EXPONENTIAL STABILITY OF COUPLED BEAMS WITH DISSIPATIVE JOINTS: A FREQUENCY DOMAIN APPROACH*

RICHARD REBARBER[†]

Abstract. Two examples of coupled Euler–Bernoulli beams with a dissipative joint are considered. The joint placements that lead to exponential stability for these systems are characterized. The technique used shows input-output stability of a related controlled, observed system, and then shows that in these examples, input-output stability implies exponential stability. In the first example, the energy dissipation arises from a discontinuity in the shear at the joint. In the second example, the energy dissipation arises from a discontinuity in the bending moment at the joint. The analysis of this system involves a complete spectrum analysis of the zero dynamics of the associated controlled, observed system.

Key words. exponential stability, beam equation, transfer function, input-output stability, dissipative joints

AMS subject classifications. 93, 93C20, 93D15

1. Introduction.

In this paper we discuss the exponential stability of two beams coupled in a dissipative joint. The problem addressed here has been posed by Chen et al. [3], and systems of this form have been discussed in detail by Chen et al. [5]. In [5] asymptotic formulas for the eigenvalues of such systems are given, and the eigenvalue placement suggests that some of these systems are exponentially stable. Further spectrum analysis for coupled beams has been done by Conrad [6]. It is well known, however, that distributed parameter systems do not necessarily have spectrum-determined growth. There are examples in Zabczyk [25] and Huang [11], among others, where the resolvent set of a generator A of a C_0-semigroup $S(t)$ contains $\mathbf{C}_\alpha^+ = \{z \in \mathbf{C} \,|\, \mathrm{Re}(z) > \alpha\}$ for $\alpha < 0$, but $S(t)$ has positive exponential growth. Although there are several classes of systems that do have spectrum-determined growth, there is no reason to expect that the boundary feedback systems considered in [5] have this property.

A useful way to show that $S(t)$ is exponentially stable has been given in [11] (or independently, Prüss [14]). If $S(t)$ is a bounded semigroup, if $R(\lambda, A)$, and if the resolvent of A satisfies

$$\sup_{\omega \in \mathbf{R}} \|R(i\omega, A)\| < M \tag{1.1}$$

for some M, then $S(t)$ is exponentially stable. This condition has been used to prove exponential stability for mechanical systems by Chen et al. [4], Liu [12], and Liu, Huang, and Chen [13].

For the systems under consideration in this paper, we show that the resolvent is bounded on the imaginary axis by first showing that a transfer function for a related controlled, observed system is bounded on the imaginary axis. This shows that the related system is *input-output stable*, and we then apply a result in Rebarber [16] to show that in this case input-output stability implies exponential stability. We describe this approach in detail in §2.

We assume that one of the beams has spatial extent from $s = 0$ to $s = s_1$ and that the other beam has extent from $s = s_1$ to $s = 1$. In [5] the eigenvalues are only computed for the joint in the middle of the span, but the results in this paper are for general s_1. We assume that both are uniform Euler–Bernoulli beams with the same mass density per unit length m and the same flexural rigidity EI. We normalize so that $EI/m = 1$. This last assumption is not necessary for our work, but it makes the calculations a bit simpler. Let $w(s, t)$ be the displacement of

the coupled beams at position $s \in [0,1]$ and time $t \in [0,\infty]$. The notation $\dot{w}(t,s)$ denotes the derivative of $w(s,t)$ with respect to time, and D denotes the spatial differentiation operator. Then w satisfies the following Euler–Bernoulli equation in both beams:

$$\ddot{w}(s,t) + D^4 w(s,t) = 0, \qquad s \in (0,s_1) \cup (s_1,1). \tag{1.2}$$

The energy of this system is given by

$$E(w(\cdot,t)) = \int_0^1 \{\dot{w}^2(s,t) + (D^2 w(s,t))^2\} ds.$$

We consider two sets of boundary and joint conditions. In both cases the energy of the system can be shown to dissipate, that is $(d/dt)E(t) \leq 0$; this is done in [5] when the beams are of equal length, and the argument can be easily modified for general s_1. The goal of this paper is to characterize those joint placements for which the energy decay is in fact exponential. We say that the system (1.2) with various boundary conditions is exponentially stable if there exists $M > 0$ and $\alpha > 0$ such that $|E(w(\cdot,t))| \leq Me^{-\alpha t}|E(w(\cdot,0))|$.

Let $w(s_1^-,t)$ be the limit of $w(s,t)$ as $x \longrightarrow s_1$ from the left and $w(s_1^+,t)$ be the limit of $w(s,t)$ as $x \longrightarrow s_1$ from the right. The two cases we consider are as follows.

Case 1. In this case the end at $s = 0$ is simply supported, and at $s = 1$ there is a shear hinge end. The dissipative joint condition at s_1 is a rigid support joint where the discontinuity in the shear is proportional to the velocity at s_1. See [3] for a discussion of the joint and end conditions for coupled beams. The boundary and joint conditions are then given by

$$\begin{aligned} w(0,t) &= D^2 w(0,t) = 0, \\ Dw(1,t) &= D^3 w(1,t) = 0, \\ w(s_1^-,t) &= w(s_1^+,t), \\ Dw(s_1^-,t) &= Dw(s_1^+,t), \\ D^2 w(s_1^-,t) &= D^2 w(s_1^+,t), \end{aligned} \tag{1.3}$$

$$D^3 w(s_1^+,t) - D^3 w(s_1^-,t) = -k\dot{w}(s_1,t), \tag{1.4}$$

where $k > 0$. In (1.4) we are assuming that $\dot{w}(s_1^-,t) = \dot{w}(s_1^+,t)$, which follows from the third equation in (1.3) when $\dot{w}(\cdot,t)$ is in $H^1[0,1]$.

The following theorem states our conclusions about the exponential stability of (1.2), (1.3), (1.4).

THEOREM 1.1. *The system described by the coupled beam equations* (1.2), (1.3), (1.4) *is exponentially stable if and only if s_1 is a rational number with coprime factorization*

$$s_1 = \frac{p}{q}, \quad \textit{where } p \textit{ is odd.} \tag{1.5}$$

Remark 1.2. The proof of this theorem, which is given in §2, is easily modified if the end conditions (the first two equations in (1.3)) are changed. However, the proof of Theorem 1.1 is very dependent on the form of the feedback (1.4). This is because the system in Case 1 is *regular* in the sense given in Weiss [22]–[24]. This will be made precise in §2. The system in Case 2 below is quite a bit more difficult to handle, because the natural associated controlled, observed system is not regular, or even well posed.

Case 2. Both ends are simply supported in this case. The dissipative joint condition at s_1 is an angle guide (see [3]), where the discontinuity in the bending moment is proportional to the angular velocity at s_1. The boundary and joint conditions are then given by

$$\begin{aligned} w(0,t) &= D^2w(0,t) = 0,\\ w(1,t) &= D^2w(1,t) = 0,\\ w(s_1^-,t) &= w(s_1^+,t),\\ Dw(s_1^-,t) &= Dw(s_1^+,t),\\ D^3w(s_1^-,t) &= D^3w(s_1^+,t), \end{aligned} \tag{1.6}$$

$$D^2w(s_1^-,t) - D^2w(s_1^+,t) = -\hat{k}\, D\dot{w}(s_1,t), \tag{1.7}$$

where $\hat{k} > 0$. In (1.7) we are assuming that $D\dot{w}(s_1^-,t) = D\dot{w}(s_1^+,t)$, which follows from (1.6) if $\dot{w}(\cdot,t)$ is in $H^2[0,1]$.

The following theorem states our conclusions about the exponential stability of (1.2), (1.6), (1.7).

THEOREM 1.3. *The system described by the coupled beam equations* (1.2), (1.6), (1.7) *is exponentially stable if and only if* s_1 *is a rational number with coprime factorization*

$$s_1 = \frac{p}{q}, \quad \text{where } q \text{ is odd.} \tag{1.8}$$

Conditions (1.5) and (1.8) indicate that exponential stability of coupled beams is highly nonrobust with respect to the placement of the joint. Conditions analogous to (1.5) and (1.8) for coupled wave equations can be found in Theorems 4.3 and 4.4 in [12]. Section 2 is devoted to the proof of Theorem 1.1, whereas Theorem 1.3 is proved in §3.

Remark 1.4. To prove Theorem 1.3 we follow the same general approach as in the proof of Theorem 1.1. However, before we apply this approach, we need to do a careful eigenvalue-eigenvector analysis of a "nonstandard" generator, defined in §3. This approach should work if the end conditions (the first two equations in (1.6)) are changed, but the eigenvalue-eigenvector analysis might be more difficult.

2. Proof of Theorem 1.1. We need to put (1.2), (1.3), (1.4) into a standard state-space form. It is important to be very precise about the state-space formulation, because the proof of exponential stability is systems theoretic in nature, rather than being motivated by classical partial differential equations techniques such as multiplier methods. For any $n \in \mathbf{Z}^+$, let $H^n[0,1]$ be the space of all functions f such that $f, Df, D^2f, \ldots, D^{n-1}f$ are absolutely continuous and in $L^2[0,1]$, and D^nf is in $L^2[0,1]$. Let the state space be

$$X = \{[x_1,x_2]^T \in H^2[0,1] \oplus L^2[0,1] \mid x_1(0) = Dx_1(1) = 0\}.$$

Then X is a Hilbert space with the inner product

$$\langle [x_1,x_2]^T, [y_1,y_2]^T \rangle = \int_0^1 \{D^2x_1(s)\overline{D^2y_1(s)} + x_2(s)\overline{y_2(s)}\}ds. \tag{2.1}$$

Let the operator A be defined on X by

$$A\begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} O & I \\ -D^4 & 0 \end{bmatrix}\begin{bmatrix} x_1 \\ x_2 \end{bmatrix} \tag{2.2}$$

with domain

$$\begin{aligned} \mathcal{D}(A) = \{[x_1,x_2]^T \in H^4[0,1] \oplus H^2[0,1] \mid x_1(0) = Dx_1(1)\\ = D^2x_1(0) = D^3x_1(1) = x_2(0) = Dx_2(1) = 0\}. \end{aligned}$$

For any $k \in \mathbf{Z}^+$, let

$$\omega_k = -\pi/2 + \pi k, \quad \lambda_{\pm k} = \pm i\omega_k^2, \quad \phi_k(s) = \sin(\omega_k s). \tag{2.3}$$

Let the index set I henceforth deote $\{\dots, -n, -(n-1), \dots, -1, 1, \dots, n, n+1, \dots\}$. It is easy to see that $\{\lambda_k\}_{k\in I}$ are the eigenvalues of A with associated eigenvectors

$$\Phi_{\pm k} = \frac{1}{\sqrt{2}} \begin{bmatrix} \phi_k/\lambda_{\pm k} \\ \phi_k \end{bmatrix}.$$

It is also easy to see tht A^*, the adjoint of A, is equal to $-A$ (in other words A is skew adjoint) and that $\{\Phi_k\}_{k\in I}$ is an orthonormal basis of X.

We need to identify the appropriate input operator for the control system (1.2), (1.3),

$$D^3 w(s_1^+, t) - D^3 w(s_1^-, t) = u(t), \tag{2.4}$$

where $u \in L^2_{\mathrm{loc}}[0, \infty)$. We follow the approach introduced by Ho and Russell in [9]. To that end let $\hat{A}$ be the extension of A with domain

$$\begin{aligned} \mathcal{D}(\hat{A}) = \{&[x_1, x_2]^T \in X \mid x_1|_{[0,s_1)} \in H^4[0, s_1),\ x_2|_{(s_1,1]} \in H^4(s_1, 1], \\ &x_2 \in H^2[0,1],\ D^2x_1(0) = D^3x_1(1) = x_2(0) = Dx_2(1) = 0, \\ &D^2x_1(s_1^-) = D^2x_1(s_1^+)\}. \end{aligned} \tag{2.5}$$

Let $x = [x_1, x_2]^T \in \mathcal{D}(\hat{A})$ and $v = [v_1, v_2]^T \in \mathcal{D}(A^*) = \mathcal{D}(A)$. Using integration by parts we find that

$$\langle \hat{A}x, v\rangle = \langle x, -Av\rangle + [D^3x_1(s_1^+) - D^3x_1(s_1^-)]\overline{v_2(s_1)}. \tag{2.6}$$

Let

$$B = \begin{bmatrix} 0 \\ \delta(\cdot - s_1) \end{bmatrix}.$$

Then B is not an element of X, but it is easy to check that B is in the larger space $X_{-1} = (\mathcal{D}(A^*))'$, the dual space of $\mathcal{D}(A)$. The notation X_{-1} is used in Weiss [21] and is motivated by the fact that if X is a Hilbert space, X_{-1} is the closure of X in the norm $\|(\lambda - A)^{-1}x\|$ for any λ in the resolvent set of A.

We also need to define another extension of A. Let $\tilde{A} : X \to X_{-1}$ be defined by

$$\langle \tilde{A}x, v\rangle = \langle x, A^*v\rangle \quad \text{for all } v \in \mathcal{D}(A^*), \tag{2.7}$$

with $\mathcal{D}(\tilde{A}) = X$. Because $\tilde{A}$ is a standard extension for A, we refer to both A and its extension $\tilde{A}$ as A whenever no confusion will arise. It follows from (2.6) that for $x \in \mathcal{D}(\hat{A})$,

$$\hat{A}x = \tilde{A}x + [D^3x_1(s_1^+) - D^3x_1(s_1^-)]B \tag{2.8}$$

in X_{-1}.

If $w(s,t)$ satisfies (1.2), (1.3), and $x(t) = [w(\cdot,t), \dot{w}(\cdot,t)]^T$, then $\dot{x}(t) = \hat{A}x(t)$. Now suppose that we further insist that $w(s,t)$ satisfy (2.4). Then it follows from (2.8) that $\hat{A}x(t) = \tilde{A}x(t) + Bu(t)$ in X_{-1}. From the above discussion, we see that our state-space equation for (1.2), (1.3), (2.4) is

$$\dot{x}(t) = Ax(t) + Bu(t), \tag{2.9}$$

where we look for generalized solutions $x(t) \in X$ such that (2.0) is true in X_{-1}.

Consider now the observation for (1.2), (1.3), (2.4) given by

$$y(t) = \dot{w}(s_1, t). \tag{2.10}$$

The observed system (1.2), (1.3), (1.4) with $k = 0$, and (2.10) is then equivalent to $\dot{x}(t) = Ax(t)$ with

$$y(t) = B^* x(t), \tag{2.11}$$

where

$$B^* \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = x_2(s_1), \qquad \mathcal{D}(B^*) = \mathcal{D}(A).$$

As is typical for colocated sensing and control, the output operator is the dual of the input operator.

For some purposes it is convenient to represent (2.9), (2.11) as a diagonal system in the basis $\{\Phi_k\}_{k\in I}$. In this basis A can be represented as the diagonal matrix $\text{diag}[\lambda_k]_{k\in I}$, and B can be represented by the column vector $[b_k]^T_{k\in I}$, where

$$b_k = B^*\Phi_k = (1/\sqrt{2})\ \sin((\pi/2 + \pi k)s_1). \tag{2.12}$$

In a general setting, letting U be a Hilbert space, we say that $B \in \mathcal{B}(U, X_{-1})$ is an *admissible* input operator for $S(t)$ if there exists t_1, $\alpha > 0$ such that for every $u \in L^2[(0, t_1); U]$,

$$\left\| \int_0^{t_1} S(t-\tau)Bu(\tau)d\tau \right\|_X \leq \alpha \|u\|_{L^2[(0,t_1);U]}.$$

Because $\{b_k\}_{k\in I}$ is a bounded sequence, it is easy to use the Carleson measure theorem, as in Ho and Russell [9] or Weiss [20], to show that in our case $B \in \mathcal{B}(\mathbf{R}, X_{-1})$ is an admissible input operator for $S(t)$.

In a general setting, letting Y be a Hilbert space, we say that $C \in \mathcal{B}(\mathcal{D}(A), Y)$ is an admissible observation operator for $S(t)$ if there exists $\alpha > 0$ such that for every $x \in \mathcal{D}(A)$,

$$\|CS(t)x\|_Y \leq \alpha\|x\|_X.$$

In our case, letting $Y = \mathbf{R}$, it follows by duality that B^* is an admissible observation operator for $S(t)$.

We are of course interested in the feedback system (1.2), (1.3), (1.4). This system is equivalent to $\dot{x}(t) = A_k x(t)$, where A_k is given by the matrix (2.2) with domain

$$\mathcal{D}(A_k) = \{[x_1, x_2]^T \in \mathcal{D}(\hat{A}) \mid D^3x_1(s_1^+) - D^3x_1(s_1^-) = -kx_2(s_1)\}$$

(cf. (2.5)).

It follows from the Lumer–Phillips theorem and an easy generalization of [5, eq. (1.4)] that A_k is a dissipative operator that generates a C_0-semigroup of contractions $S_k(t)$ on X. If we can show that $S_k(t)$ is exponentially stable, then (1.2), (1.3), (1.4) is exponentially stable in the sense discussed in §1. For our subsequent development we need that $A_k = A - kBB_L^*$, where B_L^* is the Lebesque extension of B^* defined by

$$B_L^* x = \lim_{\tau\to 0} \frac{1}{\tau} \int_0^t B^*S(t)x\,dt, \tag{2.13}$$

defined on the set $\mathcal{D}(B_L^*)$ of all $x \in X$ such that the limit on the right side exists in X (see Weiss [19], [23]). The proof of this appears in Lemma 2.6.

We now describe the approach we use to show that A_k generates an exponentially stable semigroup. Because A_k is dissipative, it suffices to show that $R(\lambda, A_k)$ is bounded on the imaginary axis as in (1.1). To do this, we consider the controlled, observed system for A_k given by (1.2), (1.3), and (2.10) with

$$D^3w(s_1^+,t) - D^3w(s_1^-,t) + k\dot{w}(s_1,t) = u(t). \tag{2.14}$$

It is easy to show that (1.2), (1.3), (2.14) is equivalent to

$$\dot{x}(t) = A_k x(t) + Bu(t) \tag{2.15}$$

in the same way that (2.9) was obtained.

In a general setting we denote the controlled, observed system

$$\dot{x}(t) = Ax(t) + Bu(t),$$

$$y(t) = Cx(t)$$

by (C, A, B). As this system is written now, it may be that the solution $x(t)$ of the first equation is not in $\mathcal{D}(C)$, so we need to put conditions on the system so that the mapping from the input to the output is continuous.

DEFINITION 2.1. *Suppose A is the generator of a C_0-semigroup $S(t)$, $B \in \mathcal{B}(U, X_{-1})$, and $C \in \mathcal{B}(\mathcal{D}(A), U)$. Then (C, A, B) is regular if*

(1) *B is an admissible input operator for $S(t)$,*
(2) *C is an admissible observation operator for $S(t)$,*
(3) *the range of $R(\lambda, A)B$ is in $\mathcal{D}(C_L)$ (see (2.13)) for some $\lambda \in \rho(A)$,*
(4) *$C_L R(\lambda, A)B$ is bounded in the half plane $\mathbf{C}_\alpha^+$ for some $\alpha \in \mathbf{R}$.*

For a regular system it would be more precise to replace the observation $y(t) = Cx(t)$ with $y(t) = C_L x(t)$, because the solution of the controlled solution $x(t)$ is in the domain of C_L (see [23]).

Recall that the transfer function $\mathbf{H}$ of a controlled, observed system is that function for which $\hat{y}(\lambda) = \mathbf{H}(\lambda)\hat{u}(\lambda)$, where $\hat{y}$ denotes the Laplace transform of y. Let H_α^∞ be the space of all bounded and analytic complex functions on $\mathbf{C}_\alpha^+$. H_α^∞ is a Banach space with the supremum norm. For a regular system (C, A, B), it is shown in [23] that the transfer function is given by $\mathbf{H}(\lambda) = C_L R(\lambda, A)B$ and $\mathbf{H}(\lambda)$ has a strong limit of $D = 0$ as $\lambda \to \infty$ along the positive real axis.

This definition is a special case of the definition of regular system given in Weiss [23] because we are assuming here that the feedthrough operator D is 0. In this paper, if a system is given by the abstract triple (C, A, B), then we assume that the feedthrough is 0. However, when the system is given by a partial differential equation with boundary control and observation, if we wish to describe it by the abstract triple, we need to verify that the feedthrough $\lim_{\lambda \to +\infty, \lambda \in \mathbf{R}} \mathbf{H}(\lambda) = D$ is zero. Therefore, we do not describe the system (1.2), (1.3), (2.10), (2.14) as an abstract triple until we verify that the feedthrough is indeed 0.

We would like to consider the closed-loop system obtained by closing the loop in $\dot{x}(t) = Ax(t) + Bu(t)$, $y(t) = Cx(t)$ with $y(t) = Ju(t)$, where $J \in \mathcal{B}(U)$. When B and C are both unbounded, the closed-loop system is not necessarily well posed, and it is not guaranteed that the closed-loop operator $A + BJC$ generates a strongly continuous semigroup. Therefore, we need to be precise about when such a feedback leads to a well-posed system. In Weiss [24] the following definition of admissible feedback is introduced. The notation H_∞^∞ is used to denote the set $\cup_{\alpha \in R} H^{\infty}_{\alpha}$, or, more precisely, the vector space of equivalence classes of elements in this set, where two functions are in the same equivalence class if one is a restriction of the other.

DEFINITION 2.2. *$J \in \mathcal{B}(U)$ is an admissible feedback for* $\mathbf{H}$, *or equivalently, for (C, A, B), if $(I - J\mathbf{H})$ is invertible in H^{∞}_{∞}.*

It is shown in [24, Thm. 6.6] that if J is an admissible feedback for a regular system (C, A, B), then the closed-loop generator obtained by letting $u(t) = Jy(t)$ is $A + BJC_L$, interpreted as follows. For $x \in \mathcal{D}(C_L)$, $\tilde{A}x + BJC_Lx$ can be evaluated in X_{-1}. Then $\mathcal{D}(A + BJC_L) = \{x \in \mathcal{D}(C_L) \mid \tilde{A}x + BJC_Lx \in X\}$. For a related result, see Salamon [18, Thms. 4.2 and 4.3].

To apply Theorem 2.5, stated below, to our system we need to show that it is *stabilizable* and *detectable*, as defined in Rebarber [16]. These definitions, which we now give, are nonstandard, but are more general than the more standard definitions (see, for example, Curtain [7]); this is because the stabilizing operator F and the detecting operator K are allowed to be unbounded.

DEFINITION 2.3. *(A, B) is stabilizable if there exists $F \in \mathcal{B}(X_1, U)$ such that (F, A, B) is regular, the identity I is an admissible feedback operator for (F, A, B), and $A + BF_L$ is the generator of an exponentially stable semigroup on X.*

DEFINITION 2.4. *(C, A) is detectable if there exists $K \in \mathcal{B}(U, X_{-1})$ such that (C, A, K) is regular, I is an admissible feedback for (C, A, K), and $A + KC_L$ is the generator of an exponentially stable semigroup on X.*

The following theorem from [16] is used to verify that $R(\lambda, A_k)$ is bounded on the imaginary axis.

THEOREM 2.5. *Suppose that (C, A, B) is a regular system with transfer function* $\mathbf{H}(\lambda)$, *(A, B) is stabilizable, and (C, A) is detectable. If* $\mathbf{H}(\lambda)$ *is bounded on the imaginary axis, then so is $R(\lambda, A)$.*

A controlled, observed system is said to be input-output (or externally) stable if its transfer function is bounded on $\mathbf{C}^{+}_{0}$. Hence, Theorem 2.5 gives conditions under which input-output stability implies exponential stability. To apply this theorem we break the work into several lemmas. In Lemma 2.6 it is shown that $A_k = A - BB^*_L$, and that the feedthrough for the system (1.2), (1.3), (2.10), (2.14) is 0, so the system can be represented by (B^*_L, A_k, B), where B^*_L is interpreted as the restriction of B^*_L to the domain of A_k. It is also shown in Lemma 2.6 that (B^*_L, A_k, B) is a regular system. In Lemma 2.8 we show that the transfer function $\mathbf{H}_k(\lambda)$ for (B^*, A_k, B) is bounded on the imaginary axis. In Lemma 2.10 we show that (A_k, B) is stabilizable and (B^*, A_k) is detectable when condition (1.5) holds. Putting this together with Lemma 2.6 and Theorem 2.5 shows that (1.5) is a sufficient condition for A_k to generate an exponentially stable semigroup. In Lemma 2.12 it is shown that (1.5) is a necessary condition for A_k to generate an exponentially stable semigroup.

LEMMA 2.6. (1) *The feedthrough for the system* (1.2), (1.3), (2.10), (2.14) *is* 0.

(2) *(B^*_L, A_k, B) is regular.*

(3) *$A_k = A - kBB^*_L$.*

Proof. We first show that the system (1.2), (1.3), (2.4), (2.10) is regular. We have already shown that B and B^* are admissible for $S(t)$. We can obtain the formula for $B^*_L R(\lambda, A)B$ by using the matrix representations of A and B in the basis $\{\Phi_k\}_{k \in I}$. Because B can be represented by

$$B = \sum_{k \in I} b_k \Phi_k,$$

(c.f. (2.12)), $R(\lambda, A)B$ can be represented by

$$R(\lambda, A)B = \sum_{k \in I} \frac{b_k}{\lambda - \lambda_k} \Phi_k. \tag{2.16}$$

To check whether $R(\lambda, A)B$ is in the domain of B_L^*, note that the right side of (2.13) is, with $x = R(\lambda, A)B$,

$$B_L^* R(\lambda, A)B = \lim_{\tau \to 0} \frac{1}{\tau} \int_0^\tau \sum_{k \in I} \frac{e^{\lambda_k t} |b_k|^2}{\lambda - \lambda_k} \, dt = \sum_{k \in I} \frac{|b_k|^2}{\lambda - \lambda_k}, \tag{2.17}$$

where the second inequality requires simple applications of Fubini's theorem and the dominated convergence theorem. It is clear that this converges for any $\lambda \neq \lambda_k$.

The proof of the following result is straightfoward but very technical, and is found in the Appendix. □

THEOREM 2.7. *Suppose* $\lambda_{\pm k} = \pm i\omega_k^2$ *for* $k \in \mathbf{Z}^+$, *where* $\omega_k \geq 0$ *and satisfies, for some real numbers* m, a, *and* b,

$$mk + b \leq \omega_k \leq mk + a. \tag{2.18}$$

Let

$$\mathbf{H}(\lambda) = \sum_{k \in I} \frac{d_k}{\lambda - \lambda_k},$$

where $\{d_k\} \in l^\infty$. *Then* $\mathbf{H} \in H_\alpha^\infty$ *for every* $\alpha > 0$, *and*

$$\lim_{\alpha \to \infty} \|\mathbf{H}\|_{H_\alpha^\infty} = 0. \tag{2.19}$$

This shows that the system (1.2), (1.3), (2.4), (2.10) is regular in the sense of [23] (with the feedthrough undetermined so far) and regular in the sense of Definition 2.1 if we can show the feedthrough is 0. We can easily obtain a transcendental description of the transfer function $\mathbf{H}(\lambda)$ by taking Laplace transforms of the partial differential equation system. Let $\lambda = i\omega^2$. There are of course two values of ω that satisfy this for any $\lambda \in \overline{\mathbf{C}_0^+}$, so we restrict ω to $\{\mathrm{r}e^{i\theta} \mid r \geq 0,\ \theta \in [-\pi/2, 0]\}$. The transfer function can then be written in the form

$$\mathbf{H}(\lambda) = \frac{i}{2\omega} \left\{ \frac{\sinh(\omega s_1) \cosh \omega(s_1 - 1)}{\cosh \omega} - \frac{\sin(\omega s_1) \cos \omega(s_1 - 1)}{\cos \omega} \right\}. \tag{2.20}$$

It is easy to use this form to see that $\mathbf{H}(\lambda) \to 0$ as $\lambda \to \infty$ along the positive real axis. Therefore, we can refer to the system as (B^*, A, B), which is regular.

Theorem 3.13 in Weiss [24] states that if (2.19) is true, then any feedback $u(t) = Jy(t)$ with $J \in \mathcal{B}(U)$ leads to a well-posed closed-loop system with generator $A + BJB_L^*$. Furthermore, from [24, Thm. 4.6], the closed-loop system is regular with feedthrough 0. We refer to this system as $(B_L^*, A + BJB_L^*, B)$, where the first operator B_L^* is interpreted as B_L^* restricted to the domain of $A + BJB_L^*$.

The system (1.2), (1.3), (2.4), (2.10) is a "boundary control system" discussed in Salamon [18]. By part (iii) of Lemma 4.4 and part (i) of Corollary 4.5 in that paper, $A - kBB_L^* = A_k$. Therefore, letting $J = -kI$, we see that (B_L^*, A_k, B) is regular.

LEMMA 2.8. *The transfer function* $\mathbf{H}_k(\lambda)$ *for* (B_L^*, A_k, B) *is bounded on the imaginary axis.*

Proof. $\mathbf{H}_k$ is that function such that $\hat{y}(\lambda) = \mathbf{H}_k(\lambda)\hat{u}(\lambda)$ when y and u are related by (2.11), (2.15), which is equivalent to

$$\dot{x}(t) = Ax(t) + Bv(t),$$

$$y(t) = B^*x(t),$$

$$v(t) = -ky(t) + u(t).$$

Therefore, $\hat{y}(\lambda) = \mathbf{H}(\lambda)\hat{v}(\lambda) = \mathbf{H}(\lambda)(-k\hat{y}(\lambda) + \hat{u}(\lambda))$. Solving for $\hat{y}$ in terms of $\hat{u}$, we see that

$$\mathbf{H}_k(\lambda) = ((\mathbf{H}(\lambda))^{-1} + k)^{-1}. \tag{2.21}$$

Because $\lambda = i\omega^2$, λ is on the imaginary axis when ω is on the real or imaginary axes. Therefore, it follows from (2.20) that $\mathbf{H}(\lambda)$ is imaginary on the imaginary axis. Hence, when λ is imaginary, (2.21) implies that $|\mathbf{H}_k(\lambda)| \leq 1/k$, finishing the lemma. □

From Lemma 2.8 and the dissipativity of A_k, it follows that $\mathbf{H}_k(\lambda)$ is bounded on $\{\text{Re}(z) \geq 0\}$, so (B^*, A_k, B) is input-output stable. This does not in general imply exponential stability, so we need to verify the conditions in Theorem 2.5 to show that we do indeed also have exponential stability. We first need to show that condition (1.5) is equivalent to a condition on the input coefficients b_k given in (2.12).

LEMMA 2.9. *Condition* (1.5) *is true if and only if there exists* $m > 0$ *such that*

$$|\sin((\pi/2 + \pi k)s_1)| > m \quad \textit{for all } k \in Z^+. \tag{2.22}$$

Proof. First suppose (1.5) is true, so $s_1 = p/q$, where p is odd. Then

$$\sin(\pi/2 + \pi k)s_1 = \sin \pi(p(2k+1))/2q.$$

Note that if j is an integer

$$|p(2k+1)/2q - j| = (1/2q)|p(2k+1) - 2qj| \geq (1/2q),$$

the last inequality following from the fact that $p(2k+1)$ is odd and $2qj$ is even. Therefore, $\sin(\pi/2 + \pi k)s_1$ is always bounded away from $|\sin j\pi| = 0$, proving (2.22).

Now suppose (1.5) is not true. Then either s_1 is irrational, or s_1 is of the form p/q, where p and q are coprime integers with p even, so q is odd and $p = 2\tilde{p}$ for some integer $\tilde{p}$. In this last case,

$$\sin(\pi/2 + \pi k)s_1 = \sin(\pi\tilde{p}(2k+1)/q).$$

When $k = (q-1)/2$, this becomes $\sin \pi\tilde{p} = 0$, so (2.22) cannot be true.

If s_1 is irrational, note that for any integer m,

$$|\sin(\pi/2 + \pi k)s_1| = |\sin \pi(s_1/2 + ks_1 + m)|.$$

The set $\{ks_1 + m \mid k, m \in \mathbf{Z}\}$ is dense in $\mathbf{R}$ if s_1 is irrational (see [10, Thm. 438]), which shows that (2.22) cannot be true, finishing the proof of Lemma 2.9. □

LEMMA 2.10. *If* (1.5) *is true, then* (A_k, B) *is stabilizable as in Definition* 2.3, *and* (B_L^*, A_k) *is detectable as in Definition* 2.4.

Proof. We first prove that (A, B) is stabilizable. In this proof we consider A to be the diagonal operator in the basis $\{\Phi_k\}_{k\in I}$ with eigenvalues $\{\lambda_k\}_{k\in I}$, and B to be the column vector $[b_k]_{k\in I}$, where b_k is given by (2.12).

We apply the results in Rebarber [15] to construct our stabilizing feedback. Let

$$p(\lambda) = \prod_{k\in I} \frac{\lambda - \lambda_k}{\lambda - \lambda_k + 2}, \qquad q(\lambda) = \prod_{k\in I} \frac{\lambda - \lambda_k + 1}{\lambda - \lambda_k + 2}.$$

Let

$$\chi_k = \sum_{j\in I} \frac{p(\lambda_k - 1)b_j}{b_k p'(\lambda_k)(\lambda_k - \lambda_j - 1)}\Phi_j,$$

$$h_j = \sum_{k\in I} \frac{q(\lambda_k)b_j p'(\lambda_j)}{q'(\lambda_j - 1)(\lambda_k - \lambda_j + 1)b_k p'(\lambda_k)}\Phi_k.$$

It is shown in [15] that $\{\chi_k\}_{k\in I}$ is a Riesz basis for X and $\langle h_k, \chi_j\rangle = \delta_{jk}$. Let

$$Fx = \sum_{k\in I} \frac{p(\lambda_k - 1)}{b_k p'(\lambda_k)}\langle h_k, x\rangle, \qquad \mathcal{D}(F) = \mathcal{D}(A).$$

We first need to show that (F, A, B) is regular. In [15] it is shown that F can also be written as

$$Fx = \sum_{k\in I} f_k\langle\Phi_k, x\rangle,$$

where

$$f_k = \frac{q(\lambda_k)}{b_k p'(\lambda_k)}\left(\sum_{j\in I} \frac{p(\lambda_j - 1)}{q'(\lambda_j - 1)(\lambda_k - \lambda_j + 1)}\right).$$

In [15] it is shown that $\{p(\lambda_j - 1)q(\lambda_k)/q'(\lambda_j - 1)p'(\lambda_k)\}_{k,j\in I}$ is a bounded set. Because $\lambda_{\pm k} = \pm i(\pi/2 + \pi k)^2$, it follows that $\{f_k\}_{k\in I} \in \ell_\infty$. Therefore, using the Carleson measure criterion as in [9] or [20], we see that F is an admissible observation operator for $S(t)$. As in the derivation of (2.17), we see that $R(\lambda, A)B \in \mathcal{D}(F_L)$ and

$$\mathbf{H}_F(\lambda) := F_L R(\lambda, A)B = \sum_{k\in L} \frac{f_k b_k}{(\lambda - \lambda_k)}.$$

Because $\{f_k b_k\} \in \ell^\infty$, we see from Theorem 2.7 that $\mathbf{H}_F(\lambda)$ is bounded in $\mathbf{C}^+_\alpha$ for any $\alpha > 0$, and that $\mathbf{H}_F(\lambda) \to 0$ as $\lambda \to \infty$ along the real axis. Therefore, (F, A, B) is regular.

Theorem 2.7 shows that (2.19) is true for this transfer function, so Theorem 3.13 in [24] shows that I is an admissible feedback for (F_L, A, B). Therefore Theorems 4.6 and 6.6 in [24] show that $(F_L, A + BF_L, B)$ is a regular system, where as usual we interpret the first F_L as the restriction of F_L to the domain of $A + BF_L$.

If (1.5) is true, then (2.12) and Lemma 2.9 show that the sequence of b_k's is bounded above and below, and Theorem 2 in [15] shows that $A + BF_L$ has eigenvalues $\{\lambda_k - 1\}_{k\in I}$ and eigenvectors $\{\chi_k\}_{k\in I}$. Because these eigenvectors are a Riesz basis for X, $A + BF_L$ generates an exponentially stable semigroup. This shows that (A, B) is stabilizable in the sense of Definition 2.3.

An obvious candidate for the operator that stabilizes $(A_k, B) = (A - kBB_L^*, B)$ is $\tilde{F} = F_L + kB_L^*$, because $(A - kBB_L^*) + B\tilde{F} = A + BF_L$ is exponentially stable. Because the transfer functions for (B^*, A, B) and (F, A, B) satisfy (2.19), it follows from Theorem 6.6 in [24] that $(B_L^*, A - kBB_L^*, B)$ and $(F_L, A - kBB_L^*, B)$ are also regular. Therefore $(\tilde{F}, A - kBB_L^*, B)$ is regular. To show that I is an admissible feedback for $(\tilde{F}, A - kBB_L^*, B)$, first note that we know from our previous work that I is an admissible feedback for (F, A, B) and (kB^*, A, B), and then apply the following lemma, which is proved in the Appendix. □

LEMMA 2.11. *Suppose K is an admissible feedback for the regular systems (C, A, B) and (C', A, B). Then K is admissible for $(C'_L - C_L, A + BKC_L, B)$.*

This finishes the proof that (A_k, B) is stabilizable in the sense given in Definition 2.3. We can use a similar dual argument to show that (B^*, A_k) is detectable in the sense of Definition 2.4, finishing the proof of Lemma 2.10.

Putting together Lemmas 2.6, 2.8, and 2.10 allows us to apply Theorem 2.5, so it follows that condition (1.5) is sufficient for exponential stability of the system (1.2), (1.3), (1.4). Therefore, to finish the proof of Theorem 1.1 we need to prove the necessity of condition (1.5). It is clear that in our case the eigenvalues satisfy the following condition.

Condition 1. For any $h > 0$, the number of eigenvalues N_h in $\{z \,|\, 0 \leq \mathrm{Re}(z) \leq h,$ $a - h \leq \mathrm{Im}(z) \leq a + h\}$ satisfies $N_h \leq Mh$ for some $M < \infty$ that is independent of a.

LEMMA 2.12. *Suppose A is a diagonal operator with eigenvalues that satisfy Condition* 1, *and suppose B is an admissible input operator for $S(t)$ that is represented by the column vector $[b_k]_{k \in I}$. Suppose there exists a functional F on X such that $A_F = A + BF$ generates an exponentially stable semigroup $S_F(t)$, and F is an admissible observation operator* (*or an extension of an admissible observation operator*) *for $S_F(t)$. Then there exists $M > 0$ such that*

$$\sum_{k \in I} |x_k / b_k|^2 \leq M \sum_{k \in I} |x_k|^2 \tag{2.23}$$

for all $\{x_k\}_{k \in I} \in \ell^2$.

Proof. Let $M > 0$, $\alpha < 0$ be such that $\|S_F(t)\| \leq Me^{\alpha t}$, and let $\beta \in (\alpha, 0)$. The variation of parameters formula implies that for $x \in X$,

$$S_F(t)x = S(t)x + \int_0^t S(t - \tau)Bu(\tau; x)d\tau, \tag{2.24}$$

where $u(\tau; x) = FS_F(\tau)x$. Then $\hat{u}(\cdot\,; x)$ is in the Hardy space $H^2(\mathbf{C}_\beta^+)$, which is the space of Laplace transforms of all u in $L^2_{\mathrm{loc}}[0, \infty)$ such that $e^{-\beta \cdot} u \in L^2[0, \infty)$. Because B is admissible, we can take the Laplace transform of (2.24), obtaining for $\mathrm{Re}(\lambda) > 0$,

$$R(\lambda, A_F)x = R(\lambda, A)x + R(\lambda, A)B\hat{u}(\lambda; x).$$

Because $R(\lambda, A_F)x$ and $\hat{u}(\lambda; x)$ are holomorphic in $\mathbf{C}_\beta^+$ and $R(\lambda, A)x$ is meromorphic in $\mathbf{C}_\beta^+$, we can consider the left side of this equation to be a holomorphic extension of the right side. Representing x in a basis $\{\Phi_k\}_{k \in I}$ of X by $\sum_{k \in I} x_k \Phi_k$, this equation is equivalent to

$$R(\lambda, A_F)x = \sum_{k \in I} \frac{x_k + b_k \hat{u}(\lambda; x)}{\lambda - \lambda_k} \Phi_k. \tag{2.25}$$

Because $R(\lambda, A_F)x$ is holomorphic on the imaginary axis, (2.25) is true only if

$$\hat{u}(\lambda_k; x) = -x_k / b_k. \tag{2.26}$$

Now define the following measure μ on the Borel subsets of $\mathbf{C}_\beta^+$:

$$\mu(\lambda_k) = 1, \qquad \mu(\{z \,|\, \mathrm{Re}(z) > \beta\} \backslash \{\lambda_k\}_{k\in I}) = 0. \tag{2.27}$$

Because $\{\lambda_k\}_{k\in I}$ satisfies Condition 1, we easily see that μ is a Carleson measure on $\mathbf{C}_\beta^+$ (see [9] and [20] for the definition of Carleson measure and for other examples along these lines). The Carleson measure theorem as stated in [9] implies that there exists $M_1 > 0$ such that for all $\phi \in H^2(\mathbf{C}_\beta^+)$,

$$\sum_{k\in I} |\phi(\lambda_k)|^2 \le M_1 \int_{-\infty}^{+\infty} \lim_{\rho\to\beta} |\phi(\rho + i\eta)|^2 \, d\eta. \tag{2.28}$$

Note that by the Plancherel theorem,

$$\int_{-\infty}^{+\infty} \lim_{\rho\to\beta} |\hat{u}(\rho + i\eta, x)|^2 \, d\eta = 2\pi \int_0^\infty |e^{-\beta t} u(t; x)|^2 \, dt. \tag{2.29}$$

Because $u(t; x) = FS_F(t)x$, F is an extension of an admissible observation operator for $S_F(t)$, and $S_F(t)$ has exponential decay α, there exist M_2, $M_3 > 0$ such that

(2.30)

$$\int_0^\infty |e^{-\beta t} u(t; x)|^2 \, dt \le M_2 \int_0^\infty |e^{-\beta t} S_F(t)x|^2 \le M_3 \left(\sum_{k\in I} |x_k|^2 \right) \int_0^\infty e^{2(\alpha-\beta)t} \, dt.$$

Let $\phi(\lambda) = \hat{u}(\lambda, x)$ in (2.28), keeping in mind (2.26), (2.29), and (2.30), and we get (2.23), finishing the lemma. □

Remark 2.13. The proof of Lemma 2.12 is motivated by the idea of *open-loop stabilizability* (see Zwart [26]). In the proof we show that (2.23) is a necessary condition for open-loop stabilizability, hence also for closed-loop stabilizability.

Now suppose that the system (1.2), (1.3), (1.4) is exponentially stable, so $A_k = A - kBB_L^*$ generates an exponentially stable semigroup. Then Lemma 2.12 is applicable with $F = -kB_L^*$, so (2.23) is true, and $\{1/b_k\}_{k\in I}$ must be a bounded sequence. This means that condition (1.5) is a necessary condition for stabilization, which completes the proof of Theorem 1.1.

3. Proof of Theorem 1.3. We need to approach the system (1.2), (1.6), (1.7) differently than the system (1.2), (1.3), (1.4). To see why this is the case, we briefly discuss the state-space formulation for the controlled, observed system associated with (1.2), (1.6), (1.7) and explain why our approach in §2 cannot be applied directly to this system.

Let

$$X = \{[x_1, x_2]^T \in H^2[0,1] \oplus L^2[0,1] \,|\, x_1(0) = x_1(1) = 0\}, \tag{3.1}$$

and let A be the matrix (2.2) with domain

$$\begin{aligned} \mathcal{D}(A) = \{[x_1, x_2]^T \in H^4[0,1] \oplus H^2[0,1] \,|\, x_1(0) &= x_1(1) \\ = D^2x_1(0) = D^2x_1(0) = x_2(0) &= x_2(1) = 0\}, \end{aligned} \tag{3.2}$$

so it is easy to see that A generates a C_0-semigroup $S(t)$ on X. If we let $x(t) = [w(\cdot, t), \dot{w}(\cdot, t)]^T$ and $B = [0, \delta'(\cdot - s_1)]^T$, then (1.2), (1.6) with control

$$D^2w(s_1^-, t) - D^2w(s_1^+, t) = u(t) \tag{3.3}$$

can be seen to be equivalent to (2.9). Similarly, (1.2), (1.6), (1.7) with $\hat{k} = 0$, and observation

$$y(t) = D\dot{w}(s_1, t) \tag{3.4}$$

is equivalent to $\dot{x}(t) = Ax(t)$ and (2.11). However, B is not an admissible input operator for $S(t)$, B^* is not an admissible observation operator for $S(t)$, and the transfer function for (1.2), (1.6), (3.3), (3.4) can easily be computed and is not bounded on any half plane $\mathbf{C}_\alpha^+$. Such a system is ill posed, and we cannot apply the approach of §2 directly to this system.

If we formally close the loop in (1.2), (1.6), (3.3), (3.4) with the feedback $u(t) = -\hat{k}y(t)$, $\hat{k} > 0$, then the resulting system is (1.2), (1.6), (1.7) is shown in [5] to have solutions with nonincreasing energy, and the underlying semigroup generator is easily seen to be dissipative using the Lumer–Phillips theorem. This implies that the controlled, observed system (1.2), (1.6), (3.3), (3.4), while possibly natural from a physical point of view, is not the appropriate systems-theoretic framework for studying the feedback system (1.2), (1.6), (1.7). This is because the input-output relation defined by (1.2), (1.6), (3.3), (3.4) is not well posed in the sense of [8], [18], [22], and [23]. In Rebarber and Townley [17] an ill-posed system is analyzed by reversing the roles of $u(t)$ and $y(t)$, which is what we do here. Therefore, we consider the "inverse" system (1.2), (1.6),

$$D\dot{w}(s_1, t) = u(t), \tag{3.5}$$

$$y(t) = D^2w(s_1^-, t) - D^2w(s_1^+, t). \tag{3.6}$$

When we put this system into state-space form, we see that it is regular. When the loop in this system is closed by $u(t) = -(1/\hat{k})y(t)$, we obtain the system (1.2), (1.6), (1.7), and we apply the approach from §2 to the inverse system. The difficulties in this approach arise in characterizing which joint placements lead to stabilizability and detectability. This is because the underlying semigroup generator is not standard, and the eigenvalues $\{\lambda_k\}$ and input coefficients $\{b_k\}$ are not easily computed. The analysis of the eigenvalues and input coefficients is done in Lemmas 3.2, 3.5, 3.6, 3.7, and 3.8.

We start by discussing the state-space formulation for (1.2), (1.6), (3.5), (3.6). We note here that we will be using most of the notation as in §2, to mirror the development in that section. However, much of the notation needs to be redefined for this new system, so the notation will not represent the same things unless explicitly stated. Once the analysis of the eigenvalues and input coefficients is completed the rest of the proof of Theorem 1.3 is almost identical to the proof of Theorem 1.1. Because many of the proofs in this section proceed like the proofs in §2, we will not repeat the details and merely refer to §2.

The state space is X, given by (3.1), with the inner product (2.1). Let A be the operator given by the matrix (2.2) with domain

$$\begin{aligned}\mathcal{D}(A) = \{[x_1, x_2]^T \in X \mid\ & x_1|_{[0,s_1)} \in H^4[0, s_1),\ x_1|_{(s_1,1]} \in H^4(s_1, 1],\\ & x_2 \in H^2[0,1],\ D^2x_1(0) = D^2x_1(1) = x_2(0) = x_2(1) = 0,\\ & Dx_2(s_1) = 0,\ D^3x_1(s_1^-) = D^3x_1(s_1^+)\}.\end{aligned} \tag{3.7}$$

Remark 3.1. The operator A here is the generator of the *zero dynamics* of (1.2), (1.6), (1.7) (see Byrnes and Gilliam [2]). The zero dynamics of a feedback system with gain parameter $\hat{k} \in \mathbf{R}$ is that system obtained formally by letting $\hat{k} \to \infty$. It is shown in Rebarber and Townley [17] that if the inverse system is regular with underlying semigroup $S(t)$, and if $T_{\hat{k}}(t)$ is the semigroup associated with $y(t) = -\hat{k}u(t)$ in the original system, then $\lim_{\hat{k}\to\infty} T_{\hat{k}}(t) = S(t)$ in the operator norm for every $t > 0$.

This generator A is not as familiar as the generator A in §2, so we briefly discuss here how to show that A is skew adjoint on X. Let $x = [x_1, x_2]^T \in \mathcal{D}(A)$. Let M be the operator given by (2.2) and $v = [v_1, v_2] \in X$ be such that $v_1|_{[0,s_1)} \in H^4[0, s_1)$, $v_1|_{s_1,1]} \in H^4(s_1, 1]$, $v_2|_{[0,s_1)} \in H^2[0, s_1)$, and $v_2|_{(s_1,1]} \in H^2(s_1, 1]$. Using integration by parts we see that $\langle Ax, v\rangle = \langle x, -Mv\rangle$ plus terms at 0, 1, and s_1. Thus A^* is given by $-M$ on the domain of all v so that the terms at 0, 1, and s_1 are zero. The terms at 0 and 1 are fairly standard and imply that $v \in \mathcal{D}(A^*)$ must satisfy $v_2(0) = D^2v_1(0) = v_2(1) = D^2v_1(1) = 0$. The terms at s_1 are as follows:

(1) $x_2(s_1^-)\overline{D^3v_1(s_1^-)} - x_2(s_1^+)\overline{D^3v_1(s_1^+)}$. Because $x_2 \in H^2[0, 1]$, $x_2(s_1^-) = x_2(s_1^+)$, which implies that $D^3v_1(s_1^-) = D^3v_1(s_1^+)$.

(2) $Dx_2(s_1^-)\overline{D^2v_1(s_1^-)} - Dx_2(s_1^+)\overline{D^2v_1(s_1^+)}$. Because $Dx_2(s_1) = 0$, this implies no condition on $D^2v_1(s_1)$.

(3) $D^2x_1(s_1^-)\overline{Dv_2(s_1^-)} - D^2x_1(s_1^+)\overline{Dv_2(s_1^+)}$. Because there is no condition on D^2x_1 at s_1, this implies that $Dv_2(s_1^+) = Dv_2(s_1^-) = 0$.

(4) $D^3x_1(s_1^-)\overline{v_2(s_1^-)} - D^3x_1(s_1^+)\overline{v_2(s_1^+)}$. Because $D^3x_1(s_1^-) = D^3x_1(s_1^+)$, this implies that $v_2(s_1^-) = v_2(s_1^+)$.

Putting this all together, we see that $\mathcal{D}(A^*) = \mathcal{D}(A)$, so $A^* = -A$ and A is skew adjoint. Because it is clear from the Rellich–Kondrachov theorem (see [1, Thm. 6.2]) that the $\mathcal{D}(A)$ is compactly embedded in X, A has compact resolvent. Therefore, the spectrum of A consists solely of eigenvalues $\{\lambda_k\}$ on the imaginary axis with associated eigenvectors $\{\Phi_k\}$ that form an orthogonal basis of X. Hence A generates a $\mathbf{C}_0$-semigroup $S(t)$ on X such that $\|S(t)\| = 1$.

To identify the appropriate input operator for the control system (1.2), (1.6), (3.5), we let $\hat{A}$ be the extension of A with domain

$$\begin{aligned}\mathcal{D}(\hat{A}) = \{[x_1, x_2]^T \in X \mid\, & x_1|_{[0,s_1)} \in H^4[0, s_1),\ x_1|_{(s_1,1]} \in H^4(s_1, 1],\\ & x_2 \in H^2[0, 1],\ D^2x_1(0) = D^2x_1(1) = x_2(0) = x_2(1) = 0,\\ & x_2(s_1^-) = x_2(s_1^+),\ D^3x_1(s_1^-) = D^3x_1(s_1^+)\}.\end{aligned}$$

Let $x = [x_1, x_2]^T \in \mathcal{D}(\hat{A})$ and $v = [v_1, v_2]^T \in \mathcal{D}(A^*)$. Using integration by parts we find that

$$\langle \hat{A}x, v\rangle = \langle x, -Av\rangle + Dx_2(s_1)\overline{D^2v_1(s_1^-) - D^2v_1(s_1^+)}. \tag{3.8}$$

Let $B \in \mathcal{D}(A^*)'$ be given by

$$B = \begin{bmatrix} \delta''(\cdot - s_1^+) - \delta''(\cdot - s_1^-) \\ 0 \end{bmatrix}. \tag{3.9}$$

We interpret B as a functional on $\mathcal{D}(A^*) = \mathcal{D}(A)$ as

$$B[v_1, v_2]^T = D^2v_1(s_1^-) - D^2v_1(s_1^+).$$

This interpretation of B is not consistent with the inner product (2.1) but is consistent with the usual interpretation of δ''. Let $\tilde{A}$ be defined by (2.7). Then from (3.8) we see that $\hat{A}x = \tilde{A}x + Dx_2(s_1)B$ in X_{-1}. As in §2, we see that if $x(t) = [w(\cdot, t), \dot{w}(\cdot, t)]^T$ and $w(s, t)$ satisfies (1.2), (1.6), and (3.5), then $\hat{A}x(t) = \tilde{A}x(t) + Bu(t)$ in X_{-1}. Therefore, the state-space equation for (1.2), (1.6), (3.5) is (2.9).

The observation (3.6) is given by $y(t) = B^*x(t)$. We prove in Lemma 3.7 that for any $s_1 \in [0, 1]$, B is an admissible input operator, and hence B^* is an admissible observation operator.

Letting $k = (1/\hat{k})$, the system (1.2), (1.6), (1.7) is equivalent to $\dot{x}(t) = A_k x(t)$, where A_k is given by the matrix (2.2) with domain

$$\mathcal{D}(A_k) = \{[x_1, x_2]^T \in \mathcal{D}(\hat{A}) \mid Dx_2(s_1) = -k(D^2x_1(s_1^-) - D^2x_1(s_1^+))\}.$$

It is again an easy consequence of [5, (1.4)] and the Lumer–Phillips theorem that A_k is a dissipative operator that generates a C_0-semigroup of contractions $S_k(t)$ on X.

As in the proof of Theorem 1.1, we show that $S_k(t)$ is exponentially stable by showing that $R(\lambda, A_k)$ is bounded on the imaginary axis. To do this, we apply Theorem 2.5 to the controlled, observed system for A_k given by (1.2), (1.6), (3.6) and

$$D\dot{w}(s,t) + k[D^2w(s_1^+,t) - D^2w(s_1^-,t)] = u(t). \tag{3.10}$$

As in the proof of Theorem 1.1, when it is shown that the feedthrough for this system is zero, it will follow that the system is equivalent to (2.15) with observation (2.11). Let $\mathbf{H}_k$ be the transfer function for this system.

To apply the approach in §2 to the generator A for this reversed system, we need to analyze the eigenvalues and eigenvectors of A in detail. Although this is a simple task if we are dealing with the generator for the "forward" system with domain (3.2) (which is unfortunately associated with a control system that is not well posed), the operator A we are working with here, with domain (3.7), is not standard. The asymptotic analysis of the eigenvalues is simpler here than in Chen et al. [5] because in that paper the eigenvalues for A_k were analyzed, whereas we are only interested in the eigenvalues for $k = 0$. However, in this case we also need a formula for the normalized eigenvectors because these are used for the computation of the input coefficients b_k. The following lemma characterizes the eigenvalues and eigenvectors of A.

LEMMA 3.2. *All of the eigenvalues and eigenvectors of A are of one of the three forms described below in parts* (a), (b), *and* (c).

(a) $\lambda = 0$ *is an eigenvalue of multiplicity one with associated eigenvector* $\Psi_0 = [\psi_0, 0]^T$, *where*

$$\psi_0(s) = s^3 + (3s_1^2 - 6s_1 + 2)s \quad \textit{for } s \in [0, s_1), \tag{3.11}$$

$$\psi_0(s) = (s-1)^3 + (3s_1^2 - 1)(s-1) \quad \textit{for } s \in (s_1, 1]. \tag{3.12}$$

(b) *If* $\cos(\pi n s_1) = 0$ *for some* $n \in \mathbf{Z}^+$, *then* $\lambda = \pm i(\pi n)^2$ *are eigenvalues of multiplicity one with associated eigenvectors*

$$\Psi_{\pm n} = \begin{bmatrix} \psi_n / \pm i\pi n^2 \\ \psi_n \end{bmatrix}, \tag{3.13}$$

where

$$\psi_n(s) = \sin(\pi n s) \quad \textit{for } s \in [0, 1]. \tag{3.14}$$

(c) *Let ω be a real positive solution of*

$$g(\omega) := \tanh(\omega s_1) - \tan(\omega s_1) - \tanh \omega(s_1 - 1) + \tan \omega(s_1 - 1) = 0. \tag{3.15}$$

Then $\lambda = \pm i\omega^2$ are eigenvalues with associated eigenvectors

$$\Psi_{\pm\omega} = \begin{bmatrix} \psi_\omega / \pm i\omega^2 \\ \psi_\omega \end{bmatrix}, \tag{3.16}$$

where

$$\psi_\omega(s) = \frac{\sinh(\omega s)}{\cosh(\omega s_1)} - \frac{\sin(\omega s)}{\cos(\omega s_1)} \quad \textit{for } s \in [0, s_1), \tag{3.17}$$

$$\psi_\omega(s) = \frac{\sinh \omega(s-1)}{\cosh \omega(s_1 - 1)} - \frac{\sin \omega(s-1)}{\cos \omega(s_1 - 1)} \quad \textit{for } s \in (s_1, 1]. \tag{3.18}$$

Proof. A is skew adjoint, so the eigenvalues are on the imaginary axis, and it is easy to show that the eigenvalues come in complex conjugate pairs. Therefore, the eigenvalues are of the form $\lambda = \pm i\omega^2$, where ω is on the nonnegative real axis.

Assume that $[\psi, \chi]^T$ is an eigenvector associated with the eigenvalue λ. Then $\chi = \lambda\psi$ and ψ satisfies

$$\lambda^2\psi(s) + D^4\psi(s) = 0 \tag{3.19}$$

with boundary conditions

$$\begin{aligned} \psi(0) &= D^2\psi(0) = 0, \\ \psi(1) &= D^2\psi(1) = 0, \\ \psi(s_1^-) &= \psi(s_1^+), \\ D\psi(s_1^-) &= D\psi(s_1^+), \\ D^3\psi(s_1^-) &= D^3\psi(s_1^+), \end{aligned} \tag{3.20}$$

$$\lambda D\psi(s_1) = 0. \tag{3.21}$$

It is easy to verify that if $\lambda = 0$, then all solutions of (3.19), (3.20), (3.21) are given by $c\psi(s)$, where c is a scalar and ψ is given by (3.11), (3.12).

Now assume $\lambda \neq 0$, so (3.21) becomes

$$D\psi(s_1) = 0. \tag{3.22}$$

Equation (3.19) and the first line of (3.20) imply that

$$\psi(s) = C_1 \sinh(\omega s) + C_2 \sin(\omega s) \quad \text{for } s \in [0, s_1). \tag{3.23}$$

Equation (3.19) and the second line of (3.20) imply that

$$\psi(s) = C_3 \sinh \omega(s-1) + C_4 \sin \omega(s-1) \quad \text{for } s \in (s_1, 1]. \tag{3.24}$$

The third line of (3.20) is true if and only if

$$C_1 \sinh(\omega s_1) + C_2 \sin(\omega s_1) = C_3 \sinh \omega(s_1 - 1) + C_4 \sin \omega(s_1 - 1). \tag{3.25}$$

The fourth and fifth lines of (3.20) are true if and only if

$$C_1 \cosh(\omega s_1) = C_3 \cosh \omega(s_1 - 1), \tag{3.26}$$

$$C_2 \cosh(\omega s_1) = C_4 \cos \omega(s_1 - 1). \tag{3.27}$$

Equation (3.22) is true if and only if

$$C_1 \cosh(\omega s_1) = -C_2 \cos(\omega s_1), \tag{3.28}$$

$$C_3 \cosh \omega(s_1 - 1) = -C_4 \cos \omega(s_1 - 1). \tag{3.29}$$

To find real positive ω so that (3.25)–(3.29) have nonzero solutions for C_1, C_2, C_3, and C_4, we consider four cases.

Case 1. Suppose $\cos \omega(s_1 - 1) = 0$ and $\cos(\omega s_1) \neq 0$. Then (3.27) implies that $C_2 = 0$, (3.28) implies that $C_1 = 0$, and (3.26) implies that $C_3 = 0$. Finally, (3.25) implies that $C_4 = 0$, so $\pm i\omega^2$ cannot be an eigenvalue.

Case 2. Suppose $\cos \omega(s_1 - 1) \neq 0$ and $\cos(\omega s_1) = 0$. Then (3.27) implies that $C_4 = 0$, (3.29) implies that $C_3 = 0$, and (3.26) implies that $C_1 = 0$. Finally, (3.25) implies that $C_2 = 0$, so $\pm i\omega^2$ cannot be an eigenvalue.

Case 3. Suppose $\cos \omega(s_1 - 1) = 0$ and $\cos(\omega s_1) = 0$. Then $\omega(s_1 - 1) = \pi(1/2 - j)$ and $\omega s_1 = \pi(-1/2 + k)$ for some j, $k \in Z^+$. Therefore $\omega = \pi n$ for some $n \in Z^+$. Then (3.28) is true if and only if $C_1 = 0$, and (3.29) is true if and only if $C_3 = 0$. Equation (3.25) is true if and only if

$$C_2 \sin(n\pi s_1) = C_4 \sin n\pi(s_1 - 1).$$

Therefore

$$C_4 = C_2(-1)^n.$$

Hence, using (3.23) and (3.24), we see that $\psi(s)$ is a solution of (3.25)–(3.29) if and only if

$$\psi(s) = C_2 \sin(\pi n s) \quad \text{for } s \in [0, s_1),$$

$$\psi(s) = C_2(-1)^n \sin \pi n(s - 1) = C_2 \sin(\pi n s) \quad \text{for } s \in (s_1, 1].$$

Therefore (3.13), (3.14) give eigenvectors associated with $\omega = \pi n$, where n is such that $\cos(\pi n s_1) = 0$, and $\pm i(\pi n)^2$ are eigenvalues of multiplicity one.

Case 4. Suppose $\cos \omega(s_1 - 1) \neq 0$ and $\cos(\omega s_1) \neq 0$. Then (3.26) is true if and only if

$$C_3 = C_1(\cosh(\omega s_1)/\cosh \omega(s_1 - 1)). \tag{3.30}$$

Equation (3.28) is true if and only if

$$C_2 = C_1(-\cosh(\omega s_1)/\cos(\omega s_1)). \tag{3.31}$$

Using this, we see that (3.27) is true if and only if

$$C_4 = C_1(-\cosh(\omega s_1)/\cos \omega(s_1 - 1)). \tag{3.32}$$

Equation (3.29) is also satisfied if C_3 and C_4 are given by (3.30) and (3.32). Plugging (3.30), (3.31), and (3.32) into (3.25) and dividing by $\cosh(\omega s_1)$, we see that $\pm i\omega^2$ is an eigenvalue in Case 4 if and only if (3.15) is true. Plugging (3.30), (3.31), (3.32) into (3.23) and (3.24) and letting $C_1 = 1/\cosh(\omega s_1)$, we obtain the eigenvectors given by (3.16), (3.17), (3.18). □

It is proved in Proposition 3.3, below, that the eigenvalues of A described in part (c) of Lemma 3.2 are also of multiplicity 1.

For our purposes we need the normalized eigenvectors of A. For the eigenvector in part (a) of Lemma 3.2, let $C_0 = 1/\|\Psi_0\|$ and let Φ_0 be the normalized eigenvector $C_0\Psi_0$. For the eigenvectors in part (b) of Lemma 3.2, we easily find that the normalizing constant is 1, so let $\Phi_{\pm n} = \Psi_{\pm n}$. For the eigenvectors in part (c) of Lemma 3.2, let ω be a positive solution of (3.15). Let

$$\Phi_{\pm\omega} = C_\omega \Psi_{\pm\omega}, \tag{3.33}$$

where

$$1/C_\omega^2 = \|[\psi_\omega/\omega^2, \psi_\omega]^T\|^2 = \int_0^1 \{|D^2\psi_w(s)/\omega^2|^2 + |\psi_\omega(s)|^2\}ds. \tag{3.34}$$

Using (3.17) on $[0, s_1)$, we compute that

$$\begin{aligned}\int_0^{s_1} \{|D^2\psi_\omega(s)/\omega^2|^2 + |\psi_\omega(s)|^2\}ds = {}& \frac{1}{\cosh^2(\omega s_1)}\left[\frac{\sinh(2\omega s_1)}{2\omega} - s_2\right] \\ & - \frac{1}{\cos^2(\omega s_1)}\left[\frac{\sin(2\omega s_1)}{2\omega} - s_1\right].\end{aligned} \tag{3.35}$$

Using (3.18) on $(s_1, 1]$, we compute that

(3.36)

$$\begin{aligned}\int_{s_1}^1 \{|D^2\psi_\omega(s)/\omega^2|^2 + |\psi_\omega(s)|^2\}ds = {}& \frac{-1}{\cosh^2\,\omega(s_1-1)}\left[\frac{\sinh\,2\omega(s_1-1)}{2\omega} - (s_1-1)\right] \\ & + \frac{1}{\cos^2\,\omega(s_1-1)}\left[\frac{\sin\,2\omega(s_1-1)}{2\omega} - (s_1-1)\right].\end{aligned}$$

Putting (3.35) and (3.36) together, we see that

(3.37)

$$\begin{aligned}1/C_\omega^2 = {}& (1/\omega)(\tanh(\omega s_1) - \tan(\omega s_1) - \tanh\,\omega(s_1-1) + \tan\,\omega(s_1-1)) \\ & + s_1(\sec^2(\omega s_1) - \operatorname{sech}^2(\omega s_1)) + (s_1-1)(\operatorname{sech}^2\omega(s_1-1) - \sec^2\,\omega(s_1-1)).\end{aligned}$$

Because ω satisfies (3.15), we can simplify this expression to

(3.38)

$$C_\omega = [s_1(\sec^2(\omega s_1) - \operatorname{sech}^2(\omega s_1)) + (s_1-1)(\operatorname{sech}^2\omega(s_1-1) - \sec^2\,\omega(s_1-1))]^{-1/2}.$$

PROPOSITION 3.3. *The eigenvalues of A are all of multiplicity one.*

Proof. We only need to show that the zeros of g given by (3.15) are of multiplicity one. If ω is a zero of g, then comparing (3.15) to (3.38) we see that $g'(\omega) = -1/C_\omega^2$, which is always negative. □

We can now compute the input coefficients $B^*\Phi$ associated with B given by (3.9). The input coefficient associated with Φ_0 is $b_0 = -6C_0$, and all we need to note about this is that it is not 0. The input coefficients associated with $\Phi_{\pm n}$ are

$$b_{\pm n} = 0. \tag{3.39}$$

The input coefficients associated with $\Phi_{\pm\omega}$ are $b_{\pm\omega} = B\Phi_{\pm\omega}$, where B is given by (3.9). Using (3.17) and (3.18), these are easily computed to be $b_{\pm\omega} = \pm b_\omega$, where

$$b_\omega = iC_\omega[\tanh\,\omega(s_1-1) + \tan\,\omega(s_1-1) - \tanh(\omega s_1) - \tan(\omega s_1)],$$

and C_ω is given by (3.38). Using (3.15) we see that

$$b_\omega = -2iC_\omega[\tanh(\omega s_1) - \tanh \omega(s_1 - 1)]. \tag{3.40}$$

The next lemma is proved in almost exactly the same way as Lemma 2.9, so the proof is omitted.

LEMMA 3.4. *Condition* (1.8) *is true if and only if there exists $m > 0$ such that*

$$|\cos(\pi k s_1)| > m \quad \text{for all } k \in Z^+. \tag{3.41}$$

Now we can relate the behavior of the eigenvalues to condition (1.8).

LEMMA 3.5. (a) *Suppose that* (1.8) *is true for some $m > 0$. Then there exists $m_1 > 0$ and $m_2 > 0$ such that for any positive zero ω* of g,

$$|\cos(\omega s_1)| > m_1, \tag{3.42}$$

$$|\cos \omega(s_1 - 1)| > m_2. \tag{3.43}$$

Furthermore, there exists $m_3 > 0$ such that for any two zeros ω_1 and ω_2 of g,

$$|w_1 - w_2| > m_3. \tag{3.44}$$

(b) *Suppose there exists a sequence of positive integers $\{n_l\}$ such that*

$$\lim_{l \to \infty} \cos(n_l \pi s_1) = 0. \tag{3.45}$$

There there exists a sequence $\{\omega_k\}$ of positive zeros of g such that

$$\lim_{k \to \infty} |\cos(\omega_k s_1)| = 0. \tag{3.46}$$

Proof. We first prove part (a), so we assume that (1.8), hence (3.41), is true. Suppose $\{\omega_k\}$ is a sequence of positive zeros of g such that (3.46) is true. Examining g in (3.15), we see that this can only happen if $\lim_{k\to\infty} |\cos \omega_k(s_1 - 1)| = 0$. Therefore there exists a sequence of integers $\{m_k\}$ and $\{n_k\}$ such that

$$\lim_{k \to \infty} |w_k s_1 - \pi(1/2 + n_k)| = 0,$$

$$\lim_{k \to \infty} |w_k(s_1 - 1) - \pi(1/2 + m_k)| = 0.$$

This means that

$$\lim_{k \to \infty} |w_k - \pi j_k| = 0,$$

where $j_k = n_k - m_k$, so

$$\lim_{k \to \infty} |\cos \pi j_k s_1| = 0,$$

contradicting (3.41). From this we see that if (3.41) is true, then (3.46) cannot be true. Note that if ω is a zero of g, (3.15) shows that $\cos(\omega s_1) \neq 0$ and $\cos \omega(s_1 - 1) \neq 0$. Therefore, if (3.41) is true, then (3.42) is true for some m_1 and all real positive zeros of g. It is clear from the form of g given in (3.15) that if (3.42) is true, then (3.43) must also be true.

The vertical asymptotes of the graph of $g(\omega)$ for ω on the real positive axis are the lines $\omega = \eta_k$ and $\omega = \tilde{\eta}_j$, where

$$\eta_k = \pi(k + 1/2)/(1 - s_1), \qquad \tilde{\eta}_j = \pi(j + 1/2)/s_1, \tag{3.47}$$

where k and j are nonnegative integers. Note that $g'(\omega) = (s_1 - 1)[\sec^2 \omega(s_1 - 1) - \operatorname{sech}^2 \omega(s_1 - 1)] + s_1[\operatorname{sech}^2(\omega s_1) - \sec^2(\omega s_1)]$, which is always negative where it is defined. Therefore, between any adjacent numbers in

$$\Lambda := \{\eta_k\}_{k=0}^{\infty} \cup \{\tilde{\eta}_j\}_{j=0}^{\infty} \tag{3.48}$$

there is exactly one positive zero of g.

We show that when (3.41) is true the points in Λ are separated in the sense that there exists $m > 0$ such that if $\eta, \mu \in \Lambda$, then $|\eta - \mu| > m$. Because $|\eta_{k_1} - \eta_{k_2}| \geq \pi|k_1 - k_2|/(1 - s_1)$ and $|\tilde{\eta}_{j_1} - \tilde{\eta}_{j_2}| \geq \pi|j_1 - j_2|/s_1$, we need to find $m > 0$ so that $|\eta_k - \tilde{\eta}_j| > m$ for all nonnegative integers k and j. To that end, note that

$$|\eta_k - \tilde{\eta}_j| = \frac{\pi|s_1(1 + k + j) - (1/2 + j)|}{s_1(1 - s_1)}. \tag{3.49}$$

By (3.41), there exists an $m_1 > 0$ such that

$$|ns_1 - (1/2 + j)| > m_1$$

for all nonnegative integers n and j. Comparing this with (3.49) (with $n = 1 + k + j$), we see that

$$|\eta_k - \tilde{\eta}_j| > \pi m_1/s_1(1 - s_1)$$

for all nonnegative integers k and j, showing that the points in Λ are separated.

Let ω be a positive zero of g, so (3.42) and (3.43) are true. Because $\cos \eta_k(s_1 - 1) = 0$ and $\cos(\tilde{\eta}_j s_1) = 0$, we see that there exists $m_2, m_3 > 0$ such that

$$|\omega s_1 - \tilde{\eta}_j s_1| > m_2,$$

$$|\omega(s_1 - 1) - \eta_k(s_1 - 1)| > m_3.$$

Let m_4 be the minimum of $\{m_2/s_1, m_3/(1 - s_1)\}$. Therefore, if $\eta \in \Lambda$, $|\eta - \omega| > m_4$. Because the points in Λ are separated and there is only one positive real zero·ω of g between any adjacent points of Λ, this shows that the positive real zeros of f are separated in the sense given in (3.44).

We now prove part (b). Suppose (3.45) is true for a sequence of positive integers $\{n_l\}$. Therefore there exists a sequence of positive integers $\{m_l\}$ such that

$$\lim_{l \to \infty} |n_l s_1 - (1/2 + m_l)| = 0. \tag{3.50}$$

In (3.49) let $j = m_l$ and $k = n_l - m_l - 1$, so we obtain

$$|\eta_{n_l - m_l - 1} - \tilde{\eta}_{m_l}| = \frac{\pi|s_1 n_l - (1/2 + m_l)|}{s_1(1 - s_1)}.$$

Comparing this with (3.50) we see that

$$\lim_{l \to \infty} |\eta_{n_l - m_l - 1} - \tilde{\eta}_{m_l}| = 0.$$

Because there is at least one real positive zero ω_l of g between $\eta_{n_l-m_l-1}$ and $\tilde{\eta}_{m_l}$, we see that

$$\lim_{l\to\infty} |\cos(\omega_l s_1) - \cos(\tilde{\eta}_{m_l} s_1)| = 0. \tag{3.51}$$

Applying, in order, (3.51), (3.47), (3.50), and (3.45), we see that

$$\lim_{l\to\infty} |\cos(\omega_l s_1)| = \lim_{l\to\infty} |\cos(\tilde{\eta}_{m_l} s_1)| = \lim_{l\to\infty} |\cos \pi(1/2 + m_l)| = \lim_{l\to\infty} |\cos(\pi n_l s_1)| = 0.$$

This finishes the proof of part (b). □

In the proof of Lemma 3.5 it is shown that the positive zeros of $g(\omega)$ are countable. We append to this set the values $\{\pi n\}$, where n satisfies $\cos(\pi n s_1) = 0$, and label them $\{\omega_k\}_{k\in\mathbf{Z}^+}$, where we assume that the sequence is increasing. Recall from Lemma 3.2 that these are the nonzero values of ω for which $\pm i\omega^2$ are eigenvalues.

The following lemma is useful in the proofs of Lemmas 3.7 and 3.9.

LEMMA 3.6. $\{\omega_k\}_{k\in\mathbf{Z}^+}$ *satisfies condition* (2.18).

Proof. For some values of s_1 all of the η_k's and $\tilde{\eta}_j$'s, as defined in (3.47), are distinct, whereas for some values of s_1 there are nonnegative integers k and j such that $\eta_k = \tilde{\eta}_j$. It is easy to verify that the latter values of s_1 are the set of rational numbers in [0,1] of the form n/m, where n is an odd integer and m is an even integer. If s_1 is of this form, let l be any odd integer, and we see that if $k = (l(m-n)-1)/2$ and $j = (nl-1)/2$, then $\eta_k = \tilde{\eta}_j = \pi lm/2$. It is also easy to see that these are the only nonnegative integer values of j and k such that $\eta_k = \tilde{\eta}_j$. The integers $lm/2$ are precisely the integers ω such that $\cos(\pi\omega s_1) = 0$. The statement "between any two adjacent elements of Λ (see (3.48)) there is exactly one zero of g" (see (3.15)) was proved in the proof of Lemma 3.5. This statement can be extended to "between any two adjacent elements of Λ there is exactly one element of $\{\omega_k\}$," interpreted to mean that if two elements of Λ are equal, then the number "between" them is the common value.

In a closed interval of length M, there are at most $1 + M(1-s_1)/\pi$ values of η_k, and at most $1 + Ms_1/\pi$ values of $\tilde{\eta}_j$. Therefore there are at most $2 + M/\pi$ elements of Λ (not necessarily distinct) in an interval of length M. In light of the above paragraph, we see that there are at most $3 + M/\pi$ values of ω_k in an interval of length M. Therefore, ω_{k+4} must be outside of the interval $[0, k\pi]$, that is,

$$\omega_{4+k} > k\pi,$$

or

$$\omega_k > k\pi - 4\pi. \tag{3.52}$$

In a closed interval of length M, there are at least $-1 + M(1-s_1)/\pi$ values of η_k and at least $-1 + Ms_1/\pi$ values of $\tilde{\eta}_j$. Therefore there are at least $-2 + M/\pi$ elements of Λ (not necessarily distinct) in an interval of length M. We then see that there are at least $-3 + M/\pi$ values of ω_k in an interval of length M. Hence ω_{k-3} must be inside of the interval $[0, k\pi]$, that is,

$$\omega_{k-3} \leq k\pi$$

or

$$\omega_k \leq k\pi + 3\pi.$$

Combining this with (3.52) completes the proof of the lemma. □

We can now prove the admissibility of the input and observation operators.

LEMMA 3.7. *For any s_1, the input operator B and the observation operator B^* are admissible for $S(t)$.*

Proof. It follows from (3.38) that for positive zeros ω of g,

$$\lim_{\omega\to\infty} |C_\omega - [s_1 \sec^2(\omega s_1) + (1-s_1)\sec^2 \omega(s_1 - 1)]^{-1/2}| = 0. \tag{3.53}$$

Therefore $\{C_\omega\}$ is a bounded sequence. It is then clear from (3.40) for b_ω that $\{b_\omega\}$ is a bounded sequence. Taking (3.39) into account, we see that the input coefficients are all bounded.

To conclude that B is an admissible input operator, we use the Carleson measure criterion found in Ho and Russell [9] or Weiss [20]. This criterion applies here if the eigenvalues are on the imaginary axis and Condition 1, defined before Lemma 2.12, is satisfied. In the proof of Lemma 3.6 we see that the number of ω_k's in an interval of length M is at most $3 + M/\pi$, so the number of eigenvalues of A in

$$S_{a,M} = \{z \,|\, \mathrm{Re}(z) = 0, a^2 \le \mathrm{Im}(z) \le (a+M)^2\}$$

is less than or equal to $3 + M/\pi$. This shows that Condition 1 preceding Lemma 2.12 is satisfied, so B is an admissible input operator. By duality, B^* is an admissible observation operator. □

We now see how condition (1.8) effects the behavior of the input coefficients $\{b_\omega\}$.

LEMMA 3.8. (a) *Suppose* (1.8) *is true. Then there exists $m > 0$ such that for all positive zeros ω of g,*

$$|b_\omega| > m. \tag{3.54}$$

(b) *Suppose there exists a sequence of positive integers $\{n_l\}$ such that* (3.45) *is true. Then there exists a sequence of zeros $\{\omega_k\}$ of g such that*

$$\lim_{k\to\infty} |b_{\omega_k}| = 0. \tag{3.55}$$

Proof. We first prove part (a). Because (1.8) is true, (3.42) and (3.43) are true. Combining this with (3.53), we see that $\{C_\omega^{-1}\}$ is a bounded sequence, so $\{C_\omega\}$ is bounded below away from zero. Because $(\tanh(\omega s_1) + \tanh \omega(1-s_1)) \to 2$ as $\omega \to \infty$ along the real axis, we see from (3.40) that (3.54) is true.

To prove part (b), note that if (3.45) is true, then part (b) of Lemma 3.5 gives a sequence $\{\omega_k\}$ such that (3.46) is true. Therefore, we see from (3.53) that $\{C_{\omega_k}^{-1}\}$ is an unbounded sequence. Because $\{\tanh(\omega_k s_1) - \tanh \omega_k(s_1 - 1)\}$ is a bounded sequence, we see from (3.40) that (3.55) is true. □

We are now in a position to follow the approach given in the proof of Theorem 1.1. Because many of the details are the same, we frequently refer to the corresponding proofs in §2.

LEMMA 3.9. (1) *The feedthrough for the system* (1.2), (1.6), (3.6), (3.10) *is* 0.

(2) *(B^*, A_k, B) is regular.*

(3) $A_k = A - kBB_L^*$.

Proof. We first show that the system (1.2), (1.6), (3.5), (3.6) is regular. We have already shown that B and B^* are admissible for $S(t)$. As in the proof of Lemma 2.6, we obtain the formula for $B_L^*R(\lambda, A)B$ by using the matrix representations of A and B in the basis $\{\Phi_k\}_{k\in I}$, so

$$B_L^*R(\lambda, A)B = \frac{|b_0|^2}{\lambda} + \sum_{k=1}^{\infty}\left\{\frac{|b_{\omega_k}|^2}{\lambda - i\omega_k^2} + \frac{|b_{\omega_k}|^2}{\lambda + i\omega_k^2}\right\}.$$

Because Lemma 3.6 shows that $\{\omega_k\}$ satisfies condition (2.18), we can apply Theorem 2.7 to conclude that the system (1.2), (1.6), (3.5), (3.6) is regular in the sense of [23] (with the feedthrough undetermined so far), and in fact satisfies (2.19).

We can compute the transfer function $\mathbf{H}(\lambda)$ of this system by taking the Laplace transform of (1.2), (1.6), (3.5), (3.6). Recall that in this paper $\lambda = i\omega^2$, where we can restrict ω to $\{\mathrm{r}e^{i\theta} \mid r \geq 0,\ \theta \in [-\pi/2, 0]\}$.

Let

$$p(s_{\mathrm{I}}, \omega) = \frac{\sinh(\omega s_{\mathrm{I}}) - \cosh(\omega s_{\mathrm{I}}) \tanh \omega(s_{\mathrm{I}} - 1)}{\cos(\omega s_{\mathrm{I}}) \tan \omega(s_{\mathrm{I}} - 1) - \sin(\omega s_{\mathrm{I}})}. \tag{3.56}$$

We find that

$$\mathbf{H}(\lambda) = \frac{-2i}{\omega}\left\{\frac{\sinh(\omega s_{\mathrm{I}}) - \cosh(\omega s_{\mathrm{I}}) \tanh \omega(s_{\mathrm{I}} - 1)}{\cosh(\omega s_{\mathrm{I}}) + p(s_{\mathrm{I}}, \omega)\cos(\omega s_{\mathrm{I}})}\right\}. \tag{3.57}$$

From this it is easy to see that $\mathbf{H}(\lambda) \to 0$ as $\lambda \to \infty$ along the positive real axis. Therefore, the system (1.2), (1.6), (3.5), (3.6) is regular in the sense of Definition 2.1 and can be represented by (B^*, A, B).

As in the proof of Lemma 2.6, if $J \in \mathcal{B}(U)$, then $A + BJB_L^*$ is the generator of a C_0-semigroup, and the closed-loop system obtained by letting $u(t) = Jy(t)$ is regular in the sense of Definition 2.1 and can be represented by $(B_L^*, A - BJB_L^*, B)$. Also as in the proof of Lemma 2.6, $A - kBB_L^* = A_k$, so we can take $J = -kI$ to finish the proof of Lemma 3.9. □

The proof of Lemma 2.8 applies to this system, so $\mathbf{H}_k(\lambda)$ is bounded on the imaginary axis.

LEMMA 3.10. *If* (1.8) *is true, then* (A_k, B) *is stabilizable as in Definition* 2.3, *and* (B^*, A_k) *is detectable as in Definition* 2.4.

Proof. This lemma is proved in exactly the same way as Lemma 2.10. Therefore, rather than give the proof, we explain why the proof of Lemma 2.10 also goes through in this case. That proof relied on three properties of A that are needed to be able to apply results in [15]. These follow from Lemmas 3.2, 3.6, and 3.8 and Proposition 3.3.

(1) The eigenvectors of A form a Riesz basis for X.

(2) The eigenvalues of A are of multiplicity 1 and grow quadratically on the imaginary axis.

(3) The input coefficients for (A, B) are bounded above and bounded below away from zero. □

Therefore, if (1.8) is true, then an application of Theorem 2.5 shows that A_k is exponentially stable. To finish the proof of Theorem 1.3, suppose (1.8) is not true, so (3.41) is not true by Lemma 3.5. There are then two possibilities. If $\cos(\pi m s_{\mathrm{I}}) = 0$ for some positive integer m, then part (b) of Lemma 3.2 and (3.39) show that $\lambda = \pm i(\pi m)^2$ are eigenvalues with associated input coefficients $b_{\pm m} = 0$. The other possibility is that there exists a sequence of positive integers $\{n_l\}$ such that (3.45) is true. Then part (b) of Lemma 3.8 gives a sequence of eigenvalues $\{\pm i\omega_k^2\}$ with associated input coefficients satisfying (3.55). In either case we see that (3.54) is not true. Therefore, (2.23) cannot be satisfied. Because the eigenvalues of A are shown in the proof of Lemma 3.7 to satisfy Condition 1 stated before Lemma 2.12, Lemma 2.12 shows that $A_k = A - kBB^*$ cannot generate an exponentially stable semigroup. This finishes the proof of Theorem 1.3.

4. Appendix.

In this Appendix we prove Lemma 2.11 and Theorem 2.7.

We start with Lemma 2.11. The result seems almost obvious formally, because $(A + BKC_L) + BK(C_L' - C_L) = A + BKC_L'$ and K is an admissible feedback for (C_L', A, B).

However, to prove the result rigorously we need to show that $(C'_L - C_L, A + BC_L, B)$ satisfies Definition 2.2 with feedback K.

Proof of Lemma 2.11. Let $\mathbf{H}_1$ be the transfer function for (C, A, B) and $\mathbf{H}_2$ be the transfer function for (C', A, B). Let $\mathbf{H}_1^K$ be the closed-loop transfer function for (C, A, B) under the feedback $u = Ky + v$, that is, the transfer function for the system

$$\dot{x}(t) = (A + BKC_L)x(t) + Bv(t) \tag{4.1}$$

$$y(t) = C_L x(t). \tag{4.2}$$

Then it is shown in [24] that

$$\mathbf{H}_1^K = \mathbf{H}_1(I - K\mathbf{H}_1)^{-1}, \tag{4.3}$$

where all inverses are in H_∞^∞.

Let $\mathbf{H}$ be the transfer function for $(C'_L - C_L, A + BKC_L, B)$, so $\mathbf{H}$ can be written as $\mathbf{H}_3 - \mathbf{H}_1^K$, where $\mathbf{H}_3$ is the transfer function for $(C'_L, A + BKC_L, B)$. We need to show that $(I - K\mathbf{H})$ is invertible in H_∞^∞. To do this we need to find a formula for $\mathbf{H}_3$ in terms of $\mathbf{H}_2$ and $\mathbf{H}_1$.

Consider the system

$$\dot{x}(t) = Ax(t) + Bu(t),$$

$$y(t) = [C_L, C'_L]^T x(t).$$

The transfer function for this system is $\tilde{\mathbf{H}} = [\mathbf{H}_1, \mathbf{H}_2]^T$. It is easy to see that $\tilde{K} = [K, 0]$ is an admissible feedback for $\tilde{\mathbf{H}}$, because $(I - \tilde{K}\tilde{\mathbf{H}}) = I - K\mathbf{H}_1$, which is invertible by hypothesis. The closed-loop system with the feedback $u = \tilde{K}y + v$ is then

$$\dot{x}(t) = (A + BKC_L)x(t) + Bv(t),$$

$$y(t) = [C_L, C'_L]x(t),$$

which has the transfer function $\tilde{\mathbf{H}}^{\tilde{K}}$. Because $\mathbf{H}_1^K$ is the transfer function for (4.1), (4.2), $\tilde{\mathbf{H}}^{\tilde{K}} = [\mathbf{H}_1^K, \mathbf{H}_3]$. Using Proposition 3.6 in [24], we see that the admissibility of $\tilde{K}$ for $\tilde{\mathbf{H}}$ implies that

$$\tilde{\mathbf{H}}^{\tilde{K}} - \tilde{\mathbf{H}} = \tilde{\mathbf{H}}^{\tilde{K}}\tilde{K}\tilde{\mathbf{H}}.$$

Writing down the second component in this identity gives

$$\mathbf{H}_3 - \mathbf{H}_2 = \mathbf{H}_3 K\mathbf{H}_1.$$

Solving this for $\mathbf{H}_3$, we obtain

$$\mathbf{H}_3 = \mathbf{H}_2(I - K\mathbf{H}_1)^{-1}.$$

Combining this with (4.3) we see that

$$\mathbf{H} = \mathbf{H}_3 - \mathbf{H}_1^K = (\mathbf{H}_2 - \mathbf{H}_1)(I - K\mathbf{H}_1)^{-1}. \tag{4.4}$$

Let

$$\mathbf{H}^K = (\mathbf{H}_2 - \mathbf{H}_1)(I - K\mathbf{H}_2)^{-1}, \tag{4.5}$$

where we are using the fact that K is an admissible feedback for (C_L', A, B), so $(I - K\mathbf{H}_2)$ is invertible. It is now easy but tedious to use (4.4) and (4.5) to verify algebraically that

$$(I - K\mathbf{H})^{-1} = (I + K\mathbf{H}^K).$$

This shows that $(I - K\mathbf{H})$ is invertible in H_∞^∞, so K is an admissible feedback for $\mathbf{H}$ according to Definition 2.2, finishing the lemma. □

Proof of Theorem 2.7. Because $\{d_k\}_{k\in I} \in l^\infty$, there exists $M > 0$ such that

$$|\mathbf{H}(s)| \leq M \sum_{k=1}^{\infty} \left| \frac{1}{s - i\omega_k^2} \right| + M \sum_{k=1}^{\infty} \left| \frac{1}{s + i\omega_k^2} \right| .$$

We analyze the first sum and note that the second sum can be analyzed in the same way. Let a, b, and m be as in the statement of Theorem 2.9, and let K be the smallest nonnegative integer greater than or equal to $-b/m$. So if $k > K$, then $(mk + a)$ and $(mk + b)$ are both positive. We can write the first sum above as

$$\sum_{k=1}^{K} \left| \frac{1}{s - i\omega_k^2} \right| + \sum_{k=K+1}^{\infty} \left| \frac{1}{s - i\omega_k^2} \right|, \tag{4.6}$$

where the first finite sum (interpreted as 0 if $K = 0$) clearly satisfies (2.19). To analyze the second sum in (4.6), let $s = x + iy$, where $x > 0$. The second sum is then less than or equal to

$$\frac{1}{\sqrt{2}} \sum_{k=K+1}^{\infty} \frac{1}{x + |y - \omega_k^2|}. \tag{4.7}$$

We show that this sum has a bound that is independent of y and dependent of x. If $y \geq (m(K+1) + a)^2$, let $K_1(y)$ be the largest integer less than or equal to $(\sqrt{y} - a)/m$. If $y < (m(K+1) + a)^2$, let $K_1(y) = K$. Then

$$y - \omega_k^2 \geq y - (mk + a)^2 \geq 0 \quad \text{for } K < k \leq K_1(y). \tag{4.8}$$

If $y \geq (mK + b)^2$, let $K_2(y)$ be the smallest integer greater than $(\sqrt{y} - b)/m$. If $y < (mK + b)^2$, let $K_2(y) = K + 1$. Then

$$y - \omega_k^2 \leq y - (mk + b)^2 < 0 \quad \text{for } k \geq K_2(y). \tag{4.9}$$

Now we see that (4.7) is equal to

$$\frac{1}{\sqrt{2}} \left(\sum_{k=K_1(y)+1}^{K_2(y)} \frac{1}{x + |y - \omega_k^2|} + \sum_{k=K+1}^{K_1(y)} \frac{1}{x + y - \omega_k^2} + \sum_{k=K_2(y)+1}^{\infty} \frac{1}{x + \omega_k^2 - y} \right)$$
$$=: \frac{1}{\sqrt{2}}(S_1 + S_2 + S_3),$$

where S_2 is interpreted as 0 if $K_1(y) = K$. To analyze S_1, note that there are $K_2(y) - K_1(y)$ terms in S_1, each of modulus less than or equal to $1/x$. Because $K_2(y) > (\sqrt{y} - b)/m + 1$ and $K_1(y) \leq (\sqrt{y} - a)/m - 1$, we see that

$$S_1 \leq (2 + (a - b)/m)/x. \tag{4.10}$$

We now analyze S_2. Note that if $y < (m(K+1)+a)^2$ then $S_2 = 0$, so we assume that $y \geq (m(K+1)+a)^2$. Using (4.8), we see that

$$S_2 \leq \sum_{k=K+1}^{K_1(y)} \frac{1}{x+y-(mk+a)^2}.$$

Therefore,

$$\begin{aligned} S_2 &\leq \int_{K+1}^{K_1(y)} \frac{d\eta}{x+y-(m\eta+a)^2} \\ &= \frac{1}{m}\int_{m(K+1)+a}^{mK_1(y)+a} \frac{d\zeta}{x+y-\zeta^2}. \end{aligned}$$

Because $mK_1(y)+a \leq \sqrt{y}$ and $m(K+1)+a > 0$, this is

$$\leq \frac{1}{m}\int_0^{\sqrt{y}} \frac{d\zeta}{x+y-\zeta^2}.$$

This integral is evaluated as

$$\frac{1}{m}\frac{1}{\sqrt{x+y}}\ln\left|\sqrt{1+\frac{y}{x}}+\sqrt{\frac{y}{x}}\right| = \frac{1}{m\sqrt{x}}\frac{1}{\sqrt{1+\psi}}\ln\left|\sqrt{1+\psi}+\sqrt{\psi}\right|,$$

where $\psi = y/x$. This is

$$\leq \frac{1}{m\sqrt{x}}\left(1+\sqrt{\psi/(1+\psi)}\right) \leq \frac{2}{m\sqrt{x}}$$

when $\psi > 0$, which is the case here, because $y \geq (m(K+1)+a)^2$ and $x > 0$. Therefore there exists a constant $M > 0$ independent of y such that

$$S_2 \leq \frac{M}{\sqrt{x}}. \tag{4.11}$$

We now analyze S_3. Using (4.9) we see that

$$\begin{aligned} S_3 &\leq \sum_{k=K_2(y)+1}^{\infty} \frac{1}{x+(mk+b)^2-y} \\ &\leq \int_{K_2(y)}^{\infty} \frac{d\eta}{x+(m\eta+b)^2-y} = \frac{1}{m}\int_{mK_2(y)+b}^{\infty} \frac{d\zeta}{x-y+\zeta^2}. \end{aligned} \tag{4.12}$$

To analyze this integral we consider several cases. If $x > y \geq 0$, we use the fact that $mK_2(y)+b > \sqrt{y}$, so this integral is

$$\begin{aligned} &\leq \frac{1}{m}\int_{\sqrt{y}}^{\infty} \frac{d\zeta}{x-y+\zeta^2} = \frac{1}{m\sqrt{x-y}}\left(\frac{\pi}{2} - \tan^{-1}\sqrt{\frac{y}{x-y}}\right) \\ &= \frac{1}{m\sqrt{x}}\frac{1}{\sqrt{1-1/\psi}}\left(\frac{\pi}{2} - \tan^{-1}\sqrt{\frac{1}{\psi-1}}\right), \end{aligned}$$

where $\psi = x/y > 1$. (If $y = 0$ the modifications are obvious.) If we let $g(\psi) = (\frac{\pi}{2} - \tan^{-1}((\psi - 1)^{-1/2}))/\sqrt{1 - 1/\psi}$, it is easy to use L'Hôpital's rule to see that $g(\psi)$ is bounded on $(1, \infty)$. Therefore, for $x > y \geq 0$, there exists $M > 0$ such that

$$S_3 \leq \frac{M}{\sqrt{x}}. \tag{4.13}$$

If $x > y$ and $y < 0$, then the last integral in (4.12) is less than or equal to

$$\frac{1}{m}\int_0^\infty \frac{d\zeta}{x - y + \zeta^2} = \frac{\pi}{2m\sqrt{x - y}} \leq \frac{\pi}{2m\sqrt{x}},$$

so in this case (4.13) is also true.

If $x = y$, then the last integral in (4.12) is

$$= \frac{1}{m(mK_2(y) + b)} \leq \frac{1}{m\sqrt{y}} = \frac{1}{m\sqrt{x}},$$

so (4.13) is true in this case.

If $x < y$, then the last integral in (4.12) is less than or equal to

$$\frac{1}{m}\int_{\sqrt{y}}^\infty \frac{d\zeta}{x - y + \zeta^2} = \frac{1}{m\sqrt{y - x}} \ln\left|\sqrt{\frac{y}{x}} + \sqrt{\frac{y}{x} - 1}\right|.$$

Letting $\psi = y/x > 1$, we see that this is

$$= \frac{1}{m\sqrt{x}}\frac{1}{\sqrt{\psi - 1}} \ln\left|\sqrt{\psi} + \sqrt{\psi - 1}\right|.$$

It is easy to use L'Hôpital's rule to show that $g(\psi) = \ln|\sqrt{\psi} + \sqrt{\psi - 1}|/\sqrt{\psi - 1}$ is bounded on $(1, \infty)$, so we see that in this case (4.13) is again true. Therefore, there exists an M such that for all $x > 0$, (4.13) is true.

Combining (4.10), (4.11), and (4.13), we see that for any $\alpha > 0$, the second sum in (4.6) is bounded by $M/\sqrt{x}$ for some M and all $x \geq \alpha$. This shows that the conclusions of Theorem 2.7 are true, finishing the proof. □

DYNAMIC PROGRAMMING AND PRICING OF CONTINGENT CLAIMS IN AN INCOMPLETE MARKET*

NICOLE EL KAROUI† AND MARIE-CLAIRE QUENEZ†

Abstract. The problem of pricing contingent claims or options from the price dynamics of certain securities is well understood in the context of a complete financial market. This paper studies the same problem in an incomplete market. When the market is incomplete, prices cannot be derived from the absence of arbitrage, since it is not possible to replicate the payoff of a given contingent claim by a controlled portfolio of the basic securities. In this situation, there is a price range for the actual market price of the contingent claim. The maximum and minimum prices are studied using stochastic control methods.

The main result of this work is the determination that the maximum price is the smallest price that allows the seller to hedge completely by a controlled portfolio of the basic securities. A similar result is obtained for the minimum price (which corresponds to the purchase price).

Key words. option pricing, incomplete market, equivalent martingale measures, portfolio processes, stochastic control

AMS subject classifications. 90A09, 90C39, 93E25

Introduction. We study the problem of determining the price of a contingent claim from the price dynamics of certain securities (such as stocks and bonds). However, the price system alone cannot give a complete description of the exogenous uncertain environment; other information that is inside or outside the market is available and might influence market fluctuations. Therefore, the information structure used is as general as possible; in particular, it is not supposed to be generated by Brownian motions.

The primitive securities consist of a bond and n stocks, the latter being driven by a d-dimensional Brownian motion. Absence of arbitrage is assumed. The fluctuation in those prices is linked to the rest of the market (market fluctuations, change in rates, prices of other securities, and so on) and to other factors that are outside the market. The contingent claim is not linked only to the basic securities.

In §1, we formulate the basic problem of hedging by constructing a portfolio of the basic securities that attains (at least) the payoff of the contingent claim as its terminal wealth. Unlike in the complete market case, it is not possible to replicate the payoff of every contingent claim by a portfolio, and there are several probability measures that are equivalent to the initial probability, such that the discounted price processes are martingales. Several price systems are associated by duality to those martingale measures. Thus in this situation there is a price range for the actual market price of the contingent claim.

In §2, we study the maximum price using stochastic control methods. We show that the maximum price can be written as the difference of the (discounted) value of a portfolio and an optional increasing process that is equal to zero at time zero. We then state that the maximum price is the selling price defined as the smallest price that allows the seller to hedge completely by a controlled portfolio of the basic securities. A similar result is obtained for the minimum price (which corresponds to the purchase price). We also state that the class of contingent claims for which the supremum price is obtained for an optimal martingale measure is exactly the set of attainable claims.

In §3, we give a few methods for computing the maximum price (approximation methods, use of Bellman equations in the Markovian case). We also give two examples that illustrate the obtained results.

1. Formulation of the problem.

1.1. The model. The basic securities consist of $n + 1$ assets; they are the only assets that are available to agents for trading. One of them is a nonrisky asset (the bond), with price-per-unit $P_0(t)$ governed by the equation

$$dP_0(t) = P_0(t)r(t)dt. \tag{1}$$

The interest rate $r(t)$ is positive and bounded.

In addition to the bond, there are n risky securities (stocks). The price $P_i(t)$ for one share of the ith stock is modeled by the linear stochastic differential equation

$$dP_i(t) = P_i(t)\left[b_i(t)dt + \sum_{j=1}^{d} \sigma_{i,j}(t)dW_t^j\right]. \tag{2}$$

The information structure is modeled by a filtration $(F_t,\ 0 \leq t \leq T)$ that satisfies the standard hypotheses and is left quasi-continuous. The coefficients of the model r, b_i, $\sigma_{i,j}$ are taken to be predictable with respect to $\{F_t\}$. $W = (W_1, \ldots, W_d)^*$ is a d-dimensional (F_t)-Brownian motion under P, with the "objective" probability taken as a primitive. We suppose that $n \leq d$.

To be a reasonable model of securities markets, the prices of the basic securities should not allow one to create something out of nothing or to create free lunches. Thus, we will suppose the existence of d coefficients $\theta_1, \theta_2, \ldots, \theta_d$ that are (F_t)-predictable processes such that

$$b_i(t) - r(t) = \sum_{j=1}^{d} \sigma_{ij}(t)\theta_j(t), \quad P\text{ a.s.}, \quad 1 \leq i \leq n.$$

$\theta_j(t)$ represents the risk premium associated with the source of uncertainty W_j; we suppose that θ_j is bounded.[1]

We adopt the following notation and make the following assumptions:

- We denote by b the column vector of stock appreciation rates $b = (b_1, \ldots, b_n)^*$.
- For $1 \leq i \leq n$, let σ_i be the volatility row vector of the ith stock $\sigma_i = (\sigma_{i,1}, \ldots, \sigma_{i,n})$
- Let $\sigma(t)$ be the volatility $(n \times d)$ matrix whose rows are $\sigma_1(t), \ldots, \sigma_n(t)$. $\sigma(t)$ is supposed to be bounded.
- Let θ_t be the relative risk column vector $\theta = (\theta_1, \theta_2, \ldots, \theta_d)^*$.

If we denote by $\mathbf{1}$ the vector whose every component is 1, the above equations are written as

$$b(t) - r_t\mathbf{1} = \sigma_t\theta_t, \quad P\text{ a.s.}$$

Furthermore, we will suppose that there exists a predictable vector α_t for which $\theta_t = \sigma_t^*\alpha_t$. (This hypothesis, which is not restrictive, will be explained in §1.8.)

Remark. Notice that if σ_t is taken to be injective, the above hypotheses are satisfied.

In the next section, we recall the characteristics of portfolios.

[1] For information concerning the equivalence between the assumption of no arbitrage and the existence of θ, one is referred to [Fö-Sc], [H-J-M], [An-St]. We thank the reviewers for the following references concerning this point: [Ch-Mu], [He-Pe], [Sch].

1.2. The portfolios. Let us consider an investor who can invest in the $n+1$ basic securities. At time 0, he invests the amount $x \geq 0$ in the $n+1$ securities. We shall denote by $X(t)$ the value of the amount invested at time t in the $n+1$ securities; $X(0) = x$. For $i = 1, \dots, d$, we denote by $\pi_i(t)$ the amount that he invests in the ith stock at time t.

DEFINITION 1.2.1. *A portfolio strategy* $\pi(t) = (\pi_1(t), \dots, \pi_n(t))$; $0 \leq t \leq T$, *is an* R^n*-valued process that is predictable with respect to* (F_t) *and satisfies*

$$\int_0^T \|\sigma_t^* \pi_t\|^2 \, dt < +\infty, \quad P\text{a.s.}$$

The amount invested in the bond at time t is then given by

$$X(t) - \sum_{i=1}^n \pi_i(t).$$

Let $N(t)$ be the cumulative total sum of additional amounts that have been invested by the agent in the $n+1$ securities between 0 and t; N is a right-continuous left-limited (RCLL), (F_t)-optional process that satisfies $N_0 = 0$.

The value of the portfolio $X(t)$ is given by

$$dX_t = \sum_{i=1}^n \pi_i(t)[b_i(t) + \sigma_i(t) dW_t] + \left(X_t - \sum_{i=1}^n \pi_i(t)\right) r(t)dt + dN_t,$$

or equivalently,

$$dX_t = r_t X_t \, dt + \pi_t^*(b_t - r_t \mathbf{1})dt + \pi_t^* \sigma_t \, dW_t + dN_t.$$

Remark. Loosely speaking, dN_t is the amount saved (or consumed if negative) during the time period $[t, \, t + dt]$.

We denote by $X^{\pi,N,x}(t)$ the value of the portfolio corresponding to the strategy (π, N) and the initial investment x.

- If $N = 0$, the portfolio is called *self-financing*, then $X^{\pi,0,x}(t)$ is the value at time t of the self-financing portfolio corresponding to the initial investment x and the portfolio π.
- If $N_t = -C_t$, where $(C_t, 0 \leq t \leq T)$ is an RCLL, (F_t)-optional increasing process that satisfies $C_0 = 0$, the portfolio is called a *portfolio strategy with consumption*; $X^{\pi,-C,x}(t)$ is the value at time t of the portfolio corresponding to the initial investment x, the portfolio π, and the process C_t that represents the cumulative amount the agent withdraws up to time t for consumption.
- If $N_t = D_t$ where $(D_t, 0 \leq t \leq T)$ is an RCLL, (F_t)-optional increasing process that satisfies $D_0 = 0$, the portfolio is called a *portfolio strategy with savings*; $X^{\pi,D,x}(t)$ is the value at time t of the portfolio corresponding to the initial investment x, the portfolio π, and the process D_t that represents the cumulative amount the agent adds in the portfolio up to time t.

1.3. Contingent claim B, selling price. Let T, a positive constant, be the terminal time for the problem.

DEFINITION 1.3.1. *A* contingent claim *B is a nonnegative, F_T-measurable random variable. It can be thought of as a contract or agreement that pays B at maturity T.*

The problem is to price this contingent claim. Let us consider a seller who wants to sell some contingent claim with payoff B and maturity T, between time 0 and time T. Suppose the seller chooses the price Y_t for B at any time t; more precisely, the seller must choose his price process $(Y_t,\ t \geq 0)$ (i.e., an RCLL optional nonnegative process that satisfies $Y_T = B$). Also, the seller does not want to run any risk of losing money. Therefore, he will only choose price processes that allow him to hedge completely by a controlled portfolio of the basic securities in the sense that, if at any time t, he sells the option B, and if at a later date, he buys it back, he wants to make a profit. More precisely, suppose that at time t, the seller sells the contingent claim at the price Y_t. He then invests this amount in the self-financing portfolio determined by π_t. At time $t + dt$, he buys back the contingent claim at the price Y_{t+dt} and sells the portfolio; he then makes a profit equal to

$$r_t Y_t\, dt + \pi_t^* \sigma_t (dWt + \theta_t\, dt) - dY_t.$$

Hence, we have the following definition.

DEFINITION 1.3.2. *A process Y_t is called a* price admissible for sellers *if Y_t is an* RCLL *nonnegative optional process that satisfies $Y_T = B$ and such that there exist a portfolio process π_t and an* RCLL, *(F_t)-optional increasing process $(C_t,\ 0 \leq t \leq T)$ such that $C_0 = 0$ and $dY_t = r_t Y_t\, dt + \pi_t^*\, \sigma_t (dWt + \theta_t\, dt) - dC_t$.*

Remark. It is equivalent to say that a process Y_t is a price admissible for sellers if there exists a hedging portfolio of B that is a portfolio with consumption (i.e., with withdrawals) whose value is equal to the price, that is, if there exists a portfolio process π_t and an RCLL, (F_t)-optional increasing process $(C_t,\ 0 \leq t \leq T)$ that satisfies $C_0 = 0$ and an initial investment x such that

$$X^{\pi,-C,x}(T) = B \quad \text{and} \quad Y_t = X^{\pi,-C,x}(t) \geq 0, \qquad 0 \leq t < T.$$

Note that every price admissible for sellers corresponds to one (and only one) hedging portfolio with consumption.

For the seller who sells the contingent claim B to an investor, such a strategy can be interpreted as follows:

- x is the price paid by the investor to the seller at time 0.
- π characterizes the hedging portfolio held by the seller.
- $C(t)$ represents the cumulative amount the seller withdraws from the hedging portfolio up to time t (which should be given to the investor, and since it is not, it is a profit for the seller).

Hence, it follows that x is the price paid not only for getting B at maturity T but also for getting additional amounts represented by the process $(C(t),\ 0 \leq t \leq T)$. Also, the seller's price will be the lowest price admissible for sellers. Thus, we define the selling price by Definition 1.3.3.

DEFINITION 1.3.3. *If it exists, the lowest price process admissible for sellers is called the* selling price.

Remark 1. We will see in §2 that such a process always exists, which is not obvious.

Remark 2. We could have defined the selling price as the essential infimum of the price processes admissible for sellers (but this would not define a stochastic process).

(Note that by symmetry, we can define the purchase price for B; it will be studied in §4.)

1.4. Discounting. Let β_t be the discount process given by

$$\beta_t = \exp\left\{-\int_0^t r_s\, ds\right\}, \qquad 0 \leq t \leq T.$$

We denote by $P_i^d(t)$, $\pi^d(t)$, $C^d(t)$ the discounted price process, the discounted portfolio process associated with the portfolio $\pi(t)$, and the discounted consumption process associated with the consumption $C(t)$, respectively. For $0 \le t \le T$, we have

$$\begin{aligned} P_i^d(t) &= \beta_t P_i(t) \qquad (1 \le i \le n),\\ \pi^d(t) &= \beta_t \pi(t),\\ C_t^d &= \int_0^t \beta_s \, dC_s. \end{aligned}$$

We have the following equation for the discounted price process:

$$dP_i^d(t) = P_i^d(t)[(b_i(t) - r(t))dt + \sigma_i(t)dW_t]. \tag{3}$$

The discounted value of the portfolio with withdrawals X^d associated with the portfolio-consumption strategy (π_t, C_t) is governed by the equation

$$dX_t^d = (\pi_t^d)^*[(b(t) - r(t)\,\mathbf{1})dt + \sigma(t)dW_t] - dC_t^d,$$

that is,

$$dX_t^d = (\pi_t^d)^* \sigma_t(\theta_t \, dt + dW_t) - dC_t^d. \tag{4}$$

Also, for a contingent claim B, we denote by B^d the discounted contingent claim

$$B^d = \beta_T B.$$

We now come back to the problem of pricing the contingent claim B from the price dynamics of the $n+1$ securities. We begin by recalling the theory of contingent claim valuation in the context of a complete market (see [Ha-Kr], [Ha-Pl], [Duf], and [Kar]). It is well known that the reference probability Q defined below has a fundamental role. Hereafter, we will often use the Girsanov theorem. (See §A.1, where we recall a general form of this theorem.)

1.5. The reference probability Q.

Notation. Let N_t be a local martingale (RCLL) under P with respect to $\{F_t\}$, such that $N_0 = 0$. We denote by $\mathcal{E}(N)_t$ the *exponential of N*, that is, the solution of the stochastic differential equation (SDE)

$$dZ_t = Z_{t^-} \, dN_t, \quad 0 \le t \le T, \quad Z_0 = 1.$$

This process is a local martingale under P.

Let $Z_0(t)$ be the exponential local martingale of

$$\left(- \int_0^t \theta_s^* \, dW_s, \, 0 \le t \le T \right)$$

that is,

$$Z_0(t) = \exp\left\{ - \int_0^t \theta_s^* \, dW_s - \frac{1}{2} \int_0^t \|\theta_s\|^2 \, ds \right\}.$$

Because θ is bounded, $Z_0(t)$, $0 \le t \le T$ is martingale under P.

We then define Q as the probability measure equivalent to P on F_T that admits the Radon–Nikodym derivative $Z_0(T)$. Let

$$\widetilde{W}_t = W_t + \int_0^t \theta_s \, ds, \qquad 0 \le t \le T.$$

By the Girsanov theorem, $(\widetilde{W}_t,\ 0 \leq t \leq T)$ is an (F_t)-Brownian motion under Q.

The SDE (3) relative to the discounted prices may be written as

$$dP_i^d(t) = P_i^d(t)\sigma_i(t)d\widetilde{W}_t. \tag{5}$$

Also, the discounted value X^d of the portfolio with withdrawals associated with the portfolio π_t, consumption C_t, and initial investment x is given by

$$X_t^d = x + \int_0^t (\pi_s^d)^* \sigma_s \, d\widetilde{W}_s - C_t^d, \quad Q\text{ a.s.}, \quad 0 \leq t \leq T. \tag{6}$$

Notice that the prices of the basic securities are Q-martingales and the prices (of the contingent claim) admissible for sellers are Q-supermartingales.

1.6. Pricing in a complete market. We review briefly in this section important results for use later in the treatment of the incomplete market case.

DEFINITION 1.6.1. *The security market is said to be* complete *if the filtration (F_t) is that generated by the Brownian motion W_t, $n = d$, and σ has full rank. It means that all the sources of uncertainty can be explained by the price dynamics of the basic securities. If it is not complete, the market will be called* incomplete.

Recall that if the market is complete, it is possible to construct a portfolio that attains as its final wealth any contingent chain B that is integrable under Q, that is, there exist some $x \geq 0$ and some portfolio (π_t) satisfying

$$B^d = x + \int_0^T (\pi_u^d)^* \sigma_u \, d\widetilde{W}_u, \quad P\text{ a.s.}$$

and such that the process defined by

$$x + \int_0^t (\pi_u^d)^* \sigma_u \, d\widetilde{W}_u, \qquad 0 \leq t \leq T$$

is a martingale under Q.

It is clear that $x = E_Q(B^d)$. This property allows us to derive the price for any contingent claim from an absence of arbitrage.

PROPOSITION 1.6.1. *In a complete market, every contingent claim (Q-integrable) is priced by arbitrage. This price is given by the expectation of the discounted contingent claim under Q, which is the unique probability measure under which the discounted prices of the basic stocks are martingales.*

Proof. Let P_B be the price for the contingent claim B. Suppose that P_B is strictly greater than $E_Q(B^d)$; then there exists some opportunity for arbitrage. For example, you can sell the contingent claim at $t = 0$ at the price P_B and invest the amount P_B in the hedging portfolio determined by π. At time T, you pay the amount B to your buyer and sell the portfolio, whose value is given by

$$\beta_T^{-1}\left(P_B + \int_0^T (\pi_u^d)^* \sigma_u \, d\widetilde{W}_u\right).$$

From an initial wealth equal to 0, at time T, you make a strictly positive profit equal to $(\beta_T)^{-1}(P_B - x)$. Also, if $P_B < E_Q(B^d)$, there exists an arbitrage opportunity. Hence, $P_B = E_Q(B^d)$.

The fact that Q is the unique probability that is equivalent to P such that the discounted price processes of the basic stocks are martingales can be easily proved using the Girsanov theorem. (The proof is similar to that of Proposition 1.8.1.) □

Remark 1. The price at time t for the contingent claim B can be determined by an absence of arbitrage and it is given by $E_Q[B^d/F_t]$.

Remark 2. It should be emphasized that the price system is associated by duality to the probability measure Q, which is equivalent to P and under which the discounted price processes are martingales.

Remark 3. In the case of a complete market, the arbitrage-free price coincides with the selling price. The hedging portfolio is a self-financing portfolio associated with the portfolio process π and the initial investment x. Clearly, if the market is complete the consumption processes are unnecessary since it is always possible to replicate the payoff of a given contingent claim by a self-financing portfolio. In the complete market contingent claim valuation, notice the fundamental roles of the construction of a hedging portfolio and the reference probability Q, which is the unique probability measure equivalent to P and under which the discounted price processes are martingales. Those remarks should be kept in mind when considering the more difficult case of an incomplete market.

We now turn to the consideration of an incomplete market. Recall that, contrary to the complete market case, the price system cannot suffice in itself to give a complete description of the environment. As a result, agents will not be able to replicate the payoff of every contingent claim by a self-financing portfolio of the basic securities and to price every contingent claim by arbitrage. Also, there exist several probability measures that are equivalent to P and under which the discounted price processes are martingales, associated by duality to different price systems.

1.7. The P-martingale measures and the attainable contingent claims.

DEFINITION 1.7.1. *Any probability measure that is equivalent to P on F_T and is such that the discounted price processes* (*of the basic claims*) *are martingales is called a P-martingale measure.*

We denote by $\mathcal{P}$ the set of all P-martingale measures. Notice that Q belongs to $\mathcal{P}$ and that, if the market is complete, $\mathcal{P} = \{Q\}$. If the market is incomplete, there are several P-martingale measures. Each martingale measure can naturally be associated by duality with a price system (for more details see [Ha-Kr]).

Assumption. Hereafter, the contingent claim B is supposed to be such that there exists a price admissible for sellers, or equivalently B is supposed to be smaller than the value of a self-financing portfolio, that is, B satisfies

$$B \leq X^{H,0,y}(T), \quad P\,\text{a.s.}$$

for some portfolio strategy H and initial investment $y \geq 0$. Also, we make the following technical assumption: $(X^{H,0,y})^d$ is supposed to be a square-integrable martingale under each P-martingale measure. This assumption will allow us to work with square integrable martingales but the main results of this paper remain true under the weaker hypothesis (see §A.3).

$$\sup_{R \in \mathcal{P}} E_R(B^d) < +\infty.$$

DEFINITION 1.7.2. *Every real that can be written $E_R(B^d)$, where R is a P-martingale measure, is called a* possible price at time $t = 0$ for B.

More generally, any random variable $E_R(B^d/F_t)$, where R is a P-martingale measure, is called a possible price at time t for B. However, there exists a class of contingent claims such that the price is unique, that is, the set of possible prices contains a unique element. We will show that this class is exactly the set of contingent claims that can be synthetized by a controlled portfolio of the basic securities (called "attainable").

DEFINITION 1.7.3. *A contingent claim B is said to be* attainable *if there exist some $x \geq 0$ and some portfolio process π such that*

$$B^d = x + \int_0^T (\pi_u^d)^* \sigma_u \, d\widetilde{W}_u, \quad P\, a.s.$$

and

$$E_Q\left[\int_0^T \|\sigma_s^* \pi_s^d\|^2 \, ds\right] < +\infty.$$

As in the complete market case, an attainable contingent claim B can be priced by arbitrage; therefore, $x = E_Q(B^d)$ is the arbitrage-free price at $t = 0$. Also, we state the following property.

PROPOSITION 1.7.1. *B is attainable if and only if $E_R(B^d)$ is constant over all $R \in \mathcal{P}$, that is, there is only one possible price.*

Remark. We show only one implication. The opposite implication follows from Theorem 2.3.2.

Proof. Let $x \geq 0$ and a portfolio process π such that

$$B^d = x + \int_0^T (\pi_u^d)^* \sigma_u \, d\widetilde{W}_u, \quad P \text{ a.s.}$$

and

$$E_Q\left[\int_0^T \|\sigma_s^* \pi_s^d\|^2 \, ds\right] < +\infty.$$

Let R be a P-martingale measure. The discounted prices $P_i^d(t)$ are martingales under R. Hence, the process defined by

$$x + \int_0^t \sum_{i=1}^n \pi_i^d(u)\sigma_i(u) d\widetilde{W}_u = x + \int_0^t \sum_{i=1}^n \frac{\pi_i^d(u)}{P_i^d(u)} \, dP_i^d(u), \qquad 0 \leq t \leq T$$

is clearly a local martingale under R. It is lower than $(X^{H,0,y})^d$, the discounted value of the portfolio (associated with H and y), because it is equal to $E_Q[B^d/F_t]$. Therefore, it is a martingale under R (by Proposition 1.a in the Appendix) because $(X^{H,0,y})^d$ is a martingale under R. Hence, $E_R(B^d) = x$. □

Remark. If B is attainable, then the price for B at $t \geq 0$ can be derived by an absence of arbitrage and $E_R[B^d/F_t]$ does not depend on $R \in \mathcal{P}$, that is, the set of possible prices contains only one element given by

$$x + \int_0^t \pi_u^{d^*} \sigma_u \, d\widetilde{W}_u.$$

If B is not attainable, there are several prices for B and B cannot be priced by arbitrage. Thus, it seems interesting to determine the bounds of the set of possible prices for B. At $t = 0$, the price for B is worth not less than $\inf_{R \in \mathcal{P}} E_R(B^d)$ and not more than $\sup_{R \in \mathcal{P}} E_R(B^d)$.

Using optimal control techniques, we shall study dynamically those maximum and minimum prices. In particular, we shall show that the supremum of the possible prices is equal to the selling price.

Before proceeding with the analysis of the maximum price, let us characterize the set of P-martingale measures. Recall that Pagès [Pag] has already characterized this set in the context of a Brownian model (see also [KLSX] for utility maximization problems in that context). Also, Ansel and Stricker [An-St] have shown that the market model contains no arbitrage opportunities if and only if $\mathcal{P}$ is nonempty. Furthermore, they have characterized the set of P-martingale measures in a different context: $n = 1$ and the price process (one-dimensional) is supposed to be any continuous semimartingale (actually, the arbitrage-free hypothesis implies that it can be written $M + \int \alpha_s d\langle M\rangle_s$ for some continuous local martingale M and some predictable process α).

1.8. Characterization of the P-martingale measures.

PROPOSITION 1.8.1. *The following properties are equivalent*:

(i) *R is a P-martingale measure.*

(ii) *R is a probability equivalent to P that admits the density*

$$\frac{dR}{dP}\bigg|_{F_T} = \varepsilon\left(-\int_0^{\cdot} \theta_s^*\, dW_s + N\right)_T$$

where N_t is a local martingale that is orthogonal (*in the quadratic variation sense*) *to the prices of the basic securities*

$$\left\langle N, \int_0^{\cdot} \sigma_i(s)d\widetilde{W}_s\right\rangle_T = 0 \quad \forall i \in \{1, 2, \dots, n\}, \quad Q\,\text{a.s.}$$

Proof. Let us show that (i) and (ii) are equivalent. Let R be some probability measure that is equivalent to P on F_T. Put

$$L_t = \frac{dR}{dP}\bigg|_{F_t}, \qquad 0 \le t \le T.$$

L_t is a strictly positive martingale under P. We introduce the local martingale M given by

$$M_t = \int_{0+}^t \frac{1}{L_{s-}}\, dL_s, \qquad 0 \le t \le T,$$

so that

$$L_t = \varepsilon(M)_t, \qquad 0 \le t \le T.$$

Note that, for any $i \le n$, $P_i^d(t)$ is continuous, and hence locally bounded; therefore, by Proposition 1.b in the Appendix, it follows that $\langle M, P_i^d\rangle$ exists. By the Girsanov theorem (Appendix Corollary 1.A (i)), for any $i = 1, \dots, n$, $P_i^d(t)$ is a local martingale under R if and only if

$$(b_i(t) - r_t)dt + d\left\langle M, \int_0^{\cdot} \sigma_i(s)dW_s\right\rangle_t = 0,$$

which can also be written, because $b_i - r = \sigma_i\theta$, as

$$\left\langle M + \int_0^{\cdot} \theta_s^*\, dW_s, \int_0^{\cdot} \sigma_i(s)dW_s\right\rangle_T = 0, \quad P\,\text{a.s.}$$

The result therefore follows. □

In particular, the reference probability Q is an equivalent martingale measure. Also, if we suppose that θ belongs to the range of σ^*, then Q is a minimal P-martingale measure, in the following sense (see [Fö-Sc] or [An-St]).

DEFINITION 1.8.1. *A P-martingale measure R will be called minimal if any local P-martingale that is orthogonal to $\int \sigma_i \, dW$, for $1 \leq i \leq n$, under P, remains a local martingale under R.*

We state the following property.

