Most of this paper is devoted to examining the efficacy of various search strategies and establishing upper bounds on the rendezvous values for particular or specific search spaces.

2.1. Homogeneous search regions. In most of the problems to be analyzed in the paper, the group G will act transitively on the search region X. In such cases we will say that X is homogeneous. (Roughly speaking, the region looks the same viewed from any point.) In these cases the definitions given above can be simplified. First, we may take the distributions of the players as given by the one induced by the Haar measure ν on G. In the cases of the circle, torus, or sphere, this will give a uniform distribution (normalized Lebesgue measure). The pure strategy space can be identified with the space of equivalence classes of paths $\tilde{P}$. Thus the normal form is given simply by (2).

2.2. Relation to search games. The reader familiar with search games with mobile hiders may wonder why the spatial symmetries of the search region are not so important in that theory. In search games, it is usually assumed that the hider and searcher can pick their starting points, hence their entire paths. If there is a symmetry, say rotationally on the circle, either player can symmetrize his strategy. If one player symmetrizes, it is the same as if the game had been played with a symmetrical initial placement. Now in a zero-sum game, if there is a condition (such as symmetrical-uniform initial placement) which *either* player can force, then there is no loss in generality if it is assumed. Hence there is no need to make this condition part of the definition of the game.

3. Rendezvous on a network. There are some classes of search strategies which may be applied to a whole family of search regions. They may be used to obtain general bounds on the rendezvous value (or the search game value V) for the whole family. For example, if the search region is a network of unit length arcs, the following elementary estimates are easily established.

PROPOSITION 1. *Let (X, ρ) be a connected network consisting of m unit arcs which intersect only at endpoints. Let G be the group of all isometries of (X, ρ), the detection radius δ be zero, and D denote the metric diameter of X. Then*

1. $V(X,G) \leq 2mD \leq 2m^2$,
2. $R^s(X,G) \leq 4m$, *and*
3. $R^a(X,G) \leq m$.

Proof. To obtain the first estimate, consider the following search strategy. In time intervals of length D, starting at time zero, search as follows: Pick a random arc and choose a path which arrives at the center of this arc in time D and one of the endpoints of this arc (equiprobably) in time $D - 1/2$. Such a path will meet any continuously moving player with probability at least $1/2m$. Hence the independent repetition of such paths meets any continuously moving player in expected time no more than $2mD$.

For the second estimate double every arc so that the resulting network is Eulerian. Thus it takes no more time than $2m$ to complete a circuit of the original network. Consider the following mixed search strategy called *Eulerian or Wait* (EW): With probability p follow some Eulerian path on the doubled graph. With probability $(1-p)$ wait for a time period $2m$. If p is taken to be 1/2 (which is not optimal but gives the best simplified estimate for this proof), then in each time period of length $2m$, two players using this strategy will meet with probability at least 1/2, i.e., the probability that one waits and one searches. Hence the expected meeting time (neglecting meetings when both are searching) is no more than $4m$.

In the asymmetric case, the players can agree on who will search and who will wait. If some Eulerian circuit of the doubled network is traversed equiprobably in either direction by the player who searches, the players will meet before time $2m$ and on average before time m, giving the third of these elementary results. □

Since $D \geq 2$ (if $m > 3$ and there are no multiple arcs with equality for the network based on the complete graph), the estimate for the rendezvous value is less than that for the search value. The second estimate can be improved for the network based on the complete graph by optimizing for p [5], and the first can be extended to networks with arcs of varying lengths [3]. One obvious improvement to investigate is for the waiter to move to a nearby node and wait, and for the searcher to use a traveling salesman route on the nodes. All these estimates are very crude, but it seems likely that they are better than those achieved in general by random walks. Of course, if the network has no symmetries ($G = \{\text{identity}\}$) then the players can pick a point at which to rendezvous and the rendezvous times are much reduced as shown for the circle in the next section.

4. Rendezvous on the circle. To illustrate the symmetry notions of §2 and show how the general network estimates of §3 can be improved for specific cases, we now investigate rendezvous on a circle C. For convenience we take C to have circumference 2. We will consider three isometry groups on C: group G_1 consisting of just the identity, group G_2 consisting of all rotations, and group G_3 consisting of all isometries of C (rotations and reflections). We define the allowability of a search strategy (or strategy pair in the asymmetric case) to be the highest indexed group G_i with which it is consistent. In this section we obtain estimates on the rendezvous values $R^j(C,G_i)$, $j \in \{s,a\}, i \in \{1,2,3\}$ by analyzing some particular search strategies. But before we begin this analysis we have two observations. Since the search value of C is known to be 3/2 (using the COHATU strategy described below) [17], [1], this is an upper bound for all the rendezvous values. Also, by observing that C can be viewed as a network with $m = 2$, and the last two estimates of Proposition 1 can be reduced by a factor of 2 for Eulerian networks, we see that $R^s(C,G) \leq 4$ and $R^a(X,G) \leq 1$ for any isometry group G. We now consider four search strategies (the last two are strategy pairs for use in the asymmetric problem):

- GOTOZ: This strategy takes the shortest route from the initial point to a given rendezvous point Z. The allowability of GOTOZ is clearly G_1, since its implementation requires the exact knowledge of both the initial point and Z. As a strategy for symmetric rendezvous on (C, G_1) it has expected meeting time 2/3 for any (agreed) Z.

- COHATU: This strategy is short for *coin half tour*, and has been shown to be optimal for *both* the hider and the seeker in the circle search game. It moves from the initial point to the antipodal point (distance 1) at unit speed, equiprobably via either route, and then continues to oscillate between these points equiprobably via one of the routes. Its allowability is G_3 and results in expected meeting time of 3/2 if either player adopts it.
- OPDIR: This is the strategy pair in which one player goes clockwise at unit speed and the other goes counterclockwise at unit speed. Its allowability is G_2, since it doesn't require knowledge of the initial position but does require knowledge of up, which is not preserved under reflections. The expected meeting time is 1/2.
- GOSTAY: This strategy pair has one player wait while the other player chooses a random direction to go around the circle at unit speed. Its allowability is G_3 and it has an expected meeting time of 1.

The examples given here provide upper bounds (which may be exact) on the various rendezvous values for the circle, which are summarized in Table 1.

TABLE 1
Rendezvous bounds for the circle.

	G_1	G_2	G_3
R^s	$\frac{2}{3}$ (GOTOZ)	$\frac{3}{2}$ (COHATU)	$\frac{3}{2}$ (COHATU)
R^a	$\frac{1}{2}$ (OPDIR)	$\frac{1}{2}$ (OPDIR)	1 (GOSTAY)

5. Rendezvous on a cycle graph.

The problem of rendezvous may also be formulated on a graph. Suppose at time $t = 0$ the two players are placed independently and equiprobably on the nodes of a given graph. At each integer time t they may move to an adjacent node until the first time T that they occupy the same node. (If they transpose their positions on adjacent nodes they remain unaware of the other's position.) The problem for a complete graph has been analyzed in [5].

In this section we recast a search problem of Ruckle [14], [15] in a rendezvous context. Ruckle considered the problem faced by two players placed randomly on the nodes of the cycle graph C_m with m nodes labelled $i = 0, 1, \ldots, m-1$, where node i is adjacent to node j if $|i-j| = 1 \pmod m$. He restricted the players to symmetric Markovian strategies. That is, each player picks some number p in (0,1/2) and moves counterclockwise with probability p, clockwise with probability p, and remains still with probability $1-2p$. Ruckle considered the zero-sum game with payoff as expected meeting time $T(p,q)$, where the maximizing hider picks *move probability* p and the minimizing searcher picks *move probability* q. We use the same game dynamics but consider the simpler rendezvous problem of minimizing the expected meeting time $f_m(p) = T(p,p)$, when both players move with probability p. Our analysis of the dynamics is a simpler version of [14].

We consider a reduced state game where the difference between the two nodes (mod m) is the state. At each stage the state moves according to the independent randomizations of the players, except that the state 0 is an absorbing state. The m-state Markov chain which describes the dynamics is given for $m > 4$ by the matrix $A = \{a_{ij}\}$, where

$$a_{ij} = \begin{cases} 1 & \text{if } i = j = 0, \\ 0 & \text{if } i = 0, j \neq 0, \\ p^2 & \text{if } j = i \pm 2 \pmod m, \\ 2p(1-2p) & \text{if } j = i \pm 1 \pmod m, \\ (1-2p)^2 + 2p^2 & \text{if } i = j \neq 0, \\ 0 & \text{otherwise.} \end{cases} \tag{6}$$

If $m = 4$ there is a small modification such that

$$a_{ij} = 2p^2 \quad \text{when } j = i \pm 2 \, (\operatorname{mod} 4). \tag{7}$$

The expected meeting time is the same as the expected number of periods that the state is in $\{1, 2, \ldots, m-1\}$. Let B denote the $(m-1) \times (m-1)$ submatrix of A corresponding to these states. Then it is easy to see that the expected meeting time is given by

$$f_m(p) = \left(\frac{1}{m}\right) \sum_{k=0}^{\infty} e' B^k e = \left(\frac{1}{m}\right) e'(I-B)^{-1} e, \tag{8}$$

where e and e' are the column and row vectors consisting of $m-1$ ones. The full justification of a more complicated version of this formula is given in [14], [15], where it is also shown that f_m is convex. Now it is easy to see that the minimum of f_m cannot be at either endpoint 0 or 1. At 0 the players don't move, so they don't meet unless they start together. At $p = 1/2$, the distance between the players changes by ± 2 in each period. So if they started an odd distance apart they can never meet. So we now determine the optimal *rendezvous speed* $\hat{p}_m$ and the corresponding rendezvous value (a restricted version) $R_m = f_m(\hat{p}_m)$ for $m > 3$. For $m = 4, 5$ we can calculate an exact value, but for $m \geq 6$ we present only numerical approximations.

5.1. Rendezvous on C_4 or C_5. When m is 4 we evaluate (8) using (6) with (7) to obtain the expected meeting time function

$$f_4(p) = \frac{5 - 9p}{4(2p - 6p^2 + 4p^3)}. \tag{9}$$

This function has a local minimum (which is global between 0 and 1/2) at

$$\hat{p}_4 = \frac{1}{3}, \qquad \hat{R}_4 = f_4(\hat{p}_4) = \frac{27}{8} \doteq 3.375. \tag{10}$$

Similarly, the expected meeting time formula for $m = 5$ is

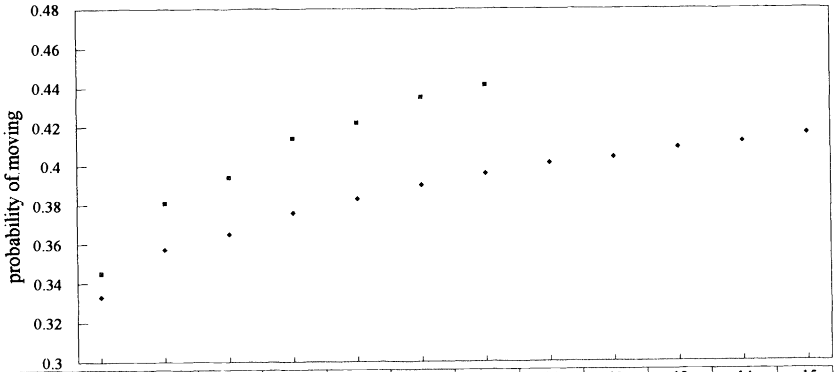
$$f_5(p) = \frac{4 - 6p}{4p - 10p^2 + 5p^3}, \tag{11}$$

which has a minimum at

$$\hat{p}_5 = \frac{2}{3}\left(1 - \frac{1}{\sqrt[3]{10}}\right), \qquad \hat{R}_5 = f_5(\hat{p}_5) \doteq 4.88. \tag{12}$$

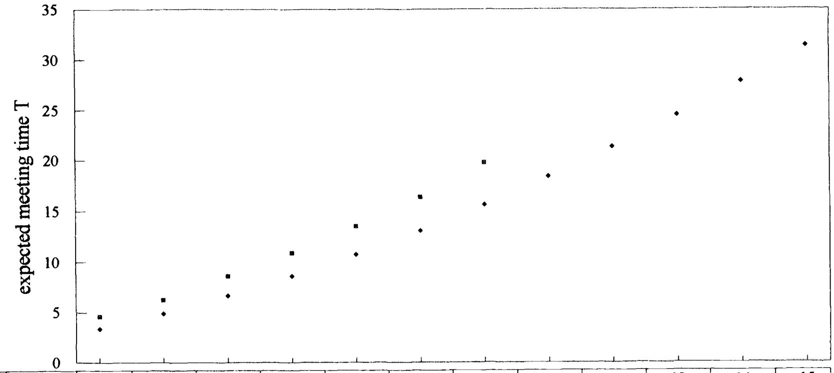
It seems likely that with some additional work a pattern for the rational functions f_m could be found, but we find it easier to proceed numerically for larger values of m.

5.2. Rendezvous vs. search game on C_m. Since Ruckle [14], [15] has given such a complete analysis of the search game on C_m, it is easy to compare our numerical results with his (which he gives for $m \leq 10$). In Fig. 1 we state and plot the optimal probabilities of moving $p = \hat{p}_m$ and $q = \hat{q}_m$ for our rendezvouser and Ruckle's searcher. Note that in each case the move probabilities are increasing in m (presumably to a limiting value of 1/2) and the probabilities for even m are slightly lower than the interpolated curve generated by odd values. There is a blip in the data at $m = 4$, which is not surprising given that the Markov chain has a different formula. The main observation is that it is necessary to move faster to catch an evader than to meet a rendezvouser, i.e., $q > p$. In Fig. 2 we present our numerical results for the



m=#(nodes)	4	5	6	7	8	9	10	11	12	13	14	15
▪ Search: q	0.345	0.381	0.394	0.414	0.422	0.435	0.441					
◆ Rendezvous: p	0.333	0.357	0.365	0.376	0.383	0.39	0.396	0.401	0.404	0.409	0.412	0.416

FIG. 1. *Optimal probability of moving.*



m = #(nodes)	4	5	6	7	8	9	10	11	12	13	14	15
▪ Search Val V	4.61	6.23	8.58	10.88	13.54	16.41	19.77					
◆ Rendezvous R	3.37	4.88	6.64	8.58	10.74	13.09	15.65	18.4	21.34	24.48	27.81	31.33

FIG. 2. *Rendezvous vs. search values.*

rendezvous value $R = R_m$ along with Ruckle's search values V_m for $m \leq 10$. Surprisingly, making the evader cooperate does not significantly reduce the expected meeting time, that is, R_m is not very much less than V_m.

The main reason for going through the analysis of this section is that it gives us, admittedly in a very restricted context, a direct comparison of the search game and rendezvous values, and of the respective optimal search strategies.

6. Rendezvous search on the line. Up to this point in the paper the search region X has been compact. We now consider the natural starting point for an investigation of noncompact regions, the real line. There has been much work by Beck and others [7], [8] on variations of the *linear search problem*, where a searcher starting at 0 and moving at unit speed attempts to find a stationary hider whose distribution is known. The problem posed in this section may therefore be called the *linear rendezvous search problem.*

The story behind this problem is as follows: Two friends have agreed to meet at noon on a certain street but have neglected to specify a specific point on the street. Assuming they know the distribution of their arrival points on the street (at noon), how should they move to meet in minimum expected time?

To formalize the problem, we first observe that everything is translation invariant, so we need to assume only a known cumulative distribution function F for the distance between them at time zero. Both players know F but neither knows the direction of the other player. So we assume that their mixed strategies are invariant with respect to reflection about their starting point. Let the rendezvous value $R^s(F)$ be the minimum expected meeting time achievable by players using the same reflection-invariant strategies. Both bounded and unbounded distributions will be of interest, but since we have nothing to say here about the latter, we will assume there is maximum initial distance $D = D_F = \min\{x : F(x) = 1\}$ and hence a finite mean initial distance $\mu = \mu_F$. Also, we may assume without loss of generality that the two players will not be placed at the same point or $F(0) = 0$.

One method the players may employ to keep a bound on their distance is to return periodically to their respective starting points. However, a less obvious and perhaps more effective way of achieving the same result is the following strategy, which I call 1F2B(x) for *one step forwards, two steps backwards*: pick either direction to call forward equiprobably; go a distance x forward at unit speed; then go a distance $2x$ backwards at unit speed; repeat the entire process indefinitely with independent randomization. A player following strategy 1F2B is globally following a random walk of step length x in time unit $3x$, so his position is certainly unbounded in time. However, the *relative* positions of *two* players following this strategy (until they meet) are maintained as described in the following proposition.

PROPOSITION 2. *Suppose two players are using strategy* $1F2B(x)$, *where* $x \geq D/2$, *and they have not met by time* $3x$. *Then the conditional distribution of their distance at time* $3x$ *is the same as their initial distance distribution* F. *In fact, their distance at time* $3x$ *is the same as their initial distance.*

Proof. It suffices to prove the last sentence. This is easily established by considering two cases: the players move in the same direction, or they move in opposite directions. In the latter case we either have $T \leq x$ (if they move toward each other) or $2x \leq T \leq 3x$ (if they move away from each other first). In the former case, the distance between them is preserved for all times $t \in [0, 3x]$, and they will not meet by time $3x$ (since we are assuming that $F(0) = 0$). Hence if the game has not ended by time $3x$ (that is, if $T > 3x$) then they must have gone in the same direction, and, therefore, their distance at time $3x$ equals their initial distance. □

PROPOSITION 3. *For any bounded distribution* F, $R^s(F) \leq 2D_F + \mu_F/2$.

Proof. We show that the bound is the expected meeting time $\hat{T}$ for two players using 1F2B$(D/2)$, where $D = D_F$ and $\mu = \mu_F$. First observe that $\hat{T}$ is certainly finite because the probability of meeting by time $3nD/2$ is at least 2^{-n}. To calculate $\hat{T}$ we consider separately the three cases where the players move in the same direction (probability 1/2), towards each other (probability 1/4), or away from each other (probability 1/4). In the first case the expected meeting time is $\hat{T} + 3D/2$ by the previous proposition. In the second case the cumulative distribution of meeting times is given by $G(t) = F(2t)$, so the expected meeting time is $\mu/2$. Finally, the third case reduces to the second case after time D, so the expected meeting time is $D + \mu/2$. Combining these observations, we obtain the equation

$$\hat{T} = \frac{1}{2}\left(\hat{T} + \frac{3D}{2}\right) + \frac{1}{4}\left(\frac{\mu}{2}\right) + \frac{1}{4}\left(D + \frac{\mu}{2}\right), \tag{13}$$

which has, as claimed, the unique solution

$$\hat{T} = 2D + \mu/2. \qquad \square \tag{14}$$

A particularly simple version of the rendezvous linear search problem is one in which the two players know the initial distance (say 1) between them, but neither knows the direction of the other. In this case $D = \mu = 1$, so the above estimate gives $R^s \leq 5/2$. We conjecture that the rendezvous value is in fact 5/2 for this problem and that 1F2B (1/2) is optimal. It is also likely to be optimal for the uniform distribution over [0,1], in which case that rendezvous value would be 9/4. If the initial distribution F is very sparse near D or unbounded, then of course 1F2B is not effective. However, it can still be used with finitely many repetitions with the step length successively increased as the conditional distribution changes.

The work done in this section is of course very preliminary. However, we are sure the linear rendezvous search problem defined here will prove to be a very productive sidekick to its cousin, the linear search problem.

7. Questions for further work. While we feel that the formalization of the rendezvous search problem given here is important, we are aware of the very preliminary and exploratory nature of the results. Even in cases (such as COHATU on the circle or 1F2B on the line) where we think our suggested search strategies are effective, we have not shown them to be optimal. In other cases (such as search on a network) even the suggested strategies are not very good and serve only to give preliminary upper bounds on the generic rendezvous value. However, we hope these first attacks on the problem of rendezvous search will stimulate further work in this area.

We conclude the paper with a number of questions on rendezvous search that would extend the scope of the theory.

- Many players: For simplicity, we have limited the discussion in this paper to the case of two players wishing to rendezvous. In general, when two players meet (out of $n > 2$) they may exchange information about where they have been (which is their only private information). There are two cases to consider: they may be restricted to stay together once they have met, or they may be allowed to agree on a joint strategy which may allow separate motion. The former is probably easier to analyze.
- Local vision: The formulation given in this paper assumes the players can see the whole search region. An alternative is to assume they know the search region but can perceive it only locally (within a given distance). For example, our formulation, for the unit interval $X = [0, 1]$, allows the strategy of *go to* 1/2 even if the isometry of reflecting about 1/2 is given. With a local vision restriction the players would only know where 1/2 was when they were close to 0 or 1, when they would know the whole interval (possibly up to reflection).
- Rendezvous in a maze: We may further limit the players' information by giving them local vision and not telling them the nature of the search region X. Perhaps they are only told, for example, that they will land in a network of total length 1. This is a two-sided version of maze search problems.
- Adversary-rendezvous games: Suppose the two searchers' initial position in X is chosen by another player who wishes to maximize their meeting time. This other may even choose X, possibly in a maze or local vision scenario. This becomes a two-person zero-sum game where the rendezvousers are a single player.
- Lower bounds on R: Upper bounds on the rendezvous value may be obtained by guessing good search strategies. How can lower bounds be obtained? (Of course half the expected initial distance is a lower bound, but hardly a good one.)
- Extremal theory: For regions which can be searched in, say, unit time, which have the smallest and largest rendezvous values?
- A calculus of rendezvous: Suppose $2X$ denotes the search region consisting of two copies of X, each with the same symmetries as the original. Suppose a player may move between (perhaps corresponding) points in the two copies in a given time L, but that two players so moving will not meet. Furthermore, suppose the original distribution is split equiprobably between the two copies. This defines a search game on the region $2X$. Similarly, $X + Y$ could be defined with allowed transport between any pair of points in the two regions. This seems to

be a good model of a couple trying to meet who have been invited to two large parties, where the only transport between them is via taxi. The transport time L is probably significant. We can either assume the taxi is free or add an additional cost other than time.

H_∞ BOUNDARY CONTROL WITH STATE FEEDBACK: THE HYPERBOLIC CASE*

VIOREL BARBU†

Abstract. Necessary and sufficient conditions of existence for the H_∞ control problem associated with infinite dimensional boundary control systems of hyperbolic type are given.

Key words. boundary control systems, feedback controller, differential game, exponentially stable semigroup

AMS subject classifications. 93B50, 93C35, 49A40

1. Introduction and problem function. Let X, U, W, Z be real Hilbert spaces and A be the infinitesimal generator of C_0-semigroup e^{At} on X, $B_1 \in L(W,Z)$, $B_2 \in L(U,(D(A^*))')$, $C_1 \in L(X,Z)$, $D_{12} \in L(U,Z)$. Here A^* is the adjoint of A, $D(A^*)$ is the domain of A^* endowed with the graph norm, and $(D(A^*))'$ is the dual space to $D(A^*)$. Consider the input-output system defined by

$$x'(t) = Ax(t) + B_1w(t) + B_2u(t), \qquad t \in R^+ = [0,\infty[, \tag{1.1}$$

$$z(t) = C_1x(t) + D_{12}u(t), \qquad t \in R^+. \tag{1.2}$$

Here $x(t) \in X$ is the state of the system, $u(t) \in U$ is the control input, $w(t) \in W$ is an exogeneous input, and $z(t) \in Z$ is the controlled output.

We shall assume

(i) $A^{-1}B_2 \in L(U,X)$, and for every $T > 0$ the operator $B_2^*e^{A^*t}$ admits a continuous extension from X to $L^2(0,T;U)$, i.e.,

$$\int_0^T |B_2^*e^{A^*t}x|_U^2 \le C_T|x|^2 \quad \forall x \in X. \tag{1.3}$$

We denoted the adjoint of $B_2 \in L(U,(D(A^*))')$ by $B_2^* \in L(D(A^*),U)$. We shall denote the norms of X, Z, U, W by $|\cdot|_X$, $|\cdot|_Z$, $|\cdot|_U$, $|\cdot|_W$ and the corresponding scalar products by $(\cdot,\cdot)$, $(\cdot,\cdot)_Z$, $(\cdot,\cdot)_U$, $(\cdot,\cdot)_W$. By assumption (i) it follows that for every $T > 0$, system (1.1) with initial condition $x(0) = x_0 \in X$, and inputs $u \in L^2(0,T;U)$, $w \in L^2(0,T;W)$ has a mild solution $x \in C([0,T];X)$ given by

$$x(t) = e^{At}x_0 + \int_0^t e^{A(t-s)}(B_1w(s) + B_2u(s))ds \quad \forall t \in [0,T]. \tag{1.4}$$

More precisely, for every $T > 0$ the operator $u \to \int_0^t e^{A(t-s)}B_2u(s)ds$ is continuous from $L^2(0,T;U)$ to $C([0,T];X)$ (see, e.g., [5]).

This is the abstract formulation of a large class of boundary control systems with distributed disturbance input including the one governed by the wave equation with Dirichlet and Neumann boundary control, first-order hyperbolic systems, and Euler–Bernoulli equations (see [5], [8]). For instance, the input-output system

$$\begin{aligned} y_{tt} - \Delta y = w \quad &\text{in}\,\Omega \times R^+, \\ y = u \quad &\text{in}\,\partial\Omega \times R^+, \end{aligned} \tag{1.5}$$

where $u \in L^2(R^+; L^2(\partial\Omega))$, $w \in L^2(R^+; L^2(\Omega))$ can be written in the form (1.1) when $X = L^2(\Omega) \times H^{-1}(\Omega)$, $U = L^2(\partial\Omega)$, $W = L^2(\Omega)$, and

$$A = \left\| \begin{matrix} 0 & I \\ \Delta & 0 \end{matrix} \right\|, \quad B_1 w = \left\| \begin{matrix} 0 \\ w \end{matrix} \right\|, \quad B_2 u = \left\| \begin{matrix} 0 \\ -\Delta D u \end{matrix} \right\|.$$

Here Δ is the Laplace operator with the domain $H_0^1(\Omega) \cap H^2(\Omega)$ (Ω is an open-bounded subset of R^n with a smooth boundary $\partial\Omega$) and $D \in L(L^2(\partial\Omega),\ L^2(\Omega))$ is the Dirichlet map, i.e., $\Delta D u = D$ in Ω, $Du = u$ in $\partial\Omega$ (see, e.g., [5]).

We shall denote by $\mathcal{F}$ the class of feedback controllers $F \in L(D(A), U)$ having the property that $A_F = A + B_2 F$ generates an exponentially stable C_0-semigroup $e^{A_F t}$ on X and $D(A_F) \subset D(F)$; $Fe^{A_F t} \in L(X, L^2(R^+; U))$. We note that the operator $A + B_2 F$ is continuous from $D(A)$ to $(D(A^*))'$, so A_F, which is its restriction to H, is well defined. Since $B_1 \in L(W, Z)$, we see that for $F \in \mathcal{F}$ the closed loop operator $S_F : L^2(R^+; W) \to L^2(R^+; Z)$, $(S_F w)(t) = (C_1 + D_{12} F) \int_0^t e^{A_F(t-s)} B_1 w(s) ds$; $t \geq 0$, is well defined.

As a matter of fact $x = Sw$ is the mild solution of (1.1) with feedback control $u = Fx$ and initial value condition $x(0) = 0$ (see [7] for a definition of mild solutions of an infinite dimensional Cauchy problem).

Let $\gamma > 0$. Following the standard H_∞ control theory (see [2]) we say that the feedback controller $F : X \to U$ is an H_∞ controller for system (1.1), (1.2) if $F \in \mathcal{F}$ and $\|S_F\| < \gamma$. Here $\|S_F\|$ is the norm of the operator $S_F \in L(L^2(R^+; W), L^2(R^+; Z))$.

In addition to assumption (i), we shall assume that

(ii) The pair (A, C_1) is exponentially detectable, i.e., there exists $K \in L(Z, X)$ such that $A + KC_1$ generates an exponentially stable semigroup;

(iii) $D_{12}^* |C_1, D_{12}| = |0, I|$.

Assumption (iii) simply says that

$$|C_1 x + D_{12} u|_Z^2 = |C_1 x|_Z^2 + |u|_U^2 \quad \forall (x, u) \in X \times U. \tag{1.6}$$

Theorem 1 below represents the main result of this paper.

THEOREM 1. *Let $\gamma > 0$ and suppose that assumptions* (i), (ii), *and* (iii) *hold. Then there exists an H_∞ controller $F \in \mathcal{F}$ such that $\|S_F\| < \gamma$ if and only if there exists $P \in L(X, X)$, $P = P^* \geq 0$ such that $A_P = A - B_2 B_2^* + \gamma^{-2} B_1 B_1^* P$ is the infinitesimal generator of an exponentially stable C_0-semigroup and*

$$B_2^* P \in L(D(A), U) \cap L(D(A_P), U), \qquad A^* P \in L(D(A_P), U), \tag{1.7}$$

$$(Ax, Py) + (Px, Ay) - (P(B_2 B_2^* - \gamma^{-2} B_1 B_1^*) Px, y) + (C_1 x, C_1 y) = 0 \tag{1.8}$$

for all $x, y \in D(A)$ or else for all $x, y \in D(A_P)$. Moreover, in this case the state feedback $F = -B_2^* P$ is an H_∞ control, $\|S_F\| < \gamma$, and the solution P of Riccati equation (1.8) *is unique in the class of $P \in L(X, X^*)$, $P = P^* \geq 0$, having the property that A_P is exponentially stable.*

We note that by (1.7) the operator $x \to Ax - B_2 B_2^* Px + \gamma^{-2} B_1 B_1^* P$ is continuous from $D(A)$ to $(D(A^*))'$. A_P is the restriction of this operator to H.

Theorem 1 resembles the standard finite dimensional results [2]. The case $B_2 \in L(U, X)$, i.e., the case of distributed input controllers, was previously studied in [9].

A standard approach to the suboptimal H_∞ controllers is to associate with system (1.1), (1.2) the differential game

$$\sup_{w \in L^2(R^+; W)} \inf_{u \in L^2(R^+; U)} \int_0^\infty (|z(t)|_Z^2 - \gamma^2 |w(t)|_W^2) dt \tag{1.9}$$

and write the closed loop strategies in terms of an algebraic Riccati equation [2], [9]. However, the extension of [9] to the present situation is not trivial and relies on some recent results [3] on synthesis of quadratic optimal control problems with infinite horizon. Related results were recently obtained for the differential game (1.9) by McMillan and Triggiani [6] under the additional hypothesis that either e^{At} is exponentially stable or the system $x' = A^*x + (C_1^*C_1)^*v$ is exactly controllable in finite time.

2. The sup–inf problem. Here we shall study the differential game (1.9) under assumptions (i), (ii), (iii), and

(j) the pair (A, B_2) is exponentially stabilizable, i.e., $\exists F \in L(D(A), U)$ such that $A + B_2F$ generates an exponentially stable semigroup $e^{(A+B_2F)t}$ and the following inequality holds:

$$\sup_{w\in L^2(R^+;W)} \inf\left\{\int_0^\infty (|C_1x|_Z^2 + |u|_U^2)dt;\ x' = Ax + B_2u + B_1w;\right.$$
$$\left. x(0) = 0,\ u \in L^2(R^+;U)\right\}\left(\int_0^\infty |w|_W^2\,dt\right)^{-1} < \gamma^2.$$

In particular, assumption (j) holds if there is an H_∞ control $F \in \mathcal{F}$ for system (1.1).

LEMMA 1. *If assumption* (j) *holds then*

(2.1)
$$\inf\left\{\int_0^\infty (|C_1y|_Z^2 + |u|_U^2)dt; y = Ay + B_2u + B_1w; y(0) = x_0,\ u \in L^2(R^+;U)\right\}$$
$$< (\gamma^2 - \varepsilon)\int_0^\infty |w|_W^2\,dt + C|x_0|^2 \quad \forall x_0 \in X \quad \forall w \in L^2(R^+;W)$$

for some $\varepsilon > 0$ *and* $C \in R$ *independent of* w.

Proof. If condition (j) holds, then $\exists\,\varepsilon > 0$ such that

$$\inf\left\{\int_0^\infty (|C_1x|_Z^2 + |u|_U^2)dt;\ x' = Ax + B_2u + B_1w, x(0) = 0,\ u \in L^2(R^+;U)\right\}$$
$$< (\gamma^2 - \varepsilon)\int_0^\infty |w|_W^2\,dt \quad \forall w \in L^2(R^+;W).$$

Under assumptions (i), (ii), (j), $\exists P_0 \in L(X,X)$, $P_0 = P_0^* \geq 0$ such that $A_{P_0} = A - B_2B_2^*P_0$ is exponentially stable and $B_2^*P_0e^{A_{P_0}t}x_0 \in L^2(R^+;U)$, $\forall x_0 \in X$ (see [3]). This implies that

$$\inf\left\{\int_0^\infty (|C_1x|_Z^2 + |u + B_2^*P_0e^{A_{P_0}t}x_0|_U^2)dt;\right.$$
$$\left. u \in L^2(R^+;U),\ x' = Ax + B_2u + B_1w,\ x(0) = 0\right\}$$
$$< (\gamma^2 - 2^{-1}\varepsilon)\int_0^\infty |w|_W^2\,dt + C|x_0|^2 \quad \forall w \in L^2(R^+;W),\ x_0 \in X.$$

Hence

$$\inf\left\{\int_0^\infty (|C_1x|_Z^2 + |u|_U^2)dt;\ x' = Ax + B_2(u - B_2^*P_0e^{A_{P_0}t}x_0) + B_1w;\right.$$
$$\left. x(0) = 0,\ u \in L^2(R^+;U)\right\} < (\gamma^2 - 2^{-1}\varepsilon)\int_0^\infty |w|_W^2\,dt + C|x_0|^2.$$

Since the solution y of (1.1) with the initial value condition $y(0) = x_0$ can be represented as $y(t) = x(t) + e^{A_{P_0}t}x_0$, where $x' = Ax + B_2(u - B_2^* P_0 e^{A_{P_0}t}x_0) + B_1 w$, $x(0) = 0$, the latter inequality implies (2.1) as desired.

Let $K_{x_0} : L^2(R^+; U) \times L^2(R^+; W) \to [-\infty, +\infty]$ be defined by

$$K_{x_0}(u,w) = \int_0^\infty (|C_1 x + D_{12}u|_Z^2 - \gamma^2 |w|_W^2)dt = \int_0^\infty (|C_1 x|_Z^2 + |u|_U^2 - \gamma^2|w|_W^2)dt,$$

where x is the mild solution of (1.1) with $x(0) = x_0$.

In terms of K_{x_0} we may equivalently write (1.9) as

$$\sup_{w \in \mathcal{W}} \inf_{u \in \mathcal{U}} K_{x_0}(u,w), \tag{2.2}$$

where $\mathcal{U} = L^2(R^+; U)$ and $\mathcal{W} = L^2(R^+; W)$. In this section we shall prove the following result.

PROPOSITION 1. *Problem* (2.2) *has a unique solution* (u^*, w^*) *characterized by*

$$u^*(t) = B_2^* p^*(t) \quad a.e.\, t > 0, \tag{2.3}$$

$$w^*(t) = -\gamma^{-2} B_1^* p^*(t) \quad a.e.\, t > 0, \tag{2.4}$$

where $p^* \in C(R^+; X)$ *is the solution of*

$$\begin{gathered}(p^*)' = -A^* p^* + C_1^* C_1 x^* \quad in\, R^+, \\ p^*(\infty) = 0,\end{gathered} \tag{2.5}$$

and x^* *is the solution of* (1.1) *with* $x^*(0) = x_0$, $u = u^*$, *and* $w = w^*$.

Equation (2.5) should be understood, of course, in the following mild sense:

$$p(t) = e^{A^*(T-t)}p(T) - \int_t^T e^{A^*(s-t)} C_1^* C_1 x^*(s) ds \tag{2.6}$$

for all $0 \le t \le T < \infty$.

We shall first study the minimization problem

$$\inf\{K_{x_0}(u,v);\ u \in \mathcal{U}\}, \tag{2.7}$$

where $w \in \mathcal{W}$ is arbitrary but fixed.

This is a linear quadratic optimal control problem on $R^+ = [0, \infty[$.

LEMMA 2. *For each* $w \in \mathcal{W}$, *problem* (2.7) *has a unique solution* $\bar{u} = \Gamma_{x_0} w$.

Proof. By assumption (j) the function $u \to K_{x_0}(u,w)$ is not identically $+\infty$ for each $w \in \mathcal{W}$.

Moreover, it is strictly convex and continuous, and

$$K_{x_0}(u,w) \ge \|u\|_U^2 + C \quad \forall\, u \in \mathcal{U}. \tag{2.8}$$

This implies that (2.7) has a unique solution $\bar{u}$ by the standard existence result.

LEMMA 3. *The function* $\bar{u}$ *is the solution of* (2.7) *if and only if there exists* $p \in C(R^+; X)$ *such that*

$$p' = -A^* p + C_1^* C_1 \bar{x} \quad in\, R^+;\ p(\infty) = 0, \tag{2.9}$$

$$B_2^* p(t) = \bar{u}(t) \quad a.e.\, t > 0. \tag{2.10}$$

Here $\bar{x}$ *is the solution of* (1.1) *with* $u = \bar{u} = \Gamma_{x_0}\bar{w}$.

Proof of Lemma 2. Let $\bar{u}$ be the solution of (2.7). Consider the family of approximating control problems

$$\varphi_n(x_0) = \inf\left\{\frac{1}{2}\int_0^\infty (|C_1x|_Z^2 + |u|_U^2)dt; x' = Ax + B_2u + B_1w;\ x(0) = x_0\right\}, \tag{2.11}$$

and denote the corresponding solution by (x_n, u_n). We have

$$\varphi_n(x_0) \leq \inf\left\{\frac{1}{2}\int_0^\infty (|C_1x|_Z^2 + |u|_U^2)dt;\ x' = Ax + B_2u + B_1w;\ x(0) = x_0\right\},$$

and since the function $(x, u) \to \int_0^\infty (|C_1x|_Z^2 + |u|_U^2)dt$ is weakly lower semicontinuous we get

$$\begin{aligned} u_n &\to \bar{u} \quad \text{strongly in } L^2(R^+; U), \\ x_n(t) &\to \bar{x} \quad \text{uniformly on compacta}, \\ C_1x_n &\to C_1\bar{x} \quad \text{strongly in } L^2(R^+; Z). \end{aligned}$$

On the other hand if we write the state system (1.1) as

$$x' = (A + KC_1)x - KC_1x + B_2u + B_1w, \tag{2.12}$$

where $K \in L(Z, X)$ is as in assumption (ii), we have

$$x_n(t) - \bar{x}(t) = \int_0^t e^{A_K(t-s)}((B_2(u_n(s) - \bar{u}(s)) - K(C_1x_n(s) - C_1\bar{x}(s))ds.$$

Next, by Lemma 5.2 in [3] we have

$$\int_0^\infty |B_2^* e^{A_K^* t}x_0|_U^2\, dt \leq C|x_0|^2 \quad \forall\, x_0 \in X.$$

This yields

$$x_n(t) \to \bar{x}(t) \quad \text{uniformly on } R^+.$$

Moreover, since $\bar{u} \in L^2(R^+; U)$ and $w \in L^2(R^+; W)$, by the same argument it follows that $\bar{x} \in L^2(R^+; X)$ and

$$\lim_{t\to\infty} \bar{x}(t) = 0 \quad \text{strongly in } X.$$

Moreover, according to a standard result in the theory of linear quadratic control problems $\exists p_n \in C([0, n]; X)$ such that

$$\begin{aligned} p_n' &= -A^*p_n + C_1^*C_1x_n \quad \text{in } [0, n], \\ p_n(n) &= 0, \end{aligned} \tag{2.13}$$

$$u_n(t) = B_2^*p_n(t) \quad \text{a.e. in } (0, n). \tag{2.14}$$

Equation (2.13) should be viewed in the mild sense, i.e.,

$$\text{(2.15)}\quad p_n(t) = e^{A^*(T-t)}p_n(T) - \int_t^T e^{A^*(\tau-t)}C_1^*C_1x_n(\tau)d\tau, \qquad 0 \le t \le T \le n.$$

We set

(2.16)

$$\varphi_n(t, x_0) = \inf\left\{\frac{1}{2}\int_t^n (|C_1x|_Z^2 + |u|_U^2)ds;\ x' = Ax + B_2u + B_1w \,\text{in}\, (t,n);\ x(t) = x_0\right\}.$$

The function $\varphi_n(t,\cdot)$ is convex (in fact it is quadratic) and differentiable. Moreover, we have

$$\text{(2.17)}\qquad p_n(t) = -\nabla\varphi_n(t, x_n(t)) \quad \forall\, t \in [0,n].$$

where ∇ stands for Fréchet differential. Indeed since (x_n, u_n) is optimal in (2.11), where $x_0 = x_n(t)$, we have

$$\begin{aligned}
&\varphi_n(t, x_n(t)) - \varphi_n(t, y_0)\\
&\quad = \frac{1}{2}\int_t^n (|C_1x_n|_Z^2 - |C_1y|_Z^2)d\tau + \frac{1}{2}\int_t^n (|u_n|_U^2 - |u|_U^2)d\tau\\
&\quad \le \int_t^n ((C_1x_n, C_1(x_n - y)) + (u_n, u_n - u)_U)d\tau,
\end{aligned}$$

where $y' = Ay + B_2u + B_1w;\ y(t) = y_0$.

Then, by (2.13), (2.14), and Lemma 7 in the appendix, we see that

$$\text{(2.18)}\qquad \varphi_n(t, x_n(t)) - \varphi_n(t, y_0) \le -(p_n(t), x_n(t) - y_0) \quad \forall\, y_0 \in X$$

as claimed.

If in (2.18) we take $y_0 = x_n(t) - \rho\theta$, where $|\theta| = 1$, we get

$$\text{(2.19)}\qquad |p_n(t)| \le |x_n(t)||p_n(t)| + \varphi_n(t, \rho\theta)$$

for all $t \in [0,n]$, $|\theta| = 1$, and $\rho < 0$. On the other hand, we have

$$\begin{aligned}
\varphi_n(t, \rho\theta) &\le \inf\left\{\frac{1}{2}\int_t^\infty (|C_1x|_Z^2 + |u|_U^2)ds;, x' = Ax + B_2u + B_1w;\ x(t) = \rho\theta\right\}\\
&\le \frac{1}{2}\int_t^\infty (|C_1\tilde{x}|_Z^2 + |B_2^*P_0\tilde{x}|_U^2)dt,
\end{aligned}$$

where $\tilde{x}' = (A - B_2B_2^*P_0)\tilde{x} + B_1w,\ \tilde{x}(t) = \rho\theta$, and $P_0 \in L(X, X)$ is such that $A_{P_0} = A - B_2B_2^*P_0$ generates an exponentially stable semigroup with $B_2^*P_0e^{A_{P_0}t}x_0 \in L^2(R^+; U)$, $\forall\, x_0 \in X$ (see [3]). Here $\tilde{x}$ is given by $\tilde{x}(s) = e^{A_{P_0}(s-t)}(\rho\theta) + \int_t^s e^{A_{P_0}(s-\tau)}B_1w(\tau)d\tau$, $s \ge t$, and, therefore,

$$\begin{aligned}
&|C_1\tilde{x}(s)|_Z^2 + |B_2^*P_0\tilde{x}(s)|_U^2\\
&\quad \le C\Bigg(e^{-\alpha(s-t)}\rho^2 + \left(\int_t^s e^{-\alpha(s-\tau)}|B_1w(\tau)|d\tau\right)^2\\
&\qquad + \left(\int_t^s \|B_2^*P_0e^{A_{P_0}(s-\tau)}\||B_1w(\tau)|d\tau\right)^2\Bigg),\\
&\qquad s \ge t \ge 0, \qquad \rho > 0,
\end{aligned}$$

for some $\alpha > 0$. Hence, by the Young formula we have

$$\varphi_n(t, \rho\theta) \leq C\left(\rho^2 + \int_t^\infty |w|_W^2\, d\tau\right) \quad \forall t, \rho > 0, \tag{2.20}$$

where C is independent of t and ρ.

In particular, we conclude by (2.19) and (2.20) that

$$|p_n(t)| \leq C(\rho - |x_n(t)|)^{-1}\left(\rho^2 + \int_t^\infty |w|_W^2\, d\tau\right) \quad \forall t \in [0, n]. \tag{2.21}$$

Since $x_n(t) \to \tilde{x}(t)$ uniformly in R^+ we infer that

$$\limsup_{n\to\infty} |p_n(t)| \leq C(\rho - |\tilde{x}(t)|)^{-1}\left(\rho^2 + \int_t^\infty |w|_W^2\, d\tau\right).$$

In particular, it follows that $\{p_n\}$ is bounded in $L^\infty(R^+; X)$, so on a subsequence $p_n \to p$ weak star in $L^\infty(R^+; X)$. By (2.13) we have

$$\begin{aligned}&\int_0^T (p_n(t), \psi(t))dt\\ &\quad= \int_0^T (p_n(T), e^{A(T-t)}\psi(t))dt - \int_0^T \left(\psi(t), \int_t^T e^{A^*(\tau-t)}C_1^*C_1x_n(\tau)d\tau\right)dt\\ &\quad\forall \psi \in C^1(0, T; X).\end{aligned}$$

Letting $n \to \infty$ we get

$$\begin{aligned}&\int_0^T (p(t), \psi(t))dt\\ &\quad= \left(p_T, \int_0^T e^{A(T-t)}\psi(t)dt\right) - \int_0^T \left(\psi(t), \int_t^T e^{A^*(\tau-t)}C_1^*C_1x(\tau)d\tau\right)dt\\ &\quad\forall \psi \in C^1(0, T; X),\end{aligned}$$

where $p_T = w - \lim_{n\to\infty} p_n(T)$ on a subsequence. Hence

$$p(t) = e^{A^*(T-t)}p_T - \int_t^T e^{A^*(\tau-t)}C_1^*C_1x(\tau)d\tau \quad \text{a.e. } t \in (0, T).$$

Extend p by continuity on $[0, T]$ so we get $p \in C(R^+; X)$, which satisfies (2.9), i.e.,

$$p(t) = e^{A^*(T-t)}p(T) - \int_t^T e^{A^*(\tau-t)}C_1^*C_1x(\tau)d\tau \quad \text{for all } 0 \leq t \leq T < \infty.$$

By (2.21) we have

$$|p(t)| \leq \lim_{n\to\infty} |p_n(t)| \leq C(\rho - |\bar{x}(t)|)^{-1}\left(\rho^2 + \int_t^\infty |w|_W^2\, d\tau\right) \quad \forall t \geq 0.$$

Since, as seen earlier, $\lim_{t\to\infty} \bar{x}(t) = 0$,

$$|p(t)| \leq C\left(\rho + \rho^{-1}\int_t^\infty |w(\tau)|_W^2\, d\tau\right) \quad \text{for } t \geq T(\rho).$$

For $\rho = (\int_t^\infty |w(\tau)|_W^2\, d\tau)^{1/2}$ we have, therefore, that

$$\lim_{t\to\infty} |p(t)| = 0.$$

On the other hand, by (2.14) we have

$$\begin{aligned} u_n(t) =& B_2^* p_n(t) = B_2^* e^{A^*(T-t)} p_n(T) - \int_t^T B_2^* e^{A^*(\tau-t)} C_1^* C_1 x_n \, d\tau \\ &\text{for } t \in [0,T] \subset [0,n]. \end{aligned}$$

Since the map $q \to B_2^* e^{A^*(T-t)} q$ is continuous from X to $L^2(0,T;U)$, and the map $v \to \int_t^T B_2^* e^{A^*(\tau-t)} v(\tau) d\tau$ is continuous from $L^1(0,T;X)$ to $L^2(0,T;U)$ (see [3]), we may pass to limit in the previous equation to get that

$$u^*(t) = B_2^* p(t) \quad \text{a.e. } t > 0$$

as claimed.

To prove that system (2.9), (2.10) is sufficient for the optimality of $\bar{u}$ in problem (2.7), consider a solution $(\bar{x}, \bar{u}, p)$ of (1.1), (2.9), (2.10) with $\bar{x}(0) = x_0$. We have

$$(2.22) \qquad |C_1 \bar{x}|_Z^2 \le |C_1 x|_Z^2 + 2(C_1^* C_1 \bar{x}, \bar{x} - x) \quad \forall x \in X.$$

Now consider an arbitrary solution (x,u) of (1.1); it follows by Lemma 7 that

$$(2.23) \qquad \begin{aligned} &\int_0^T (C_1^* C_1 \bar{x}, \bar{x} - x) dt \\ &\quad = (p(T), \bar{x}(T) - x(T)) - \int_0^T (\bar{u}, \bar{u} - u)_U \, dt \quad \forall T > 0. \end{aligned}$$

Now if we write system (1.1) in the form (2.12) and use assumption (ii), it follows as above that $\bar{x}$, $x \in L^2(R^+;X)$ for any solution x of (1.1) having the property that $Cx \in L^2(R^+;Z)$.

Since $\lim_{T\to\infty} p(T) = 0$ by (2.22) and (2.23), we see that $\bar{u}$ is optimal in problem (2.7) as claimed.

LEMMA 4. *The solution* $\bar{u} = \Gamma_{x_0}$ *of problem* (2.7) *can be represented as*

$$(2.24) \qquad \Gamma_{x_0} w = \Gamma_0 w + f_{x_0} \quad \forall w \in W,$$

where $\Gamma_0 \in L(\mathcal{W}, \mathcal{U})$ *and* $f_{x_0} = \arg\inf\{K_{x_0}(u,0);\ u \in \mathcal{U}\}$.

Proof. Let

$$\Gamma_0 w = \arg\inf\{K_0(u,w);\ u \in \mathcal{U}\}.$$

By Lemma 3 it follows that $\Gamma_0 w + f_{x_0} = B_2^* p$, where p is the solution of (2.9); this implies (2.24). According to the same lemma, Γ_0 is linear from $\mathcal{W}$ to $\mathcal{U}$. It is also readily seen that Γ_0 is bounded.

Proof of Proposition 1. Consider the function $\psi : \mathcal{W} \to R$ defined by

$$\psi(w) = -K_{x_0}(\Gamma_{x_0} w, w), \qquad w \in \mathcal{W}.$$

By Lemma 4, we may write ψ as

$$\psi(w) = \|Dw\|_W^2 + (Dw, f) + \alpha \quad \forall w \in \mathcal{W},$$

where $D \in L(\mathcal{W}, \mathcal{W})$, $f \in \mathcal{W}$, and $\alpha \in R$. On the other hand, by assumption (j) it follows that

$$\psi(w) \geq \omega \|w\|_{\mathcal{W}}^2 + \beta \quad \forall w \in \mathcal{W},$$

where $\omega > 0$ and $\alpha \in R$.

This implies that D^*D is positive definite, so ψ attains its infimum on $\mathcal{W} = L^2(R^+; W)$ in a unique point w^*. Clearly $(u^* = \Gamma_{x_0} w^*, w^*)$ is the unique solution to sup–inf problem (1.9). To conclude the proof it remains to show that

$$w^*(t) = -\gamma^{-2} B_1^* p^*(t) \quad \text{a.e. } t > 0. \tag{2.25}$$

We have

$$\begin{aligned}&\int_0^\infty (\gamma^2 |w^*|_W^2 - |\Gamma_0 w^* + f_{x_0}|_U^2 - |C_1 x^*|_Z^2) dt \\ &\quad \leq \int_0^\infty (\gamma^2 |w^* + \lambda w|_W^2 - |\Gamma_0(w^* + \lambda w) + f_{x_0}|_U^2 - |C_1(x^* + \lambda \tilde{x})|_Z^2) dt \\ &\quad \forall w \in \mathcal{W},\ \lambda \in R,\end{aligned}$$

where

$$\tilde{x}' = A\tilde{x} + B_2 \Gamma_0 w + B_1 w \qquad t \geq 0, \quad \tilde{x}(0) = 0. \tag{2.26}$$

This yields

$$\int_0^\infty (\gamma^2 (w^*, w)_W - (\Gamma_0^*(\Gamma_0 w^* + f_{x_0}), w)_W - (C_1^* C_1 x^*, \tilde{x})) dt = 0 \quad \forall w \in \mathcal{W}. \tag{2.27}$$

We note that

$$\tilde{x} = \text{arg inf} \left\{ \int_0^\infty (|C_1 x|_Z^2 + |u|_U^2) dt;\ x' = Ax + B_2 u + B_1 w;\ x(0) = 0 \right\},$$

so $C_1 \tilde{x} \in L^2(R^+; X)$, $\Gamma_0 w \in L^2(R^+; U)$.

Next, by Lemma 7 we have

$$\begin{aligned}&\int_0^T (C_1^* C_1 x^*, \tilde{x}) dt \\ &\quad = (p^*(T), \tilde{x}(T)) - \int_0^T (\Gamma_0 w, B_2^* p)_U \, dt + \int_0^T (B_1 w, p^*)_W \, dt \\ &\quad = (p^*(T), \tilde{x}(T)) - \int_0^T (w, \Gamma_0^*(\Gamma_0 w^* + f_{x_0}))_W \, dt + \int_0^T (B_1^* p^*, w)_W \, dt.\end{aligned}$$

Let $w \in L^2(R^+; W)$ be arbitrary but with compact support in R^+. Since (A, C_1) is detectable and $C_1 \tilde{x} \in L^2(R^+; X)$, we infer that $\lim_{t \to \infty} \tilde{x}(t) = 0$. Then letting $T \to \infty$ it follows that

$$\int_0^\infty (C_1^* C_1 x^*, \tilde{x}) dt = -\int_0^\infty ((B_1^* p^*, w)_W + (w, u^*)_U) dt,$$

so by (2.27) we get

$$\int_0^\infty (B_1^* p^* - \gamma^2 w^*, w)_W \, dt = 0.$$

This implies (2.25) as desired, and the proof of (2.4) is complete.

Let us now prove that (2.3) – (2.5) are also sufficient for the optimality of (u^*, w^*) in problem (2.2). Indeed, by Lemma 3, if (u^*, w^*, p^*) satisfy system (2.3)–(2.5) then $u^* = \Gamma w^*$. Then, since $B_1^* p^* = -\gamma^2 w^*$ by Lemma 7, it follows equality (2.27) for all $(\tilde{x}, w)$ satisfying (2.26). Hence,

$$\int_0^\infty (\gamma^2 |w^*|_W^2 - |u^*|_U^2 - |C_1 x^*|_Z^2) dt$$
$$\leq \int_0^\infty (\gamma^2 |w^* + \lambda w|_W^2 - |\Gamma_0(w^* + \lambda w) + f_{x_0}|_U^2 - |C_1 x^* + \lambda \tilde{x}|_Z^2) dt + 0(\lambda),$$
$$\lambda > 0.$$

Equivalently,

$$\psi(w^*) \leq \psi(w^* + \lambda w) + 0(\lambda) \quad \forall w \in W, \ \lambda > 0.$$

Since ψ is convex, this implies that

$$w^* = \text{arg inf}\, \psi(w) = \text{arg sup}\, K_{x_0}(\Gamma_{x_0} w, w)$$

as claimed. This completes the proof of Proposition 1.

3. Proof of Theorem 1. Assume first that the H_∞ problem has a solution, i.e., hypothesis (j) holds. Then, as seen in Proposition 1, problem (2.1) has a unique solution $(u^*, w^*) \in \mathcal{U} \times \mathcal{W}$ given by (2.2) – (2.4). We set

$$Px_0 = -p^*(0), \tag{3.1}$$

where p^* is a solution of (2.5).

LEMMA 5. *We have*

$$P \in L(X, X), \quad P = P^*, \quad P \geq 0; \tag{3.2}$$

$$(Px_0, x_0) = K_{x_0}(u^*, w^*); \tag{3.3}$$

$$p^*(t) = -Px^*(t) \quad \forall t \geq 0. \tag{3.4}$$

Proof. Let us first prove that

$$-(p^*(0), x_0) = K_{x_0}(u^*, w^*). \tag{3.5}$$

Indeed, by using the mild form of (1.1) and (2.5), we get by Lemma 7 that

$$(p(T), x^*(T)) - (p(0), x^*(0))$$
$$= \int_0^T |C_1 x^*(t)|_Z^2 dt + \int_0^T (|B_2^* p(t)|_U^2 - \gamma^{-2} |B_2^* p(t)|_W^2) dt$$
$$= \int_0^T |C_1 x^*(t)|_Z^2 + |u^*|_U^2) - \gamma^2 |w^*|_W^2) dt \quad \forall T > 0.$$

Letting T approach $+\infty$ and recalling that $\lim_{T \to \infty} p(T) = \lim_{T \to \infty} x^*(T) = 0$ we get (3.5). Next, by (3.1) and (3.5) we see that P is single valued and linear. Once again using system (2.5) we see that $(Px_0, y_0) = (Py_0, x_0)$ for all $x_0, y_0 \in X$, while by (3.3) we have

$$(Px_0, x_0) \geq \inf\{K_{x_0}(u, 0);\ u \in \mathcal{U}\} \geq 0 \quad \forall x_0 \in X, \quad \text{i.e., } P = P^* \geq 0.$$

As a supremum of lower semicontinuous convex functions $x_0 \to K_{x_0}(\Gamma_{x_0}w, w)$, the function $x_0 \to (Px_0, x_0)$ is itself lower semicontinuous. Since it is convex and everywhere finite we infer that it is continuous. Hence $P \in L(X, X)$. Note also that by inequality (2.1) it follows that

$$(Px_0, x_0) + \varepsilon \int_0^\infty |w^*|_W^2\, dt \le C|x_0|^2 \tag{3.6}$$

for some $\varepsilon > 0$ and $C > 0$ independent of x_0.

Then, again using the detectability hypothesis along with (2.12), where $x = x^*$, $u = u^*$, and $w = w^*$, we see that

$$|(x^*(t), h)| \le |e^{A_K t}x_0||h| + \int_0^t |u^*(s)|_U |B_2^* e^{A_K^*(t-s)}h|_U ds$$
$$+|h| \int_0^t \|e^{A_K(t-s)}\|_{L(X,X)}(|KC_1x^*(s)| + |B_1w^*(s)|)ds \quad \forall\, h \in X.$$

Hence

$$|x^*(t)| \le Ce^{-\omega t}|x_0| + \int_0^t e^{-\omega(t-s)}(|u^*(s)|_U + |C_1x^*(s)|_Z + |w(s)|_W)ds,$$

and by (3.6) we get

$$|x^*|_{L^2(R^+;X)} + |x^*|_{L^\infty(R^+;X)} \le C|x_0|, \tag{3.7}$$

where C is independent of x_0.

Note that for every $t \ge 0$, (u^*, w^*) is the solution of the following problem:

$$\sup_{w\in L^2(R_t^+;W)} \inf_{u\in L^2(R_t^+;U)} \left\{ \int_t^\infty (|C_1x|_Z^2 + |u|_U^2 - \gamma^2|w|_W^2)ds; \right.$$
$$\left. x' = Ax + B_2u + B_1w \,\text{in}\, R_t^+ = (t, \infty);\ x(t) = x^*(t) \right\}. \tag{3.8}$$

We may prove (3.8) by a dynamic programming argument, but we may also use Proposition 1 observing that u^*, w^*, x^*, p^* satisfy on $[t, \infty)$ system (1.1), (2.3)–(2.5) with the initial condition $x(t) = x^*(t)$, which is sufficient for optimality. Then (3.4) follows by (3.1).

Denote by $S_P(t) : X \to X$ the family of linear operators

$$S_P(t)x_0 = x^*(t) \quad \forall\, t \ge 0,$$

where x^* is the optimal state in problem (2.2).

Since $x \to x^*(t + s)$ is the solution to problem (3.8), we infer that $S_P(t + s)x_0 = S_P(t)S_P(s)x_0$, $\forall\, t, s \ge 0$.

Next, by (3.7) we see that $S_P(t) \in L(X, X)$, $\forall\, t \ge 0$. Hence $S_P(t)$ is a C_0-semigroup on X.

Let A_P be the infinitesimal generator of S_P. In Lemma 6 below we collect some properties of A_P and B_2^*P for later use.

LEMMA 6. *We have*

$$D(A_P) \subset D(B_2^*P), \tag{3.9}$$

$$B_2^* P \in L(D(A_P), U) \cap L(D(A), U), \tag{3.10}$$

$$A_P x_0 = (A - B_2 B_2^* P + \gamma^{-2} B_1 B_1^* P) x_0 \quad \forall x_0 \in D(A_P). \tag{3.11}$$

Proof. This proof is essentially the same as that of Lemma 4.5 in [3]; however, we sketch it for the reader's convenience.

By (2.6) and (3.1) we have

$$P x_0 = -e^{A^* T} P e^{A_P T} x_0 - \int_0^T e^{A^* t} C_1^* C_1 e^{A_P t} x_0 \, dt \quad \forall T > 0. \tag{3.12}$$

If $x_0 \in D(A_P)$ this yields

$$\begin{aligned} B_2^* P x_0 =& B_2^* e^{A^* T} P e^{A_P T} x_0 - B_2^* (A^*)^{-1} (e^{A^* T} C_1^* C_1 e^{A_P T} x_0 - C_1^* C_1 x_0) \\ & - \int_0^T e^{A^* t} C_1^* C_1 e^{A_P t} A_P x_0 \, dt. \end{aligned}$$

Since $B_2^* e^{A^* t} P e^{A_P t} x_0 \in L^2_{\text{loc}}(R^+; U)$, the latter makes sense for almost all $T > 0$, so $B_2^* P x_0 \in X$. Hence $D(A_P) \subset D(B_2^* P)$. In particular, this implies that $B_2^* P$ is densely defined and continuous from $D(A_P)$ to U.

On the other hand, for all $x_0 \in H$ and $z \in D(A^*)$ we have

$$\begin{aligned} &\frac{d}{dt}(S_P(t) x_0, z) \\ &\quad = (S_P(t) x_0, A^* z) + (B_2 u^*(t) + B_1 w^*(t), z) \\ &\quad = (S_P(t) x_0, A^* z) - (B_2 B_2^* P S_P(t) x_0 - \gamma^{-2} B_1 B_1^* P S_P(t) x_0, z) \quad \text{a.e. } t > 0. \end{aligned}$$

Since $B_2^* P \in L(D(A_P), U)$ and $A^{-1} B_2 \in L(X, X)$, we have

$$\begin{aligned} (A_P x_0, z) &= (x_0, A^* z) - (B_2 B_2^* P x_0 - \gamma^{-2} B_1 B_1^* P x_0, z) \\ & \quad \forall x_0 \in D(A_P) \quad \forall z \in D(A^*). \end{aligned} \tag{3.13}$$

By (3.10) the operator $A - B_2 B_2^* P + \gamma^{-2} B_1 B_1^* P$ is well defined from $D(A_P)$ to $(D(A^*))'$. Then, (3.13) follows by (3.11).

Next, arguing as in the proof of Lemma 4.1 in [3], we see that

$$A^* P \in L(D(A_P), X), \qquad A_P^* P \in L(D(A), X). \tag{3.14}$$

For $x_0 \in D(A_P)$ and $z \in X$ we have

$$\begin{aligned} (A_P x_0, P z) &= (P(A - B_2 B_2^* P + \gamma^{-2} B_1 B_1^* P) x_0, z) \\ &= (P A x_0, z) - (B_2^* P x_0, B_2^* P z) + \gamma^{-2} (B_1^* P x_0, B_1^* P z)_W. \end{aligned}$$

Hence

$$(B_2^* P x_0, B_2^* P z)_U = -(A_P x_0, P z) + (P A x_0, z) + \gamma^{-2} (B_1^* P x_0, B_1^* P z)_W,$$

and by virtue of (3.14) we get

$$|(B_2^* P x_0, B_2^* P z)_U| \le C |x_0|_{D(A_P)} |z|_{D(A)} \quad \forall x_0 \in D(A_P), \ z \in D(A),$$

and

$$|(B_2^*Px_0, B_2^*Pz)_U| \le C|x_0|_{D(A)}|z|_{D(A_P)} \quad \forall x_0 \in D(A),\ z \in D(A_P).$$

In particular, this yields $B_2^*P \in L(D(A),U) \cap L(D(A_P),U)$ as claimed.

Proof of Theorem 1 (continued). To prove that P is a solution to Riccati equation (1.8), we note first that by (3.3), (3.4), and (3.8) we have

$$(Px^*(t), x^*(t)) = \int_t^\infty (|C_1x^*(s)|_Z^2 + |u^*(s)|_U^2 - \gamma^2|w^*(s)|_W^2)ds, \qquad t \ge 0.$$

For $x_0 \in D(A_P)$ this yields

$$2(Px^*(t), A_Px^*(t)) + |C_1x^*(t)|_Z^2 - |B_2^*Px^*(t)|_U^2 = -\gamma^{-2}|B_1^*Px^*(t)|_W^2 \quad \text{a.e. } t > 0,$$

and since $B_2^*P \in L(D(A_P), X)$, we get

(3.15) $$2(Px_0, A_Px_0) + |C_1x_0|_Z^2 - |B_2^*Px_0|_U^2 + \gamma^{-2}|B_1^*Px_0|_W^2 = 0 \quad \forall x_0 \in D(A_P).$$

By (3.10) and (3.14), the previous equality extends to all $x_0 \in D(A)$, and in virtue of (3.11) we may write it as

$$2(Px_0, Ax_0) + |C_1x_0|_Z^2 - |B_2^*Px_0|_U^2 + \gamma^{-2}|B_1^*Px_0|_W^2 = 0 \quad \forall x_0 \in D(A).$$

If we differentiate the latter equation in the space $D(A)$ we get (1.8).

To prove that the semigroup e^{A_Pt} is exponentially stable we use detectability assumption (ii). Let $K \in L(X,Z)$ as in this assumption. Then we have

$$\begin{aligned} x^*(t) = e^{(A+KC_1)}x_0 &+ \int_0^t e^{(A+KC_1)(t-s)}(B_2u^*(s) + B_1w^*(s))ds \\ &- \int_0^t e^{(A+KC_1)(t-s)}KC_1x^*(s)ds \quad \forall t \ge 0. \end{aligned}$$

Since $B_1w^*,\ KC_1x^* \in L^2(R^+; X)$, it remains to show that

$$\int_0^t e^{(A+KC_1)(t-s)}B_2u^*(s)ds \in L^2(R^+; X).$$

The latter follows by assumption (i) and Lemma 5.2 in [3].

Clearly $A - B_2B_2^*P = A_P - \gamma^{-2}B_1B_1^*P$ is the infinitesimal generator of a C_0-semigroup on X. Let $x_0 \in D(A_P)$. Then, multiplying the equation

(3.16) $$x' = (A - B_2B_2^*P)x, \qquad x(0) = x_0$$

by Px and using (3.15), we get

$$\frac{d}{dt}(Px(t), x(t)) = -|Cx(t)|_Z^2 - |B_2^*Px(t)|_U^2 - \gamma^{-2}|B_1^*Px(t)|_W^2, \qquad t > 0.$$

Hence

$$\int_0^\infty (|C_1x(t)|_Z^2 + |B_2^*Px(t)|_U^2 + |B_1^*Px(t)|_W^2)dt < \infty.$$

If we write (3.16) as

$$x' = A_P x - \gamma^{-2} B_1^* P x, \qquad x(0) = 0,$$

and use the facts that $B_1^* P x \in L^2(R^+; W)$ and $e^{A_P t}$ is exponentially stable, we conclude that $x \in L^2(R^+; X)$. Hence, by Datko's theorem, $e^{(A - B_2 B_2^* P)t}$ is exponentially stable.

Let $w \in L^2(R^+; W) \cap C^1(R^+; W)$ be arbitrary but fixed, and let $y \in C^1(R^+; X)$ be the solution of the following equation:

$$y' = (A - B_2 B_2^* P) y + B_1 w, \qquad y(0) = x_0 \in D(A_P). \tag{3.17}$$

This yields

$$\begin{aligned}\frac{d}{dt}&(Py(t), y(t)) \\ &= -|C_1 y(t)|_Z^2 - |B_2^* P y(t)|_U^2 - \gamma^{-2} |B_1^* P x(t)|_W^2 + 2(B_1^* P y(t), w(t))_W \\ &= -|C_1 y(t)|_Z^2 - |B_2^* P y(t)|_U^2 - |\gamma w - \gamma^{-1} B_1^* P y(t)|_W^2 + \gamma^2 |w|_W^2 \qquad \forall t \geq 0.\end{aligned}$$

Hence

$$\begin{aligned}\int_0^\infty &(|C_1 y(t)|_Z^2 + |B_2^* P y(t)|_U^2 - \gamma^2 |w(t)|_W^2) dt \\ &= -\gamma^2 \int_0^\infty |\bar{w}(t)|_W^2 \, dt + (P x_0, x_0),\end{aligned} \tag{3.18}$$

where $\bar{w} = w - \gamma^{-2} B_1^* P y$.

On the other hand, we have for $x_0 = 0$,

$$\|w\|_{L^2(R^+;W)} \leq \|\bar{w}\|_{L^2(R^+;W)} + \beta \|y\|_{L^2(R^+;X)} \leq \alpha \|\bar{w}\|_{L^2(R^+;W)},$$

because $y' = A_P y + B_1 \bar{w}$.

Substituting the latter in (3.18) we get

$$\int_0^\infty (|C_1 y|_Z^2 + |B_2^* P y|_U^2 - \gamma^2 |w|_W^2) dt \leq -\delta \|w\|_{L^2(R^+;W)}^2 \quad \forall w \in L^2(R^+; W),$$

where $\delta > 0$ is independent of w. Hence $\|S_{-B_2^* P}\| < \gamma$, which completes the "only if" part of the proof.

We now complete the "if" part of the proof. Suppose that $P = P^* \geq 0$ is a solution of (1.8) satisfying (1.7) such that $A_P = A - B_2 B_2^* P + \gamma^{-2} B_1 B_1^* P$ is exponentially stable. Then, arguing as above, we infer that $A - B_2 B_2^* P = A_P - \gamma^{-2} B_1 B_1^* P$ is exponentially stable. Then if y is the solution of Cauchy problem (3.17), we get as above (see (3.18)) that

$$B_2^* P e^{(A - B_2 B_2^* P)t} \in L(X, L^2(R^+; U)),$$

i.e., $-B_2^* P \in \mathcal{F}$. Moreover, by (3.18) we infer as above that $\|S_{-B_2^* P}\| < \gamma$.

Let us show now that the solution P of Riccati equation (1.8) having the properties stated in Theorem 1 is unique. Indeed, if P_1 and P_2 are two such solutions of (1.8) we have

$$(A_{P_1} x, (P_1 - P_2) y) + ((P_1 - P_2) x, A_{P_2} y) = 0 \quad \forall x, y \in D(A_{P_1}) \cap D(A_{P_2}),$$

and this yields

$$\frac{d}{dt}(e^{A_{P_1} t} x, (P_1 - P_2) e^{A_{P_2} t} y) = 0 \quad \forall t \geq 0.$$

Since $e^{A_{P_i} t}$, $i = 1, 2$, are exponentially stable, we get

$$((P_1 - P_2) y, x) = 0 \quad \forall x, y \in D(A_{P_1}) \cap D(A_{P_2}),$$

and by density we infer that $P_1 = P_2$. This completes the proof of Theorem 1.

4. H_∞ control with boundary disturbance input. We shall consider here system (1.1), where assumption (i) is replaced by

(k) $B_2 \in L(U, X)$, $A^{-1}B_1 \in L(U, X)$, and

$$\int_0^T |B_1^* e^{A^* t} x|_W^2 \, dt \le C_T |x|^2 \quad \forall x \in X,\ T > 0. \tag{4.1}$$

Then, for every $w \in L^2(R^+; W)$ and $u \in L^2(R^+; U)$, system (1.1) has a unique mild solution x given by the variation of constant formula (1.4). Given $\gamma > 0$, an H_∞ controller is by definition a stabilizing feedback controller that guarantees the inequality $\|S_F\| < \gamma$, where $S_F \in L(L^2(R^+; W),\ L^2(R^+; Z))$ is the closed loop operator $S_F(w) = C_1 x + D_{12} F x$. It is not clear whether Theorem 1 remains valid in this case. Proposition 2 below represents only a partial result (see [6] for other recent results on this case).

PROPOSITION 2. *Let $\gamma > 0$ and suppose that assumptions* (k), (ii), (iii), *and* (j) *hold. Then there exists $P \in L(X, X)$ such that $P = P^* \ge 0$, $B_1^* P \in L(D(A), U) \cap L(D(A_P), U)$, P satisfies Riccati equation* (1.8), *$A_P = A - B_2 B_2^* P + \gamma^{-2} B_1 B_1^* P$, and $A - B_2 B_2^* P$ generates exponentially stable semigroups. Conversely, if a such a solution P to* (1.8) *exists, then $F = -B_2^* P$ is an exponentially stabilizing feedback controller and guarantees $\|S_F\| \le \gamma$.*

Proof. Since the proof is essentially the same as that of Theorem 1, it will only be sketched. We note first that Proposition 1 remains valid under present assumptions. Indeed, the proof of Lemma 1 remains unchanged (with some simplifications because B_2 is bounded) and (2.4) follows by the same argument; note that by assumption (k) and (2.6), $B_1^* P \in L^2(0, T; W)$ for all $T > 0$. Then, we define $P \in L(X, X)$ by (3.1), and Lemma 5 remains valid. Define

$$\tilde{S}_P(t) x_0 = x^*(t) \quad \forall t \ge 0; \tag{4.2}$$

then $\tilde{S}_P$ is a C_0-semigroup on X. Denote by $\tilde{A}_P$ its infinitesimal generator. Arguing as in the proof of Lemma 6, and using assumption (k), it follows that

$$\begin{aligned}
&D(\tilde{A}_P) \subset D(B_1^* P),\\
&\quad B_1^* P \subset L(D(\tilde{A}_P), U) \cap L(D(A), U),\\
&\quad \tilde{A}_P x_0 = (A - B_2 B_2^* P + \gamma^{-2} B_1 B_1^* P) x_0 \quad \forall x_0 \in D(A_P).
\end{aligned}$$

Then, as in the proof of Theorem 1, it follows that P satisfies (1.8), and the semigroups generated by $\tilde{A}_P$ and $A - B_2 B_2^* P$ are exponentially stable.

Now assume the existence of $P \in L(X, X)$ satisfying Riccati equation (1.8) and the conditions stated in Proposition 2. Then, for $w \in C^1(R^+; W) \cap L^2(R^+; W)$ and $x_0 = 0$, system (3.17) has a solution $y \in C^1(R^+; D(A))$ and y is weakly differentiable. (This follows by assumption (4.1).) Hence $B_1^* P y \in L^\infty_{\mathrm{loc}}(R^+; W)$, and using (1.8) we get

$$\begin{aligned}
\frac{d}{dt}(Py(t), y(t)) = -|C_1 y(t)|_Z^2 - |B_2^* P y(t)|_U^2 - \gamma w(t) - \gamma^{-1} B_1^* P y(t)|_W^2\\
+ \gamma^2 |w(t)|_W^2 \quad \text{a.e. } t > 0.
\end{aligned}$$

This yields

$$\int_0^T (|C_1 y(t)|_Z^2 - |B_2^* P y(t)|_U^2 - \gamma^2 |w(t)|_W^2) dt \le 0 \quad \forall T > 0.$$

Hence $\|S_{-B_2^* P}\| \le \gamma$ as claimed.

5. Some remarks on H_∞ control with dynamic feedback. Consider again the input-output system

$$x' = Ax + B_2u + B_1w, \quad z = C_1x + D_{12}u \tag{5.1}$$

with the observation

$$y = C_2x + D_{12}\eta. \tag{5.2}$$

Here $C_2 \in L(X,Y)$, $D_{12} \in L(W_0,Y)$, η is a perturbation modelling the measurement error, and Y, W_0 are Hilbert spaces. The aim is to find a dynamic feedback controller of the form

$$\begin{gathered} u = Lp, \\ p' = (A+M)p + Ny, \qquad p(0) = 0 \end{gathered} \tag{5.3}$$

that exponentially stabilizes the system and reduces the influence of w on z. The linear maps $M : X \to X$, $L : X \to U$, $N : Y \to X$, define a feedback controller $K = (M,L,N)$, which substituted into system (5.1) yields

$$\begin{gathered} x' = Ax + B_2Lp + B_1w, \qquad t \in R^+, \\ p' = NC_2x + (A+M)p + ND_{12}\eta, \\ x(0) = 0, \qquad p(0) = 0. \end{gathered} \tag{5.4}$$

Equivalently,

$$\begin{gathered} \begin{pmatrix} x \\ p \end{pmatrix}' = \mathcal{A}\begin{pmatrix} x \\ p \end{pmatrix} + \left\| \begin{matrix} B_1w \\ ND_{21} \end{matrix} \right\|, \qquad t \in R^+, \\ \begin{pmatrix} x \\ p \end{pmatrix}(0) = \begin{pmatrix} 0 \\ 0 \end{pmatrix}, \end{gathered} \tag{5.4$'$}$$

where

$$\mathcal{A} = \left\| \begin{matrix} A & B_2L \\ NC_2 & A+M \end{matrix} \right\|. \tag{5.5}$$

Here we shall restrict ourselves to feedback controllers $K = (M,L,N)$ with the following properties:

(a) $M \in L(D(A),(D(A^*))'), L \in L(D(A),U)$, $N \in L(Y,X)$.

(b) The operator $\mathcal{A} : X \times X \to X \times X$ is the infinitesimal generator of an exponentially stable C_0-semigroup on $X \times X$.

(c) $D(\mathcal{A}) \subset D(L) \times X$ and $\left\| \begin{smallmatrix} 0 & L \\ 0 & 0 \end{smallmatrix} \right\| e^{\mathcal{A}t}$ is continuous from X to $L^2(R^+; X \times X)$.

For such a feedback controller K, define $S_K : L^2(R^+;W) \to L^2(R^+;Z)$, $S_K(w) = z = C_1x + D_{12}Lp$, where (x,p) is the solution of (5.4).

The feedback controller K is called an H_∞ control if it satisfies (a), (b), (c), and

$$\|S_K\| < \gamma. \tag{5.6}$$

In addition to (i), (ii), and (iii), we shall assume that

(l) the pair (B_1^*, A^*) is exponentially detectable;

(ll) $D_{12}|B_1^*, D_{12}^*| = |0, I|$.

Proposition 3 below extends only partially the standard results of H_∞ control theory with dynamic measurement feedback [2], [4].

PROPOSITION 3. *Let $\gamma > 0$. If there exists an H_∞ controller satisfying* (5.6) *then there exist $P, Q \in L(X,X)$, $P = P^* \geq 0$, $Q = Q^* \geq 0$, which satisfy the following conditions*:

(m) $B_2^*P \in L(D(A),U)$, $A + (\gamma^{-2}B_1B_1^* - B_2B_2^*)P$ *generates an exponentially stable semigroup and*

$$(Ax,Py) + (Px,Ay) - (P(B_2B_2^* - \gamma^{-2}B_1B_1^*)Px,y) + (C_1^*C_1x,y) = 0 \quad \forall\, x,y \in D(A). \tag{5.7}$$

(mm) $A^* + (\gamma^{-2}C_1^*C_1 - C_2^*C_2)Q$ *generates an exponentially stable semigroup and*

$$(Ax,Qy) + (Qx,Ay) - ((C_2^*C_2 - \gamma^{-2}C_1^*C_1)Qx,Qy) + (B_1^*B_1x,y) = 0 \quad \forall\, x,y \in D(A). \tag{5.8}$$

(mmm) $(I - \gamma^{-2}PQ)^{-1} \in L(X,X)$ *and*

$$Q(I - \gamma^{-2}PQ)^{-1} \geq 0. \tag{5.9}$$

If these conditions hold then the feedback controller $K = (M,L,N)$ given by

$$\begin{aligned} M &= (\gamma^{-2}B_1B_1^* - B_2B_2^*)P - Q(I - \gamma^{-2}PQ)^{-1}C_2^*C_2, \\ L &= B_2^*P, \\ N &= -Q(I - \gamma^{-2}PQ)^{-1}C_2^*, \end{aligned} \tag{5.10}$$

is an H_∞ controller guaranteeing the closed loop inequality $\|S_K\| \leq \gamma$.

We omit the proof, which follows by Theorem 1 and Proposition 2 by the duality arguments developed in [2], [9], and [1].

In fact, the direct approach of [1] can be used mutatis mutandis in the present situation, but we do not give details.

6. Appendix. We shall prove here the following lemma.

LEMMA 7. *Let $(x,p) \in C([a,b];X) \times C([a,b];X)$ be a mild solution to the system*

$$x' = Ax + B_2u + f, \qquad t \in [a,b], \tag{6.1}$$

$$p' = -A^*p + g, \tag{6.2}$$

where $u \in L^2(a,b;U)$ and $f,g \in L^1(0,T;X)$. Then

$$\begin{aligned} &\int_a^b ((u(t),B_2^*p(t))_U + (f(t),p(t)) + (g(t),x(t)))dt \\ &\quad = (x(b),p(b)) - (x(a),p(a)). \end{aligned} \tag{6.3}$$

Proof. For simplicity we take $a = 0$ and $b = T$. By virtue of assumption (i) and Fubini's theorem we may write

$$\begin{aligned} &\int_0^T (g(t),x(t))dt \\ &= \int_0^T \left(g(t), e^{At}x_0 + \int_0^t e^{A(t-s)}f(s)ds\right) dt \\ &\quad + \int_0^T \left(g(t), \int_0^t e^{A(t-s)}B_2u(s)ds\right) dt \\ &= \int_0^T \left(g(t), e^{At}x_0 + \int_0^t e^{A(t-s)}f(s)ds\right) dt \\ &\quad + \int_0^T \left(u(s), \int_s^T B_2^*e^{A^*(t-s)}g(t)dt\right) ds. \end{aligned} \tag{6.4}$$

Recalling that

$$p(t) = e^{A^*(T-t)}p(T) - \int_t^T e^{A^*(s-t)}g(s)ds, \qquad t \in [0,T],$$

and substituting the latter in (7.4) we get (7.3) as claimed. (We recall that, by virtue of assumption (i), the operator

$$g \to \int_s^T B_2^* e^{A^*(t-s)}g(t)dt$$

is continuous from $L^1(0,T;X)$ to $L^2(0,T;U)$.)

Acknowledgments. The author is indebted to R. Triggiani for useful remarks and for pointing out a gap in the proof of Lemma 3 in the first draft of the manuscript. The author also thanks the anonymous referee for numerous suggestions that helped improve the presentation of this work.

ALMOST SURE STABILIZABILITY AND RICCATI'S EQUATION OF LINEAR SYSTEMS WITH RANDOM PARAMETERS*

PHILIPPE BOUGEROL†

Abstract. Linear systems with stationary time-varying parameters are considered. The notions of almost sure stabilizability and almost sure detectability are explored. Under these properties the asymptotic behavior of the associated Riccati equation is described. In particular, the stability of the Kalman filter and the convergence of linear observers are proved.

Key words. Riccati equation, Kalman filtering, observers, stochastic parameters, stabilizability, detectability, linear discrete-time systems

AMS subject classifications. 93C05, 93E11, 60G35, 34F05

1. Introduction.

Consider either the filtering linear system

$$\begin{aligned} X_{n+1} &= A_n X_n + B_n \varepsilon_n, \\ Y_{n+1} &= C_n X_n + \eta_n, \end{aligned} \tag{1}$$

or the linear control system

$$X_{n+1} = A_n X_n + B_n U_n, \qquad Y_n = C_n X_n, \tag{2}$$

where $X_n \in \mathbb{R}^d$ is the state vector, $Y_n \in \mathbb{R}^q$ is an observation, $(\varepsilon_n, \eta_n) \in \mathbb{R}^p \times \mathbb{R}^q$ is a Gaussian white noise, and $U_n \in \mathbb{R}^p$ is a control. We suppose that $\{(A_n, B_n, C_n),\ n \in \mathbb{Z}\}$ is a stationary ergodic sequence of matrices of appropriate dimension. Under weak conditions we show that the error system of the Kalman filter associated with (1) is almost surely exponentially stable, and the linear system (2) can be almost surely stabilized.

When the parameters are not random, analogous results are well known under strong hypotheses (either uniform stabilizability and detectability or uniform controllability and observability); see, e.g., Jazwinski [10], Anderson and Moore [2], and the recent survey in the introduction of De Nicolao [9]. These hypotheses are too stringent and usually do not hold for systems with random parameters. We shall see that they can be significantly weakened when the parameters are stationary by making use of ideas from ergodic theory.

Systems with stationary parameters are used in several models and are worth studying in view of the applications. Stationary processes can be either deterministic (e.g., almost periodic sequences) or nondeterministic (e.g., identically independent random variables, functions of ergodic Markov chains, autoregressive moving average (ARMA) sequences, etc.). They occur, for instance, in the descriptions of random (or multirate deterministic) sampling of the control of failure-prone production plants, and in adaptive stochastic control. Some of these systems are out of order at random times; this prevents them from verifying uniform assumptions. These examples and references to previous works are described in detail in [5]. Inspired by Snyder and Fishman [14], filtering for systems with random parameters is studied, in particular, by Viano [15] under a strong stability hypothesis. Here we shall suppose that the parameters are observed. The opposite situation is studied, for instance, by Wonham [17] and De Koning [8].

Let us describe our main results. It is convenient to introduce the following, perhaps unusual, definitions. The random matrices are defined on a probability space $(\Omega, \mathcal{F}, \mathbb{P})$.

DEFINITION 1.1. *A sequence $\{A_n, n \in \mathbb{Z}\}$ of $d \times d$ random matrices is called almost surely weakly stable if*

$$\lim_{n \to +\infty} \|A_n A_{n-1} \dots A_1\| = 0 \quad a.s.$$

It is called almost surely exponentially stable if there exists $\gamma > 0$ with the following property: for any $\varepsilon > 0$ and almost all $\omega \in \Omega$, there is a $C(\omega) > 0$ such that

$$\|A_{n-1}(\omega)A_{n-2}(\omega)\dots A_{n-m}(\omega)\| \leq C(\omega)e^{-m\gamma}e^{(|n|+m)\varepsilon}$$

for all $n \in \mathbb{Z}$ and all $m \geq 1$.

Note that when (A_n) is almost surely exponentially stable, the solution of the linear equation $X_{n+1} = A_n X_n$ converges almost surely to 0 exponentially fast as time progresses. It will be proven that these definitions are exactly what is needed here, where we meet random sequences without moment. Their first properties are explored in §2. We say that the linear systems above are almost surely weakly or exponentially stabilizable if there is a feedback control such that the associated closed loop system is almost surely weakly or exponentially stable, respectively (see Definition 2.4 for precision). In §3, we show using [5] that a sufficient condition for almost sure exponential stabilizability is the existence of an integer $n \geq 1$ such that

$$\mathbb{P}(B_n B_n^* + A_n B_{n-1} B_{n-1}^* A_n^* + \dots + (A_n \dots A_2) B_1 B_1^* (A_2^* \dots A_n^*) \text{ is invertible}) \neq 0.$$

This is called weak controllability. For instance, when $d = 1$ this condition is always fulfilled unless $B_n = 0$ almost surely for all n. In §4 we prove that an almost surely weakly stabilizable system is actually almost surely exponentially stabilizable. Similar results hold for the corresponding notions of detectability and weak observability defined by duality.

In §5 we suppose that the linear system is almost surely weakly stabilizable and weakly detectable. We study the Riccati difference equation

$$P_{n+1} = B_n B_n^* + A_n P_n (I + C_n^* C_n P_n)^{-1} A_n^*, \tag{3}$$

where $P_n, n \in \mathbb{N}$, are nonnegative symmetric matrices. This equation is usually written as follows:

$$\begin{aligned} P_{n+1} &= B_n B_n^* + (A_n - K_n C_n) P_n A_n^*, \\ K_n &= A_n P_n C_n^* (I + C_n P_n C_n^*)^{-1}, \end{aligned} \tag{4}$$

where K_n is called the gain matrix associated with P_n. Let us recall how it occurs in the filtering of (1). We suppose that the Gaussian white noise (ε_n, η_n) has a covariance matrix equal to the identity and is independent of X_0 and the sigma-algebra $\mathcal{F}_0$ generated by the parameters. The random variable X_0 is Gaussian and independent of $\mathcal{F}_0$. For any $n \in \mathbb{N}$, let $\mathcal{F}_n = \sigma(\mathcal{F}_0, Y_1, \dots, Y_n)$. This represents the observation at time n. Let

$$\hat{X}_n = \mathbb{E}(X_n/\mathcal{F}_n), \qquad P_n = \mathbb{E}\left((X_n - \hat{X}_n)(X_n - \hat{X}_n)^*/\mathcal{F}_n\right).$$

Then the Kalman recursive equations are given by (4) and

$$\hat{X}_{n+1} = A_n \hat{X}_n + K_n (Y_{n+1} - C_n \hat{X}_n)$$

(see, e.g., Whittle [16, p. 260 and Thm. 5.7.1]). The main result of this section is the existence of a unique stationary solution $(\bar{P}_n)$ of the Riccati difference equation (Theorem 5.1). It is analogous to the "moving equilibrium" solution defined in Kalman [11]. This solution is attractive in the sense that if (P_n) is another solution of this equation, then $\bar{P}_n - P_n$ converges almost surely to 0 exponentially fast as n tends to $+\infty$ (Theorem 5.3). Moreover, the filter is almost surely exponentially stable and thus efficient (Theorem 5.6). The initial conditions are rapidly forgotten (this is useful since they are often chosen arbitrarily). For instance, let us suppose only that $\mathbb{E}(\log\|A_0\|) < 0$, or more generally that the Lyapunov exponents of the sequence (A_n) are negative. This is the condition under which (X_n), given by (1), is itself a stationary process (see, e.g., [6]). Then the system is almost surely weakly stabilizable and weakly detectable. Thus the results above hold, although the system does not fulfill the "uniform" conditions considered in the literature on time-varying parameter systems. In §6 we briefly consider applications to control theory. An efficient observer for linear systems with stationary coefficients is given. We also show that the quadratic cost converges almost surely when the horizon increases to infinity (this latter result is of limited practical interest for nondeterministic systems since the optimal controls depend on the parameters indexed by the future).

There are some connections between this work and multiplicative ergodic theory that are explained in [3]. The properties of $\bar{P}_n$ are related to the hyperbolicity of associated Hamiltonian matrices (see Remark 4.4), but are not only consequences of this fact. An important technical difficulty arises from the fact that, generally, $\log^+\|\bar{P}_n\|$ is not integrable. Therefore, the sequence $(A_n - K_n C_n)$ does not have Lyapunov exponents. This explains why some proofs are rather involved (see also Remark 5.7).

Let us make some technical comments on our filtering linear model (1). Several variants are often used; for instance, one could replace the second equation by $Y_n = C_n X_n + \eta_n$. Our choice is justified by the fact that duality is more transparent here. Anyway, all the models are essentially equivalent and it is easy to transpose our results to other ones. The hypotheses on the random parameters model can also be weakened. It is, in fact, sufficient that there is a sigma-algebra $\mathcal{F}_0$ such that, if $\mathcal{F}_n = \sigma(\mathcal{F}_0, Y_1, \dots, Y_n)$, then (A_n, B_n, C_n) is $\mathcal{F}_n$-measurable and (ε_n, η_n) is independent of $\mathcal{F}_n$ and X_n. In that so-called conditionally Gaussian case, the filter is also given by the previous equations (see Whittle [16], Chen, Kumar, and van Schuppen [7]), and, therefore, our results hold true. One can also eliminate the assumption that the white noise (ε_n, η_n) has a unit covariance matrix at the price of some complications. Finally, we remark that the well-known equivalence between (4) and (3) follows directly from the relation $(C_n^* C_n P_n + I)^{-1} = I - C_n^*(I + C_n P_n C_n^*)^{-1} C_n P_n$ or from Whittle [16, Thm. 5.7.1].

This paper is a logical continuation of [5]; its results were announced in [4].

2. Preliminaries. In this section we explore the notions of stability introduced in Definition 1.1. We shall also use them for nonrandom sequences (i.e., when Ω has only one element), in which case we do not write "almost surely." The definition of exponential stability given there is weaker than the usual one (in which $\varepsilon = 0$ is allowed); it thus deserves some comments. Let us first note the following result, the proof of which is straightforward. Note that the assertion is no more true with "lim sup" instead of "lim" (for instance, take $a_{2n} = \frac{1}{3}2^{|n|}, a_{2n-1} = 2^{-|n|}$).

LEMMA 2.1. *Let $\{a_n, n \in \mathbb{Z}\}$ be a sequence of positive real numbers. If for some $\alpha, \beta > 0$,*

$$\lim_{n\to+\infty} \frac{1}{n} \log(a_n \dots a_1) = -\alpha, \qquad \lim_{n\to+\infty} \frac{1}{n} \log(a_{-1} \dots a_{-n}) = -\beta,$$

then the sequence is exponentially stable.

In this paper, we will mainly be interested in stationary (in the strict sense) sequences of matrices. If (A_n) is such a sequence and $\log^+ \|A_0\|$ is integrable, then its largest Lyapunov exponent γ is defined as

$$\gamma = \lim_{n\to+\infty} \frac{1}{n}\,\mathbb{E}(\log \|A_n \dots A_1\|).$$

Throughout the paper we choose the operator norm associated with the euclidean structure for a matrix (usually, this choice is not important). In this case, we also have $\gamma = \inf_{n>0} \frac{1}{n}\mathbb{E}(\log \|A_n \dots A_1\|)$.

PROPOSITION 2.2. *Let $\{A_n, n \in \mathbb{Z}\}$ be a stationary ergodic sequence of matrices such that* $\log^+ \|A_0\|$ *is integrable. Then the following three conditions are equivalent*:

(a) *the sequence (A_n) is weakly stable almost surely*;

(b) *the Lyapunov exponents of the sequence (A_n) are negative*;

(c) *the sequence (A_n) is almost surely exponentially stable.*

We need the following well-known lemma.

LEMMA 2.3. *If $\{a_n, n \in \mathbb{Z}\}$ is a stationary sequence of real random variables such that a_0 is integrable, then, almost surely,* $\lim_{|n|\to+\infty} \frac{1}{n} a_n = 0$.

Proof. The proof follows from the Borel–Cantelli lemma since, for any $\varepsilon > 0$,

$$\sum_{k=-\infty}^{+\infty} \mathbb{P}(|a_k| > |k|\varepsilon) = \sum_{k=-\infty}^{+\infty} \mathbb{P}(|a_0| > |k|\varepsilon)$$
$$\leq \mathbb{P}(|a_0| > 0) + 2\sum_{k=1}^{+\infty} \mathbb{P}\left(\frac{|a_0|}{\varepsilon} > k\right) \leq 1 + 2\mathbb{E}\left(\frac{|a_0|}{\varepsilon}\right) < +\infty. \qquad \square$$

Proof of Proposition 2.2. (a) $\Rightarrow$ (b) is proved in [6, Lem. 3.4]. Let us assume that (b) holds. Then there exists $k > 0$ such that $\mathbb{E}(\log \|A_k \dots A_1\|)$ is negative. Let $M_n = A_{(n+1)k} \dots A_{nk+1}$. It follows from Lemma 2.1 and from Birkhoff's ergodic theorem that the sequence $\{\|M_n\|, n \in \mathbb{Z}\}$ is almost surely exponentially stable. This easily implies that (c) holds true by using the fact that if $m < qk < pk \leq n$, then

$$\|A_n A_{n-1} \dots A_{m+1}\| \leq \|A_n \dots A_{pk+1}\| \cdot \|M_{p-1} \dots M_q\| \cdot \|A_{qk} \dots A_{m+1}\|,$$

and Lemma 2.1 applied to the sequence $a_n = \log^+ \|A_n\|$. Finally, $\frac{1}{n} \log \|A_n \dots A_1\|$ converges almost surely to the largest Lyapunov exponent as $n \to +\infty$ (see, e.g., Kingman [12]). Thus (c) $\Rightarrow$ (a). $\square$

This proposition shows that "almost surely exponentially stable" is a kind of substitute for "with negative Lyapunov exponents" for stationary sequences of matrices, the norms of which are log integrable. It will appear in the following sections that non-log-integrable sequences occur naturally in the control/filtering setting, and are even unavoidable. This explains the choice of Definition 1.1. From a technical point of view the robustness properties exhibited by Lemmas 4.1 and 5.5 will be crucial for us.

Let us give a simple natural example where only our notion of stability is fulfilled. We consider a sequence $a_n, n \in \mathbb{Z}$, of independent and identically distributed positive random variables such that $\mathbb{P}(a_0 > M) > 0$ for any $M > 0$, and $\mathbb{E}(\log a_0) < 0$. This sequence is almost surely exponentially stable. On the other hand, for any $M > 0$,

$$\sum_{n=-\infty}^{+\infty} \mathbb{P}(a_n > M) = \sum_{n=-\infty}^{+\infty} \mathbb{P}(a_0 > M) = +\infty,$$

which implies by the Borel–Cantelli lemma that almost surely there is no $C > 0$ such that, for all $n \in \mathbb{Z}$, $|a_n| \leq C$. Therefore, the condition given in the definition of exponential stability does not hold when $\varepsilon = 0$. Let us introduce some definitions.

DEFINITION 2.4. *The linear system* (1), (2), *or the sequence* $\{(A_n, B_n), n \in \mathbb{Z}\}$, *is said to be almost surely weakly stabilizable if there is a sequence* $F_n, n \in \mathbb{Z}$, *of* $p \times d$ *random matrices such that, almost surely, the sequence* $\{A_n + B_nF_n, n \in \mathbb{Z}\}$ *is weakly stable. It is called almost surely exponentially stabilizable if, moreover,* $\{A_n + B_nF_n, n \in \mathbb{Z}\}$ *is almost surely exponentially stable and* $\lim_{|n|\to+\infty} \frac{1}{n} \log^+ \|F_n\| = 0$.

These systems, or the sequence $\{(A_n, C_n), n \in \mathbb{Z}\}$, *are said to be almost surely weakly detectable if there is a sequence* (G_n) *of* $d \times q$ *random matrices such that, almost surely,* $\{A_n + G_nC_n, n \in \mathbb{Z}\}$ *is weakly stable. It is called almost surely exponentially detectable if, moreover,* $\{A_n + G_nC_n, n \in \mathbb{Z}\}$ *is almost surely exponentially stable and* $\lim_{|n|\to+\infty} \frac{1}{n} \log^+ \|G_n\| = 0$.

For example, it follows from Proposition 2.2 that if the Lyapunov exponents of the sequence $\{A_n, n \in \mathbb{Z}\}$ are negative, then the system is almost surely exponentially stabilizable and detectable. In the definition of exponential stabilizability, the condition on $\frac{1}{n} \log^+ \|F_n\|$ indicates that these matrices are, in a sense, not too large. It replaces the boundedness assumption of classical systems and can be technically useful (see the proof of Theorem 5.1, for instance). Note that this condition is not required for weak stabilizability. The dual of linear system (2) is

$$x_{n+1} = A^*_{-n}x_n + C^*_{-n}v_n, \qquad y_{n+1} = B^*_{-n}x_n, \tag{5}$$

where $x_n \in \mathbb{R}^d$, $y_n \in \mathbb{R}^p$, and $v_n \in \mathbb{R}^q$. Thus a system is almost surely weakly or exponentially detectable if and only if its dual is almost surely weakly or exponentially stabilizable.

In the following sections the random variables are defined on a probability space $(\Omega, \mathcal{F}, \mathbb{P})$. Usually, we will suppose that the following hypothesis holds (where $\log^+ x = \max(0, \log x)$).

Hypothesis (H).

(i) The matrices A_n are invertible.

(ii) $\log^+ \|A_0\|, \log^+ \|A_0^{-1}\|, \log^+ \|B_0\|$, and $\log^+ \|C_0\|$ are integrable.

(iii) There exists a bijective ergodic transformation $\theta : \Omega \to \Omega$ which preserves $\mathbb{P}$ such that, for any $n \in \mathbb{Z}$ and $\omega \in \Omega$,

$$A_n(\omega) = A_0(\theta^n(\omega)), \quad B_n(\omega) = B_0(\theta^n(\omega)), \quad C_n(\omega) = C_0(\theta^n(\omega)).$$

Under condition (iii) above the sequence $\{(A_n, B_n, C_n), n \in \mathbb{Z}\}$ is stationary and ergodic. Conversely, if this latter property holds there is no loss of generality in supposing that (iii) is true.

3. Weak controllability implies, almost surely, stabilizability. We first define weak controllability and weak observability. Similar notions were already introduced in [5] for slightly different systems.

DEFINITION 3.1. *Let* $R_n = C_n^*C_n$ *and* $S_n = B_nB_n^*$. *The linear system* (1), *or the sequence* $\{(A_n, B_n), n \in \mathbb{Z}\}$, *is said to be weakly controllable if for some* $n \geq 1$,

$$\mathbb{P}(\det\{S_n + A_nS_{n-1}A_n^* + \cdots + (A_n \ldots A_2)S_1(A_2^* \ldots A_n^*)\} \neq 0) \neq 0.$$

This system, or the sequence $\{(A_n, C_n), n \in \mathbb{Z}\}$, *is said to be weakly observable if, for some* $n \geq 1$,

$$\mathbb{P}(\det\{R_1 + A_1^*R_2A_1 + \cdots + (A_1^* \ldots A_{n-1}^*)R_n(A_{n-1} \ldots A_1)\} \neq 0) \neq 0.$$

The dual of a weakly controllable system is weakly observable, and the converse is true as well. The purpose of this section is to prove that a weakly controllable or observable linear system with stationary coefficients is almost surely exponentially stabilizable or detectable, respectively. This result will be obtained as a consequence of a more precise result that will be very useful later. The strategy of the proof is the same as in the classical situation: we shall associate with the system a filtering problem that admits an almost surely exponentially stable closed loop system.

Notation. In all of the following sections $\mathfrak{P}$ denotes the set of $d \times d$ symmetric nonnegative definite matrices. It is equipped with its natural order (i.e., $P \geq Q$ when $P - Q \in \mathfrak{P}$).

For any $n \in \mathbb{Z}$ define $\phi_n : \mathfrak{P} \to \mathfrak{P}$ by

$$(6) \qquad \phi_n(P) = B_n B_n^* + A_n P (I + C_n^* C_n P)^{-1} A_n^*, \qquad P \in \mathfrak{P}.$$

It follows from (3) that Riccati's difference equation can be written as

$$\phi_n(P_n) = P_{n+1}.$$

We shall need the three ensuing lemmas. The first one is well known (see, e.g., Whittle [16, Chap. 5, §2, form. (11)]).

LEMMA 3.2. *Let (P_n) be a solution of the Riccati equation. For any $d \times q$ matrix K,*

$$P_{n+1} \leq (A_n - KC_n) P_n (A_n - KC_n)^* + KK^* + B_n B_n^*,$$

and equality holds when K is equal to the associated gain matrix K_n.

Let us prove the following variant of Lyapunov's lemma.

LEMMA 3.3. *Let $\{(A_n, B_n), n \in \mathbb{Z}\}$ be a weakly controllable sequence. We suppose that there is a sequence $\{Q_n, n \in \mathbb{Z}\}$ of invertible matrices in $\mathfrak{P}$ with the three following properties*:

(a) *for all $n \in \mathbb{Z}$, $Q_{n+1} = A_n Q_n A_n^* + B_n B_n^*$*;

(b) *the sequence $\{(A_n, B_n, Q_n), n \in \mathbb{Z}\}$ is stationary and ergodic*;

(c) *almost surely, $\lim_{|n| \to +\infty} \frac{1}{n} \log^+ \|Q_n\| = \lim_{|n| \to +\infty} \frac{1}{n} \log^+ \|Q_n^{-1}\| = 0$.*

Then the sequence $\{A_n, n \in \mathbb{Z}\}$ is almost surely exponentially stable.

Proof. Let us introduce the following notation: for $n \in \mathbb{Z}$ *and* $r \in \mathbb{N}$,

$$M_n = Q_{n+1}^{-\frac{1}{2}} A_n Q_n^{\frac{1}{2}}, \qquad T_n = Q_{n+1}^{-\frac{1}{2}} B_n B_n^* Q_{n+1}^{-\frac{1}{2}},$$

$$M_{n,r} = M_n M_{n-1} \ldots M_{n-r+1}, \qquad T_{n,r} = \sum_{i=0}^{r} M_{n,i} T_{n-i} M_{n,i}^*.$$

Then $I = M_n M_n^* + T_n$ and, more generally, $I = M_{n,r} M_{n,r}^* + T_{n,r}$, where I is the identity matrix. Hence $\|M_{n,r}\| \leq 1$. On the other hand, since $\{(A_n, B_n), n \in \mathbb{Z}\}$ is weakly controllable, there exists some $k > 0$ such that $\mathbb{P}(T_{n,k}$ is invertible$) \neq 0$ and thus $\mathbb{P}(\|M_{n,k}\| < 1) \neq 0$. These relations imply that the Lyapunov exponents of the stationary sequence (M_n) are negative. Therefore, this sequence is almost surely exponentially stable by Proposition 2.2. Since

$$\begin{aligned} \|A_n \ldots A_k\| &= \|Q_{n+1}^{\frac{1}{2}} M_n \ldots M_k Q_k^{-\frac{1}{2}}\| \\ &\leq \|Q_{n+1}^{\frac{1}{2}}\| \cdot \|M_n \ldots M_k\| \cdot \|Q_k^{-\frac{1}{2}}\|, \end{aligned}$$

it then follows from (c) that (A_n) is almost surely exponentially stable. □

The following lemma is from Wos [18]. To obtain this formulation we apply his Theorem 2 to $f = g \circ \theta - g$.

LEMMA 3.4 (Wos). *For any measurable function* $g\colon \Omega \to \mathbb{R}^+$, *if* $\limsup_{n\to+\infty} \frac{1}{n} g\circ\theta^n = 0$ *almost surely then* $\limsup_{n\to+\infty} \frac{1}{n} g\circ\theta^{-n} = 0$ almost surely.

We now derive a slight improvement of [5]. It will be generalized in §5.

THEOREM 3.5. *We consider a weakly controllable and weakly observable linear system such that Hypothesis* (H) *holds. Then there exists a unique solution* $\{\bar{P}_n, n\in\mathbb{Z}\}$ *of the Riccati difference equation* (4) *with values in* $\mathfrak{P}$ *such that* $\{(A_n, B_n, C_n, \bar{P}_n), n\in\mathbb{Z}\}$ *is a stationary and ergodic sequence. Moreover, almost surely* $\bar{P}_n$ *is invertible,*

$$\lim_{|n|\to\infty} \frac{1}{n} \log^+ \|\bar{P}_n\| = \lim_{|n|\to\infty} \frac{1}{n} \log^+ \|\bar{P}_n^{-1}\| = 0, \tag{7}$$

and the sequence $\{A_n - \bar{K}_n C_n, n\in\mathbb{Z}\}$ *is almost surely exponentially stable, where* $\bar{K}_n$ *is the gain matrix associated with* $\bar{P}_n$.

Proof. Let $S_n = B_n B_n^*$ and $R_n = C_n^* C_n$. We consider the equation

$$Q_{n+1} = (A_n Q_n A_n^* + S_n)(I + R_{n+1} A_n Q_n A_n^* + R_{n+1} S_n)^{-1}, \tag{8}$$

where $Q_n \in \mathfrak{P}$ (notice the occurrence of R_{n+1}). It follows from [3, Thm. 2.4] that this equation has a unique stationary solution, say $\{\bar{Q}_n, n\in\mathbb{Z}\}$. By construction, $\bar{Q}_n = \bar{Q}_0 \circ \theta^n$, which implies that the sequence $\{(A_n, B_n, C_n, \bar{Q}_n), n\in\mathbb{Z}\}$ is stationary and ergodic. Moreover, by [3, Prop. 3.4 and form. (24)], almost surely,

$$\lim_{n\to+\infty} \frac{1}{n} \log^+ \|\bar{Q}_n\| = \lim_{n\to+\infty} \frac{1}{n} \log^+ \|\bar{Q}_n^{-1}\| = 0.$$

It follows from Lemma 3.4 that, almost surely,

$$\lim_{n\to+\infty} \frac{1}{n} \log^+ \|\bar{Q}_{-n}\| = \lim_{n\to+\infty} \frac{1}{n} \log^+ \|\bar{Q}_{-n}^{-1}\| = 0.$$

Now, we remark that (Q_n) is a solution of (8) if and only if $P_n = A_{n-1} Q_{n-1} A_{n-1}^* + S_{n-1}$ is a solution of the Riccati recursion (4). Therefore, $\bar{P}_n = A_{n-1}\bar{Q}_{n-1}A_{n-1}^* + S_{n-1}$ is the unique stationary solution of (4). We check that (7) holds true with the relations above and Lemma 2.3. The sequence $\{(A_n, B_n), n\in\mathbb{Z}\}$ is weakly controllable, thus the sequence $\{(A_n, (B_n\, \bar{K}_n)), n\in\mathbb{Z}\}$ is also weakly controllable. By making use of the relation

$$A_n - \bar{K}_n C_n = A_n - (B_n\, \bar{K}_n)(0\, C_n^*)^*,$$

it follows from Anderson and Moore [2, Lem. 3.1] that $\{(A_n - \bar{K}_n C_n, (B_n\, \bar{K}_n)), n\in\mathbb{Z}\}$ is also weakly controllable. Since, by Lemma 3.2,

$$\bar{P}_{n+1} = (A_n - \bar{K}_n C_n)\bar{P}_n(A_n - \bar{K}_n C_n)^* + \bar{K}_n \bar{K}_n^* + B_n B_n^*,$$

the almost sure exponential stability of $(A_n - \bar{K}_n C_n)$ is a consequence of Lemma 3.3 above. □

THEOREM 3.6. *Under Hypothesis* (H), *a weakly controllable sequence is almost surely exponentially stabilizable, and a weakly observable sequence is almost surely exponentially detectable.*

Proof. Let us suppose that the sequence $\{(A_n, C_n), n\in\mathbb{Z}\}$ is weakly observable and show that this sequence is almost surely detectable. Let B_n be equal to the identity matrix of order d. Then the system associated with (A_n, B_n, C_n) is weakly observable and weakly controllable. Thus, by Theorem 3.5, $\{A_n - \bar{K}_n C_n, n\in\mathbb{Z}\}$ is almost surely exponentially stable, where $\bar{K}_n$ is the gain matrix associated with $\bar{P}_n$. On the other hand, $\|(I+C_n\bar{P}_nC_n^*)^{-1}\| \leq 1$ so that

$$\log\|\bar{K}_n\| \leq \log\|\bar{P}_n\| + \log\|C_n\| + \log\|A_n\|.$$

Using (7) and Lemma 2.3, we see that almost surely $\lim_{|n|\to\infty} \frac{1}{n}\log^+\|\bar{K}_n\| = 0$. The almost sure exponential detectability is thus proved. The other statement follows by duality. □

4. Almost sure weak stabilizability implies almost sure exponential stabilizability.

LEMMA 4.1. *Consider a sequence $\{M_n, n\in\mathbb{Z}\}$ of $d\times d$ matrices written in block form as*

$$M_n = \begin{pmatrix} A_n & B_n \\ 0 & C_n \end{pmatrix},$$

where the respective sizes of the matrices A_n, B_n, C_n are $p\times p$, $p\times q$, $q\times q$ (and $p+q=d$). We suppose that the sequences $\{A_n, n\in\mathbb{Z}\}$ and $\{C_n, n\in\mathbb{Z}\}$ are exponentially stable and that $\lim_{|n|\to+\infty}\frac{1}{n}\log^+\|B_n\| = 0$. Then $\{M_n, n\in\mathbb{Z}\}$ is exponentially stable.

Proof. For all $k,n\in\mathbb{Z}$ such that $k<n$, we consider the matrices $A_{n,k}$, $B_{n,k}$, and $C_{n,k}$, defined by the formula

$$\begin{pmatrix} A_{n,k} & B_{n,k} \\ 0 & C_{n,k} \end{pmatrix} = M_nM_{n-1}\dots M_{k+1}.$$

Since the sequences (A_n) and (C_n) are exponentially stable, there exists $\gamma>0$ such that, for any $\varepsilon>0$ and some $\alpha>0$,

$$\|A_{n,k}\| \leq \alpha e^{(k-n)\gamma+(|n|+|k|)\varepsilon}, \qquad \|C_{n,k}\| \leq \alpha e^{(k-n)\gamma+(|n|+|k|)\varepsilon},$$

when $k<n$. Besides, there exists $\beta>0$ such that $\|B_n\|\leq\beta e^{|n|\varepsilon}$ for all $n\in\mathbb{Z}$. Let $\mu>0$ be a constant such that $r\leq\mu e^{r\varepsilon}$ for any $r\in\mathbb{N}$. It is readily seen that $B_{n,k} = \sum_{m=k+1}^{n} A_{n,m}B_mC_{m-1,k}$, therefore,

$$\begin{aligned}\|B_{n,k}\| &\leq \alpha^2\beta e^{(k-n)\gamma}\sum_{m=k+1}^{n} e^{\gamma+(|m-1|+2|m|+|k|+|n|)\varepsilon} \\ &\leq \alpha^2\beta|n-k|e^{(k+1-n)\gamma}e^{4(|k|+|n|)\varepsilon} \\ &\leq \alpha^2\beta\mu e^{(k+1-n)\gamma}e^{5(|k|+|n|)\varepsilon}.\end{aligned}$$

Since all the norms on a finite-dimensional space are equivalent, there exists a universal constant λ such that

$$\|M_nM_{n-1}\dots M_{k+1}\| \leq \lambda\max\{\|A_{n,k}\|, \|B_{n,k}\|, \|C_{n,k}\|\}.$$

Thus, the previous inequalities imply that (M_n) is exponentially stable. □

The next proposition is inspired by the canonical structure theorem of linear systems.

PROPOSITION 4.2. *Consider a linear system* (1) *for which Hypothesis* (H) *holds true. Then there exists a random orthogonal matrix Γ_0 such that, if $\Gamma_n = \Gamma_0\circ\theta^n$ for all $n\in\mathbb{Z}$, we can write the ensuing decompositions in blocks as follows*:

$$\Gamma_n^{-1}A_n\Gamma_{n-1} = \begin{pmatrix} A_n^{1,1} & 0 & A_n^{1,3} \\ A_n^{2,1} & A_n^{2,2} & A_n^{2,3} \\ 0 & 0 & A_n^{3,3} \end{pmatrix}, \qquad \Gamma_n^{-1}B_n = \begin{pmatrix} B_n^{1,1} \\ B_n^{2,1} \\ 0 \end{pmatrix},$$

$$C_n\Gamma_{n-1} = (C_n^{1,1} \quad 0 \quad C_n^{1,3}),$$

where the following three properties hold:

(a) *The linear system associated with the sequence* $\{(\tilde{A}_n, \tilde{B}_n, \tilde{C}_n), n \in \mathbb{Z}\}$ *is weakly controllable*, *where*

$$\tilde{A}_n = \begin{pmatrix} A_n^{1,1} & 0 \\ A_n^{2,1} & A_n^{2,2} \end{pmatrix}, \quad \tilde{B}_n = \begin{pmatrix} B_n^{1,1} \\ B_n^{2,1} \end{pmatrix}, \quad \tilde{C}_n = (C_n^{1,1}\, 0).$$

(b) *The linear system associated with* $\{(A_n^{1,1}, B_n^{1,1}, C_n^{1,1}), n \in \mathbb{Z}\}$ *is weakly controllable and weakly observable.*

(c) *If the linear system associated with* $\{(A_n, B_n, C_n), n \in \mathbb{Z}$ *is almost surely weakly stabilizable or almost surely weakly detectable, then* $\{A_n^{3,3}, n \in \mathbb{Z}\}$ *or* $\{A_n^{2,2}, n \in \mathbb{Z}\}$ *is almost surely exponentially stable*, *respectively*.

Proof. For each $\omega \in \Omega$ and each $n \in \mathbb{Z}$, let $W_n(\omega)$ be the linear subspace of $\mathbb{R}^d$ spanned by

$$\{A_n(\omega)A_{n-1}(\omega)\ldots A_{n-k+1}(\omega)B_{n-k}(\omega)x; x \in \mathbb{R}^d, k \in \mathbb{N}\}.$$

Then $W_n = W_0 \circ \theta^n$, where θ is the transformation that appears in assumption (iii) of Hypothesis (H). We remark that $A_1 W_0$ is contained in W_1. Since A_1 is invertible, this implies that dim $W_0 \leq$ dim W_1. Thus, by ergodicity there exists an integer $r \in [0, d]$ such that dim $W_0 = r$ almost surely. Let V be the linear subspace of $\mathbb{R}^d$ spanned by the first r vectors of the canonical basis. We choose a random orthogonal matrix Q_0 such that $Q_0 V = W_0$, and set $Q_n = Q_0 \circ \theta^n$ for each $n \in \mathbb{Z}$. Then $Q_n V = W_n$, and thus $Q_n^{-1} A_n Q_{n-1} V$ is contained in V. Moreover, the image of $Q_n^{-1} B_n$ is contained in V, since the image of B_n is contained in W_n. Therefore, we can write the following in block form:

$$Q_n^{-1} A_n Q_{n-1} = \begin{pmatrix} A_n^1 & A_n^2 \\ 0 & A_n^3 \end{pmatrix}, \quad Q_n^{-1} B_n = \begin{pmatrix} B_n^1 \\ 0 \end{pmatrix}, \quad C_n Q_{n-1} = (C_n^1\, C_n^2),$$

where, for example, the respective size of the matrices A_n^1, B_n^1, and C_n^1 is $r \times r$, $r \times p$, and $q \times r$. Since V is spanned by the ranges of the matrices $A_0^1(\omega)\ldots A_{-k+1}^1(\omega)B_{-k}^1(\omega)$, $k \in \mathbb{N}$, we see that $\{(A_n^1, B_n^1, C_n^1)\}$ is weakly controllable.

Let us now suppose that the system associated with (A_n, B_n, C_n) is almost surely weakly stabilizable. Then, by definition, there is a sequence $\{F_n, n \in \mathbb{Z}\}$ such that $\{A_n + B_n F_n, n \in \mathbb{Z}\}$ is almost surely weakly stable. Of course, $\{Q_n^{-1}(A_n + B_n F_n) Q_{n-1}, n \in \mathbb{Z}\}$ is then also almost surely weakly stable. If we write in block form $F_n Q_{n-1} = (F_n^1\, F_n^2)$, where F_n^1 and F_n^2 are $p \times r$ and $(d - p) \times r$ matrices, respectively, then

$$Q_n^{-1}(A_n + B_n F_n) Q_{n-1} = \begin{pmatrix} A_n^1 + B_n^1 F_n^1 & A_n^2 + B_n^1 F_n^2 \\ 0 & A_n^3 \end{pmatrix}.$$

This means that the sequence (A_n^3) is almost surely weakly stable. Since $\log^+ \|A_0^3\|$ is integrable, this sequence is also almost surely exponentially stable by Proposition 2.2.

If we apply the previous construction to the dual of the system associated with $\{(A_n^1, B_n^1, C_n^1), n \in \mathbb{Z}\}$, we find that there exists a sequence $\Lambda_n, n \in \mathbb{Z}$, of $p \times p$ orthogonal matrices such that $\Lambda_n = \Lambda_0 \circ \theta^n$, and we can write

$$\Lambda_n^{-1} A_n^1 \Lambda_{n-1} = \begin{pmatrix} A_n^{1,1} & 0 \\ A_n^{2,1} & A_n^{2,2} \end{pmatrix}, \quad \Lambda_n^{-1} B_n^1 = \begin{pmatrix} B_n^{1,1} \\ B_n^{2,1} \end{pmatrix}, \quad C_n^1 \Lambda_{n-1} = (C_n^{1,1}\, 0),$$

where the system $\{(A_n^{1,1}, B_n^{1,1}, C_n^{1,1})\}$ is weakly observable. Let

$$\Gamma_n = Q_n \begin{pmatrix} \Lambda_n & 0 \\ 0 & I \end{pmatrix}.$$

Then the decompositions in blocks hold. The proof is completed by simple computation. □

THEOREM 4.3. *Under Hypothesis* (H), *an almost surely weakly stabilizable or detectable system is almost surely exponentially stabilizable or detectable, respectively.*

Proof. We consider a system associated with (A_n, B_n, C_n) and use the decomposition introduced in Proposition 4.2. Since $\{(\tilde{A}_n, \tilde{B}_n, \tilde{C}_n), n \in \mathbb{Z}\}$ is weakly controllable, it follows from Theorem 3.6 that this sequence is almost surely exponentially stabilizable. Thus, there is a sequence $\{\tilde{F}_n, n \in \mathbb{Z}\}$ such that $\lim_{|n|\to\infty} \frac{1}{n} \log^+ \|\tilde{F}_n\| = 0$ and $\{\tilde{A}_n + \tilde{B}_n\tilde{F}_n, n \in \mathbb{Z}\}$ is almost surely exponentially stable. Now we suppose that the original system is weakly stabilizable. Then $(A_n^{3,3})$ is also almost surely exponentially stable. Let

$$D_n = \begin{pmatrix} A_n^{1,3} \\ A_n^{2,3} \end{pmatrix}, \qquad F_n = (\tilde{F}_n\, 0)\Gamma_{n-1}^{-1}.$$

Since $\lim_{|n|\to\infty} \frac{1}{n} \log^+ \|D_n\| = 0$ by Lemma 2.3, and

$$A_n + B_nF_n = \Gamma_n \begin{pmatrix} \tilde{A}_n + \tilde{B}_n\tilde{F}_n & D_n \\ 0 & A_n^{3,3} \end{pmatrix} \Gamma_{n-1}^{-1},$$

we deduce from Lemma 4.1 that $\{A_n + B_nF_n, n \in \mathbb{Z}\}$ is an almost surely exponentially stable sequence. This proves that the system is almost surely exponentially stabilizable. The other statement is obtained by duality.

Remark 4.4. Let us consider an almost surely weakly stabilizable and detectable system. It is possible to prove that all the Lyapunov exponents of the associated Hamiltonian matrices are nonzero by using Proposition 4.2 and [3]. We will not use this fact and refer to [3] for the details of this statement.

5. Asymptotic behavior of the Riccati difference equation. In this section we establish the main properties of the Riccati equation under the assumption that the system is weakly stabilizable and detectable almost surely. For each $\omega \in \Omega$, these conditions on the parameters $(A_n(\omega), B_n(\omega), C_n(\omega))$ are very weak. Therefore, the following theorem cannot be deduced from existing results on time-varying systems. Below $\bar{K}_n$ is the gain matrix associated with $\bar{P}_n$.

THEOREM 5.1. *We consider linear system* (1). *We suppose that Hypothesis* (H) *holds and that this system is weakly stabilizable and weakly detectable almost surely. Then there exists a unique stationary process* $\{\bar{P}_n, n \in \mathbb{Z}\}$ *with values in* $\mathfrak{P}$ *that is a solution of Riccati's difference equation* (4). *The process* $\{(A_n, B_n, C_n, \bar{P}_n), n \in \mathbb{Z}\}$ *is stationary ergodic, and* $\{A_n - \bar{K}_nC_n, n \in \mathbb{Z}\}$ *is almost surely exponentially stable.*

Proof. It is well known that the mappings $\phi_n : \mathfrak{P} \to \mathfrak{P}$ defined by (6) are increasing for the usual order on $\mathfrak{P}$ (this follows, for instance, from Lemma 3.2). Therefore, for each fixed $n \in \mathbb{Z}$, the sequence of nonnegative symmetric matrices

$$P_{n,k} = (\phi_{n-1} \circ \phi_{n-2} \circ \cdots \circ \phi_{n-k})(0), \qquad k \geq 1,$$

is increasing in $\mathfrak{P}$. Since, by Theorem 4.3, the system is almost surely exponentially detectable, there exists a sequence $\{G_n, n \in \mathbb{Z}\}$ of $d \times q$ matrices such that $\{A_n - G_nC_n, n \in \mathbb{Z}\}$ is almost surely exponentially stable and $\lim_{|n|\to+\infty} \frac{1}{n}\log^+ \|G_n\| = 0$. Let $M_n = A_n - G_nC_n$ and $T_n = G_nG_n^* + B_nB_n^*$. Lemma 3.2 gives

$$P_{n,k} \leq T_{n-1} + M_{n-1}P_{n-1,k-1}M_{n-1}^*,$$

which leads, by induction, to

$$P_{n,k} \leq T_{n-1} + M_{n-1}T_{n-2}M_{n-1}^* + \cdots + (M_{n-1}\dots M_{n-k+1})T_{n-k}(M_{n-k+1}^*\dots M_{n-1}^*).$$

Since (M_n) is almost surely exponentially stable, there exists $\gamma > 0$ such that, almost surely, for any $\varepsilon > 0$ and some $\alpha \geq 1$,

$$\|M_{n-1}\dots M_{n-m}\| \leq \alpha\, e^{-\gamma m}\, e^{(|n|+m)\varepsilon}$$

for all $n \in \mathbb{Z}$ and $m \geq 1$. On the other hand, it follows from integrability condition (ii) of Hypothesis (H) and from Lemma 2.3 that, almost surely, for some $\beta > 0$, $\|T_n\| \leq \beta e^{\varepsilon|n|}$ for all $n \in \mathbb{Z}$. These inequalities yield that, almost surely,

$$\|P_{n,k}\| \leq \alpha^2\beta \sum_{m=0}^{k-1} e^{-2\gamma m} e^{3(|n|+m+1)\varepsilon},$$

and, if $3\varepsilon < 2\gamma$,

$$\|P_{n,k}\| \leq \alpha^2\beta\, e^{3(|n|+1)\varepsilon}\{1 - e^{(3\varepsilon-2\gamma)}\}^{-1}. \tag{9}$$

This shows that the increasing sequence $P_{n,k}, k \in \mathbb{N}$, is bounded. Therefore, this sequence converges almost surely when $k \to +\infty$ to a limit in $\mathfrak{P}$, denoted by $\bar{P}_n$. Since $\phi_n(\bar{P}_n) = \bar{P}_{n+1}$, $\{\bar{P}_n, n \in \mathbb{Z}\}$ is a solution of Riccati's difference equation. It follows from condition (iii) of Hypothesis (H) that, for each $n \in \mathbb{Z}$, $\bar{P}_n = \bar{P}_0 \circ \theta^n$. This implies that $\{(A_n, B_n, C_n, \bar{P}_n), n \in \mathbb{Z}\}$ is a stationary ergodic process. Inequality (9) is also satisfied by $\bar{P}_n$, and therefore, almost surely,

$$\lim_{|n|\to+\infty} \frac{1}{n}\log^+ \|\bar{P}_n\| = 0. \tag{10}$$

Let us now prove that $\{A_n - \bar{K}_nC_n, n \in \mathbb{Z}\}$ is almost surely exponentially stable. We will use Proposition 4.2 and its notation. First, we remark that if (P_n) and (K_n) are solutions of the Riccati equation associated with the sequence $\{(A_n, B_n, C_n), n \in \mathbb{Z}\}$, then $(\Gamma_{n-1}P_n\Gamma_{n-1}^{-1})$ and $(\Gamma_n^{-1}K_n)$ are solutions of the Riccati equation associated with $\{(\Gamma_n^{-1}A_n\Gamma_{n-1}, \Gamma_n^{-1}B_n, C_n\Gamma_{n-1}), n \in \mathbb{Z}\}$. Making use of this remark and writing the matrices $\Gamma_{n-1}P_{n,k}\Gamma_{n-1}^{-1}$ in block form, it is easily seen that we can write

$$\Gamma_{n-1}\bar{P}_n\Gamma_{n-1}^{-1} = \begin{pmatrix} \bar{P}_n^{1,1} & \bar{P}_n^{1,2} & 0 \\ \bar{P}_n^{2,1} & \bar{P}_n^{2,2} & 0 \\ 0 & 0 & 0 \end{pmatrix}, \qquad \Gamma_n^{-1}\bar{K}_n = \begin{pmatrix} \bar{K}_n^{1,1} \\ \bar{K}_n^{2,1} \\ 0 \end{pmatrix}, \tag{11}$$

where

$$\bar{P}_n^1 = \begin{pmatrix} \bar{P}_n^{1,1} & \bar{P}_n^{1,2} \\ \bar{P}_n^{2,1} & \bar{P}_n^{2,2} \end{pmatrix}$$

is a solution of the Riccati equation associated with $\{(\tilde{A}_n, \tilde{B}_n, \tilde{C}_n), n \in \mathbb{Z}\}$. Moreover, $(\bar{P}_n^{1,1})$ is a stationary solution of the Riccati equation associated with the sequence $(A_n^{1,1}, B_n^{1,1}, C_n^{1,1})$, and $\bar{K}_n^{1,1}$ is the associated gain matrix. Since $\{(A_n^{1,1}, B_n^{1,1}, C_n^{1,1}), n \in \mathbb{Z}\}$ is weakly controllable and weakly observable (see Proposition 4.2), it follows from Theorem 3.5 that $\{A_n^{1,1} - \bar{K}_n^{1,1}C_n^{1,1}, n \in \mathbb{Z}\}$ is almost surely exponentially stable. We note that

$$\Gamma_n^{-1}(A_n - \bar{K}_nC_n)\Gamma_{n-1} = \begin{pmatrix} A_n^{1,1} - \bar{K}_n^{1,1}C_n^{1,1} & 0 & A_n^{1,3} - \bar{K}_n^{1,1}C_n^{1,3} \\ A_n^{2,1} - \bar{K}_n^{2,1}C_n^{1,1} & A_n^{2,2} & A_n^{2,3} - \bar{K}_n^{2,1}C_n^{1,3} \\ 0 & 0 & A_n^{3,3} \end{pmatrix}.$$

The sequences $(A_n^{2,2})$ and $(A_n^{3,3})$ are almost surely exponentially stable by Proposition 4.2. On the other hand, it is easy to deduce from Lemma 2.3 and (10) that, almost surely,

$$\lim_{|n|\to+\infty} \frac{1}{n} \log^+ \|A_n - \bar{K}_nC_n\| = 0.$$

Thus it follows from Lemma 4.1 that the sequence

$$\begin{pmatrix} A_n^{1,1} - \bar{K}_n^{1,1}C_n^{1,1} & 0 \\ A_n^{2,1} - \bar{K}_n^{2,1}C_n^{1,1} & A_n^{2,2} \end{pmatrix}$$

is also almost surely exponentially stable. This in turn implies $\Gamma_n^{-1}(A_n - \bar{K}_nC_n)\Gamma_{n-1}$, and thus $A_n - \bar{K}_nC_n$ is almost surely exponentially stable by another application of Lemma 4.1. The matrices Γ_n are orthogonal, thus $\{A_n - \bar{K}_nC_n, n \in \mathbb{Z}\}$ is also almost surely exponentially stable.

Finally, let us prove that $(\bar{P}_n)$ is the unique stationary solution of Riccati's equation. Let (P_n) be another stationary solution. It follows from Lemma 3.2 that

$$(12) \qquad P_{n+1} - \bar{P}_{n+1} \leq (A_n - \bar{K}_nC_n)(P_n - \bar{P}_n)(A_n - \bar{K}_nC_n)^*.$$

This implies that, for $n \geq 0$, if $D_n = (A_{-1} - \bar{K}_{-1}C_{-1})\dots(A_{-n} - \bar{K}_{-n}C_{-n})$, then

$$P_0 - \bar{P}_0 \leq D_n(P_{-n} - \bar{P}_{-n})D_n^*.$$

By stationarity, $P_{-n} - \bar{P}_{-n}$ is bounded in probability. Since D_n converges to 0 almost surely, the right-hand side above converges to 0 in probability as $n \to +\infty$. This proves that $P_0 \leq \bar{P}_0$. On the other hand, for all $k \geq 1$, since $P_{-k} \geq 0$,

$$P_0 = (\phi_{-1} \circ \cdots \circ \phi_{-k})(P_{-k}) \geq (\phi_{-1} \circ \cdots \circ \phi_{-k})(0) = P_{0,k},$$

hence $P_0 \geq \bar{P}_0$ since $P_{0,k}$ converges to $\bar{P}_0$ as $k \to +\infty$. This proves that $P_0 = \bar{P}_0$. □

LEMMA 5.2. *Consider a weakly controllable system. Let $P_n, n \geq 0$, be the solution of the Riccati equation* (4) *such that $P_0 = 0$. Then, almost surely, P_n is positive definite for all $n \geq 0$ large enough.*

Proof. The sequence $Q_n = P_n(I + R_nP_n)^{-1}, n \in \mathbb{N}$, is a solution of the difference equation (8). Using the weak controllability assumption, we deduce from [3, Prop. 1.5 (ii) and Lem. 2.2], that, almost surely, Q_n is positive definite for all n large enough, which implies Lemma 5.2. □

The following demonstration is inspired by a proof presented in Anderson and Moore [1, § 4.4] for systems with constant coefficients.

THEOREM 5.3. *Under the assumptions of Theorem* 5.1, *there exists $\gamma > 0$ such that, for any $P \in \mathfrak{P}$ almost surely,*

$$(13) \qquad \overline{\lim_{n\to+\infty}} \frac{1}{n} \log \|\bar{P}_n - P_n\| \leq -\gamma,$$

where $P_n, n \in \mathbb{N}$, is the solution of the Riccati equation for which $P_0 = P$.

Proof. We will need the following two classical relations:

$$P_{n+1} \geq (A_n - K_n C_n) P_n (A_n - K_n C_n)^*, \tag{14}$$

$$P_{n+1} - \bar{P}_{n+1} = (A_n - K_n C_n)(P_n - \bar{P}_n)(A_n - \bar{K}_n C_n)^*. \tag{15}$$

Relation (14) follows immediately from Lemma 3.2. On the other hand, since P_n and $\bar{P}_n$ are solutions of (4),

$$P_{n+1} - \bar{P}_{n+1} = (A_n - K_n C_n) P_n A_n^* - A_n \bar{P}_n (A_n - \bar{K}_n C_n)^*,$$
$$(A_n - K_n C_n) P_n C_n^* \bar{K}_n^* = K_n \bar{K}_n^* = K_n C_n \bar{P}_n (A_n - \bar{K}_n C_n)^*,$$

which yields (15). Since the sequence $(A_n - \bar{K}_n C_n)$ is almost surely exponentially stable, we deduce from (10) and (12) that, almost surely,

$$\lim_{n \to +\infty} \frac{1}{n} \log^+ \|P_n\| = 0.$$

Let us first suppose that for some (maybe random) index $k \geq 0$, P_k is positive definite. Then, by (14) the previous relation leads to

$$\lim_{n \to +\infty} \frac{1}{n} \log^+ \|(A_n - K_n C_n)(A_{n-1} - K_{n-1} C_{n-1}) \dots (A_k - K_k C_k)\| = 0.$$

In this case, the conclusion of the theorem follows immediately from (15) and the exponential stability of the sequence $(A_n - \bar{K}_n C_n)$. In particular, it holds true when P is nondegenerate.

Now, let us suppose that $P = 0$. By making use of Proposition 4.2 and its notation (see also (11)), we can write the block decomposition

$$\Gamma_{n-1} P_n \Gamma_{n-1}^{-1} = \begin{pmatrix} P_n^1 & 0 \\ 0 & 0 \end{pmatrix}, \qquad \Gamma_{n-1} \bar{P}_n \Gamma_{n-1}^{-1} = \begin{pmatrix} \bar{P}_n^1 & 0 \\ 0 & 0 \end{pmatrix},$$

where $\{P_n^1, n \geq 0\}$ is the solution of the Riccati equation associated with the weakly controllable sequence $(\tilde{A}_n, \tilde{B}_n, \tilde{C}_n)$ that satisfies $P_0^1 = 0$, and where $(\bar{P}_n^1)$ is its stationary solution. Therefore, in order to prove that (13) holds when $P = 0$, it suffices to consider weakly controllable systems. In this case, it follows from Lemma 5.2 that, almost surely, P_k is nondegenerate for some $k > 0$ large enough. Thus we deduce from the first part of the proof that the theorem also holds when $P = 0$.

Finally, let P be an arbitrary matrix in $\mathfrak{P}$. Let P_n^0, P_n, or P_n', be the solutions of the Riccati equation such that $P_0^0 = 0$, $P_0 = P$, or $P_0' = P + I$, respectively. Then the relation $P_0^0 \leq P_0 \leq P_0'$ and the monotonicity of the transformations ϕ_n imply that $P_n^0 \leq P_n \leq P_n'$. Thus

$$\|P_n - \bar{P}_n\| \leq \max(\|P_n^0 - \bar{P}_n\|, \|P_n' - \bar{P}_n\|).$$

Since $P_0^0 = 0$ and P_0' is nondegenerate, we have just proved that (13) holds for (P_n^0) and for (P_n'). It follows from this inequality that it also holds for (P_n). □

We now consider the filtering setup. Let us suppose that X_0 is a Gaussian vector with mean $\hat{X}_0$ and covariance matrix P_0, and let $\hat{X}_n = \mathbb{E}(X_n / \mathcal{F}_n)$. We know that, conditionally on $\mathcal{F}_n$, the random vector $X_n - \hat{X}_n$ has a Gaussian law with mean 0 and covariance matrix equal to P_n. Therefore, for any $y \in \mathbb{R}^d$,

$$\mathbb{E}(\exp(i\langle y, X_n - \hat{X}_n \rangle)) = \mathbb{E}(\mathbb{E}(\exp(i\langle y, X_n - \hat{X}_n \rangle)/\mathcal{F}_n))$$
$$= \mathbb{E}\left(\exp\left(-\frac{1}{2}\langle y, P_n y \rangle\right)\right).$$

Thus the following corollary follows from the previous theorem.

COROLLARY 5.4. *Under the assumptions of Theorem* 5.1, $X_n - \hat{X}_n$ *converges in distribution to the probability measure* μ *on* $\mathbb{R}^d$ *with Fourier transform given by the following: for any* $y \in \mathbb{R}^d$,

$$\int e^{i\langle y,x\rangle}\, d\mu(x) = \mathbb{E}\left(\exp\left(-\frac{1}{2}\langle y, \bar{P}_0 y\rangle\right)\right).$$

The adaptation of Definition 1.1 to sequences indexed by $\mathbb{N}$ is obvious. Of course the following lemma also holds for sequences indexed by $\mathbb{Z}$, but we shall need this setup.

LEMMA 5.5. *Let* $\{A_n, n \in \mathbb{N}\}$ *and* $\{B_n, n \in \mathbb{N}\}$ *be two sequences of* $d \times d$ *matrices. If* $\{A_n, n \in \mathbb{N}\}$ *is exponentially stable and* $\limsup_{n\to+\infty} \frac{1}{n}\log\|B_n\| < 0$, *then* $\{A_n + B_n, n \in \mathbb{N}\}$ *is also exponentially stable.*

Proof. There exists $\gamma > 0$ such that, for any $\varepsilon > 0$ for some $C > 0$,

$$\|A_p \dots A_{q+1}\| \le Ce^{p\varepsilon}e^{(q-p)\gamma},$$

for all $0 \le q < p$. When $0 \le q < p-1$, let $M_{p,q} = B_pA_{p-1}\dots A_{q+2}A_{q+1}$ and $M_{p,p-1} = B_p$. Then, $\|M_{p,q}\| \le \xi_p e^{(q-p+1)\gamma}$, where $\xi_p = Ce^{p\varepsilon}\|B_p\|$. If $0 \le k < n$, then

$$\begin{aligned}(A_n + {}&B_n)\dots(A_{k+1} + B_{k+1})\\ &= \sum_{m=0}^{n-k}\sum_{k<r_1<\cdots<r_m\le n} A_n \dots A_{r_m+1}M_{r_m,r_{m-1}}M_{r_{m-1},r_{m-2}}\dots M_{r_1,k}.\end{aligned}$$

Thus we have

$$\begin{aligned}&\|(A_n + B_n)\dots(A_{k+1} + B_{k+1})\|\\ &\le \sum_{m=0}^{n-k}\sum_{k<r_1<\cdots<r_m\le n} Ce^{n\varepsilon}e^{(r_m-n)\gamma}\xi_{r_m}e^{(r_{m-1}-r_m+1)\gamma}\dots\xi_{r_1}e^{(k-r_1+1)\gamma}\\ &= Ce^{n\varepsilon}(e^{-\gamma} + \xi_n)\dots(e^{-\gamma} + \xi_{k+1})\\ &\le Ce^{n\varepsilon}e^{(k-n)\gamma}\prod_{r=1}^{+\infty}(1 + e^{\gamma}\xi_r).\end{aligned}$$

When ε is small enough the infinite product converges, since $\|B_n\|$ tends to 0 exponentially fast. This proves that the sequence $(A_n + B_n)$ is exponentially stable. □

THEOREM 5.6. *We suppose that Hypothesis* (H) *holds and the system is weakly stabilizable and weakly detectable almost surely. Then, for any* $P \in \mathfrak{P}$, *the sequence* $\{A_n - K_nC_n, n \in \mathbb{N}\}$ *is almost surely exponentially stable, where* $K_n, n \in \mathbb{N}$, *are the gain matrices associated with the Riccati equation* (4) *for which* $P_0 = P$.

Proof. Riccati's equation can be written as

$$P_{n+1} - B_nB_n^* = (A_n - K_nC_n)P_nA_n^*, \qquad K_n = (A_n - K_nC_n)P_nC_n^*.$$

Therefore, $K_n = (P_{n+1} - B_nB_n^*)A_n^{*-1}C_n^*$. This yields that, if $\bar{K}_n$ is the gain matrix associated with the stationary solution $\bar{P}_n$, then

$$\|(A_n - \bar{K}_nC_n) - (A_n - K_nC_n)\| \le \|P_{n+1} - \bar{P}_{n+1}\|\|A_n^{*-1}\|\|C_n^*C_n\|.$$

Thus, it follows from Theorem 5.3 and Lemma 2.3 that

$$\limsup_{n\to+\infty}\frac{1}{n}\log\|(A_n - \bar{K}_nC_n) - (A_n - K_nC_n)\| < 0.$$

The proposition is now a consequence of Lemma 5.5 since we have seen in Theorem 5.1 that the sequence $(A_n - \bar{K}_n C_n)$ is almost surely exponentially stable. □

Remark 5.7. In [4] we introduced the following strong detectability condition: there is a sequence $\{F_{-n}, n \in \mathbb{N}\}$ of random $d \times q$ matrices such that $\sup_{n>0} \mathbb{E}\|F_{-n}\|^\beta$ is finite for some $\beta > 0$ and

$$\limsup_{n\to+\infty}\{\mathbb{E}\|(A_{-1}-F_{-1}C_{-1})(A_{-2}-F_{-2}C_{-2})\dots(A_{-n}-F_{-n}C_{-n})\|^\beta\}^{\frac{1}{n}} < 1.$$

There we gave an easy direct proof of the fact that, under this condition, if for some $\alpha > 0$, $\|A_n\|^\alpha$, $\|B_n\|^\alpha$, $\|C_n\|^\alpha$ are integrable and the system is almost surely exponentially stabilizable, then the results of this section hold true. Moreover, $\mathbb{E}\|\bar{P}_n\|^r$ is finite when $r = \min(\alpha, \beta)/4$.

6. Application to control. Let us first provide an efficient observer for systems with stationary coefficients. We consider the linear control system

$$X_{n+1} = A_n X_n + V_n, \qquad Y_n = C_n X_n.$$

We suppose that $\{(A_n, C_n), n \in \mathbb{Z}\}$, is a stationary ergodic process. The sequence (V_n) is arbitrary. These parameters are known at time n. The question is whether it is possible to approach the X_n's if only the Y_n's are available. An observer is a linear system of the form

$$Z_{n+1} = D_n Z_n + F_n Y_n + W_n$$

such that, for any initial condition, $\|X_n - Z_n\| \to 0$ as $n \to +\infty$ (see, e.g., Luenberger [13] or, recently, Yaz [19], who studies systems with random parameters). It thus provides an approximation of the unknown states X_n. We consider the Riccati equation (4) in which we replace $B_n B_n^*$ by the identity matrix of order d. For any $P \in \mathfrak{P}$, let $K_n, n \in \mathbb{N}$, be the gain matrices obtained by this Riccati equation when $P_0 = P$. The following proposition provides an explicit observer.

PROPOSITION 6.1. *We suppose that Hypothesis* (H) *holds and the linear system is almost surely weakly detectable. For* $n \in \mathbb{N}$, *let* $D_n = A_n - K_n C_n, F_n = K_n$, *and* $W_n = V_n$. *Then, there exists* $\gamma > 0$ *such that for any initial condition, almost surely,*

$$\limsup_{n\to+\infty} \frac{1}{n} \log \|X_n - Z_n\| < -\gamma.$$

Proof. The proof readily follows from Theorem 5.6, since, with the chosen coefficients, $X_{n+1} - Z_{n+1} = (A_n - K_n C_n)(X_n - Z_n)$. □

Finally, we consider the quadratic control problem. For any $P \in \mathfrak{P}$ and $n \in \mathbb{N}$, we define matrices $P^{(n)}$ by the formula

$$P^{(n)} = (\phi_{-1} \circ \phi_{-2} \circ \cdots \circ \phi_{-n})(P).$$

It is straightforward to adapt the proof of uniqueness in Theorem 5.1 to see that, under the hypotheses of this theorem, almost surely,

$$\lim_{n\to+\infty} P^{(n)} = \bar{P}_0. \tag{16}$$

We define transformations ϕ_n^* of $\mathfrak{P}$ by the formula

$$\phi_n^*(P) = C_n^* C_n + A_n^* P (I + B_n B_n^* P)^{-1} A_n, \qquad P \in \mathfrak{P}. \tag{17}$$

It is well known that

$$\min\left\{X_n^*PX_n + \sum_{k=0}^{n-1}(U_k^*U_k + Y_k^*Y_k); U_0, \ldots, U_{n-1} \in \mathbb{R}^p\right\} = X_0^*Q^{(n)}X_0,$$

where $Q^{(n)} = (\phi_0^* \circ \phi_1^* \circ \cdots \circ \phi_{n-1}^*)(P)$ (see, e.g., Whittle [16]). Since the mappings (ϕ_{-n}^*) are dual to the mappings (ϕ_n), it follows from (16) applied to the dual system that $Q^{(n)}$ converges almost surely to a random matrix $\bar{Q}$ that does not depend on P as n tends to $+\infty$. In the same way it can be seen that the optimal controls converge almost surely. They depend on the future and can usually be directly implemented only for some deterministic systems, such as almost periodic ones.

Acknowledgments. We thank the referees for suggestions that improved the exposition of this paper. We are also grateful to Yves Derriennic for bringing reference [18] to our attention.

ON EXTREMAL SOLUTIONS OF CONTROLLED NONLINEAR FILTERING EQUATIONS*

VIVEK S. BORKAR† AND SUNIL KUMAR‡

Abstract. Controlled nonlinear filtering equations with "relaxed controls" arising out of the separated control problem for partially observed diffusions are considered. An equivalence relation is defined on the attainable laws of the joint state and control process by identifying any two of the latter when their one-dimensional marginals agree almost everywhere. Extreme points of the set of such equivalence classes (for fixed initial laws) are shown to correspond to Markov processes.

Key words. separated control problem, nonlinear filtering, partially observed diffusions, Markov controls, extremal measures

AMS subject classifications. Primary, 93E20; Secondary, 93E11, 60H16

1. Introduction. Consider a controlled, possibly degenerate diffusion controlled through its drift by a nonanticipative relaxed control with the initial law fixed. The set of all possible laws of the joint state and control process can be shown to be compact in the Prohorov topology. Identifying two elements of this set if their one-dimensional marginals agree a.e., the set of corresponding equivalence classes is convex compact in the quotient topology. The extremal elements of the latter were shown to correspond to Markov solutions in [2]. The aim of this paper is to extend this result to controlled nonlinear filtering equations arising out of the separated control problem for a controlled nondegenerate diffusion with partial observations [3, Chap. V], [6]. We begin with some notation.

For a compact metric "control" space V, let

(i) $m(.,.) = [m_1(.,.),\dots,m_d(.,.)]^T : \mathcal{R}^d \times U \to \mathcal{R}^d$, where $U = \mathbf{P}(V)$ (here and later, $\mathbf{P}(S)$ for a Polish space S will be the space of probability measures on S with the Prohorov topology) and is of the form

$$m_i(x,u) = \int_V \bar{m}_i(x,y)u(dy), \qquad 1 \le i \le d, \quad x \in \mathcal{R}^d, \quad u \in U$$

for $\bar{m}_i \in C_b(\mathcal{R}^d \times V)$, which are Lipschitz in the first argument uniformly with respect to the second (this is the relaxed control paradigm);

(ii) $\sigma(.) = [[\sigma_{ij}(.)]]_{i,j=1,\dots,d} : \mathcal{R}^d \to \mathcal{R}^{d\times d}$ is bounded Lipschitz with the least eigenvalue of $\sigma\sigma^T(.)$ bounded uniformly away from zero;

(iii) $l(.) = [(l_1(.),\dots,l_m(.)]^T : \mathcal{R}^d \to \mathcal{R}^m$ is bounded and twice continuously differentiable with bounded first and second derivatives.

For $\mu \in \mathbf{P}(\mathcal{R}^d)$, let $\mu(f) = \int f\,d\mu$ for $f \in C_b(\mathcal{R}^d)$. Also, for$f \in C_0(\mathcal{R}^d) = \{$bounded continuous functions $\mathcal{R}^d \to \mathcal{R}$ with bounded continuous first and second partial derivatives, all vanishing at infinity$\}$, let

$$L_u f(x) = \sum_i m_i(x,u)\frac{\partial f}{\partial x_i} + \frac{1}{2}\sum_{i,j,k}\sigma_{ik}(x)\sigma_{jk}(x)\frac{\partial^2 f}{\partial x_i \partial x_j}$$

for $x = [x_1, \ldots, x_d]^T \in \mathcal{R}^d$. Then the controlled nonlinear filtering equation describes a $\mathbf{P}(\mathcal{R}^d)$-valued process $\pi(.)$ by

$$(1)\quad \pi(t)(f) = \pi_0(f) + \int_0^t \pi(s)(L_{u(s)}f)ds + \int_0^t \langle \pi(s)(lf) - \pi(s)(f)\pi(s)(l),\, d\hat{Y}(s)\rangle,$$

where $\pi(s)(lf)$, $\pi(s)(f)$, and $\pi(s)(l)$ imply componentwise multiplication and integration. $\hat{Y}(.) = [\hat{Y}_1(.), \ldots, \hat{Y}_m(.)]^T$ is the "innovations process," which is a standard Wiener process, and $u(.)$ is a U-valued measurable "control" process satisfying the wide-sense admissibility conditions of [6]. See [3, §V.1] for a detailed derivation of the nonlinear filtering equation (1). We shall call $u(.)$ a Markov control if $u(t) = v(\pi(t), t)$, $t \geq 0$ for a measurable $v : \mathbf{P}(\mathcal{R}^d) \times \mathcal{R}^+ \to U$.

Remark. Under our hypotheses, the solution $\pi(.)$ of (1) is a.s. unique when both $u(.)$ and $\hat{Y}(.)$ are prescribed processes [3, §V.1]. When $u(.)$ is Markov, however, neither existence nor uniqueness is guaranteed for a given choice of v above.

Topologize the path space of $u(.)$ as follows. (This topology is the same as that introduced in [7].) For $T > 0$, denote by B_T the closed unit ball of $L_\infty[0, T]$ with the weak topology of $L_2[0, T]$ relativized to it. B_T is compact metrizable and therefore Polish. Let B denote the closed unit ball in $L_\infty[0, \infty)$ with the coarsest topology to render continuous the maps $B \to B_T$, $T \geq 0$, that map $f(.) \in B$ to $f([0, T]) \in B_T$. Let $\{f_i\}$ be a countable dense set in the unit ball of $C(V)$. It is then a convergence-determining class for U. Let $\alpha_i(.) = \int f_i\, du(.)$, $i \geq 1$. Then $\alpha_i(.) \in B$ for each i and $\alpha(.) = [\alpha_1(.), \alpha_2(.), \ldots] \in B^\infty$. B, B^∞ are compact Polish spaces as well. The map $\phi : \mu \in U \to [\int f_1\, d\mu, \int f_2\, d\mu, \ldots] \in [-1, 1]^\infty$ is a homeomorphism between U and $\phi(U)$ by virtue of being a continuous injection with a compact domain. We identify $u(.)$, $\alpha(.)$ via this homeomorphism and use the notation to denote either, depending on the context. Similarly, $u([0, t])$ may be viewed as a B_t^∞-valued random variable for $t \geq 0$.

The path space of $\pi(.)$ is $\hat{C} = C([0, \infty); \mathbf{P}(\mathcal{R}^d))$. Let $\hat{C}_T = C([0, T]; \mathbf{P}(\mathcal{R}^d))$. Let $\mathcal{L}(\ldots)$ denote the "law of...." Define $\Gamma'_\eta = \{\mathcal{L}(\pi(.), u(.)) | u(.)$ is wide-sense admissible, $\mathcal{L}(\pi(0)) = \eta\}$, viewed as a subset of $\mathbf{P}(\hat{C} \times B^\infty)$.

LEMMA 1. *Γ'_η is compact convex.*

The proof of Lemma 1 is postponed to the end of this section. Define an equivalence relation on Γ'_η as follows: $\mathcal{L}(\pi(.), u(.))$, $\mathcal{L}(\pi'(.), u'(.)) \in \Gamma'_\eta$ (or, equivalently, $(\pi(.), u(.))$, $(\pi'(.), u'(.))$ themselves) are said to be marginally equivalent if $\mathcal{L}(\pi(.), u(.)) = \mathcal{L}(\pi'(.), u'(.))$ a.e. It is easy to see that this is indeed an equivalence relation. The corresponding equivalence classes are said to be marginal classes. Let Γ_η denote the set of marginal classes with the quotient topology inherited from Γ'_η. Then it is compact convex as well. Let $\langle \pi(.), u(.)\rangle^\sim$ (or equivalently $\langle \mathcal{L}(\pi(.), u(.))\rangle^\sim$) denote the marginal class containing $(\pi(.), u(.))$ (resp., $\mathcal{L}(\pi(.), u(.))$). Our main result is the following theorem.

THEOREM 1. *Every representative of an extremal element of* Γ_η *is a Markov process.*

Theorem 1 will be proved in the next section. The rest of this section is devoted to a proof of Lemma 1 and another result which will be used later. Let $C^* = C([0, \infty); \mathcal{R}^m)$, $C_T^* = C([0, T]; \mathcal{R}^m)$.

Proof of Lemma 1. It suffices to prove that $\tilde{\Gamma}_\eta = \{\mathcal{L}(\pi(.), \hat{Y}(.), u(.)) | u(.)$ is wide-sense admissible and $\mathcal{L}(\pi(0)) = \eta\} \subset \mathbf{P}(\hat{C} \times C^* \times B^\infty)$ is convex compact. Let $\mathcal{F}_t$, $t \geq 0$, be the natural filtration of $(\pi(.), \hat{Y}(.), u(.))$. For $f \in C_o^2(\mathcal{R}^d)$, define

$$M(t, f) = \pi(t)(f) - \int_0^t \pi(s)(L_{u(s)}f)ds, \qquad t \geq 0.$$

To prove the convexity of $\tilde{\Gamma}_\eta$, observe that (1) is equivalent (up to a change of probability space) to the following "martingale formulation": for $h \in C_b(\mathbf{P}(\mathcal{R}^d))$,

$$E[h(\pi(0))] = \int h\, d\eta, \tag{2}$$

and the following are $\{\mathcal{F}_t\}$-martingales:

$$M(t, f),$$

$$M(t,f)\hat{Y}_i(t) - \int_0^t (\pi(s)(fl_i) - \pi(s)(f)\pi(s)(l_i))ds, \qquad 1 \leq i \leq m,$$

$$(M(t,f) - \pi_0(f))^2 - \int_0^t \|\pi(s)(fl) - \pi(s)(f)\pi(s)(l)\|^2\, ds$$

(this equivalence can be proved as in [3, pp. 116–118]; see also [4, p. 1051]). The latter is in turn equivalent to the following: for $t \geq s \geq 0$, $g \in C_b(\hat{C}_s \times C_s^* \times B_s^\infty)$,

$$E[(Z(t) - Z(s))g(\pi([0,s]), \hat{Y}([0,s]), u([0,s]))] = 0, \tag{3}$$

where $Z(.)$ is any of the above processes claimed to be martingale. (Thus (3) is a family of equations and not a single equation.) If (2), (3) hold under two elements of $\mathbf{P}(\hat{C} \times C^* \times B^\infty)$, they do so under any convex combination thereof. The convexity of $\tilde{\Gamma}_\eta$ follows. Equations (2), (3) are preserved under convergence in $\mathbf{P}(\hat{C} \times C^* \times B^\infty)$ and hence $\tilde{\Gamma}_\eta$ is closed. Thus, to prove its compactness, it suffices to prove that it is tight. Since $\mathcal{L}(\hat{Y}(.))$ is constant (i.e., the Wiener measure) and $\mathbf{P}(B^\infty)$ is compact, we only need to show the tightness of $\{\mathcal{L}(\pi(.))|u(.)$ is wide-sense admissible, $\mathcal{L}(\pi(0)) = \eta\}$. This is proved as in [3, Lem. 3.7, pp. 128–129] (see also [1], [4]). □

Note that the well-posedness of (1) for prescribed $(\hat{Y}(.), u(.))$ (see [3, §V.1]) implies that $\pi(.)$ is adapted to the natural filtration of $(\hat{Y}(.), u(.))$ and, therefore, $\{\mathcal{F}_t\}$ is in fact the natural filtration of $(\hat{Y}(.), u(.))$. The last result of this section is a technical lemma needed later. This is quite standard; see, for example, [4, p. 1043].

LEMMA 2. *For $(\pi(.), \hat{Y}(.), u(.))$ as in* (1), *$t \geq 0$, and $\mathcal{G}_t$ a sub-σ-field of $\mathcal{F}_t$ containing $\sigma(\pi(t))$, the regular conditional law of $(\pi(t+.), \hat{Y}(t+.) - \hat{Y}(t), u(t+.))$ is a.s. the law of a triplet $(\pi'(.), \hat{Y}'(.), u'(.))$ satisfying* (1) *with $\pi'(0) = \pi(t)$ and $u'(.)$ wide-sense admissible.*

2. Proof of Theorem 1. We shall prove this theorem through a sequence of lemmas. Let $\{h_i\}$ be a countable subset of $C_b(\mathbf{P}(\mathcal{R}^d) \times U)$ that separates points of $\mathbf{P}(\mathbf{P}(\mathcal{R}^d) \times U)$. For $i \geq 1$, $\alpha \in (0, \infty)$, let $F_{\alpha i} : \Gamma'_\eta \to \mathcal{R}$, $\eta \in \mathbf{P}(\mathbf{P}(\mathcal{R}^d))$ be the map

$$\mathcal{L}(\pi(.), u(.)) \in \Gamma'_\eta \to E\left[\int_0^\infty e^{-\alpha t}\, h_i(\pi(t), u(t))dt\right].$$

This map is constant on marginal classes and therefore can be viewed as a map $\Gamma_\eta \to \mathcal{R}$.

LEMMA 3. *If $\mu_1, \mu_2 \in \Gamma_\eta$ satisfy $F_{\alpha i}(\mu_1) = F_{\alpha i}(\mu_2)$ for $i \geq 1$, and rational $\alpha \in (0, \infty)$, then $\mu_1 = \mu_2$.*

This follows easily from the injectivity of the Laplace transform on $\mathcal{R}^+$ and our choice of $\{h_i\}$. Let δ_π denote the Dirac measure at $\pi \in \mathbf{P}(\mathcal{R}^d)$. For a given $\mathcal{L}(\pi(.), u(.)) \in \Gamma'_\eta$, let $p(\pi, dy)$ denote a representative of the regular conditional law of $(\pi(.), u(.))$ given $\pi(0) = \pi$. From Lemma 2, one may suppose that $p(\pi, dy) \in \Gamma_{\delta_\pi}$ for each π.

LEMMA 4. *Suppose that for π in a set of strictly positive η-measures, $\langle p(\pi, dy)\rangle^{\sim}$ is not an extreme point of Γ_{δ_π}. Then there exists relatively compact $A \subset \boldsymbol{P}(\mathcal{R}^d)$ with $\eta(A) > 0$, $i \geq 1$, α rational in $(0,1)$, $\varepsilon > 0$, and for any $\pi \in A$, there exists $\nu_{1\pi}, \nu_{2\pi} \in \Gamma_{\delta_\pi}$ for which*

$$\langle p(\pi, dy)\rangle^{\sim} = \frac{(\nu_{1\pi} + \nu_{2\pi})}{2} \tag{4}$$

and

$$|F_{\alpha i}(\nu_{1\pi}) - F_{\alpha i}(\nu_{2\pi})| \geq \varepsilon. \tag{5}$$

Proof. Let $F : \Gamma_{\delta_\pi} \times \Gamma_{\delta_\pi} \to \Gamma_{\delta_\pi}$ denote the map $(\nu_1, \nu_2) \to (\nu_1+\nu_2)/2$. Let $\bar{A}(i, n, \alpha) = \{(\nu_1, \nu_2) \in \Gamma_{\delta_\pi} \times \Gamma_{\delta_\pi} \mid |F_{\alpha i}(\nu_1) - F_{\alpha i}(\nu_2)| \geq 1/n\}$,

$$\tilde{A} = \bigcup_{i,n,\alpha} \bar{A}(i, n, \alpha).$$

Suppose $\eta(\{\pi \mid \langle p(\pi, dy)\rangle^{\sim} \in F(\tilde{A})\}) = 0$. Then for π-a.s. x, the following holds: for all $i, n \geq 1$, and all rational $\alpha > 0$,

$$|F_{\alpha i}(\nu_1) - F_{\alpha i}(\nu_2)| \leq \frac{1}{n},$$

whenever $\nu_1, \nu_2 \in \Gamma_{\delta_\pi}$ satisfy $\langle p(\pi, dy)\rangle^{\sim} = (\nu_1 + \nu_2)/2$. By Lemma 3, $\nu_1 = \nu_2$, which contradicts the hypothesis that $\langle p(\pi, dy)\rangle^{\sim}$ is not an extreme point of Γ_{δ_π}. Therefore $\eta(\{\pi|\langle p(\pi, dy)\rangle^{\sim} \in F(\tilde{A})\}) > 0$. Hence for some $i, n \geq 1$, rational $\alpha > 0$,

$$\eta(\{\pi|\langle p(\pi, dy)\rangle^{\sim} \in F(\bar{A}(i, n, \alpha))\}) > 0.$$

Clearly, $\bar{A}(i, n, \alpha)$ is closed. Let $\hat{A} = \{\pi|\langle p(\pi, dy)\rangle^{\sim} \in F(\bar{A}(i, n, \alpha))\}$. Since η is a probability measure on a Polish space $\mathbf{P}(\mathcal{R}^d)$, $\eta(\cup_n K_n) = 1$ for some compact $K_n \in \mathbf{P}(\mathcal{R}^d)$. By replacing $\hat{A}$ with $A =$ its intersection with an appropriate finite union of K_n's, we may suppose that A is compact with $\eta(A) > 0$. This A satisfies the claim. □

Let $\Delta' \subset \mathbf{P}(\hat{C} \times B^\infty)$ be defined by

$$\Delta' = \overline{\bigcup_{\pi \in A} \Gamma'_{\delta_\pi}}.$$

The arguments of the proof of Lemma 1 can be adapated to show that Δ' is compact. We define marginal equivalence on the whole of $\mathbf{P}(\hat{C} \times B^\infty)$ by deeming two elements thereof to be marginally equivalent whenever the $\mathbf{P}(\mathcal{R}^d) \times U$-valued canonical processes have the same one-dimensional marginals a.e. Let $S^{\sim}$ indicate the space of corresponding equivalence classes with the quotient topology and $\Delta \in S^{\sim}$ indicate the set corresponding to Δ'. Then Δ is compact. Define $F : \Delta \times \Delta \to S^{\sim}$ by $(\nu_1, \nu_2) \to (\nu_1 + \nu_2)/2$ and let

$$G' = \{(\nu_1, \nu_2) \in S^{\sim} \times S^{\sim}||F_{\alpha i}(\nu_1) - F_{\alpha i}(\nu_2)| \geq \varepsilon\}$$

for α, i, ε as in (5).

LEMMA 5. *If $\langle \pi(.), u(.)\rangle^{\sim}$ is an extreme point of Γ_η, then for η-a.s. π, $\langle p(\pi, dy)\rangle^{\sim}$ is an extreme point of Γ_{δ_π}.*

Proof. Suppose Lemma 5 does not hold. Let $A, \varepsilon, \alpha, i, F_{\alpha i}$ be as above. For $\pi \in A$, let

$$K_\pi = \{(\nu_1, \nu_2) \in \Gamma_{\delta_\pi} \times \Gamma_{\delta_\pi}|(4), \text{ (5) hold with } (\nu_1, \nu_2) \text{ in place of } (\nu_{1\pi}, \nu_{2\pi})\}.$$

By Lemma 4, $K_\pi \neq \emptyset$. It is also compact because (4), (5) are preserved under convergence in $\Gamma_{\delta_\pi} \times \Gamma_{\delta_\pi}$, which is compact. Let $G \subset \Delta \times \Delta$ be closed and therefore compact. Note that

$$(6) \qquad \{\pi \in A | K_\pi \cap G \neq \emptyset\} = \{\pi \in A | \langle p(\pi, dy)\rangle^\sim \in F(G \cap G')\}.$$

Since G' is closed, $F(G \cap G')$ is compact. The map $\pi \to p(\pi, dy)$ and, therefore, the map $\pi \to \langle p(\pi, dy)\rangle^\sim$ is measurable. Thus the set in (6) is measurable. We conclude that the map $\pi \in A \to K_\pi \subset \Delta \times \Delta$ is measurable and, therefore, weakly measurable in the sense of [8, p. 862], in view of the remarks in paragraph 5 of [8, p. 862]. By Theorem 4.1 of [8, p. 867], there exists a measurable map $\pi \to (\nu'_\pi, \nu''_\pi) : A \to \Delta \times \Delta$ such that (4), (5) hold with ν'_π, ν''_π in place of $\nu_{1\pi}, \nu_{2\pi}$. Define

$$A^+ = \{\pi \in A | F_{\alpha i}(\nu'_\pi) - F_{\alpha i}(\nu''_\pi) \geq \varepsilon\}$$

and A^- analogously with $-\varepsilon, \leq$ in place of $\varepsilon, \geq$. Since $\eta(A) > 0$ and $A = A^+ \cup A^-$, at least one of $\eta(A^+)$, $\eta(A^-)$ is strictly positive. Suppose $\eta(A^+) > 0$. (If not, replace A^+ by A^-.) Define

$$\begin{aligned} \bar{\nu}_\pi &= \nu'_\pi & \pi \in A^+ \\ &= \langle p(\pi, dy)\rangle^\sim & \text{otherwise,} \\ \bar{\bar{\nu}}_\pi &= \quad \nu''_\pi & \pi \in A^+ \\ &= \langle p(\pi, dy)\rangle^\sim & \text{otherwise,} \\ \mu_1(d\pi, dy) &= \eta(d\pi)\bar{\nu}_\pi(dy), \\ \mu_2(d\pi, dy) &= \eta(d\pi)\bar{\bar{\nu}}_\pi(dy). \end{aligned}$$

Since $\eta(A^+) > 0$, $\langle \mu_1\rangle^\sim \neq \langle \mu_2\rangle^\sim$. Clearly, $\langle \pi(.), u(.)\rangle^\sim = (\langle \mu_1\rangle^\sim + \langle \mu_2\rangle^\sim)/2$. Since $\bar{\nu}_\pi, \bar{\bar{\nu}}_\pi \in \Gamma_{\delta_\pi}$ for each π, $\langle \mu_i\rangle^\sim \in \Gamma_\eta$, $i = 1, 2$. Thus $\langle \pi(.), u(.)\rangle^\sim$ is not an extreme point of Γ_η. This contradiction establishes the claim. □

The following is a special case of [4, Thm. 3.2, p. 1044]. Let $(\pi_i(.), u_i(.))$, $i = 1, 2$ be two pairs that satisfy (1).

LEMMA 6. *If* $\mathcal{L}(\pi_1(T), u_1(T)) = \mathcal{L}(\pi_2(0), u_2(0))$ *for some* $T > 0$, *then there exists a* $(\pi(.), u(.))$ *satisfying* (1) *such that*

$$\begin{aligned} \mathcal{L}(\pi(t), u(t)) &= \mathcal{L}(\pi_1(t), u_1(t)) \quad \text{for } t \in [0, T] \quad \text{and} \\ &= \mathcal{L}(\pi_2(t - T), u_2(t - T)) \quad \text{for } t \geq T. \end{aligned}$$

LEMMA 7. *Let* $\langle \pi(.), u(.)\rangle^\sim$ *be an extreme point of* Γ_η *with* $\mathcal{L}(\pi(T)) = \beta$ *for some* $T > 0$. *Then* $\langle \pi(T + .), u(T + .)\rangle^\sim$ *is an extreme point of* Γ_β.

This follows easily from Lemma 6 (cf. [2]). Henceforth, let $\langle \pi(.), u(.)\rangle^\sim$ be an extreme point of Γ_η. Fix $T > 0$. Let $\pi_T(.) = \pi([0, T])$ and $\mu_0 = \mathcal{L}(\pi_T(.)) \in \mathbf{P}(\hat{C}_T)$. Let $f : \hat{C}_T \to \mathbf{P}(\mathcal{R}^d) \times \hat{C}_T$ denote the map $\pi_T(.) \to (\pi(T), \pi_T(.))$. Let $\bar{\mu}$ denote the image of μ_0 under f. Let Q denote the set of measurable maps $\mathbf{P}(\mathcal{R}^d) \to \hat{C}_T$ such that $\phi \in Q$ implies that for all $\nu \in \mathbf{P}(\mathcal{R}^d)$, $\phi(\nu)$ evaluated at T coincides with ν. Let $\nu_0 = \mathcal{L}(\pi(T))$ and $\mathcal{M} \subset \mathbf{P}(\hat{C}_T)$ be the set of probability measures obtainable as the image of ν_0 under some map belonging to Q.

LEMMA 8. $\bar{\mu}$ (*resp.*, μ_0) *is the barycenter of some probability measure supported on*

$$f_*(\mathcal{M}) = \{\mu | \mu \textit{ it is the image of some element of } \mathcal{M} \textit{ under } f\} \quad (\textit{resp.}, \mathcal{M}).$$

Proof. In the setup of Lemma 2.2 in [2], let $S_1 = \mathbf{P}(\mathcal{R}^d)$, $S_2 = \hat{C}_T$, and $\mathcal{G}_1$, $\mathcal{G}_2$ equal their respective Borel σ-fields. By Lemmas 2.2 and 2.4 of [2], it follows that $\bar{\mu}$ is the barycenter of a probability measure ξ on

$$A = \{\mu \in \mathbf{P}(\mathbf{P}(\mathcal{R}^d) \times \hat{C}_T) | \mu(dx, dy) = \nu_0(dx)v(x, dy), \text{ where } v(x, .) \text{ is Dirac for } \nu_0\text{-a.s. } x\}.$$

Let

$$A' = f_*(\mathbf{P}(\hat{C}_T)) = \{\mu \in \mathbf{P}(\mathbf{P}(\mathcal{R}^d)\times\hat{C}_T) | \mu \text{ is the image of some element of } \mathbf{P}(\hat{C}_T) \text{ under } f\}.$$

If $\xi(A') < 1$, $\xi(A'^C) > 0$. This means that

$$\bar{\mu}((\mathbf{P}(\mathcal{R}^d) \times \hat{C}_T)\backslash f(\hat{C}_T)) > 0,$$

which is a contradiction. Hence ξ is supported on A' and therefore on $A \cap A'$, which is easily seen to be identical to $f_*(\mathcal{M})$. This proves the first claim. Since f is a bijection between $\hat{C}_T$ and its image under f, the map f_* that maps elements of $\mathbf{P}(\hat{C}_T)$ to their images under f is a bijection between $\mathbf{P}(\hat{C}_T)$ and $f_*(\mathbf{P}(\hat{C}_T))$. Let ξ_0 be the image of ξ under f_*^{-1}. Then ξ_0 is supported on $\mathcal{M}$ and μ_0 is the barycenter of ξ_0, proving the second claim. □

Let $(x, y) \in \mathbf{P}(\mathcal{R}^d) \times \hat{C}_T \to q((x, y), dz) \in \mathbf{P}(\hat{C} \times B^\infty)$ by any version of the regular conditional law of $(\pi(T + .), u(T + .))$ given $(\pi(T), \pi_T(.))$. Thus the law of $(\pi(T), \pi_T(.), (\pi(T + .), u(T + .)))$ is $\phi \in \mathbf{P}(\mathbf{P}(\mathcal{R}^d) \times \hat{C}_T \times \hat{C} \times B^\infty) = \tilde{Q}$, given by

$$\phi(dx,\, dy,\, dz) = \bar{\mu}(dx,\, dy)q((x, y),\, dz).$$

Let $H \subset \tilde{Q}$ be the set of measures $\mathcal{V}$ of the form

$$\mathcal{V}(dx,\, dy,\, dz) = \nu_0(dx)\delta_{\varphi(x)}(dx)q((x, y), dz)$$

for some $\varphi \in Q$, $S_{\varphi(x)}$ being the Dirac measure at $\varphi(x)$. By the above lemma, ϕ is the barycenter of a probability measure ξ_1 on H.

LEMMA 9. *With ξ_1-probability one, the probability measure $\beta \in \mathbf{P}(\hat{C} \times B^\infty)$ defined by*

$$\int f(z)\beta(dz) = \iint \nu_0(dx)q((x, \varphi(x)), dz)f(z)$$

for $f \in C_b(\mathbf{P}(\hat{C}) \times B^\infty)$ is in Γ'_{ν_0}. Furthermore, $q((x, \varphi(x)), dz)$ can be chosen to be in Γ'_{δ_x} by choosing an appropriate version.

This is a straightforward consequence of Lemma 2. Denote φ, β above as $\varphi_{\mathcal{V}}$, $\beta_{\mathcal{V}}$ to make explicit the $\mathcal{V}$ dependence. Recall that ϕ is the barycenter of a probability measure ξ_1 on H.

LEMMA 10. *For x outside a set of zero ν_0-measure, $\langle q((x, \varphi_{\mathcal{V}}(x)), dz)\rangle^\sim$ is the same for ξ_1-a.s. $\mathcal{V}$.*

Proof. Note that $\bar{\beta} = \mathcal{L}(\pi(T + .), u(T + .))$ given by

$$\int f(z)\bar{\beta}(dz) = \iint \bar{\mu}(dx, dy)q((x, y), dz)f(z)$$

for $f \in C_b(\hat{C} \times B^\infty)$ is an extreme point of Γ_{ν_0} by Lemma 7. Disintegrate $\bar{\beta}$ as $\nu_0(dx)p(x, dz)$, where $p(x, dz)$ is a representative of the regular conditional law of $(\pi(T + .), u(T + .))$ given that $\pi(T) = x$. By Lemma 5, $\langle p(x, dz)\rangle^\sim$ is an extreme point of Γ_{δ_x} for ν_0-a.s. x. Now ϕ is the barycenter of a probability measure ξ_1 on H. Thus $\bar{\beta}$ is the barycenter of a probability measure on $\{\beta_{\mathcal{V}}, \mathcal{V} \in H\}$. By Lemma 2.3 of [2], for ν_0-a.s. x, $p(x, dz)$ is the barycenter of a probability measure on $\{q((x, \varphi_{\mathcal{V}}(x)), dz),\ \mathcal{V} \in H\}$ and, in turn, $\langle p(x, dz)\rangle^\sim$ is the barycenter of a probability measure on $\{\langle q((x, \varphi_{\mathcal{V}}(x)), dz)\rangle^\sim\}$. For x outside a set of zero ν_0-measure, outside of which the foregoing holds and $\langle p(x, dz)\rangle^\sim$ is extremal in Γ_{δ_x}, we must have

$$\langle p(x, dz)\rangle^\sim = \langle q((x, \varphi_{\mathcal{V}}(x)), dz)\rangle^\sim$$

for ξ_1-a.s. $\mathcal{V}$, thus proving the claim. □

Proof of Theorem 1. Fix $t > 0$ and let $\hat{p}(x, dz)$, $\hat{q}((x, y), dz) \in \mathbf{P}(\mathbf{P}(\mathcal{R}^d))$ denote the images of $p(x, dz)$ and $q((x, y), dz)$, resp., under the map $(x(.), y(.)) \in \hat{C} \times B^{\infty} \to x(t) \in \mathbf{P}(\mathcal{R}^d)$. Then the law of $(\pi(T), \pi_T(.), \pi(T + t))$ is

$$\begin{aligned}\mu(dx, dy)\hat{q}((x, y), dz) &= \int \xi_1(d\mathcal{V})\nu_0(dx)\delta_{\varphi_{\mathcal{V}}(x)}(dy)q((x, \varphi_{\mathcal{V}}(x)), dz)\\ &= \nu_0(dx)\eta(x, dy)\hat{p}(x, dz)\end{aligned}$$

by the above lemma, where

$$\eta(x, dy) = \int \xi_1(d\mathcal{V})\delta_{\varphi_{\mathcal{V}}(x)}(dy).$$

Thus $\pi(T + t)$, $\pi_T(.)$ are conditionally independent given $\pi(T)$. Given the arbitrary choice of T, t, the claim follows. □

STRONG STABILITY IN VARIATIONAL INEQUALITIES*

JIMING LIU†

Abstract. In this paper we consider a generalization of Kojima's strong stability in nonlinear programs to variational inequalities constrained by a system of equations and inequalities. Roughly speaking, strong stability refers to the local existence and uniqueness of a solution of a system under small perturbations. The purpose of the paper is to establish a new and complete characterization for strongly stable generalized Karush–Kuhn–Tucker points and to give a complete characterization for strongly stable stationary solutions under the Mangasarian–Fromovitz constraint qualification.

Key words. strongly stable generalized Karush–Kuhn–Tucker (GKKT) point, strongly stable stationary solution, variational inequality problem, perturbation

AMS subject classifications. 90C33, 49A29, 90C31

1. Introduction.

The notions of strong regularity and strong stability are perhaps the two most important concepts in the stability theory of optimization. The former was introduced by Robinson [22] from an analytic viewpoint as a concept in generalized equations analogous to the classical nonsingularity concept in nonlinear equations, and the latter was proposed by Kojima [8] from a topological point of view attempting to characterize the existence and local uniqueness of the perturbed local solutions of a nonlinear program. These two concepts are equivalent for polyhedrally constrained nonlinear programs [16]. For general nonlinear programs, strong regularity is referred to the nonsingularity of the Karush–Kuhn–Tucker (KKT) points, while the concept of strong stability has more flexibility; a local minimizer with nonunique multipliers, which is not strongly regular, may still have strong stability. These two concepts have been extensively studied in the context of nonlinear programming; see [5], [6], [7], [8], [9], [19], and [24]. Actually, the notion of strong regularity was originally proposed in the framework of generalized equations, or variational inequalities, and a complete characterization for strong regularity was obtained in [22]. In recent years the natural generalizations of strong stability and its related theory to variational inequalities have been addressed in several works [1], [3], [13], [25]. The conceptual aspect of the generalizations is rather straightforward. However, some technical difficulties exist in establishing complete characterizations for strong stability in variational inequalities. Only very recently was a complete characterization for local homeomorphism of normal maps, or equivalently, strong stability of the solutions of the corresponding variational inequalities over polyhedral sets, obtained by Robinson [26] with a very penetrating analysis of the structures of linear normal maps and polyhedral sets; even a short proof of this result is a very challenging task [20], [21], [27]. The major difficulty in this kind of generalization mainly stems from the additional complexity of asymmetric matrices versus symmetric matrices. This difficulty also exists in matrix theory and linear algebra.

The major objectives of this paper are to establish a new and complete characterization of strongly stable generalized Karush–Kuhn–Tucker (GKKT) points and to give the first complete characterization of strongly stable stationary solutions in variational inequalities defined on perturbed sets. To achieve these objectives, some new ideas are needed. We shall first examine the differences between a variational inequality problem and a nonlinear program. It is well known that the Karush–Kuhn–Tucker conditions or stationary conditions of a nonlinear

program can be expressed by a variational inequality. Let us look at the simplest case first. Consider an unconstrained quadratic program,

$$\underset{x}{\text{minimize}}\ \theta(x) = x^{\mathsf{T}}(Ax - b) \quad \text{s.t. } x \in R^n,$$

where A is a symmetric $n \times n$ matrix. The stationary conditions of the above program are equivalent to the following variational inequality:

$$\text{find } x \in R^n \quad \text{such that } (f(x) = (2Ax - b))^{\mathsf{T}}(x' - x) \geq 0 \quad \text{for all } x' \in R^n.$$

If we regard the vector b as the perturbation parameter, then for a particular value, say $b_0 = 0$, the condition which ensures that the above nonlinear program has a unique solution for all b near b_0 is the requirement that A, the Hessian of θ, be positive definite; however, for the above variational inequality, the corresponding condition is that A, the Jacobian matrix of f, is nonsingular. Here the distinction between these two conditions is due to the fact that a solution of a nonlinear program must satisfy some necessary optimality conditions. Now let us examine a more complicated situation:

$$\underset{x}{\text{minimize}}\ \theta(x) = x^{\mathsf{T}}(Ax - b) \quad \text{s.t. } x \in R^n_+.$$

The stationary conditions of this problem can be written down as a linear complementarity problem,

$$\text{find } x \in R^n_+ \quad \text{such that } (2Ax - b)^{\mathsf{T}}(x' - x) \geq 0 \quad \text{for all } x' \in R^n_+.$$

Now, let the vector b be the perturbation parameter and let the unperturbed parameter b_0 be zero. We know that local uniqueness of solutions of the above nonlinear program requires that A be positive definite, and that the corresponding condition for the above linear complementarity problem is that A is a P matrix, i.e., A has positive principal minors. This property is equivalent to the positive definiteness of A in our case since A is symmetric. However, the matrix A is generally asymmetric if the above linear complementarity problem arises in equilibrium problems, and in such cases this property is strictly weaker than the positive definiteness of A. These two examples demonstrate the substantial differences between nonlinear programs and variational inequalities. In the author's opinion, the present stability and sensitivity theory of variational inequalities (see the recent survey paper Kyparisis [13] in this field) follows the stability and sensitivity theory of nonlinear programs too heavily and does not reflect the substantial differences very well.

Now we consider the following more general variational inequality:

$$\text{find } x \in C \quad \text{such that } (Ax - b)^{\mathsf{T}}(x' - x) \geq 0 \quad \text{for all } x' \in C,$$

where C is a convex polyhedral cone, and A is an $n \times n$ matrix. Again, let the vector b be the perturbation parameter and let the unperturbed parameter b_0 be zero. Recently, Robinson [26] showed that the condition that completely characterizes the existence and uniqueness of solutions of the above variational inequality for all $b \in R^n$ is exactly the coherent orientedness condition (Robinson did not restrict C to a cone). To be precise, we shall briefly review the coherent orientedness condition. In what follows, for a $p \times q$ matrix B we shall use B to refer to the matrix B itself or the linear transformation from R^q to R^p represented by the matrix B according to the context. The orientation of a linear transformation B from R^t to R^t is defined to be the sign of the determinant of B, which takes three possible values, -1, 0, and $+1$. Let L be a subspace of R^n and Q be an orthogonal matrix whose columns form a basis for L. The linear transformation represented by $Q^{\mathrm{T}}AQ$ is called the section of A in the subspace L [4]. The coherent orientedness condition is the requirement that the orientations of the sections of A in the subspaces spanned by all faces of C all have a common nonzero sign.

Originally, the coherent orientedness condition was introduced [11], [26] from a piecewise affine map perspective. It is instructive to explain it from a geometric point of view, as we will do here. The advantage of this viewpoint is that it enables us to generalize this important notion to the case where C is not a polyhedral set. In what follows we shall sketch the ideas. Let A be a linear transformation in R^n and let C be a convex cone in R^n. Suppose z is a nonzero vector in C. We say that z is in general positive position with respect to (w.r.t.) a vector set $\{y_1, \dots, y_m\} \subset C$ if there exist $a_i > 0$, $i = 1, \dots, m$, such that

$$z = a_1 y_1 + \cdots + a_m y_m,$$

and the vector set $\{y_1, \dots, y_m\}$ is linearly independent. If z is in general positive position w.r.t. $\{y_1, \dots, y_m\} \subset C$, and z is not in general positive position w.r.t. $\{y_1', \dots, y_{m'}'\} \subset C$ such that $m' > m$, then we say that the vector set $\{y_1, \dots, y_m\}$ is a frame of z on C. Now let $\{y_1, \dots, y_m\}$ be a frame of z on C and let L be the subspace spanned by $\{y_1, \dots, y_m\}$. Suppose $z = a_1 y_1 + \cdots + a_m y_m$. We first assume that $\{y_1, \dots, y_m\}$ is an orthonormal basis of L. The linear transformation A maps z to Az. Consider the rectangular parallelepiped $D = \{t_1 y_1 + \cdots + t_m y_m : 0 \le t_1 \le a_1, \dots, 0 \le t_m \le a_m\}$. It is the image of the rectangle $I = \{(t_1, \dots, t_m)^{\mathrm{T}} : 0 \le t_1 \le a_1, \dots, 0 \le t_m \le a_m\}$ under the matrix $Y = (y_1, \dots, y_m)$. Suppose the linear transformation A maps D onto D'. Then $D' = \{t_1 Ay_1 + \cdots + t_m Ay_m : t = (t_1, \dots, t_m)^{\mathrm{T}} \in I\} = \{AYt : t \in I\}$. Now we project D' on L and obtain the projection $\bar{D}$. Then $\bar{D} = \{(y_1^{\mathrm{T}} AYt, \dots, y_m^{\mathrm{T}} AYt)^{\mathrm{T}} : t \in I\} = \{Y^{\mathrm{T}} AYt : t \in I\}$ in Y space. This means that $\bar{D}$ can be regarded as the image of I under the linear transformation $Y^{\mathrm{T}}AY$. Obviously, it is also a rectangular parallelepiped in L. It is not hard to see that the directed volume of $\bar{D}$ in Y space, denoted by $\mathrm{DV}(\bar{D})$, is equal to $a_1 \times \cdots \times a_m \det(Y^{\mathrm{T}}AY)$, and the directed volume of D in Y space, denoted by $\mathrm{DV}(D)$, is equal to $a_1 \times \cdots \times a_m \det(Y^{\mathrm{T}}Y)$. We define $\mathrm{GAR}(A, Y, z)$, called the general amplification rate of A in the direction z w.r.t. Y, as follows:

$$\mathrm{GAR}(A, Y, z) = \frac{\mathrm{DV}(\bar{D})}{\mathrm{DV}(D)} = \frac{\det(Y^{\mathrm{T}}AY)}{\det(Y^{\mathrm{T}}Y)}. \tag{1.1}$$

The equation above explains the geometric meaning of the determinant of the section of A in the subspace L. Note that although we have assumed that Y is an orthonormal basis of $L = \mathrm{span}(Y)$, the definition is valid even when Y is not orthonormal. To see this, note that there exists an $m \times m$ nonsingular matrix T such that $X = YT$ and X is orthonormal. Substituting $X = YT$ into (1.1) we obtain the same formula. Actually, if two vector sets Y^1 and Y^2 span the same subspace then one has $\mathrm{GAR}(A, Y^1, z) = \mathrm{GAR}(A, Y^2, z)$. This means that if two vector sets Y^1 and Y^2 are frames of z on C, then $\mathrm{GAR}(A, Y^1, z) = \mathrm{GAR}(A, Y^2, z)$ since by the definition of frame, Y^1 and Y^2 span the same subspace. Therefore, for any $z \in C \backslash \{0\}$, we define the general amplification rate of A in the direction z w.r.t. C by

$$\mathrm{GAR}(A, C, z) = \frac{\mathrm{DV}(\bar{D})}{\mathrm{DV}(D)} = \frac{\det(Y^{\mathrm{T}}AY)}{\det(Y^{\mathrm{T}}Y)}, \tag{1.2}$$

where Y is a frame of z on C.

We now introduce the notion of coherent orientedness of a linear transformation on a convex cone in terms of the general amplification rate of the linear transformation w.r.t. this cone. For a polyhedral convex cone C, denote by $\mathrm{rif}(C)$ the set of relative interior points of various faces of C. Then $\mathrm{rif}(C) = C$ if $C \cap (-C) = \{0\}$, i.e., C contains no lines and $\mathrm{rif}(C) = C\backslash\{0\}$ if $C \cap (-C) \neq \{0\}$. So for a convex cone C we define $\mathrm{rif}(C) = (C\backslash\{0\}) \cup (C \cap (-C))$. In stating the definition, we assume that $\mathrm{GAR}(A, C, 0) = 1$ or 0 for any linear transformation A and any convex cone C for the sake of convenience. For simplicity we shall abbreviate the terms "coherently oriented" to "cooriented" and "coherent orientedness" to "coorientedness," etc.

DEFINITION 1.1. *A linear transformation A in R^n is said to be positively (negatively) cooriented on a convex cone C in R^n if for all $z \in \mathrm{rif}(C)$,*

$$\mathrm{GAR}(A, C, z) > (<) 0;$$

A is said to be positively (negatively) semicooriented on C if the above inequality holds for all $z \in \mathrm{rif}(C)$ with the replacement of

$$\mathrm{GAR}(A, C, z) \geq (\leq) 0;$$

A is said to be cooriented (semicooriented) on C if A is either positively cooriented (semicooriented) or negatively cooriented (semicooriented) on C.

In view of (1.2) and the definition of frame, the above definition of coorientedness of a linear transformation on a polyhedral convex cone is equivalent to that of [26]. Evidently, a positive definite (semidefinite) matrix A is positively cooriented (semicooriented) on any convex cone C since we always have

$$\mathrm{GAR}(A, C, z) > (\geq) 0$$

for all $z \in \mathrm{rif}(C)$. The converse is not true; examine the following matrix:

$$A = \begin{bmatrix} 1 & 1 \\ -4 & 1 \end{bmatrix}.$$

It is not difficult to check that A is positively cooriented on R^2_+. However, taking $z = (1, 1)^{\mathrm{T}} \in R^2_+$, we then have $z^{\mathrm{T}} A z = -1 < 0$. Also, we note that A is not positively cooriented on the convex cone $C = \{(x_1, x_2) : x_2 - x_1 \leq 0,\ -x_2 \leq 0\}$, which is a subset of R^2_+. This suggests that the coorientedness of a linear transformation on a convex cone is an incorporating property of the linear transformation and the cone. This property of coorientedness differs substantially from that of positive definiteness. However, it was proved very recently [27] that if the linear transformation can be represented by a symmetric matrix, then the coorientedness of the linear transformation on a polyhedral convex cone containing no lines reduces to positive definiteness.

At this point let us explain our reason for attempting to draw the reader's attention to the notion of coorientedness at the very beginning of the paper. It is perhaps very well known that for nonlinear programs, the combination of the linear independence condition and strong second-order sufficient condition, and the combination of the Mangasarian–Fromovitz constraint qualification and general strong second-order sufficient condition, are necessary and sufficient conditions for strong regularity of KKT points and strong stability of local minimizers, respectively. It is natural to predict that for variational inequality problems a combination of the linear independence condition and a certain coorientedness condition, and a combination of the Mangasarian–Fromovitz constraint qualification and a certain general coorientedness condition, would provide complete characterizations for strongly regular GKKT points and strongly stable stationary solutions, respectively. This is true, as we will see in the following sections.

We organize the rest of the paper in three sections. In §2 we introduce the notions of strong stability in variational inequalities and review the known notation and basic results.

Two results that are useful in understanding strong stability are also given in this section. In §3 we establish a new and complete characterization for strongly stable GKKT points. Other characterizations are discussed. Finally, in §4 we consider strongly stable stationary solutions in the framework of the Mangasarian–Fromovitz constraint qualification and show that the so-called general coorientedness condition completely characterizes the strong stability of stationary solutions.

2. Preliminaries. The variational inequality problems we shall deal with are of the form

$$\text{VI}(f,g) \qquad \text{find } x \in R(g) \quad \text{such that } f(x)^{\mathsf{T}}(x'-x) \geq 0 \quad \text{for all } x' \in R(g),$$

where $g := (g_1, \ldots, g_m)$, $R(g) := \{x \in R^n : g_i(x) \leq 0,\ i \in L_1; g_i(x) = 0,\ i \in L_2\}$, $L_1 := \{1, \ldots, k\}$, $L_2 := \{k+1, \ldots, k+l\}$, $m = k + l$, $f : R^n \to R^n$ is once continuously differentiable, and $g_i : R^n \to R$ $(i = 1, 2, \ldots, m)$ are twice continuously differentiable.

Given a VI(f, g), if x is a local solution to VI(f, g) and an appropriate regularity condition holds at x, then the GKKT conditions or stationary conditions hold at x [13]: there exist multipliers $u \in R^m$ such that

$$\begin{gathered} f(x) + \sum_{i=1}^{m} u_i \nabla g_i(x) = 0, \\ g_i(x) \leq 0, \quad u_i \geq 0, \quad u_i g_i(x) = 0, \quad i \in L_1, \\ g_i(x) = 0, \qquad i \in L_2, \end{gathered} \tag{2.1}$$

where (here and in what follows) the notation ∇ always denotes the derivative with respect to the variable x. It is known that system (2.1) can be expressed in an equivalent form via generalized equations [22]:

$$0 \in \begin{bmatrix} f(x) + \sum_{i=1}^{m} u_i \nabla g_i(x) \\ -g(x) \end{bmatrix} + N_{R^n \times R^k_+ \times R^\ell}(x, u), \tag{2.2}$$

where the notation N denotes the normal cone operator. For a convex set $C \subset R^t$,

$$N_C(x) := \begin{cases} \{y \in R^t \colon y^{\mathsf{T}}(z - x) \leq 0 \text{ for all } z \in C\} & \text{if } x \in C, \\ \emptyset & \text{if } x \notin C. \end{cases}$$

The above generalized equation can be transformed to its corresponding normal equation [26]. To state it, define the normal map

$$F(x,y) := \begin{bmatrix} f(x) + \sum_{i \in L_1} y_i^+ \nabla g_i(x) + \sum_{i \in L_2} y_i \nabla g_i(x) \\ -g_1(x) + y_1^- \\ \vdots \\ -g_k(x) + y_k^- \\ -g_{k+1}(x) \\ \vdots \\ -g_m(x) \end{bmatrix} \tag{2.3}$$

for $(x, y) \in R^n \times R^m$, where for $\mu \in R$,

$$\mu^+ := \max\{\mu, 0\}, \qquad \mu^- := \min\{\mu, 0\}.$$

Then the normal equation of VI(f, g) is the following nonlinear equation:

$$F(x, y) = 0. \tag{2.4}$$

The relation of solutions between (2.2) and (2.4) is rather simple: suppose (x, u) is a solution of (2.2), then (x, y) with $y_i := u + g_i(x)$ $(i = 1, \dots, m)$ solves (2.4); if (x, y) is a solution of (2.4) then (x, u) with

$$u_i := \begin{cases} y_i^+ & \text{if } i \in L_1, \\ y_i & \text{if } i \in L_2, \end{cases}$$

solves (2.2). At this point let us remark that the major advantage of using a normal equation approach is that the normal map is piecewise differentiable provided that the functions involved are differentiable. We shall discuss this in a little more detail later. In this paper we mainly use the normal equation to express the stationary conditions. Therefore, we shall use somewhat different but equivalent terminology. A point $x \in R^n$ satisfying (2.4) with some $y \in R^m$ is said to be a stationary solution of VI(f, g), in symbols, $x \in S(f, g)$, and in such a case the pair (x, y) is said to be a GKKT point of VI(f, g), in symbols, $(x, y) \in$ GKKT(f, g). Let x be a stationary solution of VI(f, g). Denote the set of its associated multipliers by $M(x, f, g) := \{y \in R^m : (x, y) \in \text{GKKT}(f, g)\}$ and the set of extreme points of $M(x, f, g)$ by $E(x, f, g)$. Note that the solution conditions that ensure a stationary solution x to be a local solution of VI(f, g) are generally stronger than those in nonlinear programs. For a convex-constrained variational inequality CCVI(f, g) (i.e., each inequality constraint g_i, $i \in L_1$, is convex in x, and each equation constraint g_i, $i \in L_2$, is affine in x) a stationary solution x is then a local solution of CCVI(f, g).

For convenience, let

$$L_D(x, y) := f(x) + \sum_{i \in L_1} y_i^+ \nabla g_i(x) + \sum_{i \in L_2} y_i \nabla g_i(x).$$

For each $(x, y) \in R^n \times R^m$, some characteristic index sets are defined by

$$\begin{aligned} I_0(x, g) &:= L_2 \cup \{i \in L_1 : g_i(x) = 0\}, \\ I_+(y) &:= \{i \in L_1 : y_i > 0\}, \\ I_N(y) &:= L_2 \cup I_+(y). \end{aligned}$$

Consider the following classes of perturbations of VI(f, g):

$\mathcal{P} := \{(\Delta f, \Delta g) = (\Delta f, \Delta g_1, \dots, \Delta g_m)$: $\Delta f : R^n \to R^n$ is once continuously differentiable,

$\Delta g_i : R^n \to R$, $i \in \{1, \dots, m\}$ are twice continuously differentiable$\}$,

equipped with the family of seminorms

$$\begin{aligned} &\text{norm}(\Delta f, \Delta g, U) \\ &\quad := \sup_{1 \le i \le m} \sup_{x \in U} \max\{\|\Delta f(x)\|, \ \|\nabla \Delta f(x)\|, \ |\Delta g_i(x)|, \ \|\nabla \Delta g_i(x)\|, \ \|\nabla^2 \Delta g_i(x)\|\}, \end{aligned}$$

where U is a subset of R^n, and a subclass $\mathcal{P}^*$ of $\mathcal{P}$ defined by

$$\begin{aligned}\mathcal{P}^* := \{(\Delta f, \Delta g) \in \mathcal{P} : \Delta f(x) = Dx + c,\ \Delta g_i(x) = d_i\ (1 \le i \le m)\\ \text{for some } n \times n \text{ matrix } D,\ \text{some vector } c \in R^n,\ \text{and } d = (d_1, \dots, d_m) \in R^m\}.\end{aligned}$$

For each perturbation $(\Delta f, \Delta g) \in \mathcal{P}$ of the problem VI(f, g), we define the map $\Delta F : R^n \times R^m \to R^{n+m}$ as follows:

$$(2.5) \qquad \Delta F(x,y) := \begin{bmatrix} \Delta f(x) + \sum_{i \in L_1} y_i^+ \nabla \Delta g_i(x) + \sum_{i \in L_2} y_i \nabla \Delta g_i(x) \\ -\Delta g_1(x) \\ \vdots \\ -\Delta g_k(x) \\ -\Delta g_{k+1}(x) \\ \vdots \\ -\Delta g_m(x) \end{bmatrix}.$$

Then the normal equation for the perturbed problem VI$(f + \Delta f, g + \Delta g)$ can be written as

$$F(x, y) + \Delta F(x, y) = 0.$$

We now generalize the notion of Kojima's strong stability to variational inequalities. In what follows, we use $B(z, \delta)$ to denote $\{z' \in R^t : \|z' - z\| \le \delta\}$ for any positive number δ and $z \in R^t$.

DEFINITION 2.1. *Let $\mathcal{P}'$ be a subclass of $\mathcal{P}$. We say that a stationary solution x^* to* VI(f, g) *is strongly stable w.r.t. $\mathcal{P}'$ if for some $r > 0$ and each $\varepsilon \in (0, r]$ there exists a $\delta = \delta(\varepsilon)$ such that whenever $(\Delta f, \Delta g) \in \mathcal{P}'$ and* norm$(\Delta f, \Delta g, B(x^*, r)) \le \delta$, *$B(x^*, \varepsilon)$ contains a stationary solution $x(\Delta f, \Delta g)$ to* VI $(f + \Delta f, g + \Delta g)$, *which is unique in $B(x^*, r)$. Similarly, a GKKT point (x^*, y^*) of* VI(f, g) *is said to be strongly stable w.r.t. $\mathcal{P}'$ if for some $r > 0$ and each $\varepsilon \in (0, r]$ there exists a $\delta = \delta(\varepsilon) > 0$ such that whenever $(\Delta f, \Delta g) \in \mathcal{P}'$ and* norm$(\Delta f, \Delta g, B(x^*, r)) \le \delta$, *$B((x^*, y^*), \varepsilon)$ contains a GKKT point $(x(\Delta f, \Delta g), y(\Delta f, \Delta g))$ to* VI$(f + \Delta f, g + \Delta g)$, *which is unique in $B((x^*, y^*), r)$.*

To explain this important concept, we shall make several remarks in the following sections. In the rest of the paper, when we say that x^* is strongly stable without specifying the perturbation class, we simply mean that the perturbation class is $\mathcal{P}$.

Remark 2.2. From Definition 2.1, if x^* is a strongly stable stationary solution (w.r.t. $\mathcal{P}'$), then there are some $r, s > 0$, and some mapping $x(\cdot)$ defined on $W(0, s) := \{(\Delta f, \Delta g) \in \mathcal{P}' : \text{norm}(\Delta f, \Delta g, B(x^*, r)) \le s\}$ such that

(1) $x(\cdot)$ is continuous at $(\Delta f, \Delta g) = 0$ (w.r.t. the above norm) with $x(0) = x^*$;

(2) $S(f+\Delta f, g+\Delta g) \cap B(x^*, r) = \{x(\Delta f, \Delta g)\}$ for all $(\Delta f, \Delta g)$ belonging to $W(0, s)$.

Properties (1) and (2) may be explained informally as follows: if a stationary solution is strongly stable, then the slightly perturbed stationary solution is locally unique and continuous as a function of the perturbation.

Remark 2.3. The above definition about strong stability of GKKT points is different from Kojima's definition when restricted to nonlinear programs. According to Kojima [8], a KKT point (x^*, y^*) of a nonlinear program NLP(f, g) with objective function f and feasible set $R(g)$ is said to be strongly stable (w.r.t. $\mathcal{P}'$) if and only if x^* is a strongly stable stationary solution to NLP(f, g) (w.r.t. $\mathcal{P}'$).

Remark 2.4. (1) If $\mathcal{P}'$ and $\mathcal{P}''$ are subclasses of $\mathcal{P}$ such that $\mathcal{P}' \subset \mathcal{P}''$, then strong stability w.r.t. $\mathcal{P}''$ implies strong stability w.r.t. $\mathcal{P}'$. (2) Strong stability of GKKT points implies local uniqueness of the perturbed stationary solution as well as local uniqueness of the perturbed multipliers. However, a strongly stable stationary solution may have nonunique associated multipliers.

We now turn to discuss an important property, called piecewise differentiability, of the normal map $F(\cdot\,,\cdot)$, which plays a key role in the study of normal maps. We first define the following matrices: Given a GKKT point $(x^*\,, y^*)$, define

$$B = (\nabla g_i(x^*)), \quad i \in I_N(y^*); \qquad C(J) = (\nabla g_i(x^*)), \quad i \in J \quad \text{for } J \subset I_0(x^*, g)\backslash I_N(y^*);$$

and

$$M(J) = \begin{bmatrix} \nabla L_D & B & C(J) \\ -B^{\mathsf{T}} & 0 & 0 \\ -C(J)^{\mathsf{T}} & 0 & 0 \end{bmatrix}$$

for $J \subset I_0(x^*, g)\backslash I_N(y^*)$, where $\nabla L_D := \nabla L_D(x^*, y^*)$. For the given GKKT point (x^*, y^*), we can induce a subdivision K of $R^n \times R^m$ as follows: for any $J \subset I_0(x^*, g)\backslash I_N(y^*)$ define

$$\tau(J) = R^n \times \{y \in R^m : y_i \geq 0,\ i \in J \cup I_N(y^*);\ y_i \leq 0,\ i \in \{1, \ldots, m\}\backslash(J \cup I_N(y^*))\}.$$

Let

$$K = \{\tau(J) : J \subset I_0(x^*, g)\backslash I_N(y^*)\}.$$

Then K is a subdivision of R^{n+m} [8], and $F(\cdot\,,\cdot)$ is continuously differentiable in each piece $\tau(J) \cap B((x^*, y^*), \delta)$, where δ is a positive number, and the corresponding Jacobian matrix $DF(x, y; \tau(J))$ at a point $(x, y) \in \tau(J) \cap B((x^*, y^*), \delta)$ is

$$\bar{M}(J) = \begin{bmatrix} \nabla L_D & B & C(J) & 0 \\ -B^{\mathsf{T}} & 0 & 0 & 0 \\ -C(J)^{\mathsf{T}} & 0 & 0 & 0 \\ -C(\bar{J}) & 0 & 0 & I \end{bmatrix},$$

where $B = (\nabla g_i(x)),\ i \in I_N(y^*)$; $C(J) = (\nabla g_i(x)),\ i \in J$, $C(\bar{J}) = (\nabla g_i(x)), i \in \bar{J}$, ∇L_D is evaluated at (x, y), and $\bar{J} = (I_0(x^*, g)\backslash I_N(y^*))\backslash J$. It is easy to see that $\det \bar{M}(J) = \det M(J)$. The signs of the determinants of $F(x^*, y^*; \tau(J))$ are closely related to the strong stability at (x^*, y^*) and will be demonstrated later. For convenience we shall assume that the sign of the determinant of the matrix (0) is plus one.

According to the subdivision K, we can naturally induce a piecewise affine map LF about the point (x^*, y^*) as follows:

$$LF(x, y) := F(x^*, y^*) + DF(x^*, y^*; \sigma)((x, y) - (x^*, y^*))$$

for every $(x, y) \in \sigma$ and $\sigma \in K$, which is the linearization of the normal map $F(\cdot\,,\cdot)$ about the point (x^*, y^*).

Several commonly used regularity conditions which may hold at a stationary solution x^* to VI(f, g) are as follows:

(a) The linear independence condition (LI) holds at x^* if the set

$$\{\nabla g_i(x^*) : i \in I_0(x^*, g)\}$$

is linearly independent.

(b) The Mangasarian–Fromovitz constraint qualification (MFCQ) holds at x^* if

(i) the set $\{\nabla g_i(x^*) : i \in L_2\}$ is linearly independent,

(ii) there exists z such that $\nabla g_i(x^*)^\mathsf{T} z = 0,\ i \in L_2;\ \nabla g_i(x^*)^\mathsf{T} z < 0,\ i \in L_1 \cap I_0(x^*, g)$.

(c) The strong second-order condition (SSOC) holds at (x^*, y^*) if

$$z^\mathsf{T} \nabla_x L_D(x^*, y^*) z > 0 \quad \text{for all } z \neq 0,\ z \in Z(x^*, y^*),$$

where

$$Z(x^*, y^*) := \{z \in R^n : \nabla g_i(x^*)^\mathsf{T} z = 0,\ i \in I_N(y^*)\}.$$

(d) The general strong second-order condition (GSSOC) holds at x^* if SSOC holds at (x^*, y^*) for every $y^* \in M(x^*, f, g)$.

It is worth pointing out that strong stability is an "open" property. To be precise we have the following result, which is similar to the one given by Klatte and Tammer [7] for strong stability in nonlinear programs.

PROPOSITION 2.5. *Suppose that x^* is a strongly stable stationary solution to* VI(f, g) (*w.r.t. $\mathcal{P}'$*) *and that MFCQ holds at x^*. Let $x(\cdot)$ be the mapping appearing in Remark* 2.2. *Then for any* $(\Delta f, \Delta g) \in W(0, s)$

(i) *$x(\cdot)$ is continuous at $(\Delta f, \Delta g)$ w.r.t. the norm used in Definition* 2.1;

(ii) *$x(\Delta f, \Delta g)$ is a strongly stable stationary solution to* VI$(f + \Delta f, g + \Delta g)$ (*w.r.t. $\mathcal{P}'$*).

As in nonlinear programs (see Klatte and Tammer [7]) we have a relation between strongly stable GKKT points and strongly stable stationary solutions.

PROPOSITION 2.6. *Consider a GKKT point (x^*, y^*) to* VI(f, g). *Then the following two conditions are equivalent*:

(1) *(x^*, y^*) is a strongly stable GKKT point to* VI(f, g) (*w.r.t. $\mathcal{P}' \supset \mathcal{P}^*$*).

(2) *x^* is a strongly stable stationary solution with associated multipliers y^* to* VI(f, g) (*w.r.t. $\mathcal{P}' \supset \mathcal{P}^*$*) *and the LI condition holds at x^* for* VI(f, g).

A major tool that we use in this study is degree theory. We shall briefly review the general conditions under which a degree of a continuous function can be defined and some important properties of degrees of continuous functions. For more information the interested reader may consult Lloyd [16] and Ortega and Rheinboldt [17]. For each subset D of R^t, we use int D, bd D and $\bar{D}$ to denote the interior of D, the boundary of D, and the closure of D, respectively. Let $\phi : R^t \to R^t$ be a continuous function, D be a bounded open subset of R^t, and p be a point in R^t. If $p \notin \phi(\text{bd } D)$, then the Brouwer degree of the map ϕ at p with respect to D, denoted by $\deg(\phi, D, p)$, is well defined. Some properties of degree are as follows:

(i) If $\deg(\phi, D, p) \neq 0$ then there is a solution of $\phi(x) = p$ in D.

(ii) Suppose $\deg(\phi, D, p)$ is defined. Let ψ be a continuous function on $\bar{D}$. If $\sup\{\|\phi(x) - \psi(x)\| : x \in D\} < d(p, \phi(\text{bd } D))$, then $\deg(\psi, D, p)$ is defined and is equal to $\deg(\phi, D, p)$.

(iii) Suppose that $H : [0, 1] \times \bar{D} \to R^t$ is continuous and $p \notin H(t, \text{bd } D)$ for all $t \in [0, 1]$. Then $\deg(H(t, \cdot), D, p)$ is independent of t.

(iv) Suppose that $\deg(\phi, D, p)$ is defined. Let S be a compact subset of D such that there are no solutions of the equation $\phi(x) = p$ in S. Then $\deg(\phi, D \backslash S, p)$ is defined and is equal to $\deg(\phi, D, 0)$.

Note that from (i) we know that if $\deg(\phi, D, 0) \neq 0$, then $\phi(x) = 0$ is solvable in D. Moreover, it follows from (ii) that the solvability is preserved if the function is slightly perturbed. This fact is particularly useful for stability analysis.

3. Characterizations of strongly stable GKKT points. In the context of nonlinear programming, a strongly stable KKT point is a strongly regular KKT point and vice versa [7]. It is now well known that both concepts are related to the local homeomorphism of the linearization of the normal map $F(x,y)$ at a solution of the normal equation in question. It is not difficult to show that these relations are also retained in the context of variational inequalities. So in this section we sometimes use the term "strongly regular" and at other times we use "strongly stable" according to the context, assuming the reader is well aware of this fact. In Robinson's original paper on generalized equations [22], he obtained a complete characterization for strongly regular GKKT points, which we will state first. Then, we shall establish a new and complete characterization for strongly stable GKKT points with the aid of the idea of coorientedness. Some results in this section are direct extensions of known results from nonlinear programs. We present them here for the sake of completeness and easy reference.

We first recall Robinson's definition of a strongly regular GKKT point. Adapting Robinson's general definition of a strongly regular generalized equation [22] to our case, we say that a GKKT point (x^*,y^*) of $\mathrm{VI}(f,g)$ is strongly regular if the normal map $F_L(\cdot,\cdot)$ corresponding to the following affine variational inequality:

$$\mathrm{LVI}(f,g) \qquad \text{find } x \in LR(g) \quad \text{such that } Lf(x)^{\mathrm{T}}(x'-x) \geq 0 \quad \text{for all } x' \in LR(g),$$

where $Lf(x) := f(x^*) + \nabla f(x^*)(x - x^*)$ and $LR(g) := \{x \in R^n : Lg_i(x) := g_i(x^*) + \nabla g_i(x^*)^{\mathrm{T}}(x-x^*) \leq 0,\ i \in L_1;\ Lg_i(x) := g_i(x^*) + \nabla g_i(x^*)^{\mathrm{T}}(x-x^*) = 0,\ i \in L_2\}$, is Lipschitzian invertible at (x^*,y^*).

Recall that if a matrix H is partitioned as

$$H = \begin{bmatrix} A & B \\ C & D \end{bmatrix}$$

with A nonsingular, then the Schur complement of A in H, written (H/A), is defined as $D - CA^{-1}B$. An excellent and extensive study of this concept may be found in Oullette [18].

Below we summarize several basic results about strongly stable GKKT points and strongly regular GKKT points. A similar theorem was given by Klatte and Tammer [7] in the context of nonlinear programs.

THEOREM 3.1. *Suppose that (x^*,y^*) is a GKKT point of* $\mathrm{VI}(f,g)$. *Then the following are equivalent*:

(1) (x^*,y^*) *is a strongly regular GKKT point*;

(2) (*Robinson* [22])

(i) $M(\emptyset)$ *is nonsingular*,

(ii) $I_0(x^*,g)\backslash I_N(y^*) = \emptyset$ *or* $M(I_0(x^*,g)\backslash I_N(y^*))/M(\emptyset)$ *has positive principal minors*;

(3) (x^*,y^*) *is a strongly stable GKKT point* (*w.r.t.* $\mathcal{P}$);

(4) (x^*,y^*) *is a strongly stable GKKT point* (*w.r.t.* $\mathcal{P}^*$);

(5) $LF(\cdot,\cdot)$ *is a homeomorphism from* R^{n+m} *to* R^{n+m}.

We postpone giving the proof until we establish some basic facts for variational inequalities.

Robinson [22] applied the equivalence of (1) and (2) in Theorem 3.1 to nonlinear programming problems and proved that the LI condition and strong second-order sufficient condition are sufficient for (2). He also gave an example to show that these conditions are not necessary in general. However, combining the above theorem with Corollary 6.6 of Kojima [8], we see that if a stationary solution of a nonlinear program is known to be a local minimizer a priori, then the LI condition and strong second-order sufficient condition are also necessary for strong regularity.

The main drawback of the above characterization (Theorem 3.1 (2)) for strongly regular GKKT points may be that it uses higher-dimensional matrices instead of the Jacobian of the Lagrange function $L_D(x^*, y^*)$. Kyparisis [13] extended Robinson's results to variational inequalities showing that the LI condition and strong second-order condition are sufficient for strongly regular GKKT points. As was explained in the introduction, the strong second-order condition, although quite suitable for nonlinear programs, may not be very effective in stability analysis of variational inequalities. However, the concept of coorientedness, as we will see in the following theorem, can completely characterize the strong regularity of variational inequalities. In stating this result, for a given GKKT point (x^*, y^*), we use $C(x^*, y^*)$ to denote the critical cone at this point:

$$\begin{aligned} &C(x^*, y^*) \\ &\quad = \{z \in R^n : \nabla g_i(x^*)^{\mathsf{T}} z = 0,\ i \in I_N(y^*);\ \nabla g_i(x^*)^{\mathsf{T}} z \leq 0,\ i \in I_0(x^*, g) \backslash I_N(y^*)\}. \end{aligned}$$

THEOREM 3.2. *Let (x^*, y^*) be a GKKT point of* VI(f, g). *Then (x^*, y^*) is a strongly regular GKKT point if and only if*: (1) *The LI condition holds at x^**; *and* (2) *the coorientedness condition* (*CC*) *holds at (x^*, y^*), i.e., $\nabla L_D(x^*, y^*)$ is cooriented on $C(x^*, y^*)$.*

The coorientedness condition may not be easy to verify in general. However, in some particular cases the difficulty can be reduced. Let us see two extreme cases first. If $I_0(x^*, g) = I_N(y^*)$, i.e., the strict complementary slackness condition holds, then CC is equivalent to the condition that the restriction of $\nabla L_D(x^*, y^*)$ on the subspace $C(x^*, y^*)$ is nonsingular (in this case $C(x^*, y^*)$ is a subspace); if $I_0(x^*, g) = \emptyset$, then CC is just the nonsingular condition in the standard calculus. For the general case, we can perform the reduction procedure [27] as follows: Let E be the affine hull of $C(x^*, y^*)$, i.e., $E = \{z \in R^n : \nabla g_i(x^*)^{\mathsf{T}} z = 0,\ i \in I_N(y^*)\}$; let L be the lineality space of $C(x^*, y^*)$, i.e., $L = \{z \in R^n : \nabla g_i(x^*)^{\mathsf{T}} z = 0,\ i \in I_0(x^*, g)\}$. Now choose an orthonormal matrix partitioned as $(L\ M\ T)$ such that the columns of L, $E = (L\ M)$, and $(L\ M\ T)$ form the bases of the subspaces L, E, and R^n, respectively. Let d_L and d_E be the dimensions of L and E, respectively. If $d_L > 0$, then the section of $\nabla L_D(x^*, y^*)$ in the subspace E is

$$E^{\mathsf{T}} \nabla L_D(x^*, y^*) E = \begin{bmatrix} L^{\mathsf{T}} \nabla L_D(x^*, y^*) L & L^{\mathsf{T}} \nabla L_D(x^*, y^*) M \\ M^{\mathsf{T}} \nabla L_D(x^*, y^*) L & M^{\mathsf{T}} \nabla L_D(x^*, y^*) M \end{bmatrix}.$$

Denote by aff(M) the subspace spanned by M. If the dimension of aff(M) that is equal to $(d_E - d_L)$ is much smaller than that of $C(x^*, y^*)$ then the difficulty of checking CC can be reduced, as we will see in the following result.

THEOREM 3.2$'$. *Let (x^*, y^*) be a GKKT point of* VI(f, g). *Then (x^*, y^*) is a strongly regular GKKT point if and only if*:

(1) *the LI condition holds at x^**;

(2i) *when $d_L = 0$, $E^{\mathsf{T}} \nabla L_D(x^*, y^*) E$ is positively cooriented on* aff$(M) \cap C(x^*, y^*)$;

(2ii) *when $d_L > 0$, $L^{\mathsf{T}} \nabla L_D(x^*, y^*) L$ is nonsingular, and $E^{\mathsf{T}} \nabla L_D(x^*, y^*) E / L^{\mathsf{T}} \nabla L_D(x^*, y^*) L$ is positively cooriented on* aff$(M) \cap C(x^*, y^*)$.

Before proceeding to prove the theorems, we give an example to demonstrate a situation where the GKKT point being considered is strongly regular, but SSOC does not hold. Note that SSOC implies CC and not vice versa.

Example 3.3. Consider the following VI(f, g) with $f(x) = (1,\ x_2 + x_3,\ -4x_2 + x_3)^{\mathsf{T}}$, $g_1(x) = -x_1,\ g_2(x) = -x_2,\ g_3(x) = -x_3,\ L_1 = \{1, 2, 3\}$, and $L_2 = \emptyset$. Let $x^* = (0, 0, 0)^{\mathsf{T}}$.

It is easy to check that the point (x^*, y^*) with $y^* = (1,0,0)^{\mathrm{T}}$ is a GKKT point, and that

$$\nabla L_D(x^*, y^*) = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 1 & 1 \\ 0 & -4 & 1 \end{bmatrix},$$

and $I_0(x^*, g) = \{1,2,3\}$, $I_N(y^*) = \{1\}$. It is not difficult to check that $C(x^*, y^*) = \{z \in R^n : z_1 = 0,\ z_2 \geq 0,\ z_3 \geq 0\}$, $L = \{0\}$, aff$(M) = \{z \in R^n : z_1 = 0,\ z_2 \in R,\ z_3 \in R\}$, and $Z(x^*, y^*) =$ aff(M). Obviously, LI holds at x_0. Also, we can easily verify that condition (2i) in Theorem 3.2′ holds. Therefore, it follows that (x^*, y^*) is a strongly regular GKKT point.

We now show that SSOC does not hold at x_0. Take $z = (0,1,1)^{\mathrm{T}} \in Z(x^*, y^*)$. An algebraic calculation yields that $z^{\mathrm{T}} \nabla L_D(x^*, y^*) z = -1 < 0$. Thus SSOC does not hold at x_0.

To prove Theorem 3.2 we need several technical lemmas. The first one below presents an alternative form of characterization (2) in Theorem 3.1.

LEMMA 3.4. *Suppose (x^*, y^*) is a GKKT point of* VI(f, g). *It is a strongly regular GKKT point if and only if* signdet$M(J)$ *is a nonzero constant for all $J \subset I_0(x^*, g) \backslash I_N(y^*)$.*

Proof. It is obvious that under the hypotheses of Lemma 3.4, $M(\emptyset)$ must be nonsingular. Note that any principal submatrix of $M(I_0(x^*, g) \backslash I_N(y^*))/M(\emptyset)$ takes the form $C(J)^{\mathrm{T}} M(\emptyset)^{-1} C(J)$ for some $J \subset I_0(x^*, g) \backslash I_N(y^*)$. Conversely, for any $J \subset I_0(x^*, g) \backslash I_N(y^*)$, there is a principal submatrix of $M(I_0(x^*, g) \backslash I_N(y^*))/M(\emptyset)$ which takes the form $C(J)^{\mathrm{T}} M(\emptyset)^{-1} C(J)$. In addition, by the determinant formula of the Schur complement, we have

$$\det M(J) = \det(C(J)^{\mathrm{T}} M(\emptyset)^{-1} C(J)) \det M(\emptyset).$$

Therefore, signdet$M(J)$ has the common sign $=$ signdet$M(\emptyset)$ for all $J \subset I_0(x^*, g) \backslash I_N(y^*)$ if and only if $M(I_0(x^*, g) \backslash I_N(y^*))/M(\emptyset)$ has positive principal minors. Hence the desired conclusion follows from (2) in Theorem 3.1. □

The next lemma says that if the orientation of the section of a linear transformation in a subspace is zero, then small perturbations to the linear transformation can make the orientations of the sections of the perturbed linear transformations take any value. This lemma is an extension of Lemma 3.4 in [8].

LEMMA 3.5. *Let N be an $n \times n$ square matrix and C an $n \times p$ matrix with* rank$(C) = p$ *and $p \leq n$. Assume that* $\det(C^{\mathrm{T}} N C) = 0$. *Then there exist $n \times n$ matrices Q^+ and Q^- such that for any $\gamma > 0$,*

$$\det(C^{\mathrm{T}}(N + \gamma Q^+)C) > 0 \tag{3.1}$$

and

$$\det(C^{\mathrm{T}}(N + \gamma Q^-)C) < 0. \tag{3.2}$$

Proof. Since $C^{\mathrm{T}} N C$ is a $p \times p$ matrix with $\det(C^{\mathrm{T}} N C) = 0$, it is similar to a unique Jordan matrix D, i.e., there exists a $p \times p$ nonsingular matrix P such that

$$C^{\mathrm{T}} N C = P D P^{-1},$$

where D is a block-diagonal matrix of the form

$$D = \begin{bmatrix} D_1 & 0 & \cdots & 0 \\ 0 & D_2 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & D_s \end{bmatrix}.$$

Each D_i is a $p_i \times p_i$ Jordan matrix of a common (complex) eigenvalue λ_j $(j = p_1 + \cdots + p_{i-1} + 1, \ldots, p_1 + \cdots + p_{i-1} + p_i)$; λ_i and λ_j belonging to different D_i and D_j are distinct; $p_1 + p_2 + \cdots + p_s = p$; and there is at least one j such that $\lambda_j = 0$. Without loss of generality we assume that $\lambda_i = 0$ $(1 \le i \le k)$ and $0 \ne \lambda_j$ $(k+1 \le j \le p)$. Choose $\mu_i \in \{-1, 0, 1\}$ $(1 \le i \le p)$ such that

$$\mu_1 \cdots \mu_k \lambda_{k+1} \cdots \lambda_p > 0 \quad \text{and} \quad \mu_j = 0 \qquad (k+1 \le j \le p). \tag{3.3}$$

Now define a $p \times p$ matrix

$$V^+ = P \begin{bmatrix} \mu_1 & & 0 \\ & \ddots & \\ 0 & & \mu_p \end{bmatrix} P^{-1}.$$

From this construction, it is not difficult to see that

$$\det(C^{\mathrm{T}} N C + \gamma V^+) = \gamma^k \det(P) \det(P^{-1}) \mu_1 \ldots \mu_k \lambda_{k+1} \ldots \lambda_p > 0.$$

On the other hand, since C has full column rank, without loss of generality we can assume that the set of the first p rows of C is linearly independent, and then partition the matrix C into

$$C = \begin{bmatrix} C_1 \\ C_2 \end{bmatrix}$$

with $p \times p$ matrix C_1 nonsingular. Define the $n \times n$ matrix Q^+ as follows:

$$Q^+ = \begin{bmatrix} (C_1^{-1})^{\mathrm{T}} V^+ C_1^{-1} & 0 \\ 0 & 0 \end{bmatrix}.$$

Then a simple calculation shows that Q^+ satisfies (3.1) for every $\gamma > 0$. The existence of an $n \times n$ matrix Q^- satisfying (3.2) for any $\gamma > 0$ can be proved similarly by replacing (3.3) with

$$\mu_1 \ldots \mu_k \lambda_{k+1} \ldots \lambda_p < 0 \quad \text{and} \quad \mu_j = 0 \quad (k+1 \le j \le p).$$

This completes the proof. □

The following lemma presents a connection between the orientation of a linear transformation with a particular form and the orientation of the section of the linear transformation in a particular subspace. This lemma extends Theorem 3.5 of Kojima [8], where he considered the symmetric case. The proof is analogous to that of the aforementioned result in [8] except that it uses Lemma 3.5 instead of the results in [8].

LEMMA 3.6. *Consider the following square matrix M:*

$$M = \begin{bmatrix} N & B \\ -B^{\mathrm{T}} & 0 \end{bmatrix}$$

with an $n \times n$ square matrix N and an $n \times m$ matrix B, and $n \ge m$. If $\operatorname{rank}(B) = m$ *then* $\operatorname{signdet}(M) = \operatorname{signdet}(N(\ker(B^{\mathrm{T}})))$, *where* $N(\ker(B^{\mathrm{T}}))$ *is a matrix that represents the section of the linear transformation N in the subspace* $\ker(B^{\mathrm{T}})$.

Using Lemma 3.6, we can easily give the proof of Theorem 3.2.

Proof of Theorem 3.2. We prove this theorem by showing the equivalence of the hypotheses of the theorem and those of Lemma 3.4. We shall show first that the assumptions of Theorem

3.2 imply those of Lemma 3.4. Take any $J \subset I_0(x^*, g)\backslash I_N(y^*)$. Let $N = \nabla L_D(x^*, y^*)$ and let $B = (\nabla g_i(x^*)), \ (i \in I_N(y^*))$ and $C(J) = (\nabla g_i(x^*)), \ (i \in J)$. Then

$$\begin{aligned}\ker((B\ C(J))^{\mathsf{T}}) = \{z \in R^n : \nabla g_i(x^*)^{\mathsf{T}} z = 0,\ i \in I_N(y^*);\\ \nabla g_i(x^*)^{\mathsf{T}} z = 0,\ i \in J\}.\end{aligned}$$

Denote $\ker((B\ C(J))^{\mathsf{T}})$ by L. It is easy to see that $F = L \cap C(x^*, y^*)$ is a face of $C(x^*, y^*)$. Choose an orthogonal basis $V = (v_i)$ of the subspace L. By definition $V^{\mathsf{T}} N V$ is a section of N in the subspace L. Since the LI condition holds, Lemma 3.6 is applicable here, and consequently we obtain that $\mathrm{signdet}(M(J)) = \mathrm{signdet}(V^{\mathsf{T}} N V)$. Therefore, CC implies that $\mathrm{signdet} M(J)$ is a nonzero constant for all $J \subset I_0(x^*, g)\backslash I_N(y^*)$.

Similarly it is not hard to show that the hypotheses of Lemma 3.6 imply those of Theorem 3.2; we omit the details. □

Proof of the equivalence of Theorems 3.2 *and* 3.2′. The equivalence of Theorems 3.2 and 3.2′ readily follows from some results in Robinson [27]. Note that the homeomorphism condition of a normal map induced by a linear transformation A on a polyhedral convex cone C is equivalent to the coorientedness of A on C. Therefore, Propositions 2.2 and 2.3 in [27] imply that $\nabla L_D(x^*, y^*)$ is cooriented on $C(x^*, y^*)$ if and only if $E^{\mathsf{T}} \nabla L_D(x^*, y^*) E$ is cooriented on $\mathrm{aff}(M) \cap C(x^*, y^*)$ if $d_L = 0$, $L^{\mathsf{T}} \nabla L_D(x^*, y^*) L$ is nonsingular, and $E^{\mathsf{T}} \nabla L_D(x^*, y^*) E / L^{\mathsf{T}} \nabla L_D(x^*, y^*) L$ is cooriented on $\mathrm{aff}(M) \cap C(x^*, y^*)$ if $d_L > 0$. On the other hand, since $\mathrm{aff}(M) \cap C(x^*, y^*)$ is a polyhedral convex cone containing no lines, any linear transformation B is cooriented on $\mathrm{aff}(M) \cap C(x^*, y^*)$ if and only if it is positively cooriented. This completes the proof. □

Below we cite two results from [8] that are applicable here. The first one says that the linearization $LF(\cdot\,,\cdot)$ of the normal map $F(\cdot\,,\cdot)$ about the point (x^*, y^*) is a homeomorphism if and only if the determinants of $DF(x^*, y^*; \sigma)$ for all pieces σ in K have a common sign.

PROPOSITION 3.7 [8, Thm. 3.3]. *Let* (x^*, y^*) *be a GKKT point to* VI(f, g). *The linearization* $LF(\cdot\,,\cdot)$ *is a homeomorphism if and only if* $\mathrm{signdet} DF(x^*, y^*; \sigma)$ *is a nonzero constant for all* $\sigma \in K$.

The second proposition below says that if the normal map itself is a local homeomorphism then the local degree of the normal map is ± 1 and the determinants of $DF(x^*, y^*; \sigma)$ obey some inequality. Note that the homeomorphism property of $LF(\cdot\,,\cdot)$ implies the local homeomorphism property of $F(\cdot, \cdot)$ but the converse is not true in general.

PROPOSITION 3.8 [8, Lem. 2.3]. *Suppose that* $F(\cdot\,,\cdot)$ *is a local homeomorphism at* (x^*, y^*). *Then, for some* $\delta^* > 0$ *one has*

$$\deg(F, \mathrm{int}\, B(x^*, y^*, \delta), 0) = +1 \quad \text{for all } \delta \in (0, \delta^*] \tag{3.4}$$

or

$$\deg(F, \mathrm{int}\, B(x^*, y^*, \delta), 0) = -1 \quad \text{for all } \delta \in (0, \delta^*]. \tag{3.5}$$

Moreover, if (3.4) (*or* (3.5)) *holds then*

$$\mathrm{det} DF(x, y; \sigma) \geq 0 \quad (\text{or } \leq 0)$$

for all $(x, y) \in \sigma \cap \mathrm{int}\, B(x^*, y^*, \delta^*)$ *and* $\sigma \in K$.

Now we are ready to prove Theorem 3.1.

Proof of Theorem 3.1. The equivalence of (1) ⇔ (2) was shown in [22] and the equivalence of (2) ⇔ (5) follows from Lemma 3.4 and Proposition 3.7. To complete the proof, we shall show the following implications: (1) ⇒ (3), (3) ⇒ (4), and (4) ⇒ (5).

(1) $\Rightarrow$ (3): This implication readily follows from Theorem 2.1 of [22].

(3) $\Rightarrow$ (4): Since $\mathcal{P}^* \subset \mathcal{P}$, the implication is obvious.

(4) $\Rightarrow$ (5): From Proposition 2.6 we see that the LI condition holds at x^*. The rest of the proof is similar to that of Theorem 4.2 in [8] except that it uses Lemma 3.5, Lemma 3.6, Proposition 3.7, and Proposition 3.8 instead of Lemma 3.4, Theorem 3.5, Theorem 3.3, and Lemma 2.3 in [8], respectively. □

From Theorem 3.1 and Proposition 3.8 we know that the local degree of the normal map at a strongly stable GKKT point is either $+1$ or -1. We now claim that the sign of the local degree of the normal map at a strongly stable GKKT point can be determined if we have additional information about the coorientedness condition.

COROLLARY 3.9. *Let (x^*, y^*) be a strongly stable GKKT point of* VI(f, g). *Then for some $\delta^* > 0$ one has*

$$\deg(F, \operatorname{int}B(x^*, y^*, \delta), 0) = +(-)1 \quad \textit{for all } \delta \in (0, \delta^*]$$

if and only if $\nabla L_D(x^*, y^*)$ is positively (negatively) cooriented on $C(x^*, y^*)$.

Proof. Since (x^*, y^*) is a strongly stable GKKT point, the normal map $F(\cdot\,, \cdot)$ is then a local homeomorphism. Therefore, by Proposition 3.8 there exists $\delta^* > 0$ such that

$$\deg(F, \operatorname{int}B(x^*, y^*, \delta), 0) = +1$$

or

$$\deg(F, \operatorname{int}B(x^*, y^*, \delta), 0) = -1$$

for all $\delta \in (0, \delta^*]$. By Theorem 3.2 we know that $\nabla L_D(x^*, y^*)$ is either positively or negatively cooriented on $C(x^*, y^*)$. On the other hand, choose any $\sigma \in K$. If $\nabla L_D(x^*, y^*)$ is positively (negatively) cooriented on $C(x^*, y^*)$, from the proof of Theorem 3.2 we know that $\operatorname{sign}\det DF(x^*, y^*; \sigma) = +(-)1$. Then the desired result follows from the second conclusion in Proposition 3.8. □

Finally, we note a connection of strongly stable GKKT points with Clark's notion of nonsingularity of nondifferentiable maps: a GKKT point (x^*, y^*) is strongly stable if and only if $\partial F(x^*, y^*)$, the generalized Jacobian of the normal map $F(\cdot\,, \cdot)$ at (x^*, y^*), is nonsingular. The interested reader may consult Jongen, Klatte, and Tammer [6] for details.

4. Strongly stable stationary solutions.

As we have seen in the previous section, various complete characterizations for strongly stable GKKT points from different perspectives have been established, and strong stability behavior of GKKT points has been more or less well understood. However, when we are concerned with a parametric variational inequality, the assumption of the LI condition seems to be too strong because at some value of the parameter more than n constraints can be active, and in such a case the LI condition certainly fails. A reasonable replacement of the LI condition will be MFCQ. It is now known that the latter constraint qualification is necessary and sufficient for the topological stability of the feasible set [2]. In this section we shall establish the first complete characterization of strongly stable stationary solutions in the framework of MFCQ.

For convenience of reference, we list below some important properties of MFCQ.

PROPOSITION 4.1. *Suppose x^* is a feasible point of* VI(f, g) *and MFCQ holds at x^* for* VI(f, g). *Then there exist some r, $\delta > 0$ such that*

(i) *$M(x^*, f, g)$ is bounded*;

(ii) *MFCQ holds at any feasible point $x \in B(x^*, r)$ of* VI$(f + \Delta f, g + \Delta g)$ *provided that* $\operatorname{norm}(\Delta f, \Delta g, B(x^*, r)) \le \delta$;

(iii) *$M(x, f + \Delta f, g + \Delta g)$ as a function of $(x, \Delta f, \Delta g)$ is upper semicontinuous.*

Our characterization for strongly stable stationary solutions under MFCQ should reduce to the one for strongly stable stationary solutions under the LI condition when MFCQ reduces to the LI condition. Note that under MFCQ the set of associated multipliers with a stationary solution may not be a singleton. Therefore, it is reasonable to imagine that when MFCQ holds, but the LI condition does not, we shall impose a condition similar to the LI case for all GKKT points associated with the stationary solution in question. Such a condition, called the general coorientedness condition, together with MFCQ provides a complete characterization for strongly stable stationary solutions.

To motivate the general coorientedness condition, we shall briefly examine what additional difficulties would occur if the LI condition were weakened to MFCQ. We have seen in the previous sections that the coorientedness condition requires that the sections of the Jacobian matrix $\nabla L_D(x,y)$ in all subspaces spanned by the faces of the polyhedral cone $C(x,y)$ have the same nonzero orientation, so it is indeed closely related to the combinatorial structures of $C(x,y)$. Note that although both the LI condition and MFCQ are sufficient for the topological stability of the feasible set, an essential difference between the LI condition and MFCQ is that the former ensures the stability of the combinatorial structure of the polyhedral set $C(x,y)$ but the latter does not. Therefore, in the case in which MFCQ holds but the LI condition does not, we have to take care of all possible combinatorial structures that a slightly perturbed polyhedral cone $C(x,y)$ can have.

We now introduce the general coorientedness condition.

DEFINITION 4.2. *Let $x \in R^n$ be a stationary solution to* VI(f,g). *We say that the general positive (or negative) coorientedness condition (GPCC or GNCC) holds at x if for each $y \in M(x,f,g)$,*

$$\nabla L_D(x,y) \text{ is positively (or negatively) cooriented on } C(x,y;J) \quad \text{for all } J \subset I_0(x,g)\backslash I_N(y),$$

where $C(x,y;J)$ is defined as

$$C(x,y;J) = \{z \in R^n : \nabla g_i(x)^{\mathsf{T}} z = 0,\ i \in I_N(y);\ \nabla g_i(x)^{\mathsf{T}} z \le 0,\ i \in J\}.$$

We say that the general coorientedness condition (GCC) holds at x if either GPCC or GNCC holds at x.

Here is the main result of the paper.

THEOREM 4.3. *Suppose that x^* is a stationary solution of* VI(f,g) *and that MFCQ holds there. Then x^* is a strongly stable stationary solution if and only if GCC holds at x^*.*

The verification of GCC involves checking CC for each multiplier in $M(x^*,f,g)$, and this may not be an easy task. We will give more verifiable sufficient conditions later. Note that the reduction procedure described in §3 is applicable for verifying CC at a particular GKKT point (x^*,y^*) on $C(x^*,y^*;J)$.

The proof of our main result is rather long. We shall first establish some technical lemmas and then go to the main part of the proof. Although an elementary and self-contained proof is possible, we have decided to present a proof which relies on degree theory. The reasons for this choice are not only that such a proof is much shorter, but that we think the generic nature of the LI condition is the essence of the problem here. This is more in keeping with the spirit of degree theory.

An important property of GCC is that it is locally preservable. To be precise, we have the following result.

LEMMA 4.4. *Assume that x^* is a stationary solution to* VI(f,g) *and that MFCQ holds at x^*. Assume further that GPCC (or GNCC) holds at x^* for* VI(f,g). *Then there exist some $r,\ \delta > 0$ such that for any stationary solution $x \in B(x^*,r)$ to* VI$(f+\Delta f, g+\Delta g)$

satisfying $(\Delta f, \Delta g) \in \mathcal{P}$ *and* $\operatorname{norm}(\Delta f, \Delta g, B(x^*, r)) \leq \delta$, *GPCC* (*or GNCC*) *holds at* x *for* $\mathrm{VI}(f + \Delta f, g + \Delta g)$.

Proof. We only prove the case where GPCC holds at x^*. The other case can be shown similarly. Suppose the contrary. Then there exist sequences of perturbations $\{(\Delta^j f, \Delta^j g)\} \subset \mathcal{P}$, stationary solutions $\{x_j\} \subset S(f + \Delta^j f, g + \Delta^j g)$, multipliers $\{y_j\} \in M(x_j, f + \Delta^j f, g + \Delta^j g)$, index sets $\{J_j\} \subset I_0(x_j, g + \Delta^j g) \backslash I_N(y_j)$, and some orthonormal matrices $\{W_j\}$ such that $\operatorname{norm}(\Delta^j f, \Delta^j g, B(x^*, r)) \to 0$, $x_j \to x^*$, the columns of the matrices $\{W_j\}$ form bases of the subspaces spanned by some faces F_j of $C(x, y; J_j)$, and $\det((W_j)^{\mathrm{T}} \nabla L_D(x_j, y_j)(W_j)) \leq 0$. Without loss of generality we may assume that

(1) $y_j \to y^*$ (Proposition 4.1);

(2) $J_j \to J \subset I_0(x^*, g)$;

(3) $\{W_j\} \to$ some matrix W.

Then $J \subset I_0(x^*, g) \backslash I_N(y^*)$, the columns of the matrix W form a basis for a face of $C(x^*, y^*; J)$, and $\det(W^{\mathrm{T}} \nabla L_D(x^*, y^*) W) \leq 0$. This contradicts GPCC. □

In addition to the hypotheses of Lemma 4.4, if the multiplier set $M(x^*, f, g)$ is a singleton, say $\{y^*\}$, then (x^*, y^*) is a strongly stable GKKT point; if $M(x^*, f, g)$ is not a singleton, we can take an extreme point of $M(x^*, f, g)$, say y^*. We then perturb the original problem by defining

$$\begin{aligned} &\Delta^\varepsilon f(x) = 0, \\ &\Delta^\varepsilon g_i(x) = \begin{cases} 0 & \text{if } i \in I_N(y^*), \\ -\varepsilon & \text{otherwise} \end{cases} \end{aligned} \tag{4.1}$$

for $i = 1, \ldots, m$, $\varepsilon \geq 0$, and $x \in R^n$. Let

$$y_i^\varepsilon = \begin{cases} y_i^* & \text{if } i \in I_N(y^*), \\ y_i^* - \varepsilon & \text{otherwise} \end{cases}$$

for $i = 1, \ldots, m$. Then

$$F(x^*, y^\varepsilon) + \Delta^\varepsilon F(x^*, y^\varepsilon) = F(x^*, y^*) = 0 \tag{4.2}$$

for all $\varepsilon \geq 0$. This shows that x^* is also a stationary solution to $\mathrm{VI}(f + \Delta^\varepsilon f, g + \Delta^\varepsilon g)$ for all $\varepsilon \geq 0$. Actually, we can obtain more than this conclusion.

LEMMA 4.5. *Assume the hypotheses of Lemma* 4.4. *Then in the above setting there exist* δ, $\varepsilon^* > 0$ *such that* x^* *is the unique stationary solution to* $\mathrm{VI}(f + \Delta^\varepsilon f, g + \Delta^\varepsilon g)$ *in* $B(x^*, \delta)$ *for all* $\varepsilon \in [0, \varepsilon^*]$.

Proof. To avoid piecewise differentiability arguments, we shall use the generalized equation (2.2) to express the stationary conditions in the proof. Also, we shall assume without loss of generality that all constraints are active at x^*, i.e., $I_0(x^*, g) = \{1, \ldots, m\}$. Suppose the assertion is false. Then there exist sequences of perturbations $\{(\Delta^{\varepsilon_j} f, \Delta^{\varepsilon_j} g)\} \in \mathcal{P}$ and GKKT points $\{(x^j, u^j)\}$ to $\mathrm{VI}(f + \Delta^{\varepsilon_j} f, g + \Delta^{\varepsilon_j} g)$ such that $\varepsilon_j \to 0$ and $x^j \neq x^*$. Note that for all $x \in R^n$, $(f + \Delta^{\varepsilon_j} f)(x) = f(x)$ and $\nabla(g + \Delta^{\varepsilon_j} g)(x) = \nabla g(x)$. Hence for each j the point (x^j, u^j) satisfies

$$0 \in \begin{bmatrix} L_D(x^j, u^j) \\ -(g + \Delta^{\varepsilon_j} g)(x^j) \end{bmatrix} + N_{R^n \times R^k_+ \times R^l}(x^j, u^j),$$

where $L_D(x^j, u^j) := f(x^j) + \sum_{i=1}^m u_i^j \nabla g_i(x^j)$. Without loss of generality we can assume that

(i) $u^j \to \bar{u} \in M(x^*, f, g)$ and $I_+(u^j) = I_+$ for all j;

(ii) $z_j = (x^j - x^*)/\|(x^j - x^*)\| \to z$.

Then we claim that

(iii) $I_+ \supset I_+(\bar{u}),\ I_N \supset I_N(\bar{u})$ and $z \neq 0$, where $I_N = I_+ \cup L_2$;

(iv) $\nabla g_i(x^*)^{\mathsf{T}} z = 0$ for $i \in I_N(\bar{u})$ and $\nabla g_i(x^*)^{\mathsf{T}} z \geq 0$ for $i \in I_N \backslash I_N(\bar{u})$;

(v) $(\nabla_x L_D(x^*, \bar{u})z)^{\mathsf{T}} y \geq 0$ if y satisfies $\nabla g_i(x^*)^{\mathsf{T}} y = 0$ for $i \in I_N(\bar{u})$ and $\nabla g_i(x^*)^{\mathsf{T}} y \leq 0$ for $i \in I_N \backslash I_N(\bar{u})$.

Conclusion (iii) above is obvious. To prove (iv), we note first that for any $i \in I_+(y^*)$,

$$g_i(x^j) \leq 0,$$

and for any $i \in L_2$,

$$g_i(x^j) = 0.$$

Therefore, for $i \in I_+(y^*)$,

$$g_i(x^j) = g_i(x^*) + \nabla g_i(x^*)^{\mathsf{T}}(x^j - x^*) + o(\|x^j - x^*\|) \Rightarrow \nabla g_i(x^*)^{\mathsf{T}} z \leq 0, \tag{4.3}$$

and for $i \in L_2$,

$$g_i(x^j) = g_i(x^*) + \nabla g_i(x^*)^{\mathsf{T}}(x^j - x^*) + o(\|x^j - x^*\|) \Rightarrow \nabla g_i(x^*)^{\mathsf{T}} z = 0. \tag{4.4}$$

Since

$$f(x^*) + \sum_{i \in I_+(y^*)} y_i^* \nabla g_i(x^*) + \sum_{i \in L_2} y_i^* \nabla g_i(x^*) = 0,$$

we obtain from (4.3) and (4.4) that

$$f(x^*)^{\mathsf{T}} z = - \sum_{i \in I_+(y^*)} y_i^* \nabla g_i(x^*)^{\mathsf{T}} z - \sum_{i \in L_2} y_i^* \nabla g_i(x^*)^{\mathsf{T}} z \geq 0. \tag{4.5}$$

On the other hand, we have that for any $i \in I_+ = I_+(u^j)$,

$$g_i(x^j) = \varepsilon_j \quad \text{or} \quad 0 \geq 0.$$

Using the above argument we can deduce that for any $i \in I_+$,

$$\nabla g_i(x^*)^{\mathsf{T}} z \geq 0. \tag{4.6}$$

From

$$f(x^*) + \sum_{i \in I_+(\bar{u})} \bar{u}_i \nabla g_i(x^*) + \sum_{i \in L_2} \bar{u} \nabla g_i(x^*) = 0, \tag{4.7}$$

we have that using (4.4), (4.6), and the fact that $I_+(\bar{u}) \subset I_+$,

$$f(x^*)^{\mathsf{T}} z = - \sum_{i \in I_+(\bar{u})} \bar{u}_i \nabla g_i(x^*)^{\mathsf{T}} z - \sum_{i \in L_2} \bar{u}_i \nabla g_i(x^*)^{\mathsf{T}} z \leq 0. \tag{4.8}$$

Inequalities (4.5) and (4.8) imply that

$$f(x^*)^{\mathsf{T}} z = 0. \tag{4.9}$$

Then from (4.4), (4.6), (4.8), and (4.9) we can deduce that for any $i \in I_N(\bar{u})$

$$\nabla g_i(x^*)^{\mathsf{T}} z = 0.$$

Hence conclusion (iv) readily follows from the above assertion and (4.6).

We now proceed to prove conclusion (v). Since

$$\begin{aligned}
0 &= L_D(x^j, u^j) - L_D(x^*, \bar{u}) \\
&= f(x^j) + \sum_{i \in I_N(\bar{u})} u_i^j \nabla g_i(x^j) + \sum_{i \in I_N \backslash I_N(\bar{u})} u_i^j \nabla g_i(x^j) - \left[f(x^*) + \sum_{i \in I_N(\bar{u})} \bar{u}_i \nabla g_i(x^*) \right] \\
&= \nabla L_D(x^*, \bar{u})(x^j - x^*) + \sum_{i \in I_N(\bar{u})} (u_i^j - \bar{u}_i) \nabla g_i(x^*) \\
&\quad + \sum_{i \in I_N \backslash I_N(\bar{u})} u_i^j \nabla g_i(x^*) + o(\|x^j - x^*\|),
\end{aligned}$$

it follows that for any y such that $\nabla g_i(x^*)^{\mathsf{T}} y = 0$ for $i \in I_N(\bar{u})$ and $\nabla g_i(x^*)^{\mathsf{T}} y \leq 0$ for $i \in I_N \backslash I_N(\bar{u})$,

$$\begin{aligned}
&[\nabla L_D(x^*, \bar{u})(x^j - x^*) + o(\|x^j - x^*\|)]^{\mathsf{T}} y \\
&\quad = - \sum_{i \in I_N(\bar{u})} (u_i^j - \bar{u}_i) \nabla g_i(x^*)^{\mathsf{T}} y - \sum_{i \in I_N \backslash I_N(\bar{u})} u_i^j \nabla g_i(x^*)^{\mathsf{T}} y \geq 0.
\end{aligned}$$

Dividing by $\|x^j - x^*\|$ and passing to the limit, we obtain

$$(\nabla L_D(x^*, \bar{u}) z)^{\mathsf{T}} y \geq 0.$$

Hence we have completed the proof of conclusion (v).

Now consider the following affine variational inequality:

$$\text{find } x \in K \quad \text{such that } (\nabla L_D(x^*, \bar{u}) x + b)^{\mathsf{T}} (x' - x) \geq 0 \quad \text{for all } x' \in K,$$

where $K = \{x \in R^n : \nabla g_i(x^*)^{\mathsf{T}} x = 0 \text{ for } i \in I_N(\bar{u}) \text{ and } \nabla g_i(x^*)^{\mathsf{T}} x \leq 0 \text{ for } i \in I_N \backslash I_N(\bar{u})\}$ and $b \in R^n$. By assumption we know that $\nabla L_D(x^*, \bar{u})$ is cooriented on K. Therefore, it follows from Robinson's homeomorphism theorem [26, Thm. 4.3] that the above variational inequality has a unique solution for each $b \in R^n$. However, it is easy to verify that both $x = 0$ and $x = -z$ are solutions of the above variational inequality when $b = \nabla L_D(x^*, \bar{u}) z$. Thus we have a contradiction. □

The reason for our interest in the perturbed problems is that in addition to the fact that for small $\varepsilon \geq 0$, x^* is the unique stationary solution to $\mathrm{VI}(f + \Delta^\varepsilon f, g + \Delta^\varepsilon g)$ in a neighborhood of x^*, the LI condition holds at x^* for $\mathrm{VI}(f + \Delta^\varepsilon f, g + \nabla^\varepsilon g)$ provided that $\varepsilon > 0$. Since GCC is an open property, under the hypotheses of Lemma 4.4, GCC and the LI condition hold at x^* for $\mathrm{VI}(f + \Delta^\varepsilon f, g + \Delta^\varepsilon g)$ with small $\varepsilon > 0$, and, consequently, in such a case (x^*, y^ε) is a strongly stable GKKT point to $\mathrm{VI}(f + \Delta^\varepsilon f, g + \Delta^\varepsilon g)$. Therefore, we can find a sequence of strongly stable GKKT points (x^*, y^ε) to $\mathrm{VI}(f + \Delta^\varepsilon f, g + \Delta^\varepsilon g)$ which converges to (x^*, y^*). This fact readily leads to the following degree conclusion, which plays a key role in deriving the existence result for our main theorem.

LEMMA 4.6. *Assume that x^* is a stationary solution to* $\mathrm{VI}(f, g)$ *and that MFCQ holds at x^*. If GPCC (or GNCC) holds at x^* for* $\mathrm{VI}(f, g)$ *then there exist some compact set $C \subset R^m$ and $\delta^* > 0$ such that $M(x^*, f, g) \subset \mathrm{int} C$ and*

$$\deg(F, \mathrm{int}(B(x^*, \delta) \times C), 0) = +(\text{or}-)1 \quad \textit{for all } \delta \in (0, \delta^*].$$

Proof. We only prove the result when GPCC holds at x^* for VI(f, g); the other case can be proved similarly. From Proposition 4.1 and Lemmas 4.4 and 4.5 we conclude that there exist positive numbers α, δ^*, ε^*, and a compact set $C \subset R^m$ such that for any $x' \in B(x^*, \delta^*)$ and $(\Delta f, \Delta g) \in \mathcal{P}$ with $\text{norm}(\Delta f, \Delta g, B(x^*, \delta^*)) \leq \alpha$ one has

(i) $M(x', f + \Delta f, g + \Delta g) \subset \text{int}C$;

(ii) MFCQ and GPCC hold at x' for VI$(f + \Delta f, g + \Delta g)$ provided that x' is a stationary solution to VI$(f + \Delta f, g + \Delta g)$;

(iii) x^* is the unique stationary solution to VI$(f + \Delta^\varepsilon f, g + \Delta^\varepsilon g)$ in $B(x^*, \delta^*)$ for all $\varepsilon \in [0, \varepsilon^*]$, where $(\Delta^\varepsilon f, \Delta^\varepsilon g)$ was defined by (4.1).

From (i) and (iii) we have that

$$\text{GKKT}(f, g) \cap (B(x^*, \delta) \times C) = \{x^*\} \times M(x^*, f, g) \subset \text{int}(B(x^*, \delta) \times C)$$

$$\text{for all } \delta \in (0, \delta^*],$$

so $\deg(F, \text{int}(B(x^*, \delta) \times C), 0)$ is well defined for $\delta \in (0, \delta^*]$.

Without loss of generality we may assume that $\text{norm}(\Delta^\varepsilon f, \Delta^\varepsilon g, B(x^*, \delta^*)) \leq \alpha$ for all $\varepsilon \in [0, \varepsilon^*]$. Now let $\delta \in (0, \delta^*]$. From (i) and (iii) we see that for each $\varepsilon \in [0, \varepsilon^*]$ the map $F + \Delta^\varepsilon F$ cannot take the zero value on $\text{bd}(B(x^*, \delta) \times C)$. Hence from degree property (iii) listed in §2 we deduce that

$$\deg(F, \text{int}(B(x^*, \delta) \times C), 0) = \deg(F + \Delta^\varepsilon F, \text{int}(B(x^*, \delta) \times C), 0) = \text{constant} \tag{4.10}$$

for any $\varepsilon \in [0, \varepsilon^*]$. On the other hand, since LI and GPCC hold at x^* for VI$(f + \Delta^\varepsilon f, g + \Delta^\varepsilon g)$, if ε is positive and sufficiently small, it follows from Corollary 3.9 and the fact that in such a case the map $F + \Delta^\varepsilon F$ takes the zero value only at (x^*, y^ε) in $B(x^*, \delta) \times C$ that

$$\deg(F + \Delta^\varepsilon F, \text{int}(B(x^*, \delta) \times C), 0) = +1$$

for sufficiently small $\varepsilon \in (0, \varepsilon^*]$. Thus from (4.10) we obtain

$$\deg(F, \text{int}(B(x^*, \delta) \times C), 0) = +1.$$

This completes the proof. □

The following lemma gives a result concerning the subspaces spanned by the faces of a polyhedral set.

LEMMA 4.7. *Let I, J be finite index sets and let $a_i \in R^t$, $i \in I$, and $b_j \in R^t$, $j \in J$. Assume that the set $\{a_i,\ i \in I\}$ is linearly independent. Consider a polyhedral cone P defined by $P = \{z \in R^t\colon a_i^\mathsf{T} z = 0,\ i \in I;\ b_j^\mathsf{T} z \leq 0,\ j \in J\}$. Suppose that F is a face of P and L is the subspace in R^t spanned by F. Then there is a subset J_L of J such that $L = \{z \in R^t : a_i^\mathsf{T} z = 0,\ i \in I;\ b_j^\mathsf{T} z = 0,\ j \in J_L\}$ and the set $\{a_i,\ i \in I;\ b_j,\ j \in J_L\}$ is linearly independent.*

Proof. Note that L can be expressed by $\{z \in R^t : a_i^\mathsf{T} z = 0,\ i \in I;\ b_j^\mathsf{T} z = 0,\ j \in J_0\}$, where J_0 (maybe empty) is a subset of J. Therefore, we can choose a subset J_L of J_0 such that the set $\{a_i,\ i \in I;\ b_j,\ j \in J_L\}$ is a maximal linearly independent subset of $\{a_i,\ i \in I;\ b_j,\ j \in J_0\}$. Obviously we have $L = \{z \in R^t : a_i^\mathsf{T} z = 0,\ i \in I;\ b_j^\mathsf{T} z = 0,\ j \in J_L\}$. □

The next lemma provides necessary conditions for strongly stable stationary solutions under MFCQ.

LEMMA 4.8. *Assume that x^* is a strongly stable stationary solution to* VI(f, g) *and that MFCQ holds at x^*. Then there exist some compact set $C \subset R^m$ and $\delta^* > 0$ such that $M(x^*, f, g) \subset \text{int}C$ and*

$$\deg(F, \text{int}(B(x^*, \delta) \times C), 0) = +1 \quad \textit{for all } \delta \in (0, \delta^*] \tag{4.11}$$

or

$$\deg(F, \mathrm{int}(B(x^*,\delta) \times C), 0) = -1 \quad \textit{for all } \delta \in (0, \delta^*]. \tag{4.12}$$

Furthermore, if (4.11) (*or* (4.12)) *holds then for any* $y^* \in M(x^*, f, g)$ *and any* $J \subset I_0(x^*, g) \backslash I_N(y^*)$, $\nabla L_D(x^*, y^*)$ *is positively* (*or negatively*) *cooriented on* $C(x^*, y^*; J)$.

Proof. Without loss of generality we assume that $I_0(x^*, g) = \{1, \ldots, m\}$. Since x^* is a strongly stable stationary solution to VI(f, g) and MFCQ holds at x^* for VI(f, g), it follows from Propositions 2.5 and 4.1 that there exist positive numbers α, δ^*, a compact set $C \subset R^m$, and a mapping $x(\cdot)$ defined on $U(0, \alpha) = \{(\Delta f, \Delta g) \in \mathcal{P} : \mathrm{norm}(\Delta f, \Delta g, B(x^*, \delta^*)) \leq \alpha\}$ such that for any $x' \in B(x^*, \delta^*)$ and $(\Delta f, \Delta g) \in U(0, \alpha)$ one has

(i) $M(x', f + \Delta f, g + \Delta g) \subset \mathrm{int} C$;

(ii) $x(\Delta f, \Delta g)$ is the unique stationary solution and a strongly stable stationary solution to VI($f + \Delta f, g + \Delta g$) in $B(x^*, \delta^*)$.

Let $\delta \in (0, \delta^*]$. Choose an extreme point of $M(x^*, f, g)$, say $y^* \in E(x^*, f, g)$. Consider the perturbed problem VI($f + \Delta^\varepsilon f, g + \Delta^\varepsilon g$) defined by (4.1) for $\varepsilon > 0$. Then x^* is a stationary solution with associated multipliers y^ε to VI($f + \Delta^\varepsilon f, g + \Delta^\varepsilon g$) and the LI condition holds at x^* for VI($f + \Delta^\varepsilon f, g + \Delta^\varepsilon g$). On the other hand, for every sufficiently small ε satisfying $(\Delta^\varepsilon f, \Delta^\varepsilon g) \in U(0, \alpha)$, statement (ii) above implies $\{x^*\} = x(\Delta^\varepsilon f, \Delta^\varepsilon g)$. Hence, for such an ε, it follows from Proposition 2.6 that (x^*, y^ε) is a strongly stable GKKT point to VI($f + \Delta^\varepsilon f, g + \Delta^\varepsilon g$).

By (i) and (ii) we know that $\deg(F, \mathrm{int}(B(x^*, \delta) \times C), 0)$ and $\deg(F + \Delta^\varepsilon F, \mathrm{int}(B(x^*, \delta) \times C), 0)$ are well defined for every sufficiently small ε. Using degree property (iii) in §2 and the above properties (i) and (ii) again, we can deduce from Corollary 3.9 that

$$\deg(F, \mathrm{int}(B(x^*, \delta) \times C), 0) = \deg(F + \Delta^\varepsilon F, \mathrm{int}(B(x^*, \delta) \times C), 0) = \pm 1$$

for sufficiently small ε. This proves the first conclusion.

For the second conclusion we only prove the case when (4.11) holds. The other case can be proved in the same way. Suppose (4.11) holds. For the desired conclusion we shall divide our proof into three steps. In the first step we consider any extreme point of $M(x^*, f, g)$. In the second step we show that for any $y^* \in M(x^*, f, g)$ and any $J \subset I_0(x^*, g) \backslash I_N(y^*)$, $\nabla L_D(x^*, y^*)$ is cooriented on $C(x^*, y^*; J)$. In the third and final step we prove that $\nabla L_D(x^*, y^*)$ is positively cooriented on $C(x^*, y^*; J)$.

Take any $y^* \in E(x^*, f, g)$ and any $J \subset I_0(x^*, g) \backslash I_N(y^*)$. To show that $\nabla L_D(x^*, y^*)$ is positively cooriented on $C(x^*, y^*; J)$, it is sufficient to prove that for any face F of $C(x^*, y^*; J)$, letting L be the subspace spanned by F, and Q be a matrix whose columns form a basis for L, we have that $\det(Q^\mathsf{T} \nabla L_D(x^*, y^*) Q) > 0$. Now by Lemma 4.7 we find that there exists a subset J_L of J such that $L = \{z \in R^n : \nabla g_i(x^*)^\mathsf{T} z = 0,\ i \in I_N(y^*);\ \nabla g_j(x^*)^\mathsf{T} z = 0,\ j \in J_L\}$ and the set $\{\nabla g_i(x^*),\ i \in I_N(y^*);\ \nabla g_j(x^*),\ j \in J_L\}$ is linearly independent. Define the following perturbations:

$$\Delta_L^\varepsilon f(x) = 0,$$

and

$$\Delta_L^\varepsilon g_i(x) = \begin{cases} 0 & \text{if } i \in I_N(y^*) \cup J_L, \\ -\varepsilon & \text{otherwise} \end{cases}$$

for $i = 1, \ldots, m$, $\varepsilon \geq 0$, and $x \in R^n$. Let

$$y_{L_i}^\varepsilon = \begin{cases} y_i^* & \text{if } i \in I_N(y^*) \cup J_L, \\ y_i^* - \varepsilon & \text{otherwise} \end{cases}$$

for $i = 1, \ldots, m$. Then we have

$$F(x^*, y_L^\varepsilon) + \Delta_L^\varepsilon F(x^*, y_L^\varepsilon) = F(x^*, y^*) = 0$$

for all $\varepsilon \geq 0$. This means that x^* is a stationary solution to VI$(f + \Delta_L^\varepsilon f, g + \Delta_L^\varepsilon g)$ for all $\varepsilon \geq 0$. Also, the LI condition holds at x^* for VI$(f + \Delta_L^\varepsilon f, g + \Delta_L^\varepsilon g)$ when $\varepsilon > 0$ since $I_0(x^*, g + \Delta_L^\varepsilon g) = I_N(y^*) \cup J_L$. From assertion (ii) above and Proposition 2.6 we conclude that (x^*, y_L^ε) is a strongly stable GKKT point to VI $(f + \Delta_L^\varepsilon f, g + \Delta_L^\varepsilon g)$ for every sufficiently small $\varepsilon > 0$. Using the same reasoning as we did in the first part of the proof yields that for $\delta \in (0, \delta^*]$ we have

$$\deg(F + \Delta_L^\varepsilon F, \operatorname{int}(B(x^*, \delta) \times C), 0) = +1 \tag{4.13}$$

for sufficiently small $\varepsilon > 0$. Note that the function $L_D(x, y)$ takes the same value at (x^*, y^*) for the problem VI(f, g) and at (x^*, y_L^ε) for the problem VI$(f + \Delta_L^\varepsilon f, g + \Delta_L^\varepsilon g)$, and that L itself is a face of $C(x, y)$ at (x^*, y_L^ε) for VI$(f + \Delta_L^\varepsilon f, g + \Delta_L^\varepsilon g)$. Therefore, using (4.13) we find from Corollary 3.9 that $\det(Q^{\mathrm{T}} \nabla L_D(x^*, y^*) Q) > 0$. Hence we have proved that for any $y^* \in E(x^*, f, g)$, $\nabla L_D(x^*, y^*)$ is positively cooriented on $C(x^*, y^*; J)$, where $J \subset I_0(x^*, g) \backslash I_N(y^*)$.

We now show that for any $y^* \in M(x^*, f, g)$, any $J \subset I_0(x^*, g) \backslash I_N(y^*)$, $\nabla L_D(x^*, y^*)$ is cooriented on $C(x^*, y^*; J)$. To do so, note that for polyhedrally constrained variational inequalities, strong stability is equivalent to the coorientedness condition [16]. We shall first relax the original problem to discard those inequality constraints whose indexes are not in $I_N(y^*) \cup J$, and then consider the linearization of the relaxed problem about (x^*, y^*) to obtain the desired conclusion. Define

$$\begin{aligned}
&f^\varepsilon(x) := f(x^*) + \nabla L_D(x^*, y^*)(x - x^*), \\
&g_i^\varepsilon(x) := g_i(x^*) + \nabla g_i(x^*)^{\mathrm{T}}(x - x^*) \quad \text{if } i \in I_N(y^*) \cup J, \\
&g_i^\varepsilon(x) := g_i(x) - \varepsilon, \quad \text{otherwise}
\end{aligned}$$

for all $\varepsilon \geq 0$ and $x \in R^n$. Consider the following VI problem:

$$\text{VI}(\varepsilon) \qquad \text{find } x \in K^\varepsilon \quad \text{such that } f^\varepsilon(x)^{\mathrm{T}}(x' - x) \geq 0 \quad \text{for all } x' \in K^\varepsilon,$$

where $K^\varepsilon = \{x \in R^n : g_i^\varepsilon(x) \leq 0,\ i \in L_1; g_i^\varepsilon(x) = 0,\ i \in L_2\}$. The normal map corresponding to VI(ε) takes the following form:

$$F^\varepsilon(x, y) = \begin{bmatrix} f(x^*) + \nabla L_D(x^*, y^*)(x - x^*) + \sum_{i \in L_1} y_i^+ \nabla g_i^\varepsilon(x) + \sum_{i \in L_2} y_i \nabla g_i^\varepsilon(x) \\ -g_i^\varepsilon(x) + y_i^- \\ -g_j^\varepsilon(x) \end{bmatrix}.$$

For any $\gamma > 0$ such that $B(x^*, 2\gamma) \subset B(x^*, \delta^*)$, define

$$\begin{aligned}
&f^{\gamma,\varepsilon}(x) := \lambda(x, \gamma) f^\varepsilon(x) + (1 - \lambda(x, \gamma)) f(x), \\
&g_i^{\gamma,\varepsilon}(x) := \lambda(x, \gamma) g_i^\varepsilon(x) + (1 - \lambda(x, \gamma)) g_i(x), \\
&F^{\gamma,\varepsilon}(x, y) := \lambda(x, \gamma) F^\varepsilon(x, y) + (1 - \lambda(x, \gamma)) F(x, y),
\end{aligned}$$

where the function $\lambda(x, \gamma)$ is defined on R^n such that $\lambda(x, \gamma) \in C^2$, $0 \leq \lambda(x, \gamma) \leq 1$, and

$$\begin{aligned}
&\text{for any } x \in B(x^*, \gamma) \Rightarrow \lambda(x, \gamma) = 1, \\
&\text{for any } x \notin B(x^*, 2\gamma) \Rightarrow \lambda(x, \gamma) = 0.
\end{aligned}$$

The existence of such functions $\lambda(x,\gamma)$ is obvious. Define the following VI problem:

$$\text{VI}(\gamma,\varepsilon) \quad \text{find } x \in K^{\gamma,\varepsilon} \quad \text{such that } f^{\gamma,\varepsilon}(x)^{\mathsf{T}}(x'-x) \geq 0 \quad \text{for all } x' \in K^{\gamma,\varepsilon},$$

where $K^{\gamma,\varepsilon} = \{x \in R^n : g_i^{\gamma,\varepsilon}(x) \leq 0,\ i \in L_1;\ g_i^{\gamma,\varepsilon}(x) = 0,\ i \in L_2\}$. Note first that x^*, together with

$$y_i^\varepsilon = \begin{cases} y_i^* & \text{if } i \in I_N(y^*) \cup J, \\ y_i^* - \varepsilon & \text{otherwise,} \end{cases}$$

is a solution to $F^\varepsilon(x,y) = 0$ and $F^{\gamma,\varepsilon}(x,y) = 0$. Hence x^* is a stationary solution to VI(ε) and VI(γ,ε). Furthermore, we can choose sufficiently small γ' and ε' such that $(f^{\gamma',\varepsilon'} - f, g^{\gamma',\varepsilon'} - g) \in U(0,\alpha)$. Then x^* is a strongly stable stationary solution to VI(γ',ε') from statement (ii). However, from the definitions of VI(ε) and VI(γ,ε) we know that there exists a neighborhood N of x^* such that for all $x \in N$, $f^\varepsilon(x) = f^{\gamma,\varepsilon}(x)$ and $g_i^\varepsilon(x) = g_i^{\gamma,\varepsilon}(x)$, and hence VI($\varepsilon'$) is equivalent to VI($\gamma',\varepsilon'$) in this neighborhood. So x^* is also a strongly stable stationary solution of VI (ε'). Now note that for VI(ε') the possible nonlinear constraints are those whose indexes do not belong to the set $I_N(y^*) \cup J$, and these constraints can be eliminated locally at x^* without loss of generality. Therefore, VI(ε') can be treated as a polyhedrally constrained variational inequality in a small neighborhood (depending on ε) of x^*. Hence, from the fact that x^* is a strongly stable stationary solution to VI(ε'), we can deduce that the cooriented condition holds at x^* for VI(ε') [15], [26]. Therefore, $\nabla L_D(x^*,y^*)$ is cooriented on $C(x^*,y^*;J)$.

Finally, we prove that for any $y^* \in M(x^*,f,g)$ and any $J \subset I_0(x^*,g)\backslash I_N(y^*)$, $\nabla L_D(x^*,y^*)$ is positively cooriented on $C(x^*,y^*;J)$. Suppose the contrary. Then $\nabla L_D(x^*,y^*)$ is negatively cooriented on $C(x^*,y^*;J)$ since we have shown that $\nabla L_D(x^*,y^*)$ is cooriented on $C(x^*,y^*;J)$. Therefore, there exist a subspace L spanned by a face of $C(x^*,y^*;J)$ and a matrix Q whose columns form a basis of L such that $\det(Q^{\mathsf{T}}\nabla L_D(x^*,y^*)Q) < 0$. Choose a face F of $M(x^*,f,g)$ such that y^* is in the relative interior of F, and choose an extreme point y' of $M(x^*,f,g)$ such that $y' \in F$. Then we have $I_+(y') \subset I_+(y^*)$ and thus $I_N(y') \subset I_N(y^*)$. Therefore, there exists a face of $C(x^*,y';J)$ that spans L. Recall that in the second step we showed that $\nabla L_D(x^*,y')$ is positively cooriented on $C(x^*,y';J)$. This implies that $\det(Q^{\mathsf{T}}\nabla L_D(x^*,y')Q) > 0$. Define

$$\begin{aligned} y(\lambda) &:= \lambda y^* + (1-\lambda)y', \\ d(\lambda) &:= \det(Q^{\mathsf{T}}\nabla L_D(x^*,y(\lambda))Q) \end{aligned}$$

for $\lambda \in [0,1]$. Then for any $\lambda \in (0,1)$, we have that $y(\lambda) \in M(x^*,f,g)$ and $d(\lambda)$ is continuous on $[0,1]$. Therefore, since $d(0) \times d(1) < 0$ we can find a $\lambda' \in (0,1)$ such that $d(\lambda') = 0$. However, it is easy to see that there exists a face of $C(x^*,y(\lambda');J)$ that spans L. Hence $\nabla L_D(x^*,y(\lambda'))$ is not cooriented on $C(x^*,y(\lambda');J)$. This is a contradiction. □

Now we are ready to give the proof of our main result, Theorem 4.3.

Proof of Theorem 4.3. The "if" part of the proof is as follows. Under the hypotheses we know that either GPCC or GNCC holds at x^*. We only show the case where GPCC holds. The other case can be proved in the same way. From the proof of Lemma 4.6 we find that there exist positive numbers α^*, δ^*, and a compact set $C \subset R^m$ such that for any $x' \in B(x^*,\delta^*)$ and $(\Delta f,\Delta g) \in \mathcal{P}$ with $\text{norm}(\Delta f,\Delta g,B(x^*,\delta^*)) \leq \alpha^*$, one has

(i) $M(x',f+\Delta f,g+\Delta g) \subset \text{int}C$;

(ii) MFCQ and GPCC hold at x' for VI($f+\Delta f,g+\Delta g$) provided that x' is a stationary solution of VI($f+\Delta f,g+\Delta g$);

(iii) x^* is the unique stationary solution of VI(f,g) in $B(x^*,\delta^*)$;

(iv) $\deg(F, \text{int}(B(x^*, \delta^*) \times C)) = +1$.

Then we have

$$\text{GKKT}(f, g) \cap (B(x^*, \delta^*) \times C) = \{x^*\} \times M(x^*, f, g) \subset \text{int}(B(x^*, \delta^*) \times C).$$

Hence, from degree property (iii) there exists an $\alpha \in (0, \alpha^*]$ such that if $\text{norm}(\Delta f, \Delta g, B(x^*, \delta^*)) \leq \alpha$, one has

$$F(x, y) + \Delta F(x, y) \neq 0 \quad \text{for any } (x, y) \in (B(x^*, \delta^*) \times C)\backslash\text{int}(B(x^*, \delta^*/2) \times C)$$

and

$$\deg(F + \Delta F, \text{int}(B(x^*, \delta^*/2) \times C)) = +1. \tag{4.14}$$

Then by degree property (i) we conclude that there exists a solution $(x', y') \in \text{int}(B(x^*, \delta^*/2) \times C)$ to $F(x, y) + \Delta F(x, y) = 0$. So x' is a stationary solution to $\text{VI}(f + \Delta f, g + \Delta g)$.

Now we shall show the uniqueness of the stationary solution to $\text{VI}(f + \Delta f, g + \Delta g)$. Since MFCQ and GPCC hold at any stationary solution x' to $\text{VI}(f + \Delta f, g + \Delta g)$, by Lemma 4.5 we find that x' is isolated. So $B(x^*, \delta^*/2)$ contains at most a finite number of stationary solutions of $\text{VI}(f + \Delta f, g + \Delta g)$, say $x^1, \ldots, x^t$.

For each $p = 1, \ldots, t$ by statement (ii) we know that MFCQ and GPCC hold at each x^p, $p = 1, \ldots, t$ for $\text{VI}(f + \Delta f, g + \Delta g)$. Hence there exist positive numbers $\delta^1, \ldots, \delta^t$ such that

$$B(x^*, \delta^p) \times C \subset B(x^*, \delta^*/2) \times C \quad \text{and} \quad (B(x^*, \delta^i) \times C) \cap (B(x^*, \delta^j) \times C) = \emptyset \quad (i \neq j),$$

and

$$\deg(F + \Delta F, \text{int}(B(x^*, \delta^i) \times C), 0) = +1. \tag{4.15}$$

Using the degree we deduce that

$$\sum_{p=1}^{t} \deg(F + \Delta F, \text{int}(B(x^*, \delta^i) \times C), 0) = \deg(F + \Delta F, \text{int}(B(x^*, \delta^*/2) \times C), 0).$$

From (4.14) and (4.15) we find that $t = 1$. This completes the "if" part of the proof.

The "only if" part readily follows from Lemma 4.8. □

Below we present a verifiable sufficient condition for strongly stable stationary solutions. It is a direct consequence of Theorem 4.3 and the fact that GSSOC implies GPCC.

THEOREM 4.9. *Suppose x^* is a stationary solution to* $\text{VI}(f, g)$. *If MFCQ and GSSOC hold at x^*, then x^* is a strongly stable stationary solution to* $\text{VI}(f, g)$.

We conclude the paper by mentioning the article [10] in which the notion of a strongly stable Nash equilibrium point of an n-person noncooperative game was introduced and characterized.

Acknowledgments. The author thanks Professors S. M. Robinson, J. S. Pang, A. V. Fiacco, and M. Kojima for their interests and valuable suggestions, and the two anonymous referees and the associate editor who handled this paper for the many constructive comments and corrections that greatly improved the exposition in the paper. In particular, several discussions with Professor Pang led the author to employ degree theory in this study.

THE DISTURBANCE DECOUPLING PROBLEM FOR SYSTEMS OVER A RING*

G. CONTE† AND A. M. PERDON‡

Abstract. Up to now the use of geometric methods in the study of disturbance decoupling problems (DDPs) for systems over a ring has provided only necessary conditions for the existence of solutions. In this paper we study such problems, considering separately the case in which only static feedback solutions are allowed, and the one in which dynamic feedback solutions are admitted. In the first case, we give a complete geometric characterization of the solvability conditions of such problems for injective systems with coefficients in a commutative ring. Practical procedures for testing the solvability conditions and for constructing solutions, if any exist, are given in the case of systems with coefficients in a principal ideal domain (PID). In the second case, we give a complete geometric characterization of the solvability conditions for systems with coefficients in a PID.

Key words. systems over rings, dynamical feedback disturbance decoupling, invariant subspaces

AMS subject classifications. 93B27, 93B52

1. Introduction.

In the last decade the geometric approach to the theory of linear dynamical systems has provided deep insights and elegant solutions to many synthesis and control problems, such as the disturbance decoupling problem (DDP), the model matching problem, and the tracking and regulation problem (see [10] and the references therein).

Systems with coefficients in a ring turn out to be useful in many interesting situations for modeling, e.g., delay-differential systems, families of systems depending on one parameter, and time-varying systems (see [7], [8], [9]). This motivates attempts to extend the geometric approach to the theory of systems with coefficients in a ring. The first results in this direction were obtained by M. Hautus (see [5] and [6]) and by the authors in 1982. The main difference encountered in dealing with coefficients in a ring instead of coefficients in a field concerns the fundamental notion of (A, B)-invariant subspace or controlled invariant subspace [1], [10]. From a dynamical point of view, the controlled invariance property for a subspace V of the state space of a system Σ means that the trajectories starting in V can be kept inside V by a suitable choice of the control. What makes the (A, B)-invariant subspaces so useful in the theory of systems with coefficients in a field is the fact that a control with the above property can be generated using a state feedback. This means, in other words, that by choosing a suitable state feedback, any (A, B)-invariant subspace can be made invariant with respect to the resulting closed loop dynamics. Unfortunately, such a crucial feature is generally lost in the framework of systems with coefficients in a ring, where only the so-called (A, B)-invariant submodules of feedback type [5] can be made invariant by means of a state feedback.

For that reason, the classical results obtained by means of geometric techniques for systems with coefficients in a field can be generalized only partially to systems with coefficients in a ring. An illustration of this is provided in [5] in the section devoted to the DDP and in [6]. It turns out that the well-known geometric conditions which characterize the solvability of such a problem in the case of systems with coefficients in a field [1], [10] by means of a static state feedback are necessary but not sufficient, except in restricted classes of systems, for assuring the existence of solutions in the case of coefficients in a ring.

For the case of systems with coefficients in a principal ideal domain (PID), the solvability of the DDP by means of a static state feedback was characterized in [4] in terms of a necessary and sufficient condition based on the outcome of a recursive procedure. Unlike the field case, when the coefficients are taken in a ring, one can reasonably expect to achieve more using dynamic feedback rather than just static feedback. However, no general results on the DDP

‡ Dipartimento di Matematica, Università di Ancona, via Brecce Bianche, Ancona, 60131 Italy.

seem to be known if dynamic feedback is allowed. So, in general, the problem of finding a complete characterization in geometric terms of the solvability conditions of that problem has remained open up to now (see the discussion in §2).

In this paper we consider the DDP for systems with coefficients in a ring from a geometric point of view, taking into account a restrictive formulation in which only static feedback solutions are allowed, and a more general one in which dynamic feedback solutions are accepted.

In the first case, the approach we develop differs slightly from the classical one. More precisely, instead of looking for solutions based on the properties of some maximal controlled invariant submodule (cf. [10]), we consider, as was partially done in [4], solutions constructed by means of minimal elements in particular lattices of controlled invariant submodules. This approach turns out to be feasible for systems that verify a mild geometric condition, which from a practical point of view is essentially equivalent to injectivity. For systems of this kind, in fact, it is possible to define the smallest controlled invariant submodule containing a given module. The properties of this geometric object allow us to obtain in §3 the first main result of the paper (Theorem 3.4), which provides a complete geometric characterization of the solvability conditions for the DDP by means of a static state feedback for systems with coefficients in a commutative ring under the sole assumption of injectivity.

Sections 4 and 5 are concerned with the problems of checking the solvability conditions mentioned above and constructing a static feedback solution, if any exists, to a given DDP. More precisely, in §4 we describe the computation of the relevant controlled invariant submodules, while in §5 we focus on the case of systems with coefficients in a PID. For these systems, we show that all the steps required for checking the solvability conditions of Theorem 3.4 and finding a solution can be performed by suitable algorithms, except for the construction of the maximal controlled invariant submodules contained in a given module. Actually, the algorithm used for this purpose in the case of coefficients in a field needs to be substituted by a procedure, described in this paper, that involves the computation of the limit of a possibly infinite sequence of submodules.

In §6 we look for solutions consisting of a dynamic state feedback and restrict our attention to the case of systems with coefficients in a PID. In this way we can take for granted that the submodules we need to consider have a basis and all the relevant constructions can be practically performed. The main result we obtain in this section is a complete geometric characterization of the solvability conditions for the DDP by means of a dynamic state feedback for systems with coefficients in a PID. If the disturbance is measurable, the solvability conditions are the same as those in the case of coefficients in a field. If the disturbance is not measurable, the solvability conditions are only technically more restrictive than the corresponding ones in the case of coefficients in a field. In conclusion, we can say that, allowing dynamic feedback solutions, the disturbance decoupling problem for systems with coefficients in a PID behaves essentially as it does in the case of coefficients in a field.

The last section describes some applications of the results of the paper to delay-differential systems and to families of parameter dependent systems.

2. Preliminaries and statement of the problems.

Let R denote a commutative ring. By a *system with coefficients in* R, or a *system over* R, we mean a discrete-time linear dynamical system Σ whose evolution is described by a set of difference equations of the form

$$\left\{\begin{array}{l} x(t+1) = Ax(t) + Bu(t), \\ y(t) = Cx(t), \end{array}\right. \tag{2.1}$$

where x belongs to the free state module $X = R^n$, u belongs to the free input module

$U = R^m$, y belongs to the free output module $Y = R^p$, and A, B, C are matrices of suitable dimensions with entries in R.

The control problems we want to consider in the framework of the systems over R are stated in the following section.

2.1. Statement of the DDPs. Given a system Σ over R, described by the equations

$$\left\{ \begin{array}{l} x(t+1) = Ax(t) + Bu(t) + Dq(t), \\ y(t) = Cx(t), \end{array} \right. \tag{2.2}$$

where $q \in Q = R^q$ is a disturbance, let us consider the feedback law

$$\left\{ \begin{array}{l} z(t+1) = A_{21}x(t) + A_{22}z(t) + G_1q(t), \\ u(t) = F_1x(t) + F_2z(t) + G_2q(t), \end{array} \right. \tag{2.3}$$

where z belongs to the free module $Z = R^{n'}$, and A_{21}, A_{22}, F_1, F_2, G_1, G_2 are matrices of suitable dimensions with entries in R.

The DDPs we consider consist, from a general point of view, of finding a feedback law of the form (2.3) such that the output of the closed loop system obtained by compensating Σ does not depend on q.

More precisely, we will speak of

(i) the disturbance decoupling problem by static feedback (static feedback DDP) if the class of solutions is restricted by requiring that n' equal zero and G_2 be the null matrix;

(ii) the disturbance decoupling problem by static feedback with measurable disturbance (static feedback DDPMD) if the class of solution is restricted by requiring that n' equal zero;

(iii) disturbance decoupling problems by dynamic feedback (dynamic feedback DDP) if the class of solutions is restricted by requiring that G_1 and G_2 be null matrices;

(iv) disturbance decoupling problems by dynamic feedback with measurable disturbance (dynamic feedback DDPMD) in the general case.

In the case of linear systems with coefficients in a field, a DDP that is solvable by means of a dynamic feedback law, i.e., a feedback law of the form (2.3) with n' different from zero, is also solvable by means of a static feedback law, i.e., a feedback law of the form (2.3) with n' equal to zero. As shown in Example 7.3, this is not the case for systems over a ring. In the field case, elegant solutions to the above control problems are provided by the so-called geometric approach (see [1], [10]). Early attempts to extend the geometric approach to the framework of systems over a ring and to apply geometric techniques to the solutions of the static feedback DDP and the static feedback DDPMD are reported in [5]. In order to describe the results obtained and to discuss the differences and the difficulties encountered in dealing with systems over a ring instead of a field, let us recall the following definition.

DEFINITION 2.1 [5]. *Given a system Σ over R described by* (2.1), *a submodule V of the state module X is called*

(i) *(A, B)-invariant, or controlled invariant, if and only if* $AV \subset V +$ Im B;

(ii) *(A, B)-invariant of feedback type if and only if there exists an R-linear map $F : X \to U$ such that $(A + BF)V \subset V$.*

A feedback F, if any exists, with the property described in (ii) *above is called a friend of V.*

The proof of the following proposition follows immediately from [1], [10].

PROPOSITION 2.2. *Given a system Σ over R described by* (2.2), *the static feedback DDP* (*respectively, the static feedback DDPMD*) *is solvable if and only if there exists an (A, B)-invariant submodule V of feedback type such that* Im $D \subset V \subset$ Ker C (*respectively, such that* Im $D \subset V +$ Im B *and* $V \subset$ Ker C).

For systems with coefficients in a field, the notions of (A, B)-invariance and (A, B)-invariance of feedback type described in Definition 2.1 are known to coincide. Moreover, the family of the (A, B)-invariant subspaces contained in ker C has a maximum element, usually denoted by V^*, which can be found as the limit of the sequence of subspaces V_k defined recursively by

$$\begin{cases} V_0 = \operatorname{Ker} C, \\ V_{k+1} = V_k \cap A^{-1}(V_k + \operatorname{Im} B). \end{cases} \tag{2.4}$$

Then, the necessary and sufficient condition of Proposition 2.2 can be stated as Im $D \subset V^*$ (respectively, Im $D \subset V^* +$ Im B) and, since the sequence (2.4) converges in a finite number of steps, it can be easily checked.

For systems with coefficients in a ring, the two notions described in Definition 2.1 do not coincide. In fact, any (A, B)-invariant submodule of feedback type is, in particular, (A, B)-invariant, but the converse is not true. The family of (A, B)-invariant submodules contained in Ker C also has in this case a maximum element V^* (see [5, Prop. 2.5]), but the condition $\operatorname{Im} D \subset V^*$ (respectively, $\operatorname{Im} D \subset V^* + \operatorname{Im} B$), which is, of course, necessary for the existence of solutions to the static feedback DDP (respectively, the static feedback DDPMD), is sufficient only if V^* happens to be of feedback type. Unfortunately, this is generally untrue for systems with coefficients in a ring (see [5], in particular, Ex. 5.6). Hence, the geometric conditions which characterize the existence of static solutions to the DDP in the case of coefficients in a field are too weak to provide a complete characterization of the solvability in the case of coefficients in a ring. Moreover, since, in general, a maximum (A, B)-invariant submodule of feedback type contained in Ker C does not exist (see [5, §5]), the above conditions cannot be modified in a straightforward way.

3. Solvability conditions for the static feedback DDPs. In order to overcome the difficulties we pointed out in the previous section, the strategy employed in [5] and [6] consists in characterizing those systems for which V^* turns out to be of feedback type. Systems of this kind, however, form only a small subset of the class at issue and, therefore, such an attempt does not provide a completely satisfactory result. Here we develop a different approach, based on a particular (A, B)-invariant submodule, that allows us to state a necessary and sufficient condition for the solvability of the static feedback DDP and the static feedback DDPMD for injective systems.

Let us start by stating some preliminary results about the lattice of (A, B)-invariant submodules of the state module X of a system Σ described by (2.1).

PROPOSITION 3.1. *Given Σ, let $V \subset X$ be an (A, B)-invariant submodule such that $V \cap$ Im $B = \{0\}$. Then, we have the following*:

(i) *if $V' \subset V$ and $V'' \subset V$ are two (A, B)-invariant submodules, then $V' \cap V''$ is an (A, B)-invariant submodule*;

(ii) *if V is of feedback type, then any (A, B)-invariant submodule V' such that $V' \subset V$ is of feedback type*; *moreover, if $F : X \to U$ is a friend of V, then F is also a friend of V'*;

(iii) *if $B : U \to X$ is injective, $F : X \to U$ is a friend of V, and $F' : X \to U$ is a friend of $V' \subset V$, then $F_{|V'} = F'_{|V'}$.*

Remark 3.2. The above results are a slight generalization of the results about self-bounded invariant subspaces given in [2] for systems with coefficients in a field. The condition $V \cap$ Im $B = \{0\}$ implies, in fact, that the invariant subspaces contained in V are self-bounded with respect to V, i.e., they are such that a trajectory starting in one of them, say V', and remaining in V, cannot escape from V'. The proofs given in [2] for the field case also work in our situation, and are reported here just for completeness and easy reference.

Proof of Proposition 3.1. (i) Given an element $v \in V' \cap V''$, by the (A, B)-invariance of V' and V'', we have $Av = v' + b' = v'' + b''$ for some $v' \in V'$, $v'' \in V''$, and b', $b'' \in$ Im B. Since v', $v'' \in V$, and $V\cap$ Im $B = \{0\}$, it follows that $v' = v'' \in V' \cap V''$ and $A(V' \cap V'') \subset (V' \cap V'')+$ Im B.

(ii) Given an element $v \in V' \subset V$, let $F : X \to U$ be a friend of V. By the (A, B)-invariance of V' and the property of F, we have $(A + BF)v = v' + b' + BFv = v''$ for some $v' \in V'$, $v'' \in V$, and $b' \in$ Im B. By $V\cap$ Im $B = \{0\}$, it follows that $v' = v'' \in V'$ and $b' = -BFv$, hence $(A + BF)V' \subset V'$.

(iii) By applying the same arguments as above, it is easy to get $BFv = BF'v$, and hence $Fv = F'v$ for any $v \in V'$.

Remark 3.3. We recall that a system Σ described by (2.1) is said to be injective if for any state x_0 in X and any pair of input sequences $\mathbf{u} = \{u(t), 0 \leq t\}$, $\mathbf{v} = \{v(t), 0 \leq t\}$ the equality $\mathbf{y}(x_0, \mathbf{u}) = \mathbf{y}(x_0, \mathbf{v})$ of the corresponding output sequences implies $\mathbf{u} = \mathbf{v}$. If Σ is injective and V^* denotes the maximum (A, B)-invariant submodule contained in Ker C, then $V^*\cap$ Im $B = \{0\}$ and B is injective. In fact, the injectivity of B is obviously implied from that of Σ and, if $B\bar{u} = x_0 \in V^*$, and $\mathbf{u} = \{u(t) = u_t, 0 \leq t\}$ is an input sequence that keeps the state trajectory starting at the initial state x_0 inside V^*, by $\mathbf{y}(0, \mathbf{u}') = \mathbf{y}(0, \mathbf{0_u})$, where $\mathbf{u}' = \{u(0) = \bar{u},\ u(t + 1) = u_t,\ 0 \leq t\}$ and $\mathbf{0_u}$ is the null input sequence, we have $\bar{u} = 0$ and $B\bar{u} = x_0 = 0$. The results of the above proposition, therefore, apply to the (A, B)-invariant submodules contained in Ker C. In particular, by Proposition 3.1 (i), we have that any nonempty lattice of (A, B)-invariant submodules contained in Ker C has a minimal element. From a practical point of view, injectivity is a very weak assumption since input sequences that produce the same output can be identified.

Notation. In the following, given a system Σ for which the condition $V^*\cap$ Im $B = \{0\}$ holds, and given a lattice $\mathcal{L}$ of (A, B)-invariant submodules of Ker C, we will denote by $V_*(\mathcal{L})$ the minimal element in the lattice.

We can now state the main result of this section.

