1$ on $\Omega_0\}$. For a given $\Omega \in W$ we have $\tilde{\Omega} = \Omega \cup \Omega_0$ and $\tilde{\Omega} \subset B_R$ for a certain R. Furthermore, we define the set $K_0(\Omega) = \{u \in K | u = 0$ in $\mathbb{R}^2 \backslash \tilde{\Omega}\}$, which is contained in K_R, closed and convex. The functional $\Omega \to$ En(Ω) can be written for $\mu = \chi_{\tilde{\Omega}}$ as follows:

$$\text{En } (\Omega) = \min_{K_o(\Omega)} J_\mu(u),$$

so that for every $\Omega \in W$ and every $\mu = \chi_{\tilde{\Omega}} \in C$,

$$\Phi(\mu^*) \leq \Phi(\mu) = \min_{K_R} J_\mu(u) \leq \min_{K_o(\Omega)} J_\mu(u) = \text{En}(\Omega). \tag{4.10}$$

For $\mu = \chi_{\tilde{\Omega}^*}$ there exists a $u_{\Omega^*} \in K_0(\Omega^*)$ such that $J_{\chi_{\tilde{\Omega}^*}}(u_{\Omega^*}) =$ En(Ω^*). Recall that $u^* \in K_0(\Omega^*)$, which implies that

$$\text{En } (\Omega^*) \leq J_{\chi_{\tilde{\Omega}^*}}(u^*). \tag{4.11}$$

As meas $\Omega^* \geq A$, we choose a set $E \subset \Omega^*$ with meas $E = A$ so that $E \in W$. It follows that

$$\Phi(\mu^*) \leq \text{En}(E) \leq \text{En}(\Omega^*). \tag{4.12}$$

From (4.11) and (4.12) we conclude that

$$\frac{1}{2} \int_{\Omega^*} |\nabla u^*|^2 \, d\omega - \epsilon \int_{\Omega^*} \mu^* u^* \, d\omega \leq \frac{1}{2} \int_{\Omega^*} |\nabla u^*|^2 \, d\omega - \epsilon \int_{\Omega^*} u^* \, d\omega.$$

This implies that

$$\int_{\Omega^*} \mu^* u^* \, d\omega \geq \int_{\Omega^*} u^* \, d\omega.$$

In our case this means that

$$\mu^* u^* \geq u^* \quad \text{almost everywhere on } \Omega^*,$$

but $\mu^* \leq 1$ almost everywhere on Ω^*. Moreover, the function u^* is continuous and nowhere zero in Ω^* as a result of regularity properties. We conclude that

$$\mu^* = \chi_{\Omega^*} \quad \text{almost everywhere in } D,$$

and consequently, meas $\Omega^* = A$.

It follows that $\Phi(\mu^*) = \text{En}(\Omega^*)$. This result and (4.10) prove the theorem.

Remark 4.4. We remark that, as a consequence of the fact that μ^* is a characteristic function, the sequence converges strongly in $L^2(D)$. Furthermore, we can choose a subsequence converging almost everywhere in D. Chenais [11] has shown that in this case, up to a null measure set we have $\Omega^* = \lim_n \inf \Omega_{R_n} = \cap_{l \in \mathbb{N}} \cup_{k \geq l} \Omega_{R_n k}$. It is known that in this case, as all the sets Ω_{R_n} are in a metric space, the set Ω^* is closed and connected. Consequently, if $D \backslash \overline{\Omega}^*$ is connected, it follows from Corollary 4.4 and the corresponding definitions that $\Omega^* = \Omega^+$, and this implies, for the free boundary $\Gamma^* = \partial\Omega^* \cap D$, meas $\Gamma^* = 0$. Up to now the regularity properties for Γ^* remain open, but in the case where it is regular enough so that the space $H_0^1(\Omega^*)$ is well defined, we are able to prove our main assertion.

THEOREM 4.6. *Let Γ_0 be a given closed Lipschitz continuous curve, nonintersecting itself so that the domain Ω_0 enclosed is star shaped. Let W be the set of all doubly connected domains Ω with a given measure A, Γ_0 as inner boundary, and a Lipschitz continuous outer boundary Γ. Then there exists a doubly connected domain Ω^* such that, for all $\Omega \in W$,*

$$\text{Cap}_{\Omega^*}(\Omega_0) \leq \text{Cap}_{\Omega}(\Omega_0).$$

Proof. Let us give a fixed, positive constant ϵ. For a given domain Ω with regular outer boundary Γ, the corresponding weak solution $u_\epsilon \in H^1(\Omega)$ of the boundary value problem

$$\begin{aligned} -\Delta u &= \epsilon \quad \text{in } \Omega \quad \text{in the weak sense} \\ u &= 0 \quad \text{on } \Gamma \quad \text{in the sense of traces} \\ u &= 1 \quad \text{on } \Omega_0 \quad \text{in the } H^1 \text{ sense} \end{aligned}$$

has the form $u_\epsilon = u_0 + u^\epsilon$, where u_0 is the capacity potential of the domain Ω_0 related to Ω, and u^ϵ is the corresponding solution of the Poisson equation in Ω with homogeneous Dirichlet conditions. Thus we have that

$$\text{En}_\epsilon(\Omega) = \frac{1}{2}\text{Cap}_\Omega(\Omega_0) + (\nabla u_0, \nabla u^\epsilon) + \frac{1}{2}\int_\Omega |\nabla u^\epsilon|^2 \, d\omega - \epsilon \int_\Omega u_\epsilon \, d\omega. \tag{4.13}$$

By applying Theorem 4.5 for a given ϵ, we know there exists a domain Ω^* such that, for every $\Omega \in W$,

$$\text{En}_\epsilon(\Omega^*) \leq \text{En}_\epsilon(\Omega). \tag{4.14}$$

Being u_0 harmonic in Ω, the second term of the right-hand side in (4.13) vanishes. Moreover, it is known that for fixed Ω, in the case where $\epsilon \to 0$, $u^\epsilon \to 0$ strongly in $H^1(\Omega)$. This implies that for every $\Omega \in W$,

$$\text{En}_\epsilon(\Omega) \to \tfrac{1}{2}\,\text{Cap}_\Omega(\Omega_0). \tag{4.15}$$

Applying property (4.15) to both sides of the inequality (4.14) gives the result.

Remark 4.4. We have that $\nabla u^* = 0$ in $D\backslash\overline{\Omega^*}$, which implies that, in the case where Γ^*, the boundary of Ω^* related to D, is smooth enough, it follows from formula (3.10) that

$$d\text{En}(\Omega^*, \theta) = -\frac{1}{2}\int_{\Gamma^*} |\partial u^*/\partial n|^2 \langle \theta, n\rangle \, ds.$$

Here $d\text{En}(\Omega^*, \theta)$ denotes the derivative of the energy functional related to domain deformation described by the vector field θ, (cf. Pironneau [25], Simon [26], Zolesio [30]).

It has been proved by other authors that from the necessary optimality condition $d\text{En}(\Omega^*, \theta) \geq 0$, which holds for every vector field θ preserving the measure, we obtain

$$|\partial u^*/\partial n| = |\nabla u^*| = \lambda \quad \text{on } \Gamma^*,$$

where λ is a positive constant that can be interpreted as a Lagrange multiplier for the functional $\Omega \to \int_\Omega |\nabla u_\Omega|^2 \, d\omega$ related to the measure constraint of the domain. Here u_Ω denotes the corresponding potential (cf., for example, Banichuk [4], Pironneau [25]).

Remark 4.5. It should be mentioned that Alt and Cafarelli [3] studied the following related problem: Find $v \in K$ that minimizes the functional

$$v \to J(v) = \int_\Omega |\nabla v|^2 \, d\omega + \int_\Omega Q^2 \chi_{v>0} \, d\omega,$$

where $K = \{v \in L^1_{\text{loc}}(\Omega) | \nabla v \in L^2(\Omega),\ v = u^0 \text{ on } S\}$; here $u^0 > 0, Q \geq 0$, and $S \subset \partial\Omega$ are given. For the case where Q and u^0 are constants, the solution of their problem solves ours for $A = \int_\Omega \chi_{u>0} \, d\omega$. Moreover, the stationary points of the functional J have the property

$$|\nabla u| = Q \quad \text{on } \Gamma = \Omega \cap \partial\{u > 0\}.$$

In their case, Q is given and the constant A is a result; in ours, A is given and the constant λ is a consequence of the necessary conditions of optimality (cf. another related result using different techniques in Acker [1]). This fact allows us to apply the regularity properties already known for the boundary Γ^* in our case, i.e., Γ^* is locally a $C^{1,\alpha}$ curve and even analytic.

Acknowledgments. The author thanks J. P. Zolesio and an anonymous reviewer for their advice and remarks, which were essential to the improvement of a first version of this paper. All possible errors remain the responsibility of the author.

ON THE EXISTENCE OF OPTIMAL CONTROLS OF HILBERT SPACE-VALUED DIFFUSIONS*

DARIUSZ GĄTAREK† AND JAROSŁAW SOBCZYK‡

Abstract. An optimal control problem is studied for a Hilbert space-valued diffusion. Existence of an optimal control in the class of relaxed controls is proved. As a tool, the factorization method is used. Also, a simple example is given.

Key words. optimal control, diffusion processes in Hilbert spaces, existence theory, relaxed controls

1. Introduction. We consider the following control problem. Let X^u be a solution of the following stochastic equation on $H = L^2(\mathcal{O})$:

$$\frac{\partial}{\partial t}X^u(x,t) = AX^u(x,t) + f(X^u(x,t),u(x,t),x,t) + g(X^u(t),t)\dot{W}(x,t), X^u(x,0) = X_0(x), \tag{1}$$

where W is a Wiener process on H and A is a differential operator on H. Our objective is to minimize the following cost function:

$$J(u) = E\left\{\int_0^1 \int_{\mathcal{O}} b(X^u(x,t),u(x,t),x,t)dx\,dt + \int_{\mathcal{O}} h(X^u(x,1),x)dx\right\}.$$

We answer the question of existence of an optimal control for the above problem. We will use the compactification method to prove the existence by introducing a relaxed control q and a control policy that is a probability measure, P being the law of the pair (q, X^q). Such a method is classical in both deterministic and stochastic cases in finite-dimensional spaces; for instance, see [1], [2], [6], [7], [11]. In finite-dimensional case, the compactness of the set of control policies is proved by the use of the compactness criterion for the space of continuous functions proved by Stroock and Varadhan in [15] (see also [11]). In this paper we use the factorization method introduced by Da Prato, Kwapień, Zabczyk [4]. Due to this method we can essentially shorten and clarify proofs. This paper is the first, to our knowledge, to deal with an existence theorem of an optimal control for the equation with space-time noise in infinite-dimensional spaces.

The paper is organized as follows. In §2 we formulate the problem and give some preliminary results. In §3 we give an existence result, using the factorization method. We close the paper with an example in §4.

2. Preliminaries and setting of the problem. Let $\mathcal{O}$ be an open, bounded subset of $\mathbf{R}^n$ with smooth boundary. Define the Hilbert space $H = L^2(\mathcal{O})$. Denote by $\|\cdot\|$ and $\langle\cdot,\cdot\rangle$ the norm and the scalar product in the space H. Let $V \subseteq \mathbf{R}^m$ be a closed space of control parameters. Let U be the set of positive measures q on $V \times \overline{\mathcal{O}} \times [0,1]$, such that $q(V,dx,dt) = dxdt$ is the Lebesgue measure. We will use the disintegration of q from U given by $q(du,dx,dt) = q(du,dx,t)dt$ where $q(du,dx,t)$ is a measurable kernel of bounded mass. We call the measures $q \in U$ relaxed control parameters. Notice that U is a metrizable space in the stable topology v, defined as follows: $q_n \to q$ in v if and only if

$$\int_0^1 \int_{\mathcal{O}} \int_V \psi(u,x,t)q_n(du,dx,dt) \to \int_0^1 \int_{\mathcal{O}} \int_V \psi(u,x,t)q(du,dx,dt)$$

for any measurable bounded $\psi : V \times \overline{\mathcal{O}} \times [0,1] \to \mathbf{R}$, continuous with respect to u. Denote by $\mathcal{M}(B)$ the space of all probabilistic measures on the topological space B.

Let the following be given:

(i) Q, a nuclear operator on H;

(ii) $f \in C(\mathbf{R} \times V \times \overline{\mathcal{O}} \times [0,1]; \mathbf{R})$ such that $|f(y,u,x,t)| \leq K(1+|y|+|u|)$ for any $(y,u,x,t) \in \mathbf{R} \times V \times \overline{\mathcal{O}} \times [0,1]$;

(iii) $g \in C(H \times [0,1]; L(H;H))$ such that $\|g(X,t)\|_{L(H;H)} \leq K(1+\|X\|^{\beta})$ for any $(X,t) \in H \times [0,1]$ and a certain $\beta \in (0,1)$;

(iv) A, a differential operator on H, generating a compact semigroup $S(t)$ on H;

(v) X_0, a fixed element of H;

(vi) $b \in B(\mathbf{R} \times V \times \overline{\mathcal{O}} \times [0,1]; \mathbf{R}_+)$, such that $b(y,u,x,t)$ is lower-semicontinuous (l.s.c.) in (y,u) and $b(y,u,x,t) \geq \gamma |u|^2$ for certain $\gamma > 0$;

(vii) $h \in B(\mathbf{R} \times \mathcal{O}; \mathbf{R}_+)$, such that $h(x,y)$ is l.s.c. in x.

The cost function $J_0 : U \times C(0,1;H) \to \mathbf{R}$ takes the form:

$$J_0(q,X) = \int_0^1 \int_{\mathcal{O}} \int_V b(X(x,t),u,x,t) q(du,dx,dt) + \int_{\mathcal{O}} h(X(x,1),x)dx.$$

DEFINITION 1. We say that $(\Omega, \mathcal{F}, P, \{\mathcal{F}_t\}, \{X(t)\}, \{q_t\}, X_0)$ is a relaxed control if:

(i) $(\Omega, \mathcal{F}, P, \{\mathcal{F}_t\})$ is a probability space equipped with a filtration;

(ii) $\{q_t\}$ is a U-valued, progressively measurable process;

(iii) $\{X(t)\}$ is a H-valued, progressively measurable process such that

$$C_t(\phi, X, q) = \phi(X(t),t) - L_1\phi(X,t) - L_2\phi(X,q,t)$$

is a continuous $(P, \mathcal{F}_t)$ martingale for any ϕ of the form

$$\phi(X(s),s) = \phi_0(\langle X(s), e_1\rangle, \ldots, \langle X(s), e_n\rangle, s),$$

where $\phi_0 \in C_0^{\infty}(\mathbf{R}^n \times (0,1)), e_i \in D(A^*)$ for any $i = 1,2,\ldots$ and $n = 1,2,3,\ldots$, and with the operators L_1 and L_2 of the form

$$L_1\phi(X,t) = \int_0^t \left(\langle A^* \nabla\phi(X(s),s), X(s)\rangle + \frac{\partial}{\partial s}\phi(X(s),s) + \frac{1}{2} \operatorname{Tr}[g^*(X(s),s)\nabla^2\phi(X(s),s)g(X(s),s)Q] \right) ds,$$

and

$$L_2\phi(X,q,t) = \int_0^1 \int_{\mathcal{O}} \int_V \nabla\phi(X(s),s)(x) \cdot f(X(x,s),u,x,s) q(du,dx,ds),$$

where $\nabla\phi$ and $\nabla^2\phi$ denote the first and second Frechet derivatives of the functional ϕ with respect to X. Moreover $X(0) = X_0 P$ almost surely:

(iv) The cost is $E^P(J_0(q,X))$. Define the probability space $\Omega = C(0,1;H) \times U$ with the filtration

$$\mathcal{F}_t = \sigma\left(X(s), \int_0^s \int_C \int_B q(du,dx,dr), \text{ where } B \subseteq V, C \subseteq \mathcal{O} \text{ are Borel sets and } s \leq t \right)$$

and $\mathcal{F}_t^X = \sigma(X(s), s \leq t)$. Elements of Ω will be denoted by $\omega = (X,q)$.

DEFINITION 2 (compare with [6], [11]). We say that a probabilistic measure P on Ω is an admissible control policy if and only if:

(i) $P(X(0) = X_0) = 1$;
(ii) the process $C_t(\phi, X, q)$ is a continuous $(P, \{\mathcal{F}_t\})$ martingale for any ϕ of the form as in Definition 1.
(iii) The cost is $J(P) = E^P(J_0(q, X))$.

We will work with a control policy in the sequel. The following lemma enables us to transfer a result proved in this paper concerning a control policy to a relaxed control case. Observe that if P is a control policy, then $(C(0,1;H) \times U, \mathcal{F}_1, P, \{\mathcal{F}_t\}, \{X(t)\}, \{q_t\})$ is a relaxed control.

LEMMA 1. *If $(\Omega, \mathcal{F}, P, \{\mathcal{F}_t\}, \{X(t)\}, \{q_t\}, X_0)$ is a relaxed control and $\{\mathcal{G}_t\}$ is a filtration such that $\mathcal{F}_t^X \subseteq \mathcal{G}_t \subseteq \mathcal{F}_t$, then there exists a process $\{\overline{q}_t\}$ such that $(\Omega, \mathcal{F}, P, \{\mathcal{G}_t\}, \{X(t)\}, \{\overline{q}_t\}, X_0)$ is a relaxed control and $J_0(\overline{q}, X) = J_0(q, X)$.*

Proof. We define $\overline{q}_t$ as a progressive version of $P(q_t|\mathcal{G}_t)$ such that for any $\gamma \in C_b(V \times \overline{\mathcal{O}})$,

$$\int_{\mathcal{O}} \int_V \gamma(u,x)\overline{q}(du,dx,t) = E^P\left(\int_{\mathcal{O}} \int_V \gamma(u,x)q(du,dx,t)|\mathcal{G}_t\right)$$

and $\overline{q}(du,dx,dt) = \overline{q}(du,dx,t)dt$.

The proof that such a progressive version exists is the same as in [6], [11]. Let ϕ be as in Definition 1 and let $t > r$. Denote $\psi(X(s),u,x,s) = \nabla\phi(X(s),s)(x) \cdot f(X(x,s),u,x,s)$. Since $\mathcal{F}_r \subseteq \mathcal{G}_r$ then

$$\begin{aligned}
&E^P(C_t(\phi,X,\overline{q}) - C_r(\phi,X,\overline{q})|\mathcal{G}_r) \\
&\quad = E^P\Bigg(\phi(X(t),t) - \phi(X(r),r) - L_1\phi(X,t) + L_1\phi(X,r) \\
&\qquad - \int_r^t \int_{\mathcal{O}} \int_V \psi(X(s),u,x,s)\overline{q}(du,dx,s)ds|\mathcal{G}_r\Bigg) \\
&\quad = E^P\Bigg(\phi(X(t),t) - \phi(X(r),r) - L_1\phi(X,t) + L_1\phi(X,r) \\
&\qquad - \int_r^t \left(E^P \int_{\mathcal{O}} \int_V \psi(X(s),u,x,s)\overline{q}(du,dx,s)|\mathcal{G}_s\right) ds|\mathcal{G}_r\Bigg) \\
&\quad = E^P\Bigg(\phi(X(t),t) - \phi(X(r),r) - L_1\phi(X,t) + L_1\phi(X,r) \\
&\qquad - \int_r^t \int_{\mathcal{O}} \int_V \psi(X(s),u,x,s)q(du,dx,s)ds|\mathcal{G}_r\Bigg) \\
&\quad = E^P\Bigg(E^P\Bigg(\phi(X(t),t) - \phi(X(r),r) - L_1\phi(X,t) + L_1\phi(X,r) \\
&\qquad - \int_r^t \int_{\mathcal{O}} \int_V \psi(X(s),u,x,s)q(du,dx,s)ds|\mathcal{F}_r\Bigg)|\mathcal{G}_r\Bigg) = 0,
\end{aligned}$$

because, by assumption, the internal conditional expectation is zero. Hence process $\{C_t(\phi, X, \overline{q})\}$ is $(P, \{\mathcal{G}_t\})$ martingale. The equality of the costs is obvious. □

Denote by $\mathcal{P}$ the space of all admissible control policies. The cost function associated to a measure $\mathcal{P} \in \mathcal{P}$ is given by $J(P) = E^P J_0$. Notice that $J : \mathcal{P} \to \mathbf{R}_+$ is l.s.c. with respect to the weak topology.

PROPOSITION 1 [10]. *For any admissible control policy P there exists a Wiener process W on the space H with covariance operator Q, such that*

$$X(t) = S(t)X_0 + \int_0^t S(t-s)f(X,q,s)ds + \int_0^t S(t-s)g(X(s),s)dW(s), \tag{2}$$

where the function f is extended to $f : C(0,1;H) \times U \times [0,1] \to H$ by the following: For any Borel subset B of $\overline{\mathcal{O}} \times [0,1]$,

$$\int_B f(X,q,t)(x)dxdt = \int_B \int_V f(X(x,t),u,x,t)q(du,dx,dt).$$

Here the state equation (2) takes the symbolic form:

$$dX(t) = [AX(t) + f(X,q,t)]dt + g(X(t),t)dW(t). \tag{3}$$

By Proposition 1 the set $\mathcal{P}$ is nonempty.

3. Solution of the problem. Define

$$\mathcal{P}(M) = \{P \in \mathcal{P} : J(P) \leq M\} \text{ for any } M \in \mathbf{R}_+.$$

THEOREM 1. *The set $\mathcal{P}(M)$ is compact for any $M \in \boldsymbol{R}_+$.*

The proof is based on the following facts.

We now recall the factorization method as presented in [4]. For any $h \in L^p(0,1;H)$ and $\alpha \in (0,1]$ define an operator R_α by

$$R_\alpha h(t) = \int_0^t (t-s)^{\alpha-1} S(t-s)h(s)ds.$$

LEMMA 2 ([4, Prop. 1]). *Let W be a Wiener process with covariance operator Q. Then for any $0 < p^{-1} < \alpha < \frac{1}{2}$ and any predictable $\phi \in L^p(\Omega \times [0,1]; L(H;H))$:*

$$\pi \sin(\pi\alpha)^{-1} \int_0^t S(t-s)\phi(s)dW(s) = R_\alpha Y(t),$$

where

$$Y(t) = \int_0^t (t-s)^{-\alpha} S(t-s)\phi(s)dW(s).$$

LEMMA 3 ([4, Prop. 1]). *The operator $R_\alpha : L^p(0,1;H) \to C(0,1;H)$ is compact for any $\alpha \in (p^{-1}, 1]$.*

Proof of the theorem. The proof follows [6]. Let $P \in \mathcal{P}(M)$. By Proposition 1, there exists a Wiener process W on the space H with covariance operator Q, such that X satisfies equation (2). By assumption (vi),

$$E^P \int_0^1 \int_{\mathcal{O}} \int_V |u|^2 q(du,dx,dt) \leq \gamma^{-1} M. \tag{4}$$

By the Ito formula, (2) and (4),

$$E^P \|X(t)\|^2 \leq E^P \|X_0\|^2 + K \int_0^t E^P \|X(s)\|^2 ds + K\gamma^{-1} M.$$

By the Gronwall lemma,

$$\sup_{P\in\mathcal{P}(M)}\sup_{0\le t\le 1} E^P\|X(t)\|^2 \le C < +\infty. \tag{5}$$

Let $F(t) = f(X,q,t)$ and

$$Y(t) = \int_0^t (t-s)^{-\alpha} S(t-s)g(X(s),s)dW(s).$$

Fix $p = 2\beta^{-1}$ and $p^{-1} < \alpha < \frac{1}{2}$. By the Young inequality,

$$\begin{aligned} E^P\int_0^1 \|Y(t)\|^p dt &= E^p \int_0^1 \left\| \int_0^t (t-s)^{-\alpha} S(t-s)g(X(s),s)dW(s)\right\|^p dt \\ &\le M_0 \int_0^1 E^P \left(\int_0^t (t-s)^{-2\alpha}\|g(X(s),s)\|^2 ds\right)^{\beta^{-1}} ds \\ &\le M_1 1 + M_1 E^p \int_0^1 \|X(s)\|^2 ds \le C. \end{aligned}$$

Therefore,

$$\sup_{P\in\mathcal{P}(M)} \int_0^1 E^P\|Y(t)\|^p dt \le C < +\infty. \tag{6}$$

Denote, for any $0 < r^{-1} < \delta \le 1$,

$$\Lambda(R,\delta,r) = \left\{ w \in C(0,1;H) : w = R_\delta u, u \in L^r(0,1;H), \int_0^1 \|u(s)\|^r ds \le R \right\}$$

and

$$\begin{aligned} &\Xi(R) \\ &= \{w \in C(0,1;H) : w(t) = S(t)X_0 + w_1(t) + w_2(t), w_1 \in \Lambda(R,1,2), w_2 \in \Lambda(R,\alpha,p)\}. \end{aligned}$$

By Proposition 1 the sets $\Lambda(R,\delta,r)$ and $\Xi(R)$ are relatively compact in $C(0,1;H)$. Recall that $X(t) = S(t)X_0 + \pi^{-1}\sin(\pi\alpha)R_\alpha Y(t) + R_1 F(t)$. By (5), (6), and the Chebyshev inequality, for any $\varepsilon > 0$, $P(X \in \Xi(R)) \ge 1-\varepsilon$ for sufficiently large R for any $P \in \mathcal{P}(M)$. By the Prokhorov theorem the projection of $\mathcal{P}(M)$ on $\mathcal{M}(C(0,1;H))$ is tight.

By [11], the set

$$\left\{ q \in U : \int_0^1 \int_{\mathcal{O}} \int_V |u|^2 q(du,dx,dt) \le K \right\}$$

is relatively compact in the stable topology. Hence the projection of $\mathcal{P}(M)$ on $\mathcal{M}(U)$ is tight. We will show that $\mathcal{P}(M)$ is closed. Let the functional ϕ be as in Definition 1.

Let $C_t(\phi,X,q) = \phi(X(t),t) - L_1\phi(X,t) - L_2\phi(X,q,t)$. Notice that C_t is a continuous function on $C(0,1;H)\times U$. Let $P^n \to P$ weakly and $P^n \in \mathcal{P}(M)$ for any $n \ge 0$. Let $\psi \in C_b(\Omega;\mathbf{R})$ be an $\mathcal{F}_s$-measurable function. Compute that

$$0 = E^{P^n}\psi\{C_t(\phi,X,q) - C_s(\phi,X,q)\} \to E^P\psi\{C_t(\phi,X,q) - C_s(\phi,X,q)\}.$$

Hence $E^P\psi\{C_t(\phi,X,q) - C_s(\phi,X,q)\} = 0$ for any ψ $\mathcal{F}_s$ measurable and therefore $C_t(\phi,X,q)$ is P martingale. Since the functional J is l.s.c. then $J(P) \leq M$. Hence $\mathcal{P}(M)$ is compact. □

COROLLARY. *If* $\inf_{P\in\mathcal{P}} J(P) < +\infty$ *then there exists an optimal policy* P^*,

$$J(P^*) = \inf_{P\in\mathcal{P}} J(P).$$

Proof. It suffices to notice that J is l.s.c. and $\mathcal{P}(M)$ is nonempty and compact for a sufficiently large M. □

4. Example. Let $\mathcal{O} \subseteq \mathbf{R}$ be a bounded area with smooth boundary. Let $H = L(\mathcal{O}), V = [0,\infty)$ and $A = \Delta$ be the Laplace operator on $\mathcal{O}$. Let $f : \mathbf{R}\times[0,\infty) \to \mathbf{R}$ be a function satisfying assumption (i) and $g : \mathbf{R} \to \mathbf{R}$ be a bounded continuous function.

We consider the following control problem:

$$\frac{\partial}{\partial t}X^u(x,t) = \Delta X^u(x,t) + f(X^u(x,t),u(x,t)) + g(X^u(x,t))\dot{W}(t)$$

with

$$X^u(x,0) = \xi(x) \quad \text{for } x \in \mathcal{O},$$

$$X^u(x,t) = 0 \quad \text{for } x \in \partial\mathcal{O} \quad \text{and} \quad t \geq 0,$$

where $\xi \in H$ and W is a one-dimensional Brownian motion. This is a reaction-diffusion equation with randomly disturbed source. We minimize the following functional:

$$J(u) = E\int_0^1\int_{\mathcal{O}} |X^u(x,t) - \zeta(x,t)|^2 + C|u(x,t)|^2\}dxdt + E\int_{\mathcal{O}} |X^u(x,1) - \eta(x)|^2dx,$$

where $\zeta \in L^2(\mathcal{O}\times[0,1]), \eta \in L^2(\mathcal{O})$ and C is a positive number. By our theorem we have the existence of an optimal control for this problem.

ERGODIC CONTROL OF MARKOV CHAINS WITH CONSTRAINTS—THE GENERAL CASE*

VIVEK S. BORKAR†

Abstract. The problem of controlling a Markov chain on a countable state space with ergodic or 'long run average' cost is studied in the presence of additional constraints, requiring finitely many (say, m) other ergodic costs to satisfy prescribed bounds. Under extremely general conditions, it is proved that an optimal stationary randomized strategy can be found that requires at most m randomizations. This generalizes a result of Ross.

Key words. controlled Markov chains, control under constraints, ergodic control, randomized strategy, ergodic occupation measures

AMS subject classifications. 93E20, 90C40

1. Introduction.

The study of controlled Markov chains with constraints goes back to [10]. There has been a recent upsurge of interest due to possible applications to control of queuing networks ([2], [3], [5], [12], [13], [18], [19], among others). See also [17] for a related result. An important result in this domain is due to Ross [18] who proved that for the ergodic constrained problem with finite state and action spaces, an optimal stationary randomized strategy can be found which requires at most as many randomizations as the number of constraints. In [7 (Chap. 7)] and [8], the author extended this result to countable state space and compact action space for the single constraint case. It was claimed in [7 (Chap. 7)] and [8] that the multiple constraint problem can be handled simply by iterating the argument for a single constraint. This happens to be incorrect. The present work gives a direct proof for the multiple constraint case which is simpler and more elegant than that of [7], [8] even for the single constraint case. Moreover, it does not require the "single communicating class" condition used in [7], [8].

Our approach is to treat the control problem as a constrained optimization problem on a suitably defined closed convex set G of "ergodic occupation measures." This can also be viewed as an abstract (infinite-dimensional) linear programming problem, in which case it becomes a special instance of the so-called "moment problem" of LP (see [1, p. 85], [2], [4], [14], [15], among others). These works share in common with the present work the use of some variant of Dubins' lemma (Lemma 3.1) which immediately tells us that the optimal ergodic occupation measure is a convex combination of at most $m + 1$ extreme points of G, m being the number of constraints. The identification of these extreme points with stationary nonrandomized strategies, and the fact that their convex combination (which a priori means a mixed strategy that randomizes between them) is equivalent (in the sense of yielding the same costs) to a single strategy that requires at most m randomizations, are the main contributions of this paper. Both these results are specific to controlled Markov chains and do not follow from the general theory of the aforementioned moment problem.

The remainder of this section sets up the notation and formulates the problem. The next section contains some preliminary results concerning "ergodic occupation measures." This has some overlap with [7], [8]. The full details are included here, not just to make this account self-contained, but also because they are crucially required in the proofs of the main results. The latter are proved in §3. Section 4 concludes with some relevant remarks.

Let $X_n, n \geq 0$, be a controlled Markov chain on a countable state space $S = \{1, 2, \ldots\}$, with transition matrix $P_u = [[p(i,j,u_i)]], i, j \in S$, indexed by the control vector $u = [u_1, u_2, \ldots]$. Here $u_i \in D(i)$ for prescribed compact metric spaces $D(i), i \in S$.

By replacing $D(i)$ by $\Pi_j D(j)$ and each $p(i,j,.)$ by its composition with the projection $\Pi_j D(j) \to D(i)$, we may suppose that $D(i)$'s are replicas of a fixed compact metric space D. Let $L = D^\infty$. The maps $p(i,j,.)$ are assumed to be continuous.

For any Polish space Y, let $P(Y)$ = the space of probability measures with Prohorov topology [6]. If Y is countable, say $\{1,2,\ldots\}$, write $\mu \in P(Y)$ as a row vector $[\mu(\{1\}), \mu(\{2\}), \ldots]$, or simply $[\mu(1), \mu(2), \ldots]$. Let $P_0(L) \subset P(L)$ be the compact set consisting of product measures on L.

A control strategy (CS for short) is a sequence $\{\xi_n\}, \xi_n = [\xi_n(1), \xi_n(2), \ldots]$ of L-valued random variables such that for $i \in S, n \geq 0$,

$$P(X_{n+1} = i / X_m, \xi_m, m \leq n) = p(X_n, i, \xi_n(X_n)). \tag{1.1}$$

We say that the chain $\{X_n\}$ is governed by the CS $\{\xi_n\}$. If $\{\xi_n\}$ are independently and identically distributed with a common law $\Phi \in P(L)$, call it a stationary randomized strategy, SRS for short. As argued in [7, p. 21], we may assume that $\Phi \in P_0(L)$ and write $\Phi = \Pi_i \hat{\Phi}_i$ with $\hat{\Phi}_i \in P(D)$. Denote this SRS by $\gamma[\Phi]$. Under $\gamma[\Phi]$, $\{X_n\}$ is a Markov chain with a stationary transition matrix

$$P[\Phi] = [[p_\Phi(i,j)]], \qquad p_\Phi(i,j) = \int p(i,j,y)\hat{\Phi}_i(dy).$$

If Φ is a Dirac measure at $\xi \in L$, call $\gamma[\Phi]$ a stationary strategy (SS for short), denoted by $\gamma\{\xi\}$. The corresponding transition matrix will be denoted by $P\{\xi\} = P_\xi$.

If $\pi \in P(S)$ is an invariant probability measure under an SRS $\gamma[\Phi]$, we associate with the pair $(\pi, \gamma[\Phi])$ an "ergodic occupation measure" $\nu \in P(S \times D)$ defined by

$$\nu(\{i\}, du) = \pi(i)\hat{\Phi}_i(du), \qquad i \in S. \tag{1.2}$$

The set of all ergodic occupation measures will be denoted by G. The ergodic or long run average cost control problem is to almost surely minimize

$$\lim_{n\to\infty} \sup \frac{1}{n} \sum_{m=0}^{n-1} k_0(X_m, \xi_m(X_m)) \tag{1.3}$$

for a prescribed $k_0 \in C(S \times D; R^+)$. If an SRS $\gamma[\Phi]$ is being used and the initial state is in the support of a probability measure π which is ergodic under $\gamma[\Phi]$ (i.e., is an extreme point of the simplex of invariant probability measures under $\gamma[\Phi]$), then (1.3) almost surely equals

$$\int k_0 d\nu \tag{1.4}$$

for ν defined as in (1.2). We will consider the following constrained ergodic control problem: Given $k_i \in C(S \times D; R^+), 0 \leq \beta_i < \alpha_i \in R, 1 \leq i \leq m$, minimize $\int k_0 d\nu$ subject to

$$\beta_i \leq \int k_1 d\nu \leq \alpha_i, \qquad 1 \leq i \leq m, \tag{1.5}$$

where $\nu \in G$ (i.e., over H = the subset of G satisfying (1.5) which we assume to be nonempty).

LEMMA 1.1. *G is closed.*

Proof. Let $\nu_n \to \nu$ in $P(S \times D)$. From the definition of ergodic occupation measures, we have

$$\int p(.,j,.)d\nu_n = \nu_n(\{j\} \times D), \quad j \in S, \quad n \geq 1.$$

Letting $n \to \infty$, we get the same under ν. (Recall that $p(.,j,.)$ are continuous and $\{j\} \times D$ is both open and closed in $S \times D$). Disintegrating ν as in (1.2), we have $\nu \in P(S \times D) \Longrightarrow \pi \in P(S)$ and $\pi P[\Phi] = \pi$, i.e., $\pi \in P(S)$ is invariant under $\gamma[\Phi]$. Thus $\nu \in G$. □

We will consider two cases.

Case 1 (the stable case). Here we assume that G is compact and H is closed (and hence compact). Several sufficient conditions for compactness of G can be given; see, e.g., §V.3 of [7]. Since the upper inequality in (1.5) is preserved in any case under sequential limits in G, the closedness hypothesis of H requires that the lower inequality also does so. This would be the case, e.g., if $\beta_i = 0$ for all i or if $k_1, \ldots, k_m$ are bounded.

Case 2 (the near-monotone case). Here we assume that $\beta_i = 0$ for all i and the following "near-monotonicity" condition holds:

$$\liminf_{j \to \infty} \inf_u k_i(j,u) > \alpha_i, \quad 0 \leq i \leq m, \tag{1.6}$$

where

$$\alpha_0 = \inf_{\nu \in H} \int k_0 d\nu.$$

Equation (1.6) is satisfied by $\{k_i\}$ of the form $k_i(j,u) = f_i(j)$ with $f_i(j)$ increasing in j; hence the word "near-monotone."

We conclude this section with a statement of Choquet's theorem which will play a crucial role in what follows. Let E be a Hausdorff locally convex topological vector space and $X \subset E$ a convex compact metrizable subset thereof. Given a probability measure μ on X, call x its barycenter (or "resultant") if $f(x) = \int f d\mu$ for all continuous affine $f : X \to R$. Choquet's theorem states that each $x \in X$ is the barycenter of probability measure supported on the set of extreme points of X ([9, pp. 140–141]). Metrizability of X ensures that the latter set is measurable (in fact, G_δ—see [9, p. 138]), whereas compactness of X ensures that it is nonempty ([9, p. 105]).

2. Preliminary results. We start with some properties of sets G, H.

LEMMA 2.1. *G, H are convex.*

Proof. Since (1.5) is preserved under convex combinations, it suffices to prove the claim for G. Let $\nu_k \in G$, with

$$\nu_k(\{i\}, du) = \pi_k(i)\hat{\Phi}_{ki}(du), \qquad 1 \leq k \leq n.$$

Let $a_i \in (0,1)$ with $\sum_{i=1}^n a_i = 1$ and $\nu = \sum_{k=1}^n a_k \nu_k$. Set $\pi = \sum_{k=1}^n a_k \pi_k$ and define $\Phi = \Pi_i \hat{\Phi}_i \in P_0(L)$ by

$$\hat{\Phi}_i = \sum_{k=1}^n \left[a_k \pi_k(i) \hat{\Phi}_{ki} / \left(\sum_{j=1}^n a_j \pi_j(i) \right) \right] \tag{2.1}$$

for $i \in$ support (π), arbitrary otherwise. For each k,

$$\int p(.,j,.)d\nu_k = \nu_k(\{j\} \times D), \qquad j \in S. \tag{2.2}$$

Multiply (2.2) by a_k on both sides and sum over k. Rearranging terms, we obtain

$$\int p(.\,, j, .)d\nu = \nu(\{j\} \times D), \qquad j \in S,$$

for ν as in (1.2). Thus π is invariant under $\gamma[\Phi]$ and hence $\nu \in G$. □

The next lemma is a technical fact needed later to characterize extreme points of G.

LEMMA 2.2. *Let $\nu \in G$ be as in* (1.2). *Suppose that for some $k \in$ support (π)(say, $k = 1$), $\hat{\Phi}_k = \hat{\Phi}_1 = a\varphi_1 + (1-a)\varphi_2$ for some $a \in (0,1)$ and $\varphi_1 \neq \varphi_2$ in $P(D)$. Define $\Phi', \Phi'' \in P_0(L)$ by*

$$\Phi' = \varphi_1 \times \prod_{i=2}^{\infty} \hat{\Phi}_i, \qquad \Phi'' = \varphi_2 \times \prod_{i=2}^{\infty} \hat{\Phi}_i. \tag{2.3}$$

Then $\gamma[\Phi'], \gamma[\Phi'']$ both admit invariant probability measures containing $k\,(=1)$ in their supports.

Proof. Changing $\gamma[\Phi]$ to $\gamma[\Phi']$ or $\gamma[\Phi'']$ affects only the probabilities of transitions leaving k. Letting T, T_1, T_2 denote the mean return times to k under $\gamma[\Phi], \gamma[\Phi'], \gamma[\Phi'']$, respectively, it is clear that $T = aT_1 + (1-a)T_2$. Since $T < \infty$ and $1 > a > 0, T_1, T_2 < \infty$, and the claim follows. □

LEMMA 2.3. *The extreme points of G correspond to* SS.

Proof. Let ν as in (1.2) be an extreme point of G. For $i \notin$ support (π), we may set $\hat{\Phi}_i =$ some Dirac measure without affecting ν. Let $i \in$ support (π) (say, $i = 1$). Suppose

$$\hat{\Phi}_1 = a\varphi_1 + (1-a)\varphi_2 \tag{2.4}$$

for some $a \in (0,1)$ and $\varphi_1 \neq \varphi_2$ in $P(D)$. Define Φ', Φ'' by (2.3) and let π_1, π_2 be ergodic probability measures under $\gamma[\Phi'], \gamma[\Phi'']$, respectively containing 1 in their supports. Pick $b \in (0,1)$ such that

$$a = b\pi_1(1)/(b\pi_1(1) + (1-b)\pi_2(1)).$$

This is possible because $\pi_1(1), \pi_2(1) > 0$. Let $\pi' = b\pi_1 + (1-b)\pi_2$ and define $\nu' \in P(S \times D)$ by $\nu'(\{i\}, du) = \pi'(i)\hat{\Phi}_i(du)$. A computation similar to that of Lemma 2.1 shows that

$$\int p(.\,, j, .)d\nu' = \nu'(\{j\} \times D), \qquad j \in S.$$

Thus π' is invariant under $\gamma[\Phi]$. Also, support (π') = support $(\pi_1) \cup$ support (π_2). Now

$$p_\Phi(i,j) = ap_{\Phi'}(i,j) + (1-a)p_{\Phi''}(i,j), \qquad i,j \in S. \tag{2.5}$$

Since π_1 (respectively, π_2) is an ergodic probability measure under $\gamma[\Phi']$ (respectively, $\gamma[\Phi'']$), any two states in its support communicate under $\gamma[\Phi']$ (respectively, $\gamma[\Phi'']$) and therefore under $\gamma[\Phi]$ in view of (2.5) and the fact that $1 > a > 0$. Since supports of π_1, π_2 have a nonempty intersection containing "1," support (π') is a single communicating class under $\gamma[\Phi]$. Thus π' is an ergodic probability measure under $\gamma[\Phi]$. If π is also ergodic, we must have $\pi = \pi'$ and $\nu = \nu'$. Then it is easily checked (as in the proof of Lemma 2.1) that

$$\nu' = b\nu_1 + (1-b)\nu_2$$

where

$$\nu_1(\{i\}, du) = \pi_1(i)\hat{\Phi}'_i(du), \qquad \nu_2(\{i\}, du) = \pi_2(i)\hat{\Phi}''_i(du).$$

Since ν_1, ν_2 are clearly distinct and $1 > b > 0, \nu$ cannot be an extreme point of G, a contradiction. Suppose π is not ergodic. Then $\pi = c\overline{\pi} + (1-c)\tilde{\pi}$ for some $1 > c > 0$ and $\overline{\pi}, \tilde{\pi} \in P(S)$, which are distinct invariant probability measures under $\gamma[\Phi]$. Then

$$\nu = c\overline{\nu} + (1-c)\tilde{\nu}$$

where

$$\overline{\nu}(\{i\}, du) = \overline{\pi}(i)\hat{\Phi}_i(du), \qquad \tilde{\nu}(\{i\}, du) = \tilde{\pi}(i)\hat{\Phi}_i(du).$$

Since $\overline{\nu}, \tilde{\nu}$ are distinct and $1 > c > 0$, once again ν cannot be an extreme point of G. Thus (2.4) must not be possible. That is, for all $i \in$ support (π), $\hat{\Phi}_i$ must be Dirac. This completes the proof. □

Remark. We proved in passing that if ν is an extreme point of G and ν is as in (1.2), π must be an ergodic probability measure under $\gamma[\Phi]$.

We characterize the extreme points of H in the next section. The remainder of this section is devoted to proving that (1.4) does attain its minimum at an extreme point of H. Let $\overline{S} = S \cup \{\infty\}$ denote the one point compactification of S. We view $S, P(S), P(S \times D)$ as subsets of $\overline{S}, P(\overline{S}), P(\overline{S} \times \overline{D})$, respectively, via the natural embedding. Let $\overline{G}, \overline{H}$ be closures of G, H in $P(\overline{S} \times D)$. (For Case 1, $G = \overline{G}, H = \overline{H}$). Let $H_e, \overline{H}_e, G_e, \overline{G}_e$ denote the sets of their extreme points, respectively.

LEMMA 2.4. $H_e \subset \overline{H}_e, G_e \subset \overline{G}_e$.

Proof. Any $\nu \in H_e \backslash \overline{H}_e$ must be a convex combination of two distinct elements of $\overline{H}$ at least one of which must assign strictly positive probability to $\{\infty\} \times D$. But then so would ν, a contradiction. Thus $H_e \subset \overline{H}_e$. A similar argument proves the second claim. □

LEMMA 2.5. *Any $\nu \in H$ is the barycenter of a probability measure on H_e.*

Proof. In Case 1, H is compact and hence H_e nonempty ([9, p. 105]). The claim follows from Choquet's theorem. In Case 2, Choquet's theorem implies that ν is the barycenter of a probability measure Φ on $\overline{H}_e$ which is nonempty. If $\Phi(\overline{H}_e / H_e) > 0$, we must have $\nu(\{\infty\} \times D) > 0$, a contradiction. Thus $\Phi(H_e) = 1$ and we are done. (It follows, incidentally, that H_e is nonempty.) □

LEMMA 2.6. *Each $\nu \in \overline{H}$ is of the form*

$$\nu(A) = \delta\nu'(A \cap (S \times D)) + (1-\delta)\nu''(A \cap (\{\infty\} \times D)) \tag{2.6}$$

for all A Borel in $\overline{S} \times D$ with $\delta \in [0,1], \nu' \in G$ and $\nu'' \in P(\{\infty\} \times D)$.

Proof. Equation (2.6) obviously holds for some $\nu' \in P(S \times D)$. The claim is trivial for $\delta = 0$ and for $\delta = 1, \nu = \nu' \in H \subset G$ (e.g., in Case 1). Let $\delta \in (0,1]$. Pick $\nu_n \in H, n \geq 1$, such that

$$\nu_n(\{i\}, du) = \pi_n(i)\hat{\Phi}_{ni}(du), \qquad i \in S,$$

and $\nu_n \to \nu$ in $\overline{H}$. For $j \in S$,

$$\int p(.\,, j, .)d\nu_n = \nu_n(\{j\} \times D), \qquad n \geq 1.$$

Since $\{j\} \times D$ is both open and closed in $\overline{S} \times D$,

$$\nu_n(\{j\} \times D) \to \nu(\{j\} \times D) = \delta\nu'(\{j\} \times D).$$

Also, letting $S(N) = \{1, \ldots, N\} \subset S$,

$$\begin{aligned}
\liminf_{n\to\infty} \int p(.,j,.)d\nu_n &\geq \lim_{n\to\infty} \int_{S(N)\times D} p(.,j,.)d\nu_n \\
&= \int_{S(N)\times D} p(.,j,.)d\nu \\
&= \delta \int_{S(N)\times D} p(.,j,.)d\nu' \\
&\to \delta \int p(.,j,.)d\nu'
\end{aligned}$$

as $N \to \infty$. Combining the two,

$$\int p(.,j,.)d\nu' \leq \nu'(\{j\} \times D).$$

Both sides add up to one when summed over j. Thus equality must hold for all j, implying $\nu' \in G$ as in the proof of Lemma 1.1. □

LEMMA 2.7. *Equation* (1.4) *attains its minimum in* H.

Proof. Let $\{\nu_n\} \in H$ be such that

$$\int k_0 d\nu_n \downarrow \alpha_0.$$

In Case 1, H is compact and therefore $\nu_n \to \nu$ along a subsequence (denoted $\{n\}$ again by abuse of terminology) for some $\nu \in H$. Thus

$$\alpha_0 = \liminf_{n\to\infty} \int k_0 d\nu_n \geq \int k_0 d\nu \geq \alpha_0,$$

i.e., (1.4) attains its minimum at ν. In Case 2, let $\nu_n \to \nu \in \overline{H}$ by dropping to a subsequence if necessary. Pick $\epsilon > 0, k \geq 1$ such that

$$\inf_u k_j(i,u) \geq \alpha_j + \epsilon \quad \text{for } i \geq k, \quad 0 \leq j \leq m.$$

For $n \geq 1$, let

$$k_{jn}(i,u) = k_j(i,u)I\{i \leq k+n\} + (\alpha_j + \epsilon)I\{i > k+n\}.$$

Then for each j,

$$\begin{aligned}
\alpha_j &\geq \liminf_{n\to\infty} \int k_j d\nu_n \\
&\geq \lim_{n\to\infty} \int k_{jl} d\nu_n \\
&= \delta \int k_{jl} d\nu' + (1-\delta)(\alpha_j + \epsilon).
\end{aligned}$$

Letting $l \to \infty$ on the right,

$$\alpha_j \geq \delta \int k_j d\nu' + (1-\delta)(\alpha_j + \epsilon),$$

which is possible only if $\delta > 0$ and $\int k_j d\nu' \leq \alpha_j$ for all j. Thus $\nu' \in H$ and $\int k_0 d\nu' \leq \alpha_0$, implying $\int k_0 d\nu' = \alpha_0$. That is, (1.4) attains its minimum at ν'. □

THEOREM 2.1. *Equation* (1.4) *attains its minimum on* H *at an extreme point of* H.

Proof. Let the minimum of (1.4) on H be attained at ν and let Φ be as in Lemma 2.5. Then

$$\alpha_0 = \int k_0 d\nu = \int_{H_e} \left(\int k_0 d\rho \right) \Phi(d\rho).$$

Since $\int k_0 d\rho \geq \alpha_0$ for $\rho \in H_e$, $\int k_0 d\rho = \alpha_0$ for Φ-almost surely ρ. □

3. Main results. Let $\nu_0 \in H_e$ be such that $\int k_0 d\nu_0 = \alpha_0$. In this section we prove that ν_0 corresponds to an SRS with at most m randomizations. View H, G (respectively $\overline{H}, \overline{G}$) as subsets of the topological vector space of finite signed measures on $S \times D$ (respectively, $\overline{S} \times D$). A key lemma required will be the following specialization of a result of Dubins [11]. (See also [20, p. 265]).

LEMMA 3.1. ν_0 *can be expressed as a strict convex combination (i.e., convex combination with nonzero weights) of* k *points in* G_e *for some* $k \leq m+1$.

Proof. Consider Case 1. Suppose the claim is false. For simplicity, suppose that ν_0 can be expressed as a convex combination of $k = m+2$ distinct points in G_e, but not less. (For higher k, a similar proof works.) Then ν_0 must lie in the interior of an $(m+2)$-simplex A formed by these points in G_e. Let M be the $(m+1)$-dimensional affine space (i.e., translate a linear subspace) generated by A and let B be an open ball in M centered at ν_0 and contained in the interior of A. Thus $B \subset A \subset G$. Consider the intersections of the constraint hyperplanes $\{\nu | \int k_j d\nu = \alpha_j \text{ (or } \beta_j)\}$, $1 \leq j \leq m$, with M. Since at most m distinct constraint hyperplanes can intersect each other at a time, the intersections of their intersections with M must have a codimension of at most m in M and thus cannot have a corner in the interior of B. Thus ν_0 cannot be in H_e, a contradiction. The claim follows for Case 1. For Case 2, argue as above with $\overline{G}_e$ in place of G_e and then observe that if any of the points of $\overline{G}_e$ thus obtained were not in G_e, ν_0 would assign a strictly positive probability to $\{\infty\} \times D$, a contradiction.

In case ν_0 cannot be expressed as a convex combination of finitely many extreme points of G, a simple adaptation of the above proof works. In such a case, we claim that for any $j \geq 1$, we can find j linearly independent finite line segments in G which have ν_0 at the center. If this were not so for say, $j = j_0 + 1$, ν_0 would be in a j_0-dimensional face G' of G and therefore expressible as a convex combination of $j_0 + 1$ extreme points of G' and hence of G (see [9, p. 106]). This goes against the hypothesis, proving the claim. Now take $j \geq m+2$, consider the polytope generated by the end points of these line segments, and argue as above. □

Write ν_0 as

$$\nu_0(\{i\}, du) = \pi_0(i)\hat{\Phi}_i(du), \qquad i \in S, \tag{3.1}$$

corresponding to the SRS $\gamma[\Phi]$ with $\Phi = \prod_i \hat{\Phi}_i$. By Lemmas 2.3 and 3.1, it follows that ν_0 is a strict convex combination of some $\nu_1, \nu_2, \ldots, \nu_k \in G_e, k \leq m+1$, such that

$$\nu_j(\{i\}, du) = \pi_j(i)\delta_{\xi_j}(du), \quad i \in S, \quad 1 \leq j \leq k, \tag{3.2}$$

(where δ_u is the Dirac measure at u) with π_j an ergodic probability measure under $\gamma\{\xi_j\}$ for each j (cf. the remarks following Lemma 2.3). (It does not, however, follow that π_0 is ergodic under $\gamma[\Phi]$.)

In general, let $\pi_0 = \sum_{i=1}^{n} a_i \pi_{0i}$, where $a_i \in (0,1)$ with $\sum_{i=1}^{n} a_i = 1, n \geq 1$ (possibly $+\infty$) and $\{\pi_{0i}\}$ are ergodic probability measures under $\gamma[\Phi]$ with disjoint supports, denoted $\{S_i\}$, respectively.

LEMMA 3.2. *For each $j, 1 \leq j \leq k$, support (π_j) is contained in one of the S_i's.*

Proof. If the claim were false, two states in two distinct S_i's would communicate with each other under $\nu\{\xi_j\}$, and hence under $\gamma[\Phi]$ (cf. the proof of Lemma 2.3), a contradiction. □

For each $i \in S$, define finite subsets $N(i)$ of D by $N(i) = \{u \in D | u = \xi_j(i)$ for some $j, 1 \leq j \leq k$, satisfying $\pi_j(i) > 0\}$ and let $n(i) =$ (the cardinality of $N(i)) - 1$. From (2.1), it follows that for each $i, n(i)$ is the number of randomizations at i in the SRS $\gamma[\Phi]$. (By convention, $n(i) = 0$ if $N(i)$ is empty.)

Pick $i \in S$ (if any) such that $n(i) > 0$. Let $N(i) = \{u(1), u(2), \ldots, u(n(i)+1)\}$. Then by (2.1), $\hat{\Phi}_i$ is a strict convex combination of the Dirac measures at $u(j)$'s. Define $\gamma[\psi(i,j)]$ by: $\psi(i,j) = \prod_l \hat{\psi}_l(i,j)$ with

$$\hat{\psi}_l(i,j) = \hat{\Phi}_l, \quad \text{for } l \neq i,$$
$$= \text{the Dirac measure at } u(j), \quad \text{for } l = i.$$

LEMMA 3.3. *ν_0 is a strict convex combination of distinct elements $\mu_1, \ldots, \mu_{n(i)+1}$ of G such that μ_j is an ergodic occupation measure corresponding to $\gamma[\psi(i,j)]$ for each j. Furthermore, $\mu_1, \ldots, \mu_{n(i)+1}$ form the corners of an $(n(i)+1)$ simplex.*

Proof. If π_0 is ergodic, the first claim follows by iterating the argument used in the proof of Lemma 2.3 to show that ν is a strict convex combination of ν_1, ν_2. If not, let $\{\pi_{0l}\}$ be as above and apply the same argument to the π_{0l} for which $\pi_{0l}(i) > 0$. Suppose the second claim is false. Then ν_0 can be expressed as a strict convex combination of elements from $\{\mu_1, \ldots, \mu_{n(i)+1}\}$ in at least two distinct ways. But then (2.1) allows us to express the finitely supported probability measure $\hat{\Phi}_i$ as a strict convex combination of Dirac measures in two distinct ways, which is not possible. The claim follows. □

Call this $(n(i)+1)$ simplex the perturbation simplex at i and denote it by $Q(i)$.

LEMMA 3.4. *Let $\nu_1, \nu_2 \in Q(i)$ be distinct, with disintegrations*

$$\nu_j(\{l\}, du) = \pi_j(l)\varphi_{jl}(du), \quad l \in S, \quad j = 1,2.$$

Let $\pi_j(l) > 0$. Then $\varphi_{1l} = \varphi_{2l} = \hat{\Phi}_l$ for $l \neq i$ and $\varphi_{1i} \neq \varphi_{2i}$.

Proof. The claim for $l \neq i$ is immediate from (2.1). That $\varphi_{1i} \neq \varphi_{2i}$ follows from (2.1) and the easily verifiable fact that for $n > 1, b_1, \ldots, b_n > 0$, the map that maps

$$(a_1, \ldots, a_n) \in \left\{(x_1, \ldots, x_n) | x_i \in (0,1) \text{ for all } i, \sum x_i = 1\right\}$$

to

$$(a_1 b_1/c, a_2 b_2/c, \ldots, a_n b_n/c) \in (0,1)^n$$

with $c = \sum a_i b_i$ is one-one. □

The $(n(i)+1)$-simplex $Q(i)$ generates an $n(i)$-dimensional affine space in the space of finite signed measures on $S \times D$. Denote it by $Y(i)$.

LEMMA 3.5. *Let $j \neq i$ be another element of S such that $n(j) > 0$. Then $Y(i) \cap Y(j) = \{\nu_0\}$.*

Proof. Suppose not. Then we must have a $\overline{\nu} \in Q(i) \cap Q(j), \overline{\nu} \neq \nu_0$. Consider the line segment Z joining $\overline{\nu}, \nu_0$. $Z \subset Q(i) \cap Q(j)$ by the convexity of the latter. Show a typical $\nu \in Z$ as

$$\nu(\{i\}, du) = \pi(i)\varphi_i(du), \qquad i \in S.$$

As ν moves along Z, Lemma 3.4 and the fact that $Z \subset Q(i)$ imply that $\varphi_j = \hat{\Phi}_j$ all along, but φ_i keeps changing. Using $Z \subset Q(j)$, a similar conclusion can be drawn with the roles of i and j interchanged, leading to a contradiction. The claim follows. □

LEMMA 3.6. *Let $i_1, i_2, \ldots, i_{r+1}$ be different states with $n(i_j) > 0$ for all j and $\alpha_1, \alpha_2, \ldots, \alpha_r \in [0, 1]$ with $\sum_{i=1}^{r} \alpha_i = 1$. Then,*

$$(\alpha_1 Q(i_1) + \cdots + \alpha_r Q(i_r)) \cap Q(i_{r+1}) = \{\nu_0\}.$$

Proof. For $r = 1$, it reduces to the preceding lemma. The general case follows by induction on r using an argument analogous to the above at each step. □

COROLLARY 3.1. *Letting $L(i) = Y(i) - \nu_0$ when $n(i) > 0$, $\dim(L(i_1) + \cdots + L(i_r)) = \dim L(i_1) + \cdots + \dim L(i_r)$ whenever $n(i_1), \ldots, n(i_r) > 0, r \geq 1$ (i.e., $L(i_1) + \cdots + L(i_r)$ is a direct sum).*

Proof. The proof is immediate from the preceding lemma. □

LEMMA 3.7. $\sum_{i \in S} n(i) \leq m$.

Proof. Suppose not. Then there exists a finite subset $\{i_1, \ldots, i_l\} \subset S$ such that $n(i_1) + \cdots + n(i_l) \geq m + 1$. By the foregoing, the corners of $Q(i_1), \ldots, Q(i_l)$ together form a polytope with $n(i_1) + \cdots + n(i_l) \geq m + 1$-dimensional interior that contains ν_0. Now argue as in the proof of Lemma 3.1 to obtain a contradiction. □

Summarizing, we have the following.

THEOREM 3.1. *In both Case 1 and 2, there exists an optimal* SRS $\gamma[\Phi]$ *that requires at most m randomizations. Furthermore, if H has nonempty relative interior in G, there exist $\lambda_1, \ldots, \lambda_{2m} \geq 0$ such that for all $\nu \in G$ and $\mu_1, \ldots, \mu_{2m} \geq 0$,*

$$\begin{aligned}
&\int k_0 d\nu + \sum_{i=1}^{m} \lambda_i \left(\alpha_i - \int k_i d\nu \right) + \sum_{i=1}^{m} \lambda_{m+i} \left(\int k_i d\nu - \beta_i \right) \\
&\quad \geq \int k_0 d\nu_0 + \sum_{i=1}^{m} \lambda_i \left(\alpha_i - \int k_i d\nu_0 \right) + \sum_{i=1}^{m} \lambda_{m+i} \left(\int k_i d\nu_0 - \beta_i \right) \\
&\quad \geq \int k_0 d\nu_0 + \sum_{i=1}^{m} \mu_i \left(\alpha_i - \int k_i d\nu_0 \right) + \sum_{i=1}^{m} \mu_{m+i} \left(\int k_i d\nu_0 - \beta_i \right).
\end{aligned}$$

Proof. The first two claims are immediate in view of the foregoing. The last follows from standard Lagrange multiplier theory ([16, pp. 216–219]). □

4. Concluding remarks. (i) We have a priori restricted our attention to SRS rather than consider the optimization problems over all CS. If $\{k_i\}$ are bounded and S is a single communicating class under all CS, the following "pathwise" extension is available. Assume either the near-monotonicity condition or "condition B" of [7, p. 63] (which implies compactness of G, see [7, p. 60]). Define the $P(\overline{S} \times D)$-valued process $\{\nu_n\}$ by $\nu_n(A \times B) = \frac{1}{n} \sum_{m=0}^{n-1} I\{X_m \in A, \xi_m(X_m) \in B\}$ for A, B Borel in $\overline{S}, D$, respectively,

$\{\xi_n\}$ being the CS used. Argue as in [7, Lem 1.1, pp. 55–56] to conclude that, outside a set of zero probability, every limit point ν of $\{\nu_n\}$ in $P(\overline{S} \times D)$ is a convex combination of an element of G and a probability measure on $\{\infty\} \times D$. Under "condition B" mentioned above, we have $\nu \in G$ ([7, Lem. 2.2, p. 63]). The corresponding limits $\int k_i d\nu$ of $\int k_i d\nu_n, n \geq 1, 0 \leq i \leq m$, then clearly cannot outperform the optimal SRS by virtue of considerations analogous to those of §2 above.

(ii) For other classical cost criteria (infinite horizon discounted cost, finite horizon cost, cost up to a first exit time), their "occupation measure" formulations described in Chapters 3 and 4 of [7] allow us to use the above technique to derive analogous results for the corresponding constrained problems. It should be noted that the initial law plays a much more significant role for these problems—see the discussion in [7, p. 96–97], in particular, [7, Ex. 2, p. 97].

(iii) For the optimal cost $\int k_0 d\nu_0$ in the foregoing to be attainable from arbitrary initial law, we need that support (π_0) should be reachable in finite time with probability one from the given initial law under some CS. Use this CS until support (π_0) is hit and then switch over to the optimal SRS $\gamma[\Phi]$.

(iv) We can show the following incidental result which is of some interest: Suppose $\nu_1, \nu_2 \in G_e$ are distinct and correspond to $\gamma\{\xi_1\}, \gamma\{\xi_2\}$, respectively, with $\xi_j = [\xi_{j1}, \xi_{j2}, \ldots], j = 1, 2$. Suppose that $\xi_{1i} \neq \xi_{2i}$ implies $p(i, ., \xi_1(i)) \neq p(i, ., \xi_2(i))$. If the line segment Z joining ν_1, ν_2 is a face of G, then ξ_1, ξ_2 differ at exactly one state. To see this, note that any point in Z corresponds to some $\gamma[\Phi], \Phi = \prod \hat{\Phi}_i$, where each $\hat{\Phi}_i$ is a convex combination of Dirac measures at ξ_{1i}, ξ_{2i}. On the other hand, considerations leading to Theorem 3.1 show that at most one $\hat{\Phi}_i$ need be non-Dirac, proving the claim.

FURTHER RESULTS ON LEAST SQUARES BASED ADAPTIVE MINIMUM VARIANCE CONTROL*

LEI GUO†

Abstract. Based on the recently established results on self-tuning regulators originally proposed by Åström and Wittenmark, this paper presents various novel and extended results on least squares based adaptive minimum variance control for linear stochastic systems. These results establish self-optimality, self-tuning property, and the best possible convergence rate of the control law in a variety of situations of interest.

Key words. stochastic adaptive control, self-tuning, least squares

AMS subject classifications. 93C40, 93E12, 93E10

1. Introduction.

1.1. System description. Consider the following SISO linear discrete-time stochastic system:

$$A(z)y_n = B(z)u_{n-1} + C(z)w_n, \qquad n \geq 0, \tag{1.1}$$

where $\{y_n\}, \{u_n\}$ and $\{w_n\}$ are the system output, input, and random disturbance sequences, respectively, $y_n = u_n = w_n = 0$ for all $n < 0$, and $A(z), B(z)$, and $C(z)$ are polynomials in backward-shift operator z:

$$\begin{aligned} A(z) &= 1 + a_1 z + \cdots + a_p z^p, \qquad p \geq 0, \\ B(z) &= b_1 + b_2 z + \cdots + b_q z^{q-1}, \qquad q \geq 1, \\ C(z) &= 1 + c_1 z + \cdots + c_r z^r, \qquad r \geq 0, \end{aligned}$$

with known upper bounds p, q, and r for true orders and unknown coefficients a_i, b_j, and c_k.

As usual, for the above model we adopt the following standard assumptions:

(A1) $\{w_n, \mathcal{F}_n\}$ is a martingale difference sequence, i.e., $E[w_{n+1}|\mathcal{F}_n] = 0$, and satisfies

$$\sup_n E[|w_{n+1}|^\beta | \mathcal{F}_n] < \infty, \text{ a.s. for some } \beta > 2, \tag{1.2}$$

$$\lim_{n\to\infty} \frac{1}{n} \sum_{i=1}^{n} w_i^2 = \sigma^2 > 0 \quad \text{a.s.} \tag{1.3}$$

(A2) SPR condition: $\max_{|z|=1} |C(z) - 1| < 1$.

(A3) Minimum phase condition: $B(z) \neq 0$, for all $z : |z| \leq 1$.

Condition (A1) implies that the linear minimum variance predictor for y_{i+1} generated by (1.1) coincides with the minimum variance predictor $E[y_{i+1}|\mathcal{F}_i]$ if $\{u_i, \mathcal{F}_i\}$ is an adapted sequence. Condition (A2) is the usual SPR condition

$$\text{Re}\left\{\frac{1}{C(e^{j\lambda})} - \frac{1}{2}\right\} > 0 \quad \forall \lambda \in [0, 2\pi] \qquad (j \triangleq \sqrt{-1}),$$

which implies that $\sum_{i=1}^{r} c_i^2 < 1$, and is implied by $\sum_{i=1}^{r} |c_i| < 1$ (cf. Huang and Guo [1, pp. 1731, 1755]). This condition, together with the a priori knowledge about the orders p, q, and r, can be dispensed with for recursive identification of the linear model (1.1). We will not discuss that issue here and instead refer to Huang and Guo [1] for details. Condition (A3) is necessary for internal stability of minimum variance control systems even if the parameters in (1.1) are known (see, e.g., Kumar and Varaiya [2, p. 121]).

1.2. Performance. Our objective is to construct a control sequence $\{u_n\}$ based on the past and current observations, such that the following averaged square tracking error is asymptotically minimized:

$$J_n \triangleq \frac{1}{n}\sum_{i=1}^{n}(y_i - y_i^*)^2, \tag{1.4}$$

where $\{y_i^*\}$ is a reference sequence to be tracked, which is assumed to satisfy the following condition:

(A4) $\{y_i^*\}$ is bounded almost surely and is independent of $\{w_i\}$.

For convenience of discussions, we may assume without loss of generality that $\mathcal{F}_i = \sigma\{w_j, y_{j+1}^*, j \le i\}$. Then for any adapted input sequence $\{u_i, \mathcal{F}_i\}, y_i - y_i^* - w_i$ is $\mathcal{F}_{i-1}$-measurable for all i, and so by Chow's local convergence theorem for martingales (cf. [3]), it is easy to conclude that

$$J_n = \frac{1}{n}\sum_{i=1}^{n} w_i^2 + \begin{cases} R_n(1+o(1)) & \text{on } [nR_n \xrightarrow[n\to\infty]{} \infty]; \\ O(\frac{1}{n}) & \text{on } [\lim\limits_{n\to\infty}(nR_n) < \infty] \end{cases} \tag{1.5}$$

where R_n denotes the following "averaged regret":

$$R_n = \frac{1}{n}\sum_{i=1}^{n}(y_i = y_i^* - w_i)^2. \tag{1.6}$$

Consequently, by virtue of (1.3), we know that for any adapted sequence $\{u_i, \mathcal{F}_i\}$ the asymptotic lower bound to J_n is σ^2, and that

$$J_n \xrightarrow[n\to\infty]{} \sigma^2 \text{ a.s.} \iff R_n \xrightarrow[n\to\infty]{} 0 \text{ a.s.} \tag{1.7}$$

which justifies the familiar concept "globally convergent" or "self-optimizing" for an adaptive controller that leads to $R_n \xrightarrow[n\to\infty]{} 0$ a.s.. Moreover, from (1.5) it is apparent that R_n is of essential importance for the convergence rate of J_n, since it can be regarded as a second-order quantity (see also Wei [4, p. 1668]). It is also worth noting that once the self-optimality $R_n \xrightarrow[n\to\infty]{} 0$ a.s. is proved, the global stability, i.e., $\sup_n(1/n)\sum_{i=1}^{n}(y_i^2 + u_i^2) < \infty$ a.s., can be derived trivially by using Assumptions (A1), (A3), and (A4).

1.3. Estimation algorithms. Let us denote the unknown parameters in (1.1) by

$$\theta = [-a_1 \cdots - a_p, b_1 \cdots b_q, c_1 \cdots c_r]^\tau. \tag{1.8}$$

Then the model (1.1) can be succinctly written in a regression form:

$$y_{n+1} = \theta^\tau \varphi_n^0 + w_{n+1}, \qquad n \ge 0, \tag{1.9}$$

where φ_n^0 is the regression vector defined by

$$\varphi_n^0 = [y_n \cdots y_{n-p+1}, u_n \cdots u_{n-q+1}, w_n \cdots w_{n-r+1}]^\tau. \tag{1.10}$$

The standard method for estimating θ is the following recursive extended least squares (ELS) algorithm:

$$\theta_{n+1} = \theta_n + a_n P_n \varphi_n (y_{n+1} - \theta_n^\tau \varphi_n) \tag{1.11}$$

$$P_{n+1} = P_n - a_n P_n \varphi_n \varphi_n^\tau P_n, \quad a_n = (1 + \varphi_n^\tau P_n \varphi_n)^{-1}, \tag{1.12}$$

$$\varphi_n = [y_n \cdots y_{n-p+1}, \quad u_n \cdots u_{n-q+1}, \hat{w}_n \cdots \hat{w}_{n-r+1}]^\tau, \tag{1.13}$$

$$\hat{w}_n = y_n - \theta_n^\tau \varphi_{n-1} \tag{1.14}$$

with arbitrary initial values $\theta_0, \varphi_0 \neq 0$ and $P_0 \geq 0$.

There is a vast literature on strong consistency of the above ELS algorithm (see, e.g., Caines [5], Chen and Guo [6], and the references therein). In a Bayesian framework assuming Gaussianity of both the noise $\{w_n\}$ and the parameter θ, it was shown by Sternby [7] that in the white noise case (i.e., $C(z) = 1$), the necessary and sufficient condition for strong consistency of the least squares (LS) estimate θ_n is that

$$\lambda_{\min}(n) \xrightarrow[n\to\infty]{} \infty \text{ a.s.} \tag{1.15}$$

where $\lambda_{\min}(n)$ denotes the minimum eigenvalue of P_{n+1}^{-1}, i.e.,

$$\lambda_{\min}(n) \triangleq \lambda_{\min} \left\{ \sum_{i=0}^{n} \varphi_i \varphi_i^\tau + P_0^{-1} \right\}. \tag{1.16}$$

In the non-Bayesian framework where θ is an unknown constant vector as the case considered here, Lai and Wei [8] succeeded in showing that in the white noise case, strong consistency of the LS estimate still holds if (1.15) is strengthened into

$$\lambda_{\min}(n) \xrightarrow[n\to\infty]{} \infty, \qquad \frac{\log \lambda_{\max}(n)}{\lambda_{\min}(n)} \xrightarrow[n\to\infty]{} 0 \text{ a.s.} \tag{1.17}$$

where $\lambda_{\max}(n)$ denotes the maximum eigenvalue of P_{n+1}^{-1}. They also presented an example showing that relaxing the second part of (1.17) can result in a loss of strong consistency of the LS algorithm. The above consistency result can be easily generalized to colored noise and multivariable cases by resorting to the standard SPR condition (A2), and by using the standard recursions for the Lyapunov function studied earlier in (e.g., Ledwich and Moore [9], Solo [10], and Chen [11]) together with Chow's local convergence theorem for martingales (see [12] and [13]).

Despite the celebrated convergence properties of the ELS algorithm, the basic stability issue of adaptive minimum variance control constructed by using the ELS algorithm has been a long-standing problem over the past two decades. The main difficulty is that we do not know if the condition (1.17) really holds for the closed-loop systems. In fact, over the past decade, most of the results in stochastic adaptive control theory have been established for adaptive control laws that are not based on ELS algorithm but based on a stochastic gradient (SG) algorithm (or its variant). This algorithm is formed by simply replacing the matrix gain $\{a_n P_n\}$ in (1.11) by a scalar gain $\{\mu / r_n\}$ with $\mu > 0$, where

$$r_n \triangleq 1 + \sum_{i=0}^{n} \|\varphi_i\|^2. \tag{1.18}$$

Goodwin, Ramadge, and Caines [14] obtained the first stability and optimality result on SG-based adaptive tracking algorithms, which stimulated considerable research efforts afterwards. However, as is observed in simulations, the SG algorithm exhibits much slow convergence rate as compared with the ELS algorithm. Chen and Guo [15], [16], [6] have given a comprehensive theoretical study for the convergence of SG algorithm and justified the convergence phenomena known by simulations. To be precise, for strong consistency of SG, the following condition was introduced by Chen and Guo [15]:

$$r_n \xrightarrow[n\to\infty]{} \infty, \quad \frac{\lambda_{\max}(n)}{\lambda_{\min}(n)} = O(\{\log r_n\}^{\alpha}) \text{ a.s.}, \qquad \alpha \geq 0. \tag{1.19}$$

They showed that for the SG algorithm, if (1.19) holds with $\alpha \leq \frac{1}{4}$, then $\theta_n \xrightarrow[n\to\infty]{} \theta$, a.s. (see [15, Thm. 1], [16, Thm. 2], and [6, Thm. 4.5]). They also presented an example showing that in (1.19) the constant α is not allowed to be greater than 1 for strong consistency of SG (see [6, pp. 124–129]).

Hence for strong consistency, the SG algorithm requires much more excitation than the LS algorithm does (note that (1.19) is much stronger that (1.17)). Moreover, in the white noise case under the condition (1.19) with $\alpha = \frac{1}{4}$, the guaranteed convergence rate for the SG algorithm is only of the order $O(1/\log^{\lambda} r_n)$, i.e.,

$$\|\theta_n - \theta\|^2 = O\left(\frac{1}{\log^{\lambda} r_n}\right) \text{ a.s.} \quad \text{for some } \gamma > 0 \tag{1.20}$$

(cf. [15, p. 141] or [6, p. 132]), while under the same conditions, the convergence rate for the LS algorithm is much faster: $\|\theta_n - \theta\|^2 = O(\log^{\frac{5}{4}} r_n / r_n)$ a.s. (see, e.g., [6, p. 96] or [8, p. 155]).

1.4. Background. The standard adaptive minimum variance tracking control is constructed by simply identifying the adaptive predictor with the target value, i.e.,

$$\theta_n^{\tau}\varphi_n = y_{n+1}^{*}, \qquad n \geq 1, \tag{1.21}$$

where $\{\theta_n\}$ is generated by the ELS algorithm (1.11)–(1.14).

Åström and Wittenmark [17] were, apparently, the first to attempt an analysis of adaptive minimum variance control constructed by using LS-type estimates. They showed that if the LS parameter estimates should converge to some limit with no common factor, then the adaptive controller must necessarily be optimal. However, a difficult problem is whether these estimates are indeed convergent. To overcome this difficulty, Kumar [18] considered the case where the additive noise in (1.1) is *i.i.d.* and Gaussian. By using the technique of "Bayesian embedding," he succeeded in showing that, outside an exceptional set of true parameter vectors of Lebesgue measure zero, the LS based self-tuning minimum variance control enjoys various important convergence properties.

Recently, Guo and Chen [19] solved the basic stability and optimality problem of ELS-based adaptive minimum variance control for the general system (1.1) under the standard conditions (A1)–(A3). The following was shown in [19]:

(i) If the "high frequency" gain b_1 is known, then the standard ELS-based self-tuning tracker is globally stable and self-optimizing, with a rate of convergence for the regret: $R_n = O(d_n/n^{1-\varepsilon})$ a.s. for all $\varepsilon > 0$, where $\{d_n\}$ is a positive sequence satisfying $d_n \leq d_{n+1}, \sup_{n\geq 0}(d_{n+1}/d_n) < \infty$, and

$$\|w_n\|^2 = O(d_n) \quad \text{a.s.} \tag{1.22}$$

(ii) If b_1 is unknown, instead of using a fixed a priori estimate $\hat{b}_1$ for b_1 in designing the control law as in Åström and Wittenmark [17], a natural approach is to update this estimate with the current and past data. This was done in [19] by setting the on-line estimate (say $\hat{b}_1(n)$) to be

$$\hat{b}_1(n) = \begin{cases} b_1(n) & \text{if } |b_1(n)| \geq \dfrac{1}{\sqrt{\log r_{n-1}}}, \\ b_1(n) + \operatorname{sgn}(b_1(n)) \dfrac{1}{\sqrt{\log r_{n-1}}} & \text{otherwise,} \end{cases} \tag{1.23}$$

where $\operatorname{sgn}(\cdot)$ is the sign function, r_n is defined by (1.18) and $b_1(n)$ is the $(p+1)$th component of θ_n generated by the ELS algorithm (1.11)–(1.14). Then the resulting ELS-based adaptive control law is again shown to be stable and self-optimizing, with an implicitly established convergence rate $R_n = O(1/\log n)$ a.s..

The purpose of this paper is to give further results on ELS-based adaptive minimum variance control, with emphases placed on the convergence rate of R_n. We will improve the convergence rate obtained in [19] and show that in some cases the limit of $(n/\log n)R_n$ actually exists and is finite. We will also study the standard control law (1.21) (with no modifications on $b_1(n)$) and address the consistency issue of parameter estimates.

2. Preliminaries. To begin with, consider the regulation problem where $y_i^* \equiv 0$. Let $\lambda_{\min}(X)$ denote the minimum eigenvalue of a square matrix X. Then, from (1.9) it follows that

$$\lambda_{\min}\left(\sum_{i=0}^{n-1} \varphi_i^0 \varphi_i^{0\tau}\right) \|\theta\|^2 \leq \sum_{i=0}^{n-1} (\theta^\tau \varphi_i^0)^2 = \sum_{i=0}^{n-1} (y_{i+1} - w_{i+1})^2 \tag{2.1}$$

and so by (1.6),

$$\lambda_{\min}\left(\frac{1}{n}\sum_{i=0}^{n-1} \varphi_i^0 \varphi_i^{0\tau}\right) \|\theta\|^2 \leq R_n, \tag{2.2}$$

which implies that the "self-optimality" and "persistency of excitation" cannot hold simultaneously in general for the closed-loop system resulting from regulation (see also [20, pp. 372–373] for a related discussion). Moreover, from (2.2) it is clear that the better the convergence rate of the regret R_n, the poorer the excitation of the regressor φ_i^0 will have. This explains the familiar dilemma between estimation and control. From the following theorem, we will see which kind of excitation results we may have and how the degree of excitation of $\{\varphi_i^0\}$ depends on $\{y_i^*\}$ in a general asymptotically optimal tracking system.

For future reference, we list the following identifiability conditions.

(A5) The polynomials $B(z)$ and $A(z) - C(z)$ are coprime, and either $\partial B(z) = q - 1$ or $\partial(A(z) - C(z)) = \max(p, r)$, where and hereafter $\partial X(z)$ denotes the degree for a given polynomial $X(z)$ in dummy variable z.

(A6) The polynomials $A(z)$ and $B(z)$ are coprime with $|a_p| + |b_q| \neq 0$.

The following theorem extends some related results in [22].

THEOREM 2.1. *Consider the linear model* (1.1). *Let the regret* R_n *be defined by* (1.6), *and the Assumptions* (A1) *and* (A4) *be satisfied. Suppose that* $\{\tau_n\}$ *is a strictly increasing sequence of random integers such that* $R_{\tau_n+1} \xrightarrow[n\to\infty]{} 0$ *holds on a set* D *of positive probability; then the following two conclusions hold:*

(i)

$$\liminf_{n\to\infty} \lambda_{\min}\left\{\frac{1}{\tau_n}\sum_{i=0}^{\tau_n}\psi_i\psi_i^{\tau}\right\} > 0 \qquad a.s.\ on\ D, \tag{2.3}$$

provided that (A5) *holds, where*

$$\psi_i = [y_i \cdots y_{i-p^*+1}, u_{i-1}\cdots u_{i-q+1}]^{\tau}, \qquad p^* \triangleq \max(p,r). \tag{2.4}$$

(ii)

$$\liminf_{n\to\infty} \frac{\lambda_{\min}\left(\sum_{i=0}^{\tau_n}\varphi_i^0\varphi_i^{0\tau}\right)}{\lambda^*_{\min}(\tau_n)} > 0 \qquad a.s.\ on\ D, \tag{2.5}$$

provided that (A6) *holds, and that*

$$\sqrt{R_{\tau_n+1}+\frac{\log\log\tau_n}{\tau_n}} = o\left(\frac{\lambda^*_{\min}(\tau_n)}{\tau_n}\right) \qquad a.s.\ on\ D, \tag{2.6}$$

where φ_i^0 *is defined by* (1.10), *and*

$$\lambda^*_{\min}(n) = \lambda_{\min}\left(\sum_{i=1}^{n} Y_i^* Y_i^{*\tau}\right), \qquad Y_i^* = [y_i^* y_{i-1}^* \cdots y_{i-p-q+1}^*]^{\tau}. \tag{2.7}$$

We remark that Theorem 2.1 holds irrespective of the control law structure and the minimum phase condition (A3). Following some proof ideas used in Chen and Guo [22], we preface the proof of the theorem by four simple facts, which are stated as lemmas since they will be frequently referenced in the sequel.

For any polynomial $F(z)$, denote its L_2-norm $\|F(z)\|_2$ by

$$\|F(z)\|_2^2 = \frac{1}{2\pi}\int_{-\pi}^{\pi} |F(e^{i\lambda})|^2 d\lambda.$$

In the sequel, we shall sometimes suppress the argument (z) for simplicity.

LEMMA 2.1. *Let* $F(z)$ *and* $G(z)$ *be two coprime polynomials, and* S_d *be a set of polynomials* $(M(z), N(z))$, *defined by*

$$S_d = \{(M(z),N(z)) : \|M(z)\|_2^2 + \|N(z)\|_2^2 = 1; \partial M + \partial N \le d;$$

$$\textit{and either } \partial M < \partial G \textit{ or } \partial N < \partial F\}.$$

Then for any integer $d \ge 0, \inf_{(M,N)\in S_d} \|FM + GN\|_2 > 0$.

Proof. Suppose that the converse assertion were true; then it would necessarily imply that

$$FM + GN = 0 \tag{2.8}$$

for some polynomial (M, N) in S_d and some integer $d \geq 0$. By the coprimeness of F and G, there exist polynomials L and H such that $FL + GH = 1$. If $\partial M < \partial G$, then $G \not\equiv 0$, and we have by (2.8)

$$M = M(FL + GH) = L(-GN) + MGH = G(MH - LN).$$

From this it is easy to conclude that $M = 0$. By (2.8), we then have $N = 0$ since G is a nonzero polynomial, and so $\|M\|_2 + \|N\|_2 = 0$. Similarly, if $\partial N < \partial F$, again we have $\|M\|_2 + \|N\|_2 = 0$. This contradicts with $(M, N) \in S_d$. □

LEMMA 2.2. *Let F and G be two coprime polynomials. For any integers $m \geq 0, n \geq 0$, and any sequence $\{z_k\}$, define for any $k \geq 0$,*

$$Z_k = [F(z), zF(z) \cdots z^m F(z), G(z), zG(z) \cdots z^n G(z)]^\tau z_k.$$

If either $m < \partial G$ or $n < \partial F$, then with $c \triangleq \inf_{(M,N)\in S_{m+n}} \|FM + GN\|_2^2 > 0$,

$$\lambda_{\min}\left(\sum_{i=0}^{k} Z_i Z_i^\tau\right) \geq c\lambda_{\min}\left(\sum_{i=0}^{k} Z_i^0 Z_i^{0\tau}\right) \quad \forall k \geq 1,$$

where S_{m+n} is defined as in Lemma 2.1, *and*

$$Z_k^0 = [z_k, z_{k-1} \cdots z_{k-s}]^\tau, \qquad s \triangleq \max\{m + \partial F, n + \partial G\}.$$

Proof. We first note that $c > 0$ is guaranteed by Lemma 2.1. For any $x \in \mathbb{R}^{n+m+2}$, $\|x\| = 1$, with $x = [\alpha_0 \cdots \alpha_m, \beta_0 \cdots \beta_n]^\tau$, set $M(z) = \alpha_0 + \cdots + \alpha_m z^m$ and $N(z) = \beta_0 + \cdots + \beta_n z^n$. We have for all $k \geq 1$,

$$\begin{aligned}
\lambda_{\min}\left(\sum_{i=0}^{k} Z_i Z_i^\tau\right) &= \inf_{\|x\|=1} \sum_{i=0}^{k} (x^\tau Z_i)^2 \\
&= \inf_{\|x\|=1} \sum_{i=0}^{k} [(M(z)F(z) + N(z)G(z))z_i]^2 \\
&\geq \inf_{\|x\|=1} \|MF + NG\|_2^2 \lambda_{\min}\left(\sum_{i=0}^{k} Z_i^0 Z_i^{0\tau}\right) \\
&\geq \inf_{(M,N)\in S_{m+n}} \|MF + NG\|_2^2 \lambda_{\min}\left(\sum_{i=0}^{k} Z_i^0 Z_i^{0\tau}\right). \qquad \square
\end{aligned}$$

LEMMA 2.3. *Let $x_k \in \mathbb{R}^d, (d > 0), k \geq 0$, be a vector sequence, $x_k = 0$, for all $k < 0$, and $F(z)$ be a polynomial with $\|F(z)\|_2 \not\equiv 0$. Set $\overline{x}_k = F(z)x_k$. Then we have for all $n > 0$,*

$$\lambda_{\min}\left(\sum_{k=0}^{n} x_k x_k^\tau\right) \geq \frac{1}{(\partial F + 1)\|F(z)\|_2^2} \lambda_{\min}\left(\sum_{k=0}^{n} \overline{x}_k \overline{x}_k^\tau\right).$$

Proof. Let the coefficients of $F(z)$ be $f_i, i = 0, \cdots, \partial F$. Then by the Schwarz inequality,

$$\lambda_{\min}\left(\sum_{k=0}^{n}\overline{x}_k\overline{x}_k^\tau\right) = \inf_{\|x\|=1}\sum_{k=0}^{n}(x^\tau\overline{x}_k)^2$$

$$= \inf_{\|x\|=1}\sum_{k=0}^{n}[F(z)x^\tau x_k]^2 = \inf_{\|x\|=1}\sum_{k=0}^{n}\left[\sum_{i=0}^{\partial F}f_i(x^\tau x_{k-i})\right]^2$$

$$\le \sum_{i=0}^{\partial F}f_i^2\inf_{\|x\|=1}\sum_{k=0}^{n}\sum_{i=0}^{\partial F}(x^\tau x_{k-i})^2 \le \|F(z)\|_2^2(\partial F+1)\lambda_{\min}\left(\sum_{k=0}^{n}x_kx_k^\tau\right). \qquad \square$$

We also need a simple corollary of the laws of the iterated logarithm for martingales established in Jain, Jogdeo, and Stout [21].

LEMMA 2.4. *Let* $\{w_i, \mathcal{F}_i\}$ *satisfy condition* (A1), *and* $\{f_i, \mathcal{F}_i\}$ *be an adapted sequence satisfying*

$$\sum_{i=1}^{n}f_i^2 = O(n) \quad a.s., \quad f_n^2 = O(n^\delta) \quad a.s., \text{ for some } \delta \in [0,1).$$

Then as $n \to \infty$,

$$\sum_{i=1}^{n}f_iw_{i+1} = O(\sqrt{n\log\log n}) \quad a.s.$$

Proof. We first consider the case $|f_i| \ge 1$ a.s., for all i. By the martingale convergence theorem in [3] and the Kronecker lemma it follows that

$$\sum_{i=1}^{n}(E[w_{i+1}^2|\mathcal{F}_i] - w_{i+1}^2) = o(n) \quad \text{a.s.}$$

So by (1.3)

$$\sum_{i=1}^{n}E[w_{i+1}^2|\mathcal{F}_i] = (1+o(1))\sigma^2n \quad \text{a.s.}$$

Consequently, by noting $|f_i| \ge 1$ a.s.,

$$\liminf_{n\to\infty}\frac{1}{n}\sum_{i=1}^{n}f_i^2E[w_{i+1}^2|\mathcal{F}_i] \ge \sigma^2 > 0 \quad \text{a.s.}$$

Hence by applying Theorem 3.1 in [21] it is easy to see that the lemma is true.

In the general case, noting that $f_i = [f_i + \text{ sgn }(f_i)] - \text{ sgn}(f_i)$, and applying the just proved result to $\sum_{i=1}^{n}[f_i + \text{ sgn}(f_i)]w_{i+1}$ and $\sum_{i=1}^{n}\text{ sgn}(f_i)w_{i+1}$, respectively, we see that the desired result is also true. $\square$

We are now in a position to prove Theorem 2.1.

Proof of Theorem 2.1. Following Chen and Guo [22] or [16], set $\xi_i = y_i - y_i^* - w_i$, $z_i = \xi_i + y_i^*$. Then by the assumption we have

$$\frac{1}{\tau_n}\sum_{i=0}^{\tau_n+1}\xi_i^2 \xrightarrow[n\to\infty]{} 0 \quad \text{on } D. \tag{2.9}$$

Note that

$$y_i = w_i + y_i^* + \xi_i = w_i + z_i, \tag{2.10}$$

and then by (1.1),

$$B(z)u_i = [A(z)y_{i+1} - C(z)w_{i+1}] = [A(z) - C(z)]w_{i+1} + A(z)z_{i+1}. \tag{2.11}$$

Part (i). By Lemma 2.3 we need only to consider

$$\overline{\psi}_i \triangleq B(z)\psi_i \triangleq \psi_i^w + \psi_i^z, \tag{2.12}$$

where, by (2.3), (2.9), and (2.10),

$$\psi_i^w = [B(z), zB(z), \cdots z^{p^*-1}B(z), A(z) - C(z), \cdots z^{q-2}[A(z) - C(z)]]^\tau w_i,$$
$$\psi_i^z = [B(z), zB(z), \cdots z^{p^*-1}B(z), A(z), \cdots z^{q-2}A(z)]^\tau z_i.$$

By Lemma 2.2 we know that there exists $c > 0$ such that

$$\lambda_{\min}\left\{\sum_{i=0}^{n} \psi_i^w \psi_i^{w\tau}\right\} \geq c\lambda_{\min}\left\{\sum_{i=0}^{n} [w_i \cdots w_{i-s}]^\tau [w_i \cdots w_{i-s}]\right\}$$

holds for all $n > 0$, where $s = p^* + q - 2$. Consequently, by (A1),

$$\liminf_{n\to\infty} \frac{1}{n}\lambda_{\min}\left(\sum_{i=0}^{n} \psi_i^w \psi_i^{w\tau}\right) > 0 \quad \text{a.s.} \tag{2.13}$$

Let $\psi_i^{y^*}$ and ψ_i^{ξ} be defined in the same way as ψ_i^z (i.e., in the definition of ψ_i^z replace z_i by y_i^* and ξ_i, respectively). Then by the Schwarz inequality and (2.9), it is clear that

$$\frac{1}{\tau_n}\sum_{i=0}^{\tau_n} \psi_i^{\xi}\psi_i^{w\tau} \xrightarrow[n\to\infty]{} 0 \quad \text{on } D.$$

Also, by Assumptions (A1) and (A4),

$$\frac{1}{\tau_n}\sum_{i=0}^{\tau_n} \psi_i^{y^*}\psi_i^{w\tau} \xrightarrow[n\to\infty]{} 0 \quad \text{a.s.}$$

Hence we have

$$\frac{1}{\tau_n}\sum_{i=0}^{\tau_n} \psi_i^{z}\psi_i^{w\tau} \xrightarrow[n\to\infty]{} 0 \quad \text{a.s. on } D \tag{2.14}$$

Therefore, by (2.12)–(2.14) it is easy to see that

$$\liminf_{n\to\infty} \lambda_{\min}\left(\frac{1}{\tau_n}\sum_{i=0}^{\tau_n} \overline{\psi}_i \overline{\psi}_i^\tau\right) > 0 \quad \text{a.s. on } D.$$

From this and Lemma 2.3, the assertion (i) follows immediately.

Part (ii). Similarly, we consider the transformation $\overline{\varphi}_i^0 = B(z)\varphi_i^0$. By (2.10) and (2.11), $\overline{\varphi}_i^0$ can be decomposed as $\overline{\varphi}_i^0 = \varphi_i^w + \varphi_i^z$, where

$$\varphi_i^w = [zB(z)\cdots z^pB(z), A(z) - C(z)\cdots z^{q-1}[A(z) - C(z)], zB(z)\cdots z^\tau B(z)]^\tau w_{i+1},$$
$$\varphi_i^z = [zB(z),\cdots, z^pB(z), A(z),\cdots z^{q-1}A(z), 0,\cdots, 0]^\tau z_{i+1}.$$

Let $\varphi_i^{y^*}$ and φ_i^ξ be defined in the same way as for φ_i^z. For $x = w, z, y^*$ and ξ, let $\overline{\varphi}_i^x$ be the vector composed of the first $(p+q)$ elements of φ_i^x. Then by (A1), (A4), and Lemma 2.4 it is easy to see that

$$\sum_{i=0}^{\tau_n} \varphi_i^w \overline{\varphi}_i^{y^*\tau} = O(\sqrt{\tau_n \log\log \tau_n}) \quad \text{a.s.} \tag{2.15}$$

Let $x \in \mathbb{R}^{p+q+r}$ be any (random) vector, $\|x\| = 1$. Put $x = (\alpha^\tau, \beta^\tau)^\tau, \alpha \in \mathbb{R}^{p+q}, \beta \in \mathbb{R}^r$. Then by the Schwarz inequality, (2.15) and the fact that $\overline{\varphi}_i^z = \overline{\varphi}_i^\xi + \overline{\varphi}_i^{y^*}$,

$$\begin{aligned} x^\tau \sum_{i=0}^{\tau_n} \overline{\varphi}_i^0 \overline{\varphi}_i^{0\tau} x &= \sum_{i=0}^{\tau_n} (x^\tau \varphi_i^w + x^\tau \varphi_i^z)^2 = \sum_{i=0}^{\tau_n} (x^\tau \varphi_i^w + \alpha^\tau \overline{\varphi}_i^z)^2 \\ &= \sum_{i=0}^{\tau_n} (x^\tau \varphi_i^w)^2 + O\left(\sqrt{\sum_{i=0}^{\tau_n} w_i^2 \sum_{i=0}^{\tau_n+1} \xi_i^2}\right) + O(\sqrt{\tau_n \log\log \tau_n}) \\ &\quad + \sum_{i=0}^{\tau_n} (\alpha^\tau \overline{\varphi}_i^z)^2 \\ &\geq \sum_{i=0}^{\tau_n} (x^\tau \varphi_i^w)^2 + O(\tau_n \sqrt{R_{\tau_n+1}}) + O(\sqrt{\tau_n \log\log \tau_n}) \\ &\quad + \sum_{i=0}^{\tau_n} (\alpha^\tau \overline{\varphi}_i^{y^*})^2 \\ &\geq \sum_{i=0}^{\tau_n} (x^\tau \varphi_i^w)^2 + (c\|\alpha\|^2 + o(1))\lambda_{\min}^*(\tau_n) \quad \text{a.s. on } D \end{aligned} \tag{2.16}$$

where for the last inequality we have used the assumption (2.6) and Lemma 2.2, and where the quantities $c > 0$ and "$o(1)$" are independent of the vector x.

Now, suppose that the converse assertion of (2.5) were true; then by Lemma 2.3 we know that there would be a set $D_1 \subset D$ with $P(D_1) > 0$ such that

$$\liminf_{n\to\infty} \frac{\lambda_{\min}\left(\sum_{i=0}^{\tau_n} \overline{\varphi}_i^0 \overline{\varphi}_i^{0\tau}\right)}{\lambda_{\min}^*(\tau_n)} = 0 \quad \text{on } D_1.$$

From this and (2.16) it is not difficult to find vectors $x_n \in \mathbb{R}^{p+q+r}, \|x_n\| = 1, x_n = (\alpha_n^\tau, \beta_n^\tau)^\tau, \alpha_n \in \mathbb{R}^{p+q}$, and a subsequence of $\{\tau_n\}$, which is also denoted by $\{\tau_n\}$, such that

$$\|\alpha_n\| \xrightarrow[n\to\infty]{} 0 \quad \text{a.s. on } D_1, \tag{2.17}$$

and that

$$\frac{1}{\tau_n}\sum_{i=0}^{\tau_n}(x_n^\tau\varphi_i^w)^2 = \frac{1}{\tau_n}\sum_{i=0}^{\tau_n}\{\alpha_n^\tau\overline{\varphi}_i^w + \beta_n^\tau B(z)[w_i\cdots w_{i-r+1}]^\tau\}^2 \xrightarrow[n\to\infty]{} 0 \quad \text{a.s. on } D_1. \tag{2.18}$$

From (2.17) and (2.18), it is obvious that

$$\frac{1}{\tau_n}\sum_{i=0}^{\tau_n}\{\beta_n^\tau B(z)[w_i\cdots w_{i-r+1}]^\tau\}^2 \xrightarrow[n\to\infty]{} 0 \quad \text{a.s. on } D_1.$$

Consequently, from this and (A1), it follows that

$$\begin{aligned}
0 &= \lim_{n\to\infty}\frac{1}{\tau_n}\sum_{i=0}^{\tau_n}\{\beta_n^\tau B(z)[1,\cdots,z^{r-1}]^\tau w_i\}^2 \\
&\geq \lim_{n\to\infty}\|\beta_n^\tau B(z)[1,\cdots,z^{r-1}]^\tau\|_2^2\lambda_{\min}\left\{\frac{1}{\tau_n}\sum_{i=0}^{\tau_n}[w_i,\cdots,w_{i-q-r+2}]^\tau[w_i,\cdots,w_{i-q-r+2}]\right\} \\
&= \sigma^2\lim_{n\to\infty}\|\beta_n^\tau B(z)[1,\cdots,z^{r-1}]^\tau\|_2^2 \quad \text{a.s. on } D_1,
\end{aligned}$$

which obviously implies that $\beta_n \xrightarrow[n\to\infty]{} 0$ a.s. on D_1, and so by (2.17), $\|x_n\| \xrightarrow[n\to\infty]{} 0$ a.s. on D_1. This contradicts with $\|x_n\| = 1$, and hence assertion (ii) is also true. □

Before concluding this section, we list some basic properties of the ELS algorithm here, which will be used frequently in later sections.

LEMMA 2.5. *For the system* (1.1) *and the* ELS *algorithm* (1.11)–(1.14), *if Conditions* (A1) *and* (A2) *hold and* u_n *is* $\mathcal{F}_n$*-measurable for* $n \geq 1$, *then*

(i) $$\tilde{\theta}_{n+1}^\tau P_{n+1}^{-1}\tilde{\theta}_{n+1} = O(\log r_n) \quad a.s.,$$

(ii) $$\sum_{i=1}^{n+1}\|\hat{w}_i - w_i\|^2 = O(\log r_n) \quad a.s.,$$

(iii) $$\sum_{i=1}^{n}\frac{\|\tilde{\theta}_i^\tau\varphi_i\|^2}{1+\varphi_i^\tau P_i\varphi_i} = O(\log r_n) \quad a.s.,$$

where $\tilde{\theta}_n \triangleq \theta - \theta_n$, *and* r_n *is defined by* (1.18).

Except (i), this lemma is the same as Lemma 1 in [19], but (i) is actually also established in the proof of that lemma.

COROLLARY 2.1. *Under the same conditions and notations as in Lemma 2.5, the following property holds:*

$$\|\tilde{\theta}_{n+1}\|^2 + \|\hat{w}_{n+1} - w_{n+1}\|^2 + \frac{\|\tilde{\theta}_n^\tau\varphi_n\|^2}{1+\varphi_n^\tau P_n\varphi_n} = O(\log r_n) \quad a.s. \tag{2.19}$$

Proof. We need only to note that by (1.12) and the choice of the initial condition, $P_{n+1}^{-1} \geq P_0^{-1} > 0$, for all $n \geq 0$. □

3. Adaptive minimum variance control (with b_1 fixed). Throughout this section we assume that the "high-frequency" gain b_1 in the model (1.1) is known. The main consideration behind this is that results obtained in this case are relatively complete, which can indicate the greatest expected achievement in the general case.

Similar to (1.8)–(1.10), we rewrite (1.1) in the regression form

$$y_{n+1} - b_1 u_n = \theta^\tau \varphi_n^0 + w_{n+1}, \qquad n \geq 0, \tag{3.1}$$

but here θ and φ_n^0 should be defined as

$$\theta = [-a_1 \dots - a_p \quad b_2 \dots b_q \quad c_1 \dots c_r]^\tau, \tag{3.2}$$

$$\varphi_n^0 = [y_n \dots y_{n-p+1}, u_{n-1} \dots u_{n-q+1}, w_n \dots w_{n-r+1}]^\tau. \tag{3.3}$$

The standard ELS algorithm for estimating θ is as follows:

$$\theta_{n+1} = \theta_n + a_n P_n \varphi_n (y_{n+1} - b_1 u_n - \theta_n^\tau \varphi_n), \tag{3.4}$$

$$P_{n+1} = P_n - a_n P_n \varphi_n \varphi_n^\tau P_n, \quad a_n = (1 + \varphi_n^\tau P_n \varphi_n)^{-1}, \tag{3.5}$$

$$\varphi_n = [y_n \dots y_{n-p+1}, u_{n-1} \dots u_{n-q+1}, \hat{w}_n \dots \hat{w}_{n-r+1}]^\tau, \tag{3.6}$$

$$\hat{w}_n = y_n - b_1 u_{n-1} - \theta_n^\tau \varphi_{n-1}, n \geq 0, \hat{w}_n = 0, n < 0, \tag{3.7}$$

with arbitrary initial values θ_0, φ_0, and $P_0 > 0$.

We note that Lemma 2.5 and Corollary 2.1 also hold for the present algorithm, and in what follows we shall use them directly without explanations.

The "certainty equivalent" minimum variance adaptive control is defined by

$$u_n = b_1^{-1}(y_{n+1}^* - \theta_n^\tau \varphi_n). \tag{3.8}$$

We first treat the white noise case.

THEOREM 3.1. *Consider the system* (1.1) *with* $r = 0$ *and* $E[w_{n+1}^2 | \mathcal{F}_n] = \sigma^2 > 0$, *a.s. for all* $n \geq 0$. *Suppose that* (A1) *and* (A3)–(A5) *hold. If the control law* (3.4)–(3.8) *is applied, then the closed-loop system has the following properties:*

$$\lim_{n \to \infty} \left(\frac{n}{\log n} \right) R_n = (p + q - 1)\sigma^2 \quad a.s., \tag{3.9}$$

and

$$\|\theta_n - \theta\|^2 = O\left(\frac{\log \log n}{n} \right) \quad a.s., \quad as\ n \to \infty, \tag{3.10}$$

where R_n *is defined by* (1.6), *and* θ *is given by* (3.2) *with* $r = 0$.

Proof. By Theorem 1 of Guo and Chen [19] we know that $R_n \xrightarrow[n \to \infty]{} 0$ a.s., and that

$$\sum_{i=0}^{n} \|\varphi_i\|^2 = O(n) \quad \text{a.s.} \tag{3.11}$$

Hence by Theorem 2.1 (i), we have the following persistency of excitation property:

$$\liminf_{n\to\infty} \lambda_{\min}\left(\frac{1}{n}\sum_{i=0}^{n}\varphi_i\varphi_i^\tau\right) > 0 \quad \text{a.s.} \tag{3.12}$$

Also, by combining Lemma 2, (2.9), and Theorem 1 of Guo and Chen [19] we know that

$$\|\varphi_n\|^2 = O(n^\delta), \quad \text{a.s. } \forall \delta \in \left(\frac{2}{\beta}, 1\right), \tag{3.13}$$

where β is defined in (1.2). Hence, by (3.12) and (3.13),

$$\varphi_n^\tau P_{n+1}\varphi_n \xrightarrow[n\to\infty]{} 0 \quad \text{a.s.} \tag{3.14}$$

By (3.11), (3.12), and (3.14) we know that Theorem 3 of Wei [4] is applicable (there is a slight difference between the LS estimates defined there and here due to initial conditions, but that is not essential since (3.12) has been established), and hence we have

$$\sum_{i=0}^{n-1}(\theta^\tau\varphi_i - \theta_i^\tau\varphi_i)^2 \sim \sigma^2 \log\det\left(\sum_{i=0}^{n-1}\varphi_i\varphi_i^\tau\right) \quad \text{a.s.} \tag{3.15}$$

But by (3.11) and (3.12) it is easy to verify that $\log\det\left(\sum_{i=1}^{n-1}\varphi_i\varphi_i^\tau\right) \sim (p+q-1)\log n$. Hence, by combining (1.6), (3.1), (3.8), and (3.15) we see that (3.9) holds.

As for the second assertion of the theorem, by (3.4) and (3.5) we can express the estimation error as

$$\theta_n - \theta = P_n P_0^{-1}(\theta_0 - \theta) + P_n\sum_{i=0}^{n-1}\varphi_i w_{i+1}. \tag{3.16}$$

By (3.11), (3.13), and Lemma 2.4, we know that

$$\left\|\sum_{i=0}^{n-1}\varphi_i w_{i+1}\right\| = O(\sqrt{n\log\log n}) \quad \text{a.s.} \tag{3.17}$$

Finally, combining (3.12), (3.16), and (3.17) it is easy to see that (3.10) holds. □

Remark 3.1. The property (3.9) asserts, among other things, that $O(\log n/n)$ is the best convergence rate for the regret R_n generated by LS-based adaptive control. The convergence rate $O(\log\log n/n)$ in (3.10) is also obviously the best possible for the estimation error, since it is the same rate as that in the laws of the iterated logarithm. In a Bayesian framework, assuming that $\{w_i\}$ is *i.i.d.* with a Gaussian distribution $N(0,\sigma^2)$ and that θ has a certain truncated Gaussian prior distribution π, Lai [23] showed that under some stability conditions on the system and some regularity conditions on the input sequence $\{u_n\}$, the order $(p+q-1)\sigma^2(1+o(1))\log n/n$ is a *lower bound* to the expected regret $E_\pi[R_n]$ in the regulation problem. According to Lai's definition in [23, p. 37], the control law of Theorem 3.1 is "asymptotically efficient". It is also interesting to note that when the system orders p and q are increasing with the time (or data size) n, similar results as (3.15) are also obtainable (see, Huang and Guo [1]).

Next, we consider the general colored noise case $r > 0$. Let us write θ_n defined by (3.4)–(3.7) in its component form:

$$\theta_n = [-a_{1n}, \cdots, -a_{pn}, b_{2n}, \cdots, b_{qn}, c_{1n}, \cdots, c_{rn}]^\tau, \tag{3.18}$$

and set

$$\theta_n^* = [c_{1n} - a_{1n}, \cdots, c_{p^*n} - a_{p^*n}, b_{2n}, \cdots, b_{qn}]^\tau, \qquad p^* = \max(p, r), \tag{3.19}$$

where by definition $c_{in} = a_{jn} = 0$, for $i > r, j > p$.

Similarly, denote ($c_i = a_j = 0$, for all $i > r, j > p$),

$$\theta^* = [c_1 - a_1, \cdots, c_{p^*} - a_{p^*}, b_2, \cdots, b_q]^\tau. \tag{3.20}$$

It is easy to see that (cf. [2, p. 122]) for the regulation problem $y_i^* \equiv 0$ with b_1 known, to construct the nonadaptive (asymptotically) optimal control law, it is sufficient to know only θ^*, and hence θ^* may be regarded as the "true parameter."

THEOREM 3.2. *Let* (A1)–(A4) *hold, and let the adaptive control law* (3.4)–(3.8) *be applied to the system* (1.1).

(i) *For the regulation problem* $y_i^* \equiv 0$, *if* (A5) *holds, then*

$$\|\theta_n^* - \theta^*\|^2 + R_n = O\left(\frac{d_n}{n^{1-\varepsilon}}\right) \quad a.s. \forall \varepsilon > 0, \tag{3.21}$$

where d_n *is defined as in* (1.22), *and* θ_n^* *and* θ^* *are respectively defined by* (3.19) *and* (3.20).

(ii) *For the general tracking problem, if* (A6) *holds and* $\{y_i^*\}$ *satisfies*

$$n^{\frac{1+\delta}{2}}\sqrt{d_n} = O(\lambda_{\min}^*(n)) \quad a.s. \text{ for some } \delta > 0, \tag{3.22}$$

where d_n *and* $\lambda_{\min}^*(n)$ *are defined in* (1.22) *and* (2.7), *respectively, then as* $n \to \infty$,

$$R_n = O\left(\frac{\log n}{n}\right) a.s., \qquad \|\theta_n - \theta\|^2 = O\left(\frac{\log n}{\lambda_{\min}^*(n)}\right) a.s., \tag{3.23}$$

where θ_n *and* θ *are respectively given by* (3.4) *and* (3.2).

Proof. (i) By Theorem 1 in [19] we know that $R_n = 0(d_n/n^{1-\varepsilon})$, a.s., for all $\varepsilon > 0$. So for (3.21) we need only to consider the convergence rate of the estimation error. By Lemma 2.5 (i) we know that

$$\tilde{\theta}_{n+1}^\tau P_{n+1}^{-1} \tilde{\theta}_{n+1} = O(\log r_n) = O(\log n), \text{ a.s.} \tag{3.24}$$

where $\tilde{\theta}_{n+1} = \theta_{n+1} - \theta$. By (3.19) and (3.20) and the fact that $P_{n+1}^{-1} = \sum_{i=0}^n \varphi_i \varphi_i^\tau + P_0^{-1}$, we can rewrite (3.24) as

$$\sum_{i=0}^n \left[\psi_i^\tau \tilde{\theta}_{n+1}^* + \sum_{j=1}^{p^*}(c_{jn+1} - c_j)(\hat{w}_{i-j+1} - y_{i-j+1})\right]^2 + \tilde{\theta}_{n+1}^\tau P_0^{-1} \tilde{\theta}_{n+1} = O(\log n), \text{ a.s.},$$

where $\tilde{\theta}_{n+1}^* = \theta_{n+1}^* - \theta^*$, and ψ_i and p^* are defined by (2.4). By Lemma 2.5(ii), Corollary 2.1 and the fact that

$$\sum_{i=0}^n (y_i - w_i)^2 = O(n^\varepsilon d_n) \quad \text{a.s., } \forall \varepsilon > 0,$$

it is easy to see that

$$\sum_{i=0}^n \left[\sum_{j=1}^{p^*}(c_{jn+1} - c_j)(\hat{w}_{i-j+1} - y_{i-j+1})\right]^2 = O(n^\varepsilon d_n) \quad \text{a.s. } \forall \varepsilon > 0.$$

Therefore, we have

$$\sum_{i=0}^{n}(\psi_i^\tau\tilde{\theta}_{n+1}^*)^2 = O(n^\varepsilon d_n) \quad \text{a.s.}, \forall\varepsilon > 0.$$

From this and Theorem 2.1 (i), we obtain $\|\tilde{\theta}_{n+1}^*\|^2 = O(d_n/n^{1-\varepsilon})$, a.s.. This proves assertion (i).

(ii). Again, by [19], $R_n = O\left(\frac{d_n}{n^{1-\varepsilon}}\right)$, a.s., $\forall\varepsilon > 0$. Hence, by (3.22) we know that Theorem 2.1 (ii) is applicable, and so we have

$$\liminf_{n\to\infty}\frac{\lambda_{\min}\left(\sum_{i=0}^{n}\varphi_i^0\varphi_i^{0\tau}\right)}{\lambda_{\min}^*(n)} > 0 \quad \text{a.s.}$$

Consequently, by Lemma 2.5 (ii) and the fact that

$$\lambda_{\min}\left(\sum_{i=0}^{n}\varphi_i^0\varphi_i^{0\tau}\right) \le 2\lambda_{\min}\left(\sum_{i=0}^{n}\varphi_i\varphi_i^\tau\right) + 2\sum_{i=0}^{n}\|\varphi_i^0 - \varphi_i\|^2,$$

we have

$$\liminf_{n\to\infty}\frac{\lambda_{\min}\left(\sum_{i=0}^{n}\varphi_i\varphi_i^\tau\right)}{\lambda_{\min}^*(n)} > 0 \quad \text{a.s.}, \tag{3.25}$$

which in conjunction with (3.24) yields the second assertion in (3.23). By (3.22), (3.25) and Lemma 2 in [19] it is not difficult to see that $\varphi_n^\tau P_n\varphi_n \xrightarrow[n\to\infty]{} 0$. Therefore, by Lemma 2.5(iii), $\sum_{i=0}^{n}\|\tilde{\theta}_i^\tau\varphi_i\|^2 = O(\log n)$, and hence the first assertion in (3.23) is also true. □

Remark 3.2. For the regulation problem, the one degree of freedom identifiability problem as shown in Becker, Kumar, and Wei [24] does not occur in Theorem 3.2, since b_1 is not estimated. For the general tracking problem, it is clear that in Theorem 3.2, $\{y_i^*\}$ is not necessarily required to be "sufficiently rich" or "persistently exciting." Condition (3.22) is considerably weaker than the corresponding nonpersistence of excitation condition used in [22] and [16] for the SG-based algorithm. It would be of interest to establish similar results for a lower-dimensional ELS-based adaptive controller when $\{y_i^*\}$ is generated by a homogeneous finite-order linear difference equation $H(z)y_i^* = 0$, as was done by Kumar and Praly [25] for the SG-based algorithm.

4. Adaptive minimum variance control (the general case). In the general case where b_1 is not available, the analysis becomes much more complicated. Throughout this section, we assume that $\{\theta_n\}$ is generated by the ELS algorithm (1.11)–(1.14).

First, the minimum variance adaptive control law defined from (1.21) can be explicitly written as

$$u_n = \frac{1}{b_1(n)}\{y_{n+1}^* + (b_1(n)u_n - \theta_n^\tau\varphi_n)\}, \tag{4.1}$$

provided that $b_1(n) \neq 0$ a.s., where $b_1(n)$ is the ELS estimate for b_1 given by θ_n.

When (4.1) is applied, the first problem is that the set $\{b_1(n) = 0\}$ may have a positive probability, which is known as the zero divisor problem in stochastic adaptive control (cf. Meyn and Caines [26]). There are at least three ways to deal with this problem.

(a) Guarantee $P\{b_1(n) = 0\} = 0$ by assuming that all finite-dimensional distributions of $\{w_n\}$ are absolutely continuous with respect to Lebesgue measure (see, [26] or [5, pp. 778–782]). The absolute continuity assumption can be weakened to continuity only if $\{w_n\}$ is an independent sequence (cf. [16]).

(b) Guarantee $P\{b_1(n) = 0\} = 0$ by adding an independent random sequence with continuous distributions to the input signal. Such a sequence is preferably decaying with the time so that it does not upset the control performance (cf. [22]).

(c) Replace $b_1(n)$ appearing in the denominator of (4.1) by a quantity (say $\hat{b}_1(n)$), which is close to $b_1(n)$ but does not equal to zero (see, e.g., (1.23) or [19]).

In the sequel, whenever the control law (4.1) is concerned we always assume that $P\{b_1(n) = 0\} = 0$. The following lemma plays a key role in this section.

LEMMA 4.1. *For the system* (1.1) *assume that* (A1)–(A4) *are satisfied. At each time instant* n, *let the control law* u_n *be defined from the following equation:*

$$y_{n+1}^* = \theta_n^\tau \varphi_n + \Delta\hat{b}_{1n} u_n, \tag{4.2}$$

where $\{\theta_n\}$ *is given by the* ELS *algorithm* (1.11)–(1.14), *and* $\Delta\hat{b}_{1n} \in \mathcal{F}_n$ *is such that either* $\Delta\hat{b}_{1n} \equiv 0, \forall n$ *or* $\Delta\hat{b}_{1n} \xrightarrow[n\to\infty]{} 0$ *a.s. Then for any strictly increasing random sequence* $\{\tau_n\}$ *satisfying*

$$\inf_n |b_1(\tau_n + 1) - b_1| > 0 \quad \text{a.s. on } D, \tag{4.3}$$

with $P(D) > 0$, *and with* $b_1(n)$ *being the component of* θ_n *estimating* b_1, *the following properties hold as* $n \to \infty$:

$$\sup_{k \le \tau_n} \|\varphi_k\|^2 = O(\tau_n^\varepsilon d_{\tau_n}) \quad \text{a.s. on } D, \forall \varepsilon > 0, \tag{4.4}$$

and

$$r_{\tau_n} = O(\tau_n) \quad \text{a.s. on } D, \tag{4.5}$$

where r_n *and* d_n *are defined by* (1.18) *and* (1.22), *respectively.*

Proof. Before starting the proof, we remark that the case $\Delta\hat{b}_{1n} \equiv 0$ corresponds to the control law (4.1), while the case $\Delta\hat{b}_{1n} \neq 0$ corresponds to a (slight) modification of $b_1(n)$.

We first prove (4.4). By (1.9) and (4.2) we have with $\tilde{\theta}_k \triangleq \theta - \theta_k$,

$$\begin{aligned} y_{k+1} &= \theta^\tau \varphi_k + \theta^\tau(\varphi_k^0 - \varphi_k) + w_{k+1} \\ &= \tilde{\theta}_k^\tau \varphi_k + y_{k+1}^* - \Delta\hat{b}_{1n} u_k + \theta^\tau(\varphi_k^0 - \varphi_k) + w_{k+1}. \end{aligned} \tag{4.6}$$

Following Guo and Chen [19], denoting $\delta_k = tr(P_k - P_{k+1}), \alpha_k = \|\tilde{\theta}_k^\tau \varphi_k\|^2/(1 + \varphi_k^\tau P_k \varphi_k)$, and using Corollary 2.1 and the fact that $\varphi_k^\tau P_{k+1} \varphi_k \le 1$, we have by (4.6)

$$\begin{aligned} y_{k+1}^2 &\le 3\|\tilde{\theta}_k^\tau \varphi_k\|^2 + 3(\Delta\hat{b}_{1k})^2 u_k^2 + O(\log r_k + d_k) \\ &\le 3\alpha_k\{1 + \varphi_k^\tau P_{k+1} \varphi_k + \varphi_k^\tau (P_k - P_{k+1})\varphi_k\} \\ &\qquad + 3(\Delta\hat{b}_{1k})^2 u_k^2 + O(\log r_k + d_k) \\ &\le 3\alpha_k\{2 + \delta_k \|\varphi_k\|^2\} + 3(\Delta\hat{b}_{1k})^2 u_k^2 + O(\log r_k + d_k) \\ &= 3\alpha_k \delta_k \|\varphi_k\|^2 + 3(\Delta\hat{b}_{1k})^2 u_k^2 + O(\log r_k + d_k). \end{aligned} \tag{4.7}$$

By the stability of $B(z)$ and (1.1) there exists a constant $\lambda \in (0,1)$ such that

$$u_k^2 = O\left(\sum_{i=0}^{k+1} \lambda^{k-i} y_i^2\right) + O\left(\sum_{i=0}^{k+1} \lambda^{k-i} w_i^2\right). \tag{4.8}$$

Consequently,

$$\begin{aligned}[\|\varphi_k\|^2 - u_k^2] &= O\left(\sum_{i=0}^{k} \lambda^{k-i} y_i^2\right) + O\left(\sum_{i=0}^{r} (\hat{w}_{k-i})^2\right) + O\left(\sum_{i=0}^{k} \lambda^{k-i} w_i^2\right) \\ &= O\left(\sum_{i=0}^{k} \lambda^{k-i} y_i^2\right) + O(\log r_k + d_k) \quad \text{a.s.},\end{aligned} \tag{4.9}$$

where for the last relationship we have used Lemma 2.5 (ii).

Note that $P_{n+1}^{-1} = \sum_{i=0}^{n} \varphi_i \varphi_i^\tau + P_0^{-1}$, and we have by Lemma 2.5 (i),

$$\sum_{i=0}^{n} \|\tilde{\theta}_{n+1}^\tau \varphi_i\|^2 = O(\log r_n) \quad \text{a.s.}, \tag{4.10}$$

and consequently,

$$\max_{i \le n} \|\tilde{\theta}_{n+1}^\tau \varphi_i\|^2 = O(\log r_n) \quad \text{a.s.} \tag{4.11}$$

For simplicity of statements, we shall omit the phrase "a.s. on D" in the remainder of the proof, and unless otherwise stated all relationships hold on D with a possible exception set of probability zero. Denote $\tilde{b}_1(\tau_n+1) = b_1 - b_1(\tau_n+1)$, we have by (4.3), $\inf_n |\tilde{b}_1(\tau_n+1)| > 0$. Consequently, by (4.11) and the fact that $\|\tilde{\theta}_{n+1}\|^2 = 0(\log r_n)$ a.s., we have for all $k \le \tau_n$ and all $n \ge 1$,

$$\begin{aligned} u_k^2 &= \frac{1}{(\tilde{b}_1(\tau_n+1))^2} \{\tilde{b}_1(\tau_n+1) u_k\}^2 \\ &= \frac{1}{(\tilde{b}_1(\tau_n+1))^2} \{[\tilde{\theta}_{\tau_n+1}^\tau \varphi_k - \tilde{b}_1(\tau_n+1) u_k] - \tilde{\theta}_{\tau_n+1}^\tau \varphi_k\}^2 \\ &\le \frac{2}{(\tilde{b}_1(\tau_n+1))^2} \{\|\tilde{\theta}_{\tau_n+1}^\tau \varphi_k - \tilde{b}_1(\tau_n+1) u_k\|^2 + \|\tilde{\theta}_{\tau_n+1}^\tau \varphi_k\|^2\} \\ &= O((\log r_{\tau_n})[\|\varphi_k\|^2 - u_k^2]) + O(\log r_{\tau_n}) \\ &= O((\log r_{\tau_n}) \sum_{i=0}^{k} \lambda^{k-i} y_i^2) + O(\log^2 r_{\tau_n} + d_{\tau_n} \log r_{\tau_n}), \end{aligned} \tag{4.12}$$

where for the last relationship we have used (4.9), and where and hereafter the "O" constant depends neither on k nor on n.

Combining (4.9) and (4.12) we get for all $k \le \tau_n$,

$$\|\varphi_k\|^2 = O([\log r_{\tau_n}] \sum_{i=0}^{k} \lambda^{k-i} y_i^2) + O(\log^2 r_{\tau_n} + d_{\tau_n} \log r_{\tau_n}). \tag{4.13}$$

Substituting (4.8) and (4.13) into (4.7) and noticing $\Delta \hat{b}_{1n} \xrightarrow[n \to \infty]{} 0$, it is easy to see that for all $k \le \tau_n$, and all large n,

$$y_{k+1}^2 = O\left(\alpha_k \delta_k \log r_{\tau_n} \sum_{i=0}^{k} \lambda^{k-i} y_i^2\right) + o\left(\sum_{i=0}^{k} \lambda^{k-i} y_i^2\right) + O(\log^3 r_{\tau_n} + d_{\tau_n} \log^2 r_{\tau_n}). \tag{4.14}$$

Now, following [19] we set $L_k = \sum_{i=0}^{k} \lambda^{k-i} y_i^2$. Then by (4.14) there are constants $\delta > 0$ and $c > 0$ such that $(1+\delta)\lambda < 1$ and that

$$y_{k+1}^2 \le \lambda[(1+\delta)c\alpha_k\delta_k(\log r_{\tau_n}) + \delta]L_k + O(\log^3 r_{\tau_n} + d_{\tau_n}\log^2 r_{\tau_n})$$

holds for all suitably large n and all $k \le \tau_n$. Consequently, by denoting $\gamma \triangleq (1+\delta)\lambda < 1$, we obtain for large n and for all $k \le \tau_n$,

$$L_{k+1} = \lambda L_k + y_{k+1}^2 \le \gamma(1 + c\alpha_k\delta_k \log r_{\tau_n})L_k + O(\log^3 r_{\tau_n} + d_{\tau_n}\log^2 r_{\tau_n}).$$

Hence, iterating this inequality k times we get for all large n and for all $k \le \tau_n$,

$$\begin{aligned} L_{k+1} &\le \gamma^{k+1}\prod_{i=0}^{k}(1 + c\alpha_i\delta_i \log r_{\tau_n})L_0 \\ &\quad + O\left(\sum_{i=0}^{k}\gamma^{k-i}\prod_{j=i+1}^{k}(1 + c\alpha_j\delta_j \log r_{\tau_n})[\log^3 r_{\tau_n} + d_{\tau_n}\log^2 r_{\tau_n}]\right). \end{aligned} \tag{4.15}$$

By Lemma 2.5 (iii) and the convergency of the series $\sum_{i=1}^{\infty}\delta_i$, we know that for any small $\varepsilon > 0$, there exists $i > 0$ large enough such that

$$\varepsilon^2\sum_{j=i+1}^{k}\alpha_j \le \frac{\varepsilon}{2}\log r_k, \qquad \varepsilon^{-2}c\sum_{j=i+1}^{\infty}\delta_j < \frac{\varepsilon}{2}.$$

Hence we have for all $i \le k \le \tau_n$,

$$\begin{aligned} \prod_{j=i+1}^{k}(1 + c\alpha_j\delta_j \log r_{\tau_n} &\le \prod_{j=i+1}^{k}(1+\varepsilon^2\alpha_j)\prod_{j=i+1}^{k}(1 + c\varepsilon^{-2}\delta_j \log r_{\tau_n}) \\ &\le \exp\left\{\varepsilon^2\sum_{j=i+1}^{k}\alpha_j + \sum_{j=i+1}^{k}c\varepsilon^{-2}\delta_j \log r_{\tau_n}\right\} \le r_{\tau_n}^{\varepsilon}. \end{aligned} \tag{4.16}$$

Substituting this into (4.15), it is easy to conclude that for large n,

$$L_{k+1} = O(r_{\tau_n}^{\varepsilon} d_{\tau_n}), \quad \forall k \le \tau_n, \quad \forall \varepsilon > 0. \tag{4.17}$$

Substituting this into (4.13) we know that $\sup_{k\le\tau_n}\|\varphi_k\|^2 = O(r_{\tau_n}^{\varepsilon} d_{\tau_n})$ for all $\varepsilon > 0$, and hence (4.4) will be true if (4.5) is proved.

We now prove (4.5). By (4.17) and the assumption $\Delta\hat{b}_{1n} \xrightarrow[n\to\infty]{} 0$, it follows from (4.6) that

$$\begin{aligned} \sum_{k=1}^{\tau_n} y_{k+1}^2 &= O\left(\sum_{k=1}^{\tau_n}\alpha_k(1 + \varphi_k^{\tau}P_k\varphi_k)\right) + o\left(\sum_{k=1}^{\tau_n}u_k^2\right) + O(\log r_{\tau_n} + \tau_n) \\ &= O\left(r_{\tau_n}^{\varepsilon} d_{\tau_n}\sum_{k=1}^{\tau_n}\alpha_k\right) + o(r_{\tau_n}) + O(\log r_{\tau_n} + \tau_n), \quad \forall \varepsilon > 0. \end{aligned}$$

From this, Lemma 2.5, and (4.8), it is easy to see that

$$r_{\tau_n} = O(r_{\tau_n}^{\varepsilon} d_{\tau_n}\log r_{\tau_n}) + o(r_{\tau_n}) + O(\tau_n), \quad \forall \varepsilon > 0 \tag{4.18}$$

But as noted in ([19, p. 804]), d_k can be taken as $d_k = k^\delta$ for all $\delta \in (\frac{2}{\beta}, 1)$. Hence, from (4.18) it is easy to conclude (4.5), and hence the proof is complete. □

Let D_1 be a set defined by

$$D_1 = \left\{ w : \liminf_{n\to\infty} |b_1(n)| \neq 0 \right\}, \tag{4.19}$$

where $b_1(n)$ denotes the component of θ_n estimating b_1.

For any constant $a \in (0, |b_1|)$, define a sequence $\{\tau_n\}$ recursively by

$$\tau_n = \inf\{k > \tau_{n-1} : |b_1(k+1)| < a\}, \qquad \tau_0 = 0, \quad n \geq 1. \tag{4.20}$$

Note that (A3) implies $b_1 \neq 0$, and so the interval $(0, |b_1|)$ is not empty.

On the complement set of D_1, D_1^c, it is obvious that $\tau_n < \infty$ for all $n \geq 1$. Hence, if we set

$$\sigma_n = \begin{cases} n, & w \in D_1, \\ \tau_n, & w \in D_1^c, \end{cases} \tag{4.21}$$

then $\sigma_n < \infty$ a.s. for all n, and $\sigma_n \xrightarrow[n\to\infty]{} \infty$ a.s..

THEOREM 4.1. *For the system* (1.1) *assume that* (A1)–(A4) *are satisfied, and that the control law defined by* (4.1) *is applied. Then the following hold:*

(i) *For the sequence* $\{\sigma_n\}$ *defined by* (4.19)–(4.21), *as* $n \to \infty$

$$r_{\sigma_n} = O(\sigma_n) \text{ a.s.} \quad \text{and} \quad R_{\sigma_n+1} = O\left(\frac{d_{\sigma_n}}{\sigma_n^{1-\varepsilon}}\right) \quad \text{a.s., } \forall \varepsilon > 0,$$

where R_n, r_n *and* d_n *are defined by* (1.6), (1.18), *and* (1.22), *respectively.*

(ii)

$$R_n = O\left(\frac{1}{n^{1-\delta}}\right) \quad \text{a.s. on } D, \quad \forall \delta \in \left(\frac{2}{\beta}, 1\right),$$

where β *is defined in* (1.2) *and* $D = D_1 \cup D_2$ *with* D_1 *defined by* (4.19) *and* D_2 *defined by*

$$D_2 = \left\{ w \in D_1^c : \sup_n \frac{\tau_{n+1}}{\tau_n} < \infty \right\};$$

here $\{\tau_n\}$ *is defined by* (4.20).

Proof. (i). On the set D_1, by a completely similar argument as that used for Theorem 2 in [19], it is known that $R_n = O(d_n/n^{1-\varepsilon})$ a.s. on D_1, for all $\varepsilon > 0$. So we need only to consider the complement set D_1^c. By the definition of τ_n we have

$$\inf_n |b_1(\tau_n + 1) - b_1| \geq |b_1| - a > 0 \quad \text{on } D_1^c.$$

Therefore, by Lemma 4.1 we know that $r_{\tau_n} = O(\tau_n)$ and $\sup_{i\leq\tau_n} \|\varphi_i\|^2 = O(\tau_n^\varepsilon d_{\tau_n})$ a.s. on D_1^c. Hence, by (4.6) (with $\Delta\hat{b}_{1n} \equiv 0$) and Lemma 2.5, we have

$$\begin{aligned} R_{\tau_n+1} &= \frac{1}{\tau_n+1} \sum_{i=0}^{\tau_n} (y_{i+1} - y_{i+1}^* - w_{i+1})^2 \\ &= O\left(\frac{1}{\tau_n} \sum_{i=0}^{\tau_n} \|\tilde{\theta}_i^\tau \varphi_i\|^2\right) + O\left(\frac{1}{\tau_n} \sum_{i=0}^{\tau_n} \|\varphi_i - \varphi_i^0\|^2\right) \\ &= O\left(\frac{1}{\tau_n} \sum_{i=0}^{\tau_n} \frac{\|\tilde{\theta}_i^\tau \varphi_i\|^2}{1 + \varphi_i^\tau P_i \varphi_i} (1 + \|\varphi_i\|^2)\right) + O\left(\frac{\log r_{\tau_n}}{\tau_n}\right) \\ &= O\left(\frac{d_{\tau_n} \log \tau_n}{\tau_n^{1-\varepsilon}}\right) \quad \text{a.s.} \quad \text{on } D_1^c, \forall \varepsilon > 0. \end{aligned} \tag{4.22}$$

Hence the conclusion (i) holds.

(ii) As is just mentioned above (ii) holds on D_1, since d_n can be taken as n^δ for all $\delta \in (2/\beta, 1)$. Hence we need only to consider the set D_2. By the definition of $\{\tau_n\}$, we know that on $D_2, \tau_n \to \infty, \sup_n(\tau_{n+1}/\tau_n) < \infty$, and by (4.22), $R_{\tau_n} = O(1/\tau_n^{1-\delta})$ a.s. on D_2 for all $\delta \in (2/\beta, 1)$. Consequently,

$$\begin{aligned}\sup_n[n^{1-\delta}R_n] &= \sup_k \sup_{n\in[\tau_k,\tau_{k+1}]}[n^{1-\delta}R_n] \\ &\le \sup_k \frac{\tau_{k+1}}{\tau_k}[\tau_{k+1}^{1-\delta}R_{\tau_{k+1}}] < \infty \quad \text{a.s. on } D_2.\end{aligned}$$

Hence assertion (ii) is also true. □

Remark 4.1. From Guo and Chen [19], we know that under conditions of Theorem 4.1, if $\liminf_{n\to\infty}|b_1(n)| \neq 0$ a.s., then $R_n \to 0$ a.s. Theorem 4.1 asserts, among other things, that if $\lim_{n\to\infty}|b_1(n)| = 0$ a.s. does hold, then since $P(D_2) = 1$ and again we have $R_n \to 0$ a.s.. This result is rather interesting since $b_1(n)$ appears as the divisor in the control law (4.1), and small $b_1(n)$ seems to yield large input signal u_n (but actually does not). The key idea behind the proof of Theorem 4.1 (or Lemma 4.1) is as follows: if $\lim_{n\to\infty}|b_1(n)| = 0$, then $|\tilde{b}_1(n+1)| \ge |b_1|/2 > 0$ for all suitably large n. Thus, for each fixed large n, and for all $i \le n, u_i$ will have a significant contribution to $\tilde{\theta}_{n+1}^\tau\varphi_i$ if it is not small. But by (4.11) we know that $\|\tilde{\theta}_{n+1}^\tau\varphi_i\|^2 = O(\log\ r_n)$ a.s. for all $i \le n$. Hence, for all $i \le n, u_i^2$ will be dominated by a "linear combination" of $\{y_i^2, \cdots, y_{i-p+1}^2, u_{i-1}^2 \cdots u_{i-q+1}^2, \hat{w}_i^2 \cdots \hat{w}_{i-r+1}^2\}$, and thus we can successfully sidestep the difficult "small divisor" problem in the analysis. Certainly, in this approach, it would be of considerable interest to preclude the case where the sequence $\{b_1(n)\}$ visits the interval $(-a, a)$ with $0 < a < |b_1|$ in a very scattering way (i.e., $P(D^c) > 0$).

We now consider the case where the set D defined in Theorem 4.1 does have probability one.

THEOREM 4.2. *Consider the system* (1.1), *the* ELS *algorithm* (1.11)–(1.14), *and the control law* (4.1). *If* (A1)–(A4) *and* (A6) *hold, and in addition, the reference signal* $\{y_i^*\}$ *satisfies*

$$n^{\frac{1+\varepsilon}{2}}\sqrt{d_n} = O(\lambda_{\min}^*(n)) \quad a.s., \quad \text{for some } \varepsilon > 0, \tag{4.23}$$

where d_n *and* $\lambda_{\min}^*(n)$ *are defined in* (1.22) *and* (2.7), *respectively, then as* $n \to \infty$

$$R_n = O\left(\frac{\log\ n}{n}\right) \ a.s., \qquad \|\theta_n - \theta\|^2 = O\left(\frac{\log\ n}{\lambda_{\min}^*(n)}\right) \ a.s., \tag{4.24}$$

where R_n *is the regret defined by* (1.6). *Furthermore, if* (4.23) *is replaced by* $n = O(\lambda_{\min}^*(n))$ *a.s., and* $E[w_{n+1}^2|\mathcal{F}_n] = \sigma^2$ *a.s., then for the white noise case* ($r = 0$), (4.24) *can be strengthened into*

$$\lim_{n\to\infty}\left(\frac{n}{\log\ n}\right)R_n = (p+q)\sigma^2 \quad a.s., \qquad \|\theta_n - \theta\|^2 = O\left(\frac{\log\log\ n}{n}\right) a.s.$$

Proof. By Theorem 4.1 (i) and (4.23) we know that Theorem 2.1 (ii) is applicable to the sequence $\{\sigma_n\}$, and hence we have

$$\liminf_{n\to\infty}\frac{\lambda_{\min}\left(\sum_{i=0}^{\sigma_n}\varphi_i^0\varphi_i^{0\tau}\right)}{\lambda_{\min}^*(\sigma_n)} > 0 \quad \text{a.s.}$$

Consequently, similar to the proof of (3.25), it is easy to see that

$$\liminf_{n\to\infty} \frac{\lambda_{\min}\left(\sum_{i=0}^{\sigma_n} \varphi_i\varphi_i^\tau\right)}{\lambda^*_{\min}(\sigma_n)} > 0 \quad \text{a.s.} \tag{4.25}$$

By this and Lemma 2.5 (i) it is easy to see that

$$\|\tilde{\theta}_{\sigma_n+1}\|^2 = O\left(\frac{\log r_{\sigma_n}}{\lambda^*_{\min}(\sigma_n)}\right) \quad \text{a.s.} \tag{4.26}$$

By Theorem 4.1 (i), we know that $\log r_{\sigma_n} = O(\log \sigma_n)$ a.s., and so by (4.23) and (4.26) we conclude that $\tilde{\theta}_{\sigma_n+1} \to 0$ a.s., and in particular,

$$b_1(\sigma_n + 1) \xrightarrow[n\to\infty]{} b_1 \quad \text{a.s.} \tag{4.27}$$

We now prove that $P(D_1) = 1$ where D_1 is defined by (4.19). Otherwise, we would have $P(D_1^c) > 0$, and on D_1^c by the definition of σ_n we know that $\sigma_n < \infty$ for all n, and that

$$|b_1(\sigma_n + 1)| < a \quad \forall n \geq 1 \quad \text{on } D_1^c, \tag{4.28}$$

which clearly contradicts with (4.27) since $a < |b_1|$. Hence $P(D_1) = 1$ and we have $\liminf_{n\to\infty} |b_1(n)| \neq 0$ a.s. Therefore, by a similar means as in the proof of Theorem 2 in Guo and Chen [19], we obtain $R_n = O(d_n/n^{1-\varepsilon})$ a.s. and $\|\varphi_n\|^2 = O(n^\varepsilon d_n)$ a.s. for all $\varepsilon > 0$. Using this and a similar argument as for (4.25) and (4.26), we know that (4.25) and (4.26) also hold with $\{\sigma_n\}$ replaced by $\{n\}$. Hence we have proved the second assertion in (4.24). Since (4.25) holds with $\{\sigma_n\}$ replaced by $\{n\}$ and $\|\varphi_n\|^2 = O(n^{\delta/2}\sqrt{d_n})$ a.s., for all $\delta \in (2/\beta, 1)$, we know that $\varphi_n^\tau P_n \varphi_n \xrightarrow[n\to\infty]{} 0$ a.s. By this and Lemma 2.5 it follows from (4.6) (with $\Delta\hat{b}_{1n} \equiv 0$) that the first assertion in (4.24) is also true. Finally, the last two assertions of the theorem can be proved in exactly the same way as in Theorem 3.1, and the details are not repeated. □

Remark 4.2. (i) Again, the best possible convergence rate $O(\log n/n)$ is established for the regret R_n. It is worth noting that this result is established without introducing any modifications to the standard minimum variance control law (4.1). This fact makes Theorem 4.2 differ essentially from the existing results including those in the recent work [19].

(ii) The (nonpersistent) excitation condition (4.23) on the reference signal $\{y_n^*\}$ can be easily verified for a large class of deterministic and/or stochastic signals. In principle, we can always make this condition satisfied by use of the "continually disturbed demand method" of Caines and Lafortune [27] or the "diminishing excitation technique" in Chen and Guo [16]. To be precise, for any desired trajectory $\{y_{nd}^*\}$ that is bounded and independent of $\{w_n\}$, we may take the reference signal in (4.1) to be

$$y_n^* = y_{nd}^* + v_n, \tag{4.29}$$

where $\{v_n\}$ is a zero mean independent bounded random sequence which is independent of $\{w_n, y_{nd}^*\}$. Then with some suitable moment conditions on $\{v_n\}$ it is easy to see that (4.23) holds. In order that the "dither" does not influence the self-optimality the variance of $\{v_n\}$ must be chosen to satisfy $Ev_n^2 \xrightarrow[n\to\infty]{} 0$. This is possible since the excitation requirement

(4.23) is not necessarily persistent. The disadvantage of adding the "dither" $\{v_n\}$ in such a way is that it may influence the convergence rate of tracking.

Next, we consider the case where (4.23) fails. As a typical example, we shall only consider the regulation problem ($y_n^* \equiv 0$). Similar to (1.23), we set for $n \geq 1$,

$$\hat{b}_1(n) = \begin{cases} b_1(n) & \text{if } |b_1(n)| \geq \dfrac{1}{\sqrt{n \log (n+1)}}; \\ b_1(n) + \dfrac{\operatorname{sgn}(b_1(n))}{\sqrt{n \log(n+1)}} & \text{otherwise.} \end{cases} \tag{4.30}$$

Instead of (4.1), we define the control u_n by

$$u_n = \frac{1}{\hat{b}_1(n)}\{b_1(n)u_n - \theta_n^\tau \varphi_n\}, \qquad n \geq 1, \tag{4.31}$$

which obviously has the form of (4.2):

$$\theta_n^\tau \varphi_n + \Delta\hat{b}_{1n} u_n = 0, \tag{4.32}$$

where $\Delta\hat{b}_{1n} \triangleq \hat{b}_1(n) - b_1(n)$. By (4.30) it is clear that

$$|\hat{b}_1(n)|^2 \geq \frac{1}{n \log (n+1)}, \qquad |\Delta\hat{b}_{1n}|^2 \leq \frac{1}{n \log(n+1)} \xrightarrow[n\to\infty]{} 0. \tag{4.33}$$

THEOREM 4.3. *Consider the model* (1.1) *with white additive noise (i.e., $r = 0$). Assume that* (A1), (A3), *and* (A5) *are satisfied, and that in* (1.22), $d_n = O(n^\varepsilon)$ *for all $\varepsilon > 0$. If the control law defined by* (4.30) *and* (4.31) *is applied, then as $n \to \infty$,*

$$\sum_{i=1}^{n} (y_i - w_i)^2 = O(n^\varepsilon) \quad \text{a.s.,} \quad \forall \varepsilon > 0, \tag{4.34}$$

Proof. Let D_1 and $\{\tau_n\}$ be defined by (4.19) and (4.20), respectively. As explained earlier, (4.34) holds on D_1, and so we need only to consider D_1^c. In the remainder of the proof all relationships are established on D_1^c with a possible exception set of probability zero, and we shall omit the phrase "a.s. on D_1^c" for simplicity.

By (4.20) we know that on D_1^c, $\tau_n < \infty$, for all $n \geq 1, \lim_{n\to\infty} \tau_n = \infty$, and $\inf_n |b_1(\tau_n + 1) - b_1| \geq |b_1| - a > 0$. Hence, by Lemma 4.1 we know that

$$r_{\tau_n} = O(\tau_n) \quad \text{and} \quad \sup_{k \leq \tau_n} \|\varphi_k\|^2 = O(\tau_n^\varepsilon d_{\tau_n}). \tag{4.35}$$

Consequently, by (4.6) and (4.33),

$$\begin{aligned} \sum_{i=1}^{\tau_n} (y_{i+1} - w_{i+1})^2 &= O\left(\sum_{i=1}^{\tau_n} \|\tilde{\theta}_i^\tau \varphi_i\|^2\right) + O\left(\sum_{i=1}^{\tau_n} (\Delta\hat{b}_{1i} u_i)^2\right) \\ &= O\left(\tau_n^\varepsilon d_{\tau_n} \sum_{i=1}^{\tau_n} \frac{\|\tilde{\theta}_i^\tau \varphi_i\|^2}{1 + \varphi_i^\tau P_i \varphi_i}\right) + O\left(\sum_{i=1}^{\tau_n} \frac{1}{i \log (i+1)} u_i^2\right) \\ &= O(\tau_n^\varepsilon d_{\tau_n} \log \tau_n) + O\left(\tau_n^\varepsilon d_{\tau_n} \sum_{i=1}^{\tau_n} \frac{1}{i \log (i+1)}\right) \quad \forall \varepsilon > 0, \\ &= O(\tau_n^\varepsilon) \quad \forall \varepsilon > 0. \end{aligned} \tag{4.36}$$

Hence Theorem 2.1 (i) is applicable, and we then have

$$\liminf_{n\to\infty} \lambda_{\min}\left(\frac{1}{\tau_n}\sum_{i=1}^{\tau_n}\psi_i\psi_i^\tau\right) > 0, \tag{4.37}$$

where $\{\psi_i\}$ is defined by (2.4) with $p^* = p$.

Let $a_i(n), b_j(n)$ be the estimates for a_i, b_j, $1 \le i \le p$, $1 \le j \le q$, given by θ_n. Set

$$\bar{\theta}_n = [-a_1(n), \cdots, -a_p(n), b_2(n), \cdots, b_q(n)]^\tau. \tag{4.38}$$

Then by (4.31) we have

$$u_n = -\frac{1}{\hat{b}_1(n)}\bar{\theta}_n^\tau\psi_n \tag{4.39}$$

Now, we prove that

$$\left\|\frac{1}{\hat{b}_1(\tau_n+1)}\bar{\theta}_{\tau_n+1}\right\|^2 = 0(\tau_n^\varepsilon) \quad \forall \varepsilon > 0. \tag{4.40}$$

By (4.36) we know that $\sum_{i=1}^{\tau_n}\|\theta^\tau\varphi_i\|^2 = O(\tau_n^\varepsilon)$, which in conjunction with (4.10) and (4.35) gives

$$\sum_{i=1}^{\tau_n}(\theta_{\tau_n+1}^\tau\varphi_i)^2 \le 2\sum_{i=1}^{\tau_n}(\tilde{\theta}_{\tau_n+1}^\tau\varphi_i)^2 + 2\sum_{i=1}^{\tau_n}(\theta^\tau\varphi_i)^2 = O(\tau_n^\varepsilon).$$

From this, by noting that $\theta_{\tau_n+1}^\tau\varphi_i = \bar{\theta}_{\tau_n+1}^\tau\psi_i + b_1(\tau_n+1)u_i$, we have for all $\varepsilon > 0$,

$$\begin{aligned}\sum_{i=1}^{\tau_n}(\bar{\theta}_{\tau_n+1}^\tau\psi_i)^2 &\le 2\sum_{i=1}^{\tau_n}(\theta_{\tau_n+1}^\tau\varphi_i)^2 + 2b_1^2(\tau_n+1)\sum_{i=1}^{\tau_n}u_i^2 \\ &\le O(\tau_n^\varepsilon) + 4\{[\hat{b}_1(\tau_n+1)]^2 + [\Delta\hat{b}_1(\tau_n+1)]^2\}\sum_{i=1}^{\tau_n}u_i^2.\end{aligned}$$

Multiplying $1/[\hat{b}_1(\tau_n+1)]^2$ from both sides of this inequality, and noticing (4.33) and (4.35) we get

$$\frac{1}{[\hat{b}_1(\tau_n+1)]^2}\sum_{i=1}^{\tau_n}(\bar{\theta}_{\tau_n+1}^\tau\psi_i)^2 = O\left(\frac{\tau_n^\varepsilon}{[\hat{b}_1(\tau_n+1)]^2}\right) + O\left(\sum_{i=1}^{\tau_n}u_i^2\right) = O(\tau_n^{1+\varepsilon}\log(\tau_n+1)+\tau_n).$$

From this and (4.37) we see that for all suitably large n,

$$\begin{aligned}\left\|\frac{1}{\hat{b}_1(\tau_n+1)}\bar{\theta}_{\tau_n+1}\right\|^2 &\le O\left(\left\|\frac{1}{\hat{b}_1(\tau_n+1)}\bar{\theta}_{\tau_n+1}\right\|^2\lambda_{\min}\left(\frac{1}{\tau_n}\sum_{i=1}^{\tau_n}\psi_i\psi_i^\tau\right)\right) \\ &\le O\left(\frac{1}{\tau_n[\hat{b}_1(\tau_n+1)]^2}\sum_{i=1}^{\tau_n}(\bar{\theta}_{\tau_n+1}^\tau\psi_i)^2\right) = O(\tau_n^\varepsilon\log(\tau_n+1)+1) \quad \forall\varepsilon > 0.\end{aligned}$$

Hence (4.40) holds.

Next, we prove that

$$\|\varphi_n\|^2 = O([nr_n]^\varepsilon d_n) \quad \forall \varepsilon > 0. \tag{4.41}$$

Note that by (4.20), we know that on D_1^c,

$$|b_1(k+1)| \geq a > 0, \quad \forall k \in [\tau_n + 1, \tau_{n+1} - 1], \quad \forall n \geq 1. \tag{4.42}$$

Hence from (4.39), (4.40), (4.42), and the fact that $\|\bar{\theta}_{k+1}\|^2 = O(\log r_k)$, it follows that on D_1^c

$$u_{k+1}^2 = \begin{cases} O(\tau_n^\varepsilon \|\psi_{\tau_n+1}\|^2), & \forall \varepsilon > 0, \quad k = \tau_n; \\ O((\log r_k)\|\psi_{k+1}\|^2), & k \in [\tau_n + 1, \tau_{n+1} - 1]. \end{cases} \tag{4.43}$$

Similar to (4.9) it is easy to see by (A3) that

$$\|\psi_k\|^2 = O\left(\sum_{i=0}^{k} \lambda^{k-i} y_i^2\right) + O(d_k) \quad \forall k \geq 1.$$

From this and (4.43) we have, for all $k \in [\tau_n + 2, \tau_{n+1}]$,

$$\begin{aligned} \|\varphi_k\|^2 &= \|\psi_k\|^2 + u_k^2 \\ &= O\left([\log r_k] \sum_{i=0}^{k} \lambda^{k-i} y_i^2\right) + O(d_k \log r_k). \end{aligned} \tag{4.44}$$

Substituting this together with (4.8) into (4.7) and noting that $\Delta \hat{b}_{1n} \xrightarrow[n\to\infty]{} 0$, we get for all $k \in [\tau_n + 2, \tau_{n+1}]$, and all suitably large n,

$$y_{k+1}^2 = O\left(\alpha_k \delta_k (\log r_k) \sum_{i=0}^{k} \lambda^{k-i} y_i^2\right) + o\left(\sum_{i=0}^{k} \lambda^{k-i} y_i^2\right) + O(d_k \log^2 r_k). \tag{4.45}$$

Set $L_k = \sum_{i=0}^{k} \lambda^{k-i} y_i^2$. Similar to the proof of (4.15), from (4.45) we have for some $\gamma \in (0, 1), \forall k \in [\tau_n + 2, \tau_{n+1}]$, and all large n,

$$\begin{aligned} L_{k+1} \leq{}& \gamma^{k-\tau_n-1} \prod_{i=\tau_n+2}^{k} (1 + c\alpha_i \delta_i \log r_i) L_{\tau_n+2} \\ &+ O\left(\sum_{i=\tau_n+2}^{k} \gamma^{k-i} \prod_{j=i+1}^{k} (1 + c\alpha_j \delta_j \log r_j) d_i \log^2 r_i\right), \end{aligned} \tag{4.46}$$

where $c > 0$ is a constant. Similar to the proof of (4.16) we know that for all small $\varepsilon > 0$ and all $k \geq i$, with i suitably large, $\prod_{j=i+1}^{k} (1 + c\alpha_j \delta_j \log r_j) \leq r_k^\varepsilon$. Substituting this into (4.46) yields for large n,

$$L_{k+1} = O(r_k^\varepsilon L_{\tau_n+2}) + O(r_k^\varepsilon d_k), \quad \forall k \in [\tau_n + 2, \tau_{n+1}], \quad \forall \varepsilon > 0. \tag{4.47}$$

By (4.35), (1.1), and (A3), it is easy to see that

$$L_{\tau_n+1} + \|\psi_{\tau_n+1}\|^2 = O(\tau_n^\varepsilon d_{\tau_n}), \quad \forall \varepsilon > 0. \tag{4.48}$$

Consequently by (4.43), $u^2_{\tau_n+1} = O(\tau_n^{\varepsilon} d_{\tau_n})$, for all $\varepsilon > 0$. From this, (1.1), and (4.35) again, we obtain $L_{\tau_n+2} = O(\tau_n^{\varepsilon} d_{\tau_n})$ for all $\varepsilon > 0$. This in conjunction with (4.47) and (4.48) yields

$$L_{k+1} = O([kr_k]^{\varepsilon} d_k), \quad \forall k \in [\tau_n, \tau_{n+1}], \quad \forall \varepsilon > 0. \tag{4.49}$$

From this it is easy to convince oneself that

$$\|\varphi_k\|^2 = O([kr_k]^{\varepsilon} d_k), \quad \forall k \in [\tau_n, \tau_{n+1}], \quad \forall \varepsilon > 0,$$

holds for all suitably large n. This implies (4.41), since $\tau_n \xrightarrow[n\to\infty]{} \infty$.

By (4.41) and a similar proof as for (4.18) we get $r_n = O([nr_n]^{\varepsilon} d_n \log r_n) + o(r_n) + O(n)$ for all $\varepsilon > 0$. Hence it follows that $r_n = O(n)$. Then, by (4.41) and the assumption that $d_n = O(n^{\varepsilon})$ for all $\varepsilon > 0$, we obtain $\|\varphi_n\|^2 = O(n^{\varepsilon})$ for all $\varepsilon > 0$. Therefore, similar to the proof of (4.36), we get $\sum_{i=1}^{n} (y_{i+1} - w_{i+1})^2 = O(n^{\varepsilon})$ for all $\varepsilon > 0$ a.s. on D_1^c. This completes the proof. □

Remark 4.3. The advantage of the modification (4.30) over (1.23) as used in [19] is clear. When (1.23) is used, the cumulated square errors resulting from the modification of $b_1(n)$ is of the order $O(n/\log n)$, i.e.,

$$\sum_{i=1}^{n} (\Delta \hat{b}_{1i})^2 = O\left(\sum_{i=1}^{n} \frac{1}{\log r_i}\right) = O\left(\frac{n}{\log n}\right).$$

Hence in Theorem 2 of Guo and Chen [19], the guaranteed convergence rate for the averaged regret R_n is only of the order $O(1/\log n)$, which is clearly much slower than the rate $R_n = O(1/n^{1-\varepsilon})$ a.s. for all $\varepsilon > 0$, obtained in Theorem 4.3. Of course, it would be of interest to generalize Theorem 4.3 to the colored noise case and to show that the left-hand side of (4.34) is of the order $O(\log n)$.

5. Concluding remarks. The convergence rate of least-squares–based adaptive algorithm has been observed in practice to be superior to any other type of implementable on-line recursive algorithms including the extensively studied stochastic gradient algorithm. In this paper, we have obtained various new results on the standard ELS-based adaptive minimum variance control for SISO ARMAX systems, and improved on the recent work [19] in many aspects. In particular, we have obtained the best possible convergence rate $O(\log n/n)$ for the averaged regret of tracking in several situations of interest. This rate is not believed to be achievable, for example, for the stochastic gradient based adaptive algorithm. For further study, it is desirable to generalize the result $R_n = O(\log n/n)$ to general tracking problems with arbitrarily bounded reference signal $\{y_n^*\}$, using (preferably) the control law (4.1).

TOPOLOGICAL METHODS FOR THE LOCAL CONTROLLABILITY OF NONLINEAR SYSTEMS*

W. KRYSZEWSKI† AND S. PLASKACZ‡

Abstract. Local controllability of systems using the topological degree of finite-dimensional set-valued maps is studied. For perturbed linear systems a generalization of the Lee–Markus sufficient condition of local controllability is established. For systems given by a finite family of continuous vector fields first order controllability condition is obtained. In both cases, a set of control functions sufficient for the local controllability is described, which is homeomorphic with a d-dimensional unit ball, where d is the dimension of the state space.

Key words. small-time local controllability, topological degree, perturbed linear systems, vector fields

AMS subject classifications. 93B05, 93C10

1. Introduction.

The purpose of this paper is to study local controllability of control systems

$$\begin{aligned} &x' = f(t,x,u);\\ &x(0) = 0,\\ &u(\cdot) \in U, \end{aligned} \tag{1}$$

where U is a family of control functions from [0,1] to a given set Ω.

For a given control function $u(\cdot) \in U$, by $\mathrm{Sol}_f(u)$ we denote the set of all solutions to the Cauchy problem

$$\begin{aligned} &x' = f(t,x,u(t));\\ &x(0) = 0. \end{aligned}$$

Let $T \in [0,1]$ and $U_0 \subset U$. The reachable set of system (1) controlled by U_0 at the time T (respectively, in time $\leq T$) is defined by

$$R_f(T,U_0) = \{x(T) : x \in \mathrm{Sol}_f(u) \text{ and } u \in U_0\}$$

$$\left(\text{resp. } R_f(\leq T,U_0) = \bigcup_{t\in[0,T]} R_f(t,U_0)\right).$$

We say that the system (1) is small time locally controllable (STLC) by means of U_0 if for every $T \in (0,1]$ we have

$$0 \in \mathrm{int}\, R_f(\leq T,U_0). \tag{2}$$

In the present paper we introduce an approach to the controllability of systems based on the topological degree of finite-dimensional set-valued maps used in order to establish (2). The general framework of our attitude looks as follows. First, we choose a subset K of U which is homeomorphic with the d-dimensional unit ball—say $p : B^d \to K$ is a homeomorphism; second, we deform linearly the right-hand side f of (1) to a more regular

function g, i.e., we consider a family $h_\lambda = (1-\lambda)f + \lambda^g, \lambda \in [0,1]$ and study a set-valued homotopy $\mathcal{H} : [0,1] \times K \rightsquigarrow R^d$ given by the formula

$$\mathcal{H}(\lambda, u) = \{x(l(u)) : x \in \text{Sol}_{h_\lambda}(u)\},$$

where $l : K \to [0,T]$ is a suitably choosen continuous function. For perturbed linear systems we take l as a constant function $l \equiv T$, while for systems defined by family of vector fields, l is somewhat hidden behind a certain reformulation of the system. The function g and the set K are chosen as to satisfy the following requirements:

- $\mathcal{H}(1,\cdot)$ is a homeomorphism (onto the image);
- $\mathcal{H}$ is an admissible map (in the sense of [9]; see the next section);
- $0 \notin \mathcal{H}(\lambda, u)$ for $\lambda \in [0,1]$ and $u \in \partial K$ (more precisely : $u \in p(\partial B^d)$).

In view of the properties of the topological degree, we obtain that $0 \in \text{int } \mathcal{H}(0,K)$, which implies $0 \in \text{int } R_f(\leq T, K)$.

We obtain two types of results: (i) the description of the set of controls which allow to reach in time $\leq T$ points from a neighbourhood of 0 (i.e., the set K above); (ii) some extensions of known sufficient conditions of STLC to the case of less regular (i.e., continuous instead of Lipschitz continuous or smooth) systems.

The paper is organized as follows. In §2 we briefly recall the topological degree theory of set-valued maps and provide some auxiliary lemmas. In §3 we study perturbed linear systems and establish a generalization of the classical Lee–Markus sufficient condition of local controllability. Our technics are similar to those used in [7] and [15] to study global controllability problems, In §4 we consider control systems given by a finite family of continuous vector fields $f_i : [0,1] \times R^d \to R^d, i = 1, \ldots, k$, which satisfy the following first-order controllability condition:

$$0 \in \text{int } (\text{co}\{f_i(0,0) : i = 1, \ldots, k\}),$$

where co A, int A denote the closed convex hall and the interior of a subset $A \subset R^d$, respectively. For more regular, i.e., lipschitz continuous with respect to the second variable, vector fields Frankowska proved in [6] that the above condition is sufficient for STLC.

The Appendix gives the proof of the auxiliary Lemma 4.1.

2. Preliminaries. We use the standard notation, in particular by $\langle \cdot, \cdot \rangle, |\cdot|, B^d$, and S^{d-1} we denote the scalar product, the norm, the closed unit ball and unit sphere in R^d. For $\varepsilon > 0$, the ε-neighbourhood of a set $A \subset R^d$ is denoted by $N_\varepsilon(A) = \{x \in R^d : \text{dist}(x,A) = \inf_{y \in A}|x-y| < \varepsilon\}$. Moreover, we put $I = [0,1]$. We denote by $\chi_A : I \to \{0,1\}$ the characteristic function of a subset $A \subset I$. The norms in the spaces $L^1(I,R^d), L^\infty(I,R^d), C(I,R^d)$ and $AC(I,R^d)$ of integrable, essentially bounded, continuous, and absolutely continuous functions are denoted by $\|\cdot\|_1, \|\cdot\|_\infty, \|\cdot\|$, and $\|\cdot\|_{AC}$, respectively (recall $\|x\|_{AC} = \|x'\|_1 + \|x\|$).

We say that a metric space K is acyclic if $H^*(K) = H^*(pt)$, where H^* denote the Alexander–Spanier cohomology functor (see [16]) and pt is a one point space. The continuity of the theory H^* implies that any R_δ-set K (i.e., $K = \cap_1^\infty K_i, K_{i+1} \subset K_i, K_i$ is compact and contractible—see [11]), is compact and acyclic.

A set valued map φ from the set X to a set Y will be denoted by $\varphi : X \rightsquigarrow Y$, while the ordinary arrow $\to$ refers to single-valued maps. If X, Y are metric spaces, we say that φ is acyclic whenever φ is upper semicontinuous and, for each $x \in X$, the set $\varphi(x)$ is compact acyclic. In particular an upper semicontinuous map with R_δ values is acyclic.

A map $\varphi : X \rightsquigarrow Y$ is admissible if there is a metric space Γ and continuous maps $\alpha : \Gamma \to X, \beta : \Gamma \to Y$ such that

(i) α is a proper surjection (i.e., $\alpha^{-1}(K)$ is compact for any compact $K \subset X$);
(ii) $\alpha^{-1}(x)$ is acyclic for every $x \in X$;
(iii) $\varphi(x) = \beta(\alpha^{-1}(x))$ for every $x \in X$.

The following facts are readily proven:

- an admissible map is upper semicontinuous;
- an acyclic map is admissible;
- the composition of admissible maps is again admissible.

By $\mathcal{A}$ we denote the set of all admissible maps $\varphi : B^d \rightsquigarrow R^d$ such that $0 \notin \varphi(S^{d-1})$.

THEOREM 2.1 (see [2]). *There is a set-valued map* $\mathrm{Deg} : \mathcal{A} \rightsquigarrow Z$ *such that for* $\varphi \in \mathcal{A}$:

(i) *If* φ *is a single-valued map, then* $\mathrm{Deg}\ \varphi = \{deg\ \varphi\}$, *where deg stands for the ordinary Brouwer degree (see* [5], [14]). *In particular, if* φ *is a homeomorphism (onto the image), then* $\mathrm{Deg}\ \varphi = \{1\}$ *or* $\{-1\}$.
(ii) (*Existence*) *If* $\mathrm{Deg}\ \varphi \neq \{0\}$, *then there exists a neighbourhood* $\mathcal{O}$ *of zero such that* $\mathcal{O} \subset \varphi(B^d)$.
(iii) (*Homotopy invariance*) *Let* $\mathcal{H} : I \times B^d \rightsquigarrow R^d$ *be an admissible map and* $0 \notin \mathcal{H}(I \times S^{d-1})$. *Then* $\mathcal{H}(i, \cdot) \in \mathcal{A}, i = 0, 1$ *and* $\mathrm{Deg}\ \mathcal{H}(0, \cdot) \cap \mathrm{Deg}\ \mathcal{H}(1, \cdot) \neq \emptyset$.

For more details and facts concerning admissible maps and degree theory we recommend [2] and [9].

We say that a function $f : I \times X \to R^d$ (X is a metric space) is measurable-continuous if:

- $t \to f(t, x)$ is measurable for every $x \in X$;
- $x \to f(t, x)$ is continuous for almost all $t \in I$.

In what follows, the following lemmas play an important role.

LEMMA 2.2 (see [1] and [4]). *If* $h : I \times R^d \to R^d$ *is a measurable-continuous function and* $|h(t, x)| \leq \mu(t)(1 + |x|)$, *where* $\mu \in L^1$, *then the set of solutions to the Cauchy problem*

$$\begin{cases} x'(t) = h(t, x(t)), \\ x(0) = 0 \end{cases}$$

is an R_δ*-set in* $C(I, R^d)$.

LEMMA 2.3. *If* X *is a closed convex and bounded subset of a normed space* E, V *is a metric space,* $F : V \times X \to E$ *is a continuous map and* $F(V \times X)$ *is relatively compact subset of* X, *then the map* $\mathcal{F} : V \rightsquigarrow E$ *given by the formula* $\mathcal{F}(v) = Fix\ F(v, \cdot) := \{x \in X : x = F(v, x)\}$, *for* $v \in V$, *is upper semicontinuous.*

Proof. In view of the Schauder fixed point theorem, the set $\mathcal{F}(v)$ is nonempty and compact for any $v \in V$. Take a closed set $K \subset E$ and a sequence $(v_n) \subset \mathcal{F}^{-1}(K)$ converging to $v \in V$. By the definition, there is a sequence $(x_n) \subset K$ such that $x_n = F(v_n, x_n)$ for any n. In view of the compactness of $\overline{F(V \times X)}$, passing to subsequences if necessary, we may assume that $x_n \to x \in K$ as $n \to \infty$. Therefore, $x = F(v, x)$, and hence $v \in \mathcal{F}^{-1}(K)$. □

3. Perturbed linear control systems. We shall study perturbed linear control systems of the form

$$\begin{aligned} &x' = A(t)x + B(t)u + f_1(t, x, u), \\ &x(0) = 0, \\ &u \in L^\infty(I, R^m), \end{aligned} \tag{3}$$

where

(4) $A(\cdot), B(\cdot)$ are time dependent $d \times d$ and $d \times m$, respectively, matrices with measurable coefficients and there exists an integrable function $\mu : I \to R$ such that
$|A(t)x + B(t)u| \leq \mu(t)(|x| + |u|)$ for $t \in I, x \in R^d, u \in R^m$;

(5) $$f_1 : I \times R^{d+m} \to R^d \text{ is measurable-continuous;}$$

(6) $$\lim_{x,u \to 0} \frac{f_1(t,x,u)}{|x| + |u|} = 0, \text{ uniformly for } t \in I.$$

We will reduce the problem of controllability of the system (3) to the one of controllability of its linearization

(7) $$\begin{aligned} &x' = A(t)x + B(t)u, \\ &x(0) = 0, \\ &u \in L^\infty(I, R^m). \end{aligned}$$

Let denote the right-hand side of the systems (3) and (7) by f and g, respectively.

It is well known that, for any $T \in (0,1]$, the map $\Psi_T : L^\infty(I, R^m) \to R^d; \Psi_T(u) = x(T)$, where $x \in \mathrm{Sol}_g(u)$, is linear and continuous (single-valued). For any linear subspace U of $L^\infty([0,T], R^m)$ the following conditions are equivalent:

- $0 \in \operatorname{int} R_g(T,U)$.
- $R_g(T,U) = R^d$.

Fix $T \in (0,1]$ and a linear subspace V of $L^\infty([0,T], R^m)$. In connection with perturbed linear systems of the form (3) some authors (cf. [3], [8]) consider the following operator:

$$\begin{aligned} &\Phi : AC([0,T], R^d) \times V \to L^1([0,T], R^d) \times R^{d+d}; \\ &\Phi(x,u) = (x' - A(\cdot)x - B(\cdot)u, x(0), x(T)). \end{aligned}$$

Using Banach Inverse Mapping Theorem we easily prove the following lemma.

LEMMA 3.1. *If V is an d-dimensional linear subspace of $L^\infty([0,T], R^m)$ and $\Psi(V) = R^d$, then the operator Φ is a topological isomorphism. Consequently, there is a constant $c > 0$ such that:*

$$\|x\|_{AC} + \|u\|_\infty \leq c \left(\int_0^T |x'(s) - A(s)x(s) - B(s)u(s)|ds + |x(0)| + |x(T)| \right)$$

for $x \in AC([0,T], R^d), u \in V$.

LEMMA 3.2. *Suppose that functions $h_i : I \times R^{d+m} \to R^d, i = 0, 1$, are measurable-continuous and satisfy*

$$|h_i(t,x,u)| \leq \mu(t)(1 + |x| + |u|),$$

for all $x \in R^d, u \in R^m$ and almost all $t \in I$, where $\mu \in L^1(I, R)$. Then the set valued map $S : I \times L^\infty(I, R^m) \rightsquigarrow C(I, R^d)$ which associate to any $(\lambda, u) \in I \times L^\infty(I, R^m)$ the set of solutions to the following Cauchy problem

(8) $$\begin{aligned} &x'(t) = \lambda h_1(t, x(t), u(t)) + (1 - \lambda)h_0(t, x(t), u(t)), \\ &x(0) = 0 \end{aligned}$$

is admissible.

Proof. By Lemma 2.2, the set $S(\lambda, u)$ is an R_δ-set for every $\lambda \in I$ and $u \in L^\infty$.

We shall show that the map S is upper semicontinuous on any set $I \times B_R$, where $B_R = \{u \in L^\infty : \|u\|_\infty \leq R\}$. By the Gronwall inequality (see [10, p. 36]) there is a constant r such that $\|x\| < r$ for any $x \in S(\lambda, u), \lambda \in I, u \in B_R$. We set $c = (1 + R + r)\int_0^1 \mu(t)dt, X = \{x \in C(I, R^d) : \|x\| \leq c\}$. We define an integral operator $F : I \times B_R \times X \to C(I, R^d)$

$$F(\lambda, u, x)(t) = \int_0^T \tilde{h}_\lambda(s, x(s), u(s))ds,$$

where

$$\tilde{h}_i(t, x, u) = \begin{cases} h_i(t, x, u) & \text{for } t \in I, |x| \leq r, u \in R^m; \\ h_i(t, rx/|x|, u) & \text{for } t \in I, |x| > r, u \in R^m, \end{cases}$$

$i = 0, 1$ and $\tilde{h}_\lambda = \lambda\tilde{h}_1 + (1 - \lambda)\tilde{h}_0$.

It is easy to check that $F(\lambda, x, u) \in X$ for any $\lambda \in I, u \in B_R, x \in X$ and, moreover, that $Fix\ F(\lambda, u, \cdot) = S(\lambda, u)$. By Lemma 2.3, the map S is upper semicontinuous and, therefore, admissible. □

THEOREM 3.3. *Suppose that a perturbed linear control system* (3) *satisfies* (4), (5), (6), *and V is a linear subspace of $L^\infty(I, R^m)$. Then there is $T_0 \in (0, 1]$ such that for any $T \in (0, T_0)$ if*

$$0 \in \text{int } R_g(T, V), \tag{9}$$

then, for each $\varepsilon > 0$

$$0 \in \text{int } R_f(T, \{u \in V : \|u\chi_{[0,T]}\|_\infty < \varepsilon\}).$$

Proof. By (6), there exists $\delta > 0$ such that

$$|f_1(t, x, u)| < |x| + |u| \text{ for } t \in I, |x| \leq \delta, |u| \leq \delta. \tag{10}$$

We set

$$f_2(t, x, y) = \begin{cases} f_1(t, x, y) & \text{for } t \in I, |x| \leq \delta, |y| \leq \delta, \\ f_1(t, \delta x/|x|, y) & \text{for } t \in I, |x| > \delta, |y| \leq \delta, \\ f_1(t, x, \delta y/|y|) & \text{for } t \in I, |x| \leq \delta, |y| > \delta, \\ f_1(t, \delta x/|x|, \delta y/|y|) & \text{for } t \in I, |x| > \delta, |y| > \delta. \end{cases}$$

By (4), (10), and the definition of f_2, we get that

$$|h_\lambda(t, x, u)| < (\mu(t) + 1)(|x| + |u|) \quad \text{for } t \in I, x \in R^d, u \in R^m, \tag{11}$$

where $h_\lambda(t, x, u) = A(t)x + B(t)u + \lambda f_2(t, x, u)$.

We take $T_0 \in (0, 1]$ such that

$$\int_0^{T_0} (\mu(t) + 1)2\delta\ dt < \delta \tag{12}$$

and fix $T \in (0, T_0]$.

For $\lambda \in I, u \in V$, let $S_T(\lambda, u) = \{x|_{[0,T]} : x \in \text{Sol}_{h_\lambda}(u)$ and $V_T = \{u|_{[0,T]} : u \in V\}$. Evidently S_T can be treated as a map $S_T : I \times V_T \rightsquigarrow C([0, T], R^d)$. By Lemma 3.2, the map S_T is admissible. From now on till the end of this proof all elements $u \in V_T$ and solutions $x \in S_T(\lambda, u)$ are considered on $[0, T]$ and the norms $\|u\|_\infty$ and $\|x\|$ are taken from respective spaces $L^\infty([0, T], R^m)$ and $C([0, T], R^d)$.

By the Gronwall inequality, there is a constant $c_0 > 0$ such that

$$\|x\| \leq c_0 \|u\|_\infty \tag{13}$$

for any $u \in V_T, \lambda \in I$ and $x \in S_T(\lambda, u)$.

It is easy to deduce from (11) and (12) that, if $x \in \mathrm{Sol}_{h_1}(u)$ and $\|u\|_\infty \leq \delta$, then $\|x\| \leq \delta$. By the same arguments, we get that $\|x\| \leq \delta$ for any $x \in \mathrm{Sol}_f(u)$ if $u \in V_T$ and $\|u\|_\infty \leq \delta$. Thus

$$R_f(T, W) = R_{h_1}(T, W) \tag{14}$$

for any subset $W \subset \{u \in V_T : \|u\|_\infty \leq \delta\}$.

By (9), there is a d-dimensional subspace V_0 of V_T (i.e., $V_0 \subset L^\infty([0,T], R^m)$) such that $\Psi(V_0) = R^d$. In view of Lemma 3.1, there is a constant $c > 0$ such that

$$\|x\| + \|u\|_\infty \leq c \left(\int_0^T |f_2(s, x(s), u(s))| ds + |x(T)| \right), \tag{15}$$

for any $x \in S_T(\lambda, u), u \in V_0$, and $\lambda \in I$. Once again, by (6), there is $\delta_1 (0 < \delta_1 < \delta)$ such that

$$|f_2(t, x, u)| \leq \frac{|x| + |u|}{2Tc}, \tag{16}$$

for $t \in I, |x| < \delta_1, |u| < \delta_1$. Let $\delta_2 > 0$ be such that $\delta_2 < \min(\delta_1, \varepsilon), c_0 \delta_2 < \delta_1$ and take $K \subset V_0$ be the closed ball of radius δ_2 centered at zero.

A homotopy $\mathcal{H} : I \times K \rightsquigarrow R^d$ given by the formula

$$\mathcal{H}(\lambda, u) = \{x(T) : x \in S_T(\lambda, u)\}$$

for $\lambda \in I, u \in K$, is an admissible map since it is the composition of the admissible map S_T with the continuous (single-valued) evaluation $e_T : C([0,T], R^d) \to R^d; e_T(x) = x(T)$.

We shall show that if $u \in K, \|u\|_\infty = \delta_2$ then $0 \notin \mathcal{H}(\lambda, u)$ for any $\lambda \in I$. Suppose to the contrary that for some $u \in K, \|u\|_\infty = \delta_2$ and $\lambda \in I$, there is $x \in S_T(\lambda, u)$ such that $x(T) = 0$. In view of (13), $\|x\| \leq c_0 \|u\|_\infty \leq c_0 \delta_2 < \delta_1$. By (15), (16)

$$\|x\| + \|u\|_\infty \leq c \int_0^T |f_2(s, x(s), u(s))| ds \leq 1/2(\|x\| + \|u\|_\infty),$$

a contradiction. By Theorem 2.1(i), (iii), $0 \neq \mathrm{Deg}\ \mathcal{H}(\cdot, 0) \in \mathrm{Deg}\ \mathcal{H}(\cdot, 1)$, hence, by Theorem 2.1(ii), $0 \in \mathrm{int}\ \mathcal{H}(1, K) = R_{h_1}(T, K)$. Equality (14) ends the proof. □

LEMMA 3.4. *Suppose that a linear control system* (7) *satisfies* (4). *Then the system* (7) *is* STLC *by* $L^\infty(I, R^m)$ *if and only if* $0 \in \mathrm{int}\ R_g(T, L^\infty)$ *for every* $T \in (0, 1]$.

Proof. For $t \in (0, 1]$, we have

$$R_g(t, L^\infty) = \{H(t) \int_0^t H^{-1}(s) B(s) u(s) ds : u \in L^\infty\},$$

where H denotes the resolvent of the matrix function A. Let $W(t) = H^{-1}(t)[R_g(t, L^\infty)]$. Obviously, $W(t), R_g(t, L^\infty)$ are linear subspaces of R^d and, for $t_1 < t_2, W(t_1) \subset W(t_2)$ since

$$\int_0^{t_1} H^{-1}(s) B(s) u(s) ds = \int_0^{t_2} H^{-1}(s) B(s) \chi_{[0,t_1]}(s) u(s) ds$$

for any $u \in L^\infty$.

Suppose, to the contrary, that there is $T \in (0,1]$ such that $0 \notin \text{int } R_g(T, L^\infty)$, i.e., $R_g(T, L^\infty) \neq R^d$ and $\dim W(T) < d$. Let $r = \sup_{0\le t\le 1} \|H^{-1}(t)\|$ (here $\|\cdot\|$ denotes the norm of a linear map) and let $0 < \varepsilon < 1/r$. There is $0 < \delta < T$ such that $\|H(t) - I_d\| < \varepsilon$ for $0 \le t \le \delta$, where I_d denotes the unit d-dimensional matrix. Take $a \in R^d, |a| = 1$ such that $\inf_{w\in W(T)}|a - w| = 1$. Since (7) is STLC by means of $L^\infty, R^d = \cup_{0\le t\le\delta} R_g(t, L^\infty)$, so there is $b \in W(s), 0 \le s \le \delta$ such that $a = H(s)(b)$. But $|b| \le \|H^{-1}(s)\||a| \le r$ and $|a - b| = |(H(s) - I_d)(b)| < \varepsilon|b| < 1$, contradiction.

We have proved the "only if" part, the "if" part being self-evident. □

In view of Theorem 3.3 and Lemma 3.4 we get the following corollary.

COROLLARY 3.5. *Suppose that a perturbed linear control system* (3) *satisfies* (4), (5), *and* (6). *If the linearization* (7) *is* STLC *by means of* $L^\infty(I, R^m)$, *then, for every* $\varepsilon > 0$, *the system* (3) *is* STLC *by means of* $\{u \in L^\infty(I, R^m) : \|u\|_\infty < \varepsilon\}$.

4. Control systems given by vector fields. Let $\Omega = \{1, 2, \dots, k\}, U = \{u : I \to \Omega :$ u *is nondecreasing, continuous from the right*$\}$ and $f : I \times R^d \times \Omega \to R^d$ be a continuous function. In this case, the control system (1) can be described by a family $\{f_1, f_2, \dots, f_k\}$ of continuous vector fields $f_i : I \times R^d \to R^d, f_i(t, x) = f(t, x, i)$. There are some higher-order sufficient conditions of STLC for smooth autonomous vector fields (see [17]) and for Lipschitz continuous vector fields (see [6]).

We shall study this system under the following assumption:

$$0 \in \text{int}(co\{f_i(0,0) : i = 1, 2, \dots, k\}). \tag{17}$$

If f_i are Lipschitz continuous with respect to x, then (17) implies STLC of the control system

$$x' = \sum_1^k u_i(t) f_i(t, x), \qquad x(0) = 0,$$

by means of measurable scalar controls u_i such that $\sum_1^k u_i(t) = 1$ almost everywhere in I and $u_i \ge 0$ for $i = 1, 2, \dots k$ (see [6, Cor. 2.1]).

Below, we generalize this fact to the case of continuous vector fields. Moreover, for a given sufficiently small T, we describe a d-dimensional set K_T of controls such that $0 \in$ int $R_f(\le T, K_T)$.

The following combinatorial Lemma plays a crucial role in the sequel. Let $Y = \{y_1, y_2, \dots y_k\} \subset R^d$. By $cone(Y)$ we denote the convex cone spanned by Y, i.e.,

$$\text{cone}(Y) = \left\{ \sum_1^k \alpha_i y_i : \alpha_i \ge 0, 1 \le i \le k \right\}.$$

LEMMA 4.1. *If* $\text{cone}(Y) = R^d$, *then there is a family* $\mathcal{P}$ *of subsets of* Ω *such that:*

(i) *if* $S \in \mathcal{P}$, *then the set* $\{y_i : i \in S\}$ *is linearly independent;*

(ii) *if* $S \in \mathcal{P}$ *and* $R \subset S$, *then* $R \in \mathcal{P}$;

(iii) $\text{cone}\{y_i : i \in S\} \cap \text{cone}\{y_i : i \in R\} = \text{cone}\{y_i : i \in R \cap S\}$ *for any* S, $R \in \mathcal{P}$;

(iv) $\cup_{S\in\mathcal{P}} \text{cone}\{y_i : i \in S\} = \text{cone}\{y_i : i \in \cup_{S\in\mathcal{P}} S\}$;

(v) $\text{cone}\{y_i : i \in \cup_{S\in\mathcal{P}} S\} = R^d$.

The proof of this lemma will be given in Appendix.

To point out the evaluation time of a solution corresponding to a control $u \in U$ we formally reformulate the problem. First, set $\tilde{\Omega} = \Omega \cup \{k+1\}$ and let

$$\tilde{f}(t,x,i) = \begin{cases} f(t,x,i) & \text{for } 1 \le i \le k, \\ 0 & \text{for } i = k+1 \end{cases}$$

and, for $T \in (0,1]$, let $\tilde{U}_T = \{u : [0,T] \to \tilde{\Omega} : u \textit{ is nondecreasing continuous from the right and } u(T) = k+1\}$. There is a bijection between $\tilde{U}_T$ and the set $V_T = \{\alpha = (\alpha_1, \dots \alpha_k) \in R^k : \alpha_i \ge 0 \textit{ and } \sum_1^k \alpha_i \le T\}$. Namely, to any $\alpha \in V_T$ we assign a control $u_\alpha = 1 + \sum_{i=1}^k \chi_{(\sum_{j=1}^i \alpha_j, T]}$.

By Lemma 4.1 there is a family $\mathcal{P}$ associated with $Y = \{y_i = f_i(0,0) : i = 1,2,\dots k\}$. Let us define

$$K_T = \{u_\alpha \in \tilde{U}_T : \alpha \in V_T \text{ and } \{i : \alpha_i > 0\} \in \mathcal{P}\}.$$

THEOREM 4.2. *If a function $f : I \times R^d \times \Omega \to R^d$ is continuous and satisfies* (17), *then there is $T_0 > 0$ such that*

$$0 \in R_{\tilde{f}}(T, K_T) \quad \textit{for any } T \in (0, T_0].$$

The proof of Theorem 4.2 will be proceeded with two lemmas.

To avoid too many symbols, we use the same symbol K_T to denote the set $\{\alpha \in V_T : \{i \in \Omega : \alpha_i > 0\} \in \mathcal{P}\}$.

Let $W = \{(\alpha_1, \dots \alpha_k) \in R_+^k : \{i \in \Omega : \alpha_i > 0\} \in \mathcal{P}\}$. On W and K_T we have the metric inherited from R^k.

LEMMA 4.3. *A map $\eta : W \to R^d$ defined by the formula*

$$\eta(\alpha) = \sum_1^k \alpha_i y_i$$

is a homeomorphism.

Proof. Properties 4.1(iv), (v) of $\mathcal{P}$ show that η is surjective. Suppose that $\eta(\alpha) = \eta(\beta)$. By 4.1(iii), there is $\gamma \in W$ such that $\{i \in \Omega : \gamma_i > 0\} \subset \{i \in \Omega : \alpha_i > 0\} \cap \{i \in \Omega : \beta_i > 0\}$ and $\eta(\alpha) = \eta(\gamma)$. By 4.1(i), the system $\{y_i : \alpha_i > 0\}$ is linearly independent; hence $\gamma = \alpha$. Similarly we show that $\beta = \gamma$. The continuity of η follows from its linearity. For $S \in \mathcal{P}$, η^{-1} restricted to $\operatorname{cone}\{y_i : i \in S\}$ is linear and, therefore, continuous. Since cones $\operatorname{cone}\{y_i : i \in S\}, S \in \mathcal{P}$, are closed and, by 4.1(iv), (v), cover the whole space R^d, η^{-1} is also continuous. □

LEMMA 4.4. *A map $\nu^T : B^d \to \eta(K_T)$ given by the formula*

$$\nu^T(z) = \begin{cases} \left(\sum_1^k \beta_i\right)^{-1} T|z|z & \textit{for } z \ne 0 \textit{ and } \beta = \eta^{-1}(z), \\ 0 & \textit{for } z = 0 \end{cases}$$

is a homeomorphism and $\nu^T(S^{d-1}) = \{\eta(\alpha) : \alpha \in K_T \textit{ and } \sum_1^k \alpha_i = T\}$.

Proof. Observe that a map $\Theta^T : \eta(K_T) \to B^d$ given by the formula

$$\Theta^T(z) = \begin{cases} T^{-1}\left(\sum_1^k \alpha_i\right)|z|^{-1}z & \text{for } z \ne 0 \text{ and } \alpha = \eta^{-1}(z), \\ 0 & \text{for } z = 0 \end{cases}$$

is the inverse to ν^T. Maps ν^T, Θ^T are continuous in view of the continuity of η. □

Proof of Theorem 4.2. For any $S \in \mathcal{P}$, by (4.1), $0 \notin \operatorname{co}\{y_i : i \in S\}$; hence there is $\varepsilon > 0$ such that $0 \notin N_\varepsilon(\operatorname{co}\{y_i : i \in S\})$ and there is $z_S \in R^d$ such that $\langle z_S, z\rangle > 0$ for every $z \in N_\varepsilon(\operatorname{co}\{y_i : i \in S\})$.

There is $\delta \in (0,1]$ such that $|f_i(t,x) - f_i(0,0)| < \varepsilon$ for $|x| \le \delta, 0 \le t \le \delta$ and $i \in \Omega$. Define $c = \sup\{|f_i(t,x)| : 0 \le t \le \delta, |x| \le \delta, i \in \Omega\}$ and put $T_0 = \min(\delta, \delta/c)$. Fix $T \in (0, T_0]$. Let $X = \{x \in C([0,T], R^d) : \|x\| \le \delta\}$ and consider an integral operator $H : V_T \times I \times X \to X$ given by the formula

$$H(\alpha, \lambda, x)(t) = \int_0^t [(1-\lambda)\tilde{f}(s, x(s), u_\alpha(s)) + \lambda \tilde{f}(0,0,u_\alpha(s))]\, ds$$

for $\alpha \in V_T, x \in X, \lambda \in I$. This operator is well-defined on $V_T \times I \times X$, since $|H(\alpha,\lambda,x)(t)| \le Tc < \delta$. Evidently H is continuous and the set $\overline{H(V_T \times I \times X)}$ is compact. Hence, by Lemma 2.3, the map $S : V_T \times I \rightsquigarrow X$ given by the formula $S(\alpha,\lambda) =$ Fix $H(\alpha,\lambda,\cdot)$ is upper semicontinuous. On the other hand, we easily see that $S(\alpha,\lambda) = \mathrm{Sol}_{(1-\lambda)\tilde{f}+\lambda\tilde{f}(0,0,\cdot)}(u_\alpha)$, so, by Lemma 2.2, $S(\alpha,\lambda)$ is an R_δ-set for every $\alpha \in V_T, \lambda \in I$. Hence the map $\mathcal{H} : K_T \times I \rightsquigarrow R^d$ given by $\mathcal{H}(\alpha,\lambda) = \{x(T) : x \in S(\alpha,\lambda)\}$ is admissible.

By Lemmas 4.3 and 4.4, the set K_T is homeomorphic with B^d and the boundary $\partial K_T = \{u_\alpha : \sum_1^k \alpha_i = T\}$. We will show that $0 \notin \mathcal{H}(\alpha,\lambda)$ for every $\alpha \in \partial K_T, \lambda \in I$. Let $S = \{i \in \Omega : \alpha_i > 0\} \in \mathcal{P}$. We easily see that

$$(1-\lambda)f(t,x(t),i) + \lambda f(0,0,i) = (1-\lambda)f_i(t,x(t)) + \lambda y_i \in N_\varepsilon(\mathrm{co}\{y_i : i \in S\})$$

for $i \in S, t \in [0,T]$. Thus, for $i \in S$,

$$\langle z_S, (1-\lambda)f_i(t,x(t)) + \lambda y_i\rangle > 0$$

and $\langle x(T), z_S\rangle > 0$; hence $x(T) \neq 0$.

Now, observe that $\mathcal{H}(\alpha,1) = \sum_1^k \alpha_i y_i = \eta(\alpha)$. By Lemma 4.3 and Theorem 2.1(i), (iii), $0 \neq \mathrm{Deg}\ \mathcal{H}(\cdot,1) \in \mathrm{Deg}\ \mathcal{H}(\cdot,0)$, so, in view of Theorem 2.1(ii), we have the desired conclusion. □

COROLLARY 4.5. *Suppose that a function $f : I \times R^d \times \Omega \to R^d$ is continuous and satisfies* (17). *Then the control system* (1) *is* STLC *by the set of controls $U = \{u : I \to \Omega : u$ is nondecreasing, continuous from the right$\}$.*

5. Concluding remarks. The technique introduced in the paper may also be employed to the study of the point-to-point controllability problem of control systems. Considering the system (1), we say that (1) is controllable from zero to $y \in R^d$ in time $T \in (0,1]$ by means of $U_0 \subset U$ if $y \in R_f(T, U_0)$. We easily see that the controllability in the above sense is equivalent to the solvability of the generalized (set-valued) equation

$$y \in e_T \circ \mathrm{Sol}_f(u); u \in U_0 \tag{18}$$

where $e_T : C([0,1], R^d) \to R^d$ is the evaluation in the time T. The solvability of (18) may be established by the topological methods roughly discussed in the Introduction. These techniques usually yield stronger results: namely, that of local controllability, i.e., the issue states that $y \in \mathrm{int}\ R_f(T,K)$, where $K \subset U$ is a set homeomorphic to the ball B^d.

In this manner one is in a position to provide different proofs of some results of [7] or/and get the precise description of the control sets for some special controllability problems (see [8] and [12]).

6. Appendix. In this section we prove Lemma 4.1. Let $y \in R^d$ and let $y \notin C$; by $s(C,y)$ we denote the *set of points from C that are "seen" from y*, i.e.,

$$s(C,y) = \{c \in C : y + \lambda(c-y) \notin C \text{ for each } 0 < \lambda < 1\}.$$

We start with the following self-evident result.

LEMMA 6.1. *Let C be a closed convex cone in R^d and $y \notin C$.*

(i) *If* $c \in C \backslash s(C,y)$ *and* $\alpha > 0$, *then* $\alpha c \in C \backslash s(C,y)$.
(ii) *If* $c \in C \backslash s(C,y)$ *and* $d \in C$, *then* $c + d \in C \backslash s(C,y)$.

Proof of Lemma 4.1. The family $\mathcal{P}$ will be constructed inductively in a finite number of steps. First, let us choose $i_1, \dots i_N, 1 \le i_j \le k$, such that the system $\{y_{i_j} : 1 \le j \le N\}$ is an (algebraic) basis of R^d; we define $\mathcal{P}_1$ in the following way:

$$\mathcal{P}_1 = \{S : S \subset \{i_j : 1 \le j \le N\}\}.$$

We easily see that $\mathcal{P}_1$ satisfies conditions (i)–(iv). Assume that a constructed family $\mathcal{P}_r$ satisfies conditions (i)–(iv) but fails to satisfy condition (v). We shall define a family $\mathcal{P}_{r+1}$ satisfying (i)–(iv) and such that

$$\operatorname{card}\left(\bigcup_{S\in\mathcal{P}_{r+1}} S\right) = \operatorname{card}\left(\bigcup_{S\in\mathcal{P}_r} S\right) + 1,$$

where $\operatorname{card}(\cdot)$ denotes the cardinality of a set. Hence, after at most $(k - N)$-steps the defined family should satisfy condition (v), too.

Since $\mathcal{P}_r$ does not fulfill (v), there is $1 \le i_0 \le k$ such that $i_0 \in S$ for no $S \in \mathcal{P}_r$ and $y_{i_0} \notin C := \operatorname{cone}\{y_j : j \in \cup_{S\in\mathcal{P}_r} S\}$. Let us put

$$\mathcal{P}_{r+1} = \mathcal{P}_r \cup \{\{i_0\} \cup S : S \in \mathcal{P}_r \quad \text{and} \quad \operatorname{cone}\{y_i : i \in S\} \subset s(C, y_{i_0})\}.$$

We shall show that $\mathcal{P}_{r+1}$ fulfills (i)–(iv).

(i) Let $S \in \mathcal{P}_r$ such that $\{i_0\} \cup S \in \mathcal{P}_{r+1}$ and let $S = \{i_j : 1 \le j \le t\}$. It is sufficient to prove that $y_{i_0} \notin \operatorname{span}\{y_{i_j} : 1 \le j \le t\}$. Suppose to the contrary that $y_{i_0} = \sum_{j=1}^{t} \alpha_j y_{i_j}$. If $x = \sum\{\alpha_j y_{i_j} : 1 \le j \le t \text{ and } \alpha_j \ge 0\}$ and $y = \sum\{-\alpha_j y_{i_j} : 1 \le j \le t \text{ and } \alpha_j < 0\}$, then $y_{i_0} = x - y$ and $x, y \in \operatorname{cone}\{y_i : i \in S\}$. For any $\frac{1}{2} < \lambda < 1, y_{i_0} + \lambda(y - y_{i_0}) = (1-\lambda)x + (2\lambda - 1)y \in C$. Hence $y \in s(C, y_{i_0})$, a contradiction.

(ii) is obvious.

(iii) Let $S, R \in \mathcal{P}_{r+1}$. If $S, R \in \mathcal{P}_r$, then we are done. Assume that $S \in \mathcal{P}_r$ and $R \notin \mathcal{P}_r$. There is $R' \in \mathcal{P}_r$ such that $R = R' \cup \{i_0\}$. We show that $a \notin C$ provided $a \in \operatorname{cone}\{y_i : i \in R\} \setminus \operatorname{cone}\{y_i : i \in R'\}$. Let $a = \alpha y_{i_0} + y$, where $y \in \operatorname{cone}\{y_i : i \in R'\}$ and $\alpha > 0$. Evidently $a' = (2\alpha)^{-1} a = 2^{-1} y_{i_0} + w'$, where $w' \in \operatorname{cone}\{y_i : i \in R'\}$. Since $a' = y_{i_0} + 2^{-1}(2w' - y_{i_0})$ and $w' \in \operatorname{cone}\{y_i : i \in R'\} \subset s(C, y_{i_0})$, we have $a' \in C$ and, consequently, $a \in C$. Hence

$$(\operatorname{cone}\{y_i : i \in R\} \setminus \operatorname{cone}\{y_i : i \in R'\}) \cap \operatorname{cone}\{y_i : i \in S\} = \emptyset$$

and

$$\operatorname{cone}\{y_i : i \in R\} \cap \operatorname{cone}\{y_i : i \in S\} = \operatorname{cone}\{y_i : i \in R'\} \cap \operatorname{cone}\{y_i : i \in S\} = \operatorname{cone}\{y_i : i \in R' \cap S\} = \operatorname{cone}\{y_i : i \in R \cap S\}$$

because $R', S \in \mathcal{P}_r$.

Assume now that $R, S \notin \mathcal{P}_r$; thus $R = R' \cup \{i_0\}, S = S' \cup \{i_0\}$, where $R', S' \in \mathcal{P}_r$. Let $a \in \operatorname{cone}\{y_i : i \in S\} \cap \operatorname{cone}\{y_i : i \in R\}$. Hence $a = \alpha y_{i_0} + w = \beta y_{i_0} + z$, where $\alpha, \beta \ge 0$ and $w \in \operatorname{cone}\{y_i : i \in S'\}, z \in \operatorname{cone}\{y_i : i \in R'\}$. If $\alpha = 0$ or $\beta = 0$, then we are back in the case treated above. Without any loss of generality we may therefore assume that $0 < \alpha, \beta < 1$. For $\lambda_1 = (1 - \alpha)^{-1}$,

$$y_{i_0} + \lambda_1(a - y_{i_0}) = \lambda_1 w \in \operatorname{cone}\{y_i : i \in S'\} \subset s(C, y_{i_0})$$

and, for $\lambda_2 = (1-\beta)^{-1}$,

$$y_{i_0} + \lambda_2(a - y_{i_0}) = \lambda_2 z \in s(C, y_{i_0}).$$

Consequently, $\lambda_1 w = \lambda_2 z$ and

$$w \in \text{cone}\{y_i : i \in S'\} \cap \text{cone}\{y_i : i \in R'\} = \text{cone}\{y_i : i \in R' \cap S'\}.$$

This implies that $a \in \text{cone}\{y_i : i \in R \cap S\}$. The reverse inclusion is obvious.

(iv) Suppose that $a \in \text{cone}\{y_i : i \in S$ where $S \in \mathcal{P}_{r+1}\}\backslash C$. There is $w \in C$ and $\alpha > 0$ such that $a = \alpha y_{i_0} + w$. We may assume that $\alpha < 1$. Let $\lambda_0 = \inf\{\lambda > 0 : y_{i_0} + \lambda(a - y_{i_0}) \in C\}$. The number λ_0 is well-defined since $y_{i_0} + (1-\alpha)^{-1}(a - y_{i_0}) \in C$ and $\lambda_0 > 1$. Put $w_0 = y_{i_0} + \lambda_0(a - y_{i_0})$. Evidently,

$$w_0 \in s(C, y_{i_0}). \tag{19}$$

By (iv) for $\mathcal{P}_r$, there is $\hat{S} \in \mathcal{P}_r$ such that $w_0 \in \text{cone}\{y_i : i \in \hat{S}\}$. In view of (ii) for $\mathcal{P}_r$, we may assume that $\hat{S}$ is minimal in the sense that, for any $S \subset \hat{S}, S \neq \hat{S}, w_0 \notin \text{cone}\{y_i : i \in S\}$. We shall show that $\{i_0\} \cup \hat{S} \in \mathcal{P}_{r+1}$, i.e. that $\text{cone}\{y_i : i \in \hat{S}\} \subset s(C, y_{i_0})$. Take $w' \in \text{cone}\{y_i : i \in \hat{S}\}$. The minimality of $\hat{S}$ implies the existence of $\alpha_i > 0, \beta_i \geq 0, i \in \hat{S}$, such that

$$w_0 = \sum\{\alpha_i y_i : i \in \hat{S}\}, w' = \sum\{\beta_i y_i : i \in \hat{S}\}.$$

Take $\alpha_0 > 0$ such that $\alpha_0\beta_i \leq \alpha_i$ for $i \in \hat{S}$ and put $\gamma_i = \alpha_i - \alpha_0\beta_i$ and $w'' = \sum\{\gamma_i y_i : i \in \hat{S}\}$. Evidently $w'' \in \text{cone}\{y_i : i \in \hat{S}\}$ and $w_0 = \alpha_0 w' + w''$. If $w' \in C\backslash s(C, y_{i_0})$, then, by Lemma 6.1, $w_0 \in C\backslash s(C, y_{i_0})$ contrary to (19). Hence $\hat{S} \cup \{i_0\} \in \mathcal{P}_{r+1}$ and

$$a = \lambda_0^{-1}(w_0 - (1-\lambda_0)y_{i_0}) \in \text{cone}\{y_i : i \in \hat{S} \cup \{i_0\}\}$$

which ends the proof. □

ON THE OPTIMAL CONTROL OF SYSTEMS DESCRIBED BY EVOLUTION EQUATIONS*

T. E. BAKER† AND E. POLAK†

Abstract. The authors present a mathematical foundation for the algorithmic solution of free- and fixed-time optimal control problems with evolution equation dynamics, finite-dimensional controls, and constraints on the controls and end points. In particular, (i) expressions for the derivatives of the solutions of the evolution equations are developed with respect to controls in $L_2^m[0, 1]$ and to the final time; (ii) the solutions of the relaxed evolution equations are shown to have a certain kind of directional derivative; (iii) algorithmic optimality conditions are developed with respect to both ordinary and relaxed controls and the final time; and (iv) an approximation theory is presented that shows that finite-dimensional minimax, and methods of centers-type algorithms can be used to obtain arbitrarily good approximations to stationary controls for optimal control problems with evolution equation dynamics and various constraints.

1. Introduction.

The results presented in this paper, dealing with the optimal control of evolution equations, were largely motivated by optimal slewing problems arising in the control of large, flexible, aerospace structures and in the control of various earthbound mechanisms with flexible links, which are naturally modeled by coupled systems of partial differential equations. Since, in practice, only finite element plant models may be available (which are in the form of ordinary differential equations (ODEs)), and since it is much easier to work with a canonical system representation, we assume that the plant dynamics are in evolution equation form, which permits us to treat both cases in a unified manner.

The majority of optimal control algorithms (see, for example, [May.1], [May.5], [Pir.2], [Teo.1], [Teo.2], [War.2]–[War.4], [Won.1]) are presented in *conceptual form*, i.e., the effects of numerical integration of the differential equations are ignored. In [Kle.1] we find an approximation theory for unconstrained optimal problems with ODE dynamics, in the form of an implementation of the method of steepest descent. More generally, this theory provides guidelines for adaptively increasing the precision of numerical integration so as to ensure that the numerical scheme retains the convergence properties of the conceptual one. It was later used by [Dun.1] to implement a conditional gradient method for optimal control problems with ODE dynamics. As far as optimal control problems with partial differential equation (PDE) dynamics are concerned, in [Gib.1], [Gib.2], [Gib.3], we find a detailed solution of the linear quadratic regulator problem, including conditions for the convergence of modal approximation schemes. However, for more general optimal control problems with PDE dynamics, the prevailing approach has been to use some method for constructing a *particular finite-dimensional* approximating optimal control problem and then to solve this problem by some method or other, see, e.g., [Jun.1], [Chu.1], [Ben.1], [Bur.1], [Flo.1]. The relationship between the solutions and stationary points of the approximating optimal control problem and those of the original optimal control problem is not established in these papers.

In this paper, we deal with the numerical solution of optimal control problems not by *adaptive implementation* of conceptual algorithms, but by *adaptive diagonalization*,

† Department of Electrical Engineering and Computer Science, University of California, Berkeley, California 94720.

which requires less restrictive assumptions and, in our experience, seems to produce more efficient computational schemes. In any diagonalization approach, an original optimal control problem, **P**, is decomposed into an infinite sequence of *finite-dimensional* problems $\mathbf{P}_n, n = 1, 2, 3, \ldots$, which are solvable by nonlinear programming or nonsmooth optimization algorithms. These problems $\mathbf{P}_n$ must satisfy the following minimal consistency condition. Since, in the absence of convexity, finite-dimensional optimization algorithms can only be shown to compute stationary points, rather than optimal points, the problems $\mathbf{P}_n$ must be such that not only do their solutions converge to a solution of **P**, but also their (first-order) stationary points converge to a stationary point of **P**. Next, there is considerable empirical evidence to suggest that from a computational point of view, the most efficient approach is to proceed gradually, iterating toward a solution of a problem $\mathbf{P}_n$ until some test is satisfied and then carry over the last iterate as a starting point for problem $\mathbf{P}_{n+1}$, until the value of n is increased to some preassigned maximum value n^*, rather than to solve $\mathbf{P}_{n*}$ directly. In an adaptive diagonalization scheme, we can expect to find tests which determine not only when the solution of problem $\mathbf{P}_n$ should be arrested, but also the next value if n, which may be larger than $n + 1$. In return, as we will show later, the use of adaptive tests results in stronger convergence properties for the diagonalization method.

In developing an adaptive diagonalization scheme for the numerical solution of free- and fixed-time optimal control problems with evolution equation dynamics, finite-dimensional controls, and constraints on the controls and end points, we had to deal with (i) the differentiability of solutions of PDEs with respect to controls; (ii) optimality conditions for optimal control problems, which relate to those used in finite-dimensional nonlinear programming and nonsmooth optimization;[1] (iii) relaxed control theory in a PDE setting; (iv) conditions on the numerical methods for integrating the dynamical equations, to ensure consistent discretization, and (v) tests for progressing from $\mathbf{P}_n$ to $\mathbf{P}_{n+1}$.

The results presented in this paper extend and generalize the results in [Kle.1], [Wil.1]. In particular, the results in [Kle.1] do not apply to constrained problems and hence a new generation of tests had to be invented; furthermore, the results in [Kle.1], [Wil.1] apply only to problems with ODE dynamics. Nor were algorithms for constrained minimax optimal control problems, such as those considered in this paper, addressed in [Kle.1], [Wil.1].

In §2, we give a formulation of the problems that we will consider. In §3, we develop expressions for the derivatives of the solutions of the evolution equations with respect to controls in $(L_2^m[0, 1], \|\cdot\|_2)$ and the final time, and we establish first-order optimality conditions for minimax optimal control problems with control constraints and for optimal control problems with constraints on the control and inequality constraints on the final point. In §4 we introduce relaxed controls, extensions of the optimal control problems under consideration and develop appropriate extensions of the optimality conditions introduced in §3. In §5 we present our approximation theory and our adaptive diagonalization schemes. We show that these can be combined with a finite-dimensional minimax algorithm [Pir.1], [Psh.1], [Pol.1], and a new phase I–phase II method of feasible directions [Pol.2] to obtain arbitrarily good approximations to optimal controls for optimal control problems with evolution equation dynamics and various constraints. In §6 we present computational examples.

2. Formulation of optimal control problems. Many optimal control algorithms, including the ones to be presented in this paper, are extensions of finite-dimensional optimiza-

[1] It should be clear that, because the optimality conditions for finite-dimensional problems are in terms of "weak variations," in the absence of convexity, stationary controls of finite-dimensional approximations to an optimal control problem can only converge to a control satisfying a "weak" optimality condition. Hence the Maximum Principle is generally an inappropriate optimality condition within the particular numerical approximation framework considered in this paper.

tion algorithms that deal with problems defined in the Hilbert space $\mathbb{R}^n$. Now, the natural space for establishing differentiability of solutions of a differential equation with respect to m-dimensional controls is $L_\infty^m[0,1]$. However, adoption of $L_\infty^m[0,1]$ as the space for analysis leads to the somewhat awkward situation that the extensions of the finite-dimensional algorithms do not appear to be natural, because they require that we also use the $L_2^m[0,1]$ norm, $\|\cdot\|_2$, and $L_2^m[0,1]$ scalar product, $\langle\cdot,\cdot\rangle_2$.

Fortunately, we can also establish differentiability of solutions of a differential equation with respect to controls in the Hilbert space $L_2^m[0,1]$, provided that we impose a *growth condition* on the velocity function, as we will do shortly. In the case of control constrained optimal control problems, such as the ones treated in this paper, the imposition of a growth condition on the velocity function does not restrict the class of problems that can be considered and amounts to no more than a mathematically convenient device.

Finally, we recall that for any $u \in L_2^m[0,1]$, $\|u\|_2 \triangleq [\int_0^1 \|u(t)\|^2 dt]^{1/2}$, and for any $u, \nu \in L_2^m[0,1]$, $\langle u, \nu\rangle_2 \triangleq \int_0^1 \langle u(t), \nu(t)\rangle dt$, where $\|\cdot\|$ denotes the norm on $\mathbb{R}^m$ and $\langle\cdot,\cdot\rangle$ denotes the scalar product on $\mathbb{R}^m$.

We are now ready to proceed. For any $0 < \tau < \infty$, let $G(\tau)$ be the set of admissible controls defined by

$$G(\tau) \triangleq \{u \in L_2^m[0,\tau] | u(t) \in U, \text{for almost all } t \in [0,\tau]\}, \tag{2.1}$$

where U is a compact convex subset of $\mathbb{R}^m$.

Let X denote a Hilbert space with inner product $\langle\cdot,\cdot\rangle_X$ and corresponding norm $\|\cdot\|_X$. Let $A : D(A) \to X$ be the infinitesimal generator of a strongly continuous semigroup $\{T(t)\}_{t\geq 0}$; let $F : X \times \mathbb{R} \to X$ be a nonlinear operator that is Lipschitz continuous on bounded sets. We will consider dynamical systems of the following form:

$$\frac{d}{dt}\tilde{z}(t,\tilde{u}) = A\tilde{z}(t,\tilde{u}) + F(\tilde{z}(t,\tilde{u}),\tilde{u}(t)), \quad \tilde{z}(0,\tilde{u}) = z_0 \in D(A), \quad \tilde{u} \in G(\tau), \tag{2.2a}$$

where $\tilde{z}(t,\tilde{u}) \in X$, for all $t \in [0,\tau]$.

Because the set $U \subset \mathbb{R}^m$ is compact, there exists a bound $b < \infty$ such that for all $\nu \in U, |\nu^i| \leq b, i = 1,2,\ldots,m$. Hence, since our algorithms never violate the control constraint, we may assume, without loss of generality, that the operator F has the form $F(z,\nu) = \tilde{F}(z, SAT(\nu))$, where $SAT : \mathbb{R}^m \to \mathbb{R}^m$ is such $SAT(v) = (sat(\nu^1), sat(\nu^2), \ldots, sat(\nu^m))$, where for all $z \in \mathbb{R}$,

$$sat(z) = \begin{cases} z, & \text{if } |z| \leq 2b, \\ sgn(z)(2b + 1 - e^{(2b-|z|)}), & \text{if } |z| \geq 2b. \end{cases} \tag{2.2b}$$

This *growth condition* allows us in §3 to postulate local Lipschitz continuity conditions that are independent of bounds on the control.

We will assume that (2.2a) has a unique *mild solution*, which is defined as follows (see [Paz.1]).

DEFINITION 2.1. A function $\tilde{z}(\cdot,\tilde{u}) \in C([0,\tau],X)$ is said to be a *mild solution* to (2.2a) if for all $t \in [0,\tau]$,

$$\tilde{z}(t,\tilde{u}) = T(t)\tilde{z}_0 + \int_0^t T(t-s)F(\tilde{z}(s,\tilde{u}),\tilde{u}(s))ds. \tag{2.2c}$$

We can normalize[2] the final time in *fixed-time* optimal control problems (originally defined on $[0,\tau]$) to be 1 and reduce *free-time* optimal control problems to fixed-time

[2] Failure to normalize may lead to pathological computational results; see [Cul.1], [Cul.2].

optimal control problems on the interval $[0, 1]$ by replacing (2.2a) by *scaled* dynamics, with the scaling parameter denoted by τ. Thus, with each $\tilde{u} \in G(\tau)$, we associate a $u \in G(1)$ defined by $u(t) \triangleq \tilde{u}(\tau t)$ for $t \in [0, 1]$. With each $\tilde{z} \in C([0, \tau], X)$, we associate $z \in C([0, 1], X)$ defined by $z(t) \triangleq \tilde{z}(t\tau)$ for all $t \in [0, 1]$. Then, the function $z(t, u, \tau) \triangleq \tilde{z}(t\tau, \tilde{u})$ is a mild solution of the differential equation

$$\begin{aligned} \frac{d}{dt} z(t, u, \tau) &= \frac{d}{dt} \tilde{z}(t\tau, \tilde{u}) = \tau[A\tilde{z}(t\tau, \tilde{u}) + F(\tilde{z}(t\tau), \tilde{u}(t\tau))] \\ &= \tau[Az(t, u, \tau) + F(z(t, u, \tau), u(t))]. \end{aligned} \tag{2.2d}$$

Hence we abuse notation and let $G = G(1)$, and we replace the original dynamics (2.2a), with the scaled dynamics:

$$\begin{aligned} \frac{d}{dt} z(t, u, \tau) &= \tau[Az(t, u, \tau) + F(z(t, u, \tau), u(t))], \\ z(0, u) &= z_0 \in D(A), \quad t \in [0, 1]. \end{aligned} \tag{2.2e}$$

Note that for any final-time $\tau > 0$, the operator τA generates the semigroup $\{T(\tau t)\}_{t \geq 0}$ and hence $z(t, u, \tau)$ is a mild solution of (2.2e) if

$$z(t) = T(\tau t)z_0 + \tau \int_0^t T(\tau(t - s))F(z(s), u(s))\, ds. \tag{2.2f}$$

Next, for $j = 0, 1, 2, \ldots, q$, let $f^j : X \to \mathbb{R}$ be functions that are Lipschitz continuously differentiable on bounded sets. Then, for $j = 0, 1, 2, \ldots, q$, we define the functions $g^j : G \times (0, \infty) \to \mathbb{R}$ by $g^j(u, \tau) \triangleq f^j(z(1, u, \tau))$. The simplest problem that we will consider is

$$\textbf{MMP} : \inf\{\max_{j \in \mathbf{q}} g^j(u, \tau) | u \in G, \tau \in [\tau_{\min}, \tau_{\max}]\}, \tag{2.3a}$$

where $\mathbf{q} \triangleq \{1, 2, \ldots, q\}$, and $0 < \tau_{\min} \leq \tau_{\max} < \infty$. Note that when $\tau_{\max} = \tau_{\min}$, (2.3a) is a fixed-time problem; otherwise it is a free-time problem. In minimum time problems, $\tau_{\min}$ is chosen to be very small and $\tau_{\max}$ is chosen to be large, which ensures that the optimal value of the final-time, $\hat{\tau}$, is the minimum time.