PROPOSITION 1.8.2. *The following properties are equivalent:*

(i) *Q is a minimal probability.*

(ii) *There is a predictable vector process α_t such that $\theta_t = \sigma_t^* \alpha_t$.*

Remark. Suppose that (i) or (ii) is satisfied. Let R be a P-martingale measure. By Proposition 1.8.1, there exists some local martingale N with $N_0 = 0$, orthogonal to $\int \sigma_i \, dW$, $1 \leq i \leq n$, such that

$$\left.\frac{dR}{dP}\right|_{F_T} = \varepsilon\left(-\int_0^{\cdot} \theta_s^* \, dW_s + N\right)_T .$$

Recall that

$$\left.\frac{dQ}{dP}\right|_{F_T} = \varepsilon\left(-\int_0^{\cdot} \theta_s^* \, dW_s\right)_T .$$

If N is locally square integrable, then R is minimal if and only if $N = 0$, that is, $R = Q$. Indeed, if R is minimal, then N is a local martingale under R (because it is a local P-martingale orthogonal to $\int \sigma_i \, dW$, $1 \leq i \leq n$). If N is supposed to be locally square integrable, then $\langle -\int \theta^* \, dW + N, N \rangle$ exists and we can apply the Girsanov theorem (Appendix Corollary 1.A (i))

$$\left\langle -\int \theta^* \, dW + N, \, N \right\rangle = 0,$$

that is, $\langle N, N \rangle = 0$ (because $\theta_t = \sigma_t^* \alpha_t$). Hence, $N = 0$.

Proof. The definition gives that the fact that Q is minimal is equivalent to the following property:

(**) Any local P-martingale orthogonal to $\int \sigma_i \, dW$, for $1 \leq i \leq n$, is a local martingale under Q.

By the Girsanov theorem, Corollary 1.A (i), property (**) is equivalent to the following one. Any local P-martingale orthogonal to $\int \sigma_i \, dW$, $1 \leq i \leq n$, is orthogonal to $\int \theta^* \, dW$. By some results on stable subspaces of martingales and orthogonality (see [De-Me, pp. 371, 372, VIII-46–VIII-49]), (**) is equivalent to the fact that $\int \theta^* \, dW$ belongs to the space generated by $\int \sigma_i \, dW$, $1 \leq i \leq n$, which is equivalent to the existence of n predictable processes $\alpha_i(t)$, $1 \leq i \leq n$, such that

$$\int \theta^* \, dW = \sum_{i=1}^{n} \int \alpha_i \sigma_i \, dW,$$

that is, $\theta_t = \sigma_t^* \alpha_t$ where $\alpha_t = (\alpha_1(t), \ldots, \alpha_n(t))^*$. □

Hereafter, the above hypothesis ((i) or (ii)) is supposed to be satisfied. [2]

[2] Actually, this is not restrictive because if this hypothesis is not satisfied, just replace θ_t by its orthogonal projection θ_t^{l} on the range of σ_t^* in all the equations (indeed, $\sigma_t \theta_t = \sigma_t \theta_t^{\mathrm{l}}$).

We introduce the following notation.

Notation. We denote by D the set of local (F_t)-martingales $(N_t,\, 0 \leq t \leq T)$, with $N_0 = 0$, satisfying the following three properties.

(i) The jumps of N are strictly greater than -1 so that $\varepsilon(N)_t$, $0 \leq t \leq T$, is a strictly positive local martingale.

(ii) $\varepsilon(N)_t$, $0 \leq t \leq T$, is a martingale under Q.

(iii)

$$\left\langle N, \int_0^{\cdot} \sigma_i(s) d\widetilde{W}_s \right\rangle_T = 0 \quad \forall i \in \{1,2,\dots,n\}, \quad Q\,\text{a.s.}$$

For any local (F_t)-martingale N belonging to D, define Q^N as the probability measure equivalent to Q that admits $\mathcal{E}(N)_T$ as a Radon–Nikodym derivative with respect to Q on F_T. Q^N is then a P-martingale measure.

PROPOSITION 1.8.3. *The mapping $N \longrightarrow Q^N$ is a one-to-one mapping that carries D onto $\mathcal{P}$.*

Proof. We have clearly

$$\varepsilon\left(-\int \theta_u^* \, dW_u + N\right)_T = \varepsilon\left(-\int \theta_u^* \, dW_u\right)_T \varepsilon(N)_T.$$

Indeed, $\langle N, \int \theta_u^* \, dW_u \rangle = 0$ because it is supposed that $\theta_t = \sigma_t^* \alpha_t$. The result now follows easily. □

Hereafter, to simplify notation, we will suppose that $r = 0$. Then the SDEs relative to the prices are written as

$$dP_i(t) = P_i(t)\sigma_i(t)d\widetilde{W}_t.$$

Also, the value $X^{\pi,-c,x}(t)$ of the portfolio with consumption associated with portfolio π, consumption C, and initial investment x is given by

$$X_t^{\pi,-C,x} = x + \int_0^t \pi_t^* \sigma_t \, d\widetilde{W}_t - C_t \quad \forall t \in [0,T], \quad Q\,\text{a.s.}$$

This seems highly restrictive but it is not. All the results we obtain can be generalized to the case $r \neq 0$. In all the properties, just replace B by B^d and the prices, portfolio, and consumption processes by the discounted processes defined above.

We now turn to the study of the maximum price.

2. Dynamical study of the maximum price.

2.1. Predictable decomposition of the maximum price. The supremum of the possible prices for B at time 0 is given by

$$\sup_{R \in \mathcal{P}} E_R(B) = \sup_{N \in D} E_{Q^N}(B).$$

Also, the essential supremum of the possible prices for B at time t is given by

$$\operatorname{ess\,sup}_{R \in \mathcal{P}} E_R(B/F_t) = \operatorname{ess\,sup}_{N \in D} E_{Q^N}(B/F_t).$$

Using dynamical programming methods (see [ElK]), we have the following theorem. (The proof is given in the appendix.)

THEOREM 2.1.1. *There exists an* RCLL *process* $(J_t,\ 0 \leq t \leq T)$ *so that, for each* t

$$J_t = \text{ess}\sup_{N \in D} E_{Q^N}[B/F_t].$$

J_t *is characterized as the smallest right continuous supermartingale under* Q_N, *for every* N *belonging to* D, *which is equal to* B *at time* T. *Also,* N^* *is optimal* (i.e., $J_t = E_{Q^{N^*}}(B/F_t)$, Q *a.s.*, $0 \leq t \leq T$) *if and only if* J_t *is a martingale under* Q_{N^*}.

Before continuing the dynamical study of J_t, recall the hypothesis satisfied by B (introduced in §1.7):

$$B \leq y + \int_0^T H_s^* \sigma_s \, d\widetilde{W}_s, \quad Q\,\text{a.s.},$$

where y is a positive constant and H_t is a portfolio process that satisfies

$$E_{Q^N}\left[\int_0^T \|\sigma_s^* H_s\|^2 \, ds\right] < +\infty$$

for each $N \in D$.

This hypothesis implies the following result.

PROPOSITION 2.1.1. J_t *is of class* D *and satisfies*

$$J_t \leq y + \int_0^t H_s^* \sigma_s \, d\widetilde{W}_s, \quad Q\,\text{a.s.}, \quad 0 \leq t \leq T.$$

Proof. The process given by

$$y + \int_0^t H_s^* \sigma_s \, d\widetilde{W}_s$$

is a square integrable martingale under each P-martingale measure. Thus, for each $N \in D$,

$$E_{Q^N}[B/F_t] \leq y + \int_0^t H_s^* \sigma_s \, d\widetilde{W}_s, \quad Q\,\text{a.s.}, \quad 0 \leq t \leq T,$$

and the desired result clearly follows. □

The fact that J_t is a supermartingale under Q shows that J_t can be written under Q as the difference between a local Q-martingale and a predictable increasing process (and this decomposition is unique). The above properties relative to J_t will allow us to write the Q-martingale as the sum of a portfolio and a martingale j that may be characterized.

THEOREM 2.1.2. *There exist a portfolio process* φ_t, *a right continuous increasing predictable process* A_t *with* $A_0 = 0$, *and a purely discontinuous* Q*-martingale* j_t *such that*

$$\forall t \in [0,T],\ J_t = J_0 + \int_0^t \varphi_s^* \sigma_s \, d\widetilde{W}_s + j_t - A_t, \quad Q\,\text{a.s.} \tag{7}$$

Remark. Notice that the assumption made on B is not necessary. Theorem 2.1.2 remains true under the hypothesis

$$\sup_{N \in D} E_{Q^N}(B) < \infty,$$

but in this case J_t is not generally of class D and the process j is only a local martingale. The arguments of the proof still hold, but it is a bit more complicated technically because $\langle j \rangle$ is not always defined (see §A.3).

Scheme of the proof. J_t is a Q-supermartingale; hence, it admits a unique decomposition as a local martingale M_t minus an increasing predictable process $A_t : J_t = M_t - A_t$. The martingale M_t admits the Kunita–Watanabe decomposition

$$M_t = J_0 + \int_0^t \varphi_s^* \sigma_s \, d\widetilde{W}_s + j_t \quad \forall t \in [0,T], \quad Q \,\text{a.s.}$$

for some predictable process φ and some Q-local martingale j, such that

$$\left\langle j, \int_0^\cdot \sigma_i(s) dW_s \right\rangle_T = 0, \quad Q \,\text{a.s.} \quad \forall i \in \{1, \ldots, n\}.$$

Using the fact that J_t is a supermartingale under each P-martingale measure, we show that the continuous part of j is equal to zero.

Proof. $J_t - E_Q[B/F_t]$ is a positive RCLL optional supermartingale that is equal to zero at time T and lower than the Q-martingale $X^{H,0,y}$. By the Doob–Meyer decomposition theorem (cf. [De-Me, Thm. VII.8, p. 211]), there exists a Q-integrable right continuous increasing predictable process A_t with $A_0 = 0$ such that

$$J_t - E_Q[B/F_t] = E_Q[A_T/F_t] - A_t, \qquad 0 \leq t \leq T.$$

A_T is square integrable under Q since

$$E_Q[(A_T)^2] \leq 4 \, E_Q[(\sup_{0 \leq t \leq T} J_t)^2] \leq 4 \, E_Q[(X_T^{H,0,y})^2]$$

(see [De-Me, inequality VII.15.1, p. 221]).

Put $M_t = E_Q[A_T + B/F_t]$, $0 \leq t \leq T$. $M_t = J_t + A_t$ is square integrablė martingale under Q; hence, $\langle M \rangle$ exists. Thus, M_t admits the Kunita–Watanabe decomposition with respect to the Q-square integrable martingales $\int \sigma_i \, dW_t$, that is, there exist a predictable process φ_t and a square integrable Q-martingale (RCLL) j_t with $j_0 = 0$ such that

$$E_Q \left[\int_0^T \|\sigma_s^* \varphi_s\|^2 \, ds \right] < +\infty,$$

$$\left\langle j, \int_0^\cdot \sigma_i(s) dW_s \right\rangle_T = 0, \quad Q \,\text{a.s.} \quad \forall i \in \{1, \ldots, n\},$$

and

$$M_t = J_0 + \int_0^t \varphi_s^* \sigma_s \, d\widetilde{W}_s + j_t \quad \forall t \in [0,T], \quad Q \,\text{a.s.}$$

(for the Kunita–Watanabe decompositions, see [De-Me, p. 374, VIII-52]).

Now, j can be written as the sum of its continuous martingale part j^c and its purely discontinuous martingale part j^d

$$j = j^c + j^d.$$

It remains to be shown that j^c is equal to zero.

This result can be obtained using the following lemma (which comes from the fact that J_t is a supermartingale under each P-martingale measure).

LEMMA 2.1.1. *For all $N \in D$, $A_t - \langle N, j \rangle_t$ is an increasing process.*

Proof. By Theorem 2.1.1, we have the following property: for each $N \in D$, J_t is a supermartingale under Q^N. By the Girsanov theorem (Corollary 1A (ii) in the Appendix), this property is equivalent to the following:

$$\forall N \in D, \; -A_t + \langle N, M \rangle_t \text{ is a decreasing process,}$$

which may be written, because $N \in D$, as

$$\forall N \in D, \; A_t - \langle N, j \rangle_t \text{ is an increasing process.} \qquad \square$$

Lemma 2.1.1, applied to some N that can be written as a stochastic integral with respect to j^c, will allow us to show that j^c is equal to zero. We take

$$N_t = \int_0^t n_s \, dj_s^c,$$

where n is a bounded predictable process. If $\mathcal{E}(N)_t$ is a martingale, then N belongs to D and Lemma 2.1.1 applied to N yields the fact that $A - \int n_s \, d\langle j^c \rangle_s$ is increasing. It now remains to decompose the measure dA_t with respect to $d\langle j^c \rangle_t$ and to choose n.

$\langle j^c \rangle$ is integrable because j is square integrable. By the Lebesgue decomposition theorem, there exist a positive predictable process h which belongs to $L^1([0,T] \times \Omega, d\langle j^c \rangle_t \, dQ)$ and an integrable predictable increasing process B such that

$$dA_t = h_t d\langle j^c \rangle_t + dB_t$$

and such that, Q almost surely, the measure dB_t is singular with respect to $d\langle j^c \rangle_t$. For each integer p, we can write the following decomposition:

$$dA_t = h_t \, \mathbf{1}_{\{h(t) \le p\}} d\langle j^c \rangle_t + dB_t^p,$$

where, Q almost surely, the measure dB^p is singular with respect to the measure $\mathbf{1}_{\{h(t) \le p\}} d\langle j^c \rangle_t$.

Let N be given by

$$N_t = \int_0^t \mathbf{1}_{\{h_s \le p\}} (1 + h_s) dj_s^c.$$

Clearly, we may choose a sequence of stopping times T_n, $n \ge 0$, such that $T_n \uparrow T$ almost surely as n tends to infinity and for each $n \in \mathbb{N}$, $\mathcal{E}(N)^{T_n}$ $(= \mathcal{E}(N^{T_n}))$ is a martingale. Thus, for each $n \in \mathbb{N}$, N^{T_n} belongs to D. Lemma 2.1.1 applied to N^{T_n} shows that for each $n \in \mathbb{N}$, $A_t - \langle N^{T_n}, j \rangle_t$ is an increasing process. Hence, for each $n \in \mathbb{N}$, $A^{T_n} - \langle N, j \rangle^{T_n}$ is an increasing process and thus $A - \langle N, j \rangle$ is an increasing process.

Because, Q almost surely, the measure dB^p is singular with respect to the measure $\mathbf{1}_{\{h(t) \le p\}} d\langle j^c \rangle_t$, it follows that the process given by

$$\int_0^t \mathbf{1}_{\{h_s \le p\}} h_s d\langle j^c \rangle_s - \int_0^t \mathbf{1}_{\{h_s \le p\}} (1 + h_s) d\langle j^c \rangle_s$$

is an increasing process. Hence, for all $p \in \mathbb{N}$, Q almost surely, $-\langle j^c \rangle_t$ is increasing on $\{t / h(t) \le p\}$ and this yields the equality

$$\langle j^c \rangle_T = 0, \quad Q \text{ a.s.}$$

Hence, $j^c = 0$. $\square$

2.2. The Brownian case. We now turn to the case when the filtration is generated by the Brownian motion. In this case, Theorem 2.1.2 takes a more simple form: j is equal to zero because every local martingale is continuous. Thus, the maximum price process can be written as the difference of a self-financing portfolio and a predictable increasing process that is equal to zero at time zero. This remarkable decomposition should be stressed; it is similar to that of the price for an American option in a complete market. (One is referred to the theory of American option pricing [Kar].)

THEOREM 2.2.1. *There exist a portfolio process φ_t and an increasing (F_t)-predictable right continuous process A_t with $A_0 = 0$ such that*

$$\forall t \in [0,T],\ J_t = J_0 + \int_0^t \varphi_s^* \sigma_s \, d\widetilde{W}_s - A_t, \quad Q\, q.s. \tag{8}$$

Remark. Because the process A_t is predictable, we can consider only portfolios with consumption for which the consumption process is predictable. We have the following corollaries.

COROLLARY 2.2.1. *J_t is the lowest price process admissible for sellers*; *it is the selling price for B.*

Proof. J_t is a price process admissible for sellers because

- φ_t is a portfolio process,
- A_t is an optional (because it is predictable) RCLL increasing process with $A_0 = 0$, and
- J_t is positive and $J_T = B$.

Let us show that it is the lowest, that is, that for every price process admissible for sellers X_t, we have $J_t \leq X_t$. Let X_t be a price process admissible for sellers. Suppose that X is a supermartingale under any P-martingale measure. Then, by the characterization of J_t (Theorem 2.1.1), it follows that $J_t \leq X_t$. It remains to show that X is a supermartingale under every P-martingale measure. Now, X is a positive process such that $X_T = B$ and such that there exist a portfolio process π_t and an RCLL optional increasing process C_t with $C_0 = 0$ satisfying $X_t = X^{\pi, -C, x}(t)$ (the value of the portfolio with consumption associated with (π_t, C_t)), that is,

$$X_t = x + \int_0^t \pi_u^* \sigma_u \, d\widetilde{W}_u - C_t \geq 0, \quad Q \text{ a.s.}$$

Let N be a local martingale of D. Under Q^N, $x + \int_0^t \pi_u^* \sigma_u \, d\widetilde{W}_u$ is a positive local martingale, hence, a supermartingale. Also, C_T is integrable under Q^N. Hence, X is a supermartingale under Q^N. □

2.3. Optional decomposition of the maximum price. When the filtration is not that generated by the Brownian motion, j is not equal to zero, as is shown by example 2 in §3.4. As a result of the constraint $\Delta N > -1$, Lemma 2.1.1 does not imply that j is equal to zero. Thus, the predictable decomposition of J_t under Q is not the good one. The good decomposition will be the optional decomposition (Theorem 2.3.1). Using Lemma 2.1.1 (in other words, the fact that J_t is a supermartingale under each P-martingale measure), we will show that j_t is a process with negative jumps only such that the process f defined by $f_t = A_t - j_t$ is a nondecreasing process.

Let us decompose j with respect to the sign of its jumps:

$$j = j^+ + j^-,$$

where j^+ (respectively, j^-) is the compensated integral of $\mathbf{1}_{\{\Delta j(t) > 0\}}$ (respectively, $\mathbf{1}_{\{\Delta j(t) < 0\}}$) with respect to j, that is,

$$j^+ = \mathbf{1}_{\{\Delta j > 0\}} \cdot j; \qquad j^- = \mathbf{1}_{\{\Delta j < 0\}} \cdot j.$$

Notice that j^+ and j^- are square integrable martingales.

Concerning j^+, the part of j corresponding to the positive jumps of j, Lemma 2.1.1 applied to a well-chosen local martingale N will allow us to show that $j^+ = 0$. (The proof is the same as that for $j^c = 0$ in the proof of Theorem 2.1.2.)

PROPOSITION 2.3.1. *The jumps of the purely discontinuous martingale j are negative.*

Proof. We take $N_t = \int_0^t n_s \, dj_s^+$, where n is a bounded positive predictable process. Notice that N is a square integrable martingale that admits only positive jumps.

It now remains to decompose the measure dA_t with respect to $d\langle j^+ \rangle_t$ and choose the process n_t. Using the same arguments as those used in the proof of Theorem 2.1.2 (replacing j^c by j^+), we obtain the desired result. □

We now come to the most important result, which will allow us to characterize the supremum of the possible prices for B.

THEOREM 2.3.1. *The process $A_t - j_t$ is an increasing process, hence, if we denote it by f_t,*

$$\forall t \in [0,T],\ J_t = J_0 + \int_0^t \varphi_s^* \sigma_s \, d\widetilde{W}_s - f_t, \quad Q\,a.s. \tag{9}$$

In particular,

$$B = J_0 + \int_0^T \varphi_s^* \sigma_s \, d\widetilde{W}_s - f_T, \quad Q\,a.s.$$

Remark. The results of Proposition 2.3.1 and Theorem 2.3.1 still hold under the weaker hypothesis

$$\sup_{N \in D} E_{Q^N}(B) < +\infty$$

(see §A.3).

Proof. Put $f_t = A_t - j_t$. By definition, f is an RCLL process. Hereafter, we will adopt the following notation: for any locally integrable finite variation RCLL adapted process V, we denote by V^P its predictable compensator.

For any $\mathcal{E} \in \,]0,1[$, define

$$u_t^{\mathcal{E}} = \sum_{s \le t} \Delta j_s \mathbf{1}_{\Delta j_s < -\mathcal{E}}$$

and $j^{\mathcal{E}} = u^{\mathcal{E}} - (u^{\mathcal{E}})^P$. Recall the following result (see [De-Me, p. 369, VII-44]): $j^{\mathcal{E}}$ locally converges in M^1 to j as $\mathcal{E} \to 0$, that is, there exists a sequence of stopping times T_k, $k \in \mathbb{N}$, such that $T_k \uparrow T$ almost surely as k tends to infinity and for every $k \in \mathbb{N}$,

$$E[\sup_{s \le T_k} (j_s^{\mathcal{E}})] < +\infty$$

and

$$\lim_{\mathcal{E} \to 0} E[\sup_{s \le T_k} |j_s^{\mathcal{E}} - j_s|] = 0.$$

Suppose we have shown that for all $\mathcal{E} \in \,]0,1[$, $A_t + (u^{\mathcal{E}})_t^P$ is an increasing process. Put $f^{\mathcal{E}} = A - j^{\mathcal{E}}$. We have $f_t^{\mathcal{E}} = (A_t + (u^{\mathcal{E}})_t^P) - u_t^{\mathcal{E}}$. The fact that the jumps of j are negative shows that $u^{\mathcal{E}}$ is a decreasing process. Hence, $f^{\mathcal{E}}$ is an increasing process.

We have $f(t) = f^{\mathcal{E}}(t) + j^{\mathcal{E}}(t) - j(t)$. Using the above property of convergence, it follows that

$$\lim_{\mathcal{E}\to 0} E[\sup_{s\leq T_k} |f_s^{\mathcal{E}} - f_s|] = 0.$$

Hence, f is an increasing process as the limit of increasing processes.

It remains to be shown that for all $\mathcal{E} \in]0, 1[$, $A_t + (u^{\mathcal{E}})_t^P$ is an increasing process.

For any $\mathcal{E} \in]0, 1[$, define

$$N_t^{\mathcal{E}} = -\sum_{s\leq t} \mathbf{1}_{\Delta j_s < -\mathcal{E}} + \left(\sum_{s\leq t} \mathbf{1}_{\Delta j_s < -\mathcal{E}}\right)_t^P .$$

Because the filtration is left quasi-continuous,

$$[N^{\mathcal{E}}, j] = -u^{\mathcal{E}}, \quad \text{hence } \langle N^{\mathcal{E}}, j\rangle = -(u^{\mathcal{E}})^P.$$

Then it is clear that Lemma 2.1.1 applied to $N^{\mathcal{E}}$ shows that the process $A + (u^{\mathcal{E}})^P$ is an increasing process. However, $N^{\mathcal{E}}$ does not belong to D because $N^{\mathcal{E}}$ admits only jumps equal to -1. To solve this, put

$$N = \alpha N^{\mathcal{E}} \quad \text{for } 0 < \alpha < 1,$$

so that $\Delta N > -1$.

Now, we may choose a sequence of stopping times T_n, $n \geq 0$, such that $T_n \uparrow T$ almost surely as n tends to infinity and for each $n \in \mathbb{N}$, $\mathcal{E}(N)^{T_n}$ $(= \mathcal{E}(N^{T_n}))$ is a martingale. Thus, for each $n \in \mathbb{N}$, N^{T_n} belongs to D. Lemma 2.1.1 applied to N^{T_n} shows that for each $n \in \mathbb{N}$, $A^{T_n} - \langle N, j\rangle^{T_n}$ is an increasing process; hence, $A - \langle N, j\rangle$ is an increasing process, that is, $A + \alpha(u^{\mathcal{E}})^P$ is an increasing process for each $\alpha < 1$. Hence, $A + (u^{\mathcal{E}})^P$ is an increasing process. □

To explain the consequences of the preceding theorem, we begin with the following corollary.

COROLLARY 2.3.1. *J_t is the lowest price process admissible for sellers; it is the selling price for B.*

Proof. The proof is similar to that of Corollary 2.2.1. □

The dynamic hedging strategy adopted by the seller happens continuously in time. At $t = 0$, the seller sells the claim at J_0. He invests this amount in the hedging portfolio (determined by φ). At time $t > 0$, the value of the self-financing portfolio determined by φ and J_0 is greater than the price for B at time t; hence, between 0 and t, the seller has withdrawn from the portfolio the nonnegative amount given by

$$J_0 + \int_0^t \varphi_s^* \sigma_s \, d\widetilde{W}_s - J_t.$$

At time t, the amount invested in the portfolio is only equal to J_t. At time $s > t$, the value of the self-financing portfolio determined by φ and J_t,

$$J_t + \int_t^s \varphi_u^* \sigma_u \, d\widetilde{W}_u,$$

is greater than the price for B at time s (J_s); between t and s, the seller has withdrawn the amount

$$J_t + \int_t^s \varphi_u^* \sigma_u \, d\widetilde{W}_u - J_s$$

from his portfolio. At time s, the amount invested in the portfolio is only equal to J_s, and so on.

The readjustments have to be done continuously in time so that the withdrawals correspond to the process f_t, which represents the cumulative amount withdrawn from the portfolio between 0 and t. As time passes, the amount invested in the portfolio is too high, so the seller withdraws some money from the portfolio that should be given to the buyer, which, because it is not, is a profit for the seller.

COROLLARY 2.3.2. (1) *For each* $N \in D$, $E_{Q^N}[B] = J_0 - E_{Q^N}[f_T]$.

(2) *Let* N_n, $n \geq 0$, *be an optimizing sequence of* D, *that is, such that*

$$\lim_{n \to +\infty} E_{Q^{N_n}}[B] = J_0.$$

Then

$$\lim_{n \to \infty} E_{Q^{N_n}}(f_T) = 0.$$

Remark 1. If B is only supposed to satisfy

$$\sup_{N \in D} E_{Q^N}(B) < +\infty,$$

then the second point of this corollary still holds but the first one does not (see §A.3).

Remark 2. If Q^{N_n} converges in a certain sense to a limit probability Q^0 and if f_T is smooth enough, then we have $E_{Q^0}[f_T] = 0$. In this case, J_t is a martingale under Q^0, but this limit probability is not necessarily equivalent to Q, as is shown by example 2 in §3.4. More generally, if there exists a subsequence still denoted by N_n such that $\mathcal{E}(N_n)_T$ converges almost surely and if the limit is denoted by L^*, then $f_T = 0$ on $\{L^* > 0\}$.

Proof of (1). We denote by V_t the process

$$J_0 + \int_0^t \varphi_s^* \sigma_s \, d\widetilde{W}_s.$$

Let N be an element of D. V_t is a positive continuous Q^N-local martingale, hence, a Q^N-supermartingale. f_T is Q^N-integrable because V_T and B are Q^N-integrable. We have, by the assumption made on B,

$$\sup_{t \in [0,T]} V_t \leq \sup_t (J_t + f_t) \leq \sup_t (X^{H,0,y}(t)) + f_T.$$

Now, $X^{H,0,y}(t)$ is a square integrable Q^N-martingale; hence, $\sup_t (X^{H,0,y}(t))$ is square integrable under Q^N. Hence, V_t is a uniformly integrable local martingale under Q^N, and thus it is a Q^N-martingale. It follows that for each $N \in D$,

$$E_{Q^N}[B] = J_0 - E_{Q^N}[f_T]. \qquad \square$$

Proof of (2). Equality (1) applied to the local martingales N_n gives the equalities

$$\forall n \in N, \; E_{Q^{N_n}}(B) = J_0 - E_{Q^{N_n}}(f_T).$$

Hence, if we let n tend to $+\infty$, we obtain the desired result of

$$\lim_{n \to +\infty} E_{Q^{N_n}}[f_T] = 0. \qquad \square$$

In the following theorem, we state that the class of contingent claims for which the supremum price is obtained for an optimal N is exactly the set of attainable claims. This result generalized those of Pagès [Pag] and Karatzas et al. ([KLSX, Thm. 8.5]) in the context of a Brownian model.

THEOREM 2.3.2. *The following properties are equivalent.*

(i) $\sup_{N \in D} E_{Q^N}[B]$ *is attained by* $\hat{N} \in D$.

(ii) B *is attainable, that is, there exist a constant* x *and a portfolio* π *such that*

$$B = x + \int_0^T \pi_u^* \sigma_u \, d\widetilde{W}_u, \qquad Q \text{ a.s.}$$

and

$$E_Q \left[\int_0^T \|\sigma_s^* \pi_s\|^2 \, ds \right] < +\infty.$$

(iii) *For each local martingale* $N \in D$, $E_{Q^N}(B) = E_Q(B)$.

Remark. If B is only supposed to satisfy

$$\sup_{N \in D} E_{Q^N}(B) < +\infty$$

then only a part of this theorem still holds (see §A.3).

Proof. Let us show that (ii) ⇒ (iii). Suppose that there exist a constant x and a portfolio π such that

$$B = x + \int_0^T \pi_u^* \sigma_u \, d\widetilde{W}_u \quad Q \text{ a.s.}$$

and

$$E_Q \left[\int_0^T \|\sigma_s^* \pi_s\|^2 \, ds \right] < +\infty.$$

Let S_t be the process

$$x + \int_0^t \pi_u^* \sigma_u \, d\widetilde{W}_u, \qquad 0 \leq t \leq T.$$

S_t is a square integrable Q-martingale; hence, $S_t = E_Q[B/F_t]$. Therefore, S_t is positive and lower than $X^{H,0,y}(t)$.

Let N be an element of D. Under Q^N, S_t is a local martingale of class (D), and hence, a martingale. Also, S_t is continuous; hence, the processes S and J are indistinguishable. Notice that we have also shown that each element N of D is optimal, which is equivalent to (iii).

It remains to show that (i) ⇒ (ii). Suppose that N^0 is an optimal local martingale of D. Item (1) of Corollary 2.3.2 applied to N^0 gives

$$E_{Q^0}(B) = J_0 - E_{Q^0}(f_T),$$

that is,

$$E_{Q^0}(f_T) = 0.$$

Hence,

$$f_T = 0, \quad Q^0 \text{ a.s.},$$

that is,

$$f_T = 0 \quad Q \text{ a.s.}$$

since Q and Q^0 are equivalent. □

After the study of the maximum price, we now turn to the study of the minimum price for B.

2.4. Study of the minimum price. Recall that B is lower than M_T where $M_t = X^{H,0,y}(t)$. Let us determine the buyer's price for B. Let us consider a buyer who wants to buy some contingent claims with payoff B and maturity T, between time 0 and time T. Suppose the buyer chooses the price X_t for B at any time t; more precisely, the buyer must choose his price process $(X_t, t \geq 0)$ (that is, an RCLL optional process lower than M_t with $X_T = B$) and a portfolio process π_t. Also, the buyer does not want to run any risk of losing money. Therefore, he will only choose strategies that allow him to hedge completely by the controlled portfolio of the basic securities in the sense that, for any t, any s such that $0 \leq t \leq s \leq T$.

Suppose that, at time t, the buyer buys the claim at price X_t and sells the self-financing portfolio (determined by π) at price X_t. At time s, he sells the claim at price X_s and buys the self-financing portfolio; he then makes the profit (nonnegative) given by

$$X_s - \left(X_t + \int_t^s \pi_u^* \sigma_u \, d\widetilde{W}_u \right).$$

More precisely, the process given by

$$X_t - \left(X_0 + \int_0^t \pi_u^* \sigma_u \, d\widetilde{W}_u \right), \qquad 0 \leq t \leq T$$

is an increasing process.

DEFINITION 2.4.1. *A process X_t is called a* price process admissible for buyers *if X_t is an* RCLL *optional process lower than M_t with $X_T = B$ such that there exist a portfolio π_t and an* RCLL *optional increasing process D_t with $D_0 = 0$ satisfying $dX_t = \pi_t^* \sigma_t (dW_t + \theta_t \, dt) + dD_t$.*

Remark. It is equivalent to say that a process X_t is a price process admissible for buyers if there exists a hedging portfolio of B that is a portfolio with savings whose value is equal to the price, that is, if there exist a portfolio process π_t and an RCLL optional increasing process D_t with $D_0 = 0$ satisfying

$$X^{\pi,D,x}(T) = B \quad \text{and} \quad X_t = X^{\pi,D,x}(t), \qquad 0 \leq t \leq T.$$

The purchase price is then given by Definition 2.4.2.

DEFINITION 2.4.2. *The greatest process admissible for buyers is called the* purchase price.

We have clearly the following property.

PROPOSITION 2.4.1. (i) *A process X_t is a price process for B admissible for buyers if and only if $M_t - X_t$ is a process price for $M_T - B$ admissible for sellers.*

(ii) *The purchase price for B is equal to the difference between M_t and the selling price for $M_T - B$.*

We now turn to the study of the essential infimum of the possible prices for B. Let K_t, $0 \leq t \leq T$, be the right continuous process satisfying

$$K_t = \operatorname*{ess\,inf}_{N \in D} E_{Q^N}[B/F_t], \qquad 0 \leq t \leq T.$$

Notice that the minimum price for B is given by the maximum price for $M_T - B$ by the equality

$$M_t - K_t^B = J_t^{M(T)-B}, \qquad 0 \leq t \leq T, \quad Q \text{ a.s.}$$

It follows that the properties of K can be derived from those of J.

THEOREM 2.4.1. *K_t, $0 \leq t \leq T$, is characterized as the greatest right continuous submartingale under Q_N, for any $N \in D$, with $N_T = B$. Also, N is optimal if and only if K_t is a martingale under Q_N.*

THEOREM 2.4.2. *There exist a portfolio process ψ_t and a right continuous increasing optional process g_t with $g_0 = 0$ such that*

$$K_t = K_0 + \int_0^t \psi_s^* \sigma_s \, d\widetilde{W}_s + g_t, \quad Q \text{ a.s.}, \quad 0 \leq t \leq T \tag{10}$$

Also, there exist a right continuous increasing predictable process B_t with $B_0 = 0$ and a purely discontinuous martingale i_t with negative jumps such that

$$g_t = -i_t + B_t, \qquad 0 \leq t \leq T.$$

COROLLARY 2.4.1. *K_t is the greatest of the price processes admissible for buyers, that is, K_t is the purchase price for B.*

Remark 1. The properties of K_t can be clearly derived directly without using the properties of J_t (by the use of stochastic control methods).

Remark 2. The assumption made on B is not necessary to obtain the above results. One should derive the properties of K directly; the price processes should be supposed to be lower than $E_Q(B/F_t)$ (instead of M_t).

Now, let us compare the hedging strategies associated with the maximum and minimum prices to the "optimal" strategy in Föllmer and Schweizer's sense. Recall that their optimal strategy is obtained by projecting the Q-martingale $E_Q[B/F_t]$ orthogonally on the stable subspace generated by $\int \sigma_i \, dW$, $1 \leq i \leq n$, that is,

$$B = E_Q[B] + \int_0^T \pi_u^* \sigma_u \, d\widetilde{W}_u + N_T,$$

where N is a local martingale under Q orthogonal to $\int \sigma_i \, d\widetilde{W}$, $1 \leq i \leq n$ and hence a local martingale under P, because Q is minimal. $E_Q[B]$ is called the "optimal" price for B.

Let us compare the three price-portfolio strategies:

- The price-portfolio strategy associated with the "optimal" price for B, whose value of the self-financing portfolio is given by

$$E_Q(B) + \int_0^t \pi_u^* \sigma_u \, d\widetilde{W}_u, \qquad 0 \leq t \leq T$$

and whose price process is given by $E_Q(B/F_t)$, $0 \leq t \leq T$, is characterized by the fact that the difference between the value of the self-financing portfolio and the price is a local martingale under P equal to zero at time zero that is orthogonal to $\int \sigma_i \, dW$, $1 \leq i \leq n$.

- The price-portfolio strategy associated with the maximum price for B, whose value of the self-financing portfolio is given by

$$J_0 + \int_0^t \varphi_u^* \sigma_u \, d\widetilde{W}_u, \qquad 0 \leq t \leq T$$

and whose price process is given by J_t, $0 \leq t \leq T$, is characterized by the fact that the difference between the value of the self-financing portfolio and the price is an increasing process equal to zero at time zero and by the fact that the price is minimal (in the sense defined above).

- Also, the price-portfolio strategy associated with the minimum price for B is characterized by the fact that the difference between the price and the value of the self-financing portfolio is an increasing process equal to zero at time zero and by the fact that the price is maximal (in the sense defined above).

In the next section, we give a few methods for computing the maximum price and a few examples that illustrate the obtained results.

3. Methods for computing.

3.1. Determination of J_t as the limit of a sequence of processes (in the Brownian case). The selling price for B is given by J_t, the essential supremum of $E_R(B/F_t)$, for $R \in \mathcal{P}$ (the set of martingale measures). However, J_t is generally difficult to compute. We may then restrict the control set to $\mathcal{P}_n$, $n \in N$, so that the essential supremum J^n taken over all the elements of $\mathcal{P}_n$ is attained. $\mathcal{P}_n$ is chosen so that J_t is the limit of $J^n(t)$ as n tends to infinity, and we then obtain a sequence approximating J that can be calculated explicitly. We develop this method in the context of a Brownian model. In this case, every local martingale is a stochastic integral with respect to a reference martingale (the Brownian); we will see later that this property allows us to obtain some precise results.

In this section, we will suppose that $\sup_{R \in \mathcal{P}} E_R(B) < \infty$ and $E_Q(B^2) < \infty$. Let us denote by $L^2[0,T]$ the class of predictable processes ϕ satisfying

$$\int_0^T \|\Phi_t\|^2 \, dt < \infty, \quad \text{a.s.}$$

Let $K(\sigma)$ be the subset of $L^2[0,T]$ defined by

$$\nu \in K(\sigma) \Leftrightarrow \nu \in L^2[0,T]/\sigma(t)\nu(t) = 0 \quad \forall t \in [0,T], \quad \text{a.s.}$$

and

$$\mathcal{E}\left(\int_0^{\cdot} \nu_s^* \, d\widetilde{W}_s\right)_t, \qquad 0 \leq t \leq T$$

is a Q martingale.

The following result is clear.

PROPOSITION 3.1.1. *The following properties are equivalent.*

(i) *N belongs to D.*

(ii) *There exists $\nu \in K(\sigma)$ such that*

$$N_t = \int_0^t \nu_s^* \, d\widetilde{W}_s \quad \forall t \in [0,T], \quad \text{a.s.}$$

It follows that $J_t = \text{ess sup}_{\nu \in K(\sigma)} E_{Q^\nu}[B/F_t]$, where Q^ν denotes the probability measure that admits the following Radon–Nikodym derivative with respect to Q:

$$\exp\left\{\int_0^T \nu_s^* \, d\widetilde{W}_s - \frac{1}{2}\int_0^T \|\nu_s\|^2 \, ds\right\}.$$

In this context, ν can be interpreted as a risk premium vector associated with the risks of the market that cannot be controlled using the prices of the basic securities (loosely speaking, those risks are in an another direction). Thus, this risk premium has the role of control in the determination of the maximum price of the contingent claim.

For any $n \in N$, define $K^n(\sigma)$, a subset of $K(\sigma)$ by

$$K^n(\sigma) = \{\nu \in K(\sigma)/\|\nu(t)\| \leq n \, \forall t \in [0,T], \text{ a.s.}\}.$$

For any $n \in N$, let $J^n(t)$ be the right continuous process satisfying

$$J^n(t) = \text{ess} \sup_{\nu \in K^n(\sigma)} E_{Q^\nu}[B/F_t].$$

It is characterized by the following property (similar to the characterization of J).

PROPOSITION 3.1.2. *$J^n(t)$ is characterized as the smallest right continuous supermartingale under Q^ν, for every $\nu \in K^n(\sigma)$, with $J^n(T) = B$. Also, ν is optimal (i.e., $\nu \in K^n(\sigma)$ with $J^n(t) = E_{Q^\nu}[B/F_t]$, $0 \leq t \leq T$, a.s.) if and only if $J^n(t)$ is a martingale under Q^ν.*

The properties relative to J and J^n, $n \in N$, allow us to state that J is the limit of J^n as n tends to infinity.

THEOREM 3.1.1.

$$J_t = \lim_{n \to +\infty} \uparrow J^n(t) \text{ a.s.} \quad \forall t \in [0,T].$$

Proof. Let J° be the process defined by $J_t^\circ = \lim_{n \to +\infty} \uparrow J^n(t)$. Let us show that $J_t^\circ = J_t$. We clearly have $J_t^\circ \leq J_t$. It remains to show that $J_t^\circ \geq J_t$.

J_t° is an RCLL supermartingale under every Q^ν, $\nu \in K(\sigma)$ and bounded, because it is the increasing limit of RCLL supermartingales. Using this property, one can show quite easily, by a proof similar to that of Theorem 2.1.2, that J_t° is a price process for B admissible for sellers in the sense that there exist a portfolio process π_t° and a predictable increasing process A_t° such that

$$J_t^\circ = J_0^\circ + \int_0^t (\pi_s^\circ)^* \sigma_s \, d\widetilde{W}_s - A_t^\circ, \qquad 0 \leq t \leq T,$$

hence, $J_t \leq J_t^\circ$ (because J_t is the lowest of the admissible prices). □

Whereas J_t is a priori difficult to calculate, we have a characterization of J^n that is linked to the fact that there exists an optimal control for J^n (contrary to J).

THEOREM 3.1.2. *There is an optimal control associated with J^n.*

Proof. The proof is an application of Theorem 3.30 in [ElK]. (Indeed, the model is strongly dominated and the space to which ν_t belongs is compact.) □

$J^n(t)$ can be determined explicitly as the unique solution of a backward stochastic differential equation of the type studied by E. Pardoux and S. G. Peng (see [Pa-Pe]). Thus, we have, in the general case, a construction of the value function similar to the construction of the solution of the Hamilton–Jacobi–Bellman equation in the Markovian case. We denote by $\Pi_{\text{Ker}\sigma(s)}$ the orthogonal projection that maps $\mathbb{R}^d$ onto the kernel of σ_s.

THEOREM 3.1.3. *Let $(X^n(t), Y^n(t))$ be the unique solution of the backward stochastic differential equation*

$$X_t^n - \int_t^T n \,\|\pi_{\operatorname{Ker}\sigma_s}(Y_s^n)\|\, ds + \int_t^T Y_s^{n^*}\, d\widetilde{W}_s = B, \qquad 0 \le t \le T. \tag{11}$$

Then

(1) $X^n(t) = J^n(t)$, $0 \le t \le T$, *almost surely.*

(2) *If ν^n is an optimal control associated with $J^n(t)$, then*

$$\nu_s^n = n \frac{\Pi_{\operatorname{Ker}\sigma_s}(Y_s^n)}{\|\Pi_{\operatorname{Ker}\sigma_s}(Y_s^n)\|}\, \mathbf{1}_{\{Y_s^n \neq 0\}}, \; ds\, dQ\, a.s.$$

Remark. Thus, we have $J_t = \lim_{n\to+\infty} E_{Q^{\nu^n}}(B/F_t)$ and $ds\, dQ$ almost surely. If a subsequence of $\{\|\nu^n(s)\|, n \in N\}$ converges, its limit is equal to 0 or $+\infty$. Loosely speaking, we see that the maximum price for the contingent claim is obtained by letting the norm of the risk premium tend to $+\infty$ or 0.

Proof. Let ν^n be an optimal control associated with J^n. Under Q, J^n is a supermartingale and admits the following decomposition

$$J_t^n = J_0^n + \int_0^t \varphi_s^{n^*}\, d\widetilde{W}_s - A_t^n, \qquad 0 \le t \le T,$$

where $\varphi^n \in L^2[0,T]$ and A^n is a predictable increasing process with $A^n(0) = 0$. Now, J^n is a martingale under Q^{ν_n}; hence, by the Girsanov theorem,

$$A_t^n = \int_0^t \varphi_s^{n^*} \nu_s^n\, ds, \qquad 0 \le t \le T.$$

Let $\nu \in K^n(\sigma)$. J^n is a supermartingale under Q^ν; hence, by the Girsanov theorem

$$\varphi^n(s)^* \nu^n(s) \ge \varphi^n(s)^* \nu(s), \quad ds\, dQ \text{ a.s.}$$

Because this inequality holds for each $\nu \in K^n(\sigma)$, we have

$$\varphi^n(s)^* \nu^n(s) = \operatorname*{ess\ sup}_{\nu \in K^n(\sigma)} [\varphi^n(s)^* \nu] = n \left\|\pi_{\operatorname{Ker}\sigma(s)}(\varphi^n(s))\right\|$$

and

$$\nu_s^n = n \frac{\Pi_{\operatorname{Ker}\sigma_s}(\varphi_s^n)}{\|\Pi_{\operatorname{Ker}\sigma_s}(\varphi_s^n)\|}\, \mathbf{1}_{\{\varphi_s^n \neq 0\}}, \; ds\, dQ \text{ a.s.}$$

Hence,

$$J_t^n - \int_t^T n \,\|\pi_{\operatorname{Ker}\sigma_s}(\varphi_s^n)\|\, ds + \int_t^T \varphi_s^{n^*}\, d\widetilde{W}_s = B, \qquad 0 \le t \le T. \qquad \square$$

Remark. For the results of existence and uniqueness of solutions of backward equations, see [Pa-Pe].

$M^2(0,T;\mathbb{R}^d)$ will denote the normed vectorial space of $\mathbb{R}^d$-valued processes that are predictable and belong to $L^2([0,T] \times \Omega, dt\, dQ)$.

For any $\phi \in M^2(0,T;\mathbb{R}^d)$, define its norm by

$$\|\phi\|^2_{M^2} = E_Q\left[\int_0^T \|\phi_s\|^2\,ds\right].$$

The backward equation (R) given by

$$X_t - \int_t^T n\,\|\pi_{\mathrm{Ker}\,\sigma_s}(Y_s)\|\,ds + \int_t^T Y_s^*\,d\widetilde{W}_s = B, \qquad 0 \le t \le T,$$

has Lipschitz coefficients (with respect to Y), and hence admits a unique solution $(X,Y) \in M^2(0,T;\mathbb{R}) \times M^2(0,T;\mathbb{R}^d)$. Recall that the solution can be constructed using a Picard type iteration. Y_0 is taken to be equal to 0. Let (X_p, Y_p), $p \in N^*$ be a sequence in $M^2(0,T;\mathbb{R}) \times M^2(0,T;\mathbb{R}^d)$ defined recursively by $X_p(0)$ and Y_p, which are constructed from Y_{p-1} by the representation theorem

$$E_Q\left[B - \int_0^T n\,\|\pi_{\mathrm{Ker}\,\sigma_s}(Y_{p-1}(s))\|\,ds/F_t\right] = X_p(0) + \int_0^t Y_p(s)^*\,d\widetilde{W}_s, \text{ a.s.}$$

$X_p(t)$ is then defined by

$$X_p(t) = \int_t^T n\,\|\pi_{\mathrm{Ker}\,\sigma_s}(Y_{p-1}(s))\|\,ds - \int_t^T Y_p(s)^*\,d\widetilde{W}_s + B, \qquad 0 \le t \le T.$$

Using Pardoux and Peng's result, X_p (respectively, Y_p) converges in $M^2(0,T;\mathbb{R})$ (respectively, $M^2(0,T;\mathbb{R}^d)$) to X, Y, the solution of (R) as p tends to $+\infty$.

Recall that the increasing process associated with the Q-supermartingale J is denoted by A. We denote by A^n the increasing process associated with J^n, that is,

$$A_t^n = \int_0^t n\,\|\pi_{\mathrm{Ker}\,\sigma_s}(\varphi_s^n)\|\,ds.$$

In general, the process A^n does not converge to A almost surely, but we have the following property (cf. [De-Me, Thm. VII.18, p. 223]). If J is of class D, then for each t, the sequence of random variables $A^n(t)$ converges to $A(t)$ weakly in L^1, that is, for each bounded F_T measurable variable U, $\lim_{n\to+\infty} E[A^n(t)U] = E[A(t)U]$.

In the next section, we study the Markovian case. We will see that, contrary to J, J_n is the solution of a usual Bellman equation (and this is linked to the existence of an optimal control associated with J_n, contrary to J).

3.2. The Bellman equation and the maximum price. In a particular case, we propose a numerical method to solve the problem. The general model is complete, that is, the filtration is that generated by the d-dimensional Brownian W. The market contains d securities whose volatility matrix has full rank, but only certain securities (the first n ones) can be traded. Therefore, the market is incomplete. We suppose that all the coefficients of the model are only functions of the time t and the price vector $P(t) = (P_1(t), \ldots, P_d(t))$, functions that are taken to be smooth enough so that the Bellman equations are satisfied. We denote by σ' (respectively, σ, δ) the volatility matrix of the d securities (respectively, the n first securities, the $(d-n)$ others). We have $\sigma' = \binom{\sigma}{\delta}$.

Under Q (the reference probability), the prices of the securities satisfy the following equations

$$(12) \qquad \begin{cases} dP_j(t) = P_j(t)[r(t,P_t)dt + \sigma_j(t,P_t)d\widetilde{W}_t], & 1 \le j \le n, \\ dP_k(t) = P_k(t)[\mu_k(t,P_t)dt + \delta_k(t,P_t)d\widetilde{W}_t], & n+1 \le k \le d. \end{cases}$$

The contingent claim B is taken to be equal to $g(P_1(T),\dots,P_d(T))$ for a $\mathbb{R}^+$-valued function g on $\mathbb{R}^d$ satisfying smoothness conditions (see [Kry, p. 205]). Recall that the selling price is given by

$$J_t = \operatorname{ess}\sup_{\nu\in K(\sigma)} E_{Q^\nu}[B/F_t],$$

where Q^ν denotes the probability measure that admits the following Radon–Nikodym derivative with respect to Q:

$$\exp\left\{\int_0^T \nu_s^* \, d\widetilde{W}_s - \frac{1}{2}\int_0^T \|\nu_s\|^2 \, ds\right\},$$

and $K(\sigma)$ denotes the set of Ker $\sigma(t,P(t))$-valued predictable processes ν_t that belong to $L^2[0,T]$.

Note that under Q^ν, $\widetilde{W}_t - \int_0^t \nu_s \, ds$ is a Q^ν-Brownian motion.

Using some of Krylov and El Karoui's results [Kry], [ElK], we see that the maximum price J_t (which is a function J of t and $P(t)$) is the value function for a more general problem. $(\Omega,\ F_t, P, W)$ is a fixed probability space on which W is an F-Brownian. The controlled system is described by the following equations:

$$(13)\quad \begin{cases} dP_j(t) = P_j(t)[r(t,P_t)dt + \sigma_j(t,P_t)dW_t], & 1\le j\le n,\\ dP_k(t) = P_k(t)[[\mu_k(t,P_t) + \delta_k(t,P_t)\nu_t]dt + \delta_k(t,P_t)dW_t], & n+1\le k\le d,\end{cases}$$

where the control ν belongs to $K(\sigma)$.

The value function is then given by

$$J(t,x) = \sup_{\nu\in K(\sigma)} E_{\nu,t}[g(P_T)/P_t = x]$$

for $x\in (R^+)^d$ and $t\in[0,T]$.

Because the coefficient $\mu_k + \delta_k\,\nu_t$ is not bounded, $J(t,x)$ is not the solution of the classical Bellman equation. However, if we impose some smoothness conditions on the coefficients, J satisfies the following inequality in terms of generalized derivatives:

$$(\alpha)\qquad L\varphi(t,x) + G\varphi(t,x)\nu \le 0 \quad \forall\,\nu\in \operatorname{Ker}\sigma(t,x),$$

where

$$\begin{aligned} L\varphi(t,x) &= \frac{\partial\varphi}{\partial t}(t,x) + \frac{1}{2}\sum_{1\le i,j\le d} x_i x_j(\sigma'\sigma'^*)_{ij}\frac{\partial^2\varphi}{\partial x_i\partial x_j}(t,x)\\ &\quad + \sum_{k=n+1}^{d}\frac{\partial\varphi}{\partial x_k}(t,x)\,x_k\mu_k(t,x) + \sum_{j=1}^{n}\frac{\partial\varphi}{\partial x_j}(t,x)\,x_j r(t,x).\\ G\varphi(t,x) &= \sum_{k=n+1}^{d}\frac{\partial\varphi}{\partial x_k}(t,x)x_k\delta_k(t,x). \end{aligned}$$

(J is characterized as the smallest solution of (α).) Also, equation (α) is clearly equivalent to the following system:

$$(\mathrm{A})\qquad \begin{cases} G\varphi(t,x)\nu = 0 \quad \forall\,\nu\in\operatorname{Ker}\sigma,\\ L\varphi(t,x)\le 0.\end{cases}$$

Thus, J is the smallest solution of system (A). It corresponds to the characterization of J as the smallest selling price (Thm. 2.2.1).

Notice that if J is $C^{1,2}([0,T] \times R^d)$, this system can be derived directly by applying Ito's formula to $J(T, P_1(T), \ldots, P_n(T))$ and using the fact that, by Theorem 2.2.1, J can be written as the difference of a portfolio (constructed from the first n securities) and an increasing process.

Notice that the above system can also be derived using some of Krylov's results on optimal control problems of Markov diffusion processes with unbounded coefficients. Using Krylov's results (cf. [Kry, p. 266]), one can show that, if the coefficients are taken to be smooth enough, $J(t,x)$ is solution of the normalized Bellman equation (in terms of generalized derivatives)

$$\sup_{\{\nu \in \operatorname{Ker} \sigma(t,x)\}} \left[\frac{1}{\lambda(\nu)} (L\varphi(t,x) + G\varphi(t,x)\nu) \right] = 0,$$

where $\lambda(\nu) = \sup(1, \|\nu\|)$. This equation is clearly equivalent to system (A).

To calculate J, we can use the following property (as in §3.1).

PROPOSITION 3.2.1.

$$J(t,x) = \lim_{n \to \infty} J_n(t,x),$$

where

$$J_n(t,x) = \sup_{\nu \in K^n(\sigma)} E_{t,\nu}[g(P_t)/P_t = x],$$

and $K^n(\sigma)$ *is the set of the processes* $\nu_t \in K(\sigma)$ *that are bounded by* n.

For each n, there exists an optimal control associated with J_n. Also, J_n is solution of the Bellman equation

$$\sup_{\{\nu \in \operatorname{Ker} \sigma(t,x), \|\nu\| \le n\}} [L\varphi(t,x) + G\varphi(t,x)\nu] = 0.$$

Notice that

$$\sup_{\{\nu \in \operatorname{Ker} \sigma(t,x), \|\nu\| \le 1\}} [G\varphi(t,x)\nu] = \|\pi_{t,x}(G\varphi(t,x))\|,$$

where $\Pi_{t,x}$ is the orthogonal projection from R^d onto Ker $\sigma(t,x)$ ($G\varphi(t,x)$ is a row vector). Hence, we have the following property.

PROPOSITION 3.2.2. $J_n(t,x)$ *is solution of the following equation*:

$$L\varphi(t,x) + n \|\pi_{t,x}(G\varphi(t,x))\| = 0.$$

Remark. Notice that if

$$H(\varphi)(t,x) = \sum_{j=1}^{n} \frac{\partial \varphi}{\partial x_j}(t,x)\, x_j \sigma_j(t,x) + G(\varphi)(t,x),$$

then $\Pi_{t,x}(H\varphi(t,x)) = \Pi_{t,x}(G\varphi(t,x))$. It follows that if φ is solution of the Bellman equation with $\varphi(T,x) = g(x)$, then $(\varphi(P_t), H\varphi(t,P_t))$ is solution of the backward equation given by

$$\varphi(t,P_t) - \int_t^T n \|\pi_{\operatorname{Ker}\sigma(s,P_s)}(H\varphi(s,P_s))\| \, ds + \int_t^T H\varphi(s,P_s) d\widetilde{W}_s = g(P_T).$$

We recognize the backward equation obtained in §3.1.

In the next section, we give an example that shows that there exist some discontinuous solutions of the normalized Bellman equation.

3.3. Example 1. Let W' be a (unidimensional) Brownian independent of the Brownian W_t (d-dimensional). The filtration is that generated by the Brownians W and W'. The prices of the different securities and the coefficients relative to those prices (appreciation rates and volatilities) depend only on W (that is, are adapted to the filtration of W). B is taken to be a function of the terminal value of W', that is, $B = f(W'_T)$ for a positive bounded real-valued function f on $\mathbb{R}$. In this case, we show that the maximum price for B is constant on $[0,T[$, equal to the supremum of the function f and jumps at time T to reach the value $f(W'_T)$.

Let us consider a more general case. The contingent claim B is taken to be positive bounded and to depend only on W'. Let us determine its maximum price J_t. We define the model more precisely.

Let Ω_1 be the space of all $\mathbb{R}^d$-valued continuous functions on $\mathbb{R}^+$,

$$\Omega_1 = \mathcal{C}(\mathbb{R}^+, \mathbb{R}^d).$$

We denote by F^1 the σ-field generated by the coordinate process $W_t : \omega_1 \to \omega_1(t)$ for $t \geq 0$. Let $(F_t^1, t \geq 0)$ be the filtration generated by the process W_t. Let P^1 be the Wiener measure on Ω_1 constructed so that the coordinate mapping process W_t is Brownian motion.

Let Ω_2 be the space of all real-valued continuous functions on $\mathbb{R}^+$,

$$\Omega_2 = \mathcal{C}(\mathbb{R}^+, \mathbb{R}).$$

We denote by F^2 the σ-field generated by the coordinate process $W'_t : \omega_2 \to \omega_2(t)$ for $t \geq 0$. Let (F_t^2) be the filtration generated by the process (W'_t). Let P^2 be the Wiener measure on Ω_2 constructed so that the coordinate mapping process W'_t is Brownian motion.

Let (Ω, F, P) be the cross-product probability space $(\Omega_1 \times \Omega_2, F_1 \otimes F_2, P_1 \otimes P_2)$. The filtration F_t is defined by $F_t = F_t^1 \otimes F_t^2$. We denote by ω the elements of Ω

$$\omega = (\omega_1, \omega_2), \quad \omega_1 \in \Omega_1, \quad \omega_2 \in \Omega_2.$$

We denote by W_t the first coordinate mapping process and by W'_t the second coordinate mapping process. W_t and W'_t are independent (F_t)-Brownian motions under P. The prices of the basic securities $P^i(t)$, the vector of stock appreciation $b(t)$, and the volatility matrix $\sigma(t)$ are taken to depend only on the first coordinate of the path (ω_1). B is taken to be F_T^2-measurable, positive bounded.

Clearly, if N is a stochastic integral with respect to W' and if the associated exponential martingale is a martingale, then N belongs to D. Hence,

$$J_t \geq \operatorname*{ess\,sup}_{\nu \in D'} E_{P^2}\left[B\mathcal{E}\left(\int \nu_s \, dW'_s\right)_T \Big/ F_t^2\right] \Big/ \mathcal{E}\left(\int \nu_s \, dW'_s\right)_t,$$

where D' is the set of all (F^2)-predictable processes ν defined on Ω^2 such that

$$E_{P^2}\left[\mathcal{E}\left(\int \nu_s \, dW'_s\right)_T\right] = 1.$$

Now, it follows by the representation theorem that

$$\sup_{\nu \in D'} E_{P^2}\left[B\mathcal{E}\left(\int \nu_s \, dW'_s\right)_T\right] = \sup_{\substack{X \in L^1 \\ \|X\|_1 \leq 1}} E_{P^2}[BX],$$

where $L^1 = L^1(\Omega^2, P^2, F_T^2)$ and $\|X\|_1 = E_{P^2}[|X|]$ for $X \in L^1$.

Now, because the L^∞ norm of any function on any measure space is equal to its norm as a linear functional on L^1, we have

$$\sup_{\substack{X\in L^1\\ \|X\|_1\leq 1}} E_{P^2}[BX] = \|B\|_{L^\infty(P^2)},$$

where $\|B\|_{L^\infty(P^2)}$ denotes the essential supremum of B under P^2. Therefore,

$$\sup_{\nu\in D'} E_{P^2}\left[B\mathcal{E}\left(\int \nu_s\, dW'_s\right)_T\right] = \|B\|_{L^\infty(P^2)}.$$

Hence, $J_0 = \|B\|_{L^\infty(P^2)}$.

Also, by the same argument we have

$$\operatorname{ess\,sup}_{\nu\in D'} E_{P^2}\left[B\mathcal{E}\left(\int \nu_s\, dW_s\right)_T \Big/ F_t^2\right] \Big/ \mathcal{E}\left(\int \nu_s\, dW'_s\right)_t = \|B\|_{L^\infty(P^2/F_t^2)},$$

where $\|B\|_{L^\infty(P^2/F_t^2)}$ denotes the essential supremum of B under the conditional probability measure of P^2 given F_t^2. It follows that $J_t = \|B\|_{L^\infty(P^2/F_t^2)}$ for each $t\in[0,T]$.

Remark. This example shows that there exist some discontinuous solutions of the normalized Bellman equation.

In the next section, we give an another example but not in a Brownian model. It illustrates the fact that the purely discontinuous Q-martingale j obtained in the decomposition of J_t may not be equal to zero. Consequently, the optional decomposition of J_t is the good one.

3.4. Example 2. Let N_t be a Poisson process with intensity 1 independent of W_t. The filtration is that generated by the Brownian W (d-dimensional) and the Poisson N (one-dimensional). The prices of the different securities and the coefficients relative to those prices (appreciation rates and volatilities) depend only on W (that is, are adapted to the filtration of W). The contingent claim B is taken to be positive bounded and to depend only on N. It is a contract that pays 1 if $N_T = 0$, and 0 if $N_T \neq 0$. Note that

$$B = \mathbf{1}_{N_T=0}.$$

The maximum price J_0 for B at time 0 is clearly equal to 1 (because it is impossible to hedge against the risk). To prove this result rigorously, choose P-martingale measure Q_α so that N_t is a Poisson process with intensity $1+\alpha$ under $Q_\alpha(\alpha > -1)$. Then it is easy to show that

$$J_0 = \sup_{\alpha\in]-1,+\infty[} E_Q\alpha(B) = \sup_{\alpha\in]-1,+\infty[} e^{-(1+\alpha)T} = 1.$$

Also, the maximum price J_t for B at time t will be equal to 0 if $N_t \geq 1$ (because then the event $N_T = 0$ is impossible) and 1 if $N_t = 0$.

It follows that the different processes of Theorem 2.3.1 are given by

- the price for B at time 0, $J_0 = 1$,
- the portfolio process $\varphi = 0$,
- the optional increasing process $f_t = N_{t\wedge T_1} = \mathbf{1}_{N_t\geq 1}$.

We see that $f_t = A_t - j_t$, where $j_t = -N_{t\wedge T_1} + t\wedge T_1$ is a purely discontinuous martingale with negative jumps, and $A_t = t\wedge T_1$ is a predictable increasing process. By defining the model on the canonical space, it is possible to show that the sequence Q_α converges weakly in distribution, as α tends to -1, to a probability measure that is not equivalent to P and under which the Poisson process is equal to 0 almost surely. We define the model more precisely below and give explicit calculations.

Let Ω_1 be the space of all $\mathbb{R}^d$-valued continuous functions on $\mathbb{R}^+$,

$$\Omega_1 = \mathcal{C}(\mathbb{R}^+, \mathbb{R}^d).$$

We denote by F^1 the σ-field generated by the coordinate process $W_t : \omega_1 \to \omega_1(t)$ for $t \geq 0$. Let $(F^{1_t}, t \geq 0)$ be the filtration generated by the process W_t. Let P^1 be the Wiener measure on Ω_1 constructed so that the coordinate mapping process W_t is Brownian motion.

Let Ω_2 be the space of all Radon positive measures on $\mathbb{R}^+$,

$$\Omega_2 = \mathcal{M}_+(\mathbb{R}^+).$$

We denote by F^2 the σ-field generated by all the random variables $N_t : \omega_2 \to \omega_2([0,t])$ for $t \geq 0$. Let (F_t^2) be the filtration generated by the process (N_t). Let P^2 be the probability measure on Ω_2 constructed so that the coordinate mapping process N_t is Poisson process with intensity 1.

Let (Ω, F, P) be the cross-product probability space $(\Omega_1 \times \Omega_2,\ F_1 \otimes F_2,\ P_1 \otimes P_2)$. The filtration F_t is defined by $F_t = F_t^1 \otimes F_t^2$. We denote by ω the elements of Ω

$$\omega = (\omega_1, \omega_2), \quad \omega_1 \in \Omega_1, \quad \omega_2 \in \Omega_2.$$

We denote by W_t the first coordinate mapping process and by N_t the second coordinate mapping process

$$W_t(\omega) = W_t(\omega_1) = \omega_1(t); \qquad N_t(\omega) = N_t(\omega_2) = \omega_2(0,t).$$

Under P, W_t is a (F_t)-Brownian motion, and N_t is a (F_t)-Poisson process with intensity 1.

The prices of the basic securities $P^i(t)$, the vector of stock appreciation rates $b(t)$, and the volatility matrix $\sigma(t)$ are taken to depend only on the first coordinate of the path (ω_1).

Let Q^1 be the probability measure that is equivalent to P^1 on F_T^1 such that

$$\widetilde{W_t} = W_t + \int_0^t \theta_s \, ds, \qquad 0 \leq t \leq T$$

is Brownian motion under Q^1. The reference probability measure Q on F_T is equal to $Q^1 \otimes P^2$. The contingent claim is equal to

$$B = \mathbf{1}_{N_T = 0}.$$

Let us calculate

$$J_0 = \sup_{M \in D} E_{Q^M}[\mathbf{1}_{N_T=0}].$$

Let J_0' be defined by

$$J_0' = \sup_{\alpha \in]-1, +\infty[} E_{P_\alpha^2}[\mathbf{1}_{N_T=0}].$$

Let P_α^2 be the probability measure defined on F_T^2 by

$$\frac{dP_\alpha^2}{dP^2} = \mathcal{E}(\alpha \widetilde{N})_T = e^{\log(1+\alpha)N_T - \alpha T},$$

where $\widetilde{N}_t = N_t - t$, $0 \le t \le T$. Let Q_α be defined by $Q_\alpha = Q^1 \otimes P^2_\alpha$. We have

$$\frac{dQ_\alpha}{dQ} = \mathcal{E}(\alpha\widetilde{N})_T \quad \text{and} \quad \alpha\widetilde{N} \in D,$$

hence, $J'_0 \le J_0$.

Let us show that $J'_0 = 1$. From the change of measure theorem for point processes ([Br-Ja, pp. 377–379]), we have that N is a Poisson process with intensity $1 + \alpha$ under P^2_α; hence, $P^2_\alpha(N_T = 0) = e^{-(1+\alpha)T}$ and

$$J'_0 = \sup_{\alpha \in]-1,+\infty[} P^2_\alpha(N_T = 0) = 1.$$

The supremum is obtained for $\alpha = -1$; hence

$$J_0 = 1.$$

Let us calculate

$$J_t = \text{ess}\sup_{M \in D} E_{Q^M}[\mathbf{1}_{N_T=0}/F_t].$$

Let J'_t be given by

$$J'_t = \text{ess} \sup_{\alpha \in]-1,+\infty[} E_{P^2_\alpha}[\mathbf{1}_{N_T=0}/F^2_t].$$

We have $J'_t \le J_t$. Let us determine J'_t:

$$E_{P^2_\alpha}[\mathbf{1}_{N_T=0}/F^2_t] = \mathbf{1}_{N_t=0}\, E_{P^2_\alpha}[\mathbf{1}_{N_T=0}/F^2_t] = \mathbf{1}_{N_t=0}\, e^{-(1+\alpha)(T-t)},$$

hence,

$$J'_t = \mathbf{1}_{N_t=0},$$

and the supremum is obtained for $\alpha = -1$. Now,

$$J_t \le \mathbf{1}_{N_t=0};$$

hence,

$$J_t = \mathbf{1}_{N_t=0} = 1 - N_{t\wedge T_1}.$$

The seller follows the following strategy. At $t = 0$, he receives 1 from the buyer. If the Poisson process remains equal to 0 until T, the seller does not make any profit; at time T, he gives 1 to the buyer. Otherwise, at the first instant the Poisson process is different from $0(T_1)$, the seller makes profit 1.

Let us determine the limit of the probability measures Q_α as $\alpha \to -1$:

$$\forall t \in R^+ \quad \text{and} \quad \lambda \in R^+, \lim_{\alpha \downarrow -1} E_{P^2_\alpha}[e^{-\lambda N_t}] = \lim_{\alpha \downarrow -1} e^{(1+\alpha)t(e^{-\lambda}-1)} = 1.$$

Also, for all $t_1, t_2, \ldots, t_k \in (R^+)^k$, the Laplace transform of $(N_{t_1}, \ldots, N_{t_k})$ tends to 1 under P^2_α as α tends to -1. Hence, $P^2_\alpha\,(N_{t_1}, \ldots, N_{t_k})^{-1}$ converges to the Dirac measure at zero on $(R^+)^k$ as α tends to -1, and $Q_\alpha = Q^1 \otimes P^2_\alpha$ converges in a weak sense to $Q_\alpha = Q^1 \otimes \delta_0$ as

α tends to -1. Under the limit probability measure $Q^1 \otimes \delta_0$, the increasing optional process f is equal to zero almost surely, that is,

$$Q^1 \otimes \delta_0(N_{t\wedge T_1} = 0) = 1,$$

$$J_t = 1, \quad Q^1 \otimes \delta_0 \text{ a.s.}$$

Hence, J is a martingale (constant) under the limit probability measure. But this probability measure is not equivalent to P. Notice that this probability measure makes the market complete (because it annuls the Poisson process).

The essential infimum of the possible prices at $t \geq 0$, $t < T$, is given by

$$\begin{aligned} K_t &= \text{ess} \inf_{\alpha > -1} Q^\alpha(N_T = 0/F_t), \\ &= \lim_{\alpha \to +\infty} Q^\alpha(N_T = 0/F_t), \\ &= 0. \end{aligned}$$

Hence, for each $t \in [0, T]$, we have

$$K_t = \mathbf{1}_{N_T=0}\, \mathbf{1}_{t=T}.$$

Let us determine the limit of the probability measures Q_α as $\alpha \to +\infty$. For all $t_1, t_2, \ldots, t_k \in (R^+)^k$, the Laplace transform of $(N_{t_1}, \ldots, N_{t_k})$ tends to zero under P^2_α as α tends to $+\infty$. Hence, Q_α converges in a weak sense to the null measure as $\alpha \to +\infty$. This result shows that an optimizing sequence of P-martingale measure does not necessarily converge to a probability measure.

A. Appendix.

A.1. A few useful (well-known) properties and theorems.

PROPOSITION 1.a. *A local martingale that is of class* (D) *is a martingale* (*see* [*De-Me*, *p.* 97, VI-30]).

Recall that if M and N are local martingales, their quadratic variation process $\langle M, N\rangle$ is defined only if MN is a special semimartingale. (For the definition, see [De-Me, p. 247, VII-39].) It always exists if one of the local martingales M, N is locally bounded by the following property (see [De-Me, p. 240, VII-32]).

PROPOSITION 1.b. *If X is a special semimartingale and Y is a locally bounded semimartingale, then XY is a special semimartingale.*

Proof. Using Doob's inequality, it is easy to show that $\sup_{s\leq t} |X_s Y_s|$ is locally integrable; it follows that XY is a special semimartingale (by using Thm. 25-d, p. 234 in [De-Me]). □

Notation. Let X_t be a local martingale (RCLL) under P with respect to $\{F_t\}$, such that $X_0 = 0$. We denote by $\mathcal{E}(X)_t$ the exponential of X, that is, the solution of the SDE

$$dU_t = U_{t^-}\, dX_t \quad \text{with}\, U_0 = 1.$$

The process $\mathcal{E}(X)$ is a local martingale under P.

We recall a general form of the Girsanov theorem that we shall use several times. (For more details see [De-Me, p. 259, VII-49] or [Mey, p. 377].)

Let P and Q be two probabilities equivalent on F_T, such that

$$\left.\frac{dQ}{dP}\right|_{F_T} = \mathcal{E}(N)_T,$$

where N is a local martingale which satisfies $N_0 = 0$. Let Z be a special semimartingale under P. It has the unique canonical decomposition under P

$$Z_t = Z_0 + M_t + A_t, \qquad 0 \leq t \leq T,$$

where M is a local martingale that satisfies $M_0 = 0$, and A is a predictable VF (finite variation) and RCLL process that satisfies $A_0 = 0$. Note that a supermartingale is special and that in this case, A_t is a decreasing process.

THEOREM 1.A. *Suppose that $\langle M, N\rangle$ exists. Then Z is a special semimartingale under Q and its canonical decomposition under Q is given by $Z_t = Z_0 + (M_t - \langle M, N\rangle_t) + (A_t + \langle M, N\rangle_t)$. The first term between brackets is a local martingale under Q, and the second one is a predictable finite variation process.*

COROLLARY 1.A. *Suppose that $\langle M, N\rangle$ exists. Then*

(i) *Z is a local martingale under Q if and only if the process $(A_t + \langle M, N\rangle_t)$ is equal to* 0.

(ii) *Z is a supermartingale under Q if and only if $(A_t + \langle M, N\rangle_t)$ is a decreasing process.*

A.2. Characterization of the essential supremum of all the possible prices (proofs). Let J_t be the essential supremum of the possible prices for B at time t and

$$J_t = \operatorname*{ess\ sup}_{R\in\mathcal{P}} E_R[B/F_t] = \operatorname*{ess\ sup}_{N\in D} E_{Q^N}[B/F_t].$$

We use dynamic programming methods [ElK] to solve the problem. Notice that (J_t) is not defined as a process yet because for each t, it is defined Q almost surely. Now,

$$\forall N \in D \quad \text{and} \quad t \in [0,T],\ E_{Q^N}[B/F_t] = E_{Q^{\tilde{N}}}[B/F_t],$$

where

$$\widetilde{N}_u = N_u - N_{t\wedge u},\ 0 \leq u \leq T.$$

Hence,

$$J_t = \operatorname*{ess\ sup}_{N\in D(t)} E_{Q^N}[B/F_t],$$

where $D(t) = \{N \in D/N_u = 0\ \forall u \in [0,t]\}$. For any $N \in D(t)$, put

$$\Gamma(t,N) = E_{Q^N}[B/F_t] = E[\mathcal{E}(N)_T B/F_t].$$

PROPOSITION 1. $\{\Gamma(t,N),\ N \in D(t)\}$ *is stable by supremum and infimum.*

By this property, it follows that for each t, there exists a sequence $N_p \in D(t)$ so that, almost surely, $\Gamma(t,N_p)$ is an increasing sequence of random variables that converges to J_t, that is,

$$J_t = \lim_{p\to+\infty} \uparrow \Gamma(t,N_p) = \lim_{p\to+\infty} \uparrow E_{Q^{N_p}}[B/F_t].$$

This property will allow us to invert supremum and expectation (using the monotone convergence theorem).

Proof. Let N_1, $N_2 \in D(t)$. There exists $N \in D(t)/\Gamma(t,N) = \Gamma(t,N_1) \vee \Gamma(t,N_2)$. Indeed, put $A = \{\Gamma(t,N_2) \geq \Gamma(t,N_1)\}$. We have $A \in F_t$. Put $N = N_1\mathbf{1}_{A^c} + N_2\mathbf{1}_A$. We have $N \in D(t)$;

$$\begin{aligned}\Gamma(t,N) &= E[\mathcal{E}(N_1)_T B/F_t]\mathbf{1}_{A^c} + E[\mathcal{E}(N_2)_T B/F_t]\mathbf{1}_A,\\ &= \Gamma(t,N_1)\mathbf{1}_{A^c} + \Gamma(t,N_2)\mathbf{1}_A.\end{aligned}$$

Hence, $\Gamma(t,N)=\Gamma(t,N_1)\vee\Gamma(t,N_2)$. □

For each t, take a sequence $N_p\in D(t)$ such that, Q almost surely,

$$J_t=\lim_{p\to+\infty}\uparrow\Gamma(t,N_p)=\lim_{p\to+\infty}\uparrow E_{Q^{N_p}}[B/F_t].$$

Now, J_t will denote a (F_t)-adapted process that is equal to the above limit almost everywhere.

PROPOSITION 2. *For any $N\in D$, (J_t) is a supermartingale under Q^N (that is, $\mathcal{E}(N)_t\,J_t$ is a supermartingale under Q).*

Proof. Let s, t be two positive reals such that $s<t\le T$. Take a sequence $N_p\in D(t)$ such that, Q almost surely,

$$J_t=\lim_{p\to+\infty}\uparrow\Gamma(t,N_p)=\lim_{p\to+\infty}\uparrow E_{Q^{N_p}}[B/F_t].$$

Let $N\in D$. Since we can invert limit and expectation (by the monotone convergence theorem), we have

$$\begin{aligned}E\left[\frac{\mathcal{E}(N)_t}{\mathcal{E}(N)_s}\,J_t/F_s\right]&=\lim_{p\to+\infty}\uparrow E\left[\frac{\mathcal{E}(N)_t}{\mathcal{E}(N)_s}\,E[\mathcal{E}(N_p)_TB/F_t]/F_s\right],\\&=\lim_{p\to+\infty}\uparrow E\left[\frac{\mathcal{E}(N)_t}{\mathcal{E}(N)_s}\,\mathcal{E}(N_p)_TB/F_s\right],\\&=\lim_{p\to+\infty}\uparrow E\left[\frac{\mathcal{E}(\widetilde{N}_p)_T}{\mathcal{E}(\widetilde{N}_p)_s}\,B/F_s\right],\end{aligned}$$

where $\widetilde{N}_p(u)=N(u\wedge t)+N_p(u)$, for $u\in[0,T]$. Now, $(\widetilde{N}_p(u),\ u\in[0,T])\in D$. Hence,

$$E\left[\frac{\mathcal{E}(N)_t}{\mathcal{E}(N)_s}\,J_t/F_s\right]\le J_s.\qquad\square$$

PROPOSITION 3. *(J_t) is the smallest supermartingale under Q^N, for any $N\in D$, which is equal to B at time T (unique up to a null set).*

Proof. Let (J'_t) be a supermartingale under Q^N, for any $N\in D$, which is equal to B at time T. Then,

$$\forall\,t\in[0,T]\quad\text{and}\quad N\in D,\ J'_t\ge E_{Q^N}[B/F_t],\ Q\text{ a.s.}$$

Hence,

$$\forall\,t\in[0,T],\ Q\text{ a.s., }J'_t\ge J_t.\qquad\square$$

We have also the following property.

PROPOSITION 4. *Let $\hat{N}$ be a local martingale that belongs to D. The following properties are equivalent:*

(i) *$\hat{N}$ is optimal, i.e., $\forall\,t\in[0,T]$, $J_t=E_{Q^{\hat{N}}}[B/F_t]$, Q a.s.*

(ii) *J_t is a martingale under $Q^{\hat{N}}$.*

PROPOSITION 5. *There exists an* RCLL *supermartingale still denoted by J_t so that for each $t\in[0,T]$,*

$$J_t=\operatorname*{ess\,sup}_{N\in D}E_{Q^N}[B/F_t].$$

Proof. Put $\mathbb{D} = [0,T] \cap \mathbb{Q}$. Because (J_t) is a supermartingale, we have that for P almost every ω, the mapping $t \longrightarrow J_t(\omega)$ defined on $\mathbb{D}$ has at each point t of $[0,T[$ a finite right limit

$$J_{t^+}(\omega) = \lim_{s\in\mathbb{D}, s\downarrow t} J_s(\omega)$$

and at each point of $]0,T]$ a finite left limit

$$J_{t^-}(\omega) = \lim_{s\in\mathbb{D}, s\uparrow t} J_s(\omega).$$

One can show (using a well-known property) that (J_{t^+}) is an (F_{t^+})-supermartingale under Q_N for all $N \in D$. Because the filtration is right continuous, J_{t^+} is an (F_t)-supermartingale under Q_N for all $N \in D$. Hence, by Proposition 3, for all $t \in [0,T]$, Q almost surely, $J_{t^+} \geq J_t$. Also, $J_t \geq E[J_{t^+}/F_t]$. Hence, Q almost surely, $J_t = J_{t^+}$ or else,

$$\forall t \in [0,T],\ J_{t^+} = \operatorname{ess}\sup_{N\in D} E_{Q^N}[B/F_t].$$

The result follows by taking J_t equal to the above process J_{t^+}. □

J_t is an RCLL process that satisfies

$$J_t = \operatorname{ess}\sup_{N\in D} E_{Q^N}[B/F_t].$$

J_t is characterized as the smallest right continuous supermartingale under Q_N, for every N belonging to D, which is equal to B at time T. Also, N is optimal if and only if J_t is a martingale under Q_N.

A.3. Generalization of the results of this paper. The results of Theorem 2.1.1, Theorem 2.1.2, Theorem 2.3.1, and Corollary 2.3.1 remain under the hypothesis

$$\sup_{N\in D} E_{Q^N}(B) < \infty.$$

(In fact, we shall see below that this hypothesis is equivalent to the fact that there exists a price admissible for sellers, or equivalently that B is smaller than the value of a self-financing portfolio, that is, B satisfies

$$B \leq X^{H,0,y}(T), \quad P\,\text{a.s.}$$

for some portfolio strategy H and initial investment $y \geq 0$.)

The whole proof of Theorem 2.1.1 still holds under the above hypothesis. In this case, J_t is not generally of class D. The results of Theorem 2.1.2, Proposition 2.3.1, and Theorem 2.3.1 still hold, but j is a Q-local martingale only (but not a martingale in general). The arguments of the proof still hold, but it is a bit more complicated technically because $\langle j \rangle$ is not always defined.

Proof of Theorem 2.1.2 *under the above hypothesis.* J_t is a Q-supermartingale; hence, it admits a unique decomposition as a local martingale M_t minus an increasing predictable process $A_t : J_t = M_t - A_t$. The local martingale M_t admits the following Kunita decomposition:

$$M_t = J_0 + \int_0^t \varphi_s^* \sigma_s \, d\widetilde{W}_s + j_t \quad \forall t \in [0,T],\ Q\,\text{a.s.}$$

for some predictable process φ and some Q-local martingale j such that

$$\left\langle j, \int_0^{\cdot} \sigma_i(s)dW_s \right\rangle_T = 0,\ Q\,\text{a.s.}, \quad \forall i \in \{1, \dots, n\}.$$

As in the proof of Theorem 2.1.2, we show that the continuous part j^c of j is equal to zero, using the following lemma (which follows from the fact that J_t is a supermartingale under each P-martingale measure).

LEMMA. *Let N be an element of D such that $\langle N, j\rangle$ exists. Then $A_t - \langle N, j\rangle_t$ is an increasing process.*

Now, $\langle j^c\rangle$ is locally integrable. By the Lebesgue Decomposition Theorem, there exist a positive predictable process h that belongs to $L^1_{\text{loc}}([0,T] \times \Omega, d\langle j^c\rangle_t\, dQ)$ and a locally integrable predictable increasing process B such that

$$dA_t = h_t d\langle j^c\rangle_t + dB_t$$

and such that, Q almost surely, the measure dB_t is singular with respect to $d\langle j^c\rangle_t$. Using the same arguments as in the proof of Theorem 2.1.2, we obtain the desired result. □

The proof of Theorem 2.3.1 under the weaker hypothesis is unchanged, and the result of Proposition 2.3.1 can be obtained by the same methods as before, but it is a bit longer because the lemma must be applied to some N such that $\langle N, j\rangle$ exists.

Remark. It follows from this, that the following properties are equivalent.

(i) $\sup_{N\in D} E_{Q^N}(B) < \infty$.

(ii) There exists a price admissible for sellers, or equivalently that B is smaller than the value of a self-financing portfolio, that is, B satisfies

$$B \le X^{H,0,y}(T),\ P\,\text{a.s.},$$

i.e.,

$$B \le y + \int_0^T H_s^* \sigma_s\, d\tilde{w}_s,\ Q\,\text{a.s.}$$

for some portfolio strategy H and initial investment $y \ge 0$.

Notice that the technical assumption on B given by

$$E_{Q^N}\left[\int_0^T \|\sigma_s^* H_s\|^2\, ds\right] < +\infty$$

for each $N \in D$ may be interpreted as the fact that the contingent claim B is not too risky. When we do not make the technical assumption on B, Corollary 2.3.1 still holds, but Corollary 2.3.2 must be replaced by the following.

COROLLARY 2.3.2$'$. (1) *For each $N \in D$, $E_{Q^N}(B) \le J_0 - E_{Q^N}(f_T)$.*

(2) *If N_n, $n \ge 0$, is an optimizing sequence belonging to D, that is, such that*

$$\lim_{n\to+\infty} E_{Q^{N_n}}[B] = J_0$$

then

$$\lim_{n\to\infty} E_{Q^{N_n}}(f_T) = 0.$$

Proof of (1). Let N be an element of D. The process given by

$$J_0 + \int_0^t \varphi_s^* \sigma_s \, d\widetilde{W}_s$$

is a positive continuous Q^N-local martingale, and hence a Q^N-supermartingale; this yields the inequality

$$J_0 + E_{Q^N}\left[\int_0^T \varphi_s^* \sigma_s \, d\widetilde{W}_s\right] \leq J_0.$$

Thus, f_T is Q^N-integrable and $E_{Q^N}(B) \leq J_0 - E_{Q^N}(f_T)$.

Proof of (2). Inequality (1) applied to the local martingales N_n gives the inequality

$$\forall n \in N,\ E_{Q^{N_n}}(B) \leq J_0 - E_{Q^{N_n}}(f_T).$$

Hence, if we let n tend to $+\infty$, we obtain the desired result

$$\lim_{n \to \infty} E_{Q^{N_n}}(f_T) = 0. \qquad \square$$

Also, when we do not make the technical assumption on B, Theorem 2.3.2 does not hold anymore, but we have the following result.

THEOREM 2.3.2′. *If* $\sup_{N \in D} E_{Q^N}[B]$ *is attained then* B *is attainable, that is, there exist a constant* x *and a portfolio* π *such that*

$$B = x + \int_0^T \pi_u^* \sigma_u \, d\widetilde{W}_u,\ Q \text{ a.s.}$$

Proof. Compare the proof of Theorem 2.3.2.

Thus, the contingent claims that satisfy the technical assumption (loosely speaking, those that are not too risky) are divided in two sets:

- The set of contingent claims that are attainable, which is equal to the set of contingent claims that admit a unique price.
- The set of contingent claims that are not attainable, which is equal to the set of contingent claims that admit several possible prices.

Things are not as clear for contingent claims that admit a finite selling price but do not satisfy the technical assumption. Even if they are attainable in the above sense, they may admit several possible prices. (Loosely speaking, this can be explained by the fact that, even if they are attainable, they can be too risky.) Nevertheless, we have the following properties that are equivalent.

(i) For each local martingale $N \in D$,

$$E_{Q^N}(B) = E_Q(B).$$

(ii) There exist a constant x and a portfolio π such that

$$B = x + \int_0^T \pi_u^* \sigma_u \, d\widetilde{W}_u,\ Q \text{ a.s.}$$

and such that the process given by

$$x + \int_0^{\cdot} \pi_u^* \sigma_u \, d\widetilde{W}_u$$

is a martingale under each P-martingale measure.

FINITE ELEMENT APPROXIMATIONS OF COMPENSATOR DESIGN FOR ANALYTIC GENERATORS WITH FULLY UNBOUNDED CONTROLS/OBSERVATIONS*

I. LASIECKA†

Abstract. An approximation theory leading to a design of a finite-dimensional compensator for control systems generated by analytic semigroups is presented. The novelty of this paper with respect to other results available in the literature is threefold: (i) it treats fully unbounded control/observation operators; (ii) it does not require compactness property of the underlined generator (an assumption that is often violated in practice); and (iii) the design of a finite-dimensional compensator is based on finite element approximation of the original model rather than on modal (eigenfunctions) approximations which, in turn, require the a priori knowledge of the eigenvalues for the system. Applications of the theory to heat equations and plate equations are provided.

Key words. finite element approximations, compensator design, Riccati equations, analytic semigroups, unbounded control/observation operators

AMS subject classifications. 49, 65

1. Introduction.

Consider the following control system:

$$\begin{cases} x_1 = Ax + Bu; \qquad x(0) = x_0 \in H, \\ y = Cx. \end{cases} \tag{1.1}$$

We make the following assumptions on (1.1).

(i) H, U, and Z are Hilbert spaces.

(ii) $A : H \supset \mathcal{D}(A) \to H$ is the generator of a strongly continuous analytic semigroup e^{At} on H; $t > 0$, generally unstable on H so that $\|e^{At}\|_{\mathcal{L}(H)} \leq Me^{wt}$; $t \geq 0$. We then consider throughout the translation $\hat{A} = -A + \hat{\lambda} I$, where $\hat{\lambda} > w$, so that $\hat{A}$ has well-defined fractional powers on H and $-\hat{A}$ is the generator of a strongly continuous analytic semigroup e^{-At} on H satisfying $\|e^{-\hat{A}t}\|_{\mathcal{L}(H)} \leq \hat{M}e^{\lambda t}$; $\lambda = w - \hat{\lambda}$.

(iii) $B : U \to (\mathcal{D}(A^*))'$ where $(\mathcal{D}(A^*))'$ is the dual of $\mathcal{D}(A^*)$ with respect to the H-topology. It is assumed that B is $\hat{A}^{*\gamma}$ bounded, or equivalently, as in the following hypothesis.

Hypothesis 1a. $(\hat{A})^{-\gamma} B \in \mathcal{L}(U;\, H)$; $0 \leq \gamma < 1$.

(iv) $C : \mathcal{D}(C) \subset H \to Z$ is a closed, densely defined operator such that the following hypothesis holds.

Hypothesis 1b. $C(\hat{A})^{-r} \in \mathcal{L}(H;\, Z)$; $0 < r < 1$.

Standard arguments from perturbation theory of analytic semigroups (see [K.1]) yield the fact that with any $F \in \mathcal{L}(H;\, U)$ and $K \in \mathcal{L}(Z;\, H)$, $A + BF$ and $A - KC$ generates an analytic semigroup on H. In what follows we make the following stabilizability-detectability assumptions.

Hypothesis 2. There exists $F \in \mathcal{L}(H;\, U)$ and $K \in \mathcal{L}(Z;\, H)$ such that

$$|e^{(A+BF)t}|_{\mathcal{L}(H)} + |e^{(A-KC)t}|_{\mathcal{L}(H)} \leq Me^{-w_1 t}$$

for some $w_1 > 0$. Under the above assumptions it is straightforward to show that there exists an infinite-dimensional "compensator," i.e.,

$$w_t = (A + BF - KC)w + KCx, \tag{1.2}$$

such that the feedback control

$$u = Fw \tag{1.3}$$

exponentially stabilizes system (1.1). Precise statement of this fact is given in the following theorem.

THEOREM 1.1. *Let $\mathcal{H} \equiv H \times H$. The operator $\mathcal{A} : \mathcal{D}(\mathcal{A}) \subset \mathcal{H} \to \mathcal{H}$ given by*

$$\mathcal{A} \equiv \begin{pmatrix} A & BF \\ KC & A + BF - KC \end{pmatrix}$$

with $\mathcal{D}(\mathcal{A}) \equiv \{(x, y) \in \mathcal{H};\ Ax + BFy \in H;\ KCx + (A + BF - KC)\,y \in H\}$ generates an analytic and exponentially stable semigroup on $\mathcal{H}$.

Proof of Theorem 1.1. The proof, being a rather routine exercise in perturbation theory of analytic semigroups, is omitted.

The main goal of this paper is to construct *finite-dimensional* compensator w_h (which will be based on finite element approximations of the original problem) such that the *finite-dimensional* control feedback

$$u_h(t) = F_h w_h(t), \tag{1.4}$$

once inserted into the original system, will produce the solutions that are uniformly (with respect to h) exponentially stable.

The concept of a dynamic compensator is well known in the context of finite-dimensional systems and the idea goes back to Luenberger (see [L.3]). Many of these finite-dimensional ideas have been successfully generalized to infinite-dimensional systems—mainly of parabolic type (or, more generally, analytic semigroups); see [S.1], [C.1], [G.1], [G.2]. However, the techniques employed in these references are restricted to the cases when either the control/observation operators are bounded or, if unbounded (see [C.1]), the degree of unboundedness is severely limited—typically $\gamma + r \leq \frac{1}{2}$. On the other hand, there are many physically significant examples (heat equation with Dirichlet boundary control, strongly damped plate equations, etc.; see §6) where the above restrictions are not met. Also, the mathematical difficulties encountered in dealing with "fully" unbounded control operators (i.e., $\frac{1}{2} < \gamma < 1$) are much greater. Indeed, when $\gamma > \frac{1}{2}$, the basic solution operator $u \to x(t)$ is not defined from $L_2(0T;\ U) \to H$. This fact, recognized earlier in the context of the theory of Riccati equations (see for instance [B-D-D-M] and [L-T]), is a source of substantial technical difficulties. Thus, the main feature that distinguishes this paper from the other works is the fact that we treat *fully unbounded* control/observation operators, i.e., $\gamma + r < 1$. Moreover, in most papers available in the literature, the construction of finite-dimensional compensators is based on the knowledge of the eigenfunctions/eigenvalues of the generator A (see for instance [C.1]). For partial differential equation (PDE) systems in higher dimensions defined on arbitrary domains Ω, the eigenfunctions of the open-loop systems are generally not available. In view of this, our goal is to design finite-dimensional compensators based on *finite element* approximation of the original model and, as such, it would not require any specific knowledge of the spectrum of the original, usually unstable, generator. (Finite element approximations of compensator design with control operator B *bounded* were treated in [G.2] and references cited therein, while the case of *unbounded* operator B for hyperbolic-like dynamics was considered in [L.2].) Another attractive feature of our approach is that it does not require the compactness of the resolvent of the generator A—an assumption that has been used in an essential way in all previous works. In fact, as we will see in §6.3, there are examples of damped plate equations where this assumption is violated.

To establish the appropriate convergence and stability results for the compensator, the techniques recently developed in the context of finite element approximations of Riccati equations with fully unbounded control operators (see [L-T.1]) are used in an essential way. The outline of the paper is as follows. In §2 we introduce approximating subspaces and operators together with their properties. In §3 we formulate the main results of this paper. Sections 4 and 5 are devoted to the proofs of the main results. Section 6 provides several physical examples motivating the theory.

2. Approximating subspaces and operators. We introduce a family of approximating subspaces $V_h \subset H \cap \mathcal{D}(B^*) \cap \mathcal{D}(\hat{A}^r)$, where h is a parameter of discretization that tends to zero, $h \le h_0$. Let π_h be the orthogonal projection of H onto V_h with the usual approximating property, for some $s > 0$,

$$|\pi_h x - x|_H \le M h^s |x|_{\mathcal{D}(A)}. \tag{2.1}$$

Throughout this paper, M denotes a generic constant independent on $0 \le h \le h_0$.

Approximation of A. Let $A_h : V_h \to V_h$ be an approximation of A that satisfies the requirements in Assumptions 1 and 2.

Assumption 1 (uniform analyticity). For $a > w$, there exists $\sum(A, a) =$ closed triangular sector containing the axis $[-\infty, a]$ and delimited by two rays $a + \rho e^{\pm i Q_0}$ for some $\pi/2 < Q_0 < 2\pi$, and there exists h_a such that, if $\sum^c$ denotes the complement of $\sum$ in the complex plane, then for all $0 \le h \le h_a$, we have $\sigma(A_h) =$ spectrum of $A_h \subset \sum(A, a)$,

$$|R(\lambda, A_h)\hat{A}_h^Q \pi_h|_{\mathcal{L}(H)} \le \frac{M}{|\lambda - a|^{1-Q}} \qquad \forall \lambda \in \textstyle\sum^c(A, a). \tag{2.2}$$

Assumption 2. $|\pi_h \hat{A}^{-1} - \hat{A}_h^{-1} \pi_h|_{\mathcal{L}(H)} \le M h^s$.

Approximation assumptions on the operators B and C.

Assumption 3. (i) $|B^* x_h|_U \le M h^{-\gamma s} |x_h|_H$, $x_h \in V_h$;

(ii) $|\hat{A}^r x_h|_H \le M h^{-rs} |x_h|_H$.

Assumption 4. (i) $|B^*(\pi_h - I)x|_U \le M h^{s(1-\gamma)} |x|_{\mathcal{D}(A^*)}$;

(ii) $|\hat{A}^r(\pi_h - I)x|_H \le M h^{s(1-r)} |x|_{\mathcal{D}(A)}$.

Assumption 5 (i) $|B^* \pi_h x|_U \le M |\hat{A}^{*\gamma} x|_H$;

(ii) $|\hat{A}^* \pi_h x|_H \le M |\hat{A}^r x|_H$.

Approximation of F and K.

Assumption 6. The operator $F_h : V_h \to U$ satisfies one of the following conditions:

(i) either $F_h \pi_h \to F$ strongly and $B^* R(\lambda_0, A^*)$ is compact,

(ii) or $|F_h \pi_h - F|_{\mathcal{L}(H; U)} \to 0$ as $h \to 0$.

Assumption 7. Similarly for $K, K_h : Z \to V_h$,

(i) either $K_h \to K$ strongly and $CR(\lambda_0, A)$ is compact,

(ii) or $|K_h - K|_{\mathcal{L}(Z; H)} \to 0$ as $h \to 0$.

Consequences of approximating assumptions on A. From Assumptions 1 and 2, the following "rough" data estimates follow (see [L.1, Appendix], in the form to be used later):

$$\|R(\lambda, A) - R(\lambda, A_h)\pi_h\|_{\mathcal{L}(H)} \le M h^s, \qquad s > 0 \tag{2.3}$$

uniformly in $\lambda \in \sum^c(A, a)$,

$$|B^*[R(\lambda_0, A^*) - R(\lambda_0, A_h^*)\pi_h]|_{\mathcal{L}(H; U)} \le M h^{s(1-\gamma)}, \tag{2.4}$$

$$(2.5)\qquad |R(\lambda, A_h)\pi_h B|_{\mathcal{L}(U;H)} \le \frac{M}{|\lambda - a|^{1-\gamma}},$$

where the last two inequalities follow from Lemma 3.1 in [L-T.1]. From Assumptions 4 and 5, by interpolation, we obtain

$$(2.6)\qquad |\hat{A}^r(\pi_h - I)x|_H \le Mh^{s(Q-r)}\,|\hat{A}^Q x|_H; \qquad r \le Q \le 1.$$

3. Statement of main results. Consider the following finite-dimensional dynamic compensator:

$$(3.1)\qquad w_t = (A_h\pi_h + \pi_h BF_h\pi_h - K_hC)w + K_hCx.^1$$

We associate (3.1) with the control system

$$(3.2)\qquad \begin{cases} x_t = Ax + BF_h\pi_h w, \\ x(0) = x_0 \in H. \end{cases}$$

Our main results are contained in the following theorem.

THEOREM 3.1. *Assume Hypotheses* 1 *and* 2 *and Assumptions* 1–7. *Moreover, assume* $\gamma + r < 1$. *Then system* (3.1), (3.2) *represented by*

$$\mathcal{A}_h \equiv \begin{bmatrix} A & BF_h\pi_h \\ K_hC & A_h\pi_h + \pi_h BF_h\pi_h - K_hC \end{bmatrix}$$

generates a uniformly analytic and uniformly exponentially stable semigroup, i.e.,

$$|e^{\mathcal{A}_h t}|_{\mathcal{L}(\mathcal{H})} \le Me^{-\omega_0 t} \quad \textit{for some } \omega_0 > 0,$$

where the constants M *and* ω_0 *are* uniform *with respect to* $0 < h \le h_0$.

Remark 3.1. In (3.1) one could also approximate the operator B by its approximation $B_h \in \mathcal{L}(U; V_h)$ subject to the usual consistency assumptions (see [L-T.1]). The analysis of the problem is the same.

The problem of practical interest is how to find the stabilizing feedbacks F_h and K_h. If the knowledge of unstable eigenvalues is available then this could be accomplished by a routine pole assignment procedure (see [C.1], [S.1]). Since, in general, a precise knowledge of eigenfunctions is not known, a different approach based on approximation of the algebraic Riccati equation are pursued (see [G.1] for the case of bounded control/observation operators). To accomplish this we recall recent results from [L-T] and [L-T.1] on solvability and approximations of Riccati equations arising in control dynamics with unbounded input/output operators.

We associate the following algebraic Riccati equation with the dynamics (1.1):

$$(3.3)\qquad (A^*Px, y)_H + (PAx, y)_H + (x, y)_H = (B^*Px, B^*Py)_U \quad \text{for } x, y \in \mathcal{D}(A).$$

By virtue of Hypotheses 1 and 2 we know (see [D-I], [F.2], [F.3], [L-T], [B-D-D-M]) that there exists a unique solution $P \in \mathcal{L}(H)$, $P = P^*$ such that

$$(3.4)\qquad B^*P \in \mathcal{L}(H; U),$$

[1] $\pi_h B \subset V_h$ is defined, as usual, by duality: $(\pi_h Bg, v_h)_H = (g, B^*v_h)_U$ for all $v_h \in V_h$, $g \in U$.

(3.5) $e^{(A-BB^*P)t}$ generates an analytic and exponentially stable semigroup.

On the other hand, the approximating properties (Assumptions 1–7) guarantee (see [L-T.1]) that the equation

$$A_h^* P_h + P_h A_h + \pi_h = P_h \pi_h BB^* P_h \tag{3.6}$$

is uniquely solvable with $P_h \in \mathcal{L}(V_h)$. Moreover,

$$B^* P_h \pi_h \in \mathcal{L}(H;\, U) \quad \text{uniformly in } h > 0 \tag{3.7}$$

and (see [L-T.1, Thm. 1.1])

$$|P_h \pi_h - P|_{\mathcal{L}(H)} + |B^*(P_h \pi_h - P)|_{\mathcal{L}(H;\, U)} \to 0 \quad \text{as } h \to 0. \tag{3.8}$$

The same argument can be repeated for the "dual" Riccati equation

$$(AQx, y)_H + (QA^*x, y)_H + (x, y)_H = (C^*Qx, C^*Qy)_H; \qquad x, y \in \mathcal{D}(A^*), \tag{3.9}$$

which, in view of Hypotheses 1 and 2, yields the unique solution $Q \in \mathcal{L}(H)$ such that

$$CQ \in \mathcal{L}(H;\, Z), \tag{3.10}$$

$$e^{(A^* - C^* CQ)t} \quad \text{is exponentially stable.} \tag{3.11}$$

Moreover, in view of Assumptions 1–5, approximation theory of [L-T.1] applies to provide the existence of $Q_h^* = Q_h \in \mathcal{L}(V_h)$ such that

$$A_h Q_h + Q_h A_h^* + \pi_h = Q_h CC^* Q_h \tag{3.12}$$

is satisfied and, moreover,

$$|CQ_h \pi_h|_{\mathcal{L}(H;\, Z)} \le M, \tag{3.13}$$

$$|C(Q_h \pi_h - Q)|_{\mathcal{L}(H;\, Z)} \to 0 \quad \text{as } h \to 0. \tag{3.14}$$

Thus we are in a position to apply the results of Theorem 3.1 with the specific feedbacks

$$\begin{cases} F_h \equiv B^* P_h, \\ K_h = Q_h \pi_h C^*. \end{cases} \tag{3.15}$$

Indeed, parts (ii) of Assumptions 6 and 7 are satisfied by virtue of (3.8) and (3.14), with $F \equiv B^*P$; $K \equiv QC^*$ and F_h, K_h as in (3.15). We have thus obtained the following corollary.

COROLLARY 3.1. *Assume Hypotheses* 1 *and* 2, *and Assumptions* 1–5, $\gamma + r < 1$. *Then the conclusion of Theorem* 3.1 *holds with* F_h *and* K_h *given by* (3.15).

4. Technical lemmas and the proof of Theorem 3.1. We define

$$A_{hB} \equiv A_h \pi_h + \pi_h B F_h \pi_h,$$

$$A_B \equiv A + B F_h \pi_h,$$

$$A_C \equiv A - K_h C.$$

The following result is a consequence of Theorem 4.2 in [L-T.1].

PROPOSITION 4.1 *There exist constants $M > 0$, $w_0 > 0$ such that*

$$|R(\lambda, A_{hB})|_{\mathcal{L}(H)} \leq \frac{M}{|\lambda + w_0|}, \tag{4.1}$$

$$|R(\lambda, A_B)|_{\mathcal{L}(H)} \leq \frac{M}{|\lambda + w_0|}, \tag{4.2}$$

$$|R(\lambda, A_C)|_{\mathcal{L}(H)} \leq \frac{M}{|\lambda + w_0|}, \tag{4.3}$$

where the above estimates hold uniformity in $h < h_0$ and $\lambda \in \sum^c$, where $\sum \equiv$ closed triangular sector containing the axis $(-\infty, -w_0)$ and delimited by two rays $-w_0 + \rho\, e^{\pm Qi}$ for some $\pi/2 < Q < 2\pi$. Here $w_0 < w_1$ where, we recall, w_1 is the margin of stability for $A + BF$ and $A - KC$.

Proof. By virtue of Assumption 6, for some $\lambda_0 \in \rho(A)$,

$$|R(\lambda_0, A) B (F_h \pi_h - F)|_{\mathcal{L}(H)} \to 0, \quad \text{as}\, h \to 0. \tag{4.4}$$

Hence we are in a position to apply Theorem 4.2 of [L-T.1] to conclude (4.1). To assert (4.3) it is enough to note that Assumption 7 implies

$$|(K_h^* - K^*) C R(\lambda_0, A^*)|_{\mathcal{L}(H)} \to 0 \quad \text{as}\, h \to 0. \tag{4.5}$$

Now conclusion of Theorem 4.2 applied to the operator $A^* - C^* K_h^*$ yields the desired inequality in (4.3). The estimate (4.2) holds by virtue of (4.4) and Remark 4.3 in [L-T.1]. □

The proof of Theorem 3.1 is based on the following three lemmas.

LEMMA 4.1. *We have that*

$$|A R(\lambda, A_C)|_{\mathcal{L}(H)} \leq M. \tag{4.6}$$

Let $\gamma + r < 1$. Then

$$|\hat{A}^r R(\lambda, A_C) \hat{A}^\gamma|_{\mathcal{L}(H)} \leq M, \tag{4.7}$$

$$|\hat{A}^r R(\lambda, A_B) \hat{A}^\gamma|_{\mathcal{L}(H)} \leq M, \tag{4.8}$$

where the bounds are uniform in $h \leq h_0$; $\lambda \in \sum^c$.

LEMMA 4.2. *Let $\gamma + r < 1$. Then we have the following.*

(i) *For all* $\lambda \in \sum^c(A,a)$, *the following inequality holds uniformly in* λ *and* $h \le h_0$:

$$|\hat{A}^r[R(\lambda, A_{hB}) - R(\lambda, A_B)]|_{\mathcal{L}(H)} \le \frac{M}{|\lambda - a|^{1-r}}. \tag{4.9}$$

(ii) *For any* $\lambda_0 \in \sum^c(A,a)\,(\lambda_0$ *fixed), the following inequality holds uniformly in* $h \le h_0$:

$$|\hat{A}^r[R(\lambda_0, A_{hB}) - R(\lambda_0, A_B)]|_{\mathcal{L}(H)} \le Mh^{s(1-r-\gamma)}. \tag{4.10}$$

(iii) *The estimate in* (4.10) *can be extended to hold uniformly in* λ_0 *for all* λ_0 *such that*

$$\lambda_0 \in \textstyle\sum^c \cap \{\lambda_0;\ |\lambda_0| \le R_0\} \quad \textit{where } R_0 \textit{ is fixed.} \tag{4.11}$$

The proofs of Lemmas 4.1 and 4.2, being technical, are relegated to §5.

Let us introduce the operator $T_h(\lambda) : \mathcal{D}(C) \to H$ defined by

$$T_h(\lambda) \equiv R(\lambda, A_C)(A + BF_h\pi_h - \lambda I)[R(\lambda, A_{h,B}) - R(\lambda, A_B)]K_hC. \tag{4.12}$$

We prove the following lemma.

LEMMA 4.3. *Assume* $\gamma + r < 1$. *Then*

(i) $|T_h(\lambda)|_{\mathcal{L}(\mathcal{D}(\hat{A}^r))} \le M$,

(ii) $|(I - T_h(\lambda))^{-1}|_{\mathcal{L}(\mathcal{D}(\hat{A}^r))} \le M$, *where the constant* M *is uniform in* $h < h_0$ *and* $\lambda \in \sum^c$.

Proof. To prove the lemma it suffices to show that

$$|T_h(\lambda)|_{\mathcal{L}(\mathcal{D}(\hat{A}^r))} < \frac{1}{2} \quad \text{uniformly in } h < h_0 \text{ and } \lambda \in \textstyle\sum^c. \tag{4.13}$$

From part (i) of Lemma 4.2 we obtain, for $\lambda \in \sum^c(A,a)$,

$$|\hat{A}^r[R(\lambda, A_{hB}) - R(\lambda, A_B)]K_hC|_{\mathcal{L}(H)} \le \frac{M}{|\lambda - a|^{1-r}}|C|_{\mathcal{L}(\mathcal{D}(\hat{A}^r);H)}. \tag{4.14}$$

On the other hand,

$$R(\lambda, A_C)(A + BF_h\pi_h - \lambda I) = -I + R(\lambda, A_C)(BF_h\pi_h + K_hC). \tag{4.15}$$

From (4.6) in Lemma 4.1,

$$|\hat{A}^r R(\lambda, A_C)K_hC|_{\mathcal{L}(\mathcal{D}(\hat{A}^r);H)} \le M|C|_{\mathcal{L}(\mathcal{D}(\hat{A}^r);H)} \le M, \tag{4.16}$$

and by (4.7) together with Hypothesis 1a and Assumption 6,

$$|\hat{A}^r R(\lambda, A_C)\hat{A}^\gamma \hat{A}^{-\gamma} BF_h\pi_h| \le M. \tag{4.17}$$

Combining (4.14)–(4.17) with the definition of $T_h(\lambda)$ given in (4.12) yields

$$|T_h(\lambda)|_{\mathcal{L}(\mathcal{D}(\hat{A}^r))} \le \frac{M}{|\lambda - a|^{1-r}} \tag{4.18}$$

which, in particular, implies

$$|T_h(\lambda)|_{\mathcal{L}(\mathcal{D}(A^r))} < \frac{1}{2} \quad \text{for } \lambda \in \textstyle\sum^c(A,a) \text{ and } |\lambda| > R_0,$$

where R_0 is sufficiently large. Consider next $\lambda \in \sum^c \cap \{|\lambda| \leq R_0\}$. By repeating the same arguments as above, with the only difference that instead of result (i) of Lemma 4.2 we use result (iii), we obtain

$$|T_h(\lambda_0)|_{\mathcal{L}(\mathcal{D}(\hat{A}^r))} < Ch^{s(1-\gamma-r)} < \frac{1}{2} \tag{4.19}$$

for $h < h_0$ where $\lambda_0 \in \sum^c \cap \{|\lambda| \leq R_0\}$, which then leads to the desired conclusions of Lemma 4.3. □

Proof of Theorem 3.1. We use the following transformation introduced in [S.1]:

$$Z \equiv \begin{pmatrix} I & I \\ 0 & I \end{pmatrix}; \qquad Z^{-1} = \begin{pmatrix} I & -I \\ 0 & I \end{pmatrix}, \quad \text{where } I \text{ is an identity on the Hilbert space } H.$$

To prove Theorem 3.1 it is enough to show the estimate

$$|R(\lambda, \mathcal{A}_h)|_{\mathcal{L}(\mathcal{H})} \leq \frac{M}{|\lambda + \omega_0|}, \qquad \lambda \in \sum^c, \tag{4.20}$$

or equivalently,

$$|R(\lambda, \hat{\mathcal{A}}_h)|_{\mathcal{L}(\mathcal{H})} \leq \frac{M}{|\lambda + \omega_0|}, \quad \text{where } \hat{\mathcal{A}}_h \equiv Z^{-1}\mathcal{A}_h Z, \tag{4.21}$$

holds with some $\omega_0 > 0$. It is straightforward to verify that

$$\hat{\mathcal{A}}_h = \begin{pmatrix} A - K_hC, & A - A_h\pi_h + (I - \pi_h)BF_h\pi_h \\ K_hC, & A_h\pi_h + \pi_hBF_h\pi_h \end{pmatrix}.$$

We compute $R(\lambda, \hat{\mathcal{A}}_h)$. Let

$$(\mathcal{A}_h - \lambda I)^{-1}\begin{pmatrix} f \\ g \end{pmatrix} = \begin{pmatrix} x(\lambda) \\ w(\lambda) \end{pmatrix}, \quad \text{hence}$$

$$\begin{cases} (A - K_hC - \lambda I)x(\lambda) + (A - A_h\pi_h + (I - \pi_h)BF_h\pi_h)w(\lambda) = f, \\ K_hCx(\lambda) + (A_h\pi_h + \pi_hBF_h\pi_h - \lambda I)w(\lambda) = g. \end{cases} \tag{4.22}$$

The result of Proposition 4.1 is

$$\begin{aligned} &\text{(i)} \quad w(\lambda) = R(\lambda, A_{hB})[-g + K_hCx(\lambda)], \\ &\text{(ii)} \quad x(\lambda) = R(\lambda, A_C)[-f + (A - A_h\pi_h + (I - \pi_h)BF_h\pi_h)w(\lambda)]. \end{aligned} \tag{4.23}$$

We show that

$$R(\lambda, A_{hB}) - R(\lambda, A_B) = -R(\lambda, A_B)(A - A_h\pi_h + (I - \pi_h)BF_h\pi_h)R(\lambda, A_{hB}). \tag{4.24}$$

Indeed,

$$\begin{aligned} &R(\lambda, A_B)[A - A_h\pi_h + (I - \pi_h)BF_h\pi_h]R(\lambda, A_{hB}) \\ &\quad = R(\lambda, A_B)[A_B - \lambda I - A_{hB} + \lambda I]R(\lambda, A_{hB}) \\ &\quad = R(\lambda, A_B) - R(\lambda, A_{hB}) \end{aligned}$$

as desired for (4.24). Combining (4.23) with (4.24) we arrive at

$$x(\lambda) = R(\lambda, A_C)(A + BF_h\pi_h - \lambda I)[R(\lambda, A_{hB}) - R(\lambda, A_B)]K_hCx(\lambda),$$

$$- R(\lambda, A_C)f - R(\lambda, A_C)(A + BF_h\pi_h - \lambda I)[R(\lambda, A_{hB}) - R(\lambda, A_B)]g, \quad \text{or} \tag{4.25}$$

(4.26)

$$\begin{cases} x(\lambda) = -[I - T_h(\lambda)]^{-1}[R(\lambda, A_C)f \\ \qquad\qquad\qquad + R(\lambda, A_C)(A + BF_h\pi_h - \lambda I)[R(\lambda, A_{hB}) - R(\lambda, A_B)]g], \\ w(\lambda) = R(\lambda, A_{hB})[-g + K_hCx(\lambda)]. \end{cases}$$

Noting that

$$R(\lambda, A_C)(A + BF_h\pi_h - \lambda I) = -I + R(\lambda, A_C)(BF_h\pi_h + K_hC),$$

we obtain, by Lemma 4.2 and Lemma 4.1,

(4.27)

$$\begin{aligned} &|\hat{A}^r R(\lambda, A_C)(A + BF_h\pi_h - \lambda I)[R(\lambda, A_{hB}) - R(\lambda, A_B)]g|_H \\ &\quad \leq |\hat{A}^r[R(\lambda, A_{hB}) - R(\lambda, A_B)]g|_H \\ &\qquad + |\hat{A}^r R(\lambda, A_C)(BF_h\pi_h + K_hC)[R(\lambda, A_{hB}) - R(\lambda, A_B)]g|_H \\ &\quad \leq \{M + |\hat{A}^r R(\lambda, A_C)\hat{A}^\gamma \hat{A}^{-\gamma} BF_h\pi_h|_{\mathcal{L}(H)} + |\hat{A}^r R(\lambda, A_C)K_hC\hat{A}^{-r}|_{\mathcal{L}(H)}\}|g|_H \\ &\quad \leq M|g|_H. \end{aligned}$$

From (4.27), (4.26), and Lemma 4.3 we then infer that

$$|\hat{A}^r x(\lambda)|_H \leq M[|g|_H + |f|_H], \tag{4.28}$$

and by Proposition 4.1 with (4.26),

$$|w(\lambda)|_H \leq \frac{M}{|\lambda + w_0|}[|g|_H + |f|_H] \quad \text{for } \lambda \in \sum\nolimits^c. \tag{4.29}$$

Going back to (4.25) and recalling (4.15), we obtain

(4.30)

$$\begin{aligned} &|x(\lambda)|_H \\ &\quad \leq M[|R(\lambda, A_C)|_{\mathcal{L}(H)}|f|_H + |[I - R(\lambda, A_C)\cdot(BF_h\pi_h + K_hC)](R(\lambda, A_{hB}) \\ &\qquad - R(\lambda, A_B))[g - K_hCx(\lambda)]|_H] \\ &\quad \leq M\{|R(\lambda, A_C)|_{\mathcal{L}(H)}|f|_H + |R(\lambda, A_C)\hat{A}^\gamma|_{\mathcal{L}(H)}\cdot|\hat{A}^{-\gamma}BF_h\pi_h|_{\mathcal{L}(H)}(|R(\lambda, A_{hB})|_{\mathcal{L}(H)} \\ &\qquad + |R(\lambda, A_B)|)_{\mathcal{L}(H)}\cdot|g - K_hCx(\lambda)|_H \\ &\qquad + |R(\lambda, A_C)|_{\mathcal{L}(H)}|K_hC\hat{A}^{-r}|_{\mathcal{L}(H)}\cdot|\hat{A}^r(R(\lambda, A_{hB}) \\ &\qquad - R(\lambda, A_B))|_{\mathcal{L}(H)}|g - K_hCx(\lambda)|_H \\ &\qquad + |R(\lambda, A_{hB}) - R(\lambda, A_B)|_H|g - K_hCx(\lambda)|_H\} \\ &\quad \leq \frac{M}{|\lambda + w_0|}[|f|_H + |g|_H], \end{aligned}$$

where in the last inequality, we have used once more the result of Proposition 4.1, Lemma 4.2, Lemma 4.1, and (4.28).

Inequalities (4.29) and (4.30) yield the desired conclusion in (4.21) with $\omega_0 = w_0 > 0$. □

5. Proofs of Lemmas 4.1 and 4.2. We begin with a sequence of preliminary estimates.

PROPOSITION 5.1. *Let $T : H \to (\mathcal{D}(A^*))'$ be such that $\hat{A}^{-\gamma}T \in \mathcal{L}(H)$. Then for any $\bar{\gamma} > \gamma$ there exists a constant $M > 0$ such that*

$$(5.1) \qquad |\hat{A}^{1-\bar{\gamma}}(\lambda_0 I - A - T)^{-(1-\gamma)}|_{\mathcal{L}(H)} \leq M$$

for all $\lambda_0 \in \sum^c(A + T)$, where $\sum(A + T)$ is a closed triangular sector containing in its interior the spectrum of $A + T$.

Proof. By the assumption and analyticity of A, $A + T$ generates an analytic semigroup [K.1].

Step 1. For $\mu \in \rho(A + T) \cap \rho(A)$,

$$(5.2) \qquad (\mu I - A - T)^{-1} = (I - R(\mu, A)T)^{-1}R(\mu, A).$$

On the other hand, by the definition of fractional powers of the operators (see [P.1], [K.1]),

$$(5.3) \qquad (\lambda_0 I - A - T)^{-(1-\gamma)} = \frac{1}{2\pi i}\int_\Gamma z^{-(1-\gamma)}[(\lambda_0 - z)I - A - T]^{-1}\,dz,$$

where Γ denotes the triangular path that runs in $\rho(\lambda_0 I - A - T) \cap \rho(\lambda_0 I - A)$, avoiding the real negative axis and the origin. Hence

$$(5.4) \qquad \begin{aligned} &\hat{A}^{1-\bar{\gamma}}(\lambda_0 I - A - T)^{-(1-\gamma)} \\ &= \frac{1}{2\pi i}\hat{A}^{1-\bar{\gamma}}\int_\Gamma [I - R(\lambda_0 - z;\, A)T]^{-1}R(\lambda_0 - z, A)z^{-(1-\gamma)}\,dz \\ &= \frac{1}{2\pi i}\int_\Gamma \hat{A}^{1-\bar{\gamma}}[I - R(\lambda_0 - z, A)T]^{-1}\hat{A}^{-(1-\bar{\gamma})}\hat{A}^{1-\bar{\gamma}}R(\lambda_0 - zA)z^{-(1-\gamma)}\,dz. \end{aligned}$$

Step 2. We show that for $\mu \in \rho(A) \cap \rho(A + T)$ and for $\bar{\gamma} \geq \gamma$, the following bound holds:

$$(5.5) \qquad |\hat{A}^{1-\bar{\gamma}}[I - R(\mu, A)T]^{-1}\hat{A}^{-(1-\bar{\gamma})}|_{\mathcal{L}(H)} \leq M$$

uniformly in $\mu \in \mathcal{D}$, where the set $\mathcal{D}$ is any closed set contained in $\rho(A) \cap \rho(A + T)$.

Since

$$|R(\mu, A)T|_{\mathcal{L}(H)} \leq \frac{M}{|\mu - a|^{1-\gamma}}$$

for $|\mu|$ large enough, say $|\mu| > R$, we have

$$(5.6) \qquad |[I - R(\mu, A)T]^{-1}|_{\mathcal{L}(H)} \leq M_R.$$

The above estimate can easily be extended to hold for all $\mu \in \mathcal{D}$ (with the bound uniform in μ). Indeed, for $\mu \in \rho(A + T) \cap \rho(A)$, $I - R(\mu, A)T$ is injective. Thus, in order to show (5.6) it suffices to prove that the range of $I - R(\mu, A)T$ is all of H. But this can be accomplished by routine computations involving the resolvent equation. Thus for all $\mu \in \mathcal{D}$ we can solve

$$(5.7) \qquad \hat{A}^{1-\bar{\gamma}}[I - R(\mu, A)T]^{-1}\hat{A}^{-(1-\bar{\gamma})}x = y$$

with the estimate

$$(5.8) \qquad |\hat{A}^{-(1-\bar{\gamma})}y|_H \leq M|\hat{A}^{-(1-\bar{\gamma})}x|_H.$$

On the other hand, from (5.7),

$$x = y - \hat{A}^{(1-\bar{\gamma})} R(\mu, A) T \hat{A}^{-(1-\bar{\gamma})} y; \tag{5.9}$$

and by (5.8), the analyticity of A, and the assumption assumed on T,

$$\begin{aligned} |\hat{A}^{(1-\bar{\gamma})} R(\mu, A) T \hat{A}^{-(1-\bar{\gamma})} y|_H &\le M |\hat{A}^{(1-\bar{\gamma})} R(\mu, A) \hat{A}^{\bar{\gamma}} \hat{A}^{-\bar{\gamma}} T|_{\mathcal{L}(H)} |\hat{A}^{-(1-\bar{\gamma})} x|_H \\ &\le M |\hat{A}^{-(1-\bar{\gamma})} x|_H. \end{aligned} \tag{5.10}$$

Combining (5.9) and (5.10) yields the desired conclusion in (5.5).

Step 3. By combining (5.4) with (5.5) and noting that $\lambda_0 - z \in \mathcal{D}$ for $z \in \Gamma$ we obtain

$$\begin{aligned} |\hat{A}^{1-\bar{\gamma}} (\lambda_0 I - A - T)^{-(1-\gamma)}|_{\mathcal{L}(H)} &\le M \int_\Gamma |\hat{A}^{1-\bar{\gamma}} R(\lambda_0 - z, A)|_{\mathcal{L}(H)} z^{-(1-\gamma)}\, dz \\ &\le M \int_\Gamma \frac{dz}{|-z + \lambda_0 - a|^{\bar{\gamma}} |z|^{1-\gamma}} \le M. \qquad \square \end{aligned}$$

PROPOSITION 5.2. *We have that*

$$|\hat{A}^r R(\lambda, A_h) \pi_h|_{\mathcal{L}(H)} \le \frac{M}{|\lambda - a|^{1-r}}, \tag{5.11}$$

$$|\hat{A}^r R(\lambda, A_h) \pi_h B F_h \pi_h|_{\mathcal{L}(H)} \le M \quad \textit{for } \gamma + r < 1, \tag{5.12}$$

where the estimates are uniform for all $h \le h_0$ *and* $\lambda \in \sum^c(A, a)$.

Proof. Inequality (5.11) is a consequence of Assumptions 1 and 3, and (2.3), and it can be proved by routine arguments (see [L-T.1]).