THEOREM 3.4. *Let Σ be the system described by* (2.2) *and assume that* $V^*\cap$ Im $B = \{0\}$, *where V^* is the maximum (A, B)-invariant submodule of* Ker C. *Then, the static feedback DDP for Σ is solvable if and only if* Im $D \subset V^*$ *and* $V_*(\mathcal{L})$, *where $\mathcal{L}$ is the lattice of all the (A, B)-invariant submodules of* Ker C *containing* Im D, *is of feedback type. Analogously, the static feedback DDPMD is solvable if and only if* Im $D \subset V^*+$ Im B *and* $V_*(\mathcal{L})$, *where $\mathcal{L}$ is the lattice of all the (A, B)-invariant submodules V of* Ker C *such that* Im $D \subset V+$ Im B, *is of feedback type.*

Proof. The proof follows from Propositions 2.2 and 3.1(ii).

The above theorem gives a complete geometric characterization of the solvability conditions of the static feedback DDP and static feedback DDPMD. By comparing it to the results of [5], it appears clear that Theorem 3.4 represents a substantial improvement over what was previously known. In order for us to use it to solve the static feedback DDP and the static feedback DDPMD, we should be able to construct the submodules V^* and $V_*(\mathcal{L})$ for the lattice $\mathcal{L}$ we are interested in, and check whether the latter is of feedback type. These problems are considered in the next sections.

4. Properties and computation of $V_*(\mathcal{L})$. The results of Theorem 3.4 assume a practical relevance if a procedure for computing $V_*(\mathcal{L})$ is given. In order to relate $V_*(\mathcal{L})$ to other known geometric objects, let us recall the following definition.

DEFINITION 4.1. *Given a system Σ over R described by* (2.1), *a submodule S of the state module X is called (A, C)-invariant if and only if $A(S \cap$ Ker $C) \subset S$.*

As in the case of systems with coefficients in a field, the existence of the minimum (A, C)-invariant submodule containing a given submodule $K \subset X$, denoted by $S^*(K)$, is easily proved. For the construction of $S^*(K)$, let us consider the sequence of submodules S_k of X defined recursively by

$$(4.1)\qquad \begin{cases} S_0 = K, \\ S_{k+1} = S_k + A\,(S_k \cap \operatorname{Ker} C). \end{cases}$$

As in the case of coefficients in a field [1], $\{S_k\}$ is a nondecreasing sequence and becomes stationary for $k \geq \bar{k}$ if $S_{\bar{k}+1} = S_{\bar{k}}$. If R is a Noetherian ring we can therefore state that $\{S_k\}$ converges in a finite number of steps, and, moreover, we can prove in the same way as in [1] that the limit of $\{S_k\}$ is $S^*(K)$. The computation of $S^*(K)$ as the limit of $\{S_k\}$ is usually referred to, in the case of coefficients in a field, as the conditionally invariant subspace algorithm.

It will be useful in the following sections to note the following facts about the submodule $V^* \cap S^*(\operatorname{Im} B)$.

LEMMA 4.2. (i) *The submodule $V^* \cap S^*(\operatorname{Im} B)$ is the smallest (A, B)-invariant submodule containing $V^* \cap \operatorname{Im} B$.*

(ii) *The condition $V^* \cap \operatorname{Im} B = \{0\}$ is equivalent to the condition $V^* \cap S^*(\operatorname{Im} B) = \{0\}$.*

Proof. (i) Let us first show that any element $x \in S_k$, the kth element in the sequence defined by (4.1) with $K = \operatorname{Im} B$, can be written as $x = b + As$ with $b \in \operatorname{Im} B$ and $s \in S_{k-1} \cap \operatorname{Ker} C$. The statement is true for $k = 1$. Then, assuming it holds for $k - 1$, and writing $x \in S_k$ as $x = s + As'$ with $s \in S_{k-1}$ and $s' \in S_{k-1} \cap \operatorname{Ker} C$, one has, by $s = b + As''$ with $b \in \operatorname{Im} B$ and $s'' \in S_{k-2} \cap \operatorname{Ker} C \subset S_{k-1} \cap \operatorname{Ker} C$, $x = b + A(s'' + s')$ with $(s'' + s') \in S_{k-1} \cap \operatorname{Ker} C$.

By the above result it follows that any element $x \in V^* \cap S^*(\operatorname{Im} B)$ can be written, for some integer k, as $x = b_k + As_{k-1} = b_k + A(b_{k-1} + As_{k-2}) = b_k + Ab_{k-1} + A^2 b_{k-2} + \cdots + A^{k-1} b_1 + A^k s_0$, where $b_i \in \operatorname{Im} B$ for $1 \leq i \leq k$, $s_i = b_i + As_{i-1} \in S_i \cap \operatorname{Ker} C$ for $1 \leq i \leq k - 1$, and $s_0 \in \operatorname{Im} B \cap \operatorname{Ker} C$. In particular, the above relations imply that a trajectory starting at s_i for $0 \leq i \leq k - 1$ can be kept by a suitable input inside Ker C. Then, since V^* is the largest submodule of Ker C whose points have that property [5, §2], all the points s_i for $0 \leq i \leq k - 1$ turn out to belong to V^* and, in particular, s_0 belongs to $V^* \cap$ Im B.

Now, let $V \subset V^*$ be an (A, B)-invariant submodule containing $V^* \cap \operatorname{Im} B$ and let x be a point of $V^* \cap S^*(\operatorname{Im} B)$. With the above notation, letting $x = b_k + Ab_{k-1} + A^2 b_{k-2} + \cdots + A^{k-1} b_1 + A^k s_0$, we have that s_0 belongs to V. Choosing u_1 such that $(Bu_1 + As_0)$ belongs to V, we have $(b_1 + As_0) - (Bu_1 + As_0) = (b_1 - Bu_1) \in V^* \cap \operatorname{Im} B \subset V$. It also follows that $s_1 = b_1 + As_0$ belongs to V and, iterating this argument, that x belongs to V. Hence $V^* \cap S^*(\operatorname{Im} B)$ is contained in all the (A, B)-invariant submodules containing $V^* \cap \operatorname{Im} B$.

(ii) This part is proved by (i) and the fact that $\{0\}$ is obviously an (A, B)-invariant submodule.

Then, if we restrict our attention to systems for which the condition $V^* \cap \operatorname{Im} B = \{0\}$ holds, recalling Theorem 3.4 we have the following results (see [2] for the case of systems with coefficients in a field).

PROPOSITION 4.3. *Given a system Σ over R described by* (2.2), *assume that $V^* \cap \operatorname{Im} B = \{0\}$, where V^* is the maximum (A, B)-invariant submodule of* Ker C, *and* Im$D \subset V^*$. *If $\mathcal{L}$ denotes the lattice of all the (A, B)-invariant submodules of* Ker C *containing* Im D, *then we have $V_*(\mathcal{L}) = V^* \cap S^*(\operatorname{Im} D + \operatorname{Im} B)$.*

Proof. The proof given in the field case in [2, Thm. 2.3] works in our situation.

PROPOSITION 4.4. *Given a system Σ over R described by* (2.2), *assume that $V^* \cap$ Im $B = \{0\}$, where V^* is the maximum (A, B)-invariant submodule of* Ker C, *and* Im $D \subset V^* +$Im B. *If $\mathcal{L}$ denotes the lattice of all the (A, B)-invariant submodules V of* Ker C *such that* Im $D \subset$ $V +$ Im B, *then we have $V_*(\mathcal{L}) = V^* \cap S^*(\operatorname{Im} D + \operatorname{Im} B)$.*

Proof. Let us temporarily denote $V^* \cap S^*(\operatorname{Im} D + \operatorname{Im} B)$ by V. Then, by

$$\begin{aligned} AV &= A(V^* \cap S^*(\operatorname{Im} D + \operatorname{Im} B)) \\ &\subset (V^* + \operatorname{Im} B) \cap S^*(\operatorname{Im} D + \operatorname{Im} B) \\ &\subset (V^* \cap S^*(\operatorname{Im} D + \operatorname{Im} B)) + \operatorname{Im} B \\ &= V + \operatorname{Im} B, \end{aligned}$$

V is shown to be (A, B)-invariant. By $\operatorname{Im} D \subset V^* + \operatorname{Im} B$ and $\operatorname{Im} D \subset S^*(\operatorname{Im} D + \operatorname{Im} B)$ we have

$$\begin{aligned} \operatorname{Im} D &\subset (V^* + \operatorname{Im} B) \cap S^*(\operatorname{Im} D + \operatorname{Im} B) \\ &= (V^* \cap S^*(\operatorname{Im} D + \operatorname{Im} B)) + \operatorname{Im} B \\ &= V + \operatorname{Im} B, \end{aligned}$$

hence V belongs to $\mathcal{L}$.

Now, if V' belongs to $\mathcal{L}$, the submodule $V_1 = V' \cap V$ is also (A, B)-invariant and such that $\operatorname{Im} D \subset V_1 + \operatorname{Im} B$. By

$$\begin{aligned} A((V_1 + S^*(\operatorname{Im} B)) \cap \operatorname{Ker} C) &= A(V_1 + (S^*(\operatorname{Im} B) \cap \operatorname{Ker} C)) \\ &\subset A(V_1) + S^*(\operatorname{Im} B) \\ &\subset V_1 + \operatorname{Im} B + S^*(\operatorname{Im} B) \\ &\subset V_1 + S^*(\operatorname{Im} B), \end{aligned}$$

the submodule $(V_1 + S^*(\operatorname{Im} B))$ is shown to be (A, C)-invariant. Moreover, by

$$\operatorname{Im} D + \operatorname{Im} B \subset V_1 + \operatorname{Im} B \subset (V_1 + S^*(\operatorname{Im} B))$$

and the minimality of $S^*(\operatorname{Im} D + \operatorname{Im} B)$, recalling that $V^* \cap \operatorname{Im} B = \{0\}$ implies $V^* \cap S^*(\operatorname{Im} B) = \{0\}$, we have

$$(V^* \cap S^*(\operatorname{Im} D + \operatorname{Im} B)) + \operatorname{Im} B \subset (V^* \cap (V_1 + S^*(\operatorname{Im} B))) + \operatorname{Im} B = V_1 + \operatorname{Im} B;$$

then, by $\operatorname{Im} B \cap V^* = \{0\}$, it follows that $V = V_1 \subset V'$. This implies that V is minimal in $\mathcal{L}$, that is $V_*(\mathcal{L}) = V^* \cap S^*(\operatorname{Im} D + \operatorname{Im} B)$.

As a result of the above propositions, the computation of $V_*(\mathcal{L})$ for the lattice $\mathcal{L}$ we are interested in is reduced to the computation of V^* and $S^*(\operatorname{Im} D + \operatorname{Im} B)$.

For the computation of $S^*(\operatorname{Im} D + \operatorname{Im} B)$, we have that (4.1) initialized with $S_0 = \operatorname{Im} D + \operatorname{Im} B$ yields, if R is a Noetherian ring, $S^*(\operatorname{Im} D + \operatorname{Im} B) = S_{\bar{k}}$, where $\bar{k}$ is the smallest integer for which $S_{\bar{k}+1} = S_{\bar{k}}$.

The situation is quite different for the computation of V^*. In the case of coefficients in a field, as already mentioned, V^* can be computed as the limit of the sequence of submodules V_k defined recursively by (2.4), which converges in a finite number of steps. This is no longer true for systems over a ring R, since the convergence of $\{V_k\}$ in a finite number of steps is not guaranteed. In the next section we will give a procedure for finding V^* when R is a PID, but in general its construction remains a difficult problem.

Finally, for solving a given static feedback DDP or static feedback DDPMD by means of Theorem 3.4, one needs to check whether the submodule $V_*(\mathcal{L})$ is of feedback type or not. Since no alternative general characterization of Definition 2.1(ii) is known, this may be a quite difficult task. In the next section we will show how to accomplish this when the coefficient ring R is a PID.

5. Static feedback DDPs for systems over a PID. In this section we will consider the static feedback DDP and the static feedback DDPMD in the case in which R is a PID. This assumption gives us the possibility of characterizing the (A, B)-invariant submodules of feedback type in a quite simple way and, moreover, allows us to find a procedure for the construction of V^*. To this end, let us first recall the following notions and results of the authors from [3] and [5].

DEFINITION 5.1 [3, Def. 1.9]. *Let R be a PID and let $V \subset X = R^n$ be a submodule. By the closure of V in X we mean the submodule*

$$\overline{V} = \{x \in X, \textit{ such that } ax \in V \textit{ for some } a \neq 0,\ a \in R\}.$$

If V coincides with its closure $\overline{V}$, we say that V is closed in X.

Remark 5.2. It is useful to note the following [3, Prop. 1.10]:

(i) the closure $\overline{V}$ of V in X is the smallest closed submodule of X containing V;

(ii) any submodule V of the finitely generated free module X over a PID R is closed if and only if it is a direct summand of X;

(iii) for any submodule V of X, one has $\dim_R V = \dim_R \overline{V}$.

In addition to Remark 5.2, we point out that the computation of the closure of a submodule V can be performed by computing the Smith factorization of a suitable matrix. In fact, if D is a square matrix whose first k columns form a basis of V and whose remaining columns are zero, and if $D = PSQ$ with $S = \operatorname{diag}(a_1, \dots, a_k, 0, \dots, 0)$ is a Smith factorization, then the first k columns of $D' = PS'Q$ with $S' = \operatorname{diag}(1, \dots, 1, 0 \dots, 0)$ form a basis of $\overline{V}$. Algorithms for constructing a Smith factorization of D are known.

PROPOSITION 5.3 [5, Prop. 5.3]. *Let R be a PID and let V be an (A, B)-invariant submodule of X. Then V is of feedback type only if its closure $\overline{V}$ is (A, B)-invariant.*

PROPOSITION 5.4 [5, Prop. 5.2]. *Let R be a PID and let V be a closed (A, B)-invariant submodule of X; then V is of feedback type.*

After constructing $V_*(\mathcal{L})$, the notion of closure and Proposition 5.3 gives us the possibility, when R is a PID, of checking the solvability condition for the DDP and the DDPMD stated in Theorem 3.4. More precisely, Theorem 3.4 becomes the following theorem.

THEOREM 5.5. *Let Σ be the system described by* (2.2) *over the PID R, and assume that $V^* \cap \operatorname{Im} B = \{0\}$, where V^* is the maximum (A, B)-invariant submodule of* $\operatorname{Ker} C$. *Then, the DDP for Σ is solvable if and only if* $\operatorname{Im} D \subset V^*$ *and the closure $\overline{V_*(\mathcal{L})}$ of $V_*(\mathcal{L})$ in X, where $\mathcal{L}$ is the lattice of all the (A, B)-invariant submodules of* $\operatorname{Ker} C$ *containing* $\operatorname{Im} D$, *is (A, B)-invariant. Analogously, the DDPMD is solvable if and only if* $\operatorname{Im} D \subset V^* + \operatorname{Im} B$ *and $\overline{V_*(\mathcal{L})}$, where $\mathcal{L}$ is the lattice of all the (A, B)-invariant submodules V of* $\operatorname{Ker} C$ *such that* $\operatorname{Im} D \subset V + \operatorname{Im} B$, *is (A, B)-invariant.*

As a result, we are now left with the problem of constructing V^* in the case in which R is a PID. To this end, let us consider the following result.

PROPOSITION 5.6. *Given a system Σ described by* (2.2) *over a PID R, consider the sequence of submodules $\{V_k\}$ of X defined recursively by* (2.4) *and denote its limit by $V = \bigcap_{k=0}^{\infty} V_k$.*

(i) *If $V_k = V_{k+1}$ for some k, then $V_k = V = V^*$, that is, the sequence $\{V_k\}$ converges in a finite number of steps to the maximum (A, B)-invariant submodule of* $\operatorname{Ker} C$.

(ii) *If $V_k \neq V_{k+1}$ for all k, then $\overline{V} \overset{\subset}{\neq}$* $\operatorname{Ker} C$.

Proof. (i) The proof is the same as that in [1].

(ii) Let $\dim_R V = r$ and S be an $n \times r$ matrix whose columns span V. Choose an $r \times r$ minor S_M of S whose determinant is nonzero and let $\det S_M = d_1 d_2 \dots d_q$ be a prime decomposition of $\det S_M$. Now assume that $\overline{V} = \operatorname{Ker} C$; since $V \subset V_k \subset V_0 = \operatorname{Ker} C$ for all k and $\dim V = \dim \overline{V}$, this implies that $r = \dim V = \dim \overline{V} = \dim \operatorname{Ker} C = \dim V_k$ for all k.

Denoting by S_k an $n \times r$ matrix whose columns span V_k, since $V \subset V_k \subset V_{k-1} \subset \cdots \subset V_0 = \operatorname{Ker} C$ for all k, we have $S = S_k Q_k = S_{k-1} Q_{k-1} Q_k = S_0 Q_1 Q_2 \ldots Q_k$, where Q_i denotes a nonsingular $r \times r$ matrix for $i = 0, \ldots, k$. In particular $S_M = S_{0M} Q_1 Q_2 \ldots Q_k$, where S_{0M} is a suitable minor of S_0, and det $S_M =$ (det S_{0M})(det Q_1)(det Q_2)$\ldots$(det Q_k). Now, since prime decompositions in R are unique, if $k > q$ det Q_i is a unit in R for some i and $V_i = V_{i+1}$, we have a contradiction.

A procedure for constructing V^* in the case in which R is a PID can now be described as follows.

Step 1. By (2.4) compute the sequence $\{V_k\}$ and its limit $V^1 = \cap_{k=0}^{\infty} V_k$. If V^1 is (A, B)-invariant, in particular, if $V^1 = V_k$ for some k, $V^1 = V^*$ and the procedure stops.

Step q. In (2.4) set $V_0 = \overline{V^{q-1}}$ and compute the resulting sequence $\{V_k\}$ and its limit $V^q = \cap_{k=0}^{\infty} V_k$. If V^q is (A, B)-invariant, in particular, if $V^q = V_k$ for some k, then $V^q = V^*$ and the procedure stops.

The key fact to point out in the above procedure is that at each step either the procedure stops or the dimension of the submodule that is used for initializing (2.4) is reduced by at least one. Hence, if $r = \dim \operatorname{Ker} C$, r steps of the above procedure allow us to find V^*. No algorithm for computing the limit of $\{V_k\}$ can obviously be given, and, in general, one has to find an explicit description of V_k that facilitates the computation of the limit.

So, in conclusion, the solvability condition for the static feedback DDP and the static feedback DDPMD for a system over a PID R can be checked, and a solution can possibly be constructed by using (4.1) and the above procedure, Propositions 4.3 or 4.4, Proposition 5.3, and finally Theorem 5.5.

Remark 5.7. Let us assume for a given system Σ described by (2.2) over the PID R with $V^* \cap \operatorname{Im} B = \{0\}$, that the static feedback DDP is solvable with a static feedback F. Choosing a basis of X whose first elements are a basis of $\overline{V_*(\mathcal{L})}$, $\mathcal{L}$ being the lattice of all the (A, B)-invariant submodules of Ker C containing Im D, the compensated system Σ_F is described by equations of the form

$$\text{(5.1)} \qquad \begin{cases} x_1(t+1) = \tilde{A}_{11} x_1(t) + \tilde{A}_{12} x_2(t) + \tilde{D}_1 q(t), \\ x_2(t+1) = \tilde{A}_{22} x_2(t), \\ y(t) = \tilde{C} x_2(t). \end{cases}$$

The subsystem $x_1(t+1) = \tilde{A}_{11} x_1(t)$ evolves on $\overline{V_*(\mathcal{L})}$ with a dynamic described, up to a change of basis, by the restriction of $(A + BF)$ to such a submodule. The minimality of $V_*(\mathcal{L})$ implies that this is a fixed dynamic for the considered static feedback DDP in the sense that it is present in the compensated system for any solution F. This has important consequences if we modify the static feedback DDP or the static feedback DDPMD by requiring the additional condition that $\det(zI - A - BF)$ belongs to some specific subset $\mathcal{D}$ of $R[z]$. In particular, $\mathcal{D}$ can be chosen as in [6] to characterize a notion of internal stability. Then, the static feedback DDP or the static feedback DDPMD with the additional requirement of internal stability can be solved only if $\det(zI - \tilde{A}_{11})$ belongs to $\mathcal{D}$.

6. Solvability conditions for the dynamic feedback DDPs. In this section we consider the dynamic feedback DDPs described in §2.1 (iii) and (iv) for a system Σ over a PID R. Let us first remark that, quite obviously, we can view such problems as the search for a suitable dynamic extension Σ_E of Σ of the form

$$\text{(6.1)} \qquad \begin{cases} x(t+1) = Ax(t) + Bu(t) + Dq(t), \\ z(t+1) = A_{21} x(t) + A_{22} z(t) + G_1 q(t), \\ y(t) = Cx(t), \end{cases}$$

where possibly, if the disturbance is not measurable, G_1 is the null matrix, for which the resulting DDP admits a static feedback solution. Adopting this point of view, we are able to make use of the results of the previous sections. The first main result we obtain in this section is the following theorem.

THEOREM 6.1. *Let Σ be a system described by* (2.2) *over the PID R. Then, the dynamic feedback DDP for Σ is solvable if and only if* $\overline{\operatorname{Im} D} \subset V^*$, *where V^* is the maximum (A, B)-invariant submodule of* Ker C.

Proof. We first prove sufficiency. The proof is constructive and consists of finding a suitable dynamic extension Σ_E of Σ for which the resulting DDP admits a static feedback solution. To this end, let us assume without loss of generality that the columns of

$$\begin{bmatrix} I_h \\ 0 \end{bmatrix},$$

where I_h denotes the $h \times h$ identity matrix, form a basis of $\overline{\operatorname{Im} D}$, and the columns of

$$\begin{bmatrix} I_h & 0 \\ 0 & V \end{bmatrix},$$

where V is a suitable $(n-h) \times k$ matrix, form a basis of V^*. By (A, B)-invariance, there exist a suitable $(h+k) \times (h+k)$ matrix G and a suitable $m \times (h+k)$ matrix H such that the following matrix equality holds:

$$A \begin{bmatrix} I_h & 0 \\ 0 & V \end{bmatrix} = \begin{bmatrix} I_h & 0 \\ 0 & V \end{bmatrix} G + BH. \tag{6.2}$$

Then, partitioning $[0_{k\times h}\, I_k]\, G$, where $0_{k\times h}$ is the null matrix with k rows and h columns, as $[0_{k\times h}\, I_k]\, G = [A_0\, A_{22}]$, where A_0 and A_{22} have, respectively, h and k columns, it is easy to see that the following matrix equality holds:

$$\begin{bmatrix} A & 0 \\ [A_0\, 0_{k\times(n-h)}] & A_{22} \end{bmatrix} \begin{bmatrix} I_h & 0 \\ 0 & V \\ 0 & I_k \end{bmatrix} = \begin{bmatrix} I_h & 0 \\ 0 & V \\ 0 & I_k \end{bmatrix} G + \begin{bmatrix} B \\ 0_{k\times m} \end{bmatrix} H. \tag{6.3}$$

Now, letting $A_{21} = [A_0\, 0_{k\times(n-h)}]$, we get the dynamic extension

$$\Sigma_E = \begin{cases} x(t+1) = Ax(t) + Bu(t) + Dq(t), \\ z(t+1) = A_{21}x(t) + A_{22}z(t), \\ y(t) = Cx(t), \end{cases}$$

which exhibits the desired property. In fact, the submodule V_E, spanned in $X_E = X \oplus R^k$ by the columns of the matrix

$$\begin{bmatrix} I_h & 0 \\ 0 & V \\ 0 & I_k \end{bmatrix},$$

is easily seen by (6.3) to be

$$\left(\begin{bmatrix} A & 0 \\ A_{21} & A_{22} \end{bmatrix}, \begin{bmatrix} B \\ 0_{k\times m} \end{bmatrix} \right)\text{-invariant;}$$

it is contained in Ker $C_E = \text{Ker}\,[C\,0_{p\times k}]$ and contains

$$\text{Im}\,D_E = \text{Im}\begin{bmatrix} D \\ 0_{k\times q}\end{bmatrix}.$$

Moreover, since its basis can be completed to a basis of X_E, V_E is of feedback type by Remark 5.2(ii) and Proposition 5.4. A solution to the dynamic feedback DDDP is then given by Σ_E and any friend $[F_1\,F_2] : X \oplus R^k \to U$ of V_E.

We now prove necessity. Assume that a solution of the dynamic feedback DDP consists, in particular, of a dynamic extension Σ_E of the form (6.1), with G_1 equal to the null matrix and state module $X_E = X \oplus R^k$. Also, recalling Proposition 2.2, let V_E be an

$$\left(\begin{bmatrix} A & 0 \\ A_{21} & A_{22}\end{bmatrix}, \begin{bmatrix} B \\ 0_{k\times m}\end{bmatrix}\right)\text{-invariant submodule}$$

of feedback type, contained in Ker $C_E = \text{Ker}\,[C\,0_{p\times k}]$ and containing

$$\text{Im}\,D_E = \text{Im}\begin{bmatrix} D \\ 0_{k\times q}\end{bmatrix}.$$

Since Ker C_E is closed, by Propositions 5.3 and 5.4 we can assume without loss of generality that V_E contains $\overline{\text{Im}\,D_E}$. Denoting the canonical projection by $\pi : X \oplus R^k \to X$, we have that $\overline{\text{Im}\,D} = \pi(\overline{\text{Im}\,D_E}) \subset \pi(V_E) \subset \pi(\text{Ker}\,C_E) \subset \text{Ker}\,C$. Moreover, letting

$$B_E = \begin{bmatrix} B \\ 0_{k\times m}\end{bmatrix},$$

for any element $v \in V_E$ we have

$$\pi\left(\begin{bmatrix} A & 0 \\ A_{21} & A_{22}\end{bmatrix} v\right) = A\pi(v) = \pi(v' + B_E u) = \pi(v') + Bu$$

for some $v' \in V_E$ and $u \in U$, hence $\pi(V_E)$ is (A, B)-invariant and $\overline{\text{Im}\,D} \subset V^*$.

PROPOSITION 6.2. *Let Σ be a system described by* (2.2) *over the PID R, and let $V^* \cap \overline{\text{Im}\,B} = \{0\}$, where V^* is the maximum (A, B)-invariant submodule of* Ker C. *Assuming $\overline{\text{Im}\,D}$ is contained in V^*, let $k = \dim V_*(\mathcal{L}) - \dim(\overline{\text{Im}\,D})$, where $\mathcal{L}$ is the lattice of all the (A, B)-invariant submodules of* Ker C *containing* $\overline{\text{Im}\,D}$. *Then, the dynamic feedback DDP for Σ can be solved by a dynamic feedback law of the form* (2.3) *with* $\dim Z = k$.

Proof. The proof is obvious when we substitute $V_*(\mathcal{L})$ for V^* in the proof of Theorem 6.1.

Remark 6.3. The key point in constructing a solution to the dynamic feedback DDDP in Theorem 6.1 is the possibility of finding an integer h and a matrix V such that, in a suitable basis, Im D is contained in the submodule spanned by the columns of

$$\begin{bmatrix} I_h \\ 0 \end{bmatrix},$$

and the columns of

$$\begin{bmatrix} I_h & 0 \\ 0 & V \end{bmatrix}$$

form a basis of an (A, B)-invariant submodule of Ker C. If such a condition holds, the construction of a solution can be carried on in the same way as in the proof of the theorem on any ring R.

The above theorem shows that, allowing dynamic feedback, we get a solvability condition for the DDP akin to the one we have in the case of coefficients in a field. The situation is even better if the disturbance is measurable, since in this case the condition is the same as in the field case, the only difference being that, in the latter, the existence of dynamic feedback solutions is equivalent to the existence of static feedback solutions.

THEOREM 6.4. *Let Σ be a system described by* (2.2) *over the PID R. Then, the dynamic feedback DDPMD for Σ is solvable if and only if* $\operatorname{Im} D \subset V^* + \operatorname{Im} B$, *where V^* is the maximum (A, B)-invariant submodule of* $\operatorname{Ker} C$.

Proof. We first prove sufficiency. The proof is constructive and consists of finding a suitable dynamic extension Σ_E of Σ for which the resulting DDP admits a static feedback solution. To this end, let V be a suitable $n \times k$ matrix whose columns form a basis of V^*. By (A, B)-invariance, there exist a suitable $k \times k$ matrix A_{22} and a suitable $m \times k$ matrix H such that the following matrix equality holds:

$$AV = VA_{22} + BH; \tag{6.4}$$

hence, by

$$\begin{bmatrix} A & 0 \\ 0 & A_{22} \end{bmatrix} \begin{bmatrix} V \\ I_k \end{bmatrix} = \begin{bmatrix} V \\ I_k \end{bmatrix} A_{22} + \begin{bmatrix} B \\ 0_{k\times m} \end{bmatrix} H, \tag{6.5}$$

we have that the submodule V_E spanned by the columns of

$$\begin{bmatrix} V \\ I_k \end{bmatrix}$$

in $X_E = X \oplus R^k$ is

$$\left(\begin{bmatrix} A & 0 \\ 0 & A_{22} \end{bmatrix}, \begin{bmatrix} B \\ 0_{k\times m} \end{bmatrix} \right)\text{-invariant.}$$

Since its basis can be completed to a basis of X_E, V_E is of feedback type and is clearly contained in $\operatorname{Ker} C_E = [C \; 0_{p\times k}]$. Now, let G_1 and K be matrices of dimensions $k \times q$ and $m \times q$, respectively, such that $D = VG_1 + BK$. Then, in the extended system Σ_E given by

$$\begin{cases} x(t+1) = Ax(t) + Bu(t) + Dq(t), \\ z(t+1) = A_{22}z(t) + G_1 q(t), \\ y(t) = Cx(t), \end{cases} \tag{6.6}$$

the image of the disturbance

$$\operatorname{Im} D_E = \begin{bmatrix} D \\ G_1 \end{bmatrix}$$

is contained in V_E as shown by the equality

$$\begin{bmatrix} D \\ G_1 \end{bmatrix} = \begin{bmatrix} V \\ I_k \end{bmatrix} G_1 + \begin{bmatrix} B \\ 0_{k\times m} \end{bmatrix} K,$$

and the DDP admits a static feedback solution.

We now prove necessity. Assume that a solution of the dynamic feedback DDPMD consists, in particular, of a dynamic extension Σ_E of the form (6.1) with state space $X_E = X \oplus R^k$. Also, recalling Proposition 2.2, let V_E be an

$$\left(\begin{bmatrix} A & 0 \\ A_{21} & A_{22} \end{bmatrix}, \begin{bmatrix} B \\ 0_{k\times m} \end{bmatrix} \right)\text{-invariant submodule}$$

of feedback type, contained in Ker $C_E = \text{Ker}\,[C\ 0_{p\times k}]$ such that

$$\text{Im}\,D_E = \text{Im}\begin{bmatrix} D \\ G_1 \end{bmatrix}$$

is contained in $V_E + \text{Im}\,B_E$, where

$$B_E = \begin{bmatrix} B \\ 0_{k\times m} \end{bmatrix}.$$

Denoting by $\pi : X \oplus R^k \to X$ the canonical projection, we have that $\text{Im}\,D = \pi(\text{Im}\,D_E) \subset \pi(V_E + \text{Im}\,B_E) = \pi(V_E) + \pi(\text{Im}\,B_E) = \pi(V_E) + \text{Im}\,B$. As shown in the proof of Theorem 6.1, $\pi(V_E)$ is (A, B)-invariant and hence $\text{Im}\,D \subset V^* + \text{Im}\,B$.

7. Examples.

Example 7.1. Let Σ be the delay-differential system defined by

$$\Sigma = \begin{cases} \dot{x}_1(t) = q(t-2\partial) + q(t-\partial), \\ \dot{x}_2(t) = q(t-2\partial) + 2q(t-\partial) + q(t), \\ \dot{x}_3(t) = x_1(t) + u_1(t-\partial), \\ \dot{x}_4(t) = x_2(t) + u_2(t), \\ y_1(t) = x_3(t), \\ y_2(t) = x_4(t), \end{cases}$$

where ∂ represents a fixed delay and q is a disturbance. By introducing the delay operator Δ, defined for any time function f by $\Delta(f)(t) = f(t-\partial)$, the static feedback DDP for Σ consists of finding a delay feedback law $u(t) = F(\Delta)(x(t))$, where $F(\Delta)$ is a matrix of polynomials in Δ such that the output of the compensated system $\Sigma_{F(\Delta)}$ does not depend on q. Formally, we can associate with Σ a system of the form (2.2) defined over the ring of polynomials $R[\Delta]$ by the matrices

$$A = \begin{bmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \end{bmatrix}, \quad B = \begin{bmatrix} 0 & 0 \\ 0 & 0 \\ \Delta & 0 \\ 0 & 1 \end{bmatrix}, \quad D = \begin{bmatrix} \Delta(\Delta+1) \\ (\Delta+1)^2 \\ 0 \\ 0 \end{bmatrix},$$

$$C = \begin{bmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}.$$

The static feedback DDP for Σ can then be dealt with using the methods we developed in the previous sections.

First, an easy computation shows that Ker $C = \{(a, b, 0, 0)^T; a, b \in R[\Delta]\}$ and that $V^* = \{(\Delta a, b, 0, 0)^T; a, b \in R[\Delta]\}$. Clearly, Im D is contained in V^*, whose closure $\overline{V^*}$ coincides with Ker C. Since Ker C is not (A, B)-invariant, V^* is not of feedback type and, therefore, the condition Im $D \subset V^*$ is not sufficient for assuring the solvability of the static feedback DDP.

Note, moreover, that for this example there does not exist a maximum (A, B)-invariant submodule of feedback type contained in Ker C. In fact, both submodules $V_1 = \{(\Delta a, (\Delta + 1)a, 0, 0)^T; a \in R[\Delta]\}$ and $V_2 = \{(\Delta^2 a, (\Delta + 1)a, 0, 0)^T; a \in R[\Delta]\}$ are (A, B)-invariant and closed. Hence, the maximum (A, B)-invariant submodule of feedback type contained in Ker C, if it exists, must contain both V_1 and V_2. Then, since it may be assumed to be closed, it must also contain $\overline{V_1 + V_2}$, but as $\overline{V_1 + V_2}$ coincides with Ker C, no maximum exists.

A simple computation shows that Im D is (A, B)-invariant, hence, denoting by $\mathcal{L}$ the lattice of all the (A, B)-invariant submodules of Ker C containing Im D, we have $V_*(\mathcal{L}) = \operatorname{Im} D$. Since $D_1 = \overline{V_*(\mathcal{L})} = \{(\Delta a, (\Delta + 1)a, 0, 0)^T; a \in R[\Delta]\}$ is (A, B)-invariant, $V_*(\mathcal{L})$ is of feedback type, and there exists a solution to the considered static feedback DDP.

In order to compute a solution, let us extend the basis $\{(\Delta, \Delta + 1, 0, 0)^T\}$ of $\overline{V_*(\mathcal{L})}$ to a basis $\{(\Delta, \Delta + 1, 0, 0)^T, (1, 1, 0, 0)^T, (0, 0, 1, 0)^T, (0, 0, 0, 1)^T\}$ of $(R[\Delta])^4$, and, noting that $A((\Delta, \Delta + 1, 0, 0)^T) = B((1, \Delta + 1)^T)$, let us define a map $f : (R[\Delta])^4 \to (R[\Delta])^2$ by $f((\Delta, \Delta + 1, 0, 0)^T) = (1, \Delta + 1)^T$, and, e.g., $f((1, 1, 0, 0)^T) = f((0, 0, 1, 0)^T) = f((0, 0, 0, 1)^T) = (0, 0)^T$. The matrix F associated with f with respect to the canonical basis is

$$F = \begin{bmatrix} -1 & 1 & 0 & 0 \\ -\Delta - 1 & \Delta + 1 & 0 & 0 \end{bmatrix}.$$

The compensated system Σ_F now takes the following form:

$$\Sigma_F = \begin{cases} \dot{x}_1(t) = q(t - 2\partial) + q(t - \partial), \\ \dot{x}_2(t) = q(t - 2\partial) + 2q(t - \partial) + q(t), \\ \dot{x}_3(t) = x_1(t) + x_1(t - \partial) - x_2(t - \partial), \\ \dot{x}_4(t) = x_1(t) + x_1(t - \partial) - x_2(t - \partial), \\ y_1(t) = x_3(t), \\ y_2(t) = x_4(t), \end{cases}$$

from which one can check that the second derivative $\ddot{y}(t)$ of the output $y(t)$ is equal to zero, thus proving that $y(t)$ is actually independent of q.

Example 7.2. Let $\Sigma(\mathbf{p})$ be the family of parameter dependent systems defined by

$$\Sigma(\mathbf{p}) = \begin{cases} \dot{x}_1(t) = \mathbf{p}(\mathbf{p} + 1)q(t), \\ \dot{x}_2(t) = (\mathbf{p} + 1)^2 q(t), \\ \dot{x}_3(t) = x_1(t) + \mathbf{p}u_1(t), \\ \dot{x}_4(t) = x_2(t) + u_2(t), \\ y_1(t) = x_3(t), \\ y_2(t) = x_4(t), \end{cases}$$

where $\mathbf{p}$ represents a parameter which may take values in a fixed set $\mathbf{P}$, and q is a disturbance. The static feedback DDP for the Σ we are interested in solving consists of finding a feedback law $u(t) = F(\mathbf{p})(x(t))$, where $F(\mathbf{p})$ is a matrix that depends polynomially on $\mathbf{p}$ such that the output of the compensated system $\Sigma_{F(\mathbf{p})}$ does not depend on q. Formally, we can associate with Σ a system of the form (2.2) defined over the ring of polynomials $R[\mathbf{p}]$ by the same matrices A, B, C, D as in Example 7.1 with Δ replaced by $\mathbf{p}$. The conclusion follows as in Example 7.1 and the following solution is found:

$$F = \begin{bmatrix} -1 & 1 & 0 & 0 \\ -\mathbf{p} - 1 & \mathbf{p} + 1 & 0 & 0 \end{bmatrix}.$$

Example 7.3. Let us consider the PID $R[X]$ consisting of the polynomials in one variable with real coefficients, and the system Σ over $R[X]$ given by

$$\Sigma = \begin{cases} \begin{bmatrix} x_1(t+1) \\ x_2(t+1) \end{bmatrix} = \begin{bmatrix} 0 & 0 \\ 1 & 0 \end{bmatrix} \begin{bmatrix} x_1(t) \\ x_2(t) \end{bmatrix} + \begin{bmatrix} 0 \\ X \end{bmatrix} u(t) + \begin{bmatrix} X \\ 0 \end{bmatrix} q(t), \\ y(t) = [0 \quad 1] \begin{bmatrix} x_1(t) \\ x_2(t) \end{bmatrix}, \end{cases}$$

where q is a disturbance. One can interpret Σ, e.g., as the system formally associated with a delay-differential system (cf. Example 7.1) or with a family of systems depending on a parameter (cf. Example 7.2). The analysis of the DDP for Σ is easily done. The maximum (A, B)-invariant submodule contained in Ker C is the submodule V^* spanned by $\left[\begin{smallmatrix} X \\ 0 \end{smallmatrix}\right]$ and verifies the condition $V^* \cap \operatorname{Im} B = \{0\}$. We have that $\operatorname{Im} D = V^*$ and $V^* = V_*(\mathcal{L})$, if $\mathcal{L}$ is either the lattice of all the (A, B)-invariant submodules of Ker C containing $\operatorname{Im} D$, or the lattice of all the (A, B)-invariant submodules V of Ker C such that $\operatorname{Im} D \subset V + \operatorname{Im} B$. Moreover, V^* is not closed and its closure $\overline{V^*}$ is not (A, B)-invariant. As a consequence, the static feedback DDP, the static feedback DDPMD, and the dynamic feedback DDP are not solvable, respectively, by Theorem 5.5(i), (ii) and Theorem 6.1. However, the dynamic feedback DDPMD is solvable, and a solution, obtained by means of a suitable system extension as in the proof of Theorem 6.4, is given by the dynamic feedback

$$\begin{cases} z(t+1) = q(t), \\ u(t) = -z(t). \end{cases}$$

CONTROL OF TRUNK LINE SYSTEMS IN HEAVY TRAFFIC*

HAROLD J. KUSHNER†

Abstract. The paper deals with the heavy traffic modelling and optimal control of trunk line networks. The controls concern either acceptance or rerouting. Both discounted and ergodic cost functions are used. It is shown that the sequence of optimal value functions of the physical process converges to the optimal value function for the limit model. Also, good controls for the limit system are good for the physical system. Single trunk systems with both priority and other inputs as well as networks are addressed. For the network case, the limit model is nonstandard, since the control occurs only on the boundary, and is a control over the direction of reflection.

Key words. trunk line networks, loss networks, queueing networks, optimal routing, heavy traffic limits, ergodic control, singular control, rerouting strategies, weak convergence

1. Introduction.

This paper deals with a variety of questions concerning the modelling and optimal control of large trunk line systems under heavy traffic. The basic physical structure is that of a telephone or data communications network where there are several nodes or sources of calls or data, each of which is connected to many others via a trunk line, and each trunk line contains many individual circuits. Loosely speaking, each trunk has a primary purpose, which is to handle the traffic of a priority source that wishes to communicate between its end nodes. However, the trunks are also asked to carry other calls. For example, there might be calls or data of lower priority. In addition, if the circuits in some trunk are all occupied when a request for service between its end nodes arrives, then one might attempt to reroute that request via a pair of lines through some intermediate node and that connect the end nodes of interest. One wishes to operate the network with minimal cost or loss. The control problem consists in the decisions concerning admission of the lower priority requests or of the rerouting.

There is a very large literature on the subject, e.g., [10], [20], [21], [25], [26], [23], [7], [6]. A wealth of material is in [11]. The actual physical problem is quite difficult to treat due to the sizes of the networks and the large number of individual lines. Frequently, some sort of "fluid" model or aggregation approach is taken, and the analysis presumes stationarity. Nevertheless, a good analysis from a control theory perspective seems to be lacking, and many basic questions concerning approximations and the use of the approximations to deduce good policies remain to be answered. In particular, there does not seem to be a rigorous justification of the heavy traffic limits (i.e., when the number of lines goes to infinity) for the control and network problems. This is particularly true when the system is to be used for a long time, and the ergodic control problem is of interest.

The papers [25], [26], [7], [6] do treat heavy traffic limits. They deal with a single trunk line with a main source and (in some cases) with an extra source that is modelled essentially as a "fluid" source. [25] and [26] show via numerical comparisons that the limit model can be used to obtain nearly optimal threshold policies. For the network, the optimal policies are not usually of the threshold type and need to

be deduced. [7] and [6] contain a heavy traffic analysis of a single trunk line when all the interarrival and service times are exponentially distributed but do not deal explicitly with controls. The methods do not seem to be powerful enough to deal with the general control problems. The heavy traffic limits are particularly useful since numerical methods are available for the solution of the optimal control problems for the type of reflected diffusions that arise. These processes might have their control on the boundary and so are nonstandard in the control literature. They raise new questions that are of theoretical importance. Further details on the numerical methods will appear in another paper [18].

This paper starts with the analysis of a single trunk line, since this is of practical interest and since the basic ideas for the more complicated networks can be more easily developed for this simpler case. Section 2 introduces the terminology for the uncontrolled single trunk line case. The weak convergence arguments that are basic to getting the limit models are in §3. It is simpler to get the basic weak convergence ideas without a control and then to extend to the controlled case, so these early sections do not involve controls. Section 4 introduces the control problem for the single trunk line case and gives the basic stability and weak convergence result. In this case, the control concerns only the admission of the low-priority class. It is shown that the sequence of controlled physical systems converges to a well-defined controlled reflected diffusion as the number of individual circuits goes to infinity. The ergodic control problem is defined in §5. This is of particular interest if the system is to be operated over a long time period. Basically, via an occupation measure argument, it is shown that the sequence of average costs per unit time for the physical system converges to the ergodic cost for a limit process. Quite similar arguments will be used for the more complex network case. Section 6 deals with the convergence of the sequence of optimal costs for the trunk lines to the optimal cost for the control problem for the limit model, under a discounted cost criterion.

The controlled network is introduced in §7. We work with a three-node network, which thus forms a triangle. This is the simplest network of interest, but all of the results and methods work without change (except for the more complex notation) for arbitrary networks. Here the control is the decision whether to reroute or not, although admission of low-priority inputs can be added with little extra complication. The basic weak convergence result is proved, and it is seen that the limit model has certain "singular" features, since the reflection term is what is being controlled. The control occurs on the boundary of the state space, since it is only when one trunk is fully occupied that the control question arises. Optimality results for the network under a discounted cost criterion are given in §8. It is shown that the optimal costs for the network are well approximated by optimal costs for the heavy traffic limit. We emphasize that very similar methods can be used to show the convergence of numerical approximations via the Markov chain approximation method discussed in [13], [15], [16]. Indeed, we have conducted extensive numerical studies of the three-dimensional system in order to get guides concerning the structure of good policies for systems of arbitrary sizes. Some comments appear below the statement of Theorem 8.3. Controls for the three-dimensional system were adapted for use on general networks. The resulting performance on large systems (with hundreds of trunks) was very good (and relatively easy to implement), when compared in simulations to several current alternatives. The details are in [18].

The ergodic cost problem for the network is dealt with in §9 and in the Appendix (§10). We do not require that the systems be stationary. The ergodic problem is particularly difficult, since little is known about ergodic properties of boundary-controlled reflected diffusions. An outline of the results and basic ideas is given in §9, and one half of the desired convergence result is proved there. The other half is proved in the Appendix, where we use a natural "barrier" method to approximate the system by one that is better understood and to which standard "Girsanov measure transformation" methods can be used. The proof is completed by exploiting the ideas for the ergodic control problem for recurrent strong Feller processes that were developed in [12]. The major point of the Appendix is the demonstration that, for each $\epsilon > 0$, there is a smooth ϵ-optimal control for the heavy traffic limit. The reader who is willing to accept this can skip the Appendix.

We note that appropriate jump terms can be added to account for sudden changes, without changing the machinery significantly, as can state dependent arrival and service rates. Also, discrete approximations to the heavy traffic limit can be used to explore rerouting strategies via simulation, and these might be simpler than simulating the actual physical system directly. Indeed, they provide a natural aggregation of the state space.

2. An uncontrolled trunk line system: Introduction and terminology. This section defines the form of the uncontrolled one-dimensional system whose weak convergence will be proved in the next section. Controls will be added in §4. Let the trunk line contain N individual lines, with the service time on each being exponentially distributed with rate $\mu > 0$ (the mean service time is $1/\mu$). Let $\{\alpha_k^N, k \geq 1\}$ denote the sequence of interarrival intervals of the requests for service, assumed mutually independent and identically distributed (i.i.d.) for each N and independent of the service times. The sequence of service times are also i.i.d. for each N. The system starts at time zero with some given number of lines already occupied. Define $\overline{\alpha}^N = E\alpha_k^N$. On arrival of a request, if any line is available, then the arrival is assigned to some available line and service begins. Otherwise the arrival is rejected and disappears from the system.

In the heavy traffic regime in which we will be working, the mean service rate (over all lines) needs to be "nearly" equal to the mean arrival rate. If all individual lines are occupied, then the mean rate of completion of service is $N\mu$. Thus, we suppose that the mean arrival rate $(\overline{\alpha}^N)^{-1}$ satisfies

$$(\overline{\alpha}^N)^{-1} = \mu N - b_1\sqrt{N}, \tag{2.1}$$

for some given real number b_1. The $O(\sqrt{N})$ difference between the service and arrival rates is essential if the heavy traffic limit is to be nontrivial. In particular, it can be shown that if the difference were of a larger order, then the system would be fully occupied as $N \to \infty$ if $b_1 < 0$ and a negligible percentage would be occupied if $b_1 > 0$. We also will use the condition that the set of random variables

$$\left\{ \left(\frac{\alpha_k^N}{\overline{\alpha}^N} \right)^2 ; k < \infty, N < \infty \right\} \tag{2.2}$$

is uniformly integrable and that there is $\sigma^2 < \infty$ such that

$$E[1 - \alpha_k^N/\overline{\alpha}^N]^2 = \frac{\text{var } \alpha_k^N}{(\bar{\alpha}^N)^2} \equiv \sigma_N^2 \to \sigma^2. \tag{2.3}$$

Define

$A^N(t)$ = [number of arrivals by time t] $/\sqrt{N}$,
$D^N(t)$=[number of service completions by time $t]/\sqrt{N}$,
$Q^N(t)$ = [number of circuits occupied at $t]/\sqrt{N}$,
$X^N(t) = \sqrt{N} - Q^N(t)$ = [free circuits at $t]/\sqrt{N}$,
$Y^N(t)$ = [number of arrivals rejected by time $t]/\sqrt{N}$.

Now, we can write the dynamical equation

$$Q^N(t) = Q^N(0) + A^N(t) - D^N(t) - Y^N(t),$$

or equivalently for the normalized number of available lines,

$$X^N(t) = X^N(0) - A^N(t) + D^N(t) + Y^N(t). \tag{2.4}$$

The above arrival model is used because it describes common situations. In fact, $A^N(\cdot)$ can be any sequence such that the process $\overline{A}^N(\cdot)$ defined by

$$\bar{A}^N(t) = A^N(t) - \mu\sqrt{N}t$$

converges weakly to a Wiener process with constant drift and the increments

$$\{\bar{A}^N(n+1) - \bar{A}^N(n)\,; n, N\}$$

are uniformly integrable.

In order to simplify the notation, we assume that only one arrival or departure event can occur at a time. The general case only requires that we define an order for the events that occur simultaneously. This is not hard to do, but it does complicate the notation.

3. Weak convergence of $\{X^N(\cdot)\}$. The basic ideas of the weak convergence methods for the more complex network and controlled problems starting in §4 are essentially contained in the development in this section. In all of the weak convergence analysis to follow, for appropriate values of k we use the Skorohod topology on $D^k[0,\infty)$, the space of $I\!R^k$-valued functions that are right continuous and have left hand limits [4], [1]. If $k = 1$, we write just $D[0,\infty)$. For each $t > 0$, both $A^N(t)$ and $D^N(t)$ go to infinity as $N \to \infty$. In order to prove the weak convergence of $\{X^N(\cdot)\}$ and get the desired representation for the limit process, we first need to go through the "usual" procedure of representing $A^N(t)$ and $D^N(t)$ in more useful forms; i.e., as sums of the dominant part of their values (namely, $\mu\sqrt{N}t$, which will cancel each other) plus terms that will converge to either a (bounded) drift or a martingale in the limit.

Tightness in $D[0,\infty)$ will be proved via the following special case of the "Aldous–Kurtz" criterion [4, Chap. 3, Thm. 8.6c]: Let $Z_n(\cdot), n = 1, 2, \ldots$, be a sequence of processes with paths in $D[0,\infty)$ w.p.1. For each $T < \infty$, let the set of random variables $\{Z_n(s), s \leq T, n \geq 1\}$ be tight and suppose that

$$\lim_{\Delta\to 0} \sup_n \sup_{\tau\leq T} \sup_{s\leq\Delta} E\min\{1, |Z_n(\tau+s) - Z_n(\tau)|\} = 0, \tag{3.1}$$

where τ is an arbitrary stopping time bounded by T. Then $\{Z_n(\cdot)\}$ is tight.

Representation of the arrival process $A^N(\cdot)$. If α is a positive real number, Σ_1^α always denotes the sum up to the *integer part* of α. Let $\mathcal{B}_t^N$ denote the σ-algebra induced by $\{A^N(s), D^N(s), s \leq t; X^N(0)\}$. Define the auxiliary process

$$\tilde{A}^N(t) = \frac{1}{\sqrt{N}} \sum_{k=1}^{Nt} \left(1 - \frac{\alpha_k^N}{\overline{\alpha}^N}\right).$$

Let $\tilde{B}_A^N(t)$ denote the σ-algebra that measures $\{\tilde{A}^N(s), s \leq t\}$. Then the sequence of sampled values $\{\tilde{A}^N(i/N), i = 0, 1, \ldots\}$ is a $\tilde{B}_A^N(i/N)$-martingale. Define

$$\begin{aligned} S^N(t) &= \frac{1}{N} \times \max\left\{n : \sum_{k=1}^{n} \alpha_k^N \leq t\right\} \\ &= \frac{1}{N} \times [\text{number of arrivals by time } t]. \end{aligned}$$

Since by definition

$$A^N(t) = \sum_{i=1}^{NS^N(t)} 1/\sqrt{N},$$

we can write

$$A^N(t) = \tilde{A}^N(S^N(t)) + \frac{1}{\sqrt{N}} \sum_{k=1}^{NS^N(t)} \alpha_k^N / \overline{\alpha}^N. \tag{3.2}$$

By (2.1), the last term on the right-hand side can be written as

$$\frac{1}{\sqrt{N}} \sum_{k=1}^{NS^N(t)} \alpha_k^N (\mu N - b_1 \sqrt{N}). \tag{3.3}$$

To simplify (3.3), we will use the relationship (which follows from the definition of $S^N(t)$)

$$\sum_{k=1}^{NS^N(t)} \alpha_k^N = t + O_N(t), \tag{3.4}$$

where $O_N(t) = -[t - \text{time of last arrival before } t]$ and $EO_N(t) = O(1/N)$, $EO_N^2(t) = O(1/N^2)$.

Representation of the departure process $D^N(\cdot)$. Using the fact that the service intervals are mutually independent and exponentially distributed with rate μ, we can decompose $D^N(\cdot)$ in "martingale" form as

$$\begin{aligned} D^N(t) &= \mu \int_0^t Q^N(s) ds + \tilde{D}^N(t) \\ &= -\mu \int_0^t X^N(s) ds + \sqrt{N} \mu t + \tilde{D}^N(t), \end{aligned} \tag{3.5}$$

where $\tilde{D}^N(\cdot)$ is a $\mathcal{B}_t^N$-martingale with quadratic variation

$$\langle \tilde{D}^N \rangle(t) = \mu \int_0^t Q^N(s) ds / \sqrt{N} = \mu \int_0^t \left[1 - \frac{X^N(s)}{\sqrt{N}}\right] ds. \tag{3.6}$$

Define $\tilde{A}_0^N(t) = -\tilde{A}^N(S^N(t))$. Note that $\tilde{A}_0^N(\cdot)$ is $\mathcal{B}_t^N$-measurable. Finally, using (3.2)–(3.5), (2.4) can be rewritten in the more useful form

$$\begin{aligned}X^N(t) &= X^N(0) + b_1 t - \mu\int_0^t X^N(s)ds + \tilde{A}_0^N(t)\\ &\quad + \tilde{D}^N(t) + Y^N(t) + \sqrt{N}O_N(t) = Y^N(t) + Z^N(t),\end{aligned} \tag{3.7}$$

where $Z^N(\cdot)$ is defined in the obvious way.

The first convergence theorem. We can now state the basic weak convergence theorem.

THEOREM 3.1. *Assume the conditions of this section and §2, and let* $\sup_N E|X^N(0)|^2 < \infty$. *Then* $\{X^N(\cdot), \tilde{A}_0^N(\cdot), \tilde{D}^N(\cdot), Y^N(\cdot)\}$ *is tight. Let* $(X(\cdot), W_1(\cdot), W_2(\cdot), Y(\cdot))$ *denote the limit of a weakly convergent subsequence. Then the limit processes have continuous paths w.p.*1 *and satisfy*

$$X(t) = X(0) + b_1 t - \mu\int_0^t X(s)ds + W_1(t) + W_2(t) + Y(t),\ X(t) \geq 0, \tag{3.8}$$

where the $W_i(\cdot)$ *are mutually independent Wiener processes with quadratic variations* $\langle W_1\rangle(t) = \sigma^2\mu t$, $\langle W_2\rangle(t) = \mu t$. *The other processes are nonanticipative with respect to the Wiener processes. Also* $Y(\cdot)$ *can increase only at those* t *for which* $X(t) = 0$. *The set* $\{X^N(t); N < \infty, t < \infty\}$ *is tight.*

Proof. Since the proof is essentially "classical" and closely related arguments are in [24], [17], [19], we only give the outline. It can easily be shown that $\{S^N(\cdot)\}$ converges weakly to the function with values μt, the limit of the mean number of arrivals on $[0, t]$ divided by N, and we omit the details.

Note that, for any bounded $\tilde{\mathcal{B}}_A^N(t)$-stopping time τ,

$$E[(\tilde{A}^N(\tau + t) - \tilde{A}^N(\tau))^2 | \tilde{\mathcal{B}}_A^N(\tau)] \leq \sigma_N^2 t, \tag{3.9a}$$

and the left-hand side converges to $\sigma^2 t$. For any bounded $\mathcal{B}_t^N$-stopping time τ,

$$\begin{aligned}E[(\tilde{D}^N(\tau+t) - \tilde{D}^N(\tau))^2|\mathcal{B}_\tau^N] &= \mu t - \mu E\left[\int_\tau^{\tau+t} X^N(s)ds/\sqrt{N}|\mathcal{B}_\tau^N\right]\\ &= E[\langle\tilde{D}^N\rangle(\tau+t) - \langle\tilde{D}^N\rangle(\tau)|\mathcal{B}_\tau^N],\\ E[(\tilde{A}_0^N(\tau+t) - \tilde{A}_0^N(\tau))(\tilde{D}^N(\tau+t) &- \tilde{D}^N(\tau))|\mathcal{B}_\tau^N] = 0.\end{aligned} \tag{3.9b}$$

Since $X^N(t) \leq \sqrt{N}$, (3.9a) and the first two lines of (3.9b) and the criterion (3.1) yield tightness of $\{\tilde{A}^N(\cdot), \tilde{D}^N(\cdot)\}$. (To get a bound on the expectation in (3.1) take expectations above and use Shwarz's inequality.)

The weak limits of $\{\tilde{D}^N(\cdot)\}$ are continuous because of the tightness and the fact that the "jumps" are of order $O(1/\sqrt{N})$. Next we show the continuity of the weak limits of $\{\tilde{A}^N(\cdot)\}$. To do this, it is sufficient to show that the jumps of $\tilde{A}^N(\cdot)$ go to zero as $N \to \infty$, in the sense that for any fixed $t < \infty$ and $\varepsilon > 0$

$$P\left\{\sup_{k\leq Nt}\frac{\alpha_k^N}{\bar{\alpha}^N\sqrt{N}} \geq \varepsilon\right\} \xrightarrow{N} 0. \tag{3.10}$$

Define the set

$$K_k^{N,\varepsilon} = \left\{ \omega : \frac{\alpha_k^N}{\bar{\alpha}^N \sqrt{N}} \geq \varepsilon \right\}.$$

By Chebychev's inequality, we write (and define δ_N)

$$P\{K_k^{N,\varepsilon}\} \leq \frac{1}{N\varepsilon^2} \int_{K_k^{N,\varepsilon}} \left(\frac{\alpha_k^N}{\bar{\alpha}^N} \right)^2 dP = \delta_N / N,$$

where by the uniform integrability of the set (2.2), $\delta_N \xrightarrow{N} 0$. Thus the left-hand side of (3.10) is bounded above by $(\delta_N/N)Nt$, which goes to zero as $N \to \infty$. Hence (3.10) holds. By the weak convergence of $\{S^N(\cdot)\}$ to the function with value μt at t and the continuity of the limits of $\tilde{A}^N(\cdot)$, the limits of $\tilde{A}_0^N(\cdot)$ have continuous paths w.p.1.

It will be shown below that the mean-square values of $X^N(t)$ are bounded uniformly in N, t. Assuming this fact in this paragraph, we see that the term $X^N(s)/\sqrt{N}$ disappears from (3.6) as $N \to \infty$. The limit of any weakly convergent subsequence of $\{\tilde{D}^N(\cdot)\}$ is a martingale (all the appropriate filtrations will be identified at the end of the proof). Since $\tilde{A}_0^N(\cdot)$ is a martingale and $S^N(\cdot)$ converges as stated, the weak limits of $\tilde{A}_0^N(\cdot)$ are also martingales. By the last line of (3.9b), the limit of any weakly convergent subsequence of $\{\tilde{A}_0^N(\cdot), \tilde{D}^N(\cdot)\}$ is orthogonal. By (3.9a) together with (3.6) (with $X^N(s)/\sqrt{N}$ dropped), (2.3), the convergence of $S^N(\cdot)$, and the continuity of the limits, the limit martingales have the quadratic variations asserted in the theorem; hence they are Wiener processes.

Boundedness of $\{EX^N(t)^2\}$. Suppose that $\sup_N E|X^N(0)|^2 < \infty$. Let $t_0^N = 0$, and let $\{t_i^N, i > 0\}$ denote the ordered sequence of event times (times of arrivals or departures). Then

$$\begin{aligned}[][X^N(t_{i+1}^N)]^2 - [X^N(t_i^N)]^2 &= 2X^N(t_i^N)(X^N(t_{i+1}^N) - X^N(t_i^N)) \\ &\quad + (X^N(t_{i+1}^N) - X^N(t_i^N))^2.\end{aligned}$$

Note that if a rejection of an arrival occurs at t_{i+1}^N, then $X^N(t_i^N)$ must equal 0. Thus $2X^N(t_i^N)(Y^N(t_{i+1}^N) - Y^N(t_i^N)) = 0$. Note that $X^N(t_{i+1}^N) - X^N(t_i^N) = \pm 1/\sqrt{N}$.

Using these observations, (3.7), and the martingale property, for any $t \geq 0$ and $\tau > 0$ the previous expression leads to

$$\begin{aligned} EX^N(t+\tau)^2 &= EX^N(t)^2 - 2\mu \int_t^{t+\tau} E(X^N(s))^2 ds + 2b_1 E \int_t^{t+\tau} X^N(s) ds \\ &\quad + g^N(t, t+\tau) + \delta_N, \end{aligned} \tag{3.11}$$

where $\delta_N \to 0$ uniformly in (t, τ) as $N \to \infty$ and $g^N(t, t+\tau)$ is bounded in absolute value by

$$\frac{3}{N} E\,(\text{number of arrivals and departures on } [t, t+\tau])\,.$$

This last expression is $O(\tau) + O(1/N)$. The $O(\cdot)$ functions might differ from case to case, but they will always be uniform in the sense that there is $k < \infty$ such that in all cases, for $\alpha \geq 0$, $|O(\alpha)| \leq k\alpha$. For any $c_1 \in (0, \mu)$ there is $c_2 > 0$ such that $2b_1|x| \leq c_2 + c_1 x^2$. Using this bound and the fact that $X^N(s) \geq 0$ in (3.11), redefining δ_N to account for the $O(1/N)$ and writing $m^N(t) = EX^N(t)^2$ yields that there is $c_3 > 0$ such that

$$m^N(t+\tau) \leq m^N(t) - \mu \int_t^{t+\tau} m^N(s)ds + c_3\tau + \delta_N, \tag{3.12a}$$

$$m^N(t+\tau) \geq m^N(t) - 2\mu \int_t^{t+\tau} m^N(s)ds - c_3\tau + \delta_N. \tag{3.12b}$$

The nonnegativity of $m^N(t)$ and (3.12a) yield

$$m^N(t+\tau) \leq m^N(t) + c_3\tau + \delta_N. \tag{3.12c}$$

Substituting $m^N(s) = m^N(t) + [m^N(s) - m^N(t)]$ in (3.12b) and using (3.12c) yield

$$m^N(t+\tau) \geq (1 - 2\mu\tau)m^N(t) + O(\tau) + \delta_N. \tag{3.12d}$$

Now, write $m^N(s) = m^N(t) + [m^N(s) - m^N(t)]$ in (3.12a) and use (3.12d) to get

$$m^N(t+\tau) \leq (1 - \mu\tau + O(\tau^2))m^N(\tau) + O(\tau) + \delta_N. \tag{3.13a}$$

Let $\Delta > 0$ be small and N large enough so that $|\delta_N| \leq \Delta$. Then by (3.13a) there is positive c_4 such that

$$m^N(t+\Delta) \leq m^N(t)\left[1 - \mu\Delta + O(\Delta^2)\right] + c_4\Delta. \tag{3.13b}$$

Now, letting $t = n\Delta$ in (3.13b) and iterating yield $\sup_n m^N(n\Delta) < \infty$ for large N. Combining this with (3.12c) yields that, for some $c_5 < \infty$ and large N,

$$\sup_t m^N(t) \leq c_5. \tag{3.14}$$

A similar proof yields that, for each $T < \infty$,

$$\sup_N E \max_{t \leq T} X^N(t)^2 < \infty. \tag{3.15}$$

Tightness of $\{X^N(\cdot)\}$. It follows from (3.15), the properties of $\tilde{A}_0^N(\cdot)$ and $\tilde{D}^N(\cdot)$, and the form (3.7) that $\sup_N E|Y^N(T)|^2 < \infty$ for each $T < \infty$. Thus, to prove tightness of $\{Y^N(\cdot)\}$ via (3.1) it is enough to show that

$$\lim_{\Delta \to 0} \sup_N \sup_{\tau \leq T} P\{Y^N(\tau + \Delta) - Y^N(\tau) \geq \varepsilon\} = 0 \tag{$*$}$$

for each $\varepsilon > 0, T < \infty$, where τ are stopping times. It is sufficient to use τ such that $X^N(\tau) = 0$. Recalling the definition of $Z^N(\cdot)$ in (3.7) and the definition of $Y^N(\cdot)$, we have

$$P\{Y^N(\tau+\Delta) - Y^N(\tau) \geq \varepsilon\} \leq P\left\{\sup_{s \leq \Delta}|Z^N(\tau+s) - Z^N(\tau)| \geq \varepsilon\right\}.$$

Now, the properties of $Z^N(\cdot)$ imply (*). Then $\{Y^N(\cdot)\}$ is tight. From here, it is straightforward to show tightness of $\{X^N(\cdot)\}$, and we omit the details.

The nonanticipativeness property. Let $t \geq 0, s > 0$; and let $\{t_i\}$ be real numbers no bigger than t. For an integer k, let $h(\cdot)$ be a real-valued, bounded, and continuous function of $\{X^N(t_i), \tilde{A}_0^N(t_i), \tilde{D}^N(t_i), Y^N(t_i), i \leq k\}$. Then

$$Eh(X^N(t_i), \tilde{A}_0^N(t_i), \tilde{D}^N(t_i), Y^N(t_i), i \leq k)[\tilde{D}^N(t+s) - \tilde{D}^N(t)] = 0.$$

Let $(X(\cdot), W_1(\cdot), W_2(\cdot), Y(\cdot))$ denote the limit of a weakly convergent subsequence. Then by the weak convergence

$$Eh(X(t_i), W_1(t_i), W_2(t_i), Y(t_i), i \leq k)[W_2(t+s) - W_2(t)] = 0. \tag{3.16}$$

Let $\mathcal{B}_t$ denote the σ-algebra induced by $\{X(s), W_1(s), W_2(s), Y(s), s \leq t\}$. Since $k, \{t_i\}, t, s, h(\cdot)$ are arbitrary, (3.16) implies that $W_2(\cdot)$ is a $\mathcal{B}_t$-Wiener process. A similar proof is used for $W_1(\cdot)$. This yields the nonanticipativeness assertion. □

DEFINITION. Stationary solution. *A solution of* (3.8) *is said to be* stationary *if the distribution of* $\{X(t+\cdot), W_1(t+\cdot) - W_1(t), W_2(t+\cdot) - W_2(t), Y(t+\cdot) - Y(t)\}$ *does not depend on* t. *For a sequence of real numbers* $\{t_N\}$, *define the "shifted" processes*

$$H^N(\cdot) = (X^N(t_N + \cdot), \tilde{A}_0^N(t_N + \cdot) - \tilde{A}_0^N(\cdot), \tilde{D}^N(t_N + \cdot) - \tilde{D}^N(t_N),$$

$$\tilde{Y}^N(t_N + \cdot) - Y^N(t_N)).$$

The following theorem will not be used in the sequel but is of interest if the process and the approximations are of concern over a long time period.

THEOREM 3.2. *Assume the conditions of Theorem* 3.1. *Let* t_N *be a sequence of real numbers tending to infinity. Then the set of "shifted" processes* $\{H^N(\cdot)\}$ *is tight. It converges weakly to the unique stationary solution* $(X(\cdot), W_1(\cdot), W_2(\cdot), Y(\cdot))$ *of* (3.8). *The process* $X(\cdot)$ *satisfying* (3.8) *is a strong Feller process.*

Proof. The tightness follows from Theorem 3.1 and the mean square boundedness of $\{X^N(s),\ s < \infty, N < \infty\}$. By Theorem 3.1, any subsequence of $\{H^N(\cdot)\}$ has a further subsequence that converges weakly to a solution of (3.8). Next, fix $T \in (0, \infty)$ and extract a weakly convergent subsequence of $\{X^N(t_N + \cdot), X^N(t_N - T + \cdot)\}$, with the limit denoted by $(\tilde{X}(\cdot), \tilde{X}_T(\cdot))$. Both of these processes satisfy equation (3.8) for some Wiener processes, and $\tilde{X}_T(T) = \tilde{X}(0)$. Also, for each initial condition x, the solution process $X(t)$ of (3.8) is bounded in mean, uniformly in t. It can be shown either directly or via a Girsanov transformation technique (starting with the system $X(t) = X(0) + W_1(t) + W_2(t) + Y(t)$) that the solution of (3.8) is a strong Feller process and that for $t > 0$ it has a transition density $p(x, t, y)$ that is nonzero for all $x \in [0, \infty)$ and $y \in [0, \infty)$. The last two sentences imply that there is a unique invariant measure $\pi(\cdot)$ and [3, Thm. 4]

$$\int f(y)p(x,t,y)dy \to \int f(y)\pi(dy) \tag{3.17}$$

for each x and bounded continuous real-valued $f(\cdot)$. The set of all possible values of $\{\tilde{X}_T(0), T < \infty\}$ is tight since $\{X^N(t); N < \infty, t < \infty\}$ is tight. Owing to this tightness and the arbitrariness of T, to show that $\tilde{X}(0)$ is the stationary random variable it is enough to show that the convergence in (3.17) is uniform in each compact x-set K. Given $K, t_1 > 0$, and $\delta > 0$, there is a compact set K_1 such that $\int_{K_1} p(x, t_1, y)dy \geq 1 - \delta$ for all $x \in K$. Now, let $t > t_1$ and use the representation

$$\int p(x, t_1, y_1)dy_1 \int f(y_2)p(y_1, t - t_1, y_2)dy_2, \qquad t > t_1,$$

of the left-hand side of (3.17), the arbitrariness of δ, and the pointwise convergence (3.17), to get the desired uniform convergence. □

4. A one-dimensional canonical control problem. In addition to the primary input source $A^N(\cdot)$ of §2, let there be an "exogenous" source of competing requests for the use of the N individual lines that arrive one at a time. The one-at-a-time assumption is not required, but it does save on the notation. In particular, define $G^N(t) =$ [number of requests from the exogenous source by time $t]/\sqrt{N}$. The interarrival times for this source might be correlated, and in this section we assume either

(a) that there is $b_0 > 0$ such that for any positive T_1

$$[G^N(t+T) - G^N(T)] \to b_0 t \tag{4.1a}$$

uniformly for $t \le T_1, T < \infty$, or, more generally;

(b) that $\{G^N(\cdot)\}$ is tight and converges weakly to a continuous process $G(\cdot)$. Also, suppose that the set

$$\{G^N(n+1) - G^N(n); N < \infty, n < \infty\} \tag{4.1b}$$

is uniformly integrable.

We also assume that $G^N(\cdot)$ is independent of $A^N(\cdot)$, $X^N(0)$, and the sequence of service intervals. Equation (4.1a) is similar to the "fluid" model used in [25], [26], [20], [21]. Commonly, the $G^N(\cdot)$ process is an "overflow" from another system and (4.1a) would not hold since $G^N(\cdot)$ would behave like our $Y^N(\cdot)$. The second case covers this. We note that (4.1a) might hold "approximately," if $G^N(\cdot)$ were the sum of inputs from many independent sources. The uniform integrability in condition (4.1b) holds for overflows from "trunk line" systems, as seen by the uniform integrability of the set (4.7) below.

The weak convergence assumed in (b) above implies that the mean rate of the exogenous source is $O(\sqrt{N})$. The basic control question is whether or not to accept any particular request from the exogenous sequence. Arrivals from the original sequence $A^N(\cdot)$ are always accepted if any line is available. If the order of the number of exogenous inputs per unit time were larger than $O(\sqrt{N})$, then the fraction rejected would go to unity as $N \to \infty$. Let $J^N(\cdot)$ denote the *acceptance process* defined as follows: If an exogenous arrival that occurs at time t is accepted, then $J^N(t) = 1$; otherwise $J^N(t) = 0$. Then the (scaled by $1/\sqrt{N}$) number of acceptances from the exogenous source by time t can be written as (note the definition of the Stieltjes integral)

$$\sum_{s\le t} J^N(s)[G^N(s) - G^N(s^-)] = \int_0^t J^N(s)dG^N(s) \equiv F^N(t).$$

Now we can write

$$\begin{aligned} X^N(t) &= X^N(0) + b_1 t - \mu\int_0^t X^N(s)ds \\ &\quad + \tilde{A}_0^N(t) + \tilde{D}^N(t) - F^N(t) + Y^N(t) + O_N(t)\sqrt{N}. \end{aligned} \tag{4.2}$$

The $O_N(\cdot)$ is the same as in (3.7).

A cost function. An average cost per unit time criterion will be dealt with in §5. Here, we formulate a "discounted" criterion. Recall that $Y^N(t)$ equals the (scaled) number of rejects from the primary source, due to arrivals when all lines are occupied. Let $c_1 > c_0 > 0$, $\beta > 0$, and define the cost

$$C^N(J^N, X^N(0)) = E\int_0^\infty e^{-\beta t}[c_1 dY^N(t) + c_0(1 - J^N(t))dG^N(t)]. \tag{4.3}$$

Thus c_1 (c_0, resp.) is the per unit cost of rejecting a request from the primary (exogenous, resp.) source. Redefine $\mathcal{B}_t^N$ so that it measures $\{G^N(s), F^N(s), A^N(s), D^N(S), X^N(0), s \le t\}$. Thus, $\mathcal{B}_t^N$ also measures $\{J^N(s), s \le t\}$. We say that $J^N(\cdot)$ is *admissible* if the following holds: $J^N(t) = 0$ if there is no exogeneous arrival at t; for t at which there is an exogeneous arrival, $J^N(t)$ depends only on the arrival and departure data up to and including t and on the acceptance data to t^-. Since the events occur discretely in time, $J^N(\cdot)$ is well defined.

THEOREM 4.1. *Assume the conditions of Theorem* 3.1 *and the assumptions on* $G^N(\cdot)$ *of this section. Let the* $J^N(\cdot)$ *be admissible. Then* $\{X^N(\cdot), \tilde{A}_0^N(\cdot), \tilde{D}^N(\cdot), Y^N(\cdot), F^N(\cdot), G^N(\cdot)\}$ *is tight. If* $(X(\cdot), W_1(\cdot), W_2(\cdot), Y(\cdot), F(\cdot), G(\cdot))$ *denotes the limit of a weakly convergent subsequence, then*

$$X(t) = X(0) + b_1 t - \mu\int_0^t X(s)ds + W_1(t) + W_2(t) - F(t) + Y(t), \tag{4.4}$$

where the $W_1(\cdot)$ *are as in Theorem* 3.1. *All other processes are continuous and nonanticipative with respect to the* $W_i(\cdot)$, *and* $F(\cdot)$ *has the form* (*under* (4.1a))

$$F(t) = b_0\int_0^t J(s)ds \tag{4.5a}$$

for some nonanticipative process $J(\cdot)$ *with* $J(t) \in [0,1]$. *More generally* (*under condition* (4.1b) *above*),

$$F(t) = \int_0^t J(s)dG(s). \tag{4.5b}$$

Also, if N *indexes the convergent subsequence, then* $C^N(J^N, X^N(0)) \to C(J, X(0))$, *where*

$$C(J, X(0)) = E\int_0^\infty e^{-\beta t}[c_1 dY(t) + c_0(1 - J(t))dG(t)]. \tag{4.6}$$

The set $\{EX^N(t)^2; N < \infty, t < \infty\}$ *is bounded.*

Remark. Note that $J(t)$ can be any value in $[0,1]$. The quantity $b_0 J(t)$ in (4.5a) can be viewed as the "local intensity" of the acceptance process for the exogenous requests at time t, in the limit. In (4.5b), $J(t)$ can be viewed as the "local probability" of acceptances at t when there are exogenous inputs. In typical applications where there is input control, the acceptance "local probability" is either zero or unity (i.e., reject or accept), but the theoretical development here requires that we allow the possibility of arbitrary values in $[0,1]$.

Proof. The boundedness of $\{EX^N(t)^2; N < \infty, t < \infty\}$ follows from Theorem 3.1, since the expectations are no larger when the exogenous inputs are introduced. Actually, all the assertions, except those concerning $F(\cdot)$ and the convergence of the costs, are proved in Theorem 3.1. $\{F^N(\cdot)\}$ is obviously tight by the assumed tightness of $\{G^N(\cdot)\}$. The nonanticipativeness property of $(X(\cdot), Y(\cdot), F(\cdot), G(\cdot))$ follows from the arguments used in connection with (3.16) and the independence assumptions put on $G^N(\cdot)$, since (3.16) continues to hold if $F(t_i), G(t_i)$ are added to the arguments of $h(\cdot)$. Equation (4.1a) implies that $F(\cdot)$ is absolutely continuous with respect to Lebesgue measure, with derivative bounded by b_0, hence the representation (4.5a). Analogously, (4.5b) holds since $F(\cdot)$ is always absolutely continuous with respect to $G(\cdot)$ with derivative in $[0,1]$.

If the set of increments (4.7)

$$\{Y^N(n+1) - Y^N(n); n < \infty, N < \infty\} \tag{4.7}$$

is uniformly integrable, then the weak convergence implies the convergence of the costs $C^N(J^N, X^N(0))$ to $C(J, X(0))$. To prove the uniform integrability, write

$$\begin{aligned} Y^N(n+1) \; - Y^N(n) &= (X^N(n+1) - X^N(n)) + \mu \int_n^{n+1} X^N(s)ds - b_1 \\ &\quad - (\tilde{A}_0^N(n+1) - \tilde{A}_0^N(n)) - (\tilde{D}^N(n+1) - \tilde{D}^N(n)) \\ &\quad + (F^N(n+1) - F^N(n)) - O_N(t)\sqrt{N}. \end{aligned}$$

Using the uniform integrability of the set (4.1b), the boundedness of the $EX^N(t)^2$, in N and t, and the fact that the sup over N and n of the squares of the last four terms on the right are bounded, we get the uniform integrability of (4.7). □

Remark. The above development can clearly be extended to multiple exogenous sources $G_1^N(\cdot), G_2^N(\cdot), \ldots$, each with its own cost and "acceptance" control.

Uniqueness. We say that the solution to system (4.4) *is unique in the weak sense* if the probability law of $(W_1(\cdot), W_2(\cdot), F(\cdot), X(0))$ determines the probability law of $(X(\cdot), W_1(\cdot), W_2(\cdot), F(\cdot))$. Weak sense uniqueness can easily be proved via the Girsanov measure transformation method [8, Chap. 4.4], for any $F(\cdot)$ of the form in (4.5b). To see this, let $W(\cdot)$ be a Wiener process and $G(\cdot)$ a nonnegative and nonanticipative (with respect to $W(\cdot)$) process with nondecreasing and continuous paths with $G(0) = 0$. Let $J(\cdot)$ be nonanticipative (with respect to $W(\cdot)$) and bounded. Consider the equation

$$X(t) = X(0) + W(t) - \int_0^t J(s)dG(s) + Y(t), \qquad X(t) \geq 0,$$

where $Y(\cdot)$ is the reflection term that is allowed to increase only when $X(t) = 0$. The equation has a weak sense unique solution. The Girsanov transformation method can now be used to add the drift terms $b_1 t$ and $-\mu \int_0^t X(s)ds$, exactly as done in [8, Chap. 4.4], and get the weak sense uniqueness for (4.4).

5. An ergodic control problem.

We continue with the controlled single trunk problem of the last section. Let $G^N(\cdot)$ be a process satisfying the conditions of §4. For $T > 0$, define the cost (for $x = X^N(0)$ = initial condition)

$$\gamma_T^N(J^N, x) = \frac{1}{T} E \int_0^T \left[c_1 dY^N(t) + c_0(1 - J^N(t))dG^N(t)\right]. \tag{5.1}$$

In this and in §§9 and 10, it will be shown that *stationary* controlled processes satisfying (4.4) provide very good approximations to the performance of $X^N(\cdot)$ for large

N and time. The trunk line systems tend to be of interest for a long time period, and virtually all of the current analyses assume some sort of stationarity. Here we concern ourselves with the ergodic cost problem for the single trunk case, but with an *arbitrary starting state.* Sections 9 and 10 are concerned with the ergodic control problem for the network. The very useful "occupation measure" method will be used, although we work with measures over the path space rather than over the value spaces of the state and control functions. We first introduce the needed notation.

DEFINITIONS. Stationary controlled process. *We say that the solution to* (4.4) *is* stationary *if the distribution of*

$$\begin{aligned} R_t(\cdot) = (&X(t+\cdot), W_1(t+\cdot) - W_1(t), W_2(t+\cdot) - W_2(t),\\ &F(t+\cdot) - F(t), Y(t+\cdot) - Y(t), G(t+\cdot) - G(t)) \end{aligned}$$

does not depend on t.

Assumptions and notation. Now we set up some notation for the functional occupation measure development. We need to define the canonical variables of the sample space of the above set of the six processes that are the components of $R_t(\cdot)$. We will use the 6-tuple $\rho(\cdot) = (\xi(\cdot), \psi_1(\cdot), \psi_2(\cdot), \phi(\cdot), y(\cdot), \alpha(\cdot))$ to denote the canonical element of $D^6[0,\infty)$, where each of the six components is a canonical element of $D[0,\infty)$. The element $\xi(\cdot)$ will represent the canonical sample path of either $X(\cdot)$ or $X^N(\cdot)$ or of appropriate "time-shifted" forms such as $X^N(t+\cdot)$. Similarly, $\psi_1(\cdot)$ will denote the canonical sample path of either $W_1(\cdot)$ or $\tilde{A}_0^N(\cdot)$ or of appropriate time-shifted and centered forms such as $\tilde{A}_0^N(t+\cdot) - \tilde{A}_0^N(t)$. Analogously, $\psi_2(\cdot), \phi(\cdot), y(\cdot)$, and $\alpha(\cdot)$ will denote (resp.) the canonical sample paths of either $W_2(\cdot)$ or $\tilde{D}^N(\cdot)$, either $F(\cdot)$ or $F^N(\cdot)$, either $Y(\cdot)$ or $Y^N(\cdot)$, and either $G^N(\cdot)$ or $G(\cdot)$, or appropriately time-shifted and centered forms of these processes. For $t \geq 0$, define the processes $R_t^N(\cdot)$ by

$$\begin{aligned} R_t^N(\cdot) = (&X^N(t+\cdot), \tilde{A}_0^N(t+\cdot) - \tilde{A}_0^N(t), \tilde{D}^N(t+\cdot) - \tilde{D}^N(t),\\ &F^N(t+\cdot) - F^N(t), Y^N(t+\cdot) - Y^N(t), G^N(t+\cdot) - G^N(t)). \end{aligned}$$

Effectively, $R_t^N(\cdot)$ are the original processes but shifted left by t. Let $P^{N,t}(\cdot)$ denote the measure that is induced by the process $R_t^N(\cdot)$, and define the *occupation measure* $P_T^N(\cdot)$:

$$P_T^N(\cdot) = \frac{1}{T}\int_0^T P^{N,t}(\cdot)dt.$$

Occupation measures on the path space provide a convenient method of dealing with approximations to ergodic cost problems in a variety of contexts [14].

The cost function. Let us write the cost function (5.1) in terms of $P_T^N(\cdot)$. Note that

$$\frac{1}{T}\int_0^T [F^N(t+1) - F^N(t)]dt = \frac{1}{T}F^N(T) + \delta_T^N, \tag{5.2a}$$

where

$$\delta_T^N = \frac{1}{T}\left[\int_T^{T+1} (F^N(t) - F^N(T))dt - \int_0^1 F^N(t)dt\right]. \tag{5.2b}$$

Thus, we can write

$$\begin{aligned}\gamma_T^N(J^N, X^N(0)) &= E\left[c_1Y^N(T) + c_0(G^N(T) - F^N(T))\right]/T \\ &= \frac{1}{T}E\int_0^T [c_1(Y^N(t+1) - Y^N(t)) + c_0(G^N(t+1) - G^N(t)) \\ &\quad - c_0(F^N(t+1) - F^N(t))]dt + \hat{\delta}_T^N,\end{aligned}$$

where the "error term" $\hat{\delta}_T^N$ can be obtained from the type of calculation done in connection with (5.2). Under the uniform integrability properties of (4.1b) and (4.7), $\hat{\delta}_T^N \to 0$ as $T \to 0$, uniformly in N. Now we can write (5.1) in terms of the occupation measure as

$$\gamma_T^N(J^N, X^N(0)) = \int [c_1 y(1) + c_0(\alpha(1) - \phi(1))]\, P_T^N(d\rho) + \hat{\delta}_T^N. \tag{5.3}$$

Thus, the asymptotic behavior of the costs depends on the asymptotic behavior of $\{P_T^N(\cdot)\}$. The next theorem tells us that the long-term averages are well approximated by those of a stationary limit problem. We note that the occupation measure method used in Theorem 5.1 will also be used in §§9 and 10 in essentially the same way. It is easier to understand in the context of the one-dimensional problem here. The next theorem justifies using the stationary limit problem to get approximations to the physical problems when the latter is of interest over a long time period.

THEOREM 5.1. *Assume the conditions of Theorem* 3.1, *as well as the assumptions on* $G^N(\cdot)$ *stated in* §4. *Let the* $J^N(\cdot)$ *be admissible. Then* $\{P_T^N(\cdot); N < \infty, T < \infty\}$ *is tight. Let* $\overline{P}(\cdot)$ *denote the limit of a weakly convergent subsequence* (*as* $N \to \infty, T \to \infty$). *There exists a stationary process, which we denote by* $\overline{R}(\cdot) = (X(\cdot), W_1(\cdot), W_2(\cdot), F(\cdot), Y(\cdot), G(\cdot))$, *that induces the measure* $\overline{P}(\cdot)$ *and satisfies* (4.4), *where* $F(\cdot)$ *has the representation* (4.5b) *for a nonanticipative process* $J(\cdot)$ *with values in* $[0,1]$. *The Wiener processes* $W_i(\cdot)$ *have the quadratic variation properties cited in Theorem* 3.1, *and the other processes are nonanticipative with respect to the Wiener processes. Also, as* $N \to \infty$ *and* $T \to \infty$ *through the convergent subsequence,*

$$\begin{aligned}\gamma_T^N(J^N, X^N(0)) \to \gamma(J) &\equiv \textstyle\int \overline{P}(d\rho)\, [c_1 y(1) + c_0(\alpha(1) - \phi(1))] \\ &= E\left[c_1 Y(1) + c_0\int_0^1 [1 - J(s)]dG(s)\right].\end{aligned} \tag{5.4}$$

Proof. By Theorem 4.1, the set of random variables $\{X^N(t); N < \infty, t < \infty\}$ is tight. By the proof in Theorem 4.1, this implies that the set of processes $\{R_t^N(\cdot); N < \infty, t < \infty\}$ is tight; i.e., the set of measures $\{P^{N,t}(\cdot); N < \infty, t < \infty\}$ is tight. The latter assertion implies the tightness of the set of occupation measures $\{P_T^N(\cdot); N < \infty, T < \infty\}$.

Now, abusing terminology, let N, T (both going to infinity) index a weakly convergent subsequence with limit denoted by $\overline{P}(\cdot)$. Let $\overline{R}(\cdot) = (\overline{X}(\cdot), \ldots, \overline{G}(\cdot))$ denote the process that induces $\overline{P}(\cdot)$. Note that the measure $P_T^N(\cdot)$ is that of a process $\tilde{R}_T^N(\cdot)$ that is constructed exactly as $R^N(\cdot) = R_0^N(\cdot)$ is but where one *randomizes* the initial time; i.e., $P\{\text{initial time} \in [t, t+\Delta]\} = \Delta/T$ for $0 \le t \le t + \Delta \le T$, and the initial time is independent of all other random variables in the system. By the tightness of the set $\{X^N(t); N < \infty, t < \infty\}$, the set of initial conditions for the "randomized initial time" processes $\{\tilde{R}_T^N(\cdot); N < \infty, T < \infty\}$ is tight. Then the fact that $\overline{R}(\cdot)$ satisfies (4.4) with the representation (4.5b) follows from the proofs of Theorems 3.1 and 4.1.

The paths of $\overline{R}(\cdot)$ are continuous w.p.1. Hence the functions with values $y(1), \alpha(1)$, and $\phi(1)$ are continuous in the Skorohod topology almost everywhere with respect to the measure of $\overline{R}(\cdot)$. Thus [1, Thm. 5.1] the convergence (5.4) follows from the weak convergence, the continuity of the paths of $\overline{R}(\cdot)$, the uniform integrability of the set $\{Y^N(n+1) - Y^N(n); N < \infty, n < \infty\}$ (see Theorem 4.1), and the assumed uniform integrability of $\{G^N(n+1) - G^N(n); N < \infty, n < \infty\}$. We need only prove the stationarity properties of $\overline{R}(\cdot)$.

For $g(\cdot) \in D^6[0,\infty)$ and $c > 0$, define the left shift $g_c(\cdot) = g(c + \cdot)$. For a Borel set $K \subset D^6[0,\infty)$, define the left shift $K_c = \{g(\cdot) : g_c(\cdot) \in K\}$. Then we can write

$$\begin{aligned} P_T^N(K_c) &= \frac{1}{T}\int_0^T P^{N,t}(K_c)dt = \frac{1}{T}\int_0^T P\{R_{t+c}^N(\cdot) \in K\}dt, \\ P_T^N(K_c) - P_T^N(K) &= \frac{1}{T}\int_T^{T+c} P\{R_{t+c}^N(\cdot) \in K\}dt - \frac{1}{T}\int_0^c P\{R_t^N(\cdot) \in K\}dt. \end{aligned} \tag{5.5}$$

Let $f(\cdot)$ be a bounded continuous real-valued function on $D^6[0,\infty)$. Then the "error" estimate (5.5) and the continuity of the limit process $\overline{R}(\cdot)$ imply that

$$\begin{aligned} Ef(\overline{R}(\cdot)) &= \lim_{N,T}\int f(\rho)P_T^N(d\rho) = \int f(\rho)\overline{P}(d\rho) \\ &= \lim_{N,T}\int f(\rho_c)P_T^N(d\rho) = Ef(\overline{R}_c(\cdot)). \end{aligned}$$

Since $c > 0$ is arbitrary, this last equation implies the stationarity. □

It can be shown that $\inf_J \gamma^N(J^N, x) \to \inf_J \gamma(J)$. The details are omitted since a harder problem is dealt with in Theorem 9.1.

6. Convergence and approximation of the controls: Discounted cost. We return to the discounted cost problem of §4. This section concerns convergence of the optimal costs for the physical problem to that for the limit problem. This topic is continued in §8, where the more complex network case of §7 is dealt with, and given in more detail.

DEFINITION. *A control $J(\cdot)$ for* (4.4) *is said to be* admissible *if it is a measurable process that takes values in* [0, 1] *and is nonanticipative with respect to the $W_i(\cdot)$. We were able to represent the limit $F(\cdot)$ in Theorems* 4.1 *and* 5.1 *in terms of an admissible control, since both $F(\cdot)$ and $G(\cdot)$ were nonanticipative with respect to the $W_i(\cdot)$. Define*

$$\overline{C}^N(x) = \inf\{C^N(J^N, x) : J^N(\cdot) \text{ admissible}\},$$

$$\overline{C}(x) = \inf\{C(J, x) : J(\cdot) \text{ admissible}\},$$

where $C^N(\cdot)$ and $C(\cdot)$ are defined by (4.3) *and* (4.6), *respectively. We wish to show next that*

$$\overline{C}^N(x) \to \overline{C}(x). \tag{6.1}$$

Note that no Markovian-type assumption is made on $G^N(\cdot)$ or on $G(\cdot)$.

THEOREM 6.1. *Assume the conditions of Theorem* 4.1. *Then* (6.1) *holds.*

Discussion of the proof. Theorem 4.1 implies that

$$\liminf_N \overline{C}^N(x) \geq \overline{C}(x).$$

Thus, we need only prove the "reverse" inequality

$$\limsup_N \overline{C}^N(x) \leq \overline{C}(x). \tag{6.2}$$

This is the usual problem in getting results like (6.1). In order to prove (6.2), one can proceed as follows. Let $\epsilon > 0$. A particular ϵ-optimal control (denoted by $J^\epsilon(\cdot)$) for the system $X(\cdot)$ of (4.4), (4.5b), and cost (4.6) is obtained. This control must be such that there is an adaptation, to be denoted by $J^{\epsilon,N}(\cdot)$, that can be used on the physical processes $X^N(\cdot)$. The adaptation should be such that, under $J^{\epsilon,N}(\cdot)$,

$$C^N(J^{\epsilon,N}, x) \to C(J^\epsilon, x).$$

Since $J^\epsilon(\cdot)$ is ϵ-optimal, we will then have

$$\limsup_N \bar{C}^N(x) \leq \lim_N C^N(J^{\epsilon,N}, x) = C(J^\epsilon, x) \leq \bar{C}(x) + \epsilon.$$

Since ϵ is arbitrary, this proves (6.2). The control $J^\epsilon(\cdot)$ is not to be considered to be a "practical" control. Its purpose is only to help prove (6.2).

A similar problem occurs in the proofs of the convergence of "computational approximations" to optimal stochastic control problems, and, indeed, the method of [13, Thm. 7.1] can be used to construct the desired $J^\epsilon(\cdot)$. In fact, the only difference between the requirements in [13, Thm. 7.1] and our requirements here is the need to take the input $G(\cdot)$ into account. The adaptation of the cited proof to our problem is not hard. But since an analogous problem for the more complicated controlled network will be dealt with in detail in §8 via a related approximation method, we will not pursue the matter further here but refer the reader to §8. This type of result is an important consequence of the heavy traffic analysis, since useful numerical methods are available to get the optimal value functions and controls for control problems for the limit models [13], [15], [16].

DEFINITION. *A control $J(\cdot)$ for $X(\cdot)$ is said to be a* feedback *control if there is a measurable function $u(\cdot)$ with values in* $[0, 1]$ *and such that $J(t) = u(X(t), t)$. If $u(\cdot)$ depends only on x, we say that it is a* state feedback *control. For feedback controls, we write the associated costs as $C^N(u, x), C(u, x)$. If $G(t)$ equals b_0t (as in* (4.5a)) *or is the "overflow" from another trunk line system, then one might expect $J(\cdot)$ to be of state feedback form and, more particularly, to be of the "threshold" form; namely, there is $B_0 > 0$ such that $J(t) = 1$ if $X(t) \geq B_0$ and $J(t) = 0$ otherwise. Such threshold policies are a common occurrence for queueing problems when the input can be controlled* [9], [22]. *For the network problem the optimal control will not be of the threshold type.*

For the next result, we need the following construction. Let $u(\cdot)$ be a state feedback control that is piecewise continuous in x. We can define a control $J^N(\cdot)$ from $u(\cdot)$ for use in (4.2) such that $C^N(J^N, x) \to C(J, x)$. If $u(\cdot)$ is an indicator function, then the adaptation is obvious; we use $J^N(t) = u(x^N(t))$. Otherwise, we use a randomization rule of the type that will be used in Theorem 8.3 below and where more detail will be given: In particular, use the following rule. Let there be an arrival from $G^N(\cdot)$ at t; then accept it with the conditional probability

$$P\{\text{accept} \mid \text{data}(t)\} = u(X^N(t^-)),$$

where data(t) is all the systems data up to and including time t, except for the acceptance or rejection of the request from $G^N(\cdot)$ at t. The weak convergence arguments can be carried through since $u(\cdot)$ is continuous w.p.1 with respect to the measure of $X(\cdot)$.

We can state the following extension of Theorem 6.1. Again, we omit the proof in view of the development in §8. The corollary asserts that a "nice" nearly optimal control for $x(\cdot), C(\cdot)$ is also nearly optimal for $X^N(\cdot), C^N(\cdot)$. If $u(\cdot)$ is of the threshold type, then its adaptation for use on the network does not require a randomization.

COROLLARY. *Assume the conditions of Theorem* 4.1. *Suppose that $u(\cdot)$ is a piecewise continuous state feedback control for $X(\cdot)$. Let $J^N(\cdot)$ denote its adaptation to $X^N(\cdot)$.*

Then $C^N(J^N, x) \to C(u, x)$. If $u(\cdot)$ is ε-optimal for (4.4), (4.6), *then $J^N(\cdot)$ will be 2ε-optimal for* (4.2), (4.3), *for large N.*

7. A simple controlled network. Description. The network will be defined and the basic weak convergence results of the past sections will be extended. It will be shown that the limit processes lead to well-defined control problems and that the costs converge to the cost for the limit problem. We consider a three-node network (i.e., a triangle). However, the methods and results hold for arbitrary networks provided that the basic heavy traffic conditions hold. The exogenous requests $G^N(\cdot)$ in the previous sections are now replaced by explicit requests from other trunk lines of the network. Numerical studies of the triangular network have shown how to devise very good and relatively easily implementable policies for arbitrary (hundreds of trunks) networks. Details of the numerical method and the simulation studies are given in [18].

Let the nodes be labelled A, B, C and the links $1, 2, 3$ with link 1 connecting (A, B) and links 2, 3, respectively, connecting (B, C) and (C, A). The trunk lines labelled $i = 1, 2, 3$ have $\beta_i N$ individual bidirectional lines, where $\beta_i > 0$ and N is a size parameter. The service time distribution of each individual line is exponential with rate $\mu > 0$. External arrivals appear at the nodes A, B, C. An arrival at A can be a request for service to either B or C. As far as the trunk line i is concerned, it does not matter at which end the service request originates. Thus, we use the following model for requests for service on trunk line i. Let $\{\alpha_k^{i,N}, k < \infty\}$ denote the sequence of interarrival times for trunk i, and suppose that they are independent and identically distributed and independent of all other service and interarrival times of the system. The set of all service and interarrival times are assumed to be independent.

Let $Q_r^{i,N}(t)$ denote the scaled (by $1/\sqrt{N}$) number of lines in the ith trunk that are used by rerouted requests at time t. We make the unrestrictive assumption that

$$\sup_N E|Q_r^{i,N}(0)| < \infty.$$

Set $\overline{\alpha}^{i,N} = E\alpha_k^{i,N}$, and assume (see (2.1)) that

$$(\overline{\alpha}^{i,N})^{-1} = \mu\beta_i N - b_i\sqrt{N}, \qquad i = 1, 2, 3, \tag{7.1}$$

for real b_i. This is the natural heavy traffic condition, since it implies that (modulo $O(\sqrt{N})$) the mean arrival rate to trunk i equals the mean service rate when all lines are occupied. Indeed, the heavy traffic analysis suggests that a "well-engineered" system will satisfy (7.1). Also, suppose (an unrestrictive assumption) that the sets

$$\{(\alpha_k^{i,N}/\overline{\alpha}^{i,N})^2; k < \infty, N < \infty\} \tag{7.2}$$

are uniformly integrable and that (see (2.3)) for some $\sigma_i^2 < \infty$

$$E[1 - \alpha_k^{i,N}/\overline{\alpha}^{i,N}]^2 = \text{var } \alpha_k^{i,N}/\overline{\alpha}^{i,N} \equiv (\sigma_i^N)^2 \to \sigma_i^2. \tag{7.3}$$

For $i = 1, 2, 3$, define the system variables:

$A^{i,N}(t) =$ [number of external arrivals to trunk i by t] $/\sqrt{N}$,
$D^{i,N}(t) =$ [number of service completions at trunk i by t] $/\sqrt{N}$,
$Q^{i,N}(t) =$ [number of lines of trunk i occupied at t] $/\sqrt{N}$,
$X^{i,N}(t) = \beta_i\sqrt{N} - Q^{i,N}(t)$,
$Y^{i,N}(t) =$ [number of external arrivals to i by t when i is full]/ $\sqrt{N}$.

$X^{i,N}(t)$ is the (scaled by $1/\sqrt{N}$) number of available circuits at trunk i at time t. We write $X^N(\cdot) = (X^{1,N}(\cdot), X^{2,N}(\cdot), X^{3,N}(\cdot))$ and similarly define the vectors for the other quantities defined above. Let (x^1, x^2, x^3) denote the canonical components of the vector x. Thus $\tilde{A}^N(\cdot)$ and $\tilde{D}^N(\cdot)$ are redefined to be the vectors of arrivals and departures, respectively.

Rerouting. Suppose that a request for service between A and B arrives but all $\beta_1 N$ lines of the connecting trunk 1 are occupied. We allow the possibility that the call can be routed between A and B by going through C, thus using one line on each trunk 2 and 3, if available. If not rerouted, the call is rejected from the system and disappears. The control problem is to determine when to reroute and when to reject. The same considerations apply to requests for service between A and C and between C and B.

An important restriction. We place one additional restriction on the system: There is $\Delta_0 > 0$ such that a requested rerouting from any trunk i to the *alternative pair* j, k will not be accepted if either $X^{j,N}(t) \leq \Delta_0$ or $X^{k,N}(t) \leq \Delta_0$. This restriction is not serious since Δ_0 can be made as small as desired, but it should be kept in mind since it will be exploited frequently and heavily in the sequel. It serves to prevent explosions of $Y^N(\cdot), F^N(\cdot)$ at the boundary that might be caused by the repeated rerouting of the same call. Note that this restriction is not a trunk reservation policy, since otherwise the controls are arbitrary.

An alternate assumption (which is not used here) would be to assign a small cost to each rerouting request. This would have a small effect on the limit but seems to require a more complex machinery.

Notation and the dynamical model. We use the convention that the superscript i indexing the trunk line is interpreted modulo 3. Thus, if $i = 2$, then $X^{(i+1),N} = X^{3,N}$ and $X^{(i+2),N} = X^{1,N}$. Let $J^{i,N}(t)$ denote the indicator function of the event that (an external) service request arrives at trunk i at time t, that the trunk is full, but that rerouting is accepted by the alternative pair. In order to avoid a minor notational complication, we suppose that only one event can occur at a time in the network (w.p.1). Otherwise, we need to define priorities in the timing. This is not hard to do, but it would complicate the notation. The control $J^N(\cdot) = (J^{1,N}(\cdot), \ldots)$ is said to be *admissible* if: (a) $J^{i,N}(t) = 0$ if there is no external arrival to trunk i at time t, $J^{i,N}(t)$ takes only the values 0 and 1 ; (b) $J^{i,N}(t)$ depends only on $\{A^N(s), D^N(s), s \leq t, J^N(s), s < t\}$; (c) $J^{i,N}(t) = 0$ if either $X^{(i+1),N}(t)$ or $X^{(i+2),N}(t)$ is less than Δ_0. Since the events occur singly and discretely in time, the $J^N(\cdot)$ are well defined.

Define the normalized overflow from trunk i that is actually rerouted:

$$F^{i,N}(t) = \int_0^t J^{i,N}(s)dY^{i,N}(s). \tag{7.4}$$

We have

$$Q^{1,N}(t) = Q^{1,N}(0) + A^{1,N}(t) - D^{1,N}(t) - Y^{1,N}(t) + F^{2,N}(t) + F^{3,N}(t),$$

since rerouted items from trunks 2 and 3 both use trunk 1. In general,

$$\begin{aligned} Q^{i,N}(t) = Q^{i,N}(0) &+ A^{i,N}(t) - D^{i,N}(t) - Y^{i,N}(t) \\ &+ F^{(i+1),N}(t) + F^{(i+2),N}(t). \end{aligned} \tag{7.5}$$

Let $\mathcal{B}_t^N$ denote the minimal σ-algebra that measures $\{X^{i,N}(s), A^{i,N}(s), D^{i,N}(s), J^{i,N}(s), s \leq t, i = 1, 2, 3\}$. Analogously to the definitions in §§3 and 4, define the processes

$$\tilde{A}^{i,N}(t) = \frac{1}{\sqrt{N}} \sum_{k=1}^{Nt} (1 - \alpha_k^{i,N}/\overline{\alpha}^{i,N}),$$

$$S^{i,N}(t) = \frac{1}{N} \times \max\left\{n : \sum_{k=1}^{n} \alpha_k^{i,N} \leq t\right\},$$

$$\tilde{A}_0^{i,N}(t) = -\tilde{A}^{i,N}(S^{i,N}(t)).$$

Write the martingale decomposition of $D^{i,N}(\cdot)$ analogously to the form (3.5):

$$\begin{aligned} D^{i,N}(t) &= \mu \int_0^t Q^{i,N}(s)ds + \tilde{D}^{i,N}(t) \\ &= -\mu \int_0^t X^{i,N}(s)ds + \sqrt{N}\beta_i \mu t + \tilde{D}^{i,N}(t), \end{aligned} \tag{7.6}$$

where $\tilde{D}^{i,N}(t)$ is a $\mathcal{B}_t^N$-martingale with quadratic variation

$$\begin{aligned} \langle \tilde{D}^{i,N} \rangle (t) &= \frac{\mu}{\sqrt{N}} \int_0^t Q^{i,N}(s)ds \\ &= \mu\beta_i t - \frac{\mu}{\sqrt{N}} \int_0^t X^{i,N}(s)ds. \end{aligned} \tag{7.7}$$

Now, analogously to (3.7), we have the system equations

$$\begin{aligned} X^{i,N}(t) = X^{i,N}(0) &+ b_i t - \mu \textstyle\int_0^t X^{i,N}(s)ds + (\tilde{A}_0^{i,N}(t) + \tilde{D}^{i,N}(t)) \\ &+ Y^{i,N}(t) - F^{(i+1),N}(t) - F^{(i+2),N}(t). \end{aligned} \tag{7.8}$$

Define the process

$$R^N(\cdot) = \{X^{i,N}(\cdot), \tilde{A}_0^{i,N}(\cdot), \tilde{D}^{i,N}(\cdot), Y^{i,N}(\cdot), F^{i,N}(\cdot); i = 1,2,3\}.$$

DEFINITION. *A measurable process $J(\cdot) = (J^1(\cdot), J^2(\cdot), J^3(\cdot))$ is said to be an* admissible control *for* (7.10) *below if the $J^i(t)$ are $[0,1]$-valued, nonanticipative with respect to the Wiener processes $W^j(\cdot)$ and $J^i(t) = 0$ if either $X^{(i+1)}(t)$ or $X^{(i+2)}(t)$ are less than Δ_0. The control is said to be* state feedback *if there is* measurable *$u(\cdot) = (u^1(\cdot), u^2(\cdot), u^3(\cdot))$ where $u^i(\cdot)$ is a $[0,1]$-valued function of $x^{(i+1)}, x^{(i+2)}$, and $J^i(t) = u^i(X^{(i+1)}(t), X^{(i+2)}(t))$. For simplicity, we often write this as $u^i(X(t))$. Since $u^i(\cdot)$ will occur only in the combination $u^i(X(t))dY^i(t)$, the x^i-dependence of $u^i(\cdot)$ is irrelevent.*

THEOREM 7.1. *Assume the conditions stated above in this section and let the $J^N(\cdot)$ be admissible and $\sup_N E|X^N(0)|^2 < \infty$. Then $\{R^N(\cdot)\}$ is tight and*

$$\sup_N \sup_t EX^{i,N}(t)^2 < \infty \quad \textit{for all } i. \tag{7.9}$$

Let $R(\cdot) = (X^i(\cdot), W_1^i(\cdot), W_2^i(\cdot), Y^i(\cdot), F^i(\cdot), i = 1,2,3)$ denote the limit of a weakly convergent subsequence of $\{R^N(\cdot)\}$. Write $W^i(t) = W_1^i(t) + W_2^i(t)$, $W(\cdot) = (W^1(\cdot), W^2(\cdot), W^3(\cdot))$. Then

$$X^i(t) = X^i(0) + b_i t - \mu \int_0^t X^i(s)ds + W^i(t) + Y^i(t) - F^{(i+1)}(t) - F^{(i+2)}(t). \tag{7.10}$$

The $W_j^i(\cdot)$ are mutually independent Wiener processes with quadratic variations

$$\begin{aligned} \langle W_1^i \rangle(t) &= \sigma_i^2 \beta_i \mu t, \\ \langle W_2^i \rangle(t) &= \beta_i \mu t. \end{aligned} \tag{7.11}$$

There is an admissible control $J(\cdot)$such that

$$F^i(t) = \int_0^t J^i(s)dY^i(s), \tag{7.12}$$

and the $X^i(\cdot)$ and $Y^i(\cdot)$ are nonanticipative with respect to the Wiener processes. The set

$$\{Y^{i,N}(n+1) - Y^{i,N}(n); n < \infty, N < \infty, i = 1,2,3\} \tag{7.13}$$

is uniformly integrable.

Proof. Equation (7.9) holds by Theorems 3.1 and 4.1 and the fact that the $X^{i,N}(t)$ are no greater than the values of the state when there is no rerouting.

The uniform integrability of (7.13) is proved by an argument like that below (4.7), using the fact that $J^{i,N}(t) = 0$ if either $X^{(i+1),N}(t)$ or $X^{(i+2),N}(t)$ are less than Δ_0. Now we elaborate this argument by working with a "bounding system." Let $\hat{X}^N(\cdot)$ and $\hat{Y}^N(\cdot)$, respectively, denote the state and reflection processes for the system (7.8) that is altered as follows. The state is reset to zero at $t = 1,2,3,\ldots$. Also, for each

$i, \hat{X}^{i,N}(t)$ is constrained to $[0, \Delta_0]$ by adding a reflection at Δ_0. (Thus, the F-terms do not appear in the dynamical equation.)

Note that $Y^{i,N}(n+1) - Y^{i,N}(n) \leq \hat{Y}^{i,N}(n+1) - \hat{Y}^{i,N}(n)$. We outline the proof of the uniform integrability for the altered system. Fix i and n; and define the stopping times $\sigma_0^N = n$ and for each $k \geq 0$, $\tau_{k+1}^N = \min\{t > \sigma_k^N : \hat{X}^{i,N}(t) = 0\} \wedge (n+1)$, $\sigma_{k+1}^N = \min\{t > \tau_{k+1}^N : \hat{X}^{i,N}(t) \geq \Delta_0\} \wedge (n+1)$. Define $M_n^{i,N} = \max\{k : \sigma_k^N < (n+1)\}$. Since $\hat{Y}^{i,N}(\cdot)$ cannot increase on the excursions from Δ_0 to next contact with 0, there is $K < \infty$ such that we can write

$$\begin{aligned}\hat{Y}^{i,N}(n+1) - \hat{Y}^{i,N}(n) \leq & -\sum_{k=1}^{\infty}[\tilde{A}_0^{i,N}(\sigma_k^N) - \tilde{A}_0^{i,N}(\tau_k^N)] \\ & + \text{a similar sum for } \tilde{D}^{i,N}(\cdot) + KM_n^{i,N} + K.\end{aligned}$$

The mean square value of the sums on the right are all bounded uniformly in n, i. Now, given $\delta_0 > 0$ it is not hard to show that there is $T_0 > 0$ such that with probability one

$$P\{\tau_{k+1}^N - \sigma_k^N < T_0 | \text{ data to } \sigma_k^N\} \leq 1 - \delta_0 \tag{7.14}$$

for all k, i, n and large N. By a recursion argument, this inequality can be used to show that each moment of $M_n^{i,N}$ is bounded uniformly in n, i, N and we omit the details. Thus the second moments of the set of increments in (7.13) are bounded uniformly.

The rest of the proof is like that of Theorems 3.1 and 4.1. Let τ be a (bounded) stopping time with respect to the filtration generated by the $\{\tilde{A}^{i,N}(t)\}$. Then from (7.3) we get

$$E[(\tilde{A}^{i,N}(\tau + t) - \tilde{A}^{i,N}(\tau))^2 | \tilde{A}^{i,N}(s), s \leq \tau] \leq (\sigma_i^N)^2 t$$

(and the left side converges to $\sigma_i^2 t$), which implies the tightness of $\{\tilde{A}^{i,N}(\cdot)\}$ via the criterion (3.1), analogous to the situation in Theorem 3.1. Continuity of the limits of $\{\tilde{A}^{i,N}(\cdot)\}$ follows from the uniform integrability of (7.2), again analogously to the situation in Theorem 3.1. The results for the $\tilde{D}^{i,N}(\cdot)$ sequence are also obtained essentially like that in Theorem 3.1. It can also be shown that $S^{i,N}(\cdot)$ converges weakly to the (deterministic) process with values $\mu\beta_i t$; i.e., the limit is just the limit of $(1/N)$ times the mean number of external arrivals to trunk i by time t. We have $dF^{(i+1),N}(t) = dF^{(i+2),N}(t) = 0$ for all t such that $X^{i,N}(t) \in [0, \Delta_0]$. This remark and a proof like that in Theorem 3.1 can be used to get the tightness of $Y^{i,N}(\cdot)$. The tightness of $F^{i,N}(\cdot)$ follows from this. These facts and the tightness of $\{\tilde{A}_0^N(\cdot)\}$ and $\{\tilde{D}^N(\cdot)\}$ imply the tightness of $\{X^{i,N}(\cdot)\}$. The representation (7.12) follows from the fact that $F^i(t+s) - F^i(t) \leq Y^i(t+s) - Y^i(t)$, for all $t, s \geq 0$.

Using calculations analogous to (3.9) and those leading to (3.16), we get that the $W_j^i(\cdot)$ are Wiener processes with the asserted variances as well as the nonanticipativeness assertion and the independence of the four groups of processes

$$W_1^1(\cdot), W_1^2(\cdot), W_1^3(\cdot), \{W_2^1(\cdot), W_2^2(\cdot), W_2^3(\cdot)\}.$$

The processes $\tilde{D}^{i,N}(\cdot)$ are not mutually independent since a rerouting involves the use of a line on two trunks for the same request. But the parts of, say, $\tilde{D}^{1,N}(\cdot), \tilde{D}^{2,N}(\cdot)$, which are due to the input $F^{3,N}(\cdot)$, will be shown in the next paragraph to have variance $O(1/\sqrt{N})$, and similarly for the other cases. This implies that the $\{W_2^i(\cdot), i = 1,2,3\}$ are also mutually independent.

To prove the desired assertion, first recall the definition of $Q_r^{i,N}(\cdot)$ above (7.1). We can decompose this process similarly to what was done in (3.5), (3.6). This yields

$$Q_r^{i,N}(t) = Q_r^{i,N}(0) + F^{(i+1),N}(t) + F^{(i+2),N}(t) - \mu \int_0^t Q_r^{i,N}(s)ds + \tilde{D}_r^{i,N}(t), \tag{7.15}$$

where $\tilde{D}_r^{i,N}(\cdot)$ is a martingale and is the contribution to $\tilde{D}^{i,N}(t)$ of the rerouting from other trunks. Its quadratic variation is

$$\frac{\mu}{\sqrt{N}} \int_0^t Q_r^{i,N}(s)ds. \tag{7.16}$$

By (7.15) and the uniform integrability properties of the increments of the $F^{j,N}(\cdot)$ (a consequence of (7.13)), we have that $\sup_{N,t} EQ_r^{i,N}(t) < \infty$. Thus the quadratic variation of $\tilde{D}_r^{i,N}(\cdot)$ has the asserted order and we are done. □

Note. The fact that the asymptotic effects of $Q_r^N(\cdot)$ are zero was a long-standing conjecture. But this seems to be the first proof.

8. Optimality results for the discounted cost problem. In this section, it is shown that the optimal costs for the network converge to that for the limit control problem. This is useful since numerical and analytical methods are available for the limit problem.

The cost function. We define the analogs of the costs (4.3) and (4.6) for the network. Let $X^N(0) = X(0) = x$ and $\beta > 0$: For admissible $J^N(\cdot)$ and $J(\cdot)$, set

$$C^N(J^N, x) = E\int_0^\infty e^{-\beta t} \sum_i (1 - J^{i,N}(t))dY^{i,N}(t), \tag{8.1}$$

$$C(J,x) = E\int_0^\infty e^{-\beta t} \sum_i (1 - J^i(t))dY^i(t),$$

$$\overline{C}^N(x) = \inf_{J^N} C^N(J^N, x), \quad \overline{C}(x) = \inf_J C(J,x), \tag{8.2}$$

where the infs are over the admissible controls. (8.1) is the normalized mean discounted total number of external arrivals that are rejected from the system.

We wish to show the analog of (6.1) for the network problem. As in §6, the main problem is proving (6.2). To do this, we will need to introduce a "comparison" control, as discussed in §6, and Theorem 8.1 is a preliminary result in that direction. The "comparison" controls that will be used in the convergence Theorem 8.3 are based on those constructed in Theorem 8.1.

DEFINITION. *Let $g^i(\cdot)$ be Lipschitz continuous $[0,1]$-valued functions of $(x^{(i+1)}, x^{(i+2)})$ that equal zero if either $x^{(i+1)} \le \Delta_0$ or $x^{(i+2)} \le \Delta_0$. For simplicity, we often write just $g^i(x)$. In fact, since this function only occurs in the form $g^i(X(t))dY^i(t)$, the x^i-dependence of $g^i(\cdot)$ is irrelevent. Let $\alpha^i \in [0,1]$ and define the control $J_\alpha^i(\cdot)$ by $J_\alpha^i(t) = \alpha^i g^i(X(t))$ and the transition probability under $J_\alpha(\cdot)$ by $P(x,t,\cdot|\alpha) = P\{X(t) \in \cdot | J_\alpha$ used, $X(0) = x\}$.*

THEOREM 8.1. *Assume the conditions of Theorem* 7.1 *and let $J(\cdot)$ be an admissible control for* (7.10). *Then a solution to* (7.10) *exists* (*in the strong sense*) *and* *is weak sense unique. For $t > 0, P(x,t,\cdot|\alpha)$ is mutually absolutely continuous with respect to Lebesgue measure and is continuous in x, α in the weak sense.*

Proof. The key to analyzing (7.10) is the fact that for each i at most one of the processes $Y^i(\cdot), F^{(i+1)}(\cdot)$, and $F^{(i+2)}(\cdot)$ can increase at any given time, analogous to the situation in Theorem 7.1. This observation will be used several times in the sequel, since it enables us to divide up time into disjoint intervals on each of which only one of these processes can change and to examine $X^i(\cdot)$ in "pieces."

The uniqueness can be established by a direct construction. For specificity, let $i = 1$ and $X^1(0) < \Delta_0$. Define $\sigma_0 = 0$, and for $n \geq 0$ set $\tau_{n+1} = \min\{t \geq \sigma_n : X^1(t) = 0\}$ and $\sigma_{n+1} = \min\{t \geq \tau_{n+1} : X^1(t) = \Delta_0\}$. The solution to (7.10) can be constructed by "pieces." On $[\sigma_n, \tau_{n+1}), X^1(\cdot)$ is a function of $X^1(\sigma_n)$ and the increments of $W^1(\cdot), F^2(\cdot), F^3(\cdot)$ on that interval and $dY^1(t) = 0$ there. On $[\tau_n, \sigma_n), J^2_\alpha(t) = J^3_\alpha(t) = 0$ since $X^1(t) < \Delta_0$. Thus, $dF^2(t) = dF^3(t) = 0$ on that interval, and $X^1(\cdot)$ is uncontrolled and uncoupled to $X^2(\cdot), X^3(\cdot)$ there. A continuation of this argument yields the existence and uniqueness, as asserted. The existence and uniqueness under $J_\alpha(\cdot)$ is proved in the same way.

Let $t > 0$. The fact that $P(x,t,\cdot|\alpha)$ is mutually absolutely continuous with respect to Lebesgue measure for each x and α follows from the arguments in [5, §7] for a related problem and the above observations concerning the examination of the process in "pieces."

The asserted uniform weak continuity of $P(x,t,\cdot|\alpha)$ can be proved by a weak convergence argument: Let $x_n \to x$ and $\alpha_n \to \alpha$, and use a weak convergence argument and the weak sense uniqueness of the solution to (7.10) under the given form of the control; we omit the details. □

THEOREM 8.2. *Assume the conditions of Theorem* 7.1, *and let $\{R^N(\cdot)\}$ converge weakly to $R(\cdot)$ (defined in Theorem* 7.1). *Then there is admissible $J(\cdot)$ such that*

$$C^N(J^N, x) \to C(J, x). \tag{8.3}$$

There exists an optimal admissible control for (7.10), (8.2). *Also, $\overline{C}(x)$ is continuous in x and in Δ_0 (for $\Delta_0 > 0$).*

Proof. Equation (8.3) is a consequence of Theorem 7.1. The existence of an optimal admissible control for (7.10), (8.2) can be shown by a weak convergence argument analogous to that used in Theorem 7.1 (but with system (7.10) and a minimizing sequence of controls used), and the details are omitted.

Perhaps the simplest way to prove the continuity of $\overline{C}(x)$ in x involves a change in the structure of the problem. For the physical network, the change is to allow the possibility of rejecting external inputs to a link i when $X^{i,N}(t) > 0$ and without attempting rerouting for such rejections. For $c_0 > 1$, assign a cost $c_0/\sqrt{N}$ per call rejected from i when $X^{i,N}(t) > 0$, for each i. The corresponding modification to model the limit (7.10) and cost (8.2) allows instantaneous *increases* in the components of the state, with the following cost: Let the impulsive increment move the state from x to y with $y^i \geq x^i$ for each i. Then we let the associated "impulsive" cost be $c_0\sum_i(y^i - x^i)$. Such a "reject" option would *never* be exercised in an optimal policy, so the modification does not alter the minimum costs. Now given x, let $x_n \to x$. A weak convergence argument can be used to show that there exists admissible $\tilde{J}(\cdot)$ such that $\overline{C}(x_n) \to C(\tilde{J}, x)$. Hence, $\liminf_n \overline{C}(x_n) \geq \overline{C}(x)$. Also, $\overline{C}(y) \leq \overline{C}(x)$ if $y^i \geq x^i$ for all i. These facts hold for both the original and the modified problems. The last three sentences imply that it is enough to show continuity in each component x^i separately and as x^i increases. But such continuity is guaranteed for the modified problem, since for that problem and $\delta^i > 0$

$$\overline{C}(x^1, x^2, x^3) \le \overline{C}(x^1 + \delta^1, x^2 + \delta^2, x^3 + \delta^3) + c_0(\delta^1 + \delta^2 + \delta^3),$$

$$\overline{C}(x^1, x^2, x^3) \ge \overline{C}(x^1 + \delta^1, x^2 + \delta^2, x^3 + \delta^3).$$

The continuity in Δ_0 can be shown by a related argument, and the details are omitted. □

The optimality theorem. Theorem 8.3 shows that the optimum cost for the network is well approximated by the optimum for the limit problem. This helps justify the use of the heavy traffic limit. We also note that the randomization technique used to get the comparison control in the theorem seems to be a basic technique in getting limit theorems for the trunk line type of problem.

For controls $J^i_\alpha(t) = \alpha^i g^i(X(t)), i = 1, 2, 3$, and $X(0) = x$, define the function

$$k^\delta(x, \alpha) = E\left[\int_0^\delta e^{-\beta t} \sum_i (1 - \alpha^i g^i(X(s))) dY^i(s) | X(0) = x\right].$$

THEOREM 8.3. *Under the conditions of Theorem* 7.1,

$$\overline{C}^N(x) \to \overline{C}(x). \tag{8.4}$$

Given $\varepsilon > 0$, suppose that there is a state feedback control $u(\cdot)$ for (7.10), (8.2), *which is ε-optimal and for which* (7.10) *has a unique weak sense solution. Write $u(x) = (u^1(x^2, x^3), u^2(x^1, x^3), u^3(x^1, x^2))$, and suppose that the $u^i(x)$ take values* 0 *or* 1 *and the boundary of the set where $u^i(x^{(i+1)}, x^{(i+2)}) = 0$ is piecewise C_2 and there are no cusps at the corners of the "pieces". Then $u(\cdot)$ is 2ε-optimal for* (7.8), (8.1) *for large N.*

Remark on the control. By an essentially classical argument of the type used for Itô equations, and working in "pieces" as in Theorem 8.1, it can be shown that (7.10) has a unique strong sense solution (in sense of [8]) if the $u^i(\cdot)$ are Lipschitz continuous. The discontinuous control described in the theorem statement is typical in applications, as seen from numerical results for the limit problem.

Numerical experiments support the conditions put on the ε-optimal control below (8.4). Indeed, the switching curve for a typical optimal control for a three-dimensional heavy traffic limit system is graphed in Fig. 1, where the upper region is "accept rerouting" and the lower is "reject rerouting." The graphed case is for an ergodic cost criterion, but similar results hold for the discounted cost case. For the graphed case, link 1 is full and the other axes are the state values for links two and three, respectively. The plotted contours are those of the "relative value function" from the dynamic programming equation and are used in the adaptation of the results for the three-dimensional case to the general network. Details of the numerics and algorithms will be given in a subsequent paper.

Remark on the proof. The proof of the first assertion will be done in several steps. First, an ε-optimal feedback control for (7.10), (8.2) of a special form is obtained. Then a piecewise constant approximation is derived. Then we get a continuous ε-optimal control for a time sampled form of (7.10), (8.2). Finally, this latter control is adapted for use on $X^N(\cdot)$. These controls are for theoretical use only and are not intended to be practical.

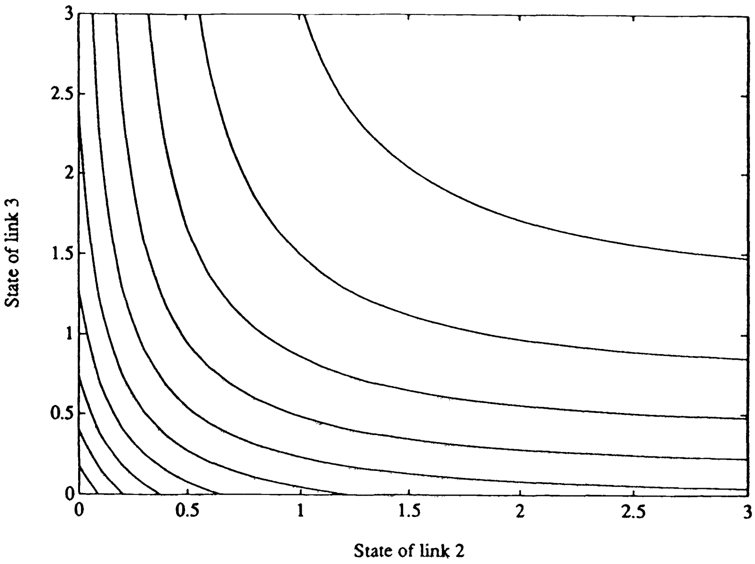

FIG. 1. *Decision curve for a particular three-dimensional system: Link* 1 *full.*

Proof. Equation (8.3) implies that

$$\liminf_N \overline{C}^N(x) \geq \overline{C}(x)$$

(for arbitrary $\varepsilon > 0$, simply let the $J^N(\cdot)$ in Theorem 8.2 be an optimal or ε-optimal policy). Thus, we need only prove

$$\limsup_N \overline{C}^N(x) \leq \overline{C}(x). \tag{8.5}$$

Let $\varepsilon > 0$. To prove (8.5), a special 3ε-optimal policy $J^\varepsilon(\cdot)$ for the limit problem will be constructed. $J^\varepsilon(\cdot)$ will be such that we can find an adaptation $J^{\varepsilon,N}(\cdot)$ for use in (7.8) such that

$$C^N(J^{\varepsilon,N}, x) \to C(J^\varepsilon, x). \tag{8.6}$$

Since $C(J^\varepsilon, x) \leq \overline{C}(x) + 3\varepsilon$ and $C^N(J^{\varepsilon,N}, x) \geq \overline{C}^N(x)$, (8.5) will follow.

Let $\delta^1 > 0$, and set $\Delta_1 = \Delta_0 + \delta^1$ and $X(0) = x$. In view of the continuity of $\overline{C}(x)$ in Δ_0 (Theorem 8.2), there is $\delta^1 > 0$ and an ε-optimal admissible policy $\tilde{J}(\cdot)$ such that $\tilde{J}^i(t) = 0$ if either $X^{(i+1)}(t) \leq \Delta_1$ or $X^{(i+2)}(t) \leq \Delta_1$. For each i, let $g^i(\cdot)$ be a function of the type introduced in Theorem 8.1 and taking the value unity when $x^{(i+1)} \geq \Delta_1$ and $x^{(i+2)} \geq \Delta_1$. Recall that $g^i(\cdot)$ is Lipschitz continuous, $[0,1]$-valued and has the value zero if $x^{(i+1)} \leq \Delta_0$ or $x^{(i+2)} \leq \Delta_0$. We suppose (without loss of generality) that the processes (7.10) for the various controls that will be used are defined on the same probability space and with the same Wiener processes $W^i(\cdot)$. The initial condition will always be $x = X(0)$. With $\tilde{J}(\cdot)$ given, let $\tilde{X}(\cdot), \tilde{F}(\cdot)$, and $\tilde{Y}(\cdot)$ denote the associated state, control, and reflection processes, with $\tilde{X}(0) = x$; i.e.,

$$\tilde{X}^i(t) = x^i + b_i t - \mu \int_0^t \tilde{X}^i(s)ds + W^i(t) + \tilde{Y}^i(t) - \tilde{F}^{(i+1)}(t) - \tilde{F}^{(i+2)}(t).$$

The control functions have the form

$$\tilde{F}^i(t) = \int_0^t \tilde{J}^i(s) g^i(\tilde{X}(s)) d\tilde{Y}^i(s).$$

Given $g(\cdot)$, let $C_g(x, J)$ denote the cost (8.2) for (7.10) when the control functions are retricted to the form

$$F^i(t) = \int_0^t J^i(s) g^i(X(s)) dY^i(s), \tag{8.7}$$

with $J(\cdot)$ admissible. Define $\overline{C}_g(x) = \inf_J C_g(J, x)$. Then $\overline{C}_g(x) \geq \overline{C}(x)$. Also, $C(\tilde{J}, x) = C_g(\tilde{J}, x) \leq \overline{C}(x) + \varepsilon$ by the definition of $\tilde{J}(\cdot)$.

In the next paragraph we define an approximation to $\tilde{J}(\cdot), \tilde{X}(\cdot)$. We will denote this new policy and associated control function, reflection, and state processes by $\tilde{F}_\delta(\cdot), \tilde{Y}_\delta(\cdot), \tilde{X}_\delta(\cdot)$, respectively. Thus the new approximating processes will satisfy

$$\begin{aligned} \tilde{X}^i_\delta(t) &= x^i + b_i t - \mu \int_0^t \tilde{X}^i_\delta(s) ds + W^i(t) + \tilde{Y}^i_\delta(t) - \tilde{F}^{(i+1)}_\delta(t) - \tilde{F}^{(i+2)}_\delta(t), \\ \tilde{F}^i_\delta(t) &= \int_0^t \tilde{J}^i_\delta(s) g^i(\tilde{X}_\delta(s)) d\tilde{Y}_\delta(s). \end{aligned} \tag{8.8}$$

If $\tilde{F}^i_\delta(t) \to \tilde{F}^i(t)$ as $\delta \to 0$, for each t and all i, then $\tilde{X}_\delta(t), \tilde{Y}_\delta(t)$ converge to $\tilde{X}(t), \tilde{Y}(t)$ for each t.

Define $\tilde{J}^i_\delta(\cdot)$ as follows. Given $\delta > 0$, define $\tilde{J}^i_\delta(\cdot)$ recursively on the intervals $[n\delta, n\delta + \delta)$. On $[0, \delta)$, set $\tilde{J}^i_\delta(s) = 0$. For $n > 0$ and on $[n\delta, n\delta + \delta)$, set $\tilde{J}^i_\delta(s) = 1$ until either (whichever comes first): (a) $t = n\delta + \delta$, or (b) the first time t that $\tilde{F}^i_\delta(t) = \tilde{F}^i(t)$. As $\delta \downarrow 0$, an argument by contradiction can be used to show that for each i and t

$$\tilde{F}^i_\delta(t) \uparrow \tilde{F}^i(t), \text{ as } \delta \downarrow 0. \tag{8.9}$$

A contradiction can be shown if one supposes that the convergence (8.9) does not hold for some i, since in that case $\lim_\delta \tilde{J}^i_\delta(t)$ would equal unity for $t \geq \inf\{s : \lim_\delta \tilde{F}^i_\delta(s) < \tilde{F}^i(s)\}$. By (8.9), $\tilde{X}^i_\delta(\cdot), \tilde{Y}^i_\delta(\cdot)$ converge to $\tilde{X}^i(\cdot), \tilde{Y}^i(\cdot)$. This convergence, (8.9), and the uniform integrability of (7.13) imply that $C_g(\tilde{J}_\delta, x) \to C_g(\tilde{J}, x)$ as $\delta \to 0$. Now, given this result, and letting δ be small, we see that the fraction of intervals on which some $\tilde{J}^i_\delta(\cdot)$ takes both values 1 and 0 goes to zero as $\delta \to 0$. Thus, we can suppose that $\tilde{J}_\delta(t)$ equals identically either 1 or 0 on the intervals $[n\delta, n\delta + \delta)$ and that $C_g(\tilde{J}_\delta, x) \leq C_g(\tilde{J}, x) + \varepsilon$ and that (8.9) holds. The value of δ will be fixed henceforth in this proof.

Let $C^\delta_g(J, x)$ denote the cost for input functions of the form in (8.7) but where the $J(\cdot)$ process is constant on each interval $[n\delta, n\delta + \delta)$. Let $\overline{C}^\delta_g(x)$ denote the infimum over this class. Note that $\overline{C}^\delta_g(x) \geq \overline{C}(x)$, $\overline{C}^\delta_g(x) \leq \overline{C}(x) + 2\varepsilon$. If there is a measurable function $u(\cdot)$ such that the control on $[n\delta, n\delta + \delta)$ can be written as $u(X(n\delta))$, then we abuse notation and call the control *state feedback* and write the costs as $C^\delta_g(u, x)$.

The optimization problem for cost $C^\delta_g(J, x)$ can be reduced to a *discrete time* problem by working with the samples $\{\tilde{X}_\delta(n\delta), n = 0, 1, \ldots\}$ and an appropriate discrete time form of the cost, and we now do this.

For the discrete time-approximating problem, we can suppose that the dynamic programming equation for the discrete time problem is

$$\overline{C}_g^\delta(x) = \min_\alpha \left[\int e^{-\beta\delta} \overline{C}_g^\delta(y) P(x,\delta,dy|\alpha) + k^\delta(x,\alpha) \right] \tag{8.10}$$

where $k^\delta(\cdot)$ is defined above the theorem. A weak convergence argument can be used to get the continuity of $k^\delta(\cdot)$. The continuity of $\overline{C}_g^\delta(\cdot)$ can be proved by the method used in Theorem 8.2. It can be shown that there is a continuous state feedback control $u^\varepsilon(\cdot)$ that is ε-optimal with respect to all controls for the problem whose dynamic programming equation is (8.10). Thus $C_g^\delta(u^\varepsilon, x) \leq \overline{C}(x) + 3\varepsilon$.

Now we are prepared to adapt $u^\varepsilon(\cdot) = (u^{1,\varepsilon}(\cdot), u^{2,\varepsilon}(\cdot), u^{3,\varepsilon}(\cdot))$ to the physical model (7.8). The adapted control law will be called $J^N(\cdot)$ and the associated state and reflection processes called $X^N(\cdot), Y^N(\cdot)$, respectively. The $J^N(\cdot)$ will be a *randomized* control. It will take values 0 or 1 and will be determined by the following conditional probability law : For $t \in (n\delta, n\delta + \delta]$, we use (and define $\tilde{u}(\cdot)$)

(8.11)

$$P\{J^{i,N}(t) = 1 | A^N(s), D^N(s), s \leq t, J^N(s), s < t; dA^{i,N}(t) > 0, X^{i,N}(t^-) = 0\}$$

$$= u^{i,\varepsilon}(X^N(n\delta)) g^i(X^N(t^-)) \equiv \tilde{u}^{i,N}(t).$$

Note that the conditioning event implies that there is an arrival to i at t and no available capacity there. Since the events occur one at a time and are separated in time, the conditional expectation is well defined.

Next we put the control terms $F^{i,N}(\cdot)$ into a manageable form by showing that the effects of the randomization disappear as $N \to \infty$. Let $\tau_n^{i,N}$ denote the time of the nth arrival to trunk i from the external sequence $A^{i,N}(\cdot)$. Let $I_n^{i,N}$ denote the indicator of the set where $X^{i,N}(\tau_n^{i,N-}) = 0$, and set $J_n^{i,N} = J^{i,N}(\tau_n^{i,N})$. Then we can write (possibly modulo $1/\sqrt{N}$)

$$Y^{i,N}(t) = \frac{1}{\sqrt{N}} \sum_{n=1}^{NS^{i,N}(t)} I_n^{i,N},$$

$$F^{i,N}(t) = \int_0^t J^{i,N}(s) dY^{i,N}(s) = \frac{1}{\sqrt{N}} \sum_{n=1}^{NS^{i,N}(t)} J_n^{i,N} I_n^{i,N}$$

$$= \frac{1}{\sqrt{N}} \sum_{n=1}^{NS^{i,N}(t)} \tilde{u}^{i,N}(\tau_n^{i,N}) I_n^{i,N} + \frac{1}{\sqrt{N}} \sum_{n=1}^{NS^{i,N}(t)} (J_n^{i,N} - \tilde{u}^{i,N}(\tau_n^{i,N})) I_n^{i,N}.$$

The first sum on the last line equals $\int_0^t \tilde{u}^{i,N}(s) dY^{i,N}(s)$. Owing to the definition of $J_n^{i,N}$ via a conditional probability, the second sum is a martingale (when a discrete index is used in place of $NS^{i,N}(t)$) and its variance is bounded by

$$\frac{\text{const}}{\sqrt{N}} E|Y^{i,N}(t)|.$$

Thus, the evolution equation for $X^n(\cdot)$ under (8.11) can be written as (7.8) but with $F^{i,N}(t)$ replaced by $\int_0^t \tilde{u}^{i,N}(s) dY^{i,N}(s)$ plus a "noise" term that goes to zero as $N \to \infty$.

Now, take a weakly convergent subsequence of the set $\{R^N(\cdot)\}$ and let $R(\cdot) = (X(\cdot), \ldots, F(\cdot))$ denote the limit processes. Then the limit satisfies (7.10) where on $[n\delta, n\delta + \delta)$

$$F^i(t) - F^i(n\delta) = \int_{n\delta}^{t} u^{i,\varepsilon}(X(n\delta))g^i(X(s))dY^i(s).$$

Owing to the continuity of $u^{i,\varepsilon}(\cdot)$ and Lipschitz continuity of $g^i(\cdot)$, the solution to (7.10) with these input functions is weak sense unique. This uniqueness implies that $R^N(\cdot) \Rightarrow R(\cdot)$, as $N \to \infty$. Also by the weak convergence and uniform integrability of (7.13),

$$C^N(J^N, x) \to C_g^\delta(u^\varepsilon, x) \leq \overline{C}(x) + 3\varepsilon.$$

Since $\overline{C}^N(x) \leq C^N(J^N, x)$ and ε is arbitrary, we have (8.5). The proof of the last assertion of the theorem uses a weak convergence argument and depends on the local properties of the Wiener process and [1, Theorem 5.1] to deal with the discontinuous control, and we omit the details. □

9. The ergodic cost function.

Now we treat the ergodic cost problem for the network and show that the optimal costs for the network converge to the optimal cost for the ergodic control problem for the limit process. The method of proof is somewhat indirect, since there does not seem to be any available technique for dealing with controlled reflection directions with the ergodic cost criterion. Owing to the many details required, the major details are in the Appendix. Again, numerical methods of the "Markov chain approximation type" are available.

The cost function. Define the cost (the mean number of rejections from the entire system per unit time for (7.8))

$$\gamma_T^N(J^N, x) = \frac{1}{T}E\int_0^T \sum_i (1 - J^{i,N}(s))dY^{i,N}(s), \qquad X^N(0) = x, \tag{9.1}$$

$$\bar{\gamma}_T^N(x) = \inf_{J^N} \gamma_T^N(J^N, x),$$

$$\gamma^N(J^N, x) = \limsup_T \gamma_T^N(J^N, x),$$

$$\overline{\gamma}^N(x) = \inf_{J^N} \gamma^N(J^N, x).$$

For (7.10) and $X(0) = x$, define the costs

$$\begin{gathered}\gamma_T(J, x) = \frac{1}{T}E\int_0^T \sum_i (1 - J^i(s))dY^i(s), \\ \gamma(J, x) = \limsup_T \gamma_T(J, x), \quad \overline{\gamma}(x) = \inf_J \gamma(J, x),\end{gathered} \tag{9.2}$$

where all the infs are over the admissible controls. The occupation measure arguments of Theorem 5.1 can be adapted to the current problem. Let $J^N(\cdot)$ be a sequence of admissible controls for (7.8). Analogously to what was done in §5, define

$$R_t^N(\cdot) = (X^{i,N}(t+\cdot), \tilde{A}_0^{i,N}(t+\cdot) - \tilde{A}_0^{i,N}(t), \tilde{D}^{i,N}(t+\cdot) - \tilde{D}^{i,N}(t),$$

$$F^{i,N}(t+\cdot) - F^{i,N}(t), Y^{i,N}(t+\cdot) - Y^{i,N}(t), i = 1,2,3)$$

and let $P^{N,t}(\cdot)$ denote the measure of $R_t^N(\cdot)$. Define the occupation measure $P_T^N(\cdot)$ from $P^{N,t}(\cdot)$ as (5.2a). We have the following theorem.

THEOREM 9.1. *Assume the conditions of Theorem* 7.1. *Then* $\{P_T^N(\cdot); N < \infty, T < \infty\}$ *is tight. Let* $\overline{P}(\cdot)$ *denote the limit of a weakly convergent subsequence. Then* $\overline{P}(\cdot)$ *is the measure induced by a process*

$$R(\cdot) = (X^i(\cdot), W_1^i(\cdot), W_2^i(\cdot), F^i(\cdot), Y^i(\cdot), i = 1,2,3),$$

which satisfies (7.10) *with the representation* (7.12), *with admissible* $J(\cdot)$. *The* $W_k^i(\cdot)$ *are as in Theorem* 7.1, *and we write* $W^i(\cdot) = W_1^i(\cdot) + W_2^i(\cdot)$. *The limit process is stationary. Let* N, T *index the weakly convergent subsequence. Then*

$$\gamma_T^N(J^N, x) \to \gamma(J), \text{ as } N \to \infty, T \to \infty, \tag{9.3}$$

where $\gamma(J)$ *is the cost for the limit stationary process.*

Remark on the proof. The proof follows very closely the lines of the occupation measure argument of Theorem 5.1 together with the details in Theorem 7.1 concerning the weak convergence, and the details are omitted.

Convergence of the optimal costs. Theorem 9.1 yields

$$\liminf_{N,T} \overline{\gamma}_T^N(x) \geq \overline{\gamma}(x). \tag{9.4}$$

Thus, in order to prove

$$\overline{\gamma}_T^N(x) \to \overline{\gamma}(x), \text{ as } N \to \infty, T \to \infty, \tag{9.5}$$

one needs the analog of (8.5) and, in particular, some "comparison" control, which serves the same purpose as that constructed in Theorem 8.3. Suppose that for each $\varepsilon > 0$ there is an ε-optimal state feedback control $u^\varepsilon(\cdot)$ that has an "adaptation" $J^{\varepsilon,N}(\cdot)$ such that $\gamma_T^N(J^{\varepsilon,N}, x) \to \gamma(u^\varepsilon, x)$. Then, as in Theorem 8.3, one has

$$\limsup_{N,T} \overline{\gamma}_T^N(x) \leq \overline{\gamma}(x) \tag{9.6}$$

and (9.5) follows.

Getting the comparison control $u^\varepsilon(\cdot)$ seems to be much harder for the ergodic cost problem, due to difficulties in dealing with approximations of stationary solutions to (7.10). Consequently, an indirect approach is used in the Appendix where the control inputs are approximated by nicer functions and classical methods are used to get (9.5). The reader who is willing to accept the existence of a smooth ε-optimal feedback comparison control can omit the Appendix. The thrust of the arguments in the appendix is essentially to replace the reflection by a "barrier," adjust the control accordingly, and then apply the methods of [8] for the unreflected problem.

10. Appendix. A modified limit system and the ergodic problem: Proof of (9.5), (9.6).

In this section, we prove (9.6) and hence obtain the result (9.5). To do this we first approximate the input functions $F^{i,N}(\cdot), F^i(\cdot)$ for (7.8) and (7.10), respectively, by functions that are easier to handle. Essentially, a natural "barrier" method will be used. Then we prove that the associated costs provide good approximations. Finally, we prove the desired result for the approximating system using results that are known for the ergodic problem for nondegenerate diffusions. Most of this section will be devoted to defining the approximation and discussing its most important properties. The approximations will be such that the associated optimal costs provide upper and lower bounds for $\overline{\gamma}(x)$. The bounds will be arbitrarily close. Then a "nice" approximating control for the bounding system can be used to complete the proof of (9.6).

For large $k_0 > 0$ and small $\delta_{k_0} > 0$, define the real-valued function $k_1(\cdot)$ on $[0, \infty) : k_1(t) = k_0$ for $t \in [0, \delta_{k_0}], k_1(t) = 0$ for $t > \delta_{k_0}$. Let $\delta_{k_0} < \Delta_0$. Recall the notation $W^i(t) = W_1^i(t) + W_2^i(t)$ and $W(\cdot) = (W^i(\cdot), i = 1, 2, 3)$. Let $\Sigma = \text{cov } W(1)$.

Recall that if $J(\cdot)$ is an admissible control, then we require $J^i(t) = 0$ if either $X^{(i+1)}(t)$ or $X^{(i+2)}(t)$ are less than Δ_0. The approximating system to (7.10) is

$$(10.1)\qquad \begin{aligned} X^i(t) = X^i(0) + b_i t - \mu \int_0^t X^i(s)ds + Y^i(t) + W^i(t) \\ + \int_0^t k_1(X^i(s))ds - \int_0^t k_1(X^{(i+1)}(s))J^{(i+1)}(s)ds \\ - \int_0^t k_1(X^{(i+2)}(s))J^{(i+2)}(s)ds. \end{aligned}$$

The motivation for the approximation appears in the paragraph below (10.3). Next we put (10.1) into a more convenient vector form. Define $k(x) = (k_1(x^1), k_1(x^2), k_1(x^3))$ and the matrix

$$K(x) = \begin{bmatrix} 0 & k_1(x^2) & k_1(x^3) \\ k_1(x^1) & 0 & k(x^3) \\ k_1(x^1) & k_1(x^2) & 0 \end{bmatrix}.$$

Then we can write (10.1) in the compact vector form

$$(10.2)\qquad \begin{aligned} X(t) = X(0) + bt - \mu \int_0^t X(s)ds + Y(t) + W(t) \\ + \int_0^t k(X(s))ds - \int_0^t K(X(s))J(s)ds. \end{aligned}$$

In (10.2), the control $J^i(t)$ might be nonzero even if $X^i(t) \neq 0$. Of course, if $X^i(t) > \delta_{k_0}$, then the value of $J^i(t)$ is irrelevent since $k_1(X^i(t)) = 0$ there. Define the costs for the approximating problem, for $X(0) = x$,

$$(10.3)\qquad \begin{aligned} \gamma_T(k_0, J, x) &= \frac{1}{T} E \left[\sum_i \int_0^T (1 - J^i(s)) k_1(X^i(s))ds \right], \\ \gamma(k_0, J, x) &= \limsup_T \gamma_T(k_0, J, x). \end{aligned}$$

If $J(\cdot)$ is of state feedback form (i.e., there is measurable $[0,1]^3$-valued $u(\cdot)$, such that $J(t) = u(X(t))$ for some $u(\cdot)$), we write the cost as $\gamma(k_0, u, x)$. Define $\overline{\gamma}(k_0, x) = \inf_J \gamma(k_0, J, x)$ where the inf is over the admissible controls. If they do not depend on the initial condition x, then we drop the x-argument from $\gamma(k_0, J, x)$ or $\overline{\gamma}(k_0, x)$.

Motivation. The basic motivation for the approximation (10.2) is that for appropriately large k_0 and small δ_{k_o}, the reflection term $Y(\cdot)$ there is small and the reflection term in (7.10) is effectively replaced by the integral $\int_0^t k(X(s))ds$. Since the reflection term can be made as small as desired by making k_0 large (Theorem 10.5), ignoring it in the cost function (10.3) is unimportant. Loosely speaking, the approximation is equivalent to not accepting external requests on the direct trunk and requesting rerouting starting "just before" a trunk fills up, with "intensity" determined by $k_1(\cdot)$, and not requesting rerouting for arrivals to a full trunk. With these approximations, the acceptances and decisions do not take place on the boundary but just before the boundary. This "smoothing" greatly facilitates the analysis.

Theorems 10.1–10.4 concern regularity, stationarity, and ergodic properties of (10.2). Theorem 10.5 is used to show that (10.2) well approximates (7.10) for large k_0 and small δ_{k_0}. Theorem 10.6 establishes that $\bar{\gamma}(k_0, x)$ is also the inf over all state feedback controls, and Theorem 10.7 yields the final convergence result. It is of general interest to know that some problems with controlled reflections can be approximated in this way.

The control problem with system (10.2) and cost (10.3). The control problem (10.2), (10.3) is relatively easy to study via existing "Girsanov measure transformation" methods, in essentially the same way as done for the "unreflected" problem, and we now show how to do this. Let $W_0(\cdot)$ be a Wiener process with covariance matrix Σt, define the solution to the *uncontrolled* problem by the equation

$$X(t) = X(0) + bt - \mu \int_0^t X(s)ds + W_0(t) + Y(t) + \int_0^t k_1(X(s))ds, \tag{10.4}$$

and let P_x^0 denote the measure of the $(X(\cdot), Y(\cdot))$ in (10.4) when $X(0) = x$. This process (10.4) is very simple since it is actually composed of three mutually independent one-dimensional processes. For all x and all $t > 0$, the transition function $P^0(x, t, \cdot) \equiv P_x^0\{X(t) \in \cdot\}$ is mutually absolutely continuous with respect to Lebesque measure. The process is a strong Markov and strong Feller process and the solution to (10.4) is weak sense unique. If $k_1(\cdot)$ were Lipschitz continuous, then the solution would be strong sense unique. Girsanov transformation methods can be used since we need only shift the drift and not the singular component $Y(\cdot)$ to get the control term in (10.2).

Following a well-known procedure for the unreflected problem, the controlled system (10.2) will be defined from the solution of (10.4) via a Girsanov measure transformation. For an admissible (with respect to $W_0(\cdot)$) control $J(\cdot)$, define

$$\psi_0^t(J) = -\int_0^t [K(X(s))J(s)]'\Sigma^{-1}dW_0(s)$$
$$-\frac{1}{2}\int_0^t [K(X(s))J(s)]'\Sigma^{-1}[K(X(s))J(s)]ds,$$

$$\zeta_0^t(J) = \exp \psi_0^t(J).$$

For admissible (with respect to $W_0(\cdot)$) $J(\cdot)$, define the measure P_x^J via its restrictions to functions on the intervals $[0,t]$ for each t by the Radon–Nikodym derivatives that take the values $dP_x^J/dP_x^0 = \zeta_0^t(J)$ at such points. Then P_x^J is induced by a process $(X(\cdot),Y(\cdot))$ solving (10.2) for appropriate $W(\cdot)$ [8, Chapter IV.4]. If $J(t)=u(X(t))$ for a state feedback $u(\cdot)$, we write $\zeta_0^t(u)$ and P_x^u in lieu of $\zeta_0^t(J)$ and P_x^J, respectively. The following result holds due to the properties of the Girsanov transformation, just as for the unreflected system, since all of the properties of the solution to (10.4) that were cited in the last paragraph (except for the strong sense uniqueness) carry over to the solution of (10.2).

THEOREM 10.1. *Let $u(\cdot)$ be a state feedback control. The process $X(\cdot)$ with transition function $P^u(x,t,\cdot) = P_x^u\{X(t) \in\}$ is a strong Markov and strong Feller process. For all x and all $t > 0, P^u(x,t,\cdot)$ is mutually absolutely continuous with respect to Lebesgue measure, and it is weakly continuous in x. Also,* (10.2) *has a weak sense unique solution.*

Due to Theorem 10.1, the analysis of the ergodic control problem is virtually identical to that for the unreflected problem in [12]. In fact, the only properties used in [12] are those asserted in Theorem 10.1 and certain stability properties, which will be stated in the next theorem. Theorems 10.3, 10.4, and 10.6 essentially rewrite the results of [12] in the terms of the problem of this paper. For future reference, note that the control term called $b^u(x)$ in [12] is our $K(x)u(x)$.

THEOREM 10.2. *Let $E|X(0)|^2<\infty$. Then there is $M_0<\infty$ such that for* (10.2) *and admissible $J(\cdot)$,*

$$\sup_t E^J|X(t)|^2 \le M_0 \tag{10.5}$$

and M_0 can be chosen independently of $J(\cdot), k_0, \delta_{k_0}$. For each state feedback $u(\cdot)$, there is a unique invariant measure $\pi_u(\cdot)$, which is mutually absolutely continuous with respect to Lebesgue measure. Also, for each Borel set A

$$P^u(x,t,A) \to \pi_u(A) \tag{10.6}$$

as $t\to\infty$.

In addition, for (10.2) *and $J(\cdot)$ admissible*

$$\sup_{\substack{J,i,n,k_0,\delta_{k_0}\\ u,x}} E_x^u\left[\int_n^{n+1} k_1(X^i(s))ds + [Y^i(n+1)-Y^i(n)]\right]^2 < \infty. \tag{10.7}$$

For each state feedback control $u(\cdot)$, $X(\cdot)$ is recurrent in the sense that for any measurable set K of nonzero Lebesgue measure

$$E\int_0^\infty I_K(X(s))ds = \infty.$$

Proof. Define

$$V(x) = \sum_i (x^i-\delta_{k_0})^2 I_{\{x^i\ge\delta_{k_0}\}}.$$

Let $J(\cdot)$ be admissible for (10.2). Since $-V_x'(X(s))K(X(s))J(s)\le 0$ for all s, Itô's lemma yields

$$V(X(t)) \leq V(X(0)) + \int_0^t V_x'(X(s))[b - \mu X(s)]ds + (\text{trace}\,\Sigma)t$$
$$+ \int_0^t V_x'(X(s))[dY(s) + dW(s)].$$

Since $V_x'(X(s))dY(s) \equiv 0$, (10.5) follows from the last inequality via the Bellman–Gronwall ineqality. (Note that the same proof can be used to show that all moments of $X(t)$ are bounded uniformly in t.) The assertions below (10.5) up to and including (10.6) follow from the stability and Theorem 10.1, exactly as in [12, Thm. 3.1], which requires only the stability and strong Markov and Feller properties. The proof of (10.7) is the same as that used to prove uniform integrability of (7.13) using the fact that $\delta_{k_0} < \Delta_0$. The recurrence property is a consequence of (10.5), the weak continuity of $P^u(x,t,\cdot)$ in x, and the fact that $P^u(x,t,\cdot)$ is absolutely continuous with respect to Lebesgue measure. □

THEOREM 10.3. *Let the sequence of state feedback controls $u_n(\cdot)$ converge to a state feedback control $u(\cdot)$ in the sense that*

$$\int_A u_n(x)dx \to \int_A u(x)dx \tag{10.8}$$

for each Borel A. Then

$$\exp \zeta_0^t(u_n) \to \exp \zeta_0^t(u) \tag{10.9}$$

in L_1 (measure P_x^0) for each t and x. Also, for each Borel set A,

$$P^{u_n}(x,t,A) \to P^u(x,t,A), \tag{10.10}$$

$$\pi_{u_n}(A) \to \pi_u(A). \tag{10.11}$$

Proof. The proof is that of [12, Thm. 4.3], which only requires the strong Feller and strong Markov and stability properties. Hence it only needs the assertions of Theorem 10.1. The only part of the proof of [8, Thm. 4.3] that is not in that paper is a reference to [2, Thm. IV-3] for the proof of (10.9). But the proof of (10.9) in [2] also requires only the strong Feller and strong Markov properties. □

THEOREM 10.4. *Let $E|X(0)|^2 < \infty$. Let $u_n(\cdot)$ and $u(\cdot)$ be state feedback controls. Then $\gamma(k_0, u, X(0))$ does not depend on $X(0)$. Under* (10.8),

$$\gamma(k_0, u_n) \to \gamma(k_0, u). \tag{10.12}$$

There exists an optimal admissible state feedback control; i.e., there is a state feedback control $\overline{u}(\cdot)$ such that $\overline{\gamma}(k_0) \equiv \inf_{u(\cdot)\ \text{adm.}} \gamma(k_0, u) = \gamma(k_0, \overline{u})$.

For any $\varepsilon > 0$, there is a Lipschitz continuous ε-optimal state feedback control $u_\varepsilon(\cdot)$; i.e.,

$$\gamma(k_0, u_\varepsilon) \leq \overline{\gamma}(k_0) + \varepsilon.$$

Proof. The proof is that of [12, Thm. 4.4], and we just review its structure. For a state feedback control $u(\cdot)$, the integrand in the first line of (10.3) can be written as $\int_0^t c^u(X(s))ds$, where

$$c^u(x) = \sum_i (1 - u^i(x))k_1(x^i).$$

In [8, Thm. 4.4], F_n is used for our $c^u(\cdot)$, where the n there refers to the use of a control $u_n(\cdot)$. Then, for each state feedback control $u(\cdot), \gamma(k_0, u) = \int c^u(x)\pi_u(dx)$. Let $u_n(\cdot), u(\cdot)$ be any state feedback controls satisfying (10.8). Then the proof of the assertion (10.12) is in the proof of Theorem 4.4 in [12]. That proof is self-contained and uses only assertions analogous to those in Theorems 10.3 and 10.2 (up to (10.6)), except for a reference to [2, Prop. IV-4] for a proof of a proposition analogous to the convergence

$$\int_0^t c^{u_n}(X(s))ds \to \int_0^t c^u(X(s))ds$$

in probability (P_x^0-measure) for each t, x. This proof of this latter fact in [2, Prop. IV-4] requires only the strong Feller and strong Markov properties, hence it needs only the assertions in Theorems 10.1 and 10.2. Now let $\{u_n(\cdot)\}$ be a minimizing sequence of admissible state feedback controls. There is $\overline{u}(\cdot)$ such that (choose a subsequence, if necessary) (10.8) holds for $\overline{u}(\cdot)$ replacing $u(\cdot)$. The last assertion of the theorem then follows from (10.12), since for any state feedback $u(\cdot)$ there are $u_n(\cdot)$, arbitrarily smooth, such that (10.8) holds with $\overline{u}(\cdot)$ replacing $u(\cdot)$. □

THEOREM 10.5. *Let $\delta_{k_0} \to 0$ as $k_0 \to \infty$ such that $k_0(\exp -q_i k_0 \delta_{k_0}) \to 0$, where $q_i = 2/E[W^i(1)]^2$. Then for $z \in (0, \Delta_0)$ and as $k_0 \to \infty$ ((10.13) defines $G_0(k_0, z)$)*

$$P^J\{X^i(t) \text{ reaches } \Delta_0 \text{ before } 0|X^i(0) = z\} \equiv G_0(k_0, z) \to 1, \tag{10.13}$$

$$\sup_{n\geq 1, i} E[Y^i(n+1) - Y^i(n)] \to 0, \tag{10.14}$$

uniformly in $J(\cdot)$.

Proof. Equation (10.13) follows from a direct calculation of the value. In fact, $J(\cdot)$ is not relevant since $X^i(t) \in [0, \Delta_0]$ in the calculation. For simplicity, suppose that we have transformed the measure so that the system on the spacial interval of concern $[0, \Delta_0]$ (with absorbtion on the boundary) can be written as $dz = k_1(z)dt + dW^1$, $\text{var}W^1(1) = 2/q_i$. Let $G(\cdot)$ denote the probability $G_0(\cdot)$ for the new system. The measures of the transformed and the original systems are mutually absolutely continuous, and the Radon–Nikodyn is bounded in mean square, uniformly in $J(\cdot), k_0, \delta_{k_0}$. Then, if (10.13) holds for the transformed system, it will hold for the original system. Then $G(k_0, z)$ satisfies the differential equation $q_i k_1(z) G_z(k_0, z) + G_{zz}(k_0, z) = 0, z \in (0, \Delta_0)$, with the boundary condition $G(k_0, 0) = 0, G(k_0, \Delta_0) = 1$. Define $U(k_0, z) = G_x(k_0, z)$. Then since $k_1(z) = k_0$ for $z \leq \delta_{k_0}$ and it equals zero otherwise:

$$\begin{aligned} U(k_0, z) &= U(k_0, 0) \exp - \int_0^z q_i k_1(y) dy \\ &= U(k_0, 0) \exp -q_i k_0 z \qquad (z \leq \delta_{k_0}) \\ &= U(k_0, 0) \exp -q_i k_0 \delta_{k_0} \qquad (z > \delta_{k_0}), \end{aligned}$$

and

$$G(k_0, \delta_{k_0}) = \frac{(1 - e^{-q_i k_0 \delta_{k_0}})}{(1 - e^{-q_i k_0 \delta_{k_0}}) + q_i k_0 (\Delta_0 - \delta_{k_0}) e^{-q_i k_0 \delta_{k_0}}}, \tag{10.15}$$

from which (10.13) follows for $z = \delta_{k_0}$. A similar calculation yields (10.13), for all $z \in (0, \Delta_0)$.

Let $T_1 > 0$. Then (10.13) can be used to show that the probability that $X^i(t) = 0$ somewhere on the interval $[T, T + T_1]$ goes to zero uniformly in $T, J(\cdot)$ (provided T is bounded away from zero if $X^i(0) = 0$ with a positive probability). This, together with the uniform integrability of $\{Y^i(n+1) - Y^i(n), n < \infty\}$ which is implied by (10.7) yields (10.14). □

A maximum principle. For our purposes, it is necessary to know that $\overline{\gamma}(k_0, x)$ is also the infimum over all state feedback controls (in which case, it would not depend on x). Such a result was not explicitly shown in [12] that worked only with state feedback controls, but it is readily obtainable from the results of that paper; we give the required adaptation here. Let $\bar{u}(\cdot)$ be an optimal state feedback control. Let $\psi^{\overline{u}}(\cdot)$ be a measurable $I\!R^3$-valued function of x, which will be defined further below. We adjust the terminology to conform with that in [8] when possible. For a state feedback control $v(\cdot)$, define ($c^u(\cdot)$ was defined in Theorem 10.4)

$$e^{\overline{u},v}(x) = [c^{\overline{u}}(x) - c^v(x)] + \psi^{\overline{u}}(x) K(x) [\overline{u}(x) - v(x)]. \tag{10.16}$$

This is the same as the $e^{u,v}(x)$ in [8, (6.3)] with $u = \overline{u}$.

In [12, Thm. 6.1] it is shown that there exists a Borel $\psi^{\overline{u}}(\cdot)$ such that the condition that $e^{\overline{u},v}(x) \le 0$ for almost all x for each admissible state feedback $v(\cdot)$ is both necessary and sufficient for $\overline{u}(\cdot)$ to be optimal for the system (10.2) and cost (10.3) in the class of state feedback controls. The proofs in [8] are for the unreflected diffusion. But, as noted earlier, the development in that paper also holds for the approximating models (10.2). The proof of the cited theorem can be adapted to show that $\bar{u}(\cdot)$ is optimal with respect to all admissible controls, and now we outline the required alterations. Henceforth $\psi^{\overline{u}}(\cdot)$ will denote the cited function. The reader who is willing to accept that the infima of the costs over feedback and general admissible controls are equal can skip the next theorem.

THEOREM 10.6. *$\overline{\gamma}(k_0)$ is the infimum of $\overline{\gamma}(k_0, J, x_0)$ either over all admissible controls or over all state feedback controls, for each initial condition $X(0) = x_0$.*

Proof. Only an outline of the adaptation of the proofs in [12] will be given. Let $J(\cdot)$ be admissible with $X(0) = x_0$, and let $t_n \to \infty$ be a sequence of real numbers such that $\gamma_{t_n}(k_0, J, x_0) \to \gamma(k_0, J, x_0)$. Let $\overline{u}(\cdot)$ be optimal for (10.2),(10.3) in the class of state feedback controls. Then, as noted above the theorem, $e^{\overline{u},v}(x) \le 0$ for almost all x for each admissible state feedback $v(\cdot)$.

Define the "centered" cost rate

$$\tilde{c}^{\overline{u}}(x) = c^{\overline{u}}(x) - \gamma(k_0, \overline{u}).$$

Following a procedure very close to that which led to the fourth equation from the bottom of [12, p. 343] (where our $\tilde{c}^u$ is their $\tilde{k}^u$), for admissible $J(\cdot)$ we have

$$\lim_{n\to\infty} \frac{1}{n} E^J \int_0^{t_n} \left\{ \tilde{c}^{\overline{u}}(X(s)) + \psi^{\overline{u}}(X(s)) K(X(s)) [\overline{u}(X(s)) - J(s)] \right\} ds = 0. \tag{10.17}$$

Analogous to the definition of $\tilde{c}^{\overline{u}}(x)$, define the "centered" cost rate

$$\tilde{c}^J(s) = \sum_i (1 - J^i(s)) k_1(X^i(s)) - \gamma(k_0, J, x_0)$$

and note that $E^J \int_0^{t_n} \tilde{c}^J(s)ds/t_n \to 0$ by the centering of $\tilde{c}^J(\cdot)$ and the definitions of $\gamma(k_0, J, x_0)$ and t_n. Then by (10.17), we can write

(10.18)
$$\lim_{n\to\infty} \frac{1}{t_n} E^J \int_0^{t_n} \left\{ \tilde{c}^{\overline{u}}(X(s)) - \tilde{c}^J(s) + \psi^{\overline{u}}(X(s))K(X(s))[\overline{u}(X(s)) - J(s)] \right\} ds = 0].$$

There is a measurable function $w(\cdot)$ mapping $[0,\infty)^3 \times [0,\infty)$ into $[0,1]^3$ such that with probability one for each s not in a set of measure zero,

$$w(X(s), s) = E^J[J(s)|X(s)].$$

For almost all $s, w(\cdot,\dot{}s)$ is defined for almost all x, since $X(s)$ has a positive density with respect to Lebesgue measure. Fix the values on the exceptional set so that it is defined for all x for almost all s.

Using the definition of $e^{\overline{u},v}(x)$ for each s and with $v(\cdot) = w(\cdot, s)$, (10.18) can be written as

$$\lim_{n\to\infty} \frac{1}{t_n} E^J \int_0^{t_n} [e^{\overline{u},v(s)}(X(s)) - \gamma(k_0, \overline{u}) + \gamma(k_0, J, x_0)]ds = 0.$$

By the optimality of $\overline{u}(\cdot)$ in the class of feedback controls and the above part of the proof, for almost all s $e^{\overline{u},w(s)}(x) \le 0$ for almost all x. Thus $e^{\overline{u},w(s)}(X(s)) \le 0$ w.p.1 for almost all s. Hence the last displayed equation yields

$$\gamma(k_0, \overline{u}) \le \gamma(k_0, J, x_0),$$

which proves that $\overline{u}(\cdot)$ is optimal with respect to all admissible controls. □

The convergence of the costs. We are finally prepared to prove (9.6). The system (10.2) will provide an upper bound to the cost $\overline{\gamma}(x)$. First, we need to introduce a "lower bounding" system. This will be of the form (10.2) but with (effectively) a slightly larger state space. Let $\delta/\mu > \delta_{k_0}$, let $\overline{\delta}$ denote the vector with components δ, and define the "δ-perturbed" form of (10.2) for state feedback $u(\cdot)$:

(10.19) $$dX = bdt + \overline{\delta}dt - \mu X dt + dY + dW + k(X)dt - K(X)u(X)dt, \qquad X^i(t) \ge 0.$$

Let $\gamma(k_0, \delta, u)$ denote the cost (10.3) for this system. We note the fact that the ergodic cost under state feedback controls does not depend on the initial condition. Set $\overline{\gamma}(k_0, \delta) = \inf \gamma(k_0, \delta, u)$, where the inf is over all state feedback controls. By Theorem 10.6, the inf is the same over admissible controls.

THEOREM 10.7. *Let* $\sup_N E|X_N(0)|^2 < \infty$. *Then* $\overline{\gamma}(x)$ *does not depend on* x *and* (*writing* $\overline{\gamma}(x) = \overline{\gamma}$)

(10.20) $$\overline{\gamma}_T^N(x) \to \overline{\gamma},$$

as $N \to \infty, T \to \infty$.

Proof. First, we get a "lower boundary" system. Let $\overline{E}^u$ denote the expectation operator for functionals of the stationary process (10.2), under state feedback control $u(\cdot)$. We have

(10.21) $$\overline{\gamma}(k_0, \delta) \le \overline{\gamma} \le \overline{\gamma}(k_0) + \sum_i \overline{E}^{\overline{u}(k_0)} Y^i(1),$$

where $\overline{u}(k_0, \cdot)$ is the optimal control for cost $\gamma(k_0, u)$ and system (10.2). The right side of (10.21) should be clear. To see the left-hand side, proceed as follows: First, define the system (10.2) on the spacial set $[-\delta/\mu, \infty)$ instead of on $[0, \infty)$; i.e., the reflection is at $-\delta/\mu$. Let $\Delta_0 - \delta/\mu$ replace Δ_0. Write the resulting system as

$$\begin{aligned} d\tilde{X}^i =& b_i dt + dW^i + d\tilde{Y}^i - \mu\tilde{X}^i dt + k_1(\tilde{X}^i + \delta/\mu)dt \\ &-k_1(\tilde{X}^{(i+1)} + \delta/\mu)\tilde{J}^{(i+1)}dt - k_1(\tilde{X}^{(i+2)} + \delta/\mu)\tilde{J}^{(i+2)}dt. \end{aligned}$$

Recall that $\delta/\mu > \delta_0$. Then clearly the inf of the cost $\gamma(k_0, \delta, u)$ for the new system is no greater than $\bar{\gamma}$. (Loosely speaking, this is true since trunk i of the new system "rejects and requests rerouting" at rate $k_1(x^i + \delta/\mu)$; i.e., it "rejects and requests rerouting" only when the state value is negative, and the reflection term is not counted in the cost.) Now change variables $x^i = \tilde{x}^i + \delta/\mu$ to get (10.19) and the cost $\gamma(k_0, \delta, u)$.

It is also true that

$$\bar{\gamma}(k_0, \delta) - \bar{\gamma}(k_0) \to 0 \tag{10.22}$$

as $\delta \to 0$, uniformly in k_0. In fact, the difference is bounded above by 3δ. (A remark on the network analog of this appears after the proof.) To see this bound, add a nondecreasing control function $H(\cdot)$ satisfying $H^i(t) \le \delta t, H^i(0) = 0$ to (10.2), and use the same cost $\gamma(k_0, J, x)$. The best that we can do with the additional control is to reduce the minimum ergodic cost by 3δ.

Now that we have a bounding system (10.2), we can proceed to get a "nice" ε-optimal control for this system. Let $\varepsilon > 0$, and let k_0 and δ_{k_0} satisfy the requirements of Theorem 10.5. By Theorem 10.5, we can choose k_0 large enough such that $\sum_i \overline{E}^u Y^i(1) \le \varepsilon$ for all $u(\cdot)$. Suppose that $|\bar{\gamma}(k_0, \delta) - \bar{\gamma}(k_0)| \le \varepsilon$, and let $u_\varepsilon(\cdot) = (u^1_\varepsilon(\cdot), u^2_\varepsilon(\cdot), u^3_\varepsilon(\cdot))$ be a state feedback Lipschitz continuous ε-optimal for cost $\gamma(k_0, u)$. Such a control exists by Theorem 10.4 together with the fact (Theorem 10.6) that $\bar{\gamma}(k_0)$ is the infimum over both all admissible controls and the state feedback controls.

Now we adapt $u_\varepsilon(\cdot)$ to the physical network by "randomizing" as done in Theorem 8.3. Recall that we supposed that only one arrival/departure event can occur in the network at a time (w.p.1). Define $\text{data}^N(t) = \{A^N(s), D^N(s),\ s \le t,$ rerouting decisions for $s < t.\}$ Then adapt $u_\varepsilon(\cdot)$ as follows. Let N be large enough so that $k_0 < \sqrt{N}$. Suppose that there is an external arrival to trunk i at time t. If the trunk is full, reject it with no request for rerouting. Otherwise, reject from i and request rerouting with the conditional probability

$$P\{\text{reject from } i \text{ and request rerouting}|\text{data}^N(t)\} = k_1(X^{i,N}(t^-))/\sqrt{N}.$$

The request is accepted on the alternative route with conditional probability

$$P\{\text{request from } i \text{ accepted on alternate route}|\text{data}^N(t)\} = u^i_\varepsilon(X^N(t^-)).$$

Since the events are separated in time, the conditional probability is well defined.

The rest of the details are similar to those in Theorems 8.3 and 9.1, and only a few comments will be made. Analogous to the case at the end of the proof of Theorem 8.3 where the rerouting policy was also randomized, we can write $(1/\sqrt{N})\times$(number of rerouting requests made by trunk i by time t) as the sum of the compensator or conditional mean value, which is (mod $O(1/\sqrt{N})$)

$$\int_0^t k_1(X^{i,N}(s))ds,$$

and a martingale ("noise") term. Similarly, $1/\sqrt{N}\times$(number of rerouting requests made by trunk i by t that are accepted by the alternative path) can be written as

$$\int_0^t k_1(X^{i,N}(s))u_\varepsilon^i(X(s))ds,$$

plus a "noise" term. As in Theorem 8.3, the variances of these "noise" terms go to zero as $N \to 0$.

Let $X^N(0) = x$, and define

(10.23)
$$\gamma_T^N(k_0, u_\varepsilon, x) = \frac{1}{T}E\left[\int_0^t \sum_i (1 - u_\varepsilon^i(X^N(s)))k_1(X^{i,N}(s))ds + \sum_i Y^{i,N}(T)\right].$$

Then, obviously,

$$\gamma_T^N(k_0, u_\varepsilon, x) \geq \bar{\gamma}_T^N(x). \tag{10.24}$$

By an occupation measure argument of the type required for Theorem 5.1, we get that

$$\gamma_T^N(k_0, u^\varepsilon, x) \to \gamma(k_0, u^\varepsilon) \tag{10.25}$$

as $N \to \infty$, $T \to \infty$. Now (10.21), (10.24), (10.25), and the fact that the right-hand sum in (10.21) and the difference in (10.22) are both less than ε give

$$\limsup_{N,T} \bar{\gamma}_T^N(x) \leq \bar{\gamma} + 3\varepsilon.$$

This together with (9.4) yields the theorem, since ε is arbitrary. □

Note. It is worth adding a comment on the analog of (10.19), (10.22) for the network. Adding δ to b_i is equivalent to cutting out external inputs to each trunk randomly so that the effective (external) arrival rate to each is reduced by $\delta\sqrt{N}$. This reduces the cost due to subsequent losses to the three-trunk network by at most 3δ. An alternative interpretation is provided by simply increasing the number of lines in each trunk by $\delta\sqrt{N}/\gamma$ and using the definition $X^{i,N}(t) = [\beta_i N + \delta\sqrt{N}/\mu -$number occupied $]/\sqrt{N}$. Then the mean total loss is also reduced by at most 3δ. If $\delta/\mu > \delta_0$, then the rejections/requests for rerouting from trunk i can occur only when the original $\beta_i N$ lines are fully occupied. This implies that $\bar{\gamma}(k_0, \delta) \leq \bar{\gamma}$.

ON THE STABILIZATION IN FINITE TIME OF LOCALLY CONTROLLABLE SYSTEMS BY MEANS OF CONTINUOUS TIME-VARYING FEEDBACK LAW*

JEAN-MICHEL CORON†

This paper is dedicated to Henry Hermes for his 60th birthday.

Abstract. It is proven that, if, for any positive time T, there exists an open-loop control $u(a,t)$ depending continuously on the initial data a, vanishing for $a=0$, and steering a small neighborhood of 0 into 0 in time T, then the control system can be locally stabilized in small time by means of continuous time-varying feedback law, provided that the dimension of the state space is at least 4 and the strong accessibility rank condition holds.

Key words. stabilization, time-varying feedback, controllability

AMS subject classifications. 93D15, 93C10

1. Introduction and statements of the main results.

Let Σ be the control system

$$\dot{x} = f(x,u), \tag{1.1}$$

where $x \in \mathbb{R}^n$ is the state, $u \in \mathbb{R}^m$ is the control, and $f : \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}^n$ satisfies

$$f(0,0) = 0. \tag{1.2}$$

Using small controls we want to steer to 0 states close to 0 and always stay close to 0. This is clearly possible by means of open-loop controls if 0 is locally reachable in small time and with small control, i.e., for any point a in a small neighborhood of 0 in $\mathbb{R}^n$ there exists a small open-loop control $u_a(\cdot)$ that steers this point a to 0 in small time. Unfortunately, for "real" systems it is well known that, for example, due to random perturbations, open-loop controls can lead to very bad practical results; see, e.g., [So2, Chap. 1, §4]. To take care of this problem one usually tries to find a closed-loop control or feedback law that asymptotically stabilizes the system; indeed, compared to open-loop control, such a feedback law has the advantage of compensating automatically for these perturbations—at least if they are small. A classical result is that for a linear system this local reachability implies that Σ can be asymptotically stabilized by means of stationary feedback law; see, e.g., [So2; Thm. 7, p. 134]. Let us recall that M. Kawski has proved in [Kaw1] (see also [DMK]) that this result still holds if f is nonlinear provided that f is analytic, $n=2$, $m=1$, and $f(x,u) = f_0(x)+uf_1(x)$. Unfortunately, it has been shown by R. Brockett in [Br] (see also [Su1, Appendix]) that this is no longer true in the general case, even if f is analytic. The goal of this paper is to show that the situation is much better if, following E. Sontag and H. Sussmann [SS] (see also [Sa] and [Co1]), one allows the feedback law to depend on time. Indeed, we will see that "many" sufficient conditions for this local reachability

*Received by the editors November 18, 1992; accepted for publication November 18, 1993.

†Centre de Mathématiques et de Leurs Applications, Centre National de la Recherche Scientifique, Unité de Recherche Associée 1611, École Normale Supérieure de Cachan, 61, avenue du Président Wilson, 94235 Cachan, France.

(including, e.g., the Hermes condition [He2] or [Su3]) imply that, if the dimension of the state space is at least 4, then Σ can be locally asymptotically—and even in finite time—stabilized by means of a continuous periodic time-varying feedback law.

In order to state precisely our main results let us first introduce three definitions.

DEFINITION 1.1. *The origin (of $\mathbb{R}^n$) is locally reachable (for Σ) in small time and with small control if, for any positive real number T, there exist $u : \mathbb{R}^n \to L^1((0,T);\mathbb{R}^m)$ and a positive real number ε such that*

$$\|u(a)\|_\infty := \text{ess. sup}\{|u(a)(t)|; t \in (0,T)\} \to 0 \quad as\, a \to 0, \tag{1.3}$$

$$(\dot{x} = f(x, u(x(0))(t)) \quad and \quad |x(0)| < \varepsilon) \Rightarrow x(T) = 0. \tag{1.4}$$

If, moreover, u can be chosen in $C^0(\mathbb{R}^n; L^1((0,T);\mathbb{R}^m))$, we say that 0 is locally continuously reachable in small time and with small control.

Of course, in (1.4) x is any *maximal* solution, and by $x(T) = 0$ we mean that $x(T)$ *exists* and is equal to zero. We use these standard conventions throughout this paper (even for vector fields that are only continuous with respect to x). Let us note that, following a method of M. Kawski [Kaw2] (see also [Hel]), we have proved in [Co2, Lem. 3.1 and §5] that "many" sufficient conditions for locally reachability of 0 in small time and with small control imply that 0 is locally *continuously* reachable in small time and with small control. In particular, this is the case for the Hermes condition [He2] or [Su3] and its generalization due to H. J. Sussmann [Su4, Thm. 7.3]; this is, in fact, also the case for the Bianchini and Stefani condition [BS, Cor., p. 970] which extends [Su4, Thm. 7.3]. We conjecture that, if f is analytic, 0 is locally continuously reachable in small time and with small control if 0 is locally reachable in small time and with small control.

DEFINITION 1.2. *System Σ is locally smoothly stabilizable in small time by means of periodic time-varying feedback law if, for any positive real number T, there exists u in $C^0(\mathbb{R}^n \times \mathbb{R}; \mathbb{R}^m)$ of class C^∞ on $(\mathbb{R}^n\backslash\{0\}) \times \mathbb{R}$, vanishing on $\{0\} \times \mathbb{R}$, T-periodic in time, and such that, for some positive real number ε,*

$$((\dot{x} = f(x, u(x,t)) \quad and \quad x(s) = 0) \Rightarrow (x(\tau) = 0 \quad \forall \tau \geq s)) \quad \forall s \in \mathbb{R}, \tag{1.5}$$

$$(\dot{x} = f(x, u(x,t)) \quad and \quad |x(\tau)| < \varepsilon) \Rightarrow (x(\tau + T) = 0) \quad \forall \tau \in \mathbb{R}. \tag{1.6}$$

In particular (see Lemma 2.15) 0 is a uniformly locally asymptotically stable point for $\dot{x} = f(x, u(x,t))$.

Let us recall that 0 is a uniformly locally asymptotically stable point for $\dot{x} = X(x,t)$ with X in $C^0(\mathbb{R}^n \times \mathbb{R}; \mathbb{R}^n)$ if it is a uniformly locally stable point (i.e., $\forall \varepsilon > 0, \exists \delta > 0$ s.t., $\forall s \in \mathbb{R}$, $\dot{x} = X(x,t)$ and $|x(s)| < \delta$ imply $|x(\tau)| < \varepsilon \forall \tau > s$) and a uniformly locally attractive point with respect to time and state (i.e., $\exists \delta > 0$ s.t., $\forall \varepsilon > 0 \, \exists M > 0$ s.t., $\forall s \in \mathbb{R}$, $\dot{x} = X(x,t)$ and $|x(s)| < \delta$ imply $|x(\tau)| < \varepsilon \forall \tau > s+M$). Note that "uniformly locally attractive" follows directly from (1.5) and (1.6); for "uniformly locally stable," see Lemma 2.15. Our last definition is as follows.

DEFINITION 1.3 [Co3]. *System Σ satisfies the strong jet accessibility rank condition at $(\bar{x}, \bar{u})$ if*

$$a(\bar{x},\bar{u}) := \text{Span}\left\{h(\bar{x}); h \in \left\{\frac{\partial^{|\alpha|} f}{\partial u^\alpha}(\cdot,\bar{u}), \alpha \in \mathbb{N}^m, |\alpha| \geq 1\right\} \cup \text{Br}(f,\bar{u})\right\} = \mathbb{R}^n, \tag{1.7}$$

where $\mathrm{Br}(f,\bar{u})$ *is the set of iterated Lie brackets of vector fields in* $\{(\partial^{|\alpha|}f/\partial u^{\alpha})(\cdot,\bar{u});\alpha\in\mathbb{N}^m\}$.

Let us point out that, in general, $f(\bar{x},\bar{u})$ does not belong to $a(\bar{x},\bar{u})$: we do not consider $\partial^{|\alpha|}f/\partial u^{\alpha}$ as an iterated Lie bracket. Let us also note that the sufficient conditions for local reachability of 0 in small time and with small control mentioned above imply that the strong jet accessibility rank condition at $(0,0)$ holds. Finally, note that, if Σ is locally smoothly stabilizable in small time by means of periodic time-varying feedback law, then $0\in\mathbb{R}^n$ is locally continuously reachable in small time and with small control. Our main result is that the converse holds if $n\geq 4$ and if Σ satisfies the strong jet accessibility rank condition at $(0,0)$, i.e., we have the following theorem.

THEOREM 1.4. *Assume* $n\geq 4$ *and*

(1.8) *0 is locally continuously reachable in small time and with small control*,

(1.9) Σ *satisfies the strong jet accessibility rank condition at* $(0,0)$.

Then Σ *is locally smoothly stabilizable in small time by means of periodic time-varying feedback law.*

This theorem is proved in §2. We do not know if the assumption $n\geq 4$ can be removed. It is proved in [Co4] that this is the case if $n=1$ and f is analytic—in this case the stabilizing feedback law can be chosen independent of time. In §3 we give other cases where the assumption $n\geq 4$ can be removed; in particular, we prove the following propositions.

PROPOSITION 1.5. *If* $f(x,u)=\sum_{i=1}^{m}u_if_i(x)$ *for some functions* f_i *in* $C^\infty(\mathbb{R}^n;\mathbb{R}^n)$ *with* $i\in[1,m]$, *and if* (1.9) *holds, then* Σ *is locally smoothly stabilizable in small time by means of periodic time-varying feedback law.*

PROPOSITION 1.6. *Assume that* (1.8) *and* (1.9) *hold. Assume that, with* $x=(x_1,x_2)\in\mathbb{R}^{n-1}\times\mathbb{R}$ *and* $u=(u_1,u_2)\in\mathbb{R}^{m-1}\times\mathbb{R}$, $f(x,u)=(f_1(x_1,u_1),u_2)\in\mathbb{R}^{n-1}\times\mathbb{R}$ *for some function* f_1 *in* $C^\infty(\mathbb{R}^{n-1}\times\mathbb{R}^{m-1};\mathbb{R}^{n-1})$. *Then* Σ *is locally smoothly stabilizable in small time by means of periodic time-varying feedback law.*

Remark 1.7. (a) Theorem 1.4 is related to the previous result [Su1] by Sussmann, where, roughly speaking, it is proved that controllability implies that the system can be steered to the origin by means of discontinuous—stationary—feedback law. Note that [Su1] has the advantage of leading to a global result, which is not the case with our theorem; on the other hand, our feedback law is continuous and 0 is uniformly locally asymptotically stable for the closed-loop system, which gives some kind of robustness, since, by a theorem of J. Kurzweil [Ku], it implies the existence of a Lyapunov function. (b) One easily checks that the usual strong accessibility subspace of Σ at $\bar{x}$ (see, e.g., [SJ, p. 101] or [So1, p. 549]) contains $a(\bar{x},\bar{u})$ for all $\bar{u}$ in $\mathbb{R}^m$ and that, if f is a polynomial with respect to u or if f is analytic with respect to x and u, these inclusions are all equalities; hence, by a theorem of H. Sussmann and V. Jurdjevic [SJ], (1.8) implies (1.9) if f is analytic. (c) For f as in Proposition 1.6, (1.9) implies (1.8) (see [Co2]), and it has already been proved in [Co3] that for such an f, (1.9) implies that Σ is uniformly locally asymptotically stabilizable by means of periodic time-varying feedback law of class C^∞. (d) This paper is a detailed and improved version of [Co2], where a weaker but related result [Co2, Thm. 1.8] has been stated with a sketch of proof. (e) The stabilization problem is a field of research that expands very quickly; for a survey on this subject see [Ba].

2. Proof of Theorem 1.4. Let I be an interval of $\mathbb{R}$. By a trajectory of the control system Σ on I we mean $(\gamma, u) \in C^\infty(I; \mathbb{R}^n \times \mathbb{R}^m)$ satisfying $\dot\gamma(t) = f(\gamma(t), u(t))$ for all t in I. The linearized control system around (γ, u) is $\dot\xi = A(t)\xi + B(t)w$, where the state is $\xi \in \mathbb{R}^n$, the control is $w \in \mathbb{R}^m$, and $A(t) = \partial f/\partial x(\gamma(t), u(t)) \in \mathcal{L}(\mathbb{R}^n; \mathbb{R}^n)$, $B(t) = \partial f/\partial u(\gamma(t), u(t)) \in \mathcal{L}(\mathbb{R}^m; \mathbb{R}^n)$ for all t in I. We first introduce the following definition.

DEFINITION 2.1. *The trajectory (γ, u) is supple on $S \subset I$ if, for all s in S,*

$$\text{Span}\{((d/dt) - A(t))^i B(t)|_{t=s} w;\ w \in \mathbb{R}^m, i \geq 0\} = \mathbb{R}^n. \tag{2.1}$$

In (2.1) we use the classical convention $(d/dt - A(t))^0 B(t) = B(t)$. Let us recall that L. Silverman and H. Meadows have shown in [SM] that (2.1) implies that the linearized control system around (γ, u) is controllable with impulsive controls at time s (in the sense of [Kai, p. 614]). Let T be a positive real number. For u in $C^0(\mathbb{R}^n \times [0,T]; \mathbb{R}^m)$ and a in $\mathbb{R}^n$, let $x(a, \cdot; u)$ be the maximal solution of $\partial x/\partial t = f(x, u(a,t))$, $x(a, 0; u) = a$. Also, let C^* be the set of $u \in C^0(\mathbb{R}^n \times [0,T]; \mathbb{R}^m)$ of class C^∞ on $(\mathbb{R}^n \backslash \{0\}) \times [0,T]$ and vanishing on $\{0\} \times [0,T]$. Unless otherwise specified we assume (1.8) and (1.9). To try to make the arguments clearer we first sketch the four steps of the proof. For simplicity, in this sketch of proof we omit some details that are important for taking care of the uniqueness property (1.5) (note that without (1.5) one does not have stability).

Step 1. Using (1.8), (1.9), and [Co2] or [Co3], one proves that there exist ε_1 in $(0, +\infty)$ and u_1 in C^*, vanishing on $\mathbb{R}^n \times \{T\}$, such that

$$|a| \leq \varepsilon_1 \Rightarrow x(a, T; u_1) = 0, \tag{2.2}$$

$$0 < |a| \leq \varepsilon_1 \Rightarrow (x(a, \cdot; u_1), u_1(a, \cdot)) \text{ is supple on } [0, T]. \tag{2.3}$$

Step 2. Let Γ be a closed submanifold of $\mathbb{R}^n \backslash \{0\}$ of dimension 1 such that $\Gamma \subset \{x \in \mathbb{R}^n; 0 < |x| < \varepsilon_1\}$ Perturbing u_1 in a suitable way, one obtains a map u_2 in C^*, vanishing on $\mathbb{R}^n \times \{T\}$, such that

$$|a| \leq \varepsilon_1 \Rightarrow x(a, T; u_2) = 0, \tag{2.4}$$

$$0 < |a| \leq \varepsilon_1 \Rightarrow (x(a, \cdot; u_2), u_2(a, \cdot)) \text{ is supple on } [0, T), \tag{2.5}$$

$$a \in \Gamma \to x(t, a; u_2) \in \mathbb{R}^n \text{ is an embedding of } \Gamma \text{ into } \mathbb{R}^n \backslash \{0\} \quad \forall t \in [0, T]. \tag{2.6}$$

Here one uses the assumption $n \geq 4$ and proceeds as in the classical proof of the Whitney embedding theorem (see, e.g., [GG, Chap. II, §5]). Let us emphasize that we use this assumption only in this step.

Step 3. From Step 2 one deduces the existence of u_3^* in C^*, vanishing on $\mathbb{R}^n \times \{T\}$, and an open neighborhood $\mathcal{N}^*$ of Γ in $\mathbb{R}^n \backslash \{0\}$ such that

$$a \in \mathcal{N}^* \Rightarrow x\,(a, T; u_3^*) = 0, \tag{2.7}$$

$$a \in \mathcal{N}^* \to x(a, t; u_3^*) \text{ is an embedding of } \mathcal{N}^* \text{ into } \mathbb{R}^n \backslash \{0\} \quad \forall t \in [0, T). \tag{2.8}$$

This embedding property allows one to transform, on $\{(x(a,t;u_3),t); a \in \mathcal{N}, t \in [0,T)\}$, the open-loop control u_3^* into a feedback law u_3. So (see, in particular, (2.7) and note that u_3^* vanishes on $\mathbb{R}^n \times \{T\}$) there exist u_3 in C^* and an open neighborhood $\mathcal{N}$ of Γ in $\mathbb{R}^n \backslash \{0\}$ such that

$$(x(0) \in \mathcal{N} \text{ and } \dot{x} = f(x, u_3(x,t))) \Rightarrow (x(T) = 0). \tag{2.9}$$

One can also impose, for all τ in $[0,T]$,

$$(\dot{x} = f(x, u_3(x,t)) \text{ and } x(\tau) = 0) \Rightarrow (x(t) = 0 \quad \forall t \in [\tau, T]). \tag{2.10}$$

Step 4. In this last step one shows the existence of a closed submanifold of $\mathbb{R}^n \backslash \{0\}$ of dimension 1 included in $\{x \in \mathbb{R}^n; 0 < |x| < \varepsilon_1\}$ such that, for any neighborhood $\mathcal{N}$ of Γ in $\mathbb{R}^n \backslash \{0\}$, there exists u_4 in C^* such that, for some ε_4 in $(0, +\infty)$,

$$(\dot{x} = f(x, u_4(x,t)) \text{ and } |x(0)| < \varepsilon_4) \Rightarrow (x(T) \in \mathcal{N} \cup \{0\}), \tag{2.11}$$

$$((\dot{x} = f(x, u_4(x,t)) \text{ and } x(\tau) = 0) \Rightarrow (x(t) = 0) \quad \forall t \in [\tau, T]))\forall \tau \in [0,T]. \tag{2.12}$$

Finally, let $u : \mathbb{R}^n \times \mathbb{R} \to \mathbb{R}^m$ be equal to u_4 on $\mathbb{R}^n \times [0,T]$, $2T$-periodic with respect to time, and such that $u(x,t) = u_3(x, t-T)$ for all (x,t) in $\mathbb{R}^n \times (T, 2T)$. Then u vanishes on $\{0\} \times \mathbb{R}$, is continuous on $\mathbb{R}^n \times (\mathbb{R} \backslash \mathbb{Z}T)$, is of class C^∞ on $(\mathbb{R}^n \backslash \{0\}) \times (\mathbb{R} \backslash \mathbb{Z}T)$, and satisfies

$$(\dot{x} = f(x, u(x,t)) \text{ and } |x(0)| < \varepsilon_4) \Rightarrow (x(2T) = 0), \tag{2.13}$$

$$(\dot{x} = f(x, u(x,t)) \text{ and } x(\tau) = 0) \Rightarrow (x(t) = 0, \quad \forall t \geq \tau) \quad \forall \tau \in \mathbb{R}, \tag{2.14}$$

which implies, as we will see, that (1.6) holds, with $4T$ instead of T and $\varepsilon > 0$ small enough, and that 0 is uniformly locally asymptotically stable for $\dot{x} = f(x, u(x,t))$. Since T is arbitrary, Theorem 1.4 is proved (modulo a problem of regularity of u at (x,t) in $\mathbb{R}^n \times \mathbb{Z}T$ that we will fix).

We now give the proofs of Steps 1 to 4.

Proof of Step 1. We prove the existence of u_1. For a positive real number ε, let $B_\varepsilon = \{x \in \mathbb{R}^n; |x| < \varepsilon\}$ and $B'_\varepsilon = B_\varepsilon \backslash \{0\}$. Let T be a positive real number. The goal of this step is to prove the following proposition.

PROPOSITION 2.2. *There exist u_1 in C^*, vanishing on $\mathbb{R}^n \times \{T\}$, and ε_1 in $(0, +\infty)$ such that* (2.2) *and* (2.3) *hold, and*

$$u_1/|a|^2 \in L^\infty(B'_1 \times [0, \tau]) \quad \forall \tau \in [0, T). \tag{2.15}$$

By (2.15) we mean that, for all τ in $[0,T)$, there exists M in $[0, +\infty)$ such that $|u_1(a,t)| \leq M|a|^2$ for all (a,t) in $B'_1 \times [0, \tau]$. To prove Proposition 2.2 one first proves the following lemma.

LEMMA 2.3. *There exists u_0 in $C^\infty(\mathbb{R}^n \times [0,T); \mathbb{R}^m \cap C^0(\mathbb{R}^n \times [0,T]; \mathbb{R}^m)$, vanishing on $\mathbb{R}^n \times \{T\}$ and on a neighborhood of $\{0\} \times [0,T)$ in $\mathbb{R}^n \times [0,T)$, such that, for some ε_0 in $(0, +\infty)$, $x(a, T; u_0) = 0$ for all a in $\mathbb{R}^n$ with $|a| \leq \varepsilon_0$.*

Proof. Without loss of generality we may assume that $T = 1$. Let i be a positive integer. Since $0 \in \mathbb{R}^n$ is locally continuously reachable in small time and with small control, there exist v_i in $C^0(\mathbb{R}^n; L^1((1-2^{1-i}, 1-2^{-i}); \mathbb{R}^m))$ and a positive real number δ_i in $(0, 1/i)$ such that

$$\|v_i(a)\|_\infty \leq 1/i \qquad \forall a \in \mathbb{R}^n, \tag{2.16}$$

$$\|v_i(a)\|_\infty \to 0 \quad \text{as } a \to 0, \tag{2.17}$$

$$(\dot{x} = f(x, v_i(x(1-2^{1-i}))(t)) \text{ and } |x(1-2^{1-i})| \leq \delta_i) \Rightarrow (x(1-2^{-i}) = 0). \tag{2.18}$$

Let K be the set of u in $\mathbb{R}^m$ of norm less than or equal to 2, and let, for a in $\mathbb{R}^n$ and v in $L^1((1-2^{1-i}, 1-2^{-i}); K)$, $P(a, v) = y(a, 1-2^{-i}; v) \in \mathbb{R}^n$, where y is defined by $\partial y/\partial t = f(y, v(t))$, $y(a, 1-2^{1-i}) = a$. Since K is compact, the map P is defined on an open subset of $\mathbb{R}^n \times L^1((1-2^{1-i}, 1-2^{-i}); K)$— $L^1((1-2^{1-i}, 1-2^{-i}); K)$ being equipped with the L^1 norm—and is continuous on this subset; so, by the continuity of v_i, (2.16), (2.17), and (2.18), there exists w_i in $C^\infty(\mathbb{R}^n \times [1-2^{1-i}, 1-2^{-i}]; \mathbb{R}^m)$ such that w_i vanishes on a neighborhood of $\{0\} \times [1-2^{1-i}, 1-2^{-i}]$ in $\mathbb{R}^n \times [1-2^{1-i}, 1-2^{-i}]$ and

$$\|w_i\|_\infty \leq 2/i, \tag{2.19}$$

$$\partial^\alpha w_i = 0 \quad \text{on} \quad \mathbb{R}^n \times \{1-2^{1-i}, 1-2^{-i}\} \qquad \forall \alpha \in \mathbb{N}^{n+1}, \tag{2.20}$$

$$(\dot{x} = f(x, w_i(x(1-2^{1-i}), t)), |x(1-2^{1-i})| \leq \delta_i) \Rightarrow (|x(1-2^{-i})| < \delta_{i+1}). \tag{2.21}$$

We now define w on $B_{\delta_1} \times [0, 1-2^{-i}]$ by induction on $i \geq 2$ by requiring $w = w_1$ on $B_{\delta_1} \times [0, 1/2]$ and $w(a, t) = w_i(x(a, 1-2^{1-i}; \bar{u}_0), t)$ if t is in $[1-2^{1-i}, 1-2^{-i}]$. One easily checks that w is well defined on $B_{\delta_1} \times [0, 1)$ and is of class C^∞ on this set. Using (2.19) one deduces that there exists u_0 in $C^\infty(\mathbb{R}^n \times [0, 1); \mathbb{R}^m) \cap C^0(\mathbb{R}^n \times [0, 1]; \mathbb{R}^m)$ vanishing on $\mathbb{R}^n \times \{T\}$ and equal to w on $B_{\delta_1/2} \times [0, 1)$. Then u_0 satisfies all the properties mentioned in Lemma 2.3—with $\varepsilon_0 = \delta_1/2$. □

Our next lemma is as follows.

LEMMA 2.4. *There exists* $\bar{u}_0$ *in* $C^\infty(\mathbb{R}^n \times [0, T]; \mathbb{R}^m)$ *and* $\bar{\varepsilon}_0$ *in* $(0, +\infty)$ *such that*

$$|\bar{u}_0(a, t)| \leq |a|^2 \qquad \forall (a, t) \in \mathbb{R}^n \times [0, T], \tag{2.22}$$

$$(x(a, \cdot; \bar{u}_0), \bar{u}_0(a, \cdot)) \text{ is supple on } [0, T) \qquad \forall a \in B'_{\bar{\varepsilon}_0}, \tag{2.23}$$

$$\partial^\alpha \bar{u}_0 = 0 \quad \text{on} \quad \mathbb{R}^n \times \{T\} \qquad \forall \alpha \in \mathbb{N}^{n+1}. \tag{2.24}$$

Proof. Let us first recall the definition of saturation introduced in [Co3, Def. 1.2]. Let p be a positive integer, let X be in $C^\infty(\mathbb{R}^p \times \mathbb{R}^m; \mathbb{R}^p)$, let N be an open subset of $\mathbb{R}^p$, and let u be in $C^\infty(N; \mathbb{R}^m)$. We say that u saturates X on N if

$$a^X(\bar{y}, u(\bar{y})) = \operatorname{Span}\left\{\left(ad^k_{X_u} \frac{\partial X}{\partial u_i}(\cdot, u(\cdot))\right)(\bar{y}); i \in [1, m], k \geq 0\right\} \qquad \forall \bar{y} \in N \tag{2.25}$$

with $X_u(y) = X(y, u(y))$, and where a^X is defined by replacing f by X in the definition of a given in (1.7). Note that the right-hand side of (2.25) is the strong accessibility algebra evaluated at time 0 of the linearized control system around the trajectory $(\gamma, u(\gamma))$ of X where γ is defined by $\dot{\gamma} = X(\gamma, u(\gamma)), \gamma(0) = \bar{y}$. The right-hand side of (2.25) is always included in the left-hand side of (2.25).

We take $p = 2n+1$ and, for all $(x, a, s, u) \in \mathbb{R}^n \times \mathbb{R}^n \times \mathbb{R} \times \mathbb{R}^m \simeq \mathbb{R}^{2n+1} \times \mathbb{R}^m$, let $X_0(x, a, s, u) = (f(x, u), 0, 1) \in \mathbb{R}^n \times \mathbb{R}^n \times \mathbb{R} \simeq \mathbb{R}^{2n+1}$. For the control system $\dot{y} = X_0(y, u)$, the state is $y = (x, a, s)$ in $\mathbb{R}^n \times \mathbb{R}^n \times \mathbb{R} \simeq \mathbb{R}^{2n+1}$ and the control is u in $\mathbb{R}^m$. We take $N = \mathbb{R}^n \times (\mathbb{R}^n \backslash \{0\}) \times (-\infty, T)$. Let h in $C^\infty(\mathbb{R}^n \times \mathbb{R}^n \times \mathbb{R}; \mathbb{R}^n \times \mathbb{R})$ be defined by $h(x, a, s) = (a, s)$ for all (x, a, s) in $\mathbb{R}^n \times \mathbb{R}^n \times \mathbb{R}$. Note that

$$(2.26) \qquad h'(x, a, s)X_0(x, a, s, u) \neq 0 \qquad \forall (x, a, s, u) \in \mathbb{R}^n \times \mathbb{R}^n \times \mathbb{R} \times \mathbb{R}^m.$$

Let $Y = (\mathbb{R}^n \backslash \{0\}) \times (-\infty, T)$ and let Ω be the set of u in $C^\infty(Y; \mathbb{R}^m)$ such that

$$(2.27) \quad |\partial^\alpha u(a, s)| < |a|^2(T-s)/T \qquad \forall (a, s, \alpha) \in Y \times \mathbb{N}^{n+1} \text{ with } |\alpha||a|(T-s) \leq 1.$$

We equip $C^\infty(Y; \mathbb{R}^m)$ with the C^∞-topology defined in [Co3, §1]. For convenience let us recall the definition of this topology. Let $\mathcal{O}$ be an open subset of $\mathbb{R}^p$ and $\bar{v}$ be in $C^\infty(\mathcal{O}; \mathbb{R}^q)$; V is a neighborhood of $\bar{v}$ if there exist two maps, A in $C^0(\mathcal{O}; (0, +\infty))$ and ε in $C^0(\mathcal{O}; (0, +\infty))$, such that all v in $C^\infty(\mathcal{O}; \mathbb{R}^q)$, satisfying $|\partial^\alpha(v - \bar{v})(x)| \leq \varepsilon(x)$ for all (x, α) in $\mathcal{O} \times \mathbb{N}^p$ such that $|\alpha| \leq A(x)$, are in V. Let us remark that Ω is an open neighborhood of 0 in $C^\infty(Y; \mathbb{R}^m)$. Applying [Co3, Thm. 1.3]—note in particular (2.26)—we get the existence of $\bar{u}$ in Ω such that

$$(2.28) \qquad \bar{u} \circ h \text{ saturates } X_0 \text{ on } N.$$

Let $\bar{u}_0 : \mathbb{R}^n \times [0, T] \to \mathbb{R}^m$ be defined by $\bar{u}_0 = \bar{u}$ on Y and $\bar{u}_0 = 0$ on $(\{0\} \times [0, T]) \cup (\mathbb{R}^n \times \{T\})$. By (2.27) $\bar{u}_0$ is of class C^∞ on $\mathbb{R}^n \times [0, T]$ and satisfies (2.22) and (2.24). The existence of $\bar{\varepsilon}_0$ in $(0, +\infty)$ such that (2.23) holds follows from (1.2), (1.9), (2.22), and (2.28). □

From Lemmas 2.3 and 2.4 we will deduce the following lemma.

LEMMA 2.5. *There exists $\bar{u}_1$ in C^*, vanishing on $\mathbb{R}^n \times \{T\}$, and $\bar{\varepsilon}_1$ in $(0, +\infty)$ such that* (2.2) *and* (2.15) *hold with $\bar{u}_1$ and $\bar{\varepsilon}_1$ instead of u_1 and ε_1 and such that*

$$(2.29) \qquad (x(a, \cdot; \bar{u}_1), \bar{u}_1(a, \cdot)) \textit{ is supple on } \{0, T\} \qquad \forall a \in B'_{\bar{\varepsilon}_1}.$$

Before proving Lemma 2.5 let us first explain how to get Proposition 2.2 from Lemma 2.5. Again we apply [Co3, Thm. 1.3] to $(\dot{x}, \dot{a}, \dot{s}) = X_0(x, a, s, u)$ with X_0 still defined as above; h is also unchanged but we define N, Y, and Ω in the following ways: N is now $\mathbb{R}^n \times (\mathbb{R}^n \times \{0\}) \times (0, T)$, $Y = (\mathbb{R}^n \times \{0\}) \times (0, T)$, and Ω is an open neighborhood of $\bar{u}_1$—restricted to Y—in $C^\infty(Y; \mathbb{R}^m)$. We will say that a property P holds if Ω is small enough, if there exists an open neighborhood Ω_1 of $\bar{u}_1$ (for the C^∞-topology) such that P holds if $\Omega \subset \Omega_1$. For example, if Ω is small enough, any u in Ω extended by $\bar{u}_1$ on $(\{0\} \times [0, T]) \cup (\mathbb{R}^n \times \{0, T\})$ is in C^*. Indeed, in this case it suffices for us to choose Ω_1 to be the set of u in $C^\infty(Y; \mathbb{R}^m)$ such that

$$(2.30) \quad |\partial^\alpha(u - \bar{u}_1)(a, s)| < |a|s(T-s) \quad \forall (a, s, \alpha) \in Y \times \mathbb{N}^{n+1} \text{ with } |\alpha||a|s(T-s) \leq 1.$$

Hence, if Ω is small enough, we have, with a slight abuse of notation, $\Omega \subset C^*$. We now assume that $\Omega \subset C^*$. For u in Ω let $y : \mathbb{R}^n \times [0, T] \to \mathbb{R}^n$ be defined by

$\partial y/\partial t = f(y, u(a,t))$, $y(a,T) = 0$. The domain of definition of y is an open subset of $\mathbb{R}^n \times [0,T]$ containing $(\{0\} \times [0,T]) \cup (\mathbb{R}^n \times \{T\})$. One easily checks that, if Ω is small enough, for any u in Ω there exists an open neighborhood ω of 0 in $\mathbb{R}^n$ such that, with φ defined by $\varphi(a) = y(a,0)$, φ is an homeomorphism from ω onto $B_{\bar{\varepsilon}_1/2}$ and φ is a diffeomorphism of class C^∞ from $\omega\backslash\{0\}$ onto $B'_{\bar{\varepsilon}_1/2}$. Let $u_1 \in C^*$, vanishing on $\mathbb{R}^n \times \{T\}$, be such that $u_1(a,t) = u(\varphi^{-1}(a), t)$ for all (a,t) in $B_{\tilde{\varepsilon}_1} \times (0,T)$ with $\tilde{\varepsilon}_1 = \bar{\varepsilon}_1/4$. Then we have (2.2) and, since $\bar{u}_1$ satisfies (2.15), u_1 also satisfies (2.15) if Ω is small enough. Moreover, by (2.29), if Ω is small enough, we have

$$(x(a,\cdot;u_1)); u_1(a,\cdot)) \text{ is supple on } \{0,T\} \quad \forall a \in B'_{\tilde{\varepsilon}_1}. \tag{2.31}$$

Finally, applying [Co3, Thm. 1.3], we get the existence of u in Ω such that $u \circ h$ saturates X_0 on N, which, with (1.2), (1.9), and the fact that u vanishes on $\{0\} \times [0,T]$, implies that, for $|a|$ small enough but not zero, $(y(a,\cdot), u(a,\cdot))$ is supple on $(0,T)$ and, therefore, if $|a|$ is small enough but not zero,

$$(x(a,\cdot;u_1), u_1(a,\cdot)) \text{ is supple on } (0,T). \tag{2.32}$$

Finally, (2.32) and (2.31) imply (2.3) if ε_1 is small enough. This ends the proof of Proposition 2.2 if Lemma 2.5 is proved.

Let us prove Lemma 2.5. We now take $N = \mathbb{R}^n \times (\mathbb{R}^n\backslash\{0\}) \times \mathbb{R}$ and consider the system $(\dot{x}, \dot{a}, \dot{s}) = X_1(x,a,s,u) := (f(x,(s-2T)u), 0, 1) \in \mathbb{R}^n \times \mathbb{R}^n \times \mathbb{R}$. We take $Y = (\mathbb{R}^n\backslash\{0\}) \times \mathbb{R}$, $h(x,a,s) = (a,s)$. By [Co3, Thm. 1.3] there exists v in $C^\infty((\mathbb{R}^n\backslash\{0\}) \times \mathbb{R}; \mathbb{R}^m)$ such that

$$v \circ h \, \text{saturates} \, X_1 \quad \text{on} \, N. \tag{2.33}$$

Let $\tilde{u} \in C^\infty((\mathbb{R}^n\backslash\{0\}) \times \mathbb{R}; \mathbb{R}^m)$ be defined by $\tilde{u}(a,s) = (s-2T)v(a,s)$, then (2.33) gives

$$\tilde{u} \circ h \text{ saturates } X_0 \quad \text{on} \, N. \tag{2.34}$$

Note that

$$\tilde{u}(a, 2T) = 0. \tag{2.35}$$

From (1.9), (2.34), and (2.35) we get that

$$(z(a,\cdot), \tilde{u}(a,\cdot)) \text{ is supple on } \{2T\} \quad \forall a \in \mathbb{R}^n\backslash\{0\}, \tag{2.36}$$

where z is defined by $\partial z/\partial t = f(z, \tilde{u}(a,\cdot))$, $z(a,2T) = 0$. Let $\tilde{\delta}$ be in $C^0(\mathbb{R}^n\backslash\{0\}; (0,+\infty))$. Using Lemma 2.3 with $[T,2T]$ instead of $[0,T]$ and modifying u_0 in a small neighborhood of $(\mathbb{R}^n\backslash\{0\}) \times \{T, 2T\}$ in $(\mathbb{R}^n\backslash\{0\}) \times [T,2T]$, we get the existence of $\tilde{u}_0$ in $C^0(\mathbb{R}^n \times [T,2T]; \mathbb{R}^m)$ of class C^∞ on $(\mathbb{R}^n \times [T,2T]) \backslash\{(0,2T)\}$ such that for some positive real number $\tilde{\varepsilon}_0$,

$$\partial^\alpha(\tilde{u}_0 - \tilde{u}) = 0 \quad \text{on} \quad (\mathbb{R}^n\backslash\{0\}) \times \{2T\} \quad \forall \alpha \in \mathbb{N}^{n+1}, \tag{2.37}$$

(2.38)
$\tilde{u}_0$ vanishes on a neighborhood of$(\{0\} \times [T,2T)) \cup (\mathbb{R}^n \times \{T\})$in $\mathbb{R}^n \times [T,2T)$,

$$0<|a|\le \tilde{\varepsilon}_0 \Rightarrow |\tilde{x}(a,T)-a|<\tilde{\delta}(a), \tag{2.39}$$

where $\tilde{x}$ is defined by $\partial\tilde{x}/\partial t = f(\tilde{x},\tilde{u}_0(a,t))$ and $\tilde{x}(a,2T)=0$. Now let $\bar{u}_0$ and $\bar{\varepsilon}_0$ be as in Lemma 2.4. Using (2.22), (2.23), and Lemma A.1 in Appendix A (with $T_1=0, T_2=T/3, T_3=2T/3, T_4=T, \Lambda=B'_{\bar{\varepsilon}_0}$) we get the following lemma.

LEMMA 2.6. *There exist $\bar{\delta}$ in $C^0(\mathbb{R}^n\backslash\{0\};(0,+\infty))$ and $\tilde{H}\in C^0(\tilde{\omega}\times[0,T];\mathbb{R}^m)$, with $\tilde{\omega}=\{(a,b)\in\mathbb{R}^n\times\mathbb{R}^n; 0<|a|<\bar{\varepsilon}_0/2, |b|<\bar{\delta}(a)\}\cup\{(0,0)\}$, such that*

$$\tilde{H}\in C^\infty((\tilde{\omega}\backslash\{0,0\})\times[0,T];\mathbb{R}^m), \tag{2.40}$$

$$\tilde{H}(a,b,t)=\bar{u}_0(a,t) \quad \forall (a,b)\in\tilde{\omega} \quad \forall t\in[0,T/3]\cup[2T/3,T], \tag{2.41}$$

$$\tilde{H}(a,0,t)=\bar{u}_0(a,t) \quad \forall a\in B_{\bar{\varepsilon}_0/2} \quad \forall t\in[0,T], \tag{2.42}$$

$$|\tilde{H}(a,b,t)|\le 2|a|^2 \quad \forall (a,b,t)\in\tilde{\omega}\times[0,T], \tag{2.43}$$

$$z(a,b,T)=x(a,T;\bar{u}_0)+b \quad \forall (a,b)\in\tilde{\omega}, \tag{2.44}$$

where z is defined by $\partial z/\partial t = f(z,\tilde{H}(a,b,t))$ and $z(a,b,0)=a$.

Let $\theta(a)=x(a,T;\bar{u}_0)$ and let $\tilde{\delta}\in C^0(\mathbb{R}^n\backslash\{0\};(0,+\infty))$ be such that $\tilde{\delta}(\theta(a))\le\bar{\delta}(a)$ if $|a|$ is small enough but positive. Using (2.24), (2.35), (2.37), (2.38), (2.39), and Lemma 2.6 we get that there exists $\bar{u}_1$ in $C^\infty((\mathbb{R}^n\backslash\{0\})\times[0;2T];\mathbb{R}^m)\cap C^0(\mathbb{R}^n\times[0,2T];\mathbb{R}^m)$, which vanishes on $\mathbb{R}^n\times\{2T\}$ and satifies, if $|a|$ is small enough,

$$\bar{u}_1(a,t)=\tilde{H}(a,\tilde{x}(\theta(a),T)-\theta(a),t) \quad \forall t\in[0,T], \tag{2.45}$$

$$\bar{u}_1(a,t)=\tilde{u}_0(\tilde{x}(\theta(a),T),t) \quad \forall t\in(T,2T). \tag{2.46}$$

Using (2.44), (2.45), and (2.46) we get that, if $|a|$ is small enough, $x(a,2T;\bar{u}_1)=0$. Using (2.23), (2.36), (2.37), (2.45), and (2.46) we get that, if $|a|$ is small enough but positive, $x(a,\cdot;\bar{u}_1)$ is supple on $\{0,2T\}$. Finally, using (2.38), (2.43), (2.45), and (2.46), we get that $\bar{u}_1/|a|^2$ is in $L^\infty(B'_1\times[0,\tau])$ for all τ in $[0,2T)$. So $\bar{u}_1$ has the properties required in Lemma 2.5 provided that $\bar{\varepsilon}_1$ is small enough and that one replaces $2T$ with T. Since T is arbitrary in $(0,+\infty)$, Lemma 2.5 is proved. This ends the proof of Proposition 2.2.

Let us end this step with some comments. It follows from our proof of Proposition 2.2 that one can use the weaker result [Co2, Thm. 2.1] instead of [Co3, Thm. 1.3]. Let us recall that this result is related to prior works by M. Gromov [G, Chap. 2, §3.8(E)] and E. Sontag [So1]; moreover, it follows from a recent work [So3] of E. Sontag that this result can be deduced from a theorem on observability of H. Sussmann [Su2] when f is analytic.

Proof of Step 2. Let u_1 and ε_1 be as in Proposition 2.2. Let Γ be a C^∞-closed submanifold of $\mathbb{R}^n\backslash\{0\}$ of dimension 1 such that $\Gamma\subset B'_{\varepsilon_1}$. The goal of this step it to prove the following proposition.

PROPOSITION 2.7. *Assume $n\ge 4$. Then there exists u_2 in C^*, vanishing on $\mathbb{R}^n\times\{T\}$, satisfying* (2.4), (2.5), (2.6), *and, with u_2 instead of u_1,* (2.15).

In this proposition, as well as in the remaining part of this paper, when we refer to embedding we mean embedding of class C^∞. Our proof of Proposition 2.7 is inspired from the classical proof of the Whitney embedding theorem (see, e.g., [GG, Chap. II, §5]). Let Ω be an open neighborhood of $u_{1|B'_{\varepsilon_1}\times(0,T)}$ in $C^\infty(B'_{\varepsilon_1}\times(0,T);\mathbb{R}^m)$. For v in Ω let $\varphi_v : B'_{\varepsilon_1}\to\mathbb{R}^n$ be defined by $\varphi_v(a)=y(0)$, where y is defined by $\dot y = f(y,v(a,t)), y(T)=0$. If Ω is small enough,

$$\text{(2.47)}\qquad \varphi_v \text{ is a diffeomorphism from } B'_{\varepsilon_1} \text{ onto } B'_{\varepsilon_1}\quad \forall v\in\Omega.$$

Let us recall that this means the existence of a neighborhood Ω_1 of $u_{1|B'_{\varepsilon_1}\times(0,T)}$ in $C^\infty(B'_{\varepsilon_1}\times(0,T);\mathbb{R}^m)$ such that (2.47) holds if $\Omega\subset\Omega_1$. From now on we assume that (2.47) holds. Let $u_v:\mathbb{R}^n\times[0,T]\to\mathbb{R}^m$ be defined by $u_v(a,t)=v(\varphi_v^{-1}(a),t)$ if (a,t) is in $B'_{\varepsilon_1}\times(0,T)$, $u_v(a,t)=u_1(a,t)$ if (a,t) is in $B'_{\varepsilon_1}\times(0,T)$. Again, if Ω is small enough, u_v is in C^*, vanishes on $\mathbb{R}^n\times\{T\}$, and satisfies

$$\text{(2.48)}\qquad (x(a,\cdot;u_v),u_v(a,\cdot)) \text{ is supple on } [0,T]\quad \forall a\in B_{\varepsilon_1}.$$

From now on we assume that all these properties hold. Let us recall that a residual subset of Ω is the countable intersection of open dense subsets of Ω. Moreover, since Ω is an open subset of the Baire space $C^\infty(B'_{\varepsilon_1}\times(0,T);\mathbb{R}^m)$, it is a Baire space; therefore, any residual subset of Ω is dense in Ω. So Proposition 2.7 is a consequence of the following lemma, the proof of which is given in Appendix B.

LEMMA 2.8. *If $n\geq 3$, $\Omega_i := \{v\in\Omega; a\in\Gamma\to x(a,t;u_v)$ is an immersion $\forall t\in(0,T)\}$ and $\Omega_0 := \{v\in\Omega; x(a,t;u_v)\neq 0\ \forall a\in\Gamma, \forall t\in(0,T)\}$ are residual subsets of Ω. If $n\geq 4$, $\Omega_1 := \{v\in\Omega; a\in\Gamma\to x(a,t;u_v)$ is one-to-one $\forall t\in(0,T)\}$ is a residual subset of Ω.*

Remark 2.9. (a) Proposition 2.7 remains true if Γ is a closed submanifold of $\mathbb{R}^n\backslash\{0\}$ included in B'_{ε_1} of dimension d provided that $n\geq 2(d+1)$. The proof is similar (use also [GG, Chap. II, Thm. 5.4]). (b) One can also prove Proposition 2.7 by using the method proposed by M. Gromov in [G, Chap. 2, §3.2 (E′)]; but note that our proof does not use the Nash (Newton–Moser) process [G, Chap. 2, §3.2]. (c) Our proof still works if one replaces $[0,T]$ by $[0,T)$ in (2.3).

Proof of Step 3. We assume that Γ is as in Step 2 and that the conclusion of Proposition 2.7 holds (we do not assume $n\geq 4$). The goal of this step is to prove the following proposition.

PROPOSITION 2.10. *There exist a time-varying feedback law u_3 in $C^*(\mathbb{R}^n\times[0,T];\mathbb{R}^m)$ and a neighborhood $\mathcal{N}$ of Γ in $\mathbb{R}^n\backslash\{0\}$ such that (2.9) and (2.10) hold, and*

$$\text{(2.49)}\qquad \partial^\alpha u_3 = 0 \quad on \quad (\mathbb{R}^n\backslash\{0\})\times\{T\}\qquad \forall\alpha\in\mathbb{N}^{n+1}.$$

Let us assume, for the moment, the following lemma.

LEMMA 2.11. *There exist u_3^* in $C^\infty((\mathbb{R}^n\backslash\{0\})\times[0,T];\mathbb{R}^m)\cap C^0(\mathbb{R}^n\times[0,T];\mathbb{R}^m)$ and an open neighborhood $\mathcal{N}^*$ of Γ in $\mathbb{R}^n\backslash\{0\}$ such that* (2.7) *and* (2.8) *hold and*

$$\text{(2.50)}\qquad u_3^* = 0 \quad on \quad (\{0\}\times[0,T])\cup(\mathbb{R}^n\times\{T\}),$$

$$\text{(2.51)}\qquad u_3^*/|a|^2 \in L^\infty(B'_1\times[0,\tau])\quad \forall\tau\in[0,T).$$

Let us prove Proposition 2.10. From (1.2) and (2.51) we get the existence of δ in $(0,\infty)$ such that

$$\text{(2.52)}\qquad \forall\tau\in[0,T)\quad \exists\varepsilon>0 \text{ such that } |x(a,t;u_3^*)|\geq\delta|a|\quad \forall a\in B_\varepsilon\quad \forall t\in[0,\tau].$$

Let $\mathcal{N}_2^* \subset \mathcal{N}_1^* \subset \mathcal{N}^*$ be two bounded open neighborhoods of Γ in $\mathbb{R}^n \backslash \{0\}$ such that, in $\mathbb{R}^n$,

$$\overline{\mathcal{N}_2^*} \subset \mathcal{N}_1^* \cup \{0\}, \quad \overline{\mathcal{N}_1^*} \subset \mathcal{N}^* \cup \{0\}. \tag{2.53}$$

For $i \in \{1,2\}$ let $\mathcal{O}_i = \{(x(a,t;u_3^*),t); a \in \mathcal{N}_i^*, t \in [0,T)\}$. Note that by (2.8) and (2.53) $\mathcal{O}_1$ and $\mathcal{O}_2$ are open in $\mathbb{R}^n \times [0,T]$, $\overline{\mathcal{O}_2}$ is included in $\mathcal{O}_1 \cup (\{0\} \times [0,T])$, and $\overline{\mathcal{O}_1}$ is included in $\mathcal{O}_1 \cup (\{0\} \times [0,T])$. Once more using (2.8) we see that there exists a (unique) $\bar{u}_3$ in $C^\infty(\mathcal{O}_1;\mathbb{R}^n)$ such that

$$\bar{u}_3(x(a,t;u_3^*),t) = u_3^*(a,t) \quad \forall (a,t) \in \mathcal{N}_1^* \times [0,T). \tag{2.54}$$

From (2.7), (2.8), (2.50), and (2.53) one gets that

$$\mathrm{Sup}\{|\bar{u}_3(x,t)|; (x,t) \in \mathcal{O}_1, |x| \leq \varepsilon\} \to 0 \quad \text{as} \quad \varepsilon \to 0. \tag{2.55}$$

Moreover, it follows from (2.52) that

$$\forall \tau \in [0,T) \quad \exists \varepsilon > 0 \text{ such that } |\bar{u}_3(x,t)| \leq |x| \quad \forall (x,t) \in \mathcal{O}_1 \cap (B_\varepsilon \times [0,\tau]). \tag{2.56}$$

Finally, using standard arguments relying on partitions of unity, we get the existence of u_3 in $C^*(\mathbb{R}^n \times [0,T];\mathbb{R}^m)$ such that

$$u_3 = 0 \text{ on a neighborhood of } (\mathbb{R}^n \backslash \{0\}) \times \{T\} \text{ in } (\mathbb{R}^n \backslash \{0\}) \times [0,T], \tag{2.57}$$

$$u_3 = \bar{u}_3 \quad \text{on} \quad \mathcal{O}_2, \tag{2.58}$$

$$\forall \tau \in [0,T) \quad \exists \varepsilon > 0 \text{ such that } |\bar{u}_3(x,t)| \leq |x| \quad \forall (x,t) \in B_\varepsilon \times [0,\tau]. \tag{2.59}$$

Then (2.57) implies (2.49); (2.58) implies (2.9) with $\mathcal{N} = \mathcal{N}_2^*$; (1.2) and (2.59) imply (2.10).

Now, only Lemma 2.11 needs to be proven. Note that in order to prove Theorem 2.7 only the case where Γ is diffeomorphic to $\mathbb{R}$ is useful (see Step 4). So, for simplicity, we study only this case, but note that our proof can be easily adapted to treat the general case. So there is a proper embedding $\gamma : \mathbb{R} \to \mathbb{R}^n \backslash \{0\}$ such that (recall that Γ is bounded) $\gamma(\mathbb{R}) = \Gamma$ and $\gamma(s) \to 0$ as $s \to 0$. Let $\pi \in C^\infty(\mathbb{R}^n \times [0,T);\mathbb{R}^n)$ be such that

$$y \in \mathbb{R}^n \to \pi(y,t) \text{ is an embedding into } \mathbb{R}^n \backslash \{0\} \quad \forall t \in [0,T), \tag{2.60}$$

$$\mathrm{Sup}\{|\pi((z,s),t)|; z \in \mathbb{R}^{n-1}, t \in [0,T)\} \to 0 \quad \text{as} \quad |s| \to +\infty, \tag{2.61}$$

$$\mathrm{Sup}\{|\pi(y,t)|; y \in \mathbb{R}^n\} \to 0 \quad \text{as} \quad t \to T, \tag{2.62}$$

$$\pi((0,s),t) = x(\gamma(s),t;u_2) \quad \forall (s,t) \in \mathbb{R} \times [0,T), \tag{2.63}$$

where u_2 satisfies the properties required in Proposition 2.7. The existence of π can be proved by slightly modifying the proof of the tubular neighborhood theorem given in [GG, Chap. II, §7]. The control system $\dot{x} = f(x,u)$ gives, by pullback using π, a time-varying control system on $\mathbb{R}^n$ $\dot{y} = \bar{F}(y,t,u)$, where the state is $y \in \mathbb{R}^n$, the control $u \in \mathbb{R}^m$, and $\bar{F} \in C^\infty(\mathbb{R}^n \times [0,T) \times \mathbb{R}^m, \mathbb{R}^n)$. Let $F : \mathbb{R}^n \times [0,T) \times \mathbb{R}^m \to \mathbb{R}^n$ be defined by $F(y,t,u) = \bar{F}(y,t,u_2(\gamma(s),t)+u)$ with $y = (z,s) \in \mathbb{R}^{n-1} \times \mathbb{R} \simeq \mathbb{R}^n$. Then $F \in C^\infty(\mathbb{R}^n \times [0,T) \times \mathbb{R}^m; \mathbb{R}^n)$ and, by (2.63), $F((0,s),t,0) = 0\ \forall (s,t)$ in $\mathbb{R} \times [0,T)$. Let $A(s,t) = \partial F/\partial y((0,s),t,0)$, $B(s,t) = \partial F/\partial u((0,s),t,0)$. Since u_2 satisfies (2.3)—with u_1 instead of u_2—we have

(2.64)
$$\operatorname{Span}\left\{ \left(\frac{\partial}{\partial t} - A(s,t)\right)^i B(s,t)\Big|_{t=\bar{t}} w; w \in \mathbb{R}^m, i \geq 0 \right\} = \mathbb{R}^n \quad \forall (s,\bar{t}) \in \mathbb{R} \times [0,T).$$

Then Lemma 2.11 follows from the following lemma, which is proved in Appendix C.

LEMMA 2.12. *Let F in $C^\infty(\mathbb{R}^n \times [0,T) \times \mathbb{R}^m; \mathbb{R}^m)$, vanishing on $(\{0\} \times \mathbb{R}) \times \mathbb{R} \times \{0\}$, be such that* (2.64) *holds. Then, for any ε in $C^0(\mathbb{R} \times [0,T); (0,+\infty))$ there exist an open neighborhood $\mathcal{N}$ of $\{0\} \times \mathbb{R} \subset \mathbb{R}^{n-1} \times \mathbb{R} \simeq \mathbb{R}^n$ and u in $C^\infty(\mathbb{R}^n \times [0,T); \mathbb{R}^m)$ such that*

$$(2.65) \qquad |u(z,s,t)| \leq \varepsilon(s,t) \quad \forall (z,s,t) \in \mathbb{R}^{n-1} \times \mathbb{R} \times [0,T),$$

$$(2.66) \qquad a \in \mathcal{N} \to y(a,t;u) \textit{ is an embedding of } \mathcal{N} \textit{ into } \mathbb{R}^n \quad \forall t \in [0,T),$$

where $y(a,t;u)$ is defined by $\partial y/\partial t = F(y,t,u(a,t))$, $y(a,0;u) = a$.

Remark 2.13. (a) Proposition 2.10 again holds regardless of the dimension of Γ. (b) It follows from its proof that Proposition 2.10 remains true if, instead of (2.5), one assumes that, for a sequence $(t_i; i \in \mathbb{N})$ such that $t_i \in [0,T)$ $\forall i$ and $t_i \to T$ as $i \to +\infty$, we have $(x(a,\cdot;u_2),u_2(a,\cdot))$ is supple on $\{t_i; i \in \mathbb{N}\}$ for all a in Γ.

Proof of Step 4. In this step we end the proof of Theorem 1.4. Let us assume for the moment that we have the following proposition, where (1.8), (1.9), and $n \geq 4$ are not assumed to be true (but where (1.2) is still assumed to be true).

PROPOSITION 2.14. *Assume*

$$(2.67) \qquad \exists \alpha \in \mathbb{N}^m \textit{ such that } \frac{\partial^{|\alpha|} f}{\partial u^\alpha}(0,0) \neq 0.$$

Let ε_1 be in $(0,+\infty)$. Then there exists a proper embedding $\gamma : \mathbb{R} \to \mathbb{R}^n \backslash \{0\}$ such that $\Gamma := \gamma(\mathbb{R})$ is included in B'_{ε_1}, and for any u_0 in $C^*(\mathbb{R}^n \times [0,T]; \mathbb{R}^m)$ and any neighborhood $\mathcal{N}$ of Γ in $\mathbb{R}^n \backslash \{0\}$ there exists u_4 in $C^*(\mathbb{R}^n \times [0,T]; \mathbb{R}^m)$ and ε_4 in $(0,+\infty)$ such that (2.11) *and* (2.12) *hold and*

$$(2.68) \qquad \partial^\alpha u_4 = 0 \textit{ on } (\mathbb{R}^n \backslash \{0\}) \times \{0\} \quad \forall \alpha \in \mathbb{N}^{n+1},$$

$$(2.69) \qquad \partial^\alpha u_4 = \partial^\alpha u_0 \textit{ on } (\mathbb{R}^n \backslash \{0\}) \times \{T\} \quad \forall \alpha \in \mathbb{N}^{n+1}.$$

Now let us assume again that (1.8), (1.9), and $n \geq 4$ hold. Let ε_1 be as in Proposition 2.2. Note that (1.9) implies (2.67), hence we may apply Proposition 2.14. Let $\Gamma = \gamma(\mathbb{R})$ be as in this proposition. Then let u_3 and $\mathcal{N}$ be as in Proposition 2.10. Let u_0 in C^* be such that

$$(2.70) \qquad \partial^\alpha u_0(x,T) = \partial^\alpha u_3(x,0) \quad \forall (x,\alpha) \in (\mathbb{R}^n \backslash \{0\}) \times \mathbb{N}^{n+1}.$$

Finally, let u_4 and ε_4 be as in Proposition 2.14 and $u : \mathbb{R}^n \times \mathbb{R} \to \mathbb{R}^m$ be 2T-periodic with respect to time, equal to u_4 on $\mathbb{R}^n \times [0, T]$, and such that

$$u(x,t) = u_3(x, t-T) \quad \forall (x,t) \in \mathbb{R}^n \times (T, 2T). \tag{2.71}$$

Then (see, in particular, (2.49), (2.68), (2.69), (2.70), and (2.71)) u is continuous on $\mathbb{R}^n \times \mathbb{R}$, of class C^∞ on $(\mathbb{R}^n \backslash \{0\}) \times \mathbb{R}$, and vanishes on $\{0\} \times \mathbb{R}$. Moreover, using (2.9), (2.10), (2.11), and (2.71), we have (2.13). Finally, note that, by (2.10), (2.12), and (2.71), we have (2.14). Since T is an arbitrary positive real number, Theorem 1.4 follows from the following lemma.

LEMMA 2.15. *Let X in $C^0(\mathbb{R}^n \times \mathbb{R}; \mathbb{R}^n)$, vanishing on $\{0\} \times \mathbb{R}$ and T-periodic in time, be such that, for some positive real number ε_0,*

$$((\dot{x} = X(x,t) \text{ and } x(\tau) = 0) \Rightarrow (x(t) = 0 \quad \forall t \geq \tau)) \quad \forall \tau \in \mathbb{R}, \tag{2.72}$$

$$(\dot{x} = X(x,t) \text{ and } |x(0)| < \varepsilon_0) \Rightarrow (x(T) = 0). \tag{2.73}$$

Then 0 is a uniformly locally asymptotically stable point for $\dot{x} = X(x,t)$ and, for some positive real number ε_1,

$$((\dot{x} = X(x,t) \text{ and } |x(\tau)| < \varepsilon_1) \Rightarrow (x(\tau + 2T) = 0)) \quad \forall \tau \in \mathbb{R}. \tag{2.74}$$

Proof. One first notices that, for any positive real number ε, there exists $\delta(\varepsilon)$ in $(0, \min(\varepsilon, \varepsilon_0))$ such that for any $0 \leq s \leq \tau \leq T$ and any maximal solution of $\dot{x} = X(x,t)$, $|x(s)| < \delta(\varepsilon)$ implies that $|x(\tau)| < \varepsilon$. Indeed , if this is not the case, there exist a positive real number ε_2, two sequences of real numbers $(s_n; n \in \mathbb{N})$, $(\tau_n; n \in \mathbb{N})$ with $0 \leq s_n \leq \tau_n \leq T$, and a sequence $(x_n; n \in \mathbb{N})$ of solutions of $\dot{x}_n = X(x_n, t)$ such that $|x(s_n)| \leq 1/n$, $|x(t)| \leq \varepsilon_2$ for all t in $[s_n, \tau_n]$, and $|x(\tau_n)| = \varepsilon_2$. Letting n go to ∞ we get, by the Ascoli theorem, the existence of two real numbers s and τ with $0 \leq s \leq \tau \leq T$, and a solution of $\dot{x} = X(x,t)$ such that $x(s) = 0$ and $|x(\tau)| = \varepsilon_2$, which contradicts (2.73). Then one easily sees that (2.74) holds with $\varepsilon_1 = \delta(\varepsilon_0)$ and that, for any positive real number ε and any real number s, $\dot{x} = X(x,t)$ and $|x(s)| < \delta(\delta(\varepsilon))$ implies that $|x(\tau)| < \varepsilon)$ for all $\tau \geq s$. □

We now prove Proposition 2.14. It follows from (2.67) that there exist c in $\mathbb{R}^m \backslash \{0\}$ and an i in $\mathbb{N}$ such that, with $\bar{f}(x,v) = f(x, vc)$ for $(x,v) \in \mathbb{R}^n \times \mathbb{R}$, $\partial^i \bar{f}/\partial v^i(0,0) \neq 0$. Hence, replacing, if necessary, $\dot{x} = f(x,u)$ by $\dot{x} = \bar{f}(x,v)$, we may assume without loss of generality that $m = 1$. Let p be the integer defined by $\partial^i f/\partial u^i(0,0) = 0$ for all i in $[0, p-1]$, $\partial^p f/\partial u^p(0,0) \neq 0$. Clearly, without loss of generality, we may assume $\partial^p f/\partial u^p(0,0) = e_n$. Let us define f_1 and f_2 by $f(x,u) = (f_1(x,u), f_2(x,u)) \in \mathbb{R}^{n-1} \times \mathbb{R} \simeq \mathbb{R}^n$. Hence, by the Malgrange preparation theorem (see, e.g., [GG, Chap. IV, §2]), there exist an open neighborhood V of (0,0) in $\mathbb{R}^n \times \mathbb{R}$, p maps $a_0, a_1, \ldots, a_{p-1}$ in $C^\infty(V; \mathbb{R})$, and a map θ in $C^\infty(V; \mathbb{R})$ such that

$$f_2(x,u) = \theta(x,u) \left(u^p + \sum_{i=0}^{p-1} a_i(x,u) u^i \right) \quad \forall (x,u) \in V, \tag{2.75}$$

$$\theta(0,0) = 1, \tag{2.76}$$

$$a_i(0,u) = 0 \quad \forall i \in [0,p-1] \;\; \forall u \in \mathbb{R} \;\text{ with }\; (0,u) \in V. \tag{2.77}$$

Let $u_5 : \mathbb{R}^n \longrightarrow \mathbb{R}$ be defined by $u_5(x) = |x|^{1/(p+1)}$. Then, from (2.75), (2.76), and (2.77), we get the existence of ε_5 in $(0, \varepsilon_1/2)$ such that

$$f_2(x, u(x)) \geq |x|^{p/(p+1)}/2 \quad \forall x \in B_{\varepsilon_5}. \tag{2.78}$$

Let $F : B_{\varepsilon_5} \longrightarrow \mathbb{R}^{n-1}$ be defined by $F(x) = f_1(x, u(x))/f_2(x, u(x))$ for all x in B'_{ε_5}, $F(0) = 0$. Then F is continuous, and straightforward computations show that, for some $C_5 > 0$,

$$|F(y_1, z) - F(y_2, z)| \leq C_5 |y_1 - y_2| / |z|^{p/(p+1)} \tag{2.79}$$

for all (y_1, z) in $\mathbb{R}^{n-1} \times \mathbb{R} \simeq \mathbb{R}^n$ and all (y_2, z) in $\mathbb{R}^{n-1} \times \mathbb{R} \simeq \mathbb{R}^n$, with $(y_1, z) \in B_{\varepsilon_5}$ and $(y_2, z) \in B_{\varepsilon_5}$. Note that

$$\int_{-1}^{1} dz/|z|^{p/p+1} < +\infty. \tag{2.80}$$

From (2.79) and (2.80) it follows (see, e.g., [F, Chap. 1, §1, Thms. 1 and 3]) that the Cauchy problem $dy/dz = F(y, z)$, $y(z_0) = y_0$, (y, z) in $\mathbb{R}^{n-1} \times \mathbb{R} \simeq \mathbb{R}^n$, $(y, z) \in B_{\varepsilon_5}$, has locally one and only one solution if (y_0, z_0) is in B_{ε_5}. Let ε_6 be a positive real number such that $dy/dz = F(y, z)$, $y(0) = 0$, $z \in \{-\varepsilon_6, \varepsilon_6\}$, $(y, z) \in B_{\varepsilon_5}$ has one and only one solution. Let $\bar{y}$ be this solution. We choose ε_6 small enough so that there exists a proper embedding γ of $\mathbb{R}$ into $\mathbb{R}^n \backslash \{0\}$ such that $\Gamma := \gamma(\mathbb{R})$ is included in B'_{ε_1} and $\{(\bar{y}(z), z); z \in (0, \varepsilon_6]\}$ is included in Γ. Since Proposition 2.14 is a local result we may assume, without loss of generality, that for some constant M in $(0, +\infty)$

$$|f(x, u)| \leq M \quad \forall (x, u) \in \mathbb{R}^n \times \mathbb{R}^m. \tag{2.81}$$

Note that by (2.78) we have , for z in $\{-\varepsilon_6, \varepsilon_6\}$, $f_2((\bar{y}(z), z), u_5(\bar{y}(z), z)) \geq |z|^{p/p+1}/2$; therefore, the Cauchy problem $dz/dt = f_2((\bar{y}(z), z), u_5(\bar{y}(z), z))$, $z(0) = 0$ has one and only one solution on $\{-\varepsilon_6/M, \varepsilon_6/M\}$ such that $tz(t) > 0$ for all t in $\{-\varepsilon_6/M, \varepsilon_6/M\} \backslash \{0\}$. Hence there exists one and only one ϕ in $C^0(\mathbb{R}^n \times \mathbb{R}; \mathbb{R}^n)$ such that $\partial \phi / \partial t = f(\phi, u_5(\phi))$, $\phi(x, 0) = x$, and, for all (x, τ) in $\mathbb{R}^n \times \mathbb{R}$,

$$(\phi(x, \tau) = 0) \Rightarrow (\phi_n(x, t) \cdot (t - \tau) > 0 \;\text{ if }\; 0 < |t - \tau| \leq \varepsilon_6/M), \tag{2.82}$$

where ϕ_n denotes the last component of ϕ.

Now, let $\mathcal{N}$ be an open neighborhood of Γ in $\mathbb{R}^n \backslash \{0\}$. Let $(d_i; i \in \mathbb{N} \cup \{\infty\})$ be a sequence of maps in $C^1((0, \varepsilon_6]; (0, +\infty))$ such that

$$d_i(z) < d_{i+1}(z), \; d_i(z) < d_\infty(z) \quad \forall (i, z) \in \mathbb{N} \times (0, \varepsilon_6], \tag{2.83}$$

$$\mathcal{N}_i := \{(y, z) \in \mathbb{R}^{n-1} \times (0, \varepsilon_6]; |y - \bar{y}(z)|^2 \leq d_i(z)\} \subset \mathcal{N} \quad \forall i \in \mathbb{N} \cup \{\infty\}, \tag{2.84}$$

$$d'_i(z) > 2C_5 d_i(z)/z^{p/(p+1)} \quad \forall (i, z) \in (\mathbb{N} \cup \{\infty\}) \times (0, \varepsilon_6]. \tag{2.85}$$

The existence of such a sequence can be easily established by letting $d_i(z) = \bar{d}_i(z) \exp\int_0^z 2C_5/\tau^{p/(p+1)}d\tau$ ($\bar{d}_i'(z) > 0$ for all (i,z) in $(\mathbb{N} \cup \{\infty\}) \times (0,\varepsilon_6]$ is equivalent to (2.85)). Let $T_0 = T - (\varepsilon_6/2M)$, $T_i = T - (T - T_0)/2^i$ for all i in $\mathbb{N}\backslash\{0\}$, and $r_i = (\varepsilon_6/2) + (T_i - T_0)/M$ for all i in $\mathbb{N}$. Then we have, with the convention $1/0 = +\infty$, the following lemma.

LEMMA 2.16. *Let i be a nonnegative integer. Then there exists a positive real number δ_i in $(0, 1/i)$ such that for any ε in $(0, +\infty)$ there exists $\tilde{u}$ in $C^\infty(\mathbb{R}^n \times [T_i, T_{i+1}]; \mathbb{R}^m)$ such that*

$$(2.86) \qquad |\tilde{u}(x,t)| \le |x|^{1/p+1} \quad \forall(x,t) \in \mathbb{R}^n \times [T_i, T_{i+1}],$$

$$(2.87) \qquad \partial^\alpha \tilde{u} = 0 \ \text{ on } \ \mathbb{R}^n \times \{T_i, T_{i+1}\} \quad \forall\alpha \in \mathbb{N}^{n+1},$$

$$(2.88) \ (\dot{x} = f(x, \tilde{u}(x,t)), x(T_i) \in (\mathcal{N}_i \cup B_{\delta_i}) \cap B_{r_i}) \Rightarrow (x(T_{i+1}) \in (\mathcal{N}_{i+1} \cup B_\varepsilon) \cap B_{r_{i+1}}).$$

Proof. Using (2.79), (2.81), and (2.85), one has

$$(2.89) \qquad (x \in \mathcal{N}_i \cap B_{r_i} \text{ and } t \in [0, T_{i+1} - T_i]) \Rightarrow (\phi(x,t) \in \mathcal{N}_i \cap B_{r_{i+1}}).$$

Note also that $\phi(0, T_{i+1} - T_i) \in \mathcal{N}_i$ and, therefore, for some δ_i small enough but positive,

$$(2.90) \qquad \phi(B_{\delta_i}, T_{i+1} - T_i) \subset \mathcal{N}_i.$$

Moreover, $\phi(0, [0, T_{i+1} - T_i]) \subset \mathcal{N}_i$, and, therefore, $\varepsilon > 0$ being given, there exists η in $(0, \varepsilon/2)$—depending on i—such that

$$(2.91) \qquad \{\phi(x,s); x \in B_\eta, s \in [0, T_{i+1} - T_i]\} \subset \mathcal{N}_i \cup B_{\varepsilon/2}.$$

Let $u^* \in C^\infty(\mathbb{R}^n; \mathbb{R}^m)$ be equal to 0 on $B_{\eta/2}$ and such that $u^*(x) = u_5(x)$ for all x in $\mathbb{R}^n\backslash B_\eta$, $|u^*(x)| \le |x|^{1/(p+1)}$ for all x in $\mathbb{R}^n$; then, using (2.81), (2.90), and (2.91), we have

$$(2.92) \ (\dot{x} = f(x, u^*(x)), x(T_i) \in (\mathcal{N}_i \cup B_{\delta_i}) \cap B_{r_i}) \Rightarrow \ x(T_{i+1}) \in (\mathcal{N}_i \cup B_{\varepsilon/2}) \cap B_{r_{i+1}}.$$

Finally, let $\tilde{u} : \mathbb{R}^n \times [T_i, T_{i+1}] \to \mathbb{R}^m$ be defined by $\tilde{u}(x,t) = \theta(t)u^*(x)$, where $\theta \in C^\infty([T_i, T_{i+1}]; [0,1])$ is equal to 1 on $[\mu, T_i + T_{i+1} - \mu]$ for some μ in $(0, +\infty)$ and vanishes on a neighborhood of $\{T_i, T_{i+1}\}$. Then $u \in C^\infty(\mathbb{R}^n \times [T_i, T_{i+1}]; \mathbb{R}^m)$ satisfies (2.87) and (2.88). Moreover, if μ is small enough, we have (2.88) from (2.92). □

Let us now end the proof of Proposition 2.14. In Lemma 2.16 we take $\varepsilon = \delta_{i+1}$; we get a map $\tilde{u}$ that we denote $\tilde{u}_i$. Let $\bar{u}_4$ be the map from $\mathbb{R}^n \times [0, T)$ into $\mathbb{R}^m$ that is equal to $\tilde{u}_i$ on $\mathbb{R}^n \times [T_i, T_{i+1}]$ for all nonnegative integers i and vanishes on $\mathbb{R}^n \times [0, T_0]$. This map is of class C^∞ and satisfies

$$(2.93) \qquad |\bar{u}_4(x,t)| \le |x|^{1/(p+1)} \quad \forall(x,t) \in \mathbb{R}^n \times [0, T],$$

$$(2.94) \qquad \partial^\alpha \bar{u}_4 = 0 \text{ on } \mathbb{R}^n \times \{0\} \quad \forall\alpha \in \mathbb{N}^{n+1}.$$

Let $\varepsilon_4 > 0$ be such that

$$(2.95) \qquad (\dot{x} = f(x,0), x(0) \in B_{\varepsilon_4}) \Rightarrow (x(T_0) \in B_{\delta_0} \cap B_{r_0}).$$

Then, using (2.88) and (2.95), we have

$$(2.96) \qquad (\dot{x} = f(x, \bar{u}_4(x,t)), x(0) \in B_{\varepsilon_4}) \Rightarrow (x(T) \in \mathcal{N}_\infty \cup \{0\}).$$

Finally, let $\bar{\theta} \in C^\infty((\mathbb{R}^n \times [0,T])\backslash\{(0,T)\}; [0,1])$ be such that $\bar{\theta}(x,t) = 1$ if $t \leq T - \bar{\mu}(x)$, $\bar{\theta}(x,t) = 0$ if $t \geq T - (\bar{\mu}(x)/2)$, where $\bar{\mu} \in C^0(\mathbb{R}^n\backslash\{0\}; (0,T))$, and let $u_4(x,t) = \bar{\theta}(x,t)\bar{u}_4(x,t) + (1 - \theta(x,t))u_0(x,t)$. Then u_4 is in $C^*(\mathbb{R}^n \times [0,T]; \mathbb{R}^m)$ and satisfies (2.68) and (2.69). Moreover, if $\bar{\mu}(x) \to 0$ as $x \to 0$, (2.12) holds and, if $\bar{\mu}$ is in a small enough neighborhood of 0 in $C^0(\mathbb{R}^n\backslash\{0\}; \mathbb{R})$ for the Whitney C^0-topology (see, e.g., [GG, Chap. II, §3] for a definition), (2.11) follows from (2.96). This ends the proof of Proposition 2.14 and also the proof of Theorem 1.4.

3. Particular control systems.

In this section we show that, for some special types of control systems, the assumption $n \geq 4$ can be removed and the proof can be simplified. Let us first remark that the assumption $n \geq 4$ is used only in Step 2 of §2. Let us also note that, in Steps 2 and 3 of §2, Γ is assumed to be without boundary, but straightforward modifications of the proofs given in these steps show that Propositions 2.7 and 2.10 remain valid if Γ has a boundary, except that for Proposition 2.10 $\mathcal{N}$ is now a neighborhood of $\Gamma\backslash\partial\Gamma$, where $\partial\Gamma$ is the boundary of Γ.

3.1. Systems without drift.

In this section we prove Proposition 1.6. Hence we now have $f(x,u) = \sum_{i=1}^m u_i f_i(x)$. By (1.9) we may assume, without loss of generality, $f_m(x) = e_n$ for all x in $\mathbb{R}^n$ and $f_i(x) \in \mathbb{R}^{n-1} \times \{0\}$ for all (x,i) in $\mathbb{R}^n \times [1, m-1]$. Therefore, our system can be written $\dot{y} = \bar{g}(y,z,v)$, $\dot{z} = w$, where the state is $x = (y,z) \in \mathbb{R}^{n-1} \times \mathbb{R}$ and the control $u = (v,w) \in \mathbb{R}^{m-1} \times \mathbb{R}$. Note that $\bar{g}(y,z,-v) = -\bar{g}(y,z,v)$ for all (y,z,v) in $\mathbb{R}^{n-1} \times \mathbb{R} \times \mathbb{R}^{m-1}$. So Proposition 1.6 is a corollary of the following proposition.

PROPOSITION 3.1. *Let $g \in C^\infty(\mathbb{R}^{n-1} \times \mathbb{R} \times \mathbb{R}^{m-1} \times \mathbb{R}; \mathbb{R}^{n-1})$ and let $\varphi \in C^\infty(\mathbb{R}^{m-1}; \mathbb{R}^{m-1})$ be such that*

$$(3.1) \qquad g(y,z,\varphi(v),-w) = -g(y,z,v,w) \quad \forall (y,z,v,w) \in \mathbb{R}^{n-1} \times \mathbb{R} \times \mathbb{R}^{m-1} \times \mathbb{R},$$

$$(3.2) \qquad g(0,z,0,w) = 0 \quad \forall (z,w) \in \mathbb{R} \times \mathbb{R},$$

$$(3.3) \qquad \varphi(0) = 0.$$

Let Σ' be the control system $\Sigma' : \dot{y} = g(y,z,v,w)$, $\dot{z} = w$, where the state is $x = (y,z) \in \mathbb{R}^{n-1} \times \mathbb{R} \simeq \mathbb{R}^n$ and the control $u = (v,w) \in \mathbb{R}^{m-1} \times \mathbb{R} \simeq \mathbb{R}^m$. Assume that Σ' satisfies the strong jet accessibility rank condition at $(0,0,0,0)$. Then Σ' is locally smoothly stabilizable in small time by means of periodic time-varying feedback law.

Proof. Indeed, let u_0 in $C^\infty(\mathbb{R}^n \times \mathbb{R}; \mathbb{R}^m)$ be such that, with the notations of Step 1 in §2,

$$(3.4) \qquad \partial^\alpha u_0 = 0 \text{ on } (\mathbb{R}^n \times \{0, T/4\}) \cup (\{0\} \times \mathbb{R}^n) \quad \forall \alpha \in \mathbb{N}^{n+1},$$

$$(3.5) \qquad u_0 \circ h \text{ saturates } X \text{ on } \mathbb{R}^n \times (\{0\} \times \mathbb{R}^n) \times (0, T/4)$$

with $X(x,a,s,u) = ((g(y,z,v,w),w),0,1) \in \mathbb{R}^n \times \mathbb{R}^n \times \mathbb{R}$. The existence of u_0 follows again from [Co3, Thm. 1.3]. Let $\bar{u}_0 : \mathbb{R} \times [0,T] \to \mathbb{R}^m$ be defined by (with $\bar{u}_0 = (\bar{v}_0, \bar{w}_0) \in \mathbb{R}^{m-1} \times \mathbb{R}, u_0 = (v_0, w_0) \in \mathbb{R}^{m-1} \times \mathbb{R}$)

$$\bar{u}_0(s,t) = u_0(se_n,t) \quad \forall (s,t) \in \mathbb{R} \times [0,T/4], \tag{3.6}$$

$$\bar{w}_0(s,t) = -w_0(se_n,(T/2)-t) \quad \forall (s,t) \in \mathbb{R} \times [T/4,T/2], \tag{3.7}$$

$$\bar{v}_0(s,t) = (\varphi \circ v_0)(se_n,(T/2)-t) \quad \forall (s,t) \in \mathbb{R} \times [T/4,T/2], \tag{3.8}$$

$$\bar{v}_0(s,t) = 0 \quad \forall (s,t) \in \mathbb{R} \times [T/2,T], \tag{3.9}$$

$$\bar{w}_0(s,t) = \frac{\partial}{\partial t}\left(\frac{s^3}{s^2+\beta(t)}\right) = \frac{-\beta'(t)s^3}{(s^2+\beta(t))^2} \quad \forall (s,t) \in \mathbb{R} \times (T/2,T), \tag{3.10}$$

$$\bar{w}_0(s,T) = 0 \quad \forall s \in \mathbb{R}, \tag{3.11}$$

with

$$\beta(t) = \exp\left(\frac{1}{T-t} - \frac{1}{t-(T/2)}\right) \quad \forall t \in (T/2,T). \tag{3.12}$$

For $\bar{\varepsilon}_0 > 0$ let $\bar{x}_0 : [0,\bar{\varepsilon}_0] \times [0,T] \to \mathbb{R}^n$ be defined by $\partial\bar{x}_0/\partial t(s,t) = f(\bar{x}_0(s,t),\ \bar{u}_0(s,t))$, $\bar{x}_0(s,0) = se_n$. This map is defined on all $[0,\bar{\varepsilon}_0] \times [0,T]$ if $\bar{\varepsilon}_0$ is small enough. Note that by (3.1), (3.7), and (3.8) $\bar{x}_0(s,T/2-t) = \bar{x}_0(s,t)$ for all (s,t) in $[0,\bar{\varepsilon}_0] \times [T/4,T/2]$. In particular, we have $\bar{x}_0(s,T/2) = se_n$ for all s in $[0,\bar{\varepsilon}_0]$ and, therefore, by (3.10), (3.11), and (3.12), $\bar{x}_0(s,t) = s^3e_n/(s^2+\beta(t))$ for all (s,t) in $[0,\bar{\varepsilon}_0] \times (T/2,T)$ and $\bar{x}_0(s,T) = 0$ for all s in $[0,\bar{\varepsilon}_0]$, which, in particular, implies that, with $\bar{x}_0 = (\bar{y}_0, \bar{z}_0) \in \mathbb{R}^{n-1} \times \mathbb{R}$, $\partial\bar{z}_0/\partial s > 0$ on $[0,\bar{\varepsilon}_0] \times [T/2,T)$. Let us remark that, if u_0 is in a small enough neighborhood of 0 in $C^\infty(\mathbb{R}^n \times \mathbb{R}; \mathbb{R}^m)$, we have $\partial\bar{z}_0/\partial s > 0$ on $[0,\bar{\varepsilon}_0] \times [0,T/2]$. Recalling that Σ satisfies the strong jet accessibility rank condition at (0, 0) we get from (3.4), (3.5), and (3.6) that $(\bar{x}_0(s,\cdot),\bar{u}_0(s,\cdot))$ is supple on $(0,T/4)$ for all s in $(0,\bar{\varepsilon}_0]$ if $\bar{\varepsilon}_0$ is still small enough. Then, using Appendix A—with $T_1 = 0$, $T_2 = T/32$, $T_3 = T/16$, $T_4 = T/8$, and $\Lambda = (0,\bar{\varepsilon}_0)$—and [Co3, Thm. 1.3] in a similar way as in Step 1 of §2, we get the existence of u_1 in $C^0(\mathbb{R} \times [0,T]; \mathbb{R}^m)$ of class C^∞ on $(\mathbb{R}\backslash\{0\}) \times [0,T]$, vanishing on $\{0\} \times [0,T]$ and on $\mathbb{R} \times \{T\}$, equal to $\bar{u}_0$ on $(\mathbb{R} \times [T/8,T])\backslash((0,\bar{\varepsilon}_0) \times (T/8,T))$, and such that

$$u_1/s^2 \in L^\infty(([-1,1]\backslash\{0\}) \times [0,\tau]) \quad \forall \tau \in [0,T), \tag{3.13}$$

$$x_1(s,0) = se_n, \tag{3.14}$$

$$\frac{\partial y_1}{\partial s} > 0 \quad \text{on} \quad (0,\bar{\varepsilon}_0] \times [0,T), \tag{3.15}$$

$$(x_1(s,\cdot),u_1(s,\cdot)) \text{ is supple on } (0,T) \quad \forall s \in (0,\varepsilon_1), \tag{3.16}$$

for some ε_1 in $(0,\bar{\varepsilon}_0)$, and where $x_1 = (y_1,z_1) : (0,\varepsilon_0] \times [T/8,T] \to \mathbb{R}^n$ is defined by $\partial x_1/\partial t(s,t) = f(x_1(s,t),u_1(s,t))$, $x_1(s,T) = 0$. Note that by (3.15) $se_n \in \Gamma = \{se_n; s \in (0,\varepsilon_1]\} \to x_1(s,t) \in \mathbb{R}^n \backslash \{0\}$ is an embedding for all t in $[0,T)$. Clearly, there exists $u_2 \in C^*(\mathbb{R}^n \times [0,T];\mathbb{R}^m)$ satisfying (2.15) with u_2 instead of u_1, vanishing on $\mathbb{R}^n \times \{T\}$, and such that $u_2(se_n,t) = u_1(s,t)$ for all (s,t) in $(0,\varepsilon_1] \times [0,T]$. Then, (2.4) holds with $a \in \Gamma$ instead of $|a| \leq \varepsilon_1$ and (2.5) holds with $(0,T)$ instead of $[0,T]$ and with $a \in \Gamma$ instead of $0 < |a| \leq \varepsilon_1$. Note also that, by (3.15), (2.6) holds. All these properties are sufficient to perform Step 3 in §2 if, with the notations of Proposition 2.10, $\mathcal{N}$ is now a neighborhood of $\{se_n; s \in (0,\varepsilon_1)\}$ in $\mathbb{R}^n \backslash \{0\}$. Moreover, using (3.2), one easily sees that the proof of Step 4 in §2 holds for this Γ. In fact, with (3.2), this proof can be simplified slightly. Indeed, let $\gamma \in C^0((0,+\infty);(0,+\infty))$ and let $\tilde{u} \in C^0(\mathbb{R}^n;\{0\} \times [0,+\infty)) \cap C^\infty(\mathbb{R}^n \backslash \{0\};\mathbb{R}^m)$ be such that $\tilde{u}(x) = (0,|x|^{1/p})$ if $|y|^2 \geq \gamma(z)$, $\tilde{u}(0,z) = 0$ if $z \geq 0$. Then one deduces from (3.2) that if $\dot{x} = f(x,\tilde{u}(x))$, $x(0) = 0$, then $x(t) = 0$ for all positive t. Moreover, one easily checks that, if γ is in a small enough neighborhood of 0 in $C^0((0,+\infty);\mathbb{R})$ for the Whitney C^0-topology, there exists $\tilde{\varepsilon}$ in $(0,+\infty), T_0$ in $(0,T)$ and $\mathcal{N}' \subset \mathbb{R}^n \backslash \{0\}$, whose closure is included $\mathcal{N} \cup \{0\}$, such that

$$(\dot{x} = f(x,\tilde{u}(x)), |x(T_0)| \leq \tilde{\varepsilon}) \Rightarrow x(T) \in \mathcal{N}'. \tag{3.17}$$

Then it suffices for one to take u_4 in $C^*(\mathbb{R}^n \times [0,T];\mathbb{R}^m)$ satisfying (2.69), vanishing on $\mathbb{R}^n \times [0,T_0]$, and such that

$$|u_4(x,t)| \leq |u_0(x,t)| + |\tilde{u}(x)| \quad \forall (x,t) \in \mathbb{R}^n \times [0,T], \tag{3.18}$$

$$u_4(x,t) = \tilde{u}(x) \quad \forall (x,t) \in (\mathbb{R}^n \times [T_0,T]) \backslash V, \tag{3.19}$$

where V is a small neighborhood of $(\mathbb{R}^n \backslash \{0\}) \times \{T_0,T\}$ in $(\mathbb{R}^n \backslash \{0\}) \times \mathbb{R}$. □

3.2. Dynamical time-varying stabilization. In this section we prove Proposition 1.6. Let us first note that this proposition is equivalent to the following proposition.

PROPOSITION 1.6*. *Assume that* (1.8) *and* (1.9) *hold for* Σ. *Then the control system*

$$\dot{x} = f(x,u), \quad \dot{y} = v \in \mathbb{R}, \tag{3.20}$$

where the state is $(x,y) \in \mathbb{R}^n \times \mathbb{R}$ *and the control* $(u,v) \in \mathbb{R}^m \times \mathbb{R}$, *is locally smoothly stabilizable in small time by means of periodic time-varying feedback law.*

Let us remark that this last proposition can be, roughly speaking, rephrased in the following manner: If (1.8) and (1.9) hold then Σ can be locally smoothly stabilizable in small time by means of dynamical time-varying feedback law, which increases the dimension of the state space by only 1. Let us also remark that in (3.20) $y \in \mathbb{R}$. If one replaces $\dot{y} = v \in \mathbb{R}$ by $\dot{y} = v \in \mathbb{R}^n$, a shorter proof is given in [Co2]—with less regularity on the feedback law but without assuming (1.9). Let us now prove Proposition 1.6*. Let u_1 be as in Proposition 3.2. By [Co3, Thm. 1.3] there exists u_0 in $C^0(\mathbb{R}^n \times [0,2T];\mathbb{R}^m) \cap C^\infty((\mathbb{R}^n \backslash \{0\}) \times [0,2T];\mathbb{R}^m)$ such that

$$u_0(a,t) = u_1(a,t-T) \quad \forall (a,t) \in \mathbb{R}^n \times [T,2T], \tag{3.21}$$

$$u_0/|a|^2 \in L^\infty(B_1' \times [0,\tau]) \quad \forall \tau \in [0,2T), \tag{3.22}$$

$$u_0 \circ h \text{ saturates } X_0 \text{ on } \mathbb{R}^n \times (\mathbb{R}^n \backslash \{0\}) \times (0,T), \tag{3.23}$$

where in (3.23) we have used the notations of Step 1 in §2. Let, for ε_2 in $(0,+\infty)$, $u_2 : [0,\varepsilon_2] \times [0,2T] \to \mathbb{R}^m$ be defined by

$$u_2(s,t) = u_0(se_n,t) \quad \forall (s,t) \in [0,\varepsilon_2] \times [0,T], \tag{3.24}$$

$$u_2(s,t) = u_1(x_0(s,T), t-T) \quad \forall (s,t) \in [0,\varepsilon_2] \times [T,2T], \tag{3.25}$$

where $x_0 : [0,\varepsilon_2] \times [0,T] \to \mathbb{R}^n$ is defined by $\partial x_0/\partial t(s,t) = f(x_0(s,t), u_0(s,t))$, $x_0(s,0) = 0$. For ε_2 small enough u_2 is well defined. Let $x_2 : [0,\varepsilon_2] \times [0,2T] \to \mathbb{R}^n$ be defined by $\partial x_2/\partial t(s,t) = f(x_2(s,t), u_2(s,t))$, $x_2(s,0) = 0$. Note that, by (1.9) and (3.23), we have, if ε_2 is small enough,

$$(x_2(s,\cdot), u_2(s,\cdot)) \text{ is supple on } (0,T) \quad \forall s \in (0,\varepsilon_2]. \tag{3.26}$$

Let us also remark that, from (2.15), (3.22), (3.24), and (3.25), we have (still for ε_2 small enough)

$$u_2/s^2 \in L^\infty((0,\varepsilon_2] \times [0,\tau]) \quad \forall \tau \in [0,2T). \tag{3.27}$$

Proceeding again as in Step 1 in §2 one can prove that, if we perturb u_2 slightly and in a suitable way, u_3 can be constructed in $C^0([0,\varepsilon_2]\times[0,2T];\mathbb{R}^m) \cap C^\infty((0,\varepsilon_2]\times[0,2T];\mathbb{R}^m)$ such that

$$u_3/s^2 \in L^\infty((0,\varepsilon_2] \times [0,2\tau]) \quad \forall \tau \in [0,2T), \tag{3.28}$$

$$x_3(s,2T) = 0 \quad \forall s \in [0,\varepsilon_2], \tag{3.29}$$

$$(x_3(s,\cdot), u_3(s,\cdot)) \text{ is supple on } (0,2T) \quad \forall s \in (0,\varepsilon_2), \tag{3.30}$$

where $x_3 : [0,\varepsilon_2] \times [0,2T]$ is defined by $\partial x_3/\partial t(s,t) = f(x_3(s,t), u_3(s,t))$, $x_3(s,0) = 0$. Let $v_3 : [0,\varepsilon_2] \times [0,2T] \to \mathbb{R}$ be defined by $v_3 = 0$ on $[0,\varepsilon_2] \times \{0,2T\}$ and

$$v_3(s,t) = \frac{\partial}{\partial t}\left(\frac{s^3}{s^2+\beta(t)}\right) = -\beta'(t)\frac{s^3}{(s^2+\beta(t))^2} \quad \forall (s,t) \in [0,\varepsilon_2] \times (0,2T) \tag{3.31}$$

with $\beta(t) = \exp(2(t-T)/t(2T-t))$ for all t in $(0,2T)$. Let $y_3 : [0,\varepsilon_2] \times [0,2T] \to \mathbb{R}$ be defined by $\partial y_3/\partial t(s,t) = v_3(s,t)$, $y_3(s,0) = s$. By (3.31) we have $y_3(s,t) = s^3/(s^2+\beta(t))$ for all (s,t) in $[0,\varepsilon_2] \times (0,2T)$, $y_3(s,2T) = 0$ for all s in $[0,\varepsilon_2]$. Finally, one just notes that $(|u_3| + |v_3|)/s^2 \in L^\infty((0,\varepsilon_2] \times [0,\tau])$ for all $\tau \in [0,2T)$ and that, for system (3.20),

$$((x_3(s,\cdot), y_3(s,\cdot)),\ (u_3(s,\cdot), v_3(s,\cdot))) \text{ is supple on } (0,2T) \quad \forall s \in (0,\varepsilon_2), \tag{3.32}$$

(3.33) $s \in (0,\varepsilon_2) \to (x_3(s,t), y_3(s,t)) \in \mathbb{R}^n \times (\mathbb{R}\backslash\{0\})$ is an embedding $\forall t \in [0,T)$.

The conclusion then follows as in the above section (note that, with obvious changes of notations, (3.2) is satisfied).

Appendix A. Let Λ be an open subset of $\mathbb{R}^p$ (or a manifold). Let T_1, T_2, T_3, and T_4 be four real numbers such that $T_1 < T_2 < T_3 < T_4$. Let $x \in C^\infty(\Lambda \times [T_1,T_4]; \mathbb{R}^n)$ and $u \in C^\infty(\Lambda \times [T_1,T_4]; \mathbb{R}^m)$ be such that

$$(A.1) \qquad \frac{\partial x}{\partial t} = f(x(\lambda,t), u(\lambda,t)) \quad \forall(\lambda,t) \in \Lambda \times [T_1,T_4],$$

$$(A.2) \qquad (x(\lambda,\cdot), u(\lambda,\cdot)) \text{ is supple on } (T_2,T_3) \quad \forall \lambda \in \Lambda.$$

The goal of this section is to prove the following lemma.

LEMMA A.1. *There exists δ in $C^0(\Lambda; (0,+\infty))$ and a map H in $C^\infty(\omega \times [T_1,T_4]; \mathbb{R}^m)$ with $\omega = \{(\lambda,b) \in \Lambda \times \mathbb{R}^n; |b| < \delta(s)\}$ such that*

$$(A.3) \qquad \textit{Support}\,(H(\lambda,b,\cdot) - u(\lambda,\cdot)) \subset (T_2,T_3) \quad \forall(\lambda,b) \in \omega,$$

$$(A.4) \qquad (\dot{y} = f(y, H(\lambda,b,t)),\ y(T_1) = x(\lambda,T_1)) \Rightarrow (y(\lambda,T_4) = x(\lambda,T_4) + b) \quad \forall(\lambda,b) \in \omega.$$

Proof. Let $P : \Lambda \times \mathbb{C}^\infty([T_1,T_4]; \mathbb{R}^m) \to \mathbb{R}^m$ be defined by $P(\lambda,v) = y(T_4)$ with $\dot{y} = f(y,v(t))$, $y(T_1) = x(\lambda,T_1)$. The map P is defined and of class C^∞ on an open neighborhood of $\{(\lambda,u(\lambda,\cdot)); \lambda \in \Lambda\}$. Moreover, it follows from $(A.2)$ that for any i in $[1,n]$ and any λ in Λ there exists w^i_λ in $C^\infty([T_1,T_4]; \mathbb{R}^m)$, the support of which is included in (T_2,T_3), and, if $(e_1,e_2,\dots,e_n)$ is the usual basis of $\mathbb{R}^n$, $\partial P/\partial v(\lambda,u)\cdot w^i_\lambda = e_i$. For $\bar{\lambda} \in \Lambda$, *let* $\mathcal{O}(\bar{\lambda})$ be an open neighborhood of $\bar{\lambda}$ in Λ whose closure is compact and such that

$$(A.5) \qquad \left|\frac{\partial P}{\partial v}(\lambda,u(\lambda,\cdot))\cdot w^i_{\bar{\lambda}} - e_i\right| \leq (1/2n)^{1/2} \quad \forall(i,\lambda) \in [1,m] \times \mathcal{O}(\bar{\lambda}).$$

The open sets $(\mathcal{O}(\bar{\lambda}); \bar{\lambda} \in \Lambda)$ cover Λ; let $(\varphi_j \in C^\infty(\Lambda; [0,1]); j \in \mathbb{N})$ be a partition of unity associated to this covering:

$$(A.6) \qquad \sum_{j=0}^{+\infty} \varphi_j(\lambda) = 1 \quad \forall \lambda \in \Lambda,$$

$$(A.7) \qquad \forall j \in \mathbb{N} \ \ \exists \lambda_j \in \Lambda \text{ such that Support } (\varphi_j) \subset \mathcal{O}(\lambda_j),$$

$$(A.8) \qquad \forall K \text{ compact } \subset \Lambda \ \ \exists p \text{ such that } \sum_{i=0}^{p} \varphi_j(\lambda) = 1 \quad \forall \lambda \in K.$$

Now, let $\widetilde{P} : \Lambda \times \mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R}^m$ be defined by—with $c = (c_1,c_2,\dots,c_n) \in \mathbb{R}^n$—$\widetilde{P}(\lambda,c) = P(\lambda, u(\lambda,\cdot) + \sum_{i=1}^n \sum_{j=0}^{+\infty} c_i\varphi_j(\lambda)w^i_{\lambda_j})$. Then $\widetilde{P}$ is defined and of class C^∞ on an open neighborhood of $\Lambda \times \{0\}$ in $\Lambda \times \mathbb{R}^n$. Moreover, it follows easily from $(A.5)$

and $(A.6)$ that the vectors $\partial\widetilde{P}/\partial c_i(\lambda, 0)$, $i \in [1,n]$, span all of $\mathbb{R}^n$. Then Lemma A.1 follows from the usual implicit function theorem. □

Appendix B. In this appendix we prove Lemma 3.8. We first prove that Ω_i is a residual subset of Ω if n is at least 3. Let e_n be the last vector of the usual basis of $\mathbb{R}^n$ and let a_n be the last component of $a \in \mathbb{R}^n$. Since Γ can be covered by many countably small compact curves with boundary and since $(0,T)$ is the countable union of the set $[T/k, (k-1)T/k], k \in \mathbb{N}\backslash\{0,1\}$, it suffices to show that for any integer $k \in \mathbb{N}\backslash\{0,1\}$

$$(B.1) \qquad \Omega_i^k := \left\{ v \in \Omega; \frac{\partial x}{\partial a_n}(se_n, t; u_v) \neq 0 \ \forall (s,t) \in \left[\frac{\varepsilon_1}{3}, \frac{2\varepsilon_1}{3}\right] \times \left[\frac{T}{k}, (k-1)\frac{T}{k}\right]\right\}$$

is a residual subset of Γ—perform a suitable diffeomorphism of $\mathbb{R}^n$. Since Ω_i^k is open, it suffices to check that Ω_i^k is dense, which will be proved if one can show that for any (v^*, s^*, t^*) in $\Omega \times (0, \varepsilon_1) \times (0,T)$ there exists an open neighborhood Ω_0^* of v^* and ε in $(0, \text{Min } (s^*, \varepsilon_1 - s^*, t^*, T - t^*))$ such that the open set

$$(B.2)$$
$$\widetilde{\Omega}_0^* = \{v \in \Omega_0^*; \partial x/\partial a_n\,(se_n, t; u_v) \neq 0 \ \forall (s,t) \in [s^* - \varepsilon, s^* + \varepsilon] \times [t^* - \varepsilon, t^* + \varepsilon]\}$$

is dense in Ω_0^*. Let Ω^* be an open neighborhood of v^* included in Ω and, for v in Ω^*, let $y \in C^\infty(B'_\varepsilon \times (0,T); \mathbb{R}^n)$ be defined by $\partial y/\partial t = f(y, v(a,t))$, $y(a,T) = 0$. The linearized control system around $(y(a,\cdot), v(a,\cdot))$ is $\dot{z} = A(a,t)z + B(a,t)w$, where $A(a,t) = \partial f/\partial x(y(a,t), v(a,t))$, $B(a,t) = \partial f/\partial u(y(a,t), v(a,t))$. By (2.48)

$$(B.3) \qquad (y(a,\cdot), v(a,\cdot)) \text{ is supple on } (0,T) \quad \forall a \in B'_{\varepsilon_1}.$$

Let Q be a closed ball of $\mathbb{R}^n \times \mathbb{R}$ centered at (s^*e_n, t^*) such that $Q \subset B'_{\varepsilon_1} \times (0,T)$. By the proof of [INS, Thm. 6.4]—or [G, Chap. 2, §3.8 (B)] and, for more details, [Col, pp. 304–305]; see also [FLMR, Prop. 1.7] for a related result—we know from (B.3) that

$$(B.4) \qquad \frac{\partial z}{\partial t} - A(a,t)z - B(a,t)w = r$$

is algebraically solvable; i.e., there exist an integer q, $(q+1)$ maps $(\mu_i)_{0 \leq i \leq q}$ in $C^\infty(Q; \mathcal{L}(\mathbb{R}^n; \mathbb{R}^n))$, and $(q+1)$ maps $(\nu_i)_{0 \leq i \leq q}$ in $C^\infty(Q; \mathcal{L}(\mathbb{R}^n; \mathbb{R}^m))$ such that, for all r in $C^\infty(Q; \mathbb{R}^n)$, z and w defined by

$$(B.5) \qquad z(a,t) = \sum_{i=0}^{q} \mu_i(a,t) \frac{\partial^i r}{\partial t^i}(a,t), \quad w(a,t) = \sum_{i=0}^{q} \nu_i(a,t) \frac{\partial^i r}{\partial t^i}(a,t)$$

are solutions of (B.4). Note that q, μ_i, and ν_i depend on v but, if Ω^* is a small enough neighborhood of v^*, using the construction of the algebraic inverse given in [Col], we may impose that q is independent of v in Ω^* and that the maps $v \in \Omega^* \to \mu_i \in C^\infty(Q; \mathcal{L}(\mathbb{R}^n; \mathbb{R}^n))$, $v \in \Omega^* \to \nu_i \in C^\infty(Q; \mathcal{L}(\mathbb{R}^n; \mathbb{R}^m))$ are continuous for all i in $[0,q]$. Recall that Q is a *compact* ball; hence the topology on $C^\infty(Q; \mathcal{L}(\mathbb{R}^n; \mathbb{R}^p))$ is the topology in which a net $\{\varphi_\beta\}$ converges to φ if and only if $\{\partial^\alpha \varphi_\beta\}$ converges to $\partial^\alpha \varphi$ uniformly in Q $\forall \alpha \in \mathbb{N}^{n+1}$. Let Q_0 be a closed ball included in the interior of Q and let η in $C^\infty(\mathbb{R}^n \times \mathbb{R}; [0,1])$ be equal to 1 on a neighborhood of Q_0 and such that its support is included in the interior of Q. For a positive integer k and a positive real number M let

$$(B.6)\qquad \Lambda = \left\{ \lambda = (\lambda_0, \lambda_1, \dots, \lambda_k) \in (\mathbb{R}^n)^{k+1} ; \lambda_0 \in B_1, \sum_{i=1}^{k} |\lambda_i|^2 < M \right\}.$$

For λ in Λ we define $\alpha_\lambda \in C^\infty(Q; \mathbb{R}^n)$ by

$$(B.7)\qquad \alpha_\lambda(a,t) = (a_n - s^*)\,\eta(a,t) \sum_{i=0}^{k} (t - t^*)^i \lambda_i$$

and $z_\lambda \in C^\infty(Q; \mathbb{R}^n)$, $w_\lambda \in (Q; \mathbb{R}^m)$ by

$$(B.8)\quad z_\lambda(a,t) = \alpha_\lambda(a,t) + \sum_{i=0}^{q} \mu_i(a,t) \frac{\partial^i r_\lambda}{\partial t^i}(a,t), \quad w_\lambda(a,t) = \sum_{i=0}^{q} \nu_i(a,t) \frac{\partial^i r_\lambda}{\partial t^i}(a,t)$$

with $r_\lambda(a,t) = -\partial\alpha_\lambda/\partial t + A(a,t)\alpha_\lambda(a,t)$. We extend the maps z_λ and w_λ by 0 on $(B'_{\varepsilon_1} \times (0,T)) \backslash Q$ and still denote these extensions by z_λ and w_λ. Then z_λ and w_λ are of class C^∞ on $B'_{\varepsilon_1} \times (0,T)$ and satisfy, on $B'_{\varepsilon_1} \times (0,T)$, $\partial z_\lambda/\partial t(a,t) = A(a,t)z_\lambda(a,t) + B(a,t)w_\lambda(a,t)$. For δ in $(0, +\infty)$ let $v_{\delta,\lambda} = v + \delta w_\lambda \in C^\infty(B'_{\varepsilon_1} \times (0,T); \mathbb{R}^m)$. Let Ω^* be fixed and also let M be fixed. Then, for δ_0 small enough but positive and Ω_0^* a small enough neighborhood of v^*, $v_{\delta,\lambda}$ is in Ω^* for all (δ, v, λ) in $[0,\delta_0] \times \Omega_0^* \times \Lambda$. For δ in $[0,\delta_0]$ and v in Ω_0^* let $G \in C^\infty(B'_{\varepsilon_1} \times (0,T) \times \Lambda; \mathbb{R}^n)$ be defined by $G(a,t,\lambda) = x\left(a,t; u_{v_{\delta,\lambda}}\right)$. Straightforward computations show that, on $Q_0 \times \Lambda$,

$$(B.9)\qquad G(a,t,\lambda) = x(a,t,u_v) + \delta z_\lambda(a,t) + R(a,t,\lambda),$$

where, for some constant C independent of (δ, v) in $[0,\delta_0] \times \Omega_0^*$,

$$(B.10)\qquad \|R\|_{C^2(Q_0\times\Lambda)} \le C\delta^2.$$

Let $G_\lambda(a,t) = G(a,t,b)$ and let $J^1(B'_{\varepsilon_1} \times (0,T); \mathbb{R}^n)$ be the set of 1-jet of mappings from $B'_{\varepsilon_1} \times (0,T)$ to $\mathbb{R}^n$ (see, e.g., [GG, Chap. II, Def. 2.1]) and $\phi : B'_{\varepsilon_1} \times (0,T) \times \Lambda \to J^1(B'_{\varepsilon_1} \times (0,T); \mathbb{R}^n)$ be the map that associates the 1-jet of G_λ at (a,t) with (a,t,λ). Let ε be a positive real number and let W be the submanifold of $J^1(B'_{\varepsilon_1} \times (0,T); \mathbb{R}^n)$ defined by

$$(B.11)\quad W = \left\{ \left(a, t, x(a,t), \frac{\partial x}{\partial a}(a,t) \right) ; (a,t) \in (0, \varepsilon_1 e_n) \times (0,T), \right.$$
$$\left. |a_n - s^*| + |t - t^*| < \varepsilon, \frac{\partial x}{\partial a_n}(a,t) = 0, \right\},$$

where $(0, \varepsilon_1 e_n) = \{\tau\varepsilon_1 e_n ; \tau \in (0,1)\}$. From (B.7) we get

$$(B.12)\quad \frac{\partial z_\lambda}{\partial a_n}(s^* e_n, t^*) = \lambda_0 + \sum_{i=0}^{q} \mu_i(s^*, t^*) \left(\frac{\partial^i}{\partial t^i} \left(-\dot{p}(t) + A(s^* e_n, t^*) p(t) \right) \right) \Bigg|_{t=t^*}$$

with $p(t) = \sum_{i=0}^{k} (t - t^*)^i \lambda_i$. We now choose the mapping v^* for v and denote by A^*, B^*, z^*_λ, ϕ^* the corresponding maps. For λ_0 in B_1 let $d : (0,T) \longrightarrow \mathbb{R}^n$ be the solution of $\dot{d} = A^*(s^* e_n, t)\, d$, $d(t^*) = \lambda_0$. Expanding d near t^* we get

$$(B.13) \qquad d(t) = \lambda_0 + \sum_{i=1}^{k} \lambda_i(\lambda_0)(t - t_i^*)^i + 0\left(|t - t^*|^{k+1}\right).$$

We choose $k > q$ and M such that $\sum_{i=1}^{k} |\lambda_i(\lambda_0)|^2 < M - 1$ for all l_0 in B_1. For $\lambda = (\lambda_0, \lambda_1(\lambda_0), \ldots, \lambda_k(\lambda_0))$ we get that

$$(B.14) \qquad \frac{\partial z^*_\lambda}{\partial a_n}(s^* e_n, t^*) = \lambda_0.$$

Using $(B.9)$, $(B.10)$, and $(B.14)$, we get that, if δ and ε are small enough but positive, ϕ^* is transversal to W; moreover, straightforward computations show that, similarly, if Ω_0^* is a small enough neighborhood of v^*, if δ and ε are small enough but positive, then

$$(B.15) \qquad \phi \text{ is transversal to } W \quad \forall v \in \Omega_0^*.$$

We take such Ω_0^*, ε, and δ. We also require Ω_0^* to be open. From $(B.15)$ and a classical result on transversality (see, e.g., [GG, Chap. II, Cor. 4.7]) we get that, if $v \in \Omega_0^*$, then, for a dense set of λ in Λ,

$$(B.16) \qquad \phi(\cdot, \lambda) \text{ is transversal to } W.$$

But the dimension of $B'_{\varepsilon_1} \times (0,T)$ is $n+1$, the dimension of W is $n^2 + n + 2$, and the dimension of $J^1(B'_\varepsilon \times (0,T); \mathbb{R}^n)$ is $n^2 + 3n + 1$. Hence, if $n \geq 3$, $(B.16)$ implies that the image of $\phi(\cdot, \lambda)$ does not meet W. Since $v_{\delta,\lambda} \longrightarrow v$ as $\lambda \longrightarrow 0$, we get that $\widetilde{\Omega}_0^*$ defined by $(B.2)$ is dense in Ω_0^*, and so Ω_i is a residual subset of Ω.

We now prove that Ω_0 is a residual subset of Ω if n is at least 3. One proceeds as for Ω_0 with the following modifications:

- in $(B.1)$ and $(B.2)$ one replaces $\partial x / \partial a_n$ by x;
- in $(B.7)$ one suppresses $(a_n - s^*)$;
- $J^1(B'_{\varepsilon_1} \times (0,T); \mathbb{R}^n)$ is replaced by $J^0(B'_{\varepsilon_1} \times (0,T); \mathbb{R}^n)$ and ϕ associates the 0-jet of G_λ at (a,t) with (a,t,λ);
- W is now submanifold of $J^0(B'_{\varepsilon_1} \times (0,T); \mathbb{R}^n)$ defined by

$$W = \{(a, t, x(a,t)) ; (a,t) \in (0, \varepsilon_1 e_n) \times (0,T); |a_n - s^*| + |t - t^*| < \varepsilon; x(a,t) = 0\};$$

- in $(B.14)$ one replaces $\partial z^* / \partial a_n$ by z^*;
- the dimension of W is 2 and the dimension of $J^0(B'_{\varepsilon_1} \times (0,T); \mathbb{R}^n)$ is $2n+1$.

We finally prove that Ω_1 is a residual subset of Ω if n is at least 4. One again proceeds as for Ω_i but with the following modifications. One first notices that it suffices to prove that for any (s_1^*, s_2^*) in $(0, \varepsilon_1 e_n)$ with $s_1^* \neq s_2^*$, any v^* in Ω, and any t^* in $(0,T)$ there exists ε in $(0, +\infty)$, an open neighborhood Ω_0^* of v^* such that if $\widetilde{\Omega}_0^*$ is the set of v in Ω_0^* satisfying for all s_1 in $[s_1^* - \varepsilon, s_1^* + \varepsilon]$, all s_2 in $[s_2^* - \varepsilon, s_2^* + \varepsilon]$, and all t in $[t^* - \varepsilon, t^* + \varepsilon]$ $x(s_1 e_n, t; u_v) \neq x(s_2 e_n, t; u_v)$, then

$$(B.17) \qquad \widetilde{\Omega}_0^* \text{ is dense in } \Omega_0^*.$$

Note that $\widetilde{\Omega}_0^*$ is open. Let $\bar{\varepsilon}$ be a positive real number such that the intersection of $[s_1^* - 2\bar{\varepsilon}, s_1^* + 2\bar{\varepsilon}]$ with $[s_2^* - 2\bar{\varepsilon}, s_2^* + 2\bar{\varepsilon}]$ is empty, $[s_1^* - 2\bar{\varepsilon}, s_1^* + 2\bar{\varepsilon}]$ and $[s_2^* - 2\bar{\varepsilon}, s_2^* + 2\bar{\varepsilon}]$ are included in $(0, \varepsilon_1)$, and $[t^* - 2\bar{\varepsilon}, t^* + 2\bar{\varepsilon}]$ is included in $(0,T)$. Let

$$(B.18) \qquad Q = \left\{(a,t) \in B'_{\varepsilon_1} \times (0,T); |a - s_1^* e_n|^2 + |t - t^*|^2 \leq 4\bar{\varepsilon}^2\right\},$$

$$(B.19) \qquad Q_0 = \left\{(a,t) \in B'_{\varepsilon_1} \times (0,T); |a - s_1^* e_n|^2 + |t - t^*|^2 \leq \bar{\varepsilon}^2\right\}.$$

Now we replace $(B.7)$ by $\alpha_\lambda(a,t) = \eta(a,t) \sum_{i=0}^k (t - t^*)^i \lambda_i$ and define G in $C^\infty(B'_{\varepsilon_1} \times B'_{\varepsilon_1} \times (0,T) \times \Lambda; \mathbb{R}^n)$ by $G(a_1, a_2, t, \lambda) = x(a_1, t; u_{v_{\delta,\lambda}}) - x(a_2, t; u_{v_{\delta,\lambda}})$, and ϕ is now the map from $B'_{\varepsilon_1} \times B'_{\varepsilon_1} \times (0,T) \times \Lambda$ to $J^0(B'_{\varepsilon_1} \times B'_{\varepsilon_1} \times (0,T); \mathbb{R}^n)$ that associates (a_1, a_2, t, λ) the 0-jet of $G(\cdot,\cdot,\cdot,\lambda)$ at (a_1, a_2, t). Computations similar to those of the proof of Lemma B.8 show that if M is large enough, Ω_0^* is a small enough open neighborhood of v^*, and δ and ε are small enough but positive, then $(B.15)$ holds again with

$$(B.20) \qquad W = ((s_1^* - \varepsilon) e_n, (s_1^* + \varepsilon) e_n) \times ((s_2^* - \varepsilon) e_n, (s_2^* + \varepsilon) e_n) \times (t^* - \varepsilon, t^* + \varepsilon) \times \{0\}.$$

Since the sum of the dimensions of W and $(B'_{\varepsilon_1} \times B'_{\varepsilon_1} \times (0,T))$ is less than the dimension of $J^0(B_{\varepsilon'_1} \times B'_{\varepsilon_1} \times (0,T); \mathbb{R}^n)$ if (and only if) $n \geq 4$ we again get $(B.17)$ by again using [GG, Chap. II, Cor. 4.7].