We will also show that algorithms for solving **MMP** are trivially adapted to solving optimal control problems with control and end point inequality constraints, of the form

$$\textbf{CMP} : \inf\{g^0(u, \tau) | \, | \max_{j \in \mathbf{q}} g^j(u, \tau) \leq 0, u \in G, \tau \in [\tau_{\min}, \tau_{\max}]\}. \tag{2.3b}$$

Our next task is to establish optimality conditions for the problems **MMP** and **CMP**.

3. Optimality conditions. We begin with a few standard assumptions.

Assumption 3.1. (i) The operator $F(\cdot, \cdot)$ is Frechet differentiable. We will denote its partial Frechet derivatives, with respect to z and u, by $\partial F/\partial z(z, u)$ and $\partial F/\partial u(z, u)$, respectively.

(ii) For all $u \in G$, and $\tau \in [\tau_{\min}, \tau_{\max}]$, a solution to (2.2f) exists.

(iii) There exists $b_1 \in (0, \infty)$ such that for all $t \in [0, 1], u \in L_2^m[0, 1]$, and $\tau \in [\tau_{\min}, \tau_{\max}]$, $\|z(t, u, \tau)\|_X \leq b_1$.

(iv) For every bounded set $S \subset X$, there exists $K_S < \infty$ such that for all $z, z' \in S$ and all $u, u' \in \mathbb{R}^m$,

(a) $\|F(z',u') - F(z,u)\|_X \leq K_S[\|z'-z\|_X + \|u'-u\|]$,
(b) $\|\partial F/\partial z(z',u') - \partial F/\partial z(z,u)\| \leq K_S[\|z'-z\|_X + \|u'-u\|]$,
(c) $\|\partial F/\partial u(z',u') - \partial F/\partial u(z,u)\| \leq K_S[\|z'-z\|_X + \|u'-u\|]$.

(v) The functions $f^j(\cdot), j = 0,1,2,\ldots,q$, are Frechet differentiable; their Frechet differentials have the form $Df(z;\delta z) = \langle \nabla f^j(z), \delta z\rangle_X$, and their *gradients*, $\nabla f^j(\cdot)$, are Lipschitz continuous on the set $\{z \in X | \|z\|_X \leq b_1\}$.

The following assumption is needed only if the scaling parameter τ is allowed to vary.

Assumption 3.2. The semigroup generated by A, $\{T(t)\}_{t\geq 0}$, is an analytic semigroup.

The following two results can be gleaned from [Paz.1].

LEMMA 3.3. *The semigroup $\{T(t)\}_{t\geq 0}$ generated by the operator A is analytic if and only if there exists a constant $C < \infty$ such that* (i) *$T(t)$ is differentiable in $t > 0$;* (ii) *$d/dtT(t) = AT(t)$; and* (iii) *$\|AT(t)\|_X \leq C/t$, for all $t > 0$.*

Since Lemma 3.3 implies local Lipschitz continuity of $T(t)$ for $t > 0$, it follows from Assumption 3.1 and Lemma 3.3 that the following must be true.

LEMMA 3.4. *There exists a $b_2 \in (0,\infty)$, such that for all $z, z' \in S \triangleq \{z \in X | \|z\|_X \leq b_1\}$, all $u, u' \in \mathbb{R}^m$, all $\tau, \tau' \in [\tau_{\min}, \tau_{\max}]$, and all $t \in [0,1]$:*

(i) $\|\partial F/\partial z(z,u)\| \leq b_2$,
(ii) $\|\partial F/\partial u(z,u)\| \leq b_2$,
(iii) $\|\partial F/\partial z(z',u') - \partial F/\partial z(z,u)\| \leq b_2[\|z'-z\|_X + \|u'-u\|]$;
(iv) $\|\partial F/\partial u(z',u') - \partial F/\partial z(z,u)\| \leq b_2[\|z'-z\|_X + \|u'-u\|]$;
(v) $\|T(\tau' t) - T(\tau t)\| \leq b_2|\tau' - \tau|$.

In view of Assumption 3.1 and Lemma 3.4, it can be concluded from the Implicit Function Theorem in Banach spaces, as stated in [Lan.1], [Ale.1], that the solutions, $z(t,u,\tau)$, with $t \in [0,1]$, of (2.2f) are Lipschitz continuously Frechet differentiable with respect to (u,τ), with the Frechet differential, $Dz(t,u,\tau;\delta u,\delta\tau) = \delta z(t)$, where $\delta z(t)$ is the solution of the variational equation:

$$\begin{aligned}\delta z(t) = \int_0^t \Bigg\{ & T(\tau(t-s))\tau\left(\frac{\partial F}{\partial z}(z(s,u,\tau),u(s)\,\delta z(s) + \frac{\partial F}{\partial u}(z(s),u(s))\,\delta u(s)\right) \\ & + (T(\tau(t-s)) + \tau(t-s)AT(\tau(t-s)))F(z(s,u,\tau),u(s))\delta\tau \Bigg\} ds \\ & + tAT(\tau t)z_0\,\delta\tau.\end{aligned} \tag{3.1a}$$

We give an independent proof of this fact in the Appendix.

Since, by Assumption 3.1(v), the gradients of the functions $f^j(\cdot)$ are Lipschitz continuous on bounded sets, we immediately obtain the following result.

THEOREM 3.5. (i) *The functions $g^j : L_2^m[0,1] \times [\tau_{\min}, \tau_{\max}] \to \mathbb{R}, j = 0,1,2,\ldots,q$, defined in §2, are Frechet differentiable in (u,τ), i.e., for all $u \in G, \tau \in [\tau_{\min}, \tau_{\max}]$, there exists a continuous linear functional $Dg^j(u,\tau): L_2^m[0,1] \times \mathbb{R} \to \mathbb{R}$, such that for any $u, u' \in L_2^m[0,1], \tau, \tau' > \tau_{\min}$*

$$\lim_{\substack{\|u'-u\|_2 \to 0 \\ |\tau'-\tau|\to 0}} \frac{|g^j(u',\tau') - g^j(u,\tau) - Dg^j(u,\tau)(u'-u,\tau'-\tau)|}{(\|u'-u\|_2^2 + |\tau'-\tau|^2)^{1/2}} = 0. \tag{3.1b}$$

(ii) *There exist* gradients $\nabla g^j: L_2^m[0,1] \times [\tau_{\min}, \tau_{\max}] \to L_2^m[0,1] \times \mathbb{R}, j = 0,1,2,\ldots, q, \nabla g^j(u,\tau) = (\nabla_u g^j(u,\tau), \nabla_\tau g^j(u,\tau))$, *such that for all $u', u \in L_2^m[0,1], \tau', \tau \in [\tau_{\min}, \tau_{\max}]$,*

$$Dg^j(u,\tau)(u'-u,\tau'-\tau) = \langle \nabla_u g^j(u,\tau), u'-u\rangle_2 + \nabla_\tau g^j(u,\tau)(\tau'-\tau). \tag{3.1c}$$

(iii) *The gradients* $\nabla g^j(\cdot,\cdot)$ *are Lipschitz continuous on bounded sets.*

We are finally ready to address the question of optimality conditions for problems (2.3a), (2.3b). Because of algorithmic requirements, we chose a multiplier-free form for the optimality conditions. It is not difficult to show that these conditions are equivalent to standard optimality conditions involving multipliers. Thus, for problem (2.3a) we define the max function $\psi : G \times [\tau_{\min}, \tau_{\max}] \to \mathbb{R}$ and the corresponding *optimality function* $\theta_{\mathbf{MMP}} : G \times [\tau_{\min}, \tau_{\max}] \to \mathbb{R}$ by

$$\psi(u',\tau) \triangleq \max_{j\in\mathbf{q}} g^j(u',\tau'), \tag{3.2a}$$

$$\begin{aligned}\theta_{\mathbf{MMP}}(u',\tau') \triangleq \min_{(u,\tau)\in G\times[\tau_{\min},\tau_{\max}]} \Big\{ & \frac{1}{2}\|u-u'\|_2^2 + \frac{1}{2}|\tau-\tau'|^2 \\ & + \max_{j\in\mathbf{q}}\{g^j(u',\tau') - \psi(u',\tau') \\ & + \langle \nabla_u g^j(u',\tau'), u-u'\rangle_2 \\ & + \nabla_\tau g^j(u',\tau')(\tau-\tau')\}\Big\}.\end{aligned} \tag{3.2b}$$

Referring to Proposition 5.5 in [Pol.1], we see that $\theta_{\mathbf{MMP}}(u,\tau)$ is the obvious extension of an optimality function used in conjunction with first-order algorithms for the solution of minimax problems in $\mathbb{R}^n$. Hence, it is a correct optimality function to use in analyzing the convergence properties of *implementable* minimax algorithms for solving (2.3a), since such algorithms must construct finite-dimensional approximations to (2.3a).

THEOREM 3.6. (i) *The function* $\theta_{\mathbf{MMP}}(\cdot,\cdot)$ *is well defined and continuous.*

(ii) *If* $h_u(u',\tau') \in G - \{u'\}, h_\tau(u',\tau') \in [\tau_{\min},\tau_{\max}] - \{\tau'\}$ *are such that* $(u' + h_u(u',\tau'), \tau' + h_\tau(u',\tau'))$ *is a solution to the minimization problem* (3.2b)*, then* $h_u(\cdot,\cdot) : G \times [\tau_{\min},\tau_{\max}] \to L_2^m[0,1]$*, and* $h_\tau(\cdot,\cdot) : G \times [\tau_{\min},\tau_{\max}] \to \mathbb{R}$ *are unique and continuous.*

Proof. With $\sum_q \triangleq \{\mu \in \mathbb{R}^q | \sum_{j=1}^q \mu^j = 1, \mu \geq 0\}$, and making use of the Fan minimax theorem [Fan.1], we obtain that

$$\begin{aligned}\theta_{\mathbf{MMP}}(u,\tau) &= \min_{(u',\tau')\in G\times[\tau_{\min},\tau_{\max}]} \max_{\mu\in\Sigma_q} \Big\{ \frac{1}{2}\|u'-u\|_2^2 + \frac{1}{2}|\tau'-\tau|^2 \\ &\quad + \sum_{j\in\mathbf{q}} \mu^j\{g^j(u,\tau) - \psi(u,\tau) \\ &\quad + \langle \nabla_u g^j(u,\tau), u'-u\rangle_2 \\ &\quad + \nabla_\tau g^j(u,\tau)(\tau'-\tau)\}\Big\} \\ &= \max_{\mu\in\Sigma_q} \min_{(u',\tau')\in G\times[\tau_{\min},\tau_{\max}]} \Big\{ \frac{1}{2}\|u'-u\|_2^2 + \frac{1}{2}\|\tau'-\tau\|^2 \\ &\quad + \sum_{j\in\mathbf{q}} \mu^j\{g^j(u,\tau) - \psi(u,\tau) \\ &\quad + \langle \nabla_u g^j(u,\tau), u'-u\rangle_2 \\ &\quad + \nabla_\tau g^j(u,\tau)(\tau'-\tau)\}\Big\}\end{aligned} \tag{3.3a}$$

The minimization with respect to (u', τ') in (3.3a) is decoupled. The minimization with respect to τ' is a simple, one-dimensional quadratic problem. Because

$$\begin{aligned}&\frac{1}{2}\|u'-u\|_2^2+\sum_{j\in\mathbf{q}}\mu^j\langle\nabla_u g^j(u,\tau),u'-u\rangle_2\\&=\int_0^1\left(\frac{1}{2}\|u'(t)-u(t)\|^2+\sum_{j\in\mathbf{q}}\mu^j\langle\nabla_u g^j(u,\tau)(t),u'(t)-u(t)\rangle\right)dt,\end{aligned}\tag{3.3b}$$

the minimizing u' for (3.3a) can be constructed by minimizing the integrand pointwise in t in (3.3b). Consequently, $\theta_{\mathbf{MMP}}(u,\tau)$ is well defined. Continuity now follows from the Maximum Theorem in [Ber.1]. Similarly, since the solution $(h_u(\cdot,\cdot), h_\tau(\cdot,\cdot))$ of the minimization problem (3.2b) is unique, it again follows from the Maximum Theorem that it is continuous. □

THEOREM 3.7. *Suppose that* $(\hat{u},\hat{\tau})\in G\times[\tau_{\min},\tau_{\max}]$ *is an optimal solution to the problem* **MMP** (2.3a). *Then* $\theta_{\mathbf{MMP}}(\hat{u},\hat{\tau})=0$.

Proof. First, note that $\theta_{\mathbf{MMP}}(\hat{u},\hat{\tau})\le 0$ must hold. Hence, for the sake of contradiction, suppose that $\theta_{\mathbf{MMP}}(\hat{u},\hat{\tau})<0$ and that (u^*,τ^*) is the corresponding solution of the minimization problem (3.2b). Then, for $\lambda\in[0,1]$, we must have that $\hat{u}+\lambda(u^*-\hat{u})\in G, \hat{\tau}+\lambda(\tau^*-\hat{\tau})\in[\tau_{\min},\tau_{\max}]$, and

$$\begin{aligned}\psi(\hat{u}+&\lambda(u^*-\hat{u}),\hat{\tau}+\lambda(\tau^*-\hat{\tau}))-\psi(\hat{u},\hat{\tau})=\max_{j\in\mathbf{q}}g^j(\hat{u},\hat{\tau})-\psi(\hat{u},\hat{\tau})\\&+\lambda(\langle\nabla_u g^j(\hat{u},\hat{\tau}),u^*-\hat{u}\rangle_2+\nabla_\tau g^j(\hat{u},\hat{\tau})(\tau^*-\hat{\tau}))\}+o(\lambda)\\&\le\lambda\left\{\frac{1}{2}\|u^*-\hat{u}\|_2^2+\frac{1}{2}|\tau^*-\hat{\tau}|^2+\max_{j\in\mathbf{q}}\{g^j(\hat{u},\hat{\tau})-\psi(\hat{u},\hat{\tau})\right.\\&\left.+\langle\nabla_u g^j(\hat{u},\hat{\tau}),u^*-\hat{u}\rangle_2+\nabla_\tau g^j(\hat{u},\hat{\tau})(\tau^*-\hat{\tau})\}+\frac{o(\lambda)}{(\lambda)}\right\}\\&\le\lambda\{\theta_{\mathbf{MMP}}(\hat{u},\hat{\tau})+o(\lambda)/\lambda\},\end{aligned}\tag{3.4}$$

where $o(\lambda)/\lambda\to 0$ as $\lambda\to 0$. Hence there exists a $\hat{\lambda}\in[0,1]$ such that $\psi(\hat{u}+\hat{\lambda}(u^*-\hat{u}),\hat{\tau}+\hat{\lambda}(\tau^*-\hat{\tau}))<\psi(\hat{u},\hat{\tau})$, which is a contradiction. □

Under a convexity assumption, the above optimality condition becomes a necessary and sufficient condition. An examination of our definition of the functions $g^j(\cdot,\cdot)$ shows that they cannot be convex for free-time problems. However, in the case of linear dynamics and fixed end time, the problem can become convex.

We can easily obtain an optimailty condition for problem **CMP** (2.3b) from the one for **MMP** (2.3a) by making use of the following observation. Suppose that $(\hat{u},\hat{\tau})$ is an optimal pair for **CMP**. Let $\Psi: G\times[\tau_{\min},\tau_{\max}]\to\mathbb{R}$ be defined by

$$\Psi(u,\tau)=\max_{j\in\mathbf{q}}\max\{g^0(u,\tau)-g^0(\hat{u},\hat{\tau}),g^j(u,\tau)\}.\tag{3.5}$$

Then $\Psi(\hat{u},\hat{\tau})=0$ and, for any (u,τ) sufficiently close to $(\hat{u},\hat{\tau}), \Psi(u,\tau)\ge 0$. Hence $(\hat{u},\hat{\tau})$ is a local minimizer for the function $\Psi(\cdot,\cdot)$. Therefore, referring to (3.2a), (3.2b), we define the *optimality function* $\theta_{\mathbf{CMP}}: G\times[\tau_{\min},\tau_{\max}]\to\mathbb{R}$ by

$$\begin{aligned}\theta_{\mathbf{CMP}}(u',\tau')\triangleq\min_{(u,\tau)\in G\times[\tau_{\min},\tau_{\max}]}&\left\{\frac{1}{2}\|u-u'\|_2^2+\frac{1}{2}|\tau-\tau'|^2\right.\\&+\max_{j\in\mathbf{q}}\{-\psi(u',\tau')_+ +\langle\nabla_u g^0(u',\tau'),u-u'\rangle_2\\&+\nabla_\tau g^0(u',\tau')(\tau-\tau'),g^j(u,\tau)-\psi(u,\tau)_+\\&+\langle\nabla_u g^j(u,\tau),u'-u\rangle_2\\&\left.+\nabla_\tau g^j(u,\tau)(\tau'-\tau),j\in\mathbf{q}\}\right\},\end{aligned}\tag{3.6}$$

where $\psi(u,\tau)_+ \triangleq \max\{0,\psi(u,\tau)\}$. Although the term $\psi(u,\tau)_+$ has no effect at feasible points and hence also at optimal points, it is introduced into the optimality function for algorithmic reasons. The following result should be obvious.

THEOREM 3.8. (i) *The optimality function* $\theta_{\mathbf{CMP}}(\cdot\,,\cdot)$ *is well defined and continuous.*

(ii) *If* $h_u(u,\tau) \in G - \{u\}, h_\tau(u,\tau) \in [\tau_{\min},\tau_{\max}] - \{\tau\}$ *are such that* $(u + h_u(u,\tau), \tau + h_\tau(u,\tau))$ *is a solution to the minimization problem* (3.6), *then* $h_u(\cdot\,,\cdot), h_\tau(\cdot\,,\cdot)$ *are unique, continuous functions.*

(iii) *Suppose that* $(\hat{u},\hat{\tau}) \in G \times [\tau_{\min},\tau_{\max}]$ *is an optimal solution to the problem* **CMP** (2.3b). *Then* $\theta_{\mathbf{CMP}}(\hat{u},\hat{\tau}) = 0$.

It is customary to add a constraint qualification to optimization problems with inequality constraints. The analogue of the Slater constraint qualification [Sla.1] commonly used in nonlinear programming for problem **CMP** is as follows.

Assumption 3.9. We will assume that for all $(u,\tau) \in G \times [\tau_{\min},\tau_{\max}]$ such that $\psi(u,\tau) \geq 0, \theta_{\mathbf{MMP}}(u,\tau) < 0$.

Assumption 3.9 is standard in phase I–phase II methods of feasible directions. It implies that the constraint violation function $\psi(\cdot\,,\cdot)$ has no local minimizers outside of feasible set $\{(u,\tau) \in G \times [\tau_{\min},\tau_{\max}] | \psi(u,\tau) \leq 0\}$, nor on the set $\{(u,\tau) \in G \times [\tau_{\min},\tau_{\max}] | \psi(u,\tau) = 0\}$, a fact that prevents phase I–phase II feasible directions algorithms from converging to infeasible points. Finally, under Assumption 3.9 and a convexity assumption, $\theta_{\mathbf{CMP}}(u,\tau) = 0$ becomes both a necessary and sufficient condition of optimality.

4. Optimality conditions in the space of relaxed controls. Since the closed unit ball in $L_2^m[0,1]$ is not compact, there may be bounded sequences $\{(u_i,\tau_i)\}_{i=0}^{\infty}$, generated by an algorithm in solving the problem **MMP** or **CMP**, which have no accumulation points in $L_2^m[0,1]$, even when these problems do have solutions. However, as was established in [Ahm.1], [Pap.1], such sequences always have accumulation points in the space of relaxed controls. Hence, it is common to show that all the accumulation points generated by algorithms for solving optimal control problems, such as **MMP** and **CMP**, satisfy both a first-order optimality condition in $L_2^m[0,1]$ and the extension of these first-order conditions to first-order conditions for relaxed controls versions of **MMP** and **CMP**.

In order to define relaxed control versions of the problems **MMP** and **CMP**, we follow Warga [War.1], by defining $\overline{G}$, the relaxed controls closure of the set G, as follows:

$$\overline{G} = \{\sigma : [0,1] \to rpm(U) | \sigma \text{ is measurable}\}, \tag{4.1a}$$

where $rpm(U)$ denotes the set of Radon probability measures, topologized as in [War.1, Chap. 4]. In this topology, a sequence $\{\sigma_i\}_{i=0}^{\infty} \subset \overline{G}$ converges to a $\sigma \in \overline{G}$ if and only if

$$\lim_{i\to\infty} \int_0^1 \int_U \phi(t,u)\sigma_i(t)(du)dt = \int_0^1 \int_U \phi(t,u)\sigma(t)(du)dt, \forall \phi \in L_1([0,1], C(U)). \tag{4.1b}$$

The set $\overline{G}$ is sequentially compact. From our point of view, the most useful concept of continuity on $\overline{G}$ is that of sequential continuity. Hence all of our continuity statements, for functions defined on $\overline{G}$, are to be understood as sequential continuity statements, e.g., when we say that a function $\overline{g}$: $\overline{G} \to \mathbb{R}$ is continuous, we mean that for any sequence of relaxed controls $\{\sigma_i\}_{i=0}^{\infty} \subset \overline{G}$ that converges to a $\sigma \in \overline{G}, \overline{g}(\sigma_i) \to \overline{g}(\sigma)$, as $i \to \infty$.

Next, we extend the map $z : G \times [\tau_{\min},\tau_{\max}] \to C([0,1],X)$ to $\overline{z} : \overline{G} \times [\tau_{\min},\tau_{\max}] \to C([0,1],X)$ by defining for each $\sigma \in \overline{G}, \overline{z}(\cdot\,,\sigma,\tau) \in C([0,1],X)$ to be the solution to

$$z(t) = T(\tau t)z_0 + \tau \int_0^t \int_U T(\tau(t-s))F(z(s),u)\sigma(s)(du)ds. \tag{4.2}$$

Assuming that Assumption 3.1 holds, it can be shown that a mild solution to (4.2) exists, that it is unique, and that it is bounded by b_1, the bound introduced in Assumption 3.1(ii). The simplest relation between the solutions of (2.2f) and (4.2) is as follows.

PROPOSITION 4.1. *If $\sigma \in \overline{G}$ is an ordinary control, i.e., there exists $u \in G$ such that $\sigma(t)(S) = \delta_{u(t)}(S)$ for all measurable sets $S \subset U$ and almost all $t \in [0,1]$, then $z(t,\sigma,\tau) = z(t,u,\tau)$ for all $t \in [0,1]$, where $\overline{z}(\cdot,\sigma,\tau)$ is the solution to* (4.2) *and $z(\cdot,u,\tau)$ is the solution to* (2.2f).

The following result follows by simple extension of results in [Pap.1].

THEOREM 4.2 (Continuity of $\overline{z}(\cdot,\sigma,\tau)$ *in* (σ,τ)). *If the sequence $\{(\sigma_i,\tau_i)\}_{i=1}^{\infty} \subset \overline{G} \times [\tau_{\min},\tau_{\max}]$, as $i \to \infty$, is such that $\sigma_i \to \sigma \in \overline{G}, \tau_i \to \tau$, as $i \to \infty$, then $\overline{z}(\cdot,\sigma,\tau_i) \to \overline{z}(\cdot,\sigma,\tau)$, as $i \to \infty$.*

With these preliminaries out of the way, we are ready to define the relaxed control versions of the problems **MMP**, **CMP**, defined in (2.3a), (2.3b). Thus, for $j = 0,1,2,\ldots,q$, we define $\overline{g}^j : \overline{G} \times [\tau_{\min},\tau_{\max}] \to \mathbb{R}$ by $\overline{g}^j(\sigma,\tau) \triangleq f^j(\overline{z}(1,\sigma,\tau))$, and

$$\overline{\mathbf{MMP}}: \quad \min\{\max_{j\in\mathbf{q}} \overline{g}^j(\sigma,\tau) \mid \sigma \in \overline{G}, \tau \in [\tau_{\min},\tau_{\max}]\}, \tag{4.3a}$$

$$\overline{\mathbf{CMP}}: \quad \min\{\overline{g}^0(\sigma,\tau) \mid \max_{j\in\mathbf{q}} \overline{g}^j(\sigma,\tau) \le 0, \sigma \in \overline{G}, \tau \in [\tau_{\min},\tau_{\max}]\}. \tag{4.3b}$$

Next, we need to obtain extensions of the optimality functions $\theta_{\mathbf{MMP}}(\cdot,\cdot)$ and $\theta_{\mathbf{CMP}}(\cdot,\cdot)$ for the problems $\overline{\mathbf{MMP}}, \overline{\mathbf{CMP}}$, with the property that these extensions assume the same values on ordinary controls as the functions $\theta_{\mathbf{MMP}}(\cdot,\cdot)$ and $\theta_{\mathbf{CMP}}(\cdot,\cdot)$. On the surface, it is not at all clear how to obtain a relaxed control version of $\theta_{\mathbf{MMP}}(\cdot,\cdot)$ or of $\theta_{\mathbf{CMP}}(\cdot,\cdot)$. However, this task becomes much easier if we observe (see Theorem 3.4) that the solution $(u(u',\tau') - u', \tau(u',\tau') - \tau')$ of the search direction finding problem (3.2b) defines a pair of continuous functions $(h_u(\cdot,\cdot), h_\tau(\cdot,\cdot))$. Hence we set that (3.2b) is equivalent to

$$\theta_{\mathbf{MMP}}(\hat{u},\hat{\tau}) \triangleq \min_{\substack{(h_u,h_\tau)\in C(G\times[\tau_{\min},\tau_{\max}],\\ (G-\hat{u})\times([\tau_{\min},\tau_{\max}]-\hat{\tau}))}} \left\{ \begin{array}{l} \frac{1}{2}\|h_u(\hat{u},\hat{\tau})\|_2^2 + |h_\tau(\hat{u},\hat{\tau})|^2 \\ + \max_{j\in q}\{g_j(\hat{u},\hat{\tau}) - \psi(\hat{u},\hat{\tau}) \\ + \langle \nabla_u g^j(\hat{u},\hat{\tau}), h_u(\hat{u},\hat{\tau})\rangle_2 \\ + \nabla_\tau g^j(\hat{u},\hat{\tau}) h_\tau(\hat{u},\hat{\tau})\} \end{array} \right\} \tag{4.4a}$$

It is now clear that to obtain a relaxed control version of $\theta_{\mathbf{MMP}}(\cdot,\cdot)$ we must first obtain a relaxed control version of the directional derivatives $\langle \nabla_u g^j(u,\tau), h_u(u,\tau)\rangle_2 + \nabla_\tau g^j(u,\tau)(\tau' - \tau)$. Now, referring to (A.3) we see that $\delta z(t,u,\tau,\delta u,\delta\tau)$ is linear in $(\delta u,\delta\tau)$, and hence can be written as $\delta z(t,u,\tau,\delta u,\delta\tau) = \delta z_u(t,u,\tau,\delta u) + \delta z_\tau(t,u,\tau,\delta\tau) = \delta z(t,u,\tau,0,\delta\tau)$. Consequently,

$$\langle \nabla_u g^j(u,\tau), h_u(u,\tau)\rangle_2 = \langle \nabla f^j(z(1,u,\tau)), \delta z_u(1,u,\tau,h_u(1,u,\tau,h_u(u,\tau))\rangle_X, \tag{4.4b}$$

and

$$\nabla_\tau g^j(u,\tau)(\tau' - \tau) = \langle \nabla f^j(z(1,u,\tau)), \delta z_\tau(1,u,\tau,\tau' - \tau)\rangle_X. \tag{4.4c}$$

Hence, the relaxed control versions of (4.4b), (4.4c) appear to be

$$\langle \nabla f^j(\overline{z}(1,\sigma,\tau)), \overline{\delta z}_u(1,\sigma,\tau,h_u)\rangle_X, \tag{4.5a}$$

$$\langle \nabla f^j(\bar{z}(1,\sigma,\tau)), \overline{\delta z}_\tau(1,\sigma,\tau,\tau'-\tau)\rangle_X, \tag{4.5b}$$

where, with $h_u \in C([0,1]\times U\times[\tau_{\min},\tau_{\max}],\mathbb{R}^m)$ (i.e., its domain has been changed), $\overline{\delta z}_u(\cdot\,,\sigma,\tau,h_u)$ is the solution to

$$\begin{aligned}\overline{\delta z}(t) = \tau\int_0^t T(\tau(t-s))\int_U &\left\{\frac{\partial F}{\partial z}(\bar{z}(s,\sigma,\tau),u)\delta z(s)\right.\\ &\left.+\frac{\partial F}{\partial u}(\bar{z}(s,\sigma,\tau),u)h_u(s,u,\tau)\right\}\sigma(s)(du)ds,\end{aligned} \tag{4.5c}$$

and $\overline{\delta z}_\tau(\cdot\,,\sigma,\tau,\tau'-\tau)$ is the solution to

$$\begin{aligned}\overline{\delta z}(t) = \int_0^t\int_U &\left\{\tau T(\tau(t-s))\tfrac{\partial F}{\partial z}(\bar{z}(s,\sigma,\tau),u)\delta z(s)\right.\\ &\left.+(T(\tau(t-s))+\tau(t-s)AT(\tau(t-s)))F(\bar{z}(s,\sigma,\tau),u)\delta\tau\right\}\\ &\cdot\sigma(s)(du)ds+tAT(\tau t)z_0\delta\tau.\end{aligned} \tag{4.5d}$$

We will now show[3] that for any $\sigma\in\overline{G}$, $\lambda\in[-1,1]$, and a class of *search direction functions* $h_u\in C([0,1]\times U\times[\tau_{\min},\tau_{\max}],\mathbb{R}^m)$, $\lambda\overline{\delta z}_u(\cdot\,,\sigma,\tau,h_u)$ is a first-order approximation, in λ, to $\bar{z}(\cdot\,,\sigma,\tau,\lambda,h_u)-\bar{z}(\cdot\,,\sigma,\tau)$, where (with some abuse of notation) $\bar{z}(\cdot\,,\sigma,\tau,\lambda,h_u)$ is the solution to

$$z(t) = T(\tau t)z_0+\tau\int_0^t\int_U T(\tau(t-s))F(z(s),\nu+\lambda h_u(s,\nu,\tau))\sigma(s)(d\nu)ds. \tag{4.6}$$

We note that (4.5c) is the first variation of (4.6) along the curve in $\overline{G}$ defined by $\{\rho(\cdot\,;\lambda,h_u)|\ \lambda\in[0,1]\}$, where

$$\rho(t;\lambda,h_u)(S)\triangleq\{\sigma(t)(R), R\triangleq\{\nu\in U|\nu+\lambda h_u(t,\nu,\tau)\in S\}\} \tag{4.7}$$

if $\nu+h_u(t,\nu,\tau)\in U$ for all $\nu\in U$ and almost all $t\in[0,1]$; otherwise ρ is undefined. It is easily seen that if ρ is well defined, then $\rho\in\overline{G}$ and $\bar{z}(1,\rho(\cdot,\lambda,h_u),\tau)=\bar{z}(1,\sigma,\tau,\lambda,h_u)$. Hence we introduce the following definition.

DEFINITION 4.3. *The search direction function $h_u\in C([0,1]\times U\times[\tau_{\min},\tau_{\max}],\mathbb{R}^m)$ will be said to be admissible if $u'+h_u(t,u',\tau')\in U$ for all $u'\in U$ and almost all $t\in[0,1]$ and $\tau\in[\tau_{\min},\tau_{\max}]$. We will denote by Γ the set of admissible search direction functions.*

LEMMA 4.4. *There exists an $L<\infty$ such that for any $h_u\in\Gamma,\sigma\in\overline{G},\tau\in[\tau_{\min},\tau_{\max}]$, $t\in[0,1]$ and λ sufficiently small, $\|\bar{z}(t,\sigma,\tau,\lambda,h_u)-\bar{z}(t,\sigma,\tau)\|\le L|\lambda|$.*

Proof. Let

$$M_U\triangleq\max\{\|u'-u''\||u',u''\in U\}. \tag{4.8a}$$

Since U is compact, $M_U<\infty$. Clearly, for every $h_u\in\Gamma$, $\|h_u(t,u',\tau')\|\le M_U$ for all $t\in[0,1]$, $u'\in U$, and $\tau'\in[\tau_{\min},\tau_{\max}]$. Hence

$$\begin{aligned}&\|\bar{z}(t,\sigma,\tau,\lambda,h_u)-\bar{z}(t,\sigma,\tau)\|_X\\ &\quad=\left\|\int_0^t\int_U\tau T(\tau(t-s))[F(\bar{z}(s,\sigma,\tau,\lambda,h_u),u+\lambda h_u(s,u,\tau))\right.\\ &\qquad\left.-F(\bar{z}(s,\sigma,\tau),u)]\sigma(s)(du)ds\right\|_X\\ &\quad\le\tau_{\max}M\int_0^t K_S[\|\bar{z}(s,\sigma,\tau,\lambda,h_u)\\ &\qquad-\bar{z}(s,\sigma,\tau)\|+|\lambda|M_U]ds,\end{aligned} \tag{4.8b}$$

[3] A similar development for ODEs can be found in [Wil.1].

where M is a bound on $\|T(\tau(t-s))\|, s \in [0,t]$, as also used in the Appendix. Applying the Bellman–Gronwall inequality, we obtain that

$$\|\overline{z}(t,\sigma,\tau,\lambda,h_u) - \overline{z}(t,\sigma,\tau)\| \leq L|\lambda|, \tag{4.8c}$$

where $L \triangleq MK_SM_Ue^{\tau_{\max}MK_S}$ and K_S is defined as in Assumption 3.1(iv). □

LEMMA 4.5. *There exists $d_1 < \infty$ such that for all $t \in [0,1], \sigma \in \overline{G}, \tau \in [\tau_{\min}, \tau_{\max}], h_u \in \Gamma$ and $\lambda \in [-1,1]$,*

$$\|\overline{z}(t,\sigma,\tau,\lambda,h_u) - \overline{z}(t,\sigma,\tau) - \lambda\overline{\delta z}_u(t,\sigma,\tau,h_u)\|_X \leq d_1|\lambda|^2. \tag{4.9}$$

Proof. Let $\Delta\overline{z}(t,\sigma,\tau,\lambda,h_u) \triangleq \overline{z}(t,\sigma,\tau,\lambda,h_u) - \overline{z}(t,\sigma,\tau)$. Then, with M_U as in (4.8a),

$$\begin{aligned}
&\|\Delta\overline{z}(t,\sigma,\tau,\lambda,h_u) - \lambda\overline{\delta z}_u(t,\sigma,\tau,h_u)\|_X \\
&\quad\leq \left\| \int_0^t \int_U \tau T(\tau(t-s)) \Big[F(\overline{z}(s,\sigma,\tau,\lambda,h_u), u + \lambda h_u(s,u)) \right. \\
&\qquad - F(\overline{z}(s,\sigma,\tau),u) - \frac{\partial F}{\partial z}(\overline{z}(s,\sigma,\tau),u)\delta\overline{z}(s,\sigma,\tau,\lambda,h_u) \\
&\qquad \left. - \frac{\partial F}{\partial u}(\overline{z}(s,\sigma,\tau),u)\cdot\lambda h_u(s,u)\Big]\sigma(s)(du)ds \right\|_X \\
&\quad\leq \tau_{\max}M \int_0^t \int_U \left[\int_0^1 \left\| \frac{\partial F}{\partial z}(\overline{z}(s,\sigma,\tau,\lambda,h_u) + r\Delta\overline{z}(s,\sigma,\tau,\lambda,h^u), u + r\lambda h_u(s,u)) \right.\right. \\
&\qquad \left. - \frac{\partial F}{\partial z}(\overline{z}(s,\sigma,\tau),u)\right\| dr \Delta\overline{z}(s,\sigma,\tau,\lambda,h_u) \Big\|_X \\
&\qquad + \int_0^1 \left\| \frac{\partial F}{\partial u}(\overline{z}(s,\sigma,\tau,\lambda,h_u) + r\Delta\overline{z}(s,\sigma,\tau,\lambda,h_u), u + r\lambda h_u(s,u)) \right. \\
&\qquad\qquad \left. - \frac{\partial F}{\partial u}(\overline{z}(s,\sigma,\tau),u)\right\| dr|\lambda|M_U \\
&\qquad + \left\| \frac{\partial F}{\partial z}(\overline{z}(s,\sigma,\tau),u)\right\| \|\Delta\overline{z}(s,\sigma,\tau,\lambda,h_u) - \overline{\delta z}_u(s,\sigma,\tau,\lambda,h_u)\|_X \Big] \sigma(s)(du)ds \\
&\quad\leq \tau_{\max}M \int_0^t \int_U [K_S(\|\Delta\overline{z}(s,\sigma,\tau,\lambda,h_u)\|_X + |\lambda|M_U)\|\Delta\overline{z}(s,\sigma,\tau,\lambda,h_u)\|_X \\
&\qquad + K_S(\|\Delta\overline{z}(s,\sigma,\tau,\lambda,h_u)\|_X + |\lambda|M_U)|\lambda M_U \\
&\qquad + b_2|\lambda|M_U\|\Delta\overline{z}(s,\sigma,\tau,\lambda,h_u) - \delta\overline{z}(s,\sigma,\tau,\lambda,h_u)\|_X]\sigma(s)(du)ds,
\end{aligned} \tag{4.10a}$$

where b_2 is defined in Lemma 3.4. Since by Lemma 4.4 $\|\Delta\overline{z}(s,\sigma\tau,\lambda,h_u)\|_X \leq L|\lambda|$, it follows from the Bellman–Gronwall inequality that

$$\begin{aligned}
&\|\Delta\overline{z}(t,\sigma,\tau,\lambda,h_u) - \lambda\overline{\delta z}_u(t,\sigma,\tau,h_u)\|_X \\
&\quad\leq MK_Se^{Mb_2}(\|\Delta\overline{z}(s,\sigma,\tau,\lambda,h_u)\| + |\lambda|M_U)^2 \\
&\quad\leq d_1|\lambda|^2,
\end{aligned} \tag{4.10b}$$

where $d_1 = MK_Se^{Mb_2}(L + M_U)^2$. □

Proceeding in a similar manner, we can also prove the following, somewhat simpler, result.

LEMMA 4.6. *There exists a $d_2 < \infty$ such that for all $h_u \in \Gamma, t \in [0,1], \sigma \in \overline{G}, \lambda \in [-1,1], \tau', \tau \in [\tau_{\min}, \tau_{\max}]$,*

$$\|\overline{z}(t,\sigma,\tau,\lambda,h_u) - \overline{z}(t,\sigma,\tau) - \lambda\overline{\delta z}(t,\sigma,\tau,\tau'-\tau)\|_X \leq d_2|\lambda|^2. \tag{4.11}$$

In addition, it is fairly easy to establish the following result.

LEMMA 4.7. *For any* $t \in [0,1], \sigma \in \overline{G}, \tau \in [\tau_{\min}, \tau_{\max}]$, *admissible* h_u, *and* $\tau' \in [\tau_{\min}, \tau_{\max}]$, *let* $\overline{\delta z}(t, \sigma, \tau, h_u, \tau' - \tau)$ *denote the solution to*

$$
\begin{aligned}
\delta z(t) = \int_0^t \int_U \tau T(\tau(t-s)) \Big\{ & \frac{\partial F}{\partial z}(\overline{z}(s,\sigma,\tau),u)\delta z(s) \\
& + \frac{\partial F}{\partial u}(\overline{z}(s,\sigma,\tau),u)h_u(s,u,\tau) \Big\} \sigma(s)(du)ds \\
+ \int_0^t & \{(T(\tau(t-s)) + \tau(t-s)AT(\tau(t-s)))F(\overline{z}(s,\sigma,\tau),u)\delta\tau\}\, ds \\
+ & tAT(\tau t)z_0\delta\tau.
\end{aligned} \tag{4.12}
$$

Then (i) $\overline{\delta z}(t,\sigma,\tau,h_u,\tau'-\tau) = \overline{\delta z}_u(t,\sigma,\tau,h_u) + \overline{\delta z}_\tau(t,\sigma,\tau,\tau'-\tau)$, *and* (ii) $\overline{\delta z}(t,\sigma,\tau,h_u,\tau'-\tau)$ *is continuous in* $(t,\sigma,\tau,h_u,\tau')$.

We are now ready to extend the optimality conditions in §3 to the relaxed optimal control problems $\overline{\mathbf{MMP}}, \overline{\mathbf{CMP}}$. We define the max function $\overline{\psi} : \overline{G} \times [\tau_{\min}, \tau_{\max}] \to \mathbb{R}$ and the optimality function $\overline{\theta}_{\mathbf{MMP}} : \overline{G} \times [\tau_{\min}, \tau_{\max}] \to \mathbb{R}$ by

$$
\overline{\psi}(\sigma,\tau) \triangleq \max_{j \in \mathbf{q}} \overline{g}^j(\sigma,\tau), \tag{4.13a}
$$

$$
\begin{aligned}
\overline{\theta}_{\mathbf{MMP}}(\sigma,\tau) \triangleq \min_{(w,\tau') \in \Gamma \times [\tau_{\min},\tau_{\max}]} \Big\{ & \frac{1}{2}\int_0^1 \int_U \|w(t,u,\tau)\|^2 \sigma(t)(du)dt + \frac{1}{2}|\tau'-\tau|^2 \\
& + \max_{j \in \mathbf{q}} \{\overline{g}^j(\sigma,\tau) - \overline{\psi}(\sigma,\tau) \\
& + \langle \nabla f^j(\overline{z}(1,\sigma,\tau)), \overline{\delta z}_u(1,\sigma,\tau,w)\rangle_X \\
& + \langle \nabla f^j(\overline{z}(1,\sigma,\tau)), \overline{\delta z}_\tau(1,\sigma,\tau,\tau'-\tau)\rangle_X \} \Big\}.
\end{aligned} \tag{4.13b}
$$

Making use of Lemmas 4.6 and 4.7, we immediately get the following extension of Theorems 3.4 and 3.5.

THEOREM 4.8. (i) *The function* $\overline{\theta_{\mathbf{MMP}}}(\cdot,\cdot)$ *is well defined and continuous.*

(ii) *Suppose that* $(\hat{\sigma},\hat{\tau}) \in \overline{G} \times [\tau_{\min}, \tau_{\max}]$ *is an optimal solution to the problem* $\overline{\mathbf{MMP}}$ (4.3a). *Then* $\overline{\theta_{\mathbf{MMP}}}(\hat{\sigma},\hat{\tau}) = 0$.

Similarly, we can define an extension, $\overline{\theta}_{\mathbf{CMP}} : \overline{G} \times [\tau_{\min}, \tau_{\max}] \to \mathbb{R}$ of the optimality function $\theta_{\mathbf{CMP}}(\cdot,\cdot)$ as follows:

$$
\begin{aligned}
\overline{\theta}_{\mathbf{CMP}}(\sigma,\tau) \triangleq \min_{(w,\tau') \in \Gamma \times [\tau_{\min},\tau_{\max}]} \Big\{ & \frac{1}{2}\int_0^1 \int_U \|w(t,u,\tau)\|^2 \sigma(t)(du)dt + \frac{1}{2}|\tau'-\tau|^2 \\
& + \max\{-\overline{\psi}(\sigma,\tau)_+ \\
& + \langle \nabla f^0(\overline{z}(1,\sigma,\tau)), \overline{\delta z}_u(1,\sigma,\tau,w)\rangle_X \\
& + \langle \nabla f^0(\overline{z}(1,\sigma,\tau), \overline{\delta z}_\tau(1,\sigma,\tau,\tau'-\tau))\rangle_X, \overline{g}^j(\sigma,\tau) \\
& - \overline{\psi}(\sigma,\tau)_+ + \langle \nabla f^j(\overline{z}(1,\sigma,\tau)), \overline{\delta z}_u(1,\sigma,\tau,w)\rangle_X \\
& + \langle \nabla f^j(\overline{z}(1,\sigma,\tau), \overline{\delta z}_\tau(1,\sigma,\tau,\tau'-\tau))\rangle_X, j \in \mathbf{q}\} \Big\},
\end{aligned} \tag{4.14}
$$

where $\overline{\psi}(\sigma,\tau)_+ \triangleq \max\{0, \overline{\psi}(\sigma,\tau)\}$. We can now state the obvious extension of Theorem 3.6.

THEOREM 4.9. (i) *The function* $\overline{\theta}_{\mathbf{CMP}}(\cdot,\cdot)$ *is well defined and continuous.*

(ii) *Suppose that* $(\hat{\sigma}, \hat{\tau}) \in \overline{G} \times [\tau_{\min}, \tau_{\max}]$ *is an optimal solution to the problem* **CMP** (4.3b). *Then* $\overline{\theta}_{\mathbf{CMP}}(\hat{\sigma}, \hat{\tau}) = 0$.

We conclude this section with a rather obvious result that is essential in the analysis of optimal control algorithms.

THEOREM 4.10. *Suppose that* $\sigma^* \in \overline{G}$ *is an ordinary control, i.e., there exists a* $u^* \in G$ *such that* $\sigma^*(t)(S) = \delta_{u^*(t)}(S)$ *for all measurable sets* $S \subset U$ *and almost all* $t \in [0,1]$. *Then*

(i) *For any* $t \in [0,1], h_u \in \Gamma, \tau', \tau \in [\tau_{\min}, \tau_{\max}], \overline{\delta z}(t, \sigma^*, \tau, h_u, \tau' - \tau) = \delta z(t, u, \tau, \delta u, \delta\tau)$, *where* $\delta u(t) = h_u(t, u^*(t), \tau)$ *and* $\delta\tau = \tau' - \tau$.

(ii) $\overline{\theta}_{\mathbf{MMP}}(\sigma^*, \tau) = \theta_{\mathbf{MMP}}(u^*, \tau)$, *and* $\overline{\theta}_{\mathbf{CMP}}(\sigma^*, \tau) = \theta_{\mathbf{CMP}}(u^*, \tau)$.

Thus we see from Theorem 4.10 that when σ^* is an ordinary control, the stationary points of (3.2b) and (3.6) are also the stationary points of (4.13b) and (4.14), respectively.

5. Approximation theory. The numerical solution of optimal control problems such as **MMP** and **CMP** is impossible without some sort of discretization of the evolution equation (2.2f). We will now develop a theory for discretization of these problems. This theory depends on the convergence of the finite element method and on error bounds, such as those to be found in [Fuj.1], [Fuj.2], [Fuj.3].

The use of a numerical method in integrating the evolution system (2.2f) results in the replacement of the set of admissible controls G by G_n, a compact, convex, finite-dimensional subset of G, and of the original functions $g^j : G \times [\tau_{\min}, \tau_{\max}] \to \mathbb{R}$ by approximating functions $g_n^j : G_n \times [\tau_{\min}, \tau_{\max}] \to \mathbb{R}$, where $n \in \mathbb{Z}_+$ is a precision control parameter. Thus, the use of numerical integration results in the replacement of the original problems **MMP** and **CMP** by approximations.

Hence, to establish an approximation theory, for each $n \in \mathbb{Z}_+$, we define the discretized problems $\mathbf{MMP}_n$ and $\mathbf{CMP}_n$ by

$$\mathbf{MMP}_n : \min\{\max_{j \in \mathbf{q}} g_n^j(u, \tau) | u \in G_n, \tau \in [\tau_{\min}, \tau_{\max}]\}, \tag{5.1a}$$

$$\mathbf{CMP}_n : \min\{g_n^0(u, \tau) | \max_{j \in \mathbf{q}} g_n^j(u, \tau) \leq 0, u \in G_n, \tau \in [\tau_{\min}, \tau_{\max}]\}. \tag{5.1b}$$

To ensure that the functions $g_n^j(\cdot, \cdot)$ inherit the continuity and differentiability properties of the functions $g^j(\cdot, \cdot)$, we make the following reasonable assumptions.

Assumption 5.1. (i) For all $n \in \mathbb{Z}_+$, the functions $g_n^j : G_n \times [\tau_{\min}, \tau_{\max}] \to \mathbb{R}$ are continuous.

(ii) For all $n \in \mathbb{Z}_+, j = 0, 1, 2, \ldots, q$, and each $(u, \tau) \in G_n \times [\tau_{\min}, \tau_{\max}]$, there exists a gradient $\nabla g_n^j(u, \tau) = (\nabla g_{u,n}^j(u, \tau), \nabla g_{\tau,n}^j(u, \tau)) \in L_2^m[0,1] \times \mathbb{R}$, such that for all $u' \in G_n, \tau' \in [\tau_{\min}, \tau_{\max}]$,

$$\lim_{\substack{\|u'-u\|_2 \to 0 \\ |\tau'-\tau| \to 0}} \frac{|g_n^j(u'\tau') - g_n^j(u, \tau) - (\langle \nabla_u g_n^j(u), \nu - u \rangle_2 + \nabla_\tau g_n^j(u, \tau)(\tau' - \tau))|}{(\|u' - u\|_2^2 + |\tau' - \tau|^2)^{1/2}} = 0. \tag{5.2a}$$

(iii) There exists a Lipschitz constant[4] $L \in (0, \infty)$, such that for all $n \in \mathbb{Z}_+, j = 0, 1, 2, \ldots, q, u', u \in G_n, \tau, \tau' \in [\tau_{\min}, \tau_{\max}]$,

$$\|\nabla g_n^j(u', \tau') - \nabla g_n^j(u, \tau)\|_2 \leq L(\|u' - u\|_2^2 + |\tau' - \tau|^2)^{1/2}. \tag{5.2b}$$

(iv) For all $n \in \mathbb{Z}_+, G_n \subset G_{n+1}$.

[4] The existence of such a Lipschitz constant is a consequence of Assumptions (3.1)(iv), (3.1)(v).

(v) The closure of $\bigcup_{n\in\mathbb{Z}_+} G_n$ is G.

(vi) (Uniform Approximation Property.) For all $\varepsilon > 0$, there exists n_ε such that for all $n \geq n_\varepsilon, j = 0, 1, 2, \ldots, q$, all $u \in G_n$, and all $\tau \in [\tau_{\min}, \tau_{\max}]$,

$$|g^j(u,\tau) - g_n^j(u,\tau)| \leq \varepsilon, \tag{5.2c}$$

$$\|\nabla g^j(u,\tau) - \nabla g_n^j(u,\tau)\|_2 \leq \varepsilon. \tag{5.2d}$$

Usually, when continuous dynamical equations are replaced by discrete dynamic equations, the resulting solutions inherit the continuity and differentiability properties of the original solutions, and hence satisfy Assumptions 5.1(i)–(iii). Assumption 5.1(vi) is satisfied at any particular u for any dynamics on which the finite element method converges. Thus the only thing we must verify is that the approximation is uniform on the finite-dimensional set, G_n, as assumed.

Referring to Proposition 5.5 in [Pol.1], we see that the following analogues of Theorems 3.11 and 3.12 must hold for the problems $\mathbf{MMP}_n, \mathbf{CMP}_n$.

THEOREM 5.2. *For $n \in \mathbb{Z}_+$, let $\psi_n : G_n \times [\tau_{\min}, \tau_{\max}] \to \mathbb{R}$ and the corresponding optimality function $\theta_{\mathbf{MMP}n} : G_n \times [\tau_{\min}, \tau_{\max}] \to \mathbb{R}$ be defined by*

$$\psi_n(u',\tau') \triangleq \max_{j\in\mathbf{q}} g_n^j(u',\tau'), \tag{5.3a}$$

$$\begin{aligned}\theta_{\mathbf{MMP}n}(u',\tau') \triangleq \min_{(u,\tau)\in G_n\times[\tau_{\min},\tau_{\max}]} \Big\{ & \frac{1}{2}\|u-u'\|_2^2 + \frac{1}{2}|\tau-\tau'|^2 \\ & + \max_{j\in\mathbf{q}}\{g_n^j(u',\tau') - \psi_n(u',\tau') \\ & + \langle \nabla_u g_n^j(u',\tau'), u-u'\rangle \\ & + \nabla_\tau g_n^j(u',\tau')(\tau-\tau')\}\Big\}.\end{aligned} \tag{5.3b}$$

Then

(i) *The optimality function $\theta_{\mathbf{CMP}}(\cdot,\cdot)$ is well defined and continuous.*

(ii) *If $h_u(u',\tau') \in G_n - \{u'\}$, $h_\tau(u',\tau') \in [\tau_{\min}, \tau_{\max}] - \{\tau'\}$ are such that $(u' + h_u(u',\tau'), \tau' + h_\tau(u',\tau'))$ is a solution to* (5.3b)*, then $h_u(\cdot,\cdot), h_\tau(\cdot,\cdot)$ are continuous functions.*

(iii) *Suppose that $(u_n', \tau_n') \in G_n \times [\tau_{\min}, \tau_{\max}]$ is an optimal solution to the problem* **CMP**. *Then $\theta_{\mathbf{CMP}}(u_n', \tau_n') = 0$.*

THEOREM 5.3. *For $n \in \mathbb{Z}_+$, let $\psi_n(u,\tau)_+ \triangleq \max\{0, \psi_n(u,\tau)\}$, and let the corresponding optimality function $\theta_{\mathbf{CMP}_n} : G_n \times [\tau_{\min}, \tau_{\max}] \to \mathbb{R}$ be defined by*

$$\begin{aligned}\theta_{\mathbf{CMP}_n}(u,\tau) \triangleq \min_{(u',\tau')\in G_n\times[\tau_{\min},\tau_{\max}]} \Big\{ & \frac{1}{2}\|u'-u\|_2^2 + \frac{1}{2}|\tau'-\tau|^2 \\ & + \max\{-\psi_n(u,\tau)_+ + \langle \nabla_u g_n^0(u,\tau), u'-u\rangle \\ & + \nabla_\tau g_n^0(u,\tau)(\tau'-\tau), g_n^j(u,\tau) - \psi(u,\tau)_+ \\ & + \langle \nabla_u g_n^j(u,\tau), u'-u\rangle \\ & + \nabla_\tau g_n^j(u,\tau)(\tau'-\tau), j \in \mathbf{q}\}\Big\}.\end{aligned} \tag{5.4}$$

Then

(i) *The optimality function $\theta_{\mathbf{CMP}}(\cdot,\cdot)$ is well defined and continuous.*

(ii) *If* $h_u(u,\tau), h_\tau(u,\tau)$ *are such that* $u + h_u(u,\tau) \in G_n, \tau + h_\tau(u,\tau) \in [\tau_{\min}, \tau_{\max}]$ *are a solution to* (5.4)*, then* $h_u(\cdot,\cdot), h_\tau(\cdot,\cdot)$ *are continuous functions.*

(iii) *Suppose that* $(\hat{u}_n, \hat{\tau}_n) \in G_n \times [\tau_{\min}, \tau_{\max}]$ *is an optimal solution to the problem* **CMP**. *Then* $\theta_{\mathbf{CMP}}(\hat{u}_n, \hat{\tau}_n) = 0$.

To simply notation, we define $H \stackrel{\Delta}{=} G \times [\tau_{\min}, \tau_{\max}]$, $H_n \stackrel{\Delta}{=} G_n \times [\tau_{\min}, \tau_{\max}]$, and $\eta = (u,\tau)$, and for any $\xi = (\xi_u, \xi_\tau) \in H$ and $\eta = (u,\tau) \in H$, we define $\langle \xi, \eta \rangle_H \stackrel{\Delta}{=} \langle \xi_u, u \rangle_2 + \xi_\tau \tau$, and $\|\eta\|_H \stackrel{\Delta}{=} (\|u\|_2^2 + |\tau|^2)^{1/2}$. Next, for any $\eta', \eta \in H$, we define

$$\hat{\psi}(\eta' - \eta|\eta) \stackrel{\Delta}{=} \max_{j \in \mathbf{q}} \{g^j(\eta) + \langle \nabla g^j(\eta), \eta' - \eta \rangle_H\} + \tfrac{1}{2}\|\eta' - \eta\|_H^2. \tag{5.5a}$$

Next, for any $n \in \mathbb{Z}_+, \eta', \eta \in H_n$, we define

$$\hat{\psi}_n(\eta' - \eta|\eta) \stackrel{\Delta}{=} \max_{j \in \mathbf{q}} \{g_n^j(\eta) + \langle \nabla g_n^j(\eta), \eta' - \eta \rangle_H\} + \tfrac{1}{2}\|\eta' - \eta\|_H^2. \tag{5.5b}$$

With this notation, we have that

$$\theta_{\mathbf{MMP}}(\eta) = \min_{\eta' \in H} \hat{\psi}(\eta' - \eta|\eta) - \psi(\eta), \tag{5.5c}$$

$$\theta_{\mathbf{MMP}_n}(\eta) = \min_{\eta' \in H_n} \hat{\psi}_n(\eta' - \eta|\eta) - \psi_n(\eta). \tag{5.5d}$$

LEMMA 5.4. *There exists a constant* $K_1 < \infty$ *such that for every* $\varepsilon > 0$*, there exists* n_ε *such that for all* $n \geq n_\varepsilon$*, and all* $\eta', \eta \in H_n$,

$$|\hat{\psi}_n(\eta' - \eta|\eta) - \hat{\psi}(\eta' - \eta|\eta)| \leq K_1 \varepsilon. \tag{5.6a}$$

Proof. It follows from Assumption 5.1 that there exists an $n_\varepsilon \in \mathbb{Z}_+$ such that for all $n \geq n_\varepsilon$,

$$\begin{aligned} \hat{\psi}_n(\eta' - \eta|\eta) - \hat{\psi}(\eta' - \eta|\eta)| &\leq \max_{j \in \mathbf{q}} \{g_n^j(\eta) - g^j(\eta) \\ &\qquad + \langle \nabla g_n^j(\eta) - \nabla g^j(\eta), \eta' - \eta \rangle_H\} \\ &\leq [1 + K_H]\varepsilon, \end{aligned} \tag{5.6b}$$

where $K_H = \max\{\|\eta' - \eta\|_H | \eta', \eta \in H\}$. Reversing the roles of $\hat{\psi}_n(\eta' - \eta|\eta)$ and $\hat{\psi}(n' - \eta|\eta)$ we get the desired result. □

THEOREM 5.5. *There exists a constant* $K_2 < \infty$ *such that for every* $\varepsilon \in (0, 1]$*, there exists* n_ε *such that for all* $n \geq n_\varepsilon$*, and all* $\eta \in H_n$,

$$|\theta_{\mathbf{MMP}_n}(\eta) - \theta_{\mathbf{MMP}}(\eta)| \leq K_2 \varepsilon. \tag{5.7}$$

Proof. For any $\eta \in H_n$, let

$$\xi(\eta) \stackrel{\Delta}{=} \arg\min_{\eta' \in H} \hat{\psi}(\eta' - \eta|\eta), \tag{5.8a}$$

$$\xi_n(\eta) \stackrel{\Delta}{=} \arg\min_{\eta' \in H_n} \hat{\psi}_n(\eta' - \eta|\eta), \tag{5.8b}$$

$$\tilde{\xi}_n(\eta) \triangleq \arg\min_{\eta' \in H_n} \|\eta' - \xi(\eta)\|_H. \tag{5.8c}$$

Let $\varepsilon > 0$ be given and let $n_\varepsilon \in \mathbb{Z}_+$ be defined as in Assumption 5.1(vi). In view of Assumption 5.1(v), there exists an $n'_\varepsilon \in \mathbb{Z}_+$, with $n'_\varepsilon \geq n_\varepsilon$, such that for any $n \geq n'_\varepsilon$ and any $\eta \in H$ there exists an $\eta_n \in H_n$ such that $\|\eta - \eta_n\|_H \leq \varepsilon$. Hence we obtain

$$\begin{aligned} \theta_{\mathbf{MMP}}(\eta) &\leq \hat{\psi}(\xi_n(\eta) - \eta|\eta) - \psi(\eta) \\ &\leq \hat{\psi}_n(\tilde{\xi}_n(\eta) - \eta|\eta) - \psi_n(\eta)] + [\psi_n(\eta) - \psi(\eta)] + K_1\varepsilon \\ &\leq \theta_{\mathbf{MMP}_n}(\eta) + [K_1 + 1]\varepsilon; \end{aligned} \tag{5.9a}$$

$$\begin{aligned} \theta_{\mathbf{MMP}_n}(\eta) &\leq \hat{\psi}_n(\tilde{\xi}_n(\eta) - \eta|\eta) - \Psi_n(\eta) \\ &\leq \hat{\psi}(\tilde{\xi}_n(\eta) - \eta|\eta) - \psi(\eta) + [\psi(\eta) - \psi_n(\eta)] + K_1\varepsilon \\ &\leq \hat{\psi}(\xi(\eta) - \eta|\eta) - \psi(\eta) + K'\|\xi(\eta) - \tilde{\xi}_n(\eta)\|_H \\ &\qquad + \frac{1}{2}|\|\xi(\eta) - \eta\|_H - \|\tilde{\xi}_n(\eta) - \eta\|_H|\|\xi(\eta) - \tilde{\xi}_n(\eta)\|_H \\ &\qquad + (K_1 + 1)\varepsilon \\ &\leq \theta_{\mathrm{MMP}}(\eta) + K_2\varepsilon, \end{aligned} \tag{5.9b}$$

where $K_2 = 1 + K_1 + K' + K''$, with $K' = \sup_{\eta \in H} \max_{j \in \mathbf{q}} \|\nabla g^j(\eta)\|_H$ and $K'' = \frac{1}{2}\sup_{\eta, \eta' \in H} \|\eta' - \eta\|_H$. The desired result now follows. □

The proof of the following result for problem **CMP** is quite similar to the one above and hence is omitted.

THEOREM 5.6. *There exists a constant $K_3 < \infty$ such that for every $\varepsilon > 0$, there exists n_ε such that for all $n \geq n_\varepsilon$, and all $\eta \in H_n$,*

$$|\theta_{\mathbf{CMP}_n}(\eta) - \theta_{\mathbf{CMP}}(\eta)| \leq K_3\varepsilon. \tag{5.10}$$

The problems **MMP** and **CMP** are finite-dimensional and hence can be solved with arbitrary precision using a finite-dimensional minimax or nonlinear programming algorithm, respectively, such as any one of the following [Pol.1], [Pol.3]. The first question we must answer is whether doing that is useful, i.e., we must establish whether our discretizations are consistent in an appropriate sense. The following pair of theorems gives an affirmative answer.

THEOREM 5.7. (i) *Suppose that $\{(\hat{u}_n, \hat{\tau}_n)\}_{n=1}^{\infty}$ is a sequence of optimal solutions to the sequence of problems $\mathbf{MMP}_n$. Let $I \subset \mathbb{Z}_+$ be such that $\hat{u}_n \xrightarrow{I} \hat{\sigma} \in \overline{G}$ (in the sense of control measures* (i.s.c.m.)*) and $\hat{\tau}_n \xrightarrow{I} \hat{\tau} \in [\tau_{\min}, \tau_{\max}]$, as $i \to \infty$, then $(\hat{\sigma}, \hat{\tau})$ is an optimal solution of $\overline{\mathbf{MMP}}$.*

(ii) *Suppose that $\{(U_n^*, \tau_n^*)\}_{n=1}^{\infty}$, with $u_n^* \in G_n$ and $\tau_n^* \in [\tau_{\min}, \tau_{\max}]$, is such that*

$$\theta_{\mathbf{MMP}_n}(u_n^*, \tau_n^*) \geq -\frac{1}{n}. \tag{5.11}$$

Let $I \subset \mathbb{Z}_+$ be such that $u_n^* \xrightarrow{I} \sigma^* \in \overline{G}$ (i.s.c.m.) *and $\tau_n^* \xrightarrow{I} \tau^* \in [\tau_{\min}, \tau_{\max}]$, as $n \to \infty$, then $\overline{\theta}_{\mathbf{MMP}}(\sigma^*, \tau^*) = 0$.*

Proof. (i) For the sake of contradiction, suppose that $(\hat{\sigma}, \hat{\tau})$ is not an optimal solution of $\overline{\mathbf{MMP}}$. Then there exists a pair (σ^{**}, τ^{**}), with $\sigma^{**} \in (\overline{G})$ and $\tau^{**} \in [\tau_{\min}, \tau_{\max}]$ such that $\overline{\psi}(\sigma^{**}, \tau^{**}) < \overline{\psi}(\hat{\sigma}, \hat{\tau})$. Since $\overline{\psi}(\cdot, \cdot)$ is continuous, and $\hat{u}_n \in G_n$ is an ordinary

control, we must have that $\overline{\psi}(\hat{u}_n, \hat{\tau}_n) \xrightarrow{I} \overline{\psi}(\hat{\sigma}, \hat{\tau})$. Hence, because of Assumption 5.1(vi), we must also have that $\psi_n(\hat{u}_n, \hat{\tau}_n) \xrightarrow{I} \overline{\psi}(\hat{\sigma}, \hat{\tau})$. Now, by Assumption 5.1(v), there exists a sequence $\{u'_n\}_{n \in I}$ such that $u'_n \xrightarrow{I} \sigma^{**}$ (i.s.c.m.), as $i \to \infty$. Hence because $\overline{\psi}(\cdot, \cdot)$ is continuous and because of Assumption 5.1(vi), $\psi_n(u'_n, \tau^{**}) \xrightarrow{I} \overline{\psi}(\sigma^{**}, \tau^{**})$ which, for n sufficiently high, contradicts the optimality of the pairs $(\hat{u}_n, \hat{\tau}_n)$.

(ii) This part follows directly from the continuity of the function $\overline{\theta}(\cdot, \cdot)$ and Theorem 5.5. □

We get a similar result for problem **CMP**, which we state without proof.

THEOREM 5.8. (i) *Suppose that* $\{(\hat{u}_n, \hat{\tau}_n)\}_{n=1}^{\infty}$ *is a sequence of optimal solutions to the sequence of problems* $\mathbf{CMP}_n$. *Let* $I \subset \mathbb{Z}_+$ *be such that* $\hat{u}_n \xrightarrow{I} \hat{\sigma} \in \overline{G}$ (i.s.c.m.) *and* $\hat{\tau}_n \xrightarrow{I} \hat{\tau} \in [\tau_{\min}, \tau_{\max}]$, *as* $n \to \infty$, *then* $(\hat{\sigma}, \hat{\tau})$ *is an optimal solution of* $\overline{\mathbf{CMP}}$.

(ii) *Suppose that* $\{(u_n^*, \tau_n^*)\}_{n=1}^{\infty}$, *with* $u_n^* \in G_n$ *and* $\tau_n^* \in [\tau_{\min}, \tau_{\max}]$ *is such that*

$$\theta_{\mathbf{MMP}_n}(u_n^*, \tau_n^*) \geq -\frac{1}{n}. \tag{5.12a}$$

$$\psi_n(u_n^*, \tau_n^*) \leq \frac{1}{n}. \tag{5.12b}$$

Let $I \subset \mathbb{Z}_+$ *be such that* $u_n^* \xrightarrow{I} \sigma^* \in \overline{G}$ (i.s.c.m.) *and* $\tau_n^* \xrightarrow{I} \tau^* \in [\tau_{\min}, \tau_{\max}]$, *as* $i \to \infty$, *then* $\overline{\theta}_{\mathbf{MMP}}(\sigma^*, \tau^*) = 0$ *and* $\overline{\psi}(\sigma^*, \tau^*) \leq 0$.

The computational scheme represented by Theorems 5.7 and 5.8 can be implemented as follows. An algorithm is applied to problem $\mathbf{MMP}_n$ (or $\mathbf{CMP}_n$), producing a sequence of iterates $(u_{n,i}, \tau_{n,i})$, $i = 0, 1, 2, \ldots, i_n$ which is arrested when (5.11) (or (5.12a) and (5.12b)) is satisfied. Then a new sequence, $(u_{n+1,i}, \tau_{n+1,i})$, $i = 0, 1, 2, \ldots$, is started for problem $\mathbf{MMP}_{n+1}$ (or $\mathbf{CMP}_{n+1}$), with $(u_{n+1,0}, \tau_{n+1,0}) = (u_{n,i_n}, \tau_{n,i_n})$. The main disadvantage of this scheme is that Theorems 5.7 and 5.8 deal only with a special subsequence of all the iterates computed, rather than with the whole sequence.

We will now show that it is possible to generalize the *algorithm implementation scheme* in [Kle.1] so as to obtain algorithms for solving **MMP** and **CMP**, with the property that *any* accumulation point of the computed sequence of iterates satisfies our first order optimality conditions. However, this requires that we strengthen Assumption 5.1(vi), as follows.

Assumption 5.9. There exists a constant $\hat{K} < \infty$ such that for all $n \in \mathbb{Z}_+, j = 0, 1, 2, \ldots, q$, all $u \in G_n$, and $\tau \in [\tau_{\min}, \tau_{\max}]$,

$$|g^j(u, \tau) - g_n^j(u, \tau)| \leq \frac{\hat{K}}{2^n}. \tag{5.13}$$

Referring to [Kle.1], we see that Assumption 5.9 is satisfied when *ordinary* differential equations are integrated numerically by a method of order at least one. It is shown in [Bak.1, §6.5], making use of the results in [Fuj.1], [Fuj.2], [Fuj.3], [Ode.1], that, when the finite element method is implemented using linear elements and Newmark's β method is used with $\beta = 0$, Assumption 5.9 is satisfied by the example treated in §6. We believe that it will also hold for many other cases as well.

For problem **MMP** we will extend a variant of the Pironneau–Polak–Pshenichnyi minimax algorithm (see [Pir.1], [Pol.1], [Psh.1]), which can be used for solving $\mathbf{MMP}_n$. To simplify proofs, we will use an exact line search step size rule; however, the results to follow remain valid also with an Armijo type step size rule (see [Pol.1], [Psh.1] for step size rule). To simplify exposition, we resume the notation $\eta = (u, \tau), H_n = G_n \times [\tau_{\min}, \tau_{\max}]$.

MINIMAX ALGORITHM 5.10 (solves MMP).

Parameter. $\gamma \in (0,1)$.

Data. $\eta_0, \eta_0 \in H_{n_0}$.

Step 0. Set $i = 0, n(0) = n_0$.

Step 1. Compute the search direction,

$$h_i = h_{n(i)}(\eta_i) \triangleq \arg \min_{\eta \in H_{n(i)}} \max_{j \in \mathbf{q}} \left\{ g^j_{n(i)}(\eta_i) + \langle \nabla g^j_{n(i)}(\eta_i), \eta - \eta_i \rangle_H + \frac{1}{2}\|\eta - \eta_i\|^2_H \right\} - \eta_i. \tag{5.14a}$$

Step 2. Compute the step size

$$\lambda_i \in \lambda_{n(i)}(\eta_i) \triangleq \arg \min_{\gamma \in [0,1]} \psi_{n(i)}(\eta_i + \lambda h_i). \tag{5.14b}$$

Step 3. Set $\eta^* = \eta_i + \lambda_i h_i$.

If

$$\psi_{n(i)}(\eta^*) - \psi_{n(i)}(\eta_i) > -\frac{1}{2^{\gamma n(i)}}, \tag{5.14c}$$

replace $n(i)$ by $n(i)+1$ and go to Step 1.

Else set $n(i+1) = n(i), \eta_{i+1} = \eta_i + \lambda_i h_i$.

Step 4. Replace i by $i+1$ and go to Step 1.

Note that (5.14c) causes the algorithm to increase precision when the decrease in cost becomes "unacceptably" small.

THEOREM 5.11. *Suppose that Algorithm* 5.10 *constructs a sequence* $\{\eta_i\}_{i=0}^{\infty}$. *Then this sequence has accumulation points in* $\overline{H} \triangleq \overline{G} \times [\tau_{\min}, \tau_{\max}]$, *and every such accumulation point,* $\hat{\eta}$, *satisfies* $\bar{\theta}_{\mathbf{MMP}}(\hat{\eta}) = 0$.

Proof. First we note that since $\overline{H}$ is sequentially compact, the sequence $\{\eta_i\}_{i=0}^{\infty}$ must have accumulation points in the relaxed controls topology. The rest of our proof is in three parts: (a) we will show that $n(i) \to \infty$ as $i \to \infty$, then (b) we will show that for any $\eta^* = (\sigma^*, \tau^*) \in \overline{H}$ such that $\bar{\theta}_{\mathbf{MMP}}(\eta^*) < 0$, there exists an integer n^* and a $\delta^* > 0$, such that for all $n(i) \geq n^*$, if $\eta_i \in H_{n(i)}$ is sufficiently close to η^*, then $\psi_{n(i)}(\eta_{i+1}) - \psi_{n(i)}(\eta_i) \leq -\delta^*$, and (c) we will obtain a contradiction by showing that if the theorem is not true, then $\psi(\eta_i) \to -\infty$.

(a) Suppose that there exists integers i_0 and n_0 such that for all $i \geq i_0, n(i) = n_0$. Then we must have that $\psi_{n_0}(\eta_{i+1}) - \psi_{n_0}(\eta_i) \leq -1/2^{\gamma n_0}$ for all $i \geq i_0$, which implies that $\Psi_{n_0}(\eta_i) \to -\infty$ as $i \to \infty$. Since H_{n_0} is compact, this is impossible, and hence we conclude that $n(i) \to \infty$ as $i \to \infty$.

(b) Suppose that for $n \in \mathbb{Z}_+, \eta_n \in H_n$ and that $\eta_n \xrightarrow{\text{i.s.c.m.}} \eta^* \in \overline{H}$, as $n \to \infty$. Furthermore, suppose that $\bar{\theta}_{\mathbf{MMP}}(\eta^*) \triangleq -8\delta^* < 0$. Since $\bar{\theta}_{\mathbf{MMP}}(\cdot)$ is continuous, and since $\theta_{\mathbf{MMP}}(\eta_n) = \bar{\theta}_{\mathbf{MMP}}(\eta_n)$ for all $n \in \mathbb{Z}_+$, it follows that there is an integer n_0 such that for all $n \in \mathbb{Z}_+, n \geq n_0, \theta_{\mathbf{MMP}}(\eta_n) \leq -4\delta^*$. It now follows from Theorem 5.5 that there exists an integer $n_1 \geq n_0$ such that for all $n \in \mathbb{Z}_+, n \geq n_1, \theta_{\mathbf{MMP}_n}(\eta_n) \leq -2\delta^*$. Hence, for all $n \geq n_1$ and $\lambda \in [0,1]$,

$$\begin{aligned}
&\psi_n(\eta_n + \lambda h_n(\eta_n)) - \psi_n(\eta_n) \\
&\quad = \max_{j \in \mathbf{q}} \{ g^j_n(\eta_n) - \psi_n(\eta_n) + \lambda \langle \nabla g^j_n(\eta_n), h_n(\eta_n) \rangle_H + \tfrac{1}{2}\|h_n(\eta_n)\|^2_H \\
&\qquad + \lambda \textstyle\int_0^1 \langle \nabla g^j_n(\eta_n + s\lambda h_n(\eta_n)) - \nabla g^j_n(\eta_n), h_n(\eta_n) \rangle_H \\
&\qquad - \tfrac{1}{2}\|h_n(\eta_n)\|^2_H \} \\
&\quad \leq \lambda [\theta_{\mathbf{MMP}_n}(\eta_n) + \lambda L \|h_n(\eta_n)\|^2_H],
\end{aligned} \tag{5.15a}$$

where L is as in (5.2b). Since the sets G_n are uniformly bounded, there exists a $b < \infty$ such that $\|h_n(\eta_i)\|_H \leq b$ for all $n \in \mathbb{Z}_+$. Hence it follows from (5.15a) that there exists a $\hat{\lambda} \in (0, 1]$, such that for all $n \geq n_1$,

$$\psi_n(\eta_n + \lambda_n(\eta_n)h_n(\eta_n)) - \psi_n(\eta_n) \leq \psi_n(\eta_n + \hat{\lambda}h_n(\eta_n)) - \psi_n(\eta_n) \leq -\hat{\lambda}\delta^*, \tag{5.15b}$$

which completes the second part of our proof.

(c) Now, by construction, we have that $\psi_{n(i)}(\eta_{i+1}) - \psi_{n(i)}(\eta_i) \leq -1/2^{\gamma n(i)}$, and hence, making use of Assumption 5.9,

$$\psi(\eta_{i+1}) - \psi(\eta_i) \leq -\frac{1}{2^{n(i)}}(2^{(1-\gamma)n(i)} - \hat{K}). \tag{5.15c}$$

Hence, since $n(i) \to \infty$ as $i \to \infty$, there exists an i_o such that for all $i \geq i_o, \psi(\eta_{i+1}) - \psi(\eta_i) \leq 0$.

Now, for the sake of contradiction, suppose that the sequence $\{\eta_i\}_{i=0}^{\infty}$ has an accumulation point $\hat{\eta} \in \overline{H}$ such that $\overline{\theta}_{\mathbf{MMP}}(\hat{\eta}) < 0$. Then there exists an infinite subset I of the positive integers such that $\eta_i \overset{I}{\to} \hat{\eta}$ (i.s.c.m.) as $i \to \infty$, and hence because $\overline{\psi}(\cdot)$ is continuous and $\psi(\eta_i) = \overline{\psi}(\eta_i), \psi(\eta_i) \overset{I}{\to} \hat{\eta}$ as $i \to \infty$. Now, $\{\psi(\eta_i)\}_{i=i_o}^{\infty}$ is monotone decreasing, and hence we conclude that $\psi(\eta_i) \to \overline{\psi}(\hat{\eta})$ as $i \to \infty$. Since $n(i) \to \infty$, it follows from (b) that there exist a $\hat{\delta} > 0$ and an integer i_1, such that for all $i \geq i_1, i \in I, \psi_{n(i)}(\eta_{i+1}) - \psi_{n(i)}(\eta_i) \leq -\hat{\delta} < 0$. Hence, for all $i \in I$,

$$\psi(\eta_{i+1}) - \psi_{n(i)}(\eta_i) \leq -\hat{\delta} + \frac{\hat{K}}{2^{n(i)}}. \tag{5.15d}$$

Since $n(i) \to \infty$ as $i \to \infty$, (5.15d) contradicts the convergence of the sequence $\{\psi(\eta_i)\}_{i=0}^{\infty}$. This completes our proof. □

Two observations are in order at this point. First, it follows from (5.15c) that the cost sequence is eventually monotone decreasing. Since it is bounded, it must converge. Second, it can be deduced from the above proof that $\theta_{\mathbf{MMP}n(i)}(\eta_i) \to 0$, which implies in turn that $h_{n(i)} \to 0$. Hence, referring to Theorem 1.3.66 in [Pol.3], we conclude that if $\psi(\cdot)$ has only a finite number of stationary points, then the sequence of trajectories $\{x^{\eta_i}\}$ must converge. Furthermore, if $\{\eta_i\}$ has an accumulation point in the H topology, then the entire sequence $\{\eta_i\}$ must converge to that point.

For problem **CMP**, we will extend the unified phase I–phase II method of feasible directions, using an Armijo step size rule, described in [Pol.2].

ALGORITHM 5.12

Parameters. $\gamma > 0, \alpha, \beta \in (0, 1)$.

Data. $n_0, \eta_0 \in H_{n_0}$.

Step 0. Set $i = 0, n(0) = n_0$.

Step 1. Compute the value of the *optimality function* $\theta_i = \theta_{\mathbf{CMP}_{n(i)}}(\eta_i)$, and the corresponding *search direction* $h_i = h_{n(i)}(\eta_i)$, where

$$\begin{aligned}\theta_{\mathbf{CMP}_{n(i)}}(\eta_i) \triangleq \min_{\eta \in H_{n(i)}} \Big\{ &\tfrac{1}{2}\|\eta - \eta_i\|_H^2 + \max\{-\psi_{n(i)}(\eta_i)_+ + \langle \nabla g^0_{n(i)}(\eta_i), \eta - \eta_i\rangle_H, \\ &g^j_{n(i)}(\eta_i) - \psi(\eta_i)_+ + \langle \nabla g^j_n(\eta_i), \eta - \eta_i\rangle_H, j \in \mathbf{q}\}\Big\}.\end{aligned} \tag{5.16a}$$

$$h_{n(i)}(\eta_i) \triangleq \arg \min_{\eta \in H_{n(i)}} \Big\{ \tfrac{1}{2}\|\eta - \eta_i\|_H^2 + \max\{-\psi_{n(i)}(\eta_i)_+ + \langle \nabla g^0_{n(i)}(\eta_i), \eta - \eta_i\rangle_H, g^j_{n(i)}(\eta_i) - \psi(\eta_i)_+ + \langle \nabla g^j_n(\eta_i), \eta - \eta_i\rangle_H, j \in \mathbf{q}\} \Big\} - \eta_i. \tag{5.16b}$$

Step 2. Compute the *step size* λ_i:

$$\lambda_i = \max\{\beta^k | k \in \mathbb{N}, F_{n(i)}(\eta_i + \beta^k h_i | \eta_i) \leq \beta^k \alpha \theta_i\}, \tag{5.16c}$$

where, for $n \in \mathbb{Z}_+, \eta, \eta* \in H_n$,

$$F_n(\eta|\eta^*) \triangleq \max\{g^0_n(\eta) - g^0_n(\eta^*) - \psi_n(\eta^*)_+, \psi_n(\eta) - \psi_n(\eta^*)_+\}. \tag{5.16d}$$

Step 3. Set $\eta^* = \eta_i + \lambda_i h_i$.
If

$$F_{n(i)}(\eta^*|\eta_i) > -\frac{1}{2^{\gamma n(i)}}. \tag{5.16e}$$

Replace $n(i)$ by $n(i)+1$, and go to Step 1. Else set $n(i+1) = n(i), \eta_{i+1} = \eta_i + \lambda_i h_i$.

Step 4. Replace i by $i+1$ and go to Step 1.

THEOREM 5.13. *Suppose that* (i) *for every* $n \in \overline{H}$ *such that* $\overline{\psi}(\eta) \geq 0, \overline{\theta}_{\mathbf{MMP}}(\eta) < 0$; *and* (ii) *for every* $n \in \mathbb{Z}_+$ *and every* $\eta \in H_n$ *such that* $\psi_n(\eta) \geq 0, \theta_{\mathbf{MMP}_n}(\eta) < 0$. *If Algorithm* 5.12 *constructs a sequence* $\{\eta_i\}_{i=0}^{\infty}$, *then this sequence has accumulation points in* $\overline{H} \triangleq \overline{G} \times [\tau_{\min}, \tau_{\max}]$, *and every such accumulation point,* η, *satisfies* $\overline{\psi}(\hat{\eta}) \leq 0, \overline{\theta}_{\mathbf{CMP}}(\hat{\eta}) = 0$.

Proof. First we note that since $\overline{H}$ is sequentially compact, the sequence $\{\eta_i\}_{i=0}^{\infty}$ must have accumulation points in the relaxed controls topology. The rest of our proof is in three parts: (a) we will show that $n(i) \to \infty$ as $i \to \infty$, then (b) we will show that for any $\eta^* = (\sigma^*, \tau^*) \in \overline{H}$ such that $\overline{\theta}_{\mathbf{CMP}}(\eta^*) < 0$, there exists an integer n^* and a $\delta^* > 0$, such that for all $n(i) \geq n^*$, and any η_i sufficiently close to $\eta^*, F_{n(i)}(\eta_{i+1}|\eta_i) \leq -\delta^*$, and (c) we will obtain a contradiction by showing that if the theorem is not true, then either $\psi(\eta_i) \to -\infty$ as $i \to \infty$ or $g^0(\eta_i) \to -\infty$ as $i \to \infty$.

(a) Suppose that there is a finite integer n^* such that $n(i) = n^*$ for all $i \geq i^*$, with $i^* < \infty$. Then the test (5.16e) fails to be satisfied for all $i \geq i^*$, and hence $F_{n^*}(\eta_{i+1}|\eta_i) \leq -(1/2^{n^*})^\gamma$ for all $i \geq i^*$. Without loss of generality, suppose that $\psi_{n^*}(\eta_{i^*}) \geq 0$ and that $\psi_{n^*}(\eta_i) > 1/n^*$ for all $i \geq i^*$. Then $\psi_{n^*}(\eta_{i+1}) - \psi_{n^*}(\eta_i)_+ \leq -(1/2^{n^*})^\gamma$ for all $i \geq i^*$, and hence there must exist an i_0 such that $\psi_{n^*}(\eta_i) \leq 0$ for all $i \geq i_0$. Furthermore, for $i \geq i_0$, we must also have that $g^0_{n^*}(\eta_{i+1}) - g^0_{n^*}(\eta_i) \leq -(1/2^{n^*})^\gamma$, which implies that $g^0_{n^*}(\eta_i) \to -\infty$ as $i \to \infty$. However, since H_n is compact and $g^0_{n^*}(\cdot)$ is continuous, this is clearly impossible, and we have a contradiction. Hence we must have that $n(i) \to \infty$ as $i \to \infty$.

(b) The proof of this part is quite similar to that of part (b) in the proof of Theorem 5.13, and is therefore omitted.

(c) For any $\eta, \eta^* \in H$, let $F_n(\eta|\eta^*)$ be defined by

$$F(\eta|\eta^*) \triangleq \max\{g^0(\eta) - g^0(\eta^*) - \psi(\eta^*)_+, \psi(\eta) - \psi(\eta^*)_+\}. \tag{5.17a}$$

Then, because of the test (5.16e) and Assumption 5.9, we have that for all $i \in \mathbb{Z}_+$,

$$F(\eta_{i+1}|\eta_i) \leq -\frac{1}{2^{n(i)}}(2^{(1-\gamma)n(i)} - 2\hat{K}). \tag{5.17b}$$

Since $\gamma \in (0,1)$ and $n(i) \to \infty$ as $i \to \infty$, it follows that there is an $i_1 \in \mathbb{Z}_+$ such that

$$F(\eta_{i+1}|\eta_i) \leq 0, \qquad \forall i \geq i_1, \tag{5.17c}$$

and hence, for all $i \geq i_1$,

$$\psi(\eta_{i+1}) - \psi(\eta_i)_+ \leq 0, \tag{5.17d}$$

and

$$g^0(\eta_{i+1}) - g^0(\eta_i) - \psi(\eta_i)_+ \leq 0. \tag{5.17e}$$

Now suppose that $\eta_i \overset{I}{\to} \hat{\eta} \in \overline{H}$ (i.s.c.m.) as $i \to \infty$ and that $\overline{\theta}(\hat{\eta}) < 0$. We distinguish between two possibilities:

(i) $\psi(\eta_i) > 0$ for all $i \geq i_1$. Then, by (5.17d), $\{\psi(\eta_i)\}_{i=i_1}^{\infty}$ is a monotone decreasing sequence, and, since by continuity $\psi(\eta_i) \overset{I}{\to} \overline{\psi}(\hat{\eta})$ as $i \to \infty$, it follows that $\psi(\eta_i) \to \overline{\psi}(\hat{\eta})$ as $i \to \infty$. It now follows from (b) and Assumption 5.9 that there exist a $\hat{\delta}$ and an $i_2 \geq i_1$ such that for all $i \in I, i \geq i_2$,

$$\psi(\eta_{i+1}) - \psi(\eta_i) \leq F_{n(i)}(\eta_{i+1}|\eta_i) + \frac{2\hat{K}}{2^{n(i)}} \leq -\hat{\delta} + \frac{2\hat{K}}{2^{n(i)}}, \tag{5.17f}$$

which contradicts the fact that $\psi(\eta_i) \to \overline{\psi}(\hat{\eta})$ as $i \to \infty$. Hence we must have that $\overline{\theta}(\hat{\eta}) = 0$, and hence, by assumption, that $\overline{\psi}(\hat{\eta}) \leq 0$ also holds.

(ii) There exists an $i_3 \geq i_1$ such that $\psi(\eta_{i_3}) \leq 0$. Then it follows from (5.17d) that $\psi(\eta_i) \leq 0$ for all $i \geq i_3$. Next, by (5.17e), $\{g^0(\eta_i)\}_{i=i_3}^{\infty}$ is a monotone decreasing sequence, and, since by continuity $g^0(\eta_i) \overset{I}{\to} \overline{g}^0(\hat{\eta})$ as $i \to \infty$, it follows that $g^0(\eta_i) \to \overline{g}^0(\eta^*)$ as $i \to \infty$, (i.s.c.m.). It now follows again from (b) and Assumption 5.9 that there exists an $i_4 \geq i_1$ such that for all $i \in I, i \geq i_4$,

$$g^0(\eta_{i+1}) - g^0(\eta_i) \leq F_{n(i)}(\eta_{i+1}|\eta_i) \leq -\hat{\delta} + \frac{2\hat{K}}{2^{n(i)}} \leq -\hat{\delta}/2, \tag{5.17g}$$

which contradicts the fact that $g^0(\eta_i) \to \overline{g}^0(\eta^*)$ as $i \to \infty$. Hence we must have that $\overline{\theta}(\eta^*) = 0$, which completes our proof. □

Again we can make some observations. First, it follows from (5.17f) that if the tail of the sequence $\{\eta_i\}$ is infeasible, then the constraint violation function $\psi(\cdot)$ eventually decreases monotonically to zero. In this case, making use of (5.17b), we can conclude that either the cost sequence $\{g^0(\eta_i)\}$ converges, or it has infinitely many accumulation points, a rather unlikely event. If the tail of the sequence $\{\eta_i\}$ is feasible, then the the tail of the cost sequence is monotone decreasing, and hence, since it is bounded, it converges. Second, it can be deduced from the above proof that $\theta_{\mathbf{CMP}n(i)}(\eta_i) \to 0$, which implies in turn that $h_{n(i)} \to 0$. Hence, referring to Theorem 1.3.66 in [Pol.3], we conclude that if $\overline{\theta}_{\mathbf{CMP}}(\cdot)$ has only a finite number of zeros, then the trajectory sequence $\{x^{\eta_i}\}$ must converge. Furthermore, if $\{\eta_i\}$ has an accumulation point in the H topology, then the entire sequence $\{\eta_i\}$ must converge to that point.

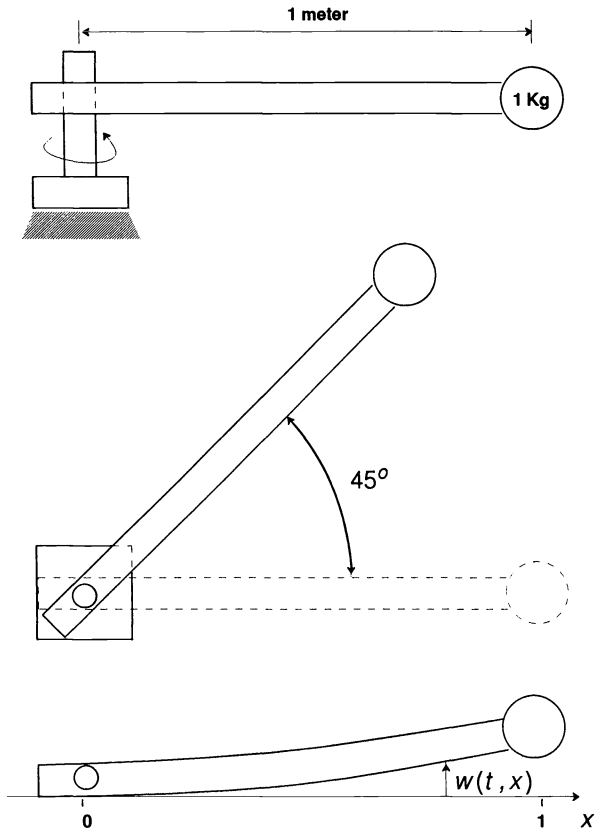

FIG. 1. *Configuration of slewing experiment.*

6. Computational results. We carried out three computational experiments involving the slewing motion of the hollow aluminum tube depicted in Fig. 1. The tube is one meter long, has a cross sectional radius of 1.0 cm, and a thickness of 1.6 mm. Attached to one end of the tube is a mass of 1 kg, and attached to the other end is a shaft connected to a motor. To reduce the computational burden, we neglected small nonlinear terms, the coupling between the flexural and extensional vibrations, and assumed that the acceleration can be controlled, instead of assigning a mass to the shaft and assuming that the torque is controlled. These simplifications lead to a model in the form of the standard Euler–Bernoulli tube with Kelvin–Voigt viscoelastic damping:

$$\begin{aligned} &mw_{tt}(t,x) + CIw_{txxxx}(t,x) + EIw_{xxxx}(t,x) - m\Omega^2(t)w(t,x) \\ &\quad = -\frac{m}{1+m/3}u(t)x, \qquad t \in [0,\tau], \quad x \in [0,1], \end{aligned} \tag{6.1a}$$

with boundary conditions:

$$w(t,0) = 0, \quad w_x(t,0) = 0, \quad CIw_{txx}(t,1) + EIw_{xx}(t,1) = 0, \quad t \in [0,\tau], \tag{6.1b}$$

$$\Omega^2(t)w(t,1) - w_{tt}(t,1) - u(t) - CIw_{txxx}(t,1) - EIw_{xxx}(t,1) = 0, \quad t \in [0,\tau], \tag{6.1c}$$

(6.1d) $$\Theta_t(t) = \Omega(t), \quad t \in [0, \tau], \quad \Omega_t(t) = u(t), \quad t \in [0, \tau],$$

where $w(t, x)$ is the displacement of the tube from the *shadow tube* (which remains undeformed during the motion) due to bending as a function of time and distance along the tube; $u(t)$ is the acceleration produced by the motor, and $\Omega(t)$ is the resulting angular velocity (in radians per second), and $\Theta(t)$ is the angular displacement of the rigid body (in radians). The values for the parameters in (6.1a)–(6.1c) were chosen to be $m = .2815$ kg/m, $I = 1.005 \times 10^{-8} m^4, C = 6.89 \times 10^7$ pascals/sec.; $E = 6.89 \times 10^9$ pascals, as given in the CRC Handbook of Material Science. The tube is very lightly damped (0.1 percent).

When time is normalized to the interval [0, 1], the dynamics become:

(6.2a) $$\begin{aligned} &mw_{tt}(t,x) + \tau CIw_{txxxx}(t,x) + \tau^2 EIw_{xxxx}(t,w) - \tau^2 m\Omega^2(t)w(t,x) \\ &\quad = -\tau^2 \frac{m}{1+m/3} u(t)x, \qquad t \in [0,1], \quad x \in [0,1], \end{aligned}$$

with boundary conditions:

(6.2b) $$w(t,0) = 0, \quad w_x(t,0) = 0, \quad CIw_{txx}(t,1) + \tau EIw_{xx}(t,1) = 0, \quad t \in [0,1],$$

(6.2c) $$\begin{aligned} &\tau^2\Omega^2(t)w(t,1) - w_{tt}(t,1) - \tau^2 u(t) - \tau CIw_{txxx}(t,1) \\ &\quad -\tau^2 EIw_{xxx}(t,1)ad = 0, \quad t \in [0,1], \end{aligned}$$

(6.2d) $$\Theta_t(t) = \tau\Omega(t), \quad t \in [0,1], \quad \Omega_t(t) = \tau u(t), \quad t \in [0,1].$$

To transcribe these dynamics into the standard form (2.2a), we proceed as follows. First we define $\zeta(t) \in X \triangleq L_2([0,1]) \times \mathbb{R}$, and $\Phi : X \times \mathbb{R}^2 \to X$ by

(6.2e) $$\begin{aligned} \zeta(t) &\triangleq \begin{bmatrix} w(t,x) \\ w(t,1) \end{bmatrix}, \\ \Phi(\zeta(t), u(t), \Omega(t)) &\triangleq \tau^2 \begin{bmatrix} \Omega^2(t)w(t,x) - u(t)x/(1+m/3) \\ \Omega^2(t)w(t,1) - u(t) \end{bmatrix}. \end{aligned}$$

Next we define the operators A_1 and Q, and their respective domains $D(A_1)$ and $D(Q)$ as follows:

(6.2f) $$\begin{aligned} D(A_1) \triangleq \Big\{ \zeta = \begin{bmatrix} \zeta_1 \\ \zeta_2 \end{bmatrix} \in X \,|\, &\zeta_{1xxxx} \in L_2([0,1]), \zeta_1(0) \\ &= \zeta_{1x}(0) = \zeta_{1xx}(1) = 0, \zeta_1(1) = \zeta_2 \Big\}, \end{aligned}$$

$A_1 : D(A_1) \to X$ is defined by

(6.2g) $$A_1 \begin{bmatrix} \zeta_1 \\ \zeta_2 \end{bmatrix} = \tau^2 \begin{bmatrix} \frac{\mathrm{EI}}{\mathrm{m}} \zeta_{1xxxx}(\cdot) \\ \mathrm{EI}\zeta_{1xxx}(1) \end{bmatrix},$$

and with $D(Q) \triangleq D(A_1), Q : D(Q) \to X$ is defined by $Q \triangleq C/\tau E A_1$. Then (6.2a)–(6.2c) can be written in the form

(6.2h) $$\zeta_{tt} + Q\zeta_t + A_1\zeta = \Phi(\zeta, u, \Omega).$$

It is shown in §6.4 and Appendix II in [Bak.1], that Φ is a an operator that is Lipschitz continuous on bounded sets, and that A_1 and Q satisfy the assumptions in [Gib.1] needed

to derive the infinitesimal generator of a contraction semigroup. We give a brief outline of this derivation; see [Gib.1] for the details. First, we define the space $V \triangleq D(A_1^{1/2}) \times X$, so that if $y = (y_1, y_2) \in V$, then

$$\|y\|^2 = \langle y_1, A_1 y_1 \rangle + \langle y_2, y_2 \rangle, \tag{6.2i}$$

where $\langle \cdot, \cdot \rangle$ is the L_2 inner product. For any given $t \in [0, 1]$, let $\nu(t) \in V$ be defined by $v(t) \triangleq (w(t,x), w(t,1), w_t(t,x), w_t(t,1))$, and let the operator $A_2 : D(A_2) \to V$, where $D(A_2) = D(A_1) \times D(A_1) \subset V$, be defined by

$$A_2\nu(t) \triangleq \begin{bmatrix} 0 & I \\ -A_1 & -Q \end{bmatrix} \nu(t) = \begin{bmatrix} w_t(t,x) \\ w_t(t,1) \\ -\tau \frac{CI}{w} w_{txxxx}(t,x) - \tau^2 \frac{EI}{m} w_{xxxx}(t,x) \\ -\tau CI w_{txxx}(t,1) - \tau^2 EI w_{xxx}(t,1) \end{bmatrix}. \tag{6.2j}$$

It is shown in §2 in [Gib.1], that there exists a unique maximal dissipative extension of A_2 to A_3, where A_3 is the generator of a contraction semigroup that represents the free response of the system (6.2h). It is shown in [Sho.1] that A_3 generates an analytic semigroup. The standard form (2.2a) is then obtained by defining the state by $z(t) \triangleq (\nu(t), \Theta, \Omega) \in V \times \mathbb{R}^2$, and

$$A \triangleq \begin{bmatrix} A_3 & 0 & 0 \\ 0 & 0 & \tau \\ 0 & 0 & 0 \end{bmatrix}, \quad F(z(t), u(t)) \triangleq \begin{bmatrix} 0 \\ 0 \\ \Phi(\zeta(t), u(t), \Omega(t)) \\ 0 \\ \tau u(t) \end{bmatrix}$$

$$= \begin{bmatrix} 0 \\ 0 \\ \tau^2 \Omega^2(t) w(t,x) - \tau^2 u(t) x/(1 + m/3) \\ \tau^2 \Omega^2(t) w(t,1) - \tau^2 u(t) \\ 0 \\ \tau u(t) \end{bmatrix}. \tag{6.2k}$$

It follows that A satisfies Assumption 3.2 and that F satisfies Assumption 3.1.

We considered three slewing problems that shared two requirements: (a) The tube had to be rotated 45 degrees, from rest[5] to rest, and (b) the acceleration produced by the motor was limited to five rads/sec^2. The first problem, $\mathbf{P_1}$, was a minimum time problem, subject to the above constraints; the second problem, $\mathbf{P_2}$, was a minimum energy problem, subject to the above constraints and an upper bound on the time allowed; and the last problem, $\mathbf{P_3}$, was a minimum time problem, subject to the above constraints and an upper bound on the potential energy due to deformation of the tube throughout the entire maneuver (i.e., a worst case deformation constraint).

The transcription of the problems $\mathbf{P_1}$, $\mathbf{P_2}$, and $\mathbf{P_3}$ into the form (2.3b) required the introduction of the following functions. With τ denoting the final time, let

$$g^1(u, \tau) \triangleq \tau. \tag{6.3}$$

The energy consumed by the maneuver is given by

$$g^2(u, \tau) \triangleq \int_0^1 u(t)^2 dt. \tag{6.4}$$

[5] We say that *the tube is at rest* when the total energy of the tube is zero. This energy is composed of the energy due to rigid body motion and energy due to vibration and deformation.

The angular error at the final time is measured by

$$g^3(u,\tau) \triangleq (\Theta(1) - \pi/4)^2. \tag{6.5}$$

The rigid body energy at final time is given by

$$g^4(u,\tau) \triangleq \Omega(1)^2. \tag{6.6}$$

The kinetic energy due to vibration of the tube at time τ is given by

$$g^5(u,\tau) \triangleq \frac{m}{2}\int_0^1 w_t(t,x)^2 dx, \tag{6.7}$$

and the potential energy due to deformation of the tube at time τ is given by

$$g^6(u,\tau) \triangleq P(\tau,u) = \frac{EI}{2}\int_0^1 w_{xx}(\tau,x)^2 dx. \tag{6.8}$$

We see that the tube is at rest when $g^4(u,\tau) = g^5(u,\tau) = g^6(u,\tau) = 0$.

The deformation constraint for problem $\mathbf{P_3}$ has the form $P(t,u) \leq f(t)$ for all $t \in [0,1]$, where $f(\cdot)$ is a given positive bound function. This is a *state-space constraint.* To reduce the computational burden, we replaced it by the equivalent requirement $g^7(u,\tau) \leq 0$, where

$$g^7(u,\tau) \triangleq \int_0^1 [\max\{P(t,u) - f(t), 0\}]^2 dt. \tag{6.9}$$

Since $P(t,u)$ is continuous, $g^7(u,\tau) = 0$ if and only if $P(t,u) \leq f(t)$ for all $t \in [0,\tau]$. Transformations such as (6.9) must be used with great care because for any feasible pair $(u,\tau), g^7(u,\tau) = 0$ and $\nabla g^7(u,\tau) = 0$, and hence $\theta(u,\tau) = 0$, which causes our algorithm to stop up at such a pair. However, the problems caused by this violation can be circumvented by initializing the algorithm with an infeasible point, keeping the parameter γ, in Algorithm 5.10, small, and introducing an ε into the problem statement, as shown below.

It can be shown that all the above functions $g^j : G \times [0,\tau] \to \mathbb{R}$ are continuously differentiable (in the $L_2[0,1] \times \mathbb{R}$ topology) in u and t for all $j \in \{1,2,\ldots,7\}$. To conform with the format of problem (2.3b), we relax each of the equality constraints by a small amount. The three problems now acquire the following mathematical form,[6] where $G \triangleq \{u \in L_2[0,1] \mid |u(t)| \leq 1 \text{ for all } t \in [0,1]\}$ and $\mathbf{T} = [\tau_0, \tau_f]$, with $\tau_0 > 0$ very small and $\tau_f < \infty$ very large.

$$\begin{aligned}\mathbf{P_1} : \min\{g^1(u,\tau) \mid & g^3(u,\tau) - \varepsilon \leq 0, g^4(u,\tau) - \varepsilon \leq 0, g^5(u,\tau) - \varepsilon \leq 0,\\ & g^6(u,\tau) - \varepsilon \leq 0, (u,\tau) \in G \times \mathbf{T}\}.\end{aligned} \tag{6.10a}$$

$$\begin{aligned}\mathbf{P_2} : \min\{g^2(u,\tau) \mid & g^1(u,\tau) - \tau_f \leq 0, g^3(u,\tau) - \varepsilon \leq 0, g^4(u,\tau) - \varepsilon \leq 0,\\ & g^5(u,\tau) - \varepsilon \leq 0, g^6(u,\tau) - \varepsilon \leq 0, (u,\tau) \in G \times \mathbf{T}\}.\end{aligned} \tag{6.10b}$$

$$\begin{aligned}\mathbf{P_3} : \min\{g^1(u,\tau) \mid & g^3(u,\tau) - \varepsilon \leq 0, g^4(u,\tau) - \varepsilon \leq 0, g^5(u,\tau) - \varepsilon \leq 0,\\ & g^6(u,\tau) - \varepsilon \leq 0, g^7(u,\tau) - \varepsilon \leq 0, (u,\tau) \in G \times \mathbf{T}\}.\end{aligned} \tag{6.10c}$$

[6] Note that we find it convenient at this point to abandon the convention that the cost function is $g^0(\cdot,\cdot)$ as well as the linear numbering of the constraints.

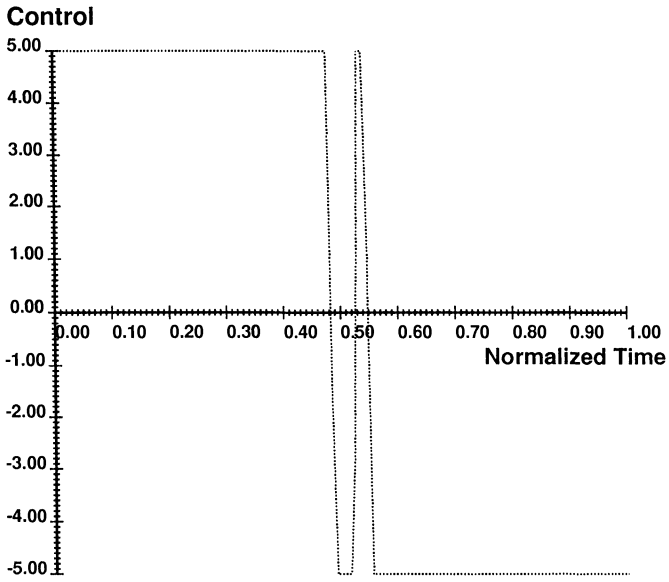

FIG. 2. *Final control for Problem* 1.

In our experiments, we set $\varepsilon = 10^{-4}$. Thus, with this relaxation, we are requiring that the final value of the angle Θ be in the interval $[45° - 0.5°, 45° + 0.5°]$. We assume that because of model simplifications and other inevitable modeling errors, a linear feedback system would be used to assure final pointing accuracy.

In the computational experiments reported in this paper, the term $\Omega^2(t)$ was neglected in (6.1a)–(6.1c). Similar results were obtained in computational experiments in which the term $\Omega^2(t)$ was kept. We used a cubic Hermit spline implementation of the Finite Element Method for spatial discretization and Newmark's β-method, with $\beta = 0$, for temporal discretization of both responses and sensitivities.[7] This approach is quite stable and gives accurate simulations. The results of our computational experiments are shown in Figs. 2–11.

PROBLEM $\mathbf{P_1}$. For simplicity, we chose the zero function as the initial control and 2 for an initial value for the maneuver time. The initial discretization consisted of 32 time steps and six finite elements. The discretization was refined at iterations 67, 99, and 123. Figure 2 is a graph of the control after 150 iterations. At this point, the number of time steps was 256 and the number of finite elements 48. Figure 3(a) is a graph of $\psi_{q_s,q_t}(u,\tau)$ as a function of the iteration number. Figure 3(b) shows $\psi_{q_s,q_t}(u,\tau)$ for the first 15 iterations. After precision refinement, the algorithm finds a control $u \in G_{q_t}$ and final time $\tau \in \mathbf{T}$ such that $\psi_{q_s,q_t}(u,\tau) < 0$ in only a few additional iterations. Note that each time precision of discretization was increased, the value of $\psi_{q_s,q_t}(u_i,\tau_i)$ increases. This is due to improvement in the accuracy of the evaluation of the partial differential equation. This increase in constraint violation $\psi_{q_s,q_t(u_i,\tau_i)}$ decreases each time the discretization is increased and we see that in the limit the increase is zero. Figure 4 is the graph of the cost as a function of iteration number. Figure 5 is the graph of $w(t,1)$, the displacement of the tip of the tube, from the *shadow tube*, as a function of time. The maximum displacement

[7] See [Bak.1, Chap 8] for implementation details, that are based on the results in [Fuj.1], [Fuj.2], [Fuj.3], [Ode.1].

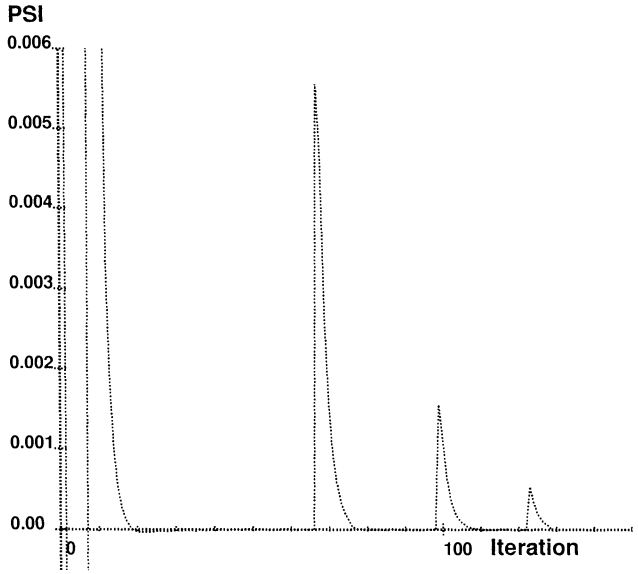

FIG. 3a. *Constraint violation in Problem* 1: 150 *iterations.*

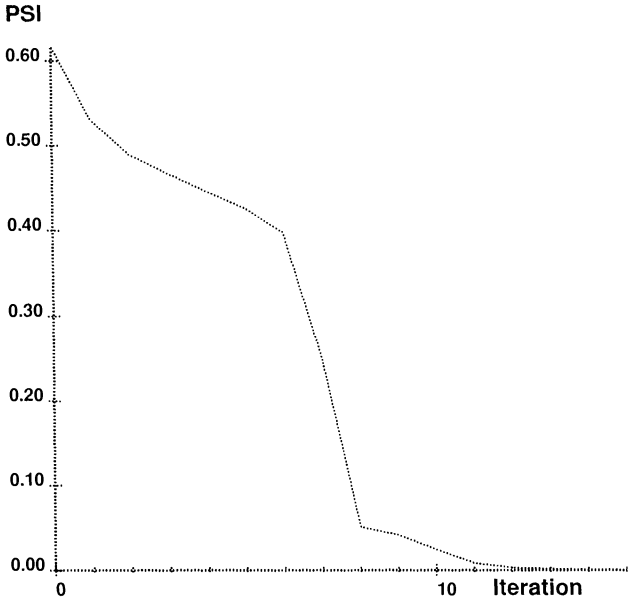

FIG. 3b. *Constraint violation in Problem* 1: *First* 15 *iterations.*

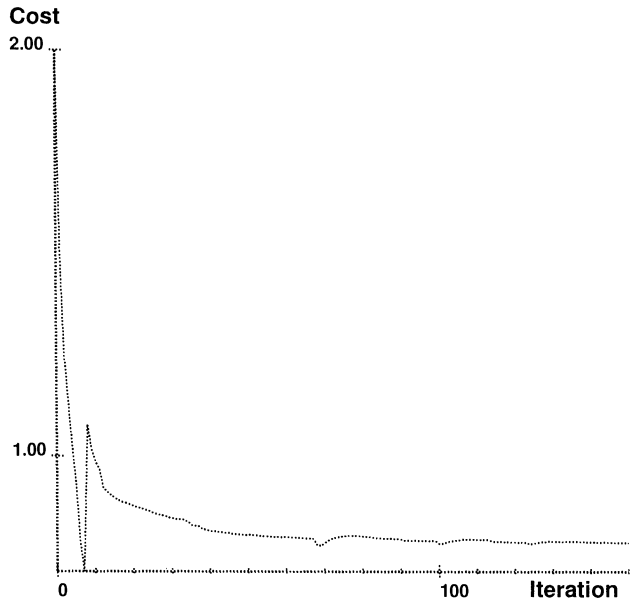

FIG. 4. *Cost v/s iteration number for Problem* 1.

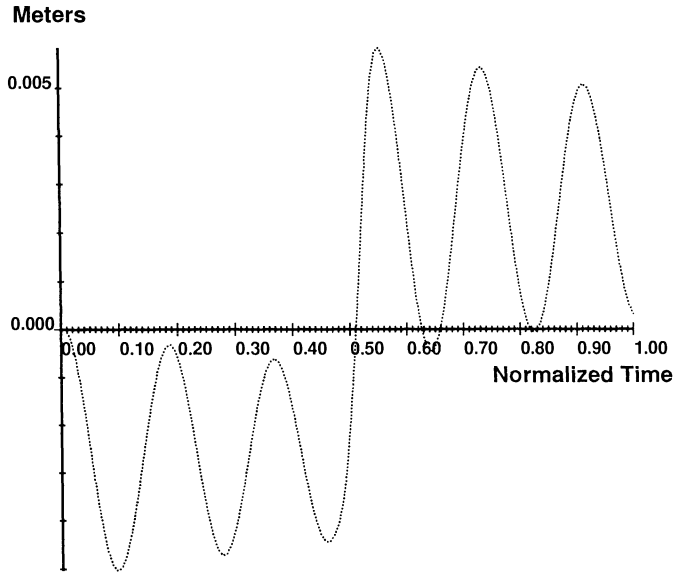

FIG. 5. *Displacement of tip of tube, Problem* 1.

of the tip is about 5 mm and is within the range of validity of the Euler–Bernoulli model. The tip displacement is large between 0.36 seconds and 0.437 seconds. Figure 6 is a profile of the tube deformation, $w(t, x)$ (see Fig. 1), during this interval. The total time for the entire maneuver is 0.7886 seconds.

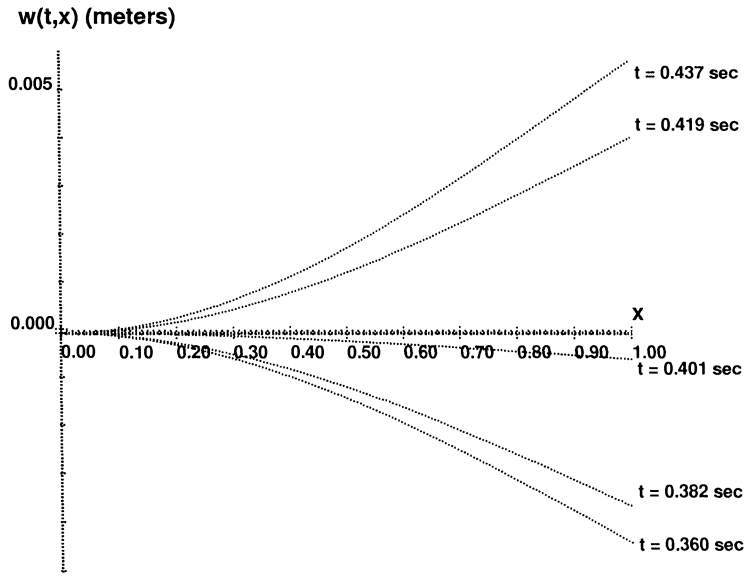

FIG. 6. *Beam profile.*

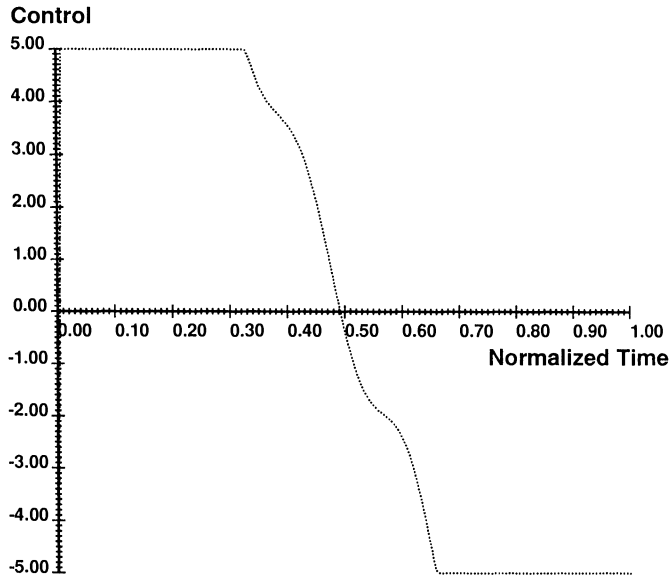

FIG. 7. *Final control for Problem* 2: *Time of maneuver* = 0.800 *seconds.*

PROBLEM $\mathbf{P_2}$. Figure 7 is the graph of the control produced by minimizing the total input energy while constraining the final time to be less than 0.800 seconds, i.e., only 1.4 percent longer than the minimum time computed for $\mathbf{P_1}$. The resulting final time is 0.800. The control is much smoother than the minimum time control, and the total energy consumption is reduced by 18 percent, from 19.15 to 15.72. Figure 8 is the graph of the control when the bound on the final time is extended to 1.00 second, 27 percent over the

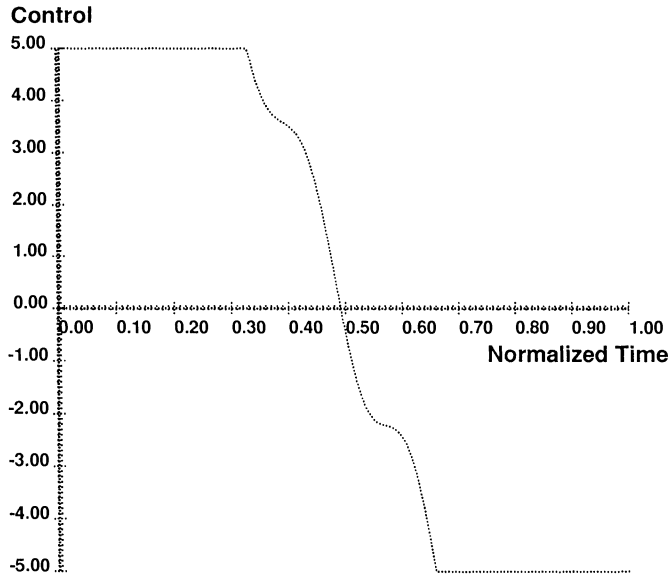

FIG. 8a. *Final control for Problem* 2: *Time of maneuver* = 0.900 *seconds.*

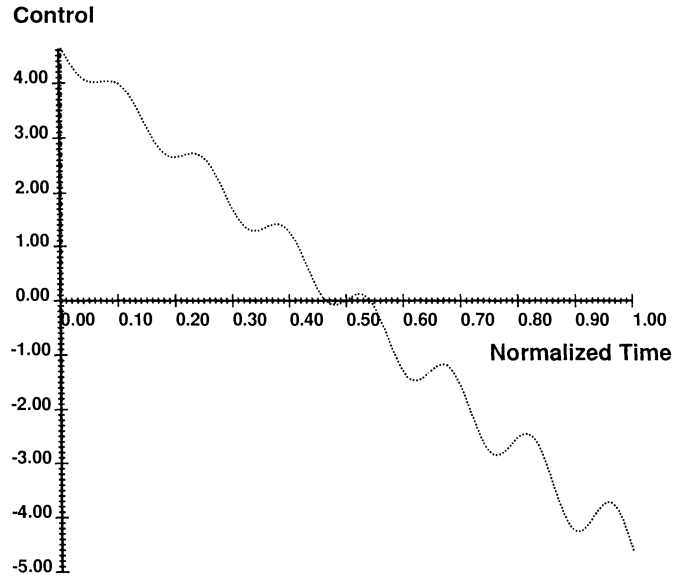

FIG. 8b. *Final control for Problem* 2: *Time of maneuver* = 1.000 *seconds.*

minimum time for the maneuver. The result is a total energy is reduction by 62 percent, to 7.27.

PROBLEM $\mathbf{P_3}$. In problem $\mathbf{P_3}$, we have the additional requirement to keep the potential energy, which is a measure of the total tube deformation, below the parabola (B) for all time. Figure 9 shows the optimal control for problem $\mathbf{P_3}$. The optimal final time for this case is 0.8177 seconds, an increase of 3.7 percent over the solution of problem $\mathbf{P_1}$. Figure 10

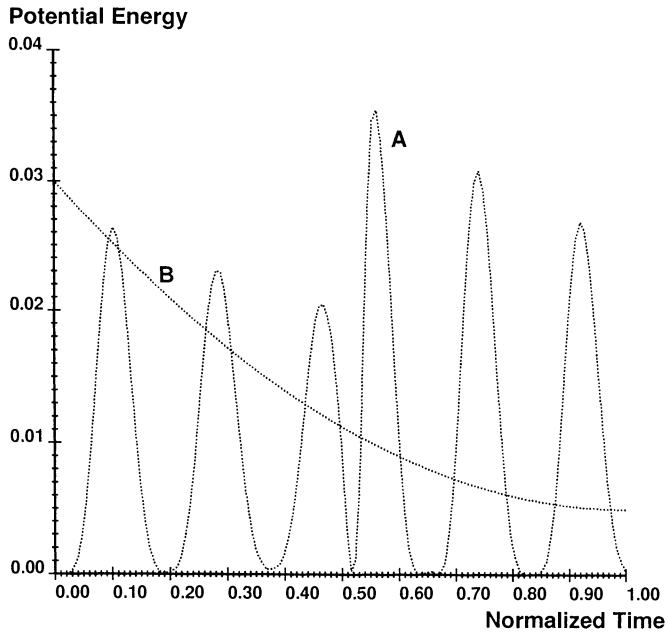

FIG. 9. *Problem* 1: *Potential energy.*

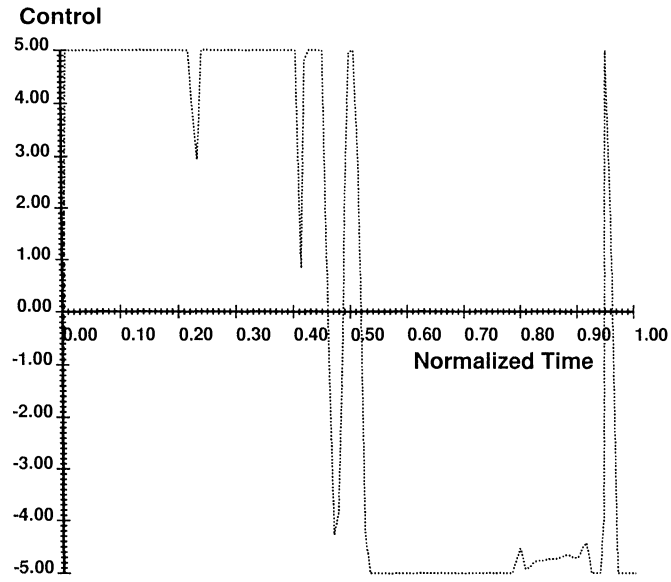

FIG. 10. *Final control for Problem* 3.

shows the potential energy curve for this case, which was constrained to lie below a parabola (B). For comparison in Fig. 11, curve A is the graph of the potential energy of the tube as a function of time for the control generated in solving the minimum time problem $\mathbf{P_1}$.

7. Conclusion. We have presented an approximation theory for the numerical solution of optimal control problems with dynamics in evolution equation form, with control and

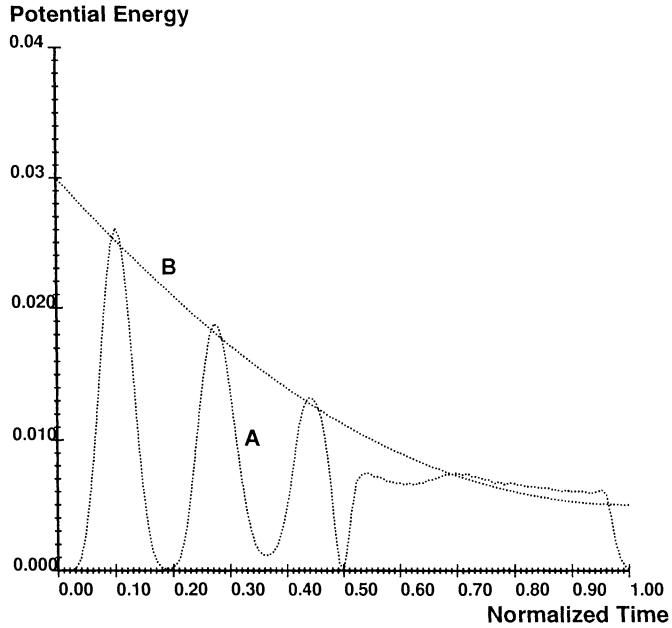

FIG. 11. *Problem* 3: *Potential energy.*

state space constraints. It should be obvious that the theory can be trivially adapted to deal with problems with constraints on the initial state, as well as with unconstrained problems. Although not included in this paper, we have results (reported in [Bak.1], [Bak.2]) which show that our theory can be used in conjunction with finite element techniques to produce reasonably efficient numerical procedures, which have the property that all the accumulation points of the control sequences that they produce satisfy the problem constraints, as well as an optimality condition either for the original or the relaxed problem, depending on whether the accumulation point is in the $L_2^m[0,1]$ topology or in the relaxed controls topology.

Appendix: Differentiability of mild solutions. We will now establish the Frechet differentiability of solutions of (2.2f) with respect to the control $u \in L_2^m[0,1]$ and the scaling parameter τ.

Let $\tilde{M}, \omega \in (0,\infty)$ be such that $\|T(t)\| \leq \tilde{M}e^{\omega t}$ for all $t \in [0,1]$, and let $M \triangleq \tilde{M}e^{\omega \tau_{\max}}$.

LEMMA A.1 (Lipschitz continuity of $z(t,u,\tau)$ in (u,τ).) *There exists* $b_3 \in (0,\infty)$ *such that for all* $u', u \in L_2^m[0,1], t \in [0,1], \tau \in [\tau_{\min}, \tau_{\max}]$,

$$\|z(t,u',\tau') - z(t,u,\tau)\|_X \leq b_3(\|u'-u\|_2^2 + |\tau'-\tau|^2)^{1/2}. \tag{A.1}$$

Proof. For any $u, u' \in L_2^m[0,1]$ and $t \in [0,1]$,

$$\begin{aligned} z(t,u',\tau') - z(t,u,\tau) &= T(\tau' t)z_0 + \int_0^t \tau' T(\tau'(t-s))F(z(s,u',\tau'),u'(s))ds \\ &\quad -T(\tau t)z_0 - \int_0^t \tau T(\tau(t-s))F(z(s,u,\tau),u(s))ds \\ &= [T(\tau' t) - T(\tau t)]z_0 \qquad \text{(A.2a)} \\ &\quad + \int_0^t \{\tau' T(\tau'(t-s))[F(z(s,u',\tau'),u'(s)) \\ &\quad -F(z(s,u,\tau),u(s))] - [\tau T(\tau(t-s)) \\ &\quad -\tau' T(\tau'(t-s))]F(z(s,u,\tau),u(s))\}ds. \end{aligned}$$

Since $\{z(t,u,\tau) \in S \triangleq \{z \in X | \|z\|_X \leq b_1\}$, by Assumption 3.1(ii), we conclude from Assumption 3.1(iii) and Lemma 3.4 that there exists constants $K_S, L \in (0,\infty)$, such that, with $y(t) \triangleq \|z(t,u',\tau) - z(t,u,\tau)\|_X$, for $t \in [0,1]$,

$$y(t) \leq \tau_{\max} M K_S \int_0^t [y(s) + \|u'(s) - u(s)\|_2]\, ds + L|\tau' - \tau|. \tag{A.2b}$$

Applying the Bellman–Gronwall Inequality, and making use of the fact that by the Schwartz Inequality, $\|u\|_1 \leq \|u\|_2$, we obtain that

$$y(t) \leq e^{t_{\max} M K_S}\{\tau_{\max} M K_S \|u' - u\|_1 + L|\tau' - \tau|\} \leq b_3(\|u' - u\|_2^2 + |\tau' - \tau|^2)^{1/2}, \tag{A.2c}$$

where $b_3 \triangleq \sqrt{2}\max\{\tau_{\max} M K_S, L\} e^{\tau_{\max} M K_S}$. □

Next, for $u', u \in L_2^m[0,1]$ and $\tau', \tau \in [\tau_{\min}, \tau_{\max}]$, we define $\delta u = u' - u, \delta\tau = \tau' - \tau$, and $\delta z(\cdot, u, \tau, \delta u, \delta\tau) \in C([0,1], X)$ to be the solution to the equation

$$\begin{aligned}\delta z(t) = \int_0^t \Big\{ & T(\tau(t-s))\tau\left(\frac{\partial F}{\partial z}(z(s,u,\tau),u(s))\delta z(s) + \frac{\partial F}{\partial u}(z(s),u(s))\delta u(s)\right) \\ & + (T(\tau(t-s)) + \tau(t-s)AT(\tau(t-s)))F(z(s,u,\tau),u(s))\delta t\Big\} ds \\ & + tAT(\tau t) z_0 \delta\tau.\end{aligned} \tag{A.3}$$

Note that (A.3) is the first variation with respect to (u,τ) of (2.2f).

THEOREM A.2 (Frechet differentiability of $z(t,u,\tau)$ with respect to (u,τ).) *For all* $u', u \in L_2^m[0,1], \tau', \tau \in [\tau_{\min}, \tau_{\max}]$

$$\|z(t,u',\tau') - z(t,u,\tau) - \delta z(t,u,\tau,u'-u,\tau'-\tau)\|_X \leq o(u'-u,\tau'-\tau), \tag{A.4}$$

where $o(\delta u,\delta\tau)/(\|\delta u\|_2^2 + |\delta\tau|^2)^{1/2} \to 0$ *as* $(\delta u,\delta\tau) \to 0$.

Proof. To simplify notation, we define $\Delta z(t) \triangleq z(t,u',\tau') - z(t,u,\tau)$, $\delta z(t) \triangleq \delta z(t,u,\tau,\delta u,\delta\tau), \delta u \triangleq u' - u, \delta\tau \triangleq \tau' - \tau$, and we remove obvious arguments by setting $F(t) \triangleq F(z(t,u,\tau),u(t)), F'(t) \triangleq F(z(t,u',\tau'),u'(t)), F_z(t) \triangleq \partial F/\partial z(z(t,u,\tau),u(t))$, $F_u(t) \triangleq \partial F/\partial u(z(t,u,\tau),u(t))$.

First, in terms of this simplified notation, we have that

$$\begin{aligned}\delta z(t) = \int_0^t & \{\tau T(\tau(t-s))[F_z(s)\delta z(s) + F_u(s)\delta u(s)] \\ & + [T(\tau(t-s)) + \tau(t-s)AT(\tau(t-s))]F(s)\delta\tau\} ds \\ & + tAT(\tau t) z_0 \delta\tau,\end{aligned} \tag{A.5}$$

$$\begin{aligned}\Delta z(t) &= [T(\tau' t) - T(\tau t)]z_0 + \int_0^t [\tau' T(\tau'(t-s))F'(s) - \tau T(\tau(t-s))F(s)] ds \\ &= [T(\tau' t) - T(\tau t)]z_0 + \tau \int_0^t T(\tau(t-s))[F'(s) - F(s)] ds \\ &\quad + \int_0^t [\tau' T(\tau'(t-s)) - \tau T(\tau(t-s))]F'(s) ds.\end{aligned} \tag{A.6}$$

Hence,

$$
\begin{aligned}
[\Delta z(t) - \delta z(t)] = {} & [T(\tau' t) - T(\tau t) - \delta\tau t A T(\tau t)] z_0 \\
& + \int_0^t t\{[\tau' T(\tau'(t-s)) - \tau T(\tau(t-s))] F'(s) \\
& - \delta\tau[\tau(t-s) A T(\tau(t-s)) + T(\tau(t-s))] F(s) t\} ds \\
& + \tau \int_0^t T(\tau(t-s))\{F_z(s)[\Delta z(s) - \delta z(s)] \\
& + [F'(s) - F(s) - F_z(s)\Delta z(s) - F_u(s)\delta u(s) t\} ds.
\end{aligned} \tag{A.7a}
$$

We will deal with the three groups of terms in the right-hand side of (A.7a) one at a time. We will give full details for the last group only, since the calculations are quite laborious. First, since by Lemma 3.3, $(d/dt)T(t) = AT(t)$,

$$\|T(s+\delta s) - T(s) - AT(t)\delta s\| = o_1(\delta s),$$

where $o_1(\delta s)/\delta s \to 0$ as $\delta s \to 0$. Now let $s = t\tau$ and $s + \delta s = t\tau'$. Hence $\delta s = t(\tau' - \tau) = t\delta\tau$ where $\delta\tau = \tau' - \tau$. Therefore,

$$\|T(t\tau') - T(t\tau) - AT(t)\delta\tau t\| \le o_1(\delta\tau t),$$

and hence

$$\|[T(\tau' t) - T(\tau t) - \delta\tau t A T(\tau t)] z_0\| \le \|z_0\|_X o_1(\delta\tau). \tag{A.7b}$$

Next, making use of Lemmas 3.3 and 3.4, we can show that

$$
\begin{aligned}
& \left\| \int_0^t [\tau' T(\tau'(t-s)) - \tau T(\tau(t-s))] F'(s) - \delta\tau[\tau(t-s) A T(\tau(t-s)) \right. \\
& \left. + T(\tau(t-s))] F(s) ds \right\|_X = o_2(\delta u, \delta\tau),
\end{aligned} \tag{A.7c}
$$

where $o_2((\delta u, \delta\tau))/(\|\delta u\|_2^2 + |\delta\tau|^2)^{1/2} \to 0$ as $(\delta u, \delta\tau) \to 0$.

Finally, making use of Assumption 3.1 and Lemmas 3.4 and A.1, we obtain that

$$
\begin{aligned}
& \tau \left\| \int_0^t (\tau(t-s))\{F_z(s)[\Delta z(s) - \delta z(s)] + F'(s) - F(s) \right. \\
& \left. - F_z(s)\Delta z(s) - F_u(s)\delta u(s)\} ds \right\|_X \\
& \le \tau_{\max} M b_2 \int_0^t \|\Delta z(s) - \delta z(s)\|_X ds + \tau_{\max} M \int_0^t \|\{F'(s) \\
& - F(s) - F_z(s)\Delta z(s) - F_u(s)\delta u(s)\}\|_X ds \\
& \le \tau_{\max} M \int_0^t \left\{ b_2 \|\Delta z(s) - \delta z(s)\|_X + \int_0^1 \left\| \frac{\partial F}{\partial z}(z(s) \right. \right. \\
& \left. + r\Delta z(s), u(s) + r\delta u(s)) - F_z(s) \right\| dr \|\Delta z(s)\|_X \\
& + \left. \int_0^1 \left\| \frac{\partial F}{\partial u}(z(s) + r\Delta z(s), u(s) + r\delta u(s)) - F_u(s) \right\| dr \delta u(s) \right\| \Big\} ds \\
& \le \tau_{\max} M \int_0^t \left\{ b_2 \|\Delta z(s) - \delta z(s)\|_X \right. \\
& + \int_0^1 K_S r(\|\Delta z(s)\|_X + \|\delta u(s)\|) dr \|\Delta z(s)\|_X \\
& \left. + \int_0^1 K_S r(\|\Delta z(s)\|_X + \|\delta u(s)\|) dr \|\delta u(s)\| \right\} ds \\
& \le \tau_{\max} M \int_0^t \{b_2 \|\Delta z(s) - \delta z(s)\|_X + K_S[\|\Delta z(s)\|_X + \|\delta u(s)\|]^2\} ds.
\end{aligned} \tag{A.7d}
$$

Since by Lemma A.1, $\|\Delta z(s)\|_X \leq b_3(\|\delta u\|_2^2 + |\delta\tau|^2)^{1/2}$, we obtain, combining (A.7b)–(A.7d) that

$$\text{(A.7e)} \qquad \|\Delta z(t) - \delta z(t)\|_X \leq \tau_{\max} M \int_0^t \{b_2 \|\Delta z(s) - \delta z(s)\|_X\} ds + \tau_{\max} M K_S [b_3 \|\delta u\|_2 + o_3((\delta u, \delta\tau))],$$

where $o_3((\delta u, \delta\tau))/(\|\delta u\|_2^2 + |\delta\tau|^2)^{1/2} \to 0$ as $(\delta u, \delta\tau) \to 0$. Applying the Bellman–Gronwall Lemma, we obtain that

$$\text{(A.7f)} \qquad \|\Delta z(t) - \delta z(t)\|_X \leq o((\delta u, \delta\tau)),$$

where

$$o((\delta u, \delta\tau))/(\|\delta u\|_2^2 + |\delta\tau|^2)^{1/2} \to 0 \quad \text{as } (\delta u, \delta\tau) \to 0,$$

which completes our proof. □

Proceeding by analogy with the proof of Lemma A.1, it is easy to establish the following result.

LEMMA A.3. *The solution* $\delta z(t, u, \tau, \delta u, \delta\tau)$, *of* (A.3), *is linear in* $(\delta u, \delta\tau)$ *for each* $t \in [0, 1], u \in L_2^m[0, 1]$, *and* $\geq \in [\tau_{\min}, \tau_{\max}]$, *and it is Lipschitz continuous in* $(u, \tau) \in G \times [\tau_{\min}, \tau_{\max}]$, *i.e., there exists* $b_4 < \infty$ *such that for all* $u', u \in L_2^m[0, 1], t \in [0, 1], \tau \in [\tau_{\min}, \tau_{\max}]$,

$$\text{(A.8)} \qquad \|\delta z(t, u', \tau', \delta u, \delta\tau) - \delta z(t, u, \tau, \delta u, \delta\tau)\|_X \leq b_4(\|u' - u\|_2^2 + |\tau' - \tau|^2)^{1/2}.$$

If we denote by $z_{u,\tau}(t, u, \tau)$ the linear map $\delta u \to \delta z(t, u, \tau, \delta u, \delta\tau)$ and make use of Assumption 3.1(v) and Theorem A.4, we obtain the following theorem.

THEOREM A.4. *For all* $u \in L_2^m[0, 1], \tau \in [\tau_{\min}, \tau_{\max}]$, *and* $t \in [0, 1], z(t, u, \tau)$ *admits a Lipschitz continuous Frechet derivative. That is, there exists a Lipschitz continuous linear operator* $Dz(t, u, \tau) = (D_u z(t, u, \tau), D_\tau z(t, u, \tau)) \in \mathbf{B}(L_2^m[0, 1], X)$ *such that for all* $\delta u \in L_2^m[0, 1]$ *and* $\delta\tau \in \mathbb{R}$,

$$\text{(A.9)} \qquad \lim_{\substack{\|\delta u\|_2 \to 0 \\ |\delta\tau| \to 0}} \frac{z(t, u + \delta u, \tau + \delta\tau) - z(t, u, \tau) - D_u z(t, u, \tau)\delta u - D_u z(t, u, \tau)\delta\tau}{(\|\delta u\|_2^2 + |\delta\tau|^2)^{1/2}} = 0.$$

REDHEFFER'S LEMMA AND H_∞-CONTROL FOR INFINITE-DIMENSIONAL SYSTEMS*

BERT VAN KEULEN†

Abstract. An infinite-dimensional version of a lemma that has been crucial in the theory of H_∞-control with measurement-feedback for finite-dimensional systems is proved. This extension is used to parametrize all controllers that solve the suboptimal H_∞-control problem for a large class of infinite-dimensional systems.

Key words. Redheffer's lemma, H_∞-control, infinite-dimensional state-space systems

AMS subject classifications. 93B36, 93C25

1. Introduction.

In this paper we prove an infinite-dimensional version of a lemma that has been crucial in the theory of H_∞-control with measurement-feedback for finite-dimensional systems (see [2, Lemma 15]). This lemma is sometimes referred to as Redheffer's lemma since it resembles some results published by Redheffer in [9]. Redheffer considered a very general Hilbert space setting, but the lemma that we present here is far from immediate from the original results in [9].

In [2] the lemma is stated in the frequency domain and proved using finite-dimensional frequency domain techniques, including a Nyquist contour argument. We note that these techniques cannot be applied to the infinite-dimensional time-domain version that we consider here. The proof in this paper depends solely on time-domain techniques and is therefore applicable to a very large class of systems. We believe that the same kind of reasoning can be used to solve the measurement-feedback H_∞-control problem for nonlinear or time-varying systems.

Using the infinite-dimensional extension, we give a parametrization of all suboptimal controllers that solve the H_∞-control problem with measurement-feedback for a large class of infinite-dimensional systems (this type of result was derived in [2] and [12] for the finite-dimensional case). This completes the results that were given in [5]. In doing so, we use procedures and formulations that have been published in [2], [12], and [11] for the finite-dimensional case.

2. Preliminary results.

In this section we introduce our class of infinite-dimensional systems, quote some known results for this class, and derive some new results that are interesting in their own right. We consider infinite-dimensional linear systems of the following form (see also [6], [5]). Suppose that A is the infinitesimal generator of a C_0-semigroup $T(\cdot)$ on the real separable Hilbert space X, $B \in \mathcal{L}(U,X), C \in \mathcal{L}(X,Y)$, and $D \in \mathcal{L}(U,Y)$, where U and Y are also real separable Hilbert spaces. For $u(\cdot) \in L_2^{\text{loc}}(0,\infty;U)$, $x_0 \in X$, and $t \geq 0$

$$\begin{aligned} x(t) &= T(t)x_0 + \textstyle\int_0^t T(t-s)Bu(s)ds \\ y(t) &= Cx(t) + Du(t) \end{aligned} \tag{2.1}$$

* Received by the editors August 21, 1991; accepted for publication (in revised form) August 25, 1992.

† Mathematics Institute, P. O. Box 800, 9700 AV Groningen, the Netherlands (bertvk@math.rug.nl).

is a well-defined system with state $x(t)$, input $u(t)$, and output $y(t)$. To simplify notation we denote such a system by

$$\begin{aligned} \dot{x} &= Ax + Bu, \qquad x(0) = x_0 \\ y &= Cx + Du, \qquad t \geq 0. \end{aligned} \tag{2.2}$$

We recall some basic facts about this class of systems (see, e.g, [1]): If $x_0 = 0$, (2.2) defines a linear map G from $L_2^{\mathrm{loc}}(0,\infty;U)$ to $L_2^{\mathrm{loc}}(0,\infty;Y)$ and in this case we call (2.2) a *realization* of G. G is *causal*, i.e., for all $T > 0$ we have

$$u_1(t) = u_2(t) \quad \text{a.e. } t \in [0,T] \Rightarrow (Gu_1)(t) = (Gu_2)(t) \quad \text{a.e. } t \in [0,T].$$

If $U = Y$ and $D \in \mathcal{L}(U)$ we can define the inverse system G^{-1} as the system given by

$$\begin{aligned} \dot{x} &= (A - BD^{-1}C)x + BD^{-1}u, \qquad x(0) = 0 \\ y &= -D^{-1}Cx + D^{-1}u, \qquad t \geq 0, \end{aligned} \tag{2.3}$$

and it is easy to see that for all $u \in L_2^{\mathrm{loc}}(0,\infty;U)$ we have $G^{-1}(Gu) = G(G^{-1}u) = u$ (use some well-known perturbation results, see, e.g., [7, §3.1]).

If A is the infinitesimal generator of an exponentially stable C_0-semigroup, it is well known that $G \in \mathcal{L}(L_2(0,\infty;U), L_2(0,\infty;Y))$. In general, G is unbounded, so we consider G as a map from $D(G) \subseteq L_2(0,\infty;U)$ to $L_2(0,\infty;Y)$, where $D(G)$ is given by

$$D(G) := \{u \in L_2(0,\infty;U) |\ \ (Gu)(\cdot) \in L_2(0,\infty;Y)\}.$$

Since for every $T > 0$, G is a bounded linear map from $L_2(0,T;U)$ to $L_2(0,T;Y)$, it is not difficult to see that $(G, D(G))$ defines a closed linear map. Hence, $G \in \mathcal{L}(L_2(0,\infty;U), L_2(0,\infty;Y))$ if and only if $D(G) = L_2(0,\infty;U)$ (apply the closed-graph theorem). If $D(G) = L_2(0,\infty;U)$, we call G *i/o-stable* (input/output stable) and we denote its operator norm by $\|G\|$. Finally, we note that if G is i/o-stable, the transfer function $G(\cdot)$ of system (2.2) satisfies $G(\cdot) \in H_\infty(\mathrm{C}^+, \mathcal{L}(U,Y))$ and $\|G\| = \|G(\cdot)\|_\infty$.

In this paper, we adopt the usual definitions of stabilizability and detectability: the pair (A,B) is called *exponentially stabilizable* if there exists an $F \in \mathcal{L}(X,U)$ such that the C_0-semigroup generated by $A + BF$ is exponentially stable, and the pair (C,A) is called *exponentially detectable* if there exists a $K \in \mathcal{L}(Y,X)$ such that the C_0-semigroup generated by $A + KC$ is exponentially stable.

In the following two lemmas, we relate i/o-stability with exponential stability and internal stability. These lemmas extend some results in [4], where finite-dimensionality of U and Y is essential. The first lemma is a result from [5, Lemma 3.2].

LEMMA 2.1. *Suppose we have a system G given by* (2.2) *with $x_0 = 0$ and suppose that (A,B) is exponentially stabilizable and (C,A) is exponentially detectable. Then the C_0-semigroup $T(\cdot)$ generated by A is exponentially stable if and only if G is i/o-stable.*

Now suppose that we have two systems of the form (2.2) given by

$$G: \begin{cases} \dot{x}_1 = A_1x_1 + B_1u_1, \qquad x_1(0) = 0 \\ \\ y_1 = C_1x_1 + D_1u_1, \end{cases} \tag{2.4}$$

$$K: \begin{cases} \dot{x}_2 = A_2 x_2 + B_2 u_2, & x_2(0) = 0 \\ y_2 = C_2 x_2 + D_2 u_2, \end{cases} \tag{2.5}$$

where A_1 and A_2 are infinitesimal generators of the C_0-semigroups $T_1(\cdot)$ and $T_2(\cdot)$ on the real separable Hilbert spaces X_1 and X_2, $u_1(t), y_2(t) \in U$, $u_2(t)$, $y_1(t) \in Y$, $B_1 \in \mathcal{L}(U, X_1)$, $C_1 \in \mathcal{L}(X_1, Y)$, $D_1 \in \mathcal{L}(U, Y)$, $B_2 \in \mathcal{L}(Y, X_2)$, $C_2 \in \mathcal{L}(X_2, U)$, and $D_2 \in \mathcal{L}(Y, U)$ with U and Y also real separable Hilbert spaces. In [5, Lemma 3.3] it is shown that if $(I - D_1 D_2)^{-1} \in \mathcal{L}(Y)$ and $(I - D_2 D_1)^{-1} \in \mathcal{L}(U)$, the closed-loop system on $X_1 \times X_2$ determined by $u_1 = y_2 + v_1$, $u_2 = y_1 + v_2$, from (v_1, v_2) to (u_1, u_2) is given by

$$\begin{pmatrix} \dot{x}_1 \\ x_2 \end{pmatrix} = \mathcal{A} \begin{pmatrix} x_1 \\ x_2 \end{pmatrix} + \mathcal{B} \begin{pmatrix} v_1 \\ v_2 \end{pmatrix}; \qquad \begin{pmatrix} x_1 \\ x_2 \end{pmatrix}(0) = \begin{pmatrix} 0 \\ 0 \end{pmatrix}$$

$$\begin{pmatrix} u_1 \\ u_2 \end{pmatrix} = \mathcal{C} \begin{pmatrix} x_1 \\ x_2 \end{pmatrix} + \mathcal{D} \begin{pmatrix} v_1 \\ v_2 \end{pmatrix},$$

where

$$\mathcal{A} = \begin{pmatrix} A_1 & 0 \\ 0 & A_2 \end{pmatrix} + \begin{pmatrix} B_1 & 0 \\ 0 & B_2 \end{pmatrix} \begin{pmatrix} I & -D_2 \\ -D_1 & I \end{pmatrix}^{-1} \begin{pmatrix} 0 & C_2 \\ C_1 & 0 \end{pmatrix},$$

$$\mathcal{B} = \begin{pmatrix} B_1 & 0 \\ 0 & B_2 \end{pmatrix} \begin{pmatrix} I & -D_2 \\ -D_1 & I \end{pmatrix}^{-1}, \tag{2.6}$$

$$\mathcal{C} = \begin{pmatrix} I & -D_2 \\ -D_1 & I \end{pmatrix}^{-1} \begin{pmatrix} 0 & C_2 \\ C_1 & 0 \end{pmatrix}, \quad \mathcal{D} = \begin{pmatrix} I & -D_2 \\ -D_1 & I \end{pmatrix}^{-1},$$

and $\mathcal{A}$ is the infinitesimal generator of a C_0-semigroup $\mathcal{T}(\cdot)$ on the Hilbert space $X_1 \times X_2$ (see also Fig. 2.1).

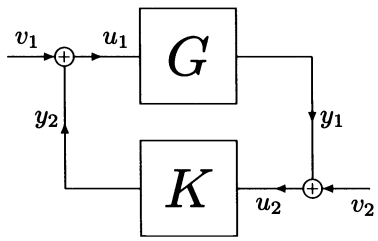

FIG. 2.1. *Internal stability.*

Using the linear maps defined by G and K, we can also formulate this as

$$\begin{pmatrix} u_1 \\ u_2 \end{pmatrix} = G_{cl} \begin{pmatrix} v_1 \\ v_2 \end{pmatrix} = \begin{pmatrix} (I - KG)^{-1} & (I - KG)^{-1} K \\ G(I - KG)^{-1} & (I - GK)^{-1} \end{pmatrix} \begin{pmatrix} v_1 \\ v_2 \end{pmatrix}. \tag{2.7}$$

(Note that since $(I - D_1 D_2)^{-1} \in \mathcal{L}(Y)$ and $(I - D_2 D_1)^{-1} \in \mathcal{L}(U)$, $(I - GK)^{-1}$ and $(I - KG)^{-1}$ are both well defined.) If G_{cl} is i/o-stable K is usually called an *internally stabilizing* controller for G.

The following result holds.

LEMMA 2.2. *Consider the systems G and K given by* (2.4) *and* (2.5). *We have the following equivalence: $\mathcal{A}$ given by* (2.6) *is the generator of an exponentially stable C_0-semigroup if and only if (A_1, B_1) and (A_2, B_2) are exponentially stabilizable, (C_1, A_1) and (C_2, A_2) are exponentially detectable and G_{cl} defined by* (2.7) *is i/o-stable.*

Proof. Necessity. Suppose that $\mathcal{A}$ generates an exponentially stable C_0-semigroup.

The fact that G_{cl} is i/o-stable follows from well-known results (see, e.g., [6, App. A.1]). The fact that (A_1, B_1) and (A_2, B_2) are exponentially stabilizable and (C_1, A_1) and (C_2, A_2) are exponentially detectable follows from [6, Rem. 5.2].

Sufficiency. Suppose that G_{cl} is i/o-stable and that (A_1, B_1) and (A_2, B_2) are exponentially stabilizable and (C_1, A_1) and (C_2, A_2) are exponentially detectable.

Since (A_1, B_1) and (A_2, B_2) are exponentially stabilizable it is easy to see from (2.6) that the pair $(\mathcal{A}, \mathcal{B})$ is exponentially stabilizable. Similarly, since (C_1, A_1) and (C_2, A_2) are exponentially detectable, we see that the pair $(\mathcal{C}, \mathcal{A})$ is exponentially detectable. The result now follows from Lemma 2.1. □

Next we quote another result from [5], which is a kind of small gain theorem with exponential stability (see again [5, Lemma 3.3]).

LEMMA 2.3. *Consider again G and K given by* (2.4) *and* (2.5). *Suppose that $T_1(\cdot)$ and $T_2(\cdot)$ are both exponentially stable, that $\|G\| \leq 1$, and that $\|K\| < 1$. Then $\mathcal{A}$ given by* (2.6) *is the generator of an exponentially stable C_0-semigroup.*

We conclude this section with some useful definitions and diagrams regarding feedback interconnections and linear fractional transformations.

Suppose that we have a system G of the form

$$G: \begin{cases} \dot{x} = Ax + B_1 w + B_2 u \\ z = C_1 x + D_{12} u, \qquad x(0) = 0 \\ y = C_2 x + D_{21} w \end{cases} \tag{2.8}$$

(interpreting (2.8) as (2.2); now $x(t) \in X$, $u(t) \in U$, $w(t) \in W$, $z(t) \in Z$, and $y(t) \in Y$, where X, U, W, Z, and Y are all real separable Hilbert spaces, A is the infinitesimal generator of a C_0-semigroup $T(\cdot)$, and $B_1, B_2, C_1, D_{12}, C_2$, and D_{21} are linear and bounded maps with the appropriate spaces).

Let us express (2.8) in the following way:

$$\begin{pmatrix} z \\ y \end{pmatrix} = \begin{pmatrix} G_{11} & G_{12} \\ G_{21} & G_{22} \end{pmatrix} \begin{pmatrix} w \\ u \end{pmatrix}, \tag{2.9}$$

where G_{ij} represent the corresponding linear maps denoted below:

$$\begin{aligned} G_{11} w &= \textstyle\int_0^t C_1 T(t-s) B_1 w(s) ds, \\ G_{12} u &= \textstyle\int_0^t C_1 T(t-s) B_2 u(s) ds + D_{12} u, \\ G_{21} w &= \textstyle\int_0^t C_2 T(t-s) B_1 w(s) ds + D_{21} w, \\ G_{22} u &= \textstyle\int_0^t C_2 T(t-s) B_2 u(s) ds. \end{aligned} \tag{2.10}$$

Furthermore, let G_2 be a system of the form

$$G_2: \begin{cases} \dot{p} = Mp + N y_1, \qquad p(0) = 0 \\ \\ u_1 = Lp + R y_1, \end{cases} \tag{2.11}$$

where M is the infinitesimal generator of the C_0-semigroup $V(\cdot)$ on the real separable Hilbert space P, $y_1(t) \in Y$, $u_1(t) \in U$, $N \in \mathcal{L}(U, P)$, $L \in \mathcal{L}(P, U)$, and $R \in \mathcal{L}(Y, U)$.

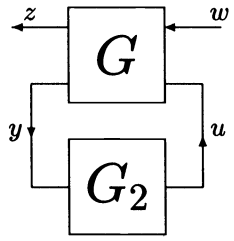

FIG. 2.2. $G_{zw} = \mathcal{F}(G, G_2)$.

We define the closed-loop system G_{zw} as the interconnection of (2.8) and (2.11) with $y_1 = y$ and $u_1 = u$ as in Fig. 2.2. Hence G_{zw} is the map from $L_2^{\mathrm{loc}}(0,\infty;W)$ to $L_2^{\mathrm{loc}}(0,\infty;Z)$ given by

$$G_{zw}: \begin{cases} \begin{pmatrix} \dot{x} \\ \dot{p} \end{pmatrix} = \mathcal{A}\begin{pmatrix} x \\ p \end{pmatrix} + \mathcal{B}w, \qquad \begin{pmatrix} x \\ p \end{pmatrix}(0) = \begin{pmatrix} 0 \\ 0 \end{pmatrix} \\ \\ z = \mathcal{D}_1\begin{pmatrix} x \\ p \end{pmatrix} + \mathcal{D}_2 w \end{cases} \tag{2.12}$$

with

$$\mathcal{A} = \begin{pmatrix} A + B_2RC_2 & B_2L \\ NC_2 & M \end{pmatrix}, \qquad \mathcal{B} = \begin{pmatrix} B_2RD_{21} + B_1 \\ ND_{21} \end{pmatrix},$$

$$\mathcal{D}_1 = (C_1 + D_{12}RC_2 \quad D_{12}L), \qquad \mathcal{D}_2 = D_{12}RD_{21}, \tag{2.13}$$

where $\mathcal{A}$ is the infinitesimal generator of the C_0-semigroup $\mathcal{T}(\cdot)$ on the Hilbert space $X \times P$. As far as $\mathcal{A}$ is concerned, the relation with (2.4)–(2.7) is clear: G_{22} plays the role of G in (2.4) and G_2 is as in (2.5).

We can formulate (2.12) differently, using (2.9) with $u = G_2y$: From (2.10) we see that the feedthrough operator of G_{22} is zero. Therefore, $I - G_{22}G_2$ is invertible as a map from $L_2^{\mathrm{loc}}(0,\infty;Y)$ to $L_2^{\mathrm{loc}}(0,\infty;Y)$ and so

$$z = G_{zw}w = (G_{11} + G_{12}G_2(I - G_{22}G_2)^{-1}G_{21})w.$$

For any G of the form (2.8)–(2.9) and G_2 of the form (2.11) we define $\mathcal{F}$ (a linear fractional transformation) as

$$\mathcal{F}(G, G_2) := G_{11} + G_{12}G_2(I - G_{22}G_2)^{-1}G_{21}. \tag{2.14}$$

We have seen above that $\mathcal{F}$ is well defined and that $\mathcal{F}(G, G_2)$ has a realization of the form (2.12), (2.13). Unless stated otherwise, we use this realization of $\mathcal{F}(G, G_2)$ on $X \times P$ throughout.

3. Redheffer's lemma. In this section we present our infinite-dimensional time-domain version of Redheffer's lemma, which is closely related to the finite-dimensional result in [2, Lemma 15]. Our version is stated in Theorem 3.2.

First we prove a crucial lemma that is related to the finite-dimensional result that if $G(\cdot) \in \mathrm{R}L_\infty$, $\|G(\cdot)\|_\infty < 1$ and $(I - G(\cdot))^{-1} \in \mathrm{R}H_\infty$ it follows that $G(\cdot) \in \mathrm{R}H_\infty$ (this finite-dimensional result is usually proved using a Nyquist contour argument; see [11, Lemma 2.11]).

LEMMA 3.1. *Suppose that G is a system of the form (2.2) with $x_0 = 0$. If $U = Y$ and D is such that $(I - D)^{-1} \in \mathcal{L}(U)$, then the inverse system $(I - G)^{-1}$ exists. If in addition $(I - G)^{-1}$ is i/o-stable and $\|Gu\|_2 \leq \|u\|_2$ for all $u \in D(G)$, then it follows that G is i/o-stable.*

Proof. Since $(I - D)^{-1} \in \mathcal{L}(U)$, $(I - G)^{-1}$ exists (see §2) and we know that $(I - G)^{-1}$ is i/o-stable and $\|Gu\|_2 \leq \|u\|_2$ for all $u \in D(G)$.

Note first that for arbitrary $u_1 \in L_2(0, \infty; U)$, we have $Gu_1 \in L_2^{\text{loc}}(0, \infty; U)$. We must prove that $D(G) = L_2(0, \infty; U)$, so we show that Gu_1 is an element of $L_2(0, \infty; U)$.

Let $T > 0$ be arbitrary and define $y_{2T} \in L_2(0, \infty; U)$ as follows:

$$y_{2T}(t) := \begin{cases} ((I - G)u_1)(t) & \text{for a.e. } t \in [0, T] \\ 0 & \text{for } t > T. \end{cases} \tag{3.1}$$

Since $(I - G)^{-1}$ is i/o stable we can define $u_{2T} \in L_2(0, \infty; U)$ by

$$u_{2T} := (I - G)^{-1} y_{2T}. \tag{3.2}$$

It follows that

$$((I - G)u_{2T})(t) = ((I - G)u_1)(t) \quad \text{for a.e. } t \in [0, T]. \tag{3.3}$$

Since $(I - G)^{-1}$ is a causal system this implies that

$$u_{2T}(t) = u_1(t) \quad \text{for a.e. } t \in [0, T]. \tag{3.4}$$

Furthermore, since $u_{2T}, y_{2T} \in L_2(0, \infty; U)$, (3.2) implies that

$$Gu_{2T} = u_{2T} - y_{2T} \in L_2(0, \infty; U) \tag{3.5}$$

and so $u_{2T} \in D(G)$.

Hence, using the fact that $\|Gu\|_2 \leq \|u\|_2$ for all $u \in D(G)$ we have

$$\|Gu_{2T}\|_2^2 = \|u_{2T} - y_{2T}\|_2^2 \leq \|u_{2T}\|_2^2. \tag{3.6}$$

Since $y_{2T}(t) = 0$ for $t > T$ (see (3.1)), we can express (3.6) as

$$\int_0^T \|u_{2T}(t) - y_{2T}(t)\|_U^2 \, dt + \int_T^\infty \|u_{2T}(t)\|_U^2 \, dt \leq \int_0^\infty \|u_{2T}(t)\|_U^2 \, dt. \tag{3.7}$$

It follows from (3.3) and (3.4) that $(Gu_{2T})(t) = (Gu_1)(t)$ for a.e. $t \in [0, T]$ and using this with (3.5) in (3.7) gives

$$\begin{aligned} \int_0^T \|Gu_1(t)\|_U^2 \, dt &\leq \int_0^\infty \|u_{2T}(t)\|_U^2 \, dt - \int_T^\infty \|u_{2T}(t)\|_U^2 \, dt \\ &= \int_0^T \|u_{2T}(t)\|_U^2 \, dt = \int_0^T \|u_1(t)\|_U^2 \, dt, \end{aligned} \tag{3.8}$$

where the last equality follows from (3.4).

T was arbitrary so (3.8) implies that

$$\int_0^T \|Gu_1(t)\|_U^2 \, dt \leq \int_0^T \|u_1(t)\|_U^2 \, dt \leq \|u_1\|_2^2 \text{ for all } T > 0$$

and this completes the proof. □

Now suppose that we have a system G of the form (2.8), (2.9) and a system G_2 of the form (2.11). Note that there is no feedthrough from w to z nor from u to y; this is done only for simplicity of presentation. The result that we give in Theorem 3.2 is also valid if these terms are included, under some mild wellposedness conditions.

We shall make the following assumptions:

(3.9) The C_0-semigroup $T(\cdot)$ generated by A is exponentially stable.

(3.10) G is inner, i.e. for all $w \in L_2(0,\infty;W)$ and $u \in L_2(0,\infty;U)$ we have $\|z\|_2^2 + \|y\|_2^2 = \|w\|_2^2 + \|u\|_2^2$.

(3.11) G_{21}^{-1} exists and is i/o-stable.

Note that assumption (3.9) implies that G is i/o-stable and that assumption (3.11) implies that $Y = W$ and $D_{21}^{-1} \in \mathcal{L}(Y)$.

The following result holds.

THEOREM 3.2. *Suppose that we have a system G of the form* (2.8), (2.9) *and a system G_2 of the form* (2.11). *Furthermore, suppose that the assumptions* (3.9)–(3.11) *are satisfied. Then the C_0-semigroup $\mathcal{T}(\cdot)$ that corresponds to the closed-loop system* (2.12) *is exponentially stable and $\|G_{zw}\| = \|\mathcal{F}(G,G_2)\| < 1$ if and only if the C_0-semigroup $V(\cdot)$ generated by M in* (2.11) *is exponentially stable and $\|G_2\| < 1$.*

Proof. First, we recall from §3 that $(I - G_{22}G_2)^{-1}$ exists so that $G_{zw} = \mathcal{F}(G,G_2)$ is well defined.

Sufficiency. Suppose that $V(\cdot)$ is exponentially stable and $\|G_2\| < 1$. Since G is i/o-stable and inner we have $\|G_{22}\| \le 1$. It follows from Lemma 2.3 that $\mathcal{T}(\cdot)$ is exponentially stable.

Now let $w \in L_2(0,\infty;W)$ be an input for the closed-loop system (2.12) and let $u \in L_2(0,\infty;U)$, $y \in L_2(0,\infty;Y)$ and $z \in L_2(0,\infty;Z)$ have the corresponding values so that (2.9) holds and $u = G_2 y$. Now since $\|G_2\| < 1$, there exists some $\epsilon > 0$ such that $\|u\|_2^2 \le (1-\epsilon)\|y\|_2^2$. We know that G is inner so

$$\|z\|_2^2 = \|w\|_2^2 + \|u\|_2^2 - \|y\|_2^2 \le \|w\|_2^2 - \epsilon\|y\|_2^2. \tag{3.12}$$

Since (2.9) holds with $u = G_2 y$, we have

$$y = (I - G_{22}G_2)^{-1}G_{21}w.$$

Since G_{21}^{-1} exists and is i/o-stable and G_2 and G_{22} are also i/o-stable, it follows that

$$\|w\|_2^2 = \left\|G_{21}^{-1}(I - G_{22}G_2)y\right\|_2^2 \le const\,\|y\|_2^2. \tag{3.13}$$

Combining (3.12) and (3.13) shows that there exists a $\delta > 0$ such that $\|z\|_2^2 = \|G_{zw}w\|_2^2 \le (1-\delta)\|w\|_2^2$ for all $w \in L_2(0,\infty;W)$, so $\|\mathcal{F}(G,G_2)\| = \|G_{zw}\| < 1$.

Necessity. Suppose that $\mathcal{T}(\cdot)$ is exponentially stable and $\|\mathcal{F}(G,G_2)\| = \|G_{zw}\| < 1$. We proceed in seven steps.

1. Note that $G_2(I - G_{22}G_2)^{-1}$ and $(I - G_{22}G_2)^{-1}$ are i/o-stable. This follows from the fact that $\mathcal{T}(\cdot)$ is exponentially stable, formula (2.7) and Lemma 2.2.

2. Prove that $\|G_2 y\|_2 \le \|y\|_2$ for all $y \in D(G_2)$. Let $y \in D(G_2)$ and define $u := G_2 y \in L_2(0,\infty;U)$. Define $w := G_{21}^{-1}(I - G_{22}G_2)y = G_{21}^{-1}y - G_{21}^{-1}G_{22}u$, so that

$w \in L_2(0,\infty;W)$. Define $z := G_{zw}w \in L_2(0,\infty;Z)$. Now it is easy to see that (2.8), (2.9) is satisfied so $\|z\|_2^2 + \|y\|_2^2 = \|w\|_2^2 + \|u\|_2^2$ (G is inner). $\|G_{zw}\| < 1$ implies that $\|z\|_2^2 \leq (1-\epsilon)\|w\|_2^2$ for some $\epsilon > 0$ and so $\|u\|_2^2 = \|G_2 y\|_2^2 = \|z\|_2^2 + \|y\|_2^2 - \|w\|_2^2 \leq \|y\|_2^2 - \epsilon\|w\|_2^2 \leq \|y\|_2^2$.

3. Note that $D(G_{22}G_2) = D(G_2)$. Since G_{22} is i/o-stable, we have $D(G_{22}G_2) \supseteq D(G_2)$. Now suppose that $y \in D(G_{22}G_2)$. It follows that $(I - G_{22}G_2)y \in L_2(0,\infty;Y)$. Since $G_2(I - G_{22}G_2)^{-1}$ is i/o-stable it follows that $G_2 y = G_2(I - G_{22}G_2)^{-1}(I - G_{22}G_2)y \in L_2(0,\infty;U)$, and so $y \in D(G_2)$.

4. Use Lemma 3.1 to prove that $G_{22}G_2$ is i/o-stable. Using steps 2 and 3 and the fact that $\|G_{22}\| \leq 1$ we have $\|G_{22}G_2 y\|_2 \leq \|G_2 y\|_2 \leq \|y\|_2$ for all $y \in D(G_{22}G_2)$. We know that $(I - G_{22}G_2)^{-1}$ is i/o-stable. Lemma 3.1 implies that $G_{22}G_2$ is i/o-stable.

5. Prove that G_2 is i/o-stable. We know that $G_2(I - G_{22}G_2)^{-1}$ and $I - G_{22}G_2$ are both i/o-stable. Now we use $G_2 = G_2(I - G_{22}G_2)^{-1}(I - G_{22}G_2)$.

6. Prove that $V(\cdot)$ is exponentially stable. Since $\mathcal{T}(\cdot)$ is exponentially stable, it follows from Lemma 2.2 that (M,N) is exponentially stabilizable and (L,M) is exponentially detectable. Since G_2 is i/o-stable, it follows from Lemma 2.1 that $V(\cdot)$ is exponentially stable.

7. Prove that $\|G_2\| < 1$. We conclude from steps 2 and 5 that $\|G_2\| \leq 1$. Now let $y \in L_2(0,\infty;Y)$, define $u := G_2 y$ and $w := G_{21}^{-1}(I - G_{22}G_2)y$. As in step 2 we have $\|G_2 y\|_2^2 \leq \|y\|_2^2 - \epsilon\|w\|_2^2$. Since $y = (I - G_{22}G_2)^{-1}G_{21}w$, we see that $\|y\|_2^2 \leq \text{const}\,\|w\|_2^2$, so there exists some $\delta > 0$ such that $\|G_2 y\|_2^2 \leq (1-\delta)\|y\|_2^2$, and so $\|G_2\| < 1$. □

Remark 3.3. Apart from the exponential stability, the sufficiency part of Theorem 3.2 follows from Redheffer's results in [9]. The necessity part might be derived by applying some results in [9], but this would give a proof that is much longer than the one we have given here. The clue would be [9, (17)] and the relation between matrix and $*$-product inverses for isometric operators. Since Redheffer considers only bounded operators and G_2 is not a priori bounded, the result should first be obtained for $L_2(0,T)$ and then somehow extended to $L_2(0,\infty)$.

In the next section we use Theorem 3.2 to parametrize all controllers that solve the regular suboptimal H_∞-control problem for a class of systems of the form (2.8).

4. Controller parametrization.

Consider again the systems given by (2.8) and (2.11). We are looking for controllers K of the form (2.11) that make the closed-loop system given by (2.12) exponentially stable, i.e., $\mathcal{T}(\cdot)$ is exponentially stable, and satisfy $\|\mathcal{F}(G,K)\| = \|G_{zw}\| < \gamma$. A controller with these properties will be called *admissible.*

Under some regularity conditions, in [5] necessary and sufficient conditions are derived for the existence of an admissible controller. As in the finite-dimensional case, these necessary and sufficient conditions are expressed by the solvability of two coupled Riccati equations. Using Theorem 3.2, in this section we simplify some of the proofs in [5] and give a parametrization of all admissible controllers. To do this, we need some a priori assumptions (see also [5]):

(4.1) there exists an $\epsilon > 0$ such that for all $(\omega,x,u) \in \mathrm{R} \times D(A) \times U$ with $i\omega x = Ax + B_2 u$, there holds $\|C_1 x + D_{12}u\|_Z^2 \geq \epsilon\|x\|_X^2$,

(4.2) $$D_{12}^*[C_1 \;\; D_{12}] = [0 \;\; I],$$

(4.3) there exists an $\epsilon > 0$ such that for all $(\omega, x, y) \in \mathrm{R} \times D(A^*) \times Y$ with $i\omega x = A^*x + C_2^*y$, there holds $\|B_1^*x + D_{21}^*y\|_W^2 \geq \epsilon \|x\|_X^2$,

$$D_{21}[B_1^* \quad D_{21}^*] = [0 \quad I]. \tag{4.4}$$

Assumptions (4.1) and (4.3) are the infinite-dimensional analogues of the weakest assumptions under which the regular version of the finite-dimensional H_∞-problem has been solved (see, e.g., [3]). Just as in the finite-dimensional case [3], (4.2) and (4.4) can be replaced by the assumption that $D_{12}^*D_{12}$ and $D_{21}D_{21}^*$ are coercive. Also, feedthrough terms from disturbance w to the to-be-controlled output z and from the control u to the measured output y can be included, but all this leads only to more complicated formulas. Furthermore, without loss of generality, we restrict ourselves to the case $\gamma = 1$ (as usual the general case can be obtained by scaling).

Before we derive the parametrization of all admissible controllers we must present two preliminary results, which follow from [5] and [6]. The first result follows from [6, Lemma 5.1] and [5, Lemma 3.10].

LEMMA 4.1. *Suppose that the assumptions* (4.1), (4.2) *hold. If there exists an exponentially stabilizing dynamic output-feedback controller K of the form* (2.11) *with* $\|G_{zw}\| = \|\mathcal{F}(G, K)\| < 1$, *then there exists a nonnegative definite operator* $P_1 \in \mathcal{L}(X)$ *satisfying*

$$\begin{aligned} &\text{for all } x \in D(A),\ P_1x \in D(A^*), \\ &(A^*P_1 + P_1A + P_1(B_1B_1^* - B_2B_2^*)P_1 + C_1^*C_1)x = 0 \\ &\text{and } A_1 := A + (B_1B_1^* - B_2B_2^*)P_1 \text{ is exponentially stable.} \end{aligned} \tag{4.5}$$

Furthermore, the C_0-semigroup generated by $A - B_2B_2^*P_1$ is exponentially stable and the system G_I given by

$$G_I : \begin{cases} \dot{x}_I = (A - B_2B_2^*P_1)x_I + B_1w + B_2u_0, \\ z = (C_1 - D_{12}B_2^*P_1)x_I + D_{12}u_0, \quad x_I(0) = 0, \\ w_0 = -B_1^*P_1x_I + w \end{cases} \tag{4.6}$$

satisfies $\|z\|_2^2 + \|w_0\|_2^2 = \|w\|_2^2 + \|u_0\|_2^2$, *for all* $w \in L_2(0, \infty; W)$ *and* $u_0 \in L_2(0, \infty; U)$.

The second result concerns system transposition.

Suppose we have a system G of the form (2.8) and a controller K of the form (2.11). Define the transposed versions of these systems as

$$G^\natural : \begin{cases} \dot{x} = A^*x + C_1^*\tilde{w} + C_2^*\tilde{u}, \\ \tilde{z} = B_1^*x + D_{21}^*\tilde{u}, \quad x(0) = 0, \\ \tilde{y} = B_2^*x + D_{12}^*\tilde{w} \end{cases} \tag{4.7}$$

and

$$K^\natural : \begin{cases} \dot{p} = M^*p + L^*\tilde{y}, \quad p(0) = 0, \\ \\ \tilde{u} = N^*p + R^*\tilde{y}. \end{cases} \tag{4.8}$$

Note that $(K^\natural)^\natural = K$ and $(G^\natural)^\natural = G$.

LEMMA 4.2. *The following are equivalent. The controller K (as in* (2.11)*) is admissible for G (as in* (2.8)*) if and only if the controller $K^\natural$ (as in* (4.8)*) is admissible for $G^\natural$ (as in* (4.7)*).*

Proof. It is straightforward to show that a realization of $\mathcal{F}(G^\natural, K^\natural)$ is given by

$$\mathcal{F}(G^\natural, K^\natural): \begin{cases} \begin{pmatrix} \dot{x} \\ p \end{pmatrix} = \mathcal{A}^* \begin{pmatrix} x \\ p \end{pmatrix} + \mathcal{D}_1^* \tilde{w}, \\ \tilde{z} = \mathcal{B}^* \begin{pmatrix} x \\ p \end{pmatrix} + \mathcal{D}_2^* \tilde{w}, \end{cases} \tag{4.9}$$

where $\mathcal{A}, \mathcal{B}, \mathcal{D}_1$ and $\mathcal{D}_2$ are as in (2.13).

We conclude that K exponentially stabilizes G if and only if $K^\natural$ exponentially stabilizes $G^\natural$. It follows from the proof of [5, Lemma 3.9] that if K is exponentially stabilizing we have $\|\mathcal{F}(G,K)\| = \|\mathcal{F}(G,K)^\natural\|$. The result now follows from the fact that $\mathcal{F}(G,K) = \mathcal{F}(G^\natural, K^\natural)^\natural$. □

To parametrize all admissible controllers for G (given by (2.8)) we proceed as follows. Using Lemma 4.1 and Theorem 3.2, we define a transformed system denoted by G_{P_1} with the following property: a controller of the form (2.11) is admissible for G if and only if it is admissible for G_{P_1} (this corresponds to [2, Lemma 9]). If there exists an admissible controller for G_{P_1}, we can apply Lemma 4.1 once again to obtain a solution P_2 to a second Riccati equation. Then we define another system $G_{P_1P_2}$ such that a controller of the form (2.11) is admissible for G if and only if it is admissible for $G_{P_1P_2}$ (this step is not taken in [2]; it is an idea from [11]). The reason for these transformations is that $G_{P_1P_2}$ has a very nice structure that enables us to find all its admissible controllers.

We now give a lemma that characterizes all admissible controllers for a system with a structure that $G_{P_1P_2}$ is going to have.

Suppose that we have a system $\bar{G}$ given by

$$\bar{G}: \begin{cases} \dot{x} = Ax + B_1 w + B_2 u, \\ z = C_1 x + u, \qquad x(0) = 0 \\ y = C_2 x + w, \end{cases} \tag{4.10}$$

where A is the infinitesimal generator of the C_0-semigroup $T(\cdot)$ on the real separable Hilbert space X, $u(t), z(t) \in U$, $y(t), w(t) \in Y$, where U and Y are also real separable Hilbert spaces, etc. (A special case of (2.8), now $U = Z$ and $Y = W$). We also consider the description of $\bar{G}$ as in (2.9), (2.10):

$$\bar{G}: \begin{pmatrix} z \\ y \end{pmatrix} = \begin{pmatrix} \bar{G}_{11} & \bar{G}_{12} \\ \bar{G}_{21} & \bar{G}_{22} \end{pmatrix} \begin{pmatrix} w \\ u \end{pmatrix}, \tag{4.11}$$

where $\bar{G}_{ij}$ represent the corresponding linear maps. Comparing with (2.9), (2.10), we see that now the feedthrough operators of $\bar{G}_{12}$ and $\bar{G}_{21}$ are both equal to the identity so that $\bar{G}_{12}$ and $\bar{G}_{21}$ are both invertible. As before, $\bar{G}_{11}$ and $\bar{G}_{22}$ have no feedthrough operator.

Define the system $\bar{G}_2$ by

$$\bar{G}_2: \begin{cases} \dot{p}_1 = (A - B_2C_1 - B_1C_2)p_1 + B_1 y_2 + B_2 v, \\ u_2 = -C_1 p_1 + v, \qquad p_1(0) = 0, \\ r = -C_2 p_1 + y_2, \end{cases} \tag{4.12}$$

or

$$\bar{G}_2: \begin{pmatrix} u_2 \\ r \end{pmatrix} = \begin{pmatrix} \bar{G}_2^{11} & \bar{G}_2^{12} \\ \bar{G}_2^{21} & \bar{G}_2^{22} \end{pmatrix} \begin{pmatrix} y_2 \\ v \end{pmatrix}, \tag{4.13}$$

where $\bar{G}_2^{ij}$ represent the corresponding linear maps. It is straightforward to show that we have

$$\begin{pmatrix} \bar{G}_{11} & \bar{G}_{12} \\ \bar{G}_{21} & \bar{G}_{22} \end{pmatrix}^{-1} = \begin{pmatrix} 0 & I \\ I & 0 \end{pmatrix} \begin{pmatrix} \bar{G}_2^{11} & \bar{G}_2^{12} \\ \bar{G}_2^{21} & \bar{G}_2^{22} \end{pmatrix} \begin{pmatrix} 0 & I \\ I & 0 \end{pmatrix}. \tag{4.14}$$

Let K be any controller for (4.10) of the form (4.15)

$$K : \begin{cases} \dot{p} = Mp + Ny_1, & p(0) = 0, \\ u_1 = Lp + Ry_1. \end{cases} \tag{4.15}$$

We show that there exists a system Λ of the form

$$\Lambda : \begin{cases} \dot{\lambda} = A_\Lambda \lambda + B_\Lambda u_\Lambda, & \lambda(0) = 0, \\ y_\Lambda = C_\Lambda \lambda + D_\Lambda u_\Lambda, \end{cases} \tag{4.16}$$

where A_Λ generates a C_0-semigroup $T_\Lambda(\cdot)$ on a Hilbert space Λ_1, $u_\Lambda(t) \in Y$, $y_\Lambda(t) \in U$ etc., such that the linear map K satisfies

$$K = \bar{G}_2^{11} + \bar{G}_2^{12}\Lambda(I - \bar{G}_2^{22}\Lambda)^{-1}\bar{G}_2^{21} = \mathcal{F}(\bar{G}_2, \Lambda), \tag{4.17}$$

i.e., K can be seen as the interconnection of (4.12) and (4.16) with $u_\Lambda = r$ and $y_\Lambda = v$ as in Fig. 4.1 (note that $(I - \bar{G}_2^{22}\Lambda)^{-1}$ exists because there is no feedthrough term in $\bar{G}_2^{22}$).

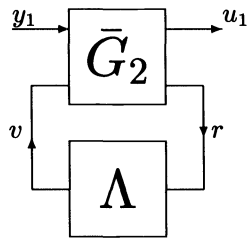

FIG. 4.1. $K = \mathcal{F}(\bar{G}_2, \Lambda)$.

Indeed, since $\bar{G}_2^{21}$ and $\bar{G}_2^{12}$ are both invertible, we can define $\tilde{\Lambda}$ as

$$\tilde{\Lambda} := (\bar{G}_2^{12})^{-1}(K - \bar{G}_2^{11})(\bar{G}_2^{21})^{-1}$$

and define Λ as

$$\Lambda := (I + \tilde{\Lambda}\bar{G}_2^{22})^{-1}\tilde{\Lambda}$$

(note that $(I + \tilde{\Lambda}\bar{G}_2^{22})^{-1}$ exists because there is no feedthrough term in $\bar{G}_2^{22}$).

Then $\tilde{\Lambda} = \Lambda(I - \bar{G}_2^{22}\Lambda)^{-1}$ and it is straightforward to show that (4.17) is satisfied. Furthermore, Λ can be realized as in (4.16).

Now let $\bar{G}_{zw}$ denote the closed-loop system determined by (4.10) and (4.15) with $y_1 = y$ and $u_1 = u$, i.e.,

$$\bar{G}_{zw} = \bar{G}_{11} + \bar{G}_{12}K(I - \bar{G}_{22}K)^{-1}\bar{G}_{21} = \mathcal{F}(\bar{G}, K).$$

The following result may seem surprising, but in fact it follows from (4.14).

LEMMA 4.3. *For all* $w \in L_2^{\mathrm{loc}}(0,\infty;W)$ *we have* $\bar{G}_{zw}w = \Lambda w$, *i.e.,*

$$\bar{G}_{zw} = \mathcal{F}(\bar{G},K) = \mathcal{F}(\bar{G},\mathcal{F}(\bar{G}_2,\Lambda)) = \Lambda \tag{4.18}$$

and

$$K = \mathcal{F}(\bar{G}_2,\Lambda) = \mathcal{F}(\bar{G}_2,\mathcal{F}(\bar{G},K)). \tag{4.19}$$

Proof. The closed-loop system $\bar{G}_{zw}$ can be described as in Fig. 4.2.

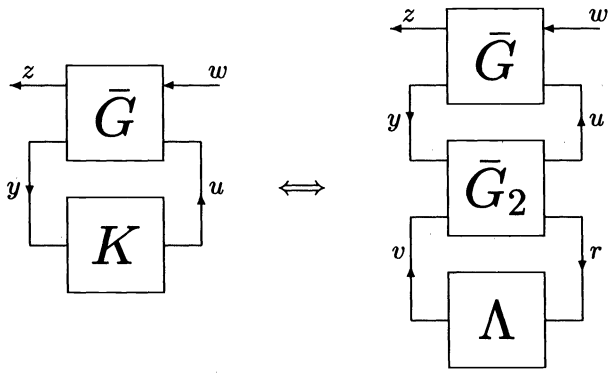

FIG. 4.2. $\bar{G}_{zw}$.

Now define $\tilde{G}$ as the interconnection of (4.10) and (4.12) with $y_2 = y$ and $u_2 = u$, as in Fig. 4.3, i.e.,

$$\tilde{G}: \begin{cases} \begin{pmatrix} \dot{x} \\ \dot{p}_1 \end{pmatrix} = \begin{pmatrix} A & -B_2C_1 \\ B_1C_2 & A - B_2C_1 - B_1C_2 \end{pmatrix} \begin{pmatrix} x \\ p_1 \end{pmatrix} \\ \qquad\qquad + \begin{pmatrix} B_1 \\ B_1 \end{pmatrix} w + \begin{pmatrix} B_2 \\ B_2 \end{pmatrix} v \\ z = (C_1 \quad -C_1) \begin{pmatrix} x \\ p_1 \end{pmatrix} + v \\ r = (C_2 \quad -C_2) \begin{pmatrix} x \\ p_1 \end{pmatrix} + w, \quad x(0) = p_1(0) = 0. \end{cases} \tag{4.20}$$

It is easy to see that

$$\begin{pmatrix} x - p_1 \\ x \end{pmatrix} = \begin{pmatrix} A - B_1C_2 & 0 \\ B_2C_1 & A - B_2C_1 \end{pmatrix} \begin{pmatrix} x - p_1 \\ x \end{pmatrix}$$

$$+ \begin{pmatrix} 0 \\ B_1 \end{pmatrix} w + \begin{pmatrix} 0 \\ B_2 \end{pmatrix} v, \tag{4.21}$$

and since $x(0) = 0$ and $p_1(0) = 0$, we see that $x - p_1 = 0$ and so

$$\begin{pmatrix} z \\ r \end{pmatrix} = \tilde{G} \begin{pmatrix} w \\ v \end{pmatrix} = \begin{pmatrix} \tilde{G}_{11} & \tilde{G}_{12} \\ \tilde{G}_{21} & \tilde{G}_{22} \end{pmatrix} \begin{pmatrix} w \\ v \end{pmatrix} = \begin{pmatrix} 0 & I \\ I & 0 \end{pmatrix} \begin{pmatrix} w \\ v \end{pmatrix}. \tag{4.22}$$

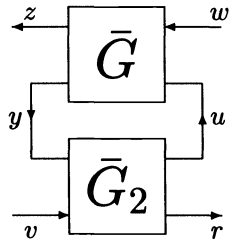

FIG. 4.3. $\tilde{G}$.

Now (4.18) follows from Figure 4.2 and (4.22), while (4.19) follows from (4.17) and (4.18). □

In fact (4.22) holds because of (4.14) and Fig. 4.3. This kind of property follows more or less from some results in [9]. There Redheffer defines the $*$-product for systems of the form $\bar{G}$ and $\bar{G}_2$ and this $*$-product corresponds to taking a feedback interconnection of $\bar{G}$ and $\bar{G}_2$ as in Fig. 4.3. A simple relation between the $*$-product inverse and the matrix inverse explains (4.22).

Using Lemma 4.3 and (4.21) we can prove the following result.

LEMMA 4.4. *Suppose that we have a controller K of the form* (4.15) *for the system $\bar{G}$ given by* (4.10) *with (M, N) exponentially stabilizable and (L, M) exponentially detectable. Furthermore, suppose that $A - B_1C_2$ and $A - B_2C_1$ both generate exponentially stable C_0-semigroups. Then K is admissible if and only if it can be realized as $\mathcal{F}(\bar{G}_2, \Lambda)$ for some Λ of the form* (4.16), *where A_Λ generates an exponentially stable C_0-semigroup and $\|\Lambda\| < 1$. In this case, $\mathcal{F}(\bar{G}_2, \Lambda)$ (with its realization on $X \times \Lambda_1$) is also itself admissible and we have $\bar{G}_{zw} = \mathcal{F}(\bar{G}, K) = \Lambda$.*

Proof. Necessity. Suppose that K of the form (4.15) is admissible for (4.10).

It follows from Lemma 4.3 that the linear map K can be expressed as $K = \mathcal{F}(\bar{G}_2, \Lambda)$ with $\Lambda = \mathcal{F}(\bar{G}, K) = \bar{G}_{zw}$. Since K is admissible, $\bar{G}_{zw}$ is of the form (2.12), where $\mathcal{A}$ is the infinitesimal generator of an exponentially stable C_0-semigroup. Hence we can realize Λ as (4.16) such that A_Λ generates an exponentially stable C_0-semigroup. Finally, $\|\Lambda\| = \|\bar{G}_{zw}\| < 1$ since K is admissible.

Sufficiency. Suppose that K of the form (4.15) allows for a realization determined by $\mathcal{F}(\bar{G}_2, \Lambda)$ with Λ of the form (4.16) such that A_Λ generates an exponentially stable C_0-semigroup and $\|\Lambda\| < 1$.

To avoid confusion we denote this realization by K_Λ, noting that $K_\Lambda y = Ky$ for all $y \in L_2^{\text{loc}}(0, \infty; Y)$).

The state-space of K_Λ is $X \times \Lambda_1$ and its realization is determined by (4.12) and (4.16) with $u_\Lambda = r$ and $y_\Lambda = v$. First we show that the closed-loop system on $X \times X \times \Lambda_1$ determined by $\bar{G}_{zw} = \mathcal{F}(\bar{G}, K_\Lambda)$ is exponentially stable and $\|\bar{G}_{zw}\| < 1$. The idea is to apply Theorem 3.2 to the right hand side of Fig. 4.2.

Using the assumption that that $A - B_1C_2$ and $A - B_2C_1$ both generate exponentially stable C_0-semigroups and (4.21), we conclude that the system $\tilde{G}$ given by (4.20) is exponentially stable (use [5, Lemmas 3.7 and 3.8], where some results of [10] are quoted). Furthermore, it follows trivially from (4.22) that $\tilde{G}$ is inner and that $(\tilde{G}_{21})^{-1}$ is i/o-stable. Now since A_Λ generates an exponentially stable semigroup and $\|\Lambda\| < 1$, we can apply Theorem 3.2 to conclude that the closed-loop system $\mathcal{F}(\bar{G}, K_\Lambda)$ on the Hilbert space $X \times X \times \Lambda_1$ is exponentially stable and that $\|\bar{G}_{zw}\| < 1$. In other words, K_Λ (with its realization on $X \times \Lambda_1$) is an admissible controller for $\bar{G}$.

We use this fact to show that K (realized as in (4.15)) is also admissible: It follows

from Lemma 2.2 that

$$\begin{pmatrix} (I-K_\Lambda\bar{G}_{22})^{-1} & (I-K_\Lambda\bar{G}_{22})^{-1}K_\Lambda \\ \bar{G}_{22}(I-K_\Lambda\bar{G}_{22})^{-1} & (I-\bar{G}_{22}K_\Lambda)^{-1} \end{pmatrix}$$

is i/o-stable and since $K_\Lambda y = Ky$ for all $y \in L_2^{\mathrm{loc}}(0,\infty;Y))$, we can replace K_Λ by K. Now the idea is to use Lemma 2.2. We have assumed that (M,N) is exponentially stabilizable and (L,M) is exponentially detectable and since $A-B_1C_2$ and $A-B_2C_1$ both generate exponentially stable semigroups, we see that also (A,B_2) is exponentially stabilizable and (C_2,A) is exponentially detectable. Hence Lemma 2.2 implies that the closed-loop system determined by (4.10) and (4.15) on the state-space $X\times P$ is exponentially stable. Now since $\|\mathcal{F}(\bar{G},K)\| = \|\mathcal{F}(\bar{G},K_\Lambda)\| = \|\bar{G}_{zw}\| < 1$, we conclude that K given by (4.15) is admissible. □

Next we define the transformed system G_{P_1} and show that it has the same admissible controllers as G, using Theorem 3.2 (this is similar to [2, Lemma 9]).

Suppose we have a system G of the form (2.8) and suppose that assumption (4.2) is satisfied (recall that without this assumption all the formulas would be more complicated). Let K again be a controller of the form (4.15). Furthermore, suppose that there exists a nonnegative definite operator $P_1 \in \mathcal{L}(X)$ that satisfies (4.5).

We define the system G_{P_1} to be

$$G_{P_1}: \begin{cases} \dot{x}_1 = (A+B_1B_1^*P_1)x_1 + B_1w_0 + B_2u, \\ u_0 = B_2^*P_1x_1 + u, \qquad x_1(0)=0 \\ y = (C_2+D_{21}B_1^*P_1)x_1 + D_{21}w_0, \end{cases} \tag{4.23}$$

or, in external representation,

$$\begin{pmatrix} u_0 \\ y \end{pmatrix} = \begin{pmatrix} {G_{P_1}}^{11} & {G_{P_1}}^{12} \\ {G_{P_1}}^{21} & {G_{P_1}}^{22} \end{pmatrix} \begin{pmatrix} w_0 \\ u \end{pmatrix}. \tag{4.24}$$

LEMMA 4.5. *We have the following equivalence. The controller K is admissible for G if and only if it is admissible for G_{P_1}.*

Proof. First, we define the auxiliary system G_I as in (4.6):

$$G_I: \begin{cases} \dot{x}_I = (A-B_2B_2^*P_1)x_I + B_1w + B_2\tilde{u}_0, \\ z = (C_1-D_{12}B_2^*P_1)x_I + D_{12}\tilde{u}_0, \qquad x_I(0)=0 \\ \tilde{w}_0 = -B_1^*P_1x_I + w \end{cases}$$

(G_I will play the role of the inner system in Theorem 3.2). It follows from Lemma 4.1 that $A-B_2B_2^*P_1$ is the infinitesimal generator of an exponentially stable C_0-semigroup and that G_I is inner. The external representation of G_I is given by

$$\begin{pmatrix} z \\ \tilde{w}_0 \end{pmatrix} = \begin{pmatrix} {G_I}^{11} & {G_I}^{12} \\ {G_I}^{21} & {G_I}^{22} \end{pmatrix} \begin{pmatrix} w \\ \tilde{u}_0 \end{pmatrix}. \tag{4.25}$$

Now ${G_I}^{21}$ is given by

$${G_I}^{21}: \begin{cases} \dot{x} = (A-B_2B_2^*P_1)x + B_1\bar{w}, \qquad x(0)=0, \\ \bar{w}_0 = -B_1^*P_1x + \bar{w}, \end{cases}$$

and it is easy to see that ${G_I}^{21}$ is invertible and that $({G_I}^{21})^{-1}$ is i/o-stable (use that $A+(B_1B_1^*-B_2B_2^*)P_1$ is exponentially stable). So we have shown that G_I satisfies the assumptions (3.9)–(3.11) of Theorem 3.2.

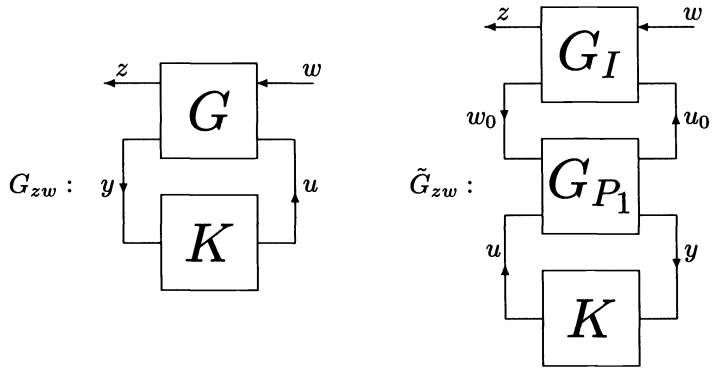

FIG. 4.4. $G_{zw} = \tilde{G}_{zw}$.

Now consider the two closed-loop systems given in Fig. 4.4, i.e., the system on the left is the interconnection of (2.8) and (4.15) with $y_1 = y$ and $u_1 = u$ and the system on the right is the interconnection of (4.6), (4.23), and (4.15) with $\tilde{w}_0 = w_0, \tilde{u}_0 = u_0, y_1 = y$, and $u_1 = u$ (recall that the system on the left is given by (2.12), (2.13)). In other words, $G_{zw} = \mathcal{F}(G, K)$ and $\tilde{G}_{zw} = \mathcal{F}(G_I, \mathcal{F}(G_{P_1}, K))$. We claim that the system on the left in Fig. 4.4 is exponentially stable if and only if the system on the right in Fig. 4.4 is and that both closed-loop maps from w to z are the same, i.e. $G_{zw} = \tilde{G}_{zw}$. Indeed, we can rewrite the state equations of the system on the right with $w = 0$ as

$$\begin{pmatrix} \dot{x_I - x_1} \\ x_1 \\ p \end{pmatrix}$$

$$= \begin{pmatrix} A + (B_1B_1^* - B_2B_2^*)P_1 & 0 & 0 \\ \times & A + B_2RC_2 & B_2L \\ \times & NC_2 & M \end{pmatrix} \begin{pmatrix} x_I - x_1 \\ x_1 \\ p \end{pmatrix}, \tag{4.26}$$

where the form of $\times$ is irrelevant. Note that the right lower 2×2-block in (4.26) represents the generator of the semigroup of the system on the left in Fig. 4.4. Since $A + (B_1B_1^* - B_2B_2^*)P_1$ generates an exponentially stable semigroup, it follows that the system on the left in Fig. 4.4 is exponentially stable if and only if the system on the right in Fig. 4.4 is exponentially stable.

Furthermore, the map $\tilde{G}_{zw}$ is determined by

$$\tilde{G}_{zw}: \begin{cases} \dot{(x_I - x_1)} &= (A + (B_1B_1^* - B_2B_2^*)P_1)(x_I - x_1), \\ \dot{x}_1 &= Ax_1 + B_1w + B_2u - B_1B_1^*P_1(x_I - x_1), \\ z &= C_1x_I + D_{12}u + D_{12}B_2^*P_1(x_1 - x_I), \\ \dot{p} &= Mp + Ny, \\ u &= Lp + Ry, \end{cases} \tag{4.27}$$

where $x_I(0) = 0, x_1(0) = 0$ and $p(0) = 0$. It follows that $(x_I - x_1) = 0$ and comparing (4.27) with (2.8) and (4.15) we see that indeed the closed-loop maps from w to z in both systems in Fig. 4.4 are the same. Therefore, K is admissible for G if and only if the system on the right in Fig. 4.4 is exponentially stable and $\|\tilde{G}_{zw}\| < 1$.

Now we can use Theorem 3.2 with G given by G_I and $G_2 = \mathcal{F}(G_{P_1}, K)$. We have already shown that G_I satisfies the assumptions (3.9)–(3.11). Hence, Theorem 3.2 implies that the system on the right in Fig. 4.4 is exponentially stable and $\|\mathcal{F}(G_I, \mathcal{F}(G_{P_1}, K))\| = \|\tilde{G}_{zw}\| < 1$ if and only if the system $\mathcal{F}(G_{P_1}, K)$ is exponentially stable and $\|\mathcal{F}(G_{P_1}, K)\| < 1$, i.e. K is admissible for G_{P_1}. This completes the proof. □

Finally, we present the main result of this section.

THEOREM 4.6. *Consider a system G of the form (2.8) and suppose that assumptions (4.1)–(4.4) are satisfied. There exists an admissible controller K (as in (4.15)) for G if and only if there exist nonnegative definite operators $P_1, P_2 \in \mathcal{L}(X)$ satisfying*

$$\begin{aligned} &\text{for all } x \in D(A),\ P_1 x \in D(A^*), \\ &(A^*P_1 + P_1A + P_1(B_1B_1^* - B_2B_2^*)P_1 + C_1^*C_1)x = 0 \\ &\text{and } A_1 := A + (B_1B_1^* - B_2B_2^*)P_1 \text{ is exponentially stable,} \end{aligned} \tag{4.5}$$

$$\begin{aligned} &\text{for all } x \in D(A^*),\ P_2 x \in D(A), \\ &((A + B_1B_1^*P_1)P_2 + P_2(A + B_1B_1^*P_1)^* + P_2(P_1B_2B_2^*P_1 - \\ &C_2^*C_2)P_2 + B_1B_1^*)x = 0 \text{ and } A_2 := A + B_1B_1^*P_1 + P_2(P_1B_2B_2^*P_1 \\ &-C_2^*C_2) \text{ is exponentially stable.} \end{aligned} \tag{4.28}$$

Moreover, in this case a controller K of the form (4.15) with (M, N) exponentially stabilizable and (L, M) exponentially detectable is admissible if and only if it can be realized as $\mathcal{F}(\tilde{K}, \Lambda)$, where $\tilde{K}$ is given by

$$\tilde{K}: \begin{cases} \dot{p}_1 = (A_1 - P_2C_2^*C_2)p_1 + P_2C_2^*y + (I + P_2P_1)B_2v, \\ u = -B_2^*P_1p_1 + v, \qquad p_1(0) = 0, \\ r = -C_2p_1 + y \end{cases} \tag{4.29}$$

and Λ is of the form

$$\Lambda: \begin{cases} \dot{\lambda} = A_\Lambda\lambda + B_\Lambda r, \qquad \lambda(0) = 0 \\ \\ v = C_\Lambda\lambda + D_\Lambda r \end{cases} \tag{4.30}$$

such that A_Λ generates an exponentially stable semigroup and $\|\Lambda\| < 1$. In this case, $\mathcal{F}(\tilde{K}, \Lambda)$ is also itself admissible.

Proof. Necessity. Suppose that K is admissible for G. It follows from Lemma 4.1 that there exists a nonnegative definite operator $P_1 \in \mathcal{L}(X)$ that satisfies (4.5). We can define G_{P_1} as in (4.23) and it follows from Lemma 4.5 that K is admissible for G_{P_1}. Lemma 4.2 implies that $K^\natural$ is admissible for $(G_{P_1})^\natural$, where $(G_{P_1})^\natural$ is given by

$$(G_{P_1})^\natural: \begin{cases} \dot{x} = (A + B_1B_1^*P_1)^*x + P_1B_2w + C_2^*u, \\ z = B_1^*x + D_{21}^*u, \qquad x(0) = 0 \\ y = B_2^*x + w \end{cases} \tag{4.31}$$

(note that now $D_{21}B_1^* = 0$).

Using assumptions (4.3), (4.4) it can be shown that $(G_{P_1})^\natural$ satisfies assumptions (4.1), (4.2), where $(G_{P_1})^\natural$ should be considered as of the form (2.8) (see [5, proof of Lemma 3.12]). Since $K^\natural$ is admissible for $(G_{P_1})^\natural$, we can therefore infer the existence of a nonnegative definite $P_2 \in \mathcal{L}(X)$ that satisfies the conditions in the theorem.

Sufficiency. Suppose that there exist nonnegative definite operators $P_1, P_2 \in \mathcal{L}(X)$ satisfying the conditions of the theorem. The existence of an admissible controller will follow from the controller parametrization part.

Controller parametrization. Suppose that there exist nonnegative definite operators $P_1, P_2 \in \mathcal{L}(X)$ satisfying the conditions of the theorem. We can define G_{P_1} as in (4.23). Then $(G_{P_1})^\natural$ is given by (4.31) and using the fact that P_2 satisfies the conditions of the theorem, we can construct $((G_{P_1})^\natural)_{P_2}$ just as we did in (4.23). Hence it follows from Lemma 4.5 that K is admissible for $(G_{P_1})^\natural$ if and only if K is admissible for $((G_{P_1})^\natural)_{P_2}$.

The transpose of $((G_{P_1})^\natural)_{P_2}$ is given by

$$(4.32)\qquad (((G_{P_1})^\natural)_{P_2})^\natural : \begin{cases} \dot{x} = ((A + B_1B_1^*P_1) + P_2P_1B_2B_2^*P_1)x \\ \qquad +P_2C_2^*w + (I + P_2P_1)B_2u, \\ z = B_2^*P_1x + u, \qquad x(0) = 0, \\ y = C_2x + w. \end{cases}$$

Now we see that $(((G_{P_1})^\natural)_{P_2})^\natural$ is of the form (4.10). We want to apply Lemma 4.4 and so we show that the system $(((G_{P_1})^\natural)_{P_2})^\natural$ satisfies the assumptions. Indeed, "$A - B_1C_2$" and "$A - B_2C_1$" are now given by $A_2 := A + B_1B_1^*P_1 + P_2(P_1B_2^*B_2P_1 - C_2^*C_2)$ and $A_1 := A + (B_1B_1^* - B_2B_2^*)P_1$. A_1 is stable because P_1 is the stabilizing solution of the Riccati equation (4.5) and A_2 is stable because P_2 is the stabilizing solution of the Riccati equation (4.28).

Hence we can apply Lemma 4.4 and it follows that a controller K of the form (4.15) with (M, N) exponentially stabilizable and (L, M) exponentially detectable is admissible for $(((G_{P_1})^\natural)_{P_2})^\natural$ if and only if it can be realized as $\mathcal{F}(\tilde{G}_2, \Lambda)$, where $\tilde{G}_2$ is constructed as $\tilde{G}_2$ in (4.12):

$$(4.33)\qquad \tilde{G}_2 : \begin{cases} \dot{p}_1 = (A + (B_1B_1^* - B_2B_2^*)P_1 - P_2C_2^*C_2)p_1 \\ \qquad + P_2C_2^*y + (I + P_2P_1)B_2v, \\ u = -B_2^*P_1p_1 + v, \qquad p_1(0) = 0, \\ r = -C_2p_1 + y, \end{cases}$$

and Λ is of the form (4.30) such that A_Λ generates an exponentially stable semigroup and $\|\Lambda\| < 1$.

Finally, the result follows from Lemmas 4.2 and 4.5. K is admissible for G if and only if K is admissible for G_{P_1} if and only if $K^\natural$ is admissible for $(G_{P_1})^\natural$ if and only if $K^\natural$ is admissible for $((G_{P_1})^\natural)_{P_2}$ if and only if K is admissible for $(((G_{P_1})^\natural)_{P_2})^\natural$. □

5. Conclusions and final remarks. In this paper we have given an infinite-dimensional time-domain version of Redheffer's lemma. The result that we have presented is a generalization of a finite-dimensional result that has been crucial in the theory of H_∞-control with measurement-feedback for finite-dimensional systems. The proof depends solely on time-domain techniques.

Using this result we have given a nice derivation of the parametrization of all controllers that solve the suboptimal regular H_∞-control problem with measurement-feedback for a large class of infinite-dimensional systems, thereby generalizing the finite-dimensional result.

Our remark in the introduction that this type of approach would be suitable for nonlinear and time-varying systems has recently been vindicated. In [8], a different approach was used to solve the finite-dimensional time-varying case.

Acknowledgment. I thank Professor Ruth Curtain for some useful comments and suggestions.

ON DYNAMIC FEEDBACK COMPENSATION AND COMPACTIFICATION OF SYSTEMS*

JOACHIM ROSENTHAL†

Abstract. This paper introduces a compactification of the space of proper $p \times m$ transfer functions with a fixed McMillan degree n. Algebraically, this compactification has the structure of a projective variety and each point of this variety can be given an interpretation as a certain autoregressive system in the sense of Willems. It is shown that the pole placement map with dynamic compensators turns out to be a central projection from this compactification to the space of closed-loop polynomials. Using this geometric point of view, necessary and sufficient conditions are given when a strictly proper or proper system can be generically pole assigned by a complex dynamic compensator of McMillan degree q.

Key words. multivariable systems, dynamic feedback compensation, compactification, central projection, autoregressive systems

1. Introduction.

In this paper we investigate the pole placement problem with dynamic compensators from a geometric point of view. For this consider a multivariable, time invariant linear system Σ_n of order n with m-inputs and p-outputs. Such a system can be represented with its state space representation

$$\Sigma_n \ : \dot{x} = Ax + Bu, \qquad y = Cx. \tag{1.1}$$

From an engineering point of view, an input–output description is natural. Mathematically, this can be achieved by taking the Laplace transform. The system Σ_n is then described in the frequency domain by the following equation:

$$\hat{y} = C(sI - A)^{-1}B\,\hat{u}. \tag{1.2}$$

The strictly proper rational matrix $G(s) := C(sI - A)^{-1}B$ is called the transfer function associated to the system Σ_n. It is well known that the dynamics of the system Σ_n depends in an essential way on the location of the poles of the transfer function $G(s)$, which are exactly the eigenvalues of the matrix A. A fundamental open problem in multivariable linear system theory is the following question: Under which conditions can a p-input, m-output system $F(s)$ of McMillan degree q be constructed that stabilizes the closed-loop system $G_F(s) := (I - G(s)F(s))^{-1}G(s)$? More generally, we can ask the following question: Given an arbitrary polynomial $\phi(s) = s^{n+q} + \lambda_{n+q-1}s^{n+q-1} + \cdots + \lambda_0$, under which conditions is it always possible to find a compensator of order q such that the poles of the closed-loop system $G_F(s)$ are exactly the roots of the polynomial $\phi(s)$? Willems and Hesselink [37] called a system $G(s)$ with this property pole assignable in the class of feedback controllers of order q. Using a dimension argument they showed that

$$q(m+p) + mp \geq n + q \tag{1.3}$$

is a necessary condition for any system $G(s)$ to have the pole assignability property in the class of feedback controllers of order q. In this paper we will show the new result that this numerical condition is not only necessary but also sufficient for a generic system $G(s)$ if the base field is algebraically closed. To establish this result, we will study for a generic system $G(s)$ the associated *pole placement map* ρ_G. The domain of ρ_G is the space of proper transfer functions of McMillan degree q and the range of ρ_G is the space of monic polynomials of degree $n+q$. In this language the system $G(s)$ has the pole assignability property in the class of feedback controllers of order q if and only if ρ_G is onto.

The question of pole assignability is fairly well understood if we restrict ourselves to the class of static compensators, in other words, compensators with McMillan degree $q=0$, and if we assume that the base field is algebraically closed. In this case we know that $mp \geq n$ is a necessary and sufficient condition for the pole placement map ρ_G to be onto generically. Indeed, Hermann and Martin [13] first showed that ρ_G is almost onto using the dominant morphism theorem. Brockett and Byrnes [2] later showed that ρ_G is even onto and the mapping degree of ρ_G in the case $mp=n$ is equal to the degree of the Grassmann variety $\mathrm{Grass}(p, p+m)$.

The pole placement problem with dynamic compensators ($q>0$) is much less understood. The following result of Brash and Pearson [1], published 1970, is still one of the strongest results available. For the generic situation their result can be quoted in the following manner. (See, e.g., [3].)

THEOREM 1.1 (Brash and Pearson [1]). *The generic degree n linear system with m–inputs and p–outputs can be arbitrarily pole assigned (over any field) using a compensator of order q, where q is any natural number satisfying*

$$\max(m,p)(q+1) \geq n. \tag{1.4}$$

It is interesting to see that the necessary condition $q(m+p)+mp \geq n+q$ of Willems and Hesselink [37] is also sufficient as soon as $\min(m,p)=1$. In §4 we will explain that this is essentially due to the fact that the space of proper transfer functions with fixed McMillan degree is a Zariski open subset of a projective space if $\min(m,p)=1$ and ρ_G is a linear map from this projective space to the space of closed-loop polynomials identified with a projective space as well. If $\min(m,p)>1$, however, this is not the case and ρ_G is a rather complicated morphism.

An important contribution to understanding the pole placement problem in general was done by Byrnes [4]. In this paper Byrnes introduced a compactification for the quasi-projective variety of proper transfer functions of degree q, which he denoted by $C^q_{m,p}$. He then explained the pole placement problem as an intersection problem in $C^q_{m,p}$. Using this point of view he achieved new results for pole assignment with compensators of degree $q=1$ not achieved by any other means. Our approach is guided in part by the philosophy of this paper and that is one of the reasons why we have chosen a similar title.

A great deal of research was devoted to the question of understanding the pole placement problem with static compensators over the reals. In 1975 Kimura [16] proved the result that $m+p-1 \geq n$ is a sufficient condition for the pole placement map ρ_G to be generically onto. Since that time, several authors have improved his results and methods in different directions. Using a geometric approach Wang [35] very recently achieved the strong result that the pole placement map ρ_G is generically onto over the reals as soon as $mp-1 \geq n$. A crucial part in Wang's proof is the fact that the pole placement map ρ_G is a central projection when $q=0$. As we will show in this paper, the same is true in general.

The paper is structured as follows. After explaining some mathematical preliminaries in §2, we will introduce a projective variety in §3 that can be viewed as a compactification of the space of proper $p \times m$ transfer functions of McMillan degree n that we denote with $K^n_{p,m}$. This compactification was originally introduced by Rosenthal in [27] and used in [28] to achieve new results for certain low-dimensional feedback problems. In Theorem 3.6 we will describe the defining equations of the variety $K^n_{p,m}$ and in Theorem 3.10 we give an interpretation in terms of certain autoregressive systems.

In §4 the pole placement problem is formulated in a geometric language. To deal with compensators that are not admissible, the notion of *q–degeneracy*, a generalization of the concept of *degeneracy* [2], is introduced. We will show that for a q–nondegenerate plant, the pole placement map can be extended in a continuous manner to the whole compactification.

The main results of the paper are given in §5. It is first shown that the q–degenerate systems form an algebraic subset in the quasi-projective variety of transfer functions. Then necessary and sufficient conditions are given when the q–nondegenerate systems are generic. We will show that the pole placement map is a central projection. Using this fact we are able to formulate conditions when the pole placement map for a q–nondegenerate strictly proper (or proper) system is onto (almost onto). These results constitute a generalization of the results of Hermann and Martin [13] and Brockett and Byrnes [2] from the problem of static to the problem of dynamic feedback compensation.

Finally some words about the base field. Most constructions we do in §§3 and 4 can be done over an arbitrary field $\mathbb{K}$. For most applications, of course, the relevant base fields are the real or complex numbers, i.e., $\mathbb{K} = \mathbb{R}$ or $\mathbb{K} = \mathbb{C}$. The results in §5 will use the projective dimension theorem (see, e.g., [9]) and this theorem is only valid if the field is algebraically closed.

2. Preliminaries. Let $\mathbb{K}$ be an arbitrary field. With $\bar{\mathbb{K}}$ we will denote the algebraic closure of $\mathbb{K}$. If V is a $\mathbb{K}$–vector space, we will denote with $\mathbb{P}(V)$ the set of one-dimensional subspaces of V. $\mathbb{P}(V)$ is called the projective space associated to V. A topology defined on V induces a topology on $\mathbb{P}(V)$, namely, the quotient topology of the canonical projection $pr : V - \{0\} \longrightarrow \mathbb{P}(V)$. As it is well known, $\mathbb{P}(\mathbb{C}^{n+1})$ and $\mathbb{P}(\mathbb{R}^{n+1})$ are compact manifolds with the induced topology coming from the natural topology on $\mathbb{C}^{n+1}$ or $\mathbb{R}^{n+1}$. If $V = \mathbb{K}^{n+1}$ we sometimes use the notation $\mathbb{P}^n_{\mathbb{K}}$ or simply $\mathbb{P}^n$.

We will identify $\mathbb{K}^n$ as a subset of $\mathbb{P}^n$ using the inclusion:

$$i : \mathbb{K}^n \longrightarrow \mathbb{P}^n_{\mathbb{K}}, \qquad (x_1, \ldots, x_n) \longmapsto (x_1, \ldots, x_n, 1). \tag{2.1}$$

In particular $\mathbb{K}$ is identified with $\{(x, 1) \mid x \in \mathbb{K}\} \subset \mathbb{P}^1_{\mathbb{K}}$. We will call the point $(1, 0)$, which is the only point in the difference set $\mathbb{P}^1_{\mathbb{K}} - i(\mathbb{K})$, the point at infinity and $\mathbb{P}^1_{\mathbb{K}}$ *the projective line* over $\mathbb{K}$.