To prove (5.12), we use duality

$$\begin{aligned} |B^* R(\lambda, A_h^*) \pi_h \hat{A}^{*r}|_{\mathcal{L}(H;U)} &\le |B^* [R(\lambda, A_h^*) \pi_h - \pi_h R(\lambda, A^*)] \hat{A}^{*r}|_{\mathcal{L}(H;U)} \\ &\quad + |B^* \pi_h R(\lambda, A^*) \hat{A}^{*r}|_{\mathcal{L}(H;U)}. \end{aligned} \tag{5.13}$$

From Assumption 5 and the analyticity of A^*,

$$|B^* \pi_h R(\lambda, A^*) \hat{A}^{*r}|_{\mathcal{L}(H;U)} \le C |R(\lambda, A^*) \hat{A}^{*r+\gamma}|_{\mathcal{L}(H)} \le \frac{M}{|\lambda - a|^{1-(\gamma+r)}} \le M. \tag{5.14}$$

From Assumption 3,

$$\begin{aligned} &|B^* [R(\lambda, A_h^*) \pi_h - \pi_h R(\lambda, A^*)] \hat{A}^{*r}|_{\mathcal{L}(H;U)} \\ &\quad \le M h^{-\gamma s} |\hat{A}^r [R(\lambda, A_h) \pi_h - R(\lambda, A) \pi_h]|_{\mathcal{L}(H)} \\ &\quad \le M h^{-\gamma s} |\hat{A}^r [R(\lambda, A_h) \pi_h - \pi_h R(\lambda, A) \pi_h]|_{\mathcal{L}(H)} \\ &\quad\quad + M h^{-\gamma s} |\hat{A}^r (I - \pi_h) R(\lambda, A) \pi_h|_{\mathcal{L}(H)}. \end{aligned} \tag{5.15}$$

As a consequence of Assumption 3, (2.3), and Assumption 1, we obtain

$$|\hat{A}^r [R(\lambda, A_h) \pi_h - \pi_h R(\lambda, A)]|_{\mathcal{L}(H)} \le M h^{s(1-r)}. \tag{5.16}$$

By (5.16), (2.6) applied with $Q = 1$ and (5.15),

$$\begin{aligned} &|B^* [R(\lambda, A_h^*) \pi_h - \pi_h R(\lambda, A^*)] \hat{A}^{*r}|_{\mathcal{L}(H,U)} \\ &\quad \le M h^{s(1-\gamma-r)} + C h^{s(1-\gamma-r)},|A R(\lambda, A)|_{\mathcal{L}(H)} \le M. \end{aligned} \tag{5.17}$$

Combining (5.13) with (5.14) and (5.17) and recalling the assumptions imposed on F_h leads to conclusion (5.12). □

PROPOSITION 5.3. *Let* $\gamma + r < 1$. *Then the following inequalities hold uniformly in* $\lambda \in \sum^c(A, a)$ *and* $h \leq h_0$:

(i) $|\hat{A}^r R(\lambda, A_B)|_{\mathcal{L}(H)} \leq M/|\lambda - a|^{1-r}$;

(ii) $|\hat{A}^r R(\lambda, A_{hB})|_{\mathcal{L}(H)} \leq M/|\lambda - a|^{1-r}$.

Proof. (i) Since, by virtue of Hypothesis 1a,

$$|\hat{A}^{-\gamma} B F_h \pi_h|_{\mathcal{L}(H)} \leq M \quad \text{uniformly in } h, \tag{5.18}$$

we can apply (5.5) in Proposition 5.1 with $T \equiv BF_h\pi_h$, $\bar{\gamma} = 1 - r \geq \gamma$. This yields

$$|\hat{A}^r [I - R(\lambda, A) B F_h \pi_h] \hat{A}^{-r}|_{\mathcal{L}(H)} \leq M \quad \text{uniformly in } \lambda \in \textstyle\sum^c(A, a). \tag{5.19}$$

On the other hand, by using the perturbation formula

$$\hat{A}^r R(\lambda, A_B) = \hat{A}^r [I - R(\lambda, A) B F_h \pi_h]^{-1} R(\lambda, A) \tag{5.20}$$

and (5.19) with (5.20), we obtain

$$|\hat{A}^r R(\lambda, A_B)|_{\mathcal{L}(H)} \leq C |\hat{A}^r R(\lambda, A)|_{\mathcal{L}(H)} \leq \frac{M}{|\lambda - a|^{1-r}}$$

desired for part (i).

(ii) We start with

$$\hat{A}^r R(\lambda, A_{hB}) = \hat{A}^r (I - R(\lambda A_h) \pi_h B F_h \pi_h)^{-1} R(\lambda, A_h). \tag*{5.21)}$$

From (2.5) for $|\lambda|$ large enough,

$$|R(\lambda, A_h) \pi_h B F_h \pi_h|_{\mathcal{L}(H)} \leq \frac{M}{|\lambda|^{1-\gamma}} < \frac{1}{2}.$$

Hence

$$|[I + R(\lambda, A_h) \pi_h B F_h \pi_h]^{-1}|_{\mathcal{L}(H)} \leq M. \tag{5.22}$$

By the uniform analyticity of A_h and the resolvent equation, the above estimate can be extended to hold for all $\lambda \in \sum^c(A, a)$. Recalling (5.12) and repeating the same arguments as in Step 2 of Proposition 5.1 (where we use $\bar{\gamma} \equiv 1 - r \geq \gamma$) yields

$$|\hat{A}^r [I - R(\lambda, A_h) \pi_h B F_h \pi_h)^{-1} \hat{A}^{-r}|_{\mathcal{L}(H)} \leq M \quad \text{uniformly in } \lambda \in \textstyle\sum^c(A, a). \tag{5.23}$$

Combining (5.21) and (5.23) with (5.11) gives

$$\begin{aligned} |\hat{A}^r R(\lambda, A_{hB})|_{\mathcal{L}(H)} &\leq M |\hat{A}^r (I - R(\lambda, A_h) B F_h)^{-1} \hat{A}^{-r}|_{\mathcal{L}(H)} |\hat{A}^r R(\lambda, A_h)|_{\mathcal{L}(H)} \\ &\leq \frac{M}{|\lambda - a|^{1-r}} \end{aligned}$$

as desired. □

Proof of Lemma 4.1.

Proof of (4.6). We first show that for $|\lambda_0| > R_0$ and R_0 being sufficiently large, we have

$$|A(A - K_h C - \lambda_0 I)^{-1}|_{\mathcal{L}(H)} \leq M. \tag{5.24}$$

Indeed, using the formula

$$A(A - K_hC - \lambda_0 I)^{-1} = -AR(\lambda_0, A)[I + K_hCR(\lambda_0, A)]^{-1}$$

and noting that for R_0 sufficiently large

$$|K_hCR(\lambda_0, A)| = \frac{M}{|\lambda_0|^{1-r}} < \frac{1}{2},$$

we obtain (5.24). The resolvent equation

(5.25)

$$A(A - K_hC)^{-1} = A(A - K_hC - \lambda_0 I)^{-1} - \lambda_0 A(A - K_hC - \lambda_0 I)^{-1}(A - K_hC)^{-1}$$

together with (5.24) and (4.3) gives

(5.26) $$|A(A - K_hC)^{-1}|_{\mathcal{L}(H)} < M \quad \text{uniformly in } h \le h_0.$$

Writing

$$|AR(\lambda, A_C)|_{\mathcal{L}(H)} \le |A(A - K_hC)^{-1}|_{\mathcal{L}(H)} |A_C R(\lambda, A_C)|_{\mathcal{L}(H)}$$

yields the result in (4.6).

Proof of (4.7). For any $\varepsilon > 0$,

(5.27)

$$\hat{A}^r R(\lambda, A_C)\hat{A}^\gamma = \hat{A}^r(-A + K_hC)^{-r-\varepsilon}(-A + K_hC)R(\lambda, A_C)(-A + K_hC)^{-(1-r-\varepsilon)}\hat{A}^\gamma.$$

By using (5.24) together with Lemma 7.3 in [K.2, p. 144], we obtain

(5.28) $$|\hat{A}^r(-A + K_hC)^{(-r-\varepsilon)}|_{\mathcal{L}(H)} \le M.$$

Uniform analyticity of A_C (see (4.3)) yields

(5.29) $$|(A - K_hC)R(\lambda, A_C)|_{\mathcal{L}(H)} \le M \quad \text{uniformly in } \textstyle\sum^c \text{ and } h \le h_0.$$

To estimate the last two terms in (5.27) we apply the result of Proposition 5.1 with $A = A^*$, $\lambda_0 = 0$, $T = -C^*K_h^*$, and $\gamma = r + \varepsilon$. This gives

(5.30) $$|\hat{A}^{*(1-\bar{r})}(-A^* + C^*K_h^*)^{-(1-r-\varepsilon)}|_{\mathcal{L}(H)} \le M$$

for all $\bar{r} > r + \varepsilon$. By duality,

(5.31) $$|(-A + K_hC)^{-(1-r-\varepsilon)}\hat{A}^{(1-\bar{r})}|_{\mathcal{L}(H)} \le M.$$

Since $\gamma + r < 1$, we take ε small so $\gamma + r + \varepsilon < 1$ and we replace $1 - \bar{r}$ by γ to obtain

(5.32) $$|(A - K_hC)^{-(1-r)}\hat{A}^\gamma|_{\mathcal{L}(H)} \le M.$$

Combining (5.27) with (5.28), (5.29), and (5.32) yields the desired result in (4.7).

Proof of 4.8. The proof is the same as that of (4.7) after noting that (4.8) is equivalent to

$$|\hat{A}^{*\gamma}(A^* + F_h^*B^* + \lambda I)^{-1}\hat{A}^{*r}|_{\mathcal{L}(H)} \le M.$$

Since $|F_h^* B^* \hat{A}^{*-\gamma}|_{\mathcal{L}(H)} \leq M$, it suffices to reverse the role of r and γ. □

Proof of Lemma 4.2. (i) Part (i) is a direct consequence of Proposition 5.3.

(ii) For $\lambda \in \sum^c(A, a)$,

$$\begin{aligned} & R(\lambda, A_B) - R(\lambda, A_{hB}) \\ & \quad = (I - R(\lambda, A)BF_h\pi_h)^{-1} \cdot [R(\lambda, A) - R(\lambda, A_h)\pi_h] \\ & \qquad + [(I - R(\lambda, A)BF_h\pi_h)^{-1} - (I - R(\lambda, A_h)\pi_h BF_h\pi_h)^{-1}]R(\lambda, A_h)\pi_h \\ & \quad \equiv I + II, \end{aligned} \tag{5.33}$$

$$|\hat{A}^r I|_{\mathcal{L}(H)} \leq |\hat{A}^r (I - R(\lambda, A)BF_h\pi_h)^{-1}\hat{A}^{-r}|_{\mathcal{L}(H)} \cdot |\hat{A}^r[R(\lambda, A) - R(\lambda, A_h)\pi_h]|_{\mathcal{L}(H)}$$

and by (5.23),

$$\leq M|\hat{A}^r[R(\lambda, A) - R(\lambda, A_h)\pi_h]|_{\mathcal{L}(H)}. \tag{5.34}$$

On the other hand, by Assumptions 3–5 and (2.3) we obtain

$$\begin{aligned} & |\hat{A}^r[R(\lambda, A) - R(\lambda, A_h)\pi_h]|_{\mathcal{L}(H)} \\ & \quad \leq |\hat{A}^r[R(\lambda, A_h)\pi_h - \pi_h R(\lambda, A)]|_{\mathcal{L}(H)} + |\hat{A}^r(I - \pi_h)R(\lambda, A)|_{\mathcal{L}(H)} \\ & \quad \leq Mh^{-sr}h^s + h^{s(1-r)}|AR(\lambda, A)|_{\mathcal{L}(H)} \leq Mh^{s(1-r)}. \end{aligned} \tag{5.35}$$

Equation (5.34) combined with (5.35) gives

$$|\hat{A}^r I|_{\mathcal{L}(H)} \leq Mh^{s(1-r)}. \tag{5.36}$$

As for term II we have

$$\begin{aligned} |\hat{A}^r \mathrm{II}|_{\mathcal{L}(H)} \leq & |\hat{A}^r(I - R(\lambda, A)BF_h\pi_h)^{-1}[R(\lambda, A) - R(\lambda, A_h)\pi_h] \\ & \cdot BF_h\pi_h(I - R(\lambda, A_h)\pi_h BF_h\pi_h)^{-1}R(\lambda, A_h)\pi_h|_H \end{aligned}$$

and by (5.23),

$$\leq M|\hat{A}^r(R(\lambda, A) - R(\lambda, A_h)\pi_h)BF_h\pi_h|_{\mathcal{L}(H)}|R(\lambda, A_{hB})|_{\mathcal{L}(H)}. \tag{5.37}$$

We prove that for $\lambda_0 \in \sum^c(A, a)$,

$$|\hat{A}^r[R(\lambda_0, A) - R(\lambda_0, A_h)\pi_h]BF_h\pi_h|_{\mathcal{L}(H)} \leq Mh^{s(1-r-\gamma)}. \tag{5.38}$$

Indeed,

$$\begin{aligned} |\hat{A}^r[R(\lambda_0, A) - R(\lambda_0, A_h)\pi_h]BF_h\pi_h|_{\mathcal{L}(H)} \leq & |\hat{A}^r[\pi_h R(\lambda_0, A) - R(\lambda_0, A_h)\pi_h]BF_h\pi_h|_{\mathcal{L}(H)} \\ & + |\hat{A}^r(\pi_h - I)R(\lambda_0, A)BF_h\pi_h|_{\mathcal{L}(H)} \end{aligned}$$

and by (ii) of Assumption 3 and (2.6) applied with $Q = 1 - \gamma > r$ and (2.4),

$$\begin{aligned} & \leq Mh^{-sr}|B^*(R(\lambda_0, A^*) - R(\lambda_0, A_h^*))|_{\mathcal{L}(H)} + Mh^{s(1-\gamma-r)}|\hat{A}^{1-\gamma}R(\lambda_0, A)BF_h\pi_h|_{\mathcal{L}(H)} \\ & \leq Mh^{-sr}h^{s(1-\gamma)} \end{aligned}$$

as desired for (5.38).

Now we are in a position to complete the proof of part (ii) of Lemma 4.2. Indeed, from (5.37), (5.38), and the uniform analyticity of $R(\lambda, A_{hB})$ (Proposition 4.1) we obtain

$$|\hat{A}^r \Pi|_{\mathcal{L}(H)} \le M h^{s(1-r-\gamma)},$$

which, combined with (5.36) and (5.37), leads to result (ii) of Lemma 4.2.

(iii) To prove part (iii) we use the resolvent equation together with the compactness of the set in (4.11). Indeed, let λ_0 be such that (4.10) holds. Then for any $\lambda \in \sum^c$ and $\lambda_0 \in \sum^c(A, a)$ we have

$$\begin{aligned}
&|\hat{A}^r[R(\lambda, A_{hB}) - R(\lambda, A_B)]|_{\mathcal{L}(H)} \\
&\quad \le |\hat{A}^r R(\lambda_0, A_{hB}) - R(\lambda_0, A_B)|_{\mathcal{L}(H)} \\
&\qquad + |\lambda - \lambda_0||\hat{A}^r R(\lambda, A_B)|_{\mathcal{L}(H)}|R(\lambda_0, A_{hB}) - R(\lambda_0, A_B)|_{\mathcal{L}(H)} \\
&\qquad + |\lambda - \lambda_0||\hat{A}^r[R(\lambda, A_{hB}) - R(\lambda, A_B)]|_{\mathcal{L}(H)}|(R(\lambda_0, A_{hB})|_{\mathcal{L}(H)}
\end{aligned}$$

and by (4.8), (4.1), and (4.10),

$$(5.39) \quad \le M_0 h^{s(1-r-\gamma)}[1 + |\lambda - \lambda_0|] + M_1|\lambda - \lambda_0||\hat{A}^r[R(\lambda, A_{hB}) - R(\lambda, A_B)]|_{\mathcal{L}(H)},$$

where the constant $M_1 \equiv |R(\lambda_0, A_{hB})|_{\mathcal{L}(H)}$ is uniform in λ_0 (and in λ). Taking λ such that $|\lambda - \lambda_0| \le 1/2M_1$ we obtain $|\hat{A}^r[R(\lambda, A_{hB}) - R(\lambda, A_B)]|_{\mathcal{L}(H)} \le M h^{s(1-r-\gamma)}$.

Repeating the same argument finitely many times leads to the desired result of part (iii). □

6. Examples. We provide several examples illustrating the theory presented. All the examples presented here refer to the situation when $\gamma + r > \frac{1}{2}$. Moreover, Example 6.3 deals with the case when the resolvent operator is *not compact*.

Let Ω be an open bounded domain in R^n with a boundary Γ. We assume that Ω is either smooth or convex.

Example 6.1. Heat equation with Dirichlet boundary control. In Ω, we consider the Dirichlet mixed problem for the heat equation in the unknown $x(t, \xi)$,

$$(6.1) \qquad \begin{cases} x_t = (\Delta + c^2)x & \text{in } (0, \infty) \times \Omega \equiv Q, \\ x(0, \cdot) = x_0 & \text{in } \Omega, \\ x|_{\Sigma} = u & \text{in } (0, \infty) \times \Gamma \equiv \sum, \end{cases}$$

with a boundary control $u \in L_2(\sum)$ and the initial data $x_0 \in L_2(\Omega)$. The solution $x(t)$ is "observed" via a finite-dimensional observation operator given by

$$(6.2) \qquad y(t, \xi) = \int_{\Omega} x(s) w(s) ds\, g(\xi), \qquad \xi \in \Gamma,$$

where $g \in L_2(\Gamma)$ and $w \in H^{-\alpha}(\Omega)$; $0 \le \alpha < \frac{1}{2}$. Here w satisfies

$$(6.3) \qquad \int_{\Omega} w\phi_j \ne 0,$$

where ϕ_j are the eigenvectors corresponding to unstable eigenvalues of $(\Delta + c^2)$, λ_j; $j = 1 \cdots N$, which (without loss of generality) are assumed to have simple multiplicity. To put problem (6.1), (6.2) into the abstract setting of the preceding sections, we introduce the following operators and spaces:

$$(6.4) \qquad Ah \equiv \Delta h + c^2 h, \qquad \mathcal{D}(A) = H^2(\Omega) \cap H_0^1(\Omega);$$

$$H = L_2(\Omega), \quad U = L_2(\Gamma), \quad Z = L_2(\Gamma); \tag{6.5}$$

$$Bu = -A\,Du; \tag{6.6}$$

where D (Dirichlet map) is defined by $h = Dg$ if and only if $(\Delta + c^2)h = 0$ in Ω; $h|_\Gamma = g$. By elliptic regularity and the identification of fractional powers of elliptic operators (see [F.1], [G.3]) we obtain

$$D : \text{continuous } L_2(\Gamma) \to H^{1/2}(\Omega) \subset \mathcal{D}(\hat{A}^{1/4-\varepsilon}); \qquad \varepsilon > 0. \tag{6.7}$$

From (6.7) and (6.6) it follows that Hypothesis 1a is satisfied with $\gamma = \frac{3}{4} + \varepsilon$, where ε is arbitrarily small,

$$\begin{aligned} Cx &\equiv \int_\Omega x(s)w(s)ds\, g(\xi), \\ C &\in \mathcal{L}(H^\alpha(\Omega), L_2(\Gamma)). \end{aligned} \tag{6.8}$$

Since $H^\alpha(\Omega) \subset \mathcal{D}(\hat{A}^{\alpha/2})$ (see [F.1] and [G.3]), for $\alpha < \frac{1}{2}$, Hypothesis 1b holds with $r = \frac{1}{4} - \rho$, where ρ is any positive constant. Hence $r + \gamma < 1$. To verify Hypothesis 2 we recall some stabilizability results proved in [T.2] for the heat equation with boundary controls. In fact, in [T.2] it was shown that the pair (A, B) (A given by (6.4) and B given by (6.6)) is stabilizable with boundary feedback $F \in \mathcal{L}(L_2(\Omega);\ L_2(\Gamma))$ given by

$$(Fx)(\xi) = \int_\Omega xz\, d\Omega\, g_1(\xi), \qquad \xi \in \Gamma, \tag{6.9}$$

where $z \in L_2(\Gamma)$; $g_1 \in L_2(\Gamma)$ and z satisfies condition (6.3) (with w replaced by z). Hence there exists $w_F > 0$ such that

$$|e^{(A+BF)t}|_{\mathcal{L}(L_2(\Omega))} \leq Ce^{-w_F t}. \tag{6.10}$$

As to the detectability condition, note that $C^*v(\xi) = \int_\Gamma vg\, d\Gamma\, w(\xi)$, $\xi \in \Omega$. Thus selecting the operator $K \in \mathcal{L}(L_2(\Gamma);\ L_2(\Omega))$ as $(Ku)(\xi) = \int_\Gamma u \cdot g\, d\Gamma\, z(\xi)$; $\xi \in \Omega$ for a suitable vector $z \in L_2(\Omega)$, we obtain

$$(C^*K^*x)(\xi) = |g|^2_{L_2(\Omega)} \int_\Omega xz\, d\Omega\, w(\xi). \tag{6.11}$$

Now the theory of [T.2] applies again to assert that under condition (6.3) there exists a vector $z \in L_2(\Omega)$ such that

$$|e^{(A^*-C^*K^*)t}|_{\mathcal{L}(L_2(\Omega))} \leq Ce^{-w_K t} \tag{6.12}$$

for some $w_K > 0$. Taking $w_1 = \min(w_K, w_F)$ yields the desired conclusion in Hypothesis 2. Thus we have verified all the continuous hypothesis. As to the approximation framework, we start by introducing the following spaces and operators:

$$V_h \subset H_0^1(\Omega) \tag{6.13}$$

a space of splines (linear, cubic, etc.) that comply with the usual approximation properties

$$|\pi_h y - y|_{H^l(\Omega)} \leq Ch^{s-l}|y|_{H^s(\Omega)}, \quad s \leq 2, \quad s - l \geq 0, \quad 0 \leq l \leq 1; \tag{6.14}$$

$$|y_h|_{H^\alpha(\Omega)} \leq Ch^{-\alpha}|y_h|_{L_2(\Omega)}, \qquad 0 \leq \alpha < 1; \tag{6.15}$$

$$(6.16) \qquad \text{(i)}\ |D^l(y-\pi_h y)|_{L_2(\Gamma)} \le Ch^{s-l-1/2}|y|_{H^s(\Omega)}, \quad \frac{3}{2} < s \le 2, \quad l=0,\,1;$$
$$\text{(ii)}\ |D^l y_h|_{L_2(\Gamma)} \le Ch^{-l-1/2}|y_h|_{L_2(\Omega)}, \qquad l=0,\,1;$$

where D^l stands for the differential operator of order l. Standard formulation of approximation properties (6.14), (6.16) (see [T.1]) involves an interpolation operator rather than an orthogonal projection. However, since inverse approximation properties (6.15), (6.16(ii)) are assumed (always satisfied on a quasi-uniform mesh), we can easily show that these properties hold with the orthogonal projection operator as well. Also, in the case of property (6.16(i)), the usual formulation requires that $s \ge 2$. However, it was pointed out by Peterson [P.2] that it suffices to assume $s > \frac{3}{2}$.

(6.17) $\qquad A_h : V_h \to V_h$ is defined as the usual Galerkin approximation,

$$(A_h, x_h, y_h)_\Omega \equiv \int_\Omega A_h x_h y_h \, d\Omega \equiv -\int_\Omega [\nabla x_h \nabla y_h - c^2 x_h y_h]\, d\Omega \quad \text{for all } x_h, y_h \in V_h.$$

It is well known (see [T.1], [B-S-T-W], and [L.1]) that the condition of uniform analyticity, i.e., Assumption 1, is satisfied. Also, classical results on approximation of elliptic problems (see [T.1]) imply that Assumption 2 holds with $s = 2$. Since

$$(6.18) \qquad B^* x = -\frac{\partial}{\partial \nu} x|_\Gamma,$$

Assumptions 3(i) and 4(i) are direct consequences of (6.16) applied with $l = 1$. Assumption 5(i) follows at once from the trace theory. Indeed by (6.16) and (6.18),

$$|B^*\pi_h x|_{L_2(\Gamma)} = \left|\frac{\partial}{\partial\nu}\pi_h x\right|_{L_2(\Gamma)} \le \left|\frac{\partial}{\partial\nu}(\pi_h - I)x\right|_{L_2(\Gamma)} + \left|\frac{\partial}{\partial\nu}x\right|_{L_2(\Gamma)}$$
$$\le ch^\varepsilon |y|_{H^{3/2+\varepsilon}(\Omega)} + C|y|_{H^{3/2+\varepsilon}(\Omega)} \le C|y|_{\mathcal{D}(\hat{A}^{3/4+\varepsilon})}.$$

As for Assumptions 3(ii), 4(ii), and 5(ii), it is enough to note that

$$|\hat{A}^r x|_{L_2(\Omega)} \simeq |x|_{H^{1/2-2\rho}(\Omega)}, \qquad \rho > 0$$

and validity of these assumptions follows directly from (6.14) and (6.15). Finally, to comply with Assumptions 6 and 7, since $B^*R(\lambda_0, A)$ and $CR(\lambda_0, A)$ are compact, it suffices to take

$$F_h \equiv F\pi_h \quad \text{and} \quad K_h \equiv \pi_h K.$$

We conclude that all the assumptions of Theorems 1.1 and 3.1 are satisfied.

Remark 6.1. Note that actual design of a finite-dimensional compensator for system 6.1 *does not* require any knowledge of the eigenfunctions/eigenvalues of A. Indeed, we can construct stabilizing feedbacks F_h and K_h from the appropriate Riccati equations (3.6) and (3.11) that involve only A_h, B_h, and C_h.

Example 6.2. Heat equation with Neumann boundary control and boundary observation. In Ω we consider

$$(6.19) \qquad \begin{cases} x_t = (\Delta + c^2)x & \text{in } Q, \\ x(0) = x_0 & \text{in } \Omega, \\ \left.\dfrac{\partial x}{\partial \nu}\right|_\Gamma = u & \text{in } \Sigma. \end{cases}$$

We observe on the boundary

$$y = x|_\Gamma. \tag{6.20}$$

To put problem (6.19), (6.20) into an abstract framework we set

$$Ah \equiv \Delta h + c^2 h, \qquad \mathcal{D}(A) = \left\{ h \in H^2(\Omega);\ \frac{\partial}{\partial\nu} h|_\Gamma = 0 \right\}; \tag{6.21}$$

$$H = L_2(\Omega), \quad U = L_2(\Gamma), \quad Z = L_2(\Gamma); \tag{6.22}$$

$$Bu = -ANu; \tag{6.23}$$

where N (Neumann map) is defined by

$$h = Ng \quad \text{iff}\, (\Delta + c^2)h = 0 \quad \text{in}\, \Omega, \qquad \frac{\partial}{\partial\nu} h|_\Gamma = g.$$

By the elliptic regularity and [F.1], [G.3],

$$N : \text{continuous}\, L_2(\Gamma) \to H^{3/2-\varepsilon}(\Omega) \subset \mathcal{D}(\hat{A}^{3/4-\varepsilon}), \tag{6.24}$$

$$Cx \equiv x|_\Gamma. \tag{6.25}$$

From (6.23) and (6.24) it follows that Hypothesis 1a is satisfied with $\gamma = \frac{1}{4} + \varepsilon$. Equation (6.25) together with trace theory and the inclusion $\mathcal{D}(\hat{A}^{1/4+\rho}) \subset H^{1/2+2\rho}(\Omega)$ (see [F.1], [G.3]) imply that Hypothesis 1b holds with $r = \frac{1}{4} + \rho$, where ρ is arbitrarily small. Hence $\gamma + r < 1$, but $\gamma + r > \frac{1}{2}$. As to the stabilizability condition (Hypothesis 2) we recall that in [T.2] it was shown that the same feedback F as in (6.9) (with appropriate choices of vectors g_1 and z) uniformly stabilizes A, i.e., there exist constants C and w_F such that

$$|e^{(A+BF)t}|_{\mathcal{L}(L_2(\Omega))} \le Ce^{-w_F t}, \qquad w_F > 0. \tag{6.26}$$

Detectability condition in Hypothesis 2 amounts to the same thing, since

$$C^* u = ANu \quad \text{and}$$
$$(A^* - C^*K^*)x = x_t \quad \text{is equivalent to}\, x_t = (\Delta + c^2)x; \quad \frac{\partial}{\partial\nu} x = -K^* x.$$

Thus, it is enough to select $K^* = F$ to obtain

$$|e^{(A^* - C^*K^*)t}|_{\mathcal{L}(L_2(\Omega))} \le Ce^{-w_F t} \tag{6.27}$$

which, in turn, implies Hypothesis 2. Approximation framework is very similar to the Dirichlet case considered in Example 6.1. Indeed, the space $V_h \subset H^1(\Omega)$ is defined as a space of splines complying with properties (6.14)–(6.16). The approximating generator $A_h : V_h \to V_h$ is defined by the same formula (6.17), and Assumptions 1 and 2 hold with $s = 2$. Since

$$B^* x = x|_\Gamma, \tag{6.28}$$

Assumptions 3(i) and 4(i) are direct consequences of (6.16) applied with $l = 0$. As for Assumption 5(i),

$$|B^* \pi_h x|_{L_2(\Gamma)} \le |\pi_h x|_{L_2(\Gamma)} \le C|\pi_h x|_{H^{1/2+2\varepsilon}(\Omega)} \le C|x|_{H^{1/2+2\varepsilon}(\Omega)} \le C|x|_{\mathcal{D}(\hat{A}^{1/4+\varepsilon})},$$

where we have used (6.14) and trace theory. Since

$$|\hat{A}^r x|_{L_2(\Omega)} \simeq |x|_{H^{2r}(\Omega)}$$

(see [F.1], [G.3]), the validity of Assumption 3(ii), 4(ii), and 5(ii) follows from (6.14) and (6.15). Assumptions 6 and 7 hold (in view of compactness of $R(\lambda, A)$) with F_h and K_h taken as the projections of F and K, respectively, i.e., $F_h \equiv F\pi_h$, $K_h \equiv \pi_h K$.

We conclude that all the hypotheses of Theorems 1.1 and 3.1 are satisfied.

Example 6.3. Structurally damped plate equation with point control and boundary observation. Consider the following model of a plate equation in the deflection $w(t,\xi)$:

$$(6.29)\qquad \begin{cases} w_{tt} + \Delta^2 w + \Delta^2 w_t = \sum_{i=1}^{3} \delta(\xi - \xi^i) u_i(t) & \text{in } Q, \\ w(0,\cdot) = w_o;\ w_t(0,\cdot) = w_1 & \text{in } \Omega, \\ \Delta w|_\Sigma + (1-\mu)B_1 w = 0 & \text{in } \sum, \\ \dfrac{\partial}{\partial \nu}\Delta w|_\Sigma + (1-\mu)B_2 w \equiv 0 & \text{on } \sum, \end{cases}$$

with load control concentrated at the interior points ξ^i of an open bounded domain Ω of R^2. Here $0 < \mu < \frac{1}{2}$ is the Poisson modulus and the boundary operators B_1 and B_2 are

$$B_1 w \equiv 2\nu_1\nu_2 w_{xy} - \nu_1^2 w_{yy} - \nu_2^2 u_{xx},$$

$$B_2 w = \frac{\partial}{\partial \tau}[(\nu_1^2 - \nu_2^2) w_{xy} + \nu_1\nu_2(w_{yy} - w_{xx})],$$

where $\partial/\partial\tau$ stands for the tangential derivative. The observation operator is given by

$$(6.30)\qquad y = \frac{\partial}{\partial \nu} w_t|_\Sigma.$$

To put problem (6.29), (6.30) into an abstract setting we introduce

$$(6.31)\qquad \begin{aligned} \mathcal{A}h &= \Delta^2 h, \\ \mathcal{D}(\mathcal{A}) &= \left\{ h \in H^4(\Omega); \Delta h + (1-\mu)B_1 h = 0; \frac{\partial}{\partial\nu}\Delta h + (1-\mu)B_2 h = 0 \text{ on } \Gamma \right\}; \end{aligned}$$

$$(6.32)\qquad H = \mathcal{D}(\mathcal{A}^{1/2}) \times L_2(\Omega) = H^2(\Omega) \times L_2(\Omega), \quad U = R^3, \quad Z = L_2(\Gamma);$$

$$(6.33)\qquad A = \begin{bmatrix} 0 & I \\ -\mathcal{A} & -\mathcal{A} \end{bmatrix};$$

$$(6.34)\qquad Bu = \begin{bmatrix} 0 \\ \sum_{i=1}^{3} \delta(\xi - \xi^i) u_i \end{bmatrix};$$

$$(6.35)\qquad Cx = C\begin{pmatrix} x_1 \\ x_2 \end{pmatrix} = \frac{\partial}{\partial\nu} x_2|_\Gamma.$$

It is known (see [L-T.1]) that A generates an analytic semigroup on H and, moreover, computations in [L-T.1, p. 536] (see also [Ch-T.2]) show that Hypothesis 1a is satisfied with $\gamma = \frac{1}{4} + \varepsilon$. As to Hypothesis 1b, we note that with $x = (x_1, x_2) \subset H$,

$$\hat{A}^{-1/2}x = \frac{\partial}{\partial\nu}[-\mathcal{A}^{1/4}[2I + \mathcal{A}^{1/2}]^{-1/2}x_1 + \mathcal{A}^{-1/4}[2I + \mathcal{A}^{1/2}]^{-1/2}x_2],$$

and by trace theory and the equivalence $\mathcal{D}(\mathcal{A}^Q) = H^{4Q}$, $0 \leq Q < \frac{1}{2}$,

$$|C\hat{A}^{-1/2}x|_Z \leq M|x|_H. \tag{6.36}$$

Hence, the value of r in Hypothesis 1b is equal to $\frac{1}{2}$ and $\gamma + r = \frac{1}{4} + \varepsilon + \frac{1}{2} < 1$. As for the stabilizability condition (Hypothesis 2), note that $\lambda = 0$ is the only unstable eigenvalue of $\mathcal{A}$ (hence of A) with the multiplicity equal to three. In fact, functions 1, ξ_1, ξ_2 are three linearly independent eigenfunctions (corresponding to the zero eigenvalue of $\mathcal{A}$). Thus, the results of [T.2] apply, provided that the points ξ^i, $i = 1 - 3$ satisfy the following rank condition:

$$\det \begin{vmatrix} 1 & \xi_1^1 & \xi_2^1 \\ 1 & \xi_1^2 & \xi_2^2 \\ 1 & \xi_2^3 & \xi_2^3 \end{vmatrix} \neq 0. \tag{6.37}$$

If (6.37) holds, then the feedback operator $F : H \to R^3$ given by

$$Fx = \int_\Omega x_1 \vec{z}\, d\Omega \quad \text{with } \vec{z} \in (L_2(\Omega))^3, \tag{6.38}$$

suitably selected vector, uniformly stabilizes the dynamics in (6.29) with $u = Fx$. This is to say that

$$|e^{(A+BF)t}|_{\mathcal{L}(H)} \leq Ce^{-w_F t}; \qquad w_F > 0.$$

To establish the detectability condition (Hypothesis 2), it suffices to note that the problem of finding $K \in \mathcal{L}(Z;\, H)$ such that $|e^{(A-KC)t}|_{\mathcal{L}(H)} \leq Ce^{-w_K t}$, $w_K > 0$ is equivalent, in our case, to finding $K^* \in \mathcal{L}(H;\, L_2(\Gamma))$ such that the system

$$\begin{cases} w_{tt} + \Delta^2 w + \Delta^2 w_t = 0; \\ w(0) = w_0, \qquad w_t(0) = w_1; \\ \Delta w + (1-\mu)B_1 w = K^*(w, w_t) \quad \text{on } \sum; \\ \dfrac{\partial}{\partial\nu}\Delta w + (1-\mu)B_2 w = 0 \quad \text{on } \sum \end{cases} \tag{6.39}$$

is exponentially stable on $\mathcal{D}(\mathcal{A}^{1/2}) \times L_2(\Omega)$. Problem (6.39) is a classical damped plate problem with boundary feedback and with one unstable pole ($\lambda = 0$). Thus the results of [T.2] apply again. Indeed, we can easily show that the feedback .

$$K^*(w) = \sum_{i=1}^{3} \int_\Omega w z_i \, dz\, g_i,$$

where $z_i \in L_2(\Omega)$ and $g_i \in L_2(\Gamma)$ are suitably selected (to guarantee the appropriate rank condition to be satisfied) exponentially stabilizes (6.39).

For the approximation part we introduce the following spaces and operators. $V_h \equiv \mathcal{V}_h \times \mathcal{V}_h$, where $\mathcal{V}_h \subset H^2(\Omega)$ is a space of splines (of order r_0) complying with the following properties:

$$|Q_h x - x|_{H^l(\Omega)} \leq Ch^{s-l}|x|_{H^s(\Omega)}, \quad 0 \leq l \leq 2, \quad l \leq s \leq r_0; \tag{6.40}$$

$$|x_h|_{H^\alpha(\Omega)} \leq Ch^{-s}|x_h|_{H^{\alpha-s}(\Omega)}, \qquad 0 \leq \alpha < 2; \tag{6.41}$$

where Q_h is the orthogonal projection of $L_2(\Omega)$ onto $\mathcal{V}_h$.

$$\begin{aligned} &\mathcal{A}_h : \mathcal{V}_h \to \mathcal{V}_h \quad \text{is given by} \\ &\mathcal{A}_h = Q_h \mathcal{A} Q_h, \quad \text{i.e., } (\mathcal{A}_h x_h, y_h)_{L_2(\Omega)} = (\Delta x_h, \Delta y_h)_{L_2(\Omega)} = (\mathcal{A} x_h, y_h)_{L_2(\Omega)}, \\ &A_h : V_h \to V_h \quad \text{is defined as} \end{aligned} \tag{6.42}$$

$$A_h = \begin{bmatrix} 0 & Q_h \\ -\mathcal{A}_h & -\mathcal{A}_h \end{bmatrix}, \tag{6.43}$$

$$\pi_h \equiv Q_h \times Q_h, \tag{6.44}$$

$$F_h \equiv F\pi_h, \qquad K_h \equiv \pi_h K. \tag{6.45}$$

Validity of the uniform analyticity hypothesis (Assumption 1) follows by applying verbatim the argument of [Ch-T.1] of the continuous case to the finite-dimensional operator A_h (note that in this example the bilinear form associated with A is *not* coercive). Assumption 2 with $s = 2$ is a consequence of

$$\|(\pi_h A^{-1} - A_h^{-1}\pi_h)x\|_H = \|(Q_h A^{-1} - \mathcal{A}_h^{-1} Q_h)x_2\|_{H^2(\Omega)} \leq Ch^2\|x_2\|_{L_2(\Omega)} \leq Ch^2\|x\|_H,$$

where we have used standard approximation properties of the biharmonic operator. To verify part (i) of Assumptions 3–5, we note first that in our case,

$$B^*x = [x_2(\xi^1), x_2(\xi^2);\ x_2(\xi^3)]. \tag{6.46}$$

Hence, by Sobolev imbeddings and (6.41),

$$|B^*x_h|_U \leq \sup_{i=1-3} |x_{2h}(\xi^i)| \leq C|x_{2h}|_{H^{1+\varepsilon}(\Omega)} \leq Ch^{-1-\varepsilon}|x_{2h}|_{L_2(\Omega)} \leq Ch^{-\gamma \cdot s}|x_h|_H$$

as $\gamma s = \frac{1}{2} + 2\varepsilon$, where ε can be taken arbitrarily small. Assumptions 4(i) and 5(i) are verified in a similar manner (see [L-T.1, p. 537]). Parts (ii) of Assumptions 3–5 follow in a direct way from the trace theory combined with approximation properties (6.40) and (6.41). Details, being straightforward, are omitted.

Finally, Assumption 6 is satisfied by the virtue of the compactness of $B^*R(\lambda_0, A^*)$ (note that $R(\lambda_0, A^*)$ is *not* compact). Indeed, from (6.46),

$$|B^*R(\lambda_0, A^*)x|_U \leq |(R(\lambda_0, A^*)x)_2|_{H^{1+\varepsilon}(\Omega)}. \tag{6.47}$$

Inequality (6.42) combined with the fact that $x \to (R(\lambda_0, A^*x))_2$ is bounded from $H \to H^2(\Omega)$, hence compact $H \to H^{1+\varepsilon}(\Omega)$; $\varepsilon < 1$ yields the desired conclusion. Similarly, validity of Assumption 7 follows from (6.45) and the compactness of $CR(\lambda_0, A)$. Indeed, note that $CR(\lambda_0, A) : H \to H^{1/2}(\Gamma)$ is bounded, hence compact $H \to L_2(\Gamma)$.

We conclude that all the hypotheses of Theorems 1.1 and 3.1 are satisfied.

WEIGHTED ESTIMATION AND TRACKING FOR ARMAX MODELS [*]

B. BERCU[†]

Abstract. For complex multivariate ARMAX models, the author studies the weighted least squares algorithm which offers, by the choice of suitable weightings, the advantages of both the extended least squares and the stochastic gradient algorithms. Concerning adaptive tracking problems, the strong consistency of the estimator and control optimality are both ensured. Almost sure rates of convergence are also provided.

Résumé. Pour les modèles ARMAX vectoriels complexes, on étudie l'algorithme des moindres carrés pondérés qui conjugue, par le choix de pondérations convenables, à la fois les avantages des algorithmes des moindres carrés généralisés et du gradient. Concernant les problèmes de poursuite adaptative, on assure la consistance de l'estimateur et l'optimalité du contrôle. On précise également les vitesses de convergence presque sûre.

Key words. linear systems, estimation, strong consistency, adaptive tracking

1. Introduction. In the study of recursive identification and adaptive tracking for ARMAX linear systems, the major goal is to find a stochastic algorithm that ensures both strong consistency of the estimator and control optimality. On one hand, if we focus our attention on the strong consistency, we choose the extended least squares (ELS) algorithm [15], [19], [22], [23], [24]. On the other hand, if we are interested in adaptive tracking, we should use the stochastic gradient (SG) algorithm [8], [18]. Therefore, a natural question is: Can we find a stochastic algorithm that combines both advantages of the ELS for strong consistency and of the SG for adaptive tracking? A positive answer was recently given by Bercu and Duflo [4] when they proposed a new weighted least squares (WLS) algorithm. In this paper we complete their work, giving a solution to the twenty-year-old adaptive tracking problem proposed by Aström and Wittenmark [1] for ARMAX models.

The paper is organized as follows. In §2, we describe the WLS algorithm. The main difference from the ELS algorithm is the introduction of a random weighting sequence $a = (a_n)$. Section 3 is devoted to the crucial choice of $a = (a_n)$. The main results of the paper are given in §4. We can see that the WLS algorithm equals the performance of the ELS for the strong consistency and matches the best result of the SG for the adaptive tracking. More precisely, the relation (24) is similar to the one obtained by Lai and Wei [24], [25] or Chen and Guo [12] for the ELS estimator. Moreover, concerning the prediction errors sequence, the relation (26) is exactly the same as the one proved by Goodwin, Ramadge, and Caines [18] for the SG algorithm. Finally, in §§5 and 6, we solve, in a simple way, the adaptive tracking problem. We prove both strong consistency of the WLS estimator and control optimality. We also provide almost sure rates of convergence. Section 7 is devoted to a survey on earlier related works on adaptive tracking. Comparing our work with previous similar results, we show how the WLS algorithm is well suited for adaptive tracking problems. A short conclusion is given in §8. All technical proofs are collected in the Appendices.

Notations. In the following sections, for any matrix A, ${}^tA$ denotes the transpose of A, ${}^*A$ represents the Hermitian adjoint of A and we set $\|A\|^2 = \text{tr}(A^*A)$. Moreover, if A is a square matrix, $\text{tr}(A)$ denotes the trace of A, $\det(A)$ the determinant of A, and $\lambda_{\min}(A)$, $\lambda_{\max}(A)$ the minimum and the maximum eigenvalues of A, respectively. In addition, if A and B are two positive definite Hermitian matrices, then $A \leq B$ if $B - A$ is positive definite. Finally, for any positive integer d, I_d is the identity matrix of order d.

2. Weighted estimation. Let $(\Omega, \mathcal{A}, P)$ be a probability space with a filtration $\mathbf{F} = (\mathcal{F}_n)_{n\geq 0}$, where $\mathcal{F}_n$ is the σ-algebra generated by events occurring up to time n. We consider the following complex multivariate ARMAX model of order (p, q, r):

$$A(R)Y_n = B(R)U_n + C(R)\varepsilon_n, \tag{1}$$

where Y, U, and ε are the d_1-dimensional output, d_2-dimensional input, and d_1-dimensional driven noise, respectively. Set for the shift-back operator R,

$$A(R) = I_{d_1} - A_1 R - \cdots - A_p R^p, \tag{2}$$

$$B(R) = B_1 R + \cdots + B_q R^q, \tag{3}$$

$$C(R) = I_{d_1} + C_1 R + \cdots + C_r R^r, \tag{4}$$

where A_i, B_j, C_k are unknown matrices. Assume that the control $U = (U_n)$ and the noise $\varepsilon = (\varepsilon_n)$ are adapted to **F** and that ε is a martingale difference sequence with

$$\sup_{n\geq 0} E[\|\varepsilon_{n+1}\|^2 \mid \mathcal{F}_n] < \sigma^2 \quad \text{a.s.}, \tag{5}$$

where σ^2 is deterministic. The initial state ${}^t\Psi_0 = ({}^tY_0^p, {}^tU_0^q, {}^t\varepsilon_0^r)$ is $\mathcal{F}_0$ measurable and, for $n \geq 0$,

$${}^t\Psi_n = ({}^tY_n^p, {}^tU_n^q, {}^t\varepsilon_n^r), \tag{6}$$

where ${}^tY_n^p = ({}^tY_n, \ldots, {}^tY_{n-p+1})$, ${}^tU_n^q = ({}^tU_n, \ldots, {}^tU_{n-q+1})$ and ${}^t\varepsilon_n^r = ({}^t\varepsilon_n, \ldots, {}^t\varepsilon_{n-r+1})$. Let $\hat{\theta}_n$ be an estimator of θ where

$${}^*\theta = (A_1, \ldots, A_p, B_1, \ldots, B_q, C_1, \ldots, C_r). \tag{7}$$

The noise ε is predicted by the a posteriori error $\hat{\varepsilon}$ with $\hat{\varepsilon}_0^r = 0$ and, for $n \geq 0$,

$$\hat{\varepsilon}_{n+1} = Y_{n+1} - {}^*\hat{\theta}_{n+1}\Phi_n, \tag{8}$$

where

$${}^t\Phi_n = ({}^tY_n^p, {}^tU_n^q, {}^t\hat{\varepsilon}_n^r). \tag{9}$$

Let $a = (a_n)$ be a sequence of random variables adapted to **F**, positive, nonincreasing, and $\leq 1. a = (a_n)$ is called a weighting sequence. We propose, in order to estimate θ, the WLS estimator $\hat{\theta}_n$ introduced by Bercu and Duflo [4] and given, for $n \geq 0$, by

$$\hat{\theta}_{n+1} = \hat{\theta}_n + a_n S_n^{-1}(a)\Phi_n{}^*(Y_{n+1} - {}^*\hat{\theta}_n\Phi_n), \tag{10}$$

where the initial value $\hat{\theta}_0$ is arbitrarily chosen and, for $n \geq 0$,

$$S_n(a) = \sum_{k=0}^{n} a_k \Phi_k{}^*\Phi_k + S \tag{11}$$

with any positive definite Hermitian and deterministic matrix S. We also write, for such a matrix Q,

$$Q_n(a) = \sum_{k=0}^{n} a_k \Psi_k{}^*\Psi_k + Q. \tag{12}$$

The inverses of the matrices $S_n(a)$ and $Q_n(a)$ are recursively generated by the matrix inversion formula of Riccati. Denote by $s_n(a)$ and $q_n(a)$ the traces of $S_n(a)$ and $Q_n(a)$, respectively. We also make use of

$$s_n = \sum_{k=0}^{n} \|\Phi_k\|^2 + s, \tag{13}$$

where $s = \text{tr}(S)$, and of the prediction errors sequence $\pi = (\pi_n)$ defined by

$$\pi_n = {}^*\theta\Psi_n - {}^*\hat{\theta}_n\Phi_n. \tag{14}$$

3. Admissibility. Consider a weighting sequence $a = (a_n)$ and set, for $n \geq 0$,

$$f_n(a) = a_n\, {}^*\Phi_n S_n^{-1}(a)\Phi_n, \qquad \Delta = \sum_{n=0}^{\infty} a_n f_n(a). \tag{15}$$

a is said to be admissible if Δ is integrable. Let F be the family of continuous and nonincreasing functions f from $\mathbf{R}^+$ to $\mathbf{R}^+$ such that $xf(x)$ converges to 0 as x goes to infinity and

$$\int_c^{+\infty} f(x)dx < +\infty \tag{16}$$

for any constant $c > 0$. We have the classical inequality

$$f_n(a) \leq \inf\{1, \log(\det S_n(a)) - \log(\det S_{n-1}(a))\}. \tag{17}$$

Using (17), Bercu and Duflo [4] have shown that a weighting sequence $a = (a_n)$ such that $a_n = f(n)$ or $a_n = f(\log s_n)$ with $f \in F$ is admissible. More precisely, they have proved that Δ is always almost surely bounded.

Throughout the following, we always assume that the weighting sequence a is admissible.

Remark. It is important to see that the WLS algorithm does not include the ELS as a special case since the weighting sequence with general constant term equal to 1 is not admissible.

4. Strong consistency. We make use of the following traditional assumption of passivity:

(A_1) $C^{-1} - \frac{1}{2}I_{d_1}$ is strictly positive real.

THEOREM 1. *For the model and the* WLS *algorithm* (1) *to* (14), *assume that* (A_1) *is satisfied. Then we have*

$$E\left[\sup_{n\geq 0} \|S_n^{1/2}(a)(\hat{\theta}_{n+1} - \theta)\|^2\right] < +\infty, \tag{18}$$

$$E\left[\sum_{n=0}^{\infty} a_n \|{}^*(\hat{\theta}_{n+1} - \theta)\Phi_n\|^2\right] < +\infty, \tag{19}$$

$$E\left[\sum_{n=0}^{\infty} \lambda_{\min} S_{n-1}(a)\|\hat{\theta}_{n+1} - \hat{\theta}_n\|^2\right] < +\infty, \tag{20}$$

$$E\left[\sum_{n=0}^{\infty} a_n \|\Phi_n - \Psi_n\|^2\right] < +\infty, \tag{21}$$

$$E\left[\sum_{n=0}^{\infty} a_n(1 - f_n(a))\|\pi_n\|^2\right] < +\infty. \tag{22}$$

Proof. The proof is given in Appendix A.

COROLLARY 1. If (A_1) *holds, the* WLS *estimator given by* (10) *is strongly consistent on*

$$I = \{\lim_{n\to+\infty} \lambda_{\min} S_n(a) = +\infty\} \tag{23}$$

and, on I, we have

$$\|\hat{\theta}_{n+1} - \theta\|^2 = O(\{\lambda_{\min} S_n(a)\}^{-1}) \quad a.s. \tag{24}$$

Remark. As $S_n(a) \geq S$, the WLS estimator is always almost surely bounded. By (24), we can conclude that the WLS algorithm behaves as well as the ELS for ARMAX parameter estimation [12], [24], [25].

COROLLARY 2. *If* (A_1) *holds, the prediction errors sequence satisfies*

$$E\left[\sum_{n=0}^{\infty} (a_n^{-1} + \|\Phi_n\|^2)^{-1}\|\pi_n\|^2\right] < +\infty. \tag{25}$$

More particularly, if, for $n \geq 0$, $s_n^{-1} \leq ca_n$ with c deterministic > 0, then

$$E\left[\sum_{n=0}^{\infty} \frac{\|\pi_n\|^2}{s_n}\right] < +\infty. \tag{26}$$

Finally, we also have

$$E\left[\sum_{n=0}^{\infty} \left(a_n^{-1} + \frac{\|\Phi_n\|^2}{\lambda_{\min} S_{n-1}(a)}\right)^{-1} \|\pi_n\|^2\right] < +\infty. \tag{27}$$

Remark. By (26), we can conclude that the WLS algorithm behaves as well as the SG for adaptive tracking [8], [18].

Proof. $\pi_n = {}^*\theta\Psi_n - {}^*\hat{\theta}_n\Phi_n$, so we can rewrite $\pi_n = \tau_{n+1} + {}^*(\hat{\theta}_{n+1} - \hat{\theta}_n)\Phi_n$ where $\tau_{n+1} = {}^*\theta\Psi_n - {}^*\hat{\theta}_{n+1}\Phi_n$. Then, by use of (19) together with (21),

$$E\left[\sum_{n=0}^{\infty} a_n\|\tau_{n+1}\|^2\right] < +\infty. \tag{28}$$

Hence, (25) and (27) immediately follow from (20) and (28). Moreover, if $s_n^{-1} \leq ca_n$ with c deterministic > 0, (20) and (28) imply (26). □

COROLLARY 3. *Assume that the driven noise ε satisfies the strong law of large numbers* (LN) *with, for $n \geq 0$,*

$$E[\varepsilon_{n+1}{}^*\varepsilon_{n+1} \mid \mathcal{F}_n] = \Gamma, \tag{29}$$

where Γ is a deterministic covariance matrix. To estimate Γ, we propose the two empirical estimators

- $\hat{\Gamma}_n = \frac{1}{n}\sum_{k=1}^{n} (Y_k - {}^*\hat{\theta}_{k-1}\Phi_{k-1})\,{}^*(Y_k - {}^*\hat{\theta}_{k-1}\Phi_{k-1})$,
- $\tilde{\Gamma}_n = \frac{1}{n}\sum_{k=1}^{n} \hat{\varepsilon}_k{}^*\hat{\varepsilon}_k$.

Suppose that (A_1) *is satisfied and that $s_n^{-1} = O(a_n)$. Then, on the set $\{s_n = O(n)$ and $s_n \to +\infty\}$, $\hat{\Gamma}_n$ and $\tilde{\Gamma}_n$ areboth strongly consistent estimators of Γ.*

Proof. The proof is obvious using (21) and (26) with Kronecker's lemma. □

5. Adaptive tracking. We still consider the model and the WLS algorithm (1) to (14). The goal of adaptive tracking is to find a control sequence $U = (U_n)$ that forces the output $Y = (Y_n)$ to follow a given reference trajectory $y = (y_n)$. We first use the traditional adaptive tracking control (ATC) introduced by Aström and Wittenmark [1] such that, for $n \geq 0$,

$$y_{n+1} = {}^*\hat{\theta}_n \Phi_n. \tag{30}$$

It is well known that the ATC is almost surely defined if the following assumption is satisfied:

(A_2) For $n \geq 0$, the $\mathcal{F}_n$ conditional distribution of ε_{n+1} is absolutely continuous with respect to the Lebesgue measure.

Remark. If (A_2) is satisfied, Caines [8] has shown how to solve the zero divisor problem for the ATC. We will see in the next section how to avoid this assumption.

Throughout the following, we assume that the driven noise ε has constant conditional covariance matrix Γ given by (29). We also make use of the two classical assumptions about ε:

(N_1) ε has finite conditional moment of order >2;

(N_2) ε is independent and identically distributed with mean 0 and covariance matrix Γ. Therefore, if (N_1) or (N_2) are fulfilled, ε satisfies LN, i.e., if

$$\Gamma_n = \frac{1}{n}\sum_{k=1}^{n} \varepsilon_k {}^*\varepsilon_k, \tag{31}$$

Γ_n converges to Γ almost surely. Finally, we need the following usual assumption of causality:

(A_3) $d_2 \leq d_1$ and the matrix B_1 is of full rank d_2. Moreover, if B_+ denotes the left inverse of B_1 and if $D(R) = B_+ R^{-1} B(R)$ for the shift-back operator R, then D is causal.

Throughout this section, we use a similar approach as that of Bercu and Duflo [4] in the ARX framework. Let $C = (C_n)$ be the average cost matrix sequence defined by

$$C_n = \frac{1}{n}\sum_{k=1}^{n}(Y_k - y_k)^*(Y_k - y_k). \tag{32}$$

The ATC is said to be optimal if C_n converges almost surely to Γ. If we use the ATC, we have from (30)

$$Y_{n+1} - y_{n+1} = \pi_n + \varepsilon_{n+1}. \tag{33}$$

Then, we can easily prove that

$$\|C_n - \Gamma_n\| = O\left(\frac{1}{n}\sum_{k=1}^{n} \|\pi_{k-1}\|^2\right) \quad \text{a.s.} \tag{34}$$

Therefore, in order to show the ATC optimality, we only have to prove that the prediction errors sequence satisfies

$$\sum_{k=1}^{n} \|\pi_k\|^2 = o(n) \quad \text{a.s.} \tag{35}$$

THEOREM 2. *For the model and the* WLS *algorithm* (1) *to* (14), *assume that* (A_1)–(A_3) *and* (N_1) *or* (N_2) *are satisfied. For the tracking trajectory* $y = (y_n)$, *suppose that, for* $n \geq 0$, y_{n+1} *is measurable with respect to* $\mathcal{F}_n$ *and*

$$\sum_{k=1}^{n} \|y_k\|^2 = O(n) \quad \textit{a.s.} \tag{36}$$

If $a_n = f(\log s_n)$ with $f \in F$ and if $s_n^{-1} = O(a_n)$, then the ATC *is optimal. Moreover, we have*

$$\sum_{n=1}^{\infty} \frac{1}{n} \|Y_n - y_n - \varepsilon_n\|^2 < +\infty \quad a.s. \tag{37}$$

Finally, $\hat{\Gamma}_n$ and $\tilde{\Gamma}_n$ are both strongly consistent estimators of Γ.

Remark. For the SG algorithm, the ATC optimality was established by Goodwin, Ramadge, and Caines [18]. Such a theorem was never proven for the ELS algorithm.

Proof. The proof is given in Appendix B.

We now give a useful excitation transfer (ET) lemma similar to the one established by Lai and Wei [25]. We begin by stating the following assumption of irreducibility which uses the same notation as (A_3):

(A_4) The matrix B_+B_q is regular and the polynomials of matrices B_+A, B_+C and D are left coprime.

EXCITATION TRANSFER LEMMA. *Suppose that (A_3) and (A_4) are satisfied. Then we can find a constant $M > 0$ such that, for $n \geq s$,*

$$\lambda_{\min}\left(\sum_{k=0}^{n} \Psi_k {}^*\Psi_k\right) \geq M \lambda_{\min}\left(\sum_{k=s}^{n} H_{k+1} {}^*H_{k+1}\right) \quad a.s., \tag{38}$$

where ${}^tH_n = ({}^tY_n^{p+s+1}, {}^t\varepsilon_n^{r+s+1})$ and $s = d_2(q-1)$.

Proof. A proof can be found in Lai and Wei [25] or Duflo [17].

THEOREM 3. *For the model and* WLS *algorithm* (1) *to* (14), *assume that* (A_1)–(A_4) *and* (N_1) *or* (N_2) *are satisfied. Assume that the covariance matrix Γ is regular. For the tracking trajectory $y = (y_n)$, suppose that y_{n+1} is $\mathcal{F}_{n-p-s} \cap \mathcal{F}_{n-r-s}$-measurable with $\|y_n\|^2 = o(n)$ and*

$$\sum_{k=1}^{n} \|y_k\|^2 = O(n) \quad a.s. \tag{39}$$

Moreover, suppose that y is exciting with order $p + s + 1$, i.e.,

$$\liminf \lambda_{\min}\left(\frac{1}{n} \sum_{k=p+s}^{n} y_k^{p+s+1*} y_k^{p+s+1}\right) > 0 \quad a.s. \tag{40}$$

If $a_n = f(\log s_n)$ with $f \in F$ and if $s_n^{-1} = O(a_n^2)$, then the ATC *is optimal*

$$\|\Phi_n\|^2 = o(n), \quad f_n(a) = o(1) \quad a.s., \tag{41}$$

$$\|C_n - \Gamma_n\| = o\left(\frac{1}{nf(\log n)}\right) \quad a.s., \tag{42}$$

$$\sum_{n=1}^{\infty} f(\log n) \|Y_n - y_n - \varepsilon_n\|^2 < +\infty \quad a.s. \tag{43}$$

Moreover, the WLS *estimator $\hat{\theta}_n$ converges almost surely to θ and we obtain*

$$\|\hat{\theta}_{n+1} - \theta\|^2 = O\left(\frac{1}{nf(\log n)}\right) \quad a.s. \tag{44}$$

Finally, $\hat{\Gamma}_n$ and $\tilde{\Gamma}_n$ are both strongly consistent estimators of Γ and we find relations similar to (42) *with $\hat{\Gamma}_n$ or $\tilde{\Gamma}_n$ instead of C_n.*

Proof. The proof is given in Appendix C.

Remark. We can prove the ATC optimality and the strong consistency with a condition less restrictive than (40) for the tracking trajectory. More precisely, let $\lambda = (\lambda_n)$ be a deterministic positive sequence, increasing to infinity, such that (λ_n) has the same behavior as (λ_{n-1}) and $\lambda_n = O(n)$. Assume that y is λ-exciting with order $p + s + 1$, i.e.,

$$\liminf \lambda_{\min}\left(\frac{1}{\lambda_n}\sum_{k=p+s}^{n} y_k^{p+s+1*}y_k^{p+s+1}\right) > 0 \quad \text{a.s.} \tag{45}$$

Then, if $\lambda_n^{-1} = O(a_n^2)$, the ATC is optimal and the WLS estimator is strongly consistent with

$$\|\hat{\theta}_{n+1} - \theta\|^2 = O\left(\frac{1}{\lambda_n f(\log n)}\right) \quad \text{a.s.} \tag{46}$$

We next consider the continually disturbed control (CDC) introduced by Caines [6], [8] such that, for $n \geq 0$,

$$y_{n+1} + \xi_{n+1} = {}^*\hat{\theta}_n\Phi_n, \tag{47}$$

where ξ is a d_1-dimensional exogenous noise, adapted to $\mathbf{F}$, with mean 0 and covariance matrix Λ. The CDC is said to be residually optimal if C_n converges almost surely to $\Gamma + \Lambda$.

THEOREM 4. *For the model and* WLS *algorithm* (1) *to* (14), *take the same assumptions as in Theorem* 3 *except condition* (40) *for the tracking trajectory y. Moreover, for the exogenous noise ξ, assume that the* LN *is satisfied with Λ regular. In addition, assume that ξ is independent of ε, of y, and of the initial state Ψ_0. If $a_n = f(\log s_n)$ with $f \in F$ and if $s_n^{-1} = O(a_n^2)$, then the* CDC *excited by ξ is residually optimal*

$$\|\Phi_n\|^2 = o(n), \quad f_n(a) = o(1) \quad \textit{a.s.}, \tag{48}$$

$$\sum_{n=1}^{\infty} f(\log n)\|Y_n - y_n - \varepsilon_n - \xi_n\|^2 < +\infty \quad \textit{a.s.} \tag{49}$$

Moreover, the WLS *estimator $\hat{\theta}_n$ converges almost surely to θ and we obtain*

$$\|\hat{\theta}_{n+1} - \theta\|^2 = O\left(\frac{1}{nf(\log n)}\right) \quad \textit{a.s.} \tag{50}$$

Proof. The proof is similar to that of Theorem 3.

6. Modified adaptive tracking. We now use a similar approach as that of Guo and Chen [19], [15] in the ELS framework. Assume that (A_1) and (A_3) are satisfied. Without assumption (A_2), to avoid the zero divisor problem with the ATC, we propose a modified WLS estimator. Throughout the following, the major restriction is that the noise is supposed to satisfy (N_1). All the results of this section are also true, without modification, if we assume that (A_2) is satisfied.

Let $\hat{B}_n^1$ be the matrix component of $\hat{\theta}_n$ that estimates B_1. P_n and Q_n are the orthogonal matrices associated with the singular value decomposition of $\hat{B}_n^1$. The columns of P_n are eigenvectors of $\hat{B}_n^{1*}\hat{B}_n^1$ and the columns of Q_n are eigenvectors of ${}^*\hat{B}_n^1\hat{B}_n^1$ [20]. We set

$$\tilde{B}_n^1 = \begin{cases} \hat{B}_n^1 & \text{if } \lambda_{\min}({}^*\hat{B}_n^1\hat{B}_n^1) > 0, \\ \hat{B}_n^1 + \sqrt{\nu_n}P_n{}^*Q_n & \text{otherwise,} \end{cases} \tag{51}$$

for any positive, deterministic and summable sequence $\nu = (\nu_n)$. By (51), $\tilde{B}_n^1$ is clearly of full rank d_2. Denote by $\tilde{\theta}_n$ the modified WLS estimator of θ where $\hat{B}_n^1$ is replaced by $\tilde{B}_n^1$ in $\hat{\theta}_n$. It immediately follows from (51) that

$$\|\hat{\theta}_n - \tilde{\theta}_n\|^2 \leq \nu_n \quad \text{a.s.} \tag{52}$$

Hence, since $\nu_n = o(1)$, the WLS algorithm is not modified for parameter estimation. We first consider the modified ATC such that, for $n \geq 0$,

$$y_{n+1} = {}^*\tilde{\theta}_n \Phi_n. \tag{53}$$

We clearly have from (53)

$$Y_{n+1} - y_{n+1} = \tilde{\pi}_n + \varepsilon_{n+1}, \tag{54}$$

where

$$\tilde{\pi}_n = \pi_n + (\hat{B}_n^1 - \tilde{B}_n^1)U_n. \tag{55}$$

Therefore, the modified ATC is optimal if

$$\sum_{k=1}^{n} \|\tilde{\pi}_k\|^2 = o(n) \quad \text{a.s} \tag{56}$$

THEOREM 5. *For the model and the* WLS *algorithm* (1) *to* (14), *assume that* (A_1), (A_3), *and* (N_1) *are satisfied. For a positive, nonincreasing and deterministic sequence* $\alpha = (\alpha_n)$ *such that* $\alpha_n = O(n)$, *assume that we have* $\|\varepsilon_n\|^2 = O(\alpha_n)$. *For the tracking trajectory* $y = (y_n)$, *suppose that, for* $n \geq 0$, y_{n+1} *is* $\mathcal{F}_n$*-measurable with* $\|y_n\|^2 = O(\alpha_n)$ *and*

$$\sum_{k=1}^{n} \|y_k\|^2 = O(n) \quad a.s. \tag{57}$$

If $a_n = f(\log s_n)$ *with* $f \in F$ *and if* $s_n^{-1} = O(a_n)$, *then the modified* ATC *is optimal. Moreover, consider the positive random sequence* $v = (v_n)$ *such that* $v_n = \alpha_n + a_n^{-1}$. *Then we also have*

$$\|\Phi_n\|^2 = O(v_{n+1}) \quad a.s., \tag{58}$$

$$\|C_n - \Gamma_n\| = o\left(\frac{v_n}{n}\right) \quad a.s., \tag{59}$$

$$\sum_{n=1}^{\infty} \frac{1}{v_n} \|Y_n - y_n - \varepsilon_n\|^2 < +\infty \quad a.s. \tag{60}$$

Finally, $\hat{\Gamma}_n$ *and* $\tilde{\Gamma}_n$ *are both strongly consistent estimators of* Γ *and we find relations similar to* (59) *with* $\hat{\Gamma}_n$ *or* $\tilde{\Gamma}_n$ *instead of* C_n.

Proof. The proof is given in Appendix D.

Concerning adaptive tracking, we now give the last but most important theorem of this paper. It ensures both strong consistency for the WLS estimator and modified continually disturbed control (CDC) optimality. We recall here that the following theorem is also true, without modification, if we assume that (A_2) is satisfied. Before stating it, we assume in (51) that the sequence $(n\nu_n)$ is summable.

Consider a deterministic positive sequence $\lambda = (\lambda_n)$, increasing to infinity, such that, for $n \geq 1$, $\lambda_n - \lambda_{n-1} \leq 1$, (λ_n) has the same behavior as (λ_{n-1}) and $\lambda_n = O(n)$. Let ξ be a d_1-dimensional exogenous noise adapted to **F** with mean 0 and covariance matrix Λ. Set, for $n \geq 1$, $\chi_n = \sqrt{\lambda_n - \lambda_{n-1}}\xi_n$. We use the CDC introduced by Bercu and Duflo [4] such that, for $n \geq 0$,

$$y_{n+1} + \chi_{n+1} =^* \tilde{\theta}_n \Phi_n. \tag{61}$$

It follows immediately from (61) that

$$Y_{n+1} - y_{n+1} - \chi_{n+1} = \tilde{\pi}_n + \varepsilon_{n+1}. \tag{62}$$

THEOREM 6. *For the model and the* WLS *algorithm* (1) *to* (14), *assume that* (A_1), (A_3), (A_4), *and* (N_1) *are satisfied and that* Γ *is regular. For a positive, nonincreasing and deterministic sequence* $\alpha = (\alpha_n)$ *such that* $\alpha_n = O(n)$, *assume that* $\|\varepsilon_n\|^2 = O(\alpha_n)$. *For the tracking trajectory* $y = (y_n)$, *suppose that* y_{n+1} *is* $\mathcal{F}_{n-p-s} \cap \mathcal{F}_{n-r-s}$*-measurable with* $\|y_n\|^2 = O(\alpha_n)$ *and*

$$\sum_{k=1}^{n} \|y_k\|^2 = O(n) \quad a.s. \tag{63}$$

Moreover, assume that the exogenous noise ξ *satisfies* (N_1) *with* Λ *regular. In addition, suppose that* ξ *is independent of* ε, *of the initial state* Ψ_0, *and of the tracking trajectory* y, *and that* $\|\xi_n\|^2 = O(\alpha_n)$. *Consider the positive random sequence* $v = (v_n)$ *such that* $v_n = \alpha_n + a_n^{-1}$. *Assume that* $v_n = o(\lambda_n)$ *and* $\lambda_n^{-1} = O(a_n^2)$. *If* $a_n = f(\log s_n)$ *with* $f \in F$ *and if* $s_n^{-1} = O(a_n^2)$, *then*

$$\|\Phi_n\|^2 = o(\lambda_n), \quad f_n(a) = o(1) \quad a.s., \tag{64}$$

$$\sum_{n=1}^{\infty} f(\log n)\|Y_n - y_n - \chi_n - \varepsilon_n\|^2 < +\infty \quad a.s., \tag{65}$$

$$\frac{1}{\lambda_n}\sum_{k=1}^{n}(Y_k - y_k - \varepsilon_k)^*(Y_k - y_k - \varepsilon_k) \to \Lambda \quad a.s., \tag{66}$$

$$\|C_n - \Gamma_n\| = O\left(\frac{\lambda_n}{n}\right) \quad a.s. \tag{67}$$

Therefore, if $\lambda_n = o(n)$, *the modified* CDC *excited by* χ *is optimal. Moreover, the* WLS *estimator* $\hat{\theta}_n$ *converges almost surely to* θ *and*

$$\|\hat{\theta}_{n+1} - \theta\|^2 = O\left(\frac{1}{\lambda_n f(\log n)}\right) \quad a.s. \tag{68}$$

Finally, $\hat{\Gamma}_n$ *and* $\tilde{\Gamma}_n$ *are both strongly consistent estimators of* Γ *and we find relations similar to* (67) *with* $\hat{\Gamma}_n$ *or* $\tilde{\Gamma}_n$ *instead of* C_n.

Proof. The proof is given in Appendix E.

Remark. If assumption (N_1) is satisfied with $\alpha > 2$, then, by use of the conditional Borel–Cantelli lemma, we can take $\alpha_n = n^{\beta}$ with $2\alpha^{-1} < \beta < 1$. We can also choose $a_n = (\log s_n)^{-1-\gamma}$ with $\gamma > 0$. Therefore, if we take $\lambda_n = n^{\delta}$ with $\beta < \delta < 1$, we obtain the convergence rates $n^{-\delta}(\log n)^{1+\gamma}$ for the strong consistency and $n^{\delta-1}$ for the optimality. In addition, if ε and ξ are Gaussian white noises, then, using again the Borel–Cantelli lemma, we can take $\alpha_n = \log n$. On one hand, if we focus our attention on the strong consistency, we can use the same choice as above and find the convergence rate $n^{-\delta}(\log n)^{1+\gamma}$. On the other hand, if we are interested in the optimality, we can take $\lambda_n = (\log n)^{\delta}$ with $2(1+\gamma) \leq \delta$ and we obtain the convergence rate $n^{-1}(\log n)^{\delta}$. One can realize that the attenuation $\lambda = (\lambda_n)$ plays a prominent part, reducing the role of the weighting sequence $a = (a_n)$.

7. Survey on adaptive tracking. We now give a short survey on earlier related works on adaptive tracking. We complete this section by comparing our work with previous similar results.

Concerning the SG algorithm, Goodwin, Ramadge, and Caines [18] proved global convergence and adaptive tracking control (ATC) optimality. In the scalar tracking problem, Becker, Kumar, and Wei [2] established convergence to a random multiple of the parameter to be estimated. If the tracking trajectory is sufficiently rich, Kumar and Praly [21] showed, in the scalar case, strong consistency and ATC optimality. Caines [6], [8] realized that, in order to enforce strong consistency, it is necessary to modify the ATC of Aström and Wittenmark [1] and he introduced the CDC. In the scalar case, Caines and Lafortune [7] obtained the first results of CDC optimality and persistent excitation. For the same purpose, Chen [9], [11] chose a weak hypothesis of excitation and using this assumption, Chen and Caines [10] proved, in the scalar case, strong consistency and CDC residual optimality. In a multidimensional framework and with a restrictive assumption on the noise, Chen and Guo [13] established both strong consistency and CDC optimality.

Concerning the ELS algorithm, Solo [27] gave, in the scalar case, a persistent excitation condition in order to guarantee strong consistency. Lai and Wei [23], [24] proposed a weaker excitation condition to obtain strong consistency. For bounded noise, they used a rather complicated control to obtain both strong consistency and CDC optimality. Under the same condition but in a multidimensional framework, Lai and Wei [25] showed strong consistency and gave an excitation transfer theorem useful in obtaining persistent excitation results. Analogously, in a multidimensional framework, Chen and Guo [12] gave conditions to obtain strong consistency. Then they used a rather complex control to prove both strong consistency and CDC optimality with almost sure rates of convergence. Chen and Zhang [14] established similar results in the multi-delay case. Recently Kumar [22] showed, for white Gaussian noise and in a regression framework, the existence of an almost sure limit for the least squares estimator, for almost all parameter values. Strong consistency and optimality results followed. Sin and Goodwin [26] introduced the modified least squares (MLS) algorithm and obtained results similar to those of Goodwin, Ramadge, and Caines [18]. Chen [9], [11] also introduced an algorithm similar to the MLS and in a multidimensional framework he proved strong consistency and CDC residual optimality.

Recently, Guo and Chen [19], [15] established the most important result concerning adaptive tracking for ARMAX models. They found a solution to the twenty-year-old adaptive tracking problem proposed by Aström and Wittenmark [1]. In a multidimensional framework, they proved both strong consistency of ELS estimator and CDC optimality. They also provided almost sure rates of convergence. The key idea was an over-estimation of the ARMAX regression vector norm.

With the WLS algorithm, we have also given a solution to the Aström and Wittenmark [1] adaptive tracking problem. We now compare our work to the results of Guo and Chen [19].

- One can remark that the WLS algorithm is similar to the ELS. The main difference is the easy introduction of a random weighting sequence $a = (a_n)$ in relation (10).
- To obtain strong consistency results, Guo and Chen [19] always required that the driven noise ε had finite conditional moment of order > 2. In §4, we showed how to avoid this assumption by the choice of an admissible weighting sequence. Moreover, it is easy to see via (24) that the WLS estimator performs as well as that of the ELS for ARMAX parameter estimation.
- Furthermore, to obtain adaptive tracking results, Guo and Chen [19] proposed a modified ELS estimator. One can realize that they established CDC optimality by use of a rather technical procedure. Our modification (51) is really simple. Moreover, via (26), we can easily prove the CDC optimality. In addition, our results are also true without modification if the continuity assumption (A_2) on the distribution of ε is satisfied. One can remark that such a result has not been proved by Guo and Chen [19] with pure ELS estimator.
- Finally, we have shown that the WLS algorithm is really easy to handle. We can choose the weighting sequence or the attenuation as we want to privilege the strong consistency or the optimality. One can also realize that our convergence rates are more precise. For example, suppose that we focus our attention on the control optimality. If ε is a Gaussian white noise, we can take the attenuation $\lambda_n = (\log n)^4$. Then, we obtain from (66) a convergence rate in power of log n. It improves the result of Guo and Chen [19] as they founded a convergence rate in power of n.

8. Conclusion. Finally, as it was done for the ELS algorithm, we have shown that the WLS algorithm has rather attractive properties. Under classical assumptions, we have proved both strong consistency of the WLS estimator and CDC optimality. We have also established almost sure rates of convergence. We can easily guess that the weighted estimation can be used in many other frameworks. For instance, the adaptive tracking problems for linear ARMAX models with time varying parameters or for functional ARMAX models remain to be studied, following the choice of suitable weighting sequences.

Appendix A. We make use of the following two lemmas.

LEMMA 1. *Set* $f_n(a) = a_n {}^*\Phi_n S_n^{-1}(a)\Phi_n$ *and* $g_n(a) = a_n {}^*\Phi_n S_{n-1}^{-1}(a)\Phi_n$. *Then*

$$(1 - f_n(a)) = (1 + g_n(a))^{-1} \quad \textit{so} \quad 0 \leq f_n(a) \leq 1;$$

$$\hat{\varepsilon}_{n+1} = (1 - f_n(a))(\pi_n + \varepsilon_{n+1}), \qquad \hat{\theta}_{n+1} = \hat{\theta}_n + a_n S_{n-1}^{-1}(a)\Phi_n {}^*\hat{\varepsilon}_{n+1};$$

$$f_n(a) \leq \inf\{1, \log(\det S_n(a)) - \log(\det S_{n-1}(a))\}.$$

LEMMA 2. *Assume that* ε *is a martingale difference sequence satisfying* (5). *For a vectorial random sequence* $\varphi = (\varphi_n)$ *adapted to* $\mathbf{F}$, *set*

$$M_{n+1} = \sum_{k=0}^{n*} \varphi_k \varepsilon_{k+1}.$$

Then we always have

$$E\left[\sup_{k \leq n+1} |M_k|^2 = O\left(E\left[\sum_{k=0}^{n} \|\varphi_k\|^2\right]\right).\right.$$

We can easily prove Lemma 1 using the same arguments as without the weighting sequence $a = (a_n)$. Lemma 2 can be established by the use of a stopping time argument together with the Kolmogorov's inequality [17]. It can also be proved via the Burkholder, Davis, and Gundy inequality [16], [28].

Proof of Theorem 1. For $n \geq 0$, set $\breve{\theta}_n = \hat{\theta}_n - \theta, \breve{\varepsilon}_n = \hat{\varepsilon}_n - \varepsilon_n$, and $v_n = \operatorname{tr}({}^*\breve{\theta}_n S_{n-1}(a)\breve{\theta}_n)$, where $S_{-1}(a) = S$. By Lemma 1, we can find the following relation similar, without the weighting sequence $a = (a_n)$, to the well-known equality due to Caines [8], Chen [11], Duflo [17], Guo and Chen [11], [15], or Lai and Wei [25]:

$$\begin{aligned} v_{n+1} + P_{n+1} \; = \; & v_0 + \sum_{k=0}^{n} a_k \|\alpha_{k+1}\|^2 + 2\sum_{k=0}^{n} a_n f_k(a) \|\varepsilon_{k+1}\|^2 \\ & +2\mathrm{Re}(M_{n+1}) - 2\mathrm{Re}(L_{n+1}), \end{aligned} \tag{A.1}$$

with $\alpha_n = -{}^*\breve{\theta}_n \Phi_{n-1}$; $\beta_n = {}^*\breve{\theta}_n \Phi_n + f_n(a)\pi_n$; and

- $P_{n+1} = \sum_{k=0}^{n} a_k f_k(a)(1 - f_k(a))\|\pi_k + \varepsilon_{k+1}\|^2$,
- $M_{n+1} = \sum_{k=0}^{n} a_k {}^*\beta_k \varepsilon_{k+1}$,
- $L_{n+1} = \sum_{k=0}^{n} a_k {}^*\alpha_{k+1} \breve{\varepsilon}_{k+1}$.

Moreover, since (A_1) is satisfied, $\alpha_n = C(R)\hat{\varepsilon}_n$ and $a = (a_n)$ is positive and nonincreasing, we can find a positive constant l and an integrable random variable L such that

$$2\mathrm{Re}(L_{n+1}) + L \geq (1 + l)\sum_{k=0}^{n} a_k \|\alpha_{k+1}\|^2. \tag{A.2}$$

In addition, it immediately follows from Lemma 2 that

$$E\left[\sup_{k \leq n+1} |M_k|^2\right] = O\left(E\left[\sum_{k=0}^{n} a_k^2 \|\beta_k\|^2\right]\right). \tag{A.3}$$

Therefore, recalling that $\beta_n = -\alpha_{n+1} - f_n(a)\varepsilon_{n+1}$, we obtain that either

$$E\left[\sup_{n \geq 1} |M_n|\right] < +\infty \tag{A.4}$$

or

$$E\left[\sup_{k \leq n+1} |M_k|\right] = o\left(E\left[\sum_{k=0}^{n} a_k(\|\alpha_{k+1}\|^2 + f_k(a)\|\varepsilon_{k+1}\|^2)\right]\right). \tag{A.5}$$

Finally, by (A.1) and (A.2), we find that

$$E\left[\sup_{k \leq n} v_{k+1}\right] = O\left(E\left[\sum_{k=0}^{n} a_k f_k(a) \|\varepsilon_{k+1}\|^2\right]\right). \tag{A.6}$$

Now, from (5) and (15) together with the monotone convergence theorem,

$$E\left[\sum_{n=0}^{\infty} a_n f_n(a) \|\varepsilon_{n+1}\|^2\right] < +\infty. \tag{A.7}$$

Then we obtain (18) from (A.6) and (A.7). Next, we also obtain (19) and (21) from (A.1), (A.2), (A.7) and the passivity assumption. It remains to show (20) and (22). Let $\pi_n = {}^*\theta\Psi_n - {}^*\hat{\theta}_n\Phi_n$

be the prediction error at time n. By use of Lemma 1, we have $(1 - f_n(a))\pi_n = \check{\varepsilon}_{n+1} + f_n(a)\varepsilon_{n+1}$. Hence, (21) and (A.7) imply

$$E\left[\sum_{n=0}^{\infty} a_n(1 - f_n(a))^2\|\pi_n\|^2\right] < +\infty. \tag{A.8}$$

Recalling (A.1), we also find that

$$E\left[\sup_{n\geq 1} P_n\right] < +\infty, \tag{A.9}$$

$$E\left[\sum_{n=0}^{\infty} a_n f_n(a)(1 - f_n(a))\|\pi_n\|^2\right] < +\infty, \tag{A.10}$$

and we clearly deduce (22) from (A.8) and (A.10). Furthermore, by the matrix inversion formula of Riccati, we obtain

$${}^*\Phi_n S_n^{-2}(a)\Phi_n = (1 - f_n(a))^{2*}\Phi_n S_{n-1}^{-2}(a)\Phi_n. \tag{A.11}$$

So if we set $d = d_1 p + d_2 q + d_1 r$, we obtain, by Lemma 1,

$$a_n\lambda_{\min}S_{n-1}(a)^*\Phi_n S_n^{-2}(a)\Phi_n \leq df_n(a)(1 - f_n(a)). \tag{A.12}$$

Finally, (10) and (14), together with (A.12) and (22), imply (20), completing the proof of Theorem 1. □

Appendix B.

Proof of Theorem 2. Denote by s_∞ and a_∞ the limits of the sequences $s = (s_n)$ and $a = (a_n)$, respectively. To use relation (26) together with Kronecker's lemma, we first have to show that $s_\infty = +\infty$. If we assume that $s_\infty < +\infty$, it follows from the assumption $s_n^{-1} = O(a_n)$ that necessarily $a_\infty > 0$. Hence, using (21), we have

$$\sum_{n=0}^{\infty} \|\Phi_n - \Psi_n\|^2 < \infty. \tag{B.1}$$

If we set $q_n = \sum_{k=0}^{n} \|\Psi_k\|^2 + s$, we can easily see that

$$q_n \leq 2\sum_{k=0}^{n} \|\Phi_k - \Psi_k\|^2 + 2s_n, \tag{B.2}$$

so $q_\infty < +\infty$ where q_∞ denotes the limit of the sequence $q = (q_n)$. But we also have from (6) that

$$q_n \geq \sum_{k=0}^{n} \|\varepsilon_k\|^2 \tag{B.3}$$

and as ε satisfies the LN, we get $n = O(q_n)$. Finally, we lead to a contradiction so that $s_\infty = +\infty$, $a_\infty = 0$. Moreover, we also have

$$s_n \leq 2\sum_{k=0}^{n} \|\Phi_k - \Psi_k\|^2 + 2q_n. \tag{B.4}$$

Then, by use of (21) together with Kronecker's lemma, we find that

$$\sum_{k=0}^{n} \|\Phi_k - \Psi_k\|^2 = o(a_n^{-1}) \tag{B.5}$$

and, as $a_n^{-1} = O(s_n)$, we obtain $s_n = O(q_n)$. In addition, from (6), we have

$$q_n = O\left(\sum_{k=0}^{n} \|Y_k\|^2 + \sum_{k=0}^{n} \|U_k\|^2 + \sum_{k=0}^{n} \|\varepsilon_k\|^2\right). \tag{B.6}$$

Hence, assumptions (N_1) or (N_2) imply that

$$q_n = O\left(n + \sum_{k=0}^{n} \|Y_k\|^2 + \sum_{k=0}^{n} \|U_k\|^2\right). \tag{B.7}$$

Recalling (1), we have $U_{n-1} = D^{-1}(R)B_+A(R)Y_n - D^{-1}(R)B_+C(R)\varepsilon_n$, where R is the shift-back operator. Then, using (B.7), we find that

$$q_{n-1} = O\left(n + \sum_{k=1}^{n} \|Y_k\|^2\right) \tag{B.8}$$

and so, as $s_n = O(q_n)$, we prove that

$$s_{n-1} = O\left(n + \sum_{k=1}^{n} \|Y_k\|^2\right). \tag{B.9}$$

By (26) and the assumption (36) for the tracking trajectory, we have

$$\sum_{k=1}^{n} \|Y_k\|^2 = o(s_{n-1}) + O(n). \tag{B.10}$$

Finally, using (B.9), we obtain that

$$\sum_{k=1}^{n} \|Y_k\|^2 = O(n), \qquad s_n = O(n). \tag{B.11}$$

From (26) together with Kronecker's lemma, we conclude that the ATC is optimal. Moreover, (26) immediately implies (37). We complete the proof using Corollary 3. □

Appendix C.

Proof of Theorem 3. Using the same ideas developed by Bercu and Duflo [4] in the ARX framework, we now prove the Theorem 3. We have already seen in Theorem 2 the ATC optimality with

$$\sum_{k=1}^{n} \|\pi_k\|^2 = o(n). \tag{C.1}$$

Set, for $n \geq 0$, ${}^tL_r = ({}^ty_n^{p+s+1} + {}^t\varepsilon_n^{p+s+1}, {}^t\varepsilon_n^{r+s+1})$. Using the notation of the ET Lemma, we obtain from (33),

$$\|H_{n+1} - L_{n+1}\|^2 = \sum_{k=1}^{p+s+1} \|\pi_{n-k+1}\|^2. \tag{C.2}$$

Then it follows from (C.1) and (C.2) that

$$\sum_{k=0}^{n} \|H_{k+1} - L_{k+1}\|^2 = o(n). \tag{C.3}$$

Moreover, as y is strongly exciting with order $p + s + 1$, we have

$$\liminf \lambda_{\min} \left(\frac{1}{n} \sum_{k=0}^{n} y_{k+1}^{p+s+1*} y_{k+1}^{p+s+1} \right) > 0. \tag{C.4}$$

Furthermore, Γ is regular. Hence, if we assume that y_{n+1} is $\mathcal{F}_{n-p-s} \cap \mathcal{F}_{n-r-s}$-measurable, we find, by use of a classical excitation transfer property proved by Duflo [17] or Lai and Wei [25], that

$$\liminf \lambda_{\min} \left(\frac{1}{n} \sum_{k=0}^{n} L_{k+1}{}^* L_{k+1} \right) > 0. \tag{C.5}$$

Then (C.3) together with (C.5) imply

$$\liminf \lambda_{\min} \left(\frac{1}{n} \sum_{k=0}^{n} H_{k+1}{}^* H_{k+1} \right) > 0. \tag{C.6}$$

Now, if we set

$$Q_n = \sum_{k=0}^{n} \Psi_k{}^* \Psi_k + Q, \qquad a_n Q_n \leq Q_n(a) \leq Q_n. \tag{C.7}$$

Hence, by use of the ET Lemma, we find that $n = O(\lambda_{\min} Q_n)$, which implies $na_n = O(\lambda_{\min} Q_n(a))$. In addition, we have already proved that $s_n = O(n)$. Consequently, from the assumption $(a_n s_n)^{-1} = O(a_n)$, we find that $\lambda_{\min} Q_n(a) \to +\infty$. Next, $q_n = O(n)$, so $\log(\lambda_{\max} Q_n(a)) = O(\log(n))$ and $\log(\lambda_{\max} Q_n(a)) = o(\lambda_{\min} Q_n(a))$. Therefore, via a well-known transfer property, we can conclude that $na_n = O(\lambda_{\min} S_n(a))$. Finally, the WLS estimator is strongly consistent and from (24) we obtain the convergence rate given in (44). Moreover, by use of (27), we also find that

$$\sum_{n=0}^{\infty} a_n \|\pi_n\|^2 < +\infty. \tag{C.8}$$

Hence, we obtain, from Kronecker's lemma,

$$\sum_{k=1}^{n} \|\pi_k\|^2 = o(a_n^{-1}). \tag{C.9}$$

Finally, from (34) and (C.9), we obtain the convergence rate given in (42). In addition, we immediately obtain (43) from (C.8). To complete the proof of Theorem 3, we now show that $\|\Phi_n\|^2 = o(n)$. It will clearly lead to $f_n(a) = o(1)_-$. From (C.8), we have $\|\pi_n\|^2 = o(n)$. Then, (33) together with the assumption $\|y_n\|^2 = o(n)$ imply $\|Y_{n+1}\|^2 = o(n)$. Recalling (1) and the causality assumption (A_3), we have

$$U_n = D^{-1}(R) B_+ A(R) Y_{n+1} - D^{-1}(R) B_+ C(R) \varepsilon_{n+1}, \tag{C.10}$$

where R is the shift-back operator. Hence, we can see that $\|U_n\|^2 = o(n)$. Finally $\|\Psi_n\|^2 = o(n)$ and from (21), $\|\Phi_n\|^2 = o(n)$, completing the proof of Theorem 3. □

Appendix D.

Proof of Theorem 5. From the causality assumption (A3), Caines [8] or Guo and Chen [19] proved that we can find a positive constant $\lambda < 1$ such that

$$\|U_{n-1}\|^2 = O(F_n + \alpha_n), \tag{D.1}$$

where

$$F_n = \sum_{k=0}^{n} \lambda^{n-k} \|Y_k\|^2. \tag{D.2}$$

Furthermore, we have from (25) that

$$\|\pi_n\|^2 = o(a_n^{-1} + \|\Phi_n\|^2). \tag{D.3}$$

In addition, (54) and (55) together with (D.1) imply

$$\|Y_{n+1}\|^2 \leq O(\alpha_{n+1}) + O(\|\pi_n\|^2) + \nu_n O(F_{n+1}). \tag{D.4}$$

Therefore, it follows from (21) and (D.1) – (D.4) that

$$\|Y_{n+1}\|^2 \leq O(v_{n+1}) + o(F_{n+1}), \tag{D.5}$$

where $v_n = \alpha_n + a_n^{-1}$. Moreover, as $F_{n+1} = \lambda F_n + \|Y_{n+1}\|^2$, we obtain

$$F_{n+1} \leq \mu F_n + O(v_{n+1}) \tag{D.6}$$

for some positive constant $\mu < 1$. Finally $F_n = O(v_n)$ and we obtain that

$$\|\Phi_n\|^2 = O(v_{n+1}). \tag{D.7}$$

Recalling (55), we also have

$$\|\tilde{\pi}_n\|^2 \leq 2\|\pi_n\|^2 + 2\nu_n \|\Phi_n\|^2. \tag{D.8}$$

Hence, by use of (26) and (D.8), since $\nu = (\nu_n)$ is summable, we find that

$$\sum_{n=0}^{\infty} \frac{\|\tilde{\pi}_n\|^2}{s_n} < +\infty. \tag{D.9}$$

Therefore, as in the proof of Theorem 2, it follows from (D.9) that $s_n = O(n)$. Finally, (56) and (D.9) imply the modified ATC optimality. In addition, it immediately follows from (D.7) that $a_n^{-1} + \|\Phi_n\|^2 = O(v_{n+1})$. Then, we establish from (25) that

$$\sum_{n=0}^{\infty} \frac{\|\tilde{\pi}_n\|^2}{v_{n+1}} < +\infty. \tag{D.10}$$

Finally, (54) and (D.10) together with Kronecker's lemma imply (59) and (60), completing the proof of Theorem 5. □

Appendix E.

Proof of Theorem 6. We prove Theorem 6 using the same approach as Bercu and Duflo [4] in the ARX framework. The exogenous noise ξ satisfies assumption (N_1). Then, as $\lambda_n - \lambda_{n-1} \leq 1$, we obtain, by use of Chow's lemma,

$$\sum_{n=1}^{\infty} \lambda_n^{-1}(\lambda_n - \lambda_{n-1})(\xi_n {}^*\xi_n - \Lambda) < +\infty. \tag{E.1}$$

But $\chi_n = \sqrt{\lambda_n - \lambda_{n-1}}\,\xi_n$, so (E.1) implies immediately that

$$\sum_{n=1}^{\infty} \lambda_n^{-1}(\chi_n {}^*\chi_n - (\lambda_n - \lambda_{n-1})\Lambda) < +\infty. \tag{E.2}$$

Then, as $\lambda = (\lambda_n)$ increases to infinity, we obtain, by Kronecker's lemma,

$$\frac{1}{\lambda_n}\sum_{k=1}^{n} \chi_k {}^*\chi_k \to \Lambda. \tag{E.3}$$

Since Λ is regular, we immediately obtain from (E.3) that

$$\liminf \lambda_{\min}\left(\frac{1}{\lambda_n}\sum_{k=1}^{n} \chi_k {}^*\chi_k\right) > 0. \tag{E.4}$$

Moreover, as $\|\xi_n\|^2 = O(\alpha_n)$, we also have $\|\chi_n\|^2 = O(\alpha_n)$. Consequently, by use of (62) together with the proof of Theorem 5, we obtain the first relation of (64). Therefore, since $v_n = o(\lambda_n)$, we obtain, from (25),

$$\sum_{k=1}^{n} \|\tilde{\pi}_k\|^2 = o(\lambda_n). \tag{E.5}$$

Set, for $n \geq 0$, ${}^tL_n = ({}^ty_n^{p+s+1} + {}^t\varepsilon_n^{p+s+1} + {}^t\chi_n^{p+s+1}, {}^t\varepsilon_n^{r+s+1})$. Using the notation of the ET Lemma, we obtain, from (62),

$$\|H_{n+1} - L_{n+1}\|^2 = \sum_{k=1}^{p+s+1} \|\tilde{\pi}_{n-k+1}\|^2. \tag{E.6}$$

Then, from (E.5) and (E.6), we obtain

$$\sum_{k=0}^{n} \|H_k - L_k\|^2 = o(\lambda_n). \tag{E.7}$$

In addition, by (E.4), we also have

$$\liminf \lambda_{\min}\left(\frac{1}{\lambda_n}\sum_{k=1}^{n} L_k {}^*L_k\right) > 0. \tag{E.8}$$

Finally, (E.7), (E.8), and the ET Lemma imply $\lambda_n = O(\lambda_{\min}Q_n)$. Therefore, as in the proof of Theorem 3, the assumption $(a_n\lambda_n)^{-1} = O(a_n)$ implies $\lambda_n a_n = O(\lambda_{\min}S_n(a))$. Hence, we clearly obtain the second relation of (64). Moreover (68) follows immediately from (24). Recalling (27), (55), and (64), as $v_n = o(\lambda_n)$ and the sequence $(n\nu_n)$ is summable, we also find that

$$\sum_{n=0}^{\infty} a_n\|\tilde{\pi}_n\|^2 < +\infty. \tag{E.9}$$

Then we clearly obtain (65) from (E.9). Finally, we obtain (66) and (67) from (62), (E.3), and (E.5), completing the proof of Theorem 6. □

NONINTERACTION AND STABILITY VIA INVERTIBLE FEEDBACK LAWS AND SOME EXISTENCE CONDITIONS *

S. BATTILOTTI†

Abstract. For a wide class of nonlinear systems with more inputs than outputs, the authors show that the asymptotic stability of suitable dynamics and the asymptotic stabilizability via dynamic state feedback of suitable systems are necessary to achieve noninteraction and stability via *invertible* feedback laws. These conditions generalize some recent results obtained for the same class of systems. Some interesting existence conditions are also given, and relationships with the above necessary conditions are identified.

Key words. noninteraction, stability, invertible feedback laws

AMS subject classification. 93

1. Formulation of the problem.

We consider nonlinear systems

$$\begin{aligned} \dot{x} &= f(x) + \sum_{j=1}^{m} g_j(x)u_j, \\ y_i &= h_i(x), \qquad i = 1, \ldots, p, \end{aligned} \tag{1}$$

where f and g_j are smooth vector fields and h_i are smooth real-valued functions. Moreover, let $x_0 = 0$ and assume that $f(x_0) = 0$ and $dh_1^T(x_0), \ldots, dh_p^T(x_0)$ are linearly independent vectors. By $G(x)$ we denote the matrix $(g_1(x) \ldots g_m(x))$, by u we denote $(u_1 \ldots u_m)^T$ and by $\mathcal{G}$ we denote the distribution span$\{g_1, \ldots, g_m\}$ or, equivalently, span$\{G\}$. Let us denote by kerdh_i the codistribution that assigns at each x the subspace of $\mathbb{R}^n$ $\{v \in \mathbb{R}^n : \langle w, v \rangle = 0 : w \in \text{span}\{dh_i(x)\}\}$, where $\langle \cdot, \cdot \rangle$ is the standard inner product of $\mathbb{R}^n$, and let $\mathcal{K}_i = \text{ker}dh_i$. Moreover, we denote by $L_\tau \varphi$ the Lie derivative of the smooth function φ along the vector field τ. Given smooth vector fields τ_1 and τ_2, we denote by $[\tau_1, \tau_2]$ the Lie bracket of τ_1 with τ_2. For a given vector field τ and covector field ω we denote by $L_\tau \omega$ the Lie derivative of τ along ω. The reader is referred to [1] for an easy introduction to the above concepts. Also, in what follows, we implicitly restrict our analysis to a neighbourhood of x_0.

A distribution Δ is *involutive* if $[\tau_1, \tau_2] \subset \Delta$ for any $\tau_1, \tau_2 \in \Delta$. A distribution Δ is *invariant* under a vector field τ if $[\Delta, \tau] \subset \Delta$, where $[\Delta, \tau]$ is the distribution spanned by the vector fields $[v, \tau]$ and v, with $v \in \Delta$. Let $\langle f, g_1, \ldots, g_m | \text{span}\{g_i : i \in I\} \rangle$, with $I \subset \{1, \ldots, m\}$, be the smallest distribution that is invariant under $f, g_1, \ldots, g_m$ and contains span$\{g_i : i \in I\}$. Moreover, let $\mathcal{R}_0 = \langle f, g_1, \ldots, g_m | \text{span}\{G\} \rangle$. It is easy to show that $\mathcal{R}_0$ is invariant under feedback laws $u = \alpha(x) + \beta(x)v$, with $\beta(x_0)$ invertible.

A distribution Δ is *controlled invariant* for (1) if $[f, \Delta] \subset \Delta + \mathcal{G}$ and $[g_j, \Delta] \subset \Delta + \mathcal{G}$, $j = 1, \ldots, m$. A distribution Δ is a *controllability distribution* for (1) if it is involutive and there exist a feedback law $u = \alpha(x) + \beta(x)v$, with $\beta(x)$ nonsingular, and a subset $I \subset \{1, \ldots, m\}$ such that $\Delta = \langle f + G\alpha, G\beta_1, \ldots, G\beta_m | \text{span}\{g\beta_j : j \in I\} \rangle$, where β_j is the jth column of the matrix β.

The system (1) is said to be *noninteractive* if there exists a partition $u_{I_1}, \ldots, u_{I_{p+1}}$ of the input vector u, with $I_i \subset \{1, \ldots, m\}$ and $I_i \cap I_j = \{\phi\}$ for $j \neq i$, $i = 1, \ldots, p+1$, such that the ith output is influenced only by u_s with $s \in I_i$. Note that the inputs u_s, $s \in I_{p+1}$, do not influence any output. The system (1) is said to be *noninteractive with stability* if it is

† Dipartimento di Informatica e Sistemistica, Università degli Studi di Roma "La Sapienza," Via Eudossiana 18, 00184 Roma, Italy.

noninteractive and locally asymptotically stable in x_0 (in the sense of Lyapunov). If (1) is not noninteractive with stability, we can try to modify its behaviour through suitable feedback laws so as to achieve these properties, while preserving the affine structure of the system and its equilibrium point. Toward this end, we consider dynamic feedback laws of the form

$$\begin{aligned} u =&\ \alpha(x,w)+\beta(x,w)v, \\ \dot{w} =&\ \delta(x,w)+\gamma(x,w)v, \qquad w\in\mathbb{R}^{n^w}, \end{aligned} \tag{2}$$

with $\alpha(0,0)=0$, $\delta(0,0)=0$. Moreover, for any (block) partition $v_1,\dots,v_{p+1}$ of the input vector v let $(\beta_1(x,w)\dots\beta_{p+1}(x,w))$ and $(\gamma_1(x,w)\dots\gamma_{p+1}(x,w))$ be the corresponding partition of $\beta(x,w)$ and $\gamma(x,w)$, respectively. If $n^w=0$, we obtain *static* feedback laws. We say that a static feedback law $u=\alpha(x)+\beta(x)v$ is *regular* at x_0 if the matrix $\beta(x_0)$ is invertible. Also, we say that a feedback law (2) is *invertible* if the system

$$\begin{aligned} &u=\alpha(x,w)+\beta(x,w)v, \\ &\dot{x}=f(x)+G(x)\alpha(x,w)+G(x)\beta(x,w)v, \\ &\dot{w}=\delta(x,w)+\gamma(x,w)v, \qquad w\in\mathbb{R}^{n^w} \end{aligned} \tag{3}$$

is invertible in the sense of Singh [2]. In the linear case, this amounts to requiring that the transfer function matrix associated with (3) has rank m. This class of feedback laws has been considered for the first time in the case of nonlinear systems in [3]. In what follows, we assume that the open and dense set, on which a given feedback law is invertible, contains the origin of the state space.

Next, we formulate the problem of achieving noninteracting control with stability via dynamic feedback. To this end, first we consider the additional dynamics (the clever trick was first introduced in [4] for linear systems)

$$\dot{w}=u^w, \qquad w\in\mathbb{R}^{n^w},$$

where u^w are auxiliary inputs, and define the extended system

$$\begin{aligned} &\dot{x}=f(x)+G(x)u, \\ &\dot{w}=u^w, \\ &y_i=h_i(x), \qquad i=1,\dots,p. \end{aligned} \tag{4}$$

If we set

$$x^e=\begin{pmatrix}x\\w\end{pmatrix},\quad x^e_0=\begin{pmatrix}x_0\\w_0\end{pmatrix}=\begin{pmatrix}0\\0\end{pmatrix},\quad u^e=\begin{pmatrix}u\\u^w\end{pmatrix},$$

$$f^e(x^e)=\begin{pmatrix}f(x)\\0_{n^w\times 1}\end{pmatrix},\quad G^e(x^e)=\begin{pmatrix}G(x) & 0_{n\times n^w}\\ 0_{n^w\times m} & I_{n^w\times n^w}\end{pmatrix},\qquad h^e_i(x^e)=h_i(x),$$
$$i=1,\dots,p,$$

where 0 and I are, respectively, the zero and identity matrices and the subscripts denote the dimensions of these matrices, then (4) can be rewritten in the following form:

$$\begin{aligned} \dot{x}^e =&\ f^e(x^e)+G^e(x^e)u^e, \\ y_i =&\ h^e_i(x^e), \qquad i=1,\dots,p. \end{aligned} \tag{5}$$

Moreover,

$$\mathcal{G}^e = \operatorname{span}\{G^e\}, \quad \mathcal{G}^w = \operatorname{span}\{\partial/\partial w\}, \quad \mathcal{K}_i^e = \ker dh_i^e.$$

According to our notation, let

$$\begin{aligned}\tilde{f}^e(x^e) &= f^e(x^e) + G^e(x^e)\begin{pmatrix}\alpha(x^e)\\ \delta(x^e)\end{pmatrix},\\ \tilde{g}_j^e(x^e) &= G^e(x^e)\begin{pmatrix}\beta_j(x^e)\\ \gamma_j(x^e)\end{pmatrix}, \qquad j = 1,\ldots,p+1,\\ \tilde{G}^e(x^e) &= (\tilde{g}_1^e(x^e)\ldots\tilde{g}_{p+1}^e(x^e)),\end{aligned}$$

and denote by $\tilde{\Sigma}^e$ the corresponding closed-loop system (1), (2). If $n^w = 0$, i.e., the feedback law is *static*, the superscript "*e*" in the above notation will be omitted. Moreover, by stability or stabilizability of a given system we mean stability and, respectively, stabilizability at the origin of its state space.

LND (local noninteracting control via dynamic state feedback). *Find* n^w *and a feedback law* (2) *such that* $\tilde{\Sigma}^e$ *is noninteractive and has vector relative degree at* x_0^e.

LNSD (local noninteracting control with stability via dynamic state feedback). *Find* n^w *and a feedback law* (2) *such that* $\tilde{\Sigma}^e$ *is noninterative, locally asymptotically stable in* x_0^e, *and has vector relative degree at* x_0^e.

The requirement of vector relative degree at x_0^e ensures that at least one input u_s for some $s \in I_i$ *does* influence the ith output (for a definition of vector relative degree see [1]).

In [5] and, more completely, in [6], using a necessary condition proved in [7], the problem of noninteracting control with stability has been completely solved for a wide class of nonlinear systems (1) with $m = p$. This class consists of the systems (1), with $m = p$, such that *noninteraction* can be achieved via static state feedback laws, *regular* at x_0, or, equivalently, the systems that have vector relative degree at x_0. A necessary and sufficient condition to achieve *noninteraction* and *stability* for this class of systems via *invertible* dynamic state feedback is that a suitable dynamics Σ_0 be asymptotically stable and certain systems Σ_i, $i = 1,\ldots,m$, be asymptotically stabilizable via dynamic state feedback law. As shown in [7], the dynamics Σ_0 is the *nonlinear* obstruction to achieve noninteraction and stability via dynamic feedback. In the case of linear systems it is indeed a trivial dynamics. By combining the results contained in [8] and [6], it is not hard to show that for a given nonlinear system (1), with $m = p$, *noninteraction* and *stability* can be achieved via dynamic state feedback law if and only if *noninteraction* can be achieved for (1) via dynamic state feedback law and *noninteraction* and *stability* can be achieved via dynamic state feedback law for a *canonical* system, which has vector relative degree at the origin of its state space and it is obtained from (1) through a *canonical* dynamic extension. This extension is *canonical* in the sense that any other system, obtained from (1) and having vector relative degree at the origin of its state space, can be obtained from the canonical extension of (1) through invertible feedback laws. This impressively generalizes a well-known result for linear systems ([4] and [9]), which states that for a given linear system *noninteraction* and *stability* can be achieved via dynamic state feedback law if and only if *noninteraction* can be achieved via dynamic state feedback law for the system itself. Indeed, as can be easily proved, *noninteraction* and *stability* can always be achieved for the canonical dynamic extension, as defined in [8], of a given linear system.

In [10] the definition of Σ_0 and Σ_i (in this case, the number of these systems is p) has been extended to the case of nonlinear systems with block-partitioned outputs, for which *noninteraction* can be achieved by means of static state feedback laws, which are *regular* at x_0. These systems are such that the controllability distributions $\mathcal{R}_1^*,\ldots,\mathcal{R}_p^*$, where $\mathcal{R}_i^*$ is the maximal controllability distribution for (1) contained in $\cap_{j\neq i}\mathcal{K}_j$ (see [1]), are *compatible* or, equivalently, there is a static feedback law $u=\alpha(x)+\beta(x)v$, regular at x_0, and a (block) partition $\beta_1(x),\dots,\beta_{p+1}(x)$ of $\beta(x)$ such that $\mathcal{R}_i^*=\langle f+G\alpha, G\beta_1,\dots,G\beta_{p+1}|\mathrm{span}\{G\beta_i,G\beta_{p+1}\}\rangle$ and $\mathrm{span}\{G\beta_i,G\beta_{p+1}\}=\mathcal{R}_i^*\cap\mathcal{G}$ for $i=1,\dots,p$ (note that here we abused the notation, since $G\beta_i$ is, in general, a matrix). This class of systems has been characterized from a geometric point of view in [11]. If $m=p$, the set of distributions $\mathcal{R}_1^*,\dots,\mathcal{R}_p^*$ is the *only* set of controllability distributions that is compatible. Moreover, in this case it is not hard to show that the systems Σ_0 and Σ_i, $i=1,\dots,p$, can be *uniquely* (up to static feedback transformation, regular at x_0, and local changes of coordinates) associated to (1). If $m>p$ this uniqueness property is lost (for an idea of the proof, see [11]) and Σ_0 and Σ_i, $i=1,\dots,p$, are *uniquely* (up to static feedback transformation, regular at x_0, and local changes of coordinates) associated to (1), once a set of compatible controllability distributions $\mathcal{R}_1,\dots,\mathcal{R}_p$ is chosen (not necessarily the *maximal* one). Many interesting interrelated properties can be found among the systems Σ_0 and Σ_i, $i=1,\dots,p$, associated to the maximal set $\mathcal{R}_1^*,\dots,\mathcal{R}_p^*$, and those correspondingly associated to a given set of compatible controllability distributions $\mathcal{R}_1,\dots,\mathcal{R}_p$, but this will be pursued elsewhere. For clarity of exposition, we denote by Σ_0^* and Σ_i^*, $i=1,\dots,p$, the systems (uniquely in the above sense) associated to the maximal set $\mathcal{R}_1^*,\dots,\mathcal{R}_p^*$.

In [10] it is also proved that for the above class of systems the asymptotic stability of Σ_0^*, plus the *exponential* stabilizability of the systems Σ_i^*, $i=1,\dots,p$, and of a suitable system Σ_{p+1}^* (which is trivial in the case $m=p$), are sufficient to achieve *noninteraction* and *stability* via dynamic state feedback law. More generally, for the same class of systems with block-partitioned outputs, it is not hard to show that the asymptotic stability of Σ_0^* and the *asymptotic* stabilizability via dynamic state feedback laws of the systems Σ_i^*, $i=1,\dots,p$, are *necessary* to achieve noninteraction and stability via dynamic feedback laws, *regular* in the sense of [13]. There is no apparent relation between this class of feedback laws and the well-known class of invertible feedback laws. Conversely, it is easy to see that the asymptotic stability of Σ_0^* and the *asymptotic* stabilizability of the systems Σ_i^*, $i=1,\dots,p+1$, are also *sufficient* to achieve *noninteraction* and *stability* via regular dynamic state feedback law. Unfortunately, as shown by a counterexample in [13], the *asymptotic* stabilizability of Σ_{p+1}^* via dynamic feedback law is *not* necessary to achieve noninteraction and stability even via *invertible* dynamic feedback laws. This fact, together with the generic nontriviality of Σ_0^*, gives an estimate of how the linear case may differ from the nonlinear case. Indeed, for linear systems, the asymptotic stabilizability of Σ_{p+1}^* is automatically guaranteed by its very definition. Yet, for the class of systems for which Σ_{p+1}^* is trivial, we obtain a set of necessary and sufficient conditions, which generalize the ones given in [6].

In this paper, for the class of nonlinear systems (1), for which *noninteraction* can be achieved via static state feedback laws, regular at x_0, we show that the asymptotic stability of Σ_0^* and the *asymptotic* stabilizability via dynamic state feedback of the systems Σ_i^*, $i=1,\dots,p$, are *necessary* to achieve noninteraction and stability via *invertible* feedback laws (Theorem 4). This generalizes the result given in [7] (and, partially, the results given in [4] and [9] for linear systems). Moreover, our result shows that (a) for the class of systems here considered any invertible feedback law, which solves LND, is also *regular* in the sense of [13], filling the gap between the class of invertible feedback laws and the class of feedback laws, regular in the sense of [13]; (b) any invertible feedback law that solves LND can be expressed as the cascade of a *static* feedback law, regular at x_0, together with an *invertible noninteraction* feedback law (see Definition 9).

A main difficulty of the problem solved in this paper is to show that the controllability distributions $\mathcal{R}_i^e=\langle\tilde{f}^e,\tilde{g}_1^e,\dots,\tilde{g}_{p+1}^e|\mathrm{span}\{\tilde{g}_i^e,\tilde{g}_{p+1}^e\}\rangle$, $i=1,\dots,p$, defined on $\mathbb{R}^{n+n^w}$, project down to well-defined controllability distributions defined on $\mathbb{R}^n$ (see the proof of Theorem 4). This is actually not needed when studying the problem of achieving noninteraction *without stability* (in this case our result is apparently trivial, since decoupling can be achieved via *static* state feedback by assumption), while it becomes essential when addressing the issue of stability. Indeed, this fact allows us to derive stabilizability properties of systems defined on the original state space from stability properties of systems defined on the extended state space. The above property of projection is guaranteed by Proposition 2 and Lemma 3, which is based on the algorithm (18). Among others, one consequence of our result is to connect explicitly the invertibility of the feedback laws, which solve NLD, with a geometric property, given in terms of the algorithm (18). Moreover, this algorithm gives a more general and intuitively geometric version of the one given in [13]. We note once again that the class of systems considered here can always be rendered noninteractive but not necessarily with internal stability. The main result of this paper is to give necessary conditions for also achieving internal stability.

Some interesting existence conditions are also given (§4). Among others, one result is that if noninteraction and stability can be achieved via dynamic feedback laws, which are possibly *noninvertible*, for each $i \in \{1, \dots, p\}$ there must exist a dynamic feedback law that asymptotically stabilizes Σ_i^* on a suitable *invariant submanifold* $\mathcal{M}^i$ of the state space of the system, resulting from Σ_i^* after applying this feedback law, and transversal to the submanifold $h_i^{-1}(0)$. This manifold depends, in general, on the decoupling feedback law, except in some significant cases (one is the case in which we consider *invertible* feedback laws).

2. Some preliminary results.

Before going through the technical details, we give some basic assumptions. In a natural way, as long as we are interested in necessary conditions, we will assume that (1) is locally asymptotically stabilizable at the origin. Let $\mathcal{V}_i^*$ be the maximal controlled invariant distribution for (1) which is contained in $\cap_{j \neq i} \mathcal{K}_j$, $\mathcal{R}_i^*$ be the maximal controllability distribution for (1) contained in $\cap_{j \neq i} \mathcal{K}_j$, $\mathcal{Q}^*$ be the maximal controllability distribution for (1) contained in $\mathcal{R}^* = \cap_{i=1}^{p} \sum_{j \neq i} \mathcal{R}_j^*$ and $\mathcal{R}_0$ be as above. These distributions can be computed by means of standard algorithms [1], which give a sequence of distributions. If these distributions have constant dimension, we will say that $\mathcal{V}_i^*$ (respectively, $\mathcal{R}_i^*$, $\mathcal{Q}^*$ or $\mathcal{R}_0$) are *regularly computable* at x_0. We make the following assumptions.

(H1) $\dim \mathcal{R}_0 = n$;

(H2) the distributions $\mathcal{R}_0$, $\mathcal{V}_i^*$, $\mathcal{R}_i^*$, $i = 1, \dots, p$, and $\mathcal{Q}^*$ are regularly computable at x_0;

(H3) the distributions $\mathcal{R}^*$, $\sum_j \mathcal{R}_j^*$, $(\sum_j \mathcal{R}_j^*) \cap \mathcal{G}$ and $\sum_j (\mathcal{R}_j^* \cap \mathcal{G})$ have constant dimension;

(H4) $\sum_{i=1}^{p} (\mathcal{R}_i^* \cap \mathcal{G}) = \mathcal{G}$.

Assumption (H1) is standard, and, under assumptions (H1)–(H3), assumption (H4) is a well-known necessary and sufficient condition to solve LND via static state feedback laws, regular at x_0 ([11]). It can be easily shown that (H4) is equivalent, under the assumption of constant dimensions of the distributions considered, to the fact that (1) has vector relative degree at x_0.

As in [12], we will use the following terminology. Let $\mathcal{R}_1, \dots, \mathcal{R}_p$ be a set of controllability distributions for (1), such that $\mathcal{R}_i \subset \cap_{j \neq i} \mathcal{K}_j$. Moreover, let $\mathcal{Q}$ be the maximal controllability distribution for (1) contained in $\mathcal{R} = \cap_{i=1}^{p} \sum_{j \neq i} \mathcal{R}_i$ (supposed to exist). We will say that $\mathcal{R}_1, \dots, \mathcal{R}_p$ is a *regular set* (in x_0) if (a) the distributions $\mathcal{Q}$, $\mathcal{Q} \cap \mathcal{G}$, $\sum_j \mathcal{R}_j$, $\mathcal{R}$, $(\sum_j \mathcal{R}_j) \cap \mathcal{G}$ and $\sum_j (\mathcal{R}_j \cap \mathcal{G})$ have constant dimension. If a regular set $\mathcal{R}_1, \dots, \mathcal{R}_p$ is such that (b) $\sum_{i=1}^{p} (\mathcal{R}_i \cap \mathcal{G}) = \mathcal{G}$, we will say that $\mathcal{R}_1, \dots, \mathcal{R}_p$ is a *regular solution* (of LND). Indeed, if the regular set $\mathcal{R}_1, \dots, \mathcal{R}_p$ satisfies (b), by standard arguments it can be shown that there exists a static feedback law $u = \alpha(x) + \beta(x)v$, regular at x_0, such that

$$\mathcal{R}_i = \langle \tilde{f}, \tilde{g}_1, \ldots, \tilde{g}_{p+1} | \mathrm{span}\{\tilde{g}_i, \tilde{g}_{p+1}\}\rangle, \qquad i = 1, \ldots, p,$$

$$\sum_{j \neq i} \mathcal{R}_j = \langle \tilde{f}, \tilde{g}_1, \ldots, \tilde{g}_{p+1} | \mathrm{span}\{\tilde{g}_j : j \neq i\}\rangle, \qquad i = 1, \ldots, p,$$

$$\sum_{j=1}^{p} \mathcal{R}_j = \mathcal{R}_0 = \langle \tilde{f}, \tilde{g}_1, \ldots, \tilde{g}_{p+1} | \mathrm{span}\{\tilde{g}_j : j = 1, \ldots, p+1\}\rangle,$$

$$\mathrm{span}\{\tilde{g}_i, \tilde{g}_{p+1}\} = \mathcal{R}_i \cap \mathcal{G}, \qquad i = 1, \ldots, p$$

(see [1], [11]–[13]). By Frobenius' theorem, since $\sum_{j \neq i} \mathcal{R}_j$, $i = 1, \ldots, p$, is involutive and invariant under $\tilde{f}$ and $\tilde{g}_j$, $j = 1, \ldots, p+1$, it is always possible to find a change of coordinates $z(x) = ((z_1(x))^T \ldots (z_{p+2}(x))^T)^T$ such that the system $\tilde{\Sigma}$, obtained from (1) with $u = \alpha(x) + \beta(x)v$, in the new coordinates has the form

$$\begin{aligned} \dot{z}_i &= \tilde{f}_i(z_i) + \tilde{g}_{ii}(z_i)v_i, \qquad i = 1, \ldots, p, \\ \dot{z}_{p+1} &= \tilde{f}_{p+1}(z_1, \ldots, z_p, z_{p+1}) + \sum_{j=1}^{p} \tilde{g}_{p+1,j}(z_1, \ldots, z_p, z_{p+1})v_j, \\ \dot{z}_{p+2} &= \tilde{f}_{p+2}(z_1, \ldots, z_{p+2}) + \sum_{j=1}^{p+1} \tilde{g}_{p+2,j}(z_1, \ldots, z_{p+2})v_j, \\ y_i &= h_i(z_i), \qquad i = 1, \ldots, p, \end{aligned} \tag{6}$$

with $\sum_{j \neq i} \mathcal{R}_j = \mathrm{span}\{\partial/\partial z_j : j \neq i\}$ and $\mathcal{Q} = \mathrm{span}\{\partial/\partial z_{p+2}\}$. In what follows, for simplicity let $z = x$ and $v = u$. Moreover, we assume that (1) is already in the form (6).

Next, we define some suitable dynamics that are crucial in all the subsequent analysis. First, let us introduce the following distribution. Let $\mathcal{I}$ be the Lie ideal generated by the vector fields $\{[\tilde{g}_i, ad_{\tilde{f}}^k \tilde{g}_j] : k \geq 0,\ i, j = 1, \ldots, p;\ i \neq j\}$ in the Lie algebra generated by $\tilde{f}, \tilde{g}_1, \ldots, \tilde{g}_{p+1}$ and let

$$\Delta_{MIX} = \mathrm{span}\{\tau : \tau \in \mathcal{I}\}. \tag{7}$$

The distribution (7) was first introduced in [10]. It is not hard to show that $\Delta_{MIX} \subset \mathcal{R} \subset \mathcal{R}_i$. Moreover, for linear systems $\Delta_{MIX} = 0$. The distribution $\Delta_{MIX} + \mathcal{Q}$ is *uniquely* associated to (1) and to the regular solution $\mathcal{R}_1, \ldots, \mathcal{R}_p$, in the sense that its definition is invariant under local change of coordinates and static feedback transformations, regular at x_0 (see [10]). Assume that the distributions $\Delta_{MIX} + \mathcal{Q}$, $\mathcal{R}_i + \Delta_{MIX}$ and $\mathcal{R} \cap (\mathcal{R}_i + \Delta_{MIX})$ have constant dimension. In what follows, we will assume that a regular set satisfies these additional assumptions.

By Frobenius' theorem, for each $i \in \{1, \ldots, p\}$ there exists a change of coordinates

$$z^i(x) = (x_1^T \ldots x_{i-1}^T\, x_{i+1}^T \ldots x_p^T\, (z_1^i(x))^T \ldots (z_5^i(x))^T)^T,$$

such that

$$\begin{aligned} \mathcal{R}_i + \mathcal{R} &= \mathrm{span}\{\partial/\partial z_1^i, \partial/\partial z_2^i, \partial/\partial z_3^i, \partial/\partial z_4^i, \partial/\partial z_5^i\}, \\ \mathcal{R}_i + \Delta_{MIX} &= \mathrm{span}\{\partial/\partial z_1^i, \partial/\partial z_3^i, \partial/\partial z_4^i, \partial/\partial z_5^i\}, \\ \mathcal{R} &= \mathrm{span}\{\partial/\partial z_2^i, \partial/\partial z_3^i, \partial/\partial z_4^i, \partial/\partial z_5^i\}, \\ \mathcal{R} \cap (\mathcal{R}_i + \Delta_{MIX}) &= \mathrm{span}\{\partial/\partial z_3^i, \partial/\partial z_4^i, \partial/\partial z_5^i\}, \\ \Delta_{MIX} + \mathcal{Q} &= \mathrm{span}\{\partial/\partial z_4^i, \partial/\partial z_5^i\}, \\ \mathcal{Q} &= \mathrm{span}\{\partial/\partial z_5^i\}. \end{aligned}$$

Note that in these coordinates the ith output function h_i depends only on the coordinate(s) z_1^i.