Appendix C. The goal of this appendix is to prove Lemma 2.12. To simplify the notations we first perform a change of variables. Let $\phi : \mathbb{R}^n \times (0,1] \to \mathbb{R}^n \times [0,T)$ be defined by $\phi(\widehat{y}, \widehat{t}) = (y(\widehat{y}, \widehat{t}), T(1 - \widehat{t}))$, where, if we denote by y_n the last component of $y \in \mathbb{R}^n$, $\partial y / \partial \widehat{t} = -TA(y_n, T(1 - \widehat{t}))\, y$, $y(\widehat{y}, 1) = \widehat{y}$. The domain of definition of ϕ is an open subset D of $\mathbb{R}^n \times (0,1]$ that contains $\mathbb{R}^n \times \{1\}$. Note that D contains $\{0\} \times \mathbb{R} \times (0,1]$ and $\phi((0,\widehat{s}), \widehat{t}) = ((0,\widehat{s}), T(1 - \widehat{t}))$ for all $(\widehat{s}, \widehat{t})$ in $\mathbb{R} \times (0,1]$. Note also that ϕ is a diffeomorphism of class C^∞ between D and $\phi(D)$. By pulling back the time-varying control system $dy/dt = F(y,t,u)$ with ϕ we get a time-varying control system that we denote by $d\widehat{y}/d\widehat{t} = \widehat{F}(\widehat{y}, \widehat{t}, u)$. One has $\widehat{F}(0, \widehat{s}, \widehat{t}, 0) = 0$ for all $(\widehat{s}, \widehat{t})$ in $\mathbb{R} \times (0,1]$. Let, for $\widehat{s}$ in $\mathbb{R}$ and $\widehat{t}$ in $(0,1]$, $\widehat{A}(\widehat{s}, \widehat{t}) = \partial \widehat{F} / \partial \widehat{y}((0,\widehat{s}), \widehat{t}, 0)$ and $\widehat{B}(\widehat{s}, \widehat{t}) = \partial \widehat{F} / \partial u((0,\widehat{s}), \widehat{t}, 0)$. One easily checks that $\widehat{A} = 0$ and, using (2.64), we have

$$(C.1) \qquad \operatorname{Span}\left\{\frac{\partial^i \widehat{B}}{\partial \widehat{t}^i}(\widehat{s}, \widehat{t}) w; \omega \in \mathbb{R}^m, i \geq 0\right\} = \mathbb{R}^n \quad \forall (\widehat{s}, \widehat{t}) \in \mathbb{R} \times (0,1].$$

Note also that, since D contains a neighborhood of $(\mathbb{R}^n \times \{1\}) \cup (\{0\} \times \mathbb{R} \times (0,1])$ in $\mathbb{R}^n \times (0,1]$, there exists g in $C^\infty(\mathbb{R}^n \times (0,1] \times \mathbb{R}^m; \mathbb{R}^n)$ such that $g = \widehat{F}$ on a neighborhood of $(\mathbb{R}^n \times \{1\}) \cup (\{0\} \times \mathbb{R} \times (0,1])$. Hence Lemma 2.12 is proved if one can show the following proposition.

PROPOSITION C.1. *Let* $g : \mathbb{R}^n \times (0,1] \times \mathbb{R}^m \to \mathbb{R}^n, (x,t,u) \to g(x,t,u)$ *be such that*

$$(C.2) \qquad g \in C^\infty(\mathbb{R}^n \times (0,1] \times \mathbb{R}^m; \mathbb{R}^n),$$

$$(C.3) \qquad g((0,s),t,0) = 0 \quad \forall (s,t) \in \mathbb{R} \times (0,1],$$

$$\frac{\partial g}{\partial x}((0,s),t,0)=0 \quad \forall (s,t)\in \mathbb{R}\times(0,1], \tag{C.4}$$

$$\operatorname{Span}\left\{\frac{\partial^i B}{\partial t^i}(s,t)w; i\geq 0, w\in\mathbb{R}^m\right\}\supset \mathbb{R}^{n-1}\times\{0\} \quad \forall (s,t)\in\mathbb{R}\times(0,1] \tag{C.5}$$

with $B(s,t)=\partial g/\partial u((0,s),t,0)$. *Then, for any* ε *in* $C^0(\mathbb{R}\times(0,1];(0,+\infty))$, *there exist* u *in* $C^\infty(Q\times(0,1];\mathbb{R}^m)$ *with* $Q=\{a=(b,s)\in\mathbb{R}^{n-1}\times\mathbb{R}\simeq\mathbb{R}^n; |b|\leq 1\}$ *and* $x\in C^\infty(Q\times(0,1];\mathbb{R}^n)$ *such that*

$$|u(a,t)|\leq\varepsilon(s,t) \quad \forall(a,t)\in Q\times(0,1], \tag{C.6}$$

$$|x(a,t)-(0,s)|\leq\varepsilon(s,t) \quad \forall(a,t)\in Q\times(0,1], \tag{C.7}$$

$$\frac{\partial x}{\partial t}(a,t)=g(x(a,t),t,u(a,t)) \quad \forall(a,t)\in Q\times(0,1], \tag{C.8}$$

$$u((0,s),t)=0 \quad \forall(s,t)\in Q\times(0,1], \tag{C.9}$$

$$x((0,s),t)=(0,s) \quad \forall(s,t)\in Q\times(0,1], \tag{C.10}$$

$$a\in Q\rightarrow x(a,t)\in\mathbb{R}^n \textit{ is an embedding of } Q \textit{ into } \mathbb{R}^n \quad \forall t\in(0,1]. \tag{C.11}$$

Let us prove Proposition C.1. For a C^∞-submanifold M of $\mathbb{R}^p$, which has a boundary and is of dimension p, we define a topology on $C^\infty(M;\mathbb{R}^q)$ in the same way as we defined our topology on $C^\infty(\mathcal{O};\mathbb{R}^q)$ in Step 1 in §2, where $\mathcal{O}$ is an open subset of $\mathbb{R}^p$: ε and A that appear in this definition are now in $C^0(M;(0,+\infty))$ instead of $C^0(\mathcal{O};(0,+\infty))$. Let us emphasize that this topology on $C^\infty(M;\mathbb{R}^q)$ is quite different from the topology induced on $C^\infty(M;\mathbb{R}^q)$ by the topology on $C^\infty(\overset{\circ}{M};\mathbb{R}^q)$. Our first lemma used to prove Proposition C.1 is the following.

LEMMA C.2. *Assume* (*C*.2) *and* (*C*.3). *Then there exist an open neighborhood* Ω *of* 0 *in* $C^\infty(Q\times(0,1];\mathbb{R}^m)$ *and a continuous map* $X:\Omega\rightarrow C^\infty(Q\times(0,1];\mathbb{R}^m)$ $u\rightarrow X(u)=x$ *such that* (*C*.8) *holds for all* u *in* Ω *and, for all* u *in* Ω *and all* $a=(b,s)$ *in* Q,

$$(u(a,t)=0 \quad \forall t\in(0,1])\Rightarrow(X(u)(a,t)=(0,s) \quad \forall t\in(0,1]). \tag{C.12}$$

Note that if g is in $C^\infty(\mathbb{R}^n\times[0,1]\times\mathbb{R}^m;\mathbb{R}^m)$ then Lemma C.2 follows directly from the classical theorems on existence and smoothness—with respect to time, parameters (a), and initial data—of the solution to the Cauchy problem (see, e.g., [Ha, Chap. V]) applied to $\dot{x}=g(x,t,u(a,t)), x(a,0)=(0,s)$. When g is only in $C^\infty(\mathbb{R}^n\times(0,1]\times\mathbb{R}^m;\mathbb{R}^m)$ one just needs to modify slightly the proof of these theorems. Let us limit ourselves to showing how to modify the usual proof of the existence of a solution to the Cauchy problem in order to get a solution to (*C*.8) and (*C*.10). For η in $C^0(\mathbb{R}\times(0,1];(0,1])$ let E be the space of maps x in $C^0(Q\times(0,1];\mathbb{R}^n)$ such that $|x(a,t)-(0,s)|\leq\eta(s,t)$ for all (a,t) in $Q\times(0,1]$. We define a metric d on E by

$d(x_1,x_2) = \text{Sup}\{\eta(s,t)\,|x_1(a,t)-x_2(a,t)|\,;(a,t)\in Q\times(0,1]\}$. Note that (E,d) is a complete metric space. For u in $C^0(Q\times(0,1];\mathbb{R}^m)$ and x in E let $T_u(x):Q\times(0,1]\to\mathbb{R}^n$ be defined by $T_u(x)(a,t)=(0,s)+\int_0^t g(x(a,\tau),\tau,u(a,\tau))d\tau$. Then straightforward computations show the existence of η and δ in $C^0(\mathbb{R}\times(0,1];(0,1])$ such that, if u is in $\Omega_0 := \{u\in C^\infty(Q\times(0,1];\mathbb{R}^m)\,;|u(a,t)|\le\lambda(s,t)\ \forall(a,t)\in Q\times(0,1]\}$, then $T_u(x)$ is defined on $Q\times(0,1]$ for all x in E and, moreover, for all x_1 and x_2 in E, $T_u(x_1)\in E$, and $d(T_u(x_1),T_u(x_2))\le d(x_1,x_2)/2$. Hence, for any u is in Ω_0, T_u has a unique fix point; this fix point is a solution to $(C.8)$ and $(C.10)$.

We now assume that the assumptions of Proposition C.1 hold. Let ε be in $C^\infty(\mathbb{R}\times(0,1];(0,+\infty))$. We are going to construct u in Ω satisfying $(C.6)$ and $(C.9)$ such that $(C.7)$ and $(C.11)$ hold with $x=X(u)$. (Note that $(C.8)$ holds for $x=X(u)$ and that $(C.10)$ for $x=X(u)$ follows from $(C.9)$ and $(C.12)$.) Let $v\in C^\infty((0,1];[0,1])$ be such that $v(t)=\exp-(1/(t-(1/(i+2))))$ for all integers i and for all t in $(1/(i+2),2/(2i+3)]$. Let Λ be the set of sequences $\lambda=(\lambda_i;i\in\mathbb{N})$ of maps in $C^\infty(\mathbb{R};(0,1])$. For λ in Λ we defined two maps $w_\lambda\in C^\infty(\mathbb{R}\times(0,1];[0,1])$ and $u_\lambda\in C^\infty(Q\times(0,1];\mathbb{R}^m)$ by $w_\lambda(s,t)=\lambda_i^2(s)v(t)$ if $t\in(1/(i+2),1/(i+1)]$, $u_\lambda(a,t)=w_\lambda(s,t)B(s,t)^*(b,0)$ if $t\in(1/(i+2),1/(i+1)]$, where $B(s,t)^*\in\mathcal{L}(\mathbb{R}^n;\mathbb{R}^m)$ is the transpose of $B(s,t)$. Note that $(C.9)$, with $u=u_\lambda$, is satisfied. We will say that a property P holds if $\lambda(\in\Lambda)$ is small enough if there exists a sequence $(\Lambda_i;i\in\mathbb{N})$ of neighborhoods of 0 in $C^\infty(\mathbb{R};\mathbb{R})$ such that, if $\lambda\in\Lambda$ satisfies $\lambda_i\in\Lambda_i$ for all i in $\mathbb{N}$, then P holds. For example, for λ small enough $u_\lambda\in\Omega$, where Ω is as in Lemma C.2, so for λ small enough $x_\lambda := X(u_\lambda)$ is defined. Note also that for any sequence $(\Lambda_i;i\in\mathbb{N})$ of neighborhoods of 0 in $C^\infty(\mathbb{R};\mathbb{R})$ there exists $\lambda\in\Lambda$ such that $\lambda_i\in\Lambda_i$ for all $i\in\mathbb{N}$. Therefore, Proposition C.1 is proved if one can show that, for λ small enough, $(C.6)$, $(C.7)$, and $(C.11)$ with $u=u_\lambda$ and $x=x_\lambda$ are satisfied. For simplicity let us write u,w, and x for u_λ,w_λ, and x_λ. Clearly $(C.6)$ is satisfied if λ is small enough. Moreover, X is continuous and, by $(C.12)$, $X(0)(a,t)=(0,s)\ \forall(a,t)\in Q\times(0,1]$; so, if λ is small enough, $(C.7)$ holds. It only remains to prove that, if λ is small enough, $(C.11)$ holds.

Let $\overline{x}:Q\times[0,1]\to\mathbb{R}^m$ be defined by $\overline{x}(a,t)=(0,s)+\int_0^t B(s,\tau)u(a,\tau)d\tau$. For λ small enough $\overline{x}$ is well defined and belongs to $C^\infty(Q\times[0,1];\mathbb{R}^m)$. Our next lemma is as follows.

LEMMA C.3. *There exists $C_1\in C^0(\mathbb{R}\times(0,1];(0,+\infty))$ such that, if λ is small enough, then, for all (a,t) in $Q\times(0,1]$,*

$$(C.13)\qquad \left|\frac{\partial x}{\partial a}-\frac{\partial\overline{x}}{\partial a}\right|(a,t)\le\int_0^t C_1(s,\tau)\left(w(s,\tau)^2+\left(\frac{\partial w}{\partial s}\right)^2(s,\tau)\right)d\tau.$$

The proof of this lemma follows easily from $(C.12)$, $(C.13)$, $(C.18)$, and usual estimates on solutions of differential equations. We omit it.

Let $M\in C^\infty(\mathbb{R}\times(0,1];\mathcal{L}(\mathbb{R}^{n-1};\mathbb{R}^{n-1}))$ and $N\in C^\infty(\mathbb{R}\times(0,1];\mathcal{L}(\mathbb{R}^{n-1};\mathbb{R}))$ be such that $\overline{x}(a,t)=(M(s,t)b,s+N(s,t)b)$. Note that $\overline{x}(a,t)=\int_0^t B(s,\tau)B^*(s,\tau)(b,0)d\tau+(0,s)$; so M and N exist, and, moreover, $M(s,t)=M^*(s,t)$ for all (s,t) in $\mathbb{R}\times(0,1]$ and $b\cdot(M(s,t)b)\ge0$ for all (b,s,t) in $\mathbb{R}^{n-1}\times\mathbb{R}\times(0,1]$, where $\cdot$ denotes the scalar product in $\mathbb{R}^{n-1}$. Let μ be positive real number. Clearly, for λ small enough,

$$(C.14)\qquad |M(s,t)|+\left|\frac{\partial M}{\partial s}(s,t)\right|+|N(s,t)|+\left|\frac{\partial N}{\partial s}(s,t)\right|\le\mu\quad\forall(s,t)\in\mathbb{R}\times(0,1]$$

and by $(C.13)$ we have, still for λ small enough,

$$(C.15)\qquad \left|\frac{\partial x}{\partial a}(a,t)-\frac{\partial\overline{x}}{\partial a}(a,t)\right|\le\mu\quad\forall(a,t)\in Q\times(0,1].$$

Let us write $x(a,t) = (y(a,t), z(a,t)) \in \mathbb{R}^{n-1} \times \mathbb{R}$. Note that

$$(C.16)\qquad \frac{\partial \overline{x}}{\partial a}(a,t)(b',s') = \left(M(s,t)b' + s'\frac{\partial M}{\partial s}(s,t)b, s' + s'\frac{\partial N}{\partial s}(s,t)b + N(s,t)b'\right).$$

Taking μ small enough and using $(C.14)$, $(C.15)$, and $(C.16)$ we get that, if λ is small enough, $|\partial z/\partial s(a,t) - 1| \leq 1/2$ and, therefore, for any b in $\mathbb{R}^{n-1}$ with $|b| \leq 1$ and any t in $[0,1]$, the map $s \in \mathbb{R} \to z((b,s),t) \in \mathbb{R}$ is a diffeomorphism of $\mathbb{R}$ onto $\mathbb{R}$. Let σ in $C^\infty(Q \times (0,1]; \mathbb{R})$ be such that $z((b, \sigma(a,t)), t) = s$ for all (a,t) in $Q \times (0,1]$. Note that, if λ is small enough, we have for all (a,t) in $Q \times (0,1]$,

$$(C.17)$$
$$\left|\frac{\partial z}{\partial b}((b,\sigma(a,t)),t)\right| \leq 2\left\{\left|\frac{\partial x}{\partial a}((b,\sigma(a,t)),t) - \frac{\partial \overline{x}}{\partial a}((b,\sigma(a,t)),t)\right| + |N(\sigma(a,t),t)|\right\}.$$

Clearly, it suffices to prove that, for λ small enough,

$$(C.18)\qquad b \in B^{n-1} \to y^*(b,s,t) \in \mathbb{R}^{n-1} \text{ is an embedding } \quad \forall (s,t) \in \mathbb{R} \times (0,1],$$

where $B^{n-1} = \{b \in \mathbb{R}^{n-1}; |b| \leq 1\}$, $y^*(b,s,t) = y((b, \sigma((b,s),t)),t)$. Using Lemma C.3, $(C.16)$, and $(C.17)$ one gets the existence of $C_2 \in C^0(\mathbb{R} \times (0,1]; (0,+\infty))$ such that, if λ is small enough and with $\sigma = \sigma((b,s),t) = \sigma(a,t)$,

$$(C.19)\qquad \left|\frac{\partial y^*}{\partial b}(b,s,t) - M(\sigma,t)\right| \leq \int_0^t C_2(\sigma,\tau)\left(w^2(\sigma,\tau) + \left(\frac{\partial w}{\partial s}\right)^2(\sigma,\tau)\right)d\tau$$

for all (a,t) in $Q \times (0,1]$. Let us assume, for the moment, the following lemma.

LEMMA C.4. *For any $K \in C^0(\mathbb{R} \times (0,1]; (0,+\infty))$ then, if λ is small enough, we have for all (b', s, t) in $\mathbb{R}^{n-1} \times \mathbb{R} \times (0,1]$,*

$$(C.20)\qquad b' \cdot (M(s,t)b') \geq |b'|^2 \int_0^t K(s,\tau)\left(w^2(s,\tau) + \left(\frac{\partial w}{\partial s}\right)^2(s,\tau)\right)d\tau.$$

From Lemma C.4 we get that, if λ is small enough,

$$(C.21)\qquad b' \cdot \frac{\partial y^*}{\partial b}(b,s,t)b' > 0 \quad \forall (b',b,s,t) \in (\mathbb{R}^{n-1}\backslash\{0\}) \times B^{n-1} \times \mathbb{R} \times (0,1].$$

Note that $(C.21)$ implies $(C.18)$. Indeed, $(C.21)$ implies that $\partial y^*/\partial b(b,s,t)$ is invertible for all (b,s,t) in $B^{n-1} \times \mathbb{R} \times (0,1]$ and that, for all (b_1, b_2, s, t) in $B^{n-1} \times B^{n-1} \times \mathbb{R} \times (0,1]$ with $b_1 \neq b_2$, the real valued function $\tau \in [0,1] \to y^*(\tau b_2 + (1-\tau)b_1, s, t) \cdot (b_2 - b_1)$ is increasing, which implies that for all (s,t) in $\mathbb{R} \times (0,1]$, $b \in B^{n-1} \to y^*(b,s,t)$ is one-to-one.

Now we need only to prove Lemma C.4. Let us assume, for the moment, the following lemma.

LEMMA C.5. *For any integer i, there exist δ_i in $C^0(\mathbb{R}; (0,+\infty))$ such that, for all (b,s,t) in $\mathbb{R}^{n-1} \times \mathbb{R} \times [1/(i+2), 1/(i+1)]$,*

$$(C.22)\qquad \int_{1/(i+2)}^t |B^*(s,\tau)(b,0)|^2 v(\tau)d\tau \geq \delta_i(s)|b|^2 \int_{1/(i+2)}^t v^2(\tau)d\tau.$$

Let $K_i(s) = \operatorname{Max}\{K(s,t); t \in [1/(i+2), 1/(i+1)]\}$; then, if for all integer i, $\lambda_i^2(s) + 4\left(d\lambda_i/ds\right)^2(s) \leq \delta_i(s)/K_i(s)$ for all s in $\mathbb{R}$, $(C.20)$ follows from $(C.22)$.

Now we need only to prove Lemma C.5. Clearly, it suffices to prove that for any $(\bar{b}, \bar{s}, i) \in (\mathbb{R}^{n-1}\backslash\{0\}) \times \mathbb{R} \times \mathbb{N}$ there exists a neighborhood V of $(\bar{b}, \bar{s}, 1/(i+2))$ in $(\mathbb{R}^{n-1}\backslash\{0\}) \times \mathbb{R} \times [1/(i+2), 1/(i+1)]$ such that

$$(C.23) \qquad \int_{1/(i+2)}^{t} |B^*(s,\tau)(b,0)|^2 v(\tau) d\tau \geq \int_{1/(i+2)}^{t} v^2 d\tau$$

for all (b,s,t) in V. It follows from $(C.5)$ that there exists an integer p such that

$$(C.24)$$
$$\frac{\partial^j}{\partial t^j} \left|B^*(\bar{s},t)(\bar{b},0)\right|^2_{|_{t=1/(i+2)}} = 0 \quad \forall j \in [0,p-1], \ \frac{\partial^p}{\partial t^p} \left|B^*(\bar{s},t)(\bar{b},0)\right|^2_{|_{t=1/(i+2)}} \neq 0.$$

From $(C.24)$ and the Malgrange preparation theorem (see, e.g., [GG, Chap. IV, §2]) it follows that there exist p maps $(\theta_j; 0 \leq j \leq p-1)$ in $C^\infty(\mathbb{R}^{n-1} \times \mathbb{R}; \mathbb{R})$, a compact neighborhood W of $(\bar{b}, \bar{s}, 1/(i+2)$ in $\mathbb{R}^{n-1} \times \mathbb{R} \times \mathbb{R}$, and a positive real number μ_1 such that, with $t_i = 1/(i+2)$, $|B^*(s,t)(b,0)|^2 \geq \mu_1 |(t-t_i)^p + \sum_{j=0}^{p-1} \theta_j(b,s)\,(t-t_i)^j|$ for all (b,s,t) in W and, therefore, since W is compact, there exists a positive real number μ_2 such that, for all (b,s,t) in W, $|B^*(s,t)(b,0)|^2 \geq \mu_1\mu_2((t-t_i)^p + \sum_{j=0}^{p-1} \theta_j(b,s)(t-t_i)^j)^2$. So Lemma C.5 is a consequence of the following lemma.

LEMMA C.6. *Let R be a positive real number and let p be an integer. Then there exists a positive real number t_0 such that*

$$(C.25) \qquad \int_0^t \left(\tau^p + \sum_{j=0}^{p-1} C_j \tau^j\right)^2 \exp(-1/\tau) d\tau \geq \int_0^t \exp(-2/\tau) d\tau$$

for all t in $[0,t_0]$ and sequence of p real numbers $(C_j; j \in [0,p-1])$ with $|C_j| \leq R$ for all j in $[0,p-1]$.

Proof. Let $\mathcal{C}$ be the set of sequences C of real numbers $(C_i; i \in [0,p-1])$ such that $|C_i| \leq M$ for all i in $[0,p-1]$. For C in $\mathcal{C}$ let $P_C(t) = t^p + \sum_{j=0}^{p-1} C_j t^j$. Let us first notice that, for all $C \in \mathcal{C}$,

$$(C.26) \quad \int_0^t P_C(\tau)^2 \exp(-1/\tau) d\tau \geq (\exp(-3/(2t))) \int_{2t/3}^t P_C(\tau)^2 d\tau \quad \forall t \in (0,+\infty).$$

Note that $\int_{2t/3}^t P_C(\tau)^2 d\tau$ is an algebraic function of t and $(C_i; i \in [0,p-1])$ which is positive if $t > 0$. Hence, by the Lojasiewicz inequality (see, e.g., [BCR, Chap. 2, §6.7]), there exist an integer N and a real number δ such that $\int_{2t/3}^t P_C(\tau)^2 d\tau \geq \delta t^N$ for all (C,t) in $\mathcal{C} \times [0,1]$, which, with $(C.26)$, gives Lemma C.6. □

SAMPLED-DATA AND DISCRETE-TIME H_2 OPTIMAL CONTROL*

H. L. TRENTELMAN† AND A. A. STOORVOGEL‡

Abstract. This paper deals with the sampled-data H_2 optimal control problem. Given a linear time-invariant continuous-time system, the problem of minimizing the H_2 performance over all sampled-data controllers with a fixed sampling period can be reduced to a pure discrete-time H_2 optimal control problem. This discrete-time H_2 problem is always singular. Motivated by this, in this paper we give a treatment of the discrete-time H_2 optimal control problem in its full generality. The results we obtain are then applied to the singular discrete-time H_2 problem arising from the sampled-data H_2 problem. In particular, we give conditions for the existence of optimal sampled data controllers. We also show that the H_2 performance of a continuous-time controller can always be recovered asymptotically by choosing the sampling period sufficiently small. Finally, we show that the optimal sampled-data H_2 performance converges to the continuous-time optimal H_2 performance as the sampling period converges to zero.

Key words. sampled-data, lifting technique, discrete-time, H_2 optimal control, algebraic Riccati equation, small sampling periods

1. Introduction.

Recently, much attention has been paid to H_2 and H_∞ optimal control of linear systems using sampled-data control (see [6], [7], [12], [2], [4] and [5], [11], [10], [1], [3], [17], [21]). For a given a continuous-time plant, a sampled-data controller consists of the cascade connection of an A/D converter, a discrete-time controller, and a D/A converter. The A/D device converts the continuous-time measured plant output into a discrete-time signal, which is used as an input for the discrete-time controller. The discrete-time controller generates a discrete-time output signal, which, in turn, is converted into a continuous-time signal that is used as a control input for the continuous-time plant.

Apart from a control input and a measurement output, the plant under consideration has an exogenous input and an output to be controlled. The quality of a controller is given by the performance of the corresponding closed-loop system. This performance measures the influence of the exogenous input on the output to be controlled. In the present paper, we will take the H_2 performance of the closed-loop system as performance measure.

In contrast to the H_∞ performance of a sampled-data control system, which in analogy with the pure continuous-time context can simply be defined as the norm of the input/output operator between the exogenous inputs and the outputs to be controlled, it is not clear from the outset how one should define the H_2 performance of a sampled-data control system. One definition was proposed in [6]: the H_2 performance of the closed-loop system is the number obtained by applying at each input channel a Dirac distribution and by taking the sum of integral squares of the resulting outputs. Of course, this definition exactly mimics the one that is common in the pure continuous-time context.

In our opinion, a more natural definition was given independently in [12] and [2]. In these references, the crucial observation is that the closed-loop system resulting from a sampled data controller, albeit time-varying, is in fact a periodic system, with period equal to the sampling period. It is then argued that, instead of applying impulsive inputs at time $t = 0$, one should in fact apply these inputs at all time instances between 0 and the sampling period and take the mean of the integral squares of the resulting outputs. This leads to an H_2 performance measure that captures the essential features of a sampled-data closed-loop system more satisfactorily. For a given continuous-time plant, the sampled-data H_2 optimal control problem is then to minimize the H_2 performance of the closed-loop system over all internally stabilizing sampled-data controllers with a fixed sampling period. It is the latter problem that will be studied in this paper.

It was shown in [12] and [2] (see also [4]) that the sampled-data H_2 optimal control problem can be reduced to a pure discrete-time H_2 optimal control problem in the following way. First one defines an auxiliary time-invariant discrete-time system (involving the parameters of the original continuous-time plant and the given sampling period). Next, one expresses the sampled-data H_2 performance in terms of the 'normal' H_2 performance of the closed-loop system obtained by interconnecting the auxiliary discrete-time system and the discrete-time controller defining the sampled-data controller. Thus, the sampled-data H_2 optimal control problem under consideration is completely resolved once the auxiliary discrete-time H_2 problem is. This procedure makes use of the so-called *lifting technique* (see [20], [1], [3])

Now it turns out that the auxiliary discrete-time H_2 problem obtained in this way *is always a singular problem*: the direct feedthrough matrix from the exogenous input to the measurement output is always equal to 0. Apart from this, in the auxiliary discrete-time system the direct feedthrough matrix from the control input to the output to be controlled is in general not injective. (Note that, in general, an H_2 optimal control problem is called *regular* if the direct feedthrough matrix from the control input to the output to be controlled is injective, and the direct feedthrough matrix from the exogenous input to the measurement output is surjective. If the problem is not regular it is called *singular*.) In [12], this difficulty is partly removed by introducing an additional noise on the sampled measured output signal and by assuming the corresponding feedthrough matrix to be surjective.

In the present paper we want to consider the completely general formulation of the sampled-data H_2 problem. As a starting point we will take the auxiliary discrete-time H_2 problem derived in [12] and [2]. As noted, this problem is inherently singular. To our best knowledge, no resolution of the discrete-time singular H_2 optimal is known in the literature. Therefore, a substantial part of this paper is devoted to a study of the completely general discrete-time H_2 problem (no assumptions on the direct feedthrough matrices, no assumptions on the absence of zeros on the unit circle). We will describe a complete resolution to this problem, including a characterization of the optimal performance, and necessary *and* sufficient conditions for the existence of optimal controllers. The expression for the optimal performance is different from the one that might be expected in analogy with the continuous-time case (see [15]). Due to the fact that the role of the imaginary axis is taken over by the unit circle, for the discrete-time H_2 performance to be finite it is no longer required that the closed-loop transfer matrix is *strictly proper*. Intuitively, this enlarges the class of admissible controllers and yields a smaller optimal performance.

We will apply our results on the discrete-time H_2 optimal control problem to the sampled-data H_2 problem by simply applying them to the auxiliary discrete-time system derived in [12] and [2]. Our expression for the optimal sampled-data H_2 performance will be an immediate consequence of these results. We will, however, also be interested in conditions guaranteeing the existence of optimal sampled-data controllers. Our results on the general discrete-time H_2 problem give such conditions in terms of the auxiliary discrete-time system, but we will reformulate these conditions *in terms of the original continuous-time plant.* Preliminary results in that direction were also found in [12].

Obviously, the sampled-data H_2 optimal performance is a function of the sampling period. An important question is: what happens if the sampling period tends to zero. In particular, we will answer the following two questions. First, if we control the original continuous-time plant by a "normal" continuous-time compensator, is it then possible to recover this performance asymptotically by using a sampled-data controller with sufficiently small sampling period? This question was also studied for the H_∞ performance and for the H_2 performance à la Chen and Francis in [6]. A second, related, question that we will answer is: does the optimal sampled-data H_2 performance converge to the optimal continuous-time H_2 performance as the sampling period decreases to zero?

The outline of this paper is as follows. In §2 we will define the sampled-data H_2 optimal control problem and recall the main results of [12] and [2]. We will also introduce some notation and recall the notions of left-invertibility and right-invertibility of linear systems, zeros, and their most important state space interpretations. In §3 we deal with the discrete-time H_2 optimal control problem. In this section we will not yet treat the completely general case but make some assumptions on the absence of zeros on the unit circle. In §4, the results of §3 will be extended to derive a resolution of the general discrete-time H_2 optimal control problem. Then, in §5, we return to the sampled-data context and apply the results of §§3 and 4 to the sampled-data H_2 optimal control problem. In particular, we will derive conditions in terms of the original continuous-time plant that guarantee the existence of optimal controllers for the sampled-data H_2 problem. Finally, in §6 we study the aforementioned questions regarding the behavior of the (optimal) performance as the sampling period tends to zero.

2. Problem formulation. Consider a continuous-time, linear, time-invariant, finite-dimensional plant Σ. Let Σ have inputs d and u and outputs z and y, where d is an exogenous input, u is a control input, z is an output to be controlled, and y is a measured output. We want to control Σ by means of sampled-data feedback control. We take a fixed $\Delta > 0$, called the *sampling period.* From the measured output y we obtain a discrete-time signal $\bar{y} = \{y_k\}$ defined by $y_k := (S_\Delta y)_k$, where S_Δ denotes the sampling operator defined by $(S_\Delta y)_k := y(k\Delta)$. This discrete-time signal is taken as input for a discrete-time, linear, time-invariant, finite-dimensional compensator Γ_{dis}. The latter compensator generates a discrete-time signal $\bar{u} = \{u_k\}$, which, in turn, yields a (piecewise constant) continuous-time input signal u for the plant by defining $u(t) := (H_\Delta \bar{u})(t)$, where H_Δ is the hold operator defined by $(H_\Delta \bar{u})(t) := u_k$ $(t \in [k\Delta, (k+1)\Delta))$. This type of feedback control is depicted in Fig. 1.

If we control the system Σ by means of a sampled-data controller with sampling period Δ, then the resulting closed-loop system will no longer be time-invariant. In [12] and [2] the following definition of H_2 performance in the context of sampled-data control is proposed. First, it is observed that the closed-loop system resulting from a sampled-data controller with sampling period Δ is always a time-varying, Δ-periodic

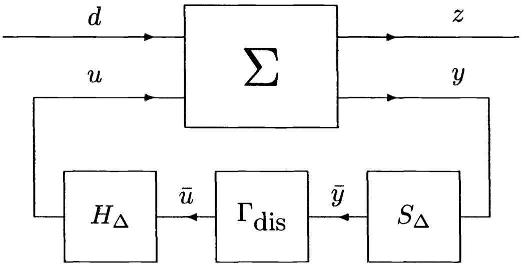

FIG. 1.

system. Then, for Δ-periodic systems the notion of H_2 performance is defined as follows. Suppose we have a finite-dimensional, time-varying, Δ-periodic system $\Sigma_{\rm per}$ described by

$$z(t) = \int_0^t G(t,s)d(s)ds. \tag{2.1}$$

It is argued in [12] and [2] that a natural way to define the H_2 performance of (2.1) is

$$\|\Sigma_{\rm per}\|_2^2 := \frac{1}{\Delta}\int_0^\Delta \mathrm{tr} \int_s^\infty G^{\rm T}(t,s)G(t,s)dt\,ds. \tag{2.2}$$

Next, if Γ is a sampled-data controller with sampling period Δ, the associated performance is defined as $J_{\Sigma,\Delta}(\Gamma) := \|\Sigma \times \Gamma\|_2^2$, the H_2 performance of the (Δ-periodic) closed-loop system $\Sigma \times \Gamma$. The sampled-data H_2 problem is then to minimize, for a fixed sampling period Δ, the performance criterion $J_{\Sigma,\Delta}(\Gamma)$ over all internally stabilizing sampled-data controllers Γ with sampling period Δ. It was shown in [12] and [2] that this problem can be reduced to a discrete-time 'normal' H_2 optimal control problem. To be specific, let the plant Σ be given by the equations

$$\begin{aligned} \dot{x}(t) &= Ax(t) + Bu(t) + Ed(t)\ , \\ y(t) &= C_1x(t)\ , \\ z(t) &= C_2x(t) + D_2u(t)\ , \end{aligned} \tag{2.3}$$

with $x(t) \in \mathbb{R}^n$, $u(t) \in \mathbb{R}^m$, $d(t) \in \mathbb{R}^r$, $y(t) \in \mathbb{R}^p$, and $z(t) \in \mathbb{R}^q$. It will be a standing assumption in this paper that (A, B) is stabilizable and that (C_1, A) is detectable, both with respect to $\mathcal{C}^- := \{s \in \mathcal{C} \mid \Re e\ s < 0\}$. Introduce a finite-dimensional linear time-invariant discrete-time system Σ_Δ:

$$\begin{aligned} x_{k+1} &= A_\Delta x_k + B_\Delta u_k + E_\Delta d_k\ , \\ y_k &= C_1 x_k\ , \\ z_k &= C_{2,\Delta}x_k + D_{2,\Delta}u_k\ , \end{aligned} \tag{2.4}$$

where we define

$$A_\Delta := e^{\Delta A}, \quad B_\Delta := \int_0^\Delta e^{tA}dtB,$$

where E_Δ is any matrix satisfying

$$E_\Delta E_\Delta^{\mathrm{T}} = \int_0^\Delta e^{tA} E E^{\mathrm{T}} e^{tA^{\mathrm{T}}}\, dt, \tag{2.5}$$

and where $C_{2,\Delta}$ and $D_{2,\Delta}$ are matrices satisfying

$$(C_{2,\Delta} \quad D_{2,\Delta})^{\mathrm{T}} (C_{2,\Delta} \quad D_{2,\Delta}) = \int_0^\Delta e^{t\underline{A}^{\mathrm{T}}} (C_2 \quad D_2)^{\mathrm{T}} (C_2 \quad D_2)\, e^{t\underline{A}}\, dt. \tag{2.6}$$

Here we have denoted

$$\underline{A} := \begin{pmatrix} A & B \\ 0 & 0 \end{pmatrix}. \tag{2.7}$$

Let $\boldsymbol{\Delta}$ denote the set of sampling periods for which either (A_Δ, B_Δ) is not stabilizable or (C_1, A_Δ) is not detectable, both with respect to the open unit disc $\{z \in \mathcal{C} \mid |z| < 1\}$. It is well known [13], [8] that if (A, B) is stabilizable and (C_1, A) is detectable, then every bounded subset of $\mathbb{R}^+$ contains only finitely many elements of $\boldsymbol{\Delta}$. We will restrict ourselves to sampling periods that are not in $\boldsymbol{\Delta}$. The plant Σ is controlled using sampled-data controllers $\Gamma := H_\Delta \Gamma_{\mathrm{dis}} S_\Delta$, with Γ_{dis} given by the equations

$$\begin{aligned} w_{k+1} &= K w_k + L y_k\ , \\ u_k &= M w_k + N y_k\ . \end{aligned} \tag{2.8}$$

Let us denote by $J_{\Sigma_\Delta}(\Gamma_{\mathrm{dis}})$ the discrete-time H_2 performance of the closed-loop system $\Sigma_\Delta \times \Gamma_{\mathrm{dis}}$, i.e., the value $\sum_k \mathrm{tr}\ (G_k G_k^{\mathrm{T}})$, where $\{G_k\}$ denotes the pulse response of the closed-loop system. The main result of [12] and [2] is the following:

THEOREM 2.1. *Assume that $\Delta \notin \boldsymbol{\Delta}$. Then there exists a sampled-data controller Γ with sampling period Δ such that the closed-loop system $\Sigma \times \Gamma$ is internally stable. The sampled-data controller $\Gamma = H_\Delta \Gamma_{\mathrm{dis}} S_\Delta$ internally stabilizes Σ if and only if the discrete-time controller Γ_{dis} internally stabilizes Σ_Δ. Furthermore, for every such controller we have*

$$J_{\Sigma,\Delta}(\Gamma) = \frac{1}{\Delta} \int_0^\Delta \int_0^{\Delta - s} \mathrm{tr}\ \left(C_2 e^{tA} E E^{\mathrm{T}} e^{tA^{\mathrm{T}}} C_2^{\mathrm{T}} \right) dt\, ds + \frac{1}{\Delta} J_{\Sigma_\Delta}(\Gamma_{\mathrm{dis}}).$$

We shall use this theorem as a starting point and study in this paper the discrete-time H_2 optimal control problem for the discrete-time system Σ_Δ given by (2.4). This H_2 problem is inherently singular, due to the fact that the direct feedthrough matrix from the disturbance input to the measured output is always equal to zero.

We conclude this section by introducing some notation and recalling some basic concepts. In this paper, any given continuous-time system $\dot{x} = Ax + Bu, y = Cx + Du$ or discrete-time system $x_{k+1} = Ax_k + Bu_k, y_k = Cx_k + Du_k$ will be denoted simply by (A, B, C, D). It will be clear from the context which interpretation we have in mind. For any such system, the *system matrix* is defined as the first-order polynomial matrix

$$P(s) = \begin{pmatrix} sI - A & -B \\ C & D \end{pmatrix}.$$

If the underlying system is discrete-time, we will rather use the indeterminate z instead of s. For a real rational matrix R, its *normal rank*, normrank R, is defined as the rank of R as a matrix with entries in the field of real rational functions. It is well known that normrank $R = \max_\sigma$ rank $R(\sigma)$. A *zero* of the system (A, B, C, D) is any complex number λ with the property that rank $P(\lambda) <$ normrank P. The system (A, B, C, D) is called left-invertible (right-invertible) if its transfer matrix $G(s) = C(sI - A)^{-1}B + D$ is a left-invertible (right-invertible) rational matrix. Assuming that $A \in \mathbb{R}^{n\times n}$, $B \in \mathbb{R}^{m\times n}$, and $C \in \mathbb{R}^{p\times n}$ we have that (A, B, C, D) is left-invertible (right-invertible) if and only if its system matrix has normal rank $n + m$ $(n + p)$.

If $M \in \mathbb{R}^{n\times n}$ and $\mathcal{L}$ is a subspace of $\mathbb{R}^n$, then $\langle M \mid \mathcal{L}\rangle$ will denote the smallest M-invariant subspace containing $\mathcal{L}$. The largest M-invariant subspace contained in $\mathcal{L}$ will be denoted by $\langle \mathcal{L} \mid M\rangle$. In particular, given (A, B, C, D), the reachable subspace is equal to $\langle A \mid \operatorname{im} B\rangle$ and the unobservable subspace is equal to $\langle \ker C \mid A\rangle$.

Given the system (A, B, C, D), we define *the weakly unobservable subspace* $\mathcal{V}$ to be the smallest subspace $\mathcal{L}$ of $\mathbb{R}^n$ with the property that there exists $F \in \mathbb{R}^{m\times n}$ such that $(A + BF)\mathcal{L} \subset \mathcal{L}$ and $(C + DF)\mathcal{L} = 0$ (see [14]). In addition, *the controllability subspace* $\mathcal{R}$ of (A, B, C, D) is defined as follows:

$$\mathcal{R} := \langle A + BF \mid \mathcal{V} \cap B \ker D\rangle,$$

for any F such that $(A + BF)\mathcal{V} \subset \mathcal{V}$ and $(C + DF)\mathcal{V} = 0$ (any such F yields the same $\mathcal{R}$). It was shown in [14] that the system (A, B, C, D) is left-invertible if and only if $\ker B \cap \ker D = 0$ and $\mathcal{V} \cap B \ker D = 0$. Note that $\mathcal{V} \cap B \ker D = 0$ if and only if $\mathcal{R} = 0$.

Finally, the set of zeros of (A, B, C, D) can be shown to be equal to $\sigma(A + BF \mid \mathcal{V}/\mathcal{R})$, for any F such that $(A + BF)\mathcal{V} \subset \mathcal{V}$ and $(C + DF)\mathcal{V} = 0$. Here, $A + BF \mid \mathcal{V}/\mathcal{R}$ is the quotient map of $A + BF \mid \mathcal{V}$ modulo $\mathcal{R}$ (see, e.g., [19]).

3. The discrete-time H_2 problem: No zeros on the unit circle. In this section we shall consider the discrete-time H_2 problem. Consider the finite-dimensional, linear, time-invariant, discrete-time system Σ_{dis} given by the equations

$$\begin{aligned} x_{k+1} &= Ax_k + Bu_k + Ed_k\,, \\ y_k &= C_1x_k \qquad\quad\; + D_1d_k\,, \\ z_k &= C_2x_k + D_2u_k\,. \end{aligned} \tag{3.1}$$

There will be no assumptions on the direct feedthrough matrices D_1 and D_2. In the present section, however, we will have assumptions on the absence of system zeros on the unit circle in the complex plane: it will be assumed that (A, B, C_2, D_2) and (A, E, C_1, D_1) do not have zeros on the unit circle $|z| = 1$. In the next section we will drop these assumptions and treat the completely general case. Of course, it will be a standing assumption that (A, B) is stabilizable and that (C_1, A) is detectable, both with respect to the open unit disc.

We will consider discrete-time controllers Γ_{dis} given by (2.8). For any internally stabilizing controller Γ_{dis}, let $J_{\Sigma_{\text{dis}}}(\Gamma_{\text{dis}})$ be its H_2 performance. Denote by J^* the optimal performance, i.e., the infimum over all internally stabilizing controllers Γ_{dis}.

For a given matrix M, we will denote by M^+ its Moore–Penrose inverse. The solution of the discrete-time H_2 optimal control problem centers around the following two algebraic Riccati equations:

$$P = A^{\mathrm{T}}PA + C_2^{\mathrm{T}}C_2 - (C_2^{\mathrm{T}}D_2 + A^{\mathrm{T}}PB)(D_2^{\mathrm{T}}D_2 + B^{\mathrm{T}}PB)^+(D_2^{\mathrm{T}}C_2 + B^{\mathrm{T}}PA), \tag{3.2}$$

$$Q = AQA^{\mathrm{T}} + EE^{\mathrm{T}} - (AQC_1^{\mathrm{T}} + ED_1^{\mathrm{T}})(D_1D_1^{\mathrm{T}} + C_1QC_1^{\mathrm{T}})^+(D_1E^{\mathrm{T}} + C_1QA^{\mathrm{T}}). \tag{3.3}$$

For any real symmetric matrix P, we shall denote

$$D_P := (D_2^{\mathrm{T}} D_2 + B^{\mathrm{T}} P B)^{\frac{1}{2}}, \tag{3.4}$$

$$C_P := D_P^{+}(D_2^{\mathrm{T}} C_2 + B^{\mathrm{T}} P A). \tag{3.5}$$

Note that, since for any matrix $M \geq 0$ we have $(M^{\frac{1}{2}})^{+} = (M^{+})^{\frac{1}{2}}$, we have $D_P^{+} C_P = (D_2^{\mathrm{T}} D_2 + B^{\mathrm{T}} P B)^{+}(D_2^{\mathrm{T}} C_2 + B^{\mathrm{T}} P A)$. If, in addition, P is a real symmetric solution of (3.2), then $C_P^{\mathrm{T}} C_P = A^{\mathrm{T}} P A - P + C_2^{\mathrm{T}} C_2$. Note also that D_P is symmetric by definition. Finally, since im $(D_2^{\mathrm{T}} C_2 + B^{\mathrm{T}} P A) \subset$ im D_P, we have $D_P C_P = D_2^{\mathrm{T}} C_2 + B^{\mathrm{T}} P A$. (Note that it is a property of the Moore–Penrose inverse that MM^{+} is the orthogonal projection onto im M.)

The following is a corrected and slightly extended version of a theorem from [14]. A proof can be given along the lines of the proof of [14, Thm. 18].

THEOREM 3.1. *Consider the system (A, B, C_2, D_2) together with the algebraic Riccati equation* (3.2). *The following two statements are equivalent* :

(i) *(A, B) is stabilizable and (A, B, C_2, D_2) has no zeros on the unit circle $|z| = 1$,*

(ii) *Equation* (3.2) *has a real symmetric solution P with the following property: there exists a matrix F_1 such that*

$$|\sigma(A - BD_P^{+} C_P + B(I - D_P^{+} D_P) F_1)| < 1. \tag{3.6}$$

Furthermore, if P satisfies this condition, it is the unique real symmetric solution of (3.2) *for which this condition holds. In addition, P is positive semidefinite and is in fact the largest real symmetric solution of* (3.2).

Next we consider the dual algebraic Riccati equation (3.3). For any real symmetric matrix Q, denote

$$D_Q := (D_1 D_1^{\mathrm{T}} + C_1 Q C_1^{\mathrm{T}})^{\frac{1}{2}}, \tag{3.7}$$

$$E_Q := (AQC_1^{\mathrm{T}} + ED_1^{\mathrm{T}}) D_Q^{+}. \tag{3.8}$$

By dualizing the previous theorem, the corresponding result on the Riccati equation (3.3) can be found:

THEOREM 3.2. *Consider the system (A, E, C_1, D_1) together with the algebraic Riccati equation* (3.3). *The following two statements are equivalent* :

(i) *(C_1, A) is detectable and (A, E, C_1, D_1) has no zeros on the unit circle $|z| = 1$.*

(ii) *Equation* (3.3) *has a real symmetric solution Q with the following property: there exists a matrix K_1 such that*

$$|\sigma(A - E_Q D_Q^{+} C_1 + K_1(I - D_Q D_Q^{+}) C_1)| < 1. \tag{3.9}$$

Furthermore, if Q satisfies this condition, it is the unique real symmetric solution of (3.3) *for which this condition holds. In addition, Q is positive semidefinite and is in fact the largest real symmetric solution of* (3.3).

In the remainder of this section we will always denote by P and Q the largest real symmetric solution of (3.2) and (3.3), respectively. Now we will state the main result of this section:

THEOREM 3.3. *Consider the system* (3.1). *Assume that (A, B) is stabilizable and (C_1, A) is detectable. Assume that (A, B, C_2, D_2) and (A, E, C_1, D_1) have no zeros on the unit circle. Then we have the following:*

(i)

$$J^* = \mathrm{tr}\,(E^{\mathrm{T}}PE) + \mathrm{tr}\,(C_PQC_P^{\mathrm{T}}) - \mathrm{tr}\,((D_PN^*D_Q)(D_PN^*D_Q)^{\mathrm{T}}), \tag{3.10}$$

where N^* is defined by

$$N^* := -(D_P^+)^2(D_PC_PQC_1^{\mathrm{T}} + B^{\mathrm{T}}PED_1^{\mathrm{T}})(D_Q^+)^2. \tag{3.11}$$

(ii) *There exists an optimal controller, i.e., an internally stabilizing controller Γ^*_{dis} such that $J_{\Sigma_{\mathrm{dis}}}(\Gamma^*_{\mathrm{dis}}) = J^*$. One such optimal controller is given by the following "construction":*

(a) *Choose a state feedback matrix F such that $|\sigma(A+BF)| < 1$ and $C_P + D_PF = 0$.*

(b) *Choose an output injection matrix G such that $|\sigma(A+GC_1)| < 1$ and $E_Q + GD_Q = 0$.*

(c) *Define $\Gamma^*_{\mathrm{dis}} = (K^*, L^*, M^*, N^*)$ by choosing N^* given by (3.11), and by choosing $K^* := A + BF + GC_1 - BN^*C_1$, $L^* := BN^* - G$, and $M^* := F - N^*C_1$.*

In the remainder of this section we shall prove this theorem. In addition to the system Σ_{dis}, consider the system $\Sigma_{\mathrm{dis},P}$ given by the equations

$$\begin{aligned} x_{k+1} &= Ax_k + Bu_k + Ed_k\,, \\ y_k &= C_1x_k + D_1d_k, \\ z_k &= C_Px_k + D_Pu_k\,, \end{aligned} \tag{3.12}$$

with P the largest real symmetric solution of the algebraic Riccati equation (3.2). The following basic lemma can be proven by a standard completion-of-the-squares argument:

LEMMA 3.4. *For every compensator $\Gamma_{\mathrm{dis}} = (K, L, M, N)$ we have Γ_{dis} internally stabilizes Σ_{dis} if and only if Γ_{dis} internally stabilizes $\Sigma_{\mathrm{dis},P}$. For any such compensator we have*

$$J_{\Sigma_{\mathrm{dis}}}(\Gamma_{\mathrm{dis}}) = \mathrm{tr}\,(E^{\mathrm{T}}PE) + 2\mathrm{tr}\,(D_1^{\mathrm{T}}N^{\mathrm{T}}B^{\mathrm{T}}PE) + J_{\Sigma_{\mathrm{dis},P}}(\Gamma_{\mathrm{dis}}). \tag{3.13}$$

In addition to $\Sigma_{\mathrm{dis},P}$ we consider the system $\Sigma_{\mathrm{dis},P,Q}$ defined by

$$\begin{aligned} x_{k+1} &= Ax_k + Bu_k + E_Qd_k\,, \\ y_k &= C_1x_k + D_Qd_k, \\ z_k &= C_Px_k + D_Pu_k\,, \end{aligned} \tag{3.14}$$

with Q the largest real symmetric solution of the dual algebraic Riccati equation (3.3). It is clear that the H_2 performance of a given compensator Γ_{dis} applied to Σ_{dis} is equal to the H_2 performance of the dual compensator $\Gamma^{\mathrm{T}}_{\mathrm{dis}} := (K^{\mathrm{T}}, M^{\mathrm{T}}, L^{\mathrm{T}}, N^{\mathrm{T}})$ applied to the dual system $\Sigma^{\mathrm{T}}_{\mathrm{dis}}$. By applying Lemma 3.4 to the dual system $\Sigma^{\mathrm{T}}_{\mathrm{dis},P}$ and the dual compensator $\Gamma^{\mathrm{T}}_{\mathrm{dis}}$ we thus arrive at the following theorem:

THEOREM 3.5. *For every compensator $\Gamma_{\mathrm{dis}} = (K, L, M, N)$ we have : Γ_{dis} internally stabilizes Σ_{dis} if and only if Γ_{dis} internally stabilizes $\Sigma_{\mathrm{dis},P,Q}$. For any such compensator we have*

$$\begin{aligned} J_{\Sigma_{\mathrm{dis}}}(\Gamma_{\mathrm{dis}}) = \mathrm{tr}\,(E^{\mathrm{T}}PE) + \mathrm{tr}\,(C_PQC_P^{\mathrm{T}}) + 2\mathrm{tr}\,(D_1^{\mathrm{T}}N^{\mathrm{T}}B^{\mathrm{T}}PE) \\ + 2\mathrm{tr}\,(C_PQC_1^{\mathrm{T}}N^{\mathrm{T}}D_P^{\mathrm{T}}) + J_{\Sigma_{\mathrm{dis},P,Q}}(\Gamma_{\mathrm{dis}}). \end{aligned}$$

Now note that in the above formula the first two terms do not depend on the compensator Γ_{dis}. The remaining three terms do depend on the compensator. Also note that in the closed-loop system $\Sigma_{\text{dis},P,Q} \times \Gamma_{\text{dis}}$ the direct feedthrough matrix from the disturbance input to the output to be controlled is equal to $D_P N D_Q$. As a consequence, $J_{\Sigma_{\text{dis},P,Q}}(\Gamma_{\text{dis}}) \geq \text{tr }((D_P N D_Q)(D_P N D_Q)^{\mathrm{T}})$, with equality if and only if the transfer matrix $G_{P,Q,\Gamma_{\text{dis}}}(z)$ of the closed-loop system $\Sigma_{\text{dis},P,Q} \times \Gamma_{\text{dis}}$ is equal to the constant matrix $D_P N D_Q$. It thus follows immediately from Theorem 3.5 that

LEMMA 3.6. *For every internally stabilizing compensator* $\Gamma_{\text{dis}} = (K, L, M, N)$ *we have*

$$J_{\Sigma_{\text{dis}}}(\Gamma_{\text{dis}}) \geq \text{tr }(E^{\mathrm{T}}PE) + \text{tr }(C_P Q C_P^{\mathrm{T}}) + 2\text{tr }(D_1^{\mathrm{T}} N^{\mathrm{T}} B^{\mathrm{T}} PE)$$

$$+ 2\text{tr }(C_P Q C_1^{\mathrm{T}} N^{\mathrm{T}} D_P^{\mathrm{T}}) + \text{tr }((D_P N D_Q)(D_P N D_Q)^{\mathrm{T}}),$$

with equality if and only if $G_{P,Q,\Gamma_{\text{dis}}}(z) = D_P N D_Q$.

This lemma shows that, in order to minimize $J_{\Sigma_{\text{dis}}}(\Gamma_{\text{dis}})$ over all internally stabilizing compensators, we should do the following:

(i) First minimize the quadratic matrix function

$$\Phi(N) := 2\text{tr }(D_1^{\mathrm{T}} N^{\mathrm{T}} B^{\mathrm{T}} PE) + 2\text{tr }(C_P Q C_1^{\mathrm{T}} N^{\mathrm{T}} D_P^{\mathrm{T}}) \tag{3.15}$$

$$+ \text{tr }((D_P N D_Q)(D_P N D_Q)^{\mathrm{T}}),$$

yielding an optimal N^*.

(ii) Next find a compensator Γ_{dis}^*, described by the quadruple (K^*, L^*, M^*, N^*), that is internally stabilizing and yields $G_{P,Q,\Gamma_{\text{dis}}^*}(z) = D_P N^* D_Q$, i.e., the closed-loop system $\Sigma_{\text{dis},P,Q} \times \Gamma_{\text{dis}}^*$ has the constant transfer matrix $D_P N^* D_Q$.

Indeed, if N^* minimizes $\Phi(N)$ and if $G_{P,Q,\Gamma_{\text{dis}}^*}(z) = D_P N^* D_Q$, then we have

$$J_{\Sigma_{\text{dis}}}(\Gamma_{\text{dis}}^*) = \text{tr }(E^{\mathrm{T}}PE) + \text{tr }(C_P Q C_P^{\mathrm{T}}) + \Phi(N^*),$$

while for any internally stabilizing compensator $\Gamma_{\text{dis}} = (K, L, M, N)$ we have

$$J_{\Sigma_{\text{dis}}}(\Gamma_{\text{dis}}) \geq \text{tr }(E^{\mathrm{T}}PE) + \text{tr }(C_P Q C_P^{\mathrm{T}}) + \Phi(N) \geq \text{tr }(E^{\mathrm{T}}PE) + \text{tr }(C_P Q C_P^{\mathrm{T}}) + \Phi(N^*).$$

This clearly implies that

$$J^* = \text{tr }(E^{\mathrm{T}}PE) + \text{tr }(C_P Q C_P^{\mathrm{T}}) + \Phi(N^*)$$

and that

$$J_{\Sigma_{\text{dis}}}(\Gamma_{\text{dis}}^*) = J^*.$$

We will first study the minimization of $\Phi(N)$.

LEMMA 3.7. *Let* $\Phi(N)$ *be defined by* (3.15). *Define*

$$R^* := D_P^+(D_P C_P Q C_1^{\mathrm{T}} + B^{\mathrm{T}} PED_1^{\mathrm{T}})D_Q^+.$$

Then

$$\Phi^* := \min\{\Phi(N) \mid N \in \mathbb{R}^{m \times p}\} = -\text{tr }(R^* R^{*T}).$$

N minimizes Φ, i.e., $\Phi(N) = \Phi^*$, if and only if N is a solution to the linear equation $D_P N D_Q = -R^*$. One particular solution of this linear equation is given by $N^* = -D_P^+ R^* D_Q^+$. We have $\Phi^* = -\text{tr }((D_P N^* D_Q)(D_P N^* D_Q)^{\mathrm{T}})$.

Proof. Using the facts that

$$\ker D_Q \subset \ker (D_P C_P Q C_1^{\mathrm{T}} + B^{\mathrm{T}} P E D_1^{\mathrm{T}}),$$
$$\mathrm{im}\, D_P \supset \mathrm{im}\, (D_P C_P Q C_1^{\mathrm{T}} + B^{\mathrm{T}} P E D_1^{\mathrm{T}}),$$

it can be shown by straightforward calculation that

$$\Phi(N) = -\mathrm{tr}\, (R^* R^{*T}) + \mathrm{tr}\, ((D_P N D_Q + R^*)(D_P N D_Q + R^*)^{\mathrm{T}}).$$

The equation $D_P N D_Q = -R^*$ has a solution since $\ker D_Q = \ker D_Q^{\mathrm{T}} = \ker D_Q^+ \subset \ker R^*$ and $\mathrm{im}\, D_P = \mathrm{im}\, D_P^{\mathrm{T}} = \mathrm{im}\, D_P^+ \supset \mathrm{im}\, R^*$. Clearly, one particular solution is then given by $N^* = -D_P^+ R^* D_Q^+$. Finally, the expression for Φ^* can be checked in a straightforward manner. □

Next we study the question whether, starting with N^* above, it is possible to find K^*, L^*, M^* such that the resulting compensator $\Gamma^*_{\mathrm{dis}} = (K^*, L^*, M^*, N^*)$ yields a closed-loop system $\Sigma_{\mathrm{dis},P,Q} \times \Gamma^*_{\mathrm{dis}}$ with constant transfer matrix $D_P N^* D_Q$. We will first prove the following lemma:

LEMMA 3.8. *Assume that (A, B) is stabilizable and that (A, B, C_2, D_2) has no zeros on the unit circle. Let P be the largest real symmetric solution of the algebraic Riccati equation* (3.2). *There exists a matrix F such that*

(i) $|\sigma(A + BF)| < 1$,

(ii) $C_P + D_P F = 0$.

Proof. Let F_1 be such that (3.6) holds, and define $F := -D_P^+ C_P + (I - D_P^+ D_P) F_1$. Then (i) is satisfied. To prove (ii), note that $\mathrm{im}\, C_P \subset \mathrm{im}\, D_P^+ = \mathrm{im}\, D_P$. Consequently, $-D_P D_P^+ C_P = -C_P$, which proves (ii). □

We will also need the dual of this lemma, which reads as follows:

LEMMA 3.9. *Assume that (C_1, A) is detectable and that (A, E, C_1, D_1) has no zeros on the unit circle. Let Q be the largest real symmetric solution of the dual algebraic Riccati equation* (3.3). *There exists a matrix G such that*

(i) $|\sigma(A + GC_1)| < 1$,

(ii) $E_Q + G D_Q = 0$.

Now we show that by suitable choice of compensator Γ_{dis}, the transfer matrix of $\Sigma_{\mathrm{dis},P,Q} \times \Gamma_{\mathrm{dis}}$ can be made equal to any constant matrix product $M_1 M_2$, as long as $\mathrm{im}\, D_P \subset \mathrm{im}\, M_1$ and $\ker D_Q \subset \ker M_2$.

LEMMA 3.10. *Consider the system* (3.1). *Assume that (A, B) is stabilizable and (C_1, A) is detectable. Assume that (A, B, C_2, D_2) and (A, E, C_1, D_1) have no zeros on the unit circle. Let P and Q be the largest real symmetric solution of the algebraic Riccati equation* (3.2) *and* (3.3), *respectively. Then for any pair of matrices M_1, M_2 such that the product $M_1 M_2$ is defined and such that* $\mathrm{im}\, D_P \subset \mathrm{im}\, M_1$ *and* $\ker D_Q \subset \ker M_2$ *there exists an internally stabilizing compensator Γ_{dis} such that the transfer matrix of $\Sigma_{\mathrm{dis},P,Q} \times \Gamma_{\mathrm{dis}}$ is equal to the constant $M_1 M_2$.*

Specifically, for given M_1 and M_2 let F_2 be a solution of $M_1 = D_P F_2$ and G_2 be a solution of $M_2 = -G_2 D_Q$ and take F such that the conditions in Lemma 3.8 *are satisfied and G such that the conditions of Lemma* 3.9 *are satisfied. Then the compensator $\Gamma_{\mathrm{dis}} := (K, L, M, N)$ with $K := A + BF + GC_1 + BF_2 G_2 C_1$, $L := -BF_2 G_2 - G$, $M := F + F_2 G_2 C_1$, and $N := -F_2 G_2$ satisfies the requirements.*

Proof. The equations of the compensator are given by (2.8). Using the specifications of K, L, M, and N given above, we find that the error $e_k := w_k - x_k$ satisfies $e_{k+1} = (A + GC_1) e_k$. Thus, if $w_0 = 0$ and $x_0 = 0$, we have $x_k = w_k$ for all k. In particular, this implies that $u_k = F x_k + F_2 M_2 w_k$. The output of the closed-loop system is then equal to $z_k = C_P x_k + D_P u_k = M_1 M_2 w_k$. This implies that the closed-loop transfer matrix is equal to the constant matrix $M_1 M_2$. Finally, the spectrum of the closed-loop system matrix A_e is easily shown to be equal to $\sigma(A+BF) \cup \sigma(A+GC_1)$. This implies that the closed-loop system is internally stable. □

Clearly, if in this lemma we take $M_1 = D_P$ and $M_2 = N^* D_Q$, we arrive at an internally stabilizing compensator Γ_{dis} such that the closed-loop transfer matrix is equal to the constant matrix $D_P N^* D_Q$. In the formulas for the compensator as given in the lemma, we should then take $F_2 = I$ and $G_2 = -N^*$. The result of Theorem 3.3 follows immediately by combining the above lemmas.

Remark 3.11. For later use we note that Lemma 3.8 also provides a resolution of the discrete-time *linear quadratic problem* for the case that (A, B, C_2, D_2) has no zeros on the unit circle (see also [14]). Given $x_{k+1} = Ax_k + Bu_k$, the problem is to minimize the cost-functional $J(x_0, u) := \sum_k \|(C_2 x_k + D_2 u_k\|^2$ over all inputs $u = \{u_k\}$ such that $x_k \to 0$. It was pointed out in [14] that for each such input u we have the completion-of-the-squares formula $J(x_0, u) = x_0^{\mathrm{T}} P x_0 + J_P(x_0, u)$, with $J_P(x_0, u) := \sum_k \|C_P x_k + D_P u_k\|^2$. Thus, if we take F satisfying (i) and (ii) of Lemma 3.8, then the input $u_k = F x_k$ leads to the optimal cost $J^*(x_0) = x_0^{\mathrm{T}} P x_0$. Note that we could also formulate the linear quadratic problem as a minimization over all internally stabilizing feedback laws: minimize the cost-functional $J(x_0, F) := \sum_k \|(C_P + D_P F) x_k\|^2$ over all $F \in \mathbb{R}^{m \times n}$ such that $|\sigma(A + BF)| < 1$. By the above argument, any F satisfying (i) and (ii) of Lemma 3.8 is then optimal and the optimal cost is again given by $x_0^{\mathrm{T}} P x_0$.

Remark 3.12. An interesting question is under what conditions the Moore–Penrose inverse $(D_2^{\mathrm{T}} D_2 + B^{\mathrm{T}} P B)^+$ reduces to the inverse $(D_2^{\mathrm{T}} D_2 + B^{\mathrm{T}} P B)^{-1}$, equivalently, under what conditions $D_2^{\mathrm{T}} D_2 + B^{\mathrm{T}} P B$ is positive definite. Using the ideas from [14] it can be shown that if P is a positive semidefinite solution of the algebraic Riccati equation (3.2), then $D_2^{\mathrm{T}} D_2 + B^{\mathrm{T}} P B > 0$ if and only if (A, B, C_2, D_2) is a left-invertible system. Of course, dually, if Q is a positive semidefinite solution of the algebraic Riccati equation (3.3), then $D_1 D_1^{\mathrm{T}} + C_1 Q C_1^{\mathrm{T}} > 0$ if and only if the system (A, E, C_1, D_1) is right-invertible. In view of this, it is perhaps more natural to call the discrete-time H_2 problem regular if (A, B, C_2, D_2) is a left-invertible system and (A, E, C_1, D_1) is a right-invertible system.

4. The discrete-time H_2 problem: The general case. In this section we will extend the results of the previous section and treat the discrete-time H_2 problem in its full generality. This means that we will drop the assumption on the absence of zeros on the unit circle that was made in the previous section. First we will prove that also without the assumption that (A, B, C_2, D_2) has no zeros on the unit circle, the Riccati equation (3.2) has a largest real symmetric solution. We will prove that this solution can be obtained as the limit of solutions of algebraic Riccati equations associated with suitable perturbations of the system (A, B, C_2, D_2).

THEOREM 4.1. *If (A, B) is stabilizable, then the Riccati equation (3.2) has a largest real symmetric solution, say P. P is positive semidefinite. We have $P = \lim_{\varepsilon \downarrow 0} P_\varepsilon$, where for $\varepsilon > 0$ P_ε is the largest real symmetric solution of the algebraic Riccati equation*

$$\begin{aligned} &A^{\mathrm{T}} P_\varepsilon A - P_\varepsilon + C_2^{\mathrm{T}} C_2 + \varepsilon^2 I \\ &\quad -(A^{\mathrm{T}} P_\varepsilon B + C_2^{\mathrm{T}} D_2)(D_2^{\mathrm{T}} D_2 + B^{\mathrm{T}} P_\varepsilon B)^+ (B^{\mathrm{T}} P_\varepsilon A + D_2^{\mathrm{T}} C_2) = 0. \end{aligned} \tag{4.1}$$

Remark 4.2. Note that (4.1) is the Riccati equation associated with the perturbed system $(A, B, \binom{C_2}{\varepsilon I}, \binom{D_2}{0})$. (Here, I denotes the $n\times n$ identity matrix, and 0 denotes the $n \times m$ zero matrix). For $\varepsilon > 0$, the perturbed system has no zeros. Consequently, the existence of P_ε follows from Theorem 3.1.

The idea of the proof of Theorem 4.1 is to show first that the P_ε indeed converge to some matrix P and next to show that P satisfies (3.2). The difficulty is that in the general case we are considering, the term $D_2^{\mathrm{T}}D_2 + B^{\mathrm{T}}PB$ need not be invertible, so that we cannot conclude that $(D_2^{\mathrm{T}}D_2+B^{\mathrm{T}}P_\varepsilon B)^+$ converges to $(D_2^{\mathrm{T}}D_2+B^{\mathrm{T}}PB)^+$. We will show, however, that we can get around this difficulty by considering the so-called linear matrix inequality. Our proof is split up in three lemmas. In the following, let $J(x_0, u)$ be the cost-functional of the linear quadratic problem, and let $J^*(x_0)$ be the optimal cost (see Remark 3.11).

LEMMA 4.3. *Let P_ε be the largest real symmetric solution of* (4.1). *There exists a real positive semidefinite matrix P such that $P_\varepsilon \downarrow P$ ($\varepsilon \downarrow 0$). For all $x_0 \in \mathbb{R}^n$ we have $J^*(x_0) = x_0^{\mathrm{T}}Px_0$.*

Proof. Let $J_\varepsilon(x_0, u) := \sum_k \|C_P x_k + D_P u_k\|^2 + \varepsilon^2\|x_k\|^2$, and let $J_\varepsilon^*(x_0)$ be the infimum of $J_\varepsilon(x_0, u)$ over all u such that $x_k \to 0$. According to Remark 3.11 we have $J_\varepsilon^*(x_0) = x_0^{\mathrm{T}}P_\varepsilon x_0$. From this interpretation it follows that P_ε is monotonically nonincreasing as $\varepsilon \downarrow 0$. Being bounded from below by 0, this yields the existence of a limit P. Obviously, for all $\varepsilon > 0$ we have $J^*(x_0) \le J_\varepsilon^*(x_0) = x_0^{\mathrm{T}}P_\varepsilon x_0$, so $J^*(x_0) \le x_0^{\mathrm{T}}Px_0$. Conversely, for all $\varepsilon > 0$ and for all u we have $J_\varepsilon(x_0, u) \ge x_0^{\mathrm{T}}P_\varepsilon x_0$. Taking the limit on both sides this yields $J(x_0, u) \ge x_0^{\mathrm{T}}Px_0$ for all u. Taking the infimum over u then yields the converse inequality. □

LEMMA 4.4. *P is the largest real symmetric solution of the linear matrix inequality*

$$M(P) := \begin{pmatrix} A^{\mathrm{T}}PA - P + C_2^{\mathrm{T}}C_2 & C_2^{\mathrm{T}}D_2 + A^{\mathrm{T}}PB \\ D_2^{\mathrm{T}}C_2 + B^{\mathrm{T}}PA & D_2^{\mathrm{T}}D_2 + B^{\mathrm{T}}PB \end{pmatrix} \ge 0.$$

Proof. Denote the left-hand side of (4.1) by $R_\varepsilon(P_\varepsilon)$. Also consider the linear matrix inequality associated with the perturbed system:

$$M_\varepsilon(P_\varepsilon) := \begin{pmatrix} A^{\mathrm{T}}P_\varepsilon A - P_\varepsilon + C_2^{\mathrm{T}}C_2 + \varepsilon^2 I & C_2^{\mathrm{T}}D_2 + A^{\mathrm{T}}P_\varepsilon B \\ D_2^{\mathrm{T}}C_2 + B^{\mathrm{T}}P_\varepsilon A & D_2^{\mathrm{T}}D_2 + B^{\mathrm{T}}P_\varepsilon B \end{pmatrix} \ge 0.$$

We have $M_\varepsilon(P_\varepsilon) \ge 0$ if and only if $R_\varepsilon(P_\varepsilon) \ge 0$. This follows from the fact that the latter is equal to the Schur complement of $D_2^{\mathrm{T}}D_2 + B^{\mathrm{T}}P_\varepsilon B$ in $M_\varepsilon(P_\varepsilon)$. The Schur complement is defined here with matrix inverse replaced by Moore–Penrose inverse. This can be done because of the fact that

$$\ker(D_2^{\mathrm{T}}D_2 + B^{\mathrm{T}}P_\varepsilon B) \subset \ker(C_2^{\mathrm{T}}D_2 + A^{\mathrm{T}}P_\varepsilon B).$$

Since $R_\varepsilon(P_\varepsilon) = 0$, we indeed have $M_\varepsilon(P_\varepsilon) \ge 0$. Taking the limit $\varepsilon \downarrow 0$ then yields $M(P) \ge 0$. To show that P is the largest real symmetric solution, let P_1 be any real symmetric solution of the linear matrix inequality. Using a standard completion-of-the-squares argument then yields $J(x_0, u) \ge x_0^{\mathrm{T}}P_1x_0$ for any x_0 and any u such that $x_k \to 0$. Taking the infimum over all such u yields $x_0^{\mathrm{T}}Px_0 = J^*(x_0) \ge x_0^{\mathrm{T}}P_1x_0$. □

Now we will show that P in fact satisfies the algebraic Riccati equation (3.2). Denote

$$R(P) := A^{\mathrm{T}}PA - P + C_2^{\mathrm{T}}C_2 - (C_2^{\mathrm{T}}D_2 + A^{\mathrm{T}}PB)(D_2^{\mathrm{T}}D_2 + B^{\mathrm{T}}PB)^+(D_2^{\mathrm{T}}C_2 + B^{\mathrm{T}}P).$$

Again, by the fact that $\ker(D_2^{\mathrm{T}}D_2 + B^{\mathrm{T}}PB) \subset \ker(C_2^{\mathrm{T}}D_2 + A^{\mathrm{T}}PB)$, $R(P)$ is equal to the Schur complement of $D_2^{\mathrm{T}}D_2 + B^{\mathrm{T}}PB$ in $M(P)$. In particular this implies that

$$\operatorname{rank} M(P) = \operatorname{rank}\,(D_2^{\mathrm{T}}D_2 + B^{\mathrm{T}}PB) + \operatorname{rank} R(P).$$

In order to prove that $R(P) = 0$ we should therefore prove that P has the property expressed in the following lemma:

LEMMA 4.5. $\operatorname{rank} M(P) = \operatorname{rank}\,(D_2^{\mathrm{T}}D_2 + B^{\mathrm{T}}PB)$.

Proof. Let $\tilde{C}$ and $\tilde{D}$ be matrices such that

$$M(P) = \begin{pmatrix} \tilde{C} & \tilde{C} \end{pmatrix}^{\mathrm{T}} \begin{pmatrix} \tilde{C} & \tilde{D} \end{pmatrix}.$$

Again using a standard completion-of-the-squares argument, for any initial state x_0 and for any input sequence u such that $x_k \to 0$ we have

$$J(x_0, u) = x_0^{\mathrm{T}}Px_0 + \sum_k \|\tilde{C}x_k + \tilde{D}u_k\|^2 \geq x_0^{\mathrm{T}}x_0 + \|\tilde{C}Px_0 + \tilde{D}u_0\|^2 \tag{4.2}$$

From Lemma 4.3 we have that $J^*(x_0) = x_0^{\mathrm{T}}Px_0$. In particular this implies that the infimum of $\|\tilde{C}x_0 + \tilde{D}u_0\|^2$ over all $u_0 \in \mathbb{R}^m$ is equal to 0. Consequently, for all x_0 there exists $u_0 \in \mathbb{R}^m$ such that $\tilde{C}x_0 + \tilde{D}u_0 = 0$. This implies $\operatorname{im} \tilde{C} \subset \operatorname{im} \tilde{D}$ so

$$\operatorname{rank} M(P) = \operatorname{rank} \begin{pmatrix} \tilde{C} & \tilde{D} \end{pmatrix} = \operatorname{rank} \tilde{D} = \operatorname{rank}\,(D_2^{\mathrm{T}}D_2 + B^{\mathrm{T}}PB). \qquad \square$$

Clearly, the proof of Theorem 4.1 follows by combining these three lemmas. The fact that P is the largest real symmetric solution of the algebraic Riccati equation follows by noting that any real symmetric solution is also a solution of the linear matrix inequality and by applying Lemma 4.4.

Remark 4.6. For later use, note that by combining the above results with Remark 3.11 we obtain that also for the general case the optimal cost $J^*(x_0)$ of the discrete-time linear quadratic problem associated with the system (A, B, C_2, D_2) is given by $J^*(x_0) = x_0^{\mathrm{T}}Px_0$, with P the largest real symmetric solution of the Riccati equation (3.2). We will also need the dual result of Theorem 4.1, which is stated below:

THEOREM 4.7. *If (C_1, A) is detectable, then the Riccati equation* (3.3) *has a largest real symmetric solution, say Q. Q is positive semidefinite. We have $Q = \lim_{\varepsilon\downarrow 0} Q_\varepsilon$, where for $\varepsilon > 0$ Q_ε is the largest real symmetric solution of the algebraic Riccati equation*

$$\begin{aligned} &AQ_\varepsilon A^{\mathrm{T}} - Q_\varepsilon + EE^{\mathrm{T}} + \varepsilon^2 I \\ &\quad -(AQ_\varepsilon C_1^{\mathrm{T}} + ED_1^{\mathrm{T}})(D_1D_1^{\mathrm{T}} + C_1Q_\varepsilon C_1^{\mathrm{T}})^+(C_1Q_\varepsilon A^{\mathrm{T}} + D_1E^{\mathrm{T}}) = 0. \end{aligned} \tag{4.3}$$

Now we are in a position to state the main results of this section. It turns out that also for the discrete-time H_2 problem in its full generality, so without any assumptions on the zeros, the optimal performance J^* is given by (3.10), with P and Q the largest real symmetric solutions of the respective Riccati equations. However, in general no optimal controller will exist. We will, however, derive necessary and sufficient conditions for the existence of an optimal controller. Our first main result deals with the optimal performance.

THEOREM 4.8. *Consider the system* (3.1). *Assume that (A, B) is stabilizable and (C_1, A) is detectable. Then the optimal performance J^* is given by* (3.10), *where P and Q are the largest real symmetric solutions of* (3.2) *and* (3.3), *respectively.*

Proof. In addition to the system (3.1), consider its perturbation $\Sigma^{\varepsilon}_{\mathrm{dis}}$:

$$\begin{aligned} x_{k+1} &= Ax_k + Bu_k + \begin{pmatrix} E & \varepsilon I \end{pmatrix} v_k\,, \\ y_k &= C_1 x_k + \begin{pmatrix} D_1 & 0 \end{pmatrix} v_k\,, \\ z_k &= \begin{pmatrix} C_2 \\ \varepsilon I \end{pmatrix} x_k + \begin{pmatrix} D_2 \\ 0 \end{pmatrix} u_k\,. \end{aligned} \tag{4.4}$$

Let $J_{\Sigma^{\varepsilon}_{\mathrm{dis}}}(\Gamma_{\mathrm{dis}})$ denote the H_2 performance, and let J^*_{ε} denote the optimal H_2 performance. Since, for $\varepsilon > 0$, neither $(A, B, \left(\begin{smallmatrix} C_2 \\ \varepsilon I \end{smallmatrix}\right), \left(\begin{smallmatrix} D_2 \\ 0 \end{smallmatrix}\right))$ nor $(A, (E\ \ \varepsilon I), C_1, (D_1\ \ 0))$ have zeros; we can apply Theorem 3.3 to obtain

$$\begin{aligned} J^*_{\varepsilon} = \operatorname{tr}\,((EE^{\mathrm{T}} + \varepsilon^2 I)P_{\varepsilon}) + \operatorname{tr}\,(A^{\mathrm{T}}P_{\varepsilon}A - P_{\varepsilon} + C_2^{\mathrm{T}}C_2 + \varepsilon^2 I)Q_{\varepsilon}) \\ -\operatorname{tr}\,((D_{P_{\varepsilon}}N^*_{\varepsilon}D_{Q_{\varepsilon}})(D_{P_{\varepsilon}}N^*_{\varepsilon}D_{Q_{\varepsilon}})^{\mathrm{T}}), \end{aligned}$$

where P_{ε} and Q_{ε} are the largest real symmetric solutions of (4.1) and (4.3), respectively, and where $D_{P_{\varepsilon}}$, N^*_{ε}, and $D_{Q_{\varepsilon}}$ are defined by (3.4), (3.11), and (3.7), with P and Q replaced by P_{ε} and Q_{ε}. From Lemma 3.7, recall that

$$-\operatorname{tr}\,((D_{P_{\varepsilon}}N^*_{\varepsilon}D_{Q_{\varepsilon}})(D_{P_{\varepsilon}}N^*_{\varepsilon}D_{Q_{\varepsilon}})^{\mathrm{T}}) = \Phi_{\varepsilon}(N^*_{\varepsilon}) = \min_{N} \Phi_{\varepsilon}(N),$$

with

$$\begin{aligned} \Phi_{\varepsilon}(N) := {} & 2\operatorname{tr}\,\left(\begin{pmatrix} D_1 \\ 0 \end{pmatrix}^{\mathrm{T}} N^{\mathrm{T}}B^{\mathrm{T}}P_{\varepsilon}(E\ \ \varepsilon I)\right) + 2\operatorname{tr}\,(C_{P_{\varepsilon}}Q_{\varepsilon}C_1^{\mathrm{T}}N^{\mathrm{T}}D_{P_{\varepsilon}}) \\ & + \operatorname{tr}\,((D_{P_{\varepsilon}}ND_{Q_{\varepsilon}})(D_{P_{\varepsilon}}ND_{Q_{\varepsilon}})^{\mathrm{T}}) \\ = {} & 2\operatorname{tr}\,(D_1^{\mathrm{T}}N^{\mathrm{T}}B^{\mathrm{T}}P_{\varepsilon}E) + 2\operatorname{tr}\,(Q_{\varepsilon}C_1^{\mathrm{T}}N^{\mathrm{T}}(D_2^{\mathrm{T}}C_2 + B^{\mathrm{T}}P_{\varepsilon}A)) \\ & + \operatorname{tr}\,((D_{P_{\varepsilon}}ND_{Q_{\varepsilon}})(D_{P_{\varepsilon}}ND_{Q_{\varepsilon}})^{\mathrm{T}}). \end{aligned}$$

Since $P_{\varepsilon} \to P$ and $Q_{\varepsilon} \to Q$, we see that for every N we have $\Phi_{\varepsilon}(N) \to \Phi(N)$ ($\varepsilon \downarrow 0$), where $\Phi(N)$ is defined by (3.15). Since of course for all $\varepsilon > 0$ we have $J^* \leq J^*_{\varepsilon}$ we see that for all $\varepsilon > 0$, for all N we have

$$J^* \leq \operatorname{tr}\,((EE^{\mathrm{T}} + \varepsilon^2 I)P_{\varepsilon}) + \operatorname{tr}\,((A^{\mathrm{T}}P_{\varepsilon}A - P_{\varepsilon} + C_2^{\mathrm{T}}C_2 + \varepsilon^2 I)Q_{\varepsilon}) + \Phi_{\varepsilon}(N).$$

Now, letting $\varepsilon \downarrow 0$ on the left in this inequality, we find that for all N

$$J^* \leq \operatorname{tr}\,(EE^{\mathrm{T}}P) + \operatorname{tr}\,((A^{\mathrm{T}}PA - P + C_2^{\mathrm{T}}C_2)Q) + \Phi(N).$$

Finally, taking the minimum over all N, this yields

$$J^* \leq \operatorname{tr}\,(EE^{\mathrm{T}}P) + \operatorname{tr}\,(C_P^{\mathrm{T}}C_PQ) - \operatorname{tr}\,((D_PN^*D_Q)(D_PN^*D_Q)^{\mathrm{T}}).$$

To prove the converse inequality note that by using the fact that P and Q satisfy (3.2) and (3.3) we can apply a repeated completion-of-the-squares argument as in §3 to obtain that for any internally stabilizing compensator Γ_{dis} we have

$$J_{\Sigma_{\mathrm{dis}}}(\Gamma_{\mathrm{dis}}) \geq \operatorname{tr}\,(E^{\mathrm{T}}PE) + \operatorname{tr}\,(C_PQC_P^{\mathrm{T}}) + \Phi(N^*). \tag{4.5}$$

Taking the infimum over all such Γ_{dis} yields the desired inequality. □

Next we will study the question: Under what conditions does there exist an optimal controller? Again, let P and Q be the largest real symmetric solutions of the respective Riccati equations. Define a system $\Sigma_{\mathrm{dis},P,Q}$ by (3.14). Again, for any internally stabilizing compensator $\Gamma_{\mathrm{dis}} = (K, L, M, N)$ we have the inequality (4.5).

As noted in §3, we have equality *if* $N = N^*$ and Γ_{dis} has the property that the closed loop system $\Sigma_{\text{dis},P,Q} \times \Gamma_{\text{dis}}$ has the constant transfer matrix $D_P N^* D_Q$. Of course, the latter statement only gives a sufficient condition for a compensator to be optimal. In the following theorem we will give necessary *and* sufficient conditions for optimality. Let R^* be as defined in Lemma 3.7.

THEOREM 4.9. *A controller* Γ_{dis} *is optimal if and only if* $\Sigma_{\text{dis},P,Q} \times \Gamma_{\text{dis}}$ *is internally stable and has constant transfer matrix* R^*.

Proof. If $\Gamma_{\text{dis}} = (K, L, M, N)$ is optimal, then we have

$$J_{\Sigma_{\text{dis}}}(\Gamma_{\text{dis}}) = \text{tr } (E^{\mathrm{T}} P E) + \text{tr } (C_P^{\mathrm{T}} Q C_P) + \Phi^*.$$

By Lemma 3.6 we also have

$$J_{\Sigma_{\text{dis}}}(\Gamma_{\text{dis}}) \geq \text{tr } (E^{\mathrm{T}} P E) + \text{tr } (C_P^{\mathrm{T}} Q C_P) + \Phi(N).$$

This clearly yields $\Phi(N) = \Phi^*$, i.e., N minimizes the function Φ. Again by Lemma 3.6 this implies that $\Sigma_{\text{dis},P,Q} \times \Gamma_{\text{dis}}$ has the constant transfer matrix $D_P N D_Q$. However, since N minimizes Φ, by Lemma 3.7 we have $D_P N D_Q = -R^*$. The converse statement is also an immediate consequence of Lemma 3.6. □

Our aim is to reformulate these conditions in terms of the original system Σ_{dis}. For any given matrix $N \in \mathbb{R}^{m \times p}$, consider the system $\Sigma^N_{\text{dis},P,Q}$ that is obtained by applying to $\Sigma_{\text{dis},P,Q}$ the static output feedback $u = Ny + v$. This system $\Sigma^N_{\text{dis},P,Q}$ is described by

$$\begin{array}{llll} x_{k+1} = & (A + BNC_1)x_k + & Bv_k + (BND_Q + E_Q)d_k\ , \\ y_k \;\;\; = & C_1 x_k & + \qquad\qquad D_Q d_k\ , \\ z_k \;\;\; & = (C_P + D_P N C_1)x_k + D_P v_k\ , \end{array} \tag{4.6}$$

Also, for a given compensator $\Gamma_{\text{dis}} = (K, L, M, N)$, let $\Gamma^0_{\text{dis}} := (K, L, M, 0)$ be the compensator with direct feedthrough matrix N replaced by 0. It is clear that the closed-loop system $\Sigma_{\text{dis},P,Q} \times \Gamma_{\text{dis}}$ has constant transfer matrix $D_P N D_Q$ if and only if $\Sigma^N_{\text{dis},P,Q} \times \Gamma^0_{\text{dis}}$ has transfer matrix equal to 0. Consequently, an internally stabilizing compensator $\Gamma_{\text{dis}} = (K, L, M, N)$ is optimal if and only if $D_P N D_Q = -R^*$ and $\Sigma^N_{\text{dis},P,Q} \times \Gamma^0_{\text{dis}}$ has transfer matrix 0. In other words, in order to find necessary and sufficient conditions for the existence of an optimal controller, we should study the problem of disturbance decoupling with internal stability. This problem has been studied extensively in [16]. One of the main results of [16] gives necessary and sufficient conditions for the existence of an internally stabilizing strictly proper compensator Γ^0_{dis} for the system Σ_{dis} given by (3.1). We will briefly recall this result here. Given Σ_{dis}, let $\mathcal{V}_g$ denote the largest subspace of $\mathbb{R}^n$ for which there exists $F \in \mathbb{R}^{m \times n}$ such that $(A + BF)\mathcal{V}_g \subset \mathcal{V}_g$, $|\sigma(A + BF \mid \mathcal{V}_g)| < 1$, and $(C_2 + D_2 F)\mathcal{V}_g = 0$. Dually, let $\mathcal{S}_g$ be the smallest subspace of $\mathbb{R}^n$ for which there exists a matrix $G \in \mathbb{R}^{n \times p}$ such that $(A + GC_1)\mathcal{S}_g \subset \mathcal{S}_g$, $|\sigma(A + GC_1 \mid \mathbb{R}^n/\mathcal{S}_g)| < 1$, and im $(E + GD_1) \subset \mathcal{S}_g$. It was shown in [16, Thm. 2.4] that there exists an internally stabilizing compensator $\Gamma^0_{\text{dis}} = (K, L, M, 0)$ such that $\Sigma_{\text{dis}} \times \Gamma^0_{\text{dis}}$ has transfer matrix 0 if and only if the following conditions hold: (i) (A, B) is stabilizable and (C_1, A) is detectable, (ii) the following four subspace inclusions hold: im $E \subset \mathcal{V}_g$, $\mathcal{S}_g \subset \ker C_2$, $\mathcal{S}_g \subset \mathcal{V}_g$, and $A\mathcal{S}_g \subset \mathcal{V}_g$.

Here, we want to apply this result to the system $\Sigma^N_{\text{dis},P,Q}$, with N any solution of $D_P N D_Q = -R^*$. In the following, we will omit some of the details. Using the fact that im $(C_P + D_P N C_1) \subset$ im D_P, it can be shown that the subspace $\mathcal{V}_g$ associated with $\Sigma^N_{\text{dis},P,Q}$ is given by

$$\mathcal{V}_g = \mathcal{X}_g(A - BD_P^+ C_P) + \langle A - BD_P^+ C_P \mid B \ker D_P \rangle, \tag{4.7}$$

where for a given matrix M, $\mathcal{X}_g(M)$ is the sum of the generalized eigenspaces of M associated with its eigenvalues in $|z| < 1$, and where $\langle M \mid \mathcal{L} \rangle$ is the smallest M-invariant subspace contained in $\mathcal{L}$. It can also be shown, using the fact that $\ker D_Q \subset \ker(BND_Q + E_Q)$, that

$$\mathcal{S}_g = \mathcal{X}_b(A - E_Q D_Q^+ C_1) \cap \langle C_1^{-1} \text{im } D_Q \mid A - E_Q D_Q^+ C_1 \rangle, \tag{4.8}$$

where $\mathcal{X}_b(M)$ is the sum of the generalized eigenspaces of M associated with its eigenvalues in $|z| \geq 1$ and where $\langle \mathcal{L} \mid M \rangle$ is the largest M-invariant subspace containing $\mathcal{L}$. Using the fact that, from (4.7), $B \ker D_P \subset \mathcal{V}_g$, it can be shown that im $(BND_Q + E_Q) \subset \mathcal{V}_g$ if and only if

$$\text{im } (E_Q - BD_P^+ R^*) \subset \mathcal{V}_g. \tag{4.9}$$

Using the fact that, by (4.8), $\mathcal{S}_g \subset C_1^{-1}$im D_Q, it can be shown that $\mathcal{S}_g \subset \ker(C_P + D_P N C_1)$ if and only if

$$\mathcal{S}_g \subset \ker(C_P - R^* D_Q^+ C_1). \tag{4.10}$$

Finally, it can be shown that $(A + BNC_1)\mathcal{S}_g \subset \mathcal{V}_g$ if and only if

$$(A - BD_P^+ R^* D_Q^+ C_1)\mathcal{S}_g \subset \mathcal{V}_g. \tag{4.11}$$

Collecting the above facts, we then obtain the following necessary and sufficient conditions for the existence of an optimal controller for the discrete-time H_2 optimal control problem associated with the system Σ_{dis}:

THEOREM 4.10. *Consider the system* (3.1). *Assume that* (A, B) *is stabilizable and* (C_1, A) *is detectable. Let P and Q be the largest real symmetric solution of* (3.2) *and* (3.3), *respectively. Let $\mathcal{V}_g$ and $\mathcal{S}_g$ be given by* (4.7) *and* (4.8). *Then we have: there exists an optimal controller, i.e., an internally stabilizing controller* $\Gamma^*_{\text{dis}} = (K^*, L^*, M^*, N^*)$ *such that* $J_{\Sigma_{\text{dis}}}(\Gamma^*_{\text{dis}}) = J^*$, *if and only if the four subspace inclusions* $\mathcal{S}_g \subset \mathcal{V}_g$, (4.9), (4.10), *and* (4.11) *are satisfied.*

5. The sampled-data H_2 problem.

Now we return to the sampled-data H_2 problem. Consider the continuous-time system Σ given by (2.3), and let $\Delta \notin \mathbf{\Delta}$ be a given sampling period. Let the discrete-time system Σ_Δ be given by (2.4). According to Theorem 2.1, the optimal sampled-data H_2 performance $J^*_{\Sigma,\Delta}$ is equal to

$$J^*_{\Sigma,\Delta} = \frac{1}{\Delta}\int_0^\Delta \int_0^{\Delta - s} \text{tr}\left(C_2 e^{tA} E E^{\mathrm{T}} e^{tA^{\mathrm{T}}} C_2^{\mathrm{T}}\right) dt\, ds + \frac{1}{\Delta} J^*_{\Sigma_\Delta}, \tag{5.1}$$

where $J^*_{\Sigma_\Delta}$ is the optimal discrete-time H_2 performance associated with Σ_Δ. According to Theorem 4.8, the optimal performance $J^*_{\Sigma_\Delta}$ can be found in terms of two algebraic Riccati equations associated with Σ_Δ. According to Theorem 4.10, an optimal compensator $\Gamma_{\text{dis},\Delta}$ exists if and only if four subspace inclusions involving subspaces associated with the system Σ_Δ are satisfied. According to Theorem 3.3, if the systems $(A_\Delta, B_\Delta, C_{2,\Delta}, D_{2,\Delta})$ and $(A_\Delta, E_\Delta, C_1, 0)$ have no zeros on the unit circle, then an optimal compensator $\Gamma_{\text{dis},\Delta}$ exists and can be calculated using the "construction" in the statement of Theorem 3.3. The sampled-data controller $\Gamma := H_\Delta \Gamma_{\text{dis},\Delta} S_\Delta$ is then optimal for the sampled-data H_2 problem under consideration.

In this section we study the following question: what are conditions *in terms of the original system* Σ that guarantee that there exists an optimal compensator for the sampled-data H_2 problem? Instead of being completely general, we will study the following question: what are necessary and sufficient conditions in terms of the original system Σ such that $(A_\Delta, B_\Delta, C_{2,\Delta}, D_{2,\Delta})$ and $(A_\Delta, E_\Delta, C_1, 0)$ have no zeros on the unit circle? In the following, let $\mathcal{R}$ be the controllability subspace of the system (A, B, C_2, D_2) (see §2). The main results of this section are the following:

THEOREM 5.1. *Consider the system* Σ. *Let* $\Delta > 0$.

(i) *Let* λ *be a zero of* $(A_\Delta, B_\Delta, C_{2,\Delta}, D_{2,\Delta})$, $\lambda \neq 1$. *Then there exists a unobservable eigenvalue* μ *of* (C_2, A) *such that* $\lambda = e^{\mu\Delta}$.

(ii) *If* (A, B, C_2, D_2) *is left-invertible, then also the converse of* (i) *holds*: *if* μ *is an unobservable eigenvalue of* (C_2, A), *then* $e^{\mu\Delta}$ *is a zero of* $(A_\Delta, B_\Delta, C_{2,\Delta}, D_{2,\Delta})$.

(iii) 1 *is a zero of* $(A_\Delta, B_\Delta, C_{2,\Delta}, D_{2,\Delta})$ *if and only if at least one of the following two conditions hold*:

(a) *0 is a zero of* (A, B, C_2, D_2),

(b)

$$\mathcal{R} \not\subset \langle \ker C_2 \mid A \rangle. \tag{5.2}$$

(iv) *If* (A, B, C_2, D_2) *is left-invertible, then* 1 *is a zero of* $(A_\Delta, B_\Delta, C_{2,\Delta}, D_{2,\Delta})$ *if and only if* 0 *is a zero of* (A, B, C_2, D_2).

COROLLARY 5.2. *Consider the system* Σ. *Let* $\Delta > 0$.

(i) *If* (C_2, A) *has no unobservable eigenvalues on the imaginary axis,* 0 *is not a zero of* (A, B, C_2, D_2), *and* $\mathcal{R} \subset \langle \ker C_2 \mid A \rangle$, *then* $(A_\Delta, B_\Delta, C_{2,\Delta}, D_{2,\Delta})$ *has no zeros on the unit circle.*

(ii) *If* (A, B, C_2, D_2) *is left-invertible, then* $(A_\Delta, B_\Delta, C_{2,\Delta}, D_{2,\Delta})$ *has no zeros on the unit circle if and only if* (C_2, A) *has no unobservable eigenvalues on the imaginary axis and* 0 *is not a zero of* (A, B, C_2, D_2).

THEOREM 5.3. *Consider the system* Σ. *Let* $\Delta > 0$.

(i) *Let* λ *be a zero of* $(A_\Delta, E_\Delta, C_1, 0)$. *Then there exists an uncontrollable eigenvalue* μ *of* (A, E) *such that* $\lambda = e^{\mu\Delta}$.

(ii) *If* $(A, E, C_1, 0)$ *is right-invertible, then also the converse of* (i) *holds*; *i.e., if* μ *is an uncontrollable eigenvalue of* (A, E), *then* $e^{\mu\Delta}$ *is a zero of* $(A_\Delta, E_\Delta, C_1, 0)$.

COROLLARY 5.4. *Consider the system* Σ. *Let* $\Delta > 0$. *If* (A, E) *has no uncontrollable eigenvalues on the imaginary axis, then* $(A_\Delta, E_\Delta, C_1, 0)$ *has no zeros on the unit circle. If, in addition,* $(A, E, C_1, 0)$ *is right-invertible, then also the converse holds*: $(A_\Delta, E_\Delta, C_1, 0)$ *has no zeros on the unit circle if and only if* (A, E) *has no uncontrollable eigenvalues on the imaginary axis.*

Note that the conditions on Σ obtained in these theorems are independent of the sampling period. In the remainder of this section we shall prove these results.

In order to study the zeros of (A, B, C_2, D_2) and $(A_\Delta, B_\Delta, C_{2,\Delta}, D_{2,\Delta})$, consider the system matrices of these systems. Let

$$P_\Delta(z) := \begin{pmatrix} zI - A_\Delta & -B_\Delta \\ C_{2,\Delta} & D_{2,\Delta} \end{pmatrix}, \quad P(s) := \begin{pmatrix} sI - A & -B \\ C_2 & D_2 \end{pmatrix}.$$

Recall that λ is a zero of $(A_\Delta, B_\Delta, C_{2,\Delta}, D_{2,\Delta})$ if and only if the rank of the complex matrix $P_\Delta(\lambda)$ is less than the normal rank of P_Δ (see §2). In order to find out in which points λ this happens, we will study for $\lambda \in \mathcal{C}$ the subspace

$$\mathcal{V}_\lambda := \ker P_\Delta(\lambda) \subset \mathcal{C}^{n+m}.$$

Clearly, for all λ we have $\dim \mathcal{V}_\lambda = n + m - \text{rank } P_\Delta(\lambda)$. Consequently, for all but finitely many λ we have $\dim \mathcal{V}_\lambda = d$, where

$$d := n + m - \text{normrank } P_\Delta.$$

Hence, λ is a zero of $(A_\Delta, B_\Delta, C_{2,\Delta}, D_{2,\Delta})$ if and only if $\dim \mathcal{V}_\lambda > d$. In the following lemma we will calculate for each λ the subspace $\mathcal{V}_\lambda$, its dimension $\dim \mathcal{V}_\lambda$, and the number d. Denote the unobservable subspace $\langle \ker C_2 \mid A \rangle$ by $\mathcal{N}$. Define a subspace $\mathcal{W}$ as follows:

$$\mathcal{W} := B^{-1}\mathcal{N} \cap \ker D_2. \tag{5.3}$$

LEMMA 5.5. *For every $\lambda \in \mathcal{C}$, $\lambda \neq 1$ we have*

$$\mathcal{V}_\lambda = (\mathcal{N} \times \mathcal{W}) \cap \ker \begin{pmatrix} \lambda I - A_\Delta & B_\Delta \end{pmatrix}, \tag{5.4}$$

$$\dim \mathcal{V}_\lambda = \dim \mathcal{N} + \dim \mathcal{W} - \dim((\lambda I - A_\Delta)\mathcal{N} + B_\Delta \mathcal{W}). \tag{5.5}$$

For all but finitely many λ we have $\dim \mathcal{V}_\lambda = d = \dim \mathcal{W}$, *equivalently,* normrank $P_\Delta = n + m - \dim \mathcal{W}$. *In addition we have*

$$\mathcal{V}_1 = \ker \begin{pmatrix} -A & -B \\ C_2 & D_2 \end{pmatrix}. \tag{5.6}$$

Proof. We will first prove (5.4). We know $\binom{x_0}{u_0} \in \mathcal{V}_\lambda$ if and only if

$$A_\Delta x_0 + B_\Delta u_0 = \lambda x_0, \tag{5.7}$$
$$C_{2,\Delta} x_0 + D_{2,\Delta} u_0 = 0. \tag{5.8}$$

Consider the differential equation $\dot{x}(t) = Ax(t) + Bu_0$, $x(0) = x_0$; and define $z(t) := C_2 x(t) + Du_0$. Clearly, $x(\Delta) = A_\Delta x_0 + B_\Delta u_0$, so (5.7) is equivalent to $x(\Delta) = \lambda x_0$. In turn, this is equivalent to

$$(\lambda - 1)x_0 = \int_0^\Delta e^{At}(Ax_0 + Bu_0)dt. \tag{5.9}$$

Using the definition (2.6) of $C_{2,\Delta}$ and $D_{2,\Delta}$, we see that (5.8) is equivalent to

$$(C_2 \;\; D_2)e^{\underline{A}t}\begin{pmatrix} x_0 \\ u_0 \end{pmatrix} = 0 \text{ for all } t \in [0, \Delta],$$

which, in turn, is equivalent to $z(t) = 0$ for all $t \in [0, \Delta]$. Obviously,

$$z(t) = C_2 e^{At} x_0 + \left[C_2 \int_0^t e^{As} B ds + D_2 \right] u_0.$$

Since $z(t) = 0$ for all $t \in [0, \Delta]$ is satisfied if and only if $z(0) = 0$ and $\dot{z}(t) = 0$ for all $t \in [0, \Delta]$, we find that (5.8) is equivalent to

$$C_2 x_0 + D_2 u_0 = 0 \quad \text{and} \quad C_2 e^{At}(Ax_0 + Bu_0) = 0, \qquad t \in [0, \Delta].$$

In other words (5.8) is satisfied if and only if

$$(5.10) \qquad C_2x_0 + D_2u_0 = 0 \quad \text{and} \quad Ax_0 + Bu_0 \in \mathcal{N}.$$

Now assume that $\lambda \neq 1$. Then (5.9) and (5.10) imply that $x_0 \in \mathcal{N} \subset \ker C_2$, so $u_0 \in \ker D_2$. Also it follows that $Ax_0 \in \mathcal{N}$, so $Bu_0 \in \mathcal{N}$ and, in fact, $u_0 \in \mathcal{W}$. We conclude that, for $\lambda \neq 1$, $\mathcal{V}_\lambda \subset (\mathcal{N} \times \mathcal{W}) \cap \ker \begin{pmatrix} \lambda I - A_\Delta & B_\Delta \end{pmatrix}$. To prove the converse inclusion, note that $u_0 \in \mathcal{W}$ implies that $D_2u_0 = 0$ and $Bu_0 \in \mathcal{N}$. If, in addition, $x_0 \in \mathcal{N}$, then we have $C_2x_0 + D_2u_0 = 0$ and $Ax_0 + Bu_0 \in \mathcal{N}$. By the above this is equivalent to (5.8). This completes the proof of (5.4).

To prove (5.5), note that, in general, if $\mathcal{L}$ is a subspace of some finite-dimensional linear space $\mathcal{X}$ and if T is a linear map acting on $\mathcal{X}$, then we have $\dim(\mathcal{L} \cap \ker T) = \dim \mathcal{L} - \dim T\mathcal{L}$. Applying this to the situation at hand, we find that for any $\lambda \neq 1$ we have

$$\dim \mathcal{V}_\lambda = \dim(\mathcal{N} \times \mathcal{W}) - \dim(\lambda I - A_\Delta \quad B_\Delta)(\mathcal{N} \times \mathcal{W}),$$

which immediately yields (5.5).

Next, we will prove the statement on the dimension of $\mathcal{V}_\lambda$. First note that since $\mathcal{N}$ is A-invariant, it is also e^{At}-invariant, for any t. In particular, this implies that $\mathcal{N}$ is A_Δ-invariant and invariant under $\int_0^\Delta e^{At}dt$. Now assume that $\lambda \notin \sigma(A_\Delta)$. Then we have $(\lambda I - A_\Delta)\mathcal{N} = \mathcal{N}$. Also, since $B\mathcal{W} \subset \mathcal{N}$, we have $B_\Delta \mathcal{W} \subset \mathcal{N}$. This implies that $(\lambda I - A_\Delta)\mathcal{N} + B_\Delta\mathcal{W} = \mathcal{N}$. If, in addition, we assume that $\lambda \neq 1$, then (5.5) yields $\dim \mathcal{V}_\lambda = \dim \mathcal{W}$.

Finally, to prove (5.6), recall that (5.7) is equivalent to (5.9). Note that for all $\Delta > 0$, $\int_0^\Delta e^{At}dt$ is a nonsingular matrix (this can be shown using the Jordan form of A). Thus, for the case that $\lambda = 1$ (5.9) is equivalent to $Ax_0 + Bu_0 = 0$. Together with the fact that (5.8) is equivalent to (5.10), this proves (5.6). □

By applying this lemma, we are now able to prove the statements (i) and (ii) of Theorem 5.1:

Proof of Theorem 5.1 (i) *and* (ii). (i) Assume that $\lambda \neq 1$ is a zero of $(A_\Delta, B_\Delta, C_{2,\Delta}, D_{2,\Delta})$. Then we must have $\dim \mathcal{V}_\lambda > \dim \mathcal{W}$. Using (5.5) this implies

$$(5.11) \qquad \dim \mathcal{N} > \dim((\lambda I - A_\Delta)\mathcal{N} + B_\Delta \mathcal{W}).$$

As noted in the proof of Lemma 5.5, $\mathcal{N}$ is A_Δ-invariant and $B_\Delta\mathcal{W} \subset \mathcal{N}$. Consequently,

$$(\lambda I - A_\Delta)\mathcal{N} + B_\Delta\mathcal{W} \subset \mathcal{N}.$$

Together with the inequality (5.11), this implies that $(\lambda I - A_\Delta)\mathcal{N}$ is a *strict* subspace of $\mathcal{N}$. This implies that the map $(\lambda I - A_\Delta)$ restricted to $\mathcal{N}$ is singular. Thus, $\ker(\lambda I - A_\Delta) \cap \mathcal{N} \neq 0$. Clearly, this intersection is A-invariant, so the restriction of A to this intersection has an eigenvalue, say μ, with corresponding eigenvector p. This eigenvector satisfies $A_\Delta p = \lambda p$. Also, since $Ap = \mu p$, we have $A_\Delta p = e^\mu p$, so $\lambda = e^\mu$. Finally, $p \in \mathcal{N} \subset \ker C_2$, so μ is an unobservable eigenvalue of (C_2, A).

(ii) We claim that if (A, B, C_2, D_2) is left-invertible, then $\dim \mathcal{W} = 0$. Indeed, left-invertibility is equivalent to the conditions $\binom{B}{D_2}$ is injective and $\mathcal{V} \cap B \ker D_2 = 0$, where $\mathcal{V}$ denotes the weakly unobservable subspace associated with (A, B, C_2, D_2) (see §2). Assume that $u_0 \in \mathcal{W}$. Then we have $D_2u_0 = 0$ and $Bu_0 \in \mathcal{N}$. Since $\mathcal{N} \subset \mathcal{V}$, this yields $Bu_0 = 0$. Combining this with $D_2u_0 = 0$ then leads to $u_0 = 0$. This proves our claim. Now let μ be a unobservable eigenvalue of (C_2, A). There exists $x_0 \neq 0$ such that $Ax_0 = \mu x_0$ and $C_2 x_0 = 0$. This yields $A_\Delta x_0 = \lambda x_0$, with $\lambda := e^{\mu\Delta}$. From the definition of $C_{2,\Delta}$ it is also easily seen that $C_{2,\Delta}x_0 = 0$. Consequently, $\binom{x_0}{0} \in \mathcal{V}_\lambda$, so $\dim \mathcal{V}_\lambda > 0 = \dim \mathcal{W}$. This implies that λ is a zero of $(A_\Delta, B_\Delta, C_{2,\Delta}, D_{2,\Delta})$. □

In order to prove statements (iii) and (iv) of Theorem 5.1, we need the following lemma.

LEMMA 5.6. *Let $\Delta > 0$. Then we have*

$$\text{normrank } P_\Delta \geq \text{normrank } P, \tag{5.12}$$

with equality if and only if $\mathcal{R} \subset \mathcal{N}$.

Proof. For each $\lambda \notin \sigma(A)$ define a subspace $\mathcal{L}_\lambda$ by

$$\mathcal{L}_\lambda := \left\{ \begin{pmatrix} x_0 \\ u_0 \end{pmatrix} \mid u_0 \in \mathcal{W}, x_0 = (\lambda I - A)^{-1} B u_0 \right\}.$$

Clearly, $\mathcal{L}_\lambda \subset \ker P(\lambda)$ and $\dim \mathcal{L}_\lambda = \dim \mathcal{W}$. Consequently, for each $\lambda \notin \sigma(A)$ we have $\dim \mathcal{W} \leq \dim \ker P(\lambda)$. This implies normrank $P \leq n + m - \dim \mathcal{W}$. The inequality (5.12) then follows from Lemma 5.5.

Of course, normrank $P_\Delta =$ normrank P if and only if $\dim \ker P(\lambda) = \dim \mathcal{W}$ for all but finitely many λ, which, in turn, is equivalent to $\ker P(\lambda) = \mathcal{L}_\lambda$ for all but finitely many λ, $\lambda \notin \sigma(A)$. We will prove that the latter statement is equivalent to $\mathcal{R} \subset \mathcal{N}$.

Let $k := \dim \mathcal{R}$, and let $\lambda_1, \ldots, \lambda_k$ be distinct complex numbers, $\lambda_i \notin \sigma(A)$, such that $\ker P(\lambda_i) = \mathcal{L}_{\lambda_i}$. There exists $F \in \mathbb{R}^{m \times n}$ such that $(A + BF)\mathcal{R} \subset \mathcal{R}$, $(C_2 + D_2 F)\mathcal{R} = 0$, and $\sigma(A + BF \mid \mathcal{R}) = \{\lambda_1, \ldots, \lambda_k\}$. Let $x_1, \ldots, x_k \in \mathcal{R}$ be corresponding eigenvectors of $A + BF \mid \mathcal{R}$. Then $\{x_1, \ldots, x_k\}$ is a basis of $\mathcal{R}$. We will prove that $x_i \in \mathcal{N}$. Indeed, define $u_i := -Fx_i$. Then $\binom{x_i}{u_i} \in \ker P(\lambda_i) = \mathcal{L}_{\lambda_i}$. Since $u_i \in \mathcal{W}$, we have $Bu_i \in \mathcal{N}$, so $x_i = (\lambda_i I - A)^{-1} B u_i \in \mathcal{N}$ by A-invariance of $\mathcal{N}$. We conclude that $x_i \in \mathcal{N}$, so $\mathcal{R} \subset \mathcal{N}$.

Conversely, assume that $\mathcal{R} \subset \mathcal{N}$. It suffices to show that $\ker P(\lambda) \subset \mathcal{L}_\lambda$ for all but finitely many λ. Let λ be arbitrary, $\lambda \notin \sigma(A)$, and λ not a zero of (A, B, C_2, D_2). Let $\binom{x_0}{u_0} \in \ker P(\lambda)$. We will prove that $x_0 \in \mathcal{R}$, so $x_0 \in \mathcal{N}$. Assume that $x_0 \neq 0$. Let $F \in \mathbb{R}^{m \times n}$ be such that $Fx_0 = u_0$. Then we have $(A + BF)x_0 = \lambda x_0$ and $(C_2 + D_2 F)x_0 = 0$. This implies $x_0 \in \mathcal{V}$, the weakly unobservable subspace associated with the system (A, B, C_2, D_2). (Indeed, the one-dimensional subspace $\mathcal{L}$ spanned by the vector x_0 has the property that $(A + BF)\mathcal{L} \subset \mathcal{L}$ and $(C_2 + D_2 F)\mathcal{L} = 0$ and so must be contained in $\mathcal{V}$, the largest subspace for which such F exists.) By extending the linear map F to the whole subspace $\mathcal{V}$, we obtain that $(A + BF)\mathcal{V} \subset \mathcal{V}$ and $(C_2 + D_2 F)\mathcal{V} = 0$, so $\lambda \in \sigma(A + BF \mid \mathcal{V})$. We have assumed that λ is not a zero. This implies $\lambda \notin \sigma(A + BF \mid \mathcal{V}/\ R)$ (the latter spectrum is equal to the set of zeros of (A, B, C_2, D_2); see [19]). But then we must have $x_0 \in \mathcal{R}$. This implies that $x_0 \in \mathcal{N}$. Now $(\lambda I - A)x_0 - Bu_0 = 0$, so $Bu_0 \in \mathcal{N}$. This implies that $u_0 \in \mathcal{W}$. For $\lambda \notin \sigma(A)$ this then yields $x_0 \in \mathcal{L}_\lambda$. This completes the proof of the lemma. □

Proof of Theorem 5.1 (iii) *and* (iv). (iii) We will prove that 1 is *not* a zero of the system $(A_\Delta, B_\Delta, C_{2,\Delta}, D_{2,\Delta})$ if and only if 0 is not a zero of (A, B, C_2, D_2) ánd normrank $P =$ normrank P_Δ. Clearly, 1 is not a zero of $(A_\Delta, B_\Delta, C_{2,\Delta}, D_{2,\Delta})$ if and only if $\dim \mathcal{V}_1 = n+m-$normrank P_Δ. By (5.6) we have $\dim \mathcal{V}_1 = n+m-$rank $P(0) \geq n + m -$ normrank P, with strict inequality if and only if 0 is a zero of (A, B, C_2, D_2). Combining these facts proves our claim. The proof of (iii) is then completed by applying Lemma 5.6.

(iv) If (A, B, C_2, D_2) is left-invertible, then $\mathcal{R} = 0$. In that case condition (5.2) is never satisfied. □

In order to study the zeros of $(A_\Delta, E_\Delta, C_1, 0)$, consider the system matrix of this system. Let

$$Q_\Delta(z) := \begin{pmatrix} zI - A_\Delta & -E_\Delta \\ C_1 & 0 \end{pmatrix}.$$

As before, λ is a zero of $(A_\Delta, E_\Delta, C_1, 0)$ if and only if the rank of the complex matrix $Q_\Delta(\lambda)$ is less than the normal rank of Q_Δ (see §2). In order to find out in which points λ this happens, we will study for $\lambda \in \mathcal{C}$ the subspace

$$\mathcal{W}_\lambda := (\text{im}\, Q_\Delta(\lambda))^\perp \subset \mathcal{C}^{n+p}.$$

For all λ we have $\dim \mathcal{W}_\lambda = n + p - \text{rank}\ Q_\Delta(\lambda)$. Consequently, for all but finitely many λ we have $\dim \mathcal{W}_\lambda = d_1$, where

$$d_1 := n + p - \text{normrank}\ Q_\Delta.$$

Hence, λ is a zero of $(A_\Delta, E_\Delta, C_1, 0)$ if and only if $\dim \mathcal{W}_\lambda > d_1$. The following lemma calculates for each λ the subspace $\mathcal{W}_\lambda$, its dimension $\dim \mathcal{W}_\lambda$, and the number d_1. Let $\mathcal{M} := \langle A \mid \text{im}\, E\rangle$, the reachable subspace of (A, E).

LEMMA 5.7. *Let* $\Delta > 0$. *Then we have*

$$\mathcal{W}_\lambda = \left(M^\perp \times (C_1^{\mathrm{T}})^{-1} M^\perp\right) \cap \ker \begin{pmatrix} \lambda I - A_\Delta^{\mathrm{T}} & C_1^{\mathrm{T}} \end{pmatrix},$$

$$\begin{aligned} \dim \mathcal{W}_\lambda = {} & \dim M^\perp + \dim (C_1^{\mathrm{T}})^{-1} M^\perp \\ & - \dim((\lambda I - A_\Delta^{\mathrm{T}}) M^\perp + C_1^{\mathrm{T}} (C_1^{\mathrm{T}})^{-1} M^\perp). \end{aligned} \tag{5.13}$$

For all but finitely many λ *we have* $\dim \mathcal{W}_\lambda = d_1 = \dim (C_1^{\mathrm{T}})^{-1} M^\perp$, *equivalently,*

$$\text{normrank}\ Q_\Delta = n + p - \dim (C_1^{\mathrm{T}})^{-1} M^\perp.$$

Proof. By definition, $\binom{x_0}{y_0} \in \mathcal{W}_\lambda$ if and only if

$$(\lambda I - A_\Delta^{\mathrm{T}}) x_0 + C_1^{\mathrm{T}} y_0 = 0 \quad \text{and} \quad x_0^{\mathrm{T}} E_\Delta = 0. \tag{5.14}$$

Since, by definition, im $E_\Delta = \mathcal{M}$, we see that it suffices to show that (5.14) implies $y_0 \in (C_1^{\mathrm{T}})^{-1} M^\perp$. From the fact that $\mathcal{M}^\perp$ is A^{T}-invariant it follows that $\mathcal{M}^\perp$ is A_Δ^{T}-invariant, so $C_1^{\mathrm{T}} y_0 \in \mathcal{M}^\perp$. The statement (5.13) on the dimension of $\mathcal{W}_\lambda$ follows in the same way as the corresponding statement in the previous lemma.

Now let λ be any complex number such that $\lambda \notin \sigma(A_\Delta^{\mathrm{T}})$. Since $\mathcal{M}^\perp$ is A_Δ^{T}-invariant, we then have $(\lambda I - A_\Delta^{\mathrm{T}}) M^\perp = M^\perp$. Also we have $C_1^{\mathrm{T}} (C_1^{\mathrm{T}})^{-1} M^\perp \subset M^\perp$ (no equality!). Thus, for such λ we have $\dim \mathcal{W}_\lambda = \dim (C_1^{\mathrm{T}})^{-1} M^\perp$. □

We are now ready to prove Theorem 5.3.

Proof of Theorem 5.3. Let λ be a zero of $(A_\Delta, E_\Delta, C_1, 0)$. Then we have $\dim \mathcal{W}_\lambda > \dim (C_1^{\mathrm{T}})^{-1} M^\perp$. Consequently, by (5.13), $\dim M^\perp > \dim((\lambda I - A_\Delta^{\mathrm{T}}) M^\perp + C_1^{\mathrm{T}} (C_1^{\mathrm{T}})^{-1} M^\perp)$. In particular, this implies that $(\lambda I - A_\Delta^{\mathrm{T}}) \mathcal{M}^\perp$ is a *strict* subspace of $\mathcal{M}^\perp$, so $\ker(\lambda I - A_\Delta^{\mathrm{T}}) \cap \mathcal{M}^\perp \neq 0$. This subspace is A^{T}-invariant, so there exist μ and

$x_0 \in \mathcal{M}^\perp$, $x_0 \neq 0$, such that $A^T x_0 = \mu x_0$, $A_\Delta^T x_0 = \lambda x_0$, and $x_0 \in \mathcal{M}^\perp$. Obviously, this implies $\lambda = e^\mu \Delta$, and μ is an uncontrollable eigenvalue of (A, E).

Assume that $(A, E, C_1, 0)$ is right-invertible. Let

$$Q(s) := \begin{pmatrix} sI - A & -E \\ C_1 & 0 \end{pmatrix}$$

be the system matrix. We have normrank $Q = n+p$. We claim that also normrank $Q_\Delta = n+p$. Indeed, assume that $y_0 \neq 0$ is an element of $(C_1^T)^{-1} M^\perp$. For $\lambda \notin \sigma(A^T)$, define $x_0 := -(\lambda I - A^T)^{-1} C_1^T y_0$. Then $x_0 \in \mathcal{M}^\perp$ and we have $(x_0^T \;\; y_0^T) Q(\lambda) = (0 \;\; 0)$. Thus, for all but finitely many λ we have rank $Q(\lambda) < n+p$, which is a contradiction. Hence we must have $(C_1^T)^{-1} M^\perp = 0$.

It follows that λ is a zero if and only if $\mathcal{W}_\lambda \neq 0$. Assume that μ is an uncontrollable eigenvalue of (A, E). Then there exists $x_0 \neq 0$, $x_0 \in \mathcal{M}^\perp$, such that $x_0^T A^T = \mu x_0$. Define $\lambda := e^{\mu\Delta}$. Then we have $x_0^T E_\Delta^T = 0$ and $x_0^T(\lambda I - A_\Delta) = 0$. It follows that $\binom{x_0}{0} \in \mathcal{W}_\lambda$, so λ is a zero of $(A_\Delta, E_\Delta, C_1, 0)$. □

6. Performance recovery and convergence of optimal performance. In this section we study the connection between the 'ordinary' continuous-time H_2 problem and the sampled-data H_2 problem. In particular, we are interested in the following questions:

- Suppose that we control the system Σ by means of an internally stabilizing continuous-time compensator Γ_{con}, yielding continuous-time H_2 performance $J_\Sigma(\Gamma_{\text{con}})$. Is it possible to recover this performance asymptotically by using a sampled-data controller with sufficiently small sampling period? More precisely, is it true that for all $\epsilon > 0$ there exists $\Delta > 0$ and an internally stabilizing sampled-data controller Γ with sampling-period Δ such that $|J_\Sigma(\Gamma_{\text{con}}) - J_{\Sigma,\Delta}(\Gamma)| < \epsilon$?
- Does the optimal sampled-data H_2 performance converge to the optimal continuous-time H_2 performance as the sampling period Δ decreases to zero? More precisely, suppose that $J^*_{\Sigma,\text{con}}$ is the optimal continuous-time H_2 performance associated with the system Σ and, as before, denote the optimal sampled-data H_2 performance by $J^*_{\Sigma,\Delta}$. Is it true that $\lim_{\Delta\downarrow 0} J^*_{\Sigma,\Delta} = J^*_{\Sigma,\text{con}}$?

The first question above was studied before in [6, Thm. 4] using a different definition of H_2 performance and for the H_∞ performance criterion [6, Thm. 5]. In this section we will show that both questions have an affirmative answer.

Let Σ be given by (2.2). If the system Σ is controlled by a continuous-time compensator Γ_{con} given by the equations

$$\begin{aligned} \dot{w}(t) &= \bar{K}w(t) + \bar{L}y(t) , \\ u(t) &= \bar{M}w(t) + \bar{N}y(t) , \end{aligned} \tag{6.1}$$

with $w(t) \in \mathbb{R}^\ell$, then the associated closed-loop system $\Sigma \times \Gamma_{\text{con}}$ is given by

$$\begin{aligned} \dot{x}_e(t) &= A_e x_e(t) + E_e y(t) , \\ z(t) &= C_e x_e(t) , \end{aligned}$$

with

$$A_e = \begin{pmatrix} A + B\bar{N}C_1 & B\bar{M} \\ \bar{L}C_1 & \bar{K} \end{pmatrix}, \; E_e := \begin{pmatrix} E \\ 0 \end{pmatrix}, \; C_e := \begin{pmatrix} C_2 + D_2\bar{N}C_1 & D_2\bar{M} \end{pmatrix}.$$

If Γ_{con} is internally stabilizing, i.e., $\sigma(A_e) \subset \mathcal{C}^-$, then the H_2 performance of the closed-loop system $\Sigma \times \Gamma_{\text{con}}$ is equal to

$$J_\Sigma(\Gamma_{\text{con}}) = \text{tr}\ (E_e P_e E_e^{\text{T}}),$$

where P_e is the unique solution of the Lyapunov equation

$$A_e^{\text{T}} P_e + P_e A_e + C_e^{\text{T}} C_e = 0. \tag{6.2}$$

On the other hand, if the system Σ is controlled by the sampled-data controller $\Gamma = H_\Delta \Gamma_{\text{dis}} S_\Delta$, with Γ_{dis} given by (2.8), then the discrete-time closed-loop system $\Sigma_\Delta \times \Gamma_{\text{dis}}$ is given by the equations

$$\begin{aligned} x_{e,k+1} &= A_{e,\Delta} x_{e,k}\ E_{e,\Delta} y_k\ , \\ z_k &= C_{e,\Delta} x_{e,k}\ , \end{aligned}$$

with

$$A_{e,\Delta} = \begin{pmatrix} A_\Delta + B_\Delta N C_1 & B_\Delta M \\ L C_1 & K \end{pmatrix},\ E_{e,\Delta} := \begin{pmatrix} E_\Delta \\ 0 \end{pmatrix},$$

$$C_{e,\Delta} := \begin{pmatrix} C_{2,\Delta} + D_{2,\Delta} N C_1 & D_{2,\Delta} M \end{pmatrix}.$$

If Γ is internally stabilizing, equivalently $|\sigma(A_{e,\Delta})| < 1$, then the H_2 performance of the closed-loop system $\Sigma \times \Gamma$ is given by

$$J_{\Sigma,\Delta}(\Gamma) = \frac{1}{\Delta}\int_0^\Delta \int_0^{\Delta - s} \text{tr}\ \left(C_2 e^{tA} E E^{\text{T}} e^{tA^{\text{T}}} C_2^{\text{T}}\right) dt\, ds + \frac{1}{\Delta}\text{tr}\ (E_{e,\Delta} P_{e,\Delta} E_{e,\Delta}^{\text{T}}), \tag{6.3}$$

where $P_{e,\Delta}$ is the unique solution of the Lyapunov equation

$$A_{e,\Delta}^{\text{T}} P_{e,\Delta} A_{e,\Delta} - P_{e,\Delta} + C_{e,\Delta}^{\text{T}} C_{e,\Delta} = 0. \tag{6.4}$$

The following theorem shows that our first question above indeed has an affirmative answer:

THEOREM 6.1. *Let Γ_{con} be an internally stabilizing continuous-time compensator. For any $\Delta > 0$ define a discrete-time controller Γ_{dis} by $\Gamma_{\text{dis}} := S_\Delta \Gamma_{\text{con}} H_\Delta$, and let $\Gamma_\Delta := H_\Delta \Gamma_{\text{dis}} S_\Delta$ be the corresponding sampled-data controller with sampling period Δ. Then we have that there exists $\Delta_1 > 0$ such that for all $\Delta \notin \boldsymbol{\Delta}$ with $0 < \Delta < \Delta_1$, Γ_Δ is internally stabilizing. Furthermore,*

$$J_{\Sigma,\Delta}(\Gamma_\Delta) \to J_\Sigma(\Gamma_{\text{con}}) \qquad (\Delta \downarrow 0).$$

Proof. It is easily verified that $\Gamma_{\text{dis}} := S_\Delta \Gamma_{\text{con}} H_\Delta$ is described by the equations

$$\begin{aligned} w_{k+1} &= K_\Delta w_k + L_\Delta y_k\ , \\ u_k &= M w_k + N y_k\ , \end{aligned}$$

with $K_\Delta := e^{\bar{K}\Delta}$ and $L_\Delta := \int_0^\Delta e^{\bar{K}t} dt \bar{L}$. Thus we have

$$A_{e,\Delta} = \begin{pmatrix} A_\Delta + B_\Delta N C_1 & B_\Delta M \\ L_\Delta C_1 & K_\Delta \end{pmatrix}.$$

Note that $A_{e,\Delta} \to I$, the $(n+\ell)\times(n+\ell)$ identity matrix, and that $\frac{1}{\Delta}(A_{e,\Delta} - I) \to A_e$ $(\Delta \downarrow 0)$. Now we will first show that for Δ sufficiently small we have $|\sigma(A_{e,\Delta})| < 1$. Since A_e is stable, there exists $Q > 0$ such that $A_e^{\mathrm{T}}Q + QA_e < 0$. Now note that

$$\frac{1}{\Delta}(A_{e,\Delta}^{\mathrm{T}}QA_{e,\Delta} - Q) = \frac{1}{\Delta}(A_{e,\Delta}^{\mathrm{T}} - I)QA_{e,\Delta} + Q\frac{1}{\Delta}(A_{e,\Delta} - I).$$

Since the right-hand term converges to $A_e^{\mathrm{T}}Q + QA_e < 0$, for Δ sufficiently small we have $A_{e,\Delta}^{\mathrm{T}}QA_{e,\Delta} - Q < 0$. This implies that for Δ sufficiently small $A_{e,\Delta}$ is stable.

Next we show the convergence of the H_2 performance. For Δ sufficiently small we have $|\sigma(A_{e,\Delta})| < 1$, so the H_2 performance is given by (6.3), with $P_{e,\Delta}$ given by the Lyapunov equation (6.4). We shall prove that $P_{e,\Delta} \to P_e$, the unique solution of (6.2). For any Δ sufficiently small define a linear map $m_\Delta : \mathbb{R}^{n\times n} \to \mathbb{R}^{n\times n}$ by

$$m_\Delta(X) := \frac{1}{\Delta}A_{e,\Delta}^{\mathrm{T}}XA_{e,\Delta} - \frac{1}{\Delta}X.$$

Also define a linear map $m : \mathbb{R}^{n\times n} \to \mathbb{R}^{n\times n}$ by

$$m(X) := A_e^{\mathrm{T}}X + XA_e.$$

Note that m and m_Δ are all bijections. We can rewrite m_Δ as

$$m_\Delta(X) = \frac{1}{\Delta}(A_{e,\Delta}^{\mathrm{T}} - I)XA_{e,\Delta} + X\frac{1}{\Delta}(A_{e,\Delta} - I).$$

Recall that $A_{e,\Delta} \to I$ and $\frac{1}{\Delta}(A_{e,\Delta} - I) \to A_e$. Thus we see that $m_\Delta \to m$ $(\Delta \downarrow 0)$. Consequently, also $m_\Delta^{-1} \to m^{-1}$ $(\Delta \downarrow 0)$. Obviously, $P_{e,\Delta} = m_\Delta^{-1}(-\frac{1}{\Delta}C_{e,\Delta}^{\mathrm{T}}C_{e,\Delta})$. In addition, it follows from (2.6) that $\frac{1}{\Delta}C_{e,\Delta}^{\mathrm{T}}C_{e,\Delta} \to C_e^{\mathrm{T}}C_e$. This implies that $P_{e,\Delta} \to m^{-1}(C_e^{\mathrm{T}}C_e)$, which, in turn, is equal to P_e. By (2.5) we see that $\frac{1}{\Delta}E_{e,\Delta}E_{e,\Delta}^{\mathrm{T}} \to E_eE_e^{\mathrm{T}}$. Combining these facts we find that

$$\frac{1}{\Delta}\mathrm{tr}\;(E_{e,\Delta}E_{e,\Delta}^{\mathrm{T}}P_{e,\Delta}) \to \mathrm{tr}\;(E_eE_e^{\mathrm{T}}P_e).$$

Finally, it is immediate that

$$\frac{1}{\Delta}\int_0^\Delta\int_0^{\Delta-s} \mathrm{tr}\;\left(C_1e^{tA}EE^{\mathrm{T}}e^{tA^{\mathrm{T}}}C_1^{\mathrm{T}}\right)dt\,ds \to 0, \qquad \Delta \downarrow 0,$$

which completes the proof of the theorem. □

Now we turn to the second question posed above. In order to be able to answer this question, it is useful to consider this question first for the *linear quadratic problem.*

For this, consider the system $\dot{x}(t) = Ax(t) + Bu(t)$, $z(t) = C_2x(t) + D_2u(t)$. Assume that (A, B) is stabilizable. For a given static state feedback control law $u = Fx$ and initial state x_0, the output function is denoted by z_{F,x_0}. The linear quadratic problem is to minimize for each x_0 the cost-functional $J(x_0, F) := \int_0^\infty \|z_{F,x_0}(t)\|^2dt$ over all $F \in \mathbb{R}^{m\times n}$ such that $\sigma(A + BF) \subset C^-$. It is well known (see [9], [18]) that for each x_0 the optimal cost

$$J^*(x_0) := \inf\{J(x_0, F) \mid F \text{ s.t. } \sigma(A + BF) \subset C^-\} = x_0^{\mathrm{T}}Px_0,$$

where P is the largest real symmetric solution of the linear matrix inequality

$$(6.5)\qquad \begin{pmatrix} A^{\mathrm{T}}P + PA^{\mathrm{T}} + C_2^{\mathrm{T}}C_2 & PB + C_2^{\mathrm{T}}D_2 \\ B^{\mathrm{T}}P + D_2^{\mathrm{T}}C_2 & D_2^{\mathrm{T}}D_2 \end{pmatrix} \geq 0.$$

We want to compare this "normal" linear quadratic problem with its sampled-data version.

In the following, take a fixed sampling period $\Delta > 0$. The sampled-data version of the linear quadratic problem is to do the minimization over all stabilizing sampled-data static state feedback laws. More precisely, for a given $F \in \mathbb{R}^{m\times n}$ define the sampled-data state feedback control law $u = \mathcal{F}_\Delta x$ by $u(t) := Fx(k\Delta)$ ($t \in [k\Delta, (k+1)\Delta)$, $k = 0, 1, 2, \ldots$, or with a slight abuse of notation: $\mathcal{F}_\Delta = H_\Delta F S_\Delta$. For a given $\mathcal{F}_\Delta$ and initial state x_0, denote the output by $z_{\mathcal{F}_\Delta, x_0}$. Define the sampled-data cost functional in the obvious way, and denote it by $J(x_0, \mathcal{F}_\Delta)$. The control law $\mathcal{F}_\Delta$ is called internally stabilizing if for each initial state the controlled state trajectory $x(t)$ converges to 0 as $t \to \infty$. The sampled-data linear quadratic problem is to minimize for each x_0 $J(x_0, \mathcal{F}_\Delta)$ over all internally stabilizing control laws $\mathcal{F}_\Delta$. Let

$$J^*_\Delta(x_0) := \inf\{J(x_0, \mathcal{F}_\Delta) \mid \mathcal{F}_\Delta \text{ is internally stabilizing}\}$$

be the optimal cost. If no internally stabilizing $\mathcal{F}_\Delta$ exists, we define $J^*_\Delta(x_0) := \infty$ for all x_0. We will briefly explain here how the sampled-data linear quadratic can be resolved. First, note that for any $\mathcal{F}_\Delta = H_\Delta F S_\Delta$ we have

$$J(x_0, \mathcal{F}_\Delta) = \sum_{k=0}^{\infty} \int_{k\Delta}^{(k+1)\Delta} \|z_{\mathcal{F}_\Delta, x_0}(t)\|^2 dt.$$

Secondly, note that for all $t \in [k\Delta, (k+1)\Delta)$ we have $\dot{x}(t) = Ax(t) + Bu(t)$, $z_{\mathcal{F}_\Delta, x_0}(t) = C_2 x(t) + D_2 u(t)$, with $u(t) = Fx(k\Delta)$. Hence, on the interval $[k\Delta, (k+1)\Delta)$, x and u satisfy

$$\begin{pmatrix} \dot{x} \\ \dot{u} \end{pmatrix} = \begin{pmatrix} A & B \\ 0 & 0 \end{pmatrix} \begin{pmatrix} x \\ u \end{pmatrix},$$

with $u(k\Delta) = Fx(k\Delta)$. Consequently,

$$\begin{pmatrix} x(t) \\ u(t) \end{pmatrix} = e^{\underline{A}(t-k\Delta)} \begin{pmatrix} x(k\Delta) \\ Fx(k\Delta) \end{pmatrix}$$

for $t \in [k\Delta, (k+1)\Delta)$, with $\underline{A}$ defined by (2.7). Using this, it follows immediately from (2.6) that for $t \in [k\Delta, (k+1)\Delta)$ we have $\|z_{\mathcal{F}_\Delta, x_0}(t)\|^2 = \|C_{2,\Delta} x(k\Delta) + D_{2,\Delta} F x(k\Delta)\|^2$. Obviously, $x(k\Delta))$ evoluates according to $x((k+1)\Delta) = A_\Delta x(k\Delta) + B_\Delta F x(k\Delta)$. Hence we see that if $\mathcal{F}_\Delta = H_\Delta F S_\Delta$, then $J(x_0, \mathcal{F}_\Delta) = \sum_{k=0}^{\infty} \|(C_{2,\Delta} + D_{2,\Delta} F) x_k\|^2$, with $x_{k+1} = (A_\Delta + B_\Delta F) x_k$. It is also easily seen that $\mathcal{F}_\Delta$ is internally stabilizing if and only if $|\sigma(A_\Delta + B_\Delta F)| < 1$. Hence, $J^*_\Delta(x_0) < \infty$ for all x_0 if and only if (A_Δ, B_Δ) is stabilizable.

Consequently, we can make the following conclusion: the sampled-data linear quadratic problem under consideration is equivalent to the "normal" discrete-time linear quadratic problem of minimizing, for the system $x_{k+1} = A_\Delta x_k + B_\Delta u_k$, the cost functional $J_{\text{dis}}(x_0, F) := \sum_{k=0}^{\infty} \|(C_{2,\Delta} x_k + D_{2,\Delta} u_k\|^2$ over all $F \in \mathbb{R}^{m\times n}$ such that $|\sigma(A_\Delta + B_\Delta F)| < 1$. The latter problem was discussed in §3, remark (3.11) and §4, remark (4.6). By applying these results to the situation under consideration we can find a characterization of the optimal cost $J^*_\Delta(x_0)$ of the sampled-data linear quadratic problem:

LEMMA 6.2. *Let $\Delta > 0$ be such that (A_Δ, B_Δ) is stabilizable. Then for each x_0 we have*

$$J^*_\Delta(x_0) = x_0^{\mathrm{T}} P_\Delta x_0,$$

where P_Δ is the largest real symmetric solution of the algebraic Riccati equation

$$A_\Delta^{\mathrm{T}} P_\Delta A_\Delta - P_\Delta + C_{2,\Delta}^{\mathrm{T}} C_{2,\Delta} \tag{6.6}$$

$$-(C_{2,\Delta}^{\mathrm{T}} D_{2,\Delta} + A_\Delta^{\mathrm{T}} P_\Delta B_\Delta)(D_{2,\Delta}^{\mathrm{T}} D_{2,\Delta} + B_\Delta^{\mathrm{T}} P_\Delta B_\Delta)^{+}(D_{2,\Delta}^{\mathrm{T}} C_{2,\Delta} + B_\Delta^{\mathrm{T}} P_\Delta A_\Delta) = 0.$$

Now we will show that as $\Delta \downarrow 0$ the largest real symmetric solution P_Δ of (6.6) converges to P, the largest real symmetric solution of (6.5). We will prove this by proving that for each x_0 we have $J_\Delta^*(x_0) \to J^*(x_0)$. Note that if (A, B) is stabilizable, then for $\Delta > 0$ sufficienly small we have that (A_Δ, B_Δ) is stabilizable.

LEMMA 6.3. *Assume that (A, B) is stabilizable. Then there exists $\Delta_1 > 0$ such that for all $0 < \Delta < \Delta_1$, for all x_0 we have $J_\Delta^*(x_0) < \infty$. For all x_0 we have $\lim_{\Delta\downarrow 0} J_\Delta^*(x_0) = J^*(x_0)$. Also, for all $0 < \Delta < \Delta_1$, P_Δ exists and we have $\lim_{\Delta\downarrow 0} P_\Delta = P$.*

Proof. First of all note that for each sampling period Δ we have $J_\Delta^*(x_0) \geq J^*(x_0)$ for all x_0. This can be shown using that, in fact, for each x_0,

$$J^*(x_0) = \inf\left\{\int_0^\infty \|C_2 x(t) + D_2 u(t)\|^2 dt \mid u \text{ is such that } \lim_{t\to\infty} x(t) = 0\right\}.$$

Hence, by taking u to be generated by the internally stabilizing sampled-data control law $\mathcal{F}_\Delta$, it follows that $J(x_0, \mathcal{F}_\Delta) \geq J^*(x_0)$.

Now, let $\delta > 0$. Let F be such that $\sigma(A+BF) \subset \mathcal{C}^-$ and $J(x_0, F) < J^*(x_0) + \frac{\delta}{2}$. Clearly, $J(x_0, F) = x_0^{\mathrm{T}} L x_0$, where L is the unique solution of the Lyapunov equation

$$(A+BF)^{\mathrm{T}} L + L(A+BF) + (C_2 + D_2 F)^{\mathrm{T}}(C_2 + D_2 F) = 0.$$

Now consider the sampled-data control law $\mathcal{F}_\Delta = H_\Delta F S_\Delta$. By previous arguments, $J(x_0, \mathcal{F}_\Delta) = x_0^{\mathrm{T}} L_\Delta x_0$, where L_Δ is the unique solution of the Lyapunov equation

$$(A_\Delta + B_\Delta F)^{\mathrm{T}} L_\Delta (A_\Delta + B_\Delta F) - L_\Delta + (C_{2,\Delta} + D_{2,\Delta} F)^{\mathrm{T}}(C_{2,\Delta} + D_{2,\Delta} F) = 0.$$

Note that $A_\Delta + B_\Delta F \to I$, $\frac{1}{\Delta}(A_\Delta + B_\Delta F - I) \to A$, and $\frac{1}{\Delta}(C_{2,\Delta} + D_{2,\Delta} F)^{\mathrm{T}}(C_{2,\Delta} + D_{2,\Delta} F) \to (C_2 + D_2 F)^{\mathrm{T}}(C_2 + D_2 F)$ as $\Delta \downarrow 0$. Using a completely similar argument as in the proof of Theorem 6.1 we derive from this that $L_\Delta \to L$, which implies $J(x_0, \mathcal{F}_\Delta) \to J(x_0, F)$. Of course, we also have $J^*(x_0) \leq J_\Delta^*(x_0) \leq J(x_0, \mathcal{F}_\Delta)$. Combining this with $J(x_0, F) < J^*(x_0) + \frac{\delta}{2}$, we find that for δ sufficiently small we have $J^*(x_0) \leq J_\Delta^*(x_0) \leq J^*(x_0) + \delta$. Since δ was arbitrary, this proves the claim. The second statement in the formulation of the theorem is then immediate. □

Let $J_{\Sigma,\mathrm{con}}^*$ be the optimal continuous-time H_2 performance, i.e., the infimum of $J_\Sigma(\Gamma_{\mathrm{con}})$ over all internally stabilizing continuous-time compensators (6.1). It was shown in [15] that if (A, B) is stabilizable and (C_1, A) is detectable, then

$$J_{\Sigma,\mathrm{con}}^* = \mathrm{tr}\,(EE^{\mathrm{T}}P) + \mathrm{tr}\,((A^{\mathrm{T}}P + PA + C_2^{\mathrm{T}}C_2)Q), \tag{6.7}$$

where P is the largest real symmetric solution of the linear matrix inequality (6.5) and Q is the largest real symmetric solution of the dual linear matrix inequality

$$\begin{pmatrix} AQ + QA^{\mathrm{T}} + EE^{\mathrm{T}} & C_1^{\mathrm{T}}Q \\ QC_1 & 0 \end{pmatrix} \geq 0. \tag{6.8}$$

Let $J^*_{\Sigma,\Delta}$ be the optimal sampled-data H_2 performance. If $\Delta \in \boldsymbol{\Delta}$, then we define $J^*_{\Sigma,\Delta} := +\infty$. Our next theorem gives an affirmative answer to the second question posed in the introduction to this section.

THEOREM 6.4. *Let (A, B) be stabilizable and (C_1, A) be detectable. Then there exists Δ_1 such that for all $0 < \Delta < \Delta_1$, $J^*_{\Sigma,\Delta} < \infty$. We have $\lim_{\Delta\downarrow 0} J^*_{\Sigma,\Delta} = J^*_{\Sigma,\mathrm{con}}$.*

In the remainder of this section we will prove this theorem. First, recall the expression (5.1) for $J^*_{\Sigma,\Delta}$. Denote the first term in (5.1) by $I(\Delta)$. Then, under the conditions that (A, B) is stabilizable and (C_1, A) is detectable, we know that for $\Delta \notin \boldsymbol{\Delta}$

$$(6.9)\quad J^*_{\Sigma,\Delta} = I(\Delta) + \frac{1}{\Delta}\mathrm{tr}\,(E_\Delta E_\Delta^{\mathrm{T}} P_\Delta) + \frac{1}{\Delta}\mathrm{tr}\,((A_\Delta^{\mathrm{T}} P_\Delta A_\Delta - P_\Delta + C_{2,\Delta}^{\mathrm{T}} C_{2,\Delta})Q_\Delta)$$

$$-\frac{1}{\Delta}\mathrm{tr}\,((D_{P_\Delta} N_\Delta^* D_{Q_\Delta})(D_{P_\Delta} N_\Delta^* D_{Q_\Delta})^{\mathrm{T}}),$$

where P_Δ is the largest real symmetric solution of (6.6), Q_Δ is the largest real symmetric solution of the dual Riccati equation

$$(6.10)\qquad A_\Delta Q_\Delta A_\Delta^{\mathrm{T}} - Q_\Delta + E_\Delta E_\Delta^{\mathrm{T}} + A_\Delta Q_\Delta C_1^{\mathrm{T}} (C_1 Q_\Delta C_1^{\mathrm{T}})^+ C_1 Q_\Delta A_\Delta = 0,$$

and

$$N_\Delta^* = -D_{P_\Delta}(D_{P_\Delta}^+)^2 D_{P_\Delta} C_{P_\Delta} Q_\Delta C_1^{\mathrm{T}} (D_{Q_\Delta}^+)^2 D_{Q_\Delta}.$$

Here, C_{P_Δ}, D_{P_Δ}, and D_{Q_Δ} are defined by (3.5), (3.4), and (3.7), respectively, with $P = P_\Delta$ and $Q = Q_\Delta$. We will prove that $J^*_{\Sigma,\Delta} \to J^*_{\Sigma,\mathrm{con}}$ by analyzing the asymptotic behavior of the four terms appearing in (6.9) separately:

- It is immediate that the first term, $I(\Delta)$, converges to 0 as $\Delta \downarrow 0$.
- From (2.5) it follows that $\frac{1}{\Delta} E_\Delta E_\Delta^{\mathrm{T}} \to EE^{\mathrm{T}}$. Since also $P_\Delta \to P$, we conclude that the second term, $\frac{1}{\Delta}\mathrm{tr}\,(E_\Delta E_\Delta^{\mathrm{T}} P_\Delta)$, converges to $\mathrm{tr}\,(EE^{\mathrm{T}}P)$.
- To prove convergence of the third term, first note that $Q_\Delta \to Q$. This follows immediately by dualizing Lemma 6.3. Next, as before, rewrite

$$\frac{1}{\Delta}\mathrm{tr}\,(A_\Delta^{\mathrm{T}} P_\Delta A_\Delta - P_\Delta + C_{2,\Delta}^{\mathrm{T}} C_{2,\Delta})Q_\Delta)$$

$$(6.11)\qquad = \frac{1}{\Delta}(A_\Delta^{\mathrm{T}} - I)P_\Delta A_\Delta + P_\Delta \frac{1}{\Delta}(A_\Delta - I) + \frac{1}{\Delta} C_{2,\Delta}^{\mathrm{T}} C_{2,\Delta}.$$

  Since $\frac{1}{\Delta}(A_\Delta - I) \to A$, $A_\Delta \to I$, and $\frac{1}{\Delta} C_{2,\Delta}^{\mathrm{T}} C_{2,\Delta} \to C_2^{\mathrm{T}} C_2$, we conclude that the third term in (6.9) converges to $\mathrm{tr}\,(A^{\mathrm{T}}P + PA + C_2^{\mathrm{T}} C_2)$.
- In order to complete the proof of Theorem 6.4, we should hence prove that the fourth term in (6.9) converges to 0 as $\Delta \downarrow 0$. This is done in the following lemma:

LEMMA 6.5. $\frac{1}{\Delta}\mathrm{tr}\,((D_{P_\Delta} N_\Delta^* D_{Q_\Delta})(D_{P_\Delta} N_\Delta^* D_{Q_\Delta})^{\mathrm{T}}) \to 0$ *as* $\Delta \downarrow 0$.

Proof. Rewrite the fourth term in (6.9) as $\frac{1}{\Delta}\|D_{P_\Delta} N_\Delta^* D_{Q_\Delta}\|^2$, where for any matrix M, $\|M\|$ denotes the Frobenius norm $\mathrm{tr}\,(MM^{\mathrm{T}})$. Note that if M is a given matrix, then M^+M and MM^+ are orthogonal projectors, so consequently $\|MM^+\| = \|MM^+\| = \mathrm{rank}\,(M)$. In particular, this implies that if M is $n \times n$ matrix, then $\|MM^+\| = \|MM^+\| \le n$. Now make the following estimates:

$$\frac{1}{\Delta}\|D_{P_\Delta} N_\Delta^* D_{Q_\Delta}\|^2$$

$$
\begin{aligned}
&\leq \frac{1}{\Delta}\|(D_{P_\Delta}D_{P_\Delta}^{+})(D_{P_\Delta}^{+}D_{P_\Delta})C_{P_\Delta}Q_\Delta C_1^{\mathrm{T}}D_{Q_\Delta}^{+}(D_{Q_\Delta}^{+}D_{Q_\Delta})\|^2\\
&\leq \frac{m^4p^2}{\Delta}\|C_{P_\Delta}Q_\Delta C_1^{\mathrm{T}}D_{Q_\Delta}^{+}\|^2\\
&\leq \frac{m^4p^2}{\Delta}\|C_{P_\Delta}\|^2\|Q_\Delta C_1^{\mathrm{T}}D_{Q_\Delta}^{+}\|^2.
\end{aligned}
$$

As noted before, $C_{P_\Delta}^{\mathrm{T}}C_{P_\Delta} = A_\Delta^{\mathrm{T}}P_\Delta A_\Delta - P_\Delta + C_{2,\Delta}^{\mathrm{T}}C_{2,\Delta}$, so $\frac{1}{\Delta}\|C_{P_\Delta}\|^2 \to \mathrm{tr}\,(A^{\mathrm{T}}P + PA + C_2^{\mathrm{T}}C_2)$. On the other hand, by noting that Q_Δ satisfies the Riccati equation (6.10), where $A_\Delta = e^{A\Delta}$ is invertible, we see that

$$
\begin{aligned}
&\|Q_\Delta C_1^{\mathrm{T}}D_{Q_\Delta}^{+}\|^2\\
&\quad = \mathrm{tr}\,(Q_\Delta C_1^{\mathrm{T}}(C_1Q_\Delta C_1)^{+}C_1Q_\Delta)\\
&\quad = \mathrm{tr}\,(Q_\Delta - A_\Delta^{-1}Q_\Delta A_\Delta^{-T} + A_\Delta^{-1}E_\Delta E_\Delta^{\mathrm{T}}A_\Delta^{-\mathrm{T}}).
\end{aligned}
$$

Since $Q_\Delta \to Q$, $A_\Delta^{-1} \to I$ and $E_\Delta E_\Delta^{\mathrm{T}} \to 0$, the latter converges to zero as $\Delta \downarrow 0$. □

A GEOMETRIC APPROACH TO THE MINIMUM SENSITIVITY DESIGN PROBLEM [*]

ERIK I. VERRIEST[†] AND W. STEVEN GRAY[‡]

Abstract. In this paper a Riemannian geometric framework is given for the minimum sensitivity design problem and its solution using a natural optimization criterion. The theory is then applied to the case of linear systems to generate a class of minimum sensitivity realizations related to the so-called balanced realizations. In particular, conditions are given which are applicable in the cases of fixed point and floating point implementations.

Key words. sensitivity, realization theory, Riemannian geometry, balanced realizations

AMS subject classifications. 93B35, 53B21

1. Introduction.

In this paper we consider the problem of selecting parameterizations for a given mathematical model which minimize the sensitivity of the model's behavior to perturbations in the parameter values. We call this problem the *minimum sensitivity design problem.* It often arises in applied mathematics and engineering, and has received a great deal of attention in a variety of applications. For example, given a digital linear filter (model structure) with some fixed input-output relationship (model's behavior), a common question is how to find an internal representation (parameterization) which minimizes the sensitivity of the input-output relationship to quantization (perturbations) of the filter coefficients (parameter values). This problem differs from the parameter identification problem in that one assumes at least one parameterization is already available. The specific context introduced for solving this problem is Riemannian geometry. The primary motivations for a geometric approach are the generality of the synthesis techniques and the success of such an approach in the area of parametric system identification [13]–[15].

Once developed, the primary focus is on applying the technique to the synthesis of minimum sensitivity state space models for dynamical systems. Only linear systems are considered in this paper. The performance index derived in the geometric context is related to (but distinct from) those found via frequency domain techniques in [21], [24], [25], [26], [30]. The main difference is that the performance index introduced here gives a bound on the sensitivity of the impulse response in terms of a mixed ℓ_∞/ℓ_2 norm rather than on the sensitivity of the frequency response using a mixed L_1/L_2 norm with respect to the realization coefficients. Both approaches compliment each other and in certain ways are closely related. A strength of the geometric method, however, is that it generalizes easily to other classes of systems where frequency domain interpretations are not as tractable [9], [11], [12], [27]. Practical applications of this research include the synthesis of state space realizations with superior coefficient quantization properties and the synthesis of analog networks with minimum component sensitivity.

The paper is composed of two main sections. The goal of the first section is to motivate and describe a geometric framework for solving the minimum sensitivity design problem that leads to a general optimality equation. It is then demonstrated in the second section how this theory can be used in the synthesis of minimum sensitivity state space realizations of discrete-time linear time-invariant systems.

2. The minimum sensitivity design problem. The goal of this section is to describe the minimum sensitivity design problem in a differential geometric setting. The main intuitive idea behind the method is as follows. Given the set of all admissible realizations for a given mathematical model, we first partition this set into equivalence classes, where two realizations are said to be equivalent if they map to the same model behavior. Since the applications which follow will deal specifically with input-output systems, the model behavior to which we refer is the (output) response to some fixed input. For linear systems, the behavior we are usually interested in is the impulse response. Generally, each equivalence class will contain more than one realization. Therefore, the idea is to define a sensitivity measure which reflects how perturbations of realization coefficients of a given realization perturb the model behavior. Within a fixed equivalence class, we then designate those realizations which have minimal sensitivity as the ones solving the minimum sensitivity design problem.

2.1. Abstract realization spaces. We consider a realization θ to be an ordered set of real numbers denoted by $\theta = (\theta^1, \theta^2, \ldots, \theta^n)$. It will be assumed that the system under consideration is completely specified by such a vector θ. Since these parameters are real attributes of the system, it is natural to assume that what can be known exactly is their membership to certain intervals. Therefore, the ambient space in which a realization exists is the cartesian product space $\Re^n$, and the usual topology (generated by cartesian products of open intervals) is the natural topology it should be endowed with. It is not natural to assume any other structure at this point. In particular, since neither the sum of two realizations nor the scalar multiple of a realization may have any physical significance, a *global* vector space structure is not naturally associated with it. Thus, the collection of all realizations will be considered as an affine space, denoted by $\mathcal{A}^n$, with a *local* vector space structure isomorphic to the usual vector space $\mathcal{V}^n$ on $\Re^n$. Therefore, there is no assumed relation between the vectors belonging to the vector spaces attached at different points. We will be interested in an open subset of $\mathcal{A}^n$ referred to as either the set of *admissible realizations* or the *realization space*, and denoted by Θ. Typically, but not exclusively, open sets arise as complements of inverse images by continuous maps.

Now we introduce perturbations in the parameters. If these perturbations must be quantified in any way one needs a metric structure, at least locally at each point (i.e., in the local vector space attached at the nominal parametrization) in order to discuss perturbations of fixed norm, and also to allow for the notion of orthogonality. The latter also allows one to talk about the *directions* of perturbations. If Θ is paracompact, then a Riemannian structure g can be put on Θ (or, more exactly, its tangent bundle). This means that for each $\theta \in \Theta$, it follows that $g(\theta)$ is a symmetric, positive definite, nondegenerate bilinear form defined on $T_\theta\Theta \times T_\theta\Theta$ with a local representation

$$g_{ij}(\theta) = g(\theta)\left(\frac{\partial}{\partial\theta^i}, \frac{\partial}{\partial\theta^j}\right), \tag{1}$$

where $\partial/\partial\theta^i$ $i = 1, 2, \ldots, n$ are the canonical basis vectors for the tangent space $T_\theta\Theta$ and each g_{ij} is a smooth function of θ. Then $g : \Theta \mapsto T_2^0\Theta$ corresponds to the

Riemannian metric on Θ, where $T_2^0\Theta$ denotes the bundle of covariant two-tensors defined on Θ. We stress again that we are not using global vector space structures, but only local ones to describe the perturbations with respect to a given nominal point. The following definition summarizes what we mean by a realization space.

DEFINITION 2.1. *A* realization space *in $\mathcal{A}^n$ is a smooth Riemannian manifold (Θ, g), where Θ is an open subset of the affine space $\mathcal{A}^n$ and g is a nondegenerate Riemannian metric on $T\Theta \times T\Theta$.*

In what follows, "g" will be understood if we speak about the realization space Θ.

Now let $T_\theta^*\Theta$ denote the dual space of the tangent space at each $\theta \in \Theta$, and let

$$\flat : T_\theta\Theta \mapsto T_\theta^*\Theta : v \mapsto g(\theta)(v, \cdot), \tag{2}$$

$$\sharp : T_\theta^*\Theta \mapsto T_\theta\Theta : g(\theta)(v, \cdot) \mapsto v \tag{3}$$

denote the natural isomorphism that the metric tensor g induces between the two spaces. Denoting the canonical basis for $T_\theta^*\Theta$ by $\{d\theta^1, d\theta^2, \ldots, d\theta^n\}$, the metric tensor can be represented in the form

$$g = g_{ij} d\theta^i \otimes d\theta^j, \tag{4}$$

where $\otimes$ denotes the usual tensor product and the Einstein summation convention is assumed. Furthermore, if f is a smooth real-valued function defined on Θ, then $df(\theta) \in T_\theta^*\Theta$, and hence can be written as the linear combination

$$df(\theta) = \left.\frac{\partial f}{\partial \theta^i}\right|_\theta d\theta^i. \tag{5}$$

The gradient of f is defined as the vector field given by

$$\nabla f : \Theta \mapsto T_\theta\Theta : \theta \mapsto (df(\theta))^\sharp = g^{ij}(\theta) \left.\frac{\partial f}{\partial \theta^i}\right|_\theta \frac{\partial}{\partial \theta^j}, \tag{6}$$

where $[g^{ij}]$ is the matrix inverse of the metric tensor $[g_{ij}]$.

Within a given realization space (Θ, g), we wish to form equivalence classes which reflect some commonality between realizations based on their associated model behavior. To this end, we adapt a notion from quantum mechanics described in the following definition (see, for example, [1]).

DEFINITION 2.2. *Let f be a smooth real-valued function defined on a realization space (Θ, g) such that the gradient ∇f is nonzero everywhere on Θ. Then, f will be called an* observable *over Θ, and the scalar $f(\theta)$, where $\theta \in \Theta$, will be referred to as the value of the observable at θ.*

The significance of an observable is that two realizations are considered equivalent relative to f if they yield the same observable value, i.e., $\theta \sim \hat{\theta}$ for $\theta, \hat{\theta} \in \Theta$ if and only if $f(\theta) = f(\hat{\theta})$. In a system theory context, an observable could be the evaluation of the transfer function for an input-output system evaluated at a particular frequency or the impulse response at a specific instant of time. Observables are also referred to as *system functions* [8]. In a topological sense, observables are smooth, regular canonical projections which map Θ to some subset of the real numbers. The assumption on the lack of critical points is technical but essential in view of the lemmas discussed below.

We designate an equivalence class on Θ relative to f and corresponding to the value $k \in f(\Theta)$ as

$$M_k(f) = f^{-1}(k), \tag{7}$$

and the set of all such classes, i.e., the quotient space, as $\Theta/\sim$. The quotient space of minimal state space realizations of linear time-invariant systems has received a great deal of attention in the system identification problem (see [13]–[15], [19]). Our interest, however, is not in the quotient space, but rather the geometric and topological aspects of *individual* equivalence classes. The following lemmas give the geometric structure of an equivalence class and the quotient space.

LEMMA 2.3 (see [6], [20]). *Let f be an observable on realization space (Θ, g) and $k \in f(\Theta)$. Then, the equivalence class $M_k(f) = f^{-1}(k)$ is a Riemannian submanifold of Θ with codimension equal to one.*

LEMMA 2.4 (see [6], [20]). *Let f be an observable on realization space (Θ, g). Then, $\Theta/\sim$ is a smooth foliation on Θ with codimension equal to one.*

An observable thus induces a decomposition of the realization space into connected submanifolds of dimension $n-1$, usually called the *leaves* of the foliation, which stack up locally like subsets of $\Re^{n-1} \times \Re$, where the second coordinate (i.e., k in the above discussion) is held fixed. Perturbations in the parameters induce perturbations in the value of the observable. Among all perturbations of fixed norm (induced by the Riemannian metric), the worst-case perturbation is the perturbation that induces the maximal change in the observable. The minimum sensitivity design problem is to determine which point in Θ (i.e., realizations) on a fixed leaf, when perturbed, will have the smallest worst-case perturbation of the corresponding observable value.

2.2. Extremal sensitivity points. Since each leaf of the foliation induced by an observable function f is itself a Riemannian manifold, it makes sense to talk about the tangent space to a fixed leaf. Furthermore, from the point of view that each leaf is really a *level surface* of the observable function f, the tangent space of a leaf $M_k(f)$ at a fixed point θ can be described by the following subset of the tangent space $T_\theta\Theta$:

$$\begin{aligned} T_\theta M_k(f) &= \{v \in T_\theta\Theta : df(\theta)(v) = 0\} \\ &= \{v \in T_\theta\Theta : g(\theta)(\nabla f, v) = 0\}. \end{aligned} \tag{8}$$

In view of the representation in (8), it follows that $\nabla f \mid_{M_k(f)}$, the restriction of ∇f to $M_k(f)$, is a normal vector field defined on the leaf corresponding to value k. Since for any perturbation $\Delta\theta \in T_{\theta_0}\mathcal{H}$ we have

$$f(\theta) = f(\theta_0) + g(\theta_0)(\nabla f(\theta_0), \Delta\theta), \tag{9}$$

it follows that the worst perturbation of f is obtained for $\Delta\theta$ proportional to the gradient ∇f. Clearly the induced *worst-case deviation* for a unit pertubation vector will be $\| \nabla f \|$. Hence, the realizations in $M_k(f)$ which have extremal sensitivity are those which minimize or maximize the norm of the vectors in this vector field, where the norm function is defined as

$$\| \cdot \| : T_\theta\Theta \mapsto \Re : v \mapsto \sqrt{g(\theta)(v,v)}. \tag{10}$$

Consequently, we have the following more convenient definition.

DEFINITION 2.5. *A realization $\theta^* \in M_k(f)$ is an* extremal sensitivity *point of $M_k(f)$ if θ^* extremizes the performance index*

$$L(\theta) = \frac{1}{2} \parallel \nabla f(\theta) \parallel^2 \tag{11}$$

over the manifold $M_k(f)$.

As an immediate consequence of this definition we get the following theorem, specifying a necessary condition for determining an extremal sensitivity point.

THEOREM 2.6 (see [28]). *If a realization $\theta^* \in M_k(f)$ is an extremal sensitivity point, then*

$$\nabla H(\theta^*) = \frac{1}{2}\nabla g(\theta^*)(\nabla f(\theta^*), \nabla f(\theta^*)) - \lambda \nabla f(\theta^*) = 0, \tag{12}$$

where H is the scalar-valued Hamiltonian function

$$H(\theta) = \frac{1}{2} g(\theta)(\nabla f(\theta), \nabla f(\theta)) - \lambda f(\theta). \tag{13}$$

Proof. The stated condition is the Euler–Lagrange equation for the constrained optimization problem. □

In order to use Theorem 2.6 in a specific problem, one needs a local representation of optimality equation (12), which interestingly has considerable structure not immediately apparent. Consider the following definition and related lemmas.

DEFINITION 2.7 (see [7]). *Let f be an observable on realization space (Θ, g). Then, the* Hessian operator *of f at $\theta \in \Theta$ is the linear operator defined by*

$$\nabla^2 f(\theta) : T_\theta \Theta \mapsto T_\theta \Theta : u \mapsto \nabla_u \nabla f(\theta) \triangleq \nabla^2 f(\theta)(u), \tag{14}$$

where ∇ denotes the unique, symmetric (Riemannian) affine connection compatible with the metric g, i.e., for $\theta \in \Theta$,

$$\nabla : T_\theta \Theta \times T_\theta \Theta \mapsto T_\theta \Theta : (u, v) \mapsto \nabla_u v = (u^i v^j \Gamma^k_{ij} + u(v^k)) \frac{\partial}{\partial \theta^k} \tag{15}$$

with $u = u^i(\partial/\partial\theta^i)$, $v = v^i(\partial/\partial\theta^i)$, and the Christoffel symbols of the Riemannian connection specified by

$$\Gamma^k_{ij} = \frac{1}{2}\left\{\frac{\partial}{\partial \theta^i} g_{jm} + \frac{\partial}{\partial \theta^j} g_{mi} - \frac{\partial}{\partial \theta^m} g_{ij}\right\} g^{mk}. \tag{16}$$

LEMMA 2.8 (see [7]). *The Hessian operator has the following properties:*

(i) *$\nabla^2 f(\theta)$ is self-adjoint;*

(ii) *the bilinear form $\nabla^2 f(\theta)(u, v) \triangleq g(\theta)(\nabla^2 f(\theta)(u), v)$ is symmetric;*

(iii) *in local coordinates,*

$$\nabla^2 f(\theta)(v) = g^{jk}\left[\frac{\partial^2 f}{\partial \theta^i \partial \theta^j} - \Gamma^\ell_{ij} \frac{\partial f}{\partial \theta^\ell}\right] v^i \frac{\partial}{\partial \theta^k}. \tag{17}$$

LEMMA 2.9. *The optimality equation in Theorem 2.6 is equivalent to*

$$(\nabla^2 f(\theta^*) - \lambda I)(\nabla f(\theta^*)) = 0, \tag{18}$$

where I is the identity operator on $T_{\theta^*}\mathcal{H}$. That is, the gradient of f at θ^* must be in the eigenspace of the Hessian operator of f at θ^*.

Proof. Assuming all vector fields below are evaluated at $\theta = \theta^*$, and using the property

$$u(g(\theta)(v, w)) = g(\theta)(\nabla_u v, w) + g(\theta)(v, \nabla_u w) \tag{19}$$

for $u, v, w \in T_\theta\Theta$, it follows that:

$$\begin{aligned}
\nabla H &= \frac{1}{2}\nabla g(\nabla f, \nabla f) - \lambda\nabla f \\
&= \frac{1}{2}(dg(\nabla f, \nabla f))^{\#} - \lambda\nabla f \\
&= \frac{1}{2}\left(\frac{\partial g}{\partial\theta^i}(\nabla f, \nabla f)d\theta^i\right)^{\#} - \lambda\nabla f \\
&= \frac{1}{2}((g(\nabla_{\frac{\partial}{\partial\theta^i}}\nabla f, \nabla f) + g(\nabla f, \nabla_{\frac{\partial}{\partial\theta^i}}\nabla f))d\theta^i)^{\#} - \lambda\nabla f \\
&= (g(\nabla f, \nabla_{\frac{\partial}{\partial\theta^i}}\nabla f)d\theta^i)^{\#} - \lambda\nabla f \\
&= \left(g\left(\nabla_{\nabla f}\nabla f, \frac{\partial}{\partial\theta^i}\right)d\theta^i\right)^{\#} - \lambda\nabla f \\
&= \nabla_{\nabla f}\nabla f - \lambda\nabla f \\
&= \nabla^2 f(\nabla f) - \lambda\nabla f = 0. \qquad \square
\end{aligned}$$

Using the local representation of $\nabla^2 f(\theta)$ given in Lemma 2.8, it follows immediately that equation (18) has the local form

$$\left(g^{jk}\left[\frac{\partial^2 f}{\partial\theta^i\partial\theta^j} - \Gamma^\ell_{ij}\frac{\partial f}{\partial\theta^\ell}\right] - \lambda\delta^k_i\right)g^{mi}\frac{\partial f}{\partial\theta^m}\frac{\partial}{\partial\theta^k} = 0. \tag{20}$$

Then by substitution of either equation (16) for Γ^k_{ij} above or a direct computation of $\nabla g(\nabla f, \nabla f)$ in local coordinates, it also follows that an equivalent expression is

$$\left(g^{jk}\left[\frac{\partial^2 f}{\partial\theta^i\partial\theta^j} + \frac{1}{2}g_{is}\frac{\partial g^{ts}}{\partial\theta^j}\frac{\partial f}{\partial\theta^t}\right] - \lambda\delta^k_i\right)g^{mi}\frac{\partial f}{\partial\theta^m}\frac{\partial}{\partial\theta^k} = 0. \tag{21}$$

This equation (in terms of only the observable, the metric tensor, and its inverse) yields a matrix representation which is far more amenable for computations and thus motivates the following definition.

DEFINITION 2.10. *Let f be an observable on realization space (Θ, g). Then, the* nonsymmetric Hessian operator *of f at $\theta \in \Theta$ is the linear operator defined in local coordinates by*

$$\hat{\nabla}^2 f(\theta) : T_\theta\Theta \mapsto T_\theta\Theta : u \mapsto g^{jk}\left[\frac{\partial^2 f}{\partial\theta^i\partial\theta^j} + \frac{1}{2}g_{is}\frac{\partial g^{ts}}{\partial\theta^j}\frac{\partial f}{\partial\theta^t}\right]u^i\frac{\partial}{\partial\theta^k}, \tag{22}$$

where $u = u^i(\partial/\partial\theta^i)$.

LEMMA 2.11. *Let f be an observable on realization space (Θ, g). Then for any $\theta \in \Theta$,*

$$\hat{\nabla}^2 f(\theta)(\nabla f(\theta)) = \nabla^2 f(\theta)(\nabla f(\theta)). \tag{23}$$

Proof. The lemma is proved by direct substitution. □

Equation (21) expressed in terms of the Vetter derivative and standard matrix calculus operators [2], [3], [4], [5] has the form

$$\left(G^{-1}\frac{\partial^2 f}{\partial\theta^2}+\frac{1}{2}G^{-1}\left(I_n\otimes\frac{\partial f}{\partial\theta^T}\right)\left(\frac{\partial}{\partial\theta}\otimes G^{-1}\right)G-\lambda I_n\right)G^{-1}\frac{\partial f}{\partial\theta}=0, \tag{24}$$

where G denotes a matrix with entries g_{ij}, I_n is an $n\times n$ identity matrix, and $\otimes$ represents the Kronecker product. We denote by $\partial f/\partial\theta$ and $\partial^2 f/\partial\theta^2$, respectively, the column vector of first-order partial derivatives of f with respect to the components of θ, and the matrix formed by the second-order partial derivatives. These are indeed the gradient and Hessian if the metric tensor is the identity, but in the general context they have no direct meaning. For this special case of the uniform metric $G = I_n$, we get a simplified version of the optimality condition which has a matrix notation representation

$$\left(\frac{\partial^2 f}{\partial\theta^2}-\lambda I_n\right)\frac{\partial f}{\partial\theta}=0. \tag{25}$$

Another matrix form may also be obtained which is entirely equivalent to equation (21), but avoids the use of Kronecker products.

DEFINITION 2.12. *Let f be an observable on realization space (Θ, g). Define the* pseudogradient *as*

$$df \triangleq \left(\frac{\partial f}{\partial\theta}\right)^T\cdot G^{-\frac{1}{2}} \tag{26}$$

and the pseudo-Hessian *matrix as*

$$d^2 f \triangleq G^{-\frac{1}{2}}\frac{\partial^2 f}{\partial\theta^2}G^{-\frac{1}{2}}+\frac{1}{2}G^{\frac{1}{2}}\left[\frac{\partial G^{-1}}{\partial\theta^1}\cdot\frac{\partial f}{\partial\theta},\ldots,\frac{\partial G^{-1}}{\partial\theta^n}\cdot\frac{\partial f}{\partial\theta}\right]G^{-\frac{1}{2}}. \tag{27}$$

The extremal sensitivity criterion has a form analogous to equation (24), but uses the pseudogradient and the pseudo-Hessian rather than the gradient and the nonsymmetric Hessian. If the realization space (Θ, g) is such that the parameters are functionally independent of each other, except for the constraint $f(\theta) = k$, then the perturbation of the parameters should be considered independently of each other. Hence, in this case we set $g_{ij} = 0$ whenever $i \neq j$. Moreover, if the perturbation metric for one parameter depends only on the nominal value of that parameter and not the others, then we call the realization space (Θ, g) a *realization space of independent parameter design.* It turns out that in this case the problem is *symmetric*, and the pseudogradient and pseudo-Hessian are, respectively,

$$df = \left(\frac{\partial f}{\partial\theta}\right)^T \operatorname{diag}\left(\frac{1}{\sqrt{g_{ii}}}\right), \tag{28}$$

and

$$d^2 f = \operatorname{diag}\left(\sqrt{g^{ii}}\right)\frac{\partial^2 f}{\partial\theta^2}\operatorname{diag}\left(\sqrt{g^{ii}}\right)+\operatorname{diag}\left(\frac{\partial\sqrt{g^{ii}}}{\partial\theta^i}\right)\operatorname{diag}(df), \tag{29}$$

where, now, $g^{ii} = 1/g_{ii}$.

While studying the sensitivity of realizations in the next section, it will be desirable not only to characterize extremal sensitivity realizations, but also to show explicitly that certain sets have *minimum* sensitivity. One can easily test for this property by examining the definiteness of the bilinear form associated with the Hessian of the Hamiltonian function H defined in (13). This test is posed as a matrix definiteness problem in the following lemma.

LEMMA 2.13. *An extremal sensitivity point $\theta^* \in M_k(f)$ has the minimum sensitivity property if the matrix*

$$\frac{\partial^2 H}{\partial \theta^2} + \frac{1}{2}\left(I_n \otimes \frac{\partial H}{\partial \theta^T}\right)\left(\frac{\partial}{\partial \theta} \otimes G^{-1}\right) G \tag{30}$$

is positive definite on the tangent space of $M_k(f)$ at θ^*, where $H = (1/2)g^{st}(\partial f/\partial \theta^s)$ $(\partial f/\partial \theta^t) - \lambda f$.

Proof. The definiteness of the Hessian of H always determines the nature of each extremal. Equation (30) is simply a matrix representation of the bilinear form $\nabla^2 H(\theta^*)(u, v)$ in local coordinates. □

Writing (30) in fully expanded form is simple to do in principle, but tedious in any notation. The special case of the uniform metric $g_{ij} = \delta_{ij}$, however, is significantly simpler and will be used in later development:

$$[\nabla^2 H] = \left[\sum_m \frac{\partial^3 f}{\partial \theta^m \partial \theta^i \partial \theta^j}\frac{\partial f}{\partial \theta^m}\right] + \left[\frac{\partial^2 f}{\partial \theta^i \partial \theta^j}\right]^2 - \lambda\left[\frac{\partial^2 f}{\partial \theta^i \partial \theta^j}\right]. \tag{31}$$

2.3. Multiple observables. We now consider extensions of the notion of an observable. In the applications which follow, the need arises for a method which will allow one to consider the sensitivity of several observables *simultaneously*. For example, one may wish to define as observables the impulse response of a system at r specific time instances where $r > 1$. The following extension of Definition 2.2 addresses this requirement.

DEFINITION 2.14. *Let (Θ, g) be a realization space and $F : \Theta \mapsto \Re^{p \times m}$ be a smooth function whose differential $dF(\theta)$ is surjective for all $\theta \in \Theta$. Then, F will be called a* (matrix) observable *over Θ, and the matrix $F(\theta)$ will be referred to as its value at θ.*

We have the following results, which are analogous to Lemmas 2.3 and 2.4.

LEMMA 2.15 (see [6], [20]). *Let $F : \Theta \mapsto \Re^{p \times m}$ be a matrix observable on realization space (Θ, g) and $K \in F(\Theta)$. Then, the equivalence class $M_K(F) = F^{-1}(K)$ is a Riemannian submanifold of Θ with codimension equal to pm.*

LEMMA 2.16 (see [6], [20]). *An observable $F : \Theta \mapsto \Re^{p \times m}$ induces a smooth foliation of codimension pm on realization space (Θ, g).*

Another useful generalization of the scalar-valued observable is given in the following definition.

DEFINITION 2.17. *Let $f : Q \times \Theta \mapsto \Re$ be a function such that for each Λ in some admissible set Q it follows that the marginal map $f_\Lambda : \Theta \mapsto \Re$ is an observable function. Then, the set $\{f_\Lambda : \Lambda \in Q\}$ is called a* family of observables.

A simple example of such a family is the linear combination of two scalar-valued observables f_1 and f_2 given by

$$f_\Lambda(\theta) = \lambda_1 f_1(\theta) + \lambda_2 f_2(\theta),$$

where $\Lambda = [\lambda_1 \ \ \lambda_2]$ and $\Lambda\Lambda^T = 1$. A generalization of this example is given in the following lemma.

LEMMA 2.18 (see [10], [28]). *Let $F : \Theta \mapsto \Re^{p\times m}$ be a matrix-valued observable on realization space (Θ, g) and $K \in F(\Theta)$. Define the set $\{f_\Lambda : \Lambda \in Q\}$, where*

$$f_\Lambda(\theta) = \sum_{i,j=1}^{p,m} \lambda_{ji}(f_{ij}(\theta) - k_{ij}) = \operatorname{Tr} \Lambda(F(\theta) - K), \tag{32}$$

$$Q = \{\Lambda \mid \Lambda\Lambda^T = I_m \ \textit{if} \ p \geq m \ \textit{or} \ \Lambda^T\Lambda = I_p \ \textit{if} \ m \geq p\}. \tag{33}$$

(Clearly $Q = O(m)$, the set of $m \times m$ orthogonal matrices, when $p = m$.) Then

(i) $\{f_\Lambda : \Lambda \in Q\}$ is a family of observables;

(ii) $f_\Lambda(\theta) = 0$ for all $\Lambda \in Q$ if and only if $F(\theta) = K$.

Proof. (i) Observe that

$$df_\Lambda(\theta) = \left.\frac{\partial f_\Lambda}{\partial \theta^k}\right|_\theta d\theta^k = \sum_{i,j=1}^{p,m} \lambda_{ji} \left.\frac{\partial f_{ij}(\theta)}{\partial \theta^k}\right|_\theta d\theta^k = 0$$

for some θ if and only if $\Lambda = 0$ since $dF(\theta)$ is surjective. But $0 \notin Q$, and thus $df_\Lambda(\theta) \neq 0$ for all $\Lambda \in Q$ and $\theta \in \Theta$.

(ii) The necessity of the condition $F(\theta) = K$ is the only nontrivial part of the proof. Define $E(\theta) = F(\theta) - K$. For fixed $\theta \in \Theta$, let $E(\theta)$ have the singular value decomposition

$$E(\theta) = \sum_{j=1}^{\min(p,m)} \sigma_j u_j v_j^T.$$

Since Λ can be arbitrarily selected from Q, and any element of Q has all of its singular values equal to unity, it follows that

$$\begin{aligned}
\operatorname{Tr}\Lambda E(\theta) &= \operatorname{Tr}\left(\sum_{i=1}^{\min(p,m)} v_i u_i^T \cdot \sum_{j=1}^{\min(p,m)} \sigma_j u_j v_j^T\right) \\
&= \operatorname{Tr}\left(\sum_{i=1}^{\min(p,m)} \sum_{j=1}^{\min(p,m)} \sigma_j \delta_{ij} v_i v_j^T\right) \\
&= \operatorname{Tr}\left(\sum_{i=1}^{\min(p,m)} \sigma_i v_i v_i^T\right) \\
&= \sum_{i=1}^{\min(p,m)} \sigma_i \\
&= 0.
\end{aligned}$$

However, by the definition of the singular value decomposition, $\sigma_i \geq 0$ for all $i = 1 \ldots \min(p, m)$, thus $E(\theta) = 0$. □

While a matrix-valued observable and a family of scalar-valued observables can each be used to describe a given equivalence class, an important advantage in working with the latter is the relative ease with which the sensitivity theory developed in §2.2 can be adapted. This is illustrated by the following example.

Example. The goal is to determine the state space realizations of a second-order linear system with the property that the coefficients of the characteristic equation have extremal sensitivity with respect to fixed point and floating point quantization of the realization coefficients. Both fixed point and floating point problems are independent parameter design problems. Fixed point parameter quantization is modelled by introducing absolute perturbations $\Delta\theta^i$ of fixed magnitude such that $\hat{\theta}^i = \theta^i + \Delta\theta^i$. Floating point parameter quantization, on the other hand, is modelled by the introduction of a relative perturbation $\Delta\theta^i/\theta^i$ of fixed magnitude since, now, $\hat{\theta}^i = \theta^i[1 + \Delta\theta^i/\theta^i]$. In a geometric context we view these models as an endowment of Θ with two different metrics, an absolute metric $g^{\alpha}_{ij}(\theta) = \delta_{ij}$ and a relative metric $g^{\rho}_{ij}(\theta) = (\theta^i)^{-2}$ if $i = j$ and zero otherwise.

The transfer function of the system is assumed to have the form

$$G(s) = \frac{\omega_n^2}{s^2 + 2\zeta\omega_n s + \omega_n^2}.$$

Thus, we are interested in the set of state space realizations (A, b, c) such that $\det(sI - A) = s^2 + 2\zeta\omega_n s + \omega_n^2$. In the fixed point case we take $\Theta \equiv \Re^4$ ($\theta = [a_{11}\ a_{21}\ a_{12}\ a_{22}]^T$) and in the floating point case we assume Θ is equivalent to $\Re^4$ minus the points along the coordinate axes, where the relative metric is unbounded. (This is always an implicit assumption when the floating point metric is used.) The *two* algebraic constraints on the realization coefficients yield the vector observable

$$F(\theta) = \begin{bmatrix} a_{11} + a_{22} + 2\zeta\omega_n \\ a_{11}a_{22} - a_{21}a_{12} - \omega_n^2 \end{bmatrix},$$

which induces a foliation on Θ with codimension equal to two. Clearly, the leaf of the foliation in which we are interested has an observable value equal to zero. The family of observables is defined by

$$f_\Lambda(\theta) = \mathrm{Tr}\ \Lambda F(\theta) = \Lambda F(\theta),$$

where $\Lambda = [\lambda_1\ \lambda_2]$ and $\Lambda\Lambda^T = 1$. Note from Lemma 2.18 it follows that $f_\Lambda(\theta) = 0$ for all Λ with $\Lambda\Lambda^T = 1$ if and only if $F(\theta) = 0$. To solve the optimization problems, apply the criterion given by equation (24) using the absolute and relative metrics. Using the absolute metric it follows easily from equation (25) that the optimality equations are as follows:

$$\lambda_1 + \lambda_2 a_{11} = \bar{\lambda}(\lambda_1 + \lambda_2 a_{22}), \tag{34}$$

$$a_{21} = -\bar{\lambda} a_{12}, \tag{35}$$

$$a_{12} = -\bar{\lambda} a_{21}, \tag{36}$$

$$\lambda_1 + \lambda_2 a_{22} = \bar{\lambda}(\lambda_1 + \lambda_2 a_{11}), \tag{37}$$

where $\lambda = \bar{\lambda}\lambda_2$. The above equations together with the constraints $F(\theta) = 0$ and $\Lambda\Lambda^T = 1$ define a system of seven (not necessarily independent) equations in seven variables. It can be easily shown that the extremal sensitivity realizations must have an A matrix of the form

$$A = \begin{cases} \begin{bmatrix} -\sigma & \pm\omega_d \\ \mp\omega_d & -\sigma \end{bmatrix} & : \quad 0 \le \zeta \le 1, \\ \begin{bmatrix} -\sigma \pm \omega_d \cos\theta & \omega_d \sin\theta \\ \omega_d \sin\theta & -\sigma \mp \omega_d \cos\theta \end{bmatrix} & : \quad \zeta \ge 1, \end{cases}$$

where $\sigma = \zeta\omega_n$, $w_d = \omega_n\sqrt{|1-\zeta^2|}$, and θ is an arbitrary real parameter. In fact, using Lemma 2.13 it can be shown that these realizations are of minimum sensitivity when $\zeta \neq 1$.

Using the relative metric, it follows directly that the optimality equations are as follows:

$$a_{11}(\lambda_1 + \lambda_2 a_{22})^2 + a_{22}^2\lambda_2(\lambda_1 + \lambda_2 a_{11}) = \lambda(\lambda_1 + \lambda_2 a_{22}), \tag{38}$$

$$2a_{21}a_{12} = -\bar{\lambda}, \tag{39}$$

$$2a_{12}a_{21} = -\bar{\lambda}, \tag{40}$$

$$a_{11}^2\lambda_2(\lambda_1 + \lambda_2 a_{22}) + a_{22}(\lambda_1 + \lambda_2 a_{11})^2 = \lambda(\lambda_1 + \lambda_2 a_{11}). \tag{41}$$

These equations, along with the constraints mentioned above, define a system of six independent equations in seven unknowns. Hence the general set of extremal sensitivity floating point A matrices when $\zeta \neq 0$ and $\zeta \neq 1$ is a one-parameter family of the form

$$A = \begin{cases} -\omega_n \begin{bmatrix} \cos(\theta_o) & t\ \sin(\theta_o) \\ -\frac{1}{t}\ \sin(\theta_o) & \cos(\theta_o) \end{bmatrix} & : \quad 0 < \zeta = \cos(\theta_o) < 1, \\ -\omega_n \begin{bmatrix} \cosh(\theta_o) & t\ \sinh(\theta_o) \\ \frac{1}{t}\sinh(\theta_o) & \cosh(\theta_o) \end{bmatrix} & : \quad \zeta = \cosh(\theta_o) > 1, \end{cases}$$

where t is an arbitrary nonzero real parameter. There is no solution for the undamped and critically damped cases.

3. An application to the design of discrete-time linear time-invariant systems.

In this section, the synthesis of minimum sensitivity state space realizations for linear time-invariant multivariable systems is considered [10], [28]. It is shown that these realizations are related to the balanced realizations of Moore [22]. This problem has been solved in a purely algebraic framework in [21], [24], [25], [26] and in a stochastic framework in [17], [18]. Unlike these approaches, however, the geometric method naturally extends to other classes of dynamical systems, e.g., singular linear systems [9], [12], and bilinear systems [9], [11].

3.1. Realization spaces.

Consider the linear time-invariant system

$$x_{k+1} = Ax_k + Bu_k, \qquad x_k \in \Re^n, u_k \in \Re^m, \tag{42}$$

$$y_k = Cx_k, \qquad y_k \in \Re^p. \tag{43}$$

The state space realization (A, B, C) is specified by $n(n+m+p)$ real numbers. Therefore, we make the natural identification of the space of all such triples, denoted by $\Sigma_{m,n,p}(\Re)$, with the cartesian product space $\Re^{n(n+m+p)}$ with the usual topology. Furthermore, since the addition and scalar multiplication of such triples are of little significance globally, the realization space is assumed to have the algebraic structure of an affine space with vector space $\mathcal{V}^{n(n+m+p)}$. For fixed m, n, and p, it is clear from Definition 2.1 that $\Sigma_{m,n,p}(\Re)$ is a realization space.

Now consider the natural C^∞ group action of $GL_n(\Re)$ on $\Sigma_{m,n,p}(\Re)$ defined by

$$\phi : GL_n(\Re) \times \Sigma_{m,n,p}(\Re) \mapsto \Sigma_{m,n,p}(\Re) : T \times (A, B, C) \mapsto (TAT^{-1}, TB, CT^{-1}), \tag{44}$$

which corresponds to a change of basis in the state space $z = Tx$. The orbit of a point $s \in \Sigma_{m,n,p}(\Re)$ for the action ϕ is defined to be the subset

$$\mathcal{O}_s(\phi) = \{\phi(T, s) \in \Sigma_{m,n,p}(\Re) \mid T \in GL_n(\Re)\}. \tag{45}$$

The isotropy subgroup of $GL_n(\Re)$ at s is defined as

$$G_s(\phi) = \{T \in GL_n(\Re) \mid \phi(T, s) = s\}. \tag{46}$$

In general, the action of a Lie group G on a manifold M is said to be a *foliated action* if for every $s \in M$ the tangent space to the orbit of ϕ passing through s has fixed dimension. Equivalently, a foliated action is characterized by the property that the dimension of the isotropy subgroup $G_s(\phi)$ has fixed dimension independent of s. It is well known that the orbits of a foliated action define the leaves of a foliation [6], [20]. However, observe that for the particular realization space described above, the group action ϕ is *not* a foliated action. For example, if we let $s_1 = (\lambda I_n, 0, 0)$, where $\lambda \in \Re$, then clearly $G_{s_1}(\phi) = GL_n(\Re)$, and thus $\dim(G_{s_1}) = n^2$. On the other hand, for $s_2 = (\lambda I_n, e_1, 0)$, where $e_1^T = (1, 0, \ldots, 0)$, $G_{s_2}(\phi) = \{T \in GL_n(\Re) \mid$ first row of $T = e_1\}$ such that $\dim(G_{s2}) = n^2 - n$. Consequently, the orbits of ϕ do not foliate the realization space $\Sigma_{m,n,p}(\Re)$. However, if we define $\Sigma^{cr}_{m,n,p}(\Re)$, $\Sigma^{co}_{m,n,p}(\Re)$, and $\Sigma^{cr,co}_{m,n,p}(\Re)$ as the open subsets of $\Sigma_{m,n,p}(\Re)$ containing realizations that are reachable, observable, or both, respectively, then we have the following lemma.

LEMMA 3.1 (see [28]). *The group action ϕ restricted to either $\Sigma^{cr}_{m,n,p}(\Re)$, $\Sigma^{co}_{m,n,p}(\Re)$, or $\Sigma^{cr,co}_{m,n,p}(\Re)$ is a foliated action.*

Proof. The lemma follows immediately from the fact that the isotropy subgroup has constant dimension on $\Sigma^{cr}_{m,n,p}(\Re)$, $\Sigma^{co}_{m,n,p}(\Re)$, and $\Sigma^{cr,co}_{m,n,p}(\Re)$ (precisely zero). □

We shall also be interested in another type of realization space for linear time-invariant systems, specifically, sets whose elements comprise the components of the reachability and observability matrices

$$\mathcal{O}_i(A, C) = \left[\begin{array}{cccc} C^T & A^TC^T & \ldots & (A^T)^iC^T \end{array}\right]^T, \tag{47}$$

$$\mathcal{R}_j(A, B) = \left[\begin{array}{cccc} B & AB & \ldots & A^jB \end{array}\right], \tag{48}$$

where $i, j \geq n$. As will be shown shortly, such a realization space will be very natural for our applications. Such realizations will be referred to as $(\mathcal{O}, \mathcal{R})$ realizations in contrast to the usual state space realizations. As with the realization space $\Sigma_{m,n,p}(\Re)$, it is tempting to identify the space of all $(\mathcal{O}, \mathcal{R})$ realizations, say $\Omega_{m,n,p}[i, j](\Re)$, with an affine space modelled on the vector space $\mathcal{V}^{n(p(i+1)+(j+1)m)}$. This identification is fallacious, however, since the matrices as defined above have definite structure, and not every point in $\Re^{n(p(i+1)+(j+1)m)}$ has an associated $(\mathcal{O}, \mathcal{R})$ matrix pair. So consider instead the following mapping:

$$\omega : \Sigma_{m,n,p}(\Re) \mapsto \Re^{p(i+1)\times n} \times \Re^{n\times(j+1)m} : (A, B, C) \mapsto (\mathcal{O}_i(A, C), \mathcal{R}_j(A, B)), \tag{49}$$

where i and j are assumed to be fixed a priori. Observe that ω is a well-defined and smooth mapping since the components of $\mathcal{O}_i(A, C)$ and $\mathcal{R}_j(A, B)$ are smooth functions of the components of (A, B, C). Define the following subsets of $\Re^{p(i+1)\times n} \times \Re^{n\times(j+1)m}$:

$$\begin{aligned} \Omega_{m,n,p}(\Re) &= \omega(\Sigma_{m,n,p}(\Re)), \\ \Omega^{cr}_{m,n,p}(\Re) &= \omega(\Sigma^{cr}_{m,n,p}(\Re)), \\ \Omega^{co}_{m,n,p}(\Re) &= \omega(\Sigma^{co}_{m,n,p}(\Re)), \\ \Omega^{cr,co}_{m,n,p}(\Re) &= \omega(\Sigma^{cr,co}_{m,n,p}(\Re)). \end{aligned}$$

LEMMA 3.2. *The subset $\Omega^{\rho}_{m,n,p}(\Re)$ is a realization space, where either $\rho = cr$, $\rho = co$, or $\rho = cr, co$.*

Proof. The conclusion follows by virtue of the fact that $\Sigma^{\rho}_{m,n,p}$ is known to be a realization space and ω restricted to $\Sigma^{\rho}_{m,n,p}$ is a diffeomorphism. □

It should be noted that since $\Sigma^{\rho}_{m,n,p}(\Re)$ and $\Omega^{\rho}_{m,n,p}(\Re)$ are diffeomorphic, $\omega(\Sigma^{\rho}_{m,n,p}(\Re))$ is a submanifold imbedded in $\Re^{p(i+1)\times n} \times \Re^{n\times(j+1)m}$ with the *same* dimension as $\Sigma^{\rho}_{m,n,p}(\Re)$. This property is of limited utility for the applications considered here, however, since sensitivity is *not* a topological property.

As was the case for realization spaces $\Sigma^{\rho}_{m,n,p}(\Re)$, we are also interested in foliations of $\Omega^{\rho}_{m,n,p}(\Re)$ induced by a group action. Consider the following C^{∞} action of $GL_n(\Re)$ on $\Omega^{\rho}_{m,n,p}(\Re)$ defined by

$$(50) \qquad \psi : GL_n(\Re) \times \Omega^{\rho}_{m,n,p}(\Re) \mapsto \Omega^{\rho}_{m,n,p}(\Re) : T \times (\mathcal{O}, \mathcal{R}) \mapsto (\mathcal{O}T^{-1}, T\mathcal{R}).$$

We have the following analogous lemma.

LEMMA 3.3. *The group action ψ restricted to $\Omega^{\rho}_{m,n,p}(\Re)$, where $\rho = cr, \rho = co$, or $\rho = cr, co$, is a foliated action.*

Proof. The lemma follows immediately from the fact that the isotropy subgroup has constant dimension on $\Omega^{\rho}_{m,n,p}(\Re)$ for $\rho = cr$, $\rho = co$, or $\rho = cr, co$ (precisely zero). □

Now that the realization spaces associated with discrete-time linear systems have been defined, we next consider in detail the corresponding minimum sensitivity design problem via the geometric techniques of §2.

3.2. Minimum sensitivity realizations. Consider the problem of finding a minimum sensitivity state space realization for a discrete-time linear system described by a $p \times m$ strictly proper rational transfer matrix

$$(51) \qquad \mathrm{H}(z) = \sum_{i=1}^{\infty} H_i z^{-i},$$

where for each i, $H_i \in \Re^{p\times m}$. If one knows the minimal system order n a priori, then it is possible to uniquely identify the system from a truncated version of the system Hankel matrix

$$(52) \qquad \mathcal{H}[pi, jm] = \begin{bmatrix} H_1 & H_2 & H_3 & \dots & H_{j+1} \\ H_2 & H_3 & H_4 & \dots & H_{j+2} \\ H_3 & H_4 & H_5 & \dots & H_{j+3} \\ \vdots & \vdots & \vdots & & \vdots \\ H_{i+1} & H_{i+2} & H_{i+3} & \dots & H_{i+j+1} \end{bmatrix}.$$

In the worst case, the transfer matrix is completely parameterized by $2npm$ parameters, so the truncation must retain at least this number of entries. An especially convenient truncated form is $\mathcal{H}[pi, jm]$, where $i, j \geq n$. Any rank n factorization

$$(53) \qquad \mathcal{H}[pi, jm] = \mathcal{O}_i \mathcal{R}_j$$

corresponds directly to a minimal state space realization. Thus we can take a finite subset of the Markov parameters as observables in our geometric sensitivity theory.

Define ℓ as the least common multiple of p and m, and integers $s = \ell/p$ and $t = \ell/m$. Then, any *square* Hankel matrix of the form $\mathcal{H}[\ell i, i\ell]$, where $i \geq n$, will uniquely identify a linear system of order n. Furthermore, any corresponding rank n $(\mathcal{O}, \mathcal{R})$ factorization

$$(54) \qquad \mathcal{H}[\ell i, i\ell] = \mathcal{O}_{si} \mathcal{R}_{it}$$

defines a matrix observable on $\Omega^{cr,co}_{m,n,p}[si,it]$. So, in light of Lemma 2.18 define the family of observables

$$f_\Lambda(\mathcal{O}_{si},\mathcal{R}_{it}) = \operatorname{Tr}\Lambda(\mathcal{H}[\ell i, i\ell] - \mathcal{O}_{si}\mathcal{R}_{it}), \tag{55}$$

where $\Lambda \in \mathcal{O}((i+1)\ell)$, the set of all orthogonal matrices of dimension $(i+1)\ell \times (i+1)\ell$. Then, it follows from the conclusion of the lemma that $f_\Lambda(\mathcal{O}_{si},\mathcal{R}_{it}) = 0$ for all $\Lambda \in \mathcal{O}((i+1)\ell)$ if and only if the equality in equation (54) holds. Thus, f_Λ induces a foliation on $\Omega^{cr,co}_{m,n,p}[si,it]$, where each leaf of the foliation corresponds to a collection of $(\mathcal{O},\mathcal{R})$ realizations with the same corresponding Hankel matrix. The leaf with an associated observable value of zero consists of all $(\mathcal{O},\mathcal{R})$ factorizations of the *given* Hankel matrix. We can also define a related observable on $\Sigma^{cr,co}_{m,n,p}(\Re)$ as follows:

$$\hat{f}_\Lambda = f_\Lambda \circ \omega(A,B,C) \tag{56}$$

$$= \operatorname{Tr}\Lambda(\mathcal{H}[\ell i, i\ell] - \mathcal{O}(A,C)_{si}\mathcal{R}(A,B)_{it}). \tag{57}$$

This observable foliates $\Sigma^{cr,co}_{m,n,p}(\Re)$ into equivalence classes characterized by the corresponding Hankel matrix.

From a systems perspective the sensitivity of state space realizations is the most natural problem to pursue. Unfortunately, this problem is difficult to attack directly since it is highly nonlinear. Thus, we first consider the essentially linear problem of finding the least-sensitive fixed point $(\mathcal{O},\mathcal{R})$ realizations (i.e., factorizations) of a given Hankel matrix, and then return to the state space realization problem later. The main theorem of this section is given below.

THEOREM 3.4 (extremal sensitivity theorem). *Given an nth order linear system with m inputs and p outputs characterized by a square Hankel matrix* $\mathcal{H}[\ell i, i\ell]$,

(i) *extremal sensitivity points under the uniform metric on the leaf of the foliation induced by the observable family*

$$f_\Lambda(\mathcal{O}_{si},\mathcal{R}_{it}) = \operatorname{Tr}\Lambda(\mathcal{H}[\ell i, i\ell] - \mathcal{O}_{si}\mathcal{R}_{it}) \tag{58}$$

have the property that

$$\mathcal{R}_{it}\mathcal{R}^T_{it} = \mathcal{O}^T_{si}\mathcal{O}_{si}, \tag{59}$$

where ℓ is the least common multiple of p and m, $s = \ell/p$, $t = \ell/m$, and $i \geq n$;

(ii) *an extremal sensitivity point under the uniform metric is also an extremal under the floating point metric if*

$$\operatorname{vec}(\mathcal{R}^T_{it})^2 + \operatorname{vec}(\mathcal{O}_{si})^2 = \amalg, \tag{60}$$

where vec *denotes the column stacking operator, $[x^m]_i = x_i^m$ for any vector x and integer m, and* $\amalg = [1\ \ 1 \dots 1]^T$.

Proof. (i) Use optimality equation (25) from the previous section. With the coefficient vector taken to be

$$\theta = \begin{bmatrix} \operatorname{vec}(\mathcal{R}^T_{it}) \\ \operatorname{vec}(\mathcal{O}_{si}) \end{bmatrix}, \tag{61}$$

one can express the observable f_Λ in terms of a quadratic form in θ:

$$f_\Lambda(\theta) = \operatorname{Tr}\Lambda(\mathcal{H}[\ell i, i\ell] - \mathcal{O}_{si}\mathcal{R}_{it}) \tag{62}$$

$$= \operatorname{Tr}\Lambda\mathcal{H}[\ell i, i\ell] - \operatorname{Tr}\mathcal{R}_{it}\Lambda\mathcal{O}_{si} \tag{63}$$

$$= \operatorname{Tr}\Lambda\mathcal{H}[\ell i, i\ell] - (\operatorname{vec}(\mathcal{R}^T_{it}))^T \cdot (I_n \otimes \Lambda) \cdot \operatorname{vec}(\mathcal{O}_{si}). \tag{64}$$

Using this representation, the gradient vector and Hessian matrix are easily computed as

$$\nabla f_\Lambda(\theta) = \frac{\partial f_\Lambda}{\partial \theta} = \begin{bmatrix} -(I_n \otimes \Lambda)\mathrm{vec}(\mathcal{O}_{si}) \\ -(I_n \otimes \Lambda)^T \mathrm{vec}(\mathcal{R}_{it}^T) \end{bmatrix} \tag{65}$$

and

$$\nabla^2 f_\Lambda(\theta) = \frac{\partial^2 f_\Lambda}{\partial \theta^2} = \begin{bmatrix} 0 & -(I_n \otimes \Lambda) \\ -(I_n \otimes \Lambda)^T & 0 \end{bmatrix}. \tag{66}$$

The optimality condition is then

$$\begin{bmatrix} -\lambda I_{nsi} & -(I_n \otimes \Lambda) \\ -(I_n \otimes \Lambda)^T & -\lambda I_{itn} \end{bmatrix} \cdot \begin{bmatrix} -(I_n \otimes \Lambda)\mathrm{vec}(\mathcal{O}_{si}) \\ -(I_n \otimes \Lambda)^T \mathrm{vec}(\mathcal{R}_{it}^T) \end{bmatrix} = 0. \tag{67}$$

Equation (67) gives

$$-\lambda(I_n \otimes \Lambda)\mathrm{vec}(\mathcal{O}_{si}) = \mathrm{vec}(\mathcal{R}_{it}^T), \tag{68}$$

$$\mathrm{vec}(\mathcal{O}_{si}) = -\lambda(I_n \otimes \Lambda)^T \mathrm{vec}(\mathcal{R}_{it}^T), \tag{69}$$

or equivalently,

$$-\lambda\Lambda\mathcal{O}_{si} = \mathcal{R}_{it}^T, \tag{70}$$

$$\mathcal{O}_{si} = -\lambda\Lambda^T\mathcal{R}_{it}^T. \tag{71}$$

Hence, the conclusion follows immediately using the facts that Λ is an orthogonal matrix, and λ, an eigenvalue of the symmetric orthogonal matrix $\nabla^2 f_\Lambda(\theta)$, is equal to ±1.

(ii) Using the general optimality equation (24) with $G(\theta) = \mathrm{diag}(\theta^{-2})$, and assuming property (59) gives

$$\mathrm{vec}(\mathcal{R}_{it}^T)^3 - \lambda(I_n \otimes \Lambda)\mathrm{vec}(\mathcal{O}_{si})^3 = \mathrm{vec}(\mathcal{R}_{it}^T). \tag{72}$$

Substitution using equation (68) proves the theorem's conclusion. □

It should be noted that the condition stated in (ii) is only a sufficient condition for a floating point extremal. Not every system has a realization which lies on the hypersphere defined by equation (60) and satisfies equation (59). The existence of general solutions of the floating point extremal sensitivity problem and the associated computational algorithms are current topics of investigation.

DEFINITION 3.5. *A realization* (A, B, C) *or* $(\mathcal{O}_{si}, \mathcal{R}_{it})$ *is said to be* essentially balanced *if* $\mathcal{R}_{it}\mathcal{R}_{it}^T = \mathcal{O}_{si}^T\mathcal{O}_{si}$.

This definition is motivated by the fact that in the discrete-time case $P_{it} \triangleq \mathcal{R}_{it}\mathcal{R}_{it}^T$ and $Q_{si} \triangleq \mathcal{O}_{si}^T\mathcal{O}_{si}$ are, respectively, the reachability grammian at time $t_1 = it$ and the observability grammian at time $t_2 = si$. Letting

$$P = \lim_{i \to \infty} \mathcal{R}_{it}\mathcal{R}_{it}^T, \tag{73}$$

$$Q = \lim_{i \to \infty} \mathcal{O}_{si}^T\mathcal{O}_{si}, \tag{74}$$

denote the usual steady-state grammians, any essentially balanced state space realization or $(\mathcal{O}, \mathcal{R})$ realization with $i \to \infty$ is only an orthogonal state space transformation away from being a truly balanced realization (in the sense of Moore [22]). Such realizations have also arisen in the context of optimal low noise filter structures [29] and gradient flow techniques for computing balanced realizations [16], [23]. Another important property of an essentially balanced $(\mathcal{O},\mathcal{R})$ realization is given in the following theorem.

THEOREM 3.6 (see [10]). *An essentially balanced $(\mathcal{O},\mathcal{R})$ realization has the minimum sensitivity property under the uniform metric.*

Proof. The conclusion follows directly from an application of Lemma 2.13. For any choice of Λ, $\nabla^2 f_\Lambda(\theta)$ clearly has a spectrum $\{\lambda_i\}$ consisting of n eigenvalues equal to one and n eigenvalues equal to minus one, and a corresponding set of orthonormal eigenvectors $\{v_i\}$. At an extremal we may also assume that v_{2n} corresponds to the normalized version of $\nabla f_\Lambda(\theta^*)$. Now let x be an arbitrary nonzero vector from the tangent space of $M_0 f_\Lambda$ at θ^* (and hence orthogonal to $\nabla f_\Lambda(\theta^*)$). Then from equation (31) it follows that

$$\begin{aligned}\nabla^2 H(\theta^*)(x,x) &= x^T(I-\lambda_{2n}\nabla^2 f_\Lambda(\theta^*))x\\ &= \sum_{i=1}^{2n-1}\alpha_i^2(1-\lambda_{2n}\lambda_i) > 0,\end{aligned}$$

where $x=\sum_{i=1}^{2n-1}\alpha_i v_i$. □

Determining minimum sensitivity state space realizations is significantly more difficult than finding minimum sensitivity $(\mathcal{O},\mathcal{R})$ realizations. The complication arises from the fact that the observables, in this case the Markov parameters, have a nonlinear dependence on the components of the A matrix. The optimality equations resulting from the direct application of Theorem 2.6 are virtually intractable analytically. The fixed point analysis above, however, does lead to a bound-optimal result which is related to the earlier work done using frequency domain techniques [21], [24], [25], [26]. Observe that in light of Definition 2.5, the performance index for the minimum sensitivity $(\mathcal{O},\mathcal{R})$ realization problem can be written in the form

$$L(\mathcal{O},\mathcal{R}) = \frac{1}{2} \parallel \nabla f_\Lambda \parallel^2 \tag{75}$$

$$= \frac{1}{2}\left|\begin{array}{c}\operatorname{vec}(\mathcal{O})\\ \operatorname{vec}(\mathcal{R}^T)\end{array}\right|^2 \tag{76}$$

$$= \frac{1}{2}(\mathrm{Tr}\ \mathcal{R}\mathcal{R}^T + \mathrm{Tr}\ \mathcal{O}^T\mathcal{O}) \tag{77}$$

$$= \frac{1}{2}(\mathrm{Tr}P + \mathrm{Tr}Q), \tag{78}$$

where the subscripts are dropped to indicate the limiting case $i \to \infty$. For a sequence of matrices $\{M_k\}$, define the ℓ_p norm

$$\parallel M_k \parallel_{F,\ell_p} \stackrel{\Delta}{=} \left(\sum_{k=1}^{\infty} \parallel M_k \parallel_F^p\right)^{\frac{1}{p}}, \tag{79}$$

where F denotes the Frobenius norm. Then it follows that

$$\left\|\frac{\partial H_k}{\partial C^T}\right\|_{F,\ell_2}^2 = \left\|\left[\frac{\partial H_1}{\partial C^T} \quad \frac{\partial H_2}{\partial C^T} \quad \frac{\partial H_3}{\partial C^T} \quad \cdots\right]\right\|_F^2 = p\mathrm{Tr}\ P, \tag{80}$$

$$(81)\qquad \left\|\frac{\partial H_k}{\partial B}\right\|_{F,\ell_2}^2 = \left\|\begin{bmatrix}\frac{\partial H_1}{\partial B} & \frac{\partial H_2}{\partial B} & \frac{\partial H_3}{\partial B} & \cdots\end{bmatrix}\right\|_F^2 = m\mathrm{Tr}\ Q.$$

Thus, Tr P and Tr Q are measures of the sensitivity of the impulse response to the components of B and C *per I/O channel.* The performance index $L(\mathcal{O},\mathcal{R})$ is the arithmetic average of the two measures. Furthermore, it can easily be shown that

$$(82)\qquad \left\|\frac{\partial H_k}{\partial A}\right\|_F^2 \le \mathrm{Tr}\ P_{k-1}\mathrm{Tr}\ Q_{k-1},$$

where $k = 1, 2, \ldots$. For stable systems, the real number sequences $\{\mathrm{Tr}\ P_{k-1}\}_{k\ge 1}$ and $\{\mathrm{Tr}\ Q_{k-1}\}_{k\ge 1}$ are bounded and monotone increasing. Therefore, it follows directly that

$$(83)\qquad \left\|\frac{\partial H_k}{\partial A}\right\|_{F,\ell_\infty} = \sup_k \left\|\frac{\partial H_k}{\partial A}\right\|_F \le \sqrt{\mathrm{Tr}\ P\ \mathrm{Tr}\ Q}.$$

However, for positive numbers Tr P and Tr Q,

$$(84)\qquad \sqrt{\mathrm{Tr}\ P\ \ \mathrm{Tr}\ Q} \le \frac{1}{2}(\mathrm{Tr}\ P + \mathrm{Tr}\ Q)$$

in general with equality if and only if Tr P = Tr Q. Thus, minimizing the performance index $L(\mathcal{O},\mathcal{R})$ will also minimize an upper bound on the sensitivity of the block Markov parameters (the observables) with respect to the components of A. In particular, when we assume $P = Q$ we have an upper bound (in the single-input, single-output case) on the sensitivity measure

$$(85)\qquad M_T \triangleq \left\|\frac{\partial H_k}{\partial A}\right\|_{F,\ell_\infty}^2 + \left\|\frac{\partial H_k}{\partial b}\right\|_{F,\ell_2}^2 + \left\|\frac{\partial H_k}{\partial c^T}\right\|_{F,\ell_2}^2$$

equal to

$$(86)\qquad M^* = \mathrm{Tr}\ P\ \ \mathrm{Tr}\ Q + \mathrm{Tr}\ P + \mathrm{Tr}\ Q.$$

This expression is identical to the general upper bound on the sensitivity of the frequency response

$$(87)\qquad M_F \triangleq \left\|\frac{\partial H(z)}{\partial A}\right\|_{F,L_1}^2 + \left\|\frac{\partial H(z)}{\partial b}\right\|_{F,L_2}^2 + \left\|\frac{\partial H(z)}{\partial c^T}\right\|_{F,L_2}^2$$

defined in [21], [24], [25], [26], where

$$(88)\qquad \|\ F(z)\ \|_{F,L_p} \triangleq \left(\frac{1}{2\pi j}\oint_\Gamma \|\ F(z)\ \|_F^p\ z^{-1}\,dz\right)^{\frac{1}{p}} = \left(\frac{1}{2\pi}\int_0^{2\pi} \|\ F(e^{j\omega})\ \|_F^p\right)^{\frac{1}{p}},$$

and Γ denotes the contour along the unit circle. A fundamental difference, however, between the time domain and frequency approaches is that M_T will not achieve the upper bound M^* in the optimal case while it is known that $M_F = M^*$ when Tr P = Tr Q [26]. This can be demonstrated by a simple first-order example as can the fact that M^* will not in general be an upper bound on M_T when the ℓ_∞ norm is replaced by either the ℓ_1 norm or the ℓ_2 norm. While using mixed norms as in equations (85) and (87) may seem somewhat artificial, at present no analytical technique has been found for direct optimization using a single norm in either the time or frequency domain approaches (see [30]).

4. Conclusions. Minimum sensitivity designs were defined as points in realization space, which preserved model behavior and minimized a geometrically motivated sensitivity measure. Such a characterization yielded a general optimality equation with a simple eigen-condition interpretation. The method was then applied to the problem of synthesizing minimum sensitivity state space realizations of discrete-time linear time-invariant systems under fixed point and floating point metrics. Optimal fixed point realizations were related to so-called balanced realizations.

Acknowledgment. The authors wish to sincerely thank the reviewers for their valuable comments and insights. Their diligence has served to significantly improve this paper.

DISCRETE APPROXIMATIONS AND REFINED EULER–LAGRANGE CONDITIONS FOR NONCONVEX DIFFERENTIAL INCLUSIONS*

BORIS S. MORDUKHOVICH[†]

This paper is dedicated to Terry Rockafeller on the occasion of his 60*th birthday.*

Abstract. This paper deals with the Bolza problem (P) for differential inclusions subject to general endpoint constraints. We pursue a twofold goal. First, we develop a finite difference method for studying (P) and construct a discrete approximation to (P) that ensures a strong convergence of optimal solutions. Second, we use this direct method to obtain necessary optimality conditions in a refined Euler–Lagrange form without standard convexity assumptions. In general, we prove necessary conditions for the so-called intermediate relaxed local minimum that takes an intermediate place between the classical concepts of strong and weak minima. In the case of a Mayer cost functional or boundary solutions to differential inclusions, this Euler–Lagrange form holds without any relaxation. The results obtained are expressed in terms of nonconvex-valued generalized differentiation constructions for nonsmooth mappings and sets.

Key words. discrete approximations, differential inclusions, nonsmooth analysis, generalized differentiation, Euler–Lagrange conditions

1. Introduction.

This paper is mainly concerned with the following problem of dynamic optimization: minimize the Bolza functional

$$J[x] := \varphi(x(a), x(b)) + \int_a^b f(x(t), \dot{x}(t), t)dt \tag{1.1}$$

over absolutely continuous trajectories $x : [a, b] \to \mathbf{R}^n$ for the differential inclusion

$$\dot{x}(t) \in F(x(t), t) \ \text{ a.e. } \ t \in [a, b] \tag{1.2}$$

subject to general endpoint constraints

$$(x(a), x(b)) \in \Omega \subset \mathbf{R}^{2n}. \tag{1.3}$$

Here $T := [a, b]$ is a fixed time interval and F is a set-valued mapping (multifunction). We label this problem (P) and call it *the Bolza problem for differential inclusions.*

The formulated problem covers a broad range of other problems in dynamic optimization, in particular, both standard and nonstandard models in optimal control for open-loop and closed-loop control systems (see, e.g., Clarke [8]). On the other hand, problem (P) can be imbedded in the so-called Generalized Problem of Bolza [39], [8] where the function f is allowed to take values in $\bar{\mathbf{R}} := \mathbf{R} \cup \{+\infty\}$. In this paper we

prefer to consider the problem in form (1.1)–(1.3) and prove results depending on the specific character of differential inclusions.

The mainstream in studying optimization problems for differential inclusions consists of obtaining necessary conditions for optimality (global or strong local minima). There are different approaches and various results in this area using one or another tool in nonsmooth analysis; we refer the reader to [5]–[10], [16], [22]–[25], [27]–[29], [35], [37], [38], [46], [51] and the bibliography therein. Most of the results are obtained for the *Mayer problem*, which corresponds to (1.1)–(1.3) in the case where $f = 0$.

In [24], Loewen and Rockafellar consider the Bolza problem (P) (with additional state constraints). Assuming that the function $f(x, \cdot, t)$ and the sets $F(x,t)$ of admissible velocities are *convex*, they obtain necessary optimality conditions under usual boundedness and Lipschitzness hypotheses but without imposing any constraint qualification such as calmness (cf. Clarke [5]–[10]). They prove that if $\bar{x}(t)$ solves problem (1.1)–(1.3), then there exist a number $\lambda \geq 0$ and an absolutely continuous function $p : [a,b] \to \mathbf{R}^n$, not both zero, such that

$$(1.4)\,(\dot{p}(t), p(t)) \in \lambda\partial_C f(\bar{x}(t), \dot{\bar{x}}(t), t) + N_C((\bar{x}(t), \dot{\bar{x}}(t)); \mathrm{gph}F(\cdot, t)) \text{ a.e. } t \in [a,b],$$

$$(1.5)\qquad (-\dot{p}(t), \dot{\bar{x}}(t)) \in \partial_C H_\lambda(\bar{x}(t), p(t), t) \text{ a.e. } t \in [a,b],$$

$$(1.6)\qquad \langle p(t), \dot{\bar{x}}(t)\rangle = H_\lambda(\bar{x}(t), p(t), t) \text{ a.e. } t \in [a,b],$$

$$(1.7)\qquad (p(a), -p(b)) \in \lambda\partial_C\varphi(\bar{x}(a), \bar{x}(b)) + N_C((\bar{x}(a), \bar{x}(b)); \Omega)$$

where $\mathrm{gph}\, F(\cdot, t) := \{(x, v) \in \mathbf{R}^{2n} | v \in F(x,t)\}$,

$$(1.8)\qquad H_\lambda(x, p, t) := \max\{\langle p, v\rangle - \lambda f(x, v, t) | v \in F(x,t)\},$$

and notation N_C and ∂_C, respectively, stand for Clarke's normal cone to a closed set at a given point and the generalized gradient of a locally Lipschitz function [8].

Condition (1.4), which is called the Euler–Lagrange inclusion, was first obtained by Clarke [5] for the Mayer problem under the calmness assumption, which ensures normality ($\lambda = 1$) in (1.4), (1.7). The Hamiltonian inclusion (1.5) was proved by Clarke first under the calmness hypothesis and then without it; see [8], [9]. Observe that (1.6) is the Weierstrass–Pontryagin maximum condition, which is implied by each of the conditions (1.4) and (1.5) under the convexity assumptions imposed. Note also that, in general, conditions (1.4) and (1.5) are independent; see examples in [22], [25].

Another version of necessary optimality conditions was obtained by Mordukhovich for the Mayer problem (1.1)–(1.3) with $f = 0$ under the convexity of $F(x,t)$ and usual boundedness and Lipschitzness assumptions but without any calmness hypotheses or something similar; see [27]–[29]. The conditions obtained are stated in the form:

$$(1.9)\qquad (\dot{p}(t), \dot{\bar{x}}(t)) \in \mathrm{co}\{(u,v) | (u, p(t)) \in N((\bar{x}(t), v); \mathrm{gph}F(\cdot, t)),$$

$$v \in M(\bar{x}(t), p(t), t)\} \text{ a.e. } t \in [a,b],$$

$$(1.10)\qquad (p(a), -p(b)) \in \lambda\partial\varphi(\bar{x}(a), \bar{x}(b)) + N((x(a), x(b)); \Omega)$$

where "co" means the convex hull of a set,

$$M(x,p,t) := \{v \in F(x,t) | \langle p, x\rangle = H(x,p,t)\}, \tag{1.11}$$

and $H(x,p,t)$ coincides with the Hamiltonian (1.8) for $f = 0$. Here N and ∂ are not Clarke's normal cone and generalized gradient but their *nonconvex* counterparts whose convex closures coincide with the corresponding constructions of Clarke; see §4 for more details. These nonconvex constructions were first used in Mordukhovich [26] for obtaining transversality conditions like (1.10) in nonsmooth problems of optimal control.

Observe that condition (1.9) implies both the maximum condition (1.6) and an analogue of the Euler–Lagrange inclusion (1.4) in the form

$$\begin{aligned} \dot p(t) \in \mathrm{co}\{u | (u, p(t)) \in N((\bar x(t), v); \mathrm{gph} F(\cdot, t)),\\ v \in M(\bar x(t), p(t), t)\} \text{ a.e. } t \in [a,b]. \end{aligned} \tag{1.12}$$

In comparison with (1.4) for $f = 0$, condition (1.12) requires less convexification: only to the components involving derivatives of the adjoint function instead of to all components at once. This makes (1.12) essentially stronger than (1.4) in certain situations. In particular, if the maximum set (1.11) is a singleton along $(\bar x(t), p(t))$ for a.e. $t \in [a,b]$ (it happens, for instance, if the sets $F(x,t)$ are strictly convex along $\bar x(t)$), then (1.12) is reduced to

$$\dot p(t) \in \mathrm{co}\{u | (u, p(t)) \in N((\bar x(t), \dot{\bar x}(t)); \mathrm{gph} F(\cdot, t))\} \text{ a.e. } t \in [a,b], \tag{1.13}$$

which is strictly better than (1.4).

So (1.9) turns out to be an advanced version of the Euler–Lagrange inclusion and the maximum condition for the Mayer problem involving convex (i.e., *convex-valued*) differential inclusions (1.2). What relationships exist between (1.9) and the Hamiltonian inclusion (1.5) under the usual convexity, boundedness, and Lipschitzness assumptions?

It follows from Rockafellar's dualization result [43] that (1.5) implies (1.9). On the other hand, it has been recently proved by Ioffe (personal communication; see also [19, §3.5]) that (1.9) implies (1.5) under the mentioned assumptions. Therefore, version (1.9) of the Euler–Lagrange condition is *equivalent* to the Hamiltonian condition in Clarke's form (with the same adjoint function) for convex differential inclusions. This prolongs the line of equivalency between the Hamiltonian and Euler–Lagrange conditions, which is well known for smooth and fully convex problems (see, e.g., [39], [43]). Now one can conclude that any improvement of the necessary optimality conditions in form (1.9) provides a strengthening of the Hamiltonian conditions in Clarke's form for convex differential inclusions.

In the recent paper [25], Loewen and Rockafellar establish that the Mayer problem for convex differential inclusions can actually be reduced to the situation where the sets $F(x,t)$ are *strictly convex* along the optimal trajectory. In the latter case, conditions (1.12) and (1.13) are equivalent while (1.9) is equivalent to the simultaneous fulfilment of (1.6) and (1.13). In the general convex case, (1.13) always implies the maximum condition in (1.8) with $f = 0$; see Proposition 4.7 stated below. Therefore, (1.13) also implies (1.12) as well as (1.9) where the improvement may be proper; see [25].

Using the mentioned strict convexification procedure and a Hamiltonian calculus, Loewen and Rockafellar prove in [25] that an optimal solution to the Mayer problem for convex differential inclusions always satisfies conditions (1.10) and (1.13) as well as (1.5) and (1.6) where $f = 0$ with the same adjoint function $p(t)$. Moreover, they also consider the case of unbounded differential inclusions, truncating it to the bounded case under suitable Lipschitzian assumptions and the convexity of $F(x,t)$. Their consideration of the unbounded case leads to improvements of necessary conditions for the Bolza problem with convex velocities.

It follows from the discussion above that the refined Euler–Lagrange and transversality conditions (1.13) and (1.10) provide the best results for convex differential inclusions. On the other hand, convexity assumptions appear to be restrictive in certain important situations, so it makes sense to release them as much as possible. Note that if the admissible velocity sets $F(x,t)$ are convex and the multifunction $F(\cdot,t)$ is Lipschitz continuous, then the differential inclusion (1.2) admits a control representation $F(x,t) = g(x,U,t)$ with a Lipschitzian function g and a control set U independent on x; see, for example, [3]. This is no longer the case when $F(x,t)$ are not convex. So when considering nonconvex differential inclusions, one should definitely study them for their own sakes.

The primary goal of this paper is to develop the theory of necessary optimality conditions in the *refined Euler–Lagrange form* for Mayer and Bolza problems involving *nonconvex* bounded differential inclusions. The results obtained below achieve the following advancements in the state of art.

1. We study a new (to the best of our knowledge) concept of local minimum for the considered variational problems involving differential inclusions. Previous results for such problems were concerned with strong (or global) minima. In contrast to the strong minimum, we compare a reference feasible trajectory $\bar{x}(\cdot)$ with other feasible ones close to it not only in the C-norm for arcs but also in the L^p-norm ($1 \leq p < \infty$) for derivatives. This means that we consider a neighborhood of $\bar{x}(\cdot)$ in the Sobolev space $W^{1,p}$ equipped with a natural topology. Such a local minimum takes an intermediate place between the classical weak and strong minima; we call it the *intermediate local minimum.* Note that the results obtained in this paper provide new information even for convex differential inclusions. In particular, they imply the maximum condition for an intermediate local minimum, which may not be strong.

2. We obtain refined necessary conditions for the Bolza problem (P) stated above with the Euler–Lagrange inclusion

$$(1.14)\quad \dot{p}(t) \in \mathrm{co}\{u | (u, p(t)) \in \lambda \partial f(\bar{x}(t), \dot{\bar{x}}(t), t) + N((\bar{x}(t), \dot{\bar{x}}(t)); \mathrm{gph} F(\cdot, t))\}$$

and the transversality inclusion (1.10) where an absolutely continuous function $p(\cdot)$ and a number $\lambda \geq 0$ are not equal to zero simultaneously.

In general, we prove the refined Euler–Lagrange inclusion (1.14) for any trajectory $\bar{x}(t)$ that is feasible for the original problem (P) and provides an intermediate local minimum for the so-called *relaxed* problem obtained from (P) by some convexification procedure. Note that in this case, condition (1.14) is expressed in terms of the original data F, f and may be quite different from its counterpart in terms of the convexifications. We discuss effective sufficient conditions when an optimal solution to (P) solves the relaxed problem as well, so the conditions obtained characterize solutions to the original problem of Bolza without any convexity.

3. In the case of a Mayer functional in (1.1)–(1.3), we prove that the refined Euler–Lagrange inclusion (1.14), coinciding with (1.13) in this case, is fulfilled for every *strong minimum* $\bar{x}(t)$ *without any relaxation.* This implies that if $\bar{x}(t)$ solves the original Mayer problem but may not solve the relaxed one, conditions (1.10) and (1.13)

still hold. Moreover, these conditions are proved to be necessary for the *weak minimum* to the Mayer problem under an additional Riemann integrability assumption that makes the technique used more transparent and in principle can be omitted.

We also establish the refined Euler–Lagrange inclusion (1.13) for any *boundary trajectory* of (1.2) without either convexity or relaxation. The latter result essentially strengthens the recent one of Kaskosz and Lojasiewicz [22] who proved the Euler–Lagrange inclusion in Clarke's form (1.4) with $f = 0$ for boundary trajectories.

So we obtain that the refined Euler–Lagrange conditions, providing strongest results for convex differential inclusions, also hold true for nonconvex problems. This is proved under the relaxability assumption (so far) for the general Bolza problem and without the latter assumption for the Mayer problem as well as for boundary trajectories. Note, however, that the maximum condition no longer follows from (1.13) or (1.14) in the nonconvex case.

The Hamiltonian inclusion (1.5) always implies the maximum condition (1.6), but for now (1.5) has been justified (as a necessary condition for the strong minimum or boundary trajectories) only in the convex case. This implies that the Hamiltonian condition also holds under the relaxability assumption because (1.5), in contrast to the Euler–Lagrange inclusions, is obviously invariant with respect to convexification. It follows from [25, Example 5.2] that the refined Euler–Lagrange inclusion may be essentially better than the Hamiltonian inclusion in the convex case. A series of examples in [22, §2] shows that the Hamiltonian inclusion does not imply even Clarke's form (1.4) of the Euler–Lagrange inclusion in nonconvex and/or convexified problems. Therefore, the results obtained in this paper sharpen known conditions under the relaxability assumption and especially in the fully nonconvex setting.

Now let us explain the principal method that we use to obtain the mentioned results. This is a direct method based on *finite difference* (*discrete*) *approximations.* Such an approach to variational problems goes back to Euler, who used it in 1744 to prove the classical Euler–Lagrange equation in the calculus of variations. (Actually Leibnitz was the first to employ a similar direct method to find the brachistochrone in the very beginning of the calculus of variations; see, for example, [1]). The basic idea is as follows: (1) to replace (approximate) the original continuous-time variational problem by a "correct" sequence of finite-dimensional optimization problems that can be solved (studied) effectively, and then (2) passing to the limit with respect to approximation parameters to obtain desirable characteristics of the original variational problem.

Finite difference methods turn out to be a powerful tool for numerical solutions of infinite-dimensional variational problems. We refer the reader to the book of Polak [36] and the survey paper of Dontchev and Lempio [13], which are devoted to numerical aspects of consistent discrete approximations in optimal control. Some results in this paper are also concerned with numerical questions. In §3 we develop a discrete approximation algorithm for nonconvex differential inclusions with strong convergence properties and error estimates. But our main interest here is to use finite difference approximations as a direct vehicle for obtaining necessary optimality conditions in infinite-dimensional problem (P) via a variational analysis of nonsmooth problems in finite dimensions. Two issues are important in this approach:

(1) to construct a correct discrete approximation of problem (P) that ensures a desirable convergence of optimal solutions for discrete problems to a given local minimum for (P);

(2) to choose "right" generalized derivative (normal) constructions for nonsmooth

mappings and sets that are suitable to the method. Such constructions need to be appropriate for obtaining optimality conditions in discrete problems and also possess robustness and calculus properties for passing to the limit in the approximation procedure. Let us observe that problem (P) and its discrete counterparts are definitely objects of *nonsmooth analysis and optimization* because of a special nature of dynamic constraints like (1.2) even under smooth data in (1.1) and (1.3).

Note that not all differentiation constructions in nonsmooth analysis fit these requirements. For example, Pshenichnyi in [38] employed some tangentially generated constructions related to the contingent cone. Such constructions possess the required properties only in special situations. This allowed him to prove necessary conditions for global (actually strong) minima in autonomous differential inclusions under some restrictive assumptions close to the graph convexity of $F(\cdot, t)$. He used a discrete approximation ensuring the uniform (C-) convergence of optimal trajectories.

In Mordukhovich [27]–[29], we used generalized normals and derivatives of another nature and somewhat different algorithms to approximate Lipschitzian differential inclusions. These generalized constructions appear in (1.9), (1.10) and possess required robustness and calculus properties that are reviewed in §4. Note that if one employs the convexification of the normal cone in (1.9), i.e., uses Clarke's normal cone to the graph of a Lipschitzian mapping, then such a construction does not ensure the convergence of adjoint functions in discrete approximations (see Remark 4.6).

Although the approximation algorithm in [28] is used to prove the C-convergence of optimal trajectories in discrete approximations, its slight modification provides the *strong* L^2-convergence of the velocities. It was first observed by Smirnov [48], who obtained the refined condition (1.13) for optimal solutions to a Mayer problem involving convex autonomous differential inclusions under some additional assumptions.

In this paper, we develop the method of discrete approximations to obtain the results mentioned above in the general setting under consideration. The remainder of the paper is organized as follows.

Section 2 is devoted to the concept of intermediate local minimum for the original and relaxed problems of Bolza. We consider sufficient conditions that ensure the relaxability of (P) when a given minimum for the original problem solves the relaxed problem as well.

Section 3 deals with discrete approximations of problem (P). We provide a construction of discrete approximations and natural assumptions that ensure the strong convergence of optimal solutions with respect to the value function, trajectories, and velocities.

In §4 we describe the tools of the generalized differentiation for nonsmooth and set-valued mappings used in the paper to obtain necessary optimality conditions for discrete and differential inclusions. The reader can find there a brief review of the basic differentiation properties that are important in the method of discrete approximations.

Section 5 is concerned with necessary optimality conditions for nonsmooth finite-dimensional problems. We obtain discrete analogues of the refined Euler–Lagrange and tranversality conditions (1.14), (1.10) without the convexity operation in (1.14) and any Lipschitzian assumptions on F, f. These results turn out to be direct consequences of the Lagrange multiplier rule in nondifferentiable programming with many geometric constraints.

Section 6 is devoted to the limiting procedure in discrete approximations that allows us to prove conditions (1.10) and (1.14) for an intermediate relaxed local minimum in (P). Under relaxation stability, the results obtained characterize optimal solutions to the original problem without imposing convexity.

In §7, we study a general Mayer problem for nonconvex differential inclusions without relaxation. We prove the refined Euler–Lagrange and transversality conditions for strong (as well as for weak) local minima on the base of results in §6 and an approximation procedure involving Ekeland's variational principle. The same approach works to prove (1.13) for any boundary trajectory.

The notation in this paper is standard. The adjoint (transposed) matrix of A is denoted by A^*; the set B is always the unit closed ball of the space in question. Some special symbols are introduced and explained in §4.

2. Intermediate local minimum and relaxation.

Recall that we consider problem (P) stated above in the class of absolutely continuous functions $x : [a,b] \to \mathbf{R}^n$ (arcs) satisfying constraints (1.2)–(1.3). Any solution to (1.2) is called an (*original*) *trajectory* for the differential inclusion, and any trajectory satisfying constraints (1.3) is called a *feasible solution* to problem (P). Let us introduce a notion of local minimum for (P) studied in the paper.

DEFINITION 2.1. *The arc $\bar{x}(\cdot)$ is called an* intermediate local minimum (*i.l.m.*) *of rank $p \in [1,\infty)$ for (P) if $\bar{x}(\cdot)$ is a feasible solution to (P) and there exist numbers $\varepsilon > 0$ and $\alpha \geq 0$ such that $J[\bar{x}] \leq J[x]$ for any other feasible solution $x(\cdot)$ to (P) satisfying*

$$|x(t) - \bar{x}(t)| < \varepsilon \;\; \forall\, t \in [a,b], \tag{2.1}$$

$$\alpha \int_a^b |\dot{x}(t) - \dot{\bar{x}}(t)|^p dt < \varepsilon. \tag{2.2}$$

If (2.2) is fulfilled, then instead of (2.1) one can obviously use $|x(a) - \bar{x}(a)| < \varepsilon$. Relationships (2.1), (2.2) mean that we consider a neighborhood of $\bar{x}(\cdot)$ in the Sobolev space $W^{1,p}$ of absolute continuous functions $x : [a,b] \to \mathbf{R}^n$ equipped with a natural norm. If there is only requirement (2.1) in Definition 2.1 (i.e., $\alpha = 0$), then one gets a *strong* local minimum (with respect to the C-norm). This actually corresponds to the L^1-weak topology for derivatives instead of the strong (L^p-norm) topology in (2.2). Obviously any *optimal solution* to problem (P) (global minimum) provides a strong local minimum (and, therefore, an i.l.m.) for (P). As we know, most necessary optimality conditions for differential inclusions are obtained for strong local minima, but it is not clear a priori whether they hold for i.l.m.

If instead of (2.2) one sets the more restrictive requirement

$$|\dot{x}(t) - \dot{\bar{x}}(t)| < \varepsilon \;\; \text{a.e.} \;\; t \in [a,b],$$

then we have a *weak* local minimum in the framework of Definition 2.1. This corresponds to considering a neighborhood of $\bar{x}(\cdot)$ in the space $W^{1,\infty}$ with the L^∞-norm for derivatives (or the C^1-norm for continuously differentiable functions in classical variational problems). Therefore, the notion of i.l.m. that we introduced takes (for any rank $p \in [1,\infty)$) an intermediate place between the familiar concepts of strong ($\alpha = 0$) and weak ($p = \alpha$) minima. Note that some aspects of this setting are related to the (local) *Lavrentiev phenomenon* in the calculus of variations.

The following example shows that the class of intermediate local minimizers differs from that of weak local minimizers in classical variational problems.

Example 2.2. Consider the simplest problem of the calculus of variations:

$$\text{minimize } J[x] = \int_0^1 \dot{x}^3(t)dt \text{ subject to } x(0) = 0, \ \ x(1) = 1.$$

It is easy to conclude that the function $\bar{x}(t) = t$ provides a weak local minimum for this problem; see [21, §2.2.2]. Now taking the functions $x_k(t) = \bar{x}(t) + y_k(t)$ with $y_k(0) = y_k(1) = 0$ and

$$\dot{y}_k(t) = \begin{cases} -\sqrt{n} & \text{if } 0 \le t \le 1/n, \\ \sqrt{n}(n-1)^{-1} & \text{if } 1/n < t \le 1, \end{cases}$$

one can check that

$$J[x_k] = \sqrt{n} + O(1) \to -\infty$$

and

$$\int_0^1 |\dot{x}_k(t) - \dot{\bar{x}}(t)|^p dt \to 0 \text{ as } k \to \infty$$

for each $p \in [1, \infty)$. Therefore, the extremal $\bar{x}(t)$ does not provide an intermediate local minimum of any rank $p \in [1, \infty)$ for the example considered.

On the other hand, intermediate local minimizers may not be strong local minimizers even for *convex* and Lipschitzian differential inclusions. Such examples are constructed by Vinter and Woodford [49] in both bounded (autonomous) and unbounded cases. They also distinguish intermediate local minimizers of different rank for some unbounded (but integrably bounded) differential inclusions.

Now we consider an extension of the original problem (P) in the line well known in the calculus of variations and optimal control (cf., e.g., [4], [6], [15], [20], [50], [52]). Let

$$f_F(x, v, t) := f(x, v, t) + \delta(v, F(x, t)) \tag{2.3}$$

where $\delta(v, \Lambda) = 0$ if $v \in \Lambda$ and $\delta(v, \Lambda) = \infty$ if $v \notin \Lambda$ (the indicator function). Denote by $\hat{f}_F(x, v, t)$ the *convexification* (the biconjugate function) for f_F in the v variable, i.e., the largest convex function majorized by $f_F(x, \cdot, t)$ for each x and t. Along with the original problem (P), we consider its *relaxation* (R) as follows:

$$\text{minimize } \hat{J}[x] := \varphi(x(a), x(b)) + \int_a^b \hat{f}_F(x(t), \dot{x}(t), t)dt \tag{2.4}$$

over absolutely continuous functions on $[a, b]$ under endpoint constraints (1.3). Note that if $\hat{J}[x] < \infty$, then $x(\cdot)$ satisfies the convexified differential inclusion

$$\dot{x}(t) \in \text{co}F(x(t), t) \ \text{ a.e. } t \in [a, b]. \tag{2.5}$$

Any trajectory for (2.5) is called a *relaxed trajectory* for (1.2). It is well known that under natural assumptions involving Lipschitzness of F in x, the following *approximation property* holds: Every relaxed trajectory $x(\cdot)$ can be uniformly approximated in $[a, b]$ by original trajectories $x_k(\cdot)$ starting with the same initial state (but may not satisfy endpoint constraints) such that

$$\underline{\lim} \int_a^b f(x_k(t), \dot{x}_k(t), t)dt \le \int_a^b \hat{f}_F(x(t), \dot{x}(t), t)dt \text{ as } k \to \infty. \tag{2.6}$$

DEFINITION 2.3. *The arc* $\bar{x}(\cdot)$ *is called an* intermediate relaxed local minimum *(i.r.l.m.) of rank* $p \in [1, \infty)$ *for the original problem* (P) *if* $\bar{x}(\cdot)$ *is a feasible solution of* (P) *and provides an intermediate local minimum of rank p for the relaxed problem* (R) *with* $J[\bar{x}] = \hat{J}[\bar{x}]$.

It is essential in Definition 2.3 that $\bar{x}(\cdot)$ is an original trajectory for (1.2). Obviously, there is no difference between i.r.l.m. and i.l.m. if problem (P) is convex in the following sense: for each $t \in [a, b]$ and x around $\bar{x}(t)$, the function f is convex in v on the convex set $F(x, t)$. One can see that the refined Euler–Lagrange inclusion that is obtained for i.r.l.m. may be different from its counterpart for arbitrary i.l.m. in the relaxed problem. This happens because the normal cone to the graph of F and to the graph of co$F$ is not the same. On the other hand, we cannot guarantee, in principle, that necessary conditions for i.r.l.m. will work for arbitrary i.l.m. (or strong minima) for the original problem. Nevertheless, the latter holds in rather general settings without any convexity assumptions. Actually this is related to the property of "hidden convexity" inherent in continuous-time systems like (1.2). In this paper, we use only one result in this direction going back to the classical Bogoljubov theorem [4].

PROPOSITION 2.4. *Let* $\bar{x}(\cdot) \in W^{1,\infty}[a, b]$ *be a strong minimum for problem* (1.1), (1.3) *where the integrand* $f(x, v, t)$ *is continuous in* (x, v) *around* $(\bar{x}(t), \dot{\bar{x}}(t))$ *uniformly in* $[a, b]$ *and measurable in t. Then* $\bar{x}(\cdot)$ *is a strong minimum for the relaxed problem* (1.3), (2.4) *with* $\hat{f}_F = \hat{f}$ *and* $J[\bar{x}] = \hat{J}[\bar{x}]$.

Proof. According to the version of Bogoljubov's theorem in [21, §9.2.4], for any $x(\cdot) \in W^{1,\infty}[a, b]$ one can find a sequence of $x_k(\cdot) \in W^{1,\infty}[a, b]$ such that $x_k(a) = x(a)$, $x_k(b) = x(b)$, $x_k(\cdot)$ converge to $x(\cdot)$ uniformly in $[a, b]$, and (2.6) is fulfilled in the case where $\hat{f}_F = \hat{f}$. If $\bar{x}(\cdot)$ is not a strong minimum for the relaxed problem (2.4), (1.3) or/and $\hat{J}[\bar{x}] < J[\bar{x}]$, then there exists a function $x(\cdot) \in W^{1,\infty}[a, b]$ with $\hat{J}[x] < J[\bar{x}]$ such that $x(\cdot)$ belongs to a C-neighborhood of $\bar{x}(\cdot)$ and satisfies constraints (1.3). This contradicts the strong minimality of $\bar{x}(\cdot)$ in the original problem, thanks to the Bogoljubov approximation for $x(\cdot)$. □

There are several generalizations and analogues of Bogoljubov's theorem that have many important applications to optimal control systems and differential inclusions; see, for example, [6], [15], [20], [28], [50] and references therein. They lead to the property of *relaxation stability* (or proper relaxation) when an optimal solution to the original problem solves the relaxed problem as well with the same optimal value. For problems (P) involving differential inclusions with endpoint constraints at either $t = a$ or $t = b$, such a relaxation stability follows directly from the approximation property for relaxed trajectories stated above.

For problems with general endpoint constraints, the relaxation stability is ensured by the *calmness* property in Clarke [6], [8]. The latter property is fulfilled for "almost all" endpoint constraints (at least of inequality type) and shows that the relaxation stability may fail only for ill-posed problems where small perturbations of boundary conditions produce proportionally unbounded variations of the minimum. According to Clarke [8], the calmness hypothesis implies that corresponding necessary optimality conditions can be taken to be *normal.* A general result that "normality implies relaxation stability" for optimal control systems has been obtained by Warga [51].

For special classes of problems (P) with arbitrary endpoint constraints, the relaxation stability holds without any calmness or normality assumptions. In particular, let differential inclusion (1.2) be represented in the *linear* form

$$\dot{x}(t) \in F_1(t)x(t) + F_2(t) \text{ a.e. } t \in [a, b]$$

where the multifunctions F_1 and F_2 are integrable in $[a,b]$, F_1 is convex-valued while F_2 is not. If, moreover, the function f in (1.1) is convex in v, then any of such problems (P) possesses the property of relaxation stability. This can be proved by using Aumann's theorem about set-valued integrals; cf. arguments in [28, Thm. 19.7]. The same situation holds for problems (P) involving nonlinear one-dimensional differential inclusions; see Remark 19.2 in [28].

3. Discrete approximations. In this section we construct a sequence of discrete approximations for the original problem of Bolza such that optimal solutions to discrete approximations converge in $W^{1,p}$ to a given i.r.l.m. for problem (P).

First let us consider a fixed original trajectory $\bar{x}(\cdot)$ for (1.2) and prove that it can be approximated by trajectories for corresponding discrete inclusions. To do this, we assume that the multifunction $F(x,t)$ is bounded and locally Lipschitzian in x around $\bar{x}(\cdot)$ and is Hausdorff continuous in t a.e. on $[a,b]$. More precisely, we impose the following hypotheses:

(H1) There are an open set $U \subset \mathbf{R}^n$ and positive numbers l_F, m_F such that $\bar{x}(t) \in U$ for any $t \in [a,b]$, the sets $F(x,t)$ are closed for all $(x,t) \in U \times [a,b]$, and one has

$$F(x,t) \subset m_F B \quad \forall (x,t) \in U \times [a,b] \tag{3.1}$$

and

$$F(x_1,t) \subset F(x_2,t) + l_F|x_1 - x_2|B \quad \forall x_1, x_2 \in U, \quad t \in [a,b]. \tag{3.2}$$

(H2) The multifunction $F(x,\cdot)$ is Hausdorff continuous for a.e. $t \in [a,b]$ uniformly in $x \in U$.

Following Dontchev and Farkhi [12], let us consider the so-called *averaged modulus of continuity* for the multifunction $F(x,t)$ in $t \in [a,b]$ when $x \in U$. This modulus $\tau(F;h)$ that depends on the parameter $h > 0$ is defined as follows:

$$\tau(F;h) := \int_a^b \sigma(F;t,h)dt \tag{3.3}$$

where $\sigma(F;t,h) := \sup\{\omega(F;x,t,h) | x \in U\}$, where

$$\omega(F;x,t,h) := \sup\{\text{haus}(F(x,t'),F(x,t'')) | t',t'' \in [t-h/2, t+h/2] \cap [a,b]\},$$

and where haus$(\cdot,\cdot)$ is the Hausdorff distance between compact sets.

It is proved in [12] that if $F(x,\cdot)$ is Hausdorff continuous for a.e. $t \in [a,b]$ uniformly in $x \in U$, then $\tau(F;h) \to 0$ as $h \to 0$.

Note that in the case of single-valued functions $f(t)$ not depending on x, the construction $\tau(f;h)$ in (3.3) was developed in Sendov and Popov [47] under the name of "averaged modulus of smoothness." It was proved in [47] that $\tau(f;h) \to 0$ as $h \to 0$ if and only if f is Riemann integrable on $[a,b]$. The latter is equivalent to f being continuous for a.e. $t \in [a,b]$. In this paper, we use the name "averaged modulus of continuity" for both single-valued and multivalued cases.

Now let us construct a finite difference (discrete) approximation for the given differential inclusion using the replacement of the derivative in (1.2) by the *Euler finite difference*

$$\dot{x}(t) \approx [x(t+h) - x(t)]/h.$$

For any natural number $k = 1, 2, \ldots$, we consider a uniform grid $T_k := \{t_j | j = 0, 1, \ldots, k\}$ with $t_0 = a$, $t_k = b$ and stepsize

$$h_k := (b-a)/k = t_{j+1} - t_j \quad (j = 0, \ldots, k-1).$$

The associate discrete inclusion is as follows:

$$x_{j+1}^k \in x_j^k + h_k F(x_j^k, t_j), \quad j = 0, \ldots, k-1. \tag{3.4}$$

THEOREM 3.1. *Let $\bar{x}(\cdot)$ be a trajectory for* (1.2) *under hypotheses* (H1) *and* (H2). *Then there is a sequence $\{z_j^k | j = 0, \ldots, k\}$, $k = 1, 2, \ldots$, of solutions to discrete inclusions* (3.4) *such that $z_0^k = \bar{x}(a)$ and the functions*

$$v^k(t) := (z_{j+1}^k - z_j^k)/h_k, \quad t \in [t_j, t_{j+1}), \quad j = 0, \ldots, k-1, \tag{3.5}$$

converge to $\dot{\bar{x}}(\cdot)$ as $k \to \infty$ in the norm topology of $L^1[a,b]$.

Proof. Let $\{w^k(\cdot)\}$, $k = 1, 2, \ldots$, be an arbitrary sequence of functions in $[a,b]$ such that $w^k(t)$ are constant in $[t_j, t_{j+1})$ for every $j = 0, \ldots, k-1$ and $w^k(t)$ converge to $\dot{\bar{x}}(t)$ as $k \to \infty$ in the norm of $L^\infty[a,b]$. Such a sequence always exists because of the density of step-functions in $L^\infty[a,b]$. Employing (3.1), one gets

$$|w^k(t)| \le m_F + 1 \;\; \forall t \in [a,b] \;\text{ as }\; k \to \infty. \tag{3.6}$$

In the arguments and estimates below, we use the number

$$\xi_k := \int_a^b |\dot{\bar{x}}(t) - w^k(t)| dt \to 0 \;\text{ as }\; k \to \infty. \tag{3.7}$$

Let us define the discrete functions $\{y_j^k | j = 0, \ldots, k\}$ as follows:

$$y_{j+1}^k = y_j^k + h_k w_j^k, \quad j = 0, \ldots, k-1, \quad y_0^k = \bar{x}(a) \tag{3.8}$$

where $w_j^k := w^k(t_j)$, $j = 0, \ldots, k-1$. Note that the functions

$$y^k(t) := \bar{x}(a) + \int_a^t w^k(s) ds, \quad a \le t \le b,$$

are piecewise linear extensions of (3.8) on the interval $[a,b]$ and

$$|y^k(t) - \bar{x}(t)| \le \xi_k \;\; \forall t \in [a,b]. \tag{3.9}$$

Therefore, $y^k(t) \in U$ for all $t \in [a,b]$ if k is big enough.

Denote by $\operatorname{dist}(w, F)$ the *Euclidean distance* between the point w and the closed set F. It is well known that the Lipschitz condition (3.2) is equivalent to

$$\operatorname{dist}(w, F(x_1, t)) \le \operatorname{dist}(w, F(x_2, t)) + l_F |x_1 - x_2| \;\; \forall w \in \mathbf{R}^n, \;\; x_1, x_2 \in U, \;\; t \in [a,b].$$

For any $w, x \in \mathbf{R}^n$ and $t_1, t_2 \in [a,b]$, one obviously has

$$\operatorname{dist}(w, F(x, t_1)) \le \operatorname{dist}(w, F(x, t_2)) + \operatorname{haus}(F(x, t_1), F(x, t_2)).$$

Now using (3.3), we get

$$\varsigma_k := \sum_{j=0}^{k-1} h_k \mathrm{dist}(w_j^k, F(y_j^k, t_j)) = \sum_{j=0}^{k-1} \int_{t_j}^{t_{j+1}} \mathrm{dist}(w_j^k, F(y_j^k, t_j))dt$$
$$\leq \sum_{j=0}^{k-1} \int_{t_j}^{t_{j+1}} \mathrm{dist}(w_j^k, F(y_j^k, t))dt + \tau(F; h_k).$$

It follows from (3.2), (3.6), and (3.9) that

$$\mathrm{dist}(w_j^k, F(y_j^k, t)) \leq \mathrm{dist}(w^k(t), F(y^k(t), t)) + l_F(m_F + 1)(t - t_j) \;\; \forall t \in [t_j, t_{j+1})$$

and

$$\mathrm{dist}(w^k(t), F(y^k(t), t)) \leq \mathrm{dist}(w^k(t), F(\bar{x}(t), t)) + l_F|y^k(t) - \bar{x}(t)|$$
$$\leq |w^k(t) - \dot{\bar{x}}(t)| + l_F \xi_k \;\; \text{a.e. } t \in [a, b].$$

Therefore, we have the estimate

$$(3.10) \qquad \varsigma_k \leq \gamma_k := (1 + l_F)\xi_k + l_F(b - a)(m_F + 1)h_k/2 + \tau(F; h_k).$$

Note that functions (3.8) are not trajectories for (3.4) because one does not get $w_j^k \in F(y_j^k, t_j)$. Now we use w_j^k to define trajectories for (3.4), which are close to y_j^k and have the convergence property stated in this theorem.

Let us construct the desirable trajectories $\{z_j^k | j = 0, \ldots, k\}$ using the following *proximal algorithm*:

$$(3.11) \qquad z_0^k = \bar{x}(a), \; v_j^k \in F(z_j^k, t_j) \text{ with } |v_j^k - w_j^k| = \mathrm{dist}(w_j^k, F(z_j^k, t_j)),$$

$$z_{j+1}^k = z_j^k + h_k v_j^k, \qquad j = 0, \ldots, k - 1.$$

Note that in (3.11) we take *projections of velocities* as in [28], [48] instead of projections of states as in [38], [12]. This will allow us to prove a strong convergence of discrete approximations with respect to velocities.

First we prove that algorithm (3.11) keeps $\{z_j^k | j = 0, \ldots, k\}$ inside the neighborhood U from (H1) if k is big enough. Indeed, we consider any number k such that $\bar{x}(t) + \eta_k B \subset U$ for all $t \in [a, b]$ where

$$\eta_k := \gamma_k \exp[l_F(b - a)] + \xi_k,$$

where ξ_k and γ_k are defined in (3.7) and (3.10), respectively. One can see that $\eta_k \to 0$ as $k \to \infty$ because $\tau(F; h_k) \to 0$ under assumption (H2).

By induction, let us show that if $z_m^k \in U$ for all $m = 0, \ldots, j$, then this also holds for $m = j + 1$. Using (3.2), (3.10), and (3.11), one gets

$$|z_{j+1}^k - y_{j+1}^k| \leq |z_j^k - y_j^k| + h_k \mathrm{dist}(w_j^k, F(z_j^k, t_j)) \leq |z_j^k - y_j^k| + h_k(\mathrm{dist}(w_j^k, F(y_j^k, t_j))$$
$$+ l_F|z_j^k - y_j^k|) \leq \cdots \leq h_k \sum_{m=0}^{j} (1 + l_F h_k)^{j-m} \mathrm{dist}(w_m^k, F(y_m^k, t_m))$$
$$\leq \exp[l_F(b - a)] \sum_{m=0}^{j} h_k \mathrm{dist}(w_m^k, F(y_m^k, t_m)) \leq \gamma_k \exp[l_F(b - a)].$$

Due to (3.9), the latter implies

$$(3.12)\qquad |z_{j+1}^k - \bar{x}(t_{j+1})| \le \gamma_k \exp[l(b-a)] + \xi_k := \eta_k,$$

which proves that $z_j^k \in U$ for all $j \in \{0,\dots,k\}$. Taking this into account, one can extract from the previous arguments the following estimate:

$$(3.13)\qquad \sum_{j=0}^{k} |z_j^k - y_j^k| \le (b-a)\exp[l_F(b-a)] \sum_{j=0}^{k-1} \operatorname{dist}(w_j^k, F(y_j^k, t_j)).$$

Now let us estimate the quantity $\vartheta_k := \int_a^b |v^k(t) - w^k(t)|dt$ where the functions $v^k(t)$ are defined in (3.5). Employing (3.10), (3.11), and (3.13), we get

$$\vartheta_k = \sum_{j=0}^{k-1} h_k|v_j^k - w_j^k| = \sum_{j=0}^{k-1} h_k \operatorname{dist}(w_j^k, F(z_j^k, t_j)) \le \sum_{j=0}^{k-1} h_k \operatorname{dist}(w_j^k, F(y_j^k, t_j))$$

$$+ l_F \sum_{j=0}^{k-1} h_k |z_j^k - y_j^k| \le \gamma_k(1 + l_F(b-a)\exp[l_F(b-a)]).$$

Thus we obtain the final estimate

$$(3.14)\quad \alpha_k := \int_a^b |v^k(t) - \dot{\bar{x}}(t)|dt \le \beta_k := \xi_k + \gamma_k(1 + l_F(b-a)\exp[l_F(b-a)]).$$

This ensures the L^1-convergence $v^k(\cdot) \to \dot{\bar{x}}(\cdot)$ due to (3.7) and $\tau(F; h_k) \to 0$ as $k \to \infty$ under (H2). □

Remark 3.2. The result obtained provides a *strong approximation* with respect to velocities of any absolutely continuous trajectory for the differential inclusion (1.2) by discrete trajectories for its Euler difference counterparts (3.4). Note that the error estimate for velocities (3.14) immediately implies the following estimate

$$|z^k(t) - \bar{x}(t)| \le \beta_k \;\; \forall t \in [a,b]$$

for the corresponding motions $z^k(t) := \bar{x}(a) + \int_a^t v^k(s)ds$, which are piecewise linear extensions of discrete trajectories (3.11). One can see that the *numerical efficiency* of the estimates obtained depends on the evaluation of $\tau(F;h)$ and the approximation accuracy in (3.7).

It has been proved in [12] that $\tau(F;h) = O(h)$ if $F(x,\cdot)$ is of *bounded variation* on $[a,b]$ uniformly in $x \in U$. Using the technique for averaged moduli of continuity (smoothness) developed in [47], one can obtain effective estimates for ξ_k in (3.7). Indeed, if $\dot{\bar{x}}(\cdot)$ is *Riemann integrable* on $[a,b]$, then we always get $\xi_k \le 2\tau(\dot{\bar{x}}; h_k)$, taking $v^k(t) = \dot{\bar{x}}(t_j)$ for $t \in [t_j, t_j + h_k)$ as $j = 0,\dots,k-1$.

Now we consider the given original trajectory $\bar{x}(\cdot)$, which is an i.r.l.m. of some rank $p \in [1,\infty)$ for problem (P). One can easily see that under boundedness assumption (3.1), the notion of i.r.l.m. for (P) *does not depend on rank* p. This means that if $\bar{x}(\cdot)$ is an i.r.l.m. of some rank $p \in [1,\infty)$, then it will be an i.r.l.m. of any other rank from $[1,\infty)$. In what follows we always take $p = 2$ and set $\alpha = 1$ in (2.2) for simplicity.

Let us construct a sequence of optimization problems (P_k) for discrete inclusions (3.4) such that optimal solutions to (P_k) *strongly* (in $W^{1,2}[a,b]$) converge to $\bar{x}(\cdot)$ as $k \to \infty$. Take a number ε in (2.1), (2.2) for the given i.r.l.m; and assume (H1), (H2) along $\bar{x}(\cdot)$. One can always suppose that $\bar{x}(t) + \varepsilon/2 \in U$ for all $t \in [a,b]$. Using Theorem 3.1, we approximate $\bar{x}(\cdot)$ by discrete trajectories $\{z_j^k | j = 0, \dots, k\}$ and compute the numbers η_k in (3.12). Now we define a sequence of discrete approximation problems (P_k), $k = 1, 2, \dots$, as follows:

$$\text{(3.15)} \qquad \text{minimize } J_k[x^k] := \varphi(x_0^k, x_k^k) + |x_0^k - \bar{x}(a)|^2$$

$$+h_k \sum_{j=0}^{k-1} f(x_j^k, (x_{j+1}^k - x_j^k)/h_k, t_j) + \sum_{j=0}^{k-1} \int_{t_j}^{t_{j+1}} |(x_{j+1}^k - x_j^k)/h_k - \dot{\bar{x}}(t)|^2 dt$$

over discrete trajectories $x^k = (x_0^k, x_1^k, \dots, x_k^k)$ for the difference inclusion (3.4) subject to the constraints

$$\text{(3.16)} \qquad (x_0^k, x_k^k) \in \Omega_k := \Omega + \eta_k B,$$

$$\text{(3.17)} \qquad |x_j^k - \bar{x}(t_j)| \le \varepsilon/2 \text{ for } j = 0, \dots, k,$$

and

$$\text{(3.18)} \qquad \sum_{j=0}^{k-1} \int_{t_j}^{t_{j+1}} |(x_{j+1}^k - x_j^k)/h_k - \dot{\bar{x}}(t)|^2 dt \le \varepsilon/2.$$

Let $x^k(\cdot)$ be the piecewise linear extension of the discrete trajectory $\{x_j^k | j = 0, \dots, k\}$ on $[a,b]$, and let $\dot{x}^k(\cdot)$ denote the piecewise constant extension of the "velocity" $(x_{j+1}^k - x_j^k)/h_k$. One has

$$\dot{x}^k(t) = (x_{j+1}^k - x_j^k)/h_k = \dot{x}^k(t_j) \text{ for any } t \in [t_j, t_{j+1}).$$

We are going to consider the (strong) $W^{1,2}$-convergence of $x^k(\cdot)$ to some absolutely continuous function $x(\cdot)$ in $[a,b]$. This means that $x^k(a) = x_0^k \to x(a)$ and $\dot{x}^k(\cdot) \to \dot{x}(\cdot)$ in $L^2[a,b]$ as $k \to \infty$. The latter obviously implies that $x^k(\cdot)$ converge to $x(\cdot)$ uniformly in $[a,b]$.

In addition to (H1) and (H2), now we impose the following hypotheses on f, φ, and Ω:

(H3) $f(x,v,\cdot)$ is continuous for a.e. $t \in [a,b]$ and bounded uniformly in $(x,v) \in U \times (m_F B)$.

(H4) There exists $\nu > 0$ such that the function $f(\cdot,\cdot,t)$ is continuous on the set

$$\text{(3.19)} \quad A_\nu(t) := \{(x,v) \in U \times (m_F + \nu)B | \; v \in F(x,t') \text{ for some } t' \in (t-\nu, t]\}$$

uniformly in $t \in [a,b]$.

(H5) φ is continuous on $U \times U$ and Ω is closed around $(\bar{x}(a), \bar{x}(b))$.

THEOREM 3.3. *Let $\bar{x}(\cdot)$ be an i.r.l.m. for problem (P), and let hypotheses* (H1)–(H5) *be fulfilled. Then any sequence $\{\bar{x}^k(\cdot)\}$, $k = 1, 2, \dots$, of optimal solutions to (P_k) converges to $\bar{x}(\cdot)$ in the space $W^{1,2}[a,b]$ as $k \to \infty$.*

Proof. First let us prove that for each k big enough, the discrete trajectory $\{z_j^k | j = 0, \ldots, k\}$ constructed in Theorem 3.1 is a feasible solution of (P_k). We need to check that this trajectory satisfies constraints (3.16)–(3.18). For the case of (3.16), it follows directly from (3.12). Taking k such that $\eta_k \leq \varepsilon/2$, we also get (3.17) from (3.12). By virtue of (3.1) and (3.14), constraint (3.18) for $x^k = z^k$ is reduced to

$$\int_a^b |v^k(t) - \dot{\bar{x}}(t)|^2 dt \leq 2m_F\alpha_k \leq 2m_F\beta_k \leq \varepsilon/2.$$

The latter is fulfilled for big numbers k due to the expression for β_k in (3.14). Therefore, x^k is a feasible solution to (P_k) for all k big enough. According to the classical Weierstrass theorem, we can conclude that there is an optimal solution $\bar{x}^k$ to (P_k) for such k under the assumptions made.

Let us prove that for any sequence of optimal solutions $\bar{x}^k$ to (P_k) one has

$$\overline{\lim}\, J_k[\bar{x}^k] \leq J[\bar{x}] \text{ as } k \to \infty. \tag{3.20}$$

To accomplish this, it suffices to show that

$$J_k[z_k] \to J[\bar{x}] \text{ as } k \to \infty \tag{3.21}$$

for the sequence of discrete trajectories z^k approximating $\bar{x}(\cdot)$ by virtue of Theorem 3.1.

Let us consider expression (3.15) for $J_k[z^k]$. Due to continuity of φ one has

$$\varphi(z_0^k, z_k^k) \to \varphi(\bar{x}(a), \bar{x}(b)) \text{ as } k \to \infty.$$

Further, the second term in this expression vanishes; the fourth term tends to zero as $k \to \infty$ because of (3.5) and (3.14). To justify (3.21), it remains to prove that

$$\sigma_k := h_k \sum_{j=0}^{k-1} f(z_j^k, (z_{j+1}^k - z_j^k)/h_k, t_j) \to \int_a^b f(\bar{x}(t), \dot{\bar{x}}(t), t)\, dt \text{ as } k \to \infty$$

under assumptions (H1)–(H4). Note that (H3) implies $\tau(f; h_k) \to 0$ as $k \to \infty$ for modulus (3.3). In what follows we use the sign "$\sim$" for expressions that are equivalent as $k \to \infty$. Due to (3.5), (3.12), and (3.14) one gets

$$\sigma_k = \sum_{j=0}^{k-1} \int_{t_j}^{t_{j+1}} f(z_j^k, v^k(t), t_j) dt \sim \sum_{j=0}^{k-1} \int_{t_j}^{t_{j+1}} f(z_j^k, v^k(t), t) dt + \tau(f; h_k)$$

$$\sim \sum_{j=0}^{k-1} \int_{t_j}^{t_{j+1}} f(\bar{x}(t), v^k(t), t) dt = \int_a^b f(\bar{x}(t), v^k(t), t) dt \sim \int_a^b f(\bar{x}(t), \dot{\bar{x}}(t), t) dt.$$

The last statement holds by virtue of the classical Lebesgue limiting theorem because $\{v^k(\cdot)\}$ contains a subsequence converging for a.e. $t \in [a, b]$. Therefore, we obtain (3.21), which implies (3.20).

In the arguments above we have not actually used the property of $\bar{x}(\cdot)$ to be an i.r.l.m. for (P). Now let us prove that in the latter case, inequality (3.20) implies

$$\lim_{k\to\infty} [c_k := |\bar{x}^k(a) - \bar{x}(a)|^2 + \int_a^b |\dot{\bar{x}}^k(t) - \dot{\bar{x}}(t)|^2 dt] = 0, \tag{3.22}$$

i.e., $\bar{x}^k(\cdot)$ converge to $\bar{x}(\cdot)$ in the norm of $W^{1,2}[a,b]$. Suppose that it is not true, and consider a limiting point $c > 0$ of the sequence $\{c_k\}$ in (3.22). Let, for simplicity, $c = \lim c_k$ for all $k \to \infty$.

Because of (3.17) and (3.18) we claim the existence of an absolutely continuous function $\tilde{x}(t)$ in $[a,b]$ such that $\bar{x}^k(\cdot) \to \tilde{x}(\cdot)$ uniformly in $[a,b]$ and $\dot{\bar{x}}^k(\cdot) \to \dot{\tilde{x}}(\cdot)$ weakly in $L^2[a,b]$ as $k \to \infty$ (we take all k without loss of generality). According to the classical Mazur theorem, there is a sequence of convex combinations of $\dot{\bar{x}}^k(\cdot)$ that converges to $\dot{\tilde{x}}(\cdot)$ in the norm topology of $L^2[a,b]$. Hence it contains a subsequence converging to $\dot{\tilde{x}}(\cdot)$ for a.e. $t \in [a,b]$.

Using these facts and taking into account that

$$h_k \sum_{j=0}^{k-1} f(\bar{x}_j^k, (\bar{x}_{j+1}^k - \bar{x}_j^k)/h_k, t_j) \sim \int_a^b f(\bar{x}^k(t), \dot{\bar{x}}^k(t), t)dt \text{ as } k \to \infty$$

and also the definition of $\hat{f}_F$ for (2.3), we get

$$\text{(3.23)} \quad \int_a^b \hat{f}_F(\tilde{x}(t), \dot{\tilde{x}}(t), t)dt \le \underline{\lim}\, h_k \sum_{j=0}^{k-1} f(\bar{x}_j^k, (\bar{x}_{j+1}^k - \bar{x}_j^k)/h_k, t_j) \text{ as } k \to \infty,$$

where $\tilde{x}(\cdot)$ satisfies the convexified differential inclusion (2.5).

Observe that the integral functional

$$I[v] := \int_a^b |v(t) - \dot{\bar{x}}(t)|^2 dt$$

is lower semicontinuous in the weak topology of $L^2[a,b]$ due to the convexity of the integrand in v. Since

$$\sum_{j=0}^{k-1} \int_{t_j}^{t_{j+1}} |(\bar{x}_{j+1}^k - \bar{x}_j^k)/h_k - \dot{\bar{x}}(t)|^2 dt = \int_a^b |\dot{\bar{x}}^k(t) - \dot{\bar{x}}(t)|^2 dt,$$

the latter implies that

$$\text{(3.24)} \int_a^b |\dot{\tilde{x}}(t) - \dot{\bar{x}}(t)|^2 dt \le \underline{\lim} \sum_{j=0}^{k-1} \int_{t_j}^{t_{j+1}} |(\bar{x}_{j+1}^k - \bar{x}_j^k)/h_k - \dot{\bar{x}}(t)|^2 dt \text{ as } k \to \infty.$$

Now passing to the limit in (3.16)–(3.18) as $k \to \infty$ and using (3.24) as well as (H5), we get that $\tilde{x}(\cdot)$ satisfies constraints (1.3) and

$$|\tilde{x}(t) - \bar{x}(t)| \le \varepsilon/2 \text{ for } t \in [a,b], \quad \int_a^b |\dot{\tilde{x}}(t) - \dot{\bar{x}}(t)|^2 dt \le \varepsilon/2.$$

The latter means that $\tilde{x}(\cdot)$ belongs to the given neighborhood of $\bar{x}(\cdot)$ in $W^{1,2}[a,b]$. Moreover, (3.23) implies

$$\text{(3.25)} \qquad \varphi(\tilde{x}(a), \tilde{x}(b)) + \int_a^b \hat{f}_F(\tilde{x}(t), \dot{\tilde{x}}(t), t)dt + c \le \underline{\lim}\, J_k[\bar{x}^k] \text{ as } k \to \infty.$$

Due to (3.20), (3.25), and $c > 0$ we get $\hat{J}[\tilde{x}] < J[\bar{x}]$. But this is impossible because $\bar{x}(\cdot)$ is an i.r.l.m. for (P). Therefore, one has $c = 0$, which establishes (3.22) and ends the proof of the theorem. □

Remark 3.4. In the convergence result of Theorem 3.3, one can avoid the continuity hypothesis (H3) on f in t by changing the approximation

$$h_k \sum_{j=0}^{k-1} f(x_j^k, (x_{j+1}^k - x_j^k)/h_k, t_j) \text{ for } \sum_{j=0}^{k-1} \int_{t_j}^{t_{j+1}} f(x_j^k, (x_{j+1}^k - x_j^k)/h_k, t)\, dt.$$

Indeed, we can handle the latter approximations in the same way as the last term in (3.15) under the measurability assumption on f in t.

The convergence theorem that we proved allows us to make a bridge between variational problems for differential inclusions and dynamic optimization problems in finite dimensions. The latter can be reduced to finite-dimensional problems of mathematical programming with *many geometric constraints.* The mathematical programming problems obtained in this way turn out to be objects of *nonsmooth optimization* even in the case of smooth initial data in the original problem (P).

For variational analysis of these problems and then for passing to the limit in optimality conditions as $k \to \infty$, we need to use generalized differential constructions with special properties. They are considered in the next section.

4. Tools of variational analysis. This section is concerned with tools of generalized differentiation that are appropriate for the main objectives of the research. The results reviewed are mostly connected with the approach in Mordukhovich [26]–[28] and recent developments in [30]–[34] dealing with *nonconvex*-valued generalized differential constructions. The reader can also consult Clarke [8], [10], Ioffe [17]–[19], Loewen [23], Rockafellar [40], [44], and Rockafellar and Wets [45] for related and additional material.

Let Ω be a nonempty set in $\mathbf{R}^n$, and let

$$\Pi(x, \Omega) := \{\omega \in \mathrm{cl}\Omega \text{ such that } |x - \omega| = \mathrm{dist}(x, \Omega)\} \tag{4.1}$$

be the Euclidean projector of x on clΩ. In the following definition, "cone" stands for the conic hull of a set and "Limsup" denotes the well-known Kuratowski–Painlevé upper limit for multifunctions.

DEFINITION 4.1. *Given $\bar{x} \in \mathrm{cl}\Omega$, the closed cone*

$$N(\bar{x}; \Omega) := \mathrm{Limsup}_{x \to \bar{x}}[\mathrm{cone}(x - \Pi(x, \Omega))] \tag{4.2}$$

is called the normal cone *to the set Ω at the point $\bar{x}$.*

If Ω is convex, then (4.2) is reduced to the normal cone of convex analysis. In general, the convex closure of (4.2) coincides with the *Clarke normal cone*:

$$N_C(\bar{x}; \Omega) = \mathrm{clco}N(\bar{x}; \Omega). \tag{4.3}$$

Note that, in contrast to (4.3), the normal cone (4.2) is always *robust* with respect to perturbations of $\bar{x}$, i.e., the multifunction $N(\cdot; \Omega)$ has closed graph.

DEFINITION 4.2. *Let $f : \mathbf{R}^n \to \bar{\mathbf{R}}$ be an extended-real-valued function, and let $|f(\bar{x})| < \infty$. The set*

$$\partial f(\bar{x}) := \{x^* \in \mathbf{R}^n | (x^*, -1) \in N((\bar{x}, f(\bar{x})); \mathrm{epi}f)\} \tag{4.4}$$

is called the subdifferential *of f at $\bar{x}$. If $|f(\bar{x})| = \infty$, we put $\partial f(\bar{x}) = \emptyset$.*

Observe that for continuous functions, the subdifferential (4.4) turns out to be the upper limit (*robust regularization*) of the subdifferential mapping used in the theory of *viscosity solutions* [11]. It is well known that if f is locally Lipschitzian around $\bar{x}$ with modulus l_f, then

$$\partial f(\bar{x}) \neq \emptyset, \quad |x^\star| \leq l_f \ \ \forall x^\star \in \partial f(\bar{x}). \tag{4.5}$$

Moreover, in this case $\partial_C f(\bar{x}) = \text{co}\partial f(\bar{x})$ for the generalized gradient of Clarke. Note also that

$$\partial\delta(\bar{x}, \Omega) = N(\bar{x}; \Omega) \ \text{ if } \ \bar{x} \in \Omega \tag{4.6}$$

for the indicator function $\delta(\cdot, \Omega)$. We also use another representation of the normal cone (4.2) in terms of the subdifferential (4.4) subdifferential of the distance function (see [28, Prop. 2.7]):

$$N(\bar{x}; \Omega) = \text{cone}[\partial\text{dist}(\bar{x}, \Omega)] \ \text{ if } \ \ \bar{x} \in \text{cl}\Omega. \tag{4.7}$$

Among the most important advantages of constructions (4.2) and (4.4), one has a *rich calculus* under general assumptions. We refer to [10], [17]–[19], [23], [28]–[33], [40], [45] for various results in this direction. For applications in this paper, we need the two following basic rules:

$$\partial(f_1 + f_2)(\bar{x}) \subset \partial f_1(\bar{x}) + \partial f_2(\bar{x}) \tag{4.8}$$

if one of the functions f_i is Lipschitz continuous around $\bar{x}$, and

$$N(\bar{x}; \Omega_1 \cap \Omega_2) \subset N(\bar{x}; \Omega_1) + N(\bar{x}; \Omega_2) \ \text{ if } \ N(\bar{x}; \Omega_1) \cap (-N(\bar{x}; \Omega_2)) = \{0\} \tag{4.9}$$

for any closed sets Ω_1 and Ω_2. Note also the useful chain rule equality

$$\partial(\varphi \circ g)(\bar{x}) = \partial\langle\nabla\varphi(\bar{y}), g\rangle(\bar{x}) \tag{4.10}$$

where $(\varphi \circ g)(x) := \varphi(g(x))$ with $\varphi : \mathbf{R}^m \to \mathbf{R}$ strictly differentiable at $\bar{y} := g(\bar{x})$ and $g : \mathbf{R}^n \to \mathbf{R}^m$ Lipschitz continuous around $\bar{x}$.

DEFINITION 4.3. *Let $F : \mathbf{R}^n \rightrightarrows \mathbf{R}^m$ be a multifunction of nonempty graph* gph$F$, *and let $(\bar{x}, \bar{y}) \in \text{cl}(\text{gph}F)$. The multifunction $D^\star F(\bar{x}, \bar{y})$ from $\mathbf{R}^m$ into $\mathbf{R}^n$ defined by*

$$D^\star F(\bar{x}, \bar{y})(y^\star) := \{x^\star \in \mathbf{R}^n | (x^\star, -y^\star) \in N((\bar{x}, \bar{y}); \text{gph}F)\} \tag{4.11}$$

is called the coderivative *of F at $(\bar{x}, \bar{y})$. The symbol $D^\star F(\bar{x})$ is used when F is single-valued at $\bar{x}$ and $\bar{y} = F(\bar{x})$.*

Note that because it is nonconvex valued, the coderivative (4.11) is *not dual* to any tangentially generated derivatives of multifunctions (see, e.g., [3, Chap. 5]). Now we review some properties of the coderivative (4.11) that are significant for applications in this paper. First we consider the multifunction F of a special form whose graph is

$$\text{gph}F := \{(x, y) \in \mathbf{R}^n \times \mathbf{R}^m | x \in \Omega, \ g(x) - y \in \Delta\} \tag{4.12}$$

where $g : \mathbf{R}^n \to \mathbf{R}^m$. The following result is proved in [28, Thm. 3.3].

PROPOSITION 4.4. (i) *Let the set* (4.12) *be closed around the point* $(\bar{x}, \bar{y}) \in \text{gph}F$. *Then*

$$[D^\star F(\bar{x}, \bar{y})(y^\star) \neq \emptyset] \Longrightarrow y^\star \in N(g(\bar{x}) - \bar{y}; \Delta).$$

(ii) *If g is Lipschitz continuous around $\bar{x}$, then*

$$D^\star F(\bar{x},\bar{y})(y^\star) = \begin{cases} \partial_x s(\bar{x},y^\star) & \textit{for } y^\star \in N(g(\bar{x})-\bar{y};\Delta), \\ \emptyset & \textit{otherwise} \end{cases} \tag{4.13}$$

where $s(x,y^\star) := \langle y^\star, g(x)\rangle + \delta(x,\Omega)$.

Setting $\Omega = \mathbf{R}^n$ and $\Delta = \{0\}$, we get from (4.13) the *scalarization formula* obtained in [17, Prop. 8]. Moreover, one has the following relation with Clarke's generalized Jacobian:

$$\mathrm{co} D^\star g(\bar{x})(y^\star) = \mathrm{co}\partial\langle y^\star, g\rangle(\bar{x}) = (J_C g(\bar{x}))^\star y^\star \quad \forall y^\star \in \mathbf{R}^m. \tag{4.14}$$

It turns out that the coderivative (4.11) enjoys a rich calculus under natural (e.g., Lipschitzian) assumptions in general multivalued settings; see [33] for various results in this direction. Furthermore, the coderivative construction allows us to get *complete dual characterizations* of Lipschitzian properties of multifunctions that are of crucial importance for applications below (see Corollary 5.3 and the proofs of Theorems 6.1 and 7.1). Now we present results for the classical locally Lipschitz property that were proved in [31, Thm. 5.11]. We refer the reader to [2], [31], [32], [34], [41], [45] for studies and applications of more general Lipschitzian properties and related topics.

PROPOSITION 4.5. *Let F be of closed graph and bounded around $\bar{x}$ with $F(\bar{x}) \neq \emptyset$. Then each of the following conditions is necessary and sufficient for F to be locally Lipschitzian around this point:*

(i) *there exist a neighborhood U of $\bar{x}$ and a constant $l \geq 0$ such that*

$$\sup\{|x^\star| : x^\star \in D^\star F(x,y)(y^\star)\} \leq l|y^\star| \quad \forall x \in U,\ y \in F(x),\ y^\star \in \mathbf{R}^m; \tag{4.15}$$

(ii) $D^\star F(\bar{x},\bar{y})(0) = \{0\}$ $\forall \bar{y} \in F(\bar{x})$.

Remark 4.6. The estimate (4.15) is crucial to ensure the convergence of adjoint functions in the approximation procedures of §§6 and 7. If one replaces the normal cone (4.2) in the coderivative construction (4.11) by the Clarke normal cone (4.3), then such a counterpart $D_C^\star F$ of the coderivative (actually appearing in Clarke's version of the Euler–Lagrange inclusion) does not provide estimate (4.15) and the "null-condition" (ii) for Lipschitzian multifunctions in many important situations. This is related to the fact that Clarke's normal cone to any *Lipschitzian manifold* (which is a set locally representable as the graph of a Lipschitz continuous vector function) is a *linear subspace*; see Rockafellar [42]. It turns out that Lipschitzian manifolds include not only Lipschitz continuous functions but also graphs of maximal monotone operators, in particular, subdifferential mappings for convex and saddle functions. For such objects, estimate (4.15) in terms of $D_C^\star F$ and the corresponding "null-condition" are fulfilled in fact only for "strictly smooth" multifunctions. We refer to [42] and [34] for more information about these and related properties.

In conclusion of this section, we present a useful result for convex-valued multifunctions [28, Thm. 3.1], hence showing that the considered Euler–Lagrange conditions for differential and discrete inclusions automatically imply the *maximum* (*minimum*) *conditions* in problems with convex velocities.

PROPOSITION 4.7. *Let F be convex-valued around $\bar{x}$ and lower semicontinuous at $\bar{x}$. Then for any $\bar{y} \in F(\bar{x})$ one has*

$$[D^\star F(\bar{x},\bar{y})(y^\star) \neq \emptyset] \Longrightarrow [\langle y^\star, \bar{y}\rangle = \min\{\langle y^\star, y\rangle |\ y \in F(\bar{x})\}].$$

5. Necessary conditions for discrete approximations. In this section we obtain necessary optimality conditions in discrete approximation problems (P_k) for each $k = 1, 2, \ldots$. These conditions will be derived from a *generalized Lagrange multiplier rule* for finite dimensional problems in mathematical programming with many geometric constraints.

Let $\phi_j : \mathbf{R}^d \to \bar{\mathbf{R}}$ for $j = 0, \ldots, s$ and $g_j : \mathbf{R}^d \to \mathbf{R}^n$ for $j = 0, \ldots, m$. Consider the following problem (MP):

$$\text{minimize } \phi_0(z) \text{ for } z \in \mathbf{R}^d \text{ subject to} \tag{5.1}$$

$$\phi_j(z) \le 0 \text{ for } j = 1, \ldots, s, \tag{5.2}$$

$$g_j(z) = 0 \text{ for } j = 0, \ldots, m, \tag{5.3}$$

$$z \in \Delta_j \text{ for } j = 0, \ldots, l. \tag{5.4}$$

PROPOSITION 5.1. *Let $\bar{z}$ be an optimal solution to problem (MP). Assume that the functions ϕ_j are Lipschitz continuous, the functions g_j are smooth, and the sets Δ_j are closed around $\bar{z}$. Then there exist real numbers $\{\mu_j | j = 0, \ldots, s\}$ as well as vectors $\{\psi_j \in \mathbf{R}^n | j = 0, \ldots, m\}$ and $\{z_j^* \in \mathbf{R}^d | j = 0, \ldots, l\}$, not all zero, such that*

$$z_j^* \in N(\bar{z}; \Delta_j) \textit{ for } j = 0, \ldots, l, \tag{5.5}$$

$$\mu_j \ge 0 \textit{ for } j = 0, \ldots, s, \tag{5.6}$$

$$\mu_j \phi_j(\bar{z}) = 0 \textit{ for } j = 1, \ldots, s, \tag{5.7}$$

$$-z_0^* - \cdots - z_l^* \in \partial \left(\sum_{j=0}^{s} \mu_j \phi_j \right)(\bar{z}) + \sum_{j=0}^{m} (\nabla g_j(\bar{z}))^* \psi_j. \tag{5.8}$$

The proof of this result, which is based on the *metric approximation method*, can be found in Mordukhovich [27, Thm. 1] and [28, Cor. 7.5.1]. Note that this method facilitates obtaining necessary conditions for (MP) in more general forms in the presence of nonsmooth equality and inequality constraints without Lipschitzian assumptions; see [28, §7] and §7 below.

Now we employ Proposition 5.1 and calculus rules for the generalized differential constructions in §4 to prove necessary optimality conditions for finite difference problems (P_k) in the following *Euler–Lagrange form*. Considering problem (P_k) in (3.4), (3.15)–(3.18) for any fixed $k = 1, 2, \ldots$, we denote

$$F_j(\cdot) := F(\cdot, t_j) \text{ and } f_j(\cdot, \cdot) := f(\cdot, \cdot, t_j) \text{ as } j = 0, \ldots, k-1.$$

THEOREM 5.2. *Let $\bar{x}^k = (\bar{x}_0^k, \ldots, \bar{x}_k^k)$ be an optimal solution to problem (P_k). Assume that the sets Ω and* gphF_j *are closed and the functions φ and f_j are Lipschitz continuous around the points $(\bar{x}_0^k, \bar{x}_k^k)$ and $(\bar{x}_j^k, (\bar{x}_{j+1}^k - \bar{x}_j^k)/h_k)$ respectively, for all*

$j = 0, \dots, k-1$. *Then there exist a number* $\lambda^k \geq 0$ *and a vector* $p^k = (p_0^k, \dots, p_k^k) \in \mathbf{R}^{(k+1)n}$, *not both zero, such that*

$$(p_0^k + 2\lambda^k(\bar{x}(a) - \bar{x}_0^k), -p_k^k) \in \lambda^k \partial\varphi(\bar{x}_0^k, \bar{x}_k^k) + N((\bar{x}_0^k, \bar{x}_k^k); \Omega_k), \tag{5.9}$$

$$\begin{aligned} ((p_{j+1}^k - p_j^k)/h_k, p_{j+1}^k - \lambda^k \theta_j^k/h_k) \in \lambda^k \partial f_j(\bar{x}_j^k, (\bar{x}_{j+1}^k - \bar{x}_j^k)/h_k) \\ + N((\bar{x}_j^k, (\bar{x}_{j+1}^k - \bar{x}_j^k)/h_k); \mathrm{gph} F_j) \ \ \textit{for}\ j = 0, \dots, k-1 \end{aligned} \tag{5.10}$$

where

$$\theta_j^k := -2\int_{t_j}^{t_{j+1}} (\dot{\bar{x}}(t) - (\bar{x}_{j+1}^k - \bar{x}_j^k)/h_k)dt. \tag{5.11}$$

Proof. Let us introduce a new variable $z = (x_0, \dots, x_k, y_0, \dots, y_{k-1}) \in \mathbf{R}^{(2k+1)n}$ and consider the following problem of mathematical programming:

$$\begin{aligned} &\text{minimize } \phi_0(z) := \varphi(x_0, x_k) + |x_0 - \bar{x}(a)|^2 + h_k \sum_{j=0}^{k-1} f_j(x_j, y_j) \\ &\quad + \sum_{j=0}^{k-1} \int_{t_j}^{t_{j+1}} |y_j - \dot{\bar{x}}(t)|^2 dt \ \text{ subject to} \end{aligned} \tag{5.12}$$

$$\phi_j(z) := |x_{j-1} - \bar{x}(t_{j-1})| - \varepsilon/2 \leq 0 \ \text{ for } j = 1, \dots, k+1, \tag{5.13}$$

$$\phi_{k+2}(z) := \sum_{j=0}^{k-1} \int_{t_j}^{t_{j+1}} |y_j - \dot{\bar{x}}(t)|^2 dt - \varepsilon/2 \leq 0, \tag{5.14}$$

$$g_j(z) := x_{j+1} - x_j - h_k y_j = 0 \ \text{ for } j = 0, \dots, k-1, \tag{5.15}$$

$$z \in \Delta_j := \{(x_0, \dots, y_{k-1}) \in \mathbf{R}^{(2k+1)n} | y_j \in F_j(x_j)\} \ \text{ for } j = 0, \dots, k-1, \tag{5.16}$$

$$z \in \Delta_k := \{(x_0, \dots, y_{k-1}) \in \mathbf{R}^{(2k+1)n} | (x_0, x_k) \in \Omega_k\}. \tag{5.17}$$

It is easy to see that problem (5.12)–(5.17) as defined is equivalent to the discrete approximation problem (P_k) in (3.4), (3.15)–(3.18). On the other hand, (5.12)–(5.17) is a problem (MP) in (5.1)–(5.4) with $d = (2k+1)n$, $s = k+2$, $m = k-1$, $l = k$, and the specified functions ϕ_j, g_j and sets Δ_j. Now we employ Proposition 5.1 for the optimal solution $\bar{z} = \bar{z}^k := (\bar{x}_0^k, \dots, \bar{x}_k^k, (\bar{x}_1^k - \bar{x}_0^k)/h_k, \dots, (\bar{x}_k^k - \bar{x}_{k-1}^k)/h_k)$ of (5.12)–(5.17) where $\bar{x}^k = (\bar{x}_0^k, \dots, \bar{x}_k^k)$ is a given optimal solution of (P_k).

According to this result, one gets real numbers $(\mu_0, \dots, \mu_{k+2})$ as well as vectors $\psi_j \in \mathbf{R}^n$ $(j = 0, \dots, k-1)$ and $z_j^\star = (x_{0j}^\star, \dots, x_{kj}^\star, y_{0j}^\star, \dots, y_{k-1\,j}^\star) \in \mathbf{R}^{(2k+1)n}$ $(j = 0, \dots, k)$, not all zero, such that conditions (5.5)–(5.8) are fulfilled for the initial data in (5.12)–(5.17). Note that these μ_j, ψ_j, and $z_j^\star$ depend on k but we omit the index "k" for simplicity, considering k big enough.

First let us observe that thanks to Theorem 3.3, $\phi_j(\bar{z}^k) < 0$ as $j = 1, \ldots, k+2$ for all big k. This implies $\mu_j = 0$ for $j = 1, \ldots, k+2$ by virtue of the corresponding complementary slackness conditions in (5.7). Now denoting $\lambda^k := \mu_0 \geq 0$, we ensure that λ^k, $(\psi_0, \ldots, \psi_{k-1})$, and $(z_0^\star, \ldots, z_k^\star)$ are not equal to zero simultaneously for k big enough.

Further, it follows from the structure of the sets Δ_j in (5.16) and (5.17) that conditions (5.5) are equivalent to

$$(x_{jj}^\star, y_{jj}^\star) \in N((\bar{x}_j^k, (\bar{x}_{j+1}^k - \bar{x}_j^k)/h_k); \mathrm{gph} F_j) \text{ and } \tag{5.18}$$

$$x_{ij}^\star = y_{ij}^\star = 0 \text{ if } i \neq j \ \forall j = 0, \ldots, k-1;$$

$$(x_{0k}^\star, x_{kk}^\star) \in N((\bar{x}_0^k, \bar{x}_k^k); \Omega_k) \text{ and } x_{ik}^\star = y_{ik}^\star = 0 \text{ otherwise.} \tag{5.19}$$

Taking this into account and using calculus rule (4.8), we get from (5.7), (5.8), (5.12), and (5.15) the following relationships:

$$-x_{00}^\star - x_{0k}^\star = \lambda^k u_0 + 2\lambda^k(\bar{x}_0^k - \bar{x}(a)) + \lambda^k h_k \vartheta_0 - \psi_0, \tag{5.20}$$

$$-x_{jj}^\star = \lambda^k h_k \vartheta_j + \psi_{j-1} - \psi_j \text{ for } j = 1, \ldots, k-1, \tag{5.21}$$

$$-x_{kk}^\star = \lambda^k u_k + \psi_{k-1}, \tag{5.22}$$

$$-y_{jj}^\star = \lambda^k h_k w_j + \lambda^k \theta_j^k - h_k \psi_j \text{ for } j = 0, \ldots, k-1 \tag{5.23}$$

where θ_j^k is defined in (5.11),

$$(u_0, u_k) \in \partial\varphi(\bar{x}_0^k, \bar{x}_k^k), \tag{5.24}$$

and

$$(\vartheta_i, w_j) \in \partial f_j(\bar{x}_j^k, (\bar{x}_{j+1}^k - \bar{x}_j^k)/h_k) \text{ for } j = 0, \ldots, k-1. \tag{5.25}$$

Now denoting

$$p_0^k := x_{0k}^\star + \lambda^k u_0 + 2\lambda^k(\bar{x}_0^k - \bar{x}(a)) \text{ and } p_j := \psi_{j-1} \text{ for } j = 1, \ldots, k,$$

one can conclude that relationships (5.18)–(5.25) imply conditions (5.9) and (5.10) where λ^k and $(p_0^k, \ldots, p_k^k)$ are not equal to zero simultaneously. This ends the proof of the theorem. □

COROLLARY 5.3. *In addition to the assumptions of Theorem* 5.2, *let us suppose that for each* $j = 0, \ldots, k-1$, *the multifunction* F_j *is bounded and Lipschitz continuous around* $\bar{x}_j^k$. *The conditions* (5.9) *and* (5.10) *are fulfilled with* $(\lambda^k, p_k^k) \neq 0$, *i.e., one can set*

$$\lambda^k + |p_k^k| = 1 \ \forall k = 1, 2, \ldots. \tag{5.26}$$

Proof. If $\lambda^k = 0$, then (5.10) is represented as

$$(p_{j+1}^k - p_j^k)/h_k \in D^\star F_j((\bar{x}_j^k, (x_{j+1}^k - \bar{x}_j^k)/h_k)(-p_{j+1}^k) \text{ for } j = 0, \ldots, k-1 \tag{5.27}$$

in terms of the coderivative (4.11). By virtue of (5.27), $p_k^k = 0$ implies that $p_j^k = 0$ for all $j = 0, \ldots, k-1$, according to Proposition 4.5. This proves the corollary. □

6. Necessary conditions for the Bolza problem. Now we come back to the original Bolza problem (P) and prove necessary optimality conditions for an i.r.l.m. in the refined Euler–Lagrange form. To accomplish it, it remains to pass to the limit in the necessary conditions for discrete approximation problems (P_k) as $k \to \infty$ (§5), taking into account the $W^{1,2}$-convergence of discrete optimal solutions (§3) and some properties of the generalized differential constructions in §4.