Consider now the polynomial ring $\mathbb{K}[s]$ in one indeterminate. Assume the set of polynomials $\{f_1(s), \ldots, f_{n+1}(s)\} \subset \mathbb{K}[s]$ has no common zeroes. Then the map

$$f : \mathbb{K} \longrightarrow \mathbb{P}^n_{\mathbb{K}}, \qquad s \longmapsto (f_1(s), \ldots, f_{n+1}(s)) \tag{2.2}$$

is well defined and called a *rational map*. The *degree* of f is defined by the highest degree of the polynomials $f_i(s)$. Assume f has degree d. The homogenization of $f(s)$

is defined by

$$\hat{f}(s,t) := t^d f\left(\frac{s}{t}\right). \tag{2.3}$$

Note that $\hat{f}$ extends the rational map f to the whole projective line $\mathbb{P}^1_{\mathbb{K}}$. Moreover, if $\mathbb{K}$ is algebraically closed, the image $\mathrm{Im}(\hat{f})$ defines a rational curve in $\mathbb{P}^n_{\mathbb{K}}$ in the sense of algebraic geometry. Note that over the complex numbers the holomorphic maps from the Riemann sphere $\mathbb{P}^1_{\mathbb{C}}$ to the complex projective space $\mathbb{P}^n_{\mathbb{C}}$ are exactly the rational maps corresponding to our definition.

The degree d of the rational map f has the following geometric interpretation: Intersect the curve $\mathrm{Im}(\hat{f})$ with a generic linear hyperplane H in $\mathbb{P}^n_{\mathbb{K}}$, which can be described by a homogeneous linear equation of the form $\sum c_i x_i = 0$. By the fundamental theorem of algebra, H intersects $\mathrm{Im}(\hat{f})$ over the algebraic closure $\bar{\mathbb{K}}$ in exactly d points when counted with multiplicities. In short, the variety $\mathrm{Im}(\hat{f})$ has degree d.

Denote with $\mathrm{Rat}_d(\mathbb{P}^1, \mathbb{P}^n)$ the set of all rational maps of degree d. $\mathrm{Rat}_d(\mathbb{P}^1, \mathbb{P}^n)$ can be exhibited as a Zariski open set in $\mathbb{P}(\mathbb{K}^{d+1} \otimes \mathbb{K}^{n+1})$. For this consider a particular embedding

$$\begin{aligned} \tau &: \mathrm{Rat}_d(\mathbb{P}^1, \mathbb{P}^n) \longrightarrow \mathbb{P}(\mathbb{K}^{d+1} \otimes \mathbb{K}^{n+1}) \\ &\left(\sum_{j=0}^{d} a_{1j} s^j, \ldots, \sum_{j=0}^{d} a_{(n+1)j} s^j\right) \longmapsto (a_{10}, \ldots, a_{1d}, a_{20}, \ldots, \ldots, a_{(n+1)d}). \end{aligned} \tag{2.4}$$

The complement of the image of $\mathrm{Rat}_d(\mathbb{P}^1, \mathbb{P}^n)$ under τ in $\mathbb{P}(\mathbb{K}^{d+1} \otimes \mathbb{K}^{n+1})$ is an algebraic set already described around the turn of the century by Macaulay [21]. If $n = 1$ this algebraic set is a hypersurface described by the well-known resultant locus of two polynomials:

$$\det \mathrm{Res}(f_1, f_2) = 0. \tag{2.5}$$

A natural generalization of the projective space is the Grassmann variety. Consider again a $\mathbb{K}$–vector space V. The set of p–dimensional subspaces in V is called the Grassmann variety which we will denote by $\mathrm{Grass}(p, V)$. If $V = \mathbb{K}^n$ we will just write $\mathrm{Grass}(p, n)$. In particular, we have $\mathrm{Grass}(1, n) = \mathbb{P}^{n-1}$.

The set $\mathrm{Grass}(p, n)$ indeed has the structure of a projective variety. For this consider the Plücker embedding φ of the Grassmann variety $\mathrm{Grass}(p, n)$, which is defined in the following way:

$$\begin{aligned} \varphi &: \mathrm{Grass}(p, n) \longrightarrow \mathbb{P}(\wedge^p \mathbb{K}^n), \\ &\mathrm{span}(v_1, \ldots, v_p) \longmapsto v_1 \wedge \cdots \wedge v_p. \end{aligned} \tag{2.6}$$

It is easy to verify that φ is an embedding. Moreover, $\mathrm{Im}(\varphi)$ is irreducible and described by a famous set of quadratic relations sometimes called "shuffle relations." (See, e.g., the survey article [17] or [25] for a characteristic free approach.) Finally we say a map $h : \mathbb{K} \longrightarrow \mathrm{Grass}(p, n)$ is a rational map if $f := \varphi \circ h$ is rational according to the definition above.

The set of all rational maps of degree d from the projective line $\mathbb{P}^1_{\mathbb{K}}$ to the Grassmann variety $\mathrm{Grass}(p, n)$ will be denoted by $\mathrm{Rat}_d(\mathbb{P}^1_{\mathbb{K}}, \mathrm{Grass}(p, n))$.

3. A compactification of the space of proper transfer functions. In the following denote with $S^n_{p,m}$ the space of proper $p \times m$ transfer functions of McMillan degree n. Algebraically, the set $S^n_{p,m}$ has the structure of a quasi-projective variety of dimension $n(m+p)+mp$. This follows directly from the fact that the space $\mathrm{Rat}_{n,m,p}$ of strictly proper transfer functions is quasi-projective (even quasi-affine) [10], has dimension $n(m+p)$, and $S^n_{p,m} \cong \mathrm{Rat}_{n,m,p} \times \mathbb{K}^{mp}$. Analytically, i.e., over the complex numbers, it is well known that $S^n_{p,m}$ and $\mathrm{Rat}_{n,m,p}$ are both connected complex manifolds. Many authors already studied topological properties of the spaces $S^n_{p,m}, \mathrm{Rat}_{n,m,p}$, and very recently Mann and Milgram [22] introduced a new stratification of $\mathrm{Rat}_{n,m,p}$ enabling them to calculate the additive structure of the homology ring $H_*(\mathrm{Rat}_{n,m,p})$.

If we consider feedback problems with high gain compensators or if we want to understand partial system failures, it is of ample importance to understand the boundary structure of the space $S^n_{p,m}$. Motivated by those problems, several authors (e.g. [4], [8], [11], [12], [20], [26], [29]) considered the problem of compactifying the space $S^n_{p,m}$. In this section we will describe a compactification of the space $S^n_{p,m}$, which turns out to be suitable for the study of dynamic feedback compensation. The basic idea is to embed $S^n_{p,m}$ into a projective space. The closure of the image with respect to the Zariski topology serves as a compactification. Our approach is geometric, indeed, we will view each transfer function $G(s) \in S^n_{p,m}$ as a rational curve of degree n into a Grassmann variety. In other words we will identify each $G(s)$ with its Hermann–Martin curve [23]. Because this curve is of crucial importance for all that follows and because we want to develop our theory over an arbitrary field $\mathbb{K}$, we explain this concept in more detail.

Consider a left coprime factorization $D_L^{-1}(s)N_L(s) = G(s)$, where $D_L(s)$ and $N_L(s)$ are polynomial matrices. The following results are well known and proofs can be found, for example, in [5]. From coprimeness it follows that the $p \times (m+p)$ polynomial matrix $(\, N_L(s)\, D_L(s)\,)$ is of full rank for all $s \in \bar{\mathbb{K}}$. If $\tilde{D}_L^{-1}(s)\tilde{N}_L(s) = G(s)$ is a second coprime factorization, then there is a $p \times p$ unimodular matrix $U(s)$, i.e., $U(s) \in Gl_p(\mathbb{K}[s])$, with $(\, \tilde{N}_L(s)\, \tilde{D}_L(s)\,) = U(s)\,(\, N_L(s)\, D_L(s)\,)$; in other words, $(\, \tilde{N}_L(s)\, \tilde{D}_L(s)\,)$ is row equivalent to $(\, N_L(s)\, D_L(s)\,)$. From these remarks it now follows that every element $s \in \mathbb{K}$ is assigned a p–dimensional subspace in $\mathbb{K}^{m+p}$, namely, the rowspace of $(\, N_L(s)\, D_L(s)\,)$. Identifying each subspace with a point of the Grassmann variety $\mathrm{Grass}(p, m+p)$ we get a well-defined map h that is independent of the selected coprime factorization and just depends on the transfer function $G(s)$:

$$h : \mathbb{K} \longrightarrow \mathrm{Grass}(p, m+p), \qquad s \longmapsto \mathrm{rowsp}(\, N_L(s)\, D_L(s)\,). \tag{3.1}$$

DEFINITION 3.1. The map h is called the Hermann–Martin map associated to the transfer function $G(s)$.

We will show that h is a rational map and $\mathrm{Im}(h)$ describes a rational curve in the sense of algebraic geometry. It is not hard to see that two different transfer functions $G(s)$ and $\tilde{G}(s)$ give rise to two different maps. In this way, the space $S^n_{p,m}$ is embedded into the space of rational maps into the Grassmannian $\mathrm{Grass}(p, m+p)$. As pointed out by Martin and Hermann [23], it is possible to extend h to "infinity" if we consider a strictly proper transfer function $G(s)$ and if we work over the complex numbers. In the case of an arbitrary field $\mathbb{K}$, we can do something similar. Moreover, we do not have to restrict our considerations to strictly proper transfer functions. We will contemplate the following general setting.

Denote with $P_{p,m}$ the space of all $p \times (m+p)$ full rank polynomial matrices

$P(s)$. We say two elements $P(s)$, $\tilde{P}(s)$ in $P_{p,m}$ are (row) equivalent if there is a $p \times p$ unimodular matrix $U(s) \in Gl_p(\mathbb{K}[s])$ with the property that $\tilde{P}(s) = U(s)P(s)$. Every $p \times (m+p)$ polynomial matrix defines a system of autoregressive equations of the form

$$(P(s)) \cdot \begin{pmatrix} u \\ y \end{pmatrix}(s) \;=\; 0. \tag{3.2}$$

If $u(s)$ and $y(s)$ are solutions from the space of rational functions, it is clear that equivalent systems have the same solution set. Using the language of Willems [38], [39] (compare also with [18], [30]) we call an equivalence class in $P_{p,m}$ an *autoregressive system* and the solution set the behavior of the system. Not all autoregressive systems actually describe a left factorization of a transfer function because the last minor of $P(s)$ is not necessarily invertible. However, if the polynomial matrix $P(s)$ can be partitioned into $(P_1(s)\, P_2(s))$ with $P_2(s) \in Gl_p(\mathbb{K}(s))$ (this is the generic situation), $P(s)$ defines a proper or improper transfer function $G(s) := P_2^{-1}(s)P_1(s)$ and equivalent systems define the same transfer function.

As shown by Kuijper and Schumacher [18], [19] it is always possible to realize an autoregressive system by a not necessarily regular descriptor system of the form

$$E\dot{x} = Ax + Bu,\; y = Cx + Du. \tag{3.3}$$

An autoregressive system $P(s)$ is called irreducible or controllable if $P(s)$ has full rank for all $s \in \bar{\mathbb{K}}$. (Compare with [7], [14], [30], [39].) Every irreducible autoregressive system $P(s) \in P_{p,m}$ gives rise to a rational map

$$h:\; \mathbb{K} \longrightarrow \mathrm{Grass}(p, m+p); \qquad s \longmapsto \mathrm{rowsp}P(s) \tag{3.4}$$

and this map depends only on the equivalence class in $P_{p,m}$. (Compare with [7].) In the following we extend h to the whole projective line $\mathbb{P}^1_{\mathbb{K}}$; in other words, we extend h to "infinity."

Without loss of generality we assume $P(s)$ is row reduced (see, e.g., [15]). Denote with $h_i(s)$ the ith row of $P(s)$ and with ν_i the degree of the polynomial vector $h_i(s)$, i.e., the highest degree of all polynomial entries. Consider the homogenization

$$\hat{h}_i(s,t) := t^{\nu_i} h_i\left(\frac{s}{t}\right) \tag{3.5}$$

Denote with $\hat{P}(s,t)$ the matrix constructed from the rows $\hat{h}_i(s,t)$. In this way we receive an extended Hermann–Martin map $\hat{h}$:

$$\hat{h}\;:\mathbb{P}^1_{\mathbb{K}} \longrightarrow \mathrm{Grass}(p, m+p), \qquad (s,t) \longmapsto \mathrm{rowsp}\hat{P}(s,t). \tag{3.6}$$

The map $\hat{h}$ is in fact rational. For this consider the Plücker embedding φ of the Grassmann variety $\mathrm{Grass}(p, m+p)$ as defined in (2.6). The combined map $\hat{f} = \varphi \circ \hat{h}$ is given by $\hat{f}(s,t) := \hat{h}_1(s,t) \wedge \cdots \wedge \hat{h}_p(s,t)$. Because the entries of $\hat{f}(s,t)$ are the principal minors of $\hat{P}(s,t)$, it is immediate that $\hat{f}(s,t)$ is homogeneous in (s,t) of degree $n = \sum \nu_i$. In other words,

$$\hat{f}\;:\;\mathbb{P}^1_{\mathbb{K}} \longrightarrow \mathbb{P}(\wedge^p \mathbb{K}^{m+p}) \tag{3.7}$$

defines a rational map. Finally note that $\hat{f}(s,t)$ is exactly the homogenization of $f(s) := h_1(s) \wedge \cdots \wedge h_p(s)$.

Note that the McMillan degree of a proper or even improper transfer function $G(s)$ represented by a coprime factorization $D_L^{-1}(s)N_L(s) = G(s)$ is equal to the highest degree of the principal minors of the matrix $\begin{pmatrix} N_L(s) \\ D_L(s) \end{pmatrix}$ (see, e.g., [7], [14]). Based on this fact we define the McMillan degree of an autoregressive system in the following way.

DEFINITION 3.2. The McMillan degree of an autoregressive system $P(s)$ is given by the maximal degree of the full size minors of $P(s)$.

We are now in a position to describe a compactification of $S_{p,m}^n$, the quasi-projective variety of proper $p \times m$ transfer functions of McMillan degree n. The Hermann–Martin identification gives rise to an embedding of $S_{p,m}^n$ into the space of rational maps $\mathrm{Rat}_n(\mathbb{P}^1_{\mathbb{K}}, \mathrm{Grass}(p, m+p))$. Using the Plücker embedding (2.6), this set can be identified with a set of rational maps into a projective space, and, as outlined earlier, this set is contained in a Zariski open set of a projective space. All those maps can be summarized by the following diagram of maps [27]:

$$\begin{aligned} S_{p,m}^n &\xrightarrow{\text{Her.–Mar.}} \mathrm{Rat}_n(\mathbb{P}^1, \mathrm{Grass}(p, m+p)) \\ &\xrightarrow{\text{Plücker}} \mathrm{Rat}_n(\mathbb{P}^1, \mathbb{P}(\wedge^p \mathbb{K}^{m+p})) \\ &\xrightarrow{\tau} \mathbb{P}(\mathbb{K}^{n+1} \otimes \wedge^p \mathbb{K}^{m+p}). \end{aligned} \tag{3.8}$$

DEFINITION 3.3. $K_{p,m}^n$ is defined as the Zariski closure of $S_{p,m}^n$ in $\mathbb{P}(\mathbb{K}^{n+1} \otimes \wedge^p \mathbb{K}^{m+p})$.

$K_{p,m}^n$ is an algebraic set of a projective space by definition. Over the reals ($\mathbb{K} = \mathbb{R}$) or over the complex numbers ($\mathbb{K} = \mathbb{C}$) we have already mentioned in §2 that $\mathbb{P}(\mathbb{K}^{n+1} \otimes \wedge^p \mathbb{K}^{m+p})$ is compact with the induced topology. In this way we can view $K_{p,m}^n$ as a compactification of $S_{p,m}^n$. Note also that $K_{p,m}^0 = \mathrm{Grass}(p, m+p)$. In other words, our compactification reduces to the Grassmannian model already widely used to study static output feedback problems (see, e.g., [3], [34]). The following theorem states that $K_{p,m}^n$ is a projective variety for all natural numbers m, p, n.

THEOREM 3.4. *$K_{p,m}^n$ is a projective variety of dimension $n(m+p)+mp$. If $S_{p,m}^n$ is irreducible then $K_{p,m}^n$ is irreducible as well.*

Proof. Because $S_{p,m}^n$ is quasi-projective the dimension of $S_{p,m}^n$ and its Zariski closure $K_{p,m}^n$ are the same. The irreducibility of $K_{p,m}^n$ follows directly from the irreducibility of $S_{p,m}^n$. Indeed, consider a decomposition $K_{p,m}^n = Y^1 \bigcup Y^2$ into Zariski closed subsets. Then $S_{p,m}^n = (S_{p,m}^n \cap Y^1) \bigcup (S_{p,m}^n \cap Y^2)$. By irreducibility of $S_{p,m}^n$ it follows that $S_{p,m}^n \subset Y^1$ or $S_{p,m}^n \subset Y^2$. But then $K_{p,m}^n$ is also contained in one of the sets Y^1, Y^2. □

Remark 3.5. 1. Over an algebraically closed field $S_{p,m}^n$ is always irreducible [10].

2. By a dimension argument it is clear that $K_{p,m}^n$ is a proper subset of $\mathbb{P}(\mathbb{K}^{n+1} \otimes \wedge^p \mathbb{K}^{m+p})$ as soon as $\min(m, p) \geq 2$. On the other hand, we have:

$$K_{1,m}^n \cong K_{m,1}^n \cong \mathbb{P}^{mn+m+n}. \tag{3.9}$$

In the following we want to describe a specific set of equations that generate the homogeneous ideal $I(K_{p,m}^n)$. For this consider a polynomial vector $f(s) \in \mathrm{Rat}_n(\mathbb{P}^1, \mathbb{P}(\wedge^p \mathbb{K}^{m+p}))$ and expand it in terms of its Plücker coordinates with respect to the standard basis:

$$f(s) = \sum_{\underline{i} \in \binom{m+p}{p}} f_{\underline{i}}(s) \cdot e_{i_1} \wedge \cdots \wedge e_{i_p}. \tag{3.10}$$

To say the map $f(s)$ factors over the Grassmannian it is necessary that the Plücker coordinates satisfy the "shuffle relations" (QR) (see, e.g., [17] or [25]), when considered as equations of the polynomial ring $\mathbb{K}[s]$:

$$(QR) \qquad \sum_{\lambda=1}^{p+1}(-1)^{\lambda} \cdot f_{i_1,\ldots,i_{p-1},j_\lambda}(s) \cdot f_{j_1,\ldots,\hat{j_\lambda},\ldots,j_{p+1}}(s) = 0. \tag{3.11}$$

In these equations, $i_1,\ldots,i_{p-1}$ and $j_1,\ldots,j_{p+1}$ are any sequence of integers with $1 \leq i_\alpha, j_\beta \leq m+p$ and the symbol $\hat{}$ means that j_λ must be removed (compare [17]). As shown in [25] the quadratic equations (QR) generate the homogeneous ideal if the base field is arbitrary but infinite. Equating polynomial coefficients we receive a set of necessary quadratic equations in $\mathbb{P}(\mathbb{K}^{n+1} \otimes \wedge^p \mathbb{K}^{m+p})$. The following theorem states that those equations are also sufficient; in other words, they really "cut out" $K^n_{p,m}$.

THEOREM 3.6. *Let $\mathbb{K}$ be an infinite field. Then the variety $K^n_{p,m} \subset \mathbb{P}(\mathbb{K}^{n+1} \otimes \wedge^p \mathbb{K}^{m+p})$ is the zero set of the ideal generated by the set of quadratic relations obtained from equating the coefficients in the shuffle relations (QR).*

Proof. Denote with $\wp$ the homogeneous ideal generated by the equations obtained when equating (QR). Because the polynomials of $\wp$ vanish on $S^n_{p,m}$, i.e., $\wp \subseteq I(S^n_{p,m})$, it follows for the sets of zeros that $Z(I(S^n_{p,m})) = K^n_{p,m} \subseteq Z(\wp)$. It therefore remains to show that $Z(\wp) \subseteq K^n_{p,m}$. For this consider in $\mathbb{P}(\mathbb{K}^{n+1} \otimes \wedge^p \mathbb{K}^{m+p})$ the Zariski open subset Y corresponding to all polynomial vectors $f(s) = (\ldots, f_i(s), \ldots)$ that have the property that $f(s) \neq 0$ for all $s \in \bar{\mathbb{K}}$ and that have the property that the last Plücker coordinate $f_{m+1,\ldots,m+p}(s)$ has degree n. Assume now that a point $f(s) \in Y \subset \mathbb{P}(\mathbb{K}^{n+1} \otimes \wedge^p \mathbb{K}^{m+p})$ satisfies the equations coming from (QR) for all $s \in \bar{\mathbb{K}}$. Viewing the entries of $f(s)$ as elements in the field $\mathbb{K}(s)$, it is immediate that there is a rational $p \times (m+p)$ matrix $R(s)$ that is mapped under the Plücker embedding on the vector $f(s)$. Using the row reduction process introduced by Forney [6], we find a $p \times (m+p)$ polynomial matrix $P(s)$ with minimal row indices and a rational matrix $Q(s) \in Gl_p(\mathbb{K}(s))$ with $P(s) = Q(s)R(s)$. The Plücker coordinates $p(s)$ of the polynomial matrix $P(s)$ are clearly given by $p(s) = \det Q(s)\, f(s)$. However, it then follows from the assumptions we made that $\det Q(s) \in \mathbb{K}$, the last entry of $p(s)$ is a polynomial of degree n, and $P(s)$ is mapped onto $f(s)$ viewed as a point of projective space. In other words, $f(s)$ describes a point of $S^n_{p,m}$. In short, $Z(\wp) \cap Y \subseteq S^n_{p,m}$, but it is then clear that $Z(\wp) \subseteq K^n_{p,m}$. □

The following example illustrates how it is possible to find a describing set of equations in a concrete case.

Example 3.7 (see [27]). $K^1_{2,2} \hookrightarrow \mathbb{P}^{11}$ is the complete intersection of three quadrics.

Indeed, $K^1_{2,2}$ is defined by $\{(f_{1,2}(s),\ldots,f_{3,4}(s)) \mid f_{1,2}(s)f_{3,4}(s) - f_{1,3}(s)f_{2,4}(s) + f_{1,4}(s)f_{2,3}(s) \equiv 0$ and $f_{i,j}(s) = a_{i,j} + b_{i,j}s\ 1 \leq i < j \leq 4\}$. In $\mathbb{P}^{11}$, we therefore have the following equations:

$$a_{1,2}a_{3,4} - a_{1,3}a_{2,4} + a_{1,4}a_{2,3} = 0, \tag{3.12}$$

$$b_{1,2}b_{3,4} - b_{1,3}b_{2,4} + b_{1,4}b_{2,3} = 0, \tag{3.13}$$

$$a_{1,2}b_{3,4} + a_{3,4}b_{1,2} - a_{1,3}b_{2,4} - a_{2,4}b_{1,3} + a_{1,4}b_{2,3} + a_{2,3}b_{1,4} = 0. \tag{3.14}$$

Because $\dim K^1_{2,2} = 8$ the intersection must be complete. In particular the degree of $K^1_{2,2}$ is equal to 8 by the classical Bézout theorem.

In the remaining part of this section we want to give a system theoretic interpretation of the boundary points that were added in the compactification $K^n_{p,m}$. For this consider a polynomial vector $f(s) \in K^n_{p,m}$. We now distinguish two cases.

Case 1. Assume $f(s) \neq 0$ for all $s \in \bar{\mathbb{K}}$. From the proof of Theorem 3.6 it immediately follows that we find a $p \times (m+p)$ polynomial matrix $P(s)$ that is mapped onto $f(s)$ under the Plücker embedding. Because $P(s)$ has full rank for all $s \in \bar{\mathbb{K}}$, it follows that the Kronecker row indices are equal to the minimal row indices in the sense of Forney [6]. (Compare [15].) In other words, if $\tilde{P}(s)$ is another polynomial matrix that is mapped onto $f(s)$, then $P(s)$ and $\tilde{P}(s)$ are row equivalent, i.e., there is a unimodular matrix $U(s)$ with $\tilde{P}(s) = U(s) \cdot P(s)$.

Case 2. There is an $s_o \in \bar{\mathbb{K}}$ with $f(s_o) = 0$. Because the minimal polynomial of s_o over $\mathbb{K}$ divides each coordinate, we find a polynomial $g(s) \in \mathbb{K}[s]$ with $f(s) = g(s)\tilde{f}(s)$ and $\tilde{f}(s) \neq 0$ for all $s \in \bar{\mathbb{K}}$. It is obvious that we again find a polynomial $p \times (m+p)$ matrix $P(s)$ that is mapped onto $f(s)$. Note that $P(s_o)$ does not have full rank. To describe all other polynomial matrices that are mapped onto $f(s)$ we introduce the following group:

$$H := \{A \in Gl_p(\mathbb{K}(s)) \mid \det A \in \mathbb{K}\backslash\{0\}\}. \tag{3.15}$$

Clearly the unimodular group is a subgroup of H consisting of all elements in H that have polynomial entries. This group enables us to introduce the following equivalence relation.

DEFINITION 3.8. Two polynomial matrices $P(s)$ and $\tilde{P}(s)$ are called H-equivalent if there is an element $U \in H$ with $\tilde{P}(s) = U \cdot P(s)$.

Note that row equivalent matrices are always H-equivalent. Moreover, if $P(s)$ has full row rank for all $s \in \bar{\mathbb{K}}$, it then follows from the proof of Theorem 3.6 that $P(s)$ and $\tilde{P}(s)$ are row equivalent if and only if they are H-equivalent. In other words, the concept of row equivalence and H-equivalence are the same for the generic set. The following example illustrates the difference of the two concepts.

Example 3.9. The following two matrices have the same Plücker coordinates and are therefore H–equivalent:

$$A = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 2s & 3s \end{pmatrix}, \qquad B = \begin{pmatrix} s & 0 & 0 \\ 0 & 2 & 3 \end{pmatrix}. \tag{3.16}$$

On the other hand, it is immediate that the matrices A, B are not row equivalent; that is, there is no unimodular matrix $U(s)$ with $B = UA$.

From the above it is now clear that every point of $K^n_{p,m}$ can be viewed as an H-equivalence class of $p \times (m+p)$ polynomial matrices and every H-equivalence class consists of one (generically) or several autoregressive systems. At this point we want to mention that $K^n_{p,m}$ has singularities and those singularities occur at points where several autoregressive systems form one H-equivalence class. As shown by Ravi and Rosenthal [26] the set of all "homogeneous autoregressive systems" of degree n constitutes a desingularisation of $K^n_{p,m}$ and we refer to [26] for details.

We summarize this section with the following theorem.

THEOREM 3.10. *$K^n_{p,m}$ consists of all H-equivalence classes of autoregressive systems of size $p \times (m+p)$ and degree less than or equal to n.*

4. Dynamic feedback and q-nondegeneracy. In the last section we introduced a compactification (denoted by $K^n_{p,m}$) of the space of proper transfer functions $S^n_{p,m}$. In this section we will show that the pole placement problem with dynamic compensators can be studied as an intersection problem in the variety $K^n_{p,m}$.

For this consider a proper transfer function $G(s) \in S^n_{p,m}$ describing the behavior between an input $\hat{u}$ and an output $\hat{y}$ in the frequency domain:

$$\hat{y} = G(s)\hat{u}. \tag{4.1}$$

The feedback compensators that we will consider are proper transfer functions $F(s) \in S^q_{m,p}$. The plant and the compensator are combined through the feedback law:

$$\hat{u} = F(s)\hat{y} + \hat{v}. \tag{4.2}$$

If the characteristic matrix $(I - G(s)F(s))$ is invertible (this is always the case if $G(s)$ is strictly proper) it is well known that the transfer function between the new input $\hat{v}$ and the output $\hat{y}$ is well defined and given by

$$G_F(s) := (I - G(s)F(s))^{-1}G(s). \tag{4.3}$$

The stability of equilibria or periodic motions of the closed-loop system depends on the position of the poles of $G_F(s)$. To describe the poles of the closed-loop transfer function, we introduce a left coprime factorization of $G(s)$ and a right coprime factorization of $F(s)$:

$$G(s) = D^{-1}_{LG}(s)N_{LG}(s), \qquad F(s) = N_{RF}(s)D^{-1}_{RF}(s). \tag{4.4}$$

A straightforward calculation results in the following form for the closed-loop transfer function:

$$G_F(s) = D_{RF}(s)(D_{LG}(s)D_{RF}(s) - N_{LG}(s)N_{RF}(s))^{-1}N_{LG}(s). \tag{4.5}$$

Note that every pole of $G_F(s)$ is a zero of the polynomial

$$\phi(s) = \det(D_{LG}(s)D_{RF}(s) - N_{LG}(s)N_{RF}(s)) \tag{4.6}$$

and every zero of $\phi(s)$ is a pole of $G_F(s)$ if no pole-zero cancellation occurred. Moreover, if $G(s)$ is a strictly proper system of McMillan degree n and $F(s)$ is a proper compensator of McMillan degree q, then $\phi(s)$ is a polynomial of degree $n+q$. Identifying the vector space $\mathbb{K}^{n+q}$ with all monic polynomials of degree $n+q$ we define the pole placement map for a strictly proper system $G(s)$ by:

$$\rho_G : S^q_{m,p} \longrightarrow \mathbb{K}^{n+q}, \qquad F(s) \longmapsto \phi(s)_{\text{monic}}. \tag{4.7}$$

This definition is in many ways unsatisfactory if $G(s)$ is proper. Indeed, if $G(s)$ is proper it is possible that $\phi(s)$ is not of degree $n+q$ anymore, in particular if $(I - G(s)F(s))$ is not invertible $\phi(s) \equiv 0$.

To extend the definition of the pole placement map to proper systems we first introduce the following set, which Ghosh [8] called the *base locus*:

$$B_G := \{F(s) \in S^q_{m,p} \mid \det(I - G(s)F(s)) \equiv 0\}. \tag{4.8}$$

To avoid difficulties with low-degree polynomials, we identify the space of polynomials with the projective space $\mathbb{P}^{n+q}$ and use the following definition.

DEFINITION 4.1. The pole placement map for a proper transfer function $G(s)$ is given by

$$\rho_G : S^q_{m,p} - B_G \longrightarrow \mathbb{P}^{n+q}, \qquad F(s) \longmapsto \phi(s). \tag{4.9}$$

It is, of course, an important problem in multivariable linear control theory: under which condition is ρ_G onto or at least almost onto? In particular, it would be of great interest to know the minimum order q of a compensator that pole assigns

or stabilizes a given generic system of order n. Using a dimension argument, we immediately obtain the following necessary condition for ρ_G to be onto:

$$q(m+p) + mp \geq n+q. \tag{4.10}$$

One of our main goals in this paper is to show that this condition is also sufficient when the field is algebraically closed and the plant $G(s)$ is generic. To achieve this result, we first give a new description of the polynomial $\phi(s)$ and this will enable us to reformulate the problem geometrically.

If $F(s) = D_{LF}^{-1}(s)N_{LF}(s) = N_{RF}(s)D_{RF}^{-1}(s)$ are a left and a right coprime factorization of $F(s)$ it is obvious that

$$(N_{LF}(s)\, D_{LF}(s)) \begin{pmatrix} D_{RF}(s) \\ -N_{RF}(s) \end{pmatrix} \equiv 0_{m\times p}. \tag{4.11}$$

In some sense we can view the matrix

$$\begin{pmatrix} D_{RF}(s) \\ -N_{RF}(s) \end{pmatrix}$$

as the dual curve of the Hermann–Martin curve $(N_{LF}(s)\, D_{LF}(s))$ of $F(s)$. The following lemma, which is well known if the compensator is static [2], is now easy to verify and the proof will be omitted.

LEMMA 4.2. *For a particular point $s_i \in \bar{\mathbb{K}}$ the following conditions are equivalent:*

$$\det\left((D_{LG}(s_i)\, N_{LG}(s_i)) \begin{pmatrix} D_{RF}(s_i) \\ -N_{RF}(s_i) \end{pmatrix}\right) = 0, \tag{4.12}$$

$$\det \begin{pmatrix} D_{LG}(s_i) & N_{LG}(s_i) \\ N_{LF}(s_i) & D_{LF}(s_i) \end{pmatrix} = 0, \tag{4.13}$$

$$\operatorname{rowsp}(D_{LG}(s_i)\, N_{LG}(s_i)) \cap \operatorname{rowsp}(N_{LF}(s_i)D_{LF}(s_i)) \neq \{0\}. \tag{4.14}$$

Note that two polynomials with the same roots are multiples of each other. In other words the following corollary holds.

COROLLARY 4.3.

$$\phi(s) = \det(D_{LG}(s)D_{RF}(s) - N_{LG}(s)N_{RF}(s)) = \mathrm{c}\cdot \det \begin{pmatrix} D_{LG}(s) & N_{LG}(s) \\ N_{LF}(s) & D_{LF}(s) \end{pmatrix} \tag{4.15}$$

The $(m+p)\times(m+p)$ matrix appearing in this equation has many nice properties. On one side the equation

$$\begin{pmatrix} D_{LG}(s) & N_{LG}(s) \\ N_{LF}(s) & D_{LF}(s) \end{pmatrix} \cdot \begin{pmatrix} y \\ -u \end{pmatrix}(s) = 0 \tag{4.16}$$

gives a combined description of the plant and the compensator equations by means of autoregressive equations. This point of view can be found, e.g., in [31], [39].

Geometrically, $(D_{LG}(s)N_{LG}(s))$ defines a rational curve $\zeta \epsilon \mathrm{Rat}_n(\mathbb{P}^1, \mathrm{Grass}(p, m+p))$ and $(N_{LF}(s)D_{LF}(s))$ defines a rational curve $\psi \epsilon \mathrm{Rat}_q(\mathbb{P}^1, \mathrm{Grass}(m, m+p))$. Using the Plücker embedding (2.6) we can represent ζ by

$$g(s) := g_1(s) \wedge \cdots \wedge g_p(s), \tag{4.17}$$

where again $g_i(s)$ denotes the ith row of $(D_{LG}(s)N_{LG}(s))$. Similarly, ψ has a representation

$$f(s) := f_1(s) \wedge \cdots \wedge f_m(s). \tag{4.18}$$

Finally the poles of the closed-loop system are the zeros of the polynomial

$$\tilde{\phi}(s) := g_1(s) \wedge \cdots \wedge g_p(s) \wedge f_1(s) \wedge \cdots \wedge f_m(s). \tag{4.19}$$

Note that $\tilde{\phi}(s)$ is, of course, a multiple of the polynomial $\phi(s)$. In addition the wedge product $g(s) \wedge f(s)$ defines a bilinear pairing $\langle\ ,\ \rangle$ that extends linearly to the product space $\mathbb{P}(\mathbb{K}^{n+1} \otimes \wedge^p \mathbb{K}^{m+p}) \times \mathbb{P}(\mathbb{K}^{q+1} \otimes \wedge^m \mathbb{K}^{m+p})$.

We are now in a position to formulate the pole placement problem with dynamic compensators in a geometric language.

Geometric problem. Given a rational curve $\zeta \epsilon \mathrm{Rat}_n(\mathbb{P}^1, \mathrm{Grass}(p, m+p))$ and a divisor $P = \{s_1, \ldots, s_{n+q}\}$. Is there a curve $\psi \epsilon \mathrm{Rat}_q(\mathbb{P}^1, \mathrm{Grass}(m, m+p))$ such that $\psi(s_i) \cap \zeta(s_i) \neq \{0\}$ for all $s_i \in P$? What is the minimal degree q needed?

Remark 4.4. Not all geometric solutions enable us to construct a proper compensator although it is always possible to represent such a solution by an autoregressive system. In addition, we want to find solutions that are admissible (compare with [31]). In geometric terms, we want to exclude a Hermann–Martin curve $\psi(s)$ with the property that $\psi(s) \cap \zeta(s) \neq \{0\}$ for all $s \in \mathbb{K}$.

To handle these difficulties we make the following definition.

DEFINITION 4.5. A rational curve $\zeta \epsilon \mathrm{Rat}_n(\mathbb{P}^1, \mathrm{Grass}(p, m+p))$ is called q-degenerate if there is a rational curve $\psi \epsilon \mathrm{Rat}_i(\mathbb{P}^1, \mathrm{Grass}(m, m+p))$ with $i \leq q$ and $\psi(s) \cap \zeta(s) \neq \{0\}$ for all $s \in \mathbb{K}$. A curve that is not q-degenerate is called q-nondegenerate. A system $G(s)$ is called q-(non)degenerate if the corresponding Hermann–Martin curve is q-(non)degenerate.

Note that our definition is a natural generalization of the concept of the degenerate system as introduced in [2], and this concept itself generalizes the concept of a degenerate curve in projective space. In a concrete example we can use the equivalent formulations in Lemma 4.2 to decide if a particular plant $G(s)$ is q-degenerate.

From the definition it now follows immediately that the pole placement map ρ_G introduced in (4.7) and (4.9) can be extended in a continuous manner to a morphism $\bar{\rho_G}$ defined on the whole compactification $K^q_{m,p}$ if the system $G(s)$ is q-nondegenerate. In other words, all autoregressive systems $P(s) \in K^q_{m,p}$ are admissible and the base locus set B_G introduced in (4.8) is empty:

$$\begin{array}{rcc} \bar{\rho_G}\ : & K^q_{m,p} & \longrightarrow \mathbb{P}^{n+q} \\ & \uparrow & \uparrow \\ \rho_G\ : & S^q_{m,p} & \longrightarrow \mathbb{K}^{n+q} \end{array} \tag{4.20}$$

The concept of q-degeneracy will be of crucial importance in the next section. The following example will illustrate the concept of q–degeneracy on a 3-input, 1-output system.

Example 4.6.

1. $G(s) = (1/s^5, 1/s^3, 1/s)$ defines a system of order 5, which is 1-degenerate. Indeed, use the first condition in Lemma 4.2 to construct a covector which will make the inner product $\langle\ ,\ \rangle$ identically zero:

$$\langle\ (1, s^2, s^4, s^5)\ ,\ (0, 0, s, -1)\ \rangle \equiv 0 \tag{4.21}$$

2. $\tilde{G}(s) = (1/s^6, 1/s^4, 1/s^2)$ defines a system of order 6 which is 1-nondegenerate because

$$\langle (1, s^2, s^4, s^6), (a_1 + b_1 s, a_2 + b_2 s, a_3 + b_3 s, a_4 + b_4 s) \rangle \equiv 0 \tag{4.22}$$

implies $a_i = b_i = 0, \quad i = 1, \ldots, 4$. Actually, we will show in the next section that the generic 1-input, 3-output system of order 6 is 1-nondegenerate.

5. On the minimal order dynamic compensator. In this section we will assume that the ground field $\mathbb{K}$ is algebraically closed. The following theorem, called the projective dimension theorem, will be used several times in this section. Our formulation can be found in Hartshorne [9], where a proof is also given.

THEOREM 5.1. *Let Y, Z be varieties of dimension r, s in $\mathbb{P}^N$. Then every irreducible component of $Y \cap Z$ has dimension $\geq r+s-N$. Furthermore, if $r+s-N \geq 0$, then $Y \cap Z$ is nonempty.*

The next theorem that we present is a strong version of the classical Bézout theorem, which we will need to prove Theorem 5.7. The theorem was originally formulated and proven by Weil [36]. The crucial part for the formulation of the theorem was the "right" definition of the intersection multiplicity i. For a broader discussion of this theorem and its generalizations we refer the reader to Vogel [33]. The following theorem is a reformulation of [33, Prop. 3.26].

THEOREM 5.2. *Let Y, Z be varieties of dimension r, s in $\mathbb{P}^N$. Assume the intersection $Y \cap Z$ is proper, i.e., $\dim(Y \cap Z) = r + s - N$. Denote with Ω the set of irreducible components of $Y \cap Z$ and with $i(Y, Z; C)$ the intersection multiplicity of Y and Z along C. Then we have*

$$\deg Y \cdot \deg Z = \sum_{C \epsilon \Omega} i(Y, Z; C) \cdot \deg C. \tag{5.1}$$

Another important concept in all that follows is the notion of a central projection. Assume E, H are linear subspaces of dimension $r, N - r - 1$ and $E \cap H = \emptyset$. In this case we can define the following map, which is well defined by basic facts of linear algebra:

$$\pi : \mathbb{P}^N - E \longrightarrow H, \qquad x \longmapsto \operatorname{span}(x, E) \cap H. \tag{5.2}$$

π is called a central projection onto H with center E. As shown by Wang [34], the pole placement map with static compensators is a central projection. As we will show, the same is true in the dynamic case.

Our first goal is a characterization of the q-nondegenerate systems.

LEMMA 5.3. *The set of q-degenerate systems is algebraic in the quasi-projective variety $S^n_{p,m}$ of proper systems with McMillan degree n.*

Proof. Consider in $S^n_{p,m} \times K^q_{m,p}$ the coincidence set

$$S := \{(N_{LG}(s)\, D_{LG}(s)), (N_{RF}(s)\, D_{RF}(s)) \mid \det(D_{LG}(s) D_{RF}(s) - N_{LG}(s) N_{RF}(s)) \equiv 0\}, \tag{5.3}$$

which defines an algebraic set in the product. Because $K^q_{m,p}$ is projective, the projection on the first factor is still an algebraic set by the main theorem of elimination theory (see, e.g., [24]). □

The next lemma shows that every system is q-degenerate for some large natural number $q \in \mathbb{N}$.

LEMMA 5.4. *If $q(m+p)+mp > n+q$, every $p \times m$ system of order n is q-degenerate.*

Proof. Assume $g(s)$ are the Plücker coordinates of a plant $G(s)$ with McMillan degree n. Consider in $\mathbb{P}(\mathbb{K}^{q+1} \otimes \wedge^m \mathbb{K}^{m+p})$ the set

$$E_G := \{f(s) \mid \langle g(s), f(s) \rangle \equiv 0\}. \tag{5.4}$$

E_G defines a plane of codimension at most $q(m+p)+mp$, the dimension of the variety $K^q_{m,p}$. The plane E_G intersects $K^q_{m,p}$ by the projective dimension theorem. □

So far it has only been shown (Lemma 5.3) that the set of q-nondegenerate systems form a Zariski-open (possibly empty) set in $S^n_{p,m}$. Using the following theorem we will be able to show that this Zariski-open set is nonempty in $S^n_{p,m}$ if q is small enough.

THEOREM 5.5. *The dimension of the coincidence set $S \subset S^n_{p,m} \times K^q_{m,p}$ introduced in* (5.3) *is given by*

$$\dim S = \dim S^n_{p,m} + \dim K^q_{m,p} - n - q - 1. \tag{5.5}$$

Proof. Consider an element of S given by

$$\det \begin{pmatrix} D_{LG}(s) & N_{LG}(s) \\ N_{LF}(s) & D_{LF}(s) \end{pmatrix} \equiv 0. \tag{5.6}$$

Without loss of generality we assume that the system $(D_{LG}(s)N_{LG}(s))$ and the compensator $(N_{LF}(s)D_{LF}(s))$ are both row reduced with minimal indices $\nu_1 \geq \cdots \geq \nu_p$, respectively, $\mu_1 \geq \cdots \geq \mu_m$ and $\nu_1 \geq \mu_1$. In particular we have $n = \sum_{i=1}^p \nu_i$ and $q = \sum_{j=1}^m \mu_j$. As explained in [30] we have a free action on $(N_{LF}(s)D_{LF}(s))$ with an algebraic group of dimension at least m^2. This group is characterized as the subgroup of the unimodular group $Gl_m(\mathbb{K}[s])$ which leaves the row indices $\mu_1, \ldots, \mu_m$ invariant. Similarly there is a free action on $(D_{LG}(s)N_{LG}(s))$ with an algebraic group of dimension at least p^2.

Denote with S_1 the parameter space of all $(m+p-1) \times (m+p)$ polynomial matrices having row indices $\nu_2, \ldots, \nu_p, \mu_1, \ldots, \mu_m$. S_1 is a vector space of dimension

$$\dim S_1 = (\sum_{i=2}^{p} \nu_i + \sum_{j=1}^{m} \mu_j + m + p - 1)(m+p). \tag{5.7}$$

Assume now that the last $m+p-1$ rows form a minimal basis in the sense of Forney [6] of the $\mathbb{K}(s)$-vector space, which these rows generate. Equivalently, the greatest common divisor of the full size $(m+p-1) \times (m+p-1)$ minors is 1. In the following we restrict the dimension calculation to this Zariski-open subset of S_1 because it is not difficult to show that the other cases lead to lower-dimensional subsets. From (5.6) it then follows that the first row is a linear combination of the last $m+p-1$ rows

$$g_1(s) = \sum_{i=2}^{p} x_i(s)g_i(s) + \sum_{j=1}^{m} y_j(s)h_j(s), \qquad x_i(s), y_j(s) \in \mathbb{K}(s). \tag{5.8}$$

From the main theorem in Forney [6] it follows that $x_i(s), y_j(s)$ are even elements of $\mathbb{K}[s]$. Moreover $\deg x_i(s) \leq \nu_1 - \nu_i$ and $\deg y_j(s) \leq \nu_1 - \mu_j$.

Denote with S_2 all polynomial vectors $g_1(s)$ of degree ν_1 that are in the rowspace of a given set of vectors $\{g_2(s), \ldots, g_p(s), \ldots h_m(s)\}$. From the above follows that

$$\dim S_2 = \sum_{i=2}^{p}(\nu_1 - \nu_i + 1) + \sum_{j=1}^{m}(\nu_1 - \mu_j + 1) = (m+p)\nu_1 - n - q + m + p - 1. \tag{5.9}$$

Finally, taking into consideration the free action of the above-mentioned groups, we obtain

$$\dim S \leq \dim S_1 + \dim S_2 - m^2 - p^2 \tag{5.10}$$

$$= n(m+p) + mp + q(m+p) + mp - n - q - 1 \tag{5.11}$$

$$= \dim S^n_{p,m} + \dim K^q_{m,p} - n - q - 1. \tag{5.12}$$

Finally, (5.6) imposes at most $n+q+1$ algebraic conditions because the characteristic equation is a polynomial of degree at most $n+q$. The inequality in (5.10) is therefore an equality. □

COROLLARY 5.6. *If $q(m+p) + mp \leq n+q$, the generic $p \times m$ proper system of order n is q-nondegenerate.*

Proof. Because $\dim K^q_{m,p} = q(m+p) + mp$ it follows from (5.5) that $\dim S \leq \dim S^n_{p,m} - 1$. In particular the projection of S onto $S^n_{p,m}$ is a proper algebraic subset in $S^n_{p,m}$. □

The previous corollary was proven for $q = 0$ (static feedback) by Brockett and Byrnes [2], from which it then followed that the pole placement map with static compensators is generically onto if $mp = n$. In the following we will extend this result to the dynamic case. The proof that we present combines ideas from a proof given by Rosenthal in [27] and a proof given by Wang in [34] for the case of static feedback.

THEOREM 5.7. *If a system $G(s)$ is q-nondegenerate and $q(m+p)+mp = n+q$, then the pole placement map*

$$\bar{\rho_G} : K^q_{m,p} \longrightarrow \mathbb{P}^{n+q} \tag{5.13}$$

is onto of degree $d_{m,p,q}$, where $d_{m,p,q}$ is the degree of the variety $K^q_{m,p}$.

Proof. Consider in $\mathbb{P}(\mathbb{K}^{q+1} \otimes \wedge^m \mathbb{K}^{m+p})$ again the linear subspace

$$E_G = \{f(s) \mid \langle g(s), f(s) \rangle \equiv 0\}. \tag{5.14}$$

Because $G(s)$ is q-nondegenerate it follows that $E_G \cap K^q_{m,p} = \emptyset$ and the codimension of E_G is equal to $q(m+p) + mp + 1$. The linear pairing $\langle , \rangle$ induces a linear map

$$\begin{aligned} L \; : \; \mathbb{P}(\mathbb{K}^{q+1} \otimes \wedge^m \mathbb{K}^{m+p}) - E_G &\longrightarrow \mathbb{P}^{n+q} \\ f(s) &\longmapsto \langle g(s), f(s) \rangle, \end{aligned} \tag{5.15}$$

which has to be onto by a linear argument. Note that $\bar{\rho_G} = L \mid_{K^q_{m,p}}$. Denote with H any linear subspace of $\mathbb{P}(\mathbb{K}^{q+1} \otimes \wedge^m \mathbb{K}^{m+p})$ for which $\dim H = n+p$ and $L(H) = \mathbb{P}^{n+q}$. We have a central projection

$$\pi \; : \; \mathbb{P}(\mathbb{K}^{q+1} \otimes \wedge^m \mathbb{K}^{m+p}) - E_G \longrightarrow H. \tag{5.16}$$

If $y \in H$ is a particular point, it follows by linear equation theory that the whole fiber $\pi^{-1}(y)$ (which is a linear plane in $\mathbb{P}(\mathbb{K}^{q+1} \otimes \wedge^m \mathbb{K}^{m+p})$) is mapped under L onto $L(y)$. In other words, we have $L = L \circ \pi$ and $\bar{\rho_G}$ is onto if and only if $\pi \mid_{K^q_{m,p}}$ is onto.

By the projective dimension theorem $\pi^{-1}(y) \cap K^q_{m,p} \neq \emptyset$. Finally every fiber $\pi^{-1}(y)$ intersects $K^q_{m,p}$ properly [32, p. 48]. By Theorem 5.2, $\pi^{-1}(y) \cap K^q_{m,p}$ consists in this case of exactly $d_{m,p,q}$ points when counted with multiplicities. □

If the system $G(s)$ is strictly proper and the compensator $F(s)$ is admissible and proper, it follows from Corollary 4.3 that the closed-loop characteristic polynomial $\phi(s)$ has degree exactly equal to $n+q$, the sum of the McMillan degrees of $G(s)$ and $F(s)$. In other words the "infinite points," that is, the points in the set $K^q_{m,p} - S^q_{m,p}$, are mapped onto the closed-loop characteristic polynomials of degree strictly less than $n+q$. We therefore obtain the following corollary.

COROLLARY 5.8. *If $G(s)$ is q-nondegenerate and strictly proper and $q(m+p)+mp = n+q$, then the pole placement map $\rho_G : S^q_{m,p} \longrightarrow \mathbb{K}^{n+q}$ introduced in* (4.7) *is onto. Moreover, if counted with multiplicities there are exactly $d_{m,p,q}$ different compensators $F(s)$ assigning a specific closed-loop characteristic polynomial.*

The degree of the variety $K^q_{m,p}$ is therefore equal to the number of compensators that will place the poles of the closed-loop system at a desired location. In particular, if $G(s)$ is a real plant and the number $d_{m,p,q}$ would turn out to be odd for certain m,p,q, we would be able to predict the existence of a real compensator because the solution set must be invariant under complex conjugation. In the case of static feedback, i.e., $q=0$, we have $K^0_{m,p} = \mathrm{Grass}(m, m+p)$ and it is well known when the degree of the Grassmann variety is odd. (Compare, e.g., [3].) As shown in [28] the degree of $K^1_{2,3}$ is equal to 55 and so such (nontrivial) cases also exist if $q > 0$. The following corollary explains the proper situation.

COROLLARY 5.9. *If $G(s)$ is q-nondegenerate and proper and $q(m+p)+mp = n+q$, then the pole placement map $\rho_G : S^q_{m,p} \longrightarrow \mathbb{P}^{n+q}$ introduced in* (4.9) *is almost onto.*

Proof. Because $G(s)$ is q-nondegenerate, the lifted map $\bar{\rho_G} : K^q_{m,p} \to \mathbb{P}^{n+q}$ exists and is onto by Theorem 5.7. The difference set $K^q_{m,p} - S^q_{m,p}$ has dimension strictly less than $n+q$. Because $\bar{\rho_G}(K^q_{m,p}) = \mathbb{P}^{n+q}$ and $\bar{\rho_G}\,|_{S^q_{m,p}} = \rho_G$ the statement follows. □

Remark 5.10. From the proof it follows in particular that those closed-loop characteristic polynomials that cannot be achieved with a proper compensator can always be achieved with a general autoregressive compensator. (Compare with Remark 4.4.)

So far we have provided only positive results, that is, results when the dimension of the domain and the range are equal. The following theorem explains the situation when the dimension of the domain is larger than the dimension of the range.

THEOREM 5.11. *If $G(s) \in S^n_{p,m}$ is a generic plant and if*

$$q(m+p)+mp \geq n+q, \tag{5.17}$$

then the pole placement map

$$\rho_G : S^q_{m,p} - B_G \longrightarrow \mathbb{P}^{n+q} \tag{5.18}$$

introduced in Definition 4.1 *is almost onto. Moreover, the extended map*

$$\bar{\rho_G} : K^q_{m,p} - E_G \longrightarrow \mathbb{P}^{n+q} \tag{5.19}$$

is onto.

Proof. Consider again the coincidence set $S \subset S^n_{p,m} \times K^q_{m,p}$ introduced in the proof of Lemma 5.3. Denote with $pr : S \to S^n_{p,m}$ the projection onto the first factor. From

Theorem 5.5 it then follows that for a generic element $G(s) \in S^n_{p,m}$ the dimension of the fiber $pr^{-1}(G(s))$ is bounded by

$$\dim(pr^{-1}(G(s))) \leq \dim K^q_{m,p} - n - q - 1. \tag{5.20}$$

In particular, using earlier notation we have

$$\dim(E_G \cap K^q_{m,p}) \leq q(m+p) + mp - n - q - 1. \tag{5.21}$$

Following the proof of Theorem 5.7 and using again the projective dimension theorem it follows that

$$\dim(\pi^{-1}(y) \cap K^q_{m,p}) > q(m+p) + mp - n - q - 1. \tag{5.22}$$

From above two inequalities it now follows in particular that for every closed-loop polynomial $p(s)$ there is an admissible autoregressive system $F(s) \in K^q_{m,p} - E_G$ with $\bar{\rho_G}(F(s)) = p(s)$. The map $\bar{\rho_G}$ is therefore onto. Finally because the fibers of $\bar{\rho_G}$ in $K^q_{m,p} - E_G$ have dimension at least $q(m+p) + mp - n - q$ and the dimension of the range of $\bar{\rho_G}$ is $n+q$, the map $\rho_G : S^q_{m,p} - B_G \to \mathbb{P}^{n+q}$ is almost onto by a dimension argument. □

Acknowledgments. The author thanks U. Helmke, M. S. Ravi, and X. Wang for helpful conversations and suggestions.

FINITE-DIMENSIONAL FILTERS WITH NONLINEAR DRIFT II: BROCKETT'S PROBLEM ON CLASSIFICATION OF FINITE-DIMENSIONAL ESTIMATION ALGEBRAS*

WEN-LIN CHIOU† AND STEPHEN S.-T. YAU‡

Abstract. The idea of using estimation algebras to construct finite-dimensional nonlinear filters was first proposed by Brockett and Mitter independently. It turns out that the concept of estimation algebra plays a crucial role in the investigation of finite-dimensional nonlinear filters. In his talk at the International Congress of Mathematics in 1983, Brockett proposed classifying all finite-dimensional estimation algebras. In this paper, all finite-dimensional algebras with maximal rank are classified if the dimension of the state space is less than or equal to two. Therefore, from the Lie algebraic point of view, all finite-dimensional filters are understood generically in the case where the dimension of state space is less than three.

Key words. nonlinear filters, estimation algebra, Wei–Norman approach

AMS subject classifications. 17B30, 35J15, 60G35, 93E11

1. Introduction. In a previous paper [Ya], Yau has studied the general class of nonlinear filtering systems that include both Kalman–Bucy and Benes filtering systems as special cases. Simple algebraic necessary and sufficient conditions were proved for an estimation algebra of such filtering system to be finite-dimensional. Using the Wei–Norman approach, he constructed explicitly finite-dimensional recursive filters for such nonlinear filtering systems. This paper is, in essence, a continuation of [Ya] and we strongly recommend that readers familiarize themselves with the results in [Ya]. However, every effort will be made to make this paper as self-contained as possible without too much duplication of the previous paper.

The idea of using estimation algebras to construct finite-dimensional nonlinear filters was first proposed in Brockett and Clark [Br-Cl], Brockett [Br1], and Mitter [Mi]. The concept of estimation algebras has proved to be an invaluable tool in the study of nonlinear filtering problems. In his famous talk at the International Congress of Mathematics in 1983, Brockett proposed classifying all finite-dimensional estimation algebras. There were some interesting results in 1987 due to Wong [Wo] under the assumptions that the observation $h(x)$ and drift term $f(x)$ are real analytic functions on $\mathbf{R}^n$, and f satisfies the following growth conditions: for any i, all the first-, second-, and third-order partial derivatives of f_i are bounded functions. Under all these conditions, Wong provides partial information toward the classification of finite-dimensional estimation algebra. Namely, he showed that if the estimation algebra is finite-dimensional, then the degree of h in x is at most one, and the estimation algebra has a basis consisting of one second-degree differential operator, L_0 (see (2.1)), first-

degree differential operators of the form

$$\sum_{i=1}^{n} \alpha_i \left(\frac{\partial}{\partial x_i} - f_i \right) + \sum_{i=1}^{n} \beta_i \frac{\partial \eta}{\partial x_i},$$

where α_i and β_i are constants and

$$\eta = -\frac{1}{2} \left(\sum_{i=1}^{n} \frac{\partial f_i}{\partial x_i} + \sum_{i=1}^{n} f_i^2 + \sum_{i=1}^{m} h_i^2 \right),$$

and zero-degree differential operators affine in x. In [T-W-Y], Tam, Wong, and Yau have introduced the concept of an estimation algebra with maximal rank. This is one of the most important general subclass of estimation algebras. Let n be the dimension of the state space. It turns out that all nontrivial finite-dimensional estimation algebras are automatically exact with maximal rank if $n = 1$. It follows from the works of Ocone [Oc], Tam, Wong, and Yau [T-W-Y], and Dong et al. [D-T-W-Y] that the finite-dimensional estimation algebras are completely classified if $n = 1$. In fact, Tam, Wong, and Yau have classified all finite-dimensional exact estimation algebras with maximal rank of arbitrary dimension. In this paper, we classify all finite-dimensional estimation algebras with maximal rank if $n = 2$. The novelty of the problem is that there is no assumption on the drift term of the nonlinear filtering system. The following is our main theorem.

MAIN THEOREM. *Suppose that the state space of the filtering system* (2.0) *below is of dimension two. If E is the finite-dimensional estimation algebra with maximal rank, then the drift term f must be linear vector field plus gradient vector field, and E is a real vector space of dimension 6 with basis given by* 1, x_1, x_2, D_1, D_2, *and* L_0.

This kind of nonlinear filtering systems was studied by Yau [Ya]. Therefore, from the Lie algebraic point of view, we have shown that the finite-dimensional filters considered in [Ya] are the most general finite-dimensional filters.

2. Basic concepts. In this section, we will recall some basic concepts and results from [Ya]. Consider a filtering problem based on the following signal observation model:

$$\begin{aligned} dx(t) &= f(x(t))dt + g(x(t))dv(t), \qquad x(0) = x_0, \\ dy(t) &= h(x(t))dt + dw(t), \qquad y(0) = 0 \end{aligned} \tag{2.0}$$

in which x, v, y, and w are, respectively, $\mathbf{R}^n$, $\mathbf{R}^p$, $\mathbf{R}^m$, and $\mathbf{R}^m$ valued processes, and v and w have components that are independent, standard Brownian processes. We further assume that $n = p$, f, h are C^∞ smooth and that g is an orthogonal matrix. We will refer to $x(t)$ as the state of the system at time t and to $y(t)$ as the observation at time t.

Let $\rho(t, x)$ denote the conditional density of the state given the observation $\{y(s) : 0 \leq s \leq t\}$. It is well known (see [Da-Ma], for example) that $\rho(t, x)$ is given by normalizing a function, $\sigma(t, x)$, which satisfies the following Duncan–Mortensen–Zakai equation:

$$d\sigma(t, x) = L_0\sigma(t, x)dt + \sum_{i=1}^{m} L_i\sigma(t, x)dy_i(t), \qquad \sigma(0, x) = \sigma_0, \tag{2.1}$$

where

$$L_0 = \frac{1}{2}\sum_{i=1}^{n}\frac{\partial^2}{\partial x_i^2} - \sum_{i=1}^{n} f_i\frac{\partial}{\partial x_i} - \sum_{i=1}^{n}\frac{\partial f_i}{\partial x_i} - \frac{1}{2}\sum_{i=1}^{m} h_i^2$$

and for $i = 1, \dots, m$, L_i is the zero-degree differential operator of multiplication by h_i. σ_0 is the probability density of the initial point x_0. In this paper, we will assume σ_0 is a C^∞ function.

Equation (2.1) is a stochastic partial differential equation. In real applications, we are interested in constructing state estimators from observed sample paths with some property of robustness. Davis in [Da] studied this problem and proposed some robust algorithms. In our case, his basic idea reduces to defining a new unnormalized density

$$\xi(t,x) = \exp\Big(-\sum_{i=1}^{m} h_i(x)y_i(t)\Big)\sigma(t,x).$$

It is easy to show that $\xi(t,x)$ satisfies the following time-varying partial differential equation

$$\begin{aligned}\frac{\partial\xi}{\partial t}(t,x) &= L_0\xi(t,x) + \sum_{j=1}^{m} y_i(t)[L_0, L_i]\xi(t,x)\\ &\quad + \frac{1}{2}\sum_{i,j=1}^{m} y_i(t)y_j(t)[[L_0, L_i], L_j]\xi(t,x),\\ \xi(0,x) &= \sigma_0,\end{aligned} \tag{2.2}$$

where $[\cdot\,,\cdot]$ is the Lie bracket defined as follows.

DEFINITION. If X and Y are differential operators, the Lie bracket of X and Y, $[X,Y]$, is defined by $[X,Y]\varphi = X(Y\varphi) - Y(X\varphi)$ for any C^∞ function φ.

Recall that a real vector space $\mathcal{F}$, with an operation $\mathcal{F}\times\mathcal{F}\to\mathcal{F}$ denoted $(x,y)\mapsto[x,y]$ and called the Lie bracket of x and y, is called a Lie algebra if the following axioms are satisfied:

(1) The Lie bracket operation is bilinear;

(2) $[x,y] = 0$ for all $x\in\mathcal{F}$;

(3) $[x,[y,z]] + [y,[z,x]] + [z,[x,y]] = 0 \quad (x,y,z\in\mathcal{F})$.

DEFINITION. The estimation algebra E of a filtering problem (2.0) is defined to be the Lie algebra generated by $\{L_0, L_1, \dots, L_m\}$ or $E = \langle L_0, L_1, \dots, L_m\rangle_{L.A.}$. If, in addition, there exists a potential function φ such that $f_i = \partial\varphi/\partial x_i$ for all $1\le i\le n$, then the estimation algebra is called exact.

In [Ya], the following proposition is proven.

PROPOSITION 1. *$\partial f_j/\partial x_i - \partial f_i/\partial x_j = c_{ij}$ are constants for all i and j if and only if $(f_1,\dots,f_n) = (\ell_1,\dots,\ell_n) + (\partial\varphi/\partial x_1,\dots,\partial\varphi/\partial x_n)$, where $\ell_1,\dots,\ell_n$ are polynomials of degree one and φ is a C^∞ function.*

Define

$$D_i = \frac{\partial}{\partial x_i} - f_i$$

and

$$\eta = \sum_{i=1}^{n}\frac{\partial f_i}{\partial x_i} + \sum_{i=1}^{n} f_i^2 + \sum_{i=1}^{m} h_i^2.$$

Then

$$L_0 = \frac{1}{2}\left(\sum_{i=1}^{n} D_i^2 - \eta\right).$$

We need the following basic results for later discussion.

THEOREM 2 (Ocone). *Let E be a finite-dimensional estimation algebra. If a function ξ is in E, then ξ is a polynomial of degree less than or equal to 2.*

Ocone's theorem ([Oc], see [Co] for an extension) says that $h_1, \dots, h_m$ in a finite-dimensional estimation algebra are polynomials of degree less than or equal to 2.

The following theorem proved in [Ya] plays a fundamental role in the classification of finite-dimensional estimation algebra.

THEOREM 3. *Let E be a finite-dimensional estimation algebra of (2.0) satisfying $\partial f_j/\partial x_i - \partial f_i/\partial x_j = c_{ij}$, where c_{ij} are constants for all $1 \le i, j \le n$. Then $h_1, \dots, h_m$ are polynomials of degree at most one.*

In view of the above theorem, we introduce the following definition.

DEFINITION. The estimation algebra E of a filtering problem (2.0) is said to be the estimation algebra with maximal rank if $x_i + c_i$ is in E for all $1 \le i \le n$ where c_i is a constant.

In [Ya], the following theorem was also proved.

THEOREM 4. *Let $F(x_1, \dots, x_n)$ be a polynomial on $\mathbf{R}^n$. Suppose that there exists a polynomial path $c : \mathbf{R} \to \mathbf{R}^n$ such that $\lim_{t\to\infty} \|c(t)\| = \infty$ and $\lim_{t\to\infty} F \circ c(t) = -\infty$. Then there is no C^∞ functions $f_1, f_2, \dots, f_n$ on $\mathbf{R}^n$ satisfying the equation*

$$\sum_{i=1}^{n} \frac{\partial f_i}{\partial x_i} + \sum_{i=1}^{n} f_i^2 = F.$$

We recall the following simple lemma proved in [Ya].

LEMMA 5. (i) $[XY, Z] = X[Y, Z] + [X, Z]Y$, *where X, Y and Z are differential operators.*

(ii) $[gD_i, h] = g\ (\partial h/\partial x_i)$, *where $D_i = \partial/\partial x_i - f_i$, g and h are functions defined on $\mathbf{R}^n$.*

(iii) $[gD_i, hD_j] = -gh\omega_{ij} + g(\partial h/\partial x_i)D_j - h(\partial g/\partial x_j)\ D_i$, *where* $\omega_{ji} = [D_i, D_j] = (\partial f_i/\partial x_j) - (\partial f_j/\partial x_i)$.

(iv) $[gD_i^2, h] = 2g(\partial h/\partial x_i)\ D_i + g(\partial^2 h/\partial x_i^2)$.

(v) $[D_i^2, hD_j] = 2(\partial h/\partial x_i)\ D_iD_j - 2h\omega_{ij}D_i + (\partial^2 h/\partial x_i^2)\ D_j - h(\partial\omega_{ij}/\partial x_i)$.

LEMMA 6.

(i) $$[D_i^2, D_j^2] = 4\omega_{ji}D_jD_i + 2(\partial\omega_{ji}/\partial x_j)D_i + (\partial\omega_{ji}/\partial x_i)D_j + (\partial^2\omega_{ji}/\partial x_i\partial x_j) + 2\omega_{ji}^2.$$

(ii) $$\begin{aligned}[D_k^2, hD_iD_j] = {} & 2\ (\partial h/\partial x_k)D_kD_iD_j + 2h\omega_{jk}D_iD_k + 2h\omega_{ik}D_kD_j \\ & + (\partial^2 h/\partial x_k^2)D_iD_j + 2h(\partial\omega_{jk}/\partial x_i)D_k + h(\partial\omega_{jk}/\partial x_k)D_i \\ & + h(\partial\omega_{ik}/\partial x_k)D_j + h(\partial^2\omega_{jk}/\partial x_i\partial x_k).\end{aligned}$$

(iii) $$\begin{aligned}[D_iD_j, hD_k] = {} & (\partial h/\partial x_j)D_iD_k + (\partial h/\partial x_i)D_jD_k + h\omega_{kj}D_i + h\omega_{ki}D_j \\ & + (\partial^2 h/\partial x_i\partial x_j)D_k + h(\partial\omega_{kj}/\partial x_i).\end{aligned}$$

Proof.

(i)
$$\begin{aligned}[D_i^2, D_j^2] &= D_i[D_i, D_j^2] + [D_i, D_j^2]D_i \\ &= -D_i\left[2\omega_{ij}D_j + \frac{\partial \omega_{ij}}{\partial x_j}\right] - \left[2\omega_{ij}D_j + \frac{\partial \omega_{ij}}{\partial x_j}\right]D_i \\ &= -2\frac{\partial \omega_{ij}}{\partial x_i}D_j - 2\omega_{ij}D_iD_j - \frac{\partial^2 \omega_{ij}}{\partial x_i \partial x_j} - \frac{\partial \omega_{ij}}{\partial x_j}D_i \\ &\quad - 2\omega_{ij}D_jD_i - \frac{\partial \omega_{ij}}{\partial x_j}D_i \\ &= 4\omega_{ji}D_jD_i + 2\frac{\partial \omega_{ji}}{\partial x_j}D_i + 2\frac{\partial \omega_{ji}}{\partial x_i}D_j + \frac{\partial^2 \omega_{ji}}{\partial x_i \partial x_j} + 2\omega_{ji}^2.\end{aligned}$$

(ii)
$$\begin{aligned}[D_k^2, hD_iD_j] &= -[hD_iD_j, D_k^2] \\ &= -h[D_iD_j, D_k^2] - [h, D_k^2]D_iD_j \\ &= -h\{D_i[D_j, D_k^2] + [D_i, D_k^2]D_j\} + \left(\frac{\partial^2 h}{\partial x_k^2} + 2\frac{\partial h}{\partial x_k}D_k\right)D_iD_j \\ &= -h\left\{D_i\left(-2\omega_{jk}D_k - \frac{\partial \omega_{jk}}{\partial x_k}\right) + \left(-2\omega_{ik}D_k - \frac{\partial \omega_{ik}}{\partial x_k}\right)D_j\right\} \\ &\quad + \left(\frac{\partial^2 h}{\partial x_k^2} + 2\frac{\partial h}{\partial x_k}D_k\right)D_iD_j \\ &= -h\left\{-2\frac{\partial \omega_{jk}}{\partial x_i}D_k - 2\omega_{jk}D_iD_k - \frac{\partial^2 \omega_{jk}}{\partial x_i \partial x_k} - \frac{\partial \omega_{jk}}{\partial x_k}D_i\right. \\ &\qquad \left. - 2\omega_{ik}D_kD_j - \frac{\partial \omega_{ik}}{\partial x_k}D_j\right\} + \left(\frac{\partial^2 h}{\partial x_k^2} + 2\frac{\partial h}{\partial x_k}D_k\right)D_iD_j \\ &= 2\frac{\partial h}{\partial x_k}D_kD_iD_j + 2h\omega_{jk}D_iD_k + 2h\omega_{ik}D_kD_j + \frac{\partial^2 h}{\partial x_k^2}D_iD_j \\ &\quad + 2h\frac{\partial \omega_{jk}}{\partial x_i}D_k + h\frac{\partial \omega_{jk}}{\partial x_k}D_i \\ &\quad + h\frac{\partial \omega_{ik}}{\partial x_k}D_j + h\frac{\partial^2 \omega_{jk}}{\partial x_i \partial x_k}.\end{aligned}$$

(iii)
$$\begin{aligned}[D_iD_j, hD_k] &= -h[D_k, D_iD_j] - [h, D_iD_j]D_k \\ &= h[D_iD_j, D_k] + [D_iD_j, h]D_k \\ &= h\{D_i[D_j, D_k] + [D_i, D_k]D_j\} \\ &\quad + D_i[D_j, h]D_k + [D_i, h]D_jD_k \\ &= h\{D_i\omega_{kj} + \omega_{ki}D_j\} \\ &\quad + D_i\frac{\partial h}{\partial x_j}D_k + \frac{\partial h}{\partial x_i}D_jD_k \\ &= h\,\omega_{kj}D_i + h\,\frac{\partial \omega_{kj}}{\partial x_i} \\ &\quad + h\omega_{ki}D_j + \frac{\partial h}{\partial x_j}D_iD_k\end{aligned}$$

$$
\begin{aligned}
&+\frac{\partial^2 h}{\partial x_i \partial x_j} D_k + \frac{\partial h}{\partial x_i} D_j D_k \\
&= \frac{\partial h}{\partial x_j}\, D_i D_k + \frac{\partial h}{\partial x_i}\, D_j D_k \\
&+ h\,\omega_{kj} D_i + h\,\omega_{ki} D_j + \frac{\partial^2 h}{\partial x_i \partial x_j} D_k \\
&+ h\,\frac{\partial \omega_{kj}}{\partial x_i}. \qquad \square
\end{aligned}
$$

LEMMA 7. *Let $\tilde{x} = Rx$ be an orthogonal change of coordinate, i.e., R is an orthogonal matrix. Then*

(1) $\tilde{f}(\tilde{x}) = Rf(x)$;

(2) $\tilde{L}_0 = L_0$;

(3) $(\tilde{\omega}_{ji}) = R(\omega_{\ell k})R^T$ *where* $\tilde{L}_0 = \frac{1}{2}\big(\sum_{i=1}^n \tilde{D}_i^2 - \tilde{\eta}(\tilde{x})\big)$, $\tilde{D}_i = \partial/\partial\tilde{x}_i - \tilde{f}_i$, $\tilde{h}(\tilde{x}) = h(x)$, $\tilde{\eta}(\tilde{x}) = \sum_{i=1}^n (\partial\tilde{f}_i(\tilde{x})/\partial\tilde{x}_i) + \tilde{f}(\tilde{x}) \cdot \tilde{f}(\tilde{x}) + \sum_{i=1}^m \tilde{h}_i^2(\tilde{x})$, *and* $\tilde{\omega}_{ji} = (\partial\tilde{f}_i/\partial\tilde{x}_j) - (\partial\tilde{f}_j/\partial\tilde{x}_i)$;

(4) $\tilde{E}$ *is isomorphic to* E *as Lie algebra, where* $\tilde{E}$ *is the Lie algebra generated by* $\tilde{L}_0, \tilde{h}_1, \ldots, \tilde{h}_m$.

Proof. Statement (1) is obvious. For (2), observe that

$$
\tilde{L}_0 = \frac{1}{2}\sum_{i=1}^{2} \frac{\partial^2}{\partial\tilde{x}_i} - \sum_{i=1}^{2} \tilde{f}_i(\tilde{x}) \frac{\partial}{\partial\tilde{x}_i} - \sum_{i=1}^{2} \frac{\partial\tilde{f}_i}{\partial\tilde{x}_i} - \frac{1}{2}\sum_{i=1}^{m} \tilde{h}_i^2.
$$

Let S be the inverse matrix of R. Then $x = S\tilde{x}$ and $S = (s_{ij}) = R^T = (r_{ji})$.

$$
\begin{aligned}
\tilde{L}_0 &= \frac{1}{2}\sum_{i=1}^{n}\Big(\sum_{j=1}^{n} \frac{\partial x_j}{\partial\tilde{x}_i}\frac{\partial}{\partial x_j}\Big)^2 - \sum_{i=1}^{n}\Big(\sum_{j=1}^{n} r_{ij} f_j(x)\Big)\Big(\sum_{j=1}^{n} \frac{\partial x_j}{\partial\tilde{x}_i}\frac{\partial}{\partial x_j}\Big) \\
&\quad - \sum_{i=1}^{n}\sum_{j=1}^{n} r_{ij}\frac{\partial f_j}{\partial\tilde{x}_i}(x) - \frac{1}{2}\sum_{i=1}^{m} h_i^2(x) \\
&= \frac{1}{2}\sum_{i=1}^{n}\Big(\sum_{j=1}^{n} s_{ji}\frac{\partial}{\partial x_j}\Big)^2 - \sum_{i=1}^{n}\Big(\sum_{j=1}^{n} r_{ij} f_j(x)\Big)\Big(\sum_{j=1}^{n} s_{ji}\frac{\partial}{\partial x_j}\Big) \\
&\quad - \sum_{i=1}^{n}\sum_{j=1}^{n} r_{ij}\sum_{k=1}^{n}\frac{\partial f_j}{\partial x_k}\frac{\partial x_k}{\partial\tilde{x}_i} - \frac{1}{2}\sum_{i=1}^{m} h_i^2(x) \\
&= \frac{1}{2}\sum_{i,j,k=1}^{n} s_{ji}s_{ki}\frac{\partial^2}{\partial x_j \partial x_k} - \sum_{i=1}^{n}\sum_{j=1}^{n}\sum_{k=1}^{n} r_{ik} f_k(x) s_{ji}\frac{\partial}{\partial x_j} \\
&\quad - \sum_{i=1}^{n}\sum_{j=1}^{n} r_{ij}\sum_{k=1}^{n} s_{ki}\frac{\partial f_j}{\partial x_k} - \frac{1}{2}\sum_{i=1}^{m} h_i^2(x) \\
&= \frac{1}{2}\sum_{j,k=1}^{n} \delta_{jk}\frac{\partial^2}{\partial x_j \partial x_k} - \sum_{j,k=1}^{n} \delta_{jk} f_k(x)\frac{\partial}{\partial x_j} - \sum_{j,k=1}^{n} \delta_{jk}\frac{\partial f_j}{\partial x_k} - \frac{1}{2}\sum_{i=1}^{m} h_i^2(x) \\
&= \frac{1}{2}\sum_{j=1}^{n} \frac{\partial^2}{\partial x_j^2} - \sum_{j=1}^{n} f_j(x)\frac{\partial}{\partial x_j} - \sum_{j=1}^{n} \frac{\partial f_j}{\partial x_j} - \frac{1}{2}\sum_{i=1}^{m} h_i^2(x)
\end{aligned}
$$

$= L_0.$

Statement (3) follows from the following computation:

$$\begin{aligned}\widetilde{\omega}_{ji} = \frac{\partial \widetilde{f}_i}{\partial \widetilde{x}_j} - \frac{\partial \widetilde{f}_j}{\partial \widetilde{x}_i} &= \sum_{k=1}^{n} r_{ik}\frac{\partial f_k}{\partial \widetilde{x}_j} - \sum_{k=1}^{n} r_{jk}\frac{\partial f_k}{\partial \widetilde{x}_i} \\ &= \sum_{k=1}^{n} r_{ik}\sum_{\ell=1}^{n}\frac{\partial x_\ell}{\partial \widetilde{x}_j}\frac{\partial f_k}{\partial x_\ell} - \sum_{k=1}^{n} r_{jk}\sum_{\ell=1}^{n}\frac{\partial x_\ell}{\partial \widetilde{x}_i}\frac{\partial f_k}{\partial x_\ell} \\ &= \sum_{k,\ell=1}^{n} r_{ik}\frac{\partial f_k}{\partial x_\ell}s_{\ell j} - \sum_{k,\ell=1}^{n} r_{jk}\frac{\partial f_k}{\partial x_\ell}s_{\ell i} \\ &= \sum_{k,\ell=1}^{n} s_{ki}\frac{\partial f_k}{\partial x_\ell}r_{j\ell} - \sum_{k,\ell=1}^{n} r_{j\ell}\frac{\partial f_\ell}{\partial x_k}s_{ki} \\ &= \sum_{k,\ell=1}^{n} r_{ik}r_{j\ell}\left(\frac{\partial f_k}{\partial x_\ell} - \frac{\partial f_\ell}{\partial x_k}\right) \\ &= \sum_{k,\ell=1}^{n} r_{ik}r_{j\ell}\omega_{\ell k}\end{aligned}$$

Statement (4) is a particular case of Brockett's result in [Br3].

3. Classification theorems. Let us first recall that the following two theorems were stated in Ocone [Oc].

THEOREM 8 (Ocone). *With the notation in* §2, *let* $n = m = p = 1$, $g = 1$. *Then* $\dim E$ *is finite only if* (i)

$$(*) \qquad h(x) = \alpha x, \quad \textit{and} \quad f' + f^2 = ax^2 + bx + c$$

or

(ii) $h(x) = \alpha x^2 + \beta x$, $\alpha \neq 0$ *and*

$$(**) \qquad f' + f^2 = -h^2 + a(2\alpha x + \beta)^2 + b + c(2\alpha x + \beta)^{-2}$$

$$(***) \qquad \textit{or} \quad f' + f^2 = -h^2 + ax^2 + bx + c.$$

THEOREM 9 (Ocone). *If* f *satisfies* $(*)$, f *must have a singularity in any unbounded interval.*

The following theorem follows easily from Ocone's Theorem 8 and Theorem 9 in the case where $m = 1$. Since Theorem 8 was stated without proof in [Oc], it is interesting to know that Theorem 9 follows from the proof of Theorem A as well. In fact we do not need to assume $m = 1$.

THEOREM A. *Suppose that the state space of the filtering system* (2.0) *is of dimension one. If the estimation algebra* E *is finite-dimensional, then one of the following holds:* (i) E *is a real vector space of dimension* 4 *with basis given by* 1, x, $D = (\partial/\partial x) - f$ *and* $L_0 = \frac{1}{2}(D^2 - \eta)$ *or* (ii) E *is a real vector space of dimension* 2 *with basis given by* 1, *and* $L_0 = \frac{1}{2}(D^2 - \eta)$ *or* (iii) E *is a real vector space of dimension* 1 *with basis given by* $L_0 = \frac{1}{2}(D^2 - \eta)$.

Proof. In view of Theorem 3, all the observation terms h_i $1 \leq i \leq m$ are necessarily affine polynomials. So we have only three cases.

If all the h_i for $1 \leq i \leq m$ are actually zero, then obviously we are in case (iii) above.

If all the h_i for $1 \leq i \leq m$ are at most constants and one of them is nonzero, then $1 \in E$. By Lemma 5 (iv), we have

$$[L_0, 1] = \frac{1}{2}[D^2 - \eta, 1] = 0.$$

Therefore we are in case (ii) above.

Finally we may assume that there is a constant c such that $x + c$ is in E. In view of Lemma 5, we have

$$[L_0, x + c] = \tfrac{1}{2}[D^2 - \eta, x + c] = D, \tag{3.1}$$

$$[D, x + c] = 1, \tag{3.2}$$

$$[L_0, D] = \frac{1}{2}[D^2 - \eta, D] = \frac{1}{2}\frac{d\eta}{dx}. \tag{3.3}$$

$d\eta/dx \in E$ implies η is a polynomial of degree at most 3 by Theorem 2. Recall that

$$\frac{df}{dx} + f^2 = \eta - \sum_{i=1}^{m} h_i^2. \tag{3.4}$$

If η is a polynomial of degree 3, then $\eta - \sum_{i=1}^{m} h_i^2$ is also a polynomial of degree 3. According to Theorem 4, (3.4) has no C^∞ solution f since

$$\lim_{x \to +\infty} (\eta - \sum_{i=1}^{m} h_i^2) = -\infty \quad \text{or} \quad \lim_{x \to -\infty} (\eta - \sum_{i=1}^{m} h_i^2) = -\infty.$$

This leads to a contradiction. Therefore, we have shown that η is a polynomial of degree 2. In view of (3.1)–(3.3), E is four-dimensional real vector space with basis 1, x, $D = (d/dx) - f$ and $L_0 = \frac{1}{2}(D^2 - \eta)$. □

THEOREM B. *Suppose that the state space of the filtering system* (2.0) *is of dimension two. If E is the finite-dimensional estimation algebra with maximal rank, then E is a real vector space of dimension* 6 *with basis given by* 1, x_1, x_2, D_1, D_2, *and* L_0.

Proof. Since E is a finite-dimensional estimation algebra with maximal rank, there are constants c_i's such that $x_i + c_i$ is in E for $i = 1, 2$. In view of Lemma 5, we have the following

$$[L_0, x_j + c_j] = \frac{1}{2}\left[\sum_{i=1}^{2} D_i^2 - \eta, x_j\right] = \frac{1}{2}\sum_{i=1}^{2}[D_i^2, x_j] = D_j \in E, \tag{3.5}$$

$$\omega_{ji} = [D_i, D_j] \in E \tag{3.6}$$

(3.7)

$$Y_j = [L_0, D_j] = \frac{1}{2}\left[\sum_{i=1}^{2} D_i^2 - \eta, D_j\right] = -\sum_{i=1}^{2}\left(\omega_{ij} D_i + \frac{1}{2}\frac{\partial \omega_{ij}}{\partial x_i}\right) + \frac{1}{2}\frac{\partial \eta}{\partial x_j}$$

$$= \sum_{i=1}^{2}\left(\omega_{ji} D_i + \frac{1}{2}\frac{\partial \omega_{ji}}{\partial x_i}\right) + \frac{1}{2}\frac{\partial \eta}{\partial x_j} \in E,$$

$$[Y_j, \omega_{k\ell}] = \left[\sum_{i=1}^{2} \omega_{ji} D_i + \frac{1}{2}\sum_{i=1}^{2} \frac{\partial \omega_{ji}}{\partial x_i} + \frac{1}{2}\frac{\partial \eta}{\partial x_j},\ \omega_{k\ell}\right] = \sum_{i=1}^{2} \omega_{ji} \frac{\partial \omega_{k\ell}}{\partial x_i} \in E, \tag{3.8}$$

$$[Y_j, D_k] = \left[\sum_{i=1}^{2} \omega_{ji} D_i + \frac{1}{2}\sum_{i=1}^{2} \frac{\partial \omega_{ji}}{\partial x_i} + \frac{1}{2}\frac{\partial \eta}{\partial x_j},\ D_k\right] = \sum_{i=1}^{2}\left(\omega_{ji}\omega_{ki} - \frac{\partial \omega_{ji}}{\partial x_k} D_i\right) - \frac{1}{2}\sum_{i=1}^{2} \frac{\partial^2 \omega_{ji}}{\partial x_k \partial x_i} - \frac{1}{2}\frac{\partial^2 \eta}{\partial x_k \partial x_j}. \tag{3.9}$$

By Theorem 2 and (3.6), ω_{ij}'s are polynomials of degree less than or equal to 2. Recall that $\omega_{11} = 0 = \omega_{22}$. By (3.8), we have

$$\omega_{12}\frac{\partial \omega_{12}}{\partial x_1} \in E \quad \text{and} \quad \omega_{12}\frac{\partial \omega_{12}}{\partial x_2} \in E,$$

which implies that

$$\frac{\partial \omega_{12}^2}{\partial x_1} \in E \quad \text{and} \quad \frac{\partial \omega_{12}^2}{\partial x_2} \in E.$$

If ω_{12} were polynomial of degree 2, then there would be a nonzero polynomial of degree 3 in E, which contradicts Theorem 2. Therefore, we conclude that ω_{12} is a polynomial of degree at most 1. We will prove that ω_{12} is actually a constant. From (3.9) and (3.5), we have

$$\sum_{i=1}^{2} \omega_{ji}\omega_{ki} - \frac{1}{2}\frac{\partial^2 \eta}{\partial x_k \partial x_j} \in E. \tag{3.10}$$

Since

$$\sum_{i=1}^{2} \omega_{ji}\omega_{ki} - \frac{1}{2}\frac{\partial^2 \eta}{\partial x_k \partial x_j}$$

is a polynomial of degree at most 2 for all $1 \le j, k \le 2$ we deduce easily that η is a polynomial of degree at most 4. Assume that $\eta = a_{40}x_1^4 + a_{31}x_1^3 x_2 + a_{22}x_1^2 x_2^2 + a_{13}x_1 x_2^3 + a_{04}x_2^4 +$ degree 3 polynomial and $\omega_{12} = ax_1 + bx_2 + c$. Equation (3.10) implies that

$$\omega_{12}^2 - \frac{1}{2}\frac{\partial^2 \eta}{\partial x_1^2}, \quad \frac{\partial^2 \eta}{\partial x_1 \partial x_2}, \quad \text{and} \quad \omega_{12}^2 - \frac{1}{2}\frac{\partial^2 \eta}{\partial x_2^2}$$

are in E. Hence we have

$$\begin{aligned} E \ni \omega_{12}^2 - \frac{1}{2}\frac{\partial^2 \eta}{\partial x_1^2} &= a^2 x_1^2 + 2abx_1x_2 + b^2 x_2^2 \\ &\quad - (6a_{40}x_1^2 + 3a_{31}x_1x_2 + a_{22}x_2^2) \\ &\quad + \text{ polynomial of degree one} \\ &= (a^2 - 6a_{40})x_1^2 + (2ab - 3a_{31})x_1x_2 + (b^2 - a_{22})x_2^2 \\ &\quad + \text{ polynomial of degree one.} \end{aligned} \tag{3.11}$$

$$E \ni \frac{\partial^2 \eta}{\partial x_1 \partial x_2} = 3a_{31}x_1^2 + 4a_{22}x_1x_2 + 3a_{13}x_2^2 + \text{polynomial of degree one.} \tag{3.12}$$

(3.13)
$$\begin{aligned} E \ni \omega_{12}^2 - \frac{1}{2}\frac{\partial^2 \eta}{\partial x_1^2} &= a^2x_1^2 + 2abx_1x_2 + b^2x_2^2 - (a_{22}x_1^2 + 3a_{13}x_1x_2 + 6a_{04}x_2^2) \\ &\quad + \text{polynomial of degree one} \\ &= (a^2 - a_{22})x_1^2 + (2ab - 3a_{13})x_1x_2 + (b^2 - 6a_{04})x_2^2 \\ &\quad + \text{polynomial of degree one.} \end{aligned}$$

Since $1 = [D_1, x_1 + c_1] \in E$, we have $1, x_1, x_2 \in E$. It follows from (3.11)–(3.13) that

$$(a^2 - 6a_{40})x_1^2 + (2ab - 3a_{31})x_1x_2 + (b^2 - a_{22})x_2^2 \in E, \tag{3.14}$$

$$3a_{31}x_1^2 + 4a_{22}x_1x_2 + 3a_{13}x_2^2 \in E, \tag{3.15}$$

$$(a^2 - a_{22})x_1^2 + (2ab - 3a_{13})x_1x_2 + (b^2 - 6a_{04})x_2^2 \in E. \tag{3.16}$$

We will prove that ω_{12} is a constant. If there is no polynomial of degree 2 in E, then we have $a = b = a_{22} = 0$. This implies that ω_{12} is a constant.

Suppose that there is a polynomial of degree 2 in E. Then, by using the affine transformation $\widetilde{x} = Rx$, where R is an orthogonal matrix, we may assume that there exists a degree 2 polynomial in E of the form $k_1x_1^2 + k_2x_2^2 +$ polynomial of degree one, where either $k_1 \neq 0$ or $k_2 \neq 0$. This can be seen by using Lemma 7 because $\widetilde{\omega}_{12} = \sum_{k,\ell=1}^{2} r_{2k}r_{1\ell}\omega_{\ell k}$ is still a polynomial in x_i of degree at most one. As $1, x_1, x_2 \in E$, we deduce that there exists a polynomial in E of the form $k_1x_1^2 + k_2x_2^2$, where either $k_1 \neq 0$ or $k_2 \neq 0$. Without loss of generality we may assume that $k_1 \neq 0$. So we have $p(x)$

$$p(x) = x_1^2 + kx_2^2 \in E \text{ where } k = k_2/k_1. \tag{3.17}$$

Case 1. $k \neq 0$.

We observe that

$$\begin{aligned} [Y_1, p(x)] &= \left[\omega_{12}D_2 + \frac{1}{2}\frac{\partial \omega_{12}}{\partial x_2} + \frac{1}{2}\frac{\partial \eta}{\partial x_1}\ ,\ x_1^2 + kx_2^2\right] \\ &= 2k\omega_{12}x_2 = 2k(ax_1x_2 + bx_2^2 + cx_2) \in E, \end{aligned} \tag{3.18}$$

$$\begin{aligned} [Y_2, p(x)] &= \left[\omega_{21}D_1 + \frac{1}{2}\frac{\partial \omega_{21}}{\partial x_1} + \frac{1}{2}\frac{\partial \eta}{\partial x_2}\ ,\ x_1^2 + kx_2^2\right] \\ &= -2\omega_{12}x_1 = -2(ax_1^2 + bx_1x_2 + cx_1) \in E. \end{aligned} \tag{3.19}$$

It follows from (3.18) and (3.19) that we have

$$ax_1x_2 + bx_2^2 \in E, \tag{3.20}$$

$$ax_1^2 + bx_1x_2 \in E. \tag{3.21}$$

Equations (3.20) and (3.21) imply that

$$a^2x_1^2 - b^2x_2^2 \in E. \tag{3.22}$$

On the other hand, we have

$$\begin{aligned}[L_0, p(x)] &= \frac{1}{2}\left[\sum_{i=1}^{2} D_i^2 - \eta,\ x_1^2 + kx_2^2\right] \\ &= \frac{1}{2}[D_1^2,\ x_1^2 + kx_2^2] + \frac{1}{2}[D_2^2,\ x_1^2 + kx_2^2] \\ &= \frac{1}{2}(2 + 4x_1D_1) + \frac{1}{2}(2k + 4kx_2D_2) \\ &= 2\left(x_1D_1 + kx_2D_2 + \frac{k+1}{2}\right) \in E,\end{aligned}$$

$$\left[x_1D_1 + kx_2D_2 + \frac{k+1}{2}\ ,\ x_1^2 + kx_2^2\right] = 2x_1^2 + 2k^2x_2^2 \in E.$$

So we have

$$x_1^2 + k^2x_2^2 \in E. \tag{3.23}$$

Equations (3.17) and (3.23) imply $(k^2 - k)x_2^2 \in E$. So if $k \neq 1$, then both x_1^2 and x_2^2 are in E. If $k = 1$, then it follows from (3.17) and (3.22) that $(a^2 + b^2)x_2^2 \in E$. If $a^2 + b^2 = 0$, then ω_{12} is constant as claimed. On the other hand, if $a^2 + b^2 \neq 0$, then we conclude that x_1^2, x_2^2 are in E. Therefore in view of Lemma 5, we have

$$\left[L_0,\ \frac{1}{2}x_1^2\right] = \frac{1}{4}[D_1^2 + D_2^2 - \eta,\ x_1^2] = \frac{1}{4}[D_1^2,\ x_2^2] = x_1D_1 + \frac{1}{2} \in E, \tag{3.24}$$

$$\left[L_0,\ \frac{1}{2}x_2^2\right] = \frac{1}{4}[D_1^2 + D_2^2 - \eta,\ x_2^2] = \frac{1}{4}[D_2^2,\ x_2^2] = x_2D_2 + \frac{1}{2} \in E, \tag{3.25}$$

$$\left[x_1D_1 + \frac{1}{2},\ x_2D_2 + \frac{1}{2}\right] = -x_1x_2\omega_{12} \in E. \tag{3.26}$$

By Theorem 2, $x_1x_2\omega_{12}$ is a polynomial of degree 2. So ω_{12} is a constant.

Case 2. $k = 0$.

By (3.19) we have $ax_1^2 + bx_1x_2 \in E$ which implies $bx_1x_2 \in E$. If $b \neq 0$, then $x_1x_2 \in E$. It follows that

$$\begin{aligned}[L_0, x_1x_2] &= \frac{1}{2}\left[\sum_{i=1}^{2} D_i^2 - \eta, x_1x_2\right] = \frac{1}{2}[D_1^2, x_1x_2] + \frac{1}{2}[D_2^2, x_1x_2] \\ &= x_2D_1 + x_1D_2 \in E,\end{aligned} \tag{3.27}$$

$$[x_2D_1 + x_1D_2,\ x_1x_2] = x_1^2 + x_2^2 \in E. \tag{3.28}$$

We deduce from (3.28) that x_1^2 and x_2^2 are in E. Hence (3.24)–(3.26) imply that ω_{12} must be a constant as claimed.

From now on, we assume that $b = 0$, i.e., $\omega_{12} = ax_1 + c$, and $p(x) = x_1^2$.

Let $Z_0 = \frac{1}{2}p(x) = \frac{1}{2}x_1^2 \in E$ and $Z_k = [L_0, Z_{k-1}]$. Then by (3.24) $Z_1 = [L_0, Z_0] = x_1D_1 + \frac{1}{2}$. In view of Lemma 5, we have

$$\begin{aligned} Z_2 = [L_0, Z_1] &= \frac{1}{2}\left[D_1^2 + D_2^2 - \eta,\ x_1D_1 + \frac{1}{2}\right] \\ &= \frac{1}{2}[D_1^2,\ x_1D_1] + \frac{1}{2}[D_2^2, x_1D_1] + \frac{1}{2}[x_1D_1,\ \eta] \\ &= D_1^2 + x_1\omega_{12}D_2 + \frac{1}{2}E_1(\eta) \text{ where } E_1 = x_1\frac{\partial}{\partial x_1}. \end{aligned}$$

Let U^k be the space of differential operators of order up to and including k. Then

$$\begin{aligned} Z_3 = [L_0, Z_2] &= \frac{1}{2}\left[D_1^2 + D_2^2 - \eta,\ D_1^2 + x_1\omega_{12}D_2 + \frac{1}{2}E_1(\eta)\right] \\ &= \frac{1}{2}[D_1^2, x_1\omega_{12}D_2] + \frac{1}{2}[D_2^2, D_1^2] + \frac{1}{2}[D_2^2, x_1\omega_{12}D_2] \bmod U^1 \\ &= \frac{\partial(x_1\omega_{12})}{\partial x_1}D_1D_2 + 2\omega_{12}D_1D_2 + \frac{\partial(x_1\omega_{12})}{\partial x_2}\ D_2^2 \bmod U^1 \\ &= (4ax_1 + 3c)D_1D_2 \bmod U^1. \end{aligned}$$

Here $(\ \cdot\ )$ mode U^k signifies a member of the affine class of operators obtained by adding members of U^k to the argument. Suppose $a \neq 0$. Then $A = Z_3/4a = \left(x_1 + 3c/4a\right)D_1D_2 \bmod U^1$ is an element in E. We claim that $(-1)^{k+1}Ad_A^kZ_2 = 2^kD_1^2D_2^k \bmod U^{k+1}$. For $k = 1$,

$$\begin{aligned} (-1)Ad_AZ_2 = [Z_2, A] &= \left[D_1^2 \bmod U^1, \left(x_1 + \frac{3c}{4a}\right)D_1D_2 \bmod U^1\right] \\ &= \left[D_1^2,\ \left(x_1 + \frac{3c}{4a}\right)D_1D_2\right] \bmod U^2 \\ &= 2D_1^2D_2 \bmod U^2. \end{aligned}$$

Suppose that it is true for $k-1$, i.e., $(-1)^kAd_A^{k-1}Z_2 = 2^{k-1}D_1^2D_2^{k-1} \bmod U^k$. Then

$$\begin{aligned} (-1)^{k+1}Ad_A^kZ_2 &= (-1)Ad_A[(-1)^kAd_A^{k-1}Z_2] \\ &= [2^{k-1}D_1^2D_2^{k-1} \bmod U^k,\ \left(x_1 + \frac{3c}{4a}\right)D_1D_2 \bmod U^1] \\ &= 2^{k-1}\left[D_1^2D_2^{k-1},\ \left(x_1 + \frac{3c}{4a}\right)D_1D_2\right] \bmod U^{k+1} \\ &= -\left(x_1 + \frac{3c}{4a}\right)[D_1D_2,\ 2^{k-1}D_1^2D_2^{k-1}] \\ &\quad - \left[x_1 + \frac{3c}{4a},\ 2^{k-1}D_1^2D_2^{k-1}\right]D_1D_2 \bmod U^{k+1}. \end{aligned} \tag{3.29}$$

We show that $[D_1D_2, D_1^2D_2^{k-1}] \equiv 0 \bmod U^{k+1}$. This can be seen easily by induction as follows. For $k = 1$, this follows from Lemma 6 (ii):

$$\begin{aligned}[D_1D_2, D_1^2D_2^{k-1}] &= -[D_1^2D_2^{k-2}D_2, D_1D_2] \\ &= -D_1^2D_2^{k-1}[D_2, D_1D_2] \\ &\quad - [D_1^2D_2^{k-2}, D_1D_2]D_2 = 0 \bmod U^{k+1}\end{aligned}$$

in view of Lemma 6 (iii) and induction hypothesis. Put this into (3.29), and we obtain

$$\begin{aligned}(-1)^{k+1}Ad_A^k Z_2 &= 2^{k-1}\left[D_1^2D_2^{k-1},\ x_1 + \frac{3c}{4a}\right]D_1D_2 \bmod U^{k+1} \\ &= 2^{k-1}D_1^2\left[D_2^{k-1},\ x_1 + \frac{3c}{4a}\right]D_1D_2 + 2^{k-1}\left[D_1^2,\ x_1 + \frac{3c}{4a}\right]D_2^{k-1}D_1D_2 \\ &= 2^{k-1}D_1^2\left\{D_2\left[D_2^{k-2}, x_1 + \frac{3c}{4a}\right] + \left[D_2,\ x_1 + \frac{3c}{4a}\right]D_2^{k-2}\right\}D_1D_2 \\ &\quad + 2^{k-1}\cdot 2D_1D_2^{k-1}D_1D_2 \bmod U^{k+1} \\ &= 2^kD_1D_2^{k-1}D_1D_2 \bmod U^{k+1} \\ &= 2^kD_1^2D_2^k \bmod U^{k+1}.\end{aligned}$$

This proves our claim. We have shown that if $a \neq 0$, then E is infinite-dimensional. Hence the finite-dimensionality of E implies that $a = 0$, i.e., ω_{12} is a constant. We can apply Theorem 6 of [Ya] to deduce our result. □

EXISTENCE THEORY AND THE MAXIMUM PRINCIPLE FOR RELAXED INFINITE-DIMENSIONAL OPTIMAL CONTROL PROBLEMS*

H. O. FATTORINI†

Abstract. Existence theorems are considered for relaxed optimal control problems described by semilinear systems in Banach spaces. Relaxed controls are used whose values are finitely additive probability measures; this class of relaxed controls does not require special assumptions (such as compactness) on the control set. Under suitable conditions, relaxed trajectories coincide with those obtained from differential inclusions. Existence theorems for relaxed controls are obtained that apply to distributed parameter systems described by semilinear parabolic and wave equations, as well as a version of Pontryagin's maximum principle for relaxed optimal control problems.

Key words. relaxed controls, optimal controls, relaxation

AMS subject classifications. 93E20, 93E25

1. Introduction. Consider a finite-dimensional control system described by a vector differential equation

$$y'(t) = f(t, y(t), u(t)) \tag{1.1}$$

in m-dimensional Euclidean space $\mathbb{R}^m$, with cost functional

$$y_0(t) = \int_0^t f_0(\sigma, y(\sigma), u(\sigma))d\sigma \tag{1.2}$$

and control constraint $u(t) \in U$. It has long been known that optimal controls may fail to exist unless the set $f(t, y, U)$ is convex in $\mathbb{R}$ and the functional is weakly lower semicontinuous. A classical example is the system $y'(t) = u(t)$ in $\mathbb{R}^1$ with $U = [-1, 1]$, terminal time $\bar{t} = 1$ and cost functional

$$y_0(t) = \int_0^t \{y(\sigma)^2 + (u(\sigma)^2 - 1)^2\}d\sigma. \tag{1.3}$$

We can construct a sequence of "handsaw" functions with derivative $y'(t) = u(t) = \pm 1$ and teeth height tending to zero (number of teeth tending to infinity) for which the cost functional (1.3) is arbitrarily small; however, the value zero is not attained by any control (see [4] for additional details and other examples). This difficulty was surmounted independently by Filippov [26], Warga [34], [35], and Gamkrelidze [29] by means of extensions of the class of trajectories of (1.1). Warga's extension uses probability measure-valued controls $\mu(t, du)$ (called *relaxed* controls) and replaces the original equation by

$$y'(t) = \int_U f(t, y(t), u)\mu(t, du), \tag{1.4}$$

with a correspondingly relaxed cost functional. Relaxed controls are a natural generalization of *Young measures* [37], [38] from calculus of variations to control problems. Under suitable assumptions on the control set, limits of relaxed trajectories are relaxed trajectories themselves, which is the basis of existence theorems. For full expositions of

finite-dimensional relaxed control theory see [36] and [38]; since this paper is primarily on infinite-dimensional problems, we have not included in the references any sample of the large existing bibliography on finite-dimensional relaxed controls. See also §3 and [19] and [21] for additional details on Filippov's solution by means of differential inclusions and on its relation to measure valued controls, and [25] for applications to existence theory of optimal fluid flow problems.

Both approaches to relaxation have been extended to semilinear systems in Banach spaces,

$$y'(t) = Ay(t) + f(t, y(t), u(t)), \tag{1.5}$$

where A is the infinitesimal generator of a strongly continuous semigroup, the measure-valued control approach in [2] and [33] and the differential inclusion approach in [3] and [28]. A different class of measure-valued relaxed controls was introduced in [19], where compactness assumptions in the control set U or weak measurability assumptions on $f(t, y, u)$ are avoided by using finitely additive measures. These measures have been used in a different vein in minimization problems; see, for instance, [7].

We present in this paper various results on the relaxed controls introduced in [19], whose definition is reproduced in §2. Sections 4–6 are on existence of relaxed optimal controls for systems described by (1.5). All existence theorems follow the same pattern: existence of a minimizing sequence with suitable properties is assumed and the optimal relaxed control is obtained by taking limits. However, the success of the finite-dimensional theory has no complete counterpart here: in finite dimensions, convergence of trajectories follows from the Arzelà–Ascoli theorem, while in infinite-dimensional spaces we must rely on compactness properties of the equation or the control operator. We present essentially two examples: the first is an abstract parabolic system where A generates a compact semigroup (§5), the second (§6) a semilinear wave equation treated as an abstract differential equation. In these applications, the setting is a reflexive separable Banach space. We cover in §7 an extension of the theory to nonreflexive Banach spaces with applications to parabolic systems in L^1 spaces and spaces of continuous functions.

The last section is on Pontryagin's maximum principle. We show that, using the theory for ordinary controls, understood in sufficient generality, the maximum principle for relaxed controls results. (In the finite-dimensional case, this is stressed in [38, §39].)

2. Spaces of ordinary and relaxed controls. The control system is

$$y'(t) = Ay(t) + f(t, y(t), u(t)), \qquad y(0) = \zeta \tag{2.1}$$

in a time interval $0 \le t \le T$, where A is the infinitesimal generator of a strongly continuous semigroup $S(t)$ in the Banach space E and $\zeta \in E$. The *control set* U is a normal topological space. By definition, solutions of (2.1) are elements of the space $C(0, T; E)$ of continuous E-valued functions defined in $0 \le t \le T$ satisfying

$$y(t) = S(t)\zeta + \int_0^t S(t-\sigma) f(\sigma, y(\sigma), u(\sigma))\, d\sigma \tag{2.2}$$

in $0 \le t \le T$, where the integral is understood in the sense of Lebesgue–Bochner. The *admissible control space* $U_{ad}(0, T; U)$ is an arbitrary space of U-valued functions $t \to u(t)$ such that

(I) for every $y(\cdot) \in C(0, T; E)$ and every $u(\cdot) \in U_{ad}(0, T; U)$ the function $t \to f(t, y(t), u(t))$ is (strongly measurable and) integrable in $0 \le t \le T$.

The key result in the definition of relaxed controls is Theorem 2.1, due to Dieudonné [9], [10], on the dual of $L^1(0,T;E)$ for an arbitrary Banach space E. The space $L^\infty_w(0,T;E^*)$ consists of all E^*-valued E-weakly measurable functions $g(\cdot)$ such that there exists C with

$$|\langle g(t), y\rangle| \le C\|y\| \qquad \text{a.e. in } 0 \le t \le T, \quad y \in E \tag{2.3}$$

(the null set implicit in "a.e." may depend on y). The norm $\|\cdot\|$ in $L^\infty_w(0,T;E^*)$ is the least C such that (2.3) holds. The equivalence relation in $L^\infty_w(0,T;E^*)$ is $f(\cdot) \approx g(\cdot)$ if and only if $\langle f(t), y\rangle = \langle g(t), y\rangle$ almost everywhere for every $y \in E$.

THEOREM 2.1. *The dual space $L^1(0,T;E)^*$ is isometrically isomorphic to $L^\infty_w(0,T;E^*)$ through the pairing*

$$\langle g(\cdot), f(\cdot)\rangle = \int_0^T \langle g(\sigma), f(\sigma)\rangle d\sigma. \tag{2.4}$$

For a complete proof see [9] and [10]. Theorem 2.1 is a simple consequence of the Dunford–Pettis theorem [11], [12, Th. 6, p. 503 and Lemma 8, p. 504], [31, Cor. 1, p. 89] on bounded linear operators from $L^1(0,T)$ into the dual E^* of a Banach space E. This theorem provides additional information on the space $L^\infty_w(0,T;E^*)$, for instance, the following result.

THEOREM 2.2. *There exists a linear operator $S : L^\infty_w(0,T;E^*) \to L^\infty_w(0,T;E^*)$ such that* (a) *Sg belongs to the equivalence class of g;* (b) *the function $t \to \|(Sg)(t)\|$ is measurable in $0 \le t \le T$;* (c) $\sup_{0\le t\le T} \|(Sg)(t)\| = \|g\|$.

For a proof see [31, Cor. 1, p. 89]. In particular, Theorem 2.2 shows that each equivalence class in $L^\infty_w(0,T;E^*)$ contains an element $g(\cdot)$ such that

$$\|g(t)\| \le \|g\| \qquad (0 \le t \le T). \tag{2.5}$$

We shall use Theorem 2.1 with various measure spaces taking the role of E^*. Let U be an arbitrary set, Φ a field of subsets of U. We denote by $\Sigma_{ba}(U,\Phi)$ the Banach space of all bounded finitely additive measures defined in Φ endowed with the total variation norm. If U is a normal topological space and Φ_c is the field generated by the closed sets of U, the space $\Sigma_{rba}(U,\Phi_c)$ of all regular, bounded finitely additive measures is a closed subspace of $\Sigma_{ba}(U,\Phi_c)$ (thus a Banach space) under the total variation norm. Finally, if Φ_b is the Borel field of $U, \Sigma_{rca}(U,\Phi_b)$ denotes the space of all regular bounded countably additive measures defined in Φ_b, and is also a Banach space under the total variation norm.

We denote by $B(U)$ the space of all real valued bounded functions in U endowed with the supremum norm: if U is a topological space, $BC(U)$ denotes the subspace of all real valued bounded continuous functions in U. Both spaces are Banach spaces; if U is compact, $BC(U) = C(U)$, the space of all continuous functions in U. Finally, given an arbitrary field Φ of subsets of U, the space $B(U,\Phi)$ is defined as the closure in $B(U)$ of the set of all finite linear combinations of characteristic functions of sets in Φ.

THEOREM 2.3. (a) *The dual space $B(U,\Phi)^*$ of $B(U,\Phi)$ is isometrically isomorphic to $\Sigma_{ba}(U,\Phi)$, the duality pairing given by*

$$\langle \mu, f\rangle = \int_U f(u)\mu(du). \tag{2.6}$$

In particular, $B(U)^* = \Sigma_{ba}(U,\Phi), \Phi$ the field of all subsets of U. (b) *If U is a normal topological space, the dual space $BC(U)^*$ of $BC(U)$ is isometrically isomorphic to $\Sigma_{rba}(U,\Phi_c)$ with the same duality pairing, Φ_c the field generated by the closed sets of U.*

(c) *If U is a compact topological space, $C(U)^*$ is isometrically isomorphic to $\Sigma_{rca}(U, \Phi_b)$ with the same duality pairing.*

For the proof of (a)–(c), see [12, pp. 258, 262, 265].

The *relaxed control space* $V_r(0,T;U)$ consists of all elements $\mu(\cdot) \in L^1(0,T;BC(U))^* = L^\infty_w(0,T;\Sigma_{rba}(U,\Phi_c))$ that satisfy the following three conditions: (i)

$$\|\mu(\cdot)\| \leq 1 \tag{2.7}$$

(norm in $L^\infty_w(0,T;\Sigma_{rba}(U,\Phi_c))$. (ii) If $f(\cdot) \in L^1(0,T;BC(U))$ is such that $f(t,u) \geq 0$ for $u \in U$ almost everywhere in $0 \leq t \leq T$, then

$$\int_0^T \int_U f(t,u)\mu(t,du)dt \geq 0. \tag{2.8}$$

(iii) If e is a measurable set in $[0,T]$ and $\chi(t,u)$ is the characteristic function of $e \times U$, then

$$\int_0^T \int_U \chi(t,u)\mu(t,du)dt = \text{meas}(e). \tag{2.9}$$

In view of (2.5) we may always assume (if necessary selecting another element of the equivalence class) that an element of $V_r(0,T;U)$ satisfies

$$\|\mu(t)\| \leq 1 \qquad (0 \leq t \leq T). \tag{2.10}$$

LEMMA 2.4. *Let $\mu(\cdot) \in V_r(0,T;U)$ be such that* (2.10) *is satisfied almost everywhere. Then*

$$\mu(t) \geq 0, \qquad \mu(t,U) = \|\mu(t)\| = 1 \quad \textit{a.e. in } 0 \leq t \leq T. \tag{2.11}$$

In fact, let $\mathbf{1}(u) \equiv 1$. Since $\mu(t,U) = \langle \mu(t), \mathbf{1} \rangle$, the function $t \to \mu(t,U)$ is measurable. If $\mu(t,U) < 1$ in a set of positive measure, we may find $\varepsilon > 0$ and a set e of positive measure such that

$$\mu(t,U) \leq 1 - \varepsilon \qquad (t \in e).$$

If $\chi(t,u)$ is the characteristic function of $e \times U$, then

$$\int_0^T \int_U \chi(t,u)\mu(t,du) = \int_0^T \chi(t)\mu(t,U) \leq \text{meas}(e)(1-\varepsilon),$$

which contradicts condition (iii), and shows the second equality (2.11). Let t belong to the set e where $\mu(t,U) = 1, \|\mu(t)\| \leq 1$. Assume there exists a set $V \subseteq U$ such that $\mu(t,V) < 0$, and let W be the complement of V. Then $1 = \mu(t,U) = \mu(t,V) + \mu(t,W)$, whereas $|\mu|(t,U) \geq |\mu(t,V)| + |\mu(t,W)| > 1$, a contradiction. Accordingly, the first equality (2.11) holds as well in e. The fact that $\|\mu(\cdot)\|$ is measurable follows from the fact that $\|\mu(t)\| = \mu(t,U)$ almost everywhere.

We note that condition (i) is a consequence of (ii) and (iii).

The *relaxed control system* associated with (2.1) is, formally,

$$y'(t) = Ay(t) + \int_U f(t,y(t),u)\mu(t,du), \qquad y(0) = \zeta, \tag{2.12}$$

with $\mu(\cdot) \in V_r(0,T;U)$ (or with $\mu(\cdot) \in L_w^\infty(0,T;\Sigma_{rba}(U,\Phi_c))$ in general). To give sense to this equation we assume that E is reflexive and separable and the following conditions hold.

(II) (a) $f(t,y,\cdot)$ is continuous and bounded in U for t,y fixed; moreover, for every compact set $K \subseteq E$ there exists $\alpha(\cdot) = \alpha(K,\cdot) \in L^1(0,T)$ such that

$$\|f(t,y,u)\| \le \alpha(t) \qquad (0 \le t \le T, y \in K, u \in U). \tag{2.13}$$

(b) If $y(\cdot) \in C(0,T;E)$ and $y^* \in E^*$ then $t \to \langle y^*, f(t,y(t),\cdot)\rangle$ is a strongly measurable $BC(U)$-valued function.

Note that (b) and the bound (2.13) imply that $t \to \langle y^*, f(t,y(t),\cdot)\rangle$ belongs to $L^1(0,T;BC(U))$; in fact, we have $\|\langle y^*, f(t,y(t),\cdot)\rangle\| \le \|y^*\|\alpha(K,t)$, where $K = \{y(t); 0 \le t \le T\}$.

Equation (2.12) is understood in the following way. Define a function $\mathbf{f}$: $[0,T] \times E \times \Sigma_{rba}(U,\Phi_c) \to E$ by: $\mathbf{f}(t,y)\mu$ is the unique element of E satisfying

$$\langle y^*, \mathbf{f}(t,y)\mu\rangle = \int_U \langle y^*, f(t,y,u)\rangle \mu(du)$$

for all $y^* \in E^*$. The integral is well defined since, in view of (a) $\langle y^*, f(t,y,\cdot)\rangle \in BC(U)$; moreover, if $y \in K$ (K a compact set in E), $\|\langle y^*, f(t,y,\cdot)\rangle\|_{BC(U)} \le \alpha(K,t)\|y^*\|$ so that

$$\|\mathbf{f}(t,y)\mu\| \le \alpha(K,t)\|\mu\|_{\Sigma_{rba}(U,\Phi_c)} \qquad (0 \le t \le T, y \in K). \tag{2.14}$$

Let $\mu(\cdot) \in L_w^\infty(0,T;\Sigma_{rba}(U,\Phi_c)), y(\cdot) \in C(0,T;E)$ and $y^* \in E^*$. By virtue of (b) the function

$$\langle y^*, \mathbf{f}(\cdot, y(\cdot))\mu(\cdot)\rangle = \int_U \langle y^*, f(\cdot, y(\cdot), u)\rangle \mu(\cdot, du)$$

belongs to $L^1(0,T)$; since y^* is arbitrary, $\mathbf{f}(\cdot, y(\cdot))\mu(\cdot)$ is E^*-weakly measurable and by separability of E $\mathbf{f}(\cdot, y(\cdot))\mu(\cdot)$ is strongly measurable [30, p. 73]. We note that $\mathbf{f}(\cdot, y(\cdot))\mu(\cdot)$ depends only on the equivalence class of $\mu(\cdot)$ in $L_w^\infty(0,T;\Sigma_{rba}(U,\Phi_c))$. We recast (2.12) in the form

$$y'(t) = Ay(t) + \mathbf{f}(t, y(t))\mu(t), \qquad y(0) = \zeta. \tag{2.15}$$

The function $\mathbf{f}(t,y,u)$ satisfies (I) with respect to the control space $V_r(0,T;U)$. This makes it possible to interpret (2.15), the same as (2.1), as the integral equation

$$y(t) = S(t)\zeta + \int_0^t S(t-\sigma)\mathbf{f}(\sigma, y(\sigma))\mu(\sigma)d\sigma. \tag{2.16}$$

In the case where U is compact, the basic space is $L_w^\infty(0,T;\Sigma_{rca}(U,\Phi_b))$ instead of $L_w^\infty(0,T;\Sigma_{rba}(U,\Phi_c))$; this corresponds to using (c) of Theorem 2.3.

A requirement of any reasonable definition of relaxed control is that $U_{ad}(0,T;U) \subseteq V_r(0,T;U)$, that is, that every ordinary control $u(\cdot)$ can be replicated by a relaxed control $\mu(\cdot)$ in the sense that

$$f(t, y(t), u(t)) = \mathbf{f}(t, y(t))\mu(t). \tag{2.17}$$

We achieve this with $\mu(t) = \delta(\cdot - u(t))$, δ the Dirac delta. This relaxed control will belong to $V_r(0,T;U)$ if $U_{ad}(0,T;U)$ satisfies the following condition:

(I′) Let $u(\cdot) \in U_{ad}(0,T;U), y(\cdot) \in BC(U)$. Then

$$t \to y(u(t)) \tag{2.18}$$

is measurable in $0 \leq t \leq T$.

This will be satisfied, for instance, if U is a subset of a Banach space F and the elements of $U_{ad}(0,T;U)$ are strongly measurable.

We may base our definition of relaxed controls on the space $B(U)$ rather than $BC(U)$. In this case, U is just an arbitrary set and the space of relaxed controls $V_r(0,T;U)$ consists of all elements $\mu(\cdot) \in L^1(0,T;B(U))^* = L^\infty_w(0,T;\Sigma_{ba}(U,\Phi))$ that satisfy (i)–(iii). The relaxed control system is again (2.15) and the only assumptions on $f(t,y,u)$ are (a) and (b) of (II), with "continuous and bounded" replaced by "bounded" and the space $BC(U)$ replaced by $B(U)$. The price we pay for this enormous generality is that, if we insist on the inclusion $U_{ad}(0,T;U) \subseteq V_r(0,T;U)$, admissible controls must make (2.18) measurable for every $y \in B(U)$, which restricts severely the space $U_{ad}(0,T;U)$. Possibly, definitions using intermediate spaces $B(U,\Phi)$ for a suitable field Φ may be useful. We do the theory below for $BC(U)$ and $\Sigma_{rba}(U,\Phi_c)$ and use the shorthand $\Sigma_{rba}(U)$ for this space; every result in the rest of the paper can be immediately translated to $B(U)$ and $\Sigma_{ba}(U,\Phi) = \Sigma_{ba}(U)$.

We shall call $y(t,\mu)$ the trajectory of (2.15) corresponding to $\mu(\cdot) \in L^\infty_w(0,T;\Sigma_{rba}(U))$. The assumptions in this section only guarantee that solutions of (2.1) and (2.15) can be defined in their integral versions; existence of solutions is not guaranteed, even locally.

The requirement that $f(t,y,\cdot) \in CB(U)$ for (t,y) fixed leaves out such natural control terms as $f(t,y,u) = Lu$ with L a bounded operator and u in an unbounded control set U. Such control terms (and more general ones) appear in viscous flow problems [24], [25]. The theory of relaxed controls can be extended to cases like this requiring that controls in $V_r(0,T;U)$ satisfy suitable integrability conditions. See [24] and [25] for details.

3. Differential inclusions, relaxation theorems. Relaxed controls and trajectories have been defined in nonparametric form (that is, using differential inclusions) in [3] and [28]. In the formulation of [28] (somewhat rephrased) a pair $(y(\cdot),g(\cdot))$, where $y(\cdot) \in C(0,T;E)$ and $g(\cdot) \in L^1(0,T;E)$ is a *trajectory* of the differential inclusion

$$y'(t) \in Ay(t) + \overline{\text{conv}}\ f(t,y(t),U) \tag{3.1}$$

($\overline{\text{conv}}$ denotes closed convex hull) if and only if

$$g(t) \in \overline{\text{conv}}\ \{f(t,y(t),U)\} \qquad \text{a.e. in } 0 \leq t \leq T \tag{3.2}$$

$$y(t) = S(t)\zeta + \int_0^t S(t-\sigma)g(\sigma)d\sigma \qquad (0 \leq t \leq T). \tag{3.3}$$

A basic question is whether the solutions $y(\cdot)$ of (3.1) and those of (2.15) are the same. The answer is affirmative, as we see in the following theorem.

THEOREM 3.1. *Assume the space E is separable and that assumption* (II) *holds. Let $y(t,\mu)$ be a solution of* (2.15) *for $\mu(\cdot) \in V_r(0,T;U)$. Then $(y(t,\mu),\mathbf{f}(t,y(t))\mu(t))$ is a trajectory of the differential inclusion* (3.1).

For a proof see [21, Th. 4.1]. The result also holds (under modified definitions and assumptions) in certain nonreflexive spaces; see [21, §6]. Another important problem is that of establishing *relaxation* theorems, that is, showing that every solution $y(t,\mu)$ of (2.15) can be uniformly approximated in their interval of existence by solutions $y(t,u)$ of the original equation (2.1). For two results of this type in reflexive spaces, see [21, Ths. 5.4 and 5.5]; a generalization for certain nonreflexive spaces can be found in [21, §6].

4. Optimal control problems. Relaxation. Optimal control problems for (2.1) include a *cost functional* $y_0(t,u)$ defined in $U_{ad}(0,T;U)$ with values in $\mathbb{R}$. In many applications, the cost functional has the form

$$y_0(t,u) = \int_0^t f_0(\sigma, y(\sigma,u), u(\sigma))d\sigma + \phi_0(t, y(t,u)), \tag{4.1}$$

where $y(t,u)$ is the trajectory of (2.1) corresponding to $u(\cdot)$, $f_0 : [0,T] \times E \times U \to \mathbb{R}$, $\phi : [0,T] \times E \to \mathbb{R}$. Also, there may be a *target condition*

$$y(\bar{t},u) \in Y = \begin{matrix}\text{target set} \\ \text{cost functional}\end{matrix} \subseteq E, \tag{4.2}$$

where the *arrival time* $\bar{t}$ (the endpoint of the control interval $0 \le t \le \bar{t}$) may be free or fixed. The companion of assumption (I) for f in §2 is

(I_0) For every $y(\cdot) \in C(0,T;E)$ and every $u(\cdot) \in U_{ad}(0,T;U)$ the function $t \to f_0(t, y(t), u(t))$ is integrable in $0 \le t \le T$.

The original optimal control problem is that of minimizing $y_0(\bar{t},u)$ among all $u \in U_{ad}(0,\bar{t};U)$ whose corresponding trajectory $y(t,u)$ satisfies the target condition (4.2). Define

$$m = \inf y_0(\bar{t},u), \tag{4.3}$$

the infimum taken over all $u \in U_{ad}(0,\bar{t};U)$, such that $y(\cdot,u)$ satisfies (4.2); for the free arrival time problem $\bar{t}$ varies in $\mathbb{R}_+$. A natural restriction on the minimum is

$$-\infty < m < \infty. \tag{4.4}$$

The second inequality simply means that there exists some control $u \in U_{ad}(0,\bar{t};U)$ such that the trajectory $y(\cdot,u)$ satisfies the target condition (4.2). On the other hand, $m = -\infty$ means we can reach the target with arbitrarily low values of the functional, hence there is no optimal control. A *minimizing sequence* for the original problem is a sequence $\{u^n(\cdot)\} \subset U_{ad}(0,t_n;U)$ such that

$$\lim_{n\to\infty} \text{dist } (y(t_n,u^n), Y)) = 0, \tag{4.5}$$

$$\limsup_{n\to\infty} y_0(t_n,u^n) \le m. \tag{4.6}$$

The *relaxed control problem* is that described by (2.15), with controls $\mu(\cdot) \in V_r(0,T;U)$ and *relaxed cost functional*

$$y_0(t,\mu) = \int_0^t \mathbf{f}_0(\sigma, y(\sigma,\mu))\mu(\sigma)d\sigma + \phi_0(t, y(t,\mu)). \tag{4.7}$$

where $y(t,\mu)$ is the trajectory of (2.15) corresponding to the relaxed control $\mu(\cdot) \in V_r(0,\bar{t};U)$ and $\mathbf{f}_0$ is defined by

$$\mathbf{f}_0(t,y)\mu = \int_U f_0(t,y,u)\mu(du). \tag{4.8}$$

The target condition is the same. The companion of assumption (II) is

(II_0) (a) $f_0(t,y,\cdot)$ is bounded and continuous in U for t,y fixed. (b) If $y(\cdot)\in C(0,T;E)$ then $t\to f_0(t,y(t),\cdot)\in L^1(0,T;BC(U))$.

Assumption (II_0) makes possible the definition of $\mathbf{f}_0(t,y,u)$ and assures that $t\to \mathbf{f}_0(t,y(t))\mu(\cdot)\in L^1(0,T)$ for every $\mu(\cdot)\in L^\infty_w(0,T;\Sigma_{rba}(U))$, in particular for $\mu(\cdot)\in V_r(0,T;U)$, so that $y_0(t,\mu)$ can be defined. Since $y(t,\mu)$ may not exist or be unique, the same applies to $y_0(t,\mu)$.

Corresponding to the relaxed control problem we define

$$\mathbf{m}=\inf y_0(\bar t,\mu), \tag{4.9}$$

the infimum taken over all $\mu\in V_r(0,t;U)$ whose trajectories $y(\cdot,\mu)$ exist in $0\le t\le\bar t$ and satisfy the target condition (4.2). The observations about m apply to $\mathbf{m}$ as well. Since there are more relaxed than ordinary controls, we will always have

$$\mathbf{m}\le m. \tag{4.10}$$

In principle, strict inequality is possible, including situations where $\mathbf{m}<\infty, m=\infty$. (The target may be attained by a trajectory $y(\cdot,\mu)$ of the relaxed system but not by a trajectory $y(\cdot,u)$ of the original system.) It is desirable that

$$\mathbf{m}=m, \tag{4.11}$$

for if $\mathbf{m}<m$ it could be maintained that the relaxed problem "generalizes too much" the ordinary problem.

The basis of all our existence theorems will be the *closure theorem* below.

THEOREM 4.1. (closure of set of trajectories). *Let* $\{y(t,\mu_n)\}$ *be a sequence of trajectories of the relaxed system* (2.15) *in* $0\le t\le\bar t$. *Assume that* (a) *there exists* $y(\cdot)\in C(0,T;E)$ *such that* $y(t,\mu_n)\to y(t)$ *weakly in* E *for each* $t, 0\le t\le\bar t$; *and* (b) *for every* $y^*\in E^*$

$$\langle y^*, f(\cdot,y(\cdot,\mu_n),\cdot)\rangle\to\langle y^*,f(\cdot,y(\cdot),\cdot)\rangle \tag{4.12}$$

in $L^1(0,T;BC(U))$. *Then* $y(t)$ *is a trajectory of* (2.15), *that is, there exists a relaxed control* $\mu(\cdot)\in V_r(0,T;U)$ *such that* $y(t)=y(t,\mu)$.

Proof. We have

$$y(t,\mu_n)=S(t)\zeta+\int_0^t\int_U S(t-\sigma)f(\sigma,y(\sigma,\mu_n),u)\mu_n(\sigma,du)d\sigma.$$

Apply a functional $y^*\in E^*$:

$$\begin{aligned}\langle y^*,y(t,\mu_n)\rangle&=\langle y^*,S(t)\zeta\rangle+\int_0^t\int_U\langle S(t-\sigma)^*y^*,f(\sigma,y(\sigma,\mu_n),u)\rangle\mu_n(\sigma,du)d\sigma\\&=\langle y^*,S(t)\zeta\rangle+\int_0^{\bar t}\int_U\langle\chi(t-\sigma)S(t-\sigma)^*y^*,f(\sigma,y(\sigma,\mu_n),u)\rangle\mu_n(\sigma,du)d\sigma,\end{aligned} \tag{4.13}$$

where $\chi(\cdot)$ is the characteristic function of $t\ge 0$. Since E is reflexive the adjoint semigroup $S(t)^*$ is strongly continuous, thus, for each t we may approximate $\chi(t-\cdot)S(t-\cdot)^*y^*$ uniformly by step functions and use (4.12) to deduce that

$$\langle\chi(t-\cdot)S^*(t-\cdot)y^*,f(\sigma,y(\cdot,\mu_n),\cdot)\rangle\to\langle\chi(t-\cdot)S^*(t-\cdot)y^*,f(\sigma,y(\cdot),\cdot)\rangle$$

in $L^1(0,T;C(U))$. Select a $L^1(0,T;C(U))$-weakly convergent (generalized) subsequence of $\{\mu_n(\cdot)\}$, denoted in the same way. Taking limits and using the fact that y^* is arbitrary,

$$y(t) = S(t)\zeta + \int_0^t \int_U S(t-\sigma) f(\sigma, y(\sigma), u)\mu(\sigma, du)d\sigma,$$

which ends the proof.

More than a usable result, Theorem 4.1 is a "template" by means of which we shall cut all of our existence theorems. In these, condition (b) will result from assumptions on $f(t,y,u)$ and convergence of $y(t,\mu_n)$.

5. Abstract parabolic equations. We examine the existence problem for (2.15) when $S(t)$ is *compact*. In applying Theorem 4.1, we use the result below [22, §3] on the operator

$$(\Lambda g)(t) = \int_0^t S(t-\sigma)g(\sigma)d\sigma, \tag{5.1}$$

where the Banach space E is completely arbitrary.

LEMMA 5.1. *The operator Λ is bounded from $L^1(0,T;E)$ into $C(0,T;E)$. If $S(t)$ is compact for $t>0$ and $\{g_n(\cdot)\}$ is a sequence in $L^1(0,T;E)$ such that the integrals of $\|g_n(\cdot)\|$ are equicontinuous in $0 \le t \le T$, then $\{\Lambda g_n(\cdot)\}$ has a convergent subsequence in $C(0,T;U)$.*

In the following result the space E is again assumed to be reflexive and separable. The following assumptions on f, f_0, reinforce (II) and (II_0), respectively, with an assumption of continuity in y. In these assumptions, the space $C(0,T;E)$ is endowed with its usual supremum norm.

(III) (a) as in (II).

(b) as in (II) but with K bounded.

(c) If $\{y_n(\cdot)\} \subset C(0,T;E)$ is such that $y_n(\cdot) \to y(\cdot)$ in $C(0,T;E)$ then

$$\langle y^*, f(\cdot, y_n(\cdot), \cdot)\rangle \to \langle y^*, f(\cdot, y(\cdot), \cdot)\rangle \tag{5.2}$$

in $L^1(0,T;BC(U))$ (or, equivalently, almost everywhere, in view of the bound (2.13) that now holds for K bounded).

(III_0) (a) and (b) as in (II_0).

(c) If $\{y_n(\cdot)\} \subset C(0,T;E)$ is such that $y_n(\cdot) \to y(\cdot)$ in $C(0,T;E)$ then

$$f_0(\cdot, y_n(\cdot), \cdot) \to f_0(\cdot, y(\cdot), \cdot) \tag{5.3}$$

in $L^1(0,T)$.

(d) $\phi_0(t,y)$ is continuous.

THEOREM 5.2. *Let E be reflexive and separable, let $S(t)$ be a compact semigroup, and let the target set Y be closed. Assume that* (III) *and* (III_0) *hold and that there exists a minimizing sequence $\{\mu_n(\cdot)\}, \mu_n(\cdot) \in V_r(0,t_n;U)$ of relaxed controls with $\{t_n\}$ bounded and $y(\cdot,\mu_n)$ uniformly bounded in $0 \le t \le t_n$. Then there exists a relaxed solution $\overline{\mu}(\cdot)$ to the relaxed optimal control problem.*

Proof. Passing if necessary to a subsequence we may assume that $t_n \to \bar{t}$. For each n, if $t_n < \bar{t}$ extend $\mu_n(t)$ to $t_n < t \le \bar{t}$ setting $\mu(t) = \delta(t-u), u \in U$ arbitrary there; if $t_n \ge \bar{t}$ chop off $\mu_n(t)$ at $t = \bar{t}$. Call $\overline{\mu}_n(\cdot)$ the extended/chopped-off control. Since the sequence $\mathbf{f}(\cdot, y(\cdot,\mu_n))\mu_n(\cdot)$ satisfies (2.14), by Lemma 5.1 there exits a generalized subsequence, which we denote with the same symbol, such that $\{y(\cdot,\mu_n)\}$ is uniformly convergent in $C(0,\bar{t};U)$ to a function $y(\cdot)$. We now apply (III) and Theorem 4.1 and

obtain $\overline{\mu}(\cdot) \in V_r(0,\bar{t};U)$ such that $y(t) = y(t,\overline{\mu})$. The fact that the approximate target conditions (4.5) imply the exact target condition (4.2) follows from uniform convergence of the sequence of trajectories $\{y(t,\mu_n)\}$ and closedness of the target set Y. It only remains to show that $\overline{\mu}$ is an optimal relaxed control. To do this it suffices to prove that $y_0(\bar{t},\overline{\mu}) = \mathbf{m}$, $\mathbf{m}$ the minimum in (4.9). This follows using (III_0) and taking limits.

Theorem 5.2 reduces the existence problem to that of finding a minimizing sequence $\{\mu_n(\cdot)\}$ having the required properties. Existence of this sequence is certainly not guaranteed by hypothesis (III), which does not even imply local existence of the trajectory for each control $\mu(\cdot) \in V_r(0,T;U)$. Local existence is implied by the following local boundedness/local Lipschitz continuity assumption.

(IV) (a) $f(t,y,\cdot)$ is continuous and bounded in U for t,y fixed.

(b) If $y(\cdot) \in C(0,T;E)$ and $y^* \in E^*$ then $t \to \langle y^*, f(t,y(t),\cdot)\rangle$ is a strongly measurable $BC(U)$-valued function.

(c) For every $c > 0$ there exist $\alpha(\cdot) = \alpha(c,\cdot)$ and $\beta(\cdot) = \beta(c,\cdot) \in L^1(0,T)$ with

$$\|f(t,y,u)\| \le \alpha(t) \qquad (0 \le t \le T, \|y\| \le c, u \in U), \tag{5.4}$$

$$\|f(t,y',u) - f(t,y,u)\| \le \beta(t)\|y' - y\| \qquad (0 \le t \le T, \|y\|, \|y'\| \le c, u \in U). \tag{5.5}$$

Assumption (IV) implies corresponding local boundedness and local Lipschitz continuity properties for $\mathbf{f}(t,y)\mu$:

$$\|\mathbf{f}(t,y)\mu\| \le \alpha(t)\|y\|\ \|\mu\|_{\Sigma_{rba}(U)} \qquad (0 \le t \le T, \|y\| \le c, \mu \in \Sigma_{rba}(U)), \tag{5.6}$$

$$\begin{gathered}\|\mathbf{f}(t,y')\mu - f(t,y)\mu\| \le \beta(t)\|y' - y\|\ \|\mu\|_{\Sigma_{rba}(U)} \\ (0 \le t \le T, \|y\|, \|y'\| \le c, \mu \in \Sigma_{rba}(U)).\end{gathered} \tag{5.7}$$

Under (5.6) and (5.7), the integral equation (2.16) can be uniquely solved in some interval $[0,T'], 0 \le T' \le T$ by successive approximations.

It is plain that (IV) $\Rightarrow$ (III) $\Rightarrow$ (II).

Under stronger hypotheses, a priori bounds can be obtained that guarantee the following statement.

(V) For every $\mu(\cdot) \in V_r(0,T;U), y(t,\mu)$ exists in $0 \le t \le T$ and $\{y(t,\mu)\}$ is bounded independently of μ.

For results of this type under somewhat different conditions see [18, Lemma 5.1]. A priori bounds can also be obtained using Lyapunov functions or, in certain cases, by means of energy estimates [32].

If (V) holds, the only requirement on the minimizing sequence in Theorem 5.2 is boundedness of $\{t_n\}$. Even this follows automatically for some cost functionals.

COROLLARY 5.3. *Assume that*

(a) (III), (III_0), *and* (V) *hold;*

(b) *there exists a relaxed or ordinary control* $\mu(\cdot)$ *such that* $y(t,\mu)$ *satisfies the target condition* (4.2);

(c) $f_0(t,y,u) \ge \delta > 0$, (d) $\phi_0(t,y) \ge 0$. *Then there exists a relaxed solution* $\overline{\mu}(\cdot)$ *to the optimal control problem.*

In fact, condition (a) allows the construction of a minimizing sequence $\{\mu_n(\cdot)\}$. If $f_0(t,y,u) \ge \delta > 0$ and $\phi_0(t,y) \ge 0$ we obtain from (4.7) that $y_0(t_n,\mu_n) \ge t_n\delta$ which shows that $\{t_n\}$ must be bounded. Property (V) applied in some interval $[0,T]$ with $T > t_n$ then shows that $y(\cdot,\mu_n)$ is uniformly bounded in $0 \le t \le t_n$, so that Theorem 5.2 applies.

Verification of (b) is a *controllability* problem of interest in its own right. In some cases, the solution is obvious, for instance, where the target set Y is a ball with center at the origin and for some $\mu(\cdot) \in V_r(0,T;U)$ all solutions of (2.1) tend to zero as $t \to \infty$.

Many compact semigroups (such as those generated by uniformly elliptic partial differential operators) are also *holomorphic*. Modulo a translation we may assume that the origin belongs to the resolvent set of the infinitesimal generator A, and fractional powers $(-A)^\alpha$ can be defined for α real: $(-A)^\alpha S(t)$ is bounded in $t > 0$ for all $\alpha > 0$ and

$$\|(-A)^\alpha S(t)\| \le C_\alpha t^{-\alpha} e^{\omega t} \qquad (t \ge 0). \tag{5.8}$$

Writing the integral equation (2.15) in the form

$$y(t) = S(t)\zeta + \int_0^t (-A)^\alpha S(t-\sigma)(-A)^{-\alpha}\mathbf{f}(t, y(\sigma))\mu(\sigma)d\sigma, \tag{5.9}$$

we may prove an analog of Theorem 5.2 where (III) is required of $(-A)^{-\alpha}f(t,y,u)$ rather than of $f(t,y,u)$.

6. A hyperbolic distributed parameter system. Existence theorems for relaxed controls can be established without compactness assumptions on the semigroup $S(\cdot)$. As an example, we consider the semilinear wave equation

$$y_{tt}(t,x) = \sum_{j=1}^{m}\sum_{k=1}^{m} \partial^j(a_{jk}(x)\partial^k y(t,x)) - \phi(y(t,x),u(t)) \qquad (x \in \Omega), \tag{6.1}$$

$$y(t,x) = 0 \qquad (x \in \Gamma) \tag{6.2}$$

in an arbitrary domain Ω with boundary Γ in m-dimensional Euclidean space $\mathbb{R}^m$; the notations are $x = (x_1, x_2, \ldots, x_m), \partial^j = \partial/\partial x_j$. We assume that $a_{jk} = a_{kj}$ and that the operator A is uniformly elliptic: $\Sigma\Sigma a_{jk}(x)\xi_j\xi_k > \kappa|\xi|^2 (\xi \in \mathbb{R}^m, x \in \overline{\Omega}, \kappa > 0)$. The nonlinear term $\phi(y,u)$ is defined in $\mathbb{R} \times U$, where U is a normal topological space. Precise assumptions on ϕ will be given below.

We reduce (6.1) to a first-order system for a two-dimensional vector function $\mathbf{y} = (y, y_t) = (y, y_1)$ in the usual way:

$$y_t(t,x) = y_1(t,x), \tag{6.3}$$

$$y_{1t}(t,x) = \sum\sum \partial^j(a_{jk}(x)\partial^k y(t,x)) - \phi(y(t,x),u(t)) \tag{6.4}$$

and examine this system as an equation of the form (2.1),

$$\mathbf{y}'(t) = \mathbf{A}\mathbf{y}(t) + \mathbf{f}(\mathbf{y}(t), u(t)) \tag{6.5}$$

in the space $E = H_0^1(\Omega) \times L^2(\Omega)$, where

$$\mathbf{A} = \begin{pmatrix} 0 & I \\ \sum\sum \partial^j(a_{jk}(x)\partial^k) & 0 \end{pmatrix},$$

$$\mathbf{f}((y,y_1),u) = \begin{pmatrix} 0 \\ \phi(y,u) \end{pmatrix}.$$

For the linear case $\phi = 0$ see for instance [16], where it is shown that $\mathbf{A}$ generates a strongly continuous group $\mathbf{S}(\cdot)$ in $E = H_0^1(\Omega) \times L^2(\Omega)$ and a precise description of the domain $D(\mathbf{A})$ is given. The assumption on the nonlinear term ϕ is (VI) below. This assumption has two parts, the latter depending on the dimension m.

(VI) (a) For each $y \in \mathbb{R}, \phi(y, \cdot) \in BC(U)$.

(b) Dimension $m > 2$. Let $\alpha = m/(m-2)$. Then

$$|\phi(y,u)| \leq C(1 + |y|^\alpha) \qquad (y \in \mathbb{R}, u \in U), \tag{6.6}$$

$$|\phi(y',u) - \phi(y,u)| \leq K(1 + |y|^{\alpha-1} + |y'|^{\alpha-1})|y' - y| \qquad (y, y' \in \mathbb{R}, u \in U). \tag{6.7}$$

Dimension $m = 2$. There exists some $\alpha > 0$ such that (6.6) and (6.7) hold.

Dimension $m = 1$. For each $c > 0$ there exist $C = C(c), K = K(c)$ such that

$$|\phi(y,u)| \leq C \qquad (y \in \mathbb{R}, |y| \leq c, u \in U), \tag{6.8}$$

$$|\phi(y',u) - \phi(y,u)| \leq K|y' - y| \qquad (y, y' \in \mathbb{R}, |y|, |y'| \leq c, u \in U). \tag{6.9}$$

We check that assumption (VI) implies (III), the local Lipschitz condition (IV), and the global existence-boundedness condition (V) in §5 beginning with the case $m > 2$. We shall use (a particular case of) Sobolev's imbedding theorem [1, p. 97]; assuming Ω satisfies the cone property [1, p. 66], the imbedding $W^{k,p}(\Omega) \to L^q(\Omega)$ holds for $kp < m, 1 \leq p \leq q \leq mp/(m-kp)$; in particular, we have the imbedding $H^1(\Omega) \to L^{2m/(m-2)}(\Omega)$; hence, if $y(\cdot) \in H^1(\Omega)$ (6.6) implies that $\phi(y(\cdot), u) \in L^{2m/(m-2)\alpha}(\Omega) = L^2(\Omega)$ with

$$\|\phi(y(\cdot),u)\|_{L^2(\Omega)} \leq C\|y(\cdot)\|_{H^1(\Omega)}, \tag{6.10}$$

so that $y(\cdot) \to \mathbf{f}(y(\cdot), u)$ maps E into E. On the other hand (6.7) implies that if $y(\cdot), y'(\cdot) \in H^1(\Omega)$,

$$\begin{aligned} &\|\phi(y'(\cdot),u) - \phi(y(\cdot),u)\|_{L^2(\Omega)} \\ &\qquad \leq K\left(\int_\Omega |y'(x) - y(x)|^2(1 + |y(x)|^{\alpha-1} + |y'(x)|^{\alpha-1})^2 dx\right)^{1/2}. \end{aligned} \tag{6.11}$$

Since $y(\cdot), y'(\cdot) \in L^{2m/(m-2)}(\Omega)$, we can apply Hölder's inequality with exponents $p = \alpha = m/(m-2), q = p/(p-1) = m/2$. The result is

$$\begin{aligned} &\|\phi(y'(\cdot),u) - \phi(y(\cdot),u)\|_{L^2(\Omega)} \\ &\leq K\left(\int_\Omega |y'(x) - y(x)|^{2m/(m-2)}\, dx\right)^{(m-2)/2m} \\ &\qquad \times \left(\int_\Omega (1 + |y(x)|^{\alpha-1} + |y'(x)|^{\alpha-1})^m\, dx\right)^{1/m}. \end{aligned}$$

Using the inequality $(a+b+c)^\beta \leq 3^\beta(a^\beta + b^\beta + c^\beta)(a, b, c, \beta \geq 0)$ and noting that $(\alpha - 1)m = 2m/(m-2)$, we obtain

$$\begin{aligned} &\|\phi(y'(\cdot),u) - \phi(y(\cdot),u)\|_{L^2(\Omega)} \\ &\qquad \leq K'(1 + \|y(\cdot)\|_{L^{2m/(m-2)}(\Omega)} + \|y'(\cdot)\|_{L^{2m/(m-2)}(\Omega)})^{2/(m-2)} \\ &\qquad\qquad \times \|y'(\cdot) - y(\cdot)\|_{L^{2m/(m-2)}(\Omega)} \\ &\qquad \leq K'(1 + \|y(\cdot)\|_{H^1(\Omega)} + \|y'(\cdot)\|_{H^1(\Omega)})^{2/(m-2)} \|y'(\cdot) - y(\cdot)\|_{H^1(\Omega)}. \end{aligned} \tag{6.12}$$

We check that $\mathbf{f}((y(\cdot), y_1(\cdot)), u) = \mathbf{f}(y(\cdot), u) = (0, \phi(y(\cdot), u)$ satisfies assumption (IV). Obviously, (a) of (VI) is (a) of (IV). The local Lipschitz condition (6.12) implies that $t \to \mathbf{f}(y, \cdot)$ is a continuous $BC(U)$-valued function of y, so that part (b) of (IV) is satisfied to excess. Finally, (6.10) and (6.12) imply the two inequalities in (c) of (IV),

$$\|\mathbf{f}((y, y_1), u)\| \le C\|(y, y_1)\|_E, \qquad (y, y_1) \in E,$$
$$\|\mathbf{f}((y', y_1'), u) - \mathbf{f}((y, y_1), u)\|_E$$
$$\le K(1 + \|(y, y_1)\|_E + \|(y', y_1')\|_E)^{2/(m-2)}\|(y', y_1') - (y, y_1)\|_E.$$

For $m = 2$, we have the imbedding $H^1(\Omega) \to L^q(\Omega)$ for every $q \ge 1$ [1, p. 97] and the arguments are essentially the same; for $m = 1$ the imbedding is $H^1(\Omega) \to C(\overline{\Omega})$. We omit the details.

Finally, the global existence-boundedness property (V) in §5 can be deduced from the present hypotheses using as a priori energy bounds: these take the form

$$\|y(t, \mu_n)\|^2_{H^1(\Omega)} + \|y_t(t, \mu_n)\|^2_{L^2(\Omega)} \le C \qquad (0 \le t \le T'), \tag{6.13}$$

where $[0, T']$ is any interval where the solution $y(t, \mu)$ exists. For details, see [32].

We consider below an optimal control problem for the nonlinear wave equation (6.1). The cost functional is arbitrary and only assumed to satisfy condition (III_0). The conditions on the nonlinear term will have to be slightly stiffened only for $m > 2$.

THEOREM 6.1. *Assume ϕ satisfies assumption* (VI) *with $\alpha < m/(m-2)$ in case $m > 2$. Let $\{\mu_n(\cdot)\}$ be a minimizing sequence with $\{t_n\}$ bounded. Then there exists a relaxed solution $\mu(\cdot)$ to the optimal control problem.*

Proof. The Rellich–Kondrachev theorem [1, p. 146] implies that the imbedding $H^1(\Omega) \to L^{2m/(m-2)}(\Omega)$ is compact. This and (6.13) justify the application of the Arzelà–Ascoli theorem below. Selecting if necessary a subsequence we may assume $\{y(\cdot, \mu_n)\}$ is uniformly convergent in $C(0, T; L^{2m/(m-2)}(\Omega))$ to $y(\cdot) \in C(0, T; L^{2m/(m-2)}(\Omega))$. Since $\phi(y(\cdot), u)$ is a locally Lipschitz operator from $L^{2m/(m-2)}(\Omega)$ into $L^2(\Omega)$ uniformly with respect to u, it follows that

$$f(y(t, \mu_n), u) \to f(y(t), u)$$

uniformly with respect to $u \in U$ and to $t \in [0, T]$. This is in excess of what is required in Theorem 4.1 and thus ends the proof.

See [16] for the treatment of other (variational) boundary conditions, addition of lower order terms, etc.

7. Abstract parabolic equations in nonreflexive spaces. We outline in this section a theory of relaxed systems that does not require the space E to be reflexive. This theory is also expounded in [21, §6] (with different objectives in mind); thus we only sketch the main facts here.

Let E be a Banach space, $S(t)$ a strongly continuous semigroup in E, and $E^\odot \subseteq E^*$ the closure of the domain of $D(A^*)$ in E^* or, equivalently, the maximal subspace where the semigroup $S(t)^*$ is strongly continuous. The restriction of the semigroup $S(t)^*$ to $E^\odot$ is a strongly continuous semigroup $S^\odot(t)$ called the *Phillips adjoint* of $S(t)$ [30, Chap. 14] The infinitesimal generator of $S^\odot(t)$ is called $A^\odot$ and is the restriction of A^* with domain $D(A^\odot) = \{y \in D(A^*); A^*y \in E^\odot\}$.

The norm $\|y\|_0 = \{\sup\langle y^*, y\rangle; y^* \in E^\odot, \|y^*\| \le 1\}$ in E is equivalent to the original norm of E; precisely, $\|y\|_0 \le \|y\| \le M\|y\|_0$ where $M = \liminf_{\lambda\to\infty} \|\lambda R(\lambda; A)\| < \infty$ [30 p. 423]. It follows that the canonical pairing of E and $E^\odot$ produces a bicontinuous

linear imbedding of E into $(E^{\odot})^*$. In fact, the imbedding is into $(E^{\odot})^{\odot} = E^{\odot\odot}$ and we have $A \subseteq (A^{\odot})^{\odot} = A^{\odot\odot}$ [30, p. 430].

Among the motivations for the theory of Phillips adjoints is the study of uniformly elliptic partial differential operators

$$Ay(x) = \sum_{j=1}^{m}\sum_{k=1}^{m} \partial^j(a_{jk}(x)\partial^k y(x)) + \sum_{j=1}^{m} b_j(x)\partial^j y(x) + c(x)y(x) \tag{7.1}$$

in a bounded domain Ω of class $C^{(2)}$, associated with either the Dirichlet boundary condition $y(x) = 0$ or a variational boundary condition $\partial^\nu y(x) = \gamma(x)y(x)$ on the boundary Γ with γ continuously differentiable, where ∂^ν denotes the *conormal derivative* $\partial^\nu = \Sigma\Sigma a_{jk}\partial^j\eta_k$ (with $(\eta_1, \ldots, \eta_m)$ the outer normal vector on Γ). The a_{jk} and the b_j are continuously differentiable and c is continuous. The *formal adjoint* A' of A is $A'y = \sum\sum \partial^j(a_{jk}(x)\partial^k y) - \sum \partial^j(b_j(x)y) + c(x)y$ and the *adjoint boundary condition* β' is $\beta' = \beta$ if β is the Dirichlet boundary condition; for a variational boundary condition, β' is $\partial^\nu y(x) = (\gamma(x) + b(x))y(x)$ with $b(x) = \Sigma b_j(x)\eta_j$.

The nonreflexive spaces of interest (the first in diffusion processes, the second in heat propagation) are $L^1(\Omega)$ and the space $C(\overline{\Omega})$ of continuous functions in $\overline{\Omega}$ endowed with the supremum norm. Given a boundary condition β, the operator A admits an extension $A_1(\beta)$ in $E = L^1(\Omega)$ that generates a compact analytic semigroup $S_1(t; A, \beta)$. The domain $D(A_1(\beta))$ of this extension can be characterized as follows: $D(A_1(\beta))$ consists of all elements $y \in L^1(\Omega)$ such that there exists $z(= A_1(\beta)y)$ in $L^1(\Omega)$ with

$$\int_\Omega y(x)(A'(\beta')v)(x)dx = \int_\Omega z(x)v(x)dx$$

for every $v \in C^{(2)}(\overline{\Omega})_\beta$, where $C^{(2)}(\overline{\Omega})$ is the space of all twice continuously differentiable functions defined in $\overline{\Omega}$ and $C^{(2)}(\overline{\Omega})_\beta$ is the subspace of $C^{(2)}(\overline{\Omega})$ consisting of all functions y that satisfy the boundary condition β on Γ.

When β is a condition of variational type A admits an extension $A_C(\beta)$ to the space $E = C(\overline{\Omega})$ which generates a compact analytic semigroup $S_C(t; A, \beta)$. The domain $D(A_C(\beta))$ can be characterized as

$$D(A_C) = \left\{ y \in \bigcap_{p\geq 1} W^{2,p}(\Omega)_\beta;\, Ay \in C(\overline{\Omega}) \right\},$$

where $W^{2,p}(\Omega)_\beta$ is the subspace of $W^{2,p}(\Omega)$ consisting of all $y(\cdot)$ that satisfy the boundary condition β on Γ. The same considerations apply when β is the Dirichlet boundary condition, but the space E is $C_0(\overline{\Omega})$, consisting of all $y \in C(\overline{\Omega})$ that vanish at the boundary Γ.

The duality theory of these spaces, operators, and semigroups is as follows: $L_1(\Omega)^* = L^\infty(\Omega), L^1(\Omega)^{\odot} = C(\overline{\Omega})$ for a variational boundary condition, $L^1(\Omega)^{\odot} = C_0(\Omega)$ for the Dirichlet boundary condition, $S_1(t; A, \beta)^{\odot} = S_C(t; A', \beta')$. The dual $C(\overline{\Omega})^*$ can be identified with the space $\Sigma(\overline{\Omega})$ consisting of all finite Borel measures μ defined in $\overline{\Omega}$ acting on elements $y(\cdot) \in C(\overline{\Omega})$ in the form $\langle \mu, y\rangle = \int_\Omega y(x)\mu(dx)$ and endowed with the total variation norm $\|\mu\| = \int_\Omega |\mu(dx)|$. The dual $C_0(\overline{\Omega})^*$ can be identified with the subspace $\Sigma_0(\overline{\Omega})$ of $\Sigma(\overline{\Omega})$ consisting of all μ vanishing on Γ. For the variational boundary condition β we have $C(\overline{\Omega})^{\odot} = L^1(\Omega)$, and $C_0(\overline{\Omega})^{\odot} = L^1(\Omega)$ for the Dirichlet boundary condition; in both cases, $S_C(t; A, \beta)^{\odot} = S_1(t; A', \beta')$.

We consider a control system

$$y'(t) = Ay(t) + f(t, y(t), u(t)), \qquad y(0) = \zeta \tag{7.2}$$

in an arbitrary Banach space E satisfying

(i) $S(t)E \subseteq D(A)$ and $AS(t)$ is continuous in the uniform norm of operators in $t > 0$.

(ii) E and $E^{\odot}$ are separable and E is $\odot$-*reflexive* with respect to $S(\cdot)$, that is, $E^{\odot\odot} = E$.

Assumption (ii) implies $S^{\odot\odot}(t) = S(t), A^{\odot\odot} = A$. It follows from the duality theory that $L^1(\Omega)$ is $^{\odot}$-reflexive with respect to $A_1(\beta)$, and that $C(\overline{\Omega}), C_0(\overline{\Omega})$ (the latter for Dirichlet boundary condition) are $^{\odot}$-reflexive with respect to $A_C(\beta)$. Moreover, both spaces are separable, and (i) is satisfied by the semigroups $S_1(t; A, \beta)$ and $S_C(t; A', \beta')$; thus the theory is applicable to this example. The space of relaxed controls is $V_r(0, T; U)$ as defined in §2 and $f(t, y, u)$ satisfies Assumption (II$^{\odot}$), which is the same as (II), but where (b) is required only for $y^* \in E^{\odot}$. The relaxed control system is defined as follows: $\mathbf{f}(t, y)\mu$ is the unique element of $(E^{\odot})^* \supseteq E$ that satisfies

$$\langle y^*, \mathbf{f}(t, y, \mu)\rangle = \int_U \langle y^*, f(t, y, u)\rangle \mu(du) \tag{7.3}$$

for every $y^* \in E^{\odot}$. As a result of the definition, the function $t \to \langle y^*, \mathbf{f}(t, y(t))\mu(t)\rangle$ is measurable for every $y^* \in E^{\odot}$ (that is, $t \to \mathbf{f}(t, y(t))\mu(t)$ is $E^{\odot}$-weakly measurable). The relaxed control system is

$$y'(t) = Ay(t) + \mathbf{f}(t, y(t))\mu(t), \qquad y(0) = \zeta. \tag{7.4}$$

Solutions of (7.4) take values in $E^{\odot\odot} = E$, but $\mathbf{f}(t, y(t))\mu(t)$ takes values in $(E^{\odot})^* \supseteq E^{\odot\odot} = E$. The corresponding integral equation is

$$y(t) = S(t)\zeta + \int_0^t S^{\odot}(t - \sigma)^* \mathbf{f}(t, y(\sigma))\mu(\sigma)d\sigma \tag{7.5}$$

if $\zeta \in E$; we may take the initial condition ζ in $(E^{\odot})^*$, in which case $S(t)\zeta$ is replaced by $S^{\odot}(t)^*\zeta$.

We note that, under (i) and (ii) we have

$$S(t)^*E^* \subseteq E^{\odot}, \qquad S^{\odot}(t)^*(E^{\odot})^* \subseteq E. \tag{7.6}$$

In fact, since $S(t)E \subseteq D(A)$ and $AS(t)$ is bounded for $t > 0$ we obtain, taking adjoints and using commutativity of A and $S(t)$, that $S(t)^*E^* \subseteq D(A^*) \subseteq E^{\odot}$. The same argument, this time applied in $E^{\odot}$ to the semigroup $S^{\odot}(\cdot)$, proves that $S^{\odot}(t)^*(E^{\odot})^* \subseteq E^{\odot\odot} = E$.

LEMMA 7.1. *Let $u(\cdot)$ be a $E^{\odot}$- weakly measurable $(E^{\odot})^*$-valued bounded function defined in $0 \le t \le T$. Then the function*

$$\sigma \to S^{\odot}(t - \sigma)^* u(\sigma) \tag{7.7}$$

is strongly measurable in $0 \le \sigma \le t$. (b) The E-valued function

$$y(t) = (\Lambda u)(t) = \int_0^t S^{\odot}(t - \sigma)^* u(\sigma)d\sigma \tag{7.8}$$

is continuous in $0 \le t \le T$.

For a proof, see [21, §6]. The theory of (7.4) is essentially the same as that of (2.15); note that, in the integral equation (7.5) that defines the solutions of (7.4), the integral is a continuous E-valued function by virtue of Corollary 7.2.

We limit ourselves to an obvious analog of Theorem 5.2. The assumption on $f(t,y,u)$ is (III$^{\odot}$), which is (III) in §5 with the difference that the element y^* now belongs to $E^{\odot}$ instead of E^*. The function f_0 satisfies (III$_0$).

THEOREM 7.2. *Let E be $^{\odot}$-reflexive with respect to a strongly continuous semigroup $S(t)$ satisfying* (i), *and assume that E and $E^{\odot}$ are separable. Assume that* (III) *and* (III$_0$) *hold and that there exists a minimizing sequence $\{\mu_n(\cdot)\}, \mu_n(\cdot) \in V_r(0,t_n;U)$ of relaxed controls with $\{t^n\}$ bounded and $\{y(\cdot,\mu_n)\}$ uniformly bounded in $0 \leq t \leq t_n$. Then there exists a solution $\overline{\mu}(\cdot)$ of the relaxed control problem.*

As Theorem 5.2, Theorem 7.2 depends on compactness of the integral operator on the right side of the integral equation (7.5) defining solutions of the equation (7.4). In this case, the operator is Λ in (7.8), and the compactness result is Lemma 7.3 below. In it, we denote by $L^1_w(0,T;(E^{\odot})^*)$ the space of all $E^{\odot}$-measurable $(E^{\odot})^*$-valued functions with integrable norm endowed with the L^1 norm (since $E^{\odot}$ is separable, the norm is measurable; see [14]).

LEMMA 7.3. *Assume $S(t)$ is compact for every $t > 0$. Then the operator $\Lambda : L^1_w(0,T;(E^{\odot})^*) \to C(0,T;E)$ satisfies the conclusions of Lemma* 5.1.

The proof is essentially the same as that of Lemma 5.1.

8. The maximum principle. Control systems of the form (2.15) or (7.4) essentially fit the model in [20] (where controls are only required to be weakly measurable), but a few modifications of the theory are necessary. To apply the nonlinear programming theory in [20] we equip the relaxed control space $V_r(0,T;U)$ with the metric

$$d(\mu(\cdot),\nu(\cdot)) = \lambda\{t \in [0,T]; \mu(t) \neq \nu(t)\}, \tag{8.1}$$

where λ is the outer measure generated by the Lebesgue measure in the real line and define as equivalent elements of $V_r(0,T;U)$ that lie at distance zero. This, however, requires explanation since $V_r(0,T;U)$ is already equipped with a different equivalence relation inherited from the space $L^{\infty}_w(0,T;\Sigma_{rba}(U))$. The precise definitions follow.

Let $F(0,T;X)$ be the space of all functions $f(\cdot), g(\cdot)$ defined in the interval $0 \leq t \leq T$ with values in an arbitrary set X. Denote by λ an arbitrary outer measure in $0 \leq t \leq T$. Two functions $f(\cdot), g(\cdot) \in F(0,T;X)$ are declared equivalent if $f(t) = g(t)$ except in a set e with $\lambda(e) = 0$; we denote by $F(0,T;X)_d$ the space of the equivalence classes corresponding to this equivalence relation. Since we have $\{t; f(t) \neq h(t)\} \subseteq \{t; f(t) \neq g(t)\} \cup \{t; g(t) \neq h(t)\}$ it follows that (8.1) depends only on the equivalence classes of $f(\cdot)$ and $g(\cdot)$ and defines a distance. The space $F(0,T;X)_d$ is a complete metric space equipped with d; Ekeland's original completeness proof [13] uses only the countable subadditivity property of the Lebesgue measure and thus generalizes to the present setting. In what follows, λ will be the outer measure generated by Lebesgue measure.

Given a Banach space E, $L^{\infty}_w(0,T;E^*)_0$ is the space of all E-weakly measurable E^*-valued functions $g(\cdot)$ with $|\langle y, g(t)\rangle| \leq C\|y\|$ almost everywhere in $0 \leq t \leq T$, *without* any equivalence relation. $L^{\infty}_w(0,T;\Sigma_{rba}(U))_d$ is the quotient of $L^{\infty}_w(0,T;\Sigma_{rba}(U))_0$ by the equivalence relation associated with the distance (8.1); two elements $\mu(\cdot), \nu(\cdot)$ of $L^{\infty}_w(0,T;\Sigma_{rba}(U))_0$ are equivalent if and only if $\{t; \mu(t) \neq \nu(t)\}$ has outer measure zero. This equivalence relation is more demanding than that of the space $L^{\infty}_w(0,T;\Sigma_{rba}(U))$, which is as follows: $\mu(\cdot)$ and $\nu(\cdot)$ are equivalent if and only if $\langle y, \mu(t)\rangle = \langle y, \nu(t)\rangle$ outside of a null set (depending on y) for every $y \in BC(U)$. The two equivalent relations are not the same. The space $V(0,T;U)_0$ is the subspace of $L^{\infty}_w(0,T;\Sigma_{rba}(U))_0$ defined by (2.7)–(2.9), and, for the present purposes, the space of (relaxed) controls is $V_r(0,T;U)_d$, quotient of $V(0,T;U)_0$ by the equivalence relation associated with the distance (8.1). Obviously,

(possibly different) controls in $V_r(0,T;U)_d$ that are equivalent in the equivalence relation of $L_w^\infty(0,T;\Sigma_{rba}(U))$ will produce the same trajectory.

LEMMA 8.1. *$V_r(0,T;U)_d$ is complete under d.*

Proof. $V_r(0,T;U)_d$ is a subspace of $F(0,T;\Sigma_{rba}(U))_d$, thus we only have to show that if $\{\mu_n(\cdot)\}$ is a sequence in $V_r(0,T;U)_d$ and $f(\cdot) \in F(0,T;\Sigma_{rba}(U))_d$ is such that $d(\mu_n,f) = \lambda\{t;\mu_n(t) \neq f(t)\} \to 0$, then $f(\cdot) \in V_r(0,T;U)_d$. This is plain, since $d(\mu_n,f) \to 0$ implies that $f(\cdot)$ is $BC(U)$-weakly measurable and the three conditions (2.6), (2.7), (2.8) defining an element of $V_r(0,T;U)$ are preserved through d-convergence.

Remark 8.2. If $f(\cdot), g(\cdot) \in L_w^\infty(0,T;E^*)$ with E separable, the set $\{t;f(t) \neq g(t)\}$, being the union of all sets $\{t;\langle e_n,f(t)\rangle \neq \langle e_n,g(t)\rangle\}(\{e_n\}$ a sequence dense in $E)$ is measurable. However, this is essentially irrelevant here since $E = BC(U)$ is not separable unless U is compact. Hence we need to use an outer measure in (8.1).

Pontryagin's maximum principle for the relaxed control system (2.15) will be obtained by application of the theory of the nonlinear programming problem

$$\text{minimize } f_0(\mu) \tag{8.2}$$

$$\text{subject to } f(\mu) \in Y, \tag{8.3}$$

where $f : V \to E$ (V a complete metric space, E a Banach space) and $F_0 : V \to \mathbb{R}$. For fixed terminal time $\bar{t}$, we choose $V = V_r(0,\bar{t};U)_d$ and

$$f(\mu) = y(\bar{t},\mu), \qquad f_0(\mu) = y_0(\bar{t},\mu), \tag{8.4}$$

where $y(t,\mu)$ is the trajectory of (2.14) corresponding to a control $\mu \in V_r(0,T;U)_d$ and $y_0(t,u)$ is the cost functional. The optimal relaxed control $\overline{\mu}$ is assumed to exist or is constructed by means of one of the existence theorems in §5 and 6. The first difficulty is that $y(t,\mu)$ (thus $f(\mu)$, a fortiori $f_0(\mu)$) may not be defined in $0 \le t \le \bar{t}$ if $\mu \neq \overline{\mu}$. Without aiming for maximum generality, we place conditions on E, U, and f that will legitimize all computations that follow. We assume that E is reflexive and separable and that U is normal; $f(t,y,u)$ satisfies (VII) below.

(VII) (a) $f(t,y,u)$ is continuous in $[0,T] \times E \times U$ uniformly with respect to u, and for every $c > 0$ there exists $\alpha(\cdot) = \alpha(c,\cdot) \in L^1(0,T)$ such that

$$\|f(t,y,u)\|_E \le \alpha(t) \qquad (0 \le t \le T, \|y\| \le c, u \in U).$$

(b) $f(t,y,u)$ has a Fréchet derivative $\partial_y f(t,y,u)$ with respect to y in $[0,T] \times E \times U$ uniformly with respect to u, i.e.,

$$f(t,y+h,u) = f(t,y,u) + \partial_y f(t,y,u)h + \rho(t,y,h,u), \tag{8.5}$$

where for each t,y we have $\|\rho(t,y,h,u)\|/\|h\| \to 0$ as $h \to 0$ uniformly with respect to $u \in U$. (c) $\partial_y f(t,y,u)$ is strongly continuous in $[0,T] \times E \times U$ uniformly with respect to u and for every $c > 0$ there exists $\beta(\cdot) = \beta(c,\cdot)$ such that

$$\|\partial_y f(t,y,u)\|_{L(E,E)} \le \beta(t) \qquad (0 \le t \le T, \|y\| \le B, u \in U). \tag{8.6}$$

These properties of $f(t,y,u)$ imply the following properties of the function $\mathbf{f}(t,y)\mu$ defined in §2: (a') $\mathbf{f}(t,y)\mu$ is continuous in $[0,T] \times E \times \Sigma_{rba}(U)$ (in fact, Lipschitz continuous with respect to μ by linearity) and

$$\|\mathbf{f}(t,y)\mu\| \le \alpha(t)\|\mu\|_{\Sigma_{rba}(U)} \qquad (0 \le t \le T, \|y\| \le B, \mu \in \Sigma_{rba}(U)). \tag{8.7}$$

Moreover, the function $t \to \mathbf{f}(t, y(t))\mu(t)$ is strongly measurable for every $y(\cdot) \in C(0, T; E)$ and $\mu(\cdot) \in L^\infty_w(0, T; \Sigma_{rba}(U))$. ($b'$) $\mathbf{f}(t, y)\mu$ has a Fréchet derivative $\partial_y \mathbf{f}(t, y)\mu$ with respect to y given by

$$\langle y^*, (\partial_y \mathbf{f}(t, y)\mu)h\rangle = \int_U \langle y^*, \partial_y f(t, y, u)h\rangle \mu(du) \qquad (y^* \in E^*). \tag{8.8}$$

Moreover, $\partial_y \mathbf{f}(t, y)\mu$ is strongly continuous in $[0, T] \times E \times \Sigma_{rba}(U)$ and satisfies

$$\|\partial_y \mathbf{f}(t, y)\mu\|_{L(E,E)} \le \beta(t)\|\mu\|_{\Sigma_{rba}(U)} \qquad (0 \le t \le T, \|y\| \le c, \mu \in \Sigma_{rba}(U)). \tag{8.9}$$

Existence of the Fréchet derivative and the mean value theorem imply the local Lipschitz condition

$$\begin{gathered}\|\mathbf{f}(t, y')\mu - \mathbf{f}(t, y)\mu\| \le \beta(t)\|y' - y\|\|\mu\|_{\Sigma_{rba}(U)} \\ (0 \le t \le T, \|y\| \le c, \mu \in \Sigma_{rba}(U))\end{gathered} \tag{8.10}$$

and the following result.

LEMMA 8.3. *Let $\overline{\mu}(\cdot) \in L^\infty_w(0, \bar{t}; \Sigma_{rba}(U))_0$ be such that the trajectory $y(t, \overline{\mu})$ exists in $0 \le t \le \bar{t}$. Then there exists $\rho > 0$ such that if $\mu(\cdot) \in L^\infty_w(0, \bar{t}; \Sigma_{rba}(U))_0, d(\mu, \overline{\mu}) \le \rho$ then the trajectory $y(t, \mu)$ exists in the same interval. If $d(\nu, \overline{\mu}) \le \rho$ as well, we have*

$$\|y(t, \mu) - y(t, \nu)\| \le C \int_{[\{t \in [0,\bar{t}]\mu(t) \ne \nu(t)\}]} \alpha(\sigma)d\sigma. \tag{8.11}$$

The notation in (8.11) is: given a set e, $[e]$ is a *measurable envelope* of e (that is, a measurable set with $e \subseteq [e], \lambda(e) = \text{meas}[e]$). The proof of Lemma 8.3 is similar to that of Lemma 5.1 in [20] (with the only minor difference that the set $\{t; \mu(t) \ne \nu(t)\}$ is measurable in [20]) thus we only sketch it. Local existence of $y(t, \mu)$ is guaranteed by (8.7) and (8.10). Let $[0, t_\mu]$ be the maximal interval where $y(t, \mu)$ exists and satisfies $\|y(t, \mu) - y(t, \overline{\mu}\| \le 1$. We have

$$\begin{aligned} y(t, \mu) - y(t, \overline{\mu}) &\\ &= \int_0^t S(t - \sigma)\{\mathbf{f}(\sigma, y(\sigma, \mu))\mu(\sigma) - \mathbf{f}(\sigma, y(\sigma, \mu))\overline{\mu}(\sigma)\}d\sigma \\ &+ \int_0^t S(t - \sigma)\{\mathbf{f}(\sigma, y(\sigma, \mu))\overline{\mu}(\sigma) - \mathbf{f}(\sigma, y(\sigma, \overline{\mu}))\overline{\mu}(\sigma)\}d\sigma. \end{aligned}$$

Estimating,

$$\|y(t, \mu) - y(t, \overline{\mu})\| \le C \int_{[\{t \in [0,\bar{t}]\mu(t) \ne \overline{\mu}(t)\}]} \alpha(\sigma)d\sigma + C \int_0^t \beta(\sigma)\|y(\sigma, \mu) - y(\sigma, \overline{\mu})\|d\sigma.$$

Using Gronwall's inequality, (8.11) for μ and $\overline{\mu}$ (with another constant) results in $[0, t_\mu]$. Taking $d(\mu, \overline{\mu})$ sufficiently small, $\|y(t, \mu) - y(t, \overline{\mu})\| < 1$ in $[0, t_\mu]$, which contradicts the maximality of this interval unless $t_\mu = \bar{t}$. A similar argument deals with the pair μ, ν.

The companion of assumption (VI) for f is as follows.

(VI$_0$) (a) $f_0(t, y, u)$ is continuous in $[0, T] \times E \times U$ uniformly with respect to u, and for every $c > 0$ there exists $\alpha_0(\cdot) = \alpha_0(c, \cdot) \in L^1(0, T)$ such that

$$\|f(t, y, u)\|_E \le \alpha_0(t) \qquad (0 \le t \le T, \|y\| \le c, u \in U).$$

(b) $f_0(t,y,u)$ has a Fréchet derivative $\partial_y f_0(t,y,u)$ with respect to y in $[0,T]\times E\times U$ uniformly with respect to u. (c) $\partial_y f_0(t,y,u)$ is continuous in $[0,T]\times E\times U$ uniformly with respect to u and for every $c>0$ there exists $\beta_0(\cdot)=\beta_0(c,\cdot)$ such that

$$\|\partial_y f_0(t,y,u)\|_{E^*}\le \beta_0(t) \qquad (0\le t\le T, \|y\|\le c, u\in U). \tag{8.12}$$

Assumption (VI_0) implies the following properties of $\mathbf{f}_0$: (a′) $\mathbf{f}_0(t,y)\mu$ is continuous in $[0,T]\times E\times \Sigma_{rba}(U)$ (Lipschitz continuous with respect to μ) and

$$|\mathbf{f}_0(t,y)\mu|\le \alpha_0(t)\|\mu\|_{\Sigma_{rba}(U)} \qquad (0\le t\le T, \|y\|\le C, \mu\in\Sigma_{rba}(U)); \tag{8.13}$$

moreover, the function $t\to \mathbf{f}_0(t,y(t))\mu(t)$ is measurable for every $y(\cdot)\in C(0,T;E)$ and $\mu\in L^\infty_w(0,T;\Sigma_{rba}(U))_0$. (b′) $\mathbf{f}_0(t,y)\mu$ has a Fréchet derivative $\partial_y\mathbf{f}_0(t,y)\mu$ given by

$$(\partial_y\mathbf{f}_0(t,y)\mu)h=\int_U \partial_y f_0(t,y,u)h\mu(du). \tag{8.14}$$

Moreover, $\partial_y\mathbf{f}_0(t,y)\mu$ is continuous in $[0,T]\times E\times\Sigma_{rba}(U)$ and

$$\|\partial_y\mathbf{f}_0(t,y)\mu\|_{E^*}\le\beta_0(t)\|\mu\|_{\Sigma_{rba}(U)} \qquad (0\le t\le T,\|y\|\le C,\mu\in\Sigma_{rba}(U)). \tag{8.15}$$

As a very particular consequence of the properties of $\mathbf{f}_0$, we obtain using Lemma 8.3 that the function $\mu\to y_0(\bar t,\mu)$ is continuous in $B(\overline{\mu},\rho)$, the ball of center $\overline{\mu}$ and radius ρ in $V_r(0,\bar t;U)_d$.

The abstract nonlinear programming theory in [20] will be applied to the functions (8.4) but in the closed ball $V=B(\overline{\mu},\rho)\subseteq V_r(0,T;U)_d$, where $\overline{\mu}$ is the optimal control and ρ is the constant in Lemma 8.3. Inequality (8.11) and the above comments on f_0 guarantee that f, f_0 are continuous, which is much more than necessary. The theory in [20] provides a Kuhn–Tucker multiplier $(z_0,z)\in\mathbb{R}\times E^*$ with $z_0\ge 0$ and such that

$$z_0\xi_0(\bar t,s,\nu,\overline{\mu})+\langle z,\xi(\bar t,s,\nu,\overline{\mu})\rangle\ge 0 \tag{8.16}$$

for all *spike variations* (ξ_0,ξ) defined as follows:

$$\xi(\bar t,s,\nu,\overline{\mu})=\lim_{h\to 0+}\frac{y(\bar t,\overline{\mu}_{h,s,\nu})-y(\bar t,\overline{\mu})}{h},$$

$$\xi_0(\bar t,s,\nu,\overline{\mu})=\lim_{h\to 0+}\frac{y_0(\bar t,\overline{\mu}_{h,s,\nu})-y_0(\bar t,\overline{\mu})}{h},$$

where $\mu_{h.s.\nu}$ denotes the *spike perturbation* of the relaxed control μ, depending on the parameters $h,s,\nu(h\ge 0, 0\le s\le\bar t,\nu\in\Sigma_{rba}(U))$ and defined by $\mu_{h,s,\nu}(t)=\nu$ $(s-h<t\le\bar t), \mu_{h,s,\nu}(t)=\mu(t)$ elsewhere. Calculation of the spike variations and subsequent computations are performed in essentially the same way as with ordinary controls [20], thus we omit the details and limit ourselves to stating the final result.

THEOREM 8.4. (Pontryagin's maximum principle). *Let $\overline{\mu}(\cdot)$ be a solution of the relaxed optimal control problem in $0\le t\le\bar t$. Then there exists $(z_0,z)\in\mathbb{R}\times E^*$ such that $z_0\le 0$ and*

$$\begin{aligned} &z_0\mathbf{f}_0(t,y(t,\overline{\mu}))\overline{\mu}(t)+\langle z(t,\overline{\mu}),\mathbf{f}(t,y(t,\overline{\mu}))\overline{\mu}(t)\rangle\\ &\quad=\max_{\nu\in\Sigma_{rba}(U)}\{z_0\mathbf{f}_0(t,y(t,\overline{\mu}))\nu+\langle z(t,\mu),\mathbf{f}(t,y(t,\overline{\mu}))\nu\rangle\}\end{aligned} \tag{8.17}$$

almost everywhere in $0 \leq t \leq \bar{t}$, where $z(t)$ is the solution of the final value problem

$$\begin{aligned} z'(t) &= -\{A^* + \partial_y \mathbf{f}(t, y(t,\overline{\mu}))\overline{\mu}(t))^*\} \\ &\quad -z_0 \partial_y \mathbf{f}_0(t, y(t,\overline{\mu}))\overline{\mu}(t), \qquad z(\bar{t}) = z \end{aligned} \tag{8.18}$$

in $0 \leq t \leq \bar{t}$.

As typical in infinite-dimensional problems, without further assumptions the multiplier (z_0, z) may be zero. We use the nontriviality condition in [20, Cor. 2.14], as follows.

LEMMA 8.5. *Assume that, for every sequence* $\{y^n\} \subseteq Y$ *such that* $y^n \to \overline{y} = y(\bar{t}, \overline{\mu})$ *and every sequence* $\{\mu_n\} \in V_r(0, \bar{t}; U)_d$ *with* $\mu_n \to \overline{\mu}$ *there exists a compact set* Q *such that*

$$\bigcap_{n=1}^{\infty} \{R_n(\bar{t}) - K_Y(y^n) + Q\}$$

contains an interior point, where $K_Y(y^n)$ *is the tangent cone to* Y *at* y^n *and* $R_n(\bar{t})$ *is the reachable space of the system*

$$\begin{aligned} z(t) &= \{A + \partial_y \mathbf{f}(t, y(t, \mu_n))\mu_n(t)\}z(t) \\ &\quad + \mathbf{f}_0(t, y(t, \mu_n))\nu(t) - \mathbf{f}_0(t, y(t, \mu_n))\mu_n(t), \qquad z(0) = 0, \end{aligned} \tag{8.19}$$

$\nu(\cdot) \in V_r(0, \bar{t}; U)_d$.

The time optimal problem needs a special treatment but the final result may be included in Theorem 8.4 and Lemma 8.5; the result guarantees a multiplier $(z_0, z) = (0, z)$ with $z \neq 0$.

The conditions of Lemma 8.5 are always satisfied if the target set Y is "large" (for instance, a ball). For small target sets (say, $Y = \{y\}$) they are satisfied by some hyperbolic systems: see [17]. They are also satisfied automatically when E is finite dimensional; we may take $Q =$ unit ball of E. For comments on this condition for abstract parabolic equations see [20, §6]. See also [20] for additional information on the vector z.

The maximum principle for relaxed controls can also be established for the control systems in nonreflexive spaces treated in §7. Under the assumption that E is $^{\odot}$- reflexive with respect to the semigroup $S(t)$ the control system (7.4), with $\mathbf{f}$ taking values in $(E^{\odot})^*$ and $\mu(\cdot) \in L^{\infty}_w(0, T; \Sigma_{rba}(U))$ and $L^1(0, T; BC(U))$-weakly measurable is precisely of the form considered in [20] in a somewhat different context, and the results there on the maximum principle apply without changes.

The maximum principle (8.17) can be easily translated in the language of differential inclusions using the equivalence results in §3. For a direct treatment of the maximum principle for finite-dimensional differential inclusions without using relaxed controls see [5] and [6].

Acknowledgment. I am grateful to Professor W. Rueβ for much useful information on the space $L^{\infty}_w(0, T; E^*)$ and on Theorems 2.1 and 2.2.

REGULAR UNITARY DILATION OF COMMUTING CONTRACTIONS AND MARKOVIAN REPRESENTATION OF GAUSSIAN STATIONARY PROCESSES ON Z^{2*}

PHILIPPE LOUBATON†

Abstract. In this paper, we show that the concept of regular unitary dilation of a pair of commuting contractions is intimately related to Markovian-like subspaces with respect to a pair of commuting unitary operators. Starting from this observation, a two-dimensional Markovian-like representation problem previously introduced by Attasi is studied geometrically. By using the geometric properties of the state spaces and some elementary properties of two-variable Hardy spaces, the spectral domain description of regular and coregular minimal representations are given.

Key words. regular unitary dilation of commuting contractions, perpendicular intersection, Attasi model, Markovian representation, wide-sense stationary random processes on Z^2, Hardy spaces, inner functions

AMS subject classifications. 60G25, 47A20

1. Introduction.

It is well-known that there exists a deep connection between the notion of Markovian space with respect to a unitary operator and the minimal unitary dilation of a contractive operator. Recently [4], the links between these objects were exploited in order to get new results concerning the Markovian representation problem of vector-valued wide-sense stationary random processes. In this paper we establish that the concept of regular minimal unitary dilation of a pair of commuting contractions is itself intimately related to Markovian-like subspaces with respect to a pair of commuting unitary operators; applications to a Markovian-like representation problem of two-parameter wide-sense stationary random processes are given.

Let us recall that if K is a Hilbert space and if U is a unitary operator, then a (closed) subspace X of K is said to be Markovian with respect to U if the spaces $X_- = \bigvee_{n\leq 0} U^n X$ and $X_+ = \bigvee_{n\geq 0} U^n X$ are conditionally orthogonal given X (we say that two subspaces A and B are conditionally orthogonal given C, written $A \perp B|C$, if $A \bigvee C \ominus C \perp B \bigvee C \ominus C$). As it is well known, [4, Lemma 1-1], this condition is equivalent to saying that $(U_{|X_\infty}, X_\infty)$ (where $X_\infty = \bigvee_{n\in Z} U^n X$) is the regular unitary dilation of $(E^X U_{|X}, X)$, i.e., $(E^X U_{|X})^n = (E^X U^n_{|X})$ for each $n \geq 0$. The operator $T = E^X U_{|X}$ is called the Markovian transition operator associated to X. The space W_f (respectively, W_b) given by $W_f = UX_- \ominus X_-$ (respectively, $W_b = X_+ \ominus UX_+$) is a wandering subspace for U called the forward (respectively, backward) innovation space of X; moreover, $W_f = \overline{(U-T)X}$ (respectively, $W_b = \overline{(I - UT^*)X)}$, and $X_\infty = U^*(W_b)_- \oplus X \oplus (W_f)_+$. Conversely, the fact that every contraction T defined on the Hilbert space X admits a minimal unitary dilation U [25] implies that X can be considered as a Markovian subspace with respect to U and that T coincides with its Markovian transition operator.

Let us now consider a pair of commuting unitary operators (U_1, U_2) defined on the Hilbert space K. A subspace X of K is said to be a forward-forward Markovian space (FFMS) with respect to (U_1, U_2) if the following conditional orthogonality relations hold:

$$X_{-,\infty} \perp X_{+,0} | X, \tag{1}$$

$$X_{\infty,-} \perp X_{0,+} | X, \tag{2}$$

where $X_{-,\infty}$ (respectively, $X_{\infty,-}$) and $X_{+,0}$ (respectively, $X_{0,+}$) are defined by $X_{-,\infty} = \bigvee_{m\leq 0}\bigvee_{n\in Z} U_1^m U_2^n X$ (respectively, $X_{\infty,-} = \bigvee_{m\in Z}\bigvee_{n\leq 0} U_1^m U_2^n X$) and by $X_{+,0} = \bigvee_{m\geq 0} U_1^m X$ (respectively, $X_{0,+} = \bigvee_{n\geq 0} U_2^n X$). X is said to be a backward-forward (BF), forward-backward (FB), backward-backward (BB) Markovian space with respect to (U_1, U_2) if X is a FFMS with respect to $(U_1^*, U_2), (U_1, U_2^*), (U_1^*, U_2^*)$ respectively; finally, X is said to be a Markovian space (MS) with respect to (U_1, U_2) if it is both a FFMS and a BBMS with respect to (U_1, U_2).

The above definitions do not correspond to those that are usually used in the literature concerning the Markov random fields (MRF). In fact, the qualificative Markovian used in (1) and (2) is rather excessive, in the sense that (1) and (2) are only connected to a restrictive class of Markov random fields. The relations (1) and (2) occur in the study of the so-called Attasi model [1] introduced in the frame of the realization theory of two-dimensional linear systems. A multivariate two-parameter wide-sense stationary process $(X_{m,n})_{(m,n)\in Z^2}$ is said to be a (stochastic) Attasi model if it is given by the following (forward-forward) state-space equation:

$$X_{m+1,n+1} = F_1 X_{m,n+1} + F_2 X_{m+1,n} - F_1 F_2 X_{m,n} + L\nu_{m,n}, \tag{3}$$

where $(\nu_{m,n})_{(m,n)\in Z^2}$ is a white noise sequence (i.e., $E(\nu_{m,n}\nu^*_{m',n'}) = I\delta_{m-m',n-n'}$, where E denotes the mathematical expectation in this context), and where F_1 and F_2 are two commuting stable matrices. Such a process is characterized by the fact [11] that

$$X_{m+1,n}/sp(X_{m-k,n-l}|k \geq 0, l \in Z) = X_{m+1,n}/X_{m,n}, \tag{4}$$

$$X_{m,n+1}/sp(X_{m-k,n-l}|k \in Z, l \geq 0) = X_{m,n+1}/X_{m,n} \tag{5}$$

(where sp(.) stands for space generated by), which is clearly equivalent to (1) and (2) in the case where X is the space generated by the components of $X_{0,0}$ and where U_1 and U_2 coincide with the horizontal and vertical shift operators associated to the stationary random process $(X_{m,n})_{(m,n)\in Z^2}$. The Attasi models also satisfy

$$\begin{aligned} &X_{m+1,n+1}/sp(X_{m-k,n-l}|k \geq 0 \text{ or } l \geq 0) \\ &\quad = X_{m+1,n+1}/sp(X_{m,n+1}, X_{m+1,n}, X_{m,n}). \end{aligned} \tag{6}$$

This property characterizes the quarter-plane Markov random fields introduced by Pickard [18] in the scalar-valued case, so that the Attasi models belong to the class of the quarter-plane MRF. But, the Pickard's random fields are considerably more general. In particular, any process $(X_{m,n})_{(m,n)\in Z^2}$ given by a state-space equation

$$X_{m+1,n+1} = A_1 X_{m,n+1} + A_2 X_{m+1,n} + A_3 X_{m,n} + B\nu_{m,n}, \tag{7}$$

where $(\nu_{m,n})_{(m,n)\in Z^2}$ is a white noise, and where (A_1, A_2, A_3) are matrices for which $\det(I - z_1^{-1}A_1 - z_2^{-1}A_2 - z_1^{-1}z_2^{-1}A_3) \neq 0$ for $|z_1| \geq 1$ and $|z_2| \geq 1$ is a quarter-plane MRF. Therefore, in view of possible applications to two-dimensional stochastic realization, it would be more interesting to study these kinds of models. However, by contrast with the case of Attasi models, the deterministic realization problem of two-dimensional linear systems by means of the deterministic counterpart of the quarter-plane MRF (i.e., the so-called Fornasini–Marchesini model [5]) does not give rise to a satisfying theory. In particular, the state-space and the corresponding matrices $(A_i)_{i=1,3}, B$ cannot be clearly extracted from the data of the realization problem. Hence, we believe that the stochastic realization problem in the class of quarter-plane MRF would give rise to considerably less

satisfying results than the realization problem by the Attasi models. In any case, as in the deterministic case, there may exists a strong connexion between the two realization problems; therefore, it is certainly useful to get a better understanding of the properties of the Attasi models in order to study the realization problem by means of the quarter-plane MRF. Finally, we mention that although quite restrictive, the Attasi models have shown to be useful in certain important applications such as two-dimensional harmonic retrieval, for example, [13].

In §2 of this paper we show that for every FFMS X with respect to a pair of commuting unitary operators (U_1, U_2) defined on the Hilbert space K, the contractions T_1 and T_2 given by $T_1 = E^X U_{1|X}$ and $T_2 = E^X U_{2|X}$ (called the horizontal and vertical Markovian transition operators of X) commute and that (U_1, U_2, K) is a regular unitary dilation of (T_1, T_2, X) [7], [25], i.e.,

$$T_1^m T_2^n = E^X U_1^m U_{2|X}^n, \tag{8}$$

$$T_2^{*n} T_1^m = E^X U_1^m U_{2|X}^{*n} \tag{9}$$

for each $(m, n) \in N^2$ (T_2^* denotes the adjoint of T_2). Moreover, X is a MS with respect to (U_1, U_2) if and only if T_1 and T_2 doubly commute (i.e., $T_1 T_2^* = T_2^* T_1$). Conversely, let (T_1, T_2) be two commuting contractions defined on X; then, it is well known [7], [25] that (T_1, T_2, X) admits a unique minimal regular unitary dilation (U_1, U_2, K) (minimal in the sense that $K = \bigvee_{(m,n)\in Z^2} U_1^m U_2^n X$) if and only if the operator $I - T_1^* T_1 - T_2^* T_2 + T_1^* T_2^* T_2 T_1$ is positive. In this case, a remarkable fact is that X is a FFMS with respect to (U_1, U_2) (cf. Theorem 2.1); if, moreover, T_1 and T_2 doubly commute, then K is an MS with respect to (U_1, U_2). This result was given in [15], but with an incorrect proof. We take advantage of this property in order to study the structure of the regular minimal unitary dilation of a pair (T_1, T_2) of commuting contractions defined on a Hilbert space X. We demonstrate in a very easy way some known results due to Halperin [7]; we present some unknown properties which are of special interest for the study of the Markovian-like representation problem considered in §3 and which make more comprehensible some of the results of Slocinski [23] devoted to the case of a pair of doubly commuting contractions.

The last section of this paper is devoted to the Markovian-like representation problem of two-parameter wide-sense stationary random processes studied by Attasi [1]. By contrast with [1], our formulation is purely geometrical; it can be seen as a generalization of the attractive approach introduced by Lindquist–Picci and Ruckebusch (see [14] and [19], respectively, for a survey of the works of these authors). Let K be a Hilbert space, and let (U_1, U_2) be a pair of commuting unitary operators defined on K. Then, if Y is a subspace of K, the problem we treat consists in the characterization of the FFMS (respectively, the MS) with respect to (U_1, U_2) containing Y; such spaces will be called forward-forward Markovian representations (FFMR in short) (respectively, Markovian representations (MR)) of Y. Although it is possible to describe geometrically the set of all (FF)MR of Y (Theorems 3.1, 3.2), the representation problem considered here leads to considerably less powerful results than those obtained by Lindquist–Picci and Ruckebusch. This is essentially due to the fact that the existence of nontrivial (FF)MR is not guaranteed in the general case (see Propositions 3.2 and 3.3); in particular, there do not exist any "canonical" (FF)MR similar to the filter and the cofilter of the one-parameter theory (i.e., the spaces $\overline{E}^{Y_-}(Y_+)$ and $\overline{E}^{Y_+}(Y_-)$). Therefore, we study a very restrictive situation; namely, we consider the case where Y is a one-dimensional subspace for which the spectral measure of the two-parameter stationary sequence $y_{m,n} = U_1^m U_2^n y$ (where y is an element of Y) has properties

that guarantee the existence of nontrivial MR. Some results concerning the structure of the minimal representations (in the sense that they do not contain other representation as proper subspace) are obtained by using the "spectral" domain description of the regular and co-regular FFMR and MR; their derivation uses extensively some of the ideas of Lindquist and Picci. Finally, let us mention that their generalization to the case where $\dim Y$ is greater than 1 seems not to be trivial.

At this point, it is appropriate to introduce some notations and definitions. If K is a Hilbert space, we say briefly that H is a subspace of K if H is a closed vector subspace of K; in this case, E^H denotes the orthogonal projection operator onto H, and if G is a subspace of K, $\overline{E}^H(G)$ represents the closure of $E^H(G)$; if $z \in K$, the vector $E^H(z)$ will also be denoted z/H. If U is a unitary operator defined on K, then a subspace Δ is said to be wandering for U if $U^k\Delta \perp \Delta$ for $k \neq 0$. The notion of wandering subspace for a pair of commuting unitary operators is defined similarly. For a fixed pair (U_1, U_2) of commuting unitary operators defined on K, we use the following system of notation (no ambiguity will occur in the paper). Let X be a subspace of K; then, we denote by $X_{0,\infty}, X_{0,+}, X_{0,-}$ the spaces $\bigvee_{n\in Z} U_2^n X, \bigvee_{n\geq 0} U_2^n X, \bigvee_{n\leq 0} U_2^n X$, respectively, and by $X_{\infty,\infty}, X_{\infty,+}, X_{\infty,-}$ the spaces $\bigvee_{m\in Z}\bigvee_{n\in Z} U_1^m U_2^n X, \bigvee_{m\in Z}\bigvee_{n\geq 0} U_1^m U_2^n X, \bigvee_{m\in Z}\bigvee_{n\leq 0} U_1^m U_2^n X$. The spaces $X_{\infty,0}, X_{+,0}, X_{-,0}, X_{+,\infty}, X_{-,\infty}$ are defined similarly by exchanging the role of U_1 and U_2. Moreover, we put $X_{+,+} = \bigvee_{m\geq 0}\bigvee_{n\geq 0} U_1^m U_2^n X$; the definition of the spaces $X_{+,-}, X_{-,+}$ and $X_{-,-}$ is similar.

We finish by giving an important result due to Kallianpur and Mandrekar ([10]; see also [22]), which concerns the existence of a Wold-type decomposition for a pair of commuting isometries. For this purpose, let us recall that two subspaces H_1 and H_2 are said to intersect perpendicularly if $\overline{E}^{H_1}(H_2) = H_1 \cap H_2$, or equivalently if $E^{H_1}E^{H_2} = E^{H_2}E^{H_1}$.

PROPOSITION 1.1. *Let (U_1, U_2) be a pair of commuting unitary operators defined on the Hilbert space K, and let X be a subspace of K. Then, we have the following equivalence* ([10, *Thm.* 4.2]):

(i) *$X_{-,\infty}$ and $X_{\infty,-}$ intersect perpendicularly in $X_{-,-}$, that is,*

$$E^{X_{-,\infty}}E^{X_{\infty,-}} = E^{X_{\infty,-}}E^{X_{-,\infty}} = E^{X_{-,-}}; \tag{10}$$

(ii) *$U^*_{1|X_{-,-}}$ and $U^*_{2|X_{-,-}}$ are doubly commuting isometries.*

In this case, the wandering subspace Δ for (U_1, U_2) defined by

$$\Delta = (U_1 X_{-,\infty} \ominus X_{-,\infty}) \cap (U_2 X_{\infty,-} \ominus X_{\infty,-}) \tag{11}$$

is also given by

$$\Delta = (U_1U_2X_{-,-} \ominus U_1X_{-,-}) \cap (U_1U_2X_{-,-} \ominus U_2X_{-,-}) \tag{12}$$

or by

$$\begin{aligned}\Delta &= U_1(U_2X_{-,-} \ominus X_{-,-}) \ominus (U_2X_{-,-} \ominus X_{-,-})\\ &= U_2(U_1X_{-,-} \ominus X_{-,-}) \ominus (U_1X_{-,-} \ominus X_{-,-}).\end{aligned} \tag{13}$$

Moreover, $X_{-,-}$ has the following four-fold Wold-type decomposition:

$$\begin{aligned}X_{-,-} = U_1^*U_2^*\Delta_{-,-} \oplus \oplus_{k=1,\infty}U_1^{*k}(U_1X_{-,-\infty} \ominus X_{-,-\infty}) \oplus\\ \oplus_{l=1,\infty}U_2^{*l}(U_2X_{-\infty,-} \ominus X_{-\infty,-}) \oplus X_{-\infty,-\infty},\end{aligned} \tag{14}$$

where $X_{-,-\infty} = \cap_{n\in Z}U_2^nX_{-,-}$, $X_{-\infty,-} = \cap_{m\in Z}U_1^mX_{-,-}$, and $X_{-\infty,-\infty} = \cap_{(m,n)\in Z^2}$ $U_1^mU_2^nX_{-,-}$.

2. Minimal regular unitary dilation of a pair of commuting contractions and forward-forward Markovian spaces. In this section we make the connections between the regular minimal unitary dilation of a pair of commuting contractions and the notion of forward-forward Markovian space with respect to a pair of commuting unitary operators. We have the following result.

THEOREM 2.1. *Let (U_1, U_2) be a pair of commuting unitary operators defined on the Hilbert space K; let us assume that there exists a subspace X of K such that $K = X_{\infty,\infty}$. If X is a* FFMS *(respectively, a* MS*) with respect to (U_1, U_2), then the contractions $T_1 = E^X U_{1|X}$ and $T_2 = E^X U_{2|X}$ commute (respectively, doubly commute), and (U_1, U_2, K) is the minimal regular unitary dilation of $(E^X U_{1|X}, E^X U_{2|X}, X)$.*

Conversely, if (T_1, T_2) are two commuting contractions defined on the Hilbert space X for which there exists a regular minimal unitary dilation (U_1, U_2) defined on the space $K = X_{\infty,\infty}$, then X is a forward-forward Markovian space with respect to (U_1, U_2). In this case, T_1 and T_2 coincide with the Markovian transition operators associated to X. Moreover, if (T_1, T_2) doubly commute, then X is an MS *with respect to (U_1, U_2).*

Proof. Let us assume that X is a FFMS with respect to (U_1, U_2). Then, $X_{-,0} \perp X_{+,0} | X$, so that X is a Markovian subspace with respect to U_1, the Markovian transition of which is $T_1 = E^X U_{1|X}$. Therefore, $T_1^m x = E^X U_1^m x$ for all $m \in N$, and for all $x \in X$; but, by (1), $E^{X_{-,\infty}} U_1^m x$ belongs to X; this implies that $E^{X_{-,\infty}} U_1^m x = T_1^m x$; similarly, if we put $T_2 x = E^X U_{2|X}$, then, $E^{X_{\infty,-}} U_2^n x = T_2^n x$ for all $n \in N$ and for all $x \in X$. On the other hand, for each $(m, n) \in N^2$ and for each element x of X, $E^X U_1^m U_2^n x = E^X E^{X_{-,\infty}} U_1^m U_2^n x$; as $U_2 X_{-,\infty} = X_{-,\infty}$, $E^{X_{-,\infty}} U_1^m U_2^n x = U_2^n E^{X_{-,\infty}} U_1^m x = U_2^n T_1^m x$; therefore, $E^X U_1^m U_2^n x = T_2^n T_1^m x$. Similarly, $E^X U_1^m U_2^n x = T_1^m T_2^n x$; from this, it follows that $E^X U_{1|X}$ and $E^X U_{2|X}$ are two commuting contractions. Moreover, $E^X U_1^m U_2^{-n} x = E^X E^{X_{-,\infty}} U_1^m U_2^{-n} x = E^X U_2^{-n} E^{X_{-,\infty}} U_1^m x = T_2^{*n} T_1^m x$. Hence, (U_1, U_2, K) is the minimal regular unitary dilation of (T_1, T_2, X). Finally, if X is a MS with respect to (U_1, U_2), then all the preceding considerations hold if U_2 is replaced by U_2^*; from this, it is easily deduced that $T_1 = E^X U_{1|X}$ and $T_2^* = E^X U_{2|X}^*$ are commuting contractions; therefore, (T_1, T_2) are doubly commuting contractions.

Conversely, suppose that (U_1, U_2, K) is the minimal regular unitary dilation of (T_1, T_2, X). Let us show that (1) holds. For this purpose, it is sufficient to establish that

$$E^{X_{-,\infty}} U_1^m x = T_1^m x \tag{15}$$

for each integer $m \geq 0$ and for each element x of X. For all $k \in N$, for all $l \in Z$, for all $y \in X$, $\langle U_1^m x - T_1^m x, U_1^{-k} U_2^l y \rangle = \langle U_1^{m+k} U_2^{-l} x, y \rangle - \langle U_1^k U_2^{-l} T_1^m x, y \rangle = \langle E^X U_1^{m+k} U_2^{-l} x, y \rangle - \langle E^X U_1^k U_2^{-l} T_1^m x, y \rangle$. But, $E^X U_1^{m+k} U_2^{-l} x = E^X U_1^k U_2^{-l} T_1^m x = T_2^{*l} T_1^{m+k} x$ because (U_1, U_2, K) is the minimal regular unitary dilation of (T_1, T_2, X). Thus, $\langle U_1^m x - T_1^m x, U_1^{-k} U_2^l y \rangle = 0$. Consequently, $U_1^m x - T_1^m x$ is orthogonal to $X_{-,\infty}$; this implies (15). The proof of (2) is analogous. If T_1 and T_2 doubly commute, the fact that $X_{+,\infty} \perp X_{-,0} | X$ (respectively, $X_{\infty,+} \perp X_{0,-} | X$) is shown similarly by exchanging (T_1, T_2) by (T_1^*, T_2) (respectively, by (T_1, T_2^*)). □

Let us illustrate the converse of the theorem in the case where X is a finite dimensional subspace of centered complex-valued square integrable random variables. Let $X_{0,0} = (x_1, \ldots, x_N)^T$ be a basis of X, and let us denote by P the covariance matrix $E(X_{0,0} X_{0,0}^*)$. Let T_1 and T_2 be two commuting contractive operators defined on X admitting a regular unitary dilation, and let F_1 and F_2 be the two matrices defined by the fact that

$$(T_i x_1, \ldots, T_i x_n)^T = F_i X_{0,0} \tag{16}$$

for $i = 1, 2$. Clearly, the matrices of T_1 and T_2 in the basis $X_{0,0}$ coincide with F_1^T and F_2^T,

respectively. Then, it is easily seen that $(T_i^* x_1, \ldots, T_i^* x_n)^T = PF_i^* P^{-1} X_{0,0}$ from which it follows that the condition $I - T_1^* T_1 - T_2^* T_2 + T_1^* T_2^* T_2 T_1$ positive is equivalent to the positivity of the matrix $P - F_1 P F_1^* - F_2 P F_2^* + F_1 F_2 P F_2^* F_1^*$. Let (U_1, U_2) be the minimal regular unitary dilation of (T_1, T_2), and let us put $X_{m,n} = U_1^m U_2^n X_{0,0}$. Then, Theorem 2.1 states that $X_{m+1,n}/sp(X_{m-k,n-l}/k \geq 0, l \in Z) = X_{m+1,n}/X_{m,n} = F_1 X_{m,n}$, and that $X_{m,n+1}/sp(X_{m-k,n-l}/k \in Z, l \geq 0) = X_{m,n+1}/X_{m,n} = F_2 X_{m,n}$. This property is known [11] to be equivalent to the fact that $(X_{m,n})_{(m,n)\in Z^2}$ is an Attasi model given by a state-space equation $X_{m+1,n+1} = F_1 X_{m,n+1} + F_2 X_{m+1,n} - F_1 F_2 X_{m,n} + L\nu_{m,n}$ where ν is a white noise sequence. In particular, the positive matrix $P - F_1 P F_1^* - F_2 P F_2^* + F_1 F_2 P F_2^* F_1^*$ is equal to LL^*.

Throughout this section, (T_1, T_2) will denote a fixed pair of commuting contractions defined on the Hilbert space X, which admits a minimal regular unitary dilation (U_1, U_2). We are going to present some useful properties of (U_1, U_2). Although the structure of (U_1, U_2) was studied by Halperin [7], most of the results to be presented in this section are new. We begin by giving some properties of the spaces $X_{-,\infty}, X_{+,\infty}, X_{\infty,-}$ and $X_{\infty,+}$. First, it follows from (1) that the space $X_{0,\infty}$ is Markovian with respect to U_1, i.e., that $X_{-,\infty} \perp X_{+,\infty} | X_{0,\infty}$. In order to establish this property, it is sufficient to show that for all $x \in X, E^{X_{-,\infty}} U_1^k U_2^l x$ belongs to $X_{0,\infty}$ for all $k \geq 0$, for all $l \in Z$; but, this derives from the fact that $E^{X_{-,\infty}} U_1^k U_2^l x = U_2^l E^{X_{-,\infty}} U_1^k x = U_2^l T_1^k x$. Therefore, the spaces $X_{-,\infty}$ and $X_{+,\infty}$ intersect perpendicularly in $X_{0,\infty}$. Likewise, $X_{\infty,0}$ is Markovian with respect to U_2, or equivalently, $X_{\infty,-}$ and $X_{\infty,+}$ intersect perpendicularly in $X_{\infty,0}$. In the sequel, we shall denote by S_1 and S_2 the Markovian transition operators of $X_{0,\infty}$ and $X_{\infty,0}$, i.e.,

$$S_1 = E^{X_{0,\infty}} U_{1|X_{0,\infty}}, \tag{17}$$

$$S_2 = E^{X_{\infty,0}} U_{2|X_{\infty,0}}. \tag{18}$$

On the other hand, the following relations hold.

PROPOSITION 2.1.

$$E^{X_{-,\infty}} E^{X_{\infty,-}} = E^{X_{\infty,-}} E^{X_{-,\infty}} = E^{X_{-,-}}, \tag{19}$$

$$E^{X_{-,\infty}} E^{X_{\infty,+}} = E^{X_{\infty,+}} E^{X_{-,\infty}} = E^{X_{-,+}}, \tag{20}$$

$$E^{X_{+,\infty}} E^{X_{\infty,-}} = E^{X_{\infty,-}} E^{X_{+,\infty}} = E^{X_{+,-}}, \tag{21}$$

Moreover,

$$X_{-,-} \perp X_{+,+} | X. \tag{22}$$

Proof. In order to demonstrate (19), it is sufficient to establish that $U_{1|X_{-,-}}^*$ and $U_{2|X_{-,-}}^*$ are doubly commuting isometries (see Proposition 1.1). The fact that these two isometries commute is obvious. Therefore, it remains to show that

$$U_1^* E^{X_{-,-}} U_2 (U_1^{-k} U_2^{-l} x) = E^{X_{-,-}} U_2 U_1^* (U_1^{-k} U_2^{-l} x) \tag{23}$$

for all $(k, l) \in N^2$, for all $x \in X$. Equation (23) is obvious if $l \geq 1$. On the other hand, $E^{X_{\infty,-}} U_2 U_1^{-k} x$ coincides with $U_1^{-k} E^{X_{\infty,-}} U_2 x$ because $U_1 X_{\infty,-} = X_{\infty,-}$. But, by (2), $E^{X_{\infty,-}} U_2 x = E^X U_2 x$, from which we deduce that $E^{X_{\infty,-}} U_2 U_1^{-k} x = U_1^{-k} E^X U_2 x$ belongs to $U_1^{-k} X$, and therefore to $X_{-,-}$. Consequently, $E^{X_{-,-}} U_2 U_1^{-k} x = E^{X_{\infty,-}} U_2 U_1^{-k} x =$

$U_1^{-k}E^X U_2 x$. Similarly, $E^{X_{-,\cdot}} U_2 U_1^* U_1^{-k} x = U_1^{-(k+1)} E^X U_2 x$, so that (23) holds for $l = 0$. We omit the proof of (20) and (21) which are based on similar arguments. Let us finally establish (22). For this purpose, we have to show that for all $x \in X$, for all $(k,l) \in N^2, E^{X_{-,\cdot}} U_1^k U_2^l x$ coincides with $E^X U_1^k U_2^l x$. By (19), $E^{X_{-,\cdot}} U_1^k U_2^l x = E^{X_{-,\infty}} E^{X_{\infty,\cdot}} U_1^k U_2^l x$. But, $E^{X_{\infty,\cdot}} U_1^k U_2^l x = U_1^k E^{X_{\infty,\cdot}} U_2^l x = U_1^k E^X U_2^l x = U_1^k T_2^l x$. Therefore, $E^{X_{-,\cdot}} U_1^k U_2^l x = E^{X_{-,\infty}} U_1^k T_2^l x$ which coincides with $E^X U_1^k T_2^l x = T_1^k T_2^l x = E^X U_1^k U_2^l x$. □

It turns out that the spaces $(X_{-,\infty}, X_{+,\infty}, X_{\infty,-})$ intersect perpendicularly two by two. Let us show that moreover,

$$X_{-,\infty} \cap X_{+,\infty} \cap X_{\infty,-} = X_{0,-}. \tag{24}$$

For this purpose, we have to establish that $E^{X_{\infty,\cdot}} z = E^{X_{0,\cdot}} z$ for each element z of $X_{-,\infty} \cap X_{+,\infty}$; as $X_{-,\infty} \cap X_{+,\infty} = X_{0,\infty}$, this is equivalent to $E^{X_{\infty,\cdot}} U_2^l x = E^{X_{0,\cdot}} U_2^l x$ for each $l \in Z$ and for each $x \in X$. If $l \leq 0$, it is obvious; if $l > 0, E^{X_{\infty,\cdot}} U_2^l x = T_2^l x = E^X U_2^l x = E^{X_{0,\cdot}} U_2^l x$. Similarly, $(X_{\infty,-}, X_{\infty,+}, X_{-,\infty})$ intersect perpendicularly two by two, and

$$X_{\infty,-} \cap X_{\infty,+} \cap X_{-,\infty} = X_{-,0}. \tag{25}$$

When T_1 and T_2 doubly commute, it is clear that the relations

$$E^{X_{+,\infty}} E^{X_{\infty,+}} = E^{X_{\infty,+}} E^{X_{+,\infty}} = E^{X_{+,+}}, \tag{26}$$

$$X_{+,-} \perp X_{-,+} | X \tag{27}$$

also hold. In this case, the four subspaces $X_{-,\infty}, X_{+,\infty}, X_{\infty,-}, X_{\infty,+}$ intersect perpendicularly two by two, and

$$X = X_{-,\infty} \cap X_{\infty,-} \cap X_{+,\infty} \cap X_{\infty,+}. \tag{28}$$

An interesting point is that the converse is also true. That is, if (26) holds, then T_1 and T_2 doubly commute. The proof is left to the reader. However, it is important to note that it is possible to exhibit examples of non doubly commuting contractions for which $E^{X_{+,\infty}} E^{X_{\infty,+}} = E^{X_{\infty,+}} E^{X_{+,\infty}}$ (see §3.2).