Since $\Delta_{MIX} + \mathcal{Q}$ is involutive and invariant under $\tilde{f}, \tilde{g}_1, \ldots, \tilde{g}_{p+1}$ (see [10] for a proof) and $\tilde{f}(x_0) = 0$, it makes sense to consider the restriction $\tilde{f}|\mathcal{L}_{x_0}^{\Delta_{MIX}+\mathcal{Q}}$, where $\mathcal{L}_{x_0}^{\Delta_{MIX}+\mathcal{Q}}$ is the leaf (or, equivalently, the maximal integral manifold) of $\Delta_{MIX} + \mathcal{Q}$ passing through x_0. This vector field defines a dynamics evolving on $\mathcal{L}_{x_0}^{\Delta_{MIX}+\mathcal{Q}}$, which in z^i-coordinates is given by

$$\begin{aligned} \dot{z}_4^i &= \tilde{f}_{z_4^i}(0, \ldots, 0, z_4^i), \\ \dot{z}_5^i &= \tilde{f}_{z_5^i}(0, \ldots, 0, z_4^i, z_5^i). \end{aligned}$$

Let us consider the subdynamics

$$\dot{z}_4^i = \tilde{f}_{z_4^i}(0, \ldots, 0, z_4^i). \tag{8}$$

The dynamics (8) is trivial in the case of linear systems, since $\Delta_{MIX} = 0$. The dynamics (8), corresponding to the maximal solution $\mathcal{R}_1^*, \ldots, \mathcal{R}_p^*$, has been referred to as Σ_0^* in the introduction. If $m = p$, under assumptions (H1)–(H4), $\mathcal{Q}^* = 0$, where $\mathcal{Q}^*$ is the maximal controllability distribution contained in $\mathcal{R}^*$, since otherwise the decoupling matrix of (1) would not be invertible at x_0 and, as a consequence, (1) would not have vector relative degree at x_0. Thus, if $m = p$, the dynamics (8) coincides with Σ_0^*, as defined in [7] or, equivalently, in [6].

Similarly, for each $i = 1, \ldots, p$, it makes sense to consider also the restrictions $\tilde{f}|\mathcal{L}_{x_0}^{\mathcal{R}_i+\Delta_{MIX}}$ and $\tilde{g}_i|\mathcal{L}_{x_0}^{\mathcal{R}_i+\Delta_{MIX}}$ (note that by definition $\tilde{g}_i \in \mathcal{R}_i$). These vector fields define a control system evolving on $\mathcal{L}_{x_0}^{\mathcal{R}_i+\Delta_{MIX}}$, expressed in z^i-coordinates by

$$\begin{pmatrix} \dot{z}_1^i \\ \dot{z}_3^i \\ \dot{z}_4^i \\ \dot{z}_5^i \end{pmatrix} = \begin{pmatrix} \tilde{f}_{z_1^i}(0, \ldots, 0, z_1^i) \\ \tilde{f}_{z_3^i}(0, \ldots, 0, z_1^i, 0, z_3^i) \\ \tilde{f}_{z_4^i}(0, \ldots, 0, z_1^i, 0, z_3^i, z_4^i) \\ \tilde{f}_{z_5^i}(0, \ldots, 0, z_1^i, 0, z_3^i, z_4^i, z_5^i) \end{pmatrix} + \begin{pmatrix} \tilde{g}_{z_1^i,i}(0, \ldots, 0, z_1^i) \\ \tilde{g}_{z_3^i,i}(0, \ldots, 0, z_1^i, 0, z_3^i) \\ \tilde{g}_{z_4^i,i}(0, \ldots, 0, z_1^i, 0, z_3^i, z_4^i) \\ \tilde{g}_{z_5^i,i}(0, \ldots, 0, z_1^i, 0, z_3^i, z_4^i, z_5^i) \end{pmatrix} u_i.$$

Let us consider the subsystem

$$\begin{pmatrix} \dot{z}_1^i \\ \dot{z}_3^i \end{pmatrix} = \begin{pmatrix} \tilde{f}_{z_1^i}(0, \ldots, 0, z_1^i) \\ \tilde{f}_{z_3^i}(0, \ldots, 0, z_1^i, 0, z_3^i) \end{pmatrix} + \begin{pmatrix} \tilde{g}_{z_1^u,i}(0, \ldots, 0, z_1^i) \\ \tilde{g}_{z_3^i,i}(0, \ldots, 0, z_1^i, 0, z_3^i) \end{pmatrix} u_i. \tag{9}$$

In the case of linear systems, (9) is a controllable system, since $\Delta_{MIX} = 0$ and $\mathcal{R}_i$ is a controllability subspace. Each system (9), corresponding to the maximal solution $\mathcal{R}_1^*, \ldots, \mathcal{R}_p^*$, has been referred to as Σ_i^* in the Introduction.

Last but not least, we consider the system

$$\dot{z}_5^i = \tilde{f}_{z_5^i}(0, \ldots, 0, z_5^i) + \tilde{g}_{z_5^i,p+1}(0, \ldots, 0, z_5^i)u_{p+1}, \tag{10}$$

which is obtained by considering the restrictions $\tilde{f}|\mathcal{L}_{x_0}^{\mathcal{Q}}$ and $\tilde{g}_{p+1}|\mathcal{L}_{x_0}^{\mathcal{Q}}$ (note that $\tilde{g}_{p+1} \in \mathcal{Q}$). The system (10), corresponding to the maximal solution $\mathcal{R}_1^*, \ldots, \mathcal{R}_p^*$, has been referred to as Σ_{p+1}^* in the Introduction.

It can be easily shown that the dynamics (8)–(10) are *uniquely* associated to (1) and to a given regular solution, in the sense that their definition is independent of static feedback transformations, regular at x_0, and local changes of coordinates.

3. Noninteraction and stability via invertible feedback laws. Let us consider the system (1) (which is assumed to be already in the form (6)) with $\mathcal{R}_i = \mathcal{R}_i^*$. Moreover, let Δ_{MIX}^* be the distribution (7), defined correspondingly to the maximal solution $\mathcal{R}_1^*, \dots, \mathcal{R}_p^*$. As previously noted, the distribution $\Delta_{MIX}^* + \mathcal{Q}^*$ is *uniquely* associated to $\mathcal{R}_1^*, \dots, \mathcal{R}_p^*$ up to local changes of coordinates and static feedback transformations, regular at x_0.

(H5) The distributions $\Delta_{MIX}^* + \mathcal{Q}^*$, $\mathcal{R}_i^* + \Delta_{MIX}^*$ and $\mathcal{R}^* \cap (\mathcal{R}_i^* + \Delta_{MIX}^*)$ have constant dimension.

In this section we prove that for the class of systems here considered the asymptotic stability of Σ_0^* and the asymptotic stabilizability via dynamic feedback law of each system Σ_i^* are necessary to achieve noninteraction and stability via *invertible* feedback laws. To this end, let $(\mathcal{V}_i^e)^*$ be the maximal distribution that is contained in $\cap_{j \neq i} \mathcal{K}_j^e$ and such that $[\tilde{f}^e, (\mathcal{V}_i^e)^*] \subset (\mathcal{V}_i^e)^* + \mathcal{G}^e$ and $[\tilde{g}_j^e, (\mathcal{V}_i^e)^*] \subset (\mathcal{V}_i^e)^* + \mathcal{G}^e$, with $j = 1, \dots, p+1$. This distribution always exists, since, given two distributions $\mathcal{V}_1$ and $\mathcal{V}_2$ that satisfy the above properties, $\mathcal{V}_1 + \mathcal{V}_2$ also has these properties. Thus, the maximal distribution, which satisfies the above properties, is given by the sum of all the distributions with such properties. As a preliminary result, we prove the following lemma.

LEMMA 1. *Under assumptions* (H1)–(H4), *we have*

$$(\mathcal{V}_i^e)^* = \mathcal{V}_i^* + \mathcal{G}^w,$$

where $\mathcal{V}_i^*$ is thought of as a distribution of $\mathbb{R}^{n+n^w}$.

Proof. Let $(\mathbb{R}^s)^*$ be the dual of $\mathbb{R}^s$. For any smooth codistribution $\Omega \subset (\mathbb{R}^s)^*$, denote by $(\Omega)^\perp$ the distribution that assigns at each point $p \in \mathbb{R}^s$ the subspace $\{v \in \mathbb{R}^s : \langle w, v \rangle = 0, w \in \Omega(p)\}$. Let us consider the following sequence of codistributions

$$\begin{aligned} \tilde{\Omega}_{i0}^e &= \sum_{j \neq i} \operatorname{span}\{dh_j^e\}, \\ \tilde{\Omega}_{ik}^e &= L_{\tilde{f}^e}(\tilde{\Omega}_{i,k-1}^e \cap (\mathcal{G}^e)^\perp) + \sum_{j=1}^{p+1} L_{\tilde{g}_j^e}(\tilde{\Omega}_{i,k-1}^e \cap (\mathcal{G}^e)^\perp) + \tilde{\Omega}_{i,k-1}^e. \end{aligned} \tag{11}$$

Using essentially the same arguments as [1, Lem. 6.3.2], it is not hard to show that, if there exists $k_i^* \geq 0$ such that $\tilde{\Omega}_{i,k_i^*}^e = \tilde{\Omega}_{i,k_i^*+1}^e$ and $\tilde{\Omega}_{i,k_i}^e$ and $\tilde{\Omega}_{i,k_i}^e \cap (\mathcal{G}^e)^\perp$ have constant dimension for all k, we have $(\tilde{\Omega}_{ik_i^*}^e)^\perp = (\mathcal{V}_i^e)^*$. Moreover, if $\tilde{\Omega}_{ik}^e = \tilde{\Omega}_{i,k+1}^e$ for some $k \geq 0$, then $\tilde{\Omega}_{ik}^e = \tilde{\Omega}_{ih}^e$ for all $h > k$.

To prove the lemma, we will show that there exists $k_i^* \geq 0$ such that $\tilde{\Omega}_{i,k_i^*}^e = \tilde{\Omega}_{i,k_i^*+1}^e = \mathcal{V}_i^* + \mathcal{G}^w$, where $\mathcal{V}_i^*$ is thought of as a distribution of $\mathbb{R}^{n+n^w}$, and that $(\tilde{\Omega}_{ik}^e)^\perp$ and $\tilde{\Omega}_{ik}^e \cap (\mathcal{G}^e)^\perp$ have constant dimension for all k. For Ω_{i0}^e has constant dimension in a neighbourhood of x_0^e. The codistribution $\tilde{\Omega}_{i0}^e \cap (\mathcal{G}^e)^\perp$ is spanned at each x^e by the rows of $\tilde{\Omega}_{i0}^e(x^e)$ that annihilate the vectors of $\mathcal{G}^e(x^e)$. Since $\tilde{\Sigma}^e$ has vector relative degree at x_0^e, $\tilde{\Omega}_{i0}^e \cap (\mathcal{G}^e)^\perp$ is spanned by the covector fields $dh_{j_l}^e$, $j_l \in \{1, \dots, i-1, i+1, \dots, p\}$, such that $\langle dh_{j_l}^e, G^e \rangle (x^e) = 0$. Since $L_{\tilde{f}^e} dh_{j_l}^e = dL_{\tilde{f}^e} h_{j_l}^e$ and $L_{\tilde{g}_j^e} dh_{j_l}^e = dL_{\tilde{g}_j^e} h_{j_l}^e$, it follows that $L_{\tilde{f}^e}(\tilde{\Omega}_{i0}^e \cap (\mathcal{G}^e)^\perp) = L_{f^e}(\tilde{\Omega}_{i0}^e \cap (\mathcal{G}^e)^\perp)$ and $L_{\tilde{g}_i^e}(\tilde{\Omega}_{i0}^e \cap (\mathcal{G}^e)^\perp) = 0$ for $j = 1, \dots, p+1$. Suppose now that for some $k > 0$ the codistribution $\tilde{\Omega}_{ik}^e$ has constant dimension in a neighbourhood of x_0^e and that $\tilde{\Omega}_{ik}^e \cap (\mathcal{G}^e)^\perp$ is spanned by the covector fields $dL_{f^e}^{k_{j_l}} h_{j_l}^e$, $j_l \in \{1, \dots, i-1, i+1, \dots, p\}$, such that $\langle dL_{f^e}^{k_{j_l}} h_{j_l}^e, G^e \rangle (x^e) = 0$ for all k_l such that $0 \leq k_{j_l} \leq \max\{k, r_{j_l} - 2\}$ ($r_1, \dots, r_p$ is the vector relative degree of (1)). Similarly, we have $L_{\tilde{f}^e}(\tilde{\Omega}_{ik}^e \cap (\mathcal{G}^e)^\perp) = L_{f^e}(\tilde{\Omega}_{ik}^e \cap (\mathcal{G}^e)^\perp)$ and $L_{\tilde{g}_j^e}(\tilde{\Omega}_{ik}^e \cap (\mathcal{G}^e)^\perp) = 0$ for $j = 1, \dots, p+1$. Since Σ^e has vector relative degree at x_0^e, the codistribution $\tilde{\Omega}_{i,k+1}^e$ has always constant dimension in a neighbourhood of x_0^e (see [1, Lem. 5.12] for a proof). Clearly $\tilde{\Omega}_{i,k+1}^e \cap (\mathcal{G}^e)^\perp$ is spanned by the covector fields $dL_{f^e}^{k_{j_l}} h_{j_l}^e$, $j_l \in \{1, \dots, i-1, i+1, \dots, p\}$, such that $\langle dL_{f^e}^{k_l} h_{j_l}^e, G^e \rangle (x^e) = 0$ for all k_{j_l} such that $0 \leq k_{j_l} \leq \max\{k+1, r_{j_l} - 2\}$. The algorithm (11) stops for $k = k_i^* = \max_i\{r_i\}$ -1, when $\tilde{\Omega}_{ik_i^*}^e \cap (\mathcal{G}^e)^\perp = \tilde{\Omega}_{i,k_i^*+1}^e \cap (\mathcal{G}^e)^\perp$ and $k_{j_l} = r_{j_l} - 1$, $l = 1, \dots, p$. This, together with the fact that $(\mathcal{V}_i^*)^\perp = \text{span}\{dh_j, \dots, dL_{\tilde{f}}^{r_j - 1} h_j : j \neq i\}$ [1, Cor. 6.3.14], proves our thesis. □

A consequence of the above lemma is the following proposition. Let $\alpha(x, w)$ and $\beta(x, w)$ be partitioned, according to the (block) partitions of the input vectors u and v, respectively, as

$$\alpha(x,w) = (\alpha_1^T(x,w) \cdots \alpha_{p+1}^T(x,w))^T, \qquad \beta(x,w) = (\beta_1(x,w) \cdots \beta_{p+1}(x,w)),$$

$$\beta_j(x,w) = (\beta_{1j}^T \cdots \beta_{p+1,j}^T)^T, \qquad j = 1, \dots, p+1.$$

PROPOSITION 2. *Under assumptions* (H1) – (H4) *we have*

$$B_{ij}(x^e) = 0, \qquad j \neq i,\ i \neq p+1, \tag{12}$$

$$L_{\tilde{g}_j^e} \tilde{D}^e \alpha_i(x^e) = 0, \qquad j \neq i,\ i \neq p+1, \tag{13}$$

$$L_{\tilde{g}_j^e} \tilde{D}^e \beta_{ii}(x^e) = 0, \qquad j \neq i,\ i \neq p+1, \tag{14}$$

where D^e is an arbitrary composition of the Lie derivatives $L_{\tilde{f}^e}$ and $L_{\tilde{g}_j^e}$, $j = 1, \dots, p+1$.

Proof. Combine Lemma 1 above with [13, Lem. 1]. □

Now let us consider an invertible feedback law that solves LNSD for (1). By definition, the system

$$\begin{aligned} u &= \alpha(x,w) + \beta(x,w)v, \\ \dot{x} &= f(x) + G(x)\alpha(x,w) + G(x)\beta(x,w)v, \\ \dot{w} &= \gamma(x,w) + \delta(x,w)v, \end{aligned} \tag{15}$$

with (1) given by $\dot{x} = f(x) + G(x)v$, is invertible in the sense of Singh. From [14, Thm. 1] it follows that there exists a dynamic feedback law such that the system, resulting from (15), is noninteractive. In particular, if we assume for the moment that $\dim(\text{span}\{\tilde{g}_i\}(x)) > 1$, from (12) it follows that for each system

$$\begin{aligned} u_i &= \alpha_i(x,w) + \beta_{ii}(x,w)v_i, \\ \dot{x} &= f(x) + G(x)\alpha(x,w) + G(x)\beta(x,w)v, \\ \dot{w} &= \gamma(x,w) + \delta(x,w)v, \end{aligned} \tag{16}$$

there exists an invertible dynamic feedback law such that the system, resulting from plugging this feedback law into (16), is noninteractive. Let us consider the following auxiliary system:

$$\begin{aligned} \dot{\zeta}^i &= \alpha_i(x,w) + \beta_{ii}(x,w)v_i, \\ \dot{x} &= f(x) + G(x)\alpha(x,w) + G(x)\beta(x,w)v, \\ \dot{w} &= \gamma(x,w) + \delta(x,w)v, \\ y^i &= h^i(\zeta^i, x, w) = \zeta^i, \end{aligned} \tag{17}$$

where y^i is a vector of fictitious outputs and let $((\zeta^i)^T, x^T, w^T)^T = x^{ie}$ and $x_0^{ie} = (0,0,0)$. Moreover, if $\dim((\text{span}\{\tilde{g}_i\})(x)) = m_i$ and $\dim((\text{span}\{\tilde{g}_i^e\})(x^e)) = m_i^e$, let

$$\tilde{f}^{ie}(x^{ie}) = \begin{pmatrix}\alpha_i(x,w)\\ \tilde{f}^e(x,w)\end{pmatrix},\ \tilde{g}_j^{ie}(x^{ie}) = \begin{cases}\begin{pmatrix}\beta_{ii}(x,w)\\ \tilde{g}_i^e(x,w)\end{pmatrix} & \text{if} j = i,\\ \begin{pmatrix}0_{m_i \times m_j^e}\\ \tilde{g}_j^e(x,w)\end{pmatrix} & \text{if} j \neq i,\end{cases}$$

$$\tilde{G}^{ie}(x^{ie}) = (\tilde{g}_1^{ie}(x^{ie}) \dots \tilde{g}_{p+1}^{ie}(x^{ie})), \qquad \tilde{\mathcal{G}}^{ie} = \text{span}\{\tilde{G}^{ie}\}.$$

With the above notation, we introduce the following sequence of distributions:

$$\begin{aligned}\mathcal{S}_0^{ie} &= \tilde{\mathcal{G}}^{ie},\\ \mathcal{S}_k^{ie} &= [\tilde{f}^{ie}, \ker d\zeta^i \cap \mathcal{S}_{k-1}^{ie}] + \sum_{j=1}^{p+1} [\tilde{g}_j^{ie}, \ker d\zeta^i \cap \mathcal{S}_{k-1}^{ie}] + \mathcal{S}_{k-1}^{ie}.\end{aligned} \tag{18}$$

Note that if the distributions $\mathcal{S}_k^{ie}$ and $\mathcal{S}_k^{ie} \cap \ker d\zeta^i$ have constant dimension for all k, then there exists $k_i^* \geq 0$ such that $\mathcal{S}_{k_i^*}^{ie} = \mathcal{S}_k^{ie}$ for all $k \geq k_i^*$. Moreover, $\mathcal{S}^{ie*} = \mathcal{S}_{k_i^*}^{ie}$ is the *minimal* distribution that contains $\tilde{\mathcal{G}}^{ie}$ and satisfies $[\tilde{f}^{ie}, \mathcal{S}^{ie*} \cap \ker d\zeta^i] \subset \mathcal{S}^{ie*}$ and $[\tilde{g}_j^{ie}, \mathcal{S}^{ie*} \cap \ker d\zeta^i] \subset \mathcal{S}^{ie*}$, $j = 1, \dots, p+1$ (see also [15]). Each distribution $\mathcal{S}_k^{ie}$ is invariant under static feedback transformations, which are regular at x_0^{ie}.

We now proceed to illustrate how the algorithm (18) can be implemented in practice.

To compute $\mathcal{S}_1^{ie}$, we first must compute $\mathcal{G}^{ie} \cap \ker d\zeta^i$. Let $A_0^i(x^e) = \beta_{ii}(x^e)$. Moreover, assume that $A_0^i(x^e)$ has constant rank s_0^i in a neighbourhood of x_0^e and $\tilde{G}^{ie}(x^{ie})$ has constant rank in a neighbourhood of x_0^{ie} (or, equivalently, that $\mathcal{S}_0^{ie} \cap \ker d\zeta^i$ and $\mathcal{S}_0^{ie}$ have constant dimension in a neighbourhood of x_0^{ie}). Moreover, let l_0^i be the number of columns of $A_0^i(x^e)$. It is always possible to find smooth matrices $A_{0h}^i(x^e)$ and $B_{0h}^i(x^e)$, $h = 1, 2$, such that (after possibly permuting the columns of $A_0^i(x^e)$) we have

$$A_0^i(x^e) = (A_{01}^i(x^e) \quad A_{02}^i(x^e)), \quad A_0^i B_{01}^i(x^e) = A_{01}^i(x^e), \quad A_0^i B_{02}^i(x^e) = 0_{m_i \times (l_0^i - s_0^i)}$$

and $(B_{01}^i(x^e) \quad B_{02}^i(x^e))$ is an invertible matrix for all x^e in a neighbourhood of x_0^e. Moreover, using (12)–(14), it is not hard to show that the matrices $B_{0h}^i(x^e)$, $h = 1, 2$, can be chosen in such a way that

$$L_{\tilde{g}_j^e} \tilde{D}^e B_{0h}^i(x^e) = 0, \qquad j \neq i, \tag{19}$$

where $\tilde{D}^e$ is an arbitrary composition of the Lie derivatives $L_{\tilde{f}^e}$ and $L_{\tilde{g}_j^e}$, $j = 1, \dots, p+1$. Let

$$\begin{aligned}\bar{T}_{01}^i &= (\tilde{g}_1^{ie} \dots \tilde{g}_{i-1}^{ie}\, \tilde{g}_{i+1}^{ie} \dots \tilde{g}_{p+1}^{ie}),\\ \bar{T}_{02}^i &= \tilde{g}_i^{ie} B_{02}^i,\\ T_{02}^i &= (\bar{T}_{01}^i\, \bar{T}_{02}^i),\\ T_{01}^i &= \tilde{g}_i^{ie} B_{01}^i,\\ T_1^i &= (T_{01}^i\, T_{02}^i\, [\tilde{g}_1^{ie}, T_{02}^i] \dots [\tilde{g}_{p+1}^{ie}, T_{02}^i]\, [\tilde{f}^{ie}, T_{02}^i]),\end{aligned}$$

and

$$\begin{aligned}\bar{R}_{02}^i &= \tilde{g}_i^e B_{02}^i,\\ R_{01}^i &= \tilde{g}_i^e B_{01}^i.\end{aligned}$$

The distribution $\tilde{\mathcal{G}}^{ie} \cap \ker\, d\zeta^i$ is spanned by the vector fields T^i_{02} and the distribution $\mathcal{S}^{ie}_1$ is spanned by the vector fields T^i_1.

At the step $(k+1)$th, $k \geq 1$, to compute $\mathcal{S}^{ie}_{k+1}$ we first must compute $\mathcal{S}^{ie}_k \cap \ker\, d\zeta^i$. Let

$$A^i_k(x^e) = (A^i_{k-1,1}(x^e) \quad L_{\bar{R}^i_{k-1,2}}\beta_{ii}(x^e) \quad L_{\bar{R}^i_{k-1,2}}\alpha_i(x^e)).$$

Moreover, assume that $A^i_k(x^e)$ has constant rank s^i_k in a neighbourhood of x^e_0 and $T^i_k(x^{ie})$ has constant rank in a neighbourhood of x^{ie}_0 (or, equivalently, that $\mathcal{S}^{ie}_k \cap \ker\, d\zeta^i$ and $\mathcal{S}^{ie}_k$ have constant dimension in a neighbourhood of x^{ie}_0). In this case, it is possible to find matrices $A^i_{kh}(x^e)$ and $B^i_{kh}(x^e)$, $h = 1, 2$, such that (after possibly permuting the columns of $A^i_k(x^e)$) we have

$$A^i_k(x^e) = (A^i_{k1}(x^e) \quad A^i_{k2}(x^e)), \quad A^i_k B^i_{k1}(x^e) = A^i_{k1}(x^e), \quad A^i_k B^i_{k2}(x^e) = 0_{m_i \times (l^i_k - s^i_k)}$$

and $(B^i_{k1}(x^e) \quad B^i_{k2}(x^e))$ is an invertible matrix for all x^e in a neighbourhood of x^e_0. Moreover, using (12)–(14), it is not hard to show that the matrices $B^i_{kh}(x^e)$, $h = 1, 2$, can be chosen in such a way that

$$L_{\tilde{g}^e_j}\tilde{D}^e B^i_{kh}(x^e) = 0, \qquad j \neq i, \tag{20}$$

where $\tilde{D}^e$ is an arbitrary composition of the Lie derivatives $L_{\tilde{f}^e}$ and $L_{\tilde{g}^e_j}$, $j = 1, \ldots, p+1$. Let

$$\begin{aligned}
\bar{T}^i_{k1} &= (T^i_{k-1,2} \quad [\tilde{g}^{ie}_1, T^i_{k-1,2}] \cdots [\tilde{g}^{ie}_{i-1}, T^i_{k-1,2}] \quad [\tilde{g}^{ie}_i, \bar{T}^i_{k-1,1}] \quad [\tilde{g}^{ie}_{i+1}, T^i_{k-1,2}] \\
&\qquad \cdots [\tilde{g}^{ie}_{p+1}, T^i_{k-1,2}] \quad [\tilde{f}^{ie}, \bar{T}^i_{k-1,1}]), \\
\bar{T}^i_{k2} &= (T^i_{k-1,1} \quad [\tilde{g}^{ie}_i, \bar{T}^i_{k-1,2}] \quad [\tilde{f}^{ie}, \bar{T}^i_{k-1,2}])\, B^i_{k2}, \\
T^i_{k2} &= (\bar{T}^i_{k1} \quad \bar{T}^i_{k2}), \\
T^i_{k1} &= (T^i_{k-1,1} \quad [\tilde{g}^{ie}_i, \bar{T}^i_{k-1,2}] \quad [\tilde{f}^{ie}, \bar{T}^i_{k-1,2}])\, B^i_{k1}, \\
T^i_{k+1} &= (T^i_{k1} \quad T^i_{k2} \quad [\tilde{g}^{ie}_1, T^i_{k2}] \cdots [\tilde{g}^{ie}_{p+1}, T^i_{k2}] \quad [\tilde{f}^{ie}, T^i_{k2}]),
\end{aligned}$$

and

$$\begin{aligned}
\bar{R}^i_{k2} &= (R^i_{k-1,1} \quad [\tilde{g}^e_i, \bar{R}^i_{k-1,2}] \quad [\tilde{f}^e, \bar{R}^i_{k-1,2}])\, B^i_{k2}, \\
R^i_{k1} &= (R^i_{k-1,1} \quad [\tilde{g}^e_i, \bar{R}^i_{k-1,2}] \quad [\tilde{f}^e, \bar{R}^i_{k-1,2}])\, B^i_{k1}.
\end{aligned}$$

The distribution $\mathcal{S}^{ie}_k \cap \ker\, d\zeta^i$ is spanned by the vector fields T^i_{k2}, since, as a direct consequence of (12)–(14), (19), and (20), the only vector fields, which have the first m_i components possibly not identically equal to zero, are of the form T^i_{h1}, $[\tilde{g}^{ie}_i, \bar{T}^i_{h2}]$ or $[\tilde{f}^{ie}, \bar{T}^i_{h2}]$, with $h \leq k-1$, and the first m_i rows of $(T^i_{k-1,1} \quad [\tilde{g}^{ie}_i, \bar{T}^i_{k-1,2}] \quad [\tilde{f}^{ie}, \bar{T}^i_{k-1,2}])\,(x^{ie})$ are identically equal to $A^i_k(x^e)$. On the other hand, the distribution $\mathcal{S}^{ie}_{k+1}$ is spanned by the vector fields T^i_{k+1}. This completes the description of a possible implementation of the algorithm (18). We note that the proposed algorithm (18) gives a more general and intuitive version of the one given in [13].

In what follows, we assume that the distributions $\mathcal{S}^{ie}_k$ and $\mathcal{S}^{ie}_k \cap \ker\, d\zeta^i$, $k \geq 0$, have constant dimension in a neighbourhood of x^{ie}_0. In this case there exists indeed $k^*_i \geq 0$ such that $\mathcal{S}^{ie}_{k^*_i} = \mathcal{S}^{ie}_{k^*_i+1} = \mathcal{S}^{ie*}$ and we will say that $\mathcal{S}^{ie}$ is *regularly computable* at x^{ie}_0. The fact that (17) can be rendered noninteractive via dynamic feedback law has some interesting consequences in terms of $\mathcal{S}^{ie*}$. This is shown in the next lemma.

LEMMA 3. *Assume that $\mathcal{S}^{ie*}$ is regularly computable at x_0^{ie}. Then, $\mathcal{S}^{ie*}$* + ker $d\zeta^i = \mathbb{R}^{m_i+n+n^w}$ *for all x^{ie} in a neighbourhood of x_0^{ie}.*

Proof. Suppose that

$$\dim\left((\mathcal{S}^{ie*} + \ker\, d\zeta^i)(x_0^{ie})\right) < m_i + n + n^w. \tag{21}$$

We will show that this gives a contradiction. Assume first that $\dim(\text{span}\{\tilde{g}_i\}(x)) = 1$. In this case, reasoning as in [7], we can easily prove that each system (16) has relative degree at x_0^e (with respect to u_i). Without loss of generality, we can assume that (16) is in *normal form* (see [1] for a definition). From here it is straightforward to check that $\mathcal{S}^{ie*}$ +ker $d\zeta^i = \mathbb{R}^{m_i+n+n^w}$.

On the other hand, assume that $\dim(\text{span}\{\tilde{g}_i\}(x)) > 1$. Following [14], from our assumptions it follows that there exists a feedback law

$$\begin{aligned} v_i &= \alpha^i(x^{ie}, \eta^i) + \beta^i(x^{ie}, \eta^i)v', \\ \dot{\eta}^i &= \gamma^i(x^{ie}, \eta^i) + \delta^i(x^{ie}, \eta^i)v', \end{aligned} \tag{22}$$

such that the input-output behaviour of the system, obtained from plugging (22) into (17) and denoted in what follows by $\bar{\Sigma}^e$, is described by

$$(\zeta_k^i)^{(l_k)} = v'_{j_k}, \qquad k = 1, \ldots, m_i, \tag{23}$$

where the subscript (l_k) denotes the number of derivatives with respect to time, ζ_k^i is the kth component of the output vector ζ^i, v'_{j_k} is the j_kth component of the input vector v', $l_k \geq 0$ and $j_k \in \{1, \ldots, m\}$ with $j_r \neq j_s$ for r, $s = 1, \ldots, m_i$ and $r \neq s$. Let

$$\bar{f}^{ie} = \begin{pmatrix} f^{ie}(x^{ie}) + \tilde{G}^{ie}(x^{ie})\alpha^i(x^{ie}, \eta^i) \\ \gamma^i(x^{ie}, \eta^i) \end{pmatrix},$$

$$\bar{G}^{ie}(x^{ie}, \eta^i) = \begin{pmatrix} \tilde{G}^{ie}(x^{ie})\beta^i(x^{ie}, \eta^i) \\ \delta^i(x^{ie}, \eta^i) \end{pmatrix}, \qquad \bar{\mathcal{G}}^{ie} = \text{span}\{\bar{G}^{ie}\},$$

and $\bar{g}_j^{ie}(x^{ie}, \eta^i)$ be the jth column (block) of $\bar{G}^{ie}(x^{ie}, \eta^i)$. From (23), it follows that, after possibly changing coordinates, $\bar{\Sigma}^e$ is in the form

$$\begin{aligned} \dot{\theta}_{k1}^i &= \theta_{k2}^i, \\ \cdots &= \cdots \\ \dot{\theta}_{kl_k}^i &= v'_{j_k}, \qquad k = 1, \ldots, m_i, \\ \dot{\varphi}^i &= \psi^i(\theta_{k1}^i, \ldots, \theta_{kl_1}^i, \ldots, \theta_{m_i1}^i, \ldots, \theta_{m_il_{m_i}}^i, \varphi^i) \\ &\quad + \lambda^i(\theta_{k1}^i, \ldots, \theta_{kl_1}^i, \ldots, \theta_{m_i1}^i, \ldots, \theta_{m_il_{m_i}}^i, \varphi_i)v', \end{aligned}$$

for some (possibly vector-valued) smooth functions ψ^i and λ^i and with output vector h^i equal to $(\theta_{11}^i, \ldots, \theta_{m_i1}^i)^T$. Now, denote by $\bar{\mathcal{S}}^{ie*}$ the minimal distribution that contains $\bar{\mathcal{G}}^{ie}$ and is such that $[\bar{f}^{ie}, \bar{\mathcal{S}}^{ie*} \cap \ker\, dh^i] \subset \bar{\mathcal{S}}^{ie*}$ and $[\bar{g}_j^{ie}, \bar{\mathcal{S}}^{ie*} \cap \ker\, dh^i] \subset \bar{\mathcal{S}}^{ie*}$ for $j = 1, \ldots, p+1$, and assume for simplicity that $\bar{\mathcal{S}}^{ie*}$ is regularly computable at the origin of the state space (the proof of the lemma can be repeated also after removing this assumption). By straightforward computations, it can be seen that the distribution $\bar{\mathcal{S}}^{ie*}$ is such that

$$\langle dh^i, \bar{\mathcal{S}}^{ie*}\rangle(x_0^{ie}) = \mathbb{R}^{m_i} \tag{24}$$

($\langle dh^i, \bar{\mathcal{S}}^{ie*}\rangle(x_0^{ie})$ denotes the subspace of $\mathbb{R}^{m_i}$ spanned by the vectors $\langle dh^i, \tau^i\rangle(x_0^{ie})$, with $\tau^i \in \bar{\mathcal{S}}^{ie*}$). On the other hand, it is not hard to show by induction that, if π is the natural projection

$\pi((x^{ie}, \eta^i)) = x^{ie}$ and $\pi_{*(x^{ie},\eta^i)}$ its differential at (x^{ie}, η^i), we have $\pi_{(x^{ie},\eta^i)*}\bar{\mathcal{S}}^{ie*}(x^{ie}, \eta^i) \subset \mathcal{S}^{ie*}(\pi(x_i^e, \eta^i))$. This, together with (24), would contradict (23). □

We are ready now to state the main result of this section. Let

$$\mathcal{R}_i^e = \langle \tilde{f}^e, \tilde{g}_1^e, \dots, \tilde{g}_{p+1}^e | \text{span}\{\tilde{g}_i^e, \tilde{g}_{p+1}^e\}\rangle, \qquad i = 1, \dots, p,$$
$$\mathcal{Q}^e = \langle \tilde{f}^e, \tilde{g}_1^e, \dots, \tilde{g}_{p+1}^e | \text{span}\{\tilde{g}_{p+1}^e\}\rangle.$$

Moreover, let Δ_{MIX}^e be the distribution defined in the same way as in (7), but with $\tilde{f}$ and $\tilde{g}_j$, $j = 1, \dots, p+1$, replaced by $\tilde{f}^e$ and $\tilde{g}_j^e$, respectively.

THEOREM 4. *Assume* (H1)–(H5) *hold. Moreover, assume that the distributions* $\mathcal{S}^{ie*}$, $i = 1, \dots, p$, *are regularly computable at* x_0^{ie}, *the distributions* $\mathcal{R}_i^e$, $i = 1, \dots, p$, *and* $\mathcal{Q}^e$ *are regularly computable at* x_0^e, *and that the distributions* $\Delta_{MIX}^e + \mathcal{R}_i^e$, $i = 1, \dots, p$, *and* $\Delta_{MIX}^e + \mathcal{Q}^e$ *have constant dimension in a neighbourhood of* x_0^e. *If* LNSD *is solvable via invertible feedback laws, then*

(a) *the dynamics* Σ_0^* *is locally asymptotically stable at the origin,*

(b) *each system* Σ_i^*, $i = 1, \dots, p$, *is locally asymptotically stabilizable via dynamic feedback laws.*

Conversely, if (a) *and* (b) *are satisfied and, in addition,* Σ_{p+1}^* *is locally asymptotically stabilizable via dynamic feedback laws, then* LNSD *is solvable via invertible feedback laws.*

Remark 5. Conditions (a) and (b) require us to check the local asymptotic stability and, respectively, the local asymptotic stabilizability of a suitable nonlinear system of the form $\dot{x} = f(x) + G(x)u$. For stability the reader is referred to the standard text [16]. On the other hand, many interesting results are available to check asymptotic stabilizability via *static* state feedback. A first kind of test is given in terms of the Jacobian $\frac{\partial f}{\partial x}(x)$ of $f(x)$, computed at $x = 0$. If the pair $\left(\frac{\partial f}{\partial x}(0), G(0)\right)$ is stabilizable (in the sense that the uncontrollable modes are asymptotically stable) then the nonlinear system can be locally asymptotically stabilized through a *linear* state feedback law ([18]). If some eigenvalues of $\frac{\partial f}{\partial x}(0)$ are not controllable and have zero real part (*critical case*), the theory of center manifold can be used in some simple cases to design stabilizing controllers ([17]).

An important class of nonlinear system, which can always be locally asymptotically stabilized through *static* state feedback, is given by the systems that have *relative degree* and are *minimum phase* ([18]–[20]).

On the other hand, it has recently been shown in [21] that a nonlinear system of the above form can be asymptotically stabilized via smooth static state feedback if and only if there exist a smooth function $\varphi(x)$ such that the system is feedback equivalent to a *strictly passive* (with respect to φ), or, equivalently, to a system that has *relative degree* $\{1, \dots, 1\}$ and is *minimum phase*.

Interesting results on state feedback stabilization have been also given in terms of *control Lyapunov functions* ([22]–[29]). Necessary and sufficient conditions for state feedback stabilization are available for two- and three-dimensional analytic systems ([30], [31]). Moreover, stabilization via *dynamic* state feedback is considered in [29].

Proof of Theorem 4. The sufficiency part can be proved as in [10].

The necessity can be proved as follows. Let π be the natural projection $\pi(x^e) = x$ and π_{*x^e} be its differential at x^e. Moreover, let $\mathcal{Q}^*$ be thought of as a distribution of $\mathbb{R}^{n+n^w}$

Now let B_{kj}^i, $\bar{R}_{k2}^i$, R_{k1}^i, and s_k^i be as above and, if $q = \dim(\mathcal{Q}^*(x^e))$, denote by $(A \bmod(\mathcal{Q}^* + \mathcal{G}^w))(x^e)$ the first $n - q$ components (respectively, rows) of a given vector (respectively, matrix) $A(x^e)$. From (12)–(14), (19), and (20) it follows that

$$([\tilde{f}^e, \bar{R}_{k2}^i] \bmod(\mathcal{Q}^* + \mathcal{G}^w))(x^e) = \tilde{g}_i(x)(L_{\bar{R}_{k2}^i}\alpha_i)(x^e),$$

$$([\tilde{g}_i^e, \bar{R}_{k2}^i] \operatorname{mod}(\mathcal{Q}^* + \mathcal{G}^w))(x^e) = \tilde{g}_i(x)(L_{\bar{R}_{k2}^i}\beta_{ii})(x^e).$$

Lemma 3 implies that the first m_i rows of $T_{k_i^*}^i(x^{ie})$ are linearly independent for all x^{ie} in a neighbourhood of x_0^{ie}. Since the first m_i rows of $(T_{k-1,1}^i \quad [\tilde{g}_i^{ie}, \bar{T}_{k-1,2}^i] \quad [\tilde{f}^{ie}, \bar{T}_{k-1,2}^i])\,(x^{ie})$ are identically equal to $A_k^i(x^e)$ for all k, the matrix $A_{k_i^*,1}^i(x^e)$ has full row rank for all x^e in a neighbourhood of x_0^e and $(R_{k_i^*,1}^i \operatorname{mod}(\mathcal{Q}^* + \mathcal{G}^w))(x^e) = \tilde{g}_i(x)A_{k_i^*,1}^i(x^e)$. Since $\mathcal{R}_i^e$ is invariant under $\tilde{f}^e, \tilde{g}_1^e, \ldots, \tilde{g}_{p+1}^e$ and from (19) and (20), it follows that $[\tilde{g}_i^e, \bar{R}_{k2}^i] \in \mathcal{R}_i^e$ and $[\tilde{f}^e, \bar{R}_{k2}^i] \in \mathcal{R}_i^e$. We conclude that $\tilde{g}_i(\pi(x^e)) \in \pi_{*x^e}(\mathcal{R}_i^e + \mathcal{Q}^*)(x^e)$.

From here, we can proceed as in [13, Thm. 1]. For completeness, we give a short sketch of the proof. Reasoning as in [7] and using the above facts, we prove that $\pi_{*x^e}(\Delta_{MIX}^e + \mathcal{Q}^e + \mathcal{Q}^*)(x^e) \supset (\Delta_{MIX}^* + \mathcal{Q}^*)(\pi(x^e))$. Since from (12)–(14) it easily follows that $\pi_{*x^e}(\Delta_{MIX}^e + \mathcal{Q}^e + \mathcal{Q}^*)(x^e) \subset (\Delta_{MIX}^* + \mathcal{Q}^*)(\pi(x^e))$, we conclude that $\pi_{*x^e}(\Delta_{MIX}^e + \mathcal{Q}^e + \mathcal{Q}^*)(x^e) = (\Delta_{MIX}^* + \mathcal{Q}^*)(\pi(x^e))$. Since $\dot{x}^e = \tilde{f}^e(x^e)$ is locally asymptotically stable in x_0^e, it is such also on the invariant submanifold $\mathcal{L}_{x_0^e}^{\Delta_{MIX}^e + \mathcal{Q}^e}$. Moreover, $\pi_{*x^e}(\tilde{f}^e|\mathcal{L}_{x_0^e}^{\Delta_{MIX}^e + \mathcal{Q}^e})(x^e) \in (\Delta_{MIX}^* + \mathcal{Q}^*)(\pi(x^e))$ and from (13) it follows that $\alpha(x^e) = 0$ for $x^e \in \mathcal{L}_{x_0^e}^{\Delta_{MIX}^e + \mathcal{Q}^e}$. This, together with $\pi_{*x^e}(\Delta_{MIX}^e + \mathcal{Q}^e + \mathcal{Q}^*)(x^e) = (\Delta_{MIX}^* + \mathcal{Q}^*)(\pi(x^e))$, implies that Σ_0^* is an invariant subdynamics of $\dot{x}^e = \tilde{f}^e(x^e)$ for $x^e \in \mathcal{L}_{x_0^e}^{\Delta_{MIX}^e + \mathcal{Q}^e}$, which proves (a). Similarly, using the fact that $\alpha_j(x^e) = 0$ for $x^e \in \mathcal{L}_{x_0^e}^{\mathcal{R}_i^e + \Delta_{MIX}^e}$ and $j \neq \{i, p+1\}$ (as a consequence of (13)), we prove that $\pi_{*x^e}(\mathcal{R}_i^e + \Delta_{MIX}^e + \mathcal{Q}^*)(x^e) = (\mathcal{R}_i^* + \Delta_{MIX}^*)(\pi(x^e))$ and, as a consequence, (b). □

Theorem 4 generalizes [7] in the case $m = p$, since any *regular noninteraction* (in the sense of [7]) feedback law, which solves LND, is also *invertible*. Indeed, using the results contained in [7], it can be shown that the system (3), corresponding to a given regular noninteraction feedback law, has vector relative degree at x_0^e (with respect to u). Moreover, Lemmas 1 and 3 and Proposition 2 show that in the case of nonlinear systems (1) any invertible feedback law, which solves LND, is also *regular* in the sense of [13].

It is possible to construct some counterexamples, which show that the dynamics Σ_{p+1}^* is not necessarily locally asymptotically stabilizable at the origin if LNSD is solvable (see [13]). On the other hand, if $\mathcal{Q}^* = 0$, similarly to [13], we obtain the following necessary and sufficient condition.

COROLLARY 6. *Assume* (H1)–(H5) *hold. Moreover, suppose that* $\mathcal{Q}^* = 0$. *If*

(a) *the dynamics* Σ_0^* *is locally asymptotically stable at the origin,*

(b) *each system* Σ_i^*, $i = 1, \ldots, p$, *is locally asymptotically stabilizable at the origin via dynamic feedback laws,*

then LNSD *is solvable via invertible dynamic feedback laws. Conversely, assume that* $\mathcal{S}^{ie*}$ *is regularly computable at* x_0^{ie}, *the distributions* $\mathcal{R}_i^e$, $i = 1, \ldots, p$, *and* $\mathcal{Q}^e$ *are regularly computable at* x_0^e *and the distributions* $\mathcal{R}_i^e + \Delta_{MIX}^e$, $i = 1, \ldots, p$, *and* $\Delta_{MIX}^e + \mathcal{Q}^e$ *have constant dimension in a neighbourhood of* x_0^e. *Then, if* LNSD *is solvable,* (a) *and* (b) *are satisfied.*

4. Some existence conditions. In this section we prove some conditions that must be satisfied for the existence of a dynamic feedback law that solves LNSD for the class of nonlinear systems (1) satisfying assumptions (H1)–(H4). We *do not* constrain the class of feedback laws and this is quite a new result in the literature. The following theorem gives an interesting existence condition, which, however, cannot be checked a priori. It simply assesses, for each $i = 1, \ldots, p$, the existence of a smooth submanifold, transversal to $h_i^{-1}(0)$, that can be rendered (locally) an asymptotically stable manifold for Σ_i^*. This manifold depends, in general, on the decoupling feedback law, except when, for example, $\pi_{*(x,w)}(\mathcal{R}_i^e + \Delta_{MIX}^e)(x,w) = (\mathcal{R}_i^* + \Delta_{MIX}^*)(\pi(x,w))$ (this is the case when considering invertible feedback laws).

THEOREM 7. *Assume* (H1)–(H4) *hold. If* LNSD *is solvable then for each system* Σ_i^*, *there exist a dynamic feedback law* $u_i = \alpha^i(z_1^i, z_3^i, w^i)$, $\dot{w}^i = \delta^i(z_1^i, z_3^i, w^i)$, $w^i \in \mathbb{R}^{n^i}$, *and, correspondingly, a smooth invariant submanifold* $\mathcal{M}_i = \{(z_1^i, z_3^i, w^i) \in \mathbb{R}^{n+n^i} \colon \varphi^i(z_1^i, z_3^i, w^i) = 0\}$, *passing through the origin of the state space and transversal to the smooth submanifold* $\{(z_1^i, z_3^i, w^i) \in \mathbb{R}^{n+n^i} : h_i(z_1^i) = 0\}$, *such that the system, resulting from* Σ_i^* *with* $u_i = \alpha^i(z_1^i, z_3^i, w^i)$, $\dot{w}^i = \delta^i(z_1^i, z_3^i, w^i)$, *is locally asymptotically stable at the origin on* $\mathcal{M}^i$.

Proof. Using (12)–(14), it is easy to prove that

$$\pi_{*x^e}(\mathcal{R}_i^e + \Delta_{MIX}^e)(x^e) \subset (\mathcal{R}_i^* + \Delta_{MIX}^*)(\pi(x^e)), \tag{25}$$

where π_{*x^e} is defined as above. Since LNSD is solvable, it follows that $\dot{x}^e = \tilde{f}^e(x^e)$ is locally asymptotically stable in x_0^e. In particular, it is such for initial conditions lying on $\mathcal{L}_{x_0^e}^{\mathcal{R}_i^e + \Delta_{MIX}^e}$. From (25) it follows that $\pi_{*x^e}(\tilde{f}^e|\mathcal{L}_{x_0^e}^{\mathcal{R}_i^e + \Delta_{MIX}^e})(x^e) \subset (\mathcal{R}_i^* + \Delta_{MIX}^*)(\pi(x^e))$. This, together with the fact that $\tilde{f}^e(x_0^e) = 0$, implies that, in z^i-coordinates, the component of $\tilde{f}^e|\mathcal{L}_{x_0^e}^{\mathcal{R}_i^e + \Delta_{MIX}^e}$ along $\operatorname{span}\{\partial/\partial x_j, \partial/\partial z_2^i : j \neq \{i, p+1, p+2\}\}$ is identically zero. The same holds for the restrictions $\tilde{g}_i^e|\mathcal{L}_{x_0^e}^{\mathcal{R}_i^e + \Delta_{MIX}^e}$ and $\tilde{g}_{p+1}^e|\mathcal{L}_{x_0^e}^{\mathcal{R}_i^e + \Delta_{MIX}^e}$, since $\tilde{g}_i^e, \tilde{g}_{p+1}^e \in \mathcal{R}_i^e$. Moreover, from (12)–(14) it follows that $\alpha_j(x^e) = 0$ for all $x^e \in \mathcal{L}_{x_0^e}^{\mathcal{R}_i^e + \Delta_{MIX}^e}$ and $j \neq \{i, p+1\}$. The dynamics, described on $\mathcal{L}_{x_0^e}^{\mathcal{R}_i^e + \Delta_{MIX}^e}$ by the vector fields $\tilde{f}^e|\mathcal{L}_{x_0^e}^{\mathcal{R}_i^e + \Delta_{MIX}^e}$, $\tilde{g}_i^e|\mathcal{L}_{x_0^e}^{\mathcal{R}_i^e + \Delta_{MIX}^e}$ and $\tilde{g}_{p+1}^e|\mathcal{L}_{x_0^e}^{\mathcal{R}_i^e + \Delta_{MIX}^e}$, is clearly an invariant subdynamics of

$$\begin{aligned} \begin{pmatrix} \dot{z}_1^i \\ \dot{z}_3^i \\ \dot{z}_4^i \\ \dot{z}_5^i \\ \dot{w} \end{pmatrix} &= \begin{pmatrix} \tilde{f}_{z_1^i}(0, \ldots, 0, z_1^i) \\ \tilde{f}_{z_3^i}(0, \ldots, 0, z_1^i, 0, z_3^i) \\ \tilde{f}_{z_4^i}(0, \ldots, 0, z_1^i, 0, z_3^i, z_4^i) \\ \tilde{f}_{z_5^i}(0, \ldots, 0, z_1^i, 0, z_3^i, z_4^i, z_5^i) \\ \delta(0, \ldots, 0, z_1^i, 0, z_3^i, z_4^i, z_5^i, w) \end{pmatrix} \\ &\quad + \sum_{j \in \{i, p+1\}} \begin{pmatrix} \tilde{g}_{z_1^i, j}(0, \ldots, 0, z_1^i) \\ \tilde{g}_{z_3^i, j}(0, \ldots, 0, z_1^i, 0, z_3^i) \\ \tilde{g}_{z_4^i, j}(0, \ldots, 0, z_1^i, 0, z_3^i, z_4^i) \\ \tilde{g}_{z_5^i, j}(0, \ldots, 0, z_1^i, 0, z_3^i, z_4^i, z_5^i) \\ 0 \end{pmatrix} \alpha_j(0, \ldots, 0, z_1^i, 0, z_3^i, z_4^i, z_5^i, w). \end{aligned} \tag{26}$$

If we let $\mathcal{M}^i = \mathcal{L}_{x_0^e}^{\mathcal{R}_i^e + \Delta_{MIX}^e}$, since (26) is locally asymptotically stable at the origin on $\mathcal{M}^i$, it follows that there exist a dynamic feedback law $u_i = \alpha^i(z_1^i, z_3^i, w^i)$, $\dot{w}^i = \delta^i(z_1^i, z_3^i, w^i)$, $w^i \in \mathbb{R}^{n^i}$, and, correspondingly, a smooth invariant submanifold $\mathcal{M}^i = \{(z_1^i, z_3^i, w^i) \in \mathbb{R}^{n+n^i} : \varphi^i(z_1^i, z_3^i, w^i) = 0\}$, passing through the origin of the state space, such that the system, resulting from Σ_i^* with $u_i = \alpha^i(z_1^i, z_3^i, w^i)$, $\dot{w}^i = \delta^i(z_1^i, z_3^i, w^i)$, is locally asymptotically stable at the origin on $\mathcal{M}^i$. Moreover, it is not hard to show that in a neighbourhood of x_0^e

$$\mathcal{R}_i^e + \ker dh_i^e = \mathbb{R}^{n+n^w}. \tag{27}$$

Indeed, by definition of LNSD, the system $\tilde{\Sigma}^e$ has vector relative degree at x_0^e and it is noninteractive. From [1, Lem. 3.3.1] and the definition of vector relative degree, it follows that for each $i \in \{1, \ldots, p\}$ there exists r_i^e such that $L_{\tilde{g}_i^e} L_{\tilde{f}^e}^k h_i^e(x^e) = 0$ for all

$k < r_i^e - 1$ and $L_{\tilde{g}_i^e} L_{\tilde{f}^e}^{r_i^e - 1} h_i^e(x_0^e) \neq 0$. Equivalently, if we define $ad_{\tilde{f}^e}^k \tilde{g}_i^e$ as $ad_{\tilde{f}^e}^0 \tilde{g}_i^e = \tilde{g}_i^e$ and $ad_{\tilde{f}^e}^k \tilde{g}_i^e = [\tilde{f}^e, ad_{\tilde{f}^e}^{k-1} \tilde{g}_i^e]$ for all $k \geq 1$, we have $L_{ad_{\tilde{f}^e}^k \tilde{g}_i^e} h_i^e(x^e) = 0$ for all $k < r_i^e - 1$ and $L_{ad_{\tilde{f}^e}^{r_i^e - 1} \tilde{g}_i^e} h_i^e(x_0^e) \neq 0$. Since by construction $ad_{\tilde{f}^e}^{r_i^e - 1} \tilde{g}_i^e \in \mathcal{R}_i^e$, we obtain (27). This proves that $\mathcal{M}^i$ is transversal to the smooth submanifold $\{(z_1^i, z_3^i, w^i) \in \mathbb{R}^{n+n^i} : h_i(z_1^i) = 0\}$. □

Remark 8. If we consider invertible feedback laws, we obtain condition (b) of Theorem 4, since in this case it can be shown that $\pi_{*x^e}(\mathcal{R}_i^e + \Delta_{MIX}^e + \mathcal{Q}^*)(x^e) = (\mathcal{R}_i^* + \Delta_{MIX}^*)(\pi(x^e))$.

In §3 we remarked that the dynamics Σ_{p+1}^* is not necessarily locally asymptotically stabilizable at the origin if LNSD is solvable. This fact accounts for an apparent gap between necessary and sufficient conditions (Theorem 4). We might ask if something more can be said by considering the dynamics (8)–(10), associated to *some* regular solution, which is not necessarily the *maximal* one. A positive fact is that if the dynamics (8) is locally asymptotically stable at the origin, each system (9) is locally asymptotically stabilizable at the origin via dynamic feedback law and, in addition, (10) is locally asymptotically stabilizable at the origin via dynamic feedback law, then LNSD is solvable. This can be proved exactly as in the case we consider the maximal regular solution $\mathcal{R}_1^*, \ldots, \mathcal{R}_p^*$. Are the above conditions also necessary to solve LNSD? Toward partially answering this question, we first give the following definition.

DEFINITION 9. *An invertible feedback law* (2) *is said to be a* noninteraction *feedback law if there exists a block partition* $J_1, \ldots, J_{p+1}$ *of* $\{1, \ldots, m\}$, *with* $J_i \cap J_h = \{\phi\}$ *for* $h \neq i$, *such that* (2) *is of the form*

$$\begin{aligned} u_{J_i} &= \alpha_{J_i}(x, w) + \beta_{J_i, i}(x, w) v_i, \qquad i = 1, \ldots, p, \\ u_{J_{p+1}} &= \alpha_{J_{p+1}}(x, w) + \sum_{j=1}^{p+1} \beta_{J_{p+1}, j}(x, w) v_j, \\ \dot{w} &= \delta(x, w) + \gamma(x, w) v, \end{aligned}$$

and

$$\begin{aligned} L_{\tilde{g}_j^e} \tilde{D}^e \alpha_{J_i}(x^e) &= 0, \qquad j \neq i,\ i \neq p+1, \\ L_{\tilde{g}_j^e} \tilde{D}^e \beta_{J_i, i}(x^e) &= 0, \qquad j \neq i,\ i \neq p+1, \end{aligned}$$

where $\tilde{D}^e$ is an arbitrary composition of the Lie derivatives $L_{\tilde{f}^e}$ and $L_{\tilde{g}_j^e}$, $j = 1, \ldots, p+1$. □

The definition of noninteraction feedback law was first given in [7] in the case $m = p$.

We have seen that any invertible feedback law, which solves LND for (1), can be expressed as the cascade of a static feedback law, *regular* at x_0, together with an *invertible noninteraction* feedback law. In the case of linear systems, the proof of this fact is extremely simple and goes as follows. Let $u = Fx^e + \sum_{j=1}^{p+1} H_j v_j$, $\dot{w} = Kx^e + \sum_{j=1}^{p+1} D_j v_j$, be a feedback law that achieves noninteraction. By reasoning as in [16], it can be shown that $\pi\mathcal{R}_1^e, \ldots, \pi\mathcal{R}_p^e$ and $\pi\mathcal{Q}^e$ are controllability subspaces and that the set $\pi\mathcal{R}_1^e, \ldots, \pi\mathcal{R}_p^e$ is a regular solution. After possibly a regular static feedback transformation, we can assume that there exists a block partition $J_1, \ldots, J_{p+1}$ of $\{1, \ldots, m\}$, with $J_i \cap J_h = \{\phi\}$ for $h \neq i$, such that $\pi\mathcal{R}_i^e = \langle \tilde{A} | \text{span}\{\tilde{B}_{J_i}, \tilde{B}_{J_{p+1}}\} \rangle$ and $\pi\mathcal{R}_i^e \cap \mathcal{G} = \text{span}\{\tilde{B}_{J_i}, \tilde{B}_{J_{p+1}}\}$ for $i = 1, \ldots, p$ (here we replaced $\tilde{f}(x)$ by $\tilde{A}x$ and $\tilde{g}_{J_i}(x^e)$ by $\tilde{B}_{J_i}$). Now, according to the partition $J_1, \ldots, J_{p+1}$, let us partition H_i as $(H_{J_1,i}^T \ldots H_{J_{p+1},i}^T)^T$ and F as $(F_{J_1}^T \ldots F_{J_{p+1}}^T)^T$. For any $X_i^e \in \mathcal{R}_i^e$, we have $\pi(\tilde{A}^e X_i^e) = \tilde{A}\pi(X_i^e) + \sum_{l=1}^{p+1} \tilde{B}_{J_l} F_{J_l} \pi(X_i^e)$ (we replaced $\tilde{f}^e(x^e)$ by $\tilde{A}^e x^e$). Since $\tilde{A}\pi(X_i^e) \in \pi\mathcal{R}_i^e$ and $\tilde{B}_{J_l} \in \pi\mathcal{R}_l^e$, we conclude that $F_{J_l}\pi(X_i^e) = 0$ for $l \neq \{i, p+1\}$. Moreover, since $\tilde{B}H_i \in \pi\mathcal{R}_i^e$

and by construction $\text{span}\{\tilde{B}_{J_h}\} \cap \pi\mathcal{R}_i^e = 0$ for $h \neq \{i, p+1\}$ (here $\tilde{G}(x)$ has been replaced by $\tilde{B}$), it follows that $H_{J_i,l} = 0$ for $l \neq i$ and $i \neq p+1$. This proves our thesis.

The subspace $\pi\mathcal{Q}^e$ is a controllability subspace contained in $\bigcap_{i=1}^p \sum_{j\neq i} \pi\mathcal{R}_j^e$, but it is not the *maximal* one with such property. Indeed, if we take the subspaces $\mathcal{R}_1^e, \ldots, \mathcal{R}_p^e$ to be linearly independent and such that $\pi\mathcal{R}_i^e = \mathcal{R}_i^*$ (this is always possible by the construction given in [32]), we have $\pi\mathcal{Q}^e = 0$ but the maximal controllability subspace contained in $\bigcap_{i=1}^p \sum_{j\neq i} \pi\mathcal{R}_j^e$ is $\mathcal{Q}^*$. This fact suggests the following approach to the case of nonlinear systems. Consider the class of feedback laws that can be expressed as the cascade of a static feedback law, regular at x_0, together with an invertible noninteraction feedback law, with the following additional property: for each system

$$
\begin{aligned}
u_{J_i} &= \alpha_{J_i}(x,w) + \beta_{J_i,i}(x,w)v_i,\\
u_{J_{p+1}} &= \alpha_{J_{p+1}}(x,w) + \sum_{l\in\{i,p+1\}} \beta_{J_{p+1},l}(x,w)v_l,\\
\dot{w} &= \delta(x,w) + \sum_{l\in\{i,p+1\}} \gamma_l(x,w)v_l,
\end{aligned}
\tag{28}
$$

and

$$
\begin{aligned}
u_{J_{p+1}} &= \alpha_{J_{p+1}}(x,w) + \beta_{J_{p+1},p+1}(x,w)v_{p+1},\\
\dot{w} &= \delta(x,w) + \gamma_{p+1}(x,w)v_{p+1},
\end{aligned}
\tag{29}
$$

where $\gamma_i(x,w)$ is the ith column block of $\gamma(x,w)$ corresponding to the partition $\tilde{g}_1^e, \ldots, \tilde{g}_{p+1}^e$, LND is solvable. This property corresponds, in the case of linear systems, to the fact that each system (28) and (29) has a transfer function matrix with rank equal to the number of its rows ([33]). Using the results and proofs of §3, it is not hard to show that, if LNSD is solvable via invertible feedback laws of the above class, we have

$$
\begin{aligned}
\pi_{*x^e}\mathcal{R}_i^e(x^e) &= \langle \tilde{f}, \tilde{g}_{J_1}, \ldots, \tilde{g}_{J_{p+1}} | \text{span}\{\tilde{g}_{J_i}, \tilde{g}_{J_{p+1}}\}\rangle(\pi(x^e)), \qquad i = 1, \ldots, p,\\
\pi_{*x^e}\mathcal{Q}^e(x^e) &= \langle \tilde{f}, \tilde{g}_{J_1}, \ldots, \tilde{g}_{J_{p+1}} | \text{span}\{\tilde{g}_{J_{p+1}}\}\rangle(\pi(x^e)).
\end{aligned}
$$

Moreover, $\pi_{*x^e}\mathcal{R}_1^e, \ldots, \pi_{*x^e}\mathcal{R}_p^e$ is a regular solution. Now, let us consider the dynamics (8)–(10), as defined in §2 with $\mathcal{R}_i = \pi_{*x^e}\mathcal{R}_i^e$ and with $\mathcal{Q}$ replaced by $\pi_{*x^e}\mathcal{Q}^e$, which, in general, is *not* the maximal controllability distribution contained in $\bigcap_{i=1}^p \sum_{j\neq i} \pi_{*x^e}\mathcal{R}_j^e$ (for this reason, the dynamics (8)–(10) in this case may depend on the feedback law, used to obtain (6) from (1)). Using the same arguments of Theorem 4, it can be easily shown that, under suitable regularity assumptions, the dynamics (8) is locally asymptotically stable at the origin and each system (9) and (10) is locally asymptotically stabilizable at the origin via dynamic feedback law. However, the problem of finding out if these conditions are also necessary to solve LNSD (or a stronger version of it) via *invertible* feedback laws is still an open question.

Conclusions. For the class of nonlinear systems (1), for which *noninteraction* can be achieved by means of static state feedback laws, regular at x_0, it results that the asymptotic stability of Σ_0^* and the asymptotic stabilizability via dynamic state feedback of the systems Σ_i^*, $i = 1, \ldots, p$, are necessary to achieve noninteraction and stability via invertible feedback laws. These conditions, plus the asymptotic stabilizability of Σ_{p+1}^* via dynamic feedback law, are also sufficient to solve LNSD via invertible feedback laws. Unfortunately, there is an apparent gap between necessary and sufficient conditions, given by the distribution $\mathcal{Q}^*$. In the case $m = p$, this is not an issue, since $\mathcal{Q}^* = 0$. Moreover, in the case of linear systems, Σ_{p+1}^* is always asymptotically stabilizable by definition.

Some interesting existence conditions have also been given. One result, among others, is that if noninteraction and stability can be achieved via dynamic feedback laws, which are possibly noninvertible, for each $i \in \{1, \ldots, p\}$ there must exist a dynamic feedback law that locally asymptotically stabilizes Σ_i^* on a suitable invariant submanifold $\mathcal{M}^i$ of the state space of the system, resulting from Σ_i^* after applying this feedback law. If we consider invertible feedback laws, we obtain a necessary condition of Theorem 4.

Acknowledgments. The author thanks Prof. A. Isidori for his constant encouragement.

NONHOLONOMIC CONTROL SYSTEMS ON RIEMANNIAN MANIFOLDS*

A. M. BLOCH† AND P. E. CROUCH‡

Abstract. This paper gives a general formulation of the theory of nonholonomic control systems on a Riemannian manifold modeled by second-order differential equations and using the unique Riemannian connection defined by the metric. The main concern is to introduce a reduction scheme, replacing some of the second-order equations by first-order equations. The authors show how constants of motion together with the nonholonomic constraints may be combined to yield such a reduction. The theory is applied to a particular class of nonholonomic control systems that may be thought of as modeling a generalized rolling ball. This class reduces to the classical example of a ball rolling without slipping on a horizontal plane.

Key words. Riemannian manifold, nonholonomic, control, optimization

1. Introduction.

In this paper we consider the formulation of controlled classical nonholonomic systems on Riemannian manifolds. As described in Vershik [1984], Vershik and Fadeev [1981], Vershik and Gershkovich [1988], and Arnold [1988], one can divide the theory of nonholonomic systems into two classes: variational systems derivable from a Lagrangian, and classical (mechanical) systems derivable from D'Alembert's principle. The latter is normally used for describing mechanical systems, and our goal here is to introduce some aspects of control into the theory at the general level of systems evolving on Riemannian manifolds. This paper expands and extends some of the results announced in Bloch and Crouch [1992].

The classical nonholonomic systems have been considered by many others. We mention some of the most important here: Cartan [1952], using the general theory of equivalence; Weber [1986], using the Hamiltonian setting; Hermann [1982], using the Lagrangian setting and Ehresmann's theory of connections on jet spaces; and finally, Bates and Sniatycki [1993], again using a Hamiltonian setting but introducing a theory of reduction under symmetry.

Although little work has been done on the role of control in such systems until very recently, for example Yang [1992] and Bloch et al. [1989], [1992b], a lot of work has been done on the kinematic problem, where the nonintegrable velocity constraints define nonlinear (kinematic) control problems through the direct control of some of the velocities. Examples of this work include Brockett and Dai [1993], Krishnaprasad and Yang [1991], Lafferiere and Sussmann [1991], Montgomery [1990], and Murray and Sastry [1990]; see Bloch et al. [1992b] for further references.

Our work sets out to show that reduction of the dynamic equations of classical nonholonomic systems with external forces or controls can be expressed in a general Lagrangian setting, and that if symmetries are also present they can be incorporated into the same setting. The reduction is effected by introducing a bundle structure, so that the reduced system is defined by first-order differential equations in the fiber space and second-order differential equations in the base, defined through the Riemannian connection induced by a natural Riemannian metric or kinetic energy. This approach is most closely aligned with the important work of Koiller [1992], who considers the reduction process on a principal bundle, the structure group of which is a symmetry group for the problem. These are termed nonabelian

Caplygin systems. Our framework incorporates this setting as a special case, even though it is an important case.

We illustrate our general prescription by introducing an extended example. We generalize the case of a ball rolling on a flat plane with external forces parallel to the plane to push the ball, as studied by Brockett and Dai [1993]. The generalization incorporates the well-known model of a generalized rigid body, using a compact semi-simple Lie group, together with velocity constraints, linking the generalized rotational motion to a generalized translational motion. We call this system the generalized rolling ball. In the case that the ball is not symmetric (i.e., has an inertia tensor not equal to a multiple of the identity), the nonholonomic velocity constraints are not symmetries, and our reduction procedure generalizes that of Koiller [1988].

We also consider some controllability and optimality properties of the generalized rolling ball in the symmetric case. The controllability result generalizes the local argument of Bloch et al. [1992b], using a general controllability result on principal bundles. We also formalize a minimum force control problem as the higher-order analogue of the minimum energy control problem. In the holonomic case the minimum force control problem for second-order Newtonian systems was studied in Noakes et al. [1989] and Crouch and Leite [1991a], [1991b]. These works treat higher-order variational problems on Riemannian manifolds. We outline the modifications necessary to treat the nonholonomic case.

The outline of the paper is as follows. In §2 we give a general formulation of holonomic control systems on Riemannian manifolds, and in §3 we give the formulation of nonholonomic systems. In §4 we introduce the concept of symmetries and describe the general reduction procedure based on the nonholonomic constraints and the constants of motion derived from the symmetries. In §5, we have four subsections dealing with the control of the generalized rolling ball, in which we describe some preliminaries on Riemannian structures on Lie groups, the generalized rigid body, the generalized rolling ball in both body fixed and inertial axes, and finally controllability and optimality questions.

2. Holonomic control systems and optimal control. In this section we give a brief formulation of mechanical systems, without any velocity constraints, under the influence of external forces. We broadly follow the formulation given by Hermann [1982]. We consider the case of systems with "nonintegrable" velocity constraints in the following section.

Mechanical systems, in which the velocity constraints are integrable, are referred to here as holonomic mechanical systems. These integrable velocity constraints yield constraints on the configuration variables only, and thereby determine a manifold in which the configuration variables are constrained to evolve (see Arnold [1978]). This provides the motivation for considering holonomic control systems in the generality discussed below.

We let M denote a smooth (infinitely differentiable), n-dimensional manifold with a Riemannian metric denoted $\mathcal{K}(\cdot,\cdot)$. TM will denote the tangent bundle to M. The norm of a vector $X_p \in T_pM$ will be denoted by

$$||X_p||_{\mathcal{K}} = \sqrt{\mathcal{K}(X_p, X_p)}.$$

M denotes the configuration space of a mechanical system, whereas TM denotes the phase (or state) space. The notion of an inertia tensor will be modeled by a bundle mapping

$$J : TM \to TM,$$

such that J is the identity on M. Thus for each $p \in M$ we have a linear mapping

$$J_p : T_pM \to T_pM.$$

We assume that for each p, J_p is an isomorphism satisfying for each X_p, $Y_p \in T_pM$

(i) $\mathcal{K}(J_p X_p, Y_p) = \mathcal{K}(X_p, J_p Y_p)$,
(ii) $\mathcal{K}(J_p X_p, X_p) \geq 0$ ($= 0$ if and only if $X_p = 0$).
From J we may define another Riemannian metric on M by setting

$$\langle X, Y\rangle = \mathcal{K}(JX, Y)$$

for all vector fields X, Y on M. We refer to $\mathcal{K}$ as the ambient metric and $\langle\cdot,\cdot\rangle$ as the mechanical metric. The norm of a vector $X_p \in T_pM$ with respect to the mechanical metric will be denoted by

$$\|X_p\| = \sqrt{(\langle X_p, X_p\rangle)}.$$

The mechanical metric determines a unique Riemannian connection on M, denoted ∇, and thereby determines a covariant derivative, denoted $D/\partial t$. A mechanical system is determined by its kinetic energy $T : TM \longrightarrow R$ given by the expression

$$T_q = \frac{1}{2}\left\langle \frac{dq}{dt}, \frac{dq}{dt}\right\rangle$$

and the potential energy $U : M \longrightarrow \mathbf{R}$ given by an arbitrary smooth function on M. Denote the cotangent bundle to M by T^*M. An external force is modeled as a covector field F on M, in general time varying. Thus, $F_p \in T_p^*M$ for each $p \in M$. We define the momentum P as a covector field along the trajectories of the mechanical system on M by setting

$$P_q = \left\langle \frac{dq}{dt}, \cdot\right\rangle = \mathcal{K}\left(J_q\frac{dq}{dt}, \cdot\right).$$

We define an holonomic mechanical system on M to be that given by the basic Newtonian system of equations in T^*M

$$\frac{DP}{\partial t} = F - dU. \tag{1}$$

For each smooth vector field W on M, we have along the motion of (1)

$$\begin{aligned}\frac{D}{\partial t}(P(W)) &= \frac{D}{\partial t}\left\langle\frac{dq}{dt}, W\right\rangle = \left\langle\frac{D^2q}{\partial t^2}, W\right\rangle + \left\langle\frac{dq}{dt}, \frac{DW}{\partial t}\right\rangle\\ &= \frac{DP}{\partial t}(W) + P\left(\frac{DW}{\partial t}\right) = \frac{DP}{\partial t}(W) + \left\langle\frac{dq}{dt}, \frac{DW}{\partial t}\right\rangle.\end{aligned}$$

We deduce that

$$\frac{DP}{\partial t} = \left\langle\frac{D^2q}{\partial t^2}, \cdot\right\rangle = \mathcal{K}\left(J_q\frac{D^2q}{\partial t^2}, \cdot\right). \tag{2}$$

From the definition of kinetic energy and potential energy, equation (1) yields

$$F\left(\frac{dq}{dt}\right) = \frac{d}{dt}U(q(t)) + \frac{d}{dt}T_{q(t)}. \tag{3}$$

We may rewrite the holonomic mechanical system (1) as a system of equations in TM as follows. Let $\hat{X}_i$, $1 \leq i \leq N$ be $N \leq n$ independent vector fields on M, and let $u_i(\cdot)$,

$1 \leq i \leq N$, be input or control functions (real valued functions of time). We then model the force field F by setting

$$F_{q(t)} = \sum_{i=1}^{N} u_i(t)\langle \hat{X}_i(q(t)), \cdot \rangle. \tag{4}$$

Let $J^* : TM \to T^*M$ denote the bundle isomorphism determined on fibers by

$$J_p^* X_p = \langle X_p, \cdot \rangle = \mathcal{K}(J_p X_p, \cdot).$$

From equations (2) and (4) we may rewrite equation (1) in the form

$$\frac{D^2 q}{\partial t^2} = \sum_{i=1}^{N} u_i \hat{X}_i(q) - J_q^{*-1}\, dU_q. \tag{5}$$

Equation (5) now represents a general holonomic mechanical system with inputs. From now on we shall ignore the potential term in this equation, but it may be added without any extra difficulty. When $F \equiv 0$ (and $U \equiv 0$) equation (5) reduces to the geodesic equations on the Riemannian manifold $(M, \langle \cdot, \cdot \rangle)$

$$\frac{D^2 q}{\partial t^2} = 0.$$

This flow is known to be an extremal of the variational problem (Milnor [1963]),

$$\min_{\substack{q \\ q(0)=q_0,\, q(T)=q_T}} \int_0^T \left\| \frac{dq}{dt} \right\|^2 dt. \tag{6}$$

We now introduce a natural optimal control problem for the system (5). First we define a norm on fibers of $T^*\, M$ in the usual way:

$$\|F_q\| = \sup_{|W_q\|_{K} \neq 0} \frac{|F(W_q)|}{\|W_q\|_K}. \tag{7}$$

Note that we use the ambient metric in this definition. We introduce the minimum force control problem as

$$\min_q \int_0^T \frac{1}{2} \|F_{q(t)}\|^2\, dt \tag{8}$$

subject to the dynamics $\frac{DP}{\partial t} = F$ and the boundary conditions

$$q(0) = q_0, \quad \frac{dq}{dt}(0) = \dot{q}_0, \quad q(T) = q_T, \quad \frac{dq}{dt}(T) = \dot{q}_T, \tag{9}$$

or equivalently we may specify $P_{q(0)}$ and $P_{q(T)}$. From (2) and (7) we obtain

$$\|F_q\| = \sup_{\|W_q\|_K \neq 0} \frac{\mathcal{K}\left(J_q \frac{D^2 q}{\partial t^2}, W_q\right)}{\sqrt{(\mathcal{K}(W_q, W_q)}} = \left\| J_q \frac{D^2 q}{\partial t^2} \right\|_{\mathcal{K}}.$$

Thus the cost functional (8) may be reformulated as

$$\min_q \int_0^T \frac{1}{2} \left\langle \frac{D^2 q}{\partial t^2}, J_q \frac{D^2 q}{\partial t^2} \right\rangle dt. \tag{10}$$

It is now natural to consider the formulation (5) of the holonomic control system. It is convenient to assume a little more structure for the force field F defined in (4). We modify the definition as follows:

$$F_{q(t)} = \sum_{i=1}^{N} u_i(t)\langle J_{q(t)}^{-1} X_i(q(t)), \cdot\rangle, \tag{11}$$

where X_i, $1 \le i \le n$ is an orthonormal base of vector fields with respect to the ambient metric

$$\mathcal{K}(X_i, X_j) = \delta_{ij}, \qquad 1 \le i, j \le n. \tag{12}$$

With the force field (11) the system (5) may be rewritten as

$$\frac{D^2 q}{\partial t^2} = \sum_{i=1}^{N} J_q^{-1} X_i(q) u_i(t). \tag{13}$$

The orthonormality assumption (12) now implies that

$$\left\langle \frac{D^2 q}{\partial t^2}, J_q \frac{D^2 q}{\partial t^2} \right\rangle = \sum_{i=1}^{N} u_i^2(t).$$

It follows that for system (13) the minimum force control problem is defined by the cost functional

$$\min_u \int_0^T \frac{1}{2} \sum_{i=1}^{N} u_i^2(t)\, dt \tag{14}$$

subject to the boundary conditions (9).

In the case $N = n$ this optimal control problem corresponds to the higher-order variational problem posed by the functional (10) with boundary conditions (9). Similar higher-order variational problems have been treated in various contexts, most notably as the minimum curvature problem (Griffiths [1983], Jurdjevic [1991]), but recently they have occurred in the context of interpolation problems in Gabriel and Kajiya [1988], Noakes et al. [1989], and Crouch and Silva-Leite [1991a], [1991b]. In the latter three works a simpler functional is considered, namely

$$\min_q \int_0^T \frac{1}{2} \left\| \frac{D^2 q}{\partial t^2} \right\|^2 dt. \tag{15}$$

The "normal" extremals of such functionals satisfy an equation of the form

$$\frac{D^4 q}{\partial t^2} + R\left(\frac{D^2 q}{\partial t^2}, \frac{Dq}{\partial t}\right) \frac{Dq}{\partial t} \equiv 0, \tag{16}$$

where R is the curvature tensor associated with the connection ∇. It follows that for $N = n$, the minimum force control problem introduced above is a natural higher-order version of the classical variational problem (6), which is often interpreted as a minimum energy problem.

In the control literature another class of optimal control problem has received much attention. It may be characterized by the cost functionals (14) subject to systems of the form

$$\frac{dq}{dt} = \sum_{i=1}^{N} v_i \bar{X}_i(q), \quad (N < n), \quad q \in M, \tag{17}$$

where $\bar{X}_i$ are independent vector fields on M and v_i are control functions. Although these problems are governed by first-order rather than second-order equations (13), the singular nature of this optimal control problem, because of the fact that $N < n$, is of the same character as that of the minimum force control problem when $N < n$. Brockett [1982] considered the control problem posed by (17) and (14) (see also Baillieul [1978]), and subsequently the analysis has been taken up in the mathematics and control theory literature as sub-Riemannian geometry. In the next section we reinterpret the class of systems (17) as kinematic nonholonomic control systems (Remark 3).

3. Nonholonomic control systems. We now consider the formulation of controlled nonholonomic control systems. Nonholonomic systems may be divided into two classes (see, e.g., Vershik and Gershkovich [1988])—variational nonholonomic systems (dubbed vakonomic systems by Arnold [1988]) and classical (or mechanical) nonholonomic systems. In either case the basic ingredients are "nonintegrable" constraints on phase space, defined by m, $m < n$, one-forms on M, $\omega_1, \dots, \omega_m$, such that their span, over the smooth functions on M, contains no nontrivial exact forms and in particular none of the forms $\omega_1, \dots, \omega_m$ is exact. These forms then define a smooth distribution H on M. For each $p \in M$, H_p is the subspace of T_pM defined by

$$H_p = \{X_p \in T_pM;\ \omega_k(X_p) = 0,\ 1 \le k \le m\}.$$

We also stipulate that the distribution H is nonsingular, so that the dimension of the subspace H_p does not vary with p, although the significance of this is not fully understood.

Variational nonholonomic systems are obtained in our context as solutions of variational problems of the form

$$\min_q \int_0^T \frac{1}{2} \left\| \frac{dq}{dt} \right\|^2 dt$$

subject to

$$\omega_k\left(\frac{dq}{dt}\right) \equiv 0, \qquad 1 \le k \le m$$

and boundary conditions $q(0) = q_0$, $q(T) = q_T$.

This problem is solved in the usual way by introducing Lagrange multipliers μ_k and solving the new variational problem defined by

$$\min_q \int_0^T \left[\frac{1}{2} \left\| \frac{dq}{dt} \right\|^2 + \sum_{k=1}^m \mu_k \omega_k\left(\frac{dq}{dt}\right)\right] dt,$$

$$\omega_k\left(\frac{dq}{dt}\right) \equiv 0, \qquad 1 \le k \le m.$$

If we consider the kinematic system (17), in which the vector fields $\hat{X}_i$ are orthonormal with respect to the mechanical metric

$$\langle \hat{X}_i, \hat{X}_j \rangle = \delta_{ij}, \qquad 1 \le i, \quad j \le m,$$

and we define $n - m$ independent dual one-forms ω_k satisfying

$$\omega_k(\hat{X}_i) = 0, \quad 1 \le k \le n - m, \quad 1 \le i \le m,$$

it follows that the variational problem described above coincides with the optimal control problem posed by the cost functional (14), and subject to the kinematics (17). In this context the reader should be aware of work by Kirshnaprasad and Yang [1991] and many others including Brockett [1982], Baillieul [1978], Murray and Sastry [1990], and Lafferiere and Sussmann [1991]. See also Remark 3 below.

Classical nonholonomic systems are not obtained from a variational principle in the usual sense (see Remark 2 below), but from D'Alembert's principle. The equations may be written in the form

$$\frac{D^2q}{\partial t^2} = \sum_{i=1}^{m} \lambda_i W_i, \tag{18}$$

$$\omega_k\left(\frac{dq}{dt}\right) \equiv 0, \qquad 1 \leq k \leq m. \tag{19}$$

The vector fields W_i on M are determined through the identity

$$\omega_k(X) = \langle W_k, X\rangle, \qquad 1 \leq k \leq M$$

for any vector field X on M. The multipliers λ_i are also uniquely determined from the equations (18) and (19) as shown in Remark 2 below.

After our formulation of a holonomic controlled mechanical system (5), we define a nonholonomic controlled mechanical system to have the form

$$\frac{D^2q}{\partial t^2} = \sum_{i=1}^{m} \lambda_i W_i + \sum_{i=1}^{N} u_i \hat{X}_i, \tag{20}$$

$$\omega_k\left(\frac{dq}{dt}\right) = \left\langle W_k, \frac{dq}{dt}\right\rangle \equiv 0, \qquad 1 \leq k \leq m. \tag{21}$$

At this point we do not impose any relation between m and N.

We now summarize some remarks about the formulation (20).

Remark 1. After our general formulation of a holonomic system with external inputs as equations in T^*M, we may similarly define a nonholonomic system with external inputs as follows:

$$\begin{aligned} &\frac{DP}{\partial t} = F, \\ &\omega_k\left(\frac{dq}{dt}\right) \equiv 0, \qquad 1 \leq k \leq m. \end{aligned} \tag{22}$$

Differentiating the constraints we obtain

$$0 = \frac{d}{dt}\omega_k\left(\frac{dq}{dt}\right) = \frac{d}{dt}\left\langle W_k, \frac{dq}{dt}\right\rangle = \left\langle \frac{DW_k}{\partial t}, \frac{dq}{dt}\right\rangle + \left\langle W_k, \frac{D^2q}{\partial t^2}\right\rangle. \tag{23}$$

From equations (2) and (22) we obtain

$$F_q(W_k) = \left\langle \frac{D^2q}{\partial t^2}, W_k\right\rangle, \qquad 1 \leq k \leq m,$$

and so from (23) we deduce that

$$F_q(W_k) + P_q\left(\frac{DW_k}{\partial t}\right) \equiv 0, \qquad 1 \le k \le m. \tag{24}$$

Thus the force field F in a nonholonomic system (22) is not arbitrary but satisfies the constraints (24). It follows that regardless of N, or the vector fields $\hat{X}_i$ in the nonholonomic control system (20), after solving for the multipliers λ_i, the resulting system has at most $n - m$ independent control directions (as specified by vector fields that multiply the control functions u_i).

Remark 2. We note that although the system (20) and (21) may not arise from a variational principle in the usual Lagrangian sense, it is a solution of an instantaneous variational problem (Vershik [1984])

$$\min_{\frac{D^2q}{\partial t^2}} \left\| \frac{D^2q}{\partial t^2} - \sum_{i=1}^{N} u_i\hat{X}_i \right\| \quad \text{subject to } \left\langle W_k, \frac{dq}{dt}\right\rangle \equiv 0, \qquad 1 \le k \le m.$$

This is made clear by differentiating the constraints, as in (23), yielding m affine constraints in $D^2q/\partial t^2$. The multipliers λ_k in (20) are the solutions of the following system of equations

$$\sum_{j=1}^{m} \langle W_k, W_j\rangle\lambda_j = -\left\langle \frac{DW_k}{\partial t}, \frac{dq}{dt}\right\rangle - \sum_{i=1}^{N} u_i\langle W_k, \hat{X}_i\rangle, \qquad 1 \le k \le m. \tag{25}$$

Remark 3. We define the kinematic nonholonomic control system, corresponding to the dynamic nonholonomic control system (20), (21), to be a system of the form

$$\frac{dq}{dt} = \sum_{i=1}^{N} v_i\bar{X}_i(q), \tag{26}$$

where v_i are also control functions and $\bar{X}_i$ are vector fields spanning the distribution H. In general $\bar{X}_i$ differ from $\hat{X}_i$ appearing in the dynamic equations (20), the particular choice governed by physical consideration of the control mechanism. However, the general principle governing the choice of $\bar{X}_i$ and v_i is that v_i control all of the independent components of the velocity $\frac{dq}{dt}$. For controllability analysis of the system (26), the assumption is made that the distribution H is completely nonholonomic (see Vershik and Gershkovich [1988]), that is, the involutive closure H_L of H satisfies

$$H_L(p) = T_pM, \qquad p \in M.$$

This is also an important observation in Brockett [1982]. It is shown in Bloch et al. [1992b] that under certain circumstances, controllability of the associated dynamic nonholonomic control system (20), (21) follows from the assumption above.

Remark 4. Computing the derivative of the kinetic energy along solutions of the nonholonomic control system (20), (21) yields

$$\frac{d}{dt}\frac{1}{2}\left\langle \frac{dq}{dt}, \frac{dq}{dt}\right\rangle = \left\langle \frac{dq}{dt}, \sum_{i=1}^{m} \lambda_iW_i\right\rangle + \left\langle \frac{dq}{dt}, \sum_{i=1}^{N} u_i\hat{X}_i\right\rangle.$$

Thus

$$\frac{d}{dt}T_{q(t)} = F_{q(t)}\left(\frac{dq}{dt}\right),$$

where F is defined by (4). Because the same equation holds for the holonomic system (equation (3) with $U \equiv 0$), it is clear that the constraints do no work, as is well known (see, e.g., Neimark and Fufaev [1972]).

Example 1. We consider a penny rolling on the x–y plane with rotation angle θ and heading angle ϕ, as in Bloch and McClamroch [1989] and Bloch et al. [1992b]. We have two controls, one that rolls the penny about its center of mass and another that turns it about its vertical axis. The constraints are given by

$$\dot{x} = \dot{\theta} \cos \phi,$$
$$\dot{y} = \dot{\theta} \sin \phi.$$

Letting $q = (x, y, \theta, \phi)^T$, the dynamic equations of motion (20) may be written as

$$\ddot{q} = u_1 \hat{X}_1 + u_2 \hat{X}_2 + \lambda_1 W_1 + \lambda_2 W_2,$$

where $\hat{X}_1 = (0,0,1,0)^T$, $\hat{X}_2 = (0,0,0,1)^T$, $W_1 = (1,0,-\cos \phi, 0)^T$, and $W_2 = (0,1,-\sin \phi, 0)^T$. It easily follows that $\lambda_1 = \frac{d}{dt}(\dot{\theta} \cos \phi)$, $\lambda_2 = \frac{d}{dt}(\dot{\theta} \sin \phi)$, and so the resulting system is given by

$$\ddot{x} = \frac{d}{dt}(\dot{\theta} \cos \phi), \quad \ddot{y} = \frac{d}{dt}(\dot{\theta} \sin \phi), \quad 2\ddot{\theta} = u_1, \quad \ddot{\phi} = u_2.$$

On the other hand, the kinematic equations are

$$\dot{q} = v_1 \bar{X}_1 + v_2 \bar{X}_2,$$

where $\bar{X}_1 = (\cos \phi, \sin \phi, 1, 0)^T$ and $\bar{X}_2 = (0,0,0,1)^T$ lie in the distribution H.

Example 2. We now consider the "Heisenberg" system (so called because its vector fields generate the Heisenberg algebra)—see Brockett [1982] and the work of Vershik et al. (see e.g., Vershik and Gershkovich [1988]). Here we have a system on $\mathbf{R}^3$ in the variables (x, y, z) and subject to the constraint

$$\dot{z} = y\dot{x} - x\dot{y}.$$

We have controls in the x and y directions and wish to control the system in $\mathbf{R}^3$. Letting $q = (x, y, z)^T$, the natural dynamic nonholonomic control system (20) may be written as

$$\ddot{q} = u_1 X_1 + u_2 X_2 + \lambda W,$$

where $X_1 = (1,0,0)^T$, $X_2 = (0,1,0)^T$, and $W = (-y, x, 1)^T$. It is easy to see that in this case

$$\lambda = (yu_1 - xu_2)/(1 + y^2 + x^2),$$

so that the dynamics become

$$\phi\ddot{x} = (1 + x^2)u_1 + xyu_2,$$
$$\phi\ddot{y} = (1 + y^2)u_2 + xyu_1,$$
$$\phi\ddot{z} = yu_1 - xu_2,$$

where $\phi(x, y) = 1 + y^2 + x^2$.

The corresponding kinematic system, as discussed in Brockett [1982] is given by

$$\dot{q} = v_1 \bar{X}_1 + v_2 \bar{X}_2,$$

where $\bar{X}_1 = (1, 0, y)^T, \bar{X}_2 = (0, 1, -x)^T$.

4. Symmetries and reduction. Symmetries in mechanics give rise to constants of the motion (see for example Abraham and Marsden [1978]). In the Riemannian context isometries are generated by Killing vector fields. Recall that Z is a Killing vector field with respect to the mechanical metric if

$$\langle \nabla_Y Z, Y\rangle = 0$$

for all vector fields Y. Further, a sufficient condition for $\langle Z(q), \frac{dq}{dt}\rangle$ to be a constant of motion for a geodesic flow is that Z is a Killing vector field. For controlled nonholonomic systems we have the following restatement of Theorem 6, p. 82 in Arnold [1988].

LEMMA 1. *Sufficient conditions for* $\langle Z, \frac{dq}{dt}\rangle$ *to be a constant of motion for the controlled nonholonomic system* (20), (21) *are*

(i) $Z \in H$,

(ii) $Z \in \operatorname{Span}\{\hat{X}_1, \dots, \hat{X}_N\}^{\perp}$ (*with respect to* $\langle\cdot,\cdot\rangle$),

(iii) Z *is a Killing vector field.*

Proof. As in equation (23) we have

$$\frac{d}{dt}\left\langle Z, \frac{dq}{dt}\right\rangle = \left\langle \frac{DZ}{\partial t}, \frac{dq}{dt}\right\rangle + \left\langle Z, \frac{D^2 q}{\partial t^2}\right\rangle.$$

The first term is zero by (iii), and the second is zero by the expression for $D^2q/\partial t^2$ in (20) and (i) and (ii). □

Note that when $M = \mathbf{R}^n$ and the metric $\langle\cdot,\cdot\rangle$ is independent of the coordinate function x_i, then $\partial/\partial x_i$ is a Killing vector field.

Note also that if the uncontrolled nonholonomic system (18) is determined by constraints (19) in which the vector fields W_i are indeed Killing vector fields, then equation (23) gives $\langle W_k, D^2q/\partial t^2\rangle \equiv 0$. It then follows from (18) that $\lambda_k = 0$, $1 \le k \le m$, so that the flow of such a nonholonomic system is a restriction of the geodesic flow. This is illustrated in Example 2.

It is often convenient to introduce a bundle structure in M, $\pi : M \to B$, with fiber F, dim. $B = r$, and dim. $F = n - r$. This structure reflects the natural geometric structure of the system induced by the constraints and must be compatible with the constraints in the sense that

$$\pi_* H_p = T_{\pi(p)} B \quad \text{for all}\, p \in M.$$

Clearly this forces dim. $H = n - m \ge$ dim. $B = r$. Our aim is to reduce the controlled nonholonomic system (20), (21) so that the evolution on the fiber is given by a first-order equation. To this end we introduce two further assumptions. Either Assumption 1 or Assumption 2 follows.

Assumption 1. dim. $H =$ dim. B, that is, $n = m + r$. In this case $\hat{H} = H$ clearly defines a horizontal distribution on the bundle.

Assumption 2. dim. $H-$ dim. $B = n - m - r = s > 0$, and there exist s linearly independent vector fields $Z_1, \dots, Z_s$ that satisfy conditions (i)–(iii) of Lemma 1. In particular,

$$\left\langle Z_i, \frac{dq}{dt}\right\rangle = c_i = \text{const.} \tag{27}$$

are constants of the motion for (20), (21). We define a distribution $\hat{H}_0$ on M by setting $X \in \hat{H}_0$ if

$$\begin{aligned} \langle W_k, X\rangle &= 0 \qquad 1 \le k \le m, \\ \langle Z_k, X\rangle &= 0 \qquad 1 \le k \le s, \end{aligned}$$

and assume that $\hat{H}_0$ satisfies

$$T_pF \cap \hat{H}_0 = \{0\} \quad \text{for all } p \in M. \tag{28}$$

Finally we define the r-dimensional affine distribution $\hat{H}$ on M by setting $X \in \hat{H}$ if

$$\begin{aligned} \langle W_k, X\rangle &= 0 \qquad 1 \le k \le m, \\ \langle Z_k, X\rangle &= c_k \qquad 1 \le k \le s. \end{aligned} \tag{29}$$

Note that Assumption 2 ensures that $\hat{H}_0$ is a constant r-dimensional distribution on M, and (28) ensures that $\hat{H}_0$ is a horizontal distribution on the bundle. If either Assumption 1 or 2 holds, we have as a direct sum of affine spaces

$$T_pM = \hat{H}_p \oplus T_pF \quad \text{for all } p \in M.$$

It follows that any vector field Y on M can be decomposed uniquely into components

$$Y_p = Y_p^H + Y_p^F, \quad p \in M,\, Y_p^H \in \hat{H}_p, \quad Y_p^F \in T_pF.$$

With this structure we may decompose the velocity

$$\frac{dq}{dt} = \dot{q}^H + \dot{q}^F, \quad \dot{q}^H \in \hat{H}_q, \quad \dot{q}^F \in T_qF.$$

In general $\dot{q}^H$ and $\dot{q}^F$ are not derivatives of functions q^H and q^F on M, although in many applications one can indeed identify such functions. From equations (21) and (29) we obtain

$$\begin{aligned} \langle W_k, \dot{q}^F\rangle &= -\langle W_k, \dot{q}^H\rangle, \qquad 1 \le k \le m, \\ \langle Z_k, \dot{q}^F\rangle &= -\langle Z_k, \dot{q}^H\rangle + c_k, \qquad 1 \le k \le s. \end{aligned}$$

Condition (28) allows us to solve these equations uniquely for $\dot{q}^F$

$$\dot{q}^F = f_F(q, \dot{q}^H). \tag{30}$$

Note that f_F is affine in $\dot{q}^H$. From the original controlled nonholonomic system (20) we may deduce equations of the form

$$\frac{D\dot{q}^H}{\partial t} = f_H(q, \dot{q}, u). \tag{31}$$

Equations (30) and (31) provide a reduction of the $2n$ first-order equations (20), with constraints (21), to $n + r$ first-order equations, without constraints. Locally we can write $\dot{q}^H = \frac{d}{dt}q^B$ for some trajectory $q^B(t) \in B$. In some cases we may be able to rewrite equations (30) and (31) globally in terms of a trajectory $q(t) = (q^B(t), q^F(t))$, $q^B \in B$, $q^F \in F$.

The class of Caplygin control systems introduced in Bloch et al. [1992b] corresponds to Assumption 1, in the case where M is a product $M = B \times F$, $B = \mathbf{R}^r$, $F = \mathbf{R}^{n-r}$, $\langle \cdot, \cdot \rangle$ is the Euclidean metric, and the whole dynamics (30), (31) is invariant with respect to q^F. A global prescription for these systems is given in the form

$$\begin{aligned} \dot{q}^F &= f_F(q^B, \dot{q}^B), \\ \ddot{q}^B &= f_B(q^B, \dot{q}^B, u), \end{aligned}$$

where f_F is affine in $\dot{q}^B$.

Another class of systems in which a global reduction is possible is the class of controlled nonabelian Caplygin systems. The uncontrolled systems of this type were discussed in Koiller [1988]. We define a controlled nonabelian Caplygin system as a system (30), (31), in which M is a principal G bundle $M(G, B)$ for a Lie group G, G acts by isometries on the mechanical metric, H (in either Assumption 1 or 2) is invariant under G in the sense that

$$H_{g \cdot p} = g_* H_p, \quad g \in G, \quad p \in M,$$

and finally the vector fields $\hat{X}_i$ are G invariant

$$g_* \hat{X}_i(p) = \hat{X}_i(g \cdot p), \quad g \in G, \quad p \in M, \quad 1 \leq i \leq N.$$

The reduced system of equations can be written (locally) (by analogy with the work of Koiller) in the form

$$\begin{aligned} \dot{g} &= f_F(q_B, \dot{q}_B, g), & g &\in G, \\ \frac{D\dot{q}_B}{\partial t} &= f_B(q_B, \dot{q}_B, u), & q_B &\in B \cong M/G, \end{aligned} \tag{32}$$

where f_F is a G invariant vector field on G.

These reduced systems fall directly within the class of control systems on principal bundles $M(G, B)$ studied by San Martin and Crouch [1984]. If D is a set of vector fields on M, we say that D is projectable if for each $X \in D$ there exists X' on B such that $\pi_* X = X' \circ \pi$. We have the following result.

THEOREM 1 (San Martin and Crouch [1984]). *Let $M(B, G)$ be a connected principal fiber bundle with G a compact Lie group and D a G-invariant, projectable family of vector fields on M defining a control system Σ_D, which is accessible. Denote by Σ'_D the system on B defined by $D' = \pi(D)$. Then Σ_D is controllable if and only if Σ'_D is controllable.*

We have the following corollary.

COROLLARY 1. *Consider a nonabelian Caplygin control system with compact structure group. Assume that the reduced system* (32) *is accessible and the system on the base is controllable. Then the reduced system on M is controllable.*

5. An example: The generalized rolling ball.

5.1. Background on Lie groups.

In this section we briefly review some of the material relating to the dynamical equations of the generalized rigid body. The material in the next two sections may be found in books by Arnold [1978], Hermann [1977], Boothby [1975], etc. Let G be an L-dimensional compact semi-simple Lie group with identity element e, and let $\mathcal{G}$ denote its Lie algebra. There exists a positive definite inner product on $\mathcal{G}$ that we denote by $\langle\langle \cdot, \cdot \rangle\rangle$, defined as a multiple of the Killing form. If X is an element of $\mathcal{G}$, then we can define left and right invariant vector fields on M by setting

$$X_g^l = L_{g_*} X, \qquad X_g^r = R_{g_*} X,$$

where L_g and R_g are the left and right translations on G by $g \in G$.

Let Ad denote the adjoint mapping on $\mathcal{G}$; if $\phi_h : G \to G$ is defined by

$$\phi_h(g) = h^{-1} g h = R_h L_{h^{-1}}(g),$$

then

$$\text{Ad } h = \phi_{h_*}|_{g=e}.$$

Note that with this definition Ad is an anti-homomorphism Ad $gh = $ Ad h Ad g. Now we have

$$X^l_g = L_{g*}X = R_{g*}(R_{g^{-1}_*}L_{g*})X = R_{g*}(\text{Ad } g^{-1}(X)).$$

Thus,

$$X^l_g = (\text{Ad } g^{-1}X)^r_g. \tag{33}$$

For compact semi-simple Lie groups, Ad g is an isometry of $\mathcal{G}$, for every $g \in G$, with respect to the Killing form. Thus we have

$$\langle\langle \text{Ad } gX, \text{ Ad } gY\rangle\rangle = \langle\langle X, Y\rangle\rangle, \quad X, Y \in \mathcal{G}, \quad g \in G. \tag{34}$$

We may now define a bi-invariant Riemannian metric on G by setting

$$\mathcal{K}(X^l_g, Y^l_g) = \langle\langle X, Y\rangle\rangle = \mathcal{K}(X^r_g, Y^r_g).$$

The bi-invariance follows directly from (33) and (34).

If $h(\cdot)$ is a curve in G satisfying the equation

$$\dot{h} = Z^r_h, \quad h(0) = e, \quad h \in G, \tag{35}$$

then

$$\frac{d}{dt} \text{ Ad } h(t)Y|_{t=0} = [Z, Y] \overset{\Delta}{=} \text{ad } Z(Y).$$

Note that the definition of Lie bracket on $\mathcal{G}$ coincides here, under the identification of $\mathcal{G}$ with T_eG, with the standard definition of the Lie bracket

$$[W, V]_g(f) = W_g(V(f)) - V_g(W(f))$$

for all functions f and G and vector fields W and V on G.

Applying (34) to Ad $h(t)$ and differentiating, yields

$$\langle\langle \text{ad } Z(X), Y\rangle\rangle + \langle\langle X, \text{ ad } Z(Y)\rangle\rangle = 0, \qquad X, Y, Z \in \mathcal{G}.$$

Let J be a positive definite linear mapping $J : \mathcal{G} \to \mathcal{G}$ satisfying

(i) $\langle\langle J(X), Y\rangle\rangle = \langle\langle X, J(Y)\rangle\rangle$,

(ii) $\langle\langle J(X), X\rangle\rangle \geq 0$ ($= 0$ if and only if $X = 0$).

We now define a right invariant metric on G by setting

$$\langle X^r_g, Y^r_g\rangle = \langle\langle X, J(Y)\rangle\rangle, \qquad X, Y \in \mathcal{G}.$$

We may extend J to a linear isomorphism $J_g : T_gG \to T_gG$ by setting

$$J_gY^r_g = (JY)^r_g, \quad g \in G, \quad Y \in \mathcal{G}.$$

It follows that

$$\langle V_g, W_g\rangle = \mathcal{K}(J_gV_g, W_g)$$

for all vector fields V and W on M. Corresponding to the right invariant metric $\langle\cdot,\cdot\rangle$ there exists a unique Riemannian connection ∇. Explicit formulas for ∇ are given in Arnold [1978] or Nomizu [1954]. Specifically, ∇ defines a bilinear form on $\mathcal{G}$

$$(X, Y) \mapsto \nabla_X Y = \frac{1}{2}\{[X, Y] + J^{-1}[X, JY] + J^{-1}[Y, JX]\}. \tag{36}$$

∇ is now extended to right invariant vector fields on G by setting

$$(\nabla_{X^r}Y^r)(g) = (\nabla_X Y)^r_g, \quad g \in G, \quad X, Y \in \mathcal{G}.$$

If J is a multiple of the identity, $\langle \cdot, \cdot \rangle$ is the same multiple of K, and ∇ reduces to

$$\nabla_{X^r}Y^r = \frac{1}{2}[X^r, Y^r]. \tag{37}$$

For the purposes of our later analysis we prove the following result.

LEMMA 2.

$$(\nabla_{X^r}Y^l)(g) = (\nabla'_X \operatorname{Ad} g^{-1}Y)^r_g, \quad g \in G, \quad X, Y \in \mathcal{G},$$

where ∇' is the bilinear form on $\mathcal{G}$ given by

$$\nabla'_X Y = \nabla_X Y - [X, Y].$$

Proof. Let $X_1, \ldots, X_L$ be a basis of $\mathcal{G}$, and write $\operatorname{Ad} g^{-1}Y = \sum_{k=1}^L f_k(g)X_k$, where f_k are functions on G. Thus

$$\begin{aligned} (\nabla_{X^r}Y^l)(g) &= \sum_{k=1}^L f_k(g)(\nabla_{X^r}X^r_k)(g) + \sum_{k=1}^L X^r(f_k)(g)X^r_k(g), \\ X^r(f_k)(g) &= \frac{d}{dt}f_k(R_g(h(t)))\Big|_{t=0}, \end{aligned} \tag{38}$$

where $h(\cdot)$ is a solution of (35). But

$$\frac{d}{dt}\operatorname{Ad}\,(R_g(h(t)))^{-1}Y\Big|_{t=0} = \frac{d}{dt}\operatorname{Ad} h^{-1}(t)\operatorname{Ad} g^{-1}Y\Big|_{t=0} = -[X, \operatorname{Ad} g^{-1}Y].$$

Thus from (38) we obtain

$$(\nabla_{X^r}Y)^l)(g) = (\nabla_X \operatorname{Ad} g^{-1}Y - [X, \operatorname{Ad} g^{-1}Y])^r_g. \qquad \square$$

5.2. Background on the generalized rigid body. In this section we briefly review material on the motion of a generalized rigid body. This is modeled by geodesic equations on a compact semi-simple Lie group G, with the right invariant metric defined by a positive definite mapping J on $\mathcal{G}$ as described in the previous section. We have two representations of the velocity defined by a right invariant frame and left invariant frame. If $X_1, \ldots, X_L$ is a basis for $\mathcal{G}$, we set

$$\frac{dg}{dt} = \sum_{i=1}^L w_i(t)X^l_i(g), \tag{39}$$

$$\frac{dg}{dt} = \sum_{i=1}^L v_i(t)X^r_i(g). \tag{40}$$

The kinetic energy expressed in terms of the representation (40) is given by

$$T(g) = \frac{1}{2}\left\langle \frac{dg}{dt}, \frac{dg}{dt} \right\rangle = \frac{1}{2}\left\langle\left\langle \sum_{i=1}^L v_iX_i, \sum_{i=1}^L v_iJX_i \right\rangle\right\rangle.$$

Thus the coordinates v_i refer to the velocity with respect to a frame moving in the body, whereas the coordinates w_i refer to the velocity with respect to a frame fixed in inertial space. (See also Arnold [1978, p. 323], but there the roles of left and right are reversed.) We have

$$\sum_{i=1}^{L} v_i X_i^r(g) = \sum_{i=1}^{L} w_i X_i^l(g).$$

Hence, if we now assume that the basis X_i of $\mathcal{G}$ is orthonormal

$$\langle\langle X_i, X_j \rangle\rangle = \delta_{ij},$$

we obtain

$$w_k = \sum_{i=1}^{L} \langle\langle X_i, \mathrm{Ad}\; g^{-1} X_k \rangle\rangle v_i.$$

We now obtain two representations for the acceleration, based on the left and right invariant settings. First we obtain the representation based on (40). Differentiating, we obtain

$$\frac{D^2 g}{\partial t^2} = \sum_{i=1}^{L} \dot{v}_i(t) X_i^r(g) + \sum_{j,i=1}^{L} v_i(t) v_j(t) (\nabla_{X_j^r} X_i^r)(g).$$

Setting $V_t = \sum_{i=1}^{L} v_i(t) X_i$ and $\partial V_t / \partial t = \sum_{i=1}^{L} \dot{v}_i(t) X_i$ as vectors in $\mathcal{G}$, using the expression (36) gives the usual expression (see, for example, Hermann [1977])

$$\frac{D^2 g}{\partial t^2} = \left(\frac{\partial V_t}{\partial t} + J^{-1}[V_t, J V_t] \right)_g^r . \tag{41}$$

Now turning to the representation (39) we have the following result in which we write

$$W_t = \sum_{i=1}^{L} w_i(t) X_i, \quad \frac{\partial W_t}{\partial t} = \sum_{i=1}^{L} \dot{w}_i(t) X_i, \quad \mathbf{J}(g) = \mathrm{Ad}\; g J \,\mathrm{Ad}\; g^{-1}. \tag{42}$$

LEMMA 3.

$$\frac{D^2 g}{\partial t^2} = \left(\frac{\partial W_t}{\partial t} + \mathbf{J}(g)^{-1} [W_t, \mathbf{J}(g) W_t] \right)_g^l . \tag{43}$$

Proof. Differentiating the representation (39), we obtain

$$\frac{D^2 g}{\partial t^2} = \sum_{i=1}^{L} \dot{w}_i(t) X_i^l(g) + \sum_{ij=1}^{L} w_i(t) w_j(t) (\nabla_{X_j^l} X_i^l)(g).$$

But $\nabla_{X_j^l} X_i^l = \nabla_{(\mathrm{Ad}\, g^{-1} X_j)^r} X_i^l$, so using (36) and Lemma (2)

$$\nabla_{X_j^l} X_i^l = \frac{1}{2} \{ -[\mathrm{Ad}\; g^{-1} X_j, \mathrm{Ad}\; g^{-1} X_i] + J^{-1}[\mathrm{Ad}\; g^{-1} X_j, J \,\mathrm{Ad}\; g^{-1} X_i]$$
$$+ J^{-1}[\mathrm{Ad}\; g^{-1} X_i, J \,\mathrm{Ad}\; g^{-1} X_j] \}_g^r .$$

Using the skew symmetry of the Lie bracket we get

$$\begin{aligned}\frac{D^2 g}{\partial t^2} &= \left(\frac{\partial W_t}{\partial t}\right)^l_g + (J^{-1}[\mathrm{Ad}\, g^{-1}W_t, J\,\mathrm{Ad}\, g^{-1}W_t])^r_g \\ &= \left(\frac{\partial W_t}{\partial t} + \mathrm{Ad}\, gJ^{-1}\,\mathrm{Ad}\, g^{-1}[W_t,\, \mathrm{Ad}\, gJ\,\mathrm{Ad}\, g^{-1}W_t]\right)^l_g .\end{aligned}$$

Now using the definition of $\mathbf{J}(g)$ we obtain the stated result in equation (43). □

5.3. The generalized rolling ball. In this section we describe a generalization of a ball rolling on a flat table, in which we model the ball as a generalized rigid body described in the preceding section. We take the configuration space to be given as $M = G \times \mathbf{R}^N$, where G is an L-dimensional compact semi-simple Lie group as in the previous sections with $L > N$. We put two Riemannian structures on M; the ambient structure is defined by setting

$$\mathcal{K}^M_{(g,x)}((X_g, V)(Y_g, W)) = \mathcal{K}_g(X_g, Y_g) + \langle V, W\rangle^E,$$

where $\langle\cdot,\cdot\rangle^E$ is the Euclidean structure on $\mathbf{R}^N$, and (X_g, V), (Y_g, W) are vectors in $T_gG \times T_x\mathbf{R}^N$. The mechanical metric is defined by setting

$$\langle (X_g, V),\, (Y_g, W)\rangle^M_{(g,x)} = \langle X_g, Y_g\rangle_g + \langle V, W\rangle^E,$$

where $\langle\cdot,\cdot\rangle$ is the right invariant mechanical metric on G, defined in terms of a positive definite mapping J of $\mathcal{G}$. The mechanical metric on M determines a Riemannian connection on M, but the product structure defined by the metric enables us to rely on the connections defined by the metrics $\langle\cdot,\cdot\rangle$ and $\langle\cdot,\cdot\rangle^E$ on G and $\mathbf{R}^N$, respectively.

We wish to define a nonholonomic control system on M according to the prescription given by the equations (20) and (21). For this example we suppose that $m = N$, that is, the number of independent control forces is equal to the number of kinematic constraints. The nonholonomic control system is completely described by defining the input forces

$$F = \sum_{i=1}^N u_i\, dx_i = \sum_{i=1}^N u_i \left\langle \frac{\partial}{\partial x_i}, \cdot \right\rangle^E , \tag{44}$$

where x_i, $1 \le i \le N$ are coordinates in $\mathbf{R}^N$, and the constraints ω_k, $1 \le k \le N$

$$\omega_k\left(\left(\frac{dg}{dt}, \frac{dx}{dt}\right)\right) = \left\langle \frac{dg}{dt}, J_g^{-1}X_k^l(g)\right\rangle - \left\langle \frac{dx}{dt}, \frac{\partial}{\partial x_k}\right\rangle^E = 0 \tag{45}$$

where $\left(\frac{dg}{dt}, \frac{dx}{dt}\right)$ is the velocity of the trajectory (g, x) in M, and $X_1, \ldots, X_L$ is an orthonormal basis for $\mathcal{G}$, with respect to $\langle\langle\cdot,\cdot\rangle\rangle$. Note that in the physical (three-dimensional) case $L = 3$, $N = 2$ (see Bloch and Crouch [1992b]) the constraints are

$$\left\langle \frac{dg}{dt}, J_g^{-1}X_1^l(g)\right\rangle - \left\langle \frac{dx}{dt}, \frac{\partial}{\partial x_2}\right\rangle^E = \left\langle \frac{dg}{dt}, J_g^{-1}X_2^l(g)\right\rangle + \left\langle \frac{dx}{dt}, \frac{\partial}{\partial x_1}\right\rangle^E = 0.$$

This follows from setting the velocity of the point of contact of the ball equal to zero and using the fact that a three-dimensional rotation has a unique axis of rotation. Because this is not true in higher dimensions, the constraint (45) appears to be the natural generalization. The system (20) and (21) now becomes

$$\frac{d^2}{dt^2}x_k = -\lambda_k + u_k, \qquad 1 \le k \le N, \tag{46}$$
$$\frac{D^2 g}{\partial t^2} = \sum_{k=1}^{N} \lambda_k J_g^{-1} X_k^l(g),$$

$$\dot{x}_k = \left\langle \frac{dg}{dt}, J_g^{-1} X_k^l(g) \right\rangle, \qquad 1 \le k \le N. \tag{47}$$

THEOREM 2. *The following are constants of motion for the controlled nonholonomic system* (46), (47).

$$\left\langle X_k^l(g), \frac{dg}{dt} \right\rangle, \qquad N < k \le L. \tag{48}$$

Proof. We show that the conditions of Lemma 1 are satisfied.

(i) We must show that X_k^l, $N < k \le L$ belong to the distribution H on M defined by the constraints (45). This is equivalent to the identity

$$\langle X_k^l, J_g^{-1} X_j^l(g) \rangle = 0, \quad 1 \le j \le N, \quad N < k \le L.$$

But this follows from the definition of the mechanical metric on G and the orthonormality of the vector fields X_j.

(ii) We must show that the vector fields X_k^l, $N < k \le L$ are orthogonal to the control vector fields $\partial/\partial x_k$. This follows trivially from the definition of the metric on M.

(iii) We must show that X_k^l, $N < k \le L$ are Killing vector fields with respect to the mechanical metric on M, which reduces to the same problem for the mechanical metric on G. Thus it is sufficient to show that

$$\langle W^r, \nabla_{W^r} X_k^l \rangle \equiv 0, \quad \text{for all vectors } W \in \mathcal{G}.$$

From Lemma 2 we obtain

$$\begin{aligned}\langle W^r, \nabla_{W^r} X_k^l \rangle_g &= \mathcal{K}_g(W_g^r, J_g(\nabla'_W \operatorname{Ad} g^{-1} X_k)_g^r) \\ &= \mathcal{K}_g(W_g^r, (J\nabla'_W \operatorname{Ad} g^{-1} X_k)_g^r) \\ &= \langle\langle W, J\nabla'_W \operatorname{Ad} g^{-1} X_k \rangle\rangle \\ &= \frac{1}{2}\langle\langle W, -J[W, \operatorname{Ad} g^{-1} X_k] + [W, J \operatorname{Ad} g^{-1} X_k] + [\operatorname{Ad} g^{-1} X_k, JW] \rangle\rangle \\ &= 0. \quad \square\end{aligned}$$

It follows directly from this result that along the trajectories of (46), (47) we have for suitable constants c_k,

$$\left\langle \frac{dg}{dt}, X_k^l(g) \right\rangle \equiv c_k, \qquad N < k \le L. \tag{49}$$

We may calculate the multipliers λ_k in (46) as was done in Remark 2. Differentiating (47) and substituting for the second derivatives given in (46), we obtain

$$-\lambda_k + u_k = \sum_{j=1}^{N} \langle J_g^{-1} X_k^l, J_g^{-1} X_j^l \rangle \lambda_j + \left\langle \frac{dg}{dt}, \frac{D}{\partial t} J_g^{-1} X_k^l \right\rangle$$

or

$$u_k - \left\langle \frac{dg}{dt}, \frac{D}{\partial t} J_g^{-1} X_k^l \right\rangle = \lambda_k + \sum_{j=1}^{N} \langle\langle \mathrm{Ad}\; g^{-1} X_k, J^{-1}\, \mathrm{Ad}\; g^{-1} X_j \rangle\rangle \lambda_j. \tag{50}$$

Define a matrix Λ with components given by

$$\Lambda_{kj} = \delta_{kj} + \langle\langle \mathrm{Ad}\; g^{-1} X_k, J^{-1}\, \mathrm{Ad}\; g^{-1} X_j \rangle\rangle, \quad 1 \le k, \quad j \le N. \tag{51}$$

The assumed positive definiteness of J ensures that Λ is always invertible, so that (50) defines the multipliers λ_k uniquely in equations (46).

We now describe the two reductions of equations (46), (47), described in §4. We first consider the reduction based on Assumption 1. In this case we take the base $B = G$ and the fiber $F = \mathbf{R}^N$. The N-independent constraints (47) ensure that dim. $H = (N + L) - N = L =$ dim. B, as required. The reduction procedure described in §4 simply rewrites the second-order equations on the fiber by the constraint equations (47). We may employ equation (50) to eliminate the multipliers λ_k; however, we first employ a simple feedback control, defined by

$$u_k = \left\langle \frac{dg}{dt}, \frac{D}{\partial t} J_g^{-1} X_k^l \right\rangle + \sum_{j=1}^{N} \Lambda_{kj} \bar{u}_j, \qquad 1 \le k \le N, \tag{52}$$

which defines $\bar{u}_j$, $1 \le j \le N$ uniquely. It follows that under this reduction and feedback the system (46), (47) becomes

$$\begin{aligned} \dot{x}_k &= \left\langle \frac{dg}{dt}, J_g^{-1} X_k^l(g) \right\rangle, \qquad 1 \le k \le N \\ \frac{D^2 g}{\partial t^2} &= \sum_{k=1}^{N} J_g^{-1} X_k^l(g) \bar{u}_k. \end{aligned} \tag{53}$$

We note that along solutions of (53), we have

$$\frac{d}{dt}\frac{1}{2}\left\langle \frac{dg}{dt}, \frac{dg}{dt} \right\rangle = \sum_{k=1}^{N} \dot{x}_k \bar{u}_k$$

compared with a similar computation for system (46), (47), given in Remark 4,

$$\frac{d}{dt}\left[\frac{1}{2}\left\langle \frac{dg}{dt}, \frac{dg}{dt} \right\rangle + \frac{1}{2}\langle \dot{x}, \dot{x} \rangle^E\right] = \sum_{k=1}^{N} \dot{x}_k u_k.$$

Thus the work done by the force control $\bar{u}$ in (53) simply changes the generalized rotational energy and not the generalized translational energy.

Finally we may rewrite the reduced system (53) in terms of an "inertial frame" (39), as described in the previous section. Using Lemma 3 to express the acceleration in terms of the velocity W_t in equation (42), we obtain

$$\begin{aligned} \dot{x}_k &= w_k, \qquad 1 \le k \le N, \\ \frac{\partial W_t}{\partial t} + \mathbf{J}(g)^{-1}[W_t, \mathbf{J}(g) W_t] &= \sum_{k=1}^{N} \mathbf{J}(g)^{-1} X_k \bar{u}_k, \end{aligned} \tag{54}$$

$$\frac{dg}{dt} = (W_t)_g^l = \sum_{k=1}^{L} w_k(t) X_k^l(g).$$

We now describe the reduction based on Assumption 2 in §4. In this case we take the base $B = \mathbf{R}^N$ and the fiber $F = G$. We employ the L constraints (47) and (49) to determine the velocity $\frac{dg}{dt}$. Note that we employ all N velocity constraints and $L - N$ constants of motion. To calculate $\frac{dg}{dt}$ explicitly, it is useful to employ the expression for it in terms of an "inertial frame" as given in equations (39). (47) and (49) can then be written as

$$\begin{aligned} \dot{x}_k &= w_k, \qquad 1 \le k \le N \\ c_k &= \sum_{i=1}^{L} \langle\langle X_k, \mathbf{J}(g) X_k \rangle\rangle w_i, \qquad N < k \le L. \end{aligned}$$

From these equations we may define functions f_j, $N < j \le L$,

$$f_j : \mathbf{R}^N \times G \to \mathbf{R}$$

by the following system of equations, using the positive definiteness of J.

$$c_k = \sum_{i=1}^{N} \langle\langle \mathbf{J}(g) X_k, X_i \rangle\rangle \dot{x}_i + \sum_{i=N+1}^{L} \langle\langle \mathbf{J}(g) X_k, X_i \rangle\rangle f_i(\dot{x}_i, g), \qquad N + 1 \le k \le L. \tag{55}$$

It follows that we may rewrite the expression (39) for the velocity $\frac{dg}{dt}$ by substituting $w_k = \dot{x}_k$, $1 \le k \le N$, $w_k = f_k(\dot{x}, g)$, $N + 1 \le k \le L$. The remaining equations of the reduced system are those for $\ddot{x}_k$ in system (46). However, we employ feedback again, expressed in vector form as

$$(\Lambda - I)u + e = \Lambda \hat{u}, \tag{56}$$

where e is the N vector with components

$$\left\langle \frac{dg}{dt}, \frac{D}{\partial t} J_g^{-1} X_k^l \right\rangle, \qquad 1 \le k \le N.$$

The control $\hat{u}$ is defined uniquely by the invertibility of the matrix Λ defined by (51). The resulting reduced equations have the form

$$\begin{aligned} \ddot{x}_k &= \hat{u}_k, \qquad 1 \le k \le N, \\ \frac{dg}{dt} &= \sum_{k=1}^{N} \dot{x}_k X_k^l(g) + \sum_{k=N+1}^{L} f_k(\dot{x}, g) X_k^l(g). \end{aligned} \tag{57}$$

Note that for this system we have

$$\frac{d}{dt} \frac{1}{2} \langle \dot{x}, \dot{x} \rangle^E = \sum_{k=1}^{N} \dot{x}_k \hat{u}_k.$$

Thus in this formulation the force control $\hat{u}$ in (57) simply changes the generalized translational energy and not the generalized rotational energy.

5.4. Controllability and optimal control. In this section we make some comments about the problems associated with the controllability and optimal control of the reduced models (54) and (57). We first comment on the controllability aspects. Clearly the system (54) as written cannot be controllable, because of the constants of motion (49), which can be reexpressed in the form

$$c_k = \langle\langle W_t, \mathbf{J}(g) X_k \rangle\rangle.$$

Reduction of the equations (54) by these constraints would be complicated to analyze, and the reduction has already been performed in the system (57). A necessary condition for controllability is accessibility (or weak controllability) (see Isidori [1989] or Nijmeijer and Van der Schaft [1990]). However, as stated, the Lie algebra associated with the system (57) is also complicated to analyze. We therefore content ourselves to the case where $J = I$, in which case it is easily deduced that both systems (54) and (57) reduce to the system

$$\begin{aligned} \dot{x}_k &= v_k, \\ \dot{v}_k &= \hat{u}_k, \\ \frac{dg}{dt} &= \sum_{k=1}^{N} v_k X_k^l(g) + \sum_{k=N+1}^{L} c_k X_k^l(g), \qquad 1 \le k \le N. \end{aligned} \tag{58}$$

To analyze the accessibility and controllability of this system, we introduce some subspaces of the Lie algebra $\mathcal{G}$. Let P be the subspace spanned by the vectors $X_1, \ldots, X_N$, let $\mathcal{G}_P$ be the subalgebra of $\mathcal{G}$ generated by P and let I_P denote the ideal of $\mathcal{G}_P$ generated by the subspace, $[P, P]$, of $\mathcal{G}_P$.