Here we keep assumptions (H1)–(H3), but instead of the continuity hypotheses in (H4) and (H5) we assume the corresponding Lipschitz continuity. Namely:

(H4$'$) There exist numbers $\nu > 0$ and $l_f \geq 0$ such that $f(\cdot,\cdot,t)$ is locally Lipschitzian with modulus l_f around any point of the set $A_\nu(t)$ in (3.19).

(H5$'$) φ is Lipschitz continuous on $U \times U$ and Ω is closed around $(\bar{x}(a), \bar{x}(b))$.

In what follows, we denote by $\partial f = \partial f(\cdot,\cdot,t)$ the subdifferential (4.4) of the function $f(x,v,t)$ with respect to (x,v) under fixed t. Similarly, $N((\cdot,\cdot);\mathrm{gph}F(\cdot,t))$ means the normal cone (4.2) to the set $\mathrm{gph}F(\cdot,t)$ at a given point $(\cdot,\cdot)$ when t is fixed. Note that the normal cone to the graph of F is related to the generalized derivative (coderivative) of F according to (4.11).

One of the fundamental properties of the generalized differential constructions under consideration is their robustness (upper semicontinuity) with respect to variables of differentiation; see §4. This is of principal importance for the method of discrete approximations. In the limiting procedure below, we also need such a robustness of $\partial f(\cdot,\cdot,t)$ and $N((\cdot,\cdot);\mathrm{gph}F(\cdot,t))$ with respect to the parameter t. More precisely, we impose the following technical assumptions:

(H6) For a.e. $t \in [a,b]$ one has

$$\limsup_{\substack{(x',v')\to(\bar{x}(t),\dot{\bar{x}}(t))\\ t'\to t,\ t'<t}} \partial f(x,'v',t') = \partial f(\bar{x}(t),\dot{\bar{x}}(t),t).$$

(H7) For a.e. $t \in [a,b]$ one has

$$\limsup_{\substack{(x',v')\to(\bar{x}(t),\dot{\bar{x}}(t))\\ t'\to t,\ t'<t}} N((x',v');\mathrm{gph}F(\cdot,t')) = N((\bar{x}(t),\dot{\bar{x}}(t));\mathrm{gph}F(\cdot,t)).$$

Properties (H6) and (H7) are obviously fulfilled if f and F do not depend on t and also if $f = f_1(x,v) + f_2(t)$, $F = F_1(x) + F_2(t)$ with F_2 satisfying (H2). Actually, (H6) and (H7) mean that the continuity in t holds under the generalized differentiation of f and F with respect to the other variables. In particular, this takes place when f and F are represented as compositions of mappings separated in t and (x,v). Note also that for functions f smooth in (x,v), (H6) means the classical continuity of $\partial f/\partial x$ and $\partial f/\partial v$ at $(\bar{x}(t),\dot{\bar{x}}(t),t)$.

Now we prove the refined Euler–Lagrange conditions for the original Bolza problem (P).

THEOREM 6.1. *Let $\bar{x}(\cdot)$ be an i.r.l.m. for problem (P) under assumptions* (H1)–(H3), (H4$'$), (H5$'$), (H6), *and* (H7). *Then there exist a number $\lambda \geq 0$ and an absolutely continuous function $p : [a,b] \to \mathbf{R}^n$, not both zero, such that*

$$\dot{p}(t) \in \mathrm{co}\{u | (u,p(t)) \in \lambda\partial f(\bar{x}(t),\dot{\bar{x}}(t),t) + N((\bar{x}(t),\dot{\bar{x}}(t));\mathrm{gph}F(\cdot,t))\} \tag{6.1}$$

for a.e. $t \in [a,b]$ and

$$(p(a), -p(b)) \in \lambda\partial\varphi(\bar{x}(a),\bar{x}(b)) + N((\bar{x}(a),\bar{x}(b));\Omega). \tag{6.2}$$

Proof. Let us construct a sequence of discrete approximations (P_k) of problem (P), which approximates $\bar{x}(\cdot)$ in the sense of Theorem 3.3. Now employing Theorem 5.2 for optimal solutions $x^k = (x_0^k, \dots, x_k^k)$ to (P_k) as $k \to \infty$, we find sequences of numbers $\lambda^k \geq 0$ and vectors $p^k = (p_0^k, \dots, p_k^k)$ satisfying conditions (5.9), (5.10), and (5.26). One can always suppose that $\lambda^k \to \lambda \geq 0$ as $k \to \infty$.

In what follows we use the notation $\bar{x}^k(t)$ and $p^k(t)$ for piecewise linear extensions of the corresponding discrete functions on $[a,b]$ with their piecewise constant derivatives $\dot{\bar{x}}^k(t)$ and $\dot{p}^k(t)$. Let us consider a sequence of the functions

$$\theta^k(t) := \theta_j^k/h_k \text{ for } t \in [t_j, t_{j+1}), \ j = 0, \dots, k-1,$$

generated by (5.11). Theorem 3.3 implies that

$$\begin{aligned} \int_a^b |\theta^k(t)|dt &= \sum_{j=0}^{k-1} |\theta_j^k| \leq 2 \sum_{j=0}^{k-1} \int_{t_j}^{t_{j+1}} |\dot{\bar{x}}(t) - (\bar{x}_{j+1}^k - \bar{x}_j^k)/h_k|dt \\ &= 2 \int_a^b |\dot{\bar{x}}(t) - \dot{\bar{x}}^k(t)|dt := \nu_k \to 0 \text{ as } k \to \infty. \end{aligned} \tag{6.3}$$

Without loss of generality we can suppose that

$$\dot{\bar{x}}^k(t) \to \dot{\bar{x}}(t) \text{ and } \theta^k(t) \to 0 \text{ a.e. } t \in [a,b] \text{ as } k \to \infty. \tag{6.4}$$

Let us estimate the adjoint functions $p^k(\cdot)$ for big k. According to (5.10) and Definition 4.3 of the coderivative D^*F_j, there exist vectors $(\vartheta_j^k, w_j^k) \in \partial f_i(\bar{x}_j^k, (\bar{x}_{j+1}^k - \bar{x}_j^k)/h_k)$ such that

$$(p_{j+1}^k - p_j^k)/h_k - \lambda^k \vartheta_j^k \in D^*F_j(\bar{x}_j^k, (\bar{x}_{j+1}^k - \bar{x}_j^k)/h_k)(\lambda^k w_j^k + \lambda^k \theta_j^k/h_k - p_{j+1}^k) \tag{6.5}$$

for all $j = 0, \dots, k-1$. Now using (6.5), (3.2), and Proposition 4.5, one has

$$|(p_{j+1}^k - p_j^k)/h_k - \lambda^k \vartheta_j^k| \leq l_F |\lambda^k w_j^k + \lambda^k \theta_j^k/h_k - p_{j+1}^k| \text{ for } j = 0, \dots, k-1. \tag{6.6}$$

It follows from (H4′) and estimate (4.5) that

$$|\vartheta_j^k| \leq l_f \text{ and } |w_j^k| \leq l_f \text{ for } j = 0, \dots, k-1. \tag{6.7}$$

Using (5.26), (6.3), (6.6), and (6.7), we get

$$\begin{aligned} |p_j^k| &\leq (1 + h_k l_F)|p_{j+1}^k| + h_k l_f (1 + l_F) + l_F |\theta_j^k| \leq \cdots \\ &\leq \exp[l_F(b-a)] + l_f(b-a)(1+l_F) + l_F \nu_k \ \forall j = 0, \dots, k-1 \text{ as } k \to \infty. \end{aligned} \tag{6.8}$$

This means that the adjoint functions $p^k(t)$ are uniformly bounded in $[a,b]$. Employing (6.6) and (6.7) to estimate the derivatives $\dot{p}^k(t)$, one has

$$|\dot{p}^k(t)| = |(p_{j+1}^k - p_j^k)/h_k| \leq l_f + l_F(l_f + |\theta^k(t)| + |p_{j+1}^k|) \text{ for } t_j \leq t < t_{j+1}.$$

By virtue of (6.4) and (6.8) this implies that the sequence $\{\dot{p}^k(\cdot)\}$ is weakly compact in $L^1[a,b]$. Therefore, we can find an absolutely continuous function $p(\cdot)$ such that $p^k(\cdot) \to p(\cdot)$ uniformly in $[a,b]$ and $\dot{p}^k(\cdot) \to \dot{p}(\cdot)$ weakly in $L^1[a,b]$ for $k \to \infty$ (as usual we take all $k = 1, 2, \dots$).

Let us rewrite (5.10) as follows:

$$\begin{aligned}\dot{p}^k(t) \in \{u | (u, p^k(t_{j+1}) - \lambda^k \theta^k(t)) \in \lambda^k \partial f(\bar{x}^k(t_j), \dot{\bar{x}}^k(t), t_j) \\ + N((\bar{x}^k(t_j), \dot{\bar{x}}^k(t)); \mathrm{gph} F(\cdot, t_j))\} \text{ for } t \in [t_j, t_{j+1}),\ j = 0, \dots, k-1.\end{aligned} \tag{6.9}$$

According to the classical results, there is a sequence of convex combinations of $\dot{p}^k(t)$ that converges to $\dot{p}(t)$ for a.e. $t \in [a, b]$. Now passing to the limit in (6.9) as $k \to \infty$ and using (6.4) as well as hypotheses (H6) and (H7), we obtain the Euler–Lagrange inclusion (6.1).

Taking the limit in (5.26), one has the normalization condition

$$\lambda + |p(b)| = 1,$$

which implies that λ and $p(\cdot)$ are not equal to zero simultaneously. It follows from (6.8) that if $p(t_0) = 0$ at some point $t_0 \in [a, b]$, then $p(t) \equiv 0$ in $[a, b]$.

It remains to establish the transversality inclusion (6.2). First note that

$$\lambda^k \partial \varphi(\bar{x}_0^k, \bar{x}^k) \to \lambda \partial \varphi(\bar{x}(a), \bar{x}(b)) \text{ as } k \to \infty$$

due to robustness of the subdifferential (4.4). Then observe that the set Ω_k in (3.16) is represented as

$$\Omega_k = \{(x_0, x_k) \in \mathbf{R}^{2n} | \operatorname{dist}((x_0, x_k), \Omega) \le \eta_k\}. \tag{6.10}$$

Now passing to the limit in (5.9) as $k \to \infty$ and using (4.7), we obtain (6.2). This completes the proof of the theorem. □

Remark 6.2. The Euler–Lagrange inclusion (6.1) can be expressed in terms of the coderivative $D_x^* F$ of the multifunction $F(\cdot, t)$ under fixed t. Indeed, one has

$$\dot{p}(t) \in \mathrm{co}\left\{ \bigcup_{(\vartheta, w) \in \partial f(\bar{x}(t), \dot{\bar{x}}(t), t)} [\lambda \vartheta + D_x^* F(\bar{x}(t), \dot{\bar{x}}(t), t)(\lambda w - p(t))] \right\} \tag{6.11}$$

for a.e. $t \in [a, b]$, which is equavalent to (6.1) by virtue of (4.11). Inclusion (6.11) implies the following:

$$\dot{p}(t) \in \mathrm{co}[\lambda \partial_x f(\bar{x}(t), \dot{\bar{x}}(t), t) + D_x^* F(\bar{x}(t), \dot{\bar{x}}(t), t)(\lambda \partial_v f(\bar{x}(t), \dot{\bar{x}}(t), t) - p(t))]$$

in the case when $\partial f(\bar{x}(t), \dot{\bar{x}}(t), t) \subset \partial_x f(\bar{x}(t), \dot{\bar{x}}(t), t) \times \partial_v f(\bar{x}(t), \dot{\bar{x}}(t), t)$ for a.e. $t \in [a, b]$. In particular, it happens when either $f(x, v, t) = f_1(x, t) + f_2(v, t)$ or f possesses some regularity (e.g., f is smooth or convex in (x, v)).

Remark 6.3. Theorem 6.1 provides necessary optimality conditions for the Bolza problem (P) in the basic case where endpoint constraints are given in the abstract (geometric) form (1.3). Using calculus rules available for the nonconvex subdifferential constructions in §4, we can obtain refined transversality conditions for special representations of the set Ω in (1.3). In particular, for the case of inequality and equality type constraints

$$\varphi_i(x(a), x(b)) \le 0 \text{ if } i = 1, \dots, q, \tag{6.12}$$

$$\varphi_i(x(a), x(b)) = 0 \text{ if } i = q+1, \dots, q+r \tag{6.13}$$

defined by locally Lipschitz functions φ_i, one has

$$(6.14)\qquad (p(a),-p(b))\in\partial\left(\sum_{i=0}^{q+r}\lambda_i\varphi_i\right)(\bar{x}(a),\bar{x}(b)),$$

$$(6.15)\qquad \lambda_i\geq 0 \text{ for } i=0,1,\ldots,q,$$

$$(6.16)\qquad \lambda_i\varphi_i(\bar{x}(a),\bar{x}(b))=0 \text{ for } i=1,\ldots,q$$

where $\varphi_0:=\varphi$ and $(\lambda_0,\ldots,\lambda_{q+r},p(\cdot))\neq 0$; cf. [27]–[29]. Due to the subdifferential sum rule, the transversality inclusion (6.14) implies the following "separated" one:

$$(p(a),-p(b))\in\sum_{i=0}^{q}\lambda_i\partial\varphi_i(\bar{x}(a),\bar{x}(b))+\sum_{i=q+1}^{q+r}\lambda_i\partial^0\varphi_i(\bar{x}(a),\bar{x}(b))$$

where $\partial^0\varphi(\bar{x}):=\partial\varphi(\bar{x})\cup[-\partial(-\varphi)(\bar{x})]$ is a symmetric subdifferential construction. In the next section we prove unified transversality conditions in the presence of both functional and geometric constraints for the case of Lipschitz as well as non-Lipschitz functions φ_i.

Remark 6.4. Developing the discrete approximation approach, we can extend necessary optimality conditions in Theorem 6.1 to the case of "Bolza constraints"

$$\varphi_i(x(a),x(b))+\int_a^b f_i(x(t),\dot{x}(t),t)dt\leq 0 \text{ for } i=1,\ldots,q,$$

$$\varphi_i(x(a),x(b))+\int_a^b f_i(x(t),\dot{x}(t),t)dt=0 \text{ for } i=q+1,\ldots,q+r,$$

which unify endpoint constraints (6.12) and (6.13) with isoperimetric type constraints in variational problems. In this case, the set of necessary conditions consists of (6.14), (6.15) and

$$\lambda_i\left[\varphi_i(\bar{x}(a),\bar{x}(b))-\int_a^b f_i(\bar{x}(t),\dot{\bar{x}}(t),t)dt\right]=0 \text{ for } i=1,\ldots,q,$$

$$\dot{p}(t)\in\operatorname{co}\left\{u\,\middle|\,(u,p(t))\in\partial\left(\sum_{i=0}^{q+r}\lambda_i f_i\right)(\bar{x}(t),\dot{\bar{x}}(t),t)+N((\bar{x}(t),\dot{\bar{x}}(t));\operatorname{gph}F)\right\}$$

for a.e. $t\in[a,b]$ where $f_0:=f$ and $(\lambda_0,\ldots,\lambda_{q+r},p(\cdot))\neq 0$.

Remark 6.5. The approach and results obtained can be extended to the Bolza problem for nonconvex differential inclusions with *free time* where a varying time interval is involved in constraints and optimization. We refer the reader to [35] for more details and discussions.

The necessary optimality conditions in Theorem 6.1 are proved for any i.r.l.m. in the Bolza problem (P). In particular, they hold for any feasible solution to (P), which turns out to be a strong local minimum for the relaxed problem. As we pointed out in §2, an optimal solution of (P) automatically solves the relaxed problem as well in some common settings. Let us present such a corollary of Theorem 6.1, which is used in the next section to obtain the refined Euler–Lagrange conditions without any relaxation.

COROLLARY 6.6. *Let the arc $\bar{x}(\cdot)$ provide a strong local minimum for the Bolza problem* (1.1) *and* (1.3) *obtained by ignoring the differential inclusion* (1.2). *Suppose that for some number $\mu > 0$ and open set $U \subset \mathbf{R}^n$ one has*:

$$\bar{x}(t) \in U \;\; \forall t \in [a,b] \;\; \text{and} \;\; |\dot{\bar{x}}(t)| < \mu \;\; \text{a.e.} \;\; t \in [a,b]; \tag{6.17}$$

$f(x,v,\cdot)$ is bounded and continuous for a.e. $t \in [a,b]$ uniformly in $(x,v) \in U \times (\mu B)$; $f(\cdot,\cdot,t)$ is Lipschitz continuous on $U \times (\mu B)$ uniformly in $t \in [a,b]$; and (H5′), (H6) *hold. Then there exists an absolutely continuous function $p : [a,b] \longrightarrow \mathbf{R}^n$ such that one has* (6.2) *with $\lambda = 1$ and*

$$\dot{p}(t) \in \operatorname{co}\{u | (u,p(t)) \in \partial f(\bar{x}(t),\dot{\bar{x}}(t),t)\} \;\; \text{a.e.} \;\; t \in [a,b]. \tag{6.18}$$

Proof. The boundedness of $\dot{\bar{x}}(t)$ in (6.17) means that $\bar{x}(\cdot) \in W^{1,\infty}[a,b]$. According to Proposition 2.4, $\bar{x}(\cdot)$ is a strong minimum for the relaxed problem (1.3), (2.4). Let us consider the (trivial) differential inclusion

$$\dot{x} \in F(x,t) := \mu B \;\; \text{a.e.} \;\; t \in [a,b]. \tag{6.19}$$

It is obvious that $\bar{x}(\cdot)$ is an i.r.l.m. for problem (P) in (1.1), (1.3), and (6.19) where all the assumptions of Theorem 6.1 are fulfilled. Moreover, $(\bar{x}(t),\dot{\bar{x}}(t)) \in (\operatorname{int} \operatorname{gph} F)$ for a.e. $t \in [a,b]$. In this case, (6.1) is equivalent to (6.18). □

Remark 6.7. Using the modified discrete approximation of the Bolza functional in Remark 3.4 and developing the procedure in the proof of Theorem 6.1, one can extend the results obtained for the case of integrands f measurable in t.

7. The Euler–Lagrange inclusion without relaxation.

In the concluding section of the paper we consider the following Mayer problem (P_{M}) for differential inclusions:

$$\text{minimize} \;\; J[x] := \varphi_0(x(a),x(b))$$

over absolutely continuous trajectories of (1.2) under geometric, inequality, and equality type endpoint constraints (1.3), (6.12), and (6.13). Obviously, problem (P_{M}) is a special case of the Bolza problem (P) with $f = 0$. On the other hand, the Bolza problem can be reduced to the Mayer form involving *unbounded* differential inclusions; see, for example, [8], [24]. Here we consider problem (P_{M}) under the boundedness assumption which is used in our technique.

The main objective of this section is to prove the refined Euler–Lagrange conditions for the nonconvex Mayer problem (P_{M}) *without any relaxability assumption.* To accomplish it, we employ the results in the previous section (namely, Corollary 6.6) and an additional approximation procedure combining ideas in [7], [22], [28]. The latter procedure allows us to approximate the Mayer problem under consideration by a sequence of nonsmooth Bolza problems without differential inclusions and endpoint constraints. In this way, we prove the refined Euler–Lagrange conditions for any *strong* local minimum in (P_{M}) and also for any *boundary* trajectory of a nonconvex differential inclusion. Moreover, these conditions are justified for a *weak* local minimum in (P_{M}) under an additional Riemann integrability assumption that simplifies the technique employed.

Keeping here assumptions (H1), (H2), and (H6) on F around the given trajectory for (1.2), we relax the Lipschitz continuity of φ_i in (H5) and Remark 6.3. Namely, we assume the following.

($\overline{\mathrm{H}5}$) The functions φ_i are lower semicontinuous for $i = 0, \dots, q$ and continuous for $i = q+1, \dots, q+r$; the set Ω is closed around $(\bar{x}(a), \bar{x}(b))$.

Consider the closed set

$$\begin{aligned}(7.1)\qquad \mathcal{E}_\Omega := \{(x_0, x_1, \nu_0, \dots, \nu_{q+r}) \in \mathbf{R}^{2n+q+r+1} | (x_0, x_1) \in \Omega,\\ \varphi_i(x_0, x_1) \le \nu_i \ \text{ for } \ i = 0, \dots, q \ \text{ and}\\ \varphi_i(x_0, x_1) = \nu_i \ \text{ for } \ i = q+1, \dots, q+r\}\end{aligned}$$

and the *essential endpoint Lagrangian*

$$(7.2)\qquad L_\Omega(x_0, x_1, \lambda_0, \dots, \lambda_{q+r}) := \sum_{i=0}^{q+r} \lambda_i \varphi_i(x_0, x_1) + \delta((x_0, x_1), \Omega).$$

THEOREM 7.1. *Let $\bar{x}(\cdot)$ be a strong minimum for the Mayer problem (P_{M}) under assumptions* (H1), (H2), ($\overline{\mathrm{H}5}$), *and* (H7). *Then there exist a vector $y^\star := (\lambda_0, \dots, \lambda_{q+r}) \in \mathbf{R}^{q+r+1}$ and an absolutely continuous function $p : [a, b] \to \mathbf{R}^n$, not both zero, such that*

$$(7.3)\qquad \dot{p}(t) \in \operatorname{co} D_x^\star F(\bar{x}(t), \dot{\bar{x}}(t), t)(-p(t)) \ \text{ a.e. } \ t \in [a, b],$$

$$(7.4)\qquad (p(a), -p(b), -y^\star) \in N((\bar{x}(a), \bar{x}(b), \bar{c}); \mathcal{E}_\Omega)$$

where $\bar{c} := (\varphi_0(\bar{x}(a), \bar{x}(b)), 0 \dots, 0) \in \mathbf{R}^{q+r+1}$. Condition (7.4) *always implies* (6.15) *and* (6.16). *Moreover,* (7.4) *is equivalent to the simultaneous fulfilment of* (6.15), (6.16), *and*

$$(7.5)\qquad (p(a), -p(b)) \in \partial L_\Omega(\cdot, \lambda_0, \dots, \lambda_{q+r})(\bar{x}(a), \bar{x}(b))$$

if all φ_i are Lipschitz continuous around $(\bar{x}(a), \bar{x}(b))$.

Proof. Let $\bar{\gamma} := \varphi_0(\bar{x}(a), \bar{x}(b))$. According to the metric approximation method in Mordukhovich [26–28], we consider the parametric functional

$$(7.6)\ I_\gamma[x] := \operatorname{dist}((x(a), x(b), c), \mathcal{E}_\Omega) \ \text{ with } \ c := (\gamma, 0, \dots, 0) \in \mathbf{R}^{q+r+1}, \quad \gamma \in \mathbf{R},$$

on trajectories for the differential inclusion (1.2). Let $U \subset \mathbf{R}^n$ be a bounded neighborhood of the strong minimum $\bar{x}(\cdot)$ where assumptions (H1), (H2), and ($\overline{\mathrm{H}5}$) are fulfilled. For every $\varepsilon > 0$, one has

$$I_\gamma[\bar{x}] \le |\gamma - \bar{\gamma}| < \varepsilon$$

if γ is close to $\bar{\gamma}$. On the other hand,

$$I_\gamma[x] > 0 \ \text{ for any } \ \gamma < \bar{\gamma}$$

whenever the trajectory $x(\cdot)$ for (1.2) belongs to the neighborhood U of the strong minimum $\bar{x}(\cdot)$.

Following Clarke [7], let us consider the set X of all trajectories $x(\cdot)$ for (1.2) satisfying $x(t) \in \mathrm{cl}U$ in $[a,b]$ and define a metric in X as follows:

$$d(x,y) := |x(a) - y(a)| + \int_a^b |\dot{x}(t) - \dot{y}(t)|dt. \tag{7.7}$$

One can easily see that X is a complete metric space with metric (7.7) and functional (7.6) is continuous in X for any γ. According to the constructions above, for every $\varepsilon > 0$ we find $\gamma_\varepsilon < \bar{\gamma}$ such that $\gamma_\varepsilon \to \bar{\gamma}$ as $\varepsilon \to 0$, $I_\varepsilon[\bar{x}] < \varepsilon$, and

$$I_\varepsilon[x] > 0 \text{ for } I_\varepsilon := I_{\gamma_\varepsilon} \tag{7.8}$$

where $x(\cdot)$ is any trajectory for (1.2) with $x(t) \in U$ in $[a,b]$. Now one can apply the Ekeland variational principle [14] and claim the existence of $x_\varepsilon(\cdot) \in X$ such that

$$d(x_\varepsilon, \bar{x}) \leq \sqrt{\varepsilon} \text{ and} \tag{7.9}$$

$$I_\varepsilon[x] + \sqrt{\varepsilon} d(x, x_\varepsilon) \geq I_\varepsilon[x_\varepsilon] \;\; \forall x(\cdot) \in X.$$

Note that (7.9) implies $x_\varepsilon(t) \in U$ for ε small enough, so $I_\varepsilon[x_\varepsilon] > 0$ by virtue of (7.8).

Now for any positive numbers M, ε and the Lipschitz constant l_F in (3.2), we define the functional

$$J_\varepsilon^M[x] := I_\varepsilon[x] + \sqrt{\varepsilon} d(x, x_\varepsilon) + M(1 + l_F^2)^{1/2} \int_a^b \mathrm{dist}((x(t), \dot{x}(t)), \mathrm{gph}F(\cdot, t))dt \tag{7.10}$$

on the set of all arcs $x(\cdot)$ (not necessarily trajectories for (1.2)) satisfying $x(t) \in U$ in $[a,b]$. We omit the proof of the following lemma, which can be furnished by the arguments in Kaskosz and Lojasiewicz [22, Lemmas 1 and 2].

LEMMA 7.2. *There exists a number $M \geq 1$ such that for every $\varepsilon \in (0, 1/M)$ the arc $x_\varepsilon(\cdot)$ provides an unconditional strong local minimum for the functional* (7.10).

Let us continue the proof of Theorem 7.1. Setting $c_\varepsilon := (\gamma_\varepsilon, 0, \ldots, 0)$, we consider any element $(z_{0\varepsilon}, z_{1\varepsilon}, e_\varepsilon) \in \Pi((x_\varepsilon(a), x_\varepsilon(b), c_\varepsilon), \mathcal{E}_\Omega)$ from the Euclidean projector (4.1) of $(x_\varepsilon(a), x_\varepsilon(b), c_\varepsilon)$ on the set $\mathcal{E}_\Omega$. Using this projection and Lemma 7.2, one can conclude that $x_\varepsilon(\cdot)$ provides a strong local minimun for the unconstrained Bolza problem

$$\text{minimize } \varphi_\varepsilon(x(a), x(b)) + \int_a^b f_\varepsilon(x(t), \dot{x}(t), t)dt \tag{7.11}$$

with the endpoint function

$$\varphi_\varepsilon(x_0, x_1) := [|x_0 - z_{0\varepsilon}|^2 + |x_1 - z_{1\varepsilon}|^2 + |c_\varepsilon - e_\varepsilon|^2]^{1/2} + \sqrt{\varepsilon}|x_0 - x_\varepsilon(a)| \tag{7.12}$$

and the integrand

$$f_\varepsilon(x, v, t) := M(1 + l_F^2)^{1/2} \mathrm{dist}((x, v), \mathrm{gph}F(\cdot, t)) + \sqrt{\varepsilon}|v - \dot{x}_\varepsilon(t)|. \tag{7.13}$$

Now we employ Corollary 6.6 in the unconstrained Bolza problem (7.11)–(7.13) taking into account the modified discrete approximation in Remark 3.4 for the last (measurable) term in (7.13); cf. the proof of Theorem 6.1. One can easily check that the assumptions in Theorem 7.1 ensure the fulfilment of the assumptions in

Corollary 6.6 around the solution $x_\varepsilon(\cdot)$ and the first term in (7.12) is smooth around $(x_\varepsilon(a), x_\varepsilon(b))$ by virtue of (7.8).

For each $\varepsilon > 0$, using the result in Corollary 6.6 and also calculus formulas (4.7) and (4.8) for functions (7.12) and (7.13), we find an arc $p_\varepsilon(\cdot)$ such that

$$\dot{p}_\varepsilon(t) \in \mathrm{co}\{u|(u, p(t)) \in N((x_\varepsilon(t), \dot{x}_\varepsilon(t)); \mathrm{gph}F(\cdot, t)) + \sqrt{\varepsilon}(0, B)\} \tag{7.14}$$

for a.e. $t \in [a, b]$ and

$$p_\varepsilon(a) = (x_\varepsilon(a) - z_{0\varepsilon})/\alpha_\varepsilon + \sqrt{\varepsilon}, \quad -p_\varepsilon(b) = (x_\varepsilon(b) - z_{1\varepsilon})/\alpha_\varepsilon \tag{7.15}$$

where $\alpha_\varepsilon := [|x_\varepsilon(a) - z_{0\varepsilon}|^2 + |x_\varepsilon(b) - z_{1\varepsilon}|^2 + |c_\varepsilon - e_\varepsilon|^2]^{1/2} > 0$.

Denoting $y_\varepsilon^\star := (e_\varepsilon - c_\varepsilon)/\alpha\varepsilon$, one has

$$|p_\varepsilon(a)|^2 + |p_\varepsilon(b)|^2 + |y_\varepsilon^\star|^2 = 1 \tag{7.16}$$

and

$$(p_\varepsilon(a), -p_\varepsilon(b), -y_\varepsilon^\star) \in \mathrm{cone}[(x_\varepsilon(a), x_\varepsilon(b), c_\varepsilon) - \Pi((x_\varepsilon(a), x_\varepsilon(b), c_\varepsilon), \mathcal{E}_\Omega)]. \tag{7.17}$$

Now let us consider the limiting procedure in (7.14)–(7.17) as $\varepsilon \to 0$. By virtue of (7.7), relationship (7.9) means that $x_\varepsilon(\cdot) \to \bar{x}(\cdot)$ in $W^{1,\infty}[a, b]$ as $\varepsilon \to 0$. This implies that $x_\varepsilon(t) \to \bar{x}(t)$ uniformly in $[a, b]$ and $\dot{x}_\varepsilon(t) \to \dot{\bar{x}}(t)$ for a.e. $t \in [a, b]$.

Further, using (7.14), (7.16), (4.11), and Proposition 4.5, one can conclude (cf. the proof of Theorem 6.1) that there exist an arc $p(\cdot)$ and a vector $y^\star \in \mathbf{R}^{q+r+1}$, not both zero, such that $y_\varepsilon^\star$ converges to $y^\star$, $p_\varepsilon(t)$ converges to $p(t)$ uniformly in $[a, b]$, and a convex combination of $\dot{p}_\varepsilon(t)$ converges to $\dot{p}(t)$ for a.e. $t \in [a, b]$ as $\varepsilon \to 0$ along some subsequence.

Now passing to the limit in (7.14), (7.16), (7.17) and using Definitions 4.1 and 4.3 as well as robustness of the normal cone (4.2), one gets the main conclusions (7.3) and (7.4) of the theorem. Representing $y^\star = (\lambda_0, \ldots, \lambda_{q+r})$, we obtain (6.15) and (6.16) directly from Proposition 4.4(i) where

$$\mathrm{gph}F = \mathcal{E}_\Omega, \quad g = (\varphi_0, \ldots, \varphi_{q+r}), \quad \bar{x} = (\bar{x}(a), \bar{x}(b)), \quad \bar{y} = (0, \ldots, 0),$$

$$\Delta = \{(\mu_0, \ldots, \mu_{q+r})|\mu_i \leq 0 \text{ for } i = 0, \ldots, q \text{ and } \mu_i = 0 \text{ for } i = q+1, \ldots, q+r\}.$$

If all φ_i are locally Lipschitzian around $(\bar{x}(a), \bar{x}(b)$, then the equivalence of (7.4) to the simultaneous fulfilment of (6.15), (6.16), and (7.5) follows from Proposition 4.4(ii) where the scalarization function $s(\bar{x}, y^\star)$ is reduced to the essential endpoint Lagrangian (7.2) in the case under consideration. This ends the proof of the theorem. □

COROLLARY 7.3. *Let all φ_i be Lipschitz continuous around $(\bar{x}(a), \bar{x}(b))$ in the framework of Theorem 7.1. Then, in addition to (7.3), one has the transversality inclusion*

$$(p(a), -p(b)) \in \partial\left(\sum_{i=0}^{q+r} \lambda_i \varphi_i\right)(\bar{x}(a), \bar{x}(b)) + N((\bar{x}(a), \bar{x}(b)); \Omega) \tag{7.18}$$

where λ_i satisfies (6.15), (6.16) and $(\lambda_0, \ldots, \lambda_{q+r}, p(\cdot)) \neq 0$.

Proof. One can derive (7.18) directly from the sum rule (4.8) and representation (4.6). Note that (7.18) implies transversality conditions of the corresponding "separated" form in Remark 6.3. □

COROLLARY 7.4. *Let $\bar{x}(\cdot)$ be a weak local minimizer for problem (P_{M}). If, in addition to the assumptions of Theorem 7.1, $\dot{\bar{x}}(\cdot)$ is Riemann intregrable on $[a, b]$, then all the conclusions of the theorem hold true.*

Proof. By definition of the weak local minimum for (P_{M}), there exists $\varepsilon > 0$ such that $\bar{x}(\cdot)$ provides the strong (actually global) minimum for the auxiliary problem $(P_{\mathrm{M}}^{\varepsilon})$ of the same structure involving the differential inclusion

$$\dot{x} \in F_{\varepsilon}(x, t) := F(x, t) \cap G_{\varepsilon}(x, t) \tag{7.19}$$

where $G_{\varepsilon}(x, t) := \{v \in \mathbf{R}^n |$ such that $|v - \dot{\bar{x}}(t)| \leq \varepsilon\}$. Due to a.e. continuity of $\dot{\bar{x}}(\cdot)$ on $[a, b]$, the differential inclusion (7.19) satisfies all the assumptions in Theorem 7.1.

Now we can employ the necessary conditions of Theorem 7.1 in problem $(P_{\mathrm{M}}^{\varepsilon})$. Taking into account the structure of G_{ε} in (7.19) and using the intersection rule (4.9) for representing $D_x^{\star} F_{\varepsilon}$, we arrive at the required Euler–Lagrange inclusion (7.3) for the weak local minimizer $\bar{x}(\cdot)$ to the original Mayer problem (P_{M}). □

Remark 7.5. One can see that the Riemann integrability (a.e. continuity) assumption on $\dot{\bar{x}}(\cdot)$ in Corollary 7.4 is required to satisfy the Hausdorff continuity assumption (H2) on $F_{\varepsilon}(x, \cdot)$ for a.e. $t \in [a, b]$. This is essential in the proof of general results in Theorem 6.1 based on discrete approximations. However, for applications to the Mayer problem in the proof of Theorem 7.1, we need to use only the result of Corollary 6.6 that was obtained for the classical (but nonsmooth) Bolza problem without differential inclusions. The latter result could be extended to the case of integrands f measurable in t; see Remark 6.7. In this way, one can obtain the Euler–Lagrange conditions in Theorem 7.1 for Mayer problems involving differential inclusions with the *measurable* t-dependence corresponding to the measurability of the distance function integrands (7.13) in the approximation problems. Now using the procedure in Corollary 7.4, we could justify the refined Euler–Lagrange inclusion (7.3) for *any* (Lipschitz continuous) *weak minimizer* to the nonconvex Mayer problem (P_{M}) under consideration.

Remark 7.6. If F is convex-valued, then the Euler–Lagrange inclusion (7.3) automatically implies the Weierstrass–Pontryagin maximum condition

$$\langle p(t), \dot{\bar{x}}(t)\rangle = \max\{\langle p(t), v\rangle |\; v \in F(\bar{x}(t), t)\} \text{ a.e. } t \in [a, b] \tag{7.20}$$

due to Proposition 4.7. It is no longer true in the nonconvex setting for arbitrary weak or intermediate local minimizers. But we believe that for the case of *strong minimum*, the refined Euler–Lagrange conditions in Theorem 7.1 are fulfilled simultaneously with the maximum condition (7.20) for nonconvex differential inclusions. This statement can be obtained directly from the proof of Theorem 7.1 if one establishes the classical Weierstrass necessary condition for the strong local minimum to the simplest variational problem like (7.11)–(7.13) with no smoothness and/or convexity assumptions.

Now let us consider an analogue of the results obtained for the case of *boundary trajectories*. Given a nonempty closed set $A \subset \mathbf{R}^n$, we denote by $R(A)$ the *reachable set* for (1.2) from A, i.e., the set of all points $x(b)$ where $x(\cdot)$ is a trajectory for (1.2) with $x(a) \in A$.

THEOREM 7.7. *Let $\bar{x}(\cdot)$ be a trajectory for* (1.2) *with $\bar{x}(a) \in A$, and let assumptions* (H1), (H2), (H7) *hold. If $g : \mathbf{R}^n \to \mathbf{R}^m$ is a locally Lipschitzian function* *around $\bar{x}(b)$ and if $g(\bar{x}(b))$ is a boundary point of the set $R(A)$, then there exist an arc $p : [a,b] \to \mathbf{R}^n$ and a unit vector $\psi \in \mathbf{R}^m$ such that $p(\cdot)$ satisfies the refined Euler–Lagrange inclusion* (7.3) *with the following boundary* (*transversality*) *conditions:*

$$p(a) \in N(\bar{x}(a); A), \quad -p(b) \in \partial\langle \psi, g\rangle(\bar{x}(b)). \tag{7.21}$$

Remark 7.8. The result formulated generalizes the recent one in Kaskosz and Lojasiewicz [22] where (7.3) is replaced by Clarke's form of the Euler–Lagrange inclusion (see (1.4) in the case where $f = 0$) and conditions (7.21) are replaced by

$$p(a) \in N_C(\bar{x}(a); A), \quad p(b) \in [J_C g(\bar{x}(b))]^* \psi$$

in terms of Clarke's normal cone and generalized Jacobian; cf. (4.3) and (4.14).

Proof of Theorem 7.7. Following the arguments in [22], for every $\varepsilon > 0$ we can find a vector $c_\varepsilon \in \mathbf{R}^m$ and a trajectory $x_\varepsilon(\cdot)$ of (1.2) with $x_\varepsilon(a) \in A$ such that $|g(x_\varepsilon(b)) - c_\varepsilon| > 0$,

$$c_\varepsilon \to g(\bar{x}(b)), \quad x_\varepsilon(\cdot) \to \bar{x}(\cdot) \ \text{ in } \ W^{1,\infty}[a,b] \ \text{ as } \ \varepsilon \to 0,$$

and $x_\varepsilon(\cdot)$ is an unconditional strong local minimizer for problem (7.11) with integrand (7.13) and the endpoint functional

$$\varphi_\varepsilon(x_0, x_1) := |g(x_1) - c_\varepsilon| + \sqrt{\varepsilon}|x_0 - x_\varepsilon(a)| + M\text{dist}(x_0, A). \tag{7.22}$$

Now employing Corollary 6.6 in problem (7.11), (7.13), (7.22) and using calculus rules (4.7), (4.8), and (4.10) to compute the subdifferential of (7.22), one gets an arc $p_\varepsilon(\cdot)$ and a unit vector $\psi_\varepsilon \in \mathbf{R}^m$ such that (7.14) holds and

$$p_\varepsilon(a) \in \sqrt{\varepsilon}B + N(x_\varepsilon(a); A), \quad -p_\varepsilon(b) \in \partial\langle \psi_\varepsilon, g\rangle(x_\varepsilon(b)). \tag{7.23}$$

Following the proof of Theorem 7.1, we obtain conditions (7.3) and (7.21) by passing to the limit in (7.14) and (7.23) as $\varepsilon \to 0$. □

Remark 7.9. Using the method of metric approximations (as in the proof of Theorem 7.1), one can extend Theorem 7.7 to a more general setting when $g(\bar{x}(b))$ is a *locally extremal point* of the set $R(A)$ relative to other given sets. We refer to [28, §6] and [33, §3] for more details about this concept.

Remark 7.10. Following the proof of Theorem 7.7, we can obtain, in addition to (7.3) and (7.21), the maximum condition (7.20) for boundary trajectories of nonconvex differential inclusions if one has the Weirestrass necessary condition for the strong mimimum to the simplest variational problem (7.11) with nonsmoothness (7.13) and (7.22).

Acknowledgments. The author is indebted to Asen Dontchev, Alexander Ioffe, Richard Vinter, and two anonymous referees for their helpful remarks.

SINGULAR OPTIMAL STOCHASTIC CONTROLS I: EXISTENCE*

ULRICH G. HAUSSMANN[†] AND WULIN SUO[‡]

Abstract. We apply the compactification method to study the control problem where the state is governed by an Ito stochastic differential equation allowing both classical and singular control. The problem is reformulated as a martingale problem on an appropriate canonical space after the relaxed form of the classical control is introduced. Under some mild continuity hypotheses on the data, it is shown by purely probabilistic arguments that an optimal control for the problem exists. The value function is shown to be Borel measurable.

Key words. singular controls, relaxed controls, control rules, existence theory, pseudopath topology, compactification method, value function

AMS subject classifications. 49J30, 49A55, 60G44, 93E20

1. Introduction.

The class of singular stochastic control problems, which has been studied extensively in recent years, deals with systems described by a stochastic differential equation in which one restricts the cumulative displacement of the state caused by control to be of an additive nature. More precisely, in this paper we study the existence of optimal controls to the problem in which the state evolves according to the d-dimensional stochastic differential equation

$$x_t = x + \int_s^t b(\theta, x_\theta, u_\theta)d\theta + \int_s^t \sigma(\theta, x_\theta, u_\theta)dB_\theta + \int_s^t g(\theta)dv_\theta$$

on some filtered probability space $(\Omega, \mathcal{F}, \mathcal{F}_t, P)$, where $b(\cdot,\cdot,\cdot)$, $\sigma(\cdot,\cdot,\cdot)$, $g(\cdot)$ are given deterministic functions, $(B_t,\ t \geq 0)$ is a d-dimensional Brownian motion (in fact B need not be d-dimensional), x is the initial state at time s, and $u:\ [0,T] \mapsto U$, $v:\ [0,T] \mapsto I\!R^k$ with v nondecreasing componentwise, stand for the controls.

The expected cost has the form

$$J(\alpha) \equiv E^P \left\{ \int_s^T f(t, x_t, u_t)dt + \int_{[s,T)} c(t) \cdot dv_t \right\},$$

where $f(\cdot,\cdot,\cdot):\ [0,T] \times I\!R^d \times U \mapsto I\!R$, $c(\cdot):\ [0,T] \mapsto I\!R^k_+$ are given. We assume that the cost of applying the singular control is positive, i.e., $c^i(\cdot) > 0$, $i = 1, \ldots, k$.

Some special cases of the one-dimensional problem of this type (without the *classical control* u) have been studied by many authors including Beněs, Shepp, and Witsenhausen [2]; Chow, Menaldi, and Robin [6]; El Karoui and Karatzas [8]; Harrison and Taksar [11]; Karatzas [19], [20]; Karatzas and Shreve [21]; Lehoczky and Shreve [23]; Ma [24]; Menaldi and Robin [25], [26]; and Sun [32]. It is shown that the value function satisfies a variational inequality which gives rise to a free-boundary problem, and the optimal state process is a diffusion reflected at the free boundary. This approach encounters substantial difficulties for the problems in high dimension

due to the lack of information about the regularity of the associated free boundary. In Soner and Shreve [30], a special two-dimensional problem ($b = 0$, $\sigma = I$) was considered. It was shown there that the associated free boundary is smooth enough to construct a reflected diffusion in the continuation region. However, as the authors pointed out, the method depends heavily on the special features of the problem and cannot be extended to general problems. Another result about high-dimensional problems can be found in Menaldi and Taksar [27], who considered the n-dimensional case with $b =$ const, $\sigma =$ const. It was shown that the value function satisfies the associated Hamilton–Jacobi–Bellman equation, and the existence of the optimal control was proved without requiring any regularity about the free boundary.

In this paper, we apply the compactification method used in Haussmann [12], Haussmann and Lepeltier [13], and El Karoui, Nguyen, and Jeanblanc-Picqué [7] to show the existence of the optimal control. An advantage of this approach is that it does not require any regularity of the value function and thus needs only very mild hypothesis on the data. Unfortunately, it does not show any particular structure of the optimal control.

This paper is organized as follows: In §2 the concept of relaxed control (for the classical control u) is introduced and the problem is reformulated as a martingale problem on a canonical space. In §2.3 a topology is given to the canonical space to make it a metrizable separable space, which is necessary to apply Prohorov's theorem. A relative compactness criterion for the subsets of the canonical space is given. In §3 it is proved that the optimal control exists, and the value function is shown to be Borel measurable. We also make some comments about possible generalizations of the model and constraints on the state in §4.

This paper is one of a series that applies the direct method to study the singular control problems. In [14] we prove the abstract form of the dynamic programming principle under the same conditions on the data assumed in this paper. When assuming Lipschitz continuity of the data, it is shown that the value function is continuous and is the unique viscosity solution of the corresponding Hamilton–Jacobi–Bellman equation. This method can also be used to show (cf. [33]) that there is a region A such that the optimal control yields no jump when the state is in A, and there exists an optimal control to keep the state in the closure of A after a possible initial jump. In [15] the adaptedness of the optimal control to the state is considered.

Note that in the literature *singular control* usually means that there is no classical control u involved. But our model obviously includes this case by letting U be a singleton (or by letting σ, b, f be independent of u). It also includes the monotone follower as well as the bounded variation problem (cf. §4).

Finally, we list some notation that will be used throughout this paper:

- $I\!R^d, I\!R$ denote the d-dimensional Euclidean space and the real line, respectively. $I\!R_+ = \{x \in I\!R, x \geq 0\}$, and $I\!R^d_+$ is defined similarly. For $x = (x^i), y = (y^i) \in I\!R^d$, $x \cdot y = \sum_{i=1}^d x^i y^i$.
- $T > 0$ is the fixed horizon, and $\Sigma = [0,T] \times I\!R^d$.
- $C[0,T]$ denotes the collection of real-valued continuous functions defined on $[0,T]$, and $C^d[0,T]$ denotes the collection of $I\!R^d$-valued continuous functions defined on $[0,T]$.
- $\mathcal{D}^d[0,T]$ denotes the collection of $I\!R^d$-valued functions defined on $[0,T]$ that are left continuous and have right limits (i.e., *lcrl* functions).
- $\mathcal{A}^k[0,T]$ denotes the collection of functions $a : [0,T] \mapsto I\!R^k$ such that $a = (a^i) \in \mathcal{D}^k[0,T]$ and a^i is nondecreasing with $a^i(0) = 0$, $i = 1, \ldots, k$.

- $\mathcal{S}^{l\times k}$ is the space of $l\times k$ matrices with the $l\times k$-dimensional Euclidean norm.
- If Y is a metric space, $\mathcal{B}(Y)$ denotes the corresponding Borel σ-field, and $f\in\mathcal{B}(Y)$ means that f is a $\mathcal{B}(Y)$-measurable real-valued function. We denote by $I\!M_+(Y)$, $I\!M_1(Y)$ the space of nonnegative Radon measures and the space of probabilities on Y, respectively.
- If X is a random variable on a probability space $(\Omega,\mathcal{F},P)$, the expectation of X will be denoted by $E^P(X)$. $\mathcal{M}_2^c$ ($\mathcal{M}_2^{c,\mathrm{loc}}$) is the family of continuous square integrable martingales (local martingales, respectively) on some given probability space $(\Omega,\mathcal{F},P)$ with a filtration $\{\mathcal{F}_t\}$.

2. Formulation of the problem. We consider the following optimal control problem in which we allow both classical control and singular control to act at the same time. The dynamics are in the form

$$x_t=x+\int_s^t b(\theta,x_\theta,u_\theta)d\theta+\int_s^t\sigma(\theta,x_\theta,u_\theta)dB_\theta+\int_s^t g(\theta)dv_\theta \quad \text{a.s.} \tag{2.1}$$

for $(s,x)\in\Sigma$, $s\le t\le T$, where

- $u_\theta\in U$, $s\le\theta\le T$, and U, called the control set, is a compact metric space;
- $(\sigma,b):\Sigma\times U\mapsto\mathcal{S}^{d\times d}\times I\!R^d$, $g:\ [0,T]\mapsto\mathcal{S}^{d\times k}$; $\sigma(t,x,u)$, $b(t,x,u)$ are bounded, measurable, and continuous with respect to (x,u); $g(t)$ is continuous on $[0,T]$;
- $(B_t, 0\le t\le T)$ is a d-dimensional Brownian motion on some probability space;
- $v\in\mathcal{A}^k[0,T]$.

We introduce the concept of controls to the stochastic differential equation (2.1).

DEFINITION 2.1. *A control is a term* $\alpha=(\Omega,\mathcal{F},\mathcal{F}_t,P,B_t,x_t,u_t,v_t,s,x)$ *such that*

(1) $(s,x)\in\Sigma$;
(2) $(\Omega,\mathcal{F},P)$ *is a probability space with the filtration* $\{\mathcal{F}_t\}_{t\ge0}$;
(3) u_t *is a* U*-valued process, progressively measurable with respect to* $\{\mathcal{F}_t\}_{t\ge0}$;
(4) v *is* $I\!R_+^k$*-valued processes, progressively measurable with respect to* $\mathcal{F}_t$; *the sample paths of* v *are in* $\mathcal{A}^k[0,T]$, *i.e., for each* $\omega\in\Omega$, $v_\cdot(\omega)\in\mathcal{A}^k[0,T]$;
(5) B_t *is a standard d-dimensional Brownian motion on* $(\Omega,\mathcal{F},\mathcal{F}_t,P)$ *and* x_t, *the state process, is* $\mathcal{F}_t$*-adapted with sample paths in* $\mathcal{D}^d[0,T]$, *and such that* (2.1) *is satisfied. We assume that* $x_r=x$ *for* $0\le r\le s$.

We call (s,x) *the initial condition of the control* α.

The collection of controls with initial condition (s,x) is denoted by $\Lambda_{s,x}$. It is well known from the theory of stochastic differential equations that, under the above conditions, the set $\Lambda_{s,x}$ is nonempty for each fixed (s,x) (e.g., take u and v to be constants). The *cost* corresponding to the control α is defined in the form

$$J(\alpha)\equiv E^P\left\{\int_s^T f(t,x_t,u_t)dt+\int_{[s,T)}c(t)\cdot dv_t\right\}, \tag{2.2}$$

where

- $f:\Sigma\times U\mapsto I\!R$ is a measurable function and is lower semicontinuous in (x,u), satisfying

$$-K\le f(t,x,u)\le C(1+\|x\|^m),\quad (t,x,u)\in\Sigma\times U$$

for some constants $m\ge0$, $K\ge0$, and $C\ge0$;

- $c = (c^i) : [0,T] \mapsto I\!R^k$ is lower semicontinuous and $c^i > 0$, $1 \le i \le k$.

Throughout this paper, we write

$$\int_s^t k(\theta) \cdot da(\theta) = \sum_{i=1}^d \int_{[s,t)} k_i(\theta) da_i(\theta)$$

for any $I\!R^k$-valued Borel measurable functions $k = (k_i)$ and $a = (a_i) \in \mathcal{A}^k[0,T]$. For $v \in \mathcal{A}^k[0,T]$, define

$$G_t(v) = \int_{[s,t)} g(\theta) dv(\theta), \quad s < t \le T, \tag{2.3}$$

and $G_t(v) = 0$ if $0 \le t \le s$. It can be verified easily that $G_.(v) \in \mathcal{D}^d[0,T]$.

The value function of the problem is defined, for $(s,x) \in \Sigma$, as

$$W(s,x) = \inf_{\alpha \in \Lambda_{s,x}} J(\alpha). \tag{2.4}$$

A control $\alpha^* \in \Lambda_{s,x}$ is called an *optimal control* if $W(s,x) = J(\alpha^*)$.

Remark 2.2. Note that there is no terminal cost in our model. Because of the way we choose the topology on the canonical space, this method cannot treat the case with terminal cost. We will return to this point at the end of the paper.

2.1. Relaxed controls. In order to apply the compactification method, we now reformulate the problem. Since the Brownian motion in the definition of controls is unknown in advance, we can reformulate the above control problem as an equivalent martingale problem. This simplifies taking limits. In fact, let

$$\mathcal{L} \equiv \frac{1}{2} \sum_{i,j} a_{ij} \frac{\partial^2}{\partial x_i \partial x_j} + \sum_i b_i \frac{\partial}{\partial x_i},$$

where $a(t,x,u) = \sigma(t,x,u)\sigma(t,x,u)^*$. Then we can show that $\alpha \in \Lambda_{s,x}$ if and only if α satisfies (1)–(4) in Definition 2.1, and

(5′) x_t is an $\mathcal{F}_t$-adapted process with sample paths in $\mathcal{D}^d[0,T]$ such that

- $P(x_r = x,\ u_r = u^0,\ v_r = 0,\ 0 \le r \le s) = 1$, where $u^0 \in U$ is arbitrary but fixed,
- $\forall \phi \in C_b^2(I\!R^d)$, $\mathcal{M}\phi \in \mathcal{M}_2^c$, i.e., $M_t\phi$ $(0 \le t \le T)$ is a continuous square integrable martingale on the filtered probability space $(\Omega, \mathcal{F}, \mathcal{F}_t, P)$, where

$$\begin{aligned} M_t\phi(\omega) \equiv \phi(x_t) - \int_s^t \mathcal{L}\phi(\theta, x_\theta, u_\theta) d\theta - \int_s^t \nabla_x \phi(x_\theta) \cdot g(\theta) dv_\theta \\ - \sum_{s \le \theta < t} \left[\phi(x_{\theta+}) - \phi(x_\theta) - \nabla_x \phi(x_\theta) \cdot \triangle x_\theta \right]. \end{aligned}$$

Therefore, we can delete the term B_t from the notation of a control. The proof of the equivalence of the existence of weak solutions to a stochastic differential equation and the existence of solutions to the corresponding martingale problem, given by Ikeda and Watanabe in Proposition IV-2.1 of [16], also works here despite the extra term $G_.(v)$.

Next we introduce the concept of relaxed controls, which gives a more suitable topological structure when applying the compactification method. In a relaxed control problem, the U-valued process $\{u_t\}$ is replaced by an $\mathbb{M}_1(U)$-valued process $\{\mu_t\}$, where $\mathbb{M}_1(U)$ is the space of probability measures on U endowed with the topology of weak convergence. $\mathbb{M}_1(U)$ is also a compact metrizable space. If $\phi : U \mapsto \mathbb{R}$ is a bounded measurable function, then we extend ϕ to $\mathbb{M}_1(U)$ by letting

$$\phi(\mu) \equiv \int_U \phi(u)\mu(du).$$

DEFINITION 2.3. *$\alpha = (\Omega, \mathcal{F}, \mathcal{F}_t, P, x_t, \mu_t, v_t, s, x)$ is called a relaxed control if it satisfies conditions* (1), (2), *and* (4) *in Definition* 2.1, *and*

(3′) *μ_t is $\mathbb{M}_1(U)$-valued, progressively measurable with respect to $\{\mathcal{F}_t\}_{t\geq 0}$;*

(5″) *x_t is an $\mathcal{F}_t$-adapted process with sample paths in $\mathcal{D}^d[0,T]$ such that*

- *$P(x_r = x,\ \mu_r = \delta^0,\ v_r = 0,\ 0 \leq r \leq s) = 1$, where δ^0 is the Dirac measure at some arbitrary but fixed $u^0 \in U$;*
- *$\forall \phi \in C_b^2(\mathbb{R}^d)$, $\mathcal{M}\phi \in \mathcal{M}_2^c$, i.e., $M_t\phi$ $(0 \leq t \leq T)$ is a continuous square integrable martingale on the filtered probability space $(\Omega, \mathcal{F}, \mathcal{F}_t, P)$, where*

$$M_t\phi(\omega) \equiv \phi(x_t) - \int_s^t \mathcal{L}\phi(\theta, x_\theta, \mu_\theta)d\theta - \int_s^t \nabla_x\phi(x_\theta)\cdot g(\theta)dv_\theta$$
$$- \sum_{s\leq\theta<t} \left[\phi(x_{\theta+}) - \phi(x_\theta) - \nabla_x\phi(x_\theta)\cdot\triangle x_\theta\right].$$

Note that we never work with $\sigma(t,x,u)$. Instead, we will be working on $a(t,x,u)$ through the martingale formulation in Definition 2.3. It is not true in general that $\sigma(t,x,\mu)\sigma(t,x,\mu)^* = a(t,x,\mu)$ (cf. El Karoui, Nguyen, and Jeanblanc-Picqué [7]).

The collection of relaxed controls starting from time s with the initial state x is denoted by $\tilde{\Lambda}_{s,x}$. Note that $\Lambda_{s,x}$ can be imbedded into $\tilde{\Lambda}_{s,x}$ by letting $\mu_t(du) \equiv \delta_{u_t}(du)$. Here, δ_u denotes the Dirac measure at the point u. Hence, $\forall\alpha \in \Lambda_{s,x}$, there exists an $\tilde{\alpha} \in \tilde{\Lambda}_{s,x}$ such that

$$J(\tilde{\alpha}) = J(\alpha),$$

and, therefore,

$$\inf_{\tilde{\alpha}\in\tilde{\Lambda}_{s,x}} J(\tilde{\alpha}) \leq \inf_{\alpha\in\Lambda_{s,x}} J(\alpha).$$

In order to get the reverse inequality, we define for each $(t,x) \in \Sigma$ a subset of $\mathcal{S}^{d\times d} \times \mathbb{R}^d \times \mathbb{R}$:

$$K(t,x) \equiv \{(a(t,x,u), b(t,x,u), z) :\ z \geq f(t,x,u), u \in U\}. \tag{2.5}$$

PROPOSITION 2.4. *Assume that $K(t,x)$ is convex $\forall(t,x) \in \Sigma$. Then $\forall\tilde{\alpha} \in \tilde{\Lambda}_{s,x}$, there exists an $\alpha \in \Lambda_{s,x}$ such that*

$$J(\alpha) \leq J(\tilde{\alpha}).$$

The proof in Haussmann and Lepeltier [13, Thm. 3.6.], can be carried over here without any change. From this result we know that when $K(t,x)$ is convex,

$$\inf_{\tilde{\alpha}\in\tilde{\Lambda}_{s,x}} J(\tilde{\alpha}) = \inf_{\alpha\in\Lambda_{s,x}} J(\alpha).$$

Hence we can restrict our attention to the case of relaxed controls. Moreover, if the infimum over relaxed controls is attained, then so is the infimum over ordinary controls.

If the convexity condition fails, our existence results pertain only to relaxed controls.

2.2. Control rules. Now we choose a canonical space to simplify the arguments in the compactification method. Define

$$\mathcal{U} \equiv \{\mu : \ [0,T] \mapsto I\!\!M_1(U) \text{ is Borel measurable}\}.$$

Consider the canonical space

$$\mathcal{X} \equiv \mathcal{D}^d[0,T] \times \mathcal{U} \times \mathcal{A}^k[0,T].$$

All the above spaces are equipped with appropriate topologies, which we will discuss later. Let $\tilde{\mathcal{D}}$, $\tilde{\mathcal{U}}$, $\tilde{\mathcal{A}}$ denote their Borel σ-fields, and $\tilde{\mathcal{D}}_t$, $\tilde{\mathcal{U}}_t$, $\tilde{\mathcal{A}}_t$ denote the σ-fields up to time t, e.g.,

$$\tilde{\mathcal{A}}_t = \sigma\{v(\theta) : \ 0 \leq \theta \leq t\}, \ \ 0 \leq t \leq T.$$

Let

$$\tilde{\mathcal{X}} \equiv \tilde{\mathcal{D}} \times \tilde{\mathcal{U}} \times \tilde{\mathcal{A}},$$
$$\tilde{\mathcal{X}}_t \equiv \tilde{\mathcal{D}}_t \times \tilde{\mathcal{U}}_t \times \tilde{\mathcal{A}}_t.$$

DEFINITION 2.5. *A control rule is a probability R on the measurable space $(\mathcal{X}, \tilde{\mathcal{X}})$ such that*

$$\tilde{\alpha} = (\mathcal{X}, \tilde{\mathcal{X}}, \tilde{\mathcal{X}}_t, R, x_t, \mu_t, v_t, s, x)$$

is a relaxed control, where

$$x_t(\omega) = x_t, \ \mu_t(\omega) = \mu_t, \ v_t = v_t(\omega)$$

for $\omega = (x_\cdot, \mu_\cdot, v_\cdot) \in \mathcal{X}$, i.e.,

(1) *$(\mathcal{X}, \tilde{\mathcal{X}}, R)$ is a probability space with the filtration $\{\tilde{\mathcal{X}}_t\}$, $(s,x) \in \Sigma$, and*

$$R(x_r = x, \ \mu_r = \delta^0, \ v_r = 0, \ 0 \leq r \leq s) = 1;$$

(2) *$\forall \phi \in C_b^2(I\!\!R^d)$, $M_t\phi$ $(s \leq t \leq T)$ is in $\mathcal{M}_2^c$ on the filtered probability space $(\mathcal{X}, \tilde{\mathcal{X}}, \tilde{\mathcal{X}}_t, R)$ $(s \leq t \leq T)$, where*

$$M_t\phi(\omega) \equiv \phi(x_t) - \int_s^t \mathcal{L}\phi(\theta, x_\theta, \mu_\theta) d\theta - \int_s^t \nabla_x \phi(x_\theta) \cdot g(\theta) dv_\theta$$
$$- \sum_{s \leq \theta < t} \left[\phi(x_{\theta+}) - \phi(x_\theta) - \nabla_x \phi(x_\theta) \cdot \triangle x_\theta\right].$$

Let $J(s,R) \equiv J(\tilde{\alpha})$.

We denote by $\mathcal{R}_{s,x}$ the space of control rules such that the above relaxed control starts from time s with initial state x. We will suppress s in $J(s,R)$ when it is clear that $R \in \mathcal{R}_{s,x}$. Now the control problem can be described completely in terms of control rules.

PROPOSITION 2.6. *Let $\alpha = (\Omega, \mathcal{F}, \mathcal{F}_t, P, x_t, \mu_t, v_t, s, x)$ be a relaxed control*; *then there exists a control rule $R \in \mathcal{R}_{s,x}$ such that*

$$J(R) = J(\alpha).$$

Proof. The proof of this result is standard. Define a map $\Phi : \Omega \mapsto \mathcal{X}$ by

$$\Phi(\omega) \equiv (x.(\omega), \mu.(\omega), v.(\omega)).$$

This map is measurable, and $\mathcal{F}_t^{x,\mu,v} \subset \Phi^{-1}(\tilde{\mathcal{X}}_t) \subset \mathcal{F}_t$. We can show that

$$\tilde{\alpha} = (\Omega, \mathcal{F}, \Phi^{-1}(\tilde{\mathcal{X}}_t), P, x_t, \mu_t, v_t, s, x)$$

is also a relaxed control such that

$$J(\tilde{\alpha}) = J(\alpha).$$

Let $R = P \circ \Phi^{-1}$, which is a probability on $(\mathcal{X}, \tilde{\mathcal{X}})$. It is easily seen that

$$(\mathcal{X}, \tilde{\mathcal{X}}, \tilde{\mathcal{X}}_t, R, x_t, \mu_t, v_t, s, x)$$

is a relaxed control satisfying the requirements in the Proposition. □

2.3. The topology on the canonical space. In this section we define the topologies on the spaces $\mathcal{D}^d[0,T]$, $\mathcal{U}$, and $\mathcal{A}^k[0,T]$.

The space $\mathcal{D}^d[0,T]$. We first give a topology on $\mathcal{D}^d[0,\infty)$, the collection of *lcrl* functions on $\mathbb{R}_+$ taking values in $\mathbb{R}^d$. Then we can take $\mathcal{D}^d[0,T]$ as a subset of $\mathcal{D}^d[0,\infty)$ by extending each $x \in \mathcal{D}^d[0,T]$ to an $x' \in \mathcal{D}^d[0,\infty)$ through

$$x'(t) = \begin{cases} x(t), & 0 \le t < T, \\ x(T), & t \ge T, \end{cases}$$

and consider the induced topology on $\mathcal{D}^d[0,T]$.

Define a measure $\lambda(\cdot)$ on the Borel subsets of $\mathbb{R}_+$ by $\lambda(dt) = \mathrm{e}^{-t}dt$. For a Borel-measurable function $f : \mathbb{R}_+ \mapsto \mathbb{R}^d$, the image of the measure $\lambda(\cdot)$ under the mapping $t \mapsto (t, f(t))$ is a called the *pseudopath* of the function f. It is a probability law on $[0,\infty] \times \bar{\mathbb{R}}^d$ and is denoted by $\Psi(f)$. It is clear that Ψ identifies two functions if and only if they are equal almost everywhere in the Lebesgue sense and, in particular, Ψ is one-to-one on $\mathcal{D}^d[0,\infty)$. Thus it provides us with an imbedding of $\mathcal{D}^d[0,\infty)$ into the compact Polish space $\bar{\mathcal{P}}$ of all the probabilities on $[0,\infty] \times \bar{\mathbb{R}}^d$ (with the topology of weak convergence). The topology that $\bar{\mathcal{P}}$ induces on $\mathcal{D}^d[0,\infty)$ via the mapping Ψ is called the *pseudopath topology*, and makes $\mathcal{D}^d[0,\infty)$ a separable metrizable space. The associated Borel σ-algebra on $\mathcal{D}^d[0,\infty)$ is the same one that we get from the Skorohod topology. In fact, Lemma 1 in [28] tells us that convergence in the pseudopath topology is just convergence in measure. Let $\tilde{\mathcal{D}}$ denote the Borel σ-field on $\mathcal{D}^d[0,T]$, and $\tilde{\mathcal{D}}_t$ be the Borel σ-field up to time t, i.e.,

$$\tilde{\mathcal{D}}_t = \sigma\{x(\theta) : 0 \le \theta \le t\}, \quad 0 \le t \le T.$$

Now we state a relative compactness criterion for subsets of $\mathcal{D}^d[0,\infty)$. For $x \in \mathcal{D}^d[0,\infty)$, define $x^* = \sup_t \|x(t)\|$. For $u = (u^i), v = (v^i) \in \mathbb{R}^d$, $u < v$ means $u^i < v^i$ $(1 \le i \le d)$. Let $N^{uv}(x) = \sum_1^d N^{u^i v^i}(x^i)$, where $N^{u^i v^i}(x^i)$ denotes the number of upcrossings of $x^i(\cdot)$ on $[0,\infty)$ between the levels u^i and v^i. Then a subset $A \subset \mathcal{D}^d[0,\infty)$ such that

$$\sup_{x \in A} x^* < \infty, \quad \sup_{x \in A} N^{uv}(x) < \infty \tag{2.6}$$

for any $u < v$ is relatively compact in $\mathcal{D}^d[0,\infty)$ with the pseudopath topology. For details, see Meyer and Zheng [28].

Remark 2.7. As pointed out by Meyer and Zheng [28], $\mathcal{D}^d[0,\infty)$ with the pseudopath topology is not a Polish space. But from the definition we know that it is homeomorphic to a subspace of the Polish space $\bar{\mathcal{P}}$, and hence is a separable metric space. □

The space $\mathcal{U}$. $\mathcal{U}$ is the space of measurable transformations $\mu : [0,T] \mapsto \mathbb{M}_1(U)$ endowed with the stable topology, which is defined as follows: for $A \in \mathcal{B}([0,T])$, $B \in \mathcal{B}(U)$, define

$$\bar{\mu}(A \times B) \equiv \int_A \mu_t(B)dt.$$

Then $\bar{\mu}$ can be extended uniquely to an element in $\mathbb{M}_+([0,T] \times U)$, the space of nonnegative Radon measures on $[0,T] \times U$. The stable topology on $\mathcal{U}$ is the weakest topology that renders continuous the mappings

$$\bar{\mu} \mapsto \int_0^T \int_U \phi(t,u)\bar{\mu}(dt,du)$$

for all bounded measurable functions ϕ that are continuous in u.

Under this topology, we know that $\mathbb{M}_+([0,T] \times U)$ is a compact separable metrizable space. $\mathcal{U}$ is also endowed with its Borel σ-field $\tilde{\mathcal{U}}$, which is the smallest σ-field such that the mappings

$$\mu \mapsto \int_0^T \int_U \mu_t(du)f(t,u)dt$$

are measurable, where f is a bounded measurable function continuous with respect to the variable u. The filtration $\tilde{\mathcal{U}}_t$ is the σ-field generated by $\{1_{[0,t]}\mu, \quad \mu \in \mathcal{U}\}$. From the definition of the stable topology, we know that $\tilde{\mathcal{U}}_t$ is generated by the sets of the form

$$\left\{\mu : \int_0^s \mu_\theta d\theta \in B\right\}$$

with $s \leq t$ and B a Borel set in $\mathbb{M}_+(U)$.

For more details, see Haussmann and Lepeltier [13].

The space $\mathcal{A}^k[0,T]$. Let $\mathcal{V}$ be the collection of functions $a : [0,T] \mapsto \mathbb{R}$ such that each $a(\cdot)$ is of bounded variation and left continuous. We assume $a(0) = 0$. We first consider a topology on $\mathcal{V}$.

Let $\mathbb{M}[0,T]$ be the collection of signed Radon measures on $[0,T]$. Then there is a one-to-one correspondence between $\mathcal{V}$ and $\mathbb{M}[0,T])$: for $a \in \mathcal{V}$, let

$$\nu_a([s,t)) \equiv a(t) - a(s) \quad \forall\, 0 \leq s \leq t \leq T.$$

So we need only consider a topology on $\mathbb{M}[0,T]$, then we can get the induced topology on $\mathcal{V}$.

Denote by $C[0,T]$ the collection of real-valued continuous functions on $[0,T]$. It is well known that $\mathbb{M}[0,T]$, and, therefore, $\mathcal{V}$ is the dual space of $C[0,T]$ with the supremum norm: for $f \in C[0,T]$,

$$\|f\| = \sup_{0 \leq t \leq T} |f(t)|,$$

and the corresponding weak* topology on $\mathbb{M}[0,T]$ is the topology induced by the weak convergence of measures. It can be easily seen that the measures of the form $\sum_1^N a_i\delta_{x_i}$ with N finite and a_i, x_i rational comprise a countable dense subset of $\mathbb{M}[0,T]$; therefore, $\mathbb{M}[0,T]$, with the weak* topology, is separable.

Let $\mathcal{A}^0 = \{a \in \mathcal{V} : a$ nondecreasing$\}$. Then it is a closed subset of $\mathcal{V}$ under the weak convergence topology, and the corresponding closed subset in $\mathbb{M}[0,T]$ is $\mathbb{M}_+[0,T]$. By Stroock and Varadhan [31] we know that $\mathbb{M}_+[0,T]$ is a metrizable space. Therefore, we can conclude that under the weak convergence topology $\mathcal{A}^0$ is a separable metric space.

We state the following theorem which will be used later.

THEOREM 2.8. *For any constant $C > 0$,*

$$\{\lambda \in \mathbb{M}_+[0,T] : \lambda([0,T]) \leq C\} \tag{2.7}$$

is a compact subset of $\mathbb{M}_+[0,T]$.

Proof. Note that the set (2.7) is a closed subset in $\mathbb{M}[0,T]$ in both the (variation) norm topology and the weak* topology. Also notice that if $\lambda \in \mathbb{M}_+[0,T] \subset \mathbb{M}[0,T]$, then the norm of λ will be

$$\|\lambda\| = \sup_{\|f\|\leq 1}\left|\int_0^T f d\lambda\right| = \lambda([0,T]),$$

i.e., the set (2.7) is a norm-bounded subset of $\mathbb{M}[0,T]$. Therefore by the Banach–Alaoglu theorem (see Larsen [22, Thm. 9.4.1]) we can conclude that (2.7) is a compact subset of $\mathbb{M}[0,T]$, and, therefore, a compact subset of $\mathbb{M}_+[0,T]$. □

Finally, observe that $\mathcal{A}^k[0,T] = (\mathcal{A}^0)^k$ and consider the product topology on $\mathcal{A}^k[0,T]$ inherited from the weak topology of $\mathcal{A}^0$. We can state the following result.

COROLLARY 2.9. *$\mathcal{A}^k[0,T]$ is metrizable and separable. For $v_n, v \in \mathcal{A}^k[0,T]$, $v_n \to v$ if and only if*

$$\int_0^T f(t)\cdot dv_n(t) \to \int_0^T f(t)\cdot dv(t)$$

for any $f \in C([0,T],\mathbb{R}^k)$. Moreover, the set

$$V_M = \{v \in \mathcal{A}^k[0,T] :\ \|v(T)\| \leq M\} \tag{2.8}$$

is compact for any constant $M > 0$.

We write down the following observation for later use. Its proof is obvious from the relative compactness criterion for pseudopath topology on $\mathcal{D}^d[0,T]$. Recall that the map $G : \mathcal{A}^k[0,T] \mapsto \mathcal{D}^d[0,T]$ is defined by (2.3).

LEMMA 2.10. *For any constant $M > 0$*

$$G(V_M) = \{G.(v) :\ v \in V_M\}$$

is a relatively compact subset of $\mathcal{D}^d[0,T]$, where V_M is defined by (2.8).

From now on we will always use the notation $\Omega = \mathcal{X}$, $\mathcal{F} = \tilde{\mathcal{X}}$, and $\mathcal{F}_t = \tilde{\mathcal{X}}_t$. It is well known that $\mathbb{M}_1(\Omega)$, endowed with the Prohorov weak convergence topology, is then a separable metrizable space. Denote the collection of all the control rules with initial condition (s,x) by $\mathcal{R}_{s,x}$, which is a subset of $\mathbb{M}_1(\Omega)$. For any real number λ, define

$$\mathcal{R}_{s,x}^{\lambda} \equiv \{P \in \mathcal{R}_{s,x}, J(s,P) \leq \lambda\}.$$

PROPOSITION 2.11. *There exists a constant $C \geq 0$ such that for*

$$\lambda(x) = C(1 + \|x\|^m), \quad x \in \mathbb{R}^d, \tag{2.9}$$

we have $\mathcal{R}_{s,x}^{\lambda(x)} \neq \emptyset$ for each $(s, x) \in \Sigma$. Recall that m is given in the definition of f.

Proof. Under our assumptions, it is known from the theory of stochastic differential equations (cf. Stroock and Varadhan [31]) that there exists a $P_0 \in \mathcal{R}_{s,x}$ with

$$P_0(v_t = 0,\ \mu_t = \delta_{u^0},\ 0 \leq t \leq T) = 1.$$

Then from the definition of control rule we know that under P_0,

$$x_t = x + \int_s^t b(\theta, x_\theta, u^0)d\theta + \int_s^t \sigma(\theta, x_\theta, u^0)dB_\theta;$$

therefore, from the boundedness of b, σ, and the Burkholder–Davis–Gundy inequality we have

$$\begin{aligned} E^{P^0}\|x_t\|^m &\leq C\left\{\|x\|^m + E^{P_0}\left\|\int_s^t b(\theta, x_\theta, u^0)d\theta\right\|^m \right. \\ &\qquad \left. + E^{P_0}\sup_{0\leq\theta\leq t}\left\|\int_s^\theta \sigma(\theta', x_{\theta'}, u^0)dB_{\theta'}\right\|^m\right\} \\ &\leq C\left\{1 + \|x\|^m + E^{P_0}\left(\int_s^t \operatorname{tr}\big(a(\theta, x_\theta, u^0)\big)d\theta\right)^{\frac{m}{2}}\right\} \\ &\leq C\left(1 + \|x\|^m\right), \end{aligned}$$

where C is a constant independent of x. Now we have by definition

$$\begin{aligned} J(s, P_0) &= E^{P_0}\left\{\int_s^T f(\theta, x_\theta, u^0)d\theta\right\} \leq C\left(1 + \int_s^T E^{P_0}\|x_\theta\|^m d\theta\right) \\ &\leq C\left(1 + \|x\|^m\right), \end{aligned}$$

where C is independent of s, x. The proposition is thus proved by letting $\lambda(x) = C(1 + \|x\|^m)$. □

3. Existence of optimal controls. In order to show the existence of optimal controls, let us reformulate the problem as follows. Consider the stochastic differential equation (2.1), and let

$$y = x - G(v);$$

then $x_t = y_t + G_t(v)$ $(0 \leq t \leq T)$, and (2.1) becomes

$$y_t = x + \int_s^t b(\theta, x_\theta, u_\theta)d\theta + \int_s^t \sigma(\theta, x_\theta, u_\theta)dB_\theta; \tag{3.1}$$

this is a continuous process. We use this idea, but in the martingale setting, to replace the definition of a control rule.

PROPOSITION 3.1. *$P \in \mathcal{R}_{s,x}$ if and only if there exists an $\mathcal{F}_t$-adapted process y such that*

(1) *$y.$ is continuous with probability one (w.p. 1) and $P(x. = y. + G.(v)) = 1$;*
(2) *$P(x_r = x,\ \mu = \delta^0,\ v_r = 0,\ 0 \le r \le s) = 1$;*
(3) *$\tilde{M}_t\phi \in \mathcal{M}_2^{\mathrm{c}}$ for every $\phi \in C_b^2(I\!R^d)$, where*

$$\tilde{M}_t\phi(\omega) = \phi(y_t(\omega)) - \int_s^t \tilde{\mathcal{L}}\phi(\theta, x_\theta, y_\theta, \mu_\theta)d\theta, \tag{3.2}$$

and

$$\tilde{\mathcal{L}}\phi(\theta, x, y, u) \equiv \frac{1}{2}\sum_{ij=1}^{d} a_{ij}(\theta, x, u)\frac{\partial^2\phi(y)}{\partial y^i \partial y^j} + \sum_{i=1}^{d} b_i(\theta, x, u)\frac{\partial\phi(y)}{\partial y^i}.$$

Proof. The proof is comparable to that in Suo [33]. □

Some routine calculations can lead to the following result.

LEMMA 3.2. *Assume $P \in \mathcal{R}_{s,x}$. For any ϕ, $\psi \in C_b^2(I\!R^d)$ we have*

$$\langle \tilde{M}\phi, \tilde{M}\psi\rangle_t = \sum_{i,j=1}^{d} \int_s^t a_{ij}(\theta, x_\theta, \mu_\theta)\frac{\partial\phi(y_\theta)}{\partial y^i}\frac{\partial\psi(y_\theta)}{\partial y^j}d\theta \tag{3.3}$$

under probability P. In particular, if we define, for $1 \le i \le d$,

$$\tilde{M}^i(t) = y^i(t) - x^i - \int_s^t b_i(\theta, x_\theta, \mu_\theta)d\theta, \tag{3.4}$$

i.e., $\tilde{M}_t\phi$ with $\phi(y) = y^i - x^i$, then $\tilde{M} \in \mathcal{M}_2^{\mathrm{c,loc}}$, and

$$\langle \tilde{M}^i, \tilde{M}^j\rangle_t = \int_s^t a_{ij}(\theta, x_\theta, \mu_\theta)d\theta,\ \ 1 \le i,\ j \le d.$$

Recall that $C^d[0,T]$ is the space of $I\!R^d$-valued continuous functions on $[0,T]$. We give $C^d[0,T]$ the uniform topology, i.e., for $x, y \in C^d[0,T]$, the distance between x and y is defined by

$$\rho(x,y) \equiv \max_{0 \le t \le T} \|x(t) - y(t)\|.$$

This makes $C^d[0,T]$ a Polish space (cf. Billingsley [3]).

For a sequence $P^n \in \mathcal{R}_{s_n,x_n}$ with $(s_n, x_n) \in \Sigma$, the probability law of the process y, defined in Proposition 3.1, under P^n is defined by

$$\bar{P}^n(C) \equiv P^n(\omega :\ y\,(\omega) \in C)$$

for $C \in \tilde{\mathcal{C}}$, where $\tilde{\mathcal{C}}$ is the Borel σ-field of $C^d[0,T]$.

PROPOSITION 3.3. *If the sequence (s_n, x_n) is bounded in Σ, then $\{\bar{P}^n\}$ is relatively compact. Moreover, for any $\varepsilon > 0$, there exists a compact subset $K \subset C^d[0,T]$ such that*

$$\bar{P}^n(K) \ge 1 - \varepsilon\ \ \forall n. \tag{3.5}$$

Proof. To show that $\{\bar{P}^n\}$ is relatively compact, we need only verify the following:

(a) $\lim_{A\to\infty}\inf_n P^n(\|y(0)\|\le A)=1$, and
(b) for any $\gamma>0$,

$$\lim_{\delta\downarrow 0}\limsup_n P^n\left[\sup_{\substack{0\le s<t\le T\\ t-s<\delta}}\|y(t)-y(s)\|\ge\gamma\right]=0. \tag{3.6}$$

Note that (a) is obvious from the fact $P^n(y(0)=x_n)=1$. By Billingsley [3, Thm. 12.3], (b) is implied by

$$E^{P^n}\|y(t_2)-y(t_1)\|^4\le C|t_2-t_1|^2 \tag{3.7}$$

for any $n\ge 1$, $0\le t_1,t_2\le T$, where C is a constant.

Recall from the definition of y that $P^n(y(t)=x_n,\ 0\le t\le s_n)=1$, and for $t\ge s_n$,

$$y(t)=x_n+\int_{s_n}^t b(\theta,x_\theta,\mu_\theta)d\theta+\tilde{M}_n(t)$$

with $\tilde{M}_n\in\mathcal{M}_2^{c,\mathrm{loc}}$ under P_n, and

$$\langle\tilde{M}_n\rangle_t=\int_{s_n}^t \mathrm{tr}\big(a(\theta,x_\theta,\mu_\theta)\big)d\theta,\ \ t\ge s_n.$$

It can be easily verified that (3.7) follows from the boundedness of the coefficients $\sigma(\cdot,\cdot,\cdot)$ and $b(\cdot,\cdot,\cdot)$ and the Burkholder–Davis–Gundy inequality.

We have therefore shown that the probability laws of y under P^n are relatively compact. The existence of a compact subset K such that (3.5) holds is a consequence of Prohorov's theorem. □

PROPOSITION 3.4. *If A is a bounded subset of $\mathbb{R}^d$, then*

$$\lim_{M\to\infty}\inf_{\substack{P\in\mathcal{R}^\lambda_{s,x}\\(s,x)\in[0,T]\times A}} P\{\omega:\|v_T\|\le M\}=1, \tag{3.8}$$

where $\|\cdot\|$ denotes the Euclidean norm in $\mathbb{R}^k$.

Proof. If $P\in\mathcal{R}^\lambda_{s,x}$, then $J(P)\le\lambda$. Since the function f is assumed to be bounded from below, there exists a constant $K>0$ such that $f\ge -K$. From the assumption that $c(t)$ is strictly positive and lower semicontinuous, there exists a constant $c_0>0$ such that $c^i(t)\ge c_0$ $(1\le i\le k,\ 0\le t\le T)$. Thus

$$\begin{aligned}\lambda\ge J(P)&=E^P\left\{\int_0^T f(\theta,x_\theta,\mu_\theta)d\theta+\int_s^T c(\theta)\cdot dv_\theta\right\}\\&\ge E^P\{-KT+c_0\|v_T\|\}.\end{aligned}$$

Therefore, $E^P\|v_T\|\le\bar{K}\equiv(\lambda+KT)/c_0$ and

$$P(\|v_T\|\ge M)\le\frac{\bar{K}}{M}.$$

The proposition is now obvious. □

Define a function on Ω by

$$\Gamma_s(\omega) \equiv \int_s^T f(\theta, x_\theta, \mu_\theta)d\theta + \int_s^T c(\theta) \cdot dv_\theta \tag{3.9}$$

for $\omega = (x., \mu., v.)$. Then we have

LEMMA 3.5. *$\Gamma_s(\cdot)$ is lower semicontinuous on Ω, i.e.,*

$$\liminf_n \Gamma_s(\omega_n) \geq \Gamma_s(\omega) \tag{3.10}$$

if $\omega_n \to \omega$ in Ω.

Proof. We show the case when $s = 0$; for general s the proof is similar. We can also assume that $f(t, \cdot, \cdot)$, $c(\cdot)$ are continuous. In fact, since they are lower semicontinuous, we can find sequences of continuous functions $\{f_m(t, \cdot, \cdot)\}$, $\{c_m(\cdot)\}$ such that

$$f_m(t, \cdot, \cdot) \uparrow f(t, \cdot, \cdot), \quad c_m^i(\cdot) \uparrow c^i(\cdot), \quad 1 \leq i \leq k,$$

and thus if the lemma is true for continuous functions, then $\forall m \geq 1$,

$$\begin{aligned}\liminf_n \Gamma_0(\omega_n) &\geq \liminf_n \left\{ \int_0^T f_m(\theta, x_n(\theta), \mu_n(\theta))d\theta + \int_0^T c_m(\theta) \cdot dv_n(\theta) \right\} \\ &\geq \int_0^T f_m(\theta, x(\theta), \mu(\theta))d\theta + \int_0^T c_m(\theta) \cdot dv(\theta).\end{aligned}$$

Let $m \to \infty$, and use the monotone convergence theorem to conclude the result.

We assume that $f(t, \cdot, \cdot)$ and $c(\cdot)$ are continuous. From $v_n \to v$ in $\mathcal{A}^k[0, T]$ we have

$$\int_0^T c(\theta) \cdot dv_n(\theta) \to \int_0^T c(\theta) \cdot dv(\theta).$$

Now we show that as $n \to \infty$,

$$\int_0^T \int_U f(\theta, x_n(\theta), u)\mu_\theta^n(du)d\theta \to \int_0^T \int_U f(\theta, x(\theta), u)\mu_\theta(du)d\theta. \tag{3.11}$$

Let $dQ^n \equiv \mu_\theta^n(du)d\theta$, $dQ \equiv \mu_\theta(du)d\theta$; then the right-hand side of (3.11) can be rewritten as

$$\begin{aligned}\int_{[0,T]\times U} f(\theta, x_n(\theta), u)dQ^n &= \int_{[0,T]\times U} f(\theta, x(\theta), u)dQ^n \\ &\quad + \int_{[0,T]\times U} [f(\theta, x_n(\theta), u) - f(\theta, x(\theta), u)]dQ^n.\end{aligned} \tag{3.12}$$

From the definition of stable topology we know as $n \to \infty$,

$$\int_{[0,T]\times U} f(\theta, x(\theta), u)dQ^n \to \int_{[0,T]\times U} f(\theta, x(\theta), u)dQ.$$

Now we show that the limit of the second integral in (3.12) is zero. For any positive integer m and constant $\gamma > 0$, let

$$\begin{aligned} g(t, x, u) &= f(t, x, u) - f(t, x(t), u), \\ A_m &= \left\{ (t, u) : \sup_{\|x - x(t)\| \leq 1/m} |g(t, x, u)| \geq \gamma \right\}. \end{aligned}$$

Then each t-section of the set A_m is a closed subset of U from the continuity of the function $f(t,\cdot,\cdot)$. Also $A_1 \supset A_2 \supset \cdots \supset A_m \supset A_{m+1} \supset \cdots$, and

$$\bigcap_m A_m = \emptyset.$$

Applying the results in Jacod and Mémin [17, Prop. 2.11] we can get

$$\limsup_n Q_n(A_m) \le Q(A_m), \quad \lim_m Q(A_m) = 0. \tag{3.13}$$

Let $B_n = \{(t,u) : |g(t,x_n(t),u)| \ge \gamma\}$. In order to show that the limit of the last integral in (3.12) is zero, we need only show

$$\lim_{n\to\infty} Q_n(B_n) = 0 \tag{3.14}$$

by Jacod and Mémin [17, Cor. 2.18]. For a given $\varepsilon > 0$, from (3.13) there exists an $M > 0$ such that $Q(A_M) \le \varepsilon$. Recall that convergence in pseudopath topology is equivalent to the convergence in Lebesgue measure, therefore, $x_n(\cdot) \to x(\cdot)$ in the Lebesgue measure l, and there exists N such that when $n \ge N$,

$$l\left\{t : \|x_n(t) - x(t)\| > \frac{1}{M}\right\} < \varepsilon.$$

Let $C_n^m = \{t : \|x_n(t) - x(t)\| > 1/m\}$; then it is obvious that

$$B_n \setminus (C_n^M \times U) \subset A_M,$$

and, therefore, we have

$$Q_n(B_n) \le Q_n(A_M) + Q_n(C_n^M \times U).$$

But $Q_n(C_n^M \times U) = l(C_n^M) < \varepsilon$, hence

$$\begin{aligned}\limsup_n Q_n(B_n) &\le \limsup_n Q_n(A_M) + \varepsilon \\ &\le Q(A_M) + \varepsilon < 2\varepsilon.\end{aligned}$$

Since ε is arbitrary, we have shown (3.14), and the lemma is thus proved. □

For $P \in \mathcal{R}_{s,x}$, we have by definition that

$$J(s,P) = E^P\Gamma_s,$$

i.e., the cost corresponding to the control rule P. We can now state the following result.

THEOREM 3.6. *The mapping $(s,x,P) \to J(s,P)$ is lower semicontinuous on $\{(s,x,P) : (s,x) \in \Sigma,\ P \in \mathcal{R}_{s,x}\}$ with the induced topology of $[0,T] \times I\!M_+(\Omega)$, i.e., if $(s_n,x_n) \in \Sigma$, $P_n \in \mathcal{R}_{s_n,x_n}$, $s_n \to s$, $x_n \to x$, and $P_n \to P \in \mathcal{R}_{s,x}$ weakly, then*

$$J(s,P) \le \liminf_n J(s_n,P_n). \tag{3.15}$$

Proof. Assume $(s_n, x_n, P_n) \to (s, x, P)$ with $P_n \in \mathcal{R}_{s_n,x_n}$, $P \in \mathcal{R}_{s,x}$. It suffices to consider two cases: $s_n \uparrow s$ or $s_n \downarrow s$. When $s_n \uparrow s$,

$$\begin{aligned} E^{P_n}(\Gamma_{s_n} - \Gamma_s) &= E^{P_n}\left\{\int_{s_n}^{s} f(\theta, x_\theta, \mu_\theta)d\theta + \int_{s_n}^{s} c(\theta)\cdot dv_\theta\right\} \\ &\geq E^{P_n}\left(\int_{s_n}^{s} f(\theta, x_\theta, \mu_\theta)d\theta\right) \geq -K(s-s_n), \end{aligned}$$

because we have assumed that $c \geq 0$. It follows that

$$\liminf_n E^{P_n}(\Gamma_{s_n} - \Gamma_s) \geq 0. \tag{3.16}$$

When $s_n \downarrow s$, (3.16) follows from

$$E^{P_n}(\Gamma_{s_n} - \Gamma_s) = \int_s^{s_n} f(\theta, x_n, u^0)d\theta,$$

where we have used the fact that $P_n(v_\theta = 0,\ 0 \leq \theta \leq s_n) = 1$.

In either case, from (3.16) and the lower semicontinuity of $\Gamma_s(\cdot)$, we have

$$\begin{aligned} \liminf_n J(s_n, P_n) &\geq \liminf_n E^{P_n}\Gamma_s + \liminf_n E^{P_n}(\Gamma_{s_n} - \Gamma_s) \\ &\geq \liminf_n E^{P_n}\Gamma_s \geq E^P\Gamma_s = J(s, P), \end{aligned}$$

i.e., $J(\cdot,\cdot)$ is lower semicontinuous. □

THEOREM 3.7. *For any $\lambda > 0$, if A is a compact set in $\mathbb{R}^d$, then $\cup\{\mathcal{R}^\lambda_{s,x} : s \in [0,T],\ x \in A\}$ is compact.*

Proof. Since $\mathbb{M}_1(\Omega)$ is metrizable, we need only to show that each sequence $\{P^n\} \subset \mathcal{R}^\lambda_{s_n,x_n}$ has a subsequence $\{P^{n_k}\}$ such that $P^{n_k} \to P \in \mathcal{R}^\lambda_{s,x}$ for some $s \in [0,T]$, $x \in A$. Because A is compact and $T < \infty$, we may assume $s_n \to s$, $x_n \to x$ for some $s \in [0,T]$, $x \in A$.

By Proposition 3.1, the process y, defined by

$$y_\cdot(\omega) = x_\cdot(\omega) - G_\cdot(v(\omega))$$

for $\omega = (x, \mu, v)$, has continuous sample paths under the probability P^n and is such that $\tilde{M}_t\phi \in \mathcal{M}_2^c$ ($\tilde{M}_t\phi$ is defined in Proposition 3.1) for each $\phi \in C_b^2(\mathbb{R}^d)$. Now we introduce the following auxiliary space:

$$\begin{aligned} \mathcal{Z} &\equiv \Omega \times C^d[0,T], \\ \tilde{\mathcal{Z}} &\equiv \mathcal{F} \times \tilde{\mathcal{C}}. \end{aligned}$$

Define a probability $\tilde{P}^n$ on $(\mathcal{Z}, \tilde{\mathcal{Z}})$ by the probability law of (x, μ, v, y) with respect to P^n, i.e., for $Z \in \tilde{\mathcal{Z}}$,

$$\tilde{P}^n(Z) \equiv P^n\left(\omega :\ (x_\cdot(\omega), \mu_\cdot(\omega), v_\cdot(\omega), y_\cdot(\omega)) \in Z\right).$$

In other words, for $F \in \mathcal{F}$, $C \in \tilde{\mathcal{C}}$,

$$\tilde{P}^n(F \times C) = \int_F \delta_C(y(\omega))dP^n(\omega).$$

We will show that the sequence $\tilde{P}^n$ is tight.

For a positive constant M, let $V_M = \{v \in \mathcal{A}^k[0,T] : \|v_T\| \leq M\}$. From Corollary 2.9 we know that V_M is a compact Borel subset of $\mathcal{A}^k[0,T]$. Proposition 3.4 implies that for any given $\varepsilon > 0$, there exists an M such that

$$P(\mathcal{D}^d[0,T] \times \mathcal{U} \times V_M) \geq 1 - \varepsilon \tag{3.17}$$

for every $P \in \mathcal{R}^\lambda_{s,x}$, $s \in [0,T]$, $x \in A$. Therefore, for the corresponding $\tilde{P}$, we have

$$\tilde{P}(\mathcal{D}^d[0,T] \times \mathcal{U} \times V_M \times C^d[0,T]) \geq 1 - \varepsilon. \tag{3.18}$$

By Proposition 3.3 we know that the probability laws of y with respect to P^n, denoted by $\bar{P}^n$, are relatively compact, and there exists a compact subset $K \subset C^d[0,T]$ with

$$\bar{P}^n(K) \geq 1 - \varepsilon,$$

or equivalently,

$$P^n(\omega : y.(\omega) \in K) \geq 1 - \varepsilon \ \forall n. \tag{3.19}$$

From Proposition 3.1, (3.19) may be written as

$$\tilde{P}^n(\Omega \times K) \geq 1 - \varepsilon \ \forall n. \tag{3.20}$$

We now consider the coordinate process x. Let

$$D = K + G(V_M) = \{y + G(v),\ y \in K,\ v \in V_M\}.$$

By Lemma 2.10 we know that $G(V_M)$ is a relatively compact subset of $\mathcal{D}^d[0,T]$ under the pseudopath topology. Since the uniform topology is stronger than the pseudopath topology, K is also a compact subset in $\mathcal{D}^d[0,T]$, hence so is D. From Proposition 3.1 we have

$$\tilde{P}^n(D \times \mathcal{U} \times V_M \times K) = \tilde{P}^n(\mathcal{D}^d[0,T] \times \mathcal{U} \times V_M \times K). \tag{3.21}$$

Let $S = D \times \mathcal{U} \times V_M \times K$. Since $\mathcal{U}$ is a compact space, we know that S is a relatively compact subset in $\mathcal{Z}$. Moreover, from (3.18), (3.20), and (3.21) we have

$$\tilde{P}^n(S) \geq 1 - 2\varepsilon$$

for every n. Thus $\{\tilde{P}^n\}$ is a tight sequence of probability measures on $\mathcal{Z}$. By the Prohorov theorem there is a subsequence $\{\tilde{P}^{n_k}\}$ and a probability $\tilde{P}$ on $(\mathcal{Z}, \tilde{\mathcal{Z}})$ such that $\tilde{P}^{n_k} \to \tilde{P}$ weakly. Define

$$P = \tilde{P}|_\Omega,$$

i.e., in the terminology of Jacod and Mémin [17], P is the *Ω-marginal* of $\tilde{P}$, then it is easy to see that $P^{n_k} \to P$ weakly. The proof of the theorem will be completed if $P \in \mathcal{R}^\lambda_{s,x}$. By Proposition 3.1 we need only to show that there exists a continuous process $Y.$ on $(\Omega, \mathcal{F}, \mathcal{F}_t, P)$ such that

(1) $P(Y. = x. - G.(v)) = 1$;
(2) $P(x_r = x,\ v_r = 0,\ 0 \leq r \leq s) = 1$;
(3) $\tilde{M}_t\phi \in \mathcal{M}_2^c \ \forall \phi \in C_b^2(\mathbb{R}^d)$; and

(4) $J(s,P) \leq \lambda$.

Note that (4) is obvious from Theorem 3.6. To show (1), note that the set $\{(\omega, y): x.(\omega) = y. + G.(v(\omega))\}$ is a closed subset of $\mathcal{Z} = \Omega \times C^d[0,T]$, and, therefore,

$$\tilde{P}(x. = y. + G.(v)) \geq \limsup \tilde{P}^n(x. = y. + G.(v)) = 1. \tag{3.22}$$

If we define $Y.(\omega) = x.(\omega) - G.(v(\omega))$, then $\tilde{P}((\omega, y): Y.(\omega) = y.) = 1$. Thus Y is a continuous process on $(\Omega, \mathcal{F}, \mathcal{F}_t, P)$, and (1) follows from (3.22). Moreover, $\{y(0) = x\}$ is closed in $\mathcal{Z}$, so

$$\tilde{P}\{y(0) = x\} \geq \limsup_k \tilde{P}^{n_k}\{y(0) = x\} = 1$$

or $P\{\omega: Y(0) = x\} = 1$. It follows that $x(0) = x$ almost surely (P).

For (2), let

$$B_m = \left\{\omega = (x., \mu., v.): \|x(t) - x\| \leq \frac{1}{m},\ v_t = 0,\ 0 < t \leq s - \frac{1}{m}\right\}.$$

It is easy to see that B_m is closed in Ω and $B_1 \supset B_2 \supset \cdots$, and

$$\bigcap_m B_m = \{\omega = (x, \mu, v): x_t = x,\ v_t = 0,\ 0 < t \leq s\}.$$

Since $P^{n_k} \in \mathcal{R}_{s_{n_k}, x_{n_k}}$, we know for each m, $P^{n_k}(B_m) = 1$ for large k since $x_{n_k} \to x$. But $P^{n_k} \to P$ weakly, so

$$P(B_m) \geq \limsup_k P^{n_k}(B_m) = 1,$$

and, therefore,

$$\begin{aligned} &P\{\omega: x_t = x, v_t = 0,\ 0 \leq t \leq s\} \\ &\quad = P\left(\bigcap_m B_m \bigcap \{x(0) = x\}\right) = \lim_m P(B_m) = 1. \end{aligned}$$

Finally, we prove (3). For any bounded continuous function $H(\cdot)$ on Ω, if we define

$$\tilde{H}(\tilde{\omega}) = H(\omega)\ \ \forall \tilde{\omega} = (\omega, y.) \in \Omega \times C^d[0,T],$$

then $\tilde{H}$ is a continuous function on $\mathcal{Z}$. For any fixed $t \geq s$, the function

$$z = (x, \mu, v, y) \in \mathcal{Z} \mapsto \bar{M}_t\phi(z) = \phi(y_t) - \int_s^t \tilde{\mathcal{L}}\phi(\theta, x_\theta, y_\theta, \mu_\theta)d\theta$$

is continuous on $\mathcal{Z}$. In fact, it can be shown as in the proof of Lemma 3.5 that the integral part of the function $\bar{M}_t\phi$ is continuous on $\mathcal{Z}$, and the continuity of the function

$$z = (x, \mu, v, y) \to \phi(y_t)$$

on $\mathcal{Z}$ follows from the fact that $C^d[0,T]$ is endowed with the uniform topology. Thus, for $0 \leq u < t \leq T$, the function

$$z = (x, \mu, v, y) \to \tilde{H}(z)\left[\bar{M}_t\phi(z) - \bar{M}_u\phi(z)\right]$$

is a bounded and continuous function on $\mathcal{Z}$, and since $\tilde{P}^{n_k} \to \tilde{P}$ weakly, we have

$$\lim_k E^{\tilde{P}^{n_k}} \left\{\tilde{H}[\bar{M}_t\phi - \bar{M}_u\phi]\right\} = E^{\tilde{P}} \left\{\tilde{H}[\bar{M}_t\phi - \bar{M}_u\phi]\right\}. \tag{3.23}$$

Again, by (3.22) and the definition of Y, we have $\tilde{P}(\tilde{M}.\phi = \bar{M}.\phi) = 1$, where $\tilde{M}_t\phi$ is defined by (3.2) with y replaced by Y. Thus (3.23) can be rewritten as

$$\lim_k E^{P^{n_k}} \left\{H[\tilde{M}_t\phi - \tilde{M}_u\phi]\right\} = E^{P} \left\{H[\tilde{M}_t\phi - \tilde{M}_u\phi]\right\}. \tag{3.24}$$

For every bounded continuous function H on Ω that is $\mathcal{F}_u$-measurable, the left-hand side of (3.24) is zero since $\tilde{M}\phi \in \mathcal{M}_2^c$ on the filtered probability space $(\Omega, \mathcal{F}, \mathcal{F}_t, P)$. By a routine limit procedure, we have

$$E^P[H(\tilde{M}_t\phi - \tilde{M}_u\phi)] = 0$$

for each bounded $\mathcal{F}_u$-measurable function H. Thus $(\tilde{M}_t\phi, \mathcal{F}_t)$ is a martingale under P. The continuity of this martingale follows from that of Y. The proof is therefore complete. □

We can now prove the main theorem of this paper.

THEOREM 3.8. *The control problem has an optimal solution, i.e., there exists a* $P^* \in \mathcal{R}_{s,x}$ *such that*

$$J(s, P^*) = \inf_{P \in \mathcal{R}_{s,x}} J(s, P).$$

Proof. By Proposition 2.11 and Theorem 3.7 we know that $\mathcal{R}_{s,x}^{\lambda(x)}$ is nonempty and compact. Moreover, it is obvious that

$$\inf_{P \in \mathcal{R}_{s,x}} J(s, P) = \inf_{P \in \mathcal{R}_{s,x}^{\lambda(x)}} J(s, P).$$

Now $J(s, \cdot)$ is a lower-semicontinuous function on $\mathcal{R}_{s,x}$, so it attains its minimum on the compact set $\mathcal{R}_{s,x}^{\lambda(x)} \subset I\!M_1(\Omega)$, i.e., there exists a $P^* \in \mathcal{R}_{s,x}^{\lambda(x)} \subset \mathcal{R}_{s,x}$ such that

$$J(s, P^*) = \inf_{P \in \mathcal{R}_{s,x}^{\lambda(x)}} J(s, P) = \inf_{P \in \mathcal{R}_{s,x}} J(s, P),$$

which completes the proof. □

Recall that the value function is defined by

$$W(s, x) = \inf_{P \in \mathcal{R}_{s,x}} J(s, P).$$

Let us define

$$\mathcal{R}_{s,x}^o = \{P \in \mathcal{R}_{s,x} : W(s, x) = J(s, P)\}.$$

By Theorem 3.8, $\mathcal{R}_{s,x}^o \neq \emptyset$ for any $(s, x) \in \Sigma$. It can be easily verified that it is a compact subset of $I\!M_1(\Omega)$.

Before we prove the measurability of the value function W, we give a result which is used in Haussmann and Suo [14]. We adopt the notations of Stroock and Varadhan [31, Chap. 12].

LEMMA 3.9. *The map $\mathcal{R}^o : \Sigma \mapsto \text{comp}(\mathbb{M}_1(\Omega))$ is Borel measurable. Moreover, there exists a measurable selector H of $\mathcal{R}^o$, i.e., $H(s,x) \in \mathcal{R}^o_{s,x}$ $\forall (s,x) \in \Sigma$ and $H : \Sigma \mapsto \mathbb{M}_1(\Omega)$ is Borel measurable.*

Proof. By [31, Lem. 12.1.8], we need only to show the following: for $(s_n, x_n) \in \Sigma$, $s_n \to s$, $x_n \to x$, $P^n \in \mathcal{R}^o_{s_n,x_n}$, there exists a subsequence P^{n_k} and $P \in \mathcal{R}^o_{s,x}$ such that $P^{n_k} \to P$.

Since $x_n \to x$, we may assume $\lambda(x_n) \leq \lambda$ for some constant λ. Therefore $\{P^n\} \subset \{\mathcal{R}^\lambda_{s,x},\ (s,x) \in [0,T] \times A\}$ with $A = \{x, x_1, x_2, \ldots\}$ a compact set. By Theorem 3.7, there exists a subsequence P^{n_k} and $P \in \mathcal{R}_{s,x}$ such that $P^{n_k} \to P$. From Theorem 3.6, it can be seen easily that $P \in \mathcal{R}^o_{s,x}$. The measurability of $\mathcal{R}^o$ is thus proved.

The existence of a measurable selector H is a consequence of [31, Thm. 12.1.10]. □

COROLLARY 3.10. *$W(\cdot,\cdot)$ is a Borel-measurable function.*

Proof. From Theorem 3.6 we know the map $(s,x,P) \mapsto J(s,P)$ is lower semicontinuous and thus Borel measurable. The corollary follows from the fact that $W(s,x) = J(s, H(s,x))$ is the composition of two Borel-measurable mappings. □

4. Some comments. (a) The model studied in this paper includes the case of the *monotone follower* problem as formulated in Karatzas [18] and Karatzas and Shreve [21] by letting $k = d$ and $g(\theta) = I$, $0 \leq \theta \leq T$, where I denotes the $d \times d$ unit matrix. Moreover, if we take $k = 2d$ and $g(\theta) = (I, -I)$, $0 \leq \theta \leq T$, then the model reduces the *bounded variation* problem as discussed in Chow, Menaldi, and Robin [6], among others.

We have assumed that $c^i(\cdot) > 0$. This condition is necessary for the existence of optimal controls to the general problem formulated in this paper (see the proof of Proposition 3.4). Thus it excludes the case of the so-called *cheap control* problems, i.e., $c(\cdot) = 0$. This type of problem is discussed in Chiarolla and Haussmann [4], [5] and Menaldi and Robin [25]. However, our method works for problems with *finite fuel* constraints, because for any $y \in \mathcal{D}^k[0,T]$, the set

$$\{v \in \mathcal{A}^k[0,T] : v^i(t) \leq y^i(t),\ \forall t,\ 1 \leq i \leq k\}$$

is closed in $\mathcal{A}^k[0,T]$. This follows from the fact that $v_n \to v$ in $\mathcal{A}^k[0,T]$, then $v^i_n(t) \to v^i(t)$ $(1 \leq i \leq k)$ at all the continuity points of v^i. For the problems with finite fuel constraints, see Karatzas [20], Karatzas and El Karoui [8], and a more recent work by Bridge and Shreve [1] among others.

(b) Now we explain why the method used in this paper is not suitable to the problem where terminal costs are allowed. If we define $\Gamma_s(\omega) = \phi(x_T(\omega))$ for $\omega = (x, \mu, v)$ with ϕ a continuous function defined in $\mathbb{R}^d$, we cannot get the lower semicontinuity for Γ_s. The reason is that $x^n \to x$ in the pseudopath topology only ensures that $x^n(\cdot) \to x(\cdot)$ in Lebesgue measure, and, therefore, $x^n(T) \to x(T)$ may not hold.

But we can modify the formulation of the problem to allow a terminal cost, i.e., let

$$J(\alpha) \equiv E^P \left\{ \int_s^T f(t, x_t, u_t)dt + \int_{[s,T]} c(t) \cdot dv_t + \phi(x_{T+}) \right\}.$$

Note the additional term $c(T) \cdot \Delta v_T$ in the second integral and the relation $x_{T+} = x_T + g(T)\Delta v_T$. We can replace $\mathcal{D}^d[0,T]$ by $\mathcal{D}^d[0,T] \times \mathbb{R}^d$ and $\mathcal{A}^d[0,T]$ by $\mathcal{A}^d[0,T] \times \mathbb{R}^d$ in the canonical space to obtain the results if ϕ is lower semicontinuous.

(c) For the same reason as explained in (b) we cannot allow pointwise constraints of the type $\Phi(x(t_0)) = 0$ almost surely for some lower-semicontinuous function Φ on $I\!R^d$ (which may take the values $\pm\infty$) and fixed $t_0 \in [0,T]$. But it is seen easily that the following kind of integral constraint may be added to the problem:

$$\int_s^T f_0(t, x_t, u_t)dt + \int_s^T c_0(t) \cdot dv_t \leq 0 \text{ a.s.},$$

where f_0, c_0 satisfy the same conditions as f and c, except that the positivity of $c_0(\cdot)$ is relaxed to *bounded below*. Moreover, from the proof of Lemma 3.5 we can conclude that the following kind of constraint may also be added to the model:

$$\int_s^T f_1(t, x_t, u_t)dt + \int_s^T c_1(t) \cdot dv_t = 0$$

with $f_1(t, \cdot, \cdot)$, $c_1(\cdot)$ continuous on Σ (for each $0 \leq t \leq T$), $[0,T]$, respectively. Of course, we must now assume the existence of an admissible control. See Haussmann and Lepeltier [13] for constraints of these types in the classical control problems.

SINGULAR OPTIMAL STOCHASTIC CONTROLS II: DYNAMIC PROGRAMMING*

ULRICH G. HAUSSMANN† AND WULIN SUO‡

Abstract. The dynamic programming principle for a multidimensional singular stochastic control problem is established in this paper. When assuming Lipschitz continuity on the data, it is shown that the value function is continuous and is the unique viscosity solution of the corresponding Hamilton–Jacobi–Bellman equation.

Key words. singular controls, control rules, value function, dynamic programming principle, Hamilton–Jacobi–Bellman equation, viscosity solution

AMS subject classifications. 49J30, 49A55, 60G44, 93E20

1. Introduction.

In [8] we applied a direct method to study the existence of optimal controls for the stochastic control problem in which the state is governed by the stochastic differential equation

$$x_t = x + \int_s^t b(\theta, x_\theta, u_\theta)d\theta + \int_s^t \sigma(\theta, x_\theta, u_\theta)dB_\theta + \int_s^t g(\theta)dv_\theta$$

on some filtered probability space $(\Omega, \mathcal{F}, \mathcal{F}_t, P)$, where $b(\cdot,\cdot,\cdot)$, $\sigma(\cdot,\cdot,\cdot)$, $g(\cdot)$ are given deterministic functions, $(B_t,\ t \geq 0)$ is a d-dimensional Brownian motion (in fact, $B.$ need not be d-dimensional), x is the initial state at time s, and $u:\ [0,T] \mapsto U$, $v:\ [0,T] \mapsto I\!R^k$, with v nondecreasing componentwise, stand for the controls.

The expected cost has the form

$$J(\alpha) \equiv E^P \left\{ \int_s^T f(t, x_t, u_t)dt + \int_{[s,T)} c(t) \cdot dv_t \right\},$$

where $f(\cdot,\cdot,\cdot):\ [0,T] \times I\!R^d \times U \mapsto I\!R$, $c(\cdot):\ [0,T] \mapsto I\!R^k_+$ are given. We assume that the cost of applying the singular control is positive, i.e., $c^i(\cdot) > 0$, $i = 1, \ldots, k$. For this type of problem, the reader may consult the paper by Haussmann and Suo [8] and the list of references therein.

This paper is a continuation of Haussmann and Suo [8]. As is well known for the classical stochastic control problem, the dynamic programming principle is satisfied and, if the value function has appropriate regularity, it satisfies a second-order nonlinear partial differential equation (the Hamilton–Jacobi–Bellman equation) (cf. Fleming and Rishel [4] and Lions [10], among others). This is still the case for singular stochastic control where the Hamilton–Jacobi–Bellman equation is a second-order variational inequality (see Fleming and Soner [5] and the list of references in Haussmann and Suo [8]). In this paper, in §3 we adopt a probabilistic approach used in Haussmann [6], Haussmann and Lepeltier [7], and El Karoui, Nguyen, and Jeanblanc-Picqué [3] to establish the dynamic programming principle under very mild conditions of the data. Then, in §4, assuming Lipschitz continuity of the coefficients, we prove

† Department of Mathematics, University of British Columbia, Vancouver, British Columbia, Canada V6T 1Z2.

‡ Faculty of Management, University of Toronto, Toronto, Ontario, Canada M5S 1V4.

that the value function is continuous. In §5 the Hamilton–Jacobi–Bellman equation is derived heuristically, and the value function is shown to be the unique viscosity solution of this equation. For the reader's convenience, the main results of Haussmann and Suo [8] are recalled in §2, along with the formulation of the problem.

We list some notation that will be used throughout this paper:

- $I\!R^d, I\!R$ denote the d-dimensional Euclidean space and the real line, respectively. $I\!R_+ = \{x \in I\!R, x \geq 0\}$ and $I\!R^d_+$ is defined similarly. For $x = (x^i), y = (y^i) \in I\!R^d$, $x \cdot y = \sum_{i=1}^d x^i y^i$.
- $T > 0$ is the fixed horizon, and $\Sigma = [0, T] \times I\!R^d$.
- $\mathcal{D}^d[0, T]$ denotes the collection of $I\!R^d$-valued functions defined on $[0, T]$ which are left continuous and have right limits.
- $\mathcal{A}^k[0, T]$ denotes the collection of functions $a : [0, T] \mapsto I\!R^k_+$ such that $a = (a^i) \in \mathcal{D}^k[0, T]$ and a^i is nondecreasing with $a^i(0) = 0$, $i = 1, \ldots, k$.
- $\mathcal{S}^{l\times k}$ is the space of $l \times k$ matrices with the $l \times k$-dimensional Euclidean norm.
- If Y is a metric space, $\mathcal{B}(Y)$ denotes the corresponding Borel σ-field, and $f \in \mathcal{B}(Y)$ means that f is a $\mathcal{B}(Y)$-measurable real-valued function. We denote by $I\!M_1(Y)$ ($I\!M_+(Y)$, respectively) the space of probabilities (nonnegative Radon measures, respectively) on Y with the weak convergence topology.
- U, called the control set, is a compact metric space. It is well known that $I\!M_1(U)$ is also a compact metrizable space. If $\phi : U \mapsto I\!R$ is a bounded measurable function, we can extend ϕ to $I\!M_1(U)$ by letting
$$\phi(\mu) \equiv \int_U \phi(u)\mu(du).$$
Define
$$\mathcal{U} \equiv \{\mu : [0, T] \mapsto I\!M_1(U) \text{ is Borel measurable}\}.$$
- If X is a random variable on a probability space $(\Omega, \mathcal{F}, P)$, the expectations of X will be denoted by $E^P(X)$. $\mathcal{M}^c_2$ is the family of continuous square integrable martingales on some given probability space $(\Omega, \mathcal{F}, P)$ with a filtration $\{\mathcal{F}_t\}$.
- C stands for a constant, but not necessarily the same one from line to line.

2. Formulation of the problem. We consider the following optimal control problem in which we allow both classical control and singular control to act at the same time, i.e., the dynamics are in the form,

$$x_t = x + \int_s^t b(\theta, x_\theta, \mu_\theta)d\theta + \int_s^t \sigma(\theta, x_\theta, \mu_\theta)dB_\theta + \int_s^t g(\theta)dv_\theta \text{ a.s.} \tag{2.1}$$

for $(t, x) \in \Sigma$, $s \leq t \leq T$, where

- $(\sigma, b) : \Sigma \times U \mapsto \mathcal{S}^{d\times d} \times I\!R^d$, $g : [0, T] \mapsto \mathcal{S}^{d\times k}$,
- $(B_t, 0 \leq t \leq T)$ is a d-dimensional Brownian motion on some probability space, and
- $v \in \mathcal{A}^k[0, T]$.

We assume that σ, b are bounded measurable functions, continuous with respect to (x, u), and g is continuous on $[0, T]$.

DEFINITION 2.1. *A relaxed control is a term* $\alpha = (\Omega, \mathcal{F}, P, \mathcal{F}_t, B_t, x_t, \mu_t, v_t, s, x)$ *such that*

(1) *$(s,x)\in\Sigma$;*
(2) *$(\Omega,\mathcal{F},P)$ is a probability space with the filtration $\{\mathcal{F}_t\}_{t\ge 0}$;*
(3) *$\mu.\in\mathcal{U}$ is progressively measurable with respect to $\mathcal{F}_t$;*
(4) *v is an $\mathbb{R}^k_+$-valued process progressively measurable with respect to $\mathcal{F}_t$; the sample paths of v are in $\mathcal{A}^k[0,T]$, i.e., for each $\omega\in\Omega$, $v.(\omega)\in\mathcal{A}^k[0,T]$;*
(5) *B_t is a standard d-dimensional Brownian motion on $(\Omega,\mathcal{F},P,\mathcal{F}_t)$ and x_t, the state process, is $\mathcal{F}_t$-adapted with sample paths in $\mathcal{D}^d[0,T]$ such that (2.1) is satisfied. We assume that $x_r=x$ for $0\le r\le s$.*

We call (s,x) the initial condition of the relaxed control α.

The collection of relaxed controls with initial condition (s,x) is denoted by $\tilde{\Lambda}_{s,x}$. For $\alpha\in\tilde{\Lambda}_{s,x}$, the associated cost is defined as follows:

$$J(\alpha)\equiv E^P\left\{\int_s^T f(t,x_t,\mu_t)dt+\int_{[s,T)}c(t)\cdot dv_t\right\},\tag{2.2}$$

where

- $f:\Sigma\times U\mapsto\mathbb{R}$ is a measurable function and is lower semicontinuous in (x,u), satisfying
$$-K\le f(t,x,u)\le C(1+\|x\|^m),\quad (t,x,u)\in\Sigma\times U$$
for some constants $m\ge 0$, $K\ge 0$ and $C\ge 0$;
- $c=(c^i):[0,T]\mapsto\mathbb{R}^k$ is lower semicontinuous and $c^i>0$, $1\le i\le k$.

The value function is defined by

$$W(s,x)=\inf_{\alpha\in\tilde{\Lambda}_{s,x}}J(\alpha).\tag{2.3}$$

A relaxed control $\alpha^*\in\tilde{\Lambda}_{s,x}$ is called an optimal relaxed control if $W(s,x)=J(\alpha^*)$.

Throughout this paper we write

$$\int_s^t k(\theta)\cdot da(\theta)=\sum_{i=1}^d\int_{[s,t)}k_i(\theta)da_i(\theta)$$

for any $\mathbb{R}^k$-valued Borel-measurable function $k=(k_i)$ and $a=(a_i)\in\mathcal{A}^k[0,T]$.

Now we introduce the canonical space for our problem. Define

$$\Omega\equiv\mathcal{D}^d[0,T]\times\mathcal{U}\times\mathcal{A}^k[0,T],$$

where $\mathcal{D}^d[0,T]$, $\mathcal{U}$ and $\mathcal{A}^k[0,T]$ are endowed with the pseudopath topology, stable topology, and weak convergence topology, respectively. Ω is metrizable and separable under the product topology; see Haussmann and Suo [8] for details. Let $\tilde{\mathcal{D}},\tilde{\mathcal{U}},\tilde{\mathcal{A}}$ denote their Borel σ-fields, $\tilde{\mathcal{D}}_t,\tilde{\mathcal{U}}_t,\tilde{\mathcal{A}}_t$, the σ-fields up to time t, and define

$$\mathcal{F}\equiv\tilde{\mathcal{D}}\times\tilde{\mathcal{U}}\times\tilde{\mathcal{A}},$$
$$\mathcal{F}_t\equiv\tilde{\mathcal{D}}_t\times\tilde{\mathcal{U}}_t\times\tilde{\mathcal{A}}_t.$$

Let $a=\sigma\sigma^*$, where $*$ denotes the transpose of a matrix, and define

$$\mathcal{L}\equiv\frac{1}{2}\sum_{i,j}a_{ij}\frac{\partial^2}{\partial x_i\partial x_j}+\sum_i b_i\frac{\partial}{\partial x_i}.$$

We recall the following definition from Haussmann and Suo [8]

DEFINITION 2.2. *A control rule is a probability R on the measurable space $(\Omega, \mathcal{F})$ such that*

$$\tilde{\alpha} = (\Omega, \mathcal{F}, \mathcal{F}_t, R, x_t, \mu_t, v_t, s, x) \in \tilde{\Lambda}_{s,x},$$

where

$$x_t(\omega) = x_t, \ \mu_t(\omega) = \mu_t, \ v_t = v_t(\omega)$$

for $\omega = (x_., \mu_., v_.) \in \Omega$, i.e.,

(1) *$(\Omega, \mathcal{F}, R)$ is a probability space with the filtration $\mathcal{F}_t$, $(s, x) \in \Sigma$, and*

$$R(x_r = x, \ \mu_r = \delta^0, \ v_r = 0, \ 0 \le r \le s) = 1,$$

where δ^0 denotes the Dirac measure at an arbitray but fixed point $u^0 \in U$;

(2) *$\forall \phi \in C_b^2(I\!R^d)$, $M_t\phi$ $(s \le t \le T)$ is in $\mathcal{M}_2^c$ on the filtered probability space $(\Omega, \mathcal{F}, \mathcal{F}_t, R)$ $(s \le t \le T)$, where*

$$M_t\phi(\omega) \equiv \phi(x_t) - \int_s^t \mathcal{L}\phi(\theta, x_\theta, \mu_\theta)d\theta - \int_s^t \nabla_x\phi(x_\theta) \cdot g(\theta)dv_\theta \\ - \sum_{s \le \theta < t} \left[\phi(x_{\theta+}) - \phi(x_\theta) - \nabla_x\phi(x_\theta) \cdot \triangle x_\theta\right]. \tag{2.4}$$

We write $J(\alpha) = J(s, R)$.

Define

$$\Gamma_s(\omega) \equiv \int_s^T f(\theta, x_\theta, \mu_\theta)d\theta + \int_s^T c(\theta) \cdot dv_\theta \tag{2.5}$$

for $\omega = (x_., \mu_., v_.)$. Then, by definition, $J(\alpha) = E^R\Gamma_s$. We denote by $\mathcal{R}_{s,x}$ the space of control rules with initial condition (s, x). We will suppress s in $J(s, R)$ when it is clear that $R \in \mathcal{R}_{s,x}$. It is shown in Haussmann and Suo [8] that for any relaxed control $\alpha \in \tilde{\Lambda}_{s.x}$, there exists a control rule $R \in \mathcal{R}_{s,x}$ such that $J(R) = J(\alpha)$. Thus the control problem can be described in terms of control rules.

We recall the main results from Haussmann and Suo [8].

THEOREM 2.3 (Haussmann and Suo [8]). (a) *For each $(s, x) \in \Sigma$ there exists an optimal control rule $P^* \in \mathcal{R}_{s,x}$, i.e., $W(s, x) = J(s, P^*)$.*

(b) *The value function $W(\cdot, \cdot)$ is Borel measurable on Σ.*

(c) *There exists a Borel-measurable map $H(\cdot, \cdot) : \Sigma \mapsto I\!M_1(\Omega)$ such that for each $(s, x) \in \Sigma$, $H(s, x) \in \mathcal{R}_{s,x}^o$, where*

$$\mathcal{R}_{s,x}^o = \{P \in \mathcal{R}_{s,x}, \ J(s, P) = W(s, x)\}.$$

We call H a *measurable selector* of $\mathcal{R}^o$.

3. The dynamic programming principle. In this section we will apply the method used in Haussmann [6], Haussmann and Lepeltier [7], and El Karoui, Nguyen, and Jeanblanc-Picqué [3] to establish the dynamic programming principle. Note that this method does not require any regularity of the value function W.

3.1. Some preparations. We denote by $\mathcal{F}^s$ the σ-algebra of events that occur after time s, i.e., $\mathcal{F}^s = \sigma\{\omega_t, s \le t \le T\}$.

Define $\Theta_{s,\bar{\omega}} : \Omega \mapsto \Omega$ by

$$\Theta_{s,\bar{\omega}}(\omega)_t = \begin{cases} \bar{\omega}_t, & 0 \le t \le s, \\ (x_t, \mu_t, \bar{v}_s + v_t - v_s), & s < t \le T. \end{cases} \tag{3.1}$$

Note that if $\tilde{\omega} = \Theta_{s,\bar{\omega}}(\omega)$, then $\tilde{\omega} = \bar{\omega}$ on $[0,s]$, $(x.(\tilde{\omega}), \mu.(\tilde{\omega})) = (x.(\omega), \mu.(\omega))$ on $(s,T]$, and $v.(\tilde{\omega}) - v_s(\tilde{\omega}) = v.(\omega) - v_s(\omega)$ on $[s,T]$.

LEMMA 3.1. *If P is a probability on $(\Omega, \mathcal{F}^s)$ $(0 \le s \le T)$ and $\bar{\omega} \in \Omega$, then there exists a unique probability measure, denoted by $\delta_{\bar{\omega}} \otimes_s P$ on $(\Omega, \mathcal{F})$ such that*

$$\delta_{\bar{\omega}} \otimes_s P(\omega : \omega_t = \bar{\omega}_t, 0 \le t \le s) = 1, \tag{3.2}$$

$$\delta_{\bar{\omega}} \otimes_s P(A) = P(\Theta^{-1}_{s,\bar{\omega}}(A)) \quad \forall\, A \in \mathcal{F}^s, \tag{3.3}$$

where by $\omega_t = \bar{\omega}_t$, $0 \le t \le s$, we mean $x_t = \bar{x}_t$, $v_t = \bar{v}_t$, $0 \le t \le s$, and $\mu_t = \bar{\mu}_t$ a.e. on $[0,s]$.

Proof. The uniqueness of such a probability measure is obvious, so we only need to show its existence.

If I is a subinterval of $[0,T]$ we write $V(I)$ for the set of measurable functions

$$I \mapsto \mathbb{M}_1(U).$$

Let us recall an equivalent definition of the stable topology on $\mathcal{U} = V([0,T])$. For $\mu \in \mathcal{U}$ define a mapping $i : \mathcal{U} \mapsto C([0,T], \mathbb{M}_+(U))$ by

$$i(\mu)(\cdot) = \int_0^{\cdot} \mu_\theta \, d\theta.$$

The topology on $\mathcal{U}$ induced by i is exactly the stable topology we introduced in Haussmann and Suo [8]. For a discussion of this see Haussmann and Lepeltier [7, §3.10]. Similarly, we can consider the topology on $V(I)$ induced by the mapping

$$i_I(\mu)(\cdot) = \int_0^{\cdot} \mathbf{1}_I(\theta)\mu_\theta d\theta \in C([0,T], \mathbb{M}_+(U)), \quad \mu \in V(I).$$

Write $\mathcal{A}^k_I$ for the $\mathbb{R}^k_+$-valued nondecreasing functions on I with the inherited topology from $\mathcal{A}^k[0,T]$. Let

$$\begin{aligned} X_0 &\equiv \mathcal{D}^d[0,s] \times i_{[0,s]}V([0,s]) \times \mathcal{A}^k_{[0,s]}, \\ X &\equiv \mathcal{D}^d[s,T] \times i_{[s,T]}V([s,T]) \times \mathcal{A}^k_{[s,T]}, \\ \tilde{X} &\equiv X_0 \times X, \end{aligned}$$

and define $\Phi_0 : \Omega \mapsto X_0$, $\Phi : \Omega \mapsto X$ by

$$\Phi_0(\omega)_t = \left(x_t, \int_0^t \mu_\theta d\theta, v_t\right), \quad 0 \le t \le s,$$

$$\Phi(\omega)_{t'} = \left(x_{t'}, \int_s^{t'} \mu_\theta d\theta, v_{t'}\right), \quad s \le t' \le T,$$

where $\omega = (x, \mu, v) \in \Omega$. Define $\Psi : \tilde{X} \mapsto \Omega$ by

$$\Psi(\omega_1, \omega_2) = \Theta_{s,\tau_0(\omega_1)}(\tau(\omega_2)),$$

where $\tau_0 :\ X_0 \mapsto \Omega,\ \tau :\ X \mapsto \Omega$:

$$\begin{aligned}\tau_0(\tilde{\omega})_t &= (\tilde{x}_{t\wedge s}, i^{-1}_{[0,s]}(\tilde{\mu})(t \wedge s), \tilde{v}_{t\wedge s}),\\ \tau(\omega)_t &= (x_{t\vee s}, i^{-1}_{[s,t]}(\mu)(t \vee s), v_{t\vee s})\end{aligned}$$

with $\tilde{\omega} = (\tilde{x}, \tilde{\mu}, \tilde{v}) \in X_0$, $\omega = (x, \mu, v) \in X$.

We define a probability $\tilde{P}$ on $\tilde{X}$ by $\tilde{P} = \delta_{\bar{\omega}} \circ \Phi_0^{-1} \times P \circ \Phi^{-1}$, and let

$$\bar{P} = \tilde{P} \circ \Psi^{-1}.$$

Now we verify that $\bar{P}$ satisfies conditions (3.2) and (3.3). Note that $\tau_0 \circ \Phi_0(\bar{\omega})_t = \bar{\omega}_t,\ 0 \le t \le s$, so we have

$$\begin{aligned}\bar{P}(\omega :\ \omega_t = \bar{\omega}_t,\ 0 \le t \le s) &= \tilde{P}((\omega_1, \omega_2) :\ \Theta_{s,\tau_0(\omega_1)}(\tau(\omega_2))_t = \bar{\omega}_t,\ \ 0 \le t \le s)\\ &= \tilde{P}((\omega_1, \omega_2) :\ \tau_0(\omega_1)_t = \bar{\omega}_t,\ \ 0 \le t \le s)\\ &= \delta_{\bar{\omega}}(\omega_1 :\ \tau_0 \circ \Phi_0(\omega_1)_t = \bar{\omega}_t,\ 0 \le t \le t)\\ &= 1.\end{aligned}$$

For $A \in \mathcal{F}^s$,

$$\begin{aligned}\bar{P}(A) &= \tilde{P}((\omega_1, \omega_2) :\ \Psi(\omega_1, \omega_2) \in A)\\ &= \tilde{P}((\omega_1, \omega_2) :\ \Theta_{s,\tau_0(\omega_1)}(\tau(\omega_2)) \in A)\\ &= \tilde{P}((\omega_1, \omega_2) :\ \tau(\omega_2) \in \Theta^{-1}_{s,\tau_0(\omega_1)}(A))\\ &= \int_{X_0} P \circ \Phi^{-1}(\omega_2 :\ \tau(\omega_2) \in \Theta^{-1}_{s,\tau_0(\omega_1)}(A))\, \delta_{\bar{\omega}} \circ \Phi_0^{-1}(d\omega_1)\\ &= \int_{X_0} P(\omega :\ \tau \circ \Phi(\omega) \in \Theta^{-1}_{s,\tau_0(\omega_1)}(A))\, \delta_{\Phi_0(\bar{\omega})}(d\omega_1)\\ &= P(\omega :\ \tau \circ \Phi(\omega) \in \Theta^{-1}_{s,\tau_0(\Phi_0(\bar{\omega}))}(A))\\ &= P(\Theta^{-1}_{s,\bar{\omega}}(A)),\end{aligned}$$

since $\tau \circ \Phi(\omega)_t = \omega_t$ holds on $[s, T]$. The lemma is proved by letting $\delta_{\bar{\omega}} \otimes_s P = \bar{P}$. □

Remark 3.2. Note that for $P \in \mathcal{R}_{s,x}$, there exists a P-null set N_0 such that if $\bar{\omega} \notin N_0$, $A \in \mathcal{F}^s$, then $P(A) = P \circ \Theta^{-1}_{s,\bar{\omega}}(A)$ and

$$E^P\left\{\int_s^t h(\theta) \cdot dv_\theta\right\} = E^{P\circ\Theta^{-1}_{s,\bar{\omega}}}\left\{\int_s^t h(\theta) \cdot dv_\theta\right\},\quad t \ge s$$

for any bounded $\mathbb{R}^k$-valued Borel-measurable function $h(\cdot)$. These properties will be used repeatedly in the rest of this section.

Assume that τ is an $\mathcal{F}_t$-stopping time, $0 \le \tau \le T$. A τ-transition probability (τ-t.p.) is a family $\{Q_\omega :\ \omega \in \Omega\}$ of probability measures on $(\Omega, \mathcal{F})$ such that

$$\omega \mapsto Q_\omega(A) \text{ is } \mathcal{F}_\tau \text{ measurable } \forall\, A \in \mathcal{F}.$$

Note that $\mathcal{F}_\tau$ is the collection of sets A such that $A\bigcap\{\tau \le t\} \in \mathcal{F}_t\ \forall\, t \le T$. For a fixed τ and ω such that $\tau(\omega) \le T$, we denote by $\mathcal{F}^{\tau(\omega)}$ the σ-field generated by the sets of the form

$$\left\{\tilde{\omega} \in \Omega :\ \tilde{x}_t \in A,\ \int_{\tau(\omega)}^t \tilde{\mu}_\theta d\theta \in B,\ \tilde{v}_t \in C\right\}, \tag{3.4}$$

where $A \in \mathcal{B}(I\!\!R^d)$, $B \in \mathcal{B}(I\!\!M_+(U))$, $C \in \mathcal{B}(I\!\!R^k)$, $\tau(\omega) \le t \le T$, so $\mathcal{F}^{\tau(\omega)}$ is the collection of events that occur after the time $\tau(\omega)$. Note that the topology on Ω is separable, so $\mathcal{F}_t$ is countably generated, and for a given probability P on $(\Omega, \mathcal{F})$, the regular conditional probability distribution (r.c.p.d.) of P for given $\mathcal{F}_\tau$ exists and will be denoted by $P_{\tau,\omega}$.

Given a stopping time τ $(0 \le \tau \le T)$ and a τ-t.p. Q_ω, if $\bar{\omega} \in \Omega$, then from Lemma 3.1 we know that there exists a unique $\delta_{\bar{\omega}} \otimes_\tau Q_\omega \in I\!\!M_1(\Omega)$ such that

$$\begin{aligned}&\delta_{\bar{\omega}} \otimes_\tau Q_\omega\{\tilde{\omega} : \tilde{\omega}_t = \bar{\omega}_t, 0 \le t \le \tau(\omega)\} = 1,\\ &\delta_{\bar{\omega}} \otimes_\tau Q_\omega(A) = Q_\omega(\Theta^{-1}_{\tau_\omega,\bar{\omega}}(A)) \quad \forall\, A \in \mathcal{F}^{\tau(\omega)}.\end{aligned}$$

We write $\delta_\omega \otimes_\tau Q_\omega = Q^\tau_\omega$. When $\bar{\omega} = (x(\tau(\omega)), \delta^0, 0)$, we write

$$\delta_{\bar{\omega}} \otimes_\tau Q_\omega = \overset{\circ}{Q}{}^\tau_\omega\ .$$

It can be seen easily that for $s \le T$ and a stopping time $\tau : s \le \tau \le T$,

$$Q_\omega(\Gamma_{\tau(\omega)}) = Q^\tau_\omega(\Gamma_{\tau(\omega)}) = \overset{\circ}{Q}{}^\tau_\omega\ (\Gamma_{\tau(\omega)}), \tag{3.5}$$

where Γ is defined by (2.5).

If $P \in I\!\!M_1(\Omega)$, τ is a stopping time, and $\{Q_\omega\}$ is a τ-t.p., then we have the following result, which is analogous to Theorem 6.1.2 in Stroock and Varadhan [11].

LEMMA 3.3. *There exists a unique probability, denoted by $P \otimes_\tau Q$, such that*

(1) $P \otimes_\tau Q(A) = P(A)$ if $A \in \mathcal{F}_\tau$,

(2) the r.c.p.d. of $P \otimes_\tau Q$ with respect to $\mathcal{F}_\tau$ is Q^τ_ω.

Proof. The proof of [11, Thm. 6.1.2] can be adopted here with minor modifications (cf. Suo [12]). □

LEMMA 3.4. *Assume $P \in \mathcal{R}_{s,x}$, τ is an $\mathcal{F}_t$-stopping time: $s \le \tau \le T$, and $\bar{\omega} \in \Omega$. Then $(M_t\phi, \mathcal{F}_t, P \circ \Theta^{-1}_{\tau_{\bar{\omega}},\bar{\omega}})$ is a martingale after $\tau_{\bar{\omega}}$ for $\phi \in C^2_b(I\!\!R^d)$.*

Proof. Since $P \in \mathcal{R}_{s,x}$, we know that $(M_t\phi, \mathcal{F}_t, P)$ is a martingale, i.e.,

$$\int_A M_t\phi dP = \int_A M_u\phi dP \ \ \forall\, A \in \mathcal{F}_u, \ \ s \le u < t \le T, \tag{3.6}$$

or

$$E^P\left\{1_A(\cdot)\left[M_t\phi(\cdot) - M_u\phi(\cdot)\right]\right\} = 0. \tag{3.7}$$

When $t \ge \tau_{\bar{\omega}}$, we have

$$\begin{aligned} M_t\phi(\Theta_{\tau_{\bar{\omega}},\bar{\omega}}(\omega)) = \phi(x_t) &- \int_{\tau_{\bar{\omega}}}^t \mathcal{L}\phi(\theta, x_\theta, \mu_\theta)d\theta - \int_{\tau_{\bar{\omega}}}^t \nabla_x\phi(x_\theta)\cdot g(\theta)dv^c_\theta\\ &- \sum_{\tau_{\bar{\omega}}<\theta<t} [\phi(x_{\theta+}) - \phi(x_\theta)] - [\phi(x_{\tau+}) - \phi(\bar{x}_\tau)]\\ &- \int_s^{\tau_{\bar{\omega}}} \mathcal{L}\phi(\theta, \bar{x}_\theta, \bar{\mu}_\theta)d\theta - \int_s^{\tau_{\bar{\omega}}} \nabla_x\phi(\bar{x}_\theta)\cdot g(\theta)d\bar{v}^c_\theta\\ &- \sum_{s\le\theta<\tau_{\bar{\omega}}} [\phi(\bar{x}_{\theta+}) - \phi(\bar{x}_\theta)]\,. \end{aligned}$$

Therefore we can get for $\tau_{\bar{\omega}} \le u \le t \le T$, $A \in \mathcal{F}_u$,

$$\begin{aligned}
&E^{P\circ\Theta^{-1}_{\tau_{\bar{\omega}},\bar{\omega}}} \{1_A(\cdot)\,[M_t\phi(\cdot) - M_u\phi(\cdot)]\} \\
&= E^P\{1_A(\Theta_{\tau_{\bar{\omega}},\bar{\omega}}(\cdot))\,[M_t\phi(\Theta_{\tau_{\bar{\omega}},\bar{\omega}}(\cdot)) - M_u\phi(\Theta_{\tau_{\bar{\omega}},\bar{\omega}}(\cdot))]\} \\
&= E^P\{1_A(\Theta_{\tau_{\bar{\omega}},\bar{\omega}}(\cdot))\,[M_t\phi(\cdot) - M_u\phi(\cdot)]\} \\
&= 0,
\end{aligned}$$

because it is obvious that $\Theta^{-1}_{\tau_{\bar{\omega}},\bar{\omega}}(A) \in \mathcal{F}_u$. The lemma is thus proved. □

Recall that for a stopping time τ, $P_{\tau,\omega}$ denotes the regular conditional probability distribution of P given $\mathcal{F}_\tau$. $P_{\tau,\omega}$ is obviously a τ-t.p., so $\overset{\circ}{P}{}^{\tau}_{\omega} \equiv \delta_{\bar{\omega}} \otimes_\tau P_{\tau,\omega}$ is defined, where $\bar{\omega} = (x(\tau(\omega)), \delta^0, 0)$.

LEMMA 3.5. *If $(M_t, \mathcal{F}_t, P)$ is a martingale and τ is an $\mathcal{F}_t$-stopping time then there is a P-null set $N \in \mathcal{F}_\tau$ such that for $\omega \notin N$, $(M_t, \mathcal{F}_t, P_{\tau,\omega})$ is a martingale for $t \ge \tau_\omega$.*

Proof. The proof is comparable to that of Stroock and Varadhan [11, Thm. 1.2.10.] □

COROLLARY 3.6. *If $P \in \mathcal{R}_{s,x}$ and τ is an $\mathcal{F}_t$-stopping time, then there is a P-null set $N \in \mathcal{F}_\tau$ such that for $\omega \notin N$, $(M_t\phi, \mathcal{F}_t, P_{\tau,\omega} \circ \Theta^{-1}_{\tau_\omega,\omega})$ is a martingale for $t \ge \tau_\omega$ when $\phi \in C_b^2(I\!R^d)$.*

Proof. The proof is obvious from Lemmas 3.4 and 3.5. □

The next two results are important for the rest of the paper. The first one states that a control rule remains a control rule for the problem starting at a later time from the point reached at that time. The second one says that if we take a control rule and at some later time switch to another control rule, then this concatenated object is still a control rule.

PROPOSITION 3.7 (closure under conditioning). *If $P \in \mathcal{R}_{s,x}$ and τ is a stopping time, $s \le \tau \le T$, then there exists a P-null set $N \in \mathcal{F}_\tau$ such that $\overset{\circ}{P}{}^{\tau}_{\omega} \in \mathcal{R}_{\tau_\omega, x_{\tau_\omega}}$ for $\omega \notin N$.*

Proof. Let $\{\phi_m\}$ be a dense subset of $C_0^\infty(I\!R^d)$. Then for each m, $(M_t\phi_m - M_{t\wedge\tau}\phi_m, \mathcal{F}_t, P)$ $(t \ge s)$ is a martingale. For $\bar{\omega} \in \Omega$ define

$$\begin{aligned}
\bar{M}_t^{\bar{\omega}}\phi_m = \phi(x_t) - \phi(x_{t\wedge\tau_{\bar{\omega}}}) &- \int_{t\wedge\tau_{\bar{\omega}}}^t \mathcal{L}\phi_m(\theta, x_\theta, \mu_\theta)d\theta \\
&- \int_{t\wedge\tau_{\bar{\omega}}}^t \nabla_x\phi_m(x_\theta)\cdot g(\theta)dv_\theta^c - \sum_{t\wedge\tau_{\bar{\omega}} \le \theta < t} [\phi_m(x_{\theta+}) - \phi(x_\theta)].
\end{aligned}$$

Then, by Lemma 3.5 there exists a P-null set $N_m \in \mathcal{F}_\tau$ such that $(\bar{M}_t^{\bar{\omega}}\phi_m, \mathcal{F}_t, P_{\tau,\bar{\omega}})$ is a martingale for $\bar{\omega} \notin N_m$. By Lemma 3.4 we know that $(\bar{M}_t^{\bar{\omega}}\phi_m, \mathcal{F}_t, P_{\tau,\bar{\omega}} \circ \Theta^{-1}_{\tau,\bar{\omega}})$ is a martingale for $t \ge \tau_{\bar{\omega}}$, $\bar{\omega} \notin N_m$. Certainly, $(\bar{M}^{\bar{\omega}}_{t\wedge\tau_{\bar{\omega}}}\phi_m, \mathcal{F}_t, \delta_{\bar{\omega}'})$ is a martingale, where $\bar{\omega}' = (\bar{x}_{\tau_{\bar{\omega}}}, \delta^0, 0)$. Therefore $(\bar{M}_{t\wedge\tau_{\bar{\omega}}}\phi_m, \mathcal{F}_t, \overset{\circ}{P}{}^{\tau}_{\omega})$ is a martingale. It is obvious from the definition that

$$\overset{\circ}{P}{}^{\tau}_{\bar{\omega}}\,(\omega :\ x_r = \bar{x}_{\tau_{\bar{\omega}}},\ \mu_r = \delta^0,\ v_r = 0,\ 0 \le r \le \tau_{\bar{\omega}}) = 1.$$

Let $N = \bigcup_m N_m$; then $P(N) = 0$. Through a limit procedure we can show that $\overset{\circ}{P}{}^{\tau}_{\omega} \in \mathcal{R}_{\tau_\omega, x_{\tau_\omega}}$ for $\omega \notin N$. □

PROPOSITION 3.8 (closure under concatenation). *Let $P \in \mathcal{R}_{s,x}$ and τ be a stopping time such that $s \leq \tau \leq T$. If Q_ω is a transition probability such that $Q_\omega \in \mathcal{R}_{\tau(\omega),x(\tau(\omega))}$, then*

$$P \otimes_\tau Q \in \mathcal{R}_{s,x}.$$

Proof. It is obvious that we need only to show that for each $\phi \in C_b^2(\mathbb{R}^d)$, $(M_t\phi, \mathcal{F}_t, P \otimes_\tau Q)$ is a martingale after time s. From Remark 3.2 and the fact that $Q_\omega \in \mathcal{R}_{\tau(\omega),x(\tau(\omega))}$, it can be easily verified that $(M_t\phi, \mathcal{F}_t, \delta_\omega \otimes_\tau Q_\omega)$ is a martingale after time τ. By definition we know that $Q_\omega^\tau = \delta_\omega \otimes_\tau Q_\omega$ equals the regular conditional probability distribution of $P \otimes_\tau Q$ given $\mathcal{F}_\tau$. The proof of the proposition now follows Theorem 1.2.10 in Stroock and Varadhan [11]. □

Set $Q_\omega = H(\tau(\omega), x(\tau(\omega)))$, where H is a measurable selector of $\mathcal{R}^o$ and, by definition, it is a τ-t.p. We denote

$$P \otimes_\tau H = P \otimes_\tau Q_\omega.$$

COROLLARY 3.9. *For P in $\mathcal{R}_{s,x}$ we have $P \otimes_\tau H \in \mathcal{R}_{s,x}$.*

3.2. The dynamic programming principle. With the preparations of §3.1, we can now establish the dynamic programming principle.

For a given probability $P \in \mathcal{R}_{s,x}$, define $\mathcal{R}_{s,x}^\tau(P)$ to be the set of probabilities in $\mathcal{R}_{s,x}$ which coincide with P up to time τ, i.e.,

$$\mathcal{R}_{s,x}^\tau(P) = \{P \otimes_\tau Q : \quad Q_\omega \in \mathcal{R}_{\tau_\omega, x_{\tau_\omega}} \text{ such that } Q_\omega \text{ is a } \tau - \text{t.p.}\} \subset \mathcal{R}_{s,x}.$$

We introduce the following notation: for a measurable function $\phi \in \mathcal{B}(\Sigma)$, let

$$\Gamma_s(t, \phi)(\omega) = \int_s^t f(\theta, x_\theta, \mu_\theta) d\theta + \int_s^t c(\theta) \cdot dv(\theta) + \phi(t, x_t),$$

where $\omega = (x, \mu, v) \in \Omega$.

THEOREM 3.10 (dynamic programming principle). (a) *If τ is an $\mathcal{F}_t$-stopping time, $s \leq \tau \leq T$, and $P \in \mathcal{R}_{s,x}$, then*

$$\begin{aligned} E^P \left\{ \int_s^\tau f(\theta, x_\theta, \mu_\theta) d\theta + \int_s^\tau c(\theta) \cdot dv_\theta + W(\tau, x_\tau) \right\} \\ = \inf \left\{ \hat{P}(\Gamma_s) : \hat{P} \in \mathcal{R}_{s,x}^\tau(P) \right\}, \end{aligned} \tag{3.8}$$

where $\Gamma_s(\cdot)$ is defined by (2.5).

(b) *For $P \in \mathcal{R}_{s,x}$, $(\Gamma_s(t, W), \mathcal{F}_t, P)$ is a submartingale.*

(c) *If $s \leq \tau \leq T$, then*

$$W(s, x) = \inf \{P\Gamma_s(\tau, W), P \in \mathcal{R}_{s,x}\}. \tag{3.9}$$

(d) *$(\Gamma_s(t, W), \mathcal{F}_t, P)$ is a martingale under P if and only if $P \in \mathcal{R}_{s,x}$ is optimal.*

Proof. (a) Recall that H denotes a measurable selector of $\mathcal{R}^o$; therefore, by (3.3) and Remark 3.2 the left-hand side (LHS) of (3.8) is

$$\begin{aligned} &E^P \left\{ \int_s^\tau f(\theta, x_\theta, \mu_\theta) d\theta + \int_s^\tau c(\theta) \cdot dv_\theta + H(\tau(\cdot), x_\tau(\cdot))\Gamma_\tau \right\} \\ &= E^P \left\{ \int_s^\tau f(\theta, x_\theta, \mu_\theta) d\theta + \int_s^\tau c(\theta) \cdot dv_\theta + \delta_. \otimes_\tau H(\Gamma_\tau) \right\} \\ &= P \otimes_\tau H(\Gamma_s), \end{aligned}$$

and by Proposition 3.8 we know that $P \otimes_\tau H \in \mathcal{R}^\tau_{s,x}(P)$. Hence, in (3.8) LHS $\geq$ RHS. On the other hand, for $\hat{P} = P \otimes_\tau Q \in \mathcal{R}^\tau_{s,x}(P)$,

$$\begin{aligned}
\hat{P}(\Gamma_s) &= P \otimes_\tau Q(\Gamma_s) \\
&= E^P \left\{ \int_s^\tau f(\theta, x_\theta, \mu_\theta) d\theta + \int_s^\tau c(\theta) \cdot d\nu_\theta + Q_\cdot(\Gamma_\tau) \right\} \\
&\geq E^P \left\{ \int_s^\tau f(\theta, x_\theta, \mu_\theta) d\theta + \int_s^\tau c(\theta) \cdot d\nu_\theta + W(\tau(\cdot), x_\tau(\cdot)) \right\} \\
&= \text{LHS of (3.8)},
\end{aligned}$$

so the proof of (a) is completed.

(b) For any $s \leq t < t + h$, we have

$$\begin{aligned}
&E^P\{\Gamma_s(t+h, W) - \Gamma_s(t, W) | \mathcal{F}_t\} \\
&= E^P \left\{ \int_s^{t+h} f(\theta, x_\theta, \mu_\theta) d\theta + \int_s^{t+h} c(\theta) \cdot d\nu_\theta + W(t+h, x_{t+h}) \right. \\
&\qquad \left. - \left[\int_s^t f(\theta, x_\theta, \mu_\theta) d\theta + \int_s^t c(\theta) \cdot d\nu_\theta + W(t, x_t) \right] \middle| \mathcal{F}_t \right\} \\
&= E^P \left\{ \int_t^{t+h} f(\theta, x_\theta, \mu_\theta) d\theta + \int_t^{t+h} c(\theta) \cdot d\nu_\theta + W(t+h, x_{t+h}) \middle| \mathcal{F}_t \right\} - W(t, x_t) \\
&= P_{t,\omega} \Gamma_t(t+h, W) - W(t, x_t) \\
&= \overset{\circ}{P}{}^t_\omega \, \Gamma_t(t+h, W) - W(t, x_t)
\end{aligned}$$

by Lemma 3.3(2). Now we apply (3.8) and the fact that $\mathcal{R}^{t+h}_{t,x_t}(\overset{\circ}{P}{}^t_\omega) \subset \mathcal{R}_{t,x_t}$, i.e., Proposition 3.7, to get

$$\begin{aligned}
&E^P\{\Gamma_s(t+h, W) - \Gamma_s(t, W) | \mathcal{F}_t\} \\
&= \inf \left\{ \hat{P}\Gamma_t : \hat{P} \in \mathcal{R}^{t+h}_{t,x_t}(\overset{\circ}{P}{}^t_\omega) \right\} - W(t, x_t) \\
&\geq \inf \left\{ \hat{P}\Gamma_t : \hat{P} \in \mathcal{R}_{t,x_t} \right\} - W(t, x_t) \\
&= 0.
\end{aligned}$$

Therefore $(\Gamma_s(t, W), \mathcal{F}_t, P)$ is a submartingale.

(c) Let $\nu(d\theta dx)$ be the distribution of (τ, x_τ) under P. Then

$$\begin{aligned}
E^P W(\tau, x_\tau) &= \int W(\theta, x) \nu(d\theta dx) \\
&= \int J(\theta, H(\theta, x)) \nu(d\theta dx) \\
&= E^P J(\tau, H(\tau, x_\tau)) \\
&= J(\tau, P \otimes_\tau H).
\end{aligned}$$

Note that

$$E^P \Gamma_s(\tau, W) = E^P \left\{ \int_s^\tau f(\theta, x_\theta, \mu_\theta) d\theta + \int_s^\tau c(\theta) \cdot d\nu_\theta \right\} + E^P W(\tau, x_\tau)$$

$$\begin{aligned}
&= E^P\left\{\int_s^\tau f(\theta,x_\theta,\mu_\theta)d\theta + \int_s^\tau c(\theta)\cdot dv_\theta\right\} + J(\tau, P\otimes_\tau H)\\
&= J(s, P\otimes_\tau H)\\
&\geq \inf\left\{J(s,Q), Q \in \mathcal{R}_{s,x}\right\}\\
&= W(s,x).
\end{aligned}$$

On the other hand, $E^P W(\tau, x_\tau) \leq E^P J(\tau, \overset{\circ}{P^\tau_\omega}) = E^P J(\tau, P^\tau_\omega) = J(\tau, P)$ and, therefore, by (b),

$$\begin{aligned}
(3.10)\qquad W(s,x) &\leq E^P\Gamma_s(\tau, W)\\
&= E^P\left\{\int_s^\tau f(\theta,x_\theta,\mu_\theta)d\theta + \int_s^\tau c(\theta)\cdot dv_\theta\right\} + E^P W(\tau, x_\tau)\\
&\leq E^P\left\{\int_s^\tau f(\theta,x_\theta,\mu_\theta)d\theta + \int_s^\tau c(\theta)\cdot dv_\theta\right\} + J(\tau, P)\\
&= J(s,P),
\end{aligned}$$

and thus (c) is proved if we take the infimum over $P \in \mathcal{R}_{s,x}$ on the right-hand side (RHS).

(d) If $\Gamma_s(t, W)$ is a P-martingale, then

$$W(s,x) = E^P\Gamma_s(s,W) = E^P\Gamma_s(T,W) = E^P\Gamma_s(T,0) = E^P\Gamma_s = J(s,P),$$

because from our assumptions, $W(T,\cdot) = 0$. So P is optimal.

If we assume that $P \in \mathcal{R}_{s,x}$ is optimal, then by (3.10), Proposition 3.7, and Corollary 3.6,

$$(3.11)\qquad W(s,x) \leq E^P\Gamma_s(t,W) = E^P\Gamma_s = W(s,x).$$

Therefore $(\Gamma_s(t,W), \mathcal{F}_t, P)$ is a submartingale with constant mean value, so it is indeed a martingale. □

4. Continuity of the value function.

In the rest of the paper we add the following assumptions:

- $c(\cdot)$ is Lipschitz continuous, $f(\cdot,\cdot,\cdot)$ is bounded, and $g = (g^{ij})$ is a constant $d \times k$-matrix;
- $f(\cdot,\cdot,\cdot)$, $b(\cdot,\cdot,\cdot)$, $\sigma(\cdot,\cdot,\cdot)$ satisfy the following conditions:

$$(4.1)\qquad \begin{aligned}
|f(t,x,u) - f(s,y,u)| &\leq C(|t-s| + \|x-y\|),\\
\|b(t,x,u) - b(s,y,u)\| &\leq C(|t-s| + \|x-y\|),\\
\|\sigma(t,x,u) - \sigma(s,y,u)\| &\leq C(|t-s| + \|x-y\|)
\end{aligned}$$

uniformly for $0 \leq s,t \leq T$, x, $y \in I\!R^d$, $u \in U$.

We will prove that under these conditions the value function $W(\cdot,\cdot)$ is uniformly continuous on Σ. In fact, there exists a constant $C \geq 0$ such that

$$|W(t,x) - W(s,y)| \leq C\left(|t-s|^{\frac{1}{2}} + \|x-y\|\right),\ 0 \leq s,t \leq T,\ x,y \in I\!R^d.$$

Note that the constancy of g is only required in the proof of Theorem 4.2.

THEOREM 4.1. *The value function $W(s,x)$ is uniformly Lipschitz continuous in the state variable x, i.e., there exists a constant $C > 0$ such that*

$$(4.2)\qquad |W(s,x') - W(s,x)| \leq C\|x' - x\|\ \forall 0 \leq t \leq T,\ x,\ x' \in I\!R^d.$$

Proof. In the following, we use the same notation C to denote the constants, which may change from time to time. For any $0 \le s \le T$, x, $x' \in I\!R^d$,

$$W(s,x') - W(s,x) \le \sup_{P \in \mathcal{R}_{s,x}} (E^Q \Gamma_s - E^P \Gamma_s)$$

for each $Q \in \mathcal{R}_{s,x'}$, where Γ is the cost function defined by (2.5).

Take an arbitrary $P \in \mathcal{R}_{s,x}$. By the definition of control rules, there exists a standard extension $(\tilde{\Omega}, \tilde{\mathcal{F}}, \tilde{\mathcal{F}}_t, \tilde{P})$ of $(\Omega, \mathcal{F}, \mathcal{F}_t, P)$, i.e., there exists another probability space $(\Omega', \mathcal{F}', \mathcal{F}'_t, P')$ such that $\tilde{\Omega} = \Omega \times \Omega'$, $\tilde{\mathcal{F}} = \mathcal{F} \times \mathcal{F}'$, $\tilde{\mathcal{F}}_t = \mathcal{F}_t \times \mathcal{F}'_t$, and $\tilde{P} = P \times P'$. We can extend the processes $x_\cdot, \mu_\cdot, v_\cdot$ to $\tilde{\Omega}$ by the following: for $\tilde{\omega} = (\omega, \omega') \in \tilde{\Omega}$,

$$x_\cdot(\tilde{\omega}) = x_\cdot(\omega),\ \mu_\cdot(\tilde{\omega}) = \mu_\cdot(\omega),\ v_\cdot(\tilde{\omega}) = v_\cdot(\omega).$$

On $(\tilde{\Omega}, \tilde{\mathcal{F}}, \tilde{\mathcal{F}}_t, \tilde{P})$ there exists a standard d-dimensional Brownian motion $B_\cdot$ such that for $s \le t \le T$,

$$x_t = x + \int_s^t b(\theta, x_\theta, \mu_\theta) d\theta + \int_s^t \sigma(\theta, x_\theta, \mu_\theta) dB_\theta + g v_t \quad \text{a.s.} \tag{4.3}$$

Consider the same equation (4.3) with the initial state x', i.e.,

$$y_t = x' + \int_s^t b(\theta, y_\theta, \mu_\theta) d\theta + \int_s^t \sigma(\theta, y_\theta, \mu_\theta) dB_\theta + g v_t \tag{4.4}$$

on the stochastic basis $(\tilde{\Omega}, \tilde{\mathcal{F}}, \tilde{\mathcal{F}}_t, \tilde{P})$. The strong solution for (4.4) exists from the assumptions on $b(\cdot,\cdot,\cdot)$ and $\sigma(\cdot,\cdot,\cdot)$, and so $\alpha \equiv (\tilde{\Omega}, \tilde{\mathcal{F}}, \tilde{\mathcal{F}}_t, \tilde{P}, y_t, \mu_t, v_t, s, x') \in \tilde{\Lambda}_{s,x'}$. Therefore, there exists a control rule $Q \in \mathcal{R}_{s,x'}$ such that

$$J(\alpha) = J(s,Q) \doteq E^Q \Gamma_s. \tag{4.5}$$

By definition,

$$\begin{aligned} E^P \Gamma_s &= E^P \left\{ \int_s^T f(\theta, x_\theta, \mu_\theta) d\theta + \int_s^T c(\theta) \cdot dv_\theta \right\} \\ &= E^{\tilde{P}} \left\{ \int_s^T f(\theta, x_\theta, \mu_\theta) d\theta + \int_s^T c(\theta) \cdot dv_\theta \right\}, \end{aligned}$$

and, by (4.5),

$$E^Q \Gamma_s = E^{\tilde{P}} \left\{ \int_s^T f(\theta, y_\theta, \mu_\theta) d\theta + \int_s^T c(\theta) \cdot dv_\theta \right\};$$

therefore, from the Lipschitz continuity of f we have

$$\begin{aligned} E^Q \Gamma_s - E^P \Gamma_s &\le E^{\tilde{P}} \left\{ \int_s^T |f(\theta, y_\theta, \mu_\theta) - f(\theta, x_\theta, \mu_\theta)| d\theta \right\} \\ &\le C E^{\tilde{P}} \int_s^T \|y_\theta - x_\theta\| d\theta \\ &\le C \left(\int_s^T E^{\tilde{P}} \|y_\theta - x_\theta\|^2 d\theta \right)^{\frac{1}{2}}. \end{aligned}$$

Now, from equations (4.3), (4.4), and the Lipschitz continuity conditions on b, σ, we have for $\theta \geq s$,

$$\begin{aligned} E^{\tilde{P}}\|y_\theta - x_\theta\|^2 &\leq C\|x' - x\|^2 + CE^{\tilde{P}}\left(\int_s^\theta \|b(h, y_h, \mu_h) - b(h, x_h, \mu_h)\|\,dh\right)^2 \\ &\quad + CE^{\tilde{P}}\sup_{\theta' \leq \theta}\left\|\int_s^{\theta'} (\sigma(h, y_h, \mu_h) - \sigma(h, x_h, \mu_h))\,dB_h\right\|^2 \\ &\leq C\|x' - x\|^2 + CE^{\tilde{P}}\int_s^\theta \|b(h, y_h, \mu_h) - b(h, x_h, \mu_h)\|^2 dh \\ &\quad + CE^{\tilde{P}}\int_s^\theta \|\sigma(h, y_h, \mu_h) - \sigma(h, x_h, \mu_h)\|^2 dh \\ &\leq C\left(\|x' - x\|^2 + \int_s^\theta E^{\tilde{P}}\|y_h - x_h\|^2 dh\right). \end{aligned}$$

We have used the Burkholder–Gundy inequality to get the second inequality. By Gronwall's inequality,

$$E^{\tilde{P}}\|y_\theta - x_\theta\|^2 \leq C\|x' - x\|^2 e^{C(\theta - s)} \leq C\|x' - x\|^2.$$

Hence we have

$$E^Q\Gamma_s - E^P\Gamma_s \leq C\|x' - x\|$$

and, therefore, $W(s, x,) - W(s, x) \leq C\|x' - x\|$.

The proof of the theorem is thus complete since x, $x' \in I\!R^d$ are arbitrary. □

Next we consider the continuity of the value function in the time variable t.

THEOREM 4.2. *The value function $W(t, x)$ is uniformly continuous in the time variable t. In fact, there exists a constant $C > 0$ such that*

$$|W(s, x) - W(s', x)| \leq C\,|s - s'|^{\frac{1}{2}} \tag{4.6}$$

for all $0 \leq s$, $s' \leq T$, $x \in I\!R^d$.

Proof. As in the proof of Theorem 4.1, we use the same notation C to denote the constants. First we assume $s \leq s'$, so that

$$W(s', x) - W(s, x) \leq \sup_{P \in \mathcal{R}_{s,x}} (E^Q\Gamma_{s'} - E^P\Gamma_s) \tag{4.7}$$

for each $Q \in \mathcal{R}_{s',x}$. From the strict positivity of $c(\cdot)$, we may actually take the supremum in (4.7) over a subset $\mathcal{R}_{s,x}(\lambda)$ for some $\lambda > 0$, where

$$\mathcal{R}_{s,x}(\lambda) = \{P \in \mathcal{R}_{s,x} :\ E^P\|v(T)\| \leq \lambda\}. \tag{4.8}$$

Now, for $P \in \mathcal{R}_{s,x}(\lambda)$, as in the proof Theorem 4.1, there exists a standard extension $(\tilde{\Omega}, \tilde{\mathcal{F}}, \tilde{\mathcal{F}}_t, \tilde{P})$ of $(\Omega, \mathcal{F}, \mathcal{F}_t, P)$ such that $x(\cdot)$ is a solution of

$$x_t = x + \int_s^t b(\theta, x_\theta, \mu_\theta)d\theta + \int_s^t \sigma(\theta, x_\theta, \mu_\theta)dB_\theta + gv_t \tag{4.9}$$

on the stochastic basis $(\tilde{\Omega}, \tilde{\mathcal{F}}, \tilde{\mathcal{F}}_t, \tilde{P})$, where $B.$ is a d-dimensional Brownian motion. Define $\hat{\mathcal{F}}_t = \tilde{\mathcal{F}}_{t-s'+s}$, $\hat{\mu}_t = \mu_{t-s'+s}$, $\hat{v}_t = v_{t-s'+s}$, and $\hat{B}_t = B_{t-s'+s}$ for $t \geq s'$. Consider the following stochastic differential equation:

$$y_t = x + \int_{s'}^{t} b(\theta, y_\theta, \hat{\mu}_\theta) d\theta + \int_{s'}^{t} \sigma(\theta, y_\theta, \hat{\mu}_\theta) d\hat{B}_\theta + g\hat{v}_t, \quad t \geq s' \tag{4.10}$$

on the stochastic basis $(\tilde{\Omega}, \tilde{\mathcal{F}}, \hat{\mathcal{F}}_t, \tilde{P})$. We know that under assumption (4.1) there exists a unique strong solution $y.$, and by definition, $\alpha = (\tilde{\Omega}, \tilde{\mathcal{F}}, \hat{\mathcal{F}}_t, \tilde{P}, y_t, \hat{\mu}_t, \hat{v}_t, s', x) \in \tilde{\Lambda}_{s'x}$. Therefore, there exists a control rule $Q \in \mathcal{R}_{s',x}$ such that

$$J(\alpha) = J(s', Q) = E^Q \Gamma_{s'}. \tag{4.11}$$

Recall that Γ_s is defined by (2.5). Thus, by definition,

$$E^P \Gamma_s = E^{\tilde{P}} \left\{ \int_s^T f(\theta, x_\theta, \mu_\theta) d\theta + \int_s^T c(\theta) \cdot dv_\theta \right\},$$

and by (4.11),

$$\begin{aligned} E^Q \Gamma_{s'} &= E^{\tilde{P}} \left\{ \int_{s'}^T f(\theta, y_\theta, \hat{\mu}_\theta) d\theta + \int_{s'}^T c(\theta) \cdot d\hat{v}_\theta \right\} \\ &= E^{\tilde{P}} \left\{ \int_s^{T-s'+s} f(\theta + s' - s, y_{\theta+s'-s}, \mu_\theta) d\theta + \int_s^{T-s'+s} c(\theta + s' - s) \cdot dv_\theta \right\}. \end{aligned}$$

Therefore, noticing that f is bounded below by a constant $-K$ ($K \geq 0$) and $P \in \mathcal{R}_{s,x}(\lambda)$, we get

$$\begin{aligned} E^Q \Gamma_{s'} - E^P \Gamma_s \leq E^{\tilde{P}} \Bigg\{ & \int_s^{T-(s'-s)} |f(\theta, x_\theta, \mu_\theta) - f(\theta + s' - s, y_{\theta+s'-s}, \mu_\theta)| d\theta \\ & + \int_s^{T-(s'-s)} \|c(\theta) - c(\theta + s' - s)\| \, d\|v_\theta\| + K|s' - s| \Bigg\} \\ \leq E^{\tilde{P}} \Bigg\{ & \int_s^{T-(s'-s)} |f(\theta, x_\theta, \mu_\theta) - f(\theta + s' - s, y_{\theta+s'-s}, \mu_\theta)| d\theta \Bigg\} \\ & + C|s' - s| \left(E^P \|v(T)\| + 1 \right). \end{aligned}$$

From the Lipschitz continuity of the function f, we have

$$|f(\theta, x_\theta, \mu_\theta) - f(\theta + s' - s, y_{\theta+s'-s}, \mu_\theta)| \leq C(|s' - s| + \|x_\theta - y_{\theta+s'-s}\|).$$

Therefore

$$E^Q \Gamma_{s'} - E^P \Gamma_s \leq C \left(|s' - s| + E^{\tilde{P}} \int_s^{T-(s'-s)} \|x_\theta - y_{\theta+s'-s}\| d\theta \right). \tag{4.12}$$

By (4.10) we have for $\theta \geq s$,

$$y_{\theta+s'-s} = x + \int_{s'}^{\theta+s'-s} b(h, y_h, \hat{\mu}_h) dh \tag{4.13}$$

$$
\begin{aligned}
&+\int_{s'}^{\theta+s'-s} \sigma(h, y_h, \hat{\mu}_h) d\hat{B}_u + g\hat{v}_{\theta+s'-s} \\
&= x + \int_s^\theta b(h+s'-s, y_{h+s'-s}, \mu_h) dh \\
&\qquad + \int_s^\theta \sigma(h+s'-s, y_{h+s'-s}, \mu_h) dB_h + gv_\theta.
\end{aligned}
$$

So from (4.9), (4.13), and the Burkholder–Davis–Gundy inequality, we have for $\theta \geq s$,

$$
\begin{aligned}
&E^{\tilde{P}} \|x_\theta - y_{\theta+s'-s}\|^2 \\
&\leq 2E\left(\int_s^\theta \|b(h, x_h, \mu_h) - b(h+s'-s, y_{h+s'-s}, \mu_h)\| dh\right)^2 \\
&\qquad + 2E^{\tilde{P}} \sup_{\theta' \leq \theta} \left\|\int_s^{\theta'} (\sigma(h, x_h, \mu_h) - \sigma(h+s'-s, y_{h+s'-s}, \mu_h)) dB_h\right\|^2 \\
&\leq 2TE^{\tilde{P}} \int_s^\theta \|b(h, x_h, \mu_h) - b(h+s'-s, y_{h+s'-s}, \mu_h)\|^2 dh \\
&\qquad + 2E^{\tilde{P}} \int_s^\theta \|\sigma(h, x_h, \mu_h) - \sigma(h+s'-s, y_{h+s'-s}, \mu_h)\|^2 dh \\
&\leq CE^{\tilde{P}} \int_s^\theta (|s'-s|^2 + \|x_h - y_{h+s'-s}\|^2) dh \\
&\leq C\left(|s'-s|^2 + \int_s^\theta E^{\tilde{P}} \|x_h - y_{h+s'-s}\|^2 dh\right).
\end{aligned}
$$

Gronwall's inequality implies

$$
E^{\tilde{P}} \|x_\theta - y_{\theta+s'-s}\|^2 \leq C|s'-s|^2 e^{C(\theta-s)} \leq C|s'-s|^2.
$$

Hence, from (4.12) we have

$$
E^Q \Gamma_{s'} - E^P \Gamma_s \leq C|s'-s|
$$

and, therefore, $W(s', x) - W(s, x) \leq C\,|s'-s|$ for $s' > s$.

Now we assume $s' < s$. By the dynamic programming principle (cf. Theorem 3.10),

$$
W(s', x) = \inf_{P \in \mathcal{R}_{s',x}} E^P \left\{\int_{s'}^s f(\theta, x_\theta, \mu_\theta) d\theta + \int_{s'}^s c(\theta) \cdot dv_\theta + W(s, x_s)\right\}.
$$

Take $P^0 \in \mathcal{R}_{s',x}$ such that $P^0(\mu_\theta = \delta_{\{u^0\}}, v_\theta = 0,\ 0 \leq \theta \leq T) = 1$ for some arbitrary but fixed $u^0 \in U$. Then

$$
\begin{aligned}
W(s', x) &\leq E^{P^0} \left\{\int_{s'}^s f(\theta, x_\theta, u^0) d\theta + W(s, x_s)\right\} \\
&\leq C|s'-s| + E^{P^0} W(s, x_s)
\end{aligned}
$$

by the boundedness of f, and by Theorem 4.1 there exists a constant C such that

$$
W(s, x_s) \leq W(s, x) + C\|x_s - x\|.
$$

Hence

$$W(s',x) - W(s,x) \le C(|s'-s| + E^{P^0}\|x_s - x\|) \le C\left(|s'-s| + (E^{P^0}\|x_s - x\|^2)^{\frac{1}{2}}\right). \tag{4.14}$$

From the definition of control rules, we know that under P^0,

$$x_s - x = \int_{s'}^{s} b(\theta, x_\theta, u^0)d\theta + M_s, \tag{4.15}$$

where M is a continuous square integrable martingale with

$$\langle M\rangle_s = \int_{s'}^{s} \operatorname{tr}(a(\theta, x_\theta, u^0))d\theta.$$

Therefore, by (4.15) and the Burkholder–Davis–Gundy inequality, we have

$$E^{P^0}\|x_s - x\|^2 \le C\left(|s'-s|^2 + |s'-s|\right). \tag{4.16}$$

Combining (4.14) and (4.16) we have

$$W(s',x) - W(s,x) \le C\,|s'-s|^{\frac{1}{2}}.$$

The theorem is thus proved. □

Remark 4.3. We have assumed that the function f is bounded. It is easy to see from the proof of Theorem 4.2 that without this condition the constant C will depend on x.

Combining Theorems 4.1 and 4.2 we can state the main result of this section.

THEOREM 4.4. *The value function W is uniformly continuous on Σ. Moreover, there exists a constant $C \ge 0$ such that*

$$|W(t,x) - W(s,y)| \le C\left(|t-s|^{\frac{1}{2}} + \|x-y\|\right), \quad 0 \le s,t \le T, \; x,y \in I\!R^d.$$

5. The dynamic programming equation. Before we derive the dynamic programming equation heuristically, we prove a result which shows that there exists a set such that the optimal state process is continuous when it is in this set.

THEOREM 5.1. (a) *Assume $(t,x) \in \Sigma$; then*

$$W(t,x) \le W(t, x+gh) + c(t)\cdot h \tag{5.1}$$

for each $h \in I\!R^k_+$. Moreover, if equality holds for some $h = (h^i) \in I\!R^k$, then the same equality holds when we replace h by $\bar h$ with $\bar h = (\bar h^i) \in I\!R^k_+$, $\bar h^i \le h^i$ $(1 \le i \le k)$.

(b) *Define, for $0 \le t \le T$,*

$$A_t \equiv \{x : \; W(t,x) < W(t,x+gh) + c(t)\cdot h, \; \forall\, h \in I\!R^k_+, \; h \ne 0\}.$$

Then the optimal state process x_t is continuous when it is in A_t. To be precise, we have

$$P(\Delta x_t \ne 0, x_t \in A_t) = 0, \quad s \le t \le T \tag{5.2}$$

for every $P \in \mathcal{R}^o_{s,x}$, $(s,x) \in \Sigma$.

Proof. (a) If (5.1) fails for some $h \in \mathbb{R}^k_+$, then

$$W(t,x) > W(t,x+gh) + c(t)\cdot h. \tag{5.3}$$

Take $P \in \mathcal{R}^o_{t,x+gh}$. We define $\Theta : \Omega \to \Omega$ by

$$\Theta(\omega)_s = \begin{cases} (x_s - gh, \mu_s, 0), & 0 \le s \le t, \\ (x_s, \mu_s, v_s + h), & t < s \le T \end{cases}$$

for $\omega = (x_\cdot, \mu_\cdot, v_\cdot)$, and let $\tilde{P} = P \circ \Theta^{-1}(\cdot)$. As in the proof of Lemma 3.4, we can show that $\tilde{P} \in \mathcal{R}_{t,x}$. From the definition of $\tilde{P}$ we have

$$\begin{aligned} J(t,\tilde{P}) &= E^{\tilde{P}}\left\{\int_t^T f(\theta, x_\theta, \mu_\theta)d\theta + \int_t^T c(\theta)\cdot dv_\theta\right\} \\ &= E^P\left\{\int_t^T f(\theta, x_\theta, \mu_\theta)d\theta + \int_t^T c(\theta)\cdot dv_\theta + c(t)\cdot h\right\} \\ &= J(t,P) + c(t)\cdot h \\ &= W(t,x+gh) + c(t)\cdot h. \end{aligned}$$

Therefore, $J(t,\tilde{P}) < W(t,x)$ from (5.3), a contradiction.

Next, if (5.1) holds as an equality for h, then for $\bar{h}$, $\bar{h}^i \le h^i$, $1 \le i \le k$,

$$\begin{aligned} W(t,x) - c(t)\cdot h &= W(t,x+gh) \\ &\ge W(t,x+g\bar{h}) - c(t)\cdot(h-\bar{h}) \\ &\ge W(t,x) - c(t)\cdot\bar{h} - c(t)\cdot(h-\bar{h}) \\ &= W(t,x) - c(t)\cdot h. \end{aligned}$$

Therefore

$$W(t,x) = W(t,x+g\bar{h}) + c(t)\cdot\bar{h}.$$

(b) For $P \in \mathcal{R}_{s,x}$, we know that P-a.s.,

$$\begin{aligned} x_t = x + \int_s^t b(\theta, x_\theta, \mu_\theta)d\theta + gv_t \\ + \text{ a continuous local martingale.} \end{aligned}$$

Thus $\triangle x_t = g\triangle v_t$, and $x_{t+} = x_t + \triangle x_t = x_t + g\triangle v_t$. Since $W(\cdot,\cdot)$ is continuous on Σ, for $t \le s \le T$,

$$W(t,x_{t+}) = \lim_{t'\downarrow\downarrow t} W(t',x_{t'}). \tag{5.4}$$

Assume $P \in \mathcal{R}^o_{s,x}$, then by the dynamic programming principle (cf. Theorem 3.10) we know that $(\Gamma_s(t,W), \mathcal{F}_t, P)$ is a martingale. Hence, for $t' > t$,

$$W(s,x) = E^P\left\{\int_s^{t'} f(\theta, x_\theta, \mu_\theta)d\theta + \int_s^{t'} c(\theta)\cdot dv_\theta + W(t',x_{t'})\right\}. \tag{5.5}$$

Let $t' \downarrow\downarrow t$; note that from our assumption we know that $c(\cdot)$ is continuous on $[0,T]$. Therefore

$$\int_s^{t'} f(\theta, x_\theta, \mu_\theta)d\theta \to \int_s^t f(\theta, x_\theta, \mu_\theta)d\theta,$$
$$\int_s^{t'} c(\theta)\cdot dv_\theta \to \int_s^t c(\theta)\cdot dv_\theta + c(t)\cdot \Delta v_t.$$

Hence if (5.2) fails, then (5.4) and (5.5) imply

$$\begin{aligned} W(s,x) &= E^P\left\{\int_s^t f(\theta, x_\theta, \mu_\theta)d\theta + \int_s^t c(\theta)\cdot dv_\theta + c(t)\cdot\Delta v_t + W(t, x_t + g\Delta v_t)\right\} \\ &> E^P\left\{\int_s^t f(\theta, x_\theta, \mu_\theta)d\theta + \int_s^t c(\theta)\cdot dv_\theta + W(t,x_t)\right\} \\ &= E^P\Gamma_s(t,W), \end{aligned}$$

which contradicts the fact that $P \in \mathcal{R}^o_{s,x}$. The inequality follows from the facts that

$$W(t,x_t) \le W(t, x_t + g\Delta x_t) + c(t)\cdot\Delta v_t$$

and the strict inequality holds if $x_t \in A_t$ and $\Delta x_t \neq 0$. □

Remark 5.2. From Theorem 5.1 (a), we can see that if the value function $W \in C^{1,2}(\Sigma)$, then

$$(g^*\nabla_x W(t,x))^i + c^i(t) \ge 0, \quad i = 1, 2, \ldots, k,$$

where $*$ means transpose and $(\cdot)^i$ denotes the ith coordinate of the point in $\mathbb{R}^k$. For $x \notin A_t$, there exists $h = (h^i) \in \mathbb{R}^k_+$ such that for $\bar{h} = (\bar{h}^i) \in \mathbb{R}^k_+$, $\bar{h}^i \le h^i$, $1 \le i \le k$,

$$W(t,x) = W(t, x + g\bar{h}) + c(t)\cdot\bar{h}.$$

Therefore we have

$$(g^*\nabla_x W(t,x))^i + c^i(t) = 0$$

for those i such that $h^i > 0$.

5.1. Heuristic derivation of the dynamic programming equation. Recall Ito's formula. For $\phi \in C^{1,2}(\Sigma)$, $(s,x) \in \Sigma$, $t \ge s$,

$$\begin{aligned} \phi(t,x_t) = \phi(s,x) &+ \int_s^t \left(\frac{\partial}{\partial t} + \mathcal{L}\right)\phi(\theta, x_\theta, \mu_\theta)d\theta \\ &+ \int_s^t \nabla_x\phi(\theta,x_\theta)\cdot a(\theta, x_\theta, \mu_\theta)dB_\theta + \int_s^t \nabla_x\phi(\theta, x_\theta)\cdot g dv_\theta \\ &+ \sum_{s\le\theta<t}\left[\phi(\theta, x_{\theta+}) - \phi(\theta, x_\theta) - \nabla_x\phi(\theta,x_\theta)\cdot\Delta x_\theta\right]. \end{aligned} \tag{5.6}$$

Let

$$\tilde{\mathcal{L}} \equiv \frac{\partial}{\partial t} + \mathcal{L} = \frac{\partial}{\partial t} + \frac{1}{2}\sum_{i,j} a_{ij}\frac{\partial^2}{\partial x^i \partial x^j} + \sum_i b_i \frac{\partial}{\partial x^i};$$

then for $P \in \mathcal{R}_{s,x}$, (5.6) may be written as

$$E^P\phi(t,x_t) = \phi(s,x) + E^P\left\{\int_s^t \tilde{\mathcal{L}}\phi(\theta,x_\theta,\mu_\theta)d\theta + \int_s^t \nabla_x\phi(\theta,x_\theta)\cdot g dv_\theta \right.$$
$$\left. + \sum_{s\le\theta<t} [\phi(\theta,x_{\theta+}) - \phi(\theta,x_\theta) - \nabla_x\phi(\theta,x_\theta)\cdot\triangle x_\theta]\right\}.$$

By the dynamic programming principle (cf. Theorem 3.10),

$$W(s,x) = \inf_{P\in\mathcal{R}_{s,x}} E^P\left\{\int_s^t f(\theta,x_\theta,\mu_\theta)d\theta + \int_s^t c(\theta)\cdot dv_\theta + W(t,x_t)\right\},$$

so if we assume $W \in C^{1,2}(\Sigma)$, then

$$\begin{aligned}(5.7)\quad 0 = \inf_{P\in\mathcal{R}_{s,x}} E^P\Bigg\{&\int_s^t (\tilde{\mathcal{L}}W + f)(\theta,x_\theta,\mu_\theta)d\theta \\ &+ \int_s^t \big(c(\theta) + g^*\nabla_x W(\theta,x_\theta)\big)\cdot dv_\theta \\ &+ \sum_{s\le\theta<t}\big[W(\theta,x_{\theta+}) - W(\theta,x_\theta) - \nabla_x W(\theta,x_\theta)\cdot\triangle x_\theta\big]\Bigg\}.\end{aligned}$$

If we take the infimum over all those $P \in \mathcal{R}_{s,x}$ such that $P(v_t = 0,\ 0 \le t \le T) = 1$, then from (5.7) we get

$$\inf_{P\in\mathcal{R}_{s,x}} E^P\left\{\int_s^t (\tilde{\mathcal{L}}W + f)(\theta,x_\theta,\mu_\theta)d\theta\right\} \ge 0.$$

Let $t \downarrow s$; we have

$$\inf_{P\in\mathcal{R}_{s,x}} E^P(\tilde{\mathcal{L}}W + f)(s,x_s,\mu_s) \ge 0.$$

Moreover, from Remark 5.2 we can conclude that on Σ,

$$(5.8)\qquad (g^*\nabla_x W)^i + c^i \ge 0,\quad i = 1,2,\dots,k.$$

Therefore we can expect that W formally satisfies the following *variational inequality*, or *Hamilton–Jacobi–Bellman equation*,

$$(5.9)\quad \min\left\{\inf_{u\in U}(\tilde{\mathcal{L}}W + f)(t,x,u), (g^*\nabla_x W(t,x))^i + c^i(t),\ i = 1,2,\dots,k\right\} = 0$$

on Σ. For simplicity of notation, we write (5.9) as

$$\min\{\inf_{u\in U}(\tilde{\mathcal{L}}W + f),\ g^*\nabla_x W + c\} = 0.$$

5.2. Viscosity solution. As is well known in classical control problems, the value function is a solution to the corresponding Hamilton–Jacobi–Bellman equation when it has sufficient regularity (cf. Fleming and Rishel [4], Krylov [9]). If it is only known that the value function is continuous, then, as observed by Lions [10], the value function is a solution to the Hamilton–Jacobi–Bellman equation in the *viscosity* sense, which we will define as follows.

DEFINITION 5.3. *A function ψ is a* viscosity solution *of* (5.9) *if $\psi \in C(\Sigma)$ and, for every $\phi \in C^{1,2}(\Sigma)$,*

(1) *for each local maximum point* (t_0, x_0) *of* $\psi - \phi$ *in the interior of* Σ, *we have*

$$\min\left\{\inf_{u\in U}(\tilde{\mathcal{L}}\phi + f),\ g^*\nabla_x\phi + c\right\} \geq 0 \tag{5.10}$$

at (t_0, x_0), *i.e.,* ψ *is a subsolution*;

(2) *for each local minimum point* (t_0, x_0) *of* $\psi - \phi$ *in the interior of* Σ, *we have*

$$\min\left\{\inf_{u\in U}(\tilde{\mathcal{L}}\phi + f),\ g^*\nabla_x\phi + c\right\} \leq 0 \tag{5.11}$$

at (t_0, x_0), *i.e.,* ψ *is a supersolution.*

For an introduction to the viscosity solution and its applications to stochastic optimal control problems, see Fleming and Soner [5]. For an extensive bibliography on viscosity solutions, see Crandall, Ishii, and Lions [2].

THEOREM 5.4. *The value function* $W(\cdot,\cdot)$ *is a viscosity solution of* (5.9).

Proof. By Theorem 4.4 we know $W \in C(\Sigma)$. We first show that W is a subsolution. For $\phi \in C^{1,2}(\Sigma)$, if $(t_0, x_0) \in \text{int}(\Sigma)$ is a local maximum point of $W - \phi$, then there is a neighborhood $O^1(t_0, x_0)$ of (t_0, x_0) in Σ such that

$$W(t,x) - \phi(t,x) \leq W(t_0,x_0) - \phi(t_0,x_0),\ \ (t,x) \in \bar{O}^1(t_0,x_0),$$

or

$$W(t,x) - W(t_0,x_0) \leq \phi(t,x) - \phi(t_0,x_0),\ \ (t,x) \in \bar{O}^1(t_0,x_0), \tag{5.12}$$

where $\bar{O}^i(t_0,x_0)$ denotes the closure of $O^i(t_0,x_0)$. If (5.10) fails, then one of the following will be true:

$$\inf_{u\in U}(\tilde{\mathcal{L}}\phi + f)(t_0,x_0,u) < 0, \tag{5.13}$$

$$(g^*\nabla_x\phi(t_0,x_0))^i + c^i(t_0) < 0 \ \text{ for some } 1 \leq i \leq k. \tag{5.14}$$

If (5.13) is true, then from assumption (4.1) and $\phi \in C^{1,2}(\Sigma)$, we can find $u^0 \in U$ and a neighborhood $O^2(t_0,x_0)$ of (t_0,x_0) such that

$$(\tilde{\mathcal{L}}\phi + f)(t,x,u^0) < 0$$

for $(t,x) \in O^2(t_0,x_0)$. Take $P \in \mathcal{R}_{t_0,x_0}$ such that

$$P(\mu_r = \delta_{\{u^0\}},\ v_r = 0,\ 0 \leq r \leq T) = 1. \tag{5.15}$$

The existence of such a $P \in \mathcal{R}_{t_0,x_0}$ is obvious. Define

$$\tau = \inf\{t > t_0,\ (t,x_t) \notin O(t_0,x_0)\},$$

where $O(t_0,x_0) = O^1(t_0,x_0) \cap O^2(t_0,x_0)$. Since the state process $x.$ is continuous a.s.(P), we can see immediately that

$$P(\tau > t_0) = 1,$$

and for $t_0 \leq \theta < \tau$,

$$(\tilde{\mathcal{L}}\phi + f)(\theta, x_\theta, \mu_\theta) < 0 \ \text{ a.s.}(P).$$

Therefore

$$E^P \int_{t_0}^{\tau} (\tilde{\mathcal{L}}\phi + f)(\theta, x_\theta, \mu_\theta) d\theta < 0.$$

By the definition of control rules,

$$\phi(\tau, x_\tau) = \phi(t_0, x_0) + \int_{t_0}^{\tau} \tilde{\mathcal{L}}\phi(\theta, x_\theta, \mu_\theta) d\theta + M_\tau \phi \ \text{ a.s.}(P),$$

where $M\phi \in \mathcal{M}_2^c$, i.e., a continuous square integrable martingale with respect to P. Note that Theorem 4.2.1 of Stroock and Varadhan [11] allows us to replace $\mathcal{L}$ by $\tilde{\mathcal{L}}$ in (2.4), at least when $v = 0$. Hence

$$E^P \phi(\tau, x_\tau) - \phi(t_0, x_0) = E^P \int_{t_0}^{\tau} \tilde{\mathcal{L}}\phi(\theta, x_\theta, \mu_\theta) d\theta.$$

Noting that $(\tau, x_\tau) \in \bar{O}(t_0, x_0)$, we have

$$\begin{aligned} E^P W(\tau, x_\tau) - W(t_0, x_0) &\leq E^P \phi(\tau, x_\tau) - \phi(t_0, x_0) \\ &= E^P \int_{t_0}^{\tau} \tilde{\mathcal{L}}\phi(\theta, x_\theta, \mu_\theta) d\theta \\ &< -E^P \int_{t_0}^{\tau} f(\theta, x_\theta, \mu_\theta) d\theta, \end{aligned}$$

which, by (5.15) can be rewritten as

$$\begin{aligned} W(t_0, x_0) &> E^P \left\{ \int_{t_0}^{\tau} f(\theta, x_\theta, \mu_\theta) d\theta + W(\tau, x_\tau) \right\} \\ &= E^P \left\{ \int_{t_0}^{\tau} f(\theta, x_\theta, \mu_\theta) d\theta + \int_{t_0}^{\tau} c(\theta) \cdot dv_\theta + W(\tau, x_\tau) \right\}. \end{aligned}$$

This contradicts the dynamic programming principle (cf. (3.9)).

Next, if (5.14) holds at (t_0, x_0) for some i, then we can take $h^i > 0$ small enough such that

$$\phi(t_0, x_0 + g^i h^i) - \phi(t_0, x_0) < -c^i(t_0) h^i,$$

where g^i denotes the ith column of the $d \times k$ matrix g. Therefore, by (5.12) we have

$$W(t_0, x + g^i h^i) - W(t_0, x_0) < -c^i(t_0) h^i$$

and, therefore,

$$W(t_0, x_0) > W(t_0, x_0 + gh) + c(t_0) \cdot h,$$

where $h = (0, \ldots, h^i, \ldots, 0)$. This is a contradiction of Theorem 5.1, and thus we have shown that W is a subsolution of (5.9)

Now we show that W is also a supersolution of (5.9). If $\phi \in C^{1,2}(\Sigma)$ such that $W - \phi$ has a local minimum point at $(t_0, x_0) \in \text{int}(\Sigma)$, then there exists a neighborhood $O^1(t_0, x_0)$ of (t_0, x_0) satisfying

$$W(t, x) - W(t_0, x_0) \geq \phi(t, x) - \phi(t_0, x_0), \quad (t, x) \in \bar{O}^1(t_0, x_0). \tag{5.16}$$

If (5.11) fails, then

$$\inf_{u\in U}\left(\tilde{\mathcal{L}}\phi + f\right) > 0,\ \left(g^*\nabla\phi\right)^i + c^i > 0$$

at (t_0, x_0) for $i = 1, \dots, k$. From assumption (4.1) and the fact that $\phi \in C^{1,2}(\Sigma)$, we can find a neighborhood $O^2(t_0, x_0)$ of (t_0, x_0) such that for some $\varepsilon > 0$,

$$\inf_{u\in U}\left(\tilde{\mathcal{L}}\phi + f\right) > \varepsilon,\ \left(g^*\nabla\phi\right)^i + c^i > \varepsilon$$

on $\bar{O}^2(t_0, x_0)$ for $i = 1, \dots, k$. Let $O(t_0, x_0) = O^1(t_0, x_0) \cap O^2(t_0, x_0)$; then for $(t, x) \in O(t_0, x_0)$, we have for small $h \in \mathbb{R}_+^k$, $h \neq 0$,

$$\phi(t, x + gh) - \phi(t, x) > -c(t) \cdot h.$$

Therefore, by (5.16),

$$W(t, x + gh) - W(t, x) > -c(t) \cdot h$$

or $x \in A_t$. Hence for $P \in \mathcal{R}^o_{t_0,x_0}$,

$$P(x_{t_0+} = x_{t_0}) = 1 \tag{5.17}$$

by Theorem 5.1. Define

$$\tau = \inf\{t \geq t_0,\ \ (t, x_t) \notin O(t_0, x_0)\};$$

then from (5.17) we see that $P(\tau > t_0) = 1$ for $P \in \mathcal{R}^o_{t_0,x_0}$, and it can be seen that

$$(t, x_t) \in \bar{O}(t_0, x_0),\ \ x_t \in A_t,\ \ t_0 \leq t \leq \tau.$$

Therefore we have

$$E^P\left\{\int_{t_0}^{\tau} (\tilde{\mathcal{L}}\phi + f)(\theta, x_\theta, \mu_\theta)d\theta + \int_{t_0}^{\tau} \left(g^*\nabla_x\phi(\theta, x_\theta) + c_\theta\right) \cdot dv_\theta\right\} \geq \varepsilon E^P(\tau - t_0).$$

Applying Ito's formula and noting that the state process $x.$ is continuous a.s. (P) when $t_0 \leq t \leq \tau$, we have

$$E^P\phi(\tau, x_\tau) = \phi(t_0, x_0) + E^P\left\{\int_{t_0}^{\tau} \tilde{\mathcal{L}}\phi(\theta, x_\theta, \mu_\theta)d\theta + \int_{t_0}^{\tau} \nabla_x\phi(\theta, x_\theta) \cdot g dv_\theta\right\},$$

which may be rewritten as

$$\begin{aligned} E^P[\phi(\tau, x_\tau) - \phi(t_0, x_0)] \geq E^P &\left\{\int_{t_0}^{\tau} -f(\theta, x_\theta, \mu_\theta)d\theta\right. \\ &\left. - \int_{t_0}^{\tau} c(\theta) \cdot dv_\theta\right\} + \varepsilon E^P(\tau - t_0). \end{aligned}$$

By (5.16) and the fact that $P(\tau > t_0) > 0$, we have

$$E^P[W(\tau, x_\tau) - W(t_0, x_0)] > E^P\left\{\int_{t_0}^{\tau} -f(\theta, x_\theta, \mu_\theta)d\theta - \int_{t_0}^{\tau} c(\theta) \cdot dv_\theta\right\}$$

or

$$W(t_0, x_0) < E^P \left\{ \int_{t_0}^{\tau} f(\theta, x_\theta, \mu_\theta) d\theta + \int_{t_0}^{\tau} c(\theta) \cdot dv_\theta + W(\tau, x_\tau) \right\},$$

which contradicts the dynamic programming principle.

The proof of this theorem is therefore complete. □

Let us define the function space

$$\begin{aligned} \mathcal{C}(\Sigma) \equiv \{W(\cdot,\cdot) : \ & W \in C(\Sigma; I\!R) \text{ with } W \text{ bounded and} \\ & |W(t,x) - W(t,y)| \le C\|x-y\| \text{ for some } C \ge 0\}. \end{aligned}$$

By Theorem 4.4 we know that the value function $W \in \mathcal{C}(\Sigma)$. The proof of the next theorem is a modification of the methods used in Fleming and Soner [5]. For details see Suo [12].

THEOREM 5.5. *There exists a unique viscosity solution in $\mathcal{C}(\Sigma)$ to the dynamic programming equation* (5.9) *with the boundary condition $W(T, x) = 0$, $x \in I\!R^d$, which can be identified as the value function.*

AN EXISTENCE RESULT IN A PROBLEM OF THE VECTORIAL CASE OF THE CALCULUS OF VARIATIONS *

ARRIGO CELLINA† AND SANDRO ZAGATTI‡

Abstract. We prove that the problem

$$\text{Minimize} \int_\Omega g(\Phi(\nabla T(x)))dx, \quad T \in T_B + W_0^{1,\infty}(\Omega, \mathbb{R}^n)$$

admits at least one solution for any lower-semicontinuous extended valued function g, for any quasi-affine real-valued function Φ, and for any piecewise-affine boundary datum T_B such that $\Phi(\nabla T_B)$ is constant.

Key words. minimum problem, Jacobian determinant, quasi-affine function

AMS subject classification. 49A50

1. Introduction. In this paper we consider the problem of existence of solutions for the problem

$$\mathcal{P}: \quad \text{Minimize} \int_\Omega g(\Phi(\nabla T(x))dx, \quad T \in T_B + W_0^{1,\infty}(\Omega, \mathbb{R}^n),$$

where Φ is a real-valued quasi-affine function defined on the space $\mathcal{M}_n$ of $n \times n$ matrices, T a transformation from Ω to $\mathbb{R}^n$, $T_B : \bar{\Omega} \mapsto \mathbb{R}^n$ is a piecewise-affine boundary datum and Ω is an open and bounded subset of $\mathbb{R}^n$.

When $\Phi(A) = \det(A)$ (the determinant is the simplest example of nonaffine quasi-affine function), the problem, which arises in the study of equilibrium of gases and constitutes a typical nonconvex problem in the vectorial case of the calculus of variations, has been considered in [D2] and [MS].

In [D2] it is proved that the relaxed problem

$$\text{Minimize} \int_\Omega g^{**}(\det(\nabla u(x))dx, \quad u \in C^\infty(\Omega, \mathbb{R}^3), \quad u = u_0 \text{ on } \partial\Omega$$

admits at least one smooth solution provided that $g : \mathbb{R}^+ \to \mathbb{R}$ satisfies some growth conditions, the boundary datum u_0 is a homeomorphism with positive Jacobian determinant, and Ω is diffeomorphic to the unit sphere.

In [MS] the authors give a proof, based on Moser's Theorem on volume-preserving diffeomorphisms (see [M], [DM]), of existence of a solution for the problem

$$\text{Minimize} \int_\Omega g(\det(\nabla u(x))dx, \quad u \in u_0 + W^{1,\infty}(\Omega, \mathbb{R}^n)$$

*Received by the editors April 21, 1993; accepted for publication (in revised form) January 4, 1994.

for $g : \mathbb{R}^+ \to \mathbb{R}$ continuous, satisfying the growth condition at 0^+ and at $+\infty$, and for a C^2 homeomorphism u_0 with positive Jacobian determinant in $\bar{\Omega}$.

In this paper we consider an extended-valued lower-semicontinuous function g, defined on $\mathbb{R}$, with superlinear growth at infinity and show that $\mathcal{P}$ admits at least one solution for any quasi-affine function Φ and for any piecewise-affine boundary datum T_B such that $\Phi(\nabla T_B)$ is constant (possibly zero).

We wish to point out that the proof is easier whenever the datum T_B is such that ∇T_B is never a critical point for Φ (in the case of the Jacobian determinant this means that the rank of ∇T_B is larger than or equal to $n-1$); in the general case the result is obtained by proving the existence of a piecewise-affine transformation $T_r \in T_B + W_0^{1,\infty}(\Omega, \mathbb{R}^n)$ such that $\Phi(\nabla T_r) = \Phi(\nabla T_B)$ and $d\Phi(\nabla T_r) \neq 0$ almost everywhere in Ω, and then by solving the equivalent problem

$$\text{Minimize} \int_\Omega g(\Phi(\nabla T(x))dx, \quad T \in T_r + W_0^{1,\infty}(\Omega, \mathbb{R}^n).$$

2. Preliminaries and notation.

In this paper we use the following notation. Vectors (of $\mathbb{R}^n$) are columns. Given $b \in \mathbb{R}^n$, b^t is the transpose of b and $(b)^\perp$ is the orthogonal complement of span(b), $a \cdot b$ is the inner product of a and b vectors of $\mathbb{R}^n$, and $|\cdot|$ is the associated norm. The canonical base in $\mathbb{R}^n$ is denoted by $\{e_i, i = 1, \ldots, n\}$. A subset of $\mathbb{R}^n$ is called n-dimensional if its linear span is the whole space; for a convex polytope P, $V(P)$ is the set of its vertices.

An $n \times n$ matrix A is written as

$$A = (a_1, \ldots, a_n) = \begin{pmatrix} a^1 \\ \vdots \\ a^n \end{pmatrix} = \begin{pmatrix} a_1^1 & \cdots & a_n^1 \\ \vdots & & \vdots \\ a_1^n & \cdots & a_n^n \end{pmatrix},$$

where the a_i are its columns and a^i are its rows. We denote by $\mathcal{M}_n$ the space of $n \times n$ matrices endowed with the inner product

$$\langle\langle A, B\rangle\rangle_n = \sum_{i,j=1}^n a_i^j b_i^j = \sum_{i=1}^n a_i \cdot b_i = \sum_{j=1}^n a^j \cdot b^j.$$

Given two vectors $v, w \in \mathbb{R}^n$ we denote by $v \otimes w$ the matrix of rank one obtained by taking the usual row-times-column product of matrices of v and w^t, i.e., writing $v = (v_1, \ldots, v_n)$ and $w = (w_1, \ldots, w_n)$,

$$v \otimes w = \begin{pmatrix} v_1 w_1 & \cdots & v_1 w_n \\ \vdots & & \vdots \\ v_n w_1 & \cdots & v_n w_n \end{pmatrix} = (w_1 v, \ldots, w_n v) = \begin{pmatrix} v_1 w \\ \vdots \\ v_n w \end{pmatrix}.$$

For T, a regular transformation from an open subset of $\mathbb{R}^n$ to $\mathbb{R}^n$, ∇T is the Jacobian matrix; for v, a scalar valued function, ∇v is its gradient, seen as a row vector. By this way, given a vector b, $b \otimes \nabla v$ is an $n \times n$ matrix, while $\nabla v \cdot b$ is a scalar (inner product). The complement of a subset E of $\mathbb{R}^n$ is E^c; the Lebesgue measure is denoted by $\mu(\cdot)$.

We use the Sobolev spaces $W_0^{1,\infty}(\Omega, \mathbb{R}^n)$ and $W_0^{1,\infty}(\Omega, \mathbb{R})$, endowed with the usual norms, and adopt the convention that an element of $W_0^{1,\infty}(\Omega, \mathbb{R})$ or $W_0^{1,\infty}(\Omega, \mathbb{R}^n)$ is said to be continuous if it admits a continuous representative.

An open bounded subset E of $\mathbb{R}^n$ is called *regular* if the divergence theorem can be applied to E and to ∂E. We call a *regular partition* of E a finite collection $\{E_i, i = 1, \dots, m\}$ such that each E_i is open and regular, $E_i \cap E_j = \emptyset$ if $i \neq j$, and $E = (\bigcup_{i=1}^m E_i) \bigcup N$, where N is a null set.

An element T of $W^{1,\infty}(\Omega, \mathbb{R}^n)$ is called *piecewise affine* if it is continuous and there exists a regular partition of Ω such that T is affine on each element of the partition.

For a smooth function Φ defined on $\mathcal{M}_n$ we denote by $d^l\Phi(A)$ the lth differential of Φ at A and, abusing the notation, by

$$(d^l\Phi(A))_{(i_1,j_1),\dots,(i_l,j_l)}, \quad i_k, j_k = 1, \dots, n$$

the tensor representing the lth differential of Φ at A with respect to the canonical base in $\mathcal{M}_n$. In particular

$$(d\Phi(A))_{(i_1,j_1)}, \quad i_1, j_1 = 1, \dots, n$$

is the $n \times n$ matrix representing the first differential, in the sense that, for any $B \in \mathcal{M}_n$,

$$(d\Phi(A))(B) = \langle\langle d\Phi(A), B \rangle\rangle_n.$$

We recall, from [D1, p. 99], the following definition.

DEFINITION 2.1. *A Borel-measurable and locally integrable function $\Phi : \mathcal{M}_n \to \mathbb{R}$ is said to be* quasi-affine *if*

$$\Phi(A) = \frac{1}{\mu(D)} \int_D \Phi(A + \nabla u(x))dx$$

for every bounded domain $D \subset \mathbb{R}^n$, for every $A \in \mathcal{M}_n$, and for every $u \in W_0^{1,\infty}(D, \mathbb{R}^n)$.

We recall also that there exists a representation theorem for quasi-affine functions (see [B] or [D1, p. 117]) expressed in terms of the map

$$L : \mathcal{M}_n \to \mathcal{M}_{\nu(1)} \times \mathcal{M}_{\nu(2)} \times \cdots \times \mathcal{M}_{\nu(n-1)} \times \mathcal{M}_{\nu(n)},$$

where $\nu(s) = \binom{n}{s} = \frac{n!}{s!(n-s)!}$, given by

$$L(A) = \left(A, \mathrm{adj}_2(A), \dots, \mathrm{adj}_{n-1}(A), \det A\right),$$

where $\mathrm{adj}_s(A)$ stands for the $\nu(s) \times \nu(s)$ matrix of $s \times s$ minors of A. Roughly speaking, $L(A)$ is a "vector" whose "components" are square matrices of order $\nu(s)$.

Ball's theorem says that any quasi-affine function of A can be represented as a "scalar product" of $L(A)$ with a constant "vector." More precisely we have the following theorem.

THEOREM 2.1. *Let $\Phi : \mathcal{M}_n \to \mathbb{R}$. Then the following conditions are equivalent.*

(i) *Φ is quasi-affine.*

(ii) *There exists*

$$\beta = (\beta_1, \dots, \beta_n) \in \mathcal{M}_{\nu(1)} \times \mathcal{M}_{\nu(2)} \times \cdots \times \mathcal{M}_{\nu(n-1)} \times \mathcal{M}_{\nu(n)}$$

such that

$$\Phi(A) = \Phi(0) + \sum_{s=1}^{n} \langle\langle \beta_s, adj_s(A) \rangle\rangle_{\nu(s)}.$$

(iii) *For any* $a, b \in \mathbb{R}^n$

$$\Phi(A + a \otimes b) = \Phi(A) + \langle\langle d\Phi(A), a \otimes b\rangle\rangle_n.$$

Remarks. 1. When $\Phi(A) = \det A$, identifying as usual the differential with the representing matrix, it is $d\Phi(A) = \mathrm{adj}_{n-1}(A)$ (see [D1, p. 191]). Hence a matrix A has rank k if and only if $d^l\Phi(A) = 0$ for $l = 1, \dots, n-k-1$ and $d^l\Phi(A) \neq 0$ for $l = n-k, \dots, n$.

2. Point (ii) implies that Φ is a polynomial of degree less or equal than n; hence, in particular, if Φ is nonconstant, for every $A \in \mathcal{M}_n$ there exists $l \in \{1, \dots, n\}$ such that $d^l\Phi(A) \neq 0$.

3. Since the matrix representing the differential of the function determinant is the matrix of its maximal minors, point (ii) implies that each entry of the tensor representing a differential of some order of Φ at A is still a quasi-affine real-valued function of A.

LEMMA 2.1. *Let E be an open bounded subset of $\mathbb{R}^n$ and $V = \{v_i, i = 1, \dots, m\}$ a set of vectors of $\mathbb{R}^n$ such that $0 \in \mathrm{int}(\mathrm{co}(V))$. Then there exist a regular partition of E: $\{E_i, i = 1, \dots, m\}$ and a continuous function $w \in W_0^{1,\infty}(E, \mathbb{R})$ such that*

(i) $\nabla w = \sum_{i=1}^m v_i \chi_{E_i}$ *a.e. on Ω and*

(ii) $\sum_{i=1}^m \mu(E_i) v_i = 0$.

Proof. Let V^* be the polar set of $\mathrm{co}\{v_i, i = 1, \dots, m\}$. By Lemma 1 in [C] there exist a collection of m polytopes $V_1^*, \dots, V_m^*$ contained in V^* and a Lipschitz continuous function u, defined on $\mathbb{R}^n$ such that $V^* = \bigcup_{i=1}^m V_i^*$, $\mathrm{int}(V_i^*) \bigcap \mathrm{int}(V_j^*) = \emptyset$ for $i \neq j$, $u\big|_{(V^*)^c} = 0$, $\nabla u = \sum_{i=1}^m v_i \chi_{V_i^*}$, and

$$\sum_{i=1}^{m} \mu(V_i^*) v_i = 0. \tag{2.1}$$

Consider the following Vitali covering of E,

$$\{x + rV^*, \quad x \in E, \quad 0 < r < \mathrm{dist}(x, E^c)\},$$

and select a denumerable subcovering $\{S^j\}_{j \in \mathbb{N}}$,

$$S^j = \{x_j + r_j V^*, \quad x_j \in E, \quad r_j > 0\}$$

such that

(a) $\mathrm{int}(S^j) \bigcap \mathrm{int}(S^k) = \emptyset$ for $j \neq k$,

(b) $E = \left(\bigcup_{j=1}^\infty S^j\right) \bigcup N$, N null set, and

(c) $\mu(E) = \mu(V^*) \sum_{j=1}^\infty r_j^n$.

For any $j \in \mathbb{N}$ we define the subsets of S^j

$$S_i^j = \{x_j + r_j V_i^*\}, \quad i = 1, \dots, m;$$

for any $x \in \mathbb{R}^n$, we set

$$u_j(x) \equiv r_j u\left(\frac{x - x_j}{r_j}\right),$$

and, for $k \in \mathbb{N}$,

$$U_k = \left(\sum_{j=1}^k u_j\right)\bigg|_E.$$

Since u_j has the same regularity of u and $u_j\big|_{(S^j)^c} \equiv 0$, U_k belongs to $W_0^{1,\infty}(E,\mathbb{R})$ and moreover, for any $l \in \mathbb{N}$,

$$U_{k+l}(x) - U_k(x) = \begin{cases} 0 & \text{for } x \in \left(\bigcup_{j=1}^k S^j\right) \cup \left(\bigcup_{j=k+l}^\infty S^j\right) \\ u_j(x) & \text{for } x \in S^j, \quad j = k, \dots, k+l. \end{cases}$$

By (b),

$$\lim_{k\to\infty} \mu\left(\{x \in E : U_{k+l}(x) - U_k(x) \neq 0\}\right) = 0,$$

hence the sequence $\{U_k\}_{k\in\mathbb{N}}$ is fundamental in $W^{1,1}(E,\mathbb{R})$.

Now set

$$E_i = \bigcup_{j=1}^\infty \operatorname{int}(S_i^j)$$

and

$$w = \lim_{k\to\infty} U_k \quad \text{in} \quad W^{1,1}(E,\mathbb{R}).$$

We remark that, since each E_i is the union of a countable family of interiors of polytopes, it is regular in the sense specified above. Obviously w belongs to $W_0^{1,1}(E,\mathbb{R})$, and, given $j \in \mathbb{N}$,

$$U_k(x) = U_j(x) = u_j(x) \quad \text{for any } x \in S^j \text{ and for any } k \geq j;$$

hence, by pointwise convergence, $w(x) = u_j(x)$ for a.e. x in S^j. Thus w is continuous and belongs to $W_0^{1,\infty}(\Omega,\mathbb{R})$, and

$$\nabla w(x) = \nabla u\left(\frac{x - x_j}{r_j}\right) = v_i \quad \text{for a.e. } x \in S_i^j.$$

This implies (i). Statement (ii) is a trivial consequence of (2.1), (c), and the fact that

$$\mu(E_i) = \mu(V_i^*) \sum_{j=1}^\infty r_j^n. \qquad \square$$

3. Main result. We shall need the following lemmas.

LEMMA 3.1. *Let $D \in \mathcal{M}_n$ be a nonzero matrix. Let $\gamma_1, \gamma_2 \in \mathbb{R}$ with $\gamma_1 < 0 < \gamma_2$. Then there exist a vector $b \in \mathbb{R}^n$ and an n-dimensional polytope $P \subset \mathbb{R}^n$ with vertices $\{v_i^1, v_i^2, i = 1, \dots, n\}$, containing zero in its relative interior, such that*

$$\langle\langle D, b \otimes v_i^j \rangle\rangle_n = \gamma_j, \quad i = 1, \dots, n, \; j = 1, 2.$$

Proof. Write

$$D = \begin{pmatrix} d^1 \\ \vdots \\ d^n \end{pmatrix}$$

take a row d^j different from zero, and choose $b = e_j$. Let S be a symplex in $(d^j)^\perp$ with vertices $\{s_i, i = 1, \dots, n\}$ containing zero in its relative interior and define

$$v_i^1 = s_i + \frac{\gamma_1}{|d^j|^2} d^j, \quad v_i^2 = s_i + \frac{\gamma_2}{|d^j|^2} d^j, \quad i = 1, \dots, n.$$

Notice that for any vector v, $e_j \otimes v$ is the matrix whose rows are all zero except the jth one, which coincides with the row vector v^t. Hence

$$\langle\langle D, e_j \otimes v_i^j \rangle\rangle_n = d^j \cdot v_i^j$$

and, by the choice of v_i^j, we have the result. □

LEMMA 3.2. *Let Φ be a nonconstant real-valued quasi-affine function defined on $\mathcal{M}_n$, and let A be a critical point for Φ. Let $k \in \{0, \dots, n-2\}$ be such that $d^{n-k}\Phi(A) \neq 0$ and $d^l\Phi(A) = 0$ for any $l = 1, \dots, n-k-1$. Then there exist a vector $b \in \mathbb{R}^n$ and an n-dimensional polytope $P \subset \mathbb{R}^n$ with vertices $\{v_i, i = 1, \dots, 2n\} = V(P)$, containing zero in its interior, such that*

$$d^{n-k-1}\Phi(A + b \otimes v_i) \neq 0, \quad i = 1, \dots, 2n,$$

$$d^l\Phi(A + b \otimes v_i) = 0, \quad i = 1, \dots, 2n, \ l = 1, \dots, n-k-2.$$

Proof. Consider the tensor representing the $(n-k-1)$th differential of Φ at A:

$$(d^{n-k-1}\Phi(A))_{(i_1, j_1), \dots, (i_{n-k-1}, j_{n-k-1})}.$$

By assumption this tensor is zero and there exists a multiindex

$$\bar{J}_{n-k-1} = (\bar{i}_1, \bar{j}_1), \dots, (\bar{i}_{n-k-1}, \bar{j}_{n-k-1})$$

such that

$$d\,(d^{n-k-1}\Phi(A))_{\bar{J}_{n-k-1}}$$

is a nonzero matrix. By Lemma 3.1 there exist a vector b and a polytope P such that

$$\langle\langle d\,(d^{n-k-1}\Phi(A))_{\bar{J}_{n-k-1}}, b \otimes v_i \rangle\rangle_n \neq 0$$

for every $v_i \in V(P)$. Now we recall that the map $A \to (d^{n-k-1}\Phi(A))_{\bar{J}_{n-k-1}}$ is real valued and quasi-affine; hence, by point (iii) of Theorem 2.1,

$$(d^{n-k-1}\Phi(A + b \otimes v_i))_{\bar{J}_{n-k-1}} = (d^{n-k-1}\Phi(A))_{\bar{J}_{n-k-1}}$$

$$+ \langle\langle d\,(d^{n-k-1}\Phi(A))_{\bar{J}_{n-k-1}}, b \otimes v_i \rangle\rangle_n \neq 0$$

for every $v_i \in V(P)$.

Moreover, for any $l \in \{1, \dots, n-k-2\}$, if we denote a generic entry of the lth differential of Φ in A by

$$d\,(d^l\Phi(A))_{J_l},$$

where $J_l = (i_1, j_1), \dots, (i_l, j_l)$, we have, as before,

$$(d^l\,(\Phi(A + b \otimes v_i))_{J_l} = (d^l\,(\Phi(A))_{J_l} + \langle\langle d\,(d^l\Phi(A))_{J_l}, b \otimes v_i \rangle\rangle_n = 0$$

for any $v_i \in V(P)$. Hence all of the differentials of Φ at A are zero up to order $(n-k-2)$, while the $(n-k-1)$st differential is different from zero. □

The following lemma defines the auxiliary transformation $T_r \in T_B + W_0^{1,\infty}(\Omega, \mathbb{R}^n)$.

LEMMA 3.3. *Let $T_B : \mathbb{R}^n \to \mathbb{R}^n$ be a piecewise-affine transformation with $\Phi(\nabla T_B)$ constant. Then there exists a piecewise-affine transformation $T_r \in T_B + W_0^{1,\infty}(\Omega, \mathbb{R}^n)$ such that*

(i) $\Phi(\nabla T_r) \equiv \Phi(\nabla T_B)$ *and*

(ii) $d\Phi(\nabla T_r) \neq 0$ *a.e. in* Ω.

Proof. By assumption

$$T_B = \sum_{h=1}^{m} T^h \chi_{\Omega_h},$$

where $\{\Omega_i, i = 1, \dots, m\}$ is a regular partition of Ω and each T^i is affine. If $d\Phi(\nabla T^i) \neq 0$ for every i, we set $T_r \equiv T_B$.

Consider a generic T^j such that $d\Phi(\nabla T^j) = 0$. We claim that there exists a piecewise-affine T_r^j in $T^j + W_0^{1,\infty}(\Omega_j, \mathbb{R}^n)$ such that $\Phi(\nabla T_r^j) \equiv \Phi(\nabla T^j)$ and $d\Phi(\nabla T_r^j) \neq 0$ a.e. in Ω_j.

To prove this claim we set, for notational convenience, $\Omega_j = E$ and $T^j = T$.

Let k ($k \geq n-2$) be such that $d^{n-k}\Phi(\nabla T) \neq 0$ and $d^l\Phi(\nabla T) = 0$ for $l = 1, \dots, n-k-1$. By Lemma 3.2 there exist $b \in \mathbb{R}^n$ and an n-dimensional polytope P containing zero in its interior such that

$$d^{n-k-1}\Phi(\nabla T + b \otimes v_i) \neq 0,$$
$$d^l\Phi(\nabla T + b \otimes v_i) = 0, \quad l = 1, \dots, n-k-2.$$

for any $v_i \in V(P)$. Let $u \in W_0^{1,\infty}(E, \mathbb{R}^n)$ be defined as in Lemma 2.1 with $V = V(P)$. Consider the transformation

$$T_1(x) = T(x) + u(x)b$$

so that

$$\nabla T_1(x) = \nabla T + b \otimes \nabla u(x), \text{ a.e. in } \Omega.$$

T_1 is continuous and belongs to $T + W_0^{1,\infty}(E, \mathbb{R}^n)$ and there exists a regular partition of E: $\{E_i^1, i = 1, \dots, 2n\}$ such that

$$T_1 = \sum_{i=1}^{2n} T_1^i \chi_{E_i^1},$$

where each T_1^i is affine and, more precisely,

$$\nabla T_1^i(x) = \nabla T + b \otimes v_i, \quad i = 1, \dots, 2n.$$

Hence, for any $i \in \{1, \dots, 2n\}$, $d^{n-k-1}\Phi(\nabla T_1^i) \neq 0$, $d^l\Phi(\nabla T_1^i) = 0$ for $l = 1, \dots, n-k-2$, and $\Phi(\nabla T_1^i) = \Phi(\nabla T)$. If $k = n-2$ we set $T_r(E) = T_1$. Otherwise, repeating the previous procedure, for each $i \in \{1, \dots, 2n\}$ we can define a piecewise-affine transformation $T_2^i \in T_1^i + W_0^{1,\infty}(E_i^1, \mathbb{R}^n)$ such that

$$d^{n-k-2}\Phi(\nabla T_2^i) \neq 0,$$

$$d^l\Phi(\nabla T_2^i) = 0, \quad l = 1, \dots, n-k-3,$$

$$\Phi(\nabla T_2^i) = \Phi(\nabla T_1^i) = \Phi(\nabla T).$$

Extend T_2^i on E by setting $T_2^i = T_1^i$ on $E \setminus E_i^1$ and define

$$T_2 = \sum_{i=1}^{2n} T_2^i \chi_{E_i^1}.$$

Then

$$T_2 = T_1 + \sum_{i=1}^{2n} (T_2^i - T_1^i)\chi_{E_i^1}.$$

Since the second term at the right-hand side is in $W_0^{1,\infty}(E, \mathbb{R}^n)$, T_2 belongs to $T_1 + W_0^{1,\infty}(E, \mathbb{R}^n) = T + W_0^{1,\infty}(E, \mathbb{R}^n)$ and has the same properties of T_1. This procedure can be iterated $n-k-1$ times to obtain the piecewise-affine transformation $T_r(E) = T_{n-k-1}$ belonging to $T + W_0^{1,\infty}(E, \mathbb{R}^n)$.

Now, for any $h = 1, \dots, m$, set $T_r^h = T^h$ if $d\Phi(\nabla T^h) \neq 0$ and $T_r^h = T_r(\Omega_h)$, defined as above, if $d\Phi(\nabla T^h) = 0$. Extend T_r^h on Ω by setting $T_r^h = T^h$ on $\Omega \setminus \Omega_h$ and define T_r as

$$T_r = \sum_{h=1}^{m} T_r^h \chi_{\Omega_h}.$$

We have

$$T_r = T_B + \sum_{h=1}^{m} \left(T_r^h - T^h\right) \chi_{\Omega_h},$$

and since the second term on the right-hand side is in $W_0^{1,\infty}(\Omega, \mathbb{R}^n)$, T_r belongs to $T_B + W_0^{1,\infty}(\Omega, \mathbb{R}^n)$. Moreover, by the above, $\Phi(\nabla T_r) = \Phi(\nabla T_B)$ and $d\Phi(\nabla T_r) \neq 0$ a.e. in Ω. □

THEOREM 3.1. *Let $\Phi : \mathcal{M}_n \to \mathbb{R}$ be nonconstant and quasi-affine. Let $T_B : \mathbb{R}^n \to \mathbb{R}^n$ be a piecewise-affine transformation such that $\Phi(\nabla T_B)$ is constant. Let $\alpha, \beta \in \mathbb{R}$ $(\alpha < \beta)$ $\lambda \in]0,1[$ be such that*

$$\Phi(\nabla T_B) = \lambda\alpha + (1-\lambda)\beta.$$

Then there exist two open regular disjoint subsets of Ω, Ω^α, and Ω^β, a null set N, and a piecewise-affine transformation $T_{\alpha,\beta} \in T_B + W_0^{1,\infty}(\Omega, \mathbb{R}^n)$, such that $\Omega = N \bigcup \Omega^\alpha \bigcup \Omega^\beta$ and

(i) $\Phi(\nabla T_{\alpha,\beta}) = \alpha\chi_{\Omega^\alpha} + \beta\chi_{\Omega^\beta}$.

(ii) $\int_\Omega \Phi(\nabla T_{\alpha,\beta}(x))dx = \mu(\Omega)\Phi(\nabla T_B)$,

or, in other words,

(ii′) $\frac{\mu(\Omega^\alpha)}{\mu(\Omega)} = \lambda$, $\frac{\mu(\Omega^\beta)}{\mu(\Omega)} = 1-\lambda$.

Proof. By the previous lemma there exists a piecewise-affine transformation $T_r \in T_B + W_0^{1,\infty}(\Omega, \mathbb{R}^n)$ such that

$$T_r = \sum_{i=1}^{m} T^i \chi_{\Omega_i},$$

where $\{\Omega_i, i = 1, \dots, m\}$ is a regular partition of Ω, each T^i is affine, $\Phi(\nabla T^i) = \Phi(\nabla T_B)$, and $d\Phi(\nabla T^i) \neq 0$ for every index i.

Fix an index $j \in \{1, \dots, m\}$ and consider the transformation T^j. Apply Lemma 3.1 with $D = \nabla T^j$, $\gamma_1 = \alpha - \Phi(\nabla T^j)$, $\gamma_2 = \beta - \Phi(\nabla T^j)$ to obtain a vector b and an

n-dimensional polytope $P \subset \mathbb{R}^n$ with vertices $\{v_i^\alpha, v_i^\beta, i = 1, \dots, 2n\}$ containing zero in its interior such that

$$\langle\!\langle d\Phi(\nabla T^j), b \otimes v_i^\alpha \rangle\!\rangle_n = \alpha - \Phi(\nabla T^j)$$

and

$$\langle\!\langle d\Phi(\nabla T^j), b \otimes v_i^\beta \rangle\!\rangle_n = \beta - \Phi(\nabla T^j).$$

Define $u \in W_0^{1,\infty}(\Omega_j, \mathbb{R})$ as in Lemma 2.1 with $V = V(P)$ and $E = \Omega_j$. Consider the transformation

$$S^j(x) = T^j(x) + u(x)b.$$

S^j is piecewise-affine and belongs to $T^j + W_0^{1,\infty}(\Omega_j, \mathbb{R}^n)$; moreover, by Lemma 2.1 and by Theorem 2.1 (iii), there exist two open regular disjoint subsets of Ω_j, Ω_j^α, and Ω_j^β and a null set N, such that $\Omega_j = N \bigcup \Omega_j^\alpha \bigcup \Omega_j^\beta$ and

$$\Phi(\nabla S^j) = \Phi(\nabla T^j + b \otimes \nabla u)$$

$$= \Phi(\nabla T^j) + \langle\!\langle d\Phi(\nabla T^j), b \otimes \nabla u \rangle\!\rangle_n = \alpha \chi_{\Omega_j^\alpha} + \beta \chi_{\Omega_j^\beta}.$$

Repeat this construction for any index $j \in \{1, \dots, m\}$ and extend S^j as T^j on $\Omega \setminus \Omega_j$.

Finally define $T_{\alpha,\beta}$ by

$$T_{\alpha,\beta} = \sum_{j=1}^m S^j \chi_{\Omega_j}.$$

$T_{\alpha,\beta}$ is piecewise affine and can be written as

$$T_{\alpha,\beta} = T_r + \sum_{j=1}^m \left(S^j - T^j\right) \chi_{\Omega_j}.$$

Since the second term on the right-hand side is in $W_0^{1,\infty}(\Omega, \mathbb{R}^n)$, $T_{\alpha,\beta}$ belongs to $T_r + W_0^{1,\infty}(\Omega, \mathbb{R}^n) = T_B + W_0^{1,\infty}(\Omega, \mathbb{R}^n)$. Setting

$$\Omega^\alpha = \bigcup_{j=1}^m \Omega_j^\alpha \quad \text{and} \quad \Omega^\beta = \bigcup_{j=1}^m \Omega_j^\beta,$$

we have, since Φ is quasi-affine,

$$\int_\Omega \Phi(\nabla T_{\alpha,\beta}(x))dx = \sum_{j=1}^m \mu(\Omega_j)\Phi(\nabla S^j)$$

$$= \sum_{j=1}^m \alpha\mu(\Omega_j^\alpha) + \beta\mu(\Omega_j^\beta) = \alpha\mu(\Omega^\alpha) + \beta\mu(\Omega^\beta) = \mu(\Omega)\Phi(\nabla T_{\alpha,\beta}),$$

i.e., point (ii). □

We are ready to prove the main result.

THEOREM 3.2. *Let Ω be an open bounded subset of $\mathbb{R}^n$ and let $g : \mathbb{R} \to \mathbb{R} \cup \{+\infty\}$ be a proper lower-semicontinuous function satisfying*

$$\lim_{|t|\to\infty} \frac{g(t)}{|t|} = +\infty.$$

Then for any piecewise-affine transformation $T_B : \mathbb{R}^n \to \mathbb{R}^n$ such that $\Phi(\nabla T_B)$ is constant and belongs to co(dom(g))*, the problem*

$$\mathcal{P}: \ \textit{Minimize} \int_\Omega g(\Phi(\nabla T(x)))dx, \qquad T \in T_B + W_0^{1,\infty}(\Omega, \mathbb{R}^n)$$

admits at least one solution.

Proof. Consider g^{**}, the bipolar of g, as defined in [ET] and call dom(g) the set in which g is strictly less than infinity.

(a) Consider first the case in which $\Phi(\nabla T_B) \in \partial(\text{co}(\text{dom}(g)))$. We claim that T_B is a solution of $\mathcal{P}$. In the case $\Phi(\nabla T_B) = \sup(\text{co}(\text{dom}(g)))$ we remark that for any $T \in T_B + W_0^{1,\infty}(\Omega, \mathbb{R}^n)$, by Theorem 1 of [D2] and the following remark, we have, since Φ is quasi-affine,

$$\int_\Omega (\Phi(\nabla T(x)) - \Phi(\nabla T_B(x)))\, dx = 0.$$

For any T such that

$$\int_\Omega g\,(\Phi(\nabla T(x)))\, dx < +\infty,$$

for a.e. $x \in \Omega$ it must be that $\Phi(\nabla T(x)) \leq \Phi(\nabla T_B(x))$. Hence $\Phi(\nabla T(x)) = \Phi(\nabla T_B(x))$ for a.e. $x \in \Omega$, so that T_B is a solution and any other solution T_1 of $\mathcal{P}$ must be such that $\Phi(\nabla T_1) = \Phi(\nabla T_B)$.

The case $\Phi(\nabla T_B) = \inf(\text{co}(\text{dom}(g)))$ is analogous.

(b) Consider now the case $\Phi(\nabla T_B) \in \text{int}(\text{co}(\text{dom}(g)))$ (where this set can be the whole $\mathbb{R}$). There exists a line ρ separating the point $(\Phi(\nabla T_B), g^{**}(\Phi(\nabla T_B)))$ from the closed convex set epi(g^{**}). Since $\Phi(\nabla T_B)$ is in the interior of dom(g^{**}), ρ cannot be vertical, i.e., there exist $\gamma, \delta \in \mathbb{R}$ such that, for $t \in \text{dom}(g^{**})$,

$$g(t) \geq g^{**}(t) \geq \gamma t + \delta$$

and

$$g^{**}(\Phi(\nabla T_B)) = \gamma \Phi(\nabla T_B) + \delta.$$

Let $T \in T_B + W_0^{1,\infty}(\Omega, \mathbb{R}^n)$. We have

$$\int_\Omega g\,(\Phi\,(\nabla T(x)))\, dx \geq \int_\Omega g^{**}\,(\Phi\,(\nabla T(x)))\, dx \geq \int_\Omega (\gamma\Phi\,(\nabla T(x)) + \delta)\, dx;$$

by the previous remark, since Φ is quasi-affine,

$$\int_\Omega (\gamma\Phi\,(\nabla T(x)) + \delta)\, dx = \int_\Omega (\gamma\Phi\,(\nabla T_B(x)) + \delta)\, dx = \int_\Omega g^{**}\,(\Phi\,(\nabla T_B(x)))\, dx.$$

When $g\,(\Phi\,(\nabla T_B)) = g^{**}\,(\Phi\,(\nabla T_B))$ the above argument shows that T_B is a solution. Otherwise, by a slight modification of IX.3.3 of [ET], taking into account the superlinear growth condition on g, we can say that there exist $\alpha, \beta \in \mathbb{R}$, $\lambda \in]0, 1[$ such that

$$\Phi\,(\nabla T_B) = \lambda\alpha + (1 - \lambda)\beta$$

and

$$g^{**}\left(\Phi\left(\nabla T_B\right)\right) = \lambda g(\alpha) + (1-\lambda)g(\beta).$$

In this case,

$$\int_{\Omega} g^{**}\left(\Phi\left(\nabla T_B(x)\right)\right) dx = \lambda\mu(\Omega)g(\alpha) + (1-\lambda)\mu(\Omega)g(\beta).$$

Hence the transformation $T_{\alpha,\beta}$ given by Theorem 3.1 is a solution of $\mathcal{P}$. □

Remark. Since the function Φ is real valued, the problem of finding a solution is underdetermined and, in general, one cannot expect uniqueness of the solution. Actually, in the case of the Jacobian determinant, it is easy to see that the problem admits infinitely many solutions. Indeed when T_B is not a solution, the assertion follows easily from the construction of the solution defined in Theorem 3.1, since it depends on a scalar function v, which can be defined in infinite ways (depending on the choice of the set of vectors which constitute the range of the gradient of v). When T_B is a solution of $\mathcal{P}$ we simply notice that, given a regular transformation $J : \Omega \to \Omega$, different from the identity, such that $\det(\nabla J) = 1$ on Ω and $J\big|_{\partial\Omega} = I\big|_{\partial\Omega}$ (I denotes the identity),

$$\det\left(\nabla\left(T_B \circ J\right)\right) = \det(\nabla T_B)$$

and

$$T_B \circ J\big|_{\partial\Omega} = T_B\big|_{\partial\Omega}.$$

Hence $T \equiv T_B \circ J$ is a solution. Since there exist infinitely many transformations J with such properties (see [DM]), the assertion is proved.

FEEDBACK LAWS FOR NONLINEAR DISTRIBUTED CONTROL PROBLEMS VIA TROTTER-TYPE PRODUCT FORMULAE*

CĂTĂLIN POPA†

Abstract. A feedback law expressed by means of a Trotter product formula approximation of the dynamic programming equation, and which provides approximately optimal controls, is established for the control systems governed by a certain class of variational inequalities of parabolic type. To this purpose, two general Lie–Trotter formulas for the dynamic programming equation are proposed, and corresponding convergence results (generalizing previous results of the author) are proved. The framework also includes the control systems described by the parabolic obstacle problem as well as those governed by semilinear parabolic equations.

Key words. optimal control, variational inequalities, Hamilton–Jacobi equation, Trotter product formula, feedback law

AMS subject classifications. 49L10, 49L20, 49N35, 93B52, 93C20

1. Introduction. The aim of this paper is to show how a Trotter product formula treatment of the dynamic programming equation leads to a certain discrete feedback law for the optimal control problem, which seems very useful in effective synthesis of optimal control.

Our framework is given by the following class of nonlinear distributed optimal control problems:

(P) minimize

$$\int_0^T (h(u(t)) + g(y(t)))dt + l(y(T)) \tag{1.1}$$

over all $u \in L^2(0, T; \mathcal{U})$, where $y \in C([0, T]; \mathcal{H})$ satisfies the state equation

$$y'(t) + Ay(t) + \partial\phi(y(t)) \ni Bu(t) \tag{1.2}$$

and the initial condition

$$y(0) = y^0. \tag{1.3}$$

Here $\mathcal{H}$ and $\mathcal{U}$ are two real Hilbert spaces whose scalar products and norms are denoted by the same symbols, $(\cdot, \cdot)$ and $|\cdot|$, respectively.

We impose the following hypotheses on the data:

(i) $h : \mathcal{U} \to (-\infty, +\infty]$ is convex, lower semicontinuous, not identically $+\infty$, and satisfies

$$h(u) \geq c_1|u|^2 - c_2 \quad \text{for all } u \in \mathcal{U}, \tag{1.4}$$

where $c_1 > 0$ and $c_2 \in \mathbf{R}$.

(ii) $g, l : \mathcal{H} \to \mathbf{R}$ are Lipschitz continuous on bounded subsets and bounded from below by affine functions.

(iii) $A : \mathcal{V} \to \mathcal{V}'$ is linear, continuous, and symmetric, $\mathcal{V}$ being a Hilbert space continuously and densely imbedded in $\mathcal{H}$ with $\mathcal{V}'$ its dual space. Identifying $\mathcal{H}$ with its own dual, we have $\mathcal{V} \subset \mathcal{H} \subset \mathcal{V}'$. Denote by $(\cdot, \cdot)$ the pairing between $\mathcal{V}$ and $\mathcal{V}'$, and by $|\cdot|_{\mathcal{V}}$ the norm of $\mathcal{V}$. These being specified, we assume, in addition, that A satisfies

$$(Ay, y) \geq \omega|y|_{\mathcal{V}}^2 \quad \text{for all } y \in \mathcal{V}, \tag{1.5}$$

† Facultatea de Matematică, Universitatea "Al.I. Cuza," B-dul Copou 11, 6600 Iaşi, Romania. (cpopa@uaic.ro).

where $\omega > 0$, and the inclusion $\mathcal{V} \subset \mathcal{H}$ is compact. Finally, set $D(A) = \{y \in \mathcal{V} : Ay \in \mathcal{H}\}$.

(iv) $\phi : \mathcal{H} \to (-\infty, +\infty]$ is convex, lower semicontinuous, not identically $+\infty$, and such that $A + \partial\phi$ is maximal monotone in $\mathcal{H} \times \mathcal{H}$. (Here $\partial\phi$ is the subdifferential of ϕ.)

(v) $B : \mathcal{U} \to \mathcal{H}$ is a linear continuous operator.

To assure the maximal monotonicity of $A + \partial\phi$ in $\mathcal{H} \times \mathcal{H}$ it suffices to have (see [2, Thm. 1.10])

$$(Ay, (\partial\phi)_\eta(y)) \geq -c(1 + |(\partial\phi)_\eta(y)|)(1 + |y|) \quad \text{for all } y \in D(A) \text{ and } \eta > 0, \tag{1.6}$$

where $c > 0$ and $(\partial\phi)_\eta$ is the Yosida approximation of $\partial\phi$, i.e., $(\partial\phi)_\eta = \eta^{-1}(I - (I + \eta\partial\phi)^{-1})$, I being the identity operator of $\mathcal{H}$.

By a standard existence result, for any $y^0 \in \overline{D(A) \cap D(\partial\phi)}$, problem (1.2), (1.3) has a unique weak (integral) solution. Moreover, under (1.6), if $y^0 \in \mathcal{V} \cap D(\phi)$, then (1.2), (1.3) has a unique solution in $W^{1,2}([0,T];\mathcal{H}) \cap C([0,T];\mathcal{V}) \cap L^2(0,T;D(A))$ (see [2, Thm. 4.3]).

According to the dynamic programming method, we associate with the optimal control problem (P) the corresponding optimal value function

$$\begin{aligned} V(t,y) = \inf\bigg\{ \int_t^T (h(u(s)) + g(y(s)))ds + l(y(T)) : y' + Ay + \partial\phi(y) \ni Bu, \\ y(t) = y, u \in L^2(t,T;\mathcal{U}) \bigg\}, \qquad (t,y) \in [0,T] \times \overline{D(A) \cap D(\partial\phi)}. \end{aligned} \tag{1.7}$$

The function V formally satisfies the following infinite-dimensional Hamilton–Jacobi equation, called, in this context, the dynamic programming equation associated with problem (P):

$$\begin{aligned} D_tV(t,y) - h^*(-B^*D_yV(t,y)) - (Ay + \partial\phi(y), D_yV(t,y)) \\ = -g(y) \quad \text{in } [0,T] \times \mathcal{H}, \end{aligned} \tag{1.8}$$

together with the final condition

$$V(T,y) = l(y), \qquad y \in \mathcal{H}. \tag{1.9}$$

Here h^* denotes the convex conjugate of h and B^* is the adjoint of B. As a matter of fact, one can show that V is the unique solution of (1.8), (1.9) in a certain viscosity sense (see [12]).

Let $u^* \in L^2(0,T;\mathcal{U})$ be an arbitrary optimal control for problem (P) and $y^* \in C([0,T];\mathcal{H})$ the corresponding optimal arc. Heuristic considerations based on the Hamilton–Jacobi equation (1.8) lead to the following feedback law:

$$u^*(t) \in \partial h^*(-B^*D_yV(t,y^*(t))), \qquad t \in (0,T). \tag{1.10}$$

However, this formula (if we should prove it) is almost inapplicable to the effective synthesis of optimal control for (P), mainly because it is very difficult to calculate V: the Hamilton–Jacobi equation (1.8) is a very complicated mathematical object even in the finite-dimensional case. At present there are no constructive theories or adequate approximation methods for such equations, except in some special cases.

A new perspective on this topic is offered by an idea of V. Barbu introduced in [3], [4]. This consists of decoupling the terms containing $D_yV(t,y)$ in the dynamic programming equation by decomposing the corresponding Cauchy problem into a sequence of several simpler problems. Performing this operation successively on small time intervals, we obtain an approximate solution to the considered Cauchy problem, which may be interpreted as a Lie–Trotter product formula for the dynamic programming equation viewed as an evolution equation on a suitable space of function on $\mathcal{H}$. As V. Arnăutu has shown in [1], this method turns out to be very efficacious in numerical computation of V, at least in the finite-dimensional case ($n = 2, 3$).

In a previous paper [11], the author decomposed the Cauchy problem (1.8), (1.9) into two problems and expressed their solution by a suitable approximation and a Hopf–Oleinik–Lax representation formula (i.e., an explicit formula for the solution of problem (1.8), (1.9) in which $A + \partial\phi = 0$ and $g = 0$ given by a variant of (1.7) where the infimum is taken over $u \in \mathcal{U}$; see [9], [10] for the original formulas). In the case when ϕ in (1.2) is the indicator function I_K of a closed convex subset K of $\mathcal{H}$, this approach yields more general convergence results (see [11, Thms. 1 and 2]) as well as simpler formulas for calculating V.

In the present paper, we shall use one of the Trotter product formulas proposed in [11] to obtain a discrete variant of the feedback law (1.10), which will offer a reasonable way for synthesis of optimal control. The aforementioned formula expresses the convergence of the scheme

(1.11)

$$\begin{cases} D_tV^\varepsilon(t,y) - h^*(-B^*D_yV^\varepsilon(t,y)) = 0 \quad \text{in}\, [i\varepsilon,(i+1)\varepsilon) \times \mathcal{H}, \\ V^\varepsilon((i+1)\varepsilon - 0, y) = V^\varepsilon((i+1)\varepsilon, (I+\varepsilon\partial\phi)^{-1}(I+\varepsilon A)^{-1}y) \\ \qquad\qquad + \varepsilon g((I+\varepsilon\partial\phi)^{-1}(I+\varepsilon A)^{-1}y) \quad \text{on}\, \mathcal{H}, i = 0,1,\dots,N-1, \\ V^\varepsilon(N\varepsilon, y) = l(y), y \in \mathcal{H}, \end{cases}$$

to the solution of the dynamic programming equation (1.8) with the final condition (1.9). Here $\varepsilon = T/N$, where N is a positive integer. Solving (1.11) by a Lax-type formula, we obtain an approximate solution to problem (1.8), (1.9). For simplicity, let us indicate it only for $t = i\varepsilon$:

(1.12)

$$\begin{cases} V^\varepsilon(i\varepsilon, y) = \inf\{\varepsilon h(u) + \varepsilon g((I+\varepsilon\partial\phi)^{-1}(I+\varepsilon A)^{-1}(y+\varepsilon Bu)) \\ \qquad + V^\varepsilon((i+1)\varepsilon, (I+\varepsilon\partial\phi)^{-1}(I+\varepsilon A)^{-1}(y+\varepsilon Bu)) : u \in \mathcal{U}\}, \quad y \in \mathcal{H}, \\ \qquad i = 0,1,\dots,N-1, \\ V^\varepsilon(T,y) = l(y), y \in \mathcal{H}. \end{cases}$$

First of all, we shall prove the following Trotter-type product formula (Theorem 3.1):

$$\lim_{\varepsilon \to 0} V^\varepsilon(t,y) = V(t,y), \qquad (t,y) \in [0,T] \times \overline{D(A) \cap D(\partial\phi)}. \tag{1.13}$$

This is a generalization of a result from [11]: the indicator function I_K from [11] is replaced by a general lower semicontinuous convex function ϕ. So we also cover the case of the control systems governed by semilinear parabolic equations (see [5] for a related result) besides that of the parabolic obstacle problem. An alternative Trotter formula is given by Theorem 3.2.

Scheme (1.12) and formula (1.13) suggest to us that problem (P) could be approximated by the following family of discrete problems:

(P^ε) minimize

$$\sum_{i=1}^{N} \varepsilon(h(u_i) + g(y_i)) + l(y_N)$$

over all $(u_1, u_2, \dots, u_N) \in \mathcal{U}^N$, where $(y_1, y_2, \dots, y_N) \in \mathcal{H}^N$ satisfies the scheme

$$\begin{cases} y_i = (I+\varepsilon\partial\phi)^{-1}(I+\varepsilon A)^{-1}(y_{i-1}+\varepsilon Bu_i), \quad i = 1,2,\dots,N, \\ y_0 = y^0. \end{cases}$$

We shall show (Theorem 5.1) that this is indeed the case: every optimal N-tuple $(u_1^\varepsilon, u_2^\varepsilon, \dots, u_N^\varepsilon)$ for problem (P^ε) may be viewed as an approximately optimal control for problem (P).

The main result of this paper (Theorem 6.1) is established for a little more restricted class of nonlinear control problems: in (P), $\mathcal{H} = L^2(\Omega)$ and the state equation is

$$y' + Ay + \beta(y) \ni Bu,$$

where β is a maximal monotone graph in $\mathbf{R}^2$. In this context, any optimal N-tuple $(u_1^\varepsilon, u_2^\varepsilon, \dots, u_N^\varepsilon)$ for problem (P^ε) satisfies the following feedback law:

$$u_i^\varepsilon \in \partial h^*(-B^*\partial_y V^\varepsilon((i-1)\varepsilon, y_{i-1}^\varepsilon)), \qquad i = 1, 2, \dots, N, \tag{1.14}$$

where

$$\begin{cases} y_i^\varepsilon = (I + \varepsilon\beta)^{-1}(I + \varepsilon A)^{-1}(y_{i-1}^\varepsilon + \varepsilon B u_i^\varepsilon), \\ y_0^\varepsilon = y^0. \end{cases} \tag{1.15}$$

Here $\partial_y V^\varepsilon$ is the Clarke generalized gradient of V^ε with respect to y. Formula (1.14) may be interpreted as an approximate feedback law for problem (P).

System (1.14), (1.15) offers us a set of necessary optimality conditions for (P^ε), which can be useful in constructing a suboptimal control for (P), but on the condition that V^ε is known. The numerical calculation of V^ε is another problem, but a glance at (1.12) or (1.11) clearly shows how much easier it is to get V^ε than V. (For the finite-dimensional case we refer to [1].)

2. Trotter schemes for the dynamic programming equation. By a simple change of unknown function, we can transform problem (1.8), (1.9) into a Cauchy problem but with initial condition, which is more convenient in our further considerations. Indeed, we define

$$W(t,y) = V(T-t,y) \quad \text{for } (t,y) \in [0,T] \times \overline{D(A) \cap D(\partial\phi)}.$$

It is easy to check that

$$\begin{aligned} W(t,y) = \inf\Big\{ &\int_0^t (h(u(s)) + g(y(s)))ds + l(y(T)) : y' + Ay + \partial\phi(y) \ni Bu, \\ &y(0) = y,\, u \in L^2(0,t;\mathcal{U})\Big\}, \qquad (t,y) \in [0,T] \times \overline{D(A) \cap D(\partial\phi)}. \end{aligned} \tag{2.1}$$

The function W is the unique viscosity solution (in the sense of [12]) of the Hamilton–Jacobi equation

$$D_t W(t,y) + h^*(-B^* D_y W(t,y)) + (Ay + \partial\phi(y),\, D_y W(t,y)) = g(y) \tag{2.2}$$

with the initial condition

$$W(0,y) = l(y), \qquad y \in \mathcal{H}. \tag{2.3}$$

Let $\varepsilon = T/N$, where N is a sufficiently large positive integer. On each subinterval $((i-1)\varepsilon, i\varepsilon]$, we decompose the Cauchy problem (2.2), (2.3) into two problems, the second of these being the following:

$$\begin{aligned} &D_t W_\varepsilon(t,y) + h^*(-B^* D_y W_\varepsilon(t,y)) = 0 \quad \text{in } ((i-1)\varepsilon, i\varepsilon] \times \mathcal{H}, \\ &W_\varepsilon((i-1)\varepsilon + 0, y) = W_\varepsilon((i-1)\varepsilon, (I + \varepsilon\partial\phi)^{-1}(I + \varepsilon A)^{-1} y) \\ &\qquad + \varepsilon g((I + \varepsilon\partial\phi)^{-1}(I + \varepsilon A)^{-1} y), \qquad y \in \mathcal{H}, \quad i = 1, 2, \dots, N, \end{aligned}$$

where

$$W_\varepsilon(0,y) = l(y), \qquad y \in \mathcal{H}.$$

Here $y \mapsto W_\varepsilon((i-1)\varepsilon, (I+\varepsilon\partial\phi)^{-1}(I+\varepsilon A)^{-1}y) + \varepsilon g((I+\varepsilon\partial\phi)^{-1}(I+\varepsilon A)^{-1}y)$ represents an approximate solution of the first problem of the decomposition (which contains the unbounded term—corresponding to the dynamics of (P)—and the right-hand side g) with $W_\varepsilon((i-1)\varepsilon,\cdot)$ as initial datum. (Note that for $\partial\phi = 0$ and $g \equiv 0$, $y \mapsto W_\varepsilon((i-1)\varepsilon, e^{-A\varepsilon}y)$ is just the exact solution of the first problem at $t = i\varepsilon$.) Now expressing the exact solution of the second problem of the decomposition by a Lax-type representation formula (cf. [10, Eq. (2.12)]), we obtain

$$\begin{aligned} W_\varepsilon(t,y) = \inf\{&(t-(i-1)\varepsilon)h(u) + \varepsilon g((I+\varepsilon\partial\phi)^{-1}(I+\varepsilon A)^{-1}(y+(t-(i-1)\varepsilon)Bu)) \\ &+ W_\varepsilon((i-1)\varepsilon, (I+\varepsilon\partial\phi)^{-1}(I+\varepsilon A)^{-1}(y+(t-(i-1)\varepsilon)Bu)) : u \in \mathcal{U}\}, \\ &(t,y) \in ((i-1)\varepsilon, i\varepsilon] \times \mathcal{H}, \quad i = 1,2,\ldots,N, \\ W_\varepsilon(0,y) = l(y)&, y \in \mathcal{H}. \end{aligned}$$

Obviously, it is natural to interpret W_ε as an approximate solution to (2.2), (2.3), but we must prove that we may do this. For technical reasons, we shall slightly modify the above scheme to obtain

$$W^\varepsilon(t,y) = \begin{cases} \inf\{\varepsilon h(u) + \varepsilon g((I+\varepsilon\partial\phi)^{-1}(I+\varepsilon A)^{-1}(y+\varepsilon Bu)) \\ \qquad + W^\varepsilon(t-\varepsilon, (I+\varepsilon\partial\phi)^{-1}(I+\varepsilon A)^{-1}(y+\varepsilon Bu)) : u \in \mathcal{U}\}, \\ (t,y) \in (\varepsilon, T] \times \mathcal{H}, \\ \inf\{th(u) + \varepsilon g((I+\varepsilon\partial\phi)^{-1}(I+\varepsilon A)^{-1}(y+tBu)) \\ \qquad + l((I+\varepsilon\partial\phi)^{-1}(I+\varepsilon A)^{-1}(y+tBu)) : u \in \mathcal{U}\}, \\ (t,y) \in (0,\varepsilon] \times \mathcal{H}, \end{cases} \tag{2.4}$$

$$W^\varepsilon(0,y) = l(y), \qquad y \in \mathcal{H}.$$

This scheme gives the same values as the preceding scheme at $t = i\varepsilon : V_\varepsilon(i\varepsilon, y) = V^\varepsilon(i\varepsilon, y)$. As we shall see in §6, only these values will matter in expressing the discrete feedback law.

We obtain the following alternative scheme by interchanging the resolvents of A and $\partial\phi$ in (2.4):

$$\overline{W}^\varepsilon(t,y) = \begin{cases} \inf\{\varepsilon h(u) + \varepsilon g((I+\varepsilon A)^{-1}(I+\varepsilon\partial\phi)^{-1}(y+\varepsilon Bu)) \\ \qquad + \overline{W}^\varepsilon(t-\varepsilon, (I+\varepsilon A)^{-1}(I+\varepsilon\partial\phi)^{-1}(y+\varepsilon Bu)) : u \in \mathcal{U}\}, \\ (t,y) \in (\varepsilon, T] \times \mathcal{H}, \\ \inf\{th(u) + \varepsilon g((I+\varepsilon A)^{-1}(I+\varepsilon\partial\phi)^{-1}(y+tBu)) \\ \qquad + l((I+\varepsilon A)^{-1}(I+\varepsilon\partial\phi)^{-1}(y+tBu)) : u \in \mathcal{U}\}, \\ (t,y) \in (0,\varepsilon] \times \mathcal{H}, \end{cases} \tag{2.5}$$

$$\overline{W}^\varepsilon(0,y) = l(y), \qquad y \in \mathcal{H}.$$

3. Convergence of Trotter product formulae. As we already mentioned in the introduction, the following two results represent generalizations of those in [11]. As a matter of fact, we shall show that the arguments from [11] also work in the present, more general framework.

THEOREM 3.1. *Under hypotheses* (i) – (v), *suppose that the following additional assumption holds*:

(vi) $(I+\varepsilon\partial\phi)^{-1}$ *maps* $\mathcal{V}$ *into itself and*

$$(A(I+\varepsilon\partial\phi)^{-1}z, (I+\varepsilon\partial\phi)^{-1}z) \leq (Az, z) \quad \textit{for all } z \in \mathcal{V}. \tag{3.1}$$

Then for every $(t,y) \in [0,T] \times \overline{D(A) \cap D(\partial\phi)}$, *we have*

$$\lim_{\varepsilon\to 0} W^\varepsilon(t,y) = W(t,y). \tag{3.2}$$

Proof. Although the proof is very similar to that of Theorem 1 in [11], for the sake of completeness (and for the reader's convenience) we outline it, emphasizing the specific points of the present situation.

Recall that $\varepsilon = T/N$. Fix $(t,y) \in [0,T] \times \overline{D(A) \cup D(\partial\phi)}$. Let us suppose that t/ε is not an integer. The successive application of (2.4) on the intervals $(t-\varepsilon, t], (t-2\varepsilon, t-\varepsilon], \dots, (t-[t/\varepsilon]\varepsilon, t-([t/\varepsilon]-1)\varepsilon], (0, t-[t/\varepsilon]\varepsilon]$ leads (after some convenient rewriting) to the following representation for W^ε:

$$\begin{aligned} W^\varepsilon(t,y) = \inf\Bigg\{ & \sum_{i=1}^{[t/\varepsilon]} \varepsilon h(u(i\varepsilon)) + \left(t - \left[\frac{t}{\varepsilon}\right]\varepsilon\right) h\left(u\left(\left(\left[\frac{t}{\varepsilon}\right]+1\right)\varepsilon\right)\right) \\ & + \sum_{i=1}^{[t/\varepsilon]} \varepsilon g(y_u^\varepsilon(i\varepsilon)) + \varepsilon g(y_u^\varepsilon(t)) \\ & + l(y_u^\varepsilon(t)) : u \text{ is a step function from } [0,T] \text{ to } \mathcal{U} \Bigg\}, \end{aligned} \tag{3.3}$$

where for any (step) function $u : [0,T] \to \mathcal{U}$, y_u^ε is defined by

$$\begin{cases} y_u^\varepsilon(t) = (I+\varepsilon\partial\phi)^{-1}(I+\varepsilon A)^{-1}(y_u^\varepsilon((i-1)\varepsilon) + (t-(i-1)\varepsilon)Bu(i\varepsilon)) \\ \qquad \text{for } t \in ((i-1)\varepsilon, i\varepsilon], \quad i = 1,2,\dots,N, \\ y_u^\varepsilon(0) = y. \end{cases} \tag{3.4}$$

If t/ε is an integer, then in (3.3) we must eliminate the two terms containing the values of h and g which are not under the sum signs.

The statement of the theorem now becomes more transparent if we look at (3.3) and recognize in (3.4) a Trotter scheme for (1.2) with the initial state y. So, the following lemma represents an important stage in the proof.

Let u be a step function from $[0,T]$ to $\mathcal{U}$ which takes constant values on $(0,\varepsilon_0], (\varepsilon_0, 2\varepsilon_0], \dots, ((N_0-1)\varepsilon_0, N_0\varepsilon_0] = (T-\varepsilon_0, T]$. Denote by y_u the unique weak solution of the Cauchy problem

$$\begin{cases} y_u' + Ay_u + \partial\phi(y_u) \ni Bu, \\ y_u(0) = y. \end{cases}$$

LEMMA 3.1. *For every* $t \in [0,T]$, *we have*

$$\lim_{\varepsilon\to 0} y_u^\varepsilon(t) = y_u(t) \quad \textit{strongly in } \mathcal{H}.$$

The main tool in the proof of Lemma 3.1 is the nonlinear version of the Chernoff formula (see [11, Lem. 2]).

Using Lemma 3.1, we obtain without serious difficulties (see also [11, Rem. 1])

$$\limsup_{\varepsilon\to 0} W^\varepsilon(t,y) \le W(t,y).$$

The other inequality, i.e.,

$$\liminf_{\varepsilon\to 0} W^\varepsilon(t,y) \ge W(t,y),$$

is somewhat more difficult. We shall treat it in detail.

For any step function $u : [0,T] \to \mathcal{U}$, denote

$$W^\varepsilon(t,y;u) = \begin{cases} \displaystyle\sum_{i=1}^{[t/\varepsilon]} \varepsilon h(u(i\varepsilon)) + \left(t - \left[\frac{t}{\varepsilon}\right]\varepsilon\right) h\left(u\left(\left(\left[\frac{t}{\varepsilon}\right]+1\right)\varepsilon\right)\right) \\ \qquad\qquad\qquad \displaystyle + \sum_{i=1}^{[t/\varepsilon]} \varepsilon g(y^\varepsilon_u(i\varepsilon)) \\ \qquad\qquad\qquad + \ \varepsilon g(y^\varepsilon_u(t)) + l(y^\varepsilon_u(t)) \quad \text{if } t/\varepsilon \text{ is not an integer,} \\ \displaystyle\sum_{i=1}^{[t/\varepsilon]} \varepsilon(h(u(i\varepsilon)) + g(y^\varepsilon_u(i\varepsilon))) + l(y^\varepsilon_u(t)) \quad \text{otherwise.} \end{cases}$$

Clearly, we may select a subsequence of $\{\varepsilon\}$, also denoted $\{\varepsilon\}$, and a corresponding sequence of step functions u^ε, each u^ε taking constant values on $(0,\varepsilon], (\varepsilon, 2\varepsilon], \ldots, (T-\varepsilon, T]$, such that

$$\lim_{\varepsilon\to 0} W^\varepsilon(t,y;u^\varepsilon) = \liminf_{\varepsilon\to 0} W^\varepsilon(t,y) \le \limsup_{\varepsilon\to 0} W^\varepsilon(t,y) \le W(t,y).$$

Hence, by using hypotheses (i) (actually (1.4)) and (ii) together with the estimate

$$|y^\varepsilon_{u^\varepsilon}(s)| \le |((I+\varepsilon\partial\phi)^{-1}(I+\varepsilon A)^{-1})^{[s/\varepsilon]+1} y| + \int_0^s |Bu^\varepsilon(\tau)|d\tau,$$

it follows that $\{u^\varepsilon\}$ is bounded in $L^2(0,t;\mathcal{U})$; consequently, on a subsequence, $u^\varepsilon \to u^0$ weakly in $L^2(0,t;\mathcal{U})$ as $\varepsilon \to 0$.

LEMMA 3.2. *Let $\{u^\varepsilon\}$ be a sequence of step functions as above and $y \in D(A) \cap D(\partial\phi)$. If $u^\varepsilon \to u^0$ weakly in $L^2(0,t;\mathcal{U})$, then for every $s \in [0,t]$,*

$$y^\varepsilon_{u^\varepsilon}(s) \to y_{u^0}(s) \quad \textit{strongly in } \mathcal{H}.$$

Proof. First we shall show that $y^\varepsilon_{u^\varepsilon}(s)$ converges strongly in $\mathcal{H}$ (possible on a subsequence) for every $s \in [0,t]$. To this end we introduce the auxiliary function $z^\varepsilon_{u^\varepsilon}$ given by

$$z^\varepsilon_{u^\varepsilon}(s) = (I+\varepsilon A)^{-1}(y^\varepsilon_{u^\varepsilon}((i-1)\varepsilon) + (s-(i-1)\varepsilon)Bu^\varepsilon(i\varepsilon)) \quad \text{for } s \in ((i-1)\varepsilon, i\varepsilon], \\ i = 1,2,\ldots,N.$$

Obviously, $y^\varepsilon_{u^\varepsilon}(s) = (I+\varepsilon\partial\phi)^{-1} z^\varepsilon_{u^\varepsilon}(s)$. For simplicity we set $z^\varepsilon_{u^\varepsilon} = z^\varepsilon$ and $y^\varepsilon_{u^\varepsilon} = y^\varepsilon$. One easily verifies that z^ε satisfies the following difference scheme:

$$\frac{1}{\varepsilon}((I+\varepsilon\partial\phi)^{-1}z^\varepsilon(i\varepsilon) - (I+\varepsilon\partial\phi)^{-1}z^\varepsilon((i-1)\varepsilon)) \\ + Az^\varepsilon(i\varepsilon) + \partial\phi_\varepsilon(z^\varepsilon(i\varepsilon)) = Bu^\varepsilon(i\varepsilon), i = 2,3,\ldots,\left[\frac{s}{\varepsilon}\right], \qquad s \in [0,t].$$

Here ϕ_ε is the convex regularization of ϕ. (Recall that $(\partial\phi)_\varepsilon = \partial\phi_\varepsilon$.) Multiplying scalarly in $\mathcal{H}$ by $z^\varepsilon(i\varepsilon) - z^\varepsilon((i-1)\varepsilon)$, we obtain after some calculation

$$\begin{aligned} &\frac{1}{\varepsilon}|y^\varepsilon(i\varepsilon) - y^\varepsilon((i-1)\varepsilon)|^2 + \frac{1}{2}(Az^\varepsilon(i\varepsilon), z^\varepsilon(i\varepsilon)) - \frac{1}{2}(Az^\varepsilon((i-1)\varepsilon), z^\varepsilon((i-1)\varepsilon)) \\ &\quad + \phi_\varepsilon(z^\varepsilon(i\varepsilon)) - \phi_\varepsilon(z^\varepsilon((i-1)\varepsilon)) \\ &\le \frac{1}{2\varepsilon}|y^\varepsilon((i-1)\varepsilon) - y^\varepsilon((i-2)\varepsilon)|^2 + 2\varepsilon|Bu^\varepsilon(i\varepsilon)|^2 + \frac{\varepsilon}{2}|Bu^\varepsilon((i-1)\varepsilon)|^2, \\ &\qquad\qquad i = 2,3,\ldots,\left[\frac{s}{\varepsilon}\right]. \end{aligned} \tag{3.5}$$

If s/ε is not an integer, we have as above

$$\begin{aligned}&\frac{1}{\varepsilon}\left|y^\varepsilon(s)-y^\varepsilon\left(\left[\frac{s}{\varepsilon}\right]\varepsilon\right)\right|^2+\frac{1}{2}(Az^\varepsilon(s),z^\varepsilon(s))-\frac{1}{2}\left(Az^\varepsilon\left(\left[\frac{s}{\varepsilon}\right]\varepsilon\right),z^\varepsilon\left(\left[\frac{s}{\varepsilon}\right]\varepsilon\right)\right)\\&\quad+\phi_\varepsilon(z^\varepsilon(s))-\phi_\varepsilon\left(z^\varepsilon\left(\left[\frac{s}{\varepsilon}\right]\varepsilon\right)\right)\\&\quad\le\frac{1}{2\varepsilon}\left|y^\varepsilon\left(\left[\frac{s}{\varepsilon}\right]\varepsilon\right)-y^\varepsilon\left(\left(\left[\frac{s}{\varepsilon}\right]-1\right)\varepsilon\right)\right|^2\\&\qquad+2\left(s-\left[\frac{s}{\varepsilon}\right]\varepsilon\right)\left|Bu^\varepsilon\left(\left(\left[\frac{s}{\varepsilon}\right]+1\right)\varepsilon\right)\right|^2+\frac{\varepsilon}{2}\left|Bu^\varepsilon\left(\left[\frac{s}{\varepsilon}\right]\varepsilon\right)\right|^2.\end{aligned}\tag{3.6}$$

Adding inequalities (3.5) ($i=2,3,\dots,[s/\varepsilon]$) and (3.6), we have

$$\begin{aligned}&\sum_{i=2}^{[s/\varepsilon]}\frac{1}{2\varepsilon}|y^\varepsilon(i\varepsilon)-y^\varepsilon((i-1)\varepsilon)|^2+\frac{1}{\varepsilon}\left|y^\varepsilon(s)-y^\varepsilon\left(\left[\frac{s}{\varepsilon}\right]\varepsilon\right)\right|^2+\frac{1}{2}(Az^\varepsilon(s),z^\varepsilon(s))\\&\quad-\frac{1}{2}(Az^\varepsilon(\varepsilon),z^\varepsilon(\varepsilon))+\phi_\varepsilon(z^\varepsilon(s))-\phi_\varepsilon(z^\varepsilon(\varepsilon))\\&\quad\le\frac{1}{2\varepsilon}|y^\varepsilon(\varepsilon)-y|^2+\frac{1}{2}\varepsilon|Bu^\varepsilon(\varepsilon)|^2+\frac{5}{2}\varepsilon\sum_{i=2}^{[s/\varepsilon]}|Bu^\varepsilon(i\varepsilon)|^2\\&\qquad+2\left(s-\left[\frac{s}{\varepsilon}\right]\varepsilon\right)\left|Bu^\varepsilon\left(\left(\left[\frac{s}{\varepsilon}\right]+1\right)\varepsilon\right)\right|^2.\end{aligned}\tag{3.7}$$

Using the definition of $y^\varepsilon(\varepsilon)$ and the fact that $(I+\varepsilon\partial\phi)^{-1}$ and $(I+\varepsilon A)^{-1}$ are contractions, we derive

$$\frac{1}{\varepsilon}|y^\varepsilon(\varepsilon)-y|^2\le 3\varepsilon|Bu^\varepsilon(\varepsilon)|^2+3\varepsilon|Ay|^2+3\varepsilon|\partial\phi(y)|^2,\tag{3.8}$$

since $y\in D(A)\cap D(\partial\phi)$. Next we have

$$z^\varepsilon(\varepsilon)-y+\varepsilon Az^\varepsilon(\varepsilon)=\varepsilon Bu^\varepsilon(\varepsilon),$$

which, after a scalar multiplication by $z^\varepsilon(\varepsilon)-y$ and a suitable estimate of the right-hand side, yields

$$\frac{1}{2}(Az^\varepsilon(\varepsilon),z^\varepsilon(\varepsilon))-\frac{1}{2}(Ay,y)\le\frac{\varepsilon}{4}|Bu^\varepsilon(\varepsilon)|^2.\tag{3.9}$$

Further,

$$\phi_\varepsilon(z^\varepsilon(s))\ge\phi((I+\varepsilon\partial\phi)^{-1}z^\varepsilon(s))=\phi(y^\varepsilon(s)).\tag{3.10}$$

Regarding $\phi_\varepsilon(z^\varepsilon(\varepsilon))$, by the definition of ϕ_ε (see [6, p. 121]), we have

$$\phi_\varepsilon(z^\varepsilon(\varepsilon))\le\frac{1}{2\varepsilon}|z^\varepsilon(\varepsilon)-y|^2+\phi(y),$$

whence

$$\phi_\varepsilon(z^\varepsilon(\varepsilon))\le\varepsilon|Bu^\varepsilon(\varepsilon)|^2+\varepsilon|Ay|^2+\phi(y).\tag{3.11}$$

Now, adding (3.8), (3.9), and (3.11) to (3.7), and taking (3.10) into account as well, we obtain

$$\sum_{i=1}^{[s/\varepsilon]} \frac{1}{\varepsilon}|y^\varepsilon(i\varepsilon) - y^\varepsilon((i-1)\varepsilon)|^2 + \frac{1}{\varepsilon}\left|y^\varepsilon(s) - y^\varepsilon\left(\left[\frac{s}{\varepsilon}\right]\varepsilon\right)\right|^2 + (Az^\varepsilon(s), z^\varepsilon(s)) \leq \text{const.},$$

where the constant is independent of ε. Hence, on the one hand, using hypothesis (3.1) and condition (1.5), we ascertain that the sequence $\{y^\varepsilon(s)\}$ is bounded in $\mathcal{V}$ for any $s \in [0,t]$. On the other hand, taking $s = t$ in the above sum, we get

$$\sum_{i=1}^{[t/\varepsilon]} |y^\varepsilon(i\varepsilon) - y^\varepsilon((i-1)\varepsilon)| + \left|y^\varepsilon(t) - y^\varepsilon\left(\left[\frac{t}{\varepsilon}\right]\varepsilon\right)\right| \leq \text{const.}$$

But we also have (it is easy to verify)

$$|y^\varepsilon(s) - y^\varepsilon(s')| \leq |s - s'||Bu^\varepsilon(i\varepsilon)| \quad \text{for}\, s, s' \in ((i-1)\varepsilon, i\varepsilon], \quad i = 1, 2, \ldots, N.$$

Thus we have obtained that functions y^ε are of bounded variation on $[0,t]$ and $V_0^t y^\varepsilon \leq$ const. Since the inclusion $\mathcal{V} \subset \mathcal{H}$ is compact, by an infinite-dimensional version of the Helly theorem (see, for instance, [6, Rem. 3.2, p. 60]) we conclude that there exists a bounded variation function $y^0 : [0,t] \to \mathcal{H}$ such that on a subsequence, also denoted $\{y^\varepsilon\}$, we have

$$y^\varepsilon_{u^\varepsilon}(s) \to y^0(s) \quad \text{strongly in}\,\mathcal{H}\,\text{for all}\, s \in [0,t]. \tag{3.12}$$

We shall now prove that $y^0(s) = y_{u^0}(s)$ for $s \in [0,t]$. For any $\eta > 0$, choose a step function $u = u_\eta$ which takes constant values on $(0, \varepsilon_\eta], (\varepsilon_\eta, 2\varepsilon_\eta], \ldots, (T - \varepsilon_\eta, T]$ (where $\varepsilon_\eta = T/N_\eta$) such that

$$\left(\int_0^t |u_\eta(s) - u^0(s)|^2\, ds\right)^{1/2} < \eta \quad \text{and} \quad |y_{u_\eta}(s) - y_{u^0}(s)| < \eta \quad \text{for all}\, s \in [0,t]. \tag{3.13}$$

It is easy to see that $y^\varepsilon_{u^\varepsilon}$ and y^ε_u satisfy the following schemes:

$$\begin{aligned}&(I+\varepsilon A)^{-1} y^\varepsilon_{u^\varepsilon}(i\varepsilon) - (I+\varepsilon A)^{-1} y^\varepsilon_{u^\varepsilon}((i-1)\varepsilon) + \varepsilon A_\varepsilon y^\varepsilon_{u^\varepsilon}(i\varepsilon) + \varepsilon\partial\phi(y^\varepsilon_{u^\varepsilon}(i\varepsilon))\\ &\quad \ni \varepsilon(I+\varepsilon A)^{-1} Bu^\varepsilon(i\varepsilon),\\ &(I+\varepsilon A)^{-1} y^\varepsilon_u(i\varepsilon) - (I+\varepsilon A)^{-1} y^\varepsilon_u((i-1)\varepsilon) + \varepsilon A_\varepsilon y^\varepsilon_u(i\varepsilon) + \varepsilon\partial\phi(y^\varepsilon_u(i\varepsilon))\\ &\quad \ni \varepsilon(I+\varepsilon A)^{-1} Bu(i\varepsilon),\end{aligned}$$

$i = 1, 2, \ldots, [t/\varepsilon]$, A_ε being the Yosida approximation of A.

Let $s \in [0,t]$ such that $s \neq [s/\varepsilon]\varepsilon$. Subtract the preceding two inclusions and multiply the difference by $y^\varepsilon_{u^\varepsilon}(i\varepsilon) - y^\varepsilon_u(i\varepsilon)$. Then, using the monotonicity of A_ε, $\partial\phi$, and adding the obtained inequalities with respect to i from 1 to $[s/\varepsilon]$, we get

$$\begin{aligned}&\frac{1}{2}\left|(I+\varepsilon A)^{-1} y^\varepsilon_{u^\varepsilon}\left(\left[\frac{s}{\varepsilon}\right]\varepsilon\right) - (I+\varepsilon A)^{-1} y^\varepsilon_u\left(\left[\frac{s}{\varepsilon}\right]\varepsilon\right)\right|^2\\ &\quad \leq \sum_{i=1}^{[s/\varepsilon]} \varepsilon(Bu^\varepsilon(i\varepsilon) - Bu(i\varepsilon), (I+\varepsilon A)^{-1} y^\varepsilon_{u^\varepsilon}(i\varepsilon) - (I+\varepsilon A)^{-1} y^\varepsilon_u(i\varepsilon)).\end{aligned}$$

Hence

$$\begin{aligned}
&\frac{1}{2}|y^\varepsilon_{u^\varepsilon}(s)-y^\varepsilon_u(s)|^2\\
&\quad\le 3\sum_{i=1}^{[s/\varepsilon]}\varepsilon(u^\varepsilon(i\varepsilon)-u(i\varepsilon),B^*(I+\varepsilon A)^{-1}y^\varepsilon_{u^\varepsilon}(i\varepsilon)-B^*(I+\varepsilon A)^{-1}y^\varepsilon_u(i\varepsilon))\\
&\qquad+\frac{3}{2}\left(s-\left[\frac{s}{\varepsilon}\right]\varepsilon\right)^2\left|Bu^\varepsilon\left(\left(\left[\frac{s}{\varepsilon}\right]+1\right)\varepsilon\right)\right|^2\\
&\qquad+\frac{3}{2}\left(s-\left[\frac{s}{\varepsilon}\right]\varepsilon\right)^2\left|Bu\left(\left(\left[\frac{s}{\varepsilon}\right]+1\right)\varepsilon\right)\right|^2.
\end{aligned}\tag{3.14}$$

In the case when $s=[s/\varepsilon]\varepsilon$, we add the same inequalities as above but only from 1 to $[s/\varepsilon]-1$ (the computations being similar).

To conclude, we write the above sum as an integral:

$$\begin{aligned}
&\sum_{i=1}^{[s/\varepsilon]}\varepsilon(u^\varepsilon(i\varepsilon)-u(i\varepsilon),B^*(I+\varepsilon A)^{-1}y^\varepsilon_{u^\varepsilon}(i\varepsilon)-B^*(I+\varepsilon A)^{-1}y^\varepsilon_u(i\varepsilon))\\
&\quad=\int_0^{[s/\varepsilon]\varepsilon}(u^\varepsilon(\tau)-\tilde{u}_\varepsilon(\tau),B^*(I+\varepsilon A)^{-1}\tilde{y}^\varepsilon_{u^\varepsilon}(\tau)-B^*(I+\varepsilon A)^{-1}\tilde{y}^\varepsilon_u(\tau))d\tau,
\end{aligned}$$

where

$$\begin{gathered}
\tilde{y}^\varepsilon_{u^\varepsilon}(\tau)=y^\varepsilon_{u^\varepsilon}(i\varepsilon),\qquad \tilde{y}^\varepsilon_u(\tau)=y^\varepsilon_u(i\varepsilon),\quad\text{and}\quad \tilde{u}_\varepsilon(\tau)=u(i\varepsilon)\\
\text{for}\,\tau\in((i-1)\varepsilon,i\varepsilon],\quad i=1,2,\dots,\left[\frac{s}{\varepsilon}\right].
\end{gathered}$$

In addition to this, since $|\tilde{y}^\varepsilon_{u^\varepsilon}(\tau)-y^\varepsilon_{u^\varepsilon}(\tau)|\longrightarrow 0$ (because $\{u^\varepsilon\}$ is bounded in $L^2(0,t;\mathcal{U})$), $|\tilde{y}^\varepsilon_u(\tau)-y^\varepsilon_u(\tau)|\longrightarrow 0$, by (3.12) and Lemma 3.1 we have

$$\tilde{y}^\varepsilon_{u^\varepsilon}(\tau)\longrightarrow y^0(\tau)\text{ (on a subsequence)},\qquad \tilde{y}^\varepsilon_u(\tau)\longrightarrow y_u(\tau)\quad\text{strongly in }\mathcal{H}\text{ for all }\tau\in[0,s].$$

Also,

$$\tilde{u}_\varepsilon(\tau)\longrightarrow u(\tau)\quad\text{for}\,\tau\in[0,s]\text{ except the possible discontinuity points of }u.$$

Letting $\varepsilon\longrightarrow 0$ in (3.14), we obtain

$$\frac{1}{2}|y^0(s)-y_{u_\eta}(s)|^2\le 3\int_0^s(Bu^0(\tau)-Bu_\eta(\tau),y^0(\tau)-y_{u_\eta}(\tau))dt,$$

which together with (3.13) (η being arbitrary) gives $y^0\equiv y_{u^0}$, and the proof of Lemma 3.2 is finished.

Now it is easy to derive the assertion of Theorem 3.1 for $y\in D(A)\cap D(\partial\phi)$. Indeed, we may write

$$W^\varepsilon(t,y;u^\varepsilon)=\int_0^t h(u^\varepsilon(s))ds+\int_0^{[t/\varepsilon]\varepsilon}g(\tilde{y}^\varepsilon_{u^\varepsilon}(s))ds+\varepsilon g(y^\varepsilon_{u^\varepsilon}(t))+l(y^\varepsilon_{u^\varepsilon}(t)),$$

where $\tilde{y}^\varepsilon_{u^\varepsilon}$ has been defined above. Hence, using the weak lower semicontinuity in $L^2(0,t;\mathcal{U})$ of $u\mapsto\int_0^t h(u(s))ds$ and the Lebesgue dominated convergence theorem combined with Lemma 3.2, we see that

$$\lim_{\varepsilon\to 0}W^\varepsilon(t,y;u^\varepsilon)\ge W(t,y).$$

To extend this conclusion to the case when $y \in \overline{D(A) \cap D(\partial\phi)}$, we need the following continuity result.

LEMMA 3.3. *Under the hypotheses of Theorem* 3.1, *for any* $t \in [0,T]$, *the function* $\overline{D(A) \cap D(\partial\phi)} \ni y \mapsto W(t,y)$ *is Lipschitz continuous on bounded subsets, and the functions* $\mathcal{H} \ni y \mapsto W^\varepsilon(t,y)$ *are Lipschitz continuous on bounded subsets, uniformly with respect to* ε.

Proof. We shall sketch only the proof of the second part of the lemma (the proof of the first is similar).

Consider y, $z \in \mathcal{H}$, arbitrary, such that $|y|, |z| \le r$. Let $\eta > 0$, also arbitrary. We choose a step function $u^\varepsilon = u^\varepsilon_\eta$ such that

$$\begin{aligned} &W^\varepsilon(t,z) - W^\varepsilon(t,y) \\ &\quad \le \sum_{i=1}^{[t/\varepsilon]} \varepsilon(g(z^\varepsilon_{u^\varepsilon}(i\varepsilon)) - g(y^\varepsilon_{u^\varepsilon}(i\varepsilon))) + \varepsilon(g(z^\varepsilon_{u^\varepsilon}(t)) - g(y^\varepsilon_{u^\varepsilon}(t))) \\ &\quad + l(z^\varepsilon_{u^\varepsilon}(t)) - l(y^\varepsilon_{u^\varepsilon}(t)) + \eta. \end{aligned}$$

Here $z^\varepsilon_{u^\varepsilon}$ is defined as in (3.4) but with z instead of y.

Taking (1.4) into account, we easily obtain

$$\sum_{i=1}^{[t/\varepsilon]} \varepsilon|u^\varepsilon_\eta(i\varepsilon)|^2 + \left(t - \left[\frac{t}{\varepsilon}\right]\varepsilon\right)\left|u^\varepsilon_\eta\left(\left(\left[\frac{t}{\varepsilon}\right]+1\right)\varepsilon\right)\right|^2 \le \text{const.},$$

where the constant depends only on r. Consequently, $y^\varepsilon_{u^\varepsilon}(i\varepsilon), y^\varepsilon_{u^\varepsilon}(t), z^\varepsilon_{u^\varepsilon}(i\varepsilon)$, and $z^\varepsilon_{u^\varepsilon}(t)$ also are bounded by a constant which depends only on r. We may now use assumption (ii) to derive the Lipschitz continuity on bounded subsets of $y \mapsto W^\varepsilon(t,y)$, uniformly with respect to ε. This completes the proof of Lemma 3.3.

A density argument based on Lemma 3.3 finishes the proof of Theorem 3.1.

Let us now establish the convergence of scheme (2.5).

THEOREM 3.2. *In addition to assumptions* (i)–(v) *we suppose that at least one of the following two hypotheses holds*:

(vii) $(I + \varepsilon\partial\phi)^{-1} = P$ *for all* $\varepsilon > 0$ (*i.e., the resolvent of* ϕ *is independent of* ε);

(viii) $(I + \varepsilon A)^{-1}D(\partial\phi) \subset \overline{D(\partial\phi)}$ *for all* $\varepsilon > 0$.

Then for every $(t,y) \in [0,T] \times \overline{D(A) \cap D(\partial\phi)}$, *we have*

$$\lim_{\varepsilon\to 0} \overline{W}^\varepsilon(t,y) = W(t,y). \tag{3.15}$$

The proof of Theorem 3.2 is very similar to that of the preceding theorem. The only differences appear in the proof of the corresponding variant of Lemma 3.2.

In the present case, for a (step) function $u : [0,T] \to \mathcal{U}$, y^ε_u is defined by

$$\begin{cases} y^\varepsilon_u(t) = (I+\varepsilon A)^{-1}(I+\varepsilon\partial\phi)^{-1}(y^\varepsilon_u((i-1)\varepsilon) + (t-(i-1)\varepsilon)Bu(i\varepsilon)) \\ \qquad\qquad \text{for } t \in ((i-1)\varepsilon, i\varepsilon], \quad i = 1,2,\ldots,N, \\ y^\varepsilon_u(0) = y. \end{cases}$$

LEMMA 3.4. *Let* $\{u^\varepsilon\}$ *be a sequence of step functions from* $[0,T]$ *to* $\mathcal{U}$ *such that each* u^ε *takes constant values on* $(0,\varepsilon], (\varepsilon, 2\varepsilon], \ldots, (T-\varepsilon, T]$, *and let* $y \in D(A) \cap D(\partial\phi)$.

If $u^\varepsilon \to u^0$ *weakly in* $L^2(0,t;\mathcal{U})$, *then for every* $s \in [0,t]$,

$$y^\varepsilon_{u^\varepsilon}(s) \to y_{u^0}(s) \quad \textit{strongly in } \mathcal{H}.$$

Proof. Set $y^\varepsilon_{u^\varepsilon} = y^\varepsilon$. As in the proof of Lemma 3.2, we have

$$\begin{aligned}&\frac{1}{\varepsilon}|(I+\varepsilon\partial\phi)^{-1}y^\varepsilon(i\varepsilon) - (I+\varepsilon\partial\phi)^{-1}y^\varepsilon((i-1)\varepsilon)|^2 + \frac{1}{2}(Ay^\varepsilon(i\varepsilon), y^\varepsilon(i\varepsilon))\\ &\quad - \frac{1}{2}(Ay^\varepsilon((i-1)\varepsilon), y^\varepsilon((i-1)\varepsilon)) + \phi_\varepsilon(y^\varepsilon(i\varepsilon)) - \phi_\varepsilon(y^\varepsilon((i-1)\varepsilon))\\ &\quad \le |Bu^\varepsilon(i\varepsilon)||y^\varepsilon(i\varepsilon) - y^\varepsilon((i-1)\varepsilon)|, \qquad i = 1,2,\ldots,\left[\frac{s}{\varepsilon}\right], \quad s\in[0,t].\end{aligned}$$

To eliminate the operator $(I+\varepsilon\partial\phi)^{-1}$ above, we use the following inequalities (easy to prove):

$$\begin{aligned}|y^\varepsilon((i+1)\varepsilon) - y^\varepsilon(i\varepsilon)|^2 &\le 3|(I+\varepsilon\partial\phi)^{-1}y^\varepsilon(i\varepsilon) - (I+\varepsilon\partial\phi)^{-1}y^\varepsilon((i-1)\varepsilon)|^2\\ &\quad + 3\varepsilon^2|Bu^\varepsilon((i+1)\varepsilon)|^2 + 3\varepsilon^2|Bu^\varepsilon(i\varepsilon)|^2,\\ &\quad i = 1,2,\ldots,\left[\frac{s}{\varepsilon}\right]-1.\end{aligned}$$

We obtain

$$\begin{aligned}&\frac{1}{3\varepsilon}|y^\varepsilon((i+1)\varepsilon) - y^\varepsilon(i\varepsilon)|^2 + \frac{1}{2}(Ay^\varepsilon(i\varepsilon), y^\varepsilon(i\varepsilon))\\ &\quad - \frac{1}{2}(Ay^\varepsilon((i-1)\varepsilon), y^\varepsilon((i-1)\varepsilon)) + \phi_\varepsilon(y^\varepsilon(i\varepsilon)) - \phi_\varepsilon(y^\varepsilon((i-1)\varepsilon))\\ &\quad \le |Bu^\varepsilon(i\varepsilon)||y^\varepsilon(i\varepsilon) - y^\varepsilon((i-1)\varepsilon)| + \varepsilon|Bu^\varepsilon((i+1)\varepsilon)|^2 + \varepsilon|Bu^\varepsilon(i\varepsilon)|^2,\\ &\qquad i = 1,2,\ldots,\left[\frac{s}{\varepsilon}\right]-1.\end{aligned}\tag{3.16}$$

Similarly, in the case when s/ε is not an integer, we have

$$\begin{aligned}&\frac{1}{3\varepsilon}\left|y^\varepsilon(s) - y^\varepsilon\left(\left[\frac{s}{\varepsilon}\right]\varepsilon\right)\right|^2 + \frac{1}{2}\left(Ay^\varepsilon\left(\left[\frac{s}{\varepsilon}\right]\varepsilon\right), y^\varepsilon\left(\left[\frac{s}{\varepsilon}\right]\varepsilon\right)\right)\\ &\quad - \frac{1}{2}\left(Ay^\varepsilon\left(\left(\left[\frac{s}{\varepsilon}\right]-1\right)\varepsilon\right), y^\varepsilon\left(\left(\left[\frac{s}{\varepsilon}\right]-1\right)\varepsilon\right)\right) + \phi_\varepsilon\left(y^\varepsilon\left(\left[\frac{s}{\varepsilon}\right]\varepsilon\right)\right)\\ &\quad - \phi_\varepsilon\left(y^\varepsilon\left(\left(\left[\frac{s}{\varepsilon}\right]-1\right)\varepsilon\right)\right)\\ &\quad \le \left|Bu^\varepsilon\left(\left[\frac{s}{\varepsilon}\right]\varepsilon\right)\right|\left|y^\varepsilon\left(\left[\frac{s}{\varepsilon}\right]\varepsilon\right) - y^\varepsilon\left(\left(\left[\frac{s}{\varepsilon}\right]-1\right)\varepsilon\right)\right|\\ &\qquad + \left(s - \left[\frac{s}{\varepsilon}\right]\varepsilon\right)\left|Bu^\varepsilon\left(\left(\left[\frac{s}{\varepsilon}\right]+1\right)\varepsilon\right)\right|^2 + \varepsilon\left|Bu^\varepsilon\left(\left[\frac{s}{\varepsilon}\right]\varepsilon\right)\right|^2,\end{aligned}\tag{3.17}$$

and also

$$\begin{aligned}&\frac{1}{2}(Ay^\varepsilon(s), y^\varepsilon(s)) - \frac{1}{2}\left(Ay^\varepsilon\left(\left[\frac{s}{\varepsilon}\right]\varepsilon\right), y^\varepsilon\left(\left[\frac{s}{\varepsilon}\right]\varepsilon\right)\right)\\ &\quad + \phi_\varepsilon(y^\varepsilon(s)) - \phi_\varepsilon\left(y^\varepsilon\left(\left[\frac{s}{\varepsilon}\right]\varepsilon\right)\right)\\ &\quad \le \left(\frac{s}{\varepsilon} - \left[\frac{s}{\varepsilon}\right]\right)\left|Bu^\varepsilon\left(\left(\left[\frac{s}{\varepsilon}\right]+1\right)\varepsilon\right)\right|\left|y^\varepsilon(s) - y^\varepsilon\left(\left[\frac{s}{\varepsilon}\right]\varepsilon\right)\right|.\end{aligned}\tag{3.18}$$

Adding inequalities (3.16) – (3.18) and (3.8) (the last multiplied by 1/3), we get

$$\begin{aligned}&\sum_{i=1}^{[s/\varepsilon]}\frac{1}{12\varepsilon}|y^\varepsilon(i\varepsilon) - y^\varepsilon((i-1)\varepsilon)|^2 + \frac{1}{12\varepsilon}\left|y^\varepsilon(s) - y^\varepsilon\left(\left[\frac{s}{\varepsilon}\right]\varepsilon\right)\right|^2\\ &\quad + \frac{1}{2}(Ay^\varepsilon(s), y^\varepsilon(s)) - \frac{1}{2}(Ay, y) + \phi_\varepsilon(y^\varepsilon(s)) - \phi_\varepsilon(y)\\ &\quad \le \varepsilon|Ay|^2 + \varepsilon|\partial\phi(y)|^2 + 3\sum_{i=1}^{[s/\varepsilon]}\varepsilon|Bu^\varepsilon(i\varepsilon)|^2 + 2\left(s - \left[\frac{s}{\varepsilon}\right]\varepsilon\right)\left|Bu^\varepsilon\left(\left(\left[\frac{s}{\varepsilon}\right]+1\right)\varepsilon\right)\right|^2.\end{aligned}$$

Then, proceeding as in the proof of Lemma 3.2, by the same infinite-dimensional variant of the Helly theorem we find a bounded variation function $y^0 : [0,t] \to \mathcal{H}$ such that, on a subsequence,

$$y^\varepsilon_{u^\varepsilon}(s) \to y^0(s) \quad \text{strongly in } \mathcal{H} \text{ for all } s \in [0,t]. \tag{3.19}$$

Next, for $\eta > 0$, arbitrary, we select a step function $u = u_\eta$ which takes constant values on the subintervals $((i-1)\varepsilon_\eta, i\varepsilon_\eta]$, $i = 1,2,\dots,N_\eta$, and satisfies (3.13). Define the function $z^\varepsilon_{u^\varepsilon}$ by

$$\begin{gathered} z^\varepsilon_{u^\varepsilon}(s) = (I + \varepsilon\partial\phi)^{-1}(y^\varepsilon_{u^\varepsilon}((i-1)\varepsilon) + (s-(i-1)\varepsilon)Bu^\varepsilon(i\varepsilon)) \\ \text{for } s \in ((i-1)\varepsilon, i\varepsilon], \quad i = 1,2,\dots,N, \end{gathered}$$

and define z^ε_u in the same way, but with u replacing u^ε. Obviously, $y^\varepsilon_{u^\varepsilon}(s) = (I+\varepsilon A)^{-1} z^\varepsilon_{u^\varepsilon}(s)$ and $y^\varepsilon_u(s) = (I+\varepsilon A)^{-1} z^\varepsilon_u(s)$, $s \in (0,T]$. We have

$$\begin{aligned} &y^\varepsilon_{u^\varepsilon}(i\varepsilon) - y^\varepsilon_{u^\varepsilon}((i-1)\varepsilon) + \varepsilon A_\varepsilon z^\varepsilon_{u^\varepsilon}(i\varepsilon) + \varepsilon\partial\phi(z^\varepsilon_{u^\varepsilon}(i\varepsilon)) \ni \varepsilon Bu^\varepsilon(i\varepsilon), \\ &y^\varepsilon_u(i\varepsilon) - y^\varepsilon_u((i-1)\varepsilon) + \varepsilon A_\varepsilon z^\varepsilon_u(i\varepsilon) + \varepsilon\partial\phi(z^\varepsilon_u(i\varepsilon)) \ni \varepsilon Bu(i\varepsilon), \qquad i = 2,3,\dots,\left[\frac{s}{\varepsilon}\right]. \end{aligned}$$

Multiplying the difference of these inclusions by $z^\varepsilon_{u^\varepsilon}(i\varepsilon) - z^\varepsilon_u(i\varepsilon)$, we obtain

$$\begin{aligned} &\frac{1}{2}(y^\varepsilon_{u^\varepsilon}(i\varepsilon) - y^\varepsilon_u(i\varepsilon), z^\varepsilon_{u^\varepsilon}(i\varepsilon) - z^\varepsilon_u(i\varepsilon)) \\ &\quad - \frac{1}{2}(y^\varepsilon_{u^\varepsilon}((i-1)\varepsilon) - y^\varepsilon_u((i-1)\varepsilon), z^\varepsilon_{u^\varepsilon}((i-1)\varepsilon) - z^\varepsilon_u((i-1)\varepsilon)) \\ &\quad \le \varepsilon(Bu^\varepsilon(i\varepsilon) - Bu(i\varepsilon), z^\varepsilon_{u^\varepsilon}(i\varepsilon) - z^\varepsilon_u(i\varepsilon)), \qquad i = 2,3,\dots,\left[\frac{s}{\varepsilon}\right]. \end{aligned} \tag{3.20}$$

Similarly, in the case when s/ε is not an integer,

$$\begin{aligned} &\frac{1}{2}(y^\varepsilon_{u^\varepsilon}(s) - y^\varepsilon_u(s), z^\varepsilon_{u^\varepsilon}(s) - z^\varepsilon_u(s)) \\ &\quad - \frac{1}{2}\left(y^\varepsilon_{u^\varepsilon}\left(\left[\frac{s}{\varepsilon}\right]\varepsilon\right) - y^\varepsilon_u\left(\left[\frac{s}{\varepsilon}\right]\varepsilon\right), z^\varepsilon_{u^\varepsilon}\left(\left[\frac{s}{\varepsilon}\right]\varepsilon\right) - z^\varepsilon_u\left(\left[\frac{s}{\varepsilon}\right]\varepsilon\right)\right) \\ &\quad \le \left(s - \left[\frac{s}{\varepsilon}\right]\varepsilon\right)\left(Bu^\varepsilon\left(\left(\left[\frac{s}{\varepsilon}\right]+1\right)\varepsilon\right)\right. \\ &\qquad \left. -Bu\left(\left(\left[\frac{s}{\varepsilon}\right]+1\right)\varepsilon\right), z^\varepsilon_{u^\varepsilon}(s) - z^\varepsilon_u(s)\right). \end{aligned} \tag{3.21}$$

The summation of (3.20) and (3.21) gives

$$\begin{aligned} &\frac{1}{2}|y^\varepsilon_{u^\varepsilon}(s) - y^\varepsilon_u(s)|^2 - \frac{1}{2}(y^\varepsilon_{u^\varepsilon}(\varepsilon) - y^\varepsilon_u(\varepsilon), z^\varepsilon_{u^\varepsilon}(\varepsilon) - z^\varepsilon_u(\varepsilon)) \\ &\quad \le \sum_{i=2}^{[s/\varepsilon]} \varepsilon(u^\varepsilon(i\varepsilon) - u(i\varepsilon), B^*(z^\varepsilon_{u^\varepsilon}(i\varepsilon) - z^\varepsilon_u(i\varepsilon))) \\ &\qquad + \left(s - \left[\frac{s}{\varepsilon}\right]\varepsilon\right)\left(u^\varepsilon\left(\left(\left[\frac{s}{\varepsilon}\right]+1\right)\varepsilon\right)\right. \\ &\qquad \left. - u\left(\left(\left[\frac{s}{\varepsilon}\right]+1\right)\varepsilon\right), B^*(z^\varepsilon_{u^\varepsilon}(s) - z^\varepsilon_u(s))\right). \end{aligned} \tag{3.22}$$

(If s/ε is an integer, we add only inequalities (3.20) to obtain a similar conclusion.)