Let us finish this discussion concerning the properties of the spaces $X_{-,\infty}, X_{+,\infty}$, $X_{\infty,-}, X_{\infty,+}$ by an interpretation of the properties (19) to (21). The property (19) plays an important role in the prediction theory of two parameters stationary random processes. Let $(X_{m,n})_{(m,n)\in Z^2}$ be such a vector-valued process; let us denote by X the space generated by the components of $X_{0,0}$, and by (U_1, U_2) the horizontal and the vertical shift operators defined on the space generated by the components of the variables $X_{m,n}, (m,n) \in Z^2$. Then, if we assume for ease of exposition that $X_{-\infty,\infty} = \cap_{m\in Z} U_1^m X_{-,\infty}$ and $X_{\infty,-\infty} = \cap_{n\in Z} U_2^n X_{\infty,-}$ are reduced to $\{0\}$ (a condition that is similar to the concept of pure non determinism of the one-parameter case), it is easy to show that (19) holds if and only if $X_{m,n}$ has the following representation

$$X_{m,n} = \sum_{(k,l)\in N^2} c_{k,l} \alpha_{m-k,n-l}, \tag{29}$$

where α is a white noise sequence for which the space $sp(\alpha_{m,n})$ coincides with $sp(X_{m,n} - X_{m,n}/sp(X_{m-k,n-l}/(k,l) \in N^2, (k,l) \neq (0,0)))$ (see [10], [12], and [24]). Therefore, X

has a quarter-plane causal and causally invertible moving-average representation in terms of a white noise α. In particular, under purely technical assumptions, the quarter-plane causal Markov random fields introduced by Pickard satisfy condition (19). Obviously, a random field satisfying both conditions (19) to (21) must possess stronger properties. In particular, the above mentioned quarter-plane MRF do not satisfy (20) and (21) in the general case. Similarly, the condition (22) is very strong, so that it does not hold for the case of Pickard's MRF. Let us finally consider the case of an Attasi model $(X_{m,n})_{(m,n)\in Z^2}$ defined by (3). Then, it is easily seen that $X_{-\infty,\infty} = X_{\infty,-\infty} = \{0\}$ if and only if the matrices F_1 and F_2 are asymptotically stable. In this case, the representation (29) can be written as

$$X_{m,n} = \sum_{(k,l)\in N^2} F_1^k F_2^l \nu_{m-k-1,n-l-1}$$

so that $\alpha_{m,n} = \nu_{m-1,n-1}$ for each $(m,n) \in Z^2$. Moreover, for $(m,n) \in N^2, X_{m,n}/sp$ $(X_{-r,-s}/(r,s) \in N^2) = \sum_{k\geq m, l\geq n} F_1^k F_2^l \nu_{m-k-1,n-l-1}$. By using the fact that $F_1F_2 = F_2F_1$, we get immediately that

$$X_{m,n}/sp(X_{-r,-s}/(r,s) \in N^2) = F_1^m F_2^n X_{0,0}$$

which illustrates (22).

Now, we will study the properties of the spaces $(Z_i)_{i=1,2}$ defined by

$$Z_i = \overline{(U_i - T_i)X} \tag{30}$$

for $i = 1, 2$. Let us begin by some obvious properties of Z_1 (similar results hold for Z_2). As the space X is Markovian with respect to U_1, the space Z_1 coincides with the forward innovation space $U_1X_{-,0} \ominus X_{-,0}$; therefore, Z_1 is a wandering subspace for U_1. Moreover, the space $U_1X_{-,\infty} \ominus X_{-,\infty}$, which is generated by the vectors $U_2^n(U_1x - E^{X_{-,\infty}}U_1x)$ for $x \in X$ and $n \in Z$, coincides with $(Z_1)_{0,\infty} = \bigvee_{n\in Z} U_2^n Z_1$ because $E^{X_{-,\infty}}U_1U_2^n x = E^{X_{0,\infty}}U_1U_2^n x$. From this, it follows that $(Z_1)_{0,\infty}$ is equal to the forward innovation space of the Markovian space (with respect to U_1) $X_{0,\infty}$; in particular, $(Z_1)_{+,\infty} = (X_{-,\infty})^\perp$ (the orthogonal is taken in $X_{\infty,\infty}$). The properties of the Z_1 with respect to the unitary operator $U_{2|(Z_1)_{0,\infty}}$ will play an important role in the following.

THEOREM 2.2. *The space Z_1 is a Markovian space with respect to $U_{2|(Z_1)_{0,\infty}}$, i.e.,*

$$(Z_1)_{0,+} \perp (Z_1)_{0,-} | Z_1. \tag{31}$$

Moreover, Z_1 reduces the operator S_2 (i.e., Z_1 is invariant under S_2 and S_2^*), and $S_{2|Z_1}$ is the Markovian transition operator of Z_1.

The proof is given in the Appendix. Obviously, the space Z_2 has the same properties. Now, we study the forward and backward innovation spaces of Z_1 and Z_2.

THEOREM 2.3. *Let Δ be the space defined by*

$$\Delta = \overline{(U_1U_2 - U_1T_2 - U_2T_1 + T_1T_2)X}. \tag{32}$$

Then, Δ is equal to the wandering subspace for (U_1, U_2) defined by $(U_1X_{-,\infty} \ominus X_{-,\infty}) \cap (U_2X_{\infty,-} \ominus X_{\infty,-})$. Moreover, Δ coincides with both the forward innovation space of Z_1 and the forward innovation space of Z_2, i.e.,

$$\Delta = \overline{(U_2 - S_2)Z_1} = U_2(Z_1)_{0,-} \ominus (Z_1)_{0,-}, \tag{33}$$

$$\Delta = \overline{(U_1 - S_1)Z_2} = U_1(Z_2)_{-,0} \ominus (Z_2)_{-,0}. \tag{34}$$

Finally, the backward innovation space of Z_1 (i.e., the space $\overline{(I - U_2 S_2^*) Z_1}$) is equal to the wandering subspace for $(U_1, U_2)\Delta_{fb}$ given by

$$\Delta_{fb} = (U_1 X_{-,\infty} \ominus X_{-,\infty}) \cap (X_{\infty,+} \ominus U_2 X_{\infty,+}). \tag{35}$$

Similarly, the backward innovation space of Z_2 is equal to the wandering subspace Δ_{bf} given by

$$\Delta_{bf} = (X_{+,\infty} \ominus U_1 X_{+,\infty}) \cap (U_2 X_{\infty,-} \ominus X_{\infty,-}). \tag{36}$$

The proof is given in the Appendix. Motivated by the previous expressions of the spaces $\Delta, \Delta_{fb}, \Delta_{bf}$, we shall call Δ (respectively, Δ_{fb}, Δ_{bf}) the forward-forward (FF) (respectively, forward-backward, backward-forward) innovation space of X. Let us illustrate Theorems 2.2 and 2.3 in the previously introduced finite-dimensional case. In view of (32), the white noise sequence $(\nu_{m,n})_{(m,n)\in Z^2}$ is such that $\nu_{m,n} = U_1^m U_2^n \nu_{0,0}$ where $\nu_{0,0}$ is a basis of Δ. The fact that Z_1 is a Markovian space with respect to U_2 with transition operator $S_{2|Z_1}$ and forward innovation space Δ is equivalent to the fact that for each m fixed, the one-parameter N-variate random process $(X_{m+1,n} - F_1 X_{m,n})_{n\in Z}$ is a wide-sense Markov process given by the state-space equation

$$(X_{m+1,n+1} - F_1 X_{m,n+1}) = F_2 (X_{m+1,n} - F_1 X_{m,n}) + L\nu_{m,n}. \tag{37}$$

Let us now formulate some remarks concerning the spaces Δ_{fb} and Δ_{bf}. Although their properties present some similarities with those of Δ, Δ_{fb} and Δ_{bf} do not play the same role as Δ. In particular, the relation (32) has no counterpart in the case of Δ_{fb} and Δ_{bf}, except in the case where T_1 and T_2 doubly commute. Let us illustrate this in our finite-dimensional example. For ease of exposition, we suppose that the dimension of Z_1 coincides with the dimension of X, i.e., that $E[(X_{m+1,n} - F_1 X_{m,n})(X_{m+1,n} - F_1 X_{m,n})^T] = P - F_1 P F_1^T$ is positive-definite. Then, the backward state-space equation corresponding to (37) is given by

$$(X_{m+1,n} - F_1 X_{m,n}) = \tilde{F}_2 (X_{m+1,n+1} - F_1 X_{m,n+1}) + \tilde{L}\tilde{\nu}_{m,n}, \tag{38}$$

where $\tilde{\nu}_{m,n}$ represents a white noise sequence such that $sp(\tilde{\nu}_{0,0})$ coincides with the space Δ_{fb}, and where $\tilde{F}_2$ is the matrix given by

$$\tilde{F}_2 = (P - F_1 P F_1^T) F_2^T (P - F_1 P F_1^T)^{-1}. \tag{39}$$

Equation (38) can be written as

$$X_{m+1,n} = F_1 X_{m,n} + \tilde{F}_2 X_{m+1,n+1} - \tilde{F}_2 F_1 X_{m,n+1} + \tilde{L}\tilde{\nu}_{m,n}. \tag{40}$$

In general, the matrices F_1 and $\tilde{F}_2$ do not commute, so that the process $\tilde{X}_{m,n} = X_{m,-n}$ is not an Attasi model, or equivalently the conditional orthogonality relation $X_{0,-} \perp X_{\infty,+} | X$ does not hold. Therefore, the expression of $\tilde{\nu}_{m,n}$ in terms of $X_{m+1,n}, X_{m+1,n+1}, X_{m,n}, X_{m,n+1}$ is not similar to that of $\nu_{m,n}$ in terms of $X_{m+1,n+1}, X_{m+1,n}, X_{m,n+1}, X_{m,n}$, or equivalently, (32) has no counterpart in the case of Δ_{fb}. However, when T_1 and T_2 doubly commute, i.e., when F_1 and $P F_2^T P^{-1}$ commute, it is easily seen that $\tilde{F}_2$ coincides with $P F_2^T P^{-1}$, so that (40) is an Attasi-like equation.

3. Application to a Markovian-like representation problem. In this section, we deal with the Markovian-like representation problem corresponding to the previously introduced Markovian properties. Its formulation can be interpreted as the two-parameter counterpart of the problem introduced by Lindquist–Picci and Ruckebusch. Throughout this section, (U_1, U_2) represents a fixed once and for all pair of commuting unitary operators defined on the Hilbert space K. Then, a subspace X of K is said to be a forward-forward Markovian representation (FFMR) of Y (with respect to (U_1, U_2)) if Y is included in X and if X is a forward-forward Markovian space with respect to (U_1, U_2). Forward-backward, backward-forward, backward-backward Markovian representations are defined in a similar way. Finally, X will be said to be a Markovian representation of Y if X is both a FFMR and a BBMR of Y. Thus, by §2, a subspace X of K containing Y is a FFMR (respectively, a MR) of Y if and only if $(U_{1|X_{\infty,\infty}}, U_{2|X_{\infty,\infty}}, X_{\infty,\infty})$ is the regular minimal unitary dilation of a pair of commuting (respectively, doubly commuting) contractions defined on X. According to [14], we shall say that a (FF)MR X of Y is internal if X is contained in $Y_{\infty,\infty}$; such representations are clearly of special interest because they can be constructed from the "data" of the realization problem (i.e., the space $Y_{\infty,\infty}$).

Let us begin by the following useful remark which derives from the fact that if X is a FF Markovian space with respect to (U_1, U_2), then $X_{0,\infty}$ (respectively, $X_{\infty,0}$) is a Markovian space with respect to U_1 (respectively, U_2): if X is FFMR of Y, then the space $X_{0,\infty}$ (respectively, the space $X_{\infty,0}$) is a Markovian representation of the space $Y_{0,\infty}$ (respectively, of $Y_{\infty,0}$) with respect to U_1 (respectively, U_2) [14], in the sense that $X_{0,\infty}$ (respectively, $X_{\infty,0}$) is a Markovian space with respect to U_1 (respectively, U_2) containing $Y_{0,\infty}$ (respectively, $Y_{\infty,0}$); moreover, its Markovian transition opertor coincides with the contraction S_1 (respectively, S_2) defined by (17) (respectively, (18)). This elementary property will allow us to use the theory of [14] and [19] in order to get some results concerning the minimality of the (FF)MR of Y with respect to (U_1, U_2).

3.1. Geometrical considerations. In this paragraph no particular assumption is made on the space Y. We give a geometrical characterization of the set of all (FF)MR of Y. We begin by the FFMR.

THEOREM 3.1. *A subspace X of K is a* FFMR *of Y if and only if*

$$X = \overline{E}^{H_1 \cap H_2}(\overline{H}), \tag{41}$$

where $H_1, H_2, \overline{H}$ are three subspaces containing Y such that

$$U_i(\overline{H}) \subset \overline{H} \quad \text{for } i = 1, 2, \tag{42}$$

$$H_i \subset U_i H_i, U_j H_i = H_i, \qquad j \neq i, \quad i = 1, 2, \tag{43}$$

$$H_1 \text{ and } H_2 \text{ intersect perpendicularly, i.e., } E^{H_1} E^{H_2} = E^{H_2} E^{H_1}. \tag{44}$$

Proof. Let X be a FFMR of Y; then, if we put $H_1 = X_{-,\infty}, H_2 = X_{\infty,-}, \overline{H} = X_{+,+}$, it follows from Proposition 2.1 that $X = \overline{E}^{H_1 \cap H_2}(\overline{H})$, and that $H_1, H_2, \overline{H}$ satisfy all the requirements of the theorem. Conversely, let us suppose that X is a subspace given by (41), and let us show that $X_{-,\infty} \perp X_{+,0} | X$; as $X_{-,\infty}$ is included in H_1, it is clearly sufficient to show that $H_1 \perp X_{+,0} | X$. From $m \in N, U_1^m X = \overline{E}^{U_1^m H_1 \cap H_2}(U_1^m \overline{H})$ is included in

$\overline{E}^{U_1^m H_1 \cap H_2}(\overline{H})$; therefore, $\overline{E}^{H_1}(U_1^m X)$ is itself included in $\overline{E}^{H_1}(\overline{E}^{U_1^m H_1 \cap H_2}(\overline{H}))$. Let us show that this subspace is contained in X; for all $z \in X, E^{H_1}(E^{U_1^m H_1 \cap H_2}(z)) = E^{H_1} E^{U_1^m H_1} E^{H_2} z = E^{H_1} E^{H_2} z = E^{H_1 \cap H_2} z$ which belongs to X; this implies that $\overline{E}^{H_1}(\overline{E}^{U_1^m H_1 \cap H_2}(\overline{H}))$ is contained in X; thus, $\overline{E}^{H_1}(U_1^m X) \subset X$ for each $m \in N$, from which we deduce that $H_1 \perp X_{+,0} | X$. The fact that $X_{\infty,-} \perp X_{0,+} | X$ is shown similarly. □

The characterization of the set of all MR of Y appears as a generalization of the basic representation Theorem 3.1 of [14].

THEOREM 3.2. *A subspace X of K is a* MR *of Y with respect to (U_1, U_2) if and only if X can be written as*

$$X = H_1 \cap H_2 \cap \overline{H_1} \cap \overline{H_2}, \tag{45}$$

where $H_1, H_2, \overline{H_1}, \overline{H_2}$ are four subspaces containing Y such that

$$U_i(\overline{H_i}) \subset \overline{H_i} \quad \text{for } i = 1,2 \; U_j \overline{H_i} = \overline{H_i}, \qquad j \neq i, \quad i = 1,2, \tag{46}$$

$$H_i \subset U_i H_i, \quad U_j H_i = H_i, \qquad j \neq i, \quad i = 1,2, \tag{47}$$

$$H_1, H_2, \overline{H_1}, \overline{H_2} \text{ intersect perpendicularly two by two.} \tag{48}$$

Moreover, if X is an internal MR, then $(X_{-,\infty}, X_{\infty,-}, X_{+,\infty}, X_{\infty,+})$ is the unique 4*-uple of subspaces contained in $Y_{\infty,\infty}$ and satisfying* (45)–(48).

Proof. If X is a MR of Y, we have already shown that $X = X_{-,\infty} \cap X_{+,\infty} \cap X_{\infty,-} \cap X_{\infty,+}$ (see (28)) and that $H_1 = X_{-,\infty}, \overline{H_1} = X_{+,\infty}, H_2 = X_{\infty,-}$ and $\overline{H_2} = X_{\infty,+}$ satisfy (46) to (48). Conversely, if X is given by (45), X can be written as $X = \overline{E}^{H_1 \cap H_2}(\overline{H_1} \cap \overline{H_2})$; by Theorem 3.1, this implies that X is a FFMR of Y. But, X is also equal to $X = \overline{E}^{(\overline{H_1} \cap \overline{H_2})}(H_1 \cap H_2)$ which is a BBMR by a trivial modification of Theorem 3.1. This in turn establishes that X is a MR of Y. The proof of the last statement of the theorem is left to the reader. □

By Theorem 3.1, the spaces $E^{Y_{-,\infty}}(Y_{+,+})$ and $E^{Y_{\infty,-}}(Y_{+,+})$ are FFMR of Y (take $\overline{H} = Y_{+,+}, H_1 = Y_{-,\infty}, H_2 = Y_{\infty,\infty}$ and $\overline{H} = Y_{+,+}, H_1 = Y_{\infty,\infty}, H_2 = Y_{\infty,-}$, respectively). However, these two FFMR are not interesting because they represent infinite-dimensional subspaces, even if Y is a finite-dimensional subspace admitting finite-dimensional FFMR (for example, $E^{Y_{-,\infty}}(Y_{+,+})$ contains $Y_{0,+}$ which is an infinite-dimensional subspace, except in trivial cases). A natural question is whether there exist less special examples of FFMR in the general case. In particular, is it possible to exhibit minimal FFMR or MR (in the sense that they do not contain another representation as proper subspace) without making any assumptions on Y, as it is the case in the one-parameter theory (the filter and the co-filter [19] are such minimal representations)? The answer to this question is negative because there may not exist a nontrivial pair of subspaces (H_1, H_2) containing Y and satisfying (43) and (44) (by a nontrivial pair, we mean that H_1 and H_2 do not contain $Y_{\infty,\infty}$, i.e., in the case where $K = Y_{\infty,\infty}$ that $H_1 \neq Y_{\infty,\infty}$ and $H_2 \neq Y_{\infty,\infty}$). This claim will be demonstrated in §3.2 (see Proposition 3.2). Therefore, it is not possible to develop a Markovian representation theory without making any extra assumptions on the space Y. Consequently, we consider in §3.2 restrictive situations for which some positive results hold. But, before going further, we introduce some useful definitions.

DEFINITION 3.1. Let X be an FFMR of Y. Then, X is said to be forward-forward observable if $X \cap (Y_{+,+})^{\perp} = \{0\}$, or equivalently, if $X = \overline{E}^{X}(Y_{+,+})$.

This definition makes sense for the following reason: let X be a non FF observable FFMR. Then, $X^0 = \overline{E}^X(Y_{+,+})$ is an FF observable FFMR contained in X. In fact, as $\overline{H} = Y_{+,+}, H_1 = X_{-,\infty}, H_2 = X_{\infty,-}$ satisfy (42)–(44), the space $\overline{E}^{X_{-,\infty} \cap X_{\infty,-}}(Y_{+,+})$ is an FFMR of Y; but, $X_{-,\infty} \cap X_{\infty,-}$ and $X_{+,+}$ are conditionally orthogonal given X; therefore, this is also the case for $X_{-,\infty} \cap X_{\infty,-}$ and $Y_{+,+}$, from which we deduce that $\overline{E}^{X_{-,\infty} \cap X_{\infty,-}}(Y_{+,+}) = \overline{E}^X(Y_{+,+})$; consequently, X^0 is an FFMR. The fact that X^0 is FF observable is obvious. Let us define now the concept of regular and coregular representation; the terminology originates from [19].

DEFINITION 3.2. Let X be an (FF)MR of Y. Then, X is said to be regular if

$$\bigcap_{m \in Z} U_1^m X_{-,\infty} = \{0\}, \tag{49}$$

$$\bigcap_{n \in Z} U_2^n X_{\infty,-} = \{0\}. \tag{50}$$

X is said to be co-regular if

$$\bigcap_{m \in Z} U_1^m X_{+,\infty} = \{0\}, \tag{51}$$

$$\bigcap_{n \in Z} U_2^n X_{\infty,+} = \{0\}. \tag{52}$$

In the sequel, we shall be concerned with regular and coregular FFMR of Y. Therefore, it will be useful to know whether a regular FFMR X is also coregular.

LEMMA 3.1. *Let X be a regular* FFMR *of Y whose forward-forward innovation space Δ is finite-dimensional. Then, X is co-regular if and only if*

$$\dim\Delta = \dim\Delta_{fb} = \dim\Delta_{bf}, \tag{53}$$

where Δ_{fb} and Δ_{bf} are the innovation spaces defined in Theorem 2.3. *In this case, $X_{-,+} = U_1^*(\Delta_{fb})_{-,+}, X_{\infty,+} = (\Delta_{fb})_{\infty,+}$ and $X_{+,-} = U_2^*(\Delta_{bf})_{+,-}, X_{+,\infty} = (\Delta_{bf})_{+,\infty}$.*

Proof. See the Appendix.

Finally, we give the following useful lemma whose proof is omitted.

LEMMA 3.2. *Let Δ be a wandering subspace for (U_1, U_2) such that*

(i) *Δ is included in $Y_{\infty,\infty}$;*

(ii) *Y is included in $U_1^* U_2^* \Delta_{-,-}$.*

Then, the subspace $X = \overline{E}^{U_1^* U_2^* \Delta_{-,-}}(Y_{+,+})$ is an internal regular FF *observable* FFMR *of Y with forward-forward innovation space Δ.*

A fundamental example. In order to illustrate what precedes, we give an example which will be very useful in §3.2. Let us denote by T the unit circle of the complex plane, and by D (respectively, $\overline{D}$) the open (respectively, closed) unit disk. Then, we consider the case where K is equal to the space $L^2(T^2)$ of all square integrable functions (with respect to the Lebesgue measure) defined on T^2, and where U_1 and U_2 coincide with the multiplication operators σ_1 and σ_2 by z_1 and z_2, respectively (in the following, the generic element of T^2 will be denoted (z_1, z_2) or $(e^{i\omega_1}, e^{i\omega_2})$).

Before going further, we have to introduce some basic notations. First, H_+^2 and H_-^2 denote the following Hardy subspaces of $L^2(T)$:

$$H_+^2 = \left\{ \sum_{k=0}^{\infty} \phi_k z^k \right\}, \qquad H_-^2 = \left\{ \sum_{k=0}^{\infty} \phi_k z^{-k} \right\}.$$

A function θ defined on T is said to be all-pass if $|\theta(z)| = 1$ almost everywhere on T; if moreover $\theta \in H_+^2$ (respectively, H_-^2), then θ is said to be inner (respectively, $*$-inner). In the following, some Hardy spaces of functions defined on T^2 will play an important role. We denote by $H_{+,\infty}^2$ and $H_{-,\infty}^2$ the subspaces

$$H_{+,\infty}^2 = \left\{ \sum_{k=0}^{\infty} \sum_{l=-\infty}^{\infty} \phi_{k,l} z_1^k z_2^l \right\}, \qquad H_{-,\infty}^2 = \left\{ \sum_{k=0}^{\infty} \sum_{l=-\infty}^{\infty} \phi_{k,l} z_1^{-k} z_2^l \right\}.$$

Clearly, the elements of $H_{+,\infty}^2$ (respectively, of $H_{-,\infty}^2$) can be extended for almost all $z_2 \in T$ and for all $z_1 \in D$ (respectively, for all $z_1 \in (\overline{D})^c$). In the sequel, the elements of $H_{+,\infty}^2$ (respectively, of $H_{-,\infty}^2$) will be called 1-analytic (respectively, $1*$-analytic) functions. The subspaces $H_{\infty,+}^2$ and $H_{\infty,-}^2$ are deduced from the previous one by exchanging the role of z_1 and z_2. $H_{+,+}^2$ represents the space

$$H_{+,+}^2 = \left\{ \sum_{k=0}^{\infty} \sum_{l=0}^{\infty} \phi_{k,l} z_1^k z_2^l \right\}$$

and $H_{-,+}^2, H_{+,-}^2, H_{-,-}^2$ are defined similarly. The subspace of $H_{+,\infty}^2$ (respectively, of $H_{\infty,+}^2$) made of the functions not depending on z_2 (respectively, on z_1) is denoted by $H_+^2(T_1)$ (respectively, $H_+^2(T_2)$); $H_-^2(T_1)$ and $H_-^2(T_2)$ are defined similarly.

Finally, an all-pass function θ defined on T^2 is said to be 1-inner (respectively, $1*$-inner) if θ belongs to $H_{+,\infty}^2$ (respectively, to $H_{-,\infty}^2$). 2-inner and $2*$-inner functions are defined similarly. If ϕ is an element of $H_{+,\infty}^2$ and if α is a 1-inner function, then we say that α is a 1-inner divisor of ϕ if ϕ can be written as $\phi = \phi'\alpha$ for some element ϕ' of $H_{+,\infty}^2$. If α does not depend on z_2 (i.e., if α is inner), α is said to be an inner divisor of ϕ. If θ is a 1-inner function, ϕ and θ are said to be 1-coprime if they have no 1-inner common divisor; when θ depends only on z_1, ϕ and θ are said to be 1-weak coprime if ϕ and θ have no common inner divisor. The above definitions can be extended to the case where $\phi \in H_{-,\infty}^2$ and where θ is a $1*$-inner function, $\phi \in H_{\infty,+}^2$ and where θ is a 2-inner function, etc.

Let ϕ be a nonzero function of $\sigma_1^* \sigma_2^* H_{-,-}^2$, i.e.,

$$\phi(z_1, z_2) = \sum_{k \geq 1, l \geq 1} \phi_{k,l} z_1^{-k} z_2^{-l}.$$

Let us denote by Y the one-dimensional subspace of $K = L^2(T^2)$ generated by ϕ, and by X the space defined by

$$X = \overline{E^{\sigma_1^* \sigma_2^* H_{-,-}^2}(\overline{\phi H_{+,+}^2})}. \tag{54}$$

Clearly, X coincides with the range of the Hankel operator $\mathcal{H}_\phi$ defined by

$$\mathcal{H}_\phi \begin{array}{ccc} H_{+,+}^2 & \longrightarrow & \sigma_1^* \sigma_2^* H_{-,-}^2, \\ f & \longrightarrow & E^{\sigma_1^* \sigma_2^* H_{-,-}^2}(\phi f). \end{array} \tag{55}$$

Then, by Theorem 3.1, X is a FFMR of Y with respect to (σ_1, σ_2) (take $\overline{H} = \overline{\phi H^2_{+,+}}$, $H_1 = \sigma_1^* H^2_{-,\infty}$, $H_2 = \sigma_2^* H^2_{\infty,-}$); let us also mention that by §2, we get that $T_1 = E^X \sigma_{1|X}$ and $T_2 = E^X \sigma_{2|X}$ are commuting contractions admitting $(\sigma_1, \sigma_2, L^2(T^2))$ as regular minimal unitary dilation (by using the fact that a nonzero function of $\sigma_1^* \sigma_2^* H^2_{-,-}$ cannot be zero on a set of positive measure [20] and that every doubly invariant subspace H under σ_1 and σ_2 can be written as $H = 1_B L^2(T^2)$ for some Borel subset B of T^2 [8], it is easily seen that $Y_{\infty,\infty} = \overline{\phi L^2(T^2)} = L^2(T^2) = X_{\infty,\infty}$). Moreover, X is FF observable, regular, and by Lemma 3.2, its forward-forward innovation space Δ coincides with the one-dimensional subspace generated by the constant functions.

Let us now describe the spaces Z_1 and Z_2; as their properties are similar, we only give the results that are relative to Z_1. Let us begin by introducing the following functions $\phi_{2,k}$ (for $k \geq 1$) and $\phi_{1,l}$ (for $l \geq 1$) defined on T by

$$\phi_{2,k}(z_2) = \int_{[-\pi,\pi]} \phi(e^{i\omega_1}, z_2) e^{ik\omega_1} d\omega_1, \tag{56}$$

$$\phi_{1,l}(z_1) = \int_{[-\pi,\pi]} \phi(z_1, e^{i\omega_2}) e^{il\omega_2} d\omega_2. \tag{57}$$

Then, by an easy calculation, we get that

$$Z_1 = \bigvee_{k \geq 1} \overline{E}^{\sigma_2^* H^2_-(T_2)} (\overline{\phi_{2,k} H^2_+(T_2)}). \tag{58}$$

Let us now investigate the conditions under which X is coregular. In view of Lemma 3.1, we have to characterize the innovation spaces Δ_{fb} and Δ_{bf}. By Theorems 2.2 and 2.3, Z_1 is Markovian with respect to $\sigma_{2|(Z_1)_{0,\infty}}$ and its forward and backward innovation spaces coincide with Δ and Δ_{fb}, respectively. In particular, this implies that the space $(Z_1)_{0,-}$ is given by $(Z_1)_{0,-} = Z_1 \ominus \sigma_2^*(\Delta_{fb})_{0,-}$. On the other hand, it is easily seen that $\cap_{n \in Z} \sigma_2^n (Z_1)_{0,-} = \{0\}$; as Δ coincides with the space generated by the constant functions, we get that $(Z_1)_{0,-} = \sigma_2^* H^2_-(T_2)$ and that $(Z_1)_{0,\infty} = L^2(T_2)$. By classical arguments of multiplicity theory, it turns out that $\dim \Delta_{fb} = 0$ or 1. Therefore, it appears that $\dim \Delta_{fb} = 1$ if and only if the space Z_1 generated by the range of the Hankel operators associated with the one-variable functions $\phi_{2,k}$ for $k \geq 1$ does not coincide with $\sigma_2^*(H^2_-(T^2))$. This condition on ϕ is similar to the concept of noncyclicity introduced in [3] (see also [2], [6]), in the sense that it can be interpreted formally as the noncyclicity of the infinite-dimensional row-vector valued-function $(\phi_{2,1}, \ldots, \phi_{2,n}, \ldots)$. In the following, we shall say that a function satisfying the above property is 2-weakly noncyclic; 1-weakly noncyclic functions are defined similarly by exchanging the role of z_1 and z_2.

Clearly, the FFMR X is coregular if and only if the function ϕ is both 1-weakly and 2-weakly noncyclic. It is therefore useful to study in more details the 1-weakly and 2-weakly noncyclic functions. The following result can be seen as a generalization of the well known characterization of one-variable noncyclic functions (see [3]).

PROPOSITION 3.1. *Let ϕ be an element of $\sigma_1^* \sigma_2^* H^2_{-,-}$. Then ϕ is 2-weakly noncyclic if and only if there exists a $*$-inner function ω_2 and a function $\psi \in \sigma_1^* H^2_{-,+}$ for which*

$$\phi(z_1, z_2) = \psi(z_1, z_2) \omega_2(z_2). \tag{59}$$

In this case, there exists a unique pair $(\phi_{-,+}, \theta_2)$ (where $\phi_{-,+} \in \sigma_1^* H^2_{-,+}$ and where θ_2 is a $*$-inner function) satisfying

$$\phi(z_1, z_2) = \phi_{-,+}(z_1, z_2) \theta_2(z_2), \tag{60}$$

(61) $\phi_{-,+}$ *and* θ_2^* $2-$ *weak coprime.*

Moreover, θ_2 *is uniquely defined by the fact that*

(62) $$\bigvee_{k\geq 1} \overline{E^{\sigma_2^* H_-^2(T_2)}(\overline{\phi_{2,k} H_+^2(T_2)})} = \sigma_2^*(H_-^2(T_2) \ominus \theta_2 H_-^2(T_2)).$$

Proof. See the Appendix.

3.2. Spectral considerations. In this section we restrict ourselves to the case where Y is a one-dimensional subspace; moreover, we will only be concerned with internal representations, so that the Hilbert space K on which are defined U_1 and U_2 will be supposed to be $Y_{\infty,\infty}$. In order to make more concrete what follows, we present our results in the framework of the two-parameter wide-sense stationary stochastic processes theory.

Let $y = (y_{m,n})_{(m,n)\in Z^2}$ be a centered two-parameter wide-sense stationary stochastic process, that is, a sequence of complex-valued centered square integrable random variables for which $E(y_{m+k,n+l} y_{k,l}^*)$ depends only on (m,n)(E denotes the mathematical expectation in this context). We suppose that K is the Hilbert space generated by the variables $y_{m,n}$ for $(m,n) \in Z^2$, endowed with the scalar product $\langle z_1, z_2\rangle = E(z_1, z_2^*)$. U_1 and U_2 are the horizontal and vertical shift operators associated to y, that is the commuting unitary operators defined on K by $U_1 y_{m,n} = y_{m+1,n}$ and $U_2 y_{m,n} = y_{m,n+1}$ for each $(m,n) \in Z^2$. Let us put $Y = sp(y_{0,0})$; then, we are concerned with the study of the (FF)MR of Y with respect to (U_1, U_2).

Before going further, let us recall some basic definitions related to the stochastic process y. If E_1 and E_2 are the spectral families of U_1 and U_2 defined on $[-\pi,\pi]$, the random spectral measure $\hat{y}$ of y if the K-valued orthogonally scattered measure whose differential element is given by $d\hat{y}(\omega_1,\omega_2) = dE_1(\omega_1) dE_2(\omega_2) y_{0,0}$. Then, it is well known that y has the following so-called spectral representation:

$$y_{m,n} = \int_{[-\pi,\pi]^2} e^{i(m\omega_1 + n\omega_2)} d\hat{y}(\omega_1,\omega_2).$$

The positive bounded measure μ defined on the Borel sets of $[-\pi,\pi]^2$ by the differential element $d\mu(\omega_1,\omega_2) = E|d\hat{y}(\omega_1,\omega_2)|^2$ is called the spectral measure of y. In what follows, we shall suppose that μ is absolutely continuous with respect to the Lebesgue measure, and that its spectral density $F(\omega_1,\omega_2)$ satisfies the Szegö condition

(63) $$\int_{[-\pi,\pi]^2} LogF(\omega_1,\omega_2) d\omega_1 d\omega_2 > -\infty.$$

In this case, the process y is purely nondeterministic with respect to the prediction problems associated to the lexicographical-like orderings of Z^2 (see [9], for example). In particular, the spaces $\cap_{m\in Z} U_1^m Y_{-,\infty} = \cap_{n\in Z} U_2^n Y_{\infty,-} = \{0\}$.

We begin by showing that there do not necessarily exist nontrivial FFMR of Y, which will demonstrate the claim of §3.1. This follows from the fact that the existence of a nontrivial pair of subspaces (H_1, H_2) containing Y and satisfying conditions (43) and (44) is not guaranteed (see Theorem 3.1). More precisely, we have the following result.

PROPOSITION 3.2. *There exists a nontrivial pair* (H_1, H_2) *containing* Y *and satisfying conditions* (43) *and* (44) *if and only if there exists a function* $\phi \in \sigma_1^* \sigma_2^* H_{-,-}^2$ *for which*

(64) $$F(\omega_1,\omega_2) = |\phi(e^{i\omega_1}, e^{i\omega_2})|^2.$$

In order to demonstrate this result, we give the following lemma whose proof is given in the Appendix.

LEMMA 3.3. *Let* (H_1, H_2) *be two subspaces of* $Y_{\infty,\infty}$ *satisfying* (43) *and* (44), *and for which*

$$\bigvee_{m\in Z} U_1^m H_1 = \bigvee_{n\in Z} U_2^n H_2 = Y_{\infty,\infty}. \tag{65}$$

Then, one of the two following conditions holds.

$$H_1 = Y_{\infty,\infty} \quad or \quad H_2 = Y_{\infty,\infty}, \tag{66}$$

$$\bigcap_{m\in Z} U_1^m H_1 = \bigcap_{n\in Z} U_2^n H_2 = \{0\}. \tag{67}$$

If (67) *holds, then*

$$H_1 \cap H_2 = \oplus_{(k,l)=1,\infty} U_1^{*k} U_2^{*l} \Delta, \tag{68}$$

where Δ *is the wandering subspace for* (U_1, U_2) *defined by*

$$\Delta = (U_1 H_1 \ominus H_1) \cap (U_2 H_2 \ominus H_2). \tag{69}$$

Now, we prove the proposition. Let us suppose the existence of a nontrivial FFMR of Y, i.e., the existence of a nontrivial pair of subspaces (H_1, H_2) containing Y and satisfying (43) and (44). Let us denote by X the FF-observable FFMR given by

$$X = \overline{E}^{H_1 \cap H_2}(Y_{+,+}).$$

As Y is included in H_1 and H_2, the pair (H_1, H_2) satisfies (65). By Lemma 3.3, we deduce that condition (67) holds. The wandering subspace Δ given by (69) is therefore not reduced to $\{0\}$; as the pair (U_1, U_2) has multiplicity one, Δ is one-dimensional. Let $\nu_{0,0}$ be a unit vector of Δ and put $\nu_{m,n} = U_1^m U_2^n \nu_{0,0}$; then, $\nu = (\nu_{m,n})_{(m,n)\in Z^2}$ is a white noise sequence satisfying $H_1 \cap H_2 = sp(\nu_{-k,-l}/k \geq 1, l \geq 1)$. This implies that the FFMR X is regular; moreover, as $y_{0,0}$ belongs to X, there exists a square summable sequence $(\phi_{k,l})_{k\geq 1, l\geq 1}$ such that

$$y_{0,0} = \sum_{k=1}^{\infty} \sum_{l=1}^{\infty} \phi_{k,l} \nu_{-k,-l}.$$

Put $\phi(z_1, z_2) = \sum_{k=1}^{\infty} \sum_{l=1}^{\infty} \phi_{k,l} z_1^{-k} z_2^{-l}$. Then, ϕ belongs to $\sigma_1^* \sigma_2^* H^2_{-,-}$, and $F(\omega_1, \omega_2) = |\phi(e^{i\omega_1}, e^{i\omega_2})|^2$.

Conversely, let us suppose the existence of a function $\phi \in \sigma_1^* \sigma_2^* H^2_{-,-}$ satisfying (64). Then, the wide-sense stationary process ν defined by the fact that $d\hat{\nu}(\omega_1, \omega_2) = \phi^{-1}(e^{i\omega_1}, e^{i\omega_2}) d\hat{y}(\omega_1, \omega_2)$ is a white noise. Let us put $\Delta = sp(\nu_{0,0})$; then, it is clear that Δ is wandering for (U_1, U_2) and that $y_{0,0} \in U_1^* U_2^* \Delta_{-,-}$. From this, we deduce immediately that the spaces H_1 and H_2 defined by $H_1 = U_1^* \Delta_{-,\infty}$ and $H_2 = U_2^* \Delta_{\infty,-}$ contain Y and satisfy (43) and (44). □

Proposition 3.2 implies that Y do not necessarily admit nontrivial FFMR. In fact, by a trivial modification of exercise 3.4.5, [20, p. 56] there exist spectral densities satisfying the Szegö condition, but which are not factorable by an element of $\sigma_1^* \sigma_2^* H^2_{-,-}$. Obviously, it would be interesting to derive the necessary and sufficient conditions on F for the existence of a spectral factor belonging to $\sigma_1^* \sigma_2^* H^2_{-,-}$. According to [20], this point seems to be an open problem. Let us mention however two sufficient conditions.

- $F > 0$, bounded and lower semi-continuous ([20, p. 55]).
- $\int_{[-\pi,\pi]^2} LogF(\omega_1,\omega_2)e^{i(m\omega_1+n\omega_2)}d\omega_1 d\omega_2 = 0$ for $mn < 0$. ([17, Lemma A1], [24], [12]).

This last condition is equivalent to the equality of the two innovation processes corresponding to the prediction problems associated to the column-by-column, and row-by-row lexicographical ordering of Z^2, respectively [12]. In this case, $Y_{-,\infty}$ and $Y_{\infty,-}$ intersect perpendicularly [24], [12], so that the space $\overline{E}^{Y_{-,\infty}\cap Y_{\infty,-}}(Y_{+,+})$ is an FFMR which is easily seen to be minimal.

Let us formulate some remarks concerning Proposition 3.2 and Lemma 3.3. First, it follows from Lemma 3.3 that an FFMR is nontrivial if and only if it is regular. Second, paralleling the proof of Proposition 3.2, it is easily seen that it is possible to associate to each regular FFMR X a spectral factor $\phi \in \sigma_1^*\sigma_2^* H^2_{-,-}$ defined by the fact that $d\hat{y}(\omega_1,\omega_2) = \phi(e^{i\omega_1}, e^{i\omega_2})d\hat{\nu}(\omega_1,\omega_2)$, where ν is a white noise sequence for which $\mathrm{sp}(\nu_{0,0})$ coincides with the FF innovation space of X. In the following, ϕ and ν will be called the forward-forward spectral factor of X and the forward-forward innovation process of X, respectively.

Let us now investigate under which conditions there exist nontrivial MR of Y; here, we mean by non trivial an MR in which none of the four internal subspaces defined by (45) coincide with $Y_{\infty,\infty}$. For this purpose, we need to introduce the following useful notation: if $\nu = (\nu_{m,n})_{(m,n)\in Z^2}$ is a (scalar) white noise sequence for which $Y_{\infty,\infty} = sp(\nu_{m,n}/(m,n) \in Z^2)$ (the existence of such a white noise is guaranteed by the Szegö condition), then we denote by Q_ν the unitary operator defined by

$$(70) \qquad Q_\nu \begin{array}{ccc} L^2(T^2) & \longrightarrow & Y_{\infty,\infty}, \\ h & \longrightarrow & \int_{[-\pi,\pi]^2} h(e^{i\omega_1}, e^{i\omega_2})d\hat{\nu}(\omega_1,\omega_2). \end{array}$$

PROPOSITION 3.3. *There exists a nontrivial* MR *of Y if and only if the spectral density F is factorable by a* 1- *and* 2-*weakly noncyclic function ϕ belonging to $\sigma_1^*\sigma_2^* H^2_{-,-}$.*

Proof. Suppose that $X = H_1 \cap H_2 \cap \overline{H_1} \cap \overline{H_2}$ is a nontrivial MR of Y. Then, by Lemma 3.3 applied to the pairs $(H_1,H_2),(H_1,\overline{H_2}),(\overline{H_1},H_2)$, we get that $\cap_{m\in Z} U_1^m H_1 = \cap_{n\in Z} U_2^n H_2 = \cap_{m\in Z} U_1^m \overline{H_1} = \cap_{n\in Z} U_2^n \overline{H_2} = \{0\}$. This implies that X is a regular and coregular MR; therefore, the FF-observable FFMR $X^0 = \overline{E}^X(Y_{+,+})$ is also regular and coregular. Let ϕ be its associated FF spectral factor, and let us denote by ν its FF innovation process. Then, it is clear that $X^0 = Q_\nu(\mathrm{Range}\mathcal{H}_\phi)$, where $\mathcal{H}_\phi$ is the Hankel operator defined by (55). Therefore, in view of the considerations concerning the fundamental example of §3.1, the fact that X^0 is coregular implies that ϕ is 1- and 2-weakly noncyclic.

Conversely, let us assume the existence of a 1- and 2-weakly noncyclic element ϕ of $\sigma_1^*\sigma_2^* H^2_{-,-}$ for which (64) holds. Then, there exist two $*$-inner functions θ_1 and θ_2 such that $\phi\theta_1^* \in \sigma_2^* H^2_{+,-}$ and $\phi\theta_2^* \in \sigma_1^* H^2_{-,+}$. Let ν be the white noise sequence defined by the fact that $d\hat{y}(\omega_1,\omega_2) = \phi(e^{i\omega_1}, e^{i\omega_2})d\hat{\nu}(\omega_1,\omega_2)$; then it is easily seen that the space X defined by

$$(71) \qquad X = Q_\nu[\sigma_1^* H^2_{-,\infty} \cap \sigma_2^* H^2_{\infty,-} \cap \theta_1 H^2_{+,\infty} \cap \theta_2 H^2_{\infty,+}]$$

$$(72) \qquad = Q_\nu[\sigma_1^*(H^2_-(T_1) \ominus \theta_1 H^2_-(T_1)) \otimes \sigma_2^*(H^2_-(T_2) \ominus \theta_2 H^2_-(T_2))]$$

(where $\otimes$ represents the Hilbertian tensor product) is a nontrivial (or equivalently, regular and coregular) MR of Y. □

Proposition 3.3 shows that the Markovian representation problem studied in this paper makes sense when the spectral density F of y is supposed to admit 1- and 2-weakly noncyclic spectral factor belonging to $\sigma_1^*\sigma_2^* H^2_{-,-}$. Therefore, we shall suppose from now

on that y satisfies this condition. This occurs, for example, if F can be written as

$$F(\omega_1,\omega_2)=\left|\sum_{k=0}^{M}\sum_{l=0}^{N}b_{k,l}e^{-i(k\omega_1+l\omega_2)}\right|^2 F_1(\omega_1)F_2(\omega_2), \tag{73}$$

where F_1 and F_2 are one-variable noncyclic spectral densities. In particular, it is easily seen that the processes admitting finite-dimensional (FF)MR are precisely those whose spectral densities are given by (73) with F_1 and F_2 rational.

Before giving the main results of this subsection, we need to introduce the notion of structural function of a regular and coregular (FF)MR; the terminology originates from [14]. Let X be a regular and coregular FFMR, and let us denote by ϕ and ν its FF spectral factor and its FF innovation process. By Theorems 2.2 and 2.3, the space $(Z_1)_{0,-}$ can be written as $(Z_1)_{0,-}=Z_1\oplus U_2^*(\Delta_{fb})_{0,-}$. As X is regular and coregular, $(Z_1)_{0,-}=U_2^*\Delta_{0,-}$, and Δ_{fb} is one-dimensional. Let ν^{fb} be a white noise sequence for which $\Delta_{fb}=sp(\nu_{0,0}^{fb})$, that we shall call the forward-backward innovation process of X. Then, as $U_2^*(\Delta_{fb})_{0,-}$ is included in $(Z_1)_{0,-}=U_2^*\Delta_{0,-}$, there exists a (uniquely-defined) $*$-inner function π_2 for which

$$d\hat{\nu}^{fb}(\omega_1,\omega_2)=\pi_2(e^{i\omega_2})d\hat{\nu}(\omega_1,\omega_2). \tag{74}$$

Similarly, there exists a uniquely defined $*$-inner function π_1 for which

$$d\hat{\nu}^{bf}(\omega_1,\omega_2)=\pi_1(e^{i\omega_1})d\hat{\nu}(\omega_1,\omega_2), \tag{75}$$

where ν^{bf} represents the backward-forward innovation process of X. In the sequel, we shall call π_1 and π_2 the structural functions of the FFMR X. Let us derive some properties of the structural functions. First, $\phi\pi_1^*$ belongs to $\sigma_2^*H^2_{+,-}$ and $\phi\pi_2^*$ belongs to $\sigma_1^*H^2_{-,+}$. In fact, by Lemma 3.1 the space $X_{-,+}$ coincides with $U_1^*(\Delta_{fb})_{-,+}$; as $y_{0,0}$ belongs to $X_{-,+}$, there exists a function $\phi^{fb}\in\sigma_1^*H^2_{-,+}$ (that we shall call the forward-backward spectral factor of K) such that

$$d\hat{y}(\omega_1,\omega_2)=\phi^{fb}(e^{i\omega_1},e^{i\omega_2})d\hat{\nu}^{fb}(\omega_1,\omega_2). \tag{76}$$

The conclusion follows immediately from the fact that $\phi\pi_2^*=\phi^{fb}$. Similarly, $\phi\pi_1^*$ coincides with the backward-forward spectral factor ϕ^{bf} of X, so that $\phi\pi_1^*\in\sigma_2^*H^2_{+,-}$.

Let us discuss now on the functional models based on π_1 and π_2. First, it is clear that $X_{-,\infty}=Q_\nu(\sigma_1^*H^2_{-,\infty})$ and that $X_{\infty,-}=Q_\nu(\sigma_2^*H^2_{\infty,-})$. Next, by Lemma 3.1, we get that $X_{+,\infty}=Q_\nu(\pi_1H^2_{+,\infty})$ and that $X_{\infty,+}=Q_\nu(\pi_2H^2_{\infty,+})$. By Theorem 3.2, it follows that the space $\tilde{X}=X_{-,\infty}\cap X_{\infty,-}\cap X_{+,\infty}\cap X_{\infty,+}$ is a MR of Y given by

$$\tilde{X}=Q_\nu[\sigma_1^*H^2_{-,\infty}\cap\sigma_2^*H^2_{\infty,-}\cap\pi_1H^2_{+,\infty}\cap\pi_2H^2_{\infty,+}] \tag{77}$$

$$=Q_\nu[\sigma_1^*(H^2_-(T_1)\ominus\pi_1H^2_-(T_1))\otimes\sigma_2^*(H^2_-(T_2)\ominus\pi_2H^2_-(T_2))]. \tag{78}$$

But again by Theorem 3.2, X is a MR if and only if X coincides with $\tilde{X}$ so that (78) gives a functional model for the regular and coregular MR of Y. This discussion also shows that the structural functions of a FFMR X depends only on the four subspaces $X_{-,\infty},X_{\infty,-},X_{+,\infty},X_{\infty,+}$, so that π_1 and π_2 do not characterize X, except in the case where X is a MR. In particular, the derivation of a general functional model for FFMR seems to be a difficult problem. However, if X is FF observable, then it is clear that

$$X=Q_\nu(\text{Range}(\mathcal{H}_\phi)). \tag{79}$$

But, this functional model is not very informative because the structure of the range of a two-dimensional Hankel operator is more complicated than in the one-dimensional case. In fact, the space $\sigma_1^*\sigma_2^* H^2_{-,-} \ominus \text{Range}(\mathcal{H}_\phi)$ is invariant by σ_1^* and σ_2^*, but except in situations similar to that of Proposition 1.1, Beurling's theorem has no extension to the two variable functions case. Let us finally mention the fact that the second structural function π_2 of a FF observable FFMR coincide with the $*$-inner function θ_2 defined by (62); similarly, π_1 is equal to the $*$-inner function θ_1 defined as θ_2 by exchanging the role of z_1 and z_2. However, the converse is not true, i.e., if the structural functions of a certain FFMR coincide with θ_1 and θ_2, then it is not necessarily FF observable.

Now, we present the main result of this section (Theorem 3.3), i.e., an explicit spectral characterization of a wide class of minimal FFMR and MR. It is obtained under the following assumption $\mathcal{A}$ on y which is somewhat more restrictive than the existence of nontrivial MR.

$\mathcal{A}$. The process y admits at least one nontrivial (i.e., regular and coregular) MR whose structural functions are Blaschke products.

Theorem 3.3 to be presented below is based on the fact that a regular and coregular MR $\tilde{X}$ whose structural functions are Blaschke products is minimal if and only if the "one-parameter" Markovian representations $\tilde{X}_{0,\infty}$ and $\tilde{X}_{\infty,0}$ of $Y_{0,\infty}$ and of $Y_{\infty,0}$ respectively, are themselves minimal. This fundamental result does not come from purely geometrical considerations. In fact, it follows from the particular properties of the functional models associated to the minimal doubly invariant under U_2 (respectively, U_1) Markovian representations of $Y_{0,\infty}$ (respectively of $Y_{\infty,0}$) when assumption $\mathcal{A}$ holds. In order to present these properties, we begin by giving general results (i.e., not depending on assumption $\mathcal{A}$) concerning the spectral description of the doubly invariant under U_2 Markovian representations of $Y_{0,\infty}$ with respect to U_1. The results which are relative to the doubly invariant under U_1 Markovian representations of $Y_{\infty,0}$ with respect to U_2 are similar. It is worth mentioning that as $Y_{0,\infty}$ is infinite-dimensional, the spectral description of [14] cannot be directly used. However, the fact that $Y_{0,\infty}$ and the considered Markovian spaces are doubly invariant under U_2 makes possible to immediately generalize the spectral analysis of [14].

PROPOSITION 3.4. *Let us suppose that the spectral density of y satisfies the Szegö condition, and that $Y_{0,\infty}$ admits at least one regular and coregular doubly invariant under U_2 Markovian representation. Let Z be such a regular and coregular* MR *of $Y_{0,\infty}$. Then, there exists a unique (up to an all pass function of z_2) pair of spectral factors $(\phi, \overline{\phi})$ of F such that*

- $\phi \in \sigma_1^* H^2_{-,\infty}, \overline{\phi} \in H^2_{+,\infty}$;
- $\theta(z_1, z_2) = \phi(z_1, z_2)/\overline{\phi}(z_1, z_2)$ *is a $1*$-inner function, called the structural function of Z.*

The white noise sequences $\nu, \overline{\nu}$ defined by the fact that $d\hat{y}(\omega_1, \omega_2) = \phi(e^{i\omega_1}, e^{i\omega_2})$ $d\hat{\nu}(\omega_1, \omega_2) = \overline{\phi}(e^{i\omega_1}, e^{i\omega_2}) d\hat{\overline{\nu}}(\omega_1, \omega_2)$ are such that $Z_{-,0} = U_1^* \nu_{-,\infty}$ and $Z_{+,0} = \overline{\nu}_{+,\infty}$. Moreover, Z is given by

$$Z = Q_\nu[\sigma_1^*(H^2_{-,\infty} \ominus \theta H^2_{-,\infty})] = Q_{\overline{\nu}}[H^2_{+,\infty} \ominus \theta^* H^2_{+,\infty}]; \tag{80}$$

- *Z is observable (i.e., $Z = \overline{E}^Z(Y_{+,\infty})$) if and only if $\overline{\phi}$ and θ^* are 1-coprime;*
- *Z is constructible (i.e., $Z = \overline{E}^Z(Y_{-,\infty})$) if and only if ϕ and θ are 1-coprime;*
- *All minimal doubly invariant under U_2 Markovian representations of $Y_{0,\infty}$ with respect to U_1 are regular, coregular, and they have the same structural function.*

Taking Lemma A.1 (below) as a starting point, Proposition 3.4 can be proved along the lines of [14]. The details are left to the reader.

If y satisfies assumption $\mathcal{A}$, the following fundamental result holds.

LEMMA 3.4. *Let us suppose that assumption $\mathcal{A}$ holds. Then, the structural function of the minimal doubly invariant under U_2 (respectively, U_1) Markovian representations of $Y_{0,\infty}$ with respect to U_1 (respectively, of $Y_{\infty,0}$ with respect to U_2) is a one-variable function $q_1(z_1)$ (respectively, $q_2(z_2)$).*

We are now in position to give the main result of this subsection.

THEOREM 3.3. *Let $\tilde{X}$ be a regular and coregular* MR *of Y with respect to (U_1, U_2), whose structural functions π_1 and π_2 are Blaschke products. Then, $\tilde{X}$ is minimal if and only if the "one-parameter" Markovian representations $\tilde{X}_{0,\infty}$ and $\tilde{X}_{\infty,0}$ of $Y_{0,\infty}$ and of $Y_{\infty,0}$, respectively, are themselves minimal, or equivalently if and only if $\pi_1 = q_1$ and $\pi_2 = q_2$. In this case, the* FF *observable* FFMR *X given by*

$$X = \overline{E}^{\tilde{X}}(Y_{+,+}) \tag{81}$$

is a minimal FFMR.

The proofs of Lemma 3.4 and of Theorem 3.3 are given in the Appendix.

Let us discuss this result. First, it appears that the minimal MR can be characterized in a rather satisfying way. Next, Theorem 3.3 shows that all the minimal MR of Y whose structural functions are Blaschke products are unitarily equivalent. In particular, if there exist finite-dimensional MR of Y, then all the minimal finite-dimensional MR have the same dimension. The results concerning the FFMR are less powerful. Although Theorem 3.3 allows to exhibit a wide class of minimal FFMR (i.e., those that are contained in a minimal MR), the characterization problem of all minimal FFMR remains open. The difficulty of this question is undoubtly related to the fact that the functional model given by (79) is not very informative, due to the complicated structure of the ranges of two-dimensional Hankel operators. Let us also mention the fact that when there exist finite-dimensional (FF)MR, there may exist minimal FFMR whose dimension do not coincide (see below).

In order to illustrate Theorem 3.3, let us consider the following simple example.

Let us suppose that y is given by $d\hat{y}(\omega_1, \omega_2) = \phi(e^{i\omega_1}, e^{i\omega_2}) d\hat{\nu}(\omega_1, \omega_2)$, where ν is a white noise and where ϕ is the element of $\sigma_1^* \sigma_2^* H^2_{-,-}$ given by

$$\phi(z_1, z_2) = \frac{1}{(z_1 - a_1)(z_2 - a_2)} + \frac{1}{(z_1 - b_1)(z_2 - b_2)},$$
$$|a_i| < 1, |b_i| < 1, a_1 \neq a_2, b_1 \neq b_2, a_i \neq b_j, (i, j) = 1, 2.$$

Then, it is obvious that the two-dimensional space X defined by

$$X = Q_\nu(\text{Range}(\mathcal{H}_\phi)) = Q_\nu \left[sp \left(\frac{1}{(z_1 - a_1)(z_2 - a_2)}, \frac{1}{(z_1 - b_1)(z_2 - b_2)} \right) \right]$$

is a regular and coregular FF observable FFMR whose structural functions θ_1 and θ_2 are given by

$$\theta_i(z_i) = \frac{1 - a_i^* z_i}{z_i - a_i} \frac{1 - b_1^* z_i}{z_i - b_i}, \qquad i = 1, 2.$$

On the other hand, it is easily seen that θ_1 and θ_2 coincide with the structural functions q_1 and q_2 introduced in Lemma 3.4. From this, we deduce that the four dimensional space $\tilde{X} = X_{-,\infty} \cap X_{\infty,-} \cap X_{+,\infty} \cap X_{\infty,+} = Q_\nu[\sigma_1^*(H^2_-(T_1) \ominus \theta_1 H^2_-(T_1)) \otimes \sigma_2^*(H^2_-(T_2) \ominus \theta_2 H^2_-(T_2))]$ is a minimal MR, and that X, which coincides $X = \overline{E}^{\tilde{X}}(Y_{+,+})$, is a minimal FFMR of Y.

Let us now exhibit a minimal FFMR X' whose dimension is four. ϕ can be written as

$$\phi(z_1,z_2)=\frac{N(z_1,z_2)}{(z_1-a_1)(z_1-b_1)(z_2-a_2)(z_2-b_2)}.$$

Let $N'(z_1,z_2)$ be the polynomial defined by $N'(z_1,z_2)=z_1z_2(N(1/z_1^*,1/z_2^*))^*$, and put

$$\phi'(z_1,z_2)=\frac{N'(z_1,z_2)}{(z_1-a_1)(z_1-b_1)(z_2-a_2)(z_2-b_2)}.$$

Then, ϕ' belongs to $\sigma_1^*\sigma_2^*H^2_{-,-}$ and represents a spectral factor of the spectral density of y. Let us consider the white noise ν' defined by the fact that $d\hat{y}(\omega_1,\omega_2)=\phi'(e^{i\omega_1},e^{i\omega_2})\,d\hat{\nu}'(\omega_1,\omega_2)$. It is easily seen that the space $X'=Q_{\nu'}(\text{Range}(\mathcal{H}_{\phi'}))$ is a minimal FF observable FFMR of Y; but, one can check that there always exist $(a_i,b_i)_{i=1,2}$ for which $\text{Range}(\mathcal{H}_{\phi'})$ is the four dimensional space $Q_{\nu'}[\sigma_1^*(H^2_-(T_1)\ominus\theta_1H^2_-(T_1))\otimes\sigma_2^*(H^2_-(T_2)\ominus\theta_2H^2_-(T_2))]$. In this case, $\dim X'=4$, so that X and X' are two minimal FFMR whose dimensions are not equal.

More generally, a process y may admit a unique minimal dimension FFMR although there always exist more than one minimal FFMR in the geometric sense; in this particular case, the stochastic realization algorithm derived by Attasi allows the calculation of the corresponding spectral factor. When there exist more than one minimal dimension FFMR, the calculation of the parameters of a stochastic realization seems to be an open problem.

Appendix.

Proof of Theorem 2.2. As $(Z_1)_{0,-}$ is included in $X_{\infty,-}$, it is sufficient to establish that $X_{\infty,-}$ and $(Z_1)_{0,+}$ are conditionally orthogonal given Z_1 in order to demonstrate (31). For this purpose, we have to show that $E^{X_{\infty,-}}U_2^n(U_1x-T_1x)$ belongs to Z_1 for all $n\geq 0$, for all $x\in X$. $E^{X_{\infty,-}}U_2^n(U_1x-T_1x)=E^{X_{\infty,-}}U_2^nU_1x-E^{X_{\infty,-}}U_2^nT_1x=U_1E^{X_{\infty,-}}U_2^nx-E^{X_{\infty,-}}U_2^nT_1x$. But, $E^{X_{\infty,-}}U_2^nx=T_2^nx$ and $E^{X_{\infty,-}}U_2^nT_1x=T_2^nT_1x=T_1T_2^nx$. Therefore, $E^{X_{\infty,-}}U_2^n(U_1x-T_1x)=(U_1-T_1)T_2^nx$, and thus belongs to Z_1. The above equality for $n=1$ also shows that Z_1 is invariant under S_2, and that the Markovian transition operator of Z_1 coincides with $S_{2|Z_1}$.

In order to establish that Z_1 is invariant under S_2^*, let us begin by showing that S_2^*x coincides with $E^{X_{-,0}}U_2^*x$, for all $x\in X$. In fact, $S_2^*x=E^{X_{\infty,0}}U_2^*x=E^{X_{\infty,0}}E^{X_{-,\infty}}U_2^*x$. As the subspaces $X_{\infty,-}, X_{\infty,+}, X_{-,\infty}$ intersect perpendicularly two by two, and as $X_{\infty,0}=X_{\infty,-}\cap X_{\infty,+}$, S_2^*x is equal to $E^{X_{\infty,-}\cap X_{\infty,+}\cap X_{-,\infty}}U_2^*x$, which coincides with $E^{X_{-,0}}U_2^*x$ by (25). In particular, $U_1S_2^*x$ belongs to $U_1X_{-,0}$. By using the same kind of arguments, it can be shown that $S_2^*T_1x=E^{X_{-,0}}U_1S_2^*x$, for all $x\in X$. Therefore, $S_2^*(U_1x-T_1x)$ coincides with $U_1S_2^*x-E^{X_{-,0}}U_1S_2^*x$, from which we deduce that $E^{X_{-,0}}S_2^*(U_1x-T_1x)=0$. On the other hand, $S_2^*(U_1x-T_1x)$ belongs to $U_1X_{-,0}$, which implies that $S_2^*(U_1x-T_1x)$ is an element of $U_1X_{-,0}\ominus X_{-,0}$. But as this last subspace is equal to Z_1, we get that Z_1 is invariant under S_2^*.

Proof of Theorem 2.3. Let us begin by showing that the space Δ given by (32) coincides with the forward innovation space of Z_1. For all $x\in X$, $(U_1U_2-U_1T_2-U_2T_1+T_1T_2)x=U_2(U_1-T_1)x-(U_1-T_1)T_2x$. But, $U_1T_2x=S_2U_1x$ and $T_1T_2x=T_2T_1x$, so that $(U_1U_2-U_1T_2-U_2T_1+T_1T_2)x$ is equal to $(U_2-S_2)(U_1-T_1)x$. This establishes (33); (34) is shown similarly. Let us show now that Δ coincides with the wandering subspace $(U_1X_{-,\infty}\ominus X_{-,\infty})\cap(U_2X_{\infty,-}\ominus X_{\infty,-})$. For this purpose, we remark that as (19) holds, then, by Proposition 1.1, the above wandering subspace is equal to$U_2(U_1X_{-,-}\ominus X_{-,-})\ominus(U_1X_{-,-}\ominus X_{-,-})$. But, it is easily seen that $U_1X_{-,-}\ominus X_{-,-}=(Z_1)_{0,-}$, from which we deduce that $(U_1X_{-,\infty}\ominus X_{-,\infty})\cap(U_2X_{\infty,-}\ominus X_{\infty,-})=U_2(Z_1)_{0,-}\ominus(Z_1)_{0,-}=\Delta$. Equation

(35) (respectively, (36)) can be deduced in a similar way from (20) (respectively, (21)) and from Proposition 1.1 applied to the pair (U_1, U_2^*) (respectively, to the pair (U_1^*, U_2)).

Proof of Lemma 3.1. Let us begin by remarking that as $X_{0,\infty}$ is a Markovian space with respect to U_1, (49) and (51) hold if and only if [25] the operator S_1 belongs to the class $C_{0,0}$ (i.e., S_1^m and S_1^{*m} converge strongly to zero as $m \to \infty$). Equations (50) and (52) are characterized in a similar way. Let X be a regular FFMR; then, let us show that X is coregular if and only if $S_{1|Z_2}$ and $S_{2|Z_1}$ belong to the class $C_{0,0}$. The direct part is obvious. Conversely, let us assume that $S_{1|Z_2}$ and $S_{2|Z_1}$ belong to the class $C_{0,0}$. As X is regular, $\cap_{m\in Z} U_1^m X_{-,+} = \{0\}$, so that $X_{-,+} = \oplus_{k\geq 1} U_1^{*k}(U_1 X_{-,+} \ominus X_{-,+})$. But, it is easily seen that $U_1 X_{-,+} \ominus X_{-,+} = (Z_1)_{0,+}$. As $S_{2|Z_1}$ belong to the class $C_{0,0}$, $(Z_1)_{0,+} = (\Delta_{fb})_{0,+}$ [25], from which we get that $X_{-,+} = U_1^*(\Delta_{fb})_{-,+}$, and that $X_{\infty,+} = (\Delta_{fb})_{\infty,+}$; this implies (51). Similarly, the fact that $S_{1|Z_2}$ belongs to the class $C_{0,0}$ implies (52), that $X_{+,-} = U_2^*(\Delta_{bf})_{+,-}$, and that $X_{+,\infty} = (\Delta_{bf})_{+,\infty}$. The first statement of the lemma follows from the well known fact [25] that if $\dim\Delta < \infty$, then $S_{2|Z_1}$ (respectively, $S_{1|Z_2}$) belongs to the class $C_{0,0}$ if and only if $\dim\Delta = \dim\Delta_{fb}$ (respectively, $\dim\Delta = \dim\Delta_{bf}$).

Proof of Proposition 3.1. Let us suppose that (59) is satisfied. Then, $\phi_{2,k}(z_2) = \psi_{2,k}(z_2)\omega_2(z_2)$, for all $k \geq 1$, where $\psi_{2,k}$ is the element of $H_+^2(T_2)$ defined in the same fashion that $\phi_{2,k}$. From this, we deduce that the range of the Hankel operator associated to $\phi_{2,k}$ is included in $\sigma_2^*(H_-^2(T_2) \ominus \omega_2 H_-^2(T_2))$ for all $k \geq 1$, and that the space Z_1 given by (58) does not coincide with $\sigma_2^* H_-^2(T_2)$. Conversely, if ϕ is 2-weakly noncyclic, then the space $\sigma_2^*(\Delta_{fb})_{0,-}$ is a nonzero subspace of $\sigma_2^* H_-^2(T_2)$ invariant under σ_2^*. By Beurling's theorem, there exists a uniquely defined $*$-inner function θ_2 for which (62) holds. From this, we get that for all $k \geq 1$, $\phi_{2,k}(z_2)$ can be written as $\phi_{2,k}(z_2) = \overline{\phi}_k(z_2)\theta_2(z_2)$ for some element ϕ_k of $H_+^2(T_2)$. Let $\phi_{-,+}$ be the function of $\sigma_1^* H_{-,+}^2$ defined by

$$\phi_{-,+}(z_1, z_2) = \sum_{k\geq 1} \overline{\phi}_k(z_2) z_2^{-k}.$$

Then, $\phi(z_1, z_2) = \phi_{-,+}(z_1, z_2)\theta_2(z_2)$. Let us show that $\phi_{-,+}$ and θ_2^* are 2-weak coprime. For this purpose, let us assume that there exist two $*$-inner functions α and β, and an element $\psi(z_1, z_2)$ of $\sigma_1^* H_{-,+}^2$ such that $\phi_{-,+}(z_1, z_2) = \psi(z_1, z_2)\alpha^*(z_2)$ and $\theta_2(z_2) = \alpha(z_2)\beta(z_2)$. Then, $\phi(z_1, z_2)$ is equal to $\psi(z_1, z_2)\beta(z_2)$, from which we deduce that Z_1 is included in $\sigma_2^*(H_-^2(T_2) \ominus \beta H_-^2(T_2))$. But, in view of (62), this is possible if and only if $\theta_2 = \beta$. Therefore, $\phi_{-,+}$ and θ_2^* are 2-weak coprime. The fact that $(\phi_{-,+}, \theta_2)$ is the unique pair satisfying (60) and (61) is shown similarly.

Proof of Lemma 3.3. As the spectral density of y satisfies the Szegö condition, there exists a white noise sequence α for which $Y_{\infty,\infty} = Q_\alpha(L^2(T^2))$, so that $Y_{\infty,\infty}$ and $L^2(T^2)$ are unitarily equivalent. Therefore, it is sufficient to establish the lemma in the case where $(U_1, U_2, Y_{\infty,\infty})$ coincides with $(\sigma_1, \sigma_2, L^2(T^2))$. We begin by giving the following result which can be proved by using arguments similar to those of the proof of Theorem 1.2.1 of [16].

LEMMA A.1. *Let H_1 be a subspace of $L^2(T^2)$ satisfying*

- $\bigvee_{m\in Z} \sigma_1^m H_1 = L^2(T^2)$,
- $\sigma_1^* H_1 \subset H_1$,
- $\sigma_2 H_1 = H_1$.

Then, there exists an all-pass function q defined on T^2 and a uniquely defined Borel set B_1 of T such that

- $H_{1,-\infty} = \cap_{m\in Z} \sigma_1^m H_1 = 1_{T\times B_1^c} L^2(T^2)$,
- $H_1 \ominus H_{1,-\infty} = 1_{T\times B_1} q H_{-,\infty}^2$,

where 1_A stands for the characteristic function of the set A. If, moreover, $H_{1,-\infty} = \{0\}$, then q is uniquely defined up to an all-pass function of z_2.

Now, we prove Lemma 3.3. First, paralleling the arguments of §1 of [10], we get that the commutation property (44) implies that

$$H_1 \cap H_2 = \sigma_1^* \sigma_2^* \Delta_{-,-} \oplus (H_1 \ominus H_{1,-\infty}) \cap H_{2,-\infty} \oplus (H_2 \ominus H_{2,-\infty}) \cap H_{1,-\infty} \oplus H_{1,-\infty} \cap H_{2,-\infty},$$

where Δ is defined by (69) and where $H_{2,-\infty}$ denotes the space $\cap_{n\in Z}\sigma_2^n H_2$. Let us consider the case where Δ is not reduced to $\{0\}$. Then, by arguments of multiplicity theory, Δ is one-dimensional. As Δ is wandering for (σ_1, σ_2), Δ coincides with the space generated by a certain all-pass function θ defined on T^2. Therefore, the space $\sigma_1^*\sigma_2^*\Delta_{-,-}$ is equal to $\theta\sigma_1^*\sigma_2^* H^2_{-,-}$. Hence, the space $\Delta_{\infty,\infty}$ coincides with $L^2(T^2)$. But, again by using (44), it is easily seen that

$$\Delta_{\infty,\infty} = \left(\bigvee_{m\in Z} \sigma_1^m H_1 \ominus H_{1,-\infty} \right) \cap \left(\bigvee_{n\in Z} \sigma_2^n H_2 \ominus H_{2,-\infty} \right),$$

i.e., in view of (65),

$$\Delta_{\infty,\infty} = (L^2(T^2) \ominus H_{1,-\infty}) \cap (L^2(T^2) \ominus H_{2,-\infty}).$$

Consequently, if Δ is not reduced to $\{0\}$, (67) and (68) hold. If $\Delta = \{0\}$, it turns out that $(L^2(T^2) \ominus H_{1,-\infty}) \cap (L^2(T^2) \ominus H_{2,-\infty}) = \{0\}$. By Lemma A.1 applied to the pairs (H_1, σ_1) and (H_2, σ_2), there exist two Borel sets B_1 and B_2 of T such that $(L^2(T^2) \ominus H_{1,-\infty}) = 1_{T\times B_1} L^2(T^2)$ and $(L^2(T^2) \ominus H_{2,-\infty}) = 1_{B_2\times T} L^2(T^2)$; therefore,

$$(L^2(T^2) \ominus H_{1,-\infty}) \cap (L^2(T^2) \ominus H_{2,-\infty}) = 1_{B_2\times B_1} L^2(T^2).$$

Consequently, if $\Delta = \{0\}$, then one of the set B_1 or B_2 must be negligible with respect to the Lebesgue measure. This in turn shows that (66) holds.

Proof of Lemma 3.4. In order to establish Lemma 3.4, we begin by showing the following fundamental result.

LEMMA A.2. *Let $\phi(z_1, z_2)$ be a function of $H^2_{+,+}$, and let $\theta(z_1)$ be an inner Blaschke product. Then, ϕ and θ are 1-weak coprime if and only if they are 1-coprime.*

Proof. Let us suppose that ϕ and θ are 1-weak coprime, and let us assume the existence of a 1-inner function α satisfying

$$\phi(z_1, z_2) = \psi(z_1, z_2)\alpha(z_1, z_2), \theta(z_1) = \gamma(z_1, z_2)\alpha(z_1, z_2)$$

almost everywhere on T^2 for some $\psi \in H^2_{+,\infty}$ and for some 1-inner function γ. Then, it is clear that, for almost all z_2 on T, the above equality also holds for each z_1 in the open unit disk. Let a be a zero of θ; then, $|a| < 1$, and $\gamma(a, z_2)\alpha(a, z_2) = 0$ almost everywhere on T. Let us denote by E_a the Borel set of T defined by $E_a = \{z_2 \in T / \alpha(a, z_2) = 0\}$. Then, the function $\phi_a : z_2 \to \phi(a, z_2)$ is zero on E_a; as ϕ belongs to $H^2_{+,+}$, ϕ_a is an element of H^2_+; therefore, it cannot be zero on a set of positive measure [21], unless in the case where it is identically zero. If $\phi(a, z_2) = 0$ almost everywhere, then ϕ can be written as $\phi(z_1, z_2) = \phi'(z_1, z_2)(z_1 - a)/(1 - a^* z_1)$ for some function ϕ' of $H^2_{+,+}$, which contradicts the fact that ϕ and θ are 1-weak coprime. Consequently, E_a is a set of zero measure, and $\gamma(a, z_2) = 0$ almost everywhere; but, this implies that $\gamma(z_1, z_2) = \gamma'(z_1, z_2)(z_1 - a)/(1 - a^* z_1)$ for some 1-inner function γ'. Repeating this procedure for each zero of θ (by taking into account

their multiplicities), we show that $\gamma(z_1, z_2) = \theta(z_1)$ (up to an all-pass function of z_2 only). This in turn shows that ϕ and θ are 1-coprime. □

Now, we prove Lemma 3.4. First, it is easily seen that if assumption $\mathcal{A}$ holds, then there exists an FF observable regular and coregular FFMR X of Y whose structural functions are Blaschke products. Let us denote by ϕ and ν its FF spectral factor and its FF innovation process. As X is FF observable, its second structural function coincides with the function θ_2 defined by (62), and its first structural function is equal to the function θ_1 defined as θ_2 by exchanging the role of z_1 and z_2. Similarly, the forward-backward spectral factor ϕ^{fb} of X coincides with the function $\phi_{-,+}$ defined in Proposition 3.1. Therefore, by proposition 3.1, ϕ^{fb} and θ_2^* are 2-weak coprime; by a straightforward modification of Lemma A.2, they are in fact 2-coprime. Similarly, ϕ^{bf} and θ_1^* are 1-coprime. On the other hand, the structural function of the doubly invariant under U_2 Markovian representation $X_{0,\infty}$ of $Y_{0,\infty}$ coincides with θ_1; therefore, it follows from Proposition 3.4 that $X_{0,\infty}$ is observable. Similarly, $X_{\infty,0}$ is observable. Now, again by using Lemma A.2, we are going to show that the structural function of the minimal Markovian representation $\overline{E}^{X_{0,\infty}}(Y_{-,\infty})$ of $Y_{0,\infty}$ is a function of z_1 only; this will demonstrate the first part of Lemma 3.4. ϕ^{bf} can be written as $\phi^{bf}(z_1, z_2) = \phi(z_1, z_2)\theta_1^*(z_1)$. By a modification of Proposition 3.1, ϕ^{bf} can be written as $\phi^{bf}(z_1, z_2) = \phi_1(z_1, z_2)q_1^*(z_1)$, where $\phi_1 \in \sigma_1^*\sigma_2^* H^2_{-,-}$ and where q_1 is a $*$-inner function such that ϕ_1 and q_1 are 1-weak coprime; moreover, there exists a $*$-inner function α_1 for which $\phi(z_1, z_2) = \phi_1(z_1, z_2)\alpha_1(z_1), \theta_1(z_1) = q_1(z_1)\alpha_1(z_1)$. As ϕ_1 and q_1 are 1-weak coprime, they are 1-coprime by Lemma A.2. On the other hand, as q_1 is a divisor of θ_1, ϕ^{bf} and q_1 are also 1-coprime. Let us denote by ν_1 the white noise defined by

$$d\hat{\nu}_1(\omega_1, \omega_2) = \alpha_1(e^{i\omega_1})d\hat{\nu}(\omega_1, \omega_2).$$

Then, it is easily seen that the subspace $Q_{\nu_1}[\sigma_1^*(H^2_{-,\infty} \ominus q_1 H^2_{-,\infty})]$ is a Markovian representation of $Y_{0,\infty}$ included in $X_{0,\infty}$, whose forward and backward spectral factors are equal to ϕ_1 and ϕ_{bf}, respectively, and whose structural function is the one-variable function $q_1(z_1)$. By Proposition 3.4, it turns out that this Markovian representation is minimal, and that it coincides with the constructible projection $\overline{E}^{X_{0,\infty}}(Y_{-,\infty})$ of $X_{0,\infty}$. This establishes the first part of the lemma.

Similarly, there exists two $*$-inner functions q_2 and α_2, and an element ϕ_2 of $\sigma_1^*\sigma_2^* H^2_{-,-}$ such that $\phi(z_1, z_2) = \phi_2(z_1, z_2)\alpha_2(z_2), \theta_2(z_2) = q_2(z_2)\alpha_2(z_2), \phi^{fb}(z_1, z_2) = \phi_2(z_1, z_2)$ $q_2^*(z_2)$, where ϕ^{fb} and q_2^*, and ϕ_2 and q_2 are 2-coprime. As previously, if we denote by ν_2 the white noise defined by the fact that

$$d\hat{\nu}_2(\omega_1, \omega_2) = \alpha_2(e^{i\omega_2})d\hat{\nu}(\omega_1, \omega_2),$$

then the subspace $Q_{\nu_2}[\sigma_2^*(H^2_{\infty,-} \ominus q_2 H^2_{\infty,-})]$ is a minimal doubly invariant under U_1 Markovian representation of $Y_{\infty,0}$ which coincides with $\overline{E}^{X_{\infty,0}}(Y_{\infty,-})$. The second part of the lemma follows from the fact that its structural function is the one-variable function $q_2(z_2)$.

Proof of Theorem 3.3. Let us begin by showing that if $\tilde{X}$ is a MR of Y for which $\tilde{X}_{0,\infty}$ and $\tilde{X}_{\infty,0}$ are minimal Markovian representations of $Y_{0,\infty}$ and of $Y_{\infty,0}$, then $\tilde{X}$ is a minimal MR of Y. For this purpose, let suppose that $\tilde{X}$ contains another MR $\tilde{X}'$ of Y. Then, $\tilde{X}'_{0,\infty} \subset \tilde{X}_{0,\infty}$ and $\tilde{X}'_{\infty,0} \subset \tilde{X}_{\infty,0}$; by the minimality of $\tilde{X}_{0,\infty}$ and $\tilde{X}_{\infty,0}$, this implies that $\tilde{X}'_{0,\infty} = \tilde{X}_{0,\infty}$ and $\tilde{X}'_{\infty,0} = \tilde{X}_{\infty,0}$. The equality $\tilde{X}' = \tilde{X}$ follows from the fact that $\tilde{X}' = \tilde{X}'_{0,\infty} \cap \tilde{X}'_{\infty,0}$ and that $\tilde{X} = \tilde{X}_{0,\infty} \cap \tilde{X}_{\infty,0}$.

Conversely, let $\tilde{X}$ be a regular and coregular MR of Y whose structural functions are Blaschke products. We have to show that it is possible to construct a MR of Y, say $\tilde{X}'$,

included in $\tilde{X}$, and for which $\tilde{X}'_{0,\infty}$ and $\tilde{X}'_{\infty,0}$ are minimal Markovian representations of $Y_{0,\infty}$ and of $Y_{\infty,0}$. Let ϕ and ν be the FF spectral factor and the FF innovation process of $\tilde{X}$, respectively. Then, there is no restriction to assume that the structural functions of $\tilde{X}$ coincide with the functions θ_1 and θ_2 defined by (62). In this case, all the reduction procedure presented in the proof of Lemma 3.4 can be applied to $(\phi, \nu, \theta_1, \theta_2)$. Let ν' be the white noise sequence defined by

$$\begin{aligned} d\hat{\nu}'(\omega_1,\omega_2) &= \alpha_1(e^{i\omega_1})\alpha_2(e^{i\omega_2})d\hat{\nu}(\omega_1,\omega_2) \\ &= \alpha_1(e^{i\omega_1})d\hat{\nu}_2(\omega_1,\omega_2) = \alpha_2(e^{i\omega_2})d\hat{\nu}_1(\omega_1,\omega_2). \end{aligned}$$

Put $\phi'(z_1,z_2) = \phi(z_1,z_2)\alpha_1^*(z_1)\alpha_2^*(z_2)$. Then, $\phi'(z_1,z_2)$ coincides with $\phi_2(z_1,z_2)\alpha_1^*(z_1)$; as ϕ_2 is an element of $\sigma_1^*\sigma_2^*H^2_{-,-}$, it appears that ϕ' belongs to $\sigma_2^*H^2_{\infty,-}$. Similarly, the fact that $\phi'(z_1,z_2) = \phi_1(z_1,z_2)\alpha_2^*(z_2)$ implies that $\phi' \in \sigma_1^*H^2_{-,\infty}$; finally, ϕ' is an element of $\sigma_1^*\sigma_2^*H^2_{-,-}$. Moreover, it is easily seen that $\phi' q_1^* \in \sigma_2^*H^2_{+,-}$, $\phi' q_2^* \in \sigma_1^*H^2_{-,+}$, and that $d\hat{y}(\omega_1,\omega_2) = \phi'(e^{i\omega_1}, e^{i\omega_2})d\hat{\nu}'(\omega_1,\omega_2)$. From this, one can deduce that the space $\tilde{X}'$ given by

$$\tilde{X}' = Q_{\nu'}[\sigma_1^*(H^2_-(T_1) \ominus q_1H^2_-(T_1)) \otimes \sigma_2^*(H^2_-(T_2) \ominus q_2H^2_-(T_2))]$$

is a MR of Y. Moreover, $\tilde{X}'_{0,\infty} = Q_{\nu'}[\sigma_1^*(H^2_{-,\infty} \ominus q_1H^2_{-,\infty})]$; but, this space coincides with $Q_{\nu_1}[\sigma_1^*(H^2_{-,\infty} \ominus q_1H^2_{-,\infty})]$, from which we deduce that $\tilde{X}'_{0,\infty}$ is a minimal Markovian representation of $Y_{0,\infty}$ with respect to U_1. The minimality of $\tilde{X}'_{\infty,0}$ is shown similarly.

Finally, let us show the last assumption of the theorem. Let $\tilde{X}$ be a minimal MR of Y whose structural functions are Blaschke products, and put $X = \overline{E}^{\tilde{X}}(Y_{+,+})$. Let us suppose that X contains a FFMR X'. Then, $X'_{0,\infty} \subset X_{0,\infty}$, so that the minimality of $X_{0,\infty}$ implies that $X'_{0,\infty} = X_{0,\infty}$; similarly, $X'_{\infty,0} = X_{\infty,0}$. Hence, $X'_{-,\infty} = X_{-,\infty}$ and $X'_{\infty,-} = X_{\infty,-}$, and

$$\overline{E}^{X'_{-,\infty} \cap X'_{\infty,-}}(Y_{+,+}) = \overline{E}^{X_{-,\infty} \cap X_{\infty,-}}(Y_{+,+}).$$

But, the right-hand side of the above equality is equal to X, and the left-hand side is included in X'. As it has been supposed that $X' \subset X$, this implies that $X = X'$, and that X is a minimal FFMR.

Acknowledgments. The author thanks Prof. H. Korezlioglu for his constant support during this work, and the referees for suggestions that helped to improve the presentation of this paper.

LINEARIZED CONTROL SYSTEMS AND APPLICATIONS TO SMOOTH STABILIZATION*

JEAN-MICHEL CORON†

Abstract. For a control system $\dot{x} = f(x, u)$, the author proves that, for generic feedback laws u such that $f(x, u(x))$ does not vanish, the linearized control systems around the trajectories of $\dot{x} = f(x, u(x))$ have the same strong accessibility algebra as f. Applications are given to the smooth stabilization problem.

Key words. nonlinear control systems, linearized control system, accessibility algebra, asymptotic stabilization

AMS subject classifications. 93D15, 93C10

Introduction. In two previous papers ([C1], [C2]) we showed that in order to stabilize asymptotically a nonlinear control system, it is sometimes useful to generate control laws which may depend—smoothly—on time, state, or initial data such that the strong accessibility algebras of the linearized control systems, around the trajectories of the nonlinear system obtained by using these control laws, are as large as possible, i.e., are equal to the strong accessibility algebra of the nonlinear control system at each point and time. If a control law has such a property we will say that it *saturates* the nonlinear system or that it is *saturating*. Such control laws can be perturbed in a suitable way in order to allow interesting local modifications of the trajectories. For example, if a saturating feedback law stabilizes the nonlinear control system, but not asymptotically, and if the strong accessibility algebra of the nonlinear system is large enough (in particular if it is equal to the tangent space at each point) then we can perturb slightly the feedback law in such a way that the new feedback law stabilizes *asymptotically* the nonlinear system. This is the well-known Jurdjevic–Quinn theorem [JQ]. This is applied in [C1]: The main idea of [C1] is to prove, for nonlinear systems without drift, the existence of saturating periodic time-varying feedback laws which stabilize, but not asymptotically, the nonlinear system; the existence of such feedback laws implies that any nonlinear system without drift which satisfies the accessibility rank condition can be *asymptotically* stabilized by means of periodic time-varying feedback laws. In [C2] we use the fact that, given an embedded curve $\mathcal{C}$ in the state space, any saturating open loop control depending smoothly on the initial data and on time can be modified slightly in such a way that, if the nonlinear control system satisfies the strong accessibility rank condition and if the dimension of the state space is at least four, with the new control the curve at any time is still embedded. This embedding property allows us to transform, along the trajectories starting on Σ, the open loop control law into a time-varying feedback control. This is important for the stabilization problem (see [C2] for more details).

In [C2] we briefly sketched the main part of a proof (relying partly on [C1]) that generic control laws depending smoothly on time and on the initial data saturate the nonlinear control system (if the strong accessibility algebra has constant rank). We give here the details of this proof (and we will see that, in fact, the constant rank hypothesis is not needed). Moreover we obtain the same result for feedback laws: Generic feedback laws such that the closed loop control system has no singular points in a fixed open set saturate the system on this open set.

Let us mention that our results are connected to the prior works [S1] and [G]. In [S1] Sontag showed that if a system is completely controllable then any two points can be joined by means of a control law such that the linearized control system around the associated trajectory is controllable. In [G, §2.3.8.E, Thm., p. 156] Gromov showed that generic underdetermined linear (partial) differential equations are algebraically solvable; saturation, when the strong accessibility rank condition is satisfied, implies (and is in fact equivalent in the analytic case) to the algebraic solvability of the linearized control systems (see [INS] or [G, §2.3.8.(B)]). In our situation the linear differential equations are not generic; only the controls are generic, but this will be sufficient to get the result.

Recently Sontag obtained, as a consequence of an important result on observability due to Sussmann [S3], the following result: If the nonlinear analytic system $\dot{x} = f(x, u)$ satisfies the usual strong accessibility rank condition, then for any generic control law u in $C^\infty([0, T])$ the linearized control systems around the trajectories of $\dot{x} = f(x, u(t))$ are controllable on $[0, T]$. The novelty of this result compared to [C2, §2] is that now the control laws do not depend on the initial data. However, the method sketched in [C2] and that we present here in detail allows us to get this result without using [S3]; it also allows two slight improvements: We can assume f to be only C^∞—we need in this case to modify the definition of the strong accessibility rank condition in a natural way—and the linearized control systems can be required to be controllable with impulsive controls for all time in $[0, T]$. Let us remark that controllability with impulsive controls of the linearized control systems is important to get the embedding property mentioned above and used in [C2].

We also give some direct applications of our results on the genericity of saturating feedback laws to the asymptotic stabilization problem. Finally, we give straightforward modifications of our main proof in order to obtain results on observability spaces and codistributions instead of accessibility algebras.

1. Definition and statements of the main theorem and corollaries. Throughout this paper "manifold" always means finite-dimensional Hausdorff, second countable manifold of class C^∞. Unless otherwise specified the manifolds have no boundary. For two manifolds V and W, and for p in $\mathbb{N} \cup \{\infty\}$, $C^p(V; W)$ denotes the set of maps from V into W which are of class C^p; for p in $\mathbb{N}$, this set is equipped with the (fine) Whitney C^p-topology (see, e.g., [GG, p. 42]) called, for simplicity, C^p-topology. On $C^\infty(V, W)$ we define a topology, called the C^∞-topology, in the following way. For an integer k, let $J^k(V, W)$ be the set of k-jets of C^∞-mappings from V into W. Let $(K_i, i \in \mathbb{N})$ be a sequence of compact subsets of V such that $K_0 = \emptyset$, $K_i \subset K_{i+1}$ for all integer i, and $\cup_{i \in \mathbb{N}} K_i = V$. For a sequence $k = (k_i; i \in \mathbb{N})$ of integers and for a sequence $U = (U_i; i \in \mathbb{N})$ where U_i is an open subset of $J^{k_i}(V, W)$ for all integer i, we consider the set $\mathcal{O}(k, U)$ of u in $C^\infty(V; W)$ such that $j^{k_i} u(V \setminus K_i) \subset U_i$ for all integers i. Our C^∞-topology is the topology whose basis is the family of set $\mathcal{O}(k, U)$ where k and U are as above. This topology is independent of the choice of $(K_i; i \in \mathbb{N})$ and is finer than the Whitney C^∞-topology if V is not compact; for example, $\{u \in C^\infty((0, +\infty); \mathbb{R}); \lim_{x \to 0} u^{(i)}(x) = 0 \text{ for all } i \in \mathbb{N}\}$ is an open set for our topology, but is not open for the Whitney C^∞-topology. Note also that $C^\infty(V; W)$ with our topology, as $C^\infty(V; W)$ with the Whitney C^∞-topology, is a Baire space (the proof is similar to the proof of [GG, Prop. II.3.3]). Let us mention that Theorem 1.3 following holds also for the Whitney C^∞-topology, but our C^∞-topology is slightly more convenient for the applications to the stabilization problem.

Let N be a manifold, TN its tangent bundle, m a positive integer, U an open subset of $\mathbb{R}^m$. We denote by $C^\infty_U(TN)$ the set of f in $C^\infty(N \times U; TN)$ such that

$$f(x, u) \in T_x N \quad \text{for all} \quad (x, u) \quad \text{in } N \times U. \tag{1.1}$$

For two elements f_1 and f_2 of $C^\infty_U(TN)$ we define the Lie bracket $[f_1, f_2] \in C^\infty_U(TN)$ by

$$[f_1, f_2](x,u) = [f_1(\cdot,u), f_2(\cdot,u)](x) \tag{1.2}$$

where, in the right-hand side of (1.2), $[\cdot,\cdot]$ denotes the usual Lie bracket of tangent vector fields on N.

Let f be in $C^\infty_U(TN)$. We define the strong jet accessibility algebra of f by the following definition.

DEFINITION 1.1. The strong jet accessibility algebra of f is the vectorial subspace $\mathcal{A}(=\mathcal{A}(f))$ of the vectorial space $C^\infty_U(TN)$ defined by

$$\mathcal{A} = \text{Span}\ \{\{\partial^{|\alpha|} f/\partial u^\alpha; \alpha \in \mathbb{N}^m, \alpha \neq 0\} \cup Br_2\{\partial^{|\alpha|} f/\partial u^\alpha; \alpha \in \mathbb{N}^m\}\} \tag{1.3}$$

where, for a family $\mathcal{F} \subset C^\infty_U(TN)$, $Br_2(\mathcal{F})$ denotes the set of iterated Lie brackets of elements in $\mathcal{F}$ of length at least two. For example, $\partial f/\partial u^i$, $[f, \partial f/\partial u^i]$, and $\partial^2 f/\partial u^i \partial u^j$ are in $\mathcal{A}$. Let us remark that the strong jet accessibility algebra differs slightly from the classical strong accessibility algebra $\mathcal{L}_0$ (see, e.g., the definitions in [S1, p. 549] and [SJ, p. 101]). Note that

$$\{g(x,u); g \in \mathcal{A}\} \subset \{g(x); g \in \mathcal{L}_0\} = \mathcal{L}_0(x) \quad \forall x \in N, \quad \forall u \in U \tag{1.4}$$

and that the inclusions in (1.4) are equalities if, for example, f is a polynomial with respect to u (e.g., the classical affine case $f(x,u) = f_0(x) + \sum_{i=1}^m u_i f_i(x)$) or if N and f are analytic and U is connected. Note that $\{g(x,u); g \in \mathcal{A}\}$ depends only on the jet (of order ∞) of f at (x,u); this is the reason for our terminology.

For (x,u) in $N \times U$, let

$$a(x,u) = \{g(x,u); g \in \mathcal{A}\} \subset T_x N. \tag{1.5}$$

Let us remark that, if (1.4) is an equality for all u in U, then

$$a(x,u^1) = a(x,u^2) \quad \text{for all} \quad (u^1,u^2) \quad \text{in } U \times U. \tag{1.6}$$

Let x be in N and u be a smooth map, with values into U, defined on a neighborhood of x. Let $f_0(y) = f(y,u(y)) \in T_y N$ and, for $i \in [1,m]$, let $f_i(y) = \partial f/\partial u_i(y,u(y))$. We define $a_\ell(x;u) \subset T_x N$ by

$$a_\ell(x;u) = \text{Span}\{ad^k_{f_0}(f_i)(x), k \geq 0, i \in [1,m]\}, \tag{1.7}$$

with, as usual, $ad^0_{f_0}(f_i) = f_i$ and $ad^k_{f_0}(f_i) = [f_0, ad^{k-1}_{f_0}(f_i)]$. Let us remark that $a_\ell(x;u)$ can be interpreted in the following way. Let γ, defined on an open interval of $\mathbb{R}$ containing 0 with values in N, be such that

$$\dot\gamma(t) = f(\gamma(t), u(\gamma(t))), \tag{1.8}$$

$$\gamma(0) = x. \tag{1.9}$$

The linearized control system around γ is the time-varying linear system

$$\dot z = A(t)z + B(t)w, \tag{1.10}$$

with

$$A(t) = \frac{\partial f}{\partial x}(\gamma(t), u(\gamma(t))), \tag{1.11}$$

$$B(t)w = \sum_{i=1}^m w_i \frac{\partial f}{\partial u_i}(\gamma(t), u(\gamma(t))), \tag{1.12}$$

and where $w \in \mathbb{R}^m$ is the control and $z(t) \in T_{\gamma(t)}N$ is the state. Then we easily check that, with obvious notations,

$$a_\ell(x;u) = \text{Span}\left\{\left(\left(\frac{d}{dt} - A(t)\right)^i B(t)\right)_{t=0} w; w \in \mathbb{R}^m, i \geq 0\right\}. \tag{1.13}$$

The right-hand side of (1.13) is just the classical strong accessibility algebra, evaluated at $t = 0$, of the time-varying linear control system (1.10).

We introduce the following definition.

DEFINITION 1.2. A control $u \in C^\infty(N;U)$ saturates f at x if

$$a_\ell(x;u) = a(x,u(x)). \tag{1.14}$$

Moreover u saturates f on a subset $S \subset N$ if it saturates f at all points of S.

Let us remark that we always have

$$a_\ell(x;u) \subset a(x,u(x)) \tag{1.15}$$

and that, if $a(x,u(x)) = T_xN$, then (1.14) is equivalent to the controllability with "impulsive controls" at time 0 of (1.10) (see, e.g., [KAI; p. 614]).

Let Y be a manifold, let h be in $C^\infty(N;Y)$, and let

$$\Omega \subset \{u \in C^\infty(Y;U); h'(x)(f(x,u \circ h(x))) \neq 0 \forall x \in N\}. \tag{1.16}$$

Then we will provide proof in §2.

THEOREM 1.3. *Assume that, for the C^∞-topology,*

$$\Omega \text{ is open.} \tag{1.17}$$

Then the set of u in Ω such that $u \circ h$ saturates f on N is residual in Ω (for the C^∞-topology).

Let us recall that a residual set is the countable intersection of open dense subsets. Since, if (1.17) holds, Ω is a Baire space, the set of u in Ω such that $u \circ h$ saturates f on N is dense in Ω (for the C^∞-topology). Let us also remark that, if in Definition 1.2 we replace $a(x,u)$ by $\mathcal{L}_0(x)$, then Theorem 1.3 is wrong, e.g., $N = U = Y = \mathbb{R}, h(x) = x, f(x,u) = 1 + \exp(-1/u^2)$, and $\Omega = C^\infty(\mathbb{R},\mathbb{R})$: With $\mathcal{L}_0(x)$ instead of $a(x,u)$ in Definition 1.2 $u \in C^\infty(\mathbb{R},\mathbb{R})$ saturates f if and only if it does not vanish, and such maps are not dense in $C^\infty(\mathbb{R};\mathbb{R})$.

We may wonder if the set of u in $C^\infty(N;U)$, which saturates f on N, is residual in $C^\infty(N;U)$. The answer is no, in general. Let us give an example.

Example 1.4. Let $N = \mathbb{R}^3, U = \mathbb{R}^2$, and

$$f(x,u) = (u_1, u_2, x_1u_2 - x_2u_1). \tag{1.18}$$

We easily check that $a(x,u) = T_xN = \mathbb{R}^3$, for all x in $\mathbb{R}^3$ and all u in $\mathbb{R}$, and that u in $C^\infty(\mathbb{R}^3;\mathbb{R}^2)$ saturates f at x if and only if

$$u(x) \neq 0. \tag{1.19}$$

But the set of $C^\infty(\mathbb{R}^3;\mathbb{R}^2)$, which do not vanish on $\mathbb{R}^3$, is not dense in $C^\infty(\mathbb{R}^3;\mathbb{R}^2)$.

For $r > 0$, let

$$B'_r = \{x \in \mathbb{R}^n; 0 < |x| < r\}. \tag{1.20}$$

In §3 we will obtain the following corollary of Theorem 1.3.

COROLLARY 1.5. *Assume* $N = \mathbb{R}^n, 0 \in U$, *and* $f(0,0) = 0$. *Assume also that* $\dot{x} = f(x,u)$ *can be globally (respectively, locally) asymptotically stabilized by means of a continuous feedback law. Then it can be globally (respectively, locally) asymptotically stabilized by means of a continuous feedback law* $x \to u_0(x), C^\infty$ *on* $\mathbb{R}^n\backslash\{0\}$ *(respectively,* B'_r *for some* $r > 0$*) which saturates* f *on* $\mathbb{R}^n\backslash\{0\}$ *(respectively,* B'_r*); in particular if* $a(x,u) = \mathbb{R}^n$ *for all* (x,u) *in* $(\mathbb{R}^n\backslash\{0\}) \times U$ *then the linearized control systems around the trajectories of* $\dot{x} = f(x, u_0(x))$ *are controllable with impulsive controls at each time* t *such that* $x(t) \neq 0$ *(respectively,* $x(t) \in B'_r$*).*

Let us mention that this corollary is related to a previous result proved by Sontag in [S1]. There it is proved, in particular, that if $\dot{x} = f(x,u)$ is completely controllable and satisfies $a(x,u) = T_x(N)$ on $N \times U$, then any two points of N can be joined by a trajectory of $\dot{x} = f(x,u(t))$ such that the linearized control system around this trajectory is controllable. Our corollary can be viewed as a "stabilization" version of this controllability result.

Our next corollary of Theorem 1.3 concerns systems on $N = \mathbb{R}^n$ such that

$$0 \in U, \tag{1.21}$$

$$f(0,0) = 0, \tag{1.22}$$

and

$$f(x,u) \cdot \nabla V(x) \leq 0 \quad \text{for all } (x,u) \quad \text{in } \mathbb{R}^n \times U, \tag{1.23}$$

where $V \in C^\infty(\mathbb{R}^n; [0, +\infty))$ satisfies

$$V(x) = 0 \Longleftrightarrow x = 0 \tag{1.24}$$

and

$$\lim_{|x| \to +\infty} V(x) = +\infty. \tag{1.25}$$

Then we have the following statement which is proved in §3.

COROLLARY 1.6. *Assume that* (1.21), (1.22), (1.23), (1.24), *and* (1.25), *hold. Assume that*

$$f(x,0) \neq 0 \quad \textit{for all } x \textit{ in } \mathbb{R}^n\backslash\{0\}, \tag{1.26}$$

and that, for all x *in* $\mathbb{R}^n\backslash\{0\}$, *there exists* g *in* $\mathcal{A} \cup \{f\}$ *such that*

$$g(x,0) \cdot \nabla V(x) \neq 0. \tag{1.27}$$

Then $\dot{x} = f(x,u)$ *can be globally asymptotically stabilized by means of a feedback law of class* C^∞.

Let us give an application of Corollary 1.6.

Example 1.7. Let $V \in C^\infty(\mathbb{R}^n; [0, +\infty))$, satisfying (1.24) and (1.25). Let X_0, X_1, X_2 be three vector fields on $\mathbb{R}^n$ of class C^∞. Assume that

$$L_{X_i} V = 0 \quad \forall i \in \{0,1\}. \tag{1.28}$$

Assume also that

$$X_0(0) = 0 \tag{1.29}$$

and that

$$L_{X_2}V(x) \neq 0 \quad \text{if} \quad x \in \mathbb{R}^n\backslash\{0\} \quad \text{and} \quad X_0(x) = 0. \tag{1.30}$$

Let $\mathcal{F}$ be the set of iterated Lie brackets of the vector fields X_0 and X_1. Assume that, for all x in $\mathbb{R}^n\backslash\{0\}$ such that $L_{X_0}V(x) = 0$, there exist X in $\mathcal{F}$ and k in $\mathbb{N}$ such that

$$L_{ad_X^k(X_2)}V(x) \neq 0. \tag{1.31}$$

Then $\dot{x} = X_0 + u_1X_1 + u_2X_2$ can be globally asymptotically stabilized by means of a feedback law of class C^∞. Indeed, let

$$f(x,u) = X_0(x) - L_{X_2}V(x)X_2(x) + u_1^2X_1(x) - u_2^2(L_{X_2}V(x))X_2(x); \tag{1.32}$$

then (1.22), (1.23), and (1.26) are satisfied. Let us remark that if X in $\mathcal{F}$, x in $\mathbb{R}^n$, and k in $\mathbb{N}$ satisfy $L_{ad_X^k(X_2)}V(x) \neq 0$ and $L_{ad_X^i(X_2)}V(x) = 0$ for all $i \in [0, k-1]$, then $L_{ad_X^{2k}((L_{X_2}V)X_2)}V(x) \neq 0$; then it follows easily from (1.31) that (1.27) holds. Note that a direct application to our situation of [JQ] would require that (1.31) hold with $X = X_0$.

Our next corollaries of Theorem 3.1 concern time-varying control systems (but also give nontrivial information for time-independent control systems). Therefore, now $f \in C^\infty(N \times I \times U; TN)$ with

$$f(x,t,u) \in T_xN \quad \text{for all } (x,t,u) \quad \text{in } N \times I \times U \tag{1.33}$$

where I is an open subset of $\mathbb{R}$. Associated with f is the time-independent system on $N \times I$

$$\Sigma : \dot{x} = f(x,\tau,u), \qquad \dot{\tau} = 1. \tag{1.34}$$

Let a^Σ and a_ℓ^Σ be the corresponding maps for system Σ. Let us remark that, for any (x,τ,u) in $N \times I \times U$,

$$a^\Sigma((x,\tau),u) \subset T_xN \times \{0\}, \tag{1.35}$$

where we have identified $T_{(x,\tau)}(N \times I)$ with $T_xN \times T_\tau I$. Let us define, for (x,τ,u) in $N \times I \times U$,

$$a(x,\tau,u) = \{X; (X,0) \in a^\Sigma((x,\tau),u)\} \tag{1.36}$$

and, for u in $C^\infty(N \times I; U)$,

$$a_\ell(x,\tau;u) = \{X; (X,0) \in a_\ell^\Sigma((x,\tau);u)\}. \tag{1.37}$$

For example, $\partial f/\partial u_i, \partial^2 f/\partial t \partial u_i + [f, \partial f/\partial u_i], \partial^2 f/\partial u_i \partial u_j$ evaluated at (x,τ,u) are in $a(x,\tau,u)$. Of course, if f does not depend on t (and u does not depend on t) then the new $a(x,t,u)$ (and the new $a_\ell(x,t;u)$) coincides with the previous $a(x,u)$ (and the previous $a_\ell(x;u)$). For $S \subset N \times I$ we will say that $u \in C^\infty(N \times I; U)$ saturates f on S if

$$a_\ell(x,t;u) = a(x,t,u(x,t)) \quad \text{for all} \quad (x,t) \quad \text{in } S. \tag{1.38}$$

Then our next corollary is the following.

COROLLARY 1.8. *The set of u in $C^\infty(N \times I; U)$ which saturate f on $N \times I$ is residual in $C^\infty(N \times I; U)$. The set of u in $C^\infty(I; U)$ which saturate f on $N \times I$ is residual in $C^\infty(I; U)$.*

Proof. Apply Theorem 1.3 to system Σ with $Y = N \times I$ (respectively, $Y = I$), $h(x,t) = (x,t)$ (respectively, $h(x,t) = t$), and $\Omega = C^\infty(Y; U)$ (let us note that the vector $h'(x,t)(f(x,t,u(h(x,t))), \partial/\partial t)$ never vanishes).

Let us remark that, in our previous work [C2, Thm. 2.1; Remark 2.2], we stated (with a sketch of proof) an open loop version of the first part of Corollary 1.8. This open loop version can be derived by applying Theorem 1.3 to the system on $N \times (0,T) \times \Lambda\, \dot{x} = g(x,u,\lambda), \dot{\tau} = 1, \dot{\lambda} = 0$ with $Y = (0,T) \times \Lambda$ and $h(x,\tau,\lambda) = (\tau,\lambda)$. Let us remark also that the second part of this corollary is strongly related to a result due to Sontag: In [S2] he proves that a consequence of [S3] is that, if $f \in C^\infty_U(TN)$ satisfies $a(x,u) = T_xN$ on $N \times U$ and is analytic, then, for $T > 0$, the set of u in $C^\infty([0,T]; U)$ such that all the trajectories of $\dot{x} = f(x,u(t))$ defined on $[0,T]$ have a controllable linearized control system is residual in $C^\infty([0,T]; U)$. This result also follows from Corollary 1.8 (take $I = (-T, 2T) \ldots$) even with controllability with impulsive controls of the linearized systems and f not necessarily analytic.

Of course, we have a similar corollary for periodic systems. More precisely, assume that $I = \mathbb{R}$ and that for some positive real number T

$$f(x, t+T, u) = f(x,t,u) \quad \text{for all} \quad (x,t,u) \quad \text{in} N \times \mathbb{R} \times U. \tag{1.39}$$

Denote by $C^\infty_T(N \times \mathbb{R}; U) \simeq C^\infty(N \times (\mathbb{R}/T\mathbb{Z}); U)$ (respectively, $C^\infty_T(\mathbb{R}; U) \simeq C^\infty(\mathbb{R}/T\mathbb{Z}; U)$) the set of u in $C^\infty(N \times \mathbb{R}; U)$ (respectively, $C^\infty(\mathbb{R}; U)$) which are T-periodic in time. Then we have the following corollary.

COROLLARY 1.9. *The set of u in $C^\infty_T(N \times \mathbb{R}; U)$ (respectively, $C^\infty_T(\mathbb{R}; U)$) which saturate f on $N \times \mathbb{R}$ is residual in $C^\infty_T(N \times \mathbb{R}; U)$ (respectively, $C^\infty_T(\mathbb{R}; U)$).*

Proof. Consider Σ has a system on $N \times (\mathbb{R}/T\mathbb{Z}) \ldots$.

A direct consequence of the first part of Corollary 1.9 is the following time-varying version of Corollary 1.5.

COROLLARY 1.10. *Assume that $f \in C^\infty(\mathbb{R}^n \times \mathbb{R} \times U; \mathbb{R}^n)$ satisfies* (1.39) *(with $N = \mathbb{R}^n$), $0 \in U$, $f = 0$ on $\{0\} \times \mathbb{R} \times \{0\}$, and that $\dot{x} = f(x,t,u)$ can be globally (respectively, locally) asymptotically stabilized by means of a continuous T-periodic time varying feedback law. Then $\dot{x} = f(x,t,u)$ can be globally (respectively, locally) asymptotically stabilized by means of a continuous T-periodic, time varying feedback law, of class C^∞ on $(\mathbb{R}^n \backslash \{0\}) \times \mathbb{R}$ (respectively, $\{x \in \mathbb{R}^n; 0 < |x| < r\} \times \mathbb{R}$ for some $r > 0$) which saturates f on $(\mathbb{R}^n \backslash \{0\}) \times \mathbb{R}$ (respectively, $\{x \in \mathbb{R}^n; 0 < |x| < r\} \times \mathbb{R}$).*

The first part of Corollary 1.9 allows us also to give a time-varying version of Corollary 1.6. Let, for $T > 0, V$ in $C^\infty(\mathbb{R}^n \times \mathbb{R}; [0, +\infty))$ be such that

$$V(x, t+T) = V(x,t) \quad \forall (x,t) \in \mathbb{R}^n \times \mathbb{R}, \tag{1.40}$$

$$V(x,t) = 0 \Longleftrightarrow x = 0, \tag{1.41}$$

and

$$\lim_{|x| \to +\infty} V(x,t) = +\infty \quad \forall t \in \mathbb{R}. \tag{1.42}$$

Assume $0 \in U$ and let $f \in C^\infty(\mathbb{R}^n \times \mathbb{R} \times U; \mathbb{R}^n)$, satisfying (1.39) be such that

$$f(0,t,0) = 0 \quad \forall t \in \mathbb{R} \tag{1.43}$$

and

$$\frac{\partial V}{\partial t}(x,t) + \sum_{i=1}^{n} f_i(x,t,u)\frac{\partial V}{\partial x_i}(x,t) \leq 0 \quad \forall (x,t,u) \in N \times \mathbb{R} \times U. \tag{1.44}$$

Then we have the following corollary.

COROLLARY 1.11. *Assume that, for all* (x,t) *in* $(\mathbb{R}^n \backslash \{0\}) \times [0,T]$ *such that*

$$\frac{\partial V}{\partial t}(x,t) + \sum_{i=1}^{n} f_i(x,t,0)\frac{\partial V}{\partial x_i}(x,t) = 0, \tag{1.45}$$

there exists h *in* $a(x,t,0)$ *such that*

$$\sum_{i=1}^{n} h_i \frac{\partial V}{\partial x_i}(x,t) < 0. \tag{1.46}$$

Then $\dot{x} = f(x,t,u)$ *can be globally asymptotically stabilized by means of a* T*-periodic, time varying feedback law of class* C^∞.

Remark 1.12. Assume that all the assumptions of Corollary 1.6 hold except (1.26). Then, applying Corollary 1.9 with $V(x,t) = V(x)$ and $f(x,t,u) = f(x,u)$, we get that, for all $T > 0, \dot{x} = f(x,u)$ can be globally asymptotically stabilized by means of a T-periodic, time varying feedback law of class C^∞. In general $\dot{x} = f(x,u)$ will not be locally asymptotically stabilizable by means of a continuous feedback law $u = u(x)$, e.g., $n = 2$, $m = 2$, $f(x,u) = (-u_2^2 u_1(u_1 x_1 + x_2), -u_2^2(u_1 x_1 + x_2))$, $V = x_1^2 + x_2^2$: The assumptions of Corollary 1.6 hold except (1.26), but f does not map a neighborhood of zero in $\mathbb{R}^2 \times \mathbb{R}^2$ onto a neighborhood of zero in $\mathbb{R}^2$ and therefore, by a theorem of Brockett [B], $\dot{x} = f(x,u)$ cannot be locally asymptotically stabilized by means of a continuous feedback law $(u = u(x))$.

In our next corollary we have again $0 \in U$ and $f \in C^\infty(\mathbb{R}^n \times \mathbb{R} \times U; \mathbb{R}^n)$ satisfying (1.39) (with $N = \mathbb{R}^n$) and (1.43). We assume that there exists $\varphi \in C^\infty(\mathbb{R} \times U; U)$ such that

$$\varphi(t+T,u) = \varphi(t,u) \quad \forall (t,u) \in \mathbb{R} \times U, \tag{1.47}$$

$$f(x,T-t,\varphi(T-t,u)) = -f(x,t,u) \quad \forall (x,t,u) \in \mathbb{R}^n \times \mathbb{R} \times U, \tag{1.48}$$

and

$$\varphi(t,0) = 0 \quad \forall t \in \mathbb{R}. \tag{1.49}$$

Let $\overline{x} : \mathbb{R}^n \times \mathbb{R} \to \mathbb{R}^n$ be defined by

$$\frac{\partial \overline{x}}{\partial t} = f(\overline{x},t,0), \tag{1.50}$$

$$\overline{x}(x,0) = x. \tag{1.51}$$

We assume also that f is such that $\overline{x}$ is defined on $\mathbb{R}^n \times \mathbb{R}$. Note that by (1.48) and (1.49) we have

$$\overline{x}(x,T) = x \quad \text{for all} \quad x \quad \text{in } \mathbb{R}^n. \tag{1.52}$$

Let $V \in C^\infty(\mathbb{R}^n; [0,+\infty))$ be such that

$$V(x) = 0 \Longleftrightarrow x = 0, \tag{1.53}$$

$$\lim_{|x|\to+\infty} V(x) = +\infty, \tag{1.54}$$

and let $W \in (\mathbb{R}^n \times \mathbb{R}; [0, +\infty))$ be defined by

$$\frac{\partial W}{\partial t} + \sum_{i=1}^{n} f_i(x,t,0)\frac{\partial W}{\partial x_i} = 0, \tag{1.55}$$

$$W(x,0) = V(x) \quad \forall x \in \mathbb{R}^n. \tag{1.56}$$

We have $W(x,t) = V(\overline{x}(x,t))$ and therefore by (1.43), (1.52), (1.53), and (1.54), W satisfies (1.40), (1.41), and (1.42). Then our next corollary follows.

COROLLARY 1.13. *Assume that for all* (x,t) *in* $(\mathbb{R}^n \setminus \{0\}) \times \mathbb{R}$ *there exists* X *in* $a(x,t,0)$ *such that*

$$\sum_{i=1}^{n} X_i \frac{\partial W}{\partial x_i}(x,t) \neq 0. \tag{1.57}$$

Then $\dot{x} = f(x,t,u)$ *can be globally asymptotically stabilized by means of a* T*-periodic, time varying feedback law of class* C^∞.

Let us give an example. Assume

$$f(x,t,u) = f(x,u) \tag{1.58}$$

$$\varphi(t,u) = \varphi(u). \tag{1.59}$$

Assume that, for $g^1, \dots, g^p$ in $\mathcal{A}(f)$ (see (1.3)), the control system

$$\Sigma_e : \dot{x} = \sum_{i=1}^{p} v_i g^i(x,0) \tag{1.60}$$

is globally asymptotically stabilized by means of continuous feedback law; then the conclusion of Corollary 1.13 holds. Indeed let $\overline{v} = (\overline{v}_1, \dots, \overline{v}_p)$ be a continuous feedback law which globally asymptotically stabilizes Σ_e. By a generalization of Kurzweil [KUR] of the converse of a classical Lyapunov's theorem there exists $V \in C^\infty(\mathbb{R}^n; [0, +\infty))$ satisfying (1.53) and (1.54) such that

$$\forall x \in \mathbb{R}^n \setminus \{0\} \quad \exists i \in [1,p] \quad \text{such that } g^i(x,0) \cdot \nabla V(x) \neq 0. \tag{1.61}$$

Hence the assumptions (and therefore the conclusion) of Corollary 1.13 hold. Note that if $f(x,u) = \sum_{i=1}^{m} u_i f_i(x)$, this result has been already proved in [C1] (see [C1, Remark 5.1]). In this case Σ_e is called, in the literature, an extended system of $\dot{x} = \sum_{i=1}^{m} u_i f_i(x)$. Links between trajectories of the extended systems and the trajectories of $\dot{x} = \sum_{i=1}^{m} u_i f_i(x)$ have already been extensively studied (see, e.g., [HH], [KW], [LS], [SL], and the references therein). Note also that Corollary 1.13 implies [C1, Thm. 1.1], [C1, Remark 5.1], [C2, Prop. 1.2], and [CA, Thm. 1].

Our proof of Theorem 1.3 can also be used to obtain similar results for observability. Let φ be in $C^\infty(N; \mathbb{R}^q)$, where q is some positive integer. Let

$$D = \{\partial^{|\alpha|} f / \partial u^\alpha; \alpha \in \mathbb{N}^m\} \subset C^\infty_U(TN) \tag{1.62}$$

and let $\mathcal{O}$ be the observation space defined, as a subspace of $C^\infty(N \times U; \mathbb{R}^q)$, by

$$\mathcal{O} = \text{Span}\{L_{X_k} L_{X_{k-1}} \dots L_{X_1} \varphi; k \geq 0, X_i \in D \, \forall i \in [1,k]\} \tag{1.63}$$

where L_{X_i} denotes the usual Lie derivative, $u \in U$ being considered as a parameter, and where, by convention, if $k = 0, L_{X_k} L_{X_{k-1}} \dots L_{X_1} \varphi = \varphi$. We define the observability codistribution $d\mathcal{O}$ by—where again $u \in U$ is a parameter—

$$d\mathcal{O} = \{d\psi; \psi \in \mathcal{O}\} \subset C_U^\infty (T^*N)^q. \tag{1.64}$$

Let $o(x,u)$ and $do(x,u)$, the observation space and the observability codistribution at $(x,u) \in N \times U$, be defined by

$$o(x,u) = \{\psi(x,u); \psi \in \mathcal{O}\} \subset \mathbb{R}^q \tag{1.65}$$

and

$$do(x,u) = \{w(x,u); w \in d\mathcal{O}\} \subset (T_x^* N)^q. \tag{1.66}$$

For u in $C^\infty(N;U)$ we define, with $X(x) = f(x,u(x))$,

$$o_\ell(x;u) = \text{Span}\{(L_X^k \varphi)(x); k \geq 0\} \subset \mathbb{R}^q \tag{1.67}$$

and

$$do_\ell(x,u) = \text{Span}\{(dL_X^k \varphi)(x); k \geq 0\} \subset (T_x^* N)^q. \tag{1.68}$$

Similarly, if I is an open subset of $\mathbb{R}$ and u is in $C^\infty(N \times I; U)$, we define, for (x,t) in $N \times I$,

$$o_\ell(x,t;u) = \text{Span}\left\{\left(\left(\frac{\partial}{\partial t} + L_X\right)^k \varphi\right)(x); k \geq 0\right\} \subset \mathbb{R}^q \tag{1.69}$$

and

$$do_\ell(x,t;u) = \text{Span}\left\{\left(\left(\frac{\partial}{\partial t} + L_X\right)^k \varphi\right)(x); k \geq 0\right\} \subset (T_x^* N)^q \tag{1.70}$$

with $X(x,t) = f(x,u(x,t))$. We have, for all x in N and all u in $C^\infty(N;U)$,

$$o_\ell(x,u) \subset o(x,u(x)), \tag{1.71}$$

and for all (x,t) in $N \times I$ and all u in $C^\infty(N \times I; U)$,

$$o_\ell(x,t;u) \subset o(x,u(x,t)). \tag{1.72}$$

Moreover, if

$$h'(x)\left(\frac{\partial}{\partial u_i} f(x,u)\right) = 0 \quad \forall (x,u) \in N \times I \quad \text{and} \quad \forall i \in [1,m], \tag{1.73}$$

then for all x in N

$$do_\ell(x;u) \subset do(x,u(x)). \tag{1.74}$$

Similarly, for all (x,t) in $N \times I$ and all $\tilde{u}$ in $C^\infty(I;U)$,

$$do_\ell(x,t;u) \subset do(x,\tilde{u}(t)) \tag{1.75}$$

with $u(x,t) = \tilde{u}(t)$.

The counterpart of Theorem 1.3 to this situation is the following theorem.

THEOREM 1.14. *Assume that* (1.16) *and* (1.17) *hold. Then the set of* u *in* Ω *such that, for all* x *in* N,

$$o_\ell(x; u \circ h) = o(x, u \circ h(x)) \tag{1.76}$$

is residual in Ω. *If, moreover,* (1.73) *holds, then the set of* u *in* Ω *such that, for all* x *in* N,

$$do_\ell(x; u \circ h) = do(x, u \circ h(x)) \tag{1.77}$$

is residual in Ω.

We will give in §3 the modifications of the proof of Theorem 1.3 in order to get Theorem 1.14. As Corollaries 1.8 and 1.9 are corollaries of Theorem 1.3, we have the following corollary of Theorem 1.14.

COROLLARY 1.15. *The set of* u *in* $C^\infty(N \times I; U)$ *(respectively,* $C^\infty_T(N \times \mathbb{R}; U)$ *where* $T > 0$*), such that* (1.72) *is an equality for all* (x,t) *in* $N \times I$ *(respectively,* $N \times \mathbb{R}$*), is residual in* $C^\infty(N \times I; U)$ *(respectively,* $C^\infty_T(N \times \mathbb{R}; U)$*). The set of* $\tilde{u}$ *in* $C^\infty(I; U)$ *(respectively,* $C^\infty_T(\mathbb{R}; U)$*) such that, with* $u(x,t) = \tilde{u}(t)$, (1.72) *is an equality for all* (x,t) *in* $N \times I$ *(respectively,* $N \times \mathbb{R}$*), is residual in* $C^\infty(I; U)$ *(respectively,* $C^\infty_T(\mathbb{R}; U)$*). The set of* $\tilde{u}$ *in* $C^\infty(I; U)$ *(respectively,* $C^\infty_T(\mathbb{R}; U)$*), such that* (1.75) *is an equality for all* (x,t) *in* $N \times I$ *(with, again,* $u(x,t) = \tilde{u}(t)$*), is residual in* $C^\infty(I; U)$ *(respectively,* $C^\infty_T(\mathbb{R}; U)$*).*

Remark 1.16. The last statement of Corollary 1.15 is related to a result obtained, independently of us and with different methods, by Wang and Sontag in [WS] when f is analytic.

As an application of Theorem 1.14 and Corollary 1.15 let us give an improvement of Example 1.7. Again let $V \in C^\infty(\mathbb{R}^n; [0, +\infty))$, satisfying (1.24) and (1.25). Let X_0, X_1, X_2 be three vector fields on $\mathbb{R}^n$ of class C^∞. Assume (1.29) and

$$L_{X_i} V \leq 0 \quad \forall i \in \{0, 1\}. \tag{1.78}$$

Assume also that, for all x in $\mathbb{R}^n \backslash \{0\}$ such that $L_{X_2} V(x) = 0$, there exist a positive integer and k vector fields $Y_1, \ldots, Y_k$ in the Lie algebra generated by X_0 and X_1 such that

$$L_{Y_1} \ldots L_{Y_k} V(x) \neq 0 \quad \text{or} \quad L_{Y_1} \ldots L_{Y_k} L_{X_2} V(x) \neq 0. \tag{1.79}$$

Then we have the following corollary.

COROLLARY 1.17. *Under the above assumptions, for any positive real number* T, $\dot{x} = X_0(x) + u_1 X_1(x) + u_2 X_2(x)$ *can be globally asymptotically stabilized by means of a time varying,* T*-periodic feedback law of class* C^∞. *If, moreover,* X_0 *does not vanish on* $\{x \in \mathbb{R}^n \backslash \{0\}; L_{X_1} V(x) = L_{X_2} V(x) = 0\}$ *then* $\dot{x} = X_0(x) + u_1 X_1(x) + u_2 X_2(x)$ *can be globally asymptotically stabilized by means of a feedback law of class* C^∞.

Proof. Let us start with the second part of this corollary. We first note that we may assume that

$$X_0(x) \neq 0 \quad \forall x \in \mathbb{R}^n \backslash \{0\}. \tag{1.80}$$

Indeed, if $\overline{X}_0 = X_0 - (L_{X_1} V) X_1 - (L_{X_2} V) X_2$, then

$$\overline{X}_0(x) \neq 0 \quad \forall x \in \mathbb{R}^n \backslash \{0\} \tag{1.81}$$

and

$$(\overline{X}_0, X_1, X_2) \tag{1.82}$$

satisfies the assumptions of Corollary 1.17. Hence replacing, if necessary, X_0 by $\overline{X}_0$, we may assume (1.80). We now apply Theorem 1.14 with $N = \mathbb{R}^n\backslash\{0\}, m = 1, U = \mathbb{R}, f(x, u_1) = X_0 + u_1^2 X_1, Y = \mathbb{R}^n\backslash\{0\}, h(x) = x, q = 3, \varphi = (L_{X_0}V, L_{X_1}V, L_{X_2}V)$ and Ω an open neighborhood of $u_1^* \equiv 0$ small enough so that (1.16) holds (see (1.80) and any u_1 in Ω extended by 0 at 0 is of class C^∞ on $\mathbb{R}^n$. We get the existence of $\overline{u}_1$ in $C^\infty(\mathbb{R}^n; [0, +\infty))$ such that

$$\overline{u}_1(0) = 0 \tag{1.83}$$

and—see (1.76) and (1.79)—

$$\{x \in \mathbb{R}^n; L_X^{k+1}V(x) = L_X^k L_{X_1}V(x) = L_X^k L_{X_2}V(x) = 0, \forall k \geq 0\} \subset \{0\} \tag{1.84}$$

with $X = X_0 + \overline{u}_1^2 X_1$. Note also that, by (1.78),

$$L_X V \leq 0. \tag{1.85}$$

Finally, using the improvements of [JQ] given in [LA, Thm. 1] or [OS, Prop. 1], we get that $u = (\overline{u}_1^2 - L_{X_1}V, -L_{X_2}V)$ globally asymptotically stabilized $\dot{x} = X_0 + u_1 X_1 + u_2 X_2$. The first part of Corollary 1.17 can be obtained in a similar way by using Corollary 1.15 (and more precisely the result dealing with $C_T^\infty(N \times \mathbb{R}; U)$ and o) instead of Theorem 1.14.

2. Proof of Theorem 1.3. For a subset S of N, let us denote by $\Omega'(S)$ the set of u in Ω such that $u \circ h$ saturates f on S. If, for all compact subsets S of N, $\Omega'(S)$ is residual in Ω, then $\Omega'(N)$ will also be residual in Ω; indeed $N = \bigcup_{n\in\mathbb{N}} S_n$ for some sequence $(S_n; n \in \mathbb{N})$ of compact subsets of N and we have $\Omega'(N) = \bigcap_{n\in\mathbb{N}} \Omega'(S_n)$. So it remains only to prove that, if

$$S \subset N \text{ is compact,} \tag{2.1}$$

then $\Omega'(S)$ is residual. Now we fix S satisfying (2.1) and, for simplicity, we will write Ω' for $\Omega'(S)$.

We equip N with a Riemannian metric. This allows us to define, for X in T_xN and $E \subset T_xN$,

$$d(X, E) = \text{Inf } \{|X - Z|; Z \in E\}, \tag{2.2}$$

where $|\cdot|$ is the norm on T_xN defined by the Riemannian metric. Let K be a compact set, let g be in $\mathcal{A}$, and let δ be a positive real number. For such K, g, and S we define

$$\Omega(K, g, \delta) = \{u \in \Omega; d(g(x, \overline{u}(x)), a_\ell(x; \overline{u})) < \delta; \forall x \in h^{-1}(K) \cap S\}, \tag{2.3}$$

where $\overline{u} = u \circ h$. Clearly, for a suitable sequence $((g_n, \delta_n); n \in \mathbb{N})$,

$$\Omega' = \bigcap_{n\in\mathbb{N}} \Omega(h(S), g_n, \delta_n).$$

Hence, if $\Omega(h(S), g, \delta)$ is open and dense in Ω, Ω' is residual in Ω. The fact that $\Omega(h(S), g, \delta)$ is open follows from the upper semicontinuity of the map $N \times C^\infty(N; U) \to [0, +\infty)$, $(x, u) \to d(g(x, u(x)), a_\ell(x; u))$ and from the compactness of S. It remains only to prove that

$$\Omega(h(S), g, \delta) \quad \text{is dense in } \Omega. \tag{2.4}$$

We equip Y with a Riemannian metric, and still denote by $|\cdot|$ the associated norm on T_yY. Let Q be a compact neighborhood of $h(S)$. For a positive real number β, let

$$\Omega_\beta = \{u \in \Omega; |h'(x)(f(x,\overline{u}(x)))| > 1/\beta \ \forall x \in S, \\ |u'(y)z| < \beta|z| \ \forall y \in Q, \forall z \in T_yY\setminus\{0\}\}, \tag{2.5}$$

and

$$\Omega_\beta(K,y,\delta) = \Omega_\beta \cap \Omega(K,g,\delta). \tag{2.6}$$

Clearly (2.4) will be proved if we check that, for all positive real number β,

$$\Omega_\beta(h(S),g,\delta) \text{ is dense in } \Omega_\beta. \tag{2.7}$$

We now consider β as a fixed positive real number. Then, from (2.5), we see that there exists a finite number of compact subsets $K_1, K_2, \dots, K_n$, each one included in a coordinate chart of Y, such that

$$h(S) = \bigcup_{i=1}^{n} K_i \tag{2.8}$$

and, for all u^0 in Ω_β, there exist n maps $\theta_1, \dots, \theta_n$ in $C^\infty(Y,\mathbb{R})$ such that, with $\overline{u}^0 = u^0 \circ h$,

$$(\theta_i \circ h)'(x)(f(x,\overline{u}_0(x))) \neq 0 \quad \forall x \in h^{-1}(K_i) \cap S. \tag{2.9}$$

Clearly,

$$\Omega_\beta(h(S),g,\delta) = \bigcap_{i=1}^{n} \Omega_\beta(K_i,g,\delta) \tag{2.10}$$

and

$$\Omega_\beta(K_i,g,\delta) \text{ is open} \quad \forall i \in [1,n]. \tag{2.11}$$

So (2.7) will be proved if we check that $\Omega_\beta(K_i,g,\delta)$ is dense in Ω_β for all i in $[1,n]$. We now fix i in $[1,n]$ and, for simplicity, we will omit this index: We will write $\Omega_\beta(K,g,\delta)$ for $\Omega_\beta(K_i,g,\delta)$ and θ_i for θ. Let u^0 be in Ω_β; we want to check that

$$u^0 \in \overline{\Omega_\beta(K,g,\delta)}. \tag{2.12}$$

Let K_1 be a compact neighborhood of K also included in a coordinate chart of Y. In order to prove (2.12) it suffices to check that, given an integer μ and a positive real number ε, there exists u in $\Omega(K,g,\delta)$ such that

$$\text{support } (u-u^0) \subset K_1, \tag{2.13}$$

$$|u-u^0|_{K_1,\mu} = \operatorname{Max}\{|\partial^\alpha(u-u^0)/\partial y^\alpha(x)|; \\ x \in K_1, |\alpha| \leq \mu - 1, \alpha \in \mathbb{N}^{\dim Y}\} < \varepsilon, \tag{2.14}$$

where, in (2.14), the derivatives are computed in a fixed coordinate chart containing K_1. We choose a function η in $C^\infty(Y;[0,1])$ such that

$$\eta = 1 \quad \text{on a neighborhood of } K \tag{2.15}$$

(2.16) $$\text{Support } (\eta) \subset K_1.$$

Let

(2.17) $$C^\infty_{2\pi}(\mathbb{R};\mathbb{R}^m) = \{b \in C^\infty(\mathbb{R};\mathbb{R}^m); b(t+2\pi) = b(t) \forall t \in \mathbb{R}\}.$$

Let $\theta(=\theta_i) \in C^\infty(Y;\mathbb{R}^m)$, satisfying (2.9) (with $K_i = K$). For b in $C^\infty_{2\pi}(\mathbb{R};\mathbb{R}^m)$, $\mu \in \mathbb{N}\backslash\{0\}$, and $\tau \in (0,1]$ we define u in $C^\infty(Y;\mathbb{R}^m)$—as in [C2, §2]—by

(2.18) $$u(y) = u^0(y) + \tau^\mu \eta(y) b(\theta(y)/\tau).$$

Then using (2.16) we have (2.13). Moreover, if τ is small enough (depending on b, μ, and ϵ), (2.14) is satisfied. We are going to check that for generic (and universal; they do not depend on $K, g, \delta, f \ldots$)b in $C^\infty_{2\pi}(\mathbb{R};\mathbb{R}^m)$ we have, if μ is large enough,

(2.19) $$u \in \Omega_\beta(K,g,\delta) \quad \text{for } \tau \text{ small enough.}$$

Let

(2.20) $$\overline{u} = u \circ h = (\overline{u}_1, \overline{u}_2, \ldots, \overline{u}_m), \qquad \overline{\theta} = \theta \circ h,$$

and

(2.21) $$Z(x) = f(x, \overline{u}(x)) \in T_x N.$$

Let us define a sequence $(X_j; j \geq 1)$ of tangent vector fields on N by

(2.22) $$X_1(x) = \tau^{\mu-1} \sum_{i=1}^m b_i^{(1)}(\overline{\theta}(x)/\tau) L_Z \overline{\theta}(x) \frac{\partial f}{\partial u_i}(x, \overline{u}(x)) \quad \forall x \in N,$$

and, for all $j \geq 2$,

(2.23) $$X_j(x) = [Z, X_{j-1}](x) + \sum_{i=1}^m L_{X_{j-1}} \overline{u}_i(x) \frac{\partial f}{\partial u_i}(x, \overline{u}(x)) \quad \forall x \in N.$$

Using (2.15), (2.18), (2.20), (2.21), (2.22), and (2.23), we easily have

(2.24) $$X_j(x) \in a_\ell(x; \overline{u}) \quad \forall x \in h^{-1}(K), \quad \forall j \geq 1.$$

In order to give a useful expression of X_j, $j \geq 1$, we introduce some combinatorial notations. Let $\mathcal{E}_k$ be the set of sequences $I = i_1 i_2 \ldots i_k$ of k elements of $\{0, 1, \ldots, m\}$; the length k of the sequence I will be denoted by $|I|$. For convenience we denote by $\mathcal{E}_0$ the set whose unique element is the empty sequence, denoted by $\emptyset$; we have $|\emptyset| = 0$. For $I = i_1 i_2 \ldots i_k$ and $J = j_1 j_2 \ldots j_{k'}$ we define $I * J \in \mathcal{E}_{k+k'}$ by

(2.25) $$I * J = i_1 i_2 \ldots i_k j_1 j_2 \ldots j_{k'}.$$

Let $\mathcal{E} = \bigcup_{k \geq 0} \mathcal{E}_k$ and $\mathcal{E}' = \mathcal{E}\backslash(\{I * 0; I \in \mathcal{E}\} \cup \{\emptyset\})$. For I in $\mathcal{E}'$ we define, by induction on $|I|$, an element f_I in $C^\infty_U(TN)$ by

(2.26) $$f_i = \frac{\partial f}{\partial u_i} \quad \forall i \in [1, m],$$

(2.27) $$f_{0*I} = [f, f_I] \quad \forall I \in \mathcal{E}',$$

and

$$f_{i*I} = \frac{\partial}{\partial u_i} f_I \quad \forall i \in [1,m], \quad \forall I \in \mathcal{E}'. \tag{2.28}$$

In a similar way as in [C1] we define a sequence $(c_r(I); r \geq 0, I \in \mathcal{E})$ of function in $C^\infty_{2\pi}(\mathbb{R};\mathbb{R})$ by

$$c_0(\emptyset) = 1, \quad c_0(I) = 0 \quad \text{if} \quad |I| \geq 1, \quad c_p(\emptyset) = 0 \quad \text{if} \quad p > 0, \tag{2.29}$$

$$c_p(i * I) = \dot{b}_i c_{p-1}(I) + \dot{c}_{p-1}(i * I) \quad \forall I \in \mathcal{E}, \quad \forall i \in [0,m], \quad \forall p \geq 1, \tag{2.30}$$

with the convention $\dot{b}_0 = 1$. For example, $c_1(i) = b_i^{(1)}$ for all $i \in [1,m]$, $c_1(I) = 0$ if $|I| \geq 2$, $c_2(i) = b_i^{(2)}$ for all $i \in [1,m]$, $c_2(0) = 0$, $c_2(i_1 i_2) = b_{i_1}^{(1)} b_{i_2}^{(1)}$ for all $i_1 \in [1,m]$, for all $i_2 \in [1,m]$. Note that

$$c_r(I) \text{ is a polynomial in the variables } b_i^{(j)}, j \leq r, i \in [1,m]. \tag{2.31}$$

For I in $\mathcal{E}$, let $\alpha(I)$ be the number of times the index 0 appear in I and let $\beta(I) = |I| - \alpha(I)$. Let also, for two integers i and j,

$$\Delta_{i,j} = \left\{ k = (k_1, \ldots, k_j) \in \mathbb{N}^j; 1 \leq k_1 \leq \ldots \leq k_j, \sum_{r=1}^{j} k_r = i \right\} \tag{2.32}$$

and, if $k \in \Delta_{i,j}$,

$$L_Z^k \overline{\theta} = L_Z^{k_1} \overline{\theta} \ldots L_Z^{k_j} \overline{\theta}. \tag{2.33}$$

Note that $\Delta_{i,j}$ is not empty if and only if $j \leq i$. By induction on $r \geq 1$ we can check that

$$\begin{aligned} X_r(x) = & \sum_{I \in \mathcal{E}', |I| \leq r} (L_Z \overline{\theta})^{r-\alpha(I)} \tau^{\alpha(I)+\mu\beta(I)-r} c_r(I)(\overline{\theta}(x)/\tau) f_I(x, \overline{u}(x)) \\ & + \sum_{I \in \mathcal{E}', |I| \leq r} \sum_{\alpha(I) < s < r} \tau^{\alpha(I)+\mu\beta(I)-s} X_{r,I,s}(x) \end{aligned} \tag{2.34}$$

with

$$X_{r,I,S}(x) = \sum_{k \in \Delta_{r-\alpha(I), s-\alpha(I)}} (L_Z^k \overline{\theta})(x) Q_{r,s,I,J}(\overline{\theta}(x)/\tau) f_I(x, \overline{u}(x))$$

where

$$Q_{r,s,I,J} \text{ is a polynomial in the variable } (b_i^{(j)}; j \geq 1, i \in [1,m]). \tag{2.35}$$

By definition of g and using Jacobi's identity we can see that, in the vectorial space $C^\infty_U(TN)$ and for some large enough integer ℓ',

$$g \in \text{Span } \{f_I; I \in \mathcal{E}', |I| \leq \ell'\}. \tag{2.36}$$

Let

$$\ell = \ell' \mu \tag{2.37}$$

and

$$q_0(\ell) = \text{cardinal of } \{I; I \in \mathcal{E}', |I| \leq \ell\} = m(m+1)^{\ell-1}. \tag{2.38}$$

Let us introduce an ordering on the I in $\mathcal{E}'$ with $0 < |I| \leq \ell$ (e.g., lexicographical) and, for $q > q_0(\ell)$, let us consider the nonsquare $q \times q_0(\ell)$ matrix with entries $(c_r(I); 1 \leq r \leq q, I \in \mathcal{E}'$ with $|I| \leq \ell)$. Let J_q be the space of jets

$$J_q = \{b_i^{(j)}; 0 \leq j \leq q, 1 \leq i \leq m\}. \tag{2.39}$$

In Appendix A we prove the following lemma.

LEMMA 2.1. *If q is large enough, then the set of $(b_i^{(j)}; 0 \leq j \leq q, 1 \leq i \leq m)$ in J_q such that*

$$\text{rank } (c_r(I); 1 \leq r \leq q, I \in \mathcal{E}', |I| \leq \ell) < q_0(\ell) \tag{2.40}$$

is of codimension at least 2 in J_q.

Let us remark that Appendix A provides an explicit value of q (which is not optimal and, of course, depends on m and ℓ) such that the conclusion of Lemma 2.1 holds. Applying Thom's transversality theorem (see, e.g., [GG, Chap. II, Thm. 4.9]) and using Lemma 2.1 we get, for $q_1(\ell)$ large enough, the existence of a b in $C^\infty_{2\pi}(\mathbb{R}; \mathbb{R}^m)$ such that

$$\text{rank } (c_r(I)(s); 1 \leq r \leq q_1(\ell), I \in \mathcal{E}', |I| \leq \ell) = q_0(\ell), \quad \forall s \in \mathbb{R}. \tag{2.41}$$

In fact, there exists a residual set $\mathcal{R}$ in $C^\infty_{2\pi}(\mathbb{R}; \mathbb{R}^m) \simeq C^\infty(\mathbb{R}/2\pi\mathbb{Z}; \mathbb{R}^m)$ such that (2.41) holds for all b in $\mathcal{R}$ and all $\ell \geq 1$. We choose a b such that (2.41) holds; we are going to check that (2.19) holds. By (2.36) we may assume

$$g = f_{I_0} \quad \text{where } I_0 \in \mathcal{E}' \quad \text{with } |I_0| \leq \ell'. \tag{2.42}$$

Let us denote by M various constants independent of τ in (0, 1] and x in $h^{-1}(K) \cap S$ (but M may depend on $K, S, \ell, h, f, b, u_0, \beta, \mu \ldots$). Let us remark that, for all τ in (0, 1],

$$|L_Z \overline{\theta}| \leq M \text{ on } h^{-1}(K) \cap S \tag{2.43}$$

and

$$|L_Z^j \overline{\theta}| \leq M\tau^{2-j} \quad \text{on } h^{-1}(K) \cap S \quad \forall j \in [2, q_1(\ell)]. \tag{2.44}$$

From these two inequalities, we get that, if $I \in \mathcal{E}'$, $\beta(I) \leq s < r \leq q_1(\ell)$, and $k \in \Delta_{r-\beta(I), s-\beta(I)}$, then

$$|L_Z^k \overline{\theta}| \leq M\tau^{s-r+1} \quad \text{on } h^{-1}(K) \cap S, \quad \forall \tau \in (0, 1]. \tag{2.45}$$

By (2.9) there exist $\gamma > 0$ and τ_0 in (0, 1] such that

$$|L_Z \overline{\theta}| \geq \gamma \quad \text{on } h^{-1}(K) \cap S, \quad \forall \tau \in (0, \tau_0). \tag{2.46}$$

From (2.34), (2.45), and (2.46) we get, on $h^{-1}(K) \cap S$ and for r in $[1, q_1(\ell)]$,

$$X_r = \sum_{I \in \mathcal{E}', |I| \leq r} (L_Z \overline{\theta})^{r-\alpha(I)} \tau^{\alpha(I)+\mu\beta(I)-r} (C_r(I)(\overline{\theta}/\tau) + \tau R(r, I, \tau)) f_I \tag{2.47}$$

where $R(r, I, \tau) \in C^0(h^{-1}(K) \cap S; \mathbb{R})$ satisfies for all $(r, I, \tau) \in [1, q_1(\ell)] \times \mathcal{E}' \times (0, \tau_0]$, with $|I| \leq q_1(\ell)$,

$$|R(r, I, \tau)| \leq M \quad \text{on } h^{-1}(K) \cap S. \tag{2.48}$$

From (2.41) and (2.48) we get, on $h^{-1}(K) \cap S$, for some $\tau_1 \in (0, \tau_0)$ and for all τ in $(0, \tau_1)$,

$$\sum_{r=1}^{q_1(\ell)} \gamma(r, \tau)(C_r(I)(\overline{\theta}/\tau) + \tau R(r, I, \tau)) = 0 \quad \forall I \in \mathcal{E}' \backslash \{I_0\} \quad \text{with } |I| \leq \ell \tag{2.49}$$

and

$$\sum_{r=1}^{q_1(\ell)} \gamma(r, \tau)(C_r(I_0)(\overline{\theta}/\tau) + \tau R(r, I_0, \tau)) = 1, \tag{2.50}$$

where $\gamma(r, \tau) \in C^0(h^{-1}(K) \cap S; \mathbb{R})$ satisfies

$$|\gamma(r, \tau)| \leq M \quad \text{on } h^{-1}(K) \cap S, \quad \forall (r, \tau) \in [1, q_1(\ell)] \times (0, \tau_1]. \tag{2.51}$$

From (2.47), (2.48), (2.49), (2.50), and (2.51) we get, on $h^{-1}(K) \cap S$,

$$\left| f_{I_0}(x, \overline{u}(x)) - \sum_{r=1}^{q_1(\ell)} (L_Z \overline{\theta})^{-r+\alpha(I_0)} \tau^{-\alpha(I_0)-\mu\beta(I_0)+r} \gamma(r, \tau)(x) X_r(x) \right| \leq M \sum_{I \in \mathcal{E}', \ell < |I| \leq r} \tau^{-\alpha(I_0)-\mu\beta(I_0)+\alpha(I)+\mu\beta(I)} \tag{2.52}$$

which proves (2.19) (and ends the proof of Theorem 1.3) since $g = f_{I_0}$ (see (2.42)) and, by (2.37),

$$\alpha(I_0) + \mu\beta(I_0) < \alpha(I) + \mu\beta(I), \quad \forall I \in \mathcal{E}' \quad \text{with } |I| > \ell. \tag{2.53}$$

(Note also that since Ω is open we have, using (2.16) and (2.18), $u \in \Omega_\beta$ if μ is large enough and, then, τ small enough.)

3. Proofs of corollaries and Theorem 1.14. In this section we give the proof of the corollaries of §1, which were not proved in that section, and the modifications of the proof of Theorem 1.3 in order to get Theorem 1.14.

3.1. Proof of Corollary 1.5. We prove the global statement only (the proof of the local statement is similar). Let $\overline{u} \in C^0(\mathbb{R}^n; U)$ be such that

$$\overline{u}(0) = 0 \text{ and } 0 \text{ is globally asymptotically stable point of } \dot{x} = f(x, \overline{u}(x)). \tag{3.1}$$

By a generalization of Kurzweil [KUR] of the converse of Lyapunov's second theorem, there exists V in $C^\infty(\mathbb{R}^n; [0, +\infty))$ such that

$$(V(x) = 0 \Longleftrightarrow x = 0), \lim_{|x| \to +\infty} V(x) = +\infty, \tag{3.2}$$

and

$$f(x, \overline{u}(x)) \cdot \nabla V(x) < 0 \quad \forall x \neq 0. \tag{3.3}$$

Let Ω be the set of u in $C^\infty(\mathbb{R}^n\backslash\{0\};U)$ such that

$$|u(x)| < |\overline{u}(x)| + |x| \quad \forall x \in \mathbb{R}^n\backslash\{0\}, \tag{3.4}$$

$$f(x,u(x)) \cdot \nabla V(x) < 0 \quad \forall x \in \mathbb{R}^n\backslash\{0\}. \tag{3.5}$$

This set Ω is open and, since $C^\infty(\mathbb{R}^n\backslash\{0\};U)$ is dense in $C^0(\mathbb{R}^n\backslash\{0\};U)$, it is nonempty by (3.3). We take $Y = N = \mathbb{R}^n\backslash\{0\}, h(x) = x$. By (3.5), (1.16) holds. Applying Theorem 1.3 we get that Ω contains at least a map u^0 which saturates f on $\mathbb{R}^n\backslash\{0\}$. This feedback law u^0 globally asymptotically stabilizes $\dot{x} = f(x,u)$, belongs to $C^\infty(\mathbb{R}^n\backslash\{0\};U)\cap C^0(\mathbb{R}^n;U)$, and satisfies $u^0(0) = 0$.

3.2. Proof of Corollary 1.6. Let Ω be an open neighborhood of 0 in $C^\infty(\mathbb{R}^n\backslash\{0\};U)$ such that, for all u in Ω,

$$f(x,u(x)) \neq 0 \quad \forall x \in \mathbb{R}^n\backslash\{0\}, \tag{3.6}$$

$$\forall x \in \mathbb{R}^n\backslash\{0\}, \quad \exists g \in \mathcal{A}\cup\{f\} \quad \text{such that } g(x,u(x)) \cdot \nabla V(x) \neq 0, \tag{3.7}$$

and

$$u \text{ extended by 0 on } \{0\} \text{ is of class } C^\infty \text{ on } \mathbb{R}^n. \tag{3.8}$$

The existence of such a Ω follows from (1.26) and (1.27). We take $Y = N = \mathbb{R}^n\backslash\{0\}, h(x) = x$. It follows from Theorem 1.3 that there exists u^0 such that

$$u^0 \in \Omega \tag{3.9}$$

$$u^0 \text{ saturates } f \text{ on } \mathbb{R}^n\backslash\{0\}. \tag{3.10}$$

We extend u^0 by 0 on $\{0\}$ and still denote by u^0 this extension. Let

$$\mathcal{O} = \{(x,v); v + u^0(x) \in U\} \tag{3.11}$$

and let $F \in C^\infty(\mathcal{O};\mathbb{R}^n)$ be defined by

$$F(x,v) = f(x,v+u^0(x)). \tag{3.12}$$

Also let

$$F_0(x) = F(x,0), \tag{3.13}$$

$$F_i(x) = \frac{\partial f}{\partial u_i}(x,u^0(x)), \qquad i \in [1,m]. \tag{3.14}$$

Then, using (1.23), (3.7), and (3.10),

$$F_0(x) \cdot \nabla V(x) \leq 0 \quad \forall x \in \mathbb{R}^n, \tag{3.15}$$

and for all x in $\mathbb{R}^n\backslash\{0\}$ such that (3.15) is an equality, there exists k in $\mathbb{N}$ and i in $[1,m]$ such that

$$L_{ad^k_{F_0}(Fi)}V(x) \neq 0. \tag{3.16}$$

The conclusion of Corollary 1.6 follows from Jurdjevic and Quinn [JQ] (see Appendix B).

3.3. Proof of Corollary 1.9. The proof is similar to the proof of Corollary 1.5. We omit it.

3.4. Proof of Corollary 1.11. The proof is similar to the proof of Corollary 1.6.; the only difference is that we use Corollary 1.9 instead of Theorem 1.3.

3.5. Proof of Corollary 1.13. Let Ω be an open neighborhood of 0 in $C^\infty((\mathbb{R}^n\backslash\{0\})\times(0,T/2);U)$ such that

(3.17) any u in Ω extended by 0 outside $(\mathbb{R}^n\backslash\{0\})\times(0,T/2)$ is C^∞ on $\mathbb{R}^n\times\mathbb{R}$.

For u in Ω we extend u to $\mathbb{R}^n\times\mathbb{R}$ by

$$u = 0 \text{ on } (\{0\}\times\mathbb{R})\cup(\mathbb{R}^n\times(T/2)\mathbb{Z}), \tag{3.18}$$

and, as in [C1],

$$u(x,t) = \varphi(T-t, u(x,T-t)) \quad \forall (x,t)\in\mathbb{R}^n\times(T/2,T), \tag{3.19}$$

$$u(x,t+T) = u(x,t) \quad \forall (x,t)\in\mathbb{R}^n\times\mathbb{R}. \tag{3.20}$$

We still denote by u this extension. Note that by (1.49), (3.17), (3.18), (3.19), and (3.20)

$$u\in C^\infty(\mathbb{R}^n\times\mathbb{R};U). \tag{3.21}$$

Hence we may consider Ω as a subset of $C^\infty(\mathbb{R}^n\times\mathbb{R};U)$. Now, as Pomet in [P], we define $W^u:\mathbb{R}^n\times\mathbb{R}\to[0,+\infty)$ by

(3.22)
$$\frac{\partial W^u}{\partial t}(x,t)+\sum_{i=1}^n f_i(x,t,u(x,t))\frac{\partial W^u}{\partial x_i}(x,t)=0, \quad W^u(x,0)=V(x) \quad \forall (x,t)\in\mathbb{R}^n\times\mathbb{R},$$

Then, using (1.47), (1.48), (3.19), and (3.20), we easily have

$$W^u(x,t+T)=W^u(x,t) \quad \forall (x,t)\in\mathbb{R}^n\times\mathbb{R}. \tag{3.23}$$

Moreover W^u satisfies (1.41) and (1.42), and, diminishing Ω if necessary, we get from (1.57) that, for all (x,t) in $\mathbb{R}^n\backslash\{0\}\times[0,T/2]$ and for all u in Ω, there exists X in $a(x,t,u(x,t))$ such that

$$\sum_{i=1}^n X_i\frac{\partial W^u}{\partial x_i}(x,t)\neq 0. \tag{3.24}$$

Now, using Corollary (1.8), we get the existence of a $\overline{u}$ in Ω such that

$$\overline{u} \text{ saturates } f \text{ on } (\mathbb{R}^n\backslash\{0\})\times(0,T/2). \tag{3.25}$$

Finally, we obtain the desired conclusion by using the version of [JQ] given in Appendix B: We take $N=(\mathbb{R}^n\backslash\{0\})\times(\mathbb{R}/T\mathbb{Z})$, $F((x,t),u)=(f(x,t,\overline{u}(x,t)+u),\partial/\partial t)$, $V((x,t))=W^{\overline{u}}(x,t)\ldots$; note that by (3.24) and (3.25)

$$Q\subset(\mathbb{R}^n\backslash\{0\})\times([T/2,T]/T\mathbb{Z}). \tag{3.26}$$

Remark 3.1. We may wonder if there exists $\overline{u} \in C^\infty(\mathbb{R}^n \times \mathbb{R}; U)$ satisfying (3.18), (3.19), and (3.20) which saturates f on all $(\mathbb{R}^n \backslash \{0\}) \times \mathbb{R}$. This is the case if

$$f(x,u) = \sum_{i=1}^{m} u_i f_i(x) \tag{3.27}$$

and

$$\varphi(u) = -u. \tag{3.28}$$

This can be seen in the following way. First, by Corollary 1.8, there exists $u_1 \in C^\infty(\mathbb{R}^n \times \mathbb{R}; U)$ which saturates f on $(\mathbb{R}^n \backslash \{0\}) \times \mathbb{R}$ and satisfies

$$u_1(0,t) = 0 \quad \text{for all } t \text{ in } \mathbb{R}. \tag{3.29}$$

Then, let $u_2(x,t) = d(tu_1(x,t^2))$ where $d \in C^\infty(\mathbb{R}^m; U)$ satisfies $d(u) = u$ for u small and $d(-u) = -d(u)$ for all u. Then u_2 satisfies (3.29), is odd and, as can be easily seen, also saturates f on $(\mathbb{R}^n \backslash \{0\}) \times \{0\}$. From u_2 we can construct u_3 in $C^\infty(\mathbb{R}^n \times \mathbb{R}; U)$ which satisfies (3.18), (3.19), and (3.20) and saturates f on $(\mathbb{R}^n \backslash \{0\}) \times (T/2)\mathbb{Z}$. Now applying Corollary 1.8 on $(\mathbb{R}^n \backslash \{0\}) \times (0,T)$ we get $u_4 \in C^\infty(\mathbb{R}^n \times [0,T]; U)$ which saturates f on $(\mathbb{R}^n \backslash \{0\}) \times (0, T/2)$ and satisfies, for all x in $\mathbb{N}$ and for all (α, β) in $\mathbb{N} \times \mathbb{N}^n$,

$$\frac{\partial^\alpha}{\partial t^\alpha} \frac{\partial^{|\beta|} u_4}{\partial x^\beta} = \frac{\partial^\alpha}{\partial t^\alpha} \frac{\partial^\beta u_3}{\partial x^\beta} \quad \text{on } (\{0\} \times [0,T]) \cup ((\mathbb{R}^n \backslash \{0\}) \times \{0, T/2\}); \tag{3.30}$$

(note that the set of u in $C^\infty(\mathbb{R}^n \times [0,T]; U)$ which satisfy (3.30) is open for the $C^\infty-$topology of $C^\infty((\mathbb{R}^n \backslash \{0\}) \times (0,T/2); U)$). We extend u_4 to $\mathbb{R}^n \times \mathbb{R}$ by requiring (3.18), (3.19), and (3.20). Then this extended u_4 saturates f on $(\mathbb{R}^n \backslash \{0\}) \times (\mathbb{R} \backslash (T/2)\mathbb{Z})$ and, by (3.30), saturates f on $(\mathbb{R}^n \backslash \{0\}) \times (T/2)\mathbb{Z}$. Therefore u_4 saturates f on $(\mathbb{R}^n \backslash \{0\}) \times \mathbb{R}$.

3.6. Proof of Theorem 1.14. To get the first (respectively, second) part of Theorem 1.14 we just use §2 with the following modifications:

- In the definition of $\Omega'(S)$ "$u \circ h$ saturates f on S" is replaced by "u satisfies (1.76) (respectively, (1.77)) for all x in S";
- in (2.2) E is now a subset of $\mathbb{R}^q$ (respectively, a subset of $(T^*_x N)^q$) and $|\ |$ is a norm on $\mathbb{R}^q$ (respectively, a norm on $(T^*_x N)^q$ which depends continuously on x in N);
- in the definition of $\Omega(K, g, \delta), g$ is now in $\mathcal{O}$) (respectively $d\mathcal{O}$) and $a_\ell(x; \overline{u})$ is replaced by $o_\ell(x; \overline{u})$ (respectively, $do_\ell(x; \overline{u})$);
- X_i is now in $C^\infty(N; \mathbb{R}^q)$ (respectively, $C^\infty(T^*N)^q$); X_1 is defined by replacing in (2.22) $\partial f / \partial u_i(x, \overline{u}(x))$ by φ (respectively, $d\varphi$),
- f_I is now in $C^\infty(N \times U; \mathbb{R}^q)$ (respectively, $C^\infty_U(T^*N)^q$) and is defined by

$$f_i(x,u) = \varphi(x) (\text{respectively, } f_i(x,u) = d\varphi(x)) \quad \forall (x,u) \in N \times U, \quad \forall i \in [1,m)$$
$$f_{0*I} = L_f f_I \quad \forall I \in \mathcal{E}'$$

and (2.28).

The remaining part of the proof is unchanged.

Appendix A. In this appendix we prove, in particular, Lemma 2.1. We consider ℓ as fixed and, in order to emphasize that $b_i^{(j)}$ are considered as independent real numbers, we will write b_i^j for $b_i^{(j)}$. Let J be the set of sequences $b = (b_i^j; 1 \le i \le m, j \ge 0)$ and, for an integer q, we denote by J_q the set of b in J such that

$$b_i^j = 0 \quad \text{for all } (i,j) \quad \text{in } [1,m] \times (q, +\infty). \tag{A.1}$$

We have $J_q \subset J_{q+1}$. We define also

$$J_q^{\perp} = \{b \in J; b_i^j = 0 \text{ for all } (i,j) \text{ in } [1,m] \times [1,q]\}. \tag{A.2}$$

Let B_q be the set of b in J_q such that

$$\operatorname{rank}\{c_r(I); 0 \leq r \leq q, I \in \mathcal{E}', 0 < |I| \leq \ell\} < q_0(\ell), \tag{A.3}$$

and let $G_q = J_q \backslash B_q$. Note that

$$G_q \subset G_{q+1}. \tag{A.4}$$

Our first statement is the following proposition.

PROPOSITION A.1. *For any integer q', there exists an integer q larger than q' such that*

$$J_{q'}^{\perp} \cap G_q \neq \phi. \tag{A.5}$$

Lemma 2.1 is a special case of the following corollary of Proposition A.1.

COROLLARY A.2. *Let s be an integer. Then, for q large enough, the codimension of B_q in J_q is at least s.*

Proof of Corollary A.2. Using Proposition A.1 we get the existence of $(s+1)$ integers $q_0, q_1, \ldots, q_s$ such that

$$0 = q_0 < q_1 < \ldots < q_s \tag{A.6}$$

and

$$J_{q_{i-1}}^{\perp} \cap G_{q_i} \neq \phi \quad \text{for all} \quad i \quad \text{in } [1,s]. \tag{A.7}$$

Let, for i in $[1,s]$, $n_i = m(q_i - q_{i-1})$ and let $x_i = (x_i^1, \ldots, x_i^{n_i}) \in \mathbb{R}^{n_i}$ be defined by

$$x_i^{k+(j-1)m} = b_k^{j+q_i}, \quad i \leq j \leq q_i - q_{i-1}, \quad k \in [1,m]. \tag{A.8}$$

Then, for all i in $[1,s]$, there exists a polynomial $P_i \in \mathbb{R}[x_1, \ldots, x_i]$ in the variables $(x_r^j; 1 \leq j \leq n_i, r \in [1,i])$ such that

$$P_i(x_1, \ldots, x_i) = 0 \Longleftrightarrow (b_r^j; r \in [1,m], 0 \leq j \leq q_i) \in B_{q_i}. \tag{A.9}$$

Let us remark that, if we multiply all the components of b by λ, then $c_r(I)$ is multiplied by $\lambda^{\beta}(I)$ where (see §2) $\beta(I)$ is the number of indices in I, counted according to their multiplicity, which are not zero. Hence we may impose that, for any integer i in $[1,s]$, there exists a positive integer m_i such that

$$P_i(\lambda x_1, \ldots, \lambda x_i) = \lambda^{m_i} P(x_1, \ldots, x_i) \quad \forall (\lambda, x_1, \ldots, x_i) \in \mathbb{R} \times \mathbb{R}^{n_1} \times \ldots \times \mathbb{R}^{n_i}. \tag{A.10}$$

By (A.10) we get that, for any x_i in $\mathbb{R}^{n_i}$ such that

$$P_i(0, \ldots, 0, x_i) \neq 0, \tag{A.11}$$

and, for any $(x_1, \ldots, x_{i-1})$ in $\mathbb{R}^{n_1} \times \ldots \times \mathbb{R}^{n_{i-1}}$,

$$P_i(x_1, \ldots, x_{i-1}, \lambda x_i) \neq 0 \quad \text{for } \lambda \text{ large enough.} \tag{A.12}$$

Therefore using (A.7) and (A.9), we get that

$$\begin{aligned} &\forall i \in [1,s], \quad \forall (x_1,\dots,x_{i-1}) \in \mathbb{R}^{n_1} \times \dots \times \mathbb{R}^{n_{i-1}}, \\ &\exists x_i \in \mathbb{R}^{n_i} \quad \text{such that } P_i(x_1,\dots,x_i) \neq 0, \end{aligned} \tag{A.13}$$

where, by convention, the meaning of (A.13), when $i = 1$, is

$$\exists x_1 \in \mathbb{R}^{n_1} \quad \text{such that} \quad P_1(x_1) \neq 0. \tag{A.14}$$

Hence Corollary A.2 is a consequence of the following lemma.

LEMMA A.3. *Let* $(P_i; 1 \leq i \leq s)$ *be a sequence of polynomials such that*

$$P_i \in \mathbb{R}[x_1,\dots,x_i]. \tag{A.15}$$

Assume that (A.13) *holds. Then the codimension in* $\mathbb{R}^{n_1+\dots+n_s}$ *of* $\Sigma_s := \{x \in \mathbb{R}^{n_1+\dots+n_s};$ $P_i(x) = 0$, *for all* $i \in [1,s]\}$, *is at least* s.

Proof of Lemma A.3. We prove the lemma by induction on s. This lemma is clearly true for $s = 1$ (see (A.14)). Assume it holds for s; we are going to check that it holds for $s+1$. Let $\theta : \Sigma_{s+1} \to \Sigma_1$ be defined by

$$\theta(x_1,\dots,x_{s+1}) = x_1.$$

By (A.14)

$$\dim \Sigma_1 \leq n_1 - 1. \tag{A.16}$$

Let x_1 be in $\mathbb{R}^{n_1}$. Let us define a new sequence of polynomials $(\overline{P}_i; 1 \leq i \leq s)$

$$\overline{P}_i \in \mathbb{R}([x_2,\dots,x_{i+1}]) \tag{A.17}$$

$$\overline{P}_i(x_2,\dots,x_{i+1}) = P_{i+1}(x_1,x_2,\dots,x_{i+1}). \tag{A.18}$$

This sequence of s polynomials satisfies the hypothesis of Lemma A.3. Hence, by the induction assumption,

$$\dim \theta^{-1}(x_1) \leq n_2 + \dots + n_s - s \quad \text{for all} \quad x_1 \quad \text{in } \Sigma_1. \tag{A.19}$$

From (A.16) and (A.19), we get

$$\dim \Sigma_{s+1} \leq n_1 + n_2 + \dots + n_s - (s+1), \tag{A.20}$$

which ends the proof of Lemma A.3.

We turn to the proof of Proposition A.1. We first introduce some notations. Let $\tilde{J}$ be the set of sequences of real numbers $\tilde{b} = (\tilde{b}_i^j; i \in [0,m], j \geq 0)$. For $\tilde{b}$ in $\tilde{J}$, I in $\mathcal{E}, r$ in $\mathbb{N}$, we define $\tilde{c}_r(I) \in \mathbb{R}$ as we have defined $c_r(I)$ in §2. Note that now, we do not have, in general, $\tilde{b}_0^0 = 1, \tilde{b}_0^j = 0$ for $j > 0$. For example, $\tilde{c}_1(i) = \tilde{b}_i^1$, for all $i \in\in [0,m]$, and $\tilde{c}_2(ij) = \tilde{b}_1^j \tilde{b}_j^1$, for all $i \in [0,m]$, and for all $j \in [0,m]$. Let, for each integer q,

$$\tilde{J}_q = \{\tilde{b} \in \tilde{J}; \tilde{b}_i^j = 0 \, \forall j \geq q+1, \forall i \in [0,m]\}, \tag{A.21}$$

$$\tilde{B}_q = \{\tilde{b} \in \tilde{J}_q; \operatorname{rank}(c_r(I); 0 \leq r \leq q, 0 \leq |I| \leq \ell) < \tilde{q}_0(\ell)\}, \tag{A.22}$$

with $\tilde{q}_0(\ell) = (m+1)((m+1)^\ell - 1)/m = \#\{I \in \mathcal{E} \backslash \{\phi\}; |I| \leq \ell)$. Let

$$\tilde{G}_q = \tilde{J}_q \backslash \tilde{B}_q. \tag{A.23}$$

We have again

$$\tilde{G}_q \subset \tilde{G}_{q+1}. \tag{A.24}$$

For a sequence of real numbers $a = (a_i; i \geq 1)$, we define a map $F_a : \tilde{J} \to \tilde{J}$ by

$$(F_a(\tilde{b}))_i^0 = \tilde{b}_i^0 \quad \forall i \in [0, m] \tag{A.25}$$

$$(F_a(\tilde{b}))_i^j = D((F_a(\tilde{b}))_i^{j-1}) \quad \forall i \in [0, m], \quad \forall j \geq 1, \tag{A.26}$$

where D denotes the differentiation on the set of polynomials in the variables $(a_i; i \geq 1), (\tilde{b}_i^j; i \in [0, m], j \geq 0)$ such that $Da_i = a_{i+1}$, for all $i \geq 1$ and $D\tilde{b}_i^j = a_1\tilde{b}_i^{j+1}$, for all $i \in [0, m]$, for all $j \geq 0$. More precisely, we first define with this differentiation, (A.25), and (A.26) polynomials $(F_a(\tilde{b}))_i^j$ in the variables $(a_i; i \geq 1), (\tilde{b}_i^j; i \in [1, m], j \geq 0)$ and then obtain an element of $\tilde{J}$, still denoted $F_a(\tilde{b})$, by substituting in these polynomials the "values" of $(a_i; i \geq 1)$ and $(\tilde{b}_i^j; i \in [1, m], j \geq 0)$. For example, we have

$$(Fa(\tilde{b}))_i^2 = a_2\tilde{b}_i^1 + a_1^2\tilde{b}_i^2 \quad \forall i \in [1, m] \tag{A.27}$$

and

$$(F_a(\tilde{b}))_i^3 = a_3\tilde{b}_i^1 + 3a_1a_2\tilde{b}_i^2 + a_1^3\tilde{b}_i^3 \quad \forall i \in [1, m]. \tag{A.28}$$

Also let, for each integer q, $\pi_q : \tilde{J} \to \tilde{J}_q$ be defined by

$$(\pi_q(\tilde{b}))_i^j = \tilde{b}_i^j \quad \forall j \leq q, \quad \forall i \in [0, m], \tag{A.29}$$

$$(\pi q(\tilde{b}))_i^j = 0 \quad \forall j > q, \quad \forall i \in [0, m]. \tag{A.30}$$

Let us assume, for the moment, the following lemma.

LEMMA A.4. *If r is an integer such that*

$$a_r \neq 0, \tag{A.31}$$

then, for all integers q,

$$(\pi_{rq} \circ F_a)(\tilde{G}_q) \subset \tilde{G}_{rq}. \tag{A.32}$$

Let $\tilde{J}_q^{\perp} = \{\tilde{b} \in \tilde{J}; \tilde{b}_i^j = 0$ for all i in $[0, m]$ and all $j \geq q + 1\}$. As a corollary of Lemma A.4 and [C1, Lem. 4.1], we have the following proposition.

PROPOSITION A.5. *For any integer q', there exists an integer $q > q'$ such that*

$$J_{q'}^{\perp} \cap \tilde{G}_q \neq \phi. \tag{A.33}$$

Proof of Proposition A.5. Let $a = (a_i; i \geq 1)$ be such that

$$a_i = 0 \quad \text{for all} \quad i \quad \text{in } [1, q'], \tag{A.34}$$

$$a_{q'+1} \neq 0. \tag{A.35}$$

From (A.34) we easily get

$$F_a(\tilde{J}) \subset \tilde{J}_{q'}^{\perp}. \tag{A.36}$$

Applying Lemma A.4 with $r = q' + 1$, we obtain from (A.35)

$$(\pi_{(q'+1)s} \circ F_a)(\tilde{G}_s) \subset \tilde{G}_{(q'+1)s}. \tag{A.37}$$

By [C1, Lem. 4.1], we know that there exists an integer s such that

$$G_s \neq \phi. \tag{A.38}$$

Let us remark that the definition of $c_r(I)$ we give here is slightly different from the one we gave previously in [C1]. Our new $c_r(I)$ correspond to our old $c_r(I)$ computed with $b_i^j = \tilde{b}_i^{j+1}$. We choose s satisfying (A.38) and take $q = (q' + 1)s$. Then (A.33) follows from (A.36), (A.37), and (A.38).

The same proof as the proof of Corollary A.2 (just replace $\beta(I)$ by $|I|$) gives, as a corollary of Proposition A.5, the following.

COROLLARY A.6. *For any integer s, there exists an integer q such that the codimension of $\tilde{B}_q$ in $\tilde{J}_q$ is at least s.*

We now give the proof of Proposition A.1. We first define a sequence of rational functions $(\bar{a}_i; i \geq 1)$ in the variables $(\tilde{b}_0^i; i \geq 0)$ by

$$\bar{a}_1 = 1/\tilde{b}_0^1 \tag{A.39}$$

$$\bar{a}_i = (d\bar{a}_{i-1})/\tilde{b}_0^1 \quad \text{for } i \geq 2 \tag{A.40}$$

where d denotes the differentiation in the field of rational functions in the variables $(\tilde{b}_0^i; i \geq 0)$ such that $d\tilde{b}_0^i = \tilde{b}_0^{i+1}$ for all integer i. Let us remark that

$$\forall i \geq 1, \quad (\tilde{b}_0^1)^{2i-1}\bar{a}_i \text{ is a polynomial in the variables } (\tilde{b}_0^j; j \geq 0). \tag{A.41}$$

Let q' be an integer. By Corollary A.6, there exist an integer q and $\tilde{b}$ in $\tilde{J}_q$ such that

$$\tilde{b} \in \tilde{G}_q, \tag{A.42}$$

$$\tilde{b}_i^j = 0 \quad \text{for all} \quad (i,j) \quad \text{in } ([0,m] \times [0,q'])\backslash\{(0,1)\}, \tag{A.43}$$

$$\tilde{b}_0^1 = 1. \tag{A.44}$$

From (A.41) and (A.44), we see that the rational functions $(\bar{a}_i; i \geq 1)$ can be evaluated for this $\tilde{b}$. This leads to a sequence of real numbers $(a_i; i \geq 1)$. Let

$$\bar{b} = F_a(\tilde{b}). \tag{A.45}$$

From (A.25), (A.26), (A.39), (A.40), and (A.45), we obtain

$$\bar{b}_0^1 = 1, \tag{A.46}$$

$$\bar{b}_0^j = 0 \quad \text{if} \quad j \geq 2. \tag{A.47}$$

From (A.25), (A.26), (A.39), (A.40), (A.43), and (A.45), we get

$$\bar{b}_i^j \quad \text{for all} \quad (i,j) \in [1,m] \times [0,q']. \tag{A.48}$$

From Lemma A.4, (A.39), (A.42), and (A.45), we have

$$\pi_q(\bar{b}) \in \tilde{G}_q. \tag{A.49}$$

Finally, let $b \in J_q$ be defined by

$$b_i^j = (\pi_q(\bar{b}))_i^j \quad \forall i \in [1,m], \quad \forall j \geq 0. \tag{A.50}$$

Then, from (A.46), (A.47), (A.48), and (A.49), we have

$$b \in J_{q'}^{\perp} \cap G_q \tag{A.51}$$

which implies (A.5).

It remains to prove Lemma A.4. We first define a sequence $(A_{i,j}; i \in \mathbb{N}, j \in \mathbb{N})$ of polynomials in the variables $(a_i; i \geq 1)$ by

$$A_{1,j} = 0 \qquad j \geq 1 \tag{A.52}$$

$$A_{1,1} = a_1 \tag{A.53}$$

$$A_{i,j} = \dot{A}_{i-1,j} + a_1 A_{i-1,j-1} \quad \forall i \geq 2 \quad \forall j \geq 1 \tag{A.54}$$

where, by convention, $A_{0,j} = 0$ for all $j \geq 1$ and $\cdot$ denotes the differentiation on the set of polynomials in the variables $(a_i; i \geq 1)$ defined by $\dot{a}_i = a_{i+1}$ for all $i \geq 1$. For example,

$$A_{i,1} = a_i \quad \text{for all} \quad i \geq 1, \tag{A.55}$$

$$A_{i,i} = a_i^i \quad \text{for all} \quad i \geq 1. \tag{A.56}$$

For $i \geq 1$ and $j \geq 1$, let

$$\Delta_{i,j} = \left\{ s = (s_1, \ldots, s_j) \in \mathbb{N}^j; \quad 1 \leq s_1 \leq \ldots \leq s_j, \sum_{k=1}^{j} s_k = i \right\} \tag{A.57}$$

and

$$\Delta = \bigcup_{\substack{i \geq 1 \\ j \geq 1}} \Delta_{i,j}. \tag{A.58}$$

We easily check (by induction on i) that there exists a map $\alpha : \Delta \to \mathbb{N}$ such that

$$\alpha(s) > 0 \quad \forall s \in \Delta, \tag{A.59}$$

$$A_{i,j} = \sum_{s \in \Delta_{i,j}} \alpha(s) a_{s_1} \ldots a_{s_j}, \tag{A.60}$$

with the convention that, if $\Delta_{i,j} = \phi$, the right-hand side of (A.60) is 0.

We consider now a sequence of real numbers $(a_i; i \geq 1)$ and still denote by $A_{i,j}$ the value of the polynomial $A_{i,j}$ evaluated for this sequence of real numbers $(a_i; i \geq 1)$. Let $\tilde{b}$ in J and let $\bar{b} = F_a(\tilde{b})$. Let $\tilde{c} = (\tilde{c}_j(I); j \geq 0, 0 < |I| \leq \ell)$ and $\bar{c} = (\bar{c}_j(I); j \geq 0, 0 < |I| \leq \ell)$ be the associated sequences. We easily check (by induction on j) that

$$\bar{c}_j(I) = \sum_{1 \leq j' \leq j} A_{j,j'} \tilde{c}_{j'}(I). \tag{A.61}$$

Let r and q be two integers and let us assume that

$$a_r \neq 0 \tag{A.62}$$

and

$$\tilde{b} \in \tilde{G}_q. \tag{A.63}$$

We want to prove

$$\pi_{rq}(\bar{b}) \in \tilde{G}_{rq}. \tag{A.64}$$

By (A.24), without loss of generality, we may assume

$$a_i = 0 \quad \forall i \in [1, r-1]. \tag{A.65}$$

From (A.59), (A.60), (A.62), and (A.65), we obtain

$$A_{rj,j} \neq 0 \quad \forall j \geq 1 \tag{A.66}$$

and

$$A_{i,j} = 0 \quad \forall j \geq 1, \quad \forall i < rj. \tag{A.67}$$

Finally (A.64) follows (A.61), (A.63), (A.66), and (A.67).

Appendix B. In this appendix, we give a "nonaffine" version of the classical result of Jurdjevic and Quinn [JQ].

We first introduce some notations. Let N be a manifold, $\eta \in C^0(N; (0, +\infty))$, and

$$M = \{(x, u) \in N \times \mathbb{R}^m; |u| < \eta(x)\}.$$

Also let $F \in C^\infty(M; TN)$ be such that

$$F(x, u) \in T_x N \quad \forall (x, u) \in M. \tag{B.1}$$

Let, for $i \in [0, m]$, $F_i \in C^\infty(TN)$ be defined by

$$F_0(x) = F(x, 0) \quad \text{for all} \quad x \quad \text{in } N \tag{B.2}$$

$$F_i(x) = \frac{\partial F}{\partial u_i}(x, 0) \quad \text{for all} \quad x \quad \text{in } N, \quad \text{for all } i \text{ in } [1, m]. \tag{B.3}$$

We denote by φ the (maximal) solution of the flow associated to F_0, i.e.,

$$\frac{\partial \varphi}{\partial t} = F_0(\varphi) \tag{B.4}$$

$$\varphi(x, 0) = x. \tag{B.5}$$

Let $V \in C^\infty(N; \mathbb{R})$ and

$$Q = \{x \in N; L_{F_0} V(x) = 0, L_{ad^j_{F_0}(F_i)} V(x) = 0, \forall j \geq 0, \forall i \in [1, m]\}. \tag{B.6}$$

We assume

$$L_{F_0} V \leq 0 \quad \text{on } M, \tag{B.7}$$

$$\forall x \in N, \quad \exists t > 0 \quad \text{such that } \varphi(x, t) \notin Q. \tag{B.8}$$

For $\theta \in C^\infty(M;(0,+\infty))$ with

$$\theta(x)|(L_{F_1}V(x),\dots,L_{F_m}V(x))| < \eta(x), \tag{B.9}$$

we define $u^\theta \in C^1(M;\mathbb{R}^m)$ by

$$u_i^\theta(x) = -\theta(x)L_{F_i}V(x) \quad \text{for } i \in [1,m], \quad x \in N, \tag{B.10}$$

and denote by φ_θ the maximal solution of the flow associated with the vector fields $x \to F(x,u^\theta(x))$. Then we have the following lemma.

LEMMA B.1. *There exists* $\epsilon \in C^\infty(M;(0,+\infty))$ *such that if* $\theta \in C^1(M;(0,+\infty))$ *satisfies*

$$\theta \le \epsilon \quad \textit{on } N, \tag{B.11}$$

then (B.9) *holds and, with* $F_\theta(x) = F(x,u^\theta(x))$,

$$L_{F_\theta}V \le 0, \tag{B.12}$$

$$\forall x \in M, \quad \exists t > 0 \quad \textit{such that } V(\varphi_\theta(x,t)) < V(x). \tag{B.13}$$

Proof. We first note that there exist $C \in C^0(N;(0,+\infty))$ and ϵ_0 in $C^0(M;(0,+\infty))$ such that, if $\theta \in C^0(N;(0,+\infty))$ satisfies

$$\theta \le \epsilon_0, \tag{B.14}$$

then (B.9) holds and

$$L_{F_\theta}V \le L_{F_0}V - \sum_{i=1}^m \theta(L_{F_i}V)^2 + C\theta^2\sum_{i=1}^m (L_FV)^2. \tag{B.15}$$

Therefore, there exists $\epsilon \in C^0(N;(0,+\infty))$ such that, if $\theta \in C^0(N;(0,+\infty))$ satisfies (B.11), then (B.9) holds and

$$L_{F_\theta}V \le L_{F_0}V - \frac{\theta}{2}\sum_{i=1}^m (L_{f_i}V)^2, \tag{B.16}$$

which, by (B.7), gives (B.12). Now, assume moreover that θ is of class C^1 (so φ_θ is defined) and that for some $\overline{x}$ in M

$$V(\varphi_\theta(\overline{x},t)) = V(\overline{x}) \tag{B.17}$$

for all $t > 0$ such that $\varphi_\theta(\overline{x},t)$ is defined. Then, by (B.16)

$$L_{F_0}(\varphi_\theta(\overline{x},t)) = 0 \tag{B.18}$$

$$L_{F_i}V(\varphi_\theta(\overline{x},t)) = 0 \tag{B.19}$$

for all $t > 0$ such that $\varphi_\theta(\overline{x},t)$ is defined. In particular, by (B.10) and (B.19),

$$\varphi_\theta(\overline{x},t) = \varphi(\overline{x},t). \tag{B.20}$$

Let $\overline{x}(t) = \varphi(\overline{x}, t)$ and let I be the set of t in $[0, +\infty)$ such that $\overline{x}(t)$ is defined. By (B.18), (B.19), and (B.20)

$$L_{F_0} V(\overline{x}(t)) = 0 \quad \forall t \in I \tag{B.21}$$

$$\alpha_i(t) := L_{F_i} V(\overline{x}(t)) = 0 \quad \forall t \in T, \quad \forall i \in [1, m]. \tag{B.22}$$

Using (B.7) and (B.21), we get, for all X in $C^\infty(TN)$,

$$L_X L_{F_0} V(\overline{x}(t)) = 0 \quad \forall t \in I. \tag{B.23}$$

Using (B.22) and (B.23), we get

$$0 = \alpha_i^{(j)}(t) = L_{ad^j_{F_0}(F_i)} V(\overline{x}(t)) \quad \forall i \in [1, m], \quad \forall j \geq 0, \quad \forall t \in I. \tag{B.24}$$

Using (B.8), (B.21), and (B.24), we get a contradiction. Hence (B.13) holds.

Acknowledgment. We thank the Forschungsinstitut für Mathematik of Eidgenössische Technische Hochschule, Zürich, where part of this work has been carried out, for its hospitality.

EQUIVALENCE OF NONLINEAR SYSTEMS TO INPUT-OUTPUT PRIME FORMS*

R. MARINO†, W. RESPONDEK‡, AND A. J. VAN DER SCHAFT§

Abstract. The problem of transforming nonlinear control systems into input-output prime forms is dealt with, using state space, static state feedback, and also output space transformations. Necessary and sufficient geometric conditions for the solvability of this problem are obtained. The results obtained generalize well-known results both on feedback linearization as well as input-output decoupling of nonlinear systems. It turns out that, from a computational point of view, the output space transformation is the crucial step, that is performed by constructing rectifying coordinates for a nested sequence of distributions on the output manifold.

Key words. equivalence, output transformation, input-output prime system, integrable distributions, input-output decoupling

AMS subject classifications. 93C10, 93B17, 58A30

1. Introduction.

We consider smooth (i.e., C^∞) nonlinear systems, depending in an affine way on the inputs $u_1, \dots, u_m$, and having m outputs $y_1, \dots, y_m$

$$(\Sigma) \qquad \begin{aligned} \dot{x} &= f(x) + \sum_{j=1}^{m} g_j(x) u_j, \qquad u = (u_1, \dots, u_m) \in \mathbb{R}^m, \\ y_j &= h_j(x), \qquad j = 1, \dots, m \end{aligned} \tag{1.1}$$

where $x = (x_1, \dots, x_n)$ and $y = (y_1, \dots, y_m)$ are local coordinates for the state space manifold M and for the output space manifold Y, respectively. We assume throughout the exisxtence of an equilibrium point $x_0 \in M$ such that $f(x_0) = 0$ and $h(x_0) = 0$. (All results can be adapted to the case $f(x_0) \neq 0$ and/or $h(x_0) \neq 0$; see Remark 2 after the proof of Theorem 6.) Our analysis will be mainly of a local nature (see, however, Theorem 10 and Corollary 11 for global extensions), i.e., we firstly study the system in neighborhoods $V_{x_0} \subset M$ and $W_{y_0} \subset Y$, where $y_0 = h(x_0)$. We also assume throughout that M and Y are connected, and that rank $dh(x)$, with $h = (h_1, \dots, h_m)$, equals m in V_{x_0}, and that the dimension of the distribution $G(x) := \text{span}\,\{g_1(x), \dots, g_m(x)\}$ is m in V_{x_0}. Note that we are restricting ourselves entirely to square systems, i.e., the number of inputs equals the number of outputs.

We address the (local) equivalence of Σ to prime (linear) systems, and to input-output prime (linear) systems. We use the following notion of equivalence.

DEFINITION 1. Consider two systems Σ_1, Σ_2 defined on $(M_1, Y_1), (M_2, Y_2)$ with equilibrium points $x_{01} \in M_1, x_{02} \in M_2$, respectively. We say that Σ_1 is *locally equivalent* to Σ_2, around x_{01} and x_{02}, if there exist:

(i) Neighborhoods $V_{x_{01}} \subset M_1, V_{x_{02}} \subset M_2$ and a diffeomorphism $\varphi : V_{x_{01}} \to V_{x_{02}}$ satisfying $\varphi(x_{01}) = x_{02}$;

§ Department of Applied Mathematics, University of Twente, P.O. Box 217, 7500 AE Enschede, the Netherlands.

(ii) a nonsingular state feedback $u = \alpha(x)+\beta(x)v$ defined on $V_{x_{01}}$ such that $\alpha(x_{01}) = 0$ and $\det \beta(x) \neq 0$;

(iii) neighborhoods $W_{y_{01}} \subset Y_1, W_{y_{02}} \subset Y_2$ of $y_{01} = h^1(x_{01})$ and $y_{02} = h^2(x_{02})$, where h^1 and h^2 denote the output maps of Σ_1 and Σ_2 respectively, and a diffeomorphism $\psi : W_{y_{01}} \to W_{y_{02}}$ satisfying $\psi(y_{01}) = y_{02}$,

such that the transformation of Σ_1 under $(\varphi, (\alpha, \beta), \psi)$ equals Σ_2 on the specified neighborhoods.

We recall from [Mo] (see also [He]) the notion of linear prime system.

DEFINITION 2. A system Σ is called a (linear) *prime system* if it is of the form

$$(P)\quad \begin{aligned} y_i &= x_{i1} \\ \dot{x}_{i1} &= x_{i2} \qquad i = 1, \dots, m \\ &\vdots \\ \dot{x}_{i\kappa_i} &= u_i \end{aligned} \tag{1.2}$$

where $x = (x_{11}, \dots, x_{1\kappa_1}, \dots, x_{m1}, \dots, x_{m\kappa_m}) \in M = \mathbb{R}^n, n = \sum_{i=1}^m \kappa_i$, for some integers $\kappa_1, \dots, \kappa_m$, and $y = (y_1, \dots, y_m) \in Y = \mathbb{R}^m$. The integers $\kappa_1, \dots, \kappa_m$ equal the *orders of the zeros at infinity* of the system or the *relative degrees*, as well as the *controllability* or *observability indices.*

More generally we define input-output prime systems.

DEFINITION 3. A system Σ is called an *input-output prime system* if it is of the form

$$(I-O-P)\quad \begin{aligned} y_i &= x_{i1} \\ \dot{x}_{i1} &= x_{i2} \qquad i = 1, \dots, m \\ &\vdots \\ \dot{x}_{i\mu_i} &= u_i \end{aligned} \tag{1.3a}$$

$$\dot{z} = a(z, x) + \sum_{j=1}^{m} b_j(z, x) u_j, \qquad a(z_0, 0) = 0, \tag{1.3b}$$

where $y = (y_1, \dots, y_m) \in Y = \mathbb{R}^m$, and where the state space manifold M has the following special structure. There exists a surjective submersion $\pi : M \to \mathbb{R}^\mu, \mu := \sum_{i=1}^m \mu_i$, with $x = (x_{11}, \dots, x_{m\mu_m}) \in \mathbb{R}^\mu$, and z being complementary local coordinates for M. The integers $\mu_1, \dots, \mu_m$ equal the *orders of the zeros at infinity* or the *relative degrees* of the system, as well as the *observability indices.*

Remark. Observe that the relative degrees are *not* invariant in our problem because we allow for output transformations (see the Example preceeding Algorithm 7); *nor* are the observability indices since they can be changed by feedback. However, the structure at infinity *does* remain unchanged under the considered transformations, and thus this is the right concept to describe the μ_i's as invariants in our problem. Here, the structure of infinity can be defined either geometrically using the V^*-algorithm [NS], [ls2], or by means of dynamic extension $[M]$ since, for input-output prime systems (and their equivalents), both definitions coincide.

We will also be interested in *input-output prime systems of special form*

$$
\begin{aligned}
& & y_i &= x_{i1} & & \\
(1.4a) \qquad & (I-O-P-S) & \dot{x}_{i1} &= x_{i2} & & i=1,\dots,m \\
& & & \vdots & & \\
& & \dot{x}_{i\mu_i} &= u_i & & \\
(1.4b) \qquad & & \dot{z} &= a(z,y) & &
\end{aligned}
$$

with the same specifications as in Definition 3, the difference being that the z-dynamics are only driven by the outputs $y=(y_1,\dots,y_m)$.

The main results of the paper are concerned with identifying, via necessary and sufficient geometric conditions, those nonlinear systems Σ which are locally equivalent to prime systems (Theorem 4), to input-output prime systems (Theorem 6), and to input-output prime systems of special form (Proposition 8). Theorem 10 and Corollary 11 deal with global equivalence issues. The results obtained generalize well-known results both on normal forms for input-output decouplable systems as well as on feedback linearization of systems with no outputs, as we will now briefly indicate.

If outputs are not considered in Σ, and therefore output change of coordinates (iii) is omitted in Definition 1, the problem of local equivalence with prime systems becomes the well-known local *feedback linearization* problem, i.e., local feedback equivalence into linear (Brunovsky) canonical forms

$$
\begin{aligned}
& & \dot{x}_{i1} &= x_{i2} & & \\
(1.5) \qquad & (B) & & \vdots & & i=1,\dots,m, \\
& & \dot{x}_{i\kappa_i} &= u_i & &
\end{aligned}
$$

which was completely solved in [JR] and [HSM]. The solution to this problem is a generalization of a linear result of Brunovsky [Br], stating that any controllable linear system

$$
(1.6) \qquad \dot{x} = Ax + Bu, \quad x \in \mathbb{R}^n, u \in \mathbb{R}^m, \quad \text{rank } B = m,
$$

can be transformed into (B) by the action of the linear feedback group taking the pair (A,B) into $(T(A+BF)T^{-1}, TBG)$ for a linear state space change of coordinates $\tilde{x}=Tx$ and a linear feedback $u=Fx+Gv, \det G \neq 0$. The set of indices $(\kappa_1,\dots,\kappa_m)$, called *controllability indices*, is uniquely associated with (6) and forms a complete set of invariants under the action of the linear feedback group (see also [Wo]). In [Mo] Morse enlarges this group by allowing also for linear output space change of coordinates $\tilde{y}=Hy$, and gives necessary and sufficient conditions for a linear system

$$
\begin{aligned}
& & \dot{x} &= Ax + Bu, \quad x \in \mathbb{R}^n, \quad u \in \mathbb{R}^m, \quad y \in \mathbb{R}^m, \\
(1.7) \qquad & (L) & & \\
& & y &= Cx, \qquad \text{rank } B = \text{rank } C = m,
\end{aligned}
$$

to be transformed into a prime system (P) given by (1.2) by the action of the group taking (A,B,C) into $(T(A+BF)T^{-1}, TBG, HCT^{-1})$. We generalize this result of Morse to nonlinear systems Σ in Theorem 4, on the basis of the local feedback linearization theorem [JR], [HSM]. We remark that nonlinear output change of coordinates was introduced in [KR] in the study of asymptotic observers. Furthermore, the problem of local feedback

equivalence (with no output change of coordinates) of Σ to a linear system was studied and solved in [CIRT].

The problem of (local) feedback equivalence, *without* output change of coordinates, of a nonlinear system Σ to an input-output prime system $I - O - P$ has been solved in [IKGM]. Indeed, this problem amounts to the (local) nonlinear *input-output decoupling problem*, as dealt with in [SR], [Fr], and [Si]. The basic tool is the *decoupling matrix*, which generalizes to nonlinear systems the Falb–Wolovich matrix [FW], used in input-output decoupling of linear systems (L). In fact a necessary and sufficient condition for Σ to be input-output decouplable around x_0 is that its decoupling matrix is nonsingular in a neighborhood of x_0. We note that the problem of local equivalence of Σ to $(I - O - P)$ studied in the present paper can be rephrased in this latter terminology as finding a (local) output transformation $\tilde{y} = \psi(y)$ such that Σ, with the resulting *transformed* output functions $\tilde{h}_1 = \psi_1 o h, \ldots, \tilde{h}_m = \psi_m o h$, is locally input-output decouplable. Finally, (local and global) feedback equivalence with no output change of coordinates of Σ into input-output prime systems of special form $(I - O - P - S)$ has been dealt with in [BI], while for linear systems (L) equivalence to $(I - O - P)$ *implies* equivalence to $(I - O - P - S)$, as was implicitly derived in [Mo] (see Remark 2 after Proposition 8).

The results obtained are useful for control applications in the following sense. It is well known (see, e.g., [Is], [NvdS]) that many nonlinear control problems are relatively easily attacked for input-output decouplable systems. Now, in many of these control problems output transformations are naturally allowed, and thus our results enable us to treat in a similar way a class of nonlinear control systems which properly *contains* the input-output decouplable systems. One obvious example of a control problem which naturally *does* allow for output transformations is the (asymptotic) output tracking problem by static state feedback control (see the example after Theorem 6).

2. Main results. Let us first recall the definitions of the following sequences of distributions for a nonlinear system Σ:

$$\begin{aligned} G_1 &:= G := \operatorname{span}\{g_1, \ldots, g_m\} \\ G_{i+1} &:= G_i + [f, G_i], \qquad i = 1, 2, \ldots \end{aligned} \tag{2.1}$$

$$\begin{aligned} S_1 &:= G, \\ S_{i+1} &:= S_i + [f, S_i \cap \ker dh] + \sum_{j=1}^{m} [g_j, S_i \cap \ker dh], \qquad i = 1, 2, \ldots \\ S^* &:= \bigcup_{i \geq 1} S_i. \end{aligned} \tag{2.2}$$

The distributions G_i were introduced in [JR] in the study of the feedback linearization problem, while the algorithm (2.2) and the definition of S^* is taken from [IKGM] (with the difference that, in [IKGM], S_i in the right-hand side of (2.2) is replaced by its involutive closure; see, however, conditions (i), (iii) of Theorem 4). S^*, the smallest conditioned invariant distribution containing G, enjoys the property (see [IKGM])

$$\begin{aligned} [f, S^* \cap \ker dh] &\subset S^*, \\ [g_j, S^* \cap \ker dh] &\subset S^*, \qquad j = 1, \ldots, m, \end{aligned} \tag{2.3}$$

and is a generalization of the notion of the smallest conditioned invariant subspace containing Im B, as introduced in [BM] for a linear system (L). If the distributions $S_i, i = 0, 1, \ldots,$ all have constant dimension, then there exists an integer $i^* \leq n$ such that $S_{i^*} = S^*$.

Following [IKGM] we also recall the construction (if it exists) of V^*, the largest locally controlled invariant distribution contained in kerdh (see also [Hi], and for the linear case [Wo], [BM]). Define the sequence of codistributions

$$\begin{aligned} P_1 &:= dh \\ P_{i+1} &:= P_i + L_f(P_i \cap \text{ann}G) + \sum_{j=1}^{m} L_{g_j}(P_i \cap \text{ann}G), \qquad i = 1, 2, \dots \\ P^* &:= \bigcup_{i \geq 1} P_i \end{aligned} \tag{2.4}$$

where L_f, L_{g_j} denote Lie derivatives, and ann$G$ is the codistribution annihilating G. Then the distribution V^* is the kernel of the codistribution P^*, i.e., $V^* = \ker P^*$ (see, e.g., [Is], [NvdS]).

We finally recall the definition of *characteristic indices* (or *relative degrees*) ρ_i, and of the *decoupling matrix*. For $i = 1, \dots, m$, ρ_i is defined by

$$\begin{aligned} &L_{g_j} L_f^k h_i(x) = 0, \quad k = 0, 1, \dots, \rho_i - 2, j = 1, \dots, m, \quad \text{for all } x \in V_{x_0} \\ &L_{g_j} L_f^{\rho_i - 1} h_i(x) \neq 0, \quad \text{for some } j \in \{1, \dots, m\} \quad \text{and } x \in V_{x_0}. \end{aligned} \tag{2.5}$$

If $\rho_i < \infty, i = 1, \dots, m$, the decoupling matrix $D(x)$ is defined as

$$D(x) = \left(L_{g_j} L_f^{\rho_i - 1} h_i(x) \right)_{i,j=1,\dots,m}. \tag{2.6}$$

We now come to our first main theorem.

THEOREM 4. *Consider a nonlinear system Σ with equilibrium x_0. Σ is locally equivalent to a prime system (P) with equilibrium 0, if and only if the following conditions are satisfied in a neighborhood of x_0:*

(i) *G_i is involutive and of constant dimension, $i = 1, \dots, n-1$;*
(ii) *$G_n = TM$;*
(iii) *$G_i = S_i, i = 1, 2, \dots, n$;*
(iv) *$G_i + \ker dh$ is involutive and of constant dimension, $i = 1, \dots, n-1$.*

Remark 1. Theorem 4 generalizes and clarifies the following result of Morse ([Mo, Thm. 3.1]): The system (L), i.e., the triple (A, B, C), is transformable by $(T, (F, G), H) : (A, B, C) \to (T(A + BF)T^{-1}, TBG, HCT^{-1})$ into a prime system (P) if and only if:

(i)′ $V^* = 0$;
(ii)′ $G_n = \text{Im}(B, AB, \dots, A^{n-1}B) = \mathbb{R}^n$;
(iii)′ $G_i = S_i, i = 1, \dots, n$.

Conditions (i) and (iv) of Theorem 4 are always satisifed for linear systems, while they are crucial integrability conditions in the nonlinear case. Conditions (ii)' and (iii)' of Morse are specializations of conditions (ii) and (iii) of Theorem 4 to the linear case. Condition (i), i.e., $V^* = 0$, is redundant; it is implied by conditions (ii) and (iii). In fact the proof that we will give is entirely different from Morse's and enables us to point out the redundancy of the condition $V^* = 0$ in the original statement of Morse.

Remark 2. Conditions (i) and (ii) are the necessary and sufficient conditions given in [JR] for the system Σ without outputs to be locally feedback equivalent to a linear system in Brunovsky form (B).

Remark 3. While Remarks 1 and 2 clarify the necessity of conditions (i), (ii), and (iii), we may wonder if condition (iv) is not redundant, since already condition (iii) enforces a rather strong compatibility between G_i and kerdh. However, the following example shows

that for $\rho > 2$ condition (iv) is *not* implied by conditions (i), (ii), and (iii). Consider the system

$$\begin{aligned} \dot{x}_1 &= u_1, & y_1 &= x_1 \\ \dot{x}_2 &= x_3, & y_2 &= x_2 + x_1 x_5 \\ \dot{x}_3 &= u_2 & & \\ \dot{x}_4 &= x_5, & y_3 &= x_4 \\ \dot{x}_5 &= x_6 & & \\ \dot{x}_6 &= u_3. & & \end{aligned} \tag{2.7}$$

We easily compute

$$\begin{aligned} G_1 = S_1 &= \operatorname{span}\left\{\frac{\partial}{\partial x_1}, \frac{\partial}{\partial x_3}, \frac{\partial}{\partial x_6}\right\} \\ \ker dh &= \operatorname{span}\left\{\frac{\partial}{\partial x_3}, \frac{\partial}{\partial x_5} - x_1\frac{\partial}{\partial x_2}, \frac{\partial}{\partial x_6}\right\} \\ G_2 = S_2 &= \operatorname{span}\left\{\frac{\partial}{\partial x_1}, \frac{\partial}{\partial x_2}, \frac{\partial}{\partial x_3}, \frac{\partial}{\partial x_5}, \frac{\partial}{\partial x_6}\right\} \\ G_3 = S_3 &= T\mathbb{R}^6 \\ G_1 + \ker dh &= \operatorname{span}\left\{\frac{\partial}{\partial x_1}, \frac{\partial}{\partial x_3}, \frac{\partial}{\partial x_5}, - x_1\frac{\partial}{\partial x_2}, \frac{\partial}{\partial x_6}\right\} \end{aligned} \tag{2.8}$$

and thus conditions (i), (ii), and (iii) are satisfied, while condition (iv) fails since $G_1 + \ker dh$ is not involutive; in fact,

$$\left[\frac{\partial}{\partial x_1}, \frac{\partial}{\partial x_5} - x_1\frac{\partial}{\partial x_2}\right] = -\frac{\partial}{\partial x_2} \notin G_1 + \ker dh. \tag{2.9}$$

It follows that (2.7) is *not* locally equivalent to a prime system (P).

Remark 4. It is easy to see that if a nonlinear system (Σ) with equilibrium x_0 is locally equivalent to a prime system, then its linearization at x_0, namely, $(\overline{x} = x - x_0, \overline{y} = y - h(x_0))$

$$\begin{aligned} \dot{\overline{x}} &= \frac{\partial f}{\partial x}(x_0)\overline{x} + \sum_{j=1}^{m} g_i(x_0)u_j \\ \overline{y} &= \frac{\partial h}{\partial x}(x_0)\overline{x} \end{aligned}$$

is also equivalent to a prime system. The converse may be false as the following example shows:

$$\begin{aligned} \dot{x}_1 &= u_1, & y_1 &= x_1 \\ \dot{x}_2 &= x_3 + (1 - e^{x_3})u_1, & y_2 &= x_2 \\ \dot{x}_3 &= u_2. & & \end{aligned}$$

In this case the distribution $G_1 = \operatorname{span}\{(\partial/\partial x_1) + (1 - e^{x_3})(\partial/\partial x_2), (\partial/\partial x_3)\}$ is not involutive, so that condition (i) of Theorem 4 is violated. On the other hand the system linearized at the origin is obviously a prime system.

Before giving the proof of Theorem 4, we first recall a lemma which clarifies the meaning of condition (iv). Let $h : M \to Y$ be such that rank $dh(x) = m = \dim Y$ on a neighborhood V_{x_0}. Then $W_{y_0} := h(V_{x_0})$ is a neighborhood of $y_0 = h(x_0)$ in Y.

Furthermore let D be a distribution on M. Then D is said to be *projectable* by h on V_{x_0} if, for all x_1, x_2 in V_{x_0}, we have

$$h(x_1) = h(x_2) \Rightarrow \frac{\partial h}{\partial x}(x_1)(D(x_1)) = \frac{\partial h}{\partial x}(x_2)(D(x_2)). \tag{2.10}$$

If D is projectable by h on V_{x_0}, then we define h_*D as the following distribution on W_{y_0}:

$$(h_*D)(y) = \partial h/\partial x(x)(D(x)), \quad \textit{with } x \in h^{-1}(y) \cap V_{x_0}, \quad y \in W_{y_0}. \tag{2.11}$$

(For the problem of projecting distributions see also [J].)

LEMMA 5. *Let h be such that* rank $dh(x) = \dim Y$ *on V_{x_0}, and let D be involutive and constant dimensional on V_{x_0}. Then D is projectable by h in V_{x_0} to a constant dimensional and involutive distribution h_*D on W_{y_0} if and only if $D + \ker dh$ is involutive and of constant dimension on V_{x_0}.*

Proof. First notice that by the Rank Theorem [Sp] we can take local coordinates $x = (x^1, x^2)$ on V_{x_0} such that $h(x^1, x^2) = x^1$. Then it follows from [vdS] (see also [NvdS, Lem. 14.3]) that if $D + \ker dh$ is involutive and of constant dimension then D is projectable and h_*D is involutive and of constant dimension. Conversely (see [vdS]) it follows trivially that if D is projectable then $D + \ker dh$ is involutive (indeed $D + \ker dh$ is of the form span $\{k(x^1)(\partial/\partial x^1) + \text{span}\{\partial/\partial x^2\}$ for some k). Furthermore, if h_*D is constant dimensional then $D + \ker dh$ is constant dimensional. □

Proof of Theorem 4 (only if). First we note from (2.2) that the definition of S_i is invariant under feedback and output transformations. Suppose that Σ is locally equivalent to (P). Clearly, (P) satisfies conditions (i)–(iv). It follows that also the definition of G_1, and inductively of $G_i, i > 1$, is invariant under feedback, and thus conditions (i)–(iv) are feedback invariant. Thus we can conclude that conditions (i)–(iv) are also satisfied for Σ.

(If.) By virtue of (i) and (iii) it follows that S_{i+1} is alternatively given as

$$S_{i+1} = S_i + [f, S_i \cap \ker dh], \qquad i = 1, 2, \ldots \tag{2.12}$$

since $[g_j, S_i \cap \ker dh] = [g_j, G_i \cap \ker dh] \subset G_i = S_i, j = 1, \ldots, m$.

By conditions (i), (iii), (iv) and Lemma 5,

$$H_i := h_*G_i = h_*S_i, \qquad i = 1, \ldots, n \tag{2.13}$$

are well-defined involutive and constant-dimensional distributions on a neighborhood $W_{y_0} \subset Y$, while by (ii) $H_n = TY$. Obviously $H_1 \subset H_2 \subset \ldots \subset H_n$. It follows that we can define integers

$$\kappa_1 > \kappa_2 > \ldots > \kappa_r > 0 \tag{2.14}$$

such that

$$0 = H_1 = \ldots = H_{\kappa_r - 1} \overset{\subset}{\neq} H_{\kappa_r} = \ldots = H_{\kappa_1 - 1} \overset{\subset}{\neq} H_{\kappa_1} = TY. \tag{2.15}$$

For ease of notation we will assume that

$$\dim H_{\kappa_i} = \dim H_{\kappa_i - 1} + 1, \qquad i = 1, \ldots, m \tag{2.16}$$

implying that $r = m$, and

$$\kappa_1 > \kappa_2 > \ldots > \kappa_m > 0, \qquad \dim H_{\kappa_i} = m - i + 1, i = 1, \ldots, m. \tag{2.17}$$

(Later on we will conclude that $\kappa_1, \ldots, \kappa_m$ are actually the controllability indices of Σ.)

Invoking the generalized Frobenius theorem for the nested sequence of distributions $H_{\kappa_m} \subset H_{\kappa_{m-1}} \subset \ldots \subset H_{\kappa_1}$ (see [JR], [NvdS]), we can choose locally about y_0 in W_{y_0} m independent functions

$$\psi_1, \ldots, \psi_m \tag{2.18}$$

such that

$$\begin{aligned} &\langle d\psi_1, H_{\kappa_1 - 1}\rangle = 0 \\ &\langle d\psi_2, H_{\kappa_2 - 1}\rangle = 0 \\ &\qquad \vdots \\ &\langle d\psi_{m-1}, H_{\kappa_{m-1} - 1}\rangle = 0 \end{aligned} \tag{2.19a}$$

while

$$\begin{aligned} &\langle d\psi_1, H_{\kappa_1}\rangle(x_0) \neq 0 \\ &\langle d\psi_2, H_{\kappa_2}\rangle(x_0) \neq 0 \\ &\qquad \vdots \\ &\langle d\psi_m, H_{\kappa_m}\rangle(x_0) \neq 0. \end{aligned} \tag{2.19b}$$

In the new local coordinates of the output manifold Y, given by

$$\tilde{y}_i := \psi_i(y), \qquad i = 1, \ldots, m, \tag{2.20}$$

we obviously have

$$H_{\kappa_i} = \operatorname{span}\left\{\frac{\partial}{\partial \tilde{y}_m}, \ldots, \frac{\partial}{\partial \tilde{y}_i}\right\}, \qquad i = 1, \ldots, m. \tag{2.21}$$

If we define new output functions

$$\tilde{h}_i := \psi_i o h, \qquad i = 1, \ldots, m \tag{2.22}$$

and recall that $H_i = h_* G_i$ (cf. (2.13)), then (2.19a) yields

$$\begin{aligned} &\langle d\tilde{h}_1, G_{\kappa_1 - 1}\rangle = 0 \\ &\langle d\tilde{h}_2, G_{\kappa_2 - 1}\rangle = 0 \\ &\qquad \vdots \\ &\langle d\tilde{h}_{m-1}, G_{\kappa_{m-1} - 1}\rangle = 0 \end{aligned} \tag{2.23a}$$

while by (2.19b),

$$\begin{aligned} &\langle d\tilde{h}_1, G_{\kappa_1}\rangle(x_0) \neq 0 \\ &\langle d\tilde{h}_2, G_{\kappa_2}\rangle(x_0) \neq 0 \\ &\qquad \vdots \\ &\langle d\tilde{h}_m, G_{\kappa_m}\rangle(x_0) \neq 0. \end{aligned} \tag{2.23b}$$

Let us now compute the decoupling matrix $\tilde{D}(x)$ (cf. (2.6)) of Σ with the newly defined output functions $\tilde{h}_1, \ldots, \tilde{h}_m$ (cf. (2.22)). It readily follows from (2.23), and the Leibniz rule, i.e.,

$$L_X\langle d\varphi, Y\rangle = \langle dL_X\varphi, Y\rangle + \langle d\varphi, ad_X Y\rangle \tag{2.24}$$

for any two vector fields X, Y and function φ, that $\tilde{D}(x)$ is given as (see, e.g., [Is], [NvdS])

$$\tilde{D}(x) = \begin{pmatrix} (-1)^{(\kappa_1 - 1)}\langle d\tilde{h}_1, ad_f^{\kappa_1 - 1} g_1\rangle(x) \ldots (-1)^{(\kappa_1 - 1)}\langle d\tilde{h}_1, ad_f^{\kappa_1 - 1} g_m\rangle(x) \\ \vdots \qquad\qquad\qquad\qquad \vdots \\ (-1)^{(\kappa_m - 1)}\langle d\tilde{h}_m, ad_f^{\kappa_m - 1} g_1\rangle(x) \ldots (-1)^{(\kappa_m - 1)}\langle d\tilde{h}_m, ad_f^{\kappa_m - 1} g_m\rangle(x) \end{pmatrix}. \tag{2.25}$$

We now make the following claim.

CLAIM. *$\tilde{D}(x)$ is nonsingular in a neighborhood U_{x_0} of $x_0 \in M$.*

Once this claim has been proved the rest of the proof of Theorem 4 follows easily. Indeed by the theory of input-output decoupling (see, e.g., [IKGM], [Is], [NvdS]) the functions

$$(\tilde{h}_1, \dots, L_f^{\kappa_1 - 1}\tilde{h}_1, \dots, \tilde{h}_m, \dots, L_f^{\kappa_m - 1}\tilde{h}_m) =: (x_{11}, \dots, x_{1\kappa_1}, \dots, x_{m1}, \dots, x_{m\kappa_m}) \tag{2.26a}$$

are independent on U_{x_0}, and the state feedback

$$u = -\tilde{D}^{-1}(x) \begin{pmatrix} L_f^{\kappa_1}\tilde{h}_1(x) \\ \vdots \\ L_f^{\kappa_m}\tilde{h}_m(x) \end{pmatrix} + \tilde{D}^{-1}(x)v \tag{2.26b}$$

brings the system into the form

$$\begin{aligned} \tilde{y}_i &= x_{i1} \\ \dot{x}_{i1} &= x_{i2} \qquad i = 1, \dots, m, \\ &\vdots \\ \dot{x}_{i\kappa_i} &= v_i \\ \dot{z} &= a(z, x) + b(z, x)v \end{aligned} \tag{2.27}$$

(where $z \in \mathbb{R}^{n-(\kappa_1 + \dots + \kappa_m)}$ are additional coordinates).

Furthermore, it is immediately seen that the S^*-algorithm (cf. (2.2)) applied to (2.27) yields $\dim S^* = \kappa_1 + \dots + \kappa_m$. Then because of feedback invariance of S_i and (ii), i.e., $S_n = G_n = TM$, it follows that $\kappa_1 + \dots + \kappa_m = n$, and thus the z-part in (2.27) is void, implying that Σ with the newly defined output functions $\tilde{h}_1, \dots, \tilde{h}_m$ is feedback equivalent to a prime system (P), with controllability indices $\kappa_1, \dots, \kappa_m$.

Proof of the claim. We use the following induction argument.

Step 1. Consider $\tilde{h}_1$. By (2.23) there exists some $i \in \{1, \dots, m\}$ such that $\langle d\tilde{h}_1, ad_f^{\kappa_1 - 1} g_i \rangle(x_0) \neq 0$. By relabeling $g_1, \dots, g_m$, if necessary, we may thus assume that

$$\langle d\tilde{h}_1, ad_f^{\kappa_1 - 1} g_1 \rangle(x_0) \neq 0. \tag{2.28}$$

Define the functions $\beta_i^1(x) := \langle d\tilde{h}_1, ad_f^{\kappa_1 - 1} g_i \rangle(x), i = 1, \dots, m$, and put locally about x_0

$$\tilde{g}_i := g_i - \frac{\beta_i^1}{\beta_1^1} g_1, \qquad i = 2, \dots, m \tag{2.29}$$

(observe that by (2.28) $\beta_1^1 \neq 0$ locally about x_0). Then, because

$$ad_f^{\kappa_1 - 1}\tilde{g}_i = ad_f^{\kappa_1 - 1} g_i - \frac{\beta_1^1}{\beta_1^1} ad_f^{\kappa_1 - 1} g_i (\mathrm{mod} G_{\kappa_1 - 1}), \tag{2.30}$$

the transformed input vectorfields $\tilde{g}_2, \dots, \tilde{g}_m$ satisfy

$$\langle d\tilde{h}_1, ad_f^{\kappa_1 - 1}\tilde{g}_i \rangle \equiv 0, \quad \text{around } x_0, \quad i = 2, \dots, m. \tag{2.31}$$

For ease of notation we will now omit the tildes above g_i, and thus denote $\tilde{g}_2, \dots \tilde{g}_m$ again by $g_2, \dots, g_m$.