THEOREM 3. *Assume that $\mathcal{G}$ is a simple Lie algebra. Then the reduced system* (58) *is controllable and accessible if and only if $\mathcal{G}_P = \mathcal{G}$ and $[P, P] \neq 0$.*

Proof. We first analyze accessibility of the system. It is sufficient to analyze the Lie algebra of the system (58) as represented by the Lie algebra L on the vector space $\mathbf{R}^{2N} \times \mathcal{G}$ with generators

$$g_k = \frac{\partial}{\partial v_k}, \quad 1 \le k \le N, \quad f = \sum_{k=1}^{N} v_k \left(\frac{\partial}{\partial x_k} + X_k \right) + \sum_{j=N+1}^{L} c_j X_j.$$

Because the elements of L depend only on $v \in \mathbf{R}^N$, accessibility of (58) is equivalent to the fact that $L_v = \mathbf{R}^{2N} \times \mathcal{G}$, where L_v is the subspace of $\mathbf{R}^{2N} \times \mathcal{G}$ spanned by elements of L evaluated at v. We construct a subalgebra $\hat{L} \subset L$ with the property that none of its elements depend on v and such that $\hat{L} = L_0$. Accessibility is therefore equivalent to $\hat{L} = \mathbf{R}^{2N} \times \mathcal{G}$. (Because $\hat{L}$ does not depend on v, we may identify it with a subspace of $\mathbf{R}^{2N} \times \mathcal{G}$.) Explicitly we set $\hat{L}$ to be the subalgebra of L generated by the vectors $\{g_k, [g_k, f];\ 1 \le k \le N\}$. All Lie brackets of generators g_k and f not in $\hat{L}$ vanish at $v = 0$. It is easily verified that

$$\hat{L} = \text{span}\left\{ \frac{\partial}{\partial v_k};\ \frac{\partial}{\partial x_k} + X_k,\ 1 \le k \le N;\ I_P \right\}.$$

Indeed, span $\{[[f, g_j], [f, g_i]];\ 1 \le j, i \le N\} = [P, P]$. Now $\hat{L} = \mathbf{R}^{2N} \times \mathcal{G}$ if and only if $I_P = \mathcal{G}$, and so accessibility is equivalent to $I_P = \mathcal{G}$. Consider the situation in which $I_P \subseteq \mathcal{G}_P = \mathcal{G}$. Thus I_P is an ideal of a simple Lie algebra $\mathcal{G}$, so that $I_P = 0$ or $I_P = \mathcal{G}$. Because $I_P = 0$ if and only if $[P, P] = 0$, accessibility is equivalent to $\mathcal{G}_P = \mathcal{G}$ and $[P, P] \neq 0$.

We now turn to controllability. We appeal to the result in Theorem 1. Specifically, we treat system (58) as a system on a principal bundle $G \times \mathbf{R}^{2N}$, in which the system is G invariant and projectable. Because we have already assumed that G is compact and the projected system on the base $B = \mathbf{R}^{2N}$ is a controllable linear system, controllability of the total system is equivalent to accessibility of the system. □

We now turn to the question of minimum force control for the reduced systems (53) and (57). First recall the minimum force control problem for the holonomic system (13) with cost functional (14). The reduced nonholonomic system (53) with cost functional

$$\min_u \int_0^T \frac{1}{2} \sum_{i=1}^{N} \bar{u}_k(t)^2 \, dt$$

may be considered as a generalization of the holonomic problem in which we consider the nonholonomic constraints as defining motion on fibers of a bundle over the original holonomic base dynamics. The optimal control minimizes force in the base as measured by the analogue of equation (10)

$$\int_0^T \frac{1}{2} \left\langle \frac{D^2 g}{\partial t^2}, J_g \frac{D^2 g}{\partial t^2} \right\rangle dt.$$

In this setting the minimum force control problem for the nonholonomic system (53) may be viewed as a direct generalization of the optimal control problems posed by nonholonomic kinematic systems discussed at the end of §2 and Remark 3 of §3.

However, the constants of motion (49) for the system (53) make the optimal control problem well posed only on level sets. Thus we consider instead the formulation (57) of the reduced nonholonomic system. The remarks above may be applied equally to the minimal force optimal control problem for this system in which the optimal control minimizes force in the base $B = \mathbf{R}^{2N}$ as measured by the functional

$$\int_0^T \frac{1}{2} \langle \ddot{x}, \ddot{x} \rangle^E \, dt, \tag{59}$$

while subject to the motion in the fibers $F = G$ described in (57). The difficulty in establishing controllability results, except in the case where $J = I$ directs consideration at the system (58). We show how to define the associated minimum force control problem as a constrained variational problem.

Using the skew symmetry of the connection on G in the case $J = I$ (see equation (37)), differentiating along trajectories of (58) gives

$$\frac{D^2 g}{\partial t^2} = \sum_{k=1}^{N} \ddot{x}_k X_k^l(g),$$

so that the functional (59) may be rewritten as

$$\int_0^T \frac{1}{2} \mathcal{K} \left(\frac{D^2 g}{\partial t^2}, \frac{D^2 g}{\partial t^2} \right) dt. \tag{60}$$

The constraints on the evolution of g may be expressed as

$$\frac{dg}{dt} = \sum_{k=1}^{N} \dot{x}_k X_k^l(g) + \sum_{k=N+1}^{L} c_k X_k^l(g).$$

Setting $Z_t(g) = \sum_{k=1}^{L} \delta_k(t) X_k^l(g)$, we obtain

$$\mathcal{K}\left(\frac{dg}{dt}, Z_t(g)\right) - \sum_{k=1}^{N} \delta_k(t)\dot{x}_k - \sum_{k=N+1}^{L} \delta_k(t)c_k \equiv 0. \tag{61}$$

Thus the minimum force control problem for the system (58) has been reduced to the variational problem defined by the functional (60) subject to the constraints (61). Clearly, δ_k, $1 \le k \le L$ are Lagrange multipliers, and in fact δ_k, $1 \le k \le N$ are constants. In this setting the problem now becomes a generalization of the one described in §2 for a certain class of holonomic control problems, where the functional (15) coincides with (60). Although a full resolution of the optimal control problem must consider exceptional (or rigid) trajectories (see Bliss [1946]), the nonexceptional trajectories may be analyzed as in Crouch and Silva-Leite [1991b]. Indeed it is shown there that the necessary conditions for nonexceptional trajectories of the problem (60) subject to (61) are given by

$$\frac{D^3 W_t}{\partial t^3} + R\left(\frac{DW_t}{\partial t}, W_t\right) W_t - \frac{DZ_t}{\partial t} + \frac{1}{2}[Z_t, W_t] \equiv 0,$$

where $W_t = \sum_{k=1}^{L} w_k(t) X_k^l(g)$, generalizing the expression (16) in the unconstrained case. Crouch and Silva-Leite [1991b] show how to reduce these equations to the algebra $\mathcal{G}$, using a well-known expression for the curvature tensor R.

A specific application of the results presented in §5 is given by the ball rolling on a plane, as analyzed in Bloch and Crouch [1992a]. This corresponds to the case where $G = SO(3), L = 3$, and $N = 2$, and the conditions of Theorem 3 are automatically satisfied.

THE MINIMIZATION OF SEMICONTINUOUS FUNCTIONS: MOLLIFIER SUBGRADIENTS*

YURI M. ERMOLIEV†, VLADIMIR I. NORKIN‡, AND ROGER J-B. WETS§

Abstract. To minimize discontinuous functions that arise in the context of systems with jumps, for example, we propose a new approach based on approximation via averaged functions (obtained by convolution with mollifiers). The properties of averaged functions are studied, after it is shown that they can be used in an approximation scheme consistent with minimization. A new notion of subgradient is introduced based on approximations generated by mollifiers and is exploited in the design of minimization procedures.

Key words. impulse control, discrete events systems, averaged functions, subgradients, subdifferentiability, stochastic quasi-gradients, epi-convergence

AMS subject classifications. 49J52, 49J55, 49J45

1. Introduction.

It is not unusual to have to deal with optimization problems involving discontinuous functions, for example: optimization problems involving set-up costs or impulse controls (Bensoussan and Lions [5]), the control of discrete events systems (Gong and Ho [14], Rubinstein [36], Ermoliev and Gaivoronski [9]), and control problems with pre- and post-accident regimes whose systems' parameters do not evolve continuously. Even a convex optimization problem is sometimes replaced by one involving discontinuous penalties such as indicator or characteristic functions. Problems defined in terms of marginal functions, expressing the dependence of the optimal value of some subproblem (as in stochastic programming problems, for example) on certain parameters are often discontinuous. To deal with such applications, a number of efforts have been made to develop a subdifferential calculus for nonsmooth, and possibly discontinuous, functions. Among the many possibilities let us mention the notions due to Rockafellar [31], Aubin [3], Clarke [6], Ioffe [18], Frankowska [11], Michel and Penot [25], and Mordukhovich [26] in the context of variational analysis; those due to Warga [43] for subdifferentials obtained via certain approximating scheme; those due to Demyanov and Rubinov [7] for quasi-differentiable functions; and those due to Ermoliev [9] and Polyak [30] in the context of stochastic approximation techniques for optimization problems.

Another approach to the differentiation of "nonclassical" functions, which eventually became known as the *theory of distributions* (in Russia, as the *theory of generalized functions*), was developed in 1930's by Sobolev [38] and Schwartz [37]. This technique is in wide use in mathematical physics and related engineering problems. Although one can find in the literature occasional reference to a connection between these two approaches, the notion of differentiability in the sense of distributions is not used in variational analysis or in the design of solution procedures for optimization problems involving "nonclassical" functions. Probably one of the reasons for this is that in the theory of distributions, (standard) functions defined on $\mathbf{R}^n$ are redefined as functionals on a certain functional space. The same applies to their gradients.

§Department of Mathematics, University of California, Davis, California 95616.

In the development of a subdifferential calculus for (discontinuous) functions, we appeal to some of the results of the theory of distributions, but our aim is to bring back the algebraic manipulations to operations that can be carried out in $\mathbf{R}^n$, in particular, by assigning certain distributions to points in $\mathbf{R}^n$. More specifically, we associate with a point $x \in \mathbf{R}^n$ a family of mollifiers (density functions) whose support tends toward x and converges to the dirac function $\delta(x - \cdot)$. Given such a family, say $\{\psi_\theta, \theta \in \mathbf{R}_+\}$, a "generalized" function associated with a function $f : \mathbf{R}^n \to \mathbf{R}$ is then defined as the clusters of all possible values generated by the pairings of f with ψ_θ. A set of generalized gradients, here called *mollifier subgradients*, is defined in a similar fashion.

From another angle, we can also link this approach to a technique involving "averaged" functions introduced by Steklov [39], [40] and Sobolev [38]. In the case of continuous functions, these averaged functions converge uniformly to f, and it is then related to an approach suggested by Warga [42]–[44] (see also Frankowska [12]).

For the gradients of averaged functions there are simple unbiased stochastic estimators based on finite differences (some will be mentioned in our development). This opens up the possibility of minimizing the original (discontinuous) function through the minimization of a sequence of smooth approximating averaged functions. Such an approach, initiated in §5, relies on the ideas inherent in stochastic quasi-gradient methods and dynamic nonstationary optimization as were used by Ermoliev and Nurminski [10], Gaivoronski [13], Katkovnik [19], and Nikolaeva [27] in convex nondifferentiable optimization; by Gupal [15], and Mayne and Polak [24] in the Lipschitz continuous case; and by Gupal and Norkin [17] in the discontinuous case.

Section 2 introduces a notion of convergence for discontinuous functions and prepares the way for a justification that averaged functions provide consistent approximations from a minimization viewpoint. Section 3 is devoted to the properties of averaged functions, and §4 introduces the notion of a mollifier subgradient based on the approximation of a discontinuous function by averaged functions. Finally, §5 outlines some potential optimization procedures.

2. eh-convergence. Let $f : \mathbf{R}^n J \to \overline{\mathbf{R}}$ be a proper ($f \not\equiv \infty$, $f > -\infty$) extended real-valued function with $\operatorname{dom} f = \{x \in \mathbf{R}^n | f(x) < \infty\}$ the (nonempty) set on which it is finite. Its *epigraphical* (*or lower semicontinuous*) *closure* $\mathrm{cl}_e f$ is given by

$$\mathrm{cl}_e f(x) := \liminf_{x' \to x} f(x') = \inf_{x^\nu \to x} \liminf_{\nu \to \infty} f(x^\nu)$$

and its *hypographical* (*or upper semicontinuous*) *closure* $\mathrm{cl}_h f$ is

$$\mathrm{cl}_h f(x) := \limsup_{x' \to x} f(x') = \sup_{x^\nu \to x} \limsup_{\nu \to \infty} f(x^\nu);$$

inf and sup are taken over all sequences x^ν converging to x. The function $\mathrm{cl}_e f$ is lower semicontinuous and $\mathrm{cl}_h f$ is upper semicontinuous.

For an arbitrary sequence of functions $\{f^\nu : \mathbf{R}^n \to \overline{\mathbf{R}}, \nu \in \mathbf{N}\}$, we denote by $\mathrm{e}\!-\!\mathrm{li}\, f^\nu$ its *lower epi-limit*, i.e.,

$$(\mathrm{e}\!-\!\mathrm{li}\, f^\nu)(x) := \inf_{x^\nu \to x} \liminf_{\nu \to \infty} f^\nu(x^\nu),$$

and by $\mathrm{h}\!-\!\mathrm{ls}\, f^\nu$ its *upper hypo-limit*, i.e.,

$$(\mathrm{h}\!-\!\mathrm{ls}\, f^\nu)(x) := \sup_{x^\nu \to x} \limsup_{\nu \to \infty} f^\nu(x^\nu);$$

here also inf and sup are calculated with respect to all sequences converging to x. It is easy to see that $\text{e-li}\, f^\nu$ is lower semicontinuous and that $\text{h-ls}\, f^\nu$ is upper semicontinuous (if necessary cf. [33] for more details); note that $\text{h-ls}\, f^\nu = -\,\text{e-li}(-f^\nu)$.

DEFINITION 2.1. *Given a sequence of functions* $\{ f^\nu : \mathbf{R}^n \to \overline{\mathbf{R}}, \nu \in \mathbf{N} \}$*, a function* $f : \mathbf{R}^n \to \overline{\mathbf{R}}$ *is an* epi-sublimit *of the sequence* $\{f^\nu\}$ *if* $\text{cl}_e f \le \text{e-li}\, f^\nu$*. It is a* hypo-suplimit *if* $\text{h-ls}\, f^\nu \le \text{cl}_h f$*. If* f *is both an epi-sublimit and a hypo-suplimit, we say that the sequence* f^ν eh-converges *to* f*.*

We can view eh-convergence as an *extended graph-convergence.* With $\text{gph}\, f^\nu$, the graph of the function f^ν, eh-convergence implies that

$$\text{Limsup}_{\nu\to\infty} \text{gph}\, f^\nu \subset \{ (x,\alpha) \in \mathbf{R}^n \times \overline{\mathbf{R}} \mid \text{cl}_e f(x) \le \alpha \le \text{cl}_h f(x) \}$$

where Limsup is the *outer* (*superior*) set-limit; for a sequence of sets C^ν, $\text{Limsup}_\nu C^\nu$ consists of the cluster points of all sequences $\{u^\nu\}$ with $u^\nu \in C^\nu$ for ν sufficiently large.

A notion of eh-convergence (for functions with values in a function space) also surfaced in the study of the stability properties of integral functionals with discontinuous integrands; cf. Artstein and Wets [1].

3. Averaged functions.

Averaged functions are defined relative of a specific family of mollifiers; our usage of the term mollifier differs somewhat from the standard one in that we do not require that mollifiers be necessarily infinitely differentiable.

DEFINITION 3.1. *Given a locally integrable function* $f : \mathbf{R}^n \to \mathbf{R}$ *and a family of bounded* mollifiers $\{ \psi_\theta : \mathbf{R}^n \to \mathbf{R}_+, \theta \in \mathbf{R}_+ \}$ *that satisfy*

$$\int_{\mathbf{R}^n} \psi_\theta(z)\, dz = 1, \quad \text{supp}\, \psi_\theta := \{ z \in \mathbf{R}^n \mid \psi_\theta(z) > 0 \} \subset \rho_\theta \mathbf{B} \quad \textit{with } \rho_\theta \downarrow 0 \quad \textit{as } \theta \downarrow 0,$$

the associated family $\{ f_\theta, \theta \in \mathbf{R}_+ \}$ *of* averaged functions *is given by*

$$f_\theta(x) := \int_{\mathbf{R}^n} f(x-z)\psi_\theta(z)\, dz = \int_{\mathbf{R}^n} f(z)\psi_\theta(x-z)\, dz.$$

For example, the family of mollifiers could be of the following type: let ψ *be a density function with* $\text{supp}\, \psi$ *bounded,* $\alpha_\theta \downarrow 0$ *as* $\theta \downarrow 0$*, and*

$$\psi_\theta(z) := \frac{\psi(z/\alpha_\theta)}{(\alpha_\theta)^n}.$$

A mollifier is thus a probability density function defined on $\mathbf{R}^n$ *but the family* $\{\psi_\theta\}$ *must possess some specific properties. We can also express* f_θ *as a convolution*

$$f_\theta = f \star \psi_\theta.$$

Sobolev [38] introduced "averaged functions" in his study of generalized functions (distributions) that could serve as solutions of certain equations in mathematical physics; he also required that the mollifiers ψ_θ be of class C^∞. In terms of the theory of distributions, $f_\theta(x)$ is the value of the distribution f at $\psi_\theta(x - \cdot)$, x playing the role of a parameter.

THEOREM 3.2. *Let* $\{ f_\theta, \theta \in \mathbf{R}_+ \}$ *be a family of averaged functions associated with a locally integrable function* $f : \mathbf{R}^n \to \mathbf{R}$*, and suppose that* $x^\theta \to x$ *as* $\theta \downarrow 0$*. Then*

$$\text{cl}_e f(x) \le \liminf_{\theta\downarrow 0} f_\theta(x^\theta) \le \limsup_{\theta\downarrow 0} f_\theta(x^\theta) \le cl_h f(x).$$

Consequently, the averaged functions f_θ eh-converge to f.

Proof. It will suffice to prove the first inequality, the second one is evident and the proof of the last one is similar to that of the first. eh-convergence is an immediate consequence of this string of inequalities.

By definition of lower semicontinuity, for all $x \in \mathbf{R}^n$ and $\varepsilon > 0$ there exists V, a neighborhood of 0, such that $f(x-z) \geq \mathrm{cl}_e f(x) - \varepsilon$ for all $z \in V$. For θ sufficiently small, $\operatorname{supp}\psi_\theta \subset V$ and then

$$f_\theta(x^\theta) = \int_{\mathbf{R}^n} f(x^\theta - z)\psi_\theta(z)\,dz = \int_V f(x^\theta - z)\psi_\theta(z)\,dz \geq \int_V \mathrm{cl}\, f(x^\theta - z)\psi_\theta(z)\,dz$$
$$\geq (\mathrm{cl}_e f(x^\theta) - \varepsilon)\int \psi_\theta(z)\,dz.$$

Hence, $\liminf_{\theta\downarrow 0} f_\theta(x^\theta) \geq \mathrm{cl}_e f(x) - \varepsilon$. The proof is completed by letting $\varepsilon \downarrow 0$. □

COROLLARY 3.3. *Let $f : \mathbf{R}^n \to \mathbf{R}$ be continuous, and let $\{f_\theta, \theta \in \mathbf{R}_+\}$ be an associated family of averaged functions. Then the averaged functions f_θ converge continuously to f, i.e., $f_\theta(x^\theta) \to f(x)$ for all $x^\theta \to x$. In fact, the averaged functions f_θ converge uniformly to f on every bounded subset of $\mathbf{R}^n$.*

Proof. The proof is evident. □

When the function f is not continuous, we cannot expect to have continuous convergence of the averaged functions to f. But that is also more than what is required. For our purposes, we only need to establish that the averaged functions converge to f in a sense that will guarantee the convergence of minimizers and infima. This is precisely what is accomplished by epi-convergence.

DEFINITION 3.4 (Aubin and Frankowska [4], Rockafellar and Wets [33]). *A sequence of functions $\{f^\nu : \mathbf{R}^n \to \overline{\mathbf{R}}, \nu \in \mathbf{N}\}$* epi-converges *to $f : \mathbf{R}^n \to \overline{\mathbf{R}}$* at *$x$ if*

(i) $\liminf_{\nu\to\infty} f^\nu(x^\nu) \geq f(x)$ *for all $x^\nu \to x$;*

(ii) $\lim_{\nu\to\infty} f^\nu(x^\nu) = f(x)$ *for some sequence $x^\nu \to x$.*

The sequence $\{f^\nu\}_{\nu\in\mathbf{N}}$ epi-converges *to f if this holds for all $x \in \mathbf{R}^n$, in which case we write $f = \mathrm{e}\text{-}\mathrm{lm}\, f^\nu$.*

Clearly, if f is the epi-limit of some sequence, then f is necessarily lower semicontinuous. Moreover, if the f^ν converge continuously, and a fortiori uniformly, to f, they also epi-converge to f.

For example, if $(x,y) \mapsto g(x,y) : \mathbf{R}^n \times \mathbf{R}^m \to \overline{\mathbf{R}}$ is (jointly) lower semicontinuous at $(\bar{x},\bar{y})$ and is continuous in y at $\bar{y}$, then for any sequence $y^\nu \to \bar{y}$, the corresponding sequence of functions $\{f^\nu = g(\cdot, y^\nu), \nu \in \mathbf{N}\}$ epi-converges to $f = g(\cdot,\bar{y})$ at $\bar{x}$.

THEOREM 3.5 (Attouch and Wets [2]). *If the sequence $\{f^\nu : \mathbf{R}^n \to \overline{\mathbf{R}}, \nu \in \mathbf{N}\}$ epi-converges to $f : \mathbf{R}^n \to \overline{\mathbf{R}}$ at all $x \in D \subset \mathbf{R}^n$, then*

$$\limsup_\nu(\inf_O f^\nu) \leq \inf_O f, \quad \forall O \subset \mathbf{R}^n \textit{ open},$$
$$\liminf_\nu(\inf_K f^\nu) \geq \inf_K f, \quad \forall K \subset \mathbf{R}^n \textit{ compact},$$

and

$$\forall x^\nu \to x : \quad [f^\nu(x^\nu) \leq \inf f^\nu + \varepsilon_\nu, \quad \varepsilon_\nu \downarrow 0,] \quad \Longrightarrow \quad x \in \operatorname{argmin} f.$$

Epi-convergence of the averaged functions f_θ to f will be guaranteed by the following property of f.

DEFINITION 3.6. *A function $f : \mathbf{R}^n \to \overline{\mathbf{R}}$ is strongly lower semicontinuous at x, if it is lower semicontinuous at x and there exists a sequence $x^\nu \to x$ with f*

continuous at x^ν (for all ν) such that $f(x^\nu) \to f(x)$. The function f is strongly lower semicontinuous if this holds at all x.

Roughly speaking, strong lower semicontinuity excludes the possibility of discontinuities at isolated points. If we think of $(x, f(x))$ as the state of a system, strong lower semicontinuity means that this state can always be reached by following a path along which the evolution of the system is continuous (with no jumps). If x is "time-dependent", then although we may expect sudden changes from one state to another, either before or after the jump, the evolution will be continuous, one doesn't expect instantaneous jumps followed by an immediate return to normal regime.

THEOREM 3.7. *For any strongly lower semicontinuous, locally integrable function $f : \mathbf{R}^n \to \mathbf{R}$, and any associated family $\{ f_\theta,\ \theta \in \mathbf{R}_+ \}$ of averaged functions, we have that $f = \mathrm{e-lm}\, f_\theta$, i.e., for any sequence $\theta^\nu \downarrow 0$, $f = \mathrm{e-lm}\, f_{\theta^\nu}$.*

Proof. Pick any x. For condition (i) of Definition 3.4, simply appeal to Theorem 3.2. For condition (ii), proceed as follows: The strong lower semicontinuity of f at x provides a sequence $x^\nu \to x$ such that $f(x^\nu) \to f(x)$ with f continuous at x^ν. From Corollary 3.3, it follows that for all ν, $f_\theta(x^\nu) \to f(x^\nu)$. Given any sequence $\theta^k \to 0$ as $k \to \infty$, we need to come up with a sequence x^k such that $f_{\theta^k}(x^k) \to f(x)$. But this follows from the following observation: The set $S := \{ f(x^\nu) \,|\, \nu \in \mathbf{N} \}$ is contained in $\mathrm{Liminf}_k\, S^k$ where $S^k := \{ f_{\theta^k}(x^\nu) \,|\, \nu \in \mathbf{N} \}$; $\mathrm{Liminf}_k\, S^k$ consists of all limits points of all sequences $\{\alpha_k\}_{k \in \mathbf{N}}$ with $\alpha_k \in S_k$. Since $\mathrm{Liminf}_k\, S^k$ is closed and $f(x) \in \mathrm{cl}\, S$, it follows that $f(x) \in \mathrm{Liminf}_k\, S^k$, and that means that there exists $\alpha^k \to f(x)$ with $\alpha^k \in S^k$. These points α^k are the $f_{\theta^k}(x^k)$ we were looking for. □

Theorem 3.7 tells us that if we have to minimize the function f, the averaged functions f_θ could be used in a consistent approximation scheme, i.e., that implies the convergence of the minimizers. However, before we follow this route, we would have to make sure that their properties make them amenable to minimization by existing—or possibly, modified—algorithmic procedures. The remainder of this section is devoted to the continuity and differentiability properties of averaged functions, in particular for the class of Steklov (averaged) functions.

DEFINITION 3.8. *Given a locally integrable function $f : \mathbf{R}^n \to \mathbf{R}$, the* Steklov (averaged) functions *are defined as follows: For $\alpha > 0$,*

$$f_\alpha(x) = \int_{\mathbf{R}^n} f(x - z)\psi_\alpha(z)\, dz,$$

where

$$\psi_\alpha(z) = \begin{cases} 1/\alpha^n & \textit{if } \max_{1,\dots,n} |z_i| \le \alpha/2; \\ 0 & \textit{otherwise.} \end{cases}$$

Equivalently,

$$f_\alpha(x) = \frac{1}{\alpha^n} \int_{x_1 - \alpha/2}^{x_1 + \alpha/2} dy_1 \dots \int_{x_n - \alpha/2}^{x_n + \alpha/2} dy_n\, f(y).$$

This class of averaged functions was introduced by Steklov [39] in 1907, and used by Kolmogorov and Fréchet for compactness tests in $\mathcal{L}^p$. In the context of smooth optimization, they were used by Katkovnik [19], Nikolaeva [27], Gupal [15] and [16], and Mayne and Polak [24].

The next proposition records the well-know fact that Steklov functions are locally Lipschitz continuous.

PROPOSITION 3.9. *For locally bounded and integrable functions $f : \mathbf{R}^n \to \mathbf{R}$, the associated Steklov functions f_α are locally Lipschitz, i.e., on each compact set $K \subset \mathbf{R}^n$,* *the function f_α is Lipschitz continuous on K with Lipschitz constant κ,*

$$\kappa = (2n/\alpha) \sup_{x\in K_\alpha} f(x), \quad \textit{where } K_\alpha := \{\, x+z \,|\, x \in K,\ \max_{i=1,\dots,n} |z_i| \le \alpha/2 \,\}.$$

Differentiability of average functions, however, cannot be guaranteed in general, unless the mollifiers ψ_θ are sufficiently smooth or if f itself has a sufficient level of continuity.

PROPOSITION 3.10 (Sobolev [38], Schwartz [37]). *Let $f : \mathbf{R}^n \to \mathbf{R}$ be locally integrable. Whenever the mollifiers ψ_θ are smooth (of class C^1), so are the associated averaged functions f_θ with gradient*

$$\nabla f_\theta(x) = \int_{\mathbf{R}^n} f(y) \nabla \psi_\theta(x-y)\, dy.$$

PROPOSITION 3.11 (Gupal [15]). *For $f : \mathbf{R}^n \to \mathbf{R}$ continuous, the Steklov (averaged) functions f_α are continuously differentiable, and their gradients are given by*

$$\begin{aligned}
&\nabla f_\alpha(x) \\
&= \sum_{i=1}^n e_i \frac{1}{\alpha^n - 1} \int_{x_1-\alpha/2}^{x_1+\alpha/2} dy_1 \cdots \int_{x_{i-1}-\alpha/2}^{x_{i-1}+\alpha/2} dy_{i-1} \int_{x_{i+1}-\alpha/2}^{x_{i+1}+\alpha/2} dy_{i+1} \cdots \int_{x_n-\alpha/2}^{x_n+\alpha/2} dy_n \\
&\quad \frac{1}{\alpha}[f(y_1,\dots,y_{i-1},x_i - \tfrac{1}{2}\alpha, y_{i+1},\dots y_n) - f(y_1,\dots,y_{i-1},x_i + \tfrac{1}{2}\alpha, y_{i+1},\dots y_n)],
\end{aligned}$$

where e_i is the ith unit coordinate vector.

This gradient can also be expressed as

$$\nabla f_\alpha(x) = \sum_{i=1}^n e_i \int_{-\frac{1}{2}}^{\frac{1}{2}} d\xi_1 \cdots \int_{-\frac{1}{2}}^{\frac{1}{2}} d\xi_{i-1} \int_{-\frac{1}{2}}^{\frac{1}{2}} d\xi_{i+1} \cdots \int_{-\frac{1}{2}}^{\frac{1}{2}} d\xi_n \, \lambda_\alpha(x,\xi),$$

where

$$\begin{aligned}
\lambda_\alpha(x,\xi) =& \frac{1}{\alpha}[f(x_1+\alpha\xi_1,\dots,x_{i-1}+\alpha\xi_{i-1}, x_i + \tfrac{1}{2}\alpha, x_{i+1}+\alpha\xi_{i+1},\dots,x_n+\alpha\xi_n) \\
&- f(x_1+\alpha\xi_1,\dots,x_{i-1}+\alpha\xi_{i-1}, x_i - \tfrac{1}{2}\alpha, x_{i+1}+\alpha\xi_{i+1},\dots,x_n+\alpha\xi_n)].
\end{aligned}$$

This means that $\nabla f_\theta(x)$ is the expectation of the random vector $\boldsymbol{\lambda}_\alpha(x,\boldsymbol{\xi})$, where $\boldsymbol{\xi} = (\boldsymbol{\xi}_1,\dots\boldsymbol{\xi}_n)$ is a random vector whose elements are independent and uniformly distributed on $[-\frac{1}{2},\frac{1}{2}]$. In other words, $\boldsymbol{\lambda}_\alpha(x,\boldsymbol{\xi})$ is an unbiased estimator of the gradient of f_α at x.

Remark 3.12. Although in the case of discontinuous functions f we cannot "reach" differentiability for Steklov functions, it is always possible to do so if the averaging process is repeated a second time. This follows immediately from Propositions 3.9 and 3.11. Given a locally integrable function $f : \mathbf{R}^n \to \mathbf{R}$, let

$$\begin{aligned}
f_{\alpha\beta}(x) :&= \int_{\mathbf{R}^n} f_\alpha(x-z)\psi_\beta(z)\, dz \\
&= \int_{\mathbf{R}^n} dy \int_{\mathbf{R}^n} dz\, f(x-y-z)\psi_\alpha(y)\psi_\beta(z)
\end{aligned}$$

with the densities ψ_α and ψ_β as in Definition 3.8. We can also express this as an expectation,

$$f_{\alpha\beta}(x) = E\{f(x - \alpha\boldsymbol{\xi} - \beta\boldsymbol{\eta})\}$$

with $\boldsymbol{\xi}$ and $\boldsymbol{\eta}$ random vectors whose elements are independent and uniformly distributed on $[-\frac{1}{2}, \frac{1}{2}]$. The gradient can be calculated from Proposition 3.11. We have

$$\begin{aligned}&\nabla f_{\alpha\beta}(x)\\ &\quad = \int_{-\frac{1}{2}}^{\frac{1}{2}} d\xi_1 \cdots \int_{-\frac{1}{2}}^{\frac{1}{2}} d\xi_n \left(\int_{-\frac{1}{2}}^{\frac{1}{2}} d\eta_1 \cdots \int_{-\frac{1}{2}}^{\frac{1}{2}} d\eta_{i-1} \int_{-\frac{1}{2}}^{\frac{1}{2}} d\eta_{i+1} \cdots \int_{-\frac{1}{2}}^{\frac{1}{2}} d\eta_n \, \lambda_{\alpha\beta}(x, \xi, \eta) \right),\end{aligned}$$

where, with $z_i^{\alpha\beta}(\xi, \eta) := x_i - \alpha\xi_i - \beta\eta_i$,

$$\begin{aligned}&\lambda_{\alpha\beta}(x,\xi,\eta)\\ &\quad := \sum_{i=1}^{n} e_i \big[f(z_1^{\alpha\beta}(\xi,\eta), \ldots, z_{i-1}^{\alpha\beta}(\xi,\eta), x_i + \alpha\xi_i + \tfrac{\beta}{2}, z_{i+1}^{\alpha\beta}(\xi,\eta), \ldots, z_n^{\alpha\beta}(\xi,\eta))\\ &\qquad\qquad - f(z_1^{\alpha\beta}(\xi,\eta), \ldots, z_{i-1}^{\alpha\beta}(\xi,\eta), x_i + \alpha\xi_i - \tfrac{\beta}{2}, z_{i+1}^{\alpha\beta}(\xi,\eta), \ldots, z_n^{\alpha\beta}(\xi,\eta)) \big] \beta^{-1}.\end{aligned}$$

Again, $\boldsymbol{\lambda}_{\alpha\beta}(x, \boldsymbol{\xi}, \boldsymbol{\eta})$ is an unbiased estimate of the gradient $\nabla f_{\alpha\beta}(x)$ with $\boldsymbol{\xi}, \boldsymbol{\eta}$ random vectors whose elements are independent and uniformly distributed on $[-\frac{1}{2}, \frac{1}{2}]$. □

Remark 3.13. Let us also record an important relationship between the estimates of the gradients of averaged functions and stochastic gradients. We consider the following averaged functions:

$$f_\theta(x) = \frac{1}{\theta^n} \int_{\mathrm{R}^n} f(z)\psi\left(\frac{x-z}{\theta}\right) dz = \int_{\mathrm{R}^n} f(x - \theta z)\psi(z)\, dz,$$

with f locally integrable, ψ is a density function with compact support and such that $\nabla\psi$ is Lipschitz continuous. Then the gradient of f_θ,

$$\nabla f_\theta = \frac{1}{\theta^{n+1}} \int_{\mathrm{R}^n} f(z)\nabla\psi\left(\frac{x-z}{\theta}\right) dz$$

is locally Lipschitz with constants proportional to $1/\theta^{n+1}$. The random vector (cf. Gupal [16])

$$\boldsymbol{\lambda}_{\theta,\triangle}(x, \boldsymbol{\xi}, \boldsymbol{\eta}) = \frac{1}{\triangle}[f(x - \theta\boldsymbol{\xi} + \triangle\boldsymbol{\eta}) - f(x - \theta\boldsymbol{\xi})]\boldsymbol{\eta}$$

is a stochastic quasi-gradient of f_θ at x (Ermoliev [9]), where $\boldsymbol{\xi}$ is distributed in accordance with the density function ψ, and $\boldsymbol{\eta}$ is a random vector whose elements are independent and uniformly distributed on $[-1, 1]$. To see this, note that

$$\begin{aligned}E^{\xi,\eta}\{\boldsymbol{\lambda}_{\theta,\triangle}(x, \boldsymbol{\xi}, \boldsymbol{\eta})\} &= E^{\eta}\frac{1}{\triangle}[f_\theta(x + \triangle\boldsymbol{\eta}) - f_\theta(x)]\boldsymbol{\eta}\\ &= \frac{2}{3}\nabla f_\theta(x) + \frac{\triangle}{2}O(x, \theta, \triangle),\end{aligned}$$

where $O(x, \theta, \triangle)$ is locally bounded.

Observe also that if $\boldsymbol{\xi}$ is distributed in accordance with the density function ψ_θ and $\boldsymbol{\eta}$ is a random vector whose elements are independent and uniformly distributed on $[-1,1]$, then

$$\boldsymbol{\lambda}_{\theta,\triangle}(x,\boldsymbol{\xi},\boldsymbol{\eta}) = \frac{1}{\triangle}[\, f(x-\boldsymbol{\xi}+\triangle\boldsymbol{\eta}) - f(x-\boldsymbol{\xi})\,]\boldsymbol{\eta}$$

is a quasi-gradient for the averaged function f_θ, i.e., it provides a, possibly biased, estimate of the gradient of f_θ as calculated in Proposition 3.10.

Remark 3.14. To complete this analysis of averaged functions, let us point out that the class of averaged functions that we have introduced is based on convolutions with mollifiers that have bounded support. We could however have worked with a more general class, including mollifiers with unbounded support, and still obtain a convergence result similar to that of Theorem 3.2; in fact, not just eh-convergence, but most of the results in this section. Let $\{\, \varphi_\theta : \mathbf{R}^n \to \mathbf{R}_+, \theta \in \mathbf{R}_+ \,\}$ be a class of integrable functions such that $\int \varphi_\theta(z)\,dz = 1$. Suppose that the function $f : \mathbf{R}^n \to \mathbf{R}$ and the $\{\varphi_\theta\}$ are such that $f_\theta = f \star \varphi_\theta$ is well defined (on $\mathbf{R}^n$) and that for all $\delta > 0$,

$$\lim\nolimits_{\theta\downarrow 0} \int_{|z|>\delta} |f(z)|\varphi_\theta(x-z)\,dz = 0, \quad \text{uniformly in } x, \quad \lim\nolimits_{\theta\downarrow 0} \int_{|z|\le\delta} \varphi_\theta(z)\,dz = 1.$$

To see that the functions f_θ still eh-converge to f, note for all $x \in \mathbf{R}^n$ and $\varepsilon > 0$ there exists V, a neighborhood of 0, such that $f(x-z) \ge \mathrm{cl}_e f(x) - \varepsilon$ for all $z \in V$ and that for $x^\theta \to x$ as $\theta\downarrow 0$, for all $\delta > 0$ and θ sufficiently small,

$$\begin{aligned} f_\theta(x^\theta) &= \int_{|z|\le\delta} f(z)\varphi_\theta(x^\theta - z)\,dz + \int_{|z|>\delta} f(z)\varphi_\theta(x^\theta - z)\,dz \\ &\ge (\mathrm{cl}_e f(x) - \varepsilon) \int_{|z|\le\delta} \varphi_\theta(z)\,dz - \frac{\varepsilon}{2} \end{aligned}$$

and hence $\liminf_{\theta\downarrow 0} f_\theta(x^\theta) \ge \mathrm{cl}_e f(x)$ (after letting $\varepsilon\downarrow 0$). For example, let φ be the Gaussian density function, i.e.,

$$\varphi(y) = \frac{1}{(2\pi)^{n/2}} e^{-|y|^2}.$$

Consider the following family of functions:

$$f_\theta(x) = \frac{1}{\theta^n} \int_{\mathbf{R}^n} f(y)\, \varphi\left(\frac{x-y}{\theta}\right) dy, \qquad \theta > 0.$$

Suppose that $|f(x)| \le \gamma_1 + \gamma_2 |x|^{\gamma_3}$ with γ_1, γ_2, γ_3 positive constants. Then the functions f_θ eh-converge to f as $\theta\downarrow 0$ and each functions f_θ is pf class C^∞. We have

$$\nabla f_\theta(x) = \frac{1}{\theta^{n+2}} \int_{\mathbf{R}^n} f(x-y) \varphi\left(\frac{y}{\theta}\right) dy = \frac{1}{\theta} \int_{\mathbf{R}^n} [\, f(x-\theta z) - f(x)\,] z \varphi(z)\,dz;$$

passing differentiation under the integral sign is justified by the theory of tempered distributions, cf. Schwartz [37]. Thus the random vector $\boldsymbol{\lambda}_\theta(x,\boldsymbol{\xi})$, defined by

$$\lambda_\theta(x,\xi) = \frac{1}{\theta}[\, f(x-\theta\xi) - f(x)\,]\xi$$

with $\boldsymbol{\xi}$ a Gaussian random variable (density φ), is an unbiased statistical estimator of $\nabla f_\theta(x)$.

4. Mollifier subgradients. We are going to exploit the fact that averaged functions determine an epi-convergent family of approximating functions, and that rather explicit expressions can be obtained for their gradients, to define a new notion of subgradient based on a family of mollifiers. In the next section, these subgradients are used to design minimization procedures aimed, in particular, at the minimization of discontinuous functions.

DEFINITION 4.1. *Let $f : \mathbf{R}^n \to \mathbf{R}$ be locally integrable and let $\{f^\nu := f_{\theta^\nu}, \nu \in \mathbf{N}\}$ be a sequence of averaged functions obtained from f by convolution with the sequence of mollifiers $\{\psi^\nu := \psi_{\theta^\nu} : \mathbf{R}^n \to \mathbf{R}_+, \nu \in \mathbf{N}\}$ where $\theta^\nu \downarrow 0$ as $\nu \to \infty$. Assume that the mollifiers are such that the averaged functions f^ν are smooth (of class C^1), as would be the case if the mollifiers ψ^ν are smooth. The* subgradient set of ψ-mollifier *of f at x is*

$$\partial_\psi f(x) := \operatorname{Limsup}_{\nu\to\infty}\{\nabla f^\nu(x^\nu) \mid x^\nu \to x\},$$

i.e., the cluster points of all possible sequences $\{\nabla f^\nu(x^\nu)\}$ such that $x^\nu \to x$. The full Ψ- mollifier subgradient set *is*

$$\partial_\Psi f(x) := \bigcup\nolimits_\psi \partial_\psi f(x),$$

where ψ ranges over all possible sequences of mollifiers that generate smooth averaged functions.

The set $\partial_\psi f(x)$ of ψ-mollifier subgradients is closed, and in general, depends on the choice of the sequence $\{\psi^\nu\}$ used in its construction. The full mollifier subgradient set $\partial_\Psi f(x)$ clearly does not depend on any particular choice of mollifiers. The sets $\partial_\psi f(x)$ and $\partial_\Psi f(x)$ are always nonempty if the function f is almost everywhere smooth and its gradient is locally bounded on the set where it exists (as in Corollary 3.3, but applied here to ∇f).

DEFINITION 4.2. *Let $f : \mathbf{R}^n \to \mathbf{R}$ be locally integrable and let $\{f^\nu := f_{\theta^\nu}, \nu \in \mathbf{N}\}$ be a sequence of averaged functions obtained from f by convolution with the sequence of mollifiers $\{\psi^\nu := \psi_{\theta^\nu} : \mathbf{R}^n \to \mathbf{R}_+, \nu \in \mathbf{N}\}$ where $\theta^\nu \downarrow 0$ as $\nu \to \infty$. Assume that the mollifiers are such that the averaged functions f^ν are smooth (of class C^1), as would be the case if the mollifiers ψ^ν are smooth (of class C^1). The ψ-*mollifier subderivative *of f at x in direction u is*

$$f'_\psi(x; u) := \mathrm{h{-}ls}\,(f^\nu)'(x; u) = \sup_{\{x^\nu \to x\}} \limsup_{\nu\to\infty} (f^\nu)'(x^\nu; u),$$

where $(f^\nu)'(x; u)$ is the derivative of f^ν at x in direction u; sup *is taking with respect to all sequences $x^\nu \to x$. The* full (Ψ-)mollifier subderivative *of f at x in direction u is*

$$f'_\Psi(x; u) := \sup_\psi f'_\psi(x; u),$$

where ψ ranges over all possible sequences of mollifiers generating smooth averaged functions.

Henceforth, when referring to f we always assume that it is locally integrable and that $\{f^\nu\}$ is a sequence of smooth averaged functions obtained from f by convolution with a sequence of mollifiers $\{\psi^\nu, \nu \in \mathbf{N}\}$.

PROPOSITION 4.3. *The ψ-mollifier subgradient mapping $x \mapsto \partial_\psi f(x)$ is outer semicontinuous (closed graph) and f'_ψ is upper semicontinuous. Also*

$$\begin{aligned} f'_\psi(x;u) &\geq \sup\{\,\langle g,u\rangle \mid g \in \partial_\psi f(x)\,\},\\ f'_\Psi(x;u) &\geq \sup\{\,\langle g,u\rangle \mid g \in \partial_\Psi f(x)\,\}. \end{aligned}$$

Proof. The proof follows directly from the definitions.

PROPOSITION 4.4. *The function $u \mapsto f'_\psi(x;u)$ is sublinear, i.e., $f'_\psi(x;\cdot)$ is convex and positively homogeneous. The set-valued mapping*

$$x \mapsto G_\psi(x) := \{\, g \in \mathbf{R}^n \mid \langle g,u\rangle \leq f'_\psi(x;u),\ \forall u \in \mathbf{R}^n \,\}$$

is closed-, convex-valued.

Proof. Since the functions f^ν are smooth, we have

$$(f^\nu)'(x^\nu;u_1+u_2) = (f^\nu)'(x^\nu;u_1) + (f^\nu)'(x^\nu;u_2).$$

Taking lim sup on both sides over all sequences $x^\nu \to x$ yields

$$f'_\psi(x;u_1+u_2) \leq f'_\psi(x;u_1) + f'_\psi(x;u_2).$$

Similarly, the positive homogeneity of $f'_\psi(x;\cdot)$ follows from the linearity of the derivatives of the functions $(f^\nu)'(x;\cdot)$. The assertions about the set-valued mapping G_ψ follow directly from the sublinearity of $f'_\psi(x;\cdot)$. □

PROPOSITION 4.5. *We always have*

$$\operatorname{con} \partial_\psi f(x) \subset G_\psi(x) := \{\, g \in \mathbf{R}^n \mid \langle g,u\rangle \leq f'_\psi(x;u),\ \forall u \in \mathbf{R}^n \,\},$$

where con *denotes the convex hull. If $G_\psi(x)$ is bounded, then* $\operatorname{con}\partial_\psi f(x) = G_\psi(x)$.

Proof. We begin with the inclusion. To any $g \in \partial_\psi f(x)$, there corresponds a subsequence $\{\nu_k\} \subset \{\nu\}$ and $x^k \to x$ such that $\nabla f^{\nu_k}(x^k) \to g$. Since $(f^{\nu_k})'(x^k;u) = \langle \nabla f^{\nu_k}(x^k), u\rangle$, it follows that

$$\langle g,u\rangle = \lim_{k\to\infty} \langle \nabla f^{\nu_k}(x^k), u\rangle = \lim_{k\to\infty} (f^{\nu_k})'(x^k;u) \leq f'_\psi(x;u).$$

Thus $\partial_\psi f(x) \subset G_\psi(x)$ and the convexity of $G_\psi(x)$ then yields $\operatorname{con}\partial_\psi f(x) \subset G_\psi(x)$.

Suppose now that $G_\psi(x)$ is bounded. If $h \in G_\psi(x) \setminus \operatorname{con}\partial_\psi f(x)$, i.e., $G_\psi(x) \not\subset \operatorname{con}\partial_\psi f(x)$, then by the separation theorem for convex sets, there exists $\bar u$ such that $\langle h,\bar u\rangle > \langle g,\bar u\rangle$ for all $g \in \operatorname{con}\partial_\psi f(x)$. But $f'_\psi(x;\bar u) \geq \langle h,\bar u\rangle$ and, passing to a subsequence whenever necessary, there exists $x^\nu \to x$ so that

$$\nabla f^\nu(x^\nu) \longrightarrow g \in \partial_\psi f(x)$$

and

$$(f^\nu)'(x^\nu;\bar u) = \langle \nabla f^\nu(x^\nu), \bar u\rangle \longrightarrow f'_\psi(x;\bar u).$$

Thus, we would have

$$f'_\psi(x;\bar u) = \langle g,\bar u\rangle \geq \langle h,\bar u\rangle > \langle g,\bar u\rangle,$$

clearly contradicting the existence of such an h. □

Remark 4.6. The approach laid out here could be used to define subdifferentials of higher order. For example, if the mollifiers ψ_{θ^ν} are of class C^2, then the resulting averaged function f^ν are also twice continuously differentiable. With $\nabla^2 f^\nu(x)$ the Hessian of f^ν at x, we could define the second-order ψ-mollifier subhessian of f at x as

$$\partial^2_\psi f(x) := \mathrm{Limsup}_{\nu\to\infty}\{\, \nabla^2 f^\nu(x^\nu) \mid x^\nu \to x \,\},$$

i.e., the cluster points of all possible sequences $\{\nabla^2 f^\nu(x^\nu)\}$ of matrices with $x^\nu \to x$. The function

$$f''_\psi(x;H) := \limsup_{x^\nu\to x} \langle \nabla^2 f^\nu(x^\nu), H\rangle = \limsup_{x^\nu \to x} \sum_{i,j=1}^{n} \frac{\partial}{\partial x_i \partial x_j} f^\nu(x^\nu) h_{ij}$$

could be called the second-order ψ-mollifier subderivative of f in direction H. The mapping $x \mapsto \partial^2_\psi f(x)$ is closed, the function $f''_\psi(x;\cdot)$ is upper semicontinuous, and we have

$$\operatorname{con} \partial^2_\psi f(x) = \{\, H \in \mathbf{R}^{n^2} \mid Hu \le f''_\psi(x;U),\ \forall U \in \mathbf{R}^{n^2} \,\}.$$

The next theorem justifies a minimization approach based on mollifier subgradients.

THEOREM 4.7. *Suppose that $f : \mathbf{R}^n \to \mathbf{R}$ is strongly lower semicontinuous and locally integrable. Then, for any sequence $\{\psi^\nu\}$ of smooth mollifiers, we have*

$$0 \in \partial_\psi f(x) \quad \textit{whenever } x \textit{ is a local minimizer of } f.$$

Proof. Let x be a local minimizer of f. For V a compact neighborhood of x sufficiently small, define

$$\varphi : V \to \mathbf{R} \quad \text{with } \varphi(z) = f(z) + |z-x|^2.$$

The function φ achieves its global minimum (on V) at x. Consider also the averaged functions

$$\varphi^\nu(z) = \int_{\mathbf{R}^n} \varphi(y-z)\psi^\nu(y)\,dy = f^\nu(z) + \beta^\nu(x,z),$$

where $\beta^\nu(x,z) = \int |y-z-x|^2 \psi^\nu(y)\,dy$. From Theorem 3.10, it follows that the functions φ^ν are continuously differentiable and Theorem 3.7 implies that they epi-converge to φ on V. Suppose φ^ν achieves its minimum at some point $z^\nu \in V$. It follows from Theorem 3.5 that $z^\nu \to x$, and thus

$$\nabla \varphi^\nu(z^\nu) = \nabla f^\nu(z^\nu) + \nabla \beta^\nu(x, z^\nu) = 0.$$

Hence

$$\nabla f^\nu(z^\nu) = -\nabla \beta^\nu(x,z^\nu) \longrightarrow 0 \quad \text{as} \quad \nu \to \infty,$$

and consequently as $0 \in \partial_\psi f(x)$. □

Although it is not really part of the objectives of this development to obtain expressions that can be manipulated by classical means, the following example might nevertheless help render more concrete some of the results and operations discussed so far.

Example 4.8. Consider the function

$$f(z) = \begin{cases} |z+1| & \text{if } z < 0, \\ (z-1) & \text{if } z \ge 0, \end{cases}$$

and the family of mollifiers $\{\psi_\theta, \theta > 0\}$, with

$$\psi_\theta(z) = \begin{cases} (1/4\theta^3)(z+2\theta)^2 & \text{if } z \in [\,-2\theta, -\theta\,], \\ (1/4\theta^3)(2\theta^2 - z^2) & \text{if } z \in [\,-\theta, \theta\,], \\ (1/4\theta^3)(z-2\theta)^2 & \text{if } z \in [\,\theta, 2\theta\,], \\ 0 & \text{otherwise.} \end{cases}$$

This is a family of smooth mollifiers and f is strongly lower semicontinuous. This means that the averaged functions f_θ are smooth (Proposition 3.10), and that they epi-converge to f (Theorem 3.7). Assuming that $\theta < 1/4$, from the formula for the gradient of f_θ in Proposition 3.10, we have

$$\nabla f_\theta(x) = \begin{cases} -1 & \text{if } x < -1 - 2\theta, \\ (1/6\theta^3)[\,x^3 + 3(1+2\theta)x^2 + 3(1+4\theta+4\theta^2)x & \\ \qquad + (1 + 6\theta + 12\theta^2 + 2\theta^3)\,] & \text{if } x \in [-1-2\theta, -1-\theta), \\ (1/6\theta^3)[\,-x^3 - 3x^2 + 3(2\theta^2 - 1)x + 6\theta^2 - 1\,] & \text{if } x \in [-1-\theta, -1+\theta), \\ (1/6\theta^3)[\,x^3 + 3(1-2\theta)x^2 + 3(1-4\theta+4\theta^2)x & \\ \qquad + (1 - 6\theta + 12\theta^2 - 2\theta^3)\,] & \text{if } x \in [-1+\theta, -1+2\theta), \\ 1 & \text{if } x \in [-1+2\theta, -2\theta), \\ (1/2\theta^3)[-x^2 - 4\theta x + 2\theta^2(\theta - 2)] & \text{if } x \in [-2\theta, -\theta), \\ (1/2\theta^3)[x^2 + 2\theta^2(\theta - 1)] & \text{if } x \in [-\theta, \theta), \\ (1/2\theta^3)[-x^2 + 4\theta x + 2\theta^2(\theta - 2)] & \text{if } x \in [\theta, 2\theta), \\ 1 & \text{if } x \geq 2\theta. \end{cases}$$

Letting $\theta \downarrow 0$ leads to the following expression for the mollifier subgradient associated with the family $\{\psi_\theta, \theta > 0\}$:

$$\partial_\psi f(x) = \begin{cases} -1 & \text{if } x < -1, \\ [-1, 1] & \text{if } x = 1, \\ 1 & \text{if } x \in (-1, 0), \\ [-\infty, 1] & \text{if } x = 0, \\ 1 & \text{if } x > 0. \end{cases}$$

The point $x = -1$ is a local minimizer, and $x = 0$ is a global minimizer. In both of these cases, $0 \in \partial_\psi f(x)$ as asserted by Theorem 4.7. Observe also that in the "convex" portions of the function f, the mollifier subgradient coincides with the subgradient from convex analysis; Remark 4.12 indicates that this is always the case when f is convex. □

In the remainder of this section we explore the relationship between the mollifier subgradient and some other subgradients notions.

For function $f : \mathbf{R}^n \to \mathbf{R}$ continuous on a neighborhood V of x, Warga [42]–[44] defines subgradients of f at x as follows: Let $\{f^k, k \in \mathbf{N}\}$ be a sequence of smooth functions converging uniformly to f on V, we refer to

$$\partial_W f(x) = \bigcap_{j=1}^{\infty} \bigcap_{\delta > 0} \text{cl} \left[\bigcup_{k \geq j, |x-y| \leq \delta} \nabla f^k(y) \right]$$

as the set of Warga-subgradients of f at x (cl denotes closure).

PROPOSITION 4.9. *For $f : \mathbf{R}^n \to \mathbf{R}$ be continuous on V a neighborhood of x and $\{f^k, k \in \mathbf{N}\}$ a sequence of smooth functions converging uniformly to f on V, then*

$$\partial_W f(x) = \text{Limsup}_{k\to\infty}\{\,\nabla f^k(x^k) \,|\, \forall x^k \to x\,\}.$$

Consequently, when f is continuous, $\partial_W f(x)$ coincides with $\partial_\psi f(x)$ if in the construction of $\partial_W f(x)$ the f^k are averaged functions generated by the sequence of smooth mollifiers $\{\psi^k\}$.

Proof. Let

$$D(x) = \mathrm{Limsup}_{k\to\infty}\{\,\nabla f^k(x^k)\,|\,\forall x^k \to x\,\}.$$

Let us first show that $D(x) \subset \partial_W f(x)$. Let $g \in D(x)$ be such that, passing to a subsequence if necessary, $g = \lim_k \nabla f^k(x^k)$ for some specific sequence $x^k \to x$. We have to show that for all j and $\delta > 0$,

$$g \in G_{j,\delta}(x) := \mathrm{cl}\left[\bigcup_{k\geq j, |x-y|\leq\delta} \nabla f^k(y)\right].$$

Obviously, if $k \geq j$ and $|x^k - x| \leq \delta$, then

$$\nabla f^k(x^k) \in G_{j,\delta}(x).$$

Since $G_{j,\delta}(x)$ is closed, each cluster point of the sequence $\{\nabla f^k(x^k)\}$ belongs to $G_{j,\delta}(x)$. Hence, $g \in \partial_W f(x)$ and $D(x) \subset \partial_W f(x)$.

To prove the converse inclusion, we must show that for each point g in $\partial_W f(x)$ we can find a sequence $x^k \to x$ such that $\nabla f^k(x^k) \to g$. By definition of ∂_W for all j and $\delta > 0$, $g \in G_{j,\delta}(x)$. Let us choose a sequence $\delta_j \downarrow 0$ as $j \to \infty$. Since $g \in G_{j,\delta_j}(x)$ for all j,

$$g \in \mathrm{cl}\{\,\nabla f^k(y)\ :\ k \geq j, |y - x| \leq \delta_j\,\}.$$

Thus in this set, there exists an element $g^j = \nabla f^{k_j}(y^j)$ such that $|g^j - g| < 1/j$. Clearly, $y^j \to x$, $k_j \to \infty$ and $g^j \to g$, so that $g \in D(x)$ and $\partial_W f(x) \subset D(x)$.

The equality between the Warga- and the ψ-mollifier subgradient sets then follow from the formula we just proved, and the definition of ψ-mollifier subgradients. □

In variational analysis, the *Clarke subderivative* of a function $f : \mathbf{R}^n \to \mathbf{R}$ is

$$(d_C f)(x; u) = \limsup_{y\to x, \lambda\downarrow 0} \frac{1}{\lambda}[\,f(y + \lambda u) - f(y)\,]$$

with the lim sup calculated with respect to all sequences $y \to x$, $\lambda \downarrow 0$. The set of *generalized* (*Clarke*) *subgradients* is

$$\partial_C f(x) = \{\,g \in \mathbf{R}^n\,|\,\langle g, u\rangle \leq d_C f(x; u),\ \forall\, u \in \mathbf{R}^n\,\}.$$

This notion was proposed by Clarke [6] for locally Lipschitz continuous functions; for lower semicontinuous functions this notion needs further adjustments (consult Rockafellar [31]).

PROPOSITION 4.10. *For $f : \mathbf{R}^n \to \mathbf{R}$ locally integrable, we have $f'_\psi(x;\cdot) \leq d_C f(x;\cdot)$. If f is also continuous, then $f'_\psi(x;\cdot) = d_C f(x;\cdot)$.*

Proof. By definition of $d_C f(x; u)$ it follows that for an arbitrary $\varepsilon > 0$, there exist δ_1, δ_2 such that whenever $|y - x| < \delta_1$ and $\lambda \in (0, \delta_2)$,

$$\frac{1}{\lambda}\,[\,f(y + \lambda u) - f(y)\,] < d_C f(x; u) + \varepsilon.$$

Let f^ν be the averaged function obtained as the convolution of f and the mollifier ψ^ν. Consider the finite differences

$$\triangle_\nu(y,u,\lambda) := \frac{1}{\lambda}\,[\,f^\nu(y+\lambda u) - f^\nu(y)\,] = \int_{\mathrm{R}^n} \frac{1}{\lambda}\,[\,f(y-z+\lambda u) - f(y-z)\,]\psi^\nu(z)\,dz.$$

If $|y-x| < \delta_1/2$, $\lambda < \delta_2/2$, and $|z| \le \delta_1/2$, then

$$\triangle_\nu(y,u,\lambda) \le (d_C f(x;u) + \varepsilon)\int_{|z|\le\delta_1/2} \psi^\nu(z)\,dz.$$

Thus for y close enough to x,

$$(f^\nu)'(y;u) = \lim_{\lambda\downarrow 0} \triangle_\nu(y,u,\lambda) \le (d_C f(x;u)+\varepsilon)\int_{|z|\le\delta_1/2}\psi^\nu(z)\,dz$$

from which, after letting $\varepsilon\downarrow 0$, it follows that $f'_\psi(x;u) \le d_C f(x;u)$.

We next set out to prove the reverse inequality, assuming that f is continuous. Let $x^\nu \to x$ and $\lambda_\nu \downarrow 0$ be such that

$$d_C f(x;u) = \lim_{\nu\to\infty} \frac{1}{\lambda_\nu}\,[\,f(x^\nu + \lambda_\nu u) - f(x^\nu)\,].$$

From Corollary 3.3, we know that when f is continuous, the averaged functions f^ν converge uniformly to f on some neighborhood, say V, of x. Thus, with $\varepsilon_\nu = \lambda_\nu/\nu$, we can always find k_ν such that

$$\sup_{y\in V} |f(y) - f^{k_\nu}(y)| < \varepsilon_\nu.$$

Now from the Mean Value Theorem follows the existence of $y^\nu := x^\nu + \tau_\nu u$, $\tau_\nu \in [\,0,\lambda_\nu\,]$ such that

$$\frac{1}{\lambda_\nu}\,[\,f^{k_\nu}(x^\nu+\lambda_\nu u) - f^{k_\nu}(x^\nu)\,] = (f^{k_\nu})'(y^\nu;u).$$

Thus for ν sufficiently large, with $x^\nu \in V$ and $x^\nu + \lambda_\mu u \in V$, we have

$$\begin{aligned} f(x^\nu+\lambda_\nu u) - f(x^\nu) &= [\,f^{k_\nu}(x^\nu+\lambda_\nu u) - f^{k_\nu}(x^\nu)\,] \\ &\quad + [\,f(x^\nu+\lambda_\nu u) - f^{k_\nu}(x^\nu+\lambda_\nu u)\,] - [\,f(x^\nu) - f^{k_\nu}(x^\nu)\,] \\ &\le \lambda_\nu((f^{k_\nu})'(y^\nu;u) + 2/\nu). \end{aligned}$$

Taking lim sup with respect to ν yields

$$d_C f(x;u) \le \limsup_{\nu\to\infty}\,(f^{k_\nu})'(y^\nu;u) \le f'_\psi(x;u),$$

which completes the proof. □

THEOREM 4.11. *If $f : \mathbf{R}^n \to \mathbf{R}$ is lower semicontinuous and locally integrable, then*

$$\operatorname{con}\partial_\psi f(x) \subset \operatorname{con}\partial_\Psi f(x) \subset \partial_C f(x).$$

If, in addition, f is locally Lipschitz continuous, then

$$\operatorname{con}\partial_\psi f(x) = \partial_\Psi f(x) = \partial_C f(x).$$

Proof. The relationship between $\partial_\psi f(x)$ and $\partial_\Psi f(x)$ yields the first inclusion, and the second inclusion follows from the preceding proposition. If f is locally Lipschitz, then also the averaged functions f^ν are equi-Lipschitz and $\partial_\psi f(x)$ is bounded. Equality then follows from Propositions 4.5 and 4.10. □

COROLLARY 4.12 (Gupal [15]). *If f is locally Lipschitz continuous, then for all $\alpha_\nu \downarrow 0$ and $x^\nu \to x$, all clusters points of the sequences $\{\nabla f_{\alpha_\nu}(x^\nu)\}$ belong to $\partial_C f(x)$.*

Remark 4.13. For the sake of completeness, let us also record the fact that for convex functions $f : \mathbf{R}^n \to \mathbf{R}$, any ψ-mollifier subgradient is equal to the subgradient of convex analysis *without* any need of taking convex hulls. More precisely, we have

$$\partial_\psi f(x) = \partial f(x) := \{\, g \in \mathbf{R}^n \mid f(z) \geq f(x) + \langle g, z - x\rangle,\ \forall\, z \in \mathbf{R}^n \,\}.$$

As is well known, convex functions of gradients can be characterized in terms of the expression on the right, cf. [32], for example. In view of the preceding theorem, it will thus be sufficient to show that if $g \in \partial f(x)$, then g is also included in $\partial_\psi f(x)$. Let us consider the function

$$\varphi(y) = f(y) + |y - x|^2 - f(x) - \langle g, y - z\rangle.$$

The function $\varphi \geq 0$ and attains its minimum $(= 0)$ at x; due to the strict convexity of φ, x is a unique minimizer of φ. Let

$$\begin{aligned}\varphi^\nu(y) &= \int_{\mathbf{R}^n} \varphi(y - z)\psi^\nu(z)\,dz \\ &= f^\nu(y) + \beta^\nu(x, y) - f(x) - \langle g, y - x\rangle - \int_{\mathbf{R}^n} \langle g, z\rangle \psi^\nu(z)\,dz\end{aligned}$$

be the averaged functions associated with φ by convolution with ψ^ν; here $\beta^\nu(x, y) = \int |y - z - x|^2 \psi^\nu(z)\,dz$. The averaged functions φ^ν uniformly converge to φ on some neighborhood V of x (Corollary 3.3). Due to the strict convexity of φ, for ν sufficiently large, the averaged functions ψ^ν have a (global) minimizer on V, say y^ν. Moreover, $y^\nu \to x$, since x is a unique minimizer of $\varphi = \text{e}-\text{lm}\,\varphi^\nu$ (Theorem 3.7). The averaged functions φ^ν, f^ν, and $\beta^\nu(x, \cdot)$ are smooth (Theorem 3.10), and thus

$$\nabla\varphi^\nu(y^\nu) = \nabla f^\nu(y^\nu) + \nabla_y \beta^\nu(x, y^\nu) - g,$$

$$\nabla_y \beta^\nu(x, y) = \int_{\mathbf{R}^n} \nabla_y |y - z - x|^2 \psi^\nu(z)\,dz = 2(y - x) - 2\gamma^\nu,$$

$$\gamma^\nu = \int_{\mathbf{R}^n} z\psi^\nu(z)\,dz.$$

From the conditions imposed on the mollifiers ψ^ν, it follows that $\gamma^\nu \to 0$, and hence $\nabla_y \beta^\nu(x, y^\nu) \to 0$, and

$$\nabla f^\nu(y^\nu) = g - \nabla_y \beta^\nu(x, y^\nu) \longrightarrow g \quad \text{as } \nu \to \infty,$$

which means that $g \in \partial_\psi f(x)$, as claimed. □

5. Numerical procedures. Let us consider the problem of minimizing a strongly lower semicontinuous φ on X, a compact subset of $\mathbf{R}^n$. Let

$$\mathbb{1}_X(x) = \begin{cases} 1 & \text{if } x \in X; \\ 0 & \text{if } x \notin X. \end{cases}$$

Then, instead of the original problem, we could work with one of the following unconstrained problems involving discontinuous penalty functions:

$$\text{minimize} f(x) := \varphi(x)\mathbb{I}_X(x) + \gamma(1 - \mathbb{I}_X(x))$$

or

$$\text{minimize} f(x) := \varphi(x)\mathbb{I}_X(x) + \gamma(1 - \mathbb{I}_X(x))d(x, X),$$

where $d(x, X) = \min\{\, |x - y| : y \in X \,\}$ and γ is sufficiently large.

If the function φ is bounded on X and $\gamma > \sup\{|\varphi(x)| : x \in X\}$, all local minima of φ on X are also local minima of the function f.

Assuming that f is also strongly lower semicontinuous, in view of Theorems 3.7 and 3.10, we can always find a sequence of smooth averaged functions f^ν (generated by mollifiers $\{\psi^\nu\}$) that epi-converge to f, and by Theorem 4.7, the condition $0 \in \partial_\psi f(x^*)$ is necessary for a point x^* to be a local minimizer of f

Let us now consider some optimization procedures for f making use of the approximating averaged function f^ν.

Method 5.1. Suppose a sequence $\{x^\nu\}$ of global minimizers of f^ν can be calculated. Then, according to Theorem 3.5 any cluster point of such a sequence is a (global) minimizer of f.

However finding global minimizers of the f^ν could be quite complicated. Let us thus consider the next method.

Method 5.2. Here a sequence of approximating solutions $\{x^\nu\}$ is built in accordance with the following rule. Each function f^ν is minimized—initiating the procedure at $x^{\nu-1}$—until a point x^ν is found such that $|\nabla f^\nu(x^\nu)| \le \varepsilon_\nu$, where $\varepsilon_\nu \downarrow 0$; the starting point x^0 is chosen arbitrarily. In this method, if $\bar{x}$ is a cluster point of the sequence $\{x^\nu\}$, then by the definition of $\partial_\psi f(\bar{x})$, passing to a subsequence if necessary,

$$\lim_{\nu\to\infty} \nabla f^\nu(x^\nu) = 0 \in \partial_\psi f(\bar{x}).$$

Moreover, this would also mean that $0 \in \partial_C f(\bar{x})$ (Theorem 4.11), i.e., $d_C f(x; u) \ge 0$ for all $u \in \mathbf{R}^n$.

This approach requires estimates of $|\nabla f^\nu(x^\nu)|$ during the iteration process. In general, this could be computationally expensive involving the calculation of multidimensional integrals. We can however, produce these estimates in parallel with the optimization process by a well-known averaging procedure (cf. Ermoliev [8]): Let

(i) x^0, z^0 be chosen arbitrarily in $\mathbf{R}^n$;
(ii) $x^{k+1} = x^k - \rho_k z^k, \quad k = 0, 1, \ldots;$
(iii) $z^{k+1} = z^k - \tau_k(z^k - \lambda_k(x^k)), \; k = 0, 1, \ldots;$

where x^k approximates $\operatorname{argmin} f^\nu$, z^k are averaged estimates of $\nabla f^\nu(x^k)$, $\lambda_\nu(x^k)$ are stochastic (finite-difference unbiased) estimates for $\nabla f^\nu(x^k)$ such that their mathematical expectation $E\{\lambda_\nu(x^k)\} = \nabla f^\nu(x^k)$ (see the observations that follow Proposition 3.11), and $\rho_k \ge 0$ and $\tau_k > 0$ are sequences such that

$$\sum_{k=0}^{\infty} \rho_k = \infty, \quad \sum_{k=0}^{\infty} \rho_k^2 < \infty, \quad \lim_{k\to\infty} \rho_k/\tau_k = 0.$$

PROPOSITION 5.3 (Ermoliev [8, theorem V.8]). *If the sequences $\{x^k\}$, $\{z^k\}$ are almost surely bounded, then almost surely*

$$\lim_{k\to\infty} |z^k - \nabla f^\nu(x^k)| = 0, \quad \textit{and } x^k \longrightarrow \{x \,|\, \nabla f^\nu(x) = 0\}.$$

Thus in Method 5.2, *we can proceed with the minimization of each f^ν until the estimate z^k of the gradient of $\nabla f^\nu(x^k)$ satisfies the condition $|z^k| \leq \varepsilon_\nu$.*

Method 5.4. A sequence of approximate solutions x^ν is generated by the following rule:

(i) $x^0 \in \mathbf{R}^n$ is chosen arbitrarily;

(ii) $x^{\nu+1} = x^\nu - \rho_\nu \lambda_\nu(x^\nu)$, $\nu = 0, 1. \dots,$

where $\boldsymbol{\lambda}_\nu(x^\nu)$ is a stochastic (finite-difference unbiased) estimator for $\nabla f^\nu(x^\nu)$ with expectation $E\{\boldsymbol{\lambda}_\nu(x^\nu)\} = \nabla f^\nu(x^\nu)$ (see the observations following Proposition 3.11 and Remark 3.12), and $\rho_\nu \geq 0$ is a deterministic sequence of multipliers.

This method combines ideas from the method of stochastic quasi-gradients with those of dynamic nonstationary optimization techniques, see Ermoliev and Nurminski [10] and Gaivoronski [13]. The following theorem is an example of the possible convergence results.

THEOREM 5.5 (Gupal and Norkin [17]). *Suppose the gradient estimates are those in Example* 3.12, *i.e., $\lambda_\nu(x) = \lambda_{\alpha_\nu \alpha_\nu}(x, \xi, \eta)$, the sequence $\{x^\nu\}$ belongs to some compact set, and $\rho_\nu \geq 0$, α_ν satisfy the conditions*

$$\sum_{\nu=1}^{\infty} \rho_\nu = \infty, \quad \sum_{\nu=1}^{\infty} \left(\frac{\rho_\nu}{\alpha_\nu^2}\right)^2 < \infty, \quad \lim_{\nu \to \infty} \alpha_\nu = \lim_{\nu \to \infty} \frac{\alpha_\nu - \alpha_{\nu+1}}{\alpha_\nu \rho_\nu} = 0.$$

Then, almost surely, the sequence $\{x^\nu\}$ admits a cluster point x^* such that $0 \in \partial_\psi f(x^*)$.

Example 5.6. Let us consider the following minimization of a probability function:

$$f(x) = \mathbf{P}\,[\,g(x, \omega) \geq 0\,].$$

We can express f as a mathematical expectation

$$f(x) = \int_\Omega \mathbb{1}_{\{g(x,\omega) \geq 0\}}(\omega)\, P(d\omega).$$

Since the function $\mathbb{1}_{\{.\}}$ is discontinuous, the function f will in general, not be differentiable. To estimate $f(x)$ and its "gradient," Tamm [41] and Lepp [21] proposed the use of Parzen–Rosenblatt kernel-type estimates [29], [35]:

$$f_\varepsilon(x) = \frac{1}{\varepsilon} \int_\Omega P(d\omega) \int_{-\infty}^{0} d\tau\, \psi\left(\frac{\tau + g(x, \omega)}{\varepsilon}\right),$$

$$\nabla f_\varepsilon(x) = \frac{1}{\varepsilon} \int_\Omega \psi\left(\frac{g(x, \omega)}{\varepsilon}\right) \nabla_x g(x, \omega)\, P(d\omega),$$

where ψ is some symmetric density function on $[-\infty, \infty]$; more recently Marti [23] has suggested a similar approach to deal with reliability constraints in structural optimization. The function f_ε can also be written as

$$f_\varepsilon(x) = \int_\Omega \psi_\varepsilon(g(x, \omega))\, P(d\omega),$$

where

$$\begin{aligned} \psi_\varepsilon(t) &= \frac{1}{\varepsilon} \int_{-\infty}^{t} \psi\left(\frac{\tau}{\varepsilon}\right) d\tau \\ &= \frac{1}{\varepsilon} \int_{-\infty}^{\infty} \mathbb{1}_{\{t-\tau \geq 0\}}(\tau) \psi\left(\frac{\tau}{\varepsilon}\right) d\tau = \frac{1}{\varepsilon} \int_{-\infty}^{\infty} \mathbb{1}_{\{t+\tau \geq 0\}}(\tau) \psi\left(-\frac{\tau}{\varepsilon}\right) d\tau. \end{aligned}$$

Thus ψ_ε is an averaged function (with base function $1\!\!1_{\{\cdot\geq 0\}}$). Instead of the original function f, we have a sequence of approximating functions f_ε constructed (indirectly) by means of averaged functions. Tamm [41] in the differentiable case, and Norkin [28] in the continuous nondifferentiable case, provided conditions under which f_ε converges uniformly to f, and they proposed methods, similar to Method 5.2, to minimize f making use of the approximating functions f_ε. Lepp [22] and Roenko [34] analyzed stochastic iterative methods, like Method 5.4, for the minimization f when it is differentiable, using statistical estimates for $\nabla f_\varepsilon(x)$.

ON A GENERALIZATION OF A NORMAL MAP AND EQUATION*

JONG-SHI PANG[†] AND JEN-CHIH YAO[‡]

Abstract. The class of normal maps was recently investigated by Robinson and Ralph in connection with the study of a variational inequality defined on a polyhedral set. In this paper a generalization of such a map is considered, and the associated generalized normal equation is studied. The latter provides a unified formulation of several generalized variational inequality and complementarity problems. Using degree theory, some sufficient conditions for the existence of a zero of a generalized normal map are established and the stability of a generalized normal equation at a solution is analyzed. Specializations of the results to various applications are discussed.

Key words. nonsmooth equation, complementarity problem, variational inequality, degree theory, stability analysis

AMS subject classifications. 90C30, 90C33

1. Introduction. In the past two decades, the finite-dimensional variational inequality (VI) and nonlinear complementarity problem (NCP) have been studied extensively; a survey of results and applications can be found in the review article by Harker and Pang [10]. Since the early work of Eaves [4] and others, it has been known that the VI defined on a closed convex set is equivalent to a certain nonsmooth equation. Recently, Robinson [25], [26], [27] introduced the class of *normal maps* to describe such an equation and derived various properties of these maps when the underlying set is a convex polyhedron. Subsequent work can be found in [21], [22].

Motivated by several extensions of the VI and the NCP, we introduce a generalization of a normal map. Using degree theory, we establish some existence results for a generalized normal map to have a zero and discuss their applications. We also apply a recent sensitivity theory for parametric nonsmooth equations [20] to investigate the stability of a generalized normal equation at a given solution.

The rest of this paper is divided into three sections. The next section introduces the generalized normal equation and discusses its applications. In the third section, we derive the existence results using degree theory. Finally, in the fourth and final section, we study the stability of the generalized normal equation at a solution.

2. The generalized normal map and equation. Let f and g be two given mappings from R^n into itself. Let K be a nonempty closed convex set in R^n. The *generalized normal map* (GNM) associated with the triple (K, g, f) is defined to be the mapping $h : R^n \to R^n$ where

$$h(x) = g(x) - \Pi_K(g(x) - f(x)) \quad \text{for } x \in R^n,$$

and Π_K is the projection operator onto K under the Euclidean norm. When K is polyhedral and g is the identity map, then h becomes the *normal map* associated with the pair (K, f). Incidentally, the latter is not quite the same as Robinson's normal

map as defined in [25], which is $f(\Pi_K(x))+x-\Pi_K(x)$; with an abuse of language and no particular harm as far as the VI is concerned, we have extended the usage of the term "normal map" to include the special case of the GNM with g being the identity.

Associated with the GNM h is the *generalized normal equation* (GNE):

$$h(x) = 0. \tag{1}$$

The major objective of this paper is to derive some sufficient conditions for the solvability of this equation and to study its stability at a solution. The derived results will be specialized to various applications that can be modeled by such an equation.

As mentioned before, our consideration of the GNM was motivated by several generalizations of the VI and NCP. We now explain the latter problems. To begin, we note that a vector x is a zero of the GNM h defined above if and only if x satisfies the following conditions: (i) $g(x) \in K$, and (ii) for all $y \in K$,

$$(y - g(x))^T f(x) \geq 0.$$

Hence, by defining the set-valued map T as follows:

$$T(z) = z - g(z) + K \quad \text{for } z \in R^n,$$

we deduce that x is a zero of h if and only if x satisfies: (i) $x \in T(x)$, and (ii) for all $v \in T(x)$,

$$(v - x)^T f(x) \geq 0.$$

The latter is a quasi-variational inequality (QVI) defined by the pair (T, f); see [2]. Conversely, associated with an arbitrary QVI (T, f), where the set-valued map T is given by

$$T(x) = m(x) + K \tag{2}$$

with m being a (point-to-point) map from R^n into itself and K a closed convex set in R^n, is the equivalent generalized normal equation (1) corresponding to

$$g(x) = x - m(x).$$

Hence we see that the generalized normal equation provides a compact representation for a QVI with the map T having the special form (2).

As we can expect from the well-known relation between a VI and a complementarity problem, when K is a cone, the generalized normal equation associated with the triple (K, g, f) is equivalent to the following complementarity problem:

$$g(x) \in K, \quad f(x) \in K^*, \quad g(x)^T f(x) = 0, \tag{3}$$

where

$$K^* = \{y \in R^n : y^T x \geq 0 \text{ for all } x \in K\}$$

is the dual cone of K. The proof of this equivalence is standard and left to the reader. A special case of the latter complementarity problem is the implicit complementarity problem (ICP), which corresponds to the case where $g(x) = x - m(x)$ and K is the nonnegative orthant [18]. In turn, an interesting instance of the ICP is the case where

$$g(x) = \min(g^i(x) : i = 1, \ldots, m) \tag{4}$$

with each g^i being a mapping from R^n into itself and "min" is the componentwise minimium operator; this instance corresponds to what has been called the (finite-dimensional) *order complementarity problem* that has received an increasing amount of attention in the literature in recent years [1], [8], [11], [12]. Note that the mapping g in (4) is in general not F-differentiable even if the individual functions $\{g^i\}_{i=1}^m$ are.

It is interesting to note that with $f(x) = 0$ for all x, (1) reduces to the feasibility problem

$$g(x) \in K. \tag{5}$$

Some of our subsequent results are concerned with this special case.

It should be pointed out that in general, when the mapping g is a bijection, then the corresponding generalized normal equation can be turned into a nonsmooth equation defined by a normal map. Indeed, in this case, it is easy to see that (1) holds if and only if

$$u - \Pi_K(u - f \circ g^{-1}(u)) = 0$$

where $u = g(x)$. This equivalence clearly fails when g is not surjective. Hence, when considering the GNM associated with triple (K, g, f), we avoid assuming that g is surjective.

There is substantial literature on various generalizations of the VI; see [31], [32]. A large portion of this literature is concerned with the derivation of existence results for these problems. These results are established by means of either a fixed point argument or some minimax theory. With the exception of only two articles [14], [8] that deal with the ICP and the order linear complementarity problem, there is no study on the sensitivity of the QVI or the complementarity problem (3). The primary goal of this paper is to derive some new existence and sensitivity results for the latter problems based on the framework of a generalized normal equation.

The tool to be employed in our study is degree theory [15], [17]; hence our approach to the derivation of existence results (in the context of the generalized VIs) is different from the previous approaches. There are two basic motivations for using degree theory in a study of this kind. One is that degree theory is known to be a powerful tool for establishing existence results. (As a matter of fact, this theory was created for this purpose by L. E. J. Brouwer.) The second is that several recent studies [5], [6], [7], [8], [9] suggest that the same theory is useful for dealing with various sensitivity and stability issues of variational inequalities and complementarity problems. Our present research extends these studies and treats some similar issues for the generalized problems.

3. Existence results.

For the discussion in this section we make use of some basic results from degree theory. Those readers who are not familiar with this theory can consult two references [15], [17] for a review of these results and other related background material.

By means of the homotopy invariance property of the degree of a continuous mapping, we can very easily state a general principle for the derivation of existence results to a system of nonlinear equations. With reference to (1) where h is continuous, it suffices to exhibit a continuous homotopy $H : [0, 1] \times R^n \to R^n$ with the property that there exists a bounded open set $\Omega \subseteq R^n$ satisfying the following properties:

(a) the degree of $H(0, \cdot)$ at 0 with respect to Ω, denoted $\deg(H(0, \cdot), \Omega, 0)$, is defined and nonzero;

(b) $0 \notin H(t, \partial\Omega)$ for all $t \in [0,1]$ with ∂ denoting the boundary of a set; and

(c) $H(1,x) = h(x)$ for all $x \in \overline{\Omega}$ with the overline denoting the closure of a set.

If such a homotopy can be identified, then there exists a scalar $\varepsilon > 0$ such that for any function $\tilde{h}$ that is continuous in $\overline{\Omega}$ and satisfies

$$d(h, \tilde{h}) := \sup_{x \in \overline{\Omega}} \|h(x) - \tilde{h}(x)\| < \varepsilon,$$

the system

$$\tilde{h}(x) = 0, \qquad x \in \Omega$$

will have a solution. Note that the conclusion asserts not only the solvability of (1) but also that of all slightly perturbed systems.

Consequently, the task of proving the existence of a solution to (1) has been reduced to the identification of an appropriate homotopy H. In the sequel, we give two basic results of this nature that are specific to a GNM.

THEOREM 3.1. *Let K be a closed convex subset of R^n, and let f and g be two continuous functions from R^n into itself. Suppose there exist a continuous function e from R^n into itself and a bounded open set Ω in R^n such that*

(i) $\deg(k, \Omega, 0)$ *is defined and nonzero where*

$$k(x) = g(x) - \Pi_K(g(x) - e(x)) \quad \textit{for } x \in R^n;$$

$$\text{(ii)} \qquad \left.\begin{array}{r} x \in \partial\Omega \cap g^{-1}(K) \\ \mu > 0 \end{array}\right\} \quad \Rightarrow \quad f(x) + \mu e(x) \notin (K - g(x))^*.$$

Then there exists a solution to the system

$$g(x) - \Pi_K(g(x) - f(x)) = 0, \qquad x \in \overline{\Omega}.$$

Proof. Assume that the GNM

$$h(x) = g(x) - \Pi_K(g(x) - f(x))$$

has no zero in $\overline{\Omega}$. Consider the homotopy defined by

$$H(t,x) = g(x) - \Pi_K(g(x) - tf(x) - (1-t)e(x)).$$

Assumption (i) implies that condition (a) of the homotopy principle is satisfied. Note that our assumption about h implies that $H(1, \cdot)$ cannot have a zero on $\partial\Omega$. Suppose $H(t,x) = 0$ for some $t \in (0,1)$ and $x \in \partial\Omega$. For this vector x, we then have $g(x) \in K$ and

$$(y - g(x))^T (tf(x) + (1-t)e(x)) \geq 0$$

for all $y \in K$. Dividing by $t > 0$ in the last inequality yields a contradiction to assumption (ii) with $\mu = (1-t)/t$. □

The main point of the above result is that the solvability of (1) can be inferred from that of the GNE associated with the triple (K, g, e) under the stated assumptions. Presumably, the auxiliary function e is simpler than f, and the associated GNE is simpler than (1) as well. In the event that such a function e can not be identified easily, the next result might be useful.

THEOREM 3.2. *Let K be a closed convex subset of R^n, and let f and g be two continuous functions from R^n into itself. Suppose there exist a continuous function e from R^n into itself, a vector $a \in K$, and a bounded open set Ω in R^n such that* (i′) $\deg(e-a,\Omega,0)$ *is defined and nonzero*;

(ii′) *with* $\gamma_t(x)=g(x)+(1-t)(e(x)-g(x))$, *we have*

$$\left.\begin{aligned} x\in\partial\Omega\cap\gamma_t^{-1}(K) \\ t\in(0,1) \end{aligned}\right\} \quad\Rightarrow\quad (1-t)(e(x)-a)+tf(x)\notin(K-\gamma_t(x))^*.$$

Then the conclusion of Theorem 3.1 *holds.*

Proof. It suffices to use the homotopy

$$H(t,x)=tg(x)-\Pi_K(t(g(x)-f(x))+(1-t)a)+(1-t)e(x)$$

and apply the same argument as in the proof of the previous theorem. The details are omitted. □

Presumably, the difference between the two theorems is that in the former, assumption (i) is more restrictive, whereas in the latter, assumption (ii) becomes more so. In the sequel, applications of both results will be illustrated. We begin with a corollary that can be derived from either one of the two results.

COROLLARY 3.3. *Let K be a closed convex subset of R^n, and let f and g be two continuous functions from R^n into itself. Suppose there exist a vector $a\in K$ and a bounded open set Ω in R^n such that*

(iii) $\deg(g-a,\Omega,0)$ *is defined and nonzero*;

(iv) $$\left.\begin{aligned} x\in\partial\Omega\cap g^{-1}(K) \\ \mu>0 \end{aligned}\right\} \quad\Rightarrow\quad f(x)+\mu(g(x)-a)\notin(K-g(x))^*.$$

Then the conclusion of Theorem 3.1 *holds.*

Proof. It suffices to take the function e to be g in Theorem 3.2. □

The next result gives a sufficient condition for assumption (iv) to be satisfied.

COROLLARY 3.4. *Let K be a closed convex subset of R^n, and let f and g be two continuous functions from R^n into itself. Suppose there exist a vector $a\in K$ and a bounded open set Ω in R^n such that*

(iii) *deg* $(g-a,\Omega,0)$ *is defined and nonzero*;

(iv′) $(g(x)-a)^Tf(x)\geq 0$ *for all* $x\in\partial\Omega\cap g^{-1}(K)$.

Then the conclusion of Theorem 3.1 holds.

Proof. We verify assumption (iv). Let $x\in\partial\Omega\cap g^{-1}(K)$ and let $\mu>0$. Then $g(x)\neq a$ because of the well-definedness of $\deg(g-a,\Omega,0)$. Hence

$$(a-g(x))^T(f(x)+\mu(g(x)-a))<0$$

by assumption (iv′). Consequently, (iv) follows. □

We should point out that in the case where the set K is the Cartesian product of a finite number of sets of lower dimensions, say,

$$K=\Pi_{q=1}^N K_q, \tag{6}$$

where each K_q is a closed convex set in R^{n_q}, then Corollary 3.4 remains valid if condition (iv′) is replaced by the weaker assumption

(v) $\max_{1\leq q\leq N}(g_q(x)-a_q)^Tf_q(x)\geq 0$ for all $x\in\partial\Omega\cap g^{-1}(K)$.

Before discussing some general conditions on the triple (K,g,f) that will ensure the satisfaction of the assumptions in the above results, we give a simple one-dimensional example to illustrate the last corollary.

Example. Let

$$g(x) = \frac{x}{x^2+1}, \qquad x \in R,$$

and $K = [0, \infty)$. We claim that if f is any continuous function with $f(t) \geq 0$ for some $t > 0$, then the generalized normal equation associated with the triple (K, g, f) has a solution in the interval $[0, t]$. Since K is a (one-dimensional) cone, the discussion in §2 shows that this equation is equivalent to the complementarity problem (3). By an elementary argument, the reader can easily verify that the latter problem must have a solution. We now prove this simple fact using Corollary 3.4. Take $a = 0$ and $\Omega = (-t, t)$. Clearly, the only zero of g is $x = 0$ and $g'(0) = 1$. Hence $\deg(g - a, \Omega, 0) = 1$. Trivially, we have $\partial\Omega \cap g^{-1}(K) = \{t\}$ and $g(t)f(t) \geq 0$. Consequently, the two assumptions of Corollary 3.4 are satisfied and the desired conclusion follows.

3.1. Some known results. The theorems established above are general enough to include as special cases many well-known existence results from diverse applications. The discussion that follows serves to illustrate this point. As we shall see, such familiar results as the famous Farkas lemma in linear programming are amenable to a degree-theoretic treatment. In the next section, we derive some new existence results for various special problems.

We begin by considering the case where $K = R^n$. This, of course, corresponds to the classical problem of finding a zero of the function f (note that g plays no role). For this simple case, we obtain a solvability result for a system of nonlinear equations that is reminiscent of the famous Leray–Schauder fixed-point theorem [15], [17].

PROPOSITION 3.5. *Let f be a continuous function from R^n into itself. Suppose there exist a continuous function e from R^n into itself and a bounded open set Ω in R^n such that* $\deg(e, \Omega, 0)$ *is defined and nonzero, and for all $x \in \partial\Omega$ and all $\mu > 0$,*

$$f(x) + \mu e(x) \neq 0.$$

Then f has a zero in $\overline{\Omega}$.

Proof. It suffices to apply Theorem 3.1 with $K = R^n$ and g arbitrary. □

Our next application concerns the famous Farkas lemma, which states that the system of linear inequalities

$$Az = b, \qquad z \geq 0, \tag{7}$$

where $A \in R^{m \times n}$ and $b \in R^m$ are given, has a solution if and only if the implication below holds:

$$A^T x \geq 0 \quad \Rightarrow \quad b^T x \geq 0. \tag{8}$$

The nontrivial part of this result is the "if" part. Normally, the proof is based on the theory of linear inequalities. In what follows, we show this using Theorem 3.2.

PROPOSITION 3.6. *Suppose* (8) *holds. Then* (7) *is consistent.*

Proof. Let K be the convex cone in R^m generated by the columns of the matrix A. Then K is closed. This is a well-known fact in the theory of linear inequalities; for the sake of completeness, we give an elementary proof, which proceeds as follows. Take an arbitrary vector $y \in \overline{K}$. Then there exist sequences of vectors $\{v^k\} \subset R^m$ converging to zero and $\{z^k\} \subseteq R^n_+$ such that $y + v^k = Az^k$; moreover, for each k, we may choose z^k with the property that the columns of A corresponding to the positive components of z^k are linearly independent. The sequence $\{z^k\}$ must have a convergent subsequence with a nonnegative limit. Thus, $y \in K$.

It suffices to show that the given vector b belongs to K. Let $g(x)$ be the constant function equal to b and let $f(x)$ be the zero function; take e to be the identity function $a = 0$ and take Ω to be any open ball (in R^m) with center at the origin. Assumption (i′) in Theorem 3.2 is clearly satisfied because the degree of the identity map is equal to one. Suppose assumption (ii′) is violated. Then for some $t \in (0,1)$ and $x \in \partial\Omega \cap \gamma_t^{-1}(K)$, we have

$$x \in (K - \gamma_t(x))^*.$$

Since K is a convex cone and $\gamma_t(x) \in K$, it can easily be shown that $x \in K^*$ and $x^T\gamma_t(x) = 0$. The former implies $A^Tx \geq 0$; hence, by assumption, we have $b^Tx \geq 0$. Now, writing out $\gamma_t(x)$, we deduce

$$0 = x^T\gamma_t(x) = x^T(b + (1-t)(x-b)) = tx^Tb + (1-t)x^Tx > 0,$$

where the last inequality holds because $x \in \partial\Omega$ and $t \in (0,1)$. This is a contradiction. Consequently, Theorem 3.2 applies and the desired conclusion follows. □

Our third result concerns the VI that corresponds to the case where the function g is the identity. The following is one of many existence results for this problem; we have chosen it partly because of its generality among such results and partly to pave the way for subsequent generalization to the QVI.

PROPOSITION 3.7. *Let K be a closed convex set in R^n and f a continuous function from R^n into itself. Suppose that there exists a vector $a \in K$ such that the set*

$$\{x \in K : (x-a)^Tf(x) < 0\} \tag{9}$$

is bounded (possibly empty). Then there exists a solution to the VI *defined by the pair (K, f).*

Proof. It suffices to employ Corollary 3.4 with g being the identity map and Ω being an open bounded set containing (9). □

3.2. New existence results. In this section we derive some new existence results for the QVI and ICP. We start with one that concerns the feasibility problem (5) and extends Proposition 3.6. The assumption to be imposed is similar to the one in Proposition 3.7; the proof is similar to that of Proposition 3.6.

PROPOSITION 3.8. *Let K be a closed convex cone and g a continuous function from R^n into itself. Suppose that the set*

$$\{x \in K^* : x^Tg(x) < 0\} \tag{10}$$

is bounded (possibly empty). Then $g^{-1}(K)$ is nonempty.

Proof. Let Ω be an open ball with center at the origin and containing the set (10). Take e to be identity map $a = 0$ and f to be the zero function. We verify that the two assumptions in Theorem 3.2 are satisfied. It suffices to verify the second one. Assume the contrary. Let $t \in (0,1)$ and $x \in \partial\Omega \cap \gamma_t^{-1}(K)$ be such that $x \in (K - \gamma_t(x))^*$. Using the cone property of K we can easily show that $x \in K^*$ and $x^T\gamma_t(x) = 0$. Since $x \in \partial\Omega$ and Ω contains (10), it follows that $x^Tg(x) \geq 0$. As in Proposition 3.6, we can see that this contradicts the equation $x^T\gamma_t(x) = 0$. □

It is possible to establish a version of the above result that does not require K to be a cone. Indeed, if K is a closed convex set containing a vector a such that the set

$$\{x \in R^n : (x-a)^T(g(x)-a) < 0\}$$

is bounded and if g is continuous, then $g^{-1}(K)$ is nonempty. We omit the proof of this statement since it is similar to that of Proposition 3.8.

In the rest of this section we derive some specialized existence results for a generalized normal equation. These results are extensions of their counterparts for the (standard) VI. In principle, many existence results for the latter problem (see [10]) can all be extended to the present context. In the sequel, we choose to focus on the class of generalized normal equations with monotone pairs (g, f). A motivation for this choice is so that we can discuss the uniqueness of a solution to the generalized normal equation. The following definition makes the monotonicity concept precise.

DEFINITION. *The function f is said to be*

(i) monotone *with respect to g on the set K if*

$$g(x), g(y) \in K \quad \Rightarrow \quad (f(x)-f(y))^T(g(x)-g(y)) \geq 0;$$

(ii) strictly monotone *with respect to g on the set K if*

$$[g(x), g(y) \in K, \text{ and } x \neq y] \quad \Rightarrow \quad (f(x)-f(y))^T(g(x)-g(y)) > 0;$$

(iii) strongly monotone *with respect to g on the set K if there exists a constant $c > 0$ such that*

$$g(x), g(y) \in K \quad \Rightarrow \quad (f(x)-f(y))^T(g(x)-g(y)) \geq c\|x-y\|^2.$$

If f and g are both affine functions, say, $f(x) = a + Ax$ and $g(x) = b + Bx$, and if $K = R^n$, then f is monotone with respect to g if and only if the matrix A^TB is positive semidefinite, and f is strongly monotone with respect to g if and only if the same matrix is positive definite. If A is nonsingular, A^TB is positive (semi-)definite if and only if BA^{-1} is; a similar statement holds if B is nonsingular. More generally, if $K = R^n$ and $f(g)$ is a (nonlinear) bijective map, then f is (strictly, strongly) monotone with respect g if and only if $g \circ f^{-1}(f \circ g^{-1})$ is (strictly, strongly) monotone in the usual sense.

The above concept of monotonicity for a pair of affine functions is closely related to a certain generalized $\mathbf{P}_0$-property for a finite family of square matrices of the same order. The latter was introduced by Wilson [29] and its application to nonlinear networks was discussed in various articles in [30]. The recent paper [28] gives a renewed look at these matrix-theoretic properties and studies their role in some generalized linear complementarity problems.

PROPOSITION 3.9. *Let K be a closed convex subset of R^n, and let f and g be two continuous functions from R^n into itself with g being injective. Suppose there exist a vector $u \in g^{-1}(K)$ and positive scalars α and L such that for all $x \in g^{-1}(K)$ with $\|x\| \geq \alpha$, $\|g(x)-g(u)\| \leq L\|x-u\|$. If f is strongly monotone with respect to g on K, then there exists a unique vector $\bar{x}$ satisfying*

$$g(x) = \Pi_K(g(x) - f(x)). \tag{11}$$

Proof. Let $a = g(u) \in K$ and $c > 0$ be the constant associated with the strong monotonicity of f with respect to g on K. Let Ω be a bounded open set such that for all $x \in \partial\Omega$, we have $\|x\| \geq \alpha$ and

$$c\|x-u\| \geq L\|f(u)\|.$$

Since g is injective, it follows that $\deg(g-a, \Omega, 0) = \pm 1$ (see [15]). We verify condition (iv′) in Corollary 3.4. Let $x \in \partial\Omega \cap g^{-1}(K)$. We have

$$\begin{aligned}(g(x)-a)^T f(x) &= (g(x)-g(u))^T(f(x)-f(u)) + (g(x)-g(u))^T f(u)\\ &\geq c\|x-u\|^2 - L\|f(u)\|\|x-u\| \geq 0\end{aligned}$$

by the choice of Ω. Consequently, Corollary 3.4 implies the existence of the vector $\bar{x}$ with the desired property. It remains to establish the uniqueness of $\bar{x}$. Suppose x' is another such solution. Then we have

$$(g(x')-g(\bar{x}))^T f(\bar{x}) \geq 0 \quad \text{and} \quad (g(\bar{x})-g(x'))^T f(x') \geq 0.$$

Adding these two inequalities and using the strong monotonicity assumption immediately yield $\bar{x} = x'$. □

We can see from the above uniqueness proof that in general if f is strictly monotone with respect to g on K, then there can exist at most one solution to the generalized normal equation (11). Another noteworthy remark is that if f is strictly (in particular, strongly) monotone with respect to g on the whole space R^n, then both f and g must be injective (on R^n). Consequently, if we assume that f is strongly monotone with respect to g on R^n (and not just on K), then we may remove the injectivity assumption on g in the above theorem as it would become redundant.

The existence conclusion of Proposition 3.9 remains valid if the strong monotonicity assumption on the entire set K is weakened to the strong monotonicity with respect to the vector u. Indeed, from the above proof, we see that if for all $x \in g^{-1}(K)$ with $\|x\|$ sufficiently large,

$$(f(x)-f(u))^T(g(x)-g(u)) \geq c\|x-u\|^2,$$

then perhaps with a larger set Ω, Corollary 3.4 is still applicable; hence the existence of a solution to (11) follows. Note that with this weakened monotonicity assumption, the uniqueness of $\bar{x}$ is no longer guaranteed.

Taking into account the remark following the proof of Corollary 3.4, which concerns the case of a set K with a Cartesian product structure, we may derive an analogous existence result for the complementarity problem (3) where K is the nonnegative orthant. The proof is similar to the one above and consists of verifying condition (v). We do not repeat this verification.

PROPOSITION 3.10. *Let f and g be two continuous functions from R^n into itself with g being injective. Suppose that there exists a vector u satisfying $g(u) \geq 0$ and there are positive scalars α and L such that for all x with $g(x) \geq 0$ and $\|x\| \geq \alpha$, $\|g(x)-g(u)\| \leq L\|x-u\|$. If there exists a scalar $c > 0$ such that, for all x with $g(x) \geq 0$ and $\|x\|$ sufficiently large,*

$$\max_{1 \leq i \leq n}(f_i(x)-f_i(u))(g_i(x)-g_i(u)) \geq c\|x-u\|^2, \tag{12}$$

then there exists a vector $\bar{x}$ satisfying

$$g(x) \geq 0, \quad f(x) \geq 0, \quad g(x)^T f(x) = 0. \tag{13}$$

We have mentioned that in §2 that for a generalized normal equation associated with the triple (K, g, f), the case where g is bijective corresponds essentially to Robinson's normal equation. In what follows, we give an example of a one-dimensional function g satisfying the assumptions of the above proposition (see also Proposition 3.9) that is not surjective.

Example. Let

$$g(x) = \frac{1 - e^x}{1 + e^x}, \qquad x \in R.$$

Since $|g(x)| \leq 1$, g is not surjective. It is easy to verify that g is injective and satisfies $|g(x) - g(0)| \leq |x|$ for $|x| \geq 1$.

When g is the identity map, (12) reduces to the assumption that f is a *uniform P-function* ([16]). As mentioned in the Introduction, the order complementarity problem (in a finite-dimensional vector lattice) is an instance of the problem (13) where the function g is of the special form (4). When f and each function g^i in the latter equation are all affine, this order complementarity problem has recently been studied extensively by Gowda and Sznajder [8]. Among other things, they give a necessary and sufficient conditions for such a *generalized order linear complementarity problem* to have a unique solution "for all constant vectors" in terms of a consistent determinantal sign property (see also [26], [21]). In the Appendix we show how the latter property is related to (12) specialized to certain piecewise affine functions f and g.

The final result in this section concerns a weakening of the strong monotonicity assumption in Proposition 3.9. In its place, we assume that f is monotone with respect to g on K. We also need two other assumptions, one of which involves the following concept.

DEFINITION. *A function $g : R^n \to R^n$ is said to be* proper *with respect to a set D if for every bounded subset S of D, $g^{-1}(S)$ is bounded.*

In the next result, "int S" and "0^+S" denote, respectively, the interior and recession cone of a set S.

PROPOSITION 3.11. *Let K be a closed convex set in R^n, and let f and g be continuous functions from R^n into itself with g being injective. Suppose there exists a vector $u \in g^{-1}(K)$ with $f(u) \in \operatorname{int}(0^+K)^*$. If f is monotone with respect to g on K and g is proper with respect to K, then* (11) *has a solution.*

Proof. Let $a = g(u)$. We claim that the set

$$\{x \in g^{-1}(K) : (g(x) - a)^T f(x) < 0\}$$

is bounded. Assume the contrary. Then there exists an unbounded sequence $\{x^k\} \subseteq g^{-1}(K)$ such that $(g(x^k) - g(u))^T f(x^k) < 0$ for each k. Since f is monotone with respect to g on K, we have

$$(g(x^k) - g(u))^T f(u) < 0$$

for each k. Since g is proper on K, the sequence $\{g(x^k)\}$ is unbounded. Without loss of generality, we may assume that the normalized sequence $\{(g(x^k) - g(u))/\|g(x^k)\|\}$ converges to a limit v that must belong to $0^+K \setminus \{0\}$ because $\{g(x^k)\} \subseteq K$ and $g(u) \in K$. Moreover, we have $v^T f(u) \leq 0$; but this contradicts the assumption that $f(u) \in \operatorname{int}(0^+K)^*$. This establishes the claim stated at the beginning of the proof. Invoking Corollary 3.4, we easily deduce the desired conclusion of the proposition. □

Remark. When K is a cone, the assumption on the vector u is a "strict feasibility" condition for the complementarity problem (3).

4. Sensitivity analysis. In this section we derive some sensitivity results for the parametric generalized normal equation

$$H(x,p) := G(x,p) - \Pi_K(G(x,p) - F(x,p)) = 0, \tag{14}$$

where $G, F : R^n \times R^m \to R^n$ and K is a closed convex subset of R^n. In this problem, $x \in R^n$ is the primary variable and $p \in R^m$ is the parameter. At a given value p^*, a zero of the function $H(\cdot, p^*)$, say x^*, is known. We are interested in analyzing the behavior of this solution when p is perturbed around p^*. The tool we employ for this analysis is the recent results in [20]. We divide the discussion into two cases. The first case assumes no particular differentiability assumption on the functions F and G and no special structure on K; whereas in the second case, the set K is assumed to be a polyhedron and the functions F and G are assumed to have some differentiability properties.

4.1. The nonsmooth case. In this case we assume that the functions $G(\cdot, p^*)$ and $F(\cdot, p^*)$ have continuous *first-order approximations* at x^* [24]; specifically, we assume that there exist continuous functions g and f such that $g(x^*) = G(x^*, p^*)$, $f(x^*) = F(x^*, p^*)$, and

$$\lim_{x \to x^*} \frac{G(x,p^*) - g(x)}{\|x - x^*\|} = 0, \quad \text{and} \quad \lim_{x \to x^*} \frac{F(x,p^*) - f(x)}{\|x - x^*\|} = 0.$$

Clearly, the function

$$h(x) = g(x) - \Pi_K(g(x) - f(x)) \tag{15}$$

is then a first-order approximation of $H(\cdot, p^*)$ at x^* by the nonexpansiveness of the projection operator. Moreover, h is continuous. By imposing a certain strong monotonicity assumption on the pair of approximating functions (g, f) at the vector x^*, we may derive the following stability result for the solution x^*.

THEOREM 4.1. *In the above setting, suppose that the functions g and f are locally Lipschitzian at x^* and that there exist an open neighborhood V of x^* and positive scalars α and β such that* (i) *g is injective in V and* (ii) *for all $x \in V$ and all p sufficiently close to p^*,*

$$(f(x) - f(x^*))^T(g(x) - g(x^*)) \geq \alpha \|x - x^*\|^2, \tag{16}$$

and

$$\max(\|F(x,p) - F(x,p^*)\|, \|G(x,p) - G(x,p^*)\|) \leq \beta \|p - p^*\|.$$

Then x^* is an isolated zero of $H(\cdot, p^*)$; moreover, there exist a scalar $L > 0$ and open neighborhoods U of p^* and W of x^* such that for all vectors $p \in U$, the system

$$H(x,p) = 0, \qquad x \in W$$

has a solution and for any such solution x,

$$\|x - x^*\| \leq L \|p - p^*\|.$$

Proof. Without loss of generality, we may assume that f and g are Lipschitzian in V. According to the results in [20], it suffices to verify three things: (i) x^* is the only zero of h in V, (ii) the inverse function h^{-1} is pseudo-upper Lipschitzian at 0 relative to x^*, and (iii) the index of h at x^* is nonzero. The "isolated" requirement (i) is easy by (16) and the uniqueness proof in Proposition 3.9. To show (ii), it suffices to verify that there exists a constant $\lambda > 0$ such that if $h(x) = y$ and $x \in V$, then $\|x - x^*\| \leq \lambda\|y\|$. Let x be any such vector. Then we have $g(x) - y \in K$ and

$$(u - g(x) + y)^T(f(x) - y) \geq 0 \quad \text{for all } u \in K.$$

Since $g(x^*) \in K$, we derive

$$(g(x^*) - g(x) + y)^T(f(x) - y)) \geq 0.$$

On the other hand, we also have

$$(g(x) - y - g(x^*))^T f(x^*) \geq 0$$

because $g(x) - y \in K$ and $h(x^*) = 0$. Adding the last two inequalities and rearranging terms, we obtain

$$(g(x) - g(x^*))^T(f(x) - f(x^*)) \leq -y^T(f(x^*) - f(x) + g(x^*) - g(x)).$$

Hence, since $x \in V$, by (16), the local Lipschitzian assumption of f and g at x^*, and the Cauchy–Schwartz inequality, we can easily deduce the existence of the desired constant λ. Finally, we need to verify that the index of h at x^* is nonzero. For this purpose, we consider the homotopy

$$\gamma(t, x) := th(x) + (1 - t)(g(x) - g(x^*)).$$

We claim that for all $t \in [0, 1]$, x^* is the only zero of $\gamma(t, \cdot)$ in V. When $t = 0$, this is true by the injectiveness assumption of g; as noted above, the same is true when $t = 1$. Consider a $t \in (0, 1)$ and suppose $\gamma(t, x) = 0$. Then we have

$$t^{-1}(g(x) - (1 - t)g(x^*)) = \Pi_K(g(x) - f(x)).$$

By an algebraic manipulation similar to the one used above, we can easily deduce that $x = x^*$. This establishes our claim. By the homotopy invariance property of the degree, we deduce that

$$\deg(\gamma(1, \cdot), V', 0) = \deg(\gamma(0, \cdot), V', 0),$$

where V' is any open neighborhood of x^* contained in V; the right-hand degree is equal to ±1 by the injectiveness of g. This completes the proof of the theorem. □

We note that similar to several previous results, if K is a Cartesian product of the form (6), then (16) can be weakened to

$$\max_{1 \leq q \leq N} (f_q(x) - f_q(x^*))^T(g_q(x) - g_q(x^*)) \geq \alpha\|x - x^*\|^2,$$

and the same conclusion of the theorem still holds. Conditions such as this last one and (16) are rather strong; in the next section we see how they can be weakened under a structural assumption on K and a differentiability property of G and F.

4.2. The differentiable and polyhedral case. Consider the parametric equation (14) where K is a polyhedron and the functions $G(\cdot,p^*)$ and $F(\cdot,p^*)$ have Fréchet derivatives at x^*. In this case, the approximating functions g and f can be taken to be

$$g(x) = G(x^*,p^*)+\nabla_x G(x^*,p^*)(x-x^*) \quad \text{and} \quad f(x) = F(x^*,p^*)+\nabla_x F(x^*,p^*)(x-x^*).$$

Moreover, instead of using the function given in (15) as a first-order approximation for $H(\cdot,p^*)$ at x^*, we may use

$$(17)\quad h(x) = \nabla_x G(x^*,p^*)(x-x^*) - \Pi_L((\nabla_x G(x^*,p^*) - \nabla_x F(x^*,p^*))(x-x^*)),$$

where L is the *critical cone* of K at $G(x^*,p^*) - F(x^*,p^*)$. We refer the reader to [19], [24] for an explanation of this cone and a demonstration of why the latter function h is a first-order approximation of $H(\cdot,p^*)$ at x^* in this case (recall that $H(x^*,p^*) = 0$). As a matter of fact, this function h is also the B-derivative of $H(\cdot,p^*)$ at x^* (see the cited references for details). With L being a polyhedral cone, h is a piecewise linear function. Hence h^{-1} is necessarily pseudo-upper Lipschitzian by a result of Robinson [23]. Consequently, the second requirement (ii) in the proof of Theorem 4.1 is easily satisfied. We now address the other two requirements (i) and (iii). The equation $h(x) = 0$ corresponds to the following generalized linear complementarity problem on the cone L:

$$\nabla_x G(x^*,p^*)(x-x^*) \in L, \qquad \nabla_x F(x^*,p^*)(x-x^*) \in L^*,$$
$$(x-x^*)^T \nabla_x G(x^*,p^*)^T \nabla_x F(x^*,p^*)(x-x^*) = 0.$$

Hence x^* is an isolated zero of h if and only if the following system has $v = 0$ as the unique solution:

$$(18)\ \nabla_x G(x^*,p^*)v \in L, \quad \nabla_x F(x^*,p^*)v \in L^*, \quad (\nabla_x G(x^*,p^*)v)^T \nabla_x F(x^*,p^*)v = 0.$$

We now come to the final requirement (iii). We claim that (a) if (18) has $v = 0$ as the unique solution, (b) if the matrix $\nabla_x G(x^*,p^*)$ is nonsingular, and (c) if

$$(19)\qquad \nabla_x G(x^*,p^*)v \in L \quad \Rightarrow \quad v^T \nabla_x G(x^*,p^*)^T \nabla_x F(x^*,p^*)v \geq 0,$$

(under (b), (c) says that the matrix $\nabla_x F(x^*,p^*)(\nabla_x G(x^*,p^*))^{-1}$ is copositive on the cone L), then the index of h given by (17) at x^* is nonzero. Indeed, by the nonsingularity of $\nabla_x G(x^*,p^*)$, the affine mapping

$$a(x) = \nabla_x G(x^*,p^*)(x-x^*)$$

has an index at x^* equal to the sign of the determinant of $\nabla_x G(x^*,p^*)$ that is nonzero; moreover,

$$\gamma(t,x) = th(x) + (1-t)a(x)$$

is a homotopy connecting h and a, and $\gamma(t,\cdot)$ has $x = x^*$ as the unique zero for all $t \in [0,1]$. Consequently, the index of h at x^* equals that of a at x^*.

Summarizing the above discussion, we present a stability result for the parametric equation (14) under the special assumptions on K, F, and G. Since we have already verified the three conditions stated at the beginning of the proof of Theorem 4.1, the proof of the following result is essentially complete.

THEOREM 4.2. *Let K be a polyhedron in R^n and H be defined by* (14). *Suppose $H(x^*,p^*) = 0$, $F(\cdot,p^*)$ and $G(\cdot,p^*)$ are Fréchet differentiable at x^*, and there exists a constant $\beta > 0$ such that for all (x,p) sufficiently close to (x^*,p^*),*

$$\max(\|F(x,p) - F(x,p^*)\|, \|G(x,p) - G(x,p^*)\|) \leq \beta\|p - p^*\|.$$

Assume further that the Jacobian matrix $\nabla_x G(x^*,p^*)$ is nonsingular, (18) *has $v = 0$ as the unique solution, and* (19) *holds. Then the same conclusion of Theorem* 4.1 *is valid for* (14).

5. Appendix. In this appendix we relate the strong monotonicity condition (12) to a consistent determinantal sign property of matrices. The latter property has been used by several authors [13], [8] to characterize the global homeomorphism of a piecewise affine mapping and the global solvability of a generalized order linear complementarity problem. We are not concerned with these characterizations here; instead, we provide some matrix-theoretic criteria for the satisfaction of (12) when the functions f and g are the componentwise mininum of certain affine mappings.

DEFINITION. *Let $(A_i : i = 1, \ldots, m)$ be a family of m square matrices of order n. A* representative matrix *of this family is an $n \times n$ matrix B whose ith row is that of one of the A_j.*

The following lemma is concerned with the case of two matrices.

LEMMA 5.1. *Let A and B be two square matrices of order n. The following statements are equivalent.*

(a) *All representative matrices of the pair (A, B) have the same nonzero determinantal sign.*

(b) *All matrices of the form D_1A+D_2B, where D_1 and D_2 are nonnegative diagonal matrices with $(D_1)_{ii} + (D_2)_{ii} > 0$ for all i, have the same nonzero determinantal sign.*

(c) *Both A and B are nonsingular and BA^{-1} is a* P*-matrix.*

(d) *There exists a scalar $c > 0$ such that*

$$\max_{1 \leq i \leq n} (Az)_i(Bz)_i \geq c\|z\|^2$$

for all vectors $z \in R^n$.

Proof. (a) $\Rightarrow$ (b). Clearly, (a) implies that det A is nonzero. Moreover, by a suitable renaming of the matrices A and B if necessary, it suffices to show that the determinant of a matrix of the form $A + DB$ where D is an arbitrary nonnegative diagonal matrix has the same sign as det A. In turn, the latter can be proved by induction on the number of nonzero diagonal entries of D. The key inductive step follows rather easily from (a) and the fact that the determinant of a matrix is a linear function of any given row.

(b) $\Rightarrow$ (c). Clearly, (b) implies that both A and B are nonsingular. Suppose that BA^{-1} is not a P-matrix. Then by a sign reversal property of a P-matrix [3, Thm. 3.3.4], it follows that there exists a nonzero vector u such that

$$u_i(BA^{-1}u)_i \leq 0 \quad \text{for all } i.$$

By letting $A^{-1}u = z$ we obtain

$$(Az)_i(Bz)_i \leq 0 \quad \text{for all } i.$$

Hence defining

$$(D_1)_{ii} = \begin{cases} 0 & \text{if } (Bz)_i = 0, \\ 1 & \text{if } (Bz)_i \neq 0, \end{cases} \quad \text{and} \quad (D_2)_{ii} = \begin{cases} 1 & \text{if } (Bz)_i = 0, \\ -\frac{(Az)_i}{(Bz)_i} & \text{if } (Bz)_i \neq 0, \end{cases}$$

and letting D_1 and D_2 be the respective (nonnegative) diagonal matrices, we see that $D_1 + D_2$ is a positive diagonal matrix and

$$(D_1A + D_2B)z = 0,$$

which contradicts the nonsingularity of the matrix $D_1A + D_2B$.

(c) $\Rightarrow$ (d). The above proof already reveals this implication (using the characterization of a P-matrix in terms of the sign reversal property).

(d) $\Rightarrow$ (a). Let us call two representative matrices C_1 and C_2 of the pair (A, B) *complementary* if for each i, $\{i\text{th row of } C_1, i\text{th row of } C_2\} = \{i\text{th row of } A, i\text{th row of } B\}$. Clearly, if C_1 and C_2 are any two complementary representative matrices, then

$$\max_{1 \leq i \leq n} (C_1z)_i(C_2z)_i \geq c\|z\|^2$$

for all z. This implies that all complementary representative matrices are nonsingular and $C_2C_1^{-1}$ is a P-matrix. Hence, any two complementary representative matrices have the same (nonzero) determinantal sign. It remains to show that any representative matrix has the same nonzero determinantal sign as A. For this purpose, we first show that if C is the (representative) matrix obtained by replacing one row of A with the corresponding row of B, then det CA^{-1} is positive. Without loss of generality, we may take this to be the first row. Then it suffices to show that $(B_1A^{-1})_1 > 0$, where B_1 is the first row of B. Let z be the first column of A^{-1}. Then Az is the first coordinate vector. Hence, by (d), we have

$$0 < c\|z\|^2 \leq \max_{1 \leq i \leq n} (Az)_i(Bz)_i = (B_1A^{-1})_1,$$

as desired. To complete the proof, we use an inductive argument. Suppose that C is a representative matrix with $k(\geq 2)$ rows coming from B (which we take to be the first k rows) and the remaining $n - k$ rows from A (which therefore are the last $n - k$). Let C' be the representative matrix whose first $k - 1$ rows come from B and the remaining $n - k + 1$ rows from A. By an inductive hypothesis, the determinantal signs of C' and A are the same. Let $\tilde{C}$ be the complementary representative matrix of C'. Clearly, C is obtained from C' by replacing its kth row with that of $\tilde{C}$; hence the proof of the case $k = 1$ implies that C and C' have the same determinantal sign. The inductive proof is now complete. □

We now generalize the above lemma to a family of matrices.

PROPOSITION 5.2. *Let $(A_1, \ldots, A_m)$ be a family of square matrices of order n. Consider the following statements.*

(a) *All representative matrices of this family have the same nonzero determinantal sign.*

(b) *All matrices of the form $\sum_{j=1}^{m} D_jA_j$, where D_j are nonnegative diagonal matrices satisfying $\sum_{j=1}^{m}(D_j)_{ii} > 0$ for all i, have the same nonzero determinantal sign.*

(c) *All representative matrices of the family $(A_j : j = 1, \ldots, m)$ are nonsingular and $B_1B_2^{-1}$ is a* P*-matrix for any two such representative matrices B_1 and B_2.*

(d) *For arbitrary vectors* $(a^1, \ldots, a^m)$ *and* u, *there exist scalars* $c, \alpha > 0$ *such that for any two subsets* J_1 *and* J_2 *of* $\{1, \ldots, m\}$,

$$\max_{1 \le i \le n} (f(z) - f(u))_i (g(z) - g(u))_i \ge c\|z - u\|^2$$

for all vectors $z \in R^n$ *with* $\|z\| \ge \alpha$, *where*

$$f(z) = \min(A_j z + a^j : j \in J_1), \qquad g(z) = \min(A_j z + a^j : j \in J_2).$$

It holds that (a) ⇔ (b) ⇔ (c) ⇒ (d).

Proof. (a) ⇒ (b) ⇒ (c). The proofs of these implications are easy extensions of the corresponding proofs for the case of $m = 2$.

(c) ⇒ (a). Fix $B_1 = A_1$. It then follows that all representative matrices have the same determinantal sign as A_1.

(c) ⇒ (d). According to Lemma 5.1 and by the fact that there are only finitely many representative matrices, it follows that there exists a constant $c_1 > 0$ such that for any two representative matrices B_1 and B_2, we have

$$\max_{1 \le i \le n} (B_1 z)_i (B_2 z)_i \ge c_1 \|z\|^2$$

for all vectors z. For the functions f and g as given in (d), it is clear that we have

$$(f(z) - f(u))_i (g(z) - g(u))_i = (A_{j_1} z)_i (A_{j_2} z)_i + \text{a linear term in } z + \text{ a constant},$$

where the two integers $j_1 \in J_1$ and $j_2 \in J_2$ depend on z, u, and i. Let B_1 and B_2 be the representative matrices with the ith row equal to that of A_{j_1} and A_{j_2}, respectively. Then we have

$$\begin{aligned} &\max\nolimits_{1 \le i \le n} (f(z) - f(u))_i (g(z) - g(u))_i \\ &\ge \max\nolimits_{1 \le i \le n} (B_1 z)_i (B_2 z)_i + \text{ a piecewise linear function of } z \\ &\ge c_1 \|z\|^2 + \text{ a piecewise linear function of } z. \end{aligned}$$

From this, the existence of the constants c and α follows easily. □

Note that in the last proposition, the reverse implication (d) ⇒ (a) is not claimed. At this time, we are not certain whether this will hold, hence the omission. Finally, we mention that many results related to the ones given in this Appendix can be found in [29], [30], [28].

Acknowledgments. Several people have made useful comments concerning this paper. M.S. Gowda pointed out the connection between the monotonicity concepts defined in §3 and the generalized $\mathbf{P}_0$-properties of matrices introduced by Wilson; he also provided references [29], [30]. Danny Ralph brought reference [27] to our attention. S. M. Robinson reminded us that the closedness of the set K was needed in Proposition 3.6. The referees and the editors also have made a number of constructive comments. We thank them all.

NONLINEAR H^∞ OPTIMIZATION: A CAUSAL POWER SERIES APPROACH*

CIPRIAN FOIAS†, CAIXING GU†, AND ALLEN TANNENBAUM‡

Abstract. In this paper, using a power series methodology a design procedure applicable to analytic nonlinear plants is described. The technique used is a generalization of the linear H^∞ theory. In contrast to previous work on this topic ([*Indiana J. Math.*, 36 (1987), pp. 693–709], [*Oper. Theory Adv. Appl.*, 41 (1989), pp. 255–277], [*SIAM J. Control Optim.*, 27 (1989), pp. 842–860]), the authors are now able to incorporate explicitly a causality constraint into the theory. In fact, it is shown that it is possible to reduce a causal optimal design problem (for nonlinear systems) to a classical interpolation problem solvable by the commutant lifting theorem [*Harmonic Analysis of Operators on Hilbert Space*, North-Holland, Amsterdam, 1970], [*The Commutant Lifitng Approach to Interpolation Problems*, Birkhäuser, Boston, 1990].

Key words. nonlinear systems, H^∞ optimization, causality, commutant lifting theorem, interpolation theory, Volterra series

AMS subject classifications. primary 47A20, secondary 47A99, 93B35, 93C05

1. Introduction. In this paper, we continue our work on finding a suitable, implementable nonlinear extension of the powerful linear H^∞ design methodology. In what follows, we will just consider discrete-time systems, even though the techniques elucidated below carry over to the continuous-time setting as well.

Our approach is based on previous work ([14], [15]) in which we considered systems described by analytic input/output operators. A key idea here involved the expression of each n-linear term of a suitable Taylor expansion of the given operator as an equivalent linear operator acting on a certain associated tensor space, which allowed us to iteratively apply the classical commutant lifting theorem in designing a compensator. (Our class of operators includes Volterra series [9].)

More precisely, in such an approach we are reduced to applying the classical (linear) commutant lifting theorem to an H^2-space defined on some D^n (where D denotes the unit disc). Now when we apply the classical result to D^n ($n \geq 2$), even though time-invariance is preserved (that is, commutation with the appropriate shift), causality may be lost. Indeed, for systems described by analytic functions on the disc D (these correspond to stable, discrete-time, one-dimensional (1D) systems), time-invariance (that is, commutation with the unilateral shift) implies causality. For analytic functions on the n-disc ($n > 1$), this is not necessarily the case. For dynamical system control design and for any physical application, this is, of course, a major drawback for such an approach. (The compensators we obtained were "weakly causal" and causal approximations were discussed.)