But we may write (3.22) in the following form:

(3.23)

$$\begin{aligned}\frac{1}{2}|y^\varepsilon_{u^\varepsilon}(s) - y^\varepsilon_u(s)|^2 \leq{}& \frac{1}{2}(y^\varepsilon_{u^\varepsilon}(\varepsilon) - y^\varepsilon_u(\varepsilon), z^\varepsilon_{u^\varepsilon}(\varepsilon) - z^\varepsilon_u(\varepsilon))\\ &+ \int_0^{([s/\varepsilon]-1)\varepsilon} (u^\varepsilon(\tau+\varepsilon) - \tilde{u}_\varepsilon(\tau), B^*(\tilde{z}^\varepsilon_{u^\varepsilon}(\tau) - \tilde{z}^\varepsilon_u(\tau)))d\tau\\ &+ \varepsilon\Big(u^\varepsilon\Big(\Big(\Big[\frac{s}{\varepsilon}\Big]+1\Big)\varepsilon\Big) - u\Big(\Big(\Big[\frac{s}{\varepsilon}\Big]+1\Big)\varepsilon\Big), B^*(z^\varepsilon_{u^\varepsilon}(s) - z^\varepsilon_u(s))\Big),\end{aligned}$$

where

$$\begin{gathered}\tilde{z}^\varepsilon_{u^\varepsilon}(\tau) = z^\varepsilon_{u^\varepsilon}((i+1)\varepsilon), \quad \tilde{z}^\varepsilon_u(\tau) = z^\varepsilon_u((i+1)\varepsilon), \quad \text{and} \quad \tilde{u}_\varepsilon(\tau) = u((i+1)\varepsilon)\\ \text{for}\, \tau \in ((i-1)\varepsilon, i\varepsilon], \quad i = 1, 2, \ldots, \Big[\frac{s}{\varepsilon}\Big] - 1.\end{gathered}$$

By obvious estimates, $|\tilde{z}^\varepsilon_{u^\varepsilon}(\tau) - (I + \varepsilon\partial\phi)^{-1}y^\varepsilon_{u^\varepsilon}(\tau)|$ and $|\tilde{z}^\varepsilon_u(\tau) - (I + \varepsilon\partial\phi)^{-1}y^\varepsilon_u(\tau)|$ tend to zero as $\varepsilon \longrightarrow 0$ for all $\tau \in [0, s]$, so that we can use (3.19) and Lemma 3.1 to find the limits of $\tilde{z}^\varepsilon_{u^\varepsilon}$ and $\tilde{z}^\varepsilon_u$. In this way, under hypothesis (vii) it immediately follows that

$$\tilde{z}^\varepsilon_{u^\varepsilon}(\tau) \longrightarrow Py^0(\tau)\,\text{(on a subsequence)} \quad \text{and}$$

$$z^\varepsilon_u(\tau) \longrightarrow Py_u(\tau)\,\text{strongly in}\,\mathcal{H}\,\text{for all}\,\tau \in [0, s].$$

Under the other additional hypothesis, we have for every $\tau \in [0, s]$

$$\tilde{z}^\varepsilon_{u^\varepsilon}(\tau) \longrightarrow y^0(\tau)\,\text{(on a subsequence)} \quad \text{and} \quad z^\varepsilon_u(\tau) \longrightarrow y_u(\tau) \quad \text{strongly in}\,\mathcal{H}.$$

This happens because $y^0(\tau) \in \overline{D(\partial\phi)}$ (since $y^\varepsilon_{u^\varepsilon}(\tau) \in \overline{D(\partial\phi)}$ for any τ), and consequently $(I + \varepsilon\partial\phi)^{-1}y^0(\tau) \longrightarrow y^0(\tau)$ as $\varepsilon \longrightarrow 0$.

Now, to conclude that in the first case the integral in (3.23) converges to $\int_0^s (u^0(\tau) - u(\tau), B^*(Py^0(\tau) - Py_u(\tau)))d\tau$ as $\varepsilon \longrightarrow 0$, it suffices to observe that

$$\int_0^{([s/\varepsilon]-1)\varepsilon} (u^\varepsilon(\tau+\varepsilon), B^*((\tilde{z}^\varepsilon_{u^\varepsilon}(\tau) - \tilde{z}^\varepsilon_u(\tau)) - (Py^0(\tau) - Py_u(\tau))))d\tau \longrightarrow 0$$

and

$$\int_\varepsilon^{[s/\varepsilon]\varepsilon} (u^\varepsilon(\tau), B^*(Py^0(\tau-\varepsilon) - Py_u(\tau)))d\tau \longrightarrow \int_0^s (u^0(\tau), B^*(Py^0(\tau) - Py_u(\tau)))d\tau.$$

For the last limit, we also use the continuity of y^0 on $[0, s]$ except a countable subset (since y^0 is a function of bounded variation). In the second case, it follows similarly that the integral in (3.23) converges to $\int_0^s (u^0(\tau) - u(\tau), B^*(y^0(\tau) - y_u(\tau)))d\tau$ as $\varepsilon \longrightarrow 0$.

Thus, letting $\varepsilon \longrightarrow 0$ in (3.23), we obtain in both situations that

$$\frac{1}{2}|y^0(s) - y_{u_\eta}(s)|^2 \leq \int_0^s |Bu^0(\tau) - Bu_\eta(\tau)||y^0(\tau) - y_{u_\eta}(\tau)|d\tau,$$

and so, by (3.13), we have $y^0 \equiv y_{u^0}$ on $[0, t]$, since η is arbitrary. Taking (3.19) into account, this completes the proof.

4. Examples. We shall now indicate some control systems to which the results of the preceding section may be applied. The problem here is whether the additional hypotheses (vi) (on the one hand) and (vii) or (viii) (on the other) are verified in the cases of interest in applications. We shall see that among the significant situations which are covered by our results we find systems governed by semilinear parabolic equations and by the parabolic obstacle problem.

First, let us see a general situation in which hypothesis (vi) is verified (so that Theorem 3.1 applies). Let Ω be an open and bounded subset of $\mathbf{R}^n$ having a sufficiently smooth boundary, and A_0 be the elliptic differential operator defined by

$$A_0 y = -\sum_{i,j=1}^{n} \frac{\partial}{\partial x_j}\left(a_{ij}(x)\frac{\partial y}{\partial x_i}\right) + a_0(x)y,$$

where $a_{ij} \in C^1(\Omega)$, $a_0 \in L^\infty(\Omega)$, $a_{ij} = a_{ji}$ for all $i, j, a_0(x) \geq 0$ a.e. $x \in \Omega$, and for a certain $\omega > 0$,

$$\sum_{i,j=1}^{n} a_{ij}(x)\xi_i\xi_j \geq \omega \sum_{i=1}^{n} |\xi_i|^2, \qquad x \in \Omega, \quad (\xi_1, \xi_2, \ldots, \xi_n) \in \mathbf{R}^n. \tag{4.1}$$

Finally, let β be a maximal monotone graph in $\mathbf{R}^2$.

Consider the control system described by the following mixed boundary value problem:

$$\begin{cases} \dfrac{\partial y}{\partial t} + A_0 y + \beta(y) \ni Bu & \text{a.e. in}\, Q = (0,T) \times \Omega, \\ y = 0 & \text{in}\,(0,T) \times \partial\Omega, \\ y(0,x) = y^0(x) & \text{in}\,\Omega, \end{cases} \tag{4.2}$$

where $y^0 \in L^2(\Omega)$ and $B : \mathcal{U} \to L^2(\Omega)$ satisfies (v).

Let us observe that problem (4.2) may be written as an evolution equation of the form (1.2) if we put $\mathcal{H} = L^2(\Omega), \mathcal{V} = H_0^1(\Omega)$, and take A and ϕ as follows (see [2, §4.2]).

The linear operator $A : H_0^1(\Omega) \to H^{-1}(\Omega)$ is defined by

$$(Ay, z) = \sum_{i,j=1}^{n} \int_\Omega a_{ij} \frac{\partial y}{\partial x_i}\frac{\partial z}{\partial x_j} dx + \int_\Omega a_0\, yz\, dx \quad \text{for all}\, y, z \in H_0^1(\Omega). \tag{4.3}$$

Clearly, $D(A) = H_0^1(\Omega) \cap H^2(\Omega)$.

Then taking $j : \mathbf{R} \to (-\infty, +\infty]$ such that $\beta = \partial j$, we define the convex and lower semicontinuous function $\phi : L^2(\Omega) \to (-\infty, +\infty]$ in the following way:

$$\phi(y) = \int_\Omega j(y(x))dx. \tag{4.4}$$

Hence (see [2, Prop. 1.9]),

$$\partial\phi(y) = \{w \in L^2(\Omega) : w(x) \in \beta(y(x))\, \text{a.e.}\, x \in \Omega\}.$$

If condition (1.6) also holds, then assumptions (iii) and (iv) are wholly satisfied. But in the present case, (1.6) takes the following form:

$$(Ay, \beta_\eta(y)) \geq -c(1 + |\beta_\eta(y)|)(1 + |y|) \quad \text{for all}\, y \in D(A)\, \text{and}\, \eta > 0, \tag{4.5}$$

where $\beta_\eta(r) = \eta^{-1}(r - (I + \eta\beta)^{-1}r)$ for $r \in \mathbf{R}$, and $c > 0$. Indeed, one easily verifies that $((\partial\phi)_\eta(y))(x) = \beta_\eta(y(x))$ a.e. $x \in \Omega$. When $0 \in \beta(0)$, one obtains without difficulty that

$$(Ay, \beta_\eta(y)) \geq 0 \quad \text{for all } y \in H_0^1(\Omega),\ \eta > 0,$$

so that (1.6) holds.

PROPOSITION 4.1. *Suppose in addition that* $0 \in \beta(0)$. *Then* A *and* ϕ *defined by* (4.3) *and* (4.4), *respectively, satisfy* (vi) *besides* (iii) *and* (iv).

Proof. It is easy to see that

$$((I + \varepsilon\partial\phi)^{-1}z)(x) = (I + \varepsilon\beta)^{-1}(z(x)) \quad \text{a.e. } x \in \Omega.$$

Thus we have to show that $(I + \varepsilon\beta)^{-1}$ maps $H_0^1(\Omega)$ into itself and

$$\begin{aligned} &\sum_{i,j=1}^{n} \int_\Omega a_{ij} \frac{\partial}{\partial x_i}(I + \varepsilon\beta)^{-1}(z) \frac{\partial}{\partial x_j}(I + \varepsilon\beta)^{-1}(z) dx \\ &\quad + \int_\Omega a_0((I + \varepsilon\beta)^{-1}(z))^2\, dx \\ &\quad \leq \sum_{i,j=1}^{n} \int_\Omega a_{ij} \frac{\partial z}{\partial x_i}\frac{\partial z}{\partial x_j}\, dx + \int_\Omega a_0 z^2\, dx \quad \text{for all } z \in H_0^1(\Omega). \end{aligned} \tag{4.6}$$

We set $(I + \varepsilon\beta)^{-1} = \gamma$. Obviously, γ is a contraction on $\mathbf{R}$ and $\gamma(0) = 0$. For any positive integer m, we define

$$\gamma_m(r) = \int_{-\infty}^{\infty} \left(\gamma\left(r - \frac{1}{m}s\right) - \gamma\left(-\frac{1}{m}s\right)\right) \rho(s) ds,$$

where ρ is a C_0^∞-mollifier on $\mathbf{R}$, i.e., $\rho \in C^\infty(\mathbf{R})$, $\rho(r) = 0$ for $|r| > 1$, and $\int_{-\infty}^{\infty} \rho(r) dr = 1$. One readily checks that $\gamma_m \in C^\infty(\mathbf{R})$, $|\gamma_m'(r)| \leq 1$ for $r \in \mathbf{R}$, $\gamma_m(0) = 0$, and γ_m tend to γ uniformly on $\mathbf{R}$ as $m \to \infty$.

Let $z \in H_0^1(\Omega)$, arbitrary. Clearly,

$$\gamma_m(z) \to \gamma(z) \quad \text{strongly in } L^2(\Omega) \text{ (in fact in } L^\infty(\Omega)) \text{ as } m \to \infty. \tag{4.7}$$

Since $\gamma_m(0) = 0$ and $|\gamma_m'(r)| \leq 1$ for $r \in \mathbf{R}$, using the chain rule in $H_0^1(\Omega)$ we see that $\gamma_m(z) \in H_0^1(\Omega)$ and

$$\begin{aligned} &\sum_{i,j=1}^{n} \int_\Omega a_{ij} \frac{\partial}{\partial x_i}\gamma_m(z) \frac{\partial}{\partial x_j}\gamma_m(z) dx + \int_\Omega a_0(\gamma_m(z))^2\, dx \\ &\quad \leq \sum_{i,j=1}^{n} \int_\Omega a_{ij} \frac{\partial z}{\partial x_i}\frac{\partial z}{\partial x_j}\, dx + \int_\Omega a_0 z^2\, dx. \end{aligned} \tag{4.8}$$

But this means (by the ellipticity condition (4.1)) that $\gamma_m(z)$ is bounded in $H_0^1(\Omega)$; therefore, there exists $y \in H_0^1(\Omega)$ such that, on a subsequence of $\{m\}$,

$$\gamma_m(z) \to y \quad \text{weakly in } H_0^1(\Omega).$$

Hence, taking (4.7) into account, we have $\gamma(z) = y \in H_0^1(\Omega)$. Consequently,

$$\gamma_m(z) \to \gamma(z) \quad \text{weakly in } H_0^1(\Omega) \text{ as } m \to \infty. \tag{4.9}$$

Now, combining (4.8) with (4.9) and the weak lower semicontinuity of the norm of $H_0^1(\Omega)$ induced by (4.3) (which obviously is equivalent to the usual norm of $H_0^1(\Omega)$), we obtain (4.6), which finishes the proof.

The most interesting situations in which (vi) is fulfilled are offered by the control systems governed on the one hand by semilinear parabolic equations, i.e., in (4.2) β is a continuous monotonically increasing function on **R** such that $\beta(0) = 0$ (see [5] for a related but less general result), and on the other hand by the parabolic obstacle problem with obstacle $\psi \equiv 0$. In the last case β is given by

$$\beta(r) = \begin{cases} 0 & \text{for}\, r > 0, \\ (-\infty, 0] & \text{for}\, r = 0, \\ \emptyset & \text{for}\, r < 0, \end{cases}$$

and (4.2) can be written as (see [2, p. 138])

$$\begin{cases} y \geq 0 & \text{a.e. in}\, Q, \\ \dfrac{\partial y}{\partial t} + A_0 y = Bu & \text{a.e. in}\, \{(t,x) \in Q : y(t,x) > 0\}, \\ \dfrac{\partial y}{\partial t} = \max\{Bu, 0\} & \text{a.e. in}\, \{(t,x) \in Q : y(t,x) = 0\}, \\ y = 0 & \text{in}\, (0,T) \times \partial\Omega, \\ y(0,x) = y^0(x) & \text{in}\, \Omega, \end{cases}$$

where $y^0(x) \geq 0$ a.e. $x \in \Omega$.

Remark 4.1. We may apply Theorem 3.1 only to those control systems (4.2) (we emphasize that here y takes only the boundary values 0) where, in addition, $0 \in \beta(0)$. In the case of the obstacle problem with boundary values 0, scheme (2.4) converges only for obstacle 0. We can say nothing concerning the validity of (vi) for any other obstacle $\psi \not\equiv 0$.

Remark 4.2. The problem of the validity of (vi) in the case of Neumann boundary conditions remains open.

For Theorem 3.2, one easily observes that (vii) is verified for the general control system described by the variational inequality (see also [11, Thm. 2]).

$$y' + Ay + \partial I_K(y) \ni Bu,$$

where I_K is the indicator function of a closed convex subset K of $\mathcal{H}$, and $A, \partial I_K, B$ satisfy hypotheses (iii) – (v). Indeed, we have

$$\partial I_K(y) = \{p \in \mathcal{H} : (p, y - z) \geq 0\, \text{for all}\, z \in K\}, \qquad y \in \mathcal{H},$$

and

$$(I + \varepsilon \partial I_K)^{-1} = P_K \quad \text{for all}\, \varepsilon > 0,$$

where P_K is the projection operator of $\mathcal{H}$ into K, so that (vii) holds.

This framework wholly covers the case of the systems governed by the parabolic obstacle problem, but this time for any obstacle $\psi \in H^2(\Omega)$ and for boundary conditions of the form

$$\alpha_1 y + \alpha_2 \frac{\partial y}{\partial \nu} = 0 \quad \text{in}\, (0,T) \times \partial\Omega, \tag{4.10}$$

where α_1, α_2 are two nonnegative real numbers which are nonsimultaneously null. In this case,

$$K = \{y \in L^2(\Omega) : y \geq \psi \text{ a.e. in } \Omega\}$$

and the operator A is properly defined (see [2, §4.2]).

Finally, alternative hypothesis (viii) is obviously implied by the following simpler condition:

$$D(\partial\phi) \text{ is dense in } \mathcal{H}. \tag{4.11}$$

If we denote, as usual, $D(\phi) = \{y \in \mathcal{H} : \phi(y) < +\infty\}$, then (4.11) is equivalent to the condition

$$\overline{D(\phi)} = \mathcal{H}, \tag{4.11$'$}$$

since $\overline{D(\phi)} = \overline{D(\partial\phi)}$ (see for instance [6, Cor. 2.2, p. 110]). Here is a significant situation in which (4.11) is easy to verify. In (4.2) (where instead of the Dirichlet condition we may take the more general boundary condition (4.10)), β is a monotonically increasing function on **R**. Then (4.11) is satisfied with $\mathcal{H} = L^2(\Omega)$. Indeed, one readily shows that $C_0(\Omega) \subset D(\phi)$, where ϕ is given by (4.4), whence (4.11)$'$ follows immediately. If, in addition, $\alpha_2 \neq 0$ in (4.10), then it is easy to see that (4.5) is fulfilled (see [2, p. 137]), and Theorem 3.2 applies. Otherwise, as we have already seen, it suffices to have $\beta(0) = 0$ (see also [2, p. 137] for a less restrictive condition).

Remark 4.3. In the case of control systems governed by semilinear parabolic equations or the parabolic obstacle problem, Theorem 3.2 gives more general results than Theorem 3.1 (and also than the related results from [4], [5]). Indeed, the Trotter scheme (2.5) converges for more general boundary conditions (including Neumann conditions), and also for any obstacle $\psi \not\equiv 0$ in the case of the obstacle problem. Nevertheless, as we shall see in the following sections (see Remark 6.1), scheme (2.4) presents certain advantages in comparison with (2.5).

5. The approximating discrete control problem. According to (3.3), (3.4), consider the following sequence of discrete control problems:

(P^ε) minimize

$$\sum_{i=1}^{N} \varepsilon(h(u_i) + g(y_i)) + l(y_N) \tag{5.1}$$

over all N-tuples $(u_1, u_2, \ldots, u_N) \in \mathcal{U}^N$, where $(y_1, y_2, \ldots, y_N) \in \mathcal{H}^N$ satisfies the scheme

$$\begin{cases} y_i = (I + \varepsilon\partial\phi)^{-1}(I + \varepsilon A)^{-1}(y_{i-1} + \varepsilon B u_i), & i = 1, 2, \ldots, N, \\ y_0 = y^0. \end{cases} \tag{5.2}$$

Obviously y_i depends on ε, but for the sake of simplicity we shall not indicate this explicitly. It is easy to see that

$$|y_i| \leq |((I + \varepsilon\partial\phi)^{-1}(I + \varepsilon A)^{-1})^i y^0| + \sum_{j=1}^{i} \varepsilon|Bu_j|, \qquad i = 1, 2, \ldots, N. \tag{5.3}$$

PROPOSITION 5.1. *Suppose that* (i)–(vi) *hold. Then, for every* $\varepsilon > 0$, *problem* (P^ε) *has at least one solution* $(u_1^\varepsilon, u_2^\varepsilon, \ldots, u_N^\varepsilon) \in \mathcal{U}^N$.

Proof. Let $\{(u_{1,m}, u_{2,m}, \ldots, u_{N,m})\} \subset \mathcal{U}^N$ be a minimizing sequence for (P^ε). Using condition (1.4) and taking assumption (ii) together with (5.3) into account, we deduce that the sequences $\{u_{i,m}\}, i = 1, 2, \ldots, N$, are bounded in $\mathcal{U}$; so, on a certain subsequence of $\{m\}$, $u_{i,m}$ converge to u_i^ε weakly in $\mathcal{U}$ as $m \to \infty$.

Now set

$$z_{i,m} = (I + \varepsilon A)^{-1}(y_{i-1,m} + \varepsilon B u_{i,m}), \qquad i = 1, 2, \ldots, N,$$

where $y_{i,m}$ is given by (5.2) with $u_i = u_{i,m}$. Obviously, $y_{i,m} = (I + \varepsilon \partial\phi)^{-1} z_{i,m}$. We easily get

$$\frac{1}{2}|z_{i,m}|^2 + \varepsilon(A z_{i,m}, z_{i,m}) \le |y_{i-1,m}|^2 + \varepsilon^2 |B u_{i,m}|^2, \qquad i = 1, 2, \ldots, N,$$

whence, by (3.1) and (1.5), we obtain that $\{y_{i,m}\}, i = 1, 2, \ldots, N$, are bounded in $\mathcal{V}$. Since the inclusion $\mathcal{V} \subset \mathcal{H}$ is compact, by extracting a subsequence, $y_{i,m}$ converges to y_i^ε strongly in $\mathcal{H}$ as $m \to \infty$.

We may rewrite (5.2) where $u_i = u_{i,m}, y_i = y_{i,m}$ as follows:

$$y_{i,m} + \varepsilon \partial\phi(y_{i,m}) \ni (I + \varepsilon A)^{-1}(y_{i-1,m} + \varepsilon B u_{i,m}).$$

Since $\partial\phi$ is demiclosed in $\mathcal{H} \times \mathcal{H}$, letting $m \to \infty$ we obtain that y_i^ε satisfies (5.2) with $u_i = u_i^\varepsilon$.

Now let $m \to \infty$ in (5.1) where $u_i = u_{i,m}$; using the weak lower semicontinuity of h as well as the continuity of g and l, we conclude that $(u_1^\varepsilon, u_2^\varepsilon, \ldots, u_N^\varepsilon)$ solves (P^ε), and the proof is complete.

A sequence of optimal N-tuples for discrete problems (P^ε) yields a sequence of approximately optimal controls (a minimizing sequence) for problem (P). Indeed, let $(u_1^\varepsilon, u_2^\varepsilon, \ldots, u_N^\varepsilon)$ be an optimal N-tuple of (P^ε). Define

$$u^\varepsilon(t) = u^\varepsilon(i\varepsilon) = u_i^\varepsilon \quad \text{for } t \in ((i-1)\varepsilon, i\varepsilon], \quad i = 1, 2, \ldots, N. \tag{5.4}$$

We shall show that if we take these functions as controls in the initial system (1.2), (1.3), the corresponding values of the performance index (1.1) approach the infimum as $\varepsilon \to 0$. We set

$$J(u) = \int_0^T (h(u(t)) + g(y(t)))dt + l(y(T)) \quad \text{for } u \in L^2(0, T; \mathcal{U}),$$

where y is the solution of (1.2), (1.3).

THEOREM 5.1. *Let $y^0 \in \mathcal{V} \cap D(\phi)$. Under hypotheses* (i) – (iii), (1.6), (v), *and* (vi), *we have*

$$\lim_{\varepsilon \to 0} J(u^\varepsilon) = \inf\{J(u) : u \in L^2(0, T; \mathcal{U})\},$$

where the controls u^ε correspond by (5.4) *to solutions of problems (P^ε). Moreover, every weak limit point of $\{u^\varepsilon\}$ in $L^2(0, T; \mathcal{U})$ is an optimal control for problem (P).*

Proof. Denote by $J_\varepsilon(u_1, u_2, \ldots, u_N)$ the value of functional (5.1) at $(u_1, u_2, \ldots, u_N) \in \mathcal{U}^N$ (where, of course, y_i is given by (5.2)) and set $J_\varepsilon = \inf\{J_\varepsilon(u_1, u_2, \ldots, u_N) : (u_1, u_2, \ldots, u_N) \in \mathcal{U}^N\}$. We have $J_\varepsilon(u_1^\varepsilon, u_2^\varepsilon, \ldots, u_N^\varepsilon) = J_\varepsilon = W^\varepsilon(T, y^0)$. We shall compare $J(u^\varepsilon)$ with $J_\varepsilon(u_1^\varepsilon, u_2^\varepsilon, \ldots, u_N^\varepsilon)$.

Let $u \in \mathcal{U}$ such that $h(u) < \infty$. Clearly,

$$J_\varepsilon(u_1^\varepsilon, u_2^\varepsilon, \ldots, u_N^\varepsilon) \le J_\varepsilon(u, u, \ldots, u) \le \text{const.},$$

where the constant is independent of ε. Hence, using (1.4) together with (ii) and (5.3), we deduce that

$$\int_0^T |u^\varepsilon(t)|^2\,dt = \sum_{i=1}^N \varepsilon |u_i^\varepsilon|^2 \leq \text{const.}$$

Consequently, on a subsequence of $\{\varepsilon\}$, $u^\varepsilon \longrightarrow u^0$ weakly in $L^2(0,T;\mathcal{U})$ as $\varepsilon \longrightarrow 0$.

Let $(y_1^\varepsilon, y_2^\varepsilon, \dots, y_N^\varepsilon)$ be the solution of (5.2) corresponding to $u_i = u_i^\varepsilon$. We may write

$$J_\varepsilon(u_1^\varepsilon, u_2^\varepsilon, \dots, u_N^\varepsilon) = \int_0^T (h(u^\varepsilon(t)) + g(y^\varepsilon(t)))dt + l(y^\varepsilon(T)),$$

where

$$y^\varepsilon(t) = y^\varepsilon(i\varepsilon) = y_i^\varepsilon \quad \text{for}\, t \in ((i-1)\varepsilon, i\varepsilon], \quad i = 1, 2, \dots, N.$$

By virtue of Lemma 3.2 (see also the end of its proof),

$$\lim_{\varepsilon \longrightarrow 0} y^\varepsilon(t) = y_{u^0}(t) \quad \text{strongly in}\, \mathcal{H}\, \text{for all}\, t \in [0,T],$$

where y_{u^0} is the solution of (1.2), (1.3) corresponding to $u = u^0$.

On the other hand, multiplying (scalarly in $\mathcal{H}$) equation (1.2), where $u = u^\varepsilon$, first by the solution $y_{u^\varepsilon} \in W^{1,2}([0,T];\mathcal{H}) \cap C([0,T];\mathcal{V}) \cap L^2(0,T;D(A))$ of (1.2), (1.3) and second by y'_{u^ε}, then integrating on $[0,T]$, after some calculation we obtain

$$|y_{u^\varepsilon}(t)| \leq \text{const.} \quad \text{and} \quad \int_0^T |y'_{u^\varepsilon}(s)|^2\,ds + |y_{u^\varepsilon}(t)|_{\mathcal{V}}^2 \leq \text{const.} \quad \text{for}\, t \in [0,T],$$

where the constants are independent of ε. Now applying the Arzelà–Ascoli theorem (do not forget that the inclusion $\mathcal{V} \subset \mathcal{H}$ is compact), we infer that, on a subsequence, $y_{u^\varepsilon} \longrightarrow y_0$ strongly in $C([0,T];\mathcal{H})$ as $\varepsilon \longrightarrow 0$. Subtracting the differential equations satisfied by $y_{u^\varepsilon}, y_{u^0}$, and multiplying the difference by $y_{u^\varepsilon} - y_{u^0}$, we get

$$\frac{1}{2}|y_{u^\varepsilon}(t) - y_{u^0}(t)|^2 \leq \int_0^t (Bu^\varepsilon - Bu^0, y_{u^\varepsilon} - y_{u^0})ds \quad \text{for all}\, t \in [0,T],$$

whence, letting $\varepsilon \longrightarrow 0$, it follows that $y_0 \equiv y_{u^0}$. Hence,

$$y_{u^\varepsilon} \longrightarrow y_{u^0} \quad \text{strongly in}\, C([0,T];\mathcal{H}).$$

Since g and l are continuous, by the Lebesgue dominated convergence theorem we have

$$\lim_{\varepsilon \longrightarrow 0} (J(u^\varepsilon) - J_\varepsilon(u_1^\varepsilon, u_2^\varepsilon, \dots, u_N^\varepsilon)) = 0.$$

But Theorem 3.1 asserts that

$$\lim_{\varepsilon \longrightarrow 0} J_\varepsilon(u_1^\varepsilon, u_2^\varepsilon, \dots, u_N^\varepsilon) = \lim_{\varepsilon \longrightarrow 0} W^\varepsilon(T, y^0) = W(T, y^0) = \inf\{J(u) : u \in L^2(0,T;\mathcal{U})\},$$

which proves the first statement of Theorem 5.1.

Finally, let u^0 be a weak limit point in $L^2(0,T;\mathcal{U})$ of $\{u^\varepsilon\}$. Then take limits in (5.1) where $u_i = u_i^\varepsilon$. Using the weak lower semicontinuity in $L^2(0,T;\mathcal{U})$ of $u \longmapsto \int_0^T h(u(t))dt$ and the first part of Theorem 5.1 (just proved), we conclude that u^0 is an optimal control for problem (P), which finishes the proof.

6. The discrete feedback law. Let Ω be an open bounded subset of $\mathbf{R}^n$. In this section, we are forced to restrict ourselves to systems governed by

$$y' + Ay + \beta(y) \ni Bu \tag{6.1}$$

with the initial condition

$$y(0) = y^0, \tag{6.2}$$

where A, B satisfy (iii), (v) with $\mathcal{H} = L^2(\Omega)$, respectively, and β is a maximal monotone graph in $\mathbf{R}^2$. As we have seen in the preceding section, (6.1) can be set in the form (1.2) where ϕ is given by (4.4). Suppose that (4.5) holds as well.

Consider the following optimal control problem:

(P_1) minimize functional (1.1) over all $u \in L^2(0,T;\mathcal{U})$, where $y \in C([0,T];\mathcal{H})$ satisfies (6.1), (6.2).

We impose on the data of (P_1) hypotheses (i) and (ii).

Let $\varepsilon = T/N$, where N is a positive integer. Define the function $V^\varepsilon : [0,T] \times \mathcal{H} \to \mathbf{R}$ by

$$V^\varepsilon(t,y) = W^\varepsilon(T-t,y), \qquad (t,y) \in [0,T] \times \mathcal{H}, \tag{6.3}$$

where in (2.4) β replaces $\partial\phi$. We may regard V^ε as an approximately optimal value function associated with problem (P_1). Indeed, if (vi) also holds, then by virtue of Theorem 3.1,

$$\lim_{\varepsilon \to 0} V^\varepsilon(t,y) = V(t,y) \quad \text{for all } (t,y) \in [0,T] \times \overline{D(A) \cap D(\partial\phi)},$$

where in (1.7) ϕ is given by (4.4). Note that only the values of V^ε calculated at $t = i\varepsilon$ $(i = 0, 1, \ldots, N)$ will be relevant in our further considerations. By (6.3) and (2.4) we have

$$\left\{ \begin{aligned} & V^\varepsilon(i\varepsilon, y) = \inf\{\varepsilon h(u) + \varepsilon g((I+\varepsilon\beta)^{-1}(I+\varepsilon A)^{-1}(y+\varepsilon Bu)) \\ & \qquad + V^\varepsilon((i+1)\varepsilon, (I+\varepsilon\beta)^{-1}(I+\varepsilon A)^{-1}(y+\varepsilon Bu)) : u \in \mathcal{U}\}, \quad y \in \mathcal{H}, \\ & \qquad i = 0, 1, \ldots, N-1, \\ & V^\varepsilon(T,y) = l(y), y \in \mathcal{H}. \end{aligned} \right. \tag{6.4}$$

Finally, let us denote by (P_1^ε) the discrete problem (P^ε) where ϕ is given by (4.4). The relationship between the components $u_1^\varepsilon, u_2^\varepsilon, \ldots, u_N^\varepsilon$ of a solution of (P_1^ε) and the corresponding $y_1^\varepsilon, y_2^\varepsilon, \ldots, y_N^\varepsilon$ via V^ε (a genuine feedback law for the discrete system) forms the content of the following theorem.

THEOREM 6.1. *Suppose that hypotheses* (i)–(iii), (4.5), (v), *and* (vi) *hold, and let* $y^0 \in \mathcal{V} \cap D(\phi)$. *If* $(u_1^\varepsilon, u_2^\varepsilon, \ldots, u_N^\varepsilon) \in \mathcal{U}^N$ *is an optimal N-tuple for* (P_1^ε) *and* $y_0^\varepsilon, y_1^\varepsilon, \ldots, y_N^\varepsilon$ *are given by* (5.2) *where* $u_i = u_i^\varepsilon, i = 1, 2, \ldots, N$ (*and* $\partial\phi$ *is replaced by* β), *then the following discrete feedback law holds*:

$$u_i^\varepsilon \in \partial h^*(-B^*\partial_y V^\varepsilon((i-1)\varepsilon, y_{i-1}^\varepsilon)), \qquad i = 1, 2, \ldots, N. \tag{6.5}$$

Here $\partial_y V^\varepsilon(t,y)$ represents the generalized gradient (in Clarke's sense) of $y \mapsto V^\varepsilon(t,y)$. (Recall that, by virtue of Lemma 3.3, V^ε is Lipschitz continuous on bounded subsets of $\mathcal{H}$ with respect to y.)

Proof. Inspired by an idea of F. H. Clarke and R. B. Vinter (see [8, Lem. 8.4]), we consider the following perturbed discrete system:

$$\begin{cases} y_i^- &= (I+\varepsilon\beta)^{-1}(I+\varepsilon A)^{-1}(y_{i-1}^+ + \varepsilon Bu_i), \\ y_{i-1}^+ &= y_{i-1}^- + v_i, \quad i = 1,2,\dots,N, \\ y_0^- &= y^0, \end{cases}$$

where $(u_1, u_2, \dots, u_N) \in \mathcal{U}^N$ and $(v_1, v_2, \dots, v_N) \in \mathcal{H}^N$. Obviously,

$$y_i^- = (I+\varepsilon\beta)^{-1}(I+\varepsilon A)^{-1}(y_{i-1}^- + \varepsilon Bu_i + v_i).$$

Fix $\delta > 0$. Let $(u_1, u_2, \dots, u_N) \in \mathcal{U}^N, (v_1, v_2, \dots, v_N) \in \mathcal{H}^N$ such that

$$|y_i^- - y_i^\varepsilon| \le \delta, |y_i^+ - y_i^\varepsilon| \le \delta \quad \text{for } i = 1,2,\dots,N-1.$$

From the definition of V^ε (see (6.4)) we have

$$\varepsilon h(u_i) + \varepsilon g(y_i^-) + V^\varepsilon(i\varepsilon, y_i^-) - V^\varepsilon((i-1)\varepsilon, y_{i-1}^+) \ge 0, \qquad i = 1,2,\dots,N.$$

For simplicity we set $y_i = y_i^-$. Adding the above inequalities, we obtain

$$(6.6)\quad \sum_{i=1}^N \varepsilon(h(u_i) + g(y_i)) + l(y_N) - \sum_{i=1}^N (V^\varepsilon((i-1)\varepsilon, y_{i-1} + v_i) - V^\varepsilon((i-1)\varepsilon, y_{i-1})) \\ \ge V^\varepsilon(0, y^0).$$

By the mean-value theorem for generalized gradient (see, for instance, [2, Cor. 1.2]),

$$V^\varepsilon((i-1)\varepsilon, y_{i-1} + v_i) - V^\varepsilon((i-1)\varepsilon, y_{i-1}) = (p_{i-1}, v_i),$$

where $p_{i-1} \in \partial_y V^\varepsilon((i-1)\varepsilon, z_{i-1})$ with $|z_{i-1} - y_{i-1}^\varepsilon| \le \delta, i = 1,2,\dots,N$. We define

$$k_{i,\delta}(v) = \sup\{(p,v) : p \in \partial_y V^\varepsilon(i\varepsilon, y), |y - y_i^\varepsilon| \le \delta\} \\ \text{for all } v \in \mathcal{H}, i = 1,2,\dots,N, \text{ and } \delta > 0.$$

Clearly, $k_{i,\delta}$ is convex, lower semicontinuous and finite everywhere (since V^ε is Lipschitz continuous on bounded subsets); therefore, it is a continuous convex function on $\mathcal{H}$. Returning to (6.6), we have

$$\sum_{i=1}^N \varepsilon(h(u_i) + g(y_i)) + \sum_{i=1}^N k_{i-1,\delta}(-v_i) + l(y_N) \ge V^\varepsilon(0, y^0).$$

Thus we have proved that $(u_1^\varepsilon, u_2^\varepsilon, \dots, u_N^\varepsilon, 0, 0, \dots, 0) \in \mathcal{U}^N \times \mathcal{H}^N$ and $(y_1^\varepsilon, y_2^\varepsilon, \dots, y_N^\varepsilon)$ solve the following problem:

(P_δ) minimize

$$(6.7)\qquad \sum_{i=1}^N \varepsilon(h(u_i) + g(y_i)) + \sum_{i=1}^N k_{i-1,\delta}(-v_i) + l(y_N)$$

over all $(u_1, u_2, \dots, u_N, v_1, v_2, \dots, v_N) \in \mathcal{U}^N \times \mathcal{H}^N$, where

$$(6.8)\qquad \begin{cases} y_i = (I+\varepsilon\beta)^{-1}(I+\varepsilon A)^{-1}(y_{i-1} + \varepsilon Bu_i + v_i), \quad i = 1,2,\dots,N, \\ y_0 = y^0, \end{cases}$$

and

$$|y_i - y_i^\varepsilon| \leq \delta, \quad |y_i + v_{i+1} - y_i^\varepsilon| \leq \delta, \quad i = 0, 1, \ldots, N-1.$$

Roughly speaking, we shall get (6.5) from a set of optimality conditions for (P_δ) as $\delta \longrightarrow 0$. To this end, we associate with (P_δ) the following family of smooth (and penalized) problems:

$(P_{\delta,\eta})$ minimize

$$\begin{aligned}(6.9)\qquad &\sum_{i=1}^N \varepsilon\left(h(u_i) + \frac{1}{2}|u_i - u_i^\varepsilon|^2 + g_\eta(y_i) + I_{i-1,\delta,\eta}(y_{i-1}) + I_{i-1,\delta,\eta}(y_{i-1} + v_i)\right) \\ &+ \sum_{i=1}^N \left(k_{i-1,\delta}(-v_i) + \frac{1}{2}|v_i|^2\right) + l_\eta(y_N)\end{aligned}$$

over all $(u_1, \ldots, u_N, v_1, \ldots, v_N) \in \mathcal{U}^N \times \mathcal{H}^N$, where y_i satisfies

$$(6.10)\qquad \begin{cases} y_i = (I + \varepsilon\tilde{\beta}_\eta)^{-1}(I + \varepsilon A)^{-1}(y_{i-1} + \varepsilon B u_i + v_i), & i = 1, 2, \ldots, N, \\ y_0 = y^0. \end{cases}$$

Here g_η and l_η are regularizations of g and l, respectively (see [2, p. 28]), $I_{i,\delta,\eta}$ is the convex regularization of the indicator function $I_{i,\delta}$ of the set $\{y \in \mathcal{H} : |y - y_i^\varepsilon| \leq \delta\}, i = 0, 1, \ldots, N-1$ (i.e., $I_{i,\delta,\eta}(y) = \inf\{|y - z|^2/2\eta : |z - y_i^\varepsilon| \leq \delta\}$), and $\tilde{\beta}_\eta$ is a regularization of $\beta_\eta = \eta^{-1}(I - (I + \eta\beta)^{-1})$ (see [2, p. 75]).

Now fix $\delta > 0$. The proof of the following lemma is similar to that of Proposition 5.1.

LEMMA 6.1. *For every* $\eta > 0$, *problem* $(P_{\delta,\eta})$ *has at least one solution* $(u_{1,\delta,\eta}, \ldots, u_{N,\delta,\eta}, v_{1,\delta,\eta}, \ldots, v_{N,\delta,\eta}) \in \mathcal{U}^N \times \mathcal{H}^N$.

For the sake of simplicity, we set $u_{i,\eta} = u_{i,\delta,\eta}, v_{i,\eta} = v_{i,\delta,\eta}$ for any optimal $2N$-tuple of $(P_{\delta,\eta})$ given by Lemma 6.1. The following result is an effect of the penalization terms.

LEMMA 6.2. *For each* $\eta > 0$, *let us consider a solution* $(u_{1,\eta}, \ldots, u_{N,\eta}, v_{1,\eta}, \ldots, v_{N,\eta})$ *for problem* $(P_{\delta,\eta})$ *and let* $(y_{1,\eta}, y_{2,\eta}, \ldots, y_{N,\eta})$ *be the solution of* (6.10) *corresponding to* $u_i = u_{i,\eta}$ *and* $v_i = v_{i,\eta}$. *We have*

$$\lim_{\eta \to 0} u_{i,\eta} = u_i^\varepsilon \quad \textit{strongly in } \mathcal{U},$$

$$\lim_{\eta \to 0} v_{i,\eta} = v_i^\varepsilon = 0 \quad \textit{strongly in } \mathcal{H},$$

$$\lim_{\eta \to 0} y_{i,\eta} = y_i^\varepsilon \quad \textit{strongly in } \mathcal{H},$$

$i = 1, 2, \ldots, N$.

Proof. Let us denote by $J_\delta(u_1, \ldots, u_N, v_1, \ldots, v_N)$ functional (6.7) and by $J_{\delta,\eta}(u_1, \ldots, u_N, v_1, \ldots, v_N)$ functional (6.9). Also, we denote by $\tilde{J}_{\delta,\eta}(u_1, \ldots, u_N, v_1, \ldots, v_N)$ the functional obtained from (6.9) by eliminating the penalization terms $(1/2)|u_i - u_i^\varepsilon|^2$ and $(1/2)|v_i|^2$.

Arguing as below, we can show that the solution of (6.10) corresponding to $u_i = u_i^\varepsilon$, $v_i = 0\,(i = 1, 2, \ldots, N)$ converges to $(y_1^\varepsilon, y_2^\varepsilon, \ldots, y_N^\varepsilon)$ as $\eta \longrightarrow 0$. But since $I_{i,\delta,\eta}(y) = 0$ when $|y - y_i^\varepsilon| \leq \delta$, for each $\delta > 0$, we can find $\eta_\delta > 0$ such that

$$(6.11)\qquad \begin{aligned} J_{\delta,\eta}(u_{1,\eta}, \ldots, u_{N,\eta}, v_{1,\eta}, \ldots, v_{N,\eta}) &\leq J_{\delta,\eta}(u_1^\varepsilon, \ldots, u_N^\varepsilon, v_1^\varepsilon, \ldots, v_N^\varepsilon) \\ &\leq \text{const.} \quad \text{for } \eta \in (0, \eta_\delta], \end{aligned}$$

where the constant is independent of δ. Hence, since $k_{i,\delta}(v) \geq -L_i|v|$ (where L_i is the Lipschitz constant of $y \mapsto V^\varepsilon(i\varepsilon, y)$ corresponding to a certain ball with y_i^ε as center), it follows that there exists $M > 0$, also independent of δ, such that

$$(6.12)\qquad |u_{i,\eta}| \leq M \quad \text{and} \quad |v_{i,\eta}| \leq M \quad \text{for } \eta \in (0, \eta_\delta], \quad i = 1, 2, \ldots, N.$$

Consequently, on a subsequence of $\{\eta\}$, $u_{i,\eta} \to u_{i,0}$ weakly in $\mathcal{U}$ and $v_{i,\eta} \to v_{i,0}$ weakly in $\mathcal{H}$ as $\eta \to 0, i = 1, 2, \ldots, N$. (Note that the independence of δ of the boundedness constants of $\{u_{i,\delta,\eta}\}$ and $\{v_{i,\delta,\eta}\}$ will be important when we let $\delta \to 0$.)

As in Proposition 5.1, we get that, on a subsequence, $y_{i,\eta} \to y_{i,0}$ strongly in $\mathcal{H}$ as $\eta \to 0, i = 1, 2, \ldots, N$. Let $j_\eta(r) = \int_0^r \beta_\eta(s)ds$. Define $\phi_\eta(y) = \int_\Omega j_\eta(y(x))dx$ for $y \in L^2(\Omega)$. We have $\nabla\phi_\eta(y) = \beta_\eta(y)$ a.e. in Ω; therefore, we may write

$$y_{i,\eta} + \varepsilon\nabla\phi_\eta(y_{i,\eta}) = (I + \varepsilon A)^{-1}(y_{i-1,\eta} + \varepsilon Bu_{i,\eta} + v_{i,\eta}) + \varepsilon(\beta_\eta(y_{i,\eta}) - \tilde{\beta}_\eta(y_{i,\eta})).$$

Since $\nabla\phi_\eta(y_{i,\eta})$ is the Yosida approximation of $\partial\phi$ calculated at y and $|\beta_\eta(r) - \tilde{\beta}_\eta(r)| \leq 2\eta$ for all $r \in \mathbf{R}$ (see [2, p. 78]), we obtain as $\eta \to 0$,

$$y_{i,0} + \varepsilon\partial\phi(y_{i,0}) \ni (I + \varepsilon A)^{-1}(y_{i-1,0} + \varepsilon Bu_{i,0} + v_{i,0}).$$

So we have shown that, if $u_{i,\eta} \to u_{i,0}$ weakly in $\mathcal{U}$ and $v_{i,\eta} \to v_{i,0}$ weakly in $\mathcal{H}$ as $\eta \to 0$, then the components $y_{i,\eta}$ converge to the components of the solution of scheme (6.8) corresponding to $u_i = u_{i,0}$ and $v_i = v_{i,0}$ strongly in $\mathcal{H}$.

We still need the following semicontinuity property:

$$\text{(6.13)} \quad \liminf_{\eta\to 0} I_{i-1,\delta,\eta}(y_{i-1,\eta} + v_{i,\eta}) \geq I_{i-1,\delta}(y_{i-1,0} + v_{i,0}), \qquad i = 1, 2, \ldots, N.$$

To see this, let us observe that, in view of (6.11), $I_{i-1,\delta,\eta}(y_{i-1,\eta} + v_{i,\eta})$ is bounded with respect to η. Hence, by a well-known expression of the convex regularization (see [6, p. 121]), it readily follows that

$$(I + \eta I_{i-1,\delta})^{-1}(y_{i-1,\eta} + v_{i,\eta}) - (y_{i-1,\eta} + v_{i,\eta}) \to 0 \quad \text{strongly in } \mathcal{H},$$

whence by the lower semicontinuity of $I_{i-1,\delta}$ we have (6.13).

Now, by the convergence of $\{u_{i,\eta}\}$, $\{v_{i,\eta}\}$, and $\{y_{i,\eta}\}$, together with (6.13) and the weak lower semicontinuity of $u \mapsto h(u) + (1/2)|u - u_i^\varepsilon|^2, v \mapsto k_{i-1,\delta}(-v) + (1/2)|v|^2, i = 1, 2, \ldots, N$, we obtain the following chain of inequalities:

$$\begin{aligned}
&\liminf_{\eta\to 0} J_{\delta,\eta}(u_{1,\eta}, \ldots, u_{N,\eta}, v_{1,\eta}, \ldots, v_{N,\eta}) \\
&\quad \geq \liminf_{\eta\to 0} \tilde{J}_{\delta,\eta}(u_{1,\eta}, \ldots, u_{N,\eta}, v_{1,\eta}, \ldots, v_{N,\eta}) \\
&\quad \geq J_\delta(u_{1,0}, \ldots, u_{N,0}, v_{1,0}, \ldots, v_{N,0}) \\
&\quad \geq J_\delta(u_1^\varepsilon, \ldots, u_N^\varepsilon, 0, \ldots, 0) \\
&\quad = \lim_{\eta\to 0} J_{\delta,\eta}(u_1^\varepsilon, \ldots, u_N^\varepsilon, 0, \ldots, 0) \\
&\quad \geq \limsup_{\eta\to 0} J_{\delta,\eta}(u_{1,\eta}, \ldots, u_{N,\eta}, v_{1,\eta}, \ldots, v_{N,\eta}) \\
&\quad \geq \limsup_{\eta\to 0} \tilde{J}_{\delta,\eta}(u_{1,\eta}, \ldots, u_{N,\eta}, v_{1,\eta}, \ldots, v_{N,\eta}).
\end{aligned}$$

So we infer that

$$\begin{aligned}
\lim_{\eta\to 0} J_{\delta,\eta}(u_{1,\eta}, \ldots, u_{N,\eta}, v_{1,\eta}, \ldots, v_{N,\eta}) &= \lim_{\eta\to 0} \tilde{J}_{\delta,\eta}(u_{1,\eta}, \ldots, u_{N,\eta}, v_{1,\eta}, \ldots, v_{N,\eta}) \\
&= J_\delta(u_1^\varepsilon, \ldots, u_N^\varepsilon, 0, \ldots, 0),
\end{aligned}$$

and hence

$$\lim_{\eta\to 0} |u_{i,\eta} - u_i^\varepsilon| = 0, \quad \lim_{\eta\to 0} |v_{i,\eta}| = 0, \qquad i = 1, 2, \ldots, N.$$

The proof is thus complete.

In order to obtain the required optimality conditions for $(P_{\delta,\eta})$, we shall compare the optimal value with the values corresponding to $u_i = u_{i,\eta} + \lambda\bar{u}_i, v_i = v_{i,\eta} + \lambda\bar{v}_i, i = 1,2,\dots,N$, where $\lambda > 0$, and $\bar{u}_i \in \mathcal{U}, \bar{v}_i \in \mathcal{H}$ are arbitrary. We have

$$\begin{aligned}(6.14)\quad & J_{\delta,\eta}(u_{1,\eta}+\lambda\bar{u}_1,\dots,u_{N,\eta}+\lambda\bar{u}_N,v_{1,\eta}+\lambda\bar{v}_1,\dots,v_{N,\eta}+\lambda\bar{v}_N)\\ & \quad - J_{\delta,\eta}(u_{1,\eta},\dots,u_{N,\eta},v_{1,\eta},\dots,v_{N,\eta}) \geq 0 \quad \text{for all } \lambda > 0 \text{ and } \bar{u}_i \in \mathcal{U}, \bar{v}_i \in \mathcal{H}.\end{aligned}$$

Denote by $y_{i,\eta,\lambda}$ the solution of (6.10) corresponding to $u_i = u_{i,\eta} + \lambda\bar{u}_i, v_i = v_{i,\eta} + \lambda\bar{v}_i$. It is easy to check that

$$\lim_{\lambda\to 0}\frac{1}{\lambda}(y_{i,\eta,\lambda} - y_{i,\eta}) = z_{i,\eta} \quad \text{strongly in } \mathcal{H},$$

where $z_{i,\eta}$ satisfies the scheme

$$(6.15)\quad \begin{cases} z_{i,\eta} = (1+\varepsilon\tilde{\beta}'_\eta(y_{i,\eta}))^{-1}(I+\varepsilon A)^{-1}(z_{i-1,\eta}+\varepsilon B\bar{u}_i+\bar{v}_i), & i = 1,2,\dots,N,\\ z_{0,\eta} = 0. \end{cases}$$

Dividing (6.14) by λ and letting $\lambda \to 0$, we get

$$\begin{aligned}(6.16)\quad & \sum_{i=1}^{N}\varepsilon(h'(u_{i,\eta};\bar{u}_i) + (u_{i,\eta}-u_i^\varepsilon,\bar{u}_i) + (\nabla g_\eta(y_{i,\eta}),z_{i,\eta})\\ &\quad +(\nabla I_{i-1,\delta,\eta}(y_{i-1,\eta}) + \nabla I_{i-1,\delta,\eta}(y_{i-1,\eta}+v_{i,\eta}),z_{i-1,\eta}))\\ &\quad +\sum_{i=1}^{N}(k'_{i-1,\delta}(-v_{i,\eta};-\bar{v}_i) + (v_{i,\eta},\bar{v}_i) + (\varepsilon\nabla I_{i-1,\delta,\eta}(y_{i-1,\eta}+v_{i,\eta}),\bar{v}_i))\\ &\quad +(\nabla l_\eta(y_{N,\eta}),z_{N,\eta}) \geq 0 \quad \text{for all } (\bar{u}_1,\bar{u}_2,\dots,\bar{u}_N) \in \mathcal{U}^N,\\ &\qquad\qquad\qquad\qquad\qquad\qquad (\bar{v}_1,\bar{v}_2,\dots,\bar{v}_N) \in \mathcal{H}^N,\end{aligned}$$

where $h'(u_{i,\eta};\bar{u}_i)$ and $k'_{i-1,\delta}(-v_{i,\eta};-\bar{v}_i)$ denote the directional derivatives of h and $k_{i-1,\delta}$ at $u_{i,\eta}$ and $-v_{i,\eta}$ in the directions $\bar{u}_i$ and $-\bar{v}_i$, respectively. Note that, for sufficiently small $\eta > 0$, we have

$$\nabla I_{i-1,\delta,\eta}(y_{i-1,\eta}) = 0, \quad \nabla I_{i-1,\delta,\eta}(y_{i-1,\eta}+v_{i,\eta}) = 0, \qquad i = 1,2,\dots,N,$$

since $y_{i,\eta} \to y_i^\varepsilon$ and $v_{i,\eta} \to 0$ strongly in $\mathcal{H}$ as $\eta \to 0$.

Now define $p_{i,\eta}$ by

$$(6.17)\quad \begin{cases} p_{i-1,\eta} = (I+\varepsilon A)^{-1}((1+\varepsilon\tilde{\beta}'_\eta(y_{i,\eta}))^{-1}(p_{i,\eta}-\varepsilon\nabla g_\eta(y_{i,\eta}))), & i = 1,2,\dots,N,\\ p_{N,\eta} = -\nabla l_\eta(y_{N,\eta}). \end{cases}$$

Some calculation in (6.16) involving (6.15), (6.17) together with the identity

$$(p_{i,\eta} - p_{i-1,\eta}, z_{i,\eta}) = (p_{i,\eta}, z_{i,\eta}) - (p_{i-1,\eta}, z_{i-1,\eta}) - (p_{i-1,\eta}, z_{i,\eta} - z_{i-1,\eta}),$$

gives, for sufficiently small $\eta > 0$,

$$\begin{aligned}&\sum_{i=1}^{N}\varepsilon(h'(u_{i,\eta};\bar{u}_i) + (u_{i,\eta}-u_i^\varepsilon - B^*p_{i-1,\eta},\bar{u}_i))\\ &\quad +\sum_{i=1}^{N}(k'_{i-1,\delta}(-v_{i,\eta};-\bar{v}_i) + (v_{i,\eta}-p_{i-1,\eta},\bar{v}_i))\\ &\quad \geq 0 \quad \text{for all } (\bar{u}_1,\bar{u}_2,\dots,\bar{u}_N) \in \mathcal{U}^N, (\bar{v}_1,\bar{v}_2,\dots,\bar{v}_N) \in \mathcal{H}^N,\end{aligned}$$

which yields, for $\eta > 0$ small enough,

$$B^* p_{i-1,\eta} \in \partial h(u_{i,\eta}) + u_{i,\eta} - u_i^\varepsilon, \tag{6.18}$$

$$-p_{i-1,\eta} \in \partial k_{i-1,\delta}(-v_{i,\eta}) - v_{i,\eta}, \qquad i = 1, 2, \dots, N. \tag{6.19}$$

Obviously, like $u_{i,\eta} = u_{i,\delta,\eta}$, $v_{i,\eta} = v_{i,\delta,\eta}$, and $y_{i,\eta} = y_{i,\delta,\eta}$, $p_{i,\eta}$ also depends on $\delta > 0$ (even if we have purposely omitted, for simplicity, the subscript δ). So, in what follows we set $p_{i,\delta,\eta} = p_{i,\eta}$. As (6.12) shows, $u_{i,\eta}$ and $v_{i,\eta}$ are bounded by constants which are independent of δ; it easily follows that $y_{i,\eta}$, $\nabla g_\eta(y_{i,\eta})$, and $\nabla l_\eta(y_{N,\eta})$ satisfy similar boundedness conditions. Hence $p_{i,\delta,\eta}$ is also bounded in the sense of (6.12) by a constant $M > 0$ which is independent of δ, i.e., for each $\delta > 0$, we find $\eta_\delta > 0$ such that

$$|p_{i,\delta,\eta}| \leq M \quad \text{for } \eta \in (0, \eta_\delta], \quad i = 0, 1, \dots, N-1.$$

(Moreover, the above condition also holds in the norm of $\mathcal{V}$, but with a different constant M.) So, for each $\delta > 0$, on a subsequence of $\{\eta\}$,

$$p_{i,\delta,\eta} \to p_{i,\delta} \quad \text{weakly (or strongly) in } \mathcal{H} \quad \text{as } \eta \to 0.$$

This, in conjunction with the boundedness condition for $p_{i,\delta,\eta}$, yields

$$|p_{i,\delta}| \leq M \quad \text{for all } \delta > 0, \quad i = 0, 1, \dots, N-1. \tag{6.20}$$

Letting $\eta \to 0$ in (6.18), (6.19), since ∂h and $\partial k_{i,\delta}$ are demiclosed we get

$$B^* p_{i-1,\delta} \in \partial h(u_i^\varepsilon), \tag{6.21}$$

$$-p_{i-1,\delta} \in \partial k_{i-1,\delta}(0) \tag{6.22}$$

for $\delta > 0, i = 1, 2, \dots, N$.

On the other hand, by (6.20) we have on a subsequence of $\{\delta\}$

$$p_{i,\delta} \to p_i^\varepsilon \quad \text{weakly in } \mathcal{H} \text{ as } \delta \to 0, \quad i = 0, 1, \dots, N-1. \tag{6.23}$$

Now, the assertion of Theorem 6.1 will follow by taking limits in (6.21), as soon as we show by interpreting (6.22) the following relationship among p_i^ε, y_i^ε, and V^ε:

$$-p_{i-1}^\varepsilon \in \partial_y V^\varepsilon((i-1)\varepsilon, y_{i-1}^\varepsilon), \qquad i = 1, 2, \dots, N. \tag{6.24}$$

This inclusion is a discrete variant of the well-known connection between the maximum principle and dynamic programming. Its proof is a simple adaptation for our discrete (but infinite-dimensional) case of the proof of Theorem 3.1 from [8].

Let us first clarify the meaning of inclusion (6.22). Observe that

$$-p_{i-1,\delta} \in \overline{co} \bigcup_{|y - y_{i-1}^\varepsilon| \leq \delta} \partial_y V^\varepsilon((i-1)\varepsilon, y), \qquad i = 1, 2, \dots, N.$$

Otherwise, there exists a hyperplane strictly separating $-p_{i-1,\delta}$ and the above closed convex set (see [6, Thm. 1.15, p. 21]), i.e., we find $v \in \mathcal{H}$ such that

$$\begin{aligned}(-p_{i-1,\delta}, -v) &> \sup\left\{(p, -v) : p \in \overline{co} \bigcup_{|y - y_{i-1}^\varepsilon| \leq \delta} \partial_y V^\varepsilon((i-1)\varepsilon, y)\right\} \\ &= \sup\left\{(p, -v) : p \in \bigcup_{|y - y_{i-1}^\varepsilon| \leq \delta} \partial_y V^\varepsilon((i-1)\varepsilon, y)\right\} \\ &= k_{i-1,\delta}(-v),\end{aligned}$$

which contradicts (6.22) because $k_{i-1,\delta}(0) = 0$.

We let δ tend to 0 in (6.21), (6.22) by using (6.23), and we get

$$B^* p^\varepsilon_{i-1} \in \partial h(u^\varepsilon_i), \tag{6.25}$$

$$-p^\varepsilon_{i-1} \in \bigcap_{\delta>0} \overline{co} \bigcup_{|y-y^\varepsilon_{i-1}|\le\delta} \partial_y V^\varepsilon((i-1)\varepsilon, y), \qquad i = 1, 2, \ldots, N. \tag{6.26}$$

Now we shall show that (6.26) implies (6.24). Indeed, if this does not happen, then $-p^\varepsilon_{i-1}$ and $\partial_y V^\varepsilon((i-1)\varepsilon, y^\varepsilon_{i-1})$ can be strictly separated by a hyperplane, i.e., there exists $v \in \mathcal{H}$ and $\gamma > 0$ such that

$$(-p^\varepsilon_{i-1}, v) - \gamma > \max\{(p, v) : p \in \partial_y V^\varepsilon((i-1)\varepsilon, y^\varepsilon_{i-1})\} = (V^\varepsilon)^\circ((i-1)\varepsilon, y^\varepsilon_{i-1}; v).$$

Here $(V^\varepsilon)^\circ((i-1)\varepsilon, y^\varepsilon_{i-1}; v)$ is the generalized directional derivative of the function $y \mapsto V^\varepsilon((i-1)\varepsilon, y)$ at y^ε_{i-1} in the direction v. (For the above equality, we refer to [7, Prop. 2.1.2].) By the upper semicontinuity of $(V^\varepsilon)^\circ$ (see [7, Prop. 2.1.1]), we find $\delta' > 0$ such that

$$(-p^\varepsilon_{i-1}, v) - \gamma > (V^\varepsilon)^\circ((i-1)\varepsilon, y; v) \quad \text{for } |y - y^\varepsilon_{i-1}| \le \delta'.$$

Now using the definition of the generalized gradient, we find

$$\begin{aligned}(-p^\varepsilon_{i-1}, v) - \gamma &\ge \sup\left\{(p, v) : p \in \bigcup_{|y-y^\varepsilon_{i-1}|\le\delta'} \partial_y V^\varepsilon((i-1)\varepsilon, y)\right\} \\ &= \sup\left\{(p, v) : p \in \overline{co} \bigcup_{|y-y^\varepsilon_{i-1}|\le\delta'} \partial_y V^\varepsilon((i-1)\varepsilon, y)\right\}.\end{aligned}$$

So we have obtained that

$$-p^\varepsilon_{i-1} \notin \overline{co} \bigcup_{|y-y^\varepsilon_{i-1}|\le\delta'} \partial_y V^\varepsilon((i-1)\varepsilon, y),$$

which contradicts (6.26).

Finally, we may rewrite (6.25) as

$$u^\varepsilon_i \in \partial h^*(B^* p^\varepsilon_{i-1}), \qquad i = 1, 2, \ldots, N.$$

But the above inclusion combined with (6.24) gives (6.5), and the proof of Theorem 6.1 is complete.

Remark 6.1. The feedback law (6.5) is expressed with the aid of the Trotter scheme (2.4). A different feedback law is given, at least formally, by scheme (2.5) (via the function $\overline{W^\varepsilon}$). However, in this case, even the existence of an optimal N-tuple for the approximating problem (P^ε) remains an open problem.

7. Concluding remarks. Theorems 5.1 and 6.1 apply to the control systems governed by (4.2) where $0 \in \beta(0)$. Thus the case of the control of the parabolic obstacle problem with obstacle and boundary values 0 as well as that of the control of semilinear parabolic equations are covered (see again §4 for details).

Let us emphasize that Theorems 5.1 and 6.1 must be regarded together. So, the knowledge of the function V^ε allows us to construct an approximately optimal control for problem (P_1) by using feedback law (6.5). In this context, pay attention to the fact that formula (6.5) is merely a *necessary* condition of optimality for problem (P_1^ε). But so is the Pontryagin maximum principle and, nevertheless, in many specific situations, this offers us an effective tool for constructing an optimal control.

Let us now see how we can use formula (6.5) to obtain an approximately optimal control for problem (P_1). Clearly, (6.5) is an exact feedback law for problem (P_1^ε). It may also be regarded as an approximate feedback law for problem (P_1), which works as follows: Starting with the initial state y^0, we select $u_1^\varepsilon \in \partial h^*(-B^*\partial_y V^\varepsilon(0, y^0))$ (the first component of an optimal N-tuple for (P_1^ε)). Next we introduce the controller $u^\varepsilon(t) = u_1^\varepsilon$ on $(0, \varepsilon]$ in the real system. (For the real system we may choose either the continuous model described by equation (6.1) or the discrete model given by scheme (5.2).) Now we assimilate y_1^ε in (6.5) with the state of the real system observed at the moment $t = \varepsilon$; let us denote it by $y^\varepsilon(\varepsilon)$. With y_1^ε so specified, we further select $u_2^\varepsilon \in \partial h^*(-B^*\partial_y V^\varepsilon(\varepsilon, y^\varepsilon(\varepsilon)))$ and we proceed as above. Consequently, we have the following synthesis scheme:

$$(7.1) \qquad u^\varepsilon(t) = u_i^\varepsilon \in \partial h^*(-B^*\partial_y V^\varepsilon((i-1)\varepsilon, y^\varepsilon((i-1)\varepsilon))) \quad \text{on}\,((i-1)\varepsilon, i\varepsilon],$$

where y^ε is the state of the real system corresponding to the initial state y^0 and the input u^ε. So, the control u^ε obtained in this way is a feedback control.

Now let us look at formula (6.5) from another point of view (which does not require the external concept of observation). According to Theorem 5.1 we can construct an approximately optimal control for problem (P_1) by starting with a solution $(u_1^\varepsilon, u_2^\varepsilon, \ldots, u_N^\varepsilon)$ of problem (P_1^ε). But, by virtue of Theorem 6.1, any such solution verifies the inclusions (6.5). Therefore to calculate $(u_1^\varepsilon, u_2^\varepsilon, \ldots, u_N^\varepsilon)$, we consider the system

$$(7.2) \qquad \begin{cases} u_i^\varepsilon \in \partial h^*(-B^*\partial_y V^\varepsilon((i-1)\varepsilon, y_{i-1}^\varepsilon)), \\ y_i^\varepsilon = (I + \varepsilon\beta)^{-1}(I + \varepsilon A)^{-1}(y_{i-1}^\varepsilon + \varepsilon B u_i^\varepsilon), \quad i = 1, 2, \ldots, N, \\ y_0^\varepsilon = y^0. \end{cases}$$

Thus, starting with y^0, one obtains alternatively all the components of two N-tuples $(u_1^\varepsilon, u_2^\varepsilon, \ldots, u_N^\varepsilon)$ and $(y_1^\varepsilon, y_2^\varepsilon, \ldots, y_N^\varepsilon)$. Here is the order in which the calculations are made:

$$y^0, u_1^\varepsilon, y_1^\varepsilon, \ldots, y_{N-1}^\varepsilon, u_N^\varepsilon, y_N^\varepsilon.$$

Certainly, it is possible to find N-tuples $(u_1^\varepsilon, u_2^\varepsilon, \ldots, u_N^\varepsilon)$ verifying (7.2) (or (6.5)) that are not optimal for problem (P_1^ε), but all optimal N-tuples lie among the solutions of system (7.2). So, an adequate criterion of selection for the components u_i^ε must be established separately for each specific situation. Naturally, this is also true for synthesis scheme (7.1).

We point out that (7.2) is in essence an open-loop scheme: in order to determine the input u_i^ε, one uses not the value observed at the moment $t = (i-1)\varepsilon$ for the state of the real system, i.e., $y^\varepsilon((i-1)\varepsilon)$, but the value y_{i-1}^ε calculated by (5.2). Moreover, as we have seen in the proof of Theorem 6.1, $\partial_y V^\varepsilon((i-1)\varepsilon, y_{i-1}^\varepsilon) \ni -p_{i-1}^\varepsilon$, where the N-tuple $(p_0^\varepsilon, p_1^\varepsilon, \ldots, p_{N-1}^\varepsilon)$ may be viewed as a dual of $(y_1^\varepsilon, y_2^\varepsilon, \ldots, y_N^\varepsilon)$ in a Pontryagin-type maximum principle implicitly contained in the proof. In fact, system (7.2) is equivalent to a maximum principle for (P_1^ε). However, in comparison with the continuous case, the attempt to establish an explicit maximum principle for the discrete problem (P_1^ε) leads to some supplementary difficulties. In the discrete case, it is a real problem to give a sense to the adjoint scheme (which must be verified by p_i^ε) even for the control of the parabolic obstacle problem or that of semilinear parabolic equations (situations that were completely treated in the continuous case by Barbu in [2]).

Any optimal pair (u^*, y^*) for problem (P_1) formally satisfies the following continuous variant of (7.2):

$$\text{(7.3)} \qquad \begin{cases} u^*(t) \in \partial h^*(-B^* \partial_y V(t, y^*(t))) \quad \text{a.e.}\, t \in (0,T), \\ y^{*\prime} + Ay^* + \beta(y^*) \ni Bu^*, \\ y^*(0) = y^0, \end{cases}$$

where V is the optimal value function associated with (P_1). If we regard (7.3) as an open-loop system, we are led to a very complicated equation whose unknown is y^*. This happens because, in the first inclusion of (7.3), $u^*(t)$ depends on $y^*(t)$. In other words, the unknown $y^*(t)$ also appears in the right-hand side, incorporated in a strongly nonlinear term. The situation is different in the discrete case. Here u_i^ε depends on y_{i-1}^ε (previously calculated) and not on y_i^ε. Now substituting u_i^ε in (5.2), we no longer obtain the unknown y_i^ε in the right-hand side. Scheme (5.2) preserves its characteristic: the calculation of y_i^ε is reduced to the solution of an elliptic problem followed by the inversion of a graph in $\mathbf{R}^2$.

For V^ε, (1.11), (1.12) indicate two alternative ways to calculate it: one by a direct approach of a relatively simple type of Hamilton–Jacobi equation and the other by solving some minimization problems on $\mathcal{U}$.

REGULARITY CONDITIONS FOR THE STABILITY MARGIN PROBLEM WITH LINEAR DEPENDENT PERTURBATIONS *

ANTONIO VICINO† AND ALBERTO TESI‡

Abstract. In this paper, the problem of continuity of the stability margin of a control system on problem input data is addressed. The case in which perturbations are linearly correlated is considered. It is shown that the existence of special points (called critical points) in the stability boundary manifold in parameter space plays a key role in the analysis of the problem. Several conditions, either sufficient or both necessary and sufficient, are given, ensuring continuity of the stability margin on problem data. The obtained conditions turn out to be easily checkable for practical applications. Numerical examples are presented to illustrate the proposed techniques.

Key words. regularity conditions, robust stability, stability margin, parametric perturbations

AMS subject classification. 93

1. Introduction.

The study of robustness properties of dynamic systems in the presence of parameter variations is a classical subject in control theory. The renewed and stronger interest of recent years in this area has produced many contributions (see [14] for a historical survey on the subject for both linear and nonlinear systems and [2], [10] for specific reference to linear systems). The (real) stability margin (or stability radius) of a control system is a key concept in this field. Roughly speaking, it represents a measure of the minimum perturbation which destabilizes a system designed to be stable in nominal operating conditions. Methods for determining this quantity for the case where plant transfer function coefficients are linear functions of physical real parameters may be found in [3], [7], [11], [15], [16], and [17], whereas [4], [12], and [19] provide algorithms for the case of nonlinear (polynomial or rational) dependence.

In this paper we make reference to the classic problem setting of Fig. 1. We assume that the plant model uncertainty is "highly structured," in the sense that plant coefficients depend on a vector of uncertain physical parameters p according to given relationships. The regularity problem addressed in this paper can be summarized as follows. Suppose that the designer has chosen a certain controller, i.e., a vector of controller coefficients λ^*, such that it guarantees a prescribed stability margin ensuring robust stability of the closed-loop system for a given uncertainty set in plant parameter space. Suppose that the controller parameters are slightly perturbed with respect to their nominal design value $\lambda = \lambda^*$. Can we predict whether the controller goes on doing its job, i.e., robustly stabilizes the system? Engineering intuition suggests that a negative answer to this question would be considered an indicator of a poor control design. In this perspective, the regularity assessment of a robust control problem with respect to input data, i.e., controller coefficients or parameters, becomes a mandatory requirement to perform a robust control design. Obviously, it would be particularly interesting to characterize real uncertainty structures for which the stability margin is continuous in the controller parameter space. Recently, results related to this problem have appeared in the literature. The possibility of existence of discontinuities of the stability margin on input data was pointed out in [1], where some examples are reported but no analysis is attempted. An analytical characterization of the behavior of the stability margin with respect to changes in system data has been given in [8] by employing the concept of strongly destabilizing perturbation. This property is strictly connected to the separating property used in the present

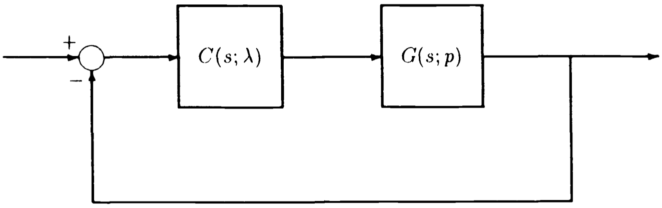

FIG. 1. *Linear feedback system.*

paper and in the preliminary conference paper [18]. Although the analysis in [8] covers general classes of perturbations, the results are not constructive, or at least how to build a technique for verifying the existence of a strongly destabilizing perturbation is not clear.

This paper represents a complete and detailed development of the theory originally presented in [18]. In particular, we exploit a geometric view of the obtained analytical results in the plant parameter space, allowing us to build an analysis technique for understanding how and why certain model parameterizations generate ill-conditioned problems, also suggesting ideas on changes to be made to regularize the problem. A distinguishing feature of this paper is that the different sufficient or necessary and sufficient conditions can be fruitfully applied to characterize completely the stability margin problem for several classes of real perturbations of continuous and discrete time systems widely investigated in the literature, such as interval feedback systems.

The uncertainty structure addressed in the present paper covers the case when plant transfer function coefficients depend affinely on the parameter vector p. Actually, this hypothesis, which may appear excessively restrictive at first glance, covers the vast majority of literature on parametric robust control. Even in this relatively simple situation, an analytic solution of the resulting stability margin nonlinear optimization problem is not available (see [3], [7], [11], [15], [16], and [17].

The regularity problem could be attacked by using general results on sensitivity analysis of nonlinear programming problems (see, e.g., [5]). Nevertheless, since the stability margin represents the minimum distance of the origin from the stability boundary manifold in parameter space, the analysis can be made considerably sharper. In fact, information on the behavior of the optimization problem can be obtained by studying the continuity of stability boundaries on problem data. Using this approach, we are able to prove a number of sufficient as well as necessary and sufficient conditions for the stability margin to be continuous on the problem data. The problem is strictly related to regularity and bifurcations of the boundary of stability in parameter space, an issue whose importance has long been recognized (see [13, pp. 404–406]). Actually, it happens that possible discontinuities of the problem solution with respect to data perturbations are strictly related to the presence of certain special points (called critical points) in the stability boundary manifold and to their behavior for small data perturbations. The basic results obtained show that under mild assumptions on the controller structure, the stability margin in the plant coefficient space is continuous on the controller parameters. One important implication of this result is that the robust stability problem for the class of interval feedback systems widely investigated in the recent literature on robust control is regular with respect to perturbations of the controller coefficients.

This paper is structured as follows. Section 2 introduces the stability margin problem and gives conditions for regularity of the boundary manifold. In §3 the main sufficient or necessary and sufficient conditions for continuity of the stability margin on problem data are given. In §4 it is shown how the results of §3 can be exploited to prove regularity of robustness problems for interval feedback systems. Section 5 reports some examples both taken from the literature and newly devised showing structural features of critical manifolds of the stability boundary in parameter space.

2. Stability margin and critical manifolds in parameter space.

2.1. The stability margin problem. Consider an nth-order polynomial whose coefficients depend on a perturbation parameter vector $p = (p_1, \dots, p_q)^T \in R^q$

$$\Delta(s;p) = s^n + c_{n-1}(p)s^{n-1} + \cdots + c_1(p)s + c_0(p) \tag{1}$$

(^{T} stands for transpose).

For notational simplicity, we will often identify p with the corresponding polynomial $\Delta(s;p)$. To avoid trivial degeneracies which are not of interest for our purposes, it is assumed that $n,\ q > 1$. We consider the case when polynomial coefficients are affine in the parameter p:

$$c(p) = T(p + p^o) + t \tag{2}$$

where $c(p) = [c_0(p), \dots, c_{n-1}(p)]^t \in R^n$ is the coefficient vector, T is a given (n, q) matrix, t is a given n-dimensional vector, and p^o is a given "nominal" parameter vector. We assume that the nominal polynomial $\Delta(s; 0)$ corresponding to the parameter p^o is Hurwitz (or stable); i.e., all its zeros have negative real part.

The (real) stability margin relative to the nominal parameter p^o is defined as the radius ρ of the maximal ball centered at p^o, such that all its interior points generate Hurwitz polynomials. If p^o is chosen as the origin of the parameter space, where parameter deviations p represent the coordinates, and the real and imaginary parts of $\Delta(j\omega; p)$ are denoted by $R(p;\omega)$ and $I(p;\omega)$, this problem can be formalized as a minimal-distance problem from the origin to the boundary manifold defined parametrically by $R(p;\omega) = 0$ and $I(p;\omega) = 0$ for $\omega \geq 0$ (see, e.g., [2] and [15]):

$$\begin{gathered}\rho = \min\nolimits_{p,\omega} \|p\| \\ \text{subject to} \\ \begin{cases} R(p;\omega) = 0 \\ I(p;\omega) = 0 \\ \omega \geq 0, \end{cases}\end{gathered} \tag{3}$$

where $R(p;\omega) = 0$ and $I(p;\omega) = 0$ are two equations affine in p whose coefficients are polynomials in ω,

$$R(p;\omega) = \sum_{i=1}^{q} a_i(\omega)p_i + a_0(\omega) = 0, \tag{4}$$

$$I(p;\omega) = \sum_{i=1}^{q} b_i(\omega)p_i + b_0(\omega) = 0. \tag{5}$$

Any point $(p^T, \omega) \doteq (p_1, \dots, p_q, \omega) \in R^{q+1}$ solving (3) will be called a *solution point* of the stability margin problem. By introducing a $(2, q+1)$ matrix $D(\omega)$, the boundary manifold equations can be written as

$$D(\omega)\pi = 0, \tag{6}$$

where

$$D(\omega) = \begin{bmatrix} a_0(\omega) & a_1(\omega) & \cdots & a_q(\omega) \\ b_0(\omega) & b_1(\omega) & \cdots & b_q(\omega) \end{bmatrix}, \qquad \pi = [1, p_1, \dots, p_q]^t. \tag{7}$$

We denote by $D_{ij}(\omega)$, $i = 0, \dots, q$, $i \neq j$ $(2,2)$ submatrices of the coefficient matrix $D(\omega)$

$$D_{ij}(\omega) = \begin{bmatrix} a_i(\omega) & a_j(\omega) \\ b_i(\omega) & b_j(\omega) \end{bmatrix} \tag{8}$$

and by $D_{0\omega}(p;\omega)$ the matrix

$$D_{0\omega}(p;\omega) = \begin{bmatrix} a_0(\omega) & \partial R(p;\omega)/\partial\omega \\ b_0(\omega) & \partial I(p;\omega)/\partial\omega \end{bmatrix}. \tag{9}$$

Note that since $a_0(\omega)$ and $b_0(\omega)$ are real and imaginary parts of the Hurwitz nominal polynomial $\Delta(s;0)$, there exist no ω such that $a_0(\omega) = b_0(\omega) = 0$, and hence the first column in D_{0j} and $D_{0\omega}$ cannot vanish.

With reference to the stability margin problem (3), we will consider entries of T, t, and p^o as the problem data. Obviously, these data may represent perturbations of the plant parameters p as well as perturbations induced by variations of the vector of controller coefficients λ. In the forthcoming subsection, we introduce the concept of the critical point of a manifold which plays a key role in assessing continuity of ρ as a function of the data.

2.2. Critical manifolds in parameter space. Let us introduce the manifold Γ_b^Ω in R^{q+1}

$$\Gamma_b^\Omega = \Gamma_o^\Omega \cup \Gamma^\Omega, \tag{10}$$

where

$$\Gamma_o^\Omega \doteq \{(p^T, \omega) \in R^{q+1} : R(p;\omega) = 0,\ \omega = 0\}, \tag{11}$$

$$\Gamma^\Omega \doteq \{(p^T, \omega) \in R^{q+1} : R(p;\omega) = 0,\ I(p;\omega) = 0,\ \omega > 0\}. \tag{12}$$

Γ_b^Ω will be referred to as the (stability) boundary manifold in R^{q+1}. The boundary manifold Γ_b in parameter space R^q, whose distance from the origin represents the stability margin, is strictly related to Γ_b^Ω. It is defined as

$$\Gamma_b = \Gamma_o \cup \Gamma, \tag{13}$$

where

$$\Gamma_o \doteq \{p \in R^q : c_0(p) = 0\}, \tag{14}$$

$$\Gamma \doteq \{p \in R^q : \exists\, \omega > 0 \text{ s.t. } (p^T, \omega) \in \Gamma^\Omega\}. \tag{15}$$

We notice that Γ (Γ_o) can be obtained as the image of Γ^Ω (Γ_o^Ω) under the identity rectangular operator $\mathcal{I} : R^{q+1} \to R^q$.

The study of sensitivity of ρ on problem data leads naturally to the investigation of the dependence of the manifolds Γ_o and Γ on the data; i.e., information about continuity of the distance ρ on problem data is strictly related to conditions under which these manifolds change smoothly with problem data. Since critical points of a manifold may undergo abrupt changes for arbitrarily small data perturbations, their study is an important issue for our problem.

Consider a manifold defined by the equation $f(x) = 0$, $x \in R^l$, $f : R^l \to R^m$, with $m \leq l$. Let ∇f_x be the Jacobian of the function $z = f(x)$.

$$\nabla f_x = \begin{bmatrix} \partial f_1/\partial x_1 & \cdots & \partial f_1/\partial x_l \\ \cdots & \cdots & \cdots \\ \partial f_m/\partial x_1 & \cdots & \partial f_m/\partial x_l \end{bmatrix}. \tag{16}$$

A point x^* of the manifold is said to be critical (or singular) if all the minors of order m of ∇f_x are null at that point. Points of a manifold which are not critical are called regular. A manifold whose points are all regular is called regular.

We study the regularity of Γ_b^Ω. However, since Γ_b is the representation of Γ_b^Ω as a parametric manifold in R^q, we observe that any regular (critical) point of Γ_b corresponds to a regular (critical) point of Γ_b^Ω.

A simple application of the above definitions to the maps defining manifolds Γ_o^Ω and Γ^Ω, given by (11) and (12), respectively, allows one to reach the following conclusions.

- Γ_o^Ω is regular (excluding the meaningless case $c_0(p) = 0$, $\forall p \in R^q$).
- Γ^Ω has singular points only if $\exists\,\omega^* > 0$ satisfying simultaneously the following algebraic equations.

$$|D_{0j}(\omega^*)| = 0, \qquad j = 1, \ldots, q, \tag{17}$$

where $|\cdot|$ denotes determinant. Notice that condition (17) implies that $R(p;\omega^*) = 0$ and $I(p;\omega^*) = 0$ represent the same $q-1$ dimensional hyperplane in parameter space. If (17) is solved for some strictly positive ω^*, according to the above definition, a critical point of Γ^Ω must satisfy the linear equation in p

$$|D_{0\omega}(p;\omega^*)| = 0. \tag{18}$$

Denoting by ω^* any real strictly positive solution of (17), critical points of Γ^Ω are the solutions of the system of two linear equations in p,

$$(p^T, \omega^*) \in R^{q+1} : \begin{cases} \sum_{i=1}^{q} a_i(\omega^*)p_i + a_0(\omega^*) = 0 \\ \sum_{i=1}^{q} \tilde{a}_i(\omega^*)p_i + \tilde{a}_0(\omega^*) = 0, \end{cases} \tag{19}$$

where the second equation represents (18) and

$$\tilde{a}_i(\omega) = a_0(\omega)b_i'(\omega) - b_0(\omega)a_i'(\omega), \qquad i = 0, 1, \ldots, q, \tag{20}$$

with $'$ denoting differentiation.

Assuming that $a_0(\omega^*) \neq 0$ in (19), we can characterize the set of critical points of Γ^Ω corresponding to each ω^* in terms of minors of order 2 of the coefficient matrix of the linear system (19). (If $a_0(\omega^*) = 0$, the first equation of (19) should be replaced by the second equation $I(p;\omega) = 0$ of (6).) Solutions of (19) in parameter space can be characterized according to three different cases.

Case 1.

$$\operatorname{rank} \begin{bmatrix} a_0(\omega^*) & a_j(\omega^*) \\ \tilde{a}_0(\omega^*) & \tilde{a}_j(\omega^*) \end{bmatrix} < 2, \qquad j = 1, \ldots, q. \tag{21}$$

In this case, corresponding to ω^*, a $q-1$ dimensional linear manifold of critical points is detected. Notice that condition (21) is equivalent to imposing that

$$|D_{0j}(\omega^*)|' = 0, \qquad j = 1, \ldots, q, \tag{22}$$

where $|D_{ij}(\omega^*)|'$ stands for $\left[\frac{d}{d\omega}|D_{ij}(\omega)|\right]_{\omega=\omega^*}$.

Case 2.

$$|D_{ij}(\omega^*)|' \neq 0 \quad \text{for some } i, j \neq 0,\ i \neq j. \tag{23}$$

In this case, it is concluded that system (19) determines a linear variety contained in Γ^Ω of dimension $q-2$.

Case 3.

$$|D_{ij}(\omega^*)|' = 0 \quad \forall i,j : i,j \neq 0,\, i \neq j \qquad \text{and} \tag{24}$$
$$|D_{0i}(\omega^*)|' \neq 0 \quad \text{for some } i \neq 0.$$

In this case, it can be easily verified that system (19) has no real solutions and hence Γ^Ω is a regular manifold.

Let us now introduce the sets of critical frequencies corresponding to the first and second cases examined above and the overall critical set Ω_c:

$$\Omega_{c_1} = \{\omega \in R^+ : |D_{0j}(\omega)| = 0, \text{ and } |D_{0j}(\omega)|' = 0,\ j = 1, \dots, q\}. \tag{25}$$

(26)
$$\Omega_{c_2} = \{\omega \in R^+ : |D_{0j}(\omega)| = 0,\ j = 1, \dots, q, \text{ and } |D_{ij}(\omega)|' \neq 0 \text{ for some } i,j \neq 0, i \neq j\},$$

$$\Omega_c = \Omega_{c_1} \cup \Omega_{c_2}. \tag{27}$$

We observe that Ω_{c_1}, Ω_{c_2}, and Ω_c have a finite number of elements. Denote by C_1 and C_2 conditions (25) and (26) defining the sets Ω_{c_1} and Ω_{c_2}, respectively, and by S_{c_1} and S_{c_2} the corresponding sets of critical points of Γ^Ω:

$$S_{c_{1(2)}} \doteq \{(p^T, \omega) \in \Gamma^\Omega \text{ s.t. } \omega \in \Omega_{c_{1(2)}}\}. \tag{28}$$

We say that a critical point of Γ^Ω is of type C_1 (C_2) if it belongs to S_{c_1} (S_{c_2}). The next lemma synthesizes the conclusions reached in the preceding discussion.

LEMMA 1. *Assume that the origin of parameter space is Hurwitz. The stability boundary manifold* Γ^Ω *is regular if and only if the set* Ω_c *is empty.*

Note that from a practical point of view, the determination of critical manifolds of Γ^Ω, if any, asks for the solution of an algebraic equation in ω. More precisely, one of the first q determinant equations of conditions C_1 or C_2 must be solved, checking successively if any of its strictly positive roots satisfies the remaining polynomial constraints of (25) or (26).

3. Regularity conditions for robust stability problems. To study regularity of the boundary manifold with respect to problem data, we introduce two vectors, x and y. The first vector contains problem variables, i.e., $x = (p_1, \dots, p_q, \omega)^T$, while the second vector $y \in R^u$ includes problem data consisting of the entries of matrix T, vector t, and nominal parameter p^o. We will be concerned only with the manifold Γ^Ω defined in (12). In fact, all solutions of the linear equation $R(p; 0) = 0$, i.e., points of the $q-1$ dimensional hyperplane Γ_o^Ω, are continuous on the problem data. Thus, in this section, with a certain abuse of notation, we will occasionally identify Γ_b^Ω with Γ^Ω. Moreover, we will refer to Γ or Γ^Ω according to the space (the parameter space R^q or the augmented space R^{q+1}) in which the boundary manifold is embedded. By taking into consideration the dependence on data y, the boundary manifold $\Gamma^\Omega(y)$ can be defined as follows:

$$\Gamma^\Omega(y) = \{x \in R^{q+1} : G(x; y) = 0,\ x_{q+1} > 0\}, \tag{29}$$

where the two components G_1 and G_2 of G are the real and imaginary parts of $\Delta(j\omega; p)$. We denote by $\rho(y)$ the stability margin as a function of input data y and assume that $G_1(x; y)$ and

$G_2(x;y)$ are continuous functions of the data y. We refer to $y=0$ as the nominal problem data, which means that our vector y is to be interpreted as a vector of data perturbations with respect to a fixed vector of data.

We say that the manifold $\Gamma^{\Omega}(y)$ is continuous at $y=0$ if for any point $x^* \in \Gamma^{\Omega}(y)$, there exist two variables x_i, x_j, defined implicitly by the two equations $G_1(x;y)=0$ and $G_2(x;y)=0$, which are continuous at $(x;y)=(x^*;0)$. We observe that, according to the previous definition, continuity of $\Gamma^{\Omega}(y)$ on y implies that a sufficiently small perturbation on the data y induces a small perturbation of points of the manifold $\Gamma^{\Omega}(y)$. We look for conditions under which the boundary manifold $\Gamma^{\Omega}(y)$ is continuous at $y=0$.

Let v_o be a vector in a given space R^l. We denote by $U_\varepsilon(v_o)$ a neighborhood of v_o of radius $\varepsilon>0$, i.e., $U_\varepsilon(v_o)=\{v \in R^l : \|v-v_o\| \leq \varepsilon\}$. Let $\nabla G_x(x;y)$ denote the Jacobian of the function G with respect to the variable x, and let $U_\varepsilon(0)$ be a neighborhood of the origin. Since the functions $G(x;y)$ and $\nabla G_x(x;y)$ are continuous in R^{q+u+1}, application of the implicit function theorem allows us to derive the following lemma.

LEMMA 2. *If $\nabla G_x(x;0)$ has row rank 2 for any $x \in \Gamma^{\Omega}(0)$, then $\Gamma^{\Omega}(y)$ is continuous at $y=0$.*

Proof. The proof is given in the appendix.

Remark 1. Note that continuity of $\Gamma_b^{\Omega}(y)$ at $y=0$ implies continuity of the boundary manifold in parameter space $\Gamma_b(y)$ at the same point. Since the stability margin $\rho(y)$ is the distance, according to some given norm, of the origin from $\Gamma_b(y)$ in parameter space, i.e., the minimum of the optimization problem (3), continuity of the manifold $\Gamma_b(y)$ implies continuity of $\rho(y)$ at $y=0$ whatever norm is used in (3).

From the above lemma and remark, we obtain the following theorem.

THEOREM 1. *The stability margin is continuous on input data at $y=0$ if Γ^{Ω} is a regular manifold.*

Remark 2. It is well known that the collection of critical values of a manifold mapped by a smooth map is a set of measure zero in the image space. This result is known as the Sard–Brown theorem (see, e.g., [9, pp. 10–11]). In our case, since we assume that $q>1$, the critical points in the boundary manifold Γ_b^{Ω} form a thin set in R^{q+1}. In particular, conditions C_1 and C_2 state that a necessary condition for the existence of critical points is that q algebraic equations in the unique unknown ω admit a common strictly positive solution. This implies that an arbitrarily small data perturbation (i.e., a perturbation of the coefficients of the q equations) generically destroys singularities. This does not mean that in general one cannot design a small perturbation affecting continuously critical points; rather, the set of perturbations destroying singularities is dense in the space of data.

The following theorem gives sufficient conditions for continuity of $\rho(y)$ improving those of Theorem 1.

THEOREM 2. *The stability margin $\rho(y)$ is continuous on the problem data at $y=0$ if at least one of the solution points of the stability margin problem for $y=0$ is either a regular point of the boundary manifold or a critical point of type C_2.*

Proof. The proof is given in the appendix.

Theorem 2 allows us to derive the following result on families of third-order polynomials.

COROLLARY 1. *Given a family of third-order polynomials defined by a matrix T of full column (or row) rank, the stability margin $\rho(y)$ is continuous on the data y.*

Proof. The proof is given in the appendix.

Before giving a theorem stating necessary and sufficient conditions for continuity of the stability margin on the problem data, we need a definition which recalls the concept of strongly destabilizing perturbation given in [8]. For the sake of clarity, in the rest of this section we will call a parameter p strictly unstable if at least one of the roots of the corresponding polynomial has strictly positive real part. Consider a solution point $x^* = (p^{*T}, \omega^*)$ of the stability margin problem.

DEFINITION. *A solution point $x^* = (p^{*T}, \omega^*)$ of the stability margin problem is called a separating point if any neighborhood $U_\varepsilon(p^*)$ contains both stable and strictly unstable points.*

The following lemma establishes a relationship between regularity and separating properties of solution points of the stability margin problem.

LEMMA 3. *A regular solution point of the stability margin problem is a separating point.*

Proof. The proof is given in the appendix.

We can now provide the following theorem.

THEOREM 3. *A necessary and sufficient condition for continuity of the stability margin at $y = 0$ is that the stability margin problem admit at least one separating solution point.*

Proof.

Necessity. Assume that $\rho(y)$ is continuous at $y = 0$. If there exists at least one regular solution point, then necessity follows immediately from Lemma 3. If the stability margin problem admits critical solution points only, necessity can be proven by contradiction. Consider an arbitrary solution point (p^{*T}, ω^*) and suppose that the critical manifold corresponding to $\omega = \omega^*$ does not separate stable from strictly unstable points in $U_\varepsilon(p^*)$. We show that there exists an arbitrarily small data perturbation which induces a noninfinitesimal perturbation of the stability margin. Consider the data perturbation generated by an arbitrarily small horizontal shift of the imaginary axis into the right half plane of the complex plane. This means to perform the change of variable $s \rightarrow \tilde{s} = s - \eta$, with $\eta > 0$ and arbitrarily small. For a given η, it is not difficult to realize that this perturbation can be generated as a sufficiently small polynomial coefficient perturbation. In this new situation, p^* becomes a stable parameter. In addition, this perturbation destroys the entire critical manifold. Thus, since points which are stable for $\eta = 0$ remain stable under the perturbation, $U_\varepsilon(p^*)$ contains only stable points. If several parameters p^* exist such that (p^{*T}, ω^*) is a solution point, the above argument holds for each of them. Hence, there exists $\eta > 0$ such that neighborhoods $U_\varepsilon(p^*)$ for all p^* contain only stable points. This means that all the solution points of the perturbed stability margin problem in parameter space must necessarily differ from the corresponding points for $\eta = 0$ for a noninfinitesimal quantity. This implies discontinuity of the stability margin.

Sufficiency. Let (p^{*T}, ω^*) be a separating solution point of the stability margin problem. For an arbitrarily small $\varepsilon > 0$, the separating property of (p^{*T}, ω^*) ensures that there exists a strictly unstable parameter $\hat{p} \in U_\varepsilon(p^*)$. Since the coefficients of the polynomial are continuous in the problem data and the roots of a polynomial are continuous in its coefficients, it follows that for any sufficiently small data perturbation, $\hat{p}$ remains strictly unstable. Thus, sufficiently small data perturbations preserve strictly unstable points $\hat{p}$ arbitrarily close to p^* and this proves that the stability margin $\rho(y)$ is continuous at $y = 0$.

Remark 3. Theorem 3 is somewhat similar to a result given in [8, p. 403]. Actually, since both results provide necessary and sufficient conditions for the same problem, they must be necessarily equivalent. However, it turns out that, as explained below, the separability concept used in Theorem 3 allows a direct characterization of continuity of the stability margin problem in terms of easily checkable conditions.

First, we notice that, if the stability margin problem admits at least one regular solution point or one critical solution point of type C_2, then Theorem 2 ensures continuity, without explicitly requiring the separating property. In the remaining cases, the condition of Theorem 3 requires that at least one of the $q - 1$ dimensional critical manifolds containing solution point(s) (p^{*T}, ω^*) of the stability margin problem (3) separates stable from strictly unstable points in a neighborhood of at least one point p^*. Since critical manifolds are hyperplanes in parameter space, verification of the separability property asked by Theorem 3 turns out to be easily tested in practice.

As a further observation, we notice that all the obtained conditions are easily checkable, and their verification provides information, if necessary, on how far the boundary manifold is from the case in which it has singularities. For example, the fact that there exist values of ω for which $|D_{0j}(\omega)| \approx 0$, $|D_{0j}(\omega)|' \approx 0$, $j = 1, \ldots, q$ in condition C_1 of (25) can be interpreted as an indicator that the problem may become critical to data perturbation.

Before concluding this section, we briefly summarize how the results obtained can be used to assess the regularity of the stability margin problem for a given family of perturbed polynomials. It is well known that many techniques for computing ρ, i.e., solving (3), are based on a one-dimensional search along the frequency positive axis (see, e.g., [2], [15], and [16]). We know that the domain of search $\Omega^+ \doteq [0, \infty)$ can be partitioned into three disjoint subsets, Ω_r, Ω_{c1}, and Ω_{c2}, such that

$$\Omega^+ = \Omega_r \cup \Omega_{c1} \cup \Omega_{c2}, \tag{30}$$

where Ω_r is the set of frequencies corresponding to regular points of Γ^Ω, while Ω_{c1} and Ω_{c2} are defined as in (25) and (26). Denote by ρ_r, ρ_{c1}, and ρ_{c2} the stability margins relative to the three sets of frequencies Ω_r, Ω_{c1}, and Ω_{c2}, i.e., solutions of problems like (3) with $\omega \in \Omega_r$, $\omega \in \Omega_{c1}$, and $\omega \in \Omega_{c2}$, respectively. It is clear that $\rho = \min\{\rho_r, \rho_{c1}, \rho_{c2}\}$. By applying Theorems 1 and 2, the following condition ensuring continuity of the stability margin on problem data is obtained:

$$\rho = \min\{\rho_r, \rho_{c2}\} \leq \rho_{c1}. \tag{31}$$

On the other hand, if

$$\rho = \rho_{c1} < \min\{\rho_r, \rho_{c2}\}, \tag{32}$$

Theorem 3 requires testing if certain $q - 1$ dimensional critical hyperplanes in parameter space separate stable from strictly unstable points around the corresponding solution point(s) of the stability margin problem relative to Ω_{c1} (see Remark 3).

4. Regularity conditions for the robust stability problem in plant coefficient space. In this section, we show how the results obtained in the previous sections can be exploited whenever the changes in system data are due to controller coefficient variations. In particular, we will study regularity of the robust stability problem in plant coefficient space. The case when plant coefficients are linear affine in the uncertain parameters falls in the general problem setting developed in the previous sections, because in this case, for any fixed controller, the closed-loop characteristic polynomial coefficients are affine linear in the parameters.

With reference to Fig. 1, we assume that $G(s;p)$ is a strictly proper plant and $C(s;\lambda)$ is a rational controller of given order

$$G(s;p) = \frac{N(s;p)}{D(s;p)} = \frac{\sum_{i=0}^{m}(p_{n+i+1} + p_{n+i+1}^o)s^i}{s^n + \sum_{i=1}^{n}(p_i + p_i^o)s^{i-1}}, \qquad m < n, \tag{33}$$

$$C(s;\lambda) = \frac{N^c(s;\lambda)}{D^c(s;\lambda)} = \frac{\sum_{i=0}^{l}\lambda_{r+i+1}s^i}{\sum_{i=0}^{r}\lambda_i s^i}, \qquad l \leq r, \tag{34}$$

where the parameters p coincide with the plant transfer function coefficients and $\lambda = (\lambda_0, \dots, \lambda_r, \lambda_{r+1}, \dots, \lambda_{r+l+1})^T$ is the controller coefficient vector. The closed-loop characteristic polynomial is

$$\Delta(s;p;\lambda) \doteq D^c(s;\lambda)D(s;p) + N^c(s;\lambda)N(s;p), \tag{35}$$

where, with a slight modification of notation with respect to (1), the arguments of Δ include the controller coefficient λ. This implies that T, t, and p^o are now suitable functions of λ. The nominal closed-loop characteristic polynomial and the controller numerator and denominator polynomials can be written as the sum of even and odd parts (subscripts e and o, respectively):

$$\begin{aligned} \Delta(s;0;\lambda) &\doteq \Delta_e(s^2;\lambda) + s\Delta_o(s^2;\lambda), \\ N^c(s;\lambda) &\doteq N_e^c(s^2;\lambda) + sN_o^c(s^2;\lambda), \\ D^c(s;\lambda) &\doteq D_e^c(s^2;\lambda) + sD_o^c(s^2;\lambda). \end{aligned} \tag{36}$$

According to these definitions, the coefficient matrix $D(\omega;\lambda)$ becomes

(37)

$$D(\omega;\lambda) = \begin{bmatrix} \Delta_e(\omega^2;\lambda) & D_e^c(\omega^2;\lambda) & -\omega^2 D_o^c(\omega^2;\lambda) & \dots & N_e^c(\omega^2;\lambda) & -\omega^2 N_o^c(\omega^2;\lambda) & \dots \\ \omega\Delta_o(\omega^2;\lambda) & \omega D_o^c(\omega^2;\lambda) & \omega D_e^c(\omega^2;\lambda) & \dots & \omega N_o^c(\omega^2;\lambda) & \omega N_e^c(\omega^2;\lambda) & \dots \end{bmatrix}.$$

Consider now the nominal characteristic polynomial $\Delta(s;0;\lambda)$ and define the stability domain Λ in controller coefficient space as the set of coefficients λ stabilizing the nominal plant, i.e.,

$$\Lambda \doteq \{\lambda \in R^{r+l+2} : \Delta(s;0;\lambda) \text{ is Hurwitz}\}. \tag{38}$$

Assuming that the set Λ is nonempty, we can give the following theorem on regularity of the stability margin $\rho = \rho(\lambda)$ in plant coefficient space.

THEOREM 4. 1) *If $m = 0$, i.e., the plant family is an all pole family, $\rho(\lambda)$ is continuous $\forall\lambda \in \Lambda$ such that $C(s;\lambda)$ does not have multiple purely imaginary poles.*

2) *If $m \geq 1$, $\rho(\lambda)$ is continuous $\forall\, \lambda \in \Lambda$.*

Proof. The proof is given in the appendix.

Observation. The above theorem holds independently of the norm used in coefficient space. In particular, when an l_∞ norm is taken into account, Theorem 4 ensures regularity of the stability margin problem for the well-known and widely investigated class of interval feedback systems.

5. Numerical examples. In this section we present three numerical examples. The first example is taken from [1]. In this case, lack of regularity is detected analytically by applying Theorem 3. A data perturbation producing a discontinuity in the stability margin is generated according to the technique used to prove necessity of Theorem 3. The second example is new. A fourth-order polynomial with two uncertain parameters is considered. A straight line of critical points is detected, showing that is is possible to generate a discontinuity of the stability margin ρ with respect to problem data. The third example reports the study of the behavior of the stability margin of a feedback system with an interval plant and a controller as a function of one coefficient of the controller. Of course, in this case, as predicted by Theorem 4, it is found that ρ is continuous as a function of the considered coefficient. In the second and third examples, perturbations on T, t, and p^o will be denoted by δT, δt, and δp^o, respectively, and will be assumed to enter additively in T, t, and p^o.

Example 1 [1]. Consider the polynomial

$$\begin{aligned} \Delta(s;p) = s^4 &+ 20(1-p_2)s^3 + (44 + 2a + 10p_1 - 40p_2)s^2 \\ &+ (20 + 8a + 20ap_1 - 20p_2)s + 5a^2(1+2p_1), \end{aligned} \tag{39}$$

where $a = 3 + \sqrt{2}$. The data are given by

(40)
$$T = \begin{bmatrix} 10a^2 & 20a & 10 & 0 \\ 0 & -20 & -40 & -20 \end{bmatrix}^T; \ t = [5a^2 \quad 20+8a \quad 2a+44 \quad 20]^T; \ p^o = [0 \quad 0]^T.$$

The boundary manifold Γ_b is made of points solving the following equation system with $\omega \geq 0$:

$$(41) \qquad \begin{cases} R(p;\omega) = 10(a^2 - \omega^2)p_1 + 40\omega^2 p_2 + 5a^2 - \omega^2(44+2a) + \omega^4 = 0, \\ I(p;\omega) = \omega[20ap_1 + 10(\omega^2 - 2)p_2 + 20 + 8a - 20\omega^2] = 0. \end{cases}$$

The manifolds Γ_o and Γ have the following expressions:

$$(42) \qquad \Gamma_o = \{p : p_1 + 0.5 = 0\},$$

$$(43) \qquad \Gamma = \{p : 5(a-1)p_1 + 20p_2 - 2(11-a) = 0\} \cup \{p : p_2 + a/10 - 1 = 0\}.$$

The stability domain is represented by the dashed area in Fig. 2(a). To investigate the existence of critical points we consider the following determinants:

$$(44) \qquad \begin{cases} |D_{o1}(\omega)| = 20\omega[(a-10)\omega^4 + 2(4a^2 - 20a + 5)\omega^2 + a^2(a-10)], \\ |D_{o2}(\omega)| = 20\omega[\omega^6 - (2a+5)\omega^4 + (4 - 14a + 5a^2)\omega^2 - 5a^2]. \end{cases}$$

Easy computations show that the equations $|D_{o1}(\omega)| = 0$, $|D_{o2}(\omega)| = 0$ admit a common positive root (of multiplicity 2) at $\omega^* = \sqrt{a}$. Since this root is multiple, it also solves the second equation of (25) and hence it satisfies condition C_1. The straight line $5(a-1)p_1 + 20p_2 - 2(11-a) = 0$, a subset of Γ, is found to be a set of critical points. The solution of the distance problem (3) according to the l_∞ norm in parameter space is attained at the nonseparating point $p^* = [(7-a)/5, (7-a)/5]^T \approx [0.234, 0.234]^T$ of this critical line (see Fig. 2(a)). The corresponding stability margin is $\rho \approx 0.234$. Since p^* is nonseparating, we deduce by Theorem 3 that there exists an infinitesimal data perturbation such that the stability margin changes are of a finite quantity. Figure 2(b) reports the perturbed boundary manifolds (1) and (2) corresponding to perturbations given according to the technique used to prove necessity of Theorem 3, with $\eta = 0.001$ and $\eta = 0.01$, respectively. The obtained stability margins are $\rho \approx 0.422$ and $\rho \approx 0.456$, respectively. The corresponding maximal stability balls are also shown in Fig. 2(b).

Example 2. Consider the polynomial

$$(45) \quad \Delta(s;p) = s^4 + (p_2+3)s^3 + (p_1+5.5)s^2 + (p_1+p_2+4.5)s + 3p_1 - p_2 + 5.5$$

with T, t, and p^o given by

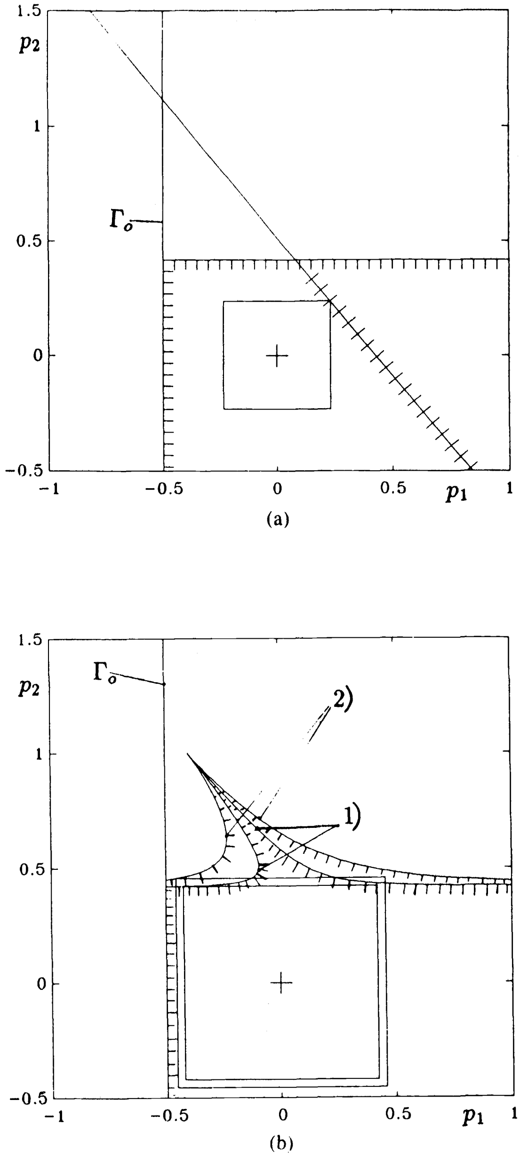
$$(46) \qquad T = \begin{bmatrix} 3 & 1 & 1 & 0 \\ -1 & 1 & 0 & 1 \end{bmatrix}^T; \quad t = [5.5 \quad 4.5 \quad 5.5 \quad 3]^T; \quad p^o = [0 \quad 0]^T$$

and data perturbation

$$(47) \qquad \delta T = \begin{bmatrix} 0 & r & 0 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix}^T; \quad \delta t = [0 \quad 1.5r \quad 0 \quad 0]^T; \quad \delta p^o = [0 \quad 0]^T.$$

This problem is obtained from the study of robust stability of the feedback control system of Fig. 1 with a plant family given by

$$(48) \qquad G(s;p) = \frac{(p_1 + 1.5)}{s^4 + (3+p_2)s^3 + (5.5+p_1)s^2 + (3+p_2)s + 5.5 + 3p_1}$$



(a)

(b)

FIG. 2. (a) *Stability domain for nominal data of example* 1. (b) *Stability domains with data perturbations of example* 1.

and a proportional controller, whose unity gain represents the problem data subject to perturbation

$$C(s;\lambda) = 1 + \lambda, \tag{49}$$

where $\lambda = r$. The nominal manifolds Γ_o and Γ are given by

$$\Gamma_o = \{p : 3p_1 - p_2 + 5.5 = 0\}, \tag{50}$$

$$\Gamma = \{p : p_2 + 2 = 0\} \cup \{p : p_1 - p_2 - 1.5 = 0\}. \tag{51}$$

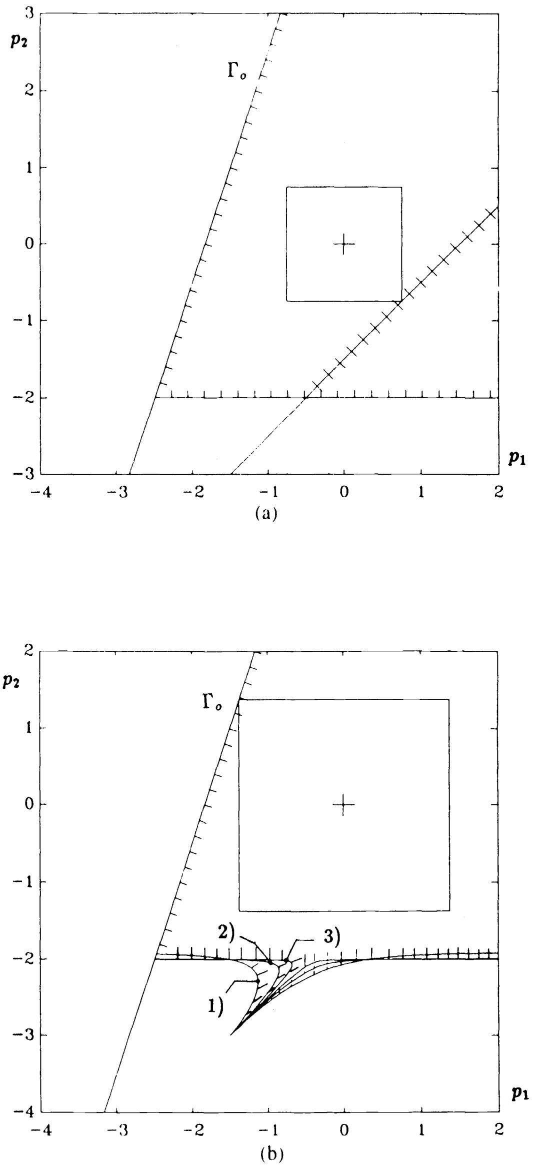


FIG. 3. (a) *Stability domain for nominal data of example* 2. (b) *Stability domains with data perturbations of example* 2.

The dashed area in Fig. 3(a) represents the stability domain in the parameter plane. Note that the straight line of equation $p_1 - p_2 - 1.5 = 0$ separates two subsets of the domain of stability.

The determinants $|D_{o1}|$ and $|D_{o2}|$ have the following expressions:

$$(52) \qquad \begin{cases} |D_{o1}(\omega)| = -2\omega(\omega^2 - 2)^2, \\ |D_{o2}(\omega)| = -\omega(\omega^2 - 2)^2(\omega^2 - 2.5). \end{cases}$$

It can be checked from (52) that $\omega^* = \sqrt{2}$ satisfies condition C_1; i.e., there exists a straight line of critical points described by the equation $p_1 - p_2 - 1.5 = 0$.

The solution of the distance problem (3) according to the l_∞ norm in parameter space is attained at the nonseparating point $p^* = (0.75, -0.75)^T$ of this critical line (see Fig. 3(a)). The corresponding stability margin is $\rho = 0.75$.

Since the point $p^* = (0.75, -0.75)^T$ is nonseparating, Theorem 3 ensures that a discontinuity in the stability margin can be generated by a suitable perturbation. Actually, it turns out that arbitrarily small values of r destroy the critical manifold, inducing a discontinuity in ρ as a function of r. Fig. 3(b) reports the perturbed boundary manifolds (1), (2), and (3) obtained for $r = 0.1, 0.01$, and 0.001, respectively, and the maximal stability ball corresponding to $\rho = 1.375$ obtained for the given data perturbations.

Example 3. Consider the feedback control system of Fig. 1, where $G(s;p)$ is an interval plant

$$G(s;p) = \frac{3+p_3}{s^2[s^2+(3+p_2)s+10+p_1]} \tag{53}$$

and the controller $C(s;\lambda)$ is given by

$$C(s;\lambda) = \frac{1+4s}{1+\lambda s}. \tag{54}$$

The closed-loop characteristic polynomial is

$$\Delta(s;p;\lambda) = \lambda s^5+[1+\lambda(3+p_2)]s^4+[3+p_2+\lambda(10+p_1)]s^3+(10+p_1)s^2+(4p_3+12)s+3+p_3. \tag{55}$$

One can compute that the stability domain in the controller parameter space is the segment $\Lambda \approx (0, 2.286)$. For any given $\lambda \in \Lambda$, the equations defining the boundary manifold Γ_b are $(\omega \geq 0)$

$$\begin{cases} R(p;\omega) = -\omega^2 p_1 + \lambda\omega^4 p_2 + p_3 + 3 - 10\omega^2 + \omega^4(1+3\lambda) = 0, \\ I(p;\omega) = \omega[-\lambda\omega^2 p_1 - \omega^2 p_2 + 4p_3 + 12 - (3+10\lambda)\omega^2 + \lambda\omega^4] = 0. \end{cases} \tag{56}$$

The determinants $|D_{o1}|$, $|D_{o2}|$, and $|D_{o3}|$ are given by

$$\begin{cases} |D_{o1}(\omega)| = -3\omega^3[\lambda^2\omega^4 + \omega^2 + \lambda - 4], \\ |D_{o2}(\omega)| = -\omega^3[\lambda^2\omega^6 + (1-10\lambda^2)\omega^4 + 2(6\lambda - 5)\omega^2 + 3], \\ |D_{o3}(\omega)| = \omega^3[(11\lambda + 4)\omega^2 + \lambda - 37]. \end{cases} \tag{57}$$

Since for any $\lambda \in \Lambda$, it can be readily verified that equations $|D_{o1}(\omega)| = 0$, $|D_{o2}(\omega)| = 0$, and $|D_{o3}(\omega)| = 0$ do not admit any positive common root, neither condition C_1 nor C_2 is satisfied so that $\Omega_c(\lambda) = \emptyset$, $\forall\, \lambda \in \Lambda$. Hence, as predicted by Theorem 4, the stability margin is continuous on λ.

6. Conclusions.

In this paper the problem of continuity of the stability margin on problem data has been addressed. The case in which the coefficients of the polynomials of an uncertain family are affine in a vector of physical parameters has been considered. It has been shown how the continuity problem is related to the presence of critical points in the manifold bounding the domain of stability in parameter space. Sufficient and necessary and sufficient conditions which are easily computable in practice have been given. By use of these conditions, it has been shown that the important and widely studied class of interval feedback systems enjoys the regularity property. Numerical examples have been illustrated to show applications of the conditions obtained.

Appendix.

Proof of Lemma 2. Suppose that for a given x^* such that $G(x^*;0) = 0$, $\nabla G_x(x^*;0)$ has row rank 2. By the implicit function theorem, there exist at least two variables, x_k and x_l, $k \neq l$, such that the equation defining $\Gamma^\Omega(y)$, i.e., $G(x;y) = 0$, is uniquely solvable with respect to x_k and x_l, for any $y \in U_\varepsilon(0)$, a sufficiently small neighborhood of $y = 0$, and any $x \in U_\eta(x^*)$, a sufficiently small neighborhood of x^*. This means that there exist functions $x_k = x_k(x_1, \ldots, x_{k-1}, x_{k+1}, \ldots, x_{l-1}, x_{l+1}, \ldots, x_{q+1}; y)$ and $x_l = x_l(x_1, \ldots, x_{k-1}, x_{k+1}, \ldots, x_{l-1}, x_{l+1}, \ldots, x_{q+1}; y)$, $\forall y \in U_\varepsilon(0)$ and $\forall x \in U_\eta(x^*)$. In addition, the same theorem ensures that these functions $x_k(\cdot;\cdot)$, $x_l(\cdot;\cdot)$ are continuous at $(x;y) = (x^*;0)$. Thus, the statement of the lemma follows immediately from the rank assumption on $\nabla G(x;0)$ in all the domain of definition of the function $z = G(x;0)$.

Proof of Theorem 2. Assume that for $y = 0$ there exists at least one regular point solving the minimal distance problem (3). Consider a sufficiently small neighborhood of the origin $U_\varepsilon(0)$ in the space of data. By the implicit function theorem (see also proof of Lemma 2), $\forall y \in U_\varepsilon(0)$ all regular points of $\Gamma^\Omega(y)$, and hence also the solution point(s) of the stability margin problem (3), are infinitesimally close to points of $\Gamma^\Omega(0)$, implying continuity of $\rho(y)$ at $y = 0$.

Suppose now that at least one solution point, say $\bar{x} = (\bar{p}^T, \bar{\omega})$, satisfies condition C_2 in (26). Of course, if a regular solution point also exists, the theorem follows from the preceding argument. In the other case, the critical set corresponding to $\omega = \bar{\omega}$ is a $q-2$ dimensional linear manifold in parameter space (see the second case in the discussion preceding Lemma 1). Since $\bar{x}$ is a solution of $G(x;0) = 0$, which is a system of equations linear in the parameter p and polynomial in ω, any neighborhood $U_\varepsilon(\bar{x})$ contains a $q-1$ dimensional set of solutions of $G(x;0) = 0$. This implies that even if the critical solution point $\bar{x}$ is destroyed by a small data perturbation, regular points of Γ^Ω in arbitrarily small neighborhoods of $\bar{x}$ ensure continuity of the distance of the origin of parameter space from Γ.

Proof of Corollary 1. Consider a third-order polynomial with q uncertain parameters. It is easy to check that a necessary condition for satisfying C_1 is that there exist values of ω such that

$$(58)\qquad \begin{cases} |D_{ij}(\omega)| = 0, \\ |D_{ij}(\omega)|' = 0, \qquad \forall i,j = 1, \ldots, q, \quad i \neq j. \end{cases}$$

Computation of determinants $|D_{ij}(\omega)|$ and their derivatives gives

$$(59)\qquad \begin{cases} |D_{ij}(\omega)| = \omega[(T_{1i}T_{2j} - T_{2i}T_{1j}) + (T_{2i}T_{3j} - T_{3i}T_{2j})\omega^2], \\ |D_{ij}(\omega)|' = (T_{1i}T_{2j} - T_{2i}T_{1j}) + 3(T_{2i}T_{3j} - T_{3i}T_{2j})\omega^2, \end{cases}$$

where T_{ij} is the generic entry of the matrix T. Therefore, solutions ω of (58) different from zero exist if and only if

$$(60)\qquad \begin{cases} T_{1i}T_{2j} - T_{2i}T_{1j} = 0, \\ T_{2i}T_{3j} - T_{3i}T_{2j} = 0 \quad \forall i,j = 1, \ldots, q, \quad i \neq j. \end{cases}$$

It can easily be checked that if there exists i such that $T_{2i} \neq 0$, then verification of (60) necessarily implies that matrix T has column (or row) rank equal to 1, which contradicts the assumption on T. On the other hand, consider any of the infinite solutions of (60) with $T_{2i} = 0$, $\forall i = 1, \ldots, q$. In this case, the manifold Γ^Ω is given by a unique $q-1$ dimensional hyperplane defined by $R(p;\bar{\omega}) = 0$, where $\bar{\omega}$ is the only strictly positive solution of $b_o(\omega) = 0$. This means that Γ^Ω is a regular manifold, excluding the existence of critical manifolds.

Since any other value of T_{ij} different from those satisfying (60) cannot verify condition C_1, it follows from Theorem 2 that the stability margin $\rho(y)$ is continuous in the problem data y.

Proof of Lemma 3. Assume that $x^* = (p^{*T}, \omega^*) \in \Gamma_b^\Omega$ is a regular solution point of the stability margin problem.

If $x^* \in \Gamma_o^\Omega$, the separating property follows from the fact that the hyperplane Γ_o separates points corresponding to polynomials such that $c_0(p) > 0$ and $c_o(p) < 0$ and the fact that any polynomial with a negative constant term is strictly unstable.

Suppose now that $x^* \in \Gamma^\Omega$. Consider the Hurwitz determinant of order $n-1$ of the polynomial $\Delta(s;p)$ and denote it by $H_{n-1}(p)$. Since $p^* \in \Gamma$ represents a polynomial which has at least one pure imaginary root and all the remaining ones in the left half-plane, we know by Orlando's formula [6] that $p^* \in \Gamma^H$, where

$$\Gamma^H = \{p \in R^q : H_{n-1}(p) = 0\}. \tag{61}$$

Moreover, continuity of roots of a polynomial on its coefficients implies that Γ coincides with Γ^H locally; that is,

$$\exists\, \varepsilon > 0 : \Gamma^H \cap U_\varepsilon(p^*) \equiv \Gamma \cap U_\varepsilon(p^*). \tag{62}$$

Thus, p^* is a regular point of Γ^H. As a consequence, Γ^H admits at $p = p^*$ a tangent hyperplane. In turn, this implies that any neighborhood $U_\varepsilon(p^*)$ of p^* contains points p where $H_{n-1}(p) > 0$ and points where $H_{n-1}(p) < 0$. Thus, $U_\varepsilon(p^*)$ contains both stable and strictly unstable points, implying that p^* is a separating point.

Proof of Theorem 4. i) Let us assume that $C(s;\lambda_o)$ does not have multiple imaginary roots and that $\lambda_o \in \Lambda$. First, we show by contradiction that the set $\Omega_c(\lambda_o)$ is empty. Suppose that $\Omega_c(\lambda_o)$ is nonempty, and take an element $\omega_o \in \Omega_c(\lambda_o)$. Since $\Delta(s;0;\lambda_o)$ is Hurwitz, the determinants $|D_{oi}(\omega_o, \lambda_o)|$ and $|D_{oi}(\omega_o, \lambda_o)|'$, $i = 1, 2$, obtained from (37) are null only if

$$\begin{aligned} D_e^{c^2}(\omega_o^2;\lambda_o) + \omega_o^2 D_o^{c^2}(\omega_o^2;\lambda_o) &= 0,\\ D_e^{c'^2}(\omega_o^2;\lambda_o) + \omega_o^2 D_o^{c'^2}(\omega_o^2;\lambda_o) &= 0. \end{aligned} \tag{63}$$

As a consequence, the denominator of $C(s;\lambda)$ can be factorized as

$$D^c(s;\lambda_o) = (s^2 + \omega_o^2)^2 \hat{D}_c(s;\lambda_o), \tag{64}$$

where $\hat{D}_c(s;\lambda)$ is a suitable polynomial. This contradicts the hypothesis that $C(s;\lambda_o)$ does not have multiple imaginary poles.

ii) First, we prove by contradiction that the set $\Omega_c(\lambda)$ is empty for $\lambda \in \Lambda$. Let us assume that $\lambda_o \in \Lambda$ and that there exists a positive value $\omega_o \in \Omega_c(\lambda_o)$. Since $m \geq 1$, we obtain from (37) and condition C_1 in (25)

$$\left\{ \begin{aligned} &\Delta_e(\omega_o^2;\lambda_o) D_o^c(\omega_o^2;\lambda_o) - \Delta_o(\omega_o^2;\lambda_o) D_e^c(\omega_o^2;\lambda_o) = 0,\\ &\Delta_e(\omega_o^2;\lambda_o) D_e^c(\omega_o^2;\lambda_o) + \omega_o^2 \Delta_o(\omega_o^2;\lambda_o) D_o^c(\omega_o^2;\lambda_o) = 0, \end{aligned} \right. \tag{65}$$

$$\left\{ \begin{aligned} &\Delta_e(\omega_o^2;\lambda_o) N_o^c(\omega_o^2;\lambda_o) - \Delta_o(\omega_o^2;\lambda_o) N_e^c(\omega_o^2;\lambda_o) = 0,\\ &\Delta_e(\omega_o^2;\lambda_o) N_e^c(\omega_o^2;\lambda_o) + \omega_o^2 \Delta_o(\omega_o^2;\lambda_o) N_o^c(\omega_o^2;\lambda_o) = 0. \end{aligned} \right. \tag{66}$$

Since $\Delta(s;0;\lambda_o)$ is Hurwitz, $\nexists\, \omega_o : \Delta_e(\omega_o^2;\lambda_o) = \Delta_o(\omega_o^2;\lambda_o) = 0$. Hence, the two equation systems (65) and (66) admit solutions only if

$$\begin{aligned} D_e^{c^2}(\omega_o^2;\lambda_o) + \omega_o^2 D_o^{c^2}(\omega_o^2;\lambda_o) &= 0,\\ N_e^{c^2}(\omega_o^2;\lambda_o) + \omega_o^2 N_o^{c^2}(\omega_o^2;\lambda_o) &= 0, \end{aligned} \tag{67}$$

which means that $N^c(j\omega_o;\lambda_o) = D^c(j\omega_o;\lambda_o) = 0$. This contradicts the hypothesis that $\Delta(s;0;\lambda_o)$ is Hurwitz. Thus, $\Omega_c(\lambda)$ is empty $\forall\,\lambda \in \Lambda$. The theorem statement follows from Theorem 1.

THE H_∞-PROBLEM FOR INFINITE-DIMENSIONAL SEMILINEAR SYSTEMS*

VIOREL BARBU†

Abstract. We study the H_∞-optimal control problem for semilinear systems in Hilbert spaces in connection with the corresponding H_∞-problem for the linearized system around an equilibrium state. The result of this paper, which expands some recent results of A. J. van der Schaft, is that if the linearized H_∞-problem has a suboptimal solution, then a suboptimal solution to the H_∞-problem for the semilinear system can be constructed in terms of a Hamilton–Jacobi equation.

Key words. Hamilton–Jacobi equation, Hamiltonian system, sup inf problem, exponentially stable semigroup

AMS subject classifications. 93B50, 93C35, 93C05

1. Introduction. Consider the input-output system

$$\begin{aligned} x' &= Ax + Fx + B_2u + B_1w, \quad t \geq 0; \quad x(0) = 0, \\ z &= C_1x + D_{12}u, \end{aligned} \tag{1.1}$$

in a real Hilbert space X. Here $x' = \frac{dx}{dt}$; A is the infinitesimal generator of a C_0-semigroup e^{At} on X; $F \in C^3(X)$; $F0 = 0$; $B_2 \in L(U, X)$; $B_1 \in L(W, X)$; $C_1 \in L(X, Z)$; $D_{12} \in L(U, Z)$; and U, W, and Z are real Hilbert spaces with the norms denoted $|\cdot|_U$, $|\cdot|_W$, and $|\cdot|_Z$, and scalar products $(\cdot,\cdot)_U$, $(\cdot,\cdot)_W$, and $(\cdot,\cdot)_Z$. The norm and the scalar product of X are denoted by $|\cdot|$ and $(\cdot,\cdot)$, respectively. In system (1.1) x is the state, u is the control input, w is an exogenous variable which includes disturbances, and z is the controlled input. We shall denote by $\nabla F : X \to L(X, X)$ the gradient of F and by $\nabla^2 F$ the second-order differential.

Consider the linearized system around 0

$$\begin{aligned} y' &= (A + \nabla F(0))y + B_2u + B_1w, \qquad t \geq 0, \\ y(0) &= 0. \end{aligned} \tag{1.2}$$

Given $\gamma > 0$ we say that $L \in L(X, U)$ is a suboptimal solution to the H_∞-problem associated with system (1.2) if the operator $A + \nabla F(0) + B_2L$ generates an exponentially stable semigroup and

$$\int_0^\infty |C_1y + D_{12}Ly|_Z^2\,dt < (\gamma^2 - \epsilon)\int_0^\infty |w(t)|_W^2\,dt, \quad \forall\, w \in L^2(R^+; W), \tag{1.3}$$

where y is the solution to (1.2) where $u = Ly$. Throughout the following we shall assume the following standard hypotheses on linearized system (1.2).

(i) The pair $(A + \nabla F(0), B_2)$ is exponentially stabilizable; i.e., there is $G \in L(X, U)$ such that $A + \nabla F(0) + B_2G$ generates an exponentially stable semigroup.

(ii) The pair $(A + \nabla F(0), C_1)$ is exponentially detectable, i.e., there is $K \in L(Z, X)$ such that $A + \nabla F(0) + KC_1$ generates an exponentially stable semigroup.

(iii) $D_{12}^*[C_1, D_{12}] = [0, I]$.

Assumption (iii) implies that

$$|C_1x + D_{12}u|_Z^2 = |C_1x|^2 + |u|^2, \quad \forall\,(x, u) \in X \times U.$$

It is well known [2] – [4], [6] that under assumptions (i), (ii), and (iii) if the H_∞-problem for the linearized system (1.2) has a suboptimal solution, then the algebraic Riccati equation

$$(1.4)\quad (A+\nabla F(0))^*P + P(A+\nabla F(0)) - P(B_2B_2^* - \gamma^{-2}B_1B_1^*)P + C_1^*C_1 = 0$$

has a unique solution $P \in L(X,X)$, $P = P^* \geq 0$ such that $A + \nabla F(0) - (B_2B_2^* - \gamma^{-2}B_1B_1^*)P$ is exponentially stable.

The main result of this work, Theorem 1 below, relates the H_∞-control problem for the linearized system (1.2) to a certain Hamilton–Jacobi equation associated with the control system (1.1).

THEOREM 1. *Let $\gamma > 0$ and assume that the H_∞-problem for the system* (1.2) *has a suboptimal solution L. Then the Hamilton–Jacobi equation*

$$(1.5)\quad \begin{aligned} 2(Ax+Fx, \nabla\varphi(x)) + \gamma^{-2}|B_1^*\nabla\varphi(x)|_W^2 - |B_2^*\nabla\varphi(x)|_U^2 \\ + |C_1x|_Z^2 = 0, \quad \forall x \in D(A)\cap X_0 \end{aligned}$$

has a solution $\varphi \in C^2(X_0)$ in a neighborhood X_0 of the origin, satisfying

$$(1.6)\quad \varphi(0) = 0, \quad \nabla\varphi(0) = 0, \quad \nabla^2\varphi(0) = P.$$

Moreover, the solutions x to the system

$$(1.7)\quad \begin{aligned} x' = Ax + Fx - (B_2B_2^* - \gamma^{-2}B_1B_1^*)\nabla\varphi(x), \\ x(0) = x_0 \in X_0, \end{aligned}$$

which remain in X_0 have the property that $x \in L^2(R^+;X)$, $\lim_{t\to\infty}$; $x(t) = 0$, and the feedback control

$$(1.8)\quad u = -B_2^*\nabla\varphi(x)$$

asymptotically stabilizes system (1.1) *on X_0 and guarantees the closed-loop inequality*

$$(1.9)\quad \int_0^\infty (|C_1x(t)|_Z^2 + |u(t)|_U^2)dt < \gamma^2 \int_0^\infty |w(t)|_W^2\, dt,$$

$\forall w \in L^2(R^+;W)$, $w \not\equiv 0$ *and all solutions x to system* (1.1) *which remain in X_0 for all $t > 0$.*

The solution to (1.5) *is unique among the functions $\varphi \in C^2(X_0)$ satisfying* (1.6) *and having the property that every solution $x \in L^2(R^+;X)$ to the corresponding closed-loop system* (1.7) *with $x(0) \in X_0$ remains in X_0 for all $t \geq 0$.*

The approach we use here is quite different, and it relies on an existence result for the Hamiltonian system (2.1) corresponding with the given H_∞-problem (Proposition 1). As a matter of fact, as we shall see below, the solution φ to (1.5) can be characterized by the property that $\{(x,p) \in X_0 \times X;\ p + \nabla\varphi(x) = 0\}$ is a positively invariant manifold for this Hamiltonian system and that the corresponding closed-loop system is asymptotically stable. In [7], [8] the existence of such an invariant manifold follows via the stable manifold theorem. It is likely, however, that the methods of [7] can be extended to the present situation by using some recent results of center manifold theory in infinite dimensions. By quite different methods this problem has also been studied by Isidori and Astolfi [5] and in the author's work [1] where the given H_∞-problem is related to generalized solutions to the Hamilton–Jacobi equation (1.5).

Theorem 1 applies to semilinear distributed control systems, but we omit examples.

2. The Hamiltonian system. We shall study the existence of the Hamiltonian system

$$
\begin{aligned}
&x' = Ax + Fx + (B_2B_2^* - \gamma^{-2}B_1B_1^*)p,\\
&p' = -(A + \nabla F(x))^*p + C_1^*C_1x,\\
&x(0) = x_0, \qquad p(\infty) = 0,
\end{aligned}
\tag{2.1}
$$

in a neighborhood $K_\varepsilon = \{(x,p) \in X \times X; |x| < \varepsilon, |p| < \varepsilon\}$ of the origin.

PROPOSITION 1. *Under assumptions* (i)–(iii) *there are* $\varepsilon > 0$ *and* $0 < \delta < \varepsilon$ *such that for* $|x_0| < \delta$, *system* (2.1) *has a unique mild solution* $(x,p) \in L^2(R^+;X) \times L^2(R^+;X)$, $(x(t),p(t)) \in K_\varepsilon$, $\forall t \geq 0$.

By mild solution to (2.1) we mean a pair of continuous functions $(x,p) : R^+ \to X \times X$ which satisfy the equations

$$x(t) = e^{At}x_0 + \int_0^t e^{A(t-s)}(Fx(s) + (B_2B_2^* - \gamma^{-2}B_1B_1^*)p(s))ds, \quad \forall t \geq 0,$$

$$p(t) = U^*(T,t)p(T) - \int_t^T U^*(s,t)C_1^*C_1x(s)ds, \qquad 0 < t \leq T < \infty$$

for all $T > 0$. Here $\{U(s,t);\ 0 \leq t \leq s < \infty\}$ is the evolution operator associated with $A + \nabla F(x(t))$.

Proof of Proposition 1. We may rewrite system (2.1) as

$$
\begin{aligned}
&x' = (A + \nabla F(0))x + (B_2B_2^* - \gamma^{-2}B_1B_1^*)p + \mu(x),\\
&p' = -(A + \nabla F(0))^*p + C_1^*C_1x + \nu(x)p,\\
&x(0) + x_0, \qquad p(\infty) = 0,
\end{aligned}
\tag{2.2}
$$

where $\mu(x) = F(x) - \nabla F(0)x$ and $\nu(x) = (\nabla F(x))^* - (\nabla F(0))^*$. Clearly, we have

$$
\begin{aligned}
&|\mu(x)| \leq C_r|x|^2, \qquad \|\nu(x)\|_{L(X,X)} \leq C_r|x|, \quad \forall x \in \textstyle\sum_r\\
&\|\mu\|_{\mathrm{Lip}(\sum_r)} + \|\nu\|_{\mathrm{Lip}(\sum_r)} \leq C_r^1 r, \quad \forall r > 0
\end{aligned}
\tag{2.3}
$$

where $\sum_r = \{x \in X;\ |x| \leq r\}$ and $\|\cdot\|_{\mathrm{Lip}(\sum_r)}$ is the Lipschitz norm on $\sum_r$. In the space $Y = L^2(R^+;X) \times L^2(R^+;X)$ define the operator $\mathcal{A}$

(a) $D(\mathcal{A})$ is the set of all $(x,p) \in Y$ such that

$$
\begin{aligned}
&x' = (A + \nabla F(0))x + (B_2B_2^* - \gamma^{-2}B_1B_1^*)p + f,\ t \in R^+,\\
&p' = -(A + \nabla F(0))^*p + C_1^*C_1x + g,\ t \in R^+,\\
&x(0) = x_0, \qquad p(\infty) = 0
\end{aligned}
\tag{2.4}
$$

for some $(f,g) \in Y$.

The solution (x,p) to system (2.4) is considered in the mild sense, i.e.,

$$
\begin{aligned}
x(t) &= e^{(A+\nabla F(0))t}x_0 + \int_0^t e^{(A+\nabla F(0))(t-s)}((B_2B_2^* - \gamma^{-2}B_1B_1^*)p(s)\\
&\qquad + f(s))ds,\\
p(t) &= e^{(A+\nabla F(0))^*(T-t)}p(T) - \int_t^T e^{(A+\nabla F(0))^*(s-t)}(C_1^*C_1x(s) + g(s))ds,
\end{aligned}
\tag{2.5}
$$

for all $0 \le t \le T < \infty$.

(b) For $(x,p) \in D(\mathcal{A})$, $\mathcal{A}(x,p) = (f,g)$.

Obviously $\mathcal{A}$ is well defined and single valued. Formally we may define $\mathcal{A}$ as

$$\begin{aligned}\mathcal{A}(x,p) = \{&x' - (A + \nabla F(0))x - (B_2B_2^* - \gamma^{-2}B_1B_1^*)p,\\ &p' + (A+\nabla F(0))^*p - C^*C_1x\}, \quad \forall\,(x,p) \in D(\mathcal{A}),\end{aligned}$$

where

$$D(\mathcal{A}) = \{(x,p) \in Y;\ x(0) = x_0,\ p(\infty) = 0;\ \mathcal{A}(x,p) \in Y\}.$$

Let us denote by $\mathcal{A}_0$ the operator $\mathcal{A}$ in the case $x_0 = 0$. We have the following lemma.

LEMMA 1. *The operator $\mathcal{A}_0^{-1}$ is continuous from Y to $Y \cap (C(R^+;X) \times C(R^+;X))$.*

Proof. One must prove that for every $(f,g) \in Y$ the Hamiltonian system

$$\begin{aligned}x' &= (A + \nabla F(0))x + (B_2B_2^* - \gamma^{-2}B_1B_1^*)p + f, \qquad t \ge 0,\\ p' &= -(A+\nabla F(0))^*p + C_1^*C_1x + g, \qquad t \ge 0,\\ x(0) &= 0, \qquad p(\infty) = 0,\end{aligned} \tag{2.6}$$

has a unique solution $(x,p) \in Y \cap (C(R^+;X) \times C(R^+;X))$ and the map $(f,g) \to (x,p)$ is continuous. To this purpose consider the sup inf problem

$$\sup_{w \in \mathcal{W}} \inf_{u \in \mathcal{U}} \left\{ \int_0^\infty (|C_1x|_Z^2 + |u|_U^2 + 2(g,x) - \gamma^2|w|_W^2)dt;\right.\\ \left. x' = (A+\nabla F(0))x + B_2u + B_1w + f,\ x(0) = 0 \right\}, \tag{2.7}$$

where $\mathcal{U} = L^2(R^+;U)$ and $\mathcal{W} = L^2(R^+;W)$. We set

$$\psi(w) = \inf_{u\in\mathcal{U}} \left\{ \int_0^\infty (|C_1x|_Z^2 + |u|_U^2 + 2(g,x))dt;\right.\\ \left. x' = (A+\nabla F(0))x + B_2u + B_1w + f,\ x(0) = 0 \right\}. \tag{2.8}$$

Then by assumption (see (1.3)) the function $\gamma^2\|w\|_W^2 - \psi(w)$ is convex and coercive, and so the problem

$$\sup\{\psi(w) - \gamma^2\|w\|_W^2\} \tag{2.9}$$

has a unique solution w^*. Hence problem (2.7) has a unique solution $(u^*, w^*) \in \mathcal{U} \times \mathcal{W}$. For every $w \in \mathcal{W}$ we shall denote by $\bar{u} = \Gamma w$ the solution to problem (2.8), i.e.,

$$\bar{u} = \Gamma w = \arg\inf \left\{ \int_0^\infty (|C_1x|_Z^2 + |u|_U^2 + 2(g,x))dt;\right.\\ \left. x' = (A+\nabla F(0))x + B_2u + B_1w;\ x(0) = 0,\ u \in \mathcal{U} \right\}.$$

Then by standard arguments in linear quadratic control theory it follows that there is $\bar{p} \in L^2(R^+; X) \cap C(R^+; X)$ such that

$$\begin{aligned} \bar{p}' &= -(A + \nabla F(0))^* \bar{p} + C_1^* C_1 \bar{x} + g \quad \text{in}\, R^+, \\ \bar{p}(\infty) &= 0. \end{aligned} \tag{2.10}$$

$$\bar{u} = B_2^* \bar{p}, \quad \forall\, t \geq 0. \tag{2.11}$$

Moreover, by assumption (i) we may write (2.10) as

$$\begin{aligned} \bar{p}' &= -(A + \nabla F(0) + B_2 G)^* \bar{p} + G^* \bar{u} + C_1^* C_1 \bar{x} + g, \\ \bar{p}(\infty) &= 0. \end{aligned} \tag{2.12}$$

Since $A + \nabla F(0) + B_2 G$ is exponentially stable, we infer that the solution $\bar{p}$ to (2.10) is unique and

$$|\bar{p}(t)| \leq C \int_t^\infty e^{-\omega(s-t)} (|\bar{u}(s)|_U + |C_1 \bar{x}(s)|_Z + |g(s)|) ds, \, \forall\, t \geq 0, \tag{2.13}$$

where $\omega > 0$. Hence $\bar{p} \in L^2(R^+; X)$.

Note also that

$$\nabla \psi(w) = -2 B_1^* \bar{p}, \quad \text{a.e.}\, t > 0, \tag{2.14}$$

where $\bar{p}$ is the solution to (2.10). Indeed if x^w is the solution to $x' = (A + \nabla F(0))x + B_2 \Gamma w + B_1 w$, $x(0) = 0$, then we have for all $\bar{w} \in \mathcal{W}$

$$\begin{aligned} \psi(w) - \psi(\bar{w}) = \int_0^\infty (|C_1 x^w|_Z^2 - |C_1 x^{\bar{w}}|_Z^2) dt + \int_0^\infty (|\Gamma w|_U^2 - |\Gamma \bar{w}|_U^2) dt \\ + 2 \int_0^\infty (g, x^w - x^{\bar{w}}) dt \leq 2 \int_0^\infty ((C_1^* C_1 x^w, x^w - x^{\bar{w}}) \\ + (\Gamma w, \Gamma(w - \bar{w}))_U + (g, x^w - x^{\bar{w}})) dt. \end{aligned}$$

Then using system (2.10) we get

$$\begin{aligned} \psi(w) - \psi(\bar{w}) \leq -2 \int_0^\infty ((p, B_1(w - \bar{w})) + (B_2^* p, \Gamma(w - \bar{w}))_U \\ + (\Gamma w, \Gamma(w - \bar{w}))_U) dt = -2 \int_0^\infty (B_1^* p, w - \bar{w})_W \end{aligned}$$

as claimed. Since w^* is the solution to (2.9), we see by (2.10) and (2.14) that system (2.6) has a solution (x, p) where $x = x^*$ is just the solution to

$$(x^*)' = (A + \nabla F(0)) x^* + B_2 u^* + B_1 w^* + f; \; x^*(0) = 0$$

and $(u^*, w^*) \in \mathcal{U} \times \mathcal{W}$ is the solution to problem (2.7). Since $C_1 x^* \in L^2(R^+; Z)$, it follows by detectability assumption (ii) that $x^* \in L^2(R^+; X)$. Similarly by (2.13) we see that $p \in L^2(R^+; X)$ and $\lim_{t \to \infty} p(t) = p(\infty) = 0$.

Now if $(x, p) \in Y$ is any solution to (2.6), we have

$$\int_0^\infty (|C_1 x|_Z^2 + |B_2^* p|_U^2 + 2(g, x)) dt \leq \int_0^\infty (|C_1 y|_Z^2 + |v|_U^2 + 2(g, y)) dt, \tag{2.15}$$

for all (y, v) satisfying the system

$$y' = (A + \nabla F(0))y + B_2 v + B_1\tilde{w} + f, \qquad y(0) = 0, \tag{2.16}$$

where $\tilde{w} = -\gamma^{-2}B^*p$. On the other hand, after some calculation involving (2.6) we see that

$$\int_0^\infty (|B_2^*p|_U^2 + |C_1x|_Z^2 + (g,x) + (f,p))dt = \gamma^{-2}\int_0^\infty |B_1^*p|_W^2\, dt. \tag{2.17}$$

Then substituting into (2.15) we get

$$\gamma^{-2}\int_0^\infty |B_1^*p|_W^2\, dt \le \int_0^\infty (|C_1y|_Z^2 + |v|_U^2 + (g, 2y - x) + (f,p))dt.$$

In system (2.16) we take $v = Ly$, provided that (1.3) holds. This yields

$$\gamma^{-2}\int_0^\infty |B_1^*p|_W^2\, dt \le (\gamma^{-2} - \rho)\int_0^\infty |B_1^*p|_W^2\, dt$$
$$+C\int_0^\infty (|f|^2 + |g|^2)dt + \int_0^\infty (|f||p| + |g||x|)dt,$$

where C and $\rho > 0$ are independent of f and g. Hence

$$\int_0^\infty |B_1^*p|_W^2\, dt \le C\rho^{-1}\left(\int_0^\infty (|f|^2 + |g|^2)dt + \int_0^\infty (|f||p| + |g||x|)dt\right)$$

and by (2.17) we have

$$\begin{aligned}&\int_0^\infty (|B_2^*p|_U^2 + |C_1x|_Z^2 + |B_1^*p|_W^2)dt\\ &\quad\le C\int_0^\infty (|f|^2 + |g|^2 + |f||p| + |g||x|)dt\end{aligned} \tag{2.18}$$

for some positive constant C independent of $(f,g) \in Y$. Then by assumptions (i) and (ii) and system (2.6) it follows that

$$|x(t)|^2 + \int_0^\infty |x(t)|^2\, dt \le C\int_0^\infty (|C_1x|_Z^2 + |B_2^*p|_U^2 + |B_1^*p|_W^2 + |f|^2)dt,$$

$$|p(t)|^2 + \int_0^\infty |p(t)|^2\, dt \le C\int_0^\infty (|C_1x|_Z^2 + |B_2^*p|_U^2 + |g|^2)dt$$

and by (2.18) we see that

$$\begin{aligned}|x(t)|^2 + |p(t)|^2 + \int_0^\infty (|x(t)|^2 + |p(t)|^2)dt &\le C\int_0^\infty (|f|^2 + |g|^2)dt,\\ &\forall\,(f,g) \in Y, \qquad t \ge 0,\end{aligned} \tag{2.19}$$

as claimed.

Proof of Proposition 1 (*continued*). We note that for all $(f,g) \in Y$,

$$\mathcal{A}^{-1}(f,g) = \mathcal{A}_0^{-1}(f,g) + (\tilde{x}, \tilde{p}), \tag{2.20}$$

where $(\tilde{x},\tilde{p})$ is the solution to the system

$$\begin{aligned} &\tilde{x}' = (A+\nabla F(0))\tilde{x} + (B_2B_2^* - \gamma^{-2}B_1B_1^*)\tilde{p}, \qquad t \geq 0,\\ &\tilde{p}' = -(A+\nabla F(0))^*\tilde{p} + C_1^*C_1\tilde{x},\\ &\tilde{x}(0) = x_0, \qquad \tilde{p}(\infty) = 0. \end{aligned} \tag{2.21}$$

We have

$$\int_0^\infty (|C_1\tilde{x}|_Z^2 + |B_2^*\tilde{p}|_U^2)dt \leq \int_0^\infty (|C_1y|_Z^2 + |v|_U^2)dt$$

and

$$\int_0^\infty (|B_2^*\tilde{p}|_U^2 + |C_1\tilde{x}|_Z^2)dt = \gamma^{-2}\int_0^\infty (|B_1^*\tilde{p}|_W^2\,dt - (\tilde{p}(0),x_0))dt.$$

Here (y,v) is the solution to system (2.16) where $y(0) = x_0$ and $f \equiv 0$. Then arguing as in the proof of Lemma 1 we get the estimate

$$\int_0^\infty (|C_1\tilde{x}|_Z^2 + |B_2^*\tilde{p}|_U^2 + |B_1^*\tilde{p}|_W^2)dt \leq C|\tilde{p}(0)||x_0|, \quad \forall x_0 \in X.$$

Once again using assumptions (i) and (ii) in system (2.21) we see that

$$|\tilde{p}(t)|^2 + |\tilde{x}(t)|^2 + \int_0^\infty (|\tilde{x}|^2 + |\tilde{p}|^2)dt \leq C|\tilde{p}(0)||x_0|, \quad \forall t \geq 0$$

and therefore

$$|\tilde{p}(t)|^2 + |\tilde{x}(t)|^2 + \int_0^\infty (|\tilde{x}|^2 + |\tilde{p}|^2)dt \leq C|x_0|^2, \quad \forall x_0 \in X. \tag{2.22}$$

Now by virtue of (2.2) we may write system (2.1) as

$$(x,p) = \mathcal{A}_0^{-1}(\mu,\nu p) + (\tilde{x},\tilde{p}). \tag{2.23}$$

Consider the subset of Y,

$$\begin{aligned} Y_\varepsilon =\{&(x,p) \in Y; \|x\|_{L^2(R^+;X)}, \|p\|_{L^2(R^+;X)} \leq \varepsilon;\\ &\|x\|_{L^\infty(R^+;X)}, \|p\|_{L^\infty(R^+;X)} \leq \varepsilon\}. \end{aligned}$$

By estimate (2.22) we see that for $|x_0| \leq \delta(\varepsilon)$, $(\tilde{x},\tilde{p}) \in Y_{\varepsilon/2}$. Moreover, by Lemma 1 and estimates (2.3) we have

$$\mathcal{A}_0^{-1}(\mu,\nu p) \in Y_{\varepsilon/2}, \quad \forall\,(x,p) \in Y_\varepsilon$$

if ε is sufficiently small. Finally, by (2.3) and (2.19) we see that

$$\|\mathcal{A}_0^{-1}(\mu,\nu p) - \mathcal{A}_0^{-1}(\bar{\mu},\bar{\nu}\bar{p})\|_Y \leq C\varepsilon(\|x-\bar{x}\|_Y + \|p-\bar{p}\|_Y)$$

for all (x,p), $(\bar{x},\bar{p}) \in Y_\varepsilon$. Here $\bar{\mu} = \mu(\bar{x})$, $\bar{\nu} = \nu(\bar{x})$, and C is some positive constant. Then by the contraction principle, (2.23) (equivalently, system (2.1)) has a unique solution $(x,p) \in Y_\varepsilon \subset X_0$ for $|x_0| < \delta$ and $0 < \delta < \varepsilon$ sufficiently small. This completes the proof.

3. Proof of Theorem 1. Let $X_0 = \{x_0 \in X;\ |x_0| \le \delta\}$ and let $\Phi : X_0 \to X$ be the map

$$\Phi(x_0) = -p(0),$$

where p is the solution to system (2.1). As seen in Proposition 1, $\Phi(X_0) \subset \{x \in X;\ |x| \le \varepsilon\}$.

LEMMA 2. *$\Phi \in C^1(X_0)$ and $\Phi(x_0) = \nabla\varphi(x_0), \forall\, x_0 \in X_0$ where*

$$\varphi(x_0) = \frac{1}{2}\int_0^\infty (|C_1x(t)|_Z^2 + |B_2^*p(t)|_U^2 - \gamma^{-2}|B_1^*p(t)|_W^2)dt, \quad \forall\, x_0 \in X_0. \tag{3.1}$$

Proof. Let $h \in X$ be arbitrary but fixed. Consider the solution $(y, q) \in Y$ to system

$$\begin{aligned} y' &= (A + \nabla F(x))y + (B_2B_2^* - \gamma^{-2}B_1B_1^*)q, \\ q' &= -(A + \nabla F(x))^*q + C_1^*C_1y - (\nabla^2F(x)y)^*q, \\ y(0) &= h, \qquad q(\infty) = 0. \end{aligned} \tag{3.2}$$

We may write (3.2) as

$$\begin{aligned} y' &= (A + \nabla F(0))y + (B_2B_2^* - \gamma^{-2}B_1B_1^*)q + \mu_1(y), \\ q' &= -(A + \nabla F(0))^*q + C_1^*C_1y + \mu_2(y, q), \\ y(0) &= h, \qquad q(\infty) = 0, \end{aligned}$$

where $|\mu_1(y)| \le C\varepsilon|y|$, $|\mu_2(y, q)| \le C\varepsilon(|y| + |q|)$. Moreover, μ_1 and μ_2 are Lipschitzian with the Lipschitz constant $C\varepsilon$. Then arguing as in Lemma 1 we infer that system (3.2) has a unique solution $(y, q) \in Y \cap (C(R^+; X) \times C(R^+; X))$.

Now let (x, p) and (x_1, p_1) be two solutions to system (2.1), corresponding to x_0 and $x_0 + h$, respectively. We set $\bar{x} = x_1 - x - y$ and $\bar{p} = p_1 - p - q$ and notice that

$$\begin{aligned} \bar{x}' &= (A + \nabla F(0))\bar{x} + (B_2B_2^* - \gamma^{-2}B_1B_1^*)\bar{q} + (\nabla F(x) - \nabla F(0))\bar{x} + \nu_1(t), \\ \bar{p}' &= -(A + \nabla F(0))^*\bar{p} + C_1^*C_1\bar{x} - (\nabla F(x)\bar{x})^*p + (\nabla F(0) - \nabla F(x))^*p + \nu_2(t), \\ \bar{x}(0) &= 0, \qquad \bar{p}(\infty) = 0, \end{aligned}$$

where $|\nu_1(t)| + |\nu_2(t)| \le C|x_1(t) - x(t)|^2$, $\forall\, t \ge 0$. Recall that by Lemma 1,

$$\|x_1 - x\|_{L^\infty(R^+;X)\cap L^2(R^+;X)} \le C|h|.$$

Then using the invertibility of $\mathcal{A}_0$ we see that for ε sufficiently small

$$\|\bar{x}\|_{L^\infty(R^+;X)\cap L^2(R^+;X)} + \|\bar{p}\|_{L^\infty(R^+;X)\cap L^2(R^+;X)} \le C|h|^2. \tag{3.3}$$

The latter implies that

$$\|\Phi(x_0 + h) - \Phi(x_0) + q(0)\| \le C|h|^2.$$

Hence $\Phi \in C^1(X_0)$ and $\nabla\Phi(x_0)h = -q(0)$. In particular it follows that $\nabla\Phi(0) = P$ where $P \in L(X, X^*)$, $P = P^* \ge 0$ is defined by $Ph = -q(0)$, q being the solution to (3.2) where $x = 0$. Hence P is the unique solution to (1.4), having the property that $A + \nabla F(0) - (B_2B_2^* - \gamma^{-2}B_1B_1^*)P$ is exponentially stable.

Let us denote by φ the function defined by the right-hand side of (3.1). Taking into account (3.3) it is readily seen that φ is differentiable on X_0 and

$$(\nabla\varphi(x_0), h) = \int_0^\infty ((C_1^*C_1x, y) + (B_2B_2^*p, q) - \gamma^{-2}(B_1B_1^*p, q))dt,$$

where (y,q) is the solution to (3.2). Then by a little calculation involving (2.1) and (3.2) we see that

$$(\nabla\varphi(x_0),h) = -(p(0),h), \qquad |h| \le \delta.$$

Hence $\nabla\varphi(x_0) = \Phi(x_0)$, $\forall\, x_0 \in X_0$ as claimed. We will now prove that φ satisfies the Hamilton–Jacobi equation (1.4) on X_0. To this purpose we note that by uniqueness in system (2.1) we have

$$p(t) = -\Phi(x(t)), \quad \forall\, t \in [0,\mu), \tag{3.4}$$

where μ is such that $x(t) \in X_0$, $\forall\, t \in [0,\mu)$. Hence on the interval $[0,\mu)$, x is the solution to the closed-loop differential system

$$\begin{gathered} x'(t) = Ax(t) + Fx(t) - (B_2B_2^* - \gamma^{-2}B_1B_1^*)\Phi(x(t)), \\ x(0) = x_0. \end{gathered} \tag{3.5}$$

Let $x_0 \in D(A) \cap X_0$. Since F and Φ are smooth, we conclude that x is continuously differentiable on $[0,\mu)$ and so is p. Then multiplying (3.5) by $\Phi(x(t))$ we get

$$\begin{aligned} \frac{d}{dt}\varphi(x(t)) &= (Ax(t) + Fx(t), \Phi(x(t))) \\ &\quad - |B_2^*\Phi(x(t))|_U^2 + \gamma^{-2}|B_1^*\Phi(x(t))|_W^2, \ \forall\, t \in [0,\mu). \end{aligned} \tag{3.6}$$

On the other hand, we have

$$\varphi(x(t)) = \frac{1}{2}\int_t^\infty (|C_1x|_Z^2 + |B_2^*p|_U^2 - \gamma^{-2}|B_1^*p|_W^2)dt, \quad \forall\, t \ge 0.$$

Along with (3.6) the latter yields

$$\begin{gathered} |C_1x_0|_Z^2 + |B_2^*\Phi(x_0)|_U^2 - \gamma^{-2}|B_1^*\Phi(x_0)|_W^2 + 2(Ax_0 + Fx_0, \Phi(x_0)) = 0, \\ \forall\, x_0 \in X_0 \cap D(A), \end{gathered}$$

as claimed.

Consider now the closed-loop system

$$\begin{gathered} x' = Ax + Fx - B_2B_2^*\nabla\varphi(x) + B_1w, \\ x(0) = x_0, \end{gathered} \tag{3.7}$$

where $x_0 \in X_0$ and $w \in L^2(R^+;W)$. We shall assume that $x_0 \in D(A)$ and $w \in C^1(R^+;W)$. Then problem (3.7) has a unique local smooth solution $x = x(t)$. We restrict ourselves to w, x_0 for which $x(t) \in X_0$ for all $t \ge 0$. (This happens, for instance, if $|x_0|$ and $\|w\|_{L^2(R^+;W)}$ are sufficiently small.) For such a solution we have

$$\begin{aligned} \frac{d}{dt}\varphi(x(t)) &= (Ax(t) + Fx(t), \nabla\varphi(x(t)) - |B_2^*\nabla\varphi(x(t))|_U^2 \\ &\quad + (w(t), B_1^*\nabla\varphi(x(t)))_W \\ &= -2^{-1}(|B_2^*\nabla\varphi(x(t))|_U^2 + \gamma^{-2}|B_1^*\nabla\varphi(x(t))|_W^2 \\ &\quad + |C_1x(t)|_Z^2) + (w(t), B_1^*\nabla\varphi(x(t)))_W, \quad \forall\, t \ge 0. \end{aligned} \tag{3.8}$$

Since by virtue of (1.6) φ is positive definite in a neighborhood of the origin (let it be X_0) the latter yields

$$\begin{aligned}\int_0^\infty (|C_1x(t)|_Z^2 + |B_2^*\nabla\varphi(x(t))|_U^2 - \gamma^{-2}|w(t)|_W^2)dt \\ = \varphi(x_0) - \gamma^{-2}\int_0^\infty |B_1^*\nabla\varphi(x(t)) - \gamma^2 w(t)|_W^2\, dt.\end{aligned} \tag{3.9}$$

This equality clearly extends to all $w \in L^2(R^+; W)$ and $x_0 \in X_0$ such that $x(t)$ remain in X_0 for all $t \geq 0$. Let $K \in L(Z, X)$ be such that $A + \nabla F(0) + KC_1$ is exponentially stable. Then writing system (3.7) with $w = 0$ as

$$x' = (A + \nabla F(0) + KC_1)x - KC_1x - B_2B_2^*\nabla\varphi(x) + F(x) - \nabla F(0)x,$$

it follows by (3.9) that

$$|x(t)| \leq C(e^{-\omega t}|x_0| + \varepsilon\int_0^t e^{-\omega(t-s)}|x(s)|ds + f_0(t)), \qquad t \geq 0,$$

where $\omega > 0$ and $f_0 \in L^2(R^+)$. Then for ε sufficiently small the previous inequality implies that $x \in L^2(R^+; X)$ and $\lim_{t\to\infty}|x(t)| = 0$. We have proved, therefore, that the feedback control (1.8) asymptotically stabilizes system (1.1) in X_0. On the other hand, inequality (3.9) for $x_0 = 0$ implies (1.9) as claimed.

Now let $x = x(t)$ be a solution to system (1.7) such that $x(t) \in X_0$, $\forall t \geq 0$. We may write (1.7) as

$$\begin{gathered}x' = (A + \nabla F(0) - B_2B_2^*P + \gamma^{-2}B_1B_1^*P)x + \mu(x),\\ x(0) = x_0,\end{gathered}$$

where $|\mu(x)| \leq C|x|^2 \leq \delta|x|$. Recalling that $A + \nabla F(0) - B_2B_2^*P + \gamma^{-2}B_1B_1^*P$ is exponentially asymptotically stable [6], we infer that if X_0 is sufficiently small, then $x \in L^2(R^+; X)$ as claimed.

The uniqueness of solution φ to (1.5) satisfying (1.6) and having the property that $A + F - (B_2B_2^* - \gamma^{-2}B_1B_1^*)\nabla\varphi$ is asymptotically stable in X_0 remains to be proven. If $\varphi \in C^2(X_0)$ is such a function, consider the solution x to system (1.7) where $x_0 \in X_0 \cap D(A)$. Then $x(t) \in X_0 \cap D(A)$, $\forall t \geq 0$. We set $p(t) = -\nabla\varphi(x(t))$ and notice that by virtue of (1.5), (x, p) is the solution to the Hamiltonian system (2.1). Indeed we have

$$p'(t) = -\nabla^2\varphi(x(t))(Ax(t) + Fx(t) - (B_2B_2^* - \gamma^{-2}B_1B_1^*)\nabla\varphi(x(t))) \quad \forall t \geq 0$$

while by (1.5),

$$\begin{aligned}&\nabla^2\varphi(x)(Ax + Fx - (B_2B_2^* - \gamma^{-2}B_1B_1^*)\nabla\varphi(x))\\ &\quad = -(A + \nabla F(x))^*\nabla\varphi(x) - C_1^*C_1x, \quad \forall x \in D(A) \cap X_0.\end{aligned}$$

Hence

$$p'(t) = -(A + \nabla F(x(t)))^*p(t) + C_1^*C_1x(t), \quad \forall t \geq 0.$$

By the uniqueness in system (2.1) (Proposition 1) we infer that $\nabla\varphi$ is uniquely defined on X_0, thereby completing the proof.

Remark. By the previous proof it follows that in a neighborhood of the origin $\{(x, p); p + \nabla\varphi(x) = 0\}$ is a positively invariant manifold of the Hamiltonian system (2.1) and the closed-loop system (1.7) is asymptotically stable. Moreover, the function φ is unique with these properties. In fact, we may reformulate Theorem 1 in these terms.

RELAXED MINIMAX CONTROL*

E. N. BARRON[†] AND R. JENSEN[‡]

Abstract. The relaxation of the optimal control problem with cost functional which is the supremum in time of some function $h(t, x, z)$ is determined. The trajectory is convexified in the usual way but the cost functional is convexified in a nonobvious manner. Thus, if the original value function is $V(t,x) = \inf_{\zeta \in \mathcal{Z}} \|h(s, \xi(s), \zeta(s))\|_{L^\infty[t,T]}$, then the relaxed value function is

$$\hat{V}(t,x) = \inf_{\mu \in \hat{\mathcal{Z}}[t,T]} \| \|h(s, \hat{\xi}(s), z)\|_{L^\infty(Z;\mu(s))} \|_{L^\infty[t,T]}$$

where the inner norm is the essential sup of h over $z \in Z$ with respect to the measure $\mu(s)$. We prove that V and $\hat{V}$ coincide.

Key words. L^∞ optimal control, relaxed problem

AMS subject classifications. 49A10, 49A40, 93C60

1. Introduction.

Nonconvex optimal control problems with integral or terminal cost functionals, the problems of Mayer, Bolza, and Lagrange, are generally not guaranteed to possess optimal controls. The usual method of getting around this problem is to enlarge the class of controls to include probability measures, the class of relaxed controls. Convexifying the trajectory dynamics and the cost functional leads in classical problems to a weakly lower semicontinuous and convex problem for which an optimal relaxed control is guaranteed to exist. In general the optimal relaxed control can be approximated by ordinary controls. The books by Warga [11] and Cesari [6] are good references (see also [9], [10]).

Considering the importance of relaxation, the question arises as to what is the relaxed control problem when the cost functional is not the standard type mentioned above but is instead a problem of minimax control. The minimax, or L^∞ problem, consists of minimizing, using controls, the supremum in time of some given function h of time, the trajectory, and the control. The value function is given by $V(t,x) = \inf_{\zeta \in \mathcal{Z}} \|h(s, \xi(s), \zeta(s))\|_{L^\infty[t,T]}$, where $\xi(\cdot)$ is the trajectory given as the solution of $d\xi/d\tau = f(\tau, \xi(\tau), \zeta(\tau))$ and $\zeta(\cdot)$ is the control. Now, there is more than one method for convexifying this problem. One way, which is probably the most obvious, is to simply convexify $f(\cdot,\cdot,z)$ and $h(\cdot,\cdot,z)$ by replacing them by $\int_Z f(t,x,z)\mu(dz)$ and $\int_Z h(t,x,z)\mu(dz)$, respectively, where μ is a probability measure on the control set Z. We present an example below where it is clear that this is *not* the appropriate relaxation.

The question is what properties does one want the relaxed problem to have. The answer, by analogy with classical problems, is that the relaxed problem should (i) possess an optimal control and (ii) the value function of the relaxed problem should coincide with the value function of the original problem for reasonably behaved functions h. In the example below, the proposed relaxation on a first attempt is incorrect because (ii) is not satisfied, even though the original problem has convex f and linear h in the z variable.

The way we approach determining the correct relaxation is to look at L^p approximations to the L^∞ norm. The L^p problem is a problem of Lagrange and can be relaxed in the usual way. When we take the limit as $p \to \infty$, we see that the L^∞ relaxation of h should not be

$\int_Z h(t,x,z)\mu(dz)$ but instead $\|h(t,x,z)\|_{L^\infty(Z;\mu)}$, i.e., the essential supremum of $h(\cdot,\cdot,z)$ with respect to the probability measure μ. However, we see that $\mu \mapsto \|h(t,x,z)\|_{L^\infty(Z;\mu)}$ is *not* convex but is rather *quasiconvex*, i.e., the level sets are all convex. Further, this map is lower semicontinuous with respect to weak convergence.

We prove that this relaxation will guarantee the existence of an optimal relaxed control. Therefore (i) above will hold. We then prove that the relaxed value function and the original value function coincide by establishing that the relaxed value function is a viscosity solution of the same Hamilton–Jacobi–Bellman equation as the original value function. Uniqueness of viscosity solutions yields the fact that they must be identical. Thus, both desirable properties of a relaxed control problem will hold.

2. Statement of the problem. Consider the controlled system of ordinary differential equations

$$d\xi(\tau)/d\tau = f(\tau,\xi(\tau),\zeta(\tau)), \qquad 0 \le t < \tau \le T, \tag{2.1}$$

$$\xi(t) = x \in R^n. \tag{2.2}$$

The control functions $\zeta(\cdot)$ are chosen from the class of functions

$$\mathcal{Z}[t,T] = \{\zeta : [t,T] \to Z | \zeta \text{ is Lebesgue measurable}\},$$

where Z, the control set, is a fixed compact subset of some euclidean space. We assume for simplicity that

(A) $f : [0,T] \times R^n \times Z \to R^n$ is jointly continuous and is Lipschitz in x. That is, there is a generic constant K such that

$$|f(t,x,z) - f(t,x',z)| \le K|x-x'|, \quad \forall\, x,x' \in R^n. \tag{2.3}$$

In addition, $|f(t,x,z)| \le K(1+|x|)$.

We are also given a function $h : [0,T] \times R^n \times Z \to R^1$ assumed to be jointly continuous and also uniformly Lipschitz in x. Without loss of generality we assume that h is a nonnegative function since otherwise we relace h by $|h|$.

Under (A), (2.1)–(2.2) has a unique solution for any $h \in \mathcal{Z}\,[t,T]$ (see [1]). The goal is to choose a control function $\zeta \in \mathcal{Z}$ that minimizes the largest that $h(r,\xi(r),\zeta(r))$ can be on the time interval $[t,T]$. We approach this problem by studying the value function $V : [0,T] \times R^n \to R^1$:

$$V(t,x) = \inf_{\zeta\in\mathcal{Z}} \operatorname*{ess\,sup}_{t\le r\le T} h(r,\xi(r),\zeta(r)). \tag{2.4}$$

It was proved in [4] (see also [2] for a direct proof) that the ess $\sup_{t\le r\le T}$ in (2.4) can be replaced by $\sup_{t\le r\le T}$. Intuitively, jumps of ζ on time intervals of Lebesgue measure zero are not necessary since they cannot change the dynamics.

The main result of [4] is that the function V is the unique continuous viscosity solution of the problem

$$\max\left\{V_t + \min_{\{z\in Z|h(t,x,z)\le V(t,x)\}} D_xV\cdot f(t,x,z),\ \min_{z\in Z} h(t,x,z) - V(t,x)\right\} = 0, \tag{2.5}$$

$$V(T,x) = \min_{z\in Z} h(T,x,z). \tag{2.6}$$

Remark 2.1. By examining the proofs of [4] one can weaken the continuity assumption of $h(t, x, z)$ in $z \in Z$ to lower semicontinuity uniformly in (t, x). This is important because we see that the corresponding relaxation involves a lower semicontinuous rather than a continuous function.

Define the hamiltonian function

$$H(t,x,r,p) = \min_{\{z \in Z | h(t,x,z) \leq r\}} p \cdot f(t,x,z) \tag{2.7}$$

for $r \in R^1$ and $p \in R^n$.

Remark 2.2. Observe that the minimum is over the set $\{z \in Z | h(t,x,z) \leq r\}$. If this set is empty, H is defined as $+\infty$. The form of (2.5) implies that the set is nonempty. Furthermore, the minimum in the hamiltonian is guaranteed since Z is compact and (A) holds.

We have that (see [4])

$$H^*(t,x,r,p) = H(t,x,r-0,p)$$

and

$$H_*(t,x,r,p) = H(t,x,r+0,p)$$

are the upper and lower semicontinuous envelopes of H, respectively. The function V then satisfies Eq. (2.5) as in the following definition [7], [8].

DEFINITION 2.1. *V is a viscosity solution of* (2.5) *if*

(i) *V is a viscosity subsolution, i.e., for any (t_0, x_0) for which $V - \varphi$ has a maximum, for a smooth function φ, it follows that*

$$\max\{\varphi_t + H^*(t_0, x_0, V(t_0, x_0), D_x\varphi(t_0, x_0)), \min_{z \in Z} h(t_0, x_0, z) - V(t_0, x_0)\} \geq 0$$

and

(ii) *V is a viscosity supersolution, i.e., for any (t_0, x_0) for which $V - \varphi$ has a minimum, for a smooth function φ, it follows that*

$$\max\{\varphi_t + H_*(t_0, x_0, V(t_0, x_0), D_x\varphi(t_0, x_0)), \min_{z \in Z} h(t_0, x_0, z) - V(t_0, x_0)\} \leq 0.$$

[4] does not consider the important problem of the existence of optimal controls. In the classical theory of optimal control one requires some sort of convexity of f and h in the controls in order to guarantee existence. Without convexity assumptions there may not exist an optimal control. In that event, one convexifies the problem by convexifying f and h. This is accomplished through the use of relaxed controls. Thus, we seek the corresponding relaxed control problem for minimax optimal control.

To motivate what follows we first take the naive approach that we convexify f and h in exactly the same way as in the problem of Lagrange. We introduce the space of relaxed controls.

Let $M(Z)$ denote the space of bounded measures on Z. Viewing $M(Z)$ as the dual space of $C(Z)$ = continuous functions on Z, we endow $M(Z)$ with the weak star topology of $C(Z)^*$. Let the space of relaxed controls be given by

$$\widehat{\mathcal{Z}}[t,T] = \{\mu \in L^\infty([t,T]; M(Z)) | \mu(\tau) \text{ is a probability measure a.e. } \tau \in [t,T]\}.$$

Let $\mathcal{M}(Z)$ be the set of probability measures on Z. Then, we may write that $\widehat{\mathcal{Z}}[t,T] = L^\infty([t,T]; \mathcal{M}(Z))$, the space of essentially bounded, Lebesgue measurable maps $\mu : [t,T] \to \mathcal{M}(Z)$. For any relaxed control $\mu \in \widehat{\mathcal{Z}}[t,T]$ there is a unique relaxed trajectory given by

$$\hat{\xi}(\tau) = x + \int_t^\tau \int_Z f(s, \hat{\xi}(s), z)\mu(s, dz)ds. \tag{2.8}$$

For any $\mu \in \mathcal{M}(Z)$ define the functions

$$\hat{f}(t,x,\mu) = \int_Z f(t,x,z)\mu(dz) \tag{2.9}$$

and

$$\hat{h}(t,x,\mu) = \mu - \operatorname*{ess\,sup}_{z\in Z} h(t,x,z) \equiv \|h(t,x,z)\|_{L^\infty(Z;\mu)}, \tag{2.10}$$

where $L^\infty(Z;\mu)$ is the space of essentially bounded, with respect to the measure $\mu \in \mathcal{M}(Z)$, real valued functions on Z. We show that the correct relaxation of the L^∞ problem involves the functions $\hat{f}$ and $\hat{h}$. The relaxed dynamic is the usual $\hat{f}$, but the classical relaxation of the cost functional uses $\int_Z h(t,x,z)\mu(dz)$ rather than $\hat{h}$. Now we show that replacing h by $\int_Z h(t,x,z)\,d\mu$ is *not* the correct relaxation.

Define the relaxed value function $\widehat{W} : [0,T] \times R^n \to R^1$ as

$$\widehat{W}(t,x) = \inf_{\mu\in\widehat{\mathcal{Z}}[t,T]} \operatorname*{ess\,sup}_{t\le r\le T} \int_Z h(r,\hat{\xi}(r),z)\mu(r,dz). \tag{2.11}$$

The function $\widehat{W}$ is easily shown to be the unique viscosity solution of

$$\begin{aligned}\max\Bigg\{\widehat{W}_t + \min_{\{\mu\in\mathcal{M}(Z)\mid \int_Z h(t,x,z)\mu(dz)\le\widehat{W}(t,x)\}} D_x\widehat{W}\cdot\int_Z f(t,x,z)\mu(dz),\\ \min_{\mu\in\mathcal{M}(Z)}\int_Z h(t,x,z)\mu(dz) - \widehat{W}(t,x)\Bigg\} = 0,\end{aligned} \tag{2.12}$$

$$\widehat{W}(T,x) = \min_{\mu\in\mathcal{M}(Z)} \int_Z h(T,x,z)\mu(dz). \tag{2.13}$$

Since it is possible that

$$\min_{\{\mu\in\mathcal{M}(Z)\mid \int_Z h(t,x,z)\mu(dz)\le r\}} p\cdot\int_Z f(t,x,z)\mu(dz) < \min_{\{z\in Z\mid h(t,x,z)\le r\}} p\cdot f(t,x,z)$$

it will not be the case, in general, that $\widehat{W} = V$. Consider the following.

Example. On the time interval $[-1,0]$, take $f(t,x,z) = z^2 - 10$, $Z = [0,10]$, and $h(t,x,z) = |x| + z$. First, we calculate an upper bound for the relaxed value for the initial conditions $x = 0$, $t = -1$. Choose the constant (in time) relaxed control

$$\mu(\tau) = 0.9\,\delta(z-0) + 0.1\,\delta(z-10).$$

We are using the notation that for any $z_0 \in Z$, $\delta(z-z_0)$ is the measure, all of whose mass is concentrated at z_0. The relaxed trajectory is given by

$$\hat{\xi}(\tau) = \int_{-1}^{\tau}\int_{[0,10]} z^2 - 10\,\mu(s,dz)ds = 0$$

for all $-1 \le \tau \le 0$ since $\int_{[0,10]} z^2\,\mu(s,dz) = 10$. Since $\int_{[0,10]} z\,\mu(s,dz) = 1$, the relaxed value function $\widehat{W}$ then satisfies

$$\widehat{W}(-1,0) \le \left\|\int_{[0,10]} z\,\mu(s,dz)\right\|_{L^\infty[-1,0]} = 1.$$

On the other hand, if $V(-1,0) \leq 1$, then it is clear that we may consider only controls for which $0 \leq \zeta(\tau) \leq 1$ for all τ. Clearly the optimal control must then be $\zeta(\tau) \equiv 1$ since that is the control that keeps ξ as close to zero as possible. But then $\xi(\tau) = -9(\tau + 1)$ and

$$V(-1,0) = \sup_{-1\leq\tau\leq 0} (|\xi(\tau)| + \zeta(\tau)) = 10 > 1.$$

We conclude that the relaxed value $\widehat{W}(-1,0) < V(-1,0)$ even though the function f is quadratic and h is linear in z in this example. Therefore, this relaxation of the L^∞ problem cannot be the correct version.

To motivate the relaxation using the function $\hat{h}$ in (2.10), we look at $L^p, p > 1$, approximations to the L^∞ problem as in [4]. Define the L^p value function

$$V_p(t,x) = \inf_{\zeta\in\mathcal{Z}[t,T]} \left(\int_t^T h^p(s,\xi(s),\zeta(s))ds\right)^{\frac{1}{p}}.$$

Then V_p is the unique continuous viscosity solution of

$$(V_p)_t + \min_{z\in Z} \left(D_x V_p \cdot f(t,x,z) + \frac{1}{p}\left(\frac{h(t,x,z)}{V_p(t,x)}\right)^p V_p(t,x)\right) = 0.$$

If we relax the L^p problem using classical theory, we obtain the value function

$$\widehat{V}_p(t,x) = \inf_{\mu\in\widehat{\mathcal{Z}}} \left(\int_t^T \int_Z h(s,\hat{\xi}(s),z)^p \, \mu(s,dz)ds\right)^{\frac{1}{p}}. \tag{2.14}$$

Remark 2.3. Observe that the function $\widehat{W}$ in (2.11) is obtained formally as a limit as $p \to \infty$ of

$$\widehat{W}_p(t,x) = \inf_{\mu\in\widehat{\mathcal{Z}}[t,T]} \left(\int_t^T \left(\int_Z h(s,\hat{\xi}(s),z)\,\mu(s,dz)\right)^p ds\right)^{\frac{1}{p}}. \tag{2.15}$$

This corresponds to relaxing h, not h^p. But the integrals on the right side of (2.15) are *not* weakly lower semicontinuous in μ for all $p > 1$ because this is a nonlinear nonconvex for odd p, functional of μ. Therefore, we are guaranteed the existence of an optimal relaxed control for the L^p problem when we relax h^p, but this is *not* the case when we relax h.

The function $\widehat{V}_p$ satisfies for each p, the problem

$$\widehat{V} + \min_{\mu\in\mathcal{M}} \left(D_x\widehat{V} \cdot \hat{f}(t,x,\mu) + \frac{1}{p}\left(\frac{\int_Z h(t,x,z)^p\,\mu(dz)}{\widehat{V}(t,x)^p}\right)\widehat{V}(t,x)\right) = 0.$$

If a limit is going to exist as $p \to \infty$, it is clear that we must have

$$(\widehat{V}_p(t,x))^p \geq \int_Z h(t,x,z)^p\,\mu(dz)$$

or, in other words, for large p,

$$\widehat{V}_p(t,x) \geq \left(\int_Z h(t,x,z)^p \mu(dz)\right)^{\frac{1}{p}}.$$

If $\widehat{V}_p$ converges to, say, $\widehat{V}$, then this puts the requirement on the measures μ that

$$\widehat{V}(t,x) \geq \|h(t,x,z)\|_{L^\infty(Z;\mu)} = \hat{h}(t,x,\mu)$$

since $(\int_Z h^p(t,x,z)\,\mu(dz))^{1/p} \to \|h(t,x,z)\|_{L^\infty(Z;\mu)}$ as $p \to \infty$. Thus, we arrive at the following statement, whose proof is similar to the proof of Proposition 2.6 and Theorem 4.2 in [4] and is therefore omitted.

THEOREM 2.1. $\lim_{p\to\infty} \widehat{V}_p(t,x) = \widehat{V}(t,x)$ *exists on* $[0,T] \times R^n$ *and* $\widehat{V}$ *is the unique, continuous viscosity solution of*

(2.16)

$$\max\left\{ \widehat{V}_t + \min_{\{\mu\in\mathcal{M}(Z)|\hat{h}(t,x,\mu)\leq\widehat{V}\}} (D_x\widehat{V}\cdot\hat{f}(t,x,\mu)),\ \min_{\mu\in\mathcal{M}(Z)} \hat{h}(t,x,\mu) - \widehat{V}(t,x) \right\} = 0$$

and terminal condition

$$\widehat{V}(T,x) = \min_{\mu\in M(Z)} \hat{h}(T,x,\mu). \tag{2.17}$$

Furthermore,

$$\widehat{V}(t,x) = \inf_{\mu(\cdot)\in\widehat{\mathcal{Z}}[t,T]} \|\hat{h}(s,\hat{\xi}(s),\mu(s))\|_{L^\infty[t,T]}.$$

With this theorem as motivation, we make the following definition.

DEFINITION 2.2. *The relaxed value function associated with the* L^∞ *problem is*

$$\widehat{V}(t,x) = \inf_{\mu(\cdot)\in\widehat{\mathcal{Z}}[t,T]} \|\hat{h}(s,\hat{\xi}(s),\mu(s))\|_{L^\infty[t,T]}. \tag{2.18}$$

It is also possible to prove directly that $\widehat{V}$ defined by (2.18) is the viscosity solution of (2.16) and (2.17) by using the dynamic programming principle

$$\widehat{V}(t,x) = \inf_{\mu\in\widehat{\mathcal{Z}}[t,s]} \max\{\|\hat{h}(r,\hat{\xi}(r),\mu(r))\|_{L^\infty[t,s]},\ \widehat{V}(s,\hat{\xi}(s))\}. \tag{2.19}$$

The proof is similar to that of Theorem 3.2 in [4]. However, one now uses the weakened assumption that $\hat{h}(\cdot,\cdot,\mu)$ is lower semicontinuous (with respect to weak convergence), which is proved in Lemma 3.2 below. Uniqueness of viscosity solutions is proved as in Theorem 4.2 in [4].

3. The relaxed L^∞ value: Existence of an optimal control. Having motivated the definition of the relaxed value function for the L^∞ optimal control problem, we must now establish that it is the appropriate relaxation in the sense that (i) an optimal relaxed control will exist and (ii) the relaxed value is the same as the original value function. To begin, we need some preliminary results.

LEMMA 3.1. *For each* (t,x) *fixed, the mapping*

$$\mu \in \mathcal{M}(Z) \mapsto \hat{h}(t,x,\mu)$$

is a quasiconvex function. In fact,

$$\hat{h}(t,x,\lambda\mu_1 + (1-\lambda)\mu_2) = \max\{\hat{h}(t,x,\mu_1),\hat{h}(t,x,\mu_2)\} \tag{3.1}$$

for $0 < \lambda < 1$.

Remark 3.1. A quasiconvex function is a function, say $g : X \to R^1$, X a convex set, satisfying

$$g(\lambda x + (1-\lambda)y) \leq \max\{g(x), g(y)\}, \quad 0 \leq \lambda \leq 1, \quad x, y \in X.$$

Equivalently, g is quasiconvex if the level set of g, $\{x \in X | g(x) \leq r\}$ is convex for all $r \in R^1$. This definition is not to be confused with quasiconvexity for functionals defined in the calculus of variations.

Proof. Fix $0 < \lambda < 1$, $\mu_1, \mu_2 \in \mathcal{M}(Z)$ and set $\nu = \lambda\mu_1 + (1-\lambda)\mu_2$. Then both μ_1 and μ_2 are absolutely continuous with respect to ν. Therefore,

$$\begin{aligned} \hat{h}(t,x,\nu) &= \inf\{\sup_{z \in E} h(t,x,z) : E \text{ such that } \nu(Z-E) = 0\} \\ &\geq \inf\{\sup_{z \in E} h(t,x,z) : E \text{ such that } \mu_i(Z-E) = 0\} \\ &= \hat{h}(t,x,\mu_i), \qquad i = 1,2. \end{aligned}$$

Recall that we are assuming that $h \geq 0$ to simplify matters.

On the other hand, if $\hat{h}(t,x,\nu) > \max\{\hat{h}(t,x,\mu_1), \hat{h}(t,x,\mu_2)\} \equiv a$, then there is a set $E \subset Z$ such that $\nu(E) > 0$ and $h(t,x,z) > a, \forall\, z \in E$. Therefore, either $\mu_1(E) > 0$ or $\mu_2(E) > 0$, or both, and so either $\hat{h}(t,x,\mu_1) > a$ or $\hat{h}(t,x,\mu_1) > a$, which contradicts the definition of a. □

To prove that $\hat{h}(\cdot,\cdot,\mu)$ is not actually convex in general, consider the following example.

Example. Suppose $h(z)$ is a continuous function that has the value 1 at z_1 and the value 0 at z_2. Let $0 < \lambda < 1$ and let $\mu_i = \delta(z - z_i), i = 1,2$, and $\nu = \lambda\mu_1 + (1-\lambda)\mu_2$. Then $\hat{h}(\nu) = 1$, $\hat{h}(\mu_1) = 1$, $\hat{h}(\mu_2) = 0$. Thus, $\hat{h}(\nu) > \lambda\hat{h}(\mu_1) + (1-\lambda)\hat{h}(\mu_2)$.

We will next prove the following lemma.

LEMMA 3.2. *For each (t,x) fixed,*

$$\mu \in \mathcal{M}(Z) \mapsto \hat{h}(t,x,\mu)$$

is weakly sequentially lower semicontinuous.

Proof. If this is not true, then, given $\varepsilon > 0$, there exists a $\mu^* \in \mathcal{M}(Z)$ and a sequence of measures $\{\mu_i\} \subset \mathcal{M}(Z)$ with $\mu_i \rightharpoonup \mu^*$, and sets $\{E_i\}$ such that $\mu_i(Z - E_i) = 0$ and

$$\sup_{z \in E_i} h(s,x,z) < \|h(t,x,z)\|_{L^\infty(Z;\mu^*)} - \varepsilon$$

for all large i. Set

$$F = \{z \in Z | h(s,x,z) \leq \|h(s,x,z)\|_{L^\infty(Z;\mu^*)} - \varepsilon\}.$$

F is a compact set. Then $\mu_i(Z-F) = 0$ for all i. The fact that $\mu_i \rightharpoonup \mu^*$ implies that $\liminf_{i\to\infty} \mu_i(Z-F) \geq \mu^*(Z-F)$ since $Z - F$ is open. We conclude that $\mu^*(Z-F) = 0$. Therefore,

$$\|h(t,x,z)\|_{L^\infty(Z;\mu^*)} \leq \sup_{z \in F} h(s,x,z) \leq \|h(s,x,z)\|_{L^\infty(Z;\mu^*)} - \varepsilon,$$

which is a contradiction. □

We are now ready to state the main theorem in this section.

THEOREM 3.3. *For each fixed* $(t,x) \in [0,T] \times R^n$, *there exists an optimal relaxed control* $\mu^*(\cdot) \in \widehat{\mathcal{Z}}[t,T]$.

This theorem is actually a corollary of the following more general statement, which is what we shall prove.

THEOREM 3.4. *For each* $(t,x,a) \in \Omega \equiv [0,T] \times R^n \times R^1$, *consider the set valued map*

$$\mathcal{L}(t,x,a) = \{\eta \in R^n | \eta = f(t,x,z), a \geq h(t,x,z), \exists z \in Z\}.$$

Assume condition (A) *weakened to assume that* $h(\cdot,\cdot,z)$ *is merely lower semicontinuous in* z. *If* $\mathcal{L}(t,x,a)$ *is a convex set for each* $(t,x,a) \in \Omega$, *then for any initial position* $(t_0,x_0) \in [0,T] \times R^n$, *there exists an optimal control* $\zeta^* \in \mathcal{Z}[t_0,T]$ *and an associated optimal trajectory* ξ^*, *with* $\xi^*(t_0) = x_0$, *for the* $L^\infty[t_0,T]$ *problem* (2.4).

Proof. Under our assumptions on f and h, $\mathcal{L}$ is upper semicontinuous and upper semicontinuous with respect to set inclusion.

To verify the last statement, pick a point $(t_0,x_0,a_0) \in \Omega$. We have to show that given $\varepsilon > 0$, there is $\delta > 0$ such that $\mathcal{L}(t,x,a) \subset [\mathcal{L}(t_0,x_0,a_0)]_\varepsilon$ for all $(t,x,a) \in B_\delta(t_0,x_0,a_0)$. Here $[A]_\varepsilon$, for any set A, is the set of points whose distance from A is $\leq \varepsilon$.

Suppose this is not the case. Then there exists $\varepsilon > 0$, a sequence of points $(t_k,x_k,a_k) \to (t_0,x_0,a_0)$, $k \to \infty$, and $\eta_k \in \mathcal{L}(t_k,x_k,a_k)$ so that $d(\eta_k, \mathcal{L}(t_0,x_0,a_0)) \geq \varepsilon$. We use the notation that $d(x,A)$ is the distance from the point x to the set A. Now, $\eta_k = f(t_k,x_k,z_k)$ and $a_k \geq h(t_k,x_k,z_k)$ for each $k = 1,2,\ldots$, for some $z_k \in Z$. Since Z is compact, $z_k \to z^*$ on a subsequence, still denoted $\{k\}$. Passing to limits and using the lower semicontinuity of $h(\cdot,\cdot,z)$, we obtain $\eta_0 \equiv f(t_0,x_0,z^*)$ and $a_0 \geq h(t_0,x_0,z^*)$, which implies that $\eta_0 \in \mathcal{L}(t_0,x_0,a_0)$, which is a contradiction.

Now, let (ζ_k, ξ_k) be a minimizing sequence, with $\xi_k(t_0) = x_0$, $k = 1,2,\ldots$. Then,

$$\|h(s,\xi_k(s),\zeta_k(s))\|_{L^\infty[t_0,T]} \to V \equiv V(t_0,x_0),$$

and, on a subsequence $\{k\}$, $\xi_k \to \xi^*$ uniformly and $d\xi_k/d\tau \rightharpoonup d\xi^*/d\tau$ weakly on $[t_0,T]$.

We claim that there is a measurable function $\lambda(\tau)$ satisfying $\|\lambda(\tau)\|_{L^\infty[t_0,T]} \leq V$ and $d\xi^*/d\tau \in \mathcal{L}(\tau,\xi^*(\tau),V)$ for almost all $\tau \in [t_0,T]$.

To see this, since $d\xi_k/d\tau \rightharpoonup d\xi^*/d\tau$ by Mazur's lemma, for every j there exists an integer n_j, a set of integers $i = 1,2,\ldots,k$, a set of nonnegative numbers $\alpha_{1j},\ldots,\alpha_{kj}$, with $\sum_{i=1}^k \alpha_{ij} = 1$, such that, $n_{j+1} > n_j + k$, and, if we define

$$y_j(\tau) = \sum_{i=1}^k \alpha_{ij} \frac{d\xi_{n_j+i}}{d\tau},$$

then $y_j(\tau) \to d\xi^*/d\tau$ for a.e. $\tau \in [t_0,T]$. We are not distinguishing between convergence on a subsequence. Now define

$$\lambda_j(\tau) = \max_{1 \leq i \leq k} h(\tau, \xi_{n_j+i}(\tau), \zeta_{n_j+i}(\tau)),$$

and

$$\lambda(\tau) \equiv \liminf_{j \to \infty} \lambda_j(\tau).$$

By lower semicontinuity,

$$\|\lambda(\tau)\|_{L^\infty[t_0,T]} \leq \liminf_{j\to\infty} \max_{1 \leq i \leq k} \|h(\tau,\xi_{n_j+i}(\tau),\zeta_{n_j+i}(\tau))\|_{L^\infty[t_0,T]} = V.$$

Set

$$\sigma_j(\tau) = \sum_{i=1}^{k} \alpha_{ij} f(\tau, \xi^*(\tau), \zeta_{n_j+i}(\tau)), \qquad \vartheta_j(\tau) = \max_{1\le i\le k} h(\tau, \xi^*(\tau), \zeta_{n_j+i}(\tau)).$$

Then, since $\xi_k \to \xi^*$ uniformly in τ, by assumption (A) it follows that on a subsequence, $\vartheta_j(\tau) \to \lambda(\tau)$, and $\sigma_j(\tau) \to d\xi^*/d\tau$ for a.e. $\tau \in [t_0, T]$. Therefore, we have that

$$f(\tau, \xi^*(\tau), \zeta_{n_j+i}(\tau)) \in \mathcal{L}(\tau, \xi^*(\tau), \vartheta_j(\tau)) \text{ a.e. } \tau \in [t_0, T].$$

Since, for τ fixed, $\mathcal{L}(\tau, \xi^*(\tau), \vartheta_j(\tau))$ is a convex set, $\sigma_j(\tau) \in \mathcal{L}(\tau, \xi^*(\tau), \vartheta_j(\tau))$. By upper semicontinuity, since $\sigma_j \to d\xi^*/d\tau$ and $\vartheta_j \to \lambda$, $d\xi^*/d\tau \in \mathcal{L}(\tau, \xi^*(\tau), \lambda(\tau))$, for a.e. $\tau \in [t_0, T]$. Hence ([5], p. 94), there is a measurable map $\zeta^* \in \mathcal{Z}[t_0, T]$, such that $d\xi^*/d\tau = f(\tau, \xi^*(\tau), \zeta^*(\tau))$ and $\lambda(\tau) \ge h(\tau, \xi^*(\tau), \zeta^*(\tau))$, a.e. $\tau \in [t_0, T]$. But $V(t_0, x_0) \ge \|\lambda(\tau)\|_{L^\infty[t_0,T]}$, and we conclude that (ζ^*, ξ^*) is optimal. □

Remark 3.2. The proof of this theorem is adapted from that in [5, Thms. 4.1 and 8.1].

Remark 3.3. The proof of Theorem 3.3 is immediate by noting that $\hat{f}(\cdot, \cdot, \mu)$ is linear and $\hat{h}(\cdot, \cdot, \mu)$ is quasiconvex.

We conclude this section by giving a result that shows that quasiconvexity of h in z is a necessary condition for weak lower semicontinuity of L^∞ functionals in the calculus of variations. The proof is adapted from [6, pp. 105–107]. The analogous result for classical variational problems is that *convexity* is necessary for weak lower semicontinuity of integral functionals [6, p. 104]. Under coercivity assumptions on $h(\cdot, \cdot, z)$, the converse is also true [6, p. 112].

THEOREM 3.5. *Let Z be R^n and assume that $h(t, x, z)$ is continuous and that $f(t, x, z) = z$. Then, considering the functional $I[\xi] \equiv \|h(s, \xi(s), \xi'(s))\|_{L^\infty[a,b]}$ in the class of absolutely continuous functions, if $I[\xi]$ is weakly lower semicontinuous for each fixed $0 \le a < b \le T$, then $h(t, x, z)$ is quasiconvex in z for each (t, x).*

Proof. Suppose that $h(t_0, x_0, z)$ is not quasiconvex in z with $t_0 \in (0, T)$. Then, there is a $\sigma > 0$ and a convex combination $z_0 = \sum_{i=1}^m \lambda_i z_i, z_i \in R^n, i = 1, \ldots, m, \lambda_i \ge 0, \sum_{i=1}^m \lambda_i = 1$, such that

$$h(t_0, x_0, z_0) \ge \max_{1\le i\le m} h(t_0, x_0, z_i) + \sigma. \tag{3.2}$$

Pick $\delta > 0$ such that $t_0 + \delta < T$ and $|h(t, x, z_i) - h(t_0, x_0, z_i)| < \sigma/3$ for $i = 0, 1, \ldots, m$, if $(t, x) \in B_\delta(t_0, x_0)$. Set $\gamma = \delta$ if $|z_0| \le 1/2$ and $\gamma = \delta/(2|z_0|)$ if $|z_0| > 1/2$.

Consider the trajectory on $[t_0, t_0 + \gamma]$ corresponding to the constant control $\zeta_0(\tau) \equiv z_0$ given by $\xi_0(\tau) = x_0 + z_0(\tau - t_0)$. Now, construct a sequence of trajectories $\xi_k(\cdot)$ on $[t_0, t_0 + \gamma]$ emanating from x_0 such that $d\xi_k(\tau)/d\tau = z_r$ if

$$\tau \in \left[t_0 + \left(j + \sum_{i=1}^{r-1} \lambda_i\right) \frac{\gamma}{k}, t_0 + \left(j + \sum_{i=1}^{r} \lambda_i\right) \frac{\gamma}{k}\right], \qquad r = 1, 2, \ldots, m$$

for each $j = 0, 1, \ldots, k$. Then [6, p. 106], $\xi_k(\tau) \to \xi_0(\tau)$ uniformly and at least on a subsequence, $d\xi_k(\tau)/d\tau \rightharpoonup d\xi_0(\tau)/d\tau$ a.e. as $k \to \infty$. Set $\tau_{jr} = t_0 + (j + \sum_{i=1}^r \lambda_i)\frac{\gamma}{k}$, $r = 1, \ldots, m, j = 0, \ldots, k$. For all k sufficiently large, $\xi_k(\tau) \in B_\delta(\xi_0(\tau))$. Now we estimate

$$\begin{aligned}
I[\xi_k] &= \|h(\tau, \xi_k(\tau), \xi_k'(\tau))\|_{L^\infty[t_0, t_0+\gamma]} \\
&= \max_{1 \le j \le k} \max_{1 \le r \le m} \|h(\tau, \xi_k(\tau), z_r)\|_{L^\infty[t_{j-1,r-1}, t_{j-1,r-1} + \gamma \frac{\lambda r}{k}]} \\
&\le \max_{1 \le j \le k} \max_{1 \le r \le m} \|h(t_0, x_0, z_r)\| + \frac{\sigma}{3} \\
&\le \max_{1 \le j \le k} h(t_0, x_0, z_0) - \sigma + \frac{\sigma}{3} \quad \text{(by (3.2))} \\
&= h(t_0, x_0, z_0) - \frac{2\sigma}{3} \\
&\le \max_{1 \le j \le k} \|h(\tau, \xi_0(\tau), z_0)\|_{L^\infty\left[t_0 + \frac{(j-1)\gamma}{k}, t_0 + \frac{j\gamma}{k}\right]} + \frac{\sigma}{3} - \frac{2\sigma}{3} \\
&= \|h(\tau, \xi_0(\tau), \xi_0'(\tau))\|_{L^\infty[t_0, t_0+\gamma]} - \frac{\sigma}{3} \\
&= I[\xi_0] - \frac{\sigma}{3}.
\end{aligned}$$

This contradicts the assumed weak lower semicontinuity of I. □

4. Relaxed value = original value: $\widehat{V} = V$. The final goal is to establish that the relaxed value and original value coincide. To do that, we prove that $\widehat{V}$, which is a viscosity solution of the relaxed Bellman equation (2.16), is also a viscosity solution of the original Bellman equation (2.5). We must also show that $\widehat{V}$ satisfies the terminal condition (2.6). Then uniqueness of viscosity solutions will yield the result.

Define the relaxed hamiltonian

$$\hat{H}(t, x, r, p) = \min_{\{\mu \in \mathcal{M}(Z) | \hat{h}(t,x,\mu) \le r\}} p \cdot \hat{f}(t, x, \mu). \tag{4.1}$$

THEOREM 4.1. *$V(t, x) \equiv \widehat{V}(t, x)$ on $[0, T] \times R^n$.*

Proof. Consider first $t = T$. We have that

$$\begin{aligned}
\widehat{V}(T, x) &= \min_{\mu \in \mathcal{M}(Z)} \hat{h}(T, x, \mu) \\
&= \min_{\mu \in \mathcal{M}(Z)} \|h(T, x, z)\|_{L^\infty(Z; \mu)} \\
&\le \min_{z \in Z} h(T, x, z) = V(T, x).
\end{aligned}$$

The last inequality is true by choosing $z = z_0 \in Z$ arbitrarily and letting $\mu = \delta(z - z_0)$. The inequality $\widehat{V}(T, x) \ge V(T, x)$ follows from

$$\widehat{V}(T, x) = \min_{\mu \in \mathcal{M}(Z)} \hat{h}(T, x, \mu) = \min_{\mu \in \mathcal{M}(Z)} \|h(T, x, z)\|_{L^\infty(Z; \mu)} \ge \min_{z \in Z} h(T, x, z).$$

Therefore, $\widehat{V}(T, x) = V(T, x)$.

Similarly,

$$\min_{\mu \in \mathcal{M}(Z)} \hat{h}(t, x, \mu) = \min_{z \in Z} h(t, x, z). \tag{4.2}$$

We show next that $\hat{H}(t, x, r, p) = H(t, x, r, p)$, i.e.,

$$\min_{\{\mu \in \mathcal{M}(Z) | \hat{h}(t,x,\mu) \le r\}} p \cdot \hat{f}(t, x, \mu) = \min_{\{z \in Z | h(t,x,z) \le r\}} p \cdot f(t, x, z). \tag{4.3}$$

First, it is clear that the set $\{\mu \in \mathcal{M}(Z) | \hat{h}(t,x,\mu) \le r\}$ is nonempty if and only if the set $\{z \in Z | h(t,x,z) \le r\}$ is nonempty. Without loss of generality, we may assume the sets are nonempty since otherwise the hamiltonians are both $+\infty$. Now, $\hat{H}(t,x,r,p) \le H(t,x,r,p)$ since, for each z_0 such that $h(t,x,z_0) \le r$, we can let $\mu = \delta(z - z_0)$. To see the opposite inequality, let $\varepsilon > 0$ be given and $\mu^* \in \mathcal{M}(Z)$ satisfy

$$\hat{H}(t,x,r,p) \ge p \cdot \hat{f}(t,x,\mu^*) - \varepsilon = \int_Z p \cdot f(t,x,z)\mu^*(dz) - \varepsilon$$

and $\|h(t,x,z)\|_{L^\infty(Z;\mu^*)} \le r$. Let $B = \{z \in Z | h(t,x,z) \le r\}$. Then $\mu^*(B) = 1, \mu^*(B^c) = 0$ and

$$\begin{aligned} \hat{H}(t,x,r,p) &\ge \int_Z p \cdot f(t,x,z)\mu^*(dz) - \varepsilon \\ &= \int_B p \cdot f(t,x,z)\mu^*(dz) + \int_{B^c} p \cdot f(t,x,z)\mu^*(dz) - \varepsilon \\ &= \int_B p \cdot f(t,x,z)\mu^*(dz) - \varepsilon \\ &\ge \min_{z\in B} p \cdot f(t,x,z) - \varepsilon = H(t,x,r,p) - \varepsilon. \end{aligned}$$

Therefore, (4.3) is true. Combining (4.3) and (4.2), we conclude that $\widehat{V}$ and V both satisfy the Bellman equation (2.5) (in the viscosity sense) and the terminal condition (2.6). Uniqueness of viscosity solutions then yields that $\widehat{V}$ and V are the same function. □

Remark 4.1. A terminal cost can also be included in the results of this paper by considering the value function

$$V(t,x) = \inf_{\zeta \in \mathcal{Z}[t,T]} \max\{\|h(s,\xi(s),\zeta(s))\|_{L^\infty[t,T]}, g(\xi(T))\}.$$

In this case, V satisfies the same Bellman equation but now satisfies the terminal condition

$$V(T,x) = \max\{\min_{z\in Z} h(T,x,z), g(x)\}.$$

This problem is relaxed exactly as before.

We conjecture that when we allow lower semicontinuous terminal data g, the corresponding relaxed value function coincides with the lower semicontinuous envelope of the unrelaxed value function. Furthermore, the relaxed value function will be the unique lower semicontinuous solution of Eq. (2.5) achieving the lower semicontinuous data g. This is analogous to the classical problem considered in [3].

Remark 4.2. A formulation of the relaxed problem using chattering controls is the following:

$$\widehat{V}(t,x) = \inf_{\alpha(\cdot),\zeta(\cdot)} \|\max_i h(\tau,\xi(\tau),\zeta(\tau))\|_{L^\infty[t,T]},$$

where, $\alpha = \{\alpha_i\}_{i=1}^{n+2}$, $\alpha_i = \alpha_i(\tau) \ge 0$, $\sum_{i=1}^{n+2} \alpha_i = 1$, $\zeta = \{\zeta_i\}_{i=1}^{n+2}$, with $\zeta_i \in \mathcal{Z}[t,T]$. The max is taken over all $1 \le i \le n+2$ for which $\alpha_i(\tau) \ne 0$, and

$$\frac{d\xi}{d\tau} = \sum_{i=1}^{n+2} \alpha_i(\tau) f(\tau,\xi(\tau),\zeta_i(\tau)), \qquad \xi(t) = x.$$

Refer to [5] for chattering controls for classical problems.

SENSITIVITY ANALYSIS IN NONLINEAR PROGRAMS AND VARIATIONAL INEQUALITIES VIA CONTINUOUS SELECTIONS*

JIMING LIU[†]

Abstract. Sufficient conditions for solution Lipschitz continuity, piecewise differentiability, and directional differentiability are presented for parametric nonlinear programs and variational inequalities using the idea of continuous selections. The gaps between the sufficient conditions obtained here and the weakest possible conditions for the corresponding conclusions are discussed and measured by known regularity conditions.

Key words. nonlinear program, variational inequality problem, sensitivity analysis, continuous selection, Lipschitz continuity, piecewise differentiability, directional differentiability, perturbed solution

AMS subject classifications. Primary, 90C30; Secondary, 49A29, 49B50

1. Introduction.

This paper deals with sensitivity analysis for parametric nonlinear programming (NLP) problems of the form

$$\text{NLP}(\varepsilon) \qquad \underset{x}{\text{minimize}}\ f(x,\varepsilon), \quad \text{s.t. } x \in K(\varepsilon),$$

as well as for parametric variational inequality (VI) problems of the form

$$\text{VI}(\varepsilon) \qquad \text{find } x \in K(\varepsilon) \quad \text{such that } F(x,\varepsilon)^{\mathrm{T}}(x'-x) \geq 0 \text{ for any } x' \in K(\varepsilon),$$

where $K(\varepsilon) = \{x \in R^n : g(x,\varepsilon) \in R^p_- \times \{0\}^q\}$, f, F, and g are functions from $R^n \times R^t$ to R, R^n, and R^{p+q}, respectively, and $\varepsilon \in R^t$ is a perturbation parameter. We always consider that $\varepsilon_0 \in R^t$ is a fixed parameter and that NLP(ε_0) or VI(ε_0) is the original nonlinear program or variational inequality problem, while NLP(ε) or VI(ε) is the perturbed version of NLP(ε_0) or VI(ε_0).

The basic theory and computational aspects of sensitivity analysis in nonlinear programming can be found in the pioneering work of Fiacco [2]. For recent developments in this field the reader may consult Fiacco and Liu [3]. In his seminal paper on the generalized equation, Robinson [29] introduced a key notion of strong regularity and proved that if the linear independence condition and strong second-order sufficient condition hold at a stationary point of a nonlinear program, then the perturbed stationary point and its associated multiplier are single-valued locally Lipschitz functions of the perturbation parameter. At nearly the same time a similar result, without the Lipschitz continuity, was established by Kojima [13] under the Mangasarian–Fromovitz constraint qualification and general strong second-order sufficient condition as part of his investigation of strong stability. Shortly afterward, Robinson [30] obtained the upper Lipschitz continuity of the perturbed stationary point and multiplier, assuming the Mangasarian–Fromovitz constraint qualification and general second-order sufficient condition. In view of these results, Robinson [30] proposed a very natural question: can one find an appropriate combination of a constraint qualification (weaker than linear independence) and a second-order condition, under which the perturbed stationary point or local solution will be a single-valued locally Lipschitz function? He also gave an example to show that under a constraint qualification stronger than the Mangasarian–Fromovitz constraint qualification and the strongest possible second-order condition, the answer to the question is no. The first purpose of the present research is to attempt to answer this question; we show that under the assumptions of the Mangasarian–Fromovitz constraint qualification and constant

rank constraint qualification as well as the general strong second-order sufficient condition, the answer is yes.

The second purpose of this research stems from a recent study Liu and Falk [24] that is concerned with nonlinear two-level optimization problems. An approach in which ascent methods are used in the upper-level problem with gradient information from the lower-level problem is proposed and investigated. In the present paper we sharpen the classical results of Jittorntrum [7] and Robinson [31] concerning the directional differentiability of the perturbed local solution of a nonlinear program and the obtained results play an important role in [24].

The third motivation for this paper, along another closely related direction, comes from a most recent work of Kyparisis [19] in which he extended the solution directional differentiability result of Jittorntrum [7] in nonlinear programming to nonlinear programs and variational inequality problems with nonunique multipliers under the assumption of constant rank constraint qualification and some other standard assumptions. We observed that in terms of solution directional differentiability, the rank assumption imposed on those inequality constraints with zero multipliers can be dropped without losing the solution directional differentiability so that the assumptions used in [19] can be weakened.

Parallel to the stability and sensitivity developments in nonlinear programs, the stability and sensitivity theory for variational inequalities has been expanding rapidly after Robinson's work [29], [30] on the generalized equation. The results obtained before 1990 have been surveyed in Kyparisis [18]. More recent advances can be found in Robinson [32], [33]; Kyparisis [20]; King and Rockafellar [11]; Gowda and Pang [4]; Pang [27]; Mordukhovich [26] and Liu [21]–[23]. As with nonlinear programs, we investigate the sensitivity issue in variational inequalities and parallel conclusions are obtained.

The overall approach of the paper is via continuous selections to obtain sensitivity results. The idea of continuous selections in sensitivity analysis study has appeared in many papers, including Jittorntrum [7]; Dontchev and Jongen [1]; Jongen, Moebert, and Tammer [8]; Jongen, Wetterling, and Zwier [9]; Jongen, Twilt, and Weber [10]; Kyparisis [19]; Kummer [15]; and Klatte [12].[1] This idea is elaborated on and systematized to some extent here. Some results concerning Lipschitz continuity, piecewise differentiability, and directional differentiability of a function that is continuously selected from a finite number of other "better" functions are provided in §2.

In §3 we concentrate on sensitivity analysis of nonlinear programs. Continuous selection results for the perturbed local solution under the Mangasarian–Fromovitz constraint qualification and general strong second-order sufficient condition are established first. Then various sensitivity results can be obtained that not only sharpen some classical sensitivity results but provide new conditions for the Lipschitz continuity, piecewise differentiability, and directional differentiability of the perturbed local solution. Parallel development for variational inequality problems is made in §4. Similar to those in §3 we give continuous selection theorems for the perturbed stationary point under the Mangasarian–Fromovitz constraint qualification and general strong second-order condition and conclude then with several sensitivity results concerning Lipschitz continuity, piecewise differentiability, and directional differentiability of the perturbed stationary point in variational inequalities.

2. Lipschitz continuity, piecewise differentiability, and directional differentiability of a continuous selection.

In order to obtain the main results of the paper, we provide in this section some results concerning Lipschitz continuity, piecewise differentiability, and directional differentiability of a continuous selection.

[1] Several references cited here were brought to our attention by a referee. Also, this referee pointed out that the whole theory of implicit function theorems for nonlinear programs essentially uses the idea of continuous selections.

We shall first define precisely what we mean by piecewise differentiability. Let K be a collection of a finite number of closed convex polyhedral cones σ. K is said to be a subdivision of R^t if the union of all σ in K is R^t and for every pair of σ_1 and σ_2 in K with $\sigma_1 \cap \sigma_2 \neq \emptyset$, $\sigma_1 \cap \sigma_2$ is a common face of σ_1 and σ_2. Each $\sigma \in K$ is called a piece of K.

Let $\varepsilon_0 \in R^t$ and $N \subset R^t$ be a neighborhood of ε_0. We say that a continuous function $x(\cdot) : N \rightarrow R^n$ is piecewise differentiable at ε_0 if there exists a subdivision K of R^t such that for each piece σ of K, there are a neighborhood $U \subset N$ of ε_0 and a function $y(\cdot) \in C^1(U) : U \rightarrow R^n$ satisfying

$$x(\varepsilon_0 + d) = y(\varepsilon_0 + d) + o(d) \quad \text{for all } d \in \sigma.$$

Intuitively, a piecewise differentiable function $x(\cdot)$ at ε_0 is a result of locally bending a C^1 function at ε_0 along some faces of a subdivision K.

By definition it is obvious that if $x(\cdot)$ is piecewise differentiable at ε_0, then it is directionally differentiable at ε_0 along any direction d. It is also true that piecewise differentiability is a stronger property than the B-differentiability introduced in Robinson [31], which in turn is stronger than directional differentiability. To see this, let $Dx(\varepsilon_0; d)$ denote the directional derivative of $x(\cdot)$ at ε_0 in any direction d. According to [31] $x(\cdot)$ is said to be B-differentiable at ε_0 if one has

$$x(\varepsilon_0 + d) = x(\varepsilon_0) + Dx(\varepsilon_0; d) + o(d).$$

It is easy to see that if in addition the homogeneous function $Dx(\varepsilon_0; d)$ is piecewise linear (see Kojima [13]), i.e., there is a subdivision K such that $Dx(\varepsilon; d)$ is a linear function of d when restricted on a piece $\sigma \in K$, then $x(\cdot)$ is piecewise differentiable at ε_0. Hence B-differentiability does not imply piecewise differentiability.

An abstract and elegant Lipschitz continuous selection result was obtained in Hager [5] which we state first. Suppose that Z is a Banach space, D is a convex subset of a Banach space, and $x : D \rightarrow Z$ is a continuous function. Furthermore, suppose $I : D \rightarrow 2^{\{1,\ldots,m\}}$ (the power set of $\{1, \ldots, m\}$) has the following property:

(2.1) If $\{z_i\} \subset D$ with $z_i \rightarrow z \in D$ as $i \rightarrow \infty$ and $J \subset I(z_i)$ for all i, then $J \subset I(z)$.

The points z', $z^* \in D$ are called compatible if $I(z') = I(z^*)$ and $I(z) \subset I(z')$ for all $z \in [z', z^*]$ (the line segment joining z' and z^*).

PROPOSITION 2.1 (Hager [5]). *If λ satisfies*

$$\|x(z') - x(z^*)\|_Z \leq \lambda \|z' - z^*\|_D \tag{2.2}$$

for all compatible z', $z^* \in D$, then λ satisfies (2.2) *for all z', $z^* \in D$.*

Specifying it to our case, we obtain the following proposition that is a simple extension of a result in Dontchev and Jongen [1].

PROPOSITION 2.2. *Let $\varepsilon_0 \in R^t$ and $B(\varepsilon_0; r) = \{\varepsilon \in R^t : \|\varepsilon - \varepsilon_0\| < r\}$, where r is a positive number, and let $x_i : B(\varepsilon_0; r) \rightarrow R^n$ be a Lipschitz continuous function with Lipschitz constant λ_i, $i = 1, \ldots, m$. Suppose $x : B(\varepsilon_0; r) \rightarrow R^n$ is a continuous function such that for all $\varepsilon \in B(\varepsilon_0; r)$, $x(\varepsilon) = x_i(\varepsilon)$ for some $i \in \{1, \ldots, m\}$. Then x is Lipschitz continuous with Lipschitz constant $\lambda :=$* $\max\{\lambda_i : i = 1, \ldots, m\}$.

Proof. See the proof of Theorem 2.2 in Dontchev and Jongen [1]. □

Similarly, we have the following result for piecewise differentiability and directional differentiability of a continuous selection. It was pointed out by a referee that this result is closely related to Kummer's theorem [14] on the representation of the Clarke subdifferential.

We say that a continuous function $x(\cdot)$ is directionally differentiable at ε_0 of order p along a direction d if there are vectors $Dx(\varepsilon_0; d)$, $D^2x(\varepsilon_0; d), \ldots, D^px(\varepsilon_0; d)$ such that for scalar $s \geq 0$

$$x(\varepsilon_0 + sd) = x(\varepsilon_0) + sDx(\varepsilon_0; d) + \frac{1}{2!}s^2D^2x(\varepsilon_0; d) + \cdots + \frac{1}{p!}s^pD^px(\varepsilon_0; d) + o(s^p).$$

THEOREM 2.3. *Let $\varepsilon_0 \in R^t$ and $B(\varepsilon_0; r) = \{\varepsilon \in R^t : \|\varepsilon - \varepsilon_0\| < r\}$, where r is a positive number, and let $x_i \in C^p : B(\varepsilon_0; r) \to R^n$, $i = 1, \ldots, m$, with integer $p \geq 1$. Suppose $x : B(\varepsilon_0; r) \to R^n$ is a continuous function selected from $\{x_i\}$, i.e., for all $\varepsilon \in B(\varepsilon_0; r)$, $x(\varepsilon) = x_i(\varepsilon)$ for some $i \in \{1, \ldots, m\}$. Then x is piecewise differentiable at ε_0 and directionally differentiable at ε_0 of order p along any direction d. Furthermore, the directional derivatives $D^qx(\varepsilon_0; d)$ of order $q \leq p$ as functions of d are Lipschitzian and $D^qx(\varepsilon_0; d) = D^qx_i(\varepsilon_0; d)$ for some i.*

Proof. We show first that x is directionally differentiable at ε_0 of order p along any given direction d. Let $I(d) := \{i : i \in \{1, \ldots, m\}$ and there is a sequence $\{s_j\}$ with $s_j \downarrow 0$ such that $x(\varepsilon_0 + s_jd) = x_i(\varepsilon_0 + s_jd)\}$. Obviously $I(d) \neq \emptyset$. We claim that for any k, $q \in I(d)$, we have that $Dx_k(\varepsilon_0; d) = Dx_q(\varepsilon_0; d)$, $D^2x_k(\varepsilon_0; d) = D^2x_q(\varepsilon_0; d), \ldots, D^px_k(\varepsilon_0; d) = D^px_q(\varepsilon_0; d)$. Then it follows that x is directionally differentiable at ε_0 of order p and $D^qx(\varepsilon_0; d) = D^qx_i(\varepsilon_0; d)$ for any $i \in I(d)$ and $1 \leq q \leq p$. Without loss of generality we may assume that when restricted on $[0, r']$ for some small $r' > 0$, $x(s) = x(\varepsilon_0 + sd)$ is continuously selected from $\{x_i(s) = x_i(\varepsilon_0 + sd) : i \in I(d)\}$. To prove the assertion claimed above, we define $R_i = \{s : 0 \leq s \leq r'$ and $x(s) = x_i(s)\}$ for any $i \in I(d)$. From the continuity of x and x_i it follows that each R_i is a closed set. Define a relation $\sim$ in $I(d)$ such that $\nu \sim \ell$ if there is a sequence $\{s_j\}$ with $s_j \downarrow 0$ satisfying both $\{s_j\} \subset R_\nu$ and $\{s_j\} \subset R_\ell$.

Suppose now $\nu \sim \ell$. Then by definition there is a sequence $\{s_j\}$ with $s_j \downarrow 0$ such that $\{s_j\} \subset R_\nu$ and $\{s_j\} \subset R_\ell$. Since x_ν and x_ℓ are in C^p, we find from $\{s_j\} \subset R_\nu$ and $\{s_j\} \subset R_\ell$ that

$$\begin{aligned} x(\varepsilon_0 + s_jd) &= x(\varepsilon_0) + s_jDx_\nu(\varepsilon_0; d) + \frac{1}{2!}s_j^2D^2x_\nu(\varepsilon_0; d) + \cdots + \frac{1}{p!}s_j^pD^px_\nu(\varepsilon_0; d) + o(s^p) \\ &= x(\varepsilon_0) + s_jDx_\ell(\varepsilon_0; d) + \frac{1}{2!}s_j^2D^2x_\ell(\varepsilon_0; d) + \cdots + \frac{1}{p!}s_j^pD^px_\ell(\varepsilon_0; d) + o(s^p). \end{aligned}$$

Then it follows from $s_j \downarrow 0$ and the above relation that

$$\begin{gathered} Dx_\nu(\varepsilon_0; d) = Dx_\ell(\varepsilon_0; d), \\ D^2x_\nu(\varepsilon_0; d) = D^2x_\ell(\varepsilon_0; d), \ldots, D^px_\nu(\varepsilon_0; d) = D^px_\ell(\varepsilon_0; d). \end{gathered} \tag{2.3}$$

Furthermore, note that for any pair k, $q \in I(d)$, since $[0, r'] = \cup_{i \in I(d)} R_i$, there is a chain such that $k \sim \ell_1$, $\ell_1 \sim \ell_2, \ldots, \ell_{h-1} \sim \ell_h$, $\ell_h \sim q$. So the desired assertion follows from (2.3).

We have proved that x is directionally differentiable at ε_0 of order p along any direction d. Note that using (2.3) and the continuity of x it is not hard to show that for $1 \leq q \leq p$ the q times directional derivative $D^qx(\varepsilon_0; d)$ is continuously selected from the directional derivatives $\{D^qx_i(\varepsilon_0; d) : i = 1, \ldots, m\}$. Since each x_i is continuously differentiable at ε_0 of order p, we find from calculus (see Marlow [25, p. 202]) that

$$D^qx_i(\varepsilon_0; d) = \nabla_\varepsilon^q x_i(\varepsilon_0)d \ldots d,$$

which is Lipschitzian as a function of d. Then from Proposition 2.2 we conclude that $D^qx(\varepsilon_0; d)$ is Lipschitzian for each $1 \leq q \leq p$.

Now what we have left is to show that x is piecewise differentiable at ε_0, i.e., the directional derivative $Dx(\varepsilon_0; d)$ as a function of d is actually piecewise linear. Let $A_i = \nabla_\varepsilon x_i(\varepsilon_0)$ for $i = 1, \dots, m$. Each A_i is an n-by-t matrix. Denote the ℓth row of A_i by A_i^ℓ. For each direction d define $J(d) = \{i : i \in \{1, \dots, m\}$ and $Dx(\varepsilon_0; d) = A_i d\}$. We shall construct a subdivision K of R^t such that for each $\sigma \in K$ there exists some $i \in \{1, \dots, m\}$, $Dx(\varepsilon_0; d) = A_i d$ for all $d \in \sigma$. Note that for each direction d the relations between $Dx(\varepsilon_0; d)$ and $A_i d$, $i = 1, \dots, m$, are such that for any $i \in J(d)$, any $j \in J(d)\backslash\{i\}$, and any $1 \le \ell \le n$, one has

$$A_i^\ell d = A_j^\ell d.$$

For any $i \in J(d)$, any $j \in \{1, \dots, m\}\backslash J(d)$, there exists some ℓ, $1 \le \ell \le n$, and one has

$$\text{either } A_i^\ell d < A_j^\ell d \quad \text{or} \quad A_i^\ell d > A_j^\ell d.$$

According to the above relationship we can construct a set $\text{Rel}(d)$ for each direction d in the following way. For any $i \in J(d)$, any $j \in J(d)\backslash\{i\}$, and any $1 \le \ell \le n$,

$$\text{put } (i, j, \ell, =) \text{ into } \text{Rel}(d).$$

For any $i \in J(d)$, any $j \in \{1, \dots, m\}\backslash J(d)$, and any $1 \le \ell \le n$,

$$\begin{aligned} &\text{put } (i, j, \ell, =) \text{ into } \text{Rel}(d) \text{ if } A_i^\ell d = A_j^\ell d; \\ &\text{put } (i, j, \ell, \le) \text{ into } \text{Rel}(d) \text{ if } A_i^\ell d \le A_j^\ell d; \\ &\text{put } (i, j, \ell, \ge) \text{ into } \text{Rel}(d) \text{ if } A_i^\ell d \ge A_j^\ell d. \end{aligned}$$

In this way we have obtained finitely many different sets, say, $\text{Rel}_1, \text{Rel}_2, \dots, \text{Rel}_L$. For each Rel_k, $1 \le k \le L$, define a convex polyhedral cone as follows:

$$\begin{aligned} \sigma(k) = \{z \in R^t : \quad & A_i^\ell z = A_j^\ell z \text{ if } (i, j, \ell, =) \in \text{Rel}_k; \\ & A_i^\ell z \le A_j^\ell z \text{ if } (i, j, \ell, \le) \in \text{Rel}_k; \\ & A_i^\ell z \ge A_j^\ell z \text{ if } (i, j, \ell, \ge) \in \text{Rel}_k\}. \end{aligned}$$

Then it is not difficult to see that $K = \cup_{k \in \{1, \dots, L\}} \sigma(k)$ forms a subdivision of R^t.

At this point what remains is to show that for each $\sigma(k) \in K$ we have that $Dx(\varepsilon_0; d) = A_i d$ for all $d \in \sigma(k)$ with some $i \in \{1, \dots, m\}$. Given a $\sigma(k) \in K$ that is defined by Rel_k, from the construction of K we know that there exists at least one direction d whose $\text{Rel}(d)$ is equal to Rel_k. Take any $i \in J(d)$. Obviously $Dx(\varepsilon_0; d) = A_i d$. We shall show that $Dx(\varepsilon_0; d') = A_i d'$ for all $d' \in \sigma(k)$ by contraposition. Suppose the contrary, i.e., there is a $d' \in \sigma(k)$ such that $Dx(\varepsilon_0; d') \ne A_i d'$. Let $d(\lambda) = (1 - \lambda)d + \lambda d'$. Define

$$\delta' = \max\{\delta : \delta \in [0, 1] \quad \text{such that } Dx(\varepsilon_0; d(\lambda)) = A_i d(\lambda) \text{ for } \lambda \in [0, \delta]\}.$$

The intuitive explanation of δ' is that $Dx(\varepsilon_0; d(\lambda))$ takes the value of $A_i d(\lambda)$ for λ from 0 to δ' and then switches to some other $A_j d(\lambda)$ such that $j \notin J(d)$ right after δ', i.e., there is a sequence $\{\lambda_h\} \downarrow \delta'$ such that $Dx(\varepsilon_0; d(\lambda_h)) = A_j d(\lambda_h)$. The existence of such j and $\{\lambda_h\}$ can be proved because otherwise we would have $Dx(\varepsilon_0; d') = A_i d'$, which contradicts our assumption. By continuity we find that

$$A_i d(\delta') = A_j d(\delta'). \tag{2.4}$$

Since $j \notin J(d)$, this means that there exists at least one ℓ, $1 \le \ell \le n$, such that either $A_i^\ell d < A_j^\ell d$ or $A_i^\ell d > A_j^\ell d$. Without loss of generality we may suppose

$$A_i^\ell d < A_j^\ell d. \tag{2.5}$$

Then from the definition of Rel(d) we know that we have put $(i, j, \ell, \leq)$ into Rel(d), and consequently it follows by the definition of $\sigma(k)$ that

$$A_i^\ell d' \leq A_j^\ell d'. \tag{2.6}$$

But (2.5) and (2.6) contradict (2.4) since $\delta' \in (0, 1)$. □

Finally we give a result concerning the directional differentiability of a continuous selection. We omit its proof because it can be shown easily by reasoning similar to that used to prove Theorem 2.3.

THEOREM 2.4. *Let $\varepsilon_0 \in R^t$ and $B(\varepsilon_0; r) = \{\varepsilon \in R^t : \|\varepsilon - \varepsilon_0\| < r\}$, where r is a positive number. Suppose $x : B(\varepsilon_0; r) \to R^n$ is a continuous function selected from continuous functions $\{x_i\}$, i.e., for all $\varepsilon \in B(\varepsilon_0; r)$, $x(\varepsilon) = x_i(\varepsilon)$ for some $i \in \{1, \ldots, m\}$. If each x_i is directionally differentiable at ε_0 in a direction d, then x is directionally differentiable at ε_0 in d and its directional derivative $Dx(\varepsilon_0; d) = Dx_i(\varepsilon_0; d)$ for some i.*

3. Lipschitz continuity, piecewise differentiability, and directional differentiability of solutions of NLP. The basic conditions we shall impose on the local solution in question of a nonlinear program are the Mangasarian–Fromovitz constraint qualification and general strong second-order sufficient condition. It is well known (see [13]) that these conditions are the weakest ones to ensure the existence and local uniqueness of the perturbed local solution. We shall show that under these basic conditions the perturbed local solution can be continuously selected from the perturbed local solutions of related binding subprograms and relaxed subprograms. These subprograms are derived based on the so-called limiting index sets. Each such limiting index set determines a binding subprogram and a relaxed subprogram of NLP(ε) that have locally unique local solutions. Then using the fruitful results established in §2, various sensitivity conclusions can be drawn that not only sharpen some classical sensitivity results but provide new conditions for the Lipschitz continuity, piecewise differentiability, and directional differentiability of the perturbed local solution of the original problem.

We briefly review the optimality conditions for NLP(ε). It is well known that if certain regularity conditions, called constraint qualifications, hold at a local minimizer x to NLP(ε), then the Karush–Kuhn–Tucker (KKT) conditions or stationary conditions hold at x. There exist multipliers $u \in R_+^p \times R^q$ such that (x, u) satisfies the following generalized equation (equivalently, a variational inequality, see Robinson [30]):

$$0 \in \begin{bmatrix} \nabla_x L(x, u, \varepsilon) \\ -g(x, \varepsilon) \end{bmatrix} + N_{R^n \times R_+^p \times R^q}(x, u), \tag{3.1}$$

where $L(x, u, \varepsilon) := f(x, \varepsilon) + u^\top g(x, \varepsilon)$, and the notation N denotes the normal cone operator. For a convex set $C \subset R^t$ and $z \in R^t$

$$N_C(z) := \begin{cases} \{y \in R^t : y^\top(z' - z) \leq 0 \text{ for all } z' \in C\} & \text{if } z \in C, \\ \emptyset & \text{if } z \notin C. \end{cases}$$

A point x that satisfies (3.1) with some u is said to be a stationary point of NLP(ε) and the pair (x, u) is said to be a KKT point of NLP(ε). We shall denote the set of multipliers associated with a stationary point x of NLP(ε) by $M(x, \varepsilon)$, i.e., $M(x, \varepsilon) = \{u : (x, u)$ is a KKT point of NLP(ε)$\}$, and denote the set of extreme points of $M(x, \varepsilon)$ by $E(x, \varepsilon)$. If $u \in R_+^p \times R^q$, define the index set $PM(u)$ that represents the inequality constraints with positive multipliers and the equation constraints, i.e., $PM(u) = \{i \in \{1, \ldots, p\} : u_i > 0\} \cup \{p + 1, \ldots, p + q\}$. The stationary point set and local minimizer set of NLP(ε) will be denoted by $SP(\varepsilon)$ and $LM(\varepsilon)$, respectively. Let x_0 be a stationary point or a local minimizer of

NLP(ε_0). For any $\delta > 0$ the localized stationary point set and local minimizer set are defined by $SP_\delta(\varepsilon) := SP(\varepsilon) \cap B(x_0;\delta)$ and $LM_\delta(\varepsilon) := LM(\varepsilon) \cap B(x_0;\delta)$, respectively, where $B(x_0;\delta) = \{x \in R^n : \|x - x_0\| < \delta\}$.

Let L be a subset of $\{1,\dots,p,p+1,\dots,p+q\}$. We define the so-called binding subprogram

$$\text{BNLP}_L(\varepsilon) \qquad \underset{x}{\text{minimize}}\ f(x,\varepsilon), \quad \text{s.t. } x \in BK_L(\varepsilon),$$

where $BK_L(\varepsilon) = \{x \in R^n : g_L(x,\varepsilon) \in \{0\}^\ell\}$, $g_L(x,\varepsilon)$ consists of functions $g_i(x,\varepsilon)$, $i \in L$, and ℓ is the appropriate corresponding dimensionality, and the relaxed subprogram

$$\text{RNLP}_L(\varepsilon) \qquad \underset{x}{\text{minimize}}\ f(x,\varepsilon), \quad \text{s.t. } x \in RK_L(\varepsilon),$$

where $RK_L(\varepsilon) = \{x \in R^n : g_L(x,\varepsilon) \in R_-^{p'} \times \{0\}^{q'}\}$, and p', q' are the appropriate corresponding dimensionalities. Loosely speaking, the binding subprogram forces some inequality constraints of the original program to be binding but relaxes some inequality constraints. Hence its solution may be or may not be a solution of the original program. The relaxed subprogram is obtained by relaxing some constraints of the original program. Therefore, any solution of the original program must be a solution of the relaxed subprogram, but not vice versa.

Suppose x_0 is a stationary point of NLP(ε_0). Two important index sets of inequality constraints are defined as follows. The active set of inequality constraints is defined by

$$I(x_0,\varepsilon_0) = \{i \in \{1,\dots,p\} : g_i(x_0,\varepsilon_0) = 0\}$$

and the Lagrange active set of inequality constraints

$$J(x_0,\varepsilon_0) = \{i \in I(x_0,\varepsilon_0) : \text{there exist some } u \in M(x_0,\varepsilon_0) \text{ such that } u_i > 0\}.$$

It should be noted that the roles of inequality constraints with different characters differ substantially. If an inequality constraint $g_i(x,\varepsilon_0)$ of NLP(ε_0) is inactive at x_0, i.e., $i \notin I(x_0,\varepsilon_0)$, then we can simply eliminate it without losing any stability information near x_0. If its associated multipliers are always positive, then it can be regarded as an equation constraint locally. Finally, if it is Lagrange inactive, i.e., $i \notin J(x_0,\varepsilon_0)$, then the solution directional differentiability will not be affected by its behavior, as we shall see later. In view of the above arguments, to simplify the presentation we shall always assume that the inactive inequality constraints have been eliminated, i.e., $I(x_0,\varepsilon_0) = \{1,\dots,p\}$.

Several regularity conditions at x_0 for the unperturbed problem NLP(ε_0) will be used in what follows.

(a) The linear independence (LI) condition holds at x_0 if

$$\{\nabla_x g_i(x_0,\varepsilon_0) : i \in I(x_0,\varepsilon_0) \cup \{p+1,\dots,p+q\}\} \quad \text{are linearly independent.}$$

(b) The Mangasarian–Fromovitz constraint qualification (MFCQ) holds at x_0 if
  (i) $\{\nabla_x g_i(x_0,\varepsilon_0) : i \in \{p+1,\dots,p+q\}\}$ are linearly independent;
  (ii) There exists a vector $z \in R^n$ such that

$$\nabla_x g_i(x_0,\varepsilon_0)^{\mathsf{T}} z < 0, \qquad i \in I(x_0,\varepsilon_0),$$
$$\nabla_x g_i(x_0,\varepsilon_0)^{\mathsf{T}} z = 0, \qquad i = p+1,\dots,p+q.$$

(c) The strict Mangasarian–Fromovitz constraint qualification (SMFCQ) [16] holds at x_0 if

(i) $\{\nabla_x g_i(x_0, \varepsilon_0) : i \in J(x_0, \varepsilon_0) \cup \{p+1, \dots, p+q\}\}$ are linearly independent;

(ii) There exists a vector $z \in R^n$ such that

$$\nabla_x g_i(x_0, \varepsilon_0)^{\mathsf{T}} z < 0, \quad i \in I(x_0, \varepsilon_0) \backslash J(x_0, \varepsilon_0),$$

$$\nabla_x g_i(x_0, \varepsilon_0)^{\mathsf{T}} z = 0, \quad i \in J(x_0, \varepsilon_0) \cup \{p+1, \dots, p+q\}.$$

(d) The strong second-order sufficient condition (SSOSC) holds at x_0 with $u \in M(x_0, \varepsilon_0)$ if

$$z^{\mathsf{T}} \nabla_x^2 L(x_0, u, \varepsilon_0) z > 0 \text{ for all } z \neq 0$$

such that $z \in Z(x_0, u)$, which is defined by

$$Z(x_0, u) := \{z \in R^n : \nabla_x g_i(x_0, \varepsilon_0)^{\mathsf{T}} z = 0 \text{ if } u_i > 0,\ i \in I(x_0, \varepsilon_0),$$
$$\nabla_x g_i(x_0, \varepsilon_0)^{\mathsf{T}} z = 0,\ i \in \{p+1, \dots, p+q\}\}.$$

(e) The general strong second-order sufficient condition (GSSOSC) holds at x_0 if

$$\text{SSOSC holds at } x_0 \text{ with } u \text{ for all } u \in M(x_0, \varepsilon_0).$$

(f) The constant rank (CR) condition holds at x_0 if for any subset $L \subset I(x_0, \varepsilon_0)$ the family $\{\nabla_x g_i(x, \varepsilon) : i \in L \cup \{p+1, \dots, p+q\}\}$ remains of constant rank near the point (x_0, ε_0).

(g) The weak constant rank (WCR) condition holds at x_0 if for any subset $L \subset J(x_0, \varepsilon_0)$ the family $\{\nabla_x g_i(x, \varepsilon) : i \in L \cup \{p+1, \dots, p+q\}\}$ remains of constant rank near the point (x_0, ε_0).

Conditions (a) – (e) are well known in the literature. The CR condition introduced in Janin [6] is a constraint qualification. The WCR is new and will be discussed later. At this point let us summarize the relations between these conditions. The notation $\Rightarrow\Rightarrow$ means "strictly stronger than" in logical sense.

PROPOSITION 3.1. (i) *LI* $\Rightarrow\Rightarrow$ *SMFCQ* $\Leftrightarrow$ *uniqueness of multipliers* $\Rightarrow\Rightarrow$ *MFCQ* + *WCR*;

(ii) *LI* $\Rightarrow\Rightarrow$ *MFCQ* + *CR* $\Rightarrow\Rightarrow$ *MFCQ* + *WCR*;

(iii) *CR* $\Rightarrow\Rightarrow$ *WCR*;

(iv) *SMFCQ* $\not\Leftarrow$ *CR*, *CR* $\not\Leftarrow$ *MFCQ*.

Remark 3.2. (1) LI $\Rightarrow\Rightarrow$ SMFCQ $\Leftrightarrow$ uniqueness of multipliers $\Rightarrow\Rightarrow$ MFCQ can be found in Kyparisis [19]. (2) LI $\Rightarrow\Rightarrow$ MFCQ + CR and SMFCQ $\not\Leftarrow$ CR were shown by Kyparisis [19]. CR $\not\Leftarrow$ MFCQ was proved in Janin [6]. (3) The implications SMFCO $\Rightarrow$ WCR and CR $\Rightarrow$ WCR are evident. The counterexamples showing MFCQ + WCR $\not\Rightarrow$ SMFCQ and WCR $\not\Rightarrow$ CR are provided later.

The differentiability assumptions about the problem functions used in the paper are described in a unified way. We say that the parametric program NLP(ε) is $C^{k,\ell}$ ($k \geq 1$, $\ell \geq 0$) near a point (x_0, ε_0) if the problem functions f and g are k times continuously differentiable with respect to x for x near x_0 with every ε near ε_0, their gradients with respect to x are ℓ times continuously differentiable in (x, ε) near (x_0, ε_0).

We shall first state below Fiacco's sensitivity result for equation constrained nonlinear programs and Kojima's strong stability theorem.

PROPOSITION 3.3 (Fiacco [2]). *Let L be a subset of* $\{1, \dots, p, p+1, \dots, p+q\}$. *Suppose KKT, SSOSC, and LI hold at* x_0 *with multipliers* u_L *for BNLP*$_L(\varepsilon_0)$ *and that BNLP*$_L(\varepsilon)$ *is* $C^{k+1,k}$ ($k \geq 1$) *near* (x_0, ε_0). *Then* (a) *for* ε *in a neighborhood of* ε_0, *there exists a unique* *function* $y_L(\varepsilon) = [x_L(\varepsilon), u_L(\varepsilon)]^{\mathrm{T}} \in C^k$ *satisfying that the KKT conditions hold at* $x_L(\varepsilon)$ *with* $u_L(\varepsilon)$ *for BNLP*$_L(\varepsilon)$ *and that* $y(\varepsilon_0) = (x_0, u_L)$.

(b) *The Jacobian* $Q_L(\varepsilon)$ *of the system*

$$\begin{aligned} \nabla_x L(x_L, u_L, \varepsilon) &= 0, \\ g_i(x_L, \varepsilon) &= 0, \quad i \in L, \end{aligned} \tag{3.2}$$

with respect to (x_L, u_L) *is locally nonsingular and*

$$\nabla_\varepsilon y(\varepsilon) = Q(\varepsilon)^{-1} N(\varepsilon),$$

where $-N(\varepsilon)$ *is the Jacobian of the system* (3.2) *with respect to* ε.

PROPOSITION 3.4 (Kojima [13]). *Let* x_0 *be a stationary point of NLP*(ε_0). *Suppose that MFCQ and GSSOSC hold at* x_0 *for NLP*(ε_0) *and that NLP*(ε) *is* $C^{2,0}$ *near* (x_0, ε_0). *Then there exist* δ, $r > 0$ *and a unique continuous function* $x : B(\varepsilon_0; r) \longrightarrow R^n$ *such that* $x(\varepsilon) = SP_\delta(\varepsilon) = LM_\delta(\varepsilon)$ *and MFCQ holds at* $x(\varepsilon)$ *for all* $\varepsilon \in B(\varepsilon_0; r)$.

Under the hypotheses of the above proposition, $M(x(\varepsilon), \varepsilon)$ is a polytope for all $\varepsilon \in B(\varepsilon_0; r)$ since MFCQ holds at $x(\varepsilon)$. For any $\varepsilon \in B(\varepsilon_0; r)$, the KKT conditions hold at $(x(\varepsilon), u)$, i.e.,

$$0 \in \begin{bmatrix} \nabla_x L(x(\varepsilon), u, \varepsilon) \\ -g(x(\varepsilon), \varepsilon) \end{bmatrix} + N_{R^n \times R^p_+ \times R^q}(x(\varepsilon), u) \tag{3.3}$$

for each $u \in E(x(\varepsilon), \varepsilon)$. For any $\varepsilon \in B(\varepsilon_0; r)$ choose one $u(\varepsilon) \in E(x(\varepsilon), \varepsilon)$ and let $L(\varepsilon) = PM(u(\varepsilon))$. It follows from (3.3) that $[x(\varepsilon), u(\varepsilon)]$ is a KKT point of the binding subprogram BNLP$_{L(\varepsilon)}(\varepsilon)$. Obviously, the number of elements in the set $\{L(\varepsilon) : \varepsilon \in B(\varepsilon_0; r)\}$ is finite. We shall call some index set L belonging to this set a limiting index set in the sense that if there exists a sequence of $\{\varepsilon_j\}$ with $\varepsilon_j \longrightarrow \varepsilon_0$ such that for all j

$$L = L(\varepsilon_j).$$

Denote by LIS(x_0, ε_0) the set of all such limiting index sets; each is a subset of $\{1, \ldots, p, p+1, \ldots, p+q\}$. Without loss of generality we may assume that LIS$(x_0, \varepsilon_0) = \{L(\varepsilon) : \varepsilon \in B(\varepsilon_0; r)\}$. Now denote the elements in LIS(x_0, ε_0) by $L(1), \ldots, L(s)$. Consider the following binding subprogram

BNLP$_{L(i)}(\varepsilon)$ $\quad$ $\underset{x}{\text{minimize}}\ f(x, \varepsilon), \quad \text{s.t. } x \in BK_{L(i)}(\varepsilon)$

for $i = 1, \ldots, s$. In addition, we assume that CR holds at x_0 for NLP(ε_0). We observe that (1) for each $L(i)$ there exist $u_i \in E(x_0, \varepsilon_0)$ such that $PM(u_i) \subset L(i)$, since by definition there exists a sequence of $\{\varepsilon_j\}$ with $\varepsilon_j \longrightarrow \varepsilon_0$ such that for all j, $L(i) = L(\varepsilon_j) = PM(u(\varepsilon_j))$. So any accumulation point of $\{u(\varepsilon_j)\}$ can be chosen as such a u_i. Consequently, the KKT conditions hold at x_0 with u_i for BNLP$_{L(i)}(\varepsilon_0)$. (2) Since we have assumed that CR holds at x_0 for NLP(ε_0), this implies that for each $L(i)$ LI condition holds at x_0 for BNLP$_{L(i)}(\varepsilon_0)$. To see this, note that for each ε_j the vectors $\{\nabla_x g_k(x(\varepsilon_j), \varepsilon_j) : k \in L(i) = PM(u(\varepsilon_j))\}$ are linearly independent since $u(\varepsilon_j)$ is an extreme point of $M(x(\varepsilon_j), \varepsilon_j)$. Therefore, LI holds at x_0 for BNLP$_{L(i)}(\varepsilon_0)$ as $\{\nabla_x g_k(x(\varepsilon), \varepsilon) : k \in L(i)\}$ remains of constant rank. Furthermore, LI condition indicates that u_i is the unique multiplier at x_0 for BNLP$_{L(i)}(\varepsilon_0)$. So the fact that GSSOSC holds at x_0 for NLP(ε_0) implies that SSOSC holds at x_0 for BNLP$_{L(i)}(\varepsilon_0)$. (3) Now applying Proposition 3.4 to BNLP$_{L(i)}(\varepsilon)$ for each $L(i)$, we find that there exist δ_i, $r_i > 0$, and a continuous function $x_i : B(\varepsilon_0; r_i) \longrightarrow R^n$ such that for any $\varepsilon \in B(\varepsilon_0; r_i)$, $x_i(\varepsilon)$ is the unique stationary point of BNLP$_{L(i)}(\varepsilon)$ in $B(x_0; \delta_i)$. Also, Proposition 3.4 says that for any $\varepsilon \in$

$B(\varepsilon_0; r)$, $x(\varepsilon)$ is the unique stationary point of NLP(ε) in $B(x_0; \delta)$. (4) We may make r small enough that a common δ can be found such that for each $\varepsilon \in B(\varepsilon_0; r)$, $x(\varepsilon)$, $x_1(\varepsilon), \ldots, x_s(\varepsilon)$ are the unique stationary points of NLP(ε), BNLP$_{L(1)}, \ldots$, BNLP$_{L(s)}$ in $B(x_0; \delta)$, respectively. For any fixed $\varepsilon \in B(\varepsilon_0; r)$, let $L(i) = PM(u(\varepsilon))$. Note that the stationary point $x(\varepsilon)$ of NLP(ε) is also a stationary point of BNLP$_{L(i)}(\varepsilon)$ since $[x(\varepsilon), u(\varepsilon)]$ satisfies the KKT conditions for BNLP$_{L(i)}(\varepsilon)$. Then by the uniqueness property of stationary points, we deduce that $x(\varepsilon) = x_i(\varepsilon)$. Therefore, we have established an interesting connection between $x(\varepsilon)$ and $x_i(\varepsilon)$ that for each $\varepsilon \in B(\varepsilon_0; r)$ $x(\varepsilon)$ can be identified to some $x_i(\varepsilon)$. We summarize this fact in the following continuous selection theorem.

THEOREM 3.5. *In the above setting, i.e., under the hypotheses of Proposition* 3.4 *and CR condition, there exist* δ, $r > 0$ *and continuous functions* x, $x_i : B(\varepsilon_0; r) \to R^n$, $i = 1, \ldots, s$, *such that for any* $\varepsilon \in B(\varepsilon_0; r)$, $x(\varepsilon)$ *and* $x_i(\varepsilon)$, $i = 1, \ldots, s$, *are the unique stationary points and local minimizers of NLP*(ε) *and BNLP*$_{L(i)}(\varepsilon)$, $i = 1, \ldots, s$, *on* $B(x_0; \delta)$, *respectively. Moreover,* $x(\cdot)$ *is a continuous selection from* $\{x_i(\cdot) : i = 1, \ldots, s\}$ *on* $B(\varepsilon_0; r)$, *i.e., for each* $\varepsilon \in B(\varepsilon_0; r)$, $x(\varepsilon) = x_i(\varepsilon)$ *for some* $i \in \{1, \ldots, s\}$.

Having established the continuous selection theorem, we give below the two main results of the section on Lipschitz continuity, piecewise differentiability, and directional differentiability. Although the first one partially answers Robinson's question, we still do not know whether the imposed conditions are necessary for Lipschitz continuity of the perturbed stationary point and local solution.

THEOREM 3.6. *Let* x_0 *be a stationary point of NLP*(ε_0). *Suppose that MFCQ, CR, and GSSOSC hold at* x_0 *for NLP*(ε_0) *and that NLP*(ε) *is* $C^{k+1,k}$ ($k \geq 1$) *near* (x_0, ε_0). *Then*

(a) *there exist* δ, $r > 0$, *and a unique Lipschitz continuous function* $x : B(\varepsilon_0; r) \to R^n$ *such that* $x(\varepsilon) = SP_\delta(\varepsilon) = LM_\delta(\varepsilon)$ *for all* $\varepsilon \in B(\varepsilon_0; r)$;

(b) x *is piecewise differentiable at* ε_0 *and directionally differentiable at* ε_0 *of order* $h \leq k$ *along any direction d*;

(c) *the directional derivatives* $D^h x(\varepsilon_0; d)$ *of order* $h \leq k$ *as functions of d are Lipschitzian.*

Proof. From Theorem 3.5 we know that there exist δ, $r > 0$, and continuous functions $x, x_i : B(\varepsilon_0; r) \to R^n$, $i = 1, \ldots, s$, such that for any $\varepsilon \in B(\varepsilon_0; r)$, $x(\varepsilon)$ and $x_i(\varepsilon)$, $i = 1, \ldots, s$, are the unique stationary points and local solutions of NLP(ε) and BNLP$_{L(i)}(\varepsilon)$, $i = 1, \ldots, s$, on $B(x_0; \delta)$, respectively and that $x(\cdot)$ is continuously selected from $\{x_i(\cdot) : i = 1, \ldots, s\}$ on $B(\varepsilon_0; r)$. Since under the hypotheses of the theorem each BNLP$_{L(i)}(\varepsilon)$ is $C^{k+1,k}$ near (x_0, ε_0), after applying Proposition 3.3 to BNLP$_{L(i)}(\varepsilon)$ we conclude that each x_i is in C^k in a neighborhood of ε_0. Then the desired conclusions readily follow from Theorem 2.3. □

The same reasoning yields the following result that sharpens some well-known classical results.

THEOREM 3.7. *Let* x_0 *be a stationary point of NLP*(ε_0) *with associated multipliers* u. *Suppose that LI and SSOSC hold at* x_0 *for NLP*(ε_0) *and that NLP*(ε) *is* $C^{k+1,k}$ ($k \geq 1$) *near* (x_0, ε_0). *Then*

(a) *for* ε *in a neighborhood of* ε_0, *there exists a unique Lipschitz continuous function* $y(\varepsilon) = [x(\varepsilon), u(\varepsilon)]^{\mathrm{T}}$ *such that* $[x(\varepsilon), u(\varepsilon)]$ *is the KKT point of NLP*(ε) *and* $y(\varepsilon_0) = [x_0, u]$;

(b) y *is piecewise differentiable at* ε_0 *and directionally differentiable at* ε_0 *of order* $h \leq k$ *along any direction d*;

(c) *the directional derivatives* $D^h y(\varepsilon_0; d)$ *of order* $h \leq k$ *as functions of d are Lipschitzian.*

Remark 3.8. (1) Conclusion (a) above was first obtained in Robinson [29] using the generalized equation approach. Here the same conclusion readily follows from a simple idea of continuous selections. (2) The directional differentiability of order 1 of the perturbed KKT points was first proved by Jittorntrum [7]. Subsequently, Robinson [31] showed that the directional differentiability of order 1 of the perturbed KKT point can be sharpened to B-differentiability. Conclusion (b) above further improves the B-differentiability to piecewise differentiability. (3) To our knowledge the high-order directional differentiability of the perturbed KKT point is obtained here for the first time in the literature.

It is interesting to compare the logical relations between LI, SMFCQ, CR, and MFCQ. From Proposition 3.1 we know that

(i) LI $\Rightarrow\!\!\!\Rightarrow$ MFCQ + CR $\Rightarrow\!\!\!\Rightarrow$ MFCQ;

(ii) LI $\Rightarrow\!\!\!\Rightarrow$ MFCQ + SMFCQ (uniqueness of multipliers) $\Rightarrow\!\!\!\Rightarrow$ MFCQ.

Bearing Theorem 3.6 in mind, the reader may wonder if KKT + MFCQ + uniqueness of muliplierss + SSOSC are sufficient for part of the conclusions derived in Theorem 3.6. The next example, modified from an example of Robinson [30], shows that the Lipschitz property (a) in Theorem 3.6 does not necessarily hold in this case. This finding was inspired by Robinson [34]. However, some conclusions of Theorem 3.6 concerning the directional derivative are still true in this case. Before proceeding to the example, we shall first give a result concerning the Lipschitz property of the directional derivative of the perturbed stationary point under the assumptions of KKT, SMFCQ, and SSOSC.

PROPOSITION 3.9. *Let x_0 be a stationary point of NLP(ε_0) with its associated multipliers u. Suppose that SMFCQ and SSOSC hold at x_0 for NLP(ε_0) and that NLP(ε) is $C^{2,1}$ near (x_0, ε_0). Then there exist δ, $r > 0$, and a unique continuous function $x : B(\varepsilon_0; r) \to R^n$ such that $x(\varepsilon) = SP_\delta(\varepsilon) = LM_\delta(\varepsilon)$ for all $\varepsilon \in B(\varepsilon_0; r)$ and that $x(\varepsilon)$ is directionally differentiable at ε_0 along any direction d, and its directional derivative $Dx(\varepsilon_0; d)$ uniquely solves the following quadratic program*

$$\text{QP}(u)$$

$$\begin{aligned} \underset{z}{\text{minimize}}\ z^{\mathsf T}\nabla_x^2 Lz + 2z^{\mathsf T}\nabla_{\varepsilon x}^2 Ld, \quad \text{s.t. } &\nabla_x g_i^{\mathsf T} z + \nabla_\varepsilon g_i^{\mathsf T} d = 0, \quad i \in PM(u), \\ &\nabla_x g_i^{\mathsf T} z + \nabla_\varepsilon g_i^{\mathsf T} d \le 0, \quad i \in I(x_0, \varepsilon_0)\backslash PM(u), \end{aligned}$$

where g_i are evaluated at (x_0, ε_0) and L at (x_0, u, ε_0). Furthermore, $Dx(\varepsilon_0; d)$ is Lipschitzian as a function of d.

Proof. The directional differentiability of the perturbed solution and the formula for its directional derivative are direct applications of Corollary 3.1 in Qiu and Magnanti [28] and thus the details are omitted. Note that if we treat the direction d in QP(u) as a parameter, we have that MFCQ, CR, and SSOSC hold at any stationary point of QP(u) for any d. Applying Theorem 3.6 to QP(u), we obtain the Lipschitz property of the directional derivative. □

Remark 3.10. The directional differentiability of the perturbed local solution under assumptions of KKT, SMFCQ, and SSOSC and its formula for directional derivative were first derived in Shapiro [35] and [36], assuming more smoothness, however. His approach explicitly resorts to the second-order derivatives of the problem functions with respect to the parameter and thus is not applicable here.

Example 3.11. Consider the following parametric convex quadratic program

$$\text{QP}(\varepsilon_1, \varepsilon_2, \varepsilon_3) \qquad \begin{aligned} &\underset{x}{\text{minimize}}\ f = \frac{1}{2}\|x - (1, 0^{\mathsf T})\|^2 + \frac{1}{2}\varepsilon_1\|x\|^2, \\ &\text{s.t. } g = A(\varepsilon_2)x + a(\varepsilon_3) \le 0, \end{aligned}$$

where

$$A(\varepsilon_2) = \begin{bmatrix} -1 & 0 \\ -1 & -\varepsilon_2 \end{bmatrix}, \qquad a(\varepsilon_3) = \begin{bmatrix} 1 \\ 1 + \varepsilon_3 \end{bmatrix},$$

$\varepsilon \in R^3$ and $\varepsilon_0 = (0,0,0)^{\mathsf{T}}$. Let $x_0 = (1,0)^{\mathsf{T}}$. Obviously, QP(ε) is $C^{k+1,k}$ for any positive integer k. It is easy to show that the constraints of QP$(0,0,0)$ satisfy MFCQ at x_0. Note that the Hessian of the objective function is always positive definite provided that $\varepsilon_1 > -1$ and the constraints are linear. So the problem satisfies the strongest possible second-order condition for ε near ε_0. It is easy to verify that x_0 is a stationary point of QP$(0,0,0)$ with the unique multipliers $(0,0)^{\mathsf{T}}$. Define for $\varepsilon_1 > 0$, $\varepsilon_2 > 0$, and $0 \le \varepsilon_3 \le \varepsilon_1\varepsilon_2^2/(1+\varepsilon_1)$,

$$x(\varepsilon_1,\varepsilon_2,\varepsilon_3) = (1,0)^{\mathsf{T}} + \varepsilon_3/\varepsilon_2(0,1)^{\mathsf{T}},$$
$$u(\varepsilon_1,\varepsilon_2,\varepsilon_3) = \varepsilon_1(1,0)^{\mathsf{T}} + (1+\varepsilon_1)\varepsilon_3/\varepsilon_2^2(-1,1)^{\mathsf{T}},$$

and for $\varepsilon_1 > 0$, $\varepsilon_2 > 0$, and $\varepsilon_3 > \varepsilon_1\varepsilon_2^2/(1+\varepsilon_1)$,

$$x(\varepsilon_1,\varepsilon_2,\varepsilon_3) = (1,0)^{\mathsf{T}} + 1/((1+\varepsilon_1)(1+\varepsilon_2^2))(\varepsilon_3+\varepsilon_1\varepsilon_3-\varepsilon_1\varepsilon_2^2, \varepsilon_2(\varepsilon_1+\varepsilon_3+\varepsilon_1\varepsilon_3))^{\mathsf{T}},$$
$$u(\varepsilon_1,\varepsilon_2,\varepsilon_3) = (\varepsilon_1+\varepsilon_3+\varepsilon_1\varepsilon_3)/(1+\varepsilon_2^2)(0,1)^{\mathsf{T}}.$$

We find that these vectors satisfy the KKT conditions of QP$(\varepsilon_1,\varepsilon_2,\varepsilon_3)$. Actually, we have

$$(1+\varepsilon_1)x(\varepsilon_1,\varepsilon_2,\varepsilon_3) - (1,0)^{\mathsf{T}} + A(\varepsilon_2)^{\mathsf{T}}u(\varepsilon_1,\varepsilon_2,\varepsilon_3) = 0,$$
$$A(\varepsilon_2)x(\varepsilon_1,\varepsilon_2,\varepsilon_3) + a(\varepsilon_3) = 0,$$
$$u(\varepsilon_1,\varepsilon_2,\varepsilon_3) \ge 0.$$

Therefore, for appropriate ε near ε_0 the above vector $x(\varepsilon)$ is the unique local minimizer of QP(ε). On the other hand, for any $\varepsilon_1 > 0$, $\varepsilon_2 > 0$ and $0 \le \varepsilon_3$, $\varepsilon_3' \le \varepsilon_1\varepsilon_2^2/(1+\varepsilon_1)$

$$\|x(\varepsilon_1,\varepsilon_2,\varepsilon_3) - x(\varepsilon_1,\varepsilon_2,\varepsilon_3')\| = (\varepsilon_2)^{-1}\|\varepsilon_3 - \varepsilon_3'\| = (\varepsilon_2)^{-1}\|(\varepsilon_1,\varepsilon_2,\varepsilon_3) - (\varepsilon_1,\varepsilon_2,\varepsilon_3')\|.$$

This means that $x(\varepsilon)$ cannot be Lipschitzian in any neighborhood of ε_0. □

The reasons why KKT + SMFCQ + SSOSC fail to ensure Lipschitz continuity of the perturbed local solution should be of interest. We think this phenomenon may be explained as follows: (1) locally Lipschitz continuity of the perturbed local solution is a *neighborhood property* rather than a *pointwise property*; (2) unlike LI and MFCQ, SMFCQ is not preservable under small perturbations; it can be destroyed even by small perturbations. Hence, in terms of properties of neighborhood-type for the generally perturbed local solution, what we can expect from SMFCQ is probably as much as that from MFCQ.

As mentioned before, in terms of directional differentiability the hypotheses of Theorem 3.6 can be weakened. Before proceeding to establish this result, we give a property of MFCQ. This property plays a key role in the rest of the section.

LEMMA 3.12. *Suppose that x_0 is a stationary point of NLP(ε_0) and MFCQ holds there and that $u \in E(x_0,\varepsilon_0)$. If an index set $L \subset \{1,\dots,p,p+1,\dots,p+q\}$ with $L \supset PM(u)$ satisfies that $\{\nabla_x g_i(x_0,\varepsilon_0) : i \in L\}$ is linearly independent, then there exist some $z \in R^n$ such that*

$$\begin{aligned} &\nabla_x g_i(x_0,\varepsilon_0)^{\mathsf{T}}z < 0, \quad i \in I(x_0,\varepsilon_0)\backslash J(x_0,\varepsilon_0),\\ &\nabla_x g_i(x_0,\varepsilon_0)^{\mathsf{T}}z < 0, \quad i \in L\backslash PM(u),\\ &\nabla_x g_i(x_0,\varepsilon_0)^{\mathsf{T}}z = 0, \quad i \in PM(u). \end{aligned} \tag{3.4}$$

Proof. By definition we find that for each $i \in J(x_0,\varepsilon_0)$, there exist some $u \in M(x_0,\varepsilon_0)$ such that $u_i > 0$. Then it is not difficult to see that there exist some $u^* \in M(x_0,\varepsilon_0)$ such that

$$u_i^* > 0 \quad \text{for each } i \in J(x_0,\varepsilon_0),$$

and

$$(3.5)\qquad \nabla_x f(x_0,\varepsilon_0)+\sum_{i\in J(x_0,\varepsilon_0)} u_i^*\nabla_x g_i(x_0,\varepsilon_0)+\sum_{i=p+1}^{p+q} u_i^*\nabla_x g_i(x_0,\varepsilon_0)=0.$$

Let A denote the subspace spanned by $\{\nabla_x g_i(x_0,\varepsilon_0),\ i\in PM(u)\}$ and B denote the convex cone $\{\lambda_i\nabla_x g_i(x_0,\varepsilon_0) : i\in (I(x_0,\varepsilon_0)\backslash J(x_0,\varepsilon_0))\cup(L\backslash PM(u)),\ \lambda_i>0\}$, respectively. Then, we claim that $A\cap B=\emptyset$. Otherwise, we have

$$\left[\sum_{i\in PM(u)} k_i\nabla_x g_i(x_0,\varepsilon_0)\right]+\sum_{i\in L_1}\lambda_i\nabla_x g_i(x_0,\varepsilon_0)+\sum_{i\in L_2}\lambda_i\nabla_x g_i(x_0,\varepsilon_0)=0,$$

where $L_1\subset I(x_0,\varepsilon_0)\backslash J(x_0,\varepsilon_0)$, $L_2\subset L\backslash PM(u)$, $k_i\in R$, and $\lambda_i>0$. Notice that $(PM(u)\cap\{1,\dots,p\})\subset J(x_0,\varepsilon_0)$. Therefore, when $L_1\neq\emptyset$, by multiplying the above equation by sufficiently small $s<0$ and adding it to (3.5), the fixed index set $J(x_0,\varepsilon_0)$ can be made larger. This is a contradiction. When $L_1=\emptyset$, the above equation contradicts the linear independence assumption. Having proved that $A\cap B=\emptyset$, by the separation theorem we can find $z\in R^n$ with $z\neq 0$ such that for any $y\in A$, $z^{\mathsf T}y\geq 0$, and that for any $y\in B$, $z^{\mathsf T}y<0$. Note that $z^{\mathsf T}y\geq 0$ for any $y\in A$ implies $z^{\mathsf T}y=0$ for any $y\in A$. This establishes (3.4). □

The conclusion of Lemma 3.12 can be interpreted as follows. For any $M\subset I(x_0,\varepsilon_0)\backslash J(x_0,\varepsilon_0)$, SMFCQ holds at x_0 for RNLP$_{M\cup L}(\varepsilon_0)$, or equivalently, the multiplier u appearing in Lemma 3.12 is the unique multiplier for RNLP$_{M\cup L}(\varepsilon_0)$ at x_0.

The next result provides sufficient conditions for the directional differentiability of the perturbed local solutions of RNLP$_L(s)$ for certain index sets L. It is a refinement of Lemma 2.1 in [19].

LEMMA 3.13. *Let x_0 be a stationary point of NLP(ε_0). Suppose that MFCQ and GSSOSC hold at x_0 for NLP(ε_0) and that NLP(ε) is $C^{2,1}$ near (x_0,ε_0). Then for every index set $L\subset\{1,\dots,p,p+1,\dots,p+q\}$ with $L\supset PM(u)$ for some $u\in E(x_0,\varepsilon_0)$ such that $\{\nabla_x g_i(x_0,\varepsilon_0) : i\in L\cap J'(x_0,\varepsilon_0)\}$ are linearly independent, where $J'(x_0,\varepsilon_0)=J(x_0,\varepsilon_0)\cup\{p+1,\dots,p+q\}$, there is a locally unique continuous local minimizer $x_L(\varepsilon)$ of RNLP$_L(\varepsilon)$. Moreover, $x_L(\varepsilon)$ is directionally differentiable at ε_0 in any direction d and its directional derivative $Dx_L(\varepsilon_0;d)$ uniquely solves the following quadratic program*:

QP$_L(u)$

$$\begin{aligned}\underset{z}{\text{minimize}}\ z^{\mathsf T}\nabla_x^2 Lz+2z^{\mathsf T}\nabla_{\varepsilon x}^2 Ld,\quad &\text{s.t. } \nabla_x g_i^{\mathsf T}z+\nabla_\varepsilon g_i^{\mathsf T}d=0, && i\in PM(u),\\ &\nabla_x g_i^{\mathsf T}z+\nabla_\varepsilon g_i^{\mathsf T}d\leq 0, && i\in L\backslash PM(u),\end{aligned}$$

where u is such that $PM(u)\subset L$, the functions g_i are evaluated at (x_0,ε_0) and the function L at (x_0,u,ε_0).

Proof. We show that the KKT conditions, SMFCQ, and SSOSC hold at x_0 for RNLP$_L(\varepsilon_0)$. Then the conclusions readily follow from Propositions 3.4 and 3.9. Note that $u_i=0$ for $i\in\{1,\dots,p\}$ and $i\notin PM(u)$. Since x_0 is a stationary point of NLP(ε_0), using the assumption that $u\in E(x_0,\varepsilon_0)$ and $L\supset PM(u)$, we find that it is also a stationary point of RNLP$_L(\varepsilon_0)$ with associated multiplier u. Evidently we have $L\cap J'(x_0,\varepsilon_0)\supset PM(u)$ since $J'(x_0,\varepsilon_0)\supset PM(u)$. Applying Lemma 3.12 to the index set $L\cap J'(x_0,\varepsilon_0)$, we can deduce that SMFCQ holds at x_0 for RNLP$_L(\varepsilon_0)$. Finally, SSOSC holds at x_0 with u for RNLP$_L(\varepsilon_0)$ because $L\supset PM(u)$ and GSSOSC holds at x_0 for NLP(ε_0). □

We give below a result that presents sufficient conditions for the directional differentiability of the perturbed local solution of NLP(ε). It partially extends Proposition 3.9 and includes the main result of Kyparisis [19] in nonlinear programs as a special case.

THEOREM 3.14. *Let x_0 be a stationary point of NLP(ε_0). Suppose that MFCQ, WCR, and GSSOSC hold at x_0 for NLP(ε_0) and that NLP(ε) is $C^{2,1}$ near (x_0, ε_0). Then for ε in some neighborhood of ε_0, there exists a locally unique continuous local solution $x(\varepsilon)$ of NLP(ε) such that $x(\varepsilon)$ is directionally differentiable at ε_0 in any direction $d \in R^t$ and its directional derivative $Dx(\varepsilon_0; d)$ uniquely solves the following quadratic program for some $u \in E(x_0, \varepsilon_0)$*

QP(u)

$$\begin{aligned}\underset{z}{\text{minimize}}\ z^{\mathsf{T}}\nabla_x^2 Lz + 2z^{\mathsf{T}}\nabla_{\varepsilon x}^2 Ld, \quad \text{s.t. } &\nabla_x g_i^{\mathsf{T}} z + \nabla_\varepsilon g_i^{\mathsf{T}} d = 0, && i \in PM(u),\\ &\nabla_x g_i^{\mathsf{T}} z + \nabla_\varepsilon g_i^{\mathsf{T}} d \le 0, && i \in I(x_0, \varepsilon_0)\backslash PM(u),\end{aligned}$$

where the functions g_i are evaluated at (x_0, ε_0) and the function L at (x_0, u, ε_0).

Proof. The idea of the proof is similar to that of the proofs for Theorems 3.5 and 3.6. Consider the KKT conditions (3.3) again. Choose any $u(\varepsilon) \in E(x(\varepsilon), \varepsilon)$ and let $L(\varepsilon) = PM(u(\varepsilon))$. Then $[x(\varepsilon), u(\varepsilon)]$ is also a KKT point of the relaxed subprogram RNLP$_{L(\varepsilon)}(\varepsilon)$. The same reasoning that served for Theorem 3.5 yields that there exist δ, $r > 0$, and continuous functions x, $x_i : B(\varepsilon_0; r) \to R^n$, $i = 1, \dots, s$, such that for all $\varepsilon \in B(\varepsilon_0; r)$, $x(\varepsilon)$ and $x_i(\varepsilon)$, $i = 1, \dots, s$, are the unique stationary points of NLP(ε) and RNLP$_{L(i)}(\varepsilon)$, $i = 1, \dots, s$, on $B(x_0; \delta)$, respectively. Furthermore, $x(\cdot)$ is a continuous selection from $\{x_i(\cdot) : i = 1, \dots, s\}$ on $B(\varepsilon_0; r)$.

Consider the relaxed subprogram

$$\text{RNLP}_{L(i)}(\varepsilon) \qquad \underset{x}{\text{minimize}}\ f(x, \varepsilon), \quad \text{s.t. } x \in RK_{L(i)}(\varepsilon)$$

for $i = 1, \dots, s$. We find using arguments similar to those used for Theorems 3.5 and 3.6 that (1) for each $L(i)$, there exist $u_i \in E(x_0, \varepsilon_0)$ such that $PM(u_i) \subset L(i)$. And the KKT conditions hold at x_0 with u_i for RNLP$_{L(i)}(\varepsilon_0)$. (2) Instead of proving that LI holds at x_0 for BNLP$_{L(i)}(\varepsilon_0)$, we can show that the index set $L(i)$ satisfies the assumption in Lemma 3.13, i.e., $\{\nabla_x g_k(x_0, \varepsilon_0) : k \in L(i) \cap J'(x_0, \varepsilon_0)\}$ are linearly independent. To show this, consider the sequence $\{\varepsilon_j\}$ with $\varepsilon_j \to \varepsilon_0$ such that for all j, $L(i) = L(\varepsilon_j) = PM(u(\varepsilon_j))$. Since $u(\varepsilon_j)$ is an extreme point of $M(x(\varepsilon_j), \varepsilon_j)$, the vectors $\{\nabla_x g_k(x(\varepsilon_j), \varepsilon_j) : k \in L(i) = PM(u(\varepsilon_j))\}$ are linearly independent. Therefore, the vectors in $\{\nabla_x g_k(x_0, \varepsilon_0) : k \in L(i) \cap J'(x_0, \varepsilon_0)\}$ are linearly independent since by WCR the set $\{\nabla_x g_k(x(\varepsilon), \varepsilon) : k \in L(i) \cap J'(x_0, \varepsilon_0)\}$ remains of constant rank. (3) It is easy to see by the definition of a relaxed subprogram that if (x_0, u) is a KKT point of RNLP$_{L(i)}(\varepsilon_0)$ then it is also a KKT point of NLP(ε_0). Hence the fact that GSSOSC holds at x_0 for NLP(ε_0) implies that GSSOSC holds at x_0 for RNLP$_{L(i)}(\varepsilon_0)$. Now applying Lemma 3.13 to each RNLP$_{L(i)}(\varepsilon)$ we obtain that x_i is directionally differentiable at ε_0 in any direction d. Then from Theorem 2.4 we find that x is directionally differentiable at ε_0 in the direction d. The calculation of $Dx(\varepsilon_0; d)$ is straightforward by Lemma 3.13 and the fact that for each $i \in I(x_0, \varepsilon_0)$, since $g_i(x(\varepsilon), \varepsilon) \le 0$, the inequality

$$\nabla_x g_i(x_0, \varepsilon_0)^{\mathsf{T}} z + \nabla_\varepsilon g_i(x_0, \varepsilon_0)^{\mathsf{T}} d \le 0$$

is always true. This completes the proof. □

The following example demonstrates a situation where the KKT conditions, MFCQ, WCR, and GSSOSC hold at a local solution, so Theorem 3.14 can apply to the case. However, SMFCQ or CR does not hold at the local solution. Hence Lemma 3.13 and the sensitivity results in Kyparisis [19] are not applicable here. It also provides a counterexample showing that WCR $\not\Rightarrow$ SMFCQ and WCR $\not\Rightarrow$ CR.

Example 3.15. Consider the parametric nonlinear program

$$\begin{aligned}\underset{x}{\text{minimize}}\ f = x_1^2 + (x_2 - 1 - \varepsilon)^2, \quad \text{s.t.}\ g_1 &= x_2 \le 0,\\ g_2 &= x_2 - \varepsilon \le 0,\\ g_3 &= -x_1 - x_2 \le 0,\\ g_4 &= (x_1 - 1)^2 + (x_2 - 1)^2 - 2 - \varepsilon \le 0,\end{aligned}$$

where $\varepsilon \in R$ and $\varepsilon_0 = 0$. Let $x_0 = (0,0)^{\mathsf{T}}$. It is easy to check that the KKT conditions, MFCQ, and GSSOSC hold at x_0 and that $I(x_0,\varepsilon_0) = \{1,2,3,4\}$, $M(x_0,\varepsilon_0) = \{(u_1,u_2,u_3,u_4)^{\mathsf{T}} : u_1 \ge 0, u_2 \ge 0, u_1 + u_2 = 2, u_3 = 0, u_4 = 0\}$, $J(x_0,\varepsilon_0) = \{1,2\}$. In addition, $\nabla_x g_1(x,\varepsilon) = (0,1)^{\mathsf{T}}$, $\nabla_x g_2(x,\varepsilon) = (0,1)^{\mathsf{T}}$, $\nabla_x g_3(x,\varepsilon) = (-1,-1)^{\mathsf{T}}$, $\nabla_x g_4(x,\varepsilon) = (2(x_1-1),2(x_2-1))^{\mathsf{T}}$. Thus WCR holds at (x_0,ε_0) and therefore by Theorem 3.14 we find that the above problem has a locally unique local minimizer $x(\varepsilon)$ near ε_0 that is directionally differentiable at ε_0 in any direction. The calculation of direction derivatives can be performed using Theorem 3.14; the details are omitted. Evidently, CR does not hold at (x_0,ε_0) since the set $\{\nabla_x g_3(x,\varepsilon), \nabla_x g_4(x,\varepsilon)\}$ does not remain a constant rank near (x_0,ε_0). Also, SMFCQ does not hold since $M(x_0,\varepsilon_0)$ is not a singleton set. □

It is worth pointing out that a major difference between CR and SMFCQ is that the former requires some rank condition on the *active* constraints while the latter imposes linear independence on the *Lagrange active* constraints. This fact somehow suggests that Lipschitz continuity of the perturbed local solution depends heavily on the stability behavior of the active constraints while directional differentiability of the perturbed local solution is mainly affected by the Lagrange active constraints. This is the main motivation for introducing the WCR condition.

As far as the directional differentiability of the perturbed local solution of a $C^{2,1}$ program is concerned, the conditions KKT + MFCQ + GSSOSC are the weakest ones for the existence and local uniqueness of the perturbed local solution (see [13]). Whether they are also sufficient for directional differentiability of the perturbed local solution should be a very interesting question. Our next counterexample gives the answer *no* to this question. This example may be regarded as a modified version of Example 3.11.

Example 3.16. Consider the following parametric convex quadratic program

$$\text{QP}(t) \qquad \begin{aligned}&\underset{x}{\text{minimize}}\ f = \frac{1}{2}\|x - (1,0)^{\mathsf{T}}\|^2 + \frac{1}{2}\|x\|^2,\\ &\text{s.t.}\ g = A(t)x + a(t) \le 0,\end{aligned}$$

where

$$A(t) = \begin{bmatrix} -1 & 0 \\ -1 & -t \end{bmatrix}, \qquad a(t) = \begin{bmatrix} 1 \\ 1 + \frac{1}{2}t^2\sin(1/t)^{1/3} \end{bmatrix} \quad [\sin(1/0) := 0],$$

$t \in R$, and $t_0 = 0$. Let $x_0 = (1,0)^{\mathsf{T}}$. The vector $a(t)$ is once continuously differentiable at t_0. Note that QP(t) is a special realization of Example 3.11 with $\varepsilon_1 = 1$, $\varepsilon_2 = t$, and $\varepsilon_3 = \frac{1}{2}t^2\sin(1/t)^{1/3}$. It is easy to check (see Example 3.11) that the KKT conditions, MFCQ and GSSOSC hold at x_0 for QP(0). And for $t > 0$ one has

$$x(t) = (1,0)^{\mathsf{T}} + \frac{1}{2}t\sin(1/t)^{1/3}(0,1)^{\mathsf{T}}.$$

Thus

$$(x(t) - x(t_0))/t = \frac{1}{2}\sin(1/t)^{1/3}(0,1)^{\mathsf{T}}.$$

This implies that $x(t)$ is not directionally differentiable at t_0 in the direction $d = 1$. □

We close this section by summarizing informally the main results obtained in this section as follows.

(1) KKT + MFCQ + CR + GSSOSC $+C^{k+1,k}$ $(k \geq 1)$ $\Rightarrow$ Lipschitz continuity + piecewise differentiability + directional differentiability of order $h \leq k$ + Lipschitz continuous directional differentiability.

(2) KKT + SMFCQ + SSOSC $+C^{2,1}$ $\Rightarrow$ Lipschitz continuous directional differentiability.

(3) KKT + MFCQ + WCR + GSSOSC $+C^{2,1}$ $\Rightarrow$ directional differentiability.

(4) KKT + SMFCQ + SSOSC $+C^{k+1,k}$ $(k \geq 1)$ $\not\Rightarrow$ Lipschitz continuity.

(5) KKT + MFCQ + GSSOSC $+C^{2,1}$ $\not\Rightarrow$ directional differentiability.

4. Lipschitz continuity and directional differentiability of solutions of VI. Similar to those in §3, parallel results for VI problems can be established. It is shown under the hypotheses of the Mangasarian–Fromovitz constraint qualification and general strong second-order condition that the perturbed stationary point of the original problem can be continuously selected from the perturbed stationary points of the binding subproblems and relaxed subproblems. Then using the idea of continuous selections, we derive several sensitivity results concerning Lipschitz continuity, piecewise differentiability, and directional differentiability of the perturbed stationary point. We should mention that we shall only consider stationary points of VI problems in this paper. The corresponding results for local solutions of VI problems can be obtained if the VI problems in question satisfy the convexity condition since then a stationary point of a VI problem is actually a local solution of the problem.

The necessary conditions for VI problems resemble those for NLP. If x is a local solution to VI(ε) and some constraint qualifications hold at x, then the general Karush–Kuhn–Tucker (GKKT) conditions or stationary conditions hold at x (see [18]). There exist multipliers $u \in R^p_+ \times R^q$ such that (x, u) satisfies the following generalized equation:

$$0 \in \begin{bmatrix} L_D(x,u,\varepsilon) \\ -g(x,\varepsilon) \end{bmatrix} + N_{R^n \times R^p_+ \times R^q}(x,u), \tag{4.1}$$

where $L_D(x,u,\varepsilon) := F(x,\varepsilon) + \nabla_x g(x,\varepsilon)^{\mathsf{T}} u$. A point x that satisfies (4.1) with some u is said to be a stationary point of VI(ε) and the pair (x, u) is said to be a GKKT point of VI(ε). The set of multipliers associated with a stationary point x of VI(ε) are denoted by $M(x,\varepsilon)$ and its extreme point set by $E(x,\varepsilon)$. The sets of stationary points and local solutions of VI(ε) are denoted by $SP(\varepsilon)$ and $LS(\varepsilon)$, respectively. These sets will be localized, i.e., assuming x_0 is a stationary point or a local solution of VI(ε_0), for any $\delta > 0$ the stationary point set and local solution set are localized by letting $SP_\delta(\varepsilon) := SP(\varepsilon) \cap B(x_0;\delta)$ and $LS_\delta(\varepsilon) := LS(\varepsilon) \cap B(x_0;\delta)$, respectively.

Note that if x is a stationary point of NLP(ε), then various second-order sufficient conditions can ensure that x is a local solution of NLP(ε). However, solution conditions for VI problems are usually more restrictive. A commonly used one is the so-called convexity assumption (see [18]). We say that VI(ε) satisfies the convexity assumption if $g_i(\cdot,\varepsilon)$, $i = 1,\ldots,p$, are convex and $g_i(\cdot,\varepsilon)$, $i = p+1,\ldots,p+q$, are affine. In this case a stationary point of VI(ε) is also a local solution.

Let L be a subset of $\{1,\ldots,p,p+1,\ldots,p+q\}$. The corresponding binding subproblem is defined by

BVI$_L(\varepsilon)$

$$\text{find}\, x \in BK_L(x) \quad \text{such that}\, F(x,\varepsilon)^{\mathsf{T}}(x'-x) \geq 0\, \text{for any}\, x' \in BK_L(\varepsilon),$$

where $BK_L(\varepsilon) = \{x \in R^n : g_L(x, \varepsilon) \in \{0\}^\ell\}$, $g_L(x, \varepsilon)$ consists of functions $g_i(x, \varepsilon)$, $i \in L$, and ℓ is the appropriate corresponding dimensionality, and the relaxed subproblem is

$\mathrm{RVI}_L(\varepsilon)$

$$\text{find}\, x \in RK_L(x) \quad \text{such that}\, F(x, \varepsilon)^{\mathsf{T}}(x' - x) \geq 0\, \text{for any}\, x' \in RK_L(\varepsilon),$$

where $RK_L(\varepsilon) = \{x \in R^n : g_L(x, \varepsilon) \in R_-^{p'} \times \{0\}^{q'}\}$, and p', q' are the appropriate corresponding dimensionalities.

Suppose x_0 is a stationary point of VI(ε_0). The index sets $I(x_0, \varepsilon_0)$, $J(x_0, \varepsilon_0)$, and the regularity conditions LI, MFCQ, SMFCQ, CR, and WCR used in §3 apply to VI(ε_0) without any modification. The difference in the second-order conditions between NLP (ε_0) and VI(ε_0) is the replacement of $\nabla_x L(x, u, \varepsilon)$ with $L_D(x, u, \varepsilon)$.

(a) The SSOC [18] holds at x_0 with $u \in M(x_0, \varepsilon_0)$ if

$$z^{\mathsf{T}} \nabla_x L_D(x_0, u, \varepsilon_0) z > 0 \quad \text{for}\, 0 \neq z \in Z(x_0, u),$$

where $Z(x_0, u)$ is defined as in §3.

(b) The GSSOC holds at x_0 if SSOC holds at x_0 with u for all $u \in M(x_0, \varepsilon_0)$.
The differentiability assumptions for the VI problem functions are introduced in the following text. We say that the parametric VI problem VI(ε) is $C^{k,\ell}$ ($k \geq 1$, $\ell \geq 0$) near a point (x_0, ε_0) if the problem functions F and g are $(k - 1)$ and k times continuously differentiable with respect to x (near x_0) for ε near ε_0, respectively, F and $\nabla_x g$ are ℓ times continuously differentiable in (x, ε) near (x_0, ε_0).

The VI versions of Fiacco's basic sensitivity theorem and Kojima's strong stability theorem in nonlinear programs were obtained in Tobin [37] and Liu [23], which we shall state first.

PROPOSITION 4.1 (Tobin [37]). *Let L be a subset of* $\{1, \ldots, p, p+1, \ldots, p+q\}$. *Suppose KKT, SSOC, and LI hold at* x_0 *with multipliers* u_L *for* $BVI_L(\varepsilon_0)$ *and that* $BVI_L(\varepsilon)$ *is* $C^{k+1,k}$ ($k \geq 1$) *near* (x_0, ε_0). *Then*

(a) *for* ε *in a neighborhood of* ε_0, *there exists a unique function* $y_L(\varepsilon) = (x_L(\varepsilon), u_L(\varepsilon))^{\mathsf{T}} \in C^k$, *where* $(x_L(\varepsilon), u_L(\varepsilon))$ *satisfies the GKKT conditions for* $BVI_L(\varepsilon)$ *and* $y(\varepsilon_0) = (x_0, u_L)$.

(b) *The Jacobian* $Q_L(\varepsilon)$ *of the system*

$$\begin{aligned} L_D(x_L, u_L, \varepsilon) &= 0, \\ g_i(x_L, \varepsilon) &= 0, \quad i \in L, \end{aligned} \tag{4.2}$$

with respect to (x_L, u_L) *is locally nonsingular and*

$$\nabla_\varepsilon y(\varepsilon) = Q(\varepsilon)^{-1} N(\varepsilon),$$

where $-N(\varepsilon)$ *is the Jacobian of the system* (4.2) *with respect to* ε.

PROPOSITION 4.2 (Liu [23]). *Let* x_0 *be a stationary point of VI*(ε_0). *Suppose that MFCQ and GSSOC hold at* x_0 *for VI*(ε_0) *and that VI*(ε) *is* $C^{2,0}$ *near* (x_0, ε_0). *Then there exist* δ, $r > 0$, *and a continuous function* $x : B(\varepsilon_0; r) \to R^n$ *such that* $x(\varepsilon) = SP_\delta(\varepsilon)$ *and MFCQ holds at* $x(\varepsilon)$ *for all* $\varepsilon \in B(\varepsilon_0; r)$.

The limiting index sets for VI(ε_0) at x_0 can be defined in a way similar to that used in §3. The union of limiting index sets are denoted again by LIS(x_0, ε_0) and its elements by $L(1), \ldots, L(s)$. For each following binding VI subproblem

$\mathrm{BVI}_{L(i)}(\varepsilon)$

$$\text{find } x \in BK_{L(i)}(x) \quad \text{such that } F(x,\varepsilon)^{\mathsf{T}}(x'-x) \geq 0 \text{ for any } x' \in BK_{L(i)}(\varepsilon),$$

where $i \in \{1,\ldots,s\}$, under the hypotheses of Proposition 4.2 and CR condition, it can be shown (similar to the case of nonlinear programs) that the GKKT conditions, MFCQ, and GSSOC hold at x_0 for $\mathrm{BVI}_{L(i)}(\varepsilon_0)$. Then by Proposition 4.2 there exist δ_i, $r_i > 0$, and a continuous function $x_i : B(\varepsilon_0; r_i) \to R^n$ such that $x_i(\varepsilon)$ is the unique stationary point of $\mathrm{BVI}_{L(i)}(\varepsilon)$ in $B(x_0;\delta_i)$. Furthermore, it can be proved that x can be continuously selected from $\{x_i\}$ locally. Thus we have the following continuous selection theorem.