Step $k + 1$. Assume that the functions $\beta_i^j := \langle d\tilde{h}_j, ad_f^{\kappa_j - 1} g_i \rangle$ satisfy

(A1) $\beta_j^j(x_0) \neq 0, \qquad j = 1, \dots, k$

(A2) $\beta_i^j \equiv 0, \quad i = j + 1, \dots, m, \quad j = 1, \dots, k.$

We will show that, after applying feedback, (A1) and (A2) also hold for $j = k+1$. First we note that since $\langle d\tilde{h}_j, G_{\kappa_j - 1}\rangle = 0$ (cf. (2.23a)) repeated use of the Leibniz rule yields

$$\langle dL_f^{\ell}\tilde{h}_j, ad_f^{\kappa_j - \ell - 1}g_i\rangle = (-1)^{\ell}\beta_i^j, \quad \ell = 0, 1, \ldots, \kappa_j - 1, \quad i, j = 1, \ldots, m. \tag{2.32}$$

By using (A1) and (A2) this implies that we have the following "table" for the expressions $\langle dL_f^{\kappa_1 - \kappa_k}\tilde{h}_j, ad_f^{\kappa_k - 1}g_i\rangle, j = 1, \ldots, k, i = 1, \ldots, m$:

$$\begin{array}{lccccccc} & ad_f^{\kappa_k-1}g_1 & ad_f^{\kappa_k-1}g_2 & \ldots & ad_f^{\kappa_k-1}g_k & \ldots & ad_f^{\kappa_k-1}g_m \\ dL_f^{\kappa_1-\kappa_k}\tilde{h}_1 & * & 0 & & & & \\ dL_f^{\kappa_2-\kappa_k}\tilde{h}_2 & & * & & & & \\ \vdots & ? & & & & & 0 \\ d\tilde{h}_k & & & & * & & \end{array} \tag{2.33}$$

where the * elements are all nonzero by (A1). It follows that the map $F = (L_f^{\kappa_1 - \kappa_k}\tilde{h}_1, L_f^{\kappa_2 - \kappa_k}\tilde{h}_2, \ldots, \tilde{h}_k)$ has rank k (the same argument is used in feedback linearization, cf. [HSM], [Is], [NvdS]) and furthermore, since $G_{\kappa_k} + \ker dF = TM$, Lemma 5 implies that G_{κ_k} is projectable by F, while

$$\dim F_* G_{\kappa_k} = k. \tag{2.34}$$

Now consider $\tilde{h}_{k+1}$. Because of (2.23) it follows that there exists some $i \in \{1, \ldots, m\}$ such that

$$\langle d\tilde{h}_{k+1}, ad_f^{\kappa_{k+1} - 1}g_i\rangle(x_0) \neq 0. \tag{2.35}$$

We *claim* that we can take $i \in \{k+1, \ldots, m\}$ having this property. Indeed, otherwise we would have

$$\langle d\tilde{h}_{k+1}, ad_f^{\kappa_{k+1} - 1}g_i\rangle(x_0) = 0, \qquad i = k+1, \ldots, m. \tag{2.36}$$

Now take any $X \in G_{\kappa_{k+1}} \cap \ker dh$, then X is of the form $X = \sum_{i=1}^n \alpha_i ad_f^{\kappa_{k+1} - 1}g_i + Z, Z \in G_{\kappa_{k+1} - 1}$, and with the functions α_i satisfying

$$\begin{aligned} 0 &= \langle d\tilde{h}_{k+1}, \textstyle\sum_{i=1}^n \alpha_i ad_f^{\kappa_{k+1} - 1}g_i\rangle(x_0) \\ &= \textstyle\sum_{i=1}^k \alpha_i(x_0)c_i, \quad \text{with } c_i := \langle d\tilde{h}_{k+1}, ad_f^{\kappa_{k+1} - 1}g_i\rangle(x_0) \end{aligned} \tag{2.37}$$

where at least one of the c_i's is unequal to zero because of (2.35). Now

$$G_{\kappa_{k+1}+1} = S_{\kappa_{k+1}+1} = [f, G_{\kappa_{k+1}} \cap \ker dh] + G_{\kappa_{k+1}}$$

and inductively,

$$G_{\kappa_k} \subset ad_f^{\kappa_k - \kappa_{k+1}}(G_{\kappa_{k+1}} \cap \ker dh) + G_{\kappa_k - 1}. \tag{2.38}$$

Therefore any element of G_{κ_k} is of the form

$$\sum_{i=1}^m \alpha_i ad_f^{\kappa_k - 1}g_i + Z, \qquad Z \in G_{\kappa_k - 1}, \tag{2.39}$$

with $\alpha_i(x_0), i = 1, \ldots k$, satisfying (2.37). Hence, because of table (2.33) and the nontrivial relation (2.37), the space $(F_* G_{\kappa_k})(F(x_0))$ is at most $(k-1)$ dimensional which is in

contradiction with (2.34). Therefore there *does* exist some $i \in \{k+1, \dots, m\}$ such that (2.35) holds. After reordering, if necessary, $g_{k+1}, \dots, g_m$ we may thus assume that

$$\langle d\tilde{h}_{k+1}, ad_f^{\kappa_{k+1}-1} g_{k+1} \rangle (x_0) \neq 0. \tag{2.40}$$

Now define $\beta_i^{k+1} := \langle d\tilde{h}_{k+1}, ad_f^{\kappa_{k+1}-1} g_i \rangle$ and set $\tilde{g}_i := g_i - (\beta_i^{k+1}/\beta_{k+1}^{k+1}) g_{k+1}, i = k+2, \dots, m$. Then as in Step 1, cf. (2.30), we obtain

$$\langle d\tilde{h}_{k+1}, ad_f^{\kappa_{k+1}-1} \tilde{g}_i \rangle \equiv 0, \quad \text{around } x_0, \quad i = k+2, \dots, m. \tag{2.41}$$

Omitting again the tildes above $\tilde{g}_i$ we have thus proved that (A1), (A2) also hold for $j = k+1$. Hence by induction we have proved that (A1), (A2) hold for every $k = 1, \dots, m$, for the feedback transformed system (the feedback arising from successively applying Step 1 up to Step m). It immediately follows from expression (2.25) that the decoupling matrix $\tilde{D}(x_0)$ for this feedback transformed is a lower triangular matrix with nonzero diagonal elements $\beta_1^1(x_0), \dots, \beta_m^m(x_0)$, and thus is nonsingular. Since the rank of the decoupling matrix is invariant under feedback [Is], [NvdS] we have proved the claim. □

As we have already remarked (see Remark 2 after Theorem 4), Theorem 4 and its proof are closely related to the local feedback linearization problem [JR], [HSM]. However, we would like to stress that from a computational point of view the transformation of Σ into a prime system (P) as given by Theorem 4 may be much simpler than the solution to the local feedback linearization problem. In fact for the latter problem we have to find, in some way or another (see [JR], [HSM]), rectifying (Frobenius) coordinates for the whole sequence of distributions $G_1 \subset G_2 \subset \dots \subset G_n = TM$, on the (possibly high-dimensional) state space manifold M. On the other hand, in order to transform Σ into (P) we basically have to find rectifying (Forbenius) coordinates for the projected distributions $H_1 \subset H_2 \subset \dots \subset H_n = TY$ on the output space manifold Y. In general the dimension of Y is much smaller than that of M, and therefore, *assuming* that the projections $H_1, \dots, H_n$ are easily computed, the latter problem is likely to be simpler. We defer a more elaborate computational implementation of Theorem 4 until after the proof of the next theorem, which deals with the more general problem of local equivalence to input-output prime systems. Recall that given two distributions D_1, D_2 on M we call D_1 involutive modulo D_2 if for any two $X, Y \in D_1$ we have $[X, Y] \in D_1 + D_2$. Furthermore, observe that if the codistributions P_i, $i = 1, 2, \dots$ in (2.4) are constant dimensional then V^*, the largest locally controlled distribution contained in kerdh, exists and is constant dimensional (and is given as $V^* = \ker P^*$).

THEOREM 6. *Consider a nonlinear system Σ with equilibrium x_0. Σ is locally equivalent to an input-output prime system $(I - O - P)$ with equilibrium $(0, z_0)$, if and only if the following conditions are satisfied in a neighborhood of x_0*

(i) *P_i is constant dimensional $i = 1, 2, \dots, n$;*
(ii) *G_i is involutive modulo V^*, and $G_i + V^*$ is constant dimensional; $i = 1, \dots, n-1$;*
(iii) *$G_n + V^* = TM$;*
(iv) *$G_i = S_i$ modulo $V^*, i = 1, 2, \dots, n$;*
(v) *$G_i +$ kerdh is involutive and of constant dimension, $i = 1, 2, \dots, n-1$.*

Proof (only if). Suppose that Σ is locally equivalent to $(I-O-P)$. Clearly, $(I-O-P)$ satisfies conditions (i)–(v) (notice that $V^* = \text{span}\{\partial/\partial z\}$). By (2.2) the definition of S_i is invariant under feedback. From the fact that $(I - O - P)$ satisfies condition (ii), it follows that also the definition of G_i is invariant under feedback modulo V^* (i.e., G_i for the feedback transformed system is equal modulo V^* to G_i for the original system). In

particular, since $V^* \subset \ker dh$, it follows that the definition of $G_i + \ker dh$ is invariant under feedback. Thus conditions (i)–(v) are feedback invariant and we can conclude that they are satisfied by Σ.

(If.) By definition of V^* (see, e.g., [IKGM], [Hi]) there exists locally around x_0 a feedback $u = \alpha(x) + \beta(x)v, \det\beta(x) \neq 0$, such that

$$[\tilde{f}, V^*] \subset V^*, \quad [\tilde{g}_j, V^*] \subset V^*, \quad j = 1, \dots, m, \tag{2.42}$$

where $\dot{x} = \tilde{f}(x) + \sum_{j=1}^{m} \tilde{g}_j(x)v_j$ denotes the feedback transformed system. Thus locally around x_0 we can factor out by the distribution V^* to obtain a manifold M' and a factor system (see [IKGM])

$$(\Sigma') \qquad \begin{aligned} \dot{x}' &= f'(x') + \sum_{j=1}^{m} g'_j(x')v_j, \qquad x' \in M', \\ y_j &= h'_j(x'), \qquad j = 1, \dots, m, \end{aligned} \tag{2.43}$$

i.e., around x_0 we have the projection $\pi : M \to M'$, with $V^* = \ker \pi_*$. (Since $V^* \subset \ker dh, h = (h_1, \dots, h_m)$ can be also factored to a map $h' = (h'_1, \dots, h'_m) : M' \to Y$ satisfying $h = h' o \pi$.)

Define the distributions G'_i and S'_i for the factor system Σ'. It is readily checked that G'_i and S'_i satisfy conditions (i)–(iv) of Theorem 4 for the factor system Σ' and around $x'_0 = \pi(x_0)$. Indeed, observe again that under conditions (ii) and (iv) of Theorem 6 the distributions G_i and S_i are feedback invariant modulo V^*. Then it immediately follows that G'_i and S'_i satisfy conditions (i)–(iii) of Theorem 4 applied to Σ'. Finally, since $V^* \subset \ker dh$ it follows that G_i are also feedback invariant modulo $\ker dh$. Thus $\pi_*(G_i + \ker dh) = G'_i + \ker dh'$, and it follows from Lemma 2 (applied to the involutive and constant-dimensional distribution $G_i + \ker dh$ and the mapping $\pi : M \to M'$) that $G'_i + \ker dh'$ is involutive and constant dimensional.

Hence by Theorem 4, Σ' is locally equivalent to a prime system (P) of the form (1.3a) (with $x'_0 = 0$, and $\mu_i, i = 1, \dots, m$, the controllability indices of Σ'). Since the remaining dynamics of Σ are of the general form (1.3b) we conclude that Σ is locally equivalent to $(I - O - P)$ with equilibrium $x_0 = (0, z_0)$. □

Remark 1. Note that the indices $\mu_1, \dots, \mu_m$ are *intrinsically* defined. Indeed if Σ satisfies the conditions of Theorem 6 then $\mu_1, \dots, \mu_m$ are the (intrinsically defined) controllability indices of the factor system Σ', living on M/V^*. In particular it follows that an input-output prime system $(I - O - P)$ *cannot* be equivalent to an input-output prime system with different indices $\mu_1, \dots, \mu_m$.

Remark 2. If Σ satisfies the conditions of Theorem 6 on a neighborhood of a point $\overline{x}$ which is *not* an equilibrium, then Σ will be locally equivalent to an input-output prime system (1.4) with the addition of a constant drift term $f(\overline{x})$. Furthermore, if $f(\overline{x}) \in G(\overline{x})$ then this drift term can be removed by additional feedback. Similarly, if $h(\overline{x}) \neq 0$, then we have to add to the output equation of (1.4a) the constant term $h(\overline{x})$. Of course, this remark already applies to Theorem 4.

Remark 3. It follows from the proof of Theorem 6 that $h_* G_i$ is a well-defined distribution on a neighborhood of $y_0 = h(x_0)$ (i.e., G_i is projectable by h on some neighborhood V_{x_0}), $i = 1, \dots, m$. In fact $h_* G_i = h'_* G'_i$ (with $'$ denoting the factor system Σ'), and the projectability of G'_i by h' to an involutive constant-dimensional distribution on a neighborhood of y_0 follows by an application of Lemma 5 to G'_i and h'. Note, however, that

Lemma 5 as it stands *cannot* be directly applied to G_i and h (satisfying condition (v)), since we do not require G_i to be involutive and constant dimensional (but only modulo V^*).

Note that Theorem 6 generalizes the well-known fact that a nonlinear system Σ whose decoupling matrix $D(x)$ (cf. (2.6)) has rank m around x_0 can be transformed by local state space and feedback transformations into (1.3), see, e.g., [IKGM]. Hence Theorem 6 can also be interpreted as giving the necessary and sufficient conditions for finding a local output transformation $\tilde{y} = \psi(y) = (\psi_1(y), \ldots, \psi_m(y))$ such that the decoupling matrix $\tilde{D}(x)$ for the transformed output functions $\tilde{h}_1 = \psi_1 oh, \ldots, \tilde{h}_m = \psi_m oh$ has rank m around x_0.

Example. Consider the following system on $M = \mathbb{R}^3, Y = \mathbb{R}^2$:

$$\begin{aligned} \dot{x}_1 &= u_2, & y_1 &= x_1 \\ \dot{x}_2 &= x_3, & y_2 &= x_2 + \frac{1}{3}x_1^3 \\ \dot{x}_3 &= u_1. \end{aligned} \tag{2.44}$$

The relative degrees are both 1, while the decoupling matrix $D(x)$ equals

$$D(x) = \begin{pmatrix} 0 & 1 \\ 0 & x_1^2 \end{pmatrix}$$

and thus is singular, implying that the system is *not* input-output decouplable by static state feedback. However it is readily seen that the system satisfies the conditions of Theorem 6 and even of Theorem 4, and in fact we only need the output transformation

$$\psi_1(y) = y_2 - \tfrac{1}{3}y_1^3, \qquad \psi_2(y) = y_1$$

to bring the system into prime form (1.2), with $\kappa_1 = 1, \kappa_2 = 2$ (being the relative degrees of the *transformed* system)! Now suppose we want to asymptotically track a desired smooth trajectory $y^d(t) = (y_1^d(t), y_2^d(t)), t \geq 0$ for (2.44). Using the above output transformation, such a trajectory is transformed into the new coordinates as $\tilde{y}^d(t) = (y_2^d(t) - \frac{1}{3}(y_1^d(t))^3, y_1^d(t)), t \geq 0$, and since (2.44) has been transformed into a prime system the tracking problem is simply solved by a control strategy which is *linear* in the transformed coordinates, namely,

$$\begin{aligned} u_1 = &- K_{11}(x_2 - (y_2^d(t) - \tfrac{1}{3}(y_1^d(t))^3) \\ &- K_{12}(x_3 - (\dot{y}_2^d(t) - (y_1^d(t))^2 \dot{y}_1^d(t))) \\ &+ \ddot{y}_2^d(t) - 2y_1^d(t)(\dot{y}_1^d(t))^2 - (y_1^d(t))^2 \ddot{y}_1^d(t) \\ u_2 = &- K_2(x_1 - y_1^d(t)) + \dot{y}_1^d(t) \end{aligned}$$

where $K_2 < 0$, and K_{11}, K_{12} are designed in such a way that the polynomial $s^2 + K_{12}s + K_{11}$ is Hurwitz.

Notice, furthermore, that the conditions of Theorem 6 imply (see, e.g., [NvdS], [Is]) that Σ is input-output decouplable by *dynamic* state feedback. (In the foregoing example, system (2.44) can be dynamically input-output decoupled for the original output functions by pre-integrating the input u_2 one time). Regarded from this viewpoint, Theorem 6 *avoids* the addition of extra pre-integrators to the system by allowing instead for output transformations.

The proofs of Theorems 4 and 6 immediately yield the following algorithm to transform Σ into a prime or input-output prime system.

ALGORITHM 7. Consider a nonlinear system Σ with equilibrium x_0, and satisfying, in a neighborhood V_{x_0} of x_0, conditions (i)–(v) of Theorem 6. Then Σ can be transformed into $(I-O-P)$ in the following way.

(a) Compute the distributions $H_i := h_* G_i$ on $W_{y_0} = h(V_{x_0}), i = 1, 2, \ldots, n-1$. (By Remark 3 above, H_i are all well defined, involutive, and constant-dimensional distributions.)

(b) Construct rectifying (Frobenius) coordinates $\psi_1, \ldots, \psi_m$ (cf. (2.18), (2.19)) defined on a possibly smaller neighborhood of y_0, for the whole sequence $H_1 \subset H_2 \subset \ldots \subset H_{n-1}$. This defines the output space transformation ψ of Definition 1.

(c) Consider the output functions $\tilde{h}_i := \psi_i o h, i = 1, \ldots, m$, for Σ. Compute the relative degrees $\mu_1, \ldots, \mu_m$ for these output functions and the decoupling matrix $\tilde{D}(x) = (L_{g_j} L_f^{\mu_i - 1} \tilde{h}_i(x))_{i,j=1,\ldots,m}$. Necessarily $\mu_i < \infty, i = 1, \ldots, m$, and rank $D(x) = m$ around x_0. Define the functions

$$x_{ij} := L_f^{(j-1)} \tilde{h}_i, \quad j = 1, \ldots, \mu_i, \quad i = 1, \ldots, m. \tag{2.45}$$

Necessarily these functions are independent around x_0, while

$$V^* = \ker \operatorname{span}\{dx_{ij}, j = 1, \ldots, \mu_i, \quad i = 1, \ldots, m\}. \tag{2.46}$$

Choose complementary coordinates $z = (z_1, \ldots, z_{n'})$ around $x_0 (n' := n - (\mu_1 + \ldots + \mu_m))$. This defines the state space transformation φ of Definition 1.

(d) Compute the regular feedback $u = \alpha(x) + \beta(x)v$ around x_0 as

$$\alpha(x) = -\tilde{D}^{-1}(x) \begin{pmatrix} L_f^{\mu_1} \tilde{h}_1(x) \\ \vdots \\ L_f^{\mu_m} \tilde{h}_m(x) \end{pmatrix}, \qquad \beta(x) = \tilde{D}^{-1}(x). \tag{2.47}$$

This defines the feedback transformation required in Definition 1.

Remark 1. Note that $\mu_1 + \ldots + \mu_m = n$ if and only if $V^* = 0$, in which case Σ is locally equivalent to a prime system.

Remark 2. At some occasions it may be more efficient *not* to check conditions (i)–(v) of Theorem 6 in order to see if Σ is locally equivalent to $(I-O-P)$, but instead to apply *directly* Algorithm 7. If the Algorithm breaks down (e.g., if some distributions H_i are not well defined or not involutive, or if $\tilde{D}(x)$ does not have full rank) then Σ is not locally equivalent to $(I-O-P)$ (while Σ is locally equivalent to $I-O-P$ if Algorithm 7 *does* work).

Example. As an illustration of the above remark we apply Algorithm 7 to the example

$$\begin{aligned} \dot{x}_1 &= u_1, & y_1 &= x_5 + x_5 x_3 - \tfrac{1}{2} x_5 x_2^2 \\ \dot{x}_2 &= u_2, & y_2 &= x_3 - \tfrac{1}{2} x_2^2 \\ \dot{x}_3 &= x_1 + x_2 u_2 \\ \dot{x}_4 &= x_2 + x_1 u_1 \\ \dot{x}_5 &= x_4 - \tfrac{1}{2} x_1^2. \end{aligned}$$

Following the proof of Lemma 5 we first express the system in local coordinates

$$\xi_1 = x_1, \quad \xi_2 = x_2, \quad \xi_3 = x_3 - \tfrac{1}{2} x_2^2, \quad \xi_4 = x_4, \quad \xi_5 = x_5 (1 + x_3 - \tfrac{1}{2} x_2^2)$$

as

$$\begin{aligned}
\dot{\xi}_1 &= u_1, \qquad y_1 = \xi_5 \\
\dot{\xi}_2 &= u_2, \qquad y_2 = \xi_3 \\
\dot{\xi}_3 &= \xi_1 \\
\dot{\xi}_4 &= \xi_2 + \xi_1 u_1 \\
\dot{\xi}_5 &= \frac{\xi_5}{1+\xi_3}(1+\xi_1) + (\xi_4 - \tfrac{1}{2}\xi_1^2)(1+\xi_3).
\end{aligned}$$

(a) Simple computations give

$$\begin{aligned}
G_1 &= \operatorname{span}\left\{\frac{\partial}{\partial \xi_1}, +\xi_1 \frac{\partial}{\partial \xi_4}, \frac{\partial}{\partial \xi_2}\right\} \\
G_2 &= \operatorname{span}\left\{\frac{\partial}{\partial \xi_1}, \frac{\partial}{\partial \xi_2}, \frac{\partial}{\partial \xi_4}, \frac{\partial}{\partial \xi_3} + \frac{\xi_5}{1+\xi_3}\frac{\partial}{\partial \xi_5}\right\} \\
G_3 &= TM \\
H_1 &= 0 \\
H_2 &= \operatorname{span}\left\{\frac{y_1}{1+y_2}\frac{\partial}{\partial y_1} + \frac{\partial}{\partial y_2}\right\} \\
H_3 &= TY.
\end{aligned}$$

According to (2.15) the indices are $\kappa_2 = 2, \kappa_1 = 3$.

(b) From (2.18) the rectifying Frobenius coordinates are

$$\psi_1(y) = \frac{y_1}{1+y_2} \qquad \psi_2(y) = y_2.$$

(c) The transformed output functions $\tilde{h}_1, \tilde{h}_2$ are

$$\tilde{h}_1 = \frac{x_5(1 + x_3 - \frac{1}{2}x_2^2)}{1 + x_3 - \frac{1}{2}x_2^2} = x_5 \qquad \tilde{h}_2 = x_3 - \tfrac{1}{2}x_2^2.$$

The relative degrees are $\mu_1 = 3, \mu_2 = 2$, while the decoupling matrix is $\tilde{D} = I_{2\times 2}$. Hence the functions

$$\begin{aligned}
z_1 &= \tilde{h}_1 = x_5 \\
z_2 &= L_f \tilde{h}_1 = x_4 - \tfrac{1}{2}x_1^2 \\
z_3 &= L_f^2 \tilde{h}_1 = x_2 \\
z_4 &= \tilde{h}_2 = x_3 - \tfrac{1}{2}x_2^2 \\
z_5 &= L_f \tilde{h}_2 = x_1
\end{aligned}$$

give the state space transformation φ of Definition 1.

(d) The regular feedback of definition 1 is

$$\alpha(x) = 0 \qquad \beta(x) = I.$$

In fact, in z-coordinates we have

$$\dot{z}_1 = z_2, \quad \dot{z}_2 = z_3, \quad \dot{z}_3 = u_2 \quad \dot{z}_4 = z_5 \quad \dot{z}_5 = u_1,$$

which is a linear prime system.

The extension of Theorem 6 to local equivalence into input-output prime systems of special form (1.3) reads as follows.

PROPOSITION 8. *Consider a nonlinear system* Σ *with equilibrium* x_0. Σ *is locally equivalent to an input-output prime system of special form* $(I-O-P-S)$, *if and only if, on a neighborhood of* x_0, *conditions (i)–(v) of Theorem 6 are satisfied and, additionally:*

(vi) $V^* \cap S^* = 0$;

(vii) S^* is involutive and constant dimensional.

Proof (only if). Suppose Σ is locally equivalent to $(I-O-P-S)$. From the (only if) part of Theorem 6 it follows that Σ satisfies conditions (i)–(v). Clearly, $(I-O-P-S)$ satisfies conditions (vi) and (vii). Furthermore the definition of S^* is feedback invariant, and thus also Σ satisfies conditions (vi) and (vii).

(If.) By (iii), (iv), and (vi) we have $V^* \oplus S^* = TM$. By Theorem 6, Σ is locally equivalent to $(I-O-P)$, i.e., (1.3). Here z are coordinate functions which are arbitrary except for the fact that they have to be complementary to the coordinate functions $x = (x_{11}, \ldots, x_{m\mu_m})$; see (2.45). In the present case, however, since $V^* \oplus S^* = TM$ and V^* and S^* are involutive and constant dimensional, we can choose z such that span dz = ann S^*. Since, by construction, span dx = ann V^*, cf. (2.46), we thus have

$$V^* = \operatorname{span}\left\{\frac{\partial}{\partial z}\right\}, \qquad S^* = \operatorname{span}\left\{\frac{\partial}{\partial x}\right\}. \tag{2.48}$$

Then, first of all, since $G = S_1 \subset S^* = \operatorname{span}\{\partial/\partial x\}$, we have in (1.3)

$$b_j(z,x) = 0, \qquad j = 1, \ldots, m. \tag{2.49}$$

Second, by definition of S^*, $[f, S^* \cap \ker dh] \subset S^*$, cf. (2.3), and thus, since f is of the form $f = *\partial/\partial x + a(z,x)\partial/\partial z$ and $S^* = \operatorname{span}\{\partial/\partial x\}$

$$\left[*\frac{\partial}{\partial x} + a(z,x)\frac{\partial}{\partial z}, \frac{\partial}{\partial x_{ij}}\right] \subset \operatorname{span}\left\{\frac{\partial}{\partial x}\right\}, \quad j = 2, \ldots, \mu_i, \quad i = 1, \ldots, m. \tag{2.50}$$

(Note that kerdh is everything minus span $\{(\partial/\partial x_{i1}), i = 1, \ldots, m\}$.) This implies that $a(z,x)$ in (1.3) may only depend on z and $x_{i1} = y_i, i = 1, \ldots, m$, and thus (1.4) results.

□

Remark 1. If conditions (ii) and (iv) in Proposition 8 are replaced by the stronger conditions

(ii)′ G_i is involutive and of constant dimension, $i = 1, 2, \ldots, n-1$,

(iv)′ $G_i = S_i, i = 1, \ldots, n$,

then, following [MBE], $a(z,y)$ in (1.4b) will only depend on those (new) output components y_i with i such that $\mu_i = \max\{\mu_1, \ldots \mu_m\}$.

Remark 2. Necessary and sufficient conditions for transforming into (1.4) (without change of output space coordinates) a nonlinear system Σ having invertible decoupling matrix have been identified in [BI]: see also [MBE]. Similar conditions were derived, in a different context, in [vdS]. Notice that in the *linear* case condition (vii) is automatically satisfied. This explains that for a linear system we can always write (even if condition (vi) is not satisfied) the V^* dynamics as being only driven by y, as follows from the Morse canonical form [Mo].

EXAMPLE. Consider the single input system

$$\dot{x}_1 = x_4^3, \qquad y = x_2$$

$$\dot{x}_2 = x_3,$$
$$\dot{x}_3 = x_4$$
$$\dot{x}_4 = u.$$

Easy computations give:

$$V^* = \text{span}\left\{\frac{\partial}{\partial x_1}\right\}, \quad \ker dh = \text{span}\left\{\frac{\partial}{\partial x_1}, \frac{\partial}{\partial x_3}, \frac{\partial}{\partial x_4}\right\}, \quad S^* = \mathbb{R}^4,$$
$$S^* \cap V^* = \text{span}\left\{\frac{\partial}{\partial x_1}\right\},$$
$$G_1 = \text{span}\left\{\frac{\partial}{\partial x_4}\right\}, \qquad G_2 = \text{span}\left\{\frac{\partial}{\partial x_4}, 3x_4^2\frac{\partial}{\partial x_1} + \frac{\partial}{\partial x_3}\right\},$$
$$G_3 = \text{span}\left\{\frac{\partial}{\partial x_4}, 3x_4^2\frac{\partial}{\partial x_1} + \frac{\partial}{\partial x_3}, \frac{\partial}{\partial x_2}\right\}.$$

Theorem 4 does not apply since G_2 is not involutive. Theorem 6 applies, while Proposition 8 does not apply since $V^* \cap S^* \neq 0$.

Now let us proceed to a *global* version of the equivalence results we have obtained so far. Instead of requiring that rank dh(x) and dim $G(x)$ are equal to m in a neighborhood of x_0, we will now have to require this on the whole M. Then by the Rank Theorem (e.g., [Sp]), $h(M)$ is an open part of Y, and without loss of generality, we may restrict to this part of Y and *assume* that $h : M \to Y$ is surjective. The global version of Definition 1 reads now as follows.

DEFINITION 9. Consider two systems Σ_1, Σ_2 defined on $(M_1, Y_1), (M_2, Y_2)$ with equilibrium points $x_{01} \in M_1, x_{02} \in M_2$, respectively. Σ_1 is globally equivalent to Σ_2 if there exist:

(i) A diffeomorphism $\varphi : M_1 \to M_2$, satisfying $\varphi(x_{01}) = x_{02}$;
(ii) a nonsingular feedback $u = \alpha(x) + \beta(x)v$ on M_1 with $\alpha(x_{01}) = 0$ and det $\beta(x) \neq 0$;
(iii) a diffeomorphism $\psi : Y_1 \to Y_2$ with $\psi(h_1(x_{01})) = h_2(x_{02})$ such that the resulting transformation of Σ_1 equals Σ_2.

Since Theorem 6 generalizes Theorem 4 we will only give the global version of Theorem 6, and state as a corollary the global version of Proposition 8.

THEOREM 10. *Consider a nonlinear system* Σ *on* (M, Y) *with equilibrium* x_0, *and assume that* $h : M \to Y$ *is a surjective submersion and that* dim $G(x) = m$, *for all* $x \in M$. *Suppose that conditions* (i)–(v) *of Theorem* 6 *are satisfied on the whole* M, *and that*

(A) There exist globally *defined independent functions* $\psi_1, \ldots, \psi_m$ *on* Y *which are rectifying coordinates for* $H_1, \ldots, H_m$, *i.e.,* (2.19a) *and* (2.19b) *are satisfied for every* $x \in M$ *(the local existence of* $\psi_1, \ldots, \psi_m$ *is already insured by conditions (i)–(v));*

then by Algorithm 7*(c), (d)* V^* *is globally given by* (2.46) *and the feedback* (2.47) *is globally defined. Furthermore, there exists a surjective submersion* $\pi : M \to M'$ *with ker* $\pi_* = V^*$, *while the factor system* Σ', *cf.* (2.43), *is globally defined on* M'.

Assume additionally that

(B) The vectorfields f' *and* $g'_j, j = 1, \ldots, m$, *on* M', *cf. (2.43), are* complete;

then M' *equals* $\mathbb{R}^\mu, \mu = \sum_{i=1}^m \mu_i$, *and thus* Σ *is* globally equivalent *to an input-output system (I − O − P) with equilibrium* $(0, z_0)$. *Conversely, if* Σ *is globally equivalent to*

$(I - O - P)$ then conditions (i)–(v) *of Theorem 6 are satisfied on the whole M, and conditions (A) and (B) hold.*

Remark. Since the feedback (α, β) depends on the choice of $\psi_1, \ldots, \psi_m$, also condition (B), i.e., the completeness of the modified vectorfields $f', g'_j, j = 1, \ldots, m$, may depend on the choice of $\psi_1, \ldots, \psi_m$. This is already illustrated by the following very simple example: Consider the system $\dot{x} = u, y = e^{-x}$ on $M = \mathbb{R}$ and $Y = (0, \infty)$. If we take $\psi(y) = \ell n\, y$ as a global coordinate on Y (which trivially is rectifying, since $H_1 = TY$) then $\tilde{h}(x) = \psi o h(x) = -x$, and $g' = \tilde{g} = -\partial/\partial x$ is complete, implying that the system is globally equivalent to the prime system $\dot{x} = u, y = x$. However if we would take the global rectifying coordinate $\psi(y) = y$, then $g' = e^x \partial/\partial x$ is not complete, and indeed, since $id : (0, \infty) \to \mathbb{R}$ is *not* a diffeomorphism onto $\mathbb{R}$, the system is *not* globally transformed into a prime system.

Proof. Suppose conditions (i)–(v) are satisfied on M, as well as condition (A). Apply Algorithm 7 using the global rectifying coordinates $\psi_1, \ldots, \psi_m$ on Y. Since V^* is constant dimensional on the whole M it follows by a slight adaptation of [HK, Thm. 3.9], see also [IKGM], that V^* can be globally factored out, i.e., there exists a surjective submersion $\pi : M \to M'$ with $\ker \pi_* = V^*$, and the feedback transformed dynamics $\tilde{f}, \tilde{g}_j, j = 1, \ldots, m$ (with (α, β) defined by (2.47)) project to dynamics $f', g'_j, j = 1, \ldots, m$ on M' (note that, in contrast to [HK, Thm. 3.9], we do not require Σ to be accessible; however, condition (iii) of Theorem 6 insures that Σ is "accessible modulo V^*"). Now assume that condition (B) is satisfied. By the local equivalence of Σ with (1.3) it follows that the vectorfields $g'_j, ad_f g'_j, \ldots, ad_f^{\mu_j - 1} g'_j, j = 1, \ldots, m$, are *commuting* and *complete* vectorfields on M' (see [Re], [DBE]). It follows that $M' = \mathbb{R}^{\mu - k} \times S^k$ for some $k \geq 0$. However, since the functions $L_f^j \tilde{h}_i, j = 0, 1, \ldots, \mu_i - 1, i = 1, \ldots, m$, are *global* coordinate functions on M' necessarily $k = 0$ (since S^k is compact). Since $y_j = x_{j1}, j = 1, \ldots, m$, we also have $Y \simeq \mathbb{R}^m$. It follows [Re], [DBE] that Σ' is globally equivalent to a linear system, and thus that Σ is globally equivalent to $I - O - P$. Conversely, if Σ is globally equivalent to $(I - O - P)$ then by the (only if) part of Theorem 6 conditions (i)–(v) are satisfied everywhere. Furthermore, clearly $(I - O - P)$ satisfies Conditions A and B. □

COROLLARY 11. *Σ is globally equivalent to $(I - O - P - S)$ if and only if, in addition to conditions (i)–(v) and conditions A and B of Theorem 10, conditions (vi), (vii) of Proposition 8 are satisfied on the whole M.*

Remark. Analogous reasoning on the global equivalence modulo V^* to a linear system was used in [MRS]. Similar conditions for the global equivalence of a nonlinear system with invertible decoupling matrix into (1.3) or (1.4) were derived in [BI].

3. Conclusions and final remarks. Necessary and sufficient geometric conditions have been given for transforming nonlinear systems into (input-output) prime form (of special form), locally as well as globally. The main novelty (e.g., as compared to normal forms for input-output decouplable systems) is that we allow for output transformations. Actually, as made explicit in Algorithm 7 (see also the example following it), the output transformation is the crucial step in the whole transformation procedure and involves the simultaneous integration of a nested sequence of distributions on the output space manifold (similar to the integration of distributions on the *state* space manifold as in the feedback linearization problem). The results obtained are applicable to control problems where output transformations are naturally allowed, such as output tracking, output regulation, (almost) disturbance decoupling [I], [NvdS], [MRS] and the servomechanism problem. The results enable us to treat the class of nonlinear systems equivalent to input-output prime form very much like the well-studied class of input-output decouplable systems. Finally, as we

have remarked, the use of output transformations may be an alternative to the use of extra pre-integrators for *dynamic* intput-output decoupling. This raises the problem of how output transformations may be used to *minimize* the amount of pre-integrators for dynamic input-output decoupling.

STABILIZATION AND EXACT BOUNDARY CONTROLLABILITY FOR MAXWELL'S EQUATIONS*

B. V. KAPITONOV†

Abstract. This paper considers Maxwell's equations with dissipative boundary conditions. Under certain geometric conditions imposed on the domain Ω, the results on uniform stabilization of the solutions are established. Exact boundary controllability is then obtained through Russell's "controllability via stabilizability" principle.

Key words. Maxwell's equations, stabilization, exact controllability

AMS subject classifications. 35L, 49E

1. Introduction and problem formulation. Throughout this paper Ω is an open, bounded domain in R^3 with sufficiently smooth boundary $\partial\Omega = S$. In $\Omega \times (0,T)$ we consider the initial boundary value problem for the Maxwell system:

$$\begin{aligned} e_t &= \operatorname{curl}(\mu h), \\ h_t &= -\operatorname{curl}(\lambda e), \\ \operatorname{div} e &= \operatorname{div} h = 0, \end{aligned} \tag{1.1}$$

$$e(x,0) = f_1(x), \qquad h(x,0) = f_2(x), \tag{1.2}$$

$$[\nu, e] - \alpha(h - \nu(h,\nu)) = 0 \qquad (x,t) \in S \times (0,T), \tag{1.3}$$

where e and h are three-dimensional vector-valued functions of $t, x = (x_1, x_2, x_3)$, ν is the unit outer normal, $[\cdot,\cdot]$ and $(\cdot,\cdot)$ are the vector and inner products, $\mu = \mu(x)$ and $\lambda = \lambda(x)$ are scalar functions in Ω (the conditions on μ and λ are presented below), and $\alpha = \alpha(x)$ is a continuously differentiable function on S with $\operatorname{Re}\alpha > 0$.

The equality (1.3) (the Leontovich condition) means that surface S is a conductor and complex-valued function is a surface impedance (cf. [12] for details).

Our first purpose is to prove the uniform stabilization as $t \to \infty$ of solutions of problem (1.1)–(1.3).

Using this result we study the following exact controllability problem:

Given the initial distribution $\{f_1(x), f_2(x)\}$, time $T > 0$, and a desired terminal state $\{g_1(x), g_2(x)\}$ with $\{f_1(x), f_2(x)\}, \{g_1(x), g_2(x)\}$ in appropriate function spaces, find a vector-valued function $p(x,t)$ in a suitable function space such that the solution of (1.1)–(1.2) with boundary condition

$$[\nu, e] - ia(x)(h - \nu(h,\nu))/_S = p(x,t) \qquad (\mathcal{J}ma(x) = 0) \tag{1.4}$$

satisfies

$$e(x,T) = g_1(x), \qquad h(x,T) = g_2(x). \tag{1.5}$$

Here $a(x)$ is scalar continuously differentiable function on S.

Remark 1.1. Due to finite speed of propagation (1.1)–(1.2) the exact controllability problem can have a solution only if T is large enough. The determination of T is part of the problem.

The exact controllability problem for Maxwell's equations ($\lambda(x) \equiv \lambda_0, \mu(x) \equiv \mu_0$ for $x \in \Omega$) with boundary control by means of currents flowing tangentially in the boundary of the region ($a(x) \equiv 0$) has been studied by Russell [17] for a circular cylindrical region, by Kime [8] for a spherical region, and by Lagnese [9] for a general region. In [17] it is assumed that the fields e and h do not depend on the axial coordinate. The control problem can then be transformed into a problem of the exact controllability of two wave equations by means of a single control. The latter control problem is then solved by the moment problem method. A moment problem approach is also used in [8]. In [9] the exact controllability problem for a general region has been studied by means of the Hilbert uniqueness method introduced by Lions [14], [15].

In this paper the controllability problem (1.1)–(1.2), (1.4)–(1.5) is solved using the energy decay of the solution of (1.1)–(1.3). This approach was applied to the wave equation by G. Chen [1]–[3], Lagnese [10], Lasiecka and Triggiani [13], and to the linear elastodynamic systems by Lagnese [11].

2. Well-posedness of (1.1)–(1.3). Let $\lambda(x)$ and $\mu(x)$ be continuously differentiable function in Ω satisfying the conditions $0 < \lambda_0 \le \lambda(x) \le \lambda_1, 0 < \mu_0 \le \mu(x) \le \mu_1$. We denote by $\mathcal{H}$ the Hilbert space of pairs $\{u_1, u_2\}$ of three-component complex-valued functions $u_i \in L_2(\Omega)$ with the inner product

$$\langle \{u_1, u_2\}, \{v_1, v_2\} \rangle_0 = \int_\Omega (\lambda(u_1, \bar{v}_1) + \mu(u_2, \bar{v}_2)) dx.$$

We denote by $\mathcal{H}_1$ the Hilbert space consisting of pairs $u = \{u_1, u_2\}$ such that $\{u_1, u_2\}$, $\{\text{curl } u_1, \text{curl } u_2\} \in \mathcal{H}$. We define the inner product in $\mathcal{H}_1$ by

$$\begin{aligned}\langle \{u_1, u_2\}, \{v_1, v_2\} \rangle_1 = \int_\Omega [&(\text{curl } \lambda u_1, \text{curl } \lambda \bar{v}_1) + (\text{curl } \mu u_2, \text{curl } \mu \bar{v}_2) \\ &+ (c + \lambda)(u_1, \bar{v}_1) + (c + \mu)(u_2, \bar{v}_2)] dx,\end{aligned}$$

where the constant c is chosen so that the norm in $\mathcal{H}_1$ is equivalent to the norm defined by the expression

$$\int_\Omega (|\text{curl } u_1|^2 + |\text{curl } u_2|^2 + |u_1|^2 + |u_2|^2) dx.$$

We further denote by $H_m(\Omega)$ and $H_q(S)$ the usual Sobolev spaces, and by $\| \cdot \|_{m,\Omega}$ and $\| \cdot \|_{q,S}$ the norms in them.

LEMMA 2.1. *Suppose* $\alpha(x) \in C^1(S)$. *The mapping* $\{u_1, u_2\} \to [\nu, u_1] - \alpha(u_2 - \nu(u_2, \nu))$ *from* $C^1(\bar{\Omega})$ *into* $C^1(S)$ *extends by continuity to a continuous linear mapping of* $\mathcal{H}_1 \to H_{-1/2}(S)$, *which we also denote by* $u \to [\nu, u_1] - \alpha(u_2 - \nu(u_2, \nu)) \equiv \omega(\alpha, u)$.

We can now introduce in $\mathcal{H}_1$ the closed subspace $\overset{\circ}{\mathcal{H}}_1(\alpha) = \{u \in \mathcal{H}_1 : \omega(\alpha, u) = 0\}$, which is dense in $\mathcal{H}$.

In $\mathcal{H}$ we define the unbounded operation A:

$$\mathcal{D}(A) = \overset{\circ}{\mathcal{H}}_1(\alpha), \quad Au = \{\text{curl } \mu u_2, -\text{curl } \lambda u_1\}, \quad \{u_1, u_2\} \in \mathcal{D}(A).$$

LEMMA 2.2. *The domain of the adjoint operator* A^* *coincides with* $\overset{\circ}{\mathcal{H}}_1(-\bar{\alpha})$. *For* $v = \{v_1, v_2\} \in \mathcal{D}(A^*)$.

$$A^* v = -\{\text{curl } \mu v_2, -\text{curl } \lambda v_1\}.$$

The proofs of Lemmas 2.1 and 2.2 are carried out in a manner similar to that in [7] for an unbounded domain (see also [6] for $\alpha(x) \equiv 0$). For this reason we do not present these arguments.

We note that the operator A is closed, since it coincides with the operator adjoint to A^*.

It can be shown that for $\mathrm{Re}\alpha(x) \geq 0$ the domain of A contains the set of smooth functions in $C^1(\Omega)$ satisfying $\omega(\alpha, u) = 0$ on the boundary as a dense set. Using this circumstance, it is easy to prove that the operators A and A^* are dissipative, i.e.,

$$\mathrm{Re}\langle Au, u\rangle_0 \leq 0, \quad u \in \mathcal{D}(A); \qquad \mathrm{Re}\langle A^*v, v\rangle_0 \leq 0, \quad v \in \mathcal{D}(A^*).$$

The operator A thus generates a strongly continuous semigroup of contractions $U(t), t > 0$.

Let $M = \{v \in \mathcal{D}(A^*) : A^*v = 0\}$, and let M_1 be the orthogonal complement of M in $\mathcal{H}$. The kernel of A^* is nonempty, since it contains the pairs $\{\lambda^{-1}\nabla\varphi_1, \mu^{-1}\nabla\varphi_2\}$ where $\varphi_i \in \overset{\circ}{H}_1(\Omega) \cap H_2(\Omega)$. It is obvious that $U(t)$ takes $M_1 \cap \mathcal{D}(A)$ into itself. Indeed, if $v \in M$ and $u \in M_1 \cap \mathcal{D}(A)$, then

$$\frac{d}{dt}\langle U(t)u, v\rangle_0 = \langle AU(t)u, v\rangle_0 = \langle U(t)u, A^*v\rangle_0 = 0.$$

We remark that elements $\{u_1, u_2\} \in M_1 \cap \mathcal{D}(A)$ possess the following property: $\mathrm{div} u_i = 0$ in the sense of distributions. It is not hard to show that a sequence of functions $u^n = \{u_1^n, u_2^n\}$ approximating an element $u \in M_1 \cap \mathcal{D}(A)$ can be chosen so that $\mathrm{div} u_i^n = 0$.

As in [7] we can now show that elements $u \in M_1 \cap \mathcal{D}(A)$ are contained in $H_1(\Omega)$ and therefore their traces on the boundary belong to $H_{1/2}(S)$, which makes it possible to treat $\omega(\alpha, u) = 0$ in the usual sense for Sobolev spaces.

The next theorem establishes the solvability of problem (1.1)–(1.3) in the class of functions needed for subsequent investigations.

THEOREM 2.1. *Suppose* $f(x) = \{f_1(x), f_2(x)\} \in M_1 \cap \mathcal{D}(A^n)$, Re $\alpha \geq 0, 0 < \lambda_0 \leq \lambda(x), 0 < \mu_0 \leq \mu(x), |\mathcal{D}_x^\beta \lambda| \leq C, |\mathcal{D}_x^\beta \mu| \leq C(|\beta| \leq n)$, *and* $\alpha(x) \in C^1(S)$. *Then there exists a unique solution* $u = \{e, h\}$ *of* (1.1)–(1.3) *such that* $A^j u \in H_1(\Omega), j = 0, 1, \cdots, n-1$. *Moreover,*

$$\|A^j u\|_0 \leq \|A^j f\|_0, \qquad j = 0, 1, \cdots, n.$$

Proof. It is obvious that the solution of (1.1)–(1.3) is given by $u = U(t)f$. Because of the properties of the semigroup $U(t)$,

$$A^j u = A^j U(t) f = U(t) A^j f \in M_1 \cap \mathcal{D}(A), \qquad j = 0, 1, \cdots, n-1.$$

From this it follows that $A^j u \in H_1(\Omega), j = 0, 1, \cdots, n-1$. Moreover,

$$\|A^j u\|_0 = \|A^j U(t) f\|_0 = \|U(t) A^j f\|_0 \leq \|A^j f\|_0 \qquad (j = 0, 1, \cdots, n),$$

which proves the assertion.

Let $f(x) = \{f_1(x), f_2(x)\} \in \mathcal{H}, f^n = \{f_1^n, f_2^n\} \in \mathcal{D}(A), \|f - f^n\|_0 \to 0$. Then $U(t)f^n$ satisfies the following identity:

$$\int_0^T \left(\left\langle U(t)f^n, \frac{d\Psi}{dt} \right\rangle_0 + \langle U(t)f^n, A^*\Psi\rangle_0 \right) dt = -\langle f, \Psi(0)\rangle_0,$$

where $\Psi \in L_2(0,T;\mathcal{D}(A^*)), \Psi_t \in L_2(0,T;\mathcal{H}), \Psi(T)=0$. From this we easily obtain

$$\int_0^T \left(\left\langle U(t)f, \frac{d\Psi}{dt} \right\rangle_0 + \langle U(t)f, A^*\Psi\rangle_0 \right) dt = -\langle f, \Psi(0)\rangle_0, \tag{2.1}$$

i.e., $U(t)f$ is the weak solution of the problem

$$u_t = Au, \qquad u|_{t=0} = f.$$

We note that $U(t)$ takes M_1 into itself. Indeed, if $g \in M$ and $\Psi(t) = (T-t)g$, then from (2.1) it follows that

$$\int_0^T \langle U(t)f, g\rangle_0 dt = \langle f, g\rangle_0 T.$$

Thus,

$$\langle U(t)f, g\rangle_0 = \langle f, g\rangle_0 \quad \text{for } t \geq 0$$

3. Stabilization. We start from geometrical conditions on Ω.

We consider the problem

$$\Delta\Phi = 1 \quad \text{in } \Omega,$$

$$\left.\frac{\partial\Phi}{\partial\nu}\right|_S = \frac{\text{mes } \Omega}{\text{mes } S},$$

which admits a solution $\Phi(x) \in C^2(\Omega) \cap C^1(\bar{\Omega})$.

For an arbitrary bounded domain Ω with smooth boundary S we define the following quantity:

$$æ(\Omega) = \sup_{\substack{x\in\Omega \\ |\xi|=1}} 2\,\text{Re}\ \Phi_{x_ix_j}\xi^i\bar{\xi}^j,$$

where $\xi = (\xi^1, \xi^2, \xi^3)$ is an arbitrary complex-valued vector. It is obvious that $æ(\Omega) \geq \frac{2}{3}$ and $æ(\{x : |x-x^0| < R\}) = \frac{2}{3}$.

We shall say that Ω is substarlike if

(i) $æ(\Omega) < 1$, or

(ii) $æ(\Omega) \geq 1$; there exists a point $x^0 \in \Omega$ such that for some $0 < \varepsilon \leq 1$

$$(x-x^0, \nu) > -\frac{1}{æ + \varepsilon - 1}\frac{\text{mes } \Omega}{\text{mes } S}.$$

We note that an arbitrary starlike domain ($(x-x^0,\nu) \geq 0$) is substarlike. It will follow from the continuity of $æ(\Omega)$ that there exist substarlike domains which are not starlike.

Henceforth we assume that Ω is substarlike domain.

LEMMA 3.1. *Assume that Ω is substarlike domain. Then there exists a function $\varphi(x) \in C^2(\Omega) \cap C^1(\bar{\Omega})$ such that*

(i) $(\nabla\varphi, \nu) > 0$ *on* S,

(ii) $2\,\text{Re}\varphi_{x_ix_j}\xi^i\bar{\xi}^j - \Delta\varphi|\xi|^2 + |\xi|^2 \leq (1-\omega)|\xi|^2$ *in* Ω, *where* $0 < \omega \leq 1$. *Moreover, for* $æ(\Omega) \geq 1$, $\omega = \varepsilon$.

Proof. For $\theta > 0, x^0 \in \Omega$ we set

$$\varphi(x) = \Phi(x) + \frac{1}{2\theta}|x - x^0|^2$$

so that

$$2\,\mathrm{Re}\ \varphi_{x_i x_j}\xi^i\bar{\xi}^j - \Delta\varphi|\xi|^2 + |\xi|^2 = 2\,\mathrm{Re}\ \Phi_{x_i x_j}\xi^i\bar{\xi}^j - \frac{1}{\theta}|\xi|^2 \leq \left(æ - \frac{1}{\theta}\right)|\xi|^2,$$

$$(\nabla\varphi, \nu) = (\nabla\Phi, \nu) + \frac{1}{\theta}(x - x^0, \nu) = \frac{\text{mes } \Omega}{\text{mes } S} + \frac{1}{\theta}(x - x^0, \nu).$$

Let $æ(\Omega) < 1$. Then for any $\theta > 0$ (ii) holds. If we choose θ so that

$$\theta > 2r(\text{mes } \Omega/\text{mes } S)^{-1} \quad (2r = d = \text{ diameter of } \Omega),$$

we obtain $(\nabla\varphi, \nu) > 0$ on S.

We now assume that $æ(\Omega) \geq 1$. In this case we choose x^0 as in the definition of Ω and set

$$\theta = \frac{1}{æ + \varepsilon - 1}.$$

The proof of Lemma 3.1 is complete.

The proof of stabilization is based on the invariance of the Maxwell system in vacuum ($\lambda(x) \equiv \lambda_0, \mu(x) \equiv \mu_0$) relative to the one-parameter group of dilations in all variables. This property of the Maxwell system leads to the identity

$$\begin{aligned}
&2\mathrm{Re}([\nabla\varphi, \bar{h}] + t\lambda\bar{e}, e_t - \mathrm{curl}(\mu h)) + 2\,\mathrm{Re}([\bar{e}, \nabla\varphi] + t\mu\bar{h}, h_t + \mathrm{curl}(\lambda e)) \\
&\quad = \frac{\partial}{\partial t}\{t(\lambda|e|^2 + \mu|h|^2) + 2\,\mathrm{Re}(\nabla\varphi, [h, \bar{e}])\} \\
&\quad -\mathrm{div}\{2t\lambda\mu\,\mathrm{Re}[h, \bar{e}] + \nabla\varphi(\lambda|e|^2 + \mu|h|^2) - 2\,\mathrm{Re}\ \lambda e(\bar{e}, \nabla\varphi) \\
&\quad -2\,\mathrm{Re}\ \mu h(\bar{h}, \nabla\varphi)\} - \{(\nabla\varphi, \nabla\lambda)|e|^2 + (\nabla\varphi, \nabla\mu)|h|^2\} \\
&\quad -\{2\,\mathrm{Re}\ \varphi_{x_i\bar{x}_j}(\lambda e^i\bar{e}^j + \mu h^i\bar{h}^j) - (\Delta\varphi - 1)(\lambda|e|^2 + \mu|h|^2)\} \\
&\quad -2\,\mathrm{Re}\ \lambda(\nabla\varphi, \bar{e})\mathrm{div}e - 2\,\mathrm{Re}\mu(\nabla\varphi, \bar{h})\mathrm{div}\ h,
\end{aligned} \tag{3.1}$$

where $\varphi(x) \in C^2(\Omega) \cap C^1(\bar{\Omega})$ is constructed in Lemma 3.1.

Let $f = \{f_1, f_2\} \in M_1 \cap \mathcal{D}(A)$ and $\{e, h\} = U(t)f$. From (3.1) after integration over the cylinder $\Omega \times (T_0, T)$ it follows that

$$\begin{aligned}
&\int_\Omega [t(\lambda|e|^2 + \mu|h|^2) + 2\,\mathrm{Re}\ (\nabla\varphi, [h, \bar{e}])]|_{t=T}dx \\
&\qquad - \int_\Omega [t(\lambda|e|^2 + \mu|h|^2) + 2\,\mathrm{Re}(\nabla\varphi, [h, \bar{e}])]|_{t=T_0}dx \\
&\quad = \int_{T_0}^T \int_\Omega [(\nabla\varphi, \nabla\lambda)|e|^2 + (\nabla\varphi, \nabla\mu)|h|^2]dx\,dt \\
&\qquad + \int_{T_0}^T \int_\Omega \{2\,\mathrm{Re}\ \varphi_{x_i x_j}(\lambda e^i\bar{e}^j + \mu h^i\bar{h}^j) \\
&\qquad -(\Delta - 1)(\lambda|e|^2 + \mu|h|^2)\}dx\,dt \\
&\qquad + \int_{T_0}^T \int_S \{2t\lambda\mu\,\mathrm{Re}(\nu, [h, \bar{e}]) + (\nabla\varphi, \nu)(\lambda|e|^2 + \mu|h|^2) \\
&\qquad -2\lambda\,\mathrm{Re}(e, \nu)(\bar{e}, \nabla\varphi) - 2\mu\mathrm{Re}(h, \nu)(\bar{h}, \nabla\varphi)\}dS\,dt \equiv I_1 + I_2 + I_3.
\end{aligned} \tag{3.2}$$

We have

$$2\int_\Omega \mathrm{Re}(\nabla\varphi,[h,\bar{e}])|_{t=T}dx \le \frac{d(\varphi)}{\sqrt{\lambda_0\mu_0}}\int_\Omega(\lambda|e|^2+\mu|h|^2)|_{t=T_0}dx,$$

where $d(\varphi)=\max_{x\in\Omega}|\nabla\varphi|$.

Using the boundary condition, we rewrite the last integral on the right side of (3.2) in the form

$$\begin{aligned}\int_{T_0}^{T}\int_S\{&-2t\lambda\mu|[h,\nu]|^2\,\mathrm{Re}\,\alpha-(\nabla\varphi,\nu)(\lambda|(e,\nu)|^2+\mu|(h,\nu)|^2)\\&+(\nabla\varphi,\nu)(\mu+\lambda|\alpha|^2)|[h,\nu]|^2-2\mathrm{Re}\lambda(\bar{e},\nu)([e,\nu],[\nabla\varphi,\nu])\\&-2\,\mathrm{Re}\,\mu(\bar{h},\nu)([h,\nu],[\nabla\varphi,\nu])\}dSdt\equiv\int_{T_0}^{T}\int_S\mathcal{B}\,dS\,dt.\end{aligned}$$

We now assume that $\mathrm{Re}\,\alpha(x)\ge b>0$. Let α_1,δ be such that

$$|\alpha(x)|\le\alpha_1, x\in S,\qquad(\nabla\varphi,\nu)\ge|\nabla\varphi|\delta,\quad x\in S.$$

We have

$$\begin{aligned}|2\,\mathrm{Re}\,\lambda(\bar{e},\nu)([e,\nu],[\nabla\varphi,\nu])|&\le|\nabla\varphi|\lambda(\delta|(e,\nu)|^2+\delta^{-1}|[e,\nu]|^2),\\|2\,\mathrm{Re}\,\mu(\bar{h},\nu)([h,\nu],[\nabla\varphi,\nu])|&\le|\nabla\varphi|\mu(\delta|(h,\nu)|^2+\delta^{-1}|[h,\nu]|^2).\end{aligned}$$

From these inequalities we obtain

$$\mathcal{B}\le-|[h,\nu]|^2\{2t\lambda_0\mu_0 b-d(\varphi)(\mu_1+\lambda_1\alpha_1^2)(1+\delta^{-1})\}.$$

We choose T_0 so that

$$T_0\ge\frac{d(\varphi)(1+\delta)(\mu_1+\lambda_1\alpha_1^2)}{2\lambda_0\mu_0 b\delta}\equiv T^*.$$

Thus, if $T>T_0\ge T^*$, it follows that

$$\int_{T_0}^{T}\int_S\mathcal{B}\,dS\,dt\le-\int_{T_0}^{T}2\lambda_0\mu_0 b(t-T^*)\int_S|[h,\nu]|^2\,dS\,dt\le0. \tag{3.3}$$

Let us assume for a moment that for some $0<\gamma\le1$

$$I_1+I_2\le(1-\gamma)\int_{T_0}^{T}\int_\Omega(\lambda|e|^2+\mu|h|^2)dxdt. \tag{3.4}$$

From (3.2) we obtain

$$T\|U(T)f\|_0^2\le\left(T^*+\frac{2d(\varphi)}{\sqrt{\lambda_0\mu_0}}\right)\|U(T^*)f\|_0^2+(1-\gamma)\int_{T^*}^{T}\|U(t)f\|_0^2dt.$$

Using the Gronwall inequality we find that

$$t\|U(t)f\|_0^2\le\left(T^*+\frac{2d(\varphi)}{\sqrt{\lambda_0\mu_0}}\right)\left(\frac{t}{T^*}\right)^{1-\gamma}\|U(T^*)f\|_0^2,\qquad t>T^*.$$

THEOREM 3.1. *Assume that* Ω *is substarlike*, Re $\alpha(x) \geq b > 0$,

$$(\nabla\varphi, \nabla\lambda) \leq \lambda(\omega - \gamma), (\nabla\varphi, \nabla\mu) \leq \mu(\omega - \gamma),$$

where $\varphi(x), \omega$ *are defined in Lemma* 3.1, $0 < \gamma \leq 1$. *Then for all* $f \in M_1, t > T^*$

$$\|U(t)f\|_0^2 \leq \left(T^* + \frac{2d(\varphi)}{\sqrt{\lambda_0\mu_0}}\right)(T^*)^{\gamma-1}\frac{1}{t^\gamma}\|f\|_0^2.$$

Proof. We approximate an arbitrary element $f \in M_1$ in the norm of $\mathcal{H}$ by pairs $g^n = \{g_1^n, g_2^n\}$ of smooth vector-functions g_i^n with $\omega(\alpha, g^n) = 0$.

Suppose $f^n = \{g_1^n - \lambda^{-1}\nabla\varphi_1^n, g_2^n - \mu^{-1}\nabla\varphi_2^n\}$, where

$$\operatorname{div}(\lambda^{-1}\nabla\varphi_1^n) = \operatorname{div} g_1^n, \quad \operatorname{div}(\mu^{-1}\nabla\varphi_2^n) = \operatorname{div} g_2^n, \qquad \varphi_i^n|_S = 0.$$

Then $f^n \in M_1 \cap \mathcal{D}(A)$ and

$$\|f^n - f\|_0^2 \leq \|g^n - f\|_0^2 + 2\|g^n\|_0\|g^n - f\|_0 \to 0, \qquad n \to \infty.$$

We have

$$t^\gamma\|U(t)f^n\|_0^2 \leq \left(T^* + \frac{2d(\varphi)}{\sqrt{\lambda_0\mu_0}}\right)\|f^n\|_0^2\frac{1}{(T^*)^{1-\gamma}}.$$

Letting $n \to \infty$, we get

$$t^\gamma\|U(t)f\|_0^2 \leq \left(T^* + \frac{2d(\varphi)}{\sqrt{\lambda_0\mu_0}}\right)\|f\|_0^2\frac{1}{(T^*)^{1-\gamma}}.$$

COROLLARY 3.1. $U(t)$ *takes the closed subspace* M_1 *into itself and*

$$\|U(t)\|_{M_1 \to M_1} < 1$$

for

$$t > T_1 = \left(T^* + \frac{2d(\varphi)}{\sqrt{\lambda_0\mu_0}}\right)^{1/\gamma}(T^*)^{1-1/\gamma}.$$

Using Pazy's theorem [16], we obtain Corollary 3.2.

COROLLARY 3.2. *Suppose* $f(x) = \{f_1, f_2\} \in M_1$. *There exist* $C, \beta > 0$ *such that*

$$\|U(t)f\|_0^2 \leq C\exp(-\beta t)\|f\|_0^2.$$

Remark 3.1. If Ω is a starlike domain, the estimate of Theorem 3.1 holds true under the following assumptions on λ, μ:

$$|\nabla\lambda| < \frac{\lambda}{2r}, \quad |\nabla\mu| < \frac{\mu}{2r} \text{ in } \bar{\Omega}, \qquad 2r = \text{diameter of } \Omega.$$

Indeed, let $\delta > 0$ be such that

$$|\nabla\lambda| \leq \frac{\lambda(1-\delta)}{2r}, \qquad |\nabla\mu| \leq \frac{\mu(1-\delta)}{2r}.$$

We choose $\theta > 0$ so that

$$\theta < \frac{2r\delta}{2r(æ + \varepsilon - 1) + |\nabla\Phi|(1-\delta)}.$$

We then obtain

$$\begin{aligned}
&\frac{1}{\lambda}(\nabla\lambda,\nabla\varphi)\lambda|e|^2+\frac{1}{\mu}(\nabla\mu,\nabla\varphi)|h|^2\\
&\quad=\left\{\frac{1}{\lambda}(\nabla\lambda,\nabla\Phi)+\frac{1}{\lambda\theta}(\nabla\lambda,x-x^0)\right\}\lambda|e|^2\\
&\quad+\left\{\frac{1}{\mu}(\nabla\mu,\nabla\Phi)+\frac{1}{\mu\theta}(\nabla\mu,x-x^0)\right\}\mu|h|^2\\
&\quad<\left(\frac{1}{\theta}-æ+1-\varepsilon\right)(\lambda|e|^2+\mu|h|^2),
\end{aligned}$$

whence we get the required inequality (3.4).

4. Exact controllability. In this section we shall use the estimate of Theorem 3.1 to prove exact controllability to an arbitrary state of solutions of (1.1), (1.2), (1.4).

In $\Omega\times(0,T)$ we consider the following problem:

$$\begin{aligned}
&e_t=\operatorname{curl}(\mu h), && \operatorname{div} e=0,\\
&h_t=-\operatorname{curl}(\lambda e), && \operatorname{div} h=0,\\
&e(x,0)=f_1(x), && h(x,0)=f_2(x),\\
&[\nu,e]-ia(x)(h-\nu(h,\nu))=p(x,t), && (x,t)\in S\times(0,T).
\end{aligned}\tag{4.1}$$

where λ,μ,S satisfy the conditions of Theorem 3.1, $a(x)\in C^i(S), f=\{f_1,f_2\}\in M_1$. Find a vector-function $p(x,t)$ such that the solution of (4.1) satisfies

$$e(x,T)=g_1(x),\qquad h(x,T)=g_2(x)$$

with an arbitrary pair $g=\{g_1,g_2\}\in M_1, T\geq T_1$.

Let $U(t)$ be the semigroup defined above ($\mathcal{J}m\alpha=a(x)$, Re $\alpha(x)=b>0$).

Consider the following equation in M_1

$$w-U^*(T)U(T)w=f-U^*(T)g.$$

The operator $G(T)=U^*(T)U(T)$ takes M_1 into itself and $\|G(T)\|<1$ for $T>T_1$. Thus we can solve this equation for any $f,g\in M_1$ and

$$\|w\|_0\leq \boldsymbol{C}(\|f\|_0+\|g\|_0).$$

Consequently, if we choose $w=(I-G(T))^{-1}(f-U^*(T)g)$, then

$$\{e(x,t),h(x,t)\}=U(t)w-(U^*(T-t)U(T)w-U^*(T-t)g)\equiv\{u,v\}-\{\tilde u,\tilde v\}$$

is a weak solution of (4.1) with

$$p(x,t)=b(v-\nu(v,\nu))+b(\tilde u-\nu(\tilde v,\nu)).$$

We observe that

$$\{e(x,T),h(x,T)\}=g(x)$$

and by the energy identity

$$\|p\|^2_{L_2(S\times(0,T))}\leq C(\|f\|_0^2+\|g\|_0^2).$$

Thus, $p(x,t)$ belongs to $L_2(S \times (0,T))$ and drives the solution of (4.1) to a desired terminal state $g = \{g_1, g_2\}$.

We have the following theorem.

THEOREM 4.1. *Assume that Ω is substarlike, $a(x) \in C^1(S), \lambda(x), \mu(x) \in C^1(\bar{\Omega}), 0 < \lambda_0 \le \lambda(x) \le \lambda_1, 0 < \mu_0 \le \mu(x) \le \mu_1$,*

$$(\nabla\varphi, \nabla\lambda) \le \lambda(w-\gamma), (\nabla\varphi, \nabla\mu) \le \mu(w-\gamma),$$

where $\varphi(x), w$ are defined in Lemma 3.1, $0 < \gamma \le 1$. Then for any $T > 2d(\varphi)(\lambda_0\mu_0)^{-1/2}(1-\gamma)^{1-1/\gamma}\gamma^{-1}$, given any pair of initial data $f = \{f_1, f_2\} \in M_1$ and any pair $g = \{g_1, g_2\} \in M_1$ there exists a boundary control $p(x,t) \in L_2(S \times (0,T))$ such that the corresponding solution of (4.1) satisfies

$$\{e(x,T), h(x,T)\} = \{g_1(x), g_2(x)\}.$$

Moreover,

$$\|p\|^2_{L_2(S\times(0,T))} \le C(\|f\|_0^2 + \|g\|_0^2).$$

We need only to explain that the control time T is an arbitrary quantity greater than

$$T_0 = \frac{2d(\varphi)}{\sqrt{\lambda_0\mu_0}} \frac{(1-\gamma)^{1-1/\gamma}}{\gamma}.$$

We note that T_1 is the function of b and

$$\inf\ T_1(b) = \frac{2d(\varphi)}{\sqrt{\lambda_0\mu_0}} \frac{(1-\gamma)^{1-1/\gamma}}{\gamma} = T_0.$$

Let $T > T_0$. We choose $b > 0$ such that

$$T_1(b) < T.$$

Then for $\alpha = b + ia(x)$ $\|U(T)\|_{M_1 \to M_1} < 1$ and we can solve the main relation

$$(I - U^*(T)U(T))w = f - U^*(T)g$$

for any $f, g \in M_1$.

Remark 4.1. If Ω is strictly starlike ($(x - x^0, \nu) > 0$) we can set $\varphi(x) = \frac{1}{2}|x - x^0|^2$. Then

$$d(\varphi) = \max_{\Omega} |\nabla\varphi| \le 2r = d = \text{diameter of } \Omega$$

and we have the best control time $T_0 = 2d/\sqrt{\lambda_0\mu_0}$ for the Maxwell system with $\lambda(x), \mu(x)$ such that

$$\frac{\partial\lambda}{\partial|x|} \le 0, \qquad \frac{\partial\mu}{\partial|x|} \le 0.$$

5. The case of discontinuous $\lambda(x), \mu(x)$. In this section we consider stabilization and exact controllability for Maxwell's equations in multilayered media.

These questions for Euler–Bernoulli beam equation in the one-dimensional case have been studied by G. Chen et al. [4].

Let us assume that $\partial\Omega = S$ is strictly star-shaped with respect to some point $x^0 \in \Omega$, i.e.,

$$(x - x^0, \nu) > 0.$$

With no loss of generality we suppose that $x^0 = 0$.

Assume that $B_k \subset \Omega$ is a bounded domain with sufficiently smooth boundary S_k, $\bar{B}_k \subset B_{k+1}$ for $k = 1, 2, \ldots, n$. Assume that $S_1, S_2, \ldots, S_n$ are star-shaped with respect to the origin, $\lambda(x)$ and $\mu(x)$ lose the continuity on these surfaces. We set

$$\Omega_0 = B_1, \quad \Omega_k = B_{k+1}\backslash\bar{B}_k \quad \text{for } k = 1, 2, \ldots, n-1, \quad \Omega_n = \Omega\backslash\bar{B}_n.$$

We consider here

$$\begin{aligned} &e_t = \operatorname{curl}(\mu h), && \operatorname{div} e = 0, \\ &h_t = -\operatorname{curl}(\lambda e), && \operatorname{div} h = 0, \\ &e(x,0) = f_1(x), && h(x,0) = f_2(x), \\ &[\nu, e] - \alpha(h - \nu(h,\nu)) = 0, && (x,t) \in S \times (0,T), \end{aligned} \tag{5.1}$$

$$\begin{aligned} [\lambda^k \nu, e^k] &= [\lambda^{k-1}\nu, e^{k-1}], \quad [\mu^k \nu, h^k] \\ &= [\mu^{k-1}\nu, h^{k-1}], \quad (x,t) \in S_k \times (0,T), \quad k = 1, \ldots, n, \end{aligned} \tag{5.2}$$

where $\nu = \nu(x)$ (for $x \in S_k$) is the unit normal vector to pointing into the exterior of B_k; $\lambda^k, \mu^k, e^k, h^k$ are the restrictions of corresponding functions on Ω_k.

In $\mathcal{H}$ we can define the unbounded operator $\tilde{A}$ in the same way as in previous sections:

$$\mathcal{D}(\tilde{A}) = \{\{e,h\} \in \mathcal{H} : \operatorname{curl} e^k, \operatorname{curl} h^k \in L_2(\Omega_k) \text{ for } k = 0, 1, \ldots, n,$$

$\omega(\alpha, \{e,h\}) = 0, \{e,h\}$ satisfies (5.2)$\} \equiv \tilde{\mathcal{H}}_1(\alpha)$, and

$$\tilde{A}\{e,h\} = \{\operatorname{curl}(\mu h), -\operatorname{curl}(\lambda e)\} \quad \text{for } \{e,h\} \in \mathcal{D}(\tilde{A}).$$

It can be shown in a similar way that $\tilde{A}$ and $\tilde{A}^*$ are dissipative for Re $\alpha \geq 0$. From it follows that $\tilde{A}$ generates a strongly continuous semigroup of contractions $\tilde{U}(t), t > 0$.

Let $\tilde{M}_1$ be the orthogonal complement of the kernel of $\tilde{A}^*$ in $\mathcal{H}$. It is not hard to show that

$$\operatorname{div} e^k = \operatorname{div} h^k = 0; \qquad e^k, h^k \in H_1(\Omega_k), \quad k = 0, 1, \ldots, n$$

for $\{e,h\} \in \mathcal{D}(\tilde{A}) \cap \tilde{M}_1$.

We remark that element $\Psi = \{\lambda^{-1}\nabla\varphi, 0\}$ belongs to the kernel of $\tilde{A}^*$ for an arbitrary $\varphi \in H_2(\Omega) \cap \overset{\circ}{H}_1(\Omega)$.

Thus, for $\{e,h\} \in \mathcal{D}(\tilde{A}) \cap \tilde{M}_1$ we have

$$\begin{aligned} 0 = \langle\{e,h\}, \Psi\rangle_0 = \int_{\Omega_0} (e^0, \nabla\bar{\varphi})dx + \ldots + \int_{\Omega_n} (e^n, \nabla\bar{\varphi})dx = \int_{S_1} (e^0, \nu)\bar{\varphi}\, dS \\ - \int_{S_1} (e^1, \nu)\bar{\varphi}\, dS + \ldots + \int_{S_n} (e^{n-1}, \nu)\bar{\varphi}\, dS - \int_{S_n} (e^n, \nu)\bar{\varphi}\, dS. \end{aligned}$$

Now we choose φ such that $\varphi = 0$ on $S_1, \dots, S_{j-1}, S_{j+1}, \dots, S_n$. Then

$$\int_{S_j} [(e^{j-1}, \nu) - (e^j, \nu)]\bar{\varphi} dS = 0$$

and we have

$$(e^{j-1}, \nu)|_{S_j} = (e^j, \nu)|_{S_j}, \qquad j = 1, 2, \dots, n. \tag{5.3}$$

It can be shown in the same way that

$$(h^{j-1}, \nu)|_{S_j} = (h^j, \nu)|_{S_j}, \qquad j = 1, 2, \dots, n. \tag{5.4}$$

The interface conditions (5.2)–(5.4) can also be found in the book by Dautray and Lions [5].

We assume that $\lambda^k(x) \equiv \lambda^k, \mu^k(x) = \mu^k$ for $x \in \Omega_k, k = 0, 1, \dots, n$.

Suppose $f \in \mathcal{D}(\tilde{A}) \cap \tilde{M}_1, \{e, h\} = \tilde{U}(t)f$. By an argument similar to the one in §3 we obtain ($\varphi = \frac{1}{2}|x|^2$)

$$\begin{aligned} &\int_\Omega \{t(\lambda|e|^2 + \mu|h|^2) + 2\,\mathrm{Re}(x, [h, \bar{e}])\}|_{t=T} dx \\ &\quad = \int_\Omega \{t(\lambda|e|^2 + \mu|h|^2) + 2\,\mathrm{Re}(x, [h, \bar{e})\}|_{t=T_0} dx \\ &\quad + \int_{T_0}^T \int_S \mathcal{B}\, dS\, dt + \sum_{k=1}^n \int_{T_0}^T \int_{S_k} (\mathcal{B}_{k-1} - \mathcal{B}_k) dS\, dt, \end{aligned} \tag{5.5}$$

where $\mathcal{B}$ is defined as in §3,

$$\begin{aligned} \mathcal{B}_k =& 2t\lambda^k\mu^k\,\mathrm{Re}(\nu, [h^k, \bar{e}^k]) + (x, \nu)(\lambda^k|e^k|^2 + \mu^k|h^k|^2) \\ &-2\,\mathrm{Re}\lambda^k(e^k, \nu)(\bar{e}^k, x) - 2\,\mathrm{Re}\ \mu^k(h^k, \nu)(\bar{h}^k, x). \end{aligned}$$

Using (5.2)–(5.4), we find that

$$\begin{aligned} t\lambda^k\mu^k(\nu, [h^k, \bar{e}^k]) &= t\lambda^{k-1}\mu^{k-1}(\nu, [h^{k-1}, \bar{e}^{k-1}]), \\ \lambda^k|e^k|^2 &= \lambda^k|(e^{k-1}, \nu)|^2 + \frac{(\lambda^{k-1})^2}{\lambda^k}|[e^{k-1}, \nu]|^2, \\ \mu^k|h^k|^2 &= \mu^k|(h^{k-1}, \nu)|^2 + \frac{(\mu^{k-1})^2}{\mu^k}|[h^{k-1}, \nu]|^2, \\ \lambda^k(e^k, \nu)(\bar{e}^k, x) &= \lambda^k(x, \nu)|(e^{k-1}, \nu)|^2 + \lambda^{k-1}(e^{k-1}, \nu)([\bar{e}^{k-1}, \nu], [x, \nu]), \\ \mu^k(h^k, \nu)(\bar{h}^k, x) &= \mu^k(x, \nu)|(h^{k-1}, \nu)|^2 + \mu^{k-1}(h^{k-1}, \nu)([\bar{h}^{k-1}, \nu], [x, \nu]). \end{aligned}$$

Hence

$$\begin{aligned} \mathcal{B}_{k-1} - \mathcal{B}_k = (x, \nu)\{&(\lambda^k - \lambda^{k-1})|(e^{k-1}, \nu)|^2 + (\mu^k - \mu^{k-1})|(h^{k-1}, \nu)|^2 \\ &+ \frac{\lambda^{k-1}}{\lambda^k}(\lambda^k - \lambda^{k-1})|[e^{k-1}, \nu]|^2 + \frac{\mu^{k-1}}{\mu^k}(\mu^k - \mu^{k-1})|[h^{k-1}, \nu]|^2\}. \end{aligned}$$

We now assume that

$$\lambda^k < \lambda^{k-1}, \quad \mu^k < \mu^{k-1}, \quad k = 1, 2, \dots, n; \qquad \mathrm{Re}\ \alpha = b(x) \geq b > 0.$$

Then $\mathcal{B}_{k-1} - \mathcal{B}_k \leq 0$ for $k = 1, 2, \ldots, n$, and from (5.5) it follows

$$T\|\tilde{U}(T)f\|_0^2 \leq \left(T_0 + \frac{2d}{\sqrt{\lambda^n \mu^n}}\right) \|\tilde{U}(T_0)f\|_0^2,$$

where

$$T > T_0 \geq \frac{d(1+\delta)(\mu^0 + \lambda^0 \alpha_1^2)}{2\lambda^n \mu^n b \delta} \equiv \tilde{T}^*, \qquad \frac{(x,\nu)}{|x|} \geq \delta > 0, \quad d = \max_{x \in \Omega} |x|.$$

As above we have

$$\|\tilde{U}(t)\|_{\tilde{M}_1 \to \tilde{M}_1} < 1$$

for

$$t > \tilde{T}^* + 2\frac{d}{\sqrt{\lambda^n \mu^n}}.$$

We can now show exact controllability for control time $T > 2d/\sqrt{\lambda^n \mu^n}$ for Maxwell's equations in multilayered media.

THEOREM 5.1. *Assume that Ω is strictly star-shaped, $\Omega_1, \Omega_2, \ldots, \Omega_n \subset \Omega$ are defined above. Suppose that $\lambda(x), \mu(x)$ are the piecewise constant functions in $\Omega, 0 < \lambda^n < \lambda^{n-1} < \ldots < \lambda^1 < \lambda^0$,*

$$0 < \mu^n < \mu^{n-1} < \ldots < \mu^1 < \mu^0 \qquad (\lambda(x) \equiv \lambda^k, \mu(x) = \mu^k, x \in \Omega_k).$$

Then for any $T > 2d(\lambda^n \mu^n)^{-1/2}$, given any pair of initial data $f = \{f_1, f_2\} \in \tilde{M}_1$ and any pair $g = \{g_1, g_2\} \in \tilde{M}_1$ there exists a boundary control $p(x,t) \in L_2(S \times (0,T))$ such that the corresponding solution of (4.1), (5.2) *satisfies*

$$\{e(x,T), h(x,T)\} = \{g_1(x), g_2(x)\}.$$

Moreover,

$$\|p\|_{L_2(S \times (0,T))}^2 \leq C(\|f\|_0^2 + \|g\|_0^2).$$

ON THE BOUNDEDNESS AND STABILITY OF SOLUTIONS TO THE AFFINE VARIATIONAL INEQUALITY PROBLEM*

M. SEETHARAMA GOWDA† AND JONG-SHI PANG‡

Abstract. This paper investigates the boundedness and stability of solutions to the affine variational inequality problem. The concept of a solution ray to a variational inequality defined by an affine mapping and on a closed convex set is introduced and characterized; the connection of such a ray with the boundedness of the solution set of the given problem is explained. In the case of the monotone affine variational inequality, a complete description of the solution set is obtained which leads to a simplified characterization of the boundedness of this set as well as to a new error bound result for approximate solutions to such a variational problem. The boundedness results are then combined with certain degree-theoretic arguments to establish the stability of the solution set of an affine variational inequality problem.

Key words. variational inequality, linear complementarity, solution ray, solution stability, degree theory, error bound

AMS subject classifications. 90C30, 90C33

1. Introduction.

This paper is a continuation of our recent effort in the study of the stability of variational inequalities, complementarity, and related problems. Our previous work [12], [11], [13], [29], which is typical among those of many authors [8], [15], [16], [19], [21], [30], [31], [34], [36], [37], has focused on the analysis of the behavior of a given solution to a problem under perturbation. In the present paper, we shall analyze the behavior of the entire solution set when the problem data are perturbed. Analysis of this kind has previously been performed for linear programs [32], [39], convex quadratic programs [4], [33], smooth generalized equations with bounded, convex solution sets [33], and linear complementarity problems of a certain type [5]. For the sensitivity analysis of a nonsmooth generalized equation, see [22].

The present paper deals with the affine variational inequality problem which is defined as follows. Given a nonempty polyhedron K in R^n, a vector $q \in R^n$, and a matrix $M \in R^{n\times n}$, this problem, denoted AVI (K, q, M), is to find a vector $x \in K$ such that

$$(y - x)^T(q + Mx) \geq 0 \text{ for all } y \in K.$$

Although the main stability results in the paper are obtained for this affine problem, they are derived with the aid of a number of auxiliary results that are valid for the more general case where K is an arbitrary closed convex set in R^n, not necessarily polyhedral. In order to distinguish the latter (semi-affine) case with the (fully) affine case, we shall drop the letter "A" in the prefix "AVI" when the set K is not restricted to be polyhedral. The solution set of the problem (A)VI (K, q, M) is denoted SOL(K, q, M). The primary objective of this paper is to study the behavior of this set as the pair (q, M) is perturbed (with K fixed). In particular, the following concept is central to our study. (Throughout this paper, $\|\cdot\|$ denotes an arbitrary vector norm in R^n.)

DEFINITION 1. The problem VI (K, q, M) is said to be stable if for every $\varepsilon > 0$, there exists $\delta > 0$ such that for every pair $(q', M') \in R^n \times R^{n\times n}$ satisfying $\|q-q'\|+\|M-M'\| < \delta$,

$$\mathrm{SOL}(K, q', M') \cap (\mathrm{SOL}(K, q, M) + \varepsilon\mathcal{B}) \neq \emptyset,$$

where $\mathcal{B}$ denotes the open unit ball associated with the norm.

This stability concept is distinct from that of stability at a solution point [13]. Indeed, in the definition, there is no mention of any particular solution; the concept concerns the solution set of the problem as a whole. Implicit in the above requirement for stability is the nonemptiness of the solution set $\mathrm{SOL}(K, q, M)$ of the given variational inequality problem. In addition, the definition demands that for every ε-neighborhood of $\mathrm{SOL}(K, q, M)$ with $\varepsilon > 0$, there exists a suitable δ-neighborhood of the pair (q, M) such that for all perturbed data (q', M') in the latter neighborhood, the perturbed VI (K, q', M'), in addition to being solvable, must have a solution that lies in the former neighborhood. Hence, stability of the problem VI (K, q, M) implies that its solutions are well behaved in the sense that they will not change too drastically as the data (q, M) are slightly perturbed. In this paper, we shall derive sufficient conditions for the problem AVI (K, q, M) to be stable and investigate some related issues.

Having introduced the above stability concept, we should immediately mention a result of Robinson [33] which states that if M is positive semidefinite (i.e., in the monotone case), the problem AVI (K, q, M) is stable if and only if $\mathrm{SOL}(K, q, M)$ is nonempty and bounded. This result suggests that the boundedness of the solution set of AVI (K, q, M) might have some significance in the stability of this problem in the nonmonotone case. Guided by this insight, we shall undertake, as the first order of business, an in-depth study of the boundedness issue; this will be done for the VI (K, q, M). We shall introduce the notion of a solution ray for a variational inequality which generalizes that for a linear complementarity problem (LCP) introduced originally by Cottle [2]. A characterization of such a ray and conditions for its nonexistence are obtained in both the monotone and general case. These results extend those in [2] and [26] for the LCP, see also [20]. In the study of the monotone affine problem, we obtain a complete description of the solution set of the AVI (K, q, M) analogous to the well-known representation of Adler–Gale [1] for the monotone LCP. This representation of $\mathrm{SOL}(K, q, M)$ can be used to derive an error bound for approximate solutions of the monotone AVI; the derived bound is somewhat different from those obtained recently in [7] by a different approach.

Armed with the boundedness results, we shall then focus on the stability issue. Following the degree-theoretic approach in [16], [11], [13], and [29], we shall introduce a key degree property under which the stability of the AVI (K, q, M) will be established. Sufficient conditions for the validity of the degree property will be derived.

2. Preliminary discussion. In this section, we consider some fundamental facts about the AVI that are motivated by the special case, namely, the LCP. Though elementary, they provide some interesting insights for the AVI and are instrumental to the subsequent development. Included in this discussion is an existence result for the monotone AVI which shows that this problem is solvable if and only if it is "feasible" (in a sense to be made precise later).

To begin, we recall the well-known fact that [3, Prop. 1.5.2] when the set K is a cone in R^n, not necessarily polyhedral, the VI (K, q, M) is equivalent to the generalized complementarity problem:

$$x \in K, q + Mx \in K^*, x^T(q + Mx) = 0,$$

where K^* is the dual cone of K, i.e.,

$$K^* = \{y \in R^n : y^T z \geq 0 \text{ for all } z \in K\}.$$

We denote the latter problem as GCP (K, q, M). The prefix GLCP will be used when K is polyhedral.

In the case of the LCP (q, M) (= GLCP (R^n_+, q, M)), the complementary range $K(M)$ and complementary kernel SOL(0, M) = SOL$(R^n_+, 0, M)$ have played an important role; see [3]. The former consists of all vectors $q \in R^n$ for which the LCP (q, M) has a solution; the latter is a generalization of the null-space concept of a linear transformation. Much is known about these two special sets. With K being an arbitrary closed convex set in R^n, a natural question to ask is what the analogs of these two sets are for the VI (K, q, M).

To deal with the generalization of $K(M)$, we let $\mathcal{R}(K, M)$ denote the set of all vectors q for which SOL(K, q, M) is nonempty. When K is a cone, $\mathcal{R}(K, M)$ is also a cone, but not necessarily convex. In what follows, we give a geometric description of $\mathcal{R}(K, M)$. For this purpose, let $\mathcal{F}_x(K)$ be the cone of feasible directions of K at the point $x \in K$; i.e., $v \in \mathcal{F}_x(K)$ if and only if $x + \tau v \in K$ for all $\tau > 0$ sufficiently small.

PROPOSITION 1. *Let K be a closed convex set in R^n. Then for any vector $q \in R^n$, x is a solution of* VI *(K, q, M) if and only if $x \in K$ and $q + Mx \in \mathcal{F}_x(K)^*$. Consequently,*

$$\mathcal{R}(K, M) = \cup_{x \in K} (\mathcal{F}_x(K)^* - Mx). \tag{1}$$

Proof. Let $q \in \mathcal{R}(K, M)$, and $x \in$ SOL(K, q, M). We claim that $q + Mx \in \mathcal{F}_x(K)^*$. Indeed, let $v \in \mathcal{F}_x(K)$; then $x + \tau v \in K$ for all $\tau > 0$ sufficiently small. Hence, it follows that

$$0 \leq (x + \tau v - x)^T (q + Mx) = \tau v^T (q + Mx),$$

which establishes the claim. Conversely, take $q \in \mathcal{F}_x(K)^* - Mx$, where $x \in K$. For $z \in K$, we have $z - x \in \mathcal{F}_x(K)$ by the convexity of K. Hence,

$$0 \leq (z - x)^T (q + Mx)$$

by the choice of q. This establishes the characterization of solutions to the VI (K, q, M) and the identity (1). □

If K is polyhedral, it is possible to derive an alternate characterization of $\mathcal{R}(K, M)$ which establishes that this set is the union of a finite number of convex polyhedra, hence closed. In order to describe this result, we need an explicit representation of the polyhedron K in terms of a system of linear inequalities:

$$K = \{x \in R^n : Ax \geq b\} \tag{2}$$

for some matrix $A \in R^{m \times n}$ and vector $b \in R^m$. (It is important to point out that although this particular representation of K is used in the proof of several results below, these results are actually valid regardless of the represetation, as long as K is polyhedral.) For each index subset α of $\{1, \ldots, m\}$ with complement $\overline{\alpha}$, the α-face of K is defined by

$$F(\alpha) = \{x \in R^n : A_\alpha x = b_\alpha, A_{\overline{\alpha}} x \geq b_{\overline{\alpha}}\},$$

where A_γ denotes the rows of A indexed by the set $\gamma \subseteq \{1, \ldots, m\}$.

For the alternate characterization of $\mathcal{R}(K, M)$ and the results in the subsequent sections, we shall need some elementary facts from convex analysis [38]. For an arbitrary matrix

C, we shall let pos C denote the polyhedral cone generated by the columns of C. If C is vacuous, we shall let pos C be the singleton $\{0\}$. Also, for an arbitrary subset S of R^n, $\mathcal{H}S$ shall denote the convex hull of S, $\mathcal{C}S$ the conical hull of S, ri S the relative interior of S, and 0^+S the recession cone of S. It is well known that ri S is nonempty and convex for any nonempty convex set $S \subseteq R^n$; moreover, for any two convex sets S_1 and S_2 in R^n, we have

$$\text{ri}(S_1 + S_2) = \text{ri } S_1 + \text{ri } S_2. \tag{3}$$

Another easy fact about the relative interior is as follows. If C is a convex cone in R^n, then

$$C + \text{ri } C = \text{ri } C. \tag{4}$$

The proof of this identity is easy and left to the reader. Finally, a cone $C \subseteq R^n$ is *pointed* if $C \cap (-C) = \{0\}$. It is known that if C is a closed convex pointed cone, then int C^* is nonempty.

The following description of $\mathcal{R}(K, M)$ is reminiscent of the representation of $K(M)$ in terms of the complementary cones in the context of the LCP.

PROPOSITION 2. *In the above setting,*

$$\mathcal{R}(K, M) = \cup_\alpha(\text{pos}(A_\alpha)^T - MF(\alpha)), \tag{5}$$

where the union ranges over all subsets α *of* $\{1, \ldots, m\}$. *Hence,*

$$\mathcal{H}(\mathcal{R}(K, M)) \subseteq (0^+K)^* - MK := \mathcal{F}(K, M). \tag{6}$$

Moreover, if K *is a (polyhedral) cone, then* $\mathcal{R}(K, M)$ *is convex if and only if*

$$\mathcal{R}(K, M) = \mathcal{F}(K, M). \tag{7}$$

Proof. With K represented by (2), it follows that $q \in \mathcal{R}(K, M)$ if and only if there exist vectors $x \in K$ and $u \in R^m_+$ such that

$$\begin{aligned} &0 = q + Mx - A^T u, \\ &v = -b + Ax \geq 0, \quad u \geq 0, \quad u^T v = 0. \end{aligned} \tag{8}$$

From this set of complementarity conditions, the equality (5) follows easily. The inclusion (6) is also obvious by noting that $(0^+K)^* = \text{pos } A^T$. Finally, to prove the last assertion of the proposition, we need to establish only the "only if" part. In turn, it suffices to prove the reverse inclusion in (6). For this purpose, let $q = A^T u - Mx$ for some $u \in R^m_+$ and $x \in K$. Let $F(\alpha)$ be the face of K containing x. Then, we have

$$q = (A_\alpha)^T u_\alpha - Mx + (A_{\overline{\alpha}})^T u_{\overline{\alpha}}.$$

Since K contains the origin, the last expression shows that q belongs to the convex cone generated by $\mathcal{R}(K, M)$. But since $\mathcal{R}(K, M)$ is itself a (generally nonconvex) cone, its conical hull coincides with its convex hull. Consequently, the desired inclusion holds. □

Remark. The identity (5) is actually a special case of (1). This follows because of the fact that a vector x belongs to K if and only if $x \in F(\alpha)$ for some index set α for which $\text{pos}(A_\alpha)^T = \mathcal{F}_x(K)^*$. Consequently, the unions in the two identities are equal.

The set $\mathcal{F}(K, M)$ deserves some further discussion. First of all, we note that its definition is independent of the representation of K. If K is represented by (2), then $\mathcal{F}(K, M)$ consists of all vectors $q \in R^n$ for which there exist vectors $x \in K$ and $u \in R^m_+$ such that $q + Mx = A^T u$; i.e., it contains all vectors q for which the complementarity system (8) is feasible. For this reason, we can think of $\mathcal{F}(K, M)$ as the set of all "feasible" q for the AVI associated with the (fixed) pair (K, M). In this vein, the last assertion of Proposition 2 says that if K is a polyhedral cone, the set of solvable q (for the AVI associated with the fixed pair (K, M)) is convex if and only if for all q, the feasibility of AVI (K, q, M) implies its solvability. This conclusion generalizes the famous observation made by Eaves [6] for the special case of the LCP.

Note that the inclusion (6) is actually valid for an arbitrary closed convex set K. Indeed, since $0^+K \subseteq \mathcal{F}_x(K)$ for all $x \in K$, Proposition 1 and duality imply $\mathcal{R}(K, M) \subseteq \mathcal{F}(K, M)$; (6) follows easily because of the convexity of the latter set.

Next, we consider the generalization of the complementary kernel. For this purpose, we recall [3, Prop. 3.9.23] that for the LCP defined by the (fixed) matrix M, the complementary kernel SOL$(0, M)$ is equal to the singleton $\{0\}$ if and only if for all $q \in K(M)$, SOL(q, M) is compact. The following result generalizes this fact to the VI.

PROPOSITION 3. *Let K be a closed convex set in R^n. Let $\mathcal{S}(K, M)$ denote the solution set of the (homogeneous) $GCP(0^+K, 0, M)$. If $\mathcal{S}(K, M)$ consists of the zero vector alone, then* SOL(K, q, M) *is compact for all $q \in \mathcal{R}(K, M)$. The converse holds if K is in addition a cone.*

Proof. Suppose that for some $q \in \mathcal{R}(K, M)$, SOL(K, q, M) contains a sequence $\{x^k\}$ with $\|x^k\| \to \infty$. Without loss of generality, we may assume that the normalized sequence $\{x^k/\|x^k\|\}$ converges to a limit vector d which is clearly nonzero. We claim that $d \in \mathcal{S}(K, M)$. Indeed, from the inequality $(z - x^k)^T(q + Mx^k) \geq 0$ which holds for all $z \in K$, we deduce, by a standard normalization argument, that $d^T M d \leq 0$. Moreover, for any $y \in 0^+K$ we have $x^k + y \in K$ and

$$y^T(q + Mx^k) \geq 0$$

for all k. The claim follows from a standard normalization argument. If K is in addition a cone, then $K = 0^+K$; the last assertion is now obvious (by the cone property of $\mathcal{S}(K, M)$). □

We note that the equality $\mathcal{S}(K, M) = \{0\}$ provides a sufficient condition for the solution set of the VI (K, q, M) to be bounded for all q. In the next section, we shall study the boundedness of the latter set for a fixed but arbitrary vector q.

In the remainder of this section, we shall relate the three sets $\mathcal{S}(K, M)$, $\mathcal{F}(K, M)$ and $\mathcal{R}(K, M)$ under some additional assumptions on K and M. For this purpose, we recall that a matrix M is said to be copositive on a cone $C \subseteq R^n$ if $x^T Mx \geq 0$ for all $x \in C$; a copositive matrix M on C is *copositive-star* there if $x \in$ SOL$(C, 0, M) \Rightarrow -M^T x \in C^*$. Examples of copositive-star matrices include the positive semidefinite matrices and the copositive-plus matrices; the latter are those copositive matrices M that satisfy $x \in C, x^T Mx = 0 \Rightarrow (M + M^T)x = 0$. See [9], [10], and [14] for more discussion of the copositive matrices and their role in the generalized complementarity problem.

Suppose that M is copositive-star on the recession cone 0^+K. Then

$$\mathcal{S}(K, M) \subseteq \{v \in 0^+K : -M^T v \in (0^+K)^*\}.$$

We claim that the reverse inclusion also holds. Let v be a vector in the right-hand set. To show $v \in \mathcal{S}(K, M)$, it suffices to verify $Mv \in (0^+K)^*$. For this purpose, let $y \in 0^+K$.

Then for all $\tau > 0, y + \tau v \in 0^+K$. The copositivity property of M yields

$$0 \leq (y + \tau v)^T M(y + \tau v) \leq y^T My + \tau y^T Mv$$

which implies $y^T Mv \geq 0$. Consequently, we deduce

$$\mathcal{S}(K, M) = \{v \in 0^+K : -M^T v \in (0^+K)^*\};$$

or equivalently,

$$\mathcal{S}(K, M) = 0^+K \cap (-M(0^+K))^*.$$

If K is polyhedral, then $-M(0^+K)$ is a polyhedral cone; hence, from elementary convex analysis [38], we may deduce

$$\mathcal{S}(K, M)^* = (0^+K)^* - M(0^+K), \tag{9}$$

which implies

$$\mathcal{S}(K, M)^* - MK = (0^+K)^* - MK = \mathcal{F}(K, M). \tag{10}$$

This is the first assertion in the following existence theorem for the AVI.

THEOREM 1. *Let K be a polyhedron in R^n. If M is a copositive-star matrix on 0^+K, then* (10) *holds. If in addition M is positive semidefinite, then* (7) *holds.*

Proof. It suffices to show

$$\mathcal{F}(K, M) \subseteq \mathcal{R}(K, M) \tag{11}$$

under the additional positive semidefiniteness assumption. For this purpose, we represent K by (2). Since M is positive semidefinite, so is the matrix

$$\begin{bmatrix} M & -A^T \\ A & 0 \end{bmatrix},$$

which is the defining matrix for the equivalent (mixed) linear complementarity problem (8). The inclusion (11) now follows from [14, Thm. 3.1]. □

3. Solution ray. Generalizing the definition for the LCP [2], we introduce the following important concept.

DEFINITION 2. A nonzero vector $v \in R^n$ is said to be a (solution) ray of SOL(K, q, M) at the solution $x \in$ SOL(K, q, M) if $x + \tau v \in$ SOL(K, q, M) for all $\tau > 0$.

Clearly, if a solution ray exists, then SOL(K, q, M) is unbounded. Conversely, if either K is polyhedral or SOL(K, q, M) is convex (the latter is true if M is positive semidefinite; see [17], e.g.), and if SOL(K, q, M) is unbounded, then a solution ray exists. To prove this converse, we note that if K is polyhedral, then SOL(K, q, M) is the union of a finite number of convex polyhedra (see, e.g., the proof of Lemma 3.1 in [24]). Hence, if this solution set is unbounded, then one of these latter polyhedra must be unbounded, and thus has an extreme ray which is easily seen to be a solution ray of SOL(K, q, M) as defined above. On the other hand, if SOL(K, q, M) is convex (with K not necessarily polyhedral), then since SOL(K, q, M) is clearly closed, from elementary convex analysis [38] we know that this solution set is unbounded if and only if it has a recession direction which must be a solution ray of SOL(K, q, M).

The next result gives a necessary and sufficient condition for a nonzero vector to be a solution ray of the VI (K, q, M).

PROPOSITION 4. *Let K be a closed convex subset of R^n, and $x \in$ SOL(K, q, M) be given. Then a vector $v \neq 0$ is a solution ray of* SOL(K, q, M) *at x if and only if the following three conditions hold:*

(a) $v \in \mathcal{S}(K, M)$,
(b) $v^T(q + Mx) = 0$,
(c) $(z - x)^T Mv \geq 0$ *for all* $z \in K$.

Proof. The nonzero vector v is a solution ray as described if and only if for all $\tau > 0$ and all $z \in K$, we have $x + \tau v \in K$ and

$$(z - x - \tau v)^T (q + Mx + \tau Mv) \geq 0.$$

Expanding the left-hand side, we obtain the equivalent inequality:

$$0 \leq (z - x)^T (q + Mx) + \tau (z - x)^T Mv - \tau v^T (q + Mx) - \tau^2 v^T Mv. \tag{12}$$

Hence, if properties (a), (b), and (c) hold, then v must be a solution ray of SOL(K, q, M) at x. Conversely, if v is such a ray, then $v \in 0^+ K$ and the inequality (12) implies $v^T Mv \leq 0$. Moreover, letting $z = x$ in the same inequality, dividing by τ and letting $\tau \downarrow 0$, we obtain

$$v^T (q + Mx) \leq 0.$$

We put $z = x + \tau^2 v$ in (12), divide by τ^3, and let $\tau \to \infty$, to obtain $v^T Mv \geq 0$. Hence, $v^T Mv = 0$. From the proof of Proposition 1 and the fact that $\mathcal{F}_x(K)^* \subseteq (0^+ K)^*$, we deduce

$$v^T (q + Mx) \geq 0.$$

Hence, (b) follows. Since (12) holds for all $\tau > 0$, property (c) also holds. Letting $z = x + d$ where $d \in 0^+ K$ is arbitrary, we deduce that $Mv \in (0^+ K)^*$. This establishes (a) and completes the proof of the proposition. Q.E.D.

An equivalent way of stating (c) above is

$$x \in \operatorname{argmin}_{z \in K} z^T Mv. \tag{13}$$

Based on this observation, we may establish a necessary and sufficient condition for SOL(K, q, M) to contain no solution ray.

COROLLARY 1. *Let K be a closed convex subset of R^n and $q \in \mathcal{R}(K, M)$. A necessary and sufficient condition for* SOL(K, q, M) *to have no solution ray is that the implication below holds:*

$$\left.\begin{array}{c} 0 \neq v \in \mathcal{S}(K, M) \\ x \in (\operatorname{argmin}_{z \in K} z^T Mv) \cap \text{SOL}(K, q, M) \end{array}\right\} \Rightarrow v^T (q + Mx) > 0. \tag{14}$$

Proof. The sufficiency is obvious. The necessity is also easy by recalling the fact that if $x \in$ SOL(K, q, M), then $(q + Mx)^T v \geq 0$ for all $v \in 0^+ K$. Hence, if there is no solution ray, the desired implication must hold. □

Motivated by the assumption of the above corollary, we introduce a special property on the pair (K, M).

DEFINITION 3. We say that (K, M) has the sharp property if

$$\left.\begin{array}{c} v \in \mathcal{S}(K, M) \\ x \in \operatorname{argmin}_{z \in K} z^T Mv \end{array}\right\} \Rightarrow v^T Mx \geq 0. \tag{15}$$

Combining the sharp property with Corollary 1, we immediately obtain Corollary 2.

COROLLARY 2. *Let K be a closed convex subset of R^n. If the pair (K, M) has the sharp property, then the* VI (K, q, M) *has no solution ray for all vectors $q \in int(\mathcal{S}(K, M)^*)$ (where* int X *denotes the (topological) interior of a set X).*

Proof. It suffices to note that $q \in \text{int } (\mathcal{S}(K,M)^*)$ if and only if $q^T v > 0$ for all $0 \neq v \in \mathcal{S}(K,M)$. □

In what follows, we shall give several sufficient conditions for the sharp property to hold. Before stating these conditions, we observe that if K is a closed convex set containing the origin, then for every x satisfying the condition (13), we must have

$$x^T M v \leq 0.$$

Moreover, if K is a closed convex cone, then conditions (a) and (c) in Proposition 4 are equivalent to (a) and

$$x^T M v = 0. \tag{16}$$

Indeed, if (a) and (c) hold and $K = 0^+ K$, then by the above observation, we obtain

$$0 \geq -x^T M v \geq 0,$$

where the first inequality holds because $Mv \in (0^+ K)^*$; hence (16) holds. The converse can be proved easily by reversing the argument.

PROPOSITION 5. *Let K be a closed convex subset of R^n. Then the sharp property holds for the pair (K, M) under any one of the following conditions:*

(a) $\mathcal{S}(K,M) = \{0\}$;

(b) *M is positive semidefinite and for every $v \in \mathcal{S}(K,M)$, there exists $y \in K$ such that $v^T M y \geq 0$ (in turn, the latter condition holds if K contains the origin);*

(c) *K contains the origin and*

$$v \in \mathcal{S}(K,M) \Rightarrow (M + M^T)v \in (\mathcal{C}K)^*;$$

(d) *K contains the origin and M is copositive on $\mathcal{C}K$;*

(e) *K is a cone and M is symmetric.*

Proof. Part (a) is trivial. Consider part (b). Let (v, x) be a pair satisfying the left-hand conditions in the sharp implication (15). Since $v^T M v = 0$, the positive semidefiniteness of M implies $Mv + M^T v = 0$. Hence, by the definition of x and the particular vector y associated with v, we obtain

$$v^T M x = -x^T M v \geq -y^T M v = v^T M y \geq 0.$$

Hence the right-hand conclusion in (15) holds.

To prove part (c), let (v, x) be any pair of vectors satisfying the left-hand conditions in (15). As pointed out above, we must have $x^T M v \leq 0$. Also since $x \in K \subseteq \mathcal{C}K$, it follows from the assumption that

$$0 \leq x^T (M + M^T) v \leq v^T (Mx)$$

which is the desired right-hand condition in (15).

If M is copositive on $\mathcal{C}K$, we argue that any vector $v \in \mathcal{C}K$ with $v^T M v = 0$ must satisfy $(M + M^T)v \in (\mathcal{C}K)^*$. Indeed, if v is such a vector, then v is an optimal solution of the following optimization problem:

$$\begin{array}{ll} \text{minimize} & \frac{1}{2} u^T M u, \\ \text{subject to} & u \in \mathcal{C}K. \end{array}$$

By the variational principle for this problem, it follows that v must satisfy $(M + M^T)v \in (\mathcal{C}K)^*$. Since $0 \in K$, we have $0^+K \subseteq \mathcal{C}K$. From this observation and the previous remark, part (d) can easily be seen to be a special case of (c).

Finally, part (e) is also a special case of (c) because if K is a cone then we must have $K = 0^+K = \mathcal{C}K$. □

Remark. In addition to (d) and (e), part (a) of the above proposition is also a special case of (c). We should also point out that $(\mathcal{C}S)^* = S^*$ for any set $S \subseteq R^n$.

In the degree-theoretic approach to be discussed later, it is essential for the solution sets of a certain family of AVIs to be uniformly bounded. The next result is concerned with this property; it generalizes Corollary 1.

PROPOSITION 6. *Let K be a polyhedral set in R^n. Let $q : [0, 1] \to R^n$ and $M : [0, 1] \to R^{n\times n}$ be continuous mappings. Suppose that for each $t \in [0, 1]$, there exists a $\delta > 0$ such that for all $t' \in [0, 1] \cap [t - \delta, t + \delta]$,*

$$(17)\quad \left.\begin{array}{c} 0 \neq v \in \mathcal{S}(K, M(t)) \\ x \in (\operatorname{argmin}_{z\in K} z^T M(t)v) \cap \operatorname{SOL}(K, q(t'), M(t')) \end{array}\right\} \Rightarrow v^T(q(t') + M(t')x) > 0.$$

Then the union

$$\bigcup_{t\in[0,1]} \operatorname{SOL}(K, q(t), M(t))$$

is bounded.

Proof. Assume the contrary. Then there exist sequences $\{t_k\} \subset [0, 1]$ and $\{x^k\}$ such that $\|x^k\| \to \infty$ and $x^k \in \operatorname{SOL}(K, q(t_k), M(t_k))$ for each k. Without loss of generality, we may assume that (i) the sequence $\{t_k\}$ converges to $\tau \in [0, 1]$, and (ii) the normalized sequence $\{x^k/\|x^k\|\}$ converges to a limit v which must be nonzero. Let K be represented by (2). As in the proof of (5), for each k, there exists an index set $\alpha_k \subseteq \{1, \ldots, m\}$ such that $x^k \in F(\alpha_k)$ and

$$\frac{1}{\|x^k\|}(q(t_k) + M(t_k)x^k) \in \operatorname{pos}(A_{\alpha_k})^T.$$

Since there are only finitely many such index sets, there exist index sets $\tilde{\alpha} \subseteq \{1, \ldots, m\}$ and $\kappa \subseteq \{1, 2, \ldots\}$ such that $\alpha_k = \tilde{\alpha}$ for all $k \in \kappa$. Let $\tilde{\beta}$ be the complement of $\tilde{\alpha}$ in $\{1, \ldots, m\}$. Then $v \in \mathcal{C}(\tilde{\alpha})$ where

$$\mathcal{C}(\tilde{\alpha}) = \{x \in R^n : A_{\tilde{\alpha}}x = 0, A_{\tilde{\beta}}x \geq 0\},$$

and $M(\tau)v \in \operatorname{pos}(A_{\tilde{\alpha}})^T$. Hence, $v \in \mathcal{S}(K, M(\tau))$. Moreover, for all $k \in \kappa$, we can easily prove that

$$x^k \in \operatorname{argmin}_{z\in K} z^T M(\tau)v \quad \text{and} \quad v^T(q(t_k) + M(t_k)x^k) = 0.$$

But this contradicts the assumption applied to $t = \tau$. □

It is useful to point out that the key requirement of the above proposition is easily satisfied if $M(t)$ is a constant for all $t \in [0, 1]$ and each individual $\operatorname{SOL}(K, q(t), M)$ is bounded. Indeed, the proof of this special case also follows from Robinson's well-known result about the locally upper Lipschitzian property of polyhedral multifunctions [35]. Nevertheless, Proposition 6 can not be proved directly from the cited result.

4. The monotone AVI. In this section, we give a complete description of the solution set of the monotone AVI. Based on this description, we derive an error bound result for approximate solutions of such a problem. First, we give a useful property of the solutions of a monotone VI.

LEMMA 1. *Let K be a closed convex set in R^n and M be positive semidefinite. Then there exist a vector $d \in R^n$ and a (nonnegative) scalar σ such that for all $x \in$* SOL(K, q, M),

$$(M + M^T)x = d \quad \text{and} \quad x^T M x = \sigma.$$

If K is a polyhedron represented by (2), *and if (x, u) is any pair satisfying* (8), *then*

$$\sigma + (q^T x - b^T u) = 0.$$

Proof. Let x^1 and x^2 be any two solutions of VI (K, q, M). Then we have

$$(x^1 - x^2)^T(q + Mx^2) \geq 0, \qquad (x^2 - x^1)^T(q + Mx^1) \geq 0.$$

Adding these two inequalities and rearranging terms, we derive

$$-(x^1 - x^2)^T M(x^1 - x^2) \geq 0.$$

The positive semidefiniteness of M easily implies

$$(M + M^T)x^1 = (M + M^T)x^2.$$

Hence, the existence of the vector d follows. From the last equality, we may deduce

$$(x^1)^T M x^1 = (x^2)^T M x^2,$$

which establishes the existence of the scalar σ.

If (x, u) satisfies the complementarity system (8), then it is easy to see that

$$0 = q^T x - b^T u + x^T M x$$

as desired. □

In the rest of this section, we shall focus on the AVI (K, q, M) where K is a nonempty polyhedral set in R^n. We introduce an important extended-valued function $\omega : R^n \to R \cup \{-\infty\}$ associated with this problem:

$$\omega(x) = \min_{z \in K} z^T(q + Mx);$$

note that $\omega(x)$ is the optimal objective value of a linear program parametrized by x. Of particular interest to us is the effective domain of ω; i.e., the set

$$\Omega = \{x \in R^n : \omega(x) > -\infty\}.$$

Since K is polyhedral, it follows that

$$K = \mathcal{H}G + \mathcal{C}H \tag{18}$$

for two finite sets G and H. With this representation, w have $0^+K = \mathcal{C}H$; moreover, it is easy to see that $\omega(x)$ is finite if and only if $q + Mx \in (0^+K)^*$. If K is represented by

(2), then $x \in \Omega$ if and only if there exists a vector $u \geq 0$ such that $0 = q + Mx + A^T u$. Summarizing this discussion, we conclude that Ω is a polyhedral set in R^n; moreover,

$$\begin{aligned} \Omega &= \{x \in R^n : q + Mx \in (0^+K)^*\} \\ &= \{x \in R^n : y^T(q + Mx) \geq 0 \text{ for all } y \in H\}. \end{aligned} \tag{19}$$

The second equality represents Ω in terms of a finite system of linear inequalities.

Next, we consider the set

$$\Omega' := \{x \in R^n : \omega(x) - (\sigma + q^T x) \geq 0\},$$

which must be a subset of Ω. This set, Ω', is also polyhedral and has the representation

$$\Omega' = \{x \in \Omega : z^T(q + Mx) - (\sigma + q^T x) \geq 0 \text{ for all } z \in G\}. \tag{20}$$

Note that if G is empty (or equivalently, if K is a cone), then $x \in \Omega \Leftrightarrow \omega(x) = 0$. In this case, the representation (20) reduces to

$$\Omega' = \{x \in \Omega : -(\sigma + q^T x) \geq 0\}.$$

In what follows, we adopt the convention that if G is empty, any term involving a vector in this vacuous set is interpreted as zero. The convention will enable us to treat this special case as a part of the general framework.

With the above preparation, we may now state the promised representation of the solution set of the monotone AVI (K, q, M).

THEOREM 2. *Let K be a polyhedron in R^n and M be a positive semidefinite matrix. Suppose* SOL$(K, q, M) \neq \emptyset$. *Let d and σ be the two invariants associated with the solutions of the* AVI *(K, q, M) (see Lemma* 1). *Then*

$$\text{SOL}(K, q, M) = \{x \in K \cap \Omega' : (M + M^T)x = d\}. \tag{21}$$

Proof. We first show the inclusion

$$\text{SOL}(K, q, M) \subseteq \{x \in K \cap \Omega' : (M + M^T)x = d\}.$$

Let $x \in$ SOL(K, q, M). It suffices to verify $x \in \Omega'$. As mentioned several times in the previous sections, we have $q + Mx \in (0^+K)^*$, which implies that $x \in \Omega$. Moreover, using the fact that $\sigma = x^T Mx$ and the inequality

$$(z - x)^T(q + Mx) \geq 0,$$

which holds for all $z \in K$, it follows easily that $x \in \Omega'$. This establishes the desired inclusion.

To prove the reverse inclusion, let $x \in K \cap \Omega'$ satisfy $(M + M^T)x = d$. Then by the definition of d, for some solution $\overline{x} \in$ SOL(K, q, M),

$$(M + M^T)x = (M + M^T)\overline{x},$$

which implies $x^T Mx = \overline{x}^T M\overline{x} = \sigma$. Let $z \in K$ be arbitrary. Since $x \in \Omega'$, we have

$$z^T(q + Mx) \geq \sigma + q^T x = x^T(q + Mx),$$

which shows that $x \in$ SOL(K, q, M) as desired. The proof of the theorem is now complete. □

When $K = R^n_+$, the above theorem reduces to the well-known polyhedral representation of the solution set of a monotone LCP [1], [3]. This theorem can also be established by applying the latter result to the equivalent complementarity system (8) and utilizing a standard theorem of the alternatives to remove the multiplier vector u. The proof given here is more direct and brings out the sets Ω and Ω' which play an important role in the error bound analysis.

According to Theorem 1, we know that for a monotone AVI (K, q, M), $\mathrm{SOL}(K, q, M) \neq \emptyset$ if and only if $q \in \mathcal{F}(K, M)$. In principle, we could use the representation (21) to give some simplified characterizations for the boundedness of $\mathrm{SOL}(K, q, M)$ when M is positive semidefinite. Nevertheless, we shall postpone the derivation of these conditions until the next section, where we shall treat a more general situation; see Theorem 7.

An error bound result. As promised, we now show how the representation (21) of the solution set of the AVI (K, q, M) yields an error bound for approximate solutions to this problem that is distinct from the one obtained in [7].

THEOREM 3. *Let K, M, d and σ be as given in Theorem 2. Then there exists a constant $L > 0$ such that for any $x \in \Omega$, there exists a $\overline{x} \in \mathrm{SOL}(K, q, M)$ such that*

$$\|x - \overline{x}\| \leq L[d(x, K) + (\omega(x) - (\sigma + q^T x))_- + \|(M + M^T)x - d\|], \tag{22}$$

where $d(x, K)$ denotes the distance from x to the set K.

Proof. Let K be represented by (2) and (18). The equation (21) defines $\mathrm{SOL}(K, q, M)$ as the solution set of a system of linear inequalities (see also (20)). By the famous Hoffman bound for approximate solutions to such a system [18,25], we deduce the existence of a constant $c > 0$ such that for each $x \in \Omega$, there exists $\overline{x} \in \mathrm{SOL}(K, q, M)$ such that

$$\|x - \overline{x}\| \leq c[\|(Ax - b)_-\| + \max\{(z^T(q + M\dot{x}) - (\sigma + q^T x))_- : z \in G\} + \|(M + M^T)x - d\|].$$

To complete the proof, it remains to show that there exists a constant $c_1 > 0$ such that for all $x \in R^n$,

$$\|(Ax - b)_-\| \leq c_1 d(x, K),$$

and for all $x \in \Omega$

$$\max\{(z^T(q + Mx) - (\sigma + q^T x))_- : z \in G\} \leq (\omega(x) - (\sigma + q^T x))_-. \tag{23}$$

The existence of the constant c_1 is a consequence for the Lipschitz continuity of the function $f(x) = \|(Ax - b)_-\|$. By the definition of the function ω, we have for all $z \in K$,

$$z^T(q + Mx) - (\sigma + q^T x) \geq \omega(x) - (\sigma + q^T x),$$

which easily implies

$$(z^T(q + Mx) - (\sigma + q^T x))_- \leq (\omega(x) - (\sigma + q^T x))_-,$$

from which (23) follows. □

The inequality (22) suggests that for the monotone AVI (K, q, M), the function

$$r(x) = d(x, K) + (\omega(x) - (\sigma + q^T x))_- + \|(M + M^T)x - d\|$$

provides an appropriate residue for all vectors $x \in \Omega$. Note that if $x \notin \Omega$, the $r(x) = \infty$. Hence, the error bound (22) is trivially valid for such a vector x, but it does not offer any

effective information about the distance $d(x, \text{SOL}(K, q, M))$. (Of course, we know for certainty that this x is not a solution of the AVI.) Assumptions similar to this restriction ($x \in \Omega$) are also needed in [7].

Two more remarks can be made about the above error bound result. (1) as can be seen from the proof of Theorem 3, if an explicit inequality representation of K is given, then the distance $d(x, K)$ can be replaced by an appropriate residue function defined by such inequalities. (2) the invariants d and σ appear in the residue function $r(x)$. We believe that, as in the case of the LCP [27] and also in [7], it might be possible to get rid of them under some additional assumptions. Since this topic is not the major concern of the present paper, we choose not to pursue it further.

We close this section by mentioning that error bound results such as Theorem 3 are in general useful for several reasons. (1) (quoting a referee) they provide insights on how approximate solutions approach the solution set; (2) they are instrumental for establishing the rate of convergence of iterative algorithms [24]; and (3) they can be used in the design of inexact iterative algorithms.

5. Main stability results. As in the previous studies [11], [13], [16], [29], our approach to analyze the stability of the AVI is based on degree theory. In addition to the review given in these references, the reader can consult [23], and [28] for the fundamentals of this powerful tool.

Consider the VI (K, q, M) and assume that this problem has a nonempty bounded solution set. Let $\mathcal{O}$ be the family of bounded open sets containing $\text{SOL}(K, q, M)$. In order to employ degree theory, we need to transform the VI into a system of equations. As it is well known (see [17], for example), the VI (K, q, M) is equivalent to

$$F_{(q,M)}(x) := x - \Pi_K(x - (q + Mx)) = 0,$$

where Π_K denotes the projection operator onto the set K. Note that the set K does not appear in the subscript of the mapping $F_{(q,M)}$. The reason for this omission is that, unlike q and M, K is fixed throughout this stability study.

Clearly, for any $D \in \mathcal{O}$, the mapping $F_{(q,M)}$ does not vanish on ∂D, the boundary of the set D. Hence, the degree, denoted deg $(F_{(q,M)}, D)$, of $F_{(q,M)}$ at zero relative to D is well defined. The following theorem is the basis for the degree-theoretic approach to stability analysis.

THEOREM 4. *Let K be a closed convex set in R^n. Suppose* $\text{SOL}(K, q, M)$ *is nonempty and bounded. Assume that for some $D \in \mathcal{O}$, deg $(F_{(q,M)}, D)$ is nonzero. Then* VI (K, q, M) *is stable in the sense of Definition* 1.

Proof. Let $\varepsilon > 0$ be given; consider the open set

$$V = \{x \in R^n : d(x, \text{SOL}(K, q, M)) < \varepsilon\}.$$

Without loss of generality, we can, by restricting ε, assume that $V \subseteq D$. By the excision property of the degree, we have deg $(F_{(q,M)}, D)$ = deg $(F_{(q,M)}, V)$. By the nonexpansiveness of the projection operator, we may choose a suitable $\delta > 0$ such that for all $\|M' - M\| + \|q' - q\| \leq \delta$,

$$\sup_{x \in V} \|F_{(q,M)}(x) - F_{(q',M')}(x)\| < d(0, F_{(q,M)}(\partial V)).$$

By the nearness property of the degree, it follows that deg $(F_{(q',M')}, V) =$ deg$(F_{(q,M)}, V) \neq 0$. Hence, the equation

$$F_{(q',M')}(x) = 0$$

has a solution in V, or equivalently,

$$\mathrm{SOL}(K, q', M') \cap V \neq \emptyset.$$

Consequently, the desired stability conclusion follows. □

Remark. In general, if the VI (K, q, M) is stable, then we must have $q \in \operatorname{int} \mathcal{F}(K, M)$.

Theorem 4 has reduced the stability question related to the VI (K, q, M) to a nonvanishing property of a degree of the (nonsmooth) mapping $F_{(q,M)}$. Our next result, which is based on the homotopy invariance of the degree, provides a useful way to validate the latter degree condition.

THEOREM 5. *Let K be a closed convex set in R^n and $(q, M) \in R^n \times R^{n\times n}$ be arbitrary. Suppose there exists $(q^*, M^*) \in R^n \times R^{n\times n}$ satisfying the following two conditions:*

(A) $\mathrm{SOL}(K, q^*, M^*)$ *is nonempty and bounded, and for some open bounded set D containing* $\mathrm{SOL}(K, q^*, M^*)$, $\deg(F_{(q^*,M^*)}, D)$ *is nonzero;*

(B) *there exists a homotopy $H : [0, 1] \to R^n \times R^{n\times n}$ connecting the pairs (q^*, M^*) and (q, M) such that the set*

$$\bigcup_{t\in[0,1]} \mathrm{SOL}(K, q(t), M(t)) \tag{24}$$

is bounded, where $H(t) = (q(t), M(t))$.

Then, the VI *(K, q, M) is stable; in particular,* $\mathrm{SOL}(K, q, M)$ *is nonempty and bounded, and $q \in \operatorname{int} \mathcal{F}(K, M)$.*

Proof. Without loss of generality, we may assume, using the excision property of the degree, if necessary, that D contains the union in (24). Clearly,

$$\tilde{F}(t) = x - \Pi_K(x - (q(t) + M(t)x))$$

defines a homotopy connecting the two mappings $F_{(q,M)}$ and $F_{(q^*,M^*)}$. By the homotopy invariance of the degree, it follows that $\deg(F_{(q,M)}, D) = \deg(F_{(q^*,M^*)}, D)$; the latter degree is nonzero by assumption. Hence the desired conclusions follow easily from the last theorem. □

Specializing the above theorem to the case where M is positive semidefinite, we obtain the following stability result for the monotone VI (K, q, M).

COROLLARY 3. *Let K be a closed convex set in R^n and M be a positive semidefinite matrix. If* $\mathrm{SOL}(K, q, M)$ *is nonempty and bounded, then the* VI *(K, q, M) is stable.*

Proof. Pick any $x^* \in \mathrm{SOL}(K, q, M)$; define $q^* = -x^*$ and $M^* = I$. Then the map $F_{(q^*,M^*)}$ is equal to the identity map translated by a constant. Hence $\deg(F_{(q^*,M^*)}, D) = 1$ for any open bounded set D containing $\mathrm{SOL}(K, q, M)$. Since M is positive semidefinite, the matrix $M(t) := tM + (1 - t)M^*$ is positive definite for all $t \in [0, 1)$.

Hence with $q(t) := tq + (1 - t)q^*$, it follows that

$$\mathrm{SOL}(K, q(t), M(t)) = \{x^*\}, \quad \text{for all } t \in [0, 1).$$

Consequently, condition (B) of Theorem 5 holds. The desired conclusion follows. □

It is important to point out that the above corollary does not follow from any existing stability theory for the VI; in particular, the results in [33] cannot be used to establish this corollary because they require a certain upper Lipschitzian assumption which has been shown to be valid only in the case of a polyhedral K. Incidentally, the proof of Corollary 3 provides a simple demonstration of one implication in Robinson's result mentioned in the Introduction. This matter will be addressed in full detail in Theorem 7.

Specializing Theorem 5 to the AVI and invoking Proposition 6, we derive the following result.

THEOREM 6. *Let K be a polyhedron in R^n, and $(q, M) \in R^n \times R^{n\times n}$ be arbitrary. Suppose that there exists $(q^*, M^*) \in R^n \times R^{n\times n}$ satisfying the following three conditions:*

(A) $|\mathrm{SOL}(K, q^*, M^*)| = 1$;

(B) *for all $\tilde{q}$ sufficiently close to q^*, $|\mathrm{SOL}(K, \tilde{q}, M^*)| \leq 1$;*

(C) *for each $t \in [0, 1]$, there exists a $\delta > 0$ such that for all $t' \in [0, 1] \cap [t - \delta, t + \delta]$, the implication* (17) *holds for the following homotopies:*

$$M(t) := tM + (1 - t)M^*, \qquad q(t) = tq + (1 - t)q^*.$$

Then the conclusions of Theorem 5 *are valid for the* AVI *(K, q, M).*

Proof. It suffices to show for some bounded open set D containing the unique solution x^* of the AVI (K, q^*, M^*), $\deg(F_{(q^*,M^*)}, D)$ is nonzero. For this purpose, let U be an open neighborhood of q^* such that for all $\tilde{q} \in U$, $|\mathrm{SOL}(K, \tilde{q}, M^*)| \leq 1$. Let ε be a positive scalar with the property that $q^* + (M^* - I)y \in U$ for all y with $\|y\| < \varepsilon$. Then for any such vector y, the equation

$$F_{(q^*,M^*)}(x) = y$$

has at most one solution. Indeed, any solution of this equation is a solution of the AVI $(K, q^* + (M^* - I)y, M^*)$; by the choice of y, the latter AVI has at most one solution. Now, choose an open neighborhood D of x^* such that $\|F_{(q^*,M^*)}(x)\| < \varepsilon$ for all $x \in D$. Hence the restricted map $F_{(q^*,M^*)}\colon D \to R^n$ is one-to-one, and $0 \in F_{(q^*,M^*)}(D)$. Since the degree of an injective map is ± 1 [23, Thm. 3.3.3], it follows that $\deg(F_{(q^*,M^*)}, D)$ is nonzero. □

The above theorem has identified a set of sufficient conditions for the satisfaction of the key assumptions (A) and (B) of Theorem 5. In what follows, we derive various consequences of the latter theorem. Our first corollary pertains to the case where $\mathcal{S}(K, M)$ is a singleton.

COROLLARY 4. *Let K be a polyhedron in R^n. Suppose that M is copositive on 0^+K and $\mathcal{S}(K, M) = \{0\}$. Then the* AVI *$(K, q, M)$ is stable for all $q \in R^n$.*

Proof. Let $M^* = I$ and q^* be arbitrary. It suffices to verify condition (C) of Theorem 6. Since M is copositive on 0^+K, it follows that for all $t \in [0, 1)$, $\mathcal{S}(K, M(t)) = \{0\}$; moreover, $\mathcal{S}(K, M(1)) = \{0\}$ by assumption. □

We shall next derive some stability results for the AVI by relaxing the assumption that $\mathcal{S}(K, M)$ is a singleton. Motivated by the sharp property of the pair (K, M) defined in Section 3, we introduce two important subsets for R^n. Specifically, let $\mathcal{B}(K, M)$ denote the set of vectors $q \in R^n$ for which the implication below holds:

$$\left.\begin{array}{r} 0 \neq v \in \mathcal{S}(K, M) \\ x \in \mathrm{argmin}_{z\in K} z^T M v \end{array}\right\} \Rightarrow v^T(q + Mx) > 0,$$

and let $\mathcal{Q}(K, M)$ denote the set of vectors $q \in R^n$ for which the following (less restrictive) implication holds:

$$\left.\begin{array}{r} v \in \mathcal{S}(K, M) \\ x \in \mathrm{argmin}_{z\in K} z^T M v \end{array}\right\} \Rightarrow v^T(q + Mx) \geq 0.$$

Clearly, the latter set is closed and contains the closure of the former set. Moreover, Corollary 1 implies that if K is polyhedral and $q \in \mathcal{B}(K, M)$, then $\mathrm{SOL}(K, q, M)$ is

bounded if it is nonempty. The next result is concerned with how the two sets just introduced are related to the range $\mathcal{R}(K, M)$ of the pair (K, M) and to the stability of the associated AVIs.

COROLLARY 5. *Let K be a polyhedron in R^n. Suppose that there exists a vector $q^* \in \mathcal{Q}(K, M)$ such that* SOL(K, q^*, M) *is nonempty and bounded, and for some open bounded set D containing* SOL(K, q^*, M), deg $(F_{(q^*, M)}, D)$ *is nonzero. Then, for all $q \in \mathcal{B}(K, M)$, the* AVI *(K, q, M) is stable and* SOL(K, q, M) *is bounded. If in addition int $(\mathcal{S}(K, M)^*)$ is nonempty, then $\mathcal{R}(K, M) \supseteq \mathcal{Q}(K, M)$.*

Proof. Consider the homotopies

$$M(t) := M, \qquad q(t) = tq + (1 - t)q^*.$$

By the choice of q and q^*, it follows that the implication below holds for all $t \in (0, 1]$:

$$\left.\begin{array}{c} 0 \neq v \in \mathcal{S}(K, M) \\ x \in (\text{argmin}_{z \in K} z^T M v) \cap \text{SOL}(K, q(t), M) \end{array}\right\} \Rightarrow v^T(q(t) + Mx) > 0.$$

By assumption, this implication is also valid for $t = 0$ (see Corollary 1). Hence, the two main conditions of Theorem 5 are satisfied; the desired stability conclusion follows readily.

To establish the second assertion, let $u \in$ int $(\mathcal{S}(K, M)^*)$ and $q \in \mathcal{Q}(K, M)$. Then clearly $q + \varepsilon u \in \mathcal{B}(K, M)$ for all $\varepsilon > 0$. Since the range $\mathcal{R}(K, M)$ is a closed set by Proposition 2, it follows that $q \in \mathcal{R}(K, M)$ in view of what has been proved above. □

The above corollary is fairly general in that no particular assumption is imposed on the pair (K, M). It identifies a sufficient condition under which a certain set of vectors q can be associated with the pair (K, M) for which the AVI (K, q, M) is stable. In the sequel, we shall derive various consequences of this corollary by making some special assumptions on (K, M).

If the pair (K, M) has the sharp property, then clearly $\mathcal{S}(K, M)^* \subseteq \mathcal{Q}(K, M)$. In this case, the last corollary implies that if there exists a vector $q^* \in \mathcal{S}(K, M)^*$ satisfying the stated assumption therein, then for all $q \in$ int $(\mathcal{S}(K, M)^*)$, the AVI (K, q, M) is stable. Moreover, if such a vector q indeed exists, then $\mathcal{S}(K, M)^* \subseteq \mathcal{R}(K, M)$.

If K is a pointed polyhedral cone in R^n and M is copositive on K, it is easy to obtain a vector q^* satisfying the degree requirement in Corollary 5. To construct this vector, note that int K^* must be nonempty by the pointedness of K. Pick any vector q^* in the latter interior. Then, by the copositivity of M on K and the interiority of q^*, it is obvious that $|\,\text{SOL}(K, \tilde{q}, M)| = 1$ for all $\tilde{q}$ sufficiently close to q^*; indeed SOL$(K, \tilde{q}, M) = \{0\}$ for any such vector $\tilde{q}$. Hence, as in Theorem 6, we may deduce that deg $(F_{(q^*, M)}, D)$ is nonzero. Summarizing this discussion and recalling part (c) of Proposition 5, we immediately obtain the following consequence of Corollary 5.

COROLLARY 6. *Let K be a pointed polyhedral cone in R^n. If M is copositive on K, then the* GLCP *(K, q, M) is stable for all $q \in$ int $(\mathcal{S}(K, M)^*)$.*

We now come to our main stability theorem for a "copositive AVI." The significance of this result is threefold. Firstly, it recovers Robinson's characterization of the stability of a monotone AVI in terms of the nonemptiness and boundedness of the solution set. Secondly, the theorem adds to this characterization several equivalent conditions each of which is interesting in its own right; collectively, these conditions have appeared in [26] for the special case of the LCP with a copositive-plus matrix. Thirdly and most importantly, the theorem deals with a nonmonotone AVI. It turns out that in order to remove the monotonicity assumption of M, we need to substitute in its place the assumption (A) of Theorem 5. In the proof of the following theorem, the two identities (3) and (4) are needed.

THEOREM 7. *Let $K = \mathcal{H}G + \mathcal{C}H$ be a polyhedron in R^n and M be copositive-plus on 0^+K. Suppose that either*

(A) *there exists a vector $q^* \in R^n$ such that* SOL(K, q^*, M) *is nonempty and bounded, and for some open bounded set D containing* SOL(K, q^*, M), *deg $(F_{(q^*,M)}, D)$ is nonzero, or*

(B) *M is positive semidefinite.*

Consider the five statements below:

(a) *the* AVI *(K, q, M) is stable in the sense of Definition* 1;

(b) SOL(K, q, M) *is nonempty and bounded;*

(c) $q \in$ int $\mathcal{F}(K, M)$;

(d) $q \in$ ri $\mathcal{S}(K, M)^* - MK$;

(e) $q \in$ ri $\mathcal{S}(K, M)^* - M(\mathcal{H}G)$. *Then the following relations hold:*

$$(a) \Leftrightarrow (b) \Leftrightarrow (c) \Rightarrow (d) \Leftrightarrow (e). \tag{25}$$

Moreover, if int $(\mathcal{S}(K, M)^*)$ *is nonempty, then all five statements are equivalent and*

$$\mathcal{R}(K, M) = \mathcal{Q}(K, M) = \mathcal{F}(K, M). \tag{26}$$

Proof. The implication (a) $\Rightarrow$ (c) follows from the remark following Theorem 4. The implication (b) $\Rightarrow$ (a) follows from Corollary 3 when (B) holds. We now show (b) $\Rightarrow$ (a) under the assumption (A). In view of Corollary 5, the proof of this implication consists of verifying that q^* belongs to the set $\mathcal{Q}(K, M)$ and $q \in \mathcal{B}(K, M)$. For the claim about q^*, we shall prove the more general inclusion:

$$\mathcal{F}(K, M) \subseteq \mathcal{Q}(K, M). \tag{27}$$

Let $p \in \mathcal{F}(K, M)$. Then there exists $u \in K$ such that $p + Mu \in \mathcal{S}(K, M)^*$. Let $v \in \mathcal{S}(K, M)$ and $x \in \operatorname{argmin}_{z \in K} z^T Mv$. Then we have

$$x^T Mv \leq u^T Mv,$$

which, by the copositivity-plus property of M on 0^+K, yields

$$v^T(p + Mx) \geq v^T(p + Mu) \geq 0.$$

This establishes (27). Hence q^* belongs to the set $\mathcal{Q}(K, M)$. That q belongs to $\mathcal{B}(K, M)$ can be proved in the following way. Let v be any nonzero vector in $\mathcal{S}(K, M)$ and $x \in \operatorname{argmin}_{z \in K} z^T Mv$. By the argument just given, we know that $q \in \mathcal{Q}(K, M)$. Suppose that $v^T(q + Mx) = 0$. Take any vector $\tilde{z} \in$ SOL(K, q, M). Then, as noted several times before, we have $q + M\tilde{z} \in \mathcal{S}(K, M)^*$. Repeating the proof of the inclusion (27) applied to $p = q$ and $u = \tilde{z}$, we obtain

$$0 = v^T(q + Mx) \geq v^T(q + M\tilde{z}) \geq 0.$$

Hence, $v^T Mx = v^T M\tilde{z}$. Since $Mv = -M^T v$, we deduce

$$x^T Mv = \tilde{z}^T Mv,$$

which implies that $\tilde{z} \in \operatorname{argmin}_{z \in K} z^T Mv$. Summarizing this discussion, we see that the pair $(\tilde{z}, v)$ violates the implication (14) which is necessary (and sufficient) for SOL(K, q, M) to be bounded. This contradiction establishes the implication (b) $\Rightarrow$ (a) under assumption (A).

We now show the implication (c) $\Rightarrow$ (b). Let $q \in \text{int } \mathcal{F}(K, M)$. When (B) holds, Theorem 1 implies that the AVI (K, q, M) is solvable. Suppose its solution set is unbounded. By Proposition 4, there exist a solution $x \in \text{SOL}(K, q, M)$ and a nonzero vector v satisfying the three properties in that proposition. By the positive semi-definiteness of M, it follows that $(M + M^T)v = 0$. The definition of q implies that for some $\varepsilon > 0$ sufficiently small, $q - \varepsilon v \in \mathcal{F}(K, M)$. Hence, there exists a vector $z \in K$ such that $q - \varepsilon v + Mz \in (0^+K)^*$ Since $v \in 0^+K$, we have

$$0 \leq v^T(q - \varepsilon v + Mz) = v^T(q + Mx) - \varepsilon\|v\|^2 - (z - x)^T Mv \leq -\varepsilon\|v\|^2,$$

which is a contradiction. This establishes the desired implication. When (A) holds, by slightly modifying the proof of the inclusion (27), we may establish

$$\text{int } \mathcal{F}(K, M) \subseteq \mathcal{B}(K, M),$$

which, in view of Corollary 5, gives (b).

The implication (c) $\Rightarrow$ (d) is an easy consequence of (10) and (3). Indeed, we have

$$\begin{aligned} \text{int } \mathcal{F}(K, M) &= \text{ri } (\mathcal{S}(K, M)^* - MK) \\ &= \text{ri } \mathcal{S}(K, M)^* - \text{ri } MK \subseteq \text{ri } \mathcal{S}(K, M)^* - MK. \end{aligned}$$

To prove the implication (d) $\Rightarrow$ (e), we first note that by (9), $-M(0^+K) \subseteq \mathcal{S}(K, M)^*$. This implies, by (4),

$$\begin{aligned} \text{ri } \mathcal{S}(K, M)^* - MK &= \text{ri } \mathcal{S}(K, M)^* - M(0^+K) - M(\mathcal{H}G) \\ &\subseteq \text{ri } \mathcal{S}(K, M)^* - M(\mathcal{H}G), \end{aligned}$$

which establishes the implication (d) $\Rightarrow$ (e). The reverse implication (e) $\Rightarrow$ (d) is obvious.

We have now completed the proof of the implications in (25). It remains to establish the two additional conclusions under the nonemptiness assumption of int $\mathcal{S}(K, M)^*$. We first demonstrate the equivalence of all the five statements by proving the implication (d) $\Rightarrow$ (c). But this is obvious from the inclusion,

$$\text{int } \mathcal{S}(K, M)^* - M(K) \subseteq \text{int } \mathcal{S}(K, M)^* - M(K)) = \text{int } \mathcal{F}(K, M),$$

which, incidentally, is easy to see. Finally, the expression (26) holds because by Corollary 5 and the inclusion (27), we have

$$\mathcal{F}(K, M) \supseteq \mathcal{R}(K, M) \supseteq \mathcal{Q}(K, M) \supseteq \mathcal{F}(K, M).$$

Hence, equality holds throughout. This completes the proof of the theorem. □

The significance of the three conditions (c), (d), and (e) can be seen as follows. The condition (c) can be interpreted as saying that the AVI (K, q, M) is "strictly feasible." Conditions (d) and (e) are very much motivated by the LCP (q, M) with a copositive matrix M for which a great deal is known about the relation between the complementary kernel $\mathcal{S}(0, M)$ and various properties of the problem [9], [10], [14]. Indeed, when $K = R^n_+$, we have $G = \{0\}$; moreover, by the argument to follow, the set int $\mathcal{S}(K, M)^*$ is nonempty, hence, statement (e) reduces to $q \in \text{int } \mathcal{S}(K, M)^*$.

The assumption that int $(\mathcal{S}(K, M)^*)$ is nonempty is essential for the validity of the reverse implication (d) $\Rightarrow$ (c) (and hence, for the equivalence of the five statements). In general, we have for any matrix M,

$$(0^+K)^* \subseteq \mathcal{S}(K, M)^*$$

which holds as a consequence of duality and the fact that $\mathcal{S}(K,M) \subseteq 0^+K$. It follows that int $(\mathcal{S}(K,M)^*)$ is nonempty if 0^+K is pointed. In turn, the latter pointedness property holds if 0^+K is contained in the nonnegative orthant R^n_+. So, for instance, if K is given as follows:

$$K = \{x \in R^n : Ax \geq b, x \geq 0\},$$

then $\mathcal{S}(K,M)^*$ must have a nonempty interior regardless of any special property the matrix M might have.

The final result of this paper identifies a sufficient condition under which the assumption (A) in Theorem 7 holds. In order to state this result, we mention an obvious property of an extreme point of a polyhedral set. Namely, if K is polyhedral, then a vector $x \in K$ is an extreme point of K if and only if the associated cone of feasible directions $\mathcal{F}_x(K)$ is pointed. The proof of this fact is easy and left to the reader. Consequently, it follows that if x is an extreme point of K, then int $(\mathcal{F}_x(K)^*)$ is nonempty. We also observe that if $0 \in K \subseteq R^n_+$, then zero must be an extreme point of K. In the following result, we postulate that the polyhedron K has an extreme point c and the matrix M is copositive on the translated set $K - c$.

COROLLARY 7. *Let K be a polyhedron in R^n and M be copositive-plus on 0^+K. Suppose that K has an extreme point c such that*

$$(y-c)^T M(y-c) \geq 0 \qquad \textit{for all } y \in K. \tag{28}$$

Then int $(\mathcal{S}(K,M)^*) \neq \emptyset$ and condition (A) *in Theorem* 7 *holds. Hence all the conclusions of this theorem are valid.*

Proof. Since $\mathcal{S}(K,M) \subseteq 0^+K \subseteq \mathcal{F}_x(K)$ for all $x \in K$, duality and the pointedness of $\mathcal{F}_c(K)$ imply that int $(\mathcal{S}(K,M)^*)$ is nonempty. Hence, it remains to verify the existence of a vector q^* satisfying the properties stipulated in condition (A) of Theorem 7. Let $q^* \in$ int $(\mathcal{F}_c(K)^*) - Mc$. Then, for all $\tilde{q}$ sufficiently close to q^*, we have $\tilde{q} + Mc \in$ int $(\mathcal{F}_c(K)^*)$. By Proposition 1, SOL$(K, \tilde{q}, M) \neq \emptyset$ for such a vector $\tilde{q}$; indeed, we have $c \in$ SOL$(K, \tilde{q}, M)$. We claim that if $\tilde{q} + Mc \in$ int $\mathcal{F}_c(K)^*$, then

$$\text{SOL}(K, \tilde{q}, M) = \{c\}.$$

Assume that $z \neq c$ is another solution of the AVI $(K, \tilde{q}, M)$. Then we have

$$0 \leq (c-z)^T(\tilde{q} + Mz) = -(z-c)^T(\tilde{q} + Mc) - (z-c)^T M(z-c) \leq -(z-c)^T(\tilde{q} + Mc)$$

where the last inequality follows from the condition (28). But since $0 \neq z - c \in \mathcal{F}_c(K)$, we must have $(z-c)^T(\tilde{q} + Mc) > 0$, which is a contradiction.

Consequently, using the same argument as in the proof of Theorem 6, we may deduce that for all vectors y with $\|y\|$ sufficiently small, the equation

$$F_{(q^*,M)}(x) = y$$

has a unique solution, namely, $c + y$. Hence, for some open neighborhood D of c, we must have deg $(F_{(q^*,M)}, D) = 1$. □

From the discussion preceding Corollary 7, we see that if $0 \in K \subseteq R^n_+$ and M is copositive on R^n_+, then $c = 0$ will satisfy the required assumption in this corollary. Alternatively, if K has an extreme point and M is copositive on $K - K$, then c can be taken to be any such extreme point. In these two cases, the conclusions of Theorem 7 are therefore valid.

OPTIMAL CONTROL OF UNBOUNDED DIFFERENTIAL INCLUSIONS*

PHILIP D. LOEWEN† AND R. T. ROCKAFELLAR‡

Abstract. A Mayer problem of optimal control, whose dynamic constraint is given by a convex-valued differential inclusion, is considered. Both state and endpoint constraints are involved. Necessary conditions are proved incorporating the Hamiltonian inclusion, the Euler–Lagrange inclusion, and the Weierstrass–Pontryagin maximum condition. These results weaken the hypotheses and strengthen the conclusions of earlier works. Their main focus is to allow the admissible velocity sets to be unbounded, provided they satisfy a certain continuity hypothesis. They also sharpen the assertion of the Euler–Lagrange inclusion by replacing Clarke's subgradient of the essential Lagrangian with a subset formed by partial convexification of limiting subgradients. In cases where the velocity sets are compact, the traditional Lipschitz condition implies the continuity hypothesis mentioned above, the assumption of "integrable boundedness" is shown to be superfluous, and this refinement of the Euler–Lagrange inclusion remains a strict improvement on previous forms of this condition.

Key words. optimal control, differential inclusion, Hamiltonian inclusion, maximum principle, nonsmooth analysis

AMS subject classification. 49K24

Introduction. This paper describes necessary conditions for optimality in the following Mayer problem of optimal control: Choose an arc (i.e., an absolutely continuous function) $x\colon [a,b] \to \mathbb{R}^n$ to

$$(P)\qquad \begin{array}{ll} \text{minimize} & \ell(x(a),x(b)) \\ \text{subject to} & \dot{x}(t) \in F(t,x(t)) \quad \text{a.e. } t \in [a,b], \\ & (x(a),x(b)) \in S, \\ & x(t) \in X(t) \quad \forall t \in [a,b]. \end{array}$$

Experts will recognize the endpoint constraint $(x(a),x(b)) \in S$ and the state constraint $x(t) \in X(t)$ for all $t \in [a,b]$ as aspects of the model that are indispensable for applications, but which account for considerable complexity in the statement and derivation of necessary conditions. Clarke [2, Chap. III] gives an excellent introduction to this problem and describes several applications. Our main result can be viewed as a generalization of Clarke's necessary conditions in [2, Thm. 3.5.2]; however, the calculus described by Ioffe [6] and Rockafellar [29], and the careful Hamiltonian analysis of Loewen and Rockafellar [13], are important steps along the way from the cited result to the work at hand. The first two sections of [13] describe our reasons for choosing the formulation (P), and the relationship between this version of the problem and others current in the literature.

The results presented here improve upon those in [2] and [13] in three important ways. First, the problem is more general than any considered before, since we do not

require the sets $F(t,x)$ of admissible velocities to be bounded. (We insist throughout, however, that these sets be convex.) Second, our necessary conditions are more precise than any previously published, since they involve sharper forms of the transversality condition and the Euler–Lagrange inclusion than those in [2] and [13]. Finally, our method of proof allows a simpler approach to the main result of [13], which is recovered as a corollary. We expect all of these improvements to serve in future developments of the theory.

Several sets of necessary conditions for optimal control problems without boundedness assumptions already exist in the literature. For example, Clarke proves necessary conditions analogous to the Euler–Lagrange equation for such a differential inclusion problem in [1] (see (5.1), below). Although his result does not require the velocity sets to be bounded, it does involve a Lipschitz hypothesis on the state dependence of F—an unacceptably strong condition when the velocity sets are actually unbounded.

Polovinkin and Smirnov [19], [20] prove a form of the Euler–Lagrange inclusion that is sharper than Clarke's using a truncation argument to weaken the Lipschitz hypothesis considerably. Their results also dispense with the convexity condition on the values of the multifunction F. Kaskosz and Łojasiewicz [10] consider a Mayer problem whose dynamic constraint is a controlled differential equation in which both the control sets and the resulting velocity sets are allowed to be unbounded. However, their adjoint inclusions involve Carathéodory selections of the resulting multifunction F, and are not directly comparable to those of our main theorem. (A simple connection in the bounded case is indicated by Loewen and Vinter [14].)

Furthermore, Lipschitz conditions enter [10] at several points, making direct comparison with our main result difficult. The current paper breaks new ground in presenting Hamiltonian necessary conditions for optimality in problem (P) without assuming either that the velocity sets are bounded, or that they display full Lipschitz dependence on the state. Like our previous paper [13], it asserts the Hamiltonian and Eulerian forms of the necessary conditions simultaneously.

Two simple themes underlie our approach: Truncation and strict convexity. Let us explain these ideas before pursuing the details. Suppose $\overline{x}$ solves problem (P). In the case where the optimal solution $\overline{x}$ is Lipschitzian, i.e., $\dot{\overline{x}} \in L^\infty([a,b], \mathbb{R}^n)$, we observe that for any $R > 0$, the arc $\overline{x}$ also solves the version of problem (P) in which the given multifunction F is truncated to produce the bounded multifunction $\widetilde{F}(t,x) := F(t,x) \cap \left(\dot{\overline{x}}(t) + R \operatorname{cl} \mathbb{B}\right)$. Therefore, $\overline{x}$ must fulfill the known necessary conditions for bounded differential inclusions, provided that $\widetilde{F}$ satisfies a suitable Lipschitz condition. Identifying hypotheses on F that ensure this is one of this paper's main contributions. Then, of course, there is the question of relating the necessary conditions derived using $\widetilde{F}$ to those one might expect for F. This is not trivial; §3 contains the detailed arguments. Finally, when $\overline{x}$ is absolutely continuous but not Lipschitzian, we must allow the truncation radius R to vary with time. Our presentation treats this case in parallel with the Lipschitz case.

By coordinating the hypotheses on the multifunction F with the regularity of the solution, we derive the same necessary conditions in both instances. If F is "integrably sub-Lipschitzian in the large" (see Definition 2.3(b)) at every point $(t, \overline{x}(t))$ of $\operatorname{gph} \overline{x}$, the necessary conditions are satisfied without any regularity hypothesis on $\overline{x}$; when $\overline{x}$ is known to be Lipschitzian, we require only that F be "sub-Lipschitzian" (see Definition 2.3(a)) at every point $(t, \overline{x}(t))$ of $\operatorname{gph} \overline{x}$. Strict convexity has a unifying effect on the necessary conditions of nonsmooth optimal control, as noted in our

previous work [13].

Continuing to assume that $\overline{x}$ solves (P), we note that $\overline{x}$ remains optimal for the problem $(\mathcal{P})$ in which the objective function $\ell(x(a), x(b))$ is augmented by an integral term to become

$$\ell(x(a), x(b)) + \int_a^b \left[\sqrt{1 + \left|\dot{x}(t) - \dot{\overline{x}}(t)\right|^2} - 1\right] dt.$$

Hence the Hamiltonian necessary conditions for optimality in $(\mathcal{P})$ must apply to $\overline{x}$. In the bounded case, the analysis of [13] shows that the Hamiltonian inclusion for $\overline{x}$ in problem $(\mathcal{P})$ implies the Hamiltonian inclusion, the sharpened Euler–Lagrange inclusion, and the Weierstrass–Pontryagin maximum condition we ultimately intend to assert for the original problem (P). (This analysis hinges upon the strict convexity of the integrand above as a function of the velocity variable $\dot{x}$.) To make the results of [13] applicable here, we first truncate the problem as described in the previous paragraph, and then introduce strict convexity. The small right-hand side in our transversality inclusion will surprise no one working in the field. Similar transversality conditions appeared first in the work of Mordukhovich [15], who has applied similar ideas to a range of problems in recent years (see [17]).

The new condition is obtained by replacing Clarke's normal cone and subgradient set with their (possibly nonconvex) subsets consisting of limits of proximal normals and proximal subgradients. Clarke actually uses limiting proximal normals to prove his transversality conditions in [2, Thm. 3.5.2], and his proof requires only the slightest modifications to obtain the transversality conditions used here. (This is noted explicitly in [4, Thm. 4.1, footnote].) The sharpened transversality condition also figures in Rowland and Vinter's recent work [31] on necessary conditions for controlled differential equations with free time. We take pains to incorporate it here in order that Theorem 4.3, below, can legitimately claim to have the weakest hypotheses and the strongest conclusions of any set of necessary conditions for the optimal control of differential inclusions on a fixed time interval.

The refinement of the Euler–Lagrange inclusion used here is also obtained by using the cone of limiting proximal normals in place of its convex hull (Clarke's normal cone) on the right-hand side in [2] and [13]. Some convexification is still required, but it now pertains only to the components involving derivatives of the adjoint function instead of to all components at once. A related inclusion has recently been given under considerably stronger hypotheses by Mordukhovich [18]. Our inclusion implies Mordukhovich's, and can be strictly better in certain cases. The key to our refined formulation is the introduction of strict convexity through a suitable integral cost term, as outlined above. A description of Mordukhovich's condition and a detailed comparison with ours appears in §5.

Section 1 describes the starting point for this work—the well known Hamiltonian necessary conditions of Clarke [2] as formulated by Loewen and Rockafellar [13]. It outlines the minor modifications to existing arguments required to sharpen the transversality inclusions as described above. Sections 2 and 3 concern truncation. Section 2 introduces the truncated multifunction $\widetilde{F}$ and describes hypotheses under which it satisfies a suitable Lipschitz condition, while §3 elucidates the relationship between the subgradients of the two Hamiltonians corresponding to the original and truncated multifunctions. Section 4 draws its antecedents together to produce a set of Hamiltonian necessary conditions for unbounded differential inclusion problems in Theorem 4.1. It then brings in strict convexity as outlined above. The methods of

§§2 and 3 (together with Loewen and Rockafellar [13]) then allow the simultaneous derivation of the Hamiltonian inclusion, the refined Euler–Lagrange inclusion, and the Weierstrass–Pontryagin maximum condition. This effort culminates in Theorem 4.3, the main result of this paper. Section 5 concludes the paper with a comparison between Theorem 4.3 and other published work, and gives some examples that clarify the distinctions between the various adjoint inclusions appearing here and elsewhere in the literature.

Readers interested in a quick overview of the work should observe that the notation for generalized derivatives and normals introduced in §1 differs from that in such standard works as Clarke [2]. Clarke subgradients and normals are indicated by the "barred" symbols $\overline{\partial} f(x)$ and $\overline{N}_C(x)$, while proximal subgradients and normals wear a double hat: $\hat{\hat{\partial}} f(x)$ and $\hat{\hat{N}}_C(x)$. The unadorned notation $\partial f(x)$ and $N_C(x)$ is reserved for sets of limiting proximal subgradients and limiting proximal normals.

1. Hypotheses and preliminary results. In this section we establish the technical foundation on which our later results rest. We state the hypotheses under which we later analyse the given problem (P), and review the constraint qualification we must impose when the state constraint is active along the optimal arc. We also review the necessary conditions for bounded differential inclusions due to Clarke [2, Thm. 3.5.2], and observe that they remain valid with a somewhat sharper transversality condition. Since our formulation of the state constraint differs from Clarke's, we use the form of his result appearing in our previous work [13, Thm. 2.8]. (The relationship between these two modes of presentation is clearly spelled out in [13]: While it is almost true to say that a simple change of variable makes them equivalent, the extra analysis appearing in Lemma 2.4 of [13] makes the nontriviality assertion of [13, Thm. 2.8] stronger than Clarke's.) We sharpen the transversality condition in the known result by replacing its right-hand side with a smaller set. Instead of the Clarke subgradient and normal cone, we use the limiting subgradient and the limiting normal cone. These are the fundamental objects in the theory of proximal analysis, which is described in Rockafellar [27], [29], and Clarke [2, § 2.5], for example; see also the book by Mordukhovich [17].

Proximal analysis. Consider a closed set $C \subseteq \mathbb{R}^m$ containing some point c. A vector $\zeta \in \mathbb{R}^m$ is called a *proximal normal to C at c,* written $\zeta \in \hat{\hat{N}}_C(c)$, if there is some $M > 0$ so large that

$$\langle \zeta\,,\, c' - c\rangle \le M|c' - c|^2 \quad \text{for all } c' \in C. \tag{1.1}$$

Theorem 1.2, below, refers to the cone of *limiting normals to C at c,* namely,

$$\begin{aligned} N_C(c) := \big\{\zeta \in \mathbb{R}^m \;:\; &\zeta = \lim_{k\to\infty} \zeta_k \text{ for some sequences} \\ &\zeta_k \in \hat{\hat{N}}_C(c_k) \text{ and } c_k \underset{C}{\to} c\big\}. \end{aligned} \tag{1.2}$$

(Here $c_k \underset{C}{\to} c$ means that $c_k \to c$ and $c_k \in C$ for all k.) The important properties of the limiting normal cone (easily deduced, for example, from [2, §2.5]) are:

(a) If $c \in \operatorname{bdry} C$, then $N_C(c)$ contains nonzero elements;
(b) The multifunction $c' \rightrightarrows N_C(c')$ has closed graph; and
(c) Clarke's normal cone $\overline{N}_C(c)$ is given by

$$\overline{N}_C(c) = \operatorname{cl}\operatorname{co} N_C(c)\,. \tag{1.3}$$

When the object of study is not a set but a locally Lipschitzian function $f: \mathbb{R}^m \to \mathbb{R}$, we apply the previous notions to the set $C := \operatorname{epi} f = \{(x, r) \in \mathbb{R}^m \times \mathbb{R} : r \geq f(x)\}$. This leads to the following definition: Given a point x, a vector ζ is called a *proximal subgradient of f at x*, written $\zeta \in \hat{\partial} f(x)$, if there is some $M > 0$ so large that, on some neighbourhood U of x, we have

$$f(x') \geq f(x) + \langle \zeta , x' - x \rangle - M|x' - x|^2 \quad \forall x' \in U. \tag{1.4}$$

The set of *limiting subgradients of f at x* is defined by

$$\begin{aligned} \partial f(x) = \{\zeta \in \mathbb{R}^m \, : \zeta = \lim_{k \to \infty} \zeta_k \text{ for some sequences} \\ \zeta_k \in \hat{\partial} f(x_k), \ x_k \to x\}. \end{aligned} \tag{1.5}$$

For locally Lipschitzian functions f, the set $\partial f(x)$ is nonempty and compact-valued everywhere, and the multifunction $x' \rightrightarrows \partial f(x')$ has closed graph. Moreover, Clarke's generalized gradient $\overline{\partial} f(x)$ may be obtained from the set of limiting subgradients as follows:

$$\overline{\partial} f(x) = \operatorname{co} \partial f(x). \tag{1.6}$$

(A relationship somewhat more complicated than (1.6) gives $\overline{\partial} f(x)$ in the case where f is assumed only to be lower semicontinuous and extended real valued.) Mordukhovich has used the limiting normal cone in the formulation of necessary conditions since 1976 in [15], [16], [17]. In collaboration with his student A. Y. Kruger, he has extended certain aspects of the theory to infinite-dimensional spaces [11]. More recently, Ioffe [6] has studied the limiting normal cone and limiting subgradient set described here under the names "approximate normal cone" and "approximate subdifferential," and given a more comprehensive extension to the infinite-dimensional case [7], [8], [9].

Hypotheses. Throughout the paper we confine our attention to a relatively open subset Ω of $[a, b] \times \mathbb{R}^n$ having nonempty sections

$$\emptyset \neq \Omega_t = \{x \in \mathbb{R}^n \, : \, (t, x) \in \Omega\} \quad \forall t \in [a, b].$$

In order to treat a local solution $\bar{x}$, we assume that $F(t, x)$ is empty-valued for $(t, x) \notin \Omega$. This makes the requirement that $x(t) \in \Omega_t$ for all t implicit for admissibility in problem (P). (Note that for any continuous function $x: [a, b] \to \mathbb{R}^n$ whose graph lies in Ω, a simple compactness argument implies the existence of some $\varepsilon > 0$ so small that $x(t) + \varepsilon \mathbb{B} \subseteq \Omega_t$ for all $t \in [a, b]$. Here, and throughout the paper, $\mathbb{B}$ denotes the open unit ball in $\mathbb{R}^n$.) Furthermore, we assume the following:

(H1) The endpoint cost functional ℓ is locally Lipschitz on the closed set $S_0 := (\operatorname{cl} \Omega_0) \times (\operatorname{cl} \Omega_1)$, and the localized endpoint constraint set $S \cap S_0$ is closed;

(H2) The sets $F(t, x)$ are nonempty, closed, and convex for each (t, x) in Ω;

(H3) The multifunction F is measurable with respect to the σ-field $\mathcal{L} \times \mathcal{B}$ generated by products of Lebesgue subsets of $[a, b]$ with Borel subsets of $\mathbb{R}^n$;

(H4) The state constraint multifunction X has closed values $X(t)$ and is lower semicontinuous in the sense that, for every point $(t_0, x_0) \in \Omega \cap (\operatorname{gph} X)$ and for every sequence $t_k \to t_0$ in $[a, b]$, there exists a sequence $x_k \to x_0$ satisfying $x_k \in X(t_k)$ for all k.

Jump directions. It is well known that the action of state constraints on an optimal trajectory manifests itself in the necessary conditions by producing discontinuities in

the corresponding adjoint arc. Roughly speaking, the adjoint vector is allowed to jump in an outward normal direction to the constraint set at an instant when the constraint is active. In the general setting proposed here, the possible jump directions lie in the closed convex cone defined as follows. For each (t,x) in $\Omega \cap (\operatorname{gph} X)$:

$$\overline{N}_X(t,x) = \operatorname{cl}\operatorname{co}\{\nu \in \mathbb{R}^n : \nu = \lim_{k\to\infty} \nu_k \text{ for some sequences } \nu_k \in \hat{\overline{N}}_{X(t_k)}(x_k),\ (t_k,x_k) \xrightarrow[\operatorname{gph} X]{} (t,x)\}. \tag{1.7}$$

A discussion of this cone and its relation to other formulations of the state constraint is given in §2 of our previous paper [13]. In that work the same cone was denoted by $N(t,x)$; the change of notation here is meant to emphasize the fact that this cone is related to the multifunction X and that, like Clarke's normal cone, it has closed convex values.

Hypothesis (H4) and definition (1.7) together imply that for any continuous function $x\colon [a,b] \to \mathbb{R}^n$ satisfying $x(t) \in X(t) \cap \Omega_t$ for all t, the convex cone valued multifunction $t \rightrightarrows \overline{N}_X(t,x(t))$ is Borel measurable. In this case, to call an $\mathbb{R}^n$-valued measure μ "$\overline{N}_X(t,x(t))$-valued" means that μ is absolutely continuous with respect to some nonnegative measure μ_0 on $[a,b]$, and that some measurable selection $\nu(t) \in \overline{N}_X(t,x(t))$ satisfies $d\mu(t) \equiv \nu(t)d\mu_0(t)$. (See Rockafellar [22, §5].) Necessary conditions for optimality in which the adjoint function is merely of bounded variation, with jump directions described in terms of cone-valued measures, were first given for convex problems of Bolza by Rockafellar [23], [24], [26].

Constraint qualification. Our necessary conditions require that the cone $\overline{N}_X(t,\overline{x}(t))$ be pointed everywhere on the graph of the optimal arc $\overline{x}$. This constraint qualification is also essential in Clarke's formulation (see [2, Remark 3.2.7(iii)]), as explained by Loewen and Rockafellar [13, §2]. Let us call the state constraint "active" (relative to $\overline{x}$) at any time t when $(t,\overline{x}(t))$ lies on the boundary of $\operatorname{gph} X$, and "inactive" when $(t,\overline{x}(t))$ lies in the interior of $\operatorname{gph} X$. It follows easily from (1.7) that $\overline{N}_X(t,\overline{x}(t))$ collapses to the trivial cone $\{0\}$ if and only if the state constraint is inactive at time t. In particular, if the state constraint is inactive for all $t \in [a,b]$—perhaps because $X(t) \equiv \mathbb{R}^n$—then the constraint qualification mentioned above holds automatically. (Note that there can be times when the state constraint is active even though $\overline{x}(t) \in \operatorname{int} X(t)$ for all t. An example is provided by the arc $\overline{x}(t) = 2t$ and the multifunction $X(t) = \{y : |y| \geq t\}$: The state constraint is active at $t = 0$ even though $\overline{x}(t) \in \operatorname{int} X(t)$ for all t.) Another common case in which the constraint qualification holds automatically arises when the state constraint sets $X(t)$ are convex and have nonempty interior; then the cone $\overline{N}_X(t,x)$ coincides with the usual normal cone $N_{X(t)}(x)$ of convex analysis, and the latter cone is pointed if and only if $\operatorname{int} X(t) \neq \emptyset$.

The state constraint we impose can be given a simple geometric interpretation, based on Rockafellar [25, Thm. 3]. That result states that if a closed subset Ξ of $\mathbb{R}^n$ contains a point ξ at which the Clarke normal cone $\overline{N}_\Xi(\xi)$ is pointed, then there is a neighborhood of ξ in which Ξ is indistinguishable from the isometric linear image of the epigraph of some Lipschitz function on $\mathbb{R}^{n-1}$. (The set Ξ is then called *epi-Lipschitzian at* ξ.) The set $\overline{N}_X(t,x)$ defined by (1.7) is generally larger than Clarke's normal cone $\overline{N}_{X(t)}(x)$ by (1.2)–(1.3), since it contains information not only about the shape of the set $X(t)$, but also about its behavior as t varies.

This leads to the following result, which makes precise the sense in which we can regard our constraint qualification as a requirement of "uniform epi-Lipschitzian behavior" of the multifunction X.

PROPOSITION 1.1. *Let (t,x) be a point in $\Omega \cap \operatorname{gph} X$ at which the cone $\overline{N}_X(t,x)$ is pointed. Then there exist a neighborhood U of (t,x) in $[a,b]\times\mathbb{R}^n$, a linear isometry A on $\mathbb{R}^n$, and a constant L with the following properties. For any $(s,y)\in U\cap\operatorname{gph} X$, there is a Lipschitz function $\phi_{(s,y)}$ of rank L having the property that*

$$A\left(\operatorname{epi}\phi_{(s,y)}\right) = X(s) \quad \text{near } y.$$

(In detail, this conclusion means that there is a neighborhood V of y such that $A\left(\operatorname{epi}\phi_{(s,y)}\right)\cap V = X(s)\cap V$.)

Proof. This result follows from a careful quantitative analysis of the cited theorem of Rockafellar. Details are available in [12]; here we merely indicate the main steps in the proof.

For any $\varepsilon\in(0,1)$ and any unit vector $v\in\mathbb{R}^n$, define the closed, pointed convex cone

$$K_\varepsilon(v) := \{\zeta\in\mathbb{R}^n \,:\, \langle\zeta\,,\,v\rangle \geq \varepsilon|\zeta|\}.$$

Deduce from the hypothesis that there exist some $\varepsilon\in(0,1)$ and some v of unit length, together with a neighborhood U_0 of (t,x) relative to Ω, such that

$$(*) \qquad \overline{N}_{X(s)}(y) \subseteq K_\varepsilon(v) \quad \forall (s,y)\in U_0.$$

Let A be any linear isometry of $\mathbb{R}^n$ into $\mathbb{R}^{n-1}\times\mathbb{R}$ such that $Av = (0,-1)$. (One certainly exists.) Then, taking polars in $(*)$ gives

$$\overline{T}_{A(X(s))}(Ay) \supseteq K_{\varepsilon'}(0,1) \quad \forall (s,y)\in U_0,$$

where $\varepsilon' = \sqrt{1-\varepsilon^2}$. For each (s,y) in U_0, Rockafellar's proof of [25, Thm. 3] provides a Lipschitzian function $\phi_{(s,y)}$ on $\mathbb{R}^{n-1}$ whose epigraph coincides with $A(X(s))$ throughout some neighborhood of Ay. The Lipschitz rank of $\phi_{(s,y)}$ can be estimated using the bound on the size of Clarke's generalized gradient of $\phi_{(s,y)}$ implicit in the identification with $A(X(s))$ and $\operatorname{epi}\phi_{(s,y)}$. (In fact, the estimate gives $L = \varepsilon/\sqrt{1-\varepsilon^2}$.) The conclusion of the proposition now follows, but we have interchanged the names of A and A^{-1} for clarity. □

Note that we have little control over the time-dependence of the functions $\phi_{(s,y)}$ in Proposition 1.1. For example, the multifunction

$$X(t) := \{(x,y) \,:\, y\geq 0\} \quad \text{if } t<\tfrac{1}{2}, \qquad X(t) := \{(x,y) \,:\, y\geq 1\} \quad \text{if } t\geq\tfrac{1}{2}$$

satisfies all our hypotheses but has a discontinuity at $t=\frac{1}{2}$. Since X is convex-valued, $\overline{N}_X(\frac{1}{2},(0,1)) = N_{X(\frac{1}{2})}(0,1) = \{0\}\times(-\infty,0]$. This cone is clearly pointed. When $s<\frac{1}{2}$ and y is near 1, the set $X(s)$ near y looks like the epigraph of $\phi_{(s,y)}\equiv 0$. However, when $s\geq\frac{1}{2}$ and y is near 1, the set $X(s)$ near y looks like the epigraph of the function $\phi_{(s,y)}\equiv 1$.

Hamiltonian necessary conditions. We are now in a position to state the necessary conditions for bounded differential inclusions on which our main results are based. These involve the *Hamiltonian* associated with the multifunction F, defined by $H(t,x,p) := \sup\{\langle p\,,\,v\rangle \,:\, v\in F(t,x)\}$. Theorem 1.2, below, is essentially a transcription of [13, Thm. 2.8], with the exception that the transversality inclusion in part (b) involves limiting subgradients and normals instead of the Clarke subgradients and normals used in [13]. (Clarke subgradients are still required in the Hamiltonian

inclusion.) This distinction is immaterial in the smooth and convex cases for which Clarke's notions are indistinguishable from the corresponding limiting constructions. In general, however, it is possible that the right-hand side of (b) is a proper subset of its counterpart in [13]. A detailed proof of Theorem 1.2 would be both long and repetitive, since many of the steps in the argument are now (or should be) well known. For this reason, we simply outline a derivation of the result based on small adjustments to proofs in the literature. Theorem 4.1, below, will significantly weaken the boundedness and Lipschitz continuity hypotheses (i) and (ii) in the following statement.

THEOREM 1.2. *Assume* (H1)–(H4). *Suppose the arc* $\overline{x}$ *solves problem* (P), *and that the constraint qualification below is satisfied:*

(CQ) *The cone* $\overline{N}_X(t,\overline{x}(t))$ *is pointed for all* t *in* $[a,b]$.

Suppose further that there exist integrable functions ϕ *and* k *such that*

(i) $F(t,x) \subseteq \phi(t)\,\mathrm{cl}\,\mathbb{B}$ *for all* $(t,x) \in \Omega$;

(ii) $F(t,y) \subseteq F(t,x) + k(t)|y-x|\,\mathrm{cl}\,\mathbb{B}$ *for all* $t \in [a,b]$, $x,y \in \Omega_t$.

Then there exist a scalar $\lambda \in \{0,1\}$ *and a function* $p \in BV([a,b];\mathbb{R}^n)$, *not both zero, together with an integrable selection* $\nu(t) \in \overline{N}_X(t,\overline{x}(t))$ *for all* $t \in [a,b]$, *such that*

(a) $(-\dot{p}(t)+\nu(t),\dot{\overline{x}}(t)) \in \overline{\partial}H(t,\overline{x}(t),p(t))$ *for almost all* $t \in [a,b]$;

(b) $(p(a),-p(b)) \in \lambda\partial\ell(\overline{x}(a),\overline{x}(b)) + N_S\,(\overline{x}(a),\overline{x}(b))$;

(c) *The singular part of the measure* dp *is* $\overline{N}_X(t,\overline{x}(t))$*-valued, and in particular is supported on the set*

$$\{t : \overline{N}_X(t,\overline{x}(t)) \neq \{0\}\} = \{t \in [a,b] : (t,\overline{x}(t)) \in \mathrm{bdry\,gph}\,X\}.$$

Outline of proof. Our first step is to reconsider Clarke's necessary conditions for optimality in [2, Thm. 3.5.2], noting that they apply to a slightly different problem than ours. We claim that these remain valid when the transversality condition at the final time [2, p. 143, (2)] is written as $-E \in N_{C_1}(x(b))$, instead of $-E \in \overline{N}_{C_1}(x(b))$. (That is, with the limiting normal cone in place of Clarke's normal cone.) To justify this, we must review the proof of [2, Thm. 3.4.3].

In the notation used there, choosing $x' = x$ in line 4 of Lemma 2 shows immediately that $-v$ is a proximal normal ("perpendicular" in [2]) to the set C_1 at the point c; hence the third displayed conclusion of Lemma 2 can be replaced by

$$\lambda\beta\zeta + p(b) + \int_{[a,b]} \gamma(s)\,\mu(ds) \in -\hat{\hat{N}}_{C_1}(x(b)-u).$$

In the limiting analysis of Step 4, this relation becomes

$$\lambda\beta_0\zeta + \widetilde{p}(b) + \int_{[a,b]} \gamma(s)\,\widetilde{\mu}(ds) = \lambda v_0 \in -N_{C_1}(x(b)).$$

The proof of [2, Thm. 3.4.3] concludes as before, and the method used to make the given solution unique, employed in the proof of [2, Thm. 3.5.2], respects the refined formulation of the transversality condition.

Our second step is to extend the necessary conditions described above to cope with an endpoint cost functional and endpoint constraint set involving both $x(a)$ and

$x(b)$ jointly. To do so, simply note that if an arc $\overline{x}$ solves (P), then the extended arc $(\overline{r}, \overline{x})$ with $\overline{r}(t) \equiv \overline{x}(a)$ solves the following problem:

$$\begin{aligned} \text{minimize} \quad & \ell(r(b), x(b)) \\ \text{subject to} \quad & \dot{r}(t) = 0, \qquad \dot{x}(t) \in F(t, x(t)) \quad \text{a.e. } t \in [a, b], \\ & (r(a), x(a)) \in D, \qquad (r(b), x(b)) \in S, \\ & (r(t), x(t)) \in \mathbb{R}^n \times X(t) \quad \forall t \in [a, b], \end{aligned}$$

where $D = \{(z, z) : z \in \mathbb{R}^n\}$ is the diagonal of $\mathbb{R}^n \times \mathbb{R}^n$. This is a situation to which our refinement of [2, Thm. 3.5.2] can be applied, and the resulting transversality condition is

$$(\dagger) \qquad (p(a), -p(b)) \in \lambda \overline{\partial} \ell(\overline{x}(a), \overline{x}(b)) + N_S(\overline{x}(a), \overline{x}(b)).$$

This differs from the desired conclusion (b) only in its use of the Clarke subgradient of the endpoint cost function ℓ.

Passing from the parametric form of the state constraint $g(t, x(t)) \leq 0$ to the intrinsic form $x(t) \in X(t)$ as described in §2 of [13] does not affect the transversality inclusion. The same methods, therefore, imply that [13, Thm. 2.8] remains valid with the transversality inclusion replaced by (†)—and in particular that conclusion (b) holds if ℓ is smooth.

We now turn to Theorem 1.2. Suppose $\overline{x}$ solves problem (P). Then the extended arc $(\overline{x}, \overline{z})$ in which $\overline{z}(t) \equiv \ell(\overline{x}(a), \overline{x}(b))$ must solve the following problem:

$$\begin{aligned} \text{minimize} \quad & z(b) \\ \text{subject to} \quad & \dot{x}(t) \in F(t, x(t)), \qquad \dot{z}(t) = 0 \quad \text{a.e. } t \in [a, b], \\ & (x(a), x(b), z(b)) \in \operatorname{epi}(\ell + \Psi_S), \qquad z(a) \in \mathbb{R}, \\ & (x(t), z(t)) \in X(t) \times \mathbb{R} \quad \forall t \in [a, b]. \end{aligned}$$

(Here Ψ_S denotes the *indicator function* of the set S, defined by setting $\Psi_S(x) = 0$ if x lies in S, and $\Psi_S(x) = +\infty$ otherwise.) Applying the intermediate form of [13, Thm. 2.8] described above leads to the conclusion that for some $\lambda \in \{0, 1\}$ and $p \in BV([a, b]; \mathbb{R}^n)$, not both zero, and some selection $\nu(t) \in \overline{N}_X(t, \overline{x}(t))$, we have the desired conclusions (a) and (c) of the current theorem, along with the transversality condition

$$(*) \qquad (p(a), -p(b), -\lambda) \in N_{\operatorname{epi}(\ell + \Psi_S)}(\overline{x}(a), \overline{x}(b), \ell(\overline{x}(a), \overline{x}(b))).$$

If $\lambda > 0$, this assertion is equivalent to

$$(p(a), -p(b)) \in \lambda \partial(\ell + \Psi_S)(\overline{x}(a), \overline{x}(b)).$$

Thanks to the calculus rules for limiting subgradients in [6, Thm. 4] of Ioffe, we deduce that

$$(\ddagger) \qquad (p(a), -p(b)) \in \lambda \partial \ell(\overline{x}(a), \overline{x}(b)) + N_S(\overline{x}(a), \overline{x}(b)).$$

In particular, when $\lambda = 1$ we obtain the desired conclusion (b). When $\lambda = 0$, the proximal subgradient formula (see Rockafellar [27, Proof of Thm. 1]) asserts that the vector $(p(a), -p(b), 0)$ appearing on the left-hand side of $(*)$ can be expressed as a limit of some sequence $(p_k(a), -p_k(b), -\lambda_k)$ with $\lambda_k > 0$, along which $(*)$ holds relative to a sequence of base points $(x_k(a), x_k(b), \ell(x_k(a), x_k(b)))$ converging to $(\overline{x}(a), \overline{x}(b), \ell(\overline{x}(a), \overline{x}(b)))$. These sequences therefore satisfy an analogue of $(\ddagger)$ in which a subscript k appears throughout. Taking the limit as $k \to \infty$, we obtain $(\ddagger)$ with $\lambda = 0$. Thus conclusion (b) is also valid in this case. □

Remark. The transversality condition $(*)$ from which (b) is derived in the foregoing proof could conceivably be sharper than (b) in some cases, since it involves the subgradients of the essential endpoint cost functional $\ell + \Psi_S$, instead of the sum of subgradients of its two terms.

2. Localization of unbounded multifunctions. Suppose the arc $\overline{x}$ solves problem (P). Then $\overline{x}$ must also solve any problem with the same objective function as (P) but fewer admissible arcs. Such a problem can be described by replacing the given velocity sets $F(t,x)$ by their bounded subsets

$$\widetilde{F}(t,x) := F(t,x) \cap \big(\dot{\overline{x}}(t) + R(t)\,\mathrm{cl}\,\mathbb{B}\big) \tag{2.1}$$

for some real-valued function $R(t)$. Known necessary conditions for differential inclusion problems with compact right-hand sides, like Theorem 1.2, above, then provide some information about $\overline{x}$. Our goal is to translate this information into necessary conditions that refer only to the data of the original problem (P). This translation is not completely straightforward; neither is it obvious which hypotheses on F and which choice of $R(t)$ will make the application of Theorem 1.2 to the reduced problem both legitimate and informative.

This section deals with the hypotheses. It is rather obvious that for any nonnegative integrable function $R(t)$, the truncated multifunction $\widetilde{F}$ defined above has compact convex values satisfying Theorem 1.2(i). We ensure nonemptiness and Lipschitz continuity by way of the following lemma, whose uncluttered notation is intended to clarify the essential geometry.

LEMMA 2.1. *Let $\overline{v} \in \mathbb{R}^n$, and let F_1 and F_2 be two subsets of $\mathbb{R}^n$ such that for some $\delta > 0$ and $0 < r < R$,*

(i) $F_2 \cap (\overline{v} + R\,\mathrm{cl}\,\mathbb{B}) \subseteq F_1 + \delta\,\mathrm{cl}\,\mathbb{B}$;

(ii) $F_1 \cap (\overline{v} + r\,\mathrm{cl}\,\mathbb{B}) \neq \emptyset$;

(iii) *F_1 is convex.*

Then $F_2 \cap (\overline{v} + R\,\mathrm{cl}\,\mathbb{B}) \subseteq F_1 \cap (\overline{v} + R\,\mathrm{cl}\,\mathbb{B}) + (2R\delta/(R-r))\,\mathrm{cl}\,\mathbb{B}$.

Proof. Without loss of generality, take $\overline{v} = 0$. Choose any $v_2 \in F_2 \cap R\,\mathrm{cl}\,\mathbb{B}$. According to (i), there exists $v_1 \in F_1$ such that $|v_2 - v_1| \leq \delta$. By (ii), we also have some $v_0 \in F_1$ such that $|v_0| \leq r$. Hypothesis (iii) ensures that

$$v_t := (1-t)v_0 + tv_1 \in F_1 \quad \forall t \in [a,b].$$

We estimate

$$\begin{aligned} |v_t| &\leq (1-t)|v_0| + t|v_1| \\ &\leq (1-t)r + t\,(\delta + |v_2|) \\ &\leq r + t(\delta + R - r). \end{aligned}$$

This implies that $v_t \in F_1 \cap R\,\mathrm{cl}\,\mathbb{B}$ when $r + t(\delta + R - r) \leq R$, in particular when

$$0 \leq t \leq \widehat{t} := \frac{R-r}{\delta + R - r}.$$

Let $\widehat{v} = v_{\widehat{t}}$. Then $\widehat{v} \in F_1 \cap (\overline{v} + R\,\mathrm{cl}\,\mathbb{B})$, and

$$\begin{aligned} |v_2 - \widehat{v}| &\leq |v_2 - v_1| + |v_1 - \widehat{v}| \\ &\leq \delta + (1 - \widehat{t})|v_0 - v_1| \\ &\leq \delta + (1 - \widehat{t})\,(|v_0| + |v_1|) \\ &\leq \delta + (1 - \widehat{t})(r + R + \delta) \\ &= 2\delta\left[1 + \frac{r}{\delta + R - r}\right]. \end{aligned}$$

The right-hand side increases if we discard the δ appearing in the denominator. This yields $|v_2 - \widehat{v}| \leq 2\delta R/(R - r)$. Since $v_2 \in F_2$ is arbitrary and $\widehat{v} \in F_1 \cap (\overline{v} + R\,\mathrm{cl}\,\mathbb{B})$, the desired inclusion follows. □

Remark. Clarke's lemma [2, Lem. 3, p. 172] is proven by a very similar argument, but starts with a stronger hypothesis.

Using Lemma 2.1, we now provide a set of sufficient conditions for our localization technique to produce a multifunction satisfying the hypotheses of Theorem 1.2.

PROPOSITION 2.2. *Let Ω and F be given as in the formulation of problem (P); assume* (H2)–(H3). *Let $\overline{x}$ be an F-trajectory. Suppose there exists $\overline{\varepsilon} > 0$ together with nonnegative integrable functions m and R such that $m/R \in L^\infty[a,b]$, and for almost every $t \in [a,b]$ we have*

$$F(t,y) \cap \left(\dot{\overline{x}}(t) + R(t)\,\mathrm{cl}\,\mathbb{B}\right) \subseteq F(t,x) + m(t)|y - x|\,\mathrm{cl}\,\mathbb{B} \quad \forall x, y \in \overline{x}(t) + \overline{\varepsilon}\mathbb{B}. \tag{2.2}$$

Then there is a relatively open subset $\widetilde{\Omega}$ of $[a,b] \times \mathbb{R}^n$ containing the graph of $\overline{x}$ on which the truncated multifunction $\widetilde{F}(t,x)$ of (2.1) *satisfies not only* (H2)–(H3), *but also hypotheses* (i)–(ii) *of Theorem* 1.2.

Proof. Note that the requirement that $\overline{x}(t) + \overline{\varepsilon}\mathbb{B} \subseteq \Omega_t$ for all t is implicit in hypothesis (2.2), since the choice $y = \overline{x}(t)$ forces $F(t,x) \neq \emptyset$ for all $x \in \overline{x}(t) + \overline{\varepsilon}\mathbb{B}$. Therefore any choice of $\varepsilon \in (0, \overline{\varepsilon}]$ will ensure that $\mathrm{gph}\,\overline{x} \subseteq \widetilde{\Omega} \subseteq \Omega$ for the set

$$\widetilde{\Omega} := \{(t,x) \,:\, t \in [a,b], |x - \overline{x}(t)| < \varepsilon\}.$$

We therefore fix $\varepsilon \in (0, \overline{\varepsilon}]$, taking care that

$$\varepsilon m(t)/R(t) \leq 1/2 \quad \text{a.e. } t \in [a,b]. \tag{$*$}$$

This is possible because m/R is essentially bounded by hypothesis.

Let us fix a time $t \in [a,b]$ at which $(*)$ and (2.2) hold, $\dot{\overline{x}}(t)$ exists, and $\dot{\overline{x}}(t) \in F(t, \overline{x}(t))$. (Such t-values form a subset of $[a,b]$ with full measure.) The sets $\widetilde{F}(t,x)$ are evidently compact and convex valued for each $x \in \overline{x}(t) + \varepsilon\mathbb{B}$. To observe that they are nonempty, we choose $y = \overline{x}(t)$ in (2.2). Then

$$\dot{\overline{x}}(t) \in F(t, \overline{x}(t)) \cap \left(\dot{\overline{x}}(t) + R(t)\,\mathrm{cl}\,\mathbb{B}\right) \subseteq F(t,x) + m(t)|\overline{x}(t) - x|\,\mathrm{cl}\,\mathbb{B} \quad \forall x \in \overline{x}(t) + \varepsilon\mathbb{B}.$$

This inclusion implies that

$$F(t,x) \cap \left(\dot{\overline{x}}(t) + \varepsilon m(t)\,\mathrm{cl}\,\mathbb{B}\right) \neq \emptyset \quad \forall x \in \overline{x}(t) + \varepsilon\mathbb{B}, \tag{$\dagger$}$$

and $\widetilde{F}(t,x)$ contains the left-hand side of $(\dagger)$ due to $(*)$. Thus (H2) holds relative to $\widetilde{\Omega}$; the measurability property required by (H3) is evident.

The choice $\phi(t) := |\dot{\bar{x}}(t)| + R(t)$ clearly proves condition (i) of Theorem 1.2. Only condition (ii) remains. With t fixed as above, choose any $x, y \in \bar{x}(t) + \varepsilon\mathbb{B}$ and let $F_1 = F(t,x)$, $F_2 = F(t,y)$. Then the hypotheses of Lemma 2.1 hold with $\bar{v} = \dot{\bar{x}}(t)$, $R = R(t)$, $\delta = m(t)|y-x|$ from (2.2), and $r = \varepsilon m(t) \leq R(t)/2$ from (†). The conclusion is that $\widetilde{F}(t,y) \subseteq \widetilde{F}(t,x) + k(t)|y-x|\,\mathrm{cl}\,\mathbb{B}$, where

$$k(t) = \frac{2R(t)m(t)}{R(t) - \varepsilon m(t)} = \frac{2m(t)}{1 - \varepsilon m(t)/R(t)} \leq 4m(t).$$

Hypothesis (ii) of Theorem 1.2 requires that the function k be integrable; this is ensured by the integrability of m. □

The central hypothesis (2.2) of Proposition 2.2 is a quantitative version of Aubin's *pseudo-Lipschitzian continuity* for the multifunctions $F(t,\cdot)$ at the points $(\bar{x}(t), \dot{\bar{x}}(t))$ along the trajectory $\bar{x}$ (see Rockafellar [28]). Although the conditions of Proposition 2.2 are sufficient for the development of our theory, they require that the arc $\bar{x}$ be known in advance, and offer few suggestions about effective choices of the functions R and m.

Before continuing the development of our argument, we pause to describe hypotheses on the multifunction F that can be used to verify (2.2) along any admissible arc. These involve the following concepts.

DEFINITION 2.3. Let $\Gamma\colon \Omega \rightrightarrows \mathbb{R}^m$ be a multifunction with closed values, and suppose Γ is $\mathcal{L} \times \mathcal{B}$ measurable on Ω. Consider a point $(\bar{t}, \bar{x})$ in Ω.

(a) The multifunction Γ is called *sub-Lipschitzian at* $(\bar{t}, \bar{x})$ if, for every constant $\rho \geq 0$, there exist constants $\varepsilon > 0$ and $\alpha \geq 0$ such that

$$\Gamma(t,y) \cap \rho\,\mathrm{cl}\,\mathbb{B} \subseteq \Gamma(t,x) + \alpha|y-x|\,\mathrm{cl}\,\mathbb{B} \tag{2.3}$$

for all $t \in (\bar{t} - \varepsilon, \bar{t} + \varepsilon) \cap [a,b]$ and all x, y in $\bar{x} + \varepsilon\mathbb{B}$.

(b) The multifunction Γ is called *integrably sub-Lipschitzian in the large at* $(\bar{t}, \bar{x})$ if there exist constants $\varepsilon > 0$ and $\beta \geq 0$, together with a nonnegative function α integrable on $(\bar{t} - \varepsilon, \bar{t} + \varepsilon)$, such that

$$\Gamma(t,y) \cap \rho\,\mathrm{cl}\,\mathbb{B} \subseteq \Gamma(t,x) + (\alpha(t) + \beta\rho)|y-x|\,\mathrm{cl}\,\mathbb{B} \tag{2.4}$$

for all $t \in (\bar{t} - \varepsilon, \bar{t} + \varepsilon) \cap [a,b]$, all x, y in $\bar{x} + \varepsilon\mathbb{B}$, and all $\rho \geq 0$.

Definition 2.3(a) is very similar to the notion of sub-Lipschitzian behaviour introduced by Rockafellar [28], the only difference being that here we consider multifunctions with explicit time-dependence, and require a certain uniformity of the parameters ε and α with respect to t. Rockafellar [28] offers a detailed discussion of (autonomous) sub-Lipschitzian multifunctions and the relationship between this property and the pseudo-Lipschitz continuity introduced by Aubin; he also describes several classes of sub-Lipschitzian multifunctions.

Definition 2.3(b) introduces a new type of sub-Lipschitzian assumption even in the autonomous case. It looks like a stricter hypothesis than that of Definition 2.3(a) because it places certain restrictions on the growth of the right-hand side with ρ. If (b) holds for a constant function $\alpha(t) \equiv \alpha$, then certainly (a) follows; it is not obvious that (b) always implies (a), however, since (b) allows α to depend on t, whereas α must be constant in (a).

Each of these hypotheses has a role as a sufficient condition for the applicability of Proposition 2.2.

PROPOSITION 2.4. *Let Ω and F be given as in the formulation of problem (P); assume* (H2)–(H3). *Let $\overline{x}$ be an F-trajectory. Under either of the two hypotheses below, all the conditions of Proposition* 2.2 *are met. In particular, there is a relatively open subset $\widetilde{\Omega}$ of Ω containing the graph of $\overline{x}$ on which the truncated multifunction $\widetilde{F}$ defined by* (2.1) *satisfies all the hypotheses of Theorem* 1.2.

(a) *The arc $\overline{x}$ is Lipschitzian, and the multifunction F is sub-Lipschitzian at every point $(t, \overline{x}(t))$ in* $\operatorname{gph} \overline{x}$.

(b) *The multifunction F is integrably sub-Lipschitzian in the large at every point $(t, \overline{x}(t))$ in* $\operatorname{gph} \overline{x}$.

Remarks. 1. Note that the two parts of Proposition 2.4 correspond exactly to the two parts of Definition 2.3. Part (b) imposes apparently stricter conditions on F and applies to any arc $\overline{x}$, while part (a) imposes apparently weaker requirements on F but pertains only to Lipschitzian arcs $\overline{x}$.

2. The proof of part (a) below allows for an arbitrarily small positive constant value of R in the localization of (2.1). This may eventually link our results with the necessary conditions for "weak local minima" in the calculus of variations.

3. The conditions of the Proposition make explicit reference to the arc $\overline{x}$, but they would obviously follow from corresponding hypotheses regarding sub-Lipschitzian behavior of F throughout the set Ω.

4. Proposition 2.4 remains valid when Definition 2.3 is weakened by replacing the phrase "$\rho \geq 0$" with "$\rho \geq 0$ sufficiently large" in parts (a) and (b).

Proof of Proposition 2.4. (b) Both hypotheses in the statement of the Proposition must first be extended to the whole interval $[a, b]$ by a compactness argument. We illustrate this just once, taking the more delicate case, situation (b).

Applying Definition 2.3(b) to a point $(s, \overline{x}(s))$ in $\operatorname{gph} \overline{x}$ yields constants $\varepsilon_s > 0$, $\beta_s \geq 0$, and a nonnegative function $\alpha_s(t)$ integrable on $(s - \varepsilon_s, s + \varepsilon_s)$ such that (2.4) holds for any $\rho \geq 0$ and any triple (t, x, y) chosen from the set

$$G_s = \{(t, x, y) \,:\, |t - s| < \varepsilon_s,\ x \in \overline{x}(s) + \varepsilon_s \mathbb{B},\ y \in \overline{x}(s) + \varepsilon_s \mathbb{B}\}.$$

Now each set G_s, $s \in [a, b]$, is open, and the family of these sets covers the compact set $\{(t, \overline{x}(t), \overline{x}(t)) \,:\, t \in [a, b]\}$. Therefore we may extract a finite subcover indexed by $s_1, \ldots, s_N$, and define

$$G := \bigcup_{j=1}^{N} G_j.$$

For simplicity, we have written G_{s_j} as G_j. We define ε_j, β_j, and $\alpha_j(t)$ similarly.

Observe that there exists $\bar{\varepsilon} > 0$ so small that for every $t \in [a, b]$,

$$\{t\} \times (\overline{x}(t) + \bar{\varepsilon}\mathbb{B}) \times (\overline{x}(t) + \bar{\varepsilon}\mathbb{B}) \subseteq G.$$

(If this were not true, then there would be a sequence of points outside G converging to some point $(\bar{t}, \overline{x}(\bar{t}), \overline{x}(\bar{t}))$ in the interior of G, which is a contradiction.) Next, choose $\beta = \max\{\beta_1, \ldots, \beta_N\}$ and define

$$\alpha(t) := \max_{j=1,\ldots,N} \{\alpha_j(t) \,:\, t \in (s_j - \varepsilon_j, s_j + \varepsilon_j)\}.$$

Clearly β is finite and $\alpha(t)$ is integrable. Moreover, for any pair of points (t, x) and (t, y) chosen from the set $\widehat{\Omega} = \{(t, x) \,:\, t \in [a, b],\ x \in \overline{x}(t) + \bar{\varepsilon}\mathbb{B}\}$, we have $(t, x, y) \in G$, so $(t, x, y) \in G_j$ for some $j = 1, \ldots, N$. Thus (2.4) holds for (t, x, y) with parameters

β_j and $\alpha_j(t)$, and therefore it holds with the larger parameters β and $\alpha(t)$. This shows that the set $\widehat{\Omega}$ is a relatively open subset of Ω containing the graph of $\overline{x}$ throughout which (2.4) holds uniformly with parameters $\overline{\varepsilon}$, β, and $\alpha(t)$.

Now consider the function $R(t) = 1 + \alpha(t) + |\dot{\overline{x}}(t)|$. For any t in $[a,b]$, choose $\rho = |\dot{\overline{x}}(t)| + R(t)$ in the extension of (2.4) just proved. This leads to the following estimate, valid for all x, y in $\overline{x}(t) + \overline{\varepsilon}\mathbb{B}$:

$$\begin{aligned} F(t,y) \cap \big(\dot{\overline{x}}(t) + R(t)\,\mathrm{cl}\,\mathbb{B}\big) &\subseteq F(t,y) \cap \big(|\dot{\overline{x}}(t)| + R(t)\big)\,\mathrm{cl}\,\mathbb{B} \\ &\subseteq F(t,x) + \big(\alpha(t) + \beta\,[|\dot{\overline{x}}(t)| + R(t)]\big)\,|y-x|\,\mathrm{cl}\,\mathbb{B}. \end{aligned}$$

This confirms (2.2), where the function

$$m(t) = \alpha(t) + \beta\,[|\dot{\overline{x}}(t)| + R(t)] = (1+\beta)\alpha(t) + 2\beta|\dot{\overline{x}}(t)| + \beta$$

is clearly integrable, as is $R(t)$, while $m(t)/R(t) \le 2 + 2\beta$ almost everywhere. All the hypotheses of Proposition 2.2 are in place; part (b) of the desired result follows.

(a) Under hypothesis (a), we fix any $R > 0$ (perhaps quite small) and let $\rho = R + \|\dot{\overline{x}}\|_\infty$. Then a compactness argument very similar to the one described in detail above leads to a pair of constants $\overline{\varepsilon} > 0$ and $\alpha \ge 0$ for which (2.3) holds for any pair of points (t,x) and (t,y) in $\widehat{\Omega} := \{(t,x) : t \in [a,b], |x - \overline{x}(t)| < \overline{\varepsilon}\}$. In particular, since $\rho \ge R + |\dot{\overline{x}}(t)|$, we have

$$\begin{aligned} F(t,y) \cap \big(\dot{\overline{x}}(t) + R\,\mathrm{cl}\,\mathbb{B}\big) &\subseteq F(t,y) \cap \rho\,\mathrm{cl}\,\mathbb{B} \\ &\subseteq F(t,x) + \alpha|y-x|\,\mathrm{cl}\,\mathbb{B}. \end{aligned}$$

Thus (2.2) holds with the constants $m = \alpha$ and R identified here. □

3. Hamiltonian calculus. We now take up the second question raised at the beginning of §2. Given a multifunction F satisfying our standing hypotheses, and an F-trajectory $\overline{x}$, suppose it is possible to choose a function $R(t)$ for which the localization (2.1) produces a multifunction $\widetilde{F}$ with suitable boundedness and Lipschitz properties. What is the relationship between the Hamiltonian of $\widetilde{F}$ and that of the given multifunction F? More specifically, how are their subgradients linked? We answer these questions using simplified notation that suppresses the time-dependence of F, since we are concerned only with partial subgradients computed at fixed times.

Throughout this section, we consider a multifunction F defined on some neighborhood $\overline{x} + \overline{\varepsilon}\mathbb{B}$ of a given point $\overline{x}$, and taking on nonempty closed convex subsets of $\mathbb{R}^n$ as values. We assume that $F(x)$ depends continuously on x in the set $\overline{x} + \overline{\varepsilon}\mathbb{B}$ in the sense that the inner and outer limits of the sets $F(x')$ share the common value $F(x)$ as $x' \to x$. Given a point $\overline{v}$ in $F(\overline{x})$, we consider the localized multifunction $\widetilde{F}(x) := F(x) \cap (\overline{v} + R\,\mathrm{cl}\,\mathbb{B})$ for some fixed $R > 0$. Like its predecessor F, the multifunction $\widetilde{F}$ has closed convex values on the set $\overline{x} + \overline{\varepsilon}\mathbb{B}$. Concerning $\widetilde{F}$, we assume that

$$\widetilde{F} \text{ is Lipschitz of rank } k \text{ on } \overline{x} + \overline{\varepsilon}\mathbb{B} \tag{3.1}$$

(in particular, $\widetilde{F}$ is nonempty-valued there), and consider a vector $\overline{p}$ with the property that

$$\langle \overline{p}, \overline{v} \rangle \ge \langle \overline{p}, v \rangle \quad \text{for all } v \in \widetilde{F}(\overline{x}). \tag{3.2}$$

Our concern is to relate the subgradients at $(\overline{x},\overline{p})$ of the two Hamiltonians corresponding to F and $\widetilde{F}$, namely

$$\begin{aligned} H(x,p) &:= \sup\{\langle p\,,\,v\rangle \;:\; v \in F(x)\},\\ \widetilde{H}(x,p) &:= \sup\{\langle p\,,\,v\rangle \;:\; v \in \widetilde{F}(x)\}. \end{aligned} \tag{3.3}$$

In particular, we prove that under the hypotheses described above,

$$\overline{\partial}\widetilde{H}(\overline{x},\overline{p}) \subseteq \overline{\partial}H(\overline{x},\overline{p}). \tag{3.4}$$

Recall the Legendre–Fenchel transform that associates to any function $f\colon \mathbb{R}^n \to \mathbb{R}\cup\{+\infty\}$ its *conjugate*

$$f^*(p) := \sup\{\langle p\,,\,v\rangle - f(v) \;:\; v \in \mathbb{R}^n\}.$$

When f is a proper convex function, its conjugate is as well, and the duality sponsored by this transformation is the cornerstone of many fundamental results in convex analysis. In our current setting, we recognize the Hamiltonians H and $\widetilde{H}$ as the conjugates of certain indicator functions. Using the notation $\Psi_C(v) := 0$ if $v \in C$ and $\Psi_C(v) := +\infty$ if $v \notin C$, we have

$$\begin{aligned} H(x,p) &= \left(\Psi_{F(x)}\right)^*(p),\\ \widetilde{H}(x,p) &= \left(\Psi_{\widetilde{F}(x)}\right)^*(p) = \left(\Psi_{F(x)} + \Psi_{\overline{v}+R\,\mathrm{cl}\,\mathbb{B}}\right)^*(p). \end{aligned}$$

One important consequence of this observation is that the possibly extended-valued function H is lower semicontinuous on $(\overline{x}+\overline{\varepsilon}\mathbb{B})\times\mathbb{R}^n$. Indeed, the continuity of F assumed above implies that epi $\Psi_{F(x)}$ varies continuously with x on $\overline{x}+\overline{\varepsilon}\mathbb{B}$. According to Wijsman's theorem [32, Thm. 6.2], epi-continuity is preserved under the Legendre–Fenchel transform. In particular, epi $H(x,\cdot)$ also varies continuously with x on $\overline{x}+\overline{\varepsilon}\mathbb{B}$. The very definition of epi-continuity now implies that H is lower semicontinuous near $(\overline{x},\overline{p})$.

Infimal convolution. Addition of proper convex functions corresponds to infimal convolution of their conjugates under the Legendre–Fenchel transform: According to *Convex Analysis* [21, Thm. 16.4], we have the following identity for all x near $\overline{x}$ and all $p \in \mathbb{R}^n$:

$$\begin{aligned} \widetilde{H}(x,p) &= \left(\Psi^*_{F(x)} \,\square\, \Psi^*_{\overline{v}+R\,\mathrm{cl}\,\mathbb{B}}\right)(p)\\ &= \inf\left\{\Psi^*_{F(x)}(p-z) + \Psi^*_{\overline{v}+R\,\mathrm{cl}\,\mathbb{B}}(z) \;:\; z \in \mathbb{R}^n\right\}\\ &= \inf\{H(x,p-z) + \langle \overline{v}\,,\,z\rangle + R|z| \;:\; z \in \mathbb{R}^n\}. \end{aligned} \tag{3.5}$$

(The hypotheses of [21, Thm. 16.4] require that for each x near $\overline{x}$, the convex sets $\mathrm{ri}(\mathrm{dom}\,H(x,\cdot))$ and $\mathrm{ri}(\mathrm{dom}\,\widetilde{H}(x,\cdot))$ have a point in common. However, because $\widetilde{F}$ is bounded, the latter set is the whole space $\mathbb{R}^n$; the former set is nonempty, so this hypothesis holds.)

Subgradient analysis. Equation (3.5) expresses $\widetilde{H}$ as the value function associated with a minimization problem depending upon the parameters x and p. Proximal analysis is a powerful technique for estimating the subgradients of such functions: the

situation we now face is covered by Rockafellar [29, Thm. 8.3]. If we write $f(z,x,p) := H(x,p-z) + \langle \overline{v}\,,\, z\rangle + R|z|$, that result affirms that

$$\begin{aligned}\overline{\partial}\widetilde{H}(\overline{x},\overline{p}) \subseteq \operatorname{cl}\operatorname{co}\Bigg[&\bigcup_{z\in\Sigma(\overline{x},\overline{p})} \left\{(\pi,v) \,:\, (0,\pi,v)\in \overline{\partial} f(z,\overline{x},\overline{p})\right\} \\ &+ \bigcup_{z\in\Sigma(\overline{x},\overline{p})} \left\{(\pi,v) \,:\, (0,\pi,v)\in \overline{\partial}^{\infty} f(z,\overline{x},\overline{p})\right\}\Bigg],\end{aligned} \tag{3.6}$$

where $\Sigma(\overline{x},\overline{p})$ denotes the set of all points $z\in\mathbb{R}^n$ at which the infimum in (3.5) is attained. Our assumption (3.2) and the convexity of the set $F(\overline{x})$ together ensure that one such point is $z=0$, where $\widetilde{H}(\overline{x},\overline{p}) = \langle \overline{p}\,,\, \overline{v}\rangle = H(\overline{x},\overline{p})$. However, because $\overline{v}\in F(\overline{x})$, we have $H(\overline{x},\overline{p}-z) \geq \langle \overline{p}-z\,,\, \overline{v}\rangle$ for any $z\in\mathbb{R}^n$; hence

$$H(\overline{x},\overline{p}-z) + \langle \overline{v}\,,\, z\rangle + R|z| \geq H(\overline{x},\overline{p}) + R|z|.$$

The right-hand side above strictly exceeds the minimum value $H(\overline{x},\overline{p})$ for all z except $z=0$. Therefore $\Sigma(\overline{x},\overline{p}) = \{0\}$, and inclusion (3.6) simplifies to

$$\begin{aligned}\overline{\partial}\widetilde{H}(\overline{x},\overline{p}) \subseteq \operatorname{cl}\operatorname{co}\Big[&\left\{(\pi,v) \,:\, (0,\pi,v)\in \overline{\partial} f(0,\overline{x},\overline{p})\right\} \\ &+ \left\{(\pi,v) \,:\, (0,\pi,v)\in \overline{\partial}^{\infty} f(0,\overline{x},\overline{p})\right\}\Big].\end{aligned} \tag{3.7}$$

Before completing our analysis of (3.7), we must confirm that the derivation of (3.6) from [29, Thm. 8.3] is justified. This requires that we verify three hypotheses. First, the function $\widetilde{H}$ must be finite at $(\overline{x},\overline{p})$. This requires only that $\widetilde{F}(\overline{x})$ be nonempty, which we have assumed from the start. Second, a certain constraint qualification must hold at $(z,\overline{x},\overline{p})$ for every $z\in\Sigma(\overline{x},\overline{p})$. This turns out to be trivial because the constraint structure of our problem is so much simpler than that involved in the general situation of the cited theorem. Third, there must exist constants $\varepsilon>0$ and $\overline{\alpha} > \widetilde{H}(\overline{x},\overline{p})$ such that the following set is bounded:

$$S := \{(z,x,p) \,:\, H(x,p-z) + \langle \overline{v}\,,\, z\rangle + R|z| \leq \overline{\alpha},\ |(x,p)-(\overline{x},\overline{p})| \leq \varepsilon\}.$$

To prove this, we apply the Lipschitz hypothesis (3.1), which implies (since $\overline{v}\in\widetilde{F}(\overline{x})$) that for any x in $\overline{x}+\overline{\varepsilon}\mathbb{B}$,

$$(\overline{v} + k|x-\overline{x}|\operatorname{cl}\mathbb{B}) \cap \widetilde{F}(x) \neq \emptyset.$$

It follows that for any such x, and for any $p,z\in\mathbb{R}^n$,

$$H(x,p-z) \geq \widetilde{H}(x,p-z) \geq \langle p-z\,,\, \overline{v}\rangle - k|x-\overline{x}||p-z|.$$

Therefore, if we choose $\varepsilon>0$ small enough that $R-\varepsilon k > \varepsilon/2$, any triple (z,x,p) satisfying the defining inequalities in S will obey

$$\begin{aligned}\overline{\alpha} &\geq H(x,p-z) + \langle \overline{v}\,,\, z\rangle + R|z| \\ &\geq R|z| + \langle p\,,\, \overline{v}\rangle - k|x-\overline{x}||p-z| \\ &\geq (R-k|x-\overline{x}|)\,|z| - (|\overline{v}| + k|x-\overline{x}|)\,|p| \\ &\geq (\varepsilon/2)|z| - (|\overline{v}| + k\varepsilon)(|\overline{p}|+\varepsilon).\end{aligned}$$

This clearly imposes an upper bound on $|z|$, and it follows that the set S is bounded. Our verification of the hypotheses of [29, Thm. 8.3] is complete, and we can apply its conclusions (3.6) and (3.7) with confidence.

To complete our derivation of inclusion (3.4), it remains only to compute the subgradient sets appearing in (3.7). Recall that $f(z,x,p) = H(x,p-z)+\langle \overline{v}\,,\, z\rangle + R|z|$; thus f is the sum of a lower semicontinuous function and a continuous convex function. According to Thm. 8.1 (the sum rule) and Cor. 7.1.2 (the chain rule) of Rockafellar [29], we have

$$\begin{aligned}\overline{\partial} f(0,\overline{x},\overline{p}) &\subseteq \{(-v,\pi,v) \,:\, (\pi,v)\in \overline{\partial} H(\overline{x},\overline{p})\} + (\overline{v}+R\,\mathrm{cl}\,\mathbb{B})\times\{(0,0)\}\\ \overline{\partial}^{\infty} f(0,\overline{x},\overline{p}) &\subseteq \left\{(-v,\pi,v) \,:\, (\pi,v)\in \overline{\partial}^{\infty} H(\overline{x},\overline{p})\right\}.\end{aligned}$$

Thus (3.7) yields

$$\begin{aligned}\overline{\partial}\widetilde{H}(\overline{x},\overline{p}) &\subseteq \mathrm{cl}\,\mathrm{co}\Big(\Big[\overline{\partial} H(\overline{x},\overline{p})\cap(\mathbb{R}^n\times(\overline{v}+R\,\mathrm{cl}\,\mathbb{B}))\Big]\\ &\qquad + \Big[\overline{\partial}^{\infty} H(\overline{x},\overline{p})\cap(\mathbb{R}^n\times\{0\})\Big]\Big)\\ &\subseteq \mathrm{cl}\,\mathrm{co}\left(\overline{\partial} H(\overline{x},\overline{p})+\overline{\partial}^{\infty} H(\overline{x},\overline{p})\right).\end{aligned}\tag{3.8}$$

Since the set on the left side is nonempty, the set on the right must also be nonvoid. This forces $\overline{\partial} H(\overline{x},\overline{p})\neq\emptyset$, a situation in which $\overline{\partial}^{\infty} H(\overline{x},\overline{p})$ is known to equal the recession cone of $\overline{\partial} H(\overline{x},\overline{p})$. In particular, $\overline{\partial} H(\overline{x},\overline{p})+\overline{\partial}^{\infty} H(\overline{x},\overline{p})$ is a subset of the closed convex set $\overline{\partial} H(\overline{x},\overline{p})$. Therefore (3.8) implies (3.4), and the objective of this section is accomplished.

4. General necessary conditions. We now combine the efforts of the first three sections to prove necessary conditions for optimality in (P) without the boundedness and Lipschitz continuity assumptions used previously.

Our first result, Theorem 4.1, extends the Hamiltonian necessary conditions of Theorem 1.2 to the unbounded case. Although this is a significant advance in itself, it is superseded by Theorem 4.3 below, in which the same hypotheses are used to produce an adjoint function satisfying the Hamiltonian inclusion, a refined Euler–Lagrange inclusion, and the Weierstrass–Pontryagin maximum condition, simultaneously. Our purpose in proving Theorem 4.1 first is to clarify the roles of §§2 and 3 in eliminating boundedness assumptions. This provides a convenient point at which to reflect on what has been achieved, and to prepare for the next step.

Hypotheses (H1)–(H4) mentioned in the statement below are listed in §1; the notions required in assumptions (i) and (ii) are described in Definition 2.3. As observed in §2, assumptions (i) and (ii) can be replaced by stronger hypotheses requiring appropriate sub-Lipschitzian behaviour at every point of Ω if the arc $\overline{x}$ is not known in advance.

THEOREM 4.1 (Hamiltonian necessary conditions). *Assume* (H1)–(H4). *Suppose that the arc $\overline{x}$ solves problem (P), and that the constraint qualification below is satisfied:*

(CQ) *The cone $\overline{N}_X(t,\overline{x}(t))$ is pointed for all t in $[a,b]$.*

Suppose further that one of the following two conditions holds:

(i) *The arc $\overline{x}$ is Lipschitzian, and the multifunction F is sub-Lipschitzian at every point $(t,\overline{x}(t))$ of* $\mathrm{gph}\,\overline{x}$; *or*

(ii) *The multifunction F is integrably sub-Lipschitzian in the large at every point $(t, \overline{x}(t))$ of* $\operatorname{gph} \overline{x}$.