Hence for a dilation result in $H^2(D^n)$ we must include the causality constraint explicitly in the set-up of the dilation problem. It is precisely this problem that motivated the mathematical operator-theoretic work of [16] and [13], which incorporated Arveson theory [1] into the dilation, commutant lifting framework.

While the general method explicated in this paper is based on a causal extension of the commutant lifting theorem, for the purposes of the operators and spaces that appear in control we will give a direct simple method for finding the optimal causal compensators. In fact, we will show that *the computation of an optimal causal nonlinear compensator may be reduced to a classical interpolation problem.*

We now briefly outline the contents of this paper. In §2, we define *causality* and *time-invariance* as applied to analytic mappings. We show in particular that while in the linear case, time-invariance and boundedness imply causality, this is not true in general in the nonlinear setting. In §3, we formulate the causal optimization problem to be studied. In §4, we discuss the Fourier representation of certain Hilbert spaces, a technique that we apply throughout the paper. In §5, we prove the main theoretical result of this paper in which we show how to reduce a causal optimization problem to a problem solvable via the classical commutant lifting theorem [25]. This is summarized in a computational algorithm in §§6 and 7. Sections 8 and 9 are then concerned with our formulation of the nonlinear generalization of the H^∞ sensitivity minimization problem, which is then solved via a *causal iterative commutant lifting* method in §10. Section 11 is devoted to a natural control interpretation of our optimization procedure, while §12 is connected to computational aspects of our work, namely a nonlinear notion of *rationality* that reduces our work to finite-dimensional skew Toeplitz calculations. We illustrate our methods with an example in §13, and finally in §14, we make some concluding remarks.

We conclude this section by noting that there have been other approaches to nonlinear H^∞. These include a nonlinear commutant lifting theorem [3], [4], and a very promising nonlinear game-theoretic approach [7] as well as a nonlinear version of Ball–Helton theory [6], and the recent work in [26].

Once again, we will just consider discrete-time systems in what follows.

2. Causal analytic mappings. In this section, we will define the class of nonlinear input/output operators that we will study in this paper. To do this, we will first need to discuss a few standard results about analytic mappings on Hilbert spaces. See [3], [4], [14], [15], [21] and the references therein for complete details.

Let $\mathcal{G}$ and $\mathcal{H}$ denote complex separable Hilbert spaces. Set

$$B_{r_o}(\mathcal{G}) := \{g \in \mathcal{G} : \|g\| < r_o\}$$

(the open ball of radius r_o in $\mathcal{G}$ about the origin). Then we say that a mapping $\phi : B_{r_o}(\mathcal{G}) \to \mathcal{H}$ is *analytic* if the complex function $(z_1, \ldots, z_n) \mapsto \langle \phi(z_1 g_1 + \ldots + z_n g_n), h\rangle$ is analytic in a neighborhood of $(1, 1, \ldots, 1) \in \mathbf{C}^n$ as a function of the complex variables $z_1, \ldots, z_n$ for all $g_1, \ldots, g_n \in \mathcal{G}$ such that $\|g_1 + \ldots + g_n\| < r_o$, for all $h \in \mathcal{H}$, and for all $n > 0$.

We will now assume that $\phi(0) = 0$. It is easy to see that if $\phi : B_{r_o}(\mathcal{G}) \to \mathcal{H}$ is analytic, then ϕ admits a convergent Taylor series expansion ([21, p. 97]), i.e.,

$$\phi(g) = \phi_1(g) + \phi_2(g, g) + \cdots + \phi_n(g, \cdots, g) + \cdots,$$

where $\phi_n : \mathcal{G} \times \cdots \times \mathcal{G} \to \mathcal{H}$ is an n-linear map. Clearly, without loss of generality we may assume that the n-linear map $(g_1, \cdots, g_n) \to \phi(g_1, \ldots, g_n)$ is symmetric in the arguments $g_1, \ldots, g_n$. This assumption will be made throughout this paper for the various analytic maps which we consider. For ϕ a Volterra series, ϕ_n is basically the nth-Volterra kernel.

Now set

$$\hat{\phi}_n(g_1 \otimes \cdots \otimes g_n) := \phi_n(g_1, \ldots, g_n).$$

Then $\hat{\phi}_n$ extends in a unique manner to a dense set of $\mathcal{G}^{\otimes n} := \mathcal{G} \otimes \cdots \otimes \mathcal{G}$ (tensor product taken n times). Note by $\mathcal{G}^{\otimes n}$ we mean the Hilbert space completion of the algebraic tensor product of the $\mathcal{G}$'s. Clearly if $\hat{\phi}_n$ has finite norm on this dense set, then $\hat{\phi}_n$ extends by continuity to a bounded linear operator $\hat{\phi}_n : \mathcal{G}^{\otimes n} \to \mathcal{H}$. By abuse of notation, we will set $\phi_n := \hat{\phi}_n$. (Recall that an n-linear map on $G \times G \times \cdots \times G$ (product taken n times) becomes linear on the tensor product $\mathcal{G}^{\otimes n}$. For details about the construction of the tensor product, see [2, pp. 24–27].)

We now recall the following standard definitions.

DEFINITION 1. (i) *Notation as above. By a* majorizing sequence *for the analytic map ϕ, we mean a positive sequence of numbers α_n $n = 1, 2, \ldots$ such that $\|\phi_n\| < \alpha_n$ for $n \geq 1$. Suppose that $\rho := \limsup {\alpha_n}^{1/n} < \infty$. Then it is completely standard that the Taylor series expansion of ϕ converges at least on the ball $B_r(\mathcal{G})$ of radius $r = 1/\rho$* ([21, p. 97]).

(ii) *If ϕ admits a majorizing sequence as in* (i), *then we will say that ϕ is* majorizable.

Let $H^2_K(D^n)$ denote the standard Hardy space of $\mathbf{C}^K$-valued analytic functions on the n-disc D^n (D denotes the unit disc) with square integrable boundary values. We set $H^2_K := H^2_K(D)$ and and $H^2 := H^2_1$. We denote the shift on $H^2_K(D^n)$ by $S_{(n)}$. Note that $S_{(n)}$ is defined by multiplication by the function $(z_1 \cdots z_n)$. On H^2_K we set $S_{(1)} =: U$ (U is given by multiplication by z).

We now consider an analytic map ϕ with $\mathcal{G} = \mathcal{H} = H^2_k$. Note that

$$H^2_k \otimes \cdots \otimes H^2_k = (H^2_k)^{\otimes n} \cong H^2_K(D^n) \quad \text{with } K = k^n, \tag{1}$$

where we map $1 \otimes \cdots \otimes z \otimes \cdots \otimes 1$ (z in the ith place) to z_i, $i = 1, \ldots, n$. Clearly, $S_{(n)}$ corresponds to $U^{\otimes n}$ under this identification.

We will identify ϕ_n as a bounded linear map from $H^2_K(D^n) \to H^2_k$ via the canonical isomorphism (1). Then we say that ϕ is *time-invariant* if

$$\phi_n S_{(n)} = U \phi_n \quad \forall n \geq 1. \tag{2}$$

(We will also say each ϕ_n is *time-invariant.*) Equivalently, this means that $U\phi = \phi \circ U$ on some open ball about the origin in which ϕ is defined.

Now set

$$P^{(j)}_{(n)} := I - S^j_{(n)} S^{*j}_{(n)}, \qquad j \geq 1, \quad n \geq 1.$$

Note

$$P^{(j)} := P^{(j)}_{(1)} = I - U^j U^{*j}.$$

Then we say that ϕ is *causal* if

$$P^{(j)} \phi_n = P^{(j)} \phi_n P^{(j)}_{(n)}, \qquad j \geq 1, \quad n \geq 1. \tag{3}$$

(We also say each ϕ_n is *causal.*) Equivalently, $\phi_n : H^2_K(D^n) \to H^2_k$ is causal if for $F(z_1, \ldots, z_n) \in H^2_K(D^n)$,

$$F(z_1, \ldots, z_n) = \sum_{i_1, \ldots, i_n \geq 0} F_{i_1, \ldots, i_n} z_1^{i_1} \ldots z_n^{i_n}, \qquad \phi_n(F)(z) := \sum_{m \geq 0} f_m z^m,$$

each f_m only depends on

$$\{F_{i_1,\ldots,i_n} : 0 \leq i_1, \ldots, i_n \leq m\}.$$

This means that for

$$F(z_1, \ldots, z_n) = \sum_{\max\{i_1,\ldots,i_n\} \geq m} F_{i_1,\ldots,i_n} z_1^{i_1} \ldots z_n^{i_n},$$

we have that

$$(I - U^m U^{*m})\phi_n(F(z_1, \ldots, z_n)) = 0. \tag{4}$$

We would now like to discuss the relationship between time-invariance and causality. For simplicity, we assume $k = 1$, i.e., we work with single-input/single-output (SISO) systems. Let $\phi : H^2 \to H^2$ be linear and time-invariant (i.e., intertwines with the shift). Then it is easy to see that ϕ is causal. Indeed, $\phi U = U\phi$ implies

$$\begin{aligned} U^m U^{*m} \phi U^m U^{*m} &= U^m U^{*m} U^m \phi U^{*m} \\ &= U^m \phi U^{*m} \\ &= \phi U^m U^{*m}, \end{aligned}$$

which immediately implies

$$P^{(m)} \phi P^{(m)} = P^{(m)} \phi \quad \forall m \geq 1,$$

that is, ϕ is causal.

In the nonlinear setting however, time-invariance may not imply causality. As a concrete example, let $\phi_o : (H^2)^{\otimes 2} \to H^2$ be a linear operator such that $U^{\otimes 2}\phi_o = \phi_o U$, defined by

$$(\phi_o(f \otimes g))(z) := \sum_{m=0}^{\infty} (f_{m+1} f_m + f_m g_m + f_m g_{m+1}) z^m,$$

where

$$f(z) = \sum_{m=0}^{\infty} f_m z^m, \qquad g(z) = \sum_{m=0}^{\infty} g_m z^m.$$

Now set

$$\phi(f) := \phi_o(f \otimes f), \qquad f \in H^2.$$

Then ϕ is an analytic, time-invariant map. (In fact ϕ is a homogeneous polynomial of degree 2.) But ϕ is not causal. Indeed,

$$\begin{aligned} (P^{(1)}\phi(f))(z) &= 2 f_1 f_0 + f_0^2, \qquad z \in D \\ (P^{(1)}\phi(P_{(2)}^{(1)} f))(z) &= f_0^2, \qquad z \in D. \end{aligned}$$

Thus $P^{(1)}\phi(f) \neq P^{(1)}\phi(P_{(2)}^{(1)} f)$, for example for $f(z) := 1 + z$ for $z \in D$. (Note that under the identification (1), $P_{(2)}^{(1)}$ corresponds to $P^{(1)} \otimes P^{(1)}$.)

3. Causal optimization problem. One of the key techniques in this paper will be to reduce a nonlinear generalization of the H^∞ sensitivity minimization problem to a series of *linear causal optimization problems.* (This will be done in §§8–10 below.) In this section, we will formulate this new causal problem.

As above, we let $S_{(n)}$ denote the unilateral shift on $H^2_K(D^n)$ given by multiplication by $(z_1 \cdots z_n)$. Since $H^2_K(D^n)$ will be fixed in the discussion we will let $S := S_{(n)}$. As above, U will denote the unilateral shift on H^2_k given by multiplication by z, and $\Theta \in H^\infty_{k\times k}$ will be an inner $k \times k$ matrix-valued H^∞ function (i.e., a $k \times k$ inner matrix with entries H^∞ scalar functions). Finally $W : H^2_K(D^n) \to H^2_k$ will denote a causal, time-invariant bounded linear operator (in the sense of (2) and (3) above).

We can now state the *causal H^∞-optimization problem* (COP): Find

$$\sigma := \inf\{\|W - \Theta Q\| : Q : H^2_K(D^n) \to H^2_k,\ Q \text{ causal, time-invariant}\}. \tag{5}$$

Moreover, we want to compute an optimal, causal, time-invariant Q_{opt} such that

$$\sigma = \|W - \Theta Q_{\text{opt}}\|. \tag{6}$$

If we drop the causality constraint the solution to problem (5) is provided by the classical commutant lifting theorem [25]. With the causality constraint, the solution to (COP) is abstractly provided by a causal commutant lifting theorem [16], [13].

In this paper, based on this work we will provide a simple solution to the problem (COP) without directly referring to the operator theoretic results of [16] and [13]. In fact, we will show how to directly reduce the computation of σ to a classical interpolation problem handled by the ordinary commutant lifting theorem, a computational procedure for which was given in [14] and [15]. We will also describe how to get the corresponding optimal parameter Q_{opt}.

Our technique will be based on a *reduction theorem* stated in §5. To formulate this result, we will first discuss the Fourier representation, which we do in the next section.

4. Fourier representation. In what follows we must use the Fourier representation of elements of $H^2_K(D^n)$. We refer the reader to [25] for all the details.

We first precisely define all the relevant spaces. First we denote by

$$\ell^2(H^2_K) := \bigoplus_{i=1}^{\infty} H^2_K,$$

the Hilbert space of all column vectors

$$f(z) = [f_1(z), f_2(z), \ldots, f_n(z), \ldots]', \tag{7}$$

($'$ stands for tranpose) such that

$$\|f\|^2 := \sum_{i=1}^{\infty} \|f_i\|^2, \tag{8}$$

is finite. ($\|\ \|$ is our generic symbol for a Hilbert space norm (2-norm) as well as the induced operator norm. So for example in (8), it stands for the usual norm on H^2_K as well as the associated norm on $\ell^2(H^2_K)$.) Thus $\ell^2(H^2_K)$ is a vector-valued Hardy space. Indeed, if $f(z)$ is given by (7), then we may write

$$f(z) = \sum_{m=0}^{\infty} a_m z^m, \tag{9}$$

where each a_m is an infinite column vector with components in $\mathbf{C}^K$, and

$$a_m = \frac{1}{m!}[f_1^{(m)}(0), \ldots, f_j^{(m)}(0), \ldots]'.$$

Clearly,

$$\|f\|^2 = \sum_{m=0}^{\infty} \|a_m\|^2.$$

Conversely, if $f(z) \in \ell^2(H_K^2)$ is given in the form (9) for

$$a_m = [a_{m1}, \ldots, a_{mj}, \ldots]',$$

then $f(z)$ can be written in the form (7), i.e.,

$$f(z) = [f_1(z), \ldots, f_j(z), \ldots]',$$

where

$$f_j(z) = \sum_{m=0}^{\infty} a_{mj} z^m.$$

In what follows, we will either use representation (7) or (9). The context should always make the meaning clear.

Next we let $S_\Phi : \ell^2(H_K^2) \to \ell^2(H_K^2)$ denote the unilateral shift defined by multiplication by z. Then the *Fourier representation of* $H_K^2(D^n)$ is given by the (linear, bounded) operator

$$\Phi := \Phi_n : H_K^2(D^n) \to \ell^2(H_K^2),$$

which is defined by

$$\begin{aligned} f(z) &:= \Phi(F(z_1, z_2, \ldots, z_n)) \\ &:= \sum_{m=0}^{\infty} z^m \begin{bmatrix} F_{m,m,\ldots,m} \\ F_{m,\ldots,m,m+1} \\ F_{m,\ldots m+1,m+1} \\ \vdots \\ F_{m+i_1,m+i_2,\ldots,m+i_n} \\ \vdots \end{bmatrix}, \end{aligned} \tag{10}$$

where

$$F(z_1, \ldots, z_n) = \sum_{j_1,\ldots,j_n \geq 0} F_{j_1,\ldots,j_n} z_1^{j_1} \cdots z_n^{j_n},$$

and $(i_1, \ldots, i_n) \in I_n$ for

$$I_n := \{(i_1, \ldots, i_n) : i_1, \ldots, i_n \geq 0, \ \min\{i_1, \ldots, i_n\} = 0\}. \tag{11}$$

We order the set I_n in the following manner. We have $(i_1, \ldots, i_n) < (i_1', \ldots, i_n')$, if $\max\{i_1, \ldots, i_n\} < \max\{i_1', \ldots, i_n'\}$. Thus

$$I_n = \bigcup_{k \geq 0} I_n^{(k)},$$

where

$$I_n^{(k)} := \{(i_1, \dots, i_n) \in I_n : \max\{i_1, \dots, i_n\} = k\}.$$

Each $I_n^{(k)}$ is then ordered by the lexicographical order.

Note that we are taking $f(z)$ in the form (9) in the above representation. Moreover, note that

$$H_K^2(D^n) = \left\{ F(z_1, \dots, z_n) = \sum_{j_1,\dots,j_n \geq 0} F_{j_1,\dots,j_n} z_1^{j_1} \cdots z_n^{j_n} : \sum_{j_1,\dots,j_n \geq 0} \|F_{j_1,\dots,j_n}\|^2 < \infty \right\}.$$

We can also write

$$f(z) = [f_{0,\dots,0}(z), f_{0,\dots,1}(z), \dots, f_{i_1,\dots,i_n}(z), \dots]', \tag{12}$$

where

$$f_{i_1,\dots,i_n}(z) := \sum_{m=0}^{\infty} F_{i_1+m,\dots,i_n+m} z^m, \tag{13}$$

and $(i_1, \dots, i_n) \in I_n$.

Next, it is easy to see that $\Phi : H_K^2(D^n) \to \ell^2(H_K^2)$ is an isometry. Indeed, using (10), (12), and (13), we have

$$\begin{aligned} \|\Phi(F)\|^2 &= \|f\|^2 \\ &= \sum_{i_1,\dots,i_n \in I_n} \|f_{i_1,\dots,i_n}\|^2 \\ &= \sum_{i_1,\dots,i_n \in I_n} \|F_{i_1+m,\dots,i_n+m}\|^2 \\ &= \sum_{j_1,\dots,j_n \geq 0} \|F_{j_1,\dots,j_n}\|^2 \\ &= \|F\|^2. \end{aligned}$$

A similar computation shows that the adjoint of Φ is also an isometry, so that Φ is an unitary operator. We next show that

$$\Phi S = S_\Phi \Phi. \tag{14}$$

Indeed, we see that

$$\begin{aligned} \Phi S(F) &= \Phi(z_1 \cdots z_n F(z_1, \dots, z_n)) \\ &= \Phi(\sum_{j_1,\dots,j_n \geq 0} F_{j_1,\dots,j_n} z_1^{j_1+1} \cdots z_n^{j_n+1}) \\ &= \sum_{m=0}^{\infty} z^{m+1} \begin{bmatrix} F_{m,\dots,m} \\ F_{m,\dots,m,m+1} \\ F_{m,\dots,m+1,m+1} \\ \vdots \\ F_{m+i_1,m+i_2,\dots,m+i_n} \\ \vdots \end{bmatrix} \\ &= z\Phi(F) \\ &= S_\Phi \Phi(F). \end{aligned}$$

By (14), we see that if $W : H^2_K(D^n) \to H^2_k$ is such that $WS = UW$, then the operator $W\Phi^* : \ell^2(H^2_K) \to H^2_k$ satisfies

$$(W\Phi^*)S_\Phi = WS\Phi^* = U(W\Phi^*);$$

that is, $W\Phi^*$ intertwines the shifts S_Φ and U. Consequently, it is standard (see, e.g., [12], or [25, p. 277]) that $W\Phi^*$ is represented by a row vector

$$[W_{0,\dots,0}(z), W_{0,\dots,1}(z), \dots, W_{i_1,\dots,i_n}(z), \dots], \tag{15}$$

for $(i_1, \dots, i_n) \in I_n$. Specifically, for any

$$f(z) = [f_{0,\dots,0}(z), f_{0,\dots,1}(z), \dots, f_{i_1,\dots,i_n}(z), \dots]' \in \ell^2(H^2_K),$$

we have

$$(W\Phi^*)f(z) = \sum_{i_1,\dots,i_n \in I_n} W_{i_1,\dots,i_n}(z) f_{i_1,\dots,i_n}(z). \tag{16}$$

We will write that

$$W\Phi^* \cong [W_{0,\dots,0}(z), W_{0,\dots,1}(z), \dots, W_{i_1,\dots,i_n}(z), \dots], \tag{17}$$

in the sense expressed by (15) and (16).

We would like to make this representation a bit more precise now. Note that the action of $W\Phi^*$ is determined by its action on

$$\ker S^*_\Phi = \{a \in \ell^2(H^2_K) : a \text{ is a column vector with components in } \mathbf{C}^K\}.$$

(This follows from the fact that

$$\ell^2(H^2_K) \cong \bigoplus_{j=0}^{\infty} S^j_\Phi(\ker S^*_\Phi),$$

and that $W\Phi^*$ intertwines the shifts S_Φ and U.) Thus we need only to compute the action of W on

$$\Phi^* \ker S^*_\Phi = \left\{ F(z_1, \dots, z_n) \in H^2_K(D^n) : F(z_1, \dots, z_n) = \sum_{i_1,\dots,i_n \in I_n} F_{i_1,\dots,i_n} z_1^{i_1} \cdots z_n^{i_n} \right\}.$$

(See (11) for the definition of I_n.) By linearity,

$$W\left(\sum_{i_1,\dots,i_n \in I_n} F_{i_1,\dots,i_n} z_1^{i_1} \cdots z_n^{i_n} \right) = \sum_{i_1,\dots,i_n \in I_n} F_{i_1,\dots,i_n} W(z_1^{i_1} \cdots z_n^{i_n}).$$

So by (10) and (16) we have

$$W\Phi^* \cong [W_{0,\dots,0}(z), W_{0,\dots,1}(z), \dots, W_{i_1,\dots,i_n}(z), \dots], \tag{18}$$

where

$$W_{i_1,\dots,i_n}(z) = W(z_1^{i_1} \cdots z_n^{i_n}) \qquad (i_1, \dots, i_n) \in I_n. \tag{19}$$

The above discussion used only the time-invariance for W. In the next proposition, we will write down an explicit expression for the row vector of (18) and (19) associated with $W\Phi^*$ in case W is causal.

PROPOSITION 4.1. *Let $W : H^2_K(D^n) \to H^2_k$ be time-invariant. Then W is causal if and only if*

$$W_{i_1,\ldots,i_n}(z) = z^{\max\{i_1,\ldots,i_n\}} W^c_{i_1,\ldots,i_n}(z) \quad \forall (i_1, \ldots, i_n) \in I_n,$$

where $W^c_{i_1,\ldots,i_n}(z) \in H^\infty_{k\times K}$ (the space of $k \times K$ matrix-valued H^∞ functions).

Proof. By definition, for all $(i_1, \ldots, i_n) \in I_n$ with $\max\{i_1, \ldots, i_n\} = m$, and for all $v \in \mathbf{C}^k$, we have by the causality condition (4) that

$$(I - U^m U^{*m}) W\Phi^*(\Phi(z_1^{i_1} \cdots z_n^{i_n} v)) = (I - U^m U^{*m}) W_{i_1,\ldots,i_n}(z) v = 0.$$

Thus

$$W_{i_1,\ldots i_n}(z) = z^m W^c_{i_1,\ldots i_n}(z) = z^{\max\{i_1,\ldots,i_n\}} W^c_{i_1,\ldots i_n}(z) \quad \forall (i_1, \ldots, i_n) \in I_n, \tag{20}$$

for some $W^c_{i_1,\ldots i_n}(z) \in H^\infty_{k\times K}$, as required. □

By the above discussion (in particular, Proposition 4.1), we see that for W, Θ as in the (COP) problem (5), we have

$$\begin{aligned}
\sigma &= \inf\{\|W - \Theta Q\| : QS = UQ, Q \text{ causal, time-invariant}\} \\
&= \inf\{\|W\Phi^* - \Theta Q\Phi^*\| : (Q\Phi^*)S_\Phi = U(Q\Phi^*), Q \text{ causal, time-invariant}\} \\
&= \inf\{\|W_1 - \Theta Q_1\| : W_1, Q_1 : \ell^2(H^2_K) \to H^2_k,\ W_1 = W\Phi^*, \\
Q_1 &\cong [q_{0,\ldots,0}(z), zq_{0,\ldots,1}(z), \ldots, zq_{1,\ldots,1,0}(z), z^2 q_{0,\ldots,2}(z), \ldots]\}.
\end{aligned}$$

From now on (unless explicitly stated otherwise), we will just work with the operators $W_1, Q_1 : \ell^2(H^2_K) \to H^2_k$. Essentially, via the unitary equivalence Φ, we are identifying the spaces $H^2_K(D^n)$ and $\ell^2(H^2_K)$. In particular, we identify W with $W_1 = W\Phi^*$, and Q with $Q_1 = Q\Phi^*$. For simplicity of notation, we will denote

$$W = W_1, \qquad Q = Q_1.$$

The context should always make the meaning clear.

We now translate the notions of causality and time-invariance for an operator $W : \ell^2(H^2_K) \to H^2_k$. We will say that W is *time-invariant* if $WS_\Phi = UW$, that is,

$$W \cong [W_{0,\ldots,0}(z), W_{0,\ldots,1}(z), \ldots, W_{i_1,\ldots,i_n}(z), \ldots].$$

Moreover, we say that W is *causal* if the operator $W\Phi : H^2_K(D^n) \to H^2_k$ is causal, which means (see Proposition 4.1) that

$$W \cong [W^c_{0,\ldots,0}(z), zW^c_{0,\ldots,1}(z), \ldots, zW^c_{1,\ldots,1,0}(z), z^2 W^c_{0,\ldots,2}(z), \ldots],$$

for some

$$\{W^c_{i_1,\ldots,i_n}(z) \in H^\infty_{k\times K} : (i_1, \ldots, i_n) \in I_n\}.$$

Motivated by the above discussion, for $W : \ell^2(H^2_K) \to H^2_k$ time-invariant and causal, we introduce the operator

$$\begin{aligned}
W_c &\cong [W^c_{0,\ldots,0}(z), W^c_{0,\ldots,1}(z), \ldots, W^c_{1,\ldots,1,0}(z), W^c_{0,\ldots,2}(z), \ldots] \\
&= [W_{0,\ldots,0}(z), W_{0,\ldots,1}(z)/z, \ldots, W_{1,\ldots,1,0}(z)/z, W_{0,\ldots,2}(z)/z^2, \ldots].
\end{aligned} \tag{21}$$

We conclude this section by noting that to solve the (COP) problem (5), we can equivalently solve the following problem: Given $W : \ell^2(H^2_K) \to H^2_k$ time-invariant and causal as above, find

$$\sigma = \inf\{\|W - \Theta Q\| : QS_\Phi = UQ,\ Q \text{ causal}\}. \tag{22}$$

Thus we must solve the optimization problem (COP) on the Fourier transformed operators. This we will show how to explicitly do via a reduction theorem in the next section.

5. Reduction theorem. In this section, we formulate and prove our main result which will allow us to reduce the computation of a causal dilation to an ordinary one based on the classical commutant lifting theorem, i.e., interpolation in H^∞. In what follows $\mathcal{H}$, $\mathcal{K}$, $\mathcal{H}_i, i \geq 1$ will denote (complex, separable) Hilbert spaces.

To prove the result we will need two elementary lemmas.

LEMMA 5.1. *Let $A : \mathcal{K} \to \mathcal{H}$ be a bounded linear operator, and let T and S^* be isometries on $\mathcal{H}$ and $\mathcal{K}$, respectively. Then*

$$\|TAS\| = \|A\|.$$

Proof. By hypothesis, $T^*T = I$, and $SS^* = I$, and so

$$\begin{aligned}\|A\|^2 &= \|A^*A\| = \|A^*T^*TA\| \\ &= \|(TA)(TA)^*\| = \|TASS^*(TA)^*\| \\ &= \|(TAS)(TAS)^*\| = \|TAS\|^2,\end{aligned}$$

as required. □

LEMMA 5.2. *Let*

$$A = [A_1, A_2, \ldots] : \bigoplus_{i=1}^{\infty} \mathcal{H}_i \to \mathcal{H},$$

where

$$A(\oplus_{i=1}^\infty h_i) := \sum_{i=1}^{\infty} A_i h_i.$$

Further, let U_i^* be an isometry on $\mathcal{H}_i$ for $i \geq 1$. Then

$$\|A\| = \|[A_1, A_2, \ldots]\| = \|[A_1U_1, A_2U_2, \ldots]\|.$$

Proof. Note that

$$[A_1U_1, A_2U_2, \ldots, A_nU_n, \ldots] = [A_1, A_2, \ldots, A_n, \ldots] \begin{bmatrix} U_1 & 0 & 0 & \ldots & \ldots \\ 0 & U_2 & 0 & \ldots & \ldots \\ \vdots & \ddots & \ddots & \vdots & \vdots \\ 0 & \ldots & \ddots & U_n & \vdots \\ \vdots & \ldots & \ldots & \ddots & \ddots \end{bmatrix}.$$

However, if we set $S := \oplus_{i=1}^\infty U_i$, by hypothesis S^* is an isometry on $\oplus_{i=1}^\infty \mathcal{H}_i$, and so by Lemma 5.1, we are done. □

THEOREM 5.3 (Reduction theorem). *Notation as above. Then*

$$
\begin{aligned}
&(23)\quad \sigma = \inf\{\|W - \Theta Q\|\} : QS = UQ,\ Q\ \textit{causal}\}\\
&(24)\quad\ \ = \inf\{\|[W_{0,\dots,0}(z) - \Theta q_{0,\dots,0}(z), z(W_{0,\dots,1}(z) - \Theta q_{0,\dots,1}(z)), \dots]\| :\\
&\qquad\qquad [q_{0,\dots,0}(z), \dots, q_{i_1,\dots,i_n}(z), \dots] \in \mathcal{L}(\ell^2(H^2_K), H^2_k),\ (i_1, \dots, i_n) \in I_n\}\\
&(25)\quad\ \ = \inf\{\|W_c - \Theta Q\| : QS = UQ\}.
\end{aligned}
$$

(*Note in* (24) *the norm is the operator norm in* $\mathcal{L}(\ell^2(H^2_K), H^2_k)$. *In general, for Hilbert spaces* $\mathcal{H}$ *and* $\mathcal{K}$, $\mathcal{L}(\mathcal{H}, \mathcal{K})$ *denotes the space of bounded linear operators from* $\mathcal{H}$ *to* $\mathcal{K}$.)

Proof. The second equality (24) follows from Proposition 4.1. To prove the third equality (25), it is enough to prove that for any causal, time-invariant operator

$$\Omega \cong [\omega_{0,\dots,0}(z), \omega_{0,\dots,1}(z), \dots, \omega_{i_1,\dots,i_n}(z), \dots],$$

we have $\|\Omega\| = \|\Omega_c\|$. (See (21) above.)

Now since

$$
\begin{aligned}
\|\Omega\| &= \text{ess sup}\{\|[\omega_{0,\dots,0}(\zeta), \omega_{0,\dots,1}(\zeta), \dots, \omega_{i_1,\dots,i_n}(\zeta), \dots]\| : |\zeta| = 1\},\\
\|\Omega_c\| &= \text{ess sup}\{\|[\omega_{0,\dots,0}(\zeta), \omega^c_{0,\dots,1}(\zeta), \dots, \omega^c_{i_1,\dots,i_n}(\zeta), \dots]\| : |\zeta| = 1\},
\end{aligned}
$$

we need to prove that for any fixed $\zeta \in \partial D$ that

$$\|[\omega_{0,\dots,0}(\zeta), \omega_{0,\dots,1}(\zeta), \dots, \omega_{i_1,\dots,i_n}(\zeta), \dots]\| = \|[\omega_{0,\dots,0}(\zeta), \omega^c_{0,\dots,1}(\zeta), \dots, \omega^c_{i_1,\dots,i_n}(\zeta), \dots]\|.$$

However, by Proposition 4.1,

$$\omega_{i_1,\dots,i_n}(\zeta) = \omega^c_{i_1,\dots,i_n}(\zeta)\zeta^{\max\{i_1,\dots,i_n\}} I_{\mathbf{C}^K},$$

where $I_{\mathbf{C}^K}$ is the identity on $\mathbf{C}^K$. Hence by Lemma 5.2 with $\mathcal{H}_i := \mathbf{C}^K$ and $U_i := \zeta^{\max\{i_1,\dots,i_n\}} I_{\mathbf{C}^K}$ $(i \geq 1)$, we are done. □

6. Algorithm for computation of σ. We would like to summarize the above discussion with a high-level algorithm for the computation of the optimal causal performance σ, and corresponding causal optimal interpolant Q_{opt} in (5) and (6).

First, using the notation of Theorem 5.3, let us denote

$$(26)\qquad \sigma_o := \inf\{\|W_c - \Theta Q\| : QS = UQ\}.$$

(See equation (25).) Then Theorem 5.3 guarantees that

$$\sigma = \sigma_o.$$

This means that a causal optimization problem can be reduced to a classical generalized interpolation problem in H^∞.

We can summarize the procedure as follows:

(i) Let W, Θ be as in (5). (Thus $W : H^2_K(D^n) \to H^2_k$ here.) We compute $W(z_1^{i_1} \cdots z_n^{i_n})$ where $(i_1, \dots, i_n) \in I_n$. By (18) and (19), we get

$$W\Phi^* \cong [W_{0,\dots,0}(z), W_{0,\dots,1}(z), \dots, W_{i_1,\dots,i_n}(z), \dots],$$

and then by (20) we obtain the row matrix

$$[W_{0,\dots,0}(z), W^c_{0,\dots,1}(z), \dots, W^c_{i_1,\dots,i_n}(z), \dots].$$

(ii) The row matrix represents an operator (see (17)) $W_c : \ell^2(H^2_K) \to H^2_k$. Let $\Pi : H^2_k \to H^2_k \ominus \Theta H^2_k$ denote orthogonal projection. Using skew Toeplitz theory ([8], [17], [20]), we can compute the norm of the operator

$$\Lambda(W, \Theta) := \Pi W_c. \tag{27}$$

This norm is σ, the optimal causal performance.

(iii) Using the classical commutant lifting theorem and skew Toeplitz theory, we can compute the optimal dilation $B_c : \ell^2(H^2_K) \to H^2_k$ of $\Lambda(W, \Theta)$. Recall this means that

$$B_c S_\Phi = U B_c, \ \ \Pi B_c = \Lambda(W, \Theta), \ \ \|B_c\| = \|\Lambda(W, \Theta)\| = \sigma.$$

We can then write

$$B_c = W_c - \Theta Q_{opt,c}.$$

Then from (21), we can find the *optimal causal dilation*

$$B = W\Phi^* - \Theta Q_{opt}\Phi^*.$$

Note that B and B_c are related as in (21), and similarly for $Q_{\text{opt},c}$ and $Q_{\text{opt}}\Phi^*$. $Q_{\text{opt}} : H^2_K(D^n) \to H^2_k$ is the *optimal causal interpolant*, i.e.,

$$\sigma = \|W - \Theta Q_{\text{opt}}\|.$$

In the next section, we will give an explicit procedure for the computation of Q_{opt} in the SISO case.

7. Maximal vectors and optimal dilations. We use the notation of the previous section. We want to show how to compute the optimal dilation for

$$A := \Lambda(W, \Theta) : \ell^2(H^2) \to H^2.$$

(We are only considering SISO systems here.)

Our discussion will be based on [15], which generalizes a well-known result of Sarason [24]. We recall that a *maximal vector* of A, $h_o \neq 0$, is a vector such that $\|Ah_o\| = \|A\|\|h_o\|$.

Given $h \in \ell^2(H^2)$,

$$h = [h_1, h_2, \ldots]',$$

we write

$$h^* = [\bar{h}_1, \bar{h}_2, \ldots].$$

Moreover, we set

$$T := \Pi U | H^2 \ominus \Theta H^2,$$

where $\Pi : H^2 \to H^2 \ominus \Theta H^2$ denotes orthogonal projection. As above, U is the unilateral shift on H^2, and S_Φ denotes the shift on $\ell^2(H^2)$.

With this notation, we can now state the following result.

PROPOSITION 7.1. *Notation as above. Let $A : \ell^2(H^2) \to H^2 \ominus \Theta H^2$ be as above (so that $AU = TA$). Suppose moreover that that A has a maximal vector h_o. Let $B_c : \ell^2(H^2) \to H^2$ be the minimal intertwining dilation of A, i.e., $\Pi B_c = A$, $B_c U = S_\Phi B_c$, and $\|A\| = \|B_c\|$. Then if we let $\lambda := \|A\|^2$, we have that*

$$B_c = \frac{\lambda h_o^*}{A h_o}.$$

Proof. We sketch the proof following [15]. First, given $h_o \in H$, we represent h_o as a column vector with components h_j, $j \geq 1$ as above. Let

$$B_c \cong [b_1, b_2, \ldots].$$

Then we have that

$$(B_c h_o)(z) = \sum_{j \geq 1} b_j(z) h_j(z)$$

(for $z \in D$), and

$$\|B_c\| = \text{ess sup} \left\{ \left(\sum_{j=1}^{\infty} |b_j(\zeta)|^2 \right)^{1/2} : |\zeta| = 1 \right\}.$$

However,

$$\|A\|^2 \|h_o\|^2 = \|A h_o\|^2 \leq \|B_c h_o\|^2 \leq \|B_c\|^2 \|h_o\|^2 = \|A\|^2 \|h_o\|^2.$$

Thus $\|A h_o\|^2 = \|B_c h_o\|^2$, and since $\Pi B_c h_o = A h_o$, we have that $A h_o = B_c h_o$. Next note that

$$\sum_{j \geq 1} |b_j(e^{it})|^2 \leq \lambda$$

almost everywhere, and

$$\frac{1}{2\pi} \int_0^{2\pi} \left(\lambda \sum_{j=1}^{\infty} |h_j(e^{it})|^2 - |\sum_{j=1}^{\infty} b_j(e^{it}) h_j(e^{it})|^2 \right) dt = 0.$$

(This follows from the fact that $\lambda \|h_o\|^2 = \|B_c h_o\|^2$.) Using the Cauchy–Schwarz inequality, the expression under the integral sign is nonnegative. Thus

$$\begin{aligned} \lambda \sum_{j \geq 1} |h_j(e^{it})|^2 &= |\sum_{j \geq 1} b_j(e^{it}) h_j(e^{it})|^2 \\ &\leq \left(\sum_{j \geq 1} |b_j(e^{it})|^2 \right) \left(\sum_{j \geq 1} |h_j(e^{it})|^2 \right) \leq \lambda \sum_{j \geq 1} |h_j(e^{it})|^2 \end{aligned}$$

almost everywhere, which implies that

$$\sum_{j \geq 1} |b_j(e^{it})|^2 = \lambda$$

almost everywhere, and

$$h_j = \phi(e^{it})\overline{b_j(e^{it})}$$

almost everywhere for all $j \geq 1$, and for some function $\phi \in H^2$ satisfying

$$Ah_o = B_c h_o = \lambda\phi.$$

Thus for

$$B_c(e^{it}) \cong [b_1(e^{it}), b_2(e^{it}), \ldots]$$

we have

$$B_c(e^{it})\overline{Ah_o(e^{it})} = \lambda h_o(e^{it})^*$$

almost everywhere, as required. □

Remarks. (i) As remarked above, from the optimal dilation B_c, we can solve for $Q_{\mathrm{opt},c}$ via

$$B_c = W_c - \Theta Q_{\mathrm{opt},c}.$$

The optimal causal interpolant is then derived as described as in the last section.

(ii) In some cases it may be more convenient to derive the optimal dilation from a maximal vector of A^*. A similar proof to the one just given shows that

$$B_c = \frac{\overline{A^* h_1}}{\overline{h_1}}, \tag{28}$$

where $h_1 \in H^2 \ominus \Theta H^2$ is a maximal vector for A^*.

8. Nonlinear Control Problem. We will now describe the physical control problem in which we are interested. In our treatment that follows, we will add the causality constraint to the results of [15], and thereby derive a physically realizable nonlinear optimization procedure. First, we will need to consider the precise kind of input/output operator we will be considering. As above, H_k^2 denotes the standard Hardy space of $\mathbf{C}^k$-valued functions on the unit disc. We now make the following definition.

Then we say an analytic input/output operator $\phi : H_k^2 \to H_k^2$ is *admissible* if it is causal, time-invariant, majorizable, and $\phi(0) = 0$. We denote

$$\mathcal{C}_l := \{\text{space of admissible operators}\}.$$

Since the theory we are considering is local, the notion of admissibility is sufficient for all of the applications we have in mind.

We now begin to formulate our control problem. Referring to Fig. 1, P represents a physical plant that we assume is modeled by an admissible operator. In our problem, we are required to design a feedback compensator C in such a way as to attentuate the effect of the filtered disturbances (filtered by the "weight" W) d. The unfiltered disturbances v are assumed to have energy (i.e., 2-norm) bounded by some fixed constant. This leads to following kind of mathematical problem. See [14] and [15] for more details.

Let P, W denote admissible operators, with W invertible. Then we say that the feedback compensator C *stabilizes* the closed loop if the operators $(I + P \circ C)^{-1}$ and

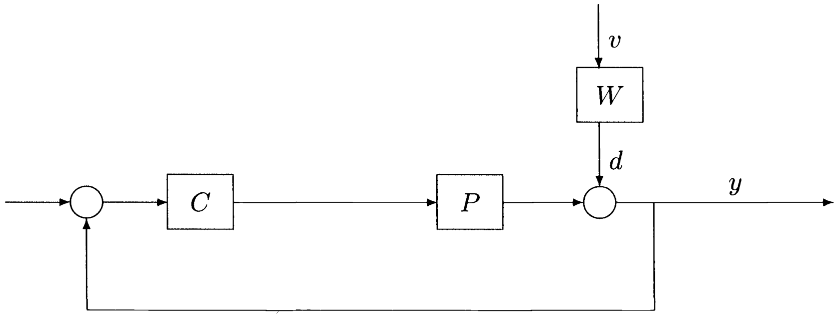

FIG. 1. *Standard feedback configuration.*

$C \circ (I + P \circ C)^{-1}$ are well defined and admissible. We can show that C stabilizes the closed loop if and only if

$$C = \hat{q} \circ (I - P \circ \hat{q})^{-1} \tag{29}$$

for some $\hat{q} \in \mathcal{C}_l$. (See [14], [15] and the references therein.) Note that the *weighted sensitivity* $(I + P \circ C)^{-1} \circ W$ can be written as $W - P \circ q$, where $q := \hat{q} \circ W$. This is precisely the operator relating the disturbance v to the output y. (Since W is invertible, the data q and $\hat{q}$ are equivalent.) In this context, we will call such a q, a *compensating parameter*. Note that from the compensating parameter q, we get a stabilizing compensator C via the formula (29).

As in [15], the problem we would like to solve here is a nonlinear version of the classical disturbance attenuation problem. This corresponds to the "minimization" of the "sensitivity" $W - P \circ q$ taken over all admissible q. To formulate a precise mathematical problem, we need to say in what sense we want to minimize $W - P \circ q$. This we will do in the next section, where we will propose a notion of "sensitivity minimization" which seems quite natural to analytic input/output operators. For the linear case of sensitivity minimization see [10], [18] and the references therein.

9. Nonlinear sensitivity function. This section follows very closely the set-up of [15]. However, now we explicitly put in the causality constraint.

We begin by defining a fundamental object, namely a nonlinear version of *sensitivity*. We should note that while the optimal H^∞ measure of performance is a real number in the linear case [18], the measure of performance that seems to be more natural in this nonlinear setting is a certain function defined in a real interval. This new kind of performance criterion is one of the keys concepts developed in [14] and [15]. See also §11 for a further analysis of the physical meaning of our nonlinear sensitivity function.

To define our notion of sensitivity, we will first have to partially order germs of analytic mappings. All of the input/output operators here will be admissible. We also follow here our convention that for given $\phi \in \mathcal{C}_l$, ϕ_n will denote the bounded linear map on the space $(H^2_k)^{\otimes n} \cong H^2_K(D^n)$ (with $K = k^n$) associated to the n-linear part of ϕ, which we also denote by ϕ_n (and which we always assume without loss of generality is symmetric in its arguments). The context will always make the meaning of ϕ_n clear.

We can now state the following definition.

DEFINITION 2. (i) *For $W, P, q \in \mathcal{C}_l$ (W is the weight, P the plant, and q the compensating parameter), we define the* sensitivity function $S(q)$,

$$S(q)(\rho) := \sum_{n=1} \rho^n \|(W - P \circ q)_n\|$$

for all $\rho > 0$ such that the sum converges. Note that for fixed P and W, for each $q \in \mathcal{C}_l$, we get an associated sensitivity function.

(ii) *We write $S(q) \preceq S(\tilde{q})$, if there exists a $\rho_o > 0$ such that $S(q)(\rho) \leq S(\tilde{q})(\rho)$ for all $\rho \in [0, \rho_o]$. If $S(q) \preceq S(\tilde{q})$ and $S(\tilde{q}) \preceq S(q)$, we write $S(q) \cong S(\tilde{q})$. This means that $S(q)(\rho) = S(\tilde{q})(\rho)$ for all $\rho > 0$ sufficiently small, i.e., $S(q)$ and $S(\tilde{q})$ are equal as germs of functions.*

(iii) *If $S(q) \preceq S(\tilde{q})$, but $S(\tilde{q}) \not\preceq S(q)$, we will say that q* ameliorates $\tilde{q}$. *Note that this means $S(q)(\rho) < S(\tilde{q})(\rho)$ for all $\rho > 0$ sufficiently small.*

Now with Definition 2, we can define a notion of "optimality" relative to the sensitivity function.

DEFINITION 3. (i) *$q_o \in \mathcal{C}_l$ is called* optimal *if $S(q_o) \preceq S(q)$ for all $q \in \mathcal{C}_l$.*

(ii) *We say $q \in \mathcal{C}_l$ is* optimal with respect to its nth term q_n, *if for every n-linear $\hat{q}_n \in \mathcal{C}_l$, we have*

$$S(q_1 + \cdots + q_{n-1} + q_n + q_{n+1} \ldots) \preceq S(q_1 + \cdots + q_{n-1} + \hat{q}_n + q_{n+1} + \cdots).$$

If $q \in \mathcal{C}_l$ is optimal with respect to all of its terms, then we say that it is partially optimal.

10. Iterative causal commutant lifting method. In this section, we discuss a construction from which we will derive both partially optimal and optimal compensators relative to the sensitivity function given in Definition 2 above. As before, P will denote the plant, and W the weighting operator, both of which we assume are admissible. We always suppose that P_1 (the linear part of P) is an isometry, i.e., P_1 is a $k \times k$ inner matrix-valued H^∞ function. (P_1 corresponds to Θ of §6.)

We begin by noting the following key relationship:

$$(W - P \circ q)_l = W_l - \sum_{1 \leq j \leq l} \sum_{i_1 + \cdots + i_j = l} P_j(q_{i_1} \otimes \cdots \otimes q_{i_j}) \quad \forall l \geq 1.$$

Note that once again for ϕ admissible, ϕ_n denotes the n-linear part of ϕ, as well as the associated linear operator on $H^2_K(D^n)$.

We are now ready to formulate the *iterative causal commutant lifting procedure.* Let $\Pi : H^2_k \to H^2_k \ominus P_1 H^2_k$ denote orthogonal projection. Using the above (see (27)) we may choose q_1 causal such that

$$\|W_1 - P_1 q_1\| = \|\Lambda(W_1, P_1)\|.$$

Now given this q_1, we choose a causal q_2 such that

$$\|W_2 - P_2(q_1 \otimes q_1) - P_1 q_2\| = \|\Lambda(W_2 - P_2(q_1 \otimes q_1)), P_1)\|.$$

Inductively, given $q_1, \ldots, q_{n-1}$, set

$$\hat{W}_n := \left(W_n - \sum_{2 \leq j \leq n} \sum_{i_1 + \cdots + i_j = n} P_j(q_{i_1} \otimes \cdots \otimes q_{i_j}) \right) \tag{30}$$

for $n \geq 2$. Then we may choose q_n such that

$$\|\hat{W}_n - P_1 q_n\| = \|\Lambda(\hat{W}_n, P_1)\|. \tag{31}$$

Note that in each step of the procedure, the new "weight" $\hat{W}_n$ is determined by the n-linear part W_n of the original weight, and the optimal causal parameters chosen previously (namely, $q_1, \ldots, q_{n-1}$). The "plant" P_1 remains fixed throughout the procedure. Thus if P_1 is rational, the iterative causal commutant lifting procedure takes place on the finite dimensional space $H_k^2 \ominus P_1 H_k^2$, and may therefore be reduced to *finite matrix computations*. This will be illustrated with an example in §13.

The following facts can be proven just as in [14] and [15], to which we refer the reader for the proofs. (See in particular [15, pp. 849–853].) First the causal iterative commutant lifting procedure converges:

PROPOSITION 10.1. *With the above notation, let $q^{(1)} := q_1 + q_2 + \cdots$. Then $q^{(1)} \in \mathcal{C}_l$.*

Next given any $q \in \mathcal{C}_l$, we can apply the causal iterative commutant lifting procedure to $W - P \circ q$. Now set

$$S_C(q)(\rho) := \sum_{n=1} \rho^n \|\Lambda(\hat{W}_n, P_1)\|.$$

Then we have the following result.

PROPOSITION 10.2. *Given $q \in \mathcal{C}_l$, there exists $\tilde{q} \in \mathcal{C}_l$, such that $S(\tilde{q}) \equiv S_C(q)$. Moreover $\tilde{q}$ may be derived from the causal iterated commutant lifting procedure.*

Moreover, as in [15] we have the following results.

PROPOSITION 10.3. *q is partially optimal if and only if $S(q) \cong S_C(q)$.*

THEOREM 10.4. *For given P and W as above, any $q \in \mathcal{C}_l$ is either partially optimal or can be ameliorated by a partially optimal compensating parameter.*

Finally we have the following result.

THEOREM 10.5. *Let P and W be single-input/single-output admissible operators. If the linear part of P is rational, then the partially optimal compensating parameter q_{opt} constructed by the iterated causal commutant lifting procedure is optimal.*

The proof of this last result is based on the uniqueness of the optimal interpolant in the case when $k = 1$, and when the space $H^2 \ominus P_1 H^2$ is finite-dimensional. In fact, the conclusion of Theorem 10.5 remains valid under the hypotheses that the operators ΠW_j, $j \geq 1$ and ΠP_i, $i \geq 2$ are compact (and $k = 1$). See [15].

11. Control interpretation of iterated lifting. We would like to mention here what we believe to be a very natural way of looking at the optimization procedure discussed above. For convenience, we will only treat SISO systems here.

We refer again to Fig. 1. We consider the problem of finding

$$\mu_\delta := \inf_C \sup_{\|v\| \leq \delta} \|[(I + P \circ C)^{-1} \circ W]v\|, \tag{32}$$

where we assume all the operators involved are admissible. Thus we are looking at a worst case disturbance attenuation problem where the energy of the signals v is required to be bounded by some prespecified level δ. (Of course in the linear case since everything scales, we can always without loss of generality take $\delta = 1$. For nonlinear systems, we must specify the energy bound a priori.) Again with the assumptions made in §8, we see that (32) is equivalent to the problem of finding

$$\mu_\delta = \inf_{q \in \mathcal{C}_l} \sup_{\|v\| \leq \delta} \|(W - P \circ q)v\|. \tag{33}$$

The iterated causal commutant lifting procedure gives an approach for approximating a solution to such a problem. Briefly, the idea is that we write

$$\begin{aligned} W &= W_1 + W_2 + \cdots, \\ P &= P_1 + P_2 + \cdots, \\ q &= q_1 + q_2 + \cdots, \end{aligned}$$

where W_j, P_j, q_j are homogeneous polynomials of degree j. Note that

$$\mu_\delta = \delta \inf_{q_1 \in H^\infty} \|W_1 - P_1 q_1\| + O(\delta^2), \tag{34}$$

where the latter norm is the operator norm (i.e., H^∞ norm). From the classical commutant lifting theorem we can find an optimal (linear, causal, time-invariant) $q_{1,\mathrm{opt}} \in H^\infty$ such that

$$\mu_\delta = \delta \|W_1 - P_1 q_{1,\mathrm{opt}}\| + O(\delta^2). \tag{35}$$

Now the iterative procedure gives a way of giving higher-order corrections to this linearization. Let us illustrate this now with the second-order correction. Indeed, having fixed now the linear part $q_{1,\mathrm{opt}}$ of q in (33), we note that

$$\begin{aligned} &W(v) - P(q(v)) - (W_1 - P_1 q_{1,\mathrm{opt}})(v) \\ &\quad = W_2(v) - P_2(q_{1,\mathrm{opt}}(v)) - P_1 q_2(v) + \text{higher-order terms.} \end{aligned}$$

Regarding $\hat{W}_2, P_2, q_2$ as linear operators on $H^2 \otimes H^2 \cong H^2(D^2, \mathbf{C})$ as above, we see that

$$\sup_{\|v\| \le \delta} \|(W - P \circ q)(v) - (W_1 - P_1 q_{1,\mathrm{opt}})v\| \le \delta^2 \|\hat{W}_2 - P_1 q_2\| + O(\delta^3),$$

where the "weight" $\hat{W}_2$ is given as in (30). The point of the iterative causal commutant lifting procedure is now to pick an optimal admissible $q_{2,\mathrm{opt}}$, and so on.

In short, instead of simply designing a linear compensator for a linearization of the given nonlinear system, this methodology allows us to explicitly take into account the higher-order terms of the nonlinear plant, and therefore increase the ball of operation for the nonlinear controller.

12. Rationality. A nice feature of the iterated procedure described above is that if we start out with rational data, then we derive compensating parameters at each step that are also rational. Thus the whole procedure is amenable to digitable implementation in such cases. Let us briefly review the notion of rationality in this context. See [14] for all the details.

Let $W : H^2_K(D^n) \to H^2_k$ be time-invariant and admit the row vector representation

$$W\Phi^* \cong [W_{0,\ldots,0}(z), W_{0,\ldots,1}(z), \ldots, W_{i_1,\ldots,i_n}(z), \ldots], \; (i_1, \ldots, i_n) \in I_n.$$

Then we say that W is *rational* if there exists a numerical polynomial $q(z) \neq 0$ such that

$$q(z)[W_{0,\ldots,0}(z), W_{0,\ldots,1}(z), \ldots, W_{i_1,\ldots,i_n}(z), \ldots]$$

is a row of matrix-valued polynomials of bounded degree. Moreover if W is causal, we say that W is *causal rational* if

$$W_c \cong [W_{0,\dots,0}(z), W^c_{0,\dots,1}(z), \dots, W^c_{i_1,\dots,i_n}(z), \dots]$$

is rational in the above sense.

The following result may be derived exactly as in [15, (see Thm. 8.7)].

THEOREM 12.1. *Notation as above. Suppose that the linear part of the plant is rational. Then the class of causal rational input/output operators is preserved under the causal iterated commutant lifting procedure.*

Hence for this important class of systems, we are reduced to rational finite-dimensional operations in carrying out our optimization procedure.

13. Example. In this section, we will give an example of our nonlinear design procedure. In what follows below, we set $H_{D^2} := H^2(D^2)$, the space of $\mathbf{C}$-valued analytic functions on the bidisc D^2 with square integrable boundary values. We should note that this example was first worked in [15] without the causality constraint that we impose now.

We let

$$W(z) = \frac{1-z}{2}$$

and $P = P_1 + P_2$ where P_1 is the operator given by multipication by z^2 (in the discrete Fourier domain), and

$$P_2(F) = \frac{1}{2\pi i}\int_{|\zeta|=1} F(z\zeta^{-1}, \zeta)\frac{d\zeta}{\zeta}$$

for $F \in H_{D^2} \cong H^2 \otimes H^2$. More precisely, as we explained above, we can regard a bilinear map P_2 on $H^2 \times H^2$ as a linear map on $H^2 \otimes H^2$, and then we identify $H^2 \otimes H^2$ with H_{D^2}. (The identification is given by $z \otimes 1 \to z_1$ and $1 \otimes z \to z_2$.) Notice that in the discrete-time domain, P_2 is just discrete Fourier transform of the "squaring" map, i.e., given the square integrable sequence $\{a_n\}$, we have that P_2 is the Fourier transform of the mapping $\{a_n\} \to \{a_n^2\}$. Thus it is clear that P_2 is causal.

We now apply our procedure to the weight W and the plant P. By slight abuse of notation, we let $W : H^2 \to H^2$ denote the operator defined by multiplication by W, and let $\Pi : H^2 \to H^2 \ominus P_1 H^2 =: H_1$ be orthogonal projection. We set $A_o := \Pi W | H_1$. Note that $H_1 \cong \mathbf{C}^2$, and that via this isomorphism, we have the identification

$$A_o = \begin{bmatrix} \frac{1}{2} & 0 \\ -\frac{1}{2} & \frac{1}{2} \end{bmatrix}.$$

However,

$$A_o^* A_o = \begin{bmatrix} \frac{1}{2} & -\frac{1}{4} \\ -\frac{1}{4} & \frac{1}{4} \end{bmatrix},$$

from which we get that $\|A_o\| = (\sqrt{5}+1)/2$, and that a maximal vector h_o (i.e., a vector such that $\|A_o h_o\| = \|A_o\|\|h_o\| \neq 0$) is given by

$$h_o := \begin{bmatrix} 1 \\ -\beta \end{bmatrix},$$

where $\beta := (\sqrt{5}-1)/2$. Using then the Sarason formula [24], we can compute that the optimal compensating parameter is

$$q_1 := \frac{\beta}{2(1-\beta z)}.$$

Of course, the above computation was based on standard linear H^∞-optimization theory. We now want to show how to get the optimal *causal* second-order compensating parameter.

For $F \in H_{D^2}$, let

$$F(z_1, z_2) = \sum_{j,k=0}^{\infty} F_{jk} z_1^j z_2^k.$$

Note that the action of the operator (see (30))

$$-\hat{W}_2 := \frac{4}{\beta^2} P_2(q_1 \otimes q_1)$$

on F is determined by its action on

$$F_{00} + \sum_{j=1}^{\infty} F_{j0} z_1^j + \sum_{k=1}^{\infty} F_{0k} z_2^k.$$

Thus to compute the row vector representing $-\hat{W}_2$, we need only compute

$$\begin{aligned}
&(-\hat{W}_2)(F_{00} + \sum_{j=1}^{\infty} F_{j0} z_1^j + \sum_{k=1}^{\infty} F_{0k} z_2^k) \\
&= \frac{1}{2\pi} \int_{|\zeta|=1} (\sum_{m\geq 0} \beta^m z^m \zeta^{-m})(\sum_{n\geq 0} \beta^n \zeta^n)(\sum_{\min\{j,k\}=0} F_{jk} z^j \zeta^{k-j}) \frac{d\zeta}{\zeta} \\
&= \sum_{\min\{j,k\}=0} (F_{jk}(\beta z)^{\max\{j,k\}})/(1-\beta^2 z).
\end{aligned}$$

We identify as above an operator $\Omega : H_K^2(D^n) \to H_k^2$ and its Fourier transformed version $\Omega\Phi^* : \ell^2(H_K^2) \to H_k^2$.

Therefore (under this identification),

$$\begin{aligned}
-\hat{W}_2 &\cong \frac{1}{1-\beta^2 z}[1, \beta z, \beta z, \beta^2 z^2, \ldots, \beta^n z^n, \ldots], \\
-\hat{W}_{2,c} &\cong \frac{1}{1-\beta^2 z}[1, \beta, \beta, \beta^2, \ldots, \beta^n, \ldots],
\end{aligned}$$

and

$$\|\hat{W}_2\| = \|\hat{W}_{2,c}\| \approx 2.4195.$$

Set $A = \Pi(-\hat{W}_{2,c})$, where $\Pi : H^2 \to H^2 \ominus z^2 H^2 =: H(z^2) \cong \mathbf{C}^2$ denotes orthogonal projection. Note that the compressed shift T on $H(z^2) \cong \mathbf{C}^2$ is given by the truncated Toeplitz operator

$$T = \begin{bmatrix} 0 & 0 \\ 1 & 0 \end{bmatrix}.$$

Using skew Toeplitz theory ([8], [17], [20]), we compute the norm of A and the corresponding optimal vector. Accordingly, we let $r(z) := 1 - \beta^2 z$. Then for $\rho > 0$, and for

$$\lambda := \frac{2-\beta}{(2\beta - 1)\rho^2},$$

we compute that

$$\begin{aligned} r(T)(\rho^2 I_{\mathbf{C}^2} - AA^*)r(T)^* &= \rho^2 r(T)r(T)^* - (1 + 2\sum_{i=1}^{\infty} \beta^{2i}) I_{\mathbf{C}^2} \\ &= (1-\beta)\rho^2 \begin{bmatrix} 1 + 1/\beta - \lambda & -1 \\ -1 & 3 - \lambda \end{bmatrix}. \end{aligned}$$

$\|A\|$ is given by the largest ρ such that the latter matrix is singular. Thus we see that

$$\|\Pi(-\hat{W}_{2,c})\| = \|A\| \approx 1.8079,$$

which is the optimal *causal* performance. If we drop the causality requirement, then we get that

$$\|\Pi(-\hat{W}_2)\| \approx 1.4314.$$

(Of course, with the additional constraint the norm of the optimal dilation increases.)

Let

$$y_o(z) := 1 + \left(1 + \frac{1}{\beta} - \lambda\right) z \in H(z^2),$$

so that we may regard

$$y_o = \begin{bmatrix} 1 \\ 1 + \frac{1}{\beta} - \lambda \end{bmatrix}$$

under the identification $H(z^2) \cong \mathbf{C}^2$. Then it is easy to compute that

$$r(T)(\|A\|^2 I_{\mathbf{C}^2} - AA^*)r(T)^* y_o = 0.$$

Therefore $r(T)^* y_o$ is a maximal vector of A^*. But from the previous section (see (28)), the optimal dilation $B_{\text{opt},c}$ of A is

$$\begin{aligned} B_{\text{opt},c} &\cong \frac{\overline{A^* r(T)^* y_o}}{\overline{r(T)^* y_o}} \\ &= \frac{(3-\lambda)z + 1}{(1 + \frac{1}{\beta} - \lambda)z + 1} [1, \beta, \beta, \beta^2, \beta^2, \ldots]. \end{aligned}$$

Thus the optimal *causal* dilation B_{opt} of $\Pi(-\hat{W}_2)$ is

$$B_{\text{opt}} \cong \frac{(3-\lambda)z + 1}{(1 + \frac{1}{\beta} - \lambda)z + 1} [1, \beta z, \beta z, \beta^2 z^2, \ldots].$$

The optimal causal interpolant q_2 is derived from

$$-\frac{4}{\beta^2} P_2(q_1 \otimes q_1) - z^2 q_2 = -B_{opt},$$

which gives that

$$q_2 \cong \frac{(\lambda - 3)\beta^2}{(1-\beta^2 z)((1+1/\beta-\lambda)z+1)}[1, \beta z, \beta z, \beta^2 z^2, \ldots].$$

Now set $q^{(2)} := q_1 + q_2$, the optimal second-order compensating parameter, and $\hat{q}^{(2)} := q^{(2)}W^{-1}$. The resulting controller is given by $C^{(2)} = \hat{q}^{(2)} \circ (I - P \circ \hat{q}^{(2)})^{-1}$. Note that it is not necessary to explicitly compute $C^{(2)}$, since it can be implemented in a feedback loop with components P and $\hat{q}^{(2)}$ as in [27].

14. Concluding remarks. In this paper, we have given an iterative approach for the construction of optimal causal compensators for input/output operators described by analytic mappings. Our procedure generalizes weighted sensitivity H^∞ minimization in a straightforward natural way. Hence, it may be regarded as a weighted nonlinear inversion procedure.

In contrast to our previous work using power series approaches ([3], [4], [14], [15]), we can now *guarantee causality* a priori. Moreover, the computation of a causal compensator can be reduced to classical dilation theory, and in fact the skew Toeplitz techniques of [8], [17], and [20] provide an explicit computational methodology.

The example which we have worked out here, has been given just for the purpose of illustrating our procedure. We plan to work out a more complicated and realistic problem, the details of which will be given in an upcoming report.

MODEL UNCERTAINTY IN DISCRETE EVENT SYSTEMS*

STANLEY YOUNG[†] AND VIJAY K. GARG[‡]

Abstract. Earlier work concerning control of discrete event systems usually assumed that a correct model of the system to be controlled was available. A goal of this work is to provide an algorithm for determining the correct model from a set of models. The result of the algorithm is a finite language that can be used to test for the correct model or notification that the remaining models cannot be controllably distinguished. We use the finite state machine model with controllable and uncontrollable events presented by Ramadge and Wonham.

Key words. discrete event systems, system identification

AMS subject classifications. 93A, 93B

1. Introduction.

A discrete event system (DES) is one that responds to distinct events occurring at asynchronous times [7]. Examples of such systems include computer networks, manufacturing systems, and other dynamic systems that require high-level coordinated control. There has been some success recently in developing a theory for the control of such systems (see [13] and the references therein). Most of this work has assumed that an accurate model for the system of interest is available.

The motivation for this work is the desire to control systems in the presence of uncertainty in the model of the system and environment in which the system operates. Part of this work is an extension of learning and inference theory [6], [2], [16] to the domain of discrete event systems. This work is also related to recent results concerning the determination of a system model when certain assumptions are made about the model and type of experiments [14], [15]. In both the learning theory and system determination work, an assumption is that all events are controllable. The uncontrollability of certain events figures prominently in this work. The approach taken in this paper is similar to the approach used for system identification in [17] in that any model that is falsified is dropped from consideration as a correct model.

There are many different types of uncertainty that might occur in a system model. To discuss such uncertainties, a model representation must be chosen. In this work, we investigate uncertainty in a deterministic finite state machine. An example of such uncertainty is an uncertainty in the transitions of a system that can be described as a state that has a single event specified as providing transitions to at least two different resulting states; however, only one of the transitions is actually present in the system. Other examples are discussed in §3. Such uncertainty results in multiple models of the system that might potentially be correct. The goal is to specify conditions and algorithms that enable the identification of the correct model in a finite number of transitions despite the presence of uncontrollable actions. In particular, an algorithm provides either notification that no more models may be controllably distinguished or a finite distinguishing language that can be used to remove an incorrect model.

Section 2 describes the method used to model the plant and the relevant controllability results. Section 3 gives some examples of how a set of potentially correct models for a system might arise. Section 4 describes the concepts and techniques used to identify a correct model from a given set of models. Section 5 provides example applications of the results.

2. Description of the model.

We use the deterministic finite state machine as a model for system behavior. In what follows, only the main features of the finite state machine model related to this work are covered in a condensed manner. A more complete development related to the finite state machine model can be found in [5], [9]. More complete descriptions of the controllability and related results can be found in [13], [3], [11].

2.1. Finite state machines and regular languages.

A finite state machine is represented by either a four or five tuple. Specifically, if M is a finite state machine (FSM), then we write $M = (Q, A, \delta, q_0)$ or $M = (Q, A, \delta, q_0, Q_m)$, where

$$\begin{array}{lcl} Q & = & \text{a finite set of states,} \\ A & = & \text{a finite set of transition labels or events,} \\ \delta & = & \text{the transition function, } \delta : Q \times A \to Q, \\ q_0 & = & \text{the initial state, } q_0 \in Q, \text{ and} \\ Q_m & = & \text{the marked states, } Q_m \subseteq Q. \end{array}$$

The transition function δ is, in general, a partial function: $\delta(q, \sigma)!$ denotes that the transition event σ is defined from state q. The marked states signify a subset of the state set that is used to determine acceptance of a given string. A string is *accepted* if the machine executing the string stops in a marked state.

A finite state machine, $P = (Q, A, \delta, q_0, Q_m)$, can also be represented as a directed graph $M = (Q, T)$, where Q and T are the sets of nodes and arcs, respectively, or states and transitions in this instance [1], [4]. Q is the set of states in the machine and $T \subseteq Q \times A \times Q$ is the set of transitions. If $q_1, q_2 \in Q$ and $\delta(q_1, \sigma) = q_2$, then one denotes the transition by the three tuple (q_1, σ, q_2).

A^* is used to denote the set of all finite sequences of symbols from the alphabet A. A language is a set of strings of elements from an alphabet. If $u \in A^*$, then $|u|$ denotes the length of u, $u(j)$ denotes the jth element of the string, and the set $pr(u)$ denotes the set of all strings that are prefixes of u, i.e. for $u \in A^*$

$$pr(u) = \{s \in A^* | s = u(1) \dots u(k), 0 < k \leq |u|\}.$$

The notation $s \leq u$ is used to denote that s is a prefix of u. Note that the empty string ε is the length zero prefix of all strings. The concept of prefix can be extended to a language in the following manner. The *prefix closure* of a language L is defined by

$$\overline{L} = \{w \in A^* | \exists u \in L : w \leq u\}.$$

We use the notation $s \in ppr(u)$ or $s < u$ to signify that s is a proper prefix of u, i.e., that $s \leq u$ and $s \neq u$. This concept is extended to a language, $L \subseteq A^*$, in the following manner:

$$ppr(L) = \{s \in A^* | \exists u \in L : s < u\}.$$

For this work, we restrict our attention to the class of regular languages that is a strict subset of the class of formal languages. A basic result relates regular languages and finite state machines: a language $L \subseteq A^*$ is regular if and only if it is generated by a finite state machine [9]. Language $L_m(M)$ is the language *marked* or *recognized* by machine $M = (Q, A, \delta, q_0, Q_m)$ if

$$w \in L_m(M) \Leftrightarrow \delta(q_0, w) \in Q_m,$$

where δ is extended in the usual manner, $\delta : Q \times A^* \longrightarrow Q$. A language $L(M)$ is the language *generated* by machine M if

$$w \in L(M) \Leftrightarrow \delta(q_0, w)!.$$

The product machine is a single machine that can be used to represent the synchronous behavior of two original machines. If machines $M_1 = (Q_1, A, \delta_1, q_{1,0}, Q_{1,m})$ and $M_2 = (Q_2, A, \delta_2, q_{2,0}, Q_{2,m})$ have the same event set A then the product of the two machines is denoted

$$M_1 \| M_2 = (Z, A, \delta_{\|}, z_0, Z_m),$$

where

$$Z = Q_1 \times Q_2 \text{ and } z_0 = (q_{1,0}, q_{2,0}),$$

$$\delta_{\|}((q_1, q_2), \sigma) = \begin{cases} (\delta_1(q_1, \sigma), \delta_2(q_2, \sigma)) & \text{if defined} \\ \text{undefined} & \text{otherwise,} \end{cases}$$

and

$$Z_m = Q_{1,m} \times Q_{2,m}.$$

The languages generated and marked by the product machine have a specific relation to the languages of the machines from which they are composed. If $M_{\|} = M_1 \| M_2$ then

$$L(M_{\|}) = L(M_1) \cap L(M_2) \quad \text{and} \quad L_m(M_{\|}) = L_m(M_1) \cap L_m(M_2).$$

2.2. Control of discrete event systems. The event set A can be partitioned into two sets A_c and A_u, representing controllable and uncontrollable events, respectively. A language K is *controllable* with respect to language L if

$$\overline{K}.A_u \cap L \subseteq \overline{K},$$

where $a.b$ denotes concatenation and is often denoted by ab. A supervisor for a plant, modeled with finite state machine P, where $L = L(P)$, is a map

$$f : L \rightarrow 2^A,$$

which specifies a set of inputs enabled by the supervisor that can be applied as a function of the string in L of events that the plant has previously executed. The closed-loop system consisting of a supervisor f and plant P has the closed-loop behavior denoted by L_f, and is defined as follows.

1. $\varepsilon \in L_f$,
2. $w\sigma \in L_f$ if and only if $w \in L_f, \sigma \in f(w)$, and $w\sigma \in \overline{L}$.

A supervisor f is *complete* with respect to a given plant P, with $L = L(P)$, if all uncontrolled actions of the plant are respected, i.e., if $x \in L_f$ and $x\sigma_u \in L$, then $x\sigma_u \in L_f$, where $\sigma_u \in A_u$ and L_f is the closed-loop behavior as discussed above. The following result is a basic theorem relating these concepts.

THEOREM 2.1 ([12]). *For nonempty $K \subseteq L$, there exists a complete supervisor f such that $L_f = K$ if and only if K is prefix closed and controllable.*

The region of weak attraction, as discussed in [3], [11], can be directly related to distinguishing different machines. The region of weak attraction for a specified set of states can be described informally as the set of states from which the system can be controlled so as to enter the set of specified states in a finite number of transitions.

The *region of weak attraction* $\Omega_M(G)$ for a machine $M = (Q, A, \delta, q_0)$, or in graph notation, $M = (Q, T)$, and a specified subset of states $G \subseteq Q$ can be determined by the algorithm in [3]. For a specific calculation of the region of weak attraction of a given set of states G, the transitions used in its construction are denoted by $T_\Omega(G)$. This algorithm builds the region of weak attraction starting from G. Each iteration of the algorithm adds states to the region defined in the previous iteration. A state is added to the region of weak attraction only if there is an event σ that describes a transition into the region defined in the previous iteration and there does not exist an uncontrolled event to a state not in the region defined by the previous iterations of the algorithm. The transition labeled by this σ is added to $T_\Omega(G)$ as are the uncontrolled transitions from this state. The states in $\Omega_M(G)$ are well defined; as discussed in [3], the transitions chosen for $T_\Omega(G)$ are not necessarily uniquely defined. The algorithm is guaranteed to terminate by the finite state description of the machine. An efficient algorithm in [11] computes the region of weak attraction in $O(|Q| \cdot |A|)$ time.

The characteristics of the region of weak attraction are most easily described by certain conditions on the directed graph that describes the finite state machine. Let the machine be described by the graph $M = (Q, T)$ with $G \subseteq Q$. The region of weak attraction satisfies three main criteria as described in the following proposition.

PROPOSITION 2.2 ([3]). *$M' = (\Omega_M(G), T_\Omega(G)) \subseteq (Q, T)$ if and only if*

(1) *M' is G-connected,*

(2) *M' is realizable,*

(3) *$M' - G$ is acyclic.*

A graph $M = (Q, T)$ is *F-connected* if $F \subseteq Q$ and from every state in Q there exists a path to a state in F. A subgraph $M' = (Q', T') \subseteq (Q, T)$ is *realizable* if

$$(((q_1, \sigma, q_2) \in T) \wedge (q_1 \in Q') \wedge (\sigma \in A_u)) \Rightarrow ((q_1, \sigma, q_2) \in T').$$

A realizable subgraph includes all uncontrollable arcs that are defined from any state in the state set of the subgraph.

If the initial state q_0 for the machine M is in the region of weak attraction, i.e., $q_0 \in \Omega_M(G)$, then we also define a machine based on the region of weak attraction $M_\Omega(G)$, where $M_\Omega(G)$ is formally defined by the tuple:

$$M_\Omega(G) = (Q, A, \delta_\Omega, q_0, G).$$

And $\delta_\Omega(q_1, \sigma) = q_2$ if and only if (q_1, σ, q_2) is an arc defined in the construction of the region of weak attraction, i.e., $(q_1, \sigma, q_2) \in T_\Omega(G)$. With M_Ω defined, the language recognized by the resulting machine is denoted by $L(M_\Omega(G))$. As mentioned above and in [3], $M_\Omega(G)$, and hence $L(M_\Omega(G))$, is not unique.

3. Model uncertainty. Uncertainties in the plant model provide a set of models that are potentially correct models of the plant. Each model in this set is obtained by assuming that the uncertainty results from a specific lack of knowledge about the structure of the plant.

Example 3.1. Consider an automatic guided vehicle system guided by wires in the floor of a manufacturing facility. The model of the guidance system may contain errors. Each error will produce an uncertain model of the correct system. For instance, two branch nodes in the wiring may be combined into a single node in the model, an extra branch may be in the model that is not installed in the plant, or the model may be lacking a branch that is installed in the plant. Each of these errors generates an uncertain model that can be used to define a set of potentially correct models.

Example 3.2. Model (A) in Fig. 1 gives an example of a system with uncertainty in the transitions. For this transition uncertainty, there is a single state q_0 in the model that has "b" transitions defined to k different states, $q_1, \ldots, q_k$; yet, in the actual system, only one of these "b" transitions is defined.

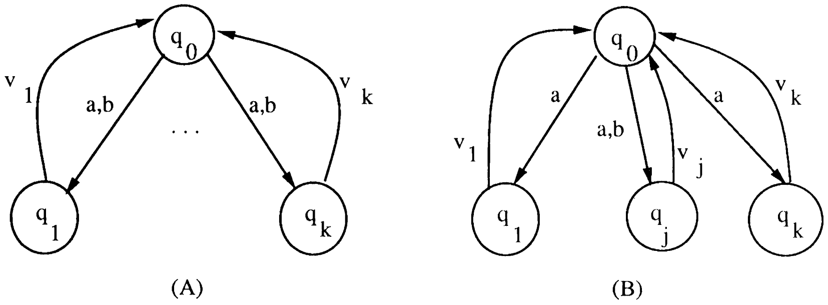

FIG. 1. *Model for transition uncertainty.* (A) *Model with transition uncertainty.* (B) *One of the possibly correct models.*

Example 3.3. Assume that the set of events that a system can accomplish is known and that there is a known upper bound on the size of the state space. Using these two assumptions, we can construct all possible models for the system. After all unique models have been constructed, a technique is required to generate tests that can distinguish the correct model.

4. Distinguishing between models. We present deterministic techniques that provide an easily checked condition and an algorithm for correctly removing inconsistent models from consideration and identifying the correct model.

Certain concepts will provide a unified framework for the development that follows. For the following definitions, we assume that there are models $M = (Q, A, \delta, q_0)$, $M_1 = (Q_1, A, \delta_1, q_{1,0})$, and $M_2 = (Q_2, A, \delta_2, q_{2,0})$ that have states $q_1 \in Q_1$, $q_2 \in Q_2$ and an event $\sigma \in A$.

DEFINITION 4.1. *Given M_1 and M_2, the predicate* different(z, w) *holds if*

$$(\delta_1(q_1, w)! \wedge \neg\delta_2(q_2, w)!) \vee (\neg\delta_1(q_1, w)! \wedge \delta_2(q_2, w)!),$$

where

$$z = (q_1, q_2) \quad \textit{and} \quad w \in A^*.$$

This predicate depends on both the state in the product machine and the string chosen to differentiate the states that make up the product state.

Example 4.1. For the machines defined in Example 3.2, let M_i and M_j be the possible models that have the b transition defined to states q_i and q_j, respectively. $\text{different}((q_{i0}, q_{j0}), bv_j)$ holds, whereas $\text{different}((q_{i0}, q_{j0}), b)$ does not hold, where (q_{i0}, q_{j0}) is the product initial state.

In the following $A \triangle B$ denotes the symmetric difference of the two sets A and B, i.e., $A \triangle B = (A \cup B) \setminus (A \cap B)$.

DEFINITION 4.2. *A string w is a* distinguishing string *for languages L_1 and L_2 if*

$$(w \in L_1 \triangle L_2).$$

DEFINITION 4.3. *A string w is a* minimally distinguishing string *for languages L_1 and L_2 if*

$$(w \in L_1 \triangle L_2) \wedge (ppr(w) \subseteq L_1 \cap L_2).$$

A minimally distinguishing string is minimal in the sense that no substring is also a distinguishing string.

DEFINITION 4.4. *A nonempty language L is a* distinguishing language *for L_1 and L_2 if $w \in L$ implies that w is a minimally distinguishing string for L_1 and L_2. Hence, a string in a distinguishing language is one that uses the last event to distinguish between L_1 and L_2. Note that, in general, there is not a unique distinguishing language for two machines M_1 and M_2.*

Example 4.2. Let $L_1 = a^*$ and $L_2 = a^*b^*$ be two languages that describe the behavior of two possible models of a black box machine. For these languages, $L_1 \cup L_2 = a^*b^*$ and $L_1 \cap L_2 = a^*$; consequently, $L_1 \triangle L_2 = a^*b^*b$. For a distinguishing language L to satisfy $(ppr(L) \subseteq L_1 \cap L_2)$, we must have that $L \subseteq a^*b$.

Observe that if the machine executes the final b, then L_2 is the correct language, and if not, then L_1 is the correct language.

For languages generated by a state machine, we have the following result.

PROPOSITION 4.5. *Let L_1 and L_2 be languages generated by the machines M_1 and M_2. There exists a distinguishing language L for L_1 and L_2 if and only if*

$$(\exists w \in A^* : \text{different}(z_0, w)), \text{ where } z_0 = (q_{1,0}, q_{2,0}).$$

Proof. $\Longrightarrow$ Let $w \in L$. Since $w \in L_1 \triangle L_2$, we immediately have that $\text{different}(z_0, w)$ holds. $\Longleftarrow$ Let w be the string that satisfies $\text{different}(z_0, w)$. From the definition of $\text{different}(\cdot, \cdot)$, there is some $v \in L_1 \cap L_2$ such that $v < w$ and a $\sigma \in A$ such that $v\sigma \notin L_1 \cap L_2$ and $v\sigma \leq w$. Set $L = \{v\sigma\}$. It is clear that L is a distinguishing language for L_1 and L_2. □

Example 4.3. For the machines in Example 4.1, $\text{different}((q_{i0}, q_{j0}), bv_i)$ holds; consequently, there is a distinguishing language, $L = bv_i + bv_j$, where $a + b = \{a, b\}$.

4.1. Distinguishing between two models. Assume that machine M has an uncertainty that causes the set of potentially correct models to consist of the models M_1 and M_2. We assume that one of these models is correct. The models are specified by the following tuples:

$$M_1 = (Q_1, A, \delta_1, q_{1,0}) \quad \text{and} \quad M_2 = (Q_2, A, \delta_2, q_{2,0}).$$

The languages generated by these models are referenced by $L(M_1)$ and $L(M_2)$. We also refer to the standard synchronous product machine:

$$M_{||} = M_1 || M_2 = (Z, A, \delta_{||}, z_0).$$

The set of states in the product machine that can be used to controllably distinguish the two models is defined in the following manner.

DEFINITION 4.6. *G is the* controllably distinguishing set *of states for M_1 and M_2 if*

$$G = \{z \in Z| \ (\exists \sigma \in A: \ \text{different}(z,\sigma)) \wedge (\neg\exists \sigma_u \in A_u : \delta_{||}(z,\sigma_u)!) \ \},$$

where $M_1 \| M_2 = (Z, A, \delta_{||}, z_0)$.

A particular event that can be used to distinguish two states is called a *controllably distinguishing event.* Hence, an event σ is a controllably distinguishing event for z if *different*(z,σ) holds and there is not an uncontrolled event σ_u defined in the product machine from z.

Example 4.4. For the machines given in Fig. 2, let $A_u = \{b\}$. The controllably distinguishing state set is $G = \{(q_1, q), (q_2, q)\}$. In this example, the set of controllably distinguishing states is the entire product space.

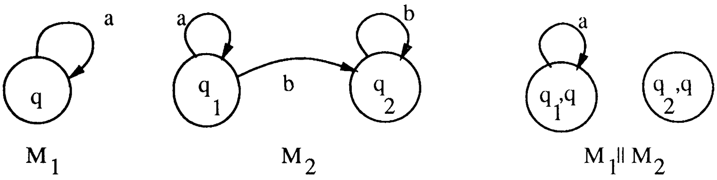

FIG. 2. *Machines for controllably distinguishing state set calculation.*

Example 4.5. Consider the same machines as Example 4.4, but let $A_u = \{a\}$. In this instance, the set of controllably distinguishing states is $G = \{(q_2, q)\}$.

To controllably distinguish states in the product machine, a string must be found which leads to a state in G. Note that G is a superset of states that can be used to distinguish states in the product machine and reached from the initial state. This inclusion is a result of defining G to be all states in the product machine that have controllably distinguishing events defined without consideration of reachability constraints.

Proposition 4.7 states that there is a finite controllable method for distinguishing between two finite state machines if and only if the initial state of the product machine is in the region of weak attraction of the set of states that can be used to distinguish between the two machines.

PROPOSITION 4.7. *Let* $M_1 = (Q_1, A, \delta_1, q_{1,0})$ *and* $M_2 = (Q_2, A, \delta_2, q_{2,0})$, *be two machines. There exists a finite language L that satisfies*

1. *L is controllable with respect to* $L(M_1) \cap L(M_2)$,
2. *L is a distinguishing language for* $L(M_1)$ *and* $L(M_2)$,

if and only if

$$z_0 \in \Omega_{M_1 \| M_2}(G),$$

where

1. $z_0 = (q_{1,0}, q_{2,0})$,
2. *G is the controllably distinguishing set of states, and*
3. $\Omega_{M_1\|M_2}(G)$ *is the region of weak attraction of G in* $M_1\|M_2$. *for* M_1 *and* M_2.

Proof. $\Longleftarrow$ We will demonstrate a language L that satisfies Definition 4.4 with respect to $L(M_1)$ and $L(M_2)$, and is controllable with respect to $L(M_1) \cap L(M_2)$.

Since $z_0 \in \Omega_{M_1\|M_2}(G)$, we can define a machine $M_\Omega(G)$, as discussed in §2.2, and let $L_m(M_\Omega)$ be the language marked by this machine with G as the marked states. Define $X \subseteq A$ such that if $t \in L_m(M_\Omega)$ then there exists $\sigma \in X$ to satisfy the definition of G, i.e., that $(\delta_{\|}(z_0,t) = z) \wedge (z \in G) \Rightarrow \neg\delta_{\|}(z,\sigma)!$. Such a symbol is defined for every string in $L_m(M_\Omega)$ by the definition of G. Further define $L = L_m(M_\Omega)X$ by $t\sigma \in L$ if $t \in L_m(M_\Omega)$, $z = \delta_{\|}(z_0,t)$, and σ is a controllably distinguishing event for z.

We must show that this language is finite, satisfies the definition for controllability, and satisfies the definition of a distinguishing language.

1. L finite:

$$\begin{array}{ll}
 & (\Omega_{M_{\|}}(G), T_\Omega(G)) - G \text{ acyclic}\\
\Rightarrow & \qquad \{\text{property of } \Omega_M(G)\}\\
 & \text{no cycles in } M_\Omega - G\\
\Rightarrow & \\
 & \neg\exists s \in L_m(M_\Omega) : |s| \geq |\Omega_{M_{\|}}(G)|\\
\Rightarrow & \\
 & L \text{ finite.}
\end{array}$$

2. L controllable with respect to $L(M_1) \cap L(M_2)$: Let $(Z_\Omega, T_\Omega) = (\Omega_{M_{\|}}(G), T_\Omega(G))$ and assume that $(t \in \overline{L}) \wedge (\sigma \in A_u) \wedge (t\sigma \in L(M_1) \cap L(M_2))$.

$$\begin{array}{ll}
 & t \in \overline{L} \wedge z_0 \in \Omega_{M_{\|}}(G)\\
\Rightarrow & \qquad \{L = L_m(M_\Omega).X \text{ and definition of } L_m(M_\Omega)\}\\
 & \delta_{\|}(z_0,t) \in Z_\Omega\\
\Rightarrow & \qquad \{t\sigma \in L(M_1) \cap L(M_2)\ ,\ \Omega_M(G) \text{ realizable, } z = \delta_{\|}(z_0,t)\}\\
 & \exists z' \in Z_\Omega : (z,\sigma,z') \in T_\Omega\\
\Rightarrow & \qquad \{\text{definition of } L_m(M_\Omega)\}\\
 & t\sigma \in L(M_\Omega)\\
\Rightarrow & \\
 & t\sigma \in \overline{L}.
\end{array}$$

Hence L is controllable with respect to $L(M_1) \cap L(M_2)$.

3. L non-empty:

$$\begin{array}{ll}
 & z_0 \in \Omega_{M_{\|}}(G)\\
\Rightarrow & \qquad \{M_\Omega \text{ is } G\text{-connected}\}\\
 & \exists v \in A^* : \delta_{\|}(z_0,v) \in G\\
\Rightarrow & \qquad \{\text{definition of } G \text{ and } X\}\\
 & \exists t = v\sigma \in A^* : t \in L_m(M_\Omega).X\\
\Rightarrow & \\
 & L \neq \emptyset.
\end{array}$$

4. $ppr(L) \subseteq L(M_1) \cap L(M_2)$:

$$\begin{array}{ll}
 & L = L_m(M_\Omega).X\\
\Rightarrow & \\
 & ppr(L) = L(M_\Omega)\\
\Rightarrow & \qquad \{\text{definition of } M_\Omega \text{ and } M_{\|}\}\\
 & ppr(L) \subseteq L(M_1\|M_2)\\
\Rightarrow & \qquad \{\text{property of regular languages and FSM}\}\\
 & ppr(L) \subseteq L(M_1) \cap L(M_2).
\end{array}$$

5. $L \subseteq L(M_1)\triangle L(M_2)$:

$$\begin{array}{ll} & (t \in L) \wedge (t = v\sigma) \\ \Rightarrow & \qquad \{\text{definition of } G \text{ and } L\} \\ & z = \delta_{\|}(z_0, v) \in G \\ \Rightarrow & \qquad \{\text{definition of } G \text{ and } X\}, \\ & \textit{different}(z, \sigma) \\ \Rightarrow & \qquad \{\text{definition of } G\} \\ & t \in L(M_1)\triangle L(M_2). \end{array}$$

The last three items combine to show that L satisfies the conditions for being a distinguishing language.

$\Longrightarrow$: Let (V, T) denote the graph representation of the product machine $M_1\|M_2$. Consider the subgraph (V_0, T_0) of (V, T) obtained by running all strings in L on (V, T). Define (V_0, T_0) by

$$\begin{array}{l} V_0 = \{z \in Q_1 \times Q_2 : (\exists w \in \overline{L} : \delta_{\|}(z_0, w) = z)\}, \\ T_0 = \{(z_1, \sigma, z_2) \in T : (\exists w \in \overline{L} : (\delta_{\|}(z_0, w) = z_1) \wedge (w\sigma \in \overline{L}))\}. \end{array}$$

Any state in the product machine reached by a string in the closure of L is included in V_0 and any transition traversed by a string in the closure of L is included in T_0. Since L is finite and $ppr(L) \subseteq L_1 \cap L_2$, it is clear that (V_0, T_0) is well defined and that a simple algorithm will generate this subgraph.

Consider the states reached by string in L/A. (Recall that L/A denotes strings in L with the last symbol removed.) The following lemma follows easily from the definition of a distinguishing language and controllability.

LEMMA 4.8. *With L as assumed in the statement of the proposition,*

$$\forall w \in L/A : \delta_{\|}(z_0, w) \in G$$

where z_0 and G are as defined in the statement of Proposition 4.7.

The following lemma provides the realizability of (V_0, T_0) with respect to (V, T) and A_u.

LEMMA 4.9. *(V_0, T_0) is realizable with respect to (V, T) and A_u.*

Proof. Let $z_1 = \delta_{\|}(z_0, w)$ where $w \in ppr(L)$, $(z_1, \sigma, z_2) \in T$, and $\sigma \in A_u$. From these facts, we must show that $(z_1, \sigma, z_2) \in T_0$. Note that from the construction of V_0, we have that $w \in ppr(L)$ implies that $z_1 \in V_0$.

$$\begin{array}{ll} & (z_1, \sigma, z_2) \in T \\ \Rightarrow & \\ & \delta_{\|}(z_0, w\sigma)! \\ \Rightarrow & \qquad \{L \text{ controllable with respect to } L_1 \cap L_2\} \\ & w\sigma \in ppr(L) \\ \Rightarrow & \\ & (z_1, \sigma, z_2) \in T_0. \qquad \Box \end{array}$$

By Lemma 4.8, (V_0, T_0) is G-connected. By Lemma 4.9, (V_0, T_0) is realizable. If there are no cycles in (V_0, T_0), then by Proposition 2.2 we have that $z_0 \in \Omega_{M_1\|M_2}(G)$ as desired.

If there are cycles, more work is required. The idea is to disable a cycle and show that the remaining subgraph is still G-connected and realizable. Since (V_0, T_0)

is a finite graph, there are only finitely many cycles; consequently, after disabling all cycles, we have a subgraph remaining that is G-connected, realizable, and acyclic. By Proposition 2.2, we have that $z_0 \in \Omega_{M_1 \| M_2}(G)$ as desired.

Now we must show that cycles may be removed while retaining the connectedness and realizability of the subgraph (V_0, T_0).

We start by classifying all transitions in T_0. A transition is included in class $\mathcal{C}$ if it must be included in T_0 for controllability reasons, i.e., if the subgraph would lose the realizability characterization by not having a specific transition, then that transition is included in $\mathcal{C}$. Hence,

$$(z_1, \sigma, z_2) \in \mathcal{C} \Leftrightarrow ((z_1, \sigma, z_2) \in T_0 \wedge \sigma \in A_u).$$

A transition is included in class $\mathcal{R}$ if it must be included in T_0 for reachability reasons, i.e., if a node would no longer be G-connected without the presence of a specific transition, then that transition is included in $\mathcal{R}$. Hence, $(z_1, \sigma, z_2) \in \mathcal{R}$ if and only if there does not exist a $w \in A^*$ such that there is a path labeled by w from z_1 to G in the subgraph (V_0, T_0), where $w(1) \neq \sigma$.

Assume that there is a cycle in (V_0, T_0). If there is a transition (z_1, σ, z_2) on the cycle that is not in $\mathcal{C} \cup \mathcal{R}$, then we can clearly remove this transition and retain the G-connectivity and realizability. This fact follows from the facts that any transition (z_1, σ, z_2) not in $\mathcal{C} \cup \mathcal{R}$ is controllable and there is another path in the subgraph from z_1 to G that does not use the transition in question.

Hence, if we can remove all cycles by deleting transitions that are not in $\mathcal{C} \cup \mathcal{R}$, then we are done.

Assume that there is a cycle remaining that only has transitions in $\mathcal{C} \cup \mathcal{R}$. Let (z_1, σ, z_2) be a transition on this cycle. From the construction of the subgraph (V_0, T_0), we have that there is a string $s \in ppr(L)$ such that $\delta_{\|}(z_0, s) = z_1$. The following lemma provides the crucial result.

LEMMA 4.10. *Let L and $\mathcal{C} \cup \mathcal{R}$ be as above. If there is a cycle that has transitions only in $\mathcal{C} \cup \mathcal{R}$, then there are strings of arbitrary length in L.*

Proof. Let $x \in A^*$ be the labels of the transitions on this cycle, i.e., $\delta_{\|}(z_1, x) = z_1$. Let $m = |x|$. Let z_i denote the state immediately preceding label $x(i)$, i.e., $(z_i, x(i), z_{i+1})$ is a transition on this cycle. Note that $z_{m+1} = z_1$.

From the controllability of L with respect to $L_1 \cap L_2$, Lemma 4.8, and the fact that every transition on the cycle is in $\mathcal{C} \cup \mathcal{R}$, it is clear that $sx(1) \in ppr(L)$. The same result holds for each i, i.e. for all $i : 1 \leq i \leq m : sx(1) \ldots x(i) \in ppr(L)$. Hence, $sx \in ppr(L)$, implying that $sx^* \subseteq ppr(L)$. This last statement contradicts the finiteness of L; consequently, there can be no cycle consisting only of transitions from $\mathcal{C} \cup \mathcal{R}$. □

As a result of Lemma 4.10, any cycle in the subgraph can be removed while retaining G-connectivity and realizability. Hence, the conditions of Proposition 2.2 are satisfied and we get that $z_0 \in \Omega_{M_1 \| M_2}(G)$. □

Based on Proposition 4.7, we define a predicate that is true if two machines can be distinguished as described in the proposition.

DEFINITION 4.11. *Given machines M_1 and M_2, where $M_1 = (Q_1, A, \delta_1, q_{1,0})$ and $M_2 = (Q_2, A, \delta_2, q_{2,0})$, the predicate* $\text{disting}(M_1, M_2)$ *holds if* $(q_{1,0}, q_{2,0}) \in \Omega_{M_1 \| M_2}(G_{1,2})$, *where*

$$G_{1,2} = \left\{ (q_1, q_2) \in Q_1 \times Q_2 \middle| \begin{array}{l} (\exists \sigma \in A : \ \text{different}((q_1, q_2), \sigma)) \\ \wedge \\ (\neg \exists \sigma_u \in A_u : \delta_{\|}((q_1, q_2), \sigma_u)!) \end{array} \right\}.$$

If two machines satisfy this predicate, then the machines, or their languages, are said to be controllably distinguishable.

The following corollary provides the application of Proposition 4.7 to resolving an uncertainty that gives two potentially correct models. If $z_0 \in \Omega_{M_{\|}}(G)$, then a supervisor corresponding to the machine represented by the graph created by the algorithm that generates the region of weak attraction can be built that will constrain the behavior of the unknown system such that an incorrect model can be identified in a finite number of transitions. (See [13] for details on how a machine representation of a supervisor is used to control a plant.)

COROLLARY 4.12. *Let M_1 and M_2 be two models, such that one of them correctly models the plant M. Let $M_{\|} = M_1 \| M_2$, $z_0 = (q_{1,0}, q_{2,0})$, and G be the controllably distinguishing set of states for M_1 and M_2.*

$z_0 \in \Omega_{M_{\|}}(G)$ if and only if the correct model can be chosen in a finite number of transitions.

Proof. $\Longrightarrow$: By Proposition 4.7, if $z_0 \in \Omega_{M_{\|}}(G)$, then there exists a finite nonempty controllable language L such that any string in the language can distinguish $L(M_1)$ and $L(M_2)$. By Theorem 2.1, a supervisor f can be constructed such that $L_f = \overline{L}$; hence, the plant can be controlled so as to execute strings from L. Since one of the models correctly models the plant, $ppr(L) \subseteq L(M)$, and any proper prefix of a string t in L can be executed by the plant. Since $L \subseteq L(M_1) \triangle L(M_2)$, the last symbol in the string will either be executed or not depending on whether $M = M_1$ or $M = M_2$ and which model has t defined in its language.

$\Longleftarrow$: By Proposition 4.7, if $z_0 \notin \Omega_{M_{\|}}(G)$, then we can construct a string of arbitrary length that the plant can execute such that no supervisor may disable events such that an inconsistency is observed. □

The complexity of this approach is governed by the necessity of considering the product machine for M_1 and M_2 to determine the distinguishing language. This operation requires $O(|Q_1||Q_2|)$ operations. In this paper, the dependency of the complexity on the size of the event set A is assumed to be a constant factor; hence it is not included in the expression for the order of complexity. As shown in §5.1, this is a sharp bound on the complexity.

4.2. Distinguishing multiple models. The technique for distinguishing between multiple models with a reset capability available is an extension of the technique used to distinguish between two models. The strategy is to construct a product machine from two models in the set of models that results from considering all possible permutations of the uncertainties. Then, from this product machine, calculate the region of weak attraction for the set of controllably distinguishing states for these two models as described in Corollary 4.12. By using the machine generated by the region of weak attraction as a supervisor for the plant, at least one of these models can be removed from the set of possibly correct models by controlling the plant to enter a state that is a component of one of the product states in the set of controllably distinguishing states. Then, after at least one of these models has been eliminated as a possibly correct model, reset the plant and start the procedure over with another pair of models. Note that it is possible that neither of the models that are chosen is the correct model for the system; hence, the plant might generate a string that is not defined in either of the models used to generate the supervisor. In this case, both models are removed and the procedure continues by choosing another two models. This procedure continues until all uncertainties have been resolved or until no pair of models can be found that satisfy the conditions of Corollary 4.12.

We denote each possible model as $M_i = (Q_i, A, \delta_i, q_{i,0}, Q_{i,m})$, where $i = 1, \ldots, k$, and k is the initial number of models from which the correct model is to be chosen. We denote the initial set of all possible models by S_0. Using the notation given,

$$S_0 = \{M_i | i = 1, \ldots, k\},$$

where each model is in minimal canonical form [5], [9].

The following algorithm specifies the procedure given above. P denotes the actual machine or the plant which is to be correctly modeled.

ALGORITHM 4.1.

```
Input:
    $S_0$ as given above.
Output:
    $S_n = \{M_i|$ no additional uncertainties can be resolved$\}$.
Algorithm:
    $p = 0$.
    While $(|S_p| > 1) \wedge (\exists M_i \in S_p \wedge \exists M_j \in S_p : disting(M_i, M_j))$:
        Calculate $\Omega_{M_i \| M_j}(G_{i,j})$.
        Use $M_\Omega(G_{i,j})$ as supervisor for $P$.
        Determine which model is still a possibly correct model and which
        model is not consistent with the plant.
        $S_{p+1} = S_p \backslash \{$ models which have been determined to be inconsistent
        with plant $\}$.
        Reset the plant.
        $p = p + 1$.
    End while.
End of algorithm.
```

In the worst case, the product for every pair of models would need to be calculated to check for pairs that satisfy $z_0 \in \Omega_{M_\|}(G_{i,j})$. Since there are k models in S, this calculation of products results in an algorithm with $O(k^2|Q|^2)$ complexity.

A slight modification of the proposed algorithm is to simulate, on all models in S_p, the strings that result from using $M_\Omega(G_{i,j})$ as a supervisor for the plant. Using this technique, any model that cannot successfully simulate the activity of the plant can be eliminated from consideration and need not be considered in any future pairing.

This modified approach also has worst case complexity of $O(k^2|Q|^2)$ since there is no guarantee that more than one model will be eliminated on each iteration. Also the actual complexity to accomplish the simulation results in an additional $O(k|Q|^2)$ term in the operation count. These counts are a result of the following reasoning. Each calculation of $\Omega_{M_\|}(G)$ adds a $|Q^2|$ term to the count. There are at most k^2 pairs that must be calculated, hence, the $O(k^2|Q^2|)$ term in the count. To simulate any test string on all remaining potential models, $O(k|Q^2|)$ operations are necessary; hence, this term is added to the count retaining an overall complexity of $O(k^2|Q^2|)$.

To demonstrate the correctness of the algorithm, several points must be addressed: insuring that only bad models are removed from S_i, that the order of choosing models for the test $disting(M_i, M_j)$ does not affect the output, and that there is no other technique which might produce a smaller set of potential models.

4.2.1. Only bad models removed. The first point is easily addressed. A model is removed if it is inconsistent with the plant. An inconsistency arises from either the plant executing a transition that is not in the model, such as an uncontrolled transition, or the plant not executing a transition that is defined in the model, such as from a state at which a single controlled or uncontrolled transition is defined in the model but is not executed by the plant. Hence, only "bad" models are removed from the set used to keep potentially correct models. Note that a consistent model will not be removed from this set.

4.2.2. Order does not affect the result. The second point is more subtle. A priori it appears that the order of testing models might be significant. That is, there might be some incorrect model A that, when combined with another incorrect model B, generates a test string that provides that model B is removed, but that when model B is combined with the correct model a test string cannot be generated.

That the order does not matter follows from the following proposition. Proposition 4.13 states that if a pair of models, M_i and M_j, satisfy $z_0 \in \Omega_{M_i \| M_j}(G_{i,j})$ and if M_i is removed from the set of possibly correct models, then the correct model M_c and M_i satisfy $z_0 \in \Omega_{M_i \| M_c}(G_{i,c})$. Hence, if model M_j can be used to remove M_i, then model M_c can be used instead.

In the statements of the following propositions, the language generated by model M_i, which is usually denoted by $L(M_i)$, is denoted by L_i. In the proof of Proposition 4.13, a language L is used to link the fact that the initial state is in the region of attraction of each of the product machines. The conditions on L are very similar to the conditions for a distinguishing language for M_i and M_j; however, the fact that neither M_i nor M_j might be the correct model requires that slightly different characteristics describe how M_j can be used with M_i to generate a supervisor that will cause M_i to be removed from the set of possibly correct models. In the following, M_c denotes the correct model. $z_{0,i,j}$ is the initial state of $M_i \| M_j$. $z_{0,i,c}$ is the initial state of $M_i \| M_c$. $G_{i,j}$ is the set of controllably distinguishing states for $M_i \| M_j$. $G_{i,c}$ is the set of controllably distinguishing states for $M_i \| M_c$.

PROPOSITION 4.13. *If $z_{0,i,j} \in \Omega_{M_i \| M_j}(G_{i,j})$ and M_i is removed from the set of possible machines, then $z_{0,i,c} \in \Omega_{M_i \| M_c}(G_{i,c})$.*

Proof. Consider the language L marked by the supervisor generated by $\Omega_{M_i \| M_j}(G_{i,j})$ and used to remove M_i. By the assumptions in the proposition statement, this language generates tests that are used to remove M_i from the set of potentially correct models.

We first describe some characteristics that this language satisfies.

LEMMA 4.14.

(a) *L controllable with respect to $L_i \cap L_j \cap L_c$,*

(b) *$L \subseteq (L_i \triangle L_c) \cap (L_j \cup L_c)$,*

(c) *$ppr(L) \subseteq L_i \cap L_j \cap L_c$, and*

(d) *L is finite and nonempty.*

Proof. The controllability of L with respect to $L_i \cap L_j$ follows from the construction of $\Omega_{M_i \| M_j}(G_{i,j})$ and the fact that $\Omega_M(G)$ is realizable. That L is controllable with respect to $L_i \cap L_j \cap L_c$, follows from the fact that all prefixes of the closed-loop behavior are necessarily constrained to L_c.

The strings that occur in the distinguishing language generated by $\Omega_{M_i \| M_j}(G_{i,j})$ consist of the following types:

(1) strings that occur in the plant, M_i, and M_j, i.e., $L_i \cap L_j \cap L_c$,

(2) strings that occur in the plant and M_j but not in M_i, i.e., $L_c \cap L_j \cap L_i^c$,

(3) strings that occur in M_i and M_j but not in the plant, i.e., $L_c^c \cap L_i \cap L_j$, and

(4) strings that occur in the plant but not in M_i and M_j, i.e., $L_c \cap (L_i \cup L_j)^c$.

For this supervisor to cause M_i to be removed from the set of possibly correct machines, the strings that occur in all three must be in the prefix of strings that will cause M_i to be removed. Hence, $ppr(L) \subseteq L_i \cap L_j \cap L_c$.

For this supervisor to cause M_i to be removed from the set of possibly correct machines in a controllable fashion, we claim that only the strings in (2), (3), and (4) above can occur as strings in the language. (See shaded areas in Fig. 3.) No other string can occur and still allow M_i to be removed from the set of possibly correct machines. Any other string would not allow M_i to be removed.

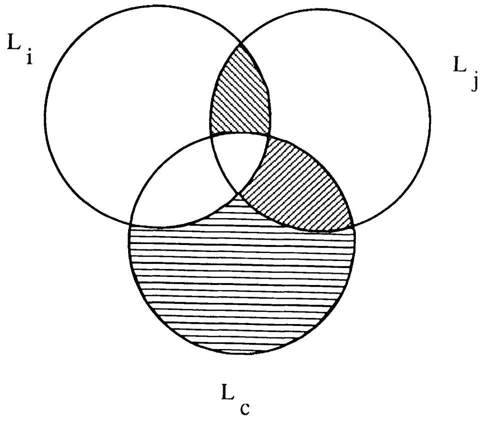

FIG. 3. *Parts of languages that allow removal of M_i.*

From this observation we have that

$$\begin{aligned} & L \subseteq (L_c \cap L_j \cap L_i^c) \cup (L_c^c \cap L_j \cap L_i) \cup (L_c \cap (L_j \cup L_i)^c) \\ \Rightarrow \quad & L \subseteq ((L_j - L_i) \cap L_c) \cup ((L_j \cap L_i) - L_c) \cup (L_c - (L_j \cup L_i)), \end{aligned}$$

which gives Lemma 4.14(b).

The finiteness of L is a result of the fact that $\Omega_{M_i \| M_j}(G_{i,j})$ is acyclic. That L is nonempty is a result of the fact that M_i is removed, i.e. at least one event must be used to determine that M_i is not correct. □

We now use this language to demonstrate that $z_{0,i,c} \in \Omega_{M_i \| M_c}(G_{i,c})$. We demonstrate this fact by verifying that L satisfies the requirements of Proposition 4.7 for M_c and M_i.

1. L finite and nonempty:

L is finite and non-empty by hypothesis.

2. L controllable with respect to $L_c \cap L_i$: From the definition of $\overline{L}$, we have that $(t \in \overline{L}) \Rightarrow t \in L \cup ppr(L)$.

$$\begin{array}{ll} & (t\sigma_u \in L_c \cap L_i) \\ \Rightarrow & \\ & t \in (L_i \cap L_c) \\ \Rightarrow & \qquad \{(b) \text{ and } (c)\} \\ & t \in ppr(L) \\ \Rightarrow & \qquad \{(a) \text{ and } (c)\} \\ & t\sigma_u \in \overline{L} \\ \Rightarrow & \\ & L \text{ controllable w.r.t. } L_i \cap L_c. \end{array}$$

3. $L \subseteq L_c \triangle L_i$:

$$
\begin{aligned}
& L \subseteq (L_i \triangle L_c) \cap (L_j \cup L_c) \\
\Leftrightarrow \\
& L \subseteq ((L_j - L_i) \cap L_c) \cup (L_c - (L_j \cup L_i)) \cup ((L_j \cap L_i) - L_c) \\
\Rightarrow \\
& L \subseteq (L_i^c \cap L_c) \cup (L_c \cap L_i^c) \cup (L_i \cap L_c^c) \\
\Rightarrow \\
& L \subseteq (L_c \cap L_i^c) \cup (L_i \cap L_c^c) \\
\Rightarrow \\
& L \subseteq L_c \triangle L_i.
\end{aligned}
$$

4. $ppr(L) \subseteq L_c \cap L_i$:

$$
\begin{aligned}
& ppr(L) \subseteq L_i \cap L_j \cap L_c \\
\Rightarrow \\
& ppr(L) \subseteq L_c \cap L_i
\end{aligned}
$$

Since L satisfies the requirements for Proposition 4.7 with respect to M_i and M_c, we immediately have that $z_{0,i,c} \in \Omega_{M_i \| M_c}(G_{i,c})$. □

Proposition 4.13 provides that the order does not matter when choosing which pair of models to use to generate the next test. When combined with the first point, that only "bad" models are removed, we have that it is sufficient to test bad models with the correct model, which will never be removed from the set of potentially correct models.

4.2.3. Optimal complexity of Algorithm 4.1. Now we address the question of whether some other procedure might be used to generate a smaller set of potentially correct models.

PROPOSITION 4.15. *Algorithm 4.1 provides a minimal set of potentially correct models. (Minimal in the sense that there does not exist another technique to controllably remove more models than are removed by Algorithm* 4.1 *from the set of potentially correct models in a finite number of transitions.)*

Proof. Let $\overline{S}$ be the set of potentially correct models output by Algorithm 4.1.

If $|\overline{S}| = 1$, then we are done, i.e., $\overline{S} = \{M_c\}$.

If $|\overline{S}| > 1$, then we know that since the test disting(M_i, M_j) is not satisfied for any pair of models in $\overline{S}$ and consequently

$$\forall i, j : M_i, M_j \in \overline{S} : z_{o,i,j} \notin \Omega_{M_i \| M_j}(G_{i,j}).$$

In particular, we know that

$$z_{o,i,c} \notin \Omega_{M_i \| M_c}(G_{i,c}). \tag{1}$$

Assume that there is some other technique that controllably removes $M_i \neq M_c$ from $\overline{S}$. To remove M_i, a test must cause M_i to reach a state at that an inconsistency with the plant arises. This state in M_i is a component to a state in $G_{i,c}$, otherwise by controllability constraints M_i cannot be removed by this test. By (1), we know that we can construct a behavior for M_i that never enters G. Hence, we have a contradiction and there cannot be any technique that can controllably generate a smaller set of potentially correct models. □

4.2.4. Resolving uncertainty without reset. To resolve uncertainty without a reset capability, a slight modification must be made to the algorithms given previously. The modification consists of updating the models still under consideration to reflect any actions that the actual plant has taken. This update is manifested by modifying the model descriptions so that the initial state has a dependence on events that have already occurred.

Hence, the old model $M = \{Q, A, \delta, q_0, Q_m\}$ is modified to incorporate the string s, which the plant has executed to this point and denoted by $M(s) = \{Q, A, \delta, q_{\hat{0}}(s), Q_{\hat{m}}\}$. Note that only the initial state needs to have this dependence. The other components of the model do not need to be modified.

Note that for this modification, all models must be updated to determine if the new initial state after a test string has been executed is in the region of attraction for the set of distinguishing states. However, the actual region of attraction does not need to be recalculated because the states that can be attracted to the distinguishing states do not change with each test string; only the initial state changes.

The need to simulate the test strings does not increase the complexity of the algorithm. In the worst case, this algorithm could require that $O(k^2)$ regions of weak attraction be calculated to find enough test strings. Hence, this algorithm also has $O(k^2|Q|^2)$ complexity.

5. Examples.

5.1. Optimality for single transition uncertainty. This example demonstrates that resolving a single uncertainty has complexity at least as great as that of creating the product machine for the two potentially correct models. This complexity arises from the fact that the product machine is used to generate the set of controllably distinguishing states and hence the minimally distinguishing language. For this example, z is the event for the uncertain arcs and $A_u = \{a, c, d\}$. Figure 4 illustrates the two possible transition functions for the machine.

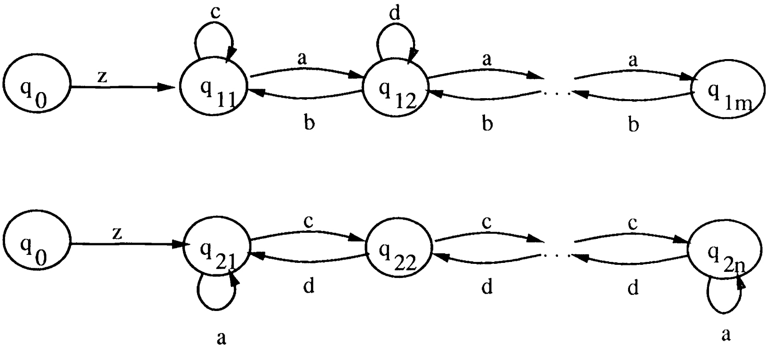

FIG. 4. *Set of models for which product method is optimal.*

Following the procedure specified in Proposition 4.7, we create the product machine (Fig. 5) and calculate the states G that can be used to distinguish q_{11} and q_{21} and the region of weak attraction for G.

From the graph representation of the transition function for the product machine, we can determine that

$$G = \{q_{1m,2n}, q_{0,11}, \dots, q_{0,1m}, q_{0,21}, \dots, q_{0,2n}, \}.$$

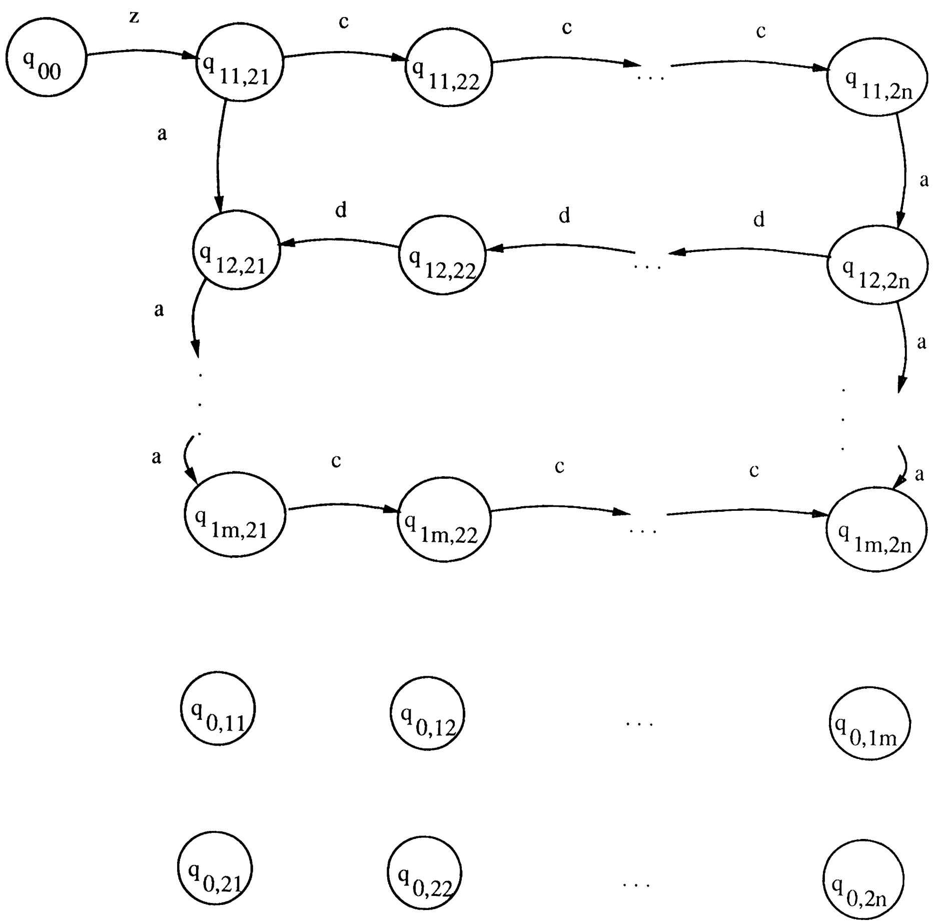

FIG. 5. *Product machine for system for which product method is optimal.*

From Fig. 5, we observe that the only state in the current G that can have $q_{0,0}$ in the region of weak attraction is $q_{1m,2n}$; hence, we will limit our calculations for a new set $G' = \{q_{1m,2n}\}$. Some of the iterations of the algorithm to calculate the region of weak attraction are given:

$$\begin{aligned} V_0 &= \{q_{1m,2n}\} \\ V_1 &= V_0 \cup \{q_{1m,2(n-1)}\} \\ &\;\;\vdots \\ V_n &= V_{n-1} \cup \{q_{1(m-1),21}\} \\ &\;\;\vdots \\ V_{m*n} &= V_{m*n-1} \cup \{q_{0,0}\}. \end{aligned}$$

Hence, by Proposition 4.7, since $z_0 \in \Omega_{M_{\|}}(G')$, the two states q_{11}, q_{21} are controllably distinguishable, and the uncertain arc can be resolved. Observe that $q_{1m,2n} \in G'$ and that there is a string $z(c^n ad^n a)^m$ that can occur uncontrollably before reaching

$q_{1m,2n}$; hence, to resolve the uncertainty, every state that can be reached in the product machine from the initial state might be visited. This fact demonstrates that resolving this uncertain transition requires $O(mn)$ operations.

To resolve the uncertainty, construct a supervisor with finite state machine representation as shown in Fig. 5 and run the unknown plant and supervisor as a closed-loop system. (See [13] for more detail on this procedure.) A distinguishing language for this example is $L = z(c^n ad^n a)^m a$.

5.2. Finiteness of languages in Proposition 4.7. This example demonstrates the requirement for finiteness in Proposition 4.7.

Let $L_1 = (av)^*$ and $L_2 = (a(u+v))^*$ be the languages for two possible models where $a \in A$ and $u, v \in A_u$. See Fig. 6 for the machine representation for these languages.

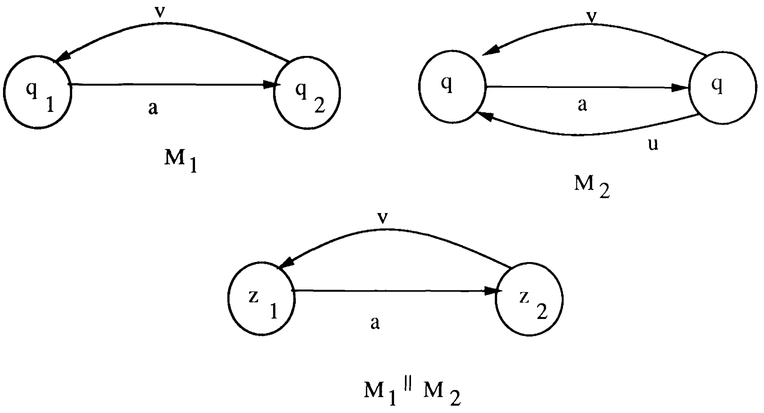

FIG. 6. *System to demonstrate requirement for finiteness.*

For this example, if $L = (av)^*au$, then L is controllable with respect to $L_1 \cap L_2$, $L \subseteq L_1 \triangle L_2$, and $ppr(L) \subseteq L_1 \cap L_2$ as required for a language that can be used to distinguish L_1 and L_2 as described in Proposition 4.7; however, the initial state of the product machine is not in the region of weak attraction of the set of controllable distinguishing states, which is empty in this example.

6. Conclusions. In this paper we have presented a model of uncertainty related to the transitions of systems modeled with finite state machines. We developed a test for determining whether or not such uncertainty can be controllably resolved. The test using a region of weak attraction calculation also provides an algorithm for constructing a supervisor which can resolve the uncertainties. An example demonstrating the optimality of the deterministic approach for a single uncertainty is provided. Also, an example is given which demonstrates how the controllability and finiteness requirements are both necessary for Proposition 4.7. This approach to choosing the correct model can be applied in any situation that has a set of models from which the correct one should be chosen.

Several possibilities exist for extensions to this work. One possibility is to expand the model used to describe a discrete event system to one that can describe a broader category of systems, such as a Petri net [8] or algebraic [10] models. Another direction of current interest is the influence that different uncertainty models have on the control and stabilization of systems modeled with discrete event system formalisms. This influence incorporates the effect that limiting the behavior of a system to a desired constraint language would have on correctly controlling the system and resolving any uncertainty in the model. A further extension is to consider how the addition of unobserved events affects the problem described in this work.

ANALYSIS OF COSTATE DISCRETIZATIONS IN PARAMETER ESTIMATION FOR LINEAR EVOLUTION EQUATIONS*

C. R. VOGEL[†] AND J. G. WADE[‡]

Abstract. A widely used approach to parameter identification is the output least-squares formulation. Numerical methods for solving the resulting minimization problem almost invariably require the computation of the gradient of the output least-squares functional. When the identification problem involves time-dependent distributed parameter systems (or approximations thereof), numerical evaluation of the gradient can be extremely time consuming. The costate method can greatly reduce the cost of computing these gradients. However, questions have been raised concerning the accuracy and convergence of costate approximations, even when the numerical methods being used are known to converge rapidly on the forward problem.

In this paper it is shown that the use of time-marching schemes that yield high-order accuracy on the forward problem does not necessarily lead to high-order accurate costate approximations. In fact, in some cases these approximations do not converge at all. However, under certain circumstances, rapidly converging gradient approximations do result because of rapid weak-star-type convergence of the costate approximations. These issues are treated both theoretically and numerically.

Key words. parameter estimation, evolution equations, costate method

AMS subject classifications. 35R30, 49D07

1. Introduction.

In this paper we analyze temporal discretizations of the costate method for computing gradients in the output least-squares approach to parameter estimation. This analysis applies to initial value problems of the form

$$\begin{aligned} \dot{u}(t) &= A(q)\,u(t) + f(t), \qquad 0 < t < t_F, \\ u(0) &= 0. \end{aligned} \tag{1.1}$$

Here $A(q)$ is a bounded linear operator on a Hilbert space H, and the inner product on H is denoted $\langle \cdot, \cdot \rangle_H$. The dot over u indicates differentiation with respect to t. We will refer to u as the state variable and to (1.1) as the state equation. We assume q lies in set $\mathcal{Q}_{AD}$ of admissible parameters contained in a normed linear "parameter" space $\mathcal{Q}$. Throughout the paper we assume that the map $q \mapsto A(q)$ is Gateaux differentiable in the operator norm.

In applications of interest, (1.1) is a finite-dimensional (i.e., $\dim(H) < \infty$) approximation of a time-dependent partial differential equation (PDE). An important example is the diffusion equation

$$\begin{aligned} \frac{\partial u}{\partial t}(t,x) &= \nabla \cdot (q(x)\nabla u(t,x)) + f(t,x),\ x \in \Omega,\ 0 < t < t_F, \\ u(t,x) &= 0, x \in \partial\Omega,\ 0 < t < t_F, \\ u(t,x) &= 0, \qquad\qquad x \in \Omega. \end{aligned} \tag{1.2}$$

In these situations, $\dim(H)$ can be arbitrarily large.

In general we assume that the solution u lies in the "state space"

$$\mathcal{H} = L^2(0, t_F; H),$$

which is a Hilbert space with inner product

$$\langle\langle f, g \rangle\rangle_{\mathcal{H}} = \int_0^{t_F} \langle f(t), g(t) \rangle_H \, dt. \tag{1.3}$$

As in Banks and Kunish [3], we assume the existence of an "observation space" $\mathcal{Z}$, which is a Hilbert space with inner product $\langle\langle \cdot, \cdot \rangle\rangle_{\mathcal{Z}}$, and an "observation operator"

$$\mathcal{C} : \mathcal{H} \to \mathcal{Z}.$$

Given an observation z of u, we wish to estimate the parameter q. In the output least-squares approach to parameter estimation, $q \in \mathcal{Q}_{AD}$ is selected to minimize the functional

$$T_\alpha(q) \overset{\text{def}}{=} \frac{1}{2} ||\mathcal{C}u(q) - z||_{\mathcal{Z}}^2 + \frac{\alpha}{2} \mathcal{N}^2(q), \tag{1.4}$$

where $u(q)$ is the solution to (1.1). Here the scalar α is a positive regularization parameter and $\mathcal{N}^2(q)$ is a regularization functional whose purpose is to stabilize the minimization. Usually, $\mathcal{N}(q)$ is a norm or seminorm on $\mathcal{Q}$.