THEOREM 4.3. *Under the hypotheses of Proposition* 4.2 *and the CR condition, there exist* δ, $r > 0$, *and continuous functions* x, $x_i : B(\varepsilon_0; r) \to R^n$, $i = 1,\ldots,s$, *such that for any* $\varepsilon \in B(\varepsilon_0; r)$, $x(\varepsilon)$ *and* $x_i(\varepsilon)$, $i = 1,\ldots,s$, *are the unique stationary points of VI*(ε) *and* $BVI_{L(i)}(\varepsilon)$, $i = 1,\ldots,s$, *on* $B(x_0;\delta)$, *respectively. Moreover,* $x(\cdot)$ *is a continuous selection from* $\{x_i(\cdot) : i = 1,\ldots,s\}$ *on* $B(\varepsilon_0; r)$, *i.e., for each* $\varepsilon \in B(\varepsilon_0; r)$, $x(\varepsilon) = x_i(\varepsilon)$ *for some* $i \in \{1,\ldots,s\}$.

The next result provides sufficient conditions for Lipschitz continuity, piecewise differentiability, and directional differentiability of the perturbed stationary point.

THEOREM 4.4. *Let* x_0 *be a stationary point of VI*(ε_0). *Suppose that MFCQ, CR, and GSSOSC hold at* x_0 *for VI*(ε_0) *and that VI*(ε) *is* $C^{k+1,k}$ $(k \geq 1)$ *near* (x_0,ε_0). *Then*

(a) *there exist* δ, $r > 0$, *and a unique Lipschitz continuous function* $x : B(\varepsilon_0; r) \to R^n$ *such that* $x(\varepsilon) = SP_\delta(\varepsilon) = LS_\delta(\varepsilon)$ *for all* $\varepsilon \in B(\varepsilon_0; r)$;

(b) x *is piecewise differentiable at* ε_0 *and directionally differentiable at* ε_0 *of order* $h \leq k$ *along any direction d*;

(c) *the directional derivatives* $D^h x(\varepsilon_0; d)$ *of order* $h \leq k$ *as functions of* d *are Lipschitzian.*

Proof. The proof of the theorem is similar to that of Theorem 3.6 except that it uses Theorem 4.3 and Proposition 4.1 instead of using Theorem 3.5 and Proposition 3.3. □

The following theorem improves the classical results of Kyparisis [17] concerning the directional differentiability of the perturbed GKKT point. Its proof is similar to that of Theorem 3.7 and is omitted. Conclusion (a) in this theorem is proved by Robinson [29].

THEOREM 4.5. *Let* x_0 *be a stationary point of VI*(ε_0) *with associated multiplier* u. *Suppose that LI and SSOC hold at* x_0 *for VI*(ε_0) *and that VI*(ε) *is* $C^{k+1,k}$ $(k \geq 1)$ *near* (x_0,ε_0). *Then*

(a) *for* ε *in a neighborhood of* ε_0, *there exists a unique Lipschitz continuous function* $y(\varepsilon) = [x(\varepsilon), u(\varepsilon)]^{\mathsf{T}}$ *such that* $[x(\varepsilon), u(\varepsilon)]$ *is the GKKT point of VI*(ε) *and* $y(\varepsilon_0) = [x_0, u]$;

(b) y *is piecewise differentiable at* ε_0 *and directionally differentiable at* ε_0 *of order* $h \leq k$ *along any direction d*;

(c) *the directional derivatives* $D^h y(\varepsilon_0; d)$ *of order* $h \leq k$ *as functions of d are Lipschitzian.*

In order to establish the directional differentiability of the perturbed stationary point, we need the following result concerning a relaxed VI subproblem.

LEMMA 4.6. *Let* x_0 *be a stationary point of VI*(ε_0). *Suppose that MFCQ and GSSOC hold at* x_0 *for VI*(ε_0) *and that VI*(ε) *is* $C^{2,1}$ *near* (x_0,ε_0). *Then, for every index set* $L \subset \{1,\ldots,p,p+1,\ldots,p+q\}$ *with* $L \supset PM(u)$ *for some* $u \in E(x_0,\varepsilon_0)$ *such that* $\{\nabla_x g_i(x_0,\varepsilon_0) : i \in L \cap J'(x_0,\varepsilon_0)\}$ *is linearly independent, where* $J'(x_0,\varepsilon_0) = J(x_0,\varepsilon_0) \cup \{p+1,\ldots,p+q\}$, *there is a locally unique continuous stationary point* $x_L(\varepsilon)$ *of* $RVI_L(\varepsilon)$. *Moreover,* $x_L(\varepsilon)$ *is directionally differentiable at* ε_0 *in any direction* d *and its directional derivative* $Dx(\varepsilon_0; d)$ *uniquely solves the following linear variational inequality*

LRVI$_L(u)$

find $z \in LRK_L(u)$ *such that* $(\nabla_x L_D z + \nabla_\varepsilon L_D d)^{\mathsf{T}}(z' - z) \geq 0$ *for all* $z' \in LRK_L(u)$

where

$$LRK_L(u) = \{z : \nabla_x g_i^{\mathsf{T}} z + \nabla_\varepsilon g_i^{\mathsf{T}} d = 0, \quad i \in M(u),$$
$$\nabla_x g_i^{\mathsf{T}} z + \nabla_\varepsilon g_i^{\mathsf{T}} d \leq 0, \quad i \in L \backslash M(u)\},$$

where the functions g_i *are evaluated at* (x_0, ε_0) *and the function* L_D *at* (x_0, u, ε_0).

Proof. The proof is analogous to that of Lemma 3.13. The differences are that we use Proposition 4.2 instead of Proposition 3.4 and Corollary 3.1 in Qiu and Magnanti [28] instead of Proposition 3.9. □

Finally, we give below a sensitivity result for VI problems concerning the directional differentiability, assuming GKKT, MFCQ, WCR, and GSSOC. It covers the results of both Kyparisis [19] and Qiu and Magnanti [28] on directional differentiability. The former [19] assumes GKKT, MFCQ, CR, and GSSOC, while the latter [28] uses GKKT, SMFCQ, and SSOC.

THEOREM 4.7. *Let* x_0 *be a stationary point of VI*(ε_0). *Suppose that MFCQ, WCR, and GSSOC hold at* x_0 *for VI*(ε_0) *and that VI*(ε) *is* $C^{2,1}$ *near* (x_0, ε_0). *Then for* ε *in some neighborhood of* ε_0, *there exists a locally unique continuous stationary point* $x(\varepsilon)$ *to VI*(ε) *that is directionally differentiable at* ε_0 *in any direction* d *and its directional derivative* $Dx(\varepsilon_0; d)$ *uniquely solves the following linear variational inequality for some* $u \in E(x_0, \varepsilon_0)$:

LVI(u)

find $z \in LK(u)$ *such that* $(\nabla_x L_D z + \nabla_\varepsilon L_D d)^{\mathsf{T}}(z' - z) \geq 0$ *for all* $z' \in LK_M(u)$,

where

$$LK(u) = \{z : \nabla_x g_i^{\mathsf{T}} z + \nabla_\varepsilon g_i^{\mathsf{T}} d = 0, \quad i \in PM(u),$$
$$\nabla_x g_i^{\mathsf{T}} z + \nabla_\varepsilon g_i^{\mathsf{T}} d \leq 0, \quad i \in I(x_0, \varepsilon_0) \backslash PM(u)\},$$

where the functions g_i *are evaluated at* (x_0, ε_0) *and the function* L_D *at* (x_0, u, ε_0). *Furthermore, if we strengthen MFCQ and WCR to SMFCQ, then the directional derivative* $Dx(\varepsilon_0; d)$ *is Lipschitzian as a function of* d.

Proof. The first part of the theorem can be proved in the same way as in the proof of Theorem 3.14 except that we use Lemma 4.6 instead of Lemma 3.13. The second part of the conclusions can be shown by applying Theorem 4.4 to LVI(u). □

To see an example where Theorem 4.7 is applicable but the sensitivity results of Kyparisis [19] and Qiu and Magnanti [28] are not, we let $F(x, \varepsilon) = \nabla_x f(x, \varepsilon)$, where $f(x, \varepsilon)$ is the objective function in Example 3.15 and there is no change in the constraints. We omit the details.

Note that the KKT conditions of the parametric convex quadratic programs in both Examples 3.11 and 3.16 are variational inequalities defined over perturbed polyhedral sets. Therefore, letting $F(x, \varepsilon) = \nabla_x f(x, \varepsilon)$, we obtain two nice examples in variational inequalities that demonstrate that GKKT + SMFCQ + SSOC $+C^{2,1} \not\Rightarrow$ Lipschitz continuity of the perturbed stationary point and that GKKT + MFCQ + GSSOC $+C^{2,1} \not\Rightarrow$ directional differentiability of the perturbed stationary point, respectively.

As in §3, we end this section by informally summarizing the main results derived as follows. Note that these relations hold only for the perturbed stationary point. But if in addition each VI(ε) meets the convexity assumption, then these conclusions are also valid for the perturbed local solution.

(1) GKKT + MFCQ + CR + GSSOC $+C^{k+1,k}$ $(k \geq 1)$ $\Rightarrow$ Lipschitz continuity + piecewise differentiability + directional differentiability of order $h \leq k$+ Lipschitz continuous directional differentiability.

(2) GKKT + SMFCQ + SSOC $+C^{2,1}$ $\Rightarrow$ Lipschitz continuous directional differentiability.

(3) GKKT + MFCQ + WCR + GSSOC $+C^{2,1}$ $\Rightarrow$ directional differentiability.

(4) GKKT + SMFCQ + SSOC $+C^{2,1}$ $\not\Rightarrow$ Lipschitz continuity.

(5) GKKT + MFCQ + GSSOC $+C^{2,1}$ $\not\Rightarrow$ directional differentiability.

Acknowledgments. The author is indebted to Professor S. M. Robinson for [34], which led to Example 3.11, to Professor A.V. Fiacco for his interest, and to two anonymous referees and the associate editor who handled this paper for their valuable comments and helpful references.

A RESULT CONCERNING CONTROLLABILITY FOR THE NAVIER–STOKES EQUATIONS*

E. FERNÁNDEZ-CARA[†]AND M. GONZÁLEZ-BURGOS[†]

Abstract. The main goal of this paper is to present a new result concerning controllability of the time-dependent Navier–Stokes equations. Here, the control variable is the trace of the velocity field on a "small" part of the boundary. The main result states that the linear space spanned by final states is dense in the L^2 space of admissible fields. For the proof, one uses a duality argument that is suggested by the linear theory. This reduces the task to an existence/regularity result for a nonlinear problem.

Key words. approximate controllability, Navier–Stokes equations, nonlinear parabolic partial differential equations

AMS subject classifications. 93C20, 93B05, 76D05, 35D05

1. Statement of the problem: The main result.

In what follows it will be assumed that $\Omega \subset \mathbb{R}^N$ is a bounded open set ($N = 2$ or 3) whose boundary $\partial\Omega$ is of class $C^{1,1}$. We denote by γ a component of $\partial\Omega$ and we assume that $\partial\Omega\backslash\gamma$ has positive measure. We consider the following spaces:

$$\tilde{\mathcal{V}}(\Omega) = \{\mathbf{v}; \mathbf{v} \in \mathcal{D}(\bar{\Omega})^N,\ \nabla \cdot \mathbf{v} = 0,\ \operatorname{Supp} \mathbf{v} \subset \Omega \cup \gamma\},$$

$$\tilde{H}(\Omega) = \text{the closure of } \tilde{\mathcal{V}}(\Omega) \text{ in the space } L^2(\Omega)^N,$$

$$\tilde{V}(\Omega) = \text{the closure of } \tilde{\mathcal{V}}(\Omega) \text{ in the space } H^1(\Omega)^N.$$

Obviously, $\tilde{V}(\Omega)$ and $\tilde{H}(\Omega)$ are Hilbert spaces for the usual scalar products in $H^1(\Omega)^N$ and $L^2(\Omega)^N$, respectively. Furthermore, in $\tilde{V}(\Omega)$, the seminorm

$$\mathbf{u} \longrightarrow \|\nabla \mathbf{u}\|_{L^2}$$

is in fact a norm, equivalent to the norm in $H^1(\Omega)^N$. For simplicity, we put $\tilde{V}$ and $\tilde{H}$ instead of $\tilde{V}(\Omega)$ and $\tilde{H}(\Omega)$, resp.

Let $T > 0$ be given. Consider the following Navier–Stokes problem in $Q_T = \Omega \times (0,T)$, where we impose nonzero Dirichlet data:

$$(1)\qquad \left\{\begin{array}{rl} \dfrac{\partial \mathbf{y}}{\partial t} + (\mathbf{y}\cdot\nabla)\mathbf{y} - \nu\Delta\mathbf{y} + \nabla\pi = 0, & \nabla\cdot\mathbf{y} = 0 \text{ in } Q_T, \\ \mathbf{y} = \mathbf{v} & \text{on } \Lambda_T = \gamma \times (0,T), \\ \mathbf{y} = 0 & \text{on } S_T = (\partial\Omega\backslash\gamma) \times (0,T), \\ \mathbf{y}(0) = 0 & \text{in } \Omega. \end{array}\right.$$

Here, ν is the kinematic viscosity ($\nu > 0$) and $\mathbf{v} \in L^2(0,T;H^{-1/2}(\gamma)^N)$.

THEOREM 1.1. (a) *Assume* $\mathbf{v} = \mathbf{curl}\,\zeta\,|_\gamma$, *with*

$$(2)\qquad \begin{array}{ll} \boldsymbol{\zeta} \in L^2(0,T;H^2(\Omega)^M), & \dfrac{\partial\boldsymbol{\zeta}}{\partial t} \in L^2(0,T;H^1(\Omega)^M), \\ \boldsymbol{\zeta} \in L^\infty(0,T;W^{1,p}(\Omega)^3) & \textit{for some } p > 3 \textit{ if } N = 3, \\ \boldsymbol{\zeta} = \zeta \in L^\infty(0,T;W^{1,p}(\Omega)) & \textit{for some } p > 2 \textit{ if } N = 2, \\ \mathbf{v}(0)\cdot\mathbf{n} = 0 & \textit{in } H^{-1/2}(\gamma)^N \end{array}$$

(here, $\mathbf{n}$ *is the unit outward normal vector on* $\partial\Omega$*;* $M = 1$ *if* $N = 2$ *and* $M = 3$ *if* $N = 3$*). Then,* (1) *possesses at least one weak solution* $(\mathbf{y}_{\mathbf{v}}, \pi_{\mathbf{v}})$*. One has*

$$\mathbf{y}_{\mathbf{v}} \in L^2(0,T;\tilde{V}) \cap L^\infty(0,T;\tilde{H}),$$

$$\frac{\partial \mathbf{y}_{\mathbf{v}}}{\partial t} \in L^\sigma(0,T;H^{-1}(\Omega)^N) \qquad (\sigma = 2 \textit{ if } N = 2 \textit{ and } \sigma = 4/3 \textit{ if } N = 3),$$

$$\mathbf{y}_{\mathbf{v}} \in C^0([0,T];L^2(\Omega)^N) \quad \textit{if } N = 2,$$

$$\pi_{\mathbf{v}} \in L^2(Q_T).$$

(b) *If* $N = 2$*, there exists at most one weak solution to* (1) *(of course,* $\pi_{\mathbf{v}}$ *is unique up to a constant).*

The proof of this result can be easily obtained arguing as in [8], [9], [12]. Now, for each $\mathbf{v} \in L^2(0,T;H^{1/2}(\gamma)^N)$, let us set

$$\tilde{Y}_{\mathbf{v}}(T) = \{\mathbf{y}_{\mathbf{v}}(T); \mathbf{y}_{\mathbf{v}} \text{ solves, together with } \pi_{\mathbf{v}}, \text{ problem } (1)\}.$$

In this paper, we are concerned with the following problems.

PROBLEM (P). *Prove that the set*

$$\left(\bigcup_{\mathbf{v}} \tilde{Y}_{\mathbf{v}}(T)\right) \cap \tilde{H}$$

is dense in $\tilde{H}$.

PROBLEM (Q). *Let* $\tilde{Z}$ *be the subspace of* $\tilde{H}$ *spanned by*

$$\left(\bigcup_{\mathbf{v}} \tilde{Y}_{\mathbf{v}}(T)\right) \cap \tilde{H}.$$

Prove that $\tilde{Z}$ *is dense in* $\tilde{H}$.

Problem (P) is an approximate controllability problem in the sense of [10]. It admits the following physical interpretation: assume (for instance) that $\Omega = \mathcal{O}\backslash\bar{\Delta}$, where $\mathcal{O}$ and Δ are bounded and simply connected open sets. Also, assume that $\gamma = \partial\Delta$. If Problem (P) is solved, then a viscous incompressible fluid in $\mathcal{O}\backslash\bar{\Delta}$ that is initially at rest can be conduced to a mechanical state arbitrarily close to a given desired field acting exclusively on $\partial\Delta$.

Unfortunately, we are not able to solve Problem (P); instead, we solve Problem (Q) in this paper (see Theorem 1.2 below). Of course, the former is a much more interesting question. However, it must be noticed that in a similar linear situation Problems (P) and (Q) are equivalent. This happens, for instance, with (1) being replaced by the Stokes problem; thus, arguing as in the proof of Theorem 1.2, we obtain approximate controllability in this case (and this no matter how small γ is!).

On the other hand, recall that in the Navier–Stokes case not much is known on the nature of the set formed by all final states $\mathbf{y}_{\mathbf{v}}(T)$. In particular, it is not clear at all whether this set is very different from its linear span $\tilde{Z}$. In our opinion, this suffices to justify an analysis of Problem (Q).

Let us denote by U_{ad} the family of all admissible control functions:

$$U_{\text{ad}} = \{\mathbf{v};\ \mathbf{v} \in L^2(0,T;H^{1/2}(\gamma)^N),\ \exists \text{ solution } (\mathbf{y}_{\mathbf{v}}, \pi_{\mathbf{v}}) \text{ to } (1)\}.$$

The main result in this paper is as follows.

THEOREM 1.2. (a) *Assume $N = 2$ and let $\tilde{Y}$ be the subspace of $\tilde{H}$ spanned by the set*

$$\{\mathbf{y}_{\mathbf{v}}(T); \mathbf{v} \in U_{\text{ad}}\}.$$

Then $\tilde{Y}$ is dense in $\tilde{H}$.

(b) *Assume $N = 3$ and let $\tilde{Z}$ be the subspace of $\tilde{H}$ spanned by*

$$\left(\bigcup_{\mathbf{v}} \tilde{Y}_{\mathbf{v}}(T)\right) \cap \tilde{H}.$$

Then $\tilde{Z}$ is dense in $\tilde{H}$.

Theorem 1.2 is related to a conjecture formulated by Lions in [11]. In this reference, one is also concerned with approximate controllability, but there one imposes vanishing Dirichlet conditions on the whole $\partial\Omega \times (0, T)$ and one introduces L^2 control functions in the right side of the Navier–Stokes equations. In what follows this will be referred to as the distributed control variant of Problem (P). Bardos and Tartar [1] have considered in their paper a similar question; this time, the control is exerted on the initial condition and boundary data and second members vanish. Our result is similar to that in [1] (for $N = 2$ and initial data control) and also to those in [4] and [5] (for distributed control). See also [6] and the references therein for some related questions.

2. Some technical lemmas. Before we give the proof of Theorem 1.2, we present some technical results. First, we establish existence and regularity for the stationary Stokes problem with boundary conditions of different kinds on γ and on $\partial\Omega\backslash\gamma$ (recall that $\partial\Omega$ is a $C^{1,1}$ boundary and γ is a component of $\partial\Omega$). Let $\mathbf{f} \in L^2(\Omega)^N$, $g \in L^2(\Omega)$, and $\mathbf{b} \in H^{-1/2}(\gamma)^N$ be given and consider the following problem:

$$-\nu\Delta\mathbf{y} + \nabla\pi = \mathbf{f}, \qquad \nabla\cdot\mathbf{y} = g \quad \text{in}\,\Omega, \tag{3}$$

$$(-\pi\mathbf{Id} + \nu\nabla\mathbf{y})\cdot\mathbf{n} = \mathbf{b} \quad \text{on}\,\gamma, \tag{4}$$

$$\mathbf{y} = 0 \quad \text{on}\,\partial\Omega\backslash\gamma. \tag{5}$$

LEMMA 2.1. *There exists one and only one solution to* (3)–(5), $(\mathbf{y}, \pi) \in \tilde{V} \times L^2(\Omega)$. *For this couple,* (3) *is satisfied almost everywhere* (*a.e.*) *in* Ω, (4) *is satisfied as an equality in* $H^{-1/2}(\gamma)^N$, *and* (5) *is satisfied in the sense of the trace on* $\partial\Omega\backslash\gamma$. *Finally, there exists a constant* $C > 0$, *only depending on* Ω *and* γ, *such that*

$$\|\mathbf{y}\|_{H^1} + \|\pi\|_{L^2} \le C(\|\mathbf{f}\|_{L^2} + \|g\|_{L^2} + \|\mathbf{b}\|_{H^{-1/2}}).$$

The proof of this lemma can be achieved by means of well-known arguments. One also has the following.

LEMMA 2.2. *Let $m \ge 0$ be an integer. If $\partial\Omega$ is $C^{m+1,1}$*, $\mathbf{f} \in H^m(\Omega)^N$, $g \in H^{m+1}(\Omega)$, *and* $\mathbf{b} \in H^{m+1/2}(\gamma)^N$, *then* $(\mathbf{y}, \pi) \in H^{m+2}(\Omega)^N \times H^{m+1}(\Omega)$. *Furthermore, there exists a constant* $C > 0$, *only depending on* Ω, γ, *and* m, *such that*

$$\|\mathbf{y}\|_{H^{m+2}} + \|\pi\|_{H^{m+1}} \le C(\|\mathbf{f}\|_{H^m} + \|g\|_{H^{m+1}} + \|\mathbf{b}\|_{H^{m+1/2}}).$$

The proof of this result is rather technical. For instance, when $m = 0$, it relies on adequate uniform bounds for the finite difference quotients

$$\frac{1}{h}(\mathbf{y}(x + he_i) - \mathbf{y}(x)) \quad \text{and} \quad \frac{1}{h}(\pi(x + he_i) - \pi(x))$$

in $H^1(\Omega)^N$ and $L^2(\Omega)$, resp. The details are given in [7] (see also [2] and the references therein for other related results).

LEMMA 2.3. *There exists a sequence* $\{\lambda_j\}$, *with*

$$0 < \lambda_1 \leq \lambda_2 \leq \cdots \leq \lambda_j \leq \lambda_{j+1} \leq \dots, \qquad \lambda_j \nearrow \infty,$$

and an orthonormal basis of $\tilde{H}$, *denoted* $\{\mathbf{w}_j\}$, *such that, for all* j, *one has*

$$\mathbf{w}_j \in C^\infty(\Omega)^N \cap H^2(\Omega)^N \cap \tilde{V}$$

and

$$\int_\Omega \nabla \mathbf{w}_j : \nabla \mathbf{v}\, dx = \lambda_j \int_\Omega \mathbf{w}_j \cdot \mathbf{v}\, dx \quad \forall \mathbf{v} \in \tilde{V}.$$

The function $\mathbf{w}_j$ *is, together with some* $q_j \in C^\infty(\Omega) \cap H^1(\Omega)$, *the unique solution to*

$$\begin{cases} -\Delta \mathbf{w}_j + \nabla q_j = \lambda_j \mathbf{w}_j, \qquad \nabla \cdot \mathbf{w}_j = 0 \quad in\, \Omega, \\ (-q_j\, \mathbf{Id} + \nabla \mathbf{w}_j) \cdot \mathbf{n} = 0 \quad on\, \gamma, \\ \mathbf{w}_j = 0 \quad on\, \partial\Omega \backslash \gamma, \\ \|\mathbf{w}_j\|_{L^2} = 1. \end{cases}$$

Of course, the proof of Lemma 2.3 relies on the fact that the embedding $\tilde{V} \hookrightarrow \tilde{H}$ is dense and compact (see [7] for the details).

DEFINITION 2.4. *We introduce the trilineal form* $\tilde{b}$ *on* $H^1(\Omega)^N$ *by putting*

$$\tilde{b}(\mathbf{u},\ \mathbf{v}, \mathbf{w}) \equiv \frac{1}{2}[((\mathbf{u} \cdot \nabla)\mathbf{v}, \mathbf{w}) - ((\mathbf{u} \cdot \nabla)\mathbf{w}, \mathbf{v})].$$

Here, $(\cdot, \cdot)$ *stands for the usual scalar product in* $L^2(\Omega)^N$. *We also introduce the bilinear operator* $\tilde{B} : \tilde{V} \times \tilde{V} \to \tilde{V}'$ *by putting*

$$\langle \tilde{B}(\mathbf{u},\ \mathbf{v}), \mathbf{w} \rangle = \tilde{b}(\mathbf{u}, \mathbf{v}, \mathbf{w}) \quad \forall \mathbf{u}, \mathbf{v}, \mathbf{w}\, \in \tilde{V}.$$

Now, $\langle \cdot, \cdot \rangle$ *stands for the duality pairing between* $\tilde{V}'$ *and* $\tilde{V}$.

Assume that $\mathbf{u}, \mathbf{v}, \mathbf{w} \in H^1(\Omega)^N$ and $\nabla \cdot \mathbf{u} = 0$ in Ω. Then

$$\tilde{b}(\mathbf{u}, \mathbf{v}, \mathbf{w}) = ((\mathbf{u} \cdot \nabla)\mathbf{v}, \mathbf{w}) - \frac{1}{2} \int_{\partial\Omega} (\mathbf{u} \cdot \mathbf{n})\mathbf{v} \cdot \mathbf{w}\, dS.$$

On the other hand,

$$\tilde{b}(\mathbf{u}, \mathbf{v}, \mathbf{v}) = 0 \quad \forall \mathbf{u}, \mathbf{v} \in H^1(\Omega)^N.$$

Finally, notice that if **u** and **v** belong to $L^2(0, T; \tilde{V}) \cap L^\infty(0, T; \tilde{H})$, then

$$\tilde{B}(\mathbf{u}, \mathbf{v}) \in L^\sigma(0, T; \tilde{V}'),$$

where σ is arbitrary in $[1, 2)$ if $N = 2$ and $\sigma = 4/3$ if $N = 3$.

3. The existence of a solution to a coupled nonlinear problem. In order to prove Theorem 1.1, it will be convenient to demonstrate an existence result for a certain nonlinear problem. More precisely, for each $\mathbf{w} \in \tilde{H}$, let us introduce the system

$$
(6) \qquad \begin{cases} \dfrac{\partial \mathbf{y}}{\partial t} + (\mathbf{y} \cdot \nabla)\mathbf{y} - \nu \Delta \mathbf{y} + \nabla \pi = 0, & \nabla \cdot \mathbf{y} = 0 \quad \text{in } Q_T, \\ -\dfrac{\partial \mathbf{q}}{\partial t} - (\mathbf{y} \cdot \nabla)\mathbf{q} - \nu \Delta \mathbf{q} + \nabla Q = 0, & \nabla \cdot \mathbf{q} = 0 \quad \text{in } Q_T, \\ (-\pi \, \mathbf{Id} + \nu \nabla \mathbf{y}) \cdot \mathbf{n} - \dfrac{1}{2}(\mathbf{y} \cdot \mathbf{n})\mathbf{y} = \mathbf{q} \quad \text{on } \Lambda_T, \\ (-Q \, \mathbf{Id} + \nu \nabla \mathbf{q}) \cdot \mathbf{n} + \dfrac{1}{2}(\mathbf{y} \cdot \mathbf{n})\mathbf{q} = 0 \quad \text{on } \Lambda_T, \\ \mathbf{y} = \mathbf{q} = 0 \quad \text{on } S_T, \\ \mathbf{y}(0) = 0, \quad \mathbf{q}(T) = \mathbf{w} \quad \text{in } \Omega. \end{cases}
$$

Then one has the following theorem.

THEOREM 3.1. *If* $\mathbf{w} \in \tilde{H}$, *then the corresponding problem* (6) *possesses at least one weak solution* $(\mathbf{y}, \pi, \mathbf{q}, Q)$ *also satisfying*:

$$
(7) \qquad \begin{cases} \mathbf{y}, \mathbf{q} \in L^2(0,T;\tilde{V}) \cap L^\infty(0,T;\tilde{H}), & \dfrac{\partial \mathbf{y}}{\partial t}, \dfrac{\partial \mathbf{q}}{\partial t} \in L^\sigma(0,T;\tilde{V}'), \\ \mathbf{y}, \mathbf{q} \in C^0([0,T];\tilde{V}') \cap C^0_w([0,T];\tilde{H}), & \pi, Q \in L^2(Q_T), \end{cases}
$$

(*again*, σ *is arbitrary in* $[1,2)$ *if* $N = 2$ *and* $\sigma = 4/3$ *if* $N = 3$). *Moreover*, $\mathbf{y}$ *satisfies the energy inequalities*

$$
(8) \qquad \|\mathbf{y}(t)\|^2_{L^2} + 2\nu \int_0^t \|\nabla \mathbf{y}(s)\|^2_{L^2} \, ds \le 2 \int_0^t \int_\gamma \mathbf{q}(s) \cdot \mathbf{y}(s) dS \, ds
$$

and one has

$$
(9) \qquad (\mathbf{y}(T), \mathbf{w}) = \int \int_{\Lambda_T} |\mathbf{q}|^2 \, dS \, dt.
$$

Proof. Let us see that there exist functions

$$
\mathbf{y}, \mathbf{q} \in L^2(0,T;\tilde{V}) \cap L^\infty(0,T;\tilde{H}),
$$

which solve the weak formulation of (6), i.e., such that

$$
(10) \qquad \begin{cases} \left\langle \dfrac{\partial \mathbf{y}}{\partial t}, \mathbf{v} \right\rangle + \tilde{b}(\mathbf{y}, \mathbf{y}, \mathbf{v}) + \nu(\nabla \mathbf{y}, \nabla \mathbf{v}) = \int_\gamma \mathbf{q}(t) \cdot \mathbf{v} \, dS \quad \forall \mathbf{v} \in \tilde{V}, \\ -\left\langle \dfrac{\partial \mathbf{q}}{\partial t}, \mathbf{v} \right\rangle - \tilde{b}(\mathbf{y}, \mathbf{q}, \mathbf{v}) + \nu(\nabla \mathbf{q}, \nabla \mathbf{v}) = 0 \quad \forall \mathbf{v} \in \tilde{V}, \\ \mathbf{y}(0) = 0, \qquad \mathbf{q}(T) = \mathbf{w}. \end{cases}
$$

The proof consists of three steps.

First step: The existence of approximate solutions. We use the orthonormal basis furnished by Lemma 2.3. We denote by $\tilde{V}_m$ the linear space spanned by $\mathbf{w}_1, \mathbf{w}_2, \dots, \mathbf{w}_m$ and we put

$$\mathbf{w}_{0m} = \sum_{j=1}^{m} (\mathbf{w}, \mathbf{w}_j)\mathbf{w}_j,$$

i.e., $\mathbf{w}_{0m}$ is the orthogonal projection of $\mathbf{w}$ on $\tilde{V}_m$. For each $m \geq 1$, we search for functions

$$\mathbf{y}_m, \mathbf{q}_m \in C^0([0,T]; \tilde{V}_m)$$

such that

$$\text{(11)} \qquad \begin{cases} (\mathbf{y}'_m, \mathbf{w}_j) + \tilde{b}(\mathbf{y}_m, \mathbf{y}_m, \mathbf{w}_j) + \nu(\nabla \mathbf{y}_m, \nabla \mathbf{w}_j) = \int_\gamma \mathbf{q}_m \cdot \mathbf{w}_j \, dS \\ (1 \leq j \leq m), \qquad \mathbf{y}_m(0) = 0, \end{cases}$$

$$\text{(12)} \qquad \begin{cases} -(\mathbf{q}'_m, \mathbf{w}_j) - \tilde{b}(\mathbf{y}_m, \mathbf{q}_m, \mathbf{w}_j) + \nu(\nabla \mathbf{q}_m, \nabla \mathbf{w}_j) = 0 \\ (1 \leq j \leq m), \qquad \mathbf{q}_m(T) = \mathbf{w}_{0m}. \end{cases}$$

We argue as follows. If the function $\mathbf{p}_m$ is given in $C^0([0,T]; \tilde{V}_m)$, there exists exactly one maximal (in time) solution $\mathbf{y}_m = \mathbf{y}_m(\mathbf{p}_m)$ to the ordinary differential problem (11) with $\mathbf{q}_m = \mathbf{p}_m$. It is not difficult to check that

$$\frac{1}{2}\frac{d}{dt}\|\mathbf{y}_m(t)\|_{L^2}^2 + \nu\|\nabla \mathbf{y}_m(t)\|_{L^2}^2 = \int_\gamma \mathbf{p}_m(t) \cdot \mathbf{y}_m(t) dS.$$

Hence,

$$\|\mathbf{y}_m(t)\|_{L^2}^2 + \nu \int_0^t \|\nabla \mathbf{y}_m(s)\|_{L^2}^2 \, ds \leq C \int\int_{\Lambda_T} |\mathbf{p}_m(t)|^2 \, dS \, dt$$

for some C only depending on Ω, γ, and ν. From this inequality, we deduce that $\mathbf{y}_m$ is defined for all $t \in [0,T]$. Now, let us denote by $\mathbf{q}_m = \mathbf{q}_m(\mathbf{y}_m)$ the unique maximal solution to (12). It is clear that $\mathbf{q}_m$ is also defined for all $t \in [0,T]$. Moreover,

$$-\frac{1}{2}\frac{d}{dt}\|\mathbf{q}_m(t)\|_{L^2}^2 + \nu\|\nabla \mathbf{q}_m(t)\|_{L^2}^2 \equiv 0,$$

whence

$$\|\mathbf{q}_m(t)\|_{L^2}^2 + 2\nu \int_t^T \|\nabla \mathbf{q}_m(s)\|_{L^2}^2 \, ds = \|\mathbf{w}_{0m}\|_{L^2}^2 \leq \|\mathbf{w}\|_{L^2}^2.$$

This proves that $\mathbf{q}_m$ is bounded in $C^0([0,T]; \tilde{V}_m)$ independently from $\mathbf{y}_m$. Let W be the ball $\bar{B}(0; \|\mathbf{w}\|_{L^2}^2)$ in $C^0([0,T]; \tilde{V}_m)$ and let Φ be given as follows:

$$\Phi(\mathbf{p}_m) = \mathbf{q}_m(\mathbf{y}_m(\mathbf{p}_m)) \quad \forall \mathbf{p}_m \in W.$$

Then $\Phi : W \to W$ is a continuous compact mapping (due to the fact that $\Phi(\mathbf{p}_m) \in C^1([0,T]; \tilde{V}_m)$ for each $\mathbf{p}_m$). Consequently, Schauders' theorem applies and Φ possesses a fixed point $\mathbf{q}_m \in W$. Obviously, $\mathbf{q}_m$ and $\mathbf{y}_m = \mathbf{y}_m(\mathbf{q}_m)$ satisfy (11) and (12).

Second step: "A priori" estimates. From (11) and (12), one easily obtains

$$\mathbf{y}_m, \mathbf{q}_m \in \text{bounded set in } L^2(0,T;\tilde{V}) \cap L^\infty(0,T;\tilde{H}). \tag{13}$$

Consequently,

$$\tilde{B}(\mathbf{y}_m, \mathbf{y}_m), \tilde{B}(\mathbf{y}_m, \mathbf{q}_m) \in \text{bounded set in } L^\sigma(0,T;\tilde{V}'),$$

with σ being as before. Now, the choice of the basis $\{\mathbf{w}_j\}$ yields

$$\mathbf{y}'_m, \mathbf{q}'_m \in \text{bounded set in } L^\sigma(0,T;\tilde{V}'). \tag{14}$$

On the other hand, from (11) and (12), one easily deduces that

$$(\mathbf{y}_m(T), \mathbf{w}_{0m}) = \int\int_{\Lambda_T} |\mathbf{q}_m|^2 \, dS \, dt. \tag{15}$$

Third step: The choice of a convergent sequence — conclusion. From (13) and (14), one deduces that functions $\mathbf{y}$ and $\mathbf{q}$ and subsequences $\{\mathbf{y}_\rho\}$ and $\{\mathbf{q}_\rho\}$ must exist with

$$\mathbf{y}, \mathbf{q} \in L^2(0,T;\tilde{V}) \cap L^\infty(0,T;\tilde{H}) \cap C^0([0,T];\tilde{V}'),$$

$$\frac{\partial \mathbf{y}}{\partial t}, \frac{\partial \mathbf{q}}{\partial t} \in L^\sigma(0,T;\tilde{V}'),$$

and

$$\begin{cases} \mathbf{y}_\rho \,(\text{resp., } \mathbf{q}_\rho) \rightharpoonup \mathbf{y} \,(\text{resp., } \mathbf{q}) \text{ weakly in } L^2(0,T;\tilde{V}), \\ \mathbf{y}_\rho \,(\text{resp., } \mathbf{q}_\rho) \rightharpoonup \mathbf{y} \,(\text{resp., } \mathbf{q}) \text{ weakly} * \text{ in } L^\infty(0,T;\tilde{H}), \\ \mathbf{y}_\rho \,(\text{resp., } \mathbf{q}_\rho) \to \mathbf{y} \,(\text{resp., } \mathbf{q}) \text{ strongly in } L^2(0,T;\tilde{V}_s), \\ \dfrac{\partial \mathbf{y}_\rho}{\partial t} \left(\text{resp., } \dfrac{\partial \mathbf{q}_\rho}{\partial t}\right) \rightharpoonup \dfrac{\partial \mathbf{y}}{\partial t} \left(\text{resp., } \dfrac{\partial \mathbf{q}}{\partial t}\right) \text{ weakly in } L^\sigma(0,T;\tilde{V}'). \end{cases}$$

Here, $1/2 < s < 1$ and $\tilde{V}_s$ stands for the closure of $\tilde{V}$ with respect to the norm in $H^s(\Omega)^N$ (a new Hilbert space for the same norm). These convergence properties allow us to take limits in (11) and (12), which proves that $\mathbf{y}$ and $\mathbf{q}$ solve (10). Obviously, (8) is satisfied; on the other hand, from (15) and the previous properties, it is easy to deduce (9). This ends the proof of Theorem 3.1.

4. The proof of the main result.

From a well-known consequence of the Hahn–Banach theorem (for instance, see [3, Cor. I.8]), we know that the following is a statement equivalent to Theorem 1.2.

THEOREM 4.1. *Assume* $\mathbf{w} \in \tilde{H}$ *satisfies*

$$\begin{gathered} (\mathbf{y}_\mathbf{v}(T), \mathbf{w}) = 0 \quad \forall \mathbf{v} \in U_{\text{ad}} \quad \text{if } N = 2, \\ (\mathbf{y}_\mathbf{v}(T), \mathbf{w}) = 0 \quad \forall \mathbf{v} \in \left(\bigcup_{\mathbf{v} \in U_{\text{ad}}} \tilde{Y}_\mathbf{v}(T) \right) \cap \tilde{H} \quad \text{if } N = 3. \end{gathered} \tag{16}$$

Then $\mathbf{w} = 0$.

Proof. Let $\mathbf{w} \in \tilde{H}$ be given and assume that (16) is satisfied. Let $(\mathbf{y}^*, \pi^*, \mathbf{q}^*, Q^*)$ be the weak solution to (6) furnished by Theorem 3.1. Recall that $(\mathbf{y}^*, \pi^*, \mathbf{q}^*, Q^*)$ satisfies (7)–(9).

Let $\mathbf{v}$ be the trace of $\mathbf{y}^*$ on $\Lambda_T = \gamma \times (0,T)$. Then $\mathbf{v} \in U_{\text{ad}}$ and, moreover, the couple $(\mathbf{y}^*, \pi^*)$ is a state associated to $\mathbf{v}$. Accordingly, taking into account (9) and (16), one has

$$\mathbf{q}^* = 0 \quad \text{on } \Lambda_T. \tag{17}$$

From (8), we also deduce that $\mathbf{y}^* \equiv 0$. Thus, we have found a function $\mathbf{q}^*$ that vanishes on Λ_T and solves, together with Q^*, the following final value-boundary value problem:

$$-\frac{\partial \mathbf{q}}{\partial t} - \nu \Delta \mathbf{q} + \nabla Q = 0, \quad \nabla \cdot \mathbf{q} = 0 \quad \text{in } Q_T, \tag{18}$$

$$(-Q\,\mathbf{Id} + \nu \nabla \mathbf{q}) \cdot \mathbf{n} = 0 \quad \text{on } \Lambda_T, \tag{19}$$

$$\mathbf{q} = 0 \quad \text{on } S_T, \tag{20}$$

$$\mathbf{q}(T) = \mathbf{w} \quad \text{in } \Omega. \tag{21}$$

It is not difficult to prove that (18)–(21) possesses exactly one solution pair $(\mathbf{q}, Q)$, with (at least)

$$\mathbf{q} \in L^2(0,T;\tilde{V}) \cap C^0([0,T];\tilde{H}),$$

$$\frac{\partial \mathbf{q}}{\partial t} \in L^2(0,T;\tilde{V}'), \qquad Q \in L^2(Q_T).$$

Necessarily, $(\mathbf{q}, Q) = (\mathbf{q}^*, Q^*)$. Consequently, Theorem 4.1 is implied by Proposition 4.2 (see below).

PROPOSITION 4.2. *Assume the couple* $(\mathbf{q}^*, Q^*)$ *satisfies*

$$\mathbf{q}^* \in L^2_{\text{loc}}(0,T;\tilde{V}) \cap L^\infty_{\text{loc}}(0,T;\tilde{H}),$$

$$\frac{\partial \mathbf{q}^*}{\partial t} \in L^2_{\text{loc}}(0,T;\tilde{V}'), \qquad Q^* \in L^2_{\text{loc}}(0,T;L^2(\Omega))$$

and (17)–(20). *Then* $\mathbf{q}^* \equiv 0$.

Proof. Let $x_0 \in \gamma$ be given. Choose $r > 0$ such that

$$B(x_0;r) \cap \partial\Omega \subset \gamma$$

and consider the open sets $\omega = B(x_0;r)$ and $\tilde{\Omega} = \Omega \cup \omega$. Let $(\tilde{\mathbf{q}}, \tilde{Q})$ be the extension by zero of $(\mathbf{q}^*, Q^*)$ to the whole cylinder $\tilde{\Omega} \times (0,T)$. From (17), we see that

$$\tilde{\mathbf{q}} \in L^2_{\text{loc}}(0,T;V(\tilde{\Omega})) \cap L^\infty_{\text{loc}}(0,T;H(\tilde{\Omega})),$$

$$\tilde{Q} \in L^2_{\text{loc}}(\tilde{\Omega} \times (0,T)).$$

Here,

$$V(\tilde{\Omega}) = \{\mathbf{v}; \mathbf{v} \in H^1_0(\tilde{\Omega})^N,\ \nabla \cdot \mathbf{v} = 0 \text{ in } \tilde{\Omega}\},$$

$$H(\tilde{\Omega}) = \{\mathbf{v}; \mathbf{v} \in L^2(\tilde{\Omega})^N, \ \nabla \cdot \mathbf{v} = 0 \,\text{in}\, \tilde{\Omega}, \ \mathbf{v} \cdot \mathbf{n} = 0 \,\text{on}\, \partial\tilde{\Omega}\}.$$

$V(\tilde{\Omega})$ and $H(\tilde{\Omega})$ are endowed with the norms of $H^1(\tilde{\Omega})^N$ and $L^2(\tilde{\Omega})^N$, resp. It is easy to check that

$$\frac{\partial \tilde{\mathbf{q}}}{\partial t} \in L^2_{\text{loc}}(0,T; V(\tilde{\Omega})')$$

and

$$\begin{cases} -\dfrac{\partial \tilde{\mathbf{q}}}{\partial t} - \nu\Delta\tilde{\mathbf{q}} + \nabla\tilde{Q} = 0, \quad \nabla \cdot \tilde{\mathbf{q}} = 0 \quad \text{in}\, \tilde{\Omega} \times (0,T), \\ \tilde{\mathbf{q}} = 0 \quad \text{on}\, \partial\tilde{\Omega} \times (0,T). \end{cases}$$

In particular, we deduce that both $\tilde{\mathbf{q}}$ and $\tilde{Q}$ are analytical functions in the space in $\tilde{\Omega} \times (0,T)$ (cf. e.g. [8]). But $\tilde{\mathbf{q}} = 0$ in $(\tilde{\Omega}\backslash\bar{\Omega}) \times (0,T)$. Hence, necessarily $\tilde{\mathbf{q}} \equiv 0$.

For the sake of completeness, let us state (and prove) a regularity result for (18)–(21).

LEMMA 4.3. *Let* $\mathbf{w} \in \tilde{H}$ *and* $\delta > 0$ *be given. Then the unique solution* $(\mathbf{q}, Q)$ *to* (18)–(21) *satisfies*

$$\mathbf{q} \in L^2(0,T-\delta; H^2(\Omega)^N) \cap L^\infty(0,T-\delta; \tilde{V}) \cap L^2(0,T;\tilde{V}) \cap C^0([0,T];\tilde{H}),$$

$$\frac{\partial \mathbf{q}}{\partial t} \in L^2(0,T-\delta; H^1(\Omega)^N) \cap L^\infty(0,T-\delta; L^2(\Omega)^N) \cap L^2(0,T;\tilde{V}'),$$

$$Q \in L^2(0,T-\delta; H^1(\Omega)) \cap L^\infty(0,T-\delta; L^2(\Omega)) \cap L^2(Q_T).$$

Sketch of the proof. Let $\theta = \theta_\delta$ be a real-valued C^∞ function on $[0,+\infty)$ such that

$$\theta \equiv 1 \,\text{in}\, [0,T-\delta), \qquad \theta \equiv 0 \,\text{in}\, \left[T - \frac{\delta}{2}, +\infty\right).$$

Using θ, we introduce

$$\hat{\mathbf{q}} = \theta\mathbf{q} \quad \text{and} \quad \hat{Q} = \theta Q.$$

Then $\hat{\mathbf{q}} \in L^2(0,T;\tilde{V}) \cap L^\infty(0,T;\tilde{H})$ and, also,

$$\begin{cases} -\left\langle \dfrac{\partial \hat{\mathbf{q}}}{\partial t}(t), \mathbf{v} \right\rangle + \nu(\nabla\hat{\mathbf{q}}(t), \nabla\mathbf{v})_{0;\Omega} = (\mathbf{f}(t), \mathbf{v})_{0;\Omega} \quad \forall \mathbf{v} \in \tilde{V}, \ t \in (0,T) \,\text{a.e.}, \\ \hat{\mathbf{q}}(T) = 0, \end{cases}$$

where $\mathbf{f} = -\theta'\mathbf{q}$. Notice that

$$\mathbf{f} \in L^2(0,T;\tilde{V}) \cap L^\infty(0,T;\tilde{H}) \quad \text{and} \quad \frac{\partial \mathbf{f}}{\partial t} \in L^2(0,T;\tilde{V}').$$

It is clear that $\hat{\mathbf{q}}$ is the limit of approximate solutions $\hat{\mathbf{q}}_m$, with

$$\hat{\mathbf{q}}_m(t) = \sum_{j=1}^{m} \hat{q}^j_m(t)\mathbf{w}_j,$$

$$(22)\qquad \begin{cases} -(\hat{\mathbf{q}}'_m(t),\mathbf{w}_j)_{0;\Omega} + \nu(\nabla\hat{\mathbf{q}}_m(t),\,\nabla\mathbf{w}_j)_{0;\Omega} = (\mathbf{f}(t),\mathbf{w}_j)_{0;\Omega}, \\ (1\le j\le m), \qquad \hat{\mathbf{q}}_m(T)=0. \end{cases}$$

Differentiation with respect to t leads to the equalities

$$(23)\qquad -(\hat{\mathbf{q}}''_m(t),\mathbf{w}_j)_{0;\Omega} + \nu(\nabla\hat{\mathbf{q}}'_m(t),\nabla\mathbf{w}_j)_{0;\Omega} = \langle\mathbf{f}',\mathbf{w}_j\rangle.$$

Now, multiplying the jth equation in (22) by $\lambda_j\hat{q}^j_m(t)$, adding for $1\le j\le m$, and integrating with respect to t, we are led to the inequalities

$$\|\nabla\hat{\mathbf{q}}_m(t)\|^2_{0;\Omega} + \nu\int_t^T \|\Delta\hat{\mathbf{q}}'_m(s)\|^2_{0;\Omega}\,ds \le C\int_0^T \|\mathbf{f}(t)\|^2_{0;\Omega}\,dt,$$

where C is a constant. This proves that

$$\hat{\mathbf{q}}\in L^2(0,T;H^2(\Omega)^N)\cap L^\infty(0,T;\tilde{V}).$$

On the other hand, multiplying (23) by $(\hat{q}^j_m)'(t)$ and adding for $1\le j\le m$, we obtain

$$-\frac{1}{2}\frac{d}{dt}\|\hat{\mathbf{q}}'_m(t)\|^2_{0;\Omega} + \nu\|\nabla\hat{\mathbf{q}}'_m(t)\|^2_{0;\Omega} = -\left\langle\frac{\partial\mathbf{f}}{\partial t}(t),\hat{\mathbf{q}}'_m(t)\right\rangle \quad \forall t\in[0,T].$$

After integration with respect to t, one has

$$\|\hat{\mathbf{q}}'_m(t)\|^2_{0;\Omega} + \nu\int_t^T \|\delta\hat{\mathbf{q}}'_m(s)\|^2_{0;\Omega}\,ds \le C\left\|\frac{\partial\mathbf{f}}{\partial t}\right\|^2_*,$$

where $\|\cdot\|_*$ stands for the norm in $L^2(0,T;\tilde{V}')$. Hence,

$$\frac{\partial\hat{\mathbf{q}}}{\partial t}\in L^2(0,T;H^1(\Omega)^N)\cap L^\infty(0,T;L^2(\Omega)^N).$$

This proves the lemma.

SMOOTHLY GLOBAL STABILIZABILITY BY DYNAMIC FEEDBACK AND GENERALIZATIONS OF ARTSTEIN'S THEOREM*

JOHN TSINIAS†

Abstract. The purpose of this paper is to explore the dynamic feedback stabilization problem for general nonlinear systems extending previous works of Artstein, Sontag, and the author. First, sufficient conditions for global stabilization by smooth dynamic feedback are provided concerning a wide class of triangular systems, where the linearization at the equilibrium is controllable. For the general nonlinear case, we derive a necessary and sufficient condition for global stabilization by means of an almost smooth dynamic feedback.

Key words. global, dynamic stabilizability, smooth, almost smooth feedback

AMS subject classification. 93D15

1. Introduction.

We consider general nonlinear single-input systems of the form

$$\dot{x} = f(x,u), \qquad (x,u) \in \mathbb{R}^n \times \mathbb{R}, \tag{1.1}$$

where the map $f : \mathbb{R}^{n+1} \to \mathbb{R}$ is continuous vanishing at zero.

We say that (1.1) is static asymptotically stabilizable (S.A.S.) at the origin if there exists an ordinary state feedback $u = u(x)$, vanishing at zero, which is smooth (C^∞) on $\mathbb{R}^n \backslash \{0\}$, such that $0 \in \mathbb{R}^n$ is asymptotically stable with respect to the closed-loop system $\dot{x} = f(x, u(x))$. We say that (1.1) is dynamic asymptotically stabilizable (D.A.S.) at the origin if the extended $(n+1)$-dimensional affine in the control system

$$\dot{x} = f(x,y); \qquad \dot{y} = v \tag{1.2}$$

is S.A.S. Finally, (1.1) is said to be smoothly S.A.S. (D.A.S.) when the corresponding feedback stabilizers are smooth on the whole space $\mathbb{R}^n$ ($\mathbb{R}^{n+1}$, respectively).

Our purpose is to analyze the feedback stabilzability problem in terms of control Lyapunov functions (clf) extending previous works on the same problem (see for instance [1], [2], [5], [8], [11], [13] and references therein).

First, we derive sufficient conditions for smoothly dynamic global stabilization for general triangular systems of the form

$$\begin{gathered} \dot{x}_1 = f_1(x_1, x_2), \\ \dot{x}_2 = f_2(x_1, x_2, x_3), \\ \cdots\cdots \\ \dot{x}_n = f_n(x_1, x_2, x_3, \ldots, x_n, x_{n+1}), x_{n+1} \div u, \end{gathered} \tag{1.3}$$

where the mappings $f_i : \mathbb{R}^{i+1} \to \mathbb{R}$, $i = 1, \ldots, n$ are C^∞ vanishing at zero. A typical example of nonlinearizable systems having triangular structure are systems of the form $x^{(n)} = \phi(x, x^{(1)}, \ldots, x^{(n-1)}, u)$, $x \in \mathbb{R}$, where the map ϕ is purely nonlinear with respect to u. Necessary and sufficient conditions for a general system to be triangularizable by applying change of coordinates plus dynamic feedback are given in [10].

The following theorem is one of the main results of our paper extending previous works on the feedback stabilization for triangular systems (see for instance [6], [9], [12], [14]).

THEOREM 1.1. *Suppose that for each $1 \le i \le n$ the following conditions hold:*

* Received by the editors December 28, 1992; accepted for publication (in revised form) March 24, 1994.

† National Technical University, Department of Mathematics, Zografou Campus, 15780 Athens, Greece.

(i) *for every* $x_1, \dots, x_i$ *the map* $f_i(x_1, \dots, x_i, \cdot) : \mathbb{R} \to \mathbb{R}$ *is a surjection, namely,* $f_i(x_1, \dots, x_i, \mathbb{R}) = \mathbb{R}$. *Furthermore, assume that*

$$f_i(0, \dots, 0, \mathbb{R}^+) = \mathbb{R}^+(\mathbb{R}^-); \qquad f_i(0, \dots, 0, \mathbb{R}^-) = \mathbb{R}^-(\mathbb{R}^+), \tag{1.4a}$$

whereas

$$f_i(0, \dots, 0, x_{i+1}) = 0 \quad \textit{iff}\ x_{i+1} = 0; \tag{1.4b}$$

(ii) *for each compact set* $A \subset \mathbb{R}^i$ *and for every unbounded subset* B *of the real line, the set*

$$\{t \in \mathbb{R} : t = f_i(x_1, \dots, x_i; y), (x_1, \dots, x_i; y) \in A \times B\}$$

is unbounded;

(iii) $$\frac{\partial f_i}{\partial x_{i+1}}(0, \dots, 0, 0) \neq 0,$$

which means that the linearization of (1.3) *at the origin is controllable.*
Then the system (1.3) *is smoothly globally D.A.S. If in addition we assume that*

(iv) $$\frac{\partial f_n}{\partial u}(x, u) \neq 0, \quad \forall (x, u) \in \mathbb{R}^n \times \mathbb{R},$$

then (1.3) *is smoothly globally S.A.S.*

Remark 1.2. A particular case of systems (1.3) satisfying all conditions of Theorem 1.1 arises when we assume that each f_i has the form

$$f_i(x_1, \dots, x_i, x_{i+1}) = x_{i+1} + g_i(x_1, \dots, x_i), \tag{1.5}$$

where each g_i is smooth and independent of x_{i+1}. It is well known that every single-input system (1.1), which is affine in the control, can locally be transformed into (1.3) with dynamics (1.5), provided that Brockett's linearization conditions are satisfied (see [3], [10]). Furthermore, as it was pointed out in [10], [14], the system (1.3) with dynamics (1.5) is globally feedback equivalent to a controllable linear system. Since the latter is globally S.A.S. by means of a linear feedback, it follows that the original system is smoothly globally S.A.S. and therefore according to [13, Thm. 4] it is smoothly globally D.A.S. Theorem 1.1 of the present paper consists of an extension of the previous case for general triangular systems (1.3).

The proof of Theorem 1.1 is based on the following result providing sufficient conditions for dynamic stabilization for the general case (1.1).

THEOREM 1.3 [15]. *Suppose that there exist a closed subset* $M \subset \mathbb{R}^{n+1}$, *a pair of disjoint open subsets* $U^+, U^- \subset \mathbb{R}^{n+1}$, *and a* C^1 *positive definite function* $V : \mathbb{R}^n \to \mathbb{R}$ *such that*

(i) $$0 \in M, \quad \mathbb{R}^{n+1} = U^+ \cup U^- \cup M, \quad \pi(M) = \mathbb{R}^n,$$

where $\pi(M)$ *denotes the projection of* M *on* $\mathbb{R}^n$ *along the y axis*;

(ii) *the following conditions hold*:

$$\{0\} \times (0 + \infty) \subset U^+, \qquad \{0\} \times (-\infty, 0) \subset U^-, \tag{1.6}$$

and further for each compact set $Q \subset \mathbb{R}^n$ *the set* $S_Q \doteqdot \{(x, y) \in M,\ x \in Q\}$ *is compact*;

(iii) *for each nonzero* $(x, y) \in M$ *we have*

$$DV(x) f(x, y) < 0, \tag{1.7}$$

where DV denotes the derivative of V;

(iv) *V is uniformly unbounded on $\mathbb{R}^n$, i.e., $V(x) \to +\infty$ as $\|x\| \to +\infty$, where $\| \ \|$ denotes the usual Euclidean norm.*
Then there exists a C^1 map $\Phi(x, y)$ such that the function $L(x, y) \div V(x) + \Phi(x, y)$ is a global clf with respect to (1.2), *namely, L is C^1, positive definite, uniformly unbounded on $\mathbb{R}^{n+1}$, and satisfies*

$$((\partial L/\partial x)f)(x,y) < 0, \quad \forall\,(x,y) \neq 0 : (\partial L/\partial y)(x,y) = 0.$$

Hence, according to Artstein's theorem (1.1) *is globally D.A.S. The system* (1.1) *is locally D.A.S., if $U^+ \cup U^- \cup M$ and $\pi(M)$ are neighborhoods of* $0 \in \mathbb{R}^{n+1}$ *and* $0 \in \mathbb{R}^n$, *respectively, and* (1.6) *and condition* (iii) *are fulfilled.*

Remark 1.4. The well-known Artstein's theorem [2] asserts that the Lyapunov condition (1.7) is satisfied for each $x \neq 0$ and for some $y = y(x)$ depending on x, if and only if (1.1) is stabilizable by means of a relaxed static feedback. Stabilization by means of an ordinary static feedback, which is smooth on $\mathbb{R}^n \backslash \{0\}$, is in general feasible if we further assume that (1.1) is affine in the control. It should be noted that conditions (i)–(iv) are satisfied in the particular case where (1.1) is S.A.S. by means of a feedback law that is continuous at zero (see [15]). In that case the assumption $0 \in M$ is equivalent to the fact that the control function V satisfies the "small control property" (see [2], [11], [13]).

A second aim of the paper is to provide a generalization of Theorem 1.3. In particular, in Theorem 3.1 we provide a necessary and sufficient condition for global stabilization of (1.1) by means of a dynamic ordinary feedback that is smooth on $\mathbb{R}^{n+1} \backslash \{0\}$. The proof of Theorem 3.1, similar to that of Theorem 1.3, is based on the construction of an appropriate clf guaranteeing feedback stabilization. However, the weaker assumptions imposed in Theorem 3.1 do not permit following the same procedure as in [15] to construct the desired clf. A more careful analysis is required.

Finally, relationships between global controllability and conditions of Theorem 1.1, as well as remarks on global stabilization by means of a continuous static feedback for planar systems, are included in §§2.2 and 3, respectively.

2. The triangular case.

2.1. Smoothly global stabilization.

To prove Theorem 1.1, we first need the following elementary lemmas.

LEMMA 2.1. *Suppose that conditions* (i) *and* (ii) *of Theorem* 1.1 *are satisfied and without any loss of generality assume that $f_i(0, \mathbb{R}^+) = \mathbb{R}^+$ and $f_i(0, \mathbb{R}^-) = \mathbb{R}^-$ for every $i = 1, \ldots, n$. Let $s : \mathbb{R}^i \to \mathbb{R}$ be a continuous function vanishing at zero. Then conditions* (i) *and* (ii) *of Theorem* 1.3 *are satisfied with*

$$\begin{gathered}
x = w_i \div (x_1, \ldots, x_i),\ y \div x_{i+1}, \\
M \div \{(w_i, y) \in \mathbb{R}^{i+1} : f_i(w_i, y) = s(w_i)\}, \\
U^+ \div \{(w_i, y) \in \mathbb{R}^{i+1} : f_i(w_i, y) > s(w_i)\}; \\
U^- \div \{(w_i, y) \in \mathbb{R}^{i+1} : f_i(w_i, y) < s(w_i)\}.
\end{gathered}$$

Proof. Conditions (i) and (1.6) of Theorem 1.3 follow immediately by taking into account the definitions of M, U^+, and U^- and the fact that $f_i(0, \mathbb{R}^\pm) = \mathbb{R}^\pm$ and $f_i(w_i, \mathbb{R}) = \mathbb{R}$ for all w_i. The latter also asserts that M, U^+, and U^- are nonempty. Next we show that for each compact set $Q \subset \mathbb{R}^i$ the set S_Q, as defined in the statement of Theorem 1.3, is compact. Indeed, suppose on the contrary that there exists a sequence $(w_{i\nu}, y_\nu) \in M$, $w_{i\nu} \in Q$, $\nu = 1, 2, \ldots$, with $w_{i\nu} \to w \in Q$ and $|y_\nu| \to +\infty$. This, in conjunction with assumption (ii) of

Theorem 1.1, implies that $\overline{\lim}|f_i(w_{i\nu}, y_\nu)| = +\infty$. On the other hand, by the definition of M, $f_i(w_{i\nu}, y_\nu) = s(w_{i\nu})$ for all ν and so $\lim f_i(w_{i\nu}, y_\nu) = s(w)$, a contradiction. □

LEMMA 2.2. *In addition to the hypothesis of Lemma* 2.1, *assume that condition* (iii) *of Theorem* 1.1 *is satisfied and the functions f_i and s are C^∞ near zero. Then there is a constant $\rho > 0$ and a unique map $\phi_i : \mathbb{R}^i \to \mathbb{R}$ vanishing at zero that is C^∞ on the region $\{(w_i, y) \in \mathbb{R}^{i+1}, \|w_i\| \le \rho\}$, where $w_i \doteq (x_1, \dots, x_i)$ and $y \doteq x_{i+1}$, such that the intersection of this region with the set M as defined in Lemma* 2.1 *coincides with the graph of the mapping $y = \phi_i(w_i)$.*

Proof. Since f_i satisfies condition (iii) of Theorem 1.1 and both f_i and s are C^∞ vanishing at zero, by the implicit function theorem there exists a constant $\rho > 0$ and a unique smooth map $\phi_i : \mathbb{R}^i \to \mathbb{R}$ with $\phi_i(0) = 0$ such that $f_i(w_i, \phi_i(w_i)) = s(w_i)$ for $\|w_i\| \le \rho$. This implies that the graph of ϕ_i restricted to the sphere S_ρ of radius ρ centered at $0 \in \mathbb{R}^{i+1}$ is contained in M. To complete the proof, suppose on the contrary that there exists a sequence $(w_{i\nu}, y_\nu) \in M \backslash S_\rho$ with $w_{i\nu} \to 0$. Then $f_i(w_{i\nu}, y_\nu) = s(w_{i\nu})$, whereas by using assumption (ii) and the continuity of f_i and s we may assume that $\lim y_\nu = \alpha < +\infty$. Consequently, $f(0, \alpha) = 0$ with $|\alpha| \ge \rho$, which contradicts (1.4b). The latter implies the desired conclusion. □

Proof of Theorem 1.1. For reasons of simplicity we consider the case $n = 2$, namely, we show that the system

$$\begin{pmatrix} \dot{x}_1 \\ \dot{x}_2 \end{pmatrix} = \begin{pmatrix} f_1(x_1, x_2) \\ f_2(x_1, x_2, x_3) \end{pmatrix}, \qquad x_3 \doteq u \tag{2.1}$$

is globally D.A.S. by means of a dynamic feedback, which is smooth on $\mathbb{R}^2$. The proof of the general case follows by induction and applying the same arguments. We divide our proof into two steps. In Step I we use assumptions (i)–(iii) of Theorem 1.1 for the map f_1 in order to establish that the system

$$\dot{x}_1 = f_1(x_1, x_2), \qquad x_2 \doteq u \tag{2.2}$$

is smoothly globally D.A.S. or, equivalently, the system

$$\dot{x}_1 = f_1(x_1, x_2), \quad \dot{x}_2 = v \tag{2.3}$$

is globally S.A.S. by means of a smooth static feedback $v = v_1(x_1, x_2)$. In Step II, taking into account the smoothness of the map ν_1, assumptions (i)–(iii) imposed for the map f_2, and following the same procedure as in Step I, we prove that (2.1) is smoothly globally D.A.S. or, equivalently, the system

$$\dot{x}_1 = f_1(x_1, x_2), \quad \dot{x}_2 = f_2(x_1, x_2, x_3), \quad \dot{x}_3 = v \tag{2.4}$$

is globally S.A.S. by means of a smooth static feedback $v = v_2(x_1, x_2, x_3)$. As in the statement of Lemma 2.1 we assume in what follows that $f_1(0, \mathbb{R}^\pm) = f_2(0, 0, \mathbb{R}^\pm) = \mathbb{R}^\pm$.

Step I: Smoothly global stabilization of (2.3). We define

$$M_1 \doteq \{(x_1, x_2) \in \mathbb{R}^2 : f_1(x_1, x_2) = -x_1\}, \qquad U_1^+ \doteq \{(x_1, x_2) \in \mathbb{R}^2 : f_1(x_1, x_2) > -x_1\},$$
$$U_1^- \doteq \{(x_1, x_2) \in \mathbb{R}^2 : f_1(x_1, x_2) < -x_1\}.$$

Taking into account assumptions (i) and (ii) of Theorem 1.1 and Lemma 2.1, it follows that these sets are nonempty, disjoint, and further that all conditions of Theorem 1.3 are fulfilled with $x_1, x_2, \mathbb{R}, V_1(x_1) \doteq \frac{1}{2}x_1^2, M_1, U_1^+$ and U_1^- instead of $x, y, \mathbb{R}^n, V(x), M, U^+$, and U^-, respectively. Hence according to Theorem 1.3 the system (2.2) is globally D.A.S. In particular, there exists a C^1 nonnegative map $\Phi(x_1, x_2)$ such that the function

$$L(x_1, x_2) \doteqdot V_1(x_1) + \Phi(x_1, x_2)$$

is a global clf with respect to (2.3). Equivalently, the following Lyapunov condition holds:

$$\text{(2.5a)}\qquad \begin{gathered} \frac{\partial L}{\partial x_2}(x_1, x_2) = \frac{\partial \Phi}{\partial x_2}(x_1, x_2) = 0, \qquad (x_1, x_2) \neq 0 \Rightarrow (x_1, x_2) \in M, \\ \left(\frac{\partial L}{\partial x_1} f_1\right)(x_1, x_2) = x_1 f_1(x_1, x_2) + \left(\frac{\partial \Phi}{\partial x_1} f_1\right)(x_1, x_2) < 0, \end{gathered}$$

$$\text{(2.5b)}\qquad \begin{gathered} \frac{\partial \Phi}{\partial x_2}(x_1, x_2) > 0 \quad \text{for } (x_1, x_2) \in U_1^+, \\ \frac{\partial \Phi}{\partial x_2}(x_1, x_2) < 0 \quad \text{for } (x_1, x_2) \in U_1^-, \end{gathered}$$

and since L is uniformly unbounded

$$\text{(2.5c)}\qquad \Phi(x_{1\nu}, x_{2\nu}) \to +\infty$$

for any sequence $\{x_{1\nu}, x_{2\nu}\}$ with $\lim |x_{1\nu}| < +\infty$ and $\lim |x_{2\nu}| = +\infty$.
Moreover, from condition (iii) we get $(\partial f_1/\partial x_2)(0,0) \neq 0$, and so by Lemma 2.2 there exist a positive constant ρ and a real map $x_2 = \phi_1(x_1)$ vanishing at zero, which is smooth on $\{(x_1, x_2) \in \mathbb{R}^2 : |x_1| < \rho\}$, and the intersection of this region with the set M_1 equals $\{(x_1, x_2) \in \mathbb{R}^2 : x_2 = \phi_1(x_1),\ |x_1| < \rho\}$; equivalently

$$\text{(2.6)}\qquad f_1(x_1, \phi_1(x_1)) = -x_1, \qquad |x_1| \leq \rho.$$

(Note that (2.6) implies that the feedback law $x_2 = \phi_2(x_1)$ locally asymptotically stabilizes (2.2) at $0 \in \mathbb{R}$.) It turns out that the map Φ can be constructed so that the following additional conditions are satisfied:

$$\text{(2.7a)}\qquad \Phi(x_1, x_2) = 0, \qquad |x_1| < \rho \Leftrightarrow x_2 = \phi_1(x_1),$$

$$\text{(2.7b)}\qquad (\partial \Phi/\partial x_2)(x_1, x_2) > 0, \quad \forall\, (x_1, x_2) \in \mathbb{R}^2 : |x_1| < \rho;\ x_2 > \phi_1(x_1),$$

$$\text{(2.7c)}\qquad (\partial \Phi/\partial x_2)(x_1, x_2) < 0, \quad \forall\, (x_1, x_2) \in \mathbb{R}^2 : |x_1| < \rho;\ x_2 < \phi_1(x_1),$$

and therefore, since Φ is positive definite,

$$\text{(2.7d)}\qquad D\Phi(x_1, x_2) = 0, \quad \forall\, (x_1, x_2) \text{ with } x_2 = \phi_1(x_1), |x_1| < \rho.$$

(See [15] or §3 of the present paper for a detailed construction of Φ.)

Until now we have shown that the function L is a global clf with respect to (2.3) and so (2.3) is globally asymptotically stabilizable by means of an ordinary static feedback that is in general discontinuous at $0 \in \mathbb{R}^2$. Next, using the additional properties (2.6), (2.7), and the fact that ϕ_1 is C^∞ near zero, we build a smooth stabilizer. First, we recall Theorem 4 in [13], which asserts that since ϕ_1 is smooth and satisfies (2.6), the function

$$\Phi_s(x_1, x_2) \doteqdot V_1(x_1) + \frac{1}{2}(x_2 - \phi_1(x_1))^2, \qquad \left(V_1(x_1) = \frac{1}{2}x_1^2\right)$$

is a local clf with respect to (2.3); in particular, there exists a smooth feedback $\nu = \nu_s(x_1, x_2)$ and a positive constant $\rho_1 \leq \rho$ such that

$$\left(\frac{\partial \Phi_s}{\partial x_1} f_1\right)(x_1, x_2) + \nu_s(x_1, x_2)\frac{\partial \Phi_s}{\partial x_2}(x_1, x_2) < 0, \quad \text{for } 0 < \|(x_1, x_2)\| \leq \rho_1. \tag{2.8}$$

Let $k : \mathbb{R}^2 \to \mathbb{R}^+$ be a smooth map taking values on the interval [0,1] such that $k(x_1, x_2) = 0$ for $\|(x_1, x_2)\| \leq \rho_1/2$ and $k(x_1, x_2) = 1$ for $\|(x_1, x_2)\| \geq \rho_1$. We define

$$V_2(x_1, x_2) \doteqdot V_1(x_1) + k(x_1, 0)\Phi(x_1, x_2) + \frac{1}{2}(1 - k(x_1, 0))(x_2 - \phi_1(x_1))^2. \tag{2.9}$$

Obviously, V_2 is C^1 positive definite. Indeed, V_2 is nonnegative definite, whereas if $V_2(x_1, x_2) = 0$ it follows that $x_1 = 0$, $k(x_1, 0) = 0$, and so $x_2 = \phi_1(0) = 0$. Next we establish that V_2 is a global clf with respect to (2.3) and construct the desired global smooth stabilizer. First, we show that V_2 is uniformly unbounded on $\mathbb{R}^2$. Consider any sequence $(x_{1\nu}, x_{2\nu}) \in \mathbb{R}^2$ with $\|(x_{1\nu}, x_{2\nu})\| \to +\infty$. Without any loss of generality we distinguish two cases. The first is $|x_{1\nu}| \to +\infty$ and $\lim |x_{2\nu}| < +\infty$. Then $k(x_{1\nu}, 0) = 1$ for sufficiently large ν and so

$$\lim V_2(x_{1\nu}, x_{2\nu}) = \lim V_1(x_{1\nu}) = +\infty.$$

The other case is $|x_{2\nu}| \to +\infty$ and $\lim |x_{1\nu}| < +\infty$. Then by (2.5c) $\Phi(x_{1\nu}, x_{2\nu}) \to +\infty$, $|x_{2\nu} - \phi_1(x_{1\nu})| \to +\infty$, $0 \leq k(x_{1\nu}, 0) \leq 1$ for all ν and so

$$\lim V_2(x_{1\nu}, x_{2\nu}) = \lim(k(x_{1\nu}, 0)\Phi(x_{1\nu}, x_{2\nu}) + \frac{1}{2}(1 - k(x_{1\nu}, 0))(x_{2\nu} - \phi_1(x_{1\nu}))^2) = +\infty;$$

therefore V_2 is uniformly unbounded on $\mathbb{R}^2$. We now show that $(\partial V_2/\partial x_1)f_1(x_1, x_2) < 0$ for every $(x_1, x_2) \neq 0$ with $(\partial V_2/\partial x_2)(x_1, x_2) = 0$, which asserts that V_2 is a global clf with respect to (2.3). Indeed, for each nonzero vector (x_1, x_2) with

$$(\partial V_2/\partial x_2)(x_1, x_2) = k(x_1, 0)(\partial \Phi/\partial x_2)(x_1, x_2) + (1 - k(x_1, 0))(x_2 - \phi_1(x_1)) = 0,$$

we get by (2.5) – (2.9) and the definition of k that $(x_1, x_2) \in M_1$ and

$$\left(\frac{\partial V_2}{\partial x_1} f_1\right)(x_1, x_2) = \begin{cases} x_1 f_1(x_1, x_2) < 0, & (x_2, x_2) \in M_1 : |x_1| \leq \rho_1, \\ x_1 f_1(x_1, x_2) + \left(\dfrac{\partial \Phi}{\partial x_1} f_1\right)(x_1, x_2) < 0; & (x_1, x_2) \in M_1, |x_1| > \rho_1. \end{cases}$$

Hence according to Artstein's theorem there exists an ordinary map $v = v_1(x_1, x_2)$ that is smooth on $\mathbb{R}^2 \backslash \{0\}$ and satisfies

$$\left(\frac{\partial V_2}{\partial x_1} f_1\right)(x_1, x_2) + v_1(x_1, x_2)\frac{\partial V_2}{\partial x_2}(x_1, x_2) < 0, \quad \forall (x_1, x_2) \neq 0. \tag{2.10}$$

We are now in a position to prove that the map

$$v_2(x_1, x_2) \doteqdot k(2x_1, 2x_2)v_1(x_1, x_2) + (1 - k(2x_1, 2x_2))v_s(x_1, x_2),$$

where v_s and v_1 are defined in (2.8) and (2.10), respectively, is the desired global smooth stabilizer for (2.3). Obviously, v_2 is smooth on the whole space $\mathbb{R}^2$ and vanishes at $0 \in \mathbb{R}^2$. We use the Lyapunov inequalities (2.8) and (2.10) to prove that the map v_2 globally asymptotically stabilizes (2.3). Indeed, we evaluate the derivative $\dot{V}_2$ of V_2 along the trajectories of the closed-loop system

$$\dot{x}_1 = f_1(x_1, x_2), \qquad \dot{x}_2 = v_2(x_1, x_2).$$

We obtain

$$\begin{aligned}\dot{V}_2(x_1, x_2) &= \left(\frac{\partial V_2}{\partial x_1} f_1\right)(x_1, x_2) + \left(v_2 \frac{\partial V_2}{\partial x_2}\right)(x_1, x_2)\\ &= k(2x_1, 2x_2)\left(\left(\frac{\partial V_2}{\partial x_1} f_1\right)(x_1, x_2) + \left(v_1 \frac{\partial V_2}{\partial x_2}\right)(x_1, x_2)\right)\\ &\quad + (1 - k(2x_1, 2x_2))\left(\left(\frac{\partial V_2}{\partial x_1} f_1\right)(x_1, x_2) + \left(v_s \frac{\partial V_2}{\partial x_2}\right)(x_1, x_2)\right).\end{aligned}$$

For $\|(x_1, x_2)\| \geq \rho_1/2$ we find $k(2x_1, 2x_2) = 1$ and so the previous expression is equal to $(\partial V_2/\partial x_1)f_1 + v_1(\partial V_2/\partial x_2)$, which by (2.10) is strictly negative. For $0 < \|(x_1, x_2)\| < \rho_1/2$ it follows that $|x_1| < \rho_1/2$, $k(x_1, 0) = 0$, $V_2(x_1, x_2) = \Phi_s(x_1, x_2)$, and so

$$\begin{aligned}\dot{V}_2(x_1, x_2) &= k(2x_1, 2x_2)\left(\frac{\partial V_2}{\partial x_1} f_1 + v_1 \frac{\partial V_2}{\partial x_2}\right)(x_1, x_2)\\ &\quad + (1 - k(2x_1, 2x_2))\left(\frac{\partial \Phi_s}{\partial x_1} f_1 + v_s \frac{\partial \Phi_s}{\partial x_2}\right)(x_1, x_2),\end{aligned}$$

which by (2.8) and (2.10) is also strictly negative. Therefore $\dot{V}_2(x_1, x_2) < 0$ for all $(x_1, x_2) \neq 0$; hence we conclude that the map v_2 globally asymptotically stabilizes (2.3) at $0 \in \mathbb{R}^2$.

Step II: Smoothly global stabilization of (2.4). We now show that (2.1) is smoothly globally D.A.S. The procedure is analogous with that of Step I so we present it briefly. Since the map f_2 satisfies conditions (i) – (iii) of Theorem 1.1 we can establish by again using Lemma 2.1 that all conditions of Theorem 1.3 are satisfied with respect to (2.1) with (x_1, x_2), $x_3, \mathbb{R}^2, V_2(x_1, x_2)$,

$$M_2 \doteq \{(x_1, x_2, x_3) \in \mathbb{R}^3 : f_2(x_1, x_2, x_3) = v_2(x_1, x_2)\},$$

$$U_2^+ \doteq \{(x_1, x_2, x_3) \in \mathbb{R}^3 : f_2(x_1, x_2, x_3) > v_2(x_1, x_2)\},$$

$$U_2^- \doteq \{(x_1, x_2, x_3) \in \mathbb{R}^3 : f_2(x_1, x_2, x_3) < v_2(x_1, x_2)\},$$

instead of $x, y, \mathbb{R}^n$, $V(x), M, U^+$, and U^-, respectively. For reasons of completeness we note that the definition of M_2 and the fact that $(\partial V_2/\partial x_1)f_1 + (\partial V_2/\partial x_2)v_2$ is strictly negative for all $(x_1, x_2) \neq 0$ imply

$$\text{(2.11)} \quad \left(\frac{\partial V_2}{\partial x_1} f_1\right)(x_1, x_2) + \frac{\partial V_2}{\partial x_2}(x_1, x_2) f_2(x_1, x_2, x_3) < 0, \quad \forall\, (x_1, x_2, x_3) \in M_2 \backslash \{0\}.$$

Furthermore, from condition (iii) of Theorem 1.1 we get $(\partial f_2/\partial x_3)(0, 0, 0) \neq 0$, which by Lemma 2.2 implies that the restriction at the set M_2 near $0 \in \mathbb{R}^3$ is the graph of a smooth mapping $x_3 = \phi_2(x_1, x_2)$ vanishing at $0 \in \mathbb{R}^2$. Hence by (2.11) and the definition of M_2 we get

$$\text{(2.12)} \qquad \left(\frac{\partial V_2}{\partial x_1} f_1\right)(x_1, x_2) + \frac{\partial V_2}{\partial x_2}(x_1, x_2) f_2(x_1, x_2, \phi_2(x_1, x_2)) < 0$$

for $(x_1, x_2) \neq 0$ near zero, which means that the map $x_3 = \phi_2(x_1, x_2)$ locally asymptotically stabilizes (2.1) at $0 \in \mathbb{R}^2$. Using (2.11), (2.12), and the same procedure as in Step I, with V_2, ϕ_2 and M_2 instead of V_1, ϕ_1 and M_1, respectively, we can construct a smooth map $v = v_3(x_1, x_2, x_3)$ vanishing at zero, which globally asymptotically stabilizes (2.4) at the origin.

Finally, assume that property (iv) of Theorem 1.1 holds for $n = 2$. In that case the equation $f_2(x_1, x_2, x_3) = v_2(x_1, x_2)$ can globally be solved with respect to x_3, namely, there exists a smooth function $x_3 = \phi_2(x_1, x_2)$ with $\phi_2(0, 0) = 0$ such that $f_2(x_1, x_2, \phi_2(x_1, x_2)) = v_2(x_1, x_2)$ for all x_1 and x_2. Therefore (2.12) is fulfilled for every nonzero $(x_1, x_2) \in \mathbb{R}^2$ and so the static feedback ϕ_2 globally asymptotically stabilizes (2.1) at the origin. □

The following proposition provides an algebraic description of the sufficient conditions of Theorem 1.1.

PROPOSITION 2.3. *Suppose that for every i there exist smooth mappings $h_i, g_i : \mathbb{R}^{i+1} \to \mathbb{R}$ vanishing at zero such that $f_i = h_i + g_i$, and furthermore assume*

(A1) *for every $x_0 = (x_{10}, \dots, x_{i0}) \in \mathbb{R}^i$ there exist an odd integer k_i and a positive constant σ_i such that*

$$\frac{\partial^{k_i} h_i}{\partial x_{i+1}^{k_i}}(w_i, y) > \sigma_i \tag{2.13}$$

for every $w_i \div (x_1, \dots, x_i)$ in a neighborhood of x_0 and for every $y \div x_{i+1}$; in particular, if $k_{\min}(x_0)$ denotes the smallest odd integer for which (2.13) *is satisfied, then we assume that*

$$k_{\min}(0) = 1; \tag{2.14}$$

(A2) *there exists a positive definite C^1 function $M_i : \mathbb{R}^i \to \mathbb{R}$ such that*

$$|g_i(w_i, y)| \leq M_i(w_i) \tag{2.15}$$

for all w_i and y.

Then conditions (i), (ii), *and* (iii) *of Theorem* 1.1 *are satisfied and so* (1.3) *is smoothly globally D.A.S.*

Proof. According to assumption (A1), for every i and x_0 there exist an odd integer k_i and a compact neighborhood S of x_0 such that f_i is written

$$\begin{aligned} f_i(w_i, y) &= \sum_{l=0}^{k_i - 1} \frac{y^l}{l} \frac{\partial^l h_i}{\partial x_{i+1}^l}(w_i, 0) + C_i(w_i, y) + g_i(w_i, y), \\ C_i(w_i, y) &\div \int_0^y \int_0^{s_1} \cdots \int_0^{s_{k_i - 1}} \frac{\partial^{k_i} h_i}{\partial x_{i+1}^{k_i}}(w_i, s_{k_i})\, ds_{k_i} \dots ds_2\, ds_1 \end{aligned} \tag{2.16}$$

and (2.13) is satisfied for each $w_i \in S$ and for all $y = x_{i+1}$. Since k_i is odd, it follows by (2.13) that

$$\underline{\lim} |y_\nu^{-k_i}| C_i(w_{i\nu}, y_\nu) > 0, \quad \text{as } |y_\nu| \to +\infty \tag{2.17}$$

for every sequence $w_{i\nu} \in S$. From (2.15), (2.16), and (2.17) we get $\lim f_i(w_{i\nu}, y_\nu) = \pm\infty$ as $y_\nu \to \pm\infty$. This in conjunction with the continuity of f_i implies that for every $a \in \mathbb{R}$ and $w_i \in \mathbb{R}^i$ there is a y with $f_i(w_i, y) = a$ from which it follows that the map $f_i(w_i, \cdot)$ is a surjection. Similarly, condition (ii) of Theorem 1.1 is a direct consequence of (2.17). Finally, notice that, since g_i is C^∞ vanishing at zero, it follows by (2.15) that $g_i(0, y) = (\partial g_i / \partial x_{i+1})(0, y) = 0$ for every $y = x_{i+1}$. The latter in conjunction with (2.13) and (2.14) implies (1.4) and condition (iii) of Theorem 1.1. □

Example 2.4. Consider the system $\dot{x}_1 = x_2(1-x_1)+x_2^3+x_1\sin x_1x_2$, $\dot{x}_2 = u(1-x_1-x_2)+u^3+x_1x_2\sin x_1x_2u$. We define $f_1 \doteqdot h_1+g_1$, $f_2 \doteqdot h_2+g_2$, $h_1 \doteqdot x_2(1-x_1)+x_2^3$, $h_2 \doteqdot u(1-x_1-x_2)+u^3$, $g_1 \doteqdot x_1\sin x_1x_2$; $g_2 \doteqdot x_1x_2\sin x_1x_2u$. Then we can easily justify that conditions (A1) and (A2) of Proposition 2.3 are satisfied and so the system is smoothly globally D.A.S.

The following corollary is a direct consequence of Proposition 2.3 and extends the main result in [14] dealing with global stabilization by linear feedback for triangular systems of the form:

$$\begin{aligned} \dot{x}_1 &= x_2+g_1(x_1,x_2)\\ \dot{x}_2 &= x_3+g_2(x_1,x_2,x_3)\\ &\vdots\\ \dot{x}_{n-1} &= x_n+g_{n-1}(x_1,x_2,\ldots,x_{n-1},x_n)\\ \dot{x}_n &= u+g_n(x_1,x_2,\ldots,x_{n-1},x_n,u), \end{aligned} \tag{2.18}$$

where the mappings g_i, $1\le i\le n$ are globally Lipschitzian.

COROLLARY 2.5. *Suppose that each g_i is smooth vanishing at zero and satisfies* (A2) *of Proposition* 2.3. *Then* (2.18) *is smoothly globally D.A.S.*

2.2. Controllability. We conclude this section by giving some links between the main assumptions of Theorem 1.1 and the null controllability of (1.3). It is well known (see [7]) that if a nonlinear system, whose linearization at the origin is controllable, is globally S.A.S., then there exists a $t>0$ such that the domain C_t consisting of all points $x_0\in\mathbb{R}^n$, each of which can be steered to zero at time t by some measurable input u, is the whole state space. It turns out that the domain of null controllability, namely, the set $C \doteqdot \cup_{t\ge 0} C_t$, covers the whole state space. It is not difficult to establish that the same result holds under the weaker assumption that the system is globally D.A.S. Moreover, for triangular systems (1.3) this result is strengthened as follows.

PROPOSITION 2.6. *If conditions* (i), (ii), *and* (iii) *of Theorem* 1.1 *are satisfied, then $C_t=\mathbb{R}^n$ for every $t>0$, namely, each initial state $x_0\in\mathbb{R}^n$, can be steered to zero at any time $t>0$ by an appropriate measurable input.*

Proof. For reasons of simplicity consider the planar case (2.1). Condition (iii) of Theorem 1.1 guarantees that for every $t_1>0$ the set C_{t_1} covers an open neighborhood S of $0\in\mathbb{R}^2$. To complete the proof it suffices to show that for any initial state $x_0=(x_{10},x_{20})\in\mathbb{R}^2$ there exists a measurable controller such that the endpoint of the corresponding trajectory of (2.1) lies in S at time $t_2\doteqdot t-t_1$. Let (a_1,a_2) be an arbitrary vector in S and let $x_1:[0,t_2]\to\mathbb{R}$ be a C^1 function with $x_1(0)=x_{10}$ and $x_1(t_2)=a_1$. Then by using assumptions (i) and (ii) of Theorem 1.1 we can find a measurable function $u_1:[0,t_2]\to\mathbb{R}$ such that

$$\dot{x}_1(s)=f_1(x_1(s),u_1(s)),\quad \forall s\in[0,t_2] \tag{2.19}$$

(see also [7, p. 162] where analogous arguments are used). From (2.19) it follows that x_1 is the solution of the subsystem $\dot{x}_1=f_1(x_1,x_2)$ with input $x_2=u_1$ starting from x_{10} with endpoint $x_1(t_2)=a_1$; equivalently

$$x_1(s)=x_{10}+\int_0^s f_1(x_1(\rho),u_1(\rho))d\rho,\quad \forall s\in[0,t_2]. \tag{2.20}$$

Let $x_{2\nu}(s)$, $s\in[0,t_2]$ be a sequence of C^1 functions such that

$$\int_0^{t_2}|x_{2\nu}(s)-u_1(s)|ds\to 0,\quad \text{as}\,\nu\to+\infty \tag{2.21}$$

and $x_{2\nu}(0) = x_{20}$; $x_{2\nu}(t_2) = a_2$ for all ν. Then by (2.20), (2.21), and using Gronwall's inequality it follows that for every $\varepsilon > 0$ there is an integer k such that $|a_1 - \hat{x}_1(t_2)| < \varepsilon$, where $\hat{x}_1(s) \doteq x_1(s, x_{10}, x_{2k})$ denotes the trajectory of $\dot{x}_1 = f_1(x_1, x_2)$ with input $\hat{x}_2(s) = x_{2k}(s)$ starting from x_{10}. Consider finally a measurable function $u_2 : [0, t_2] \longrightarrow \mathbb{R}$ such that

$$\dot{\hat{x}}_2(s) = f_2(\hat{x}_1(s), \hat{x}_2(s), u_2(s)), \quad \forall\, s \in [0, t_2], \tag{2.22}$$

whose existence is also guaranteed by assumptions (i) and (ii) of Theorem 1.1. From (2.19) and (2.22) it follows that $(\hat{x}_1, \hat{x}_2) : [0, t_2] \longrightarrow \mathbb{R}$ is the trajectory of (2.1) with input $x_3 = u_2$, starting from (x_{10}, x_{20}) and with endpoint $\|(\hat{x}_1(t_2), \hat{x}_2(t_2)) - (a_1, a_2)\| < \varepsilon$. Taking into account that $(a_1, a_2) \in S$ and by choosing ε appropriately small it follows that $\hat{x}(t_2) \doteq (\hat{x}_1(t_2), \hat{x}_2(t_2))$ also lies in S. Since $S \subset C_{t_1}$, $\hat{x}(t_2)$ can be steered to zero by some input $w : [0, t_1] \longrightarrow \mathbb{R}$. We conclude that x_0 can be steered to the origin at time $t_1 + t_2 = t$ by the concatenation of u_2 and w. The proof of the general case follows similarly by induction. □

3. The general case: A necessary and sufficient condition. The following theorem generalizes Theorem 1.3. It provides a necessary and sufficient condition for dynamic stabilization for the general nonlinear case (1.1).

THEOREM 3.1. *The system* (1.1) *is globally D.A.S. if and only if there exist a closed subset $M \subset \mathbb{R}^{n+1}$, a pair of nonempty disjoint subsets U^+ and U^- of $\mathbb{R}^{n+1}$, and a C^1 nonnegative function $W : \mathbb{R}^{n+1} \longrightarrow \mathbb{R}$ such that*

(i) $0 \in M$, $\mathbb{R}^{n+1} = U^+ \cup U^- \cup M$; $\pi(M) = \mathbb{R}^n$;

(ii) *for any $\varepsilon > 0$ the following hold*:

$$\{0\} \times (0, \varepsilon) \cap U^+ \neq \emptyset, \qquad \{0\} \times (-\varepsilon, 0) \cap U^- \neq \emptyset; \tag{3.1}$$

(iii) *the function W is strictly positive on the region $M \backslash \{0\}$, whereas $W(0, 0) = 0$. Moreover assume that*

$$(x; y) \in M : \frac{\partial W}{\partial y}(x, y) = 0 \Rightarrow \left(\frac{\partial W}{\partial x} f\right)(x, y) \leq -c(\|(x, y)\|), \tag{3.2}$$

where $c : \mathbb{R}^+ \longrightarrow \mathbb{R}^+$ is a positive definite function with $c(0) = 0$ and further

$$\frac{\partial W}{\partial y}(x, y) \geq 0, \quad \forall\, (x, y) \in U^+; \qquad \frac{\partial W}{\partial y}(x, y) \leq 0, \quad \forall\, (x, y) \in U^-; \tag{3.3}$$

(iv) *W is uniformly unbounded on $\mathbb{R}^{n+1}$.*

The system (1.1) *is locally D.A.S. if and only if $U^+ \cup U^- \cup M$ and $\pi(M)$ are neighborhoods of $0 \in \mathbb{R}^{n+1}$, $0 \in \mathbb{R}^n$, respectively, and further* (3.1), (3.2), *and* (3.3) *are satisfied.*

Proof. We establish only the global part of our theorem. Similar arguments can be repeated in a local setting. We proceed to the construction of a global clf guaranteeing global dynamic stabilization as follows. For each integer ν consider a locally finite partition of $\mathbb{R}^n$ that consists of subsets $A_{\nu i} \subseteq \mathbb{R}^n$, $i = 1, 2, \ldots$, with $\operatorname{int} A_{\nu i_1} \cap \operatorname{int} A_{\nu i_2} = \emptyset$ for $i_1 \neq i_2$. The diameter of each $A_{\nu i}$ is tending to zero as $\nu \longrightarrow +\infty$ uniformly on i, there exists an integer $i_0 = i_0(\nu)$ such that

$$0 \in \operatorname{int} A_{\nu i_0} \tag{3.4a}$$

and further for every $x \in \mathbb{R}^n$ and for almost all ν we can find an integer $i = i(\nu)$ with $x \in \operatorname{int} A_{\nu i}$. Similarly, for each ν and i consider a partition of the y axis of subintervals $B_{\nu ij} \doteq [y_{\nu ij}, y_{\nu i(j+1)}]$, $j \in \{\pm 1, \pm 2, \ldots\}$ such that $y_{\nu ij} > 0$ for $j = 1, 2, \ldots$; $y_{\nu ij} < 0$ for

$j = -1, -2, \ldots$; $|y_{\nu ij} - y_{\nu i(j+1)}| < \frac{1}{\nu}$ for all ν, i, j; and further each nonzero vector (x, y) belongs to the interior of $S_{\nu ij} \doteqdot A_{\nu i} \times B_{\nu ij}$ for almost all ν and some i and j depending on ν. Obviously, for each ν the family $\{S_{\nu ij}\}$ consists of a partition of $\mathbb{R}^{n+1}$ and due to our assumption (3.1) we may assume that there exists an integer $j_0 = j_0(\nu, i_0)$ depending on ν and i_0 (i_0 being the integer defined by (3.4a)) such that

$$0 \in \text{int} S_{\nu i_0 j_0}, \quad S_{\nu i_0(j_0-1)} \subset U^-, \quad S_{\nu i_0(j_0+1)} \subset U^+. \tag{3.4b}$$

We are in a position to construct for each ν and i a nonnegative smooth function $\phi_{\nu i}(y)$, $y \in \mathbb{R}$ such that $D\phi_{\nu i}(y) = 0$ for $y \in clB_{\nu ij}$ with $S_{\nu ij} \cap M \neq \emptyset$; $D\phi_{\nu i}(y) > 0$ for $y \in \text{int}B_{\nu ij}$ with $S_{\nu ij} \subset U^+$, $D\phi_{\nu i}(y) < 0$ for $y \in \text{int}B_{\nu ij}$ with $S_{\nu ij} \subset U^-$ and $|D\phi_{\nu i}(y)| \leq 1$; $0 \leq \phi_{\nu i}(y) < 1$, for every $y \in \mathbb{R}$. In particular, $\phi_{\nu i}(y)$ is strictly positive for $y \in \text{int}B_{\nu ij}$ with $S_{\nu ij} \subset U^+ \cup U^-$ and furthermore by (3.4) the map $\phi_{\nu i_0}$ can be constructed such that the previous conditions are satisfied and in addition

$$\phi_{\nu i_0}(y) = 0 \quad \text{for} y \in B_{\nu i_0 j_0}. \tag{3.5}$$

Consider now for every ν and i a nonnegative smooth map $a_{\nu i} : \mathbb{R}^n \to \mathbb{R}$ such that $\|Da_{\nu i}(x)\| \leq 1$ for $x \in A_{\nu i}$, $0 < a_{\nu i}(x) < 1$ for $x \in \text{int}A_{\nu i}$; $a_{\nu i}(x) = 0$ otherwise, and define

$$\psi_\nu(x, y) \doteqdot \sum_{i=1}^{\infty} \phi_{\nu i}(y) a_{\nu i}(x), \qquad (x, y) \in \mathbb{R}^n \times \mathbb{R}. \tag{3.6}$$

Obviously, ψ_ν is smooth nonnegative definite and vanishes at zero. Moreover ψ_ν as well as its derivative are bounded. Indeed, $0 \leq \psi_\nu(x, y) = \phi_{\nu i}(y) a_{\nu i}(x) \leq 1$; $|D\psi_\nu(x, y)| \leq |D\phi_{\nu i}(y)| a_{\nu i}(x) + \|Da_{\nu i}(x)\| \phi_{\nu i}(y) \leq 2$ for all $y \in \mathbb{R}$ and $x \in A_{\nu i}$. It turns out that the map

$$\Phi(x, y) \doteqdot \sum_{\nu=1}^{+\infty} 2^{-\nu} \psi_\nu(x, y) \tag{3.7}$$

is well defined and C^1. In particular, $D\Phi(x, y) = \sum 2^{-\nu} D\psi_\nu(x, y)$, where the series on the right-hand side uniformly converges to $D\Phi$. Moreover, Φ is nonnegative definite, vanishes at $0 \in \mathbb{R}^{n+1}$, and satisfies $\Phi(x, y) > 0$ for all $(x, y) \notin M$. Indeed, for $(x, y) = 0$ we get from (3.5)–(3.7) that $\Phi(0, 0) = 0$, whereas if $(x, y) \notin M$, it follows that $(x, y) \in \text{int}S_{\nu ij} \subset U^+ \cup U^-$ for almost all integers ν and for some i, j depending on ν; therefore $\psi_\nu(x, y) > 0$ and so $\Phi(x, y) > 0$. We can also easily establish that

$$\frac{\partial \Phi}{\partial y}(x, y) > 0 \Leftrightarrow (x, y) \in U^+, \tag{3.8a}$$

$$\frac{\partial \Phi}{\partial y}(x, y) < 0 \Leftrightarrow (x, y) \in U^-, \tag{3.8b}$$

$$\frac{\partial \Phi}{\partial y}(x, y) = 0 \Leftrightarrow (x, y) \in M. \tag{3.8c}$$

For reasons of completeness we prove that $(x, y) \in U^+$ implies $(\partial\Phi/\partial y)(x, y) > 0$. Indeed, let $(x, y) \in U^+$. Then for almost all integers ν there corresponds a pair of indices i_ν, j_ν

depending on ν with $(x,y) \in \mathrm{int} S_{\nu i_\nu j_\nu} \subset U^+$. Consequently, $D\phi_{\nu i_\nu}(y) > 0$, $a_{\nu i_\nu}(x) > 0$, and so $(\partial\psi_\nu/\partial y)(x,y) = a_{\nu i_\nu}(x) D\phi_{\nu i_\nu}(y) > 0$ for almost all ν, whereas $(\partial\psi_\nu/\partial y)\,(x,y) \geq 0$ otherwise. Therefore $(\partial\Phi/\partial y)(x,y) = \sum 2^{-\nu}(\partial\psi_\nu/\partial y)(x,y) > 0$.

Consider now a pair of continuous functions $a, b : \mathbb{R}^+ \longrightarrow \mathbb{R}^+$ such that b is positive definite, a is increasing and everywhere strictly positive, and furthermore

$$b(\Phi(x,y)) < c(\|(x,y)\|), \tag{3.9}$$

$$\frac{1}{2} + \left| \left(\frac{\partial\Phi}{\partial x} f \right)(x,y) \right| \leq a(W(x,y)), \quad \forall\,(x,y) \in M, \tag{3.10}$$

where c and W are defined in (3.2). Note that the existence of the map satisfying (3.10) follows from our assumption that W is strictly positive on $M\backslash\{0\}$. Finally, we define

$$L(x,y) \div \int_0^{W(x,y)} a(r)dr + \int_0^{\Phi(x,y)} b(r)dr.$$

Obviously L is C^1 and positive definite (the latter follows by our assumption that $W(x,y) > 0$ for $(x,y) \in M\backslash\{0\}$), and because of assumption (iv) it is uniformly unbounded on $\mathbb{R}^{n+1}$. We complete the proof by showing that L is a clf with respect to (1.2). Indeed, for each nonzero $(x,y) \in \mathbb{R}^{n+1}$ with

$$\frac{\partial L}{\partial y}(x,y) = 0 \tag{3.11}$$

it follows that $((\partial W/\partial y)a(W) + (\partial\Phi/\partial y)b(\Phi))(x,y) = 0$ and so by (3.3) and (3.8) we get $(\partial W/\partial y)(x,y) = (\partial\Phi/\partial y)(x,y) = 0$ and $(x,y) \in M$. Therefore by (3.2), (3.9), and (3.10) it follows that

$$\begin{aligned} \left(\frac{\partial L}{\partial x} f\right)(x,y) &= a(W(x,y)) \left(\frac{\partial W}{\partial x} f\right)(x,y) + b(\Phi(x,y)) \left(\frac{\partial \Phi}{\partial x} f\right)(x,y) \\ &\leq -\frac{1}{2} c(\|(x,y)\|) < 0. \end{aligned} \tag{3.12}$$

The implication (3.11) $\Rightarrow$ (3.12) asserts that L is a global clf with respect to (1.2); hence, the system (1.1) is globally D.A.S.

The converse part of the proof is straightforward. Assume that there exists a map $v : \mathbb{R}^{n+1} \longrightarrow \mathbb{R}$ that is smooth for $(x,y) \neq 0$ and such that $0 \in \mathbb{R}^{n+1}$ is globally asymptotically stable with respect to $\dot{x} = f(x,y), \dot{y} = v(x,y)$. Then according to Artstein's version of the well-known Kurzweil's converse stability theorem (see [2]) there exists a uniformly unbounded smooth Lyapunov function W of $0 \in \mathbb{R}^{n+1}$ with respect to (1.2), namely, $((\partial W/\partial x)f + (\partial W/\partial y)v)(x,y) < 0$ for all $(x,y) \neq 0$. Using the previous inequality we can easily justify that all conditions of Theorem 3.1 are fulfilled with W as above: $M = \{(x,y) \in \mathbb{R}^{n+1} : (\partial W/\partial y)(x,y) = 0\}$, $U^+ = \{(x,y) \in \mathbb{R}^{n+1} : (\partial W/\partial y)(x,y) > 0\}$, and $U^- = \{(x,y) \in \mathbb{R}^{n+1} : (\partial W/\partial y)(x,y) < 0\}$. For reasons of completeness we note that the previous definitions of M, U^+, and U^- and the fact that W is positive definite and uniformly unbounded on $\mathbb{R}^{n+1}$ imply conditions (i) and (ii) of the present theorem. □

Next we show that if conditions (i)–(iv) of Theorem 1.3 are fulfilled, there exists a function W satisfying conditions (iii) and (iv) of Theorem 3.1. This in conjunction with the fact that assumption (1.6) is a special case of (3.1) asserts that Theorem 3.1 is indeed a generalization of Theorem 1.3.

PROPOSITION 3.2. *If conditions* (i) – (iv) *of Theorem* 1.3 *are fulfilled, there exists a* C^1 *nonnegative map* $W : \mathbb{R}^{n+1} \to \mathbb{R}$ *satisfying conditions* (iii) *and* (iv) *of Theorem* 3.1.

Proof (outline). By using condition (ii) of Theorem 1.3 we can construct a C^1 nonnegative function $W_0(x, y)$ that vanishes in a closed neighborhood of M, is strictly positive otherwise, and satisfies

$$\frac{\partial W_0}{\partial y}(x, y) \geq 0, \quad \forall (x, y) \in U^+; \qquad \frac{\partial W_0}{\partial y}(x, y) \leq 0, \quad \forall (x, y) \in U^-; \tag{3.13}$$

(3.14)

$$W_0(x_\nu, y_\nu) \to +\infty, \quad \text{for any sequence } (x_\nu, y_\nu) \text{ with } \lim \|x_\nu\| < +\infty \text{ and } \lim |y_\nu| \to +\infty.$$

Then the map $W(x, y) = V(x) + W_0(x, y)$ is C^1, nonnegative definite, and satisfies conditions (iii) and (iv) of Theorem 3.1. Indeed, $W(0, 0) = 0$, and for each nonzero $(x, y) \in M$ with $(\partial W/\partial y)(x, y) = 0$ it follows that $DW_0(x, y) = 0$ and $((\partial W/\partial x) f)(x, y) = (DVf)(x, y)$, which by (1.7) is strictly negative. Furthermore, similar to [15], by condition (ii) of Theorem 1.3 we can establish the existence of a positive definite continuous function $c : \mathbb{R}^+ \to \mathbb{R}^+$ such that (3.2) holds. Condition (3.3) is an immediate consequence of (3.13). Finally, (3.14) and the uniform unboundedness of V imply that W is uniformly unbounded on $\mathbb{R}^{n+1}$. □

The following example has been carefully devised to show the applicability of Theorem 3.1 for systems (1.1) that are not necessarily stabilizable by ordinary static feedback.

Example 3.3. Consider a planar nonlinear system (1.1) with

$$\begin{aligned} f_1(x_1, x_2; u) &= -x_1 + x_1^2(\phi(u) - u^2)^2, \\ f_2(x_1, x_2; u) &= -x_1^3(\phi(u) - u^2) - (\phi(u)/2)^2 + (x_2 - \phi(u))^2, \end{aligned}$$

where ϕ is continuous, vanishing at zero, and satisfies $\phi(u) \geq 2u^2$ for all $u \geq 0$. We show that this system satisfies all conditions of Theorem 3.1 and so is globally D.A.S. We define

$$W(x_1, x_2, y) \doteq \begin{cases} \frac{1}{2}x_1^2 + \frac{1}{2}(x_2 - y^2)^2 + 2\int_0^y t(\phi(t) - t^2)dt, & y > 0; \\ \frac{1}{2}x_1^2 + \frac{1}{2}x_2^2, \quad -1 \leq y \leq 0; \\ \frac{1}{2}x_1^2 + \frac{1}{2}x_2^2 + (y + 1)^2, & y \leq -1; \end{cases}$$

$$M \doteq \{(x_1, x_2, y) \in \mathbb{R}^3 : x_2 = \phi(y),\ y > 0\} \cup \{(x_1, x_2, y) \in \mathbb{R}^3 : y = 0,\ x_2 < 0\};$$

$$U^+ \doteq \{(x_1, x_2, y) \in \mathbb{R}^3 : y > 0,\ x_2 < \phi(y)\};$$

$$\begin{aligned} U^- \doteq \{(x_1, x_2, y) \in \mathbb{R}^3 : x_2 > \phi(y), y > 0\} &\cup \{(x_1, x_2, y) \in \mathbb{R}^3 : y = 0, x_2 > 0\} \\ &\cup \{(x_1, x_2, y) \in \mathbb{R}^3 : y < 0\}. \end{aligned}$$

Then W is nonnegative definite ($W(x_1, x_2, y) = 0$ for $x_1 = x_2 = 0$; $y \in [-1, 0]$ and $W(x_1, x_2, y) > 0$ otherwise) and uniformly unbounded on $\mathbb{R}^3$. We now evaluate $(\partial W/\partial y)(x_1, x_2, y) = 2y(\phi(y) - x_2), y \geq 0$. It follows that for each nonzero (x_1, x_2, y) with $(\partial W/\partial y)(x_1, x_2, y) = 0$ and $y > 0$ we have $x_2 = \phi(y)$ and so $((\partial W/\partial x) f)(x_1, x_2, y) =$

$-x_1^2 - \left(\frac{\phi}{2}\right)^2 (\phi - y^2) \leq -x_1^2 - y^6$, whereas for $x_2 < 0$ and $y = 0$ we find $((\partial W/\partial x)f)\cdot (x_1, x_2, y) = -x_1^2 + x_2^3 < 0$. Therefore (3.3) is fulfilled with W and M as previously defined. We can also easily justify that the remaining conditions of Theorem 3.1 are satisfied and so the system is globally D.A.S. It must be noted that the system above is not necessarily S.A.S. Indeed, suppose for instance that ϕ has the form $\phi(u) = 2u^2 + u\left(1 + \frac{1}{2} \sin \frac{1}{u}\right)$, $u > 0$. Since the region $\{(x_1, x_2) \in \mathbb{R}^2 : x_1 = 0\}$ is invariant with respect to $\dot{x}_1 = -x_1 + x_1^2(\phi(u) - u^2)^2$, it suffices to show that the system $\dot{x}_2 = -\phi^2(u)/4 + (x_2 - \phi(u))^2$ cannot be S.A.S. Suppose on the contrary that there exists an ordinary feedback $u = u(x_2)$ that is continuous for $x_2 \neq 0$ near zero and locally asymptotically stabilizes the previous system at $0 \in \mathbb{R}$. This implies $-\frac{1}{4}\phi^2(u(x_2)) + (x_2 - \phi(u(x_2)))^2 < 0$, or $\phi(u(x_2)) < x_2 < \frac{3}{2}\phi(u(x_2))$ for $x_2 > 0$ near zero. The latter is impossible because of the particular choice of ϕ (see also [15], where an analogous example is investigated).

4. Conclusion and further remarks.

Sufficient conditions for smoothly global dynamic stabilizations for a wide class of triangular controllable systems have been presented. A necessary and sufficient condition for almost smoothly global dynamic stabilization for the general nonlinear case has also been provided.

It is worth remarking that the approach of the present work can be applied to derive further interesting results. For instance, we can combine Theorem 1.3 and a well-known result in [4], [5] concerning the local stabilization problem for planar systems

$$\dot{x} = f(x, y), \quad \dot{y} = \nu, \quad (x, y) \in \mathbb{R}^2 \tag{4.1}$$

in order to prove that (4.1) is globally S.A.S. by means of a feedback law that is smooth on $\mathbb{R}^2\backslash\{0\}$ and further it is continuous at $0 \in \mathbb{R}^2$, provided that

(B1) the map $(x, y) \to f(x, y)$ is analytic near zero;

(B2) there exists a pair of disjoint open sets $U^+, U^- \subset \mathbb{R}^2$ and a closed subset $M \subset \mathbb{R}^2$ containing zero such that conditions (i) and (ii) of Theorem 1.3 hold and further

$$xf(x, y) < 0, \quad \forall\, (x, y) \in M. \tag{4.2}$$

For the sake of completeness we note that assumption B1 in conjunction with (4.2) implies the existence of a continuous map $x \to \phi(x)$, $\phi(0) = 0$, and a real constant $\rho > 0$ such that $xf(x, \phi(x)) < 0$ for $0 < |x| \leq \rho$. Then according to [4], [5] there exists a real map $\nu = v_1(x, y)$, $v_1(0, 0) = 0$ that is smooth for $(x, y) \neq 0$ near zero and continuous at zero and that locally stabilizes (4.1) at $0 \in \mathbb{R}^2$. The assumption B1 also asserts that the system (4.1) satisfies condition (B2) with $M' = \{(x, y) \in \mathbb{R}^2;\ 0 < |x| \leq \rho,\ y = \phi(x)\} \cap \{(x, y) \in M,\ |x| \geq \rho\}$ instead of M. Then we can combine Theorem 1.3 and the approach in [4] as in the proof of Theorem 1.3 to build a feedback law $v = v_2(x, y)$ that globally asymptotically stabilizes (4.1), is smooth on $\mathbb{R}^2\backslash\{0\}$, and coincides with $v_1(x, y)$ near zero; hence it is continuous on the whole state space. Details are found in [16].

A MIXED $l_\infty/\mathcal{H}_\infty$ OPTIMIZATION APPROACH TO ROBUST CONTROLLER DESIGN*

MARIO SZNAIER[†]

Abstract. In spite of its practical importance, the problem of designing controllers capable of satisfying mixed time/frequency domain performance requirements under model uncertainty remains, to a large extent, open. In this paper we propose a design procedure for minimizing the maximum amplitude of a regulated error to a specified input while, at the same time, addressing model uncertainty through bounds on the $\mathcal{H}_\infty$ norm of a relevant transfer function. This problem is of interest in optimal tracking applications where the objective is to achieve minimum tracking error while, at the same time, maintaining an adequate robustness level. We show that for the SISO case, the problem can be solved by solving sequence of problems, each one consisting of a finite-dimensional convex optimization and an unconstrained Nehari approximation problem

Key words. robust control synthesis, $\mathcal{H}_\infty$ control, l_∞ control, discrete-time systems

1. Introduction.

A large number of control problems involve designing a controller capable of achieving acceptable performance under system uncertainty and design constraints. However, in spite of its practical importance, this problem remains, to a large extent, open. During the last decade a large research effort led to procedures for designing robust controllers, capable of achieving desirable properties under various classes of plant uncertainties while, at the same time, satisfying frequency-domain constraints. However, these design procedures cannot accommodate directly time-domain performance specifications.

Recently, some progress has been made in this direction [1]–[5]. By using a parametrization of all stabilizing linear controllers in terms of a stable transfer matrix Q, the problem of finding the "best" linear controller can be formulated as the constrained optimization problem of minimizing a weighted ∞-norm over the set of suitable Q. In this formulation, additional specifications can be imposed by further constraining the problem. The resulting optimization problem has been solved using convex programming [1] and constrained nondifferentiable optimization [2]. However, although these methods are effective when the specifications are easily expressed in terms of the frequency response, presently they can handle time-domain specifications in a conservative fashion, through the use of several approximations. Additionally, they may require solving very large nondifferentiable optimization problems. A different approach has been pursued in [3]–[5], where time-domain constraints over a finite horizon are incorporated into an $\mathcal{H}_\infty$ optimal control problem that is then transformed into a finite-dimensional optimization problem. However, at this stage constraints over an infinite horizon can be handled only indirectly.

Finally, in [6] and [7] the problems of finding an internally stabilizing compensator that minimizes the maximum error to l_∞ bounded disturbances and to a fixed, given

[†]Department of Electrical Engineering, The Pennsylvania State University, University Park, Pennsylvania 16802.

signal was solved. However, these designs cannot accommodate frequency-domain specifications.

In this paper we address the problem of finding an internally stabilizing compensator that minimizes the maximum amplitude of the error to a fixed given input subject to constraints upon the $\mathcal{H}_\infty$ norm of a relevant transfer function. This problem, which can be thought of as the dual of the problem proposed in [3]–[5], is of particular interest for optimal tracking problems where the objective is to achieve minimum error magnitude, while at the same time maintaining an adequate robustness level against model uncertainty.

The paper is organized as follows: In §2 we give a formal definition to the mixed $l_\infty/\mathcal{H}_\infty$ optimization problem. In §3 we propose a solution method using a technique similar to the one that we presented in [8]–[10]. The main result of this section shows that the mixed optimization problem can be solved by solving a sequence of modified problems, each one consisting of a finite-dimensional convex, constrained optimization problem, and an *unconstrained* Nehari approximation. In §4 we present a simple design example and compare our controller to the unconstrained optimal $\mathcal{H}_\infty$ controller. Finally, in §5, we summarize our results and indicate directions for future research.

2. Problem formulation.

2.1. Notation. By $\mathcal{L}_\infty$ we denote the Lebesgue space of complex-valued transfer functions essentially bounded on the unit circle, equipped with the norm $\|G(z)\|_\infty \stackrel{\Delta}{=} \sup_{|z|=1} |G(z)|$. $\mathcal{H}_\infty$ ($\mathcal{H}_\infty^-$) denotes the space of stable (antistable) complex functions $G(z) \in \mathcal{L}_\infty$, i.e analytic in $|z| \geq 1$ ($|z| \leq 1$), equipped with the norm $\|.\|_\infty$. The prefix $\mathcal{R}$ denotes subspaces formed by real rational transfer matrices. $\mathcal{RH}_\delta$ denotes the subspace of transfer matrices in $\mathcal{RH}_\infty$ that are analytic outside the disk of radius δ, $0 < \delta < 1$, equipped with the norm $\|G(z)\|_{\mathcal{H}_\delta} \stackrel{\Delta}{=} \sup_{0 \leq \theta \leq \pi} |G(\delta e^{j\theta})|$. l_∞ denotes the space of bounded real sequences $\{e_k\}$ equipped with the norm $\|e\|_{l_\infty} \stackrel{\Delta}{=} \sup_k |e_k|$. l_1 denotes the space of real sequences, equipped with the norm $\|q\|_1 = \sum_{k=0}^{\infty} |q_k| < \infty$. Given a sequence $q \in l_1$ we will denote its Z-transform by $Q(z) \in \mathcal{RH}_\infty$. To avoid confusion and by a slight abuse of notation, we will denote the $\|.\|_\infty$ norm of a transfer function as $\|.\|_{\mathcal{H}_\infty}$[1] and the l_∞ norm of a sequence as $\|.\|_{l_\infty}$.

Throughout the paper we will use packed notation to represent state-space realizations, i.e.,

$$G(z) = C(zI - A)^{-1}B + D \stackrel{\Delta}{=} \left(\begin{array}{c|c} A & B \\ \hline C & D \end{array} \right).$$

$P_+ \colon \mathcal{RL}_\infty \to \mathcal{RH}_\infty$ denotes the projection operator; i.e., given $G \in \mathcal{RL}_\infty$, $\mathcal{G} = P_+(G)$ is the stable part of G. For a transfer function $G(z)$, $G^{\sim} \stackrel{\Delta}{=} G(\frac{1}{z})$. Given $R \in \mathcal{RH}_\infty$, $\Gamma_{\mathrm{H}}(R)$ denotes its maximum Hankel singular value (for $R \in \mathcal{RH}_\infty^-$, $\Gamma_{\mathrm{H}}(R)$ denotes the maximum Hankel singular value of $R^{\sim}$).

Finally, given two transfer matrices $T = \begin{pmatrix} T_{11} & T_{12} \\ T_{21} & T_{22} \end{pmatrix}$ and Q with appropriate dimensions, the lower *linear fractional transformation* is defined as

$$\mathcal{F}_l(T, Q) \stackrel{\Delta}{=} T_{11} + T_{12}Q(I - T_{22}Q)^{-1}T_{21}.$$

[1] Strictly speaking this norm should be denoted as $\|.\|_{\mathcal{L}_\infty}$ since it will be applied to both functions in $\mathcal{H}_\infty$ and $\mathcal{H}_\infty^-$. However, we decided to use the notation $\|.\|_{\mathcal{H}_\infty}$ to avoid confusion with the continuous-time $\mathcal{L}_\infty$ norm.

2.2. Statement of the problem. Consider the SISO system represented by the block diagram in Fig. 1, where S represents the system to be controlled; the scalar signals w, θ, and u represent an exogenous disturbance, a *known, fixed* signal, and the control action, respectively; and ζ, e, and y represent the outputs subject to frequency-domain performance constraints, the tracking error to the signal θ, and the measurements respectively. Note that w and ζ include fictitious signals used to assess stability in the presence of model uncertainty. Then the problem that we address in this paper is the following:

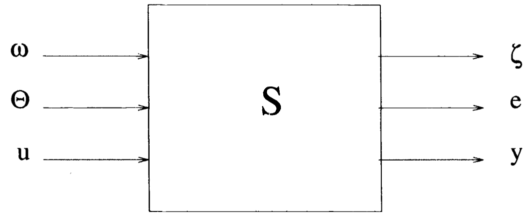

FIG. 1. *The generalized plant.*

Mixed $l_\infty/\mathcal{H}_\infty$ control problem. Given the nominal system (S), with frequency-domain performance specifications of the form

$$(P) \qquad \|W(z)T_{\zeta w}(z)\|_\infty \leq \gamma$$

where $W(z)$ is a suitable weighting function, find an internally stabilizing rational controller

$$(C) \qquad u(z) = K(z)y(z)$$

such that the maximum amplitude of the regulated output e due to θ is minimized subject to the performance specifications (P)

3. Problem solution. In this section we show that the mixed $l_\infty/\mathcal{H}_\infty$ problem can be solved by solving a sequence of problems, each one requiring the solution of a finite-dimensional convex optimization problem and an unconstrained Nehari extension problem.

3.1. Problem transformation. Assume that the system S has the following state-space realization (where without loss of generality we assume that all weighting factors have been absorbed into the plant):

$$(S) \qquad \left(\begin{array}{c|ccc} A & B_{1f} & B_{1t} & B_2 \\ \hline C_f & D_{ff} & D_{ft} & D_{f2} \\ C_t & D_{tf} & D_{tt} & D_{t2} \\ C_2 & D_{2f} & D_{2t} & D_{22} \end{array}\right)$$

where D_{f2} has full column rank, D_{2f} has full row rank, and the pairs (A, B_2) and (C_2, A) are stabilizable and detectable, respectively. It is well known (see for instance

[11]) that the set of all internally stabilizing controllers can be parametrized in terms of a free parameter $Q \in \mathcal{H}_\infty$ as

$$K = \mathcal{F}_l(J, Q) \tag{1}$$

where J has the following state-space realization:

$$(J) \qquad \left(\begin{array}{c|cc} A + B_2F + LC_2 + LD_{22}F & -L & B_2 + LD_{22} \\ \hline F & 0 & I \\ -(C_2 + D_{22}F) & I & -D_{22} \end{array}\right)$$

where F and L are selected such that $A + B_2F$ and $A + LC_2$ are stable. By using this parametrization, the closed-loop transfer functions $T_{\zeta w}$ and $T_{e\theta}$ can be written as

$$\begin{aligned} T_{\zeta w} &= \mathcal{F}_l(T, Q) = T_1 + T_2Q, \\ T_{e\theta} &= \mathcal{F}_l(T_\theta, Q) = T_1^\theta + T_2^\theta Q \end{aligned} \tag{2}$$

where $T_1 \stackrel{\Delta}{=} T_{11}$, $T_2 \stackrel{\Delta}{=} T_{12}T_{21}$, $T_1^\theta \stackrel{\Delta}{=} T_{11}^\theta$, $T_2^\theta \stackrel{\Delta}{=} T_{12}^\theta T_{21}^\theta \in \mathcal{RH}_\infty$, and T and T_θ have the following state-space realizations:

$$T = \left(\begin{array}{cc|cc} A + B_2F & -B_2F & B_{1f} & B_2 \\ 0 & A + LC_2 & B_{1f} + LD_{2f} & 0 \\ \hline C_f + D_{f2}F & -D_{f2}F & D_{ff} & D_{f2} \\ 0 & C_2 & D_{2f} & 0 \end{array}\right),$$

(3)

$$T_\theta = \left(\begin{array}{cc|cc} A + B_2F & -B_2F & B_{1t} & B_2 \\ 0 & A + LC_2 & B_{1t} + LD_{2t} & 0 \\ \hline C_t + D_{t2}F & -D_{t2}F & D_{tt} & D_{t2} \\ 0 & C_2 & D_{2t} & 0 \end{array}\right).$$

Moreover (see for instance [9]), it is possible to select F and L in such a way that $T_2(z)$ is inner (i.e., $T_2\tilde{\ }T_2 = I$). Since $\|.\|_{\mathcal{H}_\infty}$ is invariant under multiplication by an inner function, we have

$$\begin{aligned} \|T_{\zeta w}\|_{\mathcal{H}_\infty} &= \|T_1 + T_2Q\|_{\mathcal{H}_\infty} \\ &= \|T_1T_2\tilde{\ } + Q\|_{\mathcal{H}_\infty} = \|R + Q\|_{\mathcal{H}_\infty} \end{aligned} \tag{4}$$

where $R(z) \stackrel{\Delta}{=} T_1(z)T_2\tilde{\ }(z)$ has all its poles outside the unit disk [9].

By using this parametrization the mixed optimization problem can be now precisely stated as solving

$$(l_\infty/\mathcal{H}_\infty) \qquad \mu^o = \inf_{Q \in \mathcal{RH}_\infty} \|e_k\|_{l_\infty}$$

subject to

$$\|T_1(z) + T_2(z)Q(z)\|_{\mathcal{H}_\infty} \le \gamma \tag{5}$$

where

$$e_k = Z^{-1}\left\{E(z) = (T_1^\theta(z) + T_2^\theta(z)Q(z))\Theta(z)\right\}$$

and $\theta \in l_1{}^2$ is a known, fixed signal.

3.2. l_∞ Optimization analysis. In this section we analyze the l_∞ optimization and show that it can be handled by considering a finite number of constraints. We begin by recalling a result for the l_∞ problem without $\mathcal{H}_\infty$ constraints.

THEOREM 1(Dahleh and Pearson, [7]). *Let $T_2^\theta(z)\Theta(z)$ have n distinct zeros a_k outside the open unit disk. Then*

$$(6)\quad \mu^* = \inf_{K\text{stab}} \|e\|_{l_\infty} = \max_{\alpha_j}\left[\sum_{i=1}^{n} \alpha_i \text{Re}\{T_1^\theta(a_i)\Theta(a_i)\} + \sum_{i=1}^{n} \alpha_{i+n}\text{Im}\{T_1^\theta(a_i)\Theta(a_i)\}\right]$$

subject to

$$(7)\quad \sum_{j=0}^{\infty}\left|\sum_{i=1}^{n}\alpha_i\text{Re}\{a_i^{-j}\} + \sum_{i=1}^{n}\alpha_{i+n}\text{Im}\{a_i^{-j}\}\right| \leq 1.$$

Furthermore, let

$$(8)\quad r_j \stackrel{\Delta}{=} \sum_{i=1}^{n}\alpha_i\text{Re}\{a_i^{-j}\} + \sum_{i=1}^{n}\alpha_{i+n}\text{Im}\{a_i^{-j}\}.$$

Then the optimal error e_k satisfies the following condition:

$$|e_k| = \begin{cases} \mu^*, & \text{if } r_k \neq 0; \\ \leq \mu^*, & \text{if } r_k = 0. \end{cases}$$

Remark 1. Note that the optimal solution may have infinitely many terms such that $|e_i| = \mu^*$.

Since all the solutions to a suboptimal Nehari extension problem of the form $\|R + Q\|_{\mathcal{H}_\infty} \leq \gamma$ can be parametrized in terms of a free parameter $W(z) \in \mathcal{H}_\infty$, $\|W\|_{\mathcal{H}_\infty} \leq \gamma^{-1}$ problem $l_\infty/\mathcal{H}_\infty$ can be thought of as an optimization problem inside the origin centered γ^{-1}-ball. However, the γ^{-1}-ball is not compact in $\mathcal{H}_\infty$. Thus a minimizing solution may not exist. Motivated by this difficulty, we introduce the following *modified* mixed $l_\infty/\mathcal{H}_\infty$ problem: given $\delta < 1$ and $T_1(z), T_2(z)$, and $\Theta(z) \in \mathcal{RH}_\delta$, find[3]

$$(l_\infty/\mathcal{H}_\delta)\qquad \mu_o^\delta = \min_{Q \in \mathcal{RH}_\delta} \|e\|_{l_\infty}$$

subject to

$$\|T_1(z) + T_2(z)Q(z)\|_{\mathcal{H}_\delta} \leq \gamma.$$

Remark 2. Problem $l_\infty/\mathcal{H}_\delta$ can be thought of as solving the problem $l_\infty/\mathcal{H}_\infty$ with the additional constraint that all the poles of the closed-loop system must be inside the disk of radius δ. A parametrization of all achievable closed-loop transfer functions,

[2] This restriction on θ can be relaxed to include steps functions, by absorbing the pole at $z = 1$ into the plant, thus forcing a controller with integral action.

[3] Problem $l_\infty/\mathcal{H}_\delta$ was suggested by Dr. H. Rotstein and Prof. A. Sideris, Department of Electrical Engineering, Caltech.

such that T satisfies this additional constraint, can be obtained from (1) by simply changing the stability region from the unit-disk to the δ-disk using the transformation $z = \delta\hat{z}$ before performing the factorization. Furthermore, by combining this transformation with the inner factorization, the resulting $T_2(z)$ satisfies $T_2(z)T_2(\frac{1}{z})|_{|z|=\delta} = 1$ (i.e., T_2 is inner in $\mathcal{H}_\delta$).

In what follows we will show that if $l_\infty/\mathcal{H}_\delta$ is feasible, it always admits a minimizing solution. Moreover, this solution is rational (i.e., $Q \in \mathcal{RH}_\infty$) and requires considering only a finite number of elements $N(\delta)$ (independent of Q) of the sequence $\{e_k\}$. The proof is constructive and is based upon showing that $l_\infty/\mathcal{H}_\delta$ can be decoupled into a finite-dimensional convex optimization and an unconstrained Nehari approximation problem, both of them admitting a minimizing rational solution.

LEMMA 1. *Assume that $l_\infty/\mathcal{H}_\delta$ is feasible. Then there exists $N(\delta)$ such that for every $Q \in \mathcal{H}_\delta$ satisfying the constraint $\|R+Q\|_{\mathcal{H}_\delta} \le \gamma$, the corresponding sequence $\{e_k\}$ satisfies $|e_k| < \mu^*$ for all $k \ge N$, where μ^* indicates the unconstrained l_∞ optimum introduced in Theorem* 1.

Proof. Proof of Lemma 1 is given in Appendix A. □

COROLLARY 1. *Problem $l_\infty/\mathcal{H}_\delta$ is equivalent to the following semi-infinite convex optimization problem*:

$$\min_{\substack{Q\in\mathcal{H}_\delta \\ \|R+Q\|_{\mathcal{H}_\delta}\le\gamma}} \left\{ \max_{0\le k\le N-1} |(\underline{t}_1 + \tau\underline{q})_k| \right\} \tag{9}$$

where

$$\underline{t}_1 \stackrel{\Delta}{=} (\, t^\theta_{1o} \quad \cdots \quad t^\theta_{1N-1}\,)',$$

$$\tau = \begin{pmatrix} t^\theta_{2o} & 0 & \dots & 0 \\ t^\theta_{21} & t^\theta_{20} & \dots & 0 \\ \vdots & & \ddots & \\ t^\theta_{2N-1} & \dots & & t^\theta_{2o} \end{pmatrix}, \tag{10}$$

$$\underline{q}^o \stackrel{\Delta}{=} (\, q_o \quad \cdots \quad q_{N-1}\,)',$$

where t^θ_{ik}, q_k denote the kth element of the impulse response of $T^\theta_i(z)\Theta(z)$ and $Q(z)$, respectively.

Proof. Let μ^o denote the solution to $l_\infty/\mathcal{H}_\delta$. From Lemma 1 it follows that (since $\mu^o \ge \mu^*$)

$$\min_{\substack{Q\in\mathcal{H}_\delta \\ \|R+Q\|_{\mathcal{H}_\delta}\le\gamma}} \left\{ \sup_k |e_k| \right\} = \mu^o \ge \mu^* > |e_l|,\ l \ge N.$$

Therefore the peak value of $|e_k|$ is achieved for some $k < N$. The proof is completed by noting that (9) gives e_k in terms of the impulse responses of $T^\theta_1\Theta(z), T^\theta_2\Theta(z)$, and $Q(z)$. □

3.3. The $\mathcal{H}_\infty$ performance constraint. In this section we show that i) the modified $l_\infty/\mathcal{H}_\infty$ problem $l_\infty/\mathcal{H}_\delta$ has a global minimum that can be explicitly found by solving a constrained finite-dimensional convex optimization followed by the solution to an unconstrained Nehari approximation problem; and ii) the mixed $l_\infty/\mathcal{H}_\infty$ problem can be solved by solving a sequence of modified problems. Let q_i denote the terms of the impulse response of $Q(z)$. The key observation to show the first result is that (from Lemma 1) only the first N terms of this expansion appear in the l_∞ optimization. The second result follows then by constructing a nonincreasing sequence $\{\mu_i\}$.

LEMMA 2. *Consider the following Sylvester equation:*

$$A_R' Y A_q - Y = c_R' e_N' \tag{11}$$

where A_R is a nonsingular antistable matrix, c_R is a row vector, and

$$\begin{aligned} A_q &= \begin{pmatrix} 0 & \dots & 0 & 0 \\ 1 & \dots & 0 & 0 \\ \vdots & \ddots & \vdots & \vdots \\ 0 & \dots & 1 & 0 \end{pmatrix}, \\ e_N' &= \begin{pmatrix} 0 & \dots & 1 \end{pmatrix}. \end{aligned} \tag{12}$$

Then the solution Y to (11) *can be explicitly calculated as*

$$Y = -\begin{pmatrix} (A_R')^{N-1} c_R' & (A_R')^{(N-2)} c_R' & \dots & c_R' \end{pmatrix}. \tag{13}$$

Proof. The proof follows by successive right multiplications of (11) by the columns of the identity. □

In the following theorem we consider the case where the *first* N coefficients of the expansion of $Q(z)$ are *specified* and establish a necessary and sufficient condition for the existence of a tail to complete $Q(z)$ in such a way that the approximation error verifies $\|R + Q\|_{\mathcal{H}_\infty} \le \gamma$.

THEOREM 2. *Let*

$$R \stackrel{\Delta}{=} \left(\begin{array}{c|c} A_R & b_R \\ \hline c_R & d_R \end{array} \right) \in \mathcal{RH}_\infty^-,$$

with McMillan degree n, and $Q_F = \sum_{i=0}^{N-1} q_i z^{-i}$ be given. Then there exist $Q_R \in \mathcal{RH}_\infty$, such that $\|R + Q_F + z^{-N} Q_R\|_{\mathcal{H}_\infty} \le \gamma$, iff $\|\mathcal{Q}\|_2 \stackrel{\Delta}{=} \overline{\sigma}(\mathcal{Q}) \le \gamma$, where $\overline{\sigma}$ denotes the maximum singular value, $\mathcal{Q}$ is a matrix affine in the coefficients of Q_F of the following form:

$$\begin{aligned} \mathcal{Q} &= W^{\frac{1}{2}} \begin{pmatrix} I & 0 \\ 0 & \mathcal{H}' \end{pmatrix} L_c^{\frac{1}{2}}, \\ \mathcal{H} &= \begin{pmatrix} h_N & h_{N-1} & \dots & \dots & h_1 \\ & h_N & h_{N-1} & \dots & h_2 \\ & & \ddots & & \\ & & & h_N & h_{N-1} \\ & & & & h_N \end{pmatrix}, \\ h_i &= q_{N-i} + b_R' (A_R')^{N-1-i} c_R', \ 1 \le i \le N-1, \\ h_N &= q_o + d_R; \end{aligned} \tag{14}$$

and W and L_c are positive definite matrices depending only on R.

Proof. Let $G \stackrel{\Delta}{=} R + Q_F$. Given Q_F, there exist $Q_R \in \mathcal{H}_\infty$ such that $\|R + Q_F + z^{-N} Q_R\|_{\mathcal{H}_\infty} \le \gamma$ *iff* the corresponding *unconstrained* 1-block Nehari approximation problem [12] has a solution, i.e. if

$$\begin{aligned} \min_{Q_R \in \mathcal{H}_\infty} \|G + z^{-N} Q_R\|_{\mathcal{H}_\infty} &= \min_{Q_R \in \mathcal{H}_\infty} \|z^N G + Q_R\|_{\mathcal{H}_\infty} \\ &= \min_{Q_R \in \mathcal{H}_\infty} \|z^{-N} G^\sim + Q_R^\sim\|_{\mathcal{H}_\infty} \\ &= \Gamma_H(z^{-N} G^\sim) \le \gamma, \end{aligned} \tag{15}$$

where we used the facts that z^N is an inner function and $\|G\|_{\mathcal{H}_\infty} = \|G^\sim\|_{\mathcal{H}_\infty}$. Moreover, from Nehari's theorem it also follows that $Q_R \in \mathcal{RH}_\infty$. In order to compute Γ_H we need a state-space realization for the stable part of $z^{-N}G^\sim$. Let $G_1 \overset{\Delta}{=} R^\sim z^{-N}$. Standard space-state manipulations [13] yield

$$(16) \qquad R^\sim = \left(\begin{array}{c|c} (A_R')^{-1} & -(A_R')^{-1}c_R' \\ \hline b_R'(A_R')^{-1} & d_R' - b_R'(A_R')^{-1}c_R' \end{array}\right), \qquad z^{-N} = \left(\begin{array}{c|c} A_q & e_1 \\ \hline e_N' & 0 \end{array}\right)$$

where A_R^{-1} exists since $R \in \mathcal{H}_\infty{}^-$ and

$$A_q = \begin{pmatrix} 0 & \dots & 0 & 0 \\ 1 & \dots & 0 & 0 \\ \vdots & \ddots & \vdots & \vdots \\ 0 & \dots & 1 & 0 \end{pmatrix}, \qquad e_1 = \begin{pmatrix} 1 \\ 0 \\ \vdots \\ 0 \end{pmatrix},$$
$$e_N' = (\, 0 \quad \dots \quad 1 \,).$$

Hence

$$(17) \qquad G_1 = \left(\begin{array}{cc|c} (A_R')^{-1} & -(A_R')^{-1}c_R'e_N' & 0 \\ 0 & A_q & e_1 \\ \hline b_R'(A_R')^{-1} & d_R'e_N' - b_R'(A_R')^{-1}c_R'e_N' & 0 \end{array}\right).$$

Finally, the similarity transformation

$$T = \begin{pmatrix} I_n & Y \\ 0 & I_N \end{pmatrix}$$

where Y is the unique solution to the Sylvester equation

$$A_R'YA_q - Y = c_R'e_N'$$

yields

$$(18) \qquad G_1 = \left(\begin{array}{cc|c} (A_R')^{-1} & 0 & Ye_1 \\ 0 & A_q & e_1 \\ \hline b_R'(A_R')^{-1} & d_R'e_N' - b_R'(A_R')^{-1}(c_R'e_N' + Y) & 0 \end{array}\right).$$

Since A_R is antistable, A_R^{-1} is stable. Hence $P_+[G_1] = G_1$. Similarly,

$$(19) \qquad \begin{aligned} G_2 \overset{\Delta}{=} z^{-N}Q_F{}^\sim &= \sum_{i=1}^{N-1} q_{N-i}z^{-i} \\ &= \left(\begin{array}{c|c} A_q & e_1 \\ \hline c_q & 0 \end{array}\right) \end{aligned}$$

where

$$c_q = (\, q_{N-1} \quad \dots \quad q_0 \,).$$

Hence

$$\mathcal{G}\overset{\Delta}{=}P_+[G_1+G_2]=\left(\begin{array}{cc|c} (A'_R)^{-1} & 0 & Ye_1 \\ 0 & A_q & e_1 \\ \hline b'_R(A'_R)^{-1} & H & 0 \end{array}\right) \tag{20}$$

where

$$H\overset{\Delta}{=}c_q+d'_Re'_N-b'_R(A'_R)^{-1}(c'_Re'_N+Y)\overset{\Delta}{=}(\,h_1 \quad \dots \quad h_N\,)\,. \tag{21}$$

Finally, note that Y can be computed explicitly by using Lemma 2. Substituting (13) in (20) and (21) yields

$$\begin{aligned} \mathcal{G}=P_+[G_1+G_2]&=\left(\begin{array}{cc|c} (A'_R)^{-1} & 0 & -(A'_R)^{N-1}c'_R \\ 0 & A_q & e_1 \\ \hline b'_R(A'_R)^{-1} & H & 0 \end{array}\right); \\ h_i&=q_{N-i}+b'_R(A'_R)^{N-1-i}c'_R, \qquad 1\le i\le N-1; \\ h_N&=q_0+d_R. \end{aligned} \tag{22}$$

In order to compute the approximation error we need to compute the observability and controllability grammians of $\mathcal{G}$. Although, in principle, this requires the solution of two Lyapunov equations, with coefficients that are functions of Q_F, we will show that the particular structure of the problem allows for computing these solutions explicitly. For the controllability grammian L_c we have

$$\begin{aligned} &\begin{pmatrix} (A'_R)^{-1} & 0 \\ 0 & A_q \end{pmatrix}\begin{pmatrix} L^C_{11} & L^C_{12} \\ L'^C_{12} & L^C_{22} \end{pmatrix}\begin{pmatrix} (A'_R)^{-1} & 0 \\ 0 & A_q \end{pmatrix}'-\begin{pmatrix} L^C_{11} & L^C_{12} \\ L'^C_{12} & L^C_{22} \end{pmatrix} \\ &\qquad\qquad=-\begin{pmatrix} (A'_R)^{N-1}c'_Rc_R(A_R)^{N-1} & -(A'_R)^{N-1}c'_Re'_1 \\ -e_1c_R(A_R)^{N-1} & e_1e'_1 \end{pmatrix}. \end{aligned} \tag{23}$$

Solving for each of the blocks of the grammian yields

$$\begin{aligned} L^C_{11}&=L^C_o, \\ L^C_{12}&=-\left(\,(A'_R)^{N-1}c'_R \quad (A'_R)^{N-2}c'_R\dots \quad c'_R\,\right)=Y, \\ L^C_{22}&=I_N \end{aligned} \tag{24}$$

where L^C_o is the solution of the following Lyapunov equation:

$$A'_RL^C_oA_R-L^C_o=(A'_R)^Nc'_Rc_R(A_R)^N \tag{25}$$

and the expression for L^C_{12} was obtained from the corresponding equation by successive right multiplications by e_i. Note that the controllability grammian of $\mathcal{G}$ is independent of Q_F. Similarly, for the observability grammian L_o we have

$$\begin{aligned} &\begin{pmatrix} (A'_R)^{-1} & 0 \\ 0 & A_q \end{pmatrix}'\begin{pmatrix} L^0_{11} & L^0_{12} \\ L'^0_{12} & L^0_{22} \end{pmatrix}\begin{pmatrix} (A'_R)^{-1} & 0 \\ 0 & A_q \end{pmatrix}-\begin{pmatrix} L^0_{11} & L^0_{12} \\ L'^0_{12} & L^0_{22} \end{pmatrix} \\ &\qquad\qquad=-\begin{pmatrix} (A_R)^{-1}b_Rb'_R(A'_R)^{-1} & (A_R)^{-1}b_rH \\ H'b'_R(A'_R)^{-1} & H'H \end{pmatrix}. \end{aligned} \tag{26}$$

Solving for each of the blocks of the grammian yields

$$\begin{aligned} L^0_{11} &= L^0_o, \\ L^0_{12} &= \mathcal{A}\mathcal{H}', \\ L^0_{22} &= \mathcal{H}\mathcal{H}' \end{aligned} \tag{27}$$

where

$$\mathcal{H} \stackrel{\Delta}{=} \begin{pmatrix} h_N & h_{N-1} & \dots & \dots & h_1 \\ & h_N & h_{N-1} & \dots & h_2 \\ & & \ddots & & \\ & & & h_N & h_{N-1} \\ & & & & h_N \end{pmatrix}, \tag{28}$$
$$\mathcal{A} = \left(A_R^{-N} b_R \quad A_R^{-(N-1)} b_R \dots A_R^{-1} b_R \right),$$

and L^0_o is the solution to the following Lyapunov equation:

$$A_R L^0_o A'_R - L^0_o = b_R b'_R \tag{29}$$

(i.e., the controllability grammian for R), which is independent from Q_F. Finally, note that

$$\begin{aligned} L_o &= \begin{pmatrix} L^0_o & \mathcal{A}\mathcal{H}' \\ \mathcal{H}\mathcal{A}' & \mathcal{H}\mathcal{H}' \end{pmatrix} \\ &= \begin{pmatrix} I & 0 \\ 0 & \mathcal{H} \end{pmatrix} \begin{pmatrix} L^0_o & \mathcal{A} \\ \mathcal{A}' & I \end{pmatrix} \begin{pmatrix} I & 0 \\ 0 & \mathcal{H}' \end{pmatrix}. \end{aligned} \tag{30}$$

Let

$$W'^{\frac{1}{2}} W^{\frac{1}{2}} \stackrel{\Delta}{=} \begin{pmatrix} L^0_o & \mathcal{A} \\ \mathcal{A}' & I \end{pmatrix}. \tag{31}$$

Then

$$L_o = \begin{pmatrix} I & 0 \\ 0 & \mathcal{H} \end{pmatrix} W'^{\frac{1}{2}} W^{\frac{1}{2}} \begin{pmatrix} I & 0 \\ 0 & \mathcal{H}' \end{pmatrix}. \tag{32}$$

Hence, from (24) and (32) we have that

$$\begin{aligned} L_c^{\frac{1}{2}} L_o L_c^{\frac{1}{2}} &= \mathcal{Q}'\mathcal{Q} \\ \mathcal{Q} &\stackrel{\Delta}{=} W^{\frac{1}{2}} \begin{pmatrix} I & 0 \\ 0 & \mathcal{H}' \end{pmatrix} L_c^{\frac{1}{2}}. \end{aligned} \tag{33}$$

From Nehari's theorem [12] it follows that

$$\begin{aligned} \|R + Q\|_{\mathcal{H}_\infty} \le \gamma &\iff \rho^{\frac{1}{2}} \left(L_c^{\frac{1}{2}} L_o L_c^{\frac{1}{2}} \right) \le \gamma \\ &\iff \|\mathcal{Q}\|_2 \le \gamma \end{aligned} \tag{34}$$

where ρ indicates the spectral radius. □

Remark 3. Note that

$$\begin{pmatrix} L_o^0 & \mathcal{A} \\ \mathcal{A}' & I \end{pmatrix}$$

is positive definite, since from (29) it can be easily shown that

$$L_o^0 - \mathcal{A}\mathcal{A}' = A_R{}^{-N} L_o^0 A_R^{-N} > 0. \tag{35}$$

Remark 4. Although the similarity transformation used to diagonalize (17) is useful in establishing the desired result, attempting to compute $\mathcal{Q}$ from (33) may be numerically ill conditioned since the matrices L_c and $\mathcal{H}$ contain the powers A_R^i, $i = 1 \dots N$, and A_R all its eigenvalues outside the unit disk. An alternative expression for $\mathcal{Q}$ that avoids this ill-conditioning is given in Appendix B.

Remark 5. This result can be easily extended to the case $Q \in \mathcal{RH}_\delta$, $\|R+Q\|_{\mathcal{H}_\delta} \leq \gamma$ by using the change of variable $z = \delta\hat{z}$.

Combining Corollary 1 and Theorem 2 yields the main result of this section.

THEOREM 3. *$Q^o = Q_F^o + \hat{z}^{-N} Q_R^o$, where $Q_F^o = \sum_{i=0}^{N-1} q_i \hat{z}^{-i}$, solves the modified $l_\infty/\mathcal{H}_\infty$ control problem $l_\infty/\mathcal{H}_\delta$ iff $\underline{q}^o = (q_o \dots q_{N-1})'$ solves the following finite-dimensional convex optimization problem:*

$$\underline{q}^o = \underset{\substack{\underline{q} \in R^N \\ \|\mathcal{Q}\|_2 \leq \gamma}}{\operatorname{argmin}} \left\{ \max_{0 \leq k \leq N-1} |(\underline{t}_1 + \tau \underline{q})_k| \right\} \tag{36}$$

and Q_R^o solves the unconstrained Nehari approximation problem

$$Q_R^o(\hat{z}) = \underset{Q_R \in \mathcal{H}_\infty}{\operatorname{argmin}} \|R(\hat{z}) + Q_F^o + \hat{z}^{-N} Q_R(\hat{z})\|_{\mathcal{H}_\infty} \tag{37}$$

where $z = \delta\hat{z}$, R is defined in (4), N is selected such that

$$\begin{aligned} &K_e \delta^N \leq \mu^*, \\ &K_e = \left(\|T_1^\theta(\hat{z})\|_{\mathcal{H}_\infty} + \|T_2^\theta(\hat{z})\|_{\mathcal{H}_\infty} \left(\gamma + \|R(\hat{z})\|_{\mathcal{H}_\infty} \right) \right) \|\Theta(\hat{z})\|_{\mathcal{H}_\infty}, \end{aligned} \tag{38}$$

and μ^* is the unconstrained l_∞ optimum.

Remark 6. $Q^o \in \mathcal{RH}_\infty$ since Q_F^o is a finite impulse response filter and, from Nehari's theorem, $Q_R^o \in \mathcal{RH}_\infty$.

4. Synthesis algorithm. Based upon the results of Theorem 3 and §§3.2 and 3.3, the mixed $l_\infty/\mathcal{H}_\infty$ problem can be solved by using the following algorithm:

0) *Data:* An increasing sequence $\delta_i \to 1, \epsilon > 0$.
1) Solve the unconstrained l_∞ problem using Theorem 1. Compute $\|T_{\zeta w}\|_{\mathcal{H}_\infty}$. If $\|T_{\zeta w}\|_{\mathcal{H}_\infty} \leq \gamma$ stop, else set $i = 1$.
2) Solve the problem $l_\infty/\mathcal{H}_{\delta i}$ proceeding as follows:
   2.1) Let $z = \delta_i \hat{z}$ and consider the system $S(\hat{z})$.
   2.2) Perform the factorization (1) to obtain $T_i(\hat{z}), T_i^\theta(\hat{z})$.
   2.3) Compute N from (38).
   2.4) Find $\hat{Q}(\hat{z})$ and μ_i using Theorem 3.
3) Let $Q = \hat{Q}(\frac{z}{\delta_i}), K = F_l(J, Q)$. Compute $\|T_{\zeta w}(z)\|_{\mathcal{H}_\infty}$. If $\|T_{\zeta w}(z)\|_{\mathcal{H}_\infty} \geq \gamma - \epsilon$ stop, else set $i = i + 1$ and go to 2.

Step 2.4) entails solving first the nondifferentiable constrained optimization problem (36) and then the unconstrained $\mathcal{H}_\infty$ problem (37). The latter is a well-understood problem, and efficient computation techniques are available for finding the solution (see for instance [5]). The finite-dimensional problem (36) can be solved by using the deep-cut ellipsoid method [14, p. 329]. This algorithm requires computing subgradients of the objective function and the constraint $\overline{\sigma}(\mathcal{Q}) \leq \gamma$. Since the objective function is affine in Q, a subgradient is readily available. From the explicit expression for $\mathcal{Q}$ given in Appendix B. (eq. (B4)), it can be easily shown that a subgradient of the constraint is given by

$$\frac{\partial \overline{\sigma}}{\partial q_i} = (S_R^i v)u \tag{39}$$

where u and v are right and left singular vectors of $\mathcal{Q}$ corresponding to $\overline{\sigma}$ and S_R^i indicates the shift right operator applied i times, i.e.,

$$S_R^i v \overset{\Delta}{=} (0 \quad 0 \quad \dots \quad v_1 \quad \dots v_{n-i}).$$

THEOREM 4. *Assume that* $\inf_{Q \in \mathcal{RH}_\infty} \|T_1 + T_2 Q\|_{\mathcal{H}_\infty} = \Gamma_H(R) < \gamma$. *Then the sequence* $\mu_i \rightarrow \mu^o$, *the solution to the mixed* $l_\infty/\mathcal{H}_\infty$ *problem.*

Proof. From the maximum modulus theorem it follows that the solution Q_i to $l_\infty/\mathcal{H}_{\delta i}$ is a feasible solution for $l_\infty/\mathcal{H}_{\delta i+1}$. Thus, the sequence μ_i is nonincreasing, bounded below by the value of the unconstrained l_∞ controller. Therefore the sequence has a limit $\mu \geq \mu^o$. We will show next that $\mu = \mu^o$. Assume by contradiction that $\mu^o < \mu$ and select $\mu^o < \hat{\mu} < \mu$. Since $\Gamma_H(R) < \gamma$, there exists $Q_1 \in \mathcal{RH}_\infty$ such that $\|R + Q_1\|_{\mathcal{H}_\infty} < \gamma$. From the definition of μ^o it follows that, given $\eta > 0$, there exists $Q_o \in \mathcal{RH}_\infty$, $\|R + Q_o\|_{\mathcal{H}_\infty} \leq \gamma$, such that $\|e(Q_o)\|_{l_\infty} \leq \mu^o + \eta$, where $e(Q)$ denotes the output corresponding to the controller Q. Let $E(Q)$ denote the z-transform of $e(Q)$ and define $\hat{Q} \overset{\Delta}{=} Q_o + \epsilon(Q_1 - Q_o)$. Then

$$\|R + \hat{Q}\|_{\mathcal{H}_\infty} \leq (1-\epsilon)\|R + Q_o\|_{\mathcal{H}_\infty} + \epsilon\|R + Q_1\|_{\mathcal{H}_\infty} < \gamma$$

and

$$\begin{aligned} e_k(\hat{Q}) - e_k(Q_o) &= \frac{1}{2\pi j}\oint_{|z|=1} (E(\hat{Q}) - E(Q_o))z^{k-1}dz, \\ |e_k(\hat{Q}) - e_k(Q_o)| &\leq \frac{1}{2\pi}\oint_{|z|=1} |E(\hat{Q}) - E(Q_o)|dz \\ &\leq \|E(\hat{Q}) - E(Q_o)\|_{\mathcal{H}_\infty} = \epsilon\|T_2^\theta(Q_1 - Q_o)\Theta\|_{\mathcal{H}_\infty}. \end{aligned} \tag{40}$$

Hence

$$|e_k(\hat{Q})| \leq |e_k(Q_o)| + \epsilon\|T_2^\theta(Q_1 - Q_o)\Theta\|_{\mathcal{H}_\infty}.$$

It follows that

$$\begin{aligned} \|e(\hat{Q})\|_{l_\infty} &= \sup_k |e_k(\hat{Q})| \\ &\leq \sup_k |e_k(Q_o)| + \epsilon\|T_2^\theta(Q_1 - Q_o)\Theta\|_{\mathcal{H}_\infty} \\ &\leq \mu^o + \eta + \epsilon\|T_2^\theta(Q_1 - Q_o)\Theta\|_{\mathcal{H}_\infty}. \end{aligned}$$

Since $\hat{Q} \in \mathcal{RH}_\infty$, there exists $\delta_1 < 1$ such that $T_1 + T_2\hat{Q}$ is analytic in $|z| \geq \delta_1$. Moreover, since $\|T_1 + T_2\hat{Q}\|_{\mathcal{H}_\infty} < \gamma$, it follows (from continuity) that there exists $\delta_2 < 1$ such that $\|T_1 + T_2\hat{Q}\|_{\mathcal{H}_{\delta_2}} \leq \gamma$. Therefore, by taking ϵ and η small enough and $\delta \stackrel{\Delta}{=} \max\{\delta_1, \delta_2\} < 1$ we have that $\|T_1 + T_2\hat{Q}\|_{\mathcal{H}_\delta} \leq \gamma$ and $\|e(\hat{Q})\|_{l_\infty} < \hat{\mu}$. Hence for $\delta_i \geq \delta$, $\mu_i \leq \hat{\mu}$. However, this contradicts the fact that the sequence μ_i is nonincreasing and that $\hat{\mu} < \mu = \lim_{\delta_i \to 1} \mu_i$. □

Remark 7. Theorem 4 shows that as $\delta \to 1$ the objective μ_i of the modified problem converges to the solution μ of the original problem. Moreover, μ_i is a nonincreasing sequence of upper bounds of μ. Note, however, that as $\delta \to 1$, $N(\delta)$ will in general increase, thus increasing the size of the constrained optimization problem (36).

5. A simple example. Consider the problem of minimizing the step response error for the nonminimum phase plant used in [7], subject to robust stability against the unstructured multiplicative uncertainty shown in Fig. 2. Table 1 shows $\|e\|_{l_\infty}$ and $\|T_{\zeta w}\|_{\mathcal{H}_\infty}$ for different designs, with the corresponding step and frequency responses shown in Fig. 3. From Theorem 1 it can be easily shown that the infimum of the error is $\|e\|_{l_\infty} = \frac{8}{3}$, achieved with the controller $C(z) = \frac{z-1}{z}$. The same controller yields $\|T_{\zeta w}\|_{\mathcal{H}_\infty} = 5$, thus guaranteeing robust stability against unstructured perturbations $\|\Delta\|_{\mathcal{H}_\infty} \leq 0.2$. Note that this controller is *not internally stabilizing* due to the pole-zero cancellation at $z = 1$. The optimal $\mathcal{H}_\infty$ controller yields $\|T_{\zeta w}\|_{\mathcal{H}_\infty} = 3$ and $\|e\|_{l_\infty} = 4$. Mixed $l_\infty/\mathcal{H}_\infty$ optimization with $\|T_{\zeta w}\|_{\mathcal{H}_\infty} \leq 3.3$ yields $\|e\|_{l_\infty} = 3.31$. However, this procedure results in a controller with 104 states (since it can be easily shown from Appendix A that the l_∞ optimization needs to consider no more than 50 steps). Finally, the last entry in Table 1 corresponds to a reduced-order controller with five states. In spite of the substantial order reduction, this controller yields virtually the same performance as the mixed $l_\infty/\mathcal{H}_\infty$ controller.

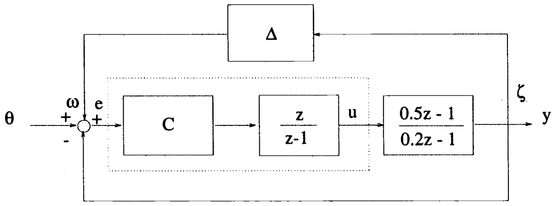

FIG. 2. *Block diagram with multiplicative uncertainty Δ "pulled-out."*

TABLE 1
$\|T_{\zeta w}\|_{\mathcal{H}_\infty}$ *vs* $\|e\|_{l_\infty}$ *for the example.*

	$\|T_{\zeta w}\|_{\mathcal{H}_\infty}$	$\|e\|_{l_\infty}$
l_∞	5	$\frac{8}{3}$
$\mathcal{H}_\infty$	3	4
$l_\infty/\mathcal{H}_\infty$	3.3	3.311
$l_\infty/\mathcal{H}_{\infty_{\mathrm{red}}}$	3.3	3.312

6. Conclusions. In this paper we address the problem of finding an internally stabilizing compensator that minimizes the maximum amplitude of the error to a fixed

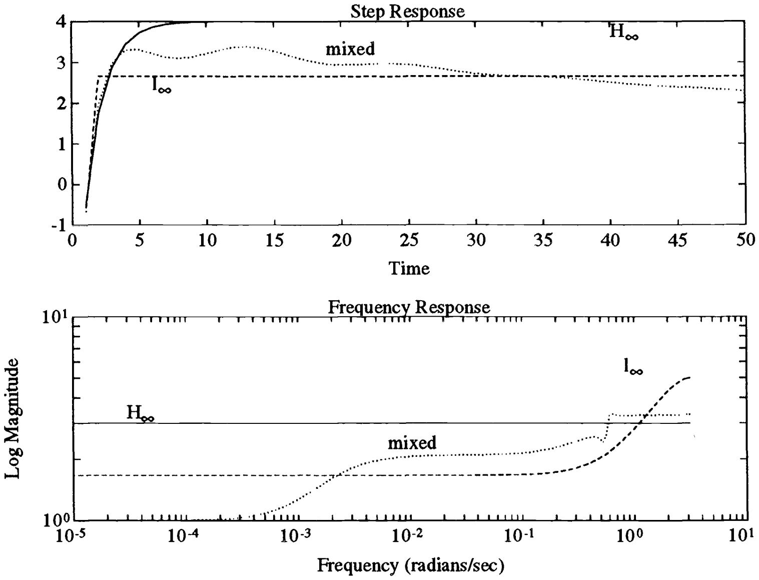

FIG. 3. *Step and frequency responses for different designs.*

given input subject to constraints upon the $\mathcal{H}_\infty$ norm of a relevant transfer function. This problem can be thought of as the problem of designing a controller capable of guaranteeing an adequate robustness level against dynamic uncertainty while using the extra available degrees of freedom to optimize a time-domain performance. We show that the problem can be solved by solving a sequence of modified problems, each one entailing solving a finite-dimensional constrained optimization problem and an unconstrained $\mathcal{H}_\infty$ problem.

Perhaps the most severe limitation of the proposed method is that may result in very-large-order controllers (roughly $2N$) necessitating some type of model reduction. The example of §5 suggests that substantial order reduction can be accomplished without performance degradation. Research is currently under way addressing this issue and pursuing the extension of the formalism to allow more control on the shape of the error response.

Acknowledgments. The author wishes to thank Dr. Héctor Rotstein and Prof. Athanasios Sideris, Department of Electrical Engineering, Caltech, for many comments and for suggesting problem $l_\infty/\mathcal{H}_\delta$.

Appendix A: Proof of Lemma 1. Since $E(z) \in \mathcal{RH}_\delta$, it is analytic in $|z| \geq \delta$ and

$$e_k = \frac{1}{2\pi j}\oint_C E(z)z^{k-1}dz \tag{A1}$$

where C is the origin centered circle with radius δ. From (A1) it follows that, for any $K_e \geq \sup_{z=\delta e^{j\theta}} |E(z)| = \|E\|_{\mathcal{H}_\delta}$, we have

$$|e_k| \leq K_e \delta^k. \tag{A2}$$

An upper bound of $\|E\|_{\mathcal{H}_\delta}$ can be found from (2) as follows. Since $\|.\|_{\mathcal{H}_\delta}$ is submultiplicative, we have

$$\begin{aligned}\|E(z)\|_{\mathcal{H}_\delta} &\leq \|T_{e\theta}\|_{\mathcal{H}_\delta}\|\Theta\|_{\mathcal{H}_\delta} \\ &\leq (\|T_1^\theta\|_{\mathcal{H}_\delta} + \|T_2^\theta\|_{\mathcal{H}_\delta}\|Q^o\|_{\mathcal{H}_\delta})\|\Theta\|_{\mathcal{H}_\delta}.\end{aligned} \tag{A3}$$

From the hypothesis we have that

$$\|Q\|_{\mathcal{H}_\delta} \leq \gamma + \|R\|_{\mathcal{H}_\delta} \stackrel{\Delta}{=} \gamma_q. \tag{A4}$$

Substitution of (A4) in (A3) yields

$$K_e = \left(\|T_1^\theta\|_{\mathcal{H}_\delta} + \|T_2^\theta\|_{\mathcal{H}_\delta}\gamma_q\right)\|\Theta\|_{\mathcal{H}_\delta} < \infty. \tag{A5}$$

It follows that if N is selected such that

$$K_e\delta^N < \mu^*, \tag{$A6$}$$

then, for $l > N$, $|e_l| < \mu^*$.

Appendix B: Some numerical considerations. In this appendix we give an alternative to (33) for computing $\mathcal{Q}$. Since this alternative expression does not involve increasing powers of A_R, it is preferable in cases where N is large or A_R has large eigenvalues. From (24) we have that

$$L_c = \begin{pmatrix} L_o^c & Y \\ Y' & I_N \end{pmatrix} = \begin{pmatrix} I & Y \\ 0 & I \end{pmatrix}\begin{pmatrix} W_{oR} & 0 \\ 0 & I \end{pmatrix}\begin{pmatrix} I & 0 \\ Y' & I \end{pmatrix} \tag{B1}$$

where $W_{oR} \stackrel{\Delta}{=} L_o^c - YY'$ satisfies

$$A'_R W_{oR} A_R - W_{oR} = c'_R c_R$$

(i.e., W_{oR} is the observability grammian of A_R). From (30) we have

$$\begin{aligned} L_o &= \begin{pmatrix} I & 0 \\ 0 & \mathcal{H} \end{pmatrix}\begin{pmatrix} L_o^0 & \mathcal{A} \\ \mathcal{A}' & I \end{pmatrix}\begin{pmatrix} I & 0 \\ 0 & \mathcal{H}' \end{pmatrix} \\ &= \begin{pmatrix} I & \mathcal{A} \\ 0 & \mathcal{H} \end{pmatrix}\begin{pmatrix} L_o^0 - \mathcal{A}\mathcal{A}' & 0 \\ 0 & I \end{pmatrix}\begin{pmatrix} I & 0 \\ \mathcal{A}' & \mathcal{H}' \end{pmatrix}. \end{aligned} \tag{B2}$$

Finally by using (35) we get

$$\begin{aligned} L_o &= \begin{pmatrix} I & \mathcal{A} \\ 0 & \mathcal{H} \end{pmatrix}\begin{pmatrix} A_R^{-N} L_o^0 A_R'^{-N} & 0 \\ 0 & I \end{pmatrix}\begin{pmatrix} I & 0 \\ \mathcal{A}' & \mathcal{H}' \end{pmatrix} \\ &= \begin{pmatrix} A_R^{-N} & \mathcal{A} \\ 0 & \mathcal{H} \end{pmatrix}\begin{pmatrix} L_o^0 & 0 \\ 0 & I \end{pmatrix}\begin{pmatrix} A_R'^{-N} & 0 \\ \mathcal{A}' & \mathcal{H}' \end{pmatrix}. \end{aligned} \tag{B3}$$

Since the spectral radius of L_oL_c is invariant under a similarity transformation, it follows that $\mathcal{Q}$ in (33) can be replaced by

$$\mathcal{Q} = \begin{pmatrix} L_o^{0\frac{1}{2}} & 0 \\ 0 & I \end{pmatrix}\begin{pmatrix} A_R'^{-N} & A_R'^{-N}Y \\ \mathcal{A}' & \mathcal{A}'Y + \mathcal{H}' \end{pmatrix}\begin{pmatrix} W_{oR}^{\frac{1}{2}} & 0 \\ 0 & I \end{pmatrix} \tag{B4}$$

where the only terms that contain powers $A_R^i, i = 1\ldots N$, are in $\mathcal{H}' + \mathcal{A}'Y$. Finally, note that by defining $\hat{H} \stackrel{\Delta}{=} H + b'_R(A'_R)^{-1}Y + b'_R(A'_R)^{-1}c'_R e'_N = (\hat{h}_1 \ldots \hat{h}_N)$, (22) yields

$$\begin{aligned} \hat{h}_i &= q_{N-i}, \qquad 1 \leq i \leq N-1; \\ \hat{h}_N &= q_0 + d_R. \end{aligned} \tag{B5}$$

Hence, we have that

$$
\tag{B6}
\begin{aligned}
\mathcal{H}' + \mathcal{A}'Y = &\begin{pmatrix}
\hat{h}_N & \hat{h}_{N-1} & \cdots & \cdots & \hat{h}_1 \\
 & \hat{h}_N & \hat{h}_{N-1} & \cdots & \hat{h}_2 \\
 & & \ddots & & \\
 & & & \hat{h}_N & \hat{h}_{N-1} \\
 & & & & \hat{h}_N
\end{pmatrix} \\
+ &\begin{pmatrix}
c_R A_R^{-1} b_R & c_R A_R^{-2} b_R & \cdots & \cdots & c_R A_R^{-N} b_R \\
 & c_R A_R^{-1} b_R & c_R A_R^{-2} b_R & \cdots & c_R A_R^{-(N-1)} b_R \\
 & & \ddots & & \\
 & & & c_R A_R^{-1} b_R & c_R A_R^{-2} b_R \\
 & & & & c_R A_R^{-1} b_R
\end{pmatrix}.
\end{aligned}
$$

Since (B6) does not contain increasing powers of A_R, it is preferable to (33), especially in cases where N or the spectral radius of A_R are large.

ORDERS OF INPUT/OUTPUT DIFFERENTIAL EQUATIONS AND STATE-SPACE DIMENSIONS*

YUAN WANG† AND EDUARDO D. SONTAG‡

Abstract. This paper deals with the orders of input/output equations satisfied by nonlinear systems. Such equations represent differential (or difference, in the discrete-time case) relations between high-order derivatives (or shifts, respectively) of input and output signals. It is shown that, under analyticity assumptions, there cannot exist equations of order less than the minimal dimension of any observable realization; this generalizes the known situation in the classical linear case. The results depend on new facts, themselves of considerable interest in control theory, regarding universal inputs for observability in the discrete case, and observation spaces in both the discrete and continuous cases. Included in the paper is also a new and simple self-contained proof of Sussmann's universal input theorem for continuous-time analytic systems.

Key words. control systems, input/output equations, observation spaces, universal inputs, observability

1. Introduction.

Previous papers by the authors (see [40], [41]) studied various relationships between realizability of continuous-time systems and the existence of algebraic or analytic input/output differential equations. These are equations of the form

$$E\left(u(t), u'(t), u''(t), \ldots, u^{(r-1)}(t), y(t), y'(t), y''(t), \ldots, y^{(r)}(t)\right) = 0 \tag{1}$$

that relate inputs $u(\cdot)$ and outputs $y(\cdot)$. Such equations, and their discrete-time analogues, are of interest in identification theory and arise also naturally in the "behavioral" approach to systems (see, e.g., [43]). They provide a natural generalization of the autoregressive moving-average representations that appear in linear systems theory, where E is linear (in that case, the Laplace transform of the equation leads to the usual transfer function).

The papers [37], [40], [41] (see also [28] for analogous work in the discrete-time case) dealt with the relationships between the existence of such equations and the possibility of realizing the corresponding input/output (i/o) operator $u(\cdot) \mapsto y(\cdot)$ by a state-space system of the type

$$x'(t) = f(x(t)) + G(x(t))u(t)\,, \quad y(t) = h(x(t)) \tag{2}$$

whose state $x(t)$ evolves in an n-dimensional manifold. (Precise definitions are given later; for the rest of the introduction we give an informal discussion. The main assumption will be that all functions appearing are analytic.) While i/o equation descriptions of type (1) are well suited to identification algorithms, state-space descriptions of type (2) are often the basis of feedback design tools and are needed for

the statement and solution of control problems. Thus, it is of great interest to study the possible relationships between the two kinds of descriptions.

A question that has not been sufficiently studied and was not addressed in [40], [41] is that of comparing the *order* r of an i/o equation (1) to the minimal possible dimension n of a realization (2). In discrete time, for the analogous equations

$$E\left(u(t-1),\, u(t-2),\, \ldots,\, u(t-r),\, y(t),\, y(t-1),\, \ldots,\, y(t-r)\right) = 0 \tag{3}$$

and systems

$$\Sigma: \quad x(t+1) = f(x(t), u(t)), \quad y(t) = h(x(t)), \quad t = 0,\, 1,\, 2, \ldots, \tag{4}$$

it was known for a long time (see [28]) that one may have $r < n$, even if the system in (4) is minimal. It turns out, perhaps surprisingly, that this cannot happen in the continuous-time case: we prove here that if there is a minimal realization of dimension n, then no i/o equation can have order less than n. Moreover, we show that the result holds true also for discrete-time systems that are *reversible*, that is, those for which the controls induce one-to-one maps on the state space (the examples in [28] were not reversible).

The results in [40], [41] depend on an important equality among observation spaces. The latter are sets of functions on the state space that are obtained by performing different kinds of "experiments" with the system and extracting infinitesimal information from the observed data. The basic fact needed was established in [39], and it related the space obtained by using piecewise constant controls (and derivatives of the output function with respect to switching times between constant pieces) to the space obtained when using differentiable inputs instead (and the corresponding jet of derivatives of the output at time zero). The new results given in this paper depend on new facts, themselves of considerable interest in control theory, regarding subspaces obtained by the application of "generic" smooth inputs.

The results in this paper were announced and their proofs sketched in the conference paper [32] (and for discrete time in [42]). To be more precise, in [32] we derived our results from an equality between observation spaces that is somewhat weaker than the corresponding one proved here; namely, instead of the current Lemma 2.1, we only had that $\mathrm{d}\mathcal{F}(x) = \mathrm{d}\mathcal{F}_\mu(x)$ for generic jets μ and for *generic* states x. This is all that is needed in order to establish the desired results on orders of i/o equations. However, while this journal version was being written, Coron [5] showed that the equality can be strengthened so that it holds for *all* (not merely generic) states (but still generic μ). Since it turns out that the stronger equality can in fact be obtained with essentially the same proof as in [32], we now present the result directly in that form. (Since we are only interested in analytic systems, we can use elementary facts from analytic geometry to present a simpler approach to the problem than in [5]; in that reference the techniques of proof are very different, as the focus is on applications to feedback control problems for smooth systems. See also [31] for remarks on applications of results of the type proved here to path planning and feedback.)

In the development of the new observation space results, we needed to extend to discrete time the well-known and fundamental theorem by Sussmann on universal inputs for distinguishability of continuous-time analytic systems. It turned out that our proof also applies in continuous time. The theorem is obtained in a fairly direct way from a stronger result, Lemma 2.1 in this work. The proof of Lemma 2.1 is very elementary and intuitive, as it does not use anything more complicated than the fact that every descending chain of sets defined by analytic equations stabilizes relative to any fixed compact. (The original proof of Sussmann's theorem relies heavily on the stratification theory of subanalytic sets, a considerably deeper set of tools. Thus one contribution of this paper is to provide an alternative and simpler proof of that important result.) In addition to its role in helping to derive the universal input theorem and our main results, Lemma 2.1 also has its own independent interest, as it provides relationships between observation spaces defined in different ways and, thus, provides connections between several different notions of observability. We also note the very recent work [33], where further results on universal inputs are presented; these results show in particular the existence of inputs that are universal uniformly over the class of all analytic systems.

Another set of results that arose naturally while studying the problems in this paper, and which are included here, deals with the relationships among various alternative notions of observability, especially those proposed in the context of the differential-algebraic approach to control theory. We are able to characterize, for instance, the notion of observability proposed in [10], [9] in terms of more standard local observability concepts.

1.1. Other related work.

In addition to the references already mentioned, work by many authors is related to the topic of i/o equations and realizability; see for instance [6], [13], [37]. In particular, [7], [8] showed that one must add inequality constraints to (1) in order to obtain a precise characterization of the behavior of a state-space system, unless stronger algebraic conditions hold. In [26], [38], [4], local i/o equations were derived under nondegeneracy rank conditions, for smooth systems, under observability assumptions. The notions of observation space and algebra that we employ were introduced for discrete-time systems in [28], and their analogous continuous-time versions were given in [2], [3].

1.2. Outline of paper.

In §2 we introduce continuous-time systems and a technical result on observation spaces for generic jets. Certain special cases for which stronger conclusions can be given, namely bilinear and rational systems, are also studied there. In §3, we define universal inputs and relate their properties to the results on equality of observation spaces and to the orders of i/o equations. The following section has a proof of the main technical results stated in §§2 and 3. After this, §5 provides the discrete-time results. There are also two appendices with some technical lemmas that are required by the proofs.

2. Observation spaces for continuous-time systems.

In this section we first discuss several natural ways of defining observation spaces for continuous-time systems and then explore the relationships between the different definitions.

2.1. Observation spaces.

Consider an *analytic system*

$$\Sigma : \begin{cases} x'(t) &= g_0(x(t)) + \sum_{i=1}^{m} g_i(x(t))u_i(t)\,, \\ y(t) &= h(x(t))\,, \end{cases} \tag{5}$$

where for each t, $x(t) \in \mathcal{M}$, which is an analytic (second countable) manifold of dimension n, $h : \mathcal{M} \longrightarrow \mathbb{R}$ is an analytic function and $g_0, g_1, \ldots, g_m$ are analytic vector fields defined on $\mathcal{M}$. Controls are measurable essentially bounded maps $u : [0, T] \longrightarrow \mathbb{R}^m$ defined on suitable intervals. In general, $\varphi(t, x, u)$ denotes the state trajectory of (5) corresponding to a control u and initial state x, defined at least for small t.

In the special case in which $\mathcal{M} = \mathbb{R}^n$ and the entries of the vector fields g_i's (on the natural global coordinates) and of the function h are rational (with no real poles), we call (5) a *rational system.* If, in addition, the entries of the g_i's and h are polynomials, we call (5) a *polynomial system.*

For a given continuous-time system, let $\mathcal{F}$ be the subspace of functions $\mathcal{M} \longrightarrow \mathbb{R}$ spanned by the Lie derivatives of h in the directions of $g_0, g_1, \dots, g_m$, i.e.,

$$\mathcal{F} := \operatorname{span}_{\mathbb{R}} \left\{ L_{g_{i_1}} L_{g_{i_2}} \dots L_{g_{i_r}} h : \ r \geq 0, \ 0 \leq i_j \leq m \right\} . \tag{6}$$

This is the *observation space* associated with (5) (see, e.g., [30, Rem. 5.4.2]) For each $x \in \mathcal{M}$, let $\mathcal{F}(x)$ denote the space obtained by evaluating the elements of $\mathcal{F}$ at x.

For each $\alpha \in \mathcal{F}$, we may consider its differential $\mathrm{d}\alpha$, seen as a 1-form. For each $x \in \mathcal{M}$, we let $\mathrm{d}\mathcal{F}(x)$ be the space of covectors defined by

$$\mathrm{d}\mathcal{F}(x) = \{\mathrm{d}\alpha(x) : \ \alpha \in \mathcal{F}\} \ .$$

We also let $\mathrm{d}\mathcal{F}$ be $\{d\alpha : \ \alpha \in \mathcal{F}\}$ as a space of 1-forms.

A related construction is as follows. First, let $\mathbb{R}^{m,\infty} = \prod_{i=1}^{\infty} \mathbb{R}^m$ endowed with the box topology, for which a base of open sets consists of all sets of the form $\prod_{i=1}^{\infty} \mathcal{U}_i$, where each $\mathcal{U}_i$ is an open set of $\mathbb{R}^m$. A *generic* subset $\mathcal{W}$ of $\mathbb{R}^{m,\infty}$ is one that contains a countable intersection of open dense sets. It can easily be shown that with the above topology, $\mathbb{R}^{m,\infty}$ is a Baire space; thus, a generic subset is always dense.

Now for any $\mu = (\mu_0, \mu_1, \dots)$ in $\mathbb{R}^{m,\infty}$, we define

$$\psi_i(x, \mu) = \left. \frac{d^i}{dt^i} \right|_{t=0} h(\varphi(t, x, u)) \tag{7}$$

for $i \geq 0$, where u is any C^∞ control with initial values $u^{(j)}(0) = \mu_j$. The functions $\psi_i(x, \mu)$ can be expressed—applying repeatedly the chain rule—as polynomials in the $\mu_j = (\mu_{1j}, \dots, \mu_{mj})$ whose coefficients are analytic functions (rational functions if the system is rational) of x. Take the single-input case

$$\dot{x} = f(x) + g(x), \quad y = h(x)$$

(for simplicity of notation) as an example. The functions are

$$\begin{aligned}
&\psi_0(x, \mu) = h(x), \\
&\psi_1(x, \mu) = L_f h(x) + \mu_0 L_g h(x), \\
&\psi_2(x, \mu) = L_f^2 h(x) + \mu_0 (L_g L_f h(x) + L_f L_g h(x)) + \mu_0^2 L_g^2 h(x) + \mu_1 L_g h(x),
\end{aligned}$$

and so forth. For instance, for single-input single-output linear systems

$$x' = Ax + bu, \quad y = cx,$$

we have,

$$\psi_l(x, \mu) = cA^l x + \sum_{i=1}^{l} \mu_{i-1} cA^{i-1} b, \quad l = 0, 1, \dots \ .$$

For each fixed $\mu \in \mathbb{R}^{m,\infty}$, let $\mathcal{F}_\mu$ be the subspace of functions from $\mathcal{M}$ to $\mathbb{R}$ defined by

$$\mathcal{F}_\mu = \operatorname{span}_{\mathbb{R}} \{\psi_0(\cdot, \mu), \ \psi_1(\cdot, \mu), \ \psi_2(\cdot, \mu), \dots\} \tag{8}$$

and let $\mathcal{F}_\mu(x)$ be the space obtained by evaluating the elements of $\mathcal{F}_\mu$ at x for each $x \in \mathcal{M}$. Let $\mathrm{d}\mathcal{F}_\mu(x)$ be the space of covectors given by

$$\mathrm{d}\mathcal{F}_\mu(x) = \{\mathrm{d}\psi(x,\mu) : \psi \in \mathcal{F}_\mu\}$$

for each $x \in \mathcal{M}$. For instance, for linear systems, $\mathrm{d}\psi_l(x,\mu) = cA^l$ and

$$\mathrm{d}\mathcal{F}_\mu(x) = \operatorname{span}\{c,\ cA,\ cA^2,\ \ldots\},$$

which is independent of μ (and x). We also let $\mathrm{d}\mathcal{F}_\mu$ be $\{d\psi(\cdot,\mu) : \psi \in \mathcal{F}_\mu\}$, seen as a space of covector fields.

Clearly, for each μ, $\mathcal{F}_\mu$ is a subspace of $\mathcal{F}$, and therefore, for each x also $\mathrm{d}\mathcal{F}_\mu(x)$ is a subspace of $\mathrm{d}\mathcal{F}(x)$. The main result in [39] says that

$$\boxed{\mathcal{F} = \sum_\mu \mathcal{F}_\mu\,.} \tag{9}$$

This equality is fundamental in establishing results linking realizability to the existence of i/o equations, in [40] and [41]. In intuitive but less rigorous terms, the equality in (9) can be interpreted as follows. We consider the successive derivatives $y(0)$, $y'(0)$, $y''(0)$, ... expressed as functions of $x(0)$ and $u(0)$, $u'(0)$, $u''(0)$, ... For particular controls $u(t)$, the $y(0)$, $y'(0)$, $y''(0)$, ... are just functions of x; taking the span of all such functions, over all possible *smooth* controls, one obtains the right-hand side of (9). On the other hand, taking all possible *piecewise-constant* instead of smooth controls and taking derivatives with respect to the times at which the controls switch values, one obtains the space $\mathcal{F}$ in the left-hand side of (9).

The following is a technical result for continuous-time systems, which will help in deriving the desired facts about i/o equations.

LEMMA 2.1. *Assume that* (5) *is an analytic system. Then there exists a generic subset $\mathcal{W}$ of $\mathbb{R}^{m,\infty}$ such that*

$$\mathcal{F}(x) = \mathcal{F}_\mu(x) \tag{10}$$

and

$$\mathrm{d}\mathcal{F}(x) = \mathrm{d}\mathcal{F}_\mu(x) \tag{11}$$

for every $x \in \mathcal{M}$ and all $\mu \in \mathcal{W}$.

Remark 2.2. The above conclusions are also true if instead of the box topology one uses the weak topology on $\mathbb{R}^{m,\infty}$. This is the topology for which a basis of open sets consists of all sets of the form $\prod_{i=1}^\infty \mathcal{U}_i$, where each $\mathcal{U}_i$ is an open subset of $\mathbb{R}^m$ and only finitely many of them are proper subsets of $\mathbb{R}^m$. Clearly, the weak topology is coarser than the topology used before. With this topology, $\mathbb{R}^{m,\infty}$ is again a Baire space. We will remark at the end of the proof of Lemma 2.1 in §4 that the conclusions of Lemma 2.1 also hold for the weak topology. Moreover, these conclusions can be established as consequences of a more general result about convergent generating series, that ensures there exists a generic subset $\mathcal{W}$ of $\mathbb{R}^{m,\infty}$ with the property that these jets suffice for distinguishing *all possible* convergent generating series; more details are given in [33].

Remark 2.3. The conclusions in Lemma 2.1 do not always hold for every $\mu \in \mathbb{R}^{m,\infty}$. Consider as an illustration the following bilinear system:

$$x_1' = x_2, \quad x_2' = x_2 + x_1 u, \quad y = x_2\,. \tag{12}$$

For this system, $\mathcal{F} = \operatorname{span}\{x_1, x_2\}$, thus, $\mathcal{F}(x) \neq 0$ for all $x \neq 0$. But on the other hand, we have

$$\psi_0(x, \mu) = x_2, \ . \ \psi_1(x, \mu) = x_2 + x_1\mu_0 \, ,$$

and in general, $\psi_k(x, \mu) = P_k(x, \mu_0, \mu_1, \ldots, \mu_{k-2}) + x_1\mu_{k-1}$, where P_k is some polynomial. Clearly, for every $x = (x_1, x_2)$ for which $x_1 \neq 0$, one can find a solution μ recursively for the equations $\psi_i(x, \mu) = 0$ for $i > 0$. Hence, as long as $x_1 \neq 0$ and $x_2 = 0$, there exists some jet μ such that $\mathcal{F}_\mu(x) = 0$, which is therefore different from $\mathcal{F}(x)$ when $x_1 \neq 0$ and $x_2 = 0$.

2.2. Algebraic formulation. In this section, we assume for simplicity that $\mathcal{M} = \mathbb{R}^n$; we could work with more general manifolds but this would complicate notation, and in any case we will only need to apply the results given here locally. We say a function β is a *meromorphic function* if $\beta = \frac{p}{q}$, where p and q are analytic functions defined on $\mathcal{M}$, and $q \not\equiv 0$. (Note that this global definition is different from the local definition usually given; see, e.g., [17]. It will be enough for our purposes.) For each function $\alpha \in \mathcal{F}$, $\mathrm{d}\alpha$ is a covector field defined on $\mathcal{M}$. If β is a meromorphic function defined on $\mathcal{M}$, then $\beta \mathrm{d}\alpha$ is a well-defined 1-form on some open dense subset of $\mathcal{M}$ and any finite sum of such partially defined covector fields is defined on a common open dense set. Thus, we may introduce the subspace $\widehat{\mathrm{d}\mathcal{F}}$ of the cotangent space defined by

$$\widehat{\mathrm{d}\mathcal{F}} := \operatorname{span}_{\mathbb{R}_x}\{\mathrm{d}\alpha : \ \alpha \in \mathcal{F}\} \, ,$$

where $\mathbb{R}_x$ is the field of meromorphic functions defined on $\mathcal{M}$. Similarly, one can define, for each $\mu \in \mathbb{R}^{m,\infty}$, the space $\widehat{\mathrm{d}\mathcal{F}}_\mu$ by

$$\widehat{\mathrm{d}\mathcal{F}}_\mu := \operatorname{span}_{\mathbb{R}_x}\{\mathrm{d}\alpha : \ \alpha \in \mathcal{F}_\mu\} \, .$$

Note that there are natural identifications $\widehat{\mathrm{d}\mathcal{F}} \simeq \mathrm{d}\mathcal{F} \otimes \mathbb{R}_x$ and $\widehat{\mathrm{d}\mathcal{F}}_\mu \simeq \mathrm{d}\mathcal{F}_\mu \otimes \mathbb{R}_x$.

Since $\mathcal{M} = \mathbb{R}^n$, we can identify elements of $\widehat{\mathrm{d}\mathcal{F}}$ with vectors

$$(\alpha_1(x), \alpha_2(x), \ldots, \alpha_n(x))$$

of meromorphic functions defined on $\mathcal{M}$. The dimension of $\widehat{\mathrm{d}\mathcal{F}}$ over $\mathbb{R}_x$ is the size of the largest matrix that can be formed out of such vectors and has full rank, i.e., has a minor that is not zero as a function. That is, $\dim_{\mathbb{R}_x} \widehat{\mathrm{d}\mathcal{F}}$ is the same as $\max_{x \in \mathcal{M}} \dim \mathrm{d}\mathcal{F}(x)$. A similar argument can be made for each $\mathrm{d}\mathcal{F}_\mu(x)$; together with Lemma 2.1, we can then conclude the following corollary.

COROLLARY 2.4. *For any analytic system, $\widehat{\mathrm{d}\mathcal{F}}_\mu = \widehat{\mathrm{d}\mathcal{F}}$ for all μ in a generic set of $\mathbb{R}^{m,\infty}$.*

Yet another object is obtained if one instead views the elements

$$\psi_i(x, U) \tag{13}$$

as rational functions (in particular polynomials), on the formal variables $U = \{U_{ij}\}$, whose coefficients are functions of x, as opposed to seeing them as functions of x for each numerical choice $U_{ij} = \mu_{ij}$. We proceed as follows. Let

$$K = \mathbb{R}\Big(\{U_{ij} : \ 1 \leq i \leq m, \, j \geq 0\} \Big)$$

be the field obtained by adjoining the indeterminates U_{ij} to $\mathbb{R}$, and let

$$K_x = \mathbb{R}_x\Big(\{U_{ij} :\ 1 \le i \le m,\, j \ge 0\}\Big)$$

be the field obtained by adjoining the indeterminates U_{ij} to $\mathbb{R}_x$. We then let $\mathfrak{F}$ be defined as the subspace of K_x spanned by the functions ψ_i over the field K, i.e.,

$$\mathfrak{F} := \operatorname{span}_K \{\psi_i :\ i \ge 0\}\ .$$

Thus, $\mathfrak{F}$ consists of finite linear combinations $\sum q_i(U)\psi_i(x,\, U)$, where the $q_i(\cdot)$ are rational functions on the variables $\{U_{ij}\}$. Such a linear combination can be seen as a rational function on the $\{U_{ij}\}$ whose coefficients are meromorphic functions of x (and hence also meromorphic functions) and, thus, elements of K_x. The differentials (with respect to x) of elements of K_x are viewed as rational functions in $\{U_{ij}\}$, whose coefficients are (in general, partially defined) covector fields. Finally we define

$$\widehat{\mathrm{d}\mathfrak{F}} := \operatorname{span}_{K_x}\{\mathrm{d}\psi :\ \psi \in \mathfrak{F}\}.$$

Then Lemma 2.1 implies the following corollary.

COROLLARY 2.5. *For any analytic system,* $\dim_{\mathbb{R}_x} \widehat{\mathrm{d}\mathcal{F}} = \dim_{K_x} \widehat{\mathrm{d}\mathfrak{F}}$.

Proof. Clearly $\dim_{K_x} \widehat{\mathrm{d}\mathfrak{F}} \le \dim_{\mathbb{R}_x} \widehat{\mathrm{d}\mathcal{F}}$. Conversely, $\dim_{K_x} \widehat{\mathrm{d}\mathfrak{F}} = \max_\mu \dim_{R_x} \widehat{\mathrm{d}\mathcal{F}}_\mu$. The desired conclusion then follows from Corollary 2.4. □

2.3. Bilinear and rational systems. Now consider the bilinear system

$$\begin{aligned} x' &= A_0 x + \sum_{i=1}^m u_i A_i x, \\ y &= cx, \end{aligned}$$

where $A_0, A_1, \ldots, A_m$ are $n \times n$ matrices and c is an $1 \times n$ matrix. For each multi-index $i_1 i_2 \ldots i_r$, where $0 \le i_j \le m$ for each $j \ge 0$,

$$L_{g_{i_1}} L_{g_{i_2}} \ldots L_{g_{i_r}} h(x) = c A_{i_r} A_{i_{r-1}} \ldots A_{i_1} x.$$

Note that ψ_i (as defined in (7)) is also linear in x for each i; for instance, in the single-input case (for simplicity of notation),

$$\psi_2(x,\, \mu_0,\, \mu_1) = c(A_0 + \mu_0 A_1)^2 x + \mu_1 c A_1 x\,.$$

Thus, for the bilinear case, we have the following corollary.

COROLLARY 2.6. *For a bilinear system,*

$$\mathcal{F} = \mathcal{F}_\mu \quad \text{and} \quad \mathrm{d}\mathcal{F} = \mathrm{d}\mathcal{F}_\mu \tag{14}$$

for every μ in a generic subset of $\mathbb{R}^{m,\infty}$.

Remark 2.7. We would like to point out that this corollary does *not* hold in general. The following simple example shows that for a general nonlinear system, $\mathcal{F}$ and $\mathcal{F}_\mu$ (respectively, $\mathrm{d}\mathcal{F}$ and $\mathrm{d}\mathcal{F}_\mu$) may not be the same for *any* μ, even though the two spaces $\widehat{\mathrm{d}\mathcal{F}}$ and $\widehat{\mathrm{d}\mathcal{F}}_\mu$ are the same.

Example 2.8. Consider the system

$$x' = x^3 + x^2 u, \quad y = x.$$

It is easy to see that

$$y = x, \quad y' = x^3 + x^2u,$$
$$y'' = 3x^5 + 5x^4u + 2x^3u^2 + x^2u',$$

and in general, $y^{(k)} = (2k-1)!!x^{2k+1} + p_k(u, u', \ldots, u^{(k-2)}, x) + x^2u^{(k-1)}$, where p_k is a polynomial in x of degree less than or equal to $2k$. It can be seen that

$$\mathcal{F} = \operatorname{span}_{\mathrm{IR}} \{x,\ x^2,\ x^3, \ldots\} \ .$$

However, $x^2 \notin \mathcal{F}_\mu$ for any μ for the following reason. Assume that

$$x^2 = \sum_{i=0}^{k} a_i\psi_i(x, \mu)$$

for some k and some $a_0, a_1, \ldots, a_k \in \mathrm{IR}$. Then $a_i = 0$ for $i \geq 2$, otherwise the degree of x in the left-hand side would be higher than 3. Thus the above equation becomes

$$x^2 = a_0x + a_1(x^3 + x^2\mu_0),$$

which is impossible. This shows that $\mathcal{F}_\mu \neq \mathcal{F}$ for any μ even though, in this case, $\widehat{\mathrm{d}}\mathcal{F} = \widehat{\mathrm{d}}\mathcal{F}_\mu = \operatorname{span}_{\mathrm{IR}_x}\{dx\}$ for all μ.

In this example, it is also true that $\mathrm{d}\mathcal{F} \neq \mathrm{d}\mathcal{F}_\mu$ for any μ. This can be shown as follows. If $\mathrm{d}\mathcal{F} = \mathrm{d}\mathcal{F}_\mu$, then $\mathrm{d}x^2 = 2x\mathrm{d}x \in \mathrm{d}\mathcal{F}_u$. From here it would follow that $x^2 = \alpha_1(x, \mu) + \alpha_2(x, \mu) + \cdots + \alpha_l(x, \mu) + c$ for some elements $\alpha_i \in \mathcal{F}_\mu$ and some constant $c \in \mathrm{IR}$. But it can be seen from the above argument that this is impossible.

Assume now that (5) is a rational system. Define $\mathcal{A}$ ($\mathcal{A}_\mu$, respectively) as the IR-algebra generated by the elements of $\mathcal{F}$ ($\mathcal{F}_\mu$, repectively). Then we define the observation field $\mathcal{Q}$ ($\mathcal{Q}_\mu$, respectively) as the quotient field of $\mathcal{A}$ ($\mathcal{A}_\mu$, respectively). For a field extension Q of IR, we use $\operatorname{trdeg}_{\mathrm{IR}}Q$ to denote the transcendence degree of Q over IR. Then we have the following conclusion for rational systems, in analogy to the above conclusion about bilinear systems.

COROLLARY 2.9. *For a rational system,*

$$\operatorname{trdeg}_{\mathrm{IR}}\mathcal{Q} = \operatorname{trdeg}_{\mathrm{IR}}\mathcal{Q}_\mu\ ,$$

for each μ in a generic subset of $\mathrm{IR}^{m,\infty}$.

3. Observability and universal inputs in continuous time. Consider an analytic system (5). Fix any two states p, $q \in \mathcal{M}$ and take an input u. We say p and q are *distinguished by u*, denoted by $p \not\sim_u q$, if $h(\varphi(\cdot, p, u)) \neq h(\varphi(\cdot, q, u))$ (considered as functions defined on the common domain of $\varphi(\cdot, p, u)$ and $\varphi(\cdot, q, u)$); otherwise we say p and q cannot be distinguished by u, denoted by $p \sim_u q$. If p and q cannot be distinguished by *any* input u, then we say p and q are *indistinguishable*, denoted by $p \sim q$. If for any two states, $p \sim q$ implies $p = q$, then we say that system (5) is *observable*. (See [30, Chap. 5].)

An input u is called a *universal* (*distinguishing*) input for system (5) if every distinguishable pair can be distinguished by u. The existence of universal inputs was first studied in [15] for bilinear systems, in [27] for analytic systems with compact state spaces, and for arbitrary analytic systems in [35] for the continuous case. In this work, we will provide a different and simpler proof of the general result in [35]. (Also, we later give a discrete-time version.) We now state the result to be proved.

For each $T > 0$, we consider $\mathcal{C}^\infty[0, T]$ endowed with the Whitney topology, that is, the topology for which a neighborhood base for each function $u(\cdot) \in \mathcal{C}^\infty[0, T]$ consists of the sets of the following form:

$$\mathcal{U}_{u,k,\delta} = \left\{ v \in \mathcal{C}^\infty[0, T] : \max_{0 \le i \le k,\ t \in [0, T]} |v^{(i)}(t) - u^{(i)}(t)| \le \delta \right\}$$

for some $k \ge 0$ and some $\delta > 0$. This is well known to be a Baire space (see [14]). By a generic subset of $\mathcal{C}^\infty[0, T]$ we mean a subset of $\mathcal{C}^\infty[0, T]$ containing a countable intersection of open dense sets.

THEOREM 3.1 (Sussmann's universal input theorem). *For any analytic system* (5), *and any fixed* $T > 0$, *the set of universal inputs is a generic subset of* $\mathcal{C}^\infty[0, T]$.

PROPOSITION 3.2. *There is always an analytic universal input for any analytic system.*

We will provide proofs of Theorem 3.1 and Proposition 3.2 in §4.1.

Consider the following more general class of systems:

$$x'(t) = f(x(t), u(t)), \quad y(t) = h(x(t)), \tag{15}$$

where for each t, $x(t) \in \mathcal{M}$, which is an analytic manifold of dimension n, $h : \mathcal{M} \to \mathbb{R}$ is an analytic function and $f : \mathcal{M} \times \mathbb{R}^m \to T\mathcal{M}$ is analytic and $f(x, u) \in T_x\mathcal{M}$ for each (x, u), so in particular, $f(\cdot, u)$ is an analytic vector field for each $u \in \mathbb{R}^m$. Controls are measurable essentially bounded maps: $u : [0, T] \longrightarrow \mathbb{R}^m$, for some $T = T_u > 0$. We apply the same definitions of distinguishability, observability, and universal inputs as for system (5) to system (15). One can then generalize the conclusion of Theorem 3.1 to systems of type (15) by means of the following argument. We consider the following system:

$$\begin{aligned} x'(t) &= f(x(t), z(t)), \quad z'(t) = v(t), \\ y(t) &= h(x(t)), \end{aligned} \tag{16}$$

where v is now a new control. By Proposition 5.1.11 in [30], one knows that if (x_1, x_2) is a distinguishable pair for (15), then x_1, x_2 can be distinguished by a differentiable (in fact, an analytic) control u. It then follows that for (16), the pair (ξ, ζ), where $\xi = (x_1, u(0))$ and $\zeta = (x_2, u(0))$, is distinguished by $v(t) = u'(t)$. On the other hand, if for (16) the pair $((x_1, z), (x_2, z))$ is distinguished by v, then for (15) (x_1, x_2) is distinguished by the control

$$z + \int_0^t v(s)\, ds.$$

Therefore, (x_1, x_2) is a distinguishable pair of (15) if and only if there exists some $z \in \mathbb{R}^m$ such that $((x_1, z), (x_2, z))$ is a distinguishable pair for (16) for some z. Applying Theorem 3.1 to system (16), we proved the following conclusion.

COROLLARY 3.3. *The universal inputs for system* (15) *form a generic subset of* $\mathcal{C}^\infty[0, T]$, *for any* $T > 0$.

3.1. Other notions of observability.

In what follows, we study relationships among several alternative notions of "observability" that have been proposed by various authors.

Take an open subset $\mathcal{U}$ of $\mathcal{M}$ and any two points p, $q \in \mathcal{U}$. If for every input u, $h(\varphi(t, p, u)) = h(\varphi(t, q, u))$ for each t for which $\varphi(T, p, u)$ and $\varphi(T, q, u)$ are both defined and in $\mathcal{U}$ for all $0 \leq t \leq T$, then we say that p and q are *$\mathcal{U}$-indistinguishable* (see, e.g., [29]).

Fix a point $p \in \mathcal{M}$. If for every neighborhood $\mathcal{U}_p$ there is a neighborhood $V_p \subset \mathcal{U}_p$ such that for any $q \in V_p$ the condition that q and p are $\mathcal{U}_p$-indistinguishable implies $p = q$, then we say the system (5) is *locally observable at* p. If (5) is locally observable at every point p, then we say (5) is *locally observable*. If there is an open dense set $\mathcal{U} \subset \mathcal{M}$ such that (5) is locally observable at every point p of $\mathcal{U}$, then we say (5) is *generically locally observable*. See [29] for details on local observability and related concepts such as the slightly different definition in [26]. The following fact is an immediate consequence of Lemma 2.10 and facts (2.4) and (2.8) in [29].

PROPOSITION 3.4. *An analytic system* (5) *is generically locally observable if and only if* $\max_x \dim \mathrm{d}\mathcal{F}(x) = n$.

PROPOSITION 3.5. *Let* $\mathcal{M} = \mathbb{R}^n$ *and let* (5) *be an analytic system. Then the following are equivalent*:

(1) *The system is generically locally observable.*

(2) $\dim_{K_x} \widehat{\mathrm{d}\mathfrak{F}} = n$.

(3) $\dim_{\mathbb{R}_x} \widehat{\mathrm{d}\mathcal{F}} = n$.

Proof. The maximum dimension of $\mathrm{d}\mathcal{F}(x)$ is the same as the $\dim_{\mathbb{R}_x} \widehat{\mathrm{d}\mathcal{F}}$. This shows that (1) and (3) are equivalent; (2) is equivalent to (3) by Corollary 2.5. □

For a polynomial system, the $\psi_i(x, U)$'s (as defined in (13)) are polynomial functions of both x and U. We say that a polynomial system is *weakly algebraically observable* if each coordinate x_i is algebraically over the field $K(\{\psi_i : i \geq 0\})$ $(= \mathbb{R}(\{U_{ij}, \psi_k, i = 1, \ldots, m;\ j, k \geq 0\}))$. It follows that Σ is weakly algebraically observable if and only if $\dim_{K(x)} \widehat{\mathrm{d}\mathfrak{F}} = n$, where $K(x)$ is the field of rational functions over K. (This is proved as follows: The dimension condition is equivalent, by [18, Thm. III of III.7], to the property that the transcendence degree of $K_0 = K(\{\psi_i : i \geq 0\})$ over K should be equal to n. On the other hand, we have the inclusions $K \subseteq K_0 \subseteq K(x)$, so $\mathrm{trdeg}_K K_0 + \mathrm{trdeg}_{K_0} K(x) = n$. Thus the dimension is n if and only if $\mathrm{trdeg}_{K_0} K(x) = 0$, i.e., if and only if $K(x)$ is algebraic over K_0.) By Proposition 3.5, we have the following corollary.

COROLLARY 3.6. *A polynomial system is weakly algebraically observable if and only if the system is generically locally observable.*

The notion of weakly algebraic observability used here was called "weak observability" in [28]. The same notion was used in [10] and extended to cover implicit systems as well.

3.2. Orders of i/o equations in continuous-time case.

3.2.1. State-space systems. We say that a state-space system Σ *admits an i/o equation* such as

$$A(u(t),\, u'(t),\, \ldots,\, u^{(k-1)}(t),\, y(t),\, y'(t),\, \ldots,\, y^{(k)}(t)) = 0\,, \tag{17}$$

where A is a nonzero analytic function from $\mathbb{R}^{mk} \times \mathbb{R}^{k+1}$ to $\mathbb{R}$, if (17) holds for every initial state x, every $\mathcal{C}^k$ i/o pair (u, y) of (5), and all t such that $y(t)$ is defined. The *order* of an equation (17) is defined to be the highest $r \leq k$ such that

$$\frac{\partial}{\partial \nu_r} A(\mu_0,\, \ldots,\, \mu_{k-1},\, \nu_0,\, \nu_1,\, \ldots,\, \nu_k)$$

is not a zero function.

For a given system Σ, we define $\delta(\Sigma)$ to be the lowest possible order of an i/o equation that Σ admits. In the case that there is no such i/o equation, $\delta(\Sigma)$ is defined to be $+\infty$.

THEOREM 3.7. *Assume Σ is an n-dimensional analytic system defined by* (5). *If Σ is generically locally observable, then $\delta(\Sigma) \geq n$. If, in addition, Σ is a rational system, then $\delta(\Sigma) = n$.*

Proof. Let $\mathcal{U} \subseteq \mathcal{M}$ be an open subset diffeomorphic to $\mathbb{R}^n$. We consider the restriction of Σ to $\mathcal{U}$. This system is still generically locally observable, and an equation for Σ is also an equation for the restriction. So without loss of generality, we assume from now on that $\mathcal{M} = \mathbb{R}^n$.

Assume that $\delta(\Sigma) = k < \infty$ and Σ admits i/o equation (17) of order k. For each integer $i \geq 0$, let

$$A_i = \frac{\partial^i}{\partial \nu_k^i} A(\mu_0, \ldots, \mu_{k-1}, \nu_0, \nu_1, \ldots, \nu_k).$$

Claim. There exists an i, such that A_i is not an i/o equation of Σ.

We prove the claim as follows. Assume that A_i is an i/o equation of Σ for every i. Then for any fixed i/o pair (u, y) and any fixed t, it holds that

$$A_i(u(t), \ldots, u^{(k-1)}(t), y(t), \ldots, y^{(k)}(t)) = 0$$

for all i. Thus, as a function of ν_k for these fixed values $u(t), \ldots, y^{(k-1)}(t)$, all derivatives of

$$A(u(t), \ldots, u^{(k-1)}(t), y(t), \ldots, y^{(k-1)}(t), \nu_k) \tag{18}$$

evaluated at $\nu_k = y^{(k)}(t)$ vanish. It then follows from the analyticity of A that (18) vanishes for all values of ν_k. Let $\bar{\nu}_k$ be such that the function

$$\tilde{A}(\mu_0, \ldots, \mu_{k-1}, \nu_0, \ldots, \nu_{k-1}) := A(\mu_0, \ldots, \mu_{k-1}, \nu_0, \ldots, \nu_{k-1}, \bar{\nu}_k)$$

is not a zero function. Clearly it holds that

$$\tilde{A}(u(t), \ldots, u^{(k-1)}(t), y(t), \ldots, y^{(k-1)}(t)) = 0 \tag{19}$$

for all i/o pairs of Σ. If one can show that $\tilde{A}$ does not depend on μ_{k-1}, then one concludes that $\tilde{A} = 0$ is an i/o equation for Σ. For this, we proceed as follows. First of all, (19) holds for all i/o pairs of (u, y) if and only if the following holds:

$$\tilde{A}(\mu_0, \ldots, \mu_{k-1}, \psi_0(x, \mu), \ldots, \psi_{k-1}(x, \mu)) = 0$$

for all $x \in \mathcal{M}$ and all μ. Note here that ψ_i defined by (7) does not depend on μ_j for $j \geq i$. It follows that for any $\bar{\mu}_{k-1}$,

$$\tilde{A}(\mu_0, \ldots, \mu_{k-2}, \bar{\mu}_{k-1}, \psi_0(x, \mu), \ldots, \psi_{k-1}(x, \mu)) = 0$$

for all x and all μ. Finally, pick $\bar{\mu}_{k-1}$ such that

$$\bar{A}(\mu_0, \ldots, \mu_{k-2}, \nu_0, \ldots, \nu_{k-1}) := \tilde{A}(\mu_0, \ldots, \mu_{k-2}, \bar{\mu}_{k-1}, \nu_0, \ldots, \nu_{k-1}, \bar{\nu}_k)$$

is not a zero function. Then $\bar{A} = 0$ is an i/o equation of order $k - 1$ for Σ. This contradicts the assumption that $\delta(\Sigma) = k$. The claim is thus proved.

Now let $r \geq 1$ be the smallest number for which $A_r = 0$ is not an i/o equation for Σ. Replace A in (17) by A_{r-1}. Evaluating (17) at $t = 0$, the equation implies the identity

$$A(\mu_0, \ldots, \mu_{k-1}, \psi_0(x, \mu), \ldots, \psi_k(x, \mu)) = 0. \tag{20}$$

Since $A_1 = 0$ is not an i/o equation of Σ, it follows that there exists some $\mu \in \mathbb{R}^{mk}$ such that

$$A_1(\mu_0, \ldots, \mu_{k-1}, \psi_0(x, \mu), \ldots, \psi_k(x, \mu)) \neq 0, \tag{21}$$

as a function of x, and hence, by analyticity, the complement of

$$B = \{\mu \in \mathbb{R}^{mk} : \ A_1(\mu_0, \ldots, \mu_{k-1}, \psi_0(x, \mu), \ldots, \psi_k(x, \mu)) = 0, \ \forall x\}$$

is an open dense subset of $\mathbb{R}^{mk}$.

Combining (20) and (21), one sees, for each $\mu \notin B$, that $\mathrm{d}\psi_k(\cdot, \mu)$ is a linear combination of $\mathrm{d}\psi_0(\cdot, \mu), \ldots, \mathrm{d}\psi_{k-1}(\cdot, \mu)$ over $\mathbb{R}_x$. Thus $\widehat{\mathrm{d}\mathcal{F}}_\mu^k = \widehat{\mathrm{d}\mathcal{F}}_\mu^{k-1}$, where, for each i, $\widehat{\mathrm{d}\mathcal{F}}_\mu^i$ is the subspace of $\widehat{\mathrm{d}\mathcal{F}}_\mu$ spanned by $\mathrm{d}\psi_0(\cdot, \mu), \mathrm{d}\psi_1(\cdot, \mu), \ldots, \mathrm{d}\psi_i(\cdot, \mu)$. Differentiating (17) with respect to time, one sees that for any $i > 1$ it holds that

$$\begin{aligned} &A_1(u(t), \ldots, u^{(k-1)}(t), y(t), \ldots, y^{(k)}(t))y^{(k+i)}(t) \\ &\quad = A_i(u(t), \ldots, u^{(k+i-1)}(t), \ldots, y(t), \ldots, y^{(k+i-1)}(t)) \end{aligned}$$

for every i/o pair (u, y) of Σ, where A_i is some analytic function. Thus, by induction, one can show that $\widehat{\mathrm{d}\mathcal{F}}_\mu^{k+i} = \widehat{\mathrm{d}\mathcal{F}}_\mu^{k-1}$ for all $\mu \notin B$. It then follows that $\dim_{R_x} \widehat{\mathrm{d}\mathcal{F}}_\mu \leq k$ for all $\mu \notin \widehat{B}$, where $\widehat{B} \subset \mathbb{R}^{m,\infty}$ is defined by $\widehat{B} = B \times \mathbb{R}^m \times \mathbb{R}^m \times \cdots$.

On the other hand, by Corollary 2.4 and Proposition 3.5, one knows that $\dim_{\mathbb{R}_x} \widehat{\mathrm{d}\mathcal{F}}_\mu = \dim_{\mathbb{R}_x} \widehat{\mathrm{d}\mathcal{F}} = n$ for all μ in a dense (in fact, even in a generic) subset of $\mathbb{R}^{m,\infty}$. Therefore, Σ cannot admit any i/o equation of order lower than n.

If Σ is a rational system, then an easy elimination argument (based on the fact that any set of $n+1$ rational functions in n variables must be algebraically dependent; see [40] for details) shows that it admits at least one i/o equation of order n; therefore, $\delta(\Sigma) = n$. □

3.2.2. i/o operators.

Next we consider i/o equations for i/o operators rather than for state-space systems. By an *i/o operator* we mean an i/o map given by a convergent generating series. For a detailed definition of i/o operators, we refer the reader to [41]. We say an i/o operator F satisfies an i/o equation (17) if every $\mathcal{C}^k$ i/o pair (u, y) of F satisfies (17).

For any given operator F, we define $\delta(F)$ to be the lowest possible order of an i/o equation for F. Again, in the case when there is no i/o equation for F, $\delta(F)$ is defined to be $+\infty$.

An operator F is said to be *realized* by an initialized analytic system

$$(\mathcal{M}, x_0, \{g_0, g_1, \ldots, g_m\}, h)$$

if every i/o pair (u, y) of F satisfies the equations

$$\begin{aligned} x'(t) &= g_0(x(t))u(t) + \sum_{i=1}^m g_i(x(t))u_i(t), \quad x(0) = x_0, \\ y(t) &= h(x(t)) \end{aligned}$$

for t small enough.

Let $\lambda(F)$ be the Lie rank of F, as defined in [11], [19], or [26]. It is well known that F is realizable if and only if $\lambda(F) < \infty$, and the dimension of any canonical realization for F is $\lambda(F)$; cf. [11] and [34]. Here, by a *canonical* realization we mean a realization by an accessible and generically locally observable system.

PROPOSITION 3.8. *Assume that F is an i/o operator. Then:*

(a) $\lambda(F) \leq \delta(F)$;

(b) *if there exists a rational canonical realization for F, then $\lambda(F) = \delta(F)$.*

Proof. It was shown in [41] that if $\delta(F) < \infty$, then $\lambda(F) < \infty$. Thus we may assume that $\lambda(F) < \infty$, and in this case, one knows that F is realizable by some canonical system $\Sigma = (\mathcal{M}, x_0, \{g_0, g_1, \ldots, g_m\}, h)$.

By Remark 4.2 and Lemma 4.3 in [41], one knows that F admits i/o equation (17) if and only if (17) holds at any point t at which $u^{(k-1)}(t)$ exists. Combining this fact with the accessibility of the system, one sees that F admits i/o equation (17) if and only if (20) holds for Σ for all x in an open subset $\mathcal{N}$ of $\mathcal{M}$ and for all μ. On the other hand, it can be seen that (20) holds for all $x \in \mathcal{N}$ and all μ for system Σ if and only if (17) is an i/o equation for Σ as a system restricted to $\mathcal{N}$. Applying Theorem 3.7, we obtain the desired conclusion. □

4. Proof of Lemma 2.1.

In this section, we will prove Lemma 2.1. We will show first that there exists a generic subset $\mathcal{W}_1$ of $\mathbb{R}^{m,\infty}$ so that

$$\mathcal{F}(x) = \mathcal{F}_\mu(x) \tag{22}$$

for all x and $\mu \in \mathcal{W}_1$ and then that there is a generic subset $\mathcal{W}_2$ of $\mathbb{R}^{m,\infty}$ so that

$$\mathrm{d}\mathcal{F}(x) = \mathrm{d}\mathcal{F}_\mu(x) \tag{23}$$

for all x and all $\mu \in \mathcal{W}_2$. Then we just let $\mathcal{W} = \mathcal{W}_1 \bigcap \mathcal{W}_2$.

Proof of first part (*equation* (22)). For system (5), let

$$\mathcal{B} := \{x \in \mathcal{M} : \mathcal{F}(x) = 0\}.$$

To prove (22), we consider, for each subset $\mathcal{N}$ of the open subset $\mathcal{M} \setminus \mathcal{B}$, the set

$$\mathcal{G}_{\mathcal{N}} := \{\mu \in \mathbb{R}^{m,\infty} : \Psi(x, \mu) \neq 0, \forall x \in \mathcal{N}\},$$

where $\Psi(x, \mu) = (\psi_0(x, \mu), \psi_1(x, \mu), \ldots)$.

To prove the desired conclusion, it is enough to show that $\mathcal{G}_{\mathcal{N}}$ is open dense whenever $\mathcal{N}$ is a compact subset of $\mathcal{M} \setminus \mathcal{B}$ (since $\mathcal{M} \setminus \mathcal{B}$ can be written as a countable union of such subsets). In the following we let $\mathcal{N}$ be a fixed compact subset of $\mathcal{M} \setminus \mathcal{B}$, and we just write $\mathcal{G}$ instead of $\mathcal{G}_{\mathcal{N}}$. To show that $\mathcal{G}$ is dense, we need the following fact.

Let $r > 1$ be an integer. For each fixed vector $\nu^r = (\nu_0, \nu_1, \ldots, \nu_{r-1}) \in \mathbb{R}^{mr}$, we say that $\mu = (\mu_1, \mu_1, \ldots) \in \mathbb{R}^{m,\infty}$ is an extension of ν^r if $\mu_i = \nu_i$ for each $i \in [0, r-1]$.

LEMMA 4.1. *Let $x_0 \in \mathcal{M}$ and let ν^r be a fixed vector in $\mathbb{R}^{mr}$. If $\Psi(x_0, \mu) = 0$ for every extension μ of ν^r, then $x \in \mathcal{B}$.*

The proof of the above lemma will be given in Appendix A. We now return to show that $\mathcal{G}$ is dense. Take any open subset $\mathcal{U}$ of $\mathbb{R}^{m,\infty}$; without loss of generality, we may assume that $\mathcal{U} = \mathcal{U}_0 \times \mathcal{U}_1 \times \cdots \times \mathcal{U}_l \times \cdots$, where each $\mathcal{U}_i$ is an open subset of $\mathbb{R}^m$. For each integer $r > 0$, let $\mathcal{U}^r = \prod_{i=0}^{r-1} \mathcal{U}_i$. For each $\mu^r \in \mathcal{U}^r$, define

$$\mathcal{B}_{\mu^r} := \{x \in \mathcal{N} : \Psi_r(x, \mu^r) = 0\}$$

where $\Psi_r(x, \mu^r) = (\psi_0(x, \mu), \psi_1(x, \mu), \ldots, \psi_{r-1}(x, \mu))$ for any extension μ of μ^r. Note that Ψ_r is well defined because $\psi_i(x, \mu)$ does not depend on μ_j for $j \geq i$. For each finite jet ν, $\mathcal{B}_\nu$ is an analytic subset of $\mathcal{N}$, that is, a set defined by analytic equalities. As a consequence of the Weierstrass preparation theorem (in the form given for instance in [17, Thm. 2.7, Cor. 3]), one knows that analytic subsets of a compact set satisfy a descending chain condition. That is, if $\mathfrak{A}_1 \supseteq \mathfrak{A}_2 \supseteq \cdots \supseteq \mathfrak{A}_l \supseteq \cdots$ are analytic subsets of a compact set, then there exists some $r > 0$ such that $\mathfrak{A}_j = \mathfrak{A}_r$ for all $j \geq r$. From here it follows immediately that there is a minimal element $\mathcal{B}_{\bar\nu}$ of the family $\{\mathcal{B}_\nu\}$ in the sense that $\mathcal{B}_{\bar\nu} = \mathcal{B}_\nu$ whenever $\mathcal{B}_\nu \subset \mathcal{B}_{\bar\nu}$. Assume now that $\bar\nu \in \mathcal{U}^r$ provides such a minimal element.

Claim. $\mathcal{B}_{\bar\nu} = \emptyset$.

Assume that the above claim is not true. Then there exists some $x_0 \in \mathcal{N}$ such that $\Psi_r(x_0, \bar\nu) = 0$. Pick such an x_0. By Lemma 4.1, there exists some extension μ of $\bar\nu$ such that $\Psi(x_0, \mu) \neq 0$, so there exists some $l > r$ such that $\psi_l(x_0, \mu) \neq 0$. Write

$$\mu^l = (\bar\nu_0, \bar\nu_1, \ldots, \bar\nu_{r-1}, \bar\mu_r, \ldots, \bar\mu_{l-1}) \in \mathbb{R}^{ml}.$$

Note that $(\bar\nu_0, \bar\nu_1, \ldots, \bar\nu_{r-1}) \in \mathcal{U}^r$ by construction. For these fixed $\bar\nu_0, \ldots, \bar\nu_{r-1}$ and x_0, the function $\psi_l(x_0, \mu)$ does not depend on μ_j for $j \geq l$ and is analytic in $(\mu_r, \mu_{r+1}, \ldots, \mu_{l-1})$. Since it does not vanish at $(\bar\mu_r, \ldots, \bar\mu_{l-1})$, there is also some

$$(\tilde\mu_r, \tilde\mu_{r+1}, \ldots, \tilde\mu_{l-1}) \in \mathcal{U}_r \times \mathcal{U}_{r+1} \times \cdots \times \mathcal{U}_{l-1}$$

such that, for $\tilde\nu := (\bar\nu_0, \ldots, \bar\nu_{r-1}, \tilde\mu_r, \ldots, \tilde\mu_{l-1})$, $\psi_l(x_0, \tilde\mu) \neq 0$ for any extension $\tilde\mu$ of $\tilde\nu$, and hence, $\Psi_l(x_0, \tilde\nu) \neq 0$. So $x_0 \in \mathcal{B}_{\bar\nu} \setminus \mathcal{B}_{\tilde\nu}$. Also, obviously $\mathcal{B}_{\tilde\nu} \subseteq \mathcal{B}_{\bar\nu}$, since $\tilde\nu$ is an extension of $\bar\nu$. This contradicts the minimality of $\mathcal{B}_{\bar\nu}$. So we proved that $\Psi_r(x, \bar\nu) \neq 0$ for all $x \in \mathcal{N}$, as claimed.

Take any extension $\mu \in \mathcal{U}$ of μ^r to an infinite jet. Then $\Psi(x, \mu) \neq 0$ for all $x \in \mathcal{N}$, that is, $\mathcal{G} \cap \mathcal{U}$ is not empty for any open subset $\mathcal{U}$ of $\mathbb{R}^{m,\infty}$. Since $\mathcal{U}$ was arbitrary, one concludes that $\mathcal{G}$ is dense.

To prove the openness of $\mathcal{G}$, let

$$\mathcal{G}^r = \{\mu^r \in \mathbb{R}^{mr} : \ \Psi_r(x, \mu^r) \neq 0, \ \forall x \in \mathcal{N}\}.$$

By the compactness of $\mathcal{N}$, $\mathcal{G}^r$ is open. Let $\mathcal{G}_r = \mathcal{G}^r \times \mathbb{R}^{m,\infty}$. Then $\mathcal{G}_r$ is open. Since $\mathcal{G} = \bigcup_{r=1}^\infty \mathcal{G}_r$, it follows that $\mathcal{G}$ is open.

Proof of second part (*equation* (23)). Clearly $\mathrm{d}\mathcal{F}_\mu(x) \subseteq \mathrm{d}\mathcal{F}(x)$ for all x and μ, and for each $\mu \in \mathbb{R}^{m,\infty}$, $\mathrm{d}\mathcal{F}_\mu(x) = \mathrm{d}\mathcal{F}(x)$ if and only if

$$\ker \mathrm{d}\mathcal{F}(x) = \ker \mathrm{d}\mathcal{F}_\mu(x). \tag{24}$$

We now let

$$\widehat{\mathcal{B}} = \{(x, v) \in T\mathcal{M} : \ v \in \ker \mathrm{d}\mathcal{F}(x)\}.$$

Then $T\mathcal{M} \backslash \widehat{\mathcal{B}}$ is open. Let $\widehat\Psi(x, v, \mu) = (\widehat\psi_0(x, v, \mu), \widehat\psi_1(x, v, \mu), \ldots)$, where $\widehat\psi_i(x, v, \mu) = \mathrm{d}\psi_i(x, \mu)v$. To prove the desired conclusion, it is enough to show that there exists a generic subset $\mathcal{W}$ of $\mathbb{R}^{m,\infty}$ such that for any $\mu \in \mathcal{W}$, $\widehat\Psi(x, v, \mu) \neq 0$ for all $(x, v) \notin \widehat{\mathcal{B}}$. For this, it is enough to show that for any compact subset $\widehat{\mathcal{N}}$ of $T\mathcal{M} \setminus \widehat{\mathcal{B}}$, the set

$$\widehat{\mathcal{G}}_{\widehat{\mathcal{N}}} := \{\mu \in \mathbb{R}^{m,\infty} : \ \widehat\Psi(x, v, \mu) \neq 0, \ \forall \ (x, v) \in \widehat{\mathcal{N}}\}$$

is open dense. We now fix a compact subset $\widehat{\mathcal{N}}$ of $T\mathcal{M}\setminus\widehat{\mathcal{B}}$ and write $\widehat{\mathcal{G}}$ instead of $\widehat{\mathcal{G}}_{\widehat{\mathcal{N}}}$. Similar to the proof of the first part, we need the following conclusion to prove the density property of $\widehat{\mathcal{G}}$. The proof of the conclusion will again be provided in Appendix A.

LEMMA 4.2. *For any given fixed point* $(x,\, v) \in T\mathcal{M}$, *if* $\widehat{\Psi}(x,\, v,\, \mu) = 0$ *for all extensions* μ *of* ν^r, *for some* $\nu^r \in \mathbb{R}^{mr}$, *then* $(x,\, v) \in \widehat{\mathcal{B}}$.

To show the density of $\widehat{\mathcal{G}}$, we take any open subset $\mathcal{U}$ of $\mathbb{R}^{m,\infty}$. Again, without loss of generality, we can assume that $\mathcal{U} = \mathcal{U}_0 \times \mathcal{U}_1 \times \cdots \times \mathcal{U}_l \times \cdots$, where each $\mathcal{U}_i$ is an open subset of $\mathbb{R}^m$. Using the same notions for μ^r and $\mathcal{U}^r$ as used before, we define

$$\widehat{\mathcal{B}}_{\mu^r} := \left\{(x,\, v) \in \widehat{\mathcal{N}} :\ \widehat{\Psi}_r(x,\, v,\, \mu^r) = 0\right\}$$

where $\widehat{\Psi}_r(x,\, \mu^r) = (\widehat{\psi}_0(x,\, v,\, \mu),\, \widehat{\psi}_1(x,\, v,\, \mu),\, \ldots,\, \widehat{\psi}_{r-1}(x,\, v,\, \mu))$ for any extension μ of μ^r. For each finite jet ν, $\widehat{\mathcal{B}}_\nu$ is an analytic subset of $\widehat{\mathcal{N}}$ (with the obvious analytic manifold structure on the tangent bundles). Using the same argument as before, one knows that there exists a minimal element of the family $\{\widehat{\mathcal{B}}_\nu\}$. Let $\nu \in \mathcal{U}^s$ be such that $\widehat{\mathcal{B}}_\nu$ is a minimal element.

Claim. $\widehat{\Psi}_s(x,\, v,\, \nu) \neq 0$ for all $(x,\, v) \in \widehat{\mathcal{N}}$.

Assume that the claim is not true. Then there exists some $(x_0,\, v_0) \in \widehat{\mathcal{N}}$ such that $\widehat{\Psi}_s(x_0,\, v_0,\, \nu) = 0$. By Lemma 4.2, there exists some extension μ of ν such that $\widehat{\Psi}(x_0,\, v_0,\, \mu) \neq 0$. This means there exists some $l \geq s$ such that $\widehat{\psi}_l(x_0,\, v_0,\, \mu) \neq 0$. By analyticity of $\widehat{\psi}_l$, one knows that there exists some

$$(\tilde{\mu}_s,\, \tilde{\mu}_{s+1},\, \ldots,\, \tilde{\mu}_{l-1}) \in \mathcal{U}_s \times \mathcal{U}_{s+1} \times \cdots \times \mathcal{U}_{l-1}$$

such that, for $\tilde{\mu} := (\nu_0,\, \ldots,\, \nu_{s-1},\, \tilde{\mu}_s,\, \ldots,\, \tilde{\mu}_{l-1})$, $\widehat{\Psi}_l(x_0,\, v_0,\, \tilde{\mu}) \neq 0$. So $(x_0,\, v_0) \in \widehat{\mathcal{B}}_\nu \setminus \widehat{\mathcal{B}}_{\tilde{\mu}}$. Also, obviously $\widehat{\mathcal{B}}_{\tilde{\mu}} \subseteq \widehat{\mathcal{B}}_\nu$, since $\tilde{\nu}$ is an extension of ν. This contradicts the minimality of $\widehat{\mathcal{B}}_\nu$. So we proved that $\widehat{\Psi}_r(x,\, v,\, \nu) \neq 0$ for all $(x,\, v) \in \widehat{\mathcal{N}}$. Noting then that for any extension μ of ν, $\widehat{\Psi}(x,\, v,\, \mu) \neq 0$ for any $(x,\, v) \in \widehat{\mathcal{N}}$, we conclude that $\mathcal{G} \bigcap \mathcal{U} \neq \emptyset$. This proves the density of $\mathcal{G}$.

To prove the openness of $\widehat{\mathcal{G}}$, we again let

$$\widehat{\mathcal{G}}^r = \{\mu^r \in \mathbb{R}^{mr} :\ \widehat{\Psi}_r(x,\, v,\, \mu^r) \neq 0,\ \forall (x,\, v) \in \widehat{\mathcal{N}}\}.$$

By compactness of $\widehat{\mathcal{N}}$, $\widehat{\mathcal{G}}^r$ is open. Let $\widehat{\mathcal{G}}_r = \widehat{\mathcal{G}}^r \times \mathbb{R}^{m,\infty}$. Then $\widehat{\mathcal{G}}_r$ is open. Since $\widehat{\mathcal{G}} = \bigcup_{r=1}^{\infty} \widehat{\mathcal{G}}_r$, it follows that $\mathcal{G}$ is open. The proof of Lemma 2.1 is then complete.

Finally, we remark that also with respect to the weak topology on $\mathbb{R}^{m,\infty}$, $\mathcal{G}_{\mathcal{N}}$ and $\widehat{\mathcal{G}}_{\widehat{\mathcal{N}}}$ are still open and dense. Density is obvious, as they are dense with respect to a stronger topology. The openness of $\mathcal{G}_{\mathcal{N}}$ and $\widehat{\mathcal{G}}_{\widehat{\mathcal{N}}}$ follows from the compactness of $\mathcal{N}$ and $\widehat{\mathcal{N}}$. Thus, the conclusions of Lemma 2.1 also hold with respect to the weak topology on $\mathbb{R}^{m,\infty}$.

4.1. Proof of Theorem 3.1. In this section, we provide a proof for Theorem 3.1.

To study the observability for system (5), we consider the system

$$\begin{aligned} \xi' &= \tilde{g}_0(\xi) + \sum_{i=1}^{m} \tilde{g}_i(\xi) u_i\,, \\ y &= \tilde{h}(\xi)\,, \end{aligned} \tag{25}$$

where

$$\xi = \begin{pmatrix} x \\ z \end{pmatrix} \in \mathcal{M} \times \mathcal{M}, \quad \tilde{g}_i(\xi) = \begin{pmatrix} g_i(x) \\ g_i(z) \end{pmatrix}, \; 0 \leq i \leq m,$$

and $\tilde{h}(\xi) = h(x) - h(z)$. Clearly, $x \not\sim_u z$ for system (5) if and only if $\xi \not\sim_u 0$ for system (25). Thus, to prove Theorem 3.1, it is enough to establish the following conclusion.

PROPOSITION 4.3. *Assume that for an analytic system* (5)*, the i/o map induced by the zero initial state is a zero map, that is,* $h \circ \varphi(t, 0, u) = 0$ *for all* t *and all* u*. Then for any* $T > 0$*, the set*

$$\mathfrak{G} = \{u \in \mathcal{C}^\infty[0,\ T] :\ x \not\sim_u 0 \text{ if } x \not\sim 0\}$$

is a generic subset of $\mathcal{C}^\infty[0,\ T]$.

Proof. Let $\mathcal{B} := \{x :\ x \sim 0\}$. Then $\mathcal{M} \setminus \mathcal{B}$ is an open subset of $\mathcal{M}$. To prove Proposition 4.3, it is enough to show that for every compact subset $\mathcal{N}$ of $\mathcal{M} \setminus \mathcal{B}$ the set

$$\mathfrak{G}_{\mathcal{N}} = \{u \in \mathcal{C}^\infty[0,\ T] :\ x \not\sim_u 0 \text{ for all } \ x \in \mathcal{N}\}$$

is an open dense subset of $\mathcal{C}^\infty[0,\ T]$.

Note that for $u \in \mathcal{C}^\infty$, $x \not\sim_u 0$ if $\psi_i(x,\ \mu) \neq 0$ for some i, where $\mu = (\mu_0,\ \mu_1,\ \ldots) \in \mathbb{R}^\infty$ with $\mu_i = u^{(i)}(0)$, and ψ_i is as defined in (7) for each i. Also, by Theorem 3-1.5 in [19], one knows that for $x \in \mathcal{M}$, if $\mathcal{F}(x) = 0$, then $x \in \mathcal{B}$. This means that for each $x \in \mathcal{N}$, $\mathcal{F}(x) \neq 0$. Thus, by Lemma 2.1, there exists a dense subset $\mathcal{G}$ of $\mathbb{R}^{m,\infty}$ such that $\Psi(x,\ \mu) \neq 0$ for all $x \in \mathcal{N}$ and all $\mu \in \mathcal{G}$.

To complete the proof of Proposition 4.3, we need to show that $\mathfrak{G}_{\mathcal{N}}$ is an open dense subset of $\mathcal{C}^\infty[0,\ T]$.

Take $\bar{\omega} \in \mathcal{C}^\infty[0,\ T]$, and let $\mathcal{U}$ be a neighborhood of $\bar{\omega}$. Without loss of generality when showing the density of $\mathfrak{G}_{\mathcal{N}}$, we may assume that

$$\mathcal{U} = \left\{\omega \in \mathcal{C}^\infty[0,\ T] :\ \max_{0 \leq i \leq k} |w^{(i)}(t) - \bar{\omega}^{(i)}(t)| < \delta,\ t \in [0,\ T]\right\},$$

for some integer $k \geq 0$ and some $\delta > 0$.

Let $\bar{\mu} := (\bar{\mu}_0,\ \bar{\mu}_1,\ \ldots)$, where $\bar{\mu}_i := \bar{\omega}^{(i)}(0)$, and let $\mathcal{W}$ be the open subset of $\mathbb{R}^{m,\infty}$ defined by

$$\mathcal{W} = \left\{\mu \in \mathbb{R}^{m,\infty} :\ |\mu_i - \bar{\mu}_i| < \delta e^{-T},\ i \geq 0\right\}.$$

As $\mathcal{W} \bigcap \mathcal{G} \neq \emptyset$, there exists some $\nu \in \mathcal{W}$ such that $\Psi(x,\ \nu) \neq 0$ for all $x \in \mathcal{N}$. By compactness of $\mathcal{N}$, there exists some $r > 0$ such that

$$\Psi_r(x,\ \nu^r) \neq 0, \text{ for any } x \in \mathcal{N}. \tag{26}$$

Without loss of generality, one can always assume that $r > k$.

Now let $\bar{\omega}_0(t) := \bar{\omega}(t) - \sum_{i=0}^{r-1} \frac{\bar{\mu}_i}{i!} t^i$. Note then that $\bar{\omega}_0^{(i)}(0) = 0$ for all $0 \leq i \leq r - 1$.

Finally, we define

$$\omega(t) := \bar{\omega}_0(t) + \sum_{i=0}^{r-1} \frac{\nu_i}{i!} t^i.$$

Then, for $0 \leq i \leq k$ and $0 \leq t \leq T$, we have

$$|\omega^{(i)}(t) - \bar{\omega}^{(i)}(t)| \leq \sum_{j=i}^{r-1} \frac{|\nu_j - \bar{\mu}_j|}{(j-i)!} t^{j-i} \leq \sum_{j=0}^{\infty} \frac{|\nu_{j+i} - \bar{\mu}_{j+i}|}{j!} t^j$$
$$< \delta e^{-T} e^t \leq \delta .$$

Thus, $\omega \in \mathcal{U}$.

On the other hand, (26) implies that for every $x \in \mathcal{N}$, there exists some $i \leq r-1$, such that

$$\left. \frac{d^i}{dt^i} \right|_{t=0} h(\varphi(t, x, w)) \neq 0 .$$

From here it follows that $x \not\sim_{\omega} 0$ for every $x \in \mathcal{N}$, that is, $\omega \in \mathfrak{G}_{\mathcal{N}}$. This proves that $\mathfrak{G}_{\mathcal{N}}$ is dense.

We then conclude the proof of Proposition 4.3 by noting that the openness of $\mathfrak{G}_{\mathcal{N}}$ follows from the compactness of $\mathcal{N}$. □

Remark 4.4. Note that the above proof only depends on the first half of Lemma 2.1, i.e., formula (22), and the proof of (22) is fairly straightforward (though it calls upon some notions and elementary results from the theory for generating series).

Proof of Proposition 3.2. As indicated in the beginning of this section, it is enough to show the following:

> Assume that for an analytic system (5), the i/o map induced by the zero initial state is a zero map, that is, $h \circ \varphi(t, 0, u) = 0$ for all t and all u. Then there exists some analytic input u such that $x \not\sim_u 0$ for all $x \not\sim 0$.

Proof. Consider the following open subset of $\mathbb{R}^{m,\infty}$:

$$\mathcal{U} = \mathcal{U}_0 \times \mathcal{U}_1 \times \mathcal{U}_2 \times \cdots$$

where $\mathcal{U}_i = (-1, 1)$ for all $i \geq 0$. By Lemma 2.1, there is at least one jet μ in $\mathcal{U}$ such that $\mathcal{F}_\mu(x) = \mathcal{F}(x)$, from which it follows that

$$\Psi(x, \mu) \neq 0, \quad \forall x \not\sim 0. \tag{27}$$

Now let

$$u(t) = \sum_{i=0}^{\infty} \frac{\mu_i}{i!} t^i .$$

Then u is an analytic function and $u^{(i)}(0) = \mu_i$. By (27), one knows that $x \not\sim_u 0$ for all $x \not\sim 0$. □

5. Main results for discrete-time systems.

In this section, we discuss our main results for discrete-time systems.

5.1. Basic definitions for discrete-time systems.

We consider *analytic systems* as in (4), where for each t, $x(t) \in \mathcal{M}$, an analytic manifold, and $u(t) \in \mathbb{R}^m$. We assume that $h : \mathcal{M} \to \mathbb{R}^p$ and $f : \mathcal{M} \times \mathbb{R}^n \to \mathcal{M}$ are analytic. If $\mathcal{M} = \mathbb{R}^n$ and the entries of f and h are rational functions with no (real) poles, then we call (4) a *rational system*. A system Σ will be called *reversible* if $f(\cdot, u)$ is one-to-one, for each fixed $u \in \mathbb{R}^m$. (Reversible systems are a more general class than the systems usually called *invertible* in the discrete-time controllability literature, for which one makes the stronger requirement that $f(\cdot, u)$ is a diffeomorphism of $\mathcal{M}$, for each u. Invertible systems arise naturally through the sampling of continuous-time systems in digital control, by integrating flows over a sampling period; their controllability properties were studied in, among other papers, [20], [12], [21], [24], [22], [23], [1].)

For each control sequence $\omega \in \mathrm{I\!R}^{km}$, we define $f^\omega : \mathcal{M} \to \mathcal{M}$ inductively by $f^e(x) = x$ for the empty sequence e and $f^{\omega u}(x) = f(f^\omega(x), u)$. We also let $h^\omega := h \circ f^\omega$. For $\mu = (\mu_0, \mu_1, \dots) \in \mathrm{I\!R}^{m,\infty}$, we let $H^\mu(x) := (h(x), h^{\mu_0}(x), h^{\mu_0\mu_1}(x), \dots)$.

Two states p and q are said to be distinguished by $\mu \in \mathrm{I\!R}^{m,\infty}$, denoted by $p \not\sim_\mu q$, if $H^\mu(p) \neq H^\mu(q)$. A discrete-time system is said to be *observable* if any two distinct states p and q can be distinguished by some μ. See [27] for a detailed introduction to observability and related concepts and, in particular, [25] for results on observability of discrete-time systems.

For an analytic system, we define the *observation space* of Σ as the following subspace of the space of analytic functions defined on $\mathcal{M}$:

$$\mathcal{F} = \operatorname{span}_{\mathrm{I\!R}} \{h^\omega : \ \omega \in \mathrm{I\!R}^{mr}, r \geq 0\}.$$

This space plays an important role in studying observability of discrete-time systems; see, e.g., [28] and [27]. See also [16] for related algebraic structures.

Associated with the above space, for each $x \in \mathcal{M}$ we let $\mathrm{d}\mathcal{F}(x)$ be the subspace of the cotangent space at x defined by

$$\mathrm{d}\mathcal{F}(x) = \{\mathrm{d}\alpha(x) : \ \alpha \in \mathcal{F}\} .$$

In analogy to the continuous-time case, we define, for each $\mu = (\mu_0, \mu_1, \dots) \in \mathrm{I\!R}^{m,\infty}$, the following subspace $\mathcal{F}_\mu$ of analytic functions:

$$\mathcal{F}_\mu = \operatorname{span}_{\mathrm{I\!R}} \{h, h^{\mu_0}, h^{\mu_0\mu_1}, \dots\}.$$

For each $\mu \in \mathrm{I\!R}^{m,\infty}$ and each $x \in \mathcal{M}$, we also consider

$$\mathrm{d}\mathcal{F}_\mu(x) = \{\mathrm{d}\alpha : \ \alpha \in \mathcal{F}_\mu\}.$$

Clearly, $\mathcal{F} = \sum_\mu \mathcal{F}_\mu$ and $\mathrm{d}\mathcal{F}(x) = \sum_\mu \mathrm{d}\mathcal{F}_\mu(x)$ for each x. Here we will need the following result.

LEMMA 5.1. *Assume that* (4) *is reversible and observable. Then there exists a generic subset* $\mathcal{W}$ *of* $\mathrm{I\!R}^{m,\infty}$ *such that for each* $\mu \in \mathcal{W}$,

$$\mathrm{d}\mathcal{F}(x) = \mathrm{d}\mathcal{F}_\mu(x) = \mathrm{I\!R}^n, \tag{28}$$

for all x *in an open dense subset of* $\mathcal{M}$.

The proof will be given later; it will rely on a result about universal inputs for discrete-time systems that is presented in the next section.

Assume now that $\mathcal{M} = \mathrm{I\!R}^n$. Still using the notation used in §2.2, we introduce

$$\widehat{\mathrm{d}}\mathcal{F} := \operatorname{span}_{\mathrm{I\!R}_x}\{\mathrm{d}\alpha : \ \alpha \in \mathcal{F}\}, \ \ \widehat{\mathrm{d}}\mathcal{F}_\mu := \operatorname{span}_{\mathrm{I\!R}_x}\{\mathrm{d}\alpha : \ \alpha \in \mathcal{F}_\mu\}.$$

From the lemma and using an argument analogous to that used in proving Corollary 2.4, we have the following corollary.

COROLLARY 5.2. *For an analytic, reversible, and observable system,* $\widehat{\mathrm{d}}\mathcal{F}_\mu = \widehat{\mathrm{d}}\mathcal{F}$ *for all* μ *in a generic set of* $\mathrm{I\!R}^{m,\infty}$.

5.2. Observability and universal inputs. An input sequence is said to be a *universal input* of a discrete-time system Σ if it distinguishes every distinguishable pair of Σ.

THEOREM 5.3. *Assume that* (4) *is analytic, reversible, and observable. Then the universal inputs of* (4) *form a generic subset of* $\mathbb{R}^{m,\infty}$.

Proof. First of all, we let

$$\mathcal{D} := \{(x, x) : \; x \in \mathcal{M}\} \subseteq \mathcal{M} \times \mathcal{M}.$$

By observability, every pair $(x, z) \in (\mathcal{M} \times \mathcal{M}) \setminus \mathcal{D}$ is a distinguishable pair of (4). For each $\nu \in \mathbb{R}^{mr}$, we let $\lambda_r(x, z, \nu) = h^\nu(x) - h^\nu(z)$, and we also let $\lambda_0(x, z) = h(x, z)$. For each $\mu = (\mu_0, \mu_1, \ldots)$, we define

$$\Lambda(x, z, \mu) = (\lambda_0(x, z), \lambda_1(x, z, \mu_0), \lambda_2(x, z, \mu_1\mu_0), \ldots).$$

To prove the desired conclusion, it is enough to show that for each compact subset $\mathcal{N}$ of $(\mathcal{M} \times \mathcal{M}) \setminus \mathcal{D}$, the set $\mathcal{G}_\mathcal{N}$ defined by

$$\mathcal{G}_\mathcal{N} := \{\mu \in \mathbb{R}^{m,\infty} : \Lambda(x, z, \mu) \neq 0, \; \forall (x, z) \in \mathcal{N}\}$$

is an open dense subset of $\mathbb{R}^{m,\infty}$.

For each open subset $\mathcal{U}$ of $\mathbb{R}^{m,\infty}$ given by $\mathcal{U}_0 \times \mathcal{U}_1 \times \cdots$, consider, for each $\nu \in \mathcal{U}^s = \prod_{i=0}^{s-1} \mathcal{U}_i$, the subset $\mathcal{B}_\nu$ of $\mathcal{N}$ defined by

$$\mathcal{B}_\nu = \{(x, z) \in \mathcal{N} : \; \Lambda_r(x, z, \nu) = 0\},$$

where $\Lambda_r(x, z, \nu) = (\lambda_0(x, z), \lambda_1(x, z, \nu_0), \ldots, \lambda_s(x, z, \nu))$. Using the same argument as that employed in the proof of Lemma 2.1, we know that there exists a minimal element $\mathcal{B}_{\bar\nu}$ of the family $\{\mathcal{B}_{\bar\nu}\}$. Suppose $\bar\nu \in \mathcal{U}^r$. We next show that $\bar\nu$ distinguishes every pair $(x, z) \in \mathcal{N}$. Assume that there would exist a pair $(x_0, z_0) \in \mathcal{N}$ such that $x_0 \sim_{\bar\nu} z_0$. Since (4) is reversible, $x_1 \neq z_1$, where $x_1 = f^\nu(x_0)$ and $z_1 = f^\nu(z_0)$. By observability of (4), one knows that there exists some $\tilde\nu \in \mathbb{R}^{ms}$ such that $x_1 \not\sim_{\tilde\nu} z_1$. Let $\widehat\nu = \tilde\nu\bar\nu$ (concatenation of sequences); then it follows that $\Lambda_{r+s}(x_0, z_0, \bar\nu\tilde\nu) \neq 0$. By the analyticity of Λ_{r+s} when fixing x_0, z_0 and $\bar\nu$, one knows that there exists some $\widehat\nu \in \mathcal{U}_r \times \cdots \times \mathcal{U}_{r+s-1}$ such that $\Lambda_{r+s}(x_0, z_0, \bar\nu\widehat\nu) \neq 0$. This implies that $(x_0, z_0) \in \mathcal{B}_{\bar\nu} \setminus \mathcal{B}_{\bar\nu\widehat\nu}$, which, in turn, implies that $\mathcal{B}_{\bar\nu\widehat\nu}$ is a proper subset of $\mathcal{B}_{\bar\nu}$, contradicting the assumed minimality of $\mathcal{B}_{\bar\nu}$. Thus, we showed that $\Lambda_r(x, z, \bar\nu) \neq 0$ for any $(x, z) \in \mathcal{N}$. Clearly, any extension μ of $\bar\nu$ in $\mathcal{U}$ is an element of $\mathcal{G}_\mathcal{N}$. This shows that $\mathcal{G}_\mathcal{N} \bigcap \mathcal{U} \neq \emptyset$ for any open subset $\mathcal{U}$ of $\mathbb{R}^{m,\infty}$. The density of $\mathcal{G}_\mathcal{N}$ is thus proved.

Again as in the proof of Lemma 2.1 for the continuous case, $\mathcal{G}_\mathcal{N}$ is open since $\mathcal{N}$ is compact. □

In the statement of Theorem 5.3, we assumed more than we did in its continuous counterpart, Theorem 3.1 (and also concluded slightly less). One of the extra conditions is observability. We needed to impose this because the counterpart of Lemma 4.1 is not available in the discrete-time case. The discrete case analogy would be that any distinguishable pair is again carried to a distinguishable pair by the flow of the system, no matter which input is applied. Unfortunately, this not true in general. The following example, suggested by F. Albertini, shows that distinguishable pairs can be carried to indistinguishable pairs. (Note that this can never happen with analytic continuous-time systems.)

Example 5.4. Consider the system

$$x(t+1) = x(t) + 1, \quad y(t) = h(x(t)), \tag{29}$$

where $h(x)$ is defined by

$$h(x) = \begin{cases} \frac{\sin \pi x}{\pi x} & \text{if } x \neq 0, \\ 1 & \text{if } x = 0. \end{cases}$$

Clearly the system is analytic and reversible. However, the distinguishable pair (0, 1) is carried to an indistinguishable pair after $t = 1$.

Proof of Lemma 5.1. To obtain the desired conclusion, it is enough to show that (28) holds in an open dense subset of $\mathcal{M}$ for every universal input μ (since universal inputs themselves form a generic subset).

Fix any universal input μ. By observability, one knows that $H(\cdot, \mu)$ is a one-to-one map. Let $k = \max_p \dim \mathcal{F}_\mu(p)$. It is sufficient to show that $k = n$. But this is an immediate consequence of Lemma B.1 (see Appendix B), applied to $\{h, h^{\mu_0}, h^{\mu_0\mu_1}, \ldots\}$ seen as a family of maps. □

5.2.1. Orders of i/o equations. We say that the discrete-time system (4) *admits the i/o equation* such as that if (3) holds for all input/output pairs of (4) (for $t \geq r$ and any possible initial state $x(0)$). The *order* of the equation is r if

$$\frac{\partial}{\partial \nu_r} E(\mu_0, \ldots, \mu_{k-1}, \nu_0, \nu_1, \ldots, \nu_k)$$

is not a zero function. For any given system Σ, we let $\delta(\Sigma)$ be the lowest possible order of an i/o equation that Σ admits. If there is no such equation, $\delta(\Sigma)$ is defined to be ∞. Following the same outline as in the proof of Theorem 3.7 but now using Lemma 5.1, we conclude as follows.

THEOREM 5.5. *Let Σ be an n-dimensional analytic system. Assume, further, that Σ is reversible and observable. Then $\delta(\Sigma) \geq n$. If, in addition, Σ is a rational system, then $\delta(\Sigma) = n$.*

Remark 5.6. The result in Lemma 5.1 is *false* if the assumption of reversability is dropped, as discussed in [28]. As a consequence of this, the above conclusions may be false without the invertibility assumption. To illustrate this, consider the following system of dimension 3:

$$\begin{aligned} &x_1(t+1) = u(t) \ , \quad x_2(t+1) = x_3(t) \ , \\ &x_3(t+1) = x_3(t)x_1(t) + x_1(t) + x_2(t)u(t) \ , \\ &y(t) = x_3(t). \end{aligned}$$

This is an observable polynomial system. However, it admits an equation of order 2:

$$y(t) = y(t-1)u(t-2) + y(t-2)u(t-1) + u(t-2).$$

Note that this system is not reversible.

Appendix A. Proofs of two lemmas. In this appendix, we will prove Lemmas 4.1 and 4.2. For this, we need to recall some basic definitions and properties of i/o operators defined by convergent generating series. For a detailed study of generating series and i/o operators, we refer the reader to [41].

Let m be a fixed integer and $I = \{0, 1, \ldots, m\}$. For any integer $k \geq 1$, we define I^k to be the set of all sequences $i_1 i_2 \ldots i_k$, where $i_s \in I$ for each s. We use I^0 to denote the set whose only element is the empty sequence ϕ. Let $I^* = \bigcup_{k \geq 0}^{\infty} I^k$.

A *generating series*

$$c = \sum_{\iota \in I^*} \langle c, \eta_\iota \rangle \eta_\iota$$

is a formal power series in the noncommutative variables $\eta_0, \eta_1, \dots, \eta_m$ for some fixed number m, where we use the notation $\eta_\iota = \eta_{i_1}\eta_{i_2}\dots\eta_{i_l}$ for each multiindex $\iota = i_1 i_2 \dots i_l$. The coefficients $\langle c, \eta_\iota \rangle$ are assumed to be real.

We shall say that a power series c is *convergent* if there exist K, $M \geq 0$ such that

$$|\langle c, \eta_\iota \rangle| \leq K M^k k! \quad \text{for each } \iota \in I^k \text{ and each } k \geq 0. \tag{30}$$

For any fixed real number $T > 0$, let $\mathcal{U}_T$ be the set of all essentially bounded measurable functions

$$u : [0, T] \to \mathbb{R}^m$$

endowed with the L^1 norm. We write $\|u\|_1$ for $\max\{\|u_i\|_1 :, 1 \leq i \leq m\}$ and $\|u\|_\infty$ for $\max\{\|u_i\|_\infty :, 1 \leq i \leq m\}$ where u_i is the ith component of u and $\|u_i\|_1$ is the L^1 norm of u_i, $\|u_i\|_\infty$ is the L^∞ norm of u_i. For each $u \in \mathcal{U}_T$ and each $\iota \in I^l$, we define inductively the functions

$$V_\iota = V_\iota[u] \ \in \ \mathcal{C}[0, T]$$

by

$$V_{i_1 \cdots i_{l+1}}[u](t) = \int_0^t u_{i_1}(s) V_{i_2 \dots i_{l+1}}(s)\, ds,$$

where $V_\phi = 1$ and u_i is the ith coordinate of $u(t)$ for $i = 1, 2, \dots, m$ and $u_0(t) \equiv 1$.

For each formal power series c in $\eta_0, \eta_1, \dots, \eta_m$, we define a formal operator on $\mathcal{U}_T$ in the following way:

$$F_c[u](t) = \sum \langle c, \eta_\iota \rangle V_\iota[u](t). \tag{31}$$

If the series is convergent and (30) holds, then it is known that for any

$$T < (\|u\|_\infty (Mm + M))^{-1},$$

the series (31) converges uniformly and absolutely for all $t \in [0, T]$. Let

$$\mathcal{V}_T := \{u \in L^m_\infty : \ \|u\|_\infty T < (Mm + M)^{-1}\}.$$

We refer the reader to [41] for the proof of the following lemmas.

LEMMA A.1. *Assume that c is a convergent power series. Then the operator*

$$F_c : \ \mathcal{V}_T \ \to \ \mathcal{C}[0, T]$$

is continuous with respect to the L^1 norm in $\mathcal{V}_T$ and the $\mathcal{C}^0$ norm in $\mathcal{C}[0, T]$.

LEMMA A.2. *Suppose c is a convergent series. Then $F_c[u]$ is analytic if $u \in \mathcal{V}_T$ is analytic.*

For each convergent series c, we let, for each $\mu \in \mathbb{R}^{m,\infty}$ and each integer $i \geq 0$,

$$c_i(\mu) \ = \ \left.\frac{d^i}{dt^i}\right|_{t=0} F_c[u](t)\,, \tag{32}$$

where u is any smooth input with $u^{(i)}(0) = \mu_i$. Note that $c_i(\mu)$ is a polynomial in μ and $c_i(\mu)$ doesn't depend on μ_j for $j \geq i$.

By Lemma 2.1 in [39], one knows that for a convergent series c, $F_c[u] = 0$ for every piecewise constant input u if and only if $c = 0$. On the other hand, it is not hard to see that for each piecewise constant function u, there exists a sequence $\{u_j\}$ of analytic functions such that $\|u_j\| \leq \|u\|$ and $u_j \to u$ as $j \to \infty$ in the L_1 norm. By Lemma A.2, one concludes that $F_c[u] = 0$ for every analytic input u if and only if $c = 0$. Since $F_c[u]$ is analytic if u is analytic, it then follows from (32) that for an analytic u with $u^{(i)}(0) = \mu_i$, $F_c[u] = 0$ if and only if $c_i(\mu) = 0$ for all $i \geq 0$. Thus we conclude that $c = 0$ if and only if $c_i(\mu) = 0$ for all μ and all i. To prove the desired conclusions, we need the following well-known fact.

LEMMA A.3. *Assume that f is a continuous function defined on* $[0,\ t_0]$ *for some* $t_0 > 0$. *Then for any given integer r and any vector* $(w_0, w_1, \ldots, w_r)$, *there exists a L_∞-bounded sequence of analytic functions f_j defined on* $[0,\ t_0]$, *such that $f_j^{(i)}(0) = w_i$ for all $i \leq r$ and f_j converges to f in the L_1 norm.*

Proof. For the given vector, let

$$\widehat{f}(t) = f(t) - \sum_{i=0}^{r} \frac{w_i t^i}{i!}.$$

Without loss of generality, one may assume that $\widehat{f}(0) = 0$. Otherwise, one can always choose a L_∞-bounded sequence of continuous functions $\widehat{f}_j$ converging to $\widehat{f}$ in the L_1 norm and such that $\widehat{f}_j(0) = 0$. Now one may apply Lemma 4.3 in [41] to $\widehat{f}$ to conclude that there exists a sequence $\tilde{f}_j$ converging to $\widehat{f}$ uniformly (hence also in L_1 norm) with the property that $\tilde{f}_j^{(i)}(0) = 0$ for all $i \leq r$. Then the functions

$$f_j(t) := \tilde{f}_j(t) + \sum_{i=0}^{r} \frac{w_i t^i}{i!}$$

give the desired sequence. □

Combining the above conclusion and Lemma A.1, one proves the following.

LEMMA A.4. *Assume that c is a convergent series and that r is an integer. Let $\bar{\mu}^r$ be a given vector in $\mathbb{R}^{mr}$. If for every extension μ of $\bar{\mu}^r$, $c_i(\mu) = 0$ for all i, then* $c = 0$.

Proof of Lemma 4.1. For analytic system (5) and for each $x \in \mathcal{M}$, we define a generating series by letting

$$\langle c^x, \eta_{i_1}\eta_{i_2}\cdots\eta_{i_r}\rangle = L_{g_{i_r}}\cdots L_{g_{i_2}} L_{g_{i_1}} h(x). \tag{33}$$

By Lemma 4.2 in [36], such a series is always convergent, and it follows from Theorem 3-1.5 in [19] that for any $\mu \in \mathbb{R}^{m,\infty}$,

$$\psi_i(x,\ \mu) = c_i(x,\ \mu), \tag{34}$$

where

$$c_i(x,\ \mu) = \left.\frac{d^i}{dt^i}\right|_{t=0} F_{c^x}[u](t)\,.$$

The conclusion of Lemma 4.1 then follows from Lemma A.4.

Proof of Lemma 4.2. For analytic system (5), instead of considering the series defined by (33), we consider, for each $(x, v) \in T\mathcal{M}$, the series defined by

$$(35) \qquad \langle d(x, v), \eta_{i_1}\eta_{i_2}\cdots\eta_{i_r}\rangle = \mathrm{d}L_{g_{i_r}}\cdots L_{g_{i_2}}L_{g_{i_1}}h(x)v.$$

Claim. For each (x, v), the series $d(x, v)$ is a convergent series.

First of all, by Lemma 4.2 in [36], there is some constant $M_0 > 0$ such that for $g_0(x), g_1(x), \ldots, g_m(x)$, $v \in T_x\mathcal{M}$, there exists some $M_0 > 0$ such that

$$(36) \quad \left|\mathrm{d}L_{g_{i_1}}L_{g_{i_2}}\cdots L_{g_{i_r}}h(x)v\right| = \left|L_vL_{g_{i_1}}L_{g_{i_2}}\cdots L_{g_{i_r}}h(x)v\right| \leq M_0^{r+1}(r+1)!.$$

It is then not hard to see that there exist some constants K and $M > M_0$ such that

$$\left|\mathrm{d}L_{g_{i_1}}L_{g_{i_2}}\cdots L_{g_{i_r}}h(x)v\right| \leq KM^r r!,$$

for all $r > 0$. Therefore $d(x, v)$ is a convergent series for each pair (x, v).

For each smooth input u with $u^{(i)}(0) = \mu_i$, let

$$d_i(x, v, \mu) = \left.\frac{d^i}{dt^i}\right|_{t=0} F_{d(x, v)}[u](t).$$

Then it follows from (34) that

$$\mathrm{d}\psi_i(x, \mu) = \mathrm{d}c_i(x, \mu),$$

from which it follows that

$$\mathrm{d}\psi_i(x, \mu)v = d_i(x, v, \mu).$$

Applying Lemma A.4 to the series $d(x, \mu)$, one obtains the desired conclusion of Lemma 4.2.

Appendix B. A simple consequence of the rank theorem The next result is a simple and well-known consequence of the rank theorem; we include its proof as it seems difficult to find a precise reference. (We provide a somewhat stronger form than needed, which applies in more generality, including to nonobservable systems.)

LEMMA A.5. *Assume that $\mathcal{H} = \{h_\lambda : Z \to \mathbb{R}, \lambda \in \Lambda\}$ is a family of continuously differentiable real-valued functions on an n-dimensional differentiable manifold Z, parameterized by a set Λ. Then there exists an open dense subset $Z_0 \subseteq Z$ with the following property. For each $z_0 \in Z_0$ there exist an integer $r = r(z_0)$, an open neighborhood V of z_0 in Z_0, and parameter values $\lambda_1, \ldots, \lambda_r$, so that, for each parameter $\lambda \in \Lambda$,*

$$h_\lambda(z) = F_\lambda(h_{\lambda_1,\ldots,\lambda_r}(z)) \;\forall z \in V,$$

where $h_{\lambda_1,\ldots,\lambda_r}(z) := (h_{\lambda_1}(z), \ldots, h_{\lambda_r}(z))$ and F_λ is some C^1 function from some neighborhood$\mathcal{U}$ of $h_{\lambda_1,\ldots,\lambda_r}(V)$ to $\mathbb{R}$. Moreover, the rank of the differential of $h_{\lambda_1,\ldots,\lambda_r}(z)$ is r at all $z \in V$ (so the nonempty fibers $h^{-1}_{\lambda_1,\ldots,\lambda_r}(q)$ intersect V at submanifolds of dimension $n - r$). In particular, if it is known that $z \mapsto (h_\lambda(z), \lambda \in \Lambda)$ is one-to-one on any open subset of Z, then $r(z_0) = n$ for some $z_0 \in Z_0$.

Proof. Consider for any s and any $\lambda_1, \ldots, \lambda_s$ the rank $\rho_{\lambda_1,\ldots,\lambda_s}(z)$ of the differential of $h_{\lambda_1,\ldots,\lambda_s}$ at z, and let $\rho(z)$ be the maximum possible value of this rank over all s and $\lambda_1, \ldots, \lambda_s$. A point z is *regular* if $\rho(z)$ is constant in a neighborhood of z. The regular points form an open set by definition, and it is an easy exercise to show, by induction on $n, n-1, \dots, 1$ that the set Z_0 of such points is also dense. Now pick any z_0 in Z_0, and let $\rho(\dot{z}_0) = r$. By definition of ρ, there are parameters $\lambda_1, \dots, \lambda_r$ so that $\rho_{\lambda_1,\dots,\lambda_r}(z) = r$ for all z in some neighborhood of z_0. By the rank theorem, there are local changes of coordinates in Z so that, in some neighborhood V of z_0, $h_{\lambda_i}(z) = z_i$ for $i = 1, \dots, r$, and without loss of generality one may assume that $\rho_{\lambda_1,\dots,\lambda_r}(z) = r$ for all z in this same V. Now pick any $\lambda \in \Lambda$. Let $f = h_\lambda$. If it were the case that $\frac{\partial f}{\partial z_j}(z)$ is nonzero for some $z \in V$ and some $j > r$, then the map $h_{\lambda_1,\dots,\lambda_s,\lambda}$ would have rank $r+1$ at z, contradicting the choice of V. It follows that h_λ depends only on $z_1, \dots, z_r$ on this neighborhood, as desired. □

Remark A.6. Observe that, when dealing with analytic mappings and Z connected, the rank is constant on regular points, and one could pick the elements $\lambda_1, \dots, \lambda_r$ globally on an open dense set. Also, in general this argument shows that locally there are always n control sequences that (locally) distinguish states, even in the nonanalytic case.

MATRIX PAIRS IN TWO-DIMENSIONAL SYSTEMS: AN APPROACH BASED ON TRACE SERIES AND HANKEL MATRICES*

ETTORE FORNASINI† AND MARIA ELENA VALCHER†

Abstract. Two-dimensional system dynamics depends on matrix pairs that represent the shift operators along coordinate axes. The structure of a matrix pair is analysed according to its characteristic polynomial and to the traces of suitable matrices in the algebra generated by the elements of the pair. Necessary and sufficient conditions for properties L and P are provided by resorting to Hankel matrix theory. Finite memory and separable systems, as well as two-dimensional systems whose characteristic polynomials exhibit one-dimensional structures, are finally characterized in terms of spectral properties and traces.

Key words. two-dimensional systems, finite memory systems, separable systems, L property, P property

AMS subject classifications. 15A22, 93C35, 93B15, 93B20, 93B25

1. Introduction.

"Two-dimensional systems theory" connotes a fairly large collection of problems and methods held together by a central theme: to understand better the behaviour of processes and devices whose dynamics depends on two independent variables. Most of two-dimensional systems theory is concerned with quarter-plane causal models, whose state variable description essentially depends on a pair of square matrices associated with the shift operators along the coordinate axes. There is a long stream of research concerned with the problem of characterizing the structure of matrix pairs (see [16] for an extended bibliography). In spite of its relatively long history, however, several questions are far from a definite solution and stimulate further research in linear algebra.

The purpose of this paper is to highlight how purely algebraic results on matrix pairs apply to two-dimensional system modelling. Conversely, assuming a complementary point of view, we shall show that system theoretic methodologies, connected with the realization problem, lead to a satisfactory algebraic characterization of some special matrix pairs.

The two-dimensional models to which we refer are quarter-plane causal two-dimensional systems, described by the following equations [3]:

$$\begin{aligned} x(h+1,k+1) &= A_1x(h,k+1)+A_2x(h+1,k) \\ &+ B_1u(h,k+1)+B_2u(h+1,k), \\ y(h,k) &= Cx(h,k), \end{aligned} \tag{1.1}$$

where the input, state, and output sequences $u(\cdot,\cdot)$, $x(\cdot,\cdot)$, and $y(\cdot,\cdot)$ are defined on the discrete plane $\mathbf{Z}\times\mathbf{Z}$ and take values in $\mathbf{R}^m$, $\mathbf{R}^n$, and $\mathbf{R}^p$, respectively. A_1, A_2, B_1, B_2, and C are real matrices of suitable dimensions. In general, the initial conditions are assigned by specifying the local state values $x(i,-i)$, $i \in \mathbf{Z}$.

The $n\times n$ matrix pair (A_1, A_2) fully encodes the free evolution of the system, providing at the same time valuable insights into the forced motion. From this point of view, (A_1, A_2) plays the same role as the state transition matrix A in the one-

dimensional discrete system

$$\begin{aligned} x(t+1) &= Ax(t)+Bu(t), \\ y(t) &= Cx(t). \end{aligned} \tag{1.2}$$

In the two-dimensional case, however, no decomposition of the state space into $\{A_1, A_2\}$-invariant subspaces can be given, allowing an effective representation of the system behaviour as a superposition of elementary modes with simple structure. As the modal analysis approach to the unforced dynamics does not extend to system (1.1), we need to resort to different tools.

The characteristic polynomial of the pair (A_1, A_2),

$$\Delta_{A_1,A_2}(z_1,z_2) := \det(I - A_1z_1 - A_2z_2), \tag{1.3}$$

is probably the most useful one. Like the characteristic polynomial of A, which in general does not capture the underlying Jordan structure, Δ_{A_1,A_2} does not identify the similarity orbit of the pair. Nevertheless, several important aspects of the two-dimensional motion completely rely on it. There is, first of all, the internal stability of system (1.1), which depends only on the variety of the zeros of Δ_{A_1,A_2}. On the other hand, the two-dimensional Cayley–Hamilton theorem implies that the free-state and output evolution of (1.1) satisfies an autoregressive equation that involves only the coefficients of Δ_{A_1,A_2}. Additional insights into the structure of two-dimensional systems come from the factorization of the characteristic polynomial. Actually, properties like finite memory and separability and interesting features of the spectrum of $\alpha A_1 + \beta A_2$ such as property L can be restated as conditions on the factors of Δ_{A_1,A_2}.

A different tool is constituted by the traces of suitable matrices in the algebra generated by A_1 and A_2 and the associated formal power series T_{A_1,A_2}. As the trace series T_{A_1,A_2} biuniquely corresponds to the characteristic polynomial Δ_{A_1,A_2}, in principle both of them provide an equivalent information on the pair (A_1, A_2). On the other hand, we shall see that some properties, originally defined as constraints on the structure of Δ_{A_1,A_2}, are better understood when the trace series point of view is undertaken. This happens, for instance, when finite memory and separable pairs are considered and, more generally, when each irreducible factor of the characteristic polynomial has a support included in some straight line of $\mathbf{Z}\times\mathbf{Z}$. Interestingly enough, resorting to trace series and to well-established realization methodologies of system theory facilitates the translation of property L of the pair (A_1, A_2) into a bound on the rank of the Hankel matrix associated with T_{A_1,A_2}.

As previously mentioned, some properties of a matrix pair and, consequently, of the associated two-dimensional systems do not reduce to conditions on the structure of the characteristic polynomial. Perhaps, the most relevant example is that, according to a celebrated result of McCoy [10], property P is equivalent to simultaneous triangularizability.

Actually, when considering only characteristic polynomials, properties P and L prove to be indistinguishable because both of them correspond to linear factorizations of Δ_{A_1,A_2}. Deeper insights into the structure of a matrix pair are offered by the traces of all matrix products $A_{i_1}A_{i_2}\dots A_{i_k}$, $k \in \mathbf{N}$, $i_j \in \{1, 2\}$, and by the associated noncommutative power series. Indeed, representation methods of recognizable and exchangeable power series [2], [14], borrowed from automata and languages theory, provide a general framework for analysing property P and, what is more important, a finite criterion for deciding whether a matrix pair is endowed with it.

This paper is organized as follows. In §2 we explore the main connections existing between characteristic polynomial and traces of a matrix pair and we present a recursive algorithm for computing the coefficients of the series T_{A_1,A_2} starting from the characteristic polynomial and vice versa. Successively a partial fraction expansion of T_{A_1,A_2}, whose terms are explicitely connected with the irreducible factors of the characteristic polynomial, is provided.

Sections 3 and 4 deal with properties L and P and their characterizations in terms of commutative and noncommutative power series, respectively. Criteria for testing both properties are provided, based on the aforementioned Hankel matrix approach.

In the last section, the previous results are applied to investigate two important classes of state models, i.e., finite memory and separable two-dimensional systems. As both classes have matrix pairs (A_1, A_2) with property L, it is natural to expect that a variety of different characterizations, typical of the L property, is made available. These are based on the factorization of Δ_{A_1,A_2}, on the structure of the trace series and on the spectrum of the linear combinations $\alpha A_1 + \beta A_2$. Here, however, we follow a somewhat different approach and analyse first matrix pairs (A_1, A_2) with the property that the support of Δ_{A_1,A_2} is a subset of a straight line. The corresponding two-dimensional systems have a free state evolution that exhibits a one-dimensional pattern and provide the building blocks for synthesizing other classes of systems, in particular finite memory and separable systems, which constitute the main concern of the section. Finally, we show how a Levitzki theorem, suitably revisited, allows for a neat characterization of finite memory and separable two-dimensional systems having property P.

2. Characteristic polynomial and traces of a matrix pair.

Given an autonomous one-dimensional system

$$x(t+1) = Ax(t), \tag{2.1}$$

the motion corresponding to any initial state $x(0)$ can be represented by the power series $(I - Az)^{-1}x(0) = \sum_{t=0}^{+\infty} A^t x(0) z^t$. Thus the knowledge of the powers of A or, equivalently, of matrix $(I - Az)^{-1}$, provides a complete information on the dynamics of (2.1).

Weaker but nevertheless significant information is given by the traces of the powers of A. Actually, as shown by the following lemma, the assignment of the traces is equivalent to that of the characteristic polynomial, which constitutes an invariant, yet not complete, relative to the similarity relation.

LEMMA 2.1. *Let A be in $\mathbf{C}^{n\times n}$, and assume* $\det(I - Az) = 1 - d_1 z - d_2 z^2 - \cdots - d_n z^n$. *Then we have*

$$\text{tr}A - d_1 = 0, \quad \text{tr}A^2 - d_1\text{tr}A - 2d_2 = 0, \ldots, \text{tr}A^n - d_1\text{tr}A^{n-1} - \cdots - nd_n = 0 \tag{2.2}$$

and, for $k > 0$,

$$\text{tr}A^{n+k} - d_1\text{tr}A^{n+k-1} - \cdots - d_n\text{tr}A^k = 0. \tag{2.3}$$

Proof. Let $\lambda_1, \lambda_2, \ldots, \lambda_n$ be the eigenvalues of A, so that $\det(zI - A) = \prod_{i=1}^n (z - \lambda_i) = z^n - d_1 z^{n-1} - \cdots - d_n$. As the symmetric polynomials $s_k = \sum_{i=1}^n \lambda_i^k$ satisfy Newton's identities [7]

$$s_k - d_1 s_{k-1} - \cdots - k\, d_k = 0, \qquad k = 1, 2, \ldots,$$

and $s_k = \mathrm{tr} A^k = \sum_{i=1}^n \lambda_i^k$, then (2.2) and (2.3) follow. □

Referring to the unforced motion of system (1.1), namely

$$x(h+1,k+1) = A_1\ x(h,k+1) + A_2\ x(h+1,k), \tag{2.4}$$

the doubly indexed sequence of local states $x(h,k)$ induced by an initial global state $\mathcal{X}_0 = \sum_{\ell=-\infty}^{+\infty} x(-\ell,\ell) z_1^{-\ell} z_2^{\ell}$ is represented by the formal power series

$$X(z_1,z_2) = \sum_{h,k} x(h,k) z_1^h z_2^k = (I - A_1 z_1 - A_2 z_2)^{-1} \mathcal{X}_0 = \sum_{i,j=0}^{\infty} (A_1{}^i \sqcup\!\sqcup{}^j A_2\ z_1^i z_2^j) \mathcal{X}_0,$$

where the matrix coefficients $A_1{}^i \sqcup\!\sqcup{}^j A_2$, $i,j \in \mathbf{N}$, of the power series expansion of $(I - A_1 z_1 - A_2 z_2)^{-1}$ are inductively defined as

$$A_1{}^i \sqcup\!\sqcup{}^0 A_2 = A_1^i, \qquad A_1{}^0 \sqcup\!\sqcup{}^j A_2 = A_2^j \tag{2.5}$$

and, when i and j are both greater than zero,

$$A_1{}^i \sqcup\!\sqcup{}^j A_2 = A_1(A_1{}^{i-1} \sqcup\!\sqcup{}^j A_2) + A_2(A_1{}^i \sqcup\!\sqcup{}^{j-1} A_2). \tag{2.6}$$

Given (2.5) and (2.6), one easily sees that $A_1{}^i \sqcup\!\sqcup{}^j A_2 = \sum_{\nu_1,\nu_2,\dots,\nu_{i+j}} A_{\nu_1} A_{\nu_2} \dots A_{\nu_{i+j}}$, where the summation is extended to all matrix products that include the factors A_1 and A_2, i and j times, respectively. The above decomposition of matrices $A_1{}^i \sqcup\!\sqcup{}^j A_2$ facilitates a better understanding of how the free-state evolution depends on the transition matrices A_1 and A_2. Actually, assuming $x(i,-i) = 0$ for $i \neq 0$, the state in (h,k) is given by

$$x(h,k) = \sum_{\nu_1,\nu_2,\dots,\nu_{i+j}} A_{\nu_1} A_{\nu_2} \dots A_{\nu_{i+j}} x(0,0), \tag{2.7}$$

and it can be interpreted as the sum of the elementary contributions along all paths connecting $(0,0)$ to (h,k) in the two-dimensional grid (Fig. 1).

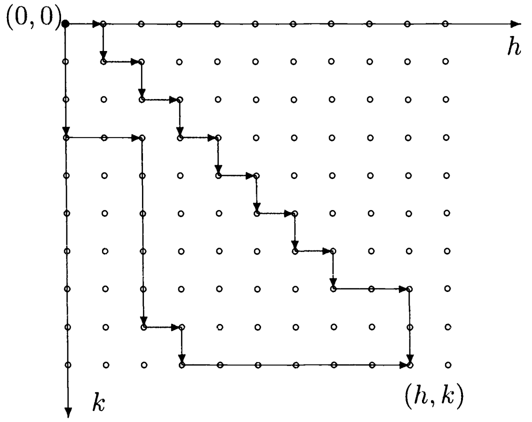

FIG. 1

The analogy between the roles played by the matrix family $\{A_1{}^i \sqcup\!\sqcup{}^j A_2\}$ and the powers of A can be further highlighted by extending both the Cayley–Hamilton theorem and Lemma 2.1 to the two-dimensional case.

PROPOSITION 2.2 (Two-dimensional Cayley–Hamilton theorem [4]). *Let*

$$\Delta_{A_1,A_2}(z_1,z_2) = 1 - \sum_{1\le i+j\le n} d_{ij} z_1^i z_2^j \tag{2.8}$$

be the characteristic polynomial of the $n\times n$ matrix pair (A_1,A_2). Then, for all pairs (h,k), with $h+k\ge n$:

$$\text{i) } A_1{}^h\shuffle^k A_2 = \sum_{1\le i+j\le n} d_{ij}\ A_1{}^{h-i}\shuffle^{k-j} A_2 \tag{2.9}$$

(where $A_1{}^i\shuffle^j A_2$; is assumed to be zero whenever i or j is negative);

$$\text{ii) } A_1{}^h\shuffle^k A_2 \in \operatorname{span}\{A_1{}^i\shuffle^j A_2 : i\le h,\ j\le k, i+j<n\}. \tag{2.10}$$

iii)$\operatorname{span}\{A_1{}^h\shuffle^k A_2 : h,k\in \mathbf{N}\} = \operatorname{span}\{A_1{}^h\shuffle^k A_2 : h,k<n\}$.

Proof. i) Since the $(n-1)$th-order minors of $I - A_1z_1 - A_2z_2$ have degrees less than n, we have

$$\operatorname{adj}(I - A_1z_1 - A_2z_2) = \sum_{0\le r+s<n} M_{rs} z_1^r z_2^s. \tag{2.11}$$

Replace (2.8) and (2.11) into $(I-A_1z_1-A_2z_2)^{-1}\Delta_{A_1,A_2}(z_1,z_2) = \operatorname{adj}(I-A_1z_1-A_2z_2)$, and use the power series expansion of $(I-A_1z_1-A_2z_2)^{-1}$, obtaining

$$\left(\sum_{h,k} A_1{}^h\shuffle^k A_2\, z_1^h z_2^k\right)\left(1 - \sum_{r+s\le n} d_{rs} z_1^r z_2^s\right) = \sum_{i+j<n} M_{ij} z_1^i z_2^j. \tag{2.12}$$

Thus, (2.9) simply states that the Cauchy product on the left-hand side of (2.12) does not include nonzero monomials with degree greater than $n-1$.

ii) If $h+k=n$, the statement is trivial. If $h+k=\nu+1>n$, assume by induction that (2.10) holds for all $(h,k)\in\mathbf{N}\times\mathbf{N}$, with $n\le h+k\le\nu$. So, for $r+s>0$, all matrices $A_1{}^{h-r}\shuffle^{k-s}A_2$ linearly depend on $\{A_1{}^i\shuffle^j A_2 : i\le h, j\le k, i+j<n\}$ and the same holds true for $A_1{}^h\shuffle^k A_2$, because of (2.9).

iii) It follows directly from ii) . □

In order to extend Lemma 2.1 to the two-dimensional case, rewrite the characteristic polynomial of the pair (A_1,A_2) as

$$\Delta_{A_1,A_2}(z_1,z_2) = 1 - \sum_{h=1}^{n}\left(\sum_{i+j=h} d_{ij} z_1^i z_2^j\right) = 1 - \sum_{h=1}^{n}\delta_h(z_1,z_2) \tag{2.13}$$

and introduce the "trace series"

$$T_{A_1,A_2}(z_1,z_2) := \sum_{h=1}^{\infty}\left(\sum_{i+j=h}\operatorname{tr}(A_1{}^i\shuffle^j A_2) z_1^i z_2^j\right) = \sum_{h=1}^{\infty}\tau_h(z_1,z_2), \tag{2.14}$$

where $\delta_h(z_1,z_2)$ and $\tau_h(z_1,z_2)$ are homogeneous forms of degree h.

PROPOSITION 2.3. *Let (A_1,A_2) be an $n\times n$ matrix pair with entries in $\mathbf{C}$, and $\Delta_{A_1,A_2}(z_1,z_2)$ and $T_{A_1,A_2}(z_1,z_2)$ its characteristic polynomial and trace series, respectively. Then:*

i) *the homogeneous components* $\delta_h(z_1,z_2)$ *and* $\tau_h(z_1,z_2)$ *satisfy*

$$\begin{aligned}&\tau_1(z_1,z_2)-\delta_1(z_1,z_2)=0,\\ &\tau_2(z_1,z_2)-\delta_1(z_1,z_2)\tau_1(z_1,z_2)-2\delta_2(z_1,z_2)=0,\\ &\dots\\ &\tau_n(z_1,z_2)-\delta_1(z_1,z_2)\tau_{n-1}(z_1,z_2)-\cdots-n\delta_n(z_1,z_2)=0\end{aligned}\tag{2.15}$$

and, for all $k>0$,

$$\tau_{n+k}(z_1,z_2)-\sum_{i=1}^{n}\tau_{n+k-i}(z_1,z_2)\delta_i(z_1,z_2)=0;\tag{2.16}$$

ii) *the traces of* $A_1{}^i\sqcup\!\sqcup^j A_2$ *and the coefficients* d_{ij} *of* $\Delta_{A_1,A_2}(z_1,z_2)$ *satisfy*

$$\operatorname{tr}(A_1{}^i\sqcup\!\sqcup^j A_2)=\sum_{0<r+s<i+j}d_{rs}\operatorname{tr}(A_1{}^{i-r}\sqcup\!\sqcup^{j-s}A_2)+(i+j)d_{ij},\tag{2.17}$$

where $d_{rs}=0$ *for* $r+s>n$ *and* $A_1{}^r\sqcup\!\sqcup^s A_2$ *is the zero matrix whenever* r *and/or* s *is negative.*

Proof. i) Let $\alpha,\beta\in\mathbf{C}$, and substitute in (2.8) z_1 and z_2 for αz and βz:

$$\det[I-(\alpha A_1+\beta A_2)z]=1-\sum_{h=1}^{n}\delta_h(\alpha,\beta)z^h.$$

Taking the traces on both sides of $(\alpha A_1+\beta A_2)^h=\sum_{i=0}^h\alpha^i\beta^{h-i}A_1{}^i\sqcup\!\sqcup^{h-i}A_2$, one gets

$$\operatorname{tr}(\alpha A_1+\beta A_2)^h=\sum_{i=0}^{h}\alpha^i\beta^{h-i}\operatorname{tr}(A_1{}^i\sqcup\!\sqcup^{h-i}A_2).\tag{2.18}$$

As (2.18) holds for all α,β in $\mathbf{C}$, it is immediate to recognize in $\operatorname{tr}(\alpha A_1+\beta A_2)^h$ the homogeneous forms $\tau_h(\alpha,\beta)$ of (2.14). Thus we can apply Lemma 2.1

$$\begin{aligned}&\tau_1(\alpha,\beta)-\delta_1(\alpha,\beta)=0,\\ &\tau_2(\alpha,\beta)-\delta_1(\alpha,\beta)\tau_1(\alpha,\beta)-2\delta_2(\alpha,\beta)=0,\\ &\dots\\ &\tau_n(\alpha,\beta)-\delta_1(\alpha,\beta)\tau_{n-1}(\alpha,\beta)-\cdots-n\delta_n(\alpha,\beta)=0\end{aligned}\tag{2.19}$$

and, for all $k>0$,

$$\tau_{n+k}(\alpha,\beta)-\sum_{i=1}^{n}\tau_{n+k-i}(\alpha,\beta)\delta_i(\alpha,\beta)=0.\tag{2.20}$$

As α and β are arbitrary, (2.15) and (2.16) follow.

ii) Substitute the expressions of $\delta_h(z_1,z_2)$ and $\tau_h(z_1,z_2)$ given in (2.13) and (2.14) into (2.15) and (2.16), and equate to zero the coefficients of all monomials on the left-hand side. □

Equation (2.15) has some simple but useful consequences. First, it provides an algorithm for recursively computing the traces of $A_1{}^i\sqcup\!\sqcup^j A_2$ from the coefficients of the characteristic polynomial. On the other hand, once the traces are given, also the converse, i.e., the computation of the coefficients of Δ, is made possible. Actually, if an upper bound $\bar{n}$ on the degree of Δ is known, assigning $\operatorname{tr}(A_1{}^{i}\sqcup\!\sqcup^{j} A_2)$ for $i+j \leq \bar{n}$ allows the recovery of both Δ and the traces of $A_1{}^{i}\sqcup\!\sqcup^{j} A_2$ for $i+j > \bar{n}$.

Consider the set of all matrix pairs $\mathcal{M} = \{(A_1, A_2) : A_1, A_2 \in \mathbf{C}^{n\times n}, n \in \mathbf{N}\}$, and introduce in $\mathcal{M}$ the equivalence relation

$$(A_1, A_2) \sim (\hat{A}_1, \hat{A}_2) \quad \Leftrightarrow \quad \Delta_{A_1 A_2}(z_1, z_2) = \Delta_{\hat{A}_1 \hat{A}_2}(z_1, z_2).$$

Corollary 2.4 below exhibits different sets of complete invariants for relation $\sim$. Actually, two matrix pairs have the same characteristic polynomial if and only if (the coefficients of) the corresponding trace series coincide. The equivalence relation on $\mathcal{M}$ can also be described in terms of spectra and traces of the linear combinations of the elements of each matrix pair.

COROLLARY 2.4. *Let A_1, A_2 be in $\mathbf{C}^{n\times n}$ and $\hat{A}_1, \hat{A}_2$ in $\mathbf{C}^{\hat{n}\times\hat{n}}$. The following statements are equivalent*:

i) $\Delta_{A_1,A_2}(z_1, z_2) = \Delta_{\hat{A}_1,\hat{A}_2}(z_1, z_2)$;

ii) *for all $\alpha, \beta \in \mathbf{C}$, $\Lambda_0(\alpha A_1 + \beta A_2) = \Lambda_0(\alpha\hat{A}_1 + \beta\hat{A}_2)$, where $\Lambda_0(M)$ denotes the set of nonzero eigenvalues of the matrix M, each of them counted according to the corresponding algebraic multiplicity*;

iii) *for all $\alpha, \beta \in \mathbf{C}$ and $k \in \mathbf{N}_+$*, $\operatorname{tr}(\alpha A_1 + \beta A_2)^k = \operatorname{tr}(\alpha\hat{A}_1 + \beta\hat{A}_2)^k$;

iv) *for all $(i, j) \neq (0, 0)$*, $\operatorname{tr}(A_1{}^{i}\sqcup\!\sqcup^{j} A_2) = \operatorname{tr}(\hat{A}_1{}^{i}\sqcup\!\sqcup^{j} \hat{A}_2)$.

Proof. i) $\Leftrightarrow$ ii) As both i) and ii) are equivalent to

$$\det[I - (\alpha A_1 + \beta A_2)z] = \det[I - (\alpha\hat{A}_1 + \beta\hat{A}_2)z] \quad \forall \alpha, \beta \in \mathbf{C},$$

they are equivalent to each other, too.

i)$\Leftrightarrow$ iii) $\Leftrightarrow$ iv) By Proposition 2.3, (A_1, A_2) and $(\hat{A}_1, \hat{A}_2)$ have the same characteristic polynomial if and only if the corresponding homogeneous forms $\operatorname{tr}(\alpha A_1 + \beta A_2)^k$ and $\operatorname{tr}(\alpha\hat{A}_1 + \beta\hat{A}_2)^k$, $k = 1, 2\ldots$, coincide. This, in turn, is equivalent to assuming $\operatorname{tr}(A_1{}^{i}\sqcup\!\sqcup^{j} A_2) = \operatorname{tr}(\hat{A}_1{}^{i}\sqcup\!\sqcup^{j} \hat{A}_2)$, for all $(i, j) \neq (0, 0)$. □

It is easy to realize that T_{A_1,A_2} has to be a rational power series, since its coefficients satisfy the recursive equations (2.17). In what remains of this section we aim to make explicit its rational structure and identify its connections with the characteristic polynomial.

PROPOSITION 2.5. *Let $\Delta(z_1, z_2) = 1 - \sum_{h=1}^{n} \delta_h(z_1, z_2)$ be the characteristic polynomial of the matrix pair (A_1, A_2). The corresponding trace series T_{A_1,A_2} can be expressed as*

$$T_{A_1,A_2}(z_1, z_2) = \frac{\delta_1(z_1, z_2) + 2\delta_2(z_1, z_2) + \cdots + n\delta_n(z_1, z_2)}{\Delta(z_1, z_2)}. \tag{2.21}$$

Proof. Consider the linear system defined on $\mathbf{C}[\alpha, \beta]$, the ring of the polynomials in the indeterminates α and β with coefficients in $\mathbf{C}$:

$$\begin{aligned} x_{i+1} &= Fx_i + gu_i, \\ y_i &= Hx_i, \end{aligned}$$

with

$$F = \begin{bmatrix} 0 & 1 & 0 & \cdots & 0 \\ 0 & 0 & 1 & \cdots & 0 \\ & & & \cdots & \\ & & & \cdots & 1 \\ \delta_n(\alpha,\beta) & \delta_{n-1}(\alpha,\beta) & \delta_{n-2}(\alpha,\beta) & \cdots & \delta_1(\alpha,\beta) \end{bmatrix}, \qquad g = \begin{bmatrix} 0 \\ 0 \\ \vdots \\ 0 \\ 1 \end{bmatrix},$$

$$H = [\ 0 \quad 0 \quad 0 \quad \cdots \quad 1\ ].$$

By assuming $x_0 = 0$ and

$$u_i = \begin{cases} (i+1)\delta_{i+1}(\alpha,\beta), & \mathrm{i} = 0, 1, \dots, \\ 0 & \text{otherwise,} \end{cases}$$

it is a matter of direct computation to check that the corresponding output sequence is given by $y_i = \tau_i(\alpha,\beta)$, $i = 1, 2, \dots$.

As the system transfer function is $H(I - zF)^{-1}gz = z/(1 - \sum_{h=1}^{n} \delta_h(\alpha,\beta)z^h)$, the input $U(z) = u_0 + u_1 z + \cdots + u_{n-1}z^{n-1}$ produces the output

$$Y(z) = \sum_{i=0}^{\infty} \tau_i(\alpha,\beta)z^i = \frac{\sum_{h=1}^{n} h\delta_h(\alpha,\beta)z^h}{1 - \sum_{h=1}^{n} \delta_h(\alpha,\beta)z^h}. \tag{2.22}$$

So, letting $z_1 = \alpha z$ and $z_2 = \beta z$, one gets (2.21). □

Representation (2.21) of T_{A_1,A_2} is not necessarily irreducible, but its special structure makes it quite easy to obtain an irreducible one. To this purpose, consider the injective homomorphism

$$\phi : \mathbf{C}[\alpha,\beta] \to \mathbf{C}[\alpha,\beta,z] : \sum_{i=0}^{n} \delta_i(\alpha,\beta) \mapsto \sum_{i=0}^{n} \delta_i(\alpha,\beta)z^i,$$

where, as usual, $\delta_i(\alpha,\beta)$ denotes a homogeneous polynomial of degree i, and introduce the derivation map

$$D_z : \mathbf{C}[\alpha,\beta,z] \to \mathbf{C}[\alpha,\beta,z]\ : \sum_{i=0}^{m} p_i(\alpha,\beta)z^i \mapsto \sum_{i=0}^{m} ip_i(\alpha,\beta)z^i. \tag{2.23}$$

Clearly (2.22) can be rewritten as

$$Y(z) = \frac{D_z(\phi(\Delta(\alpha,\beta)))}{\phi(\Delta(\alpha,\beta))}. \tag{2.24}$$

By assuming that Δ factorizes as $\Delta(z_1,z_2) = \prod_{i=1}^{t} \Delta_i(z_1,z_2)^{\nu_i}$, with Δ_i irreducible distinct factors, $\Delta_i(0,0) = 1$, $i = 1, 2, \dots, t$, one easily gets

$$Y(z) = \sum_{i=1}^{t} \nu_i \frac{D_z(\phi(\Delta_i(\alpha,\beta)))}{\phi(\Delta_i(\alpha,\beta))}. \tag{2.25}$$

Thus, letting $z_1 = \alpha z$ and $z_2 = \beta z$, we have proved the following proposition.

PROPOSITION 2.6. *Let $\Delta(z_1,z_2) = \prod_{i=1}^{t} \Delta_i(z_1,z_2)^{\nu_i}$ be a factorization of Δ, with $\Delta_i(z_1,z_2) = 1 - \sum_{j=1}^{r_i} \delta_j^{(i)}(z_1,z_2)$ irreducible distinct polynomials, $i = 1, 2, \dots, t$. For every matrix pair (A_1, A_2) such that $\Delta_{A_1,A_2}(z_1,z_2) = \Delta(z_1,z_2)$, the corresponding trace series is given by*

$$T_{A_1,A_2}(z_1,z_2) = \sum_{i=1}^{t} \nu_i \frac{\sum_{j=1}^{r_i} j\ \delta_j^{(i)}(z_1,z_2)}{1 - \sum_{j=1}^{r_i} \delta_j^{(i)}(z_1,z_2)}. \tag{2.26}$$

Equation (2.26) expresses the trace series $T_{A_1,A_2}(z_1,z_2)$ as a partial fraction expansion, whose ith term is the trace series of the irreducible factor $\Delta_i(z_1,z_2)$, weighted with the corresponding multiplicity ν_i. Thus the denominator of every irreducible rational function that represents a trace series factorizes into distinct irreducible factors. On the other hand, once an irreducible rational function $T(z_1,z_2)$ has been given, (2.26) suggests a quick way to check whether $T(z_1,z_2)$ can be expanded into a trace series.