Then there exist a scalar $\lambda \in \{0, 1\}$ and a function $p \in BV([a,b]; \mathbb{R}^n)$, not both zero, such that we have the following:

(a) *The Hamiltonian inclusion*

$$(-\dot{p}(t), \dot{\overline{x}}(t)) \in \overline{\partial} H(t, \overline{x}(t), p(t)) - \overline{N}_X(t, \overline{x}(t)) \times \{0\} \quad \text{a.e. } t \in [a,b];$$

(b) *The transversality inclusion*

$$(p(a), -p(b)) \in \lambda \partial \ell(\overline{x}(a), \overline{x}(b)) + N_S(\overline{x}(a), \overline{x}(b)); \text{ and}$$

(c) *The singular part of the measure dp is $\overline{N}_X(t, \overline{x}(t))$-valued and, in particular, is supported on the set*

$$\{t : \overline{N}_X(t, \overline{x}(t)) \neq \{0\}\} = \{t \in [a,b] : (t, \overline{x}(t)) \in \operatorname{bdry} \operatorname{gph} X\}.$$

Remark. The interpretation of inclusion (a) in Theorem 4.1 is the same as that given in Theorem 1.2. That is, (a) asserts that for some integrable selection $\nu(t) \in \overline{N}_X(t, \overline{x}(t))$ for all $t \in [a,b]$, we have

$$(-\dot{p}(t) + \nu(t), \dot{\overline{x}}(t)) \in \overline{\partial} H(t, \overline{x}(t), p(t)) \quad \text{a.e. } t \in [a,b].$$

Proof. Under either hypothesis (i) or (ii), Proposition 2.4 describes a choice of $R(t)$ for which the truncated multifunction $\widetilde{F}(t,x) := F(t,x) \cap (\dot{\overline{x}}(t) + R(t) \operatorname{cl} \mathbb{B})$ satisfies both assumptions (i) and (ii) of Theorem 1.2. Of course, the arc $\overline{x}$ is a trajectory for $\widetilde{F}$, and consequently solves the problem $(\widetilde{P})$ defined by replacing F with $\widetilde{F}$ in (P). Apply Theorem 1.2 to $\overline{x}$ in $(\widetilde{P})$; this produces a constant λ and an adjoint function p of bounded variation, not both zero, together with a selection $\nu(t)$ of $\overline{N}_X(t, \overline{x}(t))$, satisfying all the conclusions of Theorem 1.2. Let us denote these by $(\widetilde{\text{a}})$–$(\widetilde{\text{c}})$, since they involve the multifunction $\widetilde{F}$ and its associated Hamiltonian $\widetilde{H}$.

We show that these three conditions imply the desired conclusions (a)–(c) for the same λ, p, and ν. Indeed, conditions $(\widetilde{\text{b}})$ and $(\widetilde{\text{c}})$ are the same as the desired assertions (b) and (c), while $(\widetilde{\text{a}})$ implies (a). To justify the latter assertion, fix $t \in (a,b)$ and consider the multifunctions $F(t, \cdot)$ and $\widetilde{F}(t, \cdot)$. Our assumption of either (i) or (ii) implies that the given multifunction $F(t, \cdot)$ is continuous in the weak sense required in §3, and that the truncated multifunction $\widetilde{F}(t, \cdot)$ satisfies the Lipschitz condition (3.1) (see Proposition 2.4). Hypothesis (3.2) for $\overline{p} = p(t)$ is a well-known consequence of $(\widetilde{\text{a}})$ (see Clarke [2, Prop. 3.2.4(d)]). The conclusion is that for almost every time $t \in [a,b]$, $\overline{\partial} \widetilde{H}(t, \overline{x}(t), p(t)) \subseteq \overline{\partial} H(t, \overline{x}(t), p(t))$. Hence (a) follows from $(\widetilde{\text{a}})$, as required. □

Strict convexity. The crucial observation that allowed us to unify the adjoint inclusions of Hamilton, Euler–Lagrange, and Weierstrass–Pontryagin in [13] was that the Hamiltonian inclusion actually implies the other two inclusions when $\dot{\overline{x}}(t)$ is almost always an extreme point of the (convex) velocity set $F(t, \overline{x}(t))$. We now use the same observation to extend Theorem 4.1. Let us continue under the hypotheses of that result.

Consider the function

$$L(t,v) := \sqrt{1 + |v - \dot{\overline{x}}(t)|^2} - 1.$$

Notice that L is nonnegative, smooth, and strictly convex, with $L(t,\dot{\overline{x}}(t)) \equiv 0$ and $L_v(t,\dot{\overline{x}}(t)) \equiv 0$. Observe also that for each fixed t, the function $L(t,\cdot)$ is globally Lipschitzian of rank 1 on $\mathbb{R}^n$. These properties are important in our analysis of the following auxiliary problem, whose state (x,y) evolves in $\mathbb{R}^n \times \mathbb{R}$:

$$(\mathcal{P}) \qquad \begin{array}{ll} \text{minimize} & \ell(x(a),x(b)) + y(b) \\ \text{subject to} & (\dot{x}(t),\dot{y}(t)) \in [F(t,x(t)) \times \mathbb{R}] \cap \operatorname{epi} L(t,\cdot) \quad \text{a.e. } t \in [a,b], \\ & (x(a),x(b)) \in S, \qquad y(a) = 0, \\ & (x(t),y(t)) \in X(t) \times \mathbb{R} \quad \forall t \in [a,b]. \end{array}$$

It is clear that any absolutely continuous function $(x(t),y(t))$ admissible for the auxiliary problem $(\mathcal{P})$ has a first component admissible for the original problem (P), while the second component obeys $y(b) \geq 0$. Therefore, the objective value in $(\mathcal{P})$ is always at least as large as the objective value in (P). However, the arc $(\overline{x},\overline{y})$ for which $\overline{y}(t) \equiv 0$ is admissible for $(\mathcal{P})$, and has an objective value equal to the minimum value in (P). Therefore, it must be optimal in $(\mathcal{P})$.

The dynamic constraint in $(\mathcal{P})$ involves the unbounded multifunction $\mathcal{F}\colon \Omega \times \mathbb{R} \rightrightarrows \mathbb{R}^n \times \mathbb{R}$ defined by

$$\mathcal{F}(t,x,y) := [F(t,x) \times \mathbb{R}] \cap \operatorname{epi} L(t,\cdot).$$

We now show that $\mathcal{F}$ inherits the sub-Lipschitzian property of F along $\overline{x}$, and consequently admits a truncation displaying the boundedness and Lipschitz continuity properties required for the application of Theorem 1.2. Since the y dependence of $\mathcal{F}$ is trivial, we suppress it in the notation below.

LEMMA 4.2. *Suppose that hypothesis* (i) *or* (ii) *of Theorem* 4.1 *holds for the multifunction F relative to the arc $\overline{x}$. Then the same hypothesis holds for $\mathcal{F}$ relative to $\overline{x}$. Moreover, there exists a nonnegative function R such that both truncated multifunctions below satisfy hypotheses* (i) *and* (ii) *of Theorem* 1.2 *on some relatively open subset of $[a,b] \times \mathbb{R}^n$ containing the following graph of $\overline{x}$:*

$$\widetilde{F}(t,x) := F(t,x) \cap \left[\dot{\overline{x}}(t) + R(t)\,\mathrm{cl}\,\mathbb{B}\right],$$
$$\widetilde{\mathcal{F}}(t,x) := \mathcal{F}(t,x) \cap \left[(\dot{\overline{x}}(t),0) + R(t)(\mathrm{cl}\,\mathbb{B} \times [-1,1])\right].$$

Proof. (ii) Suppose F satisfies hypothesis 4.1(ii) relative to $\overline{x}$. Let any $\overline{t} \in [a,b]$ be given. Then by hypothesis, there must be constants $\varepsilon > 0$ and $\beta \geq 0$, together with a nonnegative function α integrable on $(\overline{t}-\varepsilon,\overline{t}+\varepsilon) \cap [a,b]$, such that

$$(*) \qquad F(t,x') \cap \rho\,\mathrm{cl}\,\mathbb{B} \subseteq F(t,x) + (\alpha(t) + \beta\rho)\,|x'-x|\,\mathrm{cl}\,\mathbb{B}$$

for all $t \in (\overline{t}-\varepsilon,\overline{t}+\varepsilon) \cap [a,b]$, all x,x' in $\overline{x}(\overline{t}) + \varepsilon\mathbb{B}$, and all $\rho \geq 0$.

To prove a similar statement involving $\mathcal{F}$, let any $\rho \geq 0$ and $t \in (\overline{t}-\varepsilon,\overline{t}+\varepsilon) \cap [a,b]$ be given, together with any two points $x,x' \in \overline{x}(\overline{t}) + \rho\,\mathrm{cl}\,\mathbb{B}$. Then for any point (v',r') in $\mathcal{F}(t,x') \cap \rho(\mathrm{cl}\,\mathbb{B} \times [-1,1])$, we have $v' \in F(t,x') \cap \rho\,\mathrm{cl}\,\mathbb{B}$. Thus $(*)$ provides a point $v \in F(t,x)$ such that $|v'-v| \leq (\alpha(t)+\beta\rho)|x'-x|$. Now $L(t,\cdot)$ is Lipschitz of rank 1, and $r' \geq L(t,v')$. Hence there must be a point $r \geq L(t,v)$ for which $|r'-r| \leq |v'-v|$. Thus (v,r) is a point in $\mathcal{F}(t,x)$ for which

$$\begin{aligned} |(v',r') - (v,r)| &\leq |v'-v| + |r'-r| \\ &\leq 2|v'-v| \\ &\leq 2(\alpha(t)+\beta\rho)|x'-x|. \end{aligned}$$

Since (v', r') is arbitrary, this argument proves that

$$(**) \quad \mathcal{F}(t,x') \cap \rho\,(\mathrm{cl}\,\mathbb{B} \times [-1,1]) \subseteq \mathcal{F}(t,x) + 2\,(\alpha(t) + \beta\rho)\,|x' - x|\,(\mathrm{cl}\,\mathbb{B} \times [-1,1])\,.$$

Hypothesis 4.1(ii) for $\mathcal{F}$ follows.

Now if we multiply both α and β in $(*)$ by 2, we find that both multifunctions F and $\mathcal{F}$ are integrably sub-Lipschitzian in the large at $(\bar{t}, \overline{x}(\bar{t}))$ with the same choices of ε, $2\alpha(t)$, and 2β in the definition. Reviewing the proof of Proposition 2.4, we deduce that the function $R(t) := 1 + 2\alpha(t) + \left|\dot{\overline{x}}(t)\right|$ provides a truncation radius for which each multifunction $\widetilde{F}$, $\widetilde{\mathcal{F}}$ satisfies hypotheses (i) and (ii) of Theorem 1.2 on some neighborhood of $\mathrm{gph}\,\overline{x}$. We restrict attention to the intersection of these two neighborhoods to obtain the desired conclusion.

(i) If F satisfies hypothesis 4.1(i) relative to $\overline{x}$, then an argument similar to that just given shows that for every point $\bar{t} \in [a,b]$ and every $\rho \geq 0$, there exist constants $\varepsilon > 0$ and $\alpha \geq 0$ such that

$$(\dagger) \qquad F(t,y) \cap \rho\,\mathrm{cl}\,\mathbb{B} \subseteq F(t,x) + 2\alpha|y - x|\,\mathrm{cl}\,\mathbb{B}$$

and

$$(\ddagger) \qquad \mathcal{F}(t,y) \cap \rho\,(\mathrm{cl}\,\mathbb{B} \times [-1,1]) \subseteq \mathcal{F}(t,x) + 2\alpha|y - x|\,(\mathrm{cl}\,\mathbb{B} \times [-1,1])$$

for all $t \in (\bar{t} - \varepsilon, \bar{t} + \varepsilon) \cap [a,b]$ and all x, y in $\overline{x}(\bar{t}) + \varepsilon\mathbb{B}$. Just as above, the proof of Proposition 2.4 shows that any constant value of $R > 0$ provides a truncation radius suitable for both multifunctions F and $\mathcal{F}$ at once. □

Just as in the proof of Theorem 4.1, the arc $(\overline{x}, 0)$ that solves $(\mathcal{P})$ remains optimal for the problem $(\widetilde{\mathcal{P}})$ obtained from $(\mathcal{P})$ by changing $\mathcal{F}$ to $\widetilde{\mathcal{F}}$. We apply Theorem 1.2 to deduce that there exist a scalar $\lambda \geq 0$ and a function $(p,q)\colon [a,b] \to \mathbb{R}^n \times \mathbb{R}$ of bounded variation, not both zero, together with a selection $\nu(t) \in \overline{N}_X(t, \overline{x}(t))$ for all $t \in [a,b]$ such that

(a) $(-\dot{p}(t) + \nu(t), \dot{\overline{x}}(t), 0) \in \overline{\partial}\widetilde{\mathcal{H}}(t, \overline{x}(t), p(t), q(t))$ almost everywhere in $[a,b]$, $\dot{q}(t) = 0$ almost everywhere in $[a,b]$;

(b) $(p(a), -p(b)) \in \lambda\partial\ell(\overline{x}(a), \overline{x}(b)) + N_S\,(\overline{x}(a), \overline{x}(b))$, $q(b) = -\lambda$;

(c) The singular part of the measure (dp, dq) is $\overline{N}_X(t, \overline{x}(t)) \times \{0\}$-valued and, in particular, is supported on the set

$$\left\{t \,:\, \overline{N}_X(t, \overline{x}(t)) \neq \{0\}\right\} = \{t \in [a,b] \,:\, (t, \overline{x}(t)) \in \mathrm{bdry}\,\mathrm{gph}\,X\}\,.$$

Here we use the fact that $\widetilde{\mathcal{F}}$ is independent of y to simplify the Hamiltonian inclusion; we need only deal with the reduced Hamiltonian given by

$$\widetilde{\mathcal{H}}(t,x,p,q) := \sup\left\{\langle p\,,\, v\rangle + qr \,:\, (v,r) \in \widetilde{\mathcal{F}}(t,x)\right\}.$$

Conditions (a)–(c) together imply that the adjoint function's $q(t)$ component is actually constant, with the value $-\lambda$. Thus conclusions (b) and (c) reduce to the expected transversality and support conditions associated with the adjoint function p, while conclusion (a) may be written as follows:

$$(4.1) \qquad (-\dot{p}(t) + \nu(t), \dot{\overline{x}}(t), 0) \in \overline{\partial}\widetilde{\mathcal{H}}(t, \overline{x}(t), p(t), -\lambda) \quad \text{a.e. } t \in [a,b].$$

In the remainder of this section we use inclusion (4.1) to show that the function p satisfies the Hamiltonian inclusion, a refined Euler–Lagrange inclusion, and the Weierstrass–Pontryagin maximum condition for the original problem (P).

The maximum condition. We have seen in Lemma 4.2 that $\widetilde{\mathcal{F}}$ is a multifunction satisfying hypotheses (i) and (ii) of Theorem 1.2. Under these assumptions, Clarke [2, Prop. 3.2.4(d)] shows that inclusion (4.1) implies

$$(p(t), -\lambda) \in N_{\widetilde{\mathcal{F}}(t,\overline{x}(t))}\left(\dot{\overline{x}}(t), 0\right) \quad \text{a.e. } t \in [a,b]. \tag{4.2}$$

However, for each $t \in [a,b]$, the compact set $\widetilde{\mathcal{F}}(t,\overline{x}(t))$ coincides with the unbounded set $\mathcal{F}(t,\overline{x}(t))$ on a neighborhood of $(\dot{\overline{x}}(t), 0)$. Hence these two sets have the same normal cone at this point. Using the calculus of convex normal cones (Rockafellar [21], or [29, Cor. 8.1.1]), we deduce that for almost every $t \in [a,b]$,

$$\begin{aligned}(p(t), -\lambda) &\in N_{\mathcal{F}(t,\overline{x}(t))}\left(\dot{\overline{x}}(t), 0\right) \\ &= N_{F(t,\overline{x}(t))\times\mathbb{R}\cap \operatorname{epi} L(t,\cdot)}\left(\dot{\overline{x}}(t), 0\right) \\ &\subseteq N_{F(t,\overline{x}(t))\times\mathbb{R}}\left(\dot{\overline{x}}(t), 0\right) + N_{\operatorname{epi} L(t,\cdot)}\left(\dot{\overline{x}}(t), 0\right) \\ &= N_{F(t,\overline{x}(t))}\left(\dot{\overline{x}}(t)\right) \times \{0\} + \{0\} \times (-\infty, 0].\end{aligned}$$

(The last step uses the fact that $N_{\operatorname{epi} L(t,\cdot)}\left(\dot{\overline{x}}(t), 0\right)$ is the convex cone generated by $\partial L(t,\dot{\overline{x}}(t)) \times \{-1\} = \{(0,-1)\}$.) The first component of this inclusion gives the desired maximum condition for p, namely,

$$p(t) \in N_{F(t,\overline{x}(t))}\left(\dot{\overline{x}}(t)\right) \quad \text{a.e. } t \in [a,b]. \tag{4.3}$$

The Hamiltonian inclusion. Observe that the function $\widetilde{\mathcal{H}}$ can be written as follows:

$$\widetilde{\mathcal{H}}(t,x,p,q) = \begin{cases} \sup\{\langle p\,,\, v\rangle + qL(t,v) \,:\, v \in \widetilde{F}(t,x)\}, & \text{if } q < 0, \\ \sup\{\langle p\,,\, v\rangle \,:\, v \in \widetilde{F}(t,x)\} + qR(t), & \text{if } q \geq 0. \end{cases}$$

This is precisely the sort of function studied in §4 of our previous work [13], where we examined its relationship to the function below:

$$\widetilde{\mathcal{H}}_\lambda(t,x,p) := \sup\left\{\langle p\,,\, v\rangle - \lambda L(t,v) \,:\, v \in \widetilde{F}(t,x)\right\}.$$

Lemma 4.2 ensures that for each fixed $t \in [a,b]$, the multifunction $\widetilde{F}(t,\cdot)$ in this expression obeys the standing assumptions (A1)–(A3) of [13, §4].

This observation allows us to apply [13, Thm. 4.4] to inclusion (4.1), and thereby derive

$$(-\dot{p}(t) + \nu(t), \dot{\overline{x}}(t)) \in \overline{\partial}\widetilde{\mathcal{H}}_\lambda(t,\overline{x}(t),p(t)) \quad \text{a.e. } t \in [a,b]. \tag{4.4}$$

In the case where $\lambda = 0$, $\widetilde{\mathcal{H}}_\lambda$ coincides with $\widetilde{H}$. Thus inclusion (4.4) is equivalent to

$$(-\dot{p}(t) + \nu(t), \dot{\overline{x}}(t)) \in \overline{\partial}\widetilde{H}(t,\overline{x}(t),p(t)) \quad \text{a.e. } t \in [a,b]. \tag{4.5}$$

In the case where $\lambda = 1$, inclusion (4.4) implies (4.5) via [13, Cor. 4.3(b)]. To justify this, fix any time t where (4.4) holds and apply Clarke [2, Prop. 2.5.3] to deduce that $\dot{\overline{x}}(t) \in \partial_p\widetilde{\mathcal{H}}_1(t,\overline{x}(t),p(t))$. Conversely, elementary convex analysis shows that any vector v lying in $\partial_p\widetilde{\mathcal{H}}_1(t,\overline{x}(t),p(t))$ must maximize the function $v' \mapsto \langle p\,,\, v'\rangle - L(t,v')$ over the set $\widetilde{F}(t,\overline{x}(t))$. Because this function is strictly concave by construction, only one maximizer can exist, namely $\dot{\overline{x}}(t)$. Consequently, $\overline{\partial}_p\widetilde{\mathcal{H}}_1(t,\overline{x}(t),p(t)) = \{\dot{\overline{x}}(t)\}$.

The union appearing in [13, Cor. 4.3(b)] therefore involves the choices $v = \dot{\overline{x}}(t)$ and $z \in \overline{\partial}_v L(t, \overline{x}(t)) = \{0\}$. This implies that the right-hand side of (4.4) is a subset of the right-hand side of (4.5).

With (4.5) in hand, we note that the Hamiltonian analysis of §3 allows us to replace $\widetilde{H}$ with H in (4.5) just as we did in the proof of Theorem 4.1. The result is the desired Hamiltonian inclusion for p:

$$(-\dot{p}(t) + \nu(t), \dot{\overline{x}}(t)) \in \overline{\partial} H(t, \overline{x}(t), p(t)) \quad \text{a.e. } t \in [a, b]. \tag{4.6}$$

The Euler–Lagrange inclusion. Once again we rely upon the technical results of Loewen and Rockafellar [13], as extended by Rockafellar [30]. To streamline the discussion, we fix a time $t \in [a, b]$ at which (4.1) holds, and suppress t in the notation below. Thus our starting point is the inclusion

$$(-\dot{p} + \nu, \dot{\overline{x}}, 0) \in \overline{\partial} \widetilde{\mathcal{H}}(\overline{x}, p, -\lambda). \tag{4.7}$$

Rockafellar [30, Thm. 3.1] provides a far-reaching analogue of [13, Lemma 4.5] in which limiting normals and subgradients replace Clarke normals and subgradients. Applying this result to our problem (with $f = \Psi_{\widetilde{\mathcal{F}}}$), we find that

$$\begin{aligned} -\partial(-\widetilde{\mathcal{H}})(\overline{x}, p, -\lambda) \subseteq \{(-u, v, \ell) \,:\, & (u, p, -\lambda) \in N_{\operatorname{gph} \widetilde{\mathcal{F}}}(\overline{x}, v, \ell), \\ & (p, -\lambda) \in N_{\widetilde{\mathcal{F}}(x)}(v, \ell)\}. \end{aligned} \tag{4.8}$$

Since the function $\widetilde{\mathcal{H}}$ is Lipschitzian, we have $\overline{\partial} \widetilde{\mathcal{H}} = -\overline{\partial}(-\widetilde{\mathcal{H}}) = \operatorname{co} -\partial(-\widetilde{\mathcal{H}})$.

Thus it must be possible to express the point $(-\dot{p}+\nu, \dot{\overline{x}}, 0)$ as a convex combination of elements from the right side of (4.8). That is, there must be some $N \in \mathbf{N}$ and some constants $\alpha_i \geq 0$ with $\sum \alpha_i = 1$ such that

$$(-\dot{p} + \nu, \dot{\overline{x}}, 0) = \sum_{i=1}^{N} \alpha_i (-u_i, v_i, \ell_i), \tag{4.9a}$$

where, for each i,

$$(u_i, p, -\lambda) \in N_{\operatorname{gph} \widetilde{\mathcal{F}}}(\overline{x}, v_i, \ell_i), \qquad (p, -\lambda) \in N_{\widetilde{\mathcal{F}}(\overline{x})}(v_i, \ell_i). \tag{4.9b}$$

We have already shown that $(p, -\lambda) \in N_{\widetilde{\mathcal{F}}(\overline{x})}(\dot{\overline{x}}, 0)$ (see (4.2)). We now add the observation that $(\dot{\overline{x}}, 0)$ is an extreme point of the set $\widetilde{\mathcal{F}}(\overline{x})$. This is obvious, since $\widetilde{\mathcal{F}}(\overline{x})$ is the intersection of the compact convex sets $\operatorname{epi} L$ and $\widetilde{F}(\overline{x}) \times \mathbb{R}$, and $(\dot{\overline{x}}, 0)$ is an extreme point of the first of these by the strict convexity of L. It follows that $(\dot{\overline{x}}, 0)$ is the only point (v, ℓ) for which $(p, -\lambda) \in N_{\widetilde{\mathcal{F}}(\overline{x})}(v, \ell)$. This forces $(v_i, \ell_i) = (\dot{\overline{x}}, 0)$ in (4.9), and thus implies

$$\dot{p} - \nu \in \operatorname{co} \left\{ u \,:\, (u, p, -\lambda) \in N_{\operatorname{gph} \widetilde{\mathcal{F}}}(\overline{x}, \dot{\overline{x}}, 0) \right\}. \tag{4.10}$$

To simplify this assertion, temporarily think of L as a function of both x and v ($L(x, v) \equiv L(v)$) in order to write $\operatorname{gph} \widetilde{\mathcal{F}} = \operatorname{epi}\left(L + \Psi_{\operatorname{gph} \widetilde{F}}\right)$. This allows us to transcribe the inclusion characterizing the right-hand side of (4.10) as

$$(u, p, -\lambda) \in N_{\operatorname{epi}\left(L + \Psi_{\operatorname{gph} \widetilde{F}}\right)}(\overline{x}, \dot{\overline{x}}, 0).$$

The same arguments used in the last paragraph of the proof of Theorem 1.2, together with the observation that $\partial L(\overline{x},\dot{\overline{x}}) = \{(0,0)\}$, show that this inclusion implies

$$(u,p) \in N_{\operatorname{gph}\widetilde{F}}\left(\overline{x},\dot{\overline{x}}\right) = N_{\operatorname{gph}F}\left(\overline{x},\dot{\overline{x}}\right).$$

The equality here holds because the sets $\operatorname{gph}\widetilde{F}$ and $\operatorname{gph}F$ coincide on a neighborhood of the point $(\overline{x},\dot{\overline{x}})$, so their limiting normal cones at this point are identical. Using this statement in (4.10) leads to the following inclusion, in which we revert to fully explicit notation:

$$\dot{p}(t) - \nu(t) \in \operatorname{co}\left\{u \,:\, (u,p(t)) \in N_{\operatorname{gph}F(t,\cdot)}\left(\overline{x}(t),\dot{\overline{x}}(t)\right)\right\}. \tag{4.11}$$

This inclusion holds for all t outside a null subset of $[a,b]$. It is the form of the Euler–Lagrange inclusion we wish to record.

Main result. We now summarize the results of the derivation above. Conclusions (a)–(c) in the following formal statement have already been established as lines (4.3), (4.6), and (4.11) above. We remind the reader that our notation differs slightly from that of Clarke [2], as indicated in the last paragraph of the introduction.

THEOREM 4.3 (General necessary conditions). *Assume* (H1)–(H4). *Suppose that the arc $\overline{x}$ solves problem (P), and that the constraint qualification below is satisfied:*

(CQ) *The cone $N_X(t,\overline{x}(t))$ is pointed for all t in $[a,b]$.*

Suppose further that one of the following two conditions holds:

(i) *The arc $\overline{x}$ is Lipschitzian, and the multifunction F is sub-Lipschitzian at every point $(t,\overline{x}(t))$ of $\operatorname{gph}\overline{x}$; or*

(ii) *The multifunction F is integrably sub-Lipschitzian in the large at every point $(t,\overline{x}(t))$ of $\operatorname{gph}\overline{x}$.*

Then there exist a scalar $\lambda \in \{0,1\}$ and a function $p \in BV([a,b];\mathbb{R}^n)$, not both zero, such that for almost all $t \in [a,b]$, we have

(a) *The Hamiltonian inclusion*

$$(-\dot{p}(t),\dot{\overline{x}}(t)) \in \overline{\partial}H(t,\overline{x}(t),p(t)) - N_X(t,\overline{x}(t)) \times \{0\};$$

(b) *The Euler–Lagrange inclusion*

$$\dot{p}(t) \in \operatorname{co}\left\{u \,:\, (u,p(t)) \in N_{\operatorname{gph}F(t,\cdot)}\left(\overline{x}(t),\dot{\overline{x}}(t)\right)\right\} + \overline{N}_X(t,\overline{x}(t)); \text{ and}$$

(c) *The Weierstrass–Pontryagin maximum condition*

$$\left\langle p(t)\,,\,\dot{\overline{x}}(t)\right\rangle = max\{\langle p(t)\,,\,v\rangle \,:\, v \in F(t,\overline{x}(t))\}.$$

The adjoint function p also satisfies the following:

(d) *The transversality inclusion*

$$(p(a),-p(b)) \in \lambda\partial\ell(\overline{x}(a),\overline{x}(b)) + N_S\left(\overline{x}(a),\overline{x}(b)\right); \text{ and}$$

(e) *The singular part of the measure dp is $N_X(t,\overline{x}(t))$-valued, and in particular is supported on the set*

$$\{t \,:\, N_X(t,\overline{x}(t)) \neq \{0\}\} = \{t \in [a,b] \,:\, (t,\overline{x}(t)) \in \operatorname{bdry}\operatorname{gph}X\}.$$

Remarks. 1. If the state constraint is inactive along the optimal arc $\overline{x}$ and the endpoint constraint set S has the form $C \times \mathbb{R}^n$ or $\mathbb{R}^n \times D$ for some closed sets C, D, then we may take $\lambda = 1$ in Theorem 4.3. This is not completely obvious from the theorem's statement, but it does follow from the proof given above. To see this, note that the scalar λ and the function p described in the conclusions of the theorem actually arise as the dual variables in the auxiliary problem $(\widetilde{\mathcal{P}})$.

Problem $(\widetilde{\mathcal{P}})$ has a Hamiltonian $\widetilde{\mathcal{H}}$ for which the mapping $x' \mapsto \mathcal{H}(t, x', p)$ is Lipschitz of rank $k(t)|p|$ for some integrable function k. Under the extra assumptions above, we have $\nu(t) \equiv 0$, so the adjoint function p must be absolutely continuous and satisfy the differential inequality $|\dot{p}(t)| \leq k(t)|p(t)|$ almost everywhere. If the endpoint conditions described above are satisfied, assuming $\lambda = 0$ leads to either $p(a) = 0$ or $p(b) = 0$. In either case, Gronwall's lemma implies $p(t) \equiv 0$, which is a contradiction.

2. A separated form of the Hamiltonian inclusion can be asserted concurrently with (a)–(c) above. To derive it, note that since $\widetilde{H}$ is locally Lipschitz, inclusion (4.5) implies

$$(-\dot{p}(t) + \nu(t), \dot{\overline{x}}(t)) \in \operatorname{co}\left[\partial_x \widetilde{H}(t, \overline{x}(t), p(t)) \times \partial_p \widetilde{H}(t, \overline{x}(t), p(t))\right] \quad \text{a.e. } t \in [a, b].$$

The second component simply reiterates (4.3), while the first asserts that

$$-\dot{p}(t) + \nu(t) \in \operatorname{co} \partial_x \widetilde{H}(t, \overline{x}(t), p(t)) \quad \text{a.e. } t \in [a, b].$$

Arguments similar to those in §3 allow us to replace $\widetilde{H}$ with H in this statement: The result is the separated Hamiltonian inclusion

$$\begin{aligned} -\dot{p}(t) &\in \operatorname{co} \partial_x H(t, \overline{x}(t), p(t)) - \overline{N}_X(t, \overline{x}(t)), \\ \dot{\overline{x}}(t) &\in \partial_p H(t, \overline{x}(t), p(t)) \quad \text{a.e. } t \in [a, b]. \end{aligned} \tag{4.12}$$

5. Conclusion. Theorem 4.3 is the most general set of necessary conditions available for differential inclusion control problems. To substantiate this claim, we review the literature and discuss several pertinent examples in this section.

The bounded case. Note first that Theorem 4.3 is a strict extension of our best previous result for bounded differential inclusions, the case $L \equiv 0$ of [13, Thm. 1.1]. To prove this, it suffices to show that the boundedness and Lipschitz continuity hypotheses of [13], which coincide with conditions (i)–(ii) of the current Theorem 1.2, imply the hypotheses of Theorem 4.3. Indeed, suppose that the multifunction F satisfies condition (ii) of Theorem 1.2. Then the choices $\beta = 0$ and $\alpha = k$ in Definition 2.3(b) show that F is integrably sub-Lipschitzian in the large at every point (t, x) in Ω. Hence hypothesis (ii) of Theorem 4.3 is satisfied; the conclusions either reproduce those of [13, Thm. 1.1] or are strictly stronger. Note in particular that hypothesis (i) is completely superfluous both in [13] and in Theorem 1.2.

The two conclusions of Theorem 4.3 that differ from their counterparts in [13, Thm. 1.1] are the Euler–Lagrange inclusion (b) and the transversality inclusion (d). The right-hand side of (d) is always a subset of its cognate phrased in terms of Clarke subgradients and normals, although the two right-hand sides coincide whenever the function ℓ and the set S are Clarke regular at the point $(\overline{x}(a), \overline{x}(b))$. Likewise, the Euler–Lagrange inclusion (b) readily implies (but may not be equivalent to) the more familiar form involving Clarke's normal cone,

$$(\dot{p}(t), p(t)) \in \operatorname{co} N_{\operatorname{gph} F}\left(\overline{x}(t), \dot{\overline{x}}(t)\right) - \overline{N}_X(t, \overline{x}(t)) \times \{0\} \text{ a.e.} \tag{5.1}$$

The formulation in (b) has the advantage of applying the convex hull only to variables associated with the derivatives of the adjoint function p. The routine use of weak convergence of the derivatives both in existence theory and in the derivation of necessary conditions makes it difficult to imagine making do with less convexity than this.

The possibility of refining the Euler–Lagrange inclusion in our main theorem was suggested by a recent preprint of Boris Mordukhovich, a pioneer in the systematic reduction of convexity hypotheses in nonsmooth analysis. His manuscript [18] introduces a version of the Euler–Lagrange inclusion whose counterpart in our problem would read as follows:

$$(\dot{p}(t) - \nu(t), \dot{\overline{x}}(t)) \in \operatorname{co}\{(u,v) : (u,p(t)) \in N_{\operatorname{gph} F(t,\cdot)}(\overline{x}(t),v), \quad p(t) \in N_{F(t,\overline{x}(t))}(v)\}. \tag{5.2}$$

(Here, as in §4, $\nu(t)$ is a selection of $\overline{N}_X(t,\overline{x}(t))$. Mordukhovich's work does not allow for state constraints, so his version of (5.2) involves an absolutely continuous function p and $\nu \equiv 0$.) This is clearly a consequence of inclusion (4.11). The two are equivalent if, for almost every t, the maximum value of $\langle p(t), v\rangle$ over $v \in F(t,\overline{x}(t))$ is attained at the unique point $v = \dot{\overline{x}}(t)$. Without this hypothesis, however, the right-hand side of (5.2) may be a proper superset of the right-hand side of (4.11). This is demonstrated by Example 5.2, below. Thus the necessary conditions of Mordukhovich [18] are strictly superseded by those given here. Indeed, Rockafellar's dualization result [30, Thm. 3.1], used to prove the Euler–Lagrange inclusion (4.11), implies that under Mordukhovich's hypotheses in [18], inclusion (5.2) actually follows from the Hamiltonian inclusion in Theorem 1.2.

Although several technical results from our previous work [13] were used to prove Theorem 4.3, this paper's development starts from [13, Thm. 2.8]. Since we recover [13, Thm. 1.1] as a corollary (at least in the case $L \equiv 0$), this paper provides a much simpler alternative to the formidable sequential arguments of [13, §3]. This makes sense, because the sequences of adjoint functions required there arose directly out of a less sophisticated truncation procedure than the one introduced in the current work.

The simultaneous assertion of the adjoint inclusion in both Hamiltonian and Eulerian forms is a significant feature that Theorem 4.3 shares with the main result of [13]. The relationship between these two inclusions in their various forms is still not completely understood. For example, we now show that the Euler–Lagrange inclusion in Clarke's form (5.1) bears no simple relationship to the Hamiltonian inclusion.

EXAMPLE 5.1. *There exist a compact convex valued, Lipschitzian multifunction* $F\colon \mathbb{R} \rightrightarrows \mathbb{R}$ *and a pair of arcs* x, p *on* $[a,b]$ *such that for all* $t \in [a,b]$, *the Clarke form of the Euler–Lagrange inclusion holds, i.e.,*

$$(\dot{p}(t), p(t)) \in \overline{N}_{\operatorname{gph} F}(x(t), \dot{x}(t)). \tag{5.3a}$$

However, the following two inclusions fail:

$$(\dot{p}(t), \dot{x}(t)) \in \operatorname{co}\{(u,v) : (u,p(t)) \in N_{\operatorname{gph} F}(x(t),v),\ p(t) \in N_{F(x(t))}(v)\}, \tag{5.3b}$$

$$(-\dot{p}(t), \dot{x}(t)) \in \overline{\partial} H(x(t),p(t)). \tag{5.3c}$$

Proof. Let $F(x) := [-|x|, |x|]$. This multifunction is compact convex valued and Lipschitz continuous; its graph is the plane set obtained by filling in the vertical space between the lines $y = x$ and $y = -x$. The limiting normal cone to $\operatorname{gph} F$ at the point $(0,0)$ consists of the two lines $y = \pm x$ in the plane; the corresponding Clarke normal

cone is therefore the whole space $\mathbb{R}^2$. Thus for the arc $x(t) \equiv 0$, the right-hand side in Clarke's form of the Euler–Lagrange inclusion (5.3a) is simply $\mathbb{R}^2$, so any arc p will serve. On the other hand, Mordukhovich's form of the Euler–Lagrange inclusion (5.3b) makes a nontrivial restriction on the choice of p. The inclusion $p(t) \in N_{F(0)}(v)$ forces $v = 0$, so that (5.3b) becomes

$$(\dot{p}(t), 0) \in \operatorname{co}\{(u, 0) : |u| = |p(t)|\} = [-|p(t)|, |p(t)|] \times \{0\}.$$

Any arc p that obeys $|\dot{p}(t)| > |p(t)|$ will confirm (5.3a) but violate (5.3b). For example, $p(t) = e^{2t}$ will serve. By the result of Rockafellar cited above, inclusion (5.3c) implies (5.3b). Hence the same choice of p must also violate (5.3c). Of course, this can be confirmed directly by noting that the Hamiltonian corresponding to F is

$$H(x, p) = \sup\{pv : |v| \le |x|\} = |px|,$$

and that for $p \neq 0$, we have $\overline{\partial} H(0, p) = [-|p|, |p|] \times \{0\}$. □

Note that in Example 5.1, the Mordukhovich form of the Euler–Lagrange inclusion is equivalent to the refined form used in Theorem 4.3 because $F(0)$ is a one-point set. Thus Example 5.1 shows that the Euler–Lagrange inclusion in Clarke's form (5.1) does not imply the Hamiltonian inclusion, and that (5.1) can be strictly weaker than our refined Euler–Lagrange inclusion (4.11). However, it does not rule out the possibility that (4.11) implies the Hamiltonian inclusion.

Our next example shows that the Hamiltonian inclusion implies neither Euler–Lagrange inclusion (4.11), nor (5.1) "pointwise"; recall, however, that the Hamiltonian inclusion does imply the Euler–Lagrange inclusion (5.2) in Mordukhovich's form.

EXAMPLE 5.2. *There exist a compact convex valued, Lipschitzian multifunction* $F: \mathbb{R}^2 \rightrightarrows \mathbb{R}^2$ *and a collection of points* x, v, p, u *in* $\mathbb{R}^2$ *such that*

$$(-u, v) \in \overline{\partial} H(x, p) \quad \textit{but} \quad (u, p) \notin \overline{N}_{\operatorname{gph} F}(x, v).$$

In particular,

$$u \notin \operatorname{co}\{u' : (u', p) \in N_{\operatorname{gph} F}(x, v)\}.$$

Proof. Define $F: \mathbb{R}^2 \rightrightarrows \mathbb{R}^2$ as follows:

$$F(x_1, x_2) := \{(t, t|x_1| + r) : t \in [-1, 1], r \in [a, b]\}.$$

For each $x = (x_1, x_2)$ in $\mathbb{R}^2$, the set $F(x)$ is a solid parallelogram in the plane. The corresponding Hamiltonian is

$$H(x_1, x_2, p_1, p_2) = \big|p_1 + p_2|x_1|\big| + \max\{p_2, 0\}.$$

We consider the points $x = (0, 0)$, $v = (0, 0)$, and $p = (0, -1)$. With these choices, $F(x)$ is the plane rectangle $[-1, 1] \times [a, b]$, and p is an outward normal vector to this set at the boundary point v. The crucial feature of this example is that the hyperplane $x_2 = 0$ that supports the set $F(x)$ at v intersects the set $F(x)$ in more than one point. (In other words, the maximum of $\langle p, v \rangle$ over v in $F(x)$ is attained at infinitely many points.) Clarke's subgradient of H at the point $(x, p) = (0, 0, 0, -1)$ can be calculated using [2, Thm. 2.5.1]; it is the two-dimensional square $[-1, 1] \times \{0\} \times [-1, 1] \times \{0\}$ in $\mathbb{R}^4$. One point in this square is $(1, 0, 0, 0)$, which suggests the choice $u = (-1, 0)$. We claim that $(u, p) = (-1, 0, 0, -1)$ lies outside $\overline{N}_{\operatorname{gph} F}(x, v)$.

To prove this, note that up to a permutation of the coordinates, $\operatorname{gph} F = E \times \mathbb{R}$ for the set $E := \{(x_1, t, |x_1|t + r) : x_1 \in \mathbb{R},\ t \in [-1, 1],\ r \in [a, b]\}$. Near the point $(0, 0, 0)$, E coincides with the epigraph of the function $g\colon \mathbb{R}^2 \to \mathbb{R}$ defined by $g(y, t) := t|y|$. This function g is Lipschitzian, and it is easy to show that $\overline{\partial} g(0, 0) = \{(0, 0)\}$. Therefore

$$\overline{N}_E(0,0,0) = \overline{N}_{\operatorname{epi} g}(0,0,g(0,0)) = \bigcup_{\lambda \geq 0} \lambda \left[\overline{\partial} g(0,0) \times \{-1\}\right] = \{(0,0)\} \times (-\infty, 0].$$

We deduce that

$$\overline{N}_{\operatorname{gph} F}(0,0,0,0) = \{(0,0,0)\} \times (-\infty, 0].$$

In particular, $\overline{N}_{\operatorname{gph} F}(x, v)$ does not contain the point $(u, p) = (-1, 0, 0, -1)$, even though $(-u, v) \in \overline{\partial} H(x, p)$. □

It follows from Example 5.2 that the Mordukhovich form of the Euler–Lagrange inclusion (5.2) may fail to imply either the Clarke form (5.1) or the sharper form (4.11). To see this, recall that the Hamiltonian inclusion in Example 5.2 implies the Mordukhovich inclusion (5.2) by the result of Rockafellar [30] cited above. Hence this is an example in which (5.2) holds, but both (5.1) and (4.11) fail.

The unbounded case. Since Theorem 4.3 incorporates a form of the Euler–Lagrange inclusion at least as sharp as (5.1), it subsumes the main result of Clarke [1]. That result requires the multifunction F to display integrably Lipschitz dependence on the state, a hypothesis strictly stronger than assumption (ii) of Theorem 4.3.

Conditions (i) and (ii) of Theorem 4.3 are not directly comparable to the basic hypothesis of Polovinkin and Smirnov [19]. Their truncation scheme involves a constant truncation radius in place of the positive-valued function $R(t)$ in (2.1), and their work involves explicit assumptions about the behaviour of the truncated multifunction $\widetilde{F}$ along the nominal arc $\overline{x}$. Section 2 in this paper has the advantage of introducing hypotheses only on the pointwise behaviour of the given multifunction F near the nominal arc. Indeed, the whole of §2 can be viewed as a set of verifiable sufficient conditions for a weakened form of Polovinkin and Smirnov's "Condition 1" [19, p. 662] to hold.

Polovinkin and Smirnov's conclusions [19], [20] pertain to differential inclusions whose right-hand side may take on nonconvex values, whereas the convexity of the sets $F(t, x)$ is crucial to our approach. However, their work offers only a version of the Euler–Lagrange inclusion, whereas ours incorporates a Hamiltonian inclusion as well. Even in the case of bounded differential inclusions, no one knows whether the Hamiltonian inclusion is a correct necessary condition in the absence of this convexity hypothesis.

A detailed comparison of our Euler–Lagrange inclusion with that in [19, (17)] is beyond the scope of this discussion. However, two comments are in order. First, the approach in [19], [20] is completely different from ours. It is based on "linearizing" the given differential inclusion about the nominal arc, and examining the manner in which solutions of the linearized system provide approximations for the resulting reachable set. (A similar approach is taken by Frankowska [5], and has recently been extended to second-order approximations by Zheng [33].) Second, we note that in Example 5.1, the inclusion [19, (17)] is equivalent to (5.3a). (In general, [19, (17)] is a sharper condition than (5.3a).) As such, it may generate adjoint arcs that satisfy neither the Hamiltonian inclusion (4.6), nor the refined Euler–Lagrange inclusion (4.11). Thus we have at least one example in which our results outperform those of Polovinkin and Smirnov.

Let us note that Theorem 4.3 cannot be obtained simply by reformulating problem (P) as an instance of the generalized problem of Bolza. For simplicity, we discuss only the case without state constraints by setting $X(t) \equiv \mathbb{R}^n$. Then the definition $L(t,x,v) := \Psi_{F(t,x)}(v)$ puts problem (P) into the following form:

$$(P_B) \qquad \begin{aligned} &\text{minimize } \ell(x(a),x(b)) + \int_0^1 L(t,x(t),\dot{x}(t))\,dt \\ &\text{subject to } (x(a),x(b)) \in S. \end{aligned}$$

The Hamiltonian for this problem is the same as the one we have already associated with F. In particular, since the sets $F(t,\overline{x}(t))$ are not necessarily bounded, the convex functions $p \mapsto H(t,\overline{x}(t),p)$ are not necessarily finite-valued everywhere. This places the current instance of (P_B) beyond the scope of the necessary conditions in Clarke [2, Chap. 4], since the strong Lipschitz condition used there tacitly requires the finiteness of H. (See [2, Remark 4.2.1].) Likewise, the possibility that H could take the value $+\infty$ makes it impossible to verify the basic growth condition assumed in Clarke [3].

Thus Theorem 4.3 not only generalizes the necessary conditions formulated explicitly in terms of differential inclusions, but also lies beyond the reach of the best results on the generalized problem of Bolza. Indeed, there is good reason to expect that Theorem 4.3 may lead to strict improvements of the necessary conditions for the Bolza problem. The authors are now pursuing this prospect.

AN EVASION GAME WITH AN INFINITE NUMBER OF STATES*

V. J. BASTON† AND F. A. BOSTOCK†

Abstract. The paper considers a two-person zero-sum discrete gunner-evader game Γ, which takes place on a semi-infinite line. The game is modeled as a recursive game with an infinite number of states. The theory of such games is far from being complete, and it is not even known whether they always have a solution. Even when they do have a solution, the optimal or ϵ-optimal strategies for the players may require a knowledge of past actions. It is shown that Γ has a solution and that the players have stationary optimal or ϵ-optimal strategies.

Key words. two-person game, zero-sum game, infinite recursive matrix game, time lag system

AMS subject classifications. 90D20, 90D05

1. Introduction.

Firing games in which there is a time lag have attracted attention over a period of years. This class of games occurs in different guises in a variety of situations such as a bomber-battleship problem [7], [9], [11], and [12] or a tank manoeuvring to avoid gunfire [13] (and [15]). More recently there has been considerable interest in problems in which an evader, moving on a discrete set of points, tries to avoid being hit by a gunner. Baston and Bostock [1], [2] have treated the case where the number of points is finite. Lee [16], [17] and Sakaguchi [19] have investigated the case where there is a safe point for the evader when he moves on a line, while Garnaev [10] deals with the situation where the evader moves on the infinite two-dimensional integer grid with a general set of safe points. In these papers the gunner has a given number of bullets to start with, but Bernhard, Colomb, and Papavassilopoulos [4] considered the situation in which the gunner has an unlimited supply.

The game we investigate in this paper is broadly similar to the game in [1], but it differs in the crucial aspect of having an infinite number of states. The theory of such games (i.e., infinite recursive games) is far from being complete. Indeed it is not yet known whether every bounded infinite recursive game always has a solution. In 1972 Orkin [18] presented this as an open question for games in which the components are matrices. Our search of the subsequent literature shows this important question to be as yet unanswered.

An introductory description of our game is as follows. Let A_r denote the point r of the x-axis where r is a nonnegative integer. An evader starts at some given point A_s and at discrete intervals of time $t = 1, 2, \ldots$ chooses to move to one of the points adjacent to him or stay where he is. A gunner with a single bullet may at each of the same discrete intervals of time either fire the bullet at one of the points A_r or hold his fire. It is assumed that the gunner always hits the point at which he aims and that the bullet takes one unit of time to reach its target. The payoff to the gunner is 1 if he hits the evader, μ (where $|\mu| < 1$) if he fires and misses, and 0 if he never fires. Although the above description superficially defines our game, the choices of strategy spaces for the players will play an important role when we come to model it. This is dealt with more fully in the next section.

2. Preliminary notions and the value for $\mu = 0$. We obtain a solution for our game by modeling it as a recursive matrix game Γ^μ with a countably infinite number of states $\Gamma_1^\mu, \Gamma_2^\mu, \ldots$. The fundamental paper on the theory of recursive games with a finite number n of states was written by Everett [8]. In that paper a strategy X for a player was defined as a sequence $X = X^1, X^2, \ldots$, where each term X^t was a sequence $X_1^t, \ldots, X_n^t$ with the significance that X_r^t is a mixed strategy to be used at time t when playing in state r. These strategies employed history only insofar as a player was aware of the stage t he had reached. We shall denote the sets of such strategies for player 1 and player 2 by $\mathcal{S}_1$ and $\mathcal{S}_2$, respectively; the same symbols will be used for the corresponding sets of strategies in an infinite recursive matrix game. Strategies independent of t are said to be stationary.

In a later paper [18] Orkin introduced a wider class of strategies for the players (in a finite recursive matrix game) by taking a strategy for player 1 (player 2) as a probability distribution on the rows (columns) of each component game matrix, where the probability distribution could depend on the preceding sequence of moves (i.e., the history). The sets of such strategies for P_1 and P_2 will be denoted by $\mathcal{H}_1$ and $\mathcal{H}_2$; the same symbols will be used for the corresponding sets of strategies in an infinite recursive matrix game. We shall refer to members of $\mathcal{H}_1$ and $\mathcal{H}_2$ as history-remembering strategies. We shall also need the concept of a semi-Markov strategy; this is a history-remembering strategy that ignores history apart from acknowledging the starting component and the stage play has reached. The expectation corresponding to strategies X and Y is denoted by $E(X, Y)$. A bar over a symbol for a recursive game will be used if and only if history-remembering strategies are available. It is well known that for any finite recursive matrix game Λ there always exist stationary optimal or ϵ-optimal strategies. Orkin points out that such strategies are equally effective against history-remembering strategies, but it is now known that the restriction of being stationary is unnecessary, even in the infinite case (see Lemma 2).

We now set up the matrices for the component games of Γ^μ. Note that the point A_0 is of special significance in the game; if the evader moves to A_0 in the course of play, he can then either stay at A_0 or return to A_1. In this sense we can think of A_0 as a barrier. If the game starts at A_0, it is easy to see as follows that the value is $(1 + \mu)/2$. The gunner can achieve $(1 + \mu)/2$ by firing straightaway with equal probability at A_0 and A_1, whereas the evader can clearly hold the gunner down to this by, at each stage, staying where he is or moving to the right with equal probability. The interpretation of the component game Γ_r^μ is that the evader starts at A_r. Thus the component matrices are given by

$$\Gamma_1^\mu = \begin{pmatrix} 1 & \mu & \mu \\ \mu & 1 & \mu \\ \mu & \mu & 1 \\ (1+\mu)/2 & \Gamma_1^\mu & \Gamma_2^\mu \end{pmatrix}$$

and for $r = 2, 3, \ldots$ by

$$\Gamma_r^\mu = \begin{pmatrix} 1 & \mu & \mu \\ \mu & 1 & \mu \\ \mu & \mu & 1 \\ \Gamma_{r-1}^\mu & \Gamma_r^\mu & \Gamma_{r+1}^\mu \end{pmatrix}.$$

In Γ_r^μ the columns 1, 2, 3, respectively, represent the pure strategies for the evader in which he moves to the points A_{r-1}, A_r, A_{r+1}; the first three rows, respectively, represent the pure strategies for the gunner in which he fires at the points A_{r-1}, A_r, A_{r+1}, and row 4 represents the strategy of not firing.

At this point we find it convenient to restrict our attention to the case $\mu = 0$, and for brevity write Γ^0 as Γ. For each infinite real vector $W = (w_1, w_2, \ldots)$ let $M_r(W)$ denote the real matrix obtained by substituting w_i for each game component Γ_i that occurs in the matrix M_r of Γ_r. The value map V from infinite real vectors to infinite real vectors is defined by taking the rth component of $V(W)$ as the value of $M_r(W)$, regarded as an ordinary matrix game. Let U_0 denote the infinite zero vector, and for $k = 1, 2, \ldots$ define $U_k = (u_1^k, u_2^k, \ldots)$ by $U_k = V(U_{k-1})$. Since clearly $U_1 \geq U_0$, it follows from Lemma 3 that

(a) $\bar{\Gamma}$ has a value given by the limit $u = (u_1, u_2, \ldots)$ of U_k as $k \to \infty$,

(b) U is a fixed point of the value map,

(c) the gunner has an ϵ-optimal semi-Markov strategy,

(d) the evader has an optimal stationary strategy.

A standard argument shows that the sequence U_k is increasing. Following closely the proof of [1, Lem. 3] it is easily established that

(i) for $r \geq 1$, $k \geq 1$, $1/3 \leq u_r^k \leq 1/2$ and $u_r^k \geq u_{r+1}^k$, and

(ii) for $r \geq 1$, $k \geq 2$, $u_r^k = u_{r-1}^{k-1}/(1 + 2u_{r-1}^{k-1} - u_r^{k-1} - u_{r+1}^{k-1})$, where for all $k \geq 2$ we define $u_0^{k-1} = 1/2$.

We also note that for $r \geq 1$, $u_r^1 = 1/3$. From (i) for each $r = 1, 2, \ldots$ the sequence u_r^k converges (say to u_r), and these limits satisfy the recurrence

$$u_r = u_{r-1}/(1 + 2u_{r-1} - u_r - u_{r+1}),$$

where $u_0 = 1/2$, which gives

$$u_{r+1} = 2u_{r-1} - u_r + 1 - (u_{r-1}/u_r).$$

Note that from (i) above the sequence u_r is decreasing. Clearly if we know u_1, this recurrence will define the sequence u_r.

However, in several ways this disguises an unsatisfactory situation. First, the iteration technique does not directly enable us to find sharp bounds on u_1. Second, it gives no method of determining the limit of u_r as $r \to \infty$. Third, we do not know whether Γ has a solution. Finally (c) provides only an ϵ-optimal strategy for the gunner that is far from being stationary. We will remedy these deficiencies in the subsequent sections. To do so we will need the following lemmas.

LEMMA 1. *In the bounded infinite recursive matrix game $\Lambda = (\Lambda_1, \Lambda_2, \ldots)$ let $Y \in \mathcal{S}_2$ and $W \geq 0$ be a real vector such that for all $X \in \mathcal{S}_1$ and all t, $E^t(X, Y; W) \leq W$, then for all $X \in \mathcal{S}_1$, $E(X, Y) \leq W$. [The ith component of $E^t(X, Y; W)$ is the expectation when the players use X_i^t and Y_i^t in the ordinary matrix game $M_i(W)$.]*

LEMMA 2. *Let $\Lambda = (\Lambda_1, \Lambda_2, \ldots)$ be a bounded infinite recursive matrix game. Let W be a real vector, and X^* a strategy in $\mathcal{S}_1$ such that for all $Y \in \mathcal{S}_2$ $E(X^*, Y) \geq W$. Then for all $Y \in \mathcal{H}_2$ $E(X^*, Y) \geq W$.*

We note Lemma 2 (together with the analogous result for player 2) implies that whenever a bounded infinite recursive matrix game Λ has a solution, $\bar{\Lambda}$ has the same solution.

LEMMA 3. *Let Γ be a bounded (possibly infinite) recursive finite matrix game satisfying $V(0) \geq 0$, where V is the value map. Then $\bar{\Gamma}$ has a value that is a fixed point of the value map and is the limit as $k \to \infty$ of $V^k(0)$. Player 1 has an ϵ-optimal semi-Markov strategy and player 2 has an optimal stationary strategy.*

Lemma 1 is an application of [5, Thm. 2] and Lemma 2 follows easily from [20, Prop. 9.1]. Lemma 3 is a special case of results in [14], note in particular Theorem 2 and Remark 1.

3. Evader strategies for the case $\mu = 0$. We first determine a stationary evader strategy, which, against any $X \in \mathcal{S}_1$, will hold the gunner's expectation down to at most u as defined under (a) in the previous section. Define the stationary strategy Y^* by

$$Y_r^* = (1 - u_r - u_{r+1}, u_{r-1}, u_{r-1})/(1 + 2u_{r-1} - u_r - u_{r+1}) \text{ for } r = 1, 2, \ldots,$$

where $u_0 = 1/2$. Now u is a fixed point of the value map, and in particular u_r is the value of the ordinary matrix game $M_r(u)$. It is easy to verify that the strategy Y_r^* is optimal for the minimizing player in the game $M_r(u)$, and then as a direct consequence of Lemma 1 the evader strategy Y^* will hold the gunner's expectation down to at most u against any $X \in \mathcal{S}_1$. Using the analogous result to Lemma 2 for the evader we see that Y^* is equally effective against any $X \in \mathcal{H}_1$.

We now prove the intuitively obvious result that $u_r \to 1/3$ as $r \to \infty$, which we will need in the next section. To do this we will produce a sequence $\alpha_0, \alpha_1, \ldots$, where for each $r = 0, 1, 2, \ldots$ the evader, when starting at A_r, is able to hold the gunner's expectation down to at most α_r. If the evader starts at the barrier A_0, then he is able to hold the gunner's expectation down to $1/2$, and we take $\alpha_0 = 1/2$. Suppose $Y(r) \in \mathcal{H}_2$ is a strategy for the evader, which, when he starts at A_r, holds down the gunner's expectation (using $X \in \mathcal{H}_1$) to at most α_r, where $1/3 < \alpha_r \leq 1/2$. Consider the strategy $Y^* \in \mathcal{H}_2$ defined as follows. If the evader starts at A_j with $j \neq r + 1$, he never moves. When the evader starts at A_{r+1} and finds himself at a point A_j, never having been at A_r, he moves to the points A_{j-1}, A_j, A_{j+1}, respectively, with probabilities $1 - 2p, p, p$, where $p = \sqrt{(\alpha_r/3)}$; however, should he arrive at A_r he subsequently employs $Y(r)$ as if he were starting at A_r at time $t = 1$. Note that $1/3 < p < 1/2$ and $\alpha_r > p$. Because $1 - 2p < p$, the theory of random walks shows that the probability that the evader is ever at the point A_r when starting at A_{r+1} is $(1 - 2p)/p$. Hence when the evader uses Y^*, the gunner's expectation is not more than $\alpha_r\big((1 - 2p)/p\big) + p(1 - (1 - 2p)/p) = 2\sqrt{(3\alpha_r)} - 2\alpha_r - 1$, which we define to be α_{r+1}. Now

(a) $\alpha_r - \alpha_{r+1} = (\sqrt{(3\alpha_r)} - 1)^2 > 0$, and

(b) $\alpha_{r+1} - 1/3 = 6(2/3 - \sqrt{(\alpha_r/3)})(\sqrt{(\alpha_r/3)} - 1/3) > 0$.

Thus $1/3 < \alpha_{r+1} \leq 1/2$, which means we have obtained our sequence $\alpha_0, \alpha_1, \ldots$. Since the sequence is decreasing and bounded below, it converges, say, to α. From (a) it follows that $\alpha = 1/3$. Since u is the value of the game $\bar{\Gamma}$ $\alpha_r \geq u_r (\geq 1/3)$, and it follows that $\lim_{r\to\infty} u_r = 1/3$.

4. Gunner strategies for the case $\mu = 0$. In this section we will obtain a stationary strategy for the gunner that ensures him an expectation of at least $u - \epsilon$ against any $Y \in \mathcal{H}_2$; to do this we find it convenient to define certain other recursive games. Let $N \geq 2$ be an integer and $\Gamma(N) = (\Gamma_1(N), \Gamma_2(N), \ldots, \Gamma_N(N))$ be the recursive game given by

$$\Gamma_1(N) = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1/2 & \Gamma_1(N) & \Gamma_2(N) \end{pmatrix},$$

for $r = 1, 2, \ldots, N - 1$

$$\Gamma_r(N) = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \\ \Gamma_{r-1}(N) & \Gamma_r(N) & \Gamma_{r+1}(N) \end{pmatrix},$$

and

$$\Gamma_N(N) = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \\ \Gamma_{N-1}(N) & \Gamma_N(N) & 1/3 \end{pmatrix}.$$

The interpretation of the game $\Gamma_r(N)$ is as usual, that the evader starts at A_r and there is a barrier at A_0. There is, however, the boundary condition that should the evader, at some stage, be at the point A_N and choose to move to the point A_{N+1}, whilst the gunner chooses not to fire, then the game terminates with a payoff of $1/3$. If we iterate the zero vector k times under the standard value map for $\Gamma(N)$ to form a vector $(v_1^k(N), v_2^k(N), \ldots, v_N^k(N))$, then, because the game is recursive and all the number entries in all the game components are nonnegative, it follows [8] that for each $r = 1, 2, \ldots, N$ the sequence $v_r^k(N)$ is increasing and converges to the value of the game $\Gamma_r(N)$, say, $v_r(N)$.

Furthermore, following the proof of [1, Lem. 3] it is easily shown that

(i) For $r = 1, 2, \ldots, N$; $k \geq 1$, $1/3 \leq v_r^k(N) \leq 1/2$.

(ii) For $r = 1, 2, \ldots, N-1$; $k \geq 1$, $v_r^k(N) \geq v_{r+1}^k(N)$.

(iii) For $r = 1, 2, \ldots, N$; $k \geq 2$, $v_r^k(N) = v_{r-1}^{k-1}(N)/(1 + 2v_{r-1}^{k-1}(N) - v_r^{k-1} - v_{r+1}^{k-1}(N))$, where for all $k \geq 2$ we define $v_0^{k-1}(N) = 1/2$ and $v_{N+1}^{k-1}(N) = 1/3$.

We also note that for $r = 1, 2, \ldots, N$ $v_r^1(N) = 1/3$. Using the fact that when $x \leq y$

$$\operatorname{val}\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \\ x_1 & x_2 & x_3 \end{pmatrix} \leq \operatorname{val}\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \\ y_1 & y_2 & y_3 \end{pmatrix}$$

and the above results concerning u_r^k and $v_r^k(N)$, it is not hard to see that,

(a) for each r and all $N > r$, $u_r^k \geq v_r^k(N+1) \geq v_r^k(N)$, and

(b) provided $N \geq r + k$, $u_r^k = v_r^k(N)$.

Thus $v_r^k(N)$ is monotonic increasing as a function of N and $u_r \geq v_r(N)$ for all $N > r$; a simple reductio ad absurdum argument now establishes that $u_r = \lim_{N\to\infty} v_r(N)$. We proved in §3 that $u_r \to 1/3$ as $r \to \infty$. Thus given $\epsilon > 0$, let K be such that $u_r - 1/3 < \epsilon$ for $r > K$. Now for each $r = 1, 2, \ldots, K$ choose $K_r > r$ so that $u_r - v_r(N) < \epsilon/2$ whenever $N \geq K_r$, and let $M = \max\{K_1, K_2, \ldots, K_K\}$. We may take a stationary $(\epsilon/2)$-optimal strategy $X_{(M)}^* = X_1^*, X_2^*, \ldots, X_M^*$ for the gunner in the game $\Gamma(M)$ by using strategies pioneered by Everett [8]

Define the stationary strategy X^* for the gunner in Γ by, $X^* = X_1^*, X_2^*, \ldots$, where for each $i > M$ $X_i^* = (1, 1, 1, 0)/3$. If the gunner uses X^* and the evader starts at A_r, his expectation against any $Y \in \mathcal{S}_2$ is $1/3 > u_r - \epsilon$ when $r > M$ and at least $v_r(M) - \epsilon/2 > u_r - (\epsilon/2) - (\epsilon/2) = u_r - \epsilon$ when $r \leq M$. Lemma 2 now ensures that X^* maintains $u - \epsilon$ against any $Y \in \mathcal{H}_2$. The results of this and the previous section show that both Γ and $\bar{\Gamma}$ have a solution, with the gunner having a stationary ϵ-optimal strategy and the evader a stationary optimal strategy.

Note. Later we will need to ensure that in X_r^* the probability of not firing is strictly less than one. To see this, suppose the probability of not firing were one. Then, starting at A_r, the evader could clearly hold the gunner's expectation down to zero. However, $v_r(N)$ is at least $1/3$.

5. The game for $|\mu| < 1$. From the case $\mu = 0$ we now deduce that the value of the game Γ for $\mu \geq -1/2$, starting at A_r, is $\mu + (1 - \mu)u_r$. When starting at A_0

the result is trivial. With $\mu = 0$ we may clearly interpret the gunner's expectation as the probability of his hitting the evader. Given $\epsilon > 0$, suppose the gunner uses the strategy X^* of §4, which guarantees him $u_r - \epsilon$ when the evader starts at the point A_r. Let the evader adopt a strategy $Y(\in \mathcal{H}_2)$ and the game start at the point $A_r \neq A_0$. Let H_n, M_n, B_n, respectively, be the probabilities that up to time $t = n$ the gunner has hit the evader, fired and missed, or not fired. If E_n denotes the accumulated expectation up to $t = n$, then $E_n = H_n + \mu M_n$. Since $H_n + M_n + B_n = 1$, we have $M_n \leq 1 - H_n$ so that when $\mu \leq 0$ $E_n \geq H_n + \mu(1 - H_n) = (1 - \mu)H_n + \mu$. We may choose n_1 so that for all $n \geq n_1$ $H_n \geq u_r - \epsilon$, whence $E_n \geq \mu + (1 - \mu)u_r - \epsilon(1 - \mu)$.

Now consider the case $\mu \geq 0$. We have $E_n = H_n + (1 - H_n - B_n)\mu = (1 - \mu)H_n + (1 - B_n)\mu$. Since the game starts at A_r, there are at most $r + 2M$ points that can be visited by the evader up to and including time M. Under X^*, at each of these points the probability of not firing is strictly less than 1, according to the Note. Further, under X^*, the gunner fires at time $M + 1$. Hence there is an $\alpha < 1$ such that at each stage the probability of the gunner not firing is at most α. Hence $B_n \leq \alpha^n \to 0$ as $n \to \infty$. It now easily follows that for sufficiently large n,

$$E_n \geq (1 - \mu)(u_r - \epsilon) + (1 - \epsilon)\mu = \mu + (1 - \mu)u_r - \epsilon.$$

Let the evader use the strategy Y^* of §3, which holds the gunner's expectation down to u_r when he starts at the point A_r. Now $u_r + (1 - u_r)\mu \geq 0$, since $u_r \geq 1/3$ and we are taking $\mu \geq -1/2$. Since the expectation of a strategy pair (X, Y) in a matrix game $(\mu + (1 - \mu)a_{rs})$ is $\mu + \{(1 - \mu)$times the expectation of (X, Y) in the matrix game $(a_{rs})\}$, the conditions of Lemma 1 are satisfied by $Y = Y^*$ and $W = (\mu + (1 - \mu)u_r)$ in Γ^μ because they are satisfied by $Y = Y^*$ and $W = (u_r)$ in Γ. Hence the value of the game for $\mu \geq -1/2$ is the vector $(\mu + (1 - \mu)u_r)$.

We now turn our attention to the range $-1 < \mu < -1/2$. The methods of §2 go through in the present case, and it is easily seen that the value (w_r) of the game $\bar{\Gamma}^\mu$ satisfies the recurrence

$$w_r = \frac{\mu[w_{r-1} - w_r - w_{r+1}] + w_{r-1}}{1 - \mu + 2w_{r-1} - w_r - w_{r+1}}, \quad r = 1, 2 \ldots$$

and boundary condition $w_0 = (1 + \mu)/2$. A stationary strategy that guarantees $(w - \epsilon)$ (against any $Y \in \mathcal{H}_2$) for the gunner can now be obtained using the arguments of §4. In the description of $\Gamma(N)$ the zeros are replaced by μ's, the $1/2$ by $(1 + \mu)/2$, and the $1/3$ by 0. Lemma 3 shows that the corresponding sequence $v_r^k(N)$ converges to the value of the game. Further obvious modifications now lead to an appropriate strategy.

As in §3 the evader has a stationary strategy, which against any $X \in \mathcal{H}_1$, will hold the gunner's expectation down to (w_r). Hence the value of the game for $-1 < \mu < -1/2$ is (w_r). We may prove that $w_r \to 0$ as $r \to \infty$ in a manner similar to that for the case $\mu = 0$ by taking $p = -\mu/(1 - \mu)$, independent of the starting point A_r.

6. Calculation of u_1. For further information regarding the nature of the recurrence relation on u_r we go to the related map f given by $f(x, y) = (y, 2x - y + 1 - (x/y))$, $y \neq 0$. It is easy to see that the fixed points of f are precisely those points (x, x) with $x \neq 0$. The matrix of the derivative $df(x, y)$ of f at (x, y) is

$$\begin{bmatrix} 0 & 2 - (1/y) \\ 1 & (x/y^2) - 1 \end{bmatrix}$$

so that when p and q are small, at a fixed point we have,

$$f((x,x)+(p,q)) \simeq (x,x)+(p,q)\begin{bmatrix} 0 & 2-(1/x) \\ 1 & (1/x)-1 \end{bmatrix}.$$

The eigenvalues of $df(x,x)$ are given by $\lambda^2 - ((1/x)-1)\lambda + (1/x) - 2 = 0$, which yields $\lambda = 1$ and $(1/x)-2$. The eigenvalue 1 corresponds of course to the line of fixed points. Let $\lambda_0 = (1/x) - 2$, and suppose $x \neq 1/2$ so that $\lambda_0 \neq 0$. Then, provided $q = \lambda_0 p$, we have $f((x,x)+(p,q)) \simeq (x,x) + \lambda_0(p,q)$. With the exception of $x = 1/2$ and 0, corresponding to the fixed point (x,x), there is a stable or unstable manifold accordingly as $|\lambda_0| < 1$ or $|\lambda_0| > 1$. The tangent to the stable or unstable manifold through (x,x) has gradient λ_0. Our main concern is with the region $0 < x, y < 1/2$, where for $1/3 < x < 1/2$ the manifold is stable and for $0 < x < 1/3$ unstable. Numerical investigations show that in the region in which we are interested the phase plane appears to be foliated by a family of invariant curves as indicated in Fig. 1.

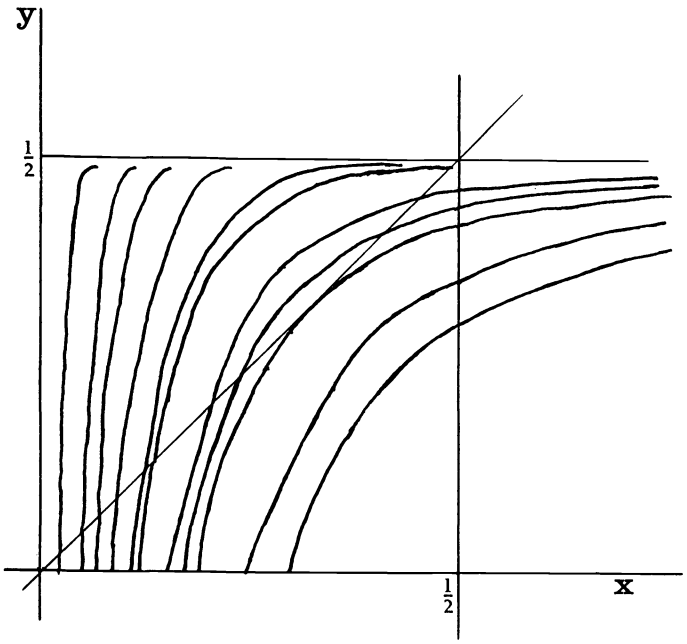

FIG. 1

In Fig. 1 the two right-hand curves are neither stable nor unstable manifolds as far as can be judged, but we put them forward as invariant curves under f and as particular members of a general family. Of particular interest for us is the curve that touches the line of fixed points at $x = 1/3$, where the eigenvalue $\lambda_0 = 1$. From the phase map standpoint it seems evident (but not conclusive) that this curve is the only one that touches the line of fixed points at $(1/3, 1/3)$. To see that this is in fact so in the region in which we are interested, we will prove that there is a unique solution to the recurrence relation on u_r with boundary conditions $u_0 = 1/2$, $1/3 < u_1 < 1/2$, and $\lim_{r\to\infty} u_r = 1/3$. First of all assume that the sequence (z_r) is another solution

with $z_1 > u_1$. Let $z_r = u_r + \epsilon_r$ so that $\epsilon_0 = 0$ and $\epsilon_1 > 0$. We show by induction that $\epsilon_t \geq \epsilon_{t-1}$ for all $t \geq 1$. The result certainly holds for $t = 1$. Suppose it holds for $t = r$. Then

$$\begin{aligned} z_{r+1} &= 2(u_{r-1} + \epsilon_{r-1}) - (u_r + \epsilon_r) + 1 - (u_{r-1} + \epsilon_{r-1})/(u_r + \epsilon_r) \\ &= u_{r+1} + 2\epsilon_{r-1} - \epsilon_r + (u_{r-1}/u_r) - (u_{r-1} + \epsilon_{r-1})/(u_r + \epsilon_r). \end{aligned}$$

So $\epsilon_{r+1} = 2\epsilon_{r-1} - \epsilon_r + (u_{r-1}\epsilon_r - u_r\epsilon_{r-1})/\{u_r(u_r + \epsilon_r)\}$

$$\begin{aligned} &\geq 2\epsilon_{r-1} + (\epsilon_r - \epsilon_{r-1})/(u_r + \epsilon_r) \qquad \text{since } u_{r-1} \geq u_r \\ &\geq 2\epsilon_{r-1} - \epsilon_r + 2\epsilon_r - 2\epsilon_{r-1} \qquad \text{since } u_r + \epsilon_r = z_r \leq 1/2 \text{ and } \epsilon_r \geq \epsilon_{r-1} \\ &= \epsilon_r. \end{aligned}$$

This completes the induction; it follows that $\epsilon_r \geq \epsilon_1$ for $r \geq 1$, and this contradicts $\lim_{r\to\infty} z_r = 1/3$. A similar method shows there is no solution with $z_r < u_1$, and hence (u_r) is the unique solution.

Hence there exists a unique number ρ with $1/3 \leq \rho \leq 1/2$ such that the orbit of the point $(1/2, \rho)$ converges to $(1/3, 1/3)$. Trial and error methods involving the phase map of the recurrence relation (with boundary conditions $u_0 = 1/2$ and $\lim_{r\to\infty} = 1/3$) have given the inequality, $0.423638 < u_1 < 0.42365$.

7. Conclusions. The sequence $u_0, u_1, \ldots$ can be thought of merely as stemming (uniquely) from the defining sequence u_r^k of §2. The sequence (u_r) was also easily seen to converge, and the determination of the limit could be regarded as a problem of pure mathematics. However, we were unable to prove in a direct manner that $\lim_{r\to\infty} u_r = 1/3$, and finally employed the game-theoretic argument used in this paper. It would be nice to have a simple direct proof of what is after all, from a game-theoretic standpoint, an intuitively obvious result. It may be of interest to note that a similar situation concerning boundary conditions arises in the general context of a simple random walk with one absorbing barrier. Here results are often obtained from a two-barrier analysis by a limiting procedure (see [6], for example). It is taken as obvious, presumably on the grounds of intuition, that this limiting process does in fact give the required probability.

When the gunner has j bullets there are two basic generalizations of Γ^μ. In one the gunner has a payoff of 1 for each hit and μ for each miss; for the special case $\mu = 0$ the gunner is effectively trying to maximize the total number of hits. In the other the gunner maximizes his chances of a single hit (this is in fact a generalization of the game Γ^0; a generalization in this direction with a general μ has little natural appeal). The methods of this paper can be used to deal with these problems by employing a dynamic programming technique. Note that, having obtained the value for one bullet, the case for two bullets can be modeled by component matrices having the same form as for one bullet (i.e., number (game component) entries where there were number (game component) entries), and so on.

In the case of a finite recursive matrix game there is always a solution in stationary strategies and we have found that to be true for our game. It would be interesting to know whether or not a bounded infinite recursive finite matrix game (with or without a bar!) that has a solution, always has one in stationary strategies. An example of a bounded infinite recursive infinite matrix game Λ such that $\bar{\Lambda}$ has a solution but Λ does not is given in [3]. We have also found an example of such a game Λ, where Λ has a solution but one of the players does not have an optimal or ϵ-optimal stationary strategy.

Acknowledgments. We would like to thank David Chillingworth and David Whitley for helpful conversations concerning §6. We would like to thank the referees

for pointing out that Lemmas 1–3 were already in the literature and for providing us with the appropriate references. One of the referees also pointed out that the game can be formulated as a dynamic game stopped at random time (depending on the position of the state), and the cost is incurred only at the final (stopping) time.

LINEAR PROGRAMMING AND AVERAGE OPTIMALITY OF MARKOV CONTROL PROCESSES ON BOREL SPACES—UNBOUNDED COSTS*

ONÉSIMO HERNÁNDEZ-LERMA† AND JEAN B. LASSERRE‡

Abstract. This paper is concerned with the linear programming formulation of Markov control processes with *Borel* state and action spaces, and the *average cost* (*AC*) criterion. The one-stage cost function may be *unbounded*. A linear program EP and its dual, EP^*, are introduced. Their values, inf EP and sup EP^*, bound the value (say, inf AC) of the AC problem, i.e., sup $EP^* \leq$ inf $AC \leq$ inf EP. Conditions are provided for the existence of *no duality gap*, viz., sup EP^*= inf EP, and also for *strong duality*, so that both EP and EP^* are solvable and their optimal values satisfy max EP^* = min EP. The latter implies (i) the existence of an AC-optimal control policy and that (ii) the AC optimality equation holds almost everywhere. These results are applied to a general vector-valued, additive-noise system with quadratic costs.

Key words. (discrete-time) Markov control processes, average cost criterion, linear programming (in general vector spaces), strong duality

AMS subject classifications. 93E20, 90C40

1. Introduction.

The linear programming (LP) formulation of Markov control problems—or stochastic dynamic programs—has been studied since the early 1960s, and it has proved to yield useful insight into some control problems. However, most of the related literature is concentrated on problems with denumerable (mainly finite) state and control spaces, which excludes of course many important applications (e.g., in engineering, economics, and operations research), where these spaces are nondenumerable (e.g., R^n).

The main objective of this paper is to study the LP formulation of *average cost* (*AC*) Markov control processes (MCPs) on *Borel* spaces, allowing *unbounded* one-stage costs. The idea is to introduce the linear program EP and its dual, EP^*, and to show that the value of the AC control problem, call it inf AC, satisfies

$$\sup EP^* \leq \inf AC \leq \inf EP. \tag{1.1}$$

(A precise formulation is given in §§4, 5.) Thus, if there is *no duality gap* for the LP problems, so that

$$\sup EP^* = \inf EP, \tag{1.2}$$

then their common value yields inf AC. Now, if (1.2) holds and, moreover, there are optimal solutions for EP and EP^* (so that inf EP = min EP and sup EP^* = max EP^*), then we have

$$\max EP^* = \min EP. \tag{1.3}$$

‡ Laboratoire d'Automatique et d'Analyse des Systems–Centre National de la Recherche Scientifique, 7 Avenue du Colonel Roche, 31077 Toulouse Cédex, France.

Therefore, in addition to getting the value inf AC, we also get an *optimal policy*. When (1.3) holds we say—following the terminology of [2]—that the *strong duality* condition holds. We illustrate (1.1)–(1.3) with a nonlinear, additive-noise, vector system of the form

$$x_{t+1} = G(x_t, a_t) + \xi_t, \quad t = 0, 1, \ldots, \tag{1.4}$$

with a quadratic cost function

$$c(x, a) = x'Hx + a'Ra \qquad (\text{"prime" denotes transpose}). \tag{1.5}$$

We also study the relation between AC, EP, EP^*, and a solution to the (so-called) AC *optimality equation* (OE). It is shown, e.g., that (1.3) implies that the OE is satisfied almost everywhere with respect to a probability measure related to an optimal solution of EP.

This paper is organized as follows: The basic MCP is introduced in §2, together with the usual AC optimality criterion and two stronger forms of optimality, namely, "strong optimality" and "F-strong optimality" (see Definition 2.3). In §3 we introduce the notion of "canonical triplet" and show that a "canonical policy" is AC-optimal, strong optimal, and F-strong optimal. This is done under condition (3.1)—weakened in §4—which allows a class of unbounded costs and thus extends the work of several authors [8], [27], [34]; see [3, §6] for a self-contained presentation of canonical triplets. Section 4 begins with the formulation of the linear programs EP and EP^*, following closely the approach of Anderson and Nash [2] for LP in general vector spaces. We also introduce the basic Assumptions 4.2 and 4.3, on which most of our results (1.1)–(1.3) are based. (It is worth noting that, in contrast to the "bounding" condition (3.1), Assumption 4.2 allows unbounded functions also in the control (or action) variable a.) Assumptions 4.2 and 4.3 yield, e.g., the standard LP results of consistency, weak duality, and complementary slackness (Proposition 4.1). For MCPs with Borel state space and *bounded* costs these results have also been obtained by other authors [11], [16], [32]. However, except for a previous report [23] dealing with *denumerable* state MCPs, the remainder of §4, as well as §5—where we give conditions for the strong duality (1.3)—seems to be new, at least in the context of Borel spaces/unbounded costs. Finally, in §6 we give conditions on (1.4)–(1.5) under which all the results in §§5 and 6 are valid.

There is an extensive literature on the LP approach to MCPs, as can be seen in the recent, excellent surveys [3], [28]; for earlier references see, e.g., [12], [22]; for constrained MCPs see, e.g., [1]. As already noted, though, virtually all of these works deal with finite or, perhaps, countably infinite spaces.

Remark 1.1.

Notation. Let S be a Borel space (i.e., a Borel subset of a complete and separable metric space). Then $\mathcal{B}(S)$ denotes the sigma-algebra of Borel subsets of S, and $\mathcal{P}(S)$ stands for the family of all probability measures on $\mathcal{B}(S)$. "Measurable" always means "Borel-measurable." If S and T are Borel spaces, a *stochastic kernel* [3], [14], [19] on S given T is a function $P(\cdot \mid \cdot)$ such that $P(\cdot \mid t)$ is a probability measure on S for each fixed $t \in T$, and $P(B \mid \cdot)$ is a measurable function on T for each fixed $B \in \mathcal{B}(S)$. The family of all stochastic kernels on S given T is denoted by $\mathcal{P}(S \mid T)$.

2. Problem definition.

The Markov control model. Let (X, A, Q, c) be a Markov control model with state space X, control (or action) set A, transition law Q, and one-stage cost function

c satisfying the following conditions. Both X and A are Borel spaces. To each $x \in X$ is associated a nonempty set $A(x) \in \mathcal{B}(A)$, which represents the set of admissible control actions when the system is in state x. The set

$$K := \{(x,a) \,|\, x \in X, \quad a \in A(x)\} \tag{2.1}$$

of admissible state-action pairs is assumed to be a Borel subset of $X \times A$. The transition law $Q(B \,|\, x,a)$, where $B \in \mathcal{B}(X)$ and $(x,a) \in K$, is a stochastic kernel on X given K, i.e., $Q \in \mathcal{P}(X \,|\, K)$ (see Remark 1.1). Finally, the one-stage cost c is a measurable function on K bounded from below. In fact, without loss of generality, we will assume that c is *nonnegative*.

The above Markov control model is standard [3], [14], [19].

DEFINITION 2.1. F denotes the set of all measurable functions $f : A \to X$ such that $f(x) \in A(x)$ for all $x \in X$, and Φ stands for the set of all stochastic kernels $\varphi \in \mathcal{P}(A \,|\, X)$ satisfying the constraint $\varphi(A(x) \,|\, x) = 1$ for all $x \in X$.

We will identify a function $f \in F$ with the stochastic kernel $\varphi \in \Phi$ for which, for every $x \in X$, $\varphi(\cdot \,|\, x)$ is the probability measure concentrated at $f(x)$. Thus we regard F as a subset of Φ. We will *assume* that F (hence Φ) is nonempty. (Equivalently, the set K in (2.1) contains the graph of a measurable map.) This condition holds, for instance, if the sets $A(x)$ are closed and the multifunction (or set-valued mapping) $x \to A(x)$ is measurable in the sense that the set $\{x \,|\, A(x) \cap C \neq \phi\}$ is in $\mathcal{B}(X)$ for every closed $C \subset A$. (See, e.g., [4] for a proof of this fact and related results.)

Consider the history spaces $H_0 := X$ and $H_t := K \times H_{t-1}$ if $t = 1, 2, \ldots$. An element h_t of H_t is a vector of the form $h_t = (x_0, a_0, \ldots, x_{t-1}, a_{t-1}, x_t)$, where $(x_n, a_n) \in K$ for all $n = 0, \cdots, t-1$, and $x_t \in X$.

DEFINITION 2.2. A control policy is a sequence $\delta = \{\delta_t\}$ of stochastic kernels $\delta_t \in \mathcal{P}(A \,|\, H_t)$ satisfying the constraint

$$\delta_t\,(A(x_t) \,|\, h_t) = 1 \qquad \forall\, h_t \in H_t,\ t \geq 0.$$

The set of all policies is denoted by Δ. A control policy $\delta = \{\delta_t\}$ is said to be a *relaxed* (or *randomized stationary*) *policy* if there exists $\varphi \in \Phi$ such that

$$\delta_t(\cdot \,|\, h_t) = \varphi(\cdot \,|\, x_t) \qquad \forall\, h_t \in H_t, t \geq 0,$$

where Φ is the set in Definition 2.1. Finally, a policy $\delta = \{\delta_t\}$ is said to be a *nonrandomized stationary policy* (or briefly *stationary policy*) if there exists $f \in F$ such that $\delta_t(\cdot \,|\, h_t)$ is concentrated at $f(x_t)$ for all $h_t \in H_t$ and $t \geq 0$.

Following a standard convention, we will identify F (respectively, Φ) with the set of all stationary (respectively, relaxed) policies. Thus we may write $F \subset \Phi \subset \Delta$.

Let $(\Omega, \mathcal{F})$ be the measurable space that consists of the sample space $\Omega := (X \times A)^\infty$ and the corresponding product σ-algebra $\mathcal{F}$. Then for each policy δ and "initial distribution" $\nu \in \mathcal{P}(X)$, a probability P_ν^δ and a stochastic process $\{(x_t, a_t), \quad t = 0, 1, \ldots\}$ are defined on $(\Omega, \mathcal{F})$ in a canonical way [3], [8], [14], [19], where x_t and a_t represent the state and the control action at time t, respectively. The expectation operator with respect to P_ν^δ is denoted by E_ν^δ. If ν is the unit mass at (the initial state) x, then we write P_ν^δ and E_ν^δ as P_x^δ and E_x^δ, respectively.

Performance criteria. Given a policy $\delta \in \Delta$, an initial distribution ν, and a measurable function $h : X \to R$, define

$$J_0\,(\delta, \nu, h) := E_\nu^\delta h(x_0),$$

and for $n \geq 1$,

$$J_n(\delta, \nu, h) := E_\nu^\delta \left[\sum_{t=0}^{n-1} c(x_t, a_t) + h(x_n) \right], \tag{2.2}$$

assuming that the expectations are well defined (which will be the case under the assumptions given below). Equation (2.2) represents the total expected cost for an n-stage control problem with *terminal cost* function h. If $h(\cdot) \equiv 0$, then we write $J_n(\delta, \nu, h)$ as $J_n(\delta, \nu)$, i.e.,

$$J_n(\delta, \nu) := E_\nu^\delta \left[\sum_{t=0}^{n-1} c(x_t, a_t) \right]. \tag{2.3}$$

If the initial distribution ν is concentrated at a point x, we write the above functions as $J_n(\delta, x, h)$ and $J_n(\delta, x)$.

The average cost (or *AC*) problem. The main problem we are concerned with is the minimization of the long-run expected *average cost* (*AC*) per unit time defined as

$$J(\delta, \nu) := \limsup_n n^{-1} J_n(\delta, \nu). \tag{2.4}$$

Thus, denoting by J^* the *AC optimal value function*, i.e.,

$$J^*(\nu) = \inf_\delta J(\delta, \nu), \qquad \nu \in \mathcal{P}(X), \tag{2.5}$$

the *AC* problem is to find a policy δ^* such that

$$J(\delta^*, \nu) = J^*(\nu) \qquad \forall \nu \in \mathcal{P}(X), \tag{2.6a}$$

that is,

$$J(\delta^*, \cdot) \leq J(\delta, \cdot) \qquad \forall \delta \in \Delta. \tag{2.6b}$$

If (2.6) holds, then δ^* is said to be an (average cost) *optimal* policy. We also define the *value* $\inf_\Delta AC$ of the *AC* problem as

$$\inf_\Delta AC := \inf_\nu J^*(\nu) = \inf_\nu \inf_\delta J(\delta, \nu), \tag{2.7}$$

and a pair (δ^*, ν^*) consisting of a policy δ^* and an initial distribution ν^* is said to be a *minimum pair* [15], [21] if $J(\delta^*, \nu^*) = \inf_\Delta AC$.

In §§4 and 5 we study the *AC* problem via a dual pair of linear programs. First, however, in §3 we approach the problem using a so-called "canonical triplet" and two notions of strong *AC* optimality defined as follows.

DEFINITION 2.3. A policy δ^* is said to be

(a) *Strong optimal* (alias "asymptotically optimal" [8]) if

$$\limsup_{n\to\infty} n^{-1} J_n(\delta^*, \nu) \leq \liminf_{n\to\infty} n^{-1} J_n(\delta, \nu) \qquad \forall \delta \in \Delta, \nu \in \mathcal{P}(X).$$

(b) *F-strong optimal* (or strong optimal in the sense of Flynn [9]) if

$$\lim_{n\to\infty} n^{-1} [J_n(\delta^*, \nu) - J_n^*(\nu)] = 0 \qquad \forall \nu \in \mathcal{P}(X),$$

where $J_n^*(\cdot)$ is the optimal value function for the n-stage cost (2.3), i.e.,

$$J_n^*(\nu) := \inf_{\delta} J_n(\delta, \nu), \qquad \nu \in \mathcal{P}(X).$$

It is obvious that strong optimality (Definition 2.3(a)) implies optimality in the sense of (2.6), and so does F-strong optimality, since it implies that

$$\limsup_n n^{-1} J_n(\delta^*, \cdot) = \limsup_n n^{-1} J_n^*(\cdot).$$

Optimality, however, implies neither strong optimality nor F-strong optimality [8, Chap. 7], [9]. (In Theorem 3.3 we give conditions under which F-strong optimal $\Rightarrow$ strong optimal.)

Sufficient conditions for strong and/or F-strong optimality are given, e.g., in [9], [16], [3], [8], [10]. The conditions in the first two of these papers are based on the existence of a *bounded* solution to the optimality equation (OE) in (3.4) below. Our approach in the following section is somehow related to that in [9], [16], except that we allow a class of unbounded solutions to the OE. It should be noted, however, that there are other approaches. For instance, the optimal policy constructed in [6] is easily shown to be both strong and F-strong optimal, although the OE does *not* hold (in fact, the equality sign in (3.4) is replaced by strict inequality, $>$). The approach to F-strong optimality in [10], on the other hand, is quite different: it is based on an analysis of associated *discounted* cost problems (see also [9, Thm. 1]).

3. Canonical triplets. In this section we consider the so-called canonical triplets (or canonical systems [8], [27]) introduced by Yushkevich [34]. Our presentation below follows closely [3, §6], except that we allow unbounded one-stage costs satisfying the following condition (which will be weakened below: see Assumption 4.2).

(3.1) There is a number $m > 0$ and a positive measurable function b_1 on X such that, for all $(x, a) \in K$,

(i) $c(x, a) \leq m b_1(x)$, and

(ii) $\int b_1(y) Q(dy \mid x, a) \leq b_1(x)$.

If c is bounded, we may take $b_1(\cdot) \equiv 1$, and $m := \sup_{(x,a)} c(x, a)$.

Condition (3.1), as well as the following definition, are of common use in Markov control theory [17], [20], [24], [27].

DEFINITION 3.1. Let S be a Borel space, and $b : S \to R$ a positive measurable function. For any real-valued measurable function v on S, let

$$\| v \|_b := \sup_s | v(s) | b(s)^{-1},$$

and define $F(S, b)$ as the Banach space of all such functions v for which $\| v \|_b < \infty$. We call b a *bounding function* on S. ($\| \cdot \|_b$ is usually referred to as a *weighted supremum norm.*)

Among other important consequences, condition (3.1) guarantees the following lemma.

LEMMA 3.1. *Let $m, b_1(\cdot)$ and $F(X, b_1)$ be as in* (3.1) *and Definition* 3.1 (*with $S = X$*). *Then for any policy $\delta \in \Delta$ and any initial state $x \in X$.*

(a) $\{b_1(x_t), t \geq 0\}$ *is a P_x^δ-supermartingale, i.e.,*

$$E_x^\delta [b_1(x_{t+1}) \mid h_t] \leq b_1(x_t) \qquad \forall\ h_t \in H_t,\ t \geq 0,$$

which implies

(b) $E_x^\delta b_1(x_{t+1}) \le E_x^\delta b_1(x_t) \le \cdots \le b_1(x) \qquad \forall t \ge 0,$

and

(c) $J(\delta, x) \le m b_1(x).$

Moreover, for any function $h \in F(X, b_1)$,

(d) $\sup_\delta n^{-1} E_x^\delta |\, h(x_n)\,| \to 0$ *as* $n \to \infty$,

(e) $\limsup_n n^{-1} J_n(\delta, x, h) = \limsup_n n^{-1} J_n(\delta, x) \qquad (=: J(\delta, x)),$

and

$\liminf_n n^{-1} J_n(\delta, x, h) = \liminf_n n^{-1} J_n(\delta, x).$

Proof. By (3.1)(ii) and the "Markov property" (cf. [3], [14], [19]),

$$\begin{aligned} E_x^\delta [b_1(x_{t+1}) \,|\, h_t] &= \int_A \int_X b_1(y) Q(dy \,|\, x_t, a_t)\, \delta_t(da_t \,|\, h_t) \\ &\le \int_A b_1(x_t)\, \delta_t(da_t \,|\, h_t) \\ &= b_1(x_t). \end{aligned}$$

This proves (a), hence (b). Part (c) follows from (b), (3.1)(i), and (2.3)–(2.4). Also (d) follows from (b), since

$$E_x^\delta |\, h(x_n)\,| \le \|h\|_{b_1} E_x^\delta b_1(x_n) \le \|h\|_{b_1} b_1(x).$$

Finally, to obtain (e) note that, from (2.2)–(2.3),

$$J_n(\delta, x, h) = J_n(\delta, x) + E_x^\delta h(x_n). \qquad (3.2)$$

□

Canonical triplets. Let ρ and h be real-valued measurable functions on X, and let δ^* be a given policy. Then (ρ, h, δ^*) is said to be a canonical triplet if

$$J_n(\delta^*, x, h) = J_n^*(x, h) = n\rho(x) + h(x) \qquad \forall n \ge 0,\ x \in X, \qquad (3.3)$$

where

$$J_n^*(x, h) := \inf_\delta J_n(\delta, x, h)$$

is the optimal value function for the n-stage cost in (2.2).

The following theorem can be proved exactly as in the case of bounded costs [3, Thm. 6.2], [8, Chap. 7], [27], [34].

THEOREM 3.2. *Let* ρ *and* h *be real-valued measurable functions on* X, *and* $f^* \in F$ *a stationary policy* (*see Definitions* 2.1, 2.2). *Suppose that* (3.1) *holds and that* h *is in* $F(X, b_1)$. *Then* (ρ, h, f^*) *is a canonical triplet if and only if, for all* $x \in X$,

(a) $\rho(x) = \inf_{a \in A(x)} \int_X \rho(y) Q(dy \,|\, x, a)$,

(b) $\rho(x) + h(x) = \inf_{a \in A(x)} \left[c(x, a) + \int_X h(y) Q(dy \,|\, x, a) \right]$,

(c) $f^*(x) \in A(x)$ *attains the infimum in* (a) *and* (b), *i.e.*,

$$\rho(x) = \int \rho(y) Q(dy \,|\, x, f^*(x)),$$

$$\rho(x) + h(x) = c(x, f^*(x)) + \int h(y) Q(dy \,|\, x, f^*(x)).$$

The existence of a policy $f^* \in F$ satisfying (c) in Theorem 3.3 is typically ensured, under appropriate assumptions, by "measurable selection theorems" [3], [4], [8], [14], [19].

The equation in (b) is called the average cost *optimality equation* (OE). In §4 we relate two linear programs EP and EP^* to the OE with $\rho(\cdot) \equiv \rho^*$ a constant, i.e.,

$$\rho^* + h(x) = \inf_{a \in A(x)} \left[c(x,a) + \int h(y) Q(dy \mid x,a) \right]. \tag{3.4}$$

If h is such that (see (d) in Lemma 3.2)

$$\lim_{n \to \infty} n^{-1} E_x^{\delta} h(x_n) = 0 \qquad \forall\, \delta \in \Delta,\ x \in X, \tag{3.5}$$

then the policy $f^* \in F$ as in Theorem 3.3(c) is optimal with optimal value ρ^*, i.e.,

$$J^*(\cdot) = J(f^*, \cdot) = \rho^*; \tag{3.6}$$

moreover, (f^*, ν) is a minimum pair for any initial distribution ν, i.e.,

$$J(f^*, \nu) = \inf_{\Delta} AC \qquad \forall \nu \in \mathcal{P}(X).$$

We will next show, in the context of Theorem 3.3, that f^* is strong optimal and F-strong optimal (Definition 2.3).

THEOREM 3.3. *Suppose that* (3.1) *holds and let* (ρ, h, f^*) *be a canonical triplet with* $f^* \in F$ *and* $h \in F(X, b_1)$. *Then*

(a) $J(f^*, x) = \lim_n n^{-1} J_n(f^*, x) = \rho(x) \qquad \forall\, x \in X,$

(b) f^* *is* F*-strong optimal and strong optimal; in fact,* F*-strong optimality implies strong optimality (which implies optimality).*

Proof. (a) From (3.2)–(3.3), with $\delta = \delta^* = f^*$, we obtain

$$J_n(f^*, x, h) = J_n(f^*, x) + E_x^{f^*} h(x_n) = n\rho(x) + h(x). \tag{3.7}$$

Dividing by n and using Lemma 3.1(d), we obtain the second equality in (a). The first equality is obtained similarly, using now Lemma 3.1(e).

(b) First we show that f^* is F-strong optimal. From (3.3) with $\delta^* = f^*$, and (3.7),

$$J_n(f^*, x) = J_n^*(x, h) - E_x^{f^*} h(x_n).$$

On the other hand,

$$\begin{aligned} J_n^*(x,h) &:= \inf_{\delta} J_n(\delta, x, h) \le \inf_{\delta} J_n(\delta, x) + \sup_{\delta} E_x^{\delta} h(x_n) \\ &= J_n^*(x) + \sup_{\delta} E_x^{\delta} h(x_n). \end{aligned}$$

Thus

$$0 \le J_n(f^*, x) - J_n^*(x) \le \sup_{\delta} E_x^{\delta} h(x_n) - E_x^{f^*} h(x_n),$$

so that, by Lemma 3.1(d), f^* is F-strong optimal. Now, to show that the latter implies strong optimality, note that, by (3.3) and (3.7),

$$J_n(f^*, x) + E_x^{f^*} h(x_n) \le J_n(\delta, x) + E_x^{\delta} h(x_n) \qquad \forall\, \delta \in \Delta,\ x \in X,$$

and, therefore,

$$\liminf n^{-1} J_n(f^*, \cdot) \leq \liminf n^{-1} J_n(\delta, \cdot) \qquad \forall\, \delta.$$

This inequality, together with (a), yields that f^* is strong optimal. □

In brief, the main conclusion of Theorem 3.3 is that if the OE has a solution (ρ, h), with h satisfying (3.5), then a policy $f^* \in F$ determined by the OE (in the sense of Theorem 3.2(c)) is F-strong optimal. Moreover (from part (a) and the definition of F-strong optimal), the optimal average cost satisfies

$$J(f^*, x) = \lim_n n^{-1} J_n^*(x) = \rho(x),$$

i.e., the optimal long-run average cost is the limit of optimal average cost problems with a *finite* horizon. This was one of the main motivations for introducing the notion of F-strong optimality, in the first place [9].

4. The linear programming formulation. In this section we consider the linear programming (LP) formulation of the average cost (or AC) problem introduced in §2. We will use some basic facts on LP in general vector spaces for which our main source is [2, Chap. 3] (cf. also [20, Chap. 4]).

Dual pairs. Let X and Y be two vector spaces and let $\langle \cdot, \cdot \rangle$ be a bilinear form on $\mathsf{X} \times \mathsf{Y}$, i.e., a function from $\mathsf{X} \times \mathsf{Y}$ to R such that $\langle x, y \rangle$ is a linear function of x for each fixed $y \in \mathsf{Y}$, and a linear function in y for each fixed $x \in \mathsf{X}$.

DEFINITION 4.1. The pair of spaces (X, Y) is said to be a *dual pair* [2, p. 36] (alias a *separated duality* [20, p. 54]) if

(a) for each $x \neq 0$ in X there is some $y \in \mathsf{Y}$ with $\langle x, y \rangle \neq 0$, and

(b) for each $y \neq 0$ in Y there is some $x \in \mathsf{X}$ with $\langle x, y \rangle \neq 0$.

Let (X, Y) be a dual pair, and let $\sigma(\mathsf{X}, \mathsf{Y})$ denote the weak topology on X, i.e., the coarsest topology on X under which all the elements of Y are continuous when regarded as linear forms $\langle \cdot, y \rangle$ on X. If (X, Y) is a dual pair, then Y is the dual of X with the topology $\sigma(\mathsf{X}, \mathsf{Y})$.

To define the linear programs we are interested in, we now introduce two dual pairs (X, Y) and (Z, W) as follows.

Let K be the subset of $X \times A$ defined in (2.1), and let b be a bounding function on K (see Definition 3.1) given by

$$b(x, a) := c_0 + c(x, a) \quad \text{for some constant } c_0 > 0. \tag{4.1a}$$

(The role of c_0 is just to ensure that b is strictly positive.)

As our space Y we take $F(K, b)$, which we now write simply as $F(K)$, i.e., $F(K)$ is the Banach space of all measurable functions v from K to R such that

$$\|v\|_b := \sup_{(x,a)} |\, v(x, a) \,|\, b(x, a)^{-1} < \infty. \tag{4.1b}$$

We consider a function v on K to be extended to all of $X \times A$ in an arbitrary way as long as measurability and (4.1) are preserved. Now let $M(K)$ (this is our X) be the vector space consisting of all the finite signed measures μ on $X \times A$ concentrated on K such that

$$\int b\, d\,|\,\mu\,| < \infty; \quad \text{equivalently } \int c d|\mu| < \infty, \tag{4.2}$$

where $|\mu|$ denotes the total variation of μ. Note that $c \in F(K)$. Finally, if $v \in F(K)$ and $\mu \in M(K)$, we define

$$\langle \mu, v \rangle := \int v d\mu. \tag{4.3}$$

With this bilinear form, the pair $(M(K), F(K))$ is a dual pair.

Now let b_1 be a bounding function on X and let $F(X, b_1) =: F(X)$. Then we define $M(X)$ as the vector space that consists of all the finite signed measures ν on X such that

$$\int b_1 d|\nu| < \infty. \tag{4.4}$$

Finally, let (Z, W) be the dual pair defined by $\mathsf{Z} := R \times M(X)$, $\mathsf{W} := R \times F(X)$, and the bilinear form

$$\langle (r, \nu),\ (\rho, h) \rangle := r\rho + \int h d\nu. \tag{4.5}$$

Throughout the rest of this paper we suppose the following assumption to hold.

Assumption 4.2. The bounding functions b (on K) and b_1 (on X) are such that

(a) $b(x, a) \geq b_1(x) \quad \forall\ (x, a) \in K$;

(b) $\int b_1(y) Q(dy \mid \cdot)$ is in $F(K)$, i.e.,

$$\sup_{(x,a)} b(x, a)^{-1} \int b_1(y) Q(dy \mid x, a) < \infty.$$

(c) There is a policy $\delta \in \Delta$ such that, for every $\nu \in \mathcal{P}(X)$, $J(\delta, \nu) < \infty$ or, equivalently,

$$\limsup_n n^{-1} E_\nu^\delta \sum_{t=0}^{n-1} b(x_t, a_t) < \infty.$$

The set of all such policies is denoted by Δ_b.

Note that if $b(x, a) \geq b_1(x)\ \forall (x, a)$, then condition (3.1), if it holds with the bounding function b_1, implies (b) in Assumption 4.2. If, on the other hand, the one-stage cost is bounded, then Assumption 4.2 trivially holds with constants b and b_1, say $b = b_1 := \sup_{(x,a)} c(x, a)$, and $\Delta_b = \Delta$.

Linear programs. Let $L : M(K) \to R \times M(X)$ and $L^* : R \times F(X) \to F(K)$ be the linear maps defined as follows. For every $\mu \in M(K)$, let $L\mu := (\overline{\mu}, L_1\mu)$ be the element of $R \times M(X)$ given by

$$\overline{\mu} := \mu(K), \tag{4.6a}$$

$$L_1\mu(B) := \mu_1(B) - \int Q(B \mid x, a) \mu(d(x, a)), \qquad B \in \mathcal{B}(X), \tag{4.6b}$$

where μ_1 denotes the *marginal* (or projection) of μ on X, i.e.,

$$\mu_1(B) := \mu(B \times A) \qquad \forall\ B \in \mathcal{B}(X). \tag{4.7}$$

Now, if (ρ, h) is in $R \times F(X)$, we let $L^*(\rho, h)$ be the function on K defined as

$$L^*(\rho,h)(x,a) := \rho + h(x) - \int_X h(y)Q(dy \mid x,a).$$

Assumption 4.2 guarantees that both L and L^* are continuous maps and that L^* is the adjoint of L, i.e.,

$$\langle L\mu, (\rho,h)\rangle = \langle \mu, L^*(\rho,h)\rangle.$$

Finally, we consider two linear programs EP and EP^* (cf. [2, pp. 38–39]).

EP: minimize $\langle \mu, c\rangle$
subject to: $L\mu = (1,0)$, $\mu \geq 0$.
EP^*: maximize $\langle (1,0), (\rho,h)\rangle$
subject to: $L^*(\rho,h) \leq c$.

Equivalently, denoting by $M^1(K)$ the family of all *probability measures* μ in $M(K)$, so that $\overline{\mu} = 1$, we may rewrite EP as

EP: minimize $\int c d\mu$
subject to: $\mu \in M^1(K)$, and

$$\mu_1(B) - \int Q(B \mid x,a)\,\mu(d(x,a)) = 0, \qquad B \in \mathcal{B}(X). \tag{4.8}$$

Similarly, in a more explicit form, EP^* reads as follows.

EP^*: maximize ρ
subject to: $(\rho, h) \in R \times F(X)$, and

$$\rho + h(x) - \int h(y)Q(dy \mid x,a) \leq c(x,a) \qquad \forall\ (x,a) \in K. \tag{4.9}$$

In the terminology of [2, pp. 38–39], EP^* is the *dual* of the linear program EP.

A linear program is said to be *consistent* if it has a feasible solution, and *solvable* if it has an optimal solution. We will next give a condition under which EP is consistent (EP^* is always consistent!) and show how EP and EP^* relate to the AC problem in §2. The solvability question is postponed until §5.

If $\varphi \in \Phi$ is a relaxed policy (see Definitions 2.1 and 2.2), then we define, for all $x \in X$,

$$v(x,\varphi) := \int_A v(x,a)\varphi(da \mid x), \qquad v \in F(K), \tag{4.10}$$

$$Q(B \mid x,\varphi) := \int_A Q(B \mid x,a)\,\varphi(da \mid x), \qquad B \in \mathcal{B}(X). \tag{4.11}$$

Assumption 4.3. There exists a relaxed policy $\varphi \in \Phi$ such that $Q(\cdot \mid \cdot, \varphi)$ has an invariant probability measure $p^\varphi \in \mathcal{P}(X)$, i.e. (using the notation (4.10), (4.11)),

$$p^\varphi(B) = \int_X Q(B \mid x,\varphi)\,p^\varphi(dx) \qquad \forall\ B \in \mathcal{B}(X), \tag{4.12a}$$

and, furthermore,

$$\int b(x,\varphi)p^\varphi(dx) < \infty \quad \text{(equivalently, } \int c(x,\varphi)p^\varphi(dx) < \infty\text{)}. \tag{4.12b}$$

A relaxed policy that satisfies Assumption 4.3 is called *stable*. The invariant probability measure p^{φ} in (4.12a) is *not* required to be unique; if it is, then the transition kernel $Q(\cdot \mid \cdot, \varphi)$ is said to be *ergodic*. Sufficient conditions for (4.12a) are given in, e.g., [8], [14], [18], [25], [33]. (See also Lemma 6.1.) Notice, on the other hand, that Assumption 4.3 is in fact *equivalent* to EP's being consistent. (This fact is due to Lemma 4.4 and (4.15).)

Parts (b) and (c) in the following proposition are consequences, of course, of general LP results.

PROPOSITION 4.1. *Suppose that Assumptions* 4.2 *and* 4.3 *hold. Then*

(a) **Consistency:** *Both EP and EP^* are consistent; their values will be denoted by $\inf EP$ and $\sup EP^*$, respectively (if the programs are solvable, then we write $\inf$ as $\min$, and $\sup$ as $\max$)*;

(b) **Weak duality:** *For any feasible solutions μ of EP and (ρ, h) of EP^*, we have $\rho \leq \int c d\mu$; hence*

$$\sup EP^* \leq \inf EP; \tag{4.13}$$

(c) **Complementary slackness:** *If μ is feasible for EP, (ρ, h) is feasible for EP^*, and*

$$\langle \mu, c - L^*(\rho, h) \rangle = 0, \tag{4.14}$$

then μ is optimal for EP, (ρ, h) is optimal for EP^*, and equality holds in (4.13). (*The converse trivially holds.*)

Proof. (a) That EP^* is consistent is trivial: take, e.g., $\rho := \inf_{(x,a)} c(x,a)$ and $h(\cdot) \equiv 0$.

To see that EP is consistent, let φ be a stable relaxed policy, and let μ^{φ} be the probability measure on $X \times A$, concentrated on K, such that

$$\mu^{\varphi}(B \times C) := \int_B \varphi(C \mid x) p^{\varphi}(dx) \qquad \forall\, B \in \mathcal{B}(X),\ C \in \mathcal{B}(A). \tag{4.15}$$

Then $\mu_1^{\varphi}(B) := \mu^{\varphi}(B \times A) = p^{\varphi}(B) \quad \forall\ B \in \mathcal{B}(X)$, and so, from (4.12), μ^{φ} satisfies (4.8) and (4.2).

(b) To obtain (b), simply integrate (4.9) with respect to a measure $\mu \in M^1(K)$ that satisfies (4.8). This would yield

$$\langle \mu, L^*(\rho, h) \rangle \leq \langle \mu, c \rangle,$$

from which one can also deduce part (c). □

One can easily relate EP^* to the OE (3.4). Indeed, if (ρ^*, h) is a pair in $R \times F(X)$ that satisfies (3.4), then (ρ^*, h) is feasible for EP^* and, therefore, $\sup EP^* \geq \rho^*$. The reverse inequality is also obvious, since (4.9) implies that for any feasible solution (ρ, h) of EP^*

$$\rho + h(x) \leq \inf_{a \in A(x)} \left[c(x,a) + \int h(y) Q(dy \mid x, a) \right].$$

Thus, if such a pair (ρ^*, h) exists, then EP^* is solvable and

$$\max EP^* = \rho^*. \tag{4.16}$$

In other words, solving EP^* is equivalent to finding a solution to the OE when the latter exists.

To obtain further relations between the different problems, let us first prove the following (compare (4.17) with Lemma 3.1(d)).

LEMMA 4.2. (a) *If the Assumptions* 4.2(a), (c) *hold, and* $h \in F(X)$, *then*

$$\lim_n n^{-1} E_\nu^\delta [h(x_n)] = 0 \qquad \forall \delta \in \Delta_b, \ \nu \in \mathcal{P}(X). \tag{4.17}$$

(Δ_b *is as in Assumption* 4.2(c).)

(b) *If, in addition,* (ρ, h) *is a pair in* $R \times F(X)$ *that satisfies* (4.9), *then*

$$\rho \leq J(\delta, \nu) \qquad \forall \delta \in \Delta_b, \ \nu \in \mathcal{P}(X). \tag{4.18}$$

Proof. (a) Since, for *all* $\delta \in \Delta$ and $\nu \in \mathcal{P}(X)$,

$$E_\nu^\delta \, | \, h(x_n) \, | \leq \| \, h \, \|_{b_1} E_\nu^\delta b_1(x_n) \leq \| \, h \, \|_{b_1} E_\nu^\delta b(x_n, a_n),$$

part (a) follows from the Assumption 4.2(c), which implies that $\lim_n n^{-1} E_\nu^\delta b(x_n, a_n) = 0$ if $\delta \in \Delta_b$.

(b) This part is standard (see e.g. [3], [14], [29]). □

As a consequence of (4.18), we obtain, under Assumption 4.2(a) and (c),

$$\sup EP^* \leq \inf_\Delta AC, \tag{4.19}$$

where $\inf_\Delta AC$ is the value of the AC problem; see (2.7).

The corresponding result for the "primal" problem EP is as follows.

THEOREM 4.3. *Suppose that Assumption* 4.2 *holds and that* EP *is consistent. Then*

$$\inf_\Delta AC \leq \inf EP. \tag{4.20}$$

Proof. Suppose that $\mu \in M^1(K)$ satisfies (4.8). Then, by Lemma 4.4, there is a relaxed policy $\varphi \in \Phi$ satisfying (4.21). Thus, by the hypothesis on μ, the policy φ and $p^\varphi := \mu_1$ satisfy Assumption 4.3. Therefore, by the Individual Ergodic Theorem [33, p. 388], the average cost $J(\varphi, \mu_1)$ when using the policy φ and the initial distribution is μ_1 satisfies (cf. Remark 5.2)

$$\int c \, d\mu = J(\varphi, \mu_1) \geq \inf_\Delta AC.$$

Since μ was an arbitrary feasible solution of EP, (4.20) follows. □

LEMMA 4.4. *If* μ *is a probability measure on* $X \times A$ *concentrated on* K, *then there exists a relaxed policy* $\varphi \in \Phi$ *such that*

$$\mu(B \times C) = \int_B \varphi(C \, | \, x) \mu_1(dx) \qquad \forall B \in \mathcal{B}(X), \ C \in \mathcal{B}(A), \tag{4.21}$$

where μ_1 *is the marginal of* μ *on* X.

Proof. See, e.g., [8, p. 89, Thm. 2] or [19, p. 89, Cor. 12.7]. □

Equation (4.19) and Theorem 4.3 yield (4.22).

COROLLARY 4.5. *Suppose that Assumptions* 4.2 *and* 4.3 *hold. Then*

$$\sup EP^* \leq \inf_\Delta AC \leq \inf EP. \tag{4.22}$$

If, moreover, (ρ^*, h, f^*) *is a canonical triplet such that* ρ^* *is a constant and* $h \in F(X)$, *then (from* (3.6) *and* (4.16)) (ρ^*, h) *is optimal for* EP^*, f^* *is optimal for the AC problem and*

$$\rho^* = \max EP^* = \min_{\Delta} AC \leq \inf EP. \tag{4.23}$$

If a linear program and its dual have the same (finite) value, i.e.,

$$\sup EP^* = \inf EP, \tag{4.24}$$

it is then said that there is *no duality gap* for the problem [2, p. 52]. If there is no duality gap and the common value is achieved in each program (in which case we write sup EP^* as max EP^*, and inf EP as min EP), then the *strong duality* condition holds, i.e.,

$$\max EP^* = \min EP. \tag{4.25}$$

There are examples in which neither of these conditions hold (see, e.g., [6], [8], [23], [29]); in fact, both inequalities in (4.22) may be strict. We will give below conditions under which (4.24) and (4.25) hold. But first let us remark on a consequence of strong duality, when it holds.

Remark 4.6. Suppose that Assumptions 4.2 and 4.3 and the *strong duality condition* (4.25) hold, i.e., there exists an optimal solution $\mu^* \in M^1(K)$ for EP, an optimal solution $(\rho^*, h) \in R \times F(X)$ for EP^* and $\rho^* = \int c d\mu^*$. Then writing μ^* as in (4.21), i.e., $\mu^*(d(x,a)) = \varphi^*(da \,|\, x)\mu_1^*(dx)$, with $\varphi^* \in \Phi$, the complementary slackness equation (4.14) can be written as

$$\int_X \left[c(x, \varphi^*) - \rho^* - h(x) + \int h(y) Q(dy \,|\, x, \varphi^*) \right] \mu_1^*(dx) = 0. \tag{4.26}$$

Thus, by the Blackwell and Ryll–Nardzewski theorem, we conclude (as in [8, §3.2]) that there is a *nonrandomized* stationary policy $f^* \in F$ such that (using the abbreviation a.a.=almost all)

$$\begin{aligned} \rho^* + h(x) &= c(x, f^*(x)) + \int h(y) Q(dy \,|\, x, f^*(x)) \\ &= \min_{a \in A(x)} \left[c(x,a) + \int h(y) Q(dy|x,a) \right] \quad \text{for } \mu_1^*\text{–a.a. } x \in X. \end{aligned} \tag{4.27}$$

This is a "weaker" form of the OE (3.4), and one can derive by standard arguments [3], [8], [14], [29], etc., the corresponding "weak" form of (3.6):

$$J^*(x) = J(f^*, x) = \rho^* \qquad \text{for } \mu_1^*\text{–a.a. } x \in X. \tag{4.28}$$

That is to say, $f^* \in F$ is *optimal* μ_1^**-almost everywhere* (by which we mean of course (4.28)). Of course, integration with respect to μ_1^* in (4.28) shows that (f^*, μ_1^*) is a minimum pair. In conclusion, we have the following proposition.

PROPOSITION 4.7. *Suppose that Assumptions* 4.2 *and* 4.3 *are satisfied, and that there is strong duality. Then there exists a (nonrandomized) stationary policy* $f^* \in F$ *that is optimal* μ_1^**–a.e., where* μ_1^* *is the marginal on* X *of an optimal solution* μ^* *for the linear ("primal") problem* EP, *and* (f^*, μ_1^*) *is a minimum pair.*

In [23, Thm. 1], it is shown that if the state space is a *countable* set and control constraint sets $A(x)$ are *finite*, then the policy f^* obtained as in Proposition 4.7 is, in fact, *optimal*—as opposed to optimal μ_1^*-a.e., if there exists an ergodic stationary policy with finite average cost.

5. Solvability and absence of duality gap. We will now give sufficient conditions for the linear program EP to be solvable and for the absence of duality gap to hold. (These results are illustrated with examples in §6.) Throughout this section we suppose that both Assumptions 4.2 and 4.3 hold so that, in particular, EP is consistent.

Let $M^*(K)$ be the set of feasible solutions for EP, and let $M^+(K)$ be the positive cone in $M(K)$, i.e.,

$$M^*(K) := \{\mu \in M^1(K) \mid (4.8) \text{ holds}\}, \tag{5.1}$$
$$M^+(K) := \{\mu \in M(K) \mid \mu \geq 0\}.$$

Observe that $M^*(K) \subset M^1(K) \subset M^+(K) \subset M(K)$.

Solvability of EP requires Assumption 5.1 below, whereas the absence of duality gap requires the stronger Assumption 5.1′.

Notation. If S is a topological space, $C(S)$ denotes the space of real-valued, continuous and bounded functions on S.

Assumption 5.1. (a) The one-stage cost function c, hence the bounding function b, is lower semicontinuous (l.s.c.);

(b) The transition law Q is weakly continuous, i.e., $\int u(y)Q(dy \mid x, a)$ is a continuous and bounded function on K for every $u \in C(X)$;

(c) The set $M_r := \{\mu \in M^*(K) \mid \int c d\mu \leq r\}$ is tight for every number $r \geq 0$.

Assumption 5.1′ This assumption is the same as Assumption 5.1 except that (c) is replaced by

(c′) The set $M_r' := \{\mu \in M^1(K) \mid \int c d\mu \leq r\}$ is tight for every $r \geq 0$.

See Remark 5.6 for information concerning the tightness assumptions (c) and (c′).

Remark 5.1. A relaxed policy $\varphi \in \Phi$ that satisfies Assumption 4.3 is said to be *stable*. If $\varphi \in \Phi$ is stable and p^φ is as in Assumption 4.3, then the average cost $J(\varphi, p^\varphi)$ when using the policy φ with initial distribution p^φ satisfies

$$J(\varphi, p^\varphi) = \int J(\varphi, x) p^\varphi(dx) = \int c(x, \varphi) p^\varphi(dx) = \int c d\mu^\varphi, \tag{5.2}$$

where $\mu^\varphi \in M^*(K)$ is as in (4.15). Indeed, by (4.12b), the integral $\int c(x, \varphi) p^\varphi(dx)$ is finite and, therefore, (5.2) follows from the Individual Ergodic Theorem [33, p. 388].

THEOREM 5.2. *If Assumptions* 4.2, 4.3, *and* 5.1 *hold, then EP is solvable, i.e., there is a feasible solution μ^* for EP such that*

$$\min EP = \int c d\mu^*. \tag{5.3}$$

Moreover, decomposing μ^* as in Proposition 4.7 *we obtain a minimum pair (φ^*, μ_1^*) for the average cost (or AC) problem and*

$$\min EP = \inf_{\Delta} AC = J(\varphi^*, \mu_1^*). \tag{5.4}$$

Proof. 1°. By a standard argument using Assumptions 5.1(a) and (c) (see, e.g., [15], [21]), for any policy $\delta \in \Delta$ and any initial distribution ν on X for which the average cost $J(\delta, \nu)$ is finite, there exists a stable relaxed policy φ such that

$$J(\delta, \nu) \geq J(\varphi, p^\varphi) = \int c d\mu^\varphi.$$

(See (5.2).) In other words, if δ and ν are such that $J(\delta,\nu) < \infty$, then there is a feasible solution μ for EP such that

$$J(\delta,\nu) \geq \int c d\mu \; (\geq \inf EP). \tag{5.5}$$

This inequality and (4.20) imply (5.3) *if* EP is solvable.

2^o. Now, to show that EP is solvable, let us write $\rho^* := \inf EP$ and let $\{\varepsilon_n\}$ be a sequence of numbers such that $\varepsilon_n \downarrow 0$. For each n, let $\mu^n \in M^*(K)$ be such that

$$\rho^* \leq \int c d\mu^n < \rho^* + \varepsilon_n. \tag{5.6}$$

By the tightness assumption, Assumption 5.1(c), and Prohorov's theorem [5, p. 37], there is a subsequence $\{\mu^{n_i}\}$ of $\{\mu^n\}$ and a probability measure μ^* such that μ^{n_i} converges weakly (in the sense of probability measures [5]) to μ^*, i.e.,

$$\lim_i \int v d\mu^{n_i} = \int v d\mu^* \qquad \forall \; v \in C(K). \tag{5.7}$$

This weak convergence and the lower semicontinuity assumption, Assumption 5.1(a), yield

$$\int c d\mu^* \leq \liminf_i \int c d\mu^{n_i}, \tag{5.8}$$

so that, from (5.6),

$$\int c d\mu^* = \rho^* := \inf EP. \tag{5.9}$$

Thus, to conclude that μ^* is an optimal solution for EP, it only remains to show that μ^* is indeed feasible for EP, i.e., that it satisfies (4.2) and (4.8).

3^o. The fact that μ^* satisfies (4.2) follows from (5.6) and (5.9). Finally, that μ^* satisfies (4.8) follows from (5.7) and the weak continuity assumption, Assumption 5.1(b); namely, (5.7) implies the weak convergence of the marginals $\mu_1^{n_i} \to \mu_1^*$ on X and, therefore, for any function $u \in C(X)$

$$\begin{aligned} \int_X u(y)\mu_1^*(dy) &= \lim_i \int_X u(y)\mu_1^{n_i}(dy) \\ &= \lim_i \int_K \int_X u(y)Q(dy \,|\, k)\mu^{n_i}(dk) \qquad \text{[by (4.8)]} \\ &= \int_K \int_X u(y)Q(dy \,|\, k)\mu^*(dk), \end{aligned} \tag{5.10}$$

where the latter equality is due to (5.7) and Assumption 5.1(b). This yields (4.8). We have thus shown that $\mu^* \in M^*(K)$, which combined with (5.9) completes the proof of (5.3). Finally, to obtain (5.4) note that [cf. (5.2)]

$$\int c d\mu^* = \int c(x,\varphi^*)\mu_1^*(dx) = J(\varphi^*,\mu_1^*). \qquad \square$$

Sufficient conditions for the absence of duality gap (4.24) in general linear programs are given in [2, Chap. 3]. Here we choose one based on the closedness of the subset H of $(R \times M(X)) \times R$ defined as

$$H := \left\{ (L\mu, \langle \mu, c \rangle + r) \,|\, \mu \in M^+(K), \; r \geq 0 \right\}, \tag{5.11}$$

where $L\mu := (\overline{\mu}, L_1\mu)$ is the pair defined in (4.6); $\langle \mu, c\rangle = \int c d\mu$, as in (4.3), $M^+(K)$ is the positive cone in $M(K)$ and r a positive scalar; see (5.1). Explicitly, Theorem 3.9 in [2, p. 52] yields the following.

LEMMA 5.3. *If EP has a finite value and the set H in* (5.11) *is closed, then there is no duality gap for EP.*

THEOREM 5.4. *If Assumptions* 4.2, 4.3, *and* 5.1′ *hold, then there is no duality gap for EP, which combined with* (5.4) *yields*

$$\sup EP^* = \min EP = \inf_{\Delta} AC. \tag{5.12}$$

Proof. Assumption 5.1′ implies Assumption 5.1, since M_r' contains M_r. Hence, by Theorem 5.2 and Lemma 5.3, we only need to prove that H is closed, i.e., if $\{(\mu^n, r^n)\}$ is a sequence in $M^+(K) \times R^+$ such that

$$((\overline{\mu}^n, L_1\mu^n), \langle \mu^n, c\rangle + r^n) \to ((r_*, \nu_*), \rho_*) \in (R \times M(X)) \times R, \tag{5.13}$$

then $((r_*, \nu_*), \rho_*)$ is in H. The latter means of course that, for some $\mu \in M^+(K)$ and $r \in R^+$,

$$r_* = \lim \overline{\mu}^n = \overline{\mu}, \tag{5.14a}$$

$$\nu_* = \lim L_1\mu^n = L_1\mu, \tag{5.14b}$$

$$\rho_* = \lim \int c d\mu^n + r^n = \int c d\mu + r, \tag{5.14c}$$

where (see (4.5)) the convergence in (a)–(b) is in the sense that for all (ρ, h) in $R \times F(X)$,

$$r_*\rho + \int h d\nu_* = \lim \left[\overline{\mu}^n \rho + \int h d(L_1\mu^n)\right]. \tag{5.15}$$

To begin, note that if $r_* = \lim \overline{\mu}^n = 0$, then we are done, for (5.14) trivially holds taking $\mu(\cdot) \equiv 0$, the null measure on Kand $r = \rho_*$. On the other hand, if $r_* > 0$, then $\overline{\mu}^n := \mu^n(K)$ is positive for all n sufficiently large. Thus (dividing $\mu^n(\cdot)$ by $\overline{\mu}^n$ if necessary) we may, and will, assume, without loss of generality, that the μ^n in (5.13)–(5.15) are *probability* measures, i.e., $\overline{\mu}^n = r_* = 1$ for all n.

Now, taking $\rho = 0$, (5.15) and the definition of L_1 in (4.6) yield

$$\lim_n \left[\int_X h d\mu_1^n - \int_K \int_X h(y) Q(dy|k)\, \mu^n(dk)\right] = \int h d\nu_* \qquad \forall h \in F(x). \tag{5.16}$$

On the other hand, by (5.14c), for any given $\varepsilon > 0$, there exists $n(\varepsilon)$ such that

$$\int c d\mu^n < \rho_* + \varepsilon \qquad \forall\, n \geq n(\varepsilon). \tag{5.17}$$

Therefore, by Assumption 5.1′(c′), there is subsequence $\{\mu^{n_i}\}$ of $\{\mu^n\}$ and a probability measure μ such that (5.17) holds for all $n = n_i \geq n(\varepsilon)$ and μ^{n_i} converges weakly to μ, i.e.,

$$\int v d\mu^{n_i} \to \int v d\mu \qquad \forall\, v \in C(K). \tag{5.18}$$

Thus, the same argument that gave (5.8) now gives

$$\int c d\mu \leq \liminf_i \int c d\mu^{n_i},$$

which in turn gives that μ satisfies (4.2), i.e., μ is in $M^1(K)$. Moreover, as in the proof of (5.10), we obtain that, for all $u \in C(X)$,

$$\lim_i \int u d\mu_1^{n_i} = \int u d\mu_1, \tag{5.19a}$$

and

$$\lim_i \int \int u(y) Q(dy \mid k) \mu^{n_i}(dk) = \int \int u(y) Q(dy \mid k) \mu(dk). \tag{5.19b}$$

Therefore $l_1 \mu = \nu^*$. In other words, we have found a measure $\mu \in M^1(K)$ that satisfies (5.14a,b) and

$$\int c d\mu \leq \rho_*.$$

Finally, by taking $r = \rho_* - \int c d\mu \geq 0$ there is a measure $\mu \in M^1(K) \subset M^+(K)$ and a positive scalar r that satisfies (5.14), i.e., H is closed. This completes the proof of the theorem. □

A trivial case in which (all) the assumptions of Lemma 5.3 and Theorem 5.4 are satisfied occurs when both X and the control set A are finite. In the nonfinite case, we know of only three papers that have obtained results similar to ours: in [23] X is a *denumerable* set and the one-stage cost c is unbounded; in [32] X is a compact subset of R^n, and in [16] X is a Borel space, but in these two papers c is *bounded*. In §6 we shall consider a general class of systems for which Lemma 5.3 and Theorem 5.4 are valid.

Remark 5.5. General sufficient conditions for tightness of, say, a subset M of $M^1(K)$ are well known [5]; in particular, for Markov control/decision processes see, e.g., [18] and references therein. On the other hand, a sufficient condition that is particularly useful when dealing with unbounded one-stage costs is the following (cf. [13], [15], [25]): $\mathsf{M} \subset M^1(K)$ is tight if

(5.20) There is a moment function v such that $\sup\{\int v d\mu \mid \mu \in \mathsf{M}\} < \infty$. (By definition, a nonnegative measurable function v on Kis a *moment* if there exists a sequence of compact sets $K_n \uparrow K$ such that $\inf\{v(x,a) \mid (x,a) \notin K_n\} \to \infty$.)

The interpretation of a moment as a *Lyapunov* function is well known; see, e.g., [13], [25] and references therein. In [15] and [23], (5.20) has been used with $v = c$, that is, the moment function v is taken as the one-stage cost itself. A similar choice is done for the system in §6.

6. An application: Additive-noise systems. To illustrate the results of §§4 and 5, we introduce below a class of nonlinear additive-noise (i.e., autoregressive-like) systems, which are common in fields such as engineering and economics. Without going into too many details the idea is to give *sufficient* conditions for Assumptions 4.2, 4.3, and 5.1/5.1′ to hold, so that, in particular, *the conclusions of Propositions* 4.1, 4.7, *and Theorems* 5.2, 5.4 *are all valid.*

The state space and the control set are $X = R^p$ and $A = R^q$, respectively, and the control system evolves according to the equation

$$x_{t+1} = G(x_t, a_t) + \xi_t, \quad t = 0, 1, \ldots; \quad x_0 \in X \text{ given}, \tag{6.1}$$

where $x_t \in X$, $a_t \in A(x_t) \subset A$, and $\{\xi_t\}$ is a sequence of independent and identically distributed random p-vectors. The sets $A(x)$ are assumed to be closed such that K is convex. If the initial state x_0 is random, then it is assumed to be independent of $\{\xi_t\}$. The one-stage cost is the quadratic function on K (the set defined in (2.1)) given by

$$c(x, a) := x'Hx + a'Ra, \quad (\text{"prime" denotes "transpose"}), \tag{6.2}$$

where H and R are symmetric and positive definite matrices. If, in particular, G is linear in both x and a, and $A(\cdot) \equiv A$, then (6.1)–(6.2) reduces to the familiar LQ (or linear-quadratic) system.

Let $c_0 \geq c_1 > 0$ be two given constants, and define the "bounding" functions

$$b(x, a) := c_0 + c(x, a);$$
$$b_1(x) := c_1 + x'Hx \quad \left(\leq c_1 + \inf_{a \in A(x)} c(x, a) \right). \tag{6.3}$$

Let us suppose the following (basically continuity and "growth") conditions.

Assumption 6.1. (a) $G(x, a) : K \to X$ is continuous;

(b) $G(x, \varphi) := \int G(x, a)\varphi(da|x)$ is locally bounded for every $\varphi \in \Phi$;

(c) For some constant $m > 0$, $G(x, a)'HG(x, a) \leq mc(x, a)$ $\forall (x, a) \in K$;

(d) The random vector ξ_t are absolutely continuous with a density γ such that:

(d_1) γ is positive λ-almost everywhere ($\lambda :=$ Lebesgue measure) and, moreover,

(d_2) the ξ_t have zero mean and $E\,|\,\xi_0\,|^2 < \infty$;

(e) There exists a relaxed policy $\varphi^* \in \Phi$ for which the following holds: there are positive constants $\rho < 1$, k_1, k_2 such that

(e_1) $E|G(x, \varphi^*) + \xi|^2 \leq \rho|x|^2 \quad \forall |x| \geq k_1$, and

(e_2) $\int (a'Ra)\varphi^*(da|x) \leq k_2|x|^2$ $\forall x$.

The key fact to be noted about Assumption 6.1 is that it allows us to use results on ergodicity of time series [7], [26], [31]. For instance, [7, Prop. 4] or [26, Prop. 3] yields the following.

LEMMA 6.1. *Suppose that Assumptions* 6.1(b) *and* 6.1(d_1) *hold. If, moreover,* $\varphi^* \in \Phi$ *satisfies Assumption* 6.1(e_1), *then, when using the policy* φ^*, *the state (Markov) process* $\{x_t\}$ *is geometrically ergodic and its (unique) stationary distribution* p^{φ^*} *is such that* $\lambda << p^{\varphi^*}$ *(in words: the Lebesque measure* λ *is absolutely continuous with respect to* p^{φ^*}), *and it has a finite second moment, i.e.,* $\int |x|^2 p^{\varphi^*}(dx) < \infty$.

The following theorem is the main result in this section.

THEOREM 6.2. *Consider the system* (6.1) *with one-stage cost* (6.2). *Then Assumption* 6.1 *implies the Assumptions* 4.2, 4.3, *and* 5.1′ (*hence* 5.1).

Proof. We first verify Assumption 4.2: Assumption 4.2(a) is trivially satisfied by the definition of b and b_1 in (6.3). With respect to 4.2(b), we have

$$\begin{aligned} \int b_1(y)Q(dy|x, a) &= E\left[b_1(x_{t+1}) \,|\, x_t = x,\, a_t = a\right] \\ &= c_1 + E\left[(G(x, a) + \xi)'\, H(G(x, a) + \xi)\right] \\ &= c_1 + G(x, a)'HG(x, a) + E(\xi'H\xi), \end{aligned}$$

where ξ stands for a generic random vector with density γ (see Assumption 6.1(d)). Thus, from Assumptions 6.1(c), (d_2), and the definition of b, we obtain

$$\int b_1(y)Q(dy|x,a) \leq \text{constant} \cdot b(x,a) \qquad \forall\,(x,a) \in K,$$

i.e., Assumption 4.2(b) holds.

To verify Assumption 4.2(c), as well as Assumption 4.3, let us first note that Assumptions 6.1(b) and $6.1(d_1)$ imply that the state (Markov) process $\{x_t\}$ when using *any* relaxed policy φ is λ-Harris recurrent [7], [26], [31]. Thus if φ^* is the "ergodic" stable policy in Assumption 6.1(e) (see Lemma 6.1), then the Strong Law of Large Numbers for functionals of Markov chains [30] yields that, for any initial distribution ν,

$$\begin{aligned}\limsup_n n^{-1}E_\nu^{\varphi^*}\sum_{t=0}^{n-1} b(x_t,a_t) &= c_0 + J(\varphi^*,\nu)\\ &= c_0 + \int c(x,\varphi^*)p^{\varphi^*}(dx) < \infty,\end{aligned}$$

where the latter inequality comes from (6.2), Assumption 6.1 (e_2), and Lemma 6.1; i.e., from some constant H_1,

$$\begin{aligned}\int c(x,\varphi^*)p^{\varphi^*}(dx) &= \int (x'Hx)\,p^{\varphi^*}(dx) + \int\int (a'Ra)\,\varphi^*(da|x)p^{\varphi^*}(dx)\\ &\leq H_1\int |x|^2 p^{\varphi^*}(dx) + k_2\int |x|^2 p^{\varphi^*}(dx) < \infty.\end{aligned}$$

It only remains to verify Assumption 5.1′. The lower semicontinuity (in fact, continuity) of c is obvious: see (6.2). Assumption 5.1(b) follows from Assumption 6.1(a) and the Dominated Convergence Theorem: they yield that for any function $u \in C(X)$, the function

$$\int u(y)Q(dy|x,a) = E\,[u(x_{t+1})\,|\,x_t = x,\ a_t = a] = \int u\,[G(x,a)+s]\,\gamma(s)ds$$

is continuous and bounded in (x,a). Finally, the tightness condition in Assumption 5.1(c) (or (c′)) follows from (5.20), since clearly the function c in (6.2) is a moment:

$$c(x,a) \geq x'Hx \to \infty \text{ as } |x| \to \infty,\ \forall a \in A(x).$$

This completes the proof of the theorem. □

We have shown that Assumption 6.1 ensures the conclusions of Theorems 5.2 and 5.4, for example, but one could try for the problem (6.1)–(6.2), as well as for the general Markov control process in §2, alternative sufficient conditions (cf. [18], [25]). On the other hand, an important problem left open is how can one compute (or "approximate") the optimal value in, say, (5.3)–(5.4). For example, for *finite* state average cost problem the relation between policy iteration and the simplex algorithm of linear programming is well known. Does it hold an analogous relation in more general spaces?

A SIMPLE FREE BOUNDARY PROBLEM IN $\mathbf{R}^d$*

GUILLERMO FERREYRA† AND OMAR HIJAB‡

Abstract. A multidimensional deterministic singular control problem is posed and solved. The interest here is the explicitness of the result and the novelty of the gradient constraint.

Key words. singular control, free boundary problem, viscosity solution, Bellman equation

AMS subject classifications. 35F30, 49L20, 49L25

Introduction. We start with the linear system

$$\dot{x} = -a(t)x, \qquad x(0) = x \in \mathbf{R}^d, \tag{0.1}$$

where $a(t) \geq 0$ is a measurable function of time—the control—valued in the space of nonnegative $d \times d$ matrices, we define

$$v^a(x) = \int_0^\infty e^{-t}[\langle b, x(t)\rangle + \operatorname{trace}(a(t))]dt, \tag{0.2}$$

where $b \in \mathbf{R}^d \setminus 0$ is fixed throughout, and we set

$$v(x) = \inf\{v^a(x) \colon a(\cdot) \geq 0\}. \tag{0.3}$$

The problem we address in this paper is the analysis of the so-called *value function* v of the variational problem (0.1), (0.2), (0.3).

The interest in this problem is twofold: First, the question is a prototype of a class of multidimensional *singular control* problems involving linear dynamics and linear cost; as such, this class of problems should be applicable in a wide setting. In fact, we were led to the above model while searching for a multidimensional analog of a one-dimensional advertising model due to Vidale and Wolfe [3], [8], [11], [15]. A two-dimensional generalization, in a different direction, is given in [4].

Second, we show that v is the unique viscosity solution of the *free boundary problem*

$$\max(u - \langle b, x\rangle, \lambda(x, \nabla u) - 2) = 0, \qquad x \in \mathbf{R}^d, \tag{0.4}$$

in the class of solutions growing at most linearly; here $\langle \cdot, \cdot \rangle$ denotes the Euclidean inner product on $\mathbf{R}^d$ and

$$\lambda(x, p) = \langle x, p\rangle + |x||p|. \tag{0.5}$$

*Received by the editors June 10, 1992; accepted for publication (in revised form) December 14, 1992. This research was supported by the Louisiana Education Quality Support Fund.

We shall see that the free boundary—the hypersurface where both terms in (0.4) equal zero—is the paraboloid in $\mathbf{R}^d$ with axis through b, vertex at $b/|b|^2$, opening in the direction of $-b$, and defining equation

$$\lambda(x, b) = 2. \tag{0.6}$$

Using the method of characteristics, we also construct, off a portion L of the axis of the paraboloid (0.6), a classical $C^{1,1}$ solution u of (0.4). We then establish $u = v$.

We also address the question of the *optimal* choice of $a(\cdot)$, i.e., for each x how should we choose $a(\cdot)$ so that $v^a(x) = v(x)$? Since the answer depends on the initial state x, it is preferable to exhibit the solution in *feedback* form, i.e., to exhibit a single matrix-valued function $\mathbf{a}(x)$ such that for each starting x the optimal choice satisfies $a(t) = \mathbf{a}(x(t))$, $t \geq 0$, where $x(\cdot)$ satisfies (0.1).

Because of the singular nature of the above variational problem, one also expects the optimal control $a(\cdot)$ to be extreme, i.e., to equal zero or infinity. Below we show that, off L, the optimal feedback is given by

$$\mathbf{a}(x) \times \begin{cases} 0 & \text{if} \quad v(x) = \langle b, x\rangle, \\ \infty & \text{if} \quad \lambda(x, \nabla v(x)) = 2, \end{cases}$$

where $\mathbf{a}(x) = \xi(x) \otimes \xi(x)$ and

$$\xi(x) = \frac{|x|\nabla v(x) + |\nabla v(x)|x}{\sqrt{2|x||\nabla v(x)|}}. \tag{0.7}$$

More explicitly, we show that if $v(x) = \langle b, x\rangle$ the optimal feedback is zero, while if $\lambda(x, \nabla v(x)) = 2$ the optimal feedback is infinite so as to cause an instantaneous jump sending x to the intersection point x_0 of the free boundary with the integral curve through x of the vector field $-\mathbf{a}(x)x = -\langle x, \xi(x)\rangle\xi(x)$ corresponding to (0.7). In general terms, this is the kind of behavior expected for these types of problems [6], [7], [10], [12], [13], [14]. The interest here is, of course, the explicitness of our results.

In fact, it turns out that for each initial state x the optimal choice is

$$a(t) = a^*\delta(t), t \geq 0, \tag{0.8}$$

where $\delta(\cdot)$ is the Dirac impulse at time zero and the constant matrix $a^* = 0$ if $v(x) = \langle b, x\rangle$, while if $\lambda(x, \nabla v(x)) = 2$, a^* equals the (time-ordered) integral of $\mathbf{a}(x)$ along the integral curve of the vector field $-\mathbf{a}(x)x$ from x to x_0.

Finally we obtain another representation $v = w$, where

$$w(x) = \inf\{\langle b, qx\rangle - \log\det(q) : 0 < q \leq 1, \lambda(qx, b) \leq 2\}, \tag{0.9}$$

exhibiting the concave function v as a (restricted) conjugate of the strictly concave function $\log\det(q)$ on the space of positive $d \times d$ matrices q. In fact, w is obtained by restricting the infimum in (0.3) to controls of the form $a(\cdot) = a\delta(\cdot)$ with $a \geq 0$ constant and satisfying $\lambda(e^{-a}x, b) \leq 2$.

In particular, since L does not intersect the hypersurface $\lambda(x, b) = 2$ (§2), we obtain the C^1 regularity of v across the free boundary, and thus the C^1 "principle of smooth fit" holds in our situation.

If $\langle b, x\rangle$ is replaced by a C^∞ function $f(x)$ in (0.2), then we obtain a broader class of variational problems. We expect, under appropriate assumptions on f, the above to continue to hold with $\langle b, \cdot\rangle$ replaced by f throughout and with the free boundary now given by $\lambda(x, \nabla f(x)) = 2$; we lose, however, the explicitness of the results.

In the context of elliptic theory, (0.4) can be viewed as a rough approximation to

$$\max(v - \epsilon\Delta v - f(x), \lambda(x, \nabla v) - 2) = 0. \tag{0.10}$$

However, because our situation is degenerate ($\epsilon = 0$), we do not expect the C^2 "principle of smooth fit" [1], [12], [13] to hold. Indeed, for (0.10) with $\epsilon = 0$, a simple check reveals that v is not C^2 at any point where the free boundary is a C^1 hypersurface. In particular, for (0.4) v is never C^2 on the free boundary.

In §1 we show that v solves the Bellman equation (0.4) and prove uniqueness, in §2 we construct u, and in §3 we show $u = v = w$ and we verify the optimality of the choice (0.7), (0.8).

1. Derivation of the Bellman Equation. For background on viscosity solutions, see [2]. For background on viscosity solutions and singular control, see [9]. Strictly speaking, all we need from these references is the definition of a "viscosity solution" in terms of local extrema or equivalently strict local extrema. Nevertheless these references provide for a fuller understanding of the point of view taken here.

For $\epsilon > 0$ set

$$v_\epsilon(x) = \inf\{v^a(x) : I \geq \epsilon a(\cdot) \geq 0\}.$$

Then an easy approximation argument shows

$$v(x) = \inf_{\epsilon > 0} v_\epsilon(x). \tag{1.1}$$

Throughout this paper $|\cdot|$ denotes Euclidean length in $\mathbf{R}^d$. We assume $d \geq 2$, and $a \geq b$ for symmetric matrices a, b means $a - b \geq 0$, i.e., the eigenvalues of $a - b$ are nonnegative.

LEMMA 1. *$v_\epsilon \to v$ locally uniformly on $\mathbf{R}^d$ as $\epsilon \downarrow 0$ and v, v_ϵ are Lipschitz on $\mathbf{R}^d$ with Lipschitz constant $|b|$ for all $\epsilon > 0$. Moreover, $v(x)$ and $v_\epsilon(x)$ are bounded above by $\langle b, x\rangle$ and below by $-|b||x|$.*

Proof. Since $d/dt|x(t)|^2 = -2\langle x(t), a(t)x(t)\rangle \leq 0$, we have $|x(t)| \leq |x|$ for every initial state x. Since

$$\langle \nabla v^a(x), \xi\rangle = \int_0^\infty e^{-t}\langle b, \xi(t)\rangle dt,$$

where $\dot{\xi}(t) = -a(t)\xi(t)$, $\xi(0) = \xi$, it follows that $|\nabla v^a(x)| \leq |b|$. Since v and v_ϵ are infima of v^a, they are Lipschitz with constant $|b|$.

Let $a(\cdot)$ be a bounded control and suppose $x_\epsilon \to x$. Then

$$v^a(x) = \limsup_{\epsilon \downarrow 0} v^a(x_\epsilon) \geq \limsup_{\epsilon \downarrow 0} v_\epsilon(x_\epsilon)$$

and so $v(x) \geq \limsup_{\epsilon \downarrow 0} v_\epsilon(x_\epsilon)$ by (1.1). Moreover, we have

$$\liminf_{\epsilon \downarrow 0} v_\epsilon(x_\epsilon) \geq \liminf_{\epsilon \downarrow 0} v(x_\epsilon) = v(x);$$

the local uniform convergence follows. The last part follows from the fact that $v^0(x) = \langle b, x\rangle$ for all x, the Lipschitz nature of v_ϵ, v, and from $v_\epsilon(0) = v(0) = 0$. □

Given a symmetric matrix a, we wish to define $a^+ \geq 0$. This can be defined by the functional calculus or more specifically as follows. If a is diagonal, we let a^+ be obtained from a by replacing the negative diagonal elements by zero. For general symmetric a we extend this definition by insisting that $(rar^t)^+ = ra^+r^t$ for all rotations r. Similarly, we define $a^- \geq 0$. Then $a = a^+ - a^-$.

Given two vectors ξ, η in $\mathbf{R}^d$, let $\xi \otimes \eta$ denote the unique symmetric matrix satisfying $\langle a\xi, \eta\rangle = \text{trace}(a(\xi \otimes \eta))$ for all symmetric matrices a.

We now derive the Bellman equation satisfied by v_ϵ.

LEMMA 2. *For all $\epsilon > 0$, v_ϵ is a viscosity solution of*

$$\frac{1}{\epsilon}H(x, \nabla v_\epsilon) + v_\epsilon - \langle b, x\rangle = 0, \qquad x \in \mathbf{R}^d, \tag{1.2}$$

where

$$H(x,p) = \sup\{\langle p, ax\rangle - \textit{trace}(a) : 0 \leq a \leq I\} = \textit{trace}((x \otimes p - I)^+). \tag{1.3}$$

Proof. We begin by recalling the dynamic programming principle, which states that

$$v_\epsilon(x) = \inf\left\{\int_0^T e^{-t}[\langle b, x(t)\rangle + \text{trace}(a(t))]dt + e^{-T}v_\epsilon(x(T))\right\}, \tag{1.4}$$

where the infimum is over all controls $a(\cdot)$ satisfying $0 \leq \epsilon a(\cdot) \leq I$, and $T > 0$ is fixed.

Now suppose $\phi \in C^1(\mathbf{R}^d)$ and $x \in \mathbf{R}^d$ with $\phi(x) = v_\epsilon(x)$ and $v_\epsilon - \phi \leq 0$ near x. Then (1.4) yields, for all $a(\cdot) = a$ constant and satisfying $0 \leq \epsilon a \leq I$,

$$\phi(x) \leq \int_0^T e^{-t}[\langle b, x(t)\rangle + \text{trace}(a)]dt + e^{-T}\phi(x(T))$$

which implies

$$0 \leq \frac{1}{T}\int_0^T e^{-t}[\langle b, x(t)\rangle + \text{trace}(a) - \phi(x(t)) - \langle \nabla\phi(x(t)), ax(t)\rangle]dt;$$

letting $T \downarrow 0$ and taking the supremum over a, we obtain

$$\frac{1}{\epsilon}H(x, \nabla\phi(x)) + \phi(x) - \langle b, x\rangle \leq 0.$$

On the other hand, suppose x and $\phi \in C^1(\mathbf{R}^d)$ are such that $\phi(x) = v_\epsilon(x)$ and $v_\epsilon - \phi \geq 0$ near x. Since

$$\sup_{I \geq \epsilon a(\cdot) \geq 0}\left(\sup_{0 \leq t \leq T}|x(t) - x|\right) \to 0 \quad \text{as} \quad T \downarrow 0, \tag{1.5}$$

(1.4) implies, for $T > 0$ sufficiently small,

$$0 \geq \inf_{a(\cdot)}\left(\frac{1}{T}\int_0^T e^{-t}[\langle b, x(t)\rangle + \text{trace}(a(t)) - \phi(x(t)) - \langle \nabla\phi(x(t)), a(t)x(t)\rangle]dt\right).$$

Now (1.5) allows us to pass to the limit $T \downarrow 0$ and obtain

$$\frac{1}{\epsilon}H(x, \nabla\phi(x)) + \phi(x) - \langle b, x\rangle \geq 0.$$

To derive (1.3), let $c = x \otimes p - I$. Then $H(x,p)$ is the sup of $\operatorname{trace}(ac)$ over $0 \leq a \leq I$. But $\operatorname{trace}(ac) = \operatorname{trace}(c^+)$ if we choose a to be the orthogonal projection onto the positive eigenspaces of c and otherwise

$$\operatorname{trace}(ac) = \operatorname{trace}(ac^+) - \operatorname{trace}(ac^-) \leq \operatorname{trace}(ac^+) \leq \operatorname{trace}(c^+). \qquad \square$$

We note that (1.5) fails for $\epsilon = 0$.

For any $\xi \in \mathbf{R}^d \setminus 0$ we set $\xi' = \xi/|\xi|$. If ξ, η are two vectors in $\mathbf{R}^d$, we always take the angle between them to be $\theta = \cos^{-1}(\langle \xi', \eta'\rangle) \in [0, \pi]$.

The wedge product $\xi \wedge \eta$ is a vector in $\wedge^2\mathbf{R}^d$ and we have

$$|\xi \wedge \eta|^2 = \sum_{i<j}(\xi_i\eta_j - \xi_j\eta_i)^2.$$

An easy computation shows that $|\xi \wedge \eta|^2 + |\langle \xi, \eta\rangle|^2 = |\xi|^2|\eta|^2$ and hence $|\xi \wedge \eta| = |\xi||\eta| \sin\theta$, where θ is the angle between ξ and η.

We now turn to the analysis of the eigenvalues of $I - x \otimes p$.

LEMMA 3. *The eigenvalues of $I - x \otimes p$ are 1 with multiplicity $d-2$ and $\lambda_\pm$, where $\lambda_- \leq 1 \leq \lambda_+$ and*

$$\lambda_\pm = 1 + \frac{1}{2}(-\langle x, p\rangle \pm |x||p|). \tag{1.6}$$

If both x and p are nonzero, a unit eigenvector η for the eigenvalue λ_- is

$$\eta = \frac{|x|p + |p|x}{\sqrt{2|x||p|\lambda(x,p)}}, \tag{1.7}$$

where $\lambda(x,p)$ is given by (0.5). *Moreover,*

$$H(x,p) = \max(0, -\lambda_-) = \frac{1}{2}\max(0, \lambda - 2) = \frac{1}{\lambda_+}\max(0, -\det(I - x \otimes p)), \tag{1.8}$$

$$\det(I - x \otimes p) = 1 - \langle x, p\rangle - \frac{1}{4}|x \wedge p|^2, \tag{1.9}$$

and $\lambda(x,p) = 2$ iff $\lambda_-(x,p) = 0$ iff $\det(I - x \otimes p) = 0$ iff $I - x \otimes p$ has a nullspace.

Proof. Let $e_1, \ldots, e_d$ denote the standard basis in $\mathbf{R}^d$. Since the range of the linear transformation $x \otimes p : \mathbf{R}^d \to \mathbf{R}^d$ is at most two-dimensional, the linear transformation $\wedge^k(x \otimes p)$ induced on the basis of k-vectors $e_{i_1} \wedge \cdots \wedge e_{i_k} \in \wedge^k\mathbf{R}^d$ equals zero if $k \geq 3$. Thus the eigenpolynomial of $x \otimes p$ is given by

$$\lambda^d - \operatorname{trace}(x \otimes p)\lambda^{d-1} + \operatorname{trace}(\wedge^2(x \otimes p))\lambda^{d-2}.$$

Since traces can be computed by applying linear transformations to basis elements e_i and $e_i \wedge e_j$, we have

$$\operatorname{trace}(x \otimes p) = \langle x, p\rangle,$$

$$\operatorname{trace}(\wedge^2(x \otimes p)) = -\frac{1}{4}\sum_{i<j}(x_ip_j - x_jp_i)^2 = -\frac{1}{4}|x \wedge p|^2.$$

Thus the eigenpolynomial of $I - x \otimes p$ equals

$$(\lambda - 1)^{d-2}\left((\lambda - 1)^2 + \langle x, p\rangle(\lambda - 1) - \frac{1}{4}|x \wedge p|^2\right).$$

Solving the quadratic and using the fact that $\langle x, p\rangle = |x||p|\cos\theta$, $|x \wedge p| = |x||p|\sin\theta$, the results for $\lambda_\pm$ follow. Formula (1.7) follows by direct computation and (1.9) follows since $\det(I - x \otimes p) = \lambda_+\lambda_-$. $\square$

THEOREM 1. *v is a Lipschitz viscosity solution of* (0.4).

Proof. Lemma 1 states that v is Lipschitz. Let x and $\phi \in C^1$ be such that $v - \phi$ has a strict local maximum at x. Since $v_\epsilon \to v$ locally uniformly, this implies that there exists $x_\epsilon \to x$ such that $v_\epsilon - \phi$ has a local maximum at x_ϵ. This implies, by (1.2),

$$\frac{1}{\epsilon} H(x_\epsilon, \nabla\phi(x_\epsilon)) + v_\epsilon(x_\epsilon) - \langle b, x_\epsilon \rangle \leq 0.$$

Since $H \geq 0$, we obtain $v_\epsilon(x_\epsilon) - \langle b, x_\epsilon \rangle \leq 0$; letting $\epsilon \downarrow 0$ yields $v(x) - \langle b, x \rangle \leq 0$. Also, multiplying by ϵ and sending $\epsilon \downarrow 0$ yields $H(x, \nabla\phi(x)) \leq 0$. By Lemma 3, we obtain $\lambda(x, \nabla\phi(x)) - 2 \leq 0$. Thus v is a subsolution of (0.4).

Let x and $\phi \in C^1$ be such that $v - \phi$ has a strict local minimum at x. Choose $x_\epsilon \to x$ such that $v_\epsilon - \phi$ has a local minimum at x_ϵ. Then by (1.2)

$$\frac{1}{\epsilon} H(x_\epsilon, \nabla\phi(x_\epsilon)) + v_\epsilon(x_\epsilon) - \langle b, x_\epsilon \rangle \geq 0.$$

Now if $v(x) - \langle b, x \rangle \geq 0$, then v is a supersolution of (0.4). If not, then it follows that $H(x_\epsilon, \nabla\phi(x_\epsilon)) > 0$, which by Lemma 3 implies $\lambda(x_\epsilon, \nabla\phi(x_\epsilon)) - 2 > 0$, which yields in the limit $\lambda(x, \nabla\phi(x)) - 2 \geq 0$. Thus v is a supersolution of (0.4). □

The proof of Theorem 2 below is standard [2], [16]; the only new twist is the observation, needed below, that the constraint $\lambda(x, p)$ satisfies $\lambda(x, p + tx) \geq \lambda(x, p)$ for $t \geq 0$.

THEOREM 2. *Suppose $f(x)$ is Lipschitz. Then there is at most one continuous viscosity solution to*

$$\max(u - f(x), \lambda(x, \nabla u) - 2) = 0, \qquad x \in \mathbf{R}^d, \tag{1.10}$$

having at most linear growth.

Proof. The result is an immediate consequence of the corresponding comparison result: If u, v are sub- and supersolutions of (1.10), respectively, with at most linear growth, then $u \leq v$ on $\mathbf{R}^d$. To establish this, assume $|f(x) - f(y)| \leq C|x - y|$, $|f(x)| \leq C(1 + |x|)$.

It is enough to show that

$$(1 - \epsilon)u(x) - v(x) - \frac{\epsilon}{2}|x|^2 \leq \epsilon\left(C + \frac{1}{2}C^2\right), \qquad 0 < \epsilon < 1, x \in \mathbf{R}^d, \tag{1.11}$$

for then sending $\epsilon \downarrow 0$ we conclude. Now (1.11) follows from

$$\Phi(x, y) = (1 - \epsilon)u(x) - v(y) - \frac{\epsilon}{2}|x|^2 - \frac{\alpha}{2}|x - y|^2 \leq \epsilon\left(C + \frac{1}{2}C^2\right) + \frac{C^2}{2\alpha},$$
$$0 < \epsilon < 1, \alpha > 1, x, y \in \mathbf{R}^d, \tag{1.12}$$

for then taking $x = y$ and sending $\alpha \uparrow \infty$ we conclude.

To establish (1.12), let $(\hat{x}, \hat{y})$ be a point at which $\Phi(x, y)$ is maximized; such a point exists since u, v have at most linear growth. Then $\Phi(\cdot, \hat{y})/(1 - \epsilon)$ is maximized at $x = \hat{x}$; since u is a subsolution, this yields $u(\hat{x}) \leq f(\hat{x})$ and $\lambda(\hat{x}, \hat{p} + \epsilon\hat{x}) \leq 2(1 - \epsilon)$, where $\hat{p} = \alpha(\hat{x} - \hat{y})$. Here we have used the fact that $\lambda(x, p)$ is first-order homogeneous

in p. Similarly, since v is a supersolution, we have two cases: either $v(\hat{y}) \geq f(\hat{y})$ or $\lambda(\hat{y}, \hat{p}) \geq 2$. In the first case we obtain

$$\begin{aligned}\Phi(\hat{x}, \hat{y}) &\leq (1-\epsilon)f(\hat{x}) - f(\hat{y}) - \frac{\epsilon}{2}|\hat{x}|^2 - \frac{\alpha}{2}|\hat{x}-\hat{y}|^2 \\ &\leq C\epsilon(1+|\hat{x}|) + C|\hat{x}-\hat{y}| - \frac{\epsilon}{2}|\hat{x}|^2 - \frac{\alpha}{2}|\hat{x}-\hat{y}|^2,\end{aligned}$$

which is bounded by the right side of (1.12). Thus in the first case the result follows.

In the second case we have, using $\lambda(x, p+tx) \geq \lambda(x,p)$ for $t \geq 0$,

$$\lambda(\hat{x}, \hat{p}) \leq \lambda(\hat{x}, \hat{p} + \epsilon\hat{x}) \leq 2(1-\epsilon) < 2,$$

which yields $\lambda(\hat{x}, \hat{p}) - \lambda(\hat{y}, \hat{p}) < 0$. But the triangle inequality shows that the left side of this last inequality is nonnegative and we conclude. □

We remark that the development of this section can be easily modified to yield the existence and uniqueness of a solution to (0.10) with at most linear growth, when $f(x)$ is Lipschitz.

2. Solution of the free boundary problem. To motivate the solution, suppose first that u is a global C^1 solution of (0.4) and let $G = \{x : \lambda(x, \nabla u(x)) < 2\}$. Then it follows that $u(x) = \langle b, x\rangle$ on G and so $G \subset \{x : \lambda(x,b) < 2\}$ since G is open. Also if $x \in \partial G$, then $\lambda(x, \nabla u(x)) = 2$ and $u(x) = \langle b, x\rangle$. Since $u - \langle b, \cdot\rangle$ has a maximum at x, it follows that $\nabla u(x) = b$, which yields $\lambda(x,b) = 2$, which yields $\partial G \subset \{x : \lambda(x,b) = 2\}$. Thus we expect $G = \{x : \lambda(x,b) < 2\}$, $\partial G = \{x : \lambda(x,b) = 2\}$.

Throughout $C = \{x : \det(I - x \otimes b) \leq 0\} = \{x : \lambda(x,b) \geq 2\}$ is the complement of G and we refer to $\partial C = \{x : \det(I - x \otimes b) = 0\} = \{x : \lambda(x,b) = 2\}$ as the "free boundary." By (1.9), the free boundary is given by

$$0 = 1 - \langle x, b\rangle - \frac{1}{4}|x \wedge b|^2.$$

It follows that the free boundary is the paraboloid in $\mathbf{R}^d$ with axis along the line through the vector b, opening in the direction of $-b$, and vertex at $b/|b|^2$ (Fig. 1).

Let $L = \{tb/|b|^2 : t \geq e^2\} \subset \text{int}(C)$ be the infinite portion of the ray through b and starting at the point $e^2 b/|b|^2$.

Let A be an arbitrary subset of Euclidean space. We say a function f is C^∞ on A if for each x in A there is a C^∞ function g defined on an open neighborhood B of x such that f and g agree on $A \cap B$.

We point out that the *closed* free boundary lies in the *open* $\mathbf{R}^d \setminus L$. In this section we establish the following result.

THEOREM 3. *There is a Lipschitz function u on $\mathbf{R}^d$ such that*

(1) *u is $C^{1,1}$ on $\mathbf{R}^d \setminus L$,*
(2) *u is C^∞ on $C \setminus L$,*
(3) *$\lambda(x, \nabla u) = 2$ on $C \setminus L$,*
(4) *$u(x) < \langle b, x\rangle$ on int(C),*
(5) *$u(x) = \langle b, x\rangle$ on the complement of C,*
(6) *$\lambda(x, \nabla u) < 2$ on the complement of C;*

in particular u is a classical solution of (0.4) *on $\mathbf{R}^d \setminus L$ and $I - x \otimes \nabla u \geq 0$ on $\mathbf{R}^d \setminus L$.*

We begin by recalling the method of characteristics, following [5; §35.1].

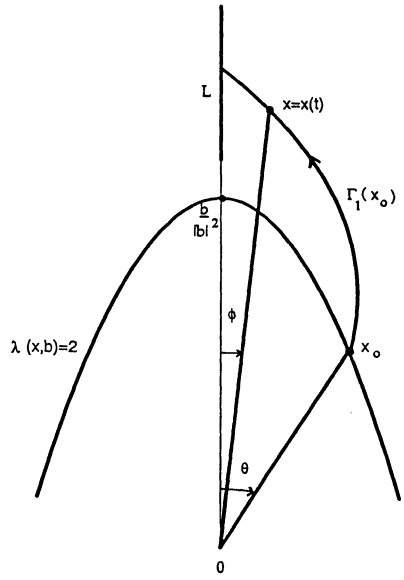

FIG. 1

Since $\lambda \in C^\infty((C \setminus L) \times (\mathbf{R}^d \setminus 0))$, the flow α_t of the Hamiltonian vector field

$$\begin{aligned} X_\lambda &= \langle \nabla_p \lambda, \nabla_x \rangle - \langle \nabla_x \lambda, \nabla_p \rangle \\ &= \langle x + p'|x|, \nabla_x \rangle - \langle p + x'|p|, \nabla_p \rangle \end{aligned}$$

is well defined (recall $\xi' = \xi/|\xi|$).

A submanifold $\Gamma \subset (C \setminus L) \times \mathbf{R}^d$ (of any dimension) is *Lagrangian* if the *symplectic form* $\langle dp \wedge dx \rangle = \sum_{i=1}^d dp_i \wedge dx_i$ vanishes on Γ. For example, let $f : C \setminus L \to \mathbf{R}^d$ be C^∞, and let $\Gamma = \{(x,p) : p = f(x)\}$ be the graph of f. Then Γ is Lagrangian if and only if $\langle dp \wedge dx \rangle = \langle df \wedge dx \rangle = d\langle f, dx \rangle = 0$; this happens iff the differential form $\langle f, dx \rangle = \sum_{i=1}^d f_i(x) dx_i$ is closed or, equivalently, the gradient $\nabla f(x)$ is a symmetric $d \times d$ matrix for all $x \in C \setminus L$. Since $C \setminus L$ is simply connected, this happens if and only if $\langle f, dx \rangle = du$ is exact or, equivalently, $f = \nabla u$ for some $u \in C^\infty(C \setminus L)$.

Given $x_0 \in \partial C$, let θ denote the angle between x_0 and b (Fig. 1), $\cos(\theta) = \langle x_0', b' \rangle$. Note $\theta < \pi$ always, since $\lambda(x_0, b) = 2$. For each $x_0 \in \partial C$ let $\Gamma(x_0)$ denote the Hamiltonian trajectory segment $\Gamma(x_0) = \{\alpha_t(x_0, b) : 0 \le t < \theta/\sin\theta\}$, where we define $\sin 0/0 = 1$. These are curves in phase (x,p)-space whose projections onto position x-space are drawn in Fig. 1. Although the Hamiltonian trajectory segments $\Gamma(x_0)$, being integral curves of the C^∞ vector field X_λ, cannot intersect, their projections $\Gamma_1(x_0)$ onto x-space—the characteristics—can and do in fact intersect. As we shall see below, the locus of points of intersections of the closures of $\Gamma_1(x_0)$ is precisely the "line of caustics" L.

Recall that the *Poisson bracket* of λ and $\beta = \beta(x,p)$

$$\{\lambda, \beta\} = X_\lambda(\beta) = \langle \nabla_p \lambda, \nabla_x \beta \rangle - \langle \nabla_x \lambda, \nabla_p \beta \rangle$$

vanishes if and only if the function β is a constant of the motion. In particular, λ is a constant of the motion and hence $\lambda(x,p) = 2$ on $\Gamma(x_0)$ for all $x_0 \in \partial C$.

Let

$$\Gamma = \bigcup_{x_0 \in \partial C} \Gamma(x_0).$$

Since $\{(x_0, b) : x_0 \in \partial C\} = \partial C \times \{b\}$ is a $(d-1)$-dimensional Lagrangian submanifold, it is a standard consequence that Γ is Lagrangian wherever it is a (d-dimensional) manifold. In particular, if we show that Γ is the graph of a C^∞ function $f : C \setminus L \to \mathbf{R}^d$, then Γ is a Lagrangian graph and hence $\lambda(x, \nabla u(x)) = \lambda(x, f(x)) = \lambda(x, p) = 2$ for $x \in C \setminus L$, since $\lambda(x, p) = 2$ on Γ.

To construct f we shall solve for the trajectories explicitly. Fix $x_0 \in \partial C$. Then the trajectory $(x(t), p(t)) = \alpha_t(x_0, b)$ starting from (x_0, b) satisfies

$$\begin{aligned} \dot{x}(t) &= x(t) + |x(t)|p(t)' \qquad x(0) = x_0, \\ \dot{p}(t) &= -|p(t)|x(t)' - p(t) \qquad p(0) = b. \end{aligned}$$

This implies ($I = I_d$ is the $d \times d$ identity matrix)

$$\frac{d}{dt}\begin{pmatrix} x(t)' \\ p(t)' \end{pmatrix} = \begin{pmatrix} -\cos\theta I & I \\ -I & \cos\theta I \end{pmatrix}\begin{pmatrix} x(t)' \\ p(t)' \end{pmatrix}, \tag{2.1}$$

$$\frac{d}{dt}|x(t)| = (1 + \cos\theta)|x(t)|, \qquad \frac{d}{dt}|p(t)| = -(1 + \cos\theta)|p(t)|. \tag{2.2}$$

Here $\theta = \theta(t)$ is the angle between $x(t)$ and $p(t)$.

Since the Poisson bracket of λ and $\beta(x, p) = \langle x, p\rangle$ vanishes, it follows that $\langle x, p\rangle$ and $|x||p|$ are constant along the trajectories $(x(t), p(t))$. In particular, θ does not depend on t and equals the angle between x_0 and b, which is always strictly less than π (Fig. 1).

If Q denotes the $2d \times 2d$ matrix appearing in (2.1), then $Q^2 = -\sin^2\theta I_{2d}$. Writing out the exponential series for e^{Qt} it follows that, when $\theta > 0$,

$$\begin{aligned} \sin\theta\, x(T)' &= \sin(\theta - T\sin\theta)\, x_0' + \sin(T\sin\theta)\, b', \\ \sin\theta\, p(T)' &= -\sin(T\sin\theta)\, x_0' + \sin(\theta + T\sin\theta)\, b'. \end{aligned} \tag{2.3}$$

Now take the inner product of the first of the pair (2.3) with b'. Let $\phi(t)$ denote the angle between $x(t)$ and b. We obtain $\cos\phi(T) = \cos(\theta - T\sin\theta)$ when $\theta > 0$ and hence

$$\phi(T) = \theta - T\sin\theta, \qquad 0 \le T < \theta/\sin\theta, \tag{2.4}$$

i.e., on Γ. It can be verified separately that (2.4) also holds when $\theta = 0$. Note that $T = \theta/\sin\theta$ is precisely when the characteristics intersect, at which point $\phi(T) = 0$, i.e., we are on the axis through b.

To see that we are actually in L, solve the first of the pair (2.2) to obtain

$$|x(T)||b| = |x_0||b|\exp(T(1 + \cos\theta)) \ge |x_0||b|, 0 \le T < \theta/\sin\theta. \tag{2.5}$$

Inserting $T = \theta/\sin\theta$ in (2.5) and noting that $\lambda(x_0, b) = |x_0||b|(1 + \cos\theta) = 2$, we obtain

$$|x(\theta/\sin\theta)||b| = \sec^2(\theta/2)\exp(\theta\cot(\theta/2)) \equiv g(\theta).$$

Since g is increasing and $g(0) = e^2$, we conclude that $x(\theta/\sin\theta) \in L$. Therefore, characteristics do not intersect the axis (which is itself the characteristic corresponding to $\theta = 0$) except in L.

The fact that we should have well-behaved (i.e., nonintersecting) characteristics *near* ∂C, even along the axis, is a reflection of the Cauchy–Kovalevska theorem; this is crucial because it is the existence of the segment of intersection of $C \setminus L$ with the axis that allows $C \setminus L$ to be simply connected.

Define $\Phi : C \setminus L \to \mathbf{R}^2$ by setting $\Phi(x) = (\mu, \phi/2)$, where $\mu = |x||b|$ and ϕ is the angle between x and b. Since $\lambda(x, b) \geq 2$ we have (Fig. 2)

$$\begin{aligned}\Phi(C \setminus L) &= \Phi(C) \setminus \Phi(L) \\ &= \{(\mu, \alpha) : \mu \geq 1, 0 \leq \alpha \leq \cos^{-1}(1/\sqrt{\mu})\} \setminus \{(\mu, 0) : \mu \geq e^2\} \subset \mathbf{R}^2.\end{aligned}$$

Moreover, $\Phi(\text{int}(C \setminus L)) = \text{int}(\Phi(C \setminus L))$ and Φ is C^∞ on $C \setminus L$.

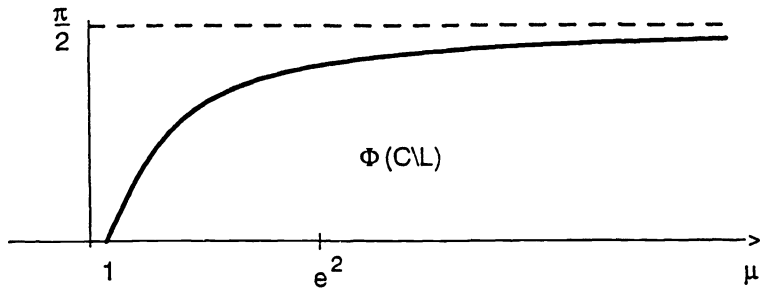

FIG. 2

We now show that θ, $T < \theta/\sin\theta$, and x_0 can be solved for uniquely in terms of $x = x(T) \in C \setminus L$, $\phi = \phi(T)$. Solving the first of the pair (2.3) for x_0' yields

$$x_0' = \frac{\sin\theta x' - \sin(\theta - \phi)b'}{\sin\phi}. \tag{2.6}$$

Integrating the second of the pair (2.2) yields

$$|p(T)| = |b| \exp(-T(1 + \cos\theta)) \leq |b|. \tag{2.7}$$

Since $\lambda(x_0, b) = |x_0||b|(1 + \cos\theta) = 2$ (2.5) implies

$$(1 + \cos\theta)|b||x| = 2\exp(T(1 + \cos\theta)). \tag{2.8}$$

Eliminating T in (2.4), (2.8) we arrive at

$$h\left(|x||b|, \frac{\theta}{2}\right) = \frac{\phi}{2}, \tag{2.9}$$

where $h(\mu,\cdot):[0,\cos^{-1}(1/\sqrt{\mu})]\to[0,\cos^{-1}(1/\sqrt{\mu})]$ is given by

$$h(\mu,\alpha)=\alpha-\frac{1}{2}\tan\alpha\log(\mu\cos^2\alpha) \tag{2.10}$$

for each $\mu=|x||b|\geq 1$.

There are two cases, depending on whether $1\leq\mu<e^2$ or $\mu\geq e^2$ (Fig. 3). In the first case, for each $\phi/2\in[0,\cos^{-1}(1/\sqrt{\mu})]$ there is a unique $\theta/2\in[0,\cos^{-1}(1/\sqrt{\mu})]$, $\mu=|x||b|$, such that (2.9) holds and so $h(\mu,\cdot)$ is a homeomorphism of $[0,\cos^{-1}(1/\sqrt{\mu})]$ onto itself. In the second case, for each $\phi/2\in(0,\cos^{-1}(1/\sqrt{\mu})]$ there is a unique $\theta/2\in(\alpha^*(\mu),\cos^{-1}(1/\sqrt{\mu})]$, $\mu=|x||b|$, such that (2.9) holds and so $h(\mu,\cdot)$ is a homeomorphism of $[\alpha^*(\mu),\cos^{-1}(1/\sqrt{\mu})]$ onto $[0,\cos^{-1}(1/\sqrt{\mu})]$; here $\alpha^*(\mu)$ is the largest zero of $h(\mu,\cdot)$ in $[0,\cos^{-1}(1/\sqrt{\mu})]$. We conclude that for each $x\in C\setminus L$ there is a unique $\theta/2\in[0,\cos^{-1}(1/\sqrt{\mu})]$, $\mu=|x||b|$, such that (2.9) holds. Defining T by (2.8), x_0 by (2.5), (2.6), we obtain $p=p(T)$ as a uniquely determined function f of $x=x(T)$ by the second of the pair (2.3) and (2.7), and hence Γ is a graph over $C\setminus L$.

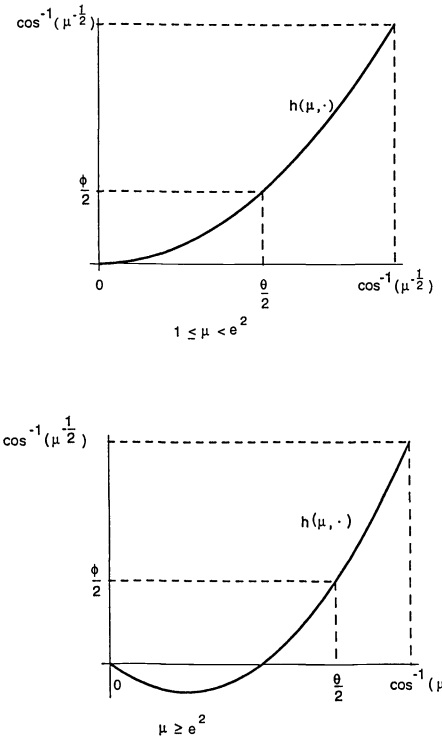

FIG. 3

Moreover, it is easy to see that $\partial h(\mu,\theta/2)/\partial\alpha\neq 0$ for all $(\mu,\phi/2)\in\Phi(C\setminus L)$ and hence, by the implicit function theorem, $\theta=\theta(\mu,\phi)$ given by (2.9) is a C^∞ function on $\Phi(C\setminus L)$. It follows that $\theta=\theta(x)$ is a C^∞ function of $x\in C\setminus L$. Thus Γ is a C^∞

graph over $C \setminus L$ and the differential form $\langle p, dx\rangle = \langle f(x), dx\rangle$ is closed and hence exact on $C \setminus L$. Setting

$$u(x) = \langle b, x_0\rangle + \int_{x_0}^{x} \langle p, dx\rangle, \tag{2.11}$$

yields a C^∞ function u satisfying $p = \nabla u(x)$, $\lambda(x, \nabla u) = 2$ on $C \setminus L$, whose value does not depend on the choice of x_0 in ∂C, since $p = b$ on ∂C.

Since $p = \nabla u(x)$, it follows from (2.7) that this solution u is Lipschitz with Lipschitz constant $|b|$ and hence extends uniquely as a Lipschitz function across L. Set $u(x) = \langle b, x\rangle$ if $x \notin C$. It then follows that u is Lipschitz on $\mathbf{R}^d$ and $u \in C^{1,1}(\mathbf{R}^d \setminus L)$, since $u(x) = \langle b, x\rangle$, $\nabla u = b$ on ∂C. Moreover, since $\nabla u = b$ on the complement of C, we have $\lambda(x, \nabla u) < 2$ on the complement of C.

To complete the proof of Theorem 3, it remains to establish (4), i.e., $u(x) < \langle b, x\rangle$ on $\operatorname{int}(C)$. We first show $u(x) \le \langle b, x\rangle$ on C.

By (2.11) and

$$\langle b, x\rangle = \langle b, x_0\rangle + \int_{x_0}^{x} \langle b, dx\rangle, \tag{2.12}$$

it is enough to show $2 = \langle p, \dot{x}\rangle \le \langle b, \dot{x}\rangle$ along $\Gamma_1(x_0)$, i.e., it is enough to show $g(t) \ge 2$ on $[0, \theta/\sin\theta]$, where

$$g(t) = \langle b, \dot{x}(t)\rangle = \langle b, x(t) + p(t)'|x(t)|\rangle.$$

To this end, note that $g(0) = 2$ and $g(\theta/\sin\theta) = |b||x|(1 + \cos\theta) = \frac{|x|}{|x_0|}|b||x_0|(1 + \cos\theta) = 2|x|/|x_0| \ge 2$ by (2.5). Thus if $g(t)$ were strictly less than 2 somewhere, it would have an interior minimum t. At this time t we would then have

$$\dot{g}(t) = 2\langle p(t)', b\rangle|x(t)|(1 + \cos\theta) = 0$$

and

$$\ddot{g}(t) = \dot{g}(t)(1 + 2\cos\theta) - 2\langle x(t), b\rangle(1 + \cos\theta) \ge 0.$$

Since θ is never equal to π, this would imply that the angle between $p(t)$ and b equals $\pi/2$ and the angle $\phi(t)$ between $x(t)$ and b is $\ge \pi/2$. But it follows from the second of the pair (2.3) that the angle between $p(t)$ and b equals $\theta - \phi(t)$. Since θ is strictly less than π, this cannot equal $\pi/2$. This contradiction establishes $g(t) \ge 2$ on the entire interval $[0, \theta/\sin\theta]$ and so $u(x) \le \langle b, x\rangle$ on C.

Since $g(t) \ge 2$ on the interval, repeating the same argument shows that $g(t) > 2$ on the interior of the interval. Thus $\langle b, x\rangle - u(x)$ is a strictly increasing function along $\Gamma_1(x_0)$ from x_0 to L; therefore $u(x) < \langle b, x\rangle$ on $\Gamma_1(x_0) \setminus x_0$ and hence on $\operatorname{int}(C)$.

Since $I - x \otimes \nabla u(x) \ge 0$ on $\mathbf{R}^d \setminus L$ follows from Lemma 3 and the above, this completes the proof of Theorem 3. □

3. Equality of u, v, and w.

THEOREM 4. *$u = v = w$ on $\mathbf{R}^d$.*

We begin by showing $u = v$. We first show that $v(x) \ge u(x)$ for all $x \in \mathbf{R}^d$. To this end it enough to establish $v^a(x) \ge u(x)$ for all bounded controls $a(\cdot)$. In fact, if we fix a bounded control $a(\cdot)$, it is enough to establish $v^a(x) \ge u(x)$ almost everywhere on $\mathbf{R}^d$, since both sides are Lipschitz.

Let $x^a(\cdot;x)$ denote the solution trajectory of (0.1) starting from x; since $x \mapsto x^a(t;x)$ is a diffeomorphism and L has measure zero, for each $t \geq 0$ we see that the set $\{x : x^a(t;x) \in L\}$ has measure zero. By Fubini, this implies that there is a null set N (depending on $a(\cdot)$) such that the set $\{t \geq 0 : x(t) = x^a(t;x) \in L\}$ has measure zero for all $x \notin N$.

Now let $x = x(0) \notin N$; then $t \mapsto e^{-t}u(x(t))$ equals the integral of its derivative and hence

$$e^{-T}u(x(T)) = u(x) + \int_0^T e^{-t}\left(-u(x(t)) - \langle \nabla u(x(t)), a(t)x(t)\rangle\right) dt$$

for all $T > 0$. Since u has linear growth, $|\nabla u| \leq |b|$, and $a(\cdot)$, $x(\cdot)$ are bounded letting $T \uparrow \infty$ yields

$$0 = u(x) + \int_0^\infty e^{-t}\left(-u(x(t)) - \langle \nabla u(x(t)), a(t)x(t)\rangle\right) dt. \tag{3.1}$$

Combining (0.2) and (3.1) yields

$$v^a(x) = u(x) + \int_0^\infty e^{-t}[\langle b, x\rangle - u(x) + \operatorname{trace}(a(I - x \otimes \nabla u))]dt. \tag{3.2}$$

Since $a(\cdot) \geq 0$, $I - x \otimes \nabla u \geq 0$, $\langle b, x\rangle - u(x) \geq 0$ on $\mathbf{R}^d \setminus L$, we obtain $v^a(x) \geq u(x)$. By the remarks above, this establishes $v \geq u$ on $\mathbf{R}^d$.

Since $v^0(x) = \langle b, x\rangle$, we have $u = v$ on the complement of $\operatorname{int}(C)$. Now define, for $x \in C \setminus L$,

$$\mathbf{a}(x) = \xi(x) \otimes \xi(x),$$

where $\xi(x)$ and $\eta(x)$ are given by

$$\xi(x) = \sqrt{2}\eta(x) = \frac{|x|\nabla u(x) + |\nabla u(x)|x}{\sqrt{2|x||\nabla u(x)|}}$$

and check that

$$\mathbf{a}(x)x = \langle x, \xi(x)\rangle\xi(x) = \nabla_p\lambda(x, \nabla u(x)) = \nabla_p\lambda(x,p); \tag{3.3}$$

here we have used $\lambda(x, \nabla u) = 2$ on $C \setminus L$.

Fix $x \in \operatorname{int}(C \setminus L)$ and let $x_1(t)$, $t \geq 0$, be the integral curve of the vector field $-\mathbf{a}(x)x$ (note the minus!) starting at x at time zero. Setting $p_1(t) = \nabla u(x_1(t))$, differentiating $\lambda(x, \nabla u(x)) = 2$, and using (3.3) shows

$$\begin{aligned} \dot{x}_1 &= -\nabla_p\lambda(x_1, p_1), \\ \dot{p}_1 &= +\nabla_x\lambda(x_1, p_1). \end{aligned}$$

Thus $(x_1(t), p_1(t))$ is the integral curve of $-X_\lambda$ through $(x, \nabla u(x))$ and, as a result, $(x_1(t), p_1(t)) = \alpha_{T-t}(x_0, b) = (x(T-t), p(T-t))$, where T, x_0, $(x(t), p(t))$ are as in §2.

We can now attempt to define a control $a_1(\cdot)$ satisfying $v^{a_1}(x) = u(x)$ for the fixed $x \in \operatorname{int}(C \setminus L)$: Set $a_1(t) = \mathbf{a}(x_1(t))$, $0 \leq t < T$, $a_1(t) = 0$, $t \geq T$. It follows

that the unique solution of (0.1) corresponding to $a_1(\cdot)$ equals $x_1(t)$, if $0 \leq t \leq T$, and equals x_0 if $t \geq T$.

Now note that $\lambda(x_1(t), \nabla u(x_1(t))) = 2$ and hence (Lemma 3) the matrix $I - x_1(t) \otimes \nabla u(x_1(t))$ has a nullspace for each $0 \leq t \leq T$. In fact, by (1.7), our control $a_1(t) = \xi(t) \otimes \xi(t)$ equals twice the orthogonal projection $\eta(t) \otimes \eta(t)$ onto the aforementioned nullspace and thus

$$\text{trace}(a_1(t)(I - x_1(t) \otimes \nabla u(x_1(t)))) = 0, 0 \leq t \leq T!$$

Armed with this information, we compute the corresponding cost $v^{a_1}(x)$ using (3.2) and obtain

$$v^{a_1}(x) = u(x) + \int_0^T e^{-t}(\langle b, x_1(t)\rangle - u(x_1(t)))dt. \tag{3.4}$$

Hence our choice $a_1(\cdot)$ does *not* satisfy $v^{a_1}(x) = u(x)$, since $u(x) < \langle b, x\rangle$ in the interior of C.

In fact, a little thought shows that no control $a(\cdot)$ can satisfy $v^a(x) = u(x)$ for any $x \in \text{int}(C \setminus L)$, since $x(\cdot)$ must spend some time in the interior of $C \setminus L$ and hence by (3.2) $v^a(x)$ is strictly greater than $u(x)$.

But now we know what to do: If we rescale time and run along the trajectory $x_1(t)$ at a very high speed, we spend less time in $C \setminus L$ and hence lower the simple running cost in (3.4). More precisely, let

$$a_\epsilon(t) = \frac{1}{\epsilon} a_1\left(\frac{t}{\epsilon}\right), t \geq 0. \tag{3.5}$$

Repeating the above steps, we obtain

$$v^{a_\epsilon}(x) = u(x) + \epsilon \int_0^T e^{-\epsilon t}(\langle b, x_1(t)\rangle - u(x_1(t)))dt.$$

Letting $\epsilon \downarrow 0$, we obtain $v(x) \leq \lim_{\epsilon \downarrow 0} v^{a_\epsilon}(x) = u(x)$. This shows $v = u$ on $\mathbf{R}^d$. Since we now know $u = v$, the claim made in §0 relating to (0.7) follows.

Now let $w^q(x)$ denote the quantity whose infimum is taken in (0.9). To establish $v = w$, fix $x \in \mathbf{R}^d$ and let $0 < q \leq 1$ be such that $\lambda(qx, b) \leq 2$. Let $a = -\log q \geq 0$, and set $a_\epsilon(t) = a/\epsilon$, if $0 \leq t < \epsilon$, and equal zero otherwise. Since $-\log \det(q) = \text{trace}(a)$, computing $v^{a_\epsilon}(x)$ according to (0.2) and passing to the limit yields

$$w^q(x) = \langle b, qx\rangle - \log \det(q) = \lim_{\epsilon \downarrow 0} v^{a_\epsilon}(x) \geq v(x) \tag{3.6}$$

and thus $w \geq v$ on $\mathbf{R}^d$.

On the other hand, if $x \notin \text{int}(C)$, $q = 1$ shows $w(x) = u(x) = v(x)$, while if $x \in C \setminus L$ choosing $a_\epsilon(\cdot)$ according to (3.5) and evaluating $v^{a_\epsilon}(x)$ according to (0.2) yields

$$w^{q^*}(x) = \langle b, q^* x\rangle - \log \det(q^*) = \lim_{\epsilon \downarrow 0} v^{a_\epsilon}(x) = v(x), \tag{3.7}$$

where q^* equals the fundamental solution of $\dot{x} = -a_1(t)x$ evaluated at time T. Thus $w = v$ on $\mathbf{R}^d \setminus L$.

It can be shown, using the strict concavity of $q \mapsto \log\det(q)$ on the space of positive matrices q and the convexity of the set of matrices q satisfying $0 < q \leq 1$, $\lambda(qx, b) \leq 2$, that the infimum in (0.9) is achieved at a unique point for each x. From this it follows that w is continuous on $\mathbf{R}^d$ and hence $w = v$ on $\mathbf{R}^d$. This completes the proof of Theorem 4.

The claim regarding (0.8) is clear if the initial state $x \notin C$, so fix an $x \in C$ and set $a^* = -\log q^*$, by definition the "time-ordered" integral of $\mathbf{a}(x_1(t))$ over $[0, T]$. Then it follows from (3.7) that we obtain equality in (3.6), which establishes the claim made in §0 regarding (0.8) for this x and hence all $x \in \mathbf{R}^d$.

ON THE GRADIENT PROJECTION METHOD FOR OPTIMAL CONTROL PROBLEMS WITH NONNEGATIVE $\mathcal{L}^2$ INPUTS*

T. TIAN† AND J. C. DUNN†

Abstract. Local convergence and active constraint identification theorems are proved for gradient-projection iterates in the cone of nonnegative $\mathcal{L}^2$ functions on $[0,1]$. The theorems are based on recently established infinite-dimensional extensions of the Kuhn–Tucker sufficient conditions and are directly applicable to a large class of continuous-time optimal control problems with smooth nonconvex nonquadratic objective functions and Hamiltonians that are quadratic in the control input u.

Key words. gradient projection, infinite-dimensional programs, nonnegativity constraints, nonconvex objectives, $\mathcal{L}^\infty$-local convergence, $\mathcal{L}^2$-local convergence, active constraint identification, optimal control

1. Introduction.

Reference [1] investigates the local convergence properties of an unscaled gradient projection (GP) algorithm for minimizing nonconvex C^2 real functions over the nonnegative orthant in $\mathbb{R}^n$. Here we consider the same gradient-projection scheme for analogous infinite-dimensional problems,

$$\min_{u\in\Omega} J(u), \tag{1A}$$

$$\Omega = \{u \in \mathcal{L}^2(0,1) : u(t) \geq 0 \text{ a.e. in } [0,1]\}. \tag{1B}$$

A comprehensive local convergence theory already exists for GP algorithms and constrained minimization problems with *convex* objective functions and closed convex feasible sets in a general real Hilbert space [2]. Portions of this theory have also been extended to problems with smooth nonconvex objective functions and feasible sets with embedded open facets [3], [4], or to feasible sets prescribed by a *finite* number of smooth inequality constraints [5]–[7]; however, further extensions are not readily made for sets of the form

$$\Omega = \{u \in \mathcal{L}^p([0,1],\mathbb{R}^m) : u(t) \overset{a.e}{\in} U\}, \tag{2}$$

where U is a closed convex set prescribed by finitely many smooth inequality constraints in $\mathbb{R}^m$. An improved understanding of algorithm convergence behavior in (2) is needed because GP schemes are readily implemented for many continuous-time optimal control problems with feasible sets of this kind [1], [8], [9], because infinite-dimensional problems are typically richer in good and bad solution types and algorithm behavior than their finite-dimensional counterparts [10], [11], and because convergence features that are characteristically infinite-dimensional are nevertheless often *almost* present in large-scale algorithm implementations in approximating finite-dimensional spaces [12], [13]. We are interested in problem (1) because its feasible

set is a prototype for the class of closed convex sets (2), and because nonnegativity constraints are important in their own right in many applications.

The analysis in [1] is fundamentally tied to the equivalence of the Euclidean and Chebychev norms in $\mathbb{R}^n$, and to the Kuhn–Tucker second-order sufficient conditions for local optimality in the nonnegative orthant. On the other hand, the $\mathcal{L}^2$ and $\mathcal{L}^\infty$ norms are not equivalent; the formal extension of the Kuhn–Tucker sufficient conditions in Ω are generally not sufficient even for $\mathcal{L}^\infty$- local optimality [14], [15]; and the proof strategies in [1] are therefore not applicable to problems (1) with general unstructured C^2 objective functions. Nevertheless, we are able to develop results similar to those in [1] for nonconvex C^2 functionals J with Hessians and gradients that satisfy the following conditions at each u in $\mathcal{L}^2(0,1)$: For all v in $\mathcal{L}^2(0,1)$

$$\left[\nabla^2 J(u)v\right](t) \overset{a.e.}{=} S(u)(t)v(t) + \int_0^1 K(u)(t,s)v(s)ds, \tag{3A}$$

where

$$S(u) \in \mathcal{L}^\infty(0,1), \tag{3B}$$

$$K(u) \in \mathcal{L}^2\left([0,1]\times[0,1]\right), \tag{3C}$$

$$K(u)(t,s) \overset{a.e.}{=} K(u)(s,t), \tag{3D}$$

$$\lim_{\|v-u\|_2\to 0} \|S(v) - S(u)\|_\infty = 0, \tag{3E}$$

$$\lim_{\|v-u\|_2\to 0} \|K(v) - K(u)\|_2 = 0, \tag{3F}$$

and

$$\nabla J(u)(t) \overset{a.e.}{=} \phi(u)(t) + S(u)(t)u(t), \tag{4A}$$

with

$$\phi(u) \in \mathcal{L}^\infty(0,1), \tag{4B}$$

$$\lim_{\|v-u\|_2\to 0} \|\phi(v) - \phi(u)\|_\infty = 0. \tag{4C}$$

Conditions (3) and (4) are met by an important class of continuous-time optimal control problems with Bolza objective functions and associated Hamiltonians that are quadratic in the control input $u(t)$. These problems are described further in §6. Extensions of the Kuhn–Tucker sufficient conditions for $\mathcal{L}^\infty$-local optimality in Ω are proved in [15] for J's that satisfy (3) and mild topological restrictions on $S(u)(\cdot)$ and the null set for u. Sufficient conditions for $\mathcal{L}^2$-local optimality are also established in [15] when (3C) is replaced by the stronger condition

$$K(u) \in \mathcal{L}^\infty\left([0,1]\times[0,1]\right). \tag{3C}'$$

These results are summarized in §2. In §§3 and 4, we use the Kuhn–Tucker conditions, the gradient representation formulas (4) and proof techniques from [15] and [16] to establish $\mathcal{L}^\infty$ and $\mathcal{L}^2$ local convergence theorems and convergence rate estimates for the projected gradient iteration

$$u \to G(u), \tag{5A}$$

where

$$G(u) = g\left(a(u), u\right), \tag{5B}$$

$$g(a,u) = P_\Omega\left(u - a\nabla J(u)\right), \tag{5C}$$

$$\left(P_\Omega v\right)(t) \overset{a.e.}{=} P_{[0,\infty)}v(t) = \max\{0, v(t)\}, \tag{5D}$$

and $a(\cdot)$ is a positive real-valued function defined by Bertsekas' modification of the Armijo step length rule [17], [1], i.e.,

$$a(u) = \min\ a \tag{5E}$$

subject to

$$a \in \{\overline{a}, \overline{a}\beta, \overline{a}\beta^2, \cdots\} \tag{5F}$$

and

$$J(u) - J\left(g(a,u)\right) \geq \sigma\langle \nabla J(u), u - g(a,u)\rangle \tag{5G}$$

with $\overline{a}$ fixed in $(0,\infty)$, and σ and β fixed in $(0,1)$.

Our development parallels [16], with the following exceptions. In [16], it is assumed that $K(u)$ is *bounded* on the square $[0,1]\times[0,1]$, and that

$$\lim_{\|v-u\|_2 \to 0} \sup_{[0,1]\times[0,1]} |K(v)(s,t) - K(u)(s,t)| = 0. \tag{3F)$'}$$

This stronger alternative to the $\mathcal{L}^2$ continuity condition (3F) secures the identity

$$\nabla J(v)(t) - \nabla J(u)(t) \overset{a.e.}{=} \int_0^1 \left[\nabla^2 J\left(u + \tau(v-u)\right)(v-u)\right](t)d\tau, \tag{6}$$

which, in [16], takes the place of the present formulas (4); however, our modified proof technique based on (4) yields theorems that apply to a somewhat larger class of optimal control problems. In addition, the $\mathcal{L}^2$-local convergence theorem in §4 establishes a uniform bound on the number of iterations that must elapse before geometric convergence ensues, and the proof given here does *not* require an essentially bounded starting point $u^{(0)}$ for (5). We also provide a new example in §3, a new active constraint identification result in §5, and a treatment of optimal control problems with nonquadratic Bolza objective functions in §6.

2. Sufficient conditions. We note that if $\langle u, v\rangle$ is the standard $\mathcal{L}^2$ inner product $\int_0^1 u(t)v(t)dt$, and if J has a second Gâteaux differential,

$$d^2J(u; v, w) = \langle v, \nabla^2 J(u)w\rangle$$

with a bounded linear operator $\nabla^2 J(u) : \mathcal{L}^2(0,1) \to \mathcal{L}^2(0,1)$ satisfying (3), then J is twice continuously Fréchet differentiable on $\mathcal{L}^2(0,1)$, $\nabla^2 J(u)$ is the Hessian of J at u, and consequently

$$J(v) - J(u) = \langle \nabla J(u), v - u\rangle + \frac{1}{2}\langle v - u, \nabla^2 J(u)(v - u)\rangle + o(\|v - u\|_2^2). \tag{7}$$

This is observed in [15] and proved in [16]. From here onward, we assume that conditions (3) hold. Our goal is to base local convergence proofs for GP sequences in the set Ω in (1B) on (3), (4), and the sufficient conditions for local optimality described below.

For each u in $\mathcal{L}^2(0,1)$ and $\epsilon > 0$, let

$$B_2(u, \epsilon) = \{v \in \mathcal{L}^2(0,1) : \|v - u\|_2 < \epsilon\},$$

$$B_\infty(u, \epsilon) = \{v \in \mathcal{L}^2(0,1) : \|v - u\|_\infty < \epsilon\},$$

where

$$\|u\|_2 = \langle u, u\rangle^{\frac{1}{2}},$$
$$\|u\|_\infty = \operatorname{ess\,sup}_{[0,1]} |u(t)|.$$

We say that u^* is an *$\mathcal{L}^2$-local minimizer* for J in Ω if and only if

$$\exists \delta > 0 \ \forall u \quad (u \in B_2(u^*, \epsilon) \cap \Omega \Rightarrow J(u) \geq J(u^*)).$$

Similarly, u^* is an *$\mathcal{L}^\infty$-local minimizer* for J in Ω if and only if

$$\exists \delta > 0 \ \forall u \quad (u \in B_\infty(u^*, \epsilon) \cap \Omega \Rightarrow J(u) \geq J(u^*)).$$

Every $\mathcal{L}^2$-local minimizer u^* is a *stationary point* for J in Ω, i.e.,

$$\forall u \in \Omega \quad \langle \nabla J(u^*), u - u^*\rangle \geq 0;$$

moreover, every $\mathcal{L}^\infty$-local minimizer u^* is also stationary [15]. We note that u^* is stationary if and only if for all $a > 0$, u^* is a fixed point of the map $g(a, \cdot)$ in (5) [3].

For each u in Ω, let

$$\alpha(u) = \{t \in [0,1] : u(t) = 0\},$$
$$T(u) = \{v \in \mathcal{L}^2(0,1) : v(t) = 0 \text{ a.e. in } \alpha(u)\}.$$

The set $\alpha(u)$ and the corresponding closed subspace $T(u)$ are analogous to the active constraint index sets and associated tangent spaces for the nonnegative orthant in $\mathbb{R}^n$ [1], and the following requirements can be seen as a formal extension of the Kuhn–Tucker sufficient conditions from the finite-dimensional orthant to the nonnegative cone Ω in $\mathcal{L}^2(0,1)$.

$$\nabla J(u^*)(t) = 0 \quad \text{a.e. in } \alpha(u^*)^c, \tag{8A}$$

(8B) $$\nabla J(u^*)(t) \geq 0 \quad \text{a.e. in } \alpha(u^*),$$

(8C) $$\forall \beta \subset INT\, \alpha(u^*)\ (\beta \text{ closed} \Rightarrow \exists c_1 > 0,\ \nabla J(u^*)(t) \geq c_1 \quad \text{a.e. in } \beta),$$

(8D) $$\exists c_2 > 0\ \forall v \in T(u^*), \quad \langle v, \nabla^2 J(u^*)v\rangle \geq 2c_2\|v\|_2^2,$$

where $\alpha(u^*)^c = [0,1] \setminus \alpha(u^*)$ = the complement of $\alpha(u^*)$ in $[0,1]$. We note that (8C) is considerably weaker than the obvious formal extension of strict complementarity in $\mathbb{R}^n_+$, namely, that $\nabla J(u^*)(t)$ be bounded away from 0 almost everywhere in $\alpha(u^*)$. The latter condition *never* holds in the commonly encountered case where u^* and $\nabla J(u^*)$ are continuous, and the sets $\alpha(u^*)$ and $\alpha(u^*)^c$ have positive measure. On the other hand, condition (8C) is not incompatible with continuity of u^* and $\nabla J(u^*)$, since this condition allows $\nabla J(u^*)(t)$ to approach 0 as t approaches the frontier of $\alpha(u^*)$ within $\alpha(u^*)$ (see §3, Example 1).

The formal sufficient conditions (8) actually *are* sufficient for $\mathcal{L}^\infty$-local optimality in Ω when (3) holds, $\alpha(u^*)$ is closed, and $S(u^*)(\cdot)$ is continuous on the frontier of $\alpha(u^*)$ in $[0,1]$; moreover, if (3C)′ is also satisfied and $S(u^*)(\cdot)$ is positive and bounded away from 0 almost everywhere on [0,1], then conditions (8) become sufficient for $\mathcal{L}^2$-local optimality in Ω [15]. The $\mathcal{L}^\infty$-local optimality proof in [15] first shows that when (8D) holds, $S(u^*)(t)$ is positive and bounded away from 0 on $\alpha(u^*)^c$, and by continuous extension, on a larger set $\mathcal{O}_o$ that is open in $[0,1]$ and contains $\overline{\alpha(u^*)^c}$ (= the closure of $\alpha(u^*)^c$). Because of (3), it then follows that a coercivity condition like (8D) also holds on a larger subspace

(9) $$T_\alpha = \{v \in \mathcal{L}^2(0,1) : v(t) = 0 \text{ a.e. in } \alpha\} \supset T(u^*)$$

with $\alpha = \mathcal{O}^c$ for some open set $\mathcal{O}$ such that $\mathcal{O}_o \supset \mathcal{O} \supset \overline{\alpha(u^*)^c}$. According to (8A)–(8C), $\nabla J(u^*)(t)$ is positive and bounded away from 0 almost everywhere in α, and the first- and second-order terms in Taylor's formula (7) will now combine to produce $\mathcal{L}^2$- quadratic growth for J, uniformly in some $\mathcal{L}^\infty$ neighborhood of u^* in Ω, i.e.,

(10) $$\exists \epsilon > 0\ \exists c > 0\ \forall u \quad \left(u \in B_\infty(u^*, \epsilon) \cap \Omega \Rightarrow J(u) - J(u^*) \geq c\|u - u^*\|_2^2\right).$$

(Two-metric local optimality results of this kind have also been proved in [18] under different hypotheses for J.) Finally, when (3C)′ holds at u^* and $S(u^*)(t)$ is positive and bounded away from 0 on $\alpha(u^*)$ as well as $\alpha(u^*)^c$, the $\mathcal{L}^2$-local optimality proof in [15] uses Taylor's formula and (3) to establish the $\mathcal{L}^2$ counterpart of (10), i.e.,

(11) $$\exists \epsilon > 0\ \exists c > 0\ \forall u \quad \left(u \in B_2(u^*, \epsilon) \cap \Omega \Rightarrow J(u) - J(u^*) \geq c\|u - u^*\|_2^2\right).$$

(In this connection, we note that u^* is an $\mathcal{L}^2$-local minimizer of J in Ω *only if* $S(u^*)(t) \geq 0$ almost everywhere in [0,1] [15].)

The following theorem collects the sufficiency results needed in the convergence analysis of §§3 and 4; these results are immediate corollaries of Lemmas 1–3 and Theorem 4 in [15].

THEOREM 1. *Let J be a twice continuously Fréchet differentiable real function on $\mathcal{L}^2(0,1)$ satisfying conditions* (3). *Suppose that the formal Kuhn–Tucker sufficient conditions* (8) *hold at u^* in the nonnegative cone Ω, that the set $\alpha(u^*)$ is closed, and that $S(u^*)$ is continuous on the frontier of $\alpha(u^*)$ in* $[0,1]$. *Then $S(u^*)(t)$ is positive and bounded away from* 0 *almost everywhere in some open neighborhood of $\overline{\alpha(u^*)^c}$*

in $[0,1]$, *there are positive numbers* c_1 *and* c_2, *a closed set* $\alpha \subset INT\alpha(u^*)$, *and a corresponding closed subspace* T_α *in* (9) *such that*

$$\nabla J(u^*)(t) = 0 \quad a.e.\ in\ \alpha(u^*)^c, \tag{12A}$$

$$\nabla J(u^*)(t) \geq 0 \quad a.e.\ in\ \alpha(u^*), \tag{12B}$$

$$\nabla J(u^*)(t) \geq c_1 \quad a.e.\ in\ \alpha, \tag{12C}$$

$$\forall v \in T_\alpha \quad \langle v, \nabla^2 J(u^*)v\rangle \geq c_2\|v\|_2^2, \tag{12D}$$

and consequently, u^* *is a strict* $\mathcal{L}^\infty$*-local minimizer of* J *in* Ω *satisfying* (10). *Furthermore, if condition* (3C)′ *also holds, and if* $S(u^*)$ *is positive and bounded away from* 0 *almost everywhere on the* entire *interval* $[0,1]$, *then* u^* *is a strict* $\mathcal{L}^2$*-local minimizer satisfying* (11).

3. $\mathcal{L}^\infty$-local convergence. To motivate our convergence proof strategy, we first outline the local convergence analysis for gradient projection iterates in [1] and indicate where this analysis fails in the infinite-dimensional setting of problem (1). If u^* satisfies the Kuhn–Tucker sufficient conditions in the nonnegative orthant $\mathbb{R}^n_+$, then iterates of the GP counterpart of (5) that begin sufficiently near u^* are eventually confined to a region of the subspace tangent to $\mathbb{R}^n_+$ at u^* where the GP algorithm reduces to a convergent unconstrained Armijo steepest descent iteration for the restriction of J to the tangent space. The proof of this result in [1] rests on the following facts for C^2 objective functions:

(i) The bounded positive step lengths $a(u)$ in (5) are bounded away from 0 in sufficiently small neighborhoods of stationary points u^*.

(ii) If the strict complementarity condition

$$\inf_{\{i:u_i^*=0\}} \frac{\partial J}{\partial u_i}(u^*) > 0$$

holds at a stationary point u^* in $\mathbb{R}^n_+$, then

$$\lim_{\substack{u\to u^*\\ u\in\mathbb{R}^n_+}} \sup_{\{i:u_i^*=0\}} \left(u_i - a(u)\frac{\partial J}{\partial u_i}(u)\right) < 0$$

and

$$\lim_{\substack{u\to u^*\\ u\in\mathbb{R}^n_+}} \inf_{\{i:u_i^*>0\}} \left(u_i - a(u)\frac{\partial J}{\partial u_i}(u)\right) > 0.$$

(iii) Every nonsingular unconstrained local minimizer u^* is a *stable* fixed point of the steepest descent map with Armijo steplengths, i.e., iterate sequences $\{u^{(k)}\}$ generated by this map will remain in any specified arbitrarily small neighborhood of u^*, provided $u^{(0)}$ lies in a sufficiently small neighborhood of u^*.

(iv) Unconstrained Armijo steepest descent iterates that remain sufficiently near a nonsingular minimizer u^* must converge to u^*.

In (ii), the limits can be taken in any norm, since all norms are equivalent in $\mathbb{R}^n$.

Assertion (i) can be demonstrated for the general version of (5) in *arbitrary* nonempty closed convex subsets of a real Hilbert space [5]. Similarly, Assertions (iii) and (iv) are true for nonsingular minimizers in $\mathbb{R}^n$ [19], and more generally for uniformly proper local minimizers that are also uniformly isolated stationary points in closed convex subsets of a Hilbert space [3], [7]. In particular, if u^* satisfies (8A) and (8D) in the formal Kuhn–Tucker sufficient conditions, then u^* is a nonsingular local minimizer for the restriction $J|_{T(u^*)}$ in the closed subspace $T(u^*)$, and hence a stable local attractor for the corresponding Armijo steepest descent iterates in $T(u^*)$. On the other hand, $\mathcal{L}^2$ continuity of $\nabla J(\cdot)$ and the sufficient conditions in Theorem 1 do *not* imply $\mathcal{L}^2$ or $\mathcal{L}^\infty$ analogs of Assertions (ii), since the quotients $\|w\|_\infty/\|w\|_2$ are unbounded on $\mathcal{L}^\infty(0,1) \setminus \{0\}$, and the values $\nabla J(u^*)(t)$ and $u^*(t)$ are typically not bounded away from 0 on the infinite sets $\alpha(u^*)$ and $\alpha(u^*)^c$, respectively. As a consequence, the map G in (5) need not send small $\mathcal{L}^2$ (or $\mathcal{L}^\infty$) neighborhoods of u^* into $T(u^*)$, and need not reduce to the Armijo steepest descent map for $J|_{T(u^*)}$ in small $\mathcal{L}^2$ (or $\mathcal{L}^\infty$) neighborhoods of u^* in $T(u^*)$. The proof strategy in [1] therefore fails for problem (1), even when J is a C^2 objective function satisfying (3). In this section and the next, we develop modified proof schemes for J's that satisfy (3) *and* the gradient representation formulas (4), and for u^* that meet the $\mathcal{L}^\infty$ or $\mathcal{L}^2$ sufficient conditions in Theorem 1. The modified proofs establish circumstances under which the iterates of (5) are eventually confined not to $T(u^*)$, but to a *larger* subspace T, or more precisely, to a closed convex G-invariant subset of T in which $J|_T$ is convex and (5) reduces to a convergent GP iteration for $J|_T$.

We begin with an $\mathcal{L}^\infty$-$\mathcal{L}^2$ variant of the general Hilbert space stability definition in [3], and then prove associated stability and convergence results for (5) and (1).

DEFINITION 1. *A stationary point u^* is $\mathcal{L}^\infty$-$\mathcal{L}^2$ stable for the GP algorithm* (5) *if and only if for each $\epsilon > 0$, there exists a $\delta > 0$ such that for all sequences $\{u^{(k)}\}$ generated by* (5),

$$u^{(0)} \in B_\infty(u^*, \delta) \cap \Omega \Rightarrow \left(\forall k \geq 0 \quad u^{(k)} \in B_2(u^*, \epsilon) \cap \Omega\right).$$

THEOREM 2. *Let $J : \mathcal{L}^2(0,1) \to \mathbb{R}^1$ be a twice continuously Fréchet differentiable function satisfying conditions* (3) *and* (4). *Suppose that the sufficient conditions for $\mathcal{L}^\infty$-local optimality in Theorem* 1 *hold at the point u^* in the nonnegative $\mathcal{L}^2$ cone Ω, and let T_α and G be the closed subspace in Theorem* 1 *and the gradient projection map in the algorithm* (5). *Then for every $\epsilon > 0$, there is a $\delta > 0$ and a G-invariant set, $\mathcal{I} \subset \overline{B_2(u^*, \epsilon)} \cap \Omega \cap T_\alpha$, such that $u^* \in \mathcal{I}$, and for all sequences $\{u^{(k)}\}$ generated by* (5),

$$u^{(0)} \in B_\infty(u^*, \delta) \cap \Omega \Rightarrow \left(\forall k \geq 1 \quad u^{(k)} \in \mathcal{I}\right).$$

It follows that u^* is $\mathcal{L}^\infty$-$\mathcal{L}^2$ stable for (5).

Proof. Let α, c_1, and c_2 be the measurable set and positive numbers in Theorem 1. For $\epsilon > 0$, define

$$\mathcal{L}_\epsilon = \{u \in \Omega : J(u) - J(u^*) \leq \tfrac{1}{4} c_2 \epsilon^2\}$$

and

$$\mathcal{I}_\epsilon = \overline{B_2(u^*, \epsilon)} \cap T_\alpha \cap \mathcal{L}_\epsilon.$$

We will prove the theorem by first showing that for ϵ sufficiently small,

$$G[\mathcal{I}_\epsilon] \subset \mathcal{I}_\epsilon \tag{13}$$

and then showing that for every $\epsilon > 0$ there is a $\delta > 0$ for which

$$G[B_\infty(u^*, \delta) \cap \Omega] \subset \mathcal{I}_\epsilon. \tag{14}$$

Since u^* is stationary and $u^* \in T(u^*) \subset T_\alpha$, condition (12D) and Taylor's formula (7) establish that for some $\epsilon_0 > 0$ and for all u,

$$u \in B_2(u^*, \epsilon_0) \cap \Omega \cap T_\alpha \Rightarrow J(u) - J(u^*) \geq \tfrac{1}{4} c_2 \|u - u^*\|_2^2. \tag{15}$$

Condition (4) implies that for all u,

$$|\nabla J(u)(t) - \nabla J(u^*)(t)| \overset{a.e.}{\leq} |\phi(u)(t) - \phi(u^*)(t)| + |S(u)(t)u(t) - S(u^*)(t)u^*(t)| \tag{16}$$

and therefore

$$u \in T_\alpha \Rightarrow |\nabla J(u)(t) - \nabla J(u^*)(t)| \leq |\phi(u)(t) - \phi(u^*)(t)| \text{ a.e. in } \alpha \subset \alpha(u^*). \tag{17}$$

According to (4), (12C), and (17), there is an $\epsilon_1 \in (0, \epsilon_0]$ such that for all u

$$\begin{aligned} u \in B_2(u^*, \epsilon_1) \cap \Omega \cap T_\alpha &\Rightarrow \nabla J(u)(t) \geq 0 \text{ a.e. in } \alpha \subset \alpha(u^*) \\ &\Rightarrow G(u)(t) = 0 \text{ a.e. in } \alpha \\ &\Rightarrow G(u) \in T_\alpha. \end{aligned}$$

Since u^* is stationary and $\nabla J(\cdot)$ is $\mathcal{L}^2$-continuous, it follows that $G(u^*) = u^*$, G is $\mathcal{L}^2$- continuous at u^* [3], and there is an $\epsilon_2 \in (0, \epsilon_1]$ such that for all u,

$$u \in B_2(u^*, \epsilon_2) \cap \Omega \cap T_\alpha \Rightarrow G(u) \in B_2(u^*, \epsilon_0) \cap \Omega \cap T_\alpha.$$

Since G also has the descent property

$$\forall u \in \Omega \quad J(G(u)) \leq J(u),$$

we therefore find that for all ϵ in $(0, \epsilon_2)$ and all u,

$$\begin{aligned} u \in \mathcal{I}_\epsilon \Rightarrow G(u) \in B_2(u^*, \epsilon_0) \cap \Omega \cap T_\alpha \text{ and} \\ \tfrac{1}{4} c_2 \|G(u) - u^*\|_2^2 \leq J(G(u)) - J(u^*) \leq \tfrac{1}{4} c_2 \epsilon^2 \\ \Rightarrow G(u) \in \mathcal{I}_\epsilon. \end{aligned} \tag{18}$$

This proves (13) and shows that $\mathcal{I}_\epsilon$ is a G-invariant set for all ϵ in $(0, \epsilon_2)$.