Computational methods to minimize $T_\alpha(q)$ typically require gradients or gradient approximations. For example, assuming a discretization of the parameter of the form

$$q = \sum_{i=1}^{n_q} \hat{q}_i \psi_i,$$

we often (see, for example, [3, §V.6]) approximate the components of the gradient using finite differences, e.g.,

$$[\nabla T_\alpha(q)]_i \approx \frac{T_\alpha(q + \tau\psi_i) - T_\alpha(q)}{\tau}, \tag{1.5}$$

for τ a small scalar. Note that in the limit as $\tau \to 0$, the ith component of $\nabla T_\alpha(q)$ is the directional (i.e., Gateaux) derivative of $T_\alpha(q)$ in the direction ψ_i. When $\dim(H)$ and n_q are large, gradient approximations based directly on (1.5) are extremely expensive, requiring $n_q + 1$ evaluations of the functional T_α, and hence, $n_q + 1$ solutions of the evolution equation (1.1).

An attractive alternative is the costate approach [3, §V.5], [7], which is described in its continuous form in §2. In sharp contrast to the $(n_q + 1)$ state equation solutions needed for the finite difference method (1.5), the costate method requires the solution of only two evolution equations, the state equation and the "costate" or "adjoint" equation, followed by n_q $\mathcal{H}$-inner products.

Unfortunately, computational experience with adjoint approximations in parameter estimation for certain evolution equations has been puzzlingly disappointing. For example, the authors of [4] concluded that this approach was unsatisfactory because "... it was extremely difficult to obtain accurate search directions with gradients computed in this manner." Also, in [2] the authors suggest the costate method for a certain class of damped elastic systems and explain how it may facilitate the efficient use of gradient-based methods such as conjugate gradients or BFGS. They also report having used it in some of their numerical experiments. However, in *none* of the specific examples upon which they report did they use this method. Subsequent private communication with two of the authors revealed that they encountered unexpected difficulty with the costate approach. Later commenting on this, in [1] Banks states that "...we experienced so much difficulty with the costate based gradient methods that we abandoned them ...."

Similar difficulties have been encountered in optimal control settings. In [5], which dealt with computational methods for control systems governed by delay differential equations, the authors observed that certain spline approximations to the solution of operator Ricatti equations failed to converge strongly. In a subsequent work [6] it was carefully shown that the underlying difficulty was lack of strong convergence of the adjoint approximations.

In this paper we focus on the temporal discretizations of the costate system in least-squares parameter estimation. Since the costate method of computing $\nabla T_\alpha(q)$ requires the solution of two evolution equations plus n_q inner products, two important components of any numerical scheme for approximating the gradient are (a) the scheme for approximating the solution of the evolution equations (which we assume is a time-marching scheme), and (b) the numerical quadrature scheme. If both of these are, say, νth-order accurate, then one would reasonably hope to attain νth-order convergence of the gradient approximations. However, if the observation operator $\mathcal{C}$ involves pointwise evaluation in time, then certain subtleties arise and we may observe unexpectedly poor convergence of the gradient approximations. Perhaps the most striking examples we present involve the fourth-order Runge–Kutta (RK4) time-marching scheme. We show that if RK4 is used in conjunction with Simpon's rule (which is fourth order) for numerical quadrature, then the gradient approximations fail altogether to converge. We show that in fact these RK4/Simpson's approximations converge with *second-order* accuracy to the (3/2) times the true gradient! More positively but perhaps equally surprisingly, we prove that RK4 together with the *second-order accurate* "trapezoidal" quadrature rule yields *fourth-order* convergence!

The underlying reason for these strange phenomena is that when $\mathcal{C}$ involves pointwise evaluation in time, the costate equation is an evolution equation with Dirac-delta functions in the forcing term. For this reason, the costate approximate solutions do not converge strongly. However, in some cases they do exhibit high-order convergence in the weak* topology of the dual space of C^ν.

These considerations are similar in spirit to the work reported in [6]. In the introduction of that paper, the authors state "We feel that many distributed parameter control systems are such that 'standard' ...schemes might lead to numerical difficulties" when used in optimization schemes, and "we hope that the reader will be motivated to think about similar problems for more complex distributed parameter systems." While that paper addresses the optimal control problem, it is nonetheless relevant to us to the extent that output least-squares parameter estimation is mathematically similar to optimal control.

Banks [1] has suggested that nonconvergence of costate approximations can also occur in parameter estimation because of a lack of convergence of the *spatial* discretization. For example, in systems such as (1.2), we must discretize with respect to each component of x as well as with respect to t. Then a result needed for the costate approximations is essentially weak* convergence to the dual semigroups. These considerations suggest directions for future work, but we do not pursue them here.

In §2 we discuss the costate method for the continuous problem, apart from any temporal approximations. In §3 we introduce a fairly wide class of time-marching schemes for (1.1) and a corresponding costate approximation scheme. We then analyze these approximations in some detail, making certain assumptions about the properties of the time-marching scheme, the observation operator, and the various operator discretizations. Section 4 contains some numerical examples that illustrate the results of the analysis. In §5, several alternative approaches that avoid the difficulties mentioned above are presented. Our conclusions are discussed in §6.

2. The continuous costate approach. As stated in the introduction, typical implementations of the output least-squares approach to parameter estimation require gradients of the functional $T_\alpha(q)$ given in (1.4). Most of the effort in obtaining this gradient lies in computing the gradient of the least-squares functional

$$T(q) \overset{\text{def}}{=} \tfrac{1}{2}||\mathcal{C}u - z||^2_{\mathcal{Z}}, \tag{2.1}$$

where $u = u(t;q)$ solves the state equation

$$\begin{aligned} \dot{u}(t) &= A(q)u(t) + f(t), \qquad 0 < t < t_F, \\ u(0) &= 0. \end{aligned} \tag{2.2}$$

Since the gradient of $T(q)$ can be obtained by computing directional derivatives, we focus throughout on the computation of the directional derivative of T at q in the direction p. This is given by

$$\delta_p T(q) \overset{\text{def}}{=} \lim_{\tau \to 0} \frac{T(q + \tau p) - T(q)}{\tau}. \tag{2.3}$$

The residual is defined by

$$r = \mathcal{C}u - z, \tag{2.4}$$

and hence,

$$\delta_p T(q) = \langle\langle\, r,\, \mathcal{C}\delta_p u \,\rangle\rangle_{\mathcal{Z}}. \tag{2.5}$$

The solution $u = u(q)$ to (2.2) is given in terms of the "solution operator" $\mathcal{S}(q)$ by

$$u(t) = [\mathcal{S}(q)f](t) \overset{\text{def}}{=} \int_0^t e^{A(q)s} f(t-s)\, ds. \tag{2.6}$$

In terms of $\mathcal{S}(q)$, we have

$$\delta_p u = \mathcal{S}(q)\left(\delta_p A(q)\right) u. \tag{2.7}$$

Thus

$$\delta_p T(q) = \langle\langle\, r,\, \mathcal{C}\mathcal{S}(q)\, \delta_p A(q)\ u \,\rangle\rangle_{\mathcal{Z}}.$$

Taking adjoints of $\mathcal{C}$ and $\mathcal{S}(q)$, we obtain

$$\delta_p T(q) = \langle\langle\, y,\, \delta_p A(q)\ u \,\rangle\rangle_{\mathcal{H}},$$

where y is the solution to the "costate equation"

$$y = \mathcal{S}^*(q)\mathcal{C}^* r. \tag{2.8}$$

The operator $\mathcal{S}^*(q)$ is given, for $g \in \mathcal{H}$, by

$$[\mathcal{S}^*(q)g](t) = \int_t^{t_F} e^{-A^*(q)s} g(t-s)\, ds.$$

The differential equation that y satisfies is

$$\begin{aligned} -\dot{y}(t) &= A^*(q)y(t) + (\mathcal{C}^* r)(t), \qquad 0 < t < t_F, \\ y(t_F) &= 0. \end{aligned}$$

Since this equation has a *final* condition instead of an initial condition, it is useful to note that it is equivalent to

$$\begin{aligned} \dot{\hat{y}} &= A^*(q)\hat{y} + J(\mathcal{C}^* r), \\ \hat{y}(0) &= 0, \\ y &= J\hat{y}. \end{aligned} \tag{2.9}$$

Here J is the "time reversal" operator on $\mathcal{H}$ defined by

$$(Jf)(t) = f(t_F - t). \tag{2.10}$$

The costate approach to computing $\nabla T(q)$ then consists of the following four steps.

The continuous costate method.

(i) Solve the state equation (2.2) for the state variable $u = u(q)$.

(ii) Compute the residual $r = \mathcal{C}u(q) - z$.

(iii) Solve the costate equation (2.9) for the costate variable y.

(iv) Compute the directional derivatives of T in directions p (cf. (1.5), where $p = \phi_i$) by

$$\delta_p T(q) = \langle\!\langle\, y,\, \delta_p A(q)\; u \,\rangle\!\rangle_{\mathcal{H}}, \tag{2.11}$$

Note that this approach requires the solution of only two evolution equations, the state equation (2.2) and costate equation (2.9), as opposed to the $(n_q + 1)$ evolution equations of (1.5). Moreover, if A is linear in q (as is the case with the approximations of (1.2), for example), then $\delta_p A(q) = A(p)$, so that the implementation of step (iv) is straightforward. Finally, we note that to complete the computation of $\nabla T_\alpha(q)$ it is necessary to compute the gradient $\nabla \mathcal{N}^2(q)$ of the regularization functional, but this is usually trivial.

3. Analysis of discrete approximations.

3.1. The discrete approximations.

Usually in solving (2.2) numerically, we use some sort of finite-difference or time-marching scheme (TMS). In this section, we pose and analyze a rather natural algorithm for computing costate approximations based on a given TMS and the continuous costate method described above.

For a given n, let

$$\mathbf{t}^n = \{t_k^n\}_{k=0}^n, \qquad 0 = t_0^n < t_1^n < \ldots < t_n^n = t_F$$

denote a specified mesh on $[0, t_F]$, and define $h_k \stackrel{\text{def}}{=} t^n_{k+1} - t^n_k$. For later use in the discussions of asymptotic rates of convergence, we define

$$|\mathbf{h}| \stackrel{\text{def}}{=} \max_{0 \leq k \leq n-1} h_k.$$

Also, let $u^n = \{u^n_k\}^n_{k=0}$, where u^n_k is the approximation to the state variable u at t^n_k, which is obtained using a particular TMS with this mesh. If we denote $\{f(t^n_k)\}$ by f^n, then we may express this approximation by

$$u^n(q) \leftarrow \mathrm{TMS}(\mathbf{t}^n, A(q), f^n).$$

This approximation is then used in a minimization scheme for $T_\alpha(q)$ in the parameter estimation problem. Corresponding to the continuous least-squares functional in (2.1), define

$$T^n(q) = \tfrac{1}{2} \| \mathcal{C}^n u^n - z^n \|^2_{\mathcal{Z}^n}. \tag{3.1}$$

Here z^n, $\mathcal{Z}^n$, and $\mathcal{C}^n$ are discretizations of z, $\mathcal{Z}$, and $\mathcal{C}$, which are discussed in detail below. If the minimization scheme requires directional derivatives (i.e., gradients), then a seemingly natural approach ([3, §V.5]), which we call the "discretized costate approximation," based on an obvious discretization of the continuous costate method, suggests itself.

The discretized costate approximation.

(i) Compute $u^n(q)$ by

$$u^n(q) \leftarrow \mathrm{TMS}(\mathbf{t}^n, A(q), f^n).$$

(ii) Compute the residual $r^n = \mathcal{C}^n u^n(q) - z^n$.

(iii) Compute y^n by

$$\begin{aligned} \tilde{\mathbf{t}}^n &\leftarrow J^n(t_F - \mathbf{t}^n), \\ \tilde{y}^n &\leftarrow \mathrm{TMS}(\tilde{\mathbf{t}}^n, A^*(q), J^n(\mathcal{C}^*)^n r^n), \\ y^n &\leftarrow J^n \tilde{y}^n. \end{aligned} \tag{3.2}$$

Here, J^n is the approximation of J (cf. (2.10)) given by

$$[J^n f^n]_k = f^n_{n-k} \tag{3.3}$$

and $(\mathcal{C}^*)^n$ is an approximation to the adjoint of $\mathcal{C} : \mathcal{H} \rightarrow \mathcal{Z}$.

(iv) Approximate directional derivatives in directions p by

$$\delta_p T(q) \approx \widetilde{\delta_p T^n} \stackrel{\text{def}}{=} \langle\!\langle\, y^n, \, (\delta_p A(q))\, u^n(q) \,\rangle\!\rangle_{\mathcal{H}^n}. \tag{3.4}$$

Here, $\langle\!\langle \cdot, \cdot \rangle\!\rangle_{\mathcal{H}^n}$ is a discretization of the continuous inner product (1.3).

The convergence of $\widetilde{\delta_p T^n}$ to $\delta_p T^n$ depends on factors such as the convergence of the time-marching scheme TMS on the forward problem, the convergence of approximations $\mathcal{C}^n$ to the observation operator $\mathcal{C}$, and convergence of the discrete inner products $\langle\!\langle \cdot, \cdot \rangle\!\rangle_{\mathcal{H}^n}$ and $\langle\!\langle \cdot, \cdot \rangle\!\rangle_{\mathcal{Z}^n}$ to the continuous inner products $\langle\!\langle \cdot, \cdot \rangle\!\rangle_{\mathcal{H}}$ and $\langle\!\langle \cdot, \cdot \rangle\!\rangle_{\mathcal{Z}}$, respectively. To carry out a convergence analysis, we first carefully state the discrete version of the problem.

Define $\mathcal{H}^n$ by

$$\mathcal{H}^n = \bigotimes_{k=0}^{n} H.$$

For $f \in C([0,t_F];H)$, we define $P_n f \in \mathcal{H}^n$ by

$$[P_n f]_k = f(t_k^n), \tag{3.5}$$

and for $f^n = \{f_k^n\}_{k=0}^n$ and $g^n = \{g_k^n\}_{k=0}^n$ in $\mathcal{H}^n$, the inner product is

$$\langle\!\langle f^n, g^n \rangle\!\rangle_{\mathcal{H}^n} \overset{\text{def}}{=} \sum_{k=0}^{n} w_k^n \langle f_k^n, g_k^n \rangle_H, \tag{3.6}$$

where $\{w_k^n\}_{k=0}^n$ is a given sequence of weights. The purpose of these weights is to facilitate the definition of $\langle\!\langle \cdot, \cdot \rangle\!\rangle_{\mathcal{H}^n}$ in such a way that it well approximates $\langle\!\langle \cdot, \cdot \rangle\!\rangle_{\mathcal{H}}$. Accordingly, we assume, essentially without loss of generality, that there exists an $M_1 < \infty$ independent of n, for which

$$\sum_{k=0}^{n} w_k^n \leq M_1. \tag{3.7}$$

This forms the basis for the following lemma.

LEMMA 1. *If a sequence $\{f^n\} \in \mathcal{H}^n$ has the property that for some constant $\nu > 0$,*

$$\max_{0 \leq k \leq n} \|f_k^n\|_H = \mathcal{O}(|\mathbf{h}|^\nu),$$

then

$$\|f^n\|_{\mathcal{H}^n} = \mathcal{O}(|\mathbf{h}|^\nu).$$

We also denote by $\langle\!\langle \cdot, \cdot \rangle\!\rangle_{E^n}$ the inner product that, loosely speaking, uses the standard Euclidean inner product for the time component. Specifically,

$$\langle\!\langle f^n, g^n \rangle\!\rangle_{E^n} \overset{\text{def}}{=} \sum_{k=0}^{n-1} \langle f_k^n, g_k^n \rangle_H. \tag{3.8}$$

This inner product will be used below in adjoint computations. The two inner products are related by

$$\begin{aligned} \langle\!\langle f^n, g^n \rangle\!\rangle_{\mathcal{H}^n} &= \langle\!\langle \mathcal{W}^n f^n, g^n \rangle\!\rangle_{E^n} \\ &= \langle\!\langle f^n, \mathcal{W}^n g^n \rangle\!\rangle_{E^n}, \end{aligned} \tag{3.9}$$

where $\mathcal{W}^n$ is the diagonal operator on $\mathcal{H}^n$ defined by

$$[\mathcal{W}^n f]_k = w_k^n f_k^n.$$

We assume that the time-marching scheme TMS is of the form

$$u^n = \mathcal{S}^n(q)\mathcal{R}^n(q) P_n f, \tag{3.10}$$

where $\mathcal{S}^n(q)$ is defined by recursion, for $g \in \mathcal{H}^n$, by

$$\begin{aligned}[][\mathcal{S}^n(q)g]_0 &= 0, \\ [\mathcal{S}^n(q)g]_{k+1} &= B_k(q)[\mathcal{S}^n(q)g]_k + h_k g_k \end{aligned} \tag{3.11}$$

for some bounded operator $B_k(q)$. Expressed in terms of components,

$$u_{k+1}^n = B_k(q)u_k^n + h_k[\mathcal{R}^n(q)P_n f]_k, \qquad k = 0, 1, \ldots, n-1. \tag{3.12}$$

See §4 for specific examples.

We make the following assumptions on the TMS.

(A1) The TMS is *stable* [10], i.e., there exists $M_2 > 0$ such that for $0 \le j \le n$,

$$\|\prod_{k=0}^{j} B_k(q)\| \le M_2.$$

The terms in this product are ordered from left to right with decreasing indices.

(A2) For some constant $\nu > 0$, $B_k(q) = e^{A(q)h_k} + \mathcal{O}(|\mathbf{h}|^{\nu+1})$.

(A3) With ν as in (A2), for any $f \in C^\nu([0, t_F]; H)$ we have

$$[\mathcal{R}^n(q)P_n f]_k = \frac{1}{h_k}\int_0^{h_k} e^{As} f(t_{k+1} - s)\, ds + \mathcal{O}(|\mathbf{h}|^\nu).$$

(A4) In the state equation (2.2), the forcing function f lies in $C^\nu([0, t_F]; H)$.

The following theorem is then readily established.

THEOREM 1. *If* (A1)–(A4) *hold, then*

$$\|u^n(q) - P_n u(q)\|_{\mathcal{H}^n} = \mathcal{O}(|\mathbf{h}|^\nu).$$

Proof. Defining $\varepsilon_k^n \overset{\text{def}}{=} u_k^n(q) - u(t_k^n; q) = u_k^n(q) - [P_n u(q)]_k$ and using (A2)–(A4), (2.2), and (3.12) we obtain

$$\varepsilon_{k+1}^n = B_k(q)\,\varepsilon_k^n + \mathcal{O}(|\mathbf{h}|^{\nu+1}). \tag{3.13}$$

From this we can use (A1) and induction to show that

$$\max_{0 \le k \le n} \|\varepsilon_k^n\|_H \le \mathcal{O}(|\mathbf{h}|^\nu).$$

The theorem now follows from Lemma 1. □

3.2. The rate of convergence of the gradients. We now address the convergence of the (state) directional derivative approximations $\delta_p T^n$ to $\delta_p T$. The results obtained in this subsection will be used later in proving convergence of the discrete costate approximations $\widetilde{\delta_p T^n}$ to $\delta_p T$.

We assume the existence of operators $Q_n : \mathcal{Z} \to \mathcal{Z}^n$, for which

$$z^n = Q_n z. \tag{3.14}$$

Also, note that $\mathcal{C}^n : \mathcal{H}^n \to \mathcal{Z}^n$. We make the following assumptions on the relationships between Q_n, $\mathcal{C}^n$, and the inner product approximations.

(A5) For $\eta, \zeta \in C^\nu([0, t_F]; Z)$, $\langle\!\langle Q_n\eta, Q_n\zeta \rangle\!\rangle_{\mathcal{Z}^n} - \langle\!\langle \eta, \zeta \rangle\!\rangle_{\mathcal{Z}} = \mathcal{O}(|\mathbf{h}|^\nu)$.

(A6) For $v \in C^\nu([0, t_F]; H)$, $\|(\mathcal{C}^n P_n - Q_n \mathcal{C})v\|_{\mathcal{Z}^n} = \mathcal{O}(|\mathbf{h}|^\nu)$.

We now consider the convergence of the directional derivatives. From (2.5) and (3.1),

$$\delta_p T^n(q) - \delta_p T(q) = \langle\!\langle r^n, \mathcal{C}^n \delta_p u^n(q) \rangle\!\rangle_{\mathcal{Z}^n} - \langle\!\langle r, \mathcal{C}\delta_p u(q) \rangle\!\rangle_{\mathcal{Z}} \\ = e_1 + e_2 + e_3, \tag{3.15}$$

where

$$e_1 = \langle\!\langle r^n - Q_n r, \mathcal{C}^n \delta_p u^n(q) \rangle\!\rangle_{\mathcal{Z}^n}, \tag{3.16}$$

$$e_2 = \langle\!\langle Q_n r, \mathcal{C}^n \delta_p u^n(q) - Q_n \mathcal{C}\delta_p u(q) \rangle\!\rangle_{\mathcal{Z}^n}, \tag{3.17}$$

$$e_3 = \langle\!\langle Q_n r, Q_n \mathcal{C}\delta_p u(q) \rangle\!\rangle_{\mathcal{Z}^n} - \langle\!\langle r, \mathcal{C}\delta_p u(q) \rangle\!\rangle_{\mathcal{Z}}. \tag{3.18}$$

If (A6) holds, the rate of convergence of e_1 is directly determined by the rate of convergence of solutions to the forward problem, while that of e_3 is assured under (A5). The rate convergence of e_2 is determined by how fast

$$\|\delta_p u_k^n(q) - P_n \delta_p u(q)\|_{\mathcal{H}^n} \longrightarrow 0.$$

Taking directional derivatives in the component form of the recursion (3.12),

$$\delta_p u_{k+1}^n = B_k(q)\delta_p u_k^n + \big(\delta_p B_k(q)\big) u_k^n + h_k [\delta_p \mathcal{R}^n(q) P_n f]_k. \tag{3.19}$$

On the other hand,

$$u(t_{k+1}^n) = e^{Ah_k} u(t_k^n) + \int_0^{h_k} e^{As} f(t_{k+1}^n - s)\, ds,$$

so taking directional derivatives gives

$$\delta_p u(t_{k+1}^n) = e^{A(q)h_k}\delta_p u(t_k^n) + \left(\delta_p e^{A(q)h_k}\right) u(t_k^n) + \delta_p \int_0^{h_k} e^{A(q)s} f(t_{k+1}^n - s)\, ds. \tag{3.20}$$

Comparing (3.19) and (3.20), one can show the desired convergence provided the directional derivative operator δ_p preserves convergence rates and smoothness in t. More precisely, we assume

(A2′) $\delta_p B_k(q) = \delta_p e^{A(q)h_k} + \mathcal{O}(|\mathbf{h}|^{\nu+1})$.

(A3′) $\delta_p[\mathcal{R}^n(q)P_n f]_k = \frac{1}{h_k}\delta_p \int_0^{h_k} e^{A(q)s} f(t_{k+1} - s)\, ds + \mathcal{O}(|\mathbf{h}|^{\nu})$.

(A4′) If $v(\cdot;q) \in C([0,t_F];H)$, then $\delta_p v(\cdot;q) \in C([0,t_F];H)$.

We then obtain the following analogue of Theorem 1.

THEOREM 2. *If assumptions* (A1)–(A4) *and* (A2′)–(A4′) *hold, then*

$$\|\delta_p u^n(q) - P_n \delta_p u(q)\|_{\mathcal{H}^n} = \mathcal{O}(|\mathbf{h}|^{\nu}).$$

Proof. For notational convenience, we suppress dependence on q. First we show that each $\|\delta_p u_k^n\|_H$ is bounded independently of k or n. Applying (3.19) recursively,

$$\delta_p u_{k+1}^n = \left(\Pi_{j=0}^k B_j\right) \delta_p u_0^n + \sum_{j=0}^{k} \left(\Pi_{i=j+1}^k B_i\right) g_j,$$

where

$$g_j = \delta_p B_j u_j^n + h_j [\delta_p \mathcal{R}^n P_n f]_j.$$

From assumption (A1),

$$\|\delta_p u_{k+1}^n\|_H \le M_2 \left(\|\delta_p u_0^n\|_H + (n+1) \max_{0\le j\le n-1} \|g_j\|_H \right).$$

But for each j, by assumptions (A2$'$)–(A3$'$) and Theorem 1,

$$\begin{aligned}\|g_j\|_H &\le \|\delta_p B_j\| \|u_j^n\|_H + h_j \|[\delta_p \mathcal{R}^n P_n f]_j\|_H \\ &\le h_j \left(\|\delta_p A\| \sup_{0\le t\le t_F} \|u(t)\|_H + \|\frac{1}{h_j}\delta_p \int_0^{h_j} e^{As} f(t_{k+1}-s)\,ds\|_H + \mathcal{O}(|\mathbf{h}|) \right).\end{aligned}$$

The integral term in the above inequality is bounded independently of j as a consequence of assumption (A4$'$).

Next, define $\varepsilon_k^n \overset{\text{def}}{=} \delta_p u_k^n - \delta_p u(t_k^n) = \delta_p u_k^n - [P_n \delta_p u]_k$. Subtracting (3.20) from (3.19);

$$\begin{aligned}\varepsilon_{k+1}^n &= B_k \varepsilon_k^n + (B_k - e^{Ah_k})\delta_p u_k^n + \delta_p B_k(u_k^n - u(t_k^n)) + (\delta_p B_k - \delta_p e^{Ah_k}) u(t_k^n) \\ &\quad + h_k \left(\delta_p [\mathcal{R}^n(q) P_n f]_k - \frac{1}{h_k}\delta_p \int_0^{h_k} e^{As} f(t_{k+1}^n - s)\,ds \right).\end{aligned} \tag{3.21}$$

From the boundedness of the $\delta_p u_k^n$'s, the result of Theorem 1, and the assumptions, all the terms on the right-hand side of this equation are $\mathcal{O}(|\mathbf{h}|^{\nu+1})$, except the first term. Thus this equation has the form (3.13), and the same argument used in the proof of Theorem 1 applies. □

From (3.15) we obtain the following result.

THEOREM 3. *Under assumptions* (A1)–(A6) *and* (A2$'$)–(A4$'$),

$$|\ \delta_p T^n(q) - \delta_p T(q)\ | = \mathcal{O}(|\mathbf{h}|^\nu).$$

Proof. Referring to (3.16), from Schwartz's inequality and the definitions of r, r^n, and z^n,

$$\begin{aligned}|e_1| &\le \|\mathcal{C}^n \delta_p u^n\|_{\mathcal{Z}^n} \|\mathcal{C}^n u^n - Q_n \mathcal{C} u\|_{\mathcal{Z}^n} \\ &\le \|\mathcal{C}^n\| \|\delta_p u^n\|_{\mathcal{H}^n} \left(\|\mathcal{C}^n\| \|u^n - P_n u\|_{\mathcal{H}^n} + \|(\mathcal{C}^n P_n - Q_n \mathcal{C})u\|_{\mathcal{Z}^n} \right).\end{aligned}$$

The first term within the above parentheses is $\mathcal{O}(|\mathbf{h}|^\nu)$ by Theorem 1, while the second is $\mathcal{O}(|\mathbf{h}|^\nu)$ by (A6). The $\|\delta_p u^n\|_{\mathcal{H}^n}$ are bounded by Theorem 2. Consequently, $|e_1| = \mathcal{O}(|\mathbf{h}|^\nu)$.

Similarly, from (3.17), Theorem 2, and assumption (A6),

$$\begin{aligned}|e_2| &\le \left(\|Q_n \mathcal{C} u\|_{\mathcal{Z}^n} + \|z^n\|_{\mathcal{Z}^n} \right) \left(\|\mathcal{C}^n\| \|\delta_p u^n - P_n \delta_p u\|_{\mathcal{H}^n} + \|(\mathcal{C}^n P_n - Q_n \mathcal{C})\delta_p u\|_{\mathcal{Z}^n} \right) \\ &= \mathcal{O}(|\mathbf{h}|^\nu).\end{aligned}$$

Finally, from (3.18) and (A5), $|e_3| = \mathcal{O}(|\mathbf{h}|^\nu)$. □

3.3. Continuous-time versus discrete-time observations.

In the following subsection we analyze the convergence of the costate approximations. In this subsection, we make some preliminary considerations toward that end, leading to a specification of two distinct classes of observation operators $\mathcal{C}$.

For brevity of notation, we set

$$\begin{aligned} \phi &\overset{\text{def}}{=} (\delta_p A)u \in \mathcal{H}, \\ \phi^n &\overset{\text{def}}{=} (\delta_p A)u^n \in \mathcal{H}^n. \end{aligned} \tag{3.22}$$

From (2.11) and (3.4) we obtain

$$\begin{aligned} \widetilde{\delta_p T^n} - \delta_p T &= \langle\!\langle y^n, \phi^n - P_n\phi \rangle\!\rangle_{\mathcal{H}^n} + \Big(\langle\!\langle y^n, P_n\phi \rangle\!\rangle_{\mathcal{H}^n} - \langle\!\langle y, \phi \rangle\!\rangle_{\mathcal{H}} \Big) \\ &\overset{\text{def}}{=} E_1 + E_2. \end{aligned} \tag{3.23}$$

As a consequence of Theorem 1, the boundedness of $\delta_p A$, and the fact that operators $\delta_p A$ and P_n commute, we have

$$\|\phi^n - P_n\phi\|_{\mathcal{H}^n} = \mathcal{O}(|\mathbf{h}|^\nu). \tag{3.24}$$

If the sequence $\{\|y^n\|_{\mathcal{H}^n}\}$ is bounded, then Schwartz's inequality and (3.24) imply that $|E_1| = \mathcal{O}(|\mathbf{h}|^\nu)$. But $\{\|y^n\|_{\mathcal{H}^n}\}$ is bounded if $|E_2| \to 0$. Hence, the rate of convergence of the costate approximations to the directional derivatives depends on the rate at which $E_2 \to 0$.

From (2.9) we see that

$$y = J\mathcal{S}_{(*)}J\mathcal{C}^* r, \tag{3.25}$$

where the operator $\mathcal{S}_{(*)} : \mathcal{H} \to \mathcal{H}$ has a representation

$$(\mathcal{S}_{(*)}g)(t) = \int_0^t e^{A(q)^* s} g(t-s)\, ds.$$

Similarly, from (3.2)

$$y^n = J^n \mathcal{S}^n_{(*)} \mathcal{R}^n_{(*)} J^n (\mathcal{C}^*)^n r^n. \tag{3.26}$$

Here, $\mathcal{S}^n_{(*)}$ and $\mathcal{R}^n_{(*)}$ are the operators that are obtained if A is replaced by $A^*(q)$ in the formation of $\mathcal{S}^n$ and $\mathcal{R}^n$; cf. (3.10), (3.11). The operator $(\mathcal{C}^*)^n : \mathcal{Z}^n \to \mathcal{H}^n$ is an approximation to the adjoint of $\mathcal{C} : \mathcal{H} \to \mathcal{Z}$. For now we select $(\mathcal{C}^*)^n = (\mathcal{C}^n)^*$, the adjoint of the operator $\mathcal{C}^n : \mathcal{H}^n \to \mathcal{Z}^n$. A different choice might be made on the basis of the discussion in §5.

Since the costate vector y is given in terms of an evolution equation with $\mathcal{C}^* r$ as the source term (and a similar statement is true for the approximations), we find it convenient to specify $\mathcal{C}$ further. This facilitates analysis of the convergence of $|E_2|$. It commonly happens in applications that $\mathcal{C}$ inherits a type of tensor-product structure from the state space $\mathcal{H} = L^2(0, t_F; H)$. In particular, we assume the existence of a bounded "spatial observation operator"

$$C : H \mapsto Z, \tag{3.27}$$

where Z is a Hilbert space related to $\mathcal{Z}$ as described below. We distinguish two cases that are of practical importance.

3.3.1. Observations continuous in time. In this first case, the observation operator $\mathcal{C}$ is "continuous in time." It is defined in terms of a space Z and a bounded operator $C : H \mapsto Z$ that acts at each t by

$$(\mathcal{C}u)(t) = Cu(\cdot, t) \in Z, \qquad 0 \le t \le t_F.$$

In this case,

$$\mathcal{Z} = C\big((0,t_F);Z\big), \qquad \mathcal{Z}^n = \bigotimes_{k=0}^{n} Z,$$

and $\mathcal{C}^n : \mathcal{H}^n \to \mathcal{Z}^n$ is defined by

$$[\mathcal{C}^n f^n]_k = C f_k^n, \qquad k = 0,1,\dots,n. \tag{3.28}$$

In addition, we define Q_n and the inner product approximation in a manner analogous to (3.5) and (3.6):

$$[Q_n \zeta]_k = \zeta(t_k^n), \qquad k = 0,1,\dots,n,$$

and

$$\langle\!\langle \eta^n, \zeta^n \rangle\!\rangle_{\mathcal{Z}^n} = \sum_{k=0}^{n} w_k^n \langle \eta_k^n, \zeta_k^n \rangle_Z.$$

Note that in this case, the validity of assumption (A5) is determined by the quadrature weights w_k^n, which also determine the accuracy by which $\langle\!\langle \cdot,\cdot \rangle\!\rangle_{\mathcal{H}^n}$ approximates $\langle\!\langle \cdot,\cdot \rangle\!\rangle_{\mathcal{H}}$. Assumption (A6) is trivially satisfied in this case since $\mathcal{C}^n P_n = Q_n \mathcal{C}$.

From (3.28) and the definition of the adjoint,

$$\begin{aligned} [\mathcal{C}^* r](t) &= C^* r(t), \qquad 0 \le t \le t_F, \\ [(\mathcal{C}^n)^* r^n]_k &= C^* r_k^n, \qquad 0 \le k \le n. \end{aligned}$$

The residuals r and r^n appearing here are given by

$$\begin{aligned} r(t) &= Cu(t) - z(t), \\ r_k^n &= Cu_k^n - z(t_k^n). \end{aligned}$$

3.3.2. Observations discrete in time. In the second case we assume that the observation operator $\mathcal{C}$ consists of some spatial observations taken at m discrete points τ_i, $i = 1,\dots,m$ in time. Accordingly, we assume a discrete observation space $\mathcal{Z}$ of the form

$$\mathcal{Z} = \bigotimes_{i=1}^{m} Z.$$

For simplicity we assume that, given the set of temporal observation points $\{\tau_i\}$, the time-marching grid $\mathbf{t}^n$ is always chosen so that $\{\tau_i\} \subset \mathbf{t}^n$, so that there is always an injective map

$$\kappa : \{1,2,\dots,m\} \mapsto \{0,1,2,\dots,n\}$$

such that for $f \in C((0,t_F];H) \subset \mathcal{H}$ and $f^n \in \mathcal{H}^n$,

$$[\mathcal{C}f]_i \overset{\text{def}}{=} Cf(t_{\kappa(i)}^n), \tag{3.29}$$

$$[\mathcal{C}^n f^n]_i \overset{\text{def}}{=} Cf_{\kappa(i)}^n. \tag{3.30}$$

In this case, since the observation space is already discrete, we define

$$\mathcal{Z}^n = \mathcal{Z}, \quad Q_n = I = \text{ the identity on } \mathcal{Z}, \tag{3.31}$$

and

$$\langle\!\langle \eta, \zeta \rangle\!\rangle_{\mathcal{Z}^n} = \langle\!\langle \eta, \zeta \rangle\!\rangle_{\mathcal{Z}} = \sum_{i=1}^{m} \langle \eta_i, \zeta_i \rangle_Z.$$

In this case, assumption (A5) is always true since $\mathcal{Z}^n = \mathcal{Z}$. Also, (A6) is always true since, as in the continuous-time observation case, $\mathcal{C}^n P_n = Q_n \mathcal{C}$. (This is true since we have assumed that $\{\tau_i\} \subset \mathbf{t}^n$.)

From (3.29) and the definition of the adjoint, we find that $\mathcal{C}^* : \mathcal{Z} \mapsto \mathcal{H}$ is given, for $r = \{r_i\}_{i=1}^m \in \mathcal{Z}$, by

$$[\mathcal{C}^* r](t) = \sum_{i=1}^{m} C^* r_i \, \delta(t - \tau_i), \qquad 0 \leq t \leq t_F, \tag{3.32}$$

where $\delta(\cdot)$ denotes the Dirac delta function. The discrete analogue of (3.32) is

$$[(\mathcal{C}^*)^n r]_k = [(\mathcal{C}^n)^* r]_k = \sum_{i=1}^{m} \frac{1}{w_k} C^* r_i \delta_{\kappa(i),k}, \qquad 0 \leq k \leq n,$$

where $\delta_{\kappa,k}$ denotes the Kronecker delta function for integer pairs.

3.4. The rate of convergence of the costate approximations. As discussed in §3.3, immediately following (3.23), it suffices to consider the convergence of the term $|E_2|$ to zero. We address the simple case, that of continuous-time observations, first. In this case, νth-order convergence of E_2 results if the observed data z is smooth enough.

THEOREM 4. *If* (A1)–(A6) *and* (A2′)–(A4′) *hold and if the data z lies in* $C^\nu([0, t_F]; Z)$, *then*

$$\|y^n - P_n y\|_{\mathcal{H}^n} = \mathcal{O}(|\mathbf{h}|^\nu). \tag{3.33}$$

Proof. From (3.25) and (3.25),

$$\begin{aligned} \|y^n - P_n y\|_{\mathcal{H}^n} \leq{}& \|J^n\| \|\mathcal{S}^n_{(*)} \mathcal{R}^n_{(*)}\| \|J^n (\mathcal{C}^n)^* r^n - P_n J \mathcal{C}^* r\|_{\mathcal{H}^n} \\ &+ \|(J^n \mathcal{S}^n_{(*)} \mathcal{R}^n_{(*)} P_n - P_n J \mathcal{S}_{(*)}) J \mathcal{C}^* r\|_{\mathcal{H}^n}. \end{aligned} \tag{3.34}$$

Note that J, $\mathcal{C}$, and $\mathcal{C}^*$ each preserve smoothness with respect to t. From the smoothness of z and the smoothness of u (which follows from (A4)), $J\mathcal{C}^* r \in C^{\nu+1}([0, t_F]; H)$. Applying Theorem 1 with $J\mathcal{C}^* r$ in place of the forcing function f and A^* in place of A, and noting that

$$P_n J = J^n P_n, \tag{3.35}$$

$$\|J^n\| = 1, \tag{3.36}$$

the last term in (3.34) is $\mathcal{O}(|\mathbf{h}|^\nu)$. Also, by (A1) and (A3), $\|\mathcal{S}^n_{(*)} \mathcal{R}^n_{(*)}\|$ is bounded independently of n. From (3.35) and (3.36), it suffices to show

$$\|(\mathcal{C}^n)^* r^n - P_n \mathcal{C}^* r\|_{\mathcal{H}^n} = \mathcal{O}(|\mathbf{h}|^\nu).$$

However, $[(C^n)^* r^n]_k - [P_n C^* r]_k = C^*C(u_k^n - u(t_k^n))$, so this follows from Theorem 1 and the boundedness of C and C^*. □

With the result of this theorem and an assumption that the quadrature weights are chosen correctly (cf. (3.6)), we obtain costate convergence.

COROLLARY 1. *If the hypotheses of Theorem* 4 *hold and if*

$$|\langle\!\langle P_n g_1, P_n g_2 \rangle\!\rangle_{\mathcal{H}^n} - \langle\!\langle g_1, g_2 \rangle\!\rangle_{\mathcal{H}}| = \mathcal{O}(|\mathbf{h}|^\nu), \tag{3.37}$$

for any g_1 *and* g_2 *in* $C^\nu([0, t_f]; H)$, *then*

$$|\widetilde{\delta_p T^n} - \delta_p T| = \mathcal{O}(|\mathbf{h}|^\nu).$$

Proof. Theorem 4 implies that the sequence $\{\|y^n\|_{\mathcal{H}^n}\}$ is bounded. From the discussion immediately following (3.23), it suffices to show that $E_2 = \mathcal{O}(|\mathbf{h}|^\nu)$. However,

$$\begin{aligned} |E_2| &= |\langle\!\langle y^n, P_n\phi \rangle\!\rangle_{\mathcal{H}^n} - \langle\!\langle y, \phi \rangle\!\rangle_{\mathcal{H}}| \\ &\leq \|y^n - P_n y\|_{\mathcal{H}^n} \|P_n \phi\|_{\mathcal{H}^n} \\ &\quad + |\langle\!\langle P_n y, P_n \phi \rangle\!\rangle_{\mathcal{H}^n} - \langle\!\langle y, \phi \rangle\!\rangle_{\mathcal{H}}|. \end{aligned}$$

The first term is $\mathcal{O}(|\mathbf{h}|^\nu)$ by Theorem 4. Since y and ϕ are sufficiently smooth, the second term is $\mathcal{O}(|\mathbf{h}|^\nu)$ by (3.37). □

We next address the case of discrete-time observations. In this case, $\mathcal{C}^* r$ is given by a linear combination of Dirac delta functions, i.e., (3.32). Since this is the forcing term in the costate equation, the question of how fast (if at all) $\widetilde{\delta_p T^n} \to \delta_p T$ is rather delicate. In particular, the smoothness of $\mathcal{C}^* r$ played a crucial role in the proof of Theorem 4. However, in the present case, $\mathcal{C}^* r$ is not smooth at all; it only exists as a distribution. Thus the proof of Theorem 4 (and hence, Corollary 1) is not valid in this case.

On the other hand, the convergence in (3.33) is stronger than what is actually needed. It is essentially a statement of *strong*, or pointwise, convergence in $\mathcal{H}$. From (3.23), we see that a sort of weak* convergence would be sufficient. Rewriting E_2 as

$$E_2 = \langle\!\langle P_n^* y^n - y, \phi \rangle\!\rangle_{\mathcal{H}} \tag{3.38}$$

and noting that $\phi \in C^{\nu+1}([0, t_F]; H)$, we need only establish νth-order weak* convergence of $P_n^* y$ to y in the dual space of $C^{\nu+1}([0, t_F]; H)$.

There are seemingly natural situations in which this weak* convergence does not apply, and a number of subtleties arise in our exploration of these matters. These will be discussed shortly. There is, however, one class of problems that we fully analyze here. It covers a variety of second-order methods with uniform meshes $\mathbf{t}^n$.

THEOREM 5. *Assume that*

(a) *Assumptions* (A1)–(A4) *hold*;

(b) *In* (A2)–(A4) *we have* $\nu = 2$;

(c) *The observation points* τ_i *all lie in the interior of* $(0, t_F)$.

(d) *The partition* $\mathbf{t}^n$ *is uniform, in the sense that* $h_k = h \overset{\text{def}}{=} t_F/n$ *for* $1 \leq k \leq n$;

(e) *The quadrature weights* w_k *in equation* (3.6) *are given by* $w_0 = h/2 = w_n$ *and* $w_k = h$ *for* $1 \leq k \leq n-1$ (*note that these weights correspond to the "trapezoid rule" for numerical quadrature*);

(f) *The operators* B_k *in terms of which* $\mathcal{S}^n$ *is defined* (*cf.* (3.11)) *are the same for all* k; *there is an operator* B *for which*

$$B_k = B, \qquad 0 \le k \le n-1; \tag{3.39}$$

(g) *The operator* $\mathcal{R}^n$ *may be written, for* $g \in \mathcal{H}^n$, *as*

$$[\mathcal{R}^n g]_k = R_0 g_k + R_1 g_{k+1}, \qquad 0 \le k \le n-1, \tag{3.40}$$

$$[\mathcal{R}^n g]_n = R_0 g_n. \tag{3.41}$$

(*Note from* (3.11) *that the last component,* $[\mathcal{R}^n f]_n$, *plays no role in the* TMS. *Our purpose in defining it this way here will become clear below.*)

(h) *The operators* B, R_0, *and* R_1 *are all rational functions of* $A(q)$.

Then

$$|\widetilde{\delta_p T^n} - \delta_p T| = \mathcal{O}(h^2).$$

Proof. As in Corollary 1, it suffices to show $|E_2| = \mathcal{O}(h^2)$. This leads us to the study of $\langle\!\langle\, y^n, P_n\phi \,\rangle\!\rangle_{\mathcal{H}^n}$. From (3.26), we see that

$$\langle\!\langle\, y^n, P_n\phi \,\rangle\!\rangle_{\mathcal{H}^n} = \langle\!\langle\, J^n \mathcal{S}^n_{(*)} \mathcal{R}^n_{(*)} J^n (\mathcal{C}^*)^n r^n,\ P_n\phi \,\rangle\!\rangle_{\mathcal{H}^n}. \tag{3.42}$$

We take adjoints in the inner product on the right-hand side of this equation, and the main effort in this proof lies in the subsequent simplification. In particular, our goal is to show that

$$\langle\!\langle\, J^n \mathcal{S}^n_{(*)} \mathcal{R}^n_{(*)} J^n (\mathcal{C}^*)^n r^n,\ P_n\phi \,\rangle\!\rangle_{\mathcal{H}^n} = \langle\!\langle\, r^n, \mathcal{C}^n \mathcal{S}^n \mathcal{R}^n P_n\phi \,\rangle\!\rangle_{\mathcal{Z}}. \tag{3.43}$$

We now proceed with the details. First note from (3.9) that

$$\langle\!\langle\, y^n, P_n\phi \,\rangle\!\rangle_{\mathcal{H}^n} = \langle\!\langle\, \mathcal{W}^n y^n, P_n\phi \,\rangle\!\rangle_{E^n}.$$

However, since $[P_n\phi]_0 = \phi(0) = 0$ and $[y^n]_n = 0$, from Theorem 5(e) we obtain

$$\langle\!\langle\, y^n, P_n\phi \,\rangle\!\rangle_{\mathcal{H}^n} = h\langle\!\langle\, y^n, P_n\phi \,\rangle\!\rangle_{E^n}. \tag{3.44}$$

Referring to (3.42) and (3.44) and noting that $J^n J^n$ equals the identity, we obtain

$$\begin{aligned}
\langle\!\langle\, y^n, P_n\phi \,\rangle\!\rangle_{\mathcal{H}^n} &= h\langle\!\langle\, \left(J^n \mathcal{S}^n_{(*)} J^n\right) \left(J^n \mathcal{R}^n_{(*)} J^n\right) (\mathcal{C}^n)^* r^n,\ P_n\phi \,\rangle\!\rangle_{E^n} \\
&= h\langle\!\langle\, (\mathcal{C}^n)^* r^n,\ \left(J^n \mathcal{R}^n_{(*)} J^n\right)^T \left(J^n \mathcal{S}^n_{(*)} J^n\right)^T P_n\phi \,\rangle\!\rangle_{E^n} \\
&= h\langle\!\langle\, (\mathcal{C}^n)^* r^n,\ \left(J^n (\mathcal{R}^n_{(*)})^T J^n\right) \left(J^n (\mathcal{S}^n_{(*)})^T J^n\right) P_n\phi \,\rangle\!\rangle_{E^n},
\end{aligned} \tag{3.45}$$

where $\cdot^T$ denotes the adjoint with respect to the E^n-inner product defined in (3.9). We have used here the fact that J^n is self-adjoint with respect to $\langle\!\langle\, \cdot, \cdot \,\rangle\!\rangle_{E^n}$.

Next we assert that

$$J^n (\mathcal{S}^n_{(*)})^T J^n = \mathcal{S}^n, \tag{3.46}$$

$$J^n (\mathcal{R}^n_{(*)})^T J^n = \mathcal{R}^n. \tag{3.47}$$

From (3.11), (3.39), and (3.40), the operators $\mathcal{S}^n$ and $\mathcal{R}^n$ have the following block Toeplitz matrix representations:

$$\mathcal{S}^n = h\begin{pmatrix} 0 & 0 & 0 & \cdots & 0 & 0 & 0 & 0 \\ I & 0 & 0 & \cdots & 0 & 0 & 0 & 0 \\ B & I & 0 & \cdots & 0 & 0 & 0 & 0 \\ B^2 & B & I & \ddots & 0 & 0 & 0 & 0 \\ B^3 & B^2 & B & \ddots & 0 & 0 & 0 & 0 \\ \vdots & \vdots & \ddots & \ddots & \ddots & \ddots & \ddots & \vdots \\ B^{n-2} & B^{n-3} & B^{n-4} & \ddots & B & I & 0 & 0 \\ B^{n-1} & B^{n-2} & B^{n-3} & \cdots & B^2 & B & I & 0 \end{pmatrix} \tag{3.48}$$

and

$$\mathcal{R}^n = \begin{pmatrix} R_0 & R_1 & 0 & \cdots & 0 & 0 & 0 \\ 0 & R_0 & R_1 & \ddots & 0 & 0 & 0 \\ \vdots & \ddots & \ddots & \ddots & \ddots & \vdots & \vdots \\ 0 & 0 & 0 & \ddots & R_0 & R_1 & 0 \\ 0 & 0 & 0 & \ddots & 0 & R_0 & R_1 \\ 0 & 0 & 0 & 0 & 0 & 0 & R_0 \end{pmatrix}. \tag{3.49}$$

The blocks are operators on H. The operators $\mathcal{S}^n_{(*)}$ and $\mathcal{R}^n_{(*)}$ have an identical block Toeplitz form, except B, R_0, and R_1 are replaced by their H-adjoints. From consideration of these block matrix representations, the action of J^n, and the E^n-adjoint, we can verify that (3.46) and (3.47) hold. Thus (3.45) simplifies to

$$\langle\!\langle y^n, P_n\phi \rangle\!\rangle_{\mathcal{H}^n} = h\langle\!\langle (\mathcal{C}^n)^* r^n,\ \mathcal{R}^n\mathcal{S}^n P_n\phi \rangle\!\rangle_{E^n}. \tag{3.50}$$

Thus the question arises as to how much $\mathcal{S}^n\mathcal{R}^n$ and $\mathcal{R}^n\mathcal{S}^n$ differ. Since B, R_0, and R_1 are rational functions of $A(q)$, they commute with each other. This and computations based directly on (3.11) and (3.40) reveal that, for arbitrary $g \in \mathcal{H}^n$,

$$\frac{1}{h}[\mathcal{S}^n\mathcal{R}^n g]_k = (R_0 + BR_1)\Big(\sum_{j=1}^{k-1} B^{k-1-j} g_j\Big) + R_0 B^{k-1} g_0 + R_1 g_k$$
$$\text{for } 0 \le k \le n,$$
$$\frac{1}{h}[\mathcal{R}^n\mathcal{S}^n g]_k = (R_0 + BR_1)\Big(\sum_{j=1}^{k-1} B^{k-1-j} g_j\Big) + (R_0 + BR_1)B^{k-1} g_0 + R_1 g_k$$
$$\text{for } 0 \le k \le n-1,$$
$$\frac{1}{h}[\mathcal{R}^n\mathcal{S}^n g]_n = R_0\Big(\sum_{j=1}^{n-1} B^{n-1-j} g_j\Big) + R_0 B^{n-1} g_0.$$

These results may also be obtained directly from the matrix representations (3.48) and (3.49). Thus the commutator $\mathcal{E}^n \overset{\text{def}}{=} \mathcal{S}^n\mathcal{R}^n - \mathcal{R}^n\mathcal{S}^n$ is given by

$$[\mathcal{E}^n g]_k = hR_1 \begin{cases} -B^k g_0 & \text{for } 0 \le k \le n-1, \\ \sum_{j=1}^{n-1} B^{n-j} g_j & \text{for } k = n. \end{cases} \tag{3.51}$$

Equation (3.51) holds for any $g \in \mathcal{H}^n$. In the case of present interest, namely (3.50), the role of g is played by $P_n\phi$, and $[P_n\phi]_0 = 0$. Thus from (3.50) and (3.51), we have

$$\langle\!\langle y^n, P_n\phi \rangle\!\rangle_{\mathcal{H}^n} = h\langle\!\langle (\mathcal{C}^n)^* r^n, \mathcal{S}^n\mathcal{R}^n P_n\phi \rangle\!\rangle_{E^n} - h^2\Big\langle [(\mathcal{C}^n)^* r^n]_n, R_1 \sum_{j=1}^{n-1} B^{n-j}\phi(t_j) \Big\rangle_H. \tag{3.52}$$

However, the observation points τ_i are all less than t_F and yet occur at mesh points—see the discussion leading up to (3.30). Thus $[(\mathcal{C}^n)^* r^n]_n = 0$, and the last term in this equation drops out. Also, since $[\mathcal{S}^n\mathcal{R}^n P_n\phi]_0 = 0$ and $[(\mathcal{C}^n)^* r^n]_n = 0$, we obtain from Theorem 5(e)

$$\begin{aligned} \langle\!\langle y^n, P_n\phi \rangle\!\rangle_{\mathcal{H}^n} &= \langle\!\langle (\mathcal{C}^n)^* r^n, \mathcal{W}^n\mathcal{S}^n\mathcal{R}^n P_n\phi \rangle\!\rangle_{E^n} \\ &= \langle\!\langle (\mathcal{C}^n)^* r^n, \mathcal{S}^n\mathcal{R}^n P_n\phi \rangle\!\rangle_{\mathcal{H}^n} \\ &= \langle\!\langle r^n, \mathcal{C}^n\mathcal{S}^n\mathcal{R}^n P_n\phi \rangle\!\rangle_{\mathcal{Z}}. \end{aligned} \tag{3.53}$$

Combining this with (3.42) yields (3.43).

Now, $\|r^n - r\|_{\mathcal{Z}} = \mathcal{O}(|\mathbf{h}|^2)$ by Theorem 1. By reasoning similar to that in the proof of Theorem 1, since ϕ is smooth, we also have $\|\mathcal{S}^n\mathcal{R}^n P_n\phi - P_n\mathcal{S}\phi\|_{\mathcal{H}^n} = \mathcal{O}(|\mathbf{h}|^2)$. Consequently, the right-hand side of (3.43) may be replaced by $\langle\!\langle r, \mathcal{C}^n P_n\mathcal{S}\phi \rangle\!\rangle_{\mathcal{Z}}$ to within second order. Using this, the definition of E_2 in (3.23), and the fact that $\langle\!\langle y, \phi \rangle\!\rangle_{\mathcal{H}} = \langle\!\langle r, \mathcal{C}\mathcal{S}\phi \rangle\!\rangle_{\mathcal{H}^n}$, we find that

$$E_2 = \langle\!\langle r, \mathcal{C}^n P_n\mathcal{S}\phi \rangle\!\rangle_{\mathcal{Z}} - \langle\!\langle r, \mathcal{C}\mathcal{S}\phi \rangle\!\rangle_{\mathcal{Z}} + \mathcal{O}(|\mathbf{h}|^2).$$

Now the result follows from assumption (A6). □

A result similar to Theorem 5 can be obtained for certain fourth-order methods (including Runge–Kutta) on a uniform mesh, provided that the forcing function f is zero at $t = 0$ and provided that appropriate quadrature weights are chosen. Surprisingly, these weights correspond to *second-order* quadrature rather than fourth-order quadrature.

THEOREM 6. *Assume that the forcing term f satisfies $f(0) = 0$, and that*

(a) *Same as Theorem* 5(a).

(b) *In* (A2)–(A4) *we have $\nu = 4$;*

(c) *Same as Theorem* 5(c).

(d) *Same as Theorem* 5(d).

(e) *Same as Theorem* 5(e).

(f) *Same as Theorem* 5(f).

(g) *The operator $\mathcal{R}^n$ may be written, for $g \in \mathcal{H}^n$ and $1 \le k \le n-2$, as*

$$[\mathcal{R}^n g]_k = R_{-1}g_{k-1} + R_0 g_k + R_1 g_{k+1} + R_2 g_{k+2}$$

with $R_{-1} = R_2 + \mathcal{O}(h)$.

(h) *Same as Theorem* 5(h).

Then,

$$|\widetilde{\delta_p T^n} - \delta_p T| = \mathcal{O}(h^4).$$

Proof. For given $g \in \mathcal{H}^n$, $[\mathcal{R}^n g]$ is defined for all $k > 0$ but $[\mathcal{R}^n g]_0$ is unspecified. Define $\widetilde{\mathcal{R}}^n$ by

$$[\widetilde{\mathcal{R}}^n g]_k = \begin{cases} R_0 g_0 + R_1 g_1 + R_2 g_2 & \text{for } k = 0, \\ [\mathcal{R}^n g]_k & \text{for } 1 \le k \le n-2, \\ R_{-1} g_{n-2} + R_0 g_{n-1} + R_1 g_n & \text{for } k = n-1, \\ R_{-1} g_{n-1} + R_0 g_n & \text{for } k = n. \end{cases} \tag{3.54}$$

Note that $\widetilde{\mathcal{R}}^n \neq \mathcal{R}^n$ (because (A3) is satisfied by $\mathcal{R}^n$ and not necessarily by $\widetilde{\mathcal{R}}^n$), but that $(\widetilde{\mathcal{R}}^n - \mathcal{R}^n)(\mathcal{C}^n)^* r^n = 0$ in $\mathcal{H}^n$ by (c). Therefore we may replace $\mathcal{R}^n$ by $\widetilde{\mathcal{R}}^n$ in (3.26). Since the block matrix representation of $\widetilde{\mathcal{R}}^n$ is Toeplitz, by following reasoning similar to that leading to (3.50) in the proof of Theorem 5 we obtain

$$\langle\langle y^n, P_n\phi \rangle\rangle_{\mathcal{H}^n} = h\langle\langle (\mathcal{C}^n)^* r^n, \widetilde{\mathcal{R}}^n \mathcal{S}^n P_n \phi \rangle\rangle_{E^n}. \tag{3.55}$$

As in the proof of Theorem 5, we now consider the extent to which $\widetilde{\mathcal{R}}^n$ and $\mathcal{S}^n$ fail to commute. Our goal here is to show that $\mathcal{E}^n P_n \phi = \mathcal{O}(h^4)$, where

$$\mathcal{E}^n \stackrel{\text{def}}{=} \widetilde{\mathcal{R}}^n \mathcal{S}^n - \mathcal{S}^n \mathcal{R}^n.$$

Then we may invoke reasoning similar to that in and following (3.52). With

$$\widetilde{\mathcal{E}^n} \stackrel{\text{def}}{=} \widetilde{\mathcal{R}}^n \mathcal{S}^n - \mathcal{S}^n \widetilde{\mathcal{R}}^n,$$

we have

$$\mathcal{E}^n = \widetilde{\mathcal{E}^n} + \mathcal{S}^n(\widetilde{\mathcal{R}}^n - \mathcal{R}^n). \tag{3.56}$$

From (3.11), (3.54), and the fact that $\phi(0) = 0$, we find after lengthy but straightforward computations that for $0 \le k \le n-2$

$$[\widetilde{\mathcal{E}^n} P_n \phi]_k = h B^k R_2 \phi(t_1^n). \tag{3.57}$$

Also, from the definitions of $\mathcal{S}^n$, $\mathcal{R}^n$ and $\widetilde{\mathcal{R}}^n$ and from (A3), we find that for $1 \le k \le n$,

$$\begin{aligned}\left[\mathcal{S}^n(\widetilde{\mathcal{R}}^n - \mathcal{R}^n)P_n\phi\right]_k = hB^{k-1}\big(&R_1\phi(t_1^n) + R_2\phi(t_2^n) \\ &-\frac{1}{h}\int_0^h e^{As}\phi(t_1^n - s)\,ds\big) + \mathcal{O}(h^4).\end{aligned}$$

Substituting these into (3.56) yields, for $0 \le k \le n-2$,

$$\begin{aligned}[\mathcal{E}^n P_n\phi]_k = hB^{k-1}\Big[&(BR_2 + R_1)\phi(t_1^n) + R_2\phi(t_2^n) \\ &-\frac{1}{h}\int_0^h e^{As}\phi(t_1^n - s)\,ds + \mathcal{O}(h^4)\Big].\end{aligned} \tag{3.58}$$

The integral term in this equation is approximated to within fourth-order accuracy if we replace $\phi(t)$ with its second-order Taylor polynomial $\pi(t)$ about $t = 0$ (this follows by arguments used to show fourth-order convergence of Simpson's rule):

$$\frac{1}{h}\int_0^h e^{As}\phi(t_1^n - s)\,ds = \frac{1}{h}\int_0^h e^{As}\pi(t_1^n - s)\,ds + \mathcal{O}(h^4).$$

Now, $\pi(t)$ can be evaluated at $t_i^n = ih$ for $i = -1, \dots, 2$, so that we can use assumption (A3) to make the substitution

$$\frac{1}{h}\int_0^h e^{As}\phi(t_1^n - s)\,ds = R_{-1}\pi(-h) + R_0\pi(0) + R_1\pi(h) + R_2\pi(2h).$$

However, $f(0) = 0$ by hypothesis, so that $u'(0) = 0 = \phi'(0)$, which means that $\pi(t) = t^2\phi''(0)/2$. Thus

$$\frac{1}{h}\int_0^h e^{As}\phi(t_1^n - s)\,ds = \frac{h^2}{2}(\,R_{-1} + R_1 + 4R_2\,)\phi''(0) + \mathcal{O}(h^4).$$

Also, $\phi(t_1^n)$ and $\phi(t_2^n)$ can be replaced by $\pi(t_1^n)$, and $\pi(t_2^n)$, respectively, to within third-order accuracy in (3.58). This yields

$$[\mathcal{E}^n P_n\phi]_k = \frac{h^3}{2}B^{k-1}(BR_2 - R_{-1})\phi''(0) + \mathcal{O}(h^4).$$

However, $BR_2 = R_{-1} + \mathcal{O}(h)$ by Theorem 6(g) and the fact that $B = I + \mathcal{O}(h)$ (which is true by (A2)). Thus we arrive at

$$[\mathcal{E}^n P_n\phi]_k = \frac{h^4}{2}B^{k-1}\phi''(0) + \mathcal{O}(h^4),$$

and so we have shown that for $1 \le k \le n-2$,

$$[\widetilde{\mathcal{R}}^n\mathcal{S}^n P_n\phi]_k = [\mathcal{S}^n\mathcal{R}^n P_n\phi]_k + \mathcal{O}(h^4). \tag{3.59}$$

Using this, (3.55), and reasoning similar to that in (3.53) we obtain

$$\begin{aligned}\langle\!\langle\, y^n, P_n\phi \,\rangle\!\rangle_{\mathcal{H}^n} &= \langle\!\langle\, r, \mathcal{S}\phi \,\rangle\!\rangle_{\mathcal{Z}} + \mathcal{O}(h^4)\\ &= \langle\!\langle\, y, \phi \,\rangle\!\rangle_{\mathcal{H}^n} + \mathcal{O}(h^4). \qquad \square\end{aligned}$$

It is also natural to ask what happens if we use a fourth-order TMS with a fourth-order quadrature scheme, such as Simpson's rule. We show that the gradient approximations thus computed fail to converge, although their *directions* in the space $\mathcal{Q}$ converge. In particular, the RK4/Simpson costate approximations converge quadratically to (3/2) times the true gradient.

COROLLARY 2. *Assume that all of the hypotheses of Theorem* 6 *hold except* (e), *and assume further that*

(e′) *The quadrature weights are those arising from Simpson's rule, so that*

$$\mathcal{W}^n = \mathcal{W}^n_{\text{Simp}} \overset{\text{def}}{=} \frac{h}{3}\,\text{diag}(1, 4, 2, \dots, 2, 4, 1). \tag{3.60}$$

(i) *The limit $n \to \infty$ is taken by repeated doubling of n. Precisely, there is an integer n_0 such that each n equals $n_0 2^l$ for some positive integer l.*

Then,

$$|\widetilde{\delta_p T^n} - (3/2)\delta_p T| = \mathcal{O}(h^2).$$

By arguments similar to those used to obtain (3.55), we find that

$$\langle\!\langle\, y^n, P_n\phi \,\rangle\!\rangle_{\mathcal{H}^n} = \langle\!\langle\, (\mathcal{C}^n)^* r^n,\ \widetilde{\mathcal{R}}^n\mathcal{S}^n\mathcal{W}^n_{\text{Simp}}P_n\phi \,\rangle\!\rangle_{E^n},$$

where $\widetilde{\mathcal{R}}^n$ is as in (3.54). Define

$$v \overset{\text{def}}{=} \mathcal{S}^n \mathcal{W}^n_{\text{Simp}} P_n \phi,$$

$$\tilde{v} \overset{\text{def}}{=} \mathcal{S}^n \mathcal{W}^n_{\text{Trap}} P_n \phi,$$

where $\mathcal{W}^n_{\text{Trap}}$ is the weight matrix corresponding to the trapezoidal rule:

$$\mathcal{W}^n = h\,\text{diag}(1/2, 1, 1, \dots, 1, 1/2).$$

We show that $\|\tilde{v} - v\|_{\mathcal{H}^n} = \mathcal{O}(h^2)$, which implies that

$$\langle\!\langle y^n, P_n\phi \rangle\!\rangle_{\mathcal{H}^n} = h \langle\!\langle (\mathcal{C}^n)^* r^n, \, \widetilde{\mathcal{R}}^n \mathcal{S}^n P_n \phi \rangle\!\rangle_{E^n} + \mathcal{O}(h^2). \tag{3.61}$$

We show by induction that $\|\tilde{v} - v\|_{\mathcal{H}^n} = \mathcal{O}(h^2)$. We note first that $\tilde{v}_0 = v_0$. So we assume that for some $k \geq 1$ we have $\tilde{v}_{k-1} = v_{k-1} + \mathcal{O}(h^2)$. We note from (3.11) that for any $k = 1, \dots, n-1$,

$$v_{k+1} = B^2 v_{k-1} + h\Big(B\phi(t^n_{k-1}) w^n_{k-1} \; + \; \phi(t^n_k) w^n_k \Big).$$

Here, $\{w^n_k\}$ are the Simpson weights—the diagonal entries of $\mathcal{W}^n_{\text{Simp}}$. Thus,

$$v_{k+1} + v_{k-1} = \big(B^2 + I \big) v_{k-1} + h\Big(B\phi(t^n_{k-1}) w^n_{k-1} \; + \; \phi(t^n_k) w^n_k \Big).$$

From the definition of $\mathcal{W}^n_{\text{Simp}}$, the smoothness of ϕ, and the fact that $B = I + \mathcal{O}(h)$, it follows that the second parenthesized term above is equal to $h\big(2h\phi(t^n_k) + \mathcal{O}(h^2) \big)$. Also, by (A2) we have $B^2 + I = 2B + \mathcal{O}(h^2)$. Using these observations and the definition of $\mathcal{W}^n_{\text{Trap}}$ and dividing by 2, we thus find that

$$\frac{v_{k+1} + v_{k-1}}{2} = \big(B + \mathcal{O}(h^2) \big) v_{k-1} + h\Big([\mathcal{W}^n_{\text{Trap}}\phi]_{k-1} \; + \; \mathcal{O}(h^2) \Big).$$

By the induction hypothesis, $v_{k-1} = \tilde{v}_{k-1} + \mathcal{O}(h^2)$, so we may replace v_{k-1} by $\tilde{v}_{k-1}$ on the right-hand side of this equation. The resulting expression is then, by definition, the formula for $\tilde{v}_k$. Thus we have

$$\big(v_{k+1} + v_{k-1} \big)/2 = \tilde{v}_k + \mathcal{O}(h^2).$$

Since it is also true that

$$\big(\tilde{v}_{k+1} + \tilde{v}_{k-1} \big)/2 = \tilde{v}_k + \mathcal{O}(h^2),$$

we obtain $\tilde{v}_{k+1} = v_{k+1} + \mathcal{O}(h^2)$ and hence also $\tilde{v}_k = v_k + \mathcal{O}(h^2)$. Thus (3.61) holds. We may then use the reasoning leading to (3.59) to obtain

$$\langle\!\langle y^n, P_n\phi \rangle\!\rangle_{\mathcal{H}^n} = h \langle\!\langle (\mathcal{C}^n)^* r^n, \, \mathcal{S}^n \widetilde{\mathcal{R}}^n P_n \phi \rangle\!\rangle_{E^n} + \mathcal{O}(h^2). \tag{3.62}$$

Next we turn our attention to $(\mathcal{C}^n)^* r^n \overset{\text{def}}{=} g$. Referring to (3.3) we see that g depends linearly on $\{1/w_k\}$. We show that if the Simpson weights are replaced by the trapezoidal weights, then the result—call it $\tilde{g}$—satisfies $g = (3/2)\tilde{g}$. Indeed, this follows easily from Corollary 2(i) by which we are guaranteed that $\kappa(i)$ is *even* for all $i = 1, \dots, m$, so that the Simpson weights w_k satisfy $w_{\kappa(i)} = (2/3)h$ for all $i = 1, \dots, m$. However, $(2/3)h$ is simply $(3/2)$ times the $\kappa(i)$th *trapezoidal* weight. Thus the right-hand side of (3.62) is equal, to within $\mathcal{O}(h^2)$, to $(3/2)$ times the right side of (3.55). Thus the result of Theorem 6 applies, and we obtain the desired result. □

4. Numerical examples. To illustrate the results of the previous section we focus on a spline-based Galerkin approximation (with fixed dimensionality) of the diffusion equation (1.2) in one space dimension and $t_F = 1$, and directional derivatives for the corresponding least-squares functional (2.1). Accordingly we take $\Omega = (0,1)$, and for fixed $N \geq 1$ take as basis functions $\{b_i\}_{i=1}^N$ the usual piecewise linear "hat" functions on a uniform mesh. With the nodal points $x_i \overset{\text{def}}{=} i/(N+1)$, these are given, for $1 \leq i \leq N$, by

$$b_i(x) = \frac{1}{N+1}\begin{cases} x - x_{i-1} & \text{for } x \in [x_{i-1}, x_i), \\ x_{i+1} - x & \text{for } x \in [x_i, x_{i+1}), \\ 0 & \text{otherwise.} \end{cases}$$

We seek approximations $\mathbf{u}$ of the solution of the diffusion equation (1.2) as linear combinations of these basis functions, i.e.,

$$\mathbf{u}(x,t) = \sum_{i=1}^{N} u_i(t) b_i(x).$$

For fixed t we denote the coefficient vector $\{u_i(t)\}$ simply by $u(t)$. An N-dimensional linear system of the form (2.2) is obtained for u from the standard Galerkin method by requiring that $\mathbf{u}(x,0) \equiv 0$ and

$$\int_0^1 \dot{\mathbf{u}}(x,t) b_i(x)\, dx = \int_0^1 \left(-q(x) \frac{\partial \mathbf{u}}{\partial x}(x,t) \frac{db_i}{dx}(x) \; + \; f(x,t) b_i(x) \right) dx.$$

In our implementation, the integrals on the left-hand side of this equation are encoded exactly, and the ones on the right-hand side are approximated using the trapezoid rule.

We report results below for six numerical experiments. In each of these, $N = 3$. Thus H is the subspace of $L^2(0,1)$ consisting of continuous functions on $[0,1]$ that equal zero at the endpoints and are piecewise linear with interior nodes at $x_1 = \frac{1}{4}$, $x_2 = \frac{1}{2}$ and $x_3 = \frac{3}{4}$. One of the experiments is an example of "continuous time observations," and the rest are based on "discrete-time observations." In each of these cases, the spatial observation operator C, as in (3.27), is the same. It is defined as pointwise evaluation of functions in H at the points $x = \frac{1}{3}$ and $x = \frac{2}{3}$.

The function $q(x)$ and the perturbations $p(x)$ are represented as linear splines on the mesh ($N = 3$) described above. Perturbations p are elements of H; specifically, they are zero at the endpoints and can vary at any of the $x_i, i = 1,2,3$.

Thus the q-dependent linear evolution equation is given by $\mathbf{M}\dot{\mathbf{u}} = \mathbf{A}(\mathbf{q})\mathbf{u} + \mathbf{f}$, where

$$\mathbf{M} = \frac{1}{6}\begin{pmatrix} 4 & 1 & 0 \\ 1 & 4 & 1 \\ 0 & 1 & 4 \end{pmatrix},$$

$$\mathbf{A}(\mathbf{q}) = 8\begin{pmatrix} -(q_0 + 2q_1 + q_2) & (q_1 + q_2) & 0 \\ (q_1 + q_2) & -(q_1 + 2q_2 + q_3) & (q_2 + q_3) \\ 0 & (q_2 + q_3) & -(q_2 + 2q_3 + q_4) \end{pmatrix},$$

and $\mathbf{f}(t) = \{f(x_i,t)\}_{i=1}^3$.

The "data" z are generated by carrying out the approximations as outlined above, with

$$q(x) = 1 + \tfrac{1}{5} e^{-20(x-1/3)^2}$$

approximated by its linear spline interpolate. The source term $f(x,t)$ is chosen so that the solution of $u(x,t)$ of (1.2) is $u(x,t) = x(1-x)te^{-t}$. Then the directional derivatives (2.3) and their approximations (3.4) are investigated based on $q(x) \equiv 1$.

Three of the experiments are based on nonuniform meshes $\mathbf{t}^n$. To explain how these meshes are generated, it is sufficient that we explain how the vectors $\{h_k\}$ are generated. To highlight the dependence on n here we denote these vectors by $\mathbf{h}^{(n)}$, and the individual h-values by $h_k^{(n)}$. To generate nonuniform $\mathbf{h}^{(n)}$ we begin with a given n and create a uniform mesh by setting $h_k^{(n)} \equiv t_F/n$. Then with a given "mesh ratio" r satisfying $0 < r < 1$, the "mesh refinement scheme" for generating $\mathbf{h}^{(2n)}$ from $\mathbf{h}^{(n)}$ is

$$\begin{aligned} h_{2k-1}^{(2n)} &= (1-r)h_k^{(n)}, \\ h_{2k}^{(2n)} &= rh_k^{(n)} \end{aligned}$$

for $k = 1, \ldots, n$. The choice $r = \frac{1}{2}$ yields refined meshes which are each uniform. This is clearly not true for any other choice of r.

We examine the convergence properties of costate approximations using four different time-marching schemes in (3.2). For the state equation (2.2), these methods are as follows.

CN. The trapezoidal, or "Crank–Nicholson," method

$$u_{k+1} = (I - Ah_k/2)^{-1}\Big((I + Ah_k/2)u_k + h^k(f_k + f_{k+1})/2 \Big).$$

RK2e. The explicit second-order Runge–Kutta method

$$u_{k+1} = (I + Ah_k + (Ah_k)^2/2)u_k + h_k((I + Ah_k)f_k + f_{k+1})/2.$$

RK2i. The implicit second-order Runge–Kutta method

$$u_{k+1} = (I - Ah_k + (Ah_k)^2/2)^{-1}\Big(u_k + h_k((I - Ah_k)f_{k+1} + f_k)/2 \Big).$$

RK4. The explicit fourth-order Runge–Kutta method

$$u_{k+1} = u_k + (K_1 + 2K_2 + 2K_3 + k_4)/6,$$

where

$$\begin{aligned} K_1 &= h_k(Au_k + f_k), \\ K_2 &= h_k(A(u_k + K_1/2) + f_{k+1/2}), \\ K_3 &= h_k(A(u_k + K_2/2) + f_{k+1/2}), \\ K_4 &= h_k(A(u_k + K_3) + f_{k+1}). \end{aligned}$$

To express the RK4 method in a form compatible with Theorem 6(g), we first obtain a fourth-order accurate approximation of $f_{k+1/2}$. This we do by evaluating at $(t_k^n + t_{k+1}^n)/2$ the cubic polynomial that interpolates (t_{k+i}^n, f_{k+i}), $-1 \le i \le 2$. For a uniform mesh, this yields

$$\begin{aligned} B &= I + Ah + (Ah)^2/2 + (Ah)^3/6 + (Ah)^4/24, \\ [\mathcal{R}^n P_n f]_k &= \frac{1}{6}\Big(-C_1 f_{k-1} + (C_2 + 9C_1)f_k + (I + 9C_1)f_{k+1} - C_1 f_{k+2} \Big), \\ C_1 &\overset{\text{def}}{=} \frac{1}{4}(I + Ah/2 + (Ah)^2/8), \\ C_2 &\overset{\text{def}}{=} I + Ah + (Ah)^2/2 + (Ah)^3/4. \end{aligned}$$

We carried out a rather extensive numerical investigation, using the MATLAB software package [9] on a Sun Sparcstation 2 and a DECstation 5000/200. In all cases, we compare the costate approximation $\widetilde{\delta_p T^n}$ to centered-difference approximations $(\delta_p T^n)_{FD}$. These are computed by evaluation of the expression under the limit sign in (2.3) with T replaced by T^n, and with $\tau = \sqrt{\epsilon}$. The value of ϵ (called "*eps*" in MATLAB) is the machine-dependent constant defined as the smallest integer-power of 2 for which "$1+\epsilon > 1$" is true. On the Sparcstation 2, $\epsilon = 2^{-52} \approx 2\times 10^{-16}$, so that numbers are represented up to sixteen decimal places. The choice of $\tau = \sqrt{\epsilon}$ in the finite difference computation reflects a desire to strike a balance between discretization error and roundoff error. By heuristics in [8, pp. 31–32], we expect that $(\delta_p T^n)_{FD}$ thus computed should agree with the correct value of $\delta_p T^n$ up to roughly half of the sixteen decimal places.

By the result of Theorem 3, the true gradient of the discrete functional $\delta_p T^n$ converges with full accuracy to $\delta_p T(q)$ (under the assumptions (A5′) and (A6′), of course). Since $(\delta_p T^n)_{FD}$ equals $\delta_p T^n$ to within eight digits or so, the triangle inequality implies that the rate of convergence of $\widetilde{\delta_p T^n}$ to $\delta_p T$ is correctly indicated by the rate of convergence of $\widetilde{\delta_p T^n}$ to $(\delta_p T^n)_{FD}$ as long as the relative difference of these two quantities is larger than about 10^{-8}.

For each of the six experiments, then, we tabulate the relative error

$$E_{|\mathbf{h}|} = \max_{1\le i\le m} \left| \frac{\widetilde{\delta_p T^n} - (\delta_p T^n)_{FD}}{(\delta_p T^n)_{FD}} \right| \tag{4.1}$$

for the four methods as $|\mathbf{h}|$ varies. From these results we then estimate the actual rate of convergence $\bar{\nu}$ based on the assumption that $E_{|\mathbf{h}|} = C|\mathbf{h}|^{\bar{\nu}}$.

Case 1. Observations are continuous in time, and the meshes are non-uniform with refinement ratio $r = 1/3$. The trapezoidal quadrature rule is used for the $\mathcal{H}^n$ inner product for the three second-order methods, and Simpson's rule is used for the RK4 method. See Table 1.

TABLE 1

4.44e-3	5.2e-7	7.8e-5	6.8e-5	2.1e-7
$\bar{\nu}$	2.7	2.7	2.7	6.4

Case 2. This experiment is motivated by Theorem 5. We take observations discrete in time on uniform meshes. The quadrature weights, as in (3.6), are those arising from the trapezoidal rule. The results are presented in the Table 2. The three Runge–Kutta methods appear to be converging at a second-order rate, as predicted by Theorem 5. Crank–Nicholson costate approximations agree with the forward-

TABLE 2

$\lvert\mathbf{h}\rvert$	CN	RK2e	RK2i	RK4
1.0e-2	8.8e-10	8.7e-5	6.9e-5	3.9e-6

$\bar{\nu}$	*	2.1	1.9	2.1

difference approximations to within nine decimal places—roughly the expected accuracy of $(\delta_p T^n)_{FD}$. In fact, for uniform meshes, $\widetilde{\delta_p T^n}$ as computed by the Crank–Nicholson method *exactly* equals $\delta_p T^n$ (neglecting roundoff error). We outline a proof of this assertion. The recursion formula (3.12) for $u^n = \mathcal{S}^n \mathcal{R}^n P_n$ takes the form

$$u^n_{k+1} = B(q) u^n_k + hR(q)(f_k + f_{k+1}) \tag{4.2}$$

with

$$R(q) = \frac{1}{2}\left(I - \frac{h}{2}A\right)^{-1},$$
$$B(q) = 2R(q)\left(I + \frac{h}{2}A\right).$$

Then,

$$\delta_p R(q) = hR(q)\big(\delta_p A(q)\big)R(q),$$
$$\delta_p B(q) = hR(q)\big(\delta_p A(q)\big)\big(B(q) + I\big).$$

Using these in (3.19) leads to

$$\delta_p u^n_{k+1} = B(q)\delta_p u^n_k + hR(q)\big(\delta_p A(q)\big)(u^n_k + u^n_{k+1}).$$

Referring to (3.22) and (4.2) we see that this last equation is just the recursion formula for $\delta_p u^n = \mathcal{S}^n \mathcal{R}^n \phi^n$. Thus

$$\delta_p T^n(q) = \langle\!\langle\, r^n, \mathcal{C}^n \mathcal{S}^n \mathcal{R}^n \phi^n \,\rangle\!\rangle_{\mathcal{Z}}$$

However, by reasoning similar to that which led to (3.43), the right-hand side of this equation can be rewritten as

$$\langle\!\langle\, r^n, \mathcal{C}^n \mathcal{S}^n \mathcal{R}^n \phi^n \,\rangle\!\rangle_{\mathcal{Z}} = \langle\!\langle\, J^n \mathcal{S}^n_{(*)} \mathcal{R}^n_{(*)} J^n (\mathcal{C}^*)^n r^n,\ \phi^n \,\rangle\!\rangle_{\mathcal{H}^n},$$

which by (3.4), (3.22), and (3.26) is the same as $\widetilde{\delta_p T^n}$. Thus $\widetilde{\delta_p T^n} = \delta_p T^n$, so that the numerator in (4.1) is nonzero only to the extent that $(\delta_p T^n)_{FD} \neq \delta_p T^n$. This explains the Crank–Nicholson column in Table 2.

Case 3. This example is the same as Case 2 but with nonuniform meshes, generated with $r = 1/3$. In this case we have no theoretical basis on which to expect convergence, and indeed Table 3 suggests that convergence is not obtained.

TABLE 3

$\lvert\mathbf{h}\rvert$	CN	RK2e	RK2i	RK4

4.4e-3	1.6e-3	2.4e-2	2.0e-2	4.2e-1
$\bar{\nu}$	0	0.3	-0.1	-9.6

Case 4. We conjecture that in some cases, even though the meshes $\mathbf{t}^n$ may be nonuniform, high-order convergence can still be achieved provided that the meshes are *"locally uniform"* in the sense that for a given n, all of the h_k's "near" a given observation point τ_i are constant. More precisely, there is a positive integer σ and a

TABLE 4

$\|h\|$	CN	RK2e	RK2i	RK4
6.7e-3	5.8e-5	6.2e-3	2.2e-3	9.8e-3

$\bar{\nu}$	2.0	2.7	1.5	0.6

real $\tilde{h}$ for which $t_{k+1}^n - t_k^n = \tilde{h}$ whenever $(\kappa(i) - \sigma) \leq k \leq (\kappa(i) + \sigma)$, where $\kappa(i)$ is from (3.30).

In this example we repeat the experiment reported under Case 3, but took steps to ensure that the refined meshes were "locally uniform" with $\sigma = 1$.

Table 4 suggests that high-order convergence can sometimes be obtained on "locally uniform" meshes. However, we do not pursue this idea further.

Case 5. Table 5 presents an example illustrating Theorem 6. The forcing term f in the state equation is changed so that $f(0) = 0$. The RK4 method is used together with the quadrature weight matrix $\mathcal{W}_{\text{Trap}}$ arising from the trapezoidal quadrature rule. These weights appear in Theorem 6(d). The mesh refinement is uniform.

5. Alternate approaches. Throughout the preceding sections we have discussed the use of the "discretized costate approximation" and have attempted to illustrate the delicacy of that procedure when pointwise (in time) observations are involved. There are at least three other possible approaches that also merit consideration when pointwise observations are involved, which we now briefly discuss.

The strategy pursued in §§2 and 3 was to take the *discretization of the adjoint* system; that is, to first derive the costate method for the continuous problem, and then to discretize the resulting equations and integrals. An alternative to this would be to use the *adjoint of the discrete* system. While this approach is straightforward when applied to boundary value problems, certain complications may arise in the implementation for evolution equations, particularly when time marching schemes are used for temporal discretization.

In particular, from the definition (3.1) of the discrete least-squares functional we have

$$\delta_p T^n(q) = \tfrac{1}{2}\langle\!\langle\, r^n, \mathcal{C}^n \delta_p u^n \,\rangle\!\rangle_{\mathcal{Z}^n}.$$

From the expression for components of $\delta_p u^n$ in (3.19) and the definition (3.11) of $\mathcal{S}^n(q)$, we see that

$$\delta_p u^n(q) = \mathcal{S}^n(q)\gamma^n(q;p),$$

where $\gamma^n(q;p)$ is given by

$$\gamma_k^n(q;p) \overset{\text{def}}{=} [\,\delta_p \mathcal{R}^n(q)\, P_n f]_k + \frac{1}{h_k}(\delta_p B_k) u_k^n. \tag{5.1}$$

Thus

$$\delta_p T^n(q) = \tfrac{1}{2}\langle\!\langle\, (\mathcal{S}^n)^*(\mathcal{C}^n)^* r^n, \gamma^n(q;p) \,\rangle\!\rangle_{\mathcal{Z}^n}.$$

The advantage of this approach is that it will yield *exact* values for the directional derivatives of T^n. Hence in numerical attempts to minimize T^n for any *fixed* n it would be ideal. However, it involves the use of $\gamma^n(q;p)$ as given in (5.1), which may require significant amounts of additional mathematical effort, code complexity, and computational execution time. These disadvantages may be negated in whole or in part for certain special cases if the expression for $\gamma^n(q;p)$ can be simplified. Such simplification occurred with the Crank–Nicholson method for uniform time meshes, as described in Case 2 of §4. However, we do not pursue this approach further here.

Another alternative [3, §V, (5.30)–(5.32)] is to retain the strategy of discretizing the continuous adjoint system, but to *transform* the costate equation (2.9) so as to increase the smoothness of the source term. This can be done by the introduction of two new variables ψ and ξ given by

$$\psi(t) \overset{\text{def}}{=} \int_0^t \big[J(\mathcal{C}^* r)\big](s)\, ds$$

and

$$\xi(t) \overset{\text{def}}{=} y(t) - \psi(t).$$

Then, ξ satisfies

$$\begin{aligned}\dot{\xi}(t) &= A^*(q)\xi(t) + A^*(q)\psi(t),\\ \xi(0) &= 0.\end{aligned}$$

The idea is that since ψ is piecewise constant (as opposed to $J(\mathcal{C}^*)r$, which is a linear combination of Dirac delta functions), it should be easier to obtain accurate numerical solutions of y by first approximating ξ as given here.

We briefly explored this idea numerically. We repeated the relevant numerical examples, which are Case 2 and Case 3 of §4. In both cases, all four of the TMSs were used to approximate ξ instead of y, and then we set $y^n = \xi^n + \psi$. In each of these runs, we observed *linear* convergence of the directional derivatives; e.g., $\bar{\nu}$ was approximately 1 in each case. Obviously, for uniform time meshes (as in Case 2) this represents a loss of accuracy, while for nonuniform meshes (Case 3) it is a definite improvement.

One other alternative is to consider modifying step (iii) of the discretized costate approximation along the following lines. Instead of attempting to integrate $\dot{y}$ over the whole interval $(0, t_F)$ in "one shot" with the TMS, we should treat each subinterval (τ_{i-1}, τ_i) separately, using the fact that $J^n(\mathcal{C}^*)^n r^n$ is zero in the interior of these subintervals and that y has jump discontinuities at τ_i. Correspondingly, the quadrature in (3.4) must be modified. Although the implementation is more complicated, analysis along the lines of the proof of Corollary 1 above then applies. Consequently, for sufficiently smooth state-variable forcing functions f, full accuracy of the TMS and the quadrature will yield full accuracy of the costate approximations.

6. Summary and conclusions. While the costate method offers potentially dramatic time savings when computing gradients in parameter estimation problems for time-dependent systems, we have indicated that care must be taken when using this approach. We have shown both analytically and numerically that the use of convergent time-marching and quadrature schemes in seemingly reasonable combinations can yield surprisingly poor results.

The difficulty lies in the fact that the forcing term of the costate equation may be very non-smooth, so that the assumptions under which the TMS and quadrature scheme converge are violated. In the description of the discretized costate approximation in §3.1.1, we assumed that the TMS is used in step (iii) as a "black box" without regard to the smoothness (or lack thereof) of $J^n(\mathcal{C}^*)^n r^n$; see (3.2).

The costate implementation that we have analyzed involves discretization of the (continuous) costate equation using standard time-marching schemes. Due to its simplicity, this approach is very desirable *when the resulting gradient approximation has the same order of accuracy as the particular time-marching scheme.* We presented conditions that guarantee this. Some of these conditions are straightforward. For instance, several popular second-order time-marching schemes yield second-order gradient approximations *provided* a uniform time mesh is used in combination with (second-order accurate) trapazoidal quadrature. Other conditions are less obvious (cf. Theorem 6). We also demonstrate that certain "reasonable" implementations yield gradient approximations that fail to converge at all, e.g., fourth-order Runge–Kutta time-marching on a uniform time mesh combined with (fourth-order) trapazoidal quadrature. Finally, several alternative (though less simple) costate implementations were presented.

BOUNDARY STABILIZATION FOR THE VON KÁRMÁN EQUATIONS *

JEAN-PIERRE PUEL† AND MARIUS TUCSNAK†

Abstract. The boundary stabilization of a nonlinear plate model is studied. The equations used take in consideration the in-plane accelerations and the rotary inertia of the cross sections. Applying linear feedbacks, the authors obtain the exponential decay of the energy.

Key words. semilinear evolution equations, feedback boundary control, Lyapounov functionals

AMS subject classifications. 93D15, 35B40, 73K50

1. Introduction.

We consider the stabilization problem for the coupled in-plane and transversal vibrations of a nonlinear plate. As far as we know, all previous work on nonlinear plate vibrations is based on models neglecting the in-plane accelerations (e.g. [1], [3, Chap. 5], [6] for boundary stabilization problems). This assumption leads, for star-shaped domains and suitable boundary conditions, to the existence of an Airy stress function, which considerably simplifies the equations.

The goal of this paper is to investigate the boundary stabilization of the complete set of von Kármán equations, as they are given, for example, in [3, p. 19]. This model can be applied for domains that are not star-shaped, but it has the inconvenience that the nonlinear terms are not well defined in the energy space. This feature makes the proof of global existence results more delicate. To our knowledge, the only mathematical result concerning this plate model are the global existence theorems proved in [11, Part 1] (for weak solutions) and [10] (for strong solutions).

For the one-dimensional corresponding rod problem, the uniform stabilization was studied in [7], which inspired our work.

The paper is organized as follows. In §2 we formulate the initial and boundary value problem and we discuss the feedback boundary controls. For the sake of completeness, in §3, we outline the proof of the main global existence theorem (the complete proof is given in [10]). Section 4 contains the stabilization results. In §5 we give an energy identity, fundamental for the proof of the stabilization theorem, which is given in §6. Our method is based on the fact that the system we consider is obtained by coupling in a nonlinear way the equations of two-dimensional (2D) linear elasticity and of a linear Kirchhoff plate. This is why we apply the technique proposed in [2], [3, Chap. 4], [4], and [7], which is based on the construction of appropriate Lyapunov functionals. The desired differential inequalities are obtained as a consequence of the energy identity proven in §5, by the use of multiplier techniques. The ideas and computations we used are similar to the one contained in [5].

The results contained in this paper were announced in [9].

2. Statement of the problem. Let $\Omega \subset \mathbf{R}^2$ be a bounded regular domain, $Q = \Omega \times (0, \infty)$, $\Gamma = \partial\Omega$, $\Gamma_0 \subset \Gamma$, $\Gamma_1 = \Gamma - \Gamma_0$, $\Sigma_i = \Gamma_i \times (0, \infty)$, $i = 0, 1$. We suppose that $\Gamma_0 \cap \Gamma_1 = \emptyset$. Let $\mathcal{S}$ be the set of all fourth-order symmetric tensors on $\mathbf{R}^2$ and $\mathcal{C} \in \mathcal{S}$ defined by

$$\mathcal{C}[\epsilon] = \frac{E}{d(1-\mu^2)}[\mu(tr\epsilon)I_{\mathcal{S}} + (1-\mu)\epsilon] \quad \forall \epsilon \in \mathcal{S},$$

where $I_{\mathcal{S}}$ is the identity of S, d is the density, E is Young's modulus, and μ is Poisson's ratio of the material. If $E > 0$ and $0 < \mu < \frac{1}{2}$ the tensor $\mathcal{C}$ satisfies the following condition:

$$\mathcal{C}[\epsilon] \cdot [\epsilon] \geq \lambda_0 |\epsilon|^2 \quad \forall \epsilon \in \mathcal{S}, \quad \text{where } \lambda_0 > 0. \tag{2.1}$$

We consider $f : \mathbf{R^2} \rightarrow \mathcal{S}$, defined by $f(x) = \frac{1}{2} x \otimes x$. With this notation the dynamic von Kármán equations can be written in the following form:

$$u'' - \operatorname{div}\{\mathcal{C}[\epsilon(u) + f(\nabla w)]\} = 0 \quad \text{in Q}, \tag{2.2}$$

$$w'' - \gamma\Delta w'' + D\Delta^2 w - div\{\mathcal{C}[\epsilon(u) + f(\nabla w)]\nabla w\} = 0 \quad \text{in Q}, \tag{2.3}$$

$$u = 0, \qquad w = \frac{\partial w}{\partial \nu} = 0 \quad \text{on } \Sigma_0, \tag{2.4}$$

$$\mathcal{C}[\epsilon(u) + f(\nabla w)]\nu = g \quad \text{on } \Sigma_1, \tag{2.5}$$

$$D[\Delta w + (1-\mu)B_1 w] = -M_s \quad \text{on } \Sigma_1, \tag{2.6}$$

(2.7)
$$D\left[\frac{\partial \Delta w}{\partial \nu} + (1-\mu)\frac{\partial B_2 w}{\partial s}\right] - \gamma \frac{\partial w''}{\partial \nu} - \mathcal{C}[\epsilon(u) + f(\nabla w)]\nu \cdot \nabla w = -\frac{\partial}{\partial s} M_\nu - h \quad \text{on } \Sigma_1,$$

$$u(0) = u^0, \quad u'(0) = u^1, \quad w(0) = w^0, \quad w'(0) = w^1, \quad \text{in } \Omega, \tag{2.8}$$

In the above equations $u = (u_1, u_2)$ is the plane displacement, $\gamma > 0$ is a constant, $\epsilon(u) = \frac{1}{2}[\nabla u + (\nabla u)^T]$, w is the transverse displacement, D represents the flexural rigidity of the plate, ν and s are the outward unit normal and tangent, respectively, to the boundary. The operators B_1, B_2 are given by

$$B_1 w = 2\nu_1\nu_2 \frac{\partial^2 w}{\partial x_1 \partial x_2} - \nu_1^2 \frac{\partial^2 w}{\partial x_2^2} - \nu_2^2 \frac{\partial^2 w}{\partial x_1^2},$$

$$B_2 w = (\nu_1^2 - \nu_2^2)\frac{\partial^2 w}{\partial x_1 \partial x_2} + \nu_1\nu_2 \left(\frac{\partial^2 w}{\partial x_2^2} - \frac{\partial^2 w}{\partial x_1^2}\right).$$

The quantities g, h, M_s, and M_ν are the boundary controls of the system. They correspond, respectively, to the tension in the plane of the plate, the effect of transverse shear force, the bending moment around the tangential vector to Γ, and the twisting moment about the normal to Γ.

Let $\{u, w\}$ be a classical solution of (2.2)–(2.8). The total energy of the plate is given (cf. [3, p. 18]) by

$$E(t) = \tfrac{1}{2}\{||u'(t)||^2 + ||w'(t)||^2 + \gamma||\nabla w'(t)||^2 + a(w(t), w(t)) \\ + (\mathcal{C}[\epsilon(u(t)) + f(\nabla w(t))], \epsilon(u(t)) + f(\nabla w(t)))\},$$

where $||\cdot||$ and $(\cdot,\cdot)$ represent the norm, respectively, the inner product, in $[L^2(\Omega)]^k$, $k \in \mathbf{N}$ and

$$\text{(2.9)} \qquad a(w,\tilde{w}) = D\int_\Omega \left[\frac{\partial^2 w}{\partial x_1^2}\frac{\partial^2 \tilde{w}}{\partial x_1^2} + \frac{\partial^2 w}{\partial x_2^2}\frac{\partial^2 \tilde{w}}{\partial x_2^2} + \mu\left(\frac{\partial^2 w}{\partial x_1^2}\frac{\partial^2 \tilde{w}}{\partial x_2^2} \right.\right. \\ \left.\left. + \frac{\partial^2 \tilde{w}}{\partial x_1^2}\frac{\partial^2 w}{\partial x_2^2}\right) + 2(1-\mu)\frac{\partial^2 w}{\partial x_1\partial x_2}\frac{\partial^2 \tilde{w}}{\partial x_1\partial x_2}\right]dx.$$

A simple calculation, based on the integration by parts formula,

$$\text{(2.10)} \quad D\int_\Omega (\Delta^2 w)\tilde{w}\,dX = a(w,\tilde{w}) - D\int_\Gamma \left\{[\Delta w + (1-\mu)B_1 w]\frac{\partial \tilde{w}}{\partial \nu} \right. \\ \left. - \left[\frac{\partial \Delta w}{\partial \nu} + (1-\mu)\frac{\partial B_2 w}{\partial s}\right]\tilde{w}\right\}d\Gamma,$$

shows that

$$\text{(2.11)} \qquad E'(t) = \int_{\Gamma_1}\left[g\cdot u' - M_s\frac{\partial w'}{\partial \nu} + \left(\frac{\partial}{\partial s}M_\nu + h\right)w'\right]d\Gamma.$$

Let $x_0 \in \mathbf{R}^2$ and $m(x) = x - x_0$. We suppose that Γ_0, Γ_1 have the property

$$\text{(2.12)} \qquad m(x)\cdot\nu(x) < 0, \quad \text{if } x \in \Gamma_0; \qquad m(x)\cdot\nu(x) \geq 0, \quad \text{if } x \in \Gamma_1.$$

If we put

$$\text{(2.13)} \qquad g = -c_1(m\cdot\nu)u', \qquad M_s = c_1(m\cdot\nu)\frac{\partial w'}{\partial \nu}, \\ \frac{\partial}{\partial s}M_\nu + h = -c_1(m\cdot\nu)w' + c_1\frac{\partial}{\partial s}\left[(m\cdot\nu)\frac{\partial w'}{\partial s}\right],$$

with $c_1 > 0$ we get

$$\text{(2.14)} \qquad E'(t) = -c_1\int_{\Gamma_1}(m\cdot\nu)(u'^2 + w'^2 + |\nabla w'|^2)d\Gamma \leq 0,$$

i.e., the total energy is nonincreasing. However, this type of feedback law does not seem to give the exponential decay of the energy, even in linear plane elasticity (see [4] for the details). This is why, following [4], we set

$$g = -c_1(m\cdot\nu)u' - c_2\left(\frac{\partial u_2}{\partial s}, -\frac{\partial u_1}{\partial s}\right), \text{ where } c_2 > 0,$$

$$M_s = c_1(m\cdot\nu)\frac{\partial w'}{\partial\nu}, \frac{\partial}{\partial s}M_\nu + h = -c_1(m\cdot\nu)w' + c_1\frac{\partial}{\partial s}\left[(m\cdot\nu)\frac{\partial w'}{\partial s}\right]. \tag{2.15}$$

The advantage of this feedback law is that, in our calculations, the classical energy density, $W(u) = \frac{1}{2}\mathcal{C}[\epsilon(u)]\cdot\epsilon(u)$ will be replaced by

$$\widetilde{W}(u) = W(u) + c_2\left(\frac{\partial u_1}{\partial x_1}\frac{\partial u_2}{\partial x_2} - \frac{\partial u_1}{\partial x_2}\frac{\partial u_2}{\partial x_1}\right),$$

which, for $c_2 > 0$, c_2 small, satisfies the condition

$$\widetilde{W}(u) \geq c_0|\nabla u|^2, \quad \text{with } c_0 > 0. \tag{2.16}$$

Define

$$\widetilde{E}(t) = E(t) + c_2\int_\Omega\left(\frac{\partial u_1}{\partial x_1}\frac{\partial u_2}{\partial x_2} - \frac{\partial u_1}{\partial x_2}\frac{\partial u_2}{\partial x_1}\right)dXdt. \tag{2.17}$$

Using the formula

$$\begin{aligned}&\int_\Gamma\left(\frac{\partial u_2}{\partial s}\phi_1 - \frac{\partial u_1}{\partial s}\phi_2\right)d\Gamma \\ &= \int_\Omega\left(\frac{\partial u_1}{\partial x_1}\frac{\partial \phi_2}{\partial x_2} + \frac{\partial u_2}{\partial x_2}\frac{\partial \phi_1}{\partial x_1} - \frac{\partial u_1}{\partial x_2}\frac{\partial \phi_2}{\partial x_1} - \frac{\partial u_2}{\partial x_1}\frac{\partial \phi_1}{\partial x_2}\right)dX,\end{aligned} \tag{2.18}$$

we get, with the feedback law (2.15),

$$\widetilde{E}'(t) = -c_1\int_{\Gamma_1}(m\cdot\nu)(u'^2 + w'^2 + |\nabla w'|^2)d\Gamma \leq 0. \tag{2.19}$$

It will be proved in §6 that the feedback law (2.15) uniformly stabilizes the system (2.2)–(2.8), in the sense that $\widetilde{E}(t) \to 0$ as $t \to \infty$ in an exponential way, on each bounded set $E(0) \leq M$ of initial data. On the other hand, it is easy to check that, for c_2 small enough, $\widetilde{E}(t)$ is equivalent to $E(t)$, in the sense that

$$K^{-1}E(t) \leq \widetilde{E}(t) \leq KE(t) \quad \forall t \geq 0, \tag{2.20}$$

for a suitable constant $K > 0$. In this way, the uniform exponential decay of the original energy functional will be established.

3. Existence of solutions. In this section we outline the proof of a global existence result for the problem (2.2)–(2.8). The complete proof is given in [10]. We begin by introducing the following function spaces:

$$W = \{w \in H^2(\Omega)|\ w_{|\Gamma_0} = \frac{\partial w}{\partial\nu}|\Gamma_0 = 0\};\ V = \{w \in H^1(\Omega)|\ w_{|\Gamma_0} = 0\};\ H = L^2(\Omega).$$

$$U = \{u \in [H^1(\Omega)]^2|\ u_{|\Gamma_0} = 0\}, \mathcal{K} = [L^2(\Omega)]^2.$$

Let $\{u, w\}$ be a classical solution of (2.2)–(2.8) with the feedback law (2.15), i.e.,

$$u \in C(0,T;[H^2(\Omega)]^2) \cap C^1(0,T;[H^1(\Omega)]^2), \qquad w \in C(0,T;H^4(\Omega) \cap C^1(0,T;H^3(\Omega)).$$

If we take the inner product in $[L^2(\Omega)]^2$ of (2.2) with $\phi \in U$ and of (2.3) with $\psi \in W$, by the use of (2.6)–(2.8) and(2.15) we get

$$(3.1)\qquad [(u',\phi)]' + (\mathcal{C}[\epsilon(u) + f(\nabla w)], \epsilon(\phi)) + c_2 \int_\Omega \left(\frac{\partial u_1}{\partial x_1}\frac{\partial \phi_2}{\partial x_2} + \frac{\partial u_2}{\partial x_2}\frac{\partial \phi_1}{\partial x_1} - \frac{\partial u_1}{\partial x_2}\frac{\partial \phi_2}{\partial x_1} - \frac{\partial u_2}{\partial x_1}\frac{\partial \phi_1}{\partial x_2} \right) dX + c_1 \left[\int_{\Gamma_1} (m\cdot\nu) u \cdot \phi d\Gamma \right]' = 0, \quad \forall \phi \in U,$$

$$(3.2)\qquad [(w',\psi) + \gamma(\nabla w', \nabla\psi)]' + a(w,\psi) + (\mathcal{C}[\epsilon(u) + f(\nabla w)]\nabla w, \nabla \psi) + c_1 \left[\int_{\Gamma_1} (m\cdot\nu)(w\psi + \nabla w \cdot \nabla\psi) d\Gamma \right]' = 0 \quad \forall \psi \in W.$$

DEFINITION 3.1. *We say that* $\{u, w\}$ *is a* strong *solution of* (2.2)–(2.8) *with the feedback law* (2.15) *if*

$$u \in C(0,T;[H^2(\Omega)]^2 \cap U) \cap C^1(0,T;U), \qquad w \in C(0,T;H^3(\Omega) \cap W) \cap C^1(0,T;W),$$

and they satisfy (3.1), (3.2), *and* (2.8).

DEFINITION 3.2. *We call* $\{u, w\}$ *a* weak *solution of* (2.2)–(2.8) *with the feedback law* (2.15) *if*

$$u \in C(0,T;U) \cap C^1(0,T;\mathcal{K}), \qquad w \in C(0,T;W) \cap C^1(0,T;V),$$

and they satisfy (3.1), (3.2), *and* (2.8).

The following theorem is the main result of this section.

THEOREM 3.1. *Suppose that* c_2 *is small enough and that* u^0, u^1, w^0, w^1 *satisfy the conditions*

$$(3.3)\qquad u^0 \in [H^2(\Omega)]^2 \cap U, \qquad u^1 \in U,$$

$$(3.4)\qquad w^0 \in H^3(\Omega) \cap W, \qquad w^1 \in W,$$

$$(3.5)\qquad \mathcal{C}[\epsilon(u^0) + f(\nabla w^0)]\nu + c_1(m\cdot\nu)u^1 + c_2\left(\frac{\partial u_2^0}{\partial s}, -\frac{\partial u_1^0}{\partial s}\right) = 0 \quad on\ \Gamma_1,$$

$$(3.6)\qquad D[\Delta w^0 + (1-\mu)B_1 w^0] = -c_1(m\cdot\nu)\frac{\partial w^1}{\partial \nu} \quad on\ \Sigma_1.$$

Then there exists a unique global strong solution $\{u, w\}$ *of* (2.2)–(2.8).

Sketch of the proof.

Step 1. The first step consists of the following local existence result.

LEMMA 3.1. *Suppose that* c_2, u^0, u^1, w^0, w^1 *satisfy the assumptions of Theorem* 3.1. *Then there exists* $T_0 > 0$ *such that problem* (2.2)–(2.8) *admits an unique strong solution for any* $T < T_0$. *Moreover, one of the following assertions holds*:

(A1) $T_0 = \infty$;

(A2) $\lim_{t\to T_0}(||u(t)||_{H^2} + ||u'(t)||_{H^1} + ||w(t)||_{H^3} + ||w'(t)||_{H^2}) = \infty$.

Idea of the proof. We first prove some well-possedness results for the linearization of (2.2)–(2.8). More precisely, we consider the following initial value problem:

$$
\begin{aligned}
(3.7)\qquad & [(u',\phi)]' + (\mathcal{C}[\epsilon(u)],\epsilon(\phi)) \\
& + c_2 \int_\Omega \left(\frac{\partial u_1}{\partial x_1}\frac{\partial \phi_2}{\partial x_2} + \frac{\partial u_2}{\partial x_2}\frac{\partial \phi_1}{\partial x_1} - \frac{\partial u_1}{\partial x_2}\frac{\partial \phi_2}{\partial x_1} - \frac{\partial u_2}{\partial x_1}\frac{\partial \phi_1}{\partial x_2} \right) dX \\
& + c_1 \left[\int_{\Gamma_1} (m\cdot\nu) u \cdot \phi d\Gamma \right]' + (f_1(t),\epsilon(\phi)) = 0 \quad \forall \phi \in U,
\end{aligned}
$$

$$(3.8)\qquad u(0) = u^0, u'(0) = u^1 \quad \text{in } \Omega,$$

where

$$f_1(t) : \Omega \to \mathcal{S} \quad \forall t \in [0,T),$$

and

$$
\begin{aligned}
(3.9)\ & [(w',\psi) + \gamma(\nabla w',\nabla\psi)]' + a(w,\psi) \\
& + c_1 \left[\int_{\Gamma_1} (m\cdot\nu)(w\psi + \nabla w\cdot\nabla\psi) d\Gamma \right]' + (f_2(t),\nabla\psi) = 0 \quad \forall \psi \in W,
\end{aligned}
$$

$$(3.10)\qquad w(0) = w^0, \qquad w'(0) = w^1,$$

where

$$f_2(t) : \Omega \to \mathbf{R}^2 \quad \forall t \geq 0.$$

The key point is to construct the operator generating the semigroup associated to (3.9) (see also [5, §4.2.1]). We present here the method we used to overcome this difficulty. The following two lemmas, which are proved in [10], are very important for our approach.

LEMMA 3.2. *For any $w \in W$ there exists at most one couple $(y,h) \in V \times H^{\frac{1}{2}}(\Gamma_1)$ such that*

$$(3.11)\qquad a(w,\psi) = (y,\psi) + \gamma(\nabla y,\nabla\psi) + \int_{\Gamma_1} h\frac{\partial\psi}{\partial\nu} \quad \forall\psi \in W.$$

LEMMA 3.3. *Suppose that* (3.11) *holds for some $(w,y,h) \in W \times V \times H^{1/2}(\Gamma_1)$. Then we have the regularity property $w \in H^3(\Omega)$. Moreover, there exists a constant $C > 0$ such that*

$$(3.12)\qquad \|w\|_{H^3(\Omega)} \leq C(\|y\|_{H^1(\Omega)} + \|h\|_{H^{1/2}(\Gamma)}),$$

and the relation $D[\Delta w + (1-\mu)B_1 w] = h$, holds in $H^{1/2}(\Gamma_1)$.

Let us now introduce the space

$$
\begin{aligned}
(3.13)\quad \mathcal{D}(A) = \Big\{ & w \in W \text{ such that it exists } (y,h) \in V \times H^{1/2}(\Gamma_1), \\
& \text{satisfying } a(w,\psi) = (y,\psi) + \gamma(\nabla y,\nabla\psi) + \int_{\Gamma_1} h\frac{\partial\psi}{\partial\nu} d\Gamma,\ \forall\psi \in W \Big\}.
\end{aligned}
$$

By Lemma 3.3 we know that $\mathcal{D}(A) \subset H^3(\Omega) \cap W$. On the other hand, for w fixed, by Lemma 3.2 we know that y and h in (3.13) are unique. This allows us to introduce the operator

$$A : \mathcal{D}(A) \to V, \qquad Aw = y. \tag{3.14}$$

We also define the operator $B : W \to V$ by
(3.15)

$$(By, \psi) + \gamma(\nabla(By), \nabla\psi) = c_1 \int_{\Gamma_1} (m \cdot \nu) y\psi d\Gamma + c_1 \int_{\Gamma_1} (m \cdot \nu) \frac{\partial y}{\partial s}\frac{\partial \psi}{\partial s} d\Gamma \quad \forall \psi \in V,$$

where the second integral is taken in the sense of the duality $H^{1/2}(\Gamma_1)$, $H^{-1/2}(\Gamma_1)$. Now consider the space

$$\mathcal{D}(\mathcal{A}) = \left\{ \begin{pmatrix} w \\ y \end{pmatrix} \in \mathcal{D}(A) \times W, \text{ s. t.} \right.$$
$$\left. D[\Delta w + (1-\mu)B_1 w] = -c_1(m \cdot \nu)\frac{\partial y}{\partial \nu} \text{ on } \Gamma_1 \right\},$$

and define the operator

$$\mathcal{A}\begin{pmatrix} w \\ y \end{pmatrix} = \begin{pmatrix} -y \\ Aw + By \end{pmatrix} \quad \forall \begin{pmatrix} w \\ y \end{pmatrix} \in \mathcal{D}(\mathcal{A}). \tag{3.16}$$

By using Lemma 3.3 we can easily obtain (see [10]) that the operator $-\mathcal{A}$ defined by (3.16) generates a strongly continous semigroup in $W \times V$. The well-possedness result for (3.9), (3.10) is now obtained by noting that (3.9), (3.10) are equivalent to the following initial value problem in $W \times V$:

$$Z' + \mathcal{A}Z + F = 0,$$

$$Z(0) = Z^0,$$

where

$$Z = \begin{pmatrix} w \\ w' \end{pmatrix}, \qquad F = \begin{pmatrix} 0 \\ \widetilde{f_2}(t) \end{pmatrix},$$

and $\widetilde{f_2}$ is defined by

$$(\widetilde{f_2}(t), \psi) + \gamma(\nabla \widetilde{f_2}(t), \nabla\psi) = (f_2(t), \nabla\psi) \quad \forall \psi \in V,$$

and by using classical results on semigroups (see [8]). The linear estimates allow us to apply a fixed point technique. As the nonlinear terms in (2.2)–(2.8) are not Lipschitz in $W \times V$, we must work in the space $[H^2(\Omega)]^2 \cap U \times U \times H^3(\Omega) \cap W \times W$, suggested by Lemma 3.3. The local character of the solutions comes from the fact that even in this more regular space the nonlinearities are only locally Lipschitz. □

Step 2. The second step consists in proving the following estimates.

LEMMA 3.4. *Suppose that* (u, w) *is a strong solution of* (2.2)–(2.8) *defined on* $[0, T)$. *Then there exists a constant* M_T *depending on* T *such that*

$$||u''(t)||^2 + ||u'(t)||^2_{H^1} + ||w''(t)||^2_{H^1} + ||w'(t)||^2_{H^2} \le M_T \quad \forall t \in [0, T).$$

LEMMA 3.5. *Suppose that* (u, w) *is a strong solution of* (2.2)–(2.8) *defined on* $[0, T)$. *Then there exists a constant* M_T *depending on* T *such that*

$$||u(t)||_{H^2}^2 + ||w(t)||_{H^3}^2 \leq M_T \quad \forall t \in [0, T).$$

As for the proofs of Lemmas 3.4 and 3.5 we only mention two ideas.

(a) To prove Lemma 3.4 we take the derivative of (3.1), (3.2) with respect to time and we choose $\phi = u''$, $\psi = w''$ in the resulting equations. By the use of the divergence structure of the nonlinearities and of some Gagliardo–Nirenberg inequalities, we obtain that the expresion

$$\tfrac{1}{2}(||u''(t)||^2 + ||u'(t)||_{H^1}^2 + ||w''(t)||_{H^1}^2 + ||w'(t)||_{H^2}^2)$$

is uniformly bounded with respect to t varying in any compact set.

(b) For the proof of Lemma 3.5 we use Lemma 3.4 combined with the elliptic estimates provided by Lemma 3.3.

Step 3. It is now sufficient to note that, by Lemmas 3.4 and 3.5, the assertion (A2) in Lemma 3.1 cannot hold. As a consequence we obtain that (A1) takes place so any local solution can be extended to a global one. □

As a consequence of Theorem 3.1 we easily obtain global existence of weak solutions of (2.2)–(2.8) (for a complete proof see [10] or [11, Part 1]).

THEOREM 3.2. *Suppose that*

$$u^0 \in U, \quad u^1 \in \mathcal{K}, \quad w^0 \in W, \quad w^1 \in V.$$

Then there exists at least one weak solution of (*2.2*)*-*(*2.8*).

Remark. The solutions provided by our proof of Theorem 3.2 are weak limits of a sequence of strong solutions. We also remark that the uniqueness of weak solutions is an open problem.

4. The stabilization results.

Our main results assert that strong solutions of (2.2)-(2.8) satisfy the following energy estimate.

THEOREM 4.1. *Let* $\{u, w\}$ *be any strong solution of* (*2.2*)*-*(*2.8*), *with the feedback law* (*2.15*) *and let* $B > 0$. *Then there exist constants* $K > 0$, *and* $\omega = \omega(B) > 0$ *such that the following estimate holds, provided that* $E(0) \leq B$:

$$E(t) \leq Ke^{-\omega t}E(0) \quad \forall t \geq 0. \tag{4.1}$$

We can hope that estimate (4.1) might be extended for weak solutions of (2.2)–(2.8). We can easily check that any sequence of strong solutions that is bounded in the energy space converges weakly to a finite energy solution (cf. [10], [11, Part 1]). However, due to the lack of Lipschitzianity there is no uniqueness result for weak solutions, so we cannot assert that any weak solution can be obtained as above. This is why the next stabilization result considers only the weak solutions that can be approached by a sequence of strong solutions. By using the lower semicontinuity of the energy functional we obtain the following result.

THEOREM 4.2. *Suppose that* b, u^0, u^1, w^0, w^1 *satisfy the assumptions of Theorem* 3.2. *Then, among the weak solution*'*of* (2.2)–(2.8), *there exists at least one satisfying the energy estimate* (4.1).

The rest of our paper is devoted to the proof of Theorem 4.1. We begin by noting that any strong solution of (2.2)–(2.8) satisfies a slight generalization of (3.1), (3.2). More precisely, we have the following result.

LEMMA 4.1. *If $\{u,w\}$ is a strong solution of* (2.2)–(2.8), *with the feedback law* (2.15), *then the following relations hold*:

$$\begin{aligned}(4.2)\qquad & [(u',\phi)]' + (\mathcal{C}[\epsilon(u)+f(\nabla w)],\epsilon(\phi)) \\ & + c_2\int_\Omega\left(\frac{\partial u_1}{\partial x_1}\frac{\partial \phi_2}{\partial x_2}+\frac{\partial u_2}{\partial x_2}\frac{\partial \phi_1}{\partial x_1}-\frac{\partial u_1}{\partial x_2}\frac{\partial \phi_2}{\partial x_1}-\frac{\partial u_2}{\partial x_1}\frac{\partial \phi_1}{\partial x_2}\right)dX \\ & + c_1\left[\int_{\Gamma_1}(m\cdot\nu)u\cdot\phi d\Gamma\right]' \\ & - \int_{\Gamma_0}\mathcal{C}[\epsilon(u)]\nu\cdot\phi d\Gamma = 0 \quad \forall\phi\in[H^1(\Omega)]^2,\end{aligned}$$

$$\begin{aligned}(4.3)\ & [(w',\psi)+\gamma(\nabla w',\nabla\psi)]' + a(w,\psi) \\ & + (\mathcal{C}[\epsilon(u)+f(\nabla w)]\nabla w,\nabla\psi) - D\int_{\Gamma_0}\Delta w\frac{\partial\psi}{\partial\nu}d\Gamma \\ & + c_1\left[\int_{\Gamma_1}(m\cdot\nu)(w\psi+\nabla w\cdot\nabla\psi)d\Gamma\right]' = 0 \quad \forall\psi\in H^2(\Omega), \psi_{|\Gamma_0}=0.\end{aligned}$$

Proof. Let us first note that, for (u,w), the strong solution of (2.2)–(2.8), the relation (3.1) implies that (3.2) holds in $C([0,T],L^2(\Omega))$. This is why, by taking the scalar product of (2.2) with $\phi\in[H^1(\Omega)]^2$, we easily obtain that (u,w) satisfy (4.2). On the other hand, according to (2.10) (see also [3, p. 71]), the relation

$$\begin{aligned}(4.4)\qquad a(w,\psi) = & -\int_\Omega\nabla(\Delta w)\cdot\nabla\psi dX + D\int_\Gamma[\Delta w+(1-\mu)B_1 w]\frac{\partial\psi}{\partial\nu}d\Gamma \\ & - D(1-\mu)\int_\Gamma\frac{\partial B_2 w}{\partial s}\psi d\Gamma,\end{aligned}$$

holds for any $w\in H^3(\Omega)$ and $\psi\in H^2(\Omega)$, where the last integral may be interpreted as the duality between $H^{1/2}(\Gamma)$ and $H^{-1/2}(\Gamma)$. As w,w' satisfy (2.6) and (2.15) from (4.4) we get

(4.5)

$$\begin{aligned} a(w,\psi) + c_1\int_{\Gamma_1}(m\cdot\nu)(w'\psi+\nabla w'\cdot\nabla\psi)d\Gamma = & -\int_\Omega\nabla(\Delta w)\cdot\nabla\psi dX \\ - D(1-\mu)\int_{\Gamma_1}\frac{\partial B_2 w}{\partial s}\psi d\Gamma + c_1\int_{\Gamma_1} & \left\{(m\cdot\nu)w' - \frac{\partial}{\partial s}\left[(m\cdot\nu)\frac{\partial w'}{\partial s}\right]\right\}\psi d\Gamma,\end{aligned}$$

for any

$$\psi\in H^2(\Omega), \qquad \psi_{|\Gamma_0} = \frac{\partial\psi}{\partial\nu}_{|\Gamma_0} = 0.$$

From (3.2) and (4.5) it follows that u,w satisfy the following relation:

(4.6)

$$\begin{aligned}(w'',\psi) + \gamma(\nabla w'',\nabla\psi) - \int_\Omega\nabla(\Delta w)\cdot\nabla\psi dX + (\mathcal{C}[\epsilon(u)+f(\nabla w)]\nabla w,\nabla\psi) \\ -D(1-\mu)\int_{\Gamma_1}\frac{\partial B_2 w}{\partial s}\psi d\Gamma + c_1\int_{\Gamma_1}\left\{(m\cdot\nu)w' - \frac{\partial}{\partial s}\left[(m\cdot\nu)\frac{\partial w'}{\partial s}\right]\right\}\psi d\Gamma = 0,\end{aligned}$$

for all

$$\psi \in H^2(\Omega), \qquad \psi_{|\Gamma_0} = \frac{\partial \psi}{\partial \nu}_{|\Gamma_0} = 0,$$

and the last two integrals may be interpreted as the duality beetween $H^{1/2}(\Gamma)$ and $H^{-1/2}(\Gamma)$. It is obvious that, by density, (4.6) still holds for $\psi \in H^1(\Omega), \psi_{|\Gamma_0} = 0$. In particular (4.6) is true for $\psi \in H^2(\Omega)$, $\psi_{|\Gamma_0} = 0$. This implies, by using once again (4.4) and the relation $B_1 w = 0$ on Γ_0, that (4.3) holds. □

In the next section we shall give an energy identity that plays a fundamental role in proving Theorem 3.1.

5. The energy identity. For $u : \Omega \to \mathbf{R}^2$ we denote by $\nabla u m$ the product of the matrix ∇u with the column vector $m \in \mathbf{R}^2$. The following result will be essential for the proof of the stabilization result.