3. Pairs of matrices with property L.

3. Pairs of matrices with property L. In the next two sections we focus specifically on matrix pairs endowed with property L and property P.

Pairs with property L occur quite frequently in the applications: indeed, the important classes of finite memory and separable two-dimensional systems that we are going to discuss in §5 are described by pairs with property L. A pair of $n \times n$ matrices, (A_1, A_2), with entries in $\mathbf{C}$, is said to have property L if the eigenvalues of A_1 and A_2 can be ordered into two n-tuples

$$\Lambda(A_1) = (\lambda_1, \lambda_2, \dots, \lambda_n) \quad \text{and} \quad \Lambda(A_2) = (\mu_1, \mu_2, \dots, \mu_n) \tag{3.1}$$

such that, for all α, β in $\mathbf{C}$, the spectrum of $\Lambda(\alpha A_1 + \beta A_2)$ is given by

$$\Lambda(\alpha A_1 + \beta A_2) = (\alpha\lambda_1 + \beta\mu_1, \dots, \alpha\lambda_n + \beta\mu_n). \tag{3.2}$$

It is not difficult to show that property L corresponds to the possibility of factorizing the characteristic polynomial into linear terms [11], [12]. Thus each term of the partial fraction expansion of T_{A_1,A_2} has the very special structure $(\lambda z_1 + \mu z_2)/(1 - \lambda z_1 - \mu z_2)$, which has far-reachıng consequences on the possibility of characterizing property L using the Hankel matrix theory.

PROPOSITION 3.1. *Let A_1, A_2 be in $\mathbf{C}^{n\times n}$, and consider the orderings of their spectra given in* (3.1). *The following statements are equivalent*:

L) *(A_1, A_2) has property* L *(w.r.t. the orderings* (3.1));

L$_1$) $\Delta_{A_1,A_2}(z_1,z_2) = \prod_{i=1}^n (1 - \lambda_i z_1 - \mu_i z_2)$;

L$_2$) *for all $\alpha, \beta \in \mathbf{C}$ and $k \in \mathbf{N}$,* $\operatorname{tr}(\alpha A_1 + \beta A_2)^k = \sum_{i=1}^n (\alpha\lambda_i + \beta\mu_i)^k$;

L$_3$) *for every $(h,k) \in \mathbf{N} \times \mathbf{N}$,* $\operatorname{tr}(A_1{}^h \sqcup\!\sqcup {}^k A_2) = \binom{h+k}{h} \sum_{i=1}^n \lambda_i^h \mu_i^k$;

L$_4$) $T_{A_1,A_2} = \sum_{h+k>0} \operatorname{tr}(A_1{}^h \sqcup\!\sqcup {}^k A_2) z_1^h z_2^k = \sum_{i=1}^n (\lambda_i z_1 + \mu_i z_2)/(1 - \lambda_i z_1 - \mu_i z_2)$.

Proof. Clearly matrices $\hat{A}_1 = \operatorname{diag}\{\lambda_1, \lambda_2, \dots, \lambda_n\}$ and $\hat{A}_2 = \operatorname{diag}\{\mu_1, \mu_2, \dots, \mu_n\}$ fulfill all conditions *L)–L$_4$)* of the proposition. Any other pair (A_1, A_2), of the same dimension, with property L w.r.t. the orderings (3.1), satisfies

$$\Lambda(\alpha A_1 + \beta A_2) = \Lambda(\alpha \hat{A}_1 + \beta \hat{A}_2), \tag{3.3}$$

which corresponds to ii) of Corollary 2.4. Therefore all equivalent statements in Proposition 2.3 hold true; in particular, property L of (A_1, A_2) is equivalent to any one of the following:

L$_1$) $\Delta_{A_1,A_2}(z_1,z_2) = \Delta_{\hat{A}_1,\hat{A}_2}(z_1,z_2) = \prod_{i=1}^n (1 - \lambda_i z_1 - \mu_i z_2)$;

L$_2$) $\operatorname{tr}(\alpha A_1 + \beta A_2)^k = \operatorname{tr}(\alpha \hat{A}_1 + \beta \hat{A}_2)^k = \sum_{i=1}^n (\alpha\lambda_i + \beta\mu_i)^k$;

L$_3$) $\operatorname{tr}(A_1{}^h \sqcup\!\sqcup {}^k A_2) = \operatorname{tr}(\hat{A}_1{}^h \sqcup\!\sqcup {}^k \hat{A}_2) = \binom{h+k}{k} \sum_{i+1}^n \lambda_i^h \mu_i^k$;

L$_4$) $\sum_{(h,k)\neq(0,0)} \operatorname{tr}(A_1{}^h \sqcup\!\sqcup {}^k A_2) z_1^h z_2^k$

$= \sum_{(h,k)\neq(0,0)} \operatorname{tr}(\hat{A}_1{}^h \sqcup\!\sqcup {}^k \hat{A}_2) z_1^h z_2^k = \sum_{i=1}^n (\lambda_i z_1 + \mu_i z_2)/(1 - \lambda_i z_1 - \mu_i z_2)$. □

Conditions *L)–L$_4$)* do not provide direct methods to check, in a finite number of steps, whether a given pair (A_1, A_2) is endowed with property L. To reach this goal, we shall analyse the rank of suitable matrices associated with the power series

$$R_{A_1,A_2}(z_1,z_2) := \sum_{i,j=0}^{\infty} \operatorname{tr}(A_1{}^{i}\sqcup\!\sqcup{}^{j}A_2)\binom{i+j}{i}^{-1} z_1^i z_2^j. \tag{3.4}$$

Let $\mathbf{C}[[z_1,z_2]]$ be the ring of formal power series in the commuting variables z_1, z_2, and denote by

$$s := \sum_{h,k} \langle s, z_1^h z_2^k\rangle z_1^h z_2^k$$

a generic element of the ring. We associate with s the infinite Hankel matrix [2]

$$\mathcal{H}(s) := \begin{bmatrix} \langle s,1\rangle & \langle s,z_1 & \langle s,z_2\rangle & \langle s,z_1^2\rangle & \langle s,z_1z_2\rangle & \langle s,z_2^2\rangle & \dots \\ \langle s,z_1\rangle & \langle s,z_1^2\rangle & \langle s,z_1z_2\rangle & \langle s,z_1^3\rangle & \langle s,z_1^2z_2\rangle & \dots & \dots \\ \langle s,z_2\rangle & \langle s,z_1z_2\rangle & \langle s,z_2^2\rangle & \dots & \dots & \dots & \dots \\ \langle s,z_1^2\rangle & \dots & \dots & \dots & \dots & \dots & \dots \\ \dots & \dots & \dots & \dots & \dots & \dots & \dots \end{bmatrix},$$

whose rows and columns take indices in the multiplicative monoid of the (commutative) terms $\mathcal{T} := \{z_1^i z_2^j : i,j \in \mathbf{N}\}$.

For all $M', M'' \in \mathbf{N}$, we shall denote by $\mathcal{H}_{M' \times M''}(s)$ the submatrix, appearing in the upper left corner of $\mathcal{H}(s)$, whose rows (columns) are indexed by the terms of homogeneous degree not greater than M' (M'').

When rank $\mathcal{H}(s)$ is $\nu < \infty$, we can choose ν rows and ν columns, indexed by the terms $r_1, r_2, \dots, r_\nu$ and $c_1, c_2, \dots, c_\nu$, respectively, so that the submatrix

$$N_0 := [\langle s, r_i c_j\rangle] \tag{3.5}$$

is nonsingular. Thus, for all terms $c \in \mathcal{T}$, the ν-tuple $[\langle s, r_1 c\rangle \dots \langle s, r_\nu c\rangle]^{\mathrm{T}}$ belongs to the range space of N_0, i.e., there exists a (unique) vector $\mathbf{x}(c) \in \mathbf{C}^\nu$ such that

$$\begin{bmatrix} \langle s, r_1 c\rangle \\ \vdots \\ \langle s, r_\nu c\rangle \end{bmatrix} = N_0\ \mathbf{x}(c).$$

Moreover, the rank assumption on $\mathcal{H}(s)$ implies

$$\langle s, rc\rangle = \sum_{j=1}^{\nu} x_j(c)\langle s, rc_j\rangle \quad \forall r \in \mathcal{T}. \tag{3.6}$$

We therefore have, for all $r, c \in \mathcal{T}$,

$$\langle s, rc\rangle = \Big[\langle s, rc_1\rangle, \dots, \langle s, rc_\nu\rangle\Big] N_0^{-1} \begin{bmatrix} \langle s, r_1 c\rangle \\ \vdots \\ \langle s, r_\nu c\rangle \end{bmatrix}. \tag{3.7}$$

We are now in a position to state the following proposition.

PROPOSITION 3.2. *Let A_1, A_2 be in $\mathbf{C}^{n\times n}$. (A_1, A_2) has property* L *if and only if*

$$\bar{n} := \operatorname{rank} \mathcal{H}_{(n-1)\times(n-1)}(R_{A_1,A_2}) = \operatorname{rank} \mathcal{H}_{n\times n}(R_{A_1,A_2}) \le n. \tag{3.8}$$

Proof. For the sake of brevity, within the proof we shall drop in R_{A_1,A_2} subscripts A_1 and A_2. Assume first that (A_1, A_2) has property L. Then, by Proposition 3.1,

$$\operatorname{tr}(A_1{}^i \sqcup\!\sqcup^j A_2) = \binom{i+j}{i} \sum_{h=1}^{n} \lambda_h^i \mu_h^j$$

and, therefore,

$$R = \sum_{i,j=0}^{\infty} \left(\sum_{h=1}^{n} \lambda_h^i \mu_h^j \right) z_1^i z_2^j.$$

Since the Hankel matrix $\mathcal{H}(R)$ factorizes as

$$(3.9) \quad \mathcal{H}(R) = \begin{bmatrix} 1 & 1 & \dots & 1 \\ \lambda_1 & \lambda_2 & \dots & \lambda_n \\ \mu_1 & \mu_2 & \dots & \mu_n \\ \lambda_1^2 & \lambda_2^2 & \dots & \lambda_n^2 \\ \lambda_1\mu_1 & \lambda_2\mu_2 & \dots & \lambda_n\mu_n \\ \mu_1^2 & \mu_2^2 & \dots & \mu_n^2 \\ & & \dots & \end{bmatrix} \begin{bmatrix} 1 & \lambda_1 & \mu_1 & \lambda_1^2 & \lambda_1\mu_1 & \mu_1^2 & \dots \\ 1 & \lambda_2 & \mu_2 & \lambda_2^2 & \lambda_2\mu_2 & \mu_2^2 & \dots \\ & & & \dots & & & \\ 1 & \lambda_n & \mu_n & \lambda_n^2 & \lambda_n\mu_n & \mu_n^2 & \dots \end{bmatrix},$$

clearly rank $\mathcal{H}(R) \leq n$.

Finally, apply the two-dimensional Cayley–Hamilton theorem to the pair of matrices $Q_1 := \operatorname{diag}\{\lambda_1, \lambda_2, \dots, \lambda_n\}$ and $Q_2 := \operatorname{diag}\{\mu_1, \mu_2, \dots, \mu_n\}$. Since the matrices

$$Q_1{}^h \sqcup\!\sqcup^k Q_2 = \binom{h+k}{k} \operatorname{diag}\{\lambda_1^h\mu_1^k, \lambda_2^h\mu_2^k, \dots, \lambda_n^h\mu_n^k\}, \qquad h+k \geq n,$$

are linear combinations of

$$Q_1{}^i \sqcup\!\sqcup^j Q_2 = \binom{i+j}{i} \operatorname{diag}\{\lambda_1^i\mu_1^j, \lambda_2^i\mu_2^j, \dots, \lambda_n^i\mu_n^j\}, \quad i+j < n,$$

all rows (columns) in the first (second) factor of (3.9) that include homogeneous terms of degree greater than or equal to n, linearly depend on the previous ones. Hence rank $\mathcal{H}_{(n-1)\times(n-1)}(R) =$ rank $\mathcal{H}(R)$ and (3.8) holds.

To prove the converse, assume that (3.8) holds and select in $\mathcal{H}_{(n-1)\times(n-1)}(R)$, $\bar{n}$ rows and $\bar{n}$ columns indexed by terms $r_1, r_2, \dots, r_{\bar{n}}$ and $c_1, c_2, \dots, c_{\bar{n}}$, respectively, such that the $\bar{n} \times \bar{n}$ submatrix $N_0 := [\langle R, r_i c_j \rangle]$ is nonsingular. The following matrices

$$(3.10) \qquad M_1 := N_0^{-1}[\langle R, r_i z_1 c_j \rangle], \qquad M_2 := N_0^{-1}[\langle R, r_i z_2 c_j \rangle]$$

commute. Indeed, $r_i z_1 z_2 c_j$ are terms of degree not greater than $2n$, and consequently assumption (3.8) allows us to resort to (3.7), which gives

$$\langle R, r_i z_1 z_2 c_j \rangle = \Big[\langle R, r_i z_1 c_1 \rangle, \dots, \langle R, r_i z_1 c_{\bar{n}} \rangle \Big] N_0^{-1} \begin{bmatrix} \langle R, r_1 z_2 c_j \rangle \\ \vdots \\ \langle R, r_{\bar{n}} z_2 c_j \rangle \end{bmatrix} \quad \forall\, i,j \in \{1, 2, \dots, \bar{n}\}.$$

This implies that

$$M_1 M_2 - M_2 M_1 = N_0^{-1} \Big[[\langle R, r_i z_1 c_j \rangle] N_0^{-1} [\langle R, r_i z_2 c_j \rangle] - [\langle R, r_i z_2 c_j \rangle] N_0^{-1} [\langle R, r_i z_1 c_j \rangle] \Big] = 0.$$

Next introduce the matrices

$$(3.11)\qquad H := \Big[\langle R, c_1\rangle\ \langle R, c_2\rangle \dots \langle R, c_{\bar n}\rangle\Big] \quad\text{and}\quad G := N_0^{-1}\begin{bmatrix}\langle R, r_1\rangle\\ \vdots \\ \langle R, r_{\bar n}\rangle\end{bmatrix},$$

and consider the commutative power series

$$(3.12)\qquad S := H(I - M_1 z_1)^{-1}(I - M_2 z_2)^{-1}G = \sum_{i,j=0}^{\infty} H M_1^i M_2^j G\, z_1^i z_2^j.$$

By resorting again to (3.7), it is easy to check that $\langle R, z_1^i z_2^j\rangle = \langle S, z_1^i z_2^j\rangle$, for $i+j \le 2n$, and therefore $\mathcal{H}_{n\times n}(R) = \mathcal{H}_{n\times n}(S)$. As M_1 and M_2 commute, they are endowed with property L, and the power series

$$\bar S := \sum_{i,j=0}^{\infty} H(M_1{}^i\sqcup\!\sqcup^j M_2)G\, z_1^i z_2^j = H(I - M_1 z_1 - M_2 z_2)^{-1}G$$

can be represented as a rational function of the form

$$(3.13)\qquad \bar S := \frac{q(z_1, z_2)}{\prod_{i=1}^{\bar n}(1 - \lambda_i z_1 - \mu_i z_2)}, \qquad \deg q < \bar n \le n.$$

Note that $\bar S$ satisfies $\langle \bar S, 1\rangle = \langle S, 1\rangle = \langle R, 1\rangle = n$, and, for $0 < i + j \le 2n$

$$(3.14)\qquad \langle \bar S, z_1^i z_2^j\rangle = \binom{i+j}{i}\langle S, z_1^i z_2^j\rangle = \binom{i+j}{i}\langle R, z_1^i z_2^j\rangle = \langle T_{A_1,A_2}, z_1^i z_2^j\rangle.$$

On the other hand, being the trace series of an $n \times n$ matrix pair, T_{A_1,A_2} can be expressed as in (2.15) and, consequently we have

$$T_{A_1,A_2} + n = \frac{p(z_1, z_2)}{\Delta_{A_1,A_2}(z_1, z_2)}, \quad \deg p \le n.$$

Therefore, in the rational function $\bar S - T_{A_1,A_2} - n$ the denominator has degree not greater than $2n$ and nonzero constant term, while the numerator has degree not greater than $2n$. As all the coefficients of the power series expansion of $\bar S - T_{A_1,A_2} - n$, namely $\langle \bar S - T_{A_1,A_2} - n, z_1^i z_2^j\rangle$, are zero for $i + j \le 2n$, then $\bar S = T_{A_1,A_2} + n$.

It is clear now from (3.13) that the denominator of an irreducible representation of T_{A_1,A_2} factorizes into linear factors. Therefore, by Proposition 3.1, (A_1, A_2) has property L. □

4. Pairs of matrices with property P. Given the alphabet $\Xi = \{\xi_1, \xi_2\}$, the free monoid Ξ^* with base Ξ is the set of all words

$$w = \xi_{i_1}\xi_{i_2}\dots\xi_{i_m}, \qquad m \in \mathbf{N},\ \xi_{i_h} \in \Xi.$$

The integer m is called the length of the word w and is denoted by $|w|$, while $|w|_i$ represents the number of occurrences of ξ_i in w, $i = 1, 2$. If $v = \xi_{j_1}\xi_{j_2}\dots\xi_{j_p}$ is another element of Ξ^*, the product is defined by concatenation:

$$wv = \xi_{i_1}\xi_{i_2}\dots\xi_{i_m}\xi_{j_1}\xi_{j_2}\dots\xi_{j_p}.$$

This produces a monoid with $1 = \emptyset$, the empty word, as unit element. Clearly, $|wv| = |v| + |w|$ and $|1| = 0$.

$\mathbf{C}\langle\xi_1,\xi_2\rangle$ and $\mathbf{C}\langle\langle\xi_1,\xi_2\rangle\rangle$ are the algebras of polynomials and formal power series, respectively, in the noncommuting indeterminates ξ_1 and ξ_2. For each pair of matrices A_1, A_2 in $\mathbf{C}^{n\times n}$, the map ψ defined on $\{1,\xi_1,\xi_2\}$ by the assignments $\psi(1) = I_n$ and $\psi(\xi_i) = A_i$, $i = 1,2$, uniquely extends to an algebra morphism of $\mathbf{C}\langle\xi_1,\xi_2\rangle$ into $\mathbf{C}^{n\times n}$. The ψ-image of a polynomial $\mathcal{P}(\xi_1,\xi_2) \in \mathbf{C}\langle\xi_1,\xi_2\rangle$ is denoted by $\mathcal{P}(A_1,A_2)$.

A pair of $n \times n$ matrices (A_1,A_2) with elements in $\mathbf{C}$ is said to have property P if the eigenvalues of A_1 and A_2 can be ordered into two n-tuples

$$(4.1) \qquad \Lambda(A_1) = (\lambda_1,\lambda_2,\dots,\lambda_n), \qquad \Lambda(A_2) = (\mu_1,\mu_2,\dots,\mu_n),$$

such that, for every polynomial $\mathcal{P}(\xi_1,\xi_2) \in \mathbf{C}\langle\xi_1,\xi_2\rangle$,

$$(4.2) \qquad \Lambda(\mathcal{P}(A_1,A_2)) = (\mathcal{P}(\lambda_1,\mu_1),\mathcal{P}(\lambda_2,\mu_2),\dots,\mathcal{P}(\lambda_n,\mu_n)).$$

It is easy to check that property P implies property L, while examples can be given [11], [15] showing that the converse is not true.

Two-dimensional systems (1.1) whose transition matrices A_1, A_2 have property P are endowed with several interesting features. Indeed, property P is equivalent to simultaneous triangularizability, a feature that allows good insight into the geometric structure of the free state evolution. In particular, it implies that there exists a maximal chain of $\{A_1,A_2\}$-invariant subspaces of the local state space X

$$\{0\} = X_0 < X_1 < X_2 < \cdots < X_n = X$$

with $\dim(X_i) = i, \; i = 0,1,2,\dots,n$.

When the local states $x(-\ell,\ell)$ of the initial global state $\mathcal{X}_0 = \sum_{\ell=-\infty}^{+\infty} x(-\ell,\ell)z_1^{-\ell}z_2^{\ell}$, are in X_i, all local states $x(h,k)$, $h+k \geq 0$, are in X_i too. Correspondingly, systems (1.1) can be viewed as cascades of two-dimensional systems of dimension one.

Moreover, systems with property P constitute a class of two-dimensional systems large enough for realizing all transfer functions $p(z_1,z_2)/q(z_1,z_2)$ with denominators of the form $q(z_1,z_2) = \prod_j(1 - \lambda_j z_1 - \mu_j z_2)$ and in particular, all transfer functions with separable denominators [1]. It should be stressed that the same is not true if we consider only commutative two-dimensional systems, i.e. systems (1.1) that satisfy the (stronger) constraint $A_1A_2 - A_2A_1 = 0$.

As a consequence of Proposition 3.1, matrix pairs endowed with property L can be equivalently described as those whose characteristic polynomials factorize into a product of linear terms. This class of polynomials, however, corresponds also to matrix pairs with property P; so there is no possibility of finding an equivalent description of property P that relies only on the characteristic polynomial. Appropriate tools turn out to be certain noncommutative polynomials [12] and power series associated with the pair, as well as the corresponding Hankel matrices.

PROPOSITION 4.1. *Let A_1, A_2 be $n \times n$ matrices with entries in $\mathbf{C}$, and consider the orderings of their spectra given in* (4.1). *The following statements are equivalent*:

P) (A_1,A_2) *has property* P *w.r.t. the orderings* (4.1);

P$_1$) *for any $w \in \Xi^*$, with $|w|_1 = h$ and $|w|_2 = k$,*

$$(4.3) \qquad \operatorname{tr}(w(A_1,A_2)) = \sum_{i=1}^{n} \lambda_i^h \mu_i^k;$$

P$_2$) *the noncommutative power series, whose coefficients are the traces of the matrices* $w(A_1, A_2)$,

$$\mathcal{N} = \sum_{w \,\in\, \Xi^*} \operatorname{tr}(w(A_1, A_2))w, \tag{4.4}$$

can be represented as $\mathcal{N} = \sum_{i=1}^{n}(1-\lambda_i\xi_1-\mu_i\xi_2)^{-1}$ *and, hence, is recognizable* [2];

P$_3$) *for any* $w \in \Xi^*$, *with* $|w|_1 = h$ *and* $|w|_2 = k$,

$$\det(zI - w(A_1, A_2)) = \prod_{i=1}^{n}(z - \lambda_i^h\mu_i^k). \tag{4.5}$$

Proof. P) $\Rightarrow$ P$_1$) If $|w|_1 = h$ and $|w|_2 = k$, the definition of property P directly implies $\Lambda(w(A_1, A_2)) = (\lambda_1^h\mu_1^k, \dots, \lambda_n^h\mu_n^k)$, and therefore (4.3) holds.

P$_1$) $\Rightarrow$ P) Extend the monoid morphisms $\phi_i : \Xi^* \to \mathbf{C} : w \mapsto \lambda_i^{|w|_1}\mu_i^{|w|_2} = w(\lambda_i, \mu_i)$, $i = 1, 2, \dots, n$, to the algebra $\mathbf{C}\langle\xi_1, \xi_2\rangle$, letting $\phi_i(\mathcal{P}) = \mathcal{P}(\lambda_i, \mu_i)$, $i = 1, 2, \dots, n$, for all $\mathcal{P}(\xi_1, \xi_2) \in \mathbf{C}\langle\xi_1, \xi_2\rangle$. Then we have

$$\phi_i(\mathcal{P}^h) = \big(\phi_i(\mathcal{P})\big)^h = \big(\mathcal{P}(\lambda_i, \mu_i)\big)^h. \tag{4.6}$$

From assumption P$_1$) we deduce that $\operatorname{tr}\big(w(A_1, A_2)\big) = \sum_{i=1}^{n} \phi_i(w)$, and hence, by the linearity of the trace operator,

$$\operatorname{tr}\big(\mathcal{P}(A_1, A_2)\big) = \sum_{i=1}^{n} \phi_i(\mathcal{P}) = \sum_{i=1}^{n} \mathcal{P}(\lambda_i, \mu_i).$$

Using (4.6), for all $h \in \mathbf{N}_+$

$$\operatorname{tr}\big(\mathcal{P}(A_1, A_2)\big)^h = \sum_{i=1}^{n} \phi_i(\mathcal{P}^h) = \sum_{i=1}^{n} \mathcal{P}(\lambda_i, \mu_i)^h, \tag{4.7}$$

which gives $\Lambda(\mathcal{P}(A_1, A_2)) = (\mathcal{P}(\lambda_1, \mu_1), \dots, \mathcal{P}(\lambda_n, \mu_n))$.

P$_1$) $\Leftrightarrow$ P$_2$) Assuming P$_1$), we may write

$$\mathcal{N} = \sum_{w \,\in\, \Xi^*} \operatorname{tr}(w(A_1, A_2)w) = \sum_{i=1}^{n} \sum_{w \,\in\, \Xi^*} \lambda_i^{|w|_1}\mu_i^{|w|_2}w.$$

On the other hand, we obtain

$$\begin{aligned}\sum_{i=1}^{n}(1 - \lambda_i\xi_1 - \mu_i\xi_2)^{-1} &= \sum_{i=1}^{n}\sum_{j=0}^{+\infty}(\lambda_i\xi_1 + \mu_i\xi_2)^j \\ &= \sum_{i=1}^{n}\sum_{j=0}^{+\infty} \sum_{\substack{w \,\in\, \Xi^* \\ |w|_1+|w|_2=j}} \lambda_i^{|w|_1}\mu_i^{|w|_2}w \\ &= \sum_{i=1}^{n} \sum_{w \,\in\, \Xi^*} \lambda_i^{|w|_1}\mu_i^{|w|_2}w,\end{aligned}$$

which proves (4.6). The converse can be shown in the same way.

P$_1$) $\Rightarrow$ P$_3$) Given $w \in \Xi^*$, for all $h \in \mathbf{N}$ we have

$$\operatorname{tr}(w(A_1, A_2))^h = \sum_{i=1}^{n} \lambda_i^{h|w|_1} \mu^{h|w|_2} = \sum_{i=1}^{n} (\lambda_i^{|w|_1} \mu_i^{|w|_2})^h.$$

Thus $(\lambda_1^{|w|_1}\mu_1^{|w|_2}, \dots, \lambda_n^{|w|_1}\mu_n^{|w|_2})$ is the spectrum of $w(A_1, A_2)$, which proves (4.5).

P$_3$) $\Rightarrow$ P$_1$) This part of the proof is obvious. □

Remark. As a consequence of P$_1$), property P can be equivalently stated referring only to the words of the free monoid Ξ^* instead of the whole algebra $\mathbf{C}\langle\xi_1, \xi_2\rangle$. Indeed, (A_1, A_2) has property P if and only if for all $w \in \Xi^*$ we have

$$\Lambda\Big(w(A_1, A_2)\Big) = (\lambda_1^{|w|_1}\mu_1^{|w|_2}, \dots, \lambda_n^{|w|_1}\mu_n^{|w|_2}),$$

where $(\lambda_1, \lambda_2, \dots, \lambda_n)$ and $(\mu_1, \mu_2, \dots, \mu_n)$ are the spectra of A_1 and A_2, suitably ordered.

As for property L, we aim now to provide an effective method for testing property P that depends on the study of the noncommutative power series $\mathcal{N}$ and the associated Hankel matrix [2], [14]. By the Hankel matrix of $\mathcal{N}$ we mean the infinite matrix $\mathcal{H}(\mathcal{N})$, whose rows and columns are indexed by the words of Ξ^* and whose element with indexes u and v is equal to $\langle \mathcal{N}, uv \rangle$.

It will be convenient to order the words in Ξ^* and, consequently, the row and column indexes in $\mathcal{H}(\mathcal{N})$, according to their length; while the lexicographical order will be adopted for words of the same length. For all $M', M'' \in \mathbf{N}$, we shall denote by $\mathcal{H}_{M' \times M''}(\mathcal{N})$ the submatrix appearing in the upper left corner of $\mathcal{H}(\mathcal{N})$, whose rows (columns) are indexed by words of length not greater than M' (M'').

LEMMA 4.2. *Let A_1, A_2 be $n \times n$ matrices with entries in $\mathbf{C}$. Then*

$$\text{rank } \mathcal{H}_{(n^2-1)\times(n^2-1)}(\mathcal{N}) = \text{rank } \mathcal{H}(\mathcal{N}) \le n^2. \tag{4.8}$$

Proof. For all $w \in \Xi^*$, we have

$$\operatorname{tr}(w(A_1, A_2)) = [\,\mathbf{e}_1^{\mathrm{T}} \quad \dots \quad \mathbf{e}_n^{\mathrm{T}}\,] \operatorname{diag}\{w(A_1, A_2), \dots, w(A_1, A_2)\} \begin{bmatrix} \mathbf{e}_1 \\ \vdots \\ \mathbf{e}_n \end{bmatrix}, \tag{4.9}$$

where $\mathbf{e}_1, \dots, \mathbf{e}_n$ are the vectors of the canonical basis of $\mathbf{C}^n$. It is clear that $\mathcal{H}(\mathcal{N})$ can be expressed as $\mathcal{H}(\mathcal{N}) = \mathcal{O}\mathcal{R}$, where $\mathcal{O}$ is the $\infty \times n^2$ matrix whose row of index $v \in \Xi^*$ is given by

$$[\,\mathbf{e}_1^{\mathrm{T}} \quad \dots \quad \mathbf{e}_n^{\mathrm{T}}\,] \ \operatorname{diag} \ \{v(A_1, A_2), \dots, v(A_1, A_2)\} \tag{4.10}$$

and, similarly, $\mathcal{R}$ is the $n^2 \times \infty$ matrix whose column of index $w \in \Xi^*$ is given by

$$\operatorname{diag} \ \{w(A_1, A_2), \dots, w(A_1, A_2)\} \begin{bmatrix} \mathbf{e}_1 \\ \vdots \\ \mathbf{e}_n \end{bmatrix}. \tag{4.11}$$

This shows that rank$\mathcal{H}(\mathcal{N}) \le n^2$.

To complete the proof, suppose that all rows of $\mathcal{O}$ indexed by words of length ν linearly depend on the rows indexed in $\mathcal{I} := \{w \in \Xi^*, |w| < \nu\}$. We deduce that any row of index $v = u\xi_i$, $|u| = \nu$, also depends on the words indexed in $\mathcal{I}$, because

$$\begin{aligned}&[\mathbf{e}_1^{\mathrm{T}} \ \dots \ \mathbf{e}_n^{\mathrm{T}}] \ \mathrm{diag}\{v(A_1, A_2), \dots, v(A_1, A_2)\}\\ &\quad = [\mathbf{e}_1^{\mathrm{T}} \ \dots \ \mathbf{e}_n^{\mathrm{T}}] \ \mathrm{diag}\{u(A_1, A_2), \dots, u(A_1, A_2)\} \ \mathrm{diag}\{A_i, \dots, A_i\}\\ &\quad = \textstyle\sum_{w\in\mathcal{I}} \alpha_w [\mathbf{e}_1^{\mathrm{T}} \ \dots \ \mathbf{e}_n^{\mathrm{T}}] \ \mathrm{diag}\{w(A_1, A_2)A_i, \dots, w(A_1, A_2)A_i\}\\ &\quad = \textstyle\sum_{w\in\mathcal{I}} \beta_w [\mathbf{e}_1^{\mathrm{T}} \ \dots \ \mathbf{e}_n^{\mathrm{T}}] \ \mathrm{diag}\{w(A_1, A_2), \dots, w(A_1, A_2)\}.\end{aligned}$$

An easy inductive argument proves that all rows of $\mathcal{O}$ linearly depend on those indexed in $\mathcal{I}$. Moreover, as rank$\mathcal{O} \le n^2$, it is clear that in the definition of $\mathcal{I}$ we can assume $\nu = n^2$. The same reasoning applies to the rows of $\mathcal{R}$, showing that

$$\mathrm{rank}\ \mathcal{H}_{(n^2-1)\times(n^2-1)}(\mathcal{N}) = \mathrm{rank}\ \mathcal{H}(\mathcal{N}). \qquad \Box$$

PROPOSITION 4.3. *Let A_1, A_2 be $n \times n$ matrices with entries in $\mathbf{C}$, and consider the associated noncommutative power series $\mathcal{N} = \sum_{w \in \Xi^*} \mathrm{tr}(w(A_1, A_2))w$. The following statements are equivalent:*

i) *(A_1, A_2) has property* P;

ii) rank $\mathcal{H}_{(n^2-1)\times(n^2-1)}(\mathcal{N}) = \bar{n} \le n$ *and, for all pairs of words $w, \bar{w}$ with length not greater than $2\bar{n}$,*

$$|w|_i = |\bar{w}|_i, \quad i = 1, 2 \quad \Rightarrow \quad \mathrm{tr}(w(A_1, A_2)) = \mathrm{tr}(\bar{w}(A_1, A_2)); \tag{4.12}$$

iii) (4.12) *holds for all pairs of words $w, \bar{w}$ with length not greater than $2n^2$.*

Proof. i) $\Rightarrow$ ii) By Proposition 4.1, property P implies that

$$\mathrm{tr}(w(A_1, A_2)) = \sum_{i=1}^{n} \lambda_i^{|w|_1} \mu_i^{|w|_2} \quad \forall w \in \Xi^*, \tag{4.13}$$

for suitable orderings of the eigenvalues of A_1 and A_2. This immediately proves (4.12). Moreover, $\mathcal{H}(\mathcal{N})$ can be expressed as $\mathcal{H}(\mathcal{N}) = \mathcal{O}\mathcal{R}$, where $\mathcal{O}$ is the $\infty \times n$ matrix whose row of index $v \in \Xi^*$ is given by $[\,v(\lambda_1, \mu_1), v(\lambda_2, \mu_2), \dots, v(\lambda_n, \mu_n)\,]$, and $\mathcal{R} = \mathcal{O}^{\mathrm{T}}$.

We deduce that rank $\mathcal{H}(\mathcal{N}) \le$ rank $\mathcal{O} \le n$ and, therefore rank $\mathcal{H}_{(n^2-1)\times(n^2-1)}$ $(\mathcal{N}) \le n$.

ii) $\Rightarrow$ iii) By the previous lemma, rank $\mathcal{H}(\mathcal{N}) = \bar{n}$. So, there exist [2], [14] $M_1, M_2 \in \mathbf{C}^{\bar{n}\times\bar{n}}, H \in \mathbf{C}^{1\times\bar{n}}$, and $G \in \mathbf{C}^{\bar{n}\times 1}$ such that $\langle\mathcal{N}, w\rangle = Hw(M_1, M_2)G$, $\forall w \in \Xi^*$, and $\mathcal{H}(\mathcal{N})$ can be expressed as $\mathcal{H}(\mathcal{N}) = \mathcal{O}\mathcal{R}$, where $\mathcal{O}$ is the $\infty \times \bar{n}$ matrix whose row indexed by $v \in \Xi^*$ is $Hv(M_1, M_2)$ and $\mathcal{R}$ is the $\bar{n} \times \infty$ matrix whose column indexed by $w \in \Xi^*$ is $w(M_1, M_2)G$.

By the same argument used in the proof of Lemma 4.2, there exist $2\bar{n}$ words $r_1, r_2, \dots, r_{\bar{n}}$ and $c_1, c_2, \dots, c_{\bar{n}}$, of length less than $\bar{n}$, such that both the $\bar{n} \times \bar{n}$ matrices $\mathcal{O}_{\bar{n}}$, and whose rows are $Hr_i(M_1, M_2)$ and $\mathcal{R}_{\bar{n}}$ and whose columns are $c_j(M_1, M_2)G$, are nonsingular. Consequently, the $\bar{n} \times \bar{n}$ submatrix of $\mathcal{H}(\mathcal{N})$

$$N_0 := [\langle\mathcal{N}, r_i c_j\rangle] = \mathcal{O}_{\bar{n}}\mathcal{R}_{\bar{n}}$$

is nonsingular too.

Introduce next the matrices

$$\bar{M}_1 := N_0^{-1}[\langle\mathcal{N}, r_i\xi_1 c_j\rangle], \qquad \bar{M}_2 := N_0^{-1}[\langle\mathcal{N}, r_i\xi_2 c_j\rangle], \tag{4.14}$$

$$\bar H := [\,\langle \mathcal{N}, c_1\rangle \quad \dots \quad \langle \mathcal{N}, c_{\bar n}\rangle\,], \quad \text{and} \quad \bar G := N_0^{-1}\begin{bmatrix} \langle \mathcal{N}, r_1\rangle \\ \vdots \\ \langle \mathcal{N}, r_{\bar n}\rangle \end{bmatrix}. \tag{4.15}$$

Using the assumption on the rank of $\mathcal{H}(\mathcal{N})$, we apply the same arguments as in §3 to derive a counterpart of (3.7) for noncommutative power series. So, for all $r, c \in \Xi^*$, we have

$$\Big[\langle \mathcal{N}, rc_1\rangle \ \dots \ \langle \mathcal{N}, rc_{\bar n}\rangle\Big] N_0^{-1}\begin{bmatrix} \langle \mathcal{N}, r_1 c\rangle \\ \vdots \\ \langle \mathcal{N}, r_{\bar n} c\rangle \end{bmatrix} = \langle \mathcal{N}, rc\rangle. \tag{4.16}$$

It follows that

$$\begin{aligned}\bar M_1 \bar M_2 - \bar M_2 \bar M_1 &= N_0^{-1}\{[\langle \mathcal{N}, r_i\xi_1 c_j\rangle] N_0^{-1}[\langle \mathcal{N}, r_i\xi_2 c_j\rangle] - [\langle \mathcal{N}, r_i\xi_2 c_j\rangle] N_0^{-1}[\langle \mathcal{N}, r_i\xi_1 c_j\rangle]\} \\ &= N_0^{-1}\ [\langle \mathcal{N}, r_i\xi_1\xi_2 c_j\rangle - \langle \mathcal{N}, r_i\xi_2\xi_1 c_j\rangle] = 0,\end{aligned}$$

because of assumption (4.12). So, $\bar M_1$ and $\bar M_2$ commute.

As an immediate consequence of (4.16) and definitions (4.14)–(4.15), we get

$$M_i G = N_0^{-1}\begin{bmatrix} \langle \mathcal{N}, r_1\xi_i\rangle \\ \vdots \\ \langle \mathcal{N}, r_{\bar n}\xi_i\rangle \end{bmatrix}, \qquad i = 1, 2, \tag{4.17}$$

and, for all $v \in \Xi^*$,

(4.18)

$$[\,\langle \mathcal{N}, v\xi_i c_1\rangle \quad \dots \quad \langle \mathcal{N}, v\xi_i c_{\bar n}\rangle\,] = [\,\langle \mathcal{N}, vc_1\rangle \quad \dots \quad \langle \mathcal{N}, vc_{\bar n}\rangle\,]\ N_0^{-1} M_i, \quad i = 1, 2.$$

Finally, we propose to prove that, for all $w \in \Xi^*$

$$\langle \mathcal{N}, w\rangle = \bar H w(\bar M_1, \bar M_2)\bar G, \tag{4.19}$$

which corresponds to showing that $\operatorname{tr}(w(A_1, A_2)) = \operatorname{tr}(\bar w(A_1, A_2))$, for all $w, \bar w \in \Xi^*$, such that $|w|_i = |\bar w|_i$, $i = 1, 2$.

Equation (4.19) is easily verified for $w = 1$. For any $w = \xi_{i_1}\xi_{i_2}\dots\xi_{i_\nu}$, $\nu \geq 1$, by (4.16) and (4.17), we have

$$\langle \mathcal{N}, \xi_{i_1}\xi_{i_2}\dots\xi_{i_\nu}\rangle = [\,\langle \mathcal{N}, \xi_{i_1}\xi_{i_2}\dots\xi_{i_{\nu-1}}c_1\rangle \dots \langle \mathcal{N}, \xi_{i_1}\xi_{i_2}\dots\xi_{i_{\nu-1}}c_{\bar n}\rangle\,]\,\bar M_{i_\nu}\bar G,$$

and, by iteratively applying (4.18),

$$\langle \mathcal{N}, \xi_{i_1}\xi_{i_2}\dots\xi_{i_\nu}\rangle = [\,\langle \mathcal{N}, c_1\rangle \quad \dots \quad \langle \mathcal{N}, c_{\bar n}\rangle\,]\,\bar M_{i_1}\bar M_{i_2}\dots\bar M_{i_\nu}\bar G = \bar H w(\bar M_1, \bar M_2)\bar G.$$

iii) ⇒ i) By Lemma 4.2, $\bar n := \operatorname{rank} \mathcal{H}_{(n^2-1)\times(n^2-1)}(\mathcal{N}) = \operatorname{rank} \mathcal{H}(\mathcal{N})$. Thus, as in the proof of ii) ⇒ iii), we can represent $\mathcal{N}$ as

$$\mathcal{N} = \bar H(I - \bar M_1\xi_1 - \bar M_2\xi_2)^{-1}\bar G, \tag{4.20}$$

where $\bar M_1, \bar M_2 \in \mathbf{C}^{\bar n\times\bar n}$ commute, and (4.12) holds for all words in Ξ^*, independently of their length. Therefore, for all w in Ξ^*, with $h = |w|_1$ and $k = |w|_2$, we have

$$\operatorname{tr}(w(A_1, A_2)) = \binom{h+k}{h}^{-1}\sum_{i=1}^{n}\operatorname{tr}({A_1}^{h}{\sqcup\!\sqcup}^{k}A_2). \tag{4.21}$$

Taking the commutative images on both sides of (4.20), we obtain

$$T_{A_1,A_2} + n = \bar{H}(I - \bar{M}_1 z_1 - \bar{M}_2 z_2)^{-1}\bar{G},$$

and, consequently,

$$T_{A_1,A_2} = -n + \frac{\bar{H}\,\mathrm{adj}(I - \bar{M}_1 z_1 - \bar{M}_2 z_2)\bar{G}}{\Delta_{\bar{M}_1,\bar{M}_2}(z_1, z_2)},$$

where $\Delta_{\bar{M}_1,\bar{M}_2}(z_1, z_2)$ splits into linear factors, because of the commutativity of $\bar{M}_1$, $\bar{M}_2$. Thus the characteristic polynomial of (A_1, A_2) is given by $\Delta_{A_1,A_2}(z_1, z_2) = \prod_{i=1}^n (1 - \lambda_i z_1 - \mu_i z_2)$, and (A_1, A_2) has property L.

As Proposition 3.1 gives $\mathrm{tr}(A_1{}^h \sqcup\!\sqcup {}^k A_2) = \binom{h+k}{h} \sum_{i=1}^n \lambda_i^h \mu_i^k$, condition (4.21) immediately implies

$$\mathrm{tr}(w(A_1, A_2)) = \sum_{i=1}^n \lambda_i^{|w|_1} \mu_i^{|w|_2} \quad \forall\, w \in \Xi^*,$$

which is equivalent to property P. □

5. Special factorizations of the characteristic polynomial. In this section, we consider a further property of a matrix pair (A_1, A_2) that, like property L, can be expressed as a constraint on the factors of Δ_{A_1,A_2} as well as a condition on the spectra of the linear combinations $\alpha A_1 + \beta A_2$, $\alpha, \beta \in \mathbf{C}$. Pairs we refer to are those whose characteristic polynomials split into the product of distinct polynomials $\Delta_i(z_1, z_2)$, each of them having support included in a straight line of the plane $\mathbf{Z} \times \mathbf{Z}$, passing through the origin. The interest in this property is mostly due to the fact that, as we shall see, it constitutes an immediate generalization of finite memory and separability.

To begin with, we consider a single polynomial $\Delta(z_1, z_2)$ whose support is a subset of a straight line in $\mathbf{Z} \times \mathbf{Z}$; i.e., there exists $(\ell, m) \neq (0, 0)$ in $\mathbf{N} \times \mathbf{N}$ such that

$$\mathrm{supp}(\Delta) \subset \{(k\ell, km), k \in \mathbf{N}\}. \tag{5.1}$$

Two-dimensional systems having Δ as characteristic polynomial exhibit several features that strictly resemble those of one-dimensional systems. Indeed, the local state at $(0, 0)$ determines a free evolution that is identically zero except on a "strip" that includes the straight line $\{(k\ell, km), k \in \mathbf{Z}\}$ (see Fig. 2, for $\ell = 2$ and $m = 1$).

So, no matter how far (h, k) is from the set $\{(i, -i) : i \in \mathbf{Z}\}$ where the initial conditions are given, the local state in (h, k) is determined only by a finite subset of the initial global state, whose cardinality does not exceed a fixed integer N.

PROPOSITION 5.1. *Let (A_1, A_2) be a pair of $n \times n$ matrices with entries in $\mathbf{C}$ and $\Delta_{A_1 A_2}(z_1, z_2)$ its characteristic polynomial. Assume moreover that (ℓ, m) is a pair of nonnegative integers and $1 = \mathrm{g.c.d.}(\ell, m)$. The following statements are equivalent:*

i) $\Delta_{A_1,A_2}(z_1, z_2) = 1 - \sum_{h=1}^r d_h (z_1^\ell z_2^m)^h$; (5.2)

ii) *there exist $c_1, c_2, \dots, c_n$ in $\mathbf{C}$ such that, for every $(\alpha, \beta) \in \mathbf{C} \times \mathbf{C}$ and every $(\ell + m)$th root of $\alpha^\ell \beta^m$,*

$$\Lambda(\alpha A_1 + \beta A_2) = \left(c_1 (\alpha^\ell \beta^m)^{\frac{1}{\ell+m}}, \dots, c_n (\alpha^\ell \beta^m)^{\frac{1}{\ell+m}}\right); \tag{5.3}$$

iii) *there exist $c_1, c_2, \dots, c_n \in \mathbf{C}$ such that*

$$\Lambda(\nu^m A_1 + \nu^{-\ell} A_2) = (c_1, c_2, \dots, c_n) \quad \forall\, \nu \in \{1, 2, \dots (\ell + m)n + 1\}; \tag{5.4}$$

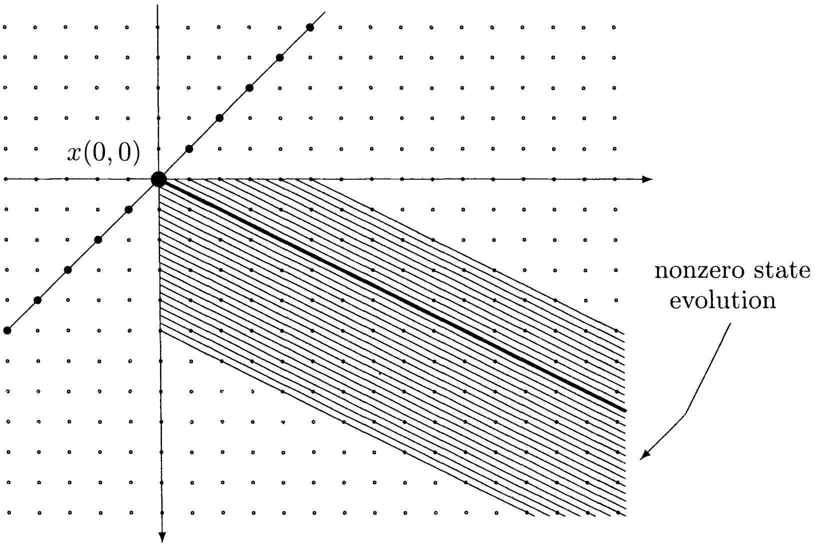

FIG. 2

iv) $(i,j) \notin \{(k\ell, km), k \in \mathbf{N}_+\}$ *implies* $\operatorname{tr}(A_1{}^i \sqcup\!\sqcup^j A_2) = 0$;
v) *for all* $\alpha, \beta \in \mathbf{C}$ *and suitable* $b_k \in \mathbf{C}$,

$$\operatorname{tr}(\alpha A_1 + \beta A_2)^k = \begin{cases} b_k(\alpha^\ell \beta^m)^\nu & \text{if } k = (\ell+m)\nu, \\ 0 & \text{otherwise;} \end{cases} \tag{5.5}$$

vi) $(i,j) \notin \mathcal{S}_n := \{(i,j) \in \mathbf{N} \times \mathbf{N} :\mid mi - \ell j \mid < \mathbf{N}\}$ *implies* $A_1{}^i \sqcup\!\sqcup^j A_2 = 0$.

Proof. i) $\Rightarrow$ ii) Since $\Delta_{A_1,A_2}(z_1,z_2) \in \mathbf{C}[z_1^\ell z_2^m]$, there exist $\lambda_1, \lambda_2, \ldots, \lambda_r \in \mathbf{C}$ such that

$$\Delta_{A_1,A_2}(z_1,z_2) = \prod_{h=1}^{r}(1 - \lambda_h z_1^\ell z_2^m)$$

and, consequently,

$$\det(zI - \alpha A_1 - \beta A_2) = z^{n-r(\ell+m)} \prod_{h=1}^{r}(z^{\ell+m} - \lambda_h \alpha^\ell \beta^m). \tag{5.6}$$

Let $(\lambda_h)^{\frac{1}{\ell+m}}$ and $(\alpha^\ell\beta^m)^{\frac{1}{\ell+m}}$ be arbitrary $(\ell{+}m)$th roots of λ_h and $\alpha^\ell\beta^m$, respectively, and ε any primitive $(\ell+m)$th root of 1. The spectrum of $(\alpha A_1 + \beta A_2)$ is given by $\Lambda(\alpha A_1 + \beta A_2) = \left(c_1(\alpha^\ell\beta^m)^{\frac{1}{\ell+m}}, \ldots, c_n(\alpha^\ell\beta^m)^{\frac{1}{\ell+m}}\right)$, where

$$\begin{aligned} c_{r\nu+h} &= (\lambda_h)^{\frac{1}{\ell+m}}\varepsilon^\nu, && h = 1,\ldots,r \quad \text{and} \quad \nu = 1,\ldots,\ell+m, \\ c_\mu &= 0, && \mu > (\ell+m)r. \end{aligned}$$

ii) $\Rightarrow$ iii) This part of the proof is obvious.

iii) $\Rightarrow$ iv) Clearly, for all $\nu \in \{1,2,\ldots,(\ell+m)n+1\}$ and $h \in \mathbf{N}_+$

$$\operatorname{tr}(\nu^m A_1 + \nu^{-\ell} A_2)^h = \sum_{i=0}^{h} \nu^{(\ell+m)i-h\ell} \operatorname{tr}(A_1{}^i \sqcup\!\sqcup^{h-i} A_2) = \sum_{i=1}^{n} c_i^h =: f_h.$$

whence $\sum_{i=0}^{h} \nu^{(\ell+m)i}\operatorname{tr}(A_1{}^{i}\sqcup\!\sqcup^{h-i}A_2) - f_h\nu^{h\ell} = 0$. As in the polynomials

$$p_h(x) := \sum_{i=0}^{h} x^{(\ell+m)i}\operatorname{tr}(A_1{}^{i}\sqcup\!\sqcup^{h-i}A_2) - f_h x^{h\ell}, \qquad h = 1, 2, \ldots, n,$$

the number of zeros exceeds the degree, all their coefficients have to be zero. We distinguish two cases.

Case 1. $k(\ell+m) = h\ell$, for some $k \in \mathbf{N}$. Since 1 is the unique common divisor of ℓ and m, there exists $t \in \mathbf{N}_+$ such that $k = \ell t$ and $h - k = mt$, and therefore

$$\operatorname{tr}(A_1{}^{i}\sqcup\!\sqcup^{h-i}A_2) = \begin{cases} f_h & \text{if } (i, h-i) = t(\ell, m), \\ 0 & \text{otherwise.} \end{cases}$$

Case 2. $k(\ell+m) \neq h\ell$ for all $h \in \mathbf{N}$. Then, for $0 \leq i \leq h$, tr $(A_1{}^{i}\sqcup\!\sqcup^{h-i}A_2) = 0$.

iv) $\Rightarrow$ v) This part of the proof is obvious.

v) $\Rightarrow$ i) Equations (2.15) and (2.16) show that the homogeneus form δ_k of the characteristic polynomial satisfies

$$\delta_k(\alpha, \beta) = \begin{cases} d_\nu(\alpha^\ell\beta^m)^\nu & \text{if } k = (\ell+m)\nu, \\ 0 & \text{otherwise.} \end{cases}$$

i) $\Rightarrow$ vi) Note that

$$\sum_{i,j=0}^{\infty} A_1{}^{i}\sqcup\!\sqcup^{j}A_2 \; z_1^i z_2^j = (I - A_1z_1 - A_2z_2)^{-1} = \frac{\operatorname{adj}(I - A_1z_1 - A_2z_2)}{1 - \sum_{h=1}^{r} d_h(z_1^\ell z_2^m)^h}.$$

As

$$\begin{aligned} \operatorname{supp}(\operatorname{adj}(I - A_1z_1 - A_2z_2)) &\subseteq \{(i,j) \in \mathbf{N}\times\mathbf{N} : i + j \leq n\}, \\ \operatorname{supp}((1 - \textstyle\sum_{h=1}^{r} d_h(z_1^\ell z_2^m)^h)^{-1}) &\subseteq \{(i,j) \in \mathbf{N}\times\mathbf{N} : mi = \ell j\}, \end{aligned}$$

it is clear that the support of $(I - A_1z_1 - A_2z_2)^{-1}$ is a subset of $\mathcal{S}_{\mathbf{N}}, \mathbf{N} = n - \max(1, m)$.

vi) $\Rightarrow$ i) Consider the injective ring homomorphism $\phi : \mathbf{C}[[z_1, z_2]] \to \mathbf{C}[[\eta, \xi, \xi^{-1}]]$ obtained by linearly extending the map that associates $z_1^i z_2^j$, $i, j \in \mathbf{N}$, with $\eta^k\xi^h$, where h, k are given by

$$\begin{bmatrix} h \\ k \end{bmatrix} = \begin{bmatrix} -m & \ell \\ 0 & 1 \end{bmatrix} \begin{bmatrix} i \\ j \end{bmatrix}.$$

ϕ maps any series in $\mathbf{C}[[z_1, z_2]]$ with support in $\mathcal{S}_{\mathbf{N}}$ into an element of $\mathbf{C}[[\eta]][\xi, \xi^{-1}]$, the ring of Laurent polynomials [12] in the indeterminate ξ, with coefficients in $\mathbf{C}[[\eta]]$. As the support of $(I - A_1z_1 - A_2z_2)^{-1}$ is included in $\mathcal{S}_{\mathbf{N}}$ and hence

$$\operatorname{supp}\Big(\det(I - A_1z_1 - A_2z_2)^{-1}\Big) \subseteq \mathcal{S}_{\mathbf{N}^2},$$

applying the map ϕ on both sides of $\det(I - A_1z_1 - A_2z_2)^{-1}\Delta_{A_1,A_1}(z_1, z_2) = 1$, one gets

$$\phi(\det(I - A_1z_1 - A_2z_2)^{-1}\phi(\Delta_{A_1,A_2}(z_1, z_2)) = 1. \tag{5.7}$$

As both factors on the left-hand side of (5.7) can be viewed as elements of $\mathbf{C}[[\eta]][\xi, \xi^{-1}]$, we have that $\phi(\Delta_{A_1,A_2}(z_1, z_2))$ is a unit of that ring, i.e. $\phi(\Delta_{A_1,A_2}(z_1, z_2)) = \xi^h s(\eta)$

for some $h \in \mathbf{Z}$ and $s(\eta) \in \mathbf{C}[[\eta]]$. Condition $\Delta_{A_1,A_2}(0,0) = 1$ implies $h = 0$ and, therefore, Δ_{A_1,A_2} is a polynomial in $z_1^\ell z_2^m$. □

An immediate consequence of property ii) in the above proposition is the following corollary.

COROLLARY 5.2. *Consider A_1, A_2 in $\mathbf{C}^{n\times n}$. If* $\operatorname{supp}(\Delta_{A_1,A_2})$ *is a subset of a straight line, different from the coordinate axes, then both A_1 and A_2 are nilpotent.*

The results of Proposition 5.1 provide a convenient framework for understanding the internal dynamics of two-dimensional finite memory state models, which arise quite naturally in several applications. For instance, when considering the realization of F.I.R. filters and dead beat regulators, the requirements on the state models that we have to use cannot be exclusively expressed as conditions on the polynomial transfer matrix that represents the input–output map. Further aspects should be taken into account, which introduce additional constraints on the choice of the matrix pair (A_1, A_2).

a) If the state–output transfer matrix $C(I - A_1z_1 - A_2z_2)^{-1}$ is not polynomial, local states $\mathbf{x}$ exist, which give rise to free output evolutions $C(I - A_1z_1 - A_2z_2)^{-1}\mathbf{x}$ with infinite supports. Clearly such states, when induced by noise, generate infinite error sequences in the output signal.

b) If the input–state transfer matrix $(I - A_1z_1 - A_2z_2)^{-1}(B_1z_1 + B_2z_2)$ is not polynomial, finite support input sequences possibly produce infinite support sequences in the state space. Therefore the system could remain indefinitely excited by a finite signal, even though the corresponding output dies out in a finite number of steps.

Both previous drawbacks can be avoided if $(I - A_1z_1 - A_2z_2)^{-1}$ is polynomial or, equivalently, if the characteristic polynomial of the system is unitary, i.e.

$$\Delta_{A_1,A_2}(z_1, z_2) = \det(I - A_1z_1 - A_2z_2) = 1. \tag{5.8}$$

Two-dimensional systems satisfying condition (5.8) are called "finite memory" [4], [6], since they reach the zero state in a finite number of steps after zeroing the input signal.

COROLLARY 5.3 (Finite memory systems [5], [9], [17]). *Let A_1, A_2 be in $\mathbf{C}^{n\times n}$. The followings are equivalent*:

FM$_1$) $\Delta_{A_1,A_2}(z_1, z_2) = 1$;

FM$_2$) $\Lambda(\alpha A_1 + \beta A_2) = (0, 0, \ldots, 0)$, $\forall \alpha, \beta \in \mathbf{C}$, *namely A_1 and A_2 are nilpotent and satisfy property* L;

FM$_3$) $\Lambda(\nu A_1 + A_2) = \Lambda(A_1 + \nu A_2) = (0, 0, \ldots, 0)$, $\nu = 1, \ldots, n + 1$;

FM$_4$) $\operatorname{tr}(A_1{}^i\sqcup\!\sqcup^j A_2) = 0$, $\forall\ (i, j) \neq (0, 0)$;

FM$_5$) $A_1{}^i\sqcup\!\sqcup^j A_2 = 0$, *for $i + j \geq n$.*

Proof. Condition FM$_1$) is equivalent to assume that the support of $\Delta_{A_1A_2}(z_1, z_2)$ is a subset of both $\{(i, 0) : i \in \mathbf{N}\}$ and $\{(0, j) : j \in \mathbf{N}\}$. Therefore finite memory systems are exactly those that satisfy properties i)–vi) of Proposition 5.1 both for $(\ell, m) = (1, 0)$ and $(\ell, m) = (0, 1)$.

FM$_2$) Choose first $(\ell, m) = (0, 1)$ and then $(\ell, m) = (1, 0)$. Then

$$\Lambda(\alpha A_1 + \beta A_2) = (c_1\beta, \ldots, c_n\beta) = (d_1\alpha, \ldots, d_n\alpha) \qquad \forall \alpha, \beta \in \mathbf{C},$$

which obviously implies $\Lambda(\alpha A_1 + \beta A_2) = (0, \ldots, 0)$.

FM$_3$) Assumptions $(\ell, m) = (0, 1)$ and $(\ell, m) = (1, 0)$ give $\Lambda(\alpha A_1 + \beta A_2) = (c_1, \ldots, c_n)$ and $\Lambda(\alpha A_1 + \beta A_2) = (d_1, \ldots, d_n)$, respectively. These imply

$$\Lambda(\alpha A_1 + \beta A_2) = (d_1\alpha, \ldots, d_n\alpha) = (c_1\beta, \ldots, c_n\beta) \qquad \forall \alpha, \beta \in \mathbf{C}.$$

Therefore $\Lambda(\nu A_1 + A_2) = \Lambda(A_1 + \nu A_2) = (0, \dots, 0)$.

FM$_4$) This part of the proof is obvious from iv) of Proposition 5.1.

FM$_5$) Assume first $(\ell, m) = (0,1)$ and then $(\ell, m) = (1,0)$. Point vi) of Proposition 5.1 gives $A_1{}^i\sqcup\!\sqcup^j A_2 = 0$, when $i \geq n$ or $j \geq n$. So $(I - A_1 z_1 - A_2 z_2)^{-1}$ is a polynomial matrix and coincides with adj $(I - A_1 z_1 - A_2 z_2)$, whose support is included in $\{(i,j) : i + j < n\}$. □

The results of Proposition 5.1 partially extend to the case of a characteristic polynomial $\Delta(z_1, z_2)$ that factorizes into irreducible factors, each of them having support on a straight line through $(0,0)$. For sake of simplicity, we confine ourselves to the case when Δ factorizes as

$$\Delta(z_1, z_2) = \Delta_1(z_1, z_2)\Delta_2(z_1, z_2), \tag{5.9}$$

with

$$\Delta_i(z_1, z_2) = 1 - \sum_{j=1}^{r_i} d_j^{(i)} (z_1^{\ell_i} z_2^{m_i})^j, \quad i = 1, 2, \tag{5.10}$$

and g.c.d.$(\ell_i, m_i) = 1$. The extension to the case of more than two factors is straightforward. If (A_1, A_2) is an $n \times n$ matrix pair with characteristic polynomial Δ, it can be easily shown that

i) there exist two positive integers ρ and σ, $\rho + \sigma \leq n$, and $\rho + \sigma$ complex numbers $c_1, \dots, c_\rho, d_1, \dots, d_\sigma$, such that, for all $\alpha, \beta \in \mathbf{C}$

$$\begin{aligned}\Lambda(\alpha A_1 + \beta A_2) = \Big(&c_1(\alpha^{\ell_1}\beta^{m_1})^{\frac{1}{\ell_1+m_1}}, \dots, c_\rho(\alpha^{\ell_1}\beta^{m_1})^{\frac{1}{\ell_1+m_1}},\\ &d_1(\alpha^{\ell_2}\beta^{m_2})^{\frac{1}{\ell_2+m_2}}, \dots, d_\sigma(\alpha^{\ell_2}\beta^{m_2})^{\frac{1}{\ell_2+m_2}}, 0, \dots, 0\Big);\end{aligned}$$

ii) $\operatorname{tr}(A_1{}^i\sqcup\!\sqcup^j A_2) \neq 0$ implies either $(i,j) = (k\ell_1, km_1)$ or $(i,j) = (h\ell_2, hm_2)$, $h, k \in \mathbf{N}_+$.

Conversely, each of the above properties guarantees that Δ factorizes as in (5.9)–(5.10).

We are now in a position to obtain a fairly complete description of two-dimensional systems whose characteristic polynomials factorize into the product of a polynomial in z_1 and a polynomial in z_2. Such systems are called "separable" [4], [5] and are usually thought of as the simplest examples of I.I.R. two-dimensional systems. Actually, many properties that one may hope to extrapolate from an understanding of one-dimensional systems carry over to separable systems. Indeed, just the knowledge that the system is separable allows one to make fairly strong statements about its behaviour; in particular, internal stability can be quickly deduced from the general theory of discrete-time one-dimensional systems, as the long-term performance of separable systems is determined by the eigenvalues of A_1 and A_2.

PROPOSITION 5.4 (Separable systems). *Let A_1, A_2 be in $\mathbf{C}^{n\times n}$. The following statements are equivalent:*

S$_1$) $\Delta_{A_1,A_2}(z_1, z_2) = r(z_1)s(z_2)$;

S$_2$) *A_1 and A_2 satisfy property* L *w.r.t. the orderings of the spectra*

$$\Lambda(A_1) = (\lambda_1, \dots, \lambda_\rho, 0, \dots, 0, 0, \dots, 0)$$

$$\Lambda(A_2) = (0, \dots, 0, \mu_1, \dots, \mu_\sigma, 0, \dots, 0),$$

so that, for every $\alpha, \beta \in \mathbf{C}$ $\Lambda(\alpha A_1 + \beta A_2) = (\alpha\lambda_1, \dots, \alpha\lambda_\rho, \beta\mu_1, \dots, \beta\mu_\sigma, 0, \dots, 0)$;

S_3) $\mathrm{tr}(A_1{}^i\sqcup\!\sqcup^j A_2) = 0$ *if both i and j are nonzero*;

S_4) $\mathrm{tr}(\alpha A_1 + \beta A_2)^k = \mathrm{tr}(\alpha A_1)^k + \mathrm{tr}(\beta A_2)^k,\ \forall \alpha, \beta \in \mathbf{C}, k \in \mathbf{N}_+$.

Property L, separability, and finite memory have been introduced by progressively strengthening the constraints on the irreducible factors of $\Delta_{A_1,A_2}(z_1, z_2)$. On the other hand, the set of matrix pairs with property L properly includes the set of pairs with property P, which in turn is strictly larger than the set of commutative pairs. So, the question naturally arises whether the above constraints on the characteristic polynomial of the pair (A_1, A_2) can be related to property P and to commutativity.

We first observe that examples can be given of commutative pairs and, hence, of pairs with property P that are not finite memory and not even separable. Actually, just by taking diagonal matrices A_1 and A_2, we easily see that commutativity and property P do not imply any particular consequence on the characteristic polynomial, except that it factorizes into first-order factors.

On the other hand, the pair

$$A_1 = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{bmatrix}, \qquad A_2 = \begin{bmatrix} 0 & 0 & 0 \\ 1 & 0 & 0 \\ 0 & -1 & 0 \end{bmatrix}$$

is finite memory (and hence separable). Yet, it does not satisfy property P.

In view of this, no implication exists between commutativity and property P on one side and finite memory and separability on the other. What is remarkable, however, is that if we restrict our analysis to matrix pairs with property P, finite memory and separable pairs can be nicely characterized in terms of semigroups of nilpotent matrices. This is made precise in the following proposition, which provides a slight extension (and an alternative proof) of a classical Levitzki theorem [8, p. 135].

PROPOSITION 5.5. *Let A_1, A_2 be in $\mathbf{C}^{n\times n}$, and consider the multiplicative semigroups*

$$S := \{w(A_1, A_2),\ w \in \Xi^*,\ |w| \geq 1\}$$

and

$$\bar{S} := \{w(A_1, A_2),\ w \in \Xi^*,\ |w|_1 \geq 1,\ |w|_2 \geq 1\}.$$

The pair (A_1, A_2) has finite memory and property P *(respectively, separability and property* P*) if and only if all matrices in S (respectively, in $\bar{S}$) are nilpotent.*

Proof. We first remark that, if (A_1, A_2) has property P, the nilpotency of all elements of S and $\bar{S}$ is equivalent to finite memory and separability, respectively. In fact, when A_1 and A_2 are in upper triangular form, the nilpotency of the elements of S and $\bar{S}$ corresponds to the assumption that the characteristic polynomial Δ_{A_1,A_2} satisfies FM_1) of Corollary 5.3 and S_1) of Proposition 5.4, respectively.

Suppose now that the multiplicative semigroup S, generated by A_1 and A_2, is constituted by nilpotents. Since we have $\mathrm{tr}\ w(A_1, A_2) = 0$ for all $w \in \Xi^*$, $|w| \geq 1$, (4.3) is clearly fulfilled. Consequently (A_1, A_2) has property P and, by the above remark, (A_1, A_2) is a finite memory pair.

On the other hand, assume that all matrices in $\bar{S}$ are nilpotent. This implies

$$\mathrm{tr}[(A_1A_2 - A_2A_1)w(A_1, A_2)] = 0 \quad \forall w \in \Xi^*, \tag{5.11}$$

which is a necessary and sufficient condition [13] for the pair (A_1, A_2) having property P. Again, the remark at the beginning of the proof shows that (A_1, A_2) is a separable pair. □

LYAPUNOV-LIKE TECHNIQUES FOR STOCHASTIC STABILITY*

PATRICK FLORCHINGER†

Abstract. The purpose of this paper is to study the stabilizability problem for control stochastic nonlinear systems driven by a Wiener process. Sufficient conditions for the existence of stabilizing feedback laws that are smooth, except possibly at the equilibrium point of the system, are provided by means of stochastic Lyapunov-like techniques. The notion of dynamic asymptotic stability in probability of control stochastic differential systems is introduced and the stabilization by means of dynamic controllers is studied.

Key words. stochastic stability, control stochastic differential equation, feedback law

AMS subject classifications. 60H10, 93C10, 93D05, 93D15, 93E15

Introduction. The stabilization of deterministic nonlinear control systems has been widely studied in the last past years by many authors (see [3], [1], [5], [17], [23], [27], and [28] for example). In these papers, sufficient conditions for the existence of smooth stabilizing feedback laws are provided using the Lyapunov machinery. Nevertheless, Sontag and Sussmann [26] have proved that in general, controllable deterministic nonlinear systems cannot be stabilized by means of continuous feedback laws. Therefore, if one does not assume the smoothness of the stabilizing feedback laws, some extensions of the results listed above have been obtained (see [3], [15], [22], and [23] for example).

Different types of stabilizing feedback laws have been studied by different authors. Sontag [22] has studied piecewise linear feedback laws, whereas Artstein has studied relaxed feedback laws [3]. Furthermore, note than in the case where the system is affine in the control, stabilizing feedback laws that are continuous for every $x \neq 0$, in a neighbourhood of the origin, can be computed by means of Lyapunov-like techniques (see [17], [24], [27], or [28]).

Actually, only few results on the stabilization of nonlinear stochastic systems can be found in the literature. The stabilization of linear stochastic control systems has been adressed by Willems and Willems [29] and by Gao and Ahmed [12]. In [29], sufficient conditions based on the properties of the solution of the algebraic Riccati equation are provided. The existence of stabilizing feedback laws for a class of nonlinear stochastic control systems has been discussed by Gao and Ahmed [13]. The procedure used in [13] is based on the properties of the solution of the stochastic algebraic Riccati equation introduced by Wonham [30]. More recently, control nonlinear stochastic systems, the drift of which is affine in the control, have been studied from the point of view of the stabilization by means of the stochastic Lyapunov theorem developed by Khasminskii [18] (see [6], [8], [10], [11] for different types of nonlinear stochastic systems and [7], [9] for stochastic bilinear systems).

The aim of this paper is to extend the stabilization results proved in [28] by Tsinias to control stochastic differential systems driven by a Wiener process.

This paper is divided in four parts and is organized as follows. In §1, we recall some definitions and results, proved by Khasminskii [18], on the Lyapunov stability

in probability of the equilibrium solution of a control stochastic differential equation. In §2, we introduce the class of control stochastic differential systems and the associated notions of stochastic stabilizability with which we deal in this paper. In §3, we study stochastic differential systems, the drift of which is affine in the control. The main results proved in this section extend the Artstein [3] and Jurdjevic–Quinn [17] theorems. Moreover, a stabilization result is also proved for a class of stochastic bilinear systems and for some nonlinear stochastic differential systems by means of a slight extension of the stochastic Jurdjevic–Quinn theorem obtained previously. In §4, we deal with the stabilization of nonlinear stochastic differential systems by means of dynamic feedback laws. Necessary and sufficient conditions for the dynamic stabilization of control nonlinear stochastic systems are provided.

1. Some elements of stochastic stability. The purpose of this section is to recall some basic facts about the Lyapunov functional approach of stochastic stability theory that we need in the sequel. For a more detailed exposition of this subject refer to Khasminskii [18], Arnold [2], and Mao [21].

Consider a complete probability space $(\Omega, \mathcal{F}, P)$ and a standard $\mathbb{R}^m$-valued Wiener process w defined on this space. Denote by $\{\mathcal{F}_t\}_{t\in\mathbb{R}_+}$ the complete right-continuous filtration generated by the Wiener process w; i.e., for any $t \in \mathbb{R}_+$,

$$\mathcal{F}_t = \sigma(w_s; 0 \leq s \leq t) \vee \mathcal{N}$$

where $\mathcal{N}$ is the class of all P-negligible sets.

In the rest of this paper, if x_t is a semimartingale on the probability space $(\Omega, \mathcal{F}, \{\mathcal{F}_t\}_{t\in\mathbb{R}_+}, P)$, the term $\circ dx_t$ (respectively, dx_t) will denote its differential in the sense of Stratonovitch (respectively, Itô) (see for example Ikeda–Watanabe [16]).

Let b and σ_k, $1 \leq k \leq m$, be $(m+1)$ functionals mapping $\mathbb{R}^n$ into $\mathbb{R}^n$ such that:

1. $b(0) = 0$ and $\sigma_k(0) = 0$ for any $k \in \{1, \dots, m\}$.
2. There exists a nonnegative constant K for which

$$\forall x \in \mathbb{R}^n, \qquad |b(x)|^2 + \sum_{k=1}^{m} |\sigma_k(x)|^2 \leq K(1 + |x|^2),$$

$$\forall x, y \in \mathbb{R}^n, \qquad |b(x) - b(y)| + \sum_{k=1}^{m} |\sigma_k(x) - \sigma_k(y)| \leq |x - y|.$$

Consider the stochastic process solution $x_t \in \mathbb{R}^n$ of the stochastic differential equation

$$x_t = x_0 + \int_0^t b(x_s)\, ds + \sum_{k=1}^{m} \int_0^t \sigma_k(x_s)\, dw_s^k \tag{1}$$

where x_0 is given in $\mathbb{R}^n$. For any $s \in \mathbb{R}_+$ and $x \in \mathbb{R}^n$, denote by $x_t^{s,x}$, $s \leq t$, the solution at time t of the stochastic differential equation (1) starting form the state x at time s.

Next, we introduce the notions of stochastic stability used in this paper.

DEFINITION 1.1. 1) *The equilibrium solution $x_t \equiv 0$ of the stochastic differential equation* (1) *is said to be stable in probability if for any $s \geq 0$ and $\epsilon > 0$,*

$$\lim_{x\to 0} P\left(\sup_{s\leq t} |x_t^{s,x}| > \epsilon\right) = 0.$$

2) *The equilibrium solution* $x_t \equiv 0$ *of the stochastic differential equation* (1) *is said to be locally asymptotically stable in probability if it is stable in probability and for any* $s \geq 0$,

$$\lim_{x \to 0} P\left(\lim_{t \to +\infty} |x_t^{s,x}| = 0\right) = 1.$$

Remark 1.2. It should be noted that, in the case $\sigma_k \equiv 0$, $1 \leq k \leq m$, these definitions reduce to the corresponding deterministic ones.

Denoting by L the infinitesimal generator of the stochastic process solution x_t of the stochastic differential equation (1), that is, L is the second-order differential operator defined for any function Ψ in $C^2(\mathbb{R}^n)$ by

$$L\Psi(x) = \sum_{i=1}^{n} b^i(x) \frac{\partial \Psi}{\partial x_i}(x) + \frac{1}{2} \sum_{i,j=1}^{n} a_{ij}(x) \frac{\partial^2 \Psi}{\partial x_i \partial x_j}(x) \tag{2}$$

where $a_{ij}(x) = \sum_{k=1}^{m} \sigma_k^i(x) \sigma_k^j(x)$, $1 \leq i, j \leq n$, one can prove the following stochastic version of the Lyapunov theorem.

THEOREM 1.3. *Assume that there exists a Lyapunov function* V *defined in a bounded open neighbourhood* D *of* $x = 0$ (*i.e., a proper function* V *of class* C^2 *mapping* D *into* $\mathbb{R}$ *that is positive definite*) *such that*

$$LV(x) \leq 0 \quad (\textit{respectively}, \;\; LV(x) < 0)$$

for any $x \in D$, $x \neq 0$; *then the equilibrium solution* $x_t \equiv 0$ *of the stochastic differential equation* (1) *is stable* (*respectively, locally asymptotically stable*) *in probability.*

Remark 1.4. If one assumes that $\sigma_k \equiv 0$, $1 \leq k \leq m$, Theorem 1.3 reduces to the well-known Lyapunov theorem for deterministic systems (see, for example, [25] or [14]).

For a detailed proof of Theorem 1.3, we refer the reader to Khasminskii [18, Chap. V, pp. 156–171] or Arnold [2, Chap. XI, pp. 176–187].

2. Setting of the problem. The purpose of this section is to introduce the class of control stochastic differential systems with which we are concerned in this paper.

Denote by $(\Omega, \mathcal{F}, P)$ a probability space and by w a standard $\mathbb{R}^m$-valued Wiener process defined on this space.

Consider the multi-input stochastic differential system in $\mathbb{R}^n$

$$x_t = x_0 + \int_0^t f(x_s, u)\, ds + \int_0^t g(x_s)\, dw_s \tag{3}$$

where

1. x_0 is given in $\mathbb{R}^n$.
2. u is an $\mathbb{R}^p$-valued control law.
3. f and g are Lipschitz functionals mapping $\mathbb{R}^n \times \mathbb{R}^p$ (respectively, $\mathbb{R}^n$) into $\mathbb{R}^n$ (respectively, $\mathbb{R}^n \times \mathbb{R}^m$) such that $f(0,0) = 0$ and $g(0) = 0$, and there exists a nonnegative constant K such that for any $x \in \mathbb{R}^n$ and $u \in \mathbb{R}^p$,

$$|f(x,u)| + |g(x)| \leq K(1 + |x| + |u|).$$

The stochastic differential system (3) is said to be locally feedback stabilizable in probability at the origin if there exist a neighbourhood D of the origin in $\mathbb{R}^n$ and a functional ϕ mapping D into $\mathbb{R}^p$ such that:

1. $\phi(0) = 0$.
2. For every $x \in D$, the solution $x_t^{0,x}$ of the closed-loop system

$$x_t = x + \int_0^t f(x_s, \phi(x_s))\, ds + \int_0^t g(x_s)\, dw_s \tag{4}$$

is uniquely defined.

3. The equilibrium solution $x_t \equiv 0$ of the closed-loop system (4) is asymptotically stable in probability.

The concept of dynamic stabilization for deterministic nonlinear control systems was introduced by Sontag and Sussmann [26]. Here, we introduce an extension of this concept to stochastic differential system as follows.

The stochastic differential system (3) is said to be locally dynamic asymptotically stabilizable in probability at the origin if the stochastic differential system

$$\begin{pmatrix} x_t \\ z_t \end{pmatrix} = \begin{pmatrix} x_0 \\ 0 \end{pmatrix} + \int_0^t \begin{pmatrix} f(x_s, z_s) \\ v \end{pmatrix} ds + \int_0^t \begin{pmatrix} g(x_s) \\ 0 \end{pmatrix} dw_s \tag{5}$$

is locally feedback stabilizable in probability at the origin.

To illustrate the main ideas of this paper, we introduce the following class of nonlinear stochastic differential systems that are affine in the control

$$x_t = x_0 + \int_0^t \left(X_0(x_s) + \sum_{j=1}^p u^j Y_j(x_s) \right) ds + \sum_{i=1}^m \int_0^t X_i(x_s) \circ dw_s^i \tag{6}$$

where $X_0, X_1, \ldots, X_m, Y_1, \ldots, Y_p$ are $(m+p+1)$ vector fields in $C_b^1(\mathbb{R}^n, \mathbb{R}^n)$, which we write for any $x \in \mathbb{R}^n$ as

$$X_i(x) = \sum_{k=1}^n X_i^k(x) \frac{\partial}{\partial x_k}\ , \quad 0 \le i \le m,$$

$$Y_j(x) = \sum_{k=1}^n Y_j^k(x) \frac{\partial}{\partial x_k}\ , \quad 1 \le j \le p,$$

and such that the vector fields X_i, $0 \le i \le m$, vanish at the origin.

Introduce the second-order differential operator L associated with the uncontrolled part of the stochastic differential system (6) defined by

$$L = X_0 + \frac{1}{2} \sum_{i=1}^m X_i^2.$$

Assume that there exists a Lyapunov function V defined in a neighbourhood D of the origin in $\mathbb{R}^n$, such that for any $x \in D$, $x \neq 0$, there exists at least one $i \in \{1, \ldots, p\}$ such that $(Y_i V)(x) \neq 0$ (here, $Y_i V$ is the Lie derivative of the functional V in the direction of the vector field Y_i). Then the feedback law ϕ whose ith component $(1 \leq i \leq p)$ is the functional ϕ_i defined on D by

$$\phi_i(x) = \begin{cases} \left(\frac{-LV(x)}{|(Y_1V(x),\ldots,Y_pV(x))|} - 1\right) Y_iV(x) & \text{if } x \neq 0, \\ 0 & \text{if } x = 0 \end{cases}$$

is smooth for $x \neq 0$ and renders the stochastic differential system (6) locally asymptotically stable in probability. Indeed, denoting by $\mathcal{L}$ the infinitesimal generator associated with the resulting closed-loop system yields

$$\mathcal{L}V(x) = -\sum_{i=1}^{p} |Y_iV(x)|^2$$

for any $x \in D$, $x \neq 0$. So, according to Theorem 1.3 the equilibrium solution $x_t \equiv 0$ of the resulting closed-loop system is locally asymptotically stable in probability. This result extends a well-known result from [4] (see also [28]) to a stochastic differential system.

A simpler formula for the feedback law may be obtained if one assumes that there exists a Lyapunov function V defined in a neighborhood D of the origin such that $LV(x) \leq 0$ for all $x \in D$ and $LV(x) < 0$ for all $x \in D \setminus \{0\}$ such that $Y_iV(x) = 0$ for all $i \in \{1,\ldots,p\}$. Then, the feedback law $\phi = -(Y_1V,\ldots,Y_pV)^\star$ (where $\star$ denotes the transpose of matrices) renders the stochastic differential system (6) locally asymptotically stable in probability at the origin.

Denoting by $\mathcal{L}$ the infinitesimal generator of the resulting closed-loop system yields

$$\mathcal{L}V(x) = LV(x) - \sum_{i=1}^{p} |Y_iV(x)|^2$$

for any $x \in D$. Therefore, $\mathcal{L}V(x) < 0$ for any $x \in D$, and according to Theorem 1.3 the equilibrium state of the closed-loop system is locally asymptotically stable in probability. A deterministic version of this result is due to Tsinias [27].

The aim of this paper is to extend the ideas developed in the above examples to compute stabilizing feedback laws for a larger class of stochastic differential systems.

3. Affine control stochastic differential systems. In order to state some sufficient conditions for the local asymptotic stability in probability of stochastic differential systems that are affine in the control, we introduce the following definition.

DEFINITION 3.1. 1) *The stochastic differential system* (6) *is said to satisfy a stochastic Lyapunov condition at the origin if there exists a Lyapunov function V defined in a neighbourhood D of the origin in $\mathbb{R}^n$ such that*

a. *For every $x \in D \setminus \{0\}$ such that $Y_iV(x) = 0$ for all $i \in \{1,\ldots,p\}$ one has $LV(x) < 0$.*

2) *The stochastic differential system* (6) *is said to satisfy a strong stochastic Lyapunov condition at the origin if there exists a Lyapunov function V defined in a neighbourhood D of the origin in $\mathbb{R}^n$ satisfying condition* 1 *above and real functions a and b defined in D such that*:

b. *The function a is smooth and nonnegative on D.*

c. *The function b is continuous and nonnegative on D.*

d. *The inequality*

$$|LV(x) + a(x)| \leq b(x)\ |(Y_1 V(x), \dots, Y_p V(x))|$$

holds for every $x \in D$.

Remark 3.2. Since the differential operator L appears in the conditions stated in Definition 3.1, the computations in the stochastic case are more tedious than in the deterministic one.

Then, one can prove the following result, which extends Artstein's theorem (see [3], [24]) to the feedback stabilization of stochastic differential systems.

THEOREM 3.3. *If the stochastic differential system* (6) *satisfies a stochastic Lyapunov condition at the origin, then it is locally feedback stabilizable in probability at the origin by means of a feedback law that is smooth in a neighbourhood D of the origin except possibly in* 0. *Moreover, if the stochastic differential system* (6) *satisfies a strong stochastic Lyapunov condition at the origin, then the stabilizing feedback law is bounded on D and is continuous at the origin if* $b(0) = 0$.

Proof of Theorem 3.3. 1) Assume that the stochastic differential system (6) satisfies a stochastic Lyapunov condition at the origin. Then, applying in (6) the control law u defined by

$$u = (\nu Y_1 V, \dots, \nu Y_p V)^\star$$

where ν is a new real-valued control law, one gets the following control stochastic differential system:

$$x_t = x_0 + \int_0^t (X_0(x_s) + \nu\, Y(x_s))\, ds + \sum_{i=1}^m \int_0^t X_i(x_s) \circ dw_s^i \tag{7}$$

where Y denotes the vector field on $\mathbb{R}^n$ defined by

$$Y = \sum_{i=1}^p (Y_i V) Y_i.$$

Then, for any $x \in D \backslash \{0\}$ such that $(YV)(x) = 0$, one can deduce easily from condition 1 in Definition 3.1 that $LV(x) < 0$. Therefore, the stochastic differential system (7) satisfies a stochastic Lyapunov condition at the origin.

To define a stabilizing feedback law for the stochastic differential system (7) we make use of the partition of unity theorem. With this aim, denote by C_1 and C_2 the two relatively closed subsets of $D \setminus \{0\}$ defined by

$$C_1 = \{x \in D \setminus \{0\} : YV(x) = 0\}$$

and

$$C_2 = \{x \in D \setminus \{0\} : LV(x) \geq 0\}.$$

Then, $C_1 \cap C_2 = \emptyset$ and there exists a C^∞ function ψ mapping $D \setminus \{0\}$ into $[0, 1]$ such that $\psi \equiv 0$ on a neighbourhood of C_1 in $D \setminus \{0\}$ and $\psi \equiv 1$ on C_2.

Consider the real-valued function H defined on D by

$$H(x) = \begin{cases} -\psi(x) \left(\dfrac{LV + a}{YV} \right)(x) - 1 & \text{if } x \in D \setminus \{0\} \text{ s.t. } (YV)(x) \neq 0, \\ 0 & \text{if } x \in \{0\} \cup C_1 \end{cases}$$

where a is any smooth and positive real-valued function defined on D.

Then, applying the feedback law $\nu = H$ in (7) yields

$$x_t = x_0 + \int_0^t (X_0(x_s) + H(x_s)Y(x_s))\, ds + \sum_{i=1}^{m} \int_0^t X_i(x_s) \circ dw_s^i. \tag{8}$$

Moreover, one can easily prove that the feedback law u given by

$$u = (H.(Y_1V), \ldots, H.(Y_pV))^\star \tag{9}$$

is smooth on $D \setminus \{0\}$, and denoting by $\mathcal{L}$ the infinitesimal generator associated with the stochastic differential system (8) yields

$$\mathcal{L}V = (1 - \psi)\ LV - YV - \psi a.$$

Hence, $\mathcal{L}V(x) < 0$ for any $x \in D\setminus\{0\}$ and, according to Theorem 1.3, the equilibrium solution $x_t \equiv 0$ of the stochastic differential system (8) is locally asymptotically stable in probability. Therefore, the control law u given by (9) is a stabilizing feedback law for the stochastic differential system (6).

2) Assume that the stochastic differential system (6) satisfies a strong stochastic Lyapunov condition at the origin. Then, one can construct a stabilizing feedback law for the stochastic differential system (6) as above where the function a in the definition of the functional H is given by assumption 2 in Definition 3.1.

On the other hand, by condition d in Definition 3.1, for any $x \in D$, it holds that

$$|LV(x) + a(x)| \leq b(x)\ |(YV)(x)|^{1/2}$$

and, since $|\psi| \leq 1$ and $|Y_iV| \leq (YV)^{1/2}$ for any $i \in \{1, \ldots, p\}$, one has

$$|H(Y_iV)| \leq |b| + |Y_iV|$$

for any $i \in \{1, \ldots, p\}$.

Therefore, by condition c in Definition 3.1, one can deduce easily that the stabilizing feedback law u defined in (9) is bounded on D.

Furthermore, if $b(0) = 0$, it is easy to prove that the feedback law u is continuous at the origin.

This completes the proof of Theorem 3.3.

Remark 3.4. The stabilizing feedback law obtained in Theorem 3.3 depends explicitly on the system coefficients and the Lyapunov function given by the hypothesis. However, the presence of the function ψ, obtained by means of the partition of unity theorem, in formula (9) makes the result rely on nonconstructive techniques.

Note that under a slightly different hypothesis (the small control property introduced by Sontag in [24]) one can obtain a more easily computable stabilizing feedback law for the stochastic differential system (6) (see [6]).

To conclude, note that a serious drawback of both approaches is the lack of information about the construction of the Lyapunov function V in the assumptions of the theorem.

To illustrate the results stated in Theorem 3.3, consider the following two examples.

Example 1. Let x_0 be given in $\mathbb{R}^3$ and denote by $x_t \in \mathbb{R}^3$ the solution of the stochastic differential system

$$dx_t = \begin{pmatrix} \frac{1}{2}x_{1,t} \\ \frac{1}{2}x_{2,t} \\ -\frac{9}{2}x_{3,t} \end{pmatrix} dt + u_1 \begin{pmatrix} x_{2,t}^2 \\ 0 \\ -x_{2,t}x_{3,t} \end{pmatrix} dt + u_2 \begin{pmatrix} x_{1,t}^2 \\ -x_{2,t}^2 \\ 0 \end{pmatrix} dt + \begin{pmatrix} x_{1,t} \\ x_{2,t} \\ x_{3,t} \end{pmatrix} \circ dw_t.$$

Then, using the Lyapunov functional V defined on $\mathbb{R}^3$ by

$$V(x) = \frac{1}{2}(x_1^2 + x_2^2 + x_3^2),$$

one can prove that the above stochastic differential system satisfies a stochastic Lyapunov condition at the origin and thus by Theorem 3.3 is feedback stabilizable at the origin by means of a feedback law that is smooth in a neighbourhood of the origin except possibly in zero.

Example 2. Consider the stochastic differential system defined in $\mathbb{R}^3$ by

$$dx_t = \begin{pmatrix} -2x_{1,t} \\ -2x_{2,t} \\ -\frac{1}{2}x_{1,t}x_{3,t} + x_{1,t}^2x_{3,t} \end{pmatrix} dt + u \begin{pmatrix} x_{2,t} \\ -x_{1,t} \\ x_{1,t}^2 + x_{3,t}^2 \end{pmatrix} dt + \begin{pmatrix} x_{1,t} \\ x_{2,t} \\ x_{1,t}x_{3,t} \end{pmatrix} \circ dw_t$$

where x_0 is given in $\mathbb{R}^3$. Then, denoting by V the Lyapunov functional defined on $\mathbb{R}^3$ by

$$V(x) = \frac{1}{2}(x_1^2 + x_2^2 + x_3^2)$$

and by a, b the two functionals mapping $\mathbb{R}^3$ into $\mathbb{R}$ defined by

$$a(x) = x_1^2 + x_2^2,$$

$$b(x) = |x_1|,$$

one can prove that the stochastic differential system introduced above satisfies a strong stochastic Lyapunov condition at the origin.

Therefore, by Theorem 3.3 this stochastic differential system is feedback stabilizable in probability at the origin by means of a feedback law that is smooth in a neighbourhood of the origin except possibly in zero and is continuous at the origin.

The method used in the proof of Theorem 3.3 leads to the following result that extends the well-known theorem of Jurdjevic and Quinn [17] for the stabilization of deterministic control systems to stochastic differential system.

DEFINITION 3.5. *The stochastic differential system* (6) *is said to satisfy a stochastic Jurdjevic–Quinn condition at the origin if there exists a Lyapunov function V defined in a neighbourhood D of the origin in $\mathbb{R}^n$ such that*:

1) *For every $x \in D \setminus \{0\}$ such that $Y_iV(x) = 0$ for all $i \in \{1, \dots, p\}$ one has $LV(z) \leq 0$ for all z in some neighbourhood D_x of x in $\mathbb{R}^n$.*

2) *For every $x \in D \setminus \{0\}$ such that $LV(x) = 0$ and $Y_iV(x) = 0$ for all $i \in \{1, \ldots, p\}$ there exist integers $k \in \mathbb{N}^\star$ and $i \in \{1, \ldots, p\}$ such that $(L^kY_i)V(x) \neq 0$.*

Remark 3.6. Condition 2) in Definition 3.5 is not as easy to check as in the deterministic case since one has to compute iterates of the differential operator L.

Then one can prove the following stabilization result.

THEOREM 3.7. *If the stochastic differential system* (6) *satisfies a stochastic Jurdjevic–Quinn condition at the origin, then it is locally feedback stabilizable in probability at the origin by means of a feedback law that is smooth in a neighbourhood of the origin except possibly at zero.*

Proof of Theorem 3.7. Under the hypothesis of the theorem, one can construct, as in the proof of Theorem 3.3, a function ψ mapping $D \setminus \{0\}$ into $[0, 1]$ except that now C_2 will denote the closure relatively to $D \setminus \{0\}$ of the set

$$\{x \in D \setminus \{0\} : LV(x) > 0\}.$$

Here, one has $C_1 \cap C_2 = \emptyset$ by condition 1) in Definition 3.5.

Therefore, the feedback law u given by

$$u = (H(Y_1V), \ldots, H(Y_pV))^\star \tag{10}$$

where the function H is defined as in the proof of Theorem 3.3, is smooth on $D \setminus \{0\}$, and denoting by $\mathcal{L}$ the infinitesimal generator of the closed-loop system deduced from (6) when the control law u is given by (10) yields

$$\mathcal{L}V = (1 - \psi)\, LV - YV - \psi a$$

where Y is the vector field defined on $\mathbb{R}^n$ by

$$Y = \sum_{i=1}^{p} (Y_iV)Y_i.$$

Hence, $\mathcal{L}V(x) \leq 0$ for any $x \in D \setminus \{0\}$, and according to Theorem 1.3, the equilibrium solution $x_t \equiv 0$ of the closed-loop system deduced from (6) when the control law u is given by (10) is stable in probability.

Moreover, according to the stochastic version of La Salle's theorem (see [19]), the stochastic process x_t tends in probability to the largest positively invariant set whose support is contained in the locus $\mathcal{L}V(x_t) = 0$ for all $t \in \mathbb{R}_+$. On the other hand, it is obvious that $\mathcal{L}V(x) = 0$ for an $x \neq 0$ if and only if $LV(x) = 0$ and $Y_iV(x) = 0$ for all $i \in \{1, \ldots, p\}$.

Then the successive application of Itô's formula yields $L^kY_iV(x) = 0$ for $i = 1, \ldots, p$, and $k \in \mathbb{N}$, which contradicts the second condition in Definition 3.5.

Thus, the equilibrium solution $x_t \equiv 0$ of the closed-loop system deduced from (6) when the control law u is given by (10) is asymptotically stable in probability. Therefore, the control law u given by (10) is a stabilizing feedback law for the stochastic differential system (6).

This completes the proof of Theorem 3.7.

Remark 3.8. If instead of condition 1) in Definition 3.5 one assumes that $LV(x) \leq 0$ for all $x \in D$, then one can choose $\psi \equiv 0$ and the stabilizing feedback law reads

$$u = (-Y_1V, \ldots, -Y_pV)^\star,$$

which is the same stabilizing formula as the one proposed in [17] for the stabilization of deterministic control systems (see also [8]). In the latter case, note that the equilibrium solution of the uncontrolled part of the stochastic differential system (6) is stable in probability.

As has been noted previously, a serious drawback for practical applications of Theorem 3.7 is the presence of the functional ψ, obtained by means of a nonconstructive technique, in the design of the stabilizing feedback law (10). Successive application of Itô's formula to the conditions deduced from the stochastic version of La Salle's theorem leads to $L^{k+1}V(x) = 0$ and $L^kY_iV(x) = 0$ for $i = 1, \dots, p$ and $k \in \mathbb{N}$. Hence, one can improve condition 2) in Definition 3.5 by assuming that the set

$$\mathcal{K} = \{x \in \mathbb{R}^n / L^{k+1}V(x) = L^kY_jV(x) = 0 \ ; \ k \in \mathbb{N} \ ; \ j = 1, \dots, p\}$$

is reduced to $\{0\}$ (see [8]).

Example 3. Let x_0 be given in $\mathbb{R}^2$, and denote by $x_t \in \mathbb{R}^2$ the solution of the stochastic differential system

$$dx_t = \begin{pmatrix} -x_{1,t} - x_{2,t} \\ \\ x_{1,t} - x_{2,t} + x_{1,t}^2\phi(x_{1,t}, x_{2,t}) \end{pmatrix} dt + u \begin{pmatrix} x_{1,t}^2 \\ \\ 0 \end{pmatrix} dt + \begin{pmatrix} x_{1,t} \\ \\ x_{2,t} \end{pmatrix} \circ dw_t$$

where ϕ is a smooth functional mapping $\mathbb{R}^2$ into $\mathbb{R}$ such that $x_2\phi(0, x_2) < 0$ for any $x_2 \in \mathbb{R}$, $x_2 \neq 0$. Then this stochastic differential system satisfies a stochastic Jurdjevic–Quinn condition at the origin with the Lyapunov function V defined on $\mathbb{R}^2$ by

$$V(x) = \frac{1}{2}(x_1^2 + x_2^2).$$

Indeed, if Y denotes the vector field defined on $\mathbb{R}^2$ by $Y(x) = \left(\begin{smallmatrix} x_1^2 \\ 0 \end{smallmatrix}\right)$, one has $LV(0, x_2) = 0$ for all $x \in \mathbb{R}^2$, $x \neq 0$, with $YV(x) = x_1^3 = 0$. Therefore, there exists a neighbourhood D_x of the point x such that $LV(z) = z_1^2z_2\phi(z_1, z_2) \leq 0$ for all $z \in D_x$. Furthermore, by means of easy computations, one can prove that $L^3YV(0, x_2) = -6x_2^3 \neq 0$ if $x_2 \neq 0$.

On the other hand, for some particular stochastic control systems, one can state, by means of stochastic Lyapunov-like approaches different from those of Theorems 3.3 and 3.7, more easily computable assumptions on the system coefficients that lead to the existence of stabilizing feedback laws.

For instance, consider the stochastic process solution $x_t \in \mathbb{R}^n$ of the single-input stochastic bilinear differential system

$$x_t = x_0 + \int_0^t (Ax_s + uBx_s)\, ds + \sum_{i=1}^{m} \int_0^t C_ix_s\, dw_s^i \tag{11}$$

where A, B, C_i, $1 \leq i \leq m$, are matrices in $\mathcal{M}_{n\times n}(\mathbb{R})$ and assume that (11) satisfies a stochastic Lyapunov condition at the origin where the Lyapunov function is quadratic. Then the stochastic Lyapunov condition at the origin leads to the following result.

PROPOSITION 3.9 (see also [9]). *If there exists a symmetric and positive definite matrix P in $\mathcal{M}_{n\times n}(\mathbb{R})$ such that*

$$\ker(PB + B^\star P) \setminus \{0\} \subset \{x \in \mathbb{R}^n \ / \ \langle \bar{P}x, x\rangle \ < 0\}$$

where $\bar{P}$ is the matrix given by $\bar{P} = A^\star P + PA + C^\star PC$, then there exists a positive constant c such that the stochastic differential system (11) *is feedback stabilizable in probability at the origin by means of the feedback law u defined by*

$$u(x) = \begin{cases} -c \, \frac{\langle PBx, x\rangle}{|x|^2} & \text{if } x \neq 0, \\ 0 & \text{if } x = 0, \end{cases} \tag{12}$$

which is smooth for $x \neq 0$ and bounded.

Proof of Proposition 3.9. Since the matrix P is symmetric and positive definite, the function V defined on $\mathbb{R}^n$ by

$$V(x) = \langle Px, x\rangle$$

is a Lyapunov function. Denoting by L the infinitesimal generator of the closed-loop system deduced from (11) when the control law u is given by (12), one has for any $x \in \mathbb{R}^n$,

$$LV(x) = \langle \bar{P}x, x\rangle - \frac{c}{||x||^2}\langle PBx, x\rangle^2. \tag{13}$$

Therefore, since for any $x \in \mathbb{R}^n \setminus \{0\}$ there exists a unique pair $(r, z) \in \mathbb{R}_+ \times S^{n-1}$ (where S^{n-1} denotes the unit sphere in $\mathbb{R}^n$) such that $x = rz$, equality (13) reads

$$LV(x) = r^2 \left(\langle \bar{P}z, z\rangle - c\langle PBz, z\rangle^2\right). \tag{14}$$

Hence, for any $x \in \mathbb{R}^n$, $x \neq 0$, one has

$$LV(x) < 0$$

provided that

$$c > \frac{\max_{z \in S^{n-1}} |\langle \bar{P}z, z\rangle|}{\min_{z \in S^{n-1}, \langle \bar{P}z, z\rangle \geq 0} \langle PBz, z\rangle^2}.$$

Then, according to Theorem 1.3, the equilibrium solution $x_t \equiv 0$ of the closed-loop system deduced from (11) when the control law u is given by (12) is asymptotically stable in probability.

This completes the proof of Proposition 3.9.

Remark 3.10. The matrix $\bar{P}$ in Proposition 3.9 appears in the stochastic Lyapunov equation that gives a necessary and sufficient condition for the exponential stability in mean square of the equilibrium solution of a linear stochastic differential equation (see Arnold [2]). Conditions for the existence and the uniqueness of the solution to the stochastic Lyapunov equation are given by Wonham [30].

For more general stochastic differential systems that are not necessarily linear in the control we are unable at this time to formulate a proper Lyapunov condition and to apply one of the above methods to achieve the feedback stabilization. Only some specific cases can be solved properly (see [9] for stochastic bilinear systems or [10] for homogeneous stochastic systems). In the following, we propose a slight extension of the stochastic version of Jurdjevic–Quinn theorem to a class of stochastic differential system given by (3) that are not linear in the control.

PROPOSITION 3.11. *Assume that there exists a Lyapunov function V defined on a neighbourhood D of the origin in $\mathbb{R}^n$ such that $LV(x) \leq 0$ for $x \in D$ where L denotes the second-order differential operator given by*

$$L = X_0 + \frac{1}{2}\sum_{i=1}^{m} X_i^2$$

and X_0, X_i, $1 \leq i \leq m$, are the vector fields on $\mathbb{R}^n$ defined for any $x \in \mathbb{R}^n$ as

$$X_0(x) = \sum_{j=1}^{n}\left(f_j(x,0) + \sum_{k=1}^{n} g_{ki}(x)\frac{\partial g_{ji}(x)}{\partial x_k}\right)\frac{\partial}{\partial x_j}$$

and

$$X_i(x) = \sum_{j=1}^{n} g_{ji}(x)\frac{\partial}{\partial x_j}.$$

For any $i \in \{1,\dots,p\}$, let $Y_i(x) = (\frac{\partial f}{\partial u_i})(x,0)$; and assume that condition 2 *of Definition* 3.5 *is fulfilled. Then the stochastic differential system* (3) *is locally feedback stabilizable in probability at the origin by means of the smooth control law u defined on $\mathbb{R}^n$ by*

$$u_i(x) = -Y_iV(x),\ i = 1,\dots,p. \tag{15}$$

Proof of Proposition 3.11. The hypothesis on the system coefficients implies that there exist a function R mapping $\mathbb{R}^n \times \mathbb{R}^p$ into $\mathbb{R}^n$ and a positive constant C such that one can write the stochastic differential system (3) as

$$x_t = x_0 + \int_0^t \left(X_0(x_s) + \sum_{j=1}^{p} u^j Y_j(x_s) + R(x_s,u)\right) ds + \sum_{i=1}^{m}\int_0^t X_i(x_s)\circ dw_s^i \tag{16}$$

where $||R(x,u)|| \leq C||u||^2$ for any (x,u) in a neighbourhood of the origin in $\mathbb{R}^n \times \mathbb{R}^p$. Then, applying the feedback law u given by (15) in equation (16) yields

$$\begin{aligned} x_t = x_0 &+ \int_0^t \left(X_0(x_s) - \sum_{j=1}^{p}(Y_jV)(x_s)Y_j(x_s)\right) ds \\ &+ \int_0^t R(x_s,(Y_1V)(x_s),\dots,(Y_pV)(x_s))ds + \sum_{i=1}^{m}\int_0^t X_i(x_s)\circ dw_s^i. \end{aligned} \tag{17}$$

Denoting by $\mathcal{L}$ the infinitesimal generator of the closed-loop system (17), one has for any $x \in D$, $x \neq 0$,

$$\mathcal{L}V(x) = LV(x) - \sum_{j=1}^{p}((Y_jV)(x))^2(1 + O(x))$$

where

$$O(x) = -\frac{\nabla V(x)R(x,(Y_1V)(x),\dots,(Y_pV)(x))}{\sum_{j=1}^{p}((Y_jV)(x))^2}$$

and $O(x)$ tends to zero when x tends to zero.

Therefore, according to the hypothesis on the function V, one can deduce that

$$\mathcal{L}V(x) \leq 0$$

for any $x \in D$, $x \neq 0$. Furthermore, one has $\mathcal{L}V(x) = 0$ for any $x \in D$, $x \neq 0$, if and only if $LV(x) = 0$ and $(Y_j V)(x) = 0$ for all $j \in \{1, \ldots, p\}$. Then, arguing as in the proof of Theorem 3.7, one can prove that the equilibrium solution $x_t \equiv 0$ of the closed-loop, system (17) is asymptotically stable in probability. Therefore, the control law u given by (15) is a stabilizing feedback law for the stochastic differential system (16). This completes the proof of Proposition 3.11.

4. Stochastic dynamic stabilization. The purpose of this section is to study the stabilization of the nonlinear stochastic differential system (3) by means of a dynamic feedback control law. With this aim, one has to extend the concept of a stochastic Lyapunov condition introduced in Definition 3.1 as follows.

DEFINITION 4.1. *The stochastic differential system* (3) *is said to satisfy a dynamic stochastic Lyapunov condition at the origin if there exists a Lyapunov functional V defined on a neighbourhhood D of the origin in $\mathbb{R}^n \times \mathbb{R}^p$ such that:*

1) *The function V is smooth on $D \setminus \{0\}$.*

2) *For any $(x,z) \in D \setminus \{0\}$ such that $\frac{\partial V}{\partial z}(x,z) = 0$ one has*

$$\sum_{i=1}^{n} f_i(x,z) \frac{\partial V}{\partial x_i}(x,z) + \frac{1}{2} \sum_{i,j=1}^{n} (g(x)g(x)^{\star})_{ij} \frac{\partial^2 V}{\partial x_i \partial x_j}(x,z) < 0.$$

Note that according to Definitions 3.1 and 4.1 the stochastic differential system (3) satisfies a dynamic stochastic Lyapunov condition at the origin if and only if the stochastic differential system (5) satisfies a stochastic Lyapunov condition at the origin.

The following result underlines the relationship between stabilization and dynamic stabilization of the stochastic differential system (3) and the dynamic stochastic Lyapunov condition.

THEOREM 4.2. 1) *If the stochastic differential system* (3) *satifies a dynamic stochastic Lyapunov condition at the origin, then it is dynamic asymptotically stabilizable in probability at the origin.*

2) *If the stochastic differential system* (3) *satisfies a dynamic stochastic Lyapunov condition at the origin and the equation $\frac{\partial V}{\partial z}(x,z) = 0$ has a solution $z = \phi(x)$, $\phi(0) = 0$, that is continuous on a neighbourhood S of the origin in $\mathbb{R}^n$, smooth on $S \setminus \{0\}$, and such that $\frac{\partial^2 V}{\partial x \partial z}(x, \phi(x)) = 0$ for any $x \in S \setminus \{0\}$, then the stochastic differential system* (3) *is locally feedback stabilizable in probability at the origin by means of the control law $u = \phi(x)$.*

3) *If the stochastic differential system* (3) *is locally feedback stabilizable in probability at the origin by means of a locally smooth feedback law $u = \phi(x)$ with $\phi(0) = 0$, then it satisfies a dynamic stochastic Lyapunov condition at the origin with V smooth in a neighbourhood of the origin.*

4) *If the stochastic differential system* (3) *satisfies a dynamic stochastic Lyapunov condition at the origin with V smooth in a neighbourhood S of the origin such that* $\det \frac{\partial^2 V}{\partial z^2}(0,0) \neq 0$ *and $\frac{\partial^2 V}{\partial x \partial z}(x,z) = 0$ for any $(x,z) \in S$ with $\frac{\partial V}{\partial z}(x,z) = 0$, then it is locally feedback stabilizable in probability at the origin by means of a locally smooth feedback law $u = \phi(x)$ with $\phi(0) = 0$.*

Proof of Theorem 4.2. 1) The first assertion of the theorem is an immediate consequence of Theorem 3.3. Indeed, if the stochastic differential system (3) satisfies a dynamic stochastic Lyapunov condition at the origin, then the stochastic differential system (5) satisfies a stochastic Lyapunov condition at the origin. Hence, according to Theorem 3.3, there exists a stabilizing feedback law $v = r(x,z)$ for the stochastic differential system (5) that is smooth for $(x,z) \neq 0$ in a neighbourhood of the origin in $\mathbb{R}^n \times \mathbb{R}^p$.

2) Let ϕ be a function mapping $\mathbb{R}^n$ into $\mathbb{R}^p$ satisfying the hypothesis of assertion 2) in Theorem 4.2. Then the closed-loop system deduced from the control stochastic differential system (3) when the control law u is given by $u(x) = \phi(x)$ reads

$$x_t = x_0 + \int_0^t f(x_s, \phi(x_s))ds + \int_0^t g(x_s)\ dw_s. \tag{18}$$

Denote by $\hat{V}$ the function mapping S into $\mathbb{R}$ defined for any $x \in S$ by

$$\hat{V}(x) = V(x, \phi(x))$$

where V is the Lyapunov function given by Definition 4.1. Then $\hat{V}$ is a Lyapunov function; and denoting by $\mathcal{L}$ the infinitesimal generator of the stochastic process x_t solution of the closed-loop system (18), one has

$$\begin{aligned}\mathcal{L}\hat{V}(x) &= \nabla V(x,\phi(x))f(x,\phi(x)) + \frac{1}{2}\mathrm{Tr}\left[g(x)g(x)^\star \nabla^2 V(x,\phi(x))\right] \\ &= \left(\frac{\partial V}{\partial x}(x,\phi(x)) + \frac{\partial V}{\partial z}(x,\phi(x))\nabla\phi(x)\right) f(x,\phi(x)) \\ &\quad + \frac{1}{2}\mathrm{Tr}\left(g(x)g(x)^\star\left(\frac{\partial^2 V}{\partial x^2}(x,\phi(x)) + 2\frac{\partial^2 V}{\partial x \partial z}(x,\phi(x))\nabla\phi(x)\right.\right. \\ &\quad \left.\left. + \frac{\partial^2 V}{\partial z^2}(x,\phi(x))(\nabla\phi(x))^2 + \frac{\partial V}{\partial z}(x,\phi(x))\nabla^2\phi(x)\right)\right)\end{aligned}$$

for any $x \in S$, $x \neq 0$.

Then since, by assumptions, one has $\frac{\partial V}{\partial z}(x,\phi(x)) = 0$ and $\frac{\partial^2 V}{\partial x \partial z}(x,\phi(x)) = 0$ for any $x \in S$, $x \neq 0$, one gets

$$\mathcal{L}\hat{V}(x) = \sum_{i=1}^n f_i(x,\phi(x))\frac{\partial V}{\partial x_i}(x,\phi(x)) + \frac{1}{2}\sum_{i,j=1}^n (g(x)g(x)^\star)_{ij}\frac{\partial^2 V}{\partial x_i \partial x_j}(x,\phi(x)).$$

Hence, condition 2) in Definition 4.1 yields

$$\mathcal{L}\hat{V}(x) < 0$$

for any $x \in S$, $x \neq 0$.

Therefore, according to Theorem 1.3 the equilibrium solution $x_t \equiv 0$ of the closed-loop system (18) is locally asymptotically stable in probability at the origin, which implies that the control law u given by $u(x) = \phi(x)$ is a stabilizing feedback law for the stochastic differential system (3).

3) Let ϕ be a smooth functional defined on a neighbourhood S of the origin in $\mathbb{R}^n$ with values in $\mathbb{R}^p$ such that $\phi(0) = 0$ and the equilibrium solution $x_t \equiv 0$ of the closed-loop system

$$x_t = x_0 + \int_0^t f(x_s, \phi(x_s))ds + \int_0^t g(x_s)dw_s \tag{19}$$

deduced from the stochastic differential system (3) when the control law u is given by $u(x) = \phi(x)$ is locally asymptotically stable in probability. Then, by the converse Lyapunov theorem proved by Kushner [20], there exists a Lyapunov function V defined on S such that

$$\sum_{i=1}^{n} f_i(x,\phi(x))\frac{\partial V}{\partial x_i}(x) + \frac{1}{2}\sum_{i,j=1}^{n} (g(x)g(x)^\star)_{ij}\frac{\partial^2 V}{\partial x_i \partial x_j}(x) < 0 \tag{20}$$

for any $x \in S$, $x \neq 0$.

Define the function $\tilde{V}$ mapping $S \times \mathbb{R}^p$ into $\mathbb{R}$ by

$$\tilde{V}(x,z) = V(x) + \frac{1}{4}||z - \phi(x)||^4. \tag{21}$$

Then, $\tilde{V}$ is smooth and positive definite on a neighbourhood D of the origin in $\mathbb{R}^n \times \mathbb{R}^p$. Furthermore, for any $(x,z) \in D \setminus \{0\}$ such that $\frac{\partial \tilde{V}}{\partial z}(x,z) = 0$, one has $z = \phi(x)$ and since (20) holds, yields

$$\sum_{i=1}^{n} f_i(x,\phi(x))\frac{\partial \tilde{V}}{\partial x_i}(x) + \frac{1}{2}\sum_{i,j=1}^{n} (g(x)g(x)^\star)_{ij}\frac{\partial^2 \tilde{V}}{\partial x_i \partial x_j}(x) < 0$$

for any $x \in S$, $x \neq 0$.

Hence, the stochastic differential system (3) satisfies a dynamic stochastic Lyapunov condition at the origin. Note that for any $x \in S$, $x \neq 0$, one has $\frac{\partial^2 \tilde{V}}{\partial x \partial z}(x,\phi(x)) = 0$.

4) If the stochastic differential system (3) satisfies a dynamic stochastic Lyapunov condition at the origin with V smooth and such that det $\frac{\partial^2 V}{\partial z^2}(0,0) \neq 0$ one can deduce, applying the implicit function theorem, that there exists a smooth functional ϕ defined on a neighbourhood S of the origin in $\mathbb{R}^n$ with values in $\mathbb{R}^p$ such that $\phi(0) = 0$ and $\frac{\partial V}{\partial x}(x,\phi(x)) = 0$ for any $x \in S$.

Moreover, since by assumptions one has $\frac{\partial^2 V}{\partial x \partial z}(x,\phi(x)) = 0$ for any $x \in S$, one can deduce by application of assertion 2) in Theorem 4.2 that the stochastic differential system (3) is locally feedback stabilizable in probability by means of the control law u defined for any $x \in S$ by $u(x) = \phi(x)$.

This completes the proof of Theorem 4.2.

Remark 4.3. In assertion 2) in Theorem 4.2 one has to assume conditions on the second derivative of the Lyapunov function V which are not needed in the deterministic case. The hypotheses stated in assertion 3) in Theorem 4.2 do not lead, as in the deterministic case, to det $\frac{\partial^2 V}{\partial z^2}(0,0) \neq 0$. Therefore, it seems that assertion (c) in Theorem 3 from [28] cannot be easily generalized to stochastic differential systems.

Example 4. Let x_0 be given in $\mathbb{R}$ and denote by $x_t \in \mathbb{R}$ the solution of the stochastic differential system

$$x_t = x_0 + \int_0^t (-x_s^2 - x_s^3 + u^4 - u^8)\, ds + \int_0^t x_s^3\, dw_s. \tag{22}$$

Then the feedback law u defined by $u(x) = ((1+\sqrt{1-4x^2})/2)^{1/4}$ which is smooth for $x \neq 0$, x in a neighbourhood of 0, and continuous at the origin renders the stochastic differential system (22) asymptotically stable in probability. Indeed, the equilibrium solution of the resulting closed-loop system

$$x_t = x_0 - \int_0^t x_s^3\, ds + \int_0^t x_s^3\, dw_s \tag{23}$$

is asymptotically stable in probability.

Furthermore, the stochastic differential system (22) can be dynamically asymptotically stabilized in probability. With this aim, one has to prove that the stochastic differential system (22) satisfies a dynamic stochastic Lyapunov condition at the origin or, equivalently, that the stochastic differential system

$$\begin{pmatrix} x_t \\ z_t \end{pmatrix} = \begin{pmatrix} x_0 \\ 0 \end{pmatrix} + \int_0^t \begin{pmatrix} -x_s^2 - x_s^3 + z_s^4 - z_s^8 \\ v \end{pmatrix} ds + \int_0^t \begin{pmatrix} x_s^3 \\ 0 \end{pmatrix} dw_s \tag{24}$$

satisfies a Lyapunov condition at the origin.

Let V be the functional mapping $\mathbb{R}^2$ into $\mathbb{R}$ defined by

$$V(x,z) = \begin{cases} x^2 + \left(z - (x^2 + z^8)^{1/4}\right)^4 & \text{if } (x,z) \neq 0, \\ 0 & \text{if } (x,z) = 0. \end{cases}$$

Then the function V is positive definite, smooth for any $(x,z) \neq 0$ on a neighbourhood S of the origin in $\mathbb{R}^2$, and continuous at 0. Moreover, for any $(x,z) \in S$, $(x,z) \neq 0$, such that $\frac{\partial V}{\partial z}(x,z) = 0$ one has $z^4 = x^2 + z^8$ and so

$$f(x,z)\frac{\partial V}{\partial z}(x,z) + \frac{1}{2}g(x)^2\frac{\partial^2 V}{\partial x^2}(x,z) = -x^4 + x^6 < 0,$$

which implies, according to Theorem 4.2, that the equilibrium solution $(x_t, z_t) = 0$ of the stochastic differential system (24) is asymptotically stable in probability.

Using a different stochastic Lyapunov approach from that of Theorems 3.3 and 4.2, one can prove the following result.

PROPOSITION 4.4. *Assume that the stochastic differential system* (3) *is asymptotically stable in probability by means of a smooth feedback law* $u(x) = \phi(x)$ *such that* $\phi(0) = 0$ (*or equivalently that condition* 4) *in Theorem* 4.2 *is fulfilled*). *Denote by* V *a Lyapunov function associated with the closed-loop system deduced from* (3) *when the control law* u *is given by* $u(x) = \phi(x)$, *and assume that there exist smooth functions* h_i, $1 \leq i \leq p$, *mapping* $\mathbb{R}^n \times \mathbb{R}^p \times \mathbb{R}^p$ *into* $\mathbb{R}$ *such that*

$$\begin{aligned} &\sum_{i=1}^n (f_i(x,z) - f_i(x,\phi(x)))\frac{\partial V}{\partial x_i}(x) + \sum_{i,j=1}^n (g(x)g(x)^\star)_{ij}\langle\frac{\partial \phi}{\partial x_i}(x), \frac{\partial \phi}{\partial x_j}(x)\rangle \\ &\qquad = \sum_{i=1}^p (z_i - \phi_i(x))h_i(x,\phi(x),z) \end{aligned} \tag{25}$$

for any x *in a neighbourhood of the origin in* $\mathbb{R}^n$. *Then the stochastic differential system* (3) *is dynamic asymptotically stable in probability by means of a smooth feedback law.*

Remark 4.5. The existence of a Lyapunov function V in the hypothesis of the theorem is given by the converse stochastic Lyapunov theorem proved by Kushner [20].

Proof of Proposition 4.4. Denote by $\bar{V}$ the function mapping $\mathbb{R}^n \times \mathbb{R}^p$ into $\mathbb{R}$ defined by

$$\bar{V}(x,z) = V(x) + \frac{1}{2}||z - \phi(x)||^2.$$

Then $\bar{V}$ is smooth and positive definite on a neighbourhood S of the origin on $\mathbb{R}^n \times \mathbb{R}^p$. Let r be the smooth feedback law mapping $\mathbb{R}^n \times \mathbb{R}^p$ into $\mathbb{R}^p$ defined by

$$\begin{aligned} r_i(x,z) = \sum_{j=1}^{n} f_j(x,z)\frac{\partial \phi_i}{\partial x_j}(x) + \sum_{j,k=1}^{n} (g(x)g(x)^\star)_{jk}\frac{\partial^2 \phi_i}{\partial x_j \partial x_k}(x) \\ -h_i(x,\phi(x),z) - (z_i - \phi_i(x)) \end{aligned} \tag{26}$$

for $i = 1,\dots,p$.

Denoting by $\mathcal{L}$ the infinitesimal generator associated with the closed-loop system deduced from (5) when the control law u is given by (26) one has

$$\begin{aligned} \mathcal{L}\bar{V}(x,z) = {} & \sum_{i=1}^{n} f_i(x,z)\frac{\partial V}{\partial x_i}(x) + \sum_{j,k=1}^{n} (g(x)g(x)^\star)_{jk}\frac{\partial^2 V}{\partial x_j \partial x_k}(x) \\ & + \sum_{j,k=1}^{n} (g(x)g(x)^\star)_{jk}\langle\frac{\partial \phi}{\partial x_j}(x), \frac{\partial \phi}{\partial x_k}(x)\rangle \\ & - \sum_{i=1}^{n}(z_i - \phi_i(x)) \left(\sum_{j=1}^{n} f_j(x,z)\frac{\partial \phi_i}{\partial x_j}(x) - r_i(x,z)\right) \\ & - \sum_{i=1}^{n}(z_i - \phi_i(x)) \left(\sum_{j,k=1}^{n} (g(x)g(x)^\star)_{jk}\frac{\partial^2 \phi}{\partial x_j \partial x_k}(x)\right). \end{aligned} \tag{27}$$

Then, denoting by $\mathcal{L}_\phi$ the infinitesimal generator associated with the closed-loop system deduced from (3) when the control law u is given by ϕ, one can deduce from (27) and (26) that

$$\mathcal{L}\bar{V}(x,z) = \mathcal{L}_\phi V(x,\phi(x)) - ||z - \phi(x)||^2 \tag{28}$$

for any $(x,z) \in \mathbb{R}^n \times \mathbb{R}^p$.

Thus, since V is a Lyapunov function associated with the closed-loop system deduced from (3) when the control law u is given by ϕ, one can deduce from (28) that for any $(x,z) \in \mathbb{R}^n \times \mathbb{R}^p$, one has

$$\mathcal{L}\bar{V}(x,z) < 0.$$

Therefore, according to Theorem 1.3, the equilibrium solution $(x_t, z_t) \equiv (0,0)$ of the stochastic differential system (5) is locally asymptotically stable in probability, which implies that the stochastic differential system (3) is dynamically asymptotically stable in probability.

This completes the proof of Proposition 4.4.

Remark 4.6. One has to assume that equality (25) is fulfilled in the hypotheses of Proposition 4.4. Indeed, equality (25) cannot be obtained by easy computations, as in its deterministic version computed in the proof of Theorem 4 in [28], since the second term in the left-hand side of this equality does not depend on $(x,z) \in \mathbb{R}^n \times \mathbb{R}^p$ but on $x \in \mathbb{R}^n$ only.

Example 5. Let x_0 be given in $\mathbb{R}^2$, and denote by $x_t \in \mathbb{R}^2$ the solution of the following composite stochastic differential system:

$$dx_t = \begin{pmatrix} x_{2,t} - \frac{1}{2}x_{1,t} \\ -x_{1,t} - \frac{1}{2}x_{2,t} \end{pmatrix} dt + \begin{pmatrix} 0 \\ r\left(x_{1,t}, x_{2,t}, u\right) \end{pmatrix} dt + \begin{pmatrix} x_{1,t} \\ x_{2,t} \end{pmatrix} dw_t \tag{29}$$

$$u = z \quad , \quad \dot{z} = v \tag{30}$$

where r is the functional defined on $\mathbb{R}^3$ by

$$r(x_1, x_2, z) = z(ax_1 + bx_2) + z^2\hat{r}(x_1, x_2, z), \tag{31}$$

$\hat{r}$ being a smooth functional defined on $\mathbb{R}^3$ and a, b real numbers such that $a^2 + b^2 \neq 0$.

Our aim is to prove that the composite stochastic differential system of (29) and (30) is asymptotically stabilizable in probability (or equivalently that the stochastic differential system (29) is dynamic asymptotically stabilizable in probability) by means of a smooth feedback law.

Denote by X_0, X_1, and Y the vector fields defined on $\mathbb{R}^2$ by

$$X_0(x) = \begin{pmatrix} x_2 \\ -x_1 \end{pmatrix}, \quad X_1(x) = \begin{pmatrix} x_1 \\ x_2 \end{pmatrix}, \quad Y(x) = \begin{pmatrix} 0 \\ ax_1 + bx_2 \end{pmatrix};$$

and let V be the Lyapunov function defined on $\mathbb{R}^2$ by

$$V(x) = \frac{1}{2}(x_1^2 + x_2^2).$$

Then, denoting by L the second-order differential operator defined by

$$L = X_0 + \frac{1}{2}X_1^2,$$

one can prove, by means of easy computations, that for any $x \in \mathbb{R}^2$, the following holds:

$$LV(x) = 0, \quad YV(x) = x_2(ax_1 + bx_2),$$

$$LYV(x) = a(x_2^2 - x_1^2) - 2bx_1x_2,$$

and

$$L^2YV(x) = -2b(x_2^2 - x_1^2) - 4ax_1x_2.$$

Therefore, since

$$\det \begin{pmatrix} a & -2b \\ -2b & -4a \end{pmatrix} = -4(a^2 + b^2) \neq 0,$$

one can deduce that for any $x \in \mathbb{R}^2$, $x \neq 0$, $LYV(x)$ and $L^2YV(x)$ are not both zero. Hence, by Proposition 3.11, the smooth feedback law $z = -YV(x) = -ax_1x_2 - bx_2^2$ renders the stochastic differential system (29) asymptotically stable in probability at the origin. Furthermore, applying Proposition 4.4, one can prove that the stochastic differential system (29) is dynamic asymptotically stable in probability at the origin by means of a smooth feedback law.

Remark 4.7. The result proved in Example 5 is an extension to stochastic differential systems of a stabilization result studied by Aeyels [1] for deterministic control systems.

ON FEEDBACK EQUIVALENCE OF A PARAMETERIZED FAMILY OF NONLINEAR SYSTEMS*

J.-B. POMET† AND I. A. K. KUPKA‡

Abstract. The following question is considered for a smoothly parameterized family of control systems: Does there exist a smooth family of transformations (feedback only, feedback plus diffeomorphism, or feedback plus diffeomorphism with some restrictions on the parameter dependence of the diffeomorphism, called "matching conditions") changing the systems of the family into a single one? Some abstract necessary and sufficient conditions are given, under which an explicit construction of the transformation is proposed. Both local and global results are obtained. No constant rank assumption is needed for the general conditions, but they can be translated more explicitly under such assumptions.

Key words. nonlinear systems, feedback equivalence, family of systems, nonlinear adaptive control

AMS subject classifications. 93B17, 93B29, 58A30

1. Introduction and problem statement.

We consider a family of nonlinear systems, indexed by a parameter vector $p = (p_1, \ldots, p_l) \in I\!R^l$. Although §6 briefly outlines the generalization of some results to nonaffine systems, most of this paper is devoted to systems that are affine in the control variables. The system $\mathcal{S}_p$ corresponding to a given value of p is therefore described by

$$\mathcal{S}_p\colon \quad \dot{x} = f_o(p,x) + g(p,x)\,u \tag{1}$$

$$\triangleq f_o(p,x) + \sum_{k=1}^{m} u_k\, f_k(p,x) \tag{2}$$

where x exists in an n-dimensional C^∞ manifold M^n, the input $u = (u_1, \ldots, u_m)$ is in $I\!R^m$, and the f_k's are $\mathcal{C}^\infty$ vector fields $\mathcal{C}^\infty$-ly depending on the parameter p.

The problem we are addressing here is finding, if possible, a family of transformations (feedback, feedback + diffeomorphism) that transforms the family of systems $(\mathcal{S}_p)$ into a family of systems that are all identical.

This implies in particular that any two systems of the family are equivalent via feedback or via feedback and diffeomorphism. This equivalence has been explored (see [3], [1], [2], and references therein) but as an equivalence between two systems, possibly on different manifolds, and one of the important questions is of course to find a set of invariants for this equivalence. Looking at the problem under the point of view of families of systems is rather new. Note that we ask the family of transformations to depend on the parameters as smoothly as the systems themselves do.

For the most general problem (feedback and diffeomorphism), we give some rather abstract infinitesimal necessary and sufficient conditions. We also consider a stronger type of equivalence, where some "matching conditions" on the diffeomorphisms are imposed. These matching conditions come from nonlinear adaptive control and are also related to the possibility of controlling the time-varying system that is obtained when p is a function of time with control laws designed for p constant. It turns out that a much more explicit characterization of this equivalence is possible since, basically, the partial differential equations that characterize the general problem degenerate here into algebraic linear equations. Actually two different kinds of matching conditions are considered. One leads to a naturally integrable set of conditions and can be thoroughly characterized in terms of some system of algebraic linear equations having some solutions; the other involves some integrability conditions, but these are automatically satisfied in small dimensions (at the most four controls). Finally, pure feedback equivalence is an even more restrictive equivalence, since no diffeomorphism is allowed (or one independent of the parameters), and it may be completely characterized.

The paper is organized as follows. Section 2 is devoted to some definitions, preliminary results, and notation. Section 3 deals with pure feedback equivalence. Necessary and sufficient conditions are given for both local and global equivalence. Section 4 deals with general feedback and diffeomorphism equivalence. Some abstract necessary and sufficient conditions are given, both for local and global equivalence, and it is explained how they translate into some systems of linear partial differential equations. Section 5 is devoted to feedback and diffeomorphism equivalence with some "matching conditions" on the family of diffeomorphisms. After giving some abstract necessary and sufficient conditions, both for the local and the global case, which are of the same kind as those for the general problem, we give an explicit characterization of these, at least for the "first type" of matching conditions considered. We find as a consequence of the present result some known characterizations for matching conditions in the case of linearizable systems ([4], [5]). The two different sets of matching conditions that are considered are similar in a lot of cases; an example is given on which we have evidence that they are not equivalent, that some integrability conditions are actually necessary, and in which it is illustrated how constructive our method is, all the transformations being explicitly written. Finally §6 presents an extension of our result to systems that are not affine in the control, and §7 gives a brief conclusion.

2. Families of systems: Definitions and basic remarks.

This section is devoted to some notation and basic preliminary results. The main notation is summed up in §2.7.

2.1. The product manifold $I\!R^l \times M^n$.

We will relate parameterized families of systems, or of vector fields, on M^n to some more ordinary systems or vector fields on the product manifold $I\!R^l \times M^n$.

$I\!R^l \times M^n$ being a product, we may define the natural projections π_1 and π_2 by

$$\pi_1(p,x) = p; \quad \pi_2(p,x) = x. \tag{3}$$

We may also write the tangent space at any point (p,x) as a product:

$$T_{(p,x)}\left(I\!R^l \times M^n\right) = T_p I\!R^l \times T_x M^n = I\!R^l \times T_x M^n, \tag{4}$$

which allows us to define the "vector" projections Π_1 and Π_2: for a vector field Y,

$$\Pi_1(Y) + \Pi_2(Y) = Y, \tag{5}$$

$$\Pi_1(Y)\,(p,x) \in T_p\mathbb{R}^l \times \{0\}, \tag{6}$$

$$\Pi_2(Y)\,(p,x) \in \{0\} \times T_xM^n. \tag{7}$$

We refer to $\Pi_1(Y)$ and $\Pi_2(Y)$ as the p-component and x-component of Y, respectively. Finally, we denote by $\frac{\partial}{\partial p_1}, \ldots, \frac{\partial}{\partial p_l}$ the natural coordinate vector fields in $\mathbb{R}^l$, and in $\mathbb{R}^l \times M^n$:

$$\frac{\partial}{\partial p_i}(p,x) = (e_i \ , \ 0) \tag{8}$$

for any (p,x), $\{e_1, \ldots, e_l\}$ being the canonical basis of the vector space $T_p\mathbb{R}^l = \mathbb{R}^l$.

2.2. Vector fields, systems. A $\mathcal{C}^\infty$ *parameterized family of vector fields* is an f that maps any $(p,x) \in \mathbb{R}^l \times M^n$ into a vector $f(p,x)$ of T_xM^n such that $f(p,x)$ is a $\mathcal{C}^\infty$ function of (p,x). In particular, for any p, f_p, also denoted by $f(p,.)$, and defined by

$$f_p(x) = f(p,x), \tag{9}$$

is a $\mathcal{C}^\infty$ vector field on M^n. A $\mathcal{C}^\infty$ *family of systems* (affine in the controls) $\mathcal{S}$ with m inputs is defined by $m+1$ $\mathcal{C}^\infty$ parameterized families of vector fields f_o, $f_1, \ldots, f_m$, and we simply write $\mathcal{S} = (f_o, f_1, \ldots, f_m)$. In this family, the control system that corresponds to the value p of the parameter is described by (2).

We say that a *vector field* on $\mathbb{R}^l \times M^n$ is *parameter preserving* if it has a zero p-component. We also say that a *control system* $(F_o, F_1, \ldots, F_m)$ on $\mathbb{R}^l \times M^n$ is *parameter preserving* if $F_o, F_1, \ldots, F_m$ are parameter-preserving vector fields.

Clearly, a "$\mathcal{C}^\infty$ parameterized family of vector fields" f on M^n may be identified with the "parameter-preserving $\mathcal{C}^\infty$ vector field" F on $\mathbb{R}^l \times M^n$ that is defined by

$$F(p,x) = (\ 0 \ , \ f(p,x)\ ). \tag{10}$$

Also, for a parameter-preserving system $(F_o, F_1, \ldots, F_m)$, the submanifolds $\pi_1^{-1}(\{p\})$ (i.e., $\{p = \text{constant}\}$) are invariant: for any p, identifying the submanifold $\pi_1^{-1}(\{p\})$ with M^n, we obtain a control system on M^n, which is exactly $\mathcal{S}_p$ defined in (1) if the f_i's are given by $F_i(p,x) = (\ 0 \ , \ f_i(p,x)\ )$. Therefore, a family of systems on M^n and a parameter-preserving system on $\mathbb{R}^l \times M^n$ describe the same object.

2.3. Lie brackets. If f and f' are two $\mathcal{C}^\infty$ parameterized families of vector fields, we define their Lie bracket $[f, f']$ to be the $\mathcal{C}^\infty$ parameterized family of vector fields such that for any p, $[f, f'](p,.)$ is the usual Lie bracket of $f(p,.)$ and $f'(p,.)$:

$$[f,f'](p,x) \ \triangleq \ [f(p,.), f'(p,.)](x). \tag{11}$$

We have the following obvious relation, if $F = (0, f)$ and $F' = (0, f')$, where the right-hand side is the usual Lie bracket on $\mathbb{R}^l \times M^n$:

$$(0\,, [f,f']) = [F\,,\, F']\,. \tag{12}$$

2.4. Derivative with respect to the parameters. Considering a $\mathcal{C}^\infty$ parameterized family of vector fields f and noticing that, for a fixed x, when p varies, $f(p,x)$ remains in the same vector space T_xM^n, one may define the $\mathcal{C}^\infty$ parameterized families of vector fields $\frac{\partial f}{\partial p_i}$ $(i = 1, \ldots, l)$, $\frac{\partial f}{\partial p_i}(.,x)$ being just the ith partial derivative of the map $p \longmapsto f(p,x)$ from $\mathbb{R}^l$ to T_xM^n. A straightforward computation provides, if f and F are related by (10) ($F = (0,f)$), the relation

$$\left(0\,,\frac{\partial f}{\partial p_i}\right) = \left[\frac{\partial}{\partial p_i}\,,\,F\right]. \tag{13}$$

2.5. Diffeomorphisms. A $\mathcal{C}^\infty$ *parameterized family of diffeomorphisms* φ on the manifold M^n is a $\mathcal{C}^\infty$ map

$$\varphi\colon \mathbb{R}^l \times M^n \longrightarrow M^n$$

such that for any p, φ_p (defined by $\varphi_p(x) = \varphi(p,x)$) is a diffeomorphism of M^n.

A $\mathcal{C}^\infty$ *diffeomorphism* Φ of $\mathbb{R}^l \times M^n$ is called *parameter preserving* if

$$\pi_1 \circ \Phi \;=\; \pi_1, \tag{14}$$

which just means that for any (p,x) the p-component of $\Phi(p,x)$ is p. There is a one-to-one correspondence between parameter-preserving diffeomorphisms on M^n and parameterized families of diffeomorphisms on $\mathbb{R}^l \times M^n$, relating Φ and φ by

$$\Phi(p,x) = (\;p\;,\;\varphi(p,x)\;) = (\;p\;,\;\varphi_p(x)\;). \tag{15}$$

It is clear that Φ is a $\mathcal{C}^\infty$ parameter-preserving diffeomorphism on $\mathbb{R}^l \times M^n$ if and only if φ is a $\mathcal{C}^\infty$ parameterized family of diffeomorphisms on M^n because Φ is one-to-one onto if and only if φ_p is so for all p, and the differential of Φ is given by

$$\Phi'(p,x) = \begin{pmatrix} I & 0 \\ \dfrac{\partial\varphi}{\partial p}(p,x) & \dfrac{\partial\varphi}{\partial x}(p,x) \end{pmatrix}. \tag{16}$$

We define the $\mathcal{C}^\infty$ parameterized family of diffeomorphisms φ^{-1} by $\varphi^{-1}(p,.) = \varphi_p^{-1}$. With this natural definition of φ^{-1} and Φ defined according to (15), we have

$$\Phi^{-1}(p,x) = (\;p\;,\;\varphi_p^{-1}(x)\;) = (\;p\;,\;\varphi^{-1}(p,x)\;). \tag{17}$$

Let f be a parameterized family of vector fields and φ be a parameterized family of diffeomorphisms. For any fixed p, f_p is a vector field on M^n and φ_p is a diffeomorphism from M^n to M^n. We may therefore define the vector field transformed of f_p by φ_p, $\varphi_{p\,*}\,f_p$, whose value at x is

$$\varphi_{p\,*}\,f_p\,(x) = \frac{\partial\varphi}{\partial x}(p,\varphi^{-1}(p,x)).f(p,\varphi^{-1}(p,x)) \tag{18}$$

(with the above definition of φ^{-1}) and whose flow at time t is

$$\varphi_p \circ \phi^t \circ \varphi_p^{-1} \tag{19}$$

if ϕ^t is the flow of $f(p,.)$ at time t. We then *define* the parameterized family of vector fields $\varphi_* f$ by

$$(\varphi_* f)\,(p,.) = \varphi_{p\,*}\,f_p. \tag{20}$$

If F and f are related according to (10), i.e., $F = (0,f)$, and Φ and φ are related according to (15), we have the following obvious relation:

$$(0\,,\,\varphi_* f) = \Phi_* F \tag{21}$$

where Φ_* is defined by $(\Phi_* F)\,(\Phi(p,x)) = \Phi'(p,x)\,.\,F(p,x)$, i.e., it is the usual transformation on vector fields induced by Φ.

Of course, all of this is also meaningful *locally.* If φ is defined only on an open subset U of $I\!R^l \times M^n$, it is a $\mathcal{C}^\infty$ family of diffeomorphism if and only if it is a $\mathcal{C}^\infty$ map and it induces, for any p (such that $p \in \pi_1(U)$), a diffeomorphism from $\{p\} \times \pi_1^{-1}(p)$ to $\varphi(\{p\} \times \pi_1^{-1}(p))$. The corresponding Φ (defined according to (5)) is simply a parameter-preserving diffeomorphism from U to $\Phi(U)$.

2.6. Modules of vector fields, distributions. Since we wish to give some results without assuming that certain ranks are constant, we will not use distributions but modules of vector fields. A module (over the ring of $\mathcal{C}^\infty$ functions) of vector fields is a set of vector fields closed under addition and multiplication by $\mathcal{C}^\infty$ functions. A module $\mathcal{F}$ of vector fields on a manifold X defines a distribution $\mathcal{D}$ on X: $\mathcal{D}$ is the subset.of TX defined as follows : for any x on X, $\mathcal{D}_x = T_xX \cap \mathcal{D} = \{F(x) \,|\, F \in \mathcal{F}\}$; it is clear that for all $x \in X$, $\mathcal{D}_x$ is a vector subspace of T_xX. If the rank of $\mathcal{D}$ is locally constant, i.e., if the function $x \in X \mapsto \dim\mathcal{D}_x \in Z\!\!\!Z_+$ is locally constant, then $\mathcal{D}$ determines $\mathcal{F}$, but otherwise there are in general several distinct modules that define the same distribution. In this sense, modules of vector fields are more precise a tool than distributions.

Of course, one may speak of modules, over the ring of $\mathcal{C}^\infty$ functions of p and x, of parameterized families of vector fields on M^n, and of modules, over the same ring, of parameter-preserving vector fields on $I\!R^l \times M^n$. If $f_1, \ldots, f_r$ are some parameterized families of vector fields on M^n (resp., $F_1, \ldots, F_r$ are some parameter-preserving vector fields on $I\!R^l \times M^n$);

$$\text{Span}\{f_1 \ldots f_r\} \quad (\text{resp.,} \quad \text{Span}\{F_1 \ldots F_r\}) \tag{22}$$

stands for the module of parameterized families of vector fields generated by $f_1, \ldots, f_r$ (resp., the module of parameter-preserving vector fields generated by $F_1, \ldots, F_r$), which is composed of all the linear combinations—on the module of $\mathcal{C}^\infty$ functions of (p,x)—of $f_1, \ldots, f_r$ (resp., $F_1, \ldots, F_r$). Therefore, if f is a parameterized family of vector fields,

$$f \in \text{Span}\{f_1, \ldots, f_r\} \tag{23}$$

means that there exists some $\mathcal{C}^\infty$ functions $a^1 \ldots a^r$ such that

$$f(p,x) = \sum_{k=1}^{m} a^k(p,x) f_k(p,x); \tag{24}$$

and if F is a parameter-preserving vector field,

$$F \in \text{Span}\{F_1, \ldots, F_r\} \tag{25}$$

means that there exists some $\mathcal{C}^\infty$ functions $a^1 \ldots a^r$ such that

$$F(p,x) = \sum_{k=1}^{m} a^k(p,x) F_k(p,x). \tag{26}$$

Of course, if f and the f_i's are related to F and the F_i's according to (10), then (23) is equivalent to (25) and one may take the same coefficients a^k in (24) and (26) if they hold.

Remark 1. A parameterized family of vector fields on M^n defines, for any p, a vector field on M^n. Therefore, a module $\mathcal{M}$ of parameterized families of vector fields on M^n (or equivalently a module of parameter-preserving vector fields on $\mathbb{R}^l \times M^n$) defines, for any p, a module $\mathcal{M}_p$ of vector fields on M^n. Then one might expect that a parameterized family of vector fields f belongs to a module of parameterized families of vector fields $\mathcal{M}$ if and only if, for any p, the corresponding vector field f_p belongs to the corresponding module of vector fields $\mathcal{M}_p$.

This is true if $\mathcal{M}$ (or the associated module of parameter-preserving vector fields $\mathcal{M}$) spans a distribution of constant rank, for both of these conditions are then equivalent to some vectors, being pointwise in some vector spaces. If the distribution spanned by the module $\mathcal{M}$ does not have constant rank, this is usually false, even if $\mathcal{M}$ is finitely generated, as shown by the following example. Let $\mathbb{R}^l$ and M^n both be $\mathbb{R}$ and f_o be the $\mathcal{C}^\infty$ parameterized family of vector fields defined by

$$f_o(p,x) = p^2 \frac{\partial}{\partial x}, \tag{27}$$

and let $\mathcal{M}$ be the module of parameterized families of vector fields generated by f_o. Consider the $\mathcal{C}^\infty$ parameterized family of vector fields f defined by

$$f(p,x) = p \frac{\partial}{\partial x}. \tag{28}$$

It does not belong to $\mathcal{M}$; i.e., there exists no $\mathcal{C}^\infty$ function a such that $f(p,x) = a(p,x) f_o(p,x)$. However, for any p (even $p = 0$), the vector field f_p defined by $f_p(x) = f(p,x)$ belongs to the module $\mathcal{M}_p$ spanned by the vector field $f_{0,p}$ ($f_{0,p}(x) = f_o(p,x)$) because there exists for any p a $\mathcal{C}^\infty$ function a_p of x such that $f_p(x) = a_p(x) f_{0,p}(x)$, given by $a_p(x) \equiv 1$ if $p = 0$ and $a_p(x) \equiv \frac{1}{p}$ if $p \neq 0$.

2.7. Notation. We use the following notation throughout this paper:

- We denote parameterized families of vector fields on M^n by lower-case letters, and by the corresponding upper-case letter the corresponding parameter-preserving vector field on $\mathbb{R}^l \times M^n$ according to (10).
- The parameterized family of systems that we are studying is $\mathcal{S} = (f_0, f_1, \dots, f_m)$; see (1)–(2). We do not distinguish it from the corresponding parameter-preserving system on $\mathbb{R}^l \times M^n$, and we write indifferently $\mathcal{S} = (f_o, f_1, \dots, f_m)$ or $\mathcal{S} = (F_o, F_1, \dots, F_m)$.
- $\mathcal{g}$ is the module of parameterized families of vector fields on M^n defined by

$$\mathcal{g} = \text{Span}\,\{f_1, \dots, f_m\}, \tag{29}$$

and $\mathcal{G}$ is the module of parameter-preserving vector fields on $\mathbb{R}^l \times M^n$ defined by

$$\mathcal{G} = \text{Span}\{\ F_1\ , \dots,\ F_m\ \}. \tag{30}$$

Of course, the "parameterized family of distributions" associated with $\mathcal{g}$ maps (p,x) into the vector subspace Range $g(p,x)$ (image of the linear mapping $g(p,x)$, spanned by the vector $f_1(p,x), \dots, f_m(p,x)$) of T_xM^n. If the rank of $g(p,x)$ is constant, $Z \in \mathcal{G}$ or $z \in \mathcal{g}$ is equivalent to $z(p,x) \in$ Range $g(p,x)$ for all (p,x).

- If Z is a parameter-preserving vector field (resp., z is a parameterized family of vector fields), $Z \in \mathcal{G}$ (resp., $z \in \mathcal{g}$) *means* that there exists some $\mathcal{C}^\infty$ functions $a^1 \dots a^m$ such that $Z = \sum_{k=1}^m a^k F_k$ (resp., such that $z = \sum_{k=1}^m a^k f_k$).

3. Pure feedback equivalence. In this section, we deal with equivalence of the systems $\mathcal{S}_p$ via feedback transformations only. We establish both local and global conditions.

As made precise by the following definitions, we say that the family of systems $\mathcal{S}$ is pure feedback equivalent (FE) if a feedback transformation that depends smoothly on the parameters transforms it into a "constant" family.

DEFINITION 3.1 (Constant). *A family $\mathcal{S} = (f_o, f_1, \dots, f_m)$ of systems is* constant *on an open subset U of $\mathbb{R}^l \times M^n$ if for all x, p^1, and p^2 such that (p^1, x) and (p^2, x) are in U, we have*

$$f_k(p^1, x) = f_k(p^2, x), \;\; k = 0, 1, \dots, m. \tag{31}$$

DEFINITION 3.2 (FE). *A family $\mathcal{S} = (f_o, f_1, \dots, f_m)$ is* FE (pure feedback equivalent) *on an open subset U of $\mathbb{R}^l \times M^n$ if there exist two C^∞ maps α and β*

$$\begin{aligned} \alpha : \;\; & U \longrightarrow \mathbb{R}^m, \\ \beta : \;\; & U \longrightarrow \mathrm{M}_{m\times m}(\mathbb{R}) \end{aligned}$$

such that $\beta(p, x)$ is invertible for any (p, x) in U and the family $\widetilde{\mathcal{S}} = (\widetilde{f_o}, \widetilde{f_1}, \dots, \widetilde{f_m})$ defined by (with g (resp., $\tilde{g}$) related to $f_1 \dots f_m$ (resp., $\tilde{f_1} \dots \tilde{f_m}$) according to (1)–(2))

$$\widetilde{f_o}(p, x) = f_o(p, x) \; + \; g(p, x) \; \alpha(p, x), \tag{32}$$

$$\widetilde{g}(p, x) = g(p, x) \; \beta(p, x) \tag{33}$$

is constant on U.

It is locally FE *at $(\bar{p}, \bar{x})$ if it is FE on a certain open neighborhood U of $(\bar{p}, \bar{x})$ in $\mathbb{R}^l \times M^n$. It is* globally FE *if it is FE on $\mathbb{R}^l \times M^n$.*

Pure feedback equivalence may be completely characterized, as seen on the following theorems. A discussion and a comparison with other results is given below.

PROPOSITION 3.3. *Let $\mathcal{S} = \{F_0, F_1, \dots, F_m\}$ be a parameterized family of systems on M^n and U be an open subset of $\mathbb{R}^l_. \times M^n$ of the form*

$$U = C \times V \tag{34}$$

where V is an open subset of M^n and $C \subset \mathbb{R}^l$ is a product of open intervals. Then the following three properties are equivalent:

1. *$\mathcal{S}$ is FE on U.*
2. *On U,*

$$\left[\frac{\partial}{\partial p_i}, F_k\right] \in \mathcal{G}, \qquad \begin{array}{l} k = 0, 1, \dots, m, \\ i = 1, \dots, l. \end{array} \tag{35}$$

3. *On U,*

$$\frac{\partial f_k}{\partial p_i} \in \mathcal{G}, \qquad \begin{array}{l} k = 0, 1, \dots, m, \\ i = 1, \dots, l. \end{array} \tag{36}$$

THEOREM 3.4. *A family $\mathcal{S} = (f_0, f_1, \dots, f_m)$ is* locally FE *at $(\bar{p}, \bar{x})$ if and only if conditions* 2 *or* 3 *hold for a certain neighborhood U of $(\bar{p}, \bar{x})$. A family $\mathcal{S} = (f_0, f_1, \dots, f_m)$ is* globally FE *if and only if conditions* 2 *or* 3 *hold with $U = \mathbb{R}^l \times M^n$.*

Theorem 3.4 is a straightforward corollary of Proposition 3.3. Proposition 3.3 is proved further.

Note that we are able to obtain a global result, which would be false if we were considering two a priori completely independent systems instead of a continuous family. Actually, we give in [7] an example of two systems with the same control module and a zero drift vector field such that no global feedback transformation can transform one into the other.

Note also that it was proved in [1] for the case of a constant rank control distribution and in [3] for the general case that two systems (without parameters) are locally pure feedback equivalent if and only if the module spanned by the control vector fields is the same for the two systems and the difference between the drift vector fields of the two systems belongs to this module. From the lemma given in the appendix, applied to the case $X = \frac{\partial}{\partial p_i}$, $\{G_1, \dots, G_s\} = \{F_1, \dots, F_m\}$, condition 2 of the above proposition implies existence of an $m \times m$ invertible matrix transforming $f_1(p,x), \dots, f_m(p,x)$ into $f_1(q,x), \dots, f_m(q,x)$ for any p and q, this matrix depending smoothly on x, p, and q; this implies that the module of vector fields generated by the control vector fields $f_1(p,.), \dots, f_m(p,.)$ of the system $\mathcal{S}_p$ does not depend on p and that for two different p, the difference between the two drift vector fields $f_0(p,.)$ belongs to this module and hence implies the necessary and sufficient condition quoted above for any two systems obtained for different values of the parameters to be pure feedback equivalent. However, the converse is not true: on one hand, condition 2 is stronger since it implies smooth dependence on the parameters of the matrix quoted above; on the other hand, FE is stronger than any two systems in the family that are pure feedback equivalent to one another, as seen on the following example.

Consider the family of systems in $\mathbb{R}$ that depends on one parameter ($\mathbb{R}^l = M^n = \mathbb{R}$) and is defined by

$$f_0(p,x) = e^{-\frac{1+p^2}{x^2}}, \quad f_1(p,x) \;=\; e^{-\frac{1}{x^2}}; \tag{37}$$

i.e., the system $\mathcal{S}_p$ is

$$\dot{x} = e^{-\frac{1+p^2}{x^2}} + e^{-\frac{1}{x^2}}\, u. \tag{38}$$

Note that, despite the vanishing denominators, f_0 and f_1 are C^∞ on $\mathbb{R}^2$. All these systems are feedback equivalent to one another. The transformation that turns $\mathcal{S}_p$ into $\mathcal{S}_0$ is $u = v + 1 - e^{-p^2/x^2}$ (i.e., $\alpha = e^{-1/x^2}$ and $\beta = 1$) if $p \neq 0$ and $u = v$ (i.e., $\alpha = 0$ and $\beta = 1$) if $p = 0$. However, it is impossible to define α as a continuous function of (p,x) since the one given here is the only solution at all points where $x \neq 0$ and cannot be prolonged at $(0,0)$. The family is therefore not FE in our sense, and one may verify that condition (35), for example, is not met.

Proof of Proposition 3.3. Points 2 and 3 are equivalent, as an obvious consequence of (13) and the facts delineated in (23)–(26).

Point 1 implies 3 because, on one hand, (33) may be written

$$f_k(p,x) = \sum_{j=1}^{m} \beta^j_{-1,k}(p,x)\, \widetilde{f}_j(p,x), \quad k = 1, \dots, m, \tag{39}$$

where the $\beta^j_{-1,k}$'s are the coefficients of $\beta(p,x)^{-1}$, and the fact that $\widetilde{\mathcal{S}}$ is constant implies that $\frac{\partial \widetilde{f}_k}{\partial p_i} = 0$, so taking the derivative of both members in (39) with respect to p_i gives (36) for $k = 1, \ldots, m$; on the other hand, (32) may be rewritten, with $\widetilde{\alpha}$ an obvious function of α and the invertible β:

$$\widetilde{f_0}(p,x) \;=\; f_0(p,x) \;+\; \sum_{j=1}^{m} \widetilde{\alpha}^j(p,x)\,\widetilde{f_j}(p,x), \tag{40}$$

which implies (36) for $k = 0$ by taking the derivative of both members in (39) with respect to p_i.

Let us prove that 2 implies 1 to conclude this proof. By applying the lemma given in the appendix to the case where $\mathcal{D}$ is $\mathcal{G}$, the G_k's are the F_k's, F is F_0, X is $\frac{\partial}{\partial p_i}$, and χ is (p,x). We get, from (35), that there exists some $\mathcal{C}^\infty$ functions $c^j_{i,k}$ such that

$$\left(\phi^{t_i}_{\frac{\partial}{\partial p_i}}\right)_* F_k\,(p,x) = \sum_{i=1}^{s} c^j_k(p,x,t_i) F_j(p,x), \tag{41}$$

$$\left(\phi^{t_i}_{\frac{\partial}{\partial p_i}}\right)_* F_0\,(p,x) = F_0(p,x) \;+\; \sum_{i=1}^{s} c^j_k(p,x,t_i) G_j(p,x), \tag{42}$$

which means

$$f_k(p_1, \ldots, p_i - t_i, p_{i+1}, \ldots, p_l, x) = \sum_{i=1}^{s} c^j_k(p,x,t_i) f_j(p,x), \tag{43}$$

$$f_0(p_1, \ldots, p_i - t_i, p_{i+1}, \ldots, p_l, x) = f_0(p,x) \;+\; \sum_{i=1}^{s} c^j_0(p,x,t_i) G_j(p,x); \tag{44}$$

and the lemma given in the appendix says, in addition, that the matrix

$$C_i(p,x,t_i) \;=\; \begin{pmatrix} 1 & 0 & \ldots & 0 \\ c^1_{0,i}(p,x,t) & c^1_{1,i}(p,x,t) & \ldots & c^1_{m,i}(p,x,t) \\ \vdots & \vdots & & \vdots \\ c^m_{0,i}(p,x,t) & c^m_{1,i}(p,x,t) & \ldots & c^m_{m,i}(p,x,t) \end{pmatrix} \tag{45}$$

is invertible for any (p,x,t) (to be precise, the lemma states that the matrix obtained by removing the first line and first column in $C_i(p,x,t)$ is invertible). Let us define the invertible $l \times l$ matrix $\beta(p,x)$ and the l-column vector $\alpha(p,x)$ by

$$\begin{pmatrix} 1 & 0 \\ \alpha(p,x) & \beta(p,x) \end{pmatrix} = B_1(p,x)\, B_2(p,x)\, \ldots\, B_l(p,x) \tag{46}$$

where

$$B_i(p_1, \ldots, p_i, p_{i+1}, \ldots, p_l, x) = C_i(p_1, \ldots, p_i, 0, \ldots, 0, x, p_i). \tag{47}$$

Using relation (43) for $i = l, \ldots, 1$, one gets

$$\begin{aligned} f_0(0, \ldots, 0, x) \;&=\; f_0(p,x) \;+\; \textstyle\sum_{i=1}^{s} \beta^j_0(p,x) f_j(p,x), \\ f_k(0, \ldots, 0, x) \;&=\; \textstyle\sum_{i=1}^{s} \beta^j_k(p,x) f_j(p,x), \quad k = 1, \ldots, m, \end{aligned} \tag{48}$$

which implies that the family $\widetilde{\mathcal{S}}$, defined by (32)–(33), is constant because $\widetilde{f_k}(p,x) = \widetilde{f_k}(0,x)$. Note that, since C is a product of intervals, this construction does define α and β over $U = C \times V$. □

4. Feedback and diffeomorphism equivalence.

4.1. Definition. Feedback and diffeomorphism equivalence, for a parameterized family of systems, means that the systems of the family are equivalent to each other via feedback and diffeomorphism, where both the feedback transformations and the diffeomorphisms are smooth functions of both the points and the parameters.

DEFINITION 4.1 (FDE). *A family $\mathcal{S} = (f_o, f_1, \ldots, f_m)$ is* locally FDE (feedback and diffeomorphism equivalent) *at $(\bar{p}, \bar{x})$ if and only if there exists a neighborhood U of $(\bar{p}, \bar{x})$ and a family of diffeomorphisms φ, defined on U, such that the family $\widetilde{\mathcal{S}} = (\widetilde{f}_o, \widetilde{f}_1, \ldots, \widetilde{f}_m)$ defined, in a neighborhood of $(\bar{p}, \varphi(\bar{p}, \bar{x}))$, by*

$$\widetilde{f}_k = \varphi_* f_k \tag{49}$$

is locally FE at $(\bar{p}, \varphi(\bar{p}, \bar{x}))$.

It is globally FDE *if and only if there exists a family of diffeomorphisms φ defined all over $I\!R^l \times M^n$ such that the family $\widetilde{\mathcal{S}} = (\widetilde{f}_o, \widetilde{f}_1, \ldots, \widetilde{f}_m)$ defined on $I\!R^l \times M^n$ by (49) is globally FE.*

This exactly means that there exist some φ, α, β and $\widetilde{f}_0, \widetilde{g}$ (or $\widetilde{f}_0, \ldots, \widetilde{f}_m$) such that if $y = \varphi(p, x)$ and $u = \alpha(p, x) + \beta(p, x)v$, (1) reads

$$\dot{y} = \tilde{f}(y) + \tilde{g}(y)\, v. \tag{50}$$

4.2. Necessary and sufficient conditions for FDE. The two following theorems give some necessary and sufficient conditions for a family of systems to be FDE, locally or globally. Each of them give two equivalent necessary and sufficient conditions, labeled 2 and 3. These conditions are given in terms of the existence of some vector fields that satisfy some relations. Their existence is necessary, and when they exist φ may be computed explicitly from them. The difference between conditions 2 and 3 is that 3 asks for vector fields $Y_1, \ldots, Y_l$ to satisfy some decoupled relations (each Y_i has to satisfy a set of relations not involving any other Y_j), whereas in 2 the vector fields $Z_1, \ldots, Z_l$ have to satisfy some individual relations *plus* commutation relations involving all of them. Condition 3 is much more practical a tool than 2 to check FDE. Actually the practical content of the theorems is 1 $\Longleftrightarrow$ 3.

These vector fields can be interpreted as elements of the "Lie Algebra" of the infinite-dimensional "Lie group" of diffeomorphisms of M^n and φ as a submanifold of this infinite dimensional Lie group, parameterized by $p = (p_1, \ldots, p_l)$, i.e., for instance, a curve in the case of one parameter.

THEOREM 4.2. *Let $\mathcal{S} = (F_0, F_1, \ldots, F_m)$ be a parameterized family of systems.*

Local FDE. The following three propositions are equivalent:

1. *$\mathcal{S}$ is locally FDE at $(\bar{p}, \bar{x})$ (resp., is globally FDE).*

2. *There exist some C^∞ vector fields $Z_1, \ldots, Z_l$, defined on a certain neighborhood of $(\bar{p}, \bar{x})$, such that, on their domain of definition,*

$$Z_i \textit{ is parameter preserving}, \qquad i = 1, \ldots, l, \tag{51}$$

$$\left[\frac{\partial}{\partial p_i} + Z_i \;,\; F_k \right] \in \mathcal{G}, \qquad i = 1, \ldots, l, \quad k = 0, 1, \ldots, m, \tag{52}$$

$$\left[\frac{\partial}{\partial p_i} + Z_i, \; \frac{\partial}{\partial p_j} + Z_j \right] = 0, \qquad i, j = 1, \ldots, l. \tag{53}$$

3. *There exist some C^∞ vector fields $Y_1, \ldots, Y_l$, defined on a certain neighborhood of $(\bar{p}, \bar{x})$, such that, on their domain of definition,*

$$Y_i \text{ is parameter preserving}, \qquad i = 1, \ldots, l, \tag{54}$$

$$\left[\frac{\partial}{\partial p_i} + Y_i \ , \ F_k \right] \in \mathcal{G}, \qquad i = 1, \ldots, l \ , \ k = 0, 1, \ldots, m. \tag{55}$$

Moreover, if these conditions are satisfied, an explicit expression of φ on a neighborhood of $(\bar{p}, \bar{x})$ is

$$\varphi(p, x) = \pi_2 \left(\phi^{\bar{p} - p}(p, x) \right), \tag{56}$$

where π_2 is defined by (3) *and ϕ by*

$$\phi^{(t_1, \ldots, t_l)} = \phi_1^{t_1} \circ \cdots \circ \phi_l^{t_l}, \tag{57}$$

ϕ_i being the flow of the vector field $\frac{\partial}{\partial p_i} + Y_i$:

$$\phi_i^0(p, x) \equiv (p, x), \tag{58}$$

$$\frac{\partial}{\partial t}[\phi_i^t(p, x)] = \frac{\partial}{\partial p_i} + Y_i(\phi_i^t(p, x)). \tag{59}$$

Global FDE. *If one adds, in* 2 *and* 3, *the condition that the vector fields $\frac{\partial}{\partial p_i} + Z_i$ and $\frac{\partial}{\partial p_i} + Y_i$ be defined all over $\mathbb{R}^l \times M^n$ and complete, then the result holds globally; i.e.,* 1 *can be replaced by "S is globally FDE" and φ may then be computed according to* (56) *all over $\mathbb{R}^l \times M^n$, choosing any $\bar{p}$ in $\mathbb{R}^l$.*

Proof of Theorem 4.2. We write the proof for the global result; the proof of the local result is similar, replacing $\mathbb{R}^l \times M^n$ with some neighborhood of $(\bar{p}, \bar{x})$ and omitting the parts concerned with the completeness of $\frac{\partial}{\partial p_i} + Z_i$ or φ being defined everywhere.

1 ⇒ 2. Let Φ be the parameter-preserving diffeomorphism on $\mathbb{R}^l \times M^n$ associated with the family of diffeomorphisms φ (see (15)). We have, from (49) and (21),

$$\widetilde{F}_k = \Phi_* F_k. \tag{60}$$

Since $\widetilde{S}$ is FE, we have, from Theorem 3.4,

$$\left[\frac{\partial}{\partial p_i} \ , \ \widetilde{F}_k \right] \in \widetilde{\mathcal{G}}, \qquad i = 1, \ldots, l \ , \ k = 0, 1, \ldots, m. \tag{61}$$

Applying $(\Phi_*)^{-1}$ to this relation between vector fields, i.e., writing its inverse image by Φ, one gets

$$\left[(\Phi_*)^{-1} \frac{\partial}{\partial p_i} \ , \ F_k \right] \in \mathcal{G}, \qquad i = 1, \ldots, l. \tag{62}$$

Therefore, if we define the Z_i's by

$$\frac{\partial}{\partial p_i} + Z_i = (\Phi_*)^{-1} \frac{\partial}{\partial p_i}, \tag{63}$$

(52) is obviously satisfied. (53) is also satisfied because

$$\left[\frac{\partial}{\partial p_i} + Z_i, \ \frac{\partial}{\partial p_j} + Z_j \right] = (\Phi_*)^{-1} \left[\frac{\partial}{\partial p_i}, \ \frac{\partial}{\partial p_j} \right] = 0; \tag{64}$$

(51) is also satisfied, i.e., the p-component of Z_i defined by (63) is zero, because, from (16),

$$\left((\Phi_*)^{-1}\frac{\partial}{\partial p_i}\right)(p,x)=\left(\frac{\partial}{\partial p_i},\ -\frac{\partial\varphi}{\partial x}(p,x)^{-1}\frac{\partial\varphi}{\partial p_i}(p,x)\right). \tag{65}$$

If φ (and therefore Φ) is defined all over $I\!R^l\times M^n$, (63) defines the Z_i's all over $I\!R^l\times M^n$, and, for any i, the vector field $\frac{\partial}{\partial p_i}+Z_i$ is complete because it is the diffeomorphic image of the complete vector field $\frac{\partial}{\partial p_i}$.

2 ⇒ 3. The Y_i's defined by $Y_i=Z_i$ obviously work.

3 ⇒ 1. *Without loss of generality, we suppose, in this part of the proof, that $\bar{p}$ is* 0 (*replace p with $p-\bar{p}$*).

Let us define φ by (56). This does define φ over $I\!R^l\times M^n$ if the Y_i's are defined on $I\!R^l\times M^n$ and are complete. If the Y_i's are only defined on a neighborhood of $(\bar{p},\bar{x})$ or are not complete, this defines φ on a neighborhood of $(\bar{p},\bar{x})$.

We now have to prove that the family $\widetilde{\mathcal{S}}$ given by (60), where Φ is the parameter-preserving diffeomorphism defined from φ according to (15), is FE on $I\!R^l\times M^n$ (on a neighborhood of $(\bar{p},\bar{x})$ for the local case). From Theorem 3.4, it is (locally or globally) FE if and only if, on a neighborhood of $(\bar{p},\bar{x})$ or on $I\!R^l\times M^n$, $[\frac{\partial}{\partial p_i},\Phi_*F_k]\in\Phi_*\mathcal{G}$ or, equivalently,

$$\left[(\Phi_*)^{-1}\frac{\partial}{\partial p_i}\,,\,F_k\right]\in\mathcal{G},\qquad i=1,\dots,l,\ k=0,1,\dots,m. \tag{66}$$

Only (66) remains to be proved. Defining φ according to (56) is equivalent to defining Φ by (remember that we suppose in this proof that $\bar{p}=0$)

$$\Phi(p,x)=\left(p\,,\,\pi_2\left(\phi^{-p}(p,x)\right)\right). \tag{67}$$

From (57), considering the fact that the p-component of $\phi^{-p}(p,x)$ is 0 and defining for any $i=1,\dots,l$ and any $t\in I\!R$ the translation τ_i^t to be the flow at time t of the vector field $\frac{\partial}{\partial p_i}$:

$$\tau_i^t(p_1,\dots,p_l,x)=(p_1,\dots,p_i+t,\dots,p_l,x), \tag{68}$$

(67) may be rewritten as

$$\Phi(p_1,\dots,p_l,x)=\tau_l^{p_l}\circ\cdots\circ\tau_1^{p_1}\circ\phi_1^{-p_1}\circ\cdots\circ\phi_l^{-p_l}\ (p_1,\dots,p_l,x), \tag{69}$$

which implies

$$\begin{aligned}\Phi^{-1}(p,x)&=\phi_l^{p_l}\circ\cdots\circ\phi_1^{p_1}\circ\tau_1^{-p_1}\circ\cdots\circ\tau_l^{-p_l}\ (p_1,\dots,p_l,x)\\&=\phi_l^{p_l}\circ\cdots\circ\phi_1^{p_1}\ (0,x).\end{aligned} \tag{70}$$

Therefore,

$$\begin{aligned}\left(\Phi^{-1}{}_*\frac{\partial}{\partial p_i}\right)(p,x)&=\left(\Phi^{-1}\right)'\left(\Phi(p,x)\right)\cdot\frac{\partial}{\partial p_i}(\Phi(p,x))\\&=\left(\phi_l^{p_l}\circ\cdots\circ\phi_{i+1}^{p_{i+1}}\right)'\left(\phi_{i+1}^{-p_{i+1}}\circ\cdots\circ\phi_l^{-p_l}\ (p,x)\right)\\&\qquad\cdot\left[\frac{\partial}{\partial p_i}+Y_i(\phi_{i+1}^{-p_{i+1}}\circ\cdots\circ\phi_l^{-p_l}\ (p,x))\right]\end{aligned} \tag{71}$$

which reads

$$
\begin{aligned}
(\Phi_*)^{-1}\frac{\partial}{\partial p_i} &= (\phi_l^{p_l} \circ \cdots \circ \phi_{i+1}^{p_{i+1}})_* \left(\frac{\partial}{\partial p_i} + Y_i\right) \\
&= \phi_l^{p_l}{}_* \cdots {}_*\phi_{i+1}^{p_{i+1}}{}_* \left(\frac{\partial}{\partial p_i} + Y_i\right)
\end{aligned}
\tag{72}
$$

so that (66) may be rewritten as

$$
\left[\frac{\partial}{\partial p_i} + Y_i \,,\, \phi_{i+1}^{-p_{i+1}}{}_* \cdots {}_*\phi_l^{-p_l}{}_* F_k\right] \in \phi_{i+1}^{-p_{i+1}}{}_* \cdots {}_*\phi_l^{-p_l}{}_*\mathcal{G}, \qquad \begin{array}{l} i = 1, \ldots, l, \\ k = 0, 1, \ldots, m. \end{array}
\tag{73}
$$

But a classical expression for the Lie bracket is

$$
\left[\frac{\partial}{\partial p_i} + Y_i \,,\, \phi_{i+1}^{-p_{i+1}}{}_* \cdots {}_*\phi_l^{-p_l}{}_* F_k\right] = \frac{d}{dt}\,\phi_i^{-t}{}_*\phi_{i+1}^{-p_{i+1}}{}_* \cdots {}_*\phi_l^{-p_l}{}_* F_k \bigg|_{t=0},
\tag{74}
$$

and from (55) and the lemma given in the appendix,

$$
\begin{aligned}
\phi_i^{-t}{}_*\phi_{i+1}^{-p_{i+1}}{}_* \cdots {}_*\phi_l^{-p_l}{}_* F_k &\in \mathcal{G}, \qquad k = 1, \ldots, m, \\
F_0 - \phi_i^{-t}{}_*\phi_{i+1}^{-p_{i+1}}{}_* \cdots {}_*\phi_l^{-p_l}{}_* F_0 &\in \mathcal{G}, \\
\phi_{i+1}^{-p_{i+1}}{}_* \cdots {}_*\phi_l^{-p_l}{}_*\mathcal{G} &= \mathcal{G},
\end{aligned}
\tag{75}
$$

which proves that (73), and therefore (66), is true. □

4.3. How to use these necessary and sufficient conditions. Given a family of systems defined by certain F_0, $F_1, \ldots, F_m$, the previous theorems tell us that the systems of the family are feedback and diffeomorphism equivalent (i.e., the family is FDE) if and only if one may find some vector fields $Y_1, \ldots, Y_l$ satisfying (54) and (55) and give a way to build the diffeomorphisms from these vector fields. The interesting question then is: how to determine whether these vector fields exist and how actually to compute them. We will not give a general answer to this question but take a look at the form of the equations for $Y_1, \ldots, Y_l$.

Locally, let us use a system of coordinates $x_1, \ldots, x_n$ on M^n (then $p_1, \ldots, p_l$, $x_1, \ldots, x_n$ is a system of coordinates on $\mathbb{R}^l \times M^n$). (54) means that the Y_i's have no component on the coordinate vector fields $\frac{\partial}{\partial p_1}, \ldots, \frac{\partial}{\partial p_l}$, so we may write

$$
Y_i(p, x) = b_i^1(p, x)\frac{\partial}{\partial x_1} + \cdots + b_i^n(p, x)\frac{\partial}{\partial x_n}.
\tag{76}
$$

We may now translate condition (55) into some equations that involve the functions b_i^j. Suppose that $\mathcal{G}$ has constant rank m' ($m' \leq m$), and let $\eta_{m'+1}, \ldots, \eta_n$ be $n - m'$ independent differential forms of the form

$$
\eta_j(p, x) = c_j^1(p, x)\,\mathrm{d}x_1 + \cdots + c_j^n(p, x)\,\mathrm{d}x_n
\tag{77}
$$

vanishing on $\mathcal{G}$ so that the equation of $\mathcal{G}$ is $\mathrm{d}p_1 = \cdots = \mathrm{d}p_l = \eta_{m'+1} = \cdots = \eta_n = 0$. (55) may then be written, for each i, $1 \leq i \leq l$, and all k, $0 \leq k \leq m$, as

$$
\begin{aligned}
\left\langle \mathrm{d}p_j, \left[\frac{\partial}{\partial p_i} + Y_i \,,\, F_k\right]\right\rangle &= 0, \qquad j = 1, \ldots, l, \\
\left\langle \eta_j, \left[\frac{\partial}{\partial p_i} + Y_i, F_k\right]\right\rangle &= 0, \qquad j = m' + 1, \ldots, n.
\end{aligned}
\tag{78}
$$

The first part of (78) is always satisfied if Y_i has no p-component (see (76)), and the second part may be rewritten as

$$(79) \qquad L_{Y_i}\langle \eta_j, F_k\rangle - L_{F_k}\langle \eta_j, Y_i\rangle + \mathrm{d}\eta_j(Y_i, F_k) = \left\langle \eta_j, \left[\frac{\partial}{\partial p_i}, F_k\right]\right\rangle.$$

This may be written as $l(n - m')(m + 1)$ equations in the b_i^j's. The first term in the left-hand side depends linearly on the b_i^j's and their first partial derivatives, the two other terms in the left-hand side depend linearly on the the b_i^j's only, and the right-hand side does not depend on the b_i^j's at all. Therefore (79) gives, for each $i = 1, \dots, l$, a set of $(n - m')(m + 1)$ linear partial differential equations in $b_i^1, \dots, b_i^n$, whose satisfaction is equivalent to the Y_i given by (76) satisfying (55). Note that if $\mathcal{G}$ does not have constant rank, it is usually not possible to find a finite number of differential forms describing $\mathcal{G}$ and, therefore, to translate (55) into a finite number of equations in the coordinates of the vector fields Y_i.

The obtained set of PDEs may provide a practical way of checking whether or not a given family is FDE, and, if a solution of these PDEs is available; building φ from this solution is an systematic process according to (58)–(59).

We understand here the superiority of Theorem 4.2 over a theorem that would only contain the set of conditions labeled 2. Looking for $Z_1, \dots, Z_l$ meeting 2, i.e., (51), (52), and (53), would mean, if we define Z_i, instead of Y_i, by (76), that the b_i^j have to satisfy not only the set of linear PDEs (79), which may be decomposed into l decoupled systems each involving $b_i^1, \dots, b_i^n$ for a different value of i, but also the commutation relation (53), which can be translated into a set of PDEs that are nonlinear and involve all the different b_i^j's (actually each involves two different i's).

In this paper, we go no further in the characterization of FDE, i.e., we make no attempt to characterize the cases where the above-described set of partial differential equations admit some solutions. However, in the following sections, we will specialize the notion of feedback and diffeomorphism equivalence by restricting the p-dependence of φ on the parameter p. This will yield some conditions similar to those given here but with some restrictions on the vector fields Z_i or Y_i, and these additional conditions are such that the above-described set of partial differential equations is transformed into a set of algebraic equations. This will allow us to give some more explicit characterizations than for the present case of general FDE.

5. Feedback and diffeomorphism equivalence with matching conditions.

5.1. Definitions: FDEM1 and FDEM2.

Let us define two properties that are more restrictive than FDE. See §5.2 for comments and interpretations.

DEFINITION 5.1 (FDEM1). *A family $\mathcal{S} = (f_o, f_1, \dots, f_m)$ is* locally FDEM1 (feedback and diffeomorphism equivalent with matching conditions of the first kind) *at $(\bar{p}, \bar{x})$ (resp., globally FDEM1) if and only if it is locally FDE at $(\bar{p}, \bar{x})$ (resp., globally FDE), and φ has the property that there exists a smooth map v_1:*

$$(p, \dot{p}, x) \longmapsto v_1(p, \dot{p}, x) \in \mathbb{R}^m$$

defined for $(p, \dot{p}, x)$ in $\mathbb{R}^l \times \mathbb{R}^l \times M^n$ such that $(p, x) \in U$ (resp., for any $(p, \dot{p}, x)$ in $\mathbb{R}^l \times \mathbb{R}^l \times M^n$) satisfying

$$(80) \qquad \frac{\partial \varphi}{\partial x}(p, x) g(p, x) v_1(p, \dot{p}, x) + \frac{\partial \varphi}{\partial p}(p, x)\dot{p} = 0$$

at any point where both sides are defined.

DEFINITION 5.2 (FDEM2). *A family $\mathcal{S} = (f_o, f_1, \ldots, f_m)$ is* locally FDEM2 (feedback and diffeomorphism equivalent with matching conditions of the second kind) *at $(\bar{p}, \bar{x})$ (resp., globally FDEM2) if and only if it is locally FDE at $(\bar{p}, \bar{x})$ (resp., globally FDE), and φ has the property that there exists a smooth map v_2:*

$$(p, q, \dot{p}, x) \longmapsto v_2(p, q, \dot{p}, x) \in I\!R^m$$

defined for $(p, q, \dot{p}, x)$ in $I\!R^l \times I\!R^l \times I\!R^l \times M^n$ such that $(p, x) \in U$ and $(q, x) \in U$ (resp., any $(p, q, \dot{p}, x)$ in $I\!R^l \times I\!R^l \times I\!R^l \times M^n$) satisfying

$$\frac{\partial \varphi}{\partial x}(p, x) g(q, x) v_2(p, q, \dot{p}, x) + \frac{\partial \varphi}{\partial p}(p, x)\dot{p} = 0 \tag{81}$$

at any point where both sides are defined.

Remark 2. We have defined five properties for a parameterized family of vector fields: a parameterized family of systems can be constant, pure feedback equivalent (FE), feedback and diffeomorphism equivalent (FDE), or feedback and diffeomorphism equivalent with one of the matching conditions (FDEM1 and FDEM2), and also it can have none of these properties (a consequence of [11] is that most of the parameterized families of systems have none of these properties). It is rather obvious that

$$\text{Constant} \;\Rightarrow\; \text{FE} \;\Rightarrow\; \text{FDEM2} \;\Rightarrow\; \text{FDEM1} \;\Rightarrow\; \text{FDE}, \tag{82}$$

and actually all these implications are strict, although we will see that for some particular classes of systems FDEM1 and FDEM2 are equivalent.

5.2. Some interpretations of the "matching conditions" in FDEM1 and FDEM2. Note that FE does not refer to any φ, but it can also be understood as FDE with φ independent of p. FDEM1 or FDEM2 allow p-dependence of φ, but they restrict it.

These "matching conditions" are generalizations of those considered in [10], [5], [4] in the following sense: the "strict matching assumption" made in [10] is equivalent to FE plus one of the systems in the family being feedback linearizable and the "extended matching assumption" in [5], [4] is equivalent to FDEM1 or FDEM2 plus one of the systems in the family being feedback linearizable (from Theorem 5.11, FDEM1 and FDEM2 are equivalent for feedback linearizable systems). In these cases, system (50) can be taken a linear system.

The main motivation for these "matching conditions" comes from adaptive nonlinear control, i.e., for instance, the problem of stabilizing a system $\mathcal{S}_p$ (p constant) without the knowledge of p, i.e., with a controller that does not depend on p. Let us very briefly outline the use of these conditions for adaptive nonlinear control. For some precisions, the reader is referred to [10], [5], [4] and to [8], [9], [6]. Assume that the family $(\mathcal{S}_p)$ is globally FDE and that a feedback law $v = v_{ST}(y)$ is known that globally asymptotically stabilizes the origin in (50); then, for each p, the control law $u_p(x) = \alpha(p, x) + \beta(p, x) v_{ST}(\varphi(p, x))$ globally asymptotically stabilizes $\varphi^{-1}(p, 0)$ in system $\mathcal{S}_p$. In addition, if $U(y)$ is a Lyapunov function for $\dot{y} = \tilde{f}_0(y) + \tilde{g}(y) u_{ST}(y)$, then $V_p(x) = U(\varphi(p, x))$ decreases along the solutions of $\mathcal{S}_p$ in closed loop with $u = u_p(x)$. This is not a solution to the problem since the control law $u_p(x)$ depends on p, but we are in the framework of the most current available solutions for nonlinear adaptive stabilization, if we also make the assumption that f_0 and g depend *linearly* on the parameter p.

Under these assumptions and if not only FDE, but FE, is met, $V_p(x)$ does not depend on p. In that case (see [10], [9], [6], [8]), one may design a controller of the form $u = u_{\hat{p}}(x)$ with $\dot{\hat{p}}$ a suitable function of x and $\hat{p}$ such that $W = V_{\hat{p}}(x) + \|\hat{p} - p\|^2$ decreases in the closed-loop system (whose state is $(\hat{p}, x)$) obtained by controlling $\mathcal{S}_p$ with this controller. This dynamic controller does not depend on p and therefore provides a solution to the problem. If FE is not met, then $V_p(x)$ does depend on p in general and the time derivative of $V_{\hat{p}}(x)$ depends explicitly on $\dot{\hat{p}}$, making the previous design method inefficient. However, FDEM1, if satisfied, provides a way (see [5], [4], [8]) of cancelling this dependence by adding $v_1(\hat{p}, \dot{\hat{p}}, x)$ to the original control; this would mean setting $u = u_{\hat{p}}(x) + v_1(\hat{p}, \dot{\hat{p}}, x)$ and applying the previous design method for $\dot{\hat{p}}$; this unfortunately provides $\dot{\hat{p}}$ as a function of x, $\hat{p}$, and v_1, i.e., of x, $\hat{p}$, and $\dot{\hat{p}}$, which results in general in some unavoidable singularities when trying to define $\dot{\hat{p}}$ as a function of $(\hat{p}, x)$. A way to counteract this fact, if FDEM2 is met, is (see [8], [9], [6]) to use a "bigger" controller, with state $(\hat{p}, \hat{q})$: $u = u_{\hat{p}}(x) + v_2(\hat{p}, \hat{q}, \dot{\hat{p}}, x)$ where the v_2-term is still designed to cancel the dependence on $\dot{\hat{p}}$ of the time derivative of $V_{\hat{p}}(x)$; $\dot{\hat{p}}$ may then be defined as a function of x and $\hat{p}$, only, and $\dot{\hat{q}}$ as a function of x, $\hat{p}$, and v_2, i.e., of x, $\hat{p}$, and $\hat{q}$ (recall that $\dot{\hat{p}}$ is a function of x and $\hat{p}$).

Let us give another interpretation of FDEM1 and FDEM2 in terms of disturbance rejection or model matching. Suppose that FDE is satisfied and, therefore, that certain φ, α, and β are defined; see (50).

The paragraph after the definition of FDE (50) allows one to understand FDE as the possibility to render the input–output behavior $v \longrightarrow y$ with $y = \varphi(p, x)$ independent of p for any *constant* p by performing a suitable change of input (feedback transformation depending on x and p): $u = \alpha(p, y) + \beta(p, y)v$. Now suppose that p is time varying; i.e., consider the following time-varying system with state x and output y ($y \in M^n$):

$$(83) \qquad \begin{cases} \dot{x} = f_0(p(t), x) \;+\; g(p(t), x)\, u, \\ y = \varphi(p(t), x). \end{cases}$$

FDEM1 is a condition on φ, necessary and sufficient for the possibility, for any possible time-dependence $p(t)$, to design a change of control

$$(84) \qquad u = v_1(p(t), \dot{p}(t), x) + \alpha(p(t), \varphi(p(t), x)) + \beta(p(t), \varphi(p(t), x))\, v$$

for (83) to "match" the time-invariant model (50). In fact, this model-matching problem also amounts to the problem of rejecting the measured disturbance w in

$$(85) \qquad \begin{cases} \dot{x} = f_0(p, x) + g(p, x)\, u, \\ \dot{p} = w, \\ y = \varphi(p, x) \end{cases}$$

where (x, p) is the state and y is the output. By "rejecting the *measured* disturbance w", we mean building a control $u = \gamma(x, p, w, v)$, nonsingular with respect to v, such that the behavior of the output is affected by v and not by w. FDEM2 is more restrictive: the existence of v_2 can be interpreted as the possibility to reject, for any value of q (maybe time-varying), the disturbance w in the following system with inputs u_1 and u_2, where only the input u_2 is allowed, as a feedback, to depend on w:

$$(86) \qquad \begin{cases} \dot{x} = f_0(p, x) + g(p, x)\, u_1 + g(q, x)\, u_2, \\ \dot{p} = w, \\ y = \varphi(p, x). \end{cases}$$

Finally, a simple interpretation of FDEM1 or FDEM2 is (see Proposition 6.4) that the family (1) is FE if and only if the following family is FDEM1 or FDEM2:

$$\dot{x} = f_0(p,x) \;+\; g(p,x)\,z, \qquad \dot{z} = u.$$

5.3. Necessary and sufficient conditions for FDEM1. The following theorem gives some necessary and sufficient conditions for a family of systems to be FDEM1. The comments given before Theorem 4.2 hold for it as well; in particular, the conditions labeled 3 are simpler than the conditions labeled 2 (2 ⇒ 3 is obvious), and the practical content of these theorems is 1 ⟺ 3. The abstract conditions given here are translated into more explicit ones in §5.5, and some practically tractable conditions are given in §§5.6 and 5.7.

THEOREM 5.3. *Let $\mathcal{S} = (F_0, F_1, \dots, F_m)$ be a parameterized family of systems.*

Local FDEM1. The following three propositions are equivalent:

1. *$\mathcal{S}$ is locally FDEM1 at $(\bar{p},\bar{x})$.*

2. *There exist some C^∞ vector fields $Z_1,\dots,Z_l$, defined on a certain neighborhood of $(\bar{p},\bar{x})$, such that, on their domain of definition,*

$$Z_i \in \mathcal{G}, \qquad i = 1,\dots,l, \tag{87}$$

$$\left[\frac{\partial}{\partial p_i} + Z_i,\ F_k\right] \in \mathcal{G}, \qquad i = 1,\dots,l\ ,\ \ k = 0,1,\dots,m, \tag{88}$$

$$\left[\frac{\partial}{\partial p_i} + Z_i,\ \frac{\partial}{\partial p_j} + Z_j\right] = 0, \qquad i,j = 1,\dots,l. \tag{89}$$

3. *There exist some C^∞ vector fields $Y_1,\dots,Y_l$, defined on a certain neighborhood of $(\bar{p},\bar{x})$, such that, on their domain of definition,*

$$Y_i \ \in\ \mathcal{G}, \qquad i = 1,\dots,l, \tag{90}$$

$$\left[\frac{\partial}{\partial p_i} + Y_i\ ,\ F_k\right] \ \in\ \mathcal{G}, \qquad i = 1,\dots,l\ ,\ \ k = 0,1,\dots,m, \tag{91}$$

$$\left[Y_i,\ \frac{\partial}{\partial p_j}\right] \ \in\ \mathcal{G}, \qquad i,j = 1,\dots,l\ ,\ \ i \neq j. \tag{92}$$

Moreover, if these conditions are satisfied, φ may then be computed according to (56) *on a neighborhood of $(\bar{p},\bar{x})$.*

Global FDEM1. If one adds, in 2 *and* 3, *the condition that the vector fields $\frac{\partial}{\partial p_i} + Z_i$ and $\frac{\partial}{\partial p_i} + Y_i$ be defined all over $I\!R^l \times M^n$ and complete, then the result holds globally, i.e.,* 1 *can be replaced by "$\mathcal{S}$ is globally FDEM1" and φ may then be computed according to* (56) *all over $I\!R^l \times M^n$, choosing any $\bar{p}$ in $I\!R^l$.*

Proof of Theorem 5.3. 1 ⇒ 2. As in the proof of Theorem 4.2, we define the vector fields $Z_1,\dots,Z_l$ according to (63). The only property to be proved is that they belong (where they are defined) to $\mathcal{G}$. This is true because, from (65), (80) may be rewritten, with $\dot{p} = (\dot{p}_1,\dots,\dot{p}_l)$ and $v_1(p,\dot{p},x) = (v_1^1(p,\dot{p},x),\dots,v_1^m(p,\dot{p},x))$ as follows:

$$\sum_{i=1}^{l} Z_i(p,x)\dot{p}_i = \sum_{k=1}^{m} v_1^k(p,\dot{p},x)\, F_k(p,x). \tag{93}$$

2 ⇒ 3. The Y_i's defined by $Y_i = Z_i$ work. (89) implies (92) because $[\frac{\partial}{\partial p_i} + Z_i, \frac{\partial}{\partial p_j}]$ $= -[\frac{\partial}{\partial p_i} + Z_i, Z_j]$ is in $\mathcal{G}$ from (88) because Z_j is in $\mathcal{G}$.

$\underline{3 \Rightarrow 1.}$ (Note that a more intuitive proof is given in Remark 3 for the case when the rank of some distributions are constant.) As in the proof of Theorem 4.2, we define φ from the Y_i's according to (56) or, equivalently, Φ according to (67). The only additional property to prove, compared to Theorem 4.2, is the existence of the smooth v_1 satisfying (80).

Let us define the Z_i's by (63) and note that, from (65), (80) is equivalent to (93). Let $\mathcal{H}$ be the module defined from $\mathcal{G}$ by

$$\mathcal{H} = \mathcal{G} + \operatorname{Span}\left\{\frac{\partial}{\partial p_1}, \dots, \frac{\partial}{\partial p_l}\right\}. \tag{94}$$

Since $\mathcal{H}$ is obviously finitely generated and (91)–(92) imply $[\frac{\partial}{\partial p_i} + Y_i, \mathcal{H}] \subset \mathcal{H}$, the lemma given in the appendix implies that, for any $t \in I\!R$ and at any point where ϕ_i^t is defined,

$$X \in \mathcal{H} \Rightarrow \phi_{i*}^t X \in \mathcal{H}, \quad i = 1, \dots, l. \tag{95}$$

Therefore (72) and (90) imply that

$$\Phi_*^{-1} \frac{\partial}{\partial p_i} \in \mathcal{H}, \quad i = 1, \dots, l; \tag{96}$$

or, considering (63) and (65),

$$Z_i \in \mathcal{G}, \quad i = 1, \dots, l. \tag{97}$$

This is equivalent to the existence of smooth functions a_i^k such that

$$Z_i = \sum_{k=1}^{m} a_i^k F_k. \tag{98}$$

Note that, from (65), (80) is equivalent to (93). One v_1 meeting (80) is then given by

$$v_1 = (v_1^1(p, \dot{p}, x), \dots, v_1^m(p, \dot{p}, x)),$$
$$v_1^k(p, \dot{p}, x) = \textstyle\sum_{i=1}^l a_i^k(p, x)\, \dot{p}_i. \qquad \square$$

Remark 3. In the case where the ranks of both the distribution spanned by $\mathcal{G}$ and the distribution spanned by the module $\mathcal{L}$ defined by (131) are constant, it is possible to give a simpler proof of 3 ⇒ 1 based only on some involutive distributions and which is independent of the proof of Theorem 4.2. If we define the module $\mathcal{K}$ by

$$\mathcal{K} = \{X \in \mathcal{H} / [X, F_k] \in \mathcal{H},\ k = 0 \dots m \text{ and } \left[\frac{\partial}{\partial p_i}, X\right] \in \mathcal{H},\ i = 1 \dots l\}, \tag{99}$$

$\mathcal{H}$ being defined by (94), it is not difficult to show that the following three facts are true. First, since it may be rewritten as

$$\mathcal{K} = \{X \in \mathcal{H} / [X, \mathcal{H}] \subset \mathcal{H} \text{ and } [X, F_0] \in \mathcal{H}\}, \tag{100}$$

$\mathcal{K}$ is stable under Lie bracket. Second, (90) and (91) exactly mean that $\frac{\partial}{\partial p_i} + Y_i$ is in $\mathcal{K}$. Third, the set of vector fields that are in $\mathcal{K}$ and have a zero p-component, i.e., the kernel of the restriction of Π_1 to $\mathcal{K}$ (see (5)–(6)), is exactly $\mathcal{L}$ defined by (131).

The two last facts plus the fact that we assume here that $\mathcal{L}$ has constant rank imply that $\mathcal{K}$ has constant rank $(l + \text{Rank}\mathcal{L})$ and, therefore, from the first fact, $\mathcal{K}$ spans an integrable distribution. Now the construction of φ according to (56) implies that two points on a level submanifold of φ might be joined by a finite concatenation of integral curves of the vector fields $\frac{\partial}{\partial p_i} + Y_i$, which, since these vector fields are in $\mathcal{K}$ and $\mathcal{K}$ is integrable, implies that the level submanifolds of φ are included in the integral submanifolds of $\mathcal{K}$. Since the tangent space to the level submanifolds of φ is spanned by the vector fields $\Phi_*^{-1}\frac{\partial}{\partial p_i}$, this proves that $\Phi_*^{-1}\frac{\partial}{\partial p_i}$ belongs to $\mathcal{K}$, which proves both (because it implies (62)) that φ transforms the family $\mathcal{S}$ into a family $\widetilde{\mathcal{S}}$, which is FE, and (because it implies (96) or (97)) that φ satisfies (80).

5.4. Necessary and sufficient conditions for FDEM2. Theorem 5.6 gives necessary and sufficient conditions for a family of systems to be locally or globally FDEM2. Unfortunately, these conditions are not as good as those given for FDE or FDEM1 in Theorems 4.2 and 5.3; i.e., we are not able to give a set of conditions similar to those labeled 3 in those theorems. The conditions we give are similar to those labeled 2 in those theorems; i.e., they contain some commutation relations that make them hard to check in practice. Actually, we give a counterexample showing that a condition like these labeled 3 in Theorems 4.2 and 5.3 would not be sufficient. This is the motivation for Theorem 5.7 which gives two different sufficient conditions for FDEM2 that do not involve any commutation relation; these conditions are not necessary. The conditions given in the present section are explained in §5.5, and §§5.7 and 5.8 present some cases where it is possible to give a simple characterization.

The conditions we are going to state require the definition of the following submodule of $\mathcal{G}$.

DEFINITION 5.4. *For U an open subset of $\mathbb{R}^l \times M^n$ of the form*

$$U = C \times V \tag{101}$$

where V is an open subset of M^n and $C \subset \mathbb{R}^l$ is a product of intervals, we define the submodule $\mathcal{G}^{\cap,U}$ of $\mathcal{G}$ the following way: a vector field Y is in $\mathcal{G}^{\cap,U}$ if and only if it is in $\mathcal{G}$ and, for any (p,x) in U and $t_1,\ldots,t_m$ such that $\tau_1^{t_1} \circ \tau_2^{t_2} \circ \cdots \circ \tau_l^{t_l}(p,x)$ is in U, we have

$$\tau_1^{t_1}{}_*\tau_2^{t_2}{}_* \cdots{}_* \tau_l^{t_l}{}_*Y(p,x) = \sum_{k=1}^{m} b^k(t_1,\ldots,t_l,p,x)F_k(p,x) \tag{102}$$

where $\tau_i^{t_i}$ is the flow at time t_i of the vector field $\frac{\partial}{\partial p_i}$ (see (68)) and $b^1 \ldots b^m$ are C^∞ functions from the part of $\mathbb{R}^l \times C \times M^n$ made of triplets (t,p,x) such that $p+t$ is in C to $\mathbb{R}$.

We will write $\mathcal{G}^{\cap,\text{glob}}$ instead of $\mathcal{G}^{\cap,\mathbb{R}^l \times M^n}$.

Remark 4. Using parameterized families of vector fields instead of parameter-preserving vector fields, we may equivalently say that a vector field Y is in $\mathcal{G}^{\cap,U}$ if and only if it is in $\mathcal{G}$ and the associated parameterized family of vector fields y is such that there exists some C^∞ functions $\widehat{b}^1 \ldots \widehat{b}^m$ of (p,q,x) such that, for any p, q, and x such that both (p,x) and (q,x) are in U, we have

$$y(q,x) = \widehat{b}^1(p,q,x)f_1(p,x) + \cdots + \widehat{b}^m(p,q,x)f_m(p,x). \tag{103}$$

The functions $\widehat{b}^1,\ldots,\widehat{b}^m$ may easily be deduced from $b^1,\ldots,b^m$ in (102) since q stands for $p-(t_1,\ldots,t_m)$.

If the module $\mathcal{G}^{\cap,U}$ is finitely generated, then a simpler characterization can be given. This is useful to actually compute $\mathcal{G}^{\cap,U}$:

PROPOSITION 5.5. • *If the largest submodule of $\mathcal{G}$ that is invariant by the vector fields $\frac{\partial}{\partial p_1}, \dots, \frac{\partial}{\partial p_m}$ on U is finitely generated, then it is equal to $\mathcal{G}^{\cap,U}$.*

• *If the module $\mathcal{G}$ spans a* distribution *of constant rank on $\mathbb{R}^l \times M^n$, which we denote by $\mathcal{G}$ as well, and if the* distribution *Δ defined on U by*

$$\Delta(p,x) = \bigcap_{q \in V} \mathcal{G}(q,x) \tag{104}$$

has constant rank on U, then the distribution spanned by $\mathcal{G}^{\cap,U}$ is exactly Δ.

Note that the intersection in (104) makes sense since the tangent space at the point (q,x) to $\mathbb{R}^l \times M^n$ is $T_q\mathbb{R}^l \times T_xM^n$, which may be identified to $\mathbb{R}^l \times T_xM^n$, so that the different $\mathcal{G}(q,x)$ may be considered as subspaces of the same vector space $\mathbb{R}^l \times T_xM^n$.

Proof of Proposition 5.5. The first point is a straightforward consequence of the lemma given in the appendix, with $\mathcal{G}$ as $\mathcal{D}$, $\frac{\partial}{\partial p_1}$, as X, and $F = 0$. Δ given by (104) is invariant by the vector fields $\frac{\partial}{\partial p_1}, \dots, \frac{\partial}{\partial p_m}$ and contains any subdistribution of $\mathcal{G}$ invariant by these vector fields; since it has constant rank, it uniquely defines a finitely generated module that, from the first point, is exactly $\mathcal{G}^{\cap,U}$ □

Let us now state our necessary and sufficient conditions.

THEOREM 5.6. *Let $\mathcal{S} = (F_0, F_1, \dots, F_m)$ be a family of systems.*

<u>*Local FDEM2.*</u> *The two following propositions are equivalent:*

1. *$\mathcal{S}$ is locally FDEM2 at $(\bar{p},\bar{x})$.*
2. *There exist some $\mathcal{C}^\infty$ vector fields $Z_1, \dots, Z_l$, defined on a certain neighborhood U of $(\bar{p},\bar{x})$, such that, on their domain of definition,*

$$Z_i \in \mathcal{G}^{\cap,U}, \qquad i = 1,\dots,l, \tag{105}$$

$$\left[\frac{\partial}{\partial p_i} + Z_i \ , \ F_k\right] \in \mathcal{G}, \qquad i = 1,\dots,l, \ k = 0,1,\dots,m, \tag{106}$$

$$\left[\ \frac{\partial}{\partial p_i} + Z_i,\ \frac{\partial}{\partial p_j} + Z_j\right] = 0, \qquad i,j = 1,\dots,l. \tag{107}$$

Moreover, if these conditions are satisfied, φ may then be computed according to (56), *with Y_i replaced by Z_i, on a neighborhood of $(\bar{p},\bar{x})$.*

<u>*Global FDEM2.*</u> *If one adds, in* 2, *the condition that the vector fields $\frac{\partial}{\partial p_i} + Z_i$ be defined all over $\mathbb{R}^l \times M^n$ and complete, and replaces* (105) *with*

$$Z_i \in \mathcal{G}^{\cap,\text{glob}}, \quad i = 1,\dots,l, \tag{108}$$

then the result holds globally, i.e., 1 *can be replaced by "$\mathcal{S}$ is globally FDEM2" and φ may then be computed according to* (56), *with Y_i replaced by Z_i, all over $\mathbb{R}^l \times M^n$, choosing any $\bar{p}$ in $\mathbb{R}^l$.*

Proof of Theorem 5.6. 1 ⇒ 2. The only thing that is not implied by Theorem 4.2 is that the Y_i's in that theorem belong to $\mathcal{G}^\cap$ under the present assumptions. This is true from Definition 5.4 because, from (63) and (65), we may rewrite (81) as

$$\sum_{i=1}^{l} y_i(p,x)\dot{p}_i = \sum_{k=1}^{m} g(q,x)v_{2,k}(p,\dot{p},q,x) \tag{109}$$

where $v_2(p,\dot p,q,x) = (v_{2,1}(p,\dot p,q,x),\dots,v_{2,m}(p,\dot p,q,x))$, $\dot p = (\dot p_1,\dots,\dot p_l)$, and y_i is the parameterized family of vector fields associated with the parameter-preserving vector field Y_i.

<u>$2 \Rightarrow 1$</u>. We can use the proof of $3 \Rightarrow 1$ in Theorem 4.2, replacing Y_i by Z_i. Relation (107) actually simplifies this proof considerably since it implies that the flows $\phi_1^{t_1},\dots,\phi_l^{t_l}$ commute. Therefore (67) and (57) imply that

$$\Phi \circ \phi_i^t \circ \Phi^{-1}\ (p_1,\dots,p_l,x) = (p_1,\dots,p_i+t,\dots,p_l,x),$$

i.e., $\Phi \circ \phi_i^t \circ \Phi^{-1}$ is the flow at time t of $\frac{\partial}{\partial p_i}$, and therefore

$$\Phi_* \left(\frac{\partial.}{\partial p_i} + Z_i\right) = \frac{\partial}{\partial p_i}. \tag{110}$$

(66) is then a consequence of (110) and (106). Note that when, as it is the case here, the vector fields from which we construct φ commute, then defining φ by (56) (substituting Z_i to Y_i) means taking φ constant along the integral submanifolds of $\{\frac{\partial}{\partial p_1} + Z_1,\dots,\frac{\partial}{\partial p_l} + Z_l\}$.

We now need to prove the existence of v_2 satisfying (81). This is a consequence of Z being in $\mathcal{G}^{\cap}$. From Definition 5.4 and (103), if z_i is the parameterized family of vector fields on M^n associated to Z_i, there exists some functions b_i^k such that

$$z_i(p,x) = \sum_{k=1}^{m} b_i^k(p,q,x)\, f_k(q,x), \tag{111}$$

so (81) is satisfied defining v_2 by

$$\begin{aligned} v_2 &= (v_2^1(p,q,\dot p,x),\dots,v_2^m(p,q,\dot p,x)),\\ v_2^k(p,q,\dot p,x) &= \textstyle\sum_{i=1}^l b_i^k(p,q,x)\,\dot p_i. \qquad \Box \end{aligned}$$

As noticed above (see also the discussion in §5.5), these theorems are not as convenient as those concerning FDE and FDEM1 since they do not give a condition free of commutation relations. The next theorem gives two different sufficient conditions for FDEM2, involving no commutation relation. The commutation relations are actually replaced by (114) or a certain module being a Lie algebra. The theorem is only proved in the case where $\mathcal{G}^{\cap,U}$ is finitely generated.

THEOREM 5.7. *Let $\mathcal{S} = (F_0,F_1,\dots,F_m)$ be a parameterized family of systems. Conditions* 1 *and* 2 *below are both sufficient for $\mathcal{S}$ to be locally FDEM*2 *at $(\bar p,\bar x)$ (resp., globally FDEM*2*).*

1. *For a certain neighborhood U of $(\bar p,\bar x)$, the module $\mathcal{G}^{\cap,U}$ is finitely generated and there exist some C^∞ vector fields $Y_1,\dots,Y_l$, defined on U, such that, on U,*

$$Y_i \in \mathcal{G}^{\cap,U}, \qquad i=1,\dots,l, \tag{112}$$

$$\left[\frac{\partial}{\partial p_i} + Y_i\ ,\ F_k\right] \in \mathcal{G}, \qquad i=1,\dots,l\ ,\ \ k=0,1,\dots,m, \tag{113}$$

$$\left[\frac{\partial}{\partial p_i} + Y_i,\ \mathcal{G}^{\cap,U}\right] \subset \mathcal{G}^{\cap,U}, \qquad i=1,\dots,l. \tag{114}$$

(resp., the same with $U = \mathbb{R}^l \times M^n$, plus the vector fields $\frac{\partial}{\partial p_1} + Y_1,\dots,\frac{\partial}{\partial p_l} + Y_l$ are complete).

2. *For a certain neighborhood U of $(\bar{p}, \bar{x})$, the module*

$$\mathcal{J}^U = \{ X \in \mathcal{G}^{\cap,U} ,\ [X, \mathcal{G}^{\cap,U}] \in \mathcal{G} \} \tag{115}$$

is finitely generated and stable under Lie bracket, and there exist some C^∞ vector fields $Y_1, \ldots, Y_l$, defined on U, satisfying (112) *and* (113) *on U (resp., the same with $U = I\!R^l \times M^n$, plus the vector fields $\frac{\partial}{\partial p_1} + Y_1, \ldots, \frac{\partial}{\partial p_l} + Y_l$ are complete).*
Moreover, φ may still then be computed according to (56).

Proof of Theorem 5.7. Condition 1 is sufficient. This is very similar to the 3 ⇒ 1 of the proof of Theorem 5.3. Replace $\mathcal{G}$ with $\mathcal{G}^{\cap,U}$ and $\mathcal{H}$ with

$$\mathcal{H}^{\cap,U} \;=\; \mathcal{G}^{\cap,U} \;+\; \text{Span}\left\{ \frac{\partial}{\partial p_1}, \ldots, \frac{\partial}{\partial p_l} \right\}. \tag{116}$$

The fact that $\mathcal{G}^{\cap,U}$, and therefore $\mathcal{H}^{\cap,U}$, are finitely generated plus condition (114) still enable one to derive (95) and therefore (96) using (72) and (112). (97) becomes $Z_i \in \mathcal{G}^{\cap,U}$, and v_2 may therefore be constructed as in the proof of Theorem 5.6; see (111) and (5.4).

Condition 2 is sufficient. This is also similar to the part 3 ⇒ 1 of the proof of Theorem 5.3. After (94), consider

$$\mathcal{M} = \{ X \in \mathcal{H}^{\cap,U} ,\ [X, \mathcal{G}^{\cap,U}] \in \mathcal{G} \}. \tag{117}$$

The vector fields $\frac{\partial}{\partial p_i} + Y_i$ are in $\mathcal{M}$ from (112) and (113). Since $\mathcal{J}^U$ is stable under the Lie bracket, $\mathcal{M}$ is stable under the Lie bracket too (use the fact that $[\frac{\partial}{\partial p_i}, \mathcal{G}^{\cap,U}] \subset \mathcal{G}^{\cap,U}$). From the lemma given in the appendix, and since $\mathcal{M}$ is finitely generated ($\mathcal{M} = \mathcal{J}^U \oplus \text{Span}\{\frac{\partial}{\partial p_1} \cdots \frac{\partial}{\partial p_l}\}$), this implies (95) and (96) with $\mathcal{H}$ replaced with $\mathcal{H}^{\cap,U}$. This implies $Z_i \in \mathcal{G}^{\cap,U}$, which allows the same construction of v_2 as in the proof of Theorem 5.6; see (111) and (5.4). □

Example. The present example in $I\!R^8$ proves that our Theorem 5.6 concerning FDEM2 is false in general if we remove the commutation conditions (107) and that the sufficient conditions given in Theorem 5.7 are not necessary.

Dimension 8 is almost minimal: from Theorem 5.13, we need $\mathcal{G}^\cap$ to have dimension at least 4 and $\mathcal{G}$ to have dimension at least 6. We do not know if it is possible to find a counterexample where the dimension is exactly 6; in the present case it is 7, so in order for the system to be nontrivial, the state must have dimension at least 8.

Let us consider the family of systems in $I\!R^8$ ($M^n = I\!R^8$) depending on two parameters ($l = 2$), with seven inputs ($m = 7$), defined by

$$\left.\begin{aligned}
&\dot{x}_1 = -x_5 u_3 - (p_1 + x_7)(p_2 + x_8) u_5 - (p_2 + x_8) u_6 - (p_1 + x_7) u_7,\\
&\dot{x}_2 = u_7 + x_6 u_2,\\
&\dot{x}_3 = u_6 - x_5 u_1,\\
&\dot{x}_4 = u_5 - x_7 u_1,\\
&\dot{x}_5 = u_4 \ , \quad \dot{x}_6 \;=\; u_3 \ , \quad \dot{x}_7 \;=\; u_2 \ , \quad \dot{x}_8 \;=\; u_1;
\end{aligned}\right\} \tag{118}$$

i.e.,

$$\left.\begin{aligned}
&F_0 = 0, \quad F_1 \;=\; -x_5 \frac{\partial}{\partial x_3} - x_7 \frac{\partial}{\partial x_4} + \frac{\partial}{\partial x_8},\\
&F_2 = x_6 \frac{\partial}{\partial x_2} + \frac{\partial}{\partial x_7}, \quad F_3 = -x_5 \frac{\partial}{\partial x_1} + \frac{\partial}{\partial x_6},\\
&F_4 = \frac{\partial}{\partial x_5}, \quad F_5 = -(p_1 + x_7)(p_2 + x_8) \frac{\partial}{\partial x_1} + \frac{\partial}{\partial x_4},\\
&F_6 = -(p_2 + x_8) \frac{\partial}{\partial x_1} + \frac{\partial}{\partial x_3}, \quad F_7 = -(p_1 + x_7) \frac{\partial}{\partial x_1} + \frac{\partial}{\partial x_2}.
\end{aligned}\right\} \tag{119}$$

The equation of $\mathcal{G}$ is $\mathrm{d}p_1 = \mathrm{d}p_2 = \omega = 0$ where ω is the differential form given by

$$\begin{aligned} \omega = {} & \mathrm{d}x_1 + (p_1+x_7)\,\mathrm{d}x_2 + (p_2+x_8)\,\mathrm{d}x_3 + (p_1+x_7)\,(p_2+x_8)\,\mathrm{d}x_4 + x_5\mathrm{d}x_6 \\ & -x_6\,(p_1+x_7)\,\mathrm{d}x_7 + x_5\,(p_2+x_8)\,\mathrm{d}x_8 + x_7\,(p_1+x_7)\,(p_2+x_8)\,\mathrm{d}x_8. \end{aligned} \tag{120}$$

We have, for any U

$$\mathcal{G}^{\cap,U} = \mathcal{G}^{\cap,\mathrm{glob}} = \mathcal{G}^{\cap} = \mathrm{Span}\{\,F_1\,,\,F_2\,,\,F_3\,,\,F_4\,\} \tag{121}$$

because the right-hand side is invariant under $\frac{\partial}{\partial p_1}$ and $\frac{\partial}{\partial p_2}$ and no linear combination of F_5, F_6, and F_7 can have both its Lie brackets with $\frac{\partial}{\partial p_1}$ and with $\frac{\partial}{\partial p_2}$ in $\mathcal{G}$.

We are looking for

$$\begin{aligned} Y_1 &= a_1^1\,F_1 + a_1^2\,F_2 + a_1^3\,F_3 + a_1^4\,F_4, \\ Y_2 &= a_2^1\,F_1 + a_2^2\,F_2 + a_2^3\,F_3 + a_2^4\,F_4 \end{aligned} \tag{122}$$

such that $[\frac{\partial}{\partial p_i} + Y_i, F_k] \in \mathcal{G}$. This is equivalent to

$$\left\langle \omega\,,\, \left[\frac{\partial}{\partial p_i} + Y_i, F_k\right]\right\rangle = 0, \quad i=1,2\ ,\ k=1,\dots,7. \tag{123}$$

Here, we have

$$\left.\begin{array}{lcl} \langle\,\omega\,,\,[\frac{\partial}{\partial p_1} +.Y_1, F_1]\,\rangle & = & -\,(p_1+x_7)\,(p_2+x_8)\,a_1^2 - (p_2+x_8)\,a_1^4, \\ \langle\,\omega\,,\,[\frac{\partial}{\partial p_1} + Y_1, F_2]\,\rangle & = & (p_1+x_7)\,(p_2+x_8)\,a_1^1\ + (p_1+x_7)\,a_1^3, \\ \langle\,\omega\,,\,[\frac{\partial}{\partial p_1} + Y_1, F_3]\,\rangle & = & -\,(p_1+x_7)\,a_1^2 - a_1^4, \\ \langle\,\omega\,,\,[\frac{\partial}{\partial p_1} + Y_1, F_4]\,\rangle & = & (p_2+x_8)\,a_1^1\ + a_1^3, \\ \langle\,\omega\,,\,[\frac{\partial}{\partial p_1} + Y_1, F_5]\,\rangle & = & -\,(p_2+x_8) - (p_1+x_7)\,a_1^1\ - (p_2+x_8)\,a_1^2, \\ \langle\,\omega\,,\,[\frac{\partial}{\partial p_1} + Y_1, F_6]\,\rangle & = & -a_1^1, \\ \langle\,\omega\,,\,[\frac{\partial}{\partial p_1} + Y_1, F_7]\,\rangle & = & -1 - a_1^2 \end{array}\right\} \tag{124}$$

and

$$\left.\begin{array}{lcl} \langle\,\omega\,,\,[\frac{\partial}{\partial p_2} + Y_2, F_1]\,\rangle & = & -\,(p_1+x_7)\,(p_2+x_8)\,a_2^2\ - (p_2+x_8)\,a_2^4, \\ \langle\,\omega\,,\,[\frac{\partial}{\partial p_2} + Y_2, F_2]\,\rangle & = & (p_1+x_7)\,(p_2+x_8)\,a_2^1\ + (p_1+x_7)\,a_2^3, \\ \langle\,\omega\,,\,[\frac{\partial}{\partial p_2} + Y_2, F_3]\,\rangle & = & -\,(p_1+x_7)\,a_2^2\ - a_2^4, \\ \langle\,\omega\,,\,[\frac{\partial}{\partial p_2} + Y_2, F_4]\,\rangle & = & (p_2+x_8)\,a_2^1\ + a_2^3, \\ \langle\,\omega\,,\,[\frac{\partial}{\partial p_2} + Y_2, F_5]\,\rangle & = & -\,(p_1+x_7) - (p_1+x_7)\,a_2^1\ - (p_2+x_8)\,a_2^2, \\ \langle\,\omega\,,\,[\frac{\partial}{\partial p_2} + Y_2, F_6]\,\rangle & = & -1 - a_2^1 \\ \langle\,\omega\,,\,[\frac{\partial}{\partial p_2} + Y_2, F_7]\,\rangle & = & -a_2^2. \end{array}\right\} \tag{125}$$

It can be seen easily that (123)–(125) has only one solution for the a_k^j's:

$$\begin{array}{llcl} a_1^1 = 0, & a_2^1 & = & -1, \\ a_1^2 = -1, & a_2^2 & = & 0, \\ a_1^3 = 0, & a_2^3 & = & p_2+x_8, \\ a_1^4 = p_1+x_7, & a_2^4 & = & p_1+x_7 \end{array}$$

yielding, from (122), a unique solution of (123):

$$Y_1 = -x_6\frac{\partial}{\partial x_2} + (p_1+x_7)\,\frac{\partial}{\partial x_5} - \frac{\partial}{\partial x_7}, \tag{126}$$

$$Y_2 = -x_5\,(p_2+x_8)\,\frac{\partial}{\partial x_1} + x_5\frac{\partial}{\partial x_3} + x_7\frac{\partial}{\partial x_4} + (p_2+x_8)\,\frac{\partial}{\partial x_6} - \frac{\partial}{\partial x_8}. \tag{127}$$

These are the *only* solutions, and their Lie bracket is not zero:

$$\left[\frac{\partial}{\partial p_1}+Y_1, \frac{\partial}{\partial p_2}+Y_2\right] = -(p_1+x_7)(p_2+x_8)\frac{\partial}{\partial x_1}+(p_2+x_8)\frac{\partial}{\partial x_2} \tag{128}$$
$$+(p_1+x_7)\frac{\partial}{\partial x_3}-\frac{\partial}{\partial x_4}.$$

The vector fields given by (126)–(127) satisfy the conditions required for the Z_i in Theorem 5.6—those for global FDEM2 since it is easy to check that they are complete—except the commutation relation (107). Since they are the only solutions, there exists no other vector field satisfying both these same relations and (107). The family therefore is not (either locally or globally) FDEM2 because the conditions given by Theorem 5.6 are necessary. This proves that condition (107) cannot be omitted from Theorem 5.6 (see first paragraph of §5.4).

This example also allows us to see that the sufficient conditions given in Theorem 5.7 are not necessary by considering the family depending on one parameter only that is obtained by fixing $p_2 = 0$. It is (globally) FDEM2 because Y_1 given by (126) satisfies the conditions of Theorem 5.6 (there is no longer any commutation relation to check because there is only one Y_i). However, we may check that neither condition 1 nor condition 2 of Theorem 5.7 is satisfied.

Condition 1. Y_1 given by (126) is the unique vector field satisfying (112) and (113), and it does not satisfy the additional requirement (114) in condition 1 of Theorem 5.7 since, for example, F_3 is in $\mathcal{G}^\cap$ and $[\frac{\partial}{\partial p_1}+Y_1, F_3] = -(p_1+x_7)\frac{\partial}{\partial x_1}+\frac{\partial}{\partial x_2}$ is not in $\mathcal{G}^\cap$ from (119) and (121).

Condition 2. Since there is no longer any dependence on p_2, $\mathcal{G}^\cap$ is larger than it was in (121): it is now spanned by F_1, F_2, F_3, F_4, $F_5 - x_8F_7$, and F_6. The vector fields Y_1 given by (126) and Y_1' given by

$$Y_1' = F_5 - x_8F_7 + (p_1+x_7)F_6$$

are in $\mathcal{J}^U$ (which does not depend on U) since they are in $\mathcal{G}^\cap$ and their Lie brackets with F_1, F_2, F_3, F_4, $F_5 - x_8F_7$, and F_6 are in $\mathcal{G}$. However, since $[Y_1, Y_1'] = F_6$, $[F_6, F_1] = -\frac{\partial}{\partial x_1}$, and $\frac{\partial}{\partial x_1}$ is not in $\mathcal{G}$, $[Y_1, Y_1']$ is not in $\mathcal{J}^U$, so $\mathcal{J}^U$ is not stable under the Lie bracket.

5.5. How to use the necessary and sufficient conditions. Let us outline, as we did in §4.3 for FDE, the way to check in practice whether FDEM1 or FDEM2 is satisfied or not.

Let us first consider the case of FDEM1. Given a family of systems defined by certain F_0, $F_1, \dots, F_m$, Theorem 5.3 tells us that the systems of the family are FDEM1 if and only if one may find some vector fields $Y_1, \dots, Y_l$ satisfying (90), (91), and (92). If we try to go through the same process as we did in §4.3, we may of course define the Y_i's according to (76) because (90) implies (54). Since (91) is similar to (55), it may be translated into (79) if $\mathcal{G}$ has constant rank. The new feature is that (90) implies that the terms $\langle \eta_j, Y_i\rangle$ are all identically zero, so the first term in (79) vanishes. Since this was the only term involving the derivatives, (79) is *no longer a set of PDEs but simply a set of linear algebraic equations* in the b_i^j's. (90) and (92) can also be translated into linear algebraic equations in the b_i^j's. It is then fairly easy to give conditions under which this system of linear equations has some solutions, at least if its rank is constant. Theorem 5.9 in §5.6 gives this condition, using a dual characterization of existence of solutions for a linear system.

The case of FDEM2 is not as simple. (106) can still be translated, if both $\mathcal{G}$ and $\mathcal{G}^{\cap}$ have constant rank, into some linear algebraic equations in the components of Z_i, but we have to add some nonlinear, coupled differential conditions in these same components to account for the commutation relations (107). This does not allow such explicit conditions as in the case of FDEM1. Sections 5.8 and 5.7 review some cases in which explicit conditions may still be given because these nonlinear conditions are consequences of the linear ones.

5.6. An explicit characterization of local FDEM1. Here, we translate the conditions on each Y_i, which lies in $\mathcal{G}$, into some conditions on its coefficients as a linear combination of $F_1, \ldots, F_m$. As noticed in §5.5, these conditions do not involve derivatives of these coefficients.

PROPOSITION 5.8. *The family $\mathcal{S}$ is locally FDEM1 if and only if there exists, around $(\bar{p}, \bar{x})$, some C^∞ functions a_i^s $(i = 1 \ldots l,\ s = 1 \ldots m)$ such that*

$$\left[\frac{\partial}{\partial p_i}, F_k\right] - \sum_{s=1}^{m} a_i^s \,[F_k, F_s] \in \mathcal{G}, \qquad \begin{array}{l} k = 0, 1, \ldots, m, \\ i = 1, \ldots, l, \end{array} \tag{129}$$

$$\sum_{s=1}^{m} a_i^s \left[\frac{\partial}{\partial p_j}, F_s\right] \in \mathcal{G}, \qquad \begin{array}{l} i, j = 1, \ldots, l \\ i \neq j. \end{array} \tag{130}$$

It is globally FDEM1 if and only if there exists some C^∞ functions a_i^s $(i = 1 \ldots l,$ $s = 1 \ldots m)$ defined on $\mathbb{R}^l \times M^n$, satisfying (129) and (130) on $\mathbb{R}^l \times M^n$, and such that the vector fields $\frac{\partial}{\partial p_i} + \sum_{s=1}^{m} a_i^s F_s$ are complete.

Proof. Use Theorem 5.3, and translate (90) into the fact that Y_i may be written as $\sum_{s=1}^{m} a_i^s F_s$. (91) reads (129) and (92) reads (130). The terms that would involve some Lie derivatives of the functions a_i^s may be dropped because they are in $\mathcal{G}$. □

If both the distribution spanned by the module $\mathcal{G}$ and the distribution spanned by the module $\mathcal{L}$ of parameter-preserving vector fields on $\mathbb{R}^l \times M^n$ defined by

$$\mathcal{L} \triangleq \left\{ X \in \mathcal{G} \,/\, [X, F_k] \in \mathcal{G},\ k = 0, 1, \ldots, m, \text{ and } \left[\frac{\partial}{\partial p_i}, X\right] \in \mathcal{G},\ i = 1, \ldots, l \right\} \tag{131}$$

have constant rank, we may translate (129) and (130) into some scalar equations and give some conditions for existence of the solutions a_i^s.

THEOREM 5.9. *Let $\mathcal{S} = (F_o, F_1, \ldots, F_m)$ be a family with $\mathcal{G}$ and $\mathcal{L}$ of constant rank around $(\bar{p}, \bar{x})$. $\mathcal{S}$ is locally FDEM1 at $(\bar{p}, \bar{x})$ if and only if the following property holds on a certain neighborhood of $(\bar{p}, \bar{x})$. Any set of $m + 1 + l$ differential forms of degree 1 on $\mathbb{R}^l \times M^n$ $\Omega_o, \Omega_1, \ldots, \Omega_m, \Omega_{m+1}, \ldots, \Omega_{m+l}$ that all vanish on $\mathcal{H}$ (i.e., vanish on $\mathcal{G}$ and have no* dp*-component):*

$$\langle \Omega_k, \mathcal{H} \rangle = 0, \qquad k = 0, 1, \ldots, m + l, \tag{132}$$

and satisfy, for any $s = 1, \ldots, m$,

$$\sum_{k=0}^{m} \langle \Omega_k, [F_k, F_s] \rangle + \sum_{j=1}^{l} \left\langle \Omega_{m+j}, \left[\frac{\partial}{\partial p_j}, F_s\right] \right\rangle = 0, \tag{133}$$

also satisfy, for any $i = 1, \ldots, l$,

$$\sum_{k=0}^{m} \left\langle \Omega_k, \left[\frac{\partial}{\partial p_i}, F_k\right] \right\rangle = 0. \tag{134}$$

In the case $l = 1$ (scalar parameter p), Ω_{m+1} can a priori be chosen zero.

Remark 5. Instead of using vector fields and differential forms on $I\!R^l \times M^n$, this could be formulated with families of vector fields and differential forms on M^n. Suppose that the parameterized families of distribution $\mathcal{g}$ and

$$\mathcal{L} = \left\{ f \in \mathcal{g} \,/\, [f, f_k] \in \mathcal{g},\ k = 0, 1, \ldots, m, \text{ and } \frac{\partial f}{\partial p_i} \in \mathcal{g},\ i = 1, \ldots, l \right\}$$

are of constant rank around $(\bar{p}, \bar{x})$. $\mathcal{S}$ is locally FDEM1 at $(\bar{p}, \bar{x})$ if and only if, on a certain neighborhood of $(\bar{p}, \bar{x})$, any $m + 1 + l$ parameterized families of 1-forms ω_o, $\omega_1, \ldots, \omega_m$, $\omega_{m+1}, \ldots, \omega_{m+l}$ that all vanish on $\mathcal{g}$ and satisfy, for $s = 1, \ldots, m$,

$$\sum_{k=0}^{m} \langle \omega_k\, ,\, [f_k, f_s] \rangle + \sum_{j=1}^{l} \left\langle \omega_{m+j}\, ,\, \frac{\partial f_s}{\partial p_j} \right\rangle = 0$$

also satisfy, for $i = 1, \ldots, l$, $\sum_{k=0}^{m} \langle \omega_k\, ,\, \frac{\partial f_k}{\partial p_i} \rangle = 0$.

Proof of Theorem 5.9. Necessity is obvious from Proposition 5.8. Let us prove sufficiency. (135) and (136) are equivalent to the vector fields $[\frac{\partial}{\partial p_i}, F_k] - \sum_{s=1}^{m} a_i^s [F_k, F_s]$ and $\sum_{s=1}^{m} a_i^s [\frac{\partial}{\partial p_j}, F_s]$ belonging to $\mathcal{H}$, because these vector fields cannot have a nonzero p-component, so they are in $\mathcal{G}$ if and only if they are in $\mathcal{H}$. $\mathcal{H}^o$, the annihilator of $\mathcal{H}$ ($\mathcal{H}^o$ is the set of 1-forms that vanish on all the F_k's and have no dp_i component) has constant rank, say $n - m'$ for a certain integer m'. Let $\overline{\Omega}_{m'+1}, \ldots, \overline{\Omega}_n$ be locally a basis of $\mathcal{H}^o$. (129) and (130) are equivalent to

$$\text{(135)}\quad \sum_{s=1}^{m} \langle\, \overline{\Omega}_q,\ [\, F_k\, ,\, F_s\,]\, \rangle\, a_i^s = \left\langle\, \overline{\Omega}_q\, ,\ \left[\, \frac{\partial}{\partial p_i}\, ,\, F_k \right] \right\rangle, \qquad \begin{array}{l} q = m' + 1\, , \ldots,\, n, \\ k = 0,\, 1\, , \ldots,\, m, \\ i = 1, \ldots, l, \end{array}$$

$$\text{(136)}\qquad \sum_{s=1}^{m} \left\langle\, \overline{\Omega}_q\, ,\ \left[\, \frac{\partial}{\partial p_j}\, ,\, F_s \right] \right\rangle a_i^s = 0, \qquad \begin{array}{l} q = m' + 1\, , \ldots,\, n, \\ i, j = 1, \ldots, l,\ j \neq i. \end{array}$$

Let us fix i. (135)–(136) is a linear system in $a_i^1, \ldots, a_i^m$. The condition of the theorem states (the Ω_k's are linear combinations of $\overline{\Omega}_{m'+1}, \ldots, \overline{\Omega}_n$) that whenever a linear combination of the left-hand sides of this system is identically zero (i.e., independently of $a_i^1, \ldots, a_i^m$), the same linear combination of the right-hand sides is also zero. This is a classical characterization of the existence of solutions for linear systems.

In the case $l = 1$, there is no equation in (136), so that, in the linear combinations, there will be no form corresponding to this equation. □

5.7. Some cases in which FDEM1 and FDEM2 are equivalent. We now consider the two particular cases when the control distributions are known either to be integrable or to be independent of the parameter. $\mathcal{L}$ is still defined by (131).

THEOREM 5.10. *Suppose that the module $\mathcal{G}$ is invariant by $\frac{\partial}{\partial p_1}, \ldots, \frac{\partial}{\partial p_l}$ (i.e., the control module does not depend on the parameter). Let $\mathcal{K}$ be defined by*

$$\text{(137)}\qquad \mathcal{K} \ \triangleq\ \{ X \in \mathcal{G} \,/\, [X, \mathcal{G}] \subset \mathcal{G} \}.$$

FDEM1 and FDEM2 are equivalent and are both locally equivalent to

$$\text{(138)}\qquad \left[\frac{\partial}{\partial p_i}\, ,\, F_o \right], \in \mathcal{G}\ +\ [\, F_o\, ,\, \mathcal{K}], \quad i = 1, \ldots, l.$$

THEOREM 5.11. *Suppose that the module $\mathcal{G}$ is stable under the Lie bracket. Then FDEM1 and FDEM2 are equivalent, and they are both equivalent locally to*

$$\left[\frac{\partial}{\partial p_i}, \mathcal{G}\right] \subset \mathcal{G}, \quad i = 1, \ldots, l; \tag{139}$$

$$\left[\frac{\partial}{\partial p_i}, F_o\right] \in \mathcal{G} + [F_o, \mathcal{G}], \quad i = 1, \ldots, l. \tag{140}$$

Remark 6. This theorem gives, as a particular case, the result stated in [5], [4], saying that, if all the systems $\mathcal{S}_p$ are fully feedback linearizable and the dependence on p is linear, then a sufficient condition for the linearizing coordinates to satisfy a condition similar to the one φ satisfies in FDEM1 is that $\mathcal{g}$ be independent of p (this is (139)) and that

$$\frac{\partial f_o}{\partial p_i} \;\in\; \mathcal{g} + [f_o, \mathcal{g}], \quad i = 1, \ldots, l, \tag{141}$$

which is (140) (linearity in p implies that $\frac{\partial f_o}{\partial p_i}$ is a vector field independent of p).

Proof of Theorem 5.10. If $\mathcal{G}$ is invariant by $\frac{\partial}{\partial p_1}, \ldots, \frac{\partial}{\partial p_l}$, then, from the lemma given in the appendix, there exists an invertible matrix $\beta(p, x)$ such that $g(\bar{p}, x) = g(p, x)\beta(p, x)$. Then FDEM1 implies FDEM2 since (80) implies (81) with

$$v_2(p, q, x, \dot{p}) = \beta(q, x)\,\beta(p, x)^{-1}\,v_1(p, x, \dot{p}).$$

Since FDEM2 always implies FDEM1 (see Remark 2), this proves the equivalence between FDEM1 and FDEM2 in this case (FDEM1⇒FDEM2 can be seen as a consequence of Theorems 5.3 and 5.6 and the fact that, since $\mathcal{G}$ is invariant by $\frac{\partial}{\partial p_1}, \ldots, \frac{\partial}{\partial p_l}$, we have $\mathcal{G}^{\cap} = \mathcal{G}$). Let us use Theorem 5.3 to prove that they are equivalent to (138). Clearly (90) and (91) imply that Y_i is in $\mathcal{K}$ (because $[\frac{\partial}{\partial p_i}, F_k] \in \mathcal{G}$, $k = 1, \ldots, m$) and then imply (138) (using (91) for $k = 0$). Conversely, the fact that $\mathcal{G}$ is invariant by $\frac{\partial}{\partial p_1}, \ldots, \frac{\partial}{\partial p_l}$ implies that (92) and (91) for $k \neq 0$ are satisfied by any Y_i in $\mathcal{K}$. (138) exactly means the existence of a Y_i in $\mathcal{K}$ satisfying (91) for $k = 0$. □

Proof of Theorem 5.11. If $\mathcal{G}$ is a Lie algebra, FDEM1 implies (139)–(140) since (90), (91) and $[\mathcal{G}, \mathcal{G}] \subset \mathcal{G}$ obviously imply (139), i.e., invariance of $\mathcal{G}$ by $\frac{\partial}{\partial p_1}, \ldots, \frac{\partial}{\partial p_l}$ and, from Theorem 5.10, FDEM1 plus invariance of $\mathcal{G}$ imply (138), which is equivalent, since $\mathcal{K} = \mathcal{G}$, to (140).

If $\mathcal{G}$ is a Lie algebra, (139)–(140) imply FDEM2 from Theorem 5.10 because (139) means that $\mathcal{G}$ is invariant by $\frac{\partial}{\partial p_1}, \ldots, \frac{\partial}{\partial p_l}$ and, since $\mathcal{K} = \mathcal{G}$, (138) is equivalent to (140).

FDEM2 implies FDEM1 in general (see (82)). □

5.8. An explicit characterization of local FDEM2 in some particular cases. To simplify our discussion, we suppose here that $\mathcal{G}$ spans a distribution of constant rank; $\mathcal{G}^{\cap, U}$ does not depend on the open set U, so that we can write simply $\mathcal{G}^{\cap}$; and the distribution spanned by this module $\mathcal{G}^{\cap}$ also has constant rank.

We will not be able to give an explicit necessary and sufficient condition for FDEM2 in general. This paragraph only gives a characterization in the case when the parameter is one dimensional ($l = 1$) and in the case when either the rank of the distribution $\mathcal{G}^{\cap}$ or the difference between this rank and the rank of $\mathcal{G}$ is small.

If l is 1, Theorem 5.6 contains no commutation relation, and we may therefore write a condition for the set of linear algebraic equations defining the coefficients of Z_1 to have a solution.

THEOREM 5.12. *Let $\mathcal{S} = (F_o, F_1, \ldots, F_m)$ be a family of systems depending on one parameter only (i.e., $l = 1$). Suppose that $\mathcal{G}$, $\mathcal{G}^\cap$, and $\mathcal{G}^\cap \cap \mathcal{L}$ ($\mathcal{L}$ is defined in* (131)) *span some constant rank distributions around $(\bar{p}, \bar{x})$. In particular, locally, some vector fields $G_1^\cap, \ldots, G_r^\cap$ span $\mathcal{G}^\cap$:*

$$\mathcal{G}^\cap = \text{Span}\,\{ G_1^\cap, \ldots, G_r^\cap \}. \tag{142}$$

The family $\mathcal{S}$ is locally FDEM2 at $(\bar{p}, \bar{x})$ if and only if the following property holds on a certain neighborhood of $(\bar{p}, \bar{x})$: any $m+1$ 1-forms on $I\!R^l \times M^n$ $\Omega_o, \Omega_1, \ldots, \Omega_m$ that vanish on $\mathcal{H}$ (i.e., vanish on $\mathcal{G}$ and have no dp*-component) and satisfy*

$$\sum_{k=0}^{m} \langle\, \Omega_k\,,\, [F_k, G_s^\cap]\,\rangle = 0, \qquad s = 1, \ldots, r, \tag{143}$$

also satisfy

$$\sum_{k=0}^{m} \left\langle\, \Omega_k\,,\, \left[\frac{\partial}{\partial p_i}, F_k\right] \right\rangle = 0, \quad i = 1. \tag{144}$$

Proof of Theorem 5.12. This condition is equivalent to the existence of some $\mathcal{C}^\infty$ functions a^s such that

$$\left[\frac{\partial}{\partial p}\,,\, F_k\right] - \sum_{s=1}^{m} a^s [\, F_k\,,\, G_s^\cap\,] \in \mathcal{G}, \qquad k = 0, 1, \ldots, m \tag{145}$$

(see the proof of Theorem 5.9), which is in turn equivalent to the conditions in Theorem 5.6, since (107) is automatically satisfied when $l = 1$. □

When $l > 1$, no such theorem holds in general, since the commutation relations required in Theorem 5.6 cannot be removed; see counterexample (118)–(119) in §5.4. However, in some situations, as illustrated by the following theorem, these commutation conditions may be implied by the others.

THEOREM 5.13. *Let $\mathcal{S} = (F_o, F_1, \ldots, F_m)$ be a family of systems. Suppose that $\mathcal{G}$, $\mathcal{G}^\cap$, $\mathcal{L}$, and $\mathcal{G}^\cap \cap \mathcal{L}$ ($\mathcal{L}$ is defined in* (131)) *span some constant rank distributions around $(\bar{p}, \bar{x})$. Suppose also that*

- *either $\mathcal{G}^\cap$ is integrable,*
- *or* Rank $\mathcal{G}^\cap \leq 3$,
- *or* Rank $\mathcal{G}$ − Rank $\mathcal{G}^\cap \leq 1$.

Then one can remove the commutation relations in Theorem 5.6. *As a consequence, in these same cases, Theorem* 5.12 *is valid even for $l > 1$.*

Proof. The last line is a consequence of the first part because the conditions in Theorem 5.12 are equivalent to the condition (105)–(106) (without the commutation relation (107)) in Theorem 5.6. Let us prove the first part of the theorem. The conditions of Theorem 5.6 obviously remain necessary if we *remove* (107). It remains to prove that they remain sufficient in the cases quoted in the theorem.

By Theorem 5.7, it is enough to prove that the module $\mathcal{J}^U$ defined by (115) is stable under the Lie bracket. Let us denote by $\mathcal{J}^U$ as well the distribution spanned by the module $\mathcal{J}^U$. Since (105) and (106) imply that $\frac{\partial}{\partial p_i} + Z_i \in \mathcal{J}^U$ and $\mathcal{L} \cap \mathcal{G}^\cap$

contains exactly all the vector fields in $\mathcal{J}$ with a zero p-component, we have $\mathcal{J}^U = (\mathcal{L} \cap \mathcal{G}^\cap) \oplus \mathrm{Span}\{\frac{\partial}{\partial p_1} + Z_1, \ldots, \frac{\partial}{\partial p_l} + Z_l\}$ and therefore $\mathcal{J}^U$ does not depend on U—we shall write simply $\mathcal{J}$—and has constant rank $l + \mathrm{Rank}\,\mathcal{L} \cap \mathcal{G}^\cap$. All we have to check is that the distribution $\mathcal{J}$ is involutive. This is the case in all but one of the cases considered in the theorem:

- If $\mathcal{G}^\cap$ itself is involutive, then $\mathcal{J}$ is equal to $\mathcal{G}^\cap$.
- If $\mathcal{G}^\cap$ has rank 1, we are in the previous case.
- If $\mathcal{G}^\cap$ has rank 2, then the rank of $\mathcal{J}$ is either 0 or 1 or 2. In the two first cases, it is obviously involutive and in the last one, it is involutive as well since then $\mathcal{J} = \mathcal{G}^\cap$, so that $[\mathcal{G}^\cap, \mathcal{G}^\cap] \subset \mathcal{G}$, which implies $[\mathcal{G}^\cap, \mathcal{G}^\cap] \subset \mathcal{G}^\cap$ since $[\mathcal{G}^\cap, \mathcal{G}^\cap]$ is invariant under the $\frac{\partial}{\partial p_i}$'s and $\mathcal{G}^\cap$ is the largest subdistribution of $\mathcal{G}$ invariant by the $\frac{\partial}{\partial p_i}$'s.
- If $\mathcal{G}^\cap$ has rank 3, then the rank of $\mathcal{J}$ is either 0 or 1 or 2 or 3. We may conclude as above if it is 0, 1, or 3 (if it is 3, $\mathcal{J} = \mathcal{G}^\cap$). It cannot be 2 because if G_1, G_2, G_3 are three vector fields locally spanning $\mathcal{G}^\cap$, then $\lambda_1 G_1 + \lambda_2 G_2 + \lambda_3 G_3$ is in $\mathcal{J}$ if and only if $(\lambda_1, \lambda_2, \lambda_3)$ is in the kernel of a certain number of skew symmetric matrices; the rank of the corresponding system in $\lambda_1, \lambda_2, \lambda_3$ cannot be 1 because the ranks of all these matrices are even.

In the last case ($\mathrm{Rank}\,\mathcal{G} - \mathrm{Rank}\,\mathcal{G}^\cap \leq 1$), $\mathcal{J}$ is not involutive in general. If $\mathrm{Rank}\,\mathcal{G} - \mathrm{Rank}\,\mathcal{G}^\cap = 0$, then $\mathcal{G} = \mathcal{G}^\cap$, so $\mathcal{G}$ is invariant under the vector fields $\frac{\partial}{\partial p_i}$ and one may conclude using Theorem 5.10. If $\mathrm{Rank}\,\mathcal{G} - \mathrm{Rank}\,\mathcal{G}^\cap = 1$, then it is possible to find, locally, some vector fields $G_1, \ldots, G_m$ such that

$$\begin{aligned} \mathcal{G} &= \mathrm{Span}\,\{G_1, \ldots, G_m\}, \\ \mathcal{G}^\cap &= \mathrm{Span}\,\{G_1, \ldots, G_{m-1}\}, \\ \mathcal{J} &= \mathrm{Span}\,\{G_1, \ldots, G_r\} \end{aligned} \tag{146}$$

where $r \leq m - 1$. Consider the module

$$\mathcal{J}_1 = \{\, X \in \mathcal{G}^\cap \,/\, [X, \mathcal{G}] \subset \mathcal{G} \,\}. \tag{147}$$

It is obvious from the definitions that $\mathcal{J}_1 \subset \mathcal{J}$. We distinguish two cases depending on whether this inclusion is strict or not:

- If $\mathcal{J}_1 = \mathcal{J}$, then $\mathcal{J}$ is involutive: for $j \leq r$ and $k \leq r$, let us prove that $[G_j, G_k]$ is in $\mathcal{J}$. First of all it is in $\mathcal{G}$ because G_j is in $\mathcal{J}$ and G_k is in $\mathcal{G}$ (see definition of $\mathcal{J}$). Now, $[\frac{\partial}{\partial p_i}, [G_j, G_k]]$ is in $\mathcal{G}$ because, from Jacobi identity, $[\frac{\partial}{\partial p_i}, [G_j, G_k]] = [G_j, [\frac{\partial}{\partial p_i}, G_k]] + [G_k, [\frac{\partial}{\partial p_i}, G_j]]$ where $[\frac{\partial}{\partial p_i}, G_k]$ and $[\frac{\partial}{\partial p_i}, G_j]$ are in $\mathcal{G}^\cap$ (G_k and G_j are in $\mathcal{G}^\cap$, which is invariant under $\frac{\partial}{\partial p_i}$). On the other hand, since $[G_j, G_k]$ is in $\mathcal{G}$, there exist some functions $\lambda_{kl}^1, \ldots, \lambda_{kl}^m$ such that

$$[G_j, G_k] = \sum_{s=1}^{m} \lambda_{kl}^s G_s, \tag{148}$$

and therefore

$$\left[\frac{\partial}{\partial p_i}, [G_j, G_k]\right] = \sum_{s=1}^{m} \frac{\partial \lambda_{kl}^s}{\partial p_i} G_s + \sum_{s=1}^{m} \lambda_{kl}^s \left[\frac{\partial}{\partial p_i}, G_s\right] \in \mathcal{G}. \tag{149}$$

This implies that the coefficient λ_{kl}^m is identically zero because $[\frac{\partial}{\partial p_i}, G_m] \notin \mathcal{G}$ (otherwise $\mathcal{G} = \mathcal{G}^\cap$) and all the other terms are in $\mathcal{G}$. This proves that $[G_j, G_k] \in \mathcal{G}^\cap$. We have now to check that $[[G_j, G_k], \mathcal{G}^\cap] \subset \mathcal{G}$: let Y be in $\mathcal{G}^\cap$, we have (Jacobi identity)

$$[\,[G_j, G_k]\,, Y\,] = [G_j, [G_k, Y]] \; - \; [G_k, [G_j, Y]],$$

which is in $\mathcal{G}$ because $[G_k, Y]$ and $[G_j, Y]$ are in $\mathcal{G}$ and G_j and G_k are in $\mathcal{J}_1 = \mathcal{J}$.

- If $\mathcal{J} \neq \mathcal{J}_1$ we shall use the following fact: condition 2 in Theorem 5.7 is also sufficient for FDEM2 if we replace the module $\mathcal{J}^U$ with $\mathcal{M}_1$:

$$\mathcal{M}_1 = \{ X \in \mathcal{H}^\cap / [X, \mathcal{H}] \subset \mathcal{H} \}. \tag{150}$$

The proof is simpler than the proof of 2 in Theorem 5.7, replacing $\mathcal{M}$ with $\mathcal{M}_1$. Here, $\mathcal{M}_1$ is finitely generated because $\mathcal{M}_1 = \mathcal{L} \oplus \text{Span}\{\frac{\partial}{\partial p_1} + Y_1, \ldots, \frac{\partial}{\partial p_l} + Y_l\}$, where the vector fields Y_i are those satisfying (105) and (106), and it is stable under the Lie bracket because the module

$$\mathcal{M}_2 = \{ X \in \mathcal{H} / [X, \mathcal{H}] \subset \mathcal{H} \} \tag{151}$$

is naturally stable under the Lie bracket; to conclude the proof, we establish that $\mathcal{M}_1 = \mathcal{M}_2$. Since the inclusion $\mathcal{J} \subset \mathcal{J}_1$ is strict, there is a nonzero vector field Y_o in $\mathcal{J}$ that is not in $\mathcal{J}_1$, i.e.,

$$Y_o \in \mathcal{J} \ ; \ [Y_o, G_m] \notin \mathcal{G}. \tag{152}$$

Then, let X be in $\mathcal{M}_2$; since it is in $\mathcal{H}$, it may be written

$$X = \sum_1^l \mu_i \frac{\partial}{\partial p_i} + \sum_1^m \nu_k G_k, \tag{153}$$

and we have

$$[X, Y_o] = \left[\sum_{i=1}^l \mu_i \frac{\partial}{\partial p_i}, Y_o \right] + \sum_{k=1}^m \nu_k [G_k, Y_o] - \sum_{k=1}^m (L_{Y_o} \nu_k) G_k$$

where the left-hand side is in $\mathcal{H}$ because X is in $\mathcal{M}_2$ and Y_o is in $\mathcal{J} \subset \mathcal{H}$, and the only term in the right-hand side that is not naturally in $\mathcal{H}$ is $\nu_m[G_m, Y_o]$; from (152), this implies than the coefficient ν_m is zero and, from (153), that X is in $\mathcal{M}_1$. We have proved that $\mathcal{M}_2 \subset \mathcal{M}_1$; $\mathcal{M}_1 \subset \mathcal{M}_2$ is obvious from (150) and (151). □

5.9. Explicit calculation of the transformations on an example. Here, we continue to work out example (118)–(119) and calculate explicitly the transformations. As seen previously, the family of systems described in (118)–(119) is not FDEM2. It is, however, globally FDEM1 from Theorem 5.3 because the Y_i's computed in (126)–(127) are in $\mathcal{G}^\cap$ and therefore satisfy (92). Let us compute the corresponding α and β. The flows ϕ_1 and ϕ_2 of vector fields $\frac{\partial}{\partial p_1} + Y_1$ and $\frac{\partial}{\partial p_2} + Y_2$ are

$$\phi_1^t(p,x) = (p_1 + t,\ p_2,\ x_1,\ x_2 - t x_6,\ x_3,\ x_4,\ x_5 + (p_1 + x_7)t,\ x_6,\ x_7 - t,\ x_8), \tag{154}$$

$$\begin{aligned} \phi_2^t(p,x) = (&p_1,\ p_2 + t,\ x_1 - t x_5 (p_2 + x_8),\ x_2,\ x_3 + t x_5,\ x_4 + t x_7, \\ &x_5,\ x_6 + t(p_2 + x_8),\ x_7,\ x_8 - t\ ), \end{aligned} \tag{155}$$

so computing φ according to (56), choosing $\bar{p} = 0$, gives

$$\begin{aligned} \varphi(p,x) = (\,&x_1 + p_2 x_5 (p_2 + x_8)\,,\ x_2 + p_1 [x_6 - p_2(p_2 + x_8)]\,,\ x_3 - p_2 x_5\,, \\ &x_4 + p_2 x_7\,,\ x_5 - p_1(p_1 + x_7)\,,\ x_6 - p_2(p_2 + x_8)\,,\ x_7 + p_1\,,\ x_8 + p_2). \end{aligned} \tag{156}$$

This φ transforms the family $\mathcal{S}$ into $\widetilde{\mathcal{S}}$ described by

$$\begin{aligned}
\dot\xi_1 &= p_2(\xi_5+p_1\xi_7)u_1-(\xi_5+p_1\xi_7)u_3+p_2\xi_8u_4 \\
&\quad -\xi_7\xi_8u_5-\xi_8u_6-\xi_7u_7, \\
\dot\xi_2 &= u_7-p_1p_2u_1+(\xi_6+p_2\xi_8)u_2-p_1u_3, \\
\dot\xi_3 &= u_6-(\xi_5+p_1\xi_7)u_1-p_2u_4, \\
\dot\xi_4 &= u_5-(\xi_7-p_1)u_1,
\end{aligned}
\qquad
\begin{aligned}
\dot\xi_5 &= u_4-p_1u_2, \\
\dot\xi_6 &= u_3-p_2u_1, \\
\dot\xi_7 &= u_2, \\
\dot\xi_8 &= u_1
\end{aligned}$$

(with $\xi=\varphi(p,x)$). $\widetilde{\mathcal{S}}$ is FE, the feedback defined by the following α and β, turning it into a constant family:

$$\alpha(p,\xi)=0;\quad \beta(p,\xi)=\begin{pmatrix} 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ p_2 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & p_1 & 0 & 1 & 0 & 0 & 0 \\ p_1 & p_2 & 0 & 0 & 1 & 0 & 0 \\ p_1\xi_7 & p_1p_2 & 0 & p_2 & 0 & 1 & 0 \\ 0 & -p_2\xi_8 & -p_1 & 0 & 0 & 0 & 1 \end{pmatrix}. \tag{157}$$

A simple computation allows one to compute explicitly $\frac{\partial\varphi}{\partial x}^{-1}\frac{\partial\varphi}{\partial p_1}$ and $\frac{\partial\varphi}{\partial x}^{-1}\frac{\partial\varphi}{\partial p_2}$ and to express them as a linear combination of $F_1\ldots F_7$, i.e., φ, defined by (156), that satisfies (80) with $v_1(p,\dot p,x)$ given by

$$v_1(p,\dot p,x)=\begin{pmatrix} -\dot p_2 \\ -\dot p_1 \\ (p_2+x_8)\dot p_2 \\ (p_1+x_7)(\dot p_1+\dot p_2) \\ \dot p_1 \\ -(p_1+x_7)\dot p_1 \\ -(p_2+x_8)\dot p_1 \end{pmatrix}; \tag{158}$$

hence, FDEM1 is met.

6. The case of nonaffine systems.

The previous sections are devoted only to systems that are affine in the control u. We now consider more general systems. Being pure feedback equivalent (FE) or feedback and diffeomorphism equivalence (FDE) is quite meaningful for a parameterized family of nonaffine systems. We give some generalizations of the main results on FE and FDE.

Let us consider the family Σ of systems parameterized by $p\in\mathbb{R}^l$ where the system corresponding to a certain value of p is Σ_p described by

$$\dot x = f(p,x,u). \tag{159}$$

Equivalence (FDE or FE) will have exactly the same meaning as for affine systems, except we cannot restrict the feedback transformation to be affine in the control, and the diffeomorphism acts on the "multi-vector field f" instead of acting separately on the vector fields $f_0,\ldots,f_m$ in the affine-in-the-control case.

DEFINITION 6.1. • *A family Σ of systems is* constant *on an open subset U of $\mathbb{R}^l\times M^n$ if, for all x, p^1, and p^2 such that (p^1,x) and (p^2,x) are in U and any u in $\mathbb{R}^m$ we have*

$$f(p^1,x,u)=f(p^2,x,u). \tag{160}$$

- *A family* Σ *is* FE (pure feedback equivalent) *on an open subset* U *of* $\mathbb{R}^l \times M^n$ *if there exists a* C^∞ *map*

$$\gamma : \; U \times \mathbb{R}^m \longrightarrow \mathbb{R}^m,$$

such that for any (p, x) *the map* $u \mapsto \gamma(p, x, u)$ *is a diffeomorphism of* $\mathbb{R}^m$ *and the family* $\widetilde{\Sigma}$ *defined by*

$$\widetilde{f}(p, x, v) = f(p, x, \gamma(p, x, v)) \tag{161}$$

is constant on U. Σ *is locally FE at* $(\bar{p}, \bar{x})$ *if it is FE on a certain open neighborhood* U *of* $(\bar{p}, \bar{x})$ *in* $\mathbb{R}^l \times M^n$. *It is globally FE if it is FE on* $\mathbb{R}^l \times M^n$.

- *A family* Σ *is locally* FDE (feedback and diffeomorphism equivalent) *at* $(\bar{p}, \bar{x})$ *if and only if there exists a neighborhood* U *of* $(\bar{p}, \bar{x})$ *and a map*

$$\psi : \; U \times \mathbb{R}^m \longrightarrow \mathbb{R}^m$$

such that for any (p, x) *the map* $x \mapsto \psi(p, x, u)$ *is a diffeomorphism from* $U \times \mathbb{R}^l$ *to its image and the family* $\widetilde{\Sigma}$, *defined in* $\psi(U \times \mathbb{R}^l)$ *by*

$$\widetilde{f} = \psi_* f, \tag{162}$$

is locally FE at $(\bar{p}, \varphi(\bar{p}, \bar{x}))$. *It is globally FDE if and only if* ψ *is defined all over* $\mathbb{R}^l \times M^n$ *and the family* $\widetilde{\Sigma}$ *defined on* $\mathbb{R}^l \times M^n$ *by* (162) *is globally FE.*

To a given (non-necessarily-affine) parameterized family of systems Σ on M^n with m controls, we may associate a parameterized family of affine systems, just adding an integrator to each control, so that the new controls appear obviously linearly. Precisely, to Σ, we associate $\mathcal{S} = \mathcal{A}(\Sigma)$, where the system $\mathcal{S}_p$ is defined by

$$\left\{ \begin{array}{rcl} \dot{x} & = & f(p, x, z), \\ \dot{z} & = & v. \end{array} \right. \tag{163}$$

Equivalently, the corresponding parameter-preserving family of systems on $\mathbb{R}^l \times M^n \times \mathbb{R}^m$ is defined by

$$\begin{array}{l} F_0(p, X) = (0, f(p, X), 0), \\ F_1 = \frac{\partial}{\partial z_1}, \ldots, F_m = \frac{\partial}{\partial z_m}. \end{array} \tag{164}$$

We have the following obvious properties as a consequence of the fact that $\mathcal{A}(\Sigma)$ is a particular family of systems (control vector fields independent of the parameter; see also Theorem 5.10).

PROPOSITION 6.2. *The family* $\mathcal{S} = \mathcal{A}(\Sigma)$ (*for any family* Σ) *is constant* (*locally/globally*) *if and only if it is FE* (*locally/globally*). *The family* Σ *is constant* (*locally/globally*) *if and only if* $\mathcal{S} = \mathcal{A}(\Sigma)$ *is constant or FE* (*locally/globally*). *The family* $\mathcal{S} = \mathcal{A}(\Sigma)$ (*for any family* Σ) *is FDEM*1 (*locally/globally*) *if and only if it is FDEM*2 (*locally/globally*).

It has already been noticed, in [3] for example, that the classification of general control systems is equivalent to the classification of affine-in-the-control systems with a control distribution of constant rank. This is the same for *families* of systems. More precisely, we also have the following two properties, the first of which is the "parametric" counterpart of the remark made in [3] and the second of which relates the property FE for a nonaffine family Σ to the notion of feedback equivalence with matching that we have developed for affine-in-the-control systems. The (elementary) proof of these propositions is given further.

PROPOSITION 6.3. *The family Σ is FDE (locally/globally) if and only if the family $\mathcal{S} = \mathcal{A}(\Sigma)$ is FDE (locally/globally).*

PROPOSITION 6.4. *The family Σ is FE (locally/globally) if and only if the family $\mathcal{S} = \mathcal{A}(\Sigma)$ is FDEM1 or FDEM2 (locally/globally).*

For the sake of ease of notation, we define F such that, for any u, $(p,x) \mapsto F(p,x,u)$ is the parameter-preserving vector field on $\mathbb{R}^l \times M^n$ (as intended in §1) defined by $F(p,x,u) = (0, f(p,x,u))$. Since for a fixed (p,x) $F(p,x,u)$ stays in the same tangent space, the "derivative" $\frac{\partial F}{\partial u_k}$ can be defined in the same way as the derivative with respect to parameters of a parameterized family of vector fields (see §2.4); $\frac{\partial F}{\partial u_k}$ is, for any fixed u, a parameter-preserving vector field on $\mathbb{R}^l \times M^n$.

The following two theorems give some characterizations of FE and FDE for a family of nonaffine systems. They are easy consequences of Theorems 4.2 and 5.3 and the above propositions. The proof of Theorem 6.6 is omitted (use Theorem 4.2 with $Y_i = (X_i, \sum_{j=1}^k a_i^j \frac{\partial}{\partial z_j})$).

THEOREM 6.5. *The family of systems Σ is locally FE at $(\bar{p},\bar{x})$ if the following relation is true for any u in $\mathbb{R}^m$ and for (p,x) in a neighborhood of $(\bar{p},\bar{x})$ (resp., if it is true for any u in $\mathbb{R}^m$ and any (p,x) in $\mathbb{R}^l \times M^n$):*

$$\left[\frac{\partial}{\partial p_i}, F\right] \in \operatorname{Span}\left\{\frac{\partial F}{\partial u_1}, \dots, \frac{\partial F}{\partial u_m}\right\}, \quad i = 1, \dots, l, \tag{165}$$

where Span$\{\frac{\partial F}{\partial u_1}, \dots, \frac{\partial F}{\partial u_m}\}$ *denotes the module over smooth functions of (p,x,u) generated by $\frac{\partial F}{\partial u_1}, \dots, \frac{\partial F}{\partial u_m}$. It is globally FE if relation* (165) *is true everywhere and if it is possible to chose the coefficients $a_i^1, \dots, a_i^m$ in the module such that the vector fields $\frac{\partial}{\partial p_i} + a_i^1 \frac{\partial}{\partial z_1} + a_i^m \frac{\partial}{\partial z_m}$ are complete.*

Proof of Theorem 6.5. From Proposition 6.4, all we have to prove is that the given condition is necessary and sufficient for $\mathcal{S} = \mathcal{A}(\Sigma)$ to be locally/globally FDEM1. For the family of systems $\mathcal{S}$, the module $\mathcal{G}$ is that generated by the vector fields $\frac{\partial}{\partial z_k}$. From Theorem 5.3, a condition for $\mathcal{S}$ to be FDEM1 is that there exists some functions a_i^j such that

$$\left[\frac{\partial}{\partial p_i} + a_i^1 \frac{\partial}{\partial z_1} + \cdots + a_i^m \frac{\partial}{\partial z_m}, F_k\right] \in \operatorname{Span}\left\{\frac{\partial}{\partial z_1}, \dots, \frac{\partial}{\partial z_m}\right\}, \tag{166}$$

where the F_k's are those defined in (164). The relation for $k = 1, \dots, m$ are automatically satisfied. The relation for $k = 0$ is equivalent to the left-hand side having a zero x-component; it is simple to prove that this is exactly equivalent to (165) (the a_i^j's are the coefficients in the module Span$\{\frac{\partial F}{\partial u_1}, \dots, \frac{\partial F}{\partial u_m}\}$). The completeness condition for global FE is exactly that for global FDEM1 in Theorem 5.3. □

THEOREM 6.6. *The family of systems Σ is locally FDE at $(\bar{p},\bar{x})$ if there exists some parameter-preserving vector fields $X_1, \dots, X_l$ on a neighborhood of $(\bar{p},\bar{x})$ in $\mathbb{R}^l \times M^n$, such that the following relation is true for any u in $\mathbb{R}^m$ and for (p,x) in a neighborhood of $(\bar{p},\bar{x})$:*

$$\left[\frac{\partial}{\partial p_i} + X_i, F\right] \in \operatorname{Span}\left\{\frac{\partial F}{\partial u_1}, \dots, \frac{\partial F}{\partial u_m}\right\}, \quad i = 1, \dots, l. \tag{167}$$

It is globally FDE if the parameter-preserving vector fields $X_1, \dots, X_l$ are defined all over $\mathbb{R}^l \times M^n$, (167) *is true for any u in $\mathbb{R}^m$ and any (p,x) in $\mathbb{R}^l \times M^n$, and it is* *possible to choose the coefficients* $a_i^1, \ldots, a_i^m$ *in the module such that the vector fields* $\frac{\partial}{\partial p_i} + X_i + a_i^1 \frac{\partial}{\partial z_1} + a_i^m \frac{\partial}{\partial z_m}$ *are complete.*

Remarks. 1. Note that X_i does not depend on u: relation (167) has to be satisfied for any u with the same X_i.

2. Of course, Theorem 4.2 is a consequence of Theorem 6.6 in the particular case where the systems are affine in the control, i.e.,

$$f(p, x, u) \quad = \quad f_o(p, x) + u_1 f_1(p, x) + \cdots + u_m f_m(p, x)$$

since in this case $\frac{\partial F}{\partial u_k}(p, x, u)$ is $F_i(p, x)$, and the fact that (167) is true for any u implies it is true separately for all the F_k's, which are independent of u. Therefore (55) is satisfied. The completeness conditions do not involve the $\frac{\partial}{\partial z_k}$ parts of the vector fields because it is always possible to choose the coefficients linear in z in the affine case (see the lemma given in the appendix).

Proof of Proposition 6.4. If Σ is (locally/globally) FE and γ is the corresponding family of feedback transformations, let us define φ by

$$\varphi(p, X) = \varphi(p, x, z) = \left(x \, , \, \gamma^{-1}(p, x, z) \right) , \tag{168}$$

where γ^{-1} means inverting γ with respect to z only:

$$\gamma^{-1}(\, p \, , \, x \, , \, \gamma(p, x, z) \,) = \gamma(\, p \, , \, x \, , \, \gamma^{-1}(p, x, z) \,) \equiv z. \tag{169}$$

The family of diffeomorphisms φ transforms the family of systems $\mathcal{S}$, described by (163), into

$$\left\{ \begin{array}{lcl} \dot{\xi} & = & f(p, \xi, \gamma(p, \xi, \zeta)), \\ \dot{\zeta} & = & \sum_{k=1}^{m} \frac{\partial \gamma^{-1}}{\partial z_k}(p, x, z) \, v_k \end{array} \right. \tag{170}$$

($\xi = x$, $\zeta = \gamma^{-1}(p, x, z)$), which is FE (locally/globally) from Theorem 3.4 since by assumption $f(p, \xi, \gamma(p, \xi, \zeta))$ does not depend on p, and the module $\widetilde{\mathcal{G}}$ is spanned by $\frac{\partial}{\partial z_1} \cdots \frac{\partial}{\partial z_m}$ because the matrix of the $\frac{\partial \gamma^{-1}}{\partial z_k}(p, x, z)$'s is invertible (for $z \mapsto \gamma^{-1}(p, x, z)$ is a diffeomorphism). In addition, φ satisfies the additional property (80) required for FDEM1, simply taking

$$v_1(p, x, z, \dot{p}) = \beta(p, x, z) \frac{\partial \gamma^{-1}}{\partial p}(p, x, z) \dot{p}$$

where $\beta(p, x, z)$ is the inverse of the matrix whose kth column is $\frac{\partial \gamma^{-1}}{\partial z_k}(p, x, z)$.

Conversely, if $\mathcal{S}$ is (locally/globally) FDEM1, let φ be a family of diffeomorphisms, transforming $\mathcal{S}$ into the FE family $\widetilde{\mathcal{S}}$. Since the affine-in-the-control family $\widetilde{\mathcal{S}}$ is FE, we have, from Theorem 3.4 and (164),

$$\varphi_* \frac{\partial}{\partial z_k} \in \operatorname{Span} \left\{ \frac{\partial}{\partial z_1}, \ldots, \frac{\partial}{\partial z_m} \right\}, \quad k = 1, \ldots, m \ , \tag{171}$$

which implies that the x component of φ does not depend on z. In addition, φ satisfies the property (80), which implies

$$\frac{\partial \varphi}{\partial z_k} \quad \in \quad \operatorname{Span} \left\{ \frac{\partial}{\partial z_1}, \ldots, \frac{\partial}{\partial z_m} \right\}, \quad k = 1, \ldots, m, \tag{172}$$

i.e., that the x component of φ does not depend on p either. Altogether, we have

$$\varphi(p,X)=\varphi(p,x,z)=(\,\varphi_1(x)\,,\,\varphi_2(p,x,z)\,)\,. \tag{173}$$

Actually, we may suppose that $\varphi_1(x)=x$:

$$\varphi(p,x,z)=(\,x\,,\,\varphi_2(p,x,z)\,) \tag{174}$$

because transforming it by the diffeomorphism $(x,z)\mapsto(\varphi_1(x),z)$, independent of p, does not change the fact that $\widetilde{\mathcal{S}}$ is FE. Let us then define γ by $\gamma(p,x,v)=\varphi_2^{-1}(p,x,v)$, where φ_2^{-1} means inverting φ_2 with respect to v (or z) only. The family of feedback transformations γ transforms the system $\widetilde{\sigma}$ that is constant because $\widetilde{\mathcal{S}}=\mathcal{A}(\widetilde{\sigma})$ and $\widetilde{\mathcal{S}}$ is FE. □

Proof of Proposition 6.3. If Σ is (locally/globally) FDE, let ψ be the corresponding family of diffeomorphisms transforming Σ into an FE family and γ be the family of feedback transformations transforming this FE family into a constant family. Let us define φ by

$$\varphi(p,X)=\varphi(p,x,z)=\left(\,\psi(p,x)\,,\,\gamma^{-1}(\psi(p,x),z)\,\right), \tag{175}$$

where γ^{-1} means inverting with respect to z for any (p,x). This does transform $\mathcal{S}$ into a family that is FE (if $(\xi,\zeta)=\varphi(p,x,z)$, $\dot{\xi}$ does not depend on p, as a function of p,ξ,ζ, and $\mathcal{G}$ is spanned by $\frac{\partial}{\partial z_1}\cdots\frac{\partial}{\partial z_m}$).

Conversely, if $\mathcal{S}$ is (locally/globally) FDE and φ is the corresponding family of feedback transformations, let us define φ_1 and φ_2 as the x and z components of φ. Since the affine-in-the-control family $\widetilde{\Sigma}$ is FE, we have, from Theorem 3.4 and (164),

$$\varphi_*\frac{\partial}{\partial z_k}\ \in\ \operatorname{Span}\left\{\frac{\partial}{\partial z_1},\ldots,\frac{\partial}{\partial z_m}\right\},\qquad k=1,\ldots,m, \tag{176}$$

which implies that φ_1 does not depend on z:

$$\varphi(p,X)=\varphi(p,x,z)=(\,\varphi_1(p,x)\,,\,\varphi_2(p,x,z)\,)\,. \tag{177}$$

It is clear that φ being a diffeomorphism implies that $x\mapsto\varphi_1(p,x)$ is a diffeomorphism for any p and $z\mapsto\varphi_2(p,x,z)$ is a diffeomorphism for any (p,x). Let us define ψ and γ by

$$\begin{array}{rcl}\psi(p,x)&=&\varphi_1(p,x),\\ \gamma(p,x,z)&=&\varphi_2^{-1}(p,x,z).\end{array} \tag{178}$$

This transforms Σ into a family $\widetilde{\Sigma}$ that is constant because φ transforms $\mathcal{S}$ into $\widetilde{\mathcal{S}}$ which is FE, and whose "$\dot{x}$" part is therefore independent of p. □

7. Conclusion. We have given some general conditions for the systems of a smoothly parameterized family to be equivalent via state feedback and diffeomorphism transformations, and the interest of the method used here is that it is constructive: under these conditions, we actually compute the transformations.

Among others, the interest of the problem considered here is to allow, if it can be solved, to control the systems of the family "in the same way": since all the systems are equivalent to a single one, it is possible to design a controller for this system and bring it back to the original systems of the family through the transformations.

The case where it is possible to choose a family of diffeomorphisms meeting some so-called "matching assumptions" has been studied in details. As mentioned above, the motivation for this study comes from adaptive nonlinear control where these conditions play an important role; they are a generalization of those introduced in the case of feedback linearizable systems; see [5], [4]. It turns out that our conditions are more explicit for feedback and diffeomorphism satisfying these matching conditions. The geometric conditions given in [5], [4] are a particular case of these.

Of course, feedback and diffeomorphism equivalence plays a very important role of its own in control theory. The point of view of parameterized families is rather unusual, and it facilitates the rather natural derivation of some global results. This has been developed in [7].

Appendix: A technical lemma. LEMMA. *Let $\mathcal{D}$ be a finitely generated module of $\mathcal{C}^\infty$ vector fields on a $\mathcal{C}^\infty$ manifold $\mathcal{N}$ and X and F be two $\mathcal{C}^\infty$ vector fields on $\mathcal{N}$. Let $G_1, \dots, G_s$ be any system of generators of $\mathcal{D}$:*

$$\mathcal{D} = \operatorname{Span}\{G_1, \dots, G_s\}. \tag{179}$$

Also let $\phi_X : J \times U \to \mathcal{N}$ be any partial flow of X, i.e., a $\mathcal{C}^\infty$ mapping ϕ_X, J an open interval of $I\!R$ containing 0, and U an open subset of $\mathcal{N}$, such that (we will often write $\phi_X^t(x)$ instead of $\phi_X(t,x)$):

$$\phi_X(0,x) = x \quad \textit{for all } x \in U,$$
$$\frac{\partial \phi_X}{\partial t} = X \circ \phi_X \quad \textit{on } J \times U.$$

Let $\mathcal{D}_U$ be the module of vector fields on U generated by the restrictions to U of the vector fields belonging to $\mathcal{D}$. Let X^U and F^U be the restrictions of X and F to U. If we have

$$\left\{ \begin{array}{l} [X^U, \mathcal{D}_U] \subset \mathcal{D}_U, \\ [X^U, F^U] \in \mathcal{D}_U, \end{array} \right. \tag{180}$$

then there exist $\mathcal{C}^\infty$ functions c_k^j, $1 \le k \le s$, $1 \le j \le s$, defined on the open subset $\mathcal{O} = \bigcup_{t \in J} (\{t\} \times \phi_X^t(U))$ of $I\!R \times \mathcal{N}$, such that, for any (t, χ) in $\mathcal{O}$,

$$\left\{ \begin{array}{l} \phi^t_{X*} G_k(\chi) = \sum_{i=1}^{s} c_k^j(\chi, t) F_j(\chi,) \quad k = 1, \dots, s, \\ \phi^t_{X*} F(\chi) = F(\chi) + \sum_{i=1}^{s} c_0^j(\chi, t) G_j(\chi). \end{array} \right. \tag{181}$$

Moreover, the $s \times s$ matrix

$$[c_k^j(\chi, t)]_{1 \le k \le s,\, 1 \le j \le s} \tag{182}$$

is invertible for any (χ, t) in $\mathcal{O}$.

Note that the converse of this lemma is obvious ((181) implies (180)) and that it is known (180) implies that for any t $\phi^t_{X*}F$ and the $\phi^t_{X*}G_k$'s are in $\mathcal{D}$. The precision here is the continuous dependence of the coefficients on t and also the fact that the matrix $[c_k^j(\chi, t)]$ remains invertible.

Proof. (180) implies that there exists some $\mathcal{C}^\infty$ functions b^j_k, $1 \le j \le s$, $0 \le k \le s$, defined on U, such that

$$\text{(183)} \qquad \left\{ \begin{array}{rcl} [X^U , G^U_k] & = & - \sum_{j=1}^s b^j_k(\chi) G^U_j(\chi), \\ {[X^U , F^U]} & = & - \sum_{i=1}^s b^j_0(\chi) G^U_j \end{array} \right.$$

where G^U_j stands for the restriction of G_j to U. Denote by F_t and $G_{k,t}$, $1 \le k \le s$, the vector fields ${\phi^t_X}_* F$ and ${\phi^t_X}_* F$ respectively, defined on the open subset $\phi(t, U)$ of $\mathcal{N}$. The mappings $(t, x) \mapsto F_t(\chi)$ and $(t, x) \mapsto G_{k,t}(\chi)$ are $\mathcal{C}^\infty$ from $\mathcal{O}$ to $T\mathcal{N}$, and by the definition of the Lie bracket,

$$\text{(184)} \qquad \frac{\partial F_t}{\partial t} = \phi^t_{X*}[X^U, F^U]; \qquad \frac{\partial G_{k,t}}{\partial t} = \phi^t_{X*}[X^U, G^U_k].$$

Hence, from (183), F_t and the $G_{k,t}$'s satisfy the linear differential system

$$\text{(185)} \qquad \left\{ \begin{array}{rcl} \dfrac{\partial F_t}{\partial t} & = & \displaystyle\sum_{i=1}^s (b^i_0 \circ \phi^{-t}_X)\, G_{i,t}, \\ \dfrac{\partial G_{k,t}}{\partial t} & = & \displaystyle\sum_{i=1}^s (b^i_k \circ \phi^{-t}_X)\, G_{i,t} \end{array} \right.$$

and the initial condition $F_0 = F$, $G_{k,0} = G_k$. The system (185) has a *unique* solution satisfying these initial conditions. Hence, to find parameterized vector fields F_t and $G_{k,t}$, all we have to do is find a solution of (185) satisfying the initial conditions. To do this, let us look for a solution of the form $F_t = F + \sum_{i=1}^s c^i_{0,t} G_i$, $G_{k,t} = \sum_{i=1}^s c^i_{k,t} G_i$, where the c^i_k are $\mathcal{C}^\infty$ functions defined on $\mathcal{O}$ to be computed such that

$$\text{(186)} \qquad c^i_k(0, x) = \left\{ \begin{array}{ll} 1 \ , \ x \in U & \text{if } i = k,\ 1 \le k \le s, \\ 0 \ , \ x \in U & \text{if } i \ne k \ \text{ or } k = 0 \end{array} \right.$$

and $c^i_{k,t} \in \mathcal{C}^\infty(\phi(t, U))$ is the function $x \in \phi(t, U) \mapsto c^i_k(t, x)$. This "ansatz" satisfies the initial conditions and satisfies (185) if

$$\text{(187)} \qquad \left\{ \begin{array}{l} \displaystyle\sum_{i=1}^s \frac{\partial c^i_{0,t}}{\partial t} G_i = \sum_{i=1}^s \sum_{j=1}^s (b^i_0 \circ \phi^{-t}_X)\, c^j_{i,t}\, G_j, \\ \displaystyle\sum_{i=1}^s \frac{\partial c^i_{k,t}}{\partial t} G_i = \sum_{i=1}^s \sum_{j=1}^s (b^i_k \circ \phi^{-t}_X)\, c^j_{i,t}\, G_j. \end{array} \right.$$

(187) will be satisfied if the functions c^i_j satisfy the linear differential system

$$\text{(188)} \qquad \left\{ \begin{array}{c} \dfrac{\partial c^i_0}{\partial t} = \displaystyle\sum_{j=1}^s \widehat{b}^j_0\, c^i_j, \\ \dfrac{\partial}{\partial t} \begin{pmatrix} c^1_1 & \cdots & c^1_s \\ \vdots & & \vdots \\ c^s_1 & \cdots & c^s_s \end{pmatrix} = \begin{pmatrix} \widehat{b}^1_1 & \cdots & \widehat{b}^1_s \\ \vdots & & \vdots \\ \widehat{b}^s_1 & \cdots & \widehat{b}^s_s \end{pmatrix} \begin{pmatrix} c^1_1 & \cdots & c^1_s \\ \vdots & & \vdots \\ c^s_1 & \cdots & c^s_s \end{pmatrix} \end{array} \right.$$

with initial conditions (186), where

$$\widehat{b}^i_k \in \mathcal{C}^\infty(\mathcal{O}); \quad \widehat{b}^i_k(t, \chi) = b^i_k(\phi^{-t}_X(\chi)).$$

This linear system has a unique solution, defined for any t, and the matrix in the right-hand side of (188), i.e. the matrix $[c_k^j(\chi,t)]_{1\leq k\leq s,\, 1\leq j\leq s}$, is always invertible. We have constructed the functions c_k^j satisfying the required conditions. □

NECESSARY CONDITIONS FOR BILEVEL DYNAMIC OPTIMIZATION PROBLEMS*

JANE J. YE[†]

Abstract. In this paper we study the bilevel dynamic optimization problem, which is a hierarchy of two optimization problems where the constraint region of the upper-level problem is determined implicitly by the solution to the lower-level problem and where the upper-level decision variable is a vector while the lower-level decision variable is an admissible control function. To obtain optimality conditions, we reformulate the bilevel dynamic optimization problem as a single-level optimal control problem that involves the value function of the lower-level problem. A sensitivity analysis of the lower-level problem with respect to the perturbation in the upper-level decision variable is given, and the first-order necessary optimality conditions are derived by using nonsmooth analysis.

Key words. necessary conditions, bilevel dynamic optimization problems, sensitivity analysis, nonsmooth analysis, value function

1. Introduction.

Let us consider a two-level hierarchical system where the higher level (hereafter the "leader") and the lower level (hereafter the "follower") must find vectors $z \in Z$ and control functions $u(\cdot)$, respectively, to minimize their individual objective functions $J_1(z, u)$ and $J_2(z, u)$. The leader is assumed first to select his decision vector $z \in Z$ and the follower next to select his decision control function $u(\cdot) \in \mathcal{U}$, where Z is a nonempty subset of R^n and $\mathcal{U}$ is the set of admissible controls. Under these assumptions on the order of play, the game will proceed as follows. Given any decision vector $z \in Z$ chosen by the leader, the follower will select his decision control function $u_z(\cdot) \in \mathcal{U}$ (depending on the decision vector z chosen by the leader) to minimize his objective $J_2(z, u_z)$. Assume that the game is cooperative, i.e., if the follower's problem has several optimal controls for a given parameter z, then the follower allows the leader to choose which of them is actually used. Thus the leader chooses his optimal decision vector $z \in Z$ to minimize the leader's objective $J_1(z, u_z)$. In other words, given any decision vector $z \in Z$ chosen by the leader, the follower faces the ordinary (*single-level*) optimal control problem involving a parameter z:

$$\begin{aligned} P_2(z) \qquad \min J_2(z,u) &= \int_{t_0}^{t_1} G(t, x(t), z, u(t))dt + g(x(t_1)), \\ \text{s.t. } \dot{x}(t) &= \phi(t, x(t), z, u(t)) \qquad \text{a.e.}, \\ x(t_0) &= x_0, \quad x(t_1) \in C_1, \\ u(t) &\in U(t) \qquad \text{a.e.}, \end{aligned}$$

while the leader faces the *bilevel dynamic optimization problem*:

$$P_1 \qquad \min J_1(z, u_z) = \int_{t_0}^{t_1} F(t, x_z(t), z, u_z(t))dt + f(x_z(t_1))$$

over $z \in Z$ and all optimal pairs (x_z, u_z) of $P_2(z)$.

The bilevel dynamic optimization problem has many applications in economics and management science. For instance, the leader may be the government that sets up the taxation policy z and the follower may be a company that seeks the optimal policy $u_z(t)$ in reaction to the government's taxation policy.

The bilevel static problem where both leader's and follower's decisions are vectors instead of control functions was first introduced by von Stackelberg [10] for an economic model. The bilevel dynamic problem where both leader's and follower's decisions are control functions was first considered by Chen and Cruz in [2]. The bilevel dynamic optimization problem studied in this paper is a special case of the bilevel dynamic problem as in Zhang [13]. Several names for bilevel (static or dynamic) optimization problems have been used in the literature, such as Stackelberg game, principal-agent problem, bilevel programming problem, and two-level hierarchical optimization problem. Most of the bilevel (static or dynamic) problems are attacked by reducing the lower-level problem through first-order necessary conditions (cf. Bard and Falk [1] and Zhang [13], [14] for the bilevel static problem and Zhang [13] for the bilevel dynamic problem). The reduction is equivalent if and only if the lower-level problem satisfies certain convexity assumptions since in this case the first-order necessary condition is also sufficient. Apart from the strong convexity assumption, the resulting optimality conditions of the above approach involve second-order (generalized in nonsmooth case [13]) derivatives and a larger system since the reduced problem minimizes over the set of original decision variables as well as the set of multipliers of the lower-level problem.

The purpose of this paper is to provide first-order necessary conditions for problem P_1 under very general assumptions (in particular, without convexity assumptions on the lower-level problem).

Define the *value function of the lower-level optimal control problem* as an extended-valued function $V : Z \to \bar{R}$ defined by

$$V(z) := \inf \left\{ \begin{array}{ll} \int_{t_0}^{t_1} G(t,x(t),z,u(t))dt + g(x(t_1)) : & \dot{x}(t) = \phi(t,x(t),z,u(t)) \text{ a.e.} \\ & u(t) \in U(t) \qquad \text{a.e.} \\ & x(t_0) = x_0, \quad x(t_1) \in C_1 \end{array} \right\},$$

where $\bar{R} := R \cup \{-\infty\} \cup \{+\infty\}$ is the extended real line and $\inf \emptyset = +\infty$ by convention. Our approach is to reformulate P_1 as in the following single-level optimal control problem:

$$\begin{aligned} \widetilde{P}_1 \qquad & \min J_1(z,u) = \int_{t_0}^{t_1} F(t,x(t),z(t),u(t))dt + f(x(t_1)), \\ & \text{s.t. } \dot{x}(t) = \phi(t,x(t),z(t),u(t)) \qquad \text{a.e.}, \\ & \dot{z}(t) = 0, \\ & x(t_0) = x_0, \quad x(t_1) \in C_1, \\ & u(t) \in U(t) \qquad \text{a.e.}, \\ & \int_{t_0}^{t_1} G(t,x(t),z(t),u(t))dt + g(x(t_1)) \le V(z(t_1)). \end{aligned}$$

The above problem is obviously equivalent to the original bilevel dynamic optimization problem P_1 and is a standard optimal control problem except that the endpoint constraints involve the value function V of the lower-level optimal control problem. In general V is not an explicit function of the problem data and is nonsmooth even in the case where all problem data are smooth functions. Recent developments in nonsmooth analysis allow us to study the generalized derivatives of the value function V and relate them to the multiplier sets for the lower-level optimal control problem, hence deriving a necessary condition for optimality. This approach was first used by Ye and Zhu [12] to derive first-order necessary conditions for the static bilevel optimization problem. The following basic assumptions are in force throughout this paper:

(A1) $Z \subset \mathbb{R}^n$ and C_1 are closed.

(A2) $U(t) : [t_0, t_1] \to \mathbb{R}^m$ is a nonempty compact-valued set-valued map. The graph of $U(t)$ (i.e., the set $\{(s,r) : s \in [t_0,t_1], r \in U(s)\}$), denoted by Gr$U$, is $\mathcal{L}\times\mathcal{B}$ measurable, where $\mathcal{L}\times\mathcal{B}$ denotes the σ-algebra of subsets of $[t_0,t_1]\times\mathbb{R}^m$ generated by product sets $M \times N$ where M is a Lebesgue measurable subset of $[t_0,t_1]$ and N is a Borel subset of $\mathbb{R}^m$.

(A3) There exists an integrable function k defined on $[t_0,t_1]$ such that for each $(t,u) \in \text{Gr}U$, the functions $\phi(t,\cdot,\cdot,u), F(t,\cdot,\cdot,u), G(t,\cdot,\cdot,u)$ are locally Lipschitz of rank $k(t)$. For each $(x,z) \in \mathbb{R}^d \times \mathbb{R}^n$, the functions $\phi(\cdot,x,z,\cdot) : [t_0,t_1] \times \mathbb{R}^m \to \mathbb{R}^d$, $F(\cdot,x,z,\cdot) : [t_0,t_1] \times \mathbb{R}^m \to \mathbb{R}$, $G(\cdot,x,z,\cdot) : [t_0,t_1] \times \mathbb{R}^m \to \mathbb{R}$ are $\mathcal{L} \times \mathcal{B}$ measurable.

(A4) The functions $f, g : \mathbb{R}^d \to \mathbb{R}$ are locally Lipschitz continuous.

(A5) For any $z \in Z$, $P_2(z)$ has an admissible pair (whose definition is given below).

A *control function* is a (Lebesgue) measurable selection $u(\cdot)$ for $U(\cdot)$, that is, a measurable function satisfying $u(t) \in U(t)$ a.e. $t \in [t_0,t_1]$. An *arc* is an absolutely continuous function. An *admissible pair* for $P_2(z)$ is a pair of functions $(x(\cdot),u(\cdot))$ on $[t_0,t_1]$ of which $u(\cdot)$ is a control function and $x(\cdot) : [t_0,t_1] \to \mathbb{R}^d$ is an arc that satisfies the differential equation $\dot{x}(t) = \phi(t,x(t),z,u(t))$ a.e., together with the initial condition $x(t_0) = x_0$ and the endpoint constraint $x(t_1) \in C_1$. The first and the second components of an admissible pair are called an *admissible trajectory* and an *admissible control*, respectively. A *solution* to problem $P_2(z)$ is an admissible pair that minimizes the value of the cost functional $J_2(z,u)$ over all admissible pairs. An *admissible strategy* for P_1 includes a vector $z \in Z$ and an optimal control u_z for $P_2(z)$. The strategy (z,u_z) is *optimal* for the bilevel dynamic optimization problem P_1 if (z,u_z) minimizes the value of the cost functional $J_1(z,u_z)$ among all admissible strategies for P_1.

A plan of the paper is as follows. In §2, we give background material on nonsmooth analysis that will be referred to in the following sections. In §3, we study generalized differentiability of the value function $V(z)$. The necessary condition for optimality is given in §4. In §5, we consider an extension to the bilevel dynamic optimization problem defined in §1 to allow opportunity costs; a fishery regulation problem is used to demonstrate applications of the necessary condition for optimality derived.

2. Nonsmooth analysis background.

In this section we shall give a concise review of the material on nonsmooth analysis that will be required.

Let C be a nonempty closed set in $\mathbb{R}^n$. A vector $\zeta \in \mathbb{R}^n$ is a *proximal normal* to C at point $\bar{x} \in C$ if for $t > 0$ sufficiently small, the unique point of C nearest to $\bar{x} + t\zeta$ (in the Euclidean norm) is $\bar{x}$. It is a *limiting proximal normal* if there exist points $x_k \in C, x_k \to \bar{x}$, and proximal normals ζ_k to C at x_k, such that $\zeta_k \to \zeta$. Let the *limiting proximal normal cone to C at $\bar{x}$* be the set

$$\hat{N}_C(\bar{x}) := \{\zeta : \zeta \text{ is a limiting proximal normal to } C \text{ at } \bar{x}\}$$

and the *Clarke normal cone to C at $\bar{x}$* to be the set

$$N_C(\bar{x}) := \text{clco}\hat{N}_C(\bar{x}).$$

Now consider a lower semicontinuous function $\phi : I\!\!R^n \to I\!\!R \cup \{+\infty\}$ and a point $\bar{x} \in I\!\!R^n$ where ϕ is finite. A vector $\zeta \in I\!\!R^n$ is called a *proximal subgradient* of $\phi(\cdot)$ at $\bar{x}$ provided that there exist $M > 0, \delta > 0$ such that

$$\langle \zeta, x' - \bar{x} \rangle \leq \phi(x') - \phi(\bar{x}) + M\|x' - \bar{x}\|^2, \qquad x' \in \bar{x} + \delta B,$$

where $\langle a, b \rangle$ denotes the inner product of vectors a and b. The set of all proximal subgradients of $\phi(\cdot)$ at $\bar{x}$ is denoted $\partial^\pi \phi(\bar{x})$. The *limiting subgradient* of ϕ at $\bar{x}$ is the set

$$\hat{\partial}\phi(\bar{x}) := \left\{ \lim_{k \to \infty} \zeta_k : \zeta_k \in \partial^\pi \phi(x_k), x_k \to \bar{x}, \phi(x_k) \to \phi(\bar{x}) \right\}.$$

The *singular limiting subgradient* of ϕ at $\bar{x}$ is the set

$$\hat{\partial}^\infty \phi(\bar{x}) := \left\{ \lim_{k \to \infty} t_k \zeta_k : \zeta_k \in \partial^\pi \phi(x_k), x_k \to \bar{x}, \phi(x_k) \to \phi(\bar{x}), t_k \downarrow 0 \right\}.$$

The limiting subgradient is a smaller object than the *Clarke generalized gradient.* In fact, if ϕ is Lipschitz continuous near x, we have $\partial\phi(x) = \mathrm{co}\hat{\partial}\phi(x)$, where $\partial\phi$ and coA denote the Clarke generalized gradient of ϕ and the convex hull of the set A, respectively. For the definition and the precise relation between the limiting subgradient and the Clarke generalized gradient, the reader is referred to Clarke [5] and Rockafellar [9].

The following proposition summarizes the prerequisites regarding limiting subgradients and limiting proximal normal cones.

PROPOSITION 2.1. (a) *If C is a nonempty closed convex set, the limiting proximal normal cone to C coincides with the normal cone in the sense of convex analysis, i.e., one has $\zeta \in \hat{N}_C(\bar{x})$ if and only if*

$$\langle \zeta, x - \bar{x} \rangle \leq 0 \quad \forall x \in C.$$

(b) *The function $\phi(\cdot)$ is Lipschitz near x if and only if $\hat{\partial}^\infty \phi(x) = \{0\}$.*

(c) *If $\hat{\partial}\phi(x) \neq \emptyset$, then*

$$\hat{\partial}(s\phi)(x) = s\hat{\partial}\phi(x) \qquad \forall s \geq 0.$$

(d) (*Clarke* [5, *Prop.* 1.5]) *Let ϕ and $\psi : I\!\!R^n \to I\!\!R \cup \{+\infty\}$ be lower semicontinuous functions finite at x, with $\hat{\partial}^\infty \phi(x) \cap (-\hat{\partial}^\infty \psi(x)) = \{0\}$. Then we have*

$$\hat{\partial}(\phi + \psi)(x) \subset \hat{\partial}\phi(x) + \hat{\partial}\psi(x).$$

(e) *Let $\Psi_C(x)$ be the indicator function of the set C. Then*

$$\hat{N}_C(x) = \hat{\partial}\Psi_C(x) = \hat{\partial}^\infty \Psi_C(x).$$

(f) *Let S_1 and S_2 be closed subets of $I\!\!R^n$ and let $\bar{x} \in S_1 \cap S_2$. If $\hat{N}_{S_1}(\bar{x}) \cap (-\hat{N}_{S_2}(\bar{x})) = \{0\}$, then we have*

$$\hat{N}_{S_1 \cap S_2}(\bar{x}) \subset \hat{N}_{S_1}(\bar{x}) + \hat{N}_{S_2}(\bar{x}).$$

(g) (*chain rule*) *Let $\phi(x) := f(F(x))$ where $F : I\!\!R^n \to I\!\!R$ is Lipschitz on some neighbourhood of $\bar{x}$, while $f : I\!\!R \to I\!\!R \cup \{+\infty\}$ is lower semicontinuous with $F(\bar{x})$ in $\mathrm{dom} f := \{y : f(y) \neq +\infty\}$. Then if*

$$0 \notin \hat{\partial}(\zeta F)(\bar{x}) \qquad \forall \text{ nonzero vectors } \zeta \in \hat{\partial}^\infty f(F(\bar{x})),$$

we have

$$\hat{\partial}\phi(\bar{x}) \subset \cup\{\hat{\partial}(\zeta F)(\bar{x}) : \zeta \in \hat{\partial} f(F(\bar{x}))\}.$$

3. Differentiability of the value function. To discuss generalized differentiability of the value function $V(z)$, we will refer to the following assumptions:

(A6) For some $\alpha \geq 0, \beta \geq 0$, the function $(\phi(t,\cdot,z,u), G(t,\cdot,z,u))$ satisfies the following growth condition: for all $z \in Z$, $(t,u) \in \mathrm{Gr}U$, one has

$$|(\phi(t,x,z,u), G(t,x,z,u))| \leq \alpha|x| + \beta.$$

(A6)$'$ The functions ϕ and G are continuously differentiable in x and z and lower semicontinuous in u. There exists an integrable function $k(t)$ such that

$$|\phi| + |\nabla_x \phi| + |G| + |\nabla_x G| \leq k(t).$$

(A7) For any $(t,x,z) \in [t_0,t_1] \times I\!R^d \times I\!R^n$, the set

$$\{(\phi(t,x,z,u), G(t,x,z,u)) : u \in U(t)\}$$

is convex.