To prove (14), we note that J is $\mathcal{L}^2$-continuous, and hence for every $\epsilon > 0$ there is a $\rho > 0$ such that

$$B_2(u^*, \rho) \cap \Omega \cap T_\alpha \subset \mathcal{I}_\epsilon. \tag{19}$$

With a slight modification of the proof of in [5, Lem. A2], it can be shown that there are positive numbers $\underline{a}$ and δ_0 such that for all u,

$$u \in B_2(u^*, \delta_0) \cap \Omega \Rightarrow a(u) \geq \underline{a}. \tag{20}$$

By (4), (12C), and (16), there is a $\delta_1 \in (0, \delta_0]$ such that for all u,

$$\begin{aligned} u \in B_\infty(u^*, \delta_1) \cap \Omega &\Rightarrow |\nabla J(u)(t) - \nabla J(u^*)(t)| \overset{a.e.}{\leq} \tfrac{1}{2} c_1 \\ &\Rightarrow \nabla J(u)(t) \geq \tfrac{1}{2} c_1 \text{ a.e. in } \alpha. \end{aligned}$$

Let $\delta_2 = \min\{\delta_1, \frac{1}{2}\underline{a}c_1\}$. Since $B_\infty(u^*, \delta_2) \subset B_2(u^*, \delta_2)$, it follows that for all u,

$$\begin{aligned} u \in B_\infty(u^*, \delta_2) \cap \Omega &\Rightarrow u(t) - a(u)\nabla J(u)(t) \leq 0 \text{ a.e. in } \alpha \\ &\Rightarrow G(u)(t) = 0 \text{ a.e. in } \alpha \\ &\Rightarrow G(u) \in \Omega \cap T_\alpha. \end{aligned}$$

We have already seen that $G(u^*) = u^*$ and G is $\mathcal{L}^2$-continuous at u^*. Therefore, for every $\rho > 0$ there is $\delta \in (0, \delta_2]$ such that for all u,

$$u \in B_\infty(u^*, \delta) \cap \Omega \Rightarrow G(u) \in B_2(u^*, \rho) \cap \Omega \cap T_\alpha. \tag{21}$$

In view of (19), this proves (14). □

THEOREM 3. *Suppose that J and u^* satisfy the hypotheses of Theorem 2. Then for some $\delta > 0$ and $\lambda \in [0, 1)$, and all sequences $\{u^{(k)}\}$ generated by (5),*

$$u^{(0)} \in B_\infty(u^*, \delta) \cap \Omega \Rightarrow \left(\forall k \geq 1 \quad J(u^{(k+1)}) - J(u^*) \leq \lambda(J(u^{(k)}) - J(u^*))\right).$$

Furthermore, for $k \geq 1$ the norms $\|u^{(k)} - u^*\|_2$ are bounded above by a real sequence that converges to 0 geometrically, with ratio $\lambda^{\frac{1}{2}}$.

Proof. We will show that for sufficiently small $\epsilon > 0$, $J|_{T_\alpha}$ is convex and satisfies the growth condition (15) on $\overline{B_2(u^*, \epsilon)} \cap \Omega \cap T_\alpha$, that the G-invariant set $\mathcal{I}_\epsilon$ in Theorem 2 is closed and convex, and that for all u in $\mathcal{I}_\epsilon$,

$$J|_{T_\alpha}(u) - J|_{T_\alpha}(G(u)) \geq \sigma\langle \nabla(J|_{T_\alpha})(u), u - G(u)\rangle, \tag{22}$$

$$G(u) = P_{\mathcal{I}_\epsilon}\left(u - a(u)\nabla\left(J|_{T_\alpha}\right)(u)\right) \tag{23}$$

with $a(u)$ determined by (5). Our assertions then follow from Theorem 2, the local steplength bound (20), and a result in [2] for GP algorithms and convex programs in Hilbert spaces.

Let α, c_1, c_2, and $\underline{a}$ be the measurable set and positive numbers in Theorem 1 and condition (20). In view of (12D), (15), (18), (20), and the continuity of $\nabla^2 J(\cdot)$, there is an $\epsilon > 0$ such that $\mathcal{I}_\epsilon$ is G-invariant, and for all u and v,

$$u \in \overline{B_2(u^*, \epsilon)} \cap T_\alpha \text{ and } v \in T_\alpha \Rightarrow \langle v, \nabla^2\left(J|_{T_\alpha}\right)(u)v\rangle = \langle v, \nabla^2 J(u)v\rangle \geq \tfrac{1}{2}c_2\|v\|_2^2, \tag{24}$$

$$u \in \mathcal{I}_\epsilon \Rightarrow J|_{T_\alpha}(u) - J|_{T_\alpha}(u^*) \geq \tfrac{1}{4}c_2\|u - u^*\|_2^2, \tag{25}$$

$$u \in \mathcal{I}_\epsilon \Rightarrow a(u) \geq \underline{a}. \tag{26}$$

According to (24), $J|_{T_\alpha}$ is convex on $\overline{B_2(u^*, \epsilon)} \cap T_\alpha$, and therefore $\mathcal{I}_\epsilon$ is closed and convex.

Since $\mathcal{I}_\epsilon$ is G-invariant, the difference $u - G(u)$ lies in T_α for all u in $\mathcal{I}_\epsilon$, and therefore

$$\begin{aligned}\langle \nabla J(u), u - G(u)\rangle &= \langle \nabla J(u), P_{T_\alpha}(u - G(u))\rangle \\ &= \langle P_{T_\alpha}\nabla J(u), u - G(u)\rangle \\ &= \langle \nabla (J|_{T_\alpha})(u), u - G(u)\rangle\end{aligned}$$

for all u in $\mathcal{I}_\epsilon$. Thus, (22) is implied by (5).

Since $G[\mathcal{I}_\epsilon] \subset \mathcal{I}_\epsilon$, it can be seen that

$$\min_{v\in\mathcal{I}_\epsilon} \|u - a(u)\nabla J(u) - v\|_2 \le \|u - a(u)\nabla J(u) - G(u)\|_2$$

for all u in $\mathcal{I}_\epsilon$. On the other hand, since $\mathcal{I}_\epsilon \subset \Omega$, conditions (5) imply that

$$\begin{aligned}\|u - a(u)\nabla J(u) - G(u)\|_2 &= \min_{v\in\Omega} \|u - a(u)\nabla J(u) - v\|_2 \\ &\le \min_{v\in\mathcal{I}_\epsilon} \|u - a(u)\nabla J(u) - v\|_2\end{aligned}$$

for u in $\mathcal{I}_\epsilon$. Consequently, for all u,

$$u \in \mathcal{I}_\epsilon \Rightarrow G(u) = P_{\mathcal{I}_\epsilon}(u - a(u)\nabla J(u)).$$

Furthermore, since $\mathcal{I}_\epsilon \subset T_\alpha$, we have for all z in $\mathcal{L}^2(0,1)$,

$$\begin{aligned}\|P_{\mathcal{I}_\epsilon}z - P_{T_\alpha}z\|_2^2 + \|P_{T_\alpha^\perp}z\|_2^2 &= \|P_{\mathcal{I}_\epsilon}z - z\|_2^2 \\ &= \min_{v\in\mathcal{I}_\epsilon} \|v - z\|_2^2 \\ &= \min_{v\in\mathcal{I}_\epsilon} \|v - P_{T_\alpha}z\|_2^2 + \|P_{T_\alpha^\perp}z\|_2^2.\end{aligned}$$

It follows that

$$\|P_{\mathcal{I}_\epsilon}z - P_{T_\alpha}z\|_2^2 = \min_{v\in\mathcal{I}_\epsilon} \|v - P_{T_\alpha}z\|_2^2$$

and therefore

$$P_{\mathcal{I}_\epsilon}z = P_{\mathcal{I}_\epsilon}(P_{T_\alpha}z)$$

for z in $\mathcal{L}^2(0,1)$. Thus, for all u in $\mathcal{I}_\epsilon$,

$$\begin{aligned}G(u) &= P_{\mathcal{I}_\epsilon}(u - a(u)\nabla J(u)) \\ &= P_{\mathcal{I}_\epsilon}(P_{T_\alpha}(u - a(u)\nabla J(u))) \\ &= P_{\mathcal{I}_\epsilon}(u - a(u)\nabla (J|_{T_\alpha})(u)),\end{aligned}$$

as claimed in (23).

Finally, let ρ and δ be positive numbers satisfying (19) and (21) with ϵ. If the sequence $\{u^{(k)}\}$ is generated by (5) with $u^{(0)} \in B_\infty(u^*, \delta) \cap \Omega$, then for $k \ge 1$, $u^{(k)}$ is confined to the closed convex G-invariant set $\mathcal{I}_\epsilon \subset T_\alpha$, where $J|_{T_\alpha}$ is convex and continuously Fréchet differentiable and (5) reduces to an iteration of the GP map,

$$u \to P_{\mathcal{I}_\epsilon}(u - a(u)\nabla (J|_{T_\alpha})(u))$$

with steplengths $a(u)$ satisfying (22)–(23) and (26). Our convergence claims now follow at once from the growth condition (25) and [2, Thm. 4.3]. □

Example 2 in [15] shows that C^2 objective functions J satisfying (3) and (4) can have $\mathcal{L}^\infty$-local minimizers u^* that are not $\mathcal{L}^2$-local minimizers in the non-negative $\mathcal{L}^2$ cone Ω. Every $\mathcal{L}^2$ neighborhood of such a u^* contains a point $u \in \Omega$ at which $J(u) < J(u^*)$. Since J is $\mathcal{L}^2$ continuous and (5) does not increase J, we see that GP iterations (5) beginning at u can not converge to u^* in the $\mathcal{L}^2$ norm. The following special case of Example 2 in [15] demonstrates that u^* can also be *unstable* for (5) in the conventional $\mathcal{L}^2$ sense.

Example 1. For $u \in \mathcal{L}^2(0,1)$, put

$$J(u) = \int_0^1 \left[r(t)u(t) + \frac{1}{2} S(t)u(t)^2 \right] dt$$

and

$$u^*(t) = \max\{0, -r(t)\}, \quad t \in [0,1],$$

where

$$r(t) = 1 - 2t, \quad t \in [0,1]$$

and

$$S(t) = \begin{cases} -1, & t \in [0, \frac{1}{2} - \Delta) \\ 1, & t \in [\frac{1}{2} - \Delta, 1] \end{cases}$$

with Δ fixed in $(0, \frac{1}{2})$. Then u^* is an $\mathcal{L}^\infty$-local minimizer of J in the nonnegative cone Ω, but u^* is *not* an $\mathcal{L}^2$-local minimizer in Ω [15]; moreover, for every δ, no matter how small, there is a v in $B_2(u^*, \delta) \cap \Omega$ such that

$$\lim_{k \to \infty} \|u^{(k)} - u^*\|_2 = \infty$$

for the GP sequence generated by (5) and beginning at v. To prove the latter assertion, we first note that J is quadratic, with $K(u)(t,s) = 0$, $S(u)(t) = S(t)$, and $\phi(u)(t) = 1 - 2t$ in (3)–(4). The gradient map $\nabla J(\cdot)$ is also $\mathcal{L}^2$-Lipschitz continuous (with Lipschitz constant 1), and this implies that the steplengths $a(u)$ in (5) are *globally* bounded away from 0 on Ω by some $\underline{a} > 0$ [2]. Furthermore, given $\delta > 0$, there are measurable sets $\theta \subset (0, \frac{1}{2} - \Delta)$ and functions $v \in \Omega$ such that,

$$\mu(\theta) > 0,$$

$$\forall t \in \theta \quad h(t) \stackrel{def}{=} v(t) - (1 - 2t) > 0,$$

$$\|v - u^*\|_2 \leq \delta.$$

If $\{u^{(k)}\}$ is generated by (5), with $u^{(0)} = v$, then a simple induction yields

$$\forall t \in \theta \; \forall k \geq 1 \quad u^{(k)}(t) \geq v(t) + k\underline{a}h(t),$$

$$\|u^{(k)} - u^*\|_2^2 \geq \int_\theta \left(u^{(k)}\right)^2 dt \geq k^2 \underline{a}^2 \int_\theta h(t)^2 dt.$$

Therefore,

$$\forall t \in \theta \quad \lim_{k\to\infty} |u^{(k)}(t) - u^*(t)| = \infty$$

and

$$\lim_{k\to\infty} \|u^{(k)} - u^*\|_2 = \infty.$$

4. $\mathcal{L}^2$-local convergence. The Hilbert space stability formulation in [3] has the following expression for (1) and (5).

DEFINITION 2. *A stationary point u^* is $(\mathcal{L}^2)$ stable for the GP algorithm* (5) *if and only if for each $\epsilon > 0$, there is a $\delta \in (0, \epsilon]$ such that for all sequences $\{u^{(k)}\}$ generated by* (5),

$$u^{(0)} \in B_2(u^*, \delta) \cap \Omega \Rightarrow \left(\forall k \geq 0 \quad u^{(k)} \in B_2(u^*, \epsilon) \cap \Omega\right).$$

As a corollary of Lemma 2.1 in [3], we find that a stationary point u^* is stable for (5) if u^* is a uniformly proper local minimizer of J in the nonnegative cone Ω, and in particular, if u^* satisfies (11). Thus, the sufficient conditions for $\mathcal{L}^2$-local optimality in Theorem 1 imply that u^* is stable. We will now prove a related $\mathcal{L}^2$-local convergence theorem for (5).

THEOREM 4. *Let $J : \mathcal{L}^2(0,1) \to \mathbb{R}^1$ be a twice continuously Fréchet differentiable function satisfying conditions* (3) *and* (4), *and suppose that the sufficient conditions for $\mathcal{L}^2$-local optimality in Theorem* 1 *hold at the point u^* in the nonnegative $\mathcal{L}^2$ cone Ω. Then there are positive numbers $\delta > 0$ and n, and a number λ in $[0,1)$, such that for all sequences $\{u^{(k)}\}$ generated by the GP algorithm* (5),

$$u^{(0)} \in B_2(u^*, \delta) \cap \Omega \Rightarrow \forall k > n \quad J(u^{(k+1)}) - J(u^*) \leq \lambda(J(u^{(k)}) - J(u^*)).$$

Furthermore, for $k > n$ the norms $\|u^{(k)} - u^*\|_2$ are bounded above by a real sequence that converges to 0 *geometrically, with ratio $\lambda^{\frac{1}{2}}$.*

Proof. Let α be the measurable set in Theorem 1. As noted earlier, u^* is stable and the iterates $\{u^{(k)}\}$ of (5) can be confined to any specified $\mathcal{L}^2$ neighborhood $\overline{B_2(u^*, \epsilon)} \cap \Omega$ by restricting $u^{(0)}$ to a suitable $\mathcal{L}^2$ subneighborhood $B_2(u^*, \delta)$. We will show that if ϵ is sufficiently small, then iterates confined to $\overline{B_2(u^*, \epsilon)} \cap \Omega$ will eventually satisfy the condition,

$$u^{(k)}(t) = 0, \text{ a.e. in } \alpha \setminus \theta$$

or equivalently,

$$u^{(k)} \in T_{\alpha\setminus\theta}$$

for some subset $\theta \subset \alpha$ with Lebesgue measure $\mu(\theta)$ so small that a coercivity condition like (24) holds on the larger closed subspace $T_{\alpha\setminus\theta} \supset T_\alpha$. Our claims are then established by applying the results of [2] once again, this time to $J|_{T_{\alpha\setminus\theta}}$ in the set $\overline{B_2(u^*, \epsilon)} \cap \Omega \cap T_{\alpha\setminus\theta}$.

Let $\underline{a}$, c, c_1, and c_2 be the positive numbers in Theorem 1 and conditions (11) and (20), let c_3 be a positive number that bounds $S(u^*)(t)$ away from 0 almost everywhere in $[0,1]$, and put

$$d = \min\{c_2, c_3\}.$$

Condition (4A) implies that

$$\nabla J(u)(t) \overset{a.e.}{\geq} \nabla J(u^*)(t) - |\phi(u)(t) - \phi(u^*)(t)| + S(u)(t)u(t) - S(u^*)(t)u^*(t).$$

Therefore, in view of (3E), (3F), (4C), (11), (20), and the continuity of $\nabla^2 J(\cdot)$, there is an $\epsilon > 0$ such that for all u in $\overline{B_2(u^*, \epsilon)} \cap \Omega$, and for all v,

$$\nabla J(u)(t) \geq \tfrac{1}{2}(c_1 + c_3 u(t)) \geq \tfrac{1}{2}c_1 \quad \text{a.e. in } \alpha, \tag{27}$$

$$a(u) \geq \underline{a}, \tag{28}$$

$$J(u) - J(u^*) \geq c\|u - u^*\|_2^2, \tag{29}$$

$$v \in T_\alpha \Rightarrow \langle v, \nabla^2 J(u)v\rangle \geq \tfrac{1}{2}c_2\|v\|_2^2, \tag{30}$$

$$S(u)(t) \overset{a.e.}{\geq} \tfrac{1}{2}c_3, \tag{31}$$

$$\|K(u) - K(u^*)\|_2 \leq \tfrac{1}{8}d. \tag{32}$$

Moreover, there is a $\rho > 0$ such that for all measurable sets $\omega \subset [0,1] \times [0,1]$,

$$\mu(\omega) \leq \rho \Rightarrow \left(\int\int_\omega K(u^*)^2(t,s)dtds\right)^{\frac{1}{2}} \leq \tfrac{1}{8}d. \tag{33}$$

Now let $\{u^{(k)}\}$ be a GP iterate sequence with range in $\overline{B_2(u^*, \epsilon)}$, and for $l > 0$ put

$$\theta_l = \{t \in \alpha : u^{(0)}(t) > l\}$$

and

$$\begin{aligned}\omega_l &= [(\alpha^c \cup \theta_l) \times (\alpha^c \cup \theta_l)] \setminus (\alpha^c \times \alpha^c) \\ &= (\alpha^c \times \theta_l) \cup (\theta_l \times \alpha^c) \cup (\theta_l \times \theta_l).\end{aligned}$$

We note that

$$\mu(\omega_l) = 2\mu(\alpha_c)\mu(\theta_l) + \mu^2(\theta_l)$$

and also

$$\mu(\theta_l)l^2 \leq \int_{\theta_l} \left(u^{(0)}(t)\right)^2 dt \leq \epsilon^2,$$

since $u^{(0)} \in \overline{B_2(u^*, \epsilon)}$ and $u^*(t) = 0$ almost everywhere in $\alpha \supset \theta_l$. Consequently,

$$\mu(\omega_l) \leq \left(2\mu(\alpha^c) + \left(\frac{\epsilon}{l}\right)^2\right)\left(\frac{\epsilon}{l}\right)^2.$$

Given $\rho > 0$ in (33), let m be the unique positive root l of

$$\left(2\mu(\alpha^c) + \left(\frac{\epsilon}{l}\right)^2\right)\left(\frac{\epsilon}{l}\right)^2 = \rho.$$

Put $\theta = \theta_m$, $\omega = \omega_m$, $\nu = \max\{0, 1 - \frac{1}{2}\underline{a}c_3\} < 1$, and

$$n = \begin{cases} -\dfrac{\log\left(1 + \frac{2m(1-\nu)}{\underline{a}c_1}\right)}{\log \nu}, & \nu \geq 0 \\ 0, & \nu = 0 \end{cases}.$$

By constuction, and conditions (5), (27), (28), and (30)–(33), it follows that

$$\mu(\omega) \leq \rho$$

and for all k,

$$\begin{aligned} k > n &\Rightarrow u^{(k)}(t) = 0 \text{ a.e. in } \alpha \setminus \theta \\ &\Rightarrow u^{(k)} \in \overline{B_2(u^*, \epsilon)} \cap \Omega \cap T_{\alpha\setminus\theta} \end{aligned}$$

and for all u in $\overline{B_2(u^*, \epsilon)}$ and v in $T_{\alpha\setminus\theta}$,

$$\begin{aligned} \langle v, \nabla^2 J(u) v\rangle &= \int_{(\alpha\setminus\theta)^c} S(u)(t)v^2(t)dt + \int\int_{(\alpha\setminus\theta)^c\times(\alpha\setminus\theta)^c} K(u)(t,s)v(t)v(s)dtds \\ &= \int_{\alpha^c} S(u)(t)v^2(t)dt + \int\int_{\alpha^c\times\alpha^c} K(u)(t,s)v(t)v(s)dtds \\ &\quad + \int_{\theta} S(u)(t)v^2(t)dt + \int\int_{\omega} K(u)(t,s)v(t)v(s)ds \\ &\geq \frac{1}{2}d\int_{\alpha^c} v^2(t)dt + \frac{1}{2}d\int_{\theta} v^2(t)dt \\ &\quad - \left(\left(\int\int_{\omega} K^2(u^*)(t,s)dtds\right)^{\frac{1}{2}} + \|K(u) - K(u^*)\|_2\right)\int_{\alpha^c\cup\theta} v^2(t)dt \\ &\geq \frac{1}{4}d\int_{(\alpha\setminus\theta)^c} v^2(t)dt \\ &= \frac{1}{4}d\|v\|_2^2. \end{aligned}$$

We have shown that if $\{u^{(k)}\}$ has range in $\overline{B_2(u^*, \epsilon)} \cap \Omega$, then for $k > n$, $u^{(k)}$ is confined to the closed convex set $\overline{B_2(u^*, \epsilon)} \cap \Omega \cap T_{\alpha\setminus\theta}$, where $J|_{T_{\alpha\setminus\theta}}$ is convex and satisfies the growth condition,

$$J|_{T_{\alpha\setminus\theta}}(u) - J|_{T_{\alpha\setminus\theta}}(u^*) \geq c\|u - u^*\|_2^2.$$

As in the proof of Theorem 3, we can also see that for all $k > n$,

$$J|_{T_{\alpha\setminus\theta}}(u^{(k)}) - J|_{T_{\alpha\setminus\theta}}(u^{(k+1)}) \geq \sigma\langle \nabla\left(J|_{T_{\alpha\setminus\theta}}\right)(u^{(k)}), u^{(k)} - u^{(k+1)}\rangle$$

and

$$u^{(k+1)} = P_{\overline{B_2(u^*,\epsilon)}\cap\Omega\cap T_{\alpha\setminus\theta}}\left[u^{(k)} - a(u^{(k)})\nabla\left(J|_{T_{\alpha\setminus\theta}}\right)(u^{(k)})\right].$$

Our convergence assertions then follow from the stability of u^*, the uniform local step length bound (28), and [2, Thm. 4.3]. □

Note 1. The closed subspace $T_{\alpha\setminus\theta}$ in the proof of Theorem 4 varies with the starting iterate $u^{(0)}$ in $\overline{B_2(u^*, \epsilon)} \cap \Omega$; however, the number n and the convergence ratio λ in Theorem 4 do *not* depend on $u^{(0)}$.

5. Active constraint identification. Again, it is appropriate to begin our development with some remarks on the finite-dimensional analysis in [1]. If the strict complementarity condition holds at a stationary point u^* in the nonnegative orthant $\mathbb{R}^n_+$, and if the GP method in [1] generates a sequence $\{u^{(k)}\}$ that converges to u^*, then for k sufficiently large, and for $i = 1, \ldots, n$,

$$u_i^{(k)} = 0 \Leftrightarrow u_i^* = 0,$$

i.e., the iterates eventually "identify" the active constraints at u^*. Formal counterparts of this result are generally false in convex sets defined by infinitely many inequality constraints; however, there are circumstances under which infinite active constraint index sets are identified *asymptotically* by GP iterates that converge in some sense. A theorem of this kind is formulated in [20] for constrained compact fixed-point problems, and related mesh independence results are established in [21] for finite-dimensional approximations to continuous-time optimal control problems. Our theorem for (1) and (5) is stated in terms of the Lebesgue measure of symmetric set differences,

$$\alpha \Delta \beta \stackrel{def}{=} (\alpha^c \cap \beta) \cup (\alpha \cap \beta^c).$$

THEOREM 5. *Let $J : \mathcal{L}^2(0,1) \to \mathbb{R}^1$ be a continuously Fréchet differentiable function satisfying* (3B), (3E), *and* (4). *Suppose that* (8C) *holds at u^* in the nonnegative $\mathcal{L}^2$ cone Ω, and that $\alpha(u^*)$ is closed. If $\{u^{(k)}\}$ is a GP iterate sequence generated by* (5), *and if $u^{(k)}$ converges to u^* in the $\mathcal{L}^2$ norm, then*

$$\lim_{k \to \infty} \mu\left(\alpha(u^*) \Delta \alpha(u^{(k)})\right) = 0.$$

Proof. Since $\mathcal{L}^2$ convergence insures convergence in measure, we have

$$\forall \eta > 0 \quad \lim_{k \to \infty} \mu\{t \in \alpha(u^{(k)}) : u^*(t) \geq \eta\} = 0, \tag{34A}$$

$$\forall \eta > 0 \quad \lim_{k \to \infty} \mu\{t \in \alpha(u^*) : u^{(k)}(t) \geq \eta\} = 0. \tag{34B}$$

We will prove the theorem by showing that (34A) implies

$$\lim_{k \to \infty} \mu\left(\alpha(u^*)^c \cap \alpha(u^{(k)})\right) = 0, \tag{35A}$$

and that (34B) and the postulated conditions on J and u^* imply

$$\lim_{k \to \infty} \mu\left(\alpha(u^*) \cap \alpha(u^{(k)})^c\right) = 0. \tag{35B}$$

The function u^* is measurable, hence for every $\epsilon > 0$, there is an $\eta > 0$ such that

$$\mu\{t \in \alpha(u^{(k)}) : \eta > u^*(t) > 0\} \leq \mu\{t \in [0,1] : \eta > u^*(t) > 0\} \leq \epsilon,$$

$$\{t \in \alpha(u^{(k)}) : u^*(t) > 0\} = \{t \in \alpha(u^{(k)}) : u^*(t) \geq \eta\} \cup \{t \in \alpha(u^{(k)}) : \eta > u^*(t) > 0\}.$$

and therefore

$$\mu\{t \in \alpha(u^{(k)}) : u^*(t) > 0\} \leq \mu\{t \in \alpha(u^{(k)}) : u^*(t) \geq \eta\} + \epsilon.$$

According to (34A), we then have

$$0 \leq \overline{\lim_{k\to\infty}} \mu\{t \in \alpha(u^{(k)}) : u^*(t) > 0\} \leq \epsilon,$$

and since ϵ can be arbitrarily small, this proves (35A).

To prove (35B), we first note that $\alpha(u^*)^c$ is open in $[0,1]$ and $\overline{\alpha(u^*)^c}$ is measurable. Consequently,

$$\mu\left(\overline{\alpha(u^*)^c}\right) = \mu\left(\alpha(u^*)^c\right),$$

and for each $\epsilon > 0$ there is an open set $\mathcal{O}$ such that

$$\overline{\alpha(u^*)^c} \subset \mathcal{O},$$

and

$$\mu\left(\overline{\alpha(u^*)^c}\right) \leq \mu(\mathcal{O}) \leq \mu\left(\overline{\alpha(u^*)^c}\right) + \epsilon,$$

and therefore

$$\mu\left(\alpha(u^*)^c\right) \leq \mu(\mathcal{O}) \leq \mu\left(\alpha(u^*)^c\right) + \epsilon.$$

Fix ϵ and put $\gamma = \mathcal{O}^c$. Then γ is closed and

$$\gamma \subset \left(\overline{\alpha(u^*)^c}\right)^c = INT\ \alpha(u^*)$$

with

$$\begin{aligned}\mu\left(\alpha(u^*) \setminus \gamma\right) &= \mu\left(\alpha(u^*) \cap \mathcal{O}\right) \\ &= \mu(\mathcal{O}) - \mu\left(\alpha(u^*)^c \cap \mathcal{O}\right) \\ &\leq \epsilon.\end{aligned}$$

Now note that

$$\begin{aligned}\alpha(u^*) \cap \alpha(u^{(k+1)})^c = &\{t \in \alpha(u^*) \setminus \gamma : u^{(k+1)}(t) > 0\} \\ &\cup \{t \in \gamma : u^{(k+1)}(t) \geq \eta\} \cup \{t \in \gamma : \eta > u^{(k+1)}(t) > 0\}\end{aligned}$$

and therefore

(36)

$$\mu\left(\alpha(u^*) \cap \alpha(u^{(k+1)})^c\right) \leq \epsilon + \mu\{t \in \gamma : u^{(k+1)}(t) \geq \eta\} + \mu\{t \in \gamma : \eta > u^{(k+1)}(t) > 0\}.$$

We will complete our proof by showing that the rightmost term in this estimate is eventually bounded above by the middle term *at the previous iteration*, i.e.,

$$\mu\{t \in \gamma : \eta > u^{(k+1)}(t) > 0\} \leq \mu\{t \in \gamma : u^{(k)}(t) \geq \eta\}. \tag{37}$$

To see this, note that by (8C), there are positive numbers c_1 and η such that

$$\nabla J(u^*)(t) \geq c_1 \text{ a.e. in } \gamma$$

and

$$\frac{1}{2}c_1 - 2\eta\|S(u^*)\|_\infty \geq \frac{\eta}{\underline{a}}.$$

Therefore, by (3B), (3E), (4), and (5), there is a $\rho > 0$ such that for all u,

$$u \in B_2(u^*, \rho) \cap \Omega \Rightarrow \nabla J(u)(t) \geq \frac{\eta}{a} \text{ a.e. in } \{t \in \gamma : \eta > u(t) \geq 0\}$$
$$\Rightarrow G(u)(t) = 0 \text{ a.e. in } \{t \in \gamma : \eta > u(t) \geq 0\}.$$

Hence there is an N such that for all k,

$$k \geq N \Rightarrow u^{(k)} \in B_2(u^*, \rho) \cap \Omega$$
$$\Rightarrow u^{(k+1)}(t) = 0 \text{ a.e. in } \{t \in \gamma : \eta > u^{(k)}(t) \geq 0\}$$
$$\Rightarrow \mu\{t \in \gamma : \eta > u^{(k+1)}(t) > 0\} \leq \mu\{t \in \gamma : u^{(k)}(t) \geq \eta\}.$$

Thus (37) is true for sufficiently large k, and it follows from (34B), (36), and (37) that

$$0 \leq \overline{\lim_{k \to \infty}} \mu\left(\alpha(u^*) \cap \alpha(u^{(k)})^c\right) \leq \epsilon.$$

Since ϵ can be arbitrarily small, this establishes (35B) and completes the proof. □

6. Optimal control problems. The sufficient conditions in §2 and the GP convergence analysis of §§3–5 rest on the structure and smoothness properties (3)–(4). These properties are exhibited by a nontrivial class of Bolza objective functions for continuous-time optimal control problems with Hamiltonians that are quadratic in u.

Bolza objective functions are defined by rules of the form,

$$J(u) = P(x(u)(1)) + \int_0^1 f_0(t, x(u)(t), u(t))\, dt, \tag{38A}$$

where $x(u)$ is the solution of an initial value problem,

$$\frac{dx}{dt}(t) \overset{a.e.}{=} f(t, x(t), u(t)) \tag{38B}$$

$$x(0) = x^0 \tag{38C}$$

with u in a domain of $\mathcal{L}^p$ functions, and x^0 fixed in $\mathbb{R}^n$. In the present context, u is in $\mathcal{L}^2(0,1)$ and the functions P, f, and f_0 map $\mathbb{R}^n$ to $\mathbb{R}^1$, $([0,1] \times \mathbb{R}^n \times \mathbb{R}^1)$ to $\mathbb{R}^n$ and $([0,1] \times \mathbb{R}^n \times \mathbb{R}^1)$ to $\mathbb{R}^1$, respectively. To insure that J is twice continuously Fréchet differentiable and meets conditions (3) and (4) on $\mathcal{L}^2(0,1)$, we will assume that:

A1. P is twice continuously differentiable.

A2. For $i = 0, \cdots, n$,

$$f_i(t, x, u) = q_i(t, x) + r_i(t, x)u + s_i(t, x)u^2,$$

where the real valued functions q_i, r_i, and s_i and their first and second partial derivatives with respect to x are continuous on $[0,1] \times \mathbb{R}^n$.

A3. For $i = 1, \ldots, n$, the first partial derivatives of q_i, r_i, and s_i with respect to x are bounded on $[0,1] \times \mathbb{R}^n$.

Assumptions A2 and A3 imply the following growth properties for f and f_0:

G1. For every compact set $X \subset \mathbb{R}^n$, there are nonnegative numbers a_X, b_X, and c_X such that for (t,x,u) in $[0,1] \times X \times \mathbb{R}^1$, $0 \le i \le n$, and $1 \le j,k \le n$,

$$\left|\frac{\partial f_0}{\partial x_j}(t,x,u)\right| \le a_X + b_X|u| + c_X|u|^2,$$
$$\left|\frac{\partial f_i}{\partial u}(t,x,u)\right| \le b_X + c_X|u|,$$
$$\left|\frac{\partial^2 f_i}{\partial x_j \partial x_k}(t,x,u)\right| \le a_X + b_X|u| + c_X|u|^2,$$
$$\left|\frac{\partial^2 f_i}{\partial x_j \partial u}(t,x,u)\right| \le b_X + c_X|u|,$$
$$\left|\frac{\partial^2 f_i}{\partial u^2}(t,x,u)\right| \le c_X.$$

G2. There are nonnegative numbers a, b, and c such that for (t,x,u) in $[0,1] \times \mathbb{R}^n \times \mathbb{R}^1$ and $1 \le i, j \le n$

$$\left|\frac{\partial f_i}{\partial x_j}(t,x,u)\right| \le a + b|u| + c|u|^2.$$

With A1, A2, G1, G2, Gronwall's lemma and standard existence-uniqueness and dependence-on-parameters arguments from the theory of ordinary differential equations [22], [23], it can be shown that:

(i) For all u in $\mathcal{L}^2(0,1)$, the initial value problem (38B)–(38C) has a unique absolutely continuous solution $x(u)$ on $[0,1]$, and the integral in (38A) exists in Lebesgue's sense.

(ii) The mapping $x(\cdot) : \mathcal{L}^2(0,1) \to C^0([0,1],\mathbb{R}^n)$ is continuous.

(iii) For all u and v in $\mathcal{L}^2(0,1)$ the mapping $x\,(u + (\cdot)v) : \mathbb{R}^1 \to C^0([0,1],\mathbb{R}^n)$ is continuously Fréchet differentiable near 0 in $\mathbb{R}^1$, with

$$d^1x(u;v) \stackrel{def}{=} \lim_{s \to 0} \frac{x(u+sv) - x(u)}{s}, \quad = y(u;v) \tag{39A}$$

where $y(u;v)$ is the unique solution of the affine *equations of variation*,

$$\frac{dy}{dt}(t) \stackrel{a.e.}{=} A(u)(t)y(t) + B(u)(t)v(t), \tag{39B}$$

$$y(0) = 0, \tag{39C}$$

on $[0,1]$, with

$$A(u)(t) = \frac{\partial f}{\partial x}\,(t, x(u)(t), u(t)) \tag{39D}$$

and

$$B(u)(t) = \frac{\partial f}{\partial u}\,(t, x(u)(t), u(t))\,. \tag{39E}$$

(iv) For all u in $\mathcal{L}^2(0,1)$ the affine *adjoint* final value problem

$$\frac{d\psi}{dt}(t) \overset{a.e.}{=} -A(u)(t)^T\psi(t) - \nabla_x f_0\,(t, x(u)(t), u(t)) \tag{40A}$$

$$\psi(1) = \nabla P\,(x(u)(1)) \tag{40B}$$

has a unique absolutely continuous solution $\psi(u)$.

(v) The mapping $\psi(\cdot) : \mathcal{L}^2(0,1) \to C^0([0,1], \mathbb{R}^n)$ is continuous.

(vi) For all u and v in $\mathcal{L}^2(0,1)$ the mapping $\psi\,(u + (\cdot)v) : \mathbb{R}^1 \to C^0([0,1], \mathbb{R}^n)$ is continuously Fréchet differentiable near 0 in $\mathbb{R}^1$, with

$$\begin{aligned} d^1\psi(u;v) &\overset{def}{=} \lim_{s\to 0} \frac{\psi(u+sv) - \psi(u)}{s} \\ &= \zeta(u;v), \end{aligned} \tag{41A}$$

where $\zeta(u;v)$ is the unique absolutely continuous solution of the *adjoint* equations of variation,

$$\frac{d\zeta}{dt}(t) \overset{a.e}{=} -A(u)(t)^T\zeta(t) - Q(u)(t)y(u;v)(t) - R(u)(t)v(t), \tag{41B}$$

$$\zeta(1) = \nabla^2 P\,(x(u)(1))\,y(u;v)(1), \tag{41C}$$

with

$$Q(u)(t) = \nabla^2_{xx} H\,(t, \psi(u)(t), x(u)(t), u(t))\,, \tag{41D}$$

$$R(u)(t) = \nabla^2_{xu} H\,(t, \psi(u)(t), x(u)(t), u(t))\,, \tag{41E}$$

and

$$H(t, \psi, x, u) = \psi^T f(t, x, u) + f_0(t, x, u) \tag{41F}$$

for (t, ψ, x, u) in $[0,1] \times \mathbb{R}^n \times \mathbb{R}^n \times \mathbb{R}^1$.

In the circumstances outlined above, the Bolza objective function J has first and second Gâteaux differentials with Riesz–Fréchet gradient and Hessian representors of the form (4A) and (3A). To see this, we note that

$$\begin{aligned} d^1J(u;v) = {} & \frac{\partial P}{\partial x}\,(x(u)(1))\,y(u;v)(1) \\ & + \int_0^1 \Big[\frac{\partial f_0}{\partial x}\,(t, x(u)(t), u(t))\,y(u;v)(t) \\ & \qquad + \frac{\partial f_0}{\partial u}\,(t, x(u)(t), u(t))\,v(t)\Big]\,dt \end{aligned} \tag{42A}$$

and

$$\frac{d}{dt}\left[\psi(t)^T y(t)\right] \overset{a.e.}{=} -\frac{\partial f_0}{\partial x}\,(t, x(u)(t), u(t))\,y(t) + \psi(t)^T B(u)(t)v(t) \tag{42B}$$

for any two solutions $y(\cdot)$ and $\psi(\cdot)$ of (39B) and (40A). By integrating (42B) from 0 to 1 and applying the boundary conditions in (39) and (40), we find that

$$d^1J(u;v) = \langle \nabla J(u), v\rangle, \tag{43A}$$

with

$$\begin{aligned}\nabla J(u)(t) &\overset{a.e.}{=} \nabla_u H\left(t, \psi(u)(t), x(u)(t), u(t)\right)\\ &= \phi(u)(t) + S(u)(t)u(t),\end{aligned} \tag{43B}$$

where

$$\phi(u)(t) = \psi(u)(t)^T r\left(t, x(u)(t)\right) + r_0\left(t, x(u)(t)\right), \tag{43C}$$

and

$$\begin{aligned}S(u)(t) &= 2\left[\psi(u)(t)^T s\left(t, x(u)(t)\right) + s_0\left(t, x(u)(t)\right)\right]\\ &= \nabla^2_{uu} H\left(t, \psi(u)(t), x(u)(t), u(t)\right).\end{aligned} \tag{43D}$$

Similarly, we have

$$\begin{aligned}d^2 J(u; v, w) &\overset{def}{=} \lim_{s\to 0} \frac{d^1 J(u+sv; w) - d^1 J(u; w)}{s}\\ &= \lim_{s\to 0} \frac{\langle \nabla J(u+sv) - \nabla J(u), w\rangle}{s}\\ &= \int_0^1 S(u)(t)v(t)w(t)dt\\ &\quad + \int_0^1 \left[\zeta(u; v)(t)^T B(u)(t) + y(u; v)(t)^T R(u)(t)\right] w(t)dt\end{aligned} \tag{44A}$$

and

$$\begin{aligned}\frac{d}{dt}[\zeta(u; v)(t)^T y(u; w)(t)] \overset{a.e.}{=}\ & -y(u; v)(t)^T Q(u)(t) y(u; w)(t) - v(t)R(u)(t)^T y(u; w)(t)\\ & + \zeta(u; v)(t)^T B(u)(t)w(t).\end{aligned} \tag{44B}$$

By integrating (44B) and applying (39C) and (41C), we obtain

$$\begin{aligned}d^2 J(u; v, w) =\ & y(u; v)(1)^T Q_1(u) y(u; w)(1)\\ & + \int_0^1 [y(u; v)(t)^T Q(u)(t) y(u; w)(t) + y(u; v)(t)^T R(u)(t)w(t)\\ & \quad + v(t)R(u)(t)^T y(u; w)(t) + S(u)(t)v(t)w(t)]dt,\end{aligned} \tag{45A}$$

with

$$Q_1(u) = \nabla^2 P\left(x(u)(1)\right). \tag{45B}$$

As in [15], (45) can be carried further by observing that

$$y(u; v)(t) = \int_0^1 \Phi(u)(t, \tau) B(u)(\tau) v(\tau) d\tau, \tag{46A}$$

where $\Phi(u)(t, \tau)$ are fundamental solution matrices uniquely prescribed by the initial value problems

$$\frac{\partial}{\partial t}\Phi(t, \tau) \overset{a.e.}{=} A(u)(t)\Phi(t, \tau), \tag{46B}$$

$$\Phi(\tau, \tau) = I \tag{46C}$$

for τ in $[0,1]$. Hence

$$d^2J(u;v) = \int_0^1 [\nabla^2 J(u)v](t)w(t)dt, \tag{47A}$$

with

$$[\nabla^2 J(u)v](t) \overset{a.e.}{=} S(u)(t)v(t) + \int_0^1 K(u)(t,s)v(s)ds, \tag{47B}$$

where

(47C)

$$\begin{aligned} K(u)(t,s) = \; & B(u)(t)^T\hat{\Phi}(u)(s,t)^T R(u)(s) + B(u)(s)^T\hat{\Phi}(u)(t,s)^T R(u)(t) \\ & + B(u)(t)^T \left[\int_{\max(t,s)}^1 \Phi(u)(\tau,t)^T Q(u)(\tau)\Phi(u)(\tau,s)d\tau\right] B(u)(s) \\ & + B(u)(t)^T\Phi(u)(1,t)^T Q_1(u)\Phi(u)(1,s)B(u)(s), \end{aligned}$$

and

$$\hat{\Phi}(u)(s,t) = \begin{cases} \Phi(u)(s,t), & t \le s \\ 0\,, & s < t \end{cases}. \tag{47D}$$

Thus far, we have shown that J has first and second Gâteaux differentials with representations (43) and (47) that are formally like (4A) and (3A). The remaining symmetry, integrability, and continuity conditions in (3) and (4) are now readily inferred from Assumptions A1–A3, and continuity of the maps $x(\cdot) : \mathcal{L}^2(0,1) \to C^0([0,1],\mathbb{R}^n)$ and $\psi(\cdot) : \mathcal{L}^2(0,1) \to C^0([0,1],\mathbb{R}^n)$. In particular, with reference to (43D), we see that $S(u)$ is in $C^0(0,1)$ and the associated map $S(\cdot) : \mathcal{L}^2(0,1) \to C^0(0,1)$ is continuous. Similarly, in view of (39D)–(39E), (41D)–(41F), (45B), (46B)–(46C), and properties G1–G2, it follows that for u in $\mathcal{L}^2(0,1)$, $A(u)$ and $Q(u)$ are in $\mathcal{L}^1([0,1],\mathbb{R}^{n\times n})$; $B(u)$ and $R(u)$ are in $\mathcal{L}^2([0,1],\mathbb{R}^{n\times 1})$; $\Phi(u)$ is in $C^0([0,1]\times[0,1],\mathbb{R}^{n\times n})$; $K(u)$ is in $\mathcal{L}^2([0,1]\times[0,1])$; and the corresponding maps $A(\cdot)$, $B(\cdot)$, $\Phi(\cdot)$, $Q(\cdot)$, $R(\cdot)$, and $K(\cdot)$ are continuous. Thus, Bolza objective functions (38) have the desired structure/continuity properties (3)–(4) when Assumptions A1–A3 hold.

Note 2. The foregoing conclusions are still valid if the smoothness restrictions in Assumption A2 are replaced by weaker conditions of the Carathéodory type [22]. In this case, the nonnegative constants in Properties G1–G2 become *functions* a and a_X in $\mathcal{L}^1(0,1)$, b and b_X in $\mathcal{L}^2(0,1)$, and c and c_X in $\mathcal{L}^\infty(0,1)$; and the resulting enlarged class of Bolza objective functions includes the general linear-quadratic regulator objectives treated in [16].

Note 3. For K in (47), condition (3C)′ will hold at u^* if u^* is in $\mathcal{L}^\infty(0,1)$, or if $s(t,x) = 0$ and $s_0(t,x)$ depends only on t (condition (3C)′ is invoked in Theorems 1 and 4).

CONTINUOUS-TIME SHORTEST PATH PROBLEMS AND LINEAR PROGRAMMING*

A. B. PHILPOTT†

Abstract. Shortest path problems are considered for a graph in which edge distances can vary with time, each edge has a transit time, and parking (with a corresponding penalty) is allowed at the vertices. The problem is formulated as a continuous-time linear program, and a dual problem is derived for which the absence of a duality gap is proved. The existence of an extreme-point solution to the continuous-time linear program is also demonstrated, and a correspondence is derived between extreme points and continuous-time shortest paths. Strong duality is then derived in the case where the edge distances satisfy a Lipschitz condition.

Key words. shortest path, continuous linear programming, extreme point optimal solution, duality

1. Introduction.

Many problems in operations research require the solution of a shortest path problem: that of computing the shortest path between two vertices of a graph. This problem arises in a natural way in routing applications, and often as a subproblem that must be solved as part of some algorithm to solve a more complicated problem. Suppose c_{jk} is the distance along the edge joining j and k in a graph with n vertices. (We set $c_{jk} = \infty$ if this edge does not exist.) Then the classical shortest path problem can be formulated as the following linear program.

$$\text{SP: minimize} \sum_j \sum_k c_{jk} x_{jk}$$

$$\text{subject to} \sum_k x_{kj} - x_{jk} = \begin{cases} -1, & j = 1, \\ 0, & j \neq 1, n, \\ 1, & j = n, \end{cases}$$

$$x_{jk} \geq 0.$$

It is well known that as a consequence of the unimodularity of the constraint matrix the basic feasible solutions of SP have components which are zero or one. Furthermore it is easy to see that the nonzero components of any basic feasible solution determine a path from vertex 1 to vertex n, and every such path corresponds to some basic feasible solution. Thus an optimal basic feasible solution to SP gives variables x_{jk}, which indicate whether the edge joining j and k is on a shortest path from vertex 1 to vertex n.

The problem SP has the following dual problem:

$$\text{SP*: maximize } \pi_n - \pi_1$$

$$\text{subject to } \pi_k - \pi_j \leq c_{jk}.$$

The difference in dual variables $\pi_k - \pi_j$ can be interpreted as the shortest distance from vertex j to vertex k. Most solution techniques for SP use some labelling procedure to construct vertex by vertex a feasible solution to SP*, along with a complementary slack solution to SP. (See, e.g., [1] for a survey of efficient procedures for solving SP.)

In this paper we consider a generalization of the problem SP to the case where there is a transit time on each edge, edge distances can vary as functions of time, and parking with some penalty is allowed at the vertices of the graph. We draw a distinction between edge distances and transit times, and assume that the transit times are constant with time. The motivation for our model comes from an application due to Mees [8] involving the scheduling of trains in a railway network. Here the transit times, which depend only on the speed that the trains traverse the arcs of the network, are independent of time but we discourage travel on given edges at certain times by imposing a time-varying penalty for traversing these edges.

A number of authors have considered generalizing SP to the time-varying case. Problems that seek a path with least total transit time have been studied in the absence of parking by Cooke and Halsey [3], who consider integer-valued transit times, and by Dreyfus [4] for real-valued transit times. A similar model described by Halpern [6] admits parking, with a unit penalty, only in certain specified time intervals, giving an effective penalty on parking that equals 1 or ∞. More recently, Orda and Rom have developed algorithms for the computation of minimum delay paths (see [9]), and minimum distance paths (see [10]), both for networks with time-varying transit times and a number of different parking models.

Given a graph G with n vertices and a time interval $[0,T]$, we define a *vertex-time pair* (VTP) to be a member of $\{1,2,\ldots,n\}\times[0,T]$. A *continuous-time path* from $(1,0)$ to (j,t) is a sequence of VTPs

$$(1,0)=(j_0,t_0),(j_1,t_1),\ldots,(j_p,t_p)=(j,t)$$

in which either $j_i = j_{i+1}$, in which case parking occurs at vertex j_i for the interval $[t_i,t_{i+1})$, or $j_i \neq j_{i+1}$, in which case traffic leaves vertex j_i for vertex j_{i+1} at time t_i and arrives at t_{i+1}. If the transit time between vertices j and k is denoted by τ_{jk} then $t_i + \tau_{j_i,j_{i+1}} = t_{i+1}$. (We assume for convenience that τ_{jk} and c_{jk} are defined for all j and k and are equal to zero when $j=k$.) The *length* of a continuous-time path is defined by

$$C=\sum_{j_i\neq j_{i+1}} c_{j_ij_{i+1}}(t_i)+\sum_{j_i=j_{i+1}}\int_{t_i}^{t_{i+1}} s_{j_i}(t)dt$$

where $c_{jk}(t)$ is the edge distance from j to k at time t, and $s_j(t)$ is the penalty on parking at node j at time t. The continuous-time shortest path problem seeks a continuous-time path that minimizes C for paths from $(1,0)$ to (n,T).

The presence of transit times in our model means that there are some VTPs (j,t) that will not appear in any path from $(1,0)$ to (n,T) because we cannot reach vertex j from 1 in time t, or we cannot reach vertex n from j in time $T-t$. The remaining VTPs are called *admissible* VTPs. We may characterize the set of admissible VTPs by computing for each vertex,

$$\rho_j=\min_{\alpha}\sum_{(p,q)\in P_\alpha}\tau_{pq},\qquad \sigma_j=T-\min_{\alpha}\sum_{(p,q)\in Q_\alpha}\tau_{pq},$$

where $\{P_\alpha\}$ is the set of paths in G from node 1 to node j, and $\{Q_\alpha\}$ is the set of paths in G from node j to node n. Thus ρ_j is the earliest time we may arrive at vertex j if we leave vertex 1 at time zero, and σ_j is the latest time that we may leave j so as to arrive at vertex n by time T. (Clearly $\rho_1=0$ and $\sigma_n=T$, and for every j and

k we have $\sigma_k \leq \sigma_j + \tau_{jk}$ and $\rho_k \leq \rho_j + \tau_{jk}$.) Admissible VTPs can now be defined as those (j,t) with $t \in [\rho_j, \sigma_j]$.

We note in passing that if the departure times in this model must be chosen from a finite set S, say, then the model is equivalent to a classical shortest path problem formulated in the time-expanded graph with vertices in $\{1,2,\ldots,n\} \times S$, and edge distances between vertices equal to infinity, except for the edges from (j,t) to (k,u) for $u \geq t + \tau_{jk}$, which have distance $c_{jk}(t) + \int_{t+\tau_{jk}}^{u} s_k(\tau)d\tau$.

In this paper we wish to address the following question. To what extent does the continuous-time shortest path problem described above have an equivalent formulation as a linear program? We show that if the problem is suitably posed as a linear program in an (infinite-dimensional) space of measures then the results outlined above for SP and SP* remain true. The analysis is based on the theory of linear programming in infinite-dimensional vector spaces as expounded in Anderson and Nash [2]. In the next section we introduce a linear programming formulation (CSP) and its dual (CSP*) and demonstrate a duality theorem that states that CSP and CSP* have the same value. We then show that the extreme-point solutions of CSP correspond to continuous-time paths. It follows that the optimal solution to CSP can be taken as a vector of measures with finite support. We conclude with a proof of strong duality in the case where the edge distances are Lipschitz functions and give a brief sketch of a computational technique for solving instances of CSP, the details of which may be found in [13] and [14].

2. Continuous-time linear programming. The central purpose of this paper is to show that the continuous-time shortest-path problem introduced in the previous section has an equivalent formulation as the following continuous-time linear programming problem:

$$\text{CSP: minimize } \sum_j \sum_k \int_{\rho_j}^{\sigma_k - \tau_{jk}} c_{jk}(t)dx_{jk}(t) + \sum_j \int_{\rho_j}^{\sigma_j} y_j(t)s_j(t)dt$$

subject to

$$(1) \quad \sum_k \int_{\rho_k}^{\sigma_j - \tau_{kj}} dx_{kj}(\tau) - \int_{\rho_j}^{\sigma_k - \tau_{jk}} dx_{jk}(\tau) = \begin{cases} -1, & j = 1, \\ 0, & j \neq 1, n, \\ 1, & j = n, \end{cases}$$

$$(2) \quad y_1(t) = 1 + \sum_k \int_{\rho_k}^{t-\tau_{k1}} dx_{k1}(\tau) - \int_{\rho_1}^{t} dx_{1k}(\tau), \quad t \in [\rho_1, \sigma_1],$$

$$(3) \quad y_j(t) = \sum_k \int_{\rho_k}^{t-\tau_{kj}} dx_{kj}(\tau) - \int_{\rho_j}^{t} dx_{jk}(\tau), \quad t \in [\rho_j, \sigma_j], \quad j = 2,\ldots,n,$$

$$y_j(t) \geq 0, \quad t \in [\rho_j, \sigma_j], \quad x_{jk}(t) \geq 0, \quad t \in [\rho_j, \sigma_k - \tau_{jk}] \quad j,k = 1,\ldots,n.$$

Here the edge distances c_{jk} are taken to be continuous functions on $[\rho_j, \sigma_k - \tau_{jk}]$, each parking cost s_j is a bounded measurable function, and x_{jk} is a regular Borel measure on $[\rho_j, \sigma_k - \tau_{jk}]$, which indicates in an optimal solution whether a shortest path involves leaving vertex j for vertex k at time t. The variables y_j are intended to indicate whether parking occurs in vertex j. To see this observe that if for some vertex j we have $x_{kj}(\{t - \tau_{kj}\}) = x_{jk}(\{t\}) = 0$ for every vertex k and time t, except for two

vertices l and m, and two time instants $t_1 < t_2$ for which $x_{lj}(\{t_1 - \tau_{lj}\}) = x_{jm}(\{t_2\}) = 1$, then $y_j(t) = 1$, $t \in [t_1, t_2)$, and zero elsewhere. Such a solution corresponds to a path leaving vertex l for j at $t_1 - \tau_{lj}$, parking in j until t_2, and then leaving vertex j for m. By summing (2) and (3) and using the nonnegativity conditions on x and y, it is easy to show that for all j, $0 \leq y_j(t) \leq 1$. This ensures that the number of arrivals at each vertex (apart from vertex 1) up to time t is always greater by at most 1 than the number of departures up to t. In what follows we show that an optimal solution to CSP exists for which $y_j(t) \in \{0, 1\}$.

We will find occasion to characterize each measure x_{jk} by a Lebesgue–Stieltjes distribution function X_{jk}, which is of bounded variation on $[\rho_j, \sigma_k - \tau_{jk}]$ and continuous from the right on $(\rho_j, \sigma_k - \tau_{jk})$. We set $X_{jk}(\rho_j) = 0$, implying that $\int_{\rho_j}^{t} dx_{jk}(\tau) = X_{jk}(t)$. (Note that this is the same as $x_{jk}([\rho_j, t])$ and $\int_{[\rho_j, t]} dx_{jk}(\tau)$, except when $t = \rho_j$, when these expressions are not necessarily equal to $X_{jk}(\rho_j) = 0$, but are both equal to $x_{jk}(\{\rho_j\}) = \lim_{\epsilon \to 0} X_{jk}(\rho_j + \mid \epsilon \mid)$). To avoid introducing complicated notation, we often interpret the values of x and y to be zero at any point where they are not defined. In particular, we assume that for every j and k

$$x_{jk}([-\tau_{jk}, \rho_j)) = x_{jk}((\sigma_k - \tau_{jk}, T]) = 0. \tag{4}$$

We say that any nonnegative $\{x, y\}$ satisfying the constraints (1)–(3) is *feasible* for CSP, and define the *value* $V(\text{CSP})$ to be the infimum of the objective function over all feasible $\{x, y\}$. For CSP to have a feasible solution, T must be chosen sufficiently large, as shown by the following lemma.

LEMMA 2.1. CSP *has a feasible solution if and only if* $\rho_n \leq T$.

Proof. If $\rho_n \leq T$, then for some path P from 1 to n in the underlying graph G, $\sum_{(j,k) \in P} \tau_{jk} \leq T$. Let $\{1 = j_0, j_1, \ldots, j_m = n\}$ be the vertices in P, which we may assume to be distinct. Define $x_{jk} = 0$ for every j and k except where $j = j_u, k = j_{u+1}$ for some u, in which case

$$x_{jk}\left(\left\{\sum_{p=1}^{p=u} \tau_{j_{p-1} j_p}\right\}\right) = 1.$$

(Here the sum is void if $u = 0$.) This x and the y it generates are easily shown to be feasible for CSP.

Conversely, suppose (x,y) is feasible for CSP. We show $\rho_n \leq T$ by constructing a path P in G from 1 to n with $\sum_{(j,k) \in P} \tau_{jk} \leq T$. Setting $j_0 = n$, we may find a vertex $j_1 \neq n$ with $x_{j_1 j_0}([0, T - \tau_{j_1 j_0}]) > 0$, otherwise (1) fails to hold for $j = j_0$. Since $T - \tau_{j_1 j_0} \leq \sigma_{j_1}$, (3) and the condition $y_{j_1}(T - \tau_{j_1 j_0}) \geq 0$ yields

$$\sum_k \int_{\rho_k}^{T - \tau_{j_1 j_0} - \tau_{k j_1}} dx_{k j_1}(t) \geq \int_{\rho_{j_1}}^{T - \tau_{j_1 j_0}} \sum_k dx_{j_1 k}(t) \geq x_{j_1 j_0}([\rho_{j_1}, T - \tau_{j_1 j_0}]) > 0.$$

Thus there is some vertex $j_2 \neq j_1$ with $x_{j_2 j_1}([\rho_{j_2}, T - \tau_{j_1 j_0} - \tau_{j_2 j_1}]) > 0$, implying that $T - \tau_{j_1 j_0} - \tau_{j_2 j_1} \geq \rho_{j_2}$.

Since there is a minimum nonzero traversal time, we may repeat this process until either some member j_u, say, of the sequence $j_0, j_1, \ldots$ equals 1, in which case the result follows because $P = \{j_u, j_{u-1}, \ldots, j_0\}$ is a path from 1 to n with $\sum_{(j,k) \in P} \tau_{jk} \leq T$, or on the other hand some subsequence $C = \{j_q, j_{q+1}, \ldots, j_{q+v} = j_q\}$ occurs with $\tau_{jk} = 0$

for j and k consecutive members of C, $j_{q-1} \notin C$, and $x_{j_q j_{q-1}}([\rho_q, T - \sum_{p=1}^{p=q} \tau_{j_p j_{p-1}}]) > 0$. In this case if we let $S = [\rho_q, T - \sum_{p=1}^{p=q} \tau_{j_p j_{p-1}}]$ then we have

$$\sum_{j \in C} \sum_{k \notin C} x_{jk}(S) > 0.$$

By virtue of the positivity of x it follows using the convention of (4) that

$$\sum_{j \in C} \sum_{k \in C} x_{jk}(S) \geq \sum_{j \in C} \sum_{k \in C} x_{kj}(S - \tau_{kj}),$$

whence

$$\sum_{j \in C} \sum_{k} x_{jk}(S) > \sum_{j \in C} \sum_{k \in C} x_{kj}(S - \tau_{kj}),$$

from which we obtain

$$\sum_{j \in C} \sum_{k \notin C} x_{kj}(S - \tau_{kj}) > \sum_{j \in C} \sum_{k} x_{kj}(S - \tau_{kj}) - x_{jk}(S).$$

The right-hand side of this inequality is nonnegative by virtue of (3), and so there must be some vertex $l \notin C$, and some vertex $j \in C$ with $x_{lj}(S - \tau_{lj}) > 0$. If $l \neq 1$ and $\tau_{lj} = 0$ then we add l to C and repeat the above argument until either $l = 1$ or $\tau_{lj} > 0$. Since there is a minimum nonzero traversal time, and a finite number of vertices, this procedure must terminate at vertex 1 at some time $t \in [0, \sigma_1]$. From the ordered set of vertices visited, it is straightforward to construct a path P from 1 to n with $\sum_{(j,k) \in P} \tau_{jk} \leq T$. □

We assume henceforth that T satisfies the conditions of Lemma 2.1. In what follows we require the following integration by parts formula, which is easily derived from a standard result.

LEMMA 2.2. *Let α and β be two functions of bounded variation on $[\rho, \sigma]$ with α continuous on $[\rho, \sigma]$, and β continuous from the right on (ρ, σ). Then*

$$\int_{\rho}^{\sigma} \alpha(t) d\beta(t) + \int_{\rho}^{\sigma} \beta(t) d\alpha(t) = \alpha(\sigma)\beta(\sigma) - \alpha(\rho)\beta(\rho)$$

Proof. For the proof see [5, p. 154]. □

LEMMA 2.3. *Suppose for each j that w_j is a Lebesgue integrable function on $[\rho_j, \sigma_j]$, and let $W_j(t) = \int_t^{\sigma_j} w_j(\tau) d\tau$. Then x is feasible for* CSP *implies that*

$$\sum_j \int_{\rho_j}^{\sigma_j} w_j(t) \sum_k [\int_{\rho_k}^{t - \tau_{kj}} dx_{kj}(\tau) - \int_{\rho_j}^{t} dx_{jk}(\tau)] dt$$

$$= \sum_j \sum_k \int_{\rho_j}^{\sigma_k - \tau_{jk}} [W_k(t + \tau_{jk}) - W_j(t)] dx_{jk}(t).$$

Proof. Since each $W_j(t)$ is a continuous function of bounded variation on $[\rho_j, \sigma_j]$ we may let $\alpha = W$ and $\beta = X$ in Lemma 2.2 to give

$$\int_{\rho_j}^{\sigma_j} w_j(t) \sum_k [\int_{\rho_k}^{t - \tau_{kj}} dx_{kj}(\tau) - \int_{\rho_j}^{t} dx_{jk}(\tau)] dt$$

$$= \left[-W_j(t) \sum_k X_{kj}(t - \tau_{kj}) - X_{jk}(t) \right]_{\rho_j}^{\sigma_j}$$

$$+ \int_{\rho_j}^{\sigma_j} W_j(t) \sum_k dx_{kj}(t - \tau_{kj}) - dx_{jk}(t)$$

$$= \int_{\rho_j}^{\sigma_j} W_j(t) \sum_k dx_{kj}(t - \tau_{kj}) - dx_{jk}(t),$$

using the fact that $W_j(\sigma_j) = 0$ and $X_{kj}(\rho_j - \tau_{kj}) = 0$ which follows from $\rho_j \leq \rho_k + \tau_{kj}$.

Now summing over j gives

$$\sum_j \int_{\rho_j}^{\sigma_j} w_j(t) \sum_k [\int_{\rho_k}^{t-\tau_{kj}} dx_{kj}(\tau) - \int_{\rho_j}^{t} dx_{jk}(\tau)]dt$$

$$= \sum_j \int_{\rho_j}^{\sigma_j} W_j(t) \sum_k dx_{kj}(t - \tau_{kj}) - dx_{jk}(t)$$

$$= \sum_j \sum_k \int_{\rho_j - \tau_{kj}}^{\sigma_j - \tau_{kj}} W_j(t + \tau_{kj}) dx_{kj}(t) - \int_{\rho_j}^{\sigma_j} W_j(t) dx_{jk}(t)$$

$$= \sum_j \sum_k \int_{\rho_k - \tau_{jk}}^{\sigma_k - \tau_{jk}} W_k(t + \tau_{jk}) dx_{jk}(t) - \int_{\rho_j}^{\sigma_j} W_j(t) dx_{jk}(t)$$

$$= \sum_j \sum_k \int_{\rho_j}^{\sigma_k - \tau_{jk}} W_k(t + \tau_{jk}) dx_{jk}(t) - \int_{\rho_j}^{\sigma_k - \tau_{jk}} W_j(t) dx_{jk}(t),$$

using (4) and the inequalities $\rho_j \geq \rho_k - \tau_{jk}$, and $\sigma_j \geq \sigma_k - \tau_{jk}$. The result now follows by combining the integrals. □

If w is chosen to be s and $S_j(t) = \int_t^{\sigma_j} s_j(\tau) d\tau$ then Lemma 2.3 may be invoked to remove the dependence on y of the objective function of CSP, giving the following problem expressed entirely in terms of x.

CSP1: minimize $\sum_j \sum_k \int_{\rho_j}^{\sigma_k - \tau_{jk}} \bar{c}_{jk}(t) dx_{jk}(t)$

(5) subject to $\sum_k \int_{\rho_k}^{\sigma_j - \tau_{kj}} dx_{kj}(\tau) - \int_{\rho_j}^{\sigma_k - \tau_{jk}} dx_{jk}(\tau) = \begin{cases} -1, & j = 1, \\ 0, & j \neq 1, n, \\ 1, & j = n, \end{cases}$

(6) $$\sum_k \int_{\rho_k}^{t - \tau_{k1}} dx_{k1}(\tau) - \int_{\rho_1}^{t} dx_{1k}(\tau) \geq -1, \quad t \in [\rho_1, \sigma_1],$$

(7) $$\sum_k \int_{\rho_k}^{t - \tau_{kj}} dx_{kj}(\tau) - \int_{\rho_j}^{t} dx_{jk}(\tau) \geq 0, \quad t \in [\rho_j, \sigma_j], \quad j = 2, \ldots, n,$$

$$x_{jk}(t) \geq 0, \quad t \in [\rho_j, \sigma_k - \tau_{jk}], \quad j, k = 1, \ldots, n,$$

where $\bar{c}_{jk}(t) = c_{jk}(t) + [S_k(t + \tau_{jk}) - S_j(t)]$ and $V(\text{CSP1}) = V(\text{CSP}) - \int_{\rho_1}^{\sigma_1} s_1(\tau) d\tau$.

The advantage of this formulation is that we can readily develop a duality theory for CSP1 based on the paired-space methodology introduced by Kretschmer [7] and adopted by Anderson and Nash [2]. Following [2] we specify two dual pairs of topological vector spaces, (X, Y) and (Z, W), each endowed with a bilinear form $\langle , \rangle$, and each having the weak topologies $\sigma(X, Y)$ and $\sigma(Z, W)$ given by the respective dual pairings. For CSP1, we choose

- X to be $\prod_{j,k} M[\rho_j, \sigma_k - \tau_{jk}]$, where $M[a, b]$ is the space of regular signed Borel measures on $[a, b]$,
- Y to be $\prod_{j,k} C[\rho_j, \sigma_k - \tau_{jk}]$, where $C[a, b]$ is the space of continuous functions on $[a, b]$,
- Z to be $R^n \times \prod_j L_1[\rho_j, \sigma_j]$,
- W to be $R^n \times \prod_j L_\infty[\rho_j, \sigma_j]$.

Observe that each of these spaces may also be endowed with their standard norm topologies, and as such are Banach spaces. The problem CSP1 is an example of the abstract linear programming problem

$$\begin{aligned} \text{IP: minimize } & \langle c, x \rangle \\ \text{subject to } & Ax - b \in Q \\ & x \in P \end{aligned}$$

presented in [2]. Here $\langle c, x \rangle$ is a linear objective functional, b is a fixed element of Z, P and Q are the positive cones in X and Z, respectively, and $A : X \to Z$ is the constraint operator. Thus for CSP1

$$\langle c, x \rangle = \sum_j \sum_k \int_{\rho_j}^{\sigma_k - \tau_{jk}} \bar{c}_{jk}(t) dx_{jk}(t),$$

$$P = \{x : x_{jk} \in M[\rho_j, \sigma_k - \tau_{jk}], x_{jk}(B) \geq 0 \text{ for every Borel set } B \subseteq [\rho_j, \sigma_k - \tau_{jk}]\},$$

$$Q = \{(0, z) : z \in \prod_j L_1[\rho_j, \sigma_j], z(t) \geq 0 \text{ a.e.}\},$$

$$b = (-1, 0, \ldots, 0, 1) \times (-1(t), 0(t), \ldots, 0(t)),$$

and the constraint operator A maps an n^2-tple of measures into a pair consisting of a real vector defined by the left-hand side of (5), and a Lebesgue-integrable vector function defined by the left-hand sides of (6) and (7).

It is straightforward to show that A is linear and continuous with respect to the weak topologies on X and Z. In order to specify a dual problem for CSP1 we must define dual cones

$$P^* = \{y \in Y : \langle x, y \rangle \quad \geq 0, \quad \forall x \in P\}, \quad Q^* = \{w \in W : \langle z, w \rangle \quad \geq 0, \quad \forall z \in Q\},$$

and an adjoint operator $A^* : W \to Y$, which satisfies $\langle Ax, w \rangle = \langle x, A^* w \rangle$. Now

$$\langle Ax, w \rangle = \left\langle Ax, \begin{pmatrix} \lambda \\ \mu \end{pmatrix} \right\rangle,$$

where $\lambda \in R^n$ and $\mu \in \prod_j L_\infty[\rho_j, \sigma_j]$, whence $\langle Ax, w\rangle$ may be written as

$$\sum_j \lambda_j \sum_k \left(\int_{\rho_k}^{\sigma_j - \tau_{kj}} dx_{kj}(\tau) - \int_{\rho_j}^{\sigma_k - \tau_{jk}} dx_{jk}(\tau) \right)$$
$$+ \sum_j \int_{\rho_j}^{\sigma_j} \mu_j(t) \left[\sum_k \int_{\rho_k}^{t-\tau_{kj}} dx_{kj}(\tau) - \int_{\rho_j}^{t} dx_{jk}(\tau) \right] dt.$$

Applying Lemma 2.3 yields

$$\langle Ax, w\rangle = \sum_j \sum_k \int_{\rho_j}^{\sigma_k - \tau_{jk}} \left[(\lambda_k - \lambda_j) + \int_{t+\tau_{jk}}^{\sigma_k} \mu_k(\tau) d\tau - \int_t^{\sigma_j} \mu_j(\tau) d\tau \right] dx_{jk}(t),$$

whereby the jkth element of $A^* \begin{pmatrix} \lambda \\ \mu \end{pmatrix}$ is given by

$$A^* \begin{pmatrix} \lambda \\ \mu \end{pmatrix}_{jk} = (\lambda_k - \lambda_j) + \int_{t+\tau_{jk}}^{\sigma_k} \mu_k(\tau) d\tau - \int_t^{\sigma_j} \mu_j(\tau) d\tau.$$

From the dual (see [2]) to IP, which is

$$\begin{aligned} \text{IP}^*\text{: maximize } & \langle b, w\rangle \\ \text{subject to } & c - A^* w \in P^* \\ & w \in Q^*, \end{aligned}$$

we may write down the following dual problem for CSP1:

$$\begin{aligned} \text{CSP1}^*\text{: maximize } & \lambda_n - \lambda_1 - \int_{\rho_1}^{\sigma_1} \mu_1(t) dt \\ \text{subject to } & (\lambda_k - \lambda_j) + \int_{t+\tau_{jk}}^{\sigma_k} \mu_k(\tau) d\tau - \int_t^{\sigma_j} \mu_j(\tau) d\tau \le \bar{c}_{jk}(t), \\ & \qquad t \in [\rho_j, \sigma_k - \tau_{jk}], \quad j, k = 1, \ldots, n, \\ & \mu_j(t) \ge 0, \quad t \in [\rho_j, \sigma_j], \quad j = 1, \ldots, n. \end{aligned}$$

Any λ and μ that satisfies the constraints for CSP1* is said to be (dual) *feasible*, and the *value* of CSP1* is the supremum of its objective function over all feasible solutions. We observe in passing that the change of variables $\pi_j(t) = \lambda_j + \int_t^{\sigma_j} (\mu_j(\tau) - s_j(\tau)) d\tau$ gives the following dual problem for CSP:

$$\begin{aligned} \text{CSP}^*\text{: maximize } & \pi_n(T) - \pi_1(0) \\ \text{subject to } & \frac{d\pi_j}{dt} \le s_j(t), \quad t \in [\rho_j, \sigma_j], \quad j = 1, \ldots, n, \\ & \pi_k(t + \tau_{jk}) - \pi_j(t) \le c_{jk}(t), \quad t \in [\rho_j, \sigma_k - \tau_{jk}], \quad j, k = 1, \ldots, n. \end{aligned}$$

The following weak duality result for CSP1 and CSP1* derives directly from the definition of the adjoint operator.

THEOREM 2.4. *For any feasible solution x to* CSP1 *and any feasible solution (λ, μ) to* CSP1*

$$\sum_j \sum_k \int_{\rho_j}^{\sigma_k - \tau_{jk}} \bar{c}_{jk}(t) dx_{jk}(t) \ge \lambda_n - \lambda_1 - \int_{\rho_1}^{\sigma_1} \mu_1(t) dt.$$

We now turn our attention to the values of CSP1 and its dual. If these differ then we say that there is a *duality gap*. We may show under the assumption stated below that CSP1 and CSP1* have no duality gap by appealing to the following theorem.

THEOREM 2.5. *Let X, Y, W and Z be normed spaces with X the normed dual of Y and W the normed dual of Z. For any $z \in Z$ let $F(z) = \{x \mid Ax - z \in Q\}$. Suppose that P and Q are closed in the appropriate weak topologies. Then if* IP *has a finite value and there exist constants K and L such that for every $z \in Z$, $x \in F(z) \Rightarrow \| x \| \leq K \| z \| + L$, then* IP *and* IP* *have no duality gap.*

Proof. See the proof of Theorem 3.15 in [2, p. 56]. □

If we are to invoke Theorem 2.5 then we must show that CSP1 has a finite value. CSP1 might be unbounded if in the underlying graph for CSP1 there exists a cycle containing edges with zero traversal times and negative total length. This situation can be avoided by making all edge distances positive, or by imposing a rank ordering on the vertices of the graph which will preclude such a cycle occurring. We adopt instead a third device, and make the following assumption.

ASSUMPTION 1. *The traversal times $\tau_{jk} > 0$ for every $j \neq k$.*

This assumption implies the existence of strictly positive $\hat{\tau} \leq \tau_{jk}$, for every j and k. The existence of this bound allows us to prove the following lemma.

LEMMA 2.6. *Suppose x is feasible for the problem* CSP1(b) *having constraints* (5) *with right-hand sides $b_j \in R$, $j = 1, 2, \ldots, n$, and constraints* (6) *and* (7) *with right-hand sides $f_j \in L_1[\rho_j, \sigma_j]$, $j = 1, 2, \ldots, n$. Then $\| x \| \leq (1/\hat{\tau}) \| f \| + (T/\hat{\tau}) \| b \|$.*

Proof. Suppose that x is a feasible solution for CSP1(b). For each $t \in [0, T]$ let $J(t) = \{j : \sigma_j < t\}$, and for notational convenience extend f_j to $[0, T]$ by setting $f_j = 0$, $t \notin [\rho_j, \sigma_j]$. For any j and t, if $t \leq \sigma_j$ then

$$f_j(t) \leq \sum_k \int_{\rho_k}^{t-\tau_{kj}} dx_{kj}(\tau) - \int_{\rho_j}^{t} dx_{jk}(\tau), \tag{8}$$

where the right-hand side becomes zero by (4) if $t < \rho_j$. On the other hand if $t > \sigma_j$ then the right-hand side of (8) becomes b_j. It follows that for every $t \in [0, T]$

$$\sum_j f_j(t) + \sum_{j \in J(t)} b_j \leq \sum_j \sum_k \int_{\rho_k}^{t-\tau_{kj}} dx_{kj}(\tau) - \int_{\rho_j}^{t} dx_{jk}(\tau) = -\sum_j \sum_k \int_{t-\tau_{jk}}^{t} dx_{jk}(\tau).$$

It follows that

$$0 \leq \sum_j \sum_k \int_{t-\tau_{jk}}^{t} dx_{jk}(\tau) \leq -\sum_j f_j(t) - \sum_{j \in J(t)} b_j$$

whence

$$\sum_j \sum_k \int_{t-\tau_{jk}}^{t} dx_{jk}(\tau) \leq \sum_j | f_j(t) | + \sum_j | b_j | .$$

It is easy to show using integration by parts and (4) that

$$\int_0^T \int_{t-\tau_{jk}}^{t} dx_{jk}(\tau) dt = \tau_{jk} \int_0^{T-\tau_{jk}} dx_{jk}(\tau),$$

yielding

$$\sum_j \sum_k \tau_{jk} \int_0^{T-\tau_{jk}} dx_{jk}(\tau) \leq \| f \| + T \| b \|$$

whence the lower bound on τ_{jk} gives

$$\| x \| = \sum_j \sum_k \int_{\rho_j}^{\sigma_k - \tau_{jk}} dx_{jk}(\tau) \leq (1/\hat{\tau}) \| f \| + (T/\hat{\tau}) \| b \|,$$

which is the desired result. □

The following simple corollaries to Lemma 2.6 are immediate.

COROLLARY 2.7. *The feasible region of* CSP1 *is bounded in the norm of* x.

COROLLARY 2.8. CSP1 *has a finite value.*

It remains to verify that the positive cones P and Q are closed in their respective weak topologies. This can be seen by observing that they are convex sets in respective locally convex topological vector spaces. Such sets are (weakly) closed by virtue of being closed in their norm topologies. We thus have the following lemmas.

LEMMA 2.9. *The set* P *is closed in the weak topology on* X.

LEMMA 2.10. *The set* $Q = \{(0, z) : z \in \prod_j L_1[\rho_j, \sigma_j], z(t) \geq 0 \text{ a.e.}\}$ *is closed in the weak topology on* Z.

We may now invoke Theorem 2.5 to give the following result.

THEOREM 2.11. $V(\text{CSP1}) = V(\text{CSP1}^*)$.

3. Extreme points. In the previous section we established a duality relationship between CSP1 and its dual. In fact, Theorem 2.5 may be used with Theorem 3.22 in [2] to show that CSP1 is solvable. Thus there exists a primal feasible x that attains the optimal value of the primal objective function. In this section we show that x may be taken to be an extreme point of the feasible region of CSP1. The approach taken is that of [2, pp. 60–61], which invokes Alaoglu's theorem (see [5, p. 424]). This states that the unit ball in the topological dual Y of a normed space X is compact in the weak topology $\sigma(X, Y)$. Thus any norm-bounded, $\sigma(X, Y)$-closed subset F of X is $\sigma(X, Y)$-compact, and by the Krein–Milman theorem is therefore the $\sigma(X, Y)$-closed convex hull of its extreme points. Any linear $\sigma(X, Y)$-continuous functional (such as the objective function of CSP1) will attain a minimum over F at such an extreme point.

Since we have shown in Corollary 2.7 that the feasible region F of CSP1 is bounded in the norm of X, it suffices to show that F is $\sigma(X, Y)$-closed. This is done by the following lemma.

LEMMA 3.1. *The feasible region of* CSP1 *is* $\sigma(X, Y)$*-closed.*

Proof. In the notation of IP, $F = \{x : Ax \in Q + b\} \cap P$. Since P is $\sigma(X, Y)$-closed by Lemma 2.9, it suffices to show that $\{x : Ax \in Q + b\}$ is $\sigma(X, Y)$-closed. This follows immediately from Lemma 2.10 and the fact that A is $\sigma(X, Y) - \sigma(W, Z)$ continuous. □

We have now established the following theorem.

THEOREM 3.2. *There exists a solution to* CSP1 *that is an extreme point of the set defined by the constraints of* CSP1.

In the classical shortest path problem, extreme points of the feasible region correspond to shortest paths. This has an analogue in the continuous-time case. The key result we require is that the extreme points of the feasible region of CSP1 are measures with finite support. We prove this result by first establishing a lemma, the full proof of which is rather long and technical, so we choose to give only a sketch proof here. (The reader is referred to [12] for a rigorous proof.)

LEMMA 3.3. *Suppose that x is feasible for* CSP1 *and that for some j and k there are disjoint Borel sets B and C and some t with*

$$x_{jk}([t, t+\hat{\tau}) \cap B) > 0, \qquad x_{jk}([t, t+\hat{\tau}) \cap C) > 0.$$

Then x is not an extreme point.

Sketch of proof. The proof proceeds by constructing for B and C, respectively, two distinct sequences of edges, each containing (j,k), and each starting at vertex 1 and ending at vertex n. For each member (p,q) in the first sequence we may add (or subtract) a nonzero measure z^B_{pq} to each x_{pq}, and for each member (p,q) in the second sequence we may respectively subtract (or add) a non-zero measure z^C_{pq} from each x_{pq} in such a way that $z^B - z^C \neq 0$, and $x \pm (z^B - z^C)$ is feasible for CSP1.

Each sequence of edges is constructed using the same labelling argument, which essentially states that if $x_{jk}(E) > 0$ for some set E then either $x_{kl}(E) > 0$ for some l, or there is parking in vertex k over some interval which intersects E. Proceeding in this fashion we can label new time intervals and new vertices until after a finite number of steps (by virtue of Assumption 1) both vertex 1 and vertex n are labelled.

Since the argument for z^C is identical, we restrict our attention to the construction of z^B from the sequence containing B. Let this consist of intervals I_{j_r}, Borel sets B_{j_r} and edges (j_{r-1}, j_r), giving

$$\{I_{j_0}, B_{j_0}, (j_0, j_1), I_{j_1}, B_{j_1}, (j_1, j_2), \ldots, I_{j_{q-1}}, B_{j_{q-1}}, (j_{q-1}, j_q), I_{j_q}\},$$

where $j_0 = 1$, $j_q = n$. We define the measure z^B by scaling down the measure x (by possibly different amounts) on the Borel sets in the sequence. This scaling gives a nonzero measure that has the property that total flow into a vertex equals total flow out, and the scale factors are chosen sufficiently small so that z^B can be subtracted from x without violating the constraints on x and y.

The nonnegativity constraints (6) and (7) require particular care. To avoid cases where a y variable equals zero at an endpoint of an interval I_{j_r} in the sequence, we can assume without loss of generality that y_{j_r} is greater than some strictly positive ϵ on such an interval. It then becomes possible to ensure by scaling z^B that any changes in y_{j_r} are less than ϵ on I_{j_r}, and zero elsewhere. The details are given in [12]. □

The previous lemma can be used to show that if x is an extreme point of CSP1 then each x_{jk} is concentrated on a finite set. We make use of the following simple result.

LEMMA 3.4. *Suppose that D is any Borel set in $[0,T]$ and ψ a regular Borel measure with $\psi(D) > 0$. Suppose further that for every B and C with $B \cup C = D$ and $B \cap C = \emptyset$, either $\psi(B) = 0$ or $\psi(C) = 0$. Then there is some $\bar{t} \in D$ with $\psi(\{\bar{t}\}) > 0$, and $\psi(D \setminus \{\bar{t}\}) = 0$.*

Proof. If $\bar{v} = \inf\{v : \psi((v,T] \cap D) = 0\}$, and $\bar{u} = \sup\{u : \psi([0,u] \cap D) = 0\}$, then since $\psi(D) > 0$, $\bar{u} \leq \bar{v}$. Suppose $\bar{u} < \bar{v}$, and define $w = (\bar{u} + \bar{v})/2$. If we then let $B = [0,w] \cap D$ and $C = (w,T] \cap D$ then either $\psi(B) = 0$ or $\psi(C) = 0$ which contradicts the definition of $\bar{u}$ and $\bar{v}$. Thus $\bar{u} = \bar{v}$, whence setting $\bar{t} = \bar{u}$ gives the result. □

COROLLARY 3.5. *If x is an extreme point of* CSP1 *then each x_{jk} is concentrated on a finite set.*

Proof. Suppose x is extreme. Since $\hat{\tau} > 0$, we may cover $[0,T]$ with a finite number of intervals of the form $[t, t+\hat{\tau})$. Then for any one of these intervals, D, say, and for each j and k, either $x_{jk}(D) = 0$, or since x is extreme by Lemma 3.3 there

exists B and C which satisfy the conditions of the previous lemma. Hence there is some $\bar{t} \in D$ with $x_{jk}(\{\bar{t}\}) > 0$, and $x_{jk}(D \setminus \{\bar{t}\}) = 0$, which gives the result. □

The importance of Corollary 3.5 is that it may be used to give the following characterization of the extreme points of the feasible region of CSP1.

THEOREM 3.6. *Every extreme point of* CSP1 *corresponds to a continuous-time path from* $(1,0)$ *to* (n,T).

Proof. Recall that the extreme points of SP correspond to paths from 1 to n. If x is an extreme point of CSP1 then each x_{jk} is concentrated on a finite set S_{jk}, say. Let $S = \bigcup_{j,k} S_{jk}$ and consider the graph having as nodes the finite number of VTPs in $\{1,2,\ldots,n\} \times S$, and as edges pairs of VTPs (j,t), (k,u) if $j \neq k$ and $u \geq t + \tau_{jk}$. Then x represents a feasible solution to SP posed in this graph, where a path is sought from $(1,0)$ to (n,T). Since x is extreme for CSP1, it must also be extreme for this version of SP, whence its nonzero components indicate a path from $(1,0)$ to (n,T). □

4. Conclusion. Theorem 3.6 implies that any extreme point of CSP1 can be characterized by a corresponding continuous-time path. It is also clear that any continuous-time path determines a feasible solution to CSP1 with finite support. Moreover this is an extreme point for CSP1, for if it were not then we could demonstrate that it was not extreme for SP formulated in the time-expanded graph

$$\{1,2,\ldots,n\} \times S,$$

where S is the set of departure times in the path. By virtue of Theorem 3.2 it follows that

1. there exists an optimal solution to CSP1 defining a shortest continuous-time path,
2. a shortest continuous-time path will define an optimal solution to CSP1.

It is tempting to consider extending the results above to models in which both the transit times and the edge distances vary, since in many situations this will be the case. As shown in [10] it is possible to construct algorithms for such problems when the paths contain a finite number of links. However, it seems impossible to incorporate varying transit times into a linear programming framework, at least without making the presentation considerably more complicated than that given above.

The assumption that all transit times are strictly positive is central to the arguments presented in this paper. This assumption, which gives a bound on the norm of x, also guarantees that the number of links traversed in any continuous-time path is finite. A similar finiteness assumption arises in [2] where the relationship between a continuous-time max flow-min cut theorem and duality theory is explored. In this context the minimum cut problem is formulated as an infinite-dimensional linear program over a space of measures, and the absence of a duality gap is demonstrated. However, in general there is no guarantee that the optimal value to the dual problem is attained, and a correspondence between solutions to the dual problem and continuous-time cuts can only be established when the cuts have a finite number of switches. (A continuous-time version of the max flow-min cut theorem without such an assumption is established in [11] using a labelling algorithm.)

It is interesting to conjecture whether a strong duality result can be derived whereby the value of CSP1* is attained and equals V(CSP1). This depends on being able to construct dual feasible μ in $\prod_j L_\infty[\rho_j, \sigma_j]$ having value V(CSP1*), which is straightforward if we assume that c satisfies a Lipschitz condition.

ASSUMPTION 2. *There exists K such that for every $j,k = 1,\ldots,n$,*

$$| c_{jk}(t_1) - c_{jk}(t_2) | < K | t_1 - t_2 |, \quad t_1, t_2 \in [\rho_j, \sigma_k - \tau_{jk}].$$

Observe that since $s \in \prod_j L_\infty[\rho_j, \sigma_j]$, this assumption implies that $\bar{c}_{jk}(t) = c_{jk}(t) + \int_{t+\tau_{jk}}^{\sigma_k} s_k(t)dt - \int_t^{\sigma_j} s_j(t)dt$ also satisfies a Lipschitz condition. This allows us to prove the following result.

THEOREM 4.1. *Suppose that c satisfies Assumption 2. Then there exists $\lambda \in R^n$, and $\mu \in \prod_j L_\infty[\rho_j, \sigma_j]$ with λ and μ feasible for* CSP1* *and*

$$V(\text{CSP1}^*) = \lambda_n - \lambda_1 - \int_{\rho_1}^{\sigma_1} \mu_1(t)dt.$$

Proof. The results of the previous section show that for every vertex j and time $t \in [\rho_j, \sigma_j]$ there exists a continuous-time shortest path from $(1,0)$ to (j,t). When $j \neq 1$ this path may be obtained by solving CSP1 with (n,T) replaced by (j,t), but because of the form of the constraints we must modify CSP1 slightly to compute a continuous-time shortest path from $(1,0)$ to $(1,t)$. Formally, we add a dummy vertex $n+1$ with $s_{n+1}(t) = \| s_1 \|_\infty$, $c_{jn+1}(t) = c_{n+1j}(t) = \infty$ for all j except $c_{1n+1}(t) = 0$, and $\tau_{1n+1} = \hat{\tau}$; a continuous-time shortest path from $(1,0)$ to $(n+1, t+\hat{\tau})$ is a solution to CSP1 with n replaced by $n+1$. This path must travel via $(1,t)$ and hence defines a shortest path from $(1,0)$ to $(1,t)$.

Now for each vertex j and $t \in [\rho_j, \sigma_j]$ let $\psi_j(t)$ be the length of a continuous-time shortest path from $(1,0)$ to (j,t), computed by solving the appropriate version of CSP1 described above. Each of these problems has edge distances $\bar{c}_{jk}(t)$ and zero parking penalties implying that ψ_j is a monotonic decreasing function of t. Furthermore, by virtue of Assumption 1, each ψ_j is a finite sum of edge distances, and thus satisfies a Lipschitz condition by Assumption 2. The functions ψ_j therefore have derivatives almost everywhere, which, being bounded except on a set of measure zero, may be taken to lie in $L_\infty[\rho_j, \sigma_j]$.

If for each j we define

$$\mu_j(t) = -\frac{d\psi_j(t)}{dt}, \qquad \lambda_j = \psi_j(\sigma_j),$$

then λ and μ are easily seen to be feasible for CSP1* since $\mu_j \geq 0$ and

$$(\lambda_k - \lambda_j) + \int_{t+\tau_{jk}}^{\sigma_k} \mu_k(\tau)d\tau - \int_t^{\sigma_j} \mu_j(\tau)d\tau = \psi_k(t+\tau_{jk}) - \psi_j(t).$$

The right-hand side of this equation cannot exceed $\bar{c}_{jk}(t)$, otherwise the length of a continuous-time shortest path from $(1,0)$ to $(k, t+\tau_{jk})$ may be improved by travelling from j to k at time t.

Moreover, λ and μ have an objective function value of

$$\lambda_n - \lambda_1 - \int_{\rho_1}^{\sigma_1} \mu_1(t)dt = \psi_n(\sigma_n) - \psi_1(\sigma_1) + \int_{\rho_1}^{\sigma_1} \frac{d\psi_1(t)}{dt}dt = \psi_n(T) - \psi_1(0),$$

which equals the length of a continuous-time shortest path from $(1,0)$ to (n,T) evaluated with edge distances $\bar{c}_{jk}(t)$ and zero parking penalties. Since this equals $V(\text{CSP1})$, the result follows immediately from Theorem 2.4. □

One might hope that the above results would lead to the development of algorithms to solve instances of continuous-time shortest path problems. Such algorithms can be derived directly using a dynamic programming approach. Orda and Rom give a conceptual labelling method in [10] for solving instances of CSP. In our notation this carries out the following steps.

Initialise: Set

$$\pi_1(t) = \int_0^t s_1(\tau)d\tau), \quad \pi_j(t) = \infty, \ j \neq 1.$$

Iterate: Replace $\pi_j(t)$ by

$$\min\{\pi_j(t), \min_{k \neq j} \min_{\tau_{kj} \leq t_0 \leq t} \left\{ \pi_k(t_0 - \tau_{kj}) + c_{kj}(t_0 - \tau_{kj}) + \int_{t_0}^t s_j(\tau)d\tau \right\}\}$$

until for every j, $\pi_j(t)$ does not change from one iteration to the next.

Upon termination this algorithm gives a solution π to CSP*, as well as a continuous-time path corresponding to a solution x which is feasible for CSP and complementary slack with π. For each j and t the value of $\pi_j(t)$ gives the length of a shortest path from $(1,0)$ to (j,t). The minimum length path (and corresponding solution x) is easy to recover from $\pi_j(t)$ by tracing back through the sequence of VTPs yielding the minimum values. The above algorithm can be shown to terminate in a finite time when the edge distances are piecewise linear functions and the parking penalties are piecewise constant functions. Details of these results are given in [14].

Acknowledgments. We are grateful to the referees of this paper for their helpful comments which have considerably improved the exposition.

SENSITIVITY ANALYSIS OF PARAMETRIZED PROGRAMS VIA GENERALIZED EQUATIONS*

ALEXANDER SHAPIRO†

Abstract. This paper investigates local behavior of optimal solutions of parametrized optimization problems with cone constraints in Banach spaces. The corresponding first-order optimality conditions are formulated in a form of generalized equations (variational inequalities) and solutions of these generalized equations are studied. It is shown that under certain second-order sufficient optimality conditions and a regularity assumption related to the associated Lagrange multipliers, the considered optimal solutions are Lipschitzian stable. This is compared with a similar result in Shapiro and Bonnans [*SIAM J. Control Optim.*, 30 (1992), pp. 1409–1422]. Under the additional assumption of uniqueness of the Lagrange multipliers, first-order expansions of the optimal solutions are given in terms of solutions of auxiliary optimization problems. Finally, as an example, semi-infinite programming problems are discussed.

Key words. nonlinear optimization, parametric programming, sensitivity analysis, generalized equations, Lipschitzian stability, directional differentiability, semi-infinite programming

1. Introduction.

In this paper we study optimization programs of the form

$$(P_t) \qquad \min_{x \in X} f(x,t) \quad \text{subject to } x \in \Phi(t),$$

depending on the parameter $t \in \Re_+$. Here

$$\Phi(t) = \{x \in S : g(x,t) \in K\},$$

S is a closed convex subset of a Banach space X, K is a closed convex cone in a Banach space Y and $g : X \times \Re_+ \to Y$. We investigate continuity and differentiability properties of an optimal solution of the program (P_t) , considered as a function of t, by writing the corresponding first-order optimality conditions in a form of *generalized equations.*

The finite-dimentional case, when the feasible set $\Phi(t)$ is defined by a finite number of constraints, has been studied extensively (cf. Fiacco [9]). In recent years its theory was developed and the local behavior of the optimal solutions in that case is now well understood [4], [5], [10], [12], [29], [31]. We refer to Bonnans, Ioffe, and Shapiro [6] for a discussion of these results. After the pioneering work of Robinson [25]–[27], sensitivity analysis of generalized equations has been discussed by several authors (e.g., [7], [14], [16], [21], [28]). In these papers the considered space is finite-dimensional and the corresponding cone (convex set) is polyhedral. The case of infinite-dimensional spaces and general cone constraints is discussed in recent publications [1], [8], [18], [32], [34]. In this paper we further develop and complement this theory. In the next section we show that under certain second-order sufficient conditions and a regularity assumption related to the corresponding Lagrange multipliers, the considered optimal solutions are Lipschitzian stable. In §3 we discuss a relation of this result to a similar result in Shapiro and Bonnans [34]. In §4 we derive, under the assumption of uniqueness of the Lagrange multipliers, various expansions of the optimal solutions of (P_t) in terms

† School of Industrial and Systems Engineering, Georgia Institute of Technology, Atlanta, Georgia 30332-0205.

of optimal solutions of auxiliary optimization problems. Finally, as an example, we briefly discuss in §5 semi-infinite programming.

We assume subsequently that $f(x,t)$ and $g(x,t)$ are *twice continuously differentiable* jointly in x and t. For $x \in X$ and $\xi \in X^*$ we use the notation $\langle \xi, x \rangle$ or $\langle x, \xi \rangle$ for the value $\xi(x)$ of the linear functional ξ at x. By $\overline{S}$ we denote the topological closure of a set S. The scalar product of two vectors x and y in the finite-dimensional space $\Re^n$ is denoted by $x \cdot y$. For a convex subset C of the dual space X^* and $\xi \in C$ we denote by $N_C(\xi)$ or $N(\xi, C)$ the normal cone to C at ξ,

$$N_C(\xi) = \{x \in X : \langle x, \zeta - \xi \rangle \leq 0 \text{ for all } \zeta \in C\}.$$

For a convex subset of X the normal cone is defined similarly. By $T_S(x)$ or $T(x,S)$ we denote the tangent cone to the convex set S at a point $x \in S$. Note that $T_S(x)$ is polar (negative dual) of the normal cone $N_S(x)$ and that if S is a convex cone, then $T_S(x) = \overline{S + [x]}$, where $[x]$ is the linear space generated by x. The linear space generated by a convex set S will be denoted by $Sp(S)$, that is

$$Sp(S) = \{z = t(x-y) : x, y \in S,\ t \in \Re\}.$$

In particular, if S is a convex cone, then $Sp(S) = S + (-S)$.

Consider the Lagrangian function

$$L(x, \lambda, t) = f(x,t) + \langle \lambda, g(x,t) \rangle,$$

$\lambda \in Y^*$, associated with the program (P_t). Then, under a constraint qualification, to an optimal solution $\bar{x}(t)$ of (P_t) corresponds a vector $\bar{\lambda}(t)$ of Lagrange multipliers satisfying the first-order necessary conditions (cf. [19], [22])

$$\begin{aligned} &0 \in D_x L(x, \lambda, t) + N_S(x), \\ &\lambda \in K^-,\ \langle \lambda, g(x,t) \rangle = 0. \end{aligned} \tag{1.1}$$

Here

$$K^- = \{\lambda \in Y^* : \langle \lambda, v \rangle \leq 0 \text{ for all } v \in K\}$$

is the polar (negative dual) cone of K. The optimality conditions (1.1), together with the feasibility conditions $g(x,t) \in K$, $x \in S$, can be written in the form of generalized equations (variational inequality) as follows (cf. [26]):

$$0 \in F(z,t) + \Omega(z), \tag{P_t^*}$$

where $z = (x, \lambda) \in X \times Y^*$,

$$F(z,t) = (D_x L(x, \lambda, t), -g(x,t)) : X \times Y^* \times \Re_+ \to X^* \times Y$$

and

$$\Omega(z) = N_{S \times K^-}(x, \lambda) = N_S(x) \times N_{K^-}(\lambda) \subset X^* \times Y.$$

In the subsequent analysis we study solutions of the generalized equations (P_t^*) rather than solutions of the optimization program (P_t). We say that $\bar{x} = \bar{x}(t) \in S$ is a *stationary solution* of the program (P_t) if $g(\bar{x}, t) \in K$ and there exists a vector $\bar{\lambda} = \bar{\lambda}(t)$ satisfying the first-order optimality conditions (1.1). The corresponding point $\bar{z} = \bar{z}(t) = (\bar{x}(t), \bar{\lambda}(t))$ is then a solution of the generalized equations (P_t^*).

Of course, generalized equations (P_t^*) have a particular structure that we exploit here. In this respect let us make the following observations.

(i) The multifunction $\Omega(z)$ is monotone, i.e., for any z_1, z_2 and $\zeta_1 \in \Omega(z_1), \zeta_2 \in \Omega(z_2)$,

$$\langle \zeta_1 - \zeta_2, z_1 - z_2 \rangle \geq 0.$$

Note that $\Omega(z) = \emptyset$ if $z \notin S \times K^-$.

(ii) Consider the mapping $F(z) = F(z, 0)$. We have that

$$DF(z) = \begin{bmatrix} D^2_{xx} L(x, \lambda, 0) & D_x g(x, 0) \\ -D_x g(x, 0)^* & 0 \end{bmatrix}$$

and hence for $z_1 = (x_1, \lambda_1)$ and $z_2 = (x_2, \lambda_2)$,

$$\begin{aligned} &\langle F(z_1) - F(z_2), z_1 - z_2 \rangle \\ &= \int_0^1 \langle z_1 - z_2, DF(z_2 + \tau(z_1 - z_2))(z_1 - z_2) \rangle d\tau \\ &= \int_0^1 \langle x_1 - x_2, D^2_{xx} L(x_2 + \tau(x_1 - x_2), \lambda_2 + \tau(\lambda_1 - \lambda_2), 0)(x_1 - x_2) \rangle d\tau. \end{aligned} \tag{1.2}$$

Equation (1.2) indicates a relation between monotonicity properties of the mapping $F(z)$ and second-order conditions for the program (P_t). That is, if for all z in a convex region W and some $\beta > 0$ and $y \in X$,

$$\langle y, D^2_{xx} L(z, 0) y \rangle \geq \beta \|y\|^2, \tag{1.3}$$

then for all $z_1 = (x_1, y_1)$, $z_2 = (x_2, y_2) \in W$ such that $x_1 - x_2 = y$ we have

$$\langle F(z_1) - F(z_2), z_1 - z_2 \rangle \geq \beta \|x_1 - x_2\|^2. \tag{1.4}$$

Note that the lower bound given in the right-hand side of (1.4) involves only components x_1 and x_2 of the respective vectors z_1 and z_2 and does not depend on λ_1 and λ_2. We will discuss this later.

2. Lipschitz stability of the solutions. In this section we study continuity properties of solutions $\bar{z}(t) = (\bar{x}(t), \bar{\lambda}(t))$ of the generalized equations (P^*_t). Before proceeding further we introduce the regularity conditions that will be responsible for a relation between continuity properties of $\bar{x}(t)$ and $\bar{\lambda}(t)$.

Let x_0 be an optimal solution of the unperturbed program (P_0). We assume that x_0 is a *regular* point of $g(x) = g(x, 0)$, with respect to S and K, in the sense of Robinson [23]. That is

$$0 \in \operatorname{int}\{g(x_0) + Dg(x_0)(S - x_0) - K\}.$$

It follows then that the set Λ_0 of Lagrange multipliers satisfying the first-order optimality conditions (1.1), with $x = x_0$ and $t = 0$, is *nonempty* and *bounded*. These optimality conditions can be written in the form

$$-\lambda \circ \bar{G} - \bar{a} \in N_S(x_0), \ \langle \lambda, \bar{c} \rangle = 0, \ \lambda \in K^-, \tag{2.1}$$

where $\bar{G} = D_x g(x_0, 0)$, $\bar{a} = D_x f(x_0, 0)$ and $\bar{c} = g(x_0, 0)$.

Consider

$$\Lambda(a, \gamma, x) = \{\lambda \in K^- : \ -\lambda \circ \bar{G} - a \in N_S(x), \ \langle \lambda, \bar{c} \rangle = \gamma \}. \tag{2.2}$$

It is clear that $\Lambda_0 = \Lambda(\bar{a}, 0, x_0)$. By $\mathrm{dom}(\Lambda)$ we denote the domain of the multifunction $\Lambda(a, \gamma, x)$, i.e., $\mathrm{dom}(\Lambda) = \{(a, \gamma, x) : \Lambda(a, \gamma, x) \neq \emptyset\}$. We assume that the multifunction $\Lambda(a, \gamma, x)$ is *upper Lipschitzian* at $(\bar{a}, 0, x_0)$ in the following sense.

ASSUMPTION A1. *There exists a positive constant k such that*

$$\sup_{\lambda \in \Lambda(a,\gamma,x)} \mathrm{dist}(\lambda, \Lambda_0) \leq k(\|a - \bar{a}\| + |\gamma| + \|x - x_0\|) \tag{2.3}$$

for all $(a, \gamma, x) \in \mathrm{dom}(\Lambda)$ in a neighborhood of $(\bar{a}, 0, x_0)$.

Since Λ_0 is bounded it follows from (2.3) that $\Lambda(a, \gamma, x)$ is uniformly bounded for all (a, γ, x) in a neighborhood of $(\bar{a}, 0, x_0)$. It also follows from (2.3) that if λ satisfies conditions (2.1) but with $\bar{a}, \bar{G}, \bar{c}$, and x_0 replaced by a, G, c, and x, respectively, then

$$\mathrm{dist}(\lambda, \Lambda_0) \leq k(\|a - \bar{a}\| + \|\lambda\|\|G - \bar{G}\| + \|\lambda\|\|c - \bar{c}\| + \|x - x_0\|).$$

Consequently, we obtain that if $\bar{\lambda}(t)$ satisfies the necessary conditions (1.1), then

$$\begin{aligned}\mathrm{dist}(\bar{\lambda}(t), \Lambda_0) = O(&\|D_x f(\bar{x}(t), t) - D_x f(x_0, 0)\| + \|D_x g(\bar{x}(t), t) - D_x g(x_0, 0)\| \\ &+ \|g(\bar{x}(t), t) - g(x_0, 0)\| + \|\bar{x}(t) - x_0\|).\end{aligned}$$

If we assume further that $\bar{x}(t) \to x_0$ as $t \to 0$, we obtain

$$\mathrm{dist}(\bar{\lambda}(t), \Lambda_0) = O(\|\bar{x}(t) - x_0\| + t). \tag{2.4}$$

This shows that Assumption A1 guarantees that perturbations of the Lagrange multipliers are of the same order as perturbations of the corresponding optimal solutions. We will discuss Assumption A1 further in the next section.

We now introduce second-order optimality conditions for the progaram (P_t) (cf. [19]). For $\eta > 0$ consider the cone

$$C_\eta = \{y \in T_S(x_0) : \ Dg(x_0)y \in T_K(g(x_0)), \ \langle Df(x_0), y\rangle \leq \eta\|y\| \ \}. \tag{2.5}$$

ASSUMPTION A2 (General second-order sufficient conditions). *There exist $\alpha > 0$ and $\eta > 0$ such that*

$$\langle y, D^2_{xx} L(x_0, \lambda, 0)y\rangle \geq \alpha\|y\|^2, \tag{2.6}$$

for all $y \in C_\eta$ and all $\lambda \in \Lambda_0$.

Note that since $D^2_{xx} L(x, \lambda, 0)$ is linear in λ, it follows from (2.6) that for a positive constant β less than α,

$$\langle y, D^2_{xx} L(x, \lambda, 0)y\rangle \geq \beta\|y\|^2$$

for all (x, λ) in a neighborhood W of $\{x_0\} \times \Lambda_0$ and all $y \in C_\eta$. Consequently condition (1.4) holds for all $z_1, z_2 \in W$ and such that $x_1 - x_2 = y$.

THEOREM 2.1. *Suppose that the point x_0 is regular, that Assumptions* A1 *and* A2 *hold and let $\bar{x}(t)$ be a stationary solution of (P_t) such that $\bar{x}(t)$ converges to x_0 as $t \to 0^+$. Then there exists a positive constant c such that*

$$\|\bar{x}(t) - x_0\| \leq ct \tag{2.7}$$

for all $t \geq 0$ sufficiently small.

Proof. Let $\bar{z}(t) = (\bar{x}(t), \bar{\lambda}(t))$ be a solution of the generalized equations (P_t^*) corresponding to the stationary solution $\bar{x}(t)$. We argue by a contradiction. Suppose that (2.7) is false. Then there are $t_n \to 0^+$, $x_n = \bar{x}(t_n)$ and $\kappa_n = \|x_n - x_0\|$ such that

$$\lim_{n\to\infty} \kappa_n^{-1} t_n = 0. \tag{2.8}$$

Consider $y_n = \kappa_n^{-1}(x_n - x_0)$, $\lambda_n = \bar{\lambda}(t_n)$ and $z_n = (x_n, \lambda_n)$. Note that it follows from the regularity of the point x_0 that Λ_0 and $\{\lambda_n\}$ are bounded.

Since $x_n \in S$ we have that $y_n \in T_S(x_0)$. Furthermore, because of (2.8),

$$g(x_n, t_n) = g(x_0) + \kappa_n Dg(x_0) y_n + o(\kappa_n).$$

Since $g(x_n, t_n) \in K$ it follows that

$$\operatorname{dist}(Dg(x_0)y_n,\ K + [g(x_0)]) = \operatorname{dist}(Dg(x_0)y_n,\ T_K(g(x_0)) \to 0.$$

By the Robinson [24]–Ursescu [35] stability theorem this implies that $\operatorname{dist}(y_n, \Sigma) \to 0$, where

$$\Sigma = \{y \in T_S(x_0) :\ Dg(x_0)y \in T_K(g(x_0))\}. \tag{2.9}$$

Therefore there exists $\bar{y}_n \in \Sigma$ such that $\bar{y}_n - y_n \to 0$.

Moreover, since

$$-D_x L(x_n, \lambda_n, t_n) \in N_S(x_n)$$

we have that

$$\langle D_x L(x_n, \lambda_n, t_n), x_n - x_0 \rangle \le 0$$

and hence

$$\langle D_x f(x_n, t_n), x_n - x_0 \rangle + \langle \lambda_n, D_x g(x_n, t_n)(x_n - x_0) \rangle \le 0. \tag{2.10}$$

We also have

$$\langle \lambda_n, g(x_n, t_n) - g(x_0, 0) \rangle = \langle \lambda_n, -g(x_0, 0) \rangle \ge 0$$

and

$$g(x_n, t_n) - g(x_0, 0) = D_x g(x_n, t_n)(x_n - x_0) + o(\kappa_n)$$

and hence

$$-\langle \lambda_n, D_x g(x_n, t_n)(x_n - x_0) \rangle \le o(\kappa_n). \tag{2.11}$$

Consequently we obtain from (2.10) and (2.11),

$$\langle D_x f(x_n, t_n), x_n - x_0 \rangle \le o(\kappa_n).$$

This implies that

$$\langle y_n, Df(x_0) \rangle \le \eta$$

and hence

$$\langle \bar{y}_n, Df(x_0) \rangle \leq \eta$$

for all n large enough. We obtain then that $\bar{y}_n \in C_\eta$.

Now let $\hat{z}_n = (x_0, \hat{\lambda}_n)$ be an element of $\{x_0\} \times \Lambda_0$ such that

$$\|\lambda_n - \hat{\lambda}_n\| = O(\|x_n - x_0\| + t_n). \tag{2.12}$$

Existence of such $\hat{\lambda}_n$ is ensured by Assumption A1. Since $-F(\hat{z}_n) \in \Omega(\hat{z}_n)$ and $-F(z_n, t_n) \in \Omega(z_n)$ and $\Omega(z)$ is monotone, we obtain that

$$\langle F(\hat{z}_n) - F(z_n, t_n), \hat{z}_n - z_n \rangle \leq 0. \tag{2.13}$$

By (1.2) we have

$$\langle F(\hat{z}_n) - F(z_n), \hat{z}_n - z_n \rangle = \kappa_n^2 \int_0^1 \langle y_n, D^2_{xx} L(z_n + \tau(\hat{z}_n - z_n), 0) y_n \rangle d\tau$$

and hence, since $\bar{y}_n - y_n \to 0$, it follows from Assumption A2 that for all n large enough and $0 < \beta < \alpha$,

$$\langle F(\hat{z}_n) - F(z_n), \hat{z}_n - z_n \rangle \geq \beta \|x_0 - x_n\|^2. \tag{2.14}$$

From (2.13) we obtain

$$\langle F(\hat{z}_n) - F(z_n), \hat{z}_n - z_n \rangle \leq \langle F(z_n, t_n) - F(z_n), \hat{z}_n - z_n \rangle$$

which, together with (2.14), implies

$$\beta \|x_0 - x_n\|^2 \leq \langle F(z_n, t_n) - F(z_n), \hat{z}_n - z_n \rangle.$$

It follows that

$$\beta \|x_0 - x_n\|^2 \leq \|F(z_n, t_n) - F(z_n)\| \|\hat{z}_n - z_n\| = O(t_n \|\hat{z}_n - z_n\|)$$

and hence, because of (2.12),

$$\|x_0 - x_n\|^2 = O(t_n \|x_n - x_0\| + t_n^2). \tag{2.15}$$

Finally we observe that (2.15) contradicts (2.8) and hence the proof is complete. □

Remarks. Denote by $\Lambda(t)$ the set of Lagrange multipliers corresponding to the optimal solution $\bar{x}(t)$. Assumption A1 was used in Theorem 2.1 only to ensure the existence of a Lagrange multiplier $\bar{\lambda}(t) \in \Lambda(t)$ satisfying condition (2.4). A similar assumption was used in Alt [1], [2] but in a considerably stronger form. It was required there that

$$\|\bar{\lambda}(t) - \lambda_0\| = O(\|\bar{x}(t) - x_0\| + t) \tag{2.16}$$

for a particular (independent of t) element λ_0 of the set Λ_0. It seems that condition (2.16) will be difficult to verify in situations where the set Λ_0 is not a singleton.

Compared with a similar result in Shapiro and Bonnans [34], the second-order conditions of Assumption A2 appear to be unnecessarily strong in cases where Λ_0 is

not a singleton. We will discuss in the next section the relation between Assumption A1 and a corresponding regularity condition used in [34].

We did not assume in Theorem 2.1 that the optimal (stationary) solution $\bar{x}(t)$ of (P_t) does exist for all t. It was only stated that if such a solution exists for some $t > 0$ in a neighborhood of zero, then condition (2.7) holds. We can consider ϵ-optimal solutions with $\epsilon = \epsilon(t) > 0$ representing a possible error in solution of the optimization problem (P_t). That is, $\bar{x}(t) \in \Phi(t)$ and

$$f(\bar{x}(t), t) \leq \inf_{x \in \Phi(t)} f(x, t) + \epsilon.$$

It follows then by Ekeland's variational principle [3], that there is an ϵ-optimal solution $\hat{x}(t)$ of (P_t) such that $\|\hat{x}(t) - \bar{x}(t)\|$ is less than $\epsilon^{1/2}$ and that $\hat{x}(t)$ is the minimizer of the function

$$f_\epsilon(x, t) = f(x, t) + \epsilon^{1/2}\|x - \hat{x}(t)\|.$$

This implies existence of $\hat{\lambda}(t)$ and $\Upsilon(t) = (\Upsilon_1(t), 0) \in X^* \times Y$ such that $\|\Upsilon_1(t)\| \leq \epsilon^{1/2}$ and $\hat{z}(t) = (\hat{x}(t), \hat{\lambda}(t))$ is a solution of the generalized equation

$$0 \in F(z, t) + \Upsilon(t) + \Omega(z). \tag{2.17}$$

It is possible then to show, in a way similar to the proof of Theorem 2.1, that if the assumptions of Theorem 2.1 are satisfied with $\bar{x}(t)$ being an $\epsilon(t)$-optimal solution of (P_t) and $\epsilon(t) = O(t^2)$, then the Lipschitz stability result (2.7) still holds.

Let us finally remark that under the assumptions of Theorem 2.1, x_0 is an *isolated* stationary solution (isolated locally optimal solution) of the program (P_0). This can be shown by arguments similar to those used in the proof of Theorem 2.1 and by taking $t_n = 0$.

3. Discussion of regularity assumptions. In this section we discuss the regularity Assumption A1. This assumption and its consequence (2.4) were crucial in derivation of the Lipschitzian stability result of Theorem 2.1.

There are at least two situations where Assumption A1 holds. That is, when $S = X$, the space Y is finite-dimensional and the cone K is *polyhedral.* This result is due to Walkup and Wets [36]. The other case where Assumption A1 holds is when $S = X$ and the point x_0 is regular with respect to the cone $K_0 = K(\lambda_0)$, $\lambda_0 \in \Lambda_0$, [32, Lem. 4.4], where

$$K(\lambda) = \{y \in K : \langle \lambda, y \rangle = 0\}.$$

Note that in this case the set $\Lambda_0 = \{\lambda_0\}$ is a singleton [32, Lem. 4.3]. Since this result will be important in the next section, we state it in the following proposition.

PROPOSITION 3.1. *Let $S = X$, x_0 be an optimal solution of (P_0), λ_0 be a Lagrange multiplier satisfying the first-order necessary conditions and suppose that x_0 is a regular point of $g(x)$ with respect to $K_0 = K(\lambda_0)$. Then $\Lambda_0 = \{\lambda_0\}$ is a singleton and Assumption* A1 *holds.*

In the remainder of this section we suppose that $S = X$ and compare assumption A1 with the following regularity condition used in Shapiro and Bonnans [34].

ASSUMPTION SB. *For some $\lambda_0 \in \Lambda_1$ the tangent cone $T(\lambda_0, \Lambda_0)$ is representable in the form*

$$T(\lambda_0, \Lambda_0) = \{\lambda \in T(\lambda_0, K^-) : \lambda \circ Dg(x_0) = 0, \langle \lambda, g(x_0) \rangle = 0\}. \tag{3.1}$$

Here Λ_1 *is a subset of* Λ_0 *defined by*

$$\Lambda_1 := \operatorname{argmax}\{D_t L(x_0, \lambda, 0) : \lambda \in \Lambda_0\}.$$

In the present case when $S = X$ the set $\Lambda(a, \gamma, x)$ depends only on a and γ and can be written as

$$\Lambda(a, \gamma) = \{\lambda \in K^- : \lambda \circ Dg(x_0) + a = 0, \ \langle \lambda, g(x_0) \rangle = \gamma\}.$$

PROPOSITION 3.2. *Assumption* A1 *implies Assumption* SB.

Proof. Let us first observe that $T(\lambda_0, \Lambda_0)$ is always contained in the set given in the right-hand side of (3.1). We argue now by a contradiction. Suppose that Assumption A1 holds and that (3.1) is false. This implies existence of a nonzero vector μ in the set given by the right-hand side of (3.1) and such that $\mu \notin T(\lambda_0, \Lambda_0)$. Since $\mu \in T(\lambda_0, K^-)$ we have that there exists a sequence $\{\lambda_n\} \subset K^-$ converging to λ_0 and $\tau_n \to 0^+$ such that $\tau_n^{-1}(\lambda_n - \lambda_0) \to \mu$. Consider $a_n = -\lambda_n \circ Dg(x_0)$ and $\gamma_n = \langle \lambda_n, g(x_0) \rangle$. We have that $\lambda_n \in \Lambda(a_n, \gamma_n)$. Also, since $\mu \notin T(\lambda_0, \Lambda_0)$, it follows that

$$\liminf_{n \to \infty} \tau_n^{-1} \operatorname{dist}(\lambda_0 + \tau_n \mu, \ \Lambda_0) \ > 0$$

and hence, since $\operatorname{dist}(\cdot, \Lambda_0)$ is Lipschitz continuous,

$$\liminf_{n \to \infty} \tau_n^{-1} \operatorname{dist}(\lambda_n, \ \Lambda_0) \ > 0.$$

Moreover,

$$\tau_n^{-1}(\bar{a} - a_n) = \tau_n^{-1}(\lambda_n - \lambda_0) \circ Dg(x_0) \to \mu \circ Dg(x_0) = 0$$

and hence

$$\|a_n - \bar{a}\| = o(\tau_n).$$

Similarly

$$|\gamma_n| = o(\tau_n).$$

Consequently we obtain that

$$(\|a_n - \bar{a}\| + |\gamma_n|)^{-1} \operatorname{dist}(\lambda_n, \Lambda_0) \to \infty,$$

which contradicts condition (2.3) of Assumption A1. □

This shows that in general Assumption A1 is stronger than Assumption SB (see further discussion in §5). It is not difficult to show that if the space Y is finite-dimensional and the set Λ_0 is a singleton, then Assumption SB implies Assumption A1 and hence in this case both assumptions are equivalent. Note that apart from Assumption SB it was also assumed in Shapiro and Bonnans [34] that the cone $Dg(x_0)X - K_0 + [g(x_0)]$ is closed.

4. First-order expansions of the solutions. In this section we discuss various expansions of solutions $\bar{z}(t) = (\bar{x}(t), \bar{\lambda}(t))$ of the generalized equations (P_t^*) and the corresponding optimal solution $\bar{x}(t)$ of the optimization problem (P_t). We assume throughout this section that a *unique* Lagrange multiplier λ_0, satisfying the first-order necessary conditions, corresponds to the optimal solution x_0. This assumption of uniqueness of λ_0 is quite restrictive. In this respect we would like to mention that some results derived in the case of finite-dimensional spaces and finite number of constraints suggest a close relation between the obtained formulas for directional derivatives of the optimal solutions and the *optimization* structure of the considered problems [4], [6], [31]. In particular, when Λ_0 is not a singleton, those formulas are related to duality properties of the optimization problems. These duality properties are not apparent in the equations representing the corresponding first-order optimality conditions. Therefore, in the author's opinion, the generalized equations approach is not very well suited for studying differentiability properties of the optimal solutions when Λ_0 is not a singleton.

Let us consider the generalized equations

$$(Q_t^*) \qquad 0 \in F(z) + H(t) + \Omega(z),$$

where $H(t) = F(z_0, t) - F(z_0, 0)$ and $z_0 = (x_0, \lambda_0)$.

ASSUMPTION A3. *For all positive t in a neighborhood of zero the generalized equations (Q_t^*) have a solution $z^*(t) = (x^*(t), \lambda^*(t))$ converging to z_0 as $t \to 0^+$.*

We employ in this section the following strong form of second-order sufficient conditions.

ASSUMPTION A4. *There exists a positive constant α such that*

$$\langle y, D_{xx}^2 L(x_0, \lambda_0, 0) y \rangle \geq \alpha \|y\|^2 \tag{4.1}$$

for all $y \in Z$, where

$$Z = \{y \in \overline{Sp(S)} : Dg(x_0)y \in \overline{Sp(K)}\}.$$

Note that $T_K(g(x_0)) \subset \overline{Sp(K)}$ and therefore Assumption A2 follows from Assumption A4. Note also that Assumption A4 implies existence of a quadratic form on the linear space Z which induces on Z a norm equivalent to the original norm of X restricted to Z. Endowed with this new norm, Z becomes a Hilbert space.

THEOREM 4.1. *Suppose that the point x_0 is regular, that the corresponding Lagrange multipliers set $\Lambda_0 = \{\lambda_0\}$ is a singleton, that Assumptions* A1, A3, *and* A4 *hold and let $\bar{z}(t) = (\bar{x}(t), \bar{\lambda}(t))$ be a solution of (P_t^*) converging to z_0. Then*

$$\|\bar{x}(t) - x^*(t)\| = o(t). \tag{4.2}$$

Proof. Let us first observe that by Theorem 2.1 it follows from Assumptions A1 and A4 that $\|\bar{z}(t) - z_0\|$, $\|z^*(t) - z_0\|$ and hence $\|\bar{z}(t) - z^*(t)\|$ are of order $O(t)$.

We argue now by a contradiction. Suppose that (4.2) is false. Then there are $t_n \to 0^+$, $\bar{z}_n = (\bar{x}_n, \bar{\lambda}_n) = \bar{z}(t_n)$ and $z_n^* = (x_n^*, \lambda_n^*) = z^*(t_n)$ such that

$$t_n \|\bar{x}_n - x_n^*\|^{-1} = O(t_n). \tag{4.3}$$

Since $-F(\bar{z}_n, t_n) \in \Omega(\bar{z}_n)$ and $-F(z_n^*) - H(t_n) \in \Omega(z_n^*)$ and $\Omega(z)$ is monotone, we have that

$$\langle F(\bar{z}_n, t_n) - F(z_n^*) - H(t_n),\ \bar{z}_n - z_n^* \rangle \leq 0. \tag{4.4}$$

We also have that

$$g(\bar{x}_n, t_n) - [g(x_n^*, 0) + g(x_0, t_n) - g(x_0, 0)] \in K + (-K). \tag{4.5}$$

By the mean value theorem, it follows from (4.5) that

$$Dg(x_0, 0)(\bar{x}_n - x_n^*) + o(t_n) \in Sp(K),$$

which, together with (4.3), implies

$$Dg(x_0, 0)(\bar{x}_n - x_n^*) + o(\|\bar{x}_n - x_n^*\|) \in Sp(K). \tag{4.6}$$

We also have that $\bar{x}_n, x_n^* \in S$ and hence $\bar{x}_n - x_n^* \in Sp(S)$. Moreover, since x_0 is regular, zero is a regular point of the linear mapping $Dg(x_0, 0)$ with respect to the set $\overline{Sp(S)}$ and the cone $\overline{Sp(K)}$. It follows therefore from (4.6) that there is $y_n \in Z$ such that $\|y_n - (\bar{x}_n - x_n^*)\| = o(\|\bar{x}_n - x_n^*\|)$.

By (1.2) and continuity arguments it follows then from Assumption A4 that for all n large enough and some $\beta > 0$,

$$\langle F(\bar{z}_n) - F(z_n^*),\ \bar{z}_n - z_n^* \rangle \geq \beta \|\bar{x}_n - x_n^*\|^2. \tag{4.7}$$

Inequalities (4.4) and (4.7) imply

$$\beta \|\bar{x}_n - x_n^*\|^2 \leq \langle F(\bar{z}_n) - F(\bar{z}_n, t_n) + H(t_n), \bar{z}_n - z_n^* \rangle$$

and hence

$$\beta \|\bar{x}_n - x_n^*\|^2 \leq \|F(\bar{z}_n, t_n) - F(\bar{z}_n) - H(t_n)\| \|\bar{z}_n - z_n^*\|. \tag{4.8}$$

Note that

$$\|F(\bar{z}_n, t_n) - F(\bar{z}_n) - H(t_n)\| = o(t_n). \tag{4.9}$$

Indeed, we have that

$$F(z_0, t) - F(z_0, 0) = t D_t F(z_0, 0) + o(t)$$

and by continuity of $D_t F(z, t)$

$$F(\bar{z}(t), t) - F(\bar{z}(t), 0) = t D_t F(z_0, 0) + o(t)$$

and hence (4.9) follows. Now since $\|\bar{z}_n - z_n^*\| = O(t_n)$ it follows then from (4.8) that

$$\|\bar{x}_n - x_n^*\|^2 = o(t_n^2)$$

which contradicts (4.3). □

Remarks. Uniqueness of the Lagrange multiplier λ_0 was used in the above theorem only to ensure that $\|\bar{\lambda}(t) - \lambda^*(t)\|$ is of order $O(t)$. If the set Λ_0 is not a singleton we can try to replace the function $H(t)$ in (Q_t^*) by

$$H(t) = F(\hat{z}(t), t) - F(\hat{z}(t), 0)$$

with $\hat{z}(t) = (x_0, \hat{\lambda}(t))$ and $\hat{\lambda}(t) \in \Lambda_0$ is such that $\|\bar{\lambda}(t) - \hat{\lambda}(t)\|$ and $\|\lambda^*(t) - \hat{\lambda}(t)\|$ are of order $O(t)$. It is not clear, however, what regularity conditions will be required to guarantee existence of such $\hat{\lambda}(t)$.

Similar results were obtained by Malanowski [18] under stronger regularity conditions and by using different techniques. Note that Assumption A4 and regularity of x_0 imply that the point x_0 is an isolated stationary solution of the program (P_0). Since the second-order conditions of Assumption A4 are retained under small perturbations, $\bar{x}(t)$ is also locally unique for all t sufficiently small. Note, however, that the assumptions of Theorem 4.1 do not guarantee local uniqueness of $\bar{\lambda}(t)$ or $\lambda^*(t)$. Therefore, to ensure that $\|\bar{z}(t) - z^*(t)\| = o(t)$, we must impose some additional conditions.

In the generalized equations (Q_t^*) we can linearize $F(z)$ and $H(t)$ as well. This leads to the following generalized equations:

$$(\mathcal{L}_t^*) \qquad 0 \in F(z_0) + DF(z_0)(z - z_0) + tD_tF(z_0, 0) + \Omega(z).$$

Suppose that for all sufficiently small $t \geq 0$ the generalized equations $(\mathcal{L}_t^*)$ have a solution $z'(t) = (x'(t), \lambda'(t))$ converging to z_0 as $t \to 0^+$. It is possible then to show that, under the assumptions of Theorem 4.1 (except Assumption A3, which is not required here),

$$\|\bar{x}(t) - x'(t)\| = o(t). \tag{4.10}$$

It is also possible to add an error term $\Upsilon(t)$ of order $o(t)$ to the right-hand sides of the generalized equations (Q_t^*) and $(\mathcal{L}_t^*)$.

Let us return to the optimization problem (P_t). The generalized equations $(\mathcal{L}_t^*)$ can be written in the form

$$\begin{aligned} 0 \in\ & D_xL(x_0, \lambda_0, 0) + D_{xx}^2L(x_0, \lambda_0, 0)(x - x_0) \\ & +(\lambda - \lambda_0) \circ Dg(x_0) + tD_{xt}^2L(x_0, \lambda_0, 0) + N_S(x), \\ & g(x_0) + Dg(x_0)(x - x_0) + tD_tg(x_0, 0) \in N_{K^-}(\lambda). \end{aligned} \tag{4.11}$$

Note that

$$D_xL(x_0, \lambda_0, 0) - \lambda_0 \circ Dg(x_0) = Df(x_0)$$

and therefore the generalized equations $(\mathcal{L}_t^*)$ correspond to the optimization problem

$$(\mathcal{L}_t) \qquad \begin{aligned} \min_{x \in S} \quad & \langle x - x_0, Df(x_0) + tD_{xt}^2L(x_0, \lambda_0, 0)\rangle \\ & + \tfrac{1}{2}\langle x - x_0, D_{xx}^2L(x_0, \lambda_0, 0)(x - x_0)\rangle \\ \text{subject to} \quad & g(x_0) + Dg(x_0)(x - x_0) + tD_tg(x_0, 0) \in K. \end{aligned}$$

For every t the feasible set of the program $(\mathcal{L}_t)$ is convex and, because of the second-order condition (4.1) of Assumption A4, the objective function of $(\mathcal{L}_t)$ is convex on the linear space generated by this feasible set. By (4.11) it follows then that x_0 is the optimal solution of $(\mathcal{L}_0)$. Moreover, by Assumption A4 and regularity of x_0 we have here that for all t the program $(\mathcal{L}_t)$ has a unique optimal solution $x'(t)$ and $x'(t) \to x_0$ as $t \to 0^+$ (see the proof of Theorem 2 in [34]). Together with Theorem 4.1 this implies the following result.

THEOREM 4.2. *Consider the optimal solution $x'(t)$ of $(\mathcal{L}_t)$. Suppose that the point x_0 is regular, that $\Lambda_0 = \{\lambda_0\}$ is a singleton, that Assumptions* A1 *and* A4 *hold and let $\bar{x}(t)$ be an optimal solution of (P_t) converging to x_0 as $t \to 0^+$. Then*

$$\|\bar{x}(t) - x'(t)\| = o(t). \tag{4.12}$$

Remarks. Let $S = X$ and suppose that the point x_0 is regular with respect to the cone $K_0 = K(\lambda_0)$. By Proposition 3.1 we have then that λ_0 is unique and Assumption A1 holds. It follows that in this case second-order conditions of Assumption A4 imply the first-order equivalence (4.12) between optimal solutions of the programs (P_t) and $(\mathcal{L}_t)$. Note also that $\bar{x}(t)$ in Theorem 4.2 can be an $\epsilon(t)$-optimal solution of (P_t) with $\epsilon(t) = o(t^2)$.

DEFINITION. *We say that a closed convex set C is conical at a point $y \in C$ if $C - y$ locally coincides with the tangent cone $T_C(y)$, i.e., there is a neighborhood W of y such that $C \cap W = (y + T_C(y)) \cap W$.*

For example, a convex polyhedron in a finite-dimensional space is conical at every point and any closed convex cone is conical at $y = 0$.

Let us consider again generalized equations (4.11). Denote $y = x - x_0$, $\mu = \lambda - \lambda_0$ and substitute $N(\mu, K^- - \lambda_0)$ in place of the cone $N(\lambda, K^-)$. Suppose now that K^- is *conical* at λ_0. Then for all t sufficiently close to zero we can further replace $K^- - \lambda_0$ by $T(\lambda_0, K^-)$. Note that

$$T(\lambda_0, K^-) = \overline{K^- + [\lambda_0]} = K(\lambda_0)^- = K_0^-.$$

Therefore the obtained generalized equations will correspond to the optimization problem

$$(\mathcal{M}_t) \qquad \begin{array}{ll} \min_{y \in S - x_0} & \langle y, D_x L(x_0, \lambda_0, 0) + t D^2_{xt} L(x_0, \lambda_0, 0) \rangle \\ & + \frac{1}{2} \langle y, D^2_{xx} L(x_0, \lambda_0, 0) y \rangle \\ \text{subject to} & g(x_0) + Dg(x_0) y + t D_t g(x_0, 0) \in K_0. \end{array}$$

We obtain the following result (cf. [32, Thm. 4.4]).

COROLLARY 4.3. *Suppose that the assumptions of Theorem 4.2 hold, that K^- is conical at λ_0 and let $y'(t)$ be the optimal solution of $(\mathcal{M}_t)$. Then*

$$\|\bar{x}(t) - x_0 - y'(t)\| = o(t). \tag{4.13}$$

Suppose further that the set S is also conical at x_0. Then for all $z = (x, \lambda)$ sufficiently close to $z_0 = (x_0, \lambda_0)$, the normal cone $N(z, S \times K^-)$ coincides with the normal cone $N(z, z_0 + \Sigma)$, where

$$\Sigma = T_{S \times K^-}(z_0) = T_S(x_0) \times T_{K^-}(\lambda_0) = T_S(x_0) \times K_0^-.$$

Therefore for t small enough, solutions of the generalized equations $(\mathcal{L}_t^*)$ will coincide with solutions of the generalized equations

$$(\mathcal{L}'_t) \qquad 0 \in F(z_0) + DF(z_0)(z - z_0) + t D_t F(z_0, 0) + N_\Sigma(z - z_0).$$

Let us consider the generalized equations

$$(\mathcal{N}_t^*) \qquad 0 \in DF(z_0) v + t D_t F(z_0, 0) + N(v, \Sigma_0),$$

where

$$\Sigma_0 = \{v \in \Sigma : \langle F(z_0), v \rangle = 0\}.$$

For $t = 1$ we write $(\mathcal{N}^*)$ to denote the generalized equations $(\mathcal{N}_1^*)$. Note that solutions of $(\mathcal{N}_t^*)$ are linear in t. That is, if $\bar{v}$ is a solution of $(\mathcal{N}^*)$, then $t\bar{v}$ is a solution of $(\mathcal{N}_t^*)$.

LEMMA 4.4. *Consider the optimal solution $x'(t)$ of $(\mathcal{L}_t)$. Suppose that the assumptions of Theorem 4.2 hold, that the sets S and K^- are conical at the points x_0 and λ_0, respectively, and let $\bar{v} = (\bar{y}, \bar{\mu})$ be a solution of $(\mathcal{N}^*)$. Then*

$$\|x'(t) - x_0 - t\bar{y}\| = o(t). \tag{4.14}$$

Proof. Let $\lambda'(t)$ be a Lagrange multiplier corresponding to the optimal solution $x'(t)$ of $(\mathcal{L}_t)$. Then $z'(t) = (x'(t), \lambda'(t))$ is a solution of $(\mathcal{L}_t^*)$. Denote $v'(t) = z'(t) - z_0$. By Theorem 2.1 we have that

$$\|v'(t)\| = O(t), \tag{4.15}$$

and hence for all t small enough $z'(t)$ is a solution of $(\mathcal{L}_t')$. Since $z'(t)$ is solution of $(\mathcal{L}_t')$ we have that

$$\langle F(z_0) + DF(z_0)v'(t) + tD_tF(z_0, 0), v'(t)\rangle = 0,$$

and since $\bar{v} \in \Sigma$

$$\langle F(z_0) + DF(z_0)v'(t) + tD_tF(z_0, 0), t\bar{v}\rangle \geq 0.$$

It follows that

$$\langle F(z_0) + DF(z_0)v'(t) + tD_tF(z_0, 0), v'(t) - t\bar{v}\rangle \leq 0. \tag{4.16}$$

Also since $\bar{v}$ is a solution of $(\mathcal{N}^*)$ we have

$$\langle DF(z_0)\bar{v} + D_tF(z_0, 0), \bar{v}\rangle = 0.$$

Moreover, by the definition of Σ_0,

$$\langle F(z_0), \bar{v}\rangle = 0$$

and hence

$$\langle F(z_0) + tDF(z_0)\bar{v} + tD_tF(z_0, 0), \bar{v}\rangle = 0. \tag{4.17}$$

Note that z_0 is a solution of $(\mathcal{L}_0')$ and that $-F(z_0) \in \Sigma^-$. We also have that

$$-DF(z_0)\bar{v} - D_tF(z_0, 0) \in \Sigma_0^- = T(-F(z_0), \Sigma^-).$$

Therefore

$$\operatorname{dist}(-F(z_0) - tDF(z_0)\bar{v} - tD_tF(z_0, 0), \Sigma^-) = o(t)$$

and hence there exists $F'(t) \in \Sigma^-$ such that

$$\| - F(z_0) - tDF(z_0)\bar{v} - tD_tF(z_0, 0) - F'(t)\| = o(t).$$

Since

$$\langle F'(t), v'(t)\rangle \leq 0$$

and because of (4.15) we obtain then

$$-\langle F(z_0) + tDF(z_0)\bar{v} + tD_tF(z_0,0), v'(t)\rangle \leq o(t^2).$$

Together with (4.17) this implies

$$-\langle F(z_0) + tDF(z_0)\bar{v} + tD_tF(z_0,0), v'(t) - t\bar{v}\rangle \leq o(t^2). \tag{4.18}$$

It follows from (4.16) and (4.18) that

$$\langle DF(z_0)(v'(t) - t\bar{v}), v'(t) - t\bar{v}\rangle \leq o(t^2). \tag{4.19}$$

On the other hand Assumption A4 implies

$$\langle DF(z_0)(v'(t) - t\bar{v}), v'(t) - t\bar{v}\rangle \geq \alpha\|x'(t) - x_0 - t\bar{y}\|^2. \tag{4.20}$$

Inequalities (4.18) and (4.20) imply (4.14) and hence the proof is complete. □

Generalized equations $(\mathcal{N}^*)$ correspond to the optimization problem

$$(\mathcal{N}) \qquad \begin{array}{ll} \min_{y\in T_0} & \langle y, D^2_{xt}L(x_0,\lambda_0,0)\rangle + \frac{1}{2}\langle y, D^2_{xx}L(x_0,\lambda_0,0)y\rangle \\ \text{subject to} & Dg(x_0)y + D_tg(x_0,0) \in T(g(x_0), K_0), \end{array}$$

where

$$T_0 = \{y \in T_S(x_0) : \ \langle D_xL(x_0,\lambda_0,0), y\rangle = 0\}.$$

Theorem 4.2 and Lemma 4.1 imply the following result.

THEOREM 4.5. *Suppose that the assumptions of Theorem* 4.2 *hold, that the sets* S *and* K^- *are conical at* x_0 *and* λ_0*, respectively, and let* $\bar{y}$ *be an optimal solution of the optimization problem* $(\mathcal{N})$*. Then* $\bar{x}(t)$ *is right side differentiable at* $t = 0$ *and* $d^+\bar{x}(0)/dt$ *is equal to* $\bar{y}$*.*

Note that under Assumption A4 the optimization problem $(\mathcal{N})$ is convex and it has a unique optimal solution provided its feasible set is nonempty.

5. Concluding remarks and semi-infinite programming example. Our basic regularity assumptions are related to the *unperturbed* optimization problems and the corresponding generalized equations when the parameter value $t = 0$. Therefore, although for $t = 0$ the generalized equations are explicitly related to the associated optimization problems, the considered generalized equations need not be connected to a particular optimization problem for other values of $t > 0$. Also we can formulate the required regularity assumptions directly in terms of generalized equations without referring to the respective optimization problems. This will make the presented theory more abstract although possibly with a wider range of applications. As another remark we mention that, for the sake of simplicity, the parameter t was considered to be a scalar varying in the parameter set $\Re_+$. It is possible to extend our results to other, normed or metric, parameter spaces as well.

In the remainder of this section we discuss, as an example, semi-infinite programming problems. This will provide us with some interesting counterexamples and will show what can go wrong. We assume now that the space X is finite-dimensional, say $X = \Re^n$, and that the feasible set $\Phi(t)$ of the program (P_t) is given in the form

$$\Phi(t) = \{x \in X : \ h(x,t,\tau) \leq 0, \ \ \tau \in T\}, \tag{5.1}$$

where $h(x,t,\tau)$ is a real-valued function and T is a compact subset of $\Re^m$ (equipped with the Euclidean norm $\|\cdot\|$). It will be assumed that for every $\tau \in T$, $h(x,t,\tau)$ is twice differentiable jointly in x and t and that $h(x,t,\tau)$ together with the first- and second-order derivativs in (x,t) are continuous on $X \times \Re_+ \times T$.

Semi-infinite programming problems can be analysed by the so-called reduction method. That is, the feasible set $\Phi(t)$ can be defined by one constraint $m(x,t) \leq 0$, where $m(x,t) = \max_{\tau \in T} h(x,t,\tau)$. In certain situations the max-function $m(x,t)$ can be represented as maximum of a finite number of smooth functions and consequently the problem can be reduced to a nonlinear programming problem with a finite number of constraints (cf. [11], [13], [15], [30]). Our approach here will be different. We propose a direct analysis of the semi-infinite programs by employing results of §§2 and 4.

Denote by $\Delta(x,t)$ the set

$$\Delta(x,t) = \{\tau \in T : h(x,t,\tau) = 0\}$$

of active at (x,t) constraints. Note that if x is a feasible point of the program (P_t) and the set $\Delta(x,t)$ is nonempty, then $\Delta(x,t)$ represents the set of maximizers of $h(x,t,\cdot)$ over T. Unless stated otherwise all gradients will be written with respect to x.

The following first-order necessary conditions for the considered semi-infinite programming problem (P_0) are well known (e.g., [20]). If x_0 is an optimal solution of (P_0), then there exist $\tau_i \in \Delta(x_0)$, $i = 1,\ldots,n$, and nonnegative multipliers $\lambda_0, \lambda_1, \ldots, \lambda_n$, not all of them zero, such that

$$\lambda_0 \nabla f(x_0) + \sum_{i=1}^{n} \lambda_i \nabla h(x_0, 0, \tau_i) = 0. \tag{5.2}$$

The feasible set $\Phi(t)$, given in (5.1), can be written in the form of cone constraints as follows. Consider the normed space $Y = C(T)$ of continuous functions $y : T \to \Re$, equipped with the sup-norm

$$\|y\|_\infty = sup\{|y(\tau)| : \tau \in T\},$$

and the cone $K \subset C(T)$ formed by nonpositive valued continuous functions $y(\tau)$. Consider also the mapping $g : X \times \Re_+ \to Y$ taking a point (x,t) into the function $y = g(x,t)$, $y(\cdot) = h(x,t,\cdot)$. Then the feasible set $\Phi(t)$ is formed by points $x \in X$ such that $g(x,t) \in K$. It follows from the above differentiability assumptions for the function $h(x,t,\tau)$ that the mapping g is twice continuously differentiable and, for example,

$$[D_x g(x,t)v](\cdot) = v \cdot \nabla h(x,t,\cdot).$$

The dual space Y^* of $Y = C(T)$ is the space of finite signed measures on $(T, \mathcal{B})$, where $\mathcal{B}$ is the Borel σ-algebra of T, with the norm given by the total variation of the corresponding measure. The polar cone K^- of the cone K is formed by the set of nonnegative Borel measures on T.

Assume further that there exist a vector $v \in X$ such that

$$v \cdot \nabla h(x_0, 0, \tau) < 0, \quad \text{for all } \tau \in \Delta(x_0). \tag{5.3}$$

(For the unperturbed program we sometimes omit $t = 0$ and write $g(x)$, $\Delta(x)$, etc.) In case the set T is finite this is the Mangasarian–Fromovitz constraint qualification.

Under condition (5.3) the multiplier λ_0 in (5.2) is nonzero and can be taken $\lambda_0 = 1$. It is also not difficult to show that (5.3) is *equivalent* to the condition that the point x_0 is a regular point (in the sense of Robinson [23]) of the mapping $g(x)$ with respect to the cone K (see [33]).

Consider the discrete measure

$$\mu = \sum_{i=1}^{n} \lambda_i \delta(\tau_i), \tag{5.4}$$

where $\delta(\tau)$ denotes the measure of mass one at the point τ and λ_i are the multipliers in (5.2) corresponding to the points $\tau_i \in \Delta(x_0)$. This measure μ represents a Lagrange multiplier, corresponding to the optimal solution x_0, in the dual space Y^*. Let us observe now that the cone K^- is *conical* at μ. Consequently Assumption SB (discussed in §3) holds at μ. (Assumption SB is implied by the property $T(\mu, K^-) = R(\mu, K^-)$, where $R(\mu, K^-)$ denotes the radial cone to K^- at μ, see [34].) On the other hand, in general, Assumption A1 is not satisfied here. The total variation norm distance between two atomic measures $\mu_1 = \alpha_1\delta(\tau_1)$ and $\mu_2 = \alpha_2\delta(\tau_2)$ equals $|\alpha_1| + |\alpha_2|$ provided $\tau_1 \neq \tau_2$. Therefore even small changes in values of τ_i in (5.4) can result in a finite jump in the distance between the corresponding measures. This shows that the results of §§2 and 4 cannot be applied in a straightforward manner in the considered framework of the space $C(T)$. The corresponding Lipschitzian stability result of Shapiro and Bonnans [34] cannot be applied here in a straightforward way either and this is becuase typically in the present case the cone $Dg(x_0) - K_0 + [g(x_0]$ is not closed. A slightly modified approach of [34], however, leads to a description of the Lipschitzian stability of optimal solutions of semi-infinite programs (see [33] for details).

It is also interesting to note that if the set $\Delta(x_0)$ is finite and the gradients $\nabla h(x_0, 0, \tau)$, $\tau \in \Delta(x_0)$, are linearly independent, then the corresponding measure μ, given in (5.4), represents the *unique* Lagrange multiplier. However, the point x_0 here is not a regular point of $g(x)$ with respect to the cone $K_0 = K(\mu)$. This can be compared with a result in [32, Lemma 4.3]. It was shown there that regularity of x_0 with respect to K_0 is ensured by (i) uniqueness of μ, (ii) the conical property, and (iii) closedness of $Dg(x_0) - K_0 + [g(x_0]$. Again the last condition (iii) is violated here.

Let us finish this section by suggesting an alternative approach to sensitivity analysis of semi-infinite programs. The above choice of the Banach space $C(T)$ was quite arbitrary. It failed because even small perturbations in the support of the considered measures could result in large changes in the corresponding distances with respect to the considered dual norm. Let us consider now the space $Y = \mathrm{Lip}(T)$ of Lipschitz continuous functions $y(\tau)$ equipped with the norm

$$\|y\|_L = \|y\|_\infty + \sigma(y),$$

where

$$\sigma(y) = \sup\left\{\frac{|y(\tau_1) - y(\tau_2)|}{\|\tau_1 - \tau_2\|} : \tau_1, \tau_2 \in T,\ \tau_1 \neq \tau_2\right\}$$

is the Lipschitz constant of the function $y(\tau)$. To every finite signed Borel measure on T will still correspond a linear bounded functional on $\mathrm{Lip}(T)$ (although such measures will not form *all* possible bounded linear functionals on $\mathrm{Lip}(T)$). If we consider now two atomic measures $\mu_1 = \alpha_1\delta(\tau_1)$ and $\mu_2 = \alpha_2\delta(\tau_2)$, then

$$\|\mu_1 - \mu_2\|_L \leq |\alpha_1|\|\tau_1 - \tau_2\| + |\alpha_1 - \alpha_2|.$$

Suppose now that for all x and t the functions $h(x,t,\cdot)$ together with the first and second-order deravatives with respect to x and t, are Lipschitz continuous on T and that these functions are continuous in (x,t) with respect to the norm $\|\cdot\|_L$. Then the mapping $g(x,t)$, defined as above, becomes a twice continuously differentiable mapping from $X \times \Re_+$ into $\mathrm{Lip}(T)$. Suppose further that

(i) The set $\Delta(x_0) = \{\tau_1, ..., \tau_k\}$ is finite.

(ii) Condition (5.3) holds.

(iii) The multifunction $\Delta(x,t)$ is upper Lipschitzian at $(x_0,0)$, i.e., there exists a positive constant c such that for all $(x,t) \in \Phi(t)$ in a neighborhood of $(x_0,0)$ and all $\tau \in \Delta(x,t)$

$$\mathrm{dist}(\tau, \Delta(x_0)) \leq c(\|x - x_0\| + |t|). \tag{5.5}$$

(iv) For all $(x,t) \in \Phi(t)$ sufficiently close to $(x_0,0)$ and all $i = 1,\ldots,k$, the set $\Delta(x,t)$ cannot have two points in a neighborhood of the point τ_i.

Consider the set Λ_0 of vectors $\lambda = (\lambda_1,\ldots,\lambda_k)$ with nonnegative components λ_i, $i = 1,\ldots,k$, satisfying the condition

$$\nabla f(x_0) + \sum_{i=1}^{k} \lambda_i \nabla h(x_0, 0, \tau_i) = 0. \tag{5.6}$$

By the above condition (ii), the set Λ_0 is nonempty and bounded. Moreover, condition (ii) guarantees that if $\bar{x}(t)$ is an optimal solution of (P_t) sufficiently close to x_0 and t is small enough, then there exist points $\bar{\tau}_i = \bar{\tau}_i(t) \in \Delta(\bar{x}(t),t)$ and nonnegative multipliers $\bar{\lambda}_i = \bar{\lambda}_i(t)$, $i = 1,\ldots,n$, such that

$$\nabla f(\bar{x}(t),t) + \sum_{i=1}^{n} \bar{\lambda}_i \nabla h(\bar{x}(t), t, \bar{\tau}_i) = 0. \tag{5.7}$$

Also by condition (iii), for every $\bar{\tau}_i$ there is $\tau_i \in \Delta(x_0)$ such that

$$\|\bar{\tau}_i - \tau_i\| = O(\|\bar{x}(t) - x_0\| + t). \tag{5.8}$$

Actually because of the condition (iv), by adding zero multipliers if necessary, we can always assume that the number of multipliers in (5.7) is the same as in (5.6) and that condition (5.8) holds for all $i = 1,\ldots,k$. Consider vector $\bar{\lambda}(t) = (\bar{\lambda}_1(t),\ldots,\bar{\lambda}_k(t))$. It follows then from (5.8) that

$$\mathrm{dist}(\bar{\lambda}(t), \Lambda_0) = O(\|\bar{x}(t) - x_0\| + t).$$

If we consider now the set M_0 of discrete mesures $\mu = \sum_{i=1}^{k} \lambda_i \delta(\tau_i)$ corresponding to the multipliers of the set Λ_0 and the discrete measure $\bar{\mu}(t)$ corresponding to $\bar{\lambda}(t)$, we obtain that the set M_0 is bounded and

$$\mathrm{dist}(\bar{\mu}(t), M_0) = O(\|\bar{x}(t) - x_0\| + t),$$

where the distance is taken with respect to the dual norm of the norm $\|\cdot\|_L$. It follows then by the results of §2 that, under suitable second-order sufficient conditions, the optimal solutions $\bar{x}(t)$ of (P_t) are *Lipschitz stable* at $t = 0$.

Finally let us remark that if in addition to the above conditions we assume that the set $\Lambda_0 = \{\lambda_0\}$ is a singleton, then the result of theorem 4.2 will apply. Consequently we obtain that, under suitable second-order conditions, an optimal solution

$\bar{x}(t)$ of (P_t) can be first-order approximated by the optimal solution of the semi-infinite programming problem

$$(\mathcal{S}_t) \qquad \begin{array}{ll} \min_{x \in X} & (x - x_0) \cdot [\nabla f(x_0) + t \nabla^2_{xt} L(x_0, \lambda_0, 0)] \\ & + \frac{1}{2}(x - x_0) \cdot \nabla^2_{xx} L(x_0, \lambda_0, 0)(x - x_0) \\ \text{subject to} & (x - x_0) \cdot a(\tau) + b(t, \tau) \leq 0, \quad \tau \in T, \end{array}$$

where $L(x, \lambda, t) = f(x, t) + \sum_{i=1}^{k} \lambda_i h(x, t, \tau_i)$ with τ_i, $i = 1, \ldots, k$, being the points forming the set $\Delta(x_0)$, $a(\tau) = \nabla h(x_0, \tau)$ *and* $b(t, \tau) = h(x_0, \tau) + t \partial h(x_0, 0, \tau)/\partial t$.

SIMULTANEOUS STABILIZATION OF THREE OR MORE PLANTS: CONDITIONS ON THE POSITIVE REAL AXIS DO NOT SUFFICE*

V. BLONDEL†, M. GEVERS†, R. MORTINI‡, AND R. RUPP‡

Abstract. The problem of the simultaneous stabilizability of a finite family of single-input, single-output time-invariant systems by a time-invariant controller is studied. The link between stabilization and avoidance is shown and is used to derive necessary conditions for the simultaneous stabilization of k plants. These necessary conditions are proved to be, in general, not sufficient. This result also disproves a long-standing conjecture on the stabilizability condition of a single plant with a stable minimum phase controller. The main result is to show that, unlike the case of two plants, the existence of a simultaneous stabilizing controller for more than two plants is not guaranteed by the existence of a controller such that the closed loops have no *real* unstable poles.

Key words. stabilization, simultaneous stabilization, strong stabilization, interpolation, avoidance

1. Introduction.

Do you believe that simple questions always have simple answers? If you do, you may consider with interest the following problem: let

$$p_1(s) = 0, \quad p_2(s) = \frac{2}{17}\frac{(s-1)}{(s+1)}, \quad \text{and } p_3(s) = \frac{(s-1)^2}{(9s-8)(s+1)}$$

be three continuous-time rational transfer functions. Is it possible to find a single rational controller $c(s)$ that simultaneously stabilizes $p_i(s)$, $i = 1, 2, 3$ (i.e., such that the closed-loop transfer functions $p_i(s)c(s)(1+p_i(s)c(s))^{-1}$ have no poles in the complex right half plane for $i = 1, 2, 3$)? The question may not look too hard: it merely asks whether or not three plants are *simultaneously stabilizable* by a single controller. At present nobody is capable of answering such a question, and this paper is devoted to it.

Let us first state the problem clearly. We restrict our attention to single-input, single-output systems that are described by linear, time-invariant, rational but not necessarily proper transfer functions. Each one of these systems is thus represented by an arbitrary real rational function $p_i(s) \in \mathbb{R}(s)$, $i = 1, \ldots, k$. To control our systems, we allow ourselves to use a dynamic but time-invariant, rational and not necessarily proper controller $c(s) \in \mathbb{R}(s)$. Finally, our goal is to achieve continuous-time closed-loop internal stability with the controller. That is, we want that, with the chosen controller $c(s)$, the four transfer functions $p_ic(1+p_ic)^{-1}, p_i(1+p_ic)^{-1}, c(1+p_ic)^{-1}$, and $(1+p_ic)^{-1}$ have no poles in the extended right half plane. Our question is now: Under what conditions on the plants $p_i(s)$, $i = 1, \ldots, k$ is it possible to find such a simultaneous stabilizing controller? This problem has been formulated for some years now (see, e.g., [3], [5], [12], [14]–[18], [26], [27], [34]) and, despite many efforts, it has remained unsolved for $k \geq 3$. It is nowadays commonly referred to

as the *simultaneous stabilization problem* and is recognized as one of the hard open problems in linear systems theory.

Although this paper does not solve the simultaneous stabilization problem, we provide some fresh angle of attack. By introducing the concept of avoidance, we produce a range of new necessary and sufficient conditions and, more importantly, we prove a negative result by showing that, unlike the case $k = 2$, the simultaneous stabilizability question of more than two plants cannot be answered by just checking whether a controller exists such that the closed-loop transfer functions have no *real* unstable poles.

We draw the reader's attention to the crucial point that we allow ourselves the use only of a *time-invariant* controller. It is not always possible to stabilize simultaneously two or more plants with such a controller. To overcome this limitation, alternative strategies have recently been developed with time-varying controllers, and we refer the reader to the existing literature for more details on this subject (see, for example, [18] and references therein). This paper deals only with the time-invariant case.

Historically, the first line of attack on the simultaneous stabilization question was given through the solution of a seemingly unrelated question: "When is it possible to stabilize a single plant with a *stable* controller?" This question, known as the *strong stabilization problem*, was fully solved by Youla, Bongiorno, and Lu [32] in a now classical paper. A plant is stabilizable by a stable controller if and only if it has an even number of real unstable poles between each pair of real unstable zeros. Such plants are said to have the *parity interlacing property*. A most remarkable feature of this condition is that it involves only the *real* unstable poles and zeros of the plant.

The link between strong stabilization and simultaneous stabilization of two plants was discovered, and used, by Saeks and Murray [23]. Roughly speaking, two plants p_1 and p_2 are simultaneously stabilizable if and only if the plant $p_1 - p_2$ is strongly stabilizable. Since a tractable condition for strong stabilization is known, this solves the problem of simultaneous stabilization of two plants. This result was further extended to a multi-input, multi-output setting by Vidyasagar and Viswanadham [26], where it was shown that from k plants p_i, $i = 1, \ldots, k$ it is possible to construct $k-1$ plants p'_i, $i = 1, \ldots, k-1$ in such a way that the plants p_i are simultaneously stabilizable if and only if the plants p'_i are simultaneously stabilizable by a *stable* controller. This equivalence, while theoretically interesting, does not provide a computable test for the simultaneous stabilization of three or more plants, since we have no criteria to decide if two or more plants are simultaneously stabilizable by a stable controller.

After these results were obtained, the main contributions to simultaneous stabilization this last decade have been in the form of necessary or sufficient conditions for simultaneous stabilization (but never necessary *and* sufficient conditions). *At present no tractable necessary and sufficient conditions exist for simultaneous stabilization except for the case of two plants.*

The simultaneous stabilization of two plants is equivalent, as stated above, to the stabilization of a single plant by a stable controller. This idea can be extended to the simultaneous stabilization of three plants. Modulo an avoidance condition, the simultaneous stabilization of three plants is equivalent to the stabilization of a single plant by a stable controller whose inverse is also stable. Such a controller is called a *unit* controller. The problem of finding a condition under which a plant p can be stabilized by a unit controller can thus be seen as an intermediate step towards the solution of the simultaneous stabilization of three plants. It is easy to see that a necessary condition is that both p and p^{-1} must have the parity interlacing

property, i.e., p must have an even number of real unstable poles between each pair of real unstable zeros and vice versa. Such plants are referred to as having the *even interlacing property*. It is shown in [29] that this even interlacing property condition is also sufficient to ensure that the plant p is stabilizable by a stable controller with no *real* unstable zeros. Note that such a controller may have complex unstable zeros, so that the result of [29] does not prove that the even interlacing property of a plant p is sufficient for stabilization by a unit controller. The even interlacing property also ensures that there exists a unit controller such that the closed-loop transfer function has no *real* unstable poles. In the same vein, [30] and [31] give a condition on three plants p_1, p_2, and p_3 under which it is possible to find a single controller such that none of the closed-loop transfer functions have *real* unstable poles.

In the first part of this paper, we pursue this line of thinking, and we give a thorough study of the question: "Given k plants p_i, $i = 1, \ldots, k$, under what condition is it possible to find a single controller such that none of the closed-loop transfer functions have *real* unstable poles?" Motivations to develop such results are threefold. First, the conditions obtained are tractable, which is seldom the case for simultaneous stabilization questions. Second, such conditions remain necessary when the closed-loop transfer functions are constrained not only to have no *real* unstable poles but no unstable poles at all. They are therefore necessary conditions for simultaneous stabilization. Third, it is known that these conditions are also sufficient for the strong stabilization of a single plant and for the simultaneous stabilization of two plants. A single plant is stabilizable by a stable controller if and only if there exists a stable controller such that the closed-loop transfer function has no *real* unstable poles. Two plants, p_1 and p_2, are simultaneously stabilizable if and only if there exists a single controller such that the closed-loop transfer functions associated to p_1 and to p_2 have no real unstable poles. By analogy, it was hoped (see, for example, the conclusion in [30]) that this property would extend to the simultaneous stabilization problem for three or more plants. As we shall see at the very end of the paper, this is unfortunately not the case.

The main contributions of this paper have been briefly described above. The layout is as follows. We introduce, in §3, the simultaneous stabilization problem as an avoidance problem in the complex plane. We show that k plants are simultaneously stabilizable if and only if there exists a controller that avoids, in a way that we will define, the k plants in the complex right half plane. This reinterpretation in terms of avoidance (i.e., nonintersection) of functions gives powerful new insights into stabilization and simultaneous stabilization problems. We use these insights in §4, where, after a quick review of some known results, we answer the question: "Given k plants p_i, $i = 1, \ldots, k$, under what condition is it possible to find a single controller such that the closed-loop transfer functions associated with each plant have no *real* unstable poles?" Strikingly, we show that under a weak assumption this can be achieved if and only if for each *pair of plants* there exist such stabilizing controllers. The fulfillment of these conditions can be checked by using the parity interlacing property so that we have a tractable test to answer the above question. Finally, in §5 we present negative results. We first show that the even interlacing property is not sufficient for stabilizability of a plant by a unit controller. It then follows that the condition given in [30] and presented in §4 is not sufficient either for simultaneous stabilization of three plants.

2. Notation. $\mathbb{R}[s]$ is the set of real polynomials. $\mathbb{R}(s)$ is the set of real rational functions. $\mathbb{C}_\infty$ is the extended complex plane, $\mathbb{C} \cup \{\infty\}$, adequately topologized, and

$\mathbb{R}_\infty$ is the extended real line, $\mathbb{R} \cup \{\infty\}$. D is the open unit disc $\{s \in \mathbb{C} :\mid s \mid < 1\}$. Ω is some chosen subset of $\mathbb{C}_\infty$. We shall assume throughout this paper that Ω is closed in the Riemann sphere topology, that it is symmetric with respect to the real axis, and that it contains at least one value of the extended real line $\mathbb{R}_\infty$ but not the whole extended real line $\mathbb{R}_\infty$. Ω is to be thought of as the complement in $\mathbb{C}_\infty$ of a region of stability. Classical examples of regions Ω are the closed unit disc $\overline{D} = \{s \in \mathbb{C} :\mid s \mid \leq 1\}$ and the extended closed right half plane $\mathbb{C}_{+\infty} = \{s \in \mathbb{C} : \Re(s) \geq 0\} \cup \{\infty\}$, which correspond, respectively, to the complement in $\mathbb{C}_\infty$ of the discrete and continuous-time stability regions. We define $I = \overline{D} \cap \mathbb{R}_\infty = [-1, 1]$ and $\mathbb{R}_{+\infty} = \mathbb{C}_{+\infty} \cap \mathbb{R}_\infty = [0, \infty]$. The subsets $\overline{D}, \mathbb{C}_{+\infty}, I$, and $\mathbb{R}_{+\infty}$ all satisfy the assumptions on Ω. A real rational function is Ω-*stable* if it has no poles in Ω. $S(\Omega)$ is the set of all Ω-stable rational functions. We use $U(\Omega)$ to denote the set of functions in $S(\Omega)$ whose inverses are in $S(\Omega)$, and we call such rational functions Ω-*units*. Finally, to shorten the notation, we define $U = U(\mathbb{C}_{+\infty})$ and $S = S(\mathbb{C}_{+\infty})$.

3. Stabilization as avoidance. The equivalence between the solvability of the simultaneous stabilization problem of two plants and interpolation conditions by real rational functions was pointed out by various authors (see [32], [25] [13], [15], [8], and [17]). By a few algebraic manipulations it is possible to show that the problem of stabilizing two plants simultaneously is equivalent to that of finding a stable rational function having a stable inverse that interpolates a set of values at a set of points in the right half plane. This interpretation of the problem has the advantage of giving a geometrical insight to the problem. In this section we develop a different view of the problem, which we call an *avoidance* approach. Roughly speaking, a controller stabilizes a set of k plants if and only if it avoids, in a sense that we shall define, the k plants in the extended right half plane. By the end of this section we hope that we will have convinced the reader that stabilization and avoidance are different names for the same mathematical question. We refer the reader to [6] or [7] for more details on avoidance concepts applied to simultaneous stabilization problems.

3.1. Internal stabilization. Throughout this paper we shall consider a controller to be within a unity feedback loop with the plant, and we shall adopt the following usual definition of stability for this closed-loop configuration.

DEFINITION 3.1. *A controller* $c(s) \in \mathbb{R}(s)$ *is an* internal stabilizer *of (or* internally stabilizes*) a plant* $p(s) \in \mathbb{R}(s)$ *if the four transfer functions* $p(s)c(s)(1 + p(s)c(s))^{-1}$, $c(s)(1 + p(s)c(s))^{-1}$, $p(s)(1 + p(s)c(s))^{-1}$, *and* $(1 + p(s)c(s))^{-1}$ *belong to* S *(i.e., they have no poles with nonnegative real part).*

These four unpractical conditions for internal stability can elegantly be condensed into a single one by using the so-called *factorization approach* described in [24] and [23]. Hereafter we give a short introduction to this approach and refer the interested reader to [24] for more details. In the sequel we will always mean *internal stability* when writing *stability.*

It is easy to check that the set S of stable rational functions is a commutative ring. The invertible elements (or units) in the ring S are the stable real rational functions whose inverses are stable, that is, the real rational functions with neither poles nor zeros in $\mathbb{C}_{+\infty}$. We have denoted this set by U. Two elements of S are called *coprime* if they have no common zeros in $\mathbb{C}_{+\infty}$. It can be proved (see [24, p. 10]) that S is an Euclidean ring and hence, if $a(s), b(s) \in S$ are coprime, then there exists $x(s), y(s) \in S$ such that $a(s)x(s) + b(s)y(s) = 1$. Such an identity is called a *Bezout identity.* Finally, the field of fractions of S is $\mathbb{R}(s)$. All this together shows that if $p(s) \in \mathbb{R}(s)$, then there exist $n_p(s), d_p(s) \in S$ and $x(s), y(s) \in S$ such that

$p(s) = n_p(s)/d_p(s)$ and $n_p(s)x(s) + d_p(s)y(s) = 1$ (such a fractional decomposition of $p(s)$ will be called a *coprime decomposition*). This is the only property of S that we will need in this paper. It provides us the following result (see [24, p. 45] for proof). For conciseness, we sometimes drop the reference to the complex variable s when writing rational functions.

THEOREM 3.2. *Let $p, c \in \mathbb{R}(s)$, and let $p = n_p/d_p$ and $c = n_c/d_c$ be any coprime decompositions of p and c. Then c stabilizes p if and only if $n_c n_p + d_c d_p \in U$.*

As a corollary of this Theorem 3.2, we may formulate the simultaneous stabilization problem as follows.

COROLLARY 3.3. *Let $p_i \in \mathbb{R}(s)$, $i = 1, \ldots, k$ and let $p_i = n_i/d_i$ be any coprime decomposition of p_i, $i = 1, \ldots, k$. Then p_i are simultaneously stabilizable if and only if there exist $n_c, d_c \in S$ such that $n_c n_i + d_c d_i \in U$, $i = 1, \ldots, k$.*

A controller $c \in \mathbb{R}(s)$ is stable if it has no poles in $\mathbb{C}_{+\infty}$, in other words, it is stable if for every coprime decomposition $c = n_c/d_c$ we have $d_c \in U$. The controller c is stable and inverse stable (we have called such functions units) if both n_c and d_c are in U. In the next section we will need the following natural definition.

DEFINITION 3.4. *Let $p \in \mathbb{R}(s)$ and let $p = n_p/d_p$ be any coprime decomposition of p in S. The plant p is* strongly stabilizable *(i.e., stabilizable by a stable controller) if and only if there exist $n_c \in S$ and $d_c \in U$ such that $n_c n_p + d_c d_p \in U$. The plant p is* unit stabilizable *(i.e., stabilizable by a stable controller whose inverse is stable) if and only if there exist $n_c \in U$ and $d_c \in U$ such that $n_c n_p + d_c d_p \in U$.*

Note that the definition above is independent of the choice of the coprime decompositions. Theorem 3.2 and Corollary 3.3 are proved for the case where the stability region is the extended closed right half plane $\mathbb{C}_{+\infty}$. It may, however, be useful to define the concept of stability in a more general framework. First, this allows us to treat continuous- and discrete-time stability questions in a general setting and, second, the use of stability regions different from the extended right half plane may be justified for practical purposes (see [25], for example). The generalization goes exactly along the same line. Let Ω be a closed subset of the extended complex plane $\mathbb{C}_\infty$ satisfying the assumptions given in §2. $S(\Omega)$ is the set of real rational functions with no poles in Ω, and $U(\Omega)$ is the set of invertible elements of $S(\Omega)$. Then the above results on the ring S carry over, namely, $S(\Omega)$ is an Euclidean commutative ring whose field of fractions is $\mathbb{R}(s)$. Since these are the only properties that are needed to prove Theorem 3.2 and Corollary 3.3, these results remain valid for a general stability region Ω. Let us state this clearly.

DEFINITION 3.5. *Let Ω be a subset of $\mathbb{C}_\infty$. A controller $c(s) \in \mathbb{R}(s)$ is an internal Ω-stabilizer of a plant $p(s) \in \mathbb{R}(s)$ if the four transfer functions $p(s)c(s)(1 + p(s)c(s))^{-1}, c(s)(1 + p(s)c(s))^{-1}, p(s)(1 + p(s)c(s))^{-1}$, and $(1 + p(s)c(s))^{-1}$ belong to $S(\Omega)$.*

We then have the following corollary.

COROLLARY 3.6. *Let Ω be a subset of $\mathbb{C}_\infty$ as described in §2. Let $p_i \in \mathbb{R}(s)$, $i = 1, \ldots, k$, and let $p_i = n_i/d_i$ be any coprime decompositions of p_i in $S(\Omega)$, $i = 1, \ldots, k$. Then p_i are simultaneously Ω-stabilizable if and only if there exist $n_c, d_c \in S(\Omega)$ such that $n_c n_i + d_c d_i \in U(\Omega)$, $i = 1, \ldots, k$.*

Proof. The proof follows exactly along the same lines as Theorem 3.2 and Corollary 3.3. See [24]. □

It is clear that if Ω' is a subset of Ω, then an Ω-stabilizing controller of a plant p is also an Ω'-stabilizing controller (indeed, if the transfer functions have no poles in Ω, they then have no poles in Ω'). In particular, if we define $\omega = \Omega \cap \mathbb{R}_\infty$, then an

Ω-stabilizing controller is also an ω-stabilizing controller. ω-stabilizability is thus a necessary condition for Ω-stabilizability. This necessary condition will play a crucial role in §4. First we show the link between stability and avoidance.

3.2. Avoidance. Functions in $\mathbb{R}(s)$ go from $\mathbb{C}_\infty$ to $\mathbb{C}_\infty$ and have the additional property that they take extended *real* values on $\mathbb{R}_\infty$. It is therefore easy to represent their behaviour on $\mathbb{R}_\infty$ with a two-dimensional graphic. On the other hand, we need four dimensions to represent their behaviour on the complex plane. With these representations in mind we may figure out where two plants $p_1(s), p_2(s) \in \mathbb{R}(s)$ possibly intersect on the $\mathbb{R}_\infty$ axis, that is, the set of points $s_0 \in \mathbb{R}_\infty$ for which $p_1(s_0) = p_2(s_0)$. It is still easy to define, but more difficult to represent geometrically, the points in $\mathbb{C}_\infty \backslash \mathbb{R}_\infty$ where two plants intersect. We give a formal definition for this.

DEFINITION 3.7. *Let $p_1(s), p_2(s) \in \mathbb{R}(s)$, let Ω be a subset of $\mathbb{C}_\infty$, and let $p_i(s) = n_i(s)/d_i(s)$ be any coprime decompositions of $p_i(s)$ in $S(\Omega)$, $i = 1, 2$. $s_0 \in \Omega$ is a point of* intersection *of multiplicity n between $p_1(s)$ and $p_2(s)$ if $n_1(s)d_2(s) - n_2(s)d_1(s) \in S(\Omega)$ has a zero of multiplicity n at s_0. $p_1(s)$ avoids $p_2(s)$ in Ω if $p_1(s)$ and $p_2(s)$ have no points of intersection in Ω.*

Note that the points of intersection in Ω between $p_1(s)$ and $p_2(s)$ do not depend on the particular choice of the coprime factorizations in $S(\Omega)$.

To illustrate Definition 3.7, consider, for example, $p_1(s) = (s+1)/s^2$ and $p_2(s) = (5s-1)/(s^3+s^2)$. The points of intersection between $p_1(s)$ and $p_2(s)$ in $\mathbb{C}_{+\infty}$ are at $s_0 = 1, s_0 = 2$, and $s_0 = \infty$ with multiplicity one and at $s_0 = 0$ with multiplicity two. The link between stabilization and avoidance is shown in the next theorem.

THEOREM 3.8. *Let $p(s), c(s) \in \mathbb{R}(s)$. Then the controller $c(s)$ Ω-stabilizes $p(s)$ if and only if $-c^{-1}(s)$ avoids $p(s)$ in Ω (or, equivalently, if and only if $-p^{-1}(s)$ avoids $c(s)$ in Ω).*

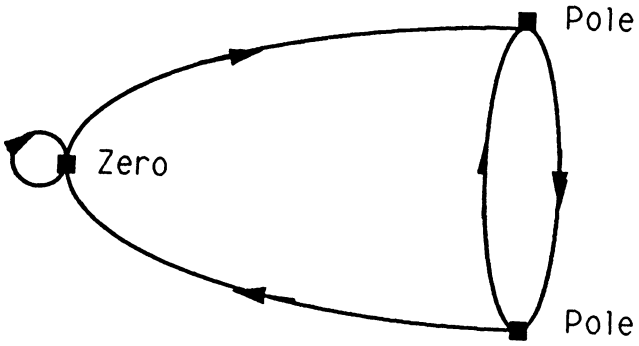
Proof. Let $p(s) = n_p(s)/d_p(s)$ and $c(s) = n_c(s)/d_c(s)$ be coprime decompositions of $p(s)$ and $c(s)$ in $S(\Omega)$. By Theorem 3.2, $c(s)$ Ω-stabilizes $p(s)$ if and only if $n_p(s)n_c(s) + d_p(s)d_c(s) \in U(\Omega)$. This last condition is satisfied if and only if $n_p(s)n_c(s) + d_p(s)d_c(s) \in S(\Omega)$ has no zeros in Ω or, alternatively, if and only if $-c(s)^{-1}$ avoids $p(s)$ in Ω. □

As a trivial consequence, notice that the plants that are Ω-stabilizable by a real constant feedback gain are precisely those that avoid a real value on Ω. With Theorem 3.8. we can formulate the general simultaneous stabilization problem of k plants in the form of an avoidance problem.

COROLLARY 3.9. *Let $p_i \in \mathbb{R}(s)$, $i = 1, \ldots, k$. The plants p_i are simultaneously Ω-stabilizable if and only if there exists a $q(s) \in \mathbb{R}(s)$ such that $q(s)$ avoids $p_i(s)$ in Ω, $i = 1, \ldots, k$, in which case $c(s) = -q^{-1}(s)$ is a Ω-stabilizing controller.*

The problem of the simultaneous Ω-stabilization of k plants thus has an easily understandable geometric interpretation. We are given a set of rational functions defined on a region Ω of the extended complex plane and we ask whether it is possible to find a rational function that avoids them all on Ω. If this is possible, then the plants are simultaneously Ω-stabilizable. Now, if it is possible to find a rational function that avoids k rational functions on Ω, then the same function avoids them all on $\omega = \mathbb{R}_\infty \cap \Omega$. *The existence of an ω-avoiding rational function is thus a necessary condition for simultaneous Ω-stabilization.* It is this necessary ω-stabilizability condition that we analyse in the next section.

When dealing with general stability regions Ω, the terminology and the notation get somewhat heavy. For our purposes a large class of such stability regions are equivalent: all the results contained in this paper are valid for closed, simply connected



GRAPH 1.1. *Parity interlacing property.*

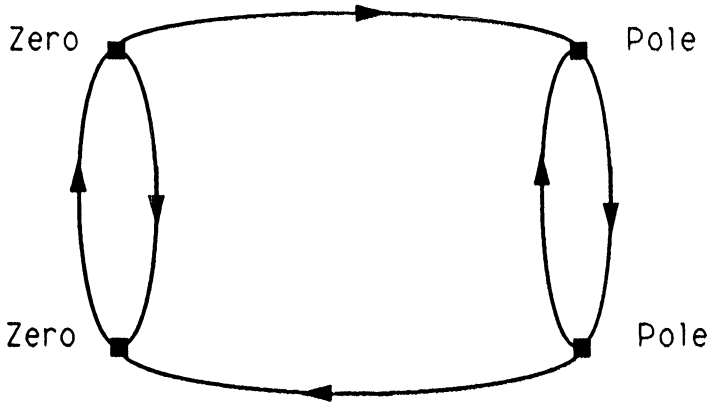
stability regions. In what follows we concentrate on *canonical* simply connected stability regions, in §4 we deal with $\mathbb{C}_{+\infty}$, and in §5 we analyse counterexamples in $\overline{D}$.

4. Stabilization on the real axis: The search for necessary conditions. The problem is simple. We examine k real rational functions on the interval $\mathbb{R}_{+\infty} = [0, \infty]$, where they are real-valued. They may have poles as well as zeros on $\mathbb{R}_{+\infty}$. Their behaviour can easily be represented on a two-dimensional graph as functions from $\mathbb{R}_{+\infty}$ to $\mathbb{R}_{\infty}$. Now we ask the question: "Is it possible to find a real rational function, with perhaps poles and zeros in $\mathbb{R}_{+\infty}$, which avoids this set of functions on the interval $\mathbb{R}_{+\infty}$?" In view of Corollary 3.9, this question is equivalent to the following: "Given a set of plants $p_i(s) \in \mathbb{R}(s)$, $i = 1, \ldots, k$, when is it possible to find a single controller $c(s) \in \mathbb{R}(s)$ such that $p_i c(1 + p_i c)^{-1}, p_i(1 + p_i c)^{-1}, c(1 + p_i c)^{-1}$, and $(1 + p_i c)^{-1}$ have no *real* unstable poles?" Obviously, this is a weaker requirement than simultaneous stabilization, where poles in the whole $\mathbb{C}_{+\infty}$ are to be avoided.

4.1. Stabilization of two plants and strong stabilization. In this section we will need the following well-known definitions.

DEFINITION 4.1. *Let $p(s) \in \mathbb{R}(s)$. $p(s)$ has the* parity interlacing property *if $p(s)$ has an even number (counting multiplicities) of poles between each pair of zeros in $\mathbb{R}_{+\infty}$. $p(s)$ has the* even interlacing property *if both $p(s)$ and $p^{-1}(s)$ have the parity interlacing property.*

An alternative way of defining this is by means of a graph. Let $z_i, p_j \in \mathbb{R}_{+\infty}$ $(i = 1, \ldots, l)$ $(j = 1, \ldots, m)$ be the l zeros and m poles of a plant $p(s) \in \mathbb{R}(s)$ in $\mathbb{R}_{+\infty}$. The plant $p(s)$ has the parity interlacing property if and only if the succession of its poles and zeros on $\mathbb{R}_{+\infty}$, as s increases from zero to infinity, corresponds to a possible path in Graph 1.1. In the same vein, $p(s)$ has the even interlacing property if and only if the succession of its poles and zeros on $\mathbb{R}_{+\infty}$ correspond to a possible path in Graph 1.2. For example, the succession of poles and zeros of $p(s) = (s-1)/((s-3)(s-2)s)$ gives the following pattern: PZPPZ and hence $p(s)$ has the parity interlacing property, but not the even interlacing property. The same kind of figure will be used in Theorem 4.13 to describe a $\mathbb{R}_{+\infty}$-stabilizability condition for three plants, but first we analyse the two-plant case.



GRAPH 1.2. *Even interlacing property.*

THEOREM 4.2. *Let $p(s) \in \mathbb{R}(s)$. If there exists a stable controller that $\mathbb{R}_{+\infty}$-stabilizes $p(s)$, then $p(s)$ has the parity interlacing property.*

Proof. Let $c(s)$ be a stable $\mathbb{R}_{+\infty}$-stabilizing controller of $p(s)$. Then by Theorem 3.8, $c(s)$ avoids $-p^{-1}(s)$ on $\mathbb{R}_{+\infty}$. Since $c(s)$ is stable, it also avoids ∞ on $\mathbb{R}_{+\infty}$. Suppose, to get a contradiction, that $p(s)$ has an odd number of poles between two zeros on $\mathbb{R}_{+\infty}$. Then $-p^{-1}(s)$ has an odd number of zeros between two poles on $\mathbb{R}_{+\infty}$. But then $c(s)$ has to avoid both a rational function $-p^{-1}(s)$, which has an odd number of zeros between two of its poles on $\mathbb{R}_{+\infty}$ and ∞ on $\mathbb{R}_{+\infty}$. This is impossible and hence $p(s)$ has an even number of poles between two zeros on $\mathbb{R}_{+\infty}$. □

A stronger version of Theorem 4.2 can be obtained. It can be shown that the parity interlacing property is in fact sufficient for $\mathbb{R}_{+\infty}$-stabilizability by a stable controller. This last result in turn is contained under a stronger form in the next theorem.

THEOREM 4.3. *Let $p(s) \in \mathbb{R}(s)$. There exists a stable controller that stabilizes $p(s)$ if and only if $p(s)$ has the parity interlacing property.*

The proof of this fundamental fact was first given in [32]. The reader may find both an elementary and an advanced proof in [24].

COROLLARY 4.4. *A plant is stabilizable by a stable controller if and only if it is $\mathbb{R}_{+\infty}$-stabilizable by a stable controller.*

Proof. Use the two previous theorems together with the fact that a stabilizing controller is also $\mathbb{R}_{+\infty}$-stabilizing. □

Using this last corollary, we stress in the next theorem a fundamental property of simultaneous stabilization of two plants: if there exists a controller such that the closed-loop transfer functions associated with each plant have no *real* unstable poles, then there exists a controller that simultaneously stabilizes the two plants.

THEOREM 4.5. *Two plants are simultaneously stabilizable if and only if they are simultaneously $\mathbb{R}_{+\infty}$-stabilizable.*

Proof. Let p_1 and $p_2 \in \mathbb{R}(s)$, and let $p_i = n_i/d_i$ be any coprime decompositions, $i = 1, 2$. By Theorem 3.2, p_i are simultaneously stabilizable if and only if there exist $n_c, d_c \in S$ such that $n_c n_i + d_c d_i \in U$, $i = 1, 2$. Since n_1, d_1 are coprime, there exists $x, y \in S$ such that $n_1 x + d_1 y = 1$. Any controller $c = (x + r d_1)/(y - r n_1)$, where $r \in S$ is a stabilizing controller of p_1. In fact, it can easily be proved (see [24] or [10]) that

any stabilizing controller of p_1 can be written in the form $c = (x + rd_1)/(y - rn_1)$ for some $r \in S$. Therefore p_1 and p_2 are simultaneously stabilizable if and only if $(x+rd_1)n_2+(y-rn_1)d_2 = xn_2+yd_2+r(d_1n_2-d_2n_1) \in U$ for some $r \in S$. If $xn_2+yd_2 = 0$, then p_1 and p_2 are both simultaneously stabilizable and simultaneously $\mathbb{R}_{+\infty}$-stabilizable, so we rule out this case. Assume that $xn_2 + yd_2 \neq 0$. By Definition 3.4 the equation above has a solution if and only if the plant $q = (d_1n_2-d_2n_1)/(xn_2+yd_2)$ is strongly stabilizable. We could have derived exactly the same computations for $\mathbb{R}_{+\infty}$-stabilizability by replacing S by $S(\mathbb{R}_{+\infty})$ and U by $U(\mathbb{R}_{+\infty})$ in our derivations. We have thus also that p_1 and p_2 are simultaneously $\mathbb{R}_{+\infty}$-stabilizable if and only if $q = (d_1n_2 - d_2n_1)/(xn_2 + yd_2)$ is strongly $\mathbb{R}_{+\infty}$-stabilizable. But now, by applying Corollary 4.4 the theorem is proved. □

In the proof we show that p_1 and p_2 are simultaneously stabilizable if and only if $q = (d_1n_2 - d_2n_1)/(xn_2 + yd_2)$ is strongly stabilizable. This intermediate plant q is constructed with the coprime decompositions $p_i = n_i/d_i$, $i = 1, 2$ together with the solutions $x, y \in S$ of $n_1x + d_1y = 1$. With a weak additional condition on the poles of p_1 and p_2, it is possible to put this equivalence between simultaneous stabilization of two plants and strong stabilization of a single plant in a new and more obvious form. Roughly speaking, two plants are simultaneously stabilizable if and only if their difference is strongly stabilizable.

THEOREM 4.6. *Let $p_i(s) \in \mathbb{R}(s)$, $i = 1, 2$ and suppose that $p_1(s)$ and $p_2(s)$ have no common poles on $\mathbb{R}_{+\infty}$. Then $p_1(s)$ and $p_2(s)$ are simultaneously stabilizable if and only if $p_1(s) - p_2(s)$ is strongly stabilizable.*

Proof. With p_1 and $p_2 \in \mathbb{R}(s)$, let $p_i = n_i/d_i$ be any coprime decomposition in $S(\mathbb{R}_{+\infty})$, $i = 1, 2$ and let $x, y \in S(\mathbb{R}_{+\infty})$ be such that $n_1x + d_1y = 1$. Then by Corollary 3.6 and Theorem 4.5, p_i are simultaneously stabilizable if and only if there exist $n_c, d_c \in S(\mathbb{R}_{+\infty})$ such that $n_cn_i + d_cd_i \in U(\mathbb{R}_{+\infty})$, $i = 1, 2$. By using the same argument as in the proof of Theorem 4.5, these two equations can be simultaneously fulfilled if and only if $(n_1d_2 - n_2d_1)r + (n_2x + d_2y) \in U(\mathbb{R}_{+\infty})$ has a solution for some $r \in S(\mathbb{R}_{+\infty})$. Such an equation has a solution if and only if (n_2x+d_2y) is nonzero and always has the same sign at the zeros of $(n_1d_2 - n_2d_1)$ on $\mathbb{R}_{+\infty}$ (this result is crucial and far reaching; a proof of it can be found in [24, p. 38]). Under the assumption that d_1 and d_2 have no common zeros on $\mathbb{R}_{+\infty}$ and with some additional algebra, this last condition can be shown to be equivalent to requiring that d_1d_2 always have the same sign at the zeros of $(n_1d_2 - n_2d_1)$. This in turn is equivalent to requiring $p_1 - p_2$ to be stabilizable by a stable controller. □

Theorem 4.6 is a stronger form of the results contained in [24] and in [30], which state, respectively, "if p_1 is stable, then p_1, p_2 are simultaneously stabilizable if and only if $p_1 - p_2$ is stabilizable by a stable controller" and "if p_1 and p_2 have no common poles in $\mathbb{C}_{+\infty}$, then they are simultaneously stabilizable if and only if $p_1 - p_2$ is stabilizable by a stable controller." Both of these results are contained in Theorem 4.6.

4.2. Stabilization of three plants and unit stabilization. We now investigate the case of three plants and its link with unit stabilization. In this subsection we consider only the case of plants that do not all intersect at the same point. This assumption is not generic (for example, strictly proper plants all intersect at infinity) and will be dropped in §4.4. We start with a crucial theorem.

THEOREM 4.7. *Let $p_i(s) \in \mathbb{R}(s)$ $i = 1, 2, 3$. Suppose that $p_1(s), p_2(s), p_3(s)$ have no common point of intersection in $\mathbb{C}_{+\infty}$ (i.e., there is no $s_0 \in \mathbb{C}_{+\infty}$ for which $p_1(s_0) = p_2(s_0) = p_3(s_0)$). Let $p_i = n_i/d_i$, $i = 1, 2, 3$ be any coprime decompositions*

and define $a_{ij} = n_i d_j - n_j d_i$, $(i,j = 1,2,3)$. *Then* $p_i(s)$, $i = 1,2,3$ *are simultaneously stabilizable if and only if there exist* $u_i \in U$, $i = 1,2,3$ *such that* $a_{12}u_3 + a_{23}u_1 + a_{31}u_2 = 0$.

Proof. Let $x, y \in S$ be solutions to $n_1 x + d_1 y = 1$ and define $b_i = n_i x + d_i y$, $i = 2,3$. It is easy to check that $b_2 a_{13} - b_3 a_{12} = a_{23}$. If $n_i n_c + d_i d_c = u_i$ for some $n_c, d_c \in S$, $i = 1,2,3$, then $a_{12}u_3 + a_{23}u_1 + a_{31}u_2 = 0$, hence the necessity is proved. For sufficiency, suppose that there exists $u_i \in U$, $i = 1,2,3$ such that $a_{12}u_3 + a_{23}u_1 + a_{31}u_2 = 0$. Using $b_2 a_{13} - b_3 a_{12} = a_{23}$, we have $a_{12}u_3 + (b_2 a_{13} - b_3 a_{12})u_1 + a_{31}u_2 = a_{12}(u_3 - b_3 u_1) + a_{31}(u_2 - b_2 u_1) = 0$. Since there is no $s_0 \in \mathbb{C}_{+\infty}$ for which $p_1(s_0) = p_2(s_0) = p_3(s_0)$, this implies in algebraic terms that a_{12} and a_{31} are coprime. Hence there exists some $r \in S$ for which $a_{31}r = u_3 - b_3 u_1$ and $a_{12}r = -u_2 + b_2 u_1$. Defining $r' = r/u_1$, we have that $a_{31}r' + b_3 = u_3/u_1 \in U$ and $a_{21}r' + b_2 = u_2/u_1 \in U$. But now, defining $n_c = x + r'd_1$ and $d_c = y - r'n_1$, the theorem is proved, since for d_c, n_c we have $n_i n_c + d_i d_c \in U$, $i = 1,2,3$. □

It is known (see [29] or [13]) that, modulo an additional condition, the three-plant problem can be reduced to one of finding a single controller that is stable, inverse stable (from here on we will refer to such controllers as unit controllers), and that stabilizes a single plant. Let us make this connection more obvious by using Theorem 4.7.

THEOREM 4.8. *Let* $p_i \in \mathbb{R}(s)$, $i = 1,2,3$ *and let* $p_i = n_i/d_i$, $i = 1,2,3$ *be arbitrary coprime decompositions in* S. *Suppose that* p_1 *avoids* p_2 *in* $\mathbb{C}_{+\infty}$. *Then* p_i, $i = 1,2,3$ *are simultaneously stabilizable if and only if* $(n_3 d_1 - n_1 d_3)/(n_2 d_3 - d_2 n_3)$ *is unit stabilizable, i.e., stabilizable by a unit controller.*

Proof. Since p_1 avoids p_2 in $\mathbb{C}_{+\infty}$ we have $n_1 d_2 - n_2 d_1 = u \in U$. Trivially, p_1, p_2, and p_3 have no common point of intersection in $\mathbb{C}_{+\infty}$, since p_1 and p_2 do not intersect in $\mathbb{C}_{+\infty}$. We may thus apply Theorem 4.7. Therefore, p_i, $i = 1,2,3$ are simultaneously stabilizable if and only if there exist $u_i \in U$, $i = 1,2,3$ such that $uu_3 + a_{23}u_1 + a_{31}u_2 = 0$. This last equation has a solution if and only if there exists u_1 and u_2 in U for which $a_{23}u_1 + a_{31}u_2 \in U$ or, equivalently, if and only if $(n_3 d_1 - n_1 d_3)/(n_2 d_3 - d_2 n_3)$ is unit stabilizable. □

Contrary to the similar result for strong stabilization of Theorem 4.6 we have no interpretation to propose for $(n_3 d_1 - n_1 d_3)/(n_2 d_3 - d_2 n_3)$ in terms of the plants p_1, p_2, and p_3.

As an illustration of the theorem, consider the plants $p_1(s) = 1, p_2(s) = -1/s$, and $p_3(s) = -(s-1)/s$. We can take for coprime decompositions $n_1 = 1, d_1 = 1$, $n_2 = -1/(s+1), d_2 = s/(s+1)$, and $n_3 = -(s-1)/(s+1), d_3 = s/(s+1)$. p_1 and p_2 have no intersections in $\mathbb{C}_{+\infty}$, since $n_1 d_2 - n_2 d_1 = 1 \in U$. We can apply Theorem 4.8. Therefore p_i, $i = 1,2,3$ are simultaneously stabilizable if and only if $(2s^2 + s - 1)/(s^2 - 2s)$ is unit stabilizable.

An important special case of the problem of the stabilizability of three plants is therefore equivalent to the stabilizability of a single plant by a unit controller. This can be proven rigorously in the sense that for any plant $p(s)$ it is possible to construct three plants $p_1(s)$, $p_2(s)$, and $p_3(s)$ such that $p(s)$ is stabilizable by a unit controller if and only if $p_i(s)$, $i = 1,2,3$ are simultaneously stabilizable. This equivalence is one of the reasons for investigating conditions under which a plant is stabilizable by a unit controller. For the same reason as before, we first examine the condition under which a single plant is $\mathbb{R}_{+\infty}$-stabilizable by a unit controller. This condition is rather simple.

THEOREM 4.9. *Let* $p(s) \in \mathbb{R}(s)$. *There exists a unit controller that* $\mathbb{R}_{+\infty}$*-stabilizes*

$p(s)$ if and only if $p(s)$ has the even interlacing property.

Proof. Necessity is trivial: Apply Theorem 4.2 to $p(s)$ and $p^{-1}(s)$. Sufficiency can be shown by modifying slightly the proof of Theorem 3.2 in [29], in which the author proves that a stable controller with no real unstable zeros exists for any plant that satisfies the even interlacing condition. □

Obviously, the even interlacing property is a necessary condition for stabilization of a plant by a unit controller. By similarity with the strong stabilization condition and with Corollary 4.4, this necessary condition was also conjectured to be sufficient. The conjecture is false, however, and we give a counterexample in §5. Before proceeding to this, we investigate additional conditions under which three plants are simultaneously $\mathbb{R}_{+\infty}$-stabilizable.

4.3. Alternative conditions for stabilization of three plants. In §4.2 we showed the connection between simultaneous stabilizability of three plants and stabilizability of a related plant with a unit controller. Here we provide new conditions for simultaneous stabilizability and $\mathbb{R}_{+\infty}$-stabilizability of three plants. We start with a theorem that is of independent interest. Roughly speaking, it says that three plants are simultaneously stabilizable if and only if there exist three *stable* plants that have pairwise the same intersections in $\mathbb{C}_{+\infty}$ as the original three plants.

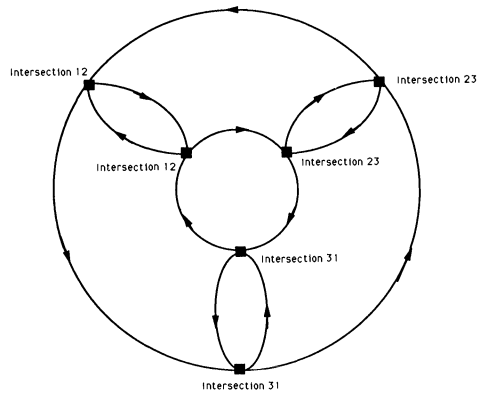
THEOREM 4.10. *Let $p_i(s) \in \mathbb{R}(s)$, $i = 1,2,3$. Suppose that $p_1(s), p_2(s), p_3(s)$ have no common point of intersection in $\mathbb{C}_{+\infty}$ (i.e., there is no $s_0 \in \mathbb{C}_{+\infty}$ for which $p_1(s_0) = p_2(s_0) = p_3(s_0)$). Then $p_i(s)$, $i = 1,2,3$ are simultaneously stabilizable if and only if there exist $p_i'(s) \in S$, $i = 1,2,3$ such that $p_i(s)$ and $p_j(s)$ have pairwise the same intersections in $\mathbb{C}_{+\infty}$ as $p_i'(s)$ and $p_j'(s)$ when $i,j = 1,2,3$.*

Proof. Let $p_i = n_i/d_i$, $i = 1,2,3$ be arbitrary coprime decompositions and define $a_{ij} = n_i d_j - n_j d_i$ $(i,j = 1,2,3)$. Suppose first that there exists $p_i'(s) \in S$, $i = 1,2,3$ such that $p_i(s)$ and $p_j(s)$ have pairwise the same intersections in $\mathbb{C}_{+\infty}$ as $p_i'(s)$ and $p_j'(s)$. In algebraic terms this means that $p_i' - p_j' = u_{ij} a_{ij}$ $(i,j = 1,2,3)$ for some units $u_{ij} \in U$ $(i,j = 1,2,3)$. Putting $u_1 = u_{23}, u_2 = u_{31}$, and $u_3 = u_{12}$ in Theorem 4.7, we get that $p_i(s)$, $i = 1,2,3$ are simultaneously stabilizable. To prove necessity, suppose that $p_i(s)$, $i = 1,2,3$ are simultaneously stabilizable and have no common intersection in $\mathbb{C}_{+\infty}$. Again, by Theorem 4.7 there exist $u_i \in U$, $i = 1,2,3$ such that $a_{12}u_3 + a_{23}u_1 + a_{31}u_2 = 0$. Take any $r_2 \in S$ and define $r_1 = r_2 + u_3 a_{12} \in S$ and $r_3 = r_2 - u_1 a_{23} \in S$. Then we have that $r_1 - r_2 = a_{12}u_3$, $r_2 - r_3 = a_{23}u_1$, but also $r_3 - r_1 = a_{31}u_2$. And thus $r_i \in S$, $i = 1,2,3$ are such that r_i and r_j have pairwise the same intersections in $\mathbb{C}_{+\infty}$ as $p_i(s)$ and $p_j(s)$ for $i,j = 1,2,3$. This ends the proof. □

As we argued in §3.2, the results that we obtain in this section are still valid for general regions Ω that satify the assumptions stated in §2. In particular, we may derive the counterpart of Theorem 4.10 for the region $\Omega = \mathbb{R}_{+\infty}$.

THEOREM 4.11. *Let $p_i(s) \in \mathbb{R}(s)$, $i = 1,2,3$. Suppose that $p_1(s), p_2(s), p_3(s)$ have no common point of intersection on $\mathbb{R}_{+\infty}$ (i.e., there is no $s_0 \in \mathbb{R}_{+\infty}$ for which $p_1(s_0) = p_2(s_0) = p_3(s_0)$). Then $p_i(s)$, $i = 1,2,3$ are simultaneously $\mathbb{R}_{+\infty}$-stabilizable if and only if there exist $p_i'(s) \in S(\mathbb{R}_{+\infty})$, $i = 1,2,3$ such that $p_i(s)$ and $p_j(s)$ have pairwise the same intersections on $\mathbb{R}_{+\infty}$ as $p_i'(s)$ and $p_j'(s)$ when $i,j = 1,2,3$.*

The interest of this last result is that, while we do not know a tractable test to check the condition in Theorem 4.10, we have one for the condition in Theorem 4.11. The existence of three rational functions with no poles on $\mathbb{R}_{+\infty}$ that *mimic* the pairwise intersections of three plants on $\mathbb{R}_{+\infty}$ relies on an interlacing property that we state hereafter.



GRAPH 1.3. *3-interlacing property.*

DEFINITION 4.12. *Let* $p_i(s) \in \mathbb{R}(s)$, $i = 1,2,3$. *Suppose that* $p_1(s), p_2(s), p_3(s)$ *have no common point of intersection on* $\mathbb{R}_{+\infty}$. *Then* $p_i(s)$, $i = 1,2,3$ *have the* 3-interlacing property *if the succession of their intersections on* $\mathbb{R}_{+\infty}$, *as* s *increases from zero to infinity, corresponds to a possible path in Graph* 1.3.

We can now prove our theorem.

THEOREM 4.13. *Let* $p_i(s) \in \mathbb{R}(s)$, $i = 1,2,3$. *Suppose that* $p_1(s), p_2(s), p_3(s)$ *have no common point of intersection on* $\mathbb{R}_{+\infty}$. *Then* $p_i(s)$, $i = 1,2,3$ *are simultaneously* $\mathbb{R}_{+\infty}$*-stabilizable if and only if they have the* 3*-interlacing property.*

Proof. Suppose that $p_1(s), p_2(s), p_3(s)$ have no common point of intersection on $\mathbb{R}_{+\infty}$. By Theorem 4.11, $p_i(s)$, $i = 1,2,3$ are simultaneously $\mathbb{R}_{+\infty}$-stabilizable if and only if there exist $p_i'(s) \in S(\mathbb{R}_{+\infty})$, $i = 1,2,3$ such that $p_i(s)$ and $p_j(s)$ have pairwise the same intersections on $\mathbb{R}_{+\infty}$ as $p_i'(s)$ and $p_j'(s)$. The fact that $p_i'(s)$ have no poles on $\mathbb{R}_{+\infty}$ implies that not all successions of pairwise intersections are possible, i.e., the succession of intersections between three continous functions from $\mathbb{R}_{+\infty}$ to $\mathbb{R}$ is not arbitrary. We claim that the successions that are possible are precisely those that represent a possible path in Graph 1.3. To prove this, note that at each point $s_0 \in \mathbb{R}_{+\infty}$ where the p_i' do not pairwise intersect we have $p_i'(s_0) > p_j'(s_0) > p_k'(s_0)$ for some $i,j,k = 1,2,3$. In this way we can associate, to each point $s_0 \in \mathbb{R}_{+\infty}$ where the plants p_i' do not pairwise intersect, one of the six orderings $p_1' < p_2' < p_3'$, $p_1' < p_3' < p_2'$, $p_2' < p_1' < p_3'$, $p_2' < p_3' < p_1'$, $p_3' < p_1' < p_2'$, or $p_3' < p_2' < p_1'$. If s_0 and s_1 are two points on $\mathbb{R}_{+\infty}$ such that $p_i'(s)$ have no pairwise intersections on $[s_0, s_1]$, then, because the $p_i'(s)$ are continuous, the ordering at s_0 and s_1 are the same. Hence, the ordering changes precisely at the pairwise intersections of the $p_i'(s)$. For example, the ordering $p_1' < p_2' < p_3'$ changes to $p_1' < p_3' < p_2'$ after an intersection between p_2' and p_3'. Note also that not all changes are admitted, for example, $p_1' < p_2' < p_3'$ cannot be changed to $p_3' < p_2' < p_1'$ after a single intersection. Representing the six possible orderings above in a graph together with all possible changes at the intersections yields the Graph 1.3. Necessity is proved. To prove sufficiency, it suffices to show that given a succession of pairwise intersections on $\mathbb{R}_{+\infty}$ that follows a path in Graph 1.3, it is always possible to construct three functions in $S(\mathbb{R}_{+\infty})$ that do not intersect simultaneously on $\mathbb{R}_{+\infty}$ and whose pairwise intersections are the given points. We do not give a technical, and tedious, proof of this here. Instead, we outline the sketch

of a constructive procedure. First translate the problem onto I by using the usual conformal equivalence. Then construct three continuous functions that satisfy the desired property. By careful use of the fact that polynomials are dense in the set of continuous functions on I, construct three polynomials that also satisfy this property. Notice then that polynomials are members of $S(I)$, so that by using the conformal equivalence again the theorem is proved. □

The case where the plants do intersect on $\mathbb{R}_{+\infty}$ is analysed in §4.4 below.

Theorem 4.13 and the 3-interlacing property are equivalent to an algebraic condition recently given in [30]. It was obtained independently by the authors. Again, it is a necessary condition for simultaneous stabilizability of three plants, since it is necessary and sufficient for $\mathbb{R}_{+\infty}$-stabilizability. In the conclusion of [30] it is conjectured that this condition is also sufficient for stabilizability, but we will prove in §5 that this is not true.

To illustrate the use of Theorem 4.13, we analyse an example given in the literature [13]. A natural question when analysing the simultaneous stabilizability of three plants is: "Given three plants that are simultaneously stabilizable, they are of course pairwise simultaneously stabilizable. Is the converse also true?" Unfortunately, the answer is no. Ghosh provided a counterexample to this: $p_1(s) = (s-7)/(s-4.6)$, $p_2(s) = (s-2)/(2s-2.6)$, and $p_3(s) = (s-6)/(4.8s-24.6)$ are pairwise simultaneously stabilizable, but it is shown in [13] that they are not simultaneously stabilizable. Application of our Theorem 4.13 easily shows that they are not even $\mathbb{R}_{+\infty}$-simultaneously stabilizable. The intersections between p_1 and p_2 are $\sigma_{12} = 1$ and $\sigma_{12} = 9$. For the other two pairwise intersections we get: $\sigma_{23} = 3$ and $\sigma_{23} = 4$, $\sigma_{31} = 7.34$ and $\sigma_{31} = 5.17$. Note that for these three plants all the intersections happen to be on $\mathbb{R}_{+\infty}$, which is by no means generic. Ordering the succesion of pairwise $\mathbb{R}_{+\infty}$-intersections we get: $\sigma_{12}, \sigma_{23}, \sigma_{23}, \sigma_{31}, \sigma_{31}, \sigma_{12}$. This does not correspond to a possible path in Graph 1.3. Hence $p_i(s)$, $i = 1, 2, 3$, do not have the 3-interlacing property and, by Theorem 4.13, the three plants are not simultaneously stabilizable.

As a final remark on Theorem 4.13, it is worth noting that our 3-interlacing property can be extended to more than three plants. If k plants are simultaneously stabilizable, then the same sequence of pairwise intersections on $\mathbb{R}_{+\infty}$ is achievable by the pairwise intersections of k $\mathbb{R}_{+\infty}$-stable plants. This provides a necessary condition for simultaneous stabilization of k plants. We do not develop this further here because we believe that the results contained in the next section overshadow the interest of stabilization conditions of k plants when the plants do not intersect. We end §4 by analysing the case where there exists some $s_0 \in \mathbb{R}_{+\infty}$ such that $p_i(s_0) = w_0$, $i = 1, \ldots, k$.

4.4. Simultaneous $\mathbb{R}_{+\infty}$ stabilization for intersecting plants. All the conditions in §§4.2 and 4.3 are for the case where the three plants have no common point of intersection on either $\mathbb{C}_{+\infty}$ or $\mathbb{R}_{+\infty}$. There exists an important special case for which this condition is not satisfied. When the plants are all strictly proper, they all take the value 0 at infinity so that they have a common point of intersection at infinity. It is this special structure that partly motivates the next result, which is the central result of this section. It shows that, for simultaneous $\mathbb{R}_{+\infty}$-stabilizability, the conditions are much simpler when the plants have a common point of intersection on $\mathbb{R}_{+\infty}$. Note that the theorem applies not just to the three-plant case but to the general k plants case.

THEOREM 4.14. *Let $p_i(s) \in \mathbb{R}(s)$, $i = 1, \ldots, k$ and suppose that there exists a value $s_0 \in \mathbb{R}_{+\infty}$ such that the plants intersect at s_0 (i.e., there exists some $s_0 \in \mathbb{R}_{+\infty}$*

and some $w_0 \in \mathbb{R}_\infty$ such that $p_i(s_0) = w_0$, $i = 1, \ldots, k$). Then the plants are simultaneously $\mathbb{R}_{+\infty}$-stabilizable if and only if they are pairwise simultaneously $\mathbb{R}_{+\infty}$-stabilizable.

Proof. Necessity is obvious. We prove sufficiency by showing that, under the assumptions that the k plants $p_i(s)$, $i = 1, \ldots, k$ intersect at $s_0 \in \mathbb{R}_{+\infty}$ and that they are pairwise simultaneously $\mathbb{R}_{+\infty}$-stabilizable, it is possible to find a rational function $q(s)$ that avoids them all on $\mathbb{R}_{+\infty}$. The result will then follow by Corollary 3.9.

For simplicity we assume that $s_0 = 0$, and we define $w_0 = p_i(s_0) = p_i(0)$; the proof for an arbitrary s_0 goes along the same line. We assume also that $w_0 \neq \infty$. If not, we can redefine $p_i' = 1/p_i$ and $w_0' = 0$. First use the bilinear transformation that maps $\mathbb{C}_{+\infty}$ onto $\overline{D}$. Under this transformation, we get $p_i'(z) = p_i((1+z)/(1-z))$. Since $p_i(0) = w_0$, we have $p_i'(-1) = w_0$ for $i = 1, \ldots, k$. In view of this, define $p_i''(z) = p_i'(z) - w_0$. It is clear that $p_i''(z)$ all have a zero at $z_0 = -1$. Also from our assumptions $p_i''(z)$, $i = 1, \ldots, k$ are real rational and are pairwise simultaneously I-stabilizable. To end the proof, it remains to show that $p_i''(z)$ are simultaneously I-stabilizable, i.e., that there exists a rational function that avoids $p_i''(z)$ on I.

To see this we define k continuous functions $v_i(z)$ from I to $\mathbb{R}$ by $v_i(z) = \arctan p_i''(z)$, $z \in I$. Here the inverse tangent function has to be taken with an *unwrapped argument*, i.e., the function $v_i(z)$ is made continuous from $\mathbb{R}_\infty$ to $\mathbb{R}$ as z increases from -1 to 1 by choosing an appropriate branch of the inverse tangent function at the real poles of $p(z)$. Since $p_i''(-1) = 0$, we may chose $v_i(-1) = 0$. Some manipulations show that a rational function $r(z)$ avoids $p_i''(z)$ on I, $i = 1, \ldots, k$, if and only if $v_i(z) - n\pi < \arctan r(z) < v_i(z) - (n-1)\pi$ for all $z \in I$, $i = 1, \ldots, k$ and for some $n \in \mathbb{N}$. In the sequel our objective is to construct such an $r(z)$. We therefore need an intermediate result.

We show that, because $p_i''(z)$ are pairwise simultaneously I-stabilizable, we have $\mid v_i(z) - v_j(z) \mid < \pi$, for all $z \in I$, $i, j = 1, \ldots, k$. Suppose, by contradiction, that for some i, j and some $z_0 \in I$ we have $\mid v_i(z_0) - v_j(z_0) \mid \geq \pi$. Then, since $\mid v_i(-1) - v_j(-1) \mid = 0$, and since $v_i(z)$ are continuous, there must exist $z_1 \in [-1, z_0]$ such that $\mid v_i(z_1) - v_j(z_1) \mid = \pi$. But then, given any rational function $r(z)$ and the continuous function $v(z) = \arctan r(z)$ from I to $\mathbb{R}$, there exists some $z_2 \in [-1, z_1]$ such that either $v_i(z_2) - v(z_2) = n\pi$ or $v_j(z_2) - v(z_2) = n\pi$ for some $n \in \mathbb{N}$. Assume $v_i(z_2) - v(z_2) = n\pi$. Then $v_i(z_2) = v(z_2) + n\pi$ and, taking the tangent of both sides, $p_i''(z_2) = r(z_2)$. This shows that every rational function intersects either $p_i''(z)$ or $p_j''(z)$ at some $z \in I$. This last statement contradicts the fact that $p_i''(z)$ and $p_j''(z)$ are simultaneously I-stabilizable and so we have proved that $\mid v_i(z) - v_j(z) \mid < \pi$, for all $z \in I$, $i, j = 1, \ldots, k$. We now construct a stabilizing controller.

Define $w(z) : z \to \min_{i=1,\ldots,k} v_i(z)$. $w(z)$ is a continuous function from I to $\mathbb{R}$. By the above argument, $\mid v_i(z) - v_j(z) \mid < \pi$, for all $z \in I$, $i, j = 1, \ldots, k$ and hence $v_i(z) - \pi < w(z) \leq v_i(z)$, for all $z \in I$, $i = 1, \ldots, k$. We define $w'(z) = w(z) - \epsilon$ with ϵ sufficiently small so that $v_i(z) - \pi < w'(z) < v_i(z)$, for all $z \in I$, $i = 1, \ldots, k$. Some algebraic manipulations, together with the fact that polynomials are uniformly dense in the set of continuous functions from I to $\mathbb{R}$, show that, given $w'(z)$ and $\epsilon > 0$ it is possible to find a rational function $q(z)$ such that $\mid w'(z) - \arctan q(z) \mid < \epsilon$, for all $z \in I$. But then, for sufficiently small ϵ, we have $v_i(z) - \pi < \arctan q(z) < v_i(z)$, for all $z \in I$, $i = 1, \ldots, k$. Taking the tangent of both sides, this last statement clearly shows that $q(z)$ avoids $p_i''(z)$ for $i = 1, \ldots, k$ and $z \in I$. This in turn implies by Corollary 3.9 that $p_i''(z)$, and hence $p_i'(z)$, are simultaneously I-stabilizable. The equivalence between the simultaneous I-stabilizability of the $p_i'(z)$ and that of the

$\mathbb{R}_{+\infty}$-stabilizability of the $p_i(s)$ ends the proof. □

Using this theorem, the next results are straightforward and their proofs are left to the reader.

COROLLARY 4.15. *Let $p_i(s) \in \mathbb{R}(s)$, $i = 1, \ldots, k$ and suppose that there exists a value $s_0 \in \mathbb{R}_{+\infty}$ such that the plants intersect at s_0. Then the plants are simultaneously $\mathbb{R}_{+\infty}$-stabilizable if and only if they are pairwise simultaneously stabilizable.*

COROLLARY 4.16. *Let $p_i(s) \in \mathbb{R}(s)$, $i = 1, \ldots, k$ and suppose that $p_i(s)$ have a common pole or a common zero on $\mathbb{R}_{+\infty}$. Then the plants are simultaneously $\mathbb{R}_{+\infty}$-stabilizable if and only if they are pairwise simultaneously $\mathbb{R}_{+\infty}$-stabilizable.*

COROLLARY 4.17. *Let $p_i(s) \in \mathbb{R}(s)$, $i = 1, \ldots, k$ be strictly proper (they all have a zero at infinity). The plants are simultaneously $\mathbb{R}_{+\infty}$-stabilizable if and only if they are pairwise simultaneously $\mathbb{R}_{+\infty}$-stabilizable.*

Note that in the above example of Ghosh the plants are not strictly proper.