(A7)$'$ For any $(t,x,z) \in [t_0,t_1] \times I\!R^d \times I\!R^n$, the set

$$\{(\phi(t,x,z,u), G(t,x,z,u) + \delta) : u \in U(t), \delta \geq 0\}$$

is convex.

The Hamiltonian for $P_2(z)$ is the function defined by

$$H_2(t,x,z,p_2;\lambda) := \sup\{p_2 \cdot \phi(t,x,z,u) - \lambda G(t,x,z,u) : u \in U(t)\}.$$

An index λ multiplier corresponding to an admissible trajectory x for $P_2(z)$ is an arc (p_2, q) such that

$$\begin{aligned} (-\dot{p_2}(t), -\dot{q}(t), \dot{x}(t)) &\in \partial_{(x,z,p_2)} H_2(t,x(t),z,p_2(t);\lambda) \qquad \text{a.e.} \\ -p_2(t_1) &\in \lambda \hat{\partial} g(x(t_1)) + \hat{N}_{C_1}(x(t_1)), \\ q(t_1) &= 0. \end{aligned}$$

The collection of all such arcs is the set $M^\lambda(x)$, the index λ multiplier set corresponding to x. Let Y be the set of all optimal trajectories x to problem $P_2(z)$. Let

$$M^\lambda(Y) := \bigcup_{x \in Y} M^\lambda(x).$$

For any index λ multiplier $(p_2,q) \in M^\lambda(x)$, we define $Q(p_2,q) = -q(t_0)$. The notation $QM^\lambda(x)$ designates the set of all possible values of $-q(t_0)$ obtained in this way, and $Q(M^\lambda(Y))$ denotes $\cup_{x \in Y} Q(M^\lambda(x))$. The following result relates the differential properities of V to the arcs q in the multiplier sets introduced above.

THEOREM 3.1. *In addition to assumptions* (A1)–(A5), *suppose either* (A6)–(A7) *or* (A6)$'$–(A7)$'$ *hold. If* $QM^0(Y) = \{0\}$, *then* V *is Lipschitz continuous near* z *and one has*

$$\hat{\partial} V(z) \subset QM^1(Y).$$

Theorem 3.1 under assumptions (A6)–(A7) can be obtained by reducing the original optimal control problem to an differential inclusion problem and applying the sensitivity result in Clarke and Loewen [6, Thm. 3.3]. Before proving Theorem 3.1 under assumptions (A1)–(A5) and (A6)$'$–(A7)$'$, we first give the following result.

LEMMA 3.2. *Let α_i be a sequence converging to α, and let (x_i, u_i) be an admissible pair for $P_2(\alpha_i)$. Then there exists a subsequence of $\{x_i\}$ converging uniformly to an arc x and a control u with (x, u) being an admissible pair for $P_2(\alpha)$ such that*

$$J_2(x,u) \leq \liminf J_2(x_i, u_i).$$

The proof can be reduced to an application of [4, Thm. 3.1.7] by studying the differential inclusion

$$(\dot{x}(t), \dot{y}(t), \dot{\alpha}(t)) \in \Gamma(t, x(t), y(t), \alpha(t)) \qquad \text{a.e.},$$

where $y \in I\!R$ and the convex multifunction Γ is defined via

$$\Gamma(t,x,y,\alpha) := \{[\phi(t,x,\alpha,u), r, 0] : G(t,x,\alpha,u) \leq r \leq k(t)+1, u \in U(t)\}.$$

The essential fact in the reduction is Filippov's lemma: (x, y, α) satisfies the above differential inclusion iff there is a control u for x such that (x, u) is an admissible pair for $P_2(\alpha)$ and y satisfies

$$G(t,x,\alpha,u) \leq \dot{y} \leq k(t)+1.$$

We now turn to the proof of the theorem. By (A5), $P_2(z)$ has an admissible pair. So $V(z)$ is finite. It follows from Lemma 3.2 that V is lower-semicontinuous.

Step 1. Let $\alpha \in Z$ be a point near z. Let $\zeta \in \partial^{\pi} V(\alpha)$, and let (x, u) be a solution of $P_2(\alpha)$ that exists by virtue of Lemma 3.2. Then by definition, for some $M > 0$ and for all α' near α, we have

$$\begin{aligned} V(\alpha') - \langle \zeta, \alpha' \rangle + M|\alpha' - \alpha|^2 &\geq V(\alpha) - \langle \zeta, \alpha \rangle \\ &= \int_{t_0}^{t_1} G(t, x(t), \alpha, u(t))dt + g(x(t_1)) - \langle \zeta, \alpha \rangle. \end{aligned}$$

Let (x', u') be an admissible pair for $P_2(\alpha')$. Then

$$\begin{aligned} &\int_{t_0}^{t_1} G(t, x'(t), \alpha', u'(t))dt + g(x(t_1)) - \langle \zeta, \alpha' \rangle + M|\alpha' - \alpha|^2 \\ &\qquad \geq \int_{t_0}^{t_1} G(t, x(t), \alpha, u(t))dt + g(x(t_1)) - \langle \zeta, \alpha \rangle. \end{aligned}$$

Hence (x, α, u) is a solution of the following optimal control problem:

$$\begin{aligned} \min \int_{t_0}^{t_1} & G(t, x'(t), \alpha'(t), u'(t))dt + g(x'(t_1)) - \langle \zeta, \alpha'(t_0) \rangle, \\ \text{s.t. } & \dot{x}'(t) = \phi(t, x'(t), \alpha'(t), u'(t)) \qquad \text{a.e.}, \\ & \alpha'(t) = 0, \\ & x'(t_0) = x_0, \quad x'(t_1) \in C_1, \\ & u'(t) \in U(t) \qquad \text{a.e.} \end{aligned}$$

In the proof of Theorem 5.2.1 of Clarke [4], if we replace the the Clarke generalized gradient ∂ by the limiting subgradient $\hat{\partial}$ in the transversality conditions, the argument goes through without modification (cf. Clarke [5]). It follows that there exist a scalar $\lambda \geq 0$ and arcs p_2, q such that

$$\begin{aligned}
&(1) \qquad -\dot{p_2}(t) = \nabla_x \phi(t, x(t), \alpha, u(t))^\top p_2(t) - \lambda \nabla_x G(t, x(t), \alpha, u(t)) \qquad \text{a.e.;}\\
&(2) \qquad -\dot{q}(t) = \nabla_\alpha \phi(t, x(t), \alpha, u(t))^\top p_2(t) - \lambda \nabla_\alpha G(t, x(t), \alpha, u(t)) \qquad \text{a.e.;}\\
&\qquad\quad \max_{u \in U(t)} \{p_2(t) \cdot \phi(t, x(t), \alpha, u) - \lambda G(t, x(t), \alpha, u)\}\\
&(3) \qquad\qquad = p_2(t) \cdot \phi(t, x(t), \alpha, u(t)) - \lambda G(t, x(t), \alpha, u(t)) \qquad \text{a.e.,}\\
&\qquad\quad -p_2(t_1) \in \lambda \hat{\partial} g(x(t_1)) + \hat{N}_{C_1}(x(t_1)),\\
&\qquad\quad q(t_0) = -\lambda \zeta, \qquad q(t_1) = 0,\\
&\qquad\quad \|p_2\|_\infty + \|q\|_\infty + \lambda > 0,
\end{aligned}$$

where ∂ denotes the Clarke generalized gradient, $\|\cdot\|_\infty$ denotes the supremum norm, and $^\top$ denotes the transpose.

By Clarke [4, Thm. 2.8.2], since ϕ and G are continuously differentiable in (x, z), $\partial_{(x,\alpha,p_2)} H_2(t, x, \alpha, p_2; \lambda)$ is the convex hull of all points of the form

$$[\nabla_x \phi(t, x, \alpha, u)^\top p_2 - \lambda \nabla_x G(t, x, \alpha, u), \nabla_\alpha \phi(t, x, \alpha, u)^\top p_2 - \lambda \nabla_\alpha G(t, x, \alpha, u), \phi(t, x, \alpha, u)],$$

where u in $U(t)$ is any point at which the maximum defining $H_2(t, x, \alpha, p_2; \lambda)$ is achieved. Hence (1), (2), and (3) imply that

$$(-\dot{p_2}(t), -\dot{q}(t), \dot{x}(t)) \in \partial_{(x,\alpha,p_2)} H_2(t, x(t), \alpha, p_2(t); \lambda) \qquad \text{a.e.}$$

Step 2. For any $\zeta \in \hat{\partial} V(z)$, by definition, $\zeta = \lim_{i \to \infty} \zeta_i$ where $\zeta_i \in \partial^\pi V(\alpha_i)$, $\alpha_i \to z$, and $V(\alpha_i) \to V(z)$. By Step 1, for each ζ_i, there exists an arc (p_2^i, q_i), a scalar λ_i, and an arc x_i that solves $P_2(\alpha_i)$ such that

$$\begin{aligned}
(-\dot{p_2}^i(t), -\dot{q}_i(t), \dot{x}_i(t)) &\in \partial_{(x,\alpha,p_2)} H_2(t, x_i(t), \alpha_i, p_2^i(t); \lambda_i) \qquad \text{a.e.,}\\
-p_2^i(t_1) &\in \lambda_i \hat{\partial} g(x_i(t_1)) + \hat{N}_{C_1}(x_i(t_1)),\\
q_i(t_0) &= -\lambda_i \zeta_i, \qquad q_i(t_1) = 0,\\
\|p_2^i\| + \|q_i\| + \lambda_i &> 0.
\end{aligned}$$

Since $M^0(Y) = \{0\}$, we must indeed have $\lambda_i = 1$ for i sufficiently large and $|p_2^i(0)|$ bounded (cf., Clarke and Loewen [6, p. 253]). Passing to a uniformly convergent subsequence of $\{(p_2^i, q_i, x_i)\}$ by Lemma 3.2 and Clarke [4, Thm. 3.1.7] leads to an optimal trajectory x for $P_2(z)$ and an arc (p_2, q) such that

$$\begin{aligned}
(-\dot{p_2}(t), -\dot{q}(t), \dot{x}(t)) &\in \partial_{(x,\alpha,p_2)} H_2(t, x(t), \alpha, p_2(t); \lambda) \qquad \text{a.e.,}\\
-p_2(t_1) &\in \hat{\partial} g(x(t_1)) + \hat{N}_{C_1}(x(t_1)),\\
q(t_0) &= -\zeta, \qquad q(t_1) = 0.
\end{aligned}$$

That is, $(p_2, q) \in QM^1(Y)$.

Similarly to Ye [11], one can show $\hat{\partial}^\infty V(z) \subset QM^0(Y)$ using results from Step 2. The Lipschitz continuity of V near z then follows by virtue of assumption $M^0(Y) = \{0\}$ and (b) of Proposition 2.1. The proof of Theorem 3.1 is now complete.

4. Necessary conditions for optimality. Define the *pseudo-Hamiltonian* for problem $(\widetilde{P}_1)$ as

$$H_1(t,x,z,p_1;\lambda,r) := p_1 \cdot \phi(t,x,z,u) - rG(t,x,z,u) - \lambda F(t,x,z,u),$$

for $t \in [t_0,t_1]$, $x, p_1 \in \mathbb{R}^d$, $z \in Z$, $\lambda, r \in \mathbb{R}$.

THEOREM 4.1. *Assume assumptions* (A1)–(A4) *hold. Let* $(z, u(t))$ *be an optimal strategy of the bilevel dynamic optimization problem* P_1 *and* $x(t)$ *the corresponding trajectory. Assume that the value function for the lower-level problem* V *is locally Lipschitz continuous. Then there exist* $\lambda \geq 0, r \geq 0$ *and arcs* p_1, η *such that:*

$$-(\dot{p_1}(t), \dot{\eta}(t)) \in \partial_{(x,z)} H_1(t,x(t),z,p_1(t),u(t);\lambda,r) \qquad a.e., \tag{4}$$

$$\max_{u\in U(t)} H_1(t,x(t),z,p_1(t),u;\lambda,r) = H_1(t,x(t),z,p_1(t),u(t);\lambda,r) \qquad a.e., \tag{5}$$

$$\eta(t_0) = 0,$$

$$-p_1(t_1) \in \lambda\hat{\partial} f(x(t_1)) + r\hat{\partial} g(x(t_1)) + \hat{N}_{C_1}(x(t_1)), \tag{6}$$

$$\eta(t_1) \in r\partial V(z), \tag{7}$$

$$\|p_1\|_\infty + \|\eta\|_\infty + \lambda + r > 0. \tag{8}$$

The following result, which is a limiting subgradient version of Corollary 1 of Theorem 2.4.7 in Clarke [4], will be useful in proving Theorem 4.1. We should prove it by using a chain rule.

LEMMA 4.2. *Let* $C = \{x : \psi(x) \leq 0\}$, *where* $\psi : \mathbb{R}^n \to \mathbb{R}$ *is Lipschitz continuous on some neighborhood of* $\bar{x} \in C$. *Suppose that* $0 \notin \hat{\partial}\psi(\bar{x})$. *Then*

$$\hat{N}_C(\bar{x}) \subset \bigcup_{r\geq 0} r\hat{\partial}\psi(\bar{x}). \tag{9}$$

Proof. If $\bar{x}$ is in the interior of C, then $\hat{N}_C(\bar{x}) = \{0\}$ and the above relation is trivially satisfied. Suppose $\bar{x}$ is in the boundary of C. By virtue of (a), (c), and (e) of Proposition 2.1, $0 \notin \hat{\partial}\psi(\bar{x})$ implies

$$0 \notin \hat{\partial} r\psi(\bar{x}) \qquad \forall \text{ nonzero scalars } r \in \mathbb{R}_+ = \hat{\partial}^\infty \Psi_{\mathbb{R}_-}(\psi(\bar{x})) = \hat{N}_{\mathbb{R}_-}(\psi(\bar{x})).$$

Since $\Psi_C(\bar{x}) = \Psi_{\mathbb{R}_-}(\psi(\bar{x}))$. by the chain rule ((g) of Proposition 2.1) we have

$$\hat{\partial}\Psi_C(\bar{x}) \subset \cup\{\hat{\partial}(r\psi)(\bar{x}) : r \in \hat{\partial}\Psi_{\mathbb{R}_-}(\psi(\bar{x}))\}, \tag{10}$$

which is the relation (9) thanks to Proposition 2.1(e). □

The proof of the following result is straightforward.

LEMMA 4.3. *Let* $F(x,y,z) : \mathbb{R}^d \times \mathbb{R}^m \times \mathbb{R}^n \to \mathbb{R} \cup \{+\infty\}$ *be a lower semicontinuous function and* $(\bar{x},\bar{y},\bar{z}) \in \operatorname{dom} F$. *Suppose* $F(x,y,z) = F_1(x) + F_2(y) + F_3(z)$. *Then*

$$\hat{\partial} F(\bar{x},\bar{y},\bar{z}) \subset \hat{\partial} F_1(\bar{x}) \times \hat{\partial} F_2(\bar{y}) \times \hat{\partial} F_3(\bar{z}).$$

Proof of Theorem 4.1. We pose the optimal control problem $\widetilde{P}_1$ equivalently as the problem

$$\widehat{P}_1 \qquad \min \int_{t_0}^{t_1} F(t,x(t),z(t),u(t))dt + f(x(t_1))$$

$$\begin{aligned} \text{s.t. } \dot{x}(t) &= \phi(t,x(t),z(t),u(t)) \quad \text{a.e.},\\ \dot{y}(t) &= G(t,x(t),z(t),u(t)) \quad \text{a.e.},\\ \dot{z}(t) &= 0,\\ u(t) &\in U(t) \quad \text{a.e.},\\ (x,y,z)(t_0) &\in \{x_0\}\times\{0\}\times I\!R,\\ (x,y,z)(t_1) &\in S := \{(x,y,z) : g(x)+y-V(z)\le 0, x\in C_1\}. \end{aligned}$$

The problem above is exactly in the form described in §5.2.1 of Clarke [4]. The pseudo-Hamiltonian is the function

$$H(t,x,y,z,p_1,p_2,\eta,u,\lambda) = p_1\cdot\phi(t,x,z,u) + p_2G(t,x,z,u) - \lambda F(t,x,z,u),$$

for $t\in[t_0,t_1], x, p_1\in I\!R^d, y, p_2, \eta, \lambda\in I\!R, z\in Z$. Applying Theorem 5.2.1 of Clarke [4] with the generalized gradient replaced by the limiting subgradient in the transversality conditions leads to the existence of a scalar $\lambda\ge 0$ and an arc (p_1,p_2,η) such that

$$-(\dot{p_1}(t),\dot{p_2}(t),\dot{\eta}(t)) \in \partial_{(x,y,z)}H(t,x(t),y(t),z(t),p_1(t),p_2(t),\eta(t),u(t),\lambda) \quad \text{a.e.,} \tag{11}$$

$$\max_{u\in U(t)} H(t,x(t),y(t),z(t),p_1(t),p_2(t),\eta(t),u,\lambda)$$

$$= H(t,x(t),y(t),z(t),p_1(t),p_2(t),\eta(t),u(t),\lambda) \quad \text{a.e.,} \tag{12}$$

$$(p_1(t_0),p_2(t_0),\eta(t_0)) \in \hat{N}_{\{x_0\}\times\{0\}\times I\!R}(x(t_0),y(t_0),z(t_0)), \tag{13}$$

$$-(p_1(t_1),p_2(t_1),\eta(t_1)) \in \lambda\hat{\partial}\hat{f}(x(t_1),y(t_1),z(t_1)) + \hat{N}_S(x(t_1),y(t_1),z(t_1)), \tag{14}$$

$$\|p_1\|_\infty + \|p_2\|_\infty + \|\eta\|_\infty + \lambda > 0, \tag{15}$$

where $\hat{f}(x,y,z) := f(x)$.

Let $\hat{F}(x,y,z) = g(x)+y-V(z)$. Then by Lemma 4.3, one has

$$\hat{\partial}\hat{F}(x,y,z) \subset \hat{\partial}g(x)\times\{1\}\times\hat{\partial}(-V(z)). \tag{16}$$

Therefore $0\notin\hat{\partial}\hat{F}(x,y,z)$.

Let $S_1 := \{(x,y,z) : g(x)+y-V(z)\le 0\}$ and $S_2 := C_1\times I\!R\times I\!R$. By Lemma 4.2 and inclusion (16), one has

$$\begin{aligned} \hat{N}_{S_1}(x,y,z) &\subset \bigcup_{r\ge 0} r\hat{\partial}\hat{F}(x,y,z)\\ &\subset \bigcup_{r\ge 0} r[\hat{\partial}g(x)\times\{1\}\times\hat{\partial}(-V)(z)]. \end{aligned}$$

Since $\Psi_{S_2}(x,y,z) = \Psi_{C_1}(x) + \Psi_{I\!R}(y) + \Psi_{I\!R}(z)$, by Lemma 4.3 and (e) of Proposition 2.1 one has

$$\hat{N}_{S_2}(x,y,z) \subset \hat{N}_{C_1}(x)\times\{0\}\times\{0\} \qquad \forall (x,y,z)\in C_1\times I\!R\times I\!R.$$

It follows that the second component of any triple in the set $-\hat{N}_{S_2}(x,y,z)$ is 0. The only vectors in $\hat{N}_{S_1}(x,y,z)$ that share this property are among those for which $r=0$ in the estimate above. Thus, $\hat{N}_{S_1}(x,y,z)\cap(-\hat{N}_{S_2}(x,y,z)) = \{0\}$ and Proposition 2.1 (f) gives

$$\begin{aligned} \hat{N}_S(x(t_1),y(t_1),z(t_1)) &\subset \hat{N}_{S_1}(x(t_1),y(t_1),z(t_1)) + \hat{N}_{S_2}(x(t_1),y(t_1),z(t_1))\\ &\subset \bigcup_{r\ge 0} r[\hat{\partial}g(x(t_1))\times\{1\}\times\hat{\partial}(-V)(z)]\\ &\quad + \hat{N}_{C_1}(x(t_1))\times\{0\}\times\{0\}. \end{aligned}$$

By Lemma 4.3, one has

$$\hat{\partial}\hat{f}(x(t_1), y(t_1), z(t_1)) \subset \hat{\partial}f(x(t_1)) \times \{0\} \times \{0\}.$$

Hence from (14), one has

$$\begin{aligned}
-(p_1(t_1), p_2(t_1), \eta(t_1)) \in\ & \lambda\hat{\partial}f(x(t_1)) \times \{0\} \times \{0\} \\
& + \bigcup_{r\geq 0} r[\hat{\partial}g(x(t_1)) \times \{1\} \times \hat{\partial}(-V)(z)] \\
& + \hat{N}_{C_1}(x(t_1)) \times \{0\} \times \{0\} \\
\subset\ & \lambda\hat{\partial}f(x(t_1)) \times \{0\} \times \{0\} \\
& + \bigcup_{r\geq 0} r[\hat{\partial}g(x(t_1)) \times \{1\} \times (-\partial V(z))] \\
& + \hat{N}_{C_1}(x(t_1)) \times \{0\} \times \{0\},
\end{aligned}$$

from which the transversality conditions (6) and (7) follow and one has $p_2(t_1) = -r$, where $r \geq 0$. Since H is independent of y, (11) implies that $\dot{p_2}(t) = 0$ and

$$(17) \quad -(\dot{p_1}(t), \dot{\eta}(t)) \in \partial_{(x,z)}H(t, x(t), y(t), z(t), p_1(t), p_2(t), \eta(t), u(t); \lambda) \qquad \text{a.e.}$$

Hence $p_2 \equiv -r$, where $r \geq 0$; and (4), (5), and (8) follow from (17), (12), and (15), respectively. From (13), one has $\eta(t_0) = 0$. The proof of the theorem is thus complete. □

Combining Theorem 4.1 and Theorem 3.1, one has the following necessary conditions for optimality for the general bilevel dynamic optimization problem.

THEOREM 4.4. *In addition to assumptions* (A1)–(A5), *suppose either assumptions* (A6)–(A7) *or* (A6)′–(A7)′ *hold. Let* (z, u) *be an optimal strategy of the bilevel dynamic optimization problem* P_1 *and* $x(t)$ *the corresponding trajectory. Suppose that* $QM^0(Y) = \{0\}$. *Then there exist scalars* $\lambda \geq 0, r \geq 0$, *integers* I, J, $\lambda_{ij} \geq 0$, $\sum_{i=1}^{I}\sum_{j=1}^{J}\lambda_{ij} = 1$, *optimal trajectories* $x_i(t)$ *of the lower-level problem* $P_2(z)$, *and arcs* $p_1, \eta, p_2^{ij}, q^{ij}$ *such that*

$$\begin{aligned}
(18) \quad & -(\dot{p_1}(t), \dot{\eta}(t)) \in \partial_{(x,z)}H_1(t, x(t), z, p_1(t), u(t); \lambda, r) \qquad \textit{a.e.}, \\
& \max_{u\in U(t)} H_1(t, x(t), z, p_1(t), u; \lambda, r) = H_1(t, x(t), z, p_1(t), u(t); \lambda, r) \qquad \textit{a.e.}, \\
& \eta(t_0) = 0, \\
& -p_1(t_1) \in \lambda\hat{\partial}f(x(t_1)) + r\hat{\partial}g(x(t_1)) + \hat{N}_{C_1}(x(t_1)), \\
& \eta(t_1) = r\sum_{ij}\lambda_{ij}q^{ij}(t_0); \\
(19) \quad & (-\dot{p}_2^{ij}(t), -\dot{q}^{ij}(t), \dot{x}_i(t)) \in \partial_{(x,z,p_2)}H_2(t, x_i(t), z, p_2^{ij}(t); 1) \qquad \textit{a.e.}, \\
& q^{ij}(t_1) = 0, \\
& -p_2^{ij}(t_1) \in \hat{\partial}g(x_i(t_1)) + \hat{N}_{C_1}(x_i(t_1)), \\
& \|p_1\|_\infty + \|\eta\|_\infty + \lambda + r > 0.
\end{aligned}$$

Remark 4.1. A sufficient condition for $QM^0(Y) = \{0\}$ to hold is $C_1 = I\!R^d$. Indeed, in this case, the index 0 multiplier set consists of all arcs (p_2, q) such that

$$(20) \quad (-\dot{p_2}(t), -\dot{q}(t), \dot{x}(t)) \in \partial_{(x,z,p_2)}H_2(t, x(t), z, p_2(t); 0) \qquad \text{a.e.}$$

$$p_2(t_1) = 0, \tag{21}$$

$$q(t_1) = 0. \tag{22}$$

Due to the Lipschitz continuity of ϕ in (x, z), by virtue of Theorem 2.8.2 of Clarke [4], (20) implies that

$$\|\dot{p_2}(t)\| \leq k(t)\|p_2(t)\|.$$

By Gronwall's Lemma, the above inequality implies that p_2 is either identically 0 or nonvanishing on $[t_0, t_1]$. Therefore (21) implies that $p_2 \equiv 0$. Hence $\dot{q}(t) = 0$ by virtue of (20). But q satisfies (22), therefore $q \equiv 0$. That is $QM^0(Y) = \{0\}$.

Another sufficient condition for $M^0(Y) = \{0\}$ to hold is that $\phi(t, x, z, u)$ be independent of z since in this case $q(t) \equiv 0$.

Remark 4.2. By Clarke [4, Thm. 2.8.2], $\partial_{(x,\alpha,p_2)}H_2(t, x, \alpha, p_2; 1)$ is the convex hull of all points of the form

$$[\nabla_x\phi(t,x,\alpha,u)^\top p_2 - \nabla_x G(t,x,\alpha,u), \nabla_\alpha\phi(t,x,\alpha,u)^\top p_2 - \nabla_\alpha G(t,x,\alpha,u), \phi(t,x,\alpha,u)],$$

where u in $U(t)$ is any point at which the maximum defining $H_2(t, x, \alpha, p_2; 1)$ is achieved. Therefore if in addition to assumptions (A1)–(A5) and (A6)′–(A7)′, we assume the set

$$\{(\nabla_x\phi(t,x,\alpha,u)^\top p_2 - \nabla_x G(t,x,\alpha,u), \nabla_\alpha\phi(t,x,\alpha,u)^\top p_2 - \nabla_\alpha G(t,x,\alpha,u) : u \in U(t)\}$$

is convex for any t, x, z, p_2, then the inclusion (19) becomes the following equations:

$$\begin{aligned}
-\dot{p}_2^{ij}(t) &= \nabla_x\phi(t, x_i(t), z, u_i(t))^\top p_2^{ij}(t) - \nabla_x G(t, x_i(t), z, u_i(t)) \qquad \text{a.e.,}\\
-\dot{q}^{ij}(t) &= \nabla_z\phi(t, x_i(t), z, u_i(t))^\top p_2^{ij}(t) - \nabla_z G(t, x_i(t), z, u_i(t)) \qquad \text{a.e.,}\\
&\max_{u\in U(t)} \{p_2^{ij}(t) \cdot \phi(t, x_i(t), z, u) - G(t, x_i(t), z, u)\}\\
&\quad = p_2^{ij}(t) \cdot \phi(t, x_i(t), z, u_i(t)) - G(t, x_i(t), z, u_i(t)) \qquad \text{a.e.,}\\
&\dot{x}_i(t) = \phi(t, x_i(t), z, u_i(t)) \qquad \text{a.e.,}
\end{aligned}$$

where $u_i(t)$ is an optimal control function associated with trajectory $x_i(t)$.

5. Extensions and an example.

There are many situations where an opportunity cost exists for the follower. That is, the follower will participate only if his optimal cost is less than or equal to the opportunity cost $L \geq 0$ that he may receive from somewhere else. In this case, the leader faces the following bilevel optimization problem:

$$\begin{aligned}
\overline{P}_1 \qquad \min J_1(z,u) &= \int_{t_0}^{t_1} F(t, x(t), z(t), u(t))dt + f(x(t_1)),\\
\text{s.t. } \dot{x}(t) &= \phi(t, x(t), z(t), u(t)) \qquad \text{a.e.,}\\
\dot{z}(t) &= 0,\\
x(t_0) &= x_0, \quad x(t_1) \in C_1,\\
u(t) &\in U(t) \qquad \text{a.e.,}\\
\int_{t_0}^{t_1} G(t, x(t), z(t), u(t))dt &+ g(x(t_1)) \leq V(z),\\
\int_{t_0}^{t_1} G(t, x(t), z(t), u(t))dt &+ g(x(t_1)) \leq L.
\end{aligned}$$

The technique described in the previous section can be applied to this more general problem in exactly the same way, and one obtains the following necessary conditions for optimality.

THEOREM 5.1. *Assume that in addition to* (A1)–(A5), *either assumptions* (A6)–(A7) *or* (A6)′–(A7)′ *hold. Let* (z, u) *be an optimal strategy of the bilevel dynamic optimization problem* $\overline{P}_1$ *and* $x(t)$ *the corresponding trajectory. Suppose that* $QM^0(Y) = \{0\}$. *Then there exist scalars* $\lambda \geq 0, r \geq 0, 0 \leq \hat{r} \leq r$, *integers* I, J, $\lambda_{ij} \geq 0$, $\sum_{i=1}^{I} \sum_{j=1}^{J} \lambda_{ij} = 1$, *optimal trajectories* $x_i(t)$ *of the lower-level problem* $P_2(z)$, *and arcs* $p_1, \eta, p_2^{ij}, q^{ij}$ *such that*

$$-(\dot{p}_1(t), \dot{\eta}(t)) \in \partial_{(x,z)} H_1(t, x(t), z, p_1(t), u(t); \lambda, r) \qquad a.e.,$$

$$\max_{u \in U(t)} H_1(t, x(t), z, p_1(t), u; \lambda, r) = H_1(t, x(t), z, p_1(t), u(t); \lambda, r) \qquad a.e.,$$

$$\eta(t_0) = 0,$$

$$-p_1(t_1) \in \lambda \hat{\partial} f(x(t_1)) + r \hat{\partial} g(x(t_1)) + \hat{N}_{C_1}(x(t_1)),$$

$$\eta(t_1) = \hat{r} \sum_{ij} \lambda_{ij} q^{ij}(t_0),$$

$$(-\dot{p}_2^{ij}(t), -\dot{q}^{ij}(t), \dot{x}_i(t)) \in \partial_{(x,z,p_2)} H_2(t, x_i(t), z, p_2^{ij}(t); 1) \qquad a.e.,$$

$$q^{ij}(t_1) = 0,$$

$$-p_2^{ij}(t_1) \in \hat{\partial} g(x_i(t_1)) + \hat{N}_{C_1}(x_i(t_1)),$$

$$\|p_1\|_\infty + \|\eta\|_\infty + \lambda + r > 0.$$

The following example is a simplified and finite horizon version of a fishery regulation problem first formulated and solved by Clarke and Munro using principal and agent analysis (see Clarke and Munro [7] and [8] for details).

Example. It has now been generally agreed that the fishery resources within the 200-mile zones are the property of the adjacent coastal states. For those coastal states opting to permit a distant water presence in their 200-mile zones, one of the problems they face is devising optimum terms and conditions of access to the Coastal State Exclusive Economic Zones to be imposed upon the distant water fleets.

Assume that the fish population follows the dynamic system

$$\dot{x}(t) = F(x(t)) - qE(t)x(t),$$

where $x(t)$ is the fish population at time t; $F(x)$ is the rate of natural growth; and $qE(t)x(t)$ is the rate of catch at time t, where $E(t)$ is the fishing effort at time t and q is a positive constant. We assume that $F(x)$ is a twice continuously differentiable function satisfying $F(x) > 0$ for $0 < x < \bar{x}, F(0) = F(\bar{x}) = 0$ and $F''(x) < 0$ for all $x > 0$, where $\bar{x}$ denotes the carrying capacity of the resource. It is also assumed that

$$0 \leq E(t) \leq E_{\max},$$

where $E_{\max}$ is an arbitary upper bound on $E(t)$. Suppose that the coastal state imposes the condition that at the terminal time T_1, the fish population cannot be less than $\widetilde{x} \geq 0$.

Suppose that the coastal states as a leader impose a unit tax n on catch $qE(t)x(t)$ and a unit tax m on effort $E(t)$. Then the distant water fleet would receive the profit in time period $[0, T_1]$

$$\int_0^{T_1} e^{-\delta t}[(p_0 - n)qx(t) - (c_0 + m)]E(t)dt$$

if he decided to use the fishing effort $E(\cdot)$ where p_0 and c_0 are the unit price on catch and unit cost on effort, respectively, $\delta > 0$ is the discount rate, and $x(\cdot)$ is the fish population corresponding to the fishing effort $E(\cdot)$. Hence for the given unit tax on catch and effort n and m, the distant water fleet as a follower faces the following optimal control problem:

$$\begin{aligned} P_2(n,m) \qquad & \max \int_0^{T_1} e^{-\delta t}[(p_0 - n)qx(t) - (c_0 + m)]E(t)dt, \\ & \text{s.t. } \dot{x}(t) = F(x(t)) - qE(t)x(t), \\ & x(0) = x_0, \quad x(T_1) \geq \widetilde{x}, \\ & E(t) \in [0, E_{\max}]. \end{aligned}$$

The optimal control problem $P_2(n,m)$ is linear. The necessary condition for (x, E) to solve $P_2(n,m)$ is the existence of an arc p_2 such that

$$-\dot{p_2}(t) = p_2(t)[F'(x(t)) - qE(t)] + e^{-\delta t}(p_0 - n)qE(t), \tag{23}$$

$$\begin{aligned} &\max_{E \in [0, E_{\max}]} \{p_2(t)[F(x(t)) - qEx(t)] + e^{-\delta t}[(p_0 - n)qx(t) - (c_0 + m)]E\} \\ &\quad = p_2(t)[F(x(t)) - qE(t)x(t)] + e^{-\delta t}[(p_0 - n)qx(t) - (c_0 + m)]E(t), \end{aligned} \tag{24}$$

$$p_2(T_1) \geq 0.$$

Since $E(t)$ has to maximize the Hamiltonian (see (24)), $E(t)$ must be either the singular control or else $E(t) = 0$ or $E_{\max}$. The singular control arises when the coefficient of E in the Hamiltonian is zero, implying that

$$p_2(\dot{t}) = e^{-\delta t}\left[(p_0 - n) - \frac{c_0 + m}{qx}\right] \tag{25}$$

$$\dot{p_2}(t) = e^{-\delta t}\left[-\delta\left[(p_0 - n) - \frac{c_0 + m}{qx}\right] + \frac{c_0 + m}{qx^2}\frac{dx}{dt}\right]. \tag{26}$$

From the adjoint equation (23), one has

$$\begin{aligned} \dot{p_2} &= -p_2[F'(x) - qE] - e^{-\delta t}[(p_0 - n)qE \\ &= -e^{-\delta t}\left\{\left[(p_0 - n) - \frac{c_0 + m}{qx}\right][F'(x) - qE] + (p_0 - n)qE\right\}, \end{aligned} \tag{27}$$

where (25) is used for p_2. When the two expressions for $\dot{p_2}(t)$, (26) and (27), are equated, the control variable E cancels out and the following equation emerges:

$$F'(x) + \frac{F(x)(c_0 + m)/qx^2}{p_0 - n - (c_0 + m)/qx} = \delta. \tag{28}$$

For fixed (n, m), this equation gives a unique solution x_* that is the optimal biomass and the optimal trajectory is the one that takes the most rapid path to the optimal biomass x_* (cf. Clark [3]).

Let $V(n,m)$ be the optimal value of the above problem. The distant water fleet will participate only when $V(n,m) \geq L$, the alternative remuneration from some other coastal state.

The coastal state as a leader now faces the following bilevel dynamic optimization problem:

$$
\begin{aligned}
P_1 \qquad & \max \int_0^{T_1} e^{-\delta t}(nqx(t)+m)E(t)dt, \\
& \text{s.t. } \dot{x}(t) = F(x(t)) - qE(t)x(t), \\
& x(0) = x_0, \quad x(T_1) \geq \widetilde{x}, \\
& E(t) \in [0, E_{\max}] \qquad \text{a.e.}, \\
V(n,m) \leq & \int_0^{T_1} e^{-\delta t}[(p_0-n)qx(t) - (c_0+m)]E(t)dt, \\
& V(n,m) \geq L.
\end{aligned}
$$

It is easy to show that all the conditions of Theorem 5.1 are satisfied. Notice that the lower-level problem $P(n,m)$ has a unique solution. By Theorem 5.1 and Remark 3.2, if (n,m,x,E) is an optimal solution to P_1, then there exist arcs $p_1, p_2, \eta_1, \eta_2, q_1, q_2$ and scalars $\lambda \geq 0$, $r \geq 0$, $0 \leq \hat{r} \leq r$ such that

$$-\dot{p_1} = p_1[F'(x) - qE) + e^{-\delta t}[r(p_0-n) + \lambda n]qE, \tag{29}$$

$$
\begin{aligned}
&\dot{\eta_1} = (r-1)e^{-\delta t}qxE, \\
&\dot{\eta_2} = (r-1)e^{-\delta t}E, \\
&\max_{E \in [0,E_{\max}]} \{p_1(t)[F(x(t)) - qEx(t)] + e^{-\delta t}[r[(p_0-n)qx(t) - (c_0+m)] \\
&\qquad\qquad\qquad +\lambda(nqx(t)+m)]E\} \\
&= p_1(t)[F(x(t)) - qE(t)x(t)] + e^{-\delta t}[r[(p_0-n)qx(t) - (c_0+m)] \\
&\qquad\qquad\qquad +\lambda(nqx(t)+m)]E(t),
\end{aligned}
\tag{30}
$$

$$(\eta_1, \eta_2)(0) = (0,0),$$

$$p_1(T_1) \geq 0, \tag{31}$$

$$(\eta_1, \eta_2)(T_1) = \hat{r}q(0),$$

$$-\dot{p_2} = p_2[F'(x) - qE] + e^{-\delta t}(p_0-n)qE, \tag{32}$$

$$
\begin{aligned}
&\dot{q_1} = e^{-\delta t}qxE, \\
&\dot{q_2} = e^{-\delta t}E,
\end{aligned}
$$

$$
\begin{aligned}
&\max_{E \in [0,E_{\max}]} \{p_2(t)[F(x(t)) - qEx(t)] + e^{-\delta t}[(p_0-n)qx(t) - (c_0+m)]E\} \\
&= p_2(t)[F(x(t) - qE(t)x(t)] + e^{-\delta t}[(p_0-n)qx(t) - (c_0+m)]E(t),
\end{aligned}
\tag{33}
$$

$$(q_1, q_2)(0) = (0,0),$$

$$p_2(T_1) \geq 0, \tag{34}$$

$$\|p_1\|_\infty + \|\eta\|_\infty + \lambda + r > 0.$$

Take $\lambda = 1$. As in the proof of (28), from (29) and (30) we can show that the steady state (n,m,x_*) for problem P_1 is a solution of the following equation:

$$F'(x_*) + \frac{F(x_*)(r(c_0+m) - m)/q{x_*}^2}{r(p_0-n) + n - (r(c_0+m)-m)/qx_*} = \delta, \tag{35}$$

and the optimal trajectory for P_1 is the one that takes the most rapid path to the optimal biomass (n, m, x_*). Since (n, m, x, E) is an optimal solution of P_1, (x, E) must be the optimal solution of the lower-level problem $P_2(n, m)$. Therefore x_* must be the optimal biomass associated with (n, m) defined by (28). Combining equations (28) and (35), one has

$$n = \rho p_0,$$
$$m = -\rho c_0,$$

where ρ is some constant to be determined. It is obvious that the optimal tax (n, m) must be such that $V(n, m) = L$. Let V_0 be the net global returns from the fishery, i.e.,

$$V_0 = \max \left\{ \int_0^{T_1} e^{-\delta t}(p_0 q x(t) - c_0) E(t) dt \right\}.$$

Then

$$\begin{aligned} (1-\rho)V_0 &= \max \left\{ \int_0^{T_1} e^{-\delta t}[(1-\rho)p_0 q x(t) - (1-\rho)c_0] E(t) dt \right\} \\ &= \max \left\{ \int_0^{T_1} e^{-\delta t}[(p_0 - n) q x(t) - (c_0 + m)] E(t) dt \right\} \\ &= V(n, m) = L, \qquad (36) \end{aligned}$$

from which it follows that $\rho = (V_0 - L)/V_0$. (36) also indicates that $E(t)$ will maximize the global net returns from the fishery. Hence the above necessary condition for optimality is indeed satisfied by $\lambda = 1$, $r = 1$, $\hat{r} = 0$, $n = \rho p_0$, $m = -\rho c_0$, and the corresponding fishing effort $E(t)$ since equations (29), (30), and (31) are necessary for $E(t)$ to maximize the net global returns from the fishery; (32), (33), and (34) are the necessary optimality conditions for the lower-level problem; and the rest of equations are easily seen to hold. The results agree with the work of Clarke and Munro [7].

Acknowledgments. The author would like to thank Philip Loewen for many helpful suggestions that led to improvements in the results of this paper and two anonymous referees for comments that led to the improvements in the style of the presentation in this version.

USING PERSISTENT EXCITATION WITH FIXED ENERGY TO STABILIZE ADAPTIVE CONTROLLERS AND OBTAIN HARD BOUNDS FOR THE PARAMETER ESTIMATION ERROR*

MILOJE S. RADENKOVIC† AND B. ERIK YDSTIE‡

Abstract. Two important instability problems in certainty equivalence adaptive control are solved by external excitation. The first instability is parameter drift along an unstable manifold when the excitation level is not high enough. The second instability is numerical and due to a division with zero in the adaptive law. Global methods based on excitation have been developed to solve this problem, but the energy of the excitation has been tuned on-line. The main contribution of the current paper is in showing that the estimator is stabilized when we apply excitation with *fixed and finite energy*. The level of excitation should be sufficiently high relative to the magnitudes of the external disturbances and the unmodeled dynamics. The approach can be generalized to more complex adaptive laws. This, together with the fact that we obtain hard bounds for the parameter estimation error, opens up for the possibility of designing robust controllers that are adaptive.

Key words. adaptive control, self-tuning regulator, stability, robustness, learning, excitation

1. Introduction.

In this paper we present the global stability analysis of a direct adaptive control system for which a persistent excitation condition is satisfied. By *global* we mean that the results are valid for all initial conditions. In this way the analysis complements averaging methods which are initial-condition dependent. Averaging has been applied for the *local* analysis of adaptive systems with considerable success, and sufficient as well as necessary conditions for the stability of integral manifolds have been obtained by exploiting hyperbolicity [2], [12], [14]. The degree of locality of these results has not been determined. But it is an important problem worth investigating since averaging can give tight results. It comes as a surprise to the authors of this paper that averaging in adaptive control can have global validity when the singularities that may arise in the control design equations are avoided.

It was recognized early that the parameter estimates in certainty-equivalent adaptive control may drift, become unbounded, or cross through regions where the control law calculation is ill conditioned. The reason for this rather disappointing behaviour is that the adaptive controller does not destabilize in such a way that excitation is generated. In the ideal case the parameters cannot diverge [4]. However, self-stabilization of the estimator does not take place, and in the nonideal case small-amplitude, chaotic bursts as well as large transients and numerical instabilities may be observed [3], [15]. The drift problems can be solved by using artificial parameter bounding. In the case of leakage [6] and parameter projection [7] the parameters are constrained to belong to compact sets and additional measures are taken to ensure that the control law calculations are well behaved. Unfortunately, while boundedness of the input/output signals can be established, these methods do not ensure that the parameter estimator is stabilized and large bursts are possible. A number of methods for solving the singularity problem have been proposed. These include the adaptive excitation approach

[1], parameter projection [7] approaches where the high-frequency gain is modified [5], and a recent method where the controller gains are switched to maintain a certain detectability property [8].

It is possible to solve the drift and singularity problems by ensuring that the estimator equations remain stable. The estimated parameters are then close to optimal and singularities and drift are avoided. The sufficient and necessary condition for such stabilization to take place is that the regression vector is persistently excited [14]. Since excitation is not automatically generated within the adaptive loop, the only possibility that remains is to generate the excitation externally. In this paper we do this by manipulating the reference signal using fixed and finite energy over a range of selected frequencies. Once excitation is generated this leads not only to stabilization of the adaptive loop but also to good conditions for the estimator. The parameter drift is arrested, and small parameter errors can be guaranteed. Reasonable system conditions can then be imposed to ensure that singularity problems in the solution of the Bezout identities do not arise, and methods can be developed to start and stop the estimator. Thus we do not only solve the problem of adaptive stabilization, we also solve the problem of identifying parameters in an uncertain environment. The latter problem has attracted considerable attention in the recent literature. See for example the recent IEEE T-AC special issue on identification. However, we believe that results developed in this paper are among the first that can be applied for the identification of an open-loop unstable plant.

We analyze a simple one step–step-ahead predictive controller with gradient estimator. Two types of data normalization are used in the analysis. In one instance we use the exponentially weighted normalization [11] to show robustness of adaptive control with respect to unmodeled dynamics and bounded noise. This approach requires knowledge of an upper bound for the largest time constant for the closed-loop system with an ideal controller. In order to relax this assumption we also analyse a second type of normalization sequence that does not require this type of a priori information. The idea here is to use the largest regressor up to time t to normalize the signals.

The results of the paper can be generalized to continuous time. Thus the projection used in [9] can be replaced with finite energy excitation of the reference.

2. Notation and terminology. For a function $x : T \longrightarrow R^+$, we define the following semi-norm

$$\|x(t)\|_\lambda = \left\{ \sum_{j=1}^{t} \lambda^{t-j} x(j)^2 \right\}^{1/2}, \qquad 0 < \lambda < 1.$$

Here T is the set of positive integers, while R^+ is the set of nonnegative real numbers. When $\|x(t)\|_\lambda$ is bounded for all $t \geq 0$, x is said to be in l_2^λ.

H_∞ will denote the space of transfer functions $T(z)$, which are analytic and bounded outside and on the unit circle in the z-plane. S^λ is the operator defined by

$$S^\lambda T(z) = T(\lambda^{1/2} z).$$

H_∞^λ is the space of transfer functions $T(z)$ such that $S^\lambda T(z) \in H_\infty$. In other words, $T(z) \in H_\infty^\lambda$, if $T(z)$ is analytic and bounded outside and on the circle $|z| = \lambda^{1/2}$ in the z-plane. For $T(z) \in H_\infty$, the H_∞ norm is defined by

$$\|T(z)\|_\infty = \max_{|z|=1} |T(z)|.$$

Likewise, the norm of the H_∞^λ space is defined by

$$\|T(z)\|_\infty^\lambda = \|S^\lambda T(z)\|_\infty = \max_{|z|=1} |T(\lambda^{1/2} z)|.$$

This norm is induced by the l_2^λ norm of the input and output signals of $T(z)$.

When performing majorizations in order to account for initial conditions, we use nonnegative functions

$$\xi_i(t) = c_i \beta_i^t, \qquad 0 \le c_i < \infty, \qquad 0 < \beta_i < 1.$$

When confusion cannot arise, we drop the subscripts.

3. Deterministic adaptive control and major assumptions. Let us consider the following discrete-time single-input single-output (SISO) system with unmodeled dynamics

$$(1) \quad A(q^{-1})y(t+1) = B(q^{-1})[1 + \Delta_1(q^{-1})]u(t) + A(q^{-1})\Delta_2(q^{-1})u(t) + w(t+1)$$

where $\{y(t)\}, \{u(t)\}$, and $\{w(t)\}$ are output, input, and disturbance sequences, respectively, while q^{-1} represents the unit delay operator. The polynomials $A(q^{-1})$ and $B(q^{-1})$ describe the nominal system model, which may be taken as being "centered" [16], and can be written as

$$A(q^{-1}) = 1 + a_1 q^{-1} + \cdots + a_{n_A} q^{-n_A},$$

$$B(q^{-1}) = b_0 + \cdots + b_{n_B} q^{-n_B}, \text{ with } b_0 \neq 0.$$

In equation (1), $\Delta_i(q^{-1})$ for $i = 1, 2$ denote multiplicative and additive system perturbations. The transfer functions $\Delta_i(q^{-1})$ for $i = 1, 2$ are causal and $\Delta_1(q^{-1})$ is stable.

The aim is to stabilize simultanously the input–output behaviour of the system (1) and estimate the parameters of the nominal model to a given precision. This is the problem of identification of open-loop unstable systems.

The nominal model is assumed to be stably invertible, the model mismatch small, the external perturbations bounded, and the reference signal excited with sufficient energy in a selected range of frequencies. In order to develop the theory we will apply direct adaptive control to minimize the criterion

$$J = [y(t) - y^*(t)]^2$$

where $y^*(t)$ is the given reference signal.

To define the adaptive law it is convenient to write system (1) in the form

$$(2) \qquad y(t+1) = \theta_0' \phi(t) + \gamma(t)$$

where

$$\theta_0' = (-a_1, -a_2, \ldots, -a_{n_A}, b_0, b_1, \ldots, b_{n_B})$$

is the vector of parameters that need to be estimated,

$$\phi(t)' = (y(t), y(t-1), \ldots, y(t - n_A + 1), u(t), u(t-1), \ldots, u(t - n_B))$$

is the regression vector, and finally, the modeling error is defined so that

$$\gamma(t) = \Delta_0(q^{-1})u(t) + w(t+1) \tag{3}$$

with

$$\Delta_0(q^{-1}) = B(q^{-1})\Delta_1(q^{-1}) + A(q^{-1})\Delta_2(q^{-1}).$$

From equation (2) it is obvious that when $\gamma(t) = 0$, the control law

$$\text{Solve for} \quad u(t): \quad \theta_0'\phi(t) - y^*(t+1) = 0 \tag{4}$$

is optimal. Internal stability is ensured by the stable invertibility of $B(q^{-1})$.

In certainty-equivalent adaptive control the parameter vector θ_0 is replaced by an estimate

$$\theta(t)' = (-\hat{a}_1(t), -\hat{a}_2(t), \ldots, -\hat{a}_{n_A}(t), \hat{b}_0(t), \hat{b}_1(t), \ldots, \hat{b}_{n_B}(t)).$$

The following algorithm is used for estimating the unknown parameter θ_0.

$$\theta(t+1) = \theta(t) + \frac{\mu}{r(t)}\phi(t)e(t) \tag{5}$$

where

$$e(t) = y(t) - y^*(t) \tag{6}$$

is the tracking error. The algorithm gain sequence may be given by

$$r(t) = r_0 + n_\phi(t)^2, \text{ with } 0 < r_0 < \infty$$

and

$$n_\phi(t)^2 = \lambda n_\phi(t-1)^2 + \|\phi(t)\|^2 \tag{7}$$

where λ is a tunable parameter chosen so that $0 < \lambda < 1$. Note that this gain sequence is similar to that proposed in [11]. In [16] the gain sequence is defined with $\lambda = 0$ so that

$$r(t) = r_0 + \|\phi(t)\|^2.$$

In the current paper we also analyse an algorithm with gain sequence chosen so that

$$r(t) = r_0 + \max_{1 \le \tau \le t} \|\phi(\tau)\|^2. \tag{8}$$

This normalization sequence does not involve the parameter λ as is the case with n_ϕ defined by equation (7). On the other hand, $r(t)$ defined by equation (8) satisfies the same property as the sequence given by (7), namely $r(t) \ge \lambda r(t-1)$. As a consequence of this we should expect that the two algorithms behave in a similar fashion as long as $\phi(t)$ remains uniformly bounded. The main results concerning normalization sequence (7) are given in Theorem 5.1. The results concerning normalization sequence (8) are given in Theorem 5.2. The analysis for the normalization sequence (7) with $\lambda = 0$ can be carried out using the approach developed in [16] for the discrete-time case and in [9] for the continuous-time case.

Equation (4) is ill defined when the estimate of b_0 is equal to zero and measures need to be taken to prevent large transients and instability of the algorithm. One approach, which is the one we follow here, is to depart from certainty equivalence on the event $A(t) = I_{\{|\hat{b}_0(t)|<\epsilon_1\}}$, where $I_{\{\cdot\}}$ is the indicator function and ϵ_1 is specified below, and implement the law

$$\text{(9)} \qquad \text{Solve for} \quad u(t): \quad \theta_c(t)'\phi(t) - y^*(t+1) = 0$$

with

$$\text{(10)} \qquad \theta_c(t)' = (-\hat{a}_1(t), -\hat{a}_2(t), \ldots, -\hat{a}_{n_A}(t), \epsilon(t) + \hat{b}_0(t), \hat{b}_1(t), \ldots, \hat{b}_{n_B}(t)).$$

Here

$$\epsilon(t) = \begin{cases} 0 & \text{if } |\hat{b}_0(t)| \geq \epsilon_1 > 0, \\ \epsilon_1 \text{sign}(\hat{b}_0(t)) & \text{if } |\hat{b}_0(t)| < \epsilon_1. \end{cases}$$

The sign function is defined so that $\text{sign}(x) = 1$ if $x \geq 0$ and $\text{sign}(x) = -1$ otherwise. The approach is similar to that used by Lozano–Leal, Collado, and Mondie [5] for the analysis of robustness of model-reference adaptive control. Other approaches include parameter projection [7] and controller switching [8]. These approaches give boundedness even when the signals are not excited, provided that projection is used to maintain finite parameters. But the modification then remains active and poor transients may result. We show that with excitation we get

$$\sum_{t=1}^{\infty} A(t) < \infty.$$

The modification applies a finite number of times, and the algorithm converges to a certainty-equivalence algorithm.

Assumption A1 (Concerning the reference signal and the disturbances): There exist constants k_w and k_{y^*} so that for all $t \geq 1$:

$$|w(t)| \leq k_w \qquad \text{and} \qquad |y^*(t)| \leq k_{y^*}.$$

In order to motivate the second assumption we develop closed-loop expressions for the adaptive system. From equations (2) and (9) it follows that

$$\text{(11)} \qquad e(t+1) = -z(t) + \gamma(t)$$

where

$$\text{(12)} \qquad z(t) = \tilde{\theta}_c'(t)\phi(t)$$

and the control parameter error satisfies

$$\tilde{\theta}_c(t) = \theta_c(t) - \theta_0.$$

From equations (9) and (12) we obtain

$$B(q^{-1})u(t) + q(1 - A(q^{-1}))y(t) = y^*(t+1) - z(t).$$

Combining this with equations (6) and (11) gives

$$B(q^{-1})u(t) = A(q^{-1})(-z(t) + y^*(t+1)) + (A(q^{-1}) - 1)\gamma(t). \tag{13}$$

Substituting this into equation (3) gives the closed loop

$$\gamma(t) = -\frac{\Delta_0(q^{-1})A(q^{-1})}{B(q^{-1}) - \Delta_0(q^{-1})(A(q^{-1}) - 1))}(z(t) - y^*(t+1)) \tag{14}$$

$$+\frac{B(q^{-1})}{B(q^{-1}) - \Delta_0(q^{-1})(A(q^{-1}) - 1))}w(t+1).$$

The transfer function from the reference signal to the model error $\gamma(t)$ plays a signficant role in the stability analysis. It is assumed to be stable and have small gain. In order to discuss this assumption and perform the analysis, define the following H_∞ norms:

$$C_{AB} = \left\| \frac{A(z)}{B(z)} \right\|_\infty^\lambda, \qquad C_A = \left\| \frac{A(z) - 1}{B(z)} \right\|_\infty^\lambda,$$

$$C_\gamma = \left\| \frac{\Delta_0(z)A(z)}{B(z) - \Delta_0(z)(A(z) - 1)} \right\|_\infty^\lambda, \qquad C_w = \left\| \frac{B(z)}{B(z) - \Delta_0(z)(A(z) - 1)} \right\|_\infty^\lambda.$$

Assumption A2 (Concerning the nominal system and unmodeled dynamics):

1. There exists a positive number $\lambda_0 < 1$ such that the zeros of $B(z^{-1})$ and the poles of the transfer functions

$$H_0(z^{-1}) = \frac{\Delta_0(z^{-1})A(z^{-1})}{B(z^{-1}) - \Delta_0(z^{-1})(A(z^{-1}) - 1)}$$

and

$$H_1(z^{-1}) = \frac{B(z^{-1})}{B(z^{-1}) - \Delta_0(z^{-1})(A(z^{-1}) - 1)}$$

are inside a circle with radius λ_0.

2. The transfer function $H_0(q^{-1})$ has small gain in the sense that the inequality

$$\rho_1(\epsilon_1) = 1 - \frac{\mu}{2} - (1-\mu)C_\gamma - \frac{\mu}{2}C_\gamma^2 - \epsilon_1 C_u(1 + C_\gamma) > 0$$

with

$$C_u = C_{AB} + C_A C_\gamma$$

is satisfied.

It is well known that the adaptive control algorithm described above may not be stable when there is no excitation. The problem is due to the presence of an unstable manifold along which the parameter estimates may drift to infinity. The problem can be avoided by applying parameter projection or leakage. However, these methods may give large transients and unrelenting bursting, unless the region into which the parameters are projected is small or the leakage center is defined close to the optimal parameter values. An alternative method, which we explore here, is to supply additional excitation. This approach has been shown to work well locally, and using averaging theory, necessary and sufficient conditions for the stability of integral manifolds have been established. The purpose of our analysis is to extend these results to be valid globally. In order to do this we introduce the following assumption about the level of excitation.

Define

$$\phi^*(t)' = \left(y^*(t),\ldots,y^*((t-n_A+1),\frac{A(q^{-1})}{B(q^{-1})}y^*(t+1),\ldots,\frac{A(q^{-1})}{B(q^{-1})}y^*(t-n_B+1)\right) \tag{15}$$

Assumption A3 (Persistent excitation): For all sufficiently large N

$$\sum_{t=1}^{N}\lambda^{N-t}\phi^*(t)\phi^*(t)' \geq \delta_1^* I$$

where, for some δ_2^*,

$$\frac{\delta_1^*}{2} - \left(n_1\Sigma_\gamma(\epsilon_1) + n_2\left[C_\gamma\Sigma_\gamma(\epsilon_1) + (C_\gamma k_{y^*} + (1+C_w)k_w)\frac{1}{(1-\lambda)^{1/2}}\right]\right) = \delta_2^* > 0 \tag{16}$$

with

$$\Sigma_\gamma(\epsilon_1)^2 = \max\left\{\frac{16}{\rho_1(\epsilon_1)^2}[(1-\mu+\mu C_\gamma+\epsilon_1 C_u)\Sigma_1+\epsilon_1(1+C_\gamma)\Sigma_2]^2;\ \frac{\mu\Sigma_1}{\rho_1(\epsilon_1)}(\Sigma_1+2\epsilon_1\Sigma_2)\right\} \tag{17}$$

with

$$\Sigma_1 = \frac{k_{y^*}C_\gamma + k_w C_w}{(1-\lambda)^{1/2}} \quad \text{and} \quad \Sigma_2 = \frac{k_{y^*}C_u + k_w C_A C_w}{(1-\lambda)^{1/2}}.$$

The constants n_1 and n_2 are defined so that

$$n_1 = \left(\sum_{i=1}^{n_A}\lambda^{-i} + C_{AB}^2\sum_{i=1}^{n_B}\lambda^{-i}\right)^{1/2} \quad \text{and} \quad n_2 = \left(\sum_{i=1}^{n_A}\lambda^{-i} + C_A^2\sum_{i=1}^{n_B}\lambda^{-i}\right)^{1/2}.$$

Comments.

1. Assumption A1 simply states that the reference and the disturbances should be uniformly bounded.
2. It is not difficult to see that Assumption A2 can be written as

$$(1-C_\gamma)\left(\left(1-\frac{\mu}{2}(1-C_\gamma)\right)-\epsilon_1 C_u\right) > 0.$$

This relation is satisfied if

$$C_\gamma < 1 \tag{18}$$

and

$$1-\frac{\mu}{2}+\frac{\mu}{2}C_\gamma - \epsilon_1 C_{AB} - \epsilon_1 C_A C_\gamma > 0. \tag{19}$$

Relationship (19) will be satisfied if ϵ_1 is selected so that

$$\epsilon_1 < \max\left\{(1-\frac{\mu}{2})\frac{1}{C_{AB}};\ \frac{\mu}{2C_A}\right\}, \tag{20}$$

and the admissible unmodeled dynamics are then specified by inequality (18).

3. Assumption A3 is more complicated and essentially means the following. The intensities of the unmodeled dynamics C_γ, the external disturbances, and the design parameter ϵ_1 should be small compared with the level of excitation. Moreover, $y^*(t)$ should have a spectral distribution function that is nonzero at $n_A + n_B + 1$ points (or more), and the transfer function of the nominal system model $B(z)/A(z)$ should be irreducible. This condition is not stronger than the similar conditions introduced in deterministic adaptive control and coincides with those obtained from the application of the averaging analysis.
4. Since we do not know the magnitude of the disturbances, the intensity of the unmodeled dynamics, and H_∞-norms C_{AB} and C_A, we cannot select ϵ_1 so that relationship (20) holds. The immediate consequence of this is that it is difficult to choose the right level of excitation, and we are still some way off from the target of having a completely adaptive control algorithm. In the following we assume that ϵ_1 and the level of excitation is chosen so that this relationship holds true.

Constants whose values are unimportant and do not depend on C_γ and C_w will be denoted by $C_i, i = 1, 2, \ldots$. Constants whose values are unimportant but depend on C_γ and C_w will be denoted by $\bar{C}_i, i = 1, 2, \ldots$.

4. Technical results. The following three results are useful for future reference. Lemma 4.1 simply states that all signals are bounded by the l_2^λ norm of the error signal $z(t)$ plus constants. Lemma 4.2 states that when the l_2^λ norm of $z(t)$ is small, the signal vector $\phi(t)$ is persistently exciting. Finally, Lemma 4.3 states that under similar conditions the parameter error vector is small.

LEMMA 4.1. *Let Assumptions* A1 *and* A2 *hold. Then*

1. $\|\gamma(t)\|_\lambda \le C_\gamma \|z(t)\|_\lambda + h_1(t)$ *where*

$$h_1(t) = \frac{C_\gamma k_{y^*} + C_w k_w}{(1-\lambda)^{1/2}} + \xi_1(t).$$

2. $\|u(t)\|_\lambda \le C_u \|z(t)\|_\lambda + h_2(t)$ *with*

$$h_2(t) = \frac{C_u k_{y^*} + C_A C_w k_w}{(1-\lambda)^{1/2}} + \xi_2(t).$$

3. $\|\phi(t)\|_\lambda \le C_{\phi_1} \|z(t)\|_\lambda + h_3(t)$ *where*

$$h_3(t) = \frac{C_{\phi_1} k_{y^*} + C_{\phi_2} k_w}{(1-\lambda)^{1/2}} + \xi_3(t),$$

$$C_{\phi_1} = C_1(\lambda^{-1/2}(1 + C_\gamma) + C_u) \; and \; C_{\phi_2} = C_1 C_w(\lambda^{-1} + C_A),$$

$$C_1 = \left(\sum_{i=0}^{\max\{n_A, n_B+1\}} \lambda^{-i} \right)^{1/2}.$$

4. *If there exists finite* t_0 *such that for all* $t \ge t_0$, $\|\theta_c(t)\| \le f_\theta < \infty$, *then*

$$r(t) \le \max\{C_\theta \|z(t-1)\|_\lambda^2, k_\theta + \xi_4(t)\}$$

with

$$C_\theta = 4\left(C_1\left(1+\frac{f_\theta C_1}{\epsilon_1}\right)(1+C_\gamma+C_u)\right)^2$$

and

$$k_\theta = 4\left(r_0^{1/2} + C_1\left(1+\frac{f_\theta C_1}{\epsilon_1}\right)\left(\frac{(1+C_\gamma+C_u)k_{y^*}+C_w(1+C_A)k_w}{(1-\lambda)^{1/2}}\right)\left(1+\frac{k_{y^*}C_1}{\epsilon_1}\right)\right)^2$$

Proof. Statement 1 of the lemma follows from equation (14). By using (13) we get

$$\|u(t)\|_\lambda \le C_{AB}(\|z(t)\|_\lambda + \|y^*(t+1)\|_\lambda) + C_A\|\gamma(t)\|_\lambda + \xi(t). \tag{21}$$

After substituting from statement 1 we have statement 2. From the definition of the regressor and equation (7) it follows that

$$\|\phi(t)\|_\lambda \le C_1(\|y(t)\|_\lambda + \|u(t)\|_\lambda) + \xi(t) \tag{22}$$

where C_1 was defined under statement 3. From equations (6) and (11) and statement 1 of the lemma we then get

$$\|y(t)\|_\lambda \le (1+C_\gamma)(\|z(t-1)\|_\lambda + \|y^*(t)\|_\lambda) + C_w\|w(t)\|_\lambda + \xi(t). \tag{23}$$

Statement 3 of the lemma follows by using the last three relations and the fact that $\|z(t-1)\|_\lambda^2 \le \lambda^{-1}\|z(t)\|_\lambda$.

From the control law (9) we get

$$\begin{aligned}\|u(t)\|_\lambda \le \frac{1}{\epsilon_1}\Bigg[& f_\theta\left(\sum_{i=1}^{n_B}\lambda^{-i}\right)^{1/2}\|u(t-1)\|_\lambda \\ & + f_\theta\left(\sum_{i=1}^{n_A}\lambda^{-i}\right)^{1/2}\|y(t)\|_\lambda + \|y^*(t+1)\|_\lambda\Bigg] + \xi(t).\end{aligned} \tag{24}$$

Substituting this into (22) we get

$$\|\phi(t)\|_\lambda \le C_1\left(1+\frac{f_\theta C_1}{\epsilon_1}\right)(\|y(t)\|_\lambda + \|u(t-1)\|_\lambda) + \frac{C_1}{\epsilon_1}\|y^*(t+1)\|_\lambda + \xi(t).$$

It is now obvious from equations (23), (24), and (21) that $\|\phi(t)\|_\lambda$ can be bounded in terms of $\|z(t-1)\|_\lambda$ and we get

$$\begin{aligned}\|\phi(t)\|_\lambda \le\ & C_1\left(1+\frac{f_\theta C_1}{\epsilon_1}\right)(1+C_\gamma+C_u)\left(\|z(t-1)\|_\lambda + \frac{k_{y^*}}{(1-\lambda)^{1/2}}\right) \\ & + C_1\left(1+\frac{f_\theta C_1}{\epsilon_1}\right)\frac{C_w(1+C_A)k_w}{(1-\lambda)^{1/2}} + \frac{C_1}{\epsilon_1}\frac{k_{y^*}}{(1-\lambda)^{1/2}} + \xi(t).\end{aligned}$$

The result follows by the application of the definition of $r(t)$. □

By using equations (6), (11), (12), and (13), the measurement vector can be written in the form

$$\phi(t) = \phi^*(t) + \phi_w(t) + \phi_z(t) + \phi_\gamma(t) \tag{25}$$

where

$$\phi^*(t)' = \left(y^*(t), \dots, y^*(t-n_A+1), \frac{A(q^{-1})}{B(q^{-1})}y^*(t+1), \dots, \frac{A(q^{-1})}{B(q^{-1})}y^*(t-n_B+1)\right),$$

$$\phi_w(t)' = \left(w(t), \dots, w(t-n_A+1), \frac{A(q^{-1})-1}{B(q^{-1})}w(t+1), \dots, \frac{A(q^{-1})-1}{B(q^{-1})}w(t-n_B+1)\right),$$

$$\phi_z(t)' = \left(-z(t-1), \dots, -z(t-n_A), -\frac{A(q^{-1})}{B(q^{-1})}z(t), \dots, -\frac{A(q^{-1})}{B(q^{-1})}z(t-n_B)\right),$$

$$\phi_\gamma(t)' = \left(\gamma(t-1), \dots, \gamma(t-n_A), \frac{A(q^{-1})-1}{B(q^{-1})}\gamma(t), \dots, \frac{A(q^{-1})-1}{B(q^{-1})}\gamma(t-n_B)\right),$$

while $\phi^*(t)$, of course, is assumed to be persistently excited.

We are now ready to establish the following lemma.

LEMMA 4.2. *Let Assumptions* A1–A3 *hold. Then, for N_p sufficiently large on every subsequence $\{N_p\}$, where*

$$\|z(N_p)\|_\lambda^2 \le \Sigma_\gamma(\epsilon_1)^2 + \xi_5(N_p),$$

the following holds:

$$\lambda_{\min}\left\{\sum_{t=1}^{N_p} \lambda^{N_p-t}\phi(t)\phi(t)'\right\} \ge \delta_2^* - \rho_0 > 0, \qquad 0 < \rho_0 << \delta_2^*.$$

Here $\lambda_{\min}(\cdot)$ denotes the minimal eigenvalue of the corresponding matrix.

Proof. From the decomposition in equation (25) we obtain

$$\sum_{t=1}^{N_p} \lambda^{N_p-t}\left(\eta'\phi_z(t)\right)^2 \le n_1^2\Sigma_\gamma(\epsilon_1)^2 + \xi(t) \tag{26}$$

where η is any vector satisfying $\|\eta\| = 1$. Similarly, using statement 1 of Lemma 4.1 we obtain

$$\sum_{t=1}^{N_p} \lambda^{N_p-t}\left(\eta'\phi_\gamma(t)\right)^2 \le n_2^2\left(C_\gamma\Sigma_\gamma(\epsilon_1) + \frac{C_\gamma k_{y^*} + C_w k_w}{(1-\lambda)^{1/2}}\right)^2 + \xi(t) \tag{27}$$

and

$$\sum_{t=1}^{N_p} \lambda^{N_p-t}\left(\eta'\phi_w(t)\right)^2 \le n_2^2\frac{k_w^2}{1-\lambda} + \xi_7(t). \tag{28}$$

Relationships (26)–(28) yield

$$\sum_{t=1}^{N_p} \lambda^{N_p-t}\left(\eta'\phi_1(t)\right)^2 \le \left(n_1\Sigma_\gamma(\epsilon_1) + n_2\left(C_\gamma\Sigma_\gamma(\epsilon_1) + \frac{C_\gamma k_{y^*} + (1+C_w)k_w}{(1-\lambda)^{1/2}}\right)\right)^2 + \xi(t) \tag{29}$$

where $\phi_1(t)$ is the component of the regressor that is not directly excited by the reference, i.e.,

$$\phi_1(t) = \phi(t) - \phi^*(t) = \phi_z(t) + \phi_\gamma(t) + \phi_w(t).$$

It then follows that

$$(\eta'\phi(t))^2 \geq \frac{1}{2}(\eta'\phi^*(t))^2 - (\eta'\phi_1(t))^2.$$

From these inequalities and Assumption A3 we then get

$$\lambda_{\min}\left\{\sum_{t=1}^{N_p}\lambda^{N_p-t}\phi(t)\phi(t)'\right\} \geq \delta_2^* - \xi(t).$$

Since $\xi(t)$ decays exponentially fast, it follows that for sufficiently large N_p we have $\xi(t) \leq \rho_0$ and the lemma is proved. □

We now have the following critical result.

LEMMA 4.3. *Let Assumptions* A1–A3 *hold. Then on the subsequence* $\{N_p\}$ *where*

$$\|z(N_p)\|_\lambda^2 \leq \Sigma_\gamma(\epsilon_1)^2 + \xi_6(N_p) \tag{30}$$

we have

$$\|\theta(N_p+1) - \theta_0\|^2 \leq d_0(\epsilon_1) + \xi_7(N_p)$$

where

$$d_0(\epsilon_1) = \frac{C_\phi^2}{(\delta_2^* - \rho_0)^2}$$

$$\times\left[\Sigma_\gamma(\epsilon_1)(1+\mu(1+C_\gamma)+\epsilon_1 C_u) + \frac{k_{y^*}(C_\gamma + C_u\epsilon_1) + C_w k_w(1+\epsilon_1 C_A)}{(1+\lambda)^{1/2}}\right]^2 \tag{31}$$

with

$$C_\phi = C_{\phi 1}\Sigma_\gamma(\epsilon_1) + \frac{C_{\phi 1}k_{y^*} + C_{\phi 2}k_w}{(1-\lambda)^{1/2}}. \tag{32}$$

Proof. From equation (11) and statement 1 of Lemma 4.1 we derive

$$\|e(t+1)\|_\lambda \leq (1+C_\gamma)\|z(t)\|_\lambda + \frac{C_\gamma k_{y^*} + C_w k_w}{(1-\lambda)^{1/2}} + \xi(t). \tag{33}$$

Using equation (30) we obtain

$$\|e(N_p)\|_\lambda^2 \leq \left((1+C_\gamma)\Sigma_\gamma(\epsilon_1) + \frac{C_\gamma k_{y^*} + C_w k_w}{(1-\lambda)^{1/2}}\right)^2 + \xi(t). \tag{34}$$

Similarly from statement 3 of Lemma 4.1 we conclude that

$$\|\phi(N_p)\|_\lambda \leq C_\phi + \xi(t) \tag{35}$$

where C_ϕ was defined in equation (32). Note also, from equations (10) and (12), it follows that

$$\tilde{\theta}(t+1)'\phi(t) = z(t) + \epsilon(t)u(t), \qquad \tilde{\theta}(t) = \theta(t) - \theta_0.$$

This together with the estimation equation (5) then yields

$$\tilde{\theta}(t+1)'p(t)^{-1} = \lambda'\tilde{\theta}(t)p(t-1)^{-1} + z(t)\phi(t)' + \epsilon(t)u(t)\phi(t)' + \frac{\mu}{r(t)}\phi(t)p(t)^{-1}e(t+1) \tag{36}$$

where

$$p(t)^{-1} = \lambda p(t-1)^{-1} + \phi(t)\phi(t)', \qquad p(0)^{-1} = p_0 I, \qquad \text{with } p_0 > 0. \tag{37}$$

It follows from (36) and (37) that

$$\tilde{\theta}(N+1)' = \lambda^N\tilde{\theta}(1)p_0p(N) + \left(\sum_{t=1}^{N}\lambda^{N-t}z(t)\phi(t)'\right)p(N)$$

$$+ \left(\sum_{t=1}^{N}\lambda^{N-t}\epsilon(t)u(t)\phi(t)'\right)p(N) + \mu\left(\sum_{t=1}^{N}\lambda^{N-t}\frac{\phi(t)p(t)^{-1}}{r(t)}e(t+1)\right)p(N).$$

Since

$$\left\|\sum_{t=1}^{N}\lambda^{N-t}\frac{\phi(t)p(t)^{-1}}{r(t)}e(t+1)\right\| \le \|e(N)\|_\lambda\|\phi(N)\|_\lambda,$$

$$\left\|\sum_{t=1}^{N}\lambda^{N-t}\epsilon(t)u(t)\phi(t)'\right\| \le \epsilon_1\|u(N)\|_\lambda\|\phi(N)\|_\lambda, \qquad \text{and}$$

$$\left\|\sum_{t=1}^{N}\lambda^{N-t}z(t)\phi(t)'\right\| \le \|z(N)\|_\lambda\|\phi(N)\|_\lambda,$$

we obtain

$$\|\tilde{\theta}(N+1)\| \le \|p(N)\|(p_0\lambda^N\|\tilde{\theta}(1)\| + (\|z(N)\|_\lambda + \epsilon_1\|u(N)\|_\lambda + \|e(N)\|_\lambda)\|\phi(N)\|_\lambda). \tag{38}$$

From Lemma 4.2 we have for p sufficiently large on the subsequence $\{N_p\}$

$$\|p(N_p)\| \le \frac{1}{\delta_2^* - \rho_0} \tag{39}$$

where δ_2^* was defined under Assumption A3. The lemma then follows by using inequalities (30), (34), (35), (38), and (39) together. □

Comments. $\Sigma_\gamma(\epsilon_1)$ is small when C_γ and k_w are small. It follows that during the intervals where $\|z(t)\|_\lambda$ is of the order of $\Sigma_\gamma(\epsilon_1)$, excitation provided by the reference signal neutralizes the effect of the unmodeled dynamics and the external disturbances and prevents the parameter drift that otherwise causes instability of the estimator and the eventual destabilization of the loop. An exact statement of this property is given in Lemma 4.2.

The remaining question to answer is: "What happens when $\|z(t)\|_\lambda$ is not small?"

5. Main results and mathematical formalization of self-stabilization. Below we give the stability result for parameter estimation and direct adaptive control with persistent excitation.

THEOREM 5.1. *Let Assumptions* A1–A3 *introduced in* §3 *hold, and assume that the estimator is implemented with gain sequence* (7) *with* $\lambda_0 \leq \lambda < 1$. *Then there exist nonnegative constants* $\delta_1^*, C_\gamma, k_w$, *and* ϵ_1 *so that*

1.

$$\limsup_{t \to \infty} \|\theta(t) - \theta_0\|^2 \leq d_0(0) \quad \textit{and} \qquad \limsup_{t \to \infty} \|\theta_c(t) - \theta(t)\|^2 = 0$$

where $d_0(0)$ *is given by equation* (31) *with* $\epsilon_1 = 0$.

2.

$$\limsup_{t \to \infty} \sum_{j=1}^{t} \lambda^{t-j} |y(j+1) - y^*(j+1)|^2 \leq ((1 + C_\gamma)\Sigma_D + \Sigma_1)^2$$

where Σ_1 *is defined in Assumption* A3 *and*

$$\Sigma_D^2 = \max\left\{\Sigma_\gamma(0)^2, \left[\frac{\lambda}{(1 + d_0(0))C_\theta} + \frac{1}{\mu\rho_1(0)}\right] d_0(0)k_\theta\right\} \exp\left(\frac{(1 + d_0(0)C_\theta}{\lambda\mu\rho_1(0)}\right)$$

where $\Sigma_\gamma(0)^2$ *is given by Assumption* A2, $d_0(0)$ *is given by equation* (31), *and* $\rho_1(0)$ *is given by Assumption* A2 *with* $\epsilon_1 = 0$.

3.

$$\limsup_{t \to \infty} \|\phi(t)\|_\lambda \leq C_{\phi 1}\Sigma_D + \frac{C_{\phi 1}k_{y^*} + C_{\phi 2}k_w}{(1 - \lambda)^{1/2}}$$

where $C_{\phi i}, i = 1, 2$, *are defined under statement* 3 *in Lemma* 4.1.

Proof. We first determine a difference inequality that describes the behaviour of the parameter estimation error. From the estimation algorithm (5) we obtain

$$V(t+1) \leq V(t) + 2\frac{\mu}{r(t)}\tilde{\theta}(t)'\phi(t)e(t+1) + \frac{\mu^2}{r(t)}e(t+1)^2 \tag{40}$$

where $V(t) = \|\tilde{\theta}(t)\|^2$. From (11), the definition of the normalizing sequence, and the above we then derive

$$V(t+1) \leq V(t) - 2\mu(1 - \frac{\mu}{2})\frac{z(t)^2}{r(t)}$$

$$+ \frac{1}{r(t)}[2\mu(1-\mu)|z(t)\gamma(t)| + \mu^2\gamma(t)^2 + 2\mu|\epsilon(t)u(t)| \cdot |z(t) + \gamma(t)|]. \tag{41}$$

We now show how global stability of the adaptive algorithm can be demonstrated by considering the following comparison function [13]:

$$S(t+1) = V(t+1) + \frac{W(t+1)}{r(t)} \tag{42}$$

where

$$\begin{aligned} W(t+1) = \ & \mu \sum_{j=1}^{t} \lambda^{t-j} \Big[\Big(1 - \frac{\mu}{2} + (1-\mu)C_\gamma + \frac{\mu}{2}C_\gamma^2 + \epsilon_1 C_u(1 + C_\gamma)\Big) z(j)^2 \\ & - 2(1-\mu)|z(j)\gamma(j)| - \mu\gamma(j)^2 - 2|\epsilon(t)u(t)| \cdot |z(t) + \gamma(t)|\Big] \end{aligned} \tag{43}$$

It will become clear in the analysis that follows that stability of the sequence $z(t)$ follows trivially whenever $W(t) \leq 0$. However, during these intervals the function $S(t)$ may increase, thus giving rise to the bursting of the sequence $z(t)$. As a consequence of this, the function $W(t)$ becomes positive, forcing $S(t)$ to converge, thus stabilizing $z(t)$. This mechanism does not rely on the use of external excitation; instead it is required that the parameters remain bounded and that singularities are avoided in order to prevent finite escape and ensure bounded growth of signals. □

We now define subsequences τ_k and $\sigma_k, k \geq 1$, as follows:

$$1 = \tau_1 < \sigma_1 < \tau_2 < \sigma_2 < \cdots < \tau_k < \sigma_k < \tau_{k+1} < \cdots$$

so that

$$W(t+1) \leq 0 \text{ for } t \in Q_k \quad \text{and} \quad W(t+1) > 0 \text{ for } t \in T_k$$

with the intervals T_k and Q_k defined so that

$$Q_k = [\tau_k, \sigma_k), \qquad T_k = [\sigma_k, \tau_{k+1}), \qquad k \geq 1.$$

If $W(2) > 0$ set $\tau_1 = 0$ and $\sigma_1 = 1$ and Q_k is defined for $k \geq 2$.

The proof is handled by considering three possible cases:

Case 1. For all finite k, we have $\tau_k < \infty$ and $\sigma_k < \infty$.

Case 2. There exists a finite $k_0 \geq 0$, such that $\tau_{k_0} < \infty$ and $\sigma_{k_0} = +\infty$.

Case 3. There exists a finite $k_1 \geq 1$ so that $\sigma_{k_1} < \infty$ and $\tau_{k_1+1} = \infty$.

In the first case $W(t+1)$ changes sign infinitely often. The main idea in analyzing this case is the following. During the time intervals Q_k the function $W(t+1)$ is nonpositive and the stability of the adaptive system follows directly from the definition of $W(t+1)$. During the intervals when $W(t+1) > 0$ the function $S(t)$ is nonincreasing or strictly decreasing. It follows that such intervals only have a finite duration since $V(t)$ is nonnegative. This is essentially the argument used in [16] to show that the normalization $r(t)$ can be replaced by $\|\phi(t)\|^2$. A similar development can be used here; however, in order to simplify the analysis we treat the case where the normalizing signal $r(t)$ is defined by equation (7) here and (8) under the heading of Theorem 5.2.

The two last cases are trivial since the sign of $W(t+1)$ eventually does not change and are analyzed at the end of the proof of this theorem.

Analysis of Case 1. Let us first consider the interval Q_k. Since $W(t+1) \leq 0$ for $t \in Q_k$, that we have from equation (43) and statement 1 of Lemma 4.1 that

$$\left(1 - \frac{\mu}{2} + (1-\mu)C_\gamma + \frac{\mu}{2}C_\gamma^2 + \epsilon_1 C_u(1+C_\gamma)\right) \|z(t)\|_\lambda^2$$

$$\leq 2(1-\mu)\|z(t)\|_\lambda(C_\gamma\|z(t)\|_\lambda + h_1(t)) + \mu(C_\gamma\|z(t)\|_\lambda^2 + h_1(t))^2$$

$$+2\epsilon_1\|u(t)\|_\lambda((1+C_\gamma)\|z(t)\|_\lambda + h_1(t))$$

where we used the fact that $|\epsilon(t)| \leq \epsilon_1$. By further manipulation it follows that we can write

$$(\rho_1(\epsilon_1) + 2\epsilon_1 C_u(1+C_\gamma))\|z(t)\|_\lambda^2 \leq 2\mu(1-\mu+\mu C_\gamma)\|z(t)\|_\lambda h_1(t)$$

$$+ \mu h_1(t)^2 + 2\epsilon_1(1+C_\gamma)\|u(t)\|_\lambda\|z(t)\|_\lambda + 2\epsilon_1\|u(t)\|_\lambda h_1(t).$$

Substituting statement 2 of Lemma 4.1 into this we have

$$\rho_1(\epsilon_1)\|z(t)\|_\lambda^2 \leq 2\|z(t)\|_\lambda[(1-\mu+\mu C_\gamma+\epsilon_1 C_u)h_1(t)+\epsilon_1(1+C_\gamma)h_2(t)]$$
$$+\mu h_1(t)^2+2\epsilon_1 h_1(t)h_2(t)$$
$$\leq 4\max\Big\{\|z(t)\|_\lambda(1-\mu+\mu C_\gamma+\epsilon_1 C_u)h_1(t)+\epsilon_1(1+C_\gamma)h_2(t));$$
$$\frac{1}{2}\mu h_1(t)^2+\epsilon_1 h_1(t)h_2(t)\Big\}.$$

From this we finally get, by applying simple inequalities,

$$\|z(t)\|_\lambda^2 \leq \Sigma_\gamma(\epsilon_1)^2+\xi(t), \qquad t\in Q_k. \tag{44}$$

We can now apply Lemma 4.3 together with the definition of the intervals Q_k to conclude that

$$\|\tilde{\theta}(t)\|^2 \leq d_0(\epsilon_1)+\xi(t), \qquad t\in[\tau_k+1,\sigma_k]. \tag{45}$$

We now analyze the intervals $T_k, k \geq 1$, where $W(t+1)$ is positive. Using the definition of $W(t+1)$ in equation (43) we obtain from equations (41), (42), and (43) that

$$S(t+1)\leq S(t)-\mu\rho_1(\epsilon_1)\frac{z(t)^2}{r(t)}, \qquad t\in T_k,$$

where the definiton of $\rho_1(\epsilon_1)$ is given in Assumption A2. After summing from $t = \sigma_k+1$ to $N < \tau_{k+1}$ we get

$$S(N+1)\leq S(\sigma_k+1)-\mu\rho_1(\epsilon_1)\sum_{t=\sigma_k+1}^{N}\frac{z(t)^2}{r(t)}. \tag{46}$$

From equation (43) it follows that

$$W(\sigma_k+1)=\mu\left(1-\frac{\mu}{2}+(1-\mu)C_\gamma+\frac{\mu}{2}C_\gamma^2+\epsilon_1 C_u(1+C_\gamma)\right)z(\sigma_k)^2$$

$$-2\mu(1-\mu)|z(\sigma_k)\gamma(\sigma_k)|-\mu^2\gamma(\sigma_k)^2+2|\epsilon(\sigma_k)u(\sigma_k)|\cdot|z(\sigma_k)+\gamma(\sigma_k)|+\lambda W(\sigma_k).$$

Since $W(\sigma_k)\leq 0$, we get, using equations (41) and (42), that

$$S(\sigma_k+1)\leq V(\sigma_k)-\mu\rho_1(\epsilon_1)\frac{z(\sigma_k)^2}{r(\sigma_k)}.$$

Using this in equation (46) we get

$$S(N+1)\leq V(\sigma_k)-\mu\rho_1(\epsilon_1)\sum_{t=\sigma_k}^{N}\frac{z(t)^2}{r(t)}, \qquad N\in T_k. \tag{47}$$

From the definition of $S(t)$ given by equation (42) and inequality (45) it then follows that

$$\|\tilde{\theta}(t+1)\|^2\leq d_0(\epsilon_1)+\xi(\sigma_k), t\in[\sigma_k,\tau_{k+1}). \tag{48}$$

Inequalities (45) and (48) imply that there exists a finite k_2 such that

$$\|\tilde{\theta}(t)\|^2 \leq d_0(\epsilon_1) + \rho_2 \tag{49}$$

for $t \in [\tau_k + 1, \tau_{k+1}], k \geq k_2$, or for all $t \geq \tau_{k_2} + 1$. Here ρ_2 is an arbitrarily small constant. From this we may conclude that

$$|\hat{b}_0(t)| \geq |b_0| - d_0(\epsilon_1)^{1/2} - \rho_2^{1/2} > 0 \quad \text{for } t \geq \tau_{k_2} + 1. \tag{50}$$

From equation (31) it follows that $d_0(\epsilon_1)$ is small if C_γ, k_w, and ϵ_1 are small relative to δ_1^*. This in turn implies that the estimate of b_0 stays close to its true value after a transient period that can be no longer than $\tau_{k_2} + 1$. After this we get $\epsilon(t) = 0$ in equation (10).

Equation (43) can now be written as

$$W(t+1) = \mu \sum_{j=1}^{t} \lambda^{t-j} \left[\left(1 - \frac{\mu}{2} + (1-\mu)C_\gamma + \frac{\mu}{2}C_\gamma^2\right) z(j)^2 \right.$$
$$\left. -2(1-\mu)|z(j)\gamma(j)| - \mu\gamma(j)^2\right] + \lambda^{t-\tau_{k_2}}\eta(\tau_{k_2}) \tag{51}$$

where

$$\eta(\tau_{k_2}) = \mu \sum_{j=1}^{\tau_{k_2}} \lambda^{\tau_{k_2}-j}[\epsilon_1 C_u(1+C_\gamma)z(j)^2 - 2|\epsilon(j)u(j)| \cdot |z(j) + \gamma(j)|].$$

Using inequality (44), which we write as

$$\|z(\tau_{k_2})\|_\lambda^2 \leq \Sigma_\gamma(\epsilon_1)^2 + \xi(\tau_{k_2}),$$

together with statements 1 and 2 of Lemma 4.1, this gives

$$\eta(\tau_{k_2})^2 \leq C_2 < \infty. \tag{52}$$

Similarly from equation (51) we get

$$\|z(t)\|_\lambda^2 \leq \Sigma_\gamma(0)^2 + \xi(t) \tag{53}$$

for all $t \in Q_k$, $k > k_2, k_2 < \infty$, where we used the fact that $\epsilon(t) = 0$ for all $t > \tau_{k_2}$. Appplying Lemma 4.3 one more time with (53) we conclude that

$$\|\tilde{\theta}(t+1)\|^2 \leq d_0(0) + \xi(t), \quad t \in Q_k, \quad k > k_2. \tag{54}$$

Following the same line of reasoning as that given in equations (46)–(47) and using the fact that $\epsilon(t) =$ 0 for all $t \geq \tau_{k_2} + 1$ we get immediately from equations (41), (42), and (51) that

$$S(N+1) \leq V(\sigma_k) - \mu\rho_1(0) \sum_{t=\sigma_k}^{N} \frac{z(t)^2}{r(t)}, \qquad N \in T_k, \quad k \geq k_2, \tag{55}$$

with $\rho_1(0)$ as defined under point 3 of Assumption A2. From (42), (54), and (55) it follows that

$$\limsup_{k\to\infty} \sup_{t\in T_k} \|\tilde{\theta}(t+1)\|^2 \leq d_0(0). \tag{56}$$

Statement 1 of Theorem 5.1 follows for the Case 1 scenario by combining (54) and (56). It now remains to show boundedness of all signals. Since the parameters are bounded, a number of different techniques can be applied. We follow the method developed by [13]. First, from (55) and (56) we have

$$\mu\rho_1(0)\sum_{t=\sigma_k}^{N}\frac{z(t)^2}{\tilde{r}(t)} \leq 1, \qquad N \in T_k, \quad k \geq k_2 \tag{57}$$

where

$$\tilde{r}(t) = (d_0(0) + \xi(\sigma_k))r(t). \tag{58}$$

From (49) we conclude that statement 4 of Lemma 4.1 can be applied for all $t \geq \tau_{k_2}+1$ with

$$f_\theta = \|\theta_0\| + d_0(0)^{1/2} + \rho_2^{1/2}.$$

Substituting the bound for $r(t)$ given by statement 4 of Lemma 4.1 into equation (58) then gives

$$\tilde{r}(t) \leq \max\{(1+d_0(0))C_\theta\|z(t-1)\|_\lambda^2, g(t)\}, \qquad t \in T_k, \quad k \geq k_2 \tag{59}$$

where

$$g(t) = (d_0(0) + \xi(\sigma_k))(k_\theta + \xi(t)). \tag{60}$$

Next we show that relationships (57) and (59) can be used together to establish stability during the intervals T_k, $k \geq k_2$. Specifically, on the one hand it follows from equation (57) that we can relate the magnitude of $z(t)$ for $t \in T_k$ to $\tilde{r}(t)$. On the other hand, from inequality (59) it follows that $\tilde{r}(t)$ is of the order of $g(t)$ or $(1+d_0(0))C_\theta\|z(t-1)\|_\lambda^2$.

We now introduce a further partitioning of the intervals T_k. Let $p_{ik} \in T_k$ and $l_{ik} \in T_k$ be defined so that

$$p_{0k} < l_{1k} < p_{1k} < \cdots < l_{ik} < p_{ik} < l_{(i+1)k} < \cdots,$$

so that for $\tilde{r}(t)$ defined by (59) the following inequality holds:

$$\tilde{r}(t) \leq (1+d_0(0))C_\theta\|z(t-1)\|_\lambda^2 \quad \text{for } t \in L_{ik}, i \geq 1, k \geq k_2, \tag{61}$$

and

$$\tilde{r}(t) \leq g(t) \quad \text{for } t \in D_{ik}, i \geq 1, k \geq k_2 \tag{62}$$

where the intervals L_{ik} and D_{ik} are defined so that

$$L_{ik} = [p_{(i-1)k}, l_{ik}) \text{ and } D_{ik} = [l_{ik}, p_{ik}).$$

We have $l_{ik} < \tau_{k+1}$ and $p_{ik} < \tau_{k+1}$ for $i \geq 1$.

$$\text{If } (1+d_0(0))C_\theta\|z(\sigma_k-1)\|_\lambda^2 \begin{cases} \geq g(\sigma_k), & \text{then } p_{0k} = \sigma_k; \\ < g(\sigma_k), & \text{then } p_{0k} = 0\,, l_{1k} = \sigma_k \\ & \quad \text{with intervals } L_{ik} \text{ defined for } i \geq 2. \end{cases}$$

If $(1+d_0(0))C_\theta\|z(t-1)\|_\lambda^2 \begin{cases} < g(t) \text{ for all } t \in T_k \text{ define } p_{0k} = 0, l_{1k} = \sigma_k, \text{ and } p_{1k} = \tau_{k+1}; \\ \geq g(t) \text{ for all } t \in T_k \text{ set } p_{0k} = \sigma_k \text{ and } l_{1k} = \tau_{k+1}. \end{cases}$

From (59) and (62) we now have

$$\|z(t-1)\|_\lambda^2 \leq \frac{g(t)}{(1+d_0(0))C_\theta} \quad \text{for } t \in D_{ik}, i \geq 1, k \geq k_2 \tag{63}$$

and relations (57), (59), and (62) imply that for $t \in D_{ik}$

$$z(t)^2 \leq \frac{\tilde{r}(t)}{\mu\rho_1(0)} \leq \frac{g(t)}{\mu\rho_1(0)}. \tag{64}$$

Since $\|z(t)\|_\lambda^2 = z(t)^2 + \lambda\|z(t-1)\|_\lambda^2$, relations (60), (63), and (64) yield

$$\|z(t)\|_\lambda^2 \leq \left(\frac{\lambda}{(1+d_0(0))C_\theta} + \frac{1}{\mu\rho_1(0)}\right) d_0(0)k_\theta + \xi(\sigma_k), \qquad t \in D_{ik}. \tag{65}$$

We now consider the intervals $L_{ik} \in T_k$ for $i \geq 1, k \geq k_2$. From (57) and (61) we obtain

$$R_{ik} = \sum_{t=p_{(i-1)k}}^{N} \frac{z(t)^2}{\|z(t-1)\|_\lambda^2} \leq \frac{(1+d_0(0))}{\mu\rho_1(0)} C_\theta, \qquad N \in L_{ik}. \tag{66}$$

From this it follows that we have

$$R_{ik} = \sum_{t=p_{(i-1)k}}^{N} \frac{\|z(t)\|_\lambda^2 - \lambda\|z(t-1)\|_\lambda^2}{\|z(t-1)\|_\lambda^2} \tag{67}$$

$$= \sum_{t=p_{(i-1)k}}^{N} \frac{\lambda}{\lambda\|z(t-1)\|_\lambda^2} \int_{\lambda\|z(t-1)\|_\lambda^2}^{\|z(t)\|_\lambda^2} dx,$$

which gives

$$R_{ik} \geq \lambda \sum_{t=p_{(i-1)k}}^{N} \int_{\lambda\|z(t-1)\|_\lambda^2}^{\|z(t)\|_\lambda^2} \frac{dx}{x} = \lambda \sum_{t=p_{(i-1)k}}^{N} (\log(\|z(t)\|_\lambda^2) - \log(\lambda\|z(t-1)\|_\lambda^2))$$

$$= \lambda \log \frac{\|z(N)\|_\lambda^2}{\|z(p_{(i-1)k} - 1)\|_\lambda^2} + \lambda(N - p_{(i-1)k}) \log \frac{1}{\lambda}. \tag{68}$$

From equations (66) and (68) we get

$$\|z(N)\|_\lambda^2 \leq \exp\left(\frac{1+d_0(0)}{\lambda\mu\rho_1(0)} C_\theta\right) \|z(p_{(i-1)k} - 1)\|_\lambda^2, \qquad N \in L_{ik}. \tag{69}$$

Since $p_{(i-1)k} - 1 \in D_{(i-1)k}$, we obtain using (65) for $t \in L_{ik}, i \geq 2$,

$$\|z(t)\|_\lambda^2 \leq d_0(0)k_\theta \left(\frac{\lambda}{(1+d_0(0))C_\theta} + \frac{1}{\mu\rho_1(0)}\right) \exp\left(\frac{1+d_0(0)}{\lambda\mu\rho_1(0)} C_\theta\right) + \xi(\sigma_k). \tag{70}$$

We now evaluate $\|z(t)\|_\lambda^2$ for the intervals $L_{1k}, k \geq k_2$. If $p_{0k} = \sigma_k$, we get from inequalities (53) and (69) that

$$\|z(t)\|_\lambda^2 \leq \Sigma_\gamma(0)^2 \exp\left(\frac{1+d_0(0)}{\lambda\mu\rho_1(0)}C_\theta\right) + \xi(\sigma_k). \tag{71}$$

In the case $p_{0k} = 0$ and $l_{1k} = \sigma_k$, the intervals L_{ik} are defined for $i \geq 2$. In equation (68), the case $\|z(N)\|_\lambda^2 \leq \|z(p_{(i-1)k} - 1)\|_\lambda^2$ is trivial and is covered by inequality (69). Therefore, from (65), (70), and (71) it follows that

$$\limsup_{k\to\infty} \sup_{t\in T_k} \|z(t)\|_\lambda^2 \leq \Sigma_D^2,$$

which together with (53) gives

$$\limsup_{t\to\infty} \|z(t)\|_\lambda^2 \leq \Sigma_D^2 \tag{72}$$

with Σ_D as given in Theorem 5.1. Statement 2 follows from the application of inequalities (33) and (72).

Analysis of Case 2. From the definition of this case it follows that relationship (44) is valid for all $t \geq \tau_{k_0}$. From this point on we apply Lemma 4.3, which demonstrates that (49) is valid for all $t \geq \tau_{k_0}$. Using the same technique as in the demonstration of (50), we conclude that there exists finite $t_1 \geq \tau_{k_0}$ such that this relation holds true for all $t \geq t_1$. This implies that $\epsilon(t) = 0$ in equation (10) for all $t \geq t_1$. $W(t+1)$ then is as in equation (51) with $\eta(\tau_{k_2})$ replaced by $\eta(t_1)$. Since $W(t+1) < 0$ for all $t \geq t_1$, we obtain as in inequality (53) that

$$\|z(t)\|_\lambda^2 \leq \Sigma_\gamma(0)^2 + \xi(t), \qquad t \geq t_1. \tag{73}$$

By application of Lemma 4.3 we then must conclude

$$\|\tilde{\theta}(t)\| \leq d_0(0) + \xi(t), \qquad t \geq t_1,$$

and we have proven statement 1 of the theorem for the Case 2 scenario.

Analysis of Case 3. There exists $k_1 < \infty$ so that $\sigma_{k_1} < \infty$ and $\tau_{k_1+1} = \infty$, and we conclude that $W(t+1) > 0$ for all $t \geq \sigma_{k_1}$ and consequently from (47) we have

$$\mu\rho_1(\epsilon_1) \sum_{t=\sigma_{k_1}}^{\infty} \frac{z(t)^2}{r(t)} < \infty.$$

This follows since $V(t) \geq 0$. Using statement 3 of Lemma 4.1 it is clear that there exists a finite $t_2 \geq \sigma_{k_1}$ such that

$$\|z(t)\|_\lambda^2 = o(1). \tag{74}$$

When we apply Lemma 4.3 together with this result we notice that

$$\|\tilde{\theta}(t)\| \leq d_0(\epsilon_1) + \xi(t), \qquad t \geq t_1 \tag{75}$$

for all $t \geq t_2$. Similarly as in the previous analysis we conclude that there exists a finite $t_3 \geq t_2$ such that $\epsilon(t) = 0$ and $|\hat{b}_0(t)| \geq \epsilon_1$ for all $t \geq t_3$. Setting $\epsilon_1 = 0$ in (75) gives what is needed to conclude that statement 1 is in fact correct.

Statements 2 and 3 of the theorem follow by application of equation (33) and (72) or (73) or (74), while statement 3 follows by application of Lemma 4.1, and Theorem 5.1 is established.

We now give the main results for normalization sequence (8).

THEOREM 5.2. *Let Assumptions* A1–A3 *hold, and assume that the algorithm gain sequence is updated using equation* (8). *Then there exists* $\delta_1^*, C_\gamma, k_w$, *and* ϵ_1 *so that*

1.

$$\limsup_{t\to\infty} \|\theta(t)-\theta_0\|^2 \le d_0(0) \quad \textit{and} \quad \limsup_{t\to\infty} \|\theta_c(t)-\theta(t)\|^2 = 0$$

where $d_0(0)$ *is given by equation* (31) *with* $\epsilon_1 = 0$.

2.

$$\limsup_{t\to\infty} |y(t+1)-y^*(t+1)|^2 \le \left(\left(1+\frac{C_\gamma}{(1-\lambda)^{1/2}}\right)\Sigma_{D1} + \frac{C_\gamma k_{y^*}+C_w k_w}{(1-\lambda)^{1/2}}\right)^2$$

where

$$\Sigma_{D1} = \max\{\Sigma_\gamma(0)^2; d_0(0)C_r\}$$

and C_r *is a constant that decreases when* C_γ *and* k_w *decrease, while* $\Sigma(0)$ *is given by equation* (17) *with* $\epsilon_1 = 0$.

Proof. The proof follows the same line of reasoning as for Theorem 5.1. Let us first consider the case when $\tau_\kappa < \infty$ and $\sigma_\kappa < \infty$ for all finite k. Then it is not difficult to see that starting from equation (33) up to equation (56), the analysis is exactly the same and holds for the case when $r(t)$ is defined by equation (8). This is because all that is required up to this point is that $r(t) \ge \lambda r(t-1)$. Therefore statement 1 of the theorem is valid.

Let us prove statement 2. First we show that $\max_{1\le\tau\le t}|z(\tau)|$ is bounded. From inequalities (54) and (55) it follows that for sufficiently large k

$$\frac{z(t)^2}{r(t)} \le d_0(0) + \beta_1 \text{ for all } t \in T_k \tag{76}$$

where $0 < \beta_1 << 1$ is a small number. On the other hand, from (8) and statement 3 of Lemma 4.1 we have

$$r(t)^{1/2} \le \frac{C_{\phi 1}}{(1-\lambda)^{1/2}} \max_{1\le\tau\le t}|z(\tau)| + C_{\phi 3} \tag{77}$$

where

$$C_{\phi 3} = r_0^{1/2} + \beta_2 + \frac{C_{\phi 1}k_{y^*} + C_{\phi 2}k_w}{(1-\lambda)^{1/2}}, \qquad 0 < \beta_2 < \infty.$$

Substituting (77) into equation (76) together with (53) gives

$$|z(t)| \le \begin{cases} (d_0(0)^{1/2} + \beta_1) r(t)^{1/2} \text{ for all } t \in T_k, \\ \Sigma_\gamma(0) + \xi(t) \text{ for all } t \in Q_k \end{cases} \tag{78}$$

and hence

$$|z(t)| \le (d_0(0)^{1/2}+\beta_1)\frac{C_{\phi 1}}{(1-\lambda)^{1/2}} \max_{1\le\tau\le t}|z(\tau)| + (d_0(0)^{1/2}+\beta_1)C_{\phi 3} + \Sigma_\gamma(0) + \xi(t) \tag{79}$$

Since β_1 can be made arbitrarily small, it follows from (31) with $\epsilon_1 = 0$ and the definition of $C_{\phi 1}$ in Lemma 4.1 that there exists numbers δ_1^*, C_γ, and k_w such that

$$(d_0(0)^{1/2} + \beta_1)\frac{C_{\phi 1}}{(1-\lambda)^{1/2}} < 1. \tag{80}$$

That is, if the level of excitation (δ_1^*) is sufficiently large relative to C_γ and k_w, then the parameter error $d_0(0)$ will be small and inequality (80) holds. From inequality (79) it then follows that

$$\max_{1\le\tau\le t} |z(\tau)| \le \frac{(d_0(0)^{1/2} + \beta_1)C_{\phi 3} + \Sigma_\gamma(0) + \xi(t)}{1 - (d_0(0)^{1/2} + \beta_1)C_{\phi 1}/(1-\lambda)^{1/2}}. \tag{81}$$

By using equation (77) we then have

$$r(t) \le C_r < \infty. \tag{82}$$

Note that when C_γ and k_w decrease then $d_0(0), C_{\phi 3}, \Sigma_\gamma(0)$, and $C_{\phi 1}$ decrease as well with the consequence that C_r decreases.

From (55) and (82) we obtain

$$\limsup_{k\to\infty} \sup_{N\in T_k} \sum_{t=\sigma_k}^{N} z(t)^2 \le d_0(0)C_r. \tag{83}$$

Combining (53) with inequality (83) gives

$$\limsup_{t\to\infty} z(t)^2 \le \Sigma_{D1}^2 \tag{84}$$

where Σ_{D1} is defined in Theorem 5.2. From (11), statement 1 of Lemma 4.1, and inequality (84) it follows that

$$\limsup_{t\to\infty} e(t+1)^2 \le \left(\left(1 + \frac{C_\gamma}{(1-\lambda)^{1/2}}\right)\Sigma_{D1} + \frac{C_\gamma k_{y^*} + C_w k_w}{(1-\lambda)^{1/2}}\right)^2.$$

Thus the theorem is proved for the case when $\sigma_k < \infty$ and $\tau_k < \infty$ for all finite k. The cases when there exists a finite κ_0 so that $\tau_{k_0} < \infty$ and $\sigma_{k_0} = \infty$ or there exists k_1 so that $\tau_{k_1+1} = \infty$ and $\sigma_{k_1} < \infty$ are trivial. □

Remarks.

1. The advantage of the normalization signal given by equation (8) over that given by equation (7) is that it does not require a knowledge of the characteristic time constant λ_0.
2. From Assumption A3 it follows that

$$\lim_{C_\gamma, k_w\to 0} \Sigma_1 = 0, \qquad \lim_{C_\gamma, k_w\to 0} \Sigma_\gamma(0) = 0, \qquad \lim_{C_\gamma, k_w\to 0} \delta_2^* = \delta_1^*/2.$$

From the definition of $d_0(\epsilon_1)$ in equation (31), the definition of Σ_D in statement 2 of Theorem 5.1, and the analysis given above it then follows that

$$\lim_{C_\gamma, k_w\to 0} d_0(0) = 0, \qquad \lim_{C_\gamma, k_w\to 0} \Sigma_D = 0.$$

Consequently from statements 1, 2 of Theorem 5.1

$$\lim_{C_\gamma, k_w \to 0} \sum_{j=1}^{t} \lambda^{t-j} |y(j+1) - y^*(j+1)|^2 = 0$$

and

$$\lim_{C_\gamma, k_w \to \infty} \|\theta(t) - \theta_0\| = 0.$$

Similar results can be derived from the expressions in Theorem 5.2. This implies that the tracking and parameter estimation errors are continuous with respect to the unmodeled dynamics and the disturbances in the sense that when the unmodeled dynamics and the external perturbations tend to zero, tracking and parameter estimation errors also tend to zero. Without the application of external excitation, the uniform convergence of the parameter error cannot be expected.

3. When persistent excitation is applied, the self-stabilization works in the following manner. Whenever the estimator produces parameters that cause the adaptive loop to become unstable, the controller stabilizes itself by producing excitation, which results in parameter tuning. This tuning is the result of "self-stabilization" and takes place even when the external signals are not excited. In fact, the analysis shows the adaptive control algorithm passes through two phases characterized by the intervals Q_k and T_k, defined in the proof of Theorem 5.1. In the intervals Q_k, the function $W(t+1)$ is nonpositive, which implies stability of the input and output signals. During these intervals of time the parameter estimates may drift unless external excitation is supplied. Furthermore, the analysis shows that the level of excitation needs to be higher, in some sense, than the intensities of the disturbances and the unmodeled dynamics. In this respect our result is equivalent to previous results that have been obtained using averaging analysis.
4. From a practical point of view it makes sense to turn the excitation and estimation algorithm off after the parameters have settled and acceptable performance has been achieved.
5. There exists a finite level of excitation and a finite time τ_{k_2} so that the estimate of the high frequency gain, $\hat{b}_0(t)$, stays away from zero, i.e., $|\hat{b}_0(t)| \geq \epsilon_1$ for all $t \geq \tau_{k_2}$. This implies that the modification introduced to avoid division with small numbers is only used during a transient period. This observation can be used to motivate the use of projection and persistent excitation to solve singularity problems associated with the solution of Bezout-like equations as well.
6. The results developed in this paper can be extended to indirect control and estimation. In particular, the obtained results lead in a natural way to the definiton of a robust controller based on the use of H_∞-like design techniques.
7. The burstings can only have finite duration. An estimate of the longest period of time a burst is tolerated by the adaptive control algorithm can be calculated from equation (68).

6. Conclusions. In this paper we show that excitation with fixed and finite energy can be used to stabilize the estimator in a direct adaptive control algorithm. We show that the parameter estimates and the input/output signals remain bounded when the level of excitation is sufficiently high relative to the magnitude of the external perturbations and the intensity of the unstructured unmodeled dynamics. We also show that the parameter estimates "converge" close to their optimal values. In other words, we show that it is possible to perform identification of open-loop unstable systems and that we can bound the parameter estimation error. The results apply to systems that have a stably invertible nominal model. It is quite straightforward to generalize the results to a broader class of systems and to apply more complex control laws. A few practical problems remain to be solved. First, it is not clear how to develop algorithms to monitor performance and turn the estimation algorithm on and off. Second, while we have been able to develop guidelines for choosing excitation level through the definition of δ_2^*, these are not so easy to implement because of the fact that bounds on certain system H_∞ norms have to be known in advance for us to be able to implement the approach.

IDENTIFICATION OF $q(x)$ IN $u_t = \Delta u - qu$ FROM BOUNDARY OBSERVATIONS*

SERGEI AVDONIN[†] AND THOMAS I. SEIDMAN[‡]

Abstract. We consider the problem of recovering the coefficient $q(x)$ in the equation $u_t = \Delta u - qu$ from boundary observations. Uniqueness of q based on knowledge of the Neumann ↦ Dirichlet response operator is shown as an implication of (known) corresponding results concerning the inverse problem for the corresponding hyperbolic equation $w_{tt} = \Delta w - qw$. This is then reduced to use of the response to a single input with some consideration of computational approximation.

Key words. identification, parabolic, partial differential equation, uniqueness, approximation

AMS subject classifications. 35R30, 35K99, 35C99

1. Introduction.

We consider the problem of identifying the (unknown) coefficient $q = q(x)$ in the parabolic partial differential equation

$$u_t = \Delta u - qu \qquad \text{on } Q := (0,T) \times \Omega, \tag{1.1}$$

assuming input/output access only at the boundary $\Sigma = \Sigma_T := (0,T) \times \partial\Omega$. More precisely, we assume that we can specify the Neumann data for (1.1) with trivial initial data

$$\frac{\partial u}{\partial \nu} = f \qquad \text{on } \Sigma_T \qquad u\Big|_{t=0} = 0 \qquad \text{on } \Omega \tag{1.2}$$

and then observe the corresponding Dirichlet data,

$$g := u\Big|_{\Sigma}. \tag{1.3}$$

Formally, then, we have a linear input/output map (Neumann ↦ Dirichlet response operator)

$$\mathbf{R}_1 = \mathbf{R}_1(T;q) : f \mapsto g, \tag{1.4}$$

defined through (1.1), (1.2), and then the observation (1.3). Our principal result is that $\mathbf{R}_1$ (for any $T > 0$) uniquely determines the coefficient function $q(\cdot)$ appearing in (1.1), i.e., that

$$q \mapsto \mathbf{R}_1(T,q) \ \text{ is injective on } \boldsymbol{\mathcal{A}} \tag{1.5}$$

when considered for q in some suitable set $\boldsymbol{\mathcal{A}}$ of admissible functions.

We note that results like (1.5) are already available for the inverse problem for the corresponding hyperbolic equation

$$w_{tt} = \Delta w - qw \qquad \text{on } (0,\bar{T}) \times \Omega. \tag{1.6}$$

Our approach — exploiting the deep connection between (1.1) and (1.6) via transforms with respect to t — is stimulated by D. Russell's argument ([14]; see also [15]) showing how to deduce exact null controllability of the heat equation for a bounded region $\Omega \subset \mathbb{R}^N$ from a corresponding wave equation result. We may restate our description above to say that our primary result is the *implication*, under fairly general hypotheses, of (1.5) from

$$q \mapsto \mathbf{R}_2(\bar{T}, q) \text{ is injective on } \boldsymbol{\mathcal{A}}, \tag{1.7}$$

where $\mathbf{R}_2$ is the corresponding Neumann ↦ Dirichlet response operator for (1.6). This argument will be given in §2.

Parenthetically, we note that a quite different argument could alternatively obtain parabolic identifiability from corresponding results to the extent that these would be available for the elliptic rather than the hyperbolic case, i.e., deriving (1.5) from (cf., e.g., [11])

$$q \mapsto \mathbf{R}_0(q) \text{ is injective on } \boldsymbol{\mathcal{A}}, \tag{1.8}$$

where $\mathbf{R}_0(q) : f \mapsto g$ is the Neumann ↦ Dirichlet operator for the elliptic equation

$$-\boldsymbol{\Delta} v + qv = 0 \qquad \text{on } \Omega, \quad \frac{\partial v}{\partial \nu} = f(x) \qquad \left[g := v\Big|_{\partial\Omega} \right]. \tag{1.9}$$

To see this, one applies (1.1) and (1.2) to f constant in t which gives u analytic in t and, assuming $q > 0$, convergent to the steady-state solution v of (1.9) as $t \to \infty$. This analyticity implies that $\mathbf{R}_1(T,q)f$ uniquely determines $g(\cdot) := u\big|_{\partial\Omega}$ not only on $[0,T]$ but for all $t > 0$; compare the approach of [16]. The limit as $t \to \infty$ is then also uniquely determined so, for any such $f = f(x)$ and any $T > 0$, one sees that $\mathbf{R}_1(T,q)f = \mathbf{R}_1(T,\hat{q})$ implies $\mathbf{R}_0(q)f = \mathbf{R}_0(\hat{q})$; compare [10].

Whereas it seems that the entire response operator $\mathbf{R}_2$ may be needed for identifiability for (1.6), we will show in §3 that a single experiment, using a suitably chosen input f_* and observing the associated output

$$g_* = \boldsymbol{\Gamma}(q) := \mathbf{R}_1(T;q)f_*, \tag{1.10}$$

suffices to identify q in (1.1), i.e., that f_* can be chosen so that $\boldsymbol{\Gamma}$ is injective on $\boldsymbol{\mathcal{A}}$. Section 3 will also include some additional remarks on possible computational implementation.

2. Principal results.

We assume throughout that Ω is a bounded region in $\mathbb{R}^n$ with sufficiently smooth boundary $\partial\Omega$ for the relevant trace theory to apply for the operators $\mathbf{B} : u \mapsto u\big|_{\partial\Omega}$ and $\mathbf{C} : u \mapsto \frac{\partial u}{\partial \nu}$ and for the consideration of Neumann conditions. We also assume that the unknown coefficient q is in $L^\infty(\Omega)$; there is then no further loss of generality in assuming, as we shall do, that $q > 0$ since a substitution $v := e^{-\alpha t}u$ replaces q by $q + \alpha$ and f, g by $e^{-\alpha t}f$, $e^{-\alpha t}g$ so $q \mapsto R_1(T,q)$ will be injective if and only if $q \mapsto R_1(T, q + \alpha)$ is injective.

Let $\mathbf{A} = \mathbf{A}_q$ be the elliptic operator $\mathbf{A} = -\boldsymbol{\Delta} + q$ on $\mathcal{H} := L^2(\Omega)$ with domain $\mathcal{D} = \mathcal{D}(\mathbf{A}) := \{u \in H^2(\Omega) : \mathbf{C}u = 0\}$. We note at this point the existence of an orthonormal (with respect to $\mathcal{H}$) basis of eigenfunctions

$$\mathbf{A}e_k = \lambda_k e_k \tag{2.1}$$

with $0 < \lambda_1 \leq \lambda_2 < \cdots \to \infty$ since we have taken $q > 0$.

We introduce the Green's operator $\mathbf{G}$ defined by $\mathbf{G} : \varphi \mapsto u$ with

$$-\mathbf{\Delta} u + qu = 0 \quad \text{on } \Omega, \qquad \mathbf{C}u = \varphi \in \mathcal{X} := L^2(\partial\Omega). \tag{2.2}$$

We certainly have $u \in H^1(\Omega)$ for arbitrary $\varphi \in \mathcal{X} = L^2(\partial\Omega)$, so noting [7], [8], and the equivalence of $H^s(\Omega)$ and $\mathcal{D}(\mathbf{A}^\vartheta)$ for $\vartheta = 2s$, we have

$$\mathbf{A}^{1/2}\mathbf{G} : \mathcal{X} \overset{\text{cont.}}{\longrightarrow} \mathcal{H} \tag{2.3}$$

(with $\mathbf{A}^\vartheta \mathbf{G} : \mathcal{X} \to \mathcal{H}$ for any $\vartheta < \frac{3}{4}$ if $\partial\Omega$ is, e.g., in C^1). Then the solution u of

$$\dot{u} + \mathbf{A}u = 0, \quad \mathbf{C}u = f(t) \quad \text{with } u\Big|_{t=0} = 0 \tag{2.4}$$

has the representation [3]

$$u(t) = \int_0^t [\mathbf{A}^{1/2}\mathbf{S}(t-s)][\mathbf{A}^{1/2}\mathbf{G}]f(s)\, ds, \tag{2.5}$$

where $\mathbf{S}(\cdot)$ is the (analytic) semigroup on $\mathcal{H}$ generated by $-\mathbf{A}$ so

$$\|\mathbf{A}^\nu \mathbf{S}(t)\| \le Mt^{-\nu}. \tag{2.6}$$

From (1.3) and the form of (2.5), we then see that $\mathbf{R}_1$ is a convolution operator,

$$[\mathbf{R}_1 f](t) = g(t) := \mathbf{B}u(t) = \int_0^\infty \mathbf{K}_1(t-s)f(s)\, ds, \tag{2.7}$$

with the kernel $\mathbf{K}_1(\cdot) = \mathbf{K}_1(\cdot; q)$ given by

$$\mathbf{K}_1(t) := \begin{cases} 0 & \text{for } t \le 0, \\ \mathbf{BAS}(t)\mathbf{G} & \text{for } t > 0, \end{cases} \tag{2.8}$$

where, noting (2.3), (2.6), and

$$\mathbf{BA}^{-\gamma} : \mathcal{H} \overset{\text{cont.}}{\longrightarrow} \mathcal{X} \qquad (\text{any } \gamma > 1/4), \tag{2.9}$$

we may write

$$\mathbf{BAS}(t)\mathbf{G} = \left[\mathbf{BA}^{-\gamma}\right]\left[\mathbf{A}^{1/2+\gamma}\mathbf{S}(t)\right]\left[\mathbf{A}^{1/2}\mathbf{G}\right]$$

with $\frac{1}{4} < \gamma < \frac{1}{2}$ to see that $\|\mathbf{K}_1(\cdot)\|$ is integrable whence $\mathbf{R}_1$ is, e.g., a continuous operator from $\mathcal{F}_T := L^2((0,T) \times \partial\Omega)$ to itself.

At this point it is convenient to shift to the Fourier representation for the semigroup. Using (2.1) in (2.8) gives the series representation

$$\mathbf{K}_1(t)\xi = \sum_k \lambda_k e^{-\lambda_k t} \langle e_k, \mathbf{G}\xi \rangle \mathbf{B}e_k \tag{2.10}$$

for $t > 0$. What we will actually need is the Laplace transform of this:

$$\begin{aligned} \hat{\mathbf{K}}_1(s)\xi &:= \int_0^\infty e^{-st}\mathbf{K}_1(t)\xi\, dt \\ &= \sum_k \lambda_k \int_0^\infty e^{-st}e^{-\lambda_k t} dt \langle e_k, \mathbf{G}\xi \rangle \mathbf{B}e_k \\ &= \sum_k \frac{\lambda_k}{s+\lambda_k} \langle e_k, \mathbf{G}\xi \rangle \mathbf{B}e_k \\ &= \mathbf{BA}(s+\mathbf{A})^{-1}\mathbf{G}\xi \qquad \text{for } s > 0. \end{aligned} \tag{2.11}$$

Note that the final form of this easily gives boundedness on $\mathcal{X}$ of $\hat{\mathbf{K}}_1(s)$ for $s \geq 0$, so we have no difficulties justifying convergence for the series and our manipulations. More precisely, we observe that everything certainly works well for the core of the operator (specification for ξ in a suitable dense set of nice functions), and then we can extend by continuity, using the final form.

With boundary conditions and initial conditions, the wave equation (1.6) now becomes

$$\ddot{w} + \mathbf{A}w = 0, \quad \mathbf{C}w = f \quad \text{with } w = 0 = \dot{w} \text{ at } t = 0, \tag{2.12}$$

and the response operator is the map

$$\mathbf{R}_2 = \mathbf{R}_2(\bar{T}, q) : f \mapsto \mathbf{B}w,$$

with w defined by (2.12) for the time interval $(0, \bar{T})$. It is well known that this $\mathbf{R}_2$ is a bounded operator from, e.g., $\mathcal{F}_{\bar{T}} := L^2((0,\bar{T}) \times \partial\Omega)$ to itself.

We proceed directly to the separation-of-variables solution, again expanding with respect to the orthonormal basis $\{e_k\}$,

$$w = \sum_k y_k(t)e_k, \qquad \mathbf{G}f = \sum_k \varphi_k(t)e_k.$$

One easily verifies from (2.12) that each $y_k(\cdot)$ is the solution of the ordinary differential equation

$$\ddot{y} + \lambda_k y = \lambda_k \varphi_k(t) \quad \text{with } y(0) = 0 = \dot{y}(0)$$

whence, noting that the assumed positivity $q > 0$ gives $\lambda_k > 0$, one has

$$y_k(t) = \mu_k \int_0^t [\sin \mu_k(t-s)]\varphi_k(s)\, ds \qquad \left(\mu_k := \sqrt{\lambda_k}\right).$$

Substituting, this gives the series representation

$$[\mathbf{R}_2 f](t) = \mathbf{B}w(t) = \int_0^t \sum_k \mu_k [\sin \mu_k(t-s)] \langle e_k, \mathbf{G}f(s)\rangle \mathbf{B}e_k\, ds, \tag{2.13}$$

so we see that $\mathbf{R}_2$ is a convolution operator$f \mapsto \mathbf{K}_2 * f$ with the kernel $\mathbf{K}_2(\cdot)$ given, corresponding to (2.10), by the series

$$\mathbf{K}_2(t)\xi = \sum_k \mu_k [\sin \mu_k t] \langle e_k, \mathbf{G}\xi\rangle \mathbf{B}e_k. \tag{2.14}$$

Again, we need the Laplace transform of this:

$$\begin{aligned} \hat{\mathbf{K}}_2(s)\xi &:= \int_0^\infty e^{-st}\mathbf{K}_2(t)\xi\, dt \\ &= \int_0^\infty e^{-st} \sum_k \mu_k [\sin \mu_k t] \langle e_k, \mathbf{G}\xi\rangle \mathbf{B}e_k\, dt \\ &= \sum_k \mu_k \int_0^\infty e^{-st} [\sin \mu_k t]\, dt\, \langle e_k, \mathbf{G}\xi\rangle \mathbf{B}e_k \\ &= \sum_k \frac{\lambda_k}{s^2 + \lambda_k} \langle e_k, \mathbf{G}\xi\rangle \mathbf{B}e_k \\ &= \mathbf{B}\mathbf{A}(s^2 + \mathbf{A})^{-1}\mathbf{G}\xi \qquad \text{for } s > 0. \end{aligned} \tag{2.15}$$

Again, we think of these manipulations as performed for nice ξ, with the result then extended by continuity, using the final form. Comparing (2.15) with (2.11) gives our key identity:

$$\hat{\mathbf{K}}_2(s;q) \equiv \hat{\mathbf{K}}_1(s^2;q) \qquad \text{for } s > 0. \tag{2.16}$$

Returning to (2.8), we observe that, since $\mathbf{S}(\cdot)$ is an analytic semigroup, the operator function $t \mapsto \mathbf{K}_1(t;q)$ is itself analytic in t (for complex t with positive real part). It follows that specification of $\mathbf{R}_1(T;q)$ implies specification of the kernel $\mathbf{K}_1(t;q)$ for $0 < t < T$ and so, by analyticity, uniqueness of the determination of $\mathbf{K}_1(\cdot;q)$ on $(0,\infty)$. This means that the Laplace transform $\hat{\mathbf{K}}_1(\cdot;q)$ is uniquely determined, as is the Laplace transform $\hat{\mathbf{K}}_2(\cdot;q)$, by the identity (2.16). By the standard uniqueness results for Laplace transforms, this means that $\mathbf{K}_2(t;q)$ is determined for $t > 0$, so the convolution operator $\mathbf{R}_2(\bar{T};q)$ is uniquely determined for arbitrary $\bar{T} > 0$. We have thus proved[1] the asserted implication in the following theorem.

THEOREM 2.1. *Suppose it is known, for some bounded Ω in $\mathbb{R}^n$ and a set $\boldsymbol{A}$ of bounded functions on Ω, that* (1.7) *holds for some $\bar{T}$. Then* (1.5) *holds for arbitrary $T > 0$.* (*Equivalently, if $q, \hat{q} \in \boldsymbol{A}$ with $q \not\equiv \hat{q}$, then $\mathbf{R}_1(T,q) \not\equiv \mathbf{R}_1(T,\hat{q})$ for all $T > 0$.*)

From [12] we have, restated in our notation, the following[2] result.

THEOREM 2.2 (R-S). *Let Ω be a bounded region in $\mathbb{R}^n$ with C^1 boundary $\partial\Omega$. Then* (1.7) *holds for $\boldsymbol{A} = L^\infty(\Omega)$.*

Combining this with Theorem 2.1, we immediately obtain the desired identifiability result for (1.1).

COROLLARY 2.3. *Let Ω be a bounded region in $\mathbb{R}^n$ with C^1 boundary $\partial\Omega$. Assume it is known that the coefficient q in* (1.1) *is in $\boldsymbol{A} = L^\infty(\Omega)$. Then q is uniqely determined by $\mathbf{R}_1(T,q)$.*

The observation that verification of our manipulations on a dense set is sufficient could become more significant if we wished to consider variations on the operator. In particular, if we wished to use Dirichlet data as input instead and then observe the corresponding Neumann data (reversing the roles of $\mathbf{B}$ and $\mathbf{C}$), then the regularity results would not be as cooperative, and it is useful to observe that equality on a core

[1] The argument also provides a partial converse to the implication. If one could independently show uniqueness of the correspondence $\mathbf{R}_1(T;q) \leftrightarrow q$ (for some T and some class of q), then one would necessarily have uniqueness for $\mathbf{R}_2(\cdot;q) \leftrightarrow q$, with observation now needed on all of $\mathbb{R}_+$ since analyticity in t is unavailable for $\mathbf{R}_2$ to obtain uniqueness from an interval without further information.

[2] We are indebted, for the reference to [12], to a referee of a previous version of this paper which referred, instead, to a sequence of recent papers, [1], [2], [4]–[6] by M. Belishev and others, which provide a reconstruction algorithm for q, justified under a control-theoretic hypothesis that the pair $[\Omega, q]$ is normal, i.e., $0 .< t < T_*$ the set of approximately reachable states by boundary control on $(0,t)$ is all of $\mathcal{H}_t := \{v \in \mathcal{H} : v(x) = 0 \text{ if } |x - \partial\Omega| > t\}$. Using duality, a sufficient condition for this normality is that $\partial\Omega$ and q be analytic for applicability of the classic Holmgren–John uniqueness theorem, although we note that this has quite recently been extended to the nonanalytic case by Tataru [17] (see, also, related results by Robbiano [13] and by Hörmander [9]). In comparison with [12], we observe that considerable regularity may be needed for normality in the reconstruction but not for the (nonconstructive) injectivity of $q \mapsto R_2(\bar{T}, q)$. On the other hand, using the results in [17] one can obtain uniqueness results applying to observation on a part of the boundary, while the results in, e.g., [6] consider more general wave equations

$$\rho(x)w_{tt} = \boldsymbol{\nabla} \cdot (\mu(x)\boldsymbol{\nabla} w) - qw, \tag{2.17}$$

where any two of the three coefficient functions ρ, μ, and q are assumed to be known, with the third coefficient to be recovered. The argument in §2 for our key identity (2.16) is valid also for these settings, so one would obtain corresponding identifiability results for the parabolic case. We view these as directions for future extensions of our present results.

suffices. Alternatively, one could obtain continuity using other boundary operators $\mathbf{B}$ and $\mathbf{C}$ by suitable adjustment of the spaces, perhaps admitting different $\mathcal{X}_{\text{in}}$ for f and $\mathcal{X}_{\text{out}}$ for g so that one can then proceed exactly as we have done. For such possible generalization, we also note that we do not need the full strength of the present self-adjointness of $\mathbf{A}$, giving orthonormality of the eigenfunctions in (2.1) but only, e.g., that $\Sigma\alpha_k e_k \mapsto \left[\Sigma|\alpha_k|^2\right]^{1/2}$ is an equivalent norm.

3. Identification with a single input. Theorem 2.1 and its corollary require complete knowledge of $\mathbf{R}_1$ in order to determine q. Interpreted directly, this would mean that one would need knowledge of all possible input/output pairs $[f, g]$ corresponding to (1.1), (1.2), and (1.3), requiring an infinite number of input/output experiments. Using the form of $\mathbf{R}_1$ given in (2.7) and (2.8), together with the regularity associated with (1.1), we now wish to show that a single experiment, observing the output g_* for a single properly chosen input f_*, will suffice to determine $\mathbf{K}_1(\cdot)$ and thus q.

Taking any total set (e.g., an orthonormal basis) $\{\xi_k\}$ for $\mathcal{X} = L^2(\partial\Omega)$ and a sequence of times $0 = t_1 < t_2 < \cdots \to T$, we may set

$$f_*(t) := \sum_{t_k<t} c_k\xi_k \qquad (0 < t < T) \tag{3.1}$$

with, e.g., $c_k := 2^{-k}$ ensuring convergence in $\mathcal{F}_T$. We set $\mathcal{I}_k := (t_k, t_{k+1})$, $\hat{\mathcal{I}}_k := (0, t_{k+1} - t_k)$ for $k = 1, 2, \dots$ so $\mathcal{I} := \bigcup_k \mathcal{I}_k = [0, T) \setminus \{t_1, t_2, \dots\}$. Clearly, $g_* := \mathbf{R}_1 f_*$ will be continuous and piecewise analytic in t on $\mathcal{I}$ with

$$\dot{g}_*(t) = \sum_{t_k<t} c_k\mathbf{K}_1(t - t_k)\xi_k \qquad (t \in \mathcal{I}). \tag{3.2}$$

Although g_* certainly depends on q, we note that no a priori information about q is needed for this construction of f_*.

From (3.2) one first notes that knowledge of g_* on $\mathcal{I}_1$ just gives $\mathbf{K}_1(\cdot)\xi_1$ on $\hat{\mathcal{I}}_1$ by differentiation and therefore determines $\mathbf{K}_1(t)\xi_1$ for all $t > 0$ by analyticity. Next, knowing g_* on $\mathcal{I}_2$ we may subtract the now-known $\frac{1}{2}\mathbf{K}_1(t)\xi_1$ from $\dot{g}_*$ to obtain $\mathbf{K}_1(\cdot)\xi_2$ on $\hat{\mathcal{I}}_2$ whence, again by analyticity, $\mathbf{K}_1(t)\xi_2$ would be known for all $t > 0$. Recursively, we similarly obtain each $\mathbf{K}_1(\cdot)\xi_k$ on $\hat{\mathcal{I}}_k$ and so on $\mathbb{R}_+$ for $k = 3, 4, \dots$. Thus, a single pair $[f_*, g_*]$ constructed in this fashion will uniquely determine $\mathbf{K}_1(t)\xi_k$ for each k and all $t > 0$ and hence will determine q.

The input function f_* is here piecewise constant in t, but we note that replacing f_* as input by its time integral just produces the time integral of g_* as output and thus also determines the original $\dot{g}_*$ of (3.2). Iterating this idea, we can use an input which is C^m in t for arbitrary m. We can get any desired spatial regularity by a suitable choice of $\{\xi_k(\cdot)\}$ as smooth functions on $\partial\Omega$.

THEOREM 3.1. *Given Ω and any $T > 0$ one can select a suitable* (*smooth*) *function $f_* \in \mathcal{F}_T$ such that the corresponding map $\mathbf{\Gamma}$ of* (1.10) *is injective when considered on $\boldsymbol{\mathcal{A}} \subset L^\infty(\Omega)$.*

Fixing Ω, T, and f_* as above, the injectivity of $\mathbf{\Gamma}$ in Theorem 3.1 means that (exact) observation of the output $g_* = \mathbf{\Gamma}(q)$ uniquely determines q. The obvious next question is whether this determination can be realized computationally: We would like an implementable procedure to recover q to any desired degree of accuracy, provided we are able to compute to arbitrary accuracy and to produce the input and measure the output with arbitrary accuracy. This is far from obvious in view of the ill-posedness of the problem for any reasonable topologies.

The argument for justification of any computational schema for the problem sets this in the context of a sequence of increasingly accurate approximating problems and then asserts the convergence of the computed approximants q_j to the true coefficient q. We begin by writing our a priori information about q in the form

$$q \in \mathcal{K} \subset \boldsymbol{\mathcal{A}} \subset L^\infty(\Omega). \tag{3.3}$$

Our principal assumptions here are that $\mathcal{K}$ is a closed subset of $L^\infty(\Omega)$ and that $\boldsymbol{\Gamma} : \mathcal{K} \overset{\text{cont.}}{\longrightarrow} \mathcal{G}$ for some suitable $\mathcal{G}$ topology with respect to which we can assume an increasingly accurate sequence of measurements $g_j \to g_*$. Standard techniques of numerical analysis enable us to provide computational solutions for the defining equations, giving a sequence of approximations $\boldsymbol{\Gamma}_j \to \boldsymbol{\Gamma}$. We assume here that this is uniform convergence on $\mathcal{K}$ but note that the convergence need only be at q if, instead, we would have uniform equicontinuity on $\mathcal{K}$ of the $\boldsymbol{\Gamma}_j$. The various approaches to ill-posed problems now each provide some selection procedure: Given $g_j, \boldsymbol{\Gamma}_j$ (with some accuracy estimate), there is a way to select $q_j \in \mathcal{K}$ so that $\boldsymbol{\Gamma}_j(q_j) \approx g_j$, and we may assume this is done in such a way as to have

$$[\boldsymbol{\Gamma}_j(q_j) - g_j] \to 0 \quad \text{as } k \to \infty. \tag{3.4}$$

If $\mathcal{K}$ is compact, the generic argument is to obtain (for a subsequence) convergence $q_j \to \bar{q}$ for some $\bar{q}$. We then have

$$\boldsymbol{\Gamma}(\bar{q}) - g_* = [\boldsymbol{\Gamma}(\bar{q}) - \boldsymbol{\Gamma}(q_j)] + [\boldsymbol{\Gamma}(q_j) - \boldsymbol{\Gamma}_j(q_j)] + [\boldsymbol{\Gamma}_j(q_j) - g_j] + [g_j - g_*],$$

and since each term on the right goes to 0, we conclude that $\boldsymbol{\Gamma}(\bar{q}) = g_*$. By our uniqueness theorem, we must then have $\bar{q} = q$. Finally, uniqueness of the limit makes the subsequence extraction irrelevant so, as desired, one has convergence of the sequence of computed approximants to the true solution $(q_j \to q)$ in the sense of the $\mathcal{K}$ topology.

As a variant of this, suppose one were to know a priori only that $q \in L^\infty(\Omega)$ but did not know any specific bound. We then propose the selection procedure: Choose

$$\|q_j\|_{L^2(\Omega)} + \|q_j\|_{L^\infty(\Omega)} \leq \min + \varepsilon_j \tag{3.5}$$

subject to a constraint on the residual error

$$\|\boldsymbol{\Gamma}_j(q_j) - g_j\| \leq \varepsilon'_j. \tag{3.6}$$

We make the assumptions that $\varepsilon_j \to 0$ and also that $\varepsilon'_j \to 0$, giving (3.4) but with ε'_j large enough (in comparison to the error estimates for the computational map $\boldsymbol{\Gamma}_j$ and for the observation g_j) that q itself is permitted to compete in the minimization, i.e., that (3.6) is satisfied with $q_j = q$.

THEOREM 3.2. *The computational procedure determined by* (3.5) *and* (3.6) *provides a sequence* (q_j) *which converges strongly to the true* q *in* $L^p(\Omega)$ *for all finite* p.

Proof. If we set

$$\alpha_j := \|q_j\|_{L^2(\Omega)}, \;\alpha := \|q\|_{L^2(\Omega)}, \;\beta_j := \|q_j\|_{L^\infty(\Omega)}, \;\beta := \|q\|_{L^\infty(\Omega)},$$

then (3.5), with the admissibility of q in (3.6), gives

$$\limsup[\alpha_j + \beta_j] \leq [\alpha + \beta]. \tag{3.7}$$

Since this means $\{\alpha_j\}$ is bounded, we must have, for a subsequence, weak convergence in $L^2(\Omega)$, i.e., $q_j \rightharpoonup \hat{q}$. Further, convexity gives

$$\|\hat{q}\|_{L^2(\Omega)} =: \hat{\alpha} \leq \liminf \alpha_j, \qquad \|\hat{q}\|_{L^\infty(\Omega)} =: \hat{\beta} \leq \liminf \beta_j. \tag{3.8}$$

The hypotheses, together with (3.6), ensure that

$$\lim \mathbf{\Gamma}(q_j) = \lim \mathbf{\Gamma}_j(q_j) = \lim g_j = g_* := \mathbf{\Gamma}(q).$$

Now let u_j be the solution of

$$u_t = \mathbf{\Delta} u - q_j u, \quad u_\nu = f_*, \quad u\Big|_{t=0} = 0 \tag{3.9}$$

and observe that the uniform L^∞ bound on q_j gives the standard (uniform) bound on u_j in $L^2([0,T] \to H^1(\Omega))$ and so also a uniform bound on $\dot{u}_j$ in $L^2([0,T] \to H^{-1}(\Omega))$. Using the Aubin compactness theorem, we may extract a further subsequence to have $u_j \to \hat{u}$ in, say, $L^2([0,T] \to H^s(\Omega))$ for any $s < 1$. From the weak formulation of the problem, one easily sees that for $q_j \rightharpoonup \hat{q}$, one has $\hat{u}$ satisfying the limit equation. Since the boundary trace is closed when applied to solutions of (3.9) and we already know that $\mathbf{C}u_j = g_j \to g_*$, it follows that $\mathbf{\Gamma}(\hat{q}) = g_*$, i.e., $\mathbf{\Gamma}(\hat{q}) = \mathbf{\Gamma}(q)$. Since (3.8) gives $\hat{q} \in L^\infty(\Omega)$, Theorem 3.1 now gives $\hat{q} = q$, and uniqueness of this limit means that we may ignore the previous extractions of subsequences. Since this gives $\hat{\alpha} = \alpha$ and $\hat{\beta} = \beta$, it follows from (3.7) and (3.8) that $\alpha_j \to \alpha$. This, together with the weak convergence $q_j \rightharpoonup q$, gives strong convergence $q_j \to q$ in the Hilbert space $L^2(\Omega)$. As Ω is bounded, this immediately gives $L^p(\Omega)$ convergence for $p \leq 2$, and the presence of an $L^\infty(\Omega)$ bound also gives $L^p(\Omega)$ convergence for all $p < \infty$. □

EXACT OBSERVABILITY OF THE TIME-VARYING HYPERBOLIC EQUATION WITH FINITELY MANY MOVING INTERNAL OBSERVATIONS*

A. YU. KHAPALOV†

Abstract. The problem of exact observability of the linear hyperbolic equation with time-varying coefficients under finitely many internal observations is considered. The question with which we are concerned in this paper is a sharp correspondence between the internal regularity of the solutions and a type of observation required to provide $L^\infty(0,T;R^{n+1})$- or $C([0,T[;R^{n+1})$-exact observability with respect to the energy norm. Two types of observations are considered: pointwise and spatially averaged, for which the existence of needed observation curves (continuous on $[0,T[$ for $n=1$) and set-valued maps (continuous on $[0,T[$ with respect to Lebesgue measure) is established. The techniques involved are related to the construction of suitable skeletons for these curves and maps.

Key words. time-varying hyperbolic equation, exact observability, moving observation

1. Introduction and problem formulation.

Let Ω be an open, bounded domain in R^n with boundary $\partial\Omega$. We consider the following initial-boundary value problem:

(1.1)
$$\frac{\partial^2 y}{\partial t^2} = \sum_{i,j=1}^{n} \frac{\partial}{\partial x_i}\left(a_{ij}(x,t)\frac{\partial y}{\partial x_j}\right) - \sum_{i=1}^{n} a_i(x,t)\frac{\partial y}{\partial x_i} - a(x,t)y \quad \text{in } Q = \Omega\times(0,T),$$

$$y = 0 \quad \text{in } \Sigma = \partial\Omega\times(0,T),$$

$$y\;|_{t=0} = y_0, \qquad y_t\;|_{t=0} = y_1.$$

We assume that the operator in the right-hand side of (1.1) is uniformly coercive:

$$\nu_1\sum_{i=1}^{n}\xi_i^2 \;\le\; \sum_{i,j=1}^{n} a_{ij}\,(x,t)\,\xi_i\xi_j \;\le\; \nu_2\sum_{i=1}^{n}\xi_i^2 \quad \text{for } \forall\xi_i\in R \quad \text{a.e. in } Q,$$

$$a_{ij}(x,t) = a_{ji}(x,t), \;\; i,j=1,\dots,n, \qquad \nu_1 = \text{const} > 0, \quad \nu_2 = \text{const} > 0.$$

The aim of this paper is to study the exact observability of (1.1) under finitely many scalar observations (as it generally occurs in applications) with respect to the energy space $H_E = H_0^1(\Omega)\times L^2(\Omega)$, which is of physical importance. The basic assumptions on the regularity of the solutions of the time-reversible problem (1.1) are

(1.2)
$$\{y,y_t\}\in C([0,T];H_E),\; dE^{1/2}(y(\cdot,t)) \le E^{1/2}(y(\cdot,0)) \le c\,E^{1/2}(y(\cdot,t)), \;\; \forall t\in[0,T],$$

where $d(= d(T))$, $c(= c(T)) > 0$ (e.g., $d = c^{-1}$) are given and $E^{1/2}(\cdot)$ is the energy norm,

$$E^{1/2}(y(\cdot,t)) = \left(\int_\Omega (\mid \nabla y(x,t) \mid^2 + y_t^2(x,t))\, dx\right)^{1/2},$$

$$\nabla = \left(\frac{\partial}{\partial x_1}, \dots, \frac{\partial}{\partial x_n}\right), \quad \mid \cdot \mid = \| \cdot \|_{R^n}.$$

(Recall that, due to Poincaré's inequality, $E^{1/2}(y(\cdot,t))$ is equivalent to the standard H_E-norm.) The general structure of the observations of our further interest is derived from (1.2):

$$(1.3) \qquad [0,T] \ni t \rightarrow z(t) = \mathbf{G}(t)\{\nabla y(\cdot,t), y_t(\cdot,t)\} \in R^{n+1}.$$

The question of primary concern in this paper is a sharp correspondence between assumptions on the internal regularity of the solutions of (1.1), which may vary (e.g., in the context of pointwise observations) with the growth of the space dimension, and a type of finite-dimensional operator (observation) in (1.3) that is required to provide $L^\infty(0,T;R^{n+1})$- or $C([0,T[;R^{n+1})$-exact observability in a given space dimension.

DEFINITION 1.1. *Given a normed space B and a linear manifold $H \subset H_E$, the system* (1.1)–(1.3) *is said to be* B-exactly observable (*this paper deals with* $B = L^\infty(0,T;R^{n+1})$ *or* $C([0,T[;R^{n+1})$) *on H with respect to the energy norm* (*we omit the latter in the text*) *if*

$$(1.4) \qquad \exists \gamma > 0 \;\; \textit{such that} \;\; \| \mathbf{G}\{\nabla y, y_t\} \|_B \geq \gamma\, E^{1/2}(y(\cdot,0))$$

for any y that satisfies (1.1)–(1.2) *and such that* $\{y(\cdot,0), y_t(\cdot,0)\} \in H$.

Remark 1.1. This definition takes into account a situation typically arising in the context of infinite-dimensional studies, namely that the domain of the observation operator may not match the regularity of the solutions of the system considered (while being, say, densely defined). Note that it treats the well-posedness of the observation (1.3) as the enclosure of the output z in (1.3) into B when $\{y(\cdot,0), y_t(\cdot,0)\}$ ranges all over H, while the continuity with respect to this pair in the energy norm is not required. On the other hand, it is clear that (1.4) (if it holds) generates some topology on H. The interrelation between Definition 1.1 and the *dual* issue of *exact controllability* is briefly discussed at the end of the next section.

In the context of the time-invariant setting the problem of exact observability for (1.1)–(1.3), being of traditional practical interest, has received considerable attention in the literature. In particular, how the Hilbert Uniqueness Method can be linked with the static pointwise sensor structure was discussed by Lions [13] (see also El Jai and others [3]) for the wave equation under the following observation: $z(t) = y(\bar{x},t)$, $t \in [0,T]$, when $B = L^2(0,T)$. For the same system the results of Triggiani and Tataru [21], [22] on exact controllability imply that for $n = 2,3$ $L^2(0,T)$-exact observability with respect to the energy norm is not possible. The techniques of the above-mentioned papers include those of harmonic and nonharmonic analysis. The $L^2(0,T)$-exact observability of the one-dimensional wave equation with *static* point observation as in (2.1) (i.e., when $\bar{x}(\cdot) \equiv \bar{x}$) was established for $T > 2 \times \max\{1 - \bar{x}, \bar{x}\}$ by Ho [5], who used the multipliers techniques. In [8], by making use of the integral formula for the general solution of the wave equation, it is shown that the infimum of the just-mentioned observation time can indeed be achieved. We stress that the techniques used in all the above works are based heavily on the time-invariant properties of the problems considered. In contrast to the time-invariant case, very little is known about the general *time-varying* problem (1.1)–(1.3).

In the present paper we establish the existence of moving (this is natural for the time-varying processes) $(n+1)$-dimensional observations (1.3) of two types: the point and the spatially averaged observations (2.1) and (2.6), which are able to ensure the $L^\infty(0,T;R^{n+1})$- or $C([0,T[;R^{n+1})$-exact observability of (1.1)–(1.3) on manifolds that are sharply linked with the assumptions on the internal regularity of the equation (1.1). The techniques employed are related to the construction of suitable skeletons for observation curves and set-valued maps, associated with (2.1) and (2.6), and based on a priori energy estimates (1.2). We remind the reader that (1.1) is *not* conservative. This approach was applied to the wave equation (in an arbitrary space dimension) with moving point observation in [6]–[8] under the assumption $\{\nabla y, y_t\} \in [C([0,T] \times \bar{\Omega})]^n$ ("$-$" stands for the closure). In this paper we show that the same approach is capable of handling the linear time-varying hyperbolic equation (1.1) under rather general and, in a certain sense, minimal assumptions on its regularity.

The paper is organized as follows. Section 2 states the main exact observability results, Theorems 2.1, 2.2, 2.4, and 2.6, which are then proven in §§3 and 5. Section 4 discusses auxiliary properties of the spatially averaged observations. In the appendix we refine the result of Theorem 2.6.

2. Main results.

We begin by the point observation

$$z(t) = \{\nabla y(\bar{x}(t),t), y_t(\bar{x}(t),t)\}, \quad t \in [0,T], \tag{2.1}$$

where $\bar{x}(t) \in \bar{\Omega}$ a.e. in $[0,T]$ (in fact, we can consider only internal curves; see Remark 3.1), is a given function (curve) measurable with respect to Lebesgue measure. In general, this observation is ill defined on the solutions of the system (1.1)–(1.2).

Assumption 2.1. $H \subset H_E \cap \{\{y(\cdot,0), y_t(\cdot,0)\} \mid \{\nabla y, y_t\} \in L^\infty(0,T;[C(\bar{\Omega})]^{n+1})\}$ is a linear manifold *separable* with respect to the following norm:

$$\| \{y(\cdot,0), y_t(\cdot,0)\} \| = \| \{y, y_t\} \|_{C([0,T];H_E)} + \operatorname*{ess\,sup}_{t\in[0,T]} \| \{\nabla y(\cdot,t), y_t(\cdot,t)\} \|_{[C(\bar{\Omega})]^{n+1}} . \tag{2.2}$$

Remark 2.1. The condition $\{\nabla y, y_t\} \in L^\infty(0,T;[C(\bar{\Omega})]^{n+1})$ in the above is to ensure the enclosure of the output in (2.1) into $L^\infty(0,T;R^{n+1})$, whereas *separability* is due to the techniques applied in this paper (recall along these lines that $L^\infty(Q)$ is not separable). A number of requirements (beginning with those providing the classical solutions) on the system (1.1) that imply Assumption 2.1 can be found in the literature (see, e.g., [15], [17], [9]).

THEOREM 2.1 (point observation). *Let $H \subset H_E$ satisfy Assumption* 2.1 *and $T > 0$ be given. Then there exists a class of measurable curves $\bar{x}(\cdot)$, which make the system* (1.1)–(1.2), (2.1) *$L^\infty(0,T;R^{n+1})$-exactly observable on H.*

THEOREM 2.2 (the one-dimensional case). *Let $\Omega =]0,1[$, $T > 0$ be given and Assumption* 2.1 *be fulfilled for H. Assume, in addition, that $y \in H^2(Q)$ when $\{y(\cdot,0), y_t(\cdot,0)\} \in H$. Then the observation curves can be selected in Theorem* 2.1 *to be arbitrarily smooth on $[0,T[$ and to lie entirely in Ω.*

The condition

$$\operatorname*{ess\,sup}_{Q} \mid a_{11t}, a_{11tt}, a_{11x}, a_1, a_{1t}, a, a_t \mid \leq \text{ const}, \quad n = 1 \tag{2.3}$$

(where all the derivatives are understood in the generalized sense), given in Ladyzhenskaya [9, pp. 162, 164], ensures the fulfillment of the assumptions of Theorem 2.2 with

$$H = (H^2(\Omega) \cap H_0^1(\Omega)) \times H_0^1(\Omega). \tag{2.4}$$

COROLLARY 2.3. *Let* (2.3) *be verified. Then Theorem* 2.2 *holds for* H *as in* (2.4).

Theorem 2.2 admits a straightforward extension to the following type of observations:

$$z(t) = \begin{pmatrix} \text{meas}^{-1}\{S_{h(t)}(\bar{x}(t))\} \int_{S_{h(t)}(\bar{x}(t))} y_x(x,t)\,dx \\ \text{meas}^{-1}\{S_{h(t)}(\bar{x}(t))\} \int_{S_{h(t)}(\bar{x}(t))} y_t(x,t)\,dx \end{pmatrix}, \quad t \in [0,T], \tag{2.5}$$

where $S_h(\bar{x}) = \{x \mid \mid x - \bar{x} \mid < h,\ x \in]0,1[\}$ and meas$\{\cdot\}$ here and elsewhere stands for Lebesgue measure.

THEOREM 2.4. [1] *Let* $\Omega =]0,1[$. *Given* $T > 0$, *there exist arbitrarily smooth functions* $\bar{x}(t) \in \Omega$, $h(t) > 0$, $t \in [0,T[$, *which make the system* (1.1)–(1.2), (2.3), (2.5) $C([0,T[;R^2)$*-exactly observable on* H *as in* (2.4).

When the space dimension is higher than one we do not manage to extend Theorem 2.4 to the general multidimensional case under the assumptions (1.2): this would require, from our point of view, an additional pointwise regularity of the solutions (e.g., as in Assumption 2.1; see Remark 3.3), which in this paper in the context of the spatially averaged observations seems to us redundant. Therefore, we enlarge the class of the spatially averaged observations (2.5) as follows:

$$z(t) = \frac{1}{\text{meas}\{\Omega(t)\}} \begin{pmatrix} \int_{\Omega(t)} v_1^0(x,t) y_{x_1}(x,t)dx \\ \vdots \\ \int_{\Omega(t)} v_n^0(x,t) y_{x_n}(x,t)dx \\ \int_{\Omega(t)} v^1(x,t) y_t(x,t)dx \end{pmatrix}, \quad t \in [0,T], \tag{2.6}$$

where $[0,T] \ni t \longrightarrow \Omega(t) \subset \Omega$ is a given set-valued map from $[0,T]$ into the set of all measurable subsets of Ω and $\{v_p^0\}_{p=1}^n$, v^1 are given measurable functions of a sign-type

$$\mid v_p^0(x,t) \mid, \mid v^1(x,t) \mid = +1 \text{ or } 0 \quad \text{a.e. in } Q, \quad p = 1,\ldots,n.$$

To avoid a misunderstanding, it is assumed here and everywhere below that if $\Omega(t)$ is of zero-measure at some t^*, then $\mathbf{G}(t^*)$ is the zero-operator. The last type of observations may be considered a generalization of the concept of a moving point observation to the case when a curve cannot be associated with a well-defined finite-dimensional observation of interest. The map $\Omega(\cdot)$ then plays a "pure" role (compared with (2.5)) of an observation curve. By virtue of (1.2), the observation (2.6) is well defined for any $t \in [0,T]$ and all the outputs are bounded when $\{y(\cdot,0), y_t(\cdot,0)\} \in H_a$, where

$$H_a = H_E \cap \{\{y(\cdot,0), y_t(\cdot,0)\} \mid \{\nabla y, y_t\} \in L^\infty(Q; R^{n+1})\}. \tag{2.7}$$

DEFINITION 2.5. *We shall say that a set-valued map* $[0,T] \ni t \longrightarrow F(t) \subset \Omega$ *is continuous with respect to Lebesgue measure at* $t = t^*$ *if*

$$\text{meas}\{F(t^*)\ \Delta\ F(t^* + \Delta t)\} \longrightarrow 0, \qquad \Delta t \longrightarrow 0,$$

[1] In the context of $L^\infty(0,T;R^2)$-exact observability this result was announced in [6].

where $A\Delta B$ stands for the symmetric difference $A\Delta B = (A\backslash B) \cup (B\backslash A)$.

Remark 2.2. The continuity of $\Omega(t)$ at $t = t^*$ in the sense of Definition 2.1 implies the continuity of the function $f(t) = \text{meas}\{\Omega(t)\}$ at $t = t^*$. Moreover, if $\text{meas}\{\Omega(t^*)\} > 0$, then all the outputs of (1.1)–(1.2), (2.6) are continuous at $t = t^*$.

THEOREM 2.6 (Spatially averaged observation). *Let $H_a \neq \emptyset$ and $T > 0$ be given. Then there exists a class of set-valued maps $\Omega(\cdot)$ continuous with respect to Lebesgue measure on $[0, T[$ and associated functions $\{v_p^0\}_{p=1}^n, v^1 \subset C([0, T[; L^2(\Omega))$ that make the system* (1.1)–(1.2), (2.6) *$C([0, T[; R^{n+1})$-exactly observable on $H = H_a$.*

We emphasize that the proof of this theorem, given in §5, is constructive (as well as those of Theorems 2.1, 2.2, and 2.4) and does not involve the constraint (2.7), which is to outline an a priori largest class of those solutions that are consistent with C (or L^∞) space for the (thus, *a priori bounded*) outputs. Once the set-valued map and functions satisfying Theorem 2.6 are found (see (5.2), (5.3)), the set H in (2.7) can be extended (due to (5.7)) to the following "a posteriori" largest set (see also §6):

$$(2.8) \qquad H_{ap} = H_E \cap \{\{y(\cdot, 0), y_t(\cdot, 0)\} \mid z \in C([0, T[; R^{n+1}), \\ \text{where } z \text{ is due to } (1.1), (1.2), (2.6)\}.$$

COROLLARY 2.7. *Let the observation* (2.6) *be defined by* (5.2), (5.3) *in §5. Then the assertion of Theorem* 2.6 *holds for $H = H_{ap}$.*

Remark 2.3. The following assumption ensures (1.2) [9, p. 167]:

$$(2.9) \qquad \operatorname*{ess\,sup}_{Q} \mid a_{ijt}, a_{ijtt}, a_{ijx}, a_i, a, \mid \leq \text{ const},$$

where the derivatives are understood in the generalized sense.

COROLLARY 2.8. *Let* (2.9) *be verified. Then Theorem* 2.6 *and Corollary* 2.7 *hold.*

Note that Theorems 2.1, 2.2, 2.4, and 2.6 deal with observations that employ the only curve or set-valued map. In the appendix we show that the usage of independent maps for each of $y_{x_p}, p = 1, \ldots, n, y_t$ can considerably improve the value of γ in (1.4) obtained by Theorem 2.6; see (5.7) and (A.4).

Controllability. Let $\mathbf{K} = \mathbf{GS}, \mathbf{K} : H \to B$, where $\mathbf{S}(t)\{y_0, y_1\} = \{\nabla y(\cdot, t), y_t(\cdot, t)\}$, $t \in [0, T]$. Then the B-exact observability property is equivalent to the bounded invertibility of the operator $\mathbf{K}$ on its range with respect to the energy norm (see Definition 1.1) and, hence, the maximal value of γ in (1.4) is equal to $(\| \mathbf{K}^{-1} \|)^{-1}$. A *direct* (duality) method (see, e.g., [19], [2], [18], [12], [20], [10], [11] and the bibliography therein) implies that if a linear manifold H is fundamental (dense) in H'_E, then B-exact observability is equivalent to exact controllability of the dual control system in $H'_E = L^2(\Omega) \times [H_0^1(\Omega)]'$ with controls from B', the dual of B. Otherwise, one has exact controllability in H', the dual of H as a linear topological manifold in H_E. A detailed study of the issue of exact controllability of the wave equation in an arbitrary space dimension under moving point control dual to (2.1) when $B = L^\infty(0, T; R^{n+1})$ or $L^2(0, T; R^{n+1})$ is given in [7].

3. Point observation.

Proof of Theorem 2.1. *Step* 1. Let Y_H be the set of all the solutions of (1.1)–(1.2) such that $\{y(\cdot, 0), y_t(\cdot)\} \in H$. We show first how for any given $y \in Y_H$ one can find a curve that ensures the estimate (1.4) for this particular solution.

Fix y and let $\beta > 0$ be given. By virtue of Assumption 2.1, both $\nabla y(x, t)$ and $y_t(x, t)$ are of Carathéodory type and, hence, for any measurable function $\bar{x}(t)$, $t \in$

$[0,T]$, the observation (2.1) is well defined. Let r be an arbitrary subinterval of $[0,T]$, $\text{meas}\{r\} > 0$. Next we set

(3.1)
$$e = \left\{ (x,t) \in \bar{\Omega} \times r \;\middle|\; |\nabla y(x,t)|^2 + y_t^2(x,t) \geq \operatorname*{ess\,sup}_{(x,t)\in\Omega\times r} (|\nabla y(x,t)|^2 + y_t^2(x,t)) - \beta \right\}.$$

Consider the set-valued map $r^* \ni t \longrightarrow F(t) = \{x \mid (x,t) \in e\}$, where $r^* = \text{dom } F(t) = \{t \mid \{x| (x,t) \in e\} \neq \emptyset\}$. By Assumption 2.1, the sets $F(t)$ are closed almost everywhere in r^*. Applying the measurable selection theorem (see, e.g., [4], [1]) then yields the existence of a measurable function $\bar{x}(t)$, $t \in [0,T]$ such that

$$\bar{x}(t) \in F(t) \quad \text{a.e. in } r^*. \tag{3.2}$$

Note next that by (1.2)

$$c^{-2}E(y(\cdot,0)) \leq \inf_{t\in r^*} E(y(\cdot,t)) \leq \text{meas}^{-1}\{r^*\} \int_{r^*}\int_{\Omega} (|\nabla y(x,t)|^2 + y_t^2(x,t))dxdt \tag{3.3}$$
$$\leq \text{meas}\,\{\Omega\} \operatorname*{ess\,sup}_{(x,t)\in\Omega\times r^*} (|\nabla y(x,t)|^2 + y_t^2(x,t)).$$

Combining (3.1)–(3.3) yields the following *basic* estimate:

$$E^{1/2}(y(\cdot,0)) \leq c\,\text{meas}^{1/2}\{\Omega\} (\| \{\nabla y(\bar{x}(\cdot),\cdot), y_t(\bar{x}(\cdot),\cdot)\} \|^2_{L^\infty(r^*;R^{n+1})} + \beta)^{1/2}. \tag{3.4}$$

Step 2. Take any $\delta > 0$. Select next in Y_H a *countable* (this can be done by Assumption 2.1) δ-net $\{y^k\}_{k=1}^\infty$ in Y_H as follows (see (2.2)): for any $y \in Y_H$ there is an element y^k for which

$$E^{1/2}(y(\cdot,t) - y^k(\cdot,t)) \leq \delta, \quad \forall t \in [0,T], \tag{3.5a}$$

$$\operatorname*{ess\,sup}_{t\in[0,T]} \| \{\nabla y(\cdot,t) - \nabla y^k(\cdot,t), y_t(\cdot,t) - y_t^k(\cdot,t)\} \|_{[C(\bar{\Omega})]^{n+1}} \leq \delta. \tag{3.5b}$$

Step 3. We proceed now with the construction of an observation curve that ensures the estimate (1.4). Let $\{t_k\}_{k=1}^\infty$ be an arbitrary strictly increasing sequence in $]0,T[$. The estimate (3.4) implies that for each k there is a curve $\{\bar{x}^k(\cdot)\}$ such that

(3.6)
$$E^{1/2}(y^k(\cdot,0)) \leq c\,\text{meas}^{1/2}\{\Omega\}(\| \{\nabla y^k(\bar{x}^k(\cdot),\cdot), y_t^k(\bar{x}^k(\cdot),\cdot)\} \|^2_{L^\infty(t_k,t_{k+1};R^{n+1})} + \beta)^{1/2}.$$

Let $\bar{x}(\cdot)$ be an arbitrary measurable trajectory defined on $[0,T]$ such that

$$\bar{x}(t) = \bar{x}^k(t), \quad t \in\,]t_k, t_{k+1}[, \qquad k = 1, \ldots. \tag{3.7}$$

Step 4. Let us show that $\bar{x}(\cdot)$ satisfies the requirements of Theorem 2.1. Take any $y \in Y_H$ and an element $y^k \in Y^\delta$ for which (3.5) is verified. In particular,

$$E^{1/2}(y(\cdot,0)) \leq E^{1/2}(y^k(\cdot,0)) + \delta.$$

This and (3.6)–(3.7) imply

$$\begin{aligned} E^{1/2}(y(\cdot,0)) &\leq c\,\text{meas}^{1/2}\{\Omega\} (\| \{\nabla y^k(\bar{x}(\cdot),\cdot), y_t^k(\bar{x}(\cdot),\cdot)\} \|^2_{L^\infty(t_k,t_{k+1};R^{n+1})} + \beta)^{1/2} + \delta \\ &\leq c\,\text{meas}^{1/2}\{\Omega\} (\| \{\nabla y^k(\bar{x}(\cdot),\cdot), y_t^k(\bar{x}(\cdot),\cdot)\} \|_{L^\infty(t_k,t_{k+1};R^{n+1})} + \sqrt{\beta}) + \delta. \end{aligned}$$

Now, by virtue of (3.5b), we arrive at

$$E^{1/2}(y(\cdot,0)) \leq c\,\mathrm{meas}^{1/2}\{\Omega\}(\| \{\nabla y(\bar{x}(\cdot),\cdot), y_t(\bar{x}(\cdot),\cdot) \|_{L^\infty(t_k,t_{k+1};R^{n+1})} + \delta + \sqrt{\beta}) + \delta. \tag{3.8}$$

In other words, we obtain the estimate (1.4) with $\gamma = (c\,\mathrm{meas}^{1/2}\{\Omega\}(1+\delta+\sqrt{\beta})+\delta)^{-1}$. This completes the proof of Theorem 2.1.

Remark 3.1. In fact, the assertion of Theorem 2.1 holds true in the class of those curves that lie entirely in the interior of Ω. Indeed, given β, y, one can replace Ω in the right-hand side of (3.1) by any strictly interior subdomain, which still preserves nonemptiness of such a modified set e $(= e(y,\beta))$. The rest of the proof is much the same as in the above.

Proof of Theorem 2.2. Let $\lim_{k\to\infty} t_k = T$. Since $y \in H^2(Q)$, due to the embedding theorem [15], [17], both $y_x(x,t)$ and $y_t(x,t)$ are continuous in x for almost all $t \in [0,T]$ and in t for almost all $x \in [0,1]$. Therefore, one can obtain the required assertion while avoiding use of the measurable selection theorem. Indeed, let $y \in Y_H$ be fixed. In Step 1 of the proof of Theorem 2.1 take any instant $t_* \in r^*$ such that $y_x(x,t_*), y_t(x,t_*) \in C[0,1]$. Without loss of generality we can assume that $F(t_*)$ contains a nontrivial interval. Then there is a point $x_* \in]0,1[$ such that $(x_*,t_*) \in e$ (see (3.1)) and $y_x(x_*,t), y_t(x_*,t) \in C[0,T]$. Using continuity of y in t, x, as was mentioned in the above, one then comes to the conclusion that (3.4) is verified for any continuous curve passing through x_* at time t_*, which is constant in some neighborhood of t_*. This allows us to compose $\bar{x}(\cdot)$ in (3.7) to be arbitrarily smooth on $[0,T[$. The rest of the proof follows along Steps 2–4 in the proof of Theorem 2.1.

Remark 3.2. The proof of Theorem 2.1 deals with a net in the set Y_H. However, by making use of the linearity of (1.1) and (2.1), this set can be replaced by its subset, which consists of those solutions whose energy norms at $t=0$ are equal to 1 (this can be applied to the proofs of Theorems 2.2, 2.4, and 2.6 as well). The estimate (3.8), being then derived only for the latter, implies (1.4) with $\gamma = (1 - c\,\mathrm{meas}^{1/2}\{\Omega\}(\delta + \sqrt{\beta}) - \delta)(c\,\mathrm{meas}^{1/2}\{\Omega\})^{-1}$ for β and δ appropriately small.

Proof of Theorem 2.4. The scheme of the proof is as much the same as that of Theorems 2.1 and 2.2.

Step 1. From the proofs of Theorem 2.1 (Step 1), Theorem 2.2, and Remark 2.2 it immediately follows that, given $\beta^* > 0$ and an interval $r \subset [0,T]$, for any solution y of (1.1)–(1.2), (2.3)–(2.4) there exists a pair of (arbitrarily smooth) functions $h(t) > 0$, $\bar{x}(t) \in]0,1[$, $t \in [0,T[$, and a nontrivial interval $r^* \subseteq r$ such that

$$\begin{aligned} &\left(\mathrm{meas}^{-1}\{S_{h(t)}(\bar{x}(t))\} \int\limits_{S_{h(t)}(\bar{x}(t))} y_x(x,t)dx\right)^2 \\ &+ \left(\mathrm{meas}^{-1}\{S_{h(t)}(\bar{x}(t))\} \int\limits_{S_{h(t)}(\bar{x}(t))} y_t(x,t)dx\right)^2 \\ &\geq \text{ ess sup}_{(x,t)\in\Omega\times r}(y_x^2(x,t) + y_t^2(x,t)) - \beta^*, \quad \forall t \in r^*. \end{aligned} \tag{3.9}$$

Step 2. Since (3.9) plays a role similar to the relations (3.1)–(3.2), we can establish an estimate analogous to (3.4) for the observation (2.5) as well. Taking into account that

$$\text{meas}^{-1}\{S_{h(t)}(\bar{x}(t))\} \int\limits_{S_{h(t)}(\bar{x}(t))} 1\, dx = 1,$$

(3.5b) implies

$$\| \mathbf{G}(\cdot)\{y_x - y_x^k,\ y_t - y_t^k\} \|_{L^\infty(t_k,t_{k+1};R^2)} \leq \sqrt{2}\,\delta,$$

where $\mathbf{G}(\cdot)$ stands for the observation operator in (2.5). Since the latter plays a crucial role in the derivation of (3.8) along (3.6)–(3.7), by taking into account Remark 2.2 one can obtain the conclusion of Theorem 2.4 with respect to $C([0,T[;R^2)$-exact observability in a similar way, constructing (as in (3.7)) a needed set-valued map $[0,T] \ni t \rightarrow S_{h(t)}(\bar{x}(t))$ to be continuous and of positive measure on $[0,T[$.

Remark 3.3. It is readily seen that the proof of Theorem 2.4 admits an extension to the general multidimensional case under Assumption 2.1.

4. Generalized spatially averaged observation. We begin by studying the properties of the observation (2.6).

Assumption 4.1. Let r be a given subinterval of $[0,T]$. A set-valued map $[0,T] \ni t \rightarrow \Omega(t) \subset \Omega$ satisfies Assumption 4.1 on r if the set $\{(x,t) \mid x \in \Omega(t),\ t \in r\}$ is measurable with respect to Lebesgue measure on $\Omega \times (0,T)$ and

$$\operatorname*{ess\,inf}_{t\in r}\ \text{meas}\{\Omega(t)\} > 0. \tag{4.1}$$

It is clear that if $\Omega(t)$ satisfies Assumption 4.1 on r, then all the outputs of the system (1.1)–(1.2), (2.6) lie in $L^\infty(r;R^{n+1})$.

The following class of set-valued maps plays a crucial role in the proof of Theorem 2.6. Let y be an arbitrary solution of the system (1.1)–(1.2) and $\beta > 0$ be given. Set

(4.2)
$$r(y,t) = \{x \in \Omega \mid |\nabla y(x,t)|^2 + y_t^2(x,t) > \text{meas}^{-1}\{\Omega\}\ E(y(\cdot,t)) - \beta^2\},\quad t \in [0,T],$$

$$\begin{aligned} r^0_{p+}(y,t) &= \{x \in r(y,t) \mid y_{x_p}(x,t) > 0\},\\ r^0_{p-}(y,t) &= \{x \in r(y,t) \mid y_{x_p}(x,t) < 0\},\quad p = 1,\dots, \end{aligned} \tag{4.3a}$$

(4.3b)
$$r^1_+(y,t) = \{x \in r(y,t) \mid y_t(x,t) > 0\},\qquad r^1_-(y,t) = \{x \in r(y,t) \mid y_t(x,t) < 0\}.$$

It is not hard to see that $r(y,t)$ is of positive measure for any $t \in [0,T]$. Furthermore, from (1.2) it follows that for any $\varepsilon > 0$

(4.4)
$$\text{meas}\{x \mid |\nabla y(x,t+\Delta t) - \nabla y(x,t)| \geq \varepsilon\} \rightarrow 0,\quad \text{when}\quad \Delta t \rightarrow 0,\quad \forall t \in [0,T],$$

$$\text{meas}\{x \mid |y_t(x,t+\Delta t) - y_t(x,t)| \geq \varepsilon\} \rightarrow 0,\quad \text{when}\quad \Delta t \rightarrow 0,\quad \forall t \in [0,T]. \tag{4.5}$$

DEFINITION 4.1. *We shall say that a set-valued map $[0,T] \ni t \rightarrow F(t) \subset \Omega$ is lower semicontinuous (see, e.g., [1] and the bibliography therein for various definitions of continuity of set-valued maps) at $t = t^*$ with respect to Lebesgue measure if $\forall \varepsilon_1 > 0$ $\exists\, \varepsilon_2 > 0$ such that*

$$\text{meas}\{F(t^*) \setminus F(t^* + \Delta t)\} \leq \varepsilon_1,\quad \forall\, \Delta t:\ |\Delta t| \leq \varepsilon_2. \tag{4.6}$$

The relations (4.4), (4.5) and the fact that the inequality in (4.2) is strict imply that $r(y,t)$ satisfies (4.6) everywhere in $[0,T]$. Hence, the function $f(t) = \text{meas}\{r(y,t)\}$ is lower semicontinuous on $[0,T]$ and, therefore, reaches its minimum on $[0,T]$ (compare with (4.1)).

Remark 4.1. Let y be an arbitrary solution of the system (1.1)–(1.2). Then one can deduce from (4.4)–(4.6) that for any sequence $\{y_i\}_{i=1}^{\infty}$ that converges to y in the $C([0,T];H_E)$-norm the following estimate holds:

$$\liminf_{i\to\infty}\left(\min_{t\in[0,T]}\text{meas}\{r(y_i,t)\}\right) \geq \min_{t\in[0,T]}\text{meas}\{r(y,t)\} > 0.$$

Given $\Omega(t)$ in (2.6), set for any $t \in [0,T]$

$$\Omega^0_{p+}(t) = \{x \mid v^0_p(x,t) = 1, \ x \in \Omega(t)\}, \ \ \Omega^0_{p-}(t) = \{x \mid v^0_p(x,t) = -1, \ x \in \Omega(t)\},$$

$$\Omega^1_{+}(t) = \{x \mid v^1(x,t) = 1, \ x \in \Omega(t)\}, \ \ \ \Omega^1_{-}(t) = \{x \mid v^1(x,t) = -1, \ x \in \Omega(t)\}.$$

LEMMA 4.2. *Let y be an arbitrary solution of the system* (1.1)–(1.2) *and $\beta > 0$, $t^* \in [0,T]$ be given. Then any set-valued map $\Omega(\cdot)$ and functions $\{v^0_p)\}_{p=1}^n$, v^1 in* (2.6) *such that*

$$\Omega(t^*) = r(y,t^*), \quad \Omega^0_{p\pm}(t^*) = r^0_{p\pm}(y,t^*), \quad \Omega^1_{\pm}(t^*) = r^1_{\pm}(y,t^*), \quad p = 1,\dots,n, \tag{4.7}$$

ensure the estimate

(4.8)

$$E(y(\cdot,0)) \leq c^2(n+2)\,\text{meas}\{\Omega\}\left(\sum_{p=1}^n\left(\text{meas}^{-1}\{\Omega(t^*)\}\int_{\Omega(t^*)} v^0_p(x,t^*)\,y_{x_p}(x,t^*)\,dx\right)^2\right.$$

$$\left. + \left(\text{meas}^{-1}\{\Omega(t^*)\}\int_{\Omega(t^*)} v^1(x,t^*)\,y_t(x,t^*)dx\right)^2 + \beta^2\right).$$

Proof. (1.2) yields

$$E(y(\cdot,0)) \leq c^2\,E(y(\cdot,t^*)).$$

Then, by (4.2)–(4.3),

$$E^{1/2}(y(\cdot,0)) \leq c\,\text{meas}^{1/2}\{\Omega\}\ \operatorname*{ess\,inf}_{x\in r(y,t^*)}(\mid \nabla y(x,t^*)\mid^2 \ + y_t^2(x,t^*) + \beta^2)^{1/2} \tag{4.9}$$

$$\leq c\,\text{meas}^{1/2}\{\Omega\}\ \operatorname*{ess\,inf}_{x\in r(y,t^*)}\left(\sum_{p=1}^n \mid y_{x_p}(x,t^*)\mid + \mid y_t(x,t^*)\mid + \beta\right).$$

From (4.9) we immediately obtain the needed result. □

5. Proof of Theorem 2.6. We stress that the constraint (2.7) is not involved in the further construction procedure.

Step 1. Let Y be the set of all the solutions of the system (1.1)–(1.2). Select an arbitrary monotone sequence $\{\delta_j\}_{j=1}^{\infty}$, $\delta_j \to 0+$, $j \to \infty$. Specify next for each j an arbitrary δ_j-net $Y^{\delta_j} = \{y_{kj}\}_{k=1}^{\infty}$ in Y uniformly with respect to the energy norm. In other words, $\{Y^{\delta_j}\}_{j=1}^{\infty}$ is dense in $Y \subset C([0,T]; H_E)$: for any $y \in Y$ there exists a sequence of elements y_{kj} such that

$$E^{1/2}(y(\cdot,t) - y_{kj}(\cdot,t)) \le \delta_j, \quad \forall t \in [0,T], \quad j = 1,\dots, \quad k = k(y,j). \tag{5.1}$$

Step 2. Select $\beta > 0$. Take an arbitrary countable set of all distinct strictly monotone sequences $\{t_k^j\}_{k=1}^{\infty} \subset]0,T[$, $j = 1,\dots$, with the *only* limit point $t = T$, that is, $\lim_{k\to\infty} t_k^j = T$, $j = 1,\dots$. Let $[0,T[\ni t \to \Omega(t)$ be an arbitrary set-valued map of positive measure, continuous with respect to Lebesgue measure and such that (see (4.2))

$$\Omega(t_k^j) = r(y_{kj}, t_k^j), \quad k,j = 1,\dots. \tag{5.2}$$

Let $\{v_p^0\}_{p=1}^n$, v^1 be arbitrary functions of a sign-type from $C([0,T[; L^2(\Omega))$ such that (see (4.3))

$$v_p^0(x,t_k^j) = \begin{cases} +1, & x \in r_{p+}^0(y_{kj},t_k^j), \\ -1, & x \in r_{p-}^0(y_{kj},t_k^j), \\ 0, & \text{otherwise}, \end{cases} \qquad k,j = 1,\dots, \qquad p = 1,\dots,n, \tag{5.3a}$$

$$v^1(x,t_k^j) = \begin{cases} +1, & x \in r_{+}^1(y_{kj},t_k^j), \\ -1, & x \in r_{-}^1(y_{kj},t_k^j), \\ 0, & \text{otherwise}. \end{cases} \qquad k,j = 1,\dots, \tag{5.3b}$$

Note that, due to Remark 2.2, all the outputs of (1.1)–(1.2), (2.6), (5.2)–(5.3) are continuous on $[0,T[$. In the next two steps we show that the constructed observation (2.6), (5.2)–(5.3) satisfies the requirements of Theorem 2.6.

Step 3. This step is to show that the net $\{y_{kj}\}_{k,j=1}^{\infty}$ specified in Step 1 generates via (2.6), (5.2)–(5.3) a certain "pointwise" net along the sequence $\{t_k^j\}_{k,j=1}^{\infty}$ in the set of all outputs, namely, in the sense of the relation (5.5a).

Take any $y \in Y$. Then, as was discussed in §4,

$$\min_{t\in[0,T]} \text{meas}\{r(y,t)\} = r(y) > 0. \tag{5.4}$$

Observe that for any $j = 1,\dots$, $k = k(y,j)$ such that (5.1) is fulfilled the following chain of estimates holds:

$$\left| \frac{1}{\text{meas}\{\Omega(t_k^j)\}} \int_{\Omega(t_k^j)} \cdot v_p^0(x,t_k^j) y_{x_p}(x,t_k^j)dx - \frac{1}{\text{meas}\{\Omega(t_k^j)\}} \int_{\Omega(t_k^j)} v_p^0(x,t_k^j) y_{kjx_p}(x,t_k^j)dx \right|$$

$$= \left| \frac{1}{\text{meas}\{r(y_{kj},t_k^j)\}} \int_{r(y_{kj},t_k^j)} v_p^0(x,t_k^j)(y_{x_p}(x,t_k^j) - y_{kjx_p}(x,t_k^j))dx \right|$$

$$\le \text{meas}^{-1/2}\{r(y_{kj},t_k^j)\}\ E^{1/2}(y(\cdot,t_k^j) - y_{kj}(\cdot,t_k^j))$$

$$\le \delta_j \,\text{meas}^{-1/2}\{r(y_{kj},t_k^j)\}, \quad p = 1,\dots,n.$$

In a similar way one can derive an analogous estimate for y_t. From these estimates, (5.2), (5.4), and Remark 4.1 it follows that for any given $y \in Y$, $\alpha > 0$ there exists an element y_{kj} such that simultaneously the following two estimates hold (compare with Assumption 2.1):

$$\| \mathbf{G}(t_k^j)\{\nabla y(\cdot, t_k^j) - \nabla y_{kj}(\cdot, t_k^j), y_t(\cdot, t_k^j) - y_{kjt}(\cdot, t_k^j)\} \|_{R^{n+1}} \leq \alpha, \tag{5.5a}$$

$$E^{1/2}(y(\cdot, t) - y_{kj}(\cdot, t)) \leq \alpha, \quad \forall t \in [0, T], \tag{5.5b}$$

where $\mathbf{G}(\cdot)$ stands for the observation operator in (2.6) under (5.2)–(5.3).

Step 4. Fix any $y \in Y$. Let $\{\alpha_i\}_{i=1}^{\infty}$ be an arbitrary sequence of positive numbers converging to zero and $\{y_{k_i j_i}\}_{i=1}^{\infty}$ be an associated sequence of solutions of (1.1)–(1.2) such that (5.5) is fulfilled for α_i, $i = 1, \ldots.$ Then (5.5b) and Lemma 4.2 imply

$$E^{1/2}(y(\cdot, 0)) \leq E^{1/2}(y_{k_i j_i}(\cdot, 0)) + \alpha_i \leq c \text{ meas}^{1/2}\{\Omega\} \sqrt{n+2} \tag{5.6}$$

$$\times(\beta^2 + \| \mathbf{G}(t_{k_i}^{j_i})\{\nabla y_{k_i j_i}(\cdot, t_{k_i}^{j_i}), y_{k_i j_i t}(\cdot, t_{k_i}^{j_i})\} \|_{R^{n+1}}^2)^{1/2} + \alpha_i, \quad i = 1, \ldots.$$

Combining (5.6) and (5.5a) yields

$$E^{1/2}(y(\cdot, 0))$$
$$\leq c \text{ meas}^{1/2}\{\Omega\} \sqrt{n+2}\ (\beta + \| \mathbf{G}(t_{k_i}^{j_i})\{\nabla y(\cdot, t_{k_i}^{j_i}), y_t(\cdot, t_{k_i}^{j_i})\} \|_{R^{n+1}} + \alpha_i) + \alpha_i,$$

and, further, with $i \to \infty$

(5.7)
$$E^{1/2}(y(\cdot, 0)) \leq c \text{ meas}^{1/2}\{\Omega\}\sqrt{n+2} \left(\beta + \sup_{t \in [0, T[} \| \mathbf{G}(t)\{\nabla y(\cdot, t), y_t(\cdot, t)\} \|_{R^{n+1}} \right),$$

which under (2.7) or (2.8) implies (1.4) with $\gamma = (c \text{ meas}^{1/2}\{\Omega\} \sqrt{n+2}\ (\beta + 1))^{-1}$. This completes the proof of Theorem 2.6 (and Corollary 2.7).

Remark 5.1.

(i) Note that the estimate (5.7) formally holds for any solution of (1.1)–(1.2), that is, even if the condition (2.7) (or (2.8)) is not verified.

(ii) In order to obtain exact observability in a prescribed subspace spanned by a finite number of solutions of (1.1)–(1.2) (as it may occur in applications), it suffices to specify a *finite* skeleton of type (5.2)–(5.3).

(iii) For the construction of suitable δ-nets in Step 1 one can use the Galerkin scheme (see also Remark 3.2).

(iv) The observation map defined by (5.2) becomes lower semicontinuous on $[0, T]$ if at $t = T$ it is of zero-measure.

6. Concluding remarks. The problem of exact observability under finitely many moving internal observations was discussed for the linear time-varying hyperbolic equation. Two types of observations linked sharply with the internal regularity of the solutions were considered, and the existence of observation curves and set-valued maps required for $L^\infty(0, T; R^{n+1})$- or $C([0, T[; R^{n+1})$-exact observability was established. The approach that was applied is related to the construction of suitable skeletons for the observations and deals with establishing a *certain countable net* in the pair of linear manifolds of the solutions and their associated outputs in the topology that is consistent with the well-posedness of the observations. It was shown that this can be achieved either a priori, when a given internal regularity implies the existence of a required net for any admissible observation operator (Assumption 2.1 and Theorems 2.1, 2.2, and 2.4, Corollary 2.3) or a posteriori, when, in order to ensure the existence of a suitable net in the set of the outputs, a particular observation operator has to be constructed (Theorem 2.6, Corollaries 2.7 and 2.8, and Theorem A.1).

Appendix A. Observe that the constant γ obtained in Theorem 2.6 (see (5.7)) is considerably "worse" than that in Theorem 2.1; see (3.8). We show now that one can improve the estimate (5.7), namely, get rid of the multiplier $\sqrt{n+2}$ if instead of (2.6) the following observation is employed:

$$\text{(A.1)} \qquad z(t) = \begin{pmatrix} \frac{1}{\text{meas}\{\Omega_1^0(t)\}} \int_{\Omega_1^0(t)} v_1^0(x,t)\; y_{x_1}(x,t)dx \\ \vdots \\ \frac{1}{\text{meas}\{\Omega_n^0(t)\}} \int_{\Omega_n^0(t)} v_n^0(x,t)\; y_{x_n}(x,t)dx \\ \frac{1}{\text{meas}\{\Omega^1(t)\}} \int_{\Omega^1(t)} v^1(x,t)\; y_t(x,t)dx \end{pmatrix}, \qquad t \in [0,T],$$

where the set-valued maps $\{\Omega_p^0(\cdot)\}_{p=1}^n$, $\Omega^1(\cdot)$ and functions $\{v_p^0\}_{p=1}^n$, v^1 are defined as in (2.6).

Let y be an arbitrary solution of the system (1.1)–(1.2) and $\beta > 0$ be given. Set for $\forall t \in [0,T]$:

(A.2a)

$$r_p^0(y,t) = \{x \in \Omega \mid \mid y_{x_p}(x,t) \mid^2 > \text{meas}^{-1}\{\Omega\} \parallel y_{x_p}(\cdot,t) \parallel^2_{L^2(\Omega)} -\beta^2\}, \quad p = 1,\dots,n,$$

$$\text{(A.2b)} \qquad r^1(y,t) = \{x \in \Omega \mid \mid y_t(x,t) \mid^2 > \text{meas}^{-1}\{\Omega\} \parallel y_t(\cdot,t) \parallel^2_{L^2(\Omega)} -\beta^2\}.$$

Let the sets $r_{p\pm}^0(y,t)$, $p = 1,\dots$, $r_\pm^1(y,t)$ be defined as in (4.3) with accordingly $r_p^0(y,t)$ and $r^1(y,t)$ substituted for $r(y,t)$.

THEOREM A.1. *Let* Y^{δ_j} *and* $\{t_k^j\}_{k=1}^\infty$, $j = 1,\dots$, *be defined as in Steps* 1–2 *in* §5 *and* $[0,T[\ \ni t \to \Omega_p^0(t)$ $(p = 1,,\dots,n)$, $\Omega^1(t)$ *be arbitrary set-valued maps of positive measure, continuous with respect to Lebesgue measure and such that* (*due to* (A.2)):

$$\text{(A.3)} \qquad \Omega_p^0(t_k^j) = r_p^0(y_{kj},t_k^j), \quad p = 1,\dots,n, \quad \Omega^1(t_k^j) = r^1(y_{kj},t_k^j), \quad k,j = 1,\dots .$$

Let $\{v_p^0\}_{p=1}^n$, v^1 *be arbitrary functions of a sign-type from* $C([0,T[;L^2(\Omega))$ *satisfying* (5.3) *under* (A.2). *Then for any solution of the system* (1.1)–(1.2), (A.1)–(A.3) *the following estimate is verified:*

(A.4)

$$E^{1/2}(y(\cdot,0)) \le c\,\text{meas}^{1/2}\{\Omega\} \left(\sqrt{n+1}\beta + \sup_{t\in[0,T[} \parallel \mathbf{G}(t)\{\nabla y(\cdot,t), y_t(\cdot,t)\} \parallel_{R^{n+1}} \right),$$

where $\mathbf{G}(\cdot)$ *is due to* (A.1)–(A.3).

Proof. The proof of this theorem follows the lines of §§4 and 5 with only one exception. Namely, the estimate (4.8) is replaced by

(A.5)

$$E(y(\cdot,0)) \le c^2\,\text{meas}\{\Omega\} \left(\sum_{p=1}^n \left(\text{meas}^{-1}\{\Omega_p^0(t^*)\} \int_{\Omega_p^0(t^*)} v_p^0(x,t^*) y_{x_p}(x,t^*)dx \right)^2 \right.$$

$$+\left(\operatorname{meas}^{-1}\{\Omega^1(t^*)\}\int\limits_{\Omega^1(t^*)} v^1(x,t^*)y_t(x,t^*)\mid dx\right)^2 + (n+1)\,\beta^2\Bigg).$$

Indeed, instead of the chain (4.9) we have now

$$E^{1/2}(y(\cdot,0)) \leq c\,\operatorname{meas}^{1/2}\{\Omega\}$$
$$\cdot\left(\sum_{p=1}^{n} \operatorname*{ess\,inf}_{x\in r_p^0(y,t^*)} \mid y_{x_p}(x,t^*)\mid^2 + \operatorname*{ess\,inf}_{x\in r^1(y,t^*)} |y_t(x,t^*)|^2 + (n+1)\beta^2\right)^{1/2},$$

from which we immediately obtain (A.5) and, eventually, the assertion of Theorem A.1. □

RENDEZVOUS SEARCH ON THE LINE WITH DISTINGUISHABLE PLAYERS*

STEVE ALPERN[†] AND SHMUEL GAL[‡]

Abstract. Two players are placed on the real line at a distance d with a distribution F known to both. Neither knows the direction of the other, nor do they have a common notion of a positive direction on the line. We seek the least expected *rendezvous time* $R = R(F)$ in which they can meet, given maximum speeds of one. We consider the cases where F is a bounded, point, discrete, or finite mean distribution. We obtain upper bounds or exact values for R and in one case an optimality condition for search strategies. A connection with Beck's linear search problem is established.

Key words. rendezvous, search

AMS subject classifications. 90B40, 90D05

1. Introduction.

We consider the problem faced by two players placed randomly on the real line, who can move at unit speed and wish to meet as soon as possible. They know the probability distribution of the distance between them, but neither knows the direction of the other. They are pointed in a random direction when placed, so they have no common notion of a positive direction on the line. We consider what we call the case of distinguishable players, which means that we allow them to use different strategies. The interpretation is that they have previously agreed which of the two roles each will take prior to the start of play. This corresponds to the *asymmetric rendezvous problem* which was defined for general spaces in a recent paper [1] by the first author. (That paper deals mainly with the *symmetric rendezvous problem,* where the players must adopt a common mixed strategy.)

The strategy space for both players is the set of speed one paths

$$P = \left\{p : \Re^+ \to \Re,\ p(0) = 0,\ |p(s) - p(t)| \leq |s - t|\right\}.$$

A player placed at a point x who chooses strategy p will have the time paths $x \pm p(t)$ equiprobably, depending on which way he is initially pointed. Without loss of generality we may fix a coordinate system where player I starts at the point 0 and player II starts equiprobably at $\pm d$, where the initial distance d between the players is drawn from the known cumulative probability distribution F. We assume that they meet in the first moment they occupy the same point. (Similar results can be obtained if the time of meeting is the first moment when their distance is smaller than some detection distance r, where r is small.) If I chooses $g \in P$ and II chooses $h \in P$, then the expected meeting time T is given by

$$T = T(g,h) = \int_0^\infty \frac{1}{4} \sum_{i,j=\pm 1} \min\{t : g(t) = id + j\,h(t)\}\ dF(d). \tag{1}$$

The integrand in the formula above represents the expected meeting time given that the initial distance is d, considering the uncertainty about whether II is placed to the right ($i = 1$) and whether II is pointed to the right ($j = 1$). For this problem we seek

the *asymmetric rendezvous value*

$$R = R(F) = \min_{g,h \in P} T(g,h) \tag{2}$$

or bounds on this value and, if possible, the strategies for which the minimum is achieved. This strategy pair can be considered to be a Nash equilibrium of a game where the players have identical interests, although we tend to see rendezvous as a team problem rather than a game. In the symmetric version of rendezvous on the line, considered in [1], it was shown why mixed strategies were required to achieve the symmetric rendezvous value R^s. However, in the asymmetric version considered here it is clear that the minimum is achieved for pure strategies.

The paper is organized as follows. In §2 we consider bounded distributions F and obtain an upper bound $R(F) \leq 9D/8 + \mu/2$ in terms of the mean μ and maximum D of F. This compares favorably with the bound $R^s(F) \leq 2D + \mu/2$ obtained for the symmetric rendezvous value in [1]. In §3 we consider the case where F is a point distribution; that is, where the initial distance d between the players is known. In this case we show that $R = 13d/8$, which in fact agrees with the general upper bound obtained in the previous section. In §4 we consider discrete distributions F, where the initial distance between the players can take only countably many values. In this case we obtain a simple optimality condition. In the case of a finite distribution, this condition reduces the search for the optimal strategy pair to a finite problem. Finally, in §5 we consider the relation between our problem and the celebrated linear search problem introduced by Bellman [3] and extensively studied by Anatole Beck (whose latest is [2]) and others (including the second author [4]). We compare the rendezvous problem to the problem faced by a single searcher starting at 0 who wants to minimize the expected time $L = L(F)$ taken to find an object at distance d with distribution F, which is located equiprobably in either direction. We show that $L/2 \leq R \leq L$, for any distibution F.

2. Bounded distributions. In this section we assume that the initial distance between the players is bounded above by some least number D for which $F(D) = 1$. For such distributions there is a simple strategy pair $(\hat{g}, \hat{h})$ (depending on D) which guarantees rendezvous for all distributions with $F(D) = 1$ and gives a uniform upper bound for all such F in terms of D and the mean $\mu = \int_0^D x \, dF(x)$. As we shall see in the next section, this bound is sometimes equal to the rendezvous value R.

The strategies referred to above are defined by the formulae

$$\hat{g}(t) = \begin{cases} t & \text{if } 0 \leq t \leq D, \\ 2D - t & \text{if } D \leq t \leq 3D, \end{cases} \qquad \hat{h}(t) = \begin{cases} t & \text{if } 0 \leq t \leq D/2, \\ D - t & \text{if } D/2 \leq t \leq 2D, \\ t - 3D & \text{if } 2D \leq t \leq 3D. \end{cases}$$

The graphs of $\hat{g}(t)$ and the four paths $\pm d \pm \hat{h}(t)$ are drawn in Fig. 1 for $d = 2D/3$. It is now easy to establish the following.

THEOREM 2.1. *Let F be any distribution with mean μ and maximum D (that is, $F(D) = 1$). Then the rendezvous value $R = R(F)$ satisfies $R \leq (4\mu + 9D)/8$.*

Proof. It is straightforward to verify, from Fig. 1 or the definitions of $\hat{g}$ and $\hat{h}$, that the meeting times forming the integrand of 1 are given by

$$\min\left\{t : \hat{g}(t) = id + j\,\hat{h}(t)\right\} = \begin{cases} d/2 & \text{if } i = 1, j = -1, \\ (D+d)/2 & \text{if } i = 1, j = 1, \\ D + (D+d)/2 & \text{if } i = -1, j = -1, \\ 2D + (D+d)/2 & \text{if } i = -1, j = 1. \end{cases}$$

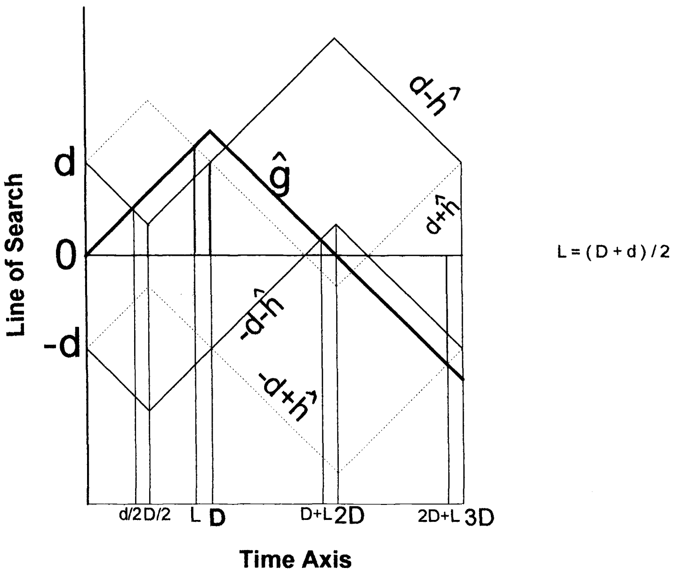

FIG. 1. *Graphs of* $\hat{g}$, $\pm d \pm \hat{h}$, *and their intersections.*

It then follows from (1) that the expected meeting time is given by

$$\begin{aligned}T\left(\hat{g},\hat{h}\right) &= \frac{1}{4}\int_0^D \left(\frac{x}{2}\right) + \left(\frac{D+x}{2}\right) + \left(D + \frac{D+x}{2}\right) + \left(2D + \frac{D+x}{2}\right)\, dF\left(x\right)\\ &= \frac{1}{8}\int_0^D \left(4x + 9D\right)\, dF\left(x\right) = \frac{1}{8}\left(4\int_0^D x\, dF\left(x\right) + 9D\right)\\ &= \frac{4\mu + 9D}{8}.\end{aligned}$$

The theorem then follows from the definition of the rendezvous value R. □

The strategy pair $(\hat{g}, \hat{h})$ seems to be effective when μ/D is close to one (indeed it is optimal at one; see Theorem 3.2). However, when $\mu/D < \frac{1}{4}$, the better estimate of $R \leq \mu + D$ is obtained by having one player stationary and the other searching D in one direction and then $2D$ in the other. Actually we can obtain a better bound than $\mu + D$, as shown in the next theorem.

THEOREM 2.1′. $R \leq \frac{3}{4}\mu + D$.

Proof. Assume that player I uses $\hat{g}$ and that player II rests until time D and then uses $\hat{h}$ (for $t \geq D$). If the initial distance is x, then the meeting time will be x with probability $\frac{1}{2}$, $D + (D + x)/2$ with probability $\frac{1}{4}$, and $2D + (D + x)/2$ with probability $\frac{1}{4}$. This gives an expected meeting time of $3x/4 + D$. To compute T we integrate with respect to the initial distance x, giving $T = 3\mu/4 + D$. □

Note that the bound given in Theorem 2.1′ is better than the bound given in Theorem 2.1 if and only if $\mu/D < \frac{1}{2}$. (For the uniform distribution these two strategy pairs yield the same expected meeting time $T = \frac{11}{8}$.)

3. Point distributions (*d* known). We now consider a special case of rendezvous on the line, where the players know the distance d to the other player but not the direction. We consider, as before, that player I starts at 0 and follows the path $g\left(t\right)$. However, we now take the view that there are four agents of player II, following the linked paths $\pm d \pm h\left(t\right)$. The time T is now simply the average of the times $t_1 \leq$

$t_2 \leq t_3 \leq t_4$ taken by I to meet the four agents of II. To obtain a lower bound on $T(g,h)$ for all g and h in P, we derive lower bounds on the numbers $t_i(g,h)$.

LEMMA 3.1. *If the initial distance between the players is d, then for all $g, h \in P$ we have that*

$$\begin{aligned} t_1 &\geq d/2, \\ t_2 &\geq d, \\ t_3 &\geq 2d, \\ t_4 &\geq 3d, \end{aligned}$$

and so $R \geq T(g,h) = (t_1 + t_2 + t_3 + t_4)/4 \geq (d/2 + d + 2d + 3d)/4 = 13d/8.$

Proof. Fix arbitrary strategies $g, h \in P$, and label the four agent II paths $\pm d \pm h$ as $L_i(t)$, indexed so that the meeting times t_i defined by $\min\{t : g(t) = L_i(t)\}$ are nondecreasing. By symmetry considerations we may assume that $L_1 = d - h$. The lower bound on t_1 is obvious, the relevant estimate being

$$L_1(t) - g(t) \geq d - (g(t) - h(t)) \geq d - 2t,$$

which is positive for $t \leq d/2$. The remainder of the proof splits into two cases depending on whether or not $L_1(0) = L_2(0)$.

First suppose that the condition is true; that is, $L_2 = d + h$. Since in this case we have $L_2(t_1) = d + h(t_1) = d + (d - g(t_1)) = 2d - g(t_1)$ and $L_2(t_2) = d + h(t_2) = g(t_2)$, we have

$$(3) \qquad 2d - g(t_1) - g(t_2) = h(t_1) - h(t_2) \leq t_2 - t_1.$$

Solving for t_2 and using the fact that $t_i \geq g(t_i)$, we have $t_2 \geq d$ because

$$(4) \qquad t_2 \geq 2d - g(t_2) + (t_1 - g(t_1)) \geq 2d - g(t_2).$$

We now consider how long after time t_2 the path $g(t)$ can intersect the nearer of the two agent paths which started at $-d$; that is, $L_3 = -d - h$. (The estimates for the case $L_3 = -d + h$ are higher and will not be given here.) Assuming that the intersection takes place at a point $g(t_3) \leq 0$ (otherwise both t_3 and t_4 will be larger than the estimates given here), we have that $t_3 - t_2 \geq g(t_2) - g(t_3)$, or

$$(5) \qquad t_3 \geq t_2 + g(t_2) - g(t_3) \geq 2d - g(t_3) \geq 2d,$$

using the result that $t_2 + g(t_2) \geq 2d$ from (4). The last estimate required for this case is for the time t_4 of the meeting of $g(t)$ with the last remaining player II agent, $L_4 = -d + h$. To this end observe that

$$t_4 - t_3 \geq |g(t_3) - L_4(t_3)|/2 = -h(t_3) = d + g(t_3), \text{ so}$$

$$t_4 \geq d + (t_3 + g(t_3)) \geq d + 2d = 3d, \text{ by (5)}.$$

We now consider the remaining case where $L_1(0) \neq L_2(0)$. With our choice of $L_1 = d - h$, this means that $L_2 = -d \pm h$. To obtain the required estimate on t_2, consider the speed one path $f(t)$ which equals L_1 until t_1 and then follows g until t_2. Since $|f(0) - L_2(0)| = 2d$, and $f(t_2) = L_2(t_2)$, we have $t_2 \geq d$. Since both f and L_2 can reach $g(t_2)$ in time t_2, we have

$$(6) \qquad t_2 \geq d + |g(t_2)|.$$

We first restrict ourselves to the case where $L_2 = -d + h$, as the alternative leads to larger estimates. Since $g(t_2) = L_2(t_2) = -d+h(t_2)$, we have $h(t_2) = g(t_2)+d$. Hence, regardless of the indexing, we have $|L_3(t_2)| = |L_4(t_2)| = 2d+|g(t_2)|$, $g(t_2)$ is between $L_3(t_2)$ and $L_4(t_2)$, and the latter two paths must move in opposite directions . Hence by symmetry we may assume without loss of generality that $g(t_2) \geq 0$ and that $L_3 = d+h$. Since $L_3(t_2)-g(t_2) = 2d$ and $L_3(t_3)-g(t_3) = 0$, it follows that $t_3- t_2 \geq d$, and hence $t_3 \geq 2d$. The final agent is $L_4 = -d-h$. Thus $L_3(t_2)-L_4(t_2) = 4d+2g(t_2)$. The path which follows L_3 from time t_2 to time t_3 and then follows g until time t_4 is a continuous path with speed bounded by one which goes from L_3 to L_4. Hence we have $t_4- t_2 \geq \frac{1}{2}[4d + 2g(t_2)]$ so that $t_4 \geq t_2 + 2d \geq 3d$ by (6). □

THEOREM 3.2. *If the distance d between the players is known, then the rendezvous value is given by $R = 13d/8$.*

Proof. By Lemma 3.1, $13d/8$ is a lower bound for R, and since $\mu = D = d$ in this case it is also an upper bound by Theorem 2.1. □

4. Discrete distributions. We now consider distributions supported on a countable set of points $0 \leq x_1 \leq x_2 \leq \ldots$, where the probability that the initial distance is x_k is p_k. For any strategy h of player II we may label the possible paths of II, the paths of the form $\pm x_k \pm h(t)$, as $L_m(t)$, $m = 1, 2, \ldots$. We call $L_m(t)$ the path of the mth agent of player II. Given a strategy g for player I such that $T(g,h) < \infty$, we may further assume that the player II paths are numbered so that player I first meets $L_m(t)$ at location y_m at time t_m, where $t_1 \leq t_2 \leq \ldots$. It turns out that any optimal strategy pair (g,h) must have a very specific and simple behaviour on each of the time intervals $[t_m, t_{m+1}]$.

THEOREM 4.1. *Suppose (g,h) is an optimal strategy pair. For $m = 1, 2, \ldots$ we have*

$$|L_{m+1}(t_m) - g(t_m)| = 2|t_{m+1} - t_m| \text{ and hence}$$

$$y_{m+1} = \frac{1}{2}g(t_m) + \frac{1}{2}L_{m+1}(t_m).$$

In other words player I *and agent $m+1$ approach each other at speed one as soon as agent m has been met.*

Proof. Suppose the first condition of the theorem is not satisfied for some times $t_m < t_{m+1}$. In this case $|L_{m+1}(t_m) - g(t_m)| < 2|t_{m+1} - t_m|$. Then change g and h to new strategies $\tilde{g}$ and $\tilde{h}$ by modifying them *only on the closed interval* $[t_m, t_{m+1}]$ so that I and L_{m+1} move at speed one to the midpoint $\frac{1}{2}g(t_m) + \frac{1}{2}L_{m+1}(t_m) = \tilde{g}(\tilde{t}_{m+1}) = \tilde{L}_{m+1}(\tilde{t}_{m+1})$, reaching it at time $\tilde{t}_{m+1} = t_m + |L_{m+1}(t_m) - g(t_m)|/2 < t_{m+1}$, and return to their original positions $g(t_{m+1})$ and $L_{m+1}(t_{m+1})$ at time t_{m+1}. (This is possible because, under the original strategy, at least one of the players reaches the midpoint at time $t \geq \tilde{t}_{m+1}$.) We will then have that $\tilde{t}_n \leq t_n$ for all n and that $\tilde{t}_{m+1} < t_{m+1}$. It follows that

$$T\left(\tilde{g}, \tilde{h}\right) = \sum_n p_n \tilde{t}_n < \sum_n p_n t_n = T(g,h). \quad □$$

In the case where there is a finite distribution concentrated on K points, the above condition reduces the search for an optimal strategy to a finite problem. Each ordering of the $4K$ agents of player II leads to at most one possible optimal strategy pair, and hence one of these strategy pairs must be optimal. Of course one need not check all $(4K)!$ orderings because some (most) are impossible. For example, if $x_i < x_j$, then I cannot meet any agent $\pm x_j \pm h(t)$ before the corresponding agent (i.e., with the same choice of signs) $\pm x_i \pm h(t)$. This means that agents with the same pair of signs must be met in increasing values of x_j. This reduces the number of cases to be checked to $(4K)!/K!^4$. This number can then be divided by 4 if we assume without loss of generality that the first agent to be met is $x_1 + h(t)$. Thus when $K = 1$ only six cases need be checked, among which two cases are dominated and the group of the other four can be split into two groups of (symmetric) equivalent cases ($h(t)$ replaced by $-h(t)$ by the third and fourth agents). Thus we actually have to check just two cases corresponding to the two optimal solutions. (Note that in Theorem 2.1 we actually have another solution with $g(t)$ and $h(t)$ interchanged.) Indeed this provides an easy alternative proof of Lemma 3.1 concerning a known initial distance.

5. Relation to the linear search problem. The problem of this paper is related to the following symmetric form of the linear search problem. A searcher with speed one and initial position 0 seeks to find an object hidden at distance d drawn from a distribution F and placed equiprobably at $\pm d$. The least expected time to find the object is denoted by $L = L(F)$. It can easily be shown that by using a geometric search pattern of, say, doubling the successive searches to the right and left, L is finite if and only if F has a finite mean. A similar approach will also give the same result for the rendezvous value R, but we prefer to employ a comparison of $R(F)$ and $L(F)$. Since $L(F)$ has been extensively studied, our comparison immediately extends those results to $R(F)$.

To begin this analysis, we first consider a variant of the rendezvous problem defined in the introduction. Instead of assuming that the players are placed on the line facing in an equiprobable direction, we will assume both are placed facing in the same direction. Alternatively, we are assuming that they have a common notion of a positive direction on the line. In this case the expected meeting time corresponding to a strategy pair $g, h \in P$ is given by

$$T^* = T^*(g,h) = \int_0^\infty \frac{1}{2} \sum_{i=\pm 1} \min\{t : g(t) = id + h(t)\}\, dF(d), \tag{7}$$

and the corresponding rendezvous value is given by

$$R^* = R^*(F) = \min_{g,h \in P} T^*(g,h). \tag{8}$$

LEMMA 5.1. *$R^* = L(F)/2$, and the minimizing $g, h \in P$ of* (8) *satisfy $g = -h$ and $|g'| \equiv 1$.*

Proof. First observe from (7) that T^* depends only on the difference $f = g - h$, which belongs to the space $2P$ of functions with Lipschitz constant (maximum speed) 2, and $f(0) = 0$. Any such function f has a derivative almost everywhere, and we may define the total distance travelled by f up to time t by $\theta(t) \equiv \int_0^t |f'(t)|\, dt \leq 2t$. Then the function $\hat{f}$ defined by the equation $\hat{f}(\theta(t)/2) = f(t)$ satisfies $|\hat{f}'(t)| \equiv 2$ almost everywhere and reaches every point on the line not later than f does. Thus there is always a minimizing function f with $|f'(t)| \equiv 2$ which therefore must be the difference of functions g and h as stated in the lemma. Furthermore we have from (8) that

$$R^* = \min_{f \in 2P} \int_0^\infty \frac{1}{2} \sum_{i=\pm 1} \min\{t : f(t) = id\}\, dF(d) = L(F)/2. \qquad \square$$

THEOREM 5.2. *For any distribution F, we have*

$$L(F)/2 \leq R(F) \leq L(F).$$

Proof. In the version of rendezvous search where the players have a common notion of direction, they could choose to ignore this information and thus play the version of the game with no common direction. Thus $R^* \leq R$, and hence $L/2 \leq R$ by the previous lemma. To obtain the right inequality, simply restrict the game to strategy pairs where one the of players doesn't move, so that the other player is faced with the linear search problem.. □

As an example, consider the point distribution where the distance between the players is 1. Here we found that $R = \frac{13}{8}$. It is easily seen that in this case $L = (1+3)/2 = 2$, and the inequalities of the theorem are strict in that $1 < \frac{13}{8} < 2$.

TOWARD A GEOMETRIC THEORY IN THE TIME-MINIMAL CONTROL OF CHEMICAL BATCH REACTORS*

B. BONNARD† AND J. DE MORANT‡

Abstract. In this article we outline a geometric theory for the time-minimal control of chemical batch reactors by analyzing the equations from Pontryagin's maximum principle applied to the optimal control problem. This theory is used for computing the optimal feedback law for a batch reactor in which three species X, Y, Z are reacting according to the scheme $X \longrightarrow Y \longrightarrow Z$ and every reaction in the sequence obeys first-order kinetics. The control variable is the derivative of the temperature in the reactor, and the terminal condition is a specified ratio of concentrations of species X and Y.

Key words. time-optimal control, optimal synthesis, chemical systems

AMS subject classifications. 49B10, 93C10

1. Introduction. The choice of best temperature schedule in a batch reactor to maximize the yield per year is one of the main problems in chemical engineering. Until now, in practise, *the reaction temperature is held constant* over the duration of a batch and hence an optimal law is computed among all the constant temperatures. Clearly, by varying the temperature of the reactions we may improve the yield. Therefore, many researchers have recently concentrated their efforts on the optimisation of chemical reactors; see for instance [6], [16]. Their studies are *mainly numerical* and based on *Pontryagin's maximum principle* (PMP) or the *Hamilton–Jacobi–Bellman equation* (HJB). If PMP is used, the optimal law is computed as an open-loop function. Moreover only the "classic" optimal control developed in the 1960s presented in [6] is used. On the other hand, the HJB approach will not lead to an optimal control, even for a small-dimensional state space, for reasons discussed in [16].

In this article, we outline a geometric theory for the time-minimal control of a chemical reactor based on the *analysis of the equations coming from the maximum principle*. In order to be implemented, the optimal law is computed as a *feedback law* (closed-loop function). Our study is in the spirit of similar approaches developed by Sussmann and Tang [30] for *mechanical systems* and uses recent results outlining a *geometric theory* of solutions of the maximum principle and providing a methodology to analyze optimal control problems and solving time-optimal control problems of reasonable complexity. It must be noted that this methodology can be successfully applied to chemical systems because in many situations—although the reaction scheme is, in general, complicated—*it can be reduced to a few reactions*. Among the numerous contributions to this theory, we shall make an intensive use of the results from Schättler and Sussmann concerning the parametrizations of the *boundary of the* (*small time*) *accessibility set* and their applications to the construction of the optimal syntheses [26]–[28].

Indeed, this set plays the role of the unit ball in Riemaniann geometry, and its complexity explains the difficulty of solving optimal control problems. Other useful tools in our problem are the results concerning the classification of extremals by Kupka [18]. Moreover, the technique established by Bonnard and Kupka in [2] allows us to obtain evaluations of the accessibility set along a singular extremal and therefore to define the concept of *conjugate points* and to obtain C^0-optimality conditions along such a trajectory. This technique will be used to show the *existence of conjugate points for even simple reaction schemes* and hence indicates the nontriviality of the control problem. Now, of course all the available tools are

not sufficient to solve our problem automatically. We have to develop the theory in different directions. Moreover the specific geometry of our problem has to be taken into account. *The analysis developed in this article has been used to implement a feedback optimal law in a* 5*-liter reactor in the department of chemical engineering at Institut National des Sciences Appliquées Rouen*; see [12], [23].

The main contributions of this article are the following. First, we have to develop the theory in the following direction. In the batch reactor problem, the terminal condition in the state space belongs to a hypersurface, which corresponds physically to a desired repartition of the concentrations at the end of the batch. Therefore we initialize a *generic classification of the optimal feedback law* for the time-optimal control problem for *planar systems*, when *the terminal set is a manifold of codimension one*. This classification is similar to the one by Sussmann for the fixed end-point problem [27], although the techniques to analyze the problem are different. Then, using [2], we develop an algorithm to determine if a reference singular extremal is optimal, for the fixed end-point problem, with respect to all trajectories contained in a (C^0-small) neighborhood of the given trajectory. This algorithm is in fact a *method for computing the conjugate points* along a singular trajectory, under generic conditions, *without any integration*. It can be modified in order to deal with the optimal problem regardless of the terminal condition (concept of *focal point*). Finally all these results are applied to solve the time-optimal control problem for a scheme of two consecutive reactions.

This article is organized as follows. In §2, we give the mathematical model and describe the optimal control problem. In §3, we briefly recall the maximum principle and some basic properties of its solutions. In §4, we outline a classification of optimal feedback laws near the terminal set. In §5, we give an algorithm to compute the conjugate points along a singular trajectory under generic and codimension-one conditions. It is presented for a system in $\mathbf{R}^3$ but can be straightforwardly extended to $\mathbf{R}^n$. In §6, we patch together all these results to compute the optimal feedback law for a batch reactor in which three species X, Y, Z are reacting according to the scheme $X \to Y \to Z$ and every reaction is irreversible and of first order, the target being a specified ratio of the concentrations of X and Y.

2. Mathematical model of a chemical batch reactor and description of the control problem.

2.1. Batch reactor. Batch reactors are used for the production of many chemicals, e.g., polymers and fine chemicals. The reactants are initially loaded into the reactor, mixed well, and allowed to react for a certain time. The ambient temperature is allowed to vary by a heat exchanger designed around the reactor. We assume that the cooling fluid has a constant flow rate. Its temperature is controlled with a regulator.

2.2. Mathematical model. The mathematical model for the process has to be divided into two distinct parts. First, we have a model describing the *chemical reactions* in the reactor, coming from experimental and physical laws of *chemical kinetics* [8]. Second, we have a model describing the *thermodynamic phenomena* obtained from standard laws and models coming from chemical thermodynamics [13] and heat exchanger models in chemical reaction engineering [23].

2.2.1. Chemical kinetics. We briefly recall some standard results from chemical kinetics (see [8] for more details).

Consider first a single chemical reaction (e.g., $2N0 + 2H_2 \to N_2 + 2H_20$):

$$\sum_{i=1}^{n_1} \alpha_i R_i \to \sum_{i=1}^{n_2} \beta_i P_i,$$

where the R_i's are called the *reactants* and the P_i's are called the *products*. The coefficients α_i, β_i are the *stoichiometric coefficients* given with the convention $\alpha_i > 0$ and $\beta_i < 0$, and since they are only defined up to a factor, one can set $\alpha_1 = 1$. Let X_i be a species R_i or P_i, with stoichiometric coefficient γ_i. Initially we have $n_i(0)$ moles of constituent X_i and $n_i(t)$ moles at time t. The *molar extent* of species X_i is given by

$$\zeta_i(t) = \frac{n_i(t) - n_i(0)}{\gamma_i},$$

and from the law of mass conservation all the ζ_i's are equal to a same number ζ called the *molar extent of the reaction.* If more than one chemical reaction is possible and ζ_k is the extent of X_i due to the kth reaction and γ_i^k stoichiometric coefficient of the species X_i in the kth reaction, the total change in the number of moles of species X_i because of p reactions is

$$n_i(t) - n_i(0) = \sum_{k=1}^{p} \gamma_i^k \zeta_k(t).$$

Now we have to model the kinetics of the reactions. For that, consider a single reaction between n species X_i with stoichiometric coefficient γ_i and assume that the reaction is at *constant volume* V. The rate of evolution of species X_i is

$$v_i = \frac{dn_i}{dt},$$

from the law of mass conservation we have

$$\gamma_j v_i = \gamma_i v_j,$$

and its *specific rate* is

$$r_i = \frac{v_i}{V} = \frac{1}{V}\frac{dn_i}{dt} = \frac{dc_i}{dt},$$

where $c_i = \frac{n_i}{V}$ is the *molar concentration* of species X_i. Let $r = r_i/\gamma_i$.

The rate r is given at constant temperature by an *empirical law* of Gulberg and Waage,

$$r = -k \prod_{i=1}^{n} c_i^{\delta_i}, \tag{2.1}$$

the reaction is said to be of the δ_i*th order* with respect to species X_i, and the overall order is $m = \sum_{i=1}^{n} \delta_i$. The numbers δ_i *are not generally related to the corresponding stoichiometric coefficients* γ_i *and have to be determined experimentally.*

The coefficient k depends on the temperature T of the reaction and is given by a *physical law* called *Arrhenius' law*,

$$k = A_r e^{-E_r/RT}, \tag{2.2}$$

where the parameters A_r and E_r are the *frequency factor* and the *activation energy*, respectively, of the reaction and R is the gas constant.

We can now model every reaction network occurring at constant volume. In this article we consider the case where $(n+1)$ species X_i whose concentration is c_i are reacting according to the scheme

$$X_1 \xrightarrow{k_1} X_2 \xrightarrow{k_2} \cdots \xrightarrow{k_n} X_n.$$

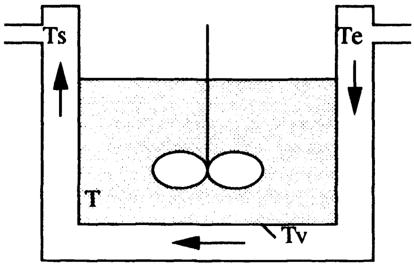

FIG. 1. *T = temperature in the reactor, T_e = temperature of the fluid at the entrance of the exchanger, T_s = temperature of the fluid at the exit, T_v = temperature of the inner shell.*

Moreover, let us assume that in this network of *consecutive* and *irreversible* reactions every reaction $X_i \overset{k_i}{\longrightarrow} X_{i+1}$ obeys first-order kinetics:

$$\frac{dc_i}{dt} = -k_i\, c_i,$$

where from (2.1), $k_i = A_i e^{-Ei/RT}$. Since we have

$$\sum_{i=1}^{n+1} c_i(0) = \sum_{i=1}^{n+1} c_i(t),$$

if we introduce $x^i = c_i / \sum_{i=1}^{n+1} c_i(0)$ and $v = k_1$, the reaction scheme is modelled by

$$\text{(2.3a)} \qquad \frac{dx}{dt} = K(v)x,$$

$$\text{(2.3b)} \qquad \frac{dv}{dt} = h(v)u,$$

where $x =^t (x^1, \ldots, x^n)$, $u = \frac{dT}{dt}, h(v) = \frac{R}{E_1} v \ln^2(v/A_1)$, K is the matrix

$$K = \begin{bmatrix} -k_1 & & \\ k_1 & 0 & \\ 0 & k_{n-1} & -k_n \end{bmatrix},$$

and x, v satisfy the inequalities

$$0 \leq x^i, \sum_{i=1}^{n} x^i \leq 1, \qquad 0 < v < A_1.$$

Moreover x^{n+1} can be computed using the law of mass conservation.

2.2.2. Heat exchanges. To get a complete mathematical model of the process represented by Fig. 1 and in which the chemical reactions are at constant volume, we have to model the heat exchanges. To analyze the optimal control problem and for reasons explained later, we don't need a mathematical model and indicate only the nature of the expected equations; see [23] for a complete description.

The equation describing the evolution of the temperature T in the reactor is of the form

$$\frac{dT}{dt} = f\left(T_v, T, \frac{dx}{dt}\right), \tag{2.4}$$

where T_v is the temperature of the shell containing the chemical species. This equation models two different properties. First, in every chemical reaction, there is a heat transfer Q, which can be positive (*exothermic reaction*) or negative (*endothermic reaction*). Hence the variation of temperature depends on the variation of concentrations, which measures the number of reactions. Second, the temperature T is modified by heat transfer with the inner shell of the reactor and, hence depends on T_v.

Now, there are relations describing the heat transfer between the inner shell whose temperature is T_v and the temperature T_f of the fluid in the jacket and the way of tuning the temperature at the entrance T_e, and the equations are of the form

$$g\left(T_v, \frac{dT_v}{dt}, \dots, T_e, \frac{dT_e}{dt}, \dots, T_f, \frac{dT_f}{dt}, \dots, u\right) = 0, \tag{2.5}$$

where $u(.)$ is the *physical control.* (The reactor is assumed to be isolated from the outside world.)

2.3. The optimal control problem. The optimal control problem is the following. Given the reaction scheme in the reactor and the *desired product*, *maximize the production of the reactor over a year.* This objective can be clearly translated into a time-optimal control problem as follows. *Fix a desired product quantity for a batch, and minimize the batch time.*

Now, for the optimal control problem, it is reasonable to assume that the control is T or $\frac{dT}{dt}$. This means that for the optimal problems, equations (2.4) and (2.5) are not taken into account and *the optimal law is computed for a given chemical reactions network and does not depend on the transfer devices.* Of course, to be implemented, *the optimal law has to be tracked* with a *regulator* (like a proportional integral-derivative feedback) whose parameters are determined using equations (2.4) and (2.5). (See [23] for such a study.) Moreover these equations are imposing the bounds u_- and u_+ (depending in general on the state variables) such that $u_- \leq \frac{dT}{dt} \leq u_+$.

The choice of T or $\frac{dT}{dt}$ as the control variable depends on the ability of the regulator to track the computed optimal law. If T can be chosen as the control variable, the bounds on T, like 20°C $\leq T \leq$ 90°C, imposed since the shell of the reactor is in glass (this can also impose constraints such as $|T - T_v| \leq M$) are then the bounds of the control variable and the optimal control problem can seem to be better posed. However, it is not true, since the control system is not linear with respect to the input and an *admissible time-optimal law may not exist.* (This is due to the well-known relaxation phenomenon; see [5] or [19].)

Hence, in this article, we shall assume that $\frac{dT}{dt}$ *is the control variable. Moreover we shall suppose that the bounds* u_- *and* u_+ *such that* $u_- \leq \frac{dT}{dt} \leq u_+$ *are fixed. The bounds on the state variable* T, $T_{\text{min}} \leq T \leq T_{\text{max}}$, *will not be taken into account.* (See [21] for a discussion of this problem.)

The optimal control problem denoted by $\mathcal{P}$ is, then, as follows: Consider system (2.3), the class of admissible controls $\mathcal{U}$ being the set of all measurable functions $u(.) = \frac{dT}{dt}(.)$ defined on $[0, t_u]$ and taking their values in the fixed interval $[u_-, u_+]$, with $u_- < 0 < u_+$. Let N be an analytic manifold in the space of concentrations $\{x\}$ and with codimension one, and let $m_0 = (x_0, v_0)$ be an initial condition in the (physical) state space. Among all the solutions of the system and starting from m_0, find the ones such that the time duration of control to reach the target is minimal. The manifold N is called the *terminal manifold.*

For practical reasons the optimal law has to be computed for each initial state m_0 to provide an optimal feedback law $m \rightarrow u^*(m)$ (*synthesis problem*). The implementation of this feedback law requires the reconstruction of the state using an *observer*. (In practise, we have only a few observations.) The observation and the estimation problems will not be studied in this article, although they are crucial in practise.

3. Pontryagin's maximum principle and some geometric properties of extremals. To make this article self-contained we shall summarize in this section some geometric properties of extremals which will be used extensively to analyze the optimal control problem.

3.1. Pontryagin's maximum principle. Consider a system of the form

$$\frac{dx}{dt}(t) = f(x(t), u(t)), \qquad x \in \mathbf{R}^n, \tag{3.1}$$

where f is an analytic mapping from $\mathbf{R}^n \times \mathbf{R}^m$ into $\mathbf{R}^n$ and the set of admissible controls $\mathcal{U}$ is the set of bounded measurable mappings $u(.)$ defined on an interval $[0, T_u]$ of $\mathbf{R}^+$ and taking their values in a subset Ω of $\mathbf{R}^m$. Let N be a regular analytic submanifold of $\mathbf{R}^n$. The PMP tells us that if $u^*(t), t \in [0, t^*]$, is an optimal control for the time-minimal control problem with terminal manifold N, then there exists an adjoint vector $p^*(t) \in \mathbf{R}^n \backslash \{0\}$, absolutely continuous (a.c.), such that the following equations are satisfied almost everywhere (a.e.) on $[0, t^*]$:

$$\frac{dx^*}{dt} = \frac{\partial H}{\partial p}(x^*, p^*, u^*), \qquad \frac{dp^*}{dt} = -\frac{\partial H}{\partial x}(x^*, p^*, u^*), \tag{3.2}$$

$$H(x^*, p^*, u^*) = \operatorname{Max} H_{u \in \Omega}(x^*, p^*, u), \tag{3.3}$$

where $H(x,p,u) = \langle p, f(x,u)\rangle$, $\langle , \rangle$ being the standard inner product in $\mathbf{R}^n$. Moreover

(3.4) the mapping $t \rightarrow \operatorname{Max} H_{u \in \Omega}(x^*(t), p^*(t), u)$ is constant everywhere and positive.

The vector p^* can be selected to satisfy the *transversality condition.*

(3.5) $p^*(t^*)$ orthogonal to $T_{x^*(t)}N$, where T_xN is the tangent space to N at x.

The system (3.2) is called the *Hamiltonian lift* of (3.1), and H is the *Hamiltonian*. A triple (x, p, u) solution of (3.2), (3.3), and (3.4) is called an *extremal*. (Sometimes we omit p.) An extremal (x,p,u) such that $H(x,p,u) = 0$ almost everywhere is called *exceptional*. Assume now that Ω is a convex polyhedron. An extremal (x,p,u) is called *regular* if, for almost every t, $u(t)$ lies on the vertices of Ω and (totally) *singular* if, for each t, $u(t)$ lies in the interior of Ω; hence $\frac{\partial H}{\partial u}(x,p,u) = 0$.

3.2. Singular extremals. We briefly recall some concepts and results concerning the singular extremals; see [1] and [2] for details.

By definition, a singular extremal (x,p,u) is a solution of (3.2), (3.3), and (3.4) contained in the variety $\frac{\partial H}{\partial u} = 0$, and from (3.3) it has to satisfy the *Legendre condition* $\partial^2 H/\partial u^2_{|(x,p,u)} \leq 0$. If for all t, this inequality is strict, it is called the *strong Legendre condition*. Then, by the implicit function theorem, the singular control u can be computed locally as a mapping $\hat{u} : (x,p) \rightarrow \hat{u}(x,p)$ by solving the equation $\frac{\partial H}{\partial u} = 0$. Consider now a *single-input affine* analytic system

$$\frac{dx}{dt} = X(x) + uY(x), \qquad x \in \mathbf{R}^n, \qquad u \in [-1, +1], \tag{3.6}$$

and let (x,p,u) be a singular extremal. The associated Hamiltonian is $H(x,p,u) = \langle p, X + uY\rangle$. Hence the equation $\frac{\partial H}{\partial u} = 0$ is equivalent to $\langle p, Y(x)\rangle = 0$, and the singular controls have to be computed as follows.

DEFINITION 3.1. *The Lie bracket of two vector fields* Z_1, Z_2 *is computed with the convention* $[Z_1, Z_2](x) = \frac{\partial Z_2}{\partial x}(x)Z_1(x) - \frac{\partial Z_1}{\partial x}(x)Z_2(x)$, *and let* ad Z_1 *be the mapping defined by* ad $Z_1(Z_2) = [Z_1, Z_2]$. *A point* (x,p) *is called* ordinary *if* $\langle p, \operatorname{ad}^2 Y(X)\rangle \neq 0$, *and let* θ *be the set of nonordinary points. A singular extremal* (x,p,u) *such that* $(x(t),p(t)) \in \boldsymbol{R}^{2n}\backslash\theta$ *is called of* order 2. *Let* Σ *be the variety* $\{(x,p);\ \langle p, Y(x)\rangle = 0\}$, *and let* $\Sigma' = \{(x,p);\ \langle p, Y(x)\rangle = \langle p, [X,Y](x)\rangle = 0\}$. *Let* $\hat{H}$ *be the restriction to* $\Sigma'\backslash\theta$ *of the mapping* $(x,p) \rightarrow \langle p, X(x) + \hat{u}(x,p)Y(x)\rangle$, *where*

$$\hat{u}(x,p) = \frac{\langle p, \operatorname{ad}^2 X(Y)(x)\rangle}{\langle p, \operatorname{ad}^2 Y(X)(x)\rangle}. \tag{3.7}$$

PROPOSITION 3.2. *The singular extremals* (x,p,u) *of order* 2 *are defined by*

(i) $u(t) = \hat{u}(x(t),p(t))$;

(ii) (x,p) *is a solution of*

$$\frac{dx}{dt} = \frac{\partial \hat{H}}{\partial p}(x,p), \qquad \frac{dp}{dt} = -\frac{\partial \hat{H}}{\partial x}(x,p); \tag{3.8}$$

and in order to be admissible they have to satisfy the constraint

(iii) $(x,p) \in \{(x,p);\ |\hat{u}(x,p)| \leq 1\}$.

DEFINITION 3.3. *Let* (x,p,u) *be a singular extremal of order* 2 *and h be the value of t* $\rightarrow$ $\operatorname{Max}_{u\in\Omega} H(x,p,u)$. *According to* 3.1, *it is called* exceptional *if* $h = 0$. *If* $h \neq 0$, *it is called* hyperbolic *if* $\langle p(t), \operatorname{ad}^2 Y(X)(x(t))\rangle < 0$ *and* elliptic *if* $\langle p(t), \operatorname{ad}^2 Y(X)(x(t))\rangle > 0$.

3.3. Time-optimality problem. Let (x,p,u) be a singular extremal of *order* 2, defined on $[0,T]$. Since the maximum principle is only a necessary condition for optimality, the main problem when the solutions of PMP are analyzed is to determine their optimality. We make the following assumptions.

Assumption 3.4. First, let us make the following assumptions:

(H0) $t \rightarrow x(t)$ is one to one. Then one may set $u \equiv 0$, and moreover, let us assume the following:

(H1) $\forall t \in [0,T]$, the $(n-1)$ vectors $\{\operatorname{ad}^k X(Y)(x(t)); k = 0,\dots,n-2\}$ are linearly independent.

(H2) $\forall t \in [0,T]$, $\operatorname{ad}^2 Y(X)(x(t)) \notin$ Span $\{\operatorname{ad}^k X(Y)(x(t)); k = 0,\dots,n-2\}$.

(H3) If $n = 2$, $X(x(t))$ and $Y(x(t))$ are linearly independent $\forall t \in [0,T]$, and if $n \geq 3$, $X(x(t)) \notin$ Span $\{\operatorname{ad}^k X(Y)(x(t)), k = 0,\dots,n-3\}\, \forall t \in [0,T]$.

THEOREM 3.5. *Let* (x,u) *be a trajectory defined on* $[0,T]$ *and satisfying* (H0) – (H3). *Then there exists a* C^o*-neighborhood U of x such that x is a time-minimizing* (*resp., maximizing*) *trajectory with respect to all solutions of* (3.6) *contained in U and joining* $x(0)$ *to* $x(T)$ *if* (x,u) *is a hyperbolic or exceptional* (*resp., elliptic*) *extremal and* $T < t_{1c}$, *where* t_{1c} *is the first conjugate time along* x.

In [2], we give an algorithm to compute t_{1c}. It is based on the *evaluation of the accessibility set* along the reference trajectory x using a *seminormal form* for the action of the *feedback group*. The computations of conjugate points in [2] require linear transformations and integration of the vector field Y and the reference trajectory. A different algorithm without integration will be described in §5. This theorem solves the time-optimality problem of singular trajectories satisfying (H0) – (H3) when the terminal manifold is a point. It has to be adapted to deal with the situation encountered with the control of batch reactors where the terminal manifold is of codimension one.

3.4. Connection between singular extremals in the affine and nonaffine case. For a batch reactor, the system is affine if $\frac{dT}{dt}$, denoted $\dot{T}$, is the control (T is then a state variable) and nonaffine if the control is T. The object of this section is to relate singular extremals in both cases.

Let us consider a general system of the form (3.1). This system can be interpreted as an affine system with respect to a new control v if we set $\dot{u} = v$, that is, if we introduce an integrator. Let us study the converse transformation, in optimal control called Goh's transformation.

DEFINITION 3.6. Let us consider an affine single-input system of $\mathbf{R}^n$, $\dot{x} = X + uY$, and let us assume $n \geq 2$. Take $x_0 \in \mathbf{R}^n$ such that $Y(x_0) \neq 0$. Hence there exists an open set U containing x_0 such that $Y_{|U} = \frac{\partial}{\partial x^n}$, $(x^1, \dots, x^n)$ are the coordinates of $\mathbf{R}^n$, and the restriction of the system to U can be written as

$$\dot{x}' = X'(x', x^n), \qquad \dot{x}^n = X^n(x) + u,$$

where $x' =^t (x^1, \dots, x^{n-1})$ and $X = X' \frac{\partial}{\partial x'} + X^n \frac{\partial}{\partial x^n}$. The system $\dot{x}' = X'(x', x^n)$, where x^n is the control variable and which is defined on an open set U' of $\mathbf{R}^{n-1}$, is called the *reduced system* associated with system (X, Y). If $H = \langle p, X + uY \rangle$ is the Hamiltonian of the original system, we set $H'(x', p', x^n) = \langle p', X'(x', x^n) \rangle$, where $p' = (p_1, \dots, p_{n-1})$ is the dual variable of x'.

LEMMA 3.7. *The pair (x, p) is the projection on the space $\{(x, p)\}$ of a solution (x, p, u) of $\dot{x} = \frac{\partial H}{\partial p}$, $\dot{p} = -\frac{\partial H}{\partial x}$, $\frac{\partial H}{\partial u} = 0$ if and only if (x', p', x^n) is a solution of $\dot{x}' = \frac{\partial H'}{\partial p'}$, $\dot{p}' = -\frac{\partial H'}{\partial x'}$, $\frac{\partial H'}{\partial x^n} = 0$. Moreover the following relations are satisfied*:

$$\text{(i)} \qquad \left(\frac{d}{dt} \frac{\partial H}{\partial u} \right)_{|(x,p,u)} = \langle p, [X, Y](x) \rangle = -\frac{\partial H'}{\partial x^n}_{|(x',p',x^n)},$$

$$\text{(ii)} \qquad \frac{\partial}{\partial u} \frac{d^2}{dt^2} \frac{\partial H}{\partial u}_{|(x,p,u)} = -\langle p, \operatorname{ad}^2 Y(X)(x) \rangle = -\frac{\partial^2 H'}{\partial {x^n}^2}_{|(x',p',x^n)}.$$

For the proof of this result, see [2].

DEFINITION 3.8. *Let (x, p, u) be an singular extremal of* (3.1). *The condition*

$$\frac{\partial}{\partial u} \frac{d^2}{dt^2} \frac{\partial H}{\partial u}_{|(x,p,u)} \geq 0$$

is called the Legendre–Clebsch condition.

COROLLARY 3.9. *The Legendre–Clebsch condition along a singular extremal is equivalent to the Legendre condition along the corresponding extremal for the reduced system.*

3.5. Projected problems. According to the theory developed in [1], symmetry properties of a control system have to be coded by symmetry properties for the differential equation whose solutions are singular trajectories. For batch reactors where every reaction is of first order, this will imply a nice projection property.

3.5.1. Statement of the problem (every object is real analytic). Let M and M' be two manifolds, π be a submersion from M into M', and N (resp., N') be a regular submanifold of M (resp., M') with $N = \pi^{-1}(N')$. Consider now the system on M : $\frac{dx}{dt} = f(x, u), u \in \Omega$, and the associated time-optimal control problem with terminal manifold N, denoted $\mathcal{P}$. Let us assume that for each fixed $u \in \Omega$, the vector field $x \longrightarrow f(x, u)$ can be π-*projected* and is complete for each admissible control $u(.)$. Hence, one may define the *projected system* on

M', $\frac{dx'}{dt} = f'(x',u), u \in \Omega$, where $x' = \pi(x)$ and $f'(x',u) = d\pi(f(x,u))$, $d\pi$ being the differential of π, and the associated time-optimal control problem $\mathcal{P}'$ with terminal manifold N' is called the *projection* of problem $\mathcal{P}$.

Our aim is to compare both extremals and optimal trajectories. Let us denote by $x(t,x_0,u)$ the solution of $\frac{dx}{dt} = f(x,u)$ starting at $t = 0$ from $x_0 \in M$ and by $x'(t,x'_0,u)$ the solution of $\frac{dx'}{dt} = f'(x',u)$ starting at $t = 0$ from $x'_0 = \pi(x_0)$. We have the following lemma.

LEMMA 3.10. *The trajectory $x^*(t,x_0,u^*)$ defined on $[0,t^*]$ is a solution of $\mathcal{P}$ if and only if $x(t,x'_0,u^*)$ is a solution of $\mathcal{P}'$.*

Proof. By completeness, we have for each t : $x'(t,x'_0,u) = \pi(x(t,x_0,u))$, and by definition $N = \pi^{-1}(N')$.

LEMMA 3.11. *Every extremal (x',p',u) defined on $[0,T]$ of the projected problem $\mathcal{P}'$ can be lifted to an extremal (x,p,u) of the original problem $\mathcal{P}$. Moreover if (x',p') satisfies the boundary conditions $x'(T) \in N'$ and $p'(T)$ orthogonal to $T_{x'(T)}N'$ imposed by $\mathcal{P}'$, then (x,p) can be selected to satisfy the boundary conditions imposed by $\mathcal{P}$.*

Proof. The system $\frac{dx}{dt} = f(x,u)$ can be written locally as

$$\frac{dx'}{dt} = f'(x',u), \qquad \frac{dx''}{dt} = f''(x',x'',u).$$

Hence every extremal (x',p',u) of $\mathcal{P}'$ can be lifted into $(x,p,u) = ((x',x''),(p',0),u)$, where x'' is any solution of the second equation. Clearly (x,p,u) is an extremal of $\mathcal{P}$, and we have $x'(T) \in N', p'(T)$ orthogonal to $TN' \Leftrightarrow x(T) \in N$ and $p(T)$ orthogonal to TN.

Conclusion 3.12. Not every extremal of $\mathcal{P}$ can be projected onto an extremal of $\mathcal{P}'$. *Hence, although $\mathcal{P}'$ is equivalent to $\mathcal{P}$, from Lemma* 3.10, *its analysis using PMP is simpler because we have fewer extremals.*

3.6. Regular extremals. Below, we shall briefly recall some useful results concerning the behavior of regular extremals for a single-input affine system (3.6) with $u \in [-1,+1]$ (which will be used extensively later). (See [18] for details.)

DEFINITION 3.13. *Let (z,u), where $z = (x,p)$, be an extremal defined on $[0,T]$. A time $s \in [0,T]$ is called a* switching time *if s belongs to the closure of the set of $t's \in [0,T]$, where z is not C^1. The set $\{z(s)\}$, z being any extremal, where s is a switching time, is called the* switching set. *Observe that this set is a subset of $\Sigma = \{z = (x,p); \langle p, Y(x)\rangle = 0\}$.*

3.7. Classification of regular extremals. Let $z = (x,p)$ be a *smooth* solution of $\dot{x} = \frac{\partial H}{\partial p}$, $\dot{p} = -\frac{\partial H}{\partial x}$ defined on $[0,T]$, where $H = \langle p, X + uY\rangle$ and corresponding to the control $u(.)$. Let us introduce the *switching function* $\Phi : t \to \langle p(t), Y(x(t))\rangle$ evaluated along z. If $u \equiv +1$ (resp., -1), we set $z = z^+$ and $\Phi = \Phi^+$ (resp., $z = z^-$ and $\Phi = \Phi^-$). By differentiating Φ twice with respect to t we get

$$\begin{aligned} \dot{\Phi}(t) &= \langle p(t), [X,Y](x(t))\rangle, \\ \ddot{\Phi}(t) &= \langle p(t), \operatorname{ad}^2 X(Y)(x(t)) - u(t) \operatorname{ad}^2 Y(X)(x(t))\rangle. \end{aligned} \tag{3.9}$$

3.7.a. Normal switching points. Let $z_0 = (x_0,p_0) \in \Sigma$, and let us assume that $Y(x_0) \neq 0$ and $z_0 \in \Sigma \backslash \Sigma'$. (Recall that $\Sigma' = \{(x,p); \langle p, Y(x)\rangle = \langle p, [X,Y](x)\rangle = 0\}$.) The point z_0 is then called *normal*. The behavior of regular extremals near z_0 is given by Fig. 2, where Σ^+ (resp., Σ^-) $= \{(x,p); \langle p, Y(x)\rangle > 0\}$ (resp., < 0). From (3.9) we have the following lemma.

LEMMA 3.14. *Let t_0 be the switching time given by $z^+(t_0) = z^-(t_0) = z_0$. Then we have*

$$\dot{\Phi}^+(t_0) = \dot{\Phi}^-(t_0) = \langle p_0, [X,Y](x_0)\rangle \quad (\textit{reflexion law}). \tag{3.10}$$

Moreover, let $z = (x,p)$ be an extremal passing through z_0; then we have

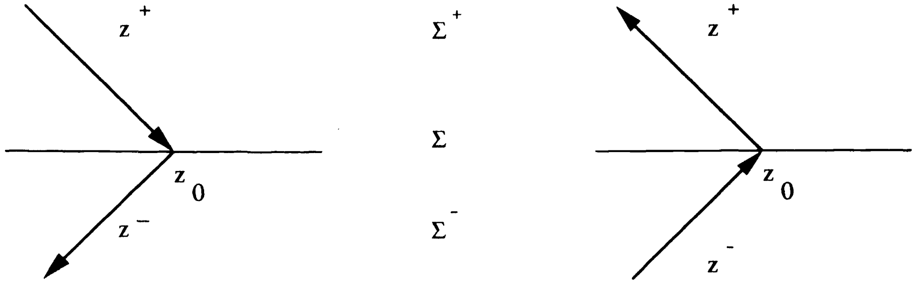

FIG. 2.

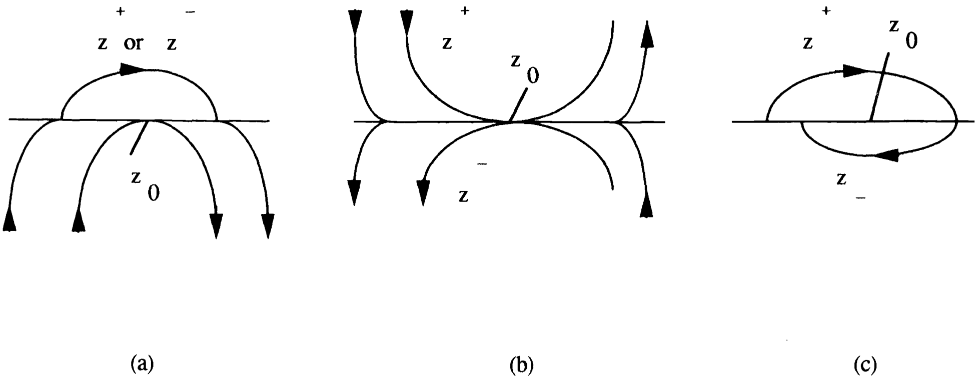

FIG. 3.

(i) *if* $\langle p_0, [X,Y](x_0)\rangle < 0$, *then* $x = \Gamma_+\Gamma_-$;

(ii) *if* $\langle p_0, [X,Y](x_0)\rangle > 0$, *then* $x = \Gamma_-\Gamma_+$,

where Γ_+ (*resp.*, Γ_-) *is an arc solution of the system corresponding to* $u \equiv 1$ (*resp.*, $u \equiv -1$) *and* $\Gamma_+\Gamma_-$ *represents the trajectory corresponding to the concatenation of* $u \equiv +1$ *with* $u \equiv -1$; *i.e., an arc* Γ_+ *is followed by an arc* Γ_-.

3.7.b. The fold case. Let $z_0 = (x_0, p_0) \in \Sigma'$, and let us assume that $Y(x_0) \neq 0$ and both λ^+ and λ^- are different from zero where

$$\lambda^\pm = \langle p_0, \mathrm{ad}^2X(Y)(x_0) \mp \mathrm{ad}^2Y(X)(x_0)\rangle.$$

Such a point is called a *fold*, and the behavior of regular extremals near z_0 has been classified in [18]. We have three distinct cases (Fig. 3), which are characterized by

a) $\lambda^+\lambda^- > 0$ (*parabolic case*),

b) $\lambda^+ > 0$ and $\lambda^- < 0$ (*hyperbolic case*),

c) $\lambda^+ < 0$ and $\lambda^- > 0$ (*elliptic case*), and from [2] and [18] we have the following lemma.

LEMMA 3.15. *The point* z_0 *is a switching point in the hyperbolic case and is not a switching point in the elliptic case. If* z_0 *is an ordinary point, the singular dynamic feedback* $\hat{u}$ *given by* (3.7) *and evaluated at* z_0 *belongs to* $]-1,+1[$ *in the hyperbolic and elliptic case, contrary to the parabolic case. Moreover the extremals near* z_0 *are of the forms* $\Gamma_+\Gamma_s\Gamma_-$, $\Gamma_+\Gamma_s\Gamma_+$, $\Gamma_+\Gamma_s\Gamma_-$, or $\Gamma_-\Gamma_s\Gamma_-$, *where* Γ_s *is a singular arc, in the hyperbolic case, and* $\Gamma_+\Gamma_-\Gamma_+$ *or* $\Gamma_-\Gamma_+\Gamma_-$ *in the parabolic case; in the elliptic case the only extremal passing through* z_0 *is* Γ_s, *and the other extremals are of the form* $\Gamma_+\Gamma_-\Gamma_+\Gamma_-\ldots$ (*no uniform bounds on the number of switchings*). *Moreover, let us assume that the singular extremal arc* *passing through* z_0 *satisfies assumptions* (H0) – (H3). *Then it is hyperbolic* (*hence fast*) *in case* b) *and elliptic* (*hence slow*) *in case* c).

Remark 3.16. The adjoint vector p has to be oriented in our terminology with the convention (3.4) of the maximum principle ($H \geq 0$).

4. Time-minimal synthesis for planar systems in the neighborhood of a terminal manifold of codimension one.

4.1. Problem statement. Consider a system in $\mathbf{R}^2$ of the form

$$\dot{v} = X(v) + uY(v), \qquad |u| \leq 1, \tag{4.1}$$

where X and Y are analytic vector fields, and let N be an analytic regular submanifold of $\mathbf{R}^2$ of codimension one. The set of admissible controls $\mathcal{U}$ is the set of measurable functions with values in $[-1, +1]$. We shall study the following *local* problem. Let $v_0 \in N$. Compute, in a sufficiently small open neighborhood U of v_0, the optimal synthesis for the time-minimal control problem with terminal manifold N and system (4.1) restricted to U. This problem is well posed because a standard theorem [19] proves the existence of an optimal solution. It is similar to the problem studied by Schättler and Sussmann in a series of articles (see, for example, [26] and [27]) when the terminal manifold is reduced to a point. (This problem is called the *point-to-point problem.*) The aim of this section is to give the tools to solve the problem and to begin a classification of optimal *syntheses* in terms of relations between the Taylor expansions of X, Y, and f at v_0, where f is the mapping whose zero set is locally N. A more complete classification is given in [4].

DEFINITION 4.1 AND NOTATION. *Consider the system* (4.1) *written as* (X, Y), *and let us denote by* (x, y) *the coordinates of* $v \in \boldsymbol{R}^2$. *A coordinate system* (U, v) *such that the restriction of* Y *to* U *is* $\frac{\partial}{\partial y}$ *and will be called* adapted. *The optimal control problem is said to be flat if* Y *is tangent to* N *everywhere. A normal to* N *at* v *is denoted by* $n(v)$. *We lift* N *by using the transversality condition into* $\hat{N} = \{(v,p) \in \boldsymbol{R}^2 \times \boldsymbol{R}^2;\ v \in N, \langle p, w\rangle = 0 \,\forall w \in T_vN\}$. *An extremal* (v, p, u) *defined on* $[T, 0]$, $T < 0$ *that satisfies the boundary conditions* $(v(0), p(0)) \in \hat{N}$ *will be called a* BC-extremal. *We shall denote by* K *the projection on the v-space of the set of switching points for BC-extremals. Let* $v_0 \in N$, *and let* W *be the set of* optimal *switching points for the time-minimal control problem for* (4.1) *restricted to a sufficiently small neighborhood of* v_0, *with* N *the terminal manifold. By convention, any piecewise analytic control is taken right-continuous. The optimal closed-loop function, if it exists, is denoted by* $v \longrightarrow u^*(v)$. *For the concepts of synthesis we follow* [28]. *A stratum of the switching curve* W *is of* first kind *if the optimal trajectories are tangent to the stratum and of second kind if they are transverse. Following* [24], *the* splitting line L *is the set of points where the optimal feedback is not unique.* (*It will form the* cut locus.)

Let $v_1 \in \boldsymbol{R}^2$, *and let us denote by* $v(t, v_1, u)$ *the trajectory of* (4.1), *when defined, associated with* $u \in \mathcal{U}$ *and starting from* v_1 *at time* $t = 0$. *Let us denote by* $A^+(v_1, t)$, $t > 0$, *the set of points* $\{v(t, v_1, u); u \in \mathcal{U})$ accessible *from* v_1 *in time* t, *and let* $A^-(v_1, t)$ *be the set of points* v_2 *such that* v_1 *is accessible from* v_2 *in time* t. *The* accessibility set *is* $A^+(v_1) = \cup_{t>0} A^+(v_1, t)$, *and let* $A^-(v_1) = \cup_{t>0} A^-(v_1, t)$. *At* v_0, *we shall denote by* $C(v_0)$ *the convex set* $\{X(v_0) + uY(v_0); |u| \leq 1\}$. *In our analysis, we shall assume that* $Y(v_0) \neq 0$ *and* $C(v_0)$ *lies entirely in one half space limited by* $T_{v_0}N$. *If* $X(v_0) + Y(v_0)$ *or* $X(v_0) - Y(v_0)$ *is tangent to* N, *we are in the* exceptional case. *In the* nonexceptional case, *near* v_0, $n(v)$ *will be oriented toward the half space containing* $C(v_0)$.

4.2. Generic case. Let us assume that both $X(v_0) \pm Y(v_0)$ are not tangent to N. Then with our convention we have $\langle n(v), X(v)\rangle > 0$ for $|v - v_0|$ small. Let (v, p, u) be a BC-extremal defined on $[T, 0]$. Since we are in the nonexceptional case, one can set $p(0) =$

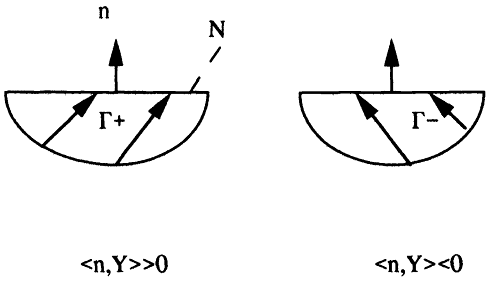

FIG. 4.

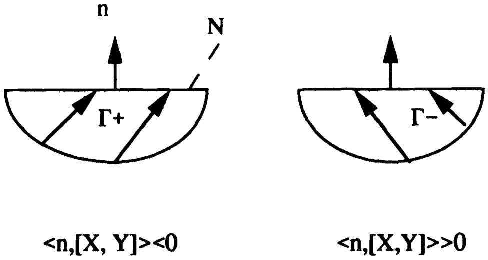

FIG. 5.

$n(v(0))$. Let us assume $\langle n(v_0), Y(v_0)\rangle \neq 0$. Then, by using the *transversality condition*, the optimal synthesis, in a sufficiently small open neighborhood of v_0, is given in Fig. 4, where Γ_+ (resp., Γ_-) are arcs corresponding to $u = 1$ (resp., -1).

4.3. Generic flat case. As before, we assume that both $X(v_0) \pm Y(v_0)$ are not tangent to N. If (v, p, u) is a BC- extremal defined on $[T, 0]$, one may set $p(0) = n(v(0))$. Since Y is tangent to N everywhere, we have $\langle n(v), Y(v)\rangle = 0$ for each $v \in N$. Hence, the transversality condition tells us nothing about the optimal synthesis. But since N lies in K (i.e., 0 is a switching time of (v, p)), then by Lemma 3.14, if $\langle n(v_0), [X, Y](v_0)\rangle \neq 0$ the arcs Γ_+ (resp., Γ_-) hitting the target N are BC-extremals if and only if $\langle n(v_0), [X, Y](v_0)\rangle < 0$ (resp., > 0), and the synthesis is seen in Fig. 5.

4.4. Generic switching point. If $\langle n(v_0), Y(v_0)\rangle = 0$, then $\hat{N}$ intersects the set $\Sigma = \langle p, Y\rangle = 0$ at $(v_0, n(v_0))$. To analyze this singularity one needs some preliminary lemmas.

LEMMA 4.2. *Let us assume $\langle n(v_0), [X, Y](v_0)\rangle \neq 0$. Then the arcs Γ_+ and Γ_- arriving at v_0 cannot be sets of input switching points.*

Proof. For instance, let us assume that $(v, p, u \equiv 1)$ is a BC-extremal on $[T, 0]$, with $v(0) = v_0$, and each point of v is an input switching point. Then, since $(v(0), p(0))$ is a normal switching point, from Lemma 3.14, there exist extremals $\Gamma = \Gamma_-\Gamma_+$, where Γ_+ are any subarcs of v. If Γ is a BC-extremal at v_0, the adjoint vector can be taken as $p(0)$. Now, since the image of $v \subset K$, we have $\langle p(t), Y(v(t))\rangle = 0$, $\forall t \in [T, 0]$. Hence the arc $v(.)$ is singular, which is absurd.

LEMMA 4.3. *Let Γ be an admissible trajectory arriving at v_0 and associated with a* constant *control u_0. Let us set $Z = X + u_0 Y$ and $\lambda(\delta, P) = \sum_{k\geq 0}((-1)^k\delta^k/k!)\,\mathrm{ad}^k Z(P)(v_0) - Z(v_0)$. Then if Γ is optimal for each $\delta \geq 0$ small and each vector field P of $\{X + uY;\ |u| \leq 1\}$, we must have $\langle n, \lambda(\delta, P)\rangle \leq 0$, where n is the unit normal to N at v_0, outwardly oriented with respect to Γ.*

Proof. We use a technique from the proof of PMP and its refinements [19]. We construct along a reference trajectory, an approximation of the accessibility set. Since the terminal manifold is of codimension one, this approximation *need not be convex* to decide about optimality. The necessary condition of the lemma is obtained as follows.

Let Γ be a reference trajectory defined on $[0,T]$ and with terminal point v_0. If V is a vector field, it is convenient to denote by $\{\exp tV\}$ the local one-parameter group generated by V. In particular the arc Γ starting from v_1 at $t=0$ is given by $\exp tZ(v_1)$ and $\exp TZ(v_1)=v_0$.

Now take δ, $\varepsilon>0$, sufficiently small and any vector field P of $\{X+uY; |u|\leq 1\}$, and consider for δ fixed the curve

$$\alpha(\varepsilon)=(\exp\delta Z)(\exp\varepsilon P)(\exp(T-\delta-\varepsilon)Z)(v_1).$$

By construction $\alpha(0)=v_0$, and $\alpha(\varepsilon)$ lies in the accessibility set $A^+(v_1,T)$. Now since $v_0=\exp TZ(v_1)$ we have

$$\alpha(\varepsilon)=(\exp\delta Z)(\exp\varepsilon P)(\exp(-\delta-\varepsilon)Z)(v_0),$$

and from the Baker–Campbell–Hausdorff formula we have

$$\alpha(\varepsilon)=\left(\exp\left(\varepsilon\left[\sum_{k\geq 0}\frac{(-1)^k\delta^k}{k!}\,\mathrm{ad}^k Z(P)-Z\right]+o(\varepsilon)\right)\right)(v_0).$$

Hence $d\alpha/d\varepsilon_{|\varepsilon=0}=\lambda(\delta,P)$. And clearly, if $\langle n,\lambda(\delta,P)\rangle>0$, the reference trajectory Γ is not optimal.

Assumption 4.4. From now on we shall assume that $\langle n(v_0),Y(v_0)\rangle=0$ and both $\langle n(v_0),X(v_0)\rangle$ and $\langle n(v_0),[X,Y](v_0)\rangle$ are nonzero.

4.4.1. Method of analysis. To evaluate the switching curve and the splitting line near v_0, it is convenient to use the following model.

First, one may set $v_0=(0,0)$, and as in [2], since X and Y are transverse at v_0, one may assume locally that $Y=\frac{\partial}{\partial y}$ and $t\to(t,0)$ is the trajectory corresponding to $u\equiv 0$. Hence (4.1) can be written

$$\begin{aligned}\dot{x}&=1+\textstyle\sum_{i=1}^{+\infty}a_i(x)y^i,\\ \dot{y}&=\textstyle\sum_{i=1}^{+\infty}b_i(x)y^i+u.\end{aligned}\tag{4.2}$$

Moreover if we change y into $-y$ and u into $-u$ if necessary, we can assume that $a=a_1(0)>0$, where $a=-\langle n(0),[X,Y](0)\rangle, n(0)=(1,0)$ being the unit normal to N at 0. The terminal manifold is given locally by $s\to(c(s),s)$, where $c(s)=ks^2+o(s^2)$ and k parametrizes the curvature of N in the adapted coordinate system. At 0, we choose $n(0)=(1,0)$, and for v small, using the convention $\langle n(v),X(v)\rangle>0$, one can set $n=(n_1,n_2), n_1=1$, and $n_2=-\frac{dc}{ds}=-2ks+o(s)$. Hence for s small we have that if $k<0$, then $n_2>0$ if $s>0$ and $n_2<0$ if $s<0$ and conversely if $k>0$. The Hamiltonian at a point (v,n) of $\hat{N}$ is $H(v,n,u)=\langle n,X(v)+uY(v)\rangle$, and for s small, its maximum over $|u|\leq 1$ is obtained as follows: If $k<0$, $s>0$, then $n_2>0$ and u maximizing H is $+1$. If $k<0$, $s<0$, then u maximizing H is -1; the converse is true if $k>0$. Hence we get the following important geometric behaviors. *If $k<0$, the arcs Γ_+ and Γ_- satisfying the transversality conditions, the normal to N being oriented as $n(v)$, can cut themselves, contrary to the case when $k>0$* (Fig. 6).

The adjoint system associated with (4.1), with $p=(p_1,p_2)$, is

$$\dot{p}_1=-p_1\sum_{i=1}^{+\infty}a_i'(x)y^i-p_2\sum_{i=1}^{+\infty}b_i'(x)y^i,\tag{4.3}$$

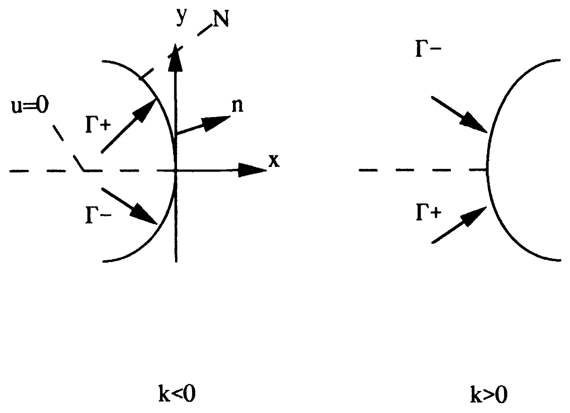

FIG. 6.

$$\dot{p}_2 = -p_1 \sum_{i=1}^{+\infty} a_i(x) y^{i-1} - p_2 \sum_{i=1}^{+\infty} b_i(x) y^{i-1},$$

where a_i' and b_i' are the derivatives with respect to x. *If u is a piecewise analytic control, every solution of* (4.2) *and* (4.3) *satisfying the boundary conditions can be evaluated for small t by analyticity.*

LEMMA 4.5. *Near* 0, *every optimal solution is of the form* $\Gamma_+\Gamma_-$.

Proof. From Lemma 3.14, we know that every BC-extremal is of form $\Gamma_+\Gamma_-$ or $\Gamma_-\Gamma_+$. In fact it follows from [27] that every optimal solution for the point-to- point optimal problem is of this form.

Since X and Y are linearly independent near 0, to compare the times along the solutions of the system we can introduce the one-form ω defined by $\omega(Y) = 0$ and $\omega(X) = 1$. If (X_1, X_2) are the components of X, we have $\omega = (1/X_1)\, dx$ and $d\omega = \frac{1}{X_1^2}\frac{\partial X_1}{\partial y} dx \wedge dy$, and by computing with (4.2), we see that the sign of $d\omega$ near 0 is the sign of $a > 0$. Let $\Gamma_1 = \Gamma_+\Gamma_-$ and $\Gamma_2 = \Gamma_-\Gamma_+$ be two arcs joining v_1 to v_2 near 0 with respective time duration t_1 and t_2. By using Stokes' theorem we have

$$\int_{\Gamma_1} \omega - \int_{\Gamma_2} \omega = t_1 - t_2 = \int_D d\omega,$$

where D is the closed domain limited by $\Gamma_1 \vee -\Gamma_2$. If the orientation is < 0 (resp., > 0), since by $d\omega > 0$ on D we have $t_2 > t_1$ (resp., $t_1 > t_2$). Therefore, optimal solutions for the point-to-point problem are of the form $\Gamma_+\Gamma_-$. Clearly, every solution for the optimal problem with N as terminal manifold has to be solution for the point to point problem.

LEMMA 4.6. *The arc* Γ_-^0 *arriving at* 0 *is not optimal.*

Proof. By computing we have $\langle n(0), [X, Y](0)\rangle = -a < 0$. Hence from Lemma 3.14 the arc Γ_-^0 is not a BC-extremal.

LEMMA 4.7. *Let us assume* $k \neq 0$; *then the switching points of BC-extremals* $\Gamma_+\Gamma_-$ *form an analytic curve* K *whose tangent space at* 0 *is* $\mathbf{R}(-2k/a, 1 + 2k/a)$.

Proof. We integrate (4.2) and (4.3) backward in time, with initial conditions given by the boundary conditions $v(0) \in N$ and $p(0) = n(v(0)) = (1, -2ks + o(s))$. We get $p_1(t) = 1 + 0(s,t)$, $p_2(t) = -2ks - at + o(s,t)$. The switching times w are given by solving

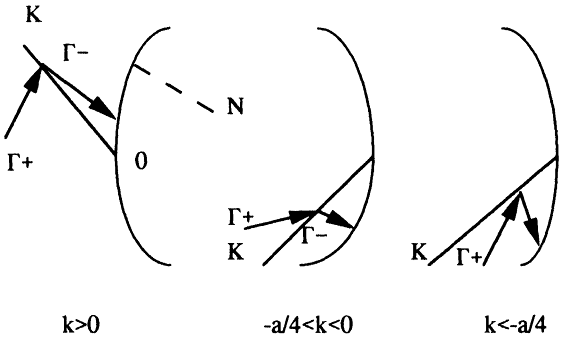

FIG. 7.

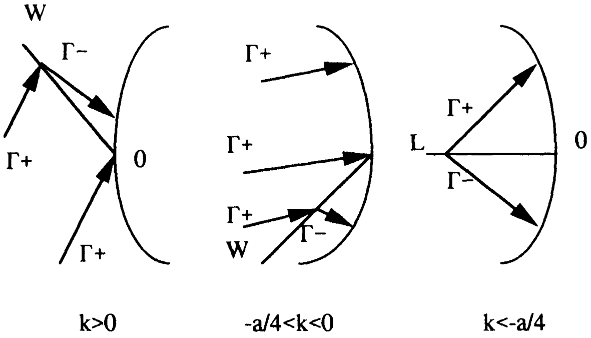

FIG. 8.

$p_2(t) = 0$, $t \leq 0$. We get $w = -2ks/a + o(s)$. If $k < 0$, we must have $s < 0$, and if $k > 0$, $s > 0$, and the BC-extremal Γ_- is switching at $(x(w), y(w)) = s(-2k/a, 1+2k/a)+o(s)$. The lemma is then proved.

Clearly the optimal synthesis depends on the fact that a BC- extremal $\Gamma_+\Gamma_-$ is *crossing* K or *reflecting* on K.

LEMMA 4.8. *A BC-extremal* $\Gamma_+\Gamma_-$ *is crossing* K *if* $k > 0$ *or* $-a/4 < k < 0$, *and it is reflecting on* K *if* $k < -a/4$.

Proof. At 0, the slope of the tangent to K is $-1 - a/2k$, and Γ_+ and Γ_- have (1,1) and $(-1, 1)$ as tangents. If $k > 0$, the slope of the tangent to K is less than -1. If $k < 0, -1 - a/2k > 1$ if and only if $-a/4 < k$. Hence the geometries are given in Fig. 7.

PROPOSITION 4.9. *The optimal syntheses are given by Fig.* 8. *In the first two cases, the switching curve* W *is an analytic curve which coincides with* K, *the slope of the tangent at* 0 *being* $-1 - a/2k$. *In the third case, there exists a splitting line* L *which is an analytic curve on which the optimal feedback can be* ± 1, *the slope of its tangent at* 0 *being* $-a/4k$.

Proof. In the first two cases, the situation is clear because from each point near 0, at the left of the target N, there is only one BC-extremal $\Gamma_+\Gamma_-$. In the third case, the situation is more complicated because more than one BC- extremal $\Gamma_+\Gamma_-$ is possible to reach the target. More precisely, let Γ_+^0 be the extremal arc arriving at 0 and A be the acute sector delimited by K and Γ_+^0. Clearly above K the optimal feedback law is $u = 1$, and below Γ_+^0 it has to be -1. Let us define the splitting line L near 0 as follows. L is the set of $v = (x, y)$, v small, $x < 0$, such that $\exists\, t \geq 0$ such that both $\exp t(X \pm Y)(v)$ intersects N (see Fig. 9).

By construction, near 0, L is an analytic curve which is located in the sector A. Clearly,

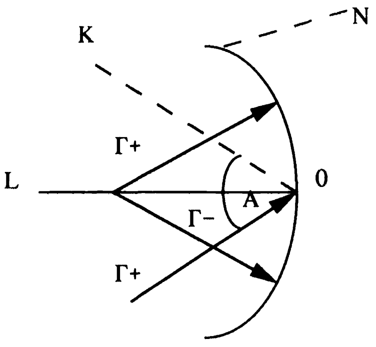

FIG. 9.

above L the optimal feedback is $+1$, and below it is -1.

In fact, everything can be evaluated by using (4.2) and (4.3). If $k + a/4 < 0$, it can be shown that the arc Γ_+^0 is not optimal. Moreover, the slope of the tangent to L at 0 is $-a/4k \in]0, 1[$.

From our analysis we deduce that $\dot{x} = 1 + ay, \dot{y} = u$ is the local model of the behaviors, and the linear approximation of K and L is given by the model.

4.5. Generic fold case. In this section, we shall analyze the situation encountered when a singular extremal satisfying the transversality condition meets the terminal manifold N. In fact, we shall only consider the *hyperbolic situation.* This situation is technically relevant because the analysis is carried on using an *evaluation of the accessibility set.* A complete analysis, which is lengthy, is given in [4].

Assumption 4.10. Let $(p, v_0) \in \hat{N}$, and let us assume $\langle p, Y(v_0)\rangle = \langle p, [X, Y](v_0)\rangle = 0$ and $\langle p, X(v_0)\rangle \neq 0$. Let $S = \{v \in \mathbf{R}^2;\ \det\,(Y(v), [X, Y](v)) = 0\}$. From §3.2, all singular extremals are contained in S, the singular control $\hat{u}$ being given by (3.7), and it is *admissible* if $\hat{u}(v) \in [-1, +1]$. We shall assume that v_0 is a *regular point* of S. Hence, since X and Y are not collinear at v_0, there exists a unique singular arc Γ_s which is a simple curve defined on $[T, 0]$, $T < 0$, with $\Gamma_s(0) = v_0$, which can be lifted into a unique extremal $(\Gamma_s, p, \hat{u})$, where p satisfies $p(0) = p_0$, unit vector transverse to N, and oriented such that $\langle p_0, X(v_0)\rangle > 0$. According to §3.7, (p_0, v_0) is a fold. Let us assume that this is an ordinary point. From §3.7, if $\hat{u}(v_0) \notin]-1, +1[$, it is parabolic, and if $\hat{u}(v_0) \in]-1, +1[$, it can be hyperbolic (hence fast) or elliptic (hence slow). We shall analyze only the hyperbolic case.

4.5.1. Model. We choose an adapted coordinate system such that $v_0 = 0$ and in which the singular arc Γ_s is identified with $t \longrightarrow (t, 0)$. Hence system (4.1) can be written

$$\begin{aligned} \dot{x} &= 1 + a(x)y^2 + o_x(y^2), \\ \dot{y} &= -\hat{u}_{|y=0} + yX_2(v) + u, \end{aligned} \tag{4.4}$$

where $a(0) = \langle n, \mathrm{ad}^2 Y(X)(0)\rangle \neq 0$, with $n(0) = (1, 0)$ unit normal to $N = (ks^2 + o(s^2), s)$. Observe that if $a(0) < 0$ (resp., > 0), the singular arc is hyperbolic (resp., elliptic).

Let $p = (p_1, p_2)$ be the adjoint variable with $p(0) = (1, -2ks + 0(s^2))$ orthogonal to N. By computing with (4.4) and $u = \varepsilon$, $\varepsilon = \pm 1$ we get

$$p_2(t) = -2ks - a(0)(\varepsilon - \hat{u}(0))t^2 + k_1 st + k_2 s^2 + o(s, t)^2, \tag{4.5}$$

where k_1, $k_2 \in \mathbf{R}$ are coefficients which are unimportant for our discussion. Hence, we get the following lemma.

LEMMA 4.11. *In the hyperbolic case, any BC- regular extremal which meets N at a point $v \neq 0$, v small, has no switching if $k \neq 0$.*

Now, let us evaluate the accessibility set near an hyperbolic singular trajectory.

PROPOSITION 4.12. *Let (v, p, u) be a hyperbolic singular extremal defined on $[0, T]$, with $\hat{u}$ given by* (3.7) *belonging to* $]-1, +1[$, *satisfying the assumptions* (H0) – (H3). *Then there exists a neighborhood U of v such that v is the time-optimal trajectory joining $v(0)$ to $v(T)$ among all solutions of* (4.1). *Moreover if U is sufficiently small, the accessibility set $A_U^+(v(0), T)$ near $v(T)$ is a closed convex set with nonempty interior whose boundary is a curve $s \mapsto d(s)$ with $d(0) = v(T)$, $d'(0) \in \mathbf{R}Y(v(T))$, C^2 but not in general C^3. Moreover in every adapted coordinate system its curvature is zero.*

Proof. From [2], since for a planar system a singular extremal satisfying (H0)–(H3) is without conjugate points, v is time minimal among all solutions of $\dot{v} = X + uY$ contained in a sufficiently small neighborhood U and joining $v(0)$ to $v(T)$ with $u \in \mathbf{R}$. Hence it has to be optimal if $|u| \leq 1$. Moreover from [2], [27], we can choose U such that every optimal trajectory starting from $v(0)$ is a singular arc Γ_s followed by Γ_+ or Γ_-. Hence, near $v(T)$, the boundary of $A_u^+(v(0), T)$ is parametrized by $s \mapsto d(s)$, where $s \geq 0$ and

$$d(s) = (\exp s(X \pm Y))(\exp (T - s)\hat{X})(v(0)),$$

with $\hat{X} = X + \hat{u}Y$. Since $v(T) = \exp T\hat{X}\,(v(0))$, we get

$$d(s) = (\exp s(X \pm Y))(\exp -s\hat{X})(v(T)),$$

and by using the Baker–Campbell–Hausdorff formula we have

$$d(s) = \exp \left[s(\pm 1 - \hat{u})Y + \frac{1}{2}s^2[X \pm Y, \hat{X}] + o(s^2) \right] (v(T)).$$

The curve $d(s)$ can be evaluated by using Chen's formula,

$$\exp\, s\,Z(v) = \sum_{n \geq 0} \frac{s^n Z^n}{n!}(\text{id})(v),$$

for s sufficiently small, where Z is any vector field acting by Lie derivative on the mappings and id is the identify mapping. If $Y = \frac{\partial}{\partial y}$, we have $Y^n(\text{id}) = 0$, where $n > 1$, and since along a singular trajectory Y and $[X, Y]$ are collinear we get

$$d(s) = v(T) + [s(\pm 1 - \hat{u}) + o(s)]Y(v(T)) + o(s^2).$$

This proves the assertion.

Higher-order dimensional expansions would tell us the nature of it singularity. For instance, if the system is given by $\dot{x} = 1 - y^2$, $\dot{y} = u$, and $v(0) = (0, 0)$, we get $d(s) = (T - \frac{s^3}{3}, \varepsilon s)$ with $\varepsilon = \pm 1$. Hence the boundary is the graph of $x = T - \frac{|y|y^2}{3}$.

PROPOSITION 4.13. *In the hyperbolic case, if $k \neq 0$, the optimal syntheses are given by Fig.* 10. *Moreover, in the flat case, the synthesis is given by the second case in Fig. 10.*

Proof. Let us assume $k \neq 0$. From Lemma 4.11, any BC-extremal which meets the target N at a point $v \neq v_0$ has no switching point. To decide if the arc Γ_s is optimal, we use the previous proposition. The system can be written as (4.4), and Γ_s identified with $t \rightarrow (t, 0)$. Let $v = (-T, 0)$, $T > 0$, be a point of Γ_s. For U small, the boundary of the accessibility set $A_U^+(v, +T)$ has zero curvature; hence we have two situations (Fig. 11).

In the first situation, N meets the interior of the accessibility set; hence Γ_s is not time optimal for our problem, contrary to the second situation or in the flat case. The syntheses follow. The analysis in the flat case is similar.

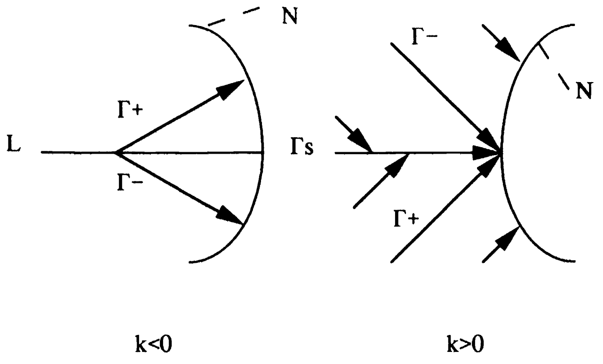

FIG. 10.

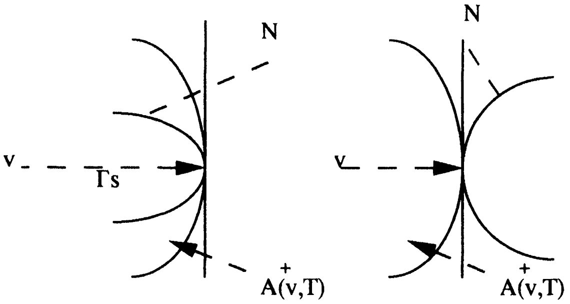

FIG. 11.

4.6. Generic exceptional case. *Assumption* 4.14 *and Normalizations*. Let $v_0 \in N$, and one may assume $v_0 = 0$. Suppose $X + Y$ tangent to N at 0. Moreover assume Y and $X - Y$ not tangent to N at 0. We can choose a coordinate system such that $Y = \frac{\partial}{\partial x}$ and N is identified to the curve $s \mapsto (0, s)$. Hence (4.1) can be written $\dot{x} = X_1 + u$, $\dot{y} = X_2$, with $X_1(0) = -1$ and $X_2(0) \neq 0$. We can suppose $X_2(0) > 0$. Moreover we assume $\frac{\partial X_1}{\partial y}(0) = a \neq 0$, which means that the contact of Γ_+ with N at 0 is one.

PROPOSITION 4.15. *Under the previous normalizations, the optimal synthesis is given by Fig.* 12.

Proof. First assume $a > 0$. The arc Γ_+^0 is a BC-extremal, $n = (1, 0)$ being the associated adjoint variable at 0. To prove that it is not optimal, we apply Lemma 4.3, the outward normal to N with respect to Γ_+^0 being $-n$, $Z = X + Y$, and $P = X - Y$. We get $\lambda(\delta, P) = -2Y(0) + o(1)$. Hence, for small δ, $\langle -n, \lambda(\delta, P)\rangle > 0$. This proves the assertion. Indeed, a simple computation shows the following. Assume that we are at distance ε from N in the domain $x > 0$. The time to reach the target N is of order $\sqrt{\varepsilon}$ along Γ_+^0 and of order ε along Γ_- because the contact of Γ_+^0 with N is one and Γ_- is transverse to N. In the domain $x < 0$, the optimal control is $u = +1$, the value function being not continuous.

When $a < 0$, the analysis is similar, but the target N is not accessible from the points in the sector $x < 0$ above Γ_+^0.

4.7. Generic flat exceptional case. The point $v_0 \in N$ is identified to 0, N to $s \mapsto (0, s)$; Y is assumed to be tangent to N, and X to be tangent to N at 0. Moreover we suppose Y, $X \pm Y$ not vanishing at 0 and $[X, Y]$ not tangent to N at 0. System (4.1) can be written $\dot{x} = ax + by + o(x, y)$, $\dot{y} = X_2 + u$, where $b = -\langle n, [X, Y](0)\rangle \neq 0$, $n = (1, 0)$ normal to N. Clearly, one may assume $a = 0$, $b = 1$, and $1 + X_2(0) > 0$.

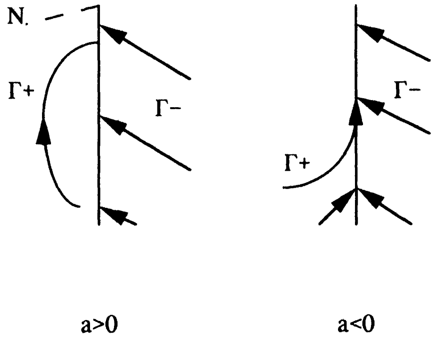

FIG. 12.

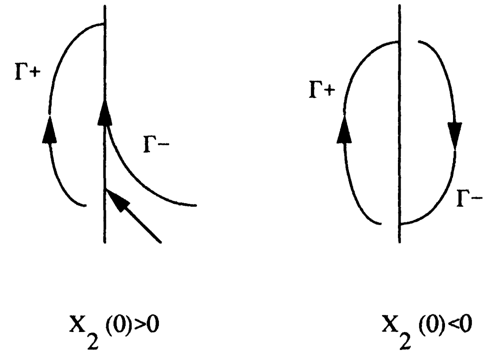

FIG. 13.

PROPOSITION 4.16. *Under the previous normalizations, the optimal synthesis is given by Fig.* 13.

Proof. According to §3.7 $z_0 = (0, n) \in \hat{N}$ is a normal switching point and hence every BC-extremal near z_0 is of the form $\Gamma_+\Gamma_-$ or $\Gamma_-\Gamma_+$. Since $\hat{N}$ is contained in $\langle p, Y\rangle = 0$, all the switching points are concentrated on N. Hence, near 0, every optimal trajectory is of an arc Γ_+ or Γ_-. Then, the synthesis follows from Lemmas 3.14 and 4.3.

5. Conjugate and focal point along a singular extremal.

5.1. Introduction. Consider a control system $\dot{x} = X + uY$ in $\mathbf{R}^n$, $|u| \leq 1$, and the time-optimal control problem for the *fixed end-point problem*. Let γ be an extremal defined on $[0, T]$. *One of the main problems is to compute the first point on γ where the extremal ceases to be minimal.* Such a point is called a *cut point*. In Riemannian geometry, a cut point can be a conjugate point which corresponds to a singularity of the exponential mapping or a point where *two isolated minimizing extremals* meet [15]. Hence, computing the cut locus splits into two problems. The second problem is clearly global, but the computation of conjugate points is *local* and accessible to the analysis when the correct topology has been identified (in fact the C^1-topology). The key tool for this analysis is *Jacobi's equation*. The behavior of the solutions of this equation depends on an invariant called the *sectional curvature*.

In time-optimal control the situation is much more complicated. We have to deal with regular and singular extremals, and the topology has to be chosen carefully. For *regular extremals* the problem has been well studied by Sussmann [27]. The computation of conjugate points along a *singular extremal* satisfying (H0)– (H3) is the object of [2]. The most interesting result is that computing a conjugate point can be done by using the equivalent of Jacobi's equation of the Riemannian case, although this equation is different if the reference extremal is hyperbolic or exceptional. This difference is due to the fact that in the hyperbolic case, an evaluation of the fixed-time accessibility set is sufficient to compute a conjugate point, contrary to the exceptional case, where its dependence with respect to the time has to be studied.

The object of this section is to give a *practical algorithm to compute conjugate and focal points* along a *singular extremal* for the batch reactor problem. For this reason and for the sake of simplicity, we consider only systems in $\mathbf{R}^3$, but our results can be extended to $\mathbf{R}^n$ by using Hamiltonian formalism [21]. A connection with the concept of *optimal synthesis* also is indicated, which is an attempt to *unify* the concept of conjugate point along a regular *and* a singular extremal.

DEFINITION 5.1. *Consider a control system* $\dot{x} = X + uY$, $x \in \mathbf{R}^n$, $u \in \mathbf{R}$, *and let* γ *be a singular extremal defined on* $[0,T]$. *The point* $y = \gamma(t_{1c}), t_{1c} \in [0,T[$ *is said to be the first conjugate point to* $x = \gamma(0)$ *if, for each* C^0*-sufficiently small neighborhood* U *of* γ, γ *is time optimal for all solutions of the system restricted to* U, *with the same initial and terminal conditions, on* $[0,t_{1c}[$ *and no more time optimal on* $[0,t]$ *if* $t > t_{1c}$.

5.2. Notation. From now on, we consider a system of the form

$$\dot{v} = X(v) + uY(v), \tag{5.1}$$

where $v = (x,y,z) \in \mathbf{R}^3$, X and Y being analytic vector fields. Let D =det $(Y,[X,Y],[Y,[X,Y]])$, $D' =$ det $(Y,[X,Y],[X,[X,Y]])$, and $D'' =$ det $(Y,[X,Y],X)$. Let us assume that D is not identically 0, and let us denote by $\hat{S}$ the vector field given on $\mathbf{R}^3\backslash\{D=0\}$ by $X - (D'/D)Y$.

LEMMA 5.2. *The singular trajectories satisfying* (H0)–(H3) *are contained in* $\mathbf{R}^3\backslash\{D=0\}$ *and are the nonperiodic solutions of the analytic differential equation* $\dot{v} = \hat{S}(v)$. *The sets* $D''=0$, $DD''>0$, *and* $DD''<0$ *are invariant sets for the solutions of this equation. The hyperbolic* (*resp., elliptic, exceptional*) *trajectories are the solutions contained in* $DD''>0$ (*resp.*, $DD''<0, D''=0$).

Proof. The proof follows from the results of §3.2. A singular extremal has to satisfy the constraints $\langle p, Y(v)\rangle = \langle p,[X,Y](v)\rangle = 0$, and the singular control is given by the dynamic feedback $\hat{u}(v,p)$ defined by (3.7). Now, on $D\backslash\{0\}$, Y and $[X,Y]$ are linearly independent, and since $p \in \mathbf{R}^3\backslash\{0\}$, the feedback $\hat{u}$ is independent of p and is clearly $\hat{u}(v) = -\frac{D'(v)}{D(v)}$.

From Definition 3.3, an exceptional singular trajectory corresponds to a zero energy level, $H=0$. This property is invariant for the singular flow, and for trajectories in $\mathbf{R}^3\backslash\{D=0\}$ it projects onto the set $D''=0$ which contains the exceptional extremals. The lemma is then proved.

5.3. First method of computing conjugate points.

5.3.1. Preliminaries. We briefly recall the method given in [2] to compute conjugate points along a reference singular extremal satisfying (H0)–(H3) in the *hyperbolic* and *exceptional* cases. (In the elliptic case, the trajectory is time *maximizing*, and according to our definition the conjugate point to $\gamma(0)$ is $\gamma(0)$ itself.) We use the fact that the optimality status of γ for (5.1) (no a priori bound is imposed on u) is left invariant under the action of the *feedback group* [1]. Hence, applying to the system a well-defined change of coordinates and a feedback law, we can transform the system near γ into the following systems.

In the *exceptional case*

$$(1+y)\frac{\partial}{\partial x} + u\frac{\partial}{\partial y} + a(t)y^2\frac{\partial}{\partial z} + R(v), \tag{5.2}$$

where $a > 0$ on $[0, T]$, and in the *hyperbolic case*

$$L(t, y, z)\frac{\partial}{\partial x} + z\frac{\partial}{\partial y} + u\frac{\partial}{\partial z} + R(v), \tag{5.3}$$

where L is the quadratic form $a(t)z^2 + 2b(t)yz + c(t)z^2$ and $a < 0$ on $[0, T]$. In both cases the reference trajectory γ is identified to $t \longrightarrow (t, 0, 0)$ and corresponds to the zero control. The remaining terms R are given in [2] and can be neglected to analyze the optimality of γ with respect to all C^0-neighboring trajectories, and R will be supposed to be zero. The corresponding systems are called *models*.

Now, observe that for the models *the input-state mapping* $u(.) \longrightarrow v(t, v_0, u)$, where $v(t, v_0, u)$ is the solution associated with u such that $v(0) = v_0$, *can be explicitly computed*, and the optimality of γ is analyzed as follows.

Fact 5.3. By definition, $\gamma : t \longrightarrow (t, 0, 0)$ is time optimal on $[0, T]$ if $\forall\, t \in]0, T[$, $(t, 0, 0)$ is not accessible from (0,0,0) in a time $t' < t$.

Hence, let $v(t) = (t, 0, 0) + \varphi(t)$, with $\varphi = (\varphi_1, \varphi_2, \varphi_3)$, be a solution of one of the models (5.2) or (5.3); then φ is a solution of

$$\dot\varphi_1 = \varphi_2, \quad \dot\varphi_2 = u, \quad \dot\varphi_3 = a(t)\varphi_2^2 \tag*{(5.2)$'$}$$

or

$$\dot\varphi_1 = L(t, \varphi_2, \varphi_3), \quad \dot\varphi_2 = \varphi_3, \quad \dot\varphi_3 = u. \tag*{(5.3)$'$}$$

Fact 5.4. In the exceptional case, $\gamma : t \longrightarrow (t, 0, 0)$ is time optimal. Indeed, let $0 < t' < t$, and if $v(t') = (t, 0, 0)$, v being the solution of (5.2), we get $\varphi_3(t') = \int_0^{t'} a(s)\varphi_2^2(s)\, ds = 0$. Since $a > 0$, this implies $\varphi_2 \equiv 0$ on $[0, t']$.

Fact 5.5. In the hyperbolic case, the condition $v(t') = (t, 0, 0)$ implies $\varphi_2(t') = \varphi_3(t') = 0$, and clearly γ is time optimal on $[0, T]$ if and only if the functional

$$J(t) = \int_0^t (a(s)\varphi_3^2 + 2b(s)\varphi_2\varphi_3 + c(s)\varphi_2^2)\, ds \tag{5.4}$$

satisfies $J(t) \le 0\, \forall\, t \in]0, T]$ when evaluated on the set of curves φ_2, φ_3 solutions of the equations $\dot\varphi_2 = \varphi_3$, $\dot\varphi_3 = u$ with boundary conditions $\varphi_2(0) = \varphi_3(0) = \varphi_2(t) = \varphi_3(t) = 0$.

Now, from [2], since $u \in \mathbf{R}$, the variable φ_3 can be taken as the control (see the concept of *reduced system* introduced in Definition 3.6), and we have to study the sign of J on the set $\mathcal{C}$ of nontrivial smooth curves φ_2, with $\dot\varphi_2 = \varphi_3$ (control) and satisfying boundary conditions $\varphi_2(0) = \varphi_2(t) = 0$. (The constraints on φ_3 have been relaxed.)

5.3.2. Notation. Let t_{1c} be the first time $0 < t \le T$ such that the maximum of $J(t)$ on $\mathcal{C}$ is zero.

According to classical calculus of variations we have the following lemma (see [9]).

LEMMA 5.6. *If $t < t_{1c}$, then $J(t) < 0$ on $\mathcal{C}$, and if $t > t_{1c}$, then $J(t)$ takes positive and negative values.*

In other words, t_{1c} is the time t such that γ is time optimal on $[0, t]$ if $t < t_{1c}$ and no more optimal if $t > t_{1c}$. Hence $\gamma(t_{1c})$ is the conjugate point to $\gamma(0)$. Now, from [9], the computation of t_{1c} is straightforward.

LEMMA 5.7. *The time t_{1c} is the first time t such that there exists a nontrivial solution φ_2 for Euler–Lagrange equation*

$$\frac{d}{dt}\left(\frac{\partial L}{\partial \dot\varphi_2}\right) - \frac{\partial L}{\partial \varphi_2} = 0, \quad \textit{with}\, \varphi_2(0) = \varphi_2(t) = 0 \tag{5.5}$$

and

$$L(t,\varphi_2,\dot\varphi_2) = a(t)\dot\varphi_2^2 + 2b(t)\varphi_2\dot\varphi_2 + c(t)\varphi_2^2.$$

Conclusion 5.8. Consider system (5.1), $u \in \mathbf{R}$, and let γ be a singular trajectory satisfying (H0)–(H3). Then we have the following:

(i) If γ is elliptic, then γ is not time optimal. (In fact, it corresponds to a slow displacement direction.)