These are only some of the possible corollaries of Theorem 4.14. Their main common interest is that, contrary to most of the results on simultaneous stabilisation, they provide tractable tests to decide whether k plants are simultaneously $\mathbb{R}_{+\infty}$-stabilizable. Most of the known results on simultaneous stabilization of more than two plants are only restatements of untractable conditions into other untractable conditions. Here we have provided tractable tests, since the simultaneous stabilizability of two plants can be tested by using only a finite number of rational operations (see [1]). On the other hand, the drawback of our conditions is that, even though they are necessary and sufficient for $\mathbb{R}_{+\infty}$-stabilizability, they are only necessary conditions for $\mathbb{C}_{+\infty}$-stabilizability. We show in §5 that the conditions that we have obtained are in general not sufficient and, as soon as k is greater than two, it is necessary to look at the behaviour of the plants in the whole extended right half complex plane and not just on the extended positive real axis.

5. Stabilization in the complex plane. In the previous section we have found necessary and sufficient conditions for $\mathbb{R}_{+\infty}$-stabilizability of a single plant by a stable controller (parity interlacing property) and by a unit controller (even interlacing property). We have also treated the case of simultaneous $\mathbb{R}_{+\infty}$-stabilization of three or more plants (3-interlacing condition in the case of three plants that do not intersect, and pairwise stabilizability in the case of k plants that intersect on $\mathbb{R}_{+\infty}$). All these conditions are, as we have shown, necessary conditions for stabilizability in the usual sense, i.e., $\mathbb{C}_{+\infty}$-stabilizability. One of these conditions has also been shown to be sufficient for $\mathbb{C}_{+\infty}$-stabilizability, namely, two plants are simultaneously stabilizable if and only if they are simultaneously $\mathbb{R}_{+\infty}$-stabilizable. It was hoped that this property would flow on to the case $k \geq 3$. The implicit conjecture "k plants are simultaneously stabilizable if and only if they are $\mathbb{R}_{+\infty}$-stabilizable" has obviously been a driving motivation for many of the partial results on simultaneous stabilization. In this section we give counterexamples showing that $\mathbb{R}_{+\infty}$-stabilizability does not, in general, imply $\mathbb{C}_{+\infty}$-stabilizability.

For convenience (mainly because $\overline{D}$ is a bounded set), we give the counterexamples of this section in $\overline{D}$ rather than in $\mathbb{C}_{+\infty}$. The counterpart of $\mathbb{R}_{+\infty}$ is then $I = \overline{D} \cap \mathbb{R}_{\infty}$. It must be clear, however, that *all our counterexamples have a counterpart in continuous time.* The equivalence can be shown by using the bilinear transformation, and we illustrate it for the first theorem.

We start with the easiest counterexample.

THEOREM 5.1. *Let $p_1(z) = 0$, $p_2(z) = z/(z+2)$, $p_3(z) = 2z/(z+2)$, and $p_4(z) = 2z/((z+2)(2-kz))$ be four discrete time systems. If $k > e^{26}$, then $p_i(z)$,*

$i = 1, \ldots, 4$ are simultaneously I-stabilizable but not simultaneously $\overline{D}$-stabilizable.

Proof. Recall that $I = [-1, 1]$. The plants have a common point of intersection at $z = 0$, since $p_i(0) = 0$, $i = 1, \ldots, 4$. It is easy to check that for any k they are pairwise stabilizable and hence, applying Theorem 4.14, they are simultaneously I-stabilizable. It remains to be shown that for $k > e^{26}$ they are not simultaneously $\overline{D}$-stabilizable. Suppose, by contradiction, that for some $k > e^{26}$ the plants are simultaneously $\overline{D}$-stabilizable. Then for this k, and by using the natural coprime decomposition of $p_i(z)$, there must exist $n_c, d_c \in S(\overline{D})$ such that $d_c \in U(\overline{D}), zn_c + (z+2)d_c \in U(\overline{D}), 2zn_c + (z+2)d_c \in U(\overline{D})$, and $2zn_c + (2-kz)(z+2)d_c \in U(\overline{D})$. We define $f = 2zn_c/d_c(z+2) + 2 \in S(\overline{D})$. By the above equations it is then clear that $f \in U(\overline{D}), f - 1 \in U(\overline{D})$, and $f - kz \in U(\overline{D})$. The first two equations imply that $f(z) \neq 0$ and $f(z) \neq 1$ for every $z \in D$. In addition to this, $f(z)$ is analytic in D and $f(0) = 2$. By applying Picard–Schottky's theorem ([2, p. 19]) we have that $\mid f(z) \mid \leq e^{24}$ for every $\mid z \mid \leq \frac{1}{2}$. But then $\mid f(z) \mid < k \mid z \mid$ for $\mid z \mid = \frac{1}{2}$. This last inequality implies by Rouché's theorem [22] that $f - kz$ has a zero in $\{z : \mid z \mid \leq \frac{1}{2}\}$. This leads to a contradiction, since $f - kz \in U(\overline{D})$, and thus the theorem is proved. □

We provide the counterpart for continuous-time stability by using the conformal mapping.

COROLLARY 5.2. *Let $p_1(s) = 0, p_2(s) = (s-1)/(s+1)$, $p_3(s) = 2(s-1)/(s+1)$, $p_4(s) = 2(s-1)/((2-k)s + (2+k))$ be four continuous time systems. If $k > e^{26}$ then $p_i(s)$, $i = 1, \ldots, 4$ are simultaneously $\mathbb{R}_{+\infty}$-stabilizable but they are not simultaneously $\mathbb{C}_{+\infty}$-stabilizable.*

Proof. The four plants are simultaneously $\mathbb{C}_{+\infty}$-stabilizable if and only if $p_1(z) = 0$, $p_2(z) = z$, $p_3(z) = 2z$ and $p_4(z) = 2z/(2-kz)$ are simultaneously $\overline{D}$-stabilizable. This, in turn, implies that the four plants are simultaneously $\mathbb{C}_{+\infty}$-stabilizable if and only if $p_1(z) = 0$, $p_2(z) = z/(z+2)$, $p_3(z) = 2z/(z+2)$, and $p_4(z) = 2z/((z+2)(2-kz))$ are simultaneously $\overline{D}$-stabilizable. The impossibility of this is proved in Theorem 5.1. □

The next counterexample is slightly stronger. It applies to the case of three plants. This result also answers negatively the question addressed in the conclusion of [30].

THEOREM 5.3. *Let n be a positive integer, and let $p_{1,n}(z) = 0$, $p_{2,n}(z) = nz/(z+2)$, and $p_{3,n}(z) = -1/(nz(z+2))$ be three discrete time plants. For every n, $p_{i,n}(z)$, $i = 1, 2, 3$ are simultaneously I-stabilizable. There exists, however, an n such that $p_{i,n}(z)$, $i = 1, 2, 3$ are not simultaneously $\overline{D}$-stabilizable.*

Proof. It can be checked that for any positive integer n these three plants are simultaneously I-stabilizable; this part is left to the reader (the result follows from Theorem 4.13). The fact that they are not simultaneously $\overline{D}$-stabilizable for all n is more difficult to prove. We suppose in the sequel that for every n they are simultaneously $\overline{D}$-stabilizable and we produce a contradiction.

Notice first, since $(z+2) \in U(\overline{D})$ that $p_{i,n}(z)$ are simultaneously $\overline{D}$-stabilizable for every integer n if and only if $p'_{1,n}(z) = 0$, $p'_{2,n}(z) = nz$, and $p'_{3,n}(z) = -1/nz$ are simultaneously $\overline{D}$-stabilizable for every n. This in turn is possible if and only if for each n there exist $n_{c,n}(z), d_{c,n}(z) \in S(\overline{D})$ such that $d_{c,n}(z) \in U(\overline{D})$, $n_{c,n}(z)nz + d_{c,n}(z) \in U(\overline{D})$, and $n_{c,n}(z) - d_{c,n}(z)nz \in U(\overline{D})$. Since $d_{c,n}(z) \in U(\overline{D})$, we may define $h_n(z) \triangleq n_{c,n}(z)/d_{c,n}(z) \in S(\overline{D})$ to be the solution associated to n. We then have that $h_n(z)nz + 1 \in U(\overline{D})$ and $h_n(z) - nz \in U(\overline{D})$ for every n. In the next part we show that the existence, for every n, of a simultaneous solution $h_n(z)$ to these two equations is impossible.

Since $h_n(z)nz+1 \in U(\overline{D})$, we can define $g_n(z) = (h_n(z)nz-n^2z^2)/(h_n(z)nz+1) \in S(\overline{D})$. These functions are analytic in D, they have no zeros in $D\backslash\{0\}$ and they take the value 1 only twice in D, namely, at $z = j/n$ and $z = -j/n$. By the generalised form of Montel's normal family criterion ([16, p. 70]) this implies that the sequence $(g_n(z))$ is a normal family in $D\backslash\{0\}$. Hence, going to a subsequence, we can assume that $g_n(z)$ converges uniformly on compact subsets of $D\backslash\{0\}$. There are only two possible cases: either $g_n(z)$ tends locally uniformly to infinity, or $g_n(z)$ tends locally uniformly to an analytic function in $D\backslash\{0\}$. We show in what follows that both these cases lead to a contradiction.

Case 1. $g_n(z)$ tends locally uniformly to infinity, i.e., the functions $1/g_n(z)$ tend locally to zero on every compact set of $D\backslash\{0\}$. Consider the compact set $\{z : |z| = \frac{1}{2}\}$. Given $\epsilon > 0$, we have $|1/g_n(z)| \leq \epsilon/2 = \epsilon|z|$ for every $n \geq n_0(\epsilon)$ and $|z| = 1/2$. By definition of $g_n(z)$ we know that $nzh_n(z)(1-1/g_n(z)) = -(1+n^2z^2/g_n(z))$. Using this equality together with the bounds obtained above we get $|h_n(z)/n| \leq (\epsilon/8)/\frac{1}{2}(1-\frac{1}{4})$ for $n \geq n_0(\epsilon) + n_0(\frac{1}{2})$ and $\{z :| z |= \frac{1}{2}\}$. For some large integer n we thus have $|h_n(z)/n| < \frac{1}{2}$ when $|z| = \frac{1}{2}$, i.e., $|h_n(z)/n| < |z|$ when $|z| = \frac{1}{2}$. The functions $h_n(z)/n$ are analytic in $\{z : |z| \leq \frac{1}{2}\}$ and hence, by Rouché's theorem, $h_n(z)/n - z$ has a zero in $\{z :| z |\leq \frac{1}{2}\}$ for some integer n. But this contradicts the fact that $h_n(z) - nz \in U(\overline{D})$ and thus Case 1 cannot occur.

Case 2. $g_n(z)$ tends locally uniformly to an analytic function in $D\backslash\{0\}$. Then $g_n(z)$ are uniformly bounded on compact subsets of $D\backslash\{0\}$. Say, $|g_n(z)| \leq M$ for $|z| = \frac{1}{2}$. We have defined $g_n(z) = (h_n(z)nz - n^2z^2)/(h_n(z)nz + 1)$ and thus also $g_n(z) = 1 - (1 + n^2z^2)/(h_n(z)nz + 1)$. This last equation, together with the bound on $g_n(z)$, implies that $|(1 + n^2z^2)/(h_n(z)nz + 1)| \leq M + 1$ for $|z| = \frac{1}{2}$. This in turn implies that $|n^2/(h_n(z)nz + 1)| \leq (M + 1)/(\frac{1}{4} - 1/n^2)$ for $|z| = \frac{1}{2}$ and $n > 3$. The function $n^2/(h_n(z)nz + 1)$ is analytic in D and hence, by the Maximum Modulus Theorem, the bound obtained above holds throughout the disc of radius $\frac{1}{2}$. In particular, it holds at $z = 0$ so that we must have $n^2 \leq (M + 1)/(\frac{1}{4} - 1/n^2)$ for $n > 3$. But this inequality is obviously violated when $n > 2\sqrt{M + 2}$. A contradiction is obtained and thus Case 2 cannot occur. □

We end this paper by providing an example of a plant that has the even interlacing property but that is not $\overline{D}$-stabilizable by a unit controller. Recall that in §4.2 we established that a plant $p(z)$ is I-stabilizable by a unit controller if and only if $p(z)$ has the even interlacing property on I.

THEOREM 5.4. *Let $p_n(z) = z/(1 + n^2z^2)$. $p_n(z)$ has the even interlacing property for every positive integer n. There exists, however, an n such that $p_n(z)$ is not unit $\overline{D}$-stabilizable.*

Proof. Suppose, by contradiction, that for every integer n there exists a unit $\overline{D}$-stabilizer of $p_n(z) = z/(1 + n^2z^2)$. Then, for every positive integer n, there exist $n_{c,n}, d_{c,n} \in U(\overline{D})$ such that $zn_{c,n} + (1 + n^2z^2)d_{c,n} = u_n \in U(\overline{D})$. Since $n_{c,n}, d_{c,n} \in U(\overline{D})$ this implies that $u_n/d_{c,n} = z(n_{c,n}/d_{c,n}) + (1 + n^2z^2) = nz((n_{c,n}/nd_{c,n}) + nz) + 1 \in U(\overline{D})$. Define $h_n = (n_{c,n}/nd_{c,n}) + nz$; then, for every n, h_n defined above is such that $h_nnz + 1 \in U(\overline{D})$ and $h_n - nz \in U(\overline{D})$. This has been proved to be impossible in the proof of Theorem 5.3 and thus the theorem is proved. □

6. Conclusion. In this paper we have analysed some aspects of the simultaneous stabilization question.

Our first contribution was to show that the problem of internal stabilization of k plants p_i, $i = 1, \ldots, k$ is equivalent to what we have called an avoidance problem: "Under what condition on $p_i(s)$, $i = 1, \ldots, k$ is it possible to find $q(s)$ such that

$p_i(s) \neq q(s)$, $\forall s \in \mathbb{C}_{+\infty}$, $i = 1, \ldots, k$?" Our first message is clear: *stabilization = avoidance.* This restatement of the problem does not answer any question, but provides new insights and new proof techniques for the establishment of other results.

The second part dealt with a subproblem of the simultaneous stabilization problem. Given two plants p_1 and p_2, we showed that there exists a controller c such that the closed-loop transfer functions associated with p_1 and p_2 are stable if and only if there exist a controller c such that the closed-loop transfer functions associated to p_1 and p_2 have no *real* unstable poles. The same property is proved for the strong stabilization problem. Motivated by these results, we have developed in that part a complete answer to the question: "Given k plants p_i, $i = 1, \ldots, k$ when is it possible to find a single controller c such that all the transfer functions have no real unstable poles?" Although such a question may seem to be of limited practical interest, we have given some motivations for it.

The third part gave answers to some of the questions raised in part two and elsewhere. In particular, we showed that, unlike the case of two plants, the existence of a simultaneous stabilizing controller for more than two plants cannot be guaranteed by the existence of a controller such that the closed-loop transfer functions have no real unstable poles.

To conclude, let us stress the fact that our results provide a much better understanding of the original simultaneous stabilization problem for more than two plants but that the problem is...still unanswered.

Acknowledgments. We wish to thank F. Callier, P. Delsarte, C. Hollot, and two anonymous reviewers for their comments on a first version of this paper.

Note added in proof. Since the submission of this paper, research on simultaneous stabilization has progressed rapidly. Many of the theorems presented here have been extended and some of the proofs have been simplified. In particular, the 3-interlacing condition of §4 and all proofs §5 are given in a new simplified form in V. Blondel, *Simultaneous Stabilization of Linear Systems*, Lecture Notes in Control and Information Sciences, Springer-Verlag, Berlin, 1993.

ON GENERALIZED SECOND-ORDER DERIVATIVES AND TAYLOR EXPANSIONS IN NONSMOOTH OPTIMIZATION*

W. L. CHAN†, L. R. HUANG†, AND K. F. NG†

Abstract. A representation of Cominetti and Correa's generalized second-order directional derivative [SIAM J. Control Optim., 28 (1990), pp. 789–809] is given and then applied to obtain a Taylor theorem type result. A conjecture in [*SIAM J. Control Optim.*, 28 (1990), pp. 789–809] concerning functions of the form $\max_{1\le i\le n} g_i(x)$ is proved under a strengthened assumption, but not true otherwise.

Key words. Dini-directional derivative, Clarke's directional derivative, generalized second-order directional derivative, Taylor expansion, nonsmooth analysis

AMS subject classifications. 26A27, 26E15, 49A52, 49B27, 49D37

Introduction. Since the pioneering works of F. Clarke and B. N. Pshenichnyi, generalized directional derivatives have been studied, and successfully applied in various fields (e.g., [1]–[8], [12]–[18]), especially in optimization and control theory. The study of generalized second-order directional derivatives is more recent; one of such derivatives is defined in Cominetti and Correa [2] by

$$f^{\infty}(x;u,v) := \lim \sup_{\substack{y\to x\\ s,t\downarrow 0}} \frac{1}{ts}\{f(y+tu+sv) - f(y+tu) - f(y+sv) + f(y)\}.$$

On the basis of their work, in Proposition 1.4 we represent $f^{\infty}(x;u,v)$ in the form of the upper limit of the rates of changes of the Dini-directional derivatives. This representation enables us to establish second-order Taylor expansions (Theorems 3.2 and 3.3) for nonsmooth functions. These extend the corresponding results of Cominetti and Correa who assumed the C^1-condition. In §5 we apply our results to a large class of functions (e.g., convex and concave functions) that are not covered by [2], Prop. 4.1. Applications to optimization theory are presented in §6.

In [2], a conjecture was made about the possible validity of $h^{\infty}(x;u,v) = \max_{1\le i\le n} D^2 g_i(x;u,v)$, where each g_i is C^2 and $D^2 g_i$ denotes the second-order directional derivative. Example 2.3 shows that the conjecture is incorrect and an affirmative answer is given in Corollary 2.5 and Corollary 2.7 under similar strengthened conditions.

1. Dini-directional derivatives, Clarke's directional derivatives, and generalized second-order directional derivatives. Let X be a locally convex space and $f : X \to \mathbb{R}$ a function. We consider the extended real field $\bar{\mathbb{R}} = \mathbb{R}\cup\{-\infty, +\infty\}$ with the usual operations, order, and topology familiar in convex analysis. Denote the upper and lower Dini-directional derivatives by

$$D^+ f(x;v) := \lim \sup_{t\downarrow 0} \frac{1}{t}(f(x+tv) - f(x)),$$

$$D_+ f(x;v) := \lim \inf_{t\downarrow 0} \frac{1}{t}(f(x+tv) - f(x)),$$

and the upper and lower Clarke's directional derivatives at x along the direction $v \in X$ by

$$f^0(x;v) := \lim \sup_{\substack{y\to x\\ t\downarrow 0}} \frac{1}{t}(f(y+tv) - f(y))$$

* Received by the editors March 12, 1992; accepted for publication (in revised form) September 21, 1992.

and

$$f_0(x;v) := \lim \inf_{\substack{y\to x\\ t\downarrow 0}} \frac{1}{t}(f(y+tv)-f(y)).$$

If $X=\mathbb{R}$ and $v=1$, we shall write $D^+f(x)$ for $D^+f(x;v)$ and similarly for $D_+f(x)$, $f^0(x)$. We shall often make use of the elementary computation rules for lim sup and lim inf without further comments, e.g., if $f=f_1-f_2$, then

$$D_+f(x)\le D_+f_1(x)-D_+f_2(x),$$

provided that the two terms on the right are finite. Also $D_+f(x)\le D^+f_1(x)-D^+f_2(x)$ with similar provisions (see, for instance, [17], p. 108).

Furthermore, as in [2], [4], and [5] we define the upper and lower generalized second-order directional derivatives at x in the direction $(u,v)\in X\times X$ by

$$f^\infty(x;u,v) := \lim \sup_{\substack{y\to x\\ t,s\downarrow 0}} \frac{1}{st}\{f(y+tu+sv)-f(y+tu)-f(y+sv)+f(y)\}$$

and

$$f_\infty(x;u,v) := \lim \inf_{\substack{y\to x\\ t,s\downarrow 0}} \frac{1}{st}\{f(y+tu+sv)-f(y+tu)-f(y+sv)+f(y)\}.$$

For the sake of convenience, we list some of its properties in the following proposition. For more detailed properties of f^∞ we refer to [2], [4].

PROPOSITION 1.1 [2]. *Let $f: X\to\mathbb{R}$ and $x\in X$. Then*

(i) *The map $(u,v)\mapsto f^\infty(x;u,v)$ is symmetric and sublinear on each variable separately.*

(ii) *The map $y\mapsto f^\infty(y;u,v)$ is upper semi-continuous at x for every $(u,v)\in X\times X$.*

(iii) $f^\infty(x;u,-v)=f^\infty(x;-u,v)=(-f)^\infty(x;u,v)=-f_\infty(x;u,v)$.

Before studying the relationships between the above directional derivatives, we give a few lemmas which will often be used in the sequel. Lemma 1.2 has appeared in [2], Lems. 1.4 and 1.5.

LEMMA 1.2. *Let $f: X\to\mathbb{R}$ be a continuous function, $x,v\in X$, and $t>0$. Then there exists $\alpha\in(0,t)$ such that*

$$\frac{f(x+tv)-f(x)}{t}\le D_+f(x+\alpha v;v).$$

Consequently,

$$\lim \sup_{y\to x} D_+f(y;v)=\lim \sup_{y\to x} D^+f(y;v)=\lim \sup_{y\to x} f^0(y;v)=f^0(x;v).$$

Remark. If let $f=-g$, then we have

$$\frac{g(x+tv)-g(x)}{t}\ge D^+g(x+\alpha v;v),$$

and so the corresponding results for $f_0(x;v)$.

From Lemma 1.2 we have the following.

LEMMA 1.3. *Suppose that* $f : X \to \mathbb{R}$ *is continuous and* $x, u, v \in X$. *Then for any* $t_0 > 0, t \in (0, t_0)$ *and* $s \in \mathbb{R}$ *there exists* $\alpha \in (0, t)$ *such that*

$$\begin{aligned} &\frac{1}{t}[f(x+sv+tu) - f(x+sv) - f(x+tu) + f(x)] \\ &\le D^+f(x+\alpha u+sv;u) - D^+f(x+\alpha u;u) \end{aligned} \tag{1.1}$$

and

$$\begin{aligned} &\frac{1}{t}[f(x+sv+tu) - f(x+sv) - f(x+tu) + f(x)] \\ &\le D_+f(x+\alpha u+sv;u) - D_+f(x+\alpha u;u) \end{aligned} \tag{1.2}$$

if $D^+f(\cdot\,;u)$ *and* $D_+f(\cdot\,;u)$ *are finite on the segments* $(x, x+t_0u)$ *and* $(x+sv, x+sv+t_0u)$.

Remark. If we let $f = -g$, then we have

$$\begin{aligned} &\frac{1}{t}[g(x+sv+tu) - g(x+sv) - g(x+tu) + g(x)] \\ &\ge D_+g(x+\alpha u+sv;u) - D_+g(x+\alpha u;u) \end{aligned} \tag{1.1$'$}$$

and

$$\begin{aligned} &\frac{1}{t}[g(x+sv+tu) - g(x+sv) - g(x+tu) + g(x)] \\ &\ge D^+g(x+\alpha u+sv;u) - D^+g(x+\alpha u;u). \end{aligned} \tag{1.2$'$}$$

Proof. Let us fix an arbitrary $s \in \mathbb{R}$ and denote the left number of (1.1) by

$$\frac{\Phi(t) - \Phi(0)}{t}$$

where $\Phi(t) := f(x+sv+tu) - f(x+tu) = \Phi_1(t) - \Phi_2(t)$ with the obvious meaning of Φ_1, Φ_2. If $t_0 > 0$ and $t \in (0, t_0)$, then by Lemma 1.2, there exists an $\alpha \in (0, t)$ such that

$$\frac{\Phi(t) - \Phi(0)}{t} \le D_+\Phi(\alpha),$$

where $D_+\Phi(\alpha)$ denotes $D_+\Phi(\alpha; 1)$ for short. By assumption $D^+\Phi_1(\alpha), D^+\Phi_2(\alpha)$ are finite, and it follows that

$$\begin{aligned} \frac{\Phi(t) - \Phi(0)}{t} &\le D_+\Phi(\alpha) \le D^+\Phi_1(\alpha) - D^+\Phi_2(\alpha) \\ &= D^+f(x+\alpha u+sv;u) - D^+f(x+\alpha u;u). \end{aligned}$$

This proves (1.1), and similarly one can prove (1.2) because

$$D_+\Phi(\alpha) \le D_+\Phi_1(\alpha) - D_+\phi_2(\alpha)$$

as the two terms on the right are finite. □

Recall that f is regular at x [1] if the one-sided directional derivative

$$f'(x;v) = \lim_{t \downarrow 0} \frac{1}{t}(f(x+tv) - f(x)),$$

exists and $f'(x;v) = f^0(x;v)$ for all v.

PROPOSITION 1.4. *Let $f : X \to R$ be a continuous function. Let $x, u, v \in X$ and suppose that $f^0(\cdot\,; u), D^+f(\cdot\,; u)$ and $D_+f(\cdot\,; u)$ are finite near x. Then one has*

$$\begin{aligned}&(f^0(\cdot\,; u))^0(x; v)\\ &\le f^\infty(x; u, v) = (D^+f(\cdot\,; u))^0(x; v) = (D_+f(\cdot\,; u))^0(x; v);\end{aligned} \tag{1.3}$$

that is,

$$\begin{aligned}&\limsup_{\substack{y\to x\\ s\downarrow 0}} \frac{1}{s}(f^0(y+sv; u) - f^0(y; u))\\ &\le f^\infty(x; u, v) = \limsup_{\substack{y\to x\\ s\downarrow 0}} \frac{1}{s}(D_+f(y+sv; u) - D_+f(y; u))\\ &= \limsup_{\substack{y\to x\\ s\downarrow 0}} \frac{1}{s}(D^+f(y+sv; u) - D^+f(y; u)).\end{aligned} \tag{1.4}$$

Dually one also has

$$\begin{aligned}&(f_0(\cdot\,; u))_0(x; v)\\ &\ge f_\infty(x; u, v) = (D_+f(\cdot\,; u))_0(x; v) = (D^+f(\cdot\,; u))_0(x; v)\end{aligned} \tag{1.5}$$

if $f_0(\cdot\,; u), D_+f(\cdot\,; u)$, and $D^+f(\cdot\,; u)$ are finite near x.

Furthermore, if f is regular near x, then the inequality in (1.3) *becomes an equality.*

Proof. We need only prove (1.3) as (1.5) will then follow by considering $-f = g$ (the assertion for the regular case is evident from (1.4) because then $D_+f(y+sv; u) = f^0(y+sv; u)$ for all y near x and small v). By Lemma 1.2 we have

$$\limsup_{z\to y} D^+f(z+sv; u) = f^0(y+sv; u).$$

Thus, since $f^0(\cdot\,; u)$ is finite near x, it follows from the subadditivity of lim sup that

$$f^0(y+sv; u) - f^0(y; u) \le \limsup_{z\to y}(D^+f(z+sv; u) - D^+f(z; u)).$$

This implies that

$$\begin{aligned}&(f^0(\cdot\,; u))^0(x, v)\\ &= \limsup_{\substack{y\to x\\ s\downarrow 0}} \frac{1}{s}(f^0(y+sv; u) - f^0(y; u))\\ &\le \limsup_{\substack{y\to x\\ s\downarrow 0}} \limsup_{z\to y} \frac{1}{s}(D^+f(z+sv; u) - D^+f(z; u))\\ &\le \limsup_{\substack{y\to x\\ s\downarrow 0}} \frac{1}{s}(D^+f(y+sv; u) - D^+f(y; u))\\ &= (D^+f(\cdot\,; u))^0(x; v),\end{aligned} \tag{1.6}$$

showing the inequality in (1.3).

On the other hand, since $D^+f(\cdot\,; u)$ and $D_+f(\cdot\,; u)$ are finite near x, one has, by the subadditivity of lim sup,

$$\begin{aligned}&D^+f(y+sv; u) - D^+f(y; u)\\ &\le \limsup_{t\downarrow 0} \frac{1}{t}[f(y+sv+tu) - f(y+sv) - f(y+tu) + f(y)]\end{aligned}$$

and also

$$\begin{aligned} &D_+f(y+sv;u)-D_+f(y;u)\\ &\le \limsup_{t\downarrow 0}\frac{1}{t}[f(y+sv+tu)-f(y+sv)-f(y+tu)+f(y)]. \end{aligned}$$

These imply that

$$\begin{aligned} &(D^+f(\cdot\,;u))^0(x;v)\\ &=\limsup_{\substack{y\to x\\ s\downarrow 0}}\frac{1}{s}(D^+f(y+sv;u)-D^+f(y;u))\\ &\le\limsup_{\substack{y\to x\\ s,t\downarrow 0}}\frac{1}{st}[f(y+sv+tu)-f(y+sv)-f(y+tv)+f(y)]\\ &=f^\infty(x;u,v) \end{aligned} \tag{1.7}$$

and, similarly,

$$\begin{aligned} &(D_+f(\cdot\,;u))^0(x;v)\\ &=\limsup_{\substack{y\to x\\ s\downarrow 0}}\frac{1}{s}(D_+f(y+sv;u)-D_+f(y;u))\\ &\le\limsup_{\substack{y\to x\\ t,s\downarrow 0}}\frac{1}{ts}[f(y+sv+tu)-f(y+sv)-f(y+tu)+f(y)]\\ &=f^\infty(x;u,v). \end{aligned} \tag{1.8}$$

By definition and (1.2) of Lemma 1.3,

$$\begin{aligned} &f^\infty(x;u,v)\\ &=\limsup_{\substack{y\to x\\ t,s\downarrow 0}}\frac{1}{ts}[f(y+sv+tu)-f(y+sv)-f(y+tu)+f(y)]\\ &\le\limsup_{\substack{y\to x\\ t,s\downarrow 0}}\frac{1}{s}(D_+f(y+\alpha u+sv;u)-D_+f(y+\alpha u;u)] \qquad \alpha\in(0,t)\\ &=\limsup_{\substack{y\to x\\ s\downarrow 0}}\frac{1}{s}(D_+f(y+sv;u)-D_+f(y;u))\\ &=(D_+f(\cdot\,;u))^0(x;v), \end{aligned} \tag{1.9}$$

where we have written α for $\alpha=\alpha(y,s,u,v)$ for the sake of simplicity in notations. Similarly,

$$f^\infty(x;u,v)\le(D^+f(\cdot\,;u))^0(x;v). \tag{1.10}$$

Together with (1.6), (1.7), (1.8), and (1.9), we have (1.3). □

Remark. There are examples of Lipschitz functions on an interval say $[0,b]$ that fail to be right-differentiable at infinitely many points near 0. Thus the representation given in the preceding proposition is valid, but cannot be expressed in the form of (3) in [2], Prop. 1.3. For example, write

$$(0,1/2\pi]=\bigcup_{k=1}^{\infty}[x_{k+1},x_k],\qquad x_k=1/2k\pi.$$

Define $f(0)=0, f(x_k)=0$ and

$$f(x)=(x-x_{k+1})(x_k-x)\sin(x-x_{k+1})^{-1}$$

if $x \in (x_{k+1}, x_k)$. Then $f'_+(x)$ does not exist at each x_k.

In view of Proposition 1.4 we introduce the following generalized second-order directional derivative in line of Clarke's derivatives as an alternative to $f^\infty(x; u, v)$.

DEFINITION 1.5. *Let $f : X \to \mathbb{R}, x, v \in X$, and suppose that $f^0(x; v)$ and $f_0(\cdot\,; v)$ are finite near x. Then the upper and lower generalized second-order directional derivatives are defined, respectively, by*

$$f^{00}(x; u, v) := \lim \sup_{\substack{y \to x \\ t \downarrow 0}} \frac{1}{t}(f^0(y + tu; v) - f^0(y; v))$$

and

$$f_{00}(x; u, v) := \lim \inf_{\substack{y \to x \\ t \downarrow 0}} \frac{1}{t}(f_0(y + tu; v) - f_0(y; v)).$$

It is easy to see that the function $u \mapsto f^{00}(x; u, v)$ is sublinear and the function $x \mapsto f^{00}(x; u, v)$ is upper semi-continuous. Furthermore, if f is continuous and $f^0(x; v)$, $f_0(x; v)$ are finite near x, then from the above proposition we have

$$f_\infty(x; u, v) \le f_{00}(x; u, v) \le f^{00}(x; u, v) \le f^\infty(x; u, v);$$

and $f^{00}(x; u, v) = f^\infty(x; u, v)$ if f is regular near x.

In §6 we shall give applications of f^∞ and f^{00} in the second-order necessary optimality condition for constrained problem.

2. On Cominetti and Correa's conjecture. In this section we study second-order directional derivative of the function h of the form

$$h(x) = \max\{g_1(x), g_2(x), \ldots, g_n(x)\} \qquad (x \in X)$$

where each g_i is a real-valued function on X. Note that $h = f \circ g$ if one writes $g = (g_1, g_2, \ldots, g_n)$ and defines

$$f(a) = \max_{i \in I}\{a_i\}, \quad \text{for any } a = (a_1, \ldots, a_n) \in \mathbb{R}^n$$

where $I := \{1, 2, \ldots, n\}$. Let $I(a)$ denote the subset of I consisting of all i for which $f(a) = a_i$.

For $x, u, v \in X$ we shall write $H(x; u, v) \underline{\propto} 0$ to denote the following condition:

$$(g'_i(x; u) - g'_j(x; u))(g'_i(x; v) - g'_j(x; v)) \le 0$$

for all $i, j \in I(g(x))$, and $H(x; u, v) \propto 0$ to denote the condition that the strict inequality holds for all distinct $i, j \in I(g(x))$.

Suppose each g_i is a C^2-function with the usual second-order directional derivative at x with respect to the directions u, v denoted by $D^2 g_i(x; u, v)$. Cominetti and Correa conjectured in [2] that if $\{g'_i(x); i \in I(g(x))\}$ is affinely independent, then the following formula holds

$$h^\infty(x; u, v) = \max_{i \in I(g(x))} D^2 g_i(x; u, v) \tag{2.1}$$

if $H(x; u, v) \underline{\propto} 0$. This is incorrect as shown by Example 2.3 below, but true if the condition is strengthened to $H(x; u, v) \propto 0$ (Corollary 2.5).

In the following we first consider a property related to the set $I(a)$.

LEMMA 2.1. *Suppose that X is a locally convex space and g is arbitrary continuous function of X into $\mathbb{R}^n$ denoted by $g = (g_1, \ldots, g_n)$. Then for the above f and any $x \in X$, there exists a neighborhood W of x such that*

$$I(g(y)) \subseteq I(g(x))$$

for all $y \in W$.

Proof. We fix $i \in I(g(x))$. Then, for each $j \in I \backslash I(g(x))$,

$$g_j(\cdot) < g_i(\cdot)$$

at x and hence on a neighborhood W_j of x. Do this for each such j and let W denote the intersection of W_j's. Then W has the required property: if $y \in W$ and $j \notin I(g(x))$, then $g_j(y) < g_i(y)$ showing that $j \notin I(g(y))$. □

LEMMA 2.2. *Suppose that $g'(\cdot) = (g_1'(\cdot), \ldots, g_n'(\cdot))$ is continuous near x and $g_1'(x), \ldots, g_n'(x)$ are affinely independent. Then either there exists a neighborhood W of x such that the following condition $H(y; u, v) \underline{\propto} 0$ holds for each $y \in W$:*

$$(g_i'(y; v) - g_j'(y; v))(g_i'(y; u) - g_j'(y; u)) \leq 0, \quad \forall i, j \in I(g(y))$$

or

$$h^{\infty}(x; u, v) = +\infty.$$

Proof. By the continuity of g' at x it is easy to show that there exists a neighborhood W_1 of x such that $g_1'(y), \ldots, g_n'(y)$ are affinely independent for all $y \in W_1$. Now if for each neighborhood U of x, there exists $y \in U \cap W_1$ so that the condition $H(y; u, v) \underline{\propto} 0$ is not satisfied, then by [2], Prop. 3.9, $h^{\infty}(y; u, v) = +\infty$. Hence by the upper semicontinuity of $h^{\infty}(\cdot\,; u, v)$,

$$h^{\infty}(x; u, v) = +\infty. \qquad \square$$

Example 2.3. Let $g = (g_1, g_2, g_3)$ with the C^2-functions $g_1(x, y, z) = \xi(x) + x + y, g_2(x, y, z) = x + 2y$ and $g_3(x, y, z) = 4(x - y) + z$ for all $x, y, z \in \mathbb{R}$, where

$$\xi(x) = \begin{cases} x^5 \sin \dfrac{1}{x}, & x \neq 0, \\ 0, & x = 0. \end{cases}$$

Let $\bar{x} = (0, 0, 0)$. Since $g_1, g_2, g_3 = 0$ at $\bar{x}, I(g(\bar{x})) = \{1, 2, 3\}$. Further, $g_1'(\bar{x}) = (1, 1, 0), g_2'(\bar{x}) = (1, 2, 0)$, and $g_3'(\bar{x}) = (4, -4, 1)$. Thus, $g_1'(\bar{x}), g_2'(\bar{x})$, and $g_3'(\bar{x})$ are linearly independent. Let

$$u = (1, 0, 0) \quad \text{and} \quad v = (1, 1, 0).$$

Then

$$g_1'(\bar{x}; u) - g_2'(\bar{x}; u) = 1 - 1 = 0 \quad \text{and} \quad g_1'(\bar{x}; v) - g_2'(\bar{x}; v) = 2 - 3 < 0.$$

Similarly we can verify, for all other pairs of distinct i, j, that $g_1'(\bar{x}; u) - g_j'(\bar{x}; u)$ and $g_i'(\bar{x}; v) - g_j'(\bar{x}; v)$ are of opposite signs (or zero); that is, the Cominetti and Correa's condition $H(\bar{x}; u, v) \underline{\propto} 0$ is satisfied. But, in constrast to their conjecture, (2.1) does not hold. In fact, we will prove that

$$h^{\infty}(\bar{x}; u, v) = +\infty. \tag{2.2}$$

Let $P_n := (x_n, y_n, 0)$ with

$$x_n = -\frac{1}{2n\pi + \frac{\pi}{2}} \quad \text{and} \quad y_n = \frac{1}{\left(2n\pi + \frac{\pi}{2}\right)^5} = -x_n^5.$$

Then

$$g_1(P_n) = -x_n^5 + x_n + y_n = g_2(P_n).$$

This implies that $I(g(P_n)) = \{1, 2\}$ because $x_n \leq 2y_n$. Further,

$$g_1'(P_n) = \left(1 - 5\left(2n\pi + \frac{\pi}{2}\right)^{-4}, 1, 0\right)$$

and so

$$g_1'(P_n; u) - g_2'(P_n; u) = -5\left(2n\pi + \frac{\pi}{2}\right)^{-4} < 0$$

and

$$g_1'(P_n; v) - g_2'(P_n; v) = 2 - 5\left(2n\pi + \frac{\pi}{2}\right)^{-4} - 3 < 0.$$

Thus the condition $H(P_n; u, v) \underline{\propto} 0$ does not hold for all n. Since $P_n \to \bar{x}$, it follows from Lemma 2.2 that (2.2) must hold.

The above example actually shows that for $n \geq 2$ (if $n = 2$, we ignore g_3), the condition $H(x; u, v) \underline{\propto} 0$ is not sufficient for

$$h^\infty(x; u, v) = \max_{i \in I(g(X))} D^2 g_i(x; u, v).$$

We shall show however that the strengthened condition $H(x; u, v) \propto 0$ will be sufficient. Before our proof, we recall an elementary fact that if each g_i is directionally differentiable at x, then one has

$$h'(x; u) = \max_{i \in I(g(x))} g_i'(x; u) \tag{2.3}$$

for all $u \in X$.

PROPOSITION 2.4. *Suppose that each g_i is a C^1-function (that is, continuous Gâteaux differentiable function) at x. If for all $i, j \in I(g(x)), i \neq j$, one has*

$$[g_i'(x; u) - g_j'(x; u)][g_i'(x; v) - g_j'(x; v)] < 0, \tag{2.4}$$

then

$$h^\infty(x; u, v) \leq \max_{i \in I(g(X))} g_i^\infty(x; u, v).$$

Proof. By Proposition 1.4, we take a net $(z_\nu, \lambda_\nu)_\nu \in X \times \mathbb{R}_+$ written for short (z, λ) with $z \to x$ and $\lambda \downarrow 0$ such that

$$\begin{aligned} h^\infty(x; u, v) &= \lim_{\substack{z \to x \\ \lambda \downarrow 0}} \frac{1}{\lambda}(h'(z + \lambda u; v) - h'(z; v)) \\ &= \lim_{\substack{z \to x \\ \lambda \downarrow 0}} \frac{1}{\lambda}\left(\max_{i \in I(g(z+\lambda u))} g_i'(z + \lambda u; v) - \max_{i \in I(g(z))} g_i'(z; v)\right). \end{aligned}$$

In view of Lemma 2.1, we can assume that

$$I(g(z)), I(g(z+\lambda u)) \subseteq I(g(x)). \tag{2.5}$$

Since I is a finite set and considering a subnet if necessary we can assume without loss of generality that

$$h'(z;v) = \max_{i\in I(g(z))} g_i'(z;v) = g_1'(z;v) \quad \text{say,}$$

and

$$h'(z+\lambda u;v) = \max_{i\in I(g(z+\lambda u))} g_i'(z+\lambda u;v) = g_{i_0}'(z+\lambda u;v)$$

for some $i_0 \in I(g(z+\lambda u))$ and for all (z,λ).

We claim that there exists a subnet (z_s,λ_s) of (z,λ) such that

$$g_{i_0}'(z_s;v) - g_1'(z_s;v) \le 0.$$

In this case we will then obtain

$$\begin{aligned} h^\infty(x;u,v) &= \lim_s \frac{1}{\lambda_s}[g_{i_0}'(z_s+\lambda u;v) - g_{i_0}'(z_s;v) \\ &\qquad + g_{i_0}'(z_s;v) - g_1'(z_s;v)] \\ &\le \limsup_s \frac{1}{\lambda_s}[g_{i_0}'(z_s+\lambda u;v) - g_{i_0}'(z_s;v))] \\ &\le g_{i_0}^\infty(x;u,v). \end{aligned}$$

By (2.5), $i_0 \in I(g(x))$ and so we are done.

If our claim is false, then by considering a subnet if necessary, we assume that for all (z,λ)

$$g_{i_0}'(z;v) - g_1'(z;v) > 0 \tag{2.6}$$

where

$$i_0 \in I(g(z+\lambda u)) \quad \text{and} \quad 1 \in I(g(z)) \tag{2.7}$$

for all (z,λ). It follows that $g_{i_0}'(x;v) - g_1'(x;v) \ge 0$ and from (2.4) that the strict inequality must hold and

$$g_{i_0}'(x;u) - g_1'(x;u) < 0. \tag{2.8}$$

Since g_i is C^1, the formula (2.8) can be rewritten as

$$\lim_{\substack{y\to x \\ t\downarrow 0}} \frac{1}{t}[g_{i_0}(y+tu) - g_{i_0}(y) - g_1(y+tu) + g_1(y)] < 0$$

and so we can choose a neighborhood W of x and $\delta > 0$ such that

$$(g_{i_0}(y+tu) - g_{i_0}(y) - g_1(y+tu) + g_1(y)) < 0 \tag{2.9}$$

for all $y \in W$ and $0 < t < \delta$. Without loss of generality, we can assume that

$$(z,\lambda) \in W \times (0,\delta).$$

From (2.6) and the choice of 1, we see that $i_0 \notin I(g(z))$ and so $g_{i_0}(z) < g_1(z)$ for all (z, λ). Thus, together with (2.9) we conclude that

$$\begin{aligned} &g_{i_0}(z+\lambda u) - g_1(z+\lambda u) \\ &< g_{i_0}(z+\lambda u) - g_{i_0}(z) - g_1(z+\lambda u) + g_1(z) < 0. \end{aligned}$$

But this is impossible since

$$i_0 \in I(g(z+\lambda u)). \qquad \square$$

COROLLARY 2.5. *Suppose that each g_i is a C^2-function at $x, 1 \le i \le n$, and the derivatives $g_i'(x)$ are affinely independent. If for all $i, j \in I(g(x)), i \ne j$, one has*

$$(g_i'(x;u) - g_j'(x;u))(g_i'(x;v) - g_j'(x;v)) < 0,$$

then

$$h^\infty(x;u,v) = \max_{i \in I(g(X))} D^2 g_i(x;u,v).$$

Proof. Since each g_i is a C^2-function,

$$g_i^\infty(x;u,v) = D^2 g_i(x;u,v).$$

It follows from Proposition 2.4 that

$$h^\infty(x;u,v) \le \max_{i \in I(g(X))} D^2 g_i(x;u,v).$$

But the assumption on affinely independence ensures

$$h^\infty(x;u,v) \ge \max_{i \in I(g(X))} D^2 g_i(x;u,v)$$

[2], Prop. 3.7 and 3.8. $\square$

For normed spaces, we have another sufficient condition result for the similar representation of h^∞.

PROPOSITION 2.6. *Let X be a normed space, $u, x \in X$ and $g_i, 1 \le i \le n$, be C^2-functions at x. Suppose that W is a neighborhood of x such that for all $y \in W$ and $i, j \in I(g(y))$, one has $g_i'(y;u) = g_j'(y;u)$. Then*

$$h^\infty(x;u,u) = \max_{i \in I(g(x))} D^2 g_i(x;u,u).$$

Proof. Note first that since $g_i, 1 \le i \le n$, are C^2-functions, $g_i'(\cdot\,;u)$ are continuous on some neighborhood $W_1 \subseteq W$ of x (see [1], p. 32, cor.). Consequently by Lemma 2.1 and (2.3) $h'(\cdot\,;u)$ is also continuous. Next we show that

$$D^+(h'(\cdot\,;u))(z;u) = \max_{i \in I(g(z))} D^2 g_i(z;u,u) \tag{2.10}$$

for any $z \in W_1$. To do this, we choose a subnet $t_\nu > 0$ written for short t such that

$$\begin{aligned} D^+(h'(\cdot\,;u))(z;u) &= \lim_{t \downarrow 0} \frac{1}{t}\{h'(z+tu;u) - h'(z;u)\} \\ &= \lim_{t \downarrow 0} \frac{1}{t}\left\{ \max_{i \in I(g(z+tu))} g_i'(z+tu;u) - \max_{i \in I(g(z))} g_i'(z;u) \right\}. \end{aligned}$$

By Lemma 2.1 we can assume that $I(g(z+tu)) \subseteq I(g(z))$ and $z+tu \in W_1$. Since I is a finite set and considering a subnet if necessary, we can assume without loss of generality that there exists $i_z \in I(g(z+tu)) \subseteq I(g(z))$ such that

$$\max_{i \in I(g(z+tu))} g_i'(z+tu;u) = g_{i_z}'(z+tu;u)$$

for all t. By assumption, $g_i'(z;u) = g_{i_z}'(z;u)$ so

$$\max_{i \in I(g(z))} g_i'(z;u) = g_{i_z}'(z;u),$$

it follows that

$$\begin{aligned} D^+(h'(\cdot\,;u))(z;u) &= \lim_{t \downarrow 0} \frac{1}{t}\{g_{i_z}'(z+tu;u) - g_{i_z}'(z;u)\} \\ &= D^2 g_{i_z}(z;u,u). \end{aligned}$$

Now if (2.10) is not true, there must exist $i \in I(g(z))$ such that

$$D^2 g_i(z;u,u) > D^2 g_{i_z}(z;u,u);$$

since $g_i'(y;u) = g_{i_z}'(y;u)$ by assumption, it follows that

$$g_i'(z+\tau u;u) - g_{i_z}'(z+\tau u;u) > 0$$

for all small enough $\tau > 0$. Now we choose a small enough t from our net $\{t_\nu\}$ and recall that $i_z \in I(g(z+tu))$. But

$$\int_0^t (g_i - g_{i_z})'(z+\tau u;u)\,d\tau = g_i(z+tu) - g_{i_z}(z+tu) > 0,$$

contradicting the given assumption. Thus (2.10) is proved. On the other hand, we have by Proposition 1.4 that

$$\begin{aligned} h^\infty(x;u,u) &= (h'(\cdot\,;u))^0(x;u) = \limsup_{z \to x} D^+(h'(\cdot\,;u))(z;u) \\ &= \limsup_{z \to x} \max_{i \in I(g(z))} D^2 g_i(z;u,u) = D^2 g_{i_0}(x;u,u) \end{aligned}$$

for some $i_0 \in I(g(x))$, where the last equality is valid because of Lemma 2.1 and the fact that I is a finite set. Since

$$h^\infty(x;u,u) \geq D^+(h'(\cdot\,;u))(x;u)$$

and by (2.10)

$$D^+(h'(\cdot\,;u))(x;u) = \max_{i \in I(g(x))} D^2 g_i(x;u,u),$$

it follows that

$$h^\infty(x;u,u) = \max_{i \in I(g(x))} D^2 g_i(x;u,u). \qquad \square$$

COROLLARY 2.7. *Let X be a normed space, $u, x \in X$ and g_i, $1 \leq i \leq n$, be C^2-functions at x. Suppose further that $g_i'(x)$ are affinely independent. Then*

$$h^\infty(x;u,u) = \max_{i \in I(g(x))} D^2 g_i(x;u,u)$$

if and only if there exists a neighborhood W of x such that

$$g_i'(y;u) = g_j'(y;u)$$

for all $y \in W$ and $i, j \in I(g(y))$.

Proof. The sufficiency follows from Proposition 2.6. Conversely if $h^\infty(x;u,u) = \max_{i\in I(g(x))} D^2 g_i(x;u,u)$, then $h^\infty(x;u,u)$ is finite and hence, by Lemma 2.2, there exists a neighborhood W of x such that the condition $H(y;u,u) \underline{\propto} 0$ holds for each $y \in W$. This implies immediately that

$$g_i'(y;u) - g_j'(y;u) = 0$$

for all $y \in W$ and $i, j \in I(g(y))$. □

3. Generalized second-order Taylor expansion. Suppose that X and f are as in §1, we define the generalized Hessian [2] of f at x by

$$\partial^2 f(x)(u) := \{x^* \in X^*; \langle x^*, v\rangle \le f^\infty(x;u,v) \text{ for all } v \in X\},$$

where the symbol X^* denotes the dual space of X. It is easy to see that $\partial^2 f(x)(u)$ is a closed convex subset of X^* with respect to the w^*-topology. If f is twice C-differentiable at x [2], that is, $f^\infty(x;\cdot\,,v)$ (or equivalently $f^\infty(x;v,\cdot)$) is lower semi-continuous for each $v \in X$, then one has

$$f^\infty(x;u,v) = \sup\langle \partial^2 f(x)(u), v\rangle. \tag{3.1}$$

Now for a, u, v, and $x \in X$, we consider the following new kinds of first- and second-order directional derivatives, respectively, defined by

$$f_a^0(x;u) := \limsup_{\substack{\lambda\to 0\\ s\downarrow 0}} \frac{1}{s}\{f(x+\lambda a+su) - f(x+\lambda a)\},$$

$$f_{+a}^0(x;u) := \limsup_{s,\lambda\downarrow 0} \frac{1}{s}\{f(x+\lambda a+su) - f(x+\lambda a)\},$$

$$f_{-a}^0(x;u) := \limsup_{\substack{\lambda\uparrow 0\\ s\downarrow 0\\ \lambda+s\le 0}} \frac{1}{s}\{f(x+\lambda a+su) - f(x+\lambda a)\},$$

$$f_{0,a}(x;u) := -(-f)_a^0(x;u), \qquad f_{0,+a}(x;u) := -(-f)_{+a}^0(x;u)$$

and

$$f_a^\infty(x;u,v) := \limsup_{\substack{\lambda\to 0\\ s,t\downarrow 0}} \frac{1}{st}\{f(x+\lambda a+tu+sv) - f(x+\lambda a+tu) - f(x+\lambda a+sv) + f(x+\lambda a)\},$$

$$f_{\infty,a}(x;u,v) := \liminf_{\substack{\lambda\to 0\\ s,t\downarrow 0}} \frac{1}{st}\{f(x+\lambda a+tu+sv) - f(x+\lambda a+tu) - f(x+\lambda a+sv) + f(x+\lambda a)\},$$

(f_a^0 and f_a^∞ are different from f^0 and f^∞ as here we only consider

$$x + \lambda a \to x$$

along the direction a).

In terms of f_a^0, f_{+a}^0, and f_{-a}^0, we have the following.

LEMMA 3.1. *Suppose that $f : X \to \mathbb{R}$ is a continuous function. Then one has*

$$f_{+a}^0(x;a) = \lim \sup_{\lambda \downarrow 0} D^+ f(x+\lambda a;a),$$
$$f_{-a}^0(x;a) = \lim \sup_{\lambda \uparrow 0} D^+ f(x+\lambda a;a),$$

and

$$f_a^0(x;a) = \lim \sup_{\lambda \to 0} D^+ f(x+\lambda a;a).$$

Proof. Let $x, a \in X$, and $\lambda < 0, s > 0$. By Lemma 1.2 there exists $\alpha \in (0,s)$ such that

$$\frac{1}{s}\{f(x+\lambda a+sa) - f(x+\lambda a)\} \le D^+ f(x+\lambda a+\alpha a;a).$$

Hence, by the definition of f_{-a}^0 we have

$$f_{-a}^0(x;a) \le \lim \sup_{\lambda \uparrow 0} D^+ f(x+\lambda a;a).$$

But

$$\begin{aligned}\lim \sup_{\lambda \uparrow 0} D^+ f(x+\lambda a;a) &= \lim \sup_{\lambda \uparrow 0} \lim \sup_{s \downarrow 0} \frac{1}{s}\{f(x+\lambda a+sa) - f(x+\lambda a)\} \\ &\le \lim \sup_{\substack{\lambda \uparrow 0 \\ s \downarrow 0 \\ \lambda + s \le 0}} \frac{1}{s}\{f(x+\lambda a+sa) - f(x+\lambda a)\} = f_{-a}^0(x;a).\end{aligned}$$

So we have $f_{-a}^0(x;a) = \lim \sup_{\lambda \uparrow 0} D^+ f(x+\lambda a;a)$. Similarly, we have $f_{+a}^0(x;a) = \lim \sup_{\lambda \downarrow 0} D^+ f(x+\lambda a;a)$. Thus, one has

$$f_a^0(x;a) = \lim \sup_{\lambda \to 0} D^+ f(x+\lambda a;a). \qquad \square$$

The following theorem provides an answer to the question of Cominetti and Correa [2] about Taylor's expansion.

THEOREM 3.2. *Let $f : [x,y] \to \mathbb{R}$ be a continuous function on a line segment in a locally convex space X. Suppose that $D^+ f(\cdot\,; y-x)$ is finite, upper semi-continuous on (x,y) and $f_{+(y-x)}^0(x; y-x)$, $f_{-(y-x)}^0(y; y-x)$ are finite. Then there exists $t_0 \in (0,1)$ such that*

$$\begin{aligned}(3.2)\quad \frac{1}{2} f_{y-x}^\infty(x+t_0(y-x); y-x, y-x) &\ge f(y) - f(x) - f_{+(y-x)}^0(x; y-x) \\ &\ge \frac{1}{2} f_{\infty, y-x}(x+t_0(y-x); y-x, y-x).\end{aligned}$$

Hence, we also have

$$\begin{aligned}(3.3)\quad \frac{1}{2} f_{y-x}^\infty(x+t_0(y-x); y-x, y-x) + f_{y-x}^0(x; y-x) &\ge f(y) - f(x) \\ &\ge f_{0, y-x}(x; y-x) + \frac{1}{2} f_{\infty, y-x}(x+t_0(y-x); y-x, y-x).\end{aligned}$$

The following theorem is a corollary of Theorem 3.2.

THEOREM 3.3. *Suppose that the assumptions in Theorem* 3.2 *hold. If in addition* f *is defined on* X *and is twice* C*-differentiable at each point of* (x, y)*, then one has*

$$f(y) - f(x) - f^0_{+(y-x)}(x; y-x) \in \frac{1}{2}\overline{\langle \partial^2 f(x + t_0(y-x))(y-x), y-x\rangle}; \tag{3.4}$$

and also

$$f(y) - f(x) \in \overline{\langle \partial f(x), y-x\rangle + \frac{1}{2}\langle \partial^2 f(x + t_0(y-x))(y-x), y-x\rangle} \tag{3.5}$$

if $\partial f(x)$ *is nonempty and* $f^0(x; y-x) = \sup_{x^* \in \partial f(x)} \langle x^*, y-x\rangle$*, where* $\partial f(x)$ *denotes the Clarke's subdifferential and the "bar" denotes the closure of the set. The bar is superfluous if* f *is* $C^{1,1}$ [2] *on* (x, y).

Indeed, granting Theorem 3.2, we have

$$\begin{aligned} &\frac{1}{2} f^\infty(x + t_0(y-x); y-x, y-x) + f^0(x; y-x) \\ &\geq f(y) - f(x) \geq f_0(x; y-x) + \frac{1}{2} f_\infty(x + t_0(y-x); y-x, y-x) \end{aligned}$$

by (3.3). Thus, by (3.1) and our assumptions for any $\varepsilon > 0$ there exist $x_1^* \in \partial f(x)$ and $x_2^* \in \partial^2 f(x + t_0(y-x))(y-x)$ such that

$$f(y) - f(x) \leq \left\langle x_1^* + \frac{1}{2} x_2^*, y-x \right\rangle + \varepsilon.$$

Similarly, since $f_\infty(x + t_0(y-x); y-x, y-x) = -f^\infty(x + t_0(y-x); y-x, x-y)$ and $f_0(x; y-x) = -f^0(x; x-y)$, there exist

$$z_1^* \in \partial f(x) \quad \text{and} \quad z_2^* \in \partial^2 f(x + t_0(y-x))(y-x)$$

such that

$$f(x) - f(y) \leq \left\langle z_1^* + \frac{1}{2} z_2^*, x-y \right\rangle + \varepsilon.$$

Hence we can choose $\lambda \in (0, 1)$ such that

$$f(y) - f(x) = \left\langle (\lambda z_1^* + (1-\lambda)x_1^*) + \frac{1}{2}(\lambda z_2^* + (1-\lambda)x_2^*), y-x \right\rangle + (1-\lambda)\varepsilon - \lambda\varepsilon.$$

Since $\partial f(x)$ and $\partial^2 f(x + t_0(y-x))(y-x)$ are convex,

$$\lambda z_1^* + (1-\lambda)x_1^* \in \partial f(x) \quad \text{and} \quad \lambda z_2^* + (1-\lambda)x_2^* \in \partial^2 f(x + t_0(y-x))(y-x).$$

We then have

$$f(y) - f(x) \in \overline{\langle \partial f(x), y-x\rangle + \frac{1}{2}\langle \partial^2 f(x + t_0(y-x))(y-x), y-x\rangle}$$

as required to show for (3.5). Similarly one can prove (3.4). Thus it remains only to prove Theorem 3.2.

4. Detailed proof of Theorem 3.2. This section is entirely devoted to the proof of Theorem 3.2. Let $\gamma : [0,1] \to \mathbb{R}$ be defined by $\gamma(t) = f(x + t(y-x))$. Then it is easy to see that

$$\begin{gathered} D^+ f(x + t(y-x); y-x) = D^+\gamma(t;1), \\ f^0_{-(y-x)}(y; y-x) = \gamma^0_-(1;1) \qquad (= \gamma^0_{-1}(1;1)), \\ f^0_{+(y-x)}(x; y-x) = \gamma^0_+(0;1) \qquad (= \gamma^0_{+1}(0;1)), \\ f^0_{y-x}(x; y-x) = \gamma^0(0;1), \qquad f_{0,y-x}(x; y-x) = \gamma_0(0;1) \end{gathered}$$

and

$$\begin{gathered} f^\infty_{y-x}(x + t_0(y-x); y-x, y-x) = \gamma^\infty(t_0;1,1), \\ f_{\infty,y-x}(x + t_0(y-x); y-x, y-x) = \gamma_\infty(t_0;1,1). \end{gathered}$$

Then Theorem 3.2 can be rewritten as follows.

THEOREM 4.1. *Let $\gamma : [0,1] \to \mathbb{R}$ be a continuous function. Suppose that $D^+\gamma(\cdot\,;1)$ is finite, upper semi-continuous on $(0,1)$ and $\gamma^0_-(1;1), \gamma^0_+(0;1)$ are finite. Then there exists $t_0 \in (0,1)$ such that*

$$\frac{1}{2}\gamma^\infty(t_0;1,1) \geq \gamma(1) - \gamma(0) - \gamma^0_+(0;1) \geq \frac{1}{2}\gamma_\infty(t_0;1,1) \tag{4.1}$$

and so

$$\frac{1}{2}\gamma^\infty(t_0;1,1) + \gamma^0(0;1) \geq \gamma(1) - \gamma(0) \geq \gamma_0(0;1) + \frac{1}{2}\gamma_\infty(t_0;1,1). \tag{4.2}$$

To show Theorem 4.1, we need the following.

LEMMA 4.2. *Suppose that the function $h : [0,1] \to \mathbb{R}$ is upper semi-continuous on* (0,1) *with $h(0) = h(1)$ and*

$$\limsup_{t \downarrow 0} h(t) = h(0), \limsup_{t \uparrow 1} h(t) = h(1).$$

Then one of the following properties holds.

(i) *h attains a local maximum at some $t_0 \in (0,1)$;*

(ii) *There exists $t_0 \in (0,1)$ such that h is decreasing on $[0,t_0)$ and increasing on $(t_0,1]$.*

Proof. By assumptions, h is upper semi-continuous on $[0,1]$. Suppose (i) does not hold. Then h is neither decreasing on $[0,1)$ nor increasing on $(0,1]$, for otherwise the assumptions of the lemma would imply that h is a constant function. Thus there exist $t_1, t_2 \in [0,1)$ with $t_1 < t_2$ and $h(t_1) < h(t_2)$. We then claim that h is increasing on $(t_2,1]$. In fact if there exist $t_3, t_4 \in (t_2,1]$ with $t_3 < t_4$ such that $h(t_3) > h(t_4)$, the upper semi-continuity of h on $[t_1,t_4]$ will imply that (i) holds at some interior point of $[t_1,t_4]$.

Let t_0 denote the greatest lower bound of the nonempty set $T := \{t \in (0,1); h \text{ is increasing on } (t,1]\}$. Then $t_0 \leq t_2 < 1$ and also $t_0 \neq 0$ because h is not increasing on $(0,1]$. Note further that h is decreasing on $[0,t_0)$, for otherwise one can show as above that there exist $\bar{t}_1, \bar{t}_2 \in [0,t_0)$ with $\bar{t}_1 < \bar{t}_2, h(\bar{t}_1) < h(\bar{t}_2)$ and hence that h is increasing on $(\bar{t}_2,1]$, contradicting the definition of t_0. It is now clear that t_0 has the properties required in (ii). □

Now we prove Theorem 4.1. Define the function h: [0,1] $\to \mathbb{R}$ by

$$h(t) := \gamma(t) - \gamma(1) + (1-t)\xi(t) + (1-t)^2[\gamma(1) - \gamma(0) - \gamma^0_+(0;1)],$$

where

$$\xi(t) := \begin{cases} \gamma_+^0(0;1) & t = 0, \\ D^+\gamma(t;1) & 0 < t < 1, \\ \gamma_-^0(1;1) & t = 1. \end{cases}$$

Then by the finiteness assumption of $\gamma_-^0(1;1)$ and $\gamma_+^0(0;1)$ it follows from Lemma 3.1 that $h(0) = h(1) = 0$,

$$\limsup_{t\downarrow 0} h(t) = \limsup_{t\downarrow 0} D^+\gamma(t;1) - \gamma_+^0(0;1) = 0 = h(0)$$

and

$$\limsup_{t\uparrow 1} h(t) = 0 = h(1).$$

Further h is upper semi-continuous on $(0,1)$ since $D^+\gamma(\cdot\,;1)$ is assumed upper semi-continuous on $(0,1)$. Thus, Lemma 4.2 is applicable to h and so there exists $t_0 \in (0,1)$ such that either (i) h attains a local maximum at t_0 or (ii) h is decreasing on $[0,t_0)$ and increasing on $(t_0,1]$.

(I) Suppose (i) holds. Then we have (a) $0 \geq D^+h(t_0;1)$ and (b) $0 \leq h^0(t_0;1)$ by a well-known result of Clarke [1], p. 38. (As h is not necessarily Lipschitz, we briefly indicate a proof here: t_0 is a local minimum point for $-h$ so $0 \leq (-h)^0(t_0;-1) = h^0(t_0;1)$). Note that, by subadditivity,

$$\begin{aligned} h^0(t_0;1) \leq \gamma^0(t_0;1) - D^+\gamma(t_0;1) + (1-t_0)(D^+\gamma(\cdot\,;1))^0(t_0;1) \\ - 2(1-t_0)[\gamma(1) - \gamma(0) - \gamma_+^0(0;1)], \end{aligned}$$

where the first two terms can be cancelled out because

$$\limsup_{t\to t_0} D^+\gamma(t;1) = \gamma^0(t_0;1)$$

by Lemma 1.2 and $\limsup_{t\to t_0} D^+\gamma(t;1) \leq D^+\gamma(t_0;1)$ by the upper semi-continuity assumption of $D^+\gamma(\cdot\,;1)$. Hence (b) and (1.3) of Proposition 1.4 imply that

$$\gamma(1) - \gamma(0) - \gamma_+^0(0;1) \leq \frac{1}{2}(D^+\gamma(\cdot\,;1))^0(t_0;1) = \frac{1}{2}\gamma^\infty(t_0;1,1). \tag{4.3}$$

This verifies one inequality required in (4.1). The other inequality in (4.1) follows similarly from (a) because, by (1.5) of Proposition 1.4, one has

$$D_+(D^+\gamma(\cdot\,;1))(t_0;1) \geq \gamma_\infty(t_0;1,1)$$

and, by elementary computation rules for D^+ and D_+, that

$$\begin{aligned} D^+h(t_0;1) \geq D^+\gamma(t_0;1) - D^+\gamma(t_0;1) + (1-t_0)D_+(D^+\gamma(\cdot\,;1))(t_0;1) \\ - 2(1-t_0)[\gamma(1) - \gamma(0) - \gamma_+^0(0;1)]. \end{aligned} \tag{4.4}$$

(II) We next consider the case when (ii) holds: h is decreasing on $[0,t_0)$ and increasing on $(t_0,1]$. Take a sequence $t_n \uparrow t_0$ and note that (ā) $0 \geq D^+\gamma(t_n;1)$ for each n and (b̄) $0 \leq h^0(t_0;1)$. As done above (b̄) ensures that (4.3) holds while (ā) implies that

$$\gamma(1) - \gamma(0) - \gamma_+^0(0;1) \geq \frac{1}{2}D_+(D^+\gamma(\cdot\,;1))(t_n;1) \geq \frac{1}{2}\gamma_\infty(t_n;1,1)$$

because (4.4) holds with t_0 replaced by t_n. Since $\gamma_\infty(\cdot\,;1,1)$ is lower semi-continuous (Proposition 1.1), we have the other inequality required in (4.1) in addition to (4.3). □

5. Corollaries of Theorem 3.2 and Theorem 3.3.

COROLLARY 5.1 [2], Prop. 4.1. *Suppose that $f : X \to \mathbb{R}$ is continuously Gâteaux differentiable and twice C-differentiable on a segment $[x, y] \subseteq X$. Then there exists $t_0 \in (0, 1)$ such that*

$$f(y) - f(x) - f'(x; y - x) \in \frac{1}{2}\overline{\langle \partial^2 f(x + t_0(y - x))(y - x), y - x\rangle}.$$

If f is $C^{1,1}$ on $[x, y]$, then the closure can be ignored.

Proof. Since f is continuously Gâteaux differentiable at each point of $[x, y]$, it satisfies the assumptions in Theorem 3.2. Now apply Theorem 3.3. □

COROLLARY 5.2. *Suppose that $f : X \to \mathbb{R}$ is continuous at each point of a segment $[x, y]$. Then f satisfies* (3.2) *in each of the following cases*:

(i) *$D^+f(\cdot; y - x)$, $f^\infty_{y-x}(\cdot; y - x, y - x)$, and $f_{\infty,y-x}(\cdot; y - x, y - x)$ are finite on (x, y) and $f^0_{+(y-x)}(x; y - x)$, $f^0_{-(y-x)}(y; y - x)$ are finite;*

(ii) *$D^+f(z; y - x) = f^0_{y-x}(z; y - x)$ at each point of (x, y) and $f^0_{+(y-x)}(x; y - x)$, $f^0_{-(y-x)}(x; y - x)$ are finite;*

(iii) *f is regular in the Clarke's sense at each point of (x, y) and $f^0_{+(y-x)}(x; y - x)$, $f^0_{-(y-x)}(y; y - x)$ are finite.*

Proof. Suppose that (i) is true. Let $\gamma(t) := f(x + t(y - x)), t \in (0, 1)$. Clearly, it suffices to show that $D^+\gamma(\cdot; 1)$ is upper semi-continuous on $(0, 1)$. Now $D^+\gamma(t; 1)$ and $\gamma^\infty(t; 1, 1)$ are finite for any $t \in (0, 1)$. Take a finite number $K > \gamma^\infty(t; 1, 1)$. Then, by (1.4) of Proposition 1.4, there exists $\delta > 0$ such that

$$K > \frac{1}{\lambda}\{D^+\gamma(t' + \lambda; 1) - D^+\gamma(t'; 1)\}$$

whenever $|t' - t| < \delta$ and $0 < \lambda < \delta$. Passing to the limits as $\lambda \downarrow 0$ and $t' \to t$, it follows that

$$0 \geq \limsup_{\substack{t' \to t \\ \lambda \downarrow 0}} \{D^+\gamma(t' + \lambda; 1) - D^+\gamma(t'; 1)\}$$

and so

$$0 \geq \limsup_{\lambda \downarrow 0} D^+\gamma(t + \lambda; 1) - D^+\gamma(t; 1).$$

Thus,

$$D^+\gamma(t; 1) \geq \limsup_{\lambda \downarrow 0} D^+\gamma(t + \lambda; 1) = \limsup_{t' \downarrow t} D^+\gamma(t'; 1). \tag{5.1}$$

Similarly, since $\gamma_\infty(t; 1, 1)$ is finite, one can apply (1.5) of Proposition 1.4 to show that

$$0 \leq \liminf_{\substack{t' \to t \\ \lambda \downarrow 0}} \{D^+\gamma(t' + \lambda; 1) - D^+\gamma(t'; 1)\}.$$

Letting $\tau' = t' + \lambda$, we then obtain

$$\begin{aligned} 0 &\geq \limsup_{\substack{\tau' \to t \\ \lambda \downarrow 0}} \{D^+\gamma(\tau' - \lambda; 1) - D^+\gamma(\tau'; 1)\} \\ &\geq \limsup_{\lambda \downarrow 0} D^+\gamma(t - \lambda; 1) - D^+\gamma(t; 1) \end{aligned}$$

and so

$$D^+\gamma(t;1) \geq \limsup_{\lambda \downarrow 0} D^+\gamma(t-\lambda;1) = \limsup_{t' \uparrow t} D^+\gamma(t';1). \tag{5.2}$$

Together with (5.1) we have

$$D^+\gamma(t;1) \geq \limsup_{t' \to t} D^+\gamma(t';1),$$

showing that $D^+\gamma(\cdot\,;1)$ is upper semi-continuous on $(0,1)$.

In the case (ii) $D^+f(\cdot\,;y-x)$ is upper semi-continuous on (x,y) since $f^0_{y-x}(z;y-x)$ is clearly so. Consequently Theorem 3.2 is applicable.

For the case (iii), let $z = x + t(y-x), t \in (0,1)$. Then, by the regularity of f, Lemmas 1.2 and 3.1, one has

$$\begin{aligned} f'(z;y-x) = f^0(z;y-x) &= \limsup_{z' \to z} f'(z';y-x) \\ &\geq \limsup_{t' \to t} f'(x+t'(y-x);y-x) = f^0_{y-x}(z;y-x) \end{aligned}$$

showing that

$$f'(z;y-x) = f^0_{y-x}(z;y-x)$$

for any $z \in (x,y)$. Thus, the result holds from the case (ii). □

COROLLARY 5.3. *Let $-f : [x,y] \to \mathbb{R}$ satisfy the assumptions in Theorem* 3.2. *Then there exists $t_0 \in (0,1)$ such that*

$$\begin{aligned} \frac{1}{2} f^\infty_{y-x}(x+t_0(y-x);y-x,y-x) &\geq f(y) - f(x) - f_{0,+(y-x)}(x;y-x) \\ &\geq \frac{1}{2} f_{\infty,y-x}(x+t_0(y-x);y-x,y-x) \end{aligned} \tag{5.1}$$

and so (3.3) *holds, where* $f_{0,+(y-x)}(x;y-x) = -(-f)^0_{+(y-x)}(x;y-x)$.

Proof. By Theorem 3.2, we have

$$\begin{aligned} \frac{1}{2}(-f)^\infty_{y-x}(x+t_0(y-x);y-x,y-x) &\geq f(x) - f(y) - (-f)^0_{+(y-x)}(x;y-x) \\ &\geq \frac{1}{2}(-f)_{\infty,y-x}(x+t_0(y-x);y-x,y-x) \end{aligned}$$

and so, by elementary results similar to (iii) of Proposition 1.1,

$$\begin{aligned} \frac{1}{2} f^\infty_{y-x}(x+t_0(y-x);y-x,y-x) &\geq f(y) - f(x) - f_{0,+(y-x)}(x;y-x) \\ &\geq \frac{1}{2} f_{\infty,y-x}(x+t_0(y-x);y-x,y-x). \end{aligned}$$

This implies immediately that

$$\begin{aligned} &\frac{1}{2} f^\infty_{y-x}(x+t_0(y-x);y-x,y-x) + f^0_{y-x}(x;y-x) \geq f(y) - f(x) \\ &\quad \geq f_{0,y-x}(x;y-x) + \frac{1}{2} f_{\infty,y-x}(x+t_0(y-x);y-x,y-x). \end{aligned}$$ □

Remark 1. By [1], Prop. 2.3.6, it follows from part (ii) of Corollary 5.2 and Corollary 5.3 that a convex function satisfies (3.2) and a concave function satisfies (5.1), respectively, and both satisfy (3.3).

Remark 2. In each of the cases (i)–(iii), it is well known that f can fail to have Gâteaux derivative at some points so [2], Prop. 4.1 is not applicable.

6. Some applications in optimization.

DEFINITION 6.1. *Let $f : X \to \mathbb{R}$ and $x \in X$. $\partial^2 f(x)$ will be said to be positively definite* [2] *if $f_\infty(x; u, u) > 0$ for every $u \in X, u \neq 0$. Furthermore, a function $f : X \to \mathbb{R}$ is called twice uniformly locally Lipschitzian at x* [2] *if there exist neighborhoods X_0 of x and U of zero such that $f^\infty(X_0; U, U)$ is bounded in $\mathbb{R}$. This condition implies in particular that f is twice C-differentiable at each point x_0 in X_0 because then, for each $u \in U$, the sublinear map $v \mapsto f^\infty(x_0; u, v)$ is bounded on U and hence continuous on X.*

PROPOSITION 6.2. *Let $x \in X = \mathbb{R}^n, f : X \to \mathbb{R}$ be locally Lipschitz near x and twice uniformly locally Lipschitzian at x. If $f^0_{+u}(x; u) \geq 0$ for all $u \in X$, then a sufficient condition for x to be a strict local minimum point of f is that $\partial^2 f(x)$ is positively definite.*

Proof. By assumption, take a constant $M > 1$ and neighborhoods X_0 of x and U of zero such that

$$|f^\infty(X_0; U, U)| < M \tag{6.1}$$

and that f on X_0 is Lipschitz. Let $B := \{u \in X; \|u\| = 1\}$ and $u \in B$. By the strict positivity of $f_\infty(x; u, u)$ and the lower semi-continuity of $f_\infty(\cdot\,; u, u)$, one has a convex neighborhood $W(u)$ of x contained in X_0 and $1 > \delta(u) > 0$ such that

$$f_\infty(y; u, u) > \delta(u)$$

for all $y \in W(u)$. Let $1 > \lambda > 0$ with $\lambda u \in U$ and $U(u) = [\lambda\delta(u)/8M]U$. For any $v \in u + U(u), y \in W(u)$, it follows from Proposition 1.1 that

$$\begin{aligned} f_\infty(y; v, v) &= f_\infty(y; u + (v - u), u + (v - u)) \\ &\geq f_\infty(y; u, u) + f_\infty(y; v - u, v - u) + 2f_\infty(y; u, v - u) \\ &> \delta(u) - \frac{\lambda^2\delta(u)^2}{8^2M^2} \cdot M - \frac{\delta(u)}{4} \geq \frac{\delta(u)}{2} > 0. \end{aligned}$$

Since $X = \mathbb{R}^n$, by the compactness of B we can choose m neighborhoods $u_1 + U(u_1), \ldots, u_m + U(u_m)$ whose union covers B. Let

$$W = \bigcap_{i=1}^{m} W(u_i) \quad \text{and} \quad \delta = \min_{1 \leq i \leq m} \{\delta(u_i)\}.$$

Then for any $v \in B, y \in W$,

$$f_\infty(y; v, v) > \delta/2;$$

consequently $f_\infty(y; v, v) > 0$ for all $v \in X$ and $y \in W$. In view of the Assumption (6.1), it follows from part (i) of Corollary 5.2, that for any $y \in W, y \neq x$, there exists $t_0 \in (0, 1)$ such that

$$f(y) - f(x) \geq f^0_{+(y-x)}(x; y - x) + \frac{1}{2} f_\infty(y + t_0(x - y); y - x, y - x) > 0$$

because $f^0_{+(y-x)}(x; y - x) \geq 0$ and $y + t_0(x - y) \in W$. Therefore x is a strictly local minimal point. □

Remark. The preceding proposition can be deduced from [2], Prop. 5.2 because the twice uniformly locally Lipschitzian of f implies $f \in C^{1,1}$ [18]. We are indebted to the referee for the reference [18].

Let $f : X \to \mathbb{R}$ and $g : X \to \mathbb{R}^n$ be locally Lipschitz functions, C be a closed subset of X.

Now we consider the minimization problem with constraint

$$(\mathbb{P}) \qquad \min\{f(x); x \in Q\},$$

where $Q := \{x \in C \text{ and } g(x) \leq 0\}$. If x_0 is a solution of problem $(\mathbb{P})$, then by Clarke's Theorem [1], Thm. 6.1.1, there exists a multiplier $(\lambda, \gamma) \in \mathbb{R}^1 \times \mathbb{R}^n$ with $\lambda, \gamma_i \geq 0, 1 \leq i \leq n$, and $\lambda + \sum_{i=1}^n \gamma_i = 1$ such that

$$\gamma g(x_0) = 0 \quad \text{and} \quad 0 \leq L^0(x_0; u) \tag{6.2}$$

for any $u \in X$, where

$$L(x) := \lambda f(x) + \gamma g(x) + \alpha d_Q(x)$$

and α is a Lipschitzian constant for both f and g on a neighborhood of x_0.

PROPOSITION 6.3. *Suppose that x_0 is a solution of the problem $(\mathbb{P})$. Let $A := \{v; \gamma g(v) \geq 0\}$ with the contingent cone $T_A(x_0)$ [3]. Then*

(i) $L^\infty(x_0; u, u) \geq 0$, *for any u in $T_A(x_0)$ with $D_+L(x_0; u) = 0$;*

(ii) $L^{00}(x_0; u, u) \geq 0$, *for any u in $T_A(x_0)$ with $L^0(x_0; u) = 0$.*

Proof. (i) Since $f(x_0) \leq f(x)$ for any $x \in Q$, by [1], Prop. 2.4.3, $f + \alpha d_Q$ attains a local minimum at x_0. Let $u \in T_A(x_0)$ with $D_+L(x_0; u) = 0$ and take sequences $u_i \to u$ and $t_i \downarrow 0$ with $x_0 + t_i u_i \in A$. Therefore, one has

$$\begin{aligned} & L(x_0 + t_i u_i) - L(x_0) \\ &= \lambda f(x_0 + t_i u_i) + \gamma g(x_0 + t_i u_i) + \alpha d_Q(x_0 + t_i u_i) - \lambda f(x_0) \\ &= \lambda\{f(x_0 + t_i u_i) + \alpha d_Q(x_0 + t_i u_i) - f(x_0)\} + \gamma g(x_0 + t_i u_i) \\ &\qquad + (1 - \lambda)\alpha d_Q(x_0 + t_i u_i) \geq 0. \end{aligned}$$

By Lemma 1.2 there exists $\tau_i \in (0, t_i)$ such that

$$D_+L(x_0 + \tau_i u; u) \geq \frac{1}{t_i}(L(x_0 + t_i u) - L(x_0)) \geq 0.$$

Therefore $\limsup_{\tau \downarrow 0} \frac{1}{\tau} D_+L(x_0 + \tau u; u) \geq 0$. Since $D_+L(x_0; u) = 0$, it follows from Proposition 1.4 that

$$\begin{aligned} L^\infty(x_0; u, u) &= \limsup_{\substack{y \to x_0 \\ t \downarrow 0}} \frac{1}{t}(D_+L(y + tu; u) - D_+L(y; u)) \\ &\geq \limsup_{t \downarrow 0} \frac{1}{t}(D_+L(x_0 + tu; u) - D_+L(x_0; u)) \\ &= \limsup_{t \downarrow 0} \frac{1}{t} D_+L(x_0 + tu; u) \geq 0. \end{aligned}$$

(ii) By Definition 1.5 and similar proof of part (i), one has

$$\begin{aligned} L^{00}(x_0; u, u) &= \limsup_{\substack{y \to x_0 \\ t \downarrow 0}} \frac{1}{t}(L^0(y + tu; u) - L^0(y; u)) \\ &\geq \limsup_{t \downarrow 0} \frac{1}{t}(L^0(x_0 + tu; u) - L^0(x_0; u)) \\ &\geq \limsup_{t \downarrow 0} \frac{1}{t} D_+L(x_0 + tu; u) \geq 0. \end{aligned}$$

OPTIMAL CONTROL ON THE L^∞ NORM OF A DIFFUSION PROCESS*

GUY BARLES†, CHRISTIAN DAHER‡, AND MARC ROMANO§

Abstract. Stochastic control problems are considered, where the cost to be minimized is either a running maximum of the state variable or more generally a running maximum of a function of the state variable and the control. In both cases it is proved that the value function, which must be defined on an augmented state space to take care of the non-Markovian feature of the running maximum, is the unique viscosity solution of the associated Bellman equation, which turns out to be, in the second case, a variational inequality with an oblique derivative boundary condition. Most of this work consists of proving the convergence of L^p approximations and this is done by purely partial differential equation (PDE) methods.

Key words. stochastic control, running maximum, variational inequality, viscosity solutions

AMS subject classifications. 93E20, 35R05, 35Q80

Introduction. This paper is concerned with stochastic control problems where the cost to be minimized is given by a running maximum of the state variable over time. For the sake of simplicity, we will consider here the following two model problems. Let X_s be a state variable in $\mathbb{R}^n$ whose dynamic is governed by the controlled stochastic differential equation

$$\begin{aligned} dX_s &= b(X_s, s, \alpha_s)ds + \sigma(X_s, s, \alpha_s)dW_s \qquad 0 \le t \le s \le T, \\ X_t &= x \in \mathbb{R}^n, \end{aligned}$$

where $(\alpha_s)_s$ denotes the control process, which takes its values in a compact metric space A, and b, σ are given continuous functions. We are interested in control problems whose cost to be minimized is given either by

$$J(x,t,(\alpha_s)_s) = E\left[\psi\left(\sup_{s\in[t,T]} |X_s|\right)\right] \tag{1}$$

or, more generally, by

$$J(x,t,(\alpha_s)_s) = E\left[\psi\left(\sup_{s\in[t,T]} f(X_s,s,\alpha_s)\right)\right], \tag{2}$$

where ψ and $f \ge 0$ are given continuous functions.

Our goal is to explain how to determine the value function

$$V(x,t) = \inf_{(\alpha_s)_s} J(x,t,(\alpha_s)_s). \tag{3}$$

This work was originally motivated by problems arising in finance theory, in particular lookback options pricing models, in which the terminal pay-off of the contingent claim is not measurable with respect to the basic's terminal price, but is defined as a function of the L^p-norm (with possibly $p = \infty$) of the whole sample path of the price process. We take this opportunity for recasting together old and new ideas for attacking these kinds of problems.

We begin by recalling that the first difficulty of (1) and (2) is that the form of the cost function does not allow a straightforward application of the dynamic programming principle:

* Received by the editors December 16, 1991; accepted for publication (in revised form) September 29, 1992. This work was done in the Caisse Autonome de Refinancement Research and Development Department.

† Faculté des Sciences et Techniques, Université de Tours, Parc de Grandmont, 37200 Tours, France.

‡ Caisse Autonome de Refinancement, 2, square de Luynes, 75007 Paris, France.

§ Ecole Normale Supérieure, 45, Rue d'Ulm, 75005 Paris, France.

typically in (1), the non-Markovian feature of the process $Z_s = \sup_{\tau\in[t,s]} |X_\tau|$ for (1) (and $Z_s = \sup_{\tau\in[t,s]} f(\tau, X_\tau, \alpha_\tau)$ for (2)) prohibits the direct use of the standard martingale approach to deduce the Hamilton–Jacobi–Bellman (HJB) equation for V. To circumvent this difficulty, it is classical to reformulate (3) by adding one extra state variable, namely Z_s, that, roughly speaking, "carries the past information." With this well-known trick, the new cost function—denoted by $u^\infty(x, z, t)$—recovers a classical form and $V(x, t)$ is nothing but $u^\infty(x, x, t)$. This device apparently cannot be avoided in a stochastic context: indeed, readers familiar with probability theory are acquainted with the fact that, for instance, the law of the running maximum of the Brownian motion is computed *jointly* with the law of the Brownian motion itself (see, for example, [26] and references therein).

The second difficulty is that Z does not solve a stochastic differential equation with regular coefficients; to solve it by partial differential equation (PDE) arguments, we replace the L^∞-norm appearing in Z by an L^p approximation. As already mentioned, this kind of problem has itself an interest in finance, in particular the $p = 1$ case. Section 1.2 investigates the characterization of the approximate value function (u^p) as unique viscosity solution of the associated HJB equation on the augmented state space.

Then the passage to the limit $(p \to +\infty)$ gives us the equation satisfied by u^∞; this turns out to be an HJB equation set in a cone with homogeneous Neumann—or more precisely oblique derivative—boundary conditions. Actually, we meet again (at the PDE level) the strong link existing between the law of the supremum of a diffusion process and the law of its reflexion, but with completely different context and tools than those encountered in probability theory (see, e.g., [26] and references therein).

It is worth mentioning that the convergence of u^p to u^∞ is not obvious; this is a striking difference with [1], where a similar method is used. We first must prove the uniform convergence of u^p to u^∞, and we obtain it by a method that *relies on purely PDE arguments* (§1.4).

We conclude the paper with the applications to finance. After stating an extension of the previous results to the case of control with optimal stopping (§3.1), we show how to apply this to price American calls on stock options (§3.2).

Our work relies on the notion of viscosity solutions introduced by Crandall and Lions [12]; we refer to the "User's Guide" [11] for a complete presentation of this notion of weak solutions for degenerate elliptic and parabolic PDEs. The links between viscosity solutions and stochastic optimal control have been first cleared out in the works of Lions [29], [30] and [31].

Similar problems, but in the deterministic case and not with the present generality, were studied in [7]. It is worth mentioning that in [7] the limiting equation is a quasi-variational inequality in the original state space variables; however, in their case, the L^p approximation reduces to a standard problem by commuting the $1/p$ of the L^p norms and the infimum.

After this work was completed, we learned that Barron [6] and Heinricher and Stockbridge [18] considered the same types of problem: in [6], the case of (1) is completely treated with an even greater generality on the diffusion processes since the functions b and σ may depend on the Z process (our methods can also treat this more general case). The main differences with our work is that [6] uses deep probabilistic results for obtaining the convergence of u^p to u^∞ while we use a far simpler PDE method to get it; moreover [6] does not consider the case of (2). In [18], the problem (1) is introduced and some special cases are solved by dynamic programming arguments.

1. The model case.

1.1. Reformulation of the basic problem. We will consider in this part the control problem with a cost function given by (1). We recall that X's dynamics are governed by the

following stochastic differential equation:

$$dX_s = b(X_s, s, \alpha_s)ds + \sigma(X_s, s, \alpha_s)dW_s \qquad 0 \le t \le s \le T, \tag{4}$$

$$X_t = x \in \mathbb{R}^n, \tag{5}$$

where b and σ are continuous functions defined on $\mathbb{R}^n \times [0,T] \times A$ with values, respectively, in $\mathbb{R}^n$ and $\mathbb{M}^{n\times m}$ (the space of $n \times m$ matrices). A is a compact metric space; $(\Omega, \mathcal{F}, (\mathcal{F}_s)_{s\in[0,T]}, (W_s)_{s\in[0,T]})$ is a standard Brownian motion in $\mathbb{R}^m$; and $(\alpha_s)_s$ is a previsible A-valued process.

For the reasons explained in the Introduction, we first augment the state space to come down to a classical cost shape. The new state space will be denoted by $Q = \mathbb{R}^n \times \mathbb{R}_+^* \times [0,T]$. Second, we approximate the L^∞ norm by L^p norms. Thus, we introduce, for all $1 \le p \le \infty$, a second state variable in $\mathbb{R}_+$ that is defined, given an initial condition $(x,z,t) \in Q$, by (if $p < \infty$)

$$Z_s^p = \left(z^p + \int_t^s |X_\tau|^p d\tau\right)^{1/p}, \tag{6}$$

and by (if $p = \infty$)

$$Z_s^\infty = \max\left\{z, \sup_{\tau\in[t,s]} |X_\tau|\right\}, \tag{7}$$

X being the solution of (4), (5).

The cost function is given by

$$J^p(x,z,t,(\alpha_s)_s) = E[\psi(Z_T^p)], \tag{8}$$

where ψ is a bounded, Lipschitz-continuous $\mathbb{R}$-valued function. The superscript emphasizes the dependence of J with respect to p. We want to minimize J^p over all admissible controls, as follows:

$$u^p(x,z,t) = \inf_{(\alpha_s)_s} J^p(x,z,t,(\alpha_s)_s). \tag{9}$$

Throughout the paper, we make the following assumption.

ASSUMPTION 1. *For $\phi = f, b_i\ (1 \le i \le n)$ and $\sigma_{ij}\ (1 \le i \le n, 1 \le j \le m), \phi$ is continuous, $\phi(.,.,\alpha) \in W^{1,\infty}(\mathbb{R}^n \times (0,+\infty))$ for any $\alpha \in A$ and*

$$\sup_{\alpha\in A} \|\phi(.,.,\alpha)\|_{1,\infty} < \infty. \tag{10}$$

We recall that $W^{1,\infty}(\mathbb{R}^n \times (0,+\infty))$ is the set of functions z such that $z, D_x z, \partial z/\partial t$ are in $L^\infty(\mathbb{R}^n \times (0,+\infty))$ and that this space is equipped with the norm

$$\|z\|_{1,\infty} = \|z\|_\infty + \|D_x z\|_\infty + \left\|\frac{\partial z}{\partial t}\right\|_\infty.$$

1.2. The control problem for $1 \le p < \infty$. In this part, we focus on the case $1 \le p < \infty$ and prove that the value function of the problem is bounded, continuous, and the unique viscosity solution of the related HJB equation.

Differentiating (6) with respect to time yields

$$dZ_s = \frac{Z_s}{p}\left(\frac{|X_s|}{Z_s}\right)^p ds, \tag{11}$$

$$Z_t = z \geq 0, \tag{12}$$

which is nothing but an ordinary differential equation. We easily show that, for almost every sample path of X, (11), (12) has a unique solution and that the apparent singularity for $z = 0$ causes, in fact, no problem. The control problem (9) has thus, with respect to the system (X_s, Z_s), a (quasi-) standard shape and the dynamic programming principle hence applies.

The related HJB equation can be written

$$\mathcal{H}^p\left(x, z, t, \frac{\partial u}{\partial t}, D_x u, D_z u, D^2_{xx} u\right) = 0 \quad \text{in } Q, \tag{13}$$

where we set, for $\xi = (x, z, t, q_t, q_x, q_z, M) \in Q \times \mathbb{R}^{n+2} \times \mathcal{S}^n$,[1]

$$\mathcal{H}^p(\xi) = \mathcal{L}(\xi) = \frac{z}{p}\left(\frac{|x|}{z}\right)^p q_z$$

and

$$\mathcal{L}(\xi) = \mathcal{L}(x, t, q_t, q_x, M) = -q_t + \sup_{\alpha \in A}\left\{-\frac{1}{2}\operatorname{Tr}((\sigma\sigma^T)(x, t, \alpha)M) - b(x, t, \alpha)q_x\right\},$$

with terminal condition

$$u(x, z, T) = \psi(z) \quad \text{in } \mathbb{R}^n \times \mathbb{R}^*_+. \tag{14}$$

Throughout the paper, we use indifferently the notation $\mathcal{L}(x, t, \partial u/\partial t, D_x u, D^2_{xx} u), \mathcal{L}(x, t)$, or $\mathcal{L}u$ both for emphasizing the important dependence of $\mathcal{L}$ with respect to the function or the current point and also for simplicity of notations.

We can state the following theorem.

THEOREM 1.2.1. *We have*

(i) u^p *defined by* (9) *is bounded and Lipschitz-continuous in* x *and* z, *uniformly for* $t \in [0, T]$,

(ii) u^p *is the unique bounded viscosity solution of* (13) *and* (14).

Proof of Theorem 1.2.1. (i) u^p is bounded since ψ is. Let (x, z, t) and (x', z', t) be in Q and denote (X, Z) and (X', Z') the related processes. It is well known that, from (10),

$$\sup_{(\alpha_s)_s} E\left[\sup_{s \in [t,T]} |X_s - X'_s|\right] \leq k|x - x'|,$$

for some constant k. Now

$$Z_T = \left(\int_0^T (z\chi_{(s<t)}t^{-1/p} + |X_s|\chi_{(s\geq t)})^p ds\right)^{1/p} \quad \text{a.s.}$$

[1] $\mathcal{S}^n$ is the space of $n \times n$ symmetric matrices.

By the Minkowski inequality for L^p norms

$$|Z_T - Z'_T| \leq \left(\int_0^T (|z - z'|\chi_{(s<t)} t^{-1/p} + |X_s - X'_s|\chi_{(s\geq t)})^p ds \right)^{1/p}$$

and

$$|Z_T - Z'_T| \leq |z - z'| + \left(\int_t^T |X_s - X'_s|^p ds \right)^{1/p}$$

and the conclusion follows easily.

(ii) For the proof, see the Appendix. □

1.3. The HJB equation for u^∞. In this section, we analyze what becomes of the HJB equation (13) as we let p go to ∞. Since limit operations with viscosity solutions will be used throughout this paper, we start by giving the main definitions and the basic theorem related to the so-called half-relaxed limits. We use the standard following notations: for any sequence of functions F^p, define

$$\limsup_p{}^* F^p(\xi) = \limsup_{\substack{\xi' \to \xi \\ p \to \infty}} F^p(\xi'),$$

and

$$\liminf_{p*} F^p(\xi) = \liminf_{\substack{\xi' \to \xi \\ p \to \infty}} F^p(\xi').$$

Following is the basic theorem.

THEOREM 1.3.1. *Let $(u^p)_{p\in\mathbb{N}}$ be a sequence of uniformly locally bounded viscosity solutions of the equation*

$$G^p(x, u, Du, D^2u) = 0 \quad \text{in } \bar{\Omega},$$

where Ω is some domain in $\mathbb{R}^N$ and $(G^p)_p$ is a sequence of uniformly locally bounded functions defined in $\bar{\Omega} \times \mathbb{R} \times \mathbb{R}^N \times \mathcal{S}^n$ and satisfying

$$G^p(x, u, p, M) \leq G^p(x, u, p, N) \quad \text{if } M \geq N,$$

for any $x \in \bar{\Omega}$, $u \in \mathbb{R}$, $p \in \mathbb{R}^N$, $M, N \in \mathcal{S}^n$. Then $u^* = \limsup^* u^p$ (respectively, $u_* = \liminf_* u^p$) is a viscosity subsolution (respectively, supersolution) of $G_* = 0$ (respectively, $G^* = 0$), where $G_* = \liminf_* G^p$ (respectively, $G^* = \limsup^* G^p$).

We refer to [11] or [5] for a detailed presentation of this method of passage to the limit and, in particular, for the proof of Theorem 1.3.1, based on ideas introduced in [2].

After these prerequisites, let us show how this result applies to the problem we are dealing with. First we must compute

$$\mathcal{H}^* = \limsup^* \mathcal{H}^p \quad \text{and} \quad \mathcal{H}_* = \liminf_* \mathcal{H}^p.$$

This is done by carefully analyzing each case. First we do it for $t < T$. Keeping the notation of the previous section, we get

$$\text{if } |x| < z, \quad \mathcal{H}^* = \mathcal{L} \quad \text{and} \quad \mathcal{H}_* = \mathcal{L},$$

$$\text{if } |x| = z \begin{cases} \text{and} & -q_z < 0, & \mathcal{H}^* = \mathcal{L} & \text{and} & \mathcal{H}_* = -\infty, \\ \text{and} & -q_z = 0, & \mathcal{H}^* = +\infty & \text{and} & \mathcal{H}_* = -\infty, \\ \text{and} & -q_z > 0, & \mathcal{H}^* = +\infty & \text{and} & \mathcal{H}_* = \mathcal{L}, \end{cases}$$

$$\text{if } |x| > z \begin{cases} \text{and} & -q_z < 0, & \mathcal{H}^* = -\infty & \text{and} & \mathcal{H}_* = -\infty, \\ \text{and} & -q_z = 0, & \mathcal{H}^* = +\infty & \text{and} & \mathcal{H}_* = -\infty, \\ \text{and} & -q_z > 0, & \mathcal{H}^* = +\infty & \text{and} & \mathcal{H}_* = +\infty. \end{cases}$$

Now, let

$$u^* = \limsup{}^* u^p \quad \text{and} \quad u_* = \liminf{}_* u^p$$

(we will show in the next section that actually $u^* = u_* = u^\infty$). From Theorem 1.3.1 we know that u^* is a *sub*solution of $\mathcal{H}_*$ and u_* is a *super*solution of $\mathcal{H}^*$. Moreover, we see that

$$\mathcal{H}_*\left(x, z, t, \frac{\partial u}{\partial t}, D_x u, D_z u, D^2_{xx} u\right) \le 0$$

$$\iff \begin{cases} \mathcal{L}\left(x, t, \dfrac{\partial u}{\partial t}, D_x u, D^2_{xx} u\right) \le 0 & \text{if } |x| < z, \\ \min\left\{\mathcal{L}\left(x, t, \dfrac{\partial u}{\partial t}, D_x u, D^2_{xx} u\right), -D_z u\right\} \le 0 & \text{if } |x| = z, \\ -D_z u \le 0 & \text{if } |x| > z, \end{cases}$$

and

$$\mathcal{H}^*\left(x, z, t, \frac{\partial u}{\partial t}, D_x u, D_z u, D^2_{xx} u\right) \ge 0$$

$$\iff \begin{cases} \mathcal{L}\left(x, t, \dfrac{\partial u}{\partial t}, D_x u, D^2_{xx} u\right) \ge 0 & \text{if } |x| < z, \\ \max\left\{\mathcal{L}\left(x, t, \dfrac{\partial u}{\partial t}, D_x u, D^2_{xx} u\right), -D_z u\right\} \ge 0 & \text{if } |x| = z, \\ -D_z u \ge 0 & \text{if } |x| > z, \end{cases}$$

with all inequalities to be taken in the viscosity sense. For $t = T$, exactly the same computations yield to

$$\begin{cases} \min\left\{u - \psi, \mathcal{L}\left(x, t, \dfrac{\partial u}{\partial t}, D_x u, D^2_{xx} u\right)\right\} \le 0 & \text{if } |x| < z, \\ \min\left\{u - \psi, \mathcal{L}\left(x, t, \dfrac{\partial u}{\partial t}, D_x u, D^2_{xx} u\right), -D_z u\right\} \le 0 & \text{if } |x| = z, \\ \min\{u - \psi, -D_z u\} \le 0 & \text{if } |x| > z, \end{cases}$$

and

$$\begin{cases} \max\left\{u - \psi, \mathcal{L}\left(x, t, \dfrac{\partial u}{\partial t}, D_x u, D^2_{xx} u\right)\right\} \ge 0 & \text{if } |x| < z, \\ \max\left\{u - \psi, \mathcal{L}\left(x, t, \dfrac{\partial u}{\partial t}, D_x u, D^2_{xx} u\right), -D_z u\right\} \ge 0 & \text{if } |x| = z, \\ \max\{u - \psi, -D_z u\} \ge 0 & \text{if } |x| > z, \end{cases}$$

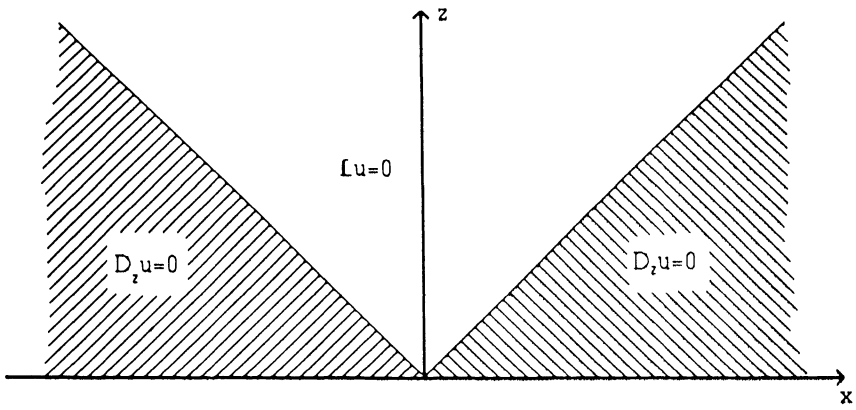

FIG. 1.

The results of [4] imply that, since the "$\mathcal{L}$" inequalities cannot hold at $t = T$ (essentially because the (x, z, t) dynamic exits through this boundary), these properties reduce to

$$\begin{cases} u - \psi \leq 0 & \text{if } |x| < z, \\ \min\{u - \psi, -D_z u\} \leq 0 & \text{if } |x| \geq z, \end{cases}$$

and

$$\begin{cases} u - \psi \geq 0 & \text{if } |x| < z, \\ \max\{u - \psi, -D_z u\} \geq 0 & \text{if } |x| \geq z, \end{cases}$$

Now let

$$\begin{aligned} \Omega &= \{(x, z) \text{ s.t. } |x| < z\} \times (0, T), \\ \bar{\Omega} &= \{(x, z) \text{ s.t. } |x| \leq z\} \times [0, T], \\ \partial_0\Omega &= \{(x, z) \text{ s.t. } |x| = z\} \times [0, T]. \end{aligned}$$

(See Fig. 1.) Readers familiar with viscosity solutions will recognize on $\partial_0\Omega$ a Neumann—or, more precisely, an oblique derivative—boundary condition in the viscosity sense (see [11]). We show now that this is indeed the case.

THEOREM 1.3.2. *u^* (respectively u_*) is a viscosity subsolution (respectively, supersolution) of*

$$\mathcal{L}\left(x, t, \frac{\partial u}{\partial t}, D_x u, D^2_{xx} u\right) = 0 \quad \text{in } \Omega, \tag{15}$$

$$-D_z u = 0 \quad \text{on } \partial_0\Omega, \tag{16}$$

$$u(x, z, T) = \psi(z) \quad \text{in } \{|x| < z\}. \tag{17}$$

Proof of Theorem 1.3.2. We only prove the result in the subsolution case and for $t < T$, the other cases being treated by similar arguments. Let $\phi \in C^2(\bar{\Omega})$ and $(\bar{x}, \bar{z}, \bar{t})$ a strict global maximum point of $(u^* - \phi)$. If $(\bar{x}, \bar{z}, \bar{t}) \in \Omega$, there is no problem, so we will suppose that $(\bar{x}, \bar{z}, \bar{t}) \in \partial_0\Omega$.

Consider a $C^2(\bar{Q})$-extension of ϕ, still denoted by ϕ. Set, for $k > 0$,

$$\tilde{\phi}_k(x,z,t) = \phi(x,z,t) + k(|x| - z)^{+4},$$

and let (x_k, z_k, t_k) be a maximum point of $u^* - \tilde{\phi}_k$. Since $(\bar{x}, \bar{z}, \bar{t})$ is a global strict maximum point of $u^* - \phi$ in $\bar{\Omega}$ and since $(|x| - z)^+ \equiv 0$ in Ω, then (x_k, z_k, t_k) necessarily lies in $\bar{Q}\backslash\Omega$. Moreover, if we let $k \to \infty$, then (x_k, z_k, t_k) tends to $(\bar{x}, \bar{z}, \bar{t})$.

If there are infinitely many $(x_k, z_k, t_k) \notin \partial_0\Omega$, then, extracting if necessary a subsequence, we have $-D_z\tilde{\phi}_k(x_k, z_k, t_k) \leq 0$, because u^* is a subsolution of $\mathcal{H}_*$. Now we notice that $D_z\tilde{\phi}_k \leq D_z\phi$. Thus, letting $k \to \infty$, from the continuity of $D\phi$, we get $D_z\phi(\bar{x}, \bar{z}, \bar{t}) \geq 0$.

Otherwise, we extract a subsequence that remains on $\partial_0\Omega$, and conclude by passing to the limit in the inequality $\min\{\mathcal{L}\phi, -D_z\phi\} \leq 0$. □

We now state the uniqueness theorem.

THEOREM 1.3.3. *Let u (respectively, v) be an upper semicontinuous (u.s.c.) subsolution (respectively, a lower semicontinuous (l.s.c.) supersolution) of* (15)–(17). *Then*

$$u \leq v \quad \text{in } \bar{\Omega}.$$

This result is proved in Dupuis and Ishii [16], [17], where uniqueness results for oblique derivative problems in domains with corners are obtained in a more general setting. In our case, the proof can be highly simplified because of the particular form of our problem, but we skip it, however, since the arguments to obtain it are easy.

By standard arguments (cf. [11]), Theorems 1.3.2 and 1.3.3 imply Theorem 1.3.4.

THEOREM 1.3.4. *u^p converges as $p \to \infty$ locally uniformly to the unique* BUC *solution $u = u^* = u_*$ of* (15)–(17).

1.4. Convergence of u^p as $p \to \infty$. The goal of this section is to show that u is actually u^∞. This will complete the proof that u^∞ is continuous and the only solution of its related HJB equation, namely (15)–(17). The following theorem states our result.

THEOREM 1.4.1. $\lim_{p\to\infty} u^p = u^\infty$ *uniformly on compact subsets of* $\bar{\Omega}$.

The main step in the proof of this result is the following lemma.

LEMMA 1.4.1. *Let $(Z_s^p)_s$ and $(Z_s^\infty)_s$ be, respectively, given by* (6) *and* (7), *then we have*

$$E(|Z_T^p - Z_T^\infty|) \to 0 \tag{18}$$

uniformly on compact subsets of $\bar{\Omega}$ and uniformly in $(\alpha_s)_s$. In particular,

$$E(|\|X\|_{L^p(t,T)} - \|X\|_{L^\infty(t,T)}|) \to 0, \tag{19}$$

uniformly on compact subsets of $\mathbb{R}^n$ and uniformly in $(\alpha_s)_s$.

Proof of Theorem 1.4.1. We first complete the proof of Theorem 1.4.1 by using Lemma 1.4.1. For $(x,z,t) \in \bar{\Omega}$, we estimate $u^p - u^\infty$,

$$\begin{aligned} |u^p(x,z,t) - u^\infty(x,z,t)| &= |\inf_{(\alpha_s)_s} E[\psi(Z_T^p)] - \inf_{(\alpha_s)_s} E[\psi(Z_T^\infty)]| \\ &\leq \sup_{(\alpha_s)_s} E|\psi(Z_T^p) - \psi(Z_T^\infty)|, \end{aligned}$$

and by the Lipschitz continuity of ψ, we have

$$|u^p(x,z,t) - u^\infty(x,z,t)| \leq C \sup_{(\alpha_s)_s} E|Z_T^p - Z_T^\infty|, \tag{20}$$

and we conclude by using Lemma 1.4.1. □

Proof of Lemma 1.4.1. We first want to point out that the proof below uses only purely PDE arguments. To prove (18), we use the device that consists in splitting the variables and we introduce another control problem: for $p, q \in (1, \infty), \xi = (x, z, z', t) \in D = \mathbb{R}^n \times \mathbb{R}_+^* \times \mathbb{R}_+^* \times [0, T]$, let X be the solution of (4) subject to initial condition $X_t = x$. Then we consider the control problem

$$\Upsilon^{p,q}(\xi) = \sup_{(\alpha_s)_s} E[|Z_T^p - Z_T^q|]. \tag{21}$$

Now let $\Upsilon^* = \limsup^*_{p,q\to\infty} \Upsilon^{p,q}$ and set

$$\mathcal{O} = \{\xi \text{ such that } |x| < z \text{ and } |x| < z'\}.$$

We want to show the following inequality:

$$\Upsilon^*(\xi) \le |z - z'| \quad \text{on } \bar{\mathcal{O}}. \tag{22}$$

This will prove Lemma 1.4.1: indeed, since $\Upsilon^* \ge 0$, this inequality implies

$$\Upsilon^*(x, z, z, t) = 0 \quad \text{in } \mathbb{R}^n \times \mathbb{R}_+ \times [0, T],$$

and (18) is an easy consequence of this property. To prove (22), we follow the method already used in §1.3.

Arguing as in the proof of Theorem 1.2.1 we easily show that $\Upsilon^{p,q}$ is Lipschitz continuous and is a viscosity solution of

$$\begin{gathered} \tilde{\mathcal{L}}u - \tfrac{z}{p}\left(\tfrac{|x|}{z}\right)^p D_z u - \tfrac{z'}{q}\left(\tfrac{|x'|}{z'}\right)^q D_{z'} u = 0 \quad \text{in } D, \\ u(x, z, z', T) = |z - z'| \quad \text{in } \mathbb{R}^n \times \mathbb{R}_+ \times \mathbb{R}_+, \end{gathered}$$

where

$$\tilde{\mathcal{L}}u = -\frac{\partial u}{\partial t} + \inf_{\alpha \in A}\left\{-\frac{1}{2} Tr(\sigma\sigma^T(x, t, \alpha) D_{xx}^2 u) - b(x, t, \alpha) D_x u\right\}. \tag{23}$$

Arguing along the lines of §1.3, Υ^* is a viscosity subsolution of

$$\tilde{\mathcal{L}}u = 0 \quad \text{in } \mathcal{O}, \tag{24}$$

$$-D_z u = 0 \quad \text{if } |x| = z, \tag{25}$$

$$-D_{z'} u = 0 \quad \text{if } |x| = z'. \tag{26}$$

Moreover, Υ^* has a sublinear growth at infinity since

$$E(Z_T^p), E(Z_T^q) \le C(1 + |x| + |z| + |z'|)$$

for some constant C depending only on b and σ. Now we remark that $w(x, z, z', t) = |z - z'|$ is a supersolution of (24)–(26) and so are the regularizations $w^\delta(x, z, z', t) = (|z - z'|^2 + \delta^2)^{1/2}$ of w. To actually show that $\Upsilon^* \le w$ in $\mathcal{O}$, we introduce the function

$$\begin{aligned} \Phi(x, z, z', t) = \Upsilon^*(x, z, z', t) - w^\delta(x, z, z', t) - \alpha e^{\gamma(T-t)}(|x|^2 + 1) + \cdots \\ + \eta[\phi(z) + \phi(z')] - \beta[|z|^2 + |z'|^2], \end{aligned}$$

where $\alpha, \beta, \delta, \eta$ are small parameters devoted to tend to zero and chosen later. Then, γ is a constant large enough chosen in such a way to have

$$\tilde{\mathcal{L}}(\alpha e^{\gamma(T-t)}(|x|^2+1)) > 0 \quad \text{in } \mathcal{O}, \tag{27}$$

and finally ϕ is a bounded C^1 strictly increasing function in $\mathbb{R}$. Since Υ^* has a sublinear growth at infinity, as soon as $\alpha, \beta > 0$, the maximum of Φ is achieved at some point $\bar{\xi} = (\bar{x}, \bar{z}, \bar{z}', \bar{t})$. Our goal is to show that $\bar{t} = 0$ for a suitable choice of the parameters α, β, and η. Since Υ^* is a viscosity subsolution of (24), $\bar{\xi} \notin \mathcal{O}$ because of (27). Then, if $|\bar{x}| = \bar{z}$, since the $\tilde{\mathcal{L}}$-inequality cannot hold again because of (27), we have necessarily

$$-D_z w^\delta(\bar{x}, \bar{z}, \bar{z}', \bar{t}) + \eta\phi'(\bar{z}) - 2\beta\bar{z} \leq 0. \tag{28}$$

However, because of the sublinear growth of Υ^*, $|\bar{x}| = O(1/\alpha)$ and therefore $|\bar{z}| = O(1/\alpha)$. If we fix $\eta > 0$, then for β small enough $\eta\phi'(\bar{z}) - 2\beta\bar{z} > 0$. Moreover,

$$-D_z w^\delta(\bar{x}, \bar{z}, \bar{z}', \bar{t}) = \frac{\bar{z}' - \bar{z}}{w^\delta(\bar{x}, \bar{z}, \bar{z}', \bar{t})} = \frac{\bar{z}' - \bar{x}}{w^\delta(\bar{x}, \bar{z}, \bar{z}', \bar{t})} \geq 0.$$

Finally, (28) cannot hold. Hence $\bar{t} = 0$ and we have

$$\begin{aligned}\Upsilon^*(x, z, z', t) \leq w^\delta(x, z, z', t) - \alpha \exp^{\gamma(T-t)}(|x|^2+1) + \cdots \\ + \eta[\phi(z) + \phi(z')] - \beta[|z|^2 + |z'|^2] + 2\eta\|\phi\|_\infty,\end{aligned}$$

And letting successively β, η, α, and finally δ to zero gives the desired conclusion. □

Remark. We want to point out that we do not use any comparison argument for the problem (24)–(26), and the fact that the domain $\mathcal{O}$ exhibits corners therefore does not really matter.

2. The general case. In this part, we consider the case where the cost function is given by

$$J(x, t, (\alpha_s)_s) = E\left[\psi\left(\sup_{s\in[t,T]} f(X_s, s, \alpha_s)\right)\right]. \tag{29}$$

We recall that $f \geq 0$ is assumed to satisfy Assumption 1 and throughout this section we also assume the following assumption holds

ASSUMPTION 2.

$$\{f(x, t, \alpha); \alpha \in A\} = [f^-(x, t), f^+(x, t)]$$

for any $x \in \mathbb{R}^n, t \in [0, T]$ *and where* $f^+(x, t) = \sup_{\alpha\in A} f(x, t, \alpha), f^-(x, t) = \inf_{\alpha\in A} f(x, t, \alpha)$.

At the end of the section we will explain why this assumption is necessary and, in some sense, natural in our approach.

Since most of the arguments developed in §1 are similar to those used here, we will only focus on the main subtleties this problem requires compared to the preceding one.

The new state variable must clearly be as follows: if $p < \infty$,

$$Z_s^p = \left(z^p + \int_t^s f(X_\tau, \tau, \alpha_\tau)^p d\tau\right)^{1/p} \tag{30}$$

and, if $p = \infty$,

$$Z_s^\infty = \max\left\{ z, \sup_{\tau\in[t,s]} f(X_\tau, \tau, \alpha_\tau)\right\}, \tag{31}$$

X being as always the solution of (4), (5). The cost function of the augmented problem is again given by

$$J^p(x, z, t, (\alpha_s)_s) = E[\psi(Z_T^p)] \tag{32}$$

We want to minimize J^p over all admissible controls

$$u^p(x, z, t) = \inf_{(\alpha_s)_s} J^p(x, z, t, \alpha). \tag{33}$$

Differentiating (30) with respect to time yields

$$dZ_s = \frac{Z_s}{p}\left(\frac{f(X_s, s, \alpha_s)}{Z_s}\right)^p.$$

Thus, if we set, for $\xi = (x, z, t, q_t, q_x, q_z, M) \in Q \times \mathbb{R}^{n+2} \times \mathcal{S}^n$ and $\alpha \in A$,

$$\mathcal{L}^\alpha(\xi) = -q_t - \tfrac{1}{2}\operatorname{Tr}((\sigma\sigma^T)(x, t, \alpha)M) - b(x, t, \alpha)q_x,$$

the Hamiltonian related to the control problem (33) is, for $p < \infty$,

$$\mathcal{H}^p(\xi) = \sup_{\alpha\in A}\left\{\mathcal{L}^\alpha(\xi) - \frac{z}{p}\left(\frac{f(x, s, \alpha)}{z}\right)^p q_z\right\}.$$

We state without proof the following result, which is a straightforward generalization of Theorem 1.2.1.

THEOREM 1.2.1. *Under Assumption* 1, *we have*

(i) u^p *is bounded and Lipschitz continuous in* x *and* z, *uniformly for* $t \in [0, T]$.

(ii) u^p *is the unique bounded viscosity solution of*

$$\mathcal{H}^p\left(x, z, t, \frac{\partial u}{\partial t}, D_x u, D_z u, D_{xx}^2 u\right) = 0 \quad \text{in } Q,$$
$$u(x, z, T) = \psi(z) \quad \text{in } \mathbb{R}^n \times \mathbb{R}_+^*.$$

Looking at the equation, which is a priori satisfied by u^∞, and showing that actually u^p tends to u^∞ is here a little more difficult than in §1, mostly because of the dependency of the cost with respect to α.

Again we take the half-relaxed limits

$$\mathcal{H}^* = \limsup{}^* \mathcal{H}^p \quad \text{and} \quad \mathcal{H}_* = \liminf{}_* \mathcal{H}^p$$

and

$$u^* = \limsup{}^* u^p \quad \text{and} \quad u_* = \liminf{}_* u^p.$$

Define

$$A_{x,z,t} = \{\alpha \in A \text{ such that } f(x, t, \alpha) \le z\},$$

TABLE 1

	$q_z < 0$	$q_z = 0$	$q_z > 0$
$z > f^+(x,t)$	$\mathcal{L}(x,z,t)$	$\mathcal{L}(x,z,t)$	$\mathcal{L}(x,z,t)$
$z = f^+(x,t)$	$+\infty$	$+\infty$	$\mathcal{L}(x,z,t)$
$f^- < z < f^+$	$+\infty$	$+\infty$	$\mathcal{L}(x,z,t)$
$z = f^-(x,t)$	$+\infty$	$+\infty$	$\mathcal{L}(x,z,t)$
$z < f^-(x,t)$	$+\infty$	$+\infty$	$-\infty$

TABLE 2

	$q_z < 0$	$q_z = 0$	$q_z > 0$
$z > f^+(x,t)$	$\mathcal{L}_*(x,z,t)$	$\mathcal{L}_*(x,z,t)$	$\mathcal{L}_*(x,z,t)$
$z = f^+(x,t)$	$\mathcal{L}_*(x,z,t)$	$\mathcal{L}_*(x,z,t)$	$\mathcal{L}_*(x,z,t)$
$f^- < z < f^+$	$+\infty$	$\mathcal{L}_*(x,z,t)$	$\mathcal{L}_*(x,z,t)$
$z = f^-(x,t)$	$+\infty$	$-\infty$	$-\infty$
$z < f^-(x,t)$	$+\infty$	$-\infty$	$-\infty$

and

$$A'_{x,z,t} = \{\alpha \in A \text{ such that } f(x,t,\alpha) < z\};$$

finally we set

$$\mathcal{L}(x,z,t) = \sup_{\alpha \in A_{x,z,t}} \mathcal{L}^\alpha.$$

Again we use in this part simplified notation by dropping the dependency of $\mathcal{L}$ with respect to the derivatives of u. It is clear enough that $\mathcal{L}$ is u.s.c. and that the l.s.c. envelope of $\mathcal{L}$ is given by

$$\mathcal{L}_*(x,z,t) = \sup_{\alpha \in A'_{x,z,t}} \mathcal{L}^\alpha.$$

We detailed only the situation when $t < T$. A simple (although not immediate) computation gives the values of $\mathcal{H}^*$ and $\mathcal{H}_*$. Table 1 gives the values for $\mathcal{H}^*$. Table 2 gives the values for $\mathcal{H}_*$.

We know by Theorem 1.3.1 that u^* (respectively, u_*) is a subsolution (respectively, supersolution) of $\mathcal{H}_* \leq 0$ (respectively, $\mathcal{H}^* \geq 0$). Table 3 gives those values.

For $t = T$, by using arguments analogous to the ones of the first section, we have in the viscosity sense

$$\max\{u(x,z,T) - \psi(z), -D_z u\} = 0 \quad \text{in } \{z \leq f^+(x,T)\},$$

and

$$u(x,z,T) = \psi(z) \quad \text{in } \{z > f^+(x,T)\}.$$

We set

$$\begin{aligned}
\Omega_1 &= \{(x,z,t) \text{ such that } z > f^+(x,t)\},\\
\Omega_2 &= \{(x,z,t) \text{ such that } f^-(x,t) \leq z \leq f^+(x,t)\},\\
\Omega &= \bar{\Omega}_1 \cup \Omega_2,\\
\partial_0\Omega &= \{(x,z,t) \text{ such that } z = f^-(x,t)\}.
\end{aligned}$$

TABLE 3

	$\mathcal{H}^* \geq 0$	$\mathcal{H}_* \leq 0$
$z > f^+(x,t)$	$\mathcal{L}(x,z,t) \geq 0$	$\mathcal{L}_*(x,z,t) \leq 0$
$z = f^+(x,t)$	$\max\{\mathcal{L}(x,z,t), -q_z\} \geq 0$	$\mathcal{L}_*(x,z,t) \leq 0$
$f^- < z < f^+$	$\max\{\mathcal{L}(x,z,t), -q_z\} \geq 0$	$\max\{\mathcal{L}_*(x,z,t), -q_z\} \leq 0$
$z = f^-(x,t)$	$\max\{\mathcal{L}(x,z,t), -q_z\} \geq 0$	$-q_z \leq 0$
$z < f^-(x,t)$	$-q_z \geq 0$	$-q_z \leq 0$

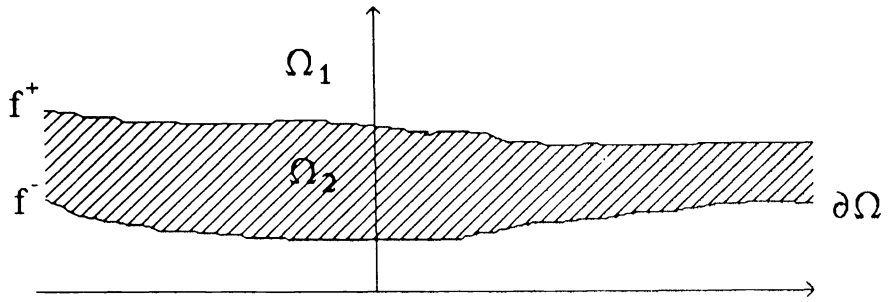

FIG. 2.

See Fig. 2.

Our first result consists in showing that we have indeed an oblique derivative boundary condition on $\partial_0\Omega$.

THEOREM 2.2. *u^* (respectively, u_*) is a viscosity subsolution (respectively, supersolution) of the mixed PDE-VI problem*

$$\sup_{\alpha\in A} \mathcal{L}^\alpha u = 0 \quad \text{in } \Omega_1, \tag{34}$$

$$\max\{\sup_{\alpha\in A_{x,z,t}} \mathcal{L}^\alpha u, -D_z u\} = 0 \quad \text{in } \Omega_2, \tag{35}$$

$$-D_z u = 0 \quad \text{on } \partial_0\Omega, \tag{36}$$

$$\max\{u(x,z,T) - \psi(z), -D_z u\} = 0 \quad \text{in } \{f^-(x,T) \leq z \leq f^+(x,T)\}, \tag{37}$$

$$u(x,z,T) = \psi(z) \quad \text{in } \{z > f^+(x,T)\}. \tag{38}$$

Proof of Theorem 2.2. Again we only prove the result in the subsolution case and for $t < T$, the other cases being treated by similar arguments. Let $\phi \in C^2(\bar{\Omega})$ and let $(\bar{x},\bar{z},\bar{t})$ be a strict global maximum point of $(u^* - \phi)$. If $(\bar{x},\bar{z},\bar{t}) \in \Omega$, there is no problem, so we will suppose that $(\bar{x},\bar{z},\bar{t}) \in \partial_0\Omega$. The additional difficulty here is that $\partial_0\Omega$ is just a Lipschitz continuous boundary; therefore we need to introduce a sequence of smooth approximations $(f_\varepsilon^-)_\varepsilon > 0$ built in such a way to have $f_\varepsilon^- \leq f$.

Consider a $C^2(\bar{Q})$-extension of ϕ, still denoted by ϕ. Set, for $k > 0$ and $\varepsilon > 0$,

$$\tilde{\phi}_k^\varepsilon(x,z,t) = \phi(x,z,t) + k(f_\varepsilon^-(x,t) - z)^{+4},$$

and let $(x_k^\varepsilon, z_k^\varepsilon, t_k^\varepsilon)$ be a maximum point of $u^* - \tilde{\phi}_k^\varepsilon$. Since $(\bar{x},\bar{z},\bar{t})$ is a global strict maximum point of $u^* - \phi$ in $\bar{\Omega}$ and since $(f_\varepsilon^-(x,t) - z)^+ \equiv 0$ in Ω (recall that $f_\varepsilon^- \leq f$), then $(x_k^\varepsilon, z_k^\varepsilon, t_k^\varepsilon)$

necessarily lies in $\bar{Q}\backslash\Omega$. Moreover, if we let $\varepsilon \to 0$ and then $k \to \infty$, $(x_k^\varepsilon, z_k^\varepsilon, t_k^\varepsilon)$ tends to $(\bar{x}, \bar{z}, \bar{t})$.

If there are infinitely many $(x_k^\varepsilon, z_k^\varepsilon, t_k^\varepsilon) \notin \partial_0\Omega$, then, extracting if necessary a subsequence, we have $-D_z\tilde{\phi}_k(x_k^\varepsilon, z_k^\varepsilon, t_k^\varepsilon) \leq 0$, because u^* is a subsolution of $\mathcal{H}_*$. Now we note that $D_z\tilde{\phi}_k^\varepsilon \leq D_z\phi$. Thus, letting $k \to \infty$, from the continuity of $D\phi$, we get $D_z\phi(\bar{x}, \bar{z}, \bar{t}) \geq 0$.

Otherwise, we extract a subsequence that remains on $\partial_0\Omega$; noting that, in this case, $(f_\varepsilon^-(x_k^\varepsilon, t_k^\varepsilon) - z_k^\varepsilon)^+ = 0$, we conclude by passing to the limit in the inequality $\min\{\mathcal{L}\phi, -D_z\phi\} \geq 0$. □

Now we turn to our uniqueness result for this problem,

THEOREM 2.3. *Assume that Assumption* 1 *holds. If* u *is an u.s.c. bounded subsolution and* v *is a l.s.c. bounded supersolution of* (34)–(38) *such that* $u(T) \leq v(T)$. *Then*

$$u \leq v \quad \text{in } \bar{\Omega}.$$

Proof of Theorem 2.3. We face here two types of difficulties: the first one is connected to the variational inequality feature while the second one is related to the a priori possible discontinuity of the Hamiltonian $\sup_{\alpha\in A_{x,z,t}} \mathcal{L}^\alpha$ in z. The main remark that allows us to solve the second difficulty is that the Hamiltonian is in fact increasing in z.

Let $\phi : [0, \infty) \to \mathbb{R}$ be bounded, strictly decreasing and such that

$$\phi'(z) = -1 \quad \text{for all } 0 \leq z \leq K = \sup_{x,t,\alpha} f(x, t, \alpha) + 1.$$

For $\beta, \gamma, \delta, \epsilon > 0$, consider the test function

$$\Phi(x, y, z, w, t, s) = \beta(|x|^2 + |y|^2 + (w - K)^{+2}) + \gamma(\phi(z) + \phi(w)) + \exp(C(T - t))\left(\frac{|x - y|^2}{\epsilon} + \frac{|t - s|^2}{\epsilon}\right) + \frac{|z - w|^2}{\delta},$$

where C is some constant large enough and let (x, y, z, w, t) be a maximum point of $u(x, z, t) - v(y, w, s) - \Phi(x, y, z, w, t, s)$.

Case 1. $(x, z) \in \Omega_2$.

Since u is a viscosity subsolution of (34)–(38), we have $\max\{\mathcal{L}(x, z, t)\Phi, -D_z\Phi\} \leq 0$. A straightforward computation gives

$$-D_z\Phi = -\frac{2(z - w)}{\delta} - \gamma\phi'(z) \leq 0;$$

thus, if K_1 is a bound on the Lipschitz constant of f^+,

$$K_1(|x - y| + |t - s|) + f^+(y, s) \geq f^+(x, t) \geq z \geq w - \frac{\delta\gamma}{2}\phi'(z) \geq w + \frac{\delta\gamma}{2}. \tag{39}$$

We recall that $|x - y|, |t - s| = o(\sqrt{\epsilon})$ and $|z - w| = o(\sqrt{\delta})$; therefore, choosing $\epsilon \ll \delta$, we can always suppose the inequality

$$|x - y| \leq -K_1^{-1}\frac{\delta\gamma}{4}\phi'(z) \tag{40}$$

to hold. Then, from (39) and (40), we get $f^+(y, t) > w$; therefore $(y, w) \in \Omega_2$ and $(w - K)^+ = 0$. However,

$$-(-D_w\Phi) = -\frac{2(z - w)}{\delta} + \gamma\phi'(w) = -D_z\Phi + \gamma\phi'(z) + \gamma\phi'(w) < 0,$$

and this inequality implies that the $\mathcal{L}$-inequality holds for v. Thus, proceeding as in the Appendix, we obtain

$$u(x,z,t) - v(y,w,t) \le (I)$$

where

$$(I) = - \sup_{\alpha \in A_{x,z,t}} \left\{ -\tfrac{1}{2} \operatorname{Tr}(\sigma\sigma^T)(x,t,\alpha) M - b(x,t,\alpha) D_x \Phi \right\} + \sup_{\beta \in A_{y,w,s}} \left\{ -\tfrac{1}{2} \operatorname{Tr}(\sigma\sigma^T)(y,t,\beta) N + b(y,t,\beta) D_y \Phi \right\}$$

Next observe that, if $K_1 \ge |f|_{0,1}$, then

$$z \ge w + K_1(|x-y| + |t-s|) \Rightarrow A'_{x,z,t} \supseteq A_{y,w,s}. \tag{41}$$

Hence (39) and our choice of the parameters imply that (41) holds and therefore

$$(I) \le - \sup_{\alpha \in A_{y,w,s}} \left\{ -\tfrac{1}{2} \operatorname{Tr}(\sigma\sigma^T)(x,t,\alpha) M - b(x,t,\alpha) D_x \Phi \right\} + \sup_{\beta \in A_{y,w,s}} \left\{ -\tfrac{1}{2} \operatorname{Tr}(\sigma\sigma^T)(y,t,\beta) N + b(y,t,\beta) D_y \Phi \right\}$$

and it is then a purely routine job to proceed as in Theorem 1.21(ii).

Case 2. $(x,z) \in \Omega_1$ and $((y,w) \in \Omega_1$ or $D_w \Phi < 0)$.

Then immediately

$$\mathcal{L}(x,z,t)\Phi \le 0 \quad \text{and} \quad \mathcal{L}(y,w,s)\Phi \ge 0,$$

and one proceeds as in Case 1, still choosing the parameters so that (40) holds.

Case 3. $(x,z) \in \Omega_1$ and $(y,w) \in \Omega_2$ and $D_w \Phi \ge 0$.

We are going to show that this case cannot happen. Since

$$D_w \Phi = -\frac{2(z-w)}{\delta} + \gamma \phi'(w) \ge 0,$$

and $(y,w) \in \Omega_2$,

$$z \le w - \frac{\delta\gamma}{2}.$$

However,

$$(x,z) \in \Omega_1 \Rightarrow z > f^+(t,x),$$
$$(y,w) \in \Omega_2 \Rightarrow w \le f^+(t,y).$$

By Lipschitz continuity of f^+,

$$K_1|x-y| \ge w - z \ge \frac{\delta\gamma}{2}.$$

However, this last inequality cannot hold since (40) does.

Theorem 2.4 concludes this part.

THEOREM 2.4. $\lim_{p\to\infty} u^p = u^\infty$ *uniformly on compact subsets of* $\bar{\Omega}$.

Proof of Theorem 2.4. The ideas of the proof of the analogous result in §1 do not extend here since it is false here that Z_T^p converges to Z_T^∞ *uniformly* with respect to $(\alpha_s)_s$; this is only true when we work with a fixed control. Therefore we will use different types of arguments. We proceed in two steps.

Step 1. $\lim_{p\to\infty} u^p \le u^\infty$.

By the very definition of u^p, we have

$$u^p(x,z,t) \le J^p(x,z,t,(\alpha_s)_s) = E[\psi(Z_T^p)]$$

for any control $(\alpha_s)_s$. We fix the control and we pass to the limit in this inequality by using the convergence of Z_T^p to Z_T^∞, we get

$$\lim_{p\to\infty} u^p(x,z,t) \le E[\psi(Z_T^\infty)].$$

Finally, taking the infimum over $(\alpha_s)_s$ in the right-hand side yields the desired inequality.

Step 2. $\lim_{p\to\infty} u^p \ge u^\infty$.

To obtain this result, we are going to prove that u^∞ is a viscosity subsolution of (34)–(38). Indeed, if this claim is true, the inequality will be an immediate consequence of Theorem 2.3 since $\lim_{p\to\infty} u^p$ is a viscosity solution of (34)–(38).

Now we prove the claim. The only difficulty comes from the region $f^-(x,t) \le z \le f^+(x,t)$. We must prove that in this region

$$-D_z u \le 0,$$

and

$$\mathcal{L}_*(x,z,t)\left(x,z,t,\frac{\partial u}{\partial t}, D_x u, D_z u, D^2_{xx} u\right) \le 0,$$

in the viscosity sense.

We are going to use a dynamic programming principle type argument. If we choose a control $\alpha_s \equiv \alpha$ on the time interval $(t, t+h), \alpha$ being also deterministic, then classical arguments (cf. Krylov [27]) implies

$$u^\infty(x,z,t) \le E_{x,z,t}[u^\infty(X_{t+h}, Z_{t+h}, t+h)]. \tag{42}$$

for any $h > 0$.

To prove that u^∞ is decreasing with respect to z if $z \le f^+(x,t)$, we consider $z < z' \le f^+(x,t)$. If $z' \le f^-(x,t)$, we have obviously $u(x,z,t) = u(x,z',t)$. Otherwise by Assumption 2 there exists $\alpha \in A$ such that $z' = f(x,t,\alpha)$. We use this constant control in (42); we obtain

$$u^\infty(x,z,t) \le E_{x,z,t}\left[u^\infty\left(X_{t+h}, \sup\left(z, \sup_{(t,t+h)} f(X_s,s,\alpha)\right), t+h\right)\right],$$

and we let h go to zero, $\sup(z, \sup_{(t,t+h)} f(X_s,s,\alpha))$ converges to $\sup(z, f(x,t,\alpha)) = z'$ and therefore

$$u^\infty(x,z,t) \le (u^\infty)^*(x,z',t).$$

Recall that we know that u^∞ is Lipschitz continuous in x and z but we do not know it is continuous in t. However, since the above inequality is true for any (x,z,t) it obviously yields $(u^\infty)^*(x,z,t) \le (u^\infty)^*(x,z',t)$ and therefore $-D_z u \le 0$.

Now if $z > f(x,t,\alpha)$, we still consider the constant control $\alpha_s \equiv \alpha$ on the interval $(t, t+h)$. By (42), we have

$$u^\infty(x,z,t) \leq E[u^\infty(X_{t+h}, Z_{t+h}, t+h)],$$

which implies

$$(u^\infty)^*(x,z,t) \leq E[(u^\infty)^*(X_{t+h}, Z_{t+h}, t+h)],$$

since the right-hand side is u.s.c. Classical arguments yield

$$\mathcal{L}^\alpha(x,z,t,\frac{\partial u}{\partial t}, D_x u, D_z u, D^2_{xx} u) \leq 0,$$

in the viscosity sense. Taking the infimum on $\alpha \in A'_{x,z,t}$ gives the result. □

We conclude this section by explaining why Assumption 2 is necessary. We consider the deterministic case when $b \equiv 0, \sigma \equiv 0, A = \{0,1\}, f(x,t,\alpha) = \alpha$, and $\psi(t) = \inf(t(t-1), 0)$. In this simple case, we can compute everything: consider z such that $0 < z < \frac{1}{4}$

$$u^\infty(x,z,t) = \inf(\psi(z), \psi(1)) = \psi(z),$$

since $Z_t = \sup(z,1) = z$, if we use the control $\alpha = 1, Z_t = z$ otherwise. On the other hand

$$u^p(x,z,t) = \inf_{s\in(0,T-t)} \psi((z^p+s)^{1/p})$$

and if $T-t$ is, say, larger than 1 there exists $s \in (0, T-t)$ such that $(z^p+s)^{1/p} = \frac{1}{2}$ and therefore

$$u^p(x,z,t) = \psi(1/2) = \inf_{\mathbb{R}} \psi.$$

Therefore $u^p(x,z,t)$ cannot converge to $u^\infty(x,z,t)$ since if $0 < z < \frac{1}{4}$ and if $T-t > 1$

$$u^\infty(x,z,t) = \psi(z) > \psi(\tfrac{1}{2}) = u^p(x,z,t).$$

The L^p problem appears as a "relaxed problem" of the L^∞ one; therefore the convexity assumption of the set $\{f(x,t,\alpha); \alpha \in A\}$ is natural in this context.

3. Extensions and applications.

3.1. Optimal stopping. All the results of §§1 and 2 can be extended readily to the case of optimal stopping time problems. We just formulate in this section the result corresponding to the problem of pricing American options on stocks that we use in the next section. We use the same notation as in the first part and we define for $(x,z,t) \in \Omega$, a control $(\alpha_s)_s$ and a stopping time θ such as $t \leq \theta \leq T$ almost surely, the cost function by

$$J(x,z,t,(\alpha_s)_s,\theta) = E[\psi(X_\theta, Z_\theta, \theta)],$$

where $\psi \in W^{1,\infty}(\mathbb{R}^n \times \mathbb{R}_+ \times [0,T])$. We recall that in this framework the control consists both in the process $(\alpha_s)_s$ and in the stopping time θ. The value function is then given by

$$u(x,z,t) = \inf_{(\alpha_s)_s,\theta} J(x,z,t,(\alpha_s)_s,\theta).$$

Our result is the following theorem.

THEOREM 3.1.1. *u is the unique viscosity of the variational inequality*

$$\max\left\{\mathcal{L}(x,z,t,\frac{\partial u}{\partial t}, D_x u, D^2_{xx} u), u-\psi\right\} = 0 \quad \text{in } \Omega, \tag{43}$$

$$\max\{-D_z u, u-\psi\} = 0 \quad \text{on } \partial_0\Omega, \tag{44}$$

$$u(x,z,T) = \psi(x,z,T) \quad \text{in } \{|x| < z\}. \tag{45}$$

3.2. Application in finance theory: path-dependent options. We show in this section how the results of the previous sections can be used to valuate look-back options. This problem was investigated also in [9]; but the martingale approach used therein, if it yields explicit formulas in the case of some European options with constant diffusion coefficients, does not allow a straightforward generalisation to the American case. The PDE approach we present here provides a very general method to treat this problem (and also the case of variable diffusion coefficients, or dividends, etc).

Let us first set up the model. We consider a stock which price $(P_t)_{t\in[0,T]}$ is given, *in the risk neutral probability*[2] by the Itô equation

$$dP_t = P_t(r(P_t,t)dt + \sigma(P_t,t)dW_t), \tag{46}$$

$$P_0 = p_0 > 0, \tag{47}$$

where $((W_t)_{t\in[0,T]}, (\mathcal{F}_t)_{t\in[0,T]})$ is a Brownian motion and r, σ are Lipschitz, bounded functions on $\mathbb{R}^*_+ \times [0,T]$. We recall that r stands for the risk-free rate available on the market and σ is the volatility parameter. We set, for $t_0 \le t \le T$, $M^{t_0}_t = \sup_{s\in[t_0,t]} P_s$.

In this set-up, an American option is given by an $\mathcal{F}$-adapted process $(\Psi_t)_{t\in[0,T]}$ that represents the cash flow to be paid if the option is exercised at time t. It can be shown that the "fair" price (with respect to finance theory) is given by the process $(U_t)_{t\in[0,T]}$ defined by

$$U_t = \sup_{\theta \text{ such that } t\le\theta\le T} E\left[\Psi_\theta \exp\left(-\int_t^\theta r(P_s,s)ds\right) \middle| \mathcal{F}_t\right], \tag{48}$$

where the supremum runs over all $\mathcal{F}$-stopping times θ such that $t \le \theta \le T$. The valuation problem is thus to determine this supremum.

In the standard case, Ψ_t is actually a deterministic function of P_t and of time (e.g., $\Psi_t = (P_t - E)^+$ for a standard American call with strike E), and we classically prove that $U_t = u(P_t,t)$ also depends only on P_t and t, u being a function that solves a variational inequality.

The so-called path-dependent options, whose financial background is described in the books of Ingersoll [19] and of Cox and Rubinstein [10], are those for which Ψ_t does not depend only on P_t, but more generally of its history $(P_s)_{s\in[0,t]}$. The cases we will consider here are those for Ψ_t depends on the supremum (in order to simplify, but one proceeds analogously for infimum and for L^p means). Let us give some examples, most of them being taken from [9].

1. Call on supremum. It is a call with a specified strike E in which the stock price is replaced by its running maximum

$$\Psi_t = \left(\sup_{s\in[0,t]} P_s - E\right)^+. \tag{49}$$

[2] For more information on finance theory, we refer to [15] or [25].

2. Put with lookback strike. A put where the strike is replaced by the running maximum

$$\Psi_t = \left(\sup_{s\in[0,t]} P_s - P_t \right)^+. \tag{50}$$

3. Lookback limited-risk put. It is like a standard lookback option, except that its strike cannot exceed a specified value M_0

$$\Psi_t = \left(\sup_{s\in[0,t]} P_s \wedge M_0 - P_t \right)^+. \tag{51}$$

We know that the fair price process is given by (48), but contrary to what happens in the standard case, U_t is no longer measurable with respect to P_t, and hence, to get a representation in terms of a deterministic function, we must add the relevant variable $M_t = \sup_{s\in[0,t]} P_s$.

It is then a purely routine job to apply the results of §1 to show that we have

$$U_t = u(P_t, M_t, t),$$

where, letting

$$\Omega = \{(p,m) \in (\mathbb{R}_+^*)^2 \text{ such that } p < m\} \times [0,T],$$

$$\partial_0\Omega = \{(p,m) \in (\mathbb{R}_+^*)^2 \text{ such that } p = m\} \times [0,T],$$

u is the (unique) solution of the variational inequality with oblique Neumann condition

$$\min\left\{ -\frac{\partial u}{\partial t} - \frac{1}{2}\sigma^2 p^2 \frac{\partial^2 u}{\partial p^2} - \beta p \frac{\partial u}{\partial p} + ru, u - \psi \right\} = 0 \quad \text{in } \Omega \tag{52}$$

$$\min\left\{ -\frac{\partial u}{\partial m}, u - \psi \right\} = 0 \quad \text{on } \partial_0\Omega, \tag{53}$$

$$u(p,m,T) = \psi(p,m,T). \tag{54}$$

The obstacle ψ is given, for example, by

$$\psi(p,m,t) = (m-E)^+ \quad \text{in case (49)}, \tag{55}$$

$$\psi(p,m,t) = (m-p)^+ \quad \text{in case (50)}, \tag{56}$$

$$\psi(p,m,t) = (m \wedge M_0 - p)^+ \quad \text{in case (51)}. \tag{57}$$

Remark. We let the reader give the corresponding formulations for European options, which is even simpler (the variational inequality is turned into a linear equation), for the case of *infimum* instead of supremum (the relevant domain is for $p \geq m$) and also the case of L^p *means* instead of extrema (see §1.1).

Let us observe that the value function u yields, as well,

- the price $u(p,m,t)$ of the option;

- the optimal exercise time θ_t after t given by the beginning time

$$\theta_t = \inf\{s \geq t \text{ such that } (P_s, \max\{M_s, m\}, s) \in \mathcal{S}\},$$

where $\mathcal{S}$ is the set

$$\mathcal{S} = \{(p, m, t) \text{ such that } u(p, m, t) = \psi(p, m, t)\};$$

- the heading ratio, that is to say the number of stocks to have in a heading portfolio of the option

$$\delta = -\frac{\partial u}{\partial p}.$$

Appendix. Proof of Theorem 1.2.1(ii). That u^p is a viscosity solution of (13) is merely a consequence of the dynamic programming principle applied to C^2 test functions as proved in [30].

Uniqueness can be treated by the general viscosity method for fully nonlinear second-order equations ([22], [21], [11]). We draw attention to the fact that we must handle an unbounded domain and show that boundedness is indeed a boundary condition for $z = 0$ and $|x|, z \to +\infty$. To take in account only the derivatives appearing in (13), we define simplified superjet and subjet for u at $(x, z, t) \in Q$,

$$\mathcal{J}^+u(x,z,t) = \left\{ \left(\frac{\partial \phi}{\partial t}, D_x\phi, D_z\phi, D^2_{xx}\phi \right) \in \mathbb{R} \times \mathbb{R}^n \times \mathbb{R} \times \mathcal{S}^n, \right. \tag{58}$$
$$\left. \text{for } \phi \in C^2 \text{ such that } u - \phi \text{ has a local maximum at } (x,z,t) \right\}$$

and

$$\mathcal{J}^-u(x,z,t) = \left\{ \left(\frac{\partial \phi}{\partial t}, D_x\phi, D_z\phi, D^2_{xx}\phi \right) \in \mathbb{R} \times \mathbb{R}^n \times \mathbb{R} \times \mathcal{S}^n, \right. \tag{59}$$
$$\left. \text{for } \phi \in C^2 \text{ such that } u - \phi \text{ has a local minimum at } (x,z,t) \right\}.$$

We take the following notation: for $(q_t, q_x, q_z, M) \in \mathbb{R}^{n+2} \times \mathcal{S}^n$ and $u \in \mathbb{R}$, let

$$F(x,z,t,u,q_x,q_z,M) = -q_t + \sup_{\alpha \in A} \left\{ -\frac{1}{2} \operatorname{Tr}(\sigma\sigma^T)(t,x,\alpha)M \right.$$
$$\left. - b(t,x,\alpha)q_x \right\} + u - \frac{z}{p} \left(\frac{|x|}{z} \right)^p q_z$$

(observing that $\mathcal{L}$ can be changed to $\mathcal{L} + I$ by the change of function $u \to e^{-t}u$). We recall that an u.s.c. function u (respectively, a l.s.c. function v) is said to be a viscosity subsolution (respectively, supersolution) of (13) if and only if, for all $(x, z, t) \in \mathbb{R}^n \times \mathbb{R}^*_+ \times (0, T)$,

$$(q_t, q_x, q_z, M) \in \mathcal{J}^+u(x,z,t) \quad (\text{respectively, } \in \mathcal{J}^-u(x,z,t))$$

implies

$$F(x,z,t,u(x,z,t),q_x,q_z,M) \leq 0 \quad (\text{respectively, } \geq 0).$$

Now let u be an u.s.c. bounded subsolution and v a l.s.c. bounded supersolution of (13) such that $u(T) \leq v(T)$. We want to prove that

$$u \leq v.$$

Assume $\max_{\bar{Q}}(u - v) > 0$ and let us show that this leads to a contradiction. As usual in viscosity solution theory, we approximate the above maximum by $\max_{Q\times Q} \psi(x, z, t, y, w, s)$, where

$$\psi(x, z, t, y, w, s) = u(x, z, t) - v(y, w, s) - \Phi(x, z, t, y, w, s)$$

with

$$\Phi(x, z, t, y, w, s) = \frac{(|t - s|^2 + |x - y|^2 + |z - w|^2)}{\varepsilon} - K(x, z, t) - K(y, w, s),$$

and

$$K(x, z, t) = \beta(|x|^2 + |z|^2) + \gamma\frac{1}{|z|^2} + \theta\frac{1}{t},$$

β, γ and θ being positive constants devoted to tend to zero. K is used to penalize the "irrelevant" boundaries (x at ∞, z at 0 and ∞, t at 0). The heart of the proof is the following property (see [11]). If $(\bar{x}, \bar{t}, \bar{z}, \bar{y}, \bar{s}, \bar{w})$ is a maximum point of ψ (such a point can only be in Q), then, for each $\varepsilon > 0$, there are matrices M, N such that

$$\left(\frac{\partial\Phi}{\partial t}, D_x\Phi, M, D_z\Phi\right) \in \bar{\mathcal{J}}^+ u(\bar{x}, \bar{t}, \bar{z}), \tag{60}$$

$$\left(-\frac{\partial\Phi}{\partial s}, -D_y\Phi, -N, -D_w\Phi\right) \in \bar{\mathcal{J}}^- v(\bar{y}, \bar{s}, \bar{w}), \tag{61}$$

$$\begin{pmatrix} M & 0 \\ 0 & N \end{pmatrix} \leq D^2_{xy}\Phi + \varepsilon(D^2_{xy}\Phi)^2, \tag{62}$$

where all derivatives are taken at $(\bar{x}, \bar{t}, \bar{z}, \bar{y}, \bar{s}, \bar{w})$.

By the definition of viscosity solution, this leads to

$$u(\bar{x}, \bar{z}, \bar{t}) - v(\bar{y}, \bar{w}, \bar{s}) \leq (I) + (II),$$

where

$$\begin{aligned}(I) = {} & \frac{\partial\Phi}{\partial t} + \frac{\partial\Phi}{\partial s} \\ & - \sup_{\alpha\in A}\left\{-\frac{1}{2}\operatorname{Tr}(\sigma\sigma^T)(\bar{t}, \bar{x}, \alpha)M - b(\bar{t}, \bar{x}, \alpha)D_x\Phi - f(\bar{t}, \bar{x}, \bar{z}, \alpha)\right\} \\ & + \sup_{\alpha\in A}\left\{-\frac{1}{2}\operatorname{Tr}(\sigma\sigma^T)(\bar{s}, \bar{y}, \alpha)N + b(\bar{s}, \bar{y}, \alpha)D_y\Phi - f(\bar{s}, \bar{y}, \bar{w}, \alpha)\right\}\end{aligned}$$

and

$$(II) = \frac{\bar{z}}{p}\left(\frac{|\bar{x}|}{\bar{z}}\right)^p D_z\Phi - \frac{\bar{w}}{p}\left(\frac{|\bar{y}|}{\bar{w}}\right)^p D_w\Phi.$$

Thus

$$
\begin{aligned}
(I) \leq \frac{\partial \Phi}{\partial t} + \frac{\partial \Phi}{\partial s} & \\
& \sup_{\alpha \in A} \frac{1}{2} |\operatorname{Tr}(\sigma\sigma^T)(\bar{t}, \bar{x}, \alpha) M - \operatorname{Tr}(\sigma\sigma^T)(\bar{s}, \bar{y}, \alpha) N| \\
& + \sup_{\alpha \in A} |b(\bar{t}, \bar{x}, \alpha) D_x \Phi + b(\bar{s}, \bar{y}, \alpha) D_y \Phi| \\
& + \sup_{\alpha \in A} |f(\bar{t}, \bar{x}, \bar{z}, \alpha) - f(\bar{s}, \bar{y}, \bar{w}, \alpha)|.
\end{aligned}
$$

Using (10) and (62), a few computations are then needed to give the following bounds[3]

$$
\begin{aligned}
(I) \leq C^{\beta\gamma\theta}\delta + C^{\beta\gamma\theta} \frac{(|\bar{t} - \bar{s}|^2 + |\bar{x} - \bar{y}|^2 + |\bar{z} - \bar{w}|^2)}{\delta} & \\
+ C^{\gamma\theta}\beta(|\bar{x}|^2 + |\bar{z}|^2 + |\bar{y}|^2 + |\bar{w}|^2) + C\gamma \left(\frac{1}{|\bar{z}|^2} + \frac{1}{|\bar{w}|^2} \right). &
\end{aligned}
$$

The second term brings

$$
(II) \leq C^{\beta\gamma\theta}\delta + \frac{2\beta\bar{z}^2}{p} \left(\frac{|\bar{x}|}{\bar{z}} \right)^p + \frac{2\beta\bar{w}^2}{p} \left(\frac{|\bar{y}|}{\bar{w}} \right)^p.
$$

We let successively δ, β, and γ go to zero. Since the penalization terms also go to zero, the contradiction follows.

Acknowledgments. The authors thank Professor Ivar Ekeland for his constant encouragement and advice and Florence Soule de Lafont for stimulating discussions concerning applications in finance. The authors also thank the referee for pointing out the existence of Barron [6] and Heinricher and Stockbridge [18] and for his (justified) criticisms of the second section. His suggestions led to an improvement of the draft and a simplification of the proof of Theorem 2.4.

ON THE GAME RICCATI EQUATIONS ARISING IN H_∞ CONTROL PROBLEMS*

PASCAL GAHINET†

Abstract. In the state-space approach to H_∞ optimal control, feasible closed-loop gains γ are characterized via a pair of game Riccati equations depending on γ. This paper is concerned with the properties of these equations as γ varies. The most general problem is considered ($D_{11} \neq 0$) and the variations of the Riccati solutions are thoroughly analyzed. Insight is gained into the behavior near the optimum and into the dependence on γ of the suboptimality conditions. In addition, concavity is established for a criterion that synthesizes the three conditions $X \geq 0, Y \geq 0$, and $\rho(XY) < \gamma^2$. This suggests a numerically reliable Newton scheme for the computation of the optimal γ.

Most results presented here are extensions of earlier contributions. The main concern is to provide a complete and synthetic overview as well as results and formulas tailored to the development of numerically sound algorithms.

Key words. H_∞ control, algebraic Riccati equation, Newton method

1. Introduction.

Many significant problems in linear system theory can be recast into the abstract framework of H_∞ optimal control. Well-known examples include model matching, disturbance attenuation, mixed sensitivity design, and robust stabilization in the face of uncertainty [5]. The general H_∞ optimal control problem can be stated as follows. Consider a linear, time-invariant plant G, which maps exogenous inputs w and control inputs u to controlled outputs z and measured outputs y. That is,

$$\begin{pmatrix} z \\ y \end{pmatrix} = G(s) \begin{pmatrix} w \\ u \end{pmatrix} = \begin{pmatrix} G_{11}(s) & G_{12}(s) \\ G_{21}(s) & G_{22}(s) \end{pmatrix} \begin{pmatrix} w \\ u \end{pmatrix}.$$

When G is closed by the output feedback law $u = K(s)y$, the closed-loop transfer function from w to z is given by the linear fractional map:

$$\mathcal{F}(G, K) = G_{11} + G_{12}K(I - G_{22}K)^{-1}G_{21}. \tag{1.1}$$

The H_∞ optimal control problem consists of finding some real-rational, proper, and causal controller K_{opt} that internally stabilizes the plant while minimizing the norm $\|\mathcal{F}(G, K)\|_\infty$; that is,

$$\|\mathcal{F}(G, K_{opt})\|_\infty = \inf\{\|\mathcal{F}(G, K)\|_\infty : K \text{ internally stabilizes } G\}. \tag{1.2}$$

The infimum of all achievable gains is denoted γ_{opt}.

Although direct computation of γ_{opt} is a hard problem, the following suboptimal problem is relatively well understood and tractable:

(1.3)

Given $\gamma > 0$, does there exist an internally stabilizing K such that $\|\mathcal{F}(G, K)\|_\infty < \gamma$?

This paper is concerned with Doyle and Glover's state-space approach [4], [9] to solving this suboptimal problem. Over the past decade, this approach has emerged as the most direct and practical solution both on design and numerical grounds. It is now briefly summarized. To begin, we introduce the following minimal realization of the plant G:

$$G(s) = \begin{pmatrix} G_{11}(s) & G_{12}(s) \\ G_{21}(s) & G_{22}(s) \end{pmatrix} = \begin{pmatrix} D_{11} & D_{12} \\ D_{21} & D_{22} \end{pmatrix} + \begin{pmatrix} C_1 \\ C_2 \end{pmatrix} (sI - A)^{-1} (B_1 \quad B_2). \tag{1.4}$$

† Institut National de Recherche en Informatique et Automatique, Rocquencourt, BP 105, 78153 Le Chesnay Cedex, France (gahinet@colorado.inria.fr.).

Here $A \in \mathbb{R}^{n\times n}$ and z, y, w, and u are vectors of size p_1, p_2, m_1, and m_2, respectively, with the assumption that $m_1 \geq p_2$ and $p_1 \geq m_2$. Accordingly, $D_{11} \in \mathbf{R}^{p_1\times m_1}$, $D_{12} \in \mathbf{R}^{p_1\times m_2}$, $D_{21} \in \mathbf{R}^{p_2\times m_1}$, and $D_{22} \in \mathbf{R}^{p_2\times m_2}$. Associate with this data the following two Hamiltonian matrices:

$$H_\gamma = \begin{pmatrix} A & 0 \\ -C_1^T C_1 & -A^T \end{pmatrix} + \begin{pmatrix} B_1 & B_2 \\ -C_1^T D_{11} & -C_1^T D_{12} \end{pmatrix} \times \begin{pmatrix} \gamma^2 I - D_{11}^T D_{11} & -D_{11}^T D_{12} \\ -D_{12}^T D_{11} & -D_{12}^T D_{12} \end{pmatrix}^{-1} \begin{pmatrix} D_{11}^T C_1 & B_1^T \\ D_{12}^T C_1 & B_2^T \end{pmatrix}; \tag{1.5}$$

$$J_\gamma = \begin{pmatrix} A^T & 0 \\ -B_1 B_1^T & -A \end{pmatrix} + \begin{pmatrix} C_1^T & C_2^T \\ -B_1 D_{11}^T & -B_1 D_{21}^T \end{pmatrix} \times \begin{pmatrix} \gamma^2 I - D_{11} D_{11}^T & -D_{11} D_{21}^T \\ -D_{21} D_{11}^T & -D_{21} D_{21}^T \end{pmatrix}^{-1} \begin{pmatrix} D_{11} B_1^T & C_1 \\ D_{21} B_1^T & C_2 \end{pmatrix}. \tag{1.6}$$

Given a Hamiltonian matrix

$$H = \begin{pmatrix} A & R \\ -Q & -A^T \end{pmatrix}$$

where R, Q are symmetric matrices, we denote by $\mathcal{X}_-(H)$ the stable invariant subspace of H. Associated with H is the algebraic Riccati equation $A^T X + XA + XRX + Q = 0$. Recall that this equation has a (unique) symmetric stabilizing solution if and only if H has no pure imaginary eigenvalue and $\mathcal{X}_-(H)$ is complementary to the subspace Im $\binom{0}{I}$. When existing, such a solution is obtained as $X = QP^{-1}$, where $\binom{P}{Q}$ is any basis of $\mathcal{X}_-(H)$. In the sequel, Ric(H) will refer to the stabilizing solution.

Throughout the paper, we call the *general problem* (GP) the problem (1.3) with the following standing assumptions.

Assumption 1. (A, B_2, C_2) is stabilizable and detectable.

Assumption 2. D_{12} has full column rank and D_{21} has full row rank.

Assumption 3.

$$\text{rank} \begin{pmatrix} j\omega I - A & -B_2 \\ C_1 & D_{12} \end{pmatrix} = n + m_2 \quad \text{and} \quad \text{rank} \begin{pmatrix} j\omega I - A & B_1 \\ -C_2 & D_{21} \end{pmatrix} = n + p_2$$

for all $\omega \in \mathbb{R}$ or equivalently, G_{12} and G_{21} have no transmission zero on the imaginary axis [11].

Assumption 4. $D_{22} = 0$.

While Assumption 1 is necessary and sufficient for solvability of the GP for γ large enough, Assumptions 2 and 3 are restrictive assumptions required for validity of Doyle and Glover's state-space results. Finally, Assumption 4 amounts to a reparametrization of the controller set [9] and hence incurs no loss of generality.

Under Assumptions 1–4, solvability of the GP with attenuation level γ is characterized in terms of the solutions of the two Riccati equations associated with H_γ and J_γ [9].

THEOREM 1.1. *With Assumptions* 1–4, *there exists an internally stabilizing controller* K *such that* $\|\mathcal{F}(G, K)\|_\infty < \gamma$ *if and only if*

$$\gamma > \sigma_d := \max\{\sigma_{\max}((I - D_{12}(D_{12}^T D_{12})^{-1} D_{12}^T) D_{11}), \sigma_{\max}(D_{11}(I - D_{21}^T (D_{21} D_{21}^T)^{-1} D_{21}))\} \tag{1.7}$$

and the following conditions hold:

(C1) *H_γ and J_γ have no eigenvalue on the imaginary axis*;
(C2) *Neither $\mathcal{X}_-(H_\gamma)$ nor $\mathcal{X}_-(J_\gamma)$ intersects* $\operatorname{Im}\binom{0}{I}$;
(C3) $\operatorname{Ric}(H_\gamma) =: X_\gamma \geq 0$ *and* $\operatorname{Ric}(J_\gamma) =: Y_\gamma \geq 0$;
(C4) $\rho(X_\gamma Y_\gamma) < \gamma^2$. □

Conditions (C1)–(C4) are often referred to as DGKF's conditions after the authors of [4]. Note that (1.7) ensures that the inverses in H_γ and J_γ are well defined (see (3.2) together with the definition of $\hat{D}_{11}$ in (3.1)). Note also that the Riccati equations associated with H_γ and J_γ have an indefinite quadratic term and are thus referred to as game Riccati equations (GRE). Finally, Theorem 1.1 characterizes γ_{opt} as the smallest $\gamma > 0$ for which the four conditions (C1)–(C4) are jointly satisfied. In turn, this suggests a straightforward bisection algorithm to compute γ_{opt}.

This paper examines the dependence on γ of conditions (C1)–(C4) and discusses the implications for the computation of the optimal gain γ_{opt}. To this purpose, the properties of the game Riccati equations associated with H_γ and J_γ are analyzed in detail. After simplifying the expressions of H_γ and J_γ by elementary reparametrizations, §3 characterizes those γ for which (C1) holds. In §4, the variations of the pseudoinverses of X_γ and Y_γ are shown to be smooth, monotonic, and even concave wherever (C1) is satisfied. These results are obtained for the GP ($D_{11} \neq 0$) and allow a complete description of the variations of X_γ and Y_γ and of the behavior near γ_{opt} (§5). Finally, the computation of γ_{opt} is reformulated as a convex zero-crossing search problem that can be numerically solved by a Newton method (§6).

We conclude with a justification of our treatment of the GP instead of the simpler *Standard Problem* (SP) considered in [4]. Recall that the SP requires the additional assumptions

Assumption 5. $D_{11} = 0$,

Assumption 6. $D_{12}^T(D_{12}, C_1) = (I, 0)$ and $D_{21}(D_{21}^T, B_1^T) = (I, 0)$.

These assumptions have the advantage of notably simplifying the expressions of H_γ and J_γ. Moreover, such simplifications can be emulated for any GP via the loop-shifting techniques of [14]. Yet, these manipulations destroy the variational and structural properties of X_γ and Y_γ. Indeed, enforcing Assumption 5 requires a γ-dependent transformation that alters the gradient and complicates its computation. In addition, the transformed problem is by no means an SP. In fact, the Riccati equations associated with GPs and SPs are structurally different as illustrated by Theorem 5.6 below. For theoretical and numerical reasons, it is therefore advisable to work in the GP framework.

2. Notation and terminology. Given a square matrix M, a subspace $\mathcal{S}$ is said to be M-invariant if $M\mathcal{S} \subset \mathcal{S}$, and stable (antistable) M-invariant if, moreover, the restriction of M to $\mathcal{S}$ is stable (antistable). The following notation and definitions are used throughout the paper:

$\mathbb{C}_-, \mathbb{C}_0, \mathbb{C}_+$	open left-half plane, imaginary axis, and open right-half plane, respectively;
$\operatorname{Ker} X$, $\operatorname{Im} X$	null and range spaces of a matrix X, respectively;
$\mathcal{X}_-(M)$	stable M-invariant subspace;
$\Lambda(X), \rho(X)$	spectrum and spectral radius of a square matrix X, respectively;
$\sigma_{\max}(X)$	largest singular value of the matrix X;
$\operatorname{In}(X)$	the inertia of $X = X^T$, that is, the triple (π, ν, ζ) where π, ν, ζ denote the number of positive, negative, and zero eigenvalues of X, respectively;
$\mathcal{V}_0(C, A)$	A-invariant subspace associated with the stable, (C, A)-unobservable modes of A.

3. Condition on the Hamiltonian spectrum. This section examines which restriction is imposed on γ by condition (C1). It is shown that the region where H_γ has no eigenvalue on the imaginary axis is a half line $\gamma > \gamma_H$. A computable formula for the threshold γ_H is also derived. These results extend earlier work in [16] to the general case $D_{11} \neq 0$.

To simplify subsequent calculations, the expressions (1.5) and (1.6) of H_γ and J_γ are first condensed in terms of compound parameters. With $D_{12}^+ = (D_{12}^T D_{12})^{-1} D_{12}^T$ denoting the pseudoinverse of D_{12}, introduce the following parameters:

$$\begin{aligned} \hat{A} &:= A - B_2 D_{12}^+ C_1; \qquad \hat{B}_1 := B_1 - B_2 D_{12}^+ D_{11}; \qquad \hat{B}_2 := B_2 (D_{12}^T D_{12})^{-1/2}; \\ &\qquad\quad \hat{C}_1 := (I - D_{12} D_{12}^+) C_1; \qquad \hat{D}_{11} := (I - D_{12} D_{12}^+) D_{11}. \end{aligned} \tag{3.1}$$

By elementary algebra, H_γ can be rewritten as

$$H_\gamma = \begin{pmatrix} \hat{A} & -\hat{B}_2 \hat{B}_2^T \\ -\hat{C}_1^T \hat{C}_1 & -\hat{A}^T \end{pmatrix} + \begin{pmatrix} \hat{B}_1 \\ -\hat{C}_1^T \hat{D}_{11} \end{pmatrix} (\gamma^2 I - \hat{D}_{11}^T \hat{D}_{11})^{-1} (\hat{D}_{11}^T \hat{C}_1, \hat{B}_1^T). \tag{3.2}$$

Similarly, with $D_{21}^+ := D_{21}^T (D_{21} D_{21}^T)^{-1}$ and

$$\begin{aligned} \tilde{A} &:= A - B_1 D_{21}^+ C_2; \qquad \tilde{C}_1 := C_1 - D_{11} D_{21}^+ C_2; \qquad \tilde{C}_2 := (D_{21} D_{21}^T)^{-1/2} C_2; \\ &\qquad\quad \tilde{B}_1 := B_1 (I - D_{21}^+ D_{21}); \qquad \tilde{D}_{11} := D_{11} (I - D_{21}^+ D_{21}), \end{aligned} \tag{3.3}$$

J_γ can be simplified to

$$J_\gamma = \begin{pmatrix} \tilde{A}^T & -\tilde{C}_2^T \tilde{C}_2 \\ -\tilde{B}_1 \tilde{B}_1^T & -\tilde{A} \end{pmatrix} + \begin{pmatrix} \tilde{C}_1^T \\ -\tilde{B}_1 \tilde{D}_{11}^T \end{pmatrix} (\gamma^2 I - \tilde{D}_{11} \tilde{D}_{11}^T)^{-1} (\tilde{D}_{11} \tilde{B}_1^T, \tilde{C}_1). \tag{3.4}$$

Note that the underlying reparametrizations are independent of γ and transparent for analytical purposes since neither H_γ nor J_γ is altered. In addition, the stabilizability of (A, B_2) is equivalent to that of $(\hat{A}, \hat{B}_2)$ and similarly for the detectability of (C_2, A) and $(\tilde{C}_2, \tilde{A})$. Finally, observe that even though $D_{12}^T \hat{C}_1 = 0$ and $D_{21} \tilde{B}_1^T = 0$, and even if $D_{11} = 0$, the reduced expressions (3.2) and (3.4) cannot be associated with any particular SP since $\hat{A}$ and $\tilde{A}$ are distinct in general.

On their domain of existence, the GRE solutions $X_\gamma = \mathrm{Ric}(H_\gamma)$ have the important property of sharing the same null space as γ varies [15]. In other words, the singular part of X_γ is independent of γ and coincides with the stable $(\hat{C}_1, \hat{A})$-unobservable subspace that we denote by $\mathcal{V}_0(\hat{C}_1, \hat{A})$. Of course a similar result holds for Y_γ. This structural property is instrumental to the subsequent variational analysis which involves forming the pseudoinverses of X_γ and Y_γ. Indeed, consider some orthogonal change of coordinates $U = (U_1, U_2)$ such that

$$\begin{aligned} U^T \hat{A} U &= \begin{pmatrix} \hat{A}_{11} & 0 \\ \star & \hat{A}_{22} \end{pmatrix}; \qquad \hat{C}_1 U = (\hat{C}_{11} \quad 0); \\ U^T \hat{B}_1 &= \begin{pmatrix} \hat{B}_{11} \\ \star \end{pmatrix}; \qquad U^T \hat{B}_2 = \begin{pmatrix} \hat{B}_{21} \\ \star \end{pmatrix}; \end{aligned} \tag{3.5}$$

where $\hat{A}_{22}$ is stable and $(\hat{C}_{11}, \hat{A}_{11})$ has no stable unobservable mode—in other words, such that

$$\mathrm{Im}\, U_2 = \mathcal{V}_0(\hat{C}_1, \hat{A}); \qquad \mathrm{Im}\, U_1 = \mathcal{V}_0^\perp(\hat{C}_1, \hat{A}). \tag{3.6}$$

Then Ker $X_\gamma = \text{Im } U_2$, and

$$U^T X_\gamma U = \begin{pmatrix} \bar{X}_\gamma & 0 \\ 0 & 0 \end{pmatrix}$$

or equivalently

$$X_\gamma = U_1 \bar{X}_\gamma U_1^T, \tag{3.7}$$

where $\bar{X}_\gamma$ is nonsingular for all γ's. Hence $X_\gamma^+ = U_1 \bar{X}_\gamma^{-1} U_1^T$ and since U_1 is independent of γ, the variations of X_γ or X_γ^+ are completely described by those of the invertible matrix $\bar{X}_\gamma$. Similarly, Y_γ can be written as

$$Y_\gamma = V_1 \bar{Y}_\gamma V_1^T, \tag{3.8}$$

where V_1 is any orthogonal complement of $\mathcal{V}_0(\tilde{B}_1^T, \tilde{A}^T)$.

Remark 3.1. The (stable) unobservable modes of $(\hat{C}_1, \hat{A})$ are exactly the (stable) invariant zeros of $G_{12}(s)$, i.e., the complex numbers $s \in \mathbb{C}_-$ for which the system matrix

$$P(s) = \begin{pmatrix} sI - A & -B_2 \\ C_1 & D_{12} \end{pmatrix}$$

loses rank. This follows from the identities

$$\begin{pmatrix} sI - \hat{A} & 0 \\ \hat{C}_1 & D_{12} \end{pmatrix} = \begin{pmatrix} I & -B_2 D_{12}^+ \\ 0 & I \end{pmatrix} P(s) \begin{pmatrix} I & 0 \\ -D_{12}^+ C_1 & I \end{pmatrix}$$

and $D_{12}^T \hat{C}_1 = 0$. Indeed, these show that $P(s)$ is (column) rank deficient if and only if $\begin{pmatrix} sI - \hat{A} \\ \hat{C}_1 \end{pmatrix}$ is rank deficient, that is, if and only if s is an unobservable mode of $(\hat{C}_1, \hat{A})$. □

The first requirement (C1) for solvability of the GP is concerned with pure imaginary eigenvalues of H_γ or J_γ. The following theorem characterizes the region where (C1) is satisfied.

THEOREM 3.2. *Assume Assumptions* 1–4 *and consider* H_γ *given by* (1.5). *Then there exists a finite real number* $\gamma_H \geq \sigma_{\max}(\hat{D}_{11})$ *such that*

$$\Lambda(H_\gamma) \cap \mathbb{C}_0 = \emptyset \qquad \textit{if and only if } \gamma > \gamma_H. \tag{3.9}$$

Moreover, γ_H *can be computed as* (*using the notation* (3.5))

$$\gamma_H = \|\hat{D}_{11} + \hat{C}_{11}(sI + \hat{A}_Z)^{-1}(\hat{B}_{11} + Z\hat{C}_{11}^T \hat{D}_{11})\|_\infty, \tag{3.10}$$

where Z *is the unique stabilizing solution of*

$$-\hat{A}_{11} Z - Z\hat{A}_{11}^T - Z\hat{C}_{11}^T \hat{C}_{11} Z + \hat{B}_{21}\hat{B}_{21}^T = 0 \tag{3.11}$$

and $\hat{A}_Z := -\hat{A}_{11} - \hat{C}_{11}^T \hat{C}_{11} Z$ *is the corresponding* (*stable*) *closed-loop matrix.*

Proof. The proof is easily adapted from [16]. See Appendix A for details. □

Hence part of the spectrum of H_γ migrates toward the imaginary axis as γ decreases. The first contact occurs for $\gamma = \gamma_H$ and those eigenvalues which then reach the imaginary axis remain on the axis for all $\sigma_{\max}(\hat{D}_{11}) < \gamma \leq \gamma_H$. If γ_J denotes the counterpart of γ_H for J_γ and γ^* is defined as

$$\gamma^* = \max(\gamma_H, \gamma_J); \tag{3.12}$$

it follows that (C1) holds if and only if $\gamma > \gamma^*$. Note that Assumption 3 is necessary and sufficient to ensure that $\gamma^* < +\infty$ (cf. Remark 3.1). Also observe that $\gamma^* \geq \sigma_d$ of Theorem 1.1 since the matrices involved in the definition of σ_d are exactly $\hat{D}_{11}$ and $\tilde{D}_{11}$, while $\gamma_H \geq \sigma_{\max}(\hat{D}_{11})$ from (3.10) and $\gamma_J \geq \sigma_{\max}(\tilde{D}_{11})$ by duality.

4. Variational properties. We now restrict our attention to the interval $(\gamma^*, +\infty)$ where (C1) is satisfied and examine the regularity and variations of the GRE stabilizing solutions X_γ and Y_γ. Direct characterization of these variations is rendered difficult by the discontinuities arising where the complementarity condition (C2) fails. Fortunately, this problem disappears when considering instead the pseudoinverses of X_γ and Y_γ. Introduced in [16] for the SP, this technique allows a simple and powerful description of the variations with γ. Indeed, the continuous extensions of X_γ^+ and Y_γ^+ turn out to be monotonic and concave functions of the parameter $\alpha = \gamma^{-2}$. These results are now extended to the GP framework ($D_{11} \neq 0$) with no major difficulty except perhaps for the concavity part. On duality grounds, only the case of X_γ is considered here.

Recall from §3 that whenever (C1) and (C2) are satisfied, X_γ can be decomposed independently of γ as $X_\gamma = U_1 \bar{X}_\gamma U_1^T$ where $\bar{X}_\gamma$ is nonsingular. Consequently the pseudoinverse X_γ^+ is obtained as $X_\gamma^+ = U_1 \bar{X}_\gamma^{-1} U_1^T$ and its variations are entirely determined by those of $\bar{X}_\gamma^{-1}$. In the sequel, we therefore restrict our attention to the continuous extension $W_X(\gamma)$ of $\bar{X}_\gamma^{-1}$ on $(\gamma^*, +\infty)$. This extension is easily defined in terms of the decomposition (3.5) and of the stable invariant subspace of the reduced Hamiltonian

$$\bar{H}_\gamma := \begin{pmatrix} \hat{A}_{11} & -\hat{B}_{21}\hat{B}_{21}^T \\ -\hat{C}_{11}^T\hat{C}_{11} & -\hat{A}_{11}^T \end{pmatrix} + \begin{pmatrix} \hat{B}_{11} \\ -\hat{C}_{11}^T\hat{D}_{11} \end{pmatrix} \times (\gamma^2 I - \hat{D}_{11}^T\hat{D}_{11})^{-1}(\hat{D}_{11}^T\hat{C}_{11} \quad \hat{B}_{11}^T). \tag{4.1}$$

Specifically, given any basis $\begin{pmatrix} \bar{P} \\ \bar{Q} \end{pmatrix}$ of $\mathcal{X}_-(\bar{H}_\gamma)$, $\bar{Q}$ is invertible since $(\hat{C}_{11}, -\hat{A}_{11})$ is detectable and $W_X(\gamma) := \bar{P}\bar{Q}^{-1}$ is well defined for all $\gamma > \gamma_H$. With this definition, $W_X(\gamma) = \bar{X}_\gamma^{-1}$ whenever $\bar{X}_\gamma$ exists. Moreover, $W_X(\gamma)$ is the unique stabilizing solution of the GRE

$$\begin{aligned} -(\hat{A}_{11} + \hat{B}_{11}R_\gamma^{-1}\hat{D}_{11}^T\hat{C}_{11})\,W_X(\gamma) - W_X(\gamma)\,(\hat{A}_{11} + \hat{B}_{11}R_\gamma^{-1}\hat{D}_{11}^T\hat{C}_{11})^T \\ - \gamma^2 W_X(\gamma)\hat{C}_{11}^T S_\gamma^{-1}\hat{C}_{11}W_X(\gamma) + \hat{B}_{21}\hat{B}_{21}^T - \hat{B}_{11}R_\gamma^{-1}\hat{B}_{11}^T = 0, \end{aligned} \tag{4.2}$$

where $R_\gamma := \gamma^2 I - \hat{D}_{11}^T\hat{D}_{11} > 0$ and $S_\gamma := \gamma^2 I - \hat{D}_{11}\hat{D}_{11}^T > 0$, and the corresponding (stable) closed-loop matrix is

$$A_W = -(\hat{A}_{11} + \hat{B}_{11}R_\gamma^{-1}\hat{D}_{11}^T\hat{C}_{11})^T - \gamma^2\hat{C}_{11}^T S_\gamma^{-1}\hat{C}_{11}W_X(\gamma). \tag{4.3}$$

Regularity and monotonicity of $W_X(\gamma)$ over the whole interval $(\gamma_H, +\infty)$ are established in the next theorem.

THEOREM 4.1. *With Assumptions* 1–4 *of* §1, *the matrix-valued function* $W_X(\gamma)$ *defined above has the following properties*:

1. $W_X(\gamma)$ *is infinitely differentiable on* $(\gamma_H, +\infty)$;
2. $W_X(\gamma)$ *is monotonically increasing with* γ;
3. $\lim_{\gamma\to+\infty} W_X(\gamma)$ *exists and is positive definite.*

Proof. (1) For $\gamma > \gamma_H$, $W_X(\gamma)$ is the stabilizing solution of the GRE (4.2) whose parameters are infinitely differentiable functions of γ. By the Implicit Function Theorem applied to the stabilizing solution of algebraic Riccati equations (see, e.g., [6], [7], [13]), W_X is therefore infinitely differentiable.

(2) It is equivalent but more convenient to show that W_X is a decreasing function of the parameter $\alpha = \gamma^{-2}$. Introduce $R_\alpha := I - \alpha\hat{D}_{11}^T\hat{D}_{11} > 0$ and $S_\alpha := I - \alpha\hat{D}_{11}\hat{D}_{11}^T > 0$, and observe that $R_\gamma^{-1} = \alpha R_\alpha^{-1}$ and $\gamma^2 S_\gamma^{-1} = S_\alpha^{-1}$. Moreover,

$$\frac{d}{d\alpha}(R_\gamma^{-1}) = R_\alpha^{-2}; \qquad \frac{d}{d\alpha}(\gamma^2 S_\gamma^{-1}) = S_\alpha^{-1}\hat{D}_{11}\hat{D}_{11}^T S_\alpha^{-1} = \hat{D}_{11}R_\alpha^{-2}\hat{D}_{11}^T, \tag{4.4}$$

where the last identity follows from $S_\alpha^{-1}\hat{D}_{11} = \hat{D}_{11}R_\alpha^{-1}$. Differentiating (4.2) with respect to $\alpha = \gamma^{-2}$ then yields

$$A_W^T\frac{dW_X}{d\alpha} + \frac{dW_X}{d\alpha}A_W - \hat{B}_{11}R_\alpha^{-2}\hat{D}_{11}^T\hat{C}_{11}W_X - W_X\hat{C}_{11}^T\hat{D}_{11}R_\alpha^{-2}\hat{B}_{11}^T$$
$$- W_X\hat{C}_{11}^T\hat{D}_{11}R_\alpha^{-2}\hat{D}_{11}^T\hat{C}_{11}W_X - \hat{B}_{11}R_\alpha^{-2}\hat{B}_{11}^T = 0,$$

which can be rewritten more compactly as

$$A_W^T\frac{dW_X}{d\alpha} + \frac{dW_X}{d\alpha}A_W - (\hat{B}_{11} + W_X\hat{C}_{11}^T\hat{D}_{11})R_\alpha^{-2}(\hat{B}_{11} + W_X\hat{C}_{11}^T\hat{D}_{11})^T = 0. \tag{4.5}$$

Since A_W is stable and $R_\alpha > 0$, it follows from the Lyapunov Theorem that $dW_X/d\alpha \le 0$, that is, W_X is a monotonically decreasing function of α and thus a monotonically increasing function of γ.

(3) As $\gamma \to +\infty$, $W_X(\gamma)$ tends to the nonnegative stabilizing solution of the LQG-type Riccati equation

$$-\hat{A}_{11}W - W\hat{A}_{11}^T - W\hat{C}_{11}^T\hat{C}_{11}W + \hat{B}_{21}\hat{B}_{21}^T = 0.$$

Since $(\hat{A}, \hat{B}_2)$ and therefore $(\hat{A}_{11}, \hat{B}_{21})$ are stabilizable, this solution is nonsingular and hence $W_X(\infty) > 0$. □

In addition, W_X turns out to be a concave function of the parameter $\alpha = \gamma^{-2}$. This property is the foundation of the Newton algorithm proposed in §6 for the computation of the optimal gain γ_{opt}.

THEOREM 4.2. *W_X is a monotonically decreasing concave function of the parameter $\alpha = \gamma^{-2}$.*

Proof. The monotonicity was established in Theorem 4.1. To establish concavity, we calculate the second derivative of W_X with respect to α. First observe from (4.3) and (4.4) that

$$\begin{aligned}\frac{dA_W}{d\alpha} &= -\hat{C}_{11}^TS_\alpha^{-1}\hat{C}_{11}\frac{dW_X}{d\alpha} - \hat{C}_{11}^T\hat{D}_{11}R_\alpha^{-2}\hat{B}_{11}^T - \hat{C}_{11}^T\hat{D}_{11}R_\alpha^{-2}\hat{D}_{11}^T\hat{C}_{11}W_X \\ &= -\hat{C}_{11}^TS_\alpha^{-1}\hat{C}_{11}\frac{dW_X}{d\alpha} - \hat{C}_{11}^T\hat{D}_{11}R_\alpha^{-2}F^T\end{aligned} \tag{4.6}$$

with $F := \hat{B}_{11} + W_X\hat{C}_{11}^T\hat{D}_{11}$. Then differentiate (4.5) with respect to α to obtain

$$A_W^T\frac{d^2W_X}{d\alpha^2} + \frac{d^2W_X}{d\alpha^2}A_W + \frac{dA_W^T}{d\alpha}\frac{dW_X}{d\alpha} + \frac{dW_X}{d\alpha}\frac{dA_W}{d\alpha}$$
$$- \frac{dW_X}{d\alpha}\hat{C}_{11}^T\hat{D}_{11}R_\alpha^{-2}F^T - FR_\alpha^{-2}\hat{D}_{11}^T\hat{C}_{11}\frac{dW_X}{d\alpha} - 2FR_\alpha^{-3}\hat{D}_{11}^T\hat{D}_{11}F^T = 0,$$

which combined to (4.6) yields

$$A_W^T\frac{d^2W_X}{d\alpha^2} + \frac{d^2W_X}{d\alpha^2}A_W - 2\left\{\frac{dW_X}{d\alpha}\hat{C}_{11}^TS_\alpha^{-1}\hat{C}_{11}\frac{dW_X}{d\alpha} + \frac{dW_X}{d\alpha}\hat{C}_{11}^T\hat{D}_{11}R_\alpha^{-2}F^T\right.$$
$$\left. + FR_\alpha^{-2}\hat{D}_{11}^T\hat{C}_{11}\frac{dW_X}{d\alpha} + FR_\alpha^{-3}\hat{D}_{11}^T\hat{D}_{11}F^T\right\} = 0. \tag{4.7}$$

A little algebra shows that

$$R_\alpha^{-3}\hat{D}_{11}^T\hat{D}_{11} = R_\alpha^{-2}\hat{D}_{11}^T\hat{D}_{11}R_\alpha^{-1} = R_\alpha^{-2}\{\hat{D}_{11}^T\hat{D}_{11}R_\alpha\}R_\alpha^{-2} = R_\alpha^{-2}\hat{D}_{11}^TS_\alpha\hat{D}_{11}R_\alpha^{-2}$$

and consequently the bracketed term in (4.7) can be factorized to obtain

$$A_W^T \frac{d^2W_X}{d\alpha^2} + \frac{d^2W_X}{d\alpha^2} A_W - 2\left(S_\alpha^{-1/2}\hat{C}_{11}\frac{dW_X}{d\alpha} + S_\alpha^{1/2}\hat{D}_{11}R_\alpha^{-2}F^T\right)^T \cdot \left(S_\alpha^{-1/2}\hat{C}_{11}\frac{dW_X}{d\alpha} + S_\alpha^{1/2}\hat{D}_{11}R_\alpha^{-2}F^T\right) = 0. \tag{4.8}$$

The stability of A_W then clearly ensures $d^2W_X/d\alpha^2 \le 0$, that is, the concavity of W_X as a function of $\alpha = \gamma^{-2}$. □

Once established for $\alpha = \gamma^{-2}$, similar conclusions in terms of the parameters γ^2 and γ^{-1} easily follow from the differentiation formulas for the composition of functions.

COROLLARY 4.3. *W_X is decreasing and concave as a function of γ^{-1} and is increasing and concave as a function of γ^2.*

Proof. Omitted for brevity. □

5. Variations with γ and behavior near the optimum. This section gathers the results accumulated so far to give a complete description of the dependence on γ of conditions (C1)–(C4) of §1. The role played by these conditions in the determination of γ_{opt} is also addressed and a few examples demonstrate that any one of (C1)–(C4) can fail at γ_{opt}.

Firstly, the theorems of §4 are applied to characterizing the behavior of X_γ and Y_γ over the half line $(\gamma^*, +\infty)$. The following technical lemma is a useful preliminary.

LEMMA 5.1. *There are at most n isolated points in $(\gamma_H, +\infty)$ where $W_X(\gamma)$ is singular.*

Proof. See Appendix B. □

We can now proceed with a corollary of Theorem 4.1 which describes the variations of X_γ.

COROLLARY 5.2. *The* GRE *stabilizing solution $X_\gamma = \mathrm{Ric}(H_\gamma)$ has the following properties on the interval $(\gamma_H, +\infty)$:*

1. *X_γ is defined for all $\gamma > \gamma_H$ except at most n points $\gamma_1 < \cdots < \gamma_k$ where $\|X_\gamma\| = +\infty$. These points of discontinuity $\gamma_1, \ldots, \gamma_k$ are exactly the points where $W_X(\gamma)$ is singular;*
2. *With the convention $\gamma_0 := \gamma_H$ and $\gamma_{k+1} := +\infty$, X_γ is monotonically decreasing and of constant inertia on each interval (γ_i, γ_{i+1}), $i = 0 : k$;*
3. *When γ traverses some point of discontinuity γ_i from γ_i^+ to γ_i^-, at least one positive eigenvalue of X_γ escapes to $+\infty$ and reappears at $-\infty$.*

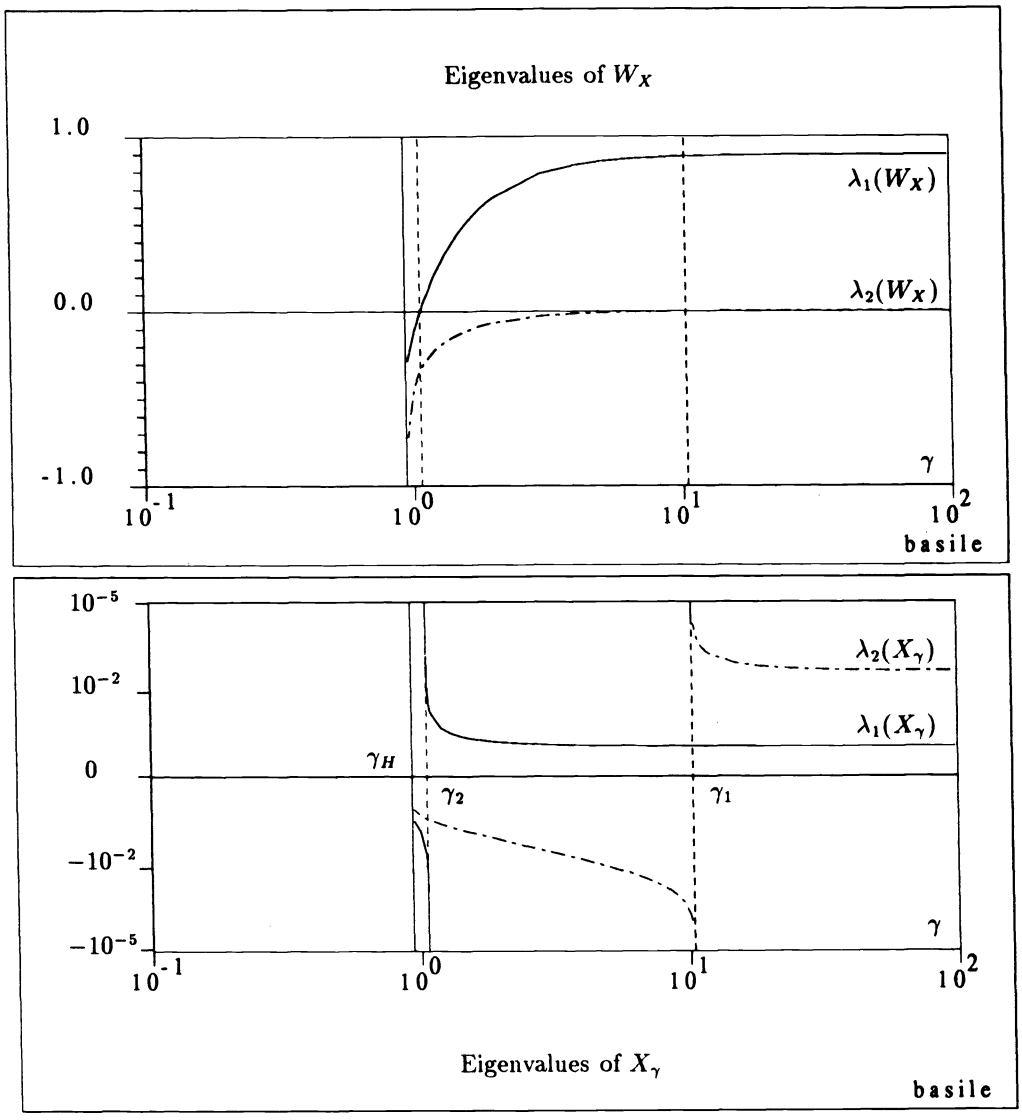
Proof. This corollary is an immediate consequence of Theorem 4.1 and of the fact that $\bar{X}_\gamma = W_X^{-1}(\gamma)$ whenever (C2) holds. To be convinced that the inertia of X_γ is constant on each (γ_i, γ_{i+1}), just observe that $\bar{X}_\gamma$ is nonsingular and continuous on these intervals which prohibits any change of inertia. □

Remarkably, sign changes in the eigenvalues of X_γ never result from zero-crossing. Instead, positive eigenvalues change sign by escaping to $+\infty$ and reappearing at $-\infty$. As γ decreases from $+\infty$ in particular, $\|X_\gamma\|$ necessarily blows up when (C3) is about to fail. Hence (C2) and (C3) first fail simultaneously. These various observations are illustrated on a simple example.

Example 5.3. Consider the GP with matrix data:

$$A = \begin{pmatrix} 10 & 2 \\ -1 & 8 \end{pmatrix}; \qquad B_1 = \begin{pmatrix} 2 & 0 \\ 0 & 2 \end{pmatrix}; \qquad B_2 = \begin{pmatrix} 2 \\ 0 \end{pmatrix};$$

$$C_1 = \begin{pmatrix} 4 & 0 \\ 0 & 4 \end{pmatrix}; \qquad D_{12} = \begin{pmatrix} 1 \\ 0 \end{pmatrix}; \qquad D_{11} = \begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix}.$$



GRAPH 5.1.

We focus on the variations of X_γ and of its inverse $W_X(\gamma)$ (here X_γ is nonsingular whenever defined). The eigenvalues of these two matrix-valued functions are plotted in Graph 5.1 for $\gamma > \gamma_H$ (here, $\gamma_H \approx 0.933$). The largest and smallest eigenvalues of W_X are denoted by $\lambda_1(W_X)$ and $\lambda_2(W_X)$, respectively, while $\lambda_1(X_\gamma)$ and $\lambda_2(X_\gamma)$ are taken as

$$\lambda_1(X_\gamma) = 1/\lambda_1(W_X); \qquad \lambda_2(X_\gamma) = 1/\lambda_2(W_X).$$

Solid lines are used for the plots of $\lambda_1(W_X)$ and $\lambda_1(X_\gamma)$ and dashed lines for the plots of $\lambda_2(W_X)$ and $\lambda_2(X_\lambda)$. Note also the semilogarithmic scale for the eigenvalues of X_γ.

Inspection of Graph 5.1 shows that X_γ has two points of discontinuity γ_1 and γ_2 in $(\gamma_H, +\infty)$ that correspond to the zero-crossings of $\lambda_1(W_X)$ and $\lambda_2(W_X)$. The inertia of X_γ changes when traversing either one of these discontinuities. Indeed, $\mathrm{In}(X_\gamma) = (2,0,0)$ for $\gamma > \gamma_1$, $\mathrm{In}(X_\gamma) = (1,0,1)$ for $\gamma_2 < \gamma < \gamma_1$, and $\mathrm{In}(X_\gamma) = (0,0,2)$ for $\gamma_H < \gamma < \gamma_2$. Finally, X_γ has a finite limit as $\gamma \to \gamma_H^+$. □

In most problems, condition (C4) is the first to fail when approaching the optimum γ_{opt}. Yet, (C1), (C2), or (C3) can sometimes be first to fail as demonstrated by the next two examples.

Example 5.4. This example illustrates that (C1) can fail first at γ_{opt}. Consider the plant $G(s)$ of realization (1.4) with $C_1 = I_2, D_{21} = 1, D_{22} = 0$, and

$$A = \begin{pmatrix} -1 & 0 \\ 0 & -1 \end{pmatrix}; \qquad B_1 = B_2 = \begin{pmatrix} 0 \\ 1 \end{pmatrix};$$
$$C_2^T = D_{11} = \begin{pmatrix} 0 \\ 0 \end{pmatrix}; \qquad D_{12} = \begin{pmatrix} 1 \\ 0 \end{pmatrix}.$$

Clearly, Assumption 1 of §1 is satisfied since A is stable and Assumptions 2 and 3 are trivially verified. After calculation of H_γ and J_γ via (1.5) and (1.6), elementary algebra shows that $\Lambda(H_\gamma)$ intersects $\mathbb{C}_0$ for $\gamma \le 1/\sqrt{2}$ while J_γ never has any eigenvalue on $\mathbb{C}_0$. Therefore $\gamma^* = 1/\sqrt{2}$. For all $\gamma \ge \gamma^*$, X_γ is obtained as the stabilizing solution of the GRE associated with H_γ,

$$X_\gamma = \begin{pmatrix} x^2\left(x + \frac{1}{2}\right) & -x^2 \\ -x^2 & x \end{pmatrix} \quad \text{where} \quad x = \frac{1}{1 + \sqrt{2 - \gamma^{-2}}}. \tag{5.1}$$

Meanwhile $Y_\gamma = 0$ for all $\gamma > \gamma^*$. Hence (C2)–(C4) reduce to the sole condition $X_\gamma \ge 0$, which is satisfied for all $\gamma \ge \gamma^*$ as it can be seen from (5.1). Consequently, $\gamma_{opt} = 1/\sqrt{2}$ and (C1) is the first condition to fail as γ decreases.

Example 5.5. This second example shows that (C3) can fail before (C4) in the GP context. That is, $\|X_\gamma\|$ or $\|Y_\gamma\|$ can become unbounded while $\rho(X_\gamma Y_\gamma)$ remains smaller than γ^2. Consider this time the plant $G(s)$ defined by the parameters $B_1 = C_1 = I_2, D_{22} = 0$, and

$$A = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}; \qquad B_2 = C_2^T = \begin{pmatrix} 1 \\ 1 \end{pmatrix};$$
$$D_{11} = \begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix}; \qquad D_{12} = \begin{pmatrix} 0 \\ 1 \end{pmatrix}; \qquad D_{21} = (1 \quad 0). \tag{5.2}$$

It is easily verified that (A, B_2, C_2) is stabilizable and detectable. Via the reparametrization ((3.1) and (3.3)) we find

$$U_1 = V_2 = \begin{pmatrix} 1 \\ 0 \end{pmatrix}, \quad V_1 = U_2 = \begin{pmatrix} 0 \\ 1 \end{pmatrix}, \quad \text{and } \bar{H}_\gamma = \bar{J}_\gamma = \begin{pmatrix} 0 & -1 + \gamma^{-2} \\ -1 & 0 \end{pmatrix}.$$

Hence $\gamma^* = 1$ and for $\gamma > 1, W_X(\gamma) = W_Y(\gamma) = \sqrt{1 - \gamma^{-2}}$ and

$$X_\gamma = U_1 W_X^{-1} U_1^T = \begin{pmatrix} \frac{1}{\sqrt{1-\gamma^{-2}}} & 0 \\ 0 & 0 \end{pmatrix}; \qquad Y_\gamma = V_1 W_X^{-1} V_1^T = \begin{pmatrix} 0 & 0 \\ 0 & \frac{1}{\sqrt{1-\gamma^{-2}}} \end{pmatrix}.$$

Consequently, $\rho(X_\gamma Y_\gamma) \equiv 0$ on $(\gamma^*, +\infty)$ while $\gamma_{opt} = 1$ since (C3) holds if and only if $\gamma > 1$. Thus, (C3) fails at γ_{opt} while (C4) is trivially satisfied everywhere. □

Incidentally, (C2) and (C3) never fail before (C4) in the restrictive framework of the SP. This fact critically relies on the particular duality relationship between H_γ and J_γ in the SP context.

THEOREM 5.6. *With the Standard Problem assumptions of* §1, $\rho(X_\gamma Y_\gamma)$ *cannot remain bounded when* $\|X_\gamma\|$ *or* $\|Y_\gamma\|$ *become unbounded. Consequently,* (C2) and (C3) *cannot fail before* (C4) *as* γ *decreases from* $+\infty$.

Proof. See Appendix C. □

6. Computation of γ_{opt} by a Newton method. The concavity results of §5 readily suggest a Newton scheme to locate the first failure of condition (C3). To extend such a scheme to the computation of γ_{opt}, (C4) must also be turned into a concave constraint. Such a reformulation is attempted in [16] but the concave criterion proposed therein has two major drawbacks: it applies only in the region where (C3) is satisfied and it mixes X_γ, Y_γ, and their pseudoinverses. In this section, we introduce an alternative criterion that combines (C2)–(C4) into a single concave constraint. First introduced in [10], this criterion applies to the whole region $\gamma > \gamma^*$ and solely involves the pseudoinverses of X_γ and Y_γ.

THEOREM 6.1. *Let* $U = (U_1, U_2)$ *and* $V = (V_1, V_2)$ *be orthogonal transformations of* $\mathbb{R}^{n\times n}$ *satisfying*

$$\text{Im } U_2 = \mathcal{V}_0(\hat{C}_1, \hat{A}); \qquad \text{Im } V_2 = \mathcal{V}_0(\tilde{B}_1^T, \tilde{A}^T). \tag{6.1}$$

With γ^* *given by* (3.12), *define for* $\gamma > \gamma^*$ *the matrix-valued function* Z *by*

$$Z(\gamma^{-1}) := \begin{pmatrix} W_X(\gamma) & \gamma^{-1}U_1^T V_1 \\ \gamma^{-1}V_1^T U_1 & W_Y(\gamma) \end{pmatrix}, \tag{6.2}$$

where W_X *denotes the continuous extension of* $\bar{X}_\gamma^{-1}$ *in* (3.7) *and* W_Y *that of* $\bar{Y}_\gamma^{-1}$ *in* (3.8). *Then* Z *is a concave function of the parameter* γ^{-1} *on the half line* $\gamma > \gamma^*$. *Moreover, there is equivalence between*

(1) *There exists a stabilizing controller* $K(s)$ *such that* $\|\mathcal{F}(K, G)\|_\infty < \gamma$;

(2) H_γ *and* J_γ *have no eigenvalue on* $\mathbb{C}_0$ *and* $Z(\gamma^{-1})$ *is positive definite.*

Proof. Both W_X, W_Y and therefore $Z(\gamma^{-1})$ are well defined for $\gamma > \gamma^*$ and the concavity follows from

$$\frac{d^2 Z}{d(\gamma^{-1})^2} = \begin{pmatrix} \dfrac{d^2 W_X}{d(\gamma^{-1})^2} & 0 \\ 0 & \dfrac{d^2 W_Y}{d(\gamma^{-1})^2} \end{pmatrix}$$

together with Corollary 4.3. As of the equivalence of (1) and (2), it can be found in [10]. □

Hence, the condition $Z(\gamma^{-1}) > 0$ emerges as a more natural and compact characterization of suboptimal γ's. Moreover, it synthesizes (C2)–(C3) into a single concave constraint so that the computation of γ_{opt} reduces to finding the zero-crossing of a concave function. Given some initial guess in the interval (γ^*, γ_{opt}), this problem can be solved by a Newton method with guaranteed quadratic convergence. Details of implementation appear in [8]. The only delicate issue is the initialization of the algorithm. Fortunately, Theorem 3.2 provides explicit formulas for γ^*. To estimate γ^* indeed, it suffices to solve the associated H_2 problem ($\gamma = +\infty$) and to compute the L_∞ norm of two transfer functions, a task for which quadratically convergent algorithms are also available [3].

7. Conclusion. The dependence on γ of the solutions to the H_∞ control problem has been precisely characterized. As a result, insight was gained into the structure, singularities, inertia, and variations of these solutions, and into their behavior near the optimum. This information is valuable for numerically stable testing of the suboptimality conditions and for the computation of the optimal γ. In particular, the concavity properties established in §§4 and 6 allow the design of Newton algorithms that quadratically converge to γ_{opt}.

Appendix A.

Proof of Theorem 3.2. Using (3.5), it is easily verified that $\Lambda(H_\gamma) \cap \mathbb{C}_0 = \Lambda(\bar{H}_\gamma) \cap \mathbb{C}_0$ with $\bar{H}_\gamma$ as in (4.1). Now, $(\hat{A}_{11}, \hat{B}_{21})$ inherits the stabilizability of $(\hat{A}, \hat{B}_2)$ and $(\hat{C}_{11}, -\hat{A}_{11})$ is detectable from (3.5) and Assumption 3 of §1. Consequently [12], (3.11) has a unique symmetric nonnegative definite stabilizing solution Z. Now, it is easily verified that

$$-\begin{pmatrix} I & -Z \\ 0 & I \end{pmatrix} \bar{H}_\gamma \begin{pmatrix} I & Z \\ 0 & I \end{pmatrix}$$
$$= \begin{pmatrix} \hat{A}_Z - F R_\gamma^{-1} \hat{D}_{11}^T \hat{C}_{11} & -F R_\gamma^{-1} F^T \\ \gamma^2 \hat{C}_{11}^T S_\gamma^{-1} \hat{C}_{11} & -\hat{A}_Z^T + \hat{C}_{11}^T \hat{D}_{11} R_\gamma^{-1} F^T \end{pmatrix} := H_Z(\gamma),$$

where $F := \hat{B}_{11} + Z\hat{C}_{11}^T \hat{D}_{11}$. This last identity shows that $-\bar{H}_\gamma$ and $H_Z(\gamma)$ share the same spectrum. Moreover, from the Bounded Real Lemma [1], [2] we know that

$$\Lambda(H_Z(\gamma)) \cap \mathbb{C}_0 = \emptyset \quad \text{iff } \|\hat{D}_{11} + \hat{C}_{11}(sI - \tilde{A}_Z)^{-1} F\|_\infty < \gamma.$$

Consequently, $\bar{H}_\gamma$ or equivalently H_γ has no eigenvalue on $\mathbb{C}_0$ if and only if $\gamma > \gamma_H := \|\hat{D}_{11} + \hat{C}_{11}(sI - \tilde{A}_Z)^{-1} F\|_\infty$. Note that $\gamma_H < +\infty$ since $\tilde{A}_Z$ is stable. □

Appendix B.

Proof of Lemma 5.1. From (2) of Theorem 4.1, the eigenvalues of W_X are monotonically increasing functions of γ. Hence it suffices to show that the singularities of W_X are isolated. To this purpose, suppose that $W_{X,0} := W_X(\gamma_0)$ is singular and let $\dot{W}_{X,0} := (dW_X/d\alpha)(\gamma_0)$ denote its derivative. To prove that γ_0 is isolated, it is sufficient to show that Ker $W_{X,0} \cap$ Ker $\dot{W}_{X,0} = \{\vec{0}\}$. This is established by contradiction.

Assume this intersection is nontrivial and spanned by the columns of a full-rank matrix L. Then $W_{X,0}L = 0$ together with (4.2) provides $L^T(\hat{B}_{21}\hat{B}_{21}^T - \hat{B}_{11}R_\gamma^{-1}\hat{B}_{11}^T)L = 0$, and $\dot{W}_{X,0}L = 0$ together with (4.5) provides $L^T \hat{B}_{11} R_\alpha^{-2} \hat{B}_{11}^T L = 0$. In turn, these two identities yield $\hat{B}_{11}^T L = \hat{B}_{21}^T L = 0$ and postmultiplying (4.2) and (4.5) by L then provides $\dot{W}_{X,0} A_W L = -\dot{W}_{X,0}\hat{A}_{11}^T L = 0$ and $W_{X,0}\hat{A}_{11}^T L = 0$, respectively. Consequently, Im $L =$ Ker $W_{X,0} \cap$ Ker $\dot{W}_{X,0}$ is $\hat{A}_{11}^T$-invariant. Now, $\binom{W_{X,0}}{I}$ spans $\mathcal{X}_-(\bar{H}_\gamma)$, and hence $\binom{W_{X,0}L}{L} = \binom{0}{L}$ is a subspace of $\mathcal{X}_-(\bar{H}_\gamma)$. Observing that

$$\bar{H}_\gamma \begin{pmatrix} 0 \\ L \end{pmatrix} = \begin{pmatrix} 0 \\ -\hat{A}_{11}^T L \end{pmatrix},$$

it follows that Im L is antistable $\hat{A}_{11}^T$-invariant. Together with $\hat{B}_{21}^T L = 0$, this contradicts the stabilizability of $(\hat{A}_{11}, \hat{B}_{21})$, which is inherited from that of $(\hat{A}, \hat{B}_2)$ or equivalently (A, B_2). □

Appendix C.

Proof of Theorem 5.6. The proof is by contradiction. Assume for instance that X_γ is unbounded at γ_{opt}, that is, $W_{X,0} = W_X(\gamma_{opt})$ is singular. Introduce a matrix L whose

columns form a basis of Ker $W_{X,0}$ and let $Z(.)$ be the function defined in Theorem 6.1. Since $Z(\gamma_{opt}^{-1}) \geq 0$, we have, for all matrix M of compatible dimensions,

$$0 \leq (L^T \quad M^T) Z(\gamma_{opt}^{-1}) \begin{pmatrix} L \\ M \end{pmatrix} = M^T W_{Y,0} M + \gamma_{opt}^{-1}(L^T U_1^T V_1 M + M^T V_1^T U_1 L).$$

This requires $V_1^T U_1 L = 0$, or equivalently Im $U_1 L \subset$ Im $V_2 = \mathcal{V}_0(\tilde{B}_1^T, \tilde{A}^T)$. Observing that $(\tilde{A}^T, \tilde{B}_1^T) = (A^T, B_1^T)$ in the SP context, it follows that Im $U_1 L$ is A^T-invariant and that $B_1^T U_1 L = 0$. Now, pre- and post-multiply (4.2) by L^T and L, respectively, and use the fact that $W_{X,0} L = 0$. This gives $L^T(\hat{B}_{21}\hat{B}_{21}^T - \gamma^{-2}\hat{B}_{11}\hat{B}_{11}^T)L = 0$, or equivalently (using (3.5)),

$$\text{(C.1)} \quad 0 = (U_1 L)^T(\hat{B}_2\hat{B}_2^T - \gamma^{-2}\hat{B}_1\hat{B}_1^T)(U_1 L) = (U_1 L)^T(B_2 B_2^T - \gamma^{-2} B_1 B_1^T)(U_1 L).$$

This together with $B_1^T U_1 L = 0$ imposes $B_2^T U_1 L = 0$. A contradiction to the stabilizability of (A, B_2) can then be derived by an argument similar to that in the proof of Lemma 5.1. □

ADAPTIVE BOUNDARY AND POINT CONTROL OF LINEAR STOCHASTIC DISTRIBUTED PARAMETER SYSTEMS*

T. E. DUNCAN†, B. MASLOWSKI‡, AND B. PASIK-DUNCAN†

Abstract. An adaptive control problem for the boundary or the point control of a linear stochastic distributed parameter system is formulated and solved in this paper. The distributed parameter system is modeled by an evolution equation with an infinitesimal generator for an analytic semigroup. Since there is boundary or point control, the linear transformation for the control in the state equation is also an unbounded operator. The unknown parameters in the model appear affinely in both the infinitesimal generator of the semigroup and the linear transformation of the control. Strong consistency is verified for a family of least squares estimates of the unknown parameters. An Itô formula is established for smooth functions of the solution of this linear stochastic distributed parameter system with boundary or point control. The certainty equivalence adaptive control is shown to be self-tuning by using the continuity of the solution of a stationary Riccati equation as a function of parameters in a uniform operator topology. For a quadratic cost functional of the state and the control, the certainty equivalence control is shown to be self-optimizing; that is, the family of average costs converges to the optimal ergodic cost. Some examples of stochastic parabolic problems with boundary control and a structurally damped plate with random loading and point control are described that satisfy the assumptions for the adaptive control problem solved in this paper.

1. Introduction.

An important family of controlled linear, distributed parameter control systems are those with boundary or point control. Perturbations or inaccuracies in the mathematical model can often be effectively modeled by white noise. Since in many control situations there are unknown parameters in these linear, stochastic distributed parameter systems, it is necessary to solve a stochastic adaptive control problem. We now give a brief summary of each of the sections in this paper. In §2 the unknown linear stochastic distributed parameter system is described by an evolution equation where the unknown parameters appear in the infinitesimal generator of an analytic semigroup and the unbounded linear transformation for the boundary control. The noise process is a cylindrical, white noise. Some properties of the optimal control for the infinite-time quadratic cost functional for the associated deterministic system are reviewed, especially the stationary Riccati equation. These results are given in [8], [11], [12], [18]. In §3 an Itô formula is obtained for smooth functions of the solution of a linear or semilinear stochastic distributed parameter system with an analytic semigroup. This result is verified using the Yosida approximation of the infinitesimal generator of the semigroup. While some other Itô formulas in infinite dimensions are available (e.g., [6], [15]), none seems to be appropriate for our applications. In §4 a family of least squares estimates are constructed from the observations of the unknown stochastic system. This family of estimates is shown to be strongly consistent under verifiable conditions. A stochastic differential equation is given for the family of estimates. This verification of the strong consistency of a family of least squares estimates is a generalization of the results in [9], [10]. In §5 the self-tuning and the self-optimizing properties of an adaptive control law are investigated. If an adaptive control is self-tuning, then it is shown that the system satisfies some stability properties and the adaptive control is self-optimizing. The certainty equivalence adaptive control, that is, using the optimal stationary control with the estimates of the

parameters, is shown to be self-optimizing; that is, the optimal ergodic cost is achieved. In §6 some examples are given that satisfy the various assumptions used in this paper.

2. A boundary control model. The unknown linear stochastic distributed parameter system with boundary or point control is formally described by the following stochastic differential equation:

$$\begin{aligned} dX(t;\alpha) &= (A(\alpha)X(t;\alpha) + B(\alpha)U(t))dt + \Phi\, dW(t), \\ X(0;\alpha) &= X_0, \end{aligned} \tag{2.1}$$

where $X(t;\alpha) \in H$; H is a real, separable, infinite-dimensional Hilbert space; $(W(t), t \geq 0)$ is a cylindrical Wiener process on H; $\Phi \in \mathcal{L}(H), \alpha = (\alpha^1, \ldots, \alpha^q)$; and $t \geq 0$.