LEMMA 5.1. *Let* $\{u, w\}$ *be a strong solution of* (2.2)–(2.8), (2.15) *and let* $t > 0$, $\alpha \in \mathbf{R}$. *Define*

$$\begin{aligned}\rho(t) = &\int_\Omega u' \cdot [\nabla u m - (2\alpha - 1)u] dX - \frac{c_1(2\alpha-1)}{2}\int_{\Gamma_1} (m\cdot\nu)u^2 d\Gamma \\ &+ \int_\Omega [w'(m\cdot\nabla w) + \gamma\nabla w' \cdot \nabla(m\cdot\nabla w)]dX - \alpha\int_\Omega (w'w + \gamma\nabla w'\cdot\nabla w)dX \\ &- \frac{c_1\alpha}{2}\int_{\Gamma_1}(m\cdot\nu)(w'^2 + |\nabla w|^2)d\Gamma.\end{aligned}$$

Then we have

$$\begin{aligned}\rho(t) - \rho(0) &+ 2\alpha\int_0^t\int_\Omega u'^2 dX ds \\ &+ (\alpha+1)\int_0^t\int_\Omega w'^2 dXds + \alpha\gamma\int_0^t\int_\Omega |\nabla w'|^2 dXds \\ &+ (1-\alpha)\int_0^t a(w,w)ds \\ &+ (1-2\alpha)\int_0^t\int_\Omega \mathcal{C}[\epsilon(u) + f(\nabla w)]\cdot[\epsilon(u) + f(\nabla w)]dXds \\ &- c_2(2\alpha-1)\int_0^t\int_\Omega\left(\frac{\partial u_1}{\partial x_1}\frac{\partial u_2}{\partial x_2} - \frac{\partial u_1}{\partial x_2}\frac{\partial u_2}{\partial x_1}\right)dXds \\ =&\frac{1}{2}\int_0^t\int_{\Gamma_1}(m\cdot\nu)(u'^2 + w'^2 + \gamma|\nabla w'|^2)d\Gamma ds \\ &+ \frac{1}{2}\int_0^t\int_{\Gamma_0}\mathcal{C}[\epsilon(u)]\cdot\epsilon(u)(m\cdot\nu)d\Gamma ds \\ &- \frac{1}{2}\int_0^t\int_{\Gamma_1}\mathcal{C}[\epsilon(u) + f(\nabla w)]\cdot[\epsilon(u) + f(\nabla w)](m\cdot\nu)d\Gamma ds \\ &- c_2\int_0^t\int_{\Gamma_1}(m\cdot\nu)\left(\frac{\partial u_1}{\partial x_1}\frac{\partial u_2}{\partial x_2} - \frac{\partial u_1}{\partial x_2}\frac{\partial u_2}{\partial x_1}\right)d\Gamma ds \\ &+ \frac{D}{2}\int_0^t\int_{\Gamma_0}(m\cdot\nu)(\Delta w)^2 d\Gamma ds \\ &- \frac{D}{2}\int_0^t\int_{\Gamma_1}(m\cdot\nu)\left[\left(\frac{\partial^2 w}{\partial x_1^2}\right)^2 + \left(\frac{\partial^2 w}{\partial x_2^2}\right)^2 + 2\mu\frac{\partial^2 w}{\partial x_1^2}\frac{\partial^2 w}{\partial x_2^2}\right.\end{aligned} \tag{5.1}$$

$$+ 2(1-\mu)\left(\frac{\partial^2 w}{\partial x_1 \partial x_2}\right)^2\Bigg] d\Gamma ds - c_1 \int_0^t \int_{\Gamma_1} (m\cdot\nu)u' \cdot (\nabla u m) d\Gamma ds$$
$$- c_1 \int_0^t \int_{\Gamma_1} (m\cdot\nu)[w'(m\cdot\nabla w) + \nabla w' \cdot \nabla(m\cdot\nabla w)] d\Gamma ds.$$

Proof. We set $\phi = \nabla u m - \beta u$, with arbitrary β, in (3.1) and integrate that equation over $(0,t)$. For the first term we have

$$\text{(5.2)}\qquad \int_0^t \int_\Omega u'' \cdot (\nabla u m - \beta u) dX ds$$
$$= \int_\Omega u' \cdot (\nabla u m - \beta u) dX|_0^t - \int_0^t \int_\Omega u' \cdot (\nabla u' m - \beta u') dX ds.$$

We notice that

$$\text{(5.3)}\; - \int_\Omega u' \cdot (\nabla u' m) dX = - \int_\Omega u_i' \frac{\partial u_i'}{\partial x_j} m_j dX$$
$$= -\frac{1}{2}\int_\Omega m_j \frac{\partial}{\partial x_j}(u_i')^2 dX = -\frac{1}{2}\int_{\Gamma_1} (m\cdot\nu)u'^2 + \int_\Omega u'^2.$$

Taking in consideration (5.2), (5.3) we have

$$\text{(5.4)}\; \int_0^t \int_\Omega u'' \cdot (\nabla u m - \beta u) dX ds = \int_\Omega u' \cdot (\nabla u m - \beta u) dX|_0^t$$
$$- \frac{1}{2}\int_0^t \int_{\Gamma_1} (m\cdot\nu) u'^2 d\Gamma ds + \beta + 1) \int_0^t \int_\Omega u'^2 dX ds.$$

For the following terms we note that

$$\text{(5.5)}\qquad \int_\Omega \Bigg[\frac{\partial u_1}{\partial x_1}\frac{\partial(m\cdot\nabla u_2)}{\partial x_2} + \frac{\partial u_2}{\partial x_2}\frac{\partial(m\cdot\nabla u_1)}{\partial x_1}$$
$$- \frac{\partial u_1}{\partial x_2}\frac{\partial(m\cdot\nabla u_2)}{\partial x_1} - \frac{\partial u_2}{\partial x_1}\frac{\partial(m\cdot\nabla u_1)}{\partial x_2}\Bigg] dX$$
$$= \int_\Gamma (m\cdot\nu)\left(\frac{\partial u_1}{\partial x_1}\frac{\partial u_2}{\partial x_2} - \frac{\partial u_1}{\partial x_2}\frac{\partial u_2}{\partial x_1}\right) d\Gamma.$$

Let us make the notation

$$\text{(5.6)}\qquad \rho_1(t) = \int_\Omega u' \cdot (\nabla u m - \beta u) dX - \frac{\beta c_1}{2}\int_0^t \int_{\Gamma_1} (m\cdot\nu) u^2 d\Gamma.$$

As a consequence of (3.1), (5.5), and (5.6) we get

$$\text{(5.7)}\qquad \rho_1(t) - \rho_1(0) + (\beta+1)\int_0^t \int_\Omega u'^2 dX ds$$
$$- c_2\beta \int_\Omega \left(\frac{\partial u_1}{\partial x_1}\frac{\partial u_2}{\partial x_2} - \frac{\partial u_1}{\partial x_2}\frac{\partial u_2}{\partial x_1}\right) dX ds$$

$$+\int_0^t\int_\Omega \mathcal{C}[\epsilon(u)+f(\nabla w)]\cdot\epsilon(\nabla um-\beta u)dXds$$
$$=\frac{1}{2}\int_0^t\int_{\Gamma_1}(m\cdot\nu)u'^2d\Gamma ds+\int_0^t\int_{\Gamma_0}(m\cdot\nu)\mathcal{C}[\epsilon(u)]\cdot\epsilon(u)d\Gamma ds$$
$$-c_1\int_0^t\int_{\Gamma_1}(m\cdot\nu)u'\cdot(\nabla um)d\Gamma ds$$
$$-c_2\int_0^t\int_{\Gamma_1}(m\cdot\nu)\left(\frac{\partial u_1}{\partial x_1}\frac{\partial u_2}{\partial x_2}-\frac{\partial u_1}{\partial x_2}\frac{\partial u_2}{\partial x_1}\right)d\Gamma ds.$$

We now set $\psi = m\cdot\nabla w-\alpha w$ in (3.4) and integrate over $[0,t]$. We obtain

$$\begin{aligned}(5.8)\quad c(w',m\cdot\nabla w-\alpha w)|_0^t &- \int_0^t c(w',m\cdot\nabla w'-\alpha w')ds\\ &+\int_0^t a(w,m\cdot\nabla w-\alpha w)ds\\ &+\int_0^t(\mathcal{C}[\epsilon(u)+f(\nabla w)]\nabla w\cdot\nabla(m\cdot\nabla w-\alpha w)ds\\ &-D\int_0^t\int_{\Gamma_0}(m\cdot\nu)(\Delta w)^2d\Gamma ds+\int_0^t b(w',m\cdot\nabla w)ds\\ &-\alpha\int_0^t b(w',w)ds=0,\end{aligned}$$

where

$$(5.9)\qquad c(v_1,v_2)=\int_\Omega(v_1v_2+\gamma\nabla v_1\cdot\nabla v_2)dX,$$

$$(5.10)\qquad b(v_1,v_2)=c_1\int_{\Gamma_1}(m\cdot\nu)(v_1v_2+\nabla v_1\cdot\nabla v_2)d\Gamma.$$

The relation

$$\begin{aligned}c(w',m\cdot\nabla w')&=\int_\Omega[w'(m\cdot\nabla w')+\gamma\nabla w'\cdot\nabla(m\cdot\nabla w')]dX\\ &=\frac{1}{2}\int_\Omega \mathrm{div}(w'^2m)dX-\int_\Omega w'^2dX+\frac{\gamma}{2}\int_\Omega\mathrm{div}(|\nabla w'|^2m)dX\\ &=\frac{1}{2}\int_{\Gamma_1}(m\cdot\nu)(w'^2+\gamma|\nabla w'|^2)d\Gamma-\int_\Omega w'^2dX,\end{aligned}$$

allows us to write in a more convenient way the sum of the first two terms in (5.8), that is,

$$\begin{aligned}(5.11)\quad c(w',m\cdot\nabla w-\alpha w)|_0^t&-\int_0^t c(w',m\cdot\nabla w'-\alpha w')ds\\ &=c(w',m\cdot\nabla w-\alpha w)|_0^t+(\alpha+1)\int_0^t\int_\Omega w'^2dXds\\ +\alpha\gamma\int_0^t\int_\Omega|\nabla w'|^2dXds&-\frac{1}{2}\int_0^t\int_{\Gamma_1}(m\cdot\nu)(w'^2+\gamma|\nabla w'|^2)d\Gamma ds.\end{aligned}$$

We note that, according to [3, p. 81],

$$
\begin{aligned}
(5.12)\qquad a(w, m\cdot\nabla w) =& a(w,w)\\
&+\frac{D}{2}\int_{\Gamma}(m\cdot\nu)\left[\left(\frac{\partial^2 w}{\partial x_1^2}\right)^2+\left(\frac{\partial^2 w}{\partial x_2^2}\right)^2+2\mu\frac{\partial^2 w}{\partial x_1^2}\frac{\partial^2 w}{\partial x_1^2}\right.\\
&\qquad\left.+2(1-\mu)\left(\frac{\partial^2 w}{\partial x_1\partial x_2}\right)^2\right]d\Gamma.
\end{aligned}
$$

Taking in consideration the boundary conditions we obtain

$$
\begin{aligned}
(5.13)\ &\frac{D}{2}\int_{\Gamma_0}(m\cdot\nu)\left[\left(\frac{\partial^2 w}{\partial x_1^2}\right)^2+\left(\frac{\partial^2 w}{\partial x_2^2}\right)^2+2\mu\frac{\partial^2 w}{\partial x_1^2}\frac{\partial^2 w}{\partial x_1^2}+2(1-\mu)\left(\frac{\partial^2 w}{\partial x_1\partial x_2}\right)^2\right]d\Gamma\\
&=\frac{D}{2}\int_{\Gamma_0}(m\cdot\nu)(\Delta w)^2 d\Gamma,
\end{aligned}
$$

The relations (5.12) and (5.13) imply

$$
\begin{aligned}
(5.14)\ a(w, m\cdot\nabla w-\alpha w)&-D\int_{\Gamma_0}(m\cdot\nu)(\Delta w)^2 d\Gamma\\
&=(1-\alpha)a(w,w)-\frac{D}{2}\int_{\Gamma_0}(m\cdot\nu)(\Delta w)^2 d\Gamma\\
&\quad+\frac{D}{2}\int_{\Gamma_1}(m\cdot\nu)\left[\left(\frac{\partial^2 w}{\partial x_1^2}\right)^2+\left(\frac{\partial^2 w}{\partial x_2^2}\right)^2+2\mu\frac{\partial^2 w}{\partial x_1^2}\frac{\partial^2 w}{\partial x_1^2}\right.\\
&\qquad\left.+2(1-\mu)\left(\frac{\partial^2 w}{\partial x_1\partial x_2}\right)^2\right]d\Gamma.
\end{aligned}
$$

Let $\rho_2(t)=c(w', m\cdot\nabla w)-\alpha c(w', w)-\frac{\alpha}{2}b(w,w)$. The relations (5.8), (5.11), (5.14) imply that

$$
\begin{aligned}
(5.15)\,&\rho_2(t)-\rho_2(0)+(\alpha+1)\int_0^t\int_\Omega w'^2 dX ds+\alpha\gamma\int_0^t\int_\Omega|\nabla w'|^2 dX ds\\
&+(1-\alpha)\int_0^t a(w,w)ds\\
&+\int_0^t\int_\Omega\{\mathcal{C}[\epsilon(u)+f(\nabla w)]\nabla w\}\cdot\nabla(m\cdot\nabla w-\alpha w)dX ds\\
=&\frac{1}{2}\int_0^t\int_{\Gamma_1}(m\cdot\nu)(w'^2+\gamma|\nabla w'|^2)d\Gamma ds+\frac{D}{2}\int_0^t\int_{\Gamma_0}(m\cdot\nu)(\Delta w)^2 d\Gamma\\
&-\frac{D}{2}\int_0^t\int_{\Gamma}(m\cdot\nu)\left[\left(\frac{\partial^2 w}{\partial x_1^2}\right)^2+\left(\frac{\partial^2 w}{\partial x_2^2}\right)^2+2\mu\frac{\partial^2 w}{\partial x_1^2}\frac{\partial^2 w}{\partial x_1^2}\right.\\
&\qquad\left.+2(1-\mu)\left(\frac{\partial^2 w}{\partial x_1\partial x_2}\right)^2\right]d\Gamma-\int_0^t b(w', m\cdot\nabla w)ds.
\end{aligned}
$$

As $\rho(t)=\rho_1(t)+\rho_2(t)$ from (5.7) and (5.15), with $\beta=2\alpha-1$, we obtain

$$
\begin{aligned}
(5.16)\quad & \rho(t) - \rho(0) \\
& + \int_0^t \int_\Omega [(\beta+1)u'^2 + (\alpha+1)w'^2 + \alpha\gamma|\nabla w'|^2] dX ds \\
& + (1-\alpha) \int_0^t a(w,w) ds \\
& + \int_0^t \int_\Omega \{\mathcal{C}[\epsilon(u) + f(\nabla w)]\nabla w\} \cdot \nabla(m \cdot \nabla w - \alpha w) dX ds \\
& + \int_0^t \int_\Omega \mathcal{C}[\epsilon(u) + f(\nabla w)] \cdot \epsilon(\nabla u m - \beta u) dX ds \\
& - c_2 \beta \int_0^t \int_\Omega \left(\frac{\partial u_1}{\partial x_1} \frac{\partial u_2}{\partial x_2} - \frac{\partial u_1}{\partial x_2} \frac{\partial u_2}{\partial x_1} \right) dX ds \\
= & \frac{1}{2} \int_0^t \int_{\Gamma_1} (m \cdot \nu)(u'^2 + w'^2 + \gamma|\nabla w'|^2) d\Gamma ds \\
& - c_2 \int_0^t \int_{\Gamma_1} (m \cdot \nu) (\frac{\partial u_1}{\partial x_1} \frac{\partial u_2}{\partial x_2} - \frac{\partial u_1}{\partial x_2} \frac{\partial u_2}{\partial x_1}) d\Gamma ds \\
& + \int_0^t \int_{\Gamma_0} (m \cdot \nu) \mathcal{C}[\epsilon(u)] \cdot \epsilon(u) dX ds + \frac{D}{2} \int_0^t \int_{\Gamma_0} (m \cdot \nu)(\Delta w)^2 d\Gamma \\
& - \frac{D}{2} \int_0^t \int_{\Gamma_1} (m \cdot \nu) \Bigg[\left(\frac{\partial^2 w}{\partial x_1^2} \right)^2 + \left(\frac{\partial^2 w}{\partial x_2^2} \right)^2 \\
& \qquad\qquad + 2\mu \frac{\partial^2 w}{\partial x_1^2} \frac{\partial^2 w}{\partial x_1^2} + 2(1-\mu) \left(\frac{\partial^2 w}{\partial x_1 \partial x_2} \right)^2 \Bigg] d\Gamma ds \\
& - c_1 \int_0^t \int_{\Gamma_1} (m \cdot \nu) u' \cdot (\nabla u m) d\Gamma ds - \int_0^t b(w', m \cdot \nabla w) ds.
\end{aligned}
$$

Let us consider the terms containing both u and w from the left side of (5.16). We note that

$$
\begin{aligned}
(5.17)\quad & \int_\Omega \mathcal{C}[\epsilon(u) + f(\nabla w)] \cdot \epsilon(\nabla u m - \beta u) dX \\
& = (1-\beta) \int_\Omega \mathcal{C}[\epsilon(u) + f(\nabla w)] \cdot \epsilon(u) dX + \int_\Omega a_{ij} \frac{\partial^2 u_i}{\partial x_k \partial x_j} m_k dX,
\end{aligned}
$$

where $a_{ij}(\epsilon(u), f(\nabla w)) = \{\mathcal{C}[\epsilon(u) + f(\nabla w)]\}_{ij}, i, j = 1, 2$. For the other coupled term we have

$$
\begin{aligned}
(5.18)\quad & \int_\Omega \{\mathcal{C}[\epsilon(u) + f(\nabla w)]\nabla w\} \cdot \nabla(m \cdot \nabla w - \alpha w) dX \\
& = 2(1-\alpha) \int_\Omega \{\mathcal{C}[\epsilon(u) + f(\nabla w)]\} \cdot f(\nabla w) dX + \int_\Omega a_{ij} \frac{\partial w}{\partial x_j} \frac{\partial^2 w}{\partial x_i \partial x_k} m_k dX.
\end{aligned}
$$

To have a good coupling of (5.17) and (5.18) we use again the condition $\beta = 2\alpha - 1$. Then (5.17), (5.18) give

$$
(5.19)\qquad \int_\Omega \mathcal{C}[\epsilon(u) + f(\nabla w)] \cdot \epsilon[\nabla u m - (2\alpha - 1)u] dX
$$

$$
\begin{aligned}
&+\int_\Omega \{\mathcal{C}[\epsilon(u)+f(\nabla w)]\nabla w\}\cdot\nabla(m\cdot\nabla w-\alpha w)dX\\
&=2(1-\alpha)\int_\Omega\{\mathcal{C}[\epsilon(u)+f(\nabla w)]\cdot[\epsilon(u)+f(\nabla w)]dX\\
&+\int_\Omega a_{ij}\left(\frac{\partial^2 u_i}{\partial x_k x_j}+\frac{\partial w}{\partial x_j}\frac{\partial^2 w}{\partial x_i\partial x_k}\right)m_k dX.
\end{aligned}
$$

By using in (5.19) the identity

$$
\begin{aligned}
&a_{ij}(\frac{\partial^2 u_i}{\partial x_k x_j}+\frac{\partial w}{\partial x_j}\frac{\partial^2 w}{\partial x_i\partial x_k})m_k\\
&=\frac{1}{2}\mathrm{div}\{\mathcal{C}[\epsilon(u)+f(\nabla w)]\cdot[\epsilon(u)+f(\nabla w)]m\}\\
&-\mathcal{C}[\epsilon(u)+f(\nabla w)]\cdot[\epsilon(u)+f(\nabla w)],
\end{aligned}
$$

we obtain

$$
\begin{aligned}
(5.20)\qquad &\int_\Omega \mathcal{C}[\epsilon(u)+f(\nabla w)]\cdot\epsilon[\nabla u m-(2\alpha-1)u]dX\\
&+\int_\Omega\{\mathcal{C}[\epsilon(u)+f(\nabla w)]\nabla w\}\cdot\nabla(m\cdot\nabla w-\alpha w)dX\\
&=\int_\Omega(1-2\alpha)\mathcal{C}[\epsilon(u)+f(\nabla w)]\cdot[\epsilon(u)+f(\nabla w)]dX\\
&+\frac{1}{2}\int_{\Gamma_0}\mathcal{C}[\epsilon(u)]\cdot\epsilon(u)(m\cdot\nu)dX\\
&+\frac{1}{2}\int_{\Gamma_1}\mathcal{C}[\epsilon(u)+f(\nabla w)]\cdot[\epsilon(u)+f(\nabla w)](m\cdot\nu)dX.
\end{aligned}
$$

Now the conclusion (5.1) follows from (5.16) and (5.20). □

6. Proof of the stabilization results. We begin this section by noting that $\rho(t)$ has another important property given by the following lemma.

LEMMA 6.1. *For all $M>0$ there is a constant $C_0>0$ such that $\rho(t)\le C_0\widetilde{E}(t)$, for all $t\ge 0$, where $\widetilde{E}(t)$ is defined by* (2.17) *and u^0,u^1,w^0,w^1 are such that $\widetilde{E}(0)\le M$.*

Proof. We obviously have

$$
\left(\frac{\partial u_i}{\partial x_j}+\frac{\partial u_j}{\partial x_i}\right)^2\le 2\left(\frac{\partial u_i}{\partial x_j}+\frac{\partial u_j}{\partial x_i}+\frac{\partial w}{\partial x_i}\frac{\partial w}{\partial x_j}\right)^2+2\left(\frac{\partial w}{\partial x_i}\frac{\partial w}{\partial x_j}\right)^2,
$$

which implies that

$$
\begin{aligned}
\int_\Omega|\epsilon(u)|^2dX&\le 2\int_\Omega[\epsilon(u)+f(\nabla w)]^2dX+\frac{1}{2}||\frac{\partial w}{\partial x_i}||^2_{L^4(\Omega)}||\frac{\partial w}{\partial x_j}||^2_{L^4(\Omega)}\\
&\le 2\int_\Omega[\epsilon(u)+f(\nabla w)]^2dX+C_1||w||^4_{H^2(\Omega)}.
\end{aligned}
$$

Here we also used the imbedding $H^1(\Omega)\subset L^4(\Omega)$ and the energy inequality (2.14). The last inequality, (2.1), the H^2 coercivity of $a(w,\widetilde{w})$, and the fact that $\widetilde{E}(t)$ is nonincreasing imply

$$
\int_\Omega|\epsilon(u)|^2dX\le K_0\widetilde{E}(t)+K_1M\widetilde{E}(t),
$$

with K_O, K_1 positive constants. From (2.17), the above inequality, the continuity of the trace mapping $\gamma : H^1(\Omega) \to L^2(\Gamma)$, and Korn inequality, we obtain the following estimate:

$$\int_{\Gamma_1} (m\cdot\nu)u^2 d\Gamma \le K_2 \int_\Omega |\epsilon(u)|^2 dX \le K_3\widetilde{E}(t),$$

with K_2 and K_3 two positive constants. In a similar way we can prove that there is a positive constant K_4 such that

$$\int_\Omega u'\cdot[\nabla u m - (2\alpha-1)u]dX \le K_4\widetilde{E}(t).$$

As the other terms in ρ are obviously dominated by $E(t)$ and (according to (2.20)) by $\widetilde{E}(t)$, the conclusion of the lemma easily follows. □

We can now give the proof of the stabilization result.

Proof of Theorem 3.1. We set $\alpha \in (0,\frac{1}{2})$ in (5.1) and by taking the derivative we obtain

$$(6.1)\ \rho'(t) = -\int_\Omega \Bigg[2\alpha u'^2 + (\alpha+1)w'^2 + \alpha\gamma|\nabla w'|^2 + c_2(1-2\alpha)\left(\frac{\partial u_1}{\partial x_1}\frac{\partial u_2}{\partial x_2} - \frac{\partial u_1}{\partial x_2}\frac{\partial u_2}{\partial x_1}\right)\Bigg]dX$$
$$- (1-\alpha)a(w,w) - (1-2\alpha)\int_\Omega \mathcal{C}[\epsilon(u)+f(\nabla w)]\cdot[\epsilon(u)+f(\nabla w)]dX$$
$$+\frac{1}{2}\int_{\Gamma_1}(m\cdot\nu)(u'^2+w'^2+\gamma|\nabla w'|^2)d\Gamma - P_\Gamma(u,w)$$
$$- c_1\int_{\Gamma_1}(m\cdot\nu)u'\cdot(\nabla u m)d\Gamma - b(w', m\cdot\nabla w),$$

where

$$P_\Gamma(u,w) = \frac{1}{2}\int_\Gamma \mathcal{C}[\epsilon(u)+f(\nabla w)]\cdot[\epsilon(u)+f(\nabla w)]|m\cdot\nu|d\Gamma$$
$$+ c_2\int_\Gamma (m\cdot\nu)(\frac{\partial u_1}{\partial x_1}\frac{\partial u_2}{\partial x_2} - \frac{\partial u_1}{\partial x_2}\frac{\partial u_2}{\partial x_1})d\Gamma$$
$$+\frac{D}{2}\int_\Gamma |m\cdot\nu|\left[\left(\frac{\partial^2 w}{\partial x_1^2}\right)^2 + \left(\frac{\partial^2 w}{\partial x_2^2}\right)^2 + 2\mu\frac{\partial^2 w}{\partial x_1^2}\frac{\partial^2 w}{\partial x_2^2} + 2(1-\mu)\left(\frac{\partial^2 w}{\partial x_1\partial x_2}\right)^2\right]d\Gamma.$$

We obviously have

(6.2)

$$P_\Gamma(u,w) \ge \frac{1}{2}\int_{\Gamma_1} \mathcal{C}[\epsilon(u)+f(\nabla w)]\cdot[\epsilon(u)+f(\nabla w)](m\cdot\nu)d\Gamma$$
$$+ c_2\int_{\Gamma_1} (m\cdot\nu)\left(\frac{\partial u_1}{\partial x_1}\frac{\partial u_2}{\partial x_2} - \frac{\partial u_1}{\partial x_2}\frac{\partial u_2}{\partial x_1}\right)d\Gamma$$
$$+\frac{D}{2}\int_{\Gamma_1} (m\cdot\nu)\left[\left(\frac{\partial^2 w}{\partial x_1^2}\right)^2 + \left(\frac{\partial^2 w}{\partial x_2^2}\right)^2 + 2\mu\frac{\partial^2 w}{\partial x_1^2}\frac{\partial^2 w}{\partial x_2^2} + 2(1-\mu)\left(\frac{\partial^2 w}{\partial x_1\partial x_2}\right)^2\right]d\Gamma.$$

By applying (2.1) and the inequality

$$(x+y)^2 \ge \delta x^2 - \frac{\delta}{1-\delta}y^2, \quad \text{for all } x,y\in\mathbf{R} \quad \text{and} \quad \delta\in(0,1),$$

we obtain

$$\frac{1}{2}\int_{\Gamma_1} \mathcal{C}[\epsilon(u)+f(\nabla w)]\cdot[\epsilon(u)+f(\nabla w)](m\cdot\nu)d\Gamma$$
$$\geq \lambda_0\delta\int_{\Gamma_1}(m\cdot\nu)|\epsilon(u)|^2 d\Gamma - \frac{\lambda_0\delta}{1-\delta}\int_{\Gamma_1}(m\cdot\nu)[f(\nabla w)]^2 d\Gamma \quad \forall\delta\in(0,1).$$

As the trace mapping from $H^2(\Omega)$ to $H^1(\Gamma)$ and the imbedding $H^{1/2}(\Gamma)\subset L^4(\Gamma)$ are continous, the inequality above and (6.2) imply that there is a constant $K_5>0$ such that

(6.3)
$$P_\Gamma(u,w)\geq\lambda_0\delta\int_{\Gamma_1}[\epsilon(u)]^2(m\cdot\nu)d\Gamma-\frac{K_5\delta}{1-\delta}a(w,w)$$
$$+c_2\int_{\Gamma_1}(m\cdot\nu)\left(\frac{\partial u_1}{\partial x_1}\frac{\partial u_2}{\partial x_2}-\frac{\partial u_1}{\partial x_2}\frac{\partial u_2}{\partial x_1}\right)d\Gamma$$
$$+\frac{D}{2}\int_{\Gamma_1}(m\cdot\nu)\left[\left(\frac{\partial^2 w}{\partial x_1^2}\right)^2+\left(\frac{\partial^2 w}{\partial x_2^2}\right)^2+2\mu\frac{\partial^2 w}{\partial x_1^2}\frac{\partial^2 w}{\partial x_2^2}+2(1-\mu)\left(\frac{\partial^2 w}{\partial x_1\partial x_2}\right)^2\right]d\Gamma.$$

Let us now choose $\delta\in(0,1)$ such that

$$1-\alpha-\frac{K_5\delta}{1-\delta}\geq\frac{1-\alpha}{2}. \tag{6.4}$$

We note that, for b small enough (with respect to δ), (6.4) implies

(6.5)
$$P_\Gamma(u,w)\geq K_6\delta\int_{\Gamma_1}|\nabla u|^2(m\cdot\nu)d\Gamma-\frac{K_5\delta}{1-\delta}a(w,w)$$
$$+\frac{D}{2}\int_{\Gamma_1}(m\cdot\nu)\left[\left(\frac{\partial^2 w}{\partial x_1^2}\right)^2+\left(\frac{\partial^2 w}{\partial x_2^2}\right)^2+2\mu\frac{\partial^2 w}{\partial x_1^2}\frac{\partial^2 w}{\partial x_2^2}+2(1-\mu)\left(\frac{\partial^2 w}{\partial x_1\partial x_2}\right)^2\right]d\Gamma,$$

where $K_6>0$. From (6.1), (6.4) and (6.5) it follows that

$$\text{(6.6)}\ \rho'(t)\leq-\int_\Omega\Big[2\alpha u'^2+(\alpha+1)w'^2+\alpha\gamma|\nabla w'|^2$$
$$+c_2(1-2\alpha)\left(\frac{\partial u_1}{\partial x_1}\frac{\partial u_2}{\partial x_2}-\frac{\partial u_1}{\partial x_2}\frac{\partial u_2}{\partial x_1}\right)\Big]dX$$
$$-\frac{1-\alpha}{2}a(w,w)-(1-2\alpha)\int_\Omega\mathcal{C}[\epsilon(u)+f(\nabla w)]\cdot[\epsilon(u)+f(\nabla w)]dX$$
$$+\frac{1}{2}\int_{\Gamma_1}(m\cdot\nu)(u'^2+w'^2+\gamma|\nabla w'|^2)d\Gamma-V_{\Gamma_1}(u,w)$$
$$-c_1\int_{\Gamma_1}(m\cdot\nu)u'\cdot(\nabla u m)d\Gamma-b(w',m\cdot\nabla w),$$

where

(6.7)
$$V_{\Gamma_1}(u,w)=K_6\delta\int_{\Gamma_1}|\nabla u|^2(m\cdot\nu)d\Gamma$$
$$+\frac{D}{2}\int_{\Gamma_1}(m\cdot\nu)\left[\left(\frac{\partial^2 w}{\partial x_1^2}\right)^2+\left(\frac{\partial^2 w}{\partial x_2^2}\right)^2+2\mu\frac{\partial^2 w}{\partial x_1^2}\frac{\partial^2 w}{\partial x_2^2}+2(1-\mu)\left(\frac{\partial^2 w}{\partial x_1\partial x_2}\right)^2\right]d\Gamma.$$

We also note that for every $\eta > 0$ we have the estimates

$$(6.8)\qquad \begin{aligned}|b(w', m\cdot\nabla w)| &\leq [b(w',w')b(m\cdot\nabla w, m\cdot\nabla w)]^{1/2}\\ &\leq \frac{1}{2\eta}b(w',w') + \frac{\eta}{2}b(m\cdot\nabla w, m\cdot\nabla w) \quad \forall\eta > 0,\end{aligned}$$

$$(6.9)\ |c_1\int_{\Gamma_1}(m\cdot\nu)u'\cdot(\nabla um)d\Gamma| \leq \frac{c_1}{2\eta}\int_{\Gamma_1}(m\cdot\nu)u'^2d\Gamma + \frac{c_1\eta}{2}\int_{\Gamma_1}(m\cdot\nu)(\nabla um)^2d\Gamma.$$

Taking in consideration (2.19), (6.8), and (6.9) it follows that

$$(6.10)\qquad \begin{aligned}&-c_1\int_{\Gamma_1}(m\cdot\nu)u'\cdot(\nabla um)d\Gamma - b(w', m\cdot\nabla w) \leq -\frac{1}{2\eta}\widetilde{E}'(t)\\ &+\frac{c_1\eta}{2}\int_{\Gamma_1}(m\cdot\nu)(\nabla um)^2d\Gamma + \frac{\eta}{2}b(m\cdot\nabla w, m\cdot\nabla w) \quad \forall\eta > 0.\end{aligned}$$

We also note that

$$(6.11)\qquad \frac{c_1\eta}{2}\int_{\Gamma_1}(m\cdot\nu)(\nabla um)^2d\Gamma \leq C_1\eta V_{\Gamma_1}(u,w),$$

with $C_1 > 0$. By using the fact that $0 < \mu < \frac{1}{2}$ we obtain

$$(6.12)\qquad b(m\cdot\nabla w, m\cdot\nabla w) \leq C_2[a(w,w) + V_{\Gamma_1}(u,w)].$$

From (6.6)–(6.12), it follows that there is a constant $k > 0$ such that

$$(6.13)\qquad \begin{aligned}\rho'(t) \leq &-(k - C_3\eta)\widetilde{E}(t)\\ &+\frac{1}{2}\int_{\Gamma_1}(m\cdot\nu)(u'^2 + w'^2 + \gamma|\nabla w'|^2)\\ &-[1-(C_1+C_2)\eta]V_{\Gamma_1}(u,w) - \frac{1}{2\eta}\widetilde{E}'(t).\end{aligned}$$

For η small enough relation (6.13) becomes

$$(6.14)\qquad \begin{aligned}\rho'(t) \leq &-\frac{1}{2\eta}\widetilde{E}'(t) - \frac{k}{2}\widetilde{E}(t)\\ &+\frac{1}{2}\int_{\Gamma_1}(m\cdot\nu)(u'^2 + w'^2 + \gamma|\nabla w'|^2) - \frac{1}{2}V_{\Gamma_1}(u,w).\end{aligned}$$

We now introduce a Lyapunov functional obtained by slightly perturbating $\widetilde{E}$ in the direction of ρ. Let $F_\epsilon(t) = \widetilde{E}(t) + \epsilon\rho(t)$. From (6.14) we obtain

$$(6.15)\qquad \begin{aligned}F_\epsilon'(t) \leq &(1 - \frac{\epsilon}{2\eta})\widetilde{E}'(t) - \frac{k\epsilon}{2}\widetilde{E}(t)\\ &+\frac{\epsilon}{2}\int_{\Gamma_1}(m\cdot\nu)(u'^2 + w'^2 + \gamma|\nabla w'|^2)d\Gamma - \frac{\epsilon}{2}V_{\Gamma_1}(u,w).\end{aligned}$$

But, for $\gamma \leq 1$,

$$\widetilde{E}'(t) = -a\int_{\Gamma_1}(m\cdot\nu)(u'^2 + w'^2 + |\nabla w'|^2)d\Gamma$$

$$\leq -c_1 \int_{\Gamma_1} (m \cdot \nu)(u'^2 + w'^2 + \gamma|\nabla w'|^2) d\Gamma,$$

so (6.15) becomes

$$F_\epsilon'(t) \leq \left[\frac{\epsilon}{2} - c_1\left(1 - \frac{\epsilon}{2\eta}\right)\right] \int_{\Gamma_1} (m \cdot \nu)(u'^2 + w'^2 + \gamma|\nabla w'|^2) d\Gamma \\ - \frac{k\epsilon}{2}\widetilde{E}(t) - \frac{\epsilon}{2} V_{\Gamma_1}(u, w). \tag{6.16}$$

We now choose ϵ in such way that $\epsilon \leq 4c_1\eta/(c_1 + \eta)$ which implies that the inequality $\epsilon/2 - c_1(1 - \epsilon/2\eta) \leq -\epsilon/4$ also holds. In this case (6.16) becomes

$$F_\epsilon'(t) \leq -\frac{k\epsilon}{2}\widetilde{E}(t) - \frac{\epsilon}{2} E_\Gamma(u, w), \tag{6.17}$$

where $E_\Gamma(u,w) = \frac{1}{2}\int_{\Gamma_1}(m \cdot \nu)(u'^2 + w'^2 + \gamma|\nabla w'|^2)d\Gamma + V_{\Gamma_1}(u,w)$. From (6.17) we obtain

$$F_\epsilon'(t) \leq -\frac{k\epsilon}{2}\widetilde{E}(t). \tag{6.18}$$

We note now that (2.20), (6.18), and Lemma 6.1 easily imply (4.1). □

AN EXTENSION OF PONTRYAGIN'S PRINCIPLE FOR STATE-CONSTRAINED OPTIMAL CONTROL OF SEMILINEAR ELLIPTIC EQUATIONS AND VARIATIONAL INEQUALITIES*

FRÉDÉRIC BONNANS† AND EDUARDO CASAS‡

Abstract. This paper deals with state-constrained optimal control problems governed by semilinear elliptic equations or variational inequalities. By using Ekeland's principle, a minimum principle of Pontryagin's type under some stability conditions of the optimal cost with respect to the state constraints is derived.

Key words. Pontryagin's principle, boundary control, semilinear elliptic operators, optimality conditions, state constraints

AMS subject classifications. 49K20, 35J65, 35J85

1. Introduction. There exists a vast literature devoted to Pontryagin's principle for optimal control problems governed by ordinary differential equations or evolution partial differential equations, but very few papers have considered the case of elliptic equations. A simple case corresponding to a linear equation was studied by Lions [19]. More recently, the authors derived Pontryagin's principle for semilinear monotone elliptic equations in [7]. Here we extend the results of the last work by letting the existence of pointwise state constraints generalize some preliminary results of Bonnans [3], [4]; in [8] we considered, assuming continuity of the data, the case of boundary as well as distributed control and obtained a "symmetric" formulation of the optimality system involving boundary and interior hamiltonians. See Bonnans and Casas [5] for a different approach to the optimality conditions of state-constrained control problems.

The difficulty of deriving the optimality conditions for control problems associated with variational inequalities is well known; see the works of Mignot [20], Mignot and Puel [21], and Barbu [2]. Zheng-Xu He [18] obtained the optimality conditions for state-constrained problems governed by variational inequalities, and Bonnans and Tiba [9] proved Pontryagin's principle for control problems of semilinear elliptic variational inequalities. Here we will derive a principle of Pontryagin's type for state-constrained control problems of semilinear elliptic variational inequalities.

In this article we prove Pontryagin's principle as follows: with the aid of Ekeland's principle, we introduce a family of control problems without state constraints for which some approximate solutions converge toward the optimal control of the initial problem; we derive the optimality conditions for the problems of this family by using some results on problems without state constraints that generalize those of Bonnans and Casas [7] and Bonnans and Tiba [9] and finally pass to the limit. In order to apply Ekeland's principle we need to assume some stability conditions of the optimal cost with respect to small perturbations of the feasible state set. We distinguish two different stability conditions, called weak and strong, respectively. Under

a weak stability condition we derive the optimality conditions in a nonqualified form, while the strong stability allows us to prove a qualified Pontryagin's principle. The weak stability condition has been used by Casas [13] to prove the convergence of the numerical approximations of state-constrained control problems.

The paper is organized as follows: in the next section we formulate the control problem associated with a monotone semilinear elliptic equation, and in §3 the statements of the weak and strong Pontryagin's principles are presented; in §4 we give some technical results used in §§5 and 6 to prove the theorems stated in the third section; finally §7 is devoted to the control of variational inequalities.

2. Setting of the problem. Let Ω be an open and bounded subset of R^n, $n \geq 1$, with a Lipschitz boundary Γ. Given a nonempty bounded set $K \subset R^m$, $m \geq 1$, and $f : \Omega \times R \times K \longrightarrow R$ we consider the following boundary value problem:

$$\tag{2.1} \left\{ \begin{array}{l} Ay = f(x, y(x), u(x)) \quad \text{in } \Omega, \\ y = 0 \quad \text{on } \Gamma, \end{array} \right.$$

where

$$Ay = -\sum_{i,j=1}^{n} \partial_{x_j} \left(a_{ij}(x) \partial_{x_i} y(x) \right),$$

$$\tag{2.2} \left\{ \begin{array}{l} a_{ij} \in C^{0,1}(\overline{\Omega}) \text{ and} \\ \exists \Lambda > 0 \text{ such that } \displaystyle\sum_{i,j=1}^{n} a_{ij}(x)\xi_i\xi_j \geq \Lambda |\xi|^2 \quad \forall \xi \in R^n, \ \forall x \in \Omega. \end{array} \right.$$

We recall that $C^{0,\alpha}(\overline{\Omega})$, with $\alpha \in (0,1]$, is the space of all continuous functions in $\overline{\Omega}$ that satisfy the Hölder condition

$$\sup_{x_1, x_2 \in \overline{\Omega}} \frac{|u(x_2) - u(x_1)|}{|x_2 - x_1|^\alpha} < +\infty.$$

Given two measurable functions $L : \Omega \times R \times K \longrightarrow R$ and $g : \overline{\Omega} \times R \longrightarrow R$, for every $\delta > 0$ we formulate the control problem

$$(P_\delta) \left\{ \begin{array}{l} \min J(y, u) = \displaystyle\int_\Omega L(x, y(x), u(x))\, dx \\ (y, u) \text{ satisfies (2.1)}, \ u(x) \in K \text{ a.e. } x \in \Omega \text{ and } g(x, y(x)) \leq \delta \ \forall x \in \Omega. \end{array} \right.$$

We will make the following assumptions on the functions defining the problem (P_δ): $g \in C(\overline{\Omega} \times R)$; g, L, and f are continuously differentiable with respect to the second variable for every $(x, u) \in \Omega \times K$; and there exist functions $M_1 \in L^s(\Omega)$, $s > n/2$, and $s \geq 2$, $M_2 \in L^1(\Omega)$, and η increasing monotone verifying for every $(x, y, u) \in \Omega \times R \times K$

$$\tag{2.3} \left\{ \begin{array}{l} |f(x,0,u)| + \left| \dfrac{\partial f}{\partial y}(x, y, u) \right| \leq M_1(x) + \eta(|y|), \\ \\ |L(x,0,u)| + \left| \dfrac{\partial L}{\partial y}(x, y, u) \right| \leq M_2(x) + \eta(|y|), \\ \\ \dfrac{\partial g}{\partial y} \in C(\overline{\Omega} \times R), \quad \dfrac{\partial f}{\partial y}(x, y, u) \leq 0. \end{array} \right.$$

We will say that a control $u : \Omega \longrightarrow R^m$ is feasible if $u(x) \in K$ a.e. $x \in \Omega$ and the mapping $(x, y) \longrightarrow (f(x, y, u(x)), L(x, y, u(x)))$ is measurable in $\Omega \times R$. The set of feasible controls is denoted by $\mathcal{K}$. In this set we define the distance, called Ekeland's distance, as

$$d(u, v) = m(\{x \in \Omega : u(x) \neq v(x)\}),$$

where m denotes the Lebesgue measure. Adapting the proof of Ekeland [16] to our case it is easy to check that $(\mathcal{K}, d)$ is a complete metric space (the only difference is that we have to check the feasibility of the limit of a Cauchy sequence, which is immediate from the definition and the fact that a limit of measurable functions is measurable).

Under the previous hypotheses and thanks to the boundedness of K, we can deduce the following theorem.

THEOREM 2.1. *There exist constants* $C_1 > 0$ *and* $\alpha \in (0, 1)$ *such that for every* $u \in \mathcal{K}$ *equation* (2.1) *has a unique solution* $y_u \in H_0^1(\Omega) \cap C^{0,\alpha}(\overline{\Omega})$ *satisfying*

$$\|y_u\|_{H_0^1(\Omega)} + \|y_u\|_{C^{0,\alpha}(\overline{\Omega})} \leq C_1. \tag{2.4}$$

Furthermore the mapping $u \in (\mathcal{K}, d) \longrightarrow y_u \in H_0^1(\Omega) \cap C^{0,\alpha}(\overline{\Omega})$ *is continuous.*

Before proving this theorem we state the following lemma.

LEMMA 2.2. *There exist* $\alpha \in (0, 1)$, C_2, *and* C_3 *such that for every* $a, b \in L^s(\Omega)$, $a(x) \geq 0$, *the problem*

$$\begin{cases} Ay + ay = b & \textit{in } \Omega, \\ y = 0 & \textit{on } \Gamma \end{cases} \tag{2.5}$$

has a unique solution $y \in H_0^1(\Omega) \cap C^{0,\alpha}(\overline{\Omega})$ *verifying*

$$\|y\|_{H_0^1(\Omega)} + \|y\|_{L^\infty(\Omega)} \leq C_2 \|b\|_{L^s(\Omega)}, \tag{2.6}$$

$$\|y\|_{C^{0,\alpha}(\overline{\Omega})} \leq C_3 \|b\|_{L^s(\Omega)} \left(1 + \|a\|_{L^s(\Omega)}\right). \tag{2.7}$$

This result follows from classical estimations in the spaces $C^{0,\alpha}(\overline{\Omega})$ (Gilbarg and Trudinger [17] or Stampacchia [22]); see Bonnans and Casas [7] for details. Now we prove Theorem 2.1.

Proof. The first part of the theorem is also proved in Bonnans and Casas [7]. Let us prove the continuity of $u \longrightarrow y_u$. Let $\{u_k\}_{k=1}^\infty \subset \mathcal{K}$ be a sequence converging to $u \in \mathcal{K}$, i.e., $d(u_k, u) \to 0$. Denote by y_k and y the states corresponding to u_k and u, respectively. From (2.3) and (2.4) we deduce the existence of $M > 0$ such that

$$b_k(x) = f(x, y_k(x), u(x)) - f(x, y_k(x), u_k(x))$$

satisfies

$$\|b_k\|_{L^s(\Omega)} = \left(\int_{\{x \,:\, u_k(x) \neq u(x)\}} |f(x, y_k(x), u(x)) - f(x, y_k(x), u_k(x))|^s \, dx \right)^{1/s} \to 0.$$

Now applying the mean value theorem we get for some function $\theta_k : \overline{\Omega} \longrightarrow (0, 1)$

$$A(y - y_k) - \frac{\partial f}{\partial y}(x, y + \theta_k(y - y_k), u(x))(y - y_k) = b_k.$$

Therefore, from Lemma 2.2 and using (2.3) we obtain

$$\|y-y_k\|_{H_0^1(\Omega)}+\|y-y_k\|_{C^{0,\alpha}(\overline{\Omega})}\le M'\|b_k\|_{L^s(\Omega)}\to 0,$$

which completes the proof. □

Remark 2.3. In order to use Lemma 2.2 in the above proof we have to check that

$$x\longrightarrow \frac{\partial f}{\partial y}(x,y(x)+\theta_k(x)(y(x)-y_k(x)),u(x))$$

is a measurable function. Although $\theta_k(x)$ itself might be nonmeasurable, this is true because by definition of θ_k as

$$\frac{\partial f}{\partial y}(x,y(x)+\theta_k(x)(y(x)-y_k(x)),u(x))$$
$$=\begin{cases}\dfrac{f(x,y(x),u(x))-f(x,y_k(x),u(x))}{y(x)-y_k(x)} & \text{if } y(x)\ne y_k(x),\\[2ex] \dfrac{\partial f}{\partial y}(x,y(x),u(x)) & \text{if } y(x)=y_k(x).\end{cases}$$

We finish this section by proving a lemma that will be used several times in this paper. First let us introduce some notation. In the sequel $M(\Omega)$ will denote the space of real regular Borel measures in Ω, which is identified with the dual space of $C_0(\Omega)$, the space formed by the real continuous functions defined in $\overline{\Omega}$ and vanishing on Γ. Let $A^\star$ denote the formal adjoint operator of A:

$$A^\star y=-\sum_{i,j=1}^{n}\partial_{x_j}\left(a_{ji}(x)\partial_{x_i}y(x)\right).$$

LEMMA 2.4. *For every function $a\in L^s(\Omega)$, with $a(x)\ge 0$ a.e. $x\in\Omega$, and every Borel measure $\mu\in M(\Omega)$ there exists a unique solution in $W_0^{1,\sigma}(\Omega)$, for all $\sigma<n/(n-1)$, of problem*

$$\begin{cases}A^\star p+ap=\mu & \text{in } \Omega,\\ y=0 & \text{on } \Gamma.\end{cases}$$

Moreover there exists a constant $M>0$ independent of a such that

$$\|p\|_{W_0^{1,\sigma}(\Omega)}\le M\|\mu\|_{M(\Omega)}. \tag{2.8}$$

Proof. The existence and uniqueness in $W_0^{1,\sigma}(\Omega)$ of solution p of the above Dirichlet problem is well known; see Stampacchia [22] or Casas [12]. Let us prove (2.8). Let t be the conjugate of σ, $1/t+1/\sigma=1$, thus $t>n$. For every $\psi\in W^{-1,t}(\Omega)=(W_0^{1,s}(\Omega))'$, the equation

$$\begin{cases}A\varphi+a\varphi=\psi & \text{in } \Omega,\\ \varphi=0 & \text{on } \Gamma\end{cases}$$

has a unique solution in $H_0^1(\Omega)\cap C_0(\Omega)$, and proceeding as in [7, Lemma 3.2], there exists $M>0$ independent of a such that

$$\|\varphi\|_\infty\le M\|\psi\|_{W^{-1,t}(\Omega)}.$$

Hence

$$\left|\int_\Omega p\psi\,dx\right| = \left|\int_\Omega p(A\varphi + a\varphi)\,dx\right| = \left|\int_\Omega \varphi\,d\mu\right|$$
$$\leq \|\varphi\|_\infty \|\mu\|_{M(\Omega)} \leq M\|\psi\|_{W^{-1,t}(\Omega)}\|\mu\|_{M(\Omega)},$$

which proves the desired inequality. □

3. The weak and strong Pontryagin's minimum principle. In this section we present the statements of the weak and strong Pontryagin's principles. First let us introduce some notation and definitions.

DEFINITION 3.1. *We will say that problem (P_δ) is weakly stable on the right if*

$$\lim_{\delta' \searrow \delta} \inf(P_{\delta'}) = \inf(P_\delta), \tag{3.9}$$

and weakly stable on the left if

$$\lim_{\delta' \nearrow \delta} \inf(P_{\delta'}) = \inf(P_\delta). \tag{3.10}$$

(P_δ) is said to be strongly stable on the right (respectively, left) if there exist $\epsilon > 0$ and $r > 0$ such that:

$$\inf(P_\delta) - \inf(P_{\delta'}) \leq r(\delta' - \delta) \quad \forall\delta' \in [\delta, \delta + \epsilon], \tag{3.11}$$

respectively,

$$\inf(P_{\delta'}) - \inf(P_\delta) \leq r(\delta - \delta') \quad \forall\delta' \in [\delta - \epsilon, \delta]. \tag{3.12}$$

If (P_δ) is weakly (respectively, strongly) stable on the left and on the right, it will be called weakly (respectively, strongly) stable.

Sufficient conditions for the weak stability were given by Casas [14] under additional regularity hypotheses on the functions L and f. In particular, if they are continuous with respect to the third variable, L is convex with respect to the same variable, K is convex and closed, and (P_{δ_0}) has a feasible pair (y, u), then (P_δ) is stable on the right for every $\delta > \delta_0$. In spite of these results, in general it is difficult to establish the stability of a problem, mainly the strong stability. However most of problems (P_δ) are weak and strongly stable. More precisely, we get the following proposition.

PROPOSITION 3.2. *Let us denote by δ_0 a real number such that (P_{δ_0}) has at least one feasible pair (y, u). Then for every $\delta \geq \delta_0$, except at most a countable number of them (respectively, a set of zero measure), the problem (P_δ) is weakly (respectively, strongly) stable.*

Proof. If we define $\phi : [\delta_0, +\infty) \longrightarrow R$ by $\phi(\delta) = \inf(P_\delta)$, then ϕ is a decreasing monotone function and therefore ϕ is continuous (respectively, differentiable) at each point except at most a countable number of them (respectively, a set of zero measure). Finally it is obvious that the continuity (respectively, differentiability) of ϕ at δ implies the weak (respectively, strong) stability of (P_δ). □

Given a number $\alpha \geq 0$, we define the Hamiltonian associated to (P_δ) by

$$H_\alpha(x, y, u, p) = \alpha L(x, y, u) + pf(x, y, u).$$

If $\alpha = 1$, we simply write H instead of H_1. Now we can formulate the following theorems.

THEOREM 3.3 (Weak Pontryagin's principle). *Let $\overline{u}$ be a solution of (P_δ) in $(\mathcal{K}, d)$, with $\overline{y}$ its associated state. If (P_δ) is weakly stable on the right, then there exist $\overline{\alpha} \geq 0$, $\overline{p} \in W_0^{1,\sigma}(\Omega)$ for every $\sigma < \frac{n}{n-1}$ and $\overline{\mu} \in M(\Omega)$ such that*

$$\overline{\alpha} + \|\overline{\mu}\|_{M(\Omega)} > 0, \tag{3.13}$$

$$\begin{cases} A^\star \overline{p} = \dfrac{\partial f}{\partial y}(x, \overline{y}(x), \overline{u}(x)) + \overline{\alpha}\dfrac{\partial L}{\partial y}(x, \overline{y}(x), \overline{u}(x)) + \dfrac{\partial g}{\partial y}(x, \overline{y}(x))\overline{\mu} & \text{in } \Omega, \\ \overline{p} = 0 \quad \text{on } \Gamma, \end{cases} \tag{3.14}$$

$$\int_\Omega (z(x) - g(x, \overline{y}(x)))d\overline{\mu}(x) \leq 0 \quad \forall z \in C_0(\Omega) \text{ with } z(x) \leq \delta \ \forall x \in \Omega, \tag{3.15}$$

and for every $v \in K$

$$H_{\overline{\alpha}}(x, \overline{y}(x), \overline{u}(x), \overline{p}(x)) \leq H_{\overline{\alpha}}(x, \overline{y}(x), v, \overline{p}(x)) \quad a.e.\ x \in \Omega. \tag{3.16}$$

Moreover if there exists a Lebesgue measurable set $\Omega_0 \subset \Omega$, with $m(\Omega_0) = m(\Omega)$, of such a kind that one of the two following conditions is satisfied

(H1) *for each $y \in C_0(\Omega)$ and $\forall v \in K$ the set of Lebesgue points of the functions $x \longrightarrow f(x, y(x), v)$ and $x \longrightarrow L(x, y(x), v)$ contains Ω_0,*

(H2) *the functions L and f are continuous with respect to the third variable for every $x \in \Omega_0$,*

then

$$H_{\overline{\alpha}}(x, \overline{y}(x), \overline{u}(x), \overline{p}(x)) = \min_{v \in K} H_{\overline{\alpha}}(x, \overline{y}(x), v, \overline{p}(x)) \quad a.e.\ x \in \Omega. \tag{3.17}$$

THEOREM 3.4 (Strong Pontryagin's principle). *Under the assumptions of Theorem* 3.3 *and assuming that (P_δ) is strongly stable on the right, there exist $\overline{p} \in W_0^{1,\sigma}(\Omega)$ and $\overline{\mu} \in M(\Omega)$ satisfying* (3.14)–(3.16), *or* (3.17) *if the conditions* (H1) *or* (H2) *hold, with $\overline{\alpha} = 1$.*

A first version of these theorems (with stronger hypotheses) was given by Bonnans in [3] and [4]. Since we will use penalization techniques to prove these theorems, the stability on the right is the proper condition to obtain the desired result. However the Slater condition, which is a stability condition on the left, is the usual hypothesis to derive the optimality conditions (different of Pontryagin's principle) in a qualified form; see Bonnans and Casas [6]. Weak stability on the left also was the assumption in [13] to prove the convergence of the numerical approximations.

4. Hamiltonian formulation of the cost variation. In this section we generalize some results of [7] that we will use later. Let us denote by $h : \overline{\Omega} \times R \longrightarrow R$ and $\phi : R \longrightarrow R$ two functions satisfying the condition that ϕ is of class C^1 and h is continuous, differentiable with respect to the second variable and $\frac{\partial h}{\partial y} \in C(\overline{\Omega} \times R)$. Now we consider the functional

$$\hat{J}(y, u) = \int_\Omega L(x, y(x), u(x))\, dx + \phi\left(\int_\Omega h(x, y(x))\, dx\right).$$

We are interested in studying this type of functionals because it plays an important role in the proof of Pontryagin's principle, the second term being particularized later to some penalization of state constraints. As in the previous section

$$H(x, y, u, p) = L(x, y, u) + pf(x, y, u).$$

In the first part of this section we will assume that the following regularity condition holds:

$$\left|\frac{\partial L}{\partial y}(x,y,u)\right| \le M_3(x) + \eta(|y|) \quad \forall (x,y,u) \in \Omega \times R \times K, \tag{4.18}$$

with $M_3 \in L^s(\Omega)$.

Let $u, v \in \mathcal{K}$ be two controls and y_u and y_v the associated states. From the mean value theorem it follows that there exist the intermediate states $\check{y}$, $\hat{y}$, and $\tilde{y}$ satisfying

$$\phi\left(\int_\Omega h(x,y_v(x))\,dx\right) = \phi\left(\int_\Omega h(x,y_u(x))\,dx\right)$$

$$+\phi'\left(\int_\Omega h(x,\check{y}(x))\,dx\right)\int_\Omega \frac{\partial h}{\partial y}(x,\check{y}(x))(y_v(x)-y_u(x))\,dx,$$

$$f(\cdot,y_v,v) = f(\cdot,y_u,v) + \frac{\partial f}{\partial y}(\cdot,\hat{y},v)(y_v - y_u),$$

$$L(\cdot,y_v,v) = L(\cdot,y_u,v) + \frac{\partial L}{\partial y}(\cdot,\tilde{y},v)(y_v - y_u),$$

with $\check{y}(x), \hat{y}(x), \tilde{y}(x) \in [y_u(x), y_v(x)]\ \forall x \in \overline{\Omega}$. Since y_u and y_v are bounded, it follows that $\tilde{y}, \hat{y}$, and $\tilde{y}$ also are bounded. Now we define the intermediate adjoint state $p_{u,v}$ as the solution of

$$\left\{\begin{array}{l} A^\star p_{u,v} = \frac{\partial f}{\partial y}(\cdot,\hat{y},v)p_{u,v} + \frac{\partial L}{\partial y}(\cdot,\tilde{y},v) + \phi'\left(\int_\Omega h(x,\check{y})dx\right)\frac{\partial h}{\partial y}(x,\check{y}) \quad \text{in } \Omega, \\ p_{u,v} = 0 \quad \text{on}\Gamma. \end{array}\right. \tag{4.19}$$

Note that if $u = v$, then $\tilde{y}, \hat{y} = \tilde{y} = y_u$ and $p_{u,v} = p_u$ is the adjoint state associated to u. Let us verify that (4.19) is well posed.

LEMMA 4.1. *If* (4.18) *holds, then equation* (4.19) *has a unique solution* $p_{u,v} \in H_0^1(\Omega) \cap C^{0,\alpha}(\overline{\Omega})$ *that moreover satisfies*

$$\|p_{u,v}\|_{H_0^1(\Omega)} + \|p_{u,v}\|_{C^{0,\alpha}(\overline{\Omega})} \le C_4 \quad \forall u, v \in \mathcal{K}. \tag{4.20}$$

Proof. The proof is a straightforward consequence of Lemma 2.2 and inequalities (2.3). □

Now we have the following Hamiltonian formulation of the cost variation.

PROPOSITION 4.2. *Assume that* (4.18) *is satisfied, and let* $u, v \in \mathcal{K}$ *and* $p_{u,v}$ *be the intermediate adjoint state associated. Then*

$$\hat{J}(y_v,v) = \hat{J}(y_u,u) + \int_\Omega [H(x,y_u(x),v(x),p_{u,v}(x)) - H(x,y_u(x),u(x),p_{u,v}(x))]\,dx.$$

Proof. We have

$$\hat{J}(y_v,v) - \hat{J}(y_u,u) = \int_\Omega [L(x,y_u(x),v(x)) - L(x,y_u(x),u(x))]dx$$

$$+\int_\Omega [L(x,y_v(x),v(x)) - L(x,y_u(x),v(x))]\,dx$$

$$+\phi\left(\int_\Omega h(x,y_v(x))\,dx\right) - \phi\left(\int_\Omega h(x,y_u(x))\,dx\right).$$

From (4.19) we deduce

$$\int_\Omega [L(x,y_v(x),v(x)) - L(x,y_u(x),v(x))]\,dx$$

$$+\phi\left(\int_\Omega h(x,y_v(x))dx\right) - \phi\left(\int_\Omega h(x,y_u(x))\,dx\right)$$

$$= \int_\Omega \frac{\partial L}{\partial y}(x,\tilde{y}(x),v(x))(y_v(x) - y_u(x))\,dx$$

$$+\phi'\left(\int_\Omega h(x,\check{y}(x))dx\right)\int_\Omega \frac{\partial h}{\partial y}(x,\check{y}(x))(y_v(x) - y_u(x))\,dx$$

$$= \int_\Omega \left[A^\star p_{u,v} - \frac{\partial f}{\partial y}(x,\hat{y}(x),v(x))p_{u,v}\right](y_v - y_u)\,dx$$

$$= \int_\Omega A(y_v - y_u)p_{u,v}dx - \int_\Omega \frac{\partial f}{\partial y}(x,\hat{y}(x),v(x))p_{u,v}(y_v - y_u)\,dx$$

$$= \int_\Omega [f(x,y_v(x),v(x)) - f(x,y_u(x),u(x))]p_{u,v}\,dx$$

$$+\int_\Omega [f(x,y_u(x),v(x)) - f(x,y_v(x),v(x))]p_{u,v}\,dx$$

$$= \int_\Omega [f(x,y_u(x),v(x)) - f(x,y_u(x),u(x))]p_{u,v}\,dx,$$

which proves the proposition. □

PROPOSITION 4.3. *Assume that* (4.18) *holds, and let* $\{v_k\}_{k=1}^\infty \subset \mathcal{K}$ *be a sequence converging to u in the topology defined by Ekeland's distance. Then the states and the adjoint states associated* $y_k = y_{v_k}$ *and* $p_k = p_{u,v_k}$ *converge to* y_u *and* p_u*, respectively, in* $H_0^1(\Omega) \cap C^{0,\alpha}(\overline{\Omega})$.

Proof. The convergence $y_k \to y_u$ follows from Theorem 2.1. The convergence of $\{p_k\}$ follows from the continuity of $v \in \mathcal{K} \longrightarrow p_{u,v} \in H_0^1(\Omega) \cap C^{0,\alpha}(\overline{\Omega})$, which can be proved arguing in a similar way to the proof of Theorem 2.1. □

Given a point $x_0 \in \Omega$, we will denote

$$\omega_k(x_0) = \{x \in \Omega : \|x - x_0\| \leq 1/k\}$$

and $m_k(x_0) = m(\omega_k(x_0))^{-1}$. We will say that a sequence $\{v_k\}$ in $\mathcal{K}$ is a spike perturbation of $u \in \mathcal{K}$ around x_0 associated to $v \in K$ if

$$v_k(x) = \begin{cases} v & \text{if } x \in \omega_k(x_0), \\ u(x) & \text{otherwise.} \end{cases}$$

PROPOSITION 4.4. *Assume that (4.18) holds, let v_k be a spike perturbation of u around x_0 associated to $v \in K$, and let y_k be the associated state. Then for every $u \in \mathcal{K}$ there exists a set $\Omega(u,v) \subset \Omega$, with $m(\Omega(u,v)) = m(\Omega)$, such that*

$$\lim_{k \to \infty} m_k(x_0)[\hat{J}(y_k, v_k) - \hat{J}(y_u, u)]$$

$$= H(x_0, y_u(x_0), v, p_u(x_0)) - H(x_0, y_u(x_0), u(x_0), p_u(x_0)) \quad \forall x_0 \in \Omega(u,v).$$

Proof. From Proposition 4.2 we have

$$\hat{J}(y_k, v_k) - \hat{J}(y_u, u) = \int_{\omega_k(x_0)} [H(x, y_u(x), v, p_k(x)) - H(x, y_u(x), u(x), p_k(x))]\, dx,$$

where $p_k = p_{u,v_k}$ converges to p_u in $H_0^1(\Omega) \cap C^{0,\alpha}(\overline{\Omega})$ as stated in Proposition 4.3. Then

$$\hat{J}(y_k, v_k) - \hat{J}(y_u, u) = \int_{\omega_k(x_0)} [H(x, y_u(x), v, p_u(x)) - H(x, y_u(x), u(x), p_u(x))]\, dx$$

$$+ \int_{\omega_k(x_0)} f(x, y_u(x), v)(p_k(x) - p_u(x))\, dx + \int_{\omega_k(x_0)} f(x, y_u(x), u)(x)(p_u(x) - p_k(x))\, dx.$$

Let $\Omega(u,v)$ be the intersection of the Lebesgue points of the following mappings:

$$\begin{aligned} x &\longrightarrow f(x, y_u(x), v), \\ x &\longrightarrow f(x, y_u(x), u(x)), \\ x &\longrightarrow H(x, y_u(x), v, p_u(x)), \\ x &\longrightarrow H(x, y_u(x), u(x), p_u(x)). \end{aligned}$$

Then $m(\Omega(u,v)) = m(\Omega)$. Now using the uniform convergence of $p_k \to p_u$, it follows that for every $x_0 \in \Omega(u,v)$

$$m_k(x_0) \left| \int_{\omega_k(x_0)} f(x, y_u(x), v)(p_u(x) - p_k(x))\, dx \right|$$

$$\leq m_k(x_0) \int_{\omega_k(x_0)} |f(x, y_u(x), v)|\, dx \|p_u - p_k\|_{L^\infty(\Omega)} \to 0.$$

Analogously

$$m_k(x_0) \left| \int_{\omega_k(x_0)} f(x, y_u(x), u(x))(p_u(x) - p_k(x))\, d\dot{x} \right|$$

$$\leq m_k(x_0)\int_{\omega_k(x_0)}|f(x,y_u(x),u(x))|\,dx\|p_u-p_k\|_{L^\infty(\Omega)}\to 0.$$

Therefore we deduce that

$$\lim_{k\to\infty} m_k(x_0)[\hat{J}(y_k,v_k)-\hat{J}(y_u,u)]$$

$$=\lim_{k\to\infty} m_k(x_0)\int_{\omega_k(x_0)}[H(x,y_u(x),v,p_u(x))-H(x,y_u(x),u(x),p_u(x))]\,dx$$

$$=H(x_0,y_u(x_0),v,p_u(x_0))-H(x_0,y_u(x_0),u(x_0),p_u(x_0)),$$

which concludes the proof. □

The last proposition allows us to deduce easily Pontryagin's principle for control problems without state constraints. In fact it is enough to suppose that $\overline{u}\in\mathcal{K}$ is a stationary point to derive a minimum principle.

DEFINITION 4.5. *We say that $\overline{u}$ is a stationary point of the control problem*

$$(P)\begin{cases}\min \hat{J}(y,u)\\ (y,u)\ \textit{satisfies}\ (2.1)\ \textit{and}\ \ u(x)\in K\ \textit{a.e.}\ x\in\Omega\end{cases}$$

if

$$\liminf_{d(u,\overline{u})\to 0}\frac{\hat{J}(y,u)-\hat{J}(\overline{y},\overline{u})}{d(u,\overline{u})}\geq 0.$$

Obviously, every local solution in $(\mathcal{K},d)$ is a stationary point. Now we can prove the following proposition

PROPOSITION 4.6. *Let us suppose that* (4.18) *holds, and let $\overline{u}$ be a stationary point of (P). Then for every $v\in K$*

$$H(x,\overline{y}(x),\overline{u}(x),\overline{p}(x))\leq H(x,\overline{y}(x),v,\overline{p}(x))\quad \textit{a.e. } x\in\Omega,$$

where $\overline{y}$ and $\overline{p}$ are the state and adjoint state associated to $\overline{u}$. Moreover, if condition (H1) *or* (H2) *is verified, then $\overline{u}$ satisfies Pontryagin's principle:*

$$H(x,\overline{y}(x),\overline{u}(x),\overline{p}(x))=\min_{v\in K}H(x,\overline{y}(x),v,\overline{p}(x))\quad \textit{a.e. } x\in\Omega.$$

Proof. The first part of the proof is an immediate consequence of Proposition 4.4; it is enough to remark that $d(v_k,\overline{u})\leq m_k(x_0)^{-1}$. To derive Pontryagin's principle under condition (H1) we use the fact that the set $\Omega(\overline{u},v)$, defined in the proof of Proposition 4.4, contains the intersection of Ω_0 and the set of Lebesgue points of the functions:

$$\begin{aligned}x&\longrightarrow f(x,\overline{y}(x),\overline{u}(x)),\\ x&\longrightarrow H(x,\overline{y}(x),\overline{u}(x),\overline{p}(x)).\end{aligned}$$

Indeed the continuity of $\overline{p}$ and condition (H1) imply that Ω_0 is a subset of the Lebesgue point set of the functions:

$$\begin{aligned}x&\longrightarrow f(x,\overline{y}(x),v),\\ x&\longrightarrow H(x,\overline{y}(x),v,\overline{p}(x)).\end{aligned}$$

Therefore

$$H(x,\overline{y}(x),\overline{u}(x),\overline{p}(x)) \leq H(x,\overline{y}(x),v,\overline{p}(x)) \ \ \forall x \in \Omega_0 \text{ and } \forall v \in K.$$

Then

$$H(x,\overline{y}(x),\overline{u}(x),\overline{p}(x)) = \min_{v\in K} H(x,\overline{y}(x),v,\overline{p}(x)) \ \ \forall x \in \Omega_0.$$

In the case of (H2), let us take a sequence $\{v_k\}_{k=1}^{\infty}$ dense in K and $\Omega_1 = \cap_k \Omega(\overline{u}, v_k)$. Then

$$H(x,\overline{y}(x),\overline{u}(x),\overline{p}(x)) \leq H(x,\overline{y}(x),v_k,\overline{p}(x)) \ \ \forall x \in \Omega_1 \text{ and } \forall k.$$

Finally the continuity of the Hamiltonian with respect to the control and the last inequality imply Pontryagin's principle in the points $x \in \Omega_0 \cap \Omega_1$. □

We now get rid of the regularity hypothesis (4.18).

PROPOSITION 4.7. *Let $\overline{u}$ be a local solution of* (P). *Then the conclusions of Proposition* 4.6 *remain true without hypothesis* (4.18).

To prove this proposition we will use Ekeland's principle.

THEOREM 4.8 (Ekeland [16]). *Let (E,d) be a complete metric space, $F : E \longrightarrow R \cup \{+\infty\}$ be a lower semicontinuous function, and let $e_\epsilon \in E$ satisfy*

$$F(e_\epsilon) \leq \inf_{e\in E} F(e) + \epsilon^2.$$

Then there exists an element $\overline{e}_\epsilon \in E$ such that

$$F(\overline{e}_\epsilon) \leq F(e_\epsilon), \quad d(\overline{e}_\epsilon, e_\epsilon) \leq \epsilon,$$

and

$$F(\overline{e}_\epsilon) \leq F(e) + \epsilon d(e, \overline{e}_\epsilon) \ \ \forall e \in E.$$

Now we proceed to prove Proposition 4.7.

Proof. The idea is to regularize L and to check that $\overline{u}$ is an approximate solution of the regularized problem. Using Ekeland's principle we get some optimality conditions as in Proposition 4.7 and finally pass to the limit in these optimality conditions and get the desired result.

The regularization is as follows. By Proj_ϵ we denote the projection onto the segment $[-1/\epsilon, +1/\epsilon]$, i.e.,

$$\text{Proj}_\epsilon(t) = \max\{-1/\epsilon, \min\{t, +1/\epsilon\}\}.$$

We define

$$\varphi_\epsilon(x,t,u) = \text{Proj}_\epsilon\left(\frac{\partial L}{\partial y}(x,t,u)\right)$$

and

$$L_\epsilon(x,t,u) = L(x,0,u) + \int_0^t \varphi_\epsilon(x,t,u)\,dt.$$

We can now state the problem

$$(P^\epsilon)\begin{cases} \min \hat{J}_\epsilon(y,u) = \displaystyle\int_\Omega L_\epsilon(x,y(x),u(x))\,dx + \phi\left(\int_\Omega h(x,y(x))\,dx\right) \\ (y,u) \text{ satisfies (2.1)}, \ u(x) \in K \text{ a.e. } x \in \Omega. \end{cases}$$

We claim that $\inf(P^\epsilon) \to \inf(P)$ when $\epsilon \searrow 0$. To prove this it is enough to check that

$$(4.21) \qquad |\hat{J}_\epsilon(y,u) - \hat{J}(y,u)| \le r_\epsilon \quad \forall u \in K \text{ and } (y,u) \text{ satisfying (2.1)},$$

with $r_\epsilon \searrow 0$ when $\epsilon \searrow 0$ and r_ϵ independent of u. Indeed, if $u_\epsilon \in \mathcal{K}$ satisfies that $\hat{J}_\epsilon(y_\epsilon,u_\epsilon) \le \inf(P_\epsilon) + \varepsilon$, y_ϵ being the state associated with u_ϵ, then by (4.21)

$$\liminf_{\epsilon\searrow 0} \inf(P_\epsilon) \ge \liminf_{\epsilon\searrow 0}(\hat{J}_\epsilon(y_\epsilon,u_\epsilon) - \epsilon) \ge \liminf_{\epsilon\searrow 0}(\hat{J}_\epsilon(\overline{y},\overline{u}) - r_\epsilon) = \inf(P)$$

and also

$$\limsup_{\epsilon\searrow 0} \inf(P_\epsilon) \le \limsup_{\epsilon\searrow 0} \hat{J}_\epsilon(\overline{y},\overline{u}) \le \limsup_{\epsilon\searrow 0}[\hat{J}(\overline{y},\overline{u}) + r_\epsilon] = \inf(P),$$

which proves that $\inf(P_\epsilon) \to \inf(P)$, as desired. Now let us check that (4.21) holds. Indeed

$$L(x,y,u) - L_\epsilon(x,y,u) = \int_0^y \left[\frac{\partial L}{\partial y}(x,t,u) - \varphi_\epsilon(x,t,u)\right] dt.$$

Let $M > 0$ be such that $|y(x)| \le M$ whenever (y,u) is solution of (2.1) and $u \in \mathcal{K}$. Then

$$|J_\epsilon(y,u) - J(y,u)| \le \int_\Omega \int_{-M}^{+M} \left|\varphi_\epsilon(x,t,u(x)) - \frac{\partial L}{\partial y}(x,t,u(x))\right| dt\,dx$$

$$= \int_{-M}^{+M} \int_\Omega \left|\varphi_\epsilon(x,t,u(x)) - \frac{\partial L}{\partial y}(x,t,u(x))\right| dx\,dt$$

$$\le 2M \int_\Omega \sup_{|t|\le M,\ v\in K} \left|\varphi_\epsilon(x,t,u(x)) - \frac{\partial L}{\partial y}(x,t,u(x))\right| dx.$$

Put

$$\Omega_\epsilon = \left\{ x \in \Omega : \sup_{|t|\le M, v\in K} \left|\frac{\partial L}{\partial y}(x,t,u(x))\right| \ge \frac{1}{\epsilon} \right\}.$$

As

$$\left|\frac{\partial L}{\partial y}(x,t,u(x))\right| \le M_2 \in L^1(\Omega),$$

it follows that $m(\Omega_\epsilon) \searrow 0$ as $\epsilon \searrow 0$ and

$$\left|\hat{J}_\epsilon(y,u) - \hat{J}(y,u)\right| \le r_\epsilon = 2M \int_{\Omega_\epsilon} M_2(x)dx \to 0.$$

As a consequence of the previous results, we can get a family of real numbers $\{\delta_\epsilon\}_{\epsilon>0}$, with $\delta_\epsilon \searrow 0$ when $\epsilon \searrow 0$, such that

$$\hat{J}_\epsilon(\overline{y},\overline{u}) \leq \inf(P_\epsilon) + \delta_\epsilon^2.$$

Therefore we can apply Ekeland's principle with $F(u) = \hat{J}_\epsilon(y_u, u)$ defined in the complete metric space $(\mathcal{K}, d)$ and deduce the existence of a control $u_\epsilon \in \mathcal{K}$ such that $d(\overline{u}, u_\epsilon) \leq \delta_\epsilon$ and

$$\hat{J}_\epsilon(y_\epsilon, u_\epsilon) \leq \hat{J}_\epsilon(y_u, u) + \delta_\epsilon d(u, u_\epsilon) \quad \forall u \in \mathcal{K}, \tag{4.22}$$

where y_ϵ is the state associated with u_ϵ. To apply Proposition 4.6 we must put the cost given by the right-hand side of inequality (4.22) into the framework of this proposition. For it we introduce the function $\chi_\epsilon : \Omega \times K \longrightarrow R$ by

$$\chi_\epsilon(x, v) = \begin{cases} 0 & \text{if } v = u_\epsilon(x), \\ 1 & \text{otherwise.} \end{cases}$$

Then (y_ϵ, u_ϵ) is the solution of the problem

$$(Q^\epsilon) \begin{cases} \min \hat{J}_\epsilon(y,u) = \hat{J}_\epsilon(y,u) + \delta_\epsilon \int_\Omega \chi_\epsilon(x, u(x)) \\ \\ (y,u) \text{ satisfies (2.1)}, \ u(x) \in K \text{ a.e. } x \in \Omega. \end{cases}$$

Then Proposition 4.6 implies that for every $v \in K$

$$H^\epsilon(x, y_\epsilon(x), u_\epsilon(x), p_\epsilon(x)) \leq H^\epsilon(x, y_\epsilon(x), v, p_\epsilon(x)) + \delta_\epsilon \quad \text{a.e. } x \in \Omega,$$

where p_ϵ is the adjoint state

$$\begin{cases} A^\star p_\epsilon = \dfrac{\partial f}{\partial y}(x, y_\epsilon, u_\epsilon)p_\epsilon + \dfrac{\partial L_\epsilon}{\partial y}(x, y_\epsilon, u_\epsilon) \text{ in } \Omega, \\ \\ p_\epsilon = 0 \text{ on } \Gamma \end{cases} \tag{4.23}$$

and

$$H^\epsilon(x, y, u, p) = L_\epsilon(x, y, u) + pf(x, y, u) + \delta_\epsilon \chi_\epsilon(x, u). \tag{4.24}$$

From Theorem 2.1 it follows that $y_\epsilon \rightarrow \overline{y}$ in $H_0^1(\Omega) \cap C^{0,\alpha}(\overline{\Omega})$. Then, thanks to hypothesis (2.3) and the definition of L_ϵ, we have

$$f(x, y_\epsilon, u_\epsilon) \rightarrow f(x, \overline{y}, \overline{u}) \quad \text{and} \quad \frac{\partial f}{\partial y}(x, y_\epsilon, u_\epsilon) \rightarrow \frac{\partial f}{\partial y}(x, \overline{y}, \overline{u}) \quad \text{in } L^s(\Omega),$$

$$L_\epsilon(x, y_\epsilon, u_\epsilon) \rightarrow L(x, \overline{y}, \overline{u}) \quad \text{and} \quad \frac{\partial L_\epsilon}{\partial y}(x, y_\epsilon, u_\epsilon) \rightarrow \frac{\partial L}{\partial y}(x, \overline{y}, \overline{u}) \quad \text{in } L^1(\Omega).$$

With the aid of these relations and Lemma 2.4 we can pass to the limit in (4.23) and (4.24) and deduce the first conclusion of Proposition 4.6. To prove the second conclusion, i.e., the Pontryagin's principles, we argue as follows. Under condition (H2), the argument used in the proof of Proposition 4.6 can be repeated here without modifications. If condition (H1) is satisfied, then, thanks to Proposition 4.6, we can take a sequence $\epsilon_j \searrow 0$ and $\delta_j = \delta_{\epsilon_j} \searrow 0$ such that

$$H^{\epsilon_j}(x, y_{\epsilon_j}(x), u_{\epsilon_j}(x), p_{\epsilon_j}(x)) \leq \min_{v\in K} H^{\epsilon_j}(x, y_{\epsilon_j}(x), v, p_{\epsilon_j}(x)) + \delta_j \quad \text{a.e.} \quad x \in \Omega_j,$$

with $m(\Omega_j) = m(\Omega)$. Now we pass to the limit and get

$$H(x, \overline{y}(x), \overline{u}(x), \overline{p}(x)) = \min_{v\in K} H(x, \overline{y}(x), v, \overline{p}(x)) \quad \text{a.e.} \quad x \in \tilde{\Omega} = \bigcap_{j=1}^{\infty} \Omega_j,$$

which concludes the proof because $m(\tilde{\Omega}) = m(\Omega)$. □

THEOREM 4.9. *The statement of Proposition* 4.6 *is still valid without hypothesis* (4.18).

Proof. From the definition of stationary point we deduce that for every $\epsilon > 0$ there exists $r_\epsilon > 0$ such that

$$\frac{\hat{J}(y,u) - \hat{J}(\overline{y},\overline{u})}{d(u,\overline{u})} \geq -\epsilon \quad \forall u \in B_{r_\epsilon}(\overline{u}),$$

where $B_{r_\epsilon}(\overline{u})$ is the open ball of $(\mathcal{K}, d)$ of radius r_ϵ and center at $\overline{u}$. Hence

$$\hat{J}(\overline{y},\overline{u}) \leq \hat{J}(y,u) + \epsilon \int_\Omega \chi(x, u(x))dx \quad \forall u \in B_{r_\epsilon}(\overline{u}),$$

with

$$\chi(x,v) = \begin{cases} 0 & \text{if } v = \overline{u}(x), \\ 1 & \text{otherwise.} \end{cases}$$

Then it is enough to apply Proposition 4.7 to the problem

$$\begin{cases} \min \hat{J}(y,u) + \epsilon \displaystyle\int_\Omega \chi(x, u(x))\, dx, \\ u \in B_{r_\epsilon}(\overline{u}), \; u(x) \in K, \end{cases}$$

and pass to the limit when $\epsilon \searrow 0$ to deduce the desired result. □

The hypotheses made about K, L, and f do not allow one to assure the existence of a solution of control problem (P). Here we will prove a principle of Pontryagin's type for ϵ-solutions.

DEFINITION 4.10. *A control* $u \in \mathcal{K}$ *is called an* ϵ*-solution of* (P) *if* $\hat{J}(y_u, u) \leq \inf(P) + \epsilon$.

THEOREM 4.11. *For every* $\epsilon > 0$ *there exists at least one* ϵ^2*-solution of* (P) *in* $\mathcal{K}$. *Furthermore for every* ϵ^2*-solution of* (P), $\overline{u}_\epsilon$, *there exists another* ϵ^2*-solution* u_ϵ *such that* $d(u_\epsilon, \overline{u}_\epsilon) \leq \epsilon$ *and for every* $v \in K$

$$H(x, y_\epsilon(x), u_\epsilon(x), p_\epsilon(x)) \leq H(x, y_\epsilon(x), v, p_\epsilon(x)) + \epsilon \quad a.e. \; x \in \Omega,$$

where $y_\epsilon = y_{u_\epsilon}$ *and* $p_\epsilon = p_{u_\epsilon}$. *Moreover, if there exists a Lebesgue measurable set* $\Omega_0 \subset \Omega$, *with* $m(\Omega_0) = m(\Omega)$, *in such a way that* (H1) *or* (H2) *holds, then* $\overline{u}$ *satisfies Pontryagin's principle*:

$$H(x, y_\epsilon(x), u_\epsilon(x), p_\epsilon(x)) = \min_{v\in K} H(x, y_\epsilon(x), v, p_\epsilon(x)) + \epsilon \quad a.e. \; x \in \Omega.$$

Proof. Thanks to hypothesis (2.3), we have that $\inf(P) \in R$. Therefore there exists at least one ϵ^2-solution of (P). Let $\overline{u}_\epsilon$ be one of them. Then we can apply Theorem 4.8, with $F(u) = \hat{J}(y_u, u)$ defined in the metric space $(\mathcal{K}, d)$, and deduce the existence of a control $u_\epsilon \in \mathcal{K}$, ϵ^2-solution of (P), such that $d(u_\epsilon, \overline{u}_\epsilon) \leq \epsilon$ and

$$\hat{J}(y_{u_\epsilon}, u_\epsilon) \leq \hat{J}(y_u, u) + \epsilon d(u, u_\epsilon) \ \ \forall u \in \mathcal{K}. \tag{4.25}$$

Now we put the cost into the framework of Proposition 4.7, using the function χ_ϵ as in its proof, and apply it to get the result. □

5. Proof of the weak minimum principle. Let $\overline{u}$ be a solution of (P_δ) and $\overline{y}$ its associated state. For every $\gamma > 0$ we define the problems

$$(Q_\gamma) \begin{cases} \min J_\gamma(y, u) = \displaystyle\int_\Omega \left[L(x, y(x), u(x)) + \frac{1}{2\gamma}((g(x, y(x)) - \delta)^+)^2 \right] dx \\ (y, u) \text{ satisfies (2.1) and } u(x) \in K \text{ a.e. } x \in \Omega. \end{cases}$$

The first issue to remark is the following.

PROPOSITION 5.1. *Let (P_δ) be weakly stable on the right. Then*

$$\lim_{\gamma \searrow 0} \inf(Q_\gamma) = \inf(P_\delta).$$

Proof. Let $\{u_\gamma\}$ be a family of γ-solutions of problems (Q_γ) and $\{y_\gamma\}$ be the associated states:

$$J(y_\gamma, u_\gamma) \leq \inf(Q_\gamma) + \gamma.$$

From the definition of (Q_γ) it follows that $(g(x, y_\gamma(x)) - \delta)^+ \to 0$ in $L^2(\Omega)$, which, together with (2.4) and the compactness of the inclusion $H_0^1(\Omega) \cap C^{0,\alpha}(\overline{\Omega}) \subset C_0(\Omega)$, implies the convergence $(g(x, y_\gamma(x)) - \delta)^+ \to 0$ in $C_0(\Omega)$. Therefore

$$\delta_\gamma = \|(g(x, y_\gamma(x)) - \delta)^+\|_{L^\infty(\Omega)} + \delta \to \delta \text{ if } \gamma \searrow 0.$$

As (y_γ, u_γ) is a feasible pair for (P_{δ_γ}) we deduce that

$$\inf(P_{\delta_\gamma}) \leq J(y_\gamma, u_\gamma) \leq \inf(Q_\gamma) + \gamma.$$

Then, using the weak stability of (P_δ) on the right, we obtain

$$\inf(P_\delta) = \lim_{\gamma \searrow 0} \inf(P_{\delta_\gamma}) \leq \lim_{\gamma \searrow 0} \{\inf(Q_\gamma) + \gamma\} = \lim_{\gamma \searrow 0} \inf(Q_\gamma) \leq \inf(P_\delta),$$

with the last inequality due to the fact that (y_u, u) is feasible for (Q_γ) whenever it is feasible for (P_δ), with the same cost. □

Proof of Theorem 3.3. Thanks to Proposition 5.1 we deduce that $\overline{u}$ is a ϵ_γ^2-solution of (Q_γ), with $\epsilon_\gamma \searrow 0$ when $\gamma \searrow 0$. Applying Theorem 4.11 we obtain the existence of a control $u_\gamma \in \mathcal{K}$, ϵ_γ^2-solution of (Q_γ), with $d(u_\gamma, \overline{u}) \leq \epsilon_\gamma$ and such that for every $v \in K$

$$H(x, y_\gamma(x), u_\gamma(x), p_\gamma(x)) \leq H(x, y_\gamma(x), v, p_\gamma(x)) + \epsilon_\gamma \ \text{ a.e. } x \in \Omega,$$

where $y_\gamma = y_{u_\gamma}$ and p_γ is the adjoint state:

$$\begin{cases} A^\star p_\gamma = \dfrac{\partial f}{\partial y}(x, y_\gamma, u_\gamma)p_\gamma + \dfrac{\partial L}{\partial y}(x, y_\gamma, u_\gamma) + \dfrac{1}{\gamma}(g(x, y_\gamma) - \delta)^+ \dfrac{\partial g}{\partial y}(x, y_\gamma) \text{ in } \Omega, \\ p_\gamma = 0 \text{ on } \Gamma. \end{cases}$$

Defining

$$\overline{\alpha}_\gamma = \left(1 + \|\frac{1}{\gamma}(g(x, y_\gamma) - \delta)^+\|_{M(\Omega)}\right)^{-1},$$

$$\overline{\mu}_\gamma = \frac{\overline{\alpha}_\gamma}{\gamma}(g(x, y_\gamma) - \delta)^+, \quad \text{and} \quad \overline{p}_\gamma = \overline{\alpha}_\gamma p_\gamma,$$

we get

$$\overline{\alpha}_\gamma + \|\overline{\mu}_\gamma\|_{M(\Omega)} = 1, \tag{5.26}$$

$$\begin{cases} A^\star \overline{p}_\gamma = \dfrac{\partial f}{\partial y}(x, y_\gamma, u_\gamma)\overline{p}_\gamma + \overline{\alpha}_\gamma \dfrac{\partial L}{\partial y}(x, y_\gamma, u_\gamma) + \overline{\mu}_\gamma \dfrac{\partial g}{\partial y}(x, y_\gamma) \text{ in } \Omega, \\ \overline{p}_\gamma = 0 \text{ on } \Gamma, \end{cases} \tag{5.27}$$

and for every $v \in K$

$$H_{\overline{\alpha}_\gamma}(x, y_\gamma(x), u_\gamma(x), \overline{p}_\gamma(x)) \leq H_{\overline{\alpha}_\gamma}(x, y_\gamma(x), v, \overline{p}_\gamma(x)) + \epsilon_\gamma \text{ a.e. } x \in \Omega. \tag{5.28}$$

If $\gamma \searrow 0$, then $d(u_\gamma, \overline{u}) \leq \epsilon_\gamma \to 0$; therefore from Theorem 2.1 we get $y_\gamma \to \overline{y}$ in $H_0^1(\Omega) \cap C^{0,\alpha}(\overline{\Omega})$. Now using (2.3), we deduce the convergences

$$f(x, y_\gamma, u_\gamma) \to f(x, \overline{y}, \overline{u}), \qquad \frac{\partial f}{\partial y}(x, y_\gamma, u_\gamma) \to \frac{\partial f}{\partial y}(x, \overline{y}, \overline{u}) \text{ in } L^s(\Omega),$$

$$L(x, y_\gamma, u_\gamma) \to L(x, \overline{y}, \overline{u}), \qquad \frac{\partial L}{\partial y}(x, y_\gamma, u_\gamma) \to \frac{\partial L}{\partial y}(x, \overline{y}, \overline{u}) \text{ in } L^s(\Omega).$$

Applying Lemma 2.4, we obtain the following estimation for $\overline{p}_\gamma$:

$$\|\overline{p}_\gamma\|_{W_0^{1,\sigma}(\Omega)} \leq M\|\overline{\alpha}_\gamma \frac{\partial L}{\partial y}(x, y_\gamma, u_\gamma) + \overline{\mu}_\gamma \frac{\partial g}{\partial y}(x, y_\gamma(x))\|_{M(\Omega)} \leq M' < +\infty$$

for every $\sigma < n/(n-1)$. Therefore, remembering (5.26), we can extract subsequences, denoted in the same way, such that $\overline{\mu}_\gamma \to \overline{\mu}$ in $M(\Omega)$ *weakly and $\overline{p}_\gamma \to \overline{p}$ weakly in $W_0^{1,\sigma}(\Omega)$. From Rellich's theorem (Adams [1]) it follows that $\overline{p}_\gamma \to \overline{p}$ strongly in $L^q(\Omega)$ for each $q < n/(n-2)$. Then

$$\frac{\partial f}{\partial y}(x, y_\gamma, u_\gamma)\overline{p}_\gamma \to \frac{\partial f}{\partial y}(x, \overline{y}, \overline{u})\overline{p} \text{ in } L^1(\Omega).$$

We can pass to the limit in (5.27) and derive (3.14). Relation (3.16) follows from (5.28). Relation (3.15) is obtained as follows: for every $z \in C_0(\Omega)$ with $z(x) \leq \delta$ for all $x \in \Omega$

$$\int_\Omega (z(x) - g(x, \overline{y}(x)))\, d\overline{\mu}(x) = \lim_{\gamma \to 0} \frac{\overline{\alpha}_\gamma}{\gamma} \int_\Omega (z(x) - g(x, y_\gamma(x)))(g(x, y_\gamma(x)) - \delta)^+ \, dx \leq 0.$$

It follows that

$$\langle \overline{\mu}, g(\cdot, \overline{y})\rangle = \max\{\langle \overline{\mu}, z\rangle : z \in C_0(\Omega), z(x) \leq \delta\};$$

hence, $\overline{\mu}$ is nonnegative and the value of the max is $\delta\|\overline{\mu}\|_{M(\Omega)}$.

To obtain (3.13) it is enough to remember (5.26) and remark that

$$\|\overline{\mu}\|_{M(\Omega)} = \frac{1}{\delta}\langle \overline{\mu}, g(\cdot, \overline{y})\rangle = \lim_{\gamma\to 0}\frac{1}{\delta}\langle \overline{\mu}_\gamma, g(\cdot, y_\gamma)\rangle = \lim_{\gamma\to 0}\|\overline{\mu}_\gamma\|_{M(\Omega)}.$$

Finally we must prove (3.17). If we assume that (H1) is satisfied, then, thanks to Theorem 4.11, (5.28) can be written as

$$H_{\overline{\alpha}_\gamma}(x, y_\gamma(x), u_\gamma(x), \overline{p}_\gamma(x)) = \min_{v\in K} H_{\overline{\alpha}_\gamma}(x, y_\gamma(x), v, \overline{p}_\gamma(x)) + \epsilon_\gamma \quad \text{a.e. } x \in \Omega.$$

Taking a subsequence $\{\gamma_j\}_{j=1}^\infty$, we pass to the limit as above and get (3.17).

If (H2) is satisfied, we can argue as in the proof of Theorem 4.9 to conclude (3.17). □

6. Proof of the strong minimum principle. In this section we establish the existence of a certain link between the stability of the cost with respect to small perturbations of the feasible state set and the viability of the exact penalization procedure of the state constraints. In the context of the abstract optimization Burke [11], generalizing an idea of Clarke [15], proved an equivalence result between stability and exact penalization. Since we are assuming the hypotheses of Theorem 3.4, we have that (P_δ) is strongly stable on the right and $(\overline{y}, \overline{u})$ is a solution of this problem. Now we consider the exact penalization of state constraints.

PROPOSITION 6.1. *If* $r > 0$ *satisfies* (3.11), *then* $\overline{u}$ *is a local solution in* $(\mathcal{K}, d)$ *of the penalized control problem*

$$\begin{cases} \min J_r(u) = \displaystyle\int_\Omega L(x, y_u(x), u(x))\, dx + r\|(g(x, y_u) - \delta)^+\|_\infty, \\ u \in \mathcal{K}. \end{cases}$$

Proof. From (3.11) it follows that

$$\inf(P_\delta) = \inf\{J(y_u, u) + r(\delta' - \delta) : u \in \mathcal{K},\ g(x, y_u(x)) \leq \delta',\ \delta' \in [\delta, \delta + \epsilon]\}.$$

Minimizing first with respect to δ' for fixed u we find

$$\inf(P_\delta) = \inf\left\{J(y_u, u) + r\|(g(x, y_u) - \delta)^+\|_\infty : u \in \mathcal{K},\ g(x, y_u(x)) \leq \delta + \epsilon\right\}.$$

Since the mapping $u \in (\mathcal{K}, d) \longrightarrow y_u \in C_0(\Omega)$ is continuous, we deduce the existence of a ball $B_\lambda(\overline{u})$, $\lambda > 0$, such that

$$\|g(x, y_u)\|_\infty < \delta + \epsilon \quad \forall u \in B_\lambda(\overline{u}),$$

which together with the previous identity proves that $\overline{u}$ is a local solution of the penalized control problem. □

Take $\lambda > 0$ as in the proof of the previous proposition and $r > 0$ verifying (3.11). We introduce the problem

$$(Q_r)\begin{cases} \min\ J_r(u) = \displaystyle\int_\Omega L(x, y_u(x), u(x))\, dx + r\|(g(x, y_u) - \delta)^+\|_\infty, \\ u \in B_\lambda(\overline{u}). \end{cases}$$

Then $\overline{u}$ is a solution of this problem. We passed from a state-constrained control problem to another control problem without state constraints. The difficulty in this new problem is that the penalization term is not differentiable. To overcome this difficulty we define

$$J_{r,q}(u) = \int_\Omega L(x, y_u(x), u(x))\, dx + r\left(q^{-q} + \int_\Omega [(g(x, y_u(x)) - \delta)^+]^q\, dx\right)^{1/q}$$

and

$$(Q_{r,q})\begin{cases} \min J_{r,q}(u) \\ u \in B_\lambda(\overline{u}), \end{cases}$$

with $q > 1$. Note that $(Q_{r,q})$ has a differentiable cost and, moreover, it represents an approximation of (Q_r) given in the following proposition.

PROPOSITION 6.2. *The following identity holds:*

$$\inf(Q_r) = \lim_{q\to\infty} \inf(Q_{r,q}).$$

Proof. From the convergence $\|z\|_{L^q(\Omega)} \to \|z\|_\infty$ for every $z \in L^\infty(\Omega)$ and the inequalities

$$\|(g(x, y_u) - \delta)^+\|_{L^q(\Omega)} \le \left(q^{-q} + \int_\Omega [(g(x, y_u(x)) - \delta)^+]^q dx\right)^{1/q}$$

$$\le \frac{1}{q} + \|(g(x, y_u) - \delta)^+\|_{L^q(\Omega)}$$

we deduce that $J_{r,q}(u) \to J_r(u)$ when $q \to +\infty$. Therefore for every $u \in B_\lambda(\overline{u})$

$$\limsup_{q\to+\infty} \inf(Q_{r,q}) \le \limsup_{q\to+\infty} J_{r,q}(u) = J_r(u);$$

hence,

$$\limsup_{q\to+\infty} \inf(Q_{r,q}) \le \inf(Q_r). \tag{6.29}$$

Now we prove the converse inequality. Let us take $\epsilon > 0$ arbitrary, and let $C_1 > 0$ be the constant given in Theorem 2.1. Since $g : \overline{\Omega} \times R \longrightarrow R$ is continuous, it follows that the existence of a constant $\rho \in (0, \epsilon)$ such that $\forall x, x' \in \overline{\Omega}$

$$|g(x,t) - g(x',t)| < \epsilon \quad \text{if} \quad |x - x'| \le \rho \text{ and } |t| \le C_1. \tag{6.30}$$

Moreover we assume ρ small enough in such a way that $m(\{x : |x| \le \rho\}) < 1$. Now we define $\Omega_\rho(x_0) = \Omega \cap B_\rho(x_0)$. Since the boundary of Γ is Lipschitz, there exists a number $\beta \in (0,1)$ verifying

$$m(\Omega_\rho(x_0)) \ge \beta m(\{x : |x| \le \rho\}) \quad \forall x_0 \in \overline{\Omega}.$$

On the other hand, from the continuity of $\frac{\partial g}{\partial y}$ we deduce the existence of another constant $M > 0$ such that

$$|g(x,t)| + \left|\frac{\partial g}{\partial y}(x,t)\right| \le M \quad \forall (x,t) \in \overline{\Omega} \times [-C_1, +C_1]. \tag{6.31}$$

Pick $u \in B_\lambda(\overline{u})$. If $\|(g(x,y_u)-\delta)^+\|_\infty = 0$, then $J_{r,q}(u) = J_r(u)$. Let us suppose that $\|(g(x,y_u)-\delta)^+\|_\infty > 0$, and take $x_0 \in \overline{\Omega}$ verifying

$$(g(x_0,y_u(x_0))-\delta)^+ = \|(g(x,y_u)-\delta)^+\|_\infty.$$

Then for each $x \in \Omega_\rho(x_0)$ we get with the aid of (2.4), (6.30), and (6.31) that

$$|g(x,y_u(x)) - g(x_0,y_u(x_0))|$$

$$\leq |g(x,y_u(x)) - g(x_0,y_u(x))| + |g(x_0,y_u(x)) - g(x_0,y_u(x_0))|$$

$$\leq \epsilon + M|y_u(x) - y_u(x_0)| \leq \epsilon + MC_1\rho^\alpha \leq M'\epsilon;$$

hence,

$$(g(x,y_u(x))-\delta)^+ \geq (g(x_0,y_u(x_0)) - \delta - M'\epsilon)^+ \quad \forall x \in \Omega_\rho(x_0).$$

Therefore, we obtain

$$\|(g(x,y_u)-\delta)^+\|_{L^q(\Omega)} \geq \left(\int_{\Omega_\rho(x_0)} [(g(x,y_u(x))-\delta)^+]^q \, dx\right)^{1/q}$$

$$\geq m(\Omega_\rho(x_0))^{1/q}(g(x_0,y_u(x_0)) - \delta - M'\epsilon)^+ \geq \|(g(x,y_u)-\delta)^+\|_\infty$$

$$+(m(\Omega_\rho(x_0))^{1/q} - 1)\|(g(x,y_u)-\delta)^+\|_\infty - M'\epsilon m(\Omega_\rho(x_0))^{1/q}$$

$$\geq \|(g(x,y_u)-\delta)^+\|_\infty + M(m(\Omega_\rho(x_0))^{1/q} - 1) - M'\epsilon.$$

Choosing $q_\epsilon > 1$ such that

$$1 - m(\Omega_\rho(x_0))^{1/q} \leq 1 - [\beta m(\{x : |x| \leq \rho\})]^{1/q} < \epsilon \quad \forall q > q_\epsilon,$$

it follows that

$$\|(g(x,y_u)-\delta)^+\|_{L^q(\Omega)} \geq \|(g(x,y_u)-\delta)^+\|_\infty - (M+M')\epsilon \quad \forall q > q_\epsilon.$$

We have proved that

$$J_{r,q}(u) \geq J_r(u) - (M+M')\epsilon$$

for each $u \in B_\lambda(\overline{u})$ and all $q \geq q_\epsilon$; hence,

$$\liminf_{q \to +\infty} \inf(Q_{r,q}) \geq \inf(Q_r) - (M+M')\epsilon$$

for $\epsilon > 0$ arbitrary; consequently,

$$\liminf_{q \to +\infty} \inf(Q_{r,q}) \geq \inf(Q_r). \tag{6.32}$$

So the proposition follows from (6.29) and (6.32). □

Proof of Theorem 3.4. Thanks to Proposition 6.2 we deduce that $\overline{u}$ is an ϵ_q^2-solution of $(Q_{r,q})$, with $\epsilon_q \to 0$ as $q \to \infty$. Then Theorem 4.11 states the existence of a control $u_q \in \mathcal{K}$, with $d(u_q, \overline{u}) \leq \epsilon_q$, satisfying for every $v \in K$

$$H(x, y_q(x), u_q(x), p_q(x)) \leq H(x, y_q(x), v, p_q(x)) + \epsilon_q \quad \text{a.e. } x \in \Omega, \tag{6.33}$$

where $y_q = y_{u_q}$ and p_q is the adjoint state:

$$\begin{cases} A^\star p_q = \dfrac{\partial f}{\partial y}(x, y_q, u_q)p_q + \dfrac{\partial L}{\partial y}(x, y_q, u_q) + \mu_q \dfrac{\partial g}{\partial y}(x, y_q) & \text{in } \Omega, \\ p_q = 0 \quad \text{on } \Gamma, \end{cases} \tag{6.34}$$

with

$$\mu_q = r\left(q^{-q} + \int_\Omega [(g(x, y_q(x)) - \delta)^+]^q \, dx\right)^{1/q-1} [(g(x, y_q) - \delta)^+]^{q-1}.$$

Now we must pass to the limit. From $d(u_q, \overline{u}) \leq \epsilon_q \to 0$ and Theorem 2.1 we obtain that $y_q \to \overline{y}$ in $H_0^1(\Omega) \cap C^{0,\alpha}(\overline{\Omega})$. On the other hand, from the definition of μ_q we get

$$\|\mu_q\|_{M(\Omega)} = \|\mu_q\|_{L^1(\Omega)} \leq r\left(\int_\Omega [g(x, y_q(x))^+]^q \, dx\right)^{1/q-1} \int_\Omega [g(x, y_q(x))^+]^{q-1} \, dx$$

$$= r\|(g(x, y_q) - \delta)^+\|_{L^q(\Omega)}^{1-q} \|(g(x, y_q) - \delta)^+\|_{L^{q-1}(\Omega)}^{q-1}.$$

Applying Hölder's inequality with exponents $q/(q-1)$ and q it follows that

$$\|z\|_{L^{q-1}(\Omega)} \leq m(\Omega)^{1/q} \|z\|_{L^q(\Omega)} \quad \forall z \in L^q(\Omega),$$

which together with the previous relation leads to

$$\|\mu_q\|_{M(\Omega)} \leq m(\Omega)^{1/q} r \|(g(x, y_q) - \delta)^+\|_{L^q(\Omega)}$$

$$\leq m(\Omega)^{2/q} r \|(g(x, y_q) - \delta)^+\|_\infty \leq M < +\infty \quad \forall q > 1.$$

As in the proof of Theorem 3.3, the boundedness of $\{\mu_q\}_{q \geq 1}$, the convergence of $\{(y_q, u_q)\}_{q \geq 1}$, and assumptions (2.3) imply the boundedness of $\{p_q\}_{q \geq 1}$ in $W_0^{1,\sigma}(\Omega)$ for every $\sigma < n/(n-1)$. Therefore we can extract subsequences $\{p_{q_k}\}$ and $\{\mu_{q_k}\}$, with $q_k \to +\infty$, converging to $\overline{p}$ and $\overline{\mu}$ in $W_0^{1,\sigma}(\Omega)$ weakly and $M(\Omega)$ $\star$-weakly, respectively. Now it is easy to pass to the limit in (6.33) and (6.34) and to obtain (3.16) and (3.14). As in the proof of Theorem 3.3 we derive (3.15) from the definition of μ_q.

Finally, as stated in Theorem 4.11, under conditions (H1) or (H2) given in Theorem 3.3, the relation (6.33) becomes

$$H(x, y_q(x), u_q(x), p_q(x)) = \min_{v \in K} H(x, y_q(x), v, p_q(x)) + \epsilon_q \quad \text{a.e. } x \in \Omega.$$

Therefore, passing to the limit in this inequality, we get (3.17). □

7. Pontryagin's principle in the control of variational inequalities. In this section we will consider the following control system:

$$(7.35)\qquad \begin{cases} Ay+\beta(y)=f(x,y(x),u(x)) \text{ in } \Omega,\\ y=0 \text{ on } \Gamma,\end{cases}$$

where A and f are as in §2 and β is a maximal monotone graph in $R\times R$ (see Brezis [10] and Barbu [2]) such that $\operatorname{dom}(\beta)\ni 0$. The control problem is

$$(P_\delta)\begin{cases} \min J(y,u)=\displaystyle\int_\Omega L(x,y(x),u(x))\,dx\\ (y,u) \text{ satisfies (7.35)}, \ u(x)\in K \text{ a.e. } x\in\Omega \text{ and } g(x,y(x))\le\delta\ \forall x\in\Omega.\end{cases}$$

We keep the assumptions stated in §2 on the data of this problem. Then we have the following result about the state equation analogous to Theorem 2.1.

THEOREM 7.1. *There exist constants $C_5>0$ and $\alpha\in(0,1)$ such that for every $u\in\mathcal{K}$ (7.35) has a unique solution $y_u\in H_0^1(\Omega)\cap C^{0,\alpha}(\overline{\Omega})$ satisfying*

$$(7.36)\qquad \|y_u\|_{H_0^1(\Omega)}+\|y_u\|_{C^{0,\alpha}(\overline{\Omega})}\le C_5.$$

Furthermore the mapping $u\in(\mathcal{K},d)\longrightarrow y_u\in H_0^1(\Omega)\cap C^{0,\alpha}(\overline{\Omega})$ is continuous.

Proof. We may assume that $\beta(0)\ni 0$. If $\operatorname{dom}(\beta)=R$ and β is Lipschitz and of class C^1, the result is consequence of Theorem 2.1. When β is a general maximal monotone graph in $R\times R$ it is enough to apply the standard procedure that consists in approximating (via Yosida's approximation and convolution with a smoothing kernel: see [2]) with a Lipschitz C^1 monotone function β_ϵ. In this way we obtain solutions $y_\epsilon\in H_0^1(\Omega)\cap C^{0,\alpha}(\overline{\Omega})$ of

$$\begin{cases} Ay+\beta_\epsilon(y)=f(x,y(x),u(x)) \text{ in } \Omega,\\ y=0 \text{ on } \Gamma.\end{cases}$$

In order to pass to the limit and derive (7.36) we need a uniform estimate of y_ϵ in $H_0^1(\Omega)\cap C^{0,\alpha}(\overline{\Omega})$. Using the mean value theorem we can write

$$\beta_\epsilon(y_\epsilon)=\beta_\epsilon'(\hat{y}_\epsilon)y_\epsilon,$$
$$f(x,y_\epsilon(x),u(x))=f(x,0,u(x))+\frac{\partial f}{\partial y}(x,\tilde{y}_\epsilon,u(x))y_\epsilon,$$

with $|\hat{y}_\epsilon(x)|\le|y_\epsilon(x)|$ and $|\tilde{y}_\epsilon(x)|\le|y_\epsilon(x)|$ for all $x\in\Omega$. Hence

$$\begin{cases} Ay_\epsilon+\left(\beta_\epsilon'(\hat{y}_\epsilon)(x))-\dfrac{\partial f}{\partial y}(x,\tilde{y}_\epsilon,u(x))\right)y_\epsilon=f(x,0,u(x)) \text{ in } \Omega,\\ y=0 \text{ on } \Gamma.\end{cases}$$

Now applying Lemma 2.2 to the above equation we get a uniform estimate of y_ϵ in $H_0^1(\Omega)\cap L^\infty(\Omega)$. Then hypotheses (2.3) on f imply that $\{f(x,y_\epsilon(x),u(x))\}_{\epsilon>0}$ is uniformly bounded in $L^s(\Omega)$. On the other hand, arguing as in [9, Appendix] we also deduce the boundedness of $\{\beta_\epsilon(y_\epsilon)\}_{\epsilon>0}$ in $L^s(\Omega)$. Therefore $\{Ay_\epsilon\}_{\epsilon>0}$ is uniformly bounded in $L^s(\Omega)$; applying Lemma 2.2 again we obtain the desired result. □

The aim of this section is to prove Pontryagin's principle for control problem (P_δ). For this purpose we need the following approximation scheme. First let us observe that Proposition 6.1 is still valid and consequently there exists a number $\lambda > 0$ such that $\overline{u}$ is a solution of the problem

$$(Q_r)\begin{cases} \min J_r(u) = \int_\Omega L(x, y_u(x), u(x))\,dx + r\|(g(x,y_u) - \delta)^+\|_\infty, \\ u \in B_\lambda(\overline{u}). \end{cases}$$

Here y_u denotes the solution of (7.35) corresponding to the control u.

The next step consists of approximating (Q_r) by a new control problem with a differentiable cost functional and a state equation with a C^1 monotone term $\beta_q(y)$. Let us begin with the last question. Following Bonnans and Tiba [9] we will say that a maximal monotone graph in $R \times R$ β_q, with $q > 1$, is an $(1/q)$-uniform approximation to β if β_q satisfies the following two conditions:

1. $\beta(t + 1/q) \geq \beta_q(t) \geq \beta(t - 1/q)$, $\forall t \in R$,
2. $\mathrm{dom}(\beta_q) \supset \mathrm{dom}(\beta)$.

Here we view β and β_q as multivalued operators extended on R with values $-\infty$ on the left of their domains and $+\infty$ on the right of their domains, and the inequality for sets means

$$\xi \geq \eta \geq \nu, \quad \forall \xi \in \beta(t + 1/q),\ \eta \in \beta_q(t),\ \nu \in \beta(t - 1/q).$$

A constructive procedure for $(1/q)$-uniform approximations of class C^1 was given in [9], and the following result was proved.

PROPOSITION 7.2. *Let $u \in \mathcal{K}$. Then the problem*

$$\begin{cases} Ay + \beta_q(y) = f(x, y(x), u(x)) & \text{in } \Omega, \\ y = 0 \quad \text{on } \Gamma \end{cases}$$

has a unique solution $y_{q,u} \in H_0^1(\Omega) \cap C^\alpha(\overline{\Omega})$ and $\|y_{q,u} - y_u\|_\infty \leq 1/q$.

Now we consider the following approximation of (Q_r):

$$(Q_{rq})\begin{cases} \min J_{r,q}(u) \\ u \in B_\lambda(\overline{u}), \end{cases}$$

where

$$J_{r,q}(u) = \int_\Omega L(x, y_{q,u}(x), u(x))dx + r\left(q^{-q} + \int_\Omega [(g(x,y_{q,u}) - \delta)^+]^q\,dx\right)^{1/q}.$$

PROPOSITION 7.3. *The following identity holds:*

$$\inf(Q_r) = \lim_{q \to \infty} \inf(Q_{r,q}).$$

Proof. With the aid of Proposition 7.2 we get

$$\left|\|(g(x,y_{q,u}) - \delta)^+\|_{L^q(\Omega)} - \|(g(x,y_{q,u}) - \delta)^+\|_\infty\right|$$

$$\leq \left|\|(g(x,y_u) - \delta)^+\|_{L^q(\Omega)} - \|(g(x,y_u) - \delta)^+\|_\infty\right|$$

$$+ \left|\|(g(x,y_{q,u}) - \delta)^+\|_{L^q(\Omega)} - \|(g(x,y_u) - \delta)^+\|_{L^q(\Omega)}\right|$$

$$+\left|\|(g(x,y_{q,u})-\delta)^+\|_\infty-\|(g(x,y_u)-\delta)^+\|_\infty\right|$$

$$\leq\left|\|(g(x,y_u)-\delta)^+\|_{L^q(\Omega)}-\|(g(x,y_u)-\delta)^+\|_\infty\right|$$

$$+\|g(x,y_{q,u})-g(x,y_u)\|_{L^q(\Omega)}+\|g(x,y_{q,u})-g(x,y_u)\|_\infty$$

$$\leq\left|\|(g(x,y_{q,u})-\delta)^+\|_{L^q(\Omega)}-\|(g(x,y_u)-\delta)^+\|_\infty\right|+\frac{m(\Omega)^{1/q}+1}{q}\longrightarrow 0 \text{ as } q\to\infty.$$

Therefore we can argue as in the proof of Proposition 6.2 to deduce that

$$\limsup_{q\to\infty}\inf(Q_{r,q})\leq\inf(Q_r). \tag{7.37}$$

Let us prove the converse inequality. Let $C_5>0$ be the constant given in Theorem 7.1. From the properties of g we obtain

$$|g(x,t)|+\left|\frac{\partial g}{\partial y}(x,t)\right|\leq M\quad\forall(x,t)\in\overline{\Omega}\times[-C_5,+C_5] \tag{7.38}$$

for some constant $M>0$. Applying the mean value theorem and using the hypotheses (2.3), (7.38), and Proposition 7.2 we get for some constant M' and all $u\in B_\lambda(\bar u)$:

$$\int_\Omega L(x,y_{q,u}(x),u(x))\,dx+r\left(q^{-q}+\int_\Omega[(g(x,y_{q,u})-\delta)^+]^q\,dx\right)^{1/q}$$

$$\geq\int_\Omega L(x,y_u(x),u(x))\,dx+r\left(q^{-q}+\int_\Omega[(g(x,y_u)-\delta)^+]^q\,dx\right)^{1/q}-\frac{M'}{q}.$$

Therefore

$$\liminf_{q\to\infty}\inf(Q_{r,q})$$

$$\geq\liminf_{q\to\infty}\inf\left\{\int_\Omega L(x,y_u(x),u(x))\,dx\right.$$

$$\left.+r\left(q^{-q}+\int_\Omega[(g(x,y_u)-\delta)^+]^q\,dx\right)^{1/q}:u\in B_\lambda(\bar u)\right\}.$$

The proof is concluded by noting that the second term of this inequality is greater than or equal to $\inf(Q_r)$, which is proved exactly in the same way than in Proposition 6.2. □

Now we are ready to state the extension of Pontryagin's principle.

THEOREM 7.4. *Let $\bar u$ be a solution of (P_δ) in $(\mathcal{K},d)$, with $\bar y$ its associated state. If (P_δ) is strongly stable on the right, then there exist $\chi\in W^{-1,\sigma}(\Omega)$, $\bar p\in W_0^{1,\sigma}(\Omega)$ for every $\sigma<\frac{n}{n-1}$, and $\bar\mu\in M(\Omega)$ such that χ is a limit point in $W^{-1,\sigma}(\Omega)$ weak of $\{\beta'_q(y_q)p_q\}$,*

$$\left\{\begin{array}{l}A^\star\bar p+\chi=\dfrac{\partial f}{\partial y}(x,\bar y(x),\bar u(x))+\dfrac{\partial L}{\partial y}(x,\bar y(x),\bar u(x))+\dfrac{\partial g}{\partial y}(x,\bar y(x))\bar\mu \textit{ in } \Omega,\\ \bar p=0 \textit{ on } \Gamma,\end{array}\right. \tag{7.39}$$

$$\int_\Omega (z(x) - g(x,\overline{y}(x)))\,d\overline{\mu}(x) \leq 0 \quad \forall z \in C_0(\Omega) \text{ with } z(x) \leq \delta \ \forall x \in \Omega, \tag{7.40}$$

and for every $v \in K$

$$H(x,\overline{y}(x),\overline{u}(x),\overline{p}(x)) \leq H(x,\overline{y}(x),v,\overline{p}(x)) \quad a.e. \ x \in \Omega. \tag{7.41}$$

Moreover if conditions (H1) *or* (H2) *of Theorem* 3.3 *hold, then*

$$H(x,\overline{y}(x),\overline{u}(x),\overline{p}(x)) = \min_{v\in K} H(x,\overline{y}(x),v,\overline{p}(x)) \quad a.e. \ x \in \Omega. \tag{7.42}$$

Proof. This theorem can be proved in the same manner as Theorem 3.4: applying Proposition 7.2 we deduce that $\overline{u}$ is a solution of (Q_r) and then Theorem 4.11 provides a minimum principle for an ϵ_q^2-solution u_q. The adjoint state corresponding to u_q satisfies the equation

$$\begin{cases} A^\star p_q + \beta_q'(y_q)p_q = \dfrac{\partial f}{\partial y}(x,y_q,u_q)p_q + \dfrac{\partial L}{\partial y}(x,y_q,u_q) + \mu_q \dfrac{\partial g}{\partial y}(x,y_q) \text{ in } \Omega, \\ p_q = 0 \text{ on } \Gamma, \end{cases}$$

with

$$\mu_q = r\left(q^{-q} + \int_\Omega [(g(x,y_q(x)) - \delta)^+]^q\,dx\right)^{1/q-1} [(g(x,y_q) - \delta)^+]^{q-1}.$$

The passage to the limit is carried out as in the proof of Theorem 3.4 with the only modification due to the term $\beta_q'(y_q)p_q$. That $\{\mu_q\}$ is bounded in $L^1(\Omega)$ can be proved as in §7; therefore, the boundedness of $\{p_q\}$ in $W_0^{1,s}(\Omega)$ is a consequence of Lemma 2.4. Finally from the adjoint state equation it follows that $\{\beta_q'(y_q)p_q\}$ is bounded in $W^{-1,\sigma}(\Omega)$, for all $\sigma < n/(n-1)$. Then there exists a subsequence, denoted in the same way, and an element $\chi \in W^{-1,\sigma}(\Omega)$ such that $\beta_q'(y_q)p_q \to \chi$ weakly in $W^{-1,\sigma}(\Omega)$ when $q \to \infty$. □

Remark 7.5. Additional information on χ can be derived from Theorem 7.4 for particular choices of β. For instance if β is Lipschitz near $y_0 \in R$ and $x_0 \in \Omega$ is such that $y(x_0) = y_0$, then $\chi(x) \in \partial_c\beta(y(x))$ with $\partial_c\beta$ the Clarke gradient [14] of β, for x close to x_0. See, for example, [9] for other illustrations.

A NONCONVEX VARIATIONAL PROBLEM WITH CONSTRAINTS*

MICÒL AMAR† AND CARLO MARICONDA‡

Abstract. A multidimensional version of Liapunov-type theorems is proven. As an application, it is proven that, under proper hypothesis on the possibly nonconvex function f, the problem $\min\int_0^T f(u'(t))\,dt$ on the subset of $W^{1,p}([0,T],\mathbb{R}^n)$ of those functions u satisfying the prescribed boundary conditions and whose trajectory lies out of a prescribed open subset of $\mathbb{R}^n$ admits at least one solution.

Key words. relaxed problem, bipolar, Liapunov, simplex, convex, extremal point

AMS subject classification. 49A05

1. Introduction. The most general scalar problem that has been investigated without the classical Tonelli convexity condition on the function $\xi \to h(t,s,\xi)$ is that of minimizing

$$\text{(P}'\text{)}\qquad \begin{gathered}\min I(u) = \min\left\{\int_0^T h(t,u(t),u'(t))\,dt\right\},\\ u\in W^{1,p}([0,T],\mathbb{R}^n),\quad u(0)=a,\quad u(T)=b.\end{gathered}$$

Under differentiability assumptions on the integrand, this problem was studied by Aubert and Tahraoui in [2] and [3], Raymond in [11], and Tahraoui in [13].

In the case $h(t,s,\xi) = g(t,s) + f(t,\xi)$, this problem was studied by Olech (see [10]), Marcellini (see [8]), Cellina and Colombo (see [4]), and Raymond (see [12]), under weaker assumptions on the regularity of g and f.

In particular, in [4] the main tool is a Liapunov-type theorem, which allows the modification of a solution to the convexified problem in order to obtain a solution of the original one. The same technique has also been used in [12] and [9].

For $n = 1$, i.e., for functions with values in $\mathbb{R}$, a more precise version of Liapunov's theorem has recently been given in [1].

THEOREM 1.1. *Let $\Phi : [0,T] \to 2^{\mathbb{R}}$ be a measurable multifunction with values in the closed intervals of $\mathbb{R}$. Then for each integrable selection $\tilde{u}'$ of $\Phi(t)$, there exists a measurable selection $\bar{u}'$ with values in the extreme points of $\Phi(t)$ such that $\int_0^T \bar{u}'(t)\,dt = \int_0^T \tilde{u}'(t)\,dt$ and for each $t\in[0,T]$, $\bar{u}(t)\le\tilde{u}(t)$.*

This result has been successfully applied in [5] in order to prove that there exists a dense subset D of $C([0,T],\mathbb{R})$ such that, for g in it, the problem of minimizing $\int_0^T g(u(t))\,dt + \int_0^T f(u'(t))\,dt$ does always admit at least one solution for each f satisfying growth conditions.

* Received by the editors July 27, 1992; accepted for publication (in revised form) September 28, 1993. This research was partially supported by a Consiglio Nazionale della Ricerche fellowship during the authors' visit to the University of Paris VI Pierre et Marie Curie.

‡ Dipartimento di Matematica Pura e Applicata, Università degli Studi di Padova, Via Belzoni 7, 35131 Padova, Italy (MARICONDA@PDMAT1.MATH.UNIPD.IT).

A more than one-dimensional version of the above Liapunov type lemma does not hold, in general.

Example. Let $n = 2$, $T = 1$, $\Phi(t) = \{\lambda(1,t) \ : \lambda \in [0,1]\}$, $\tilde{u}'(t) = (\tilde{u}_1'(t), \tilde{u}_2'(t)) = (\frac{1}{2}, (\frac{1}{2})t) \in \Phi(t)$ a.e. in $[0,1]$. Assume, by contradiction, that there exists $\bar{u}'(t) = (\bar{u_1}'(t), \bar{u_2}'(t)) \in \{(0,0),(1,t)\}$ a.e. such that

$$\int_0^1 \bar{u}'(t)\,dt = \int_0^1 \tilde{u}'(t)\,dt, \tag{1.1}$$

$$\bar{u}_1(t) \geq \tilde{u}_1(t) \quad \text{for a.e. } t \in [0,1], \tag{1.2}$$

$$\bar{u}(0) = \tilde{u}(0). \tag{1.3}$$

Then there exists a measurable subset E of $[0,1]$ such that

$$\bar{u}'(t) = (0,0)\chi_{[0,1]\setminus E} + (1,t)\chi_E;$$

whence, $\bar{u}_2'(t) = t\bar{u}_1'(t)$. Conditions (1.1) and (1.3) and integration by parts of the second component give

$$\int_0^1 \bar{u}_1(t)\,dt = \int_0^1 \tilde{u}_1(t)\,dt$$

so that, by (1.2), $\bar{u}_1(t) = \tilde{u}_1(t)$, i.e., $\chi_E = \frac{1}{2}$. This is a contradiction.

Neverthless, we prove here that a multidimensional version of the above theorem holds if the measurable function Φ is identically equal to a convex bounded subset of $\mathbb{R}^n$. As an application, we study the problem of minimizing

$$\int_0^T f(u'(t))\,dt$$

on the subset of $W^{1,p}([0,T],\mathbb{R}^n)$ of those functions u satisfying prescribed boundary conditions and whose trajectory lies out of a prescribed open subset of $\mathbb{R}^n$.

2. Notation and preliminary results. In the following, Γ will denote an open convex poligone contained in $\mathbb{R}^n$ and, given $a, b \in \mathbb{R}^n \setminus \Gamma$, K will be the set of those functions $u : [0,T] \to \mathbb{R}^n$ that are in the Sobolev space $W^{1,p}((0,T),\mathbb{R}^n)$ $(p \geq 1)$ and such that $u(0) = a, u(T) = b$.

Given a set A, we denote by ∂A the boundary of A, by $\text{extr}A$ the extremal points of A, and by $\text{meas}(A)$ the Lebesgue measure of A. Finally, given two vectors v_1 and v_2 of $\mathbb{R}^n$, we denote by $v_1 \cdot v_2$ the usual scalar product in $\mathbb{R}^n$ and by $|v_1|$ the euclidean norm of v_1 in $\mathbb{R}^n$.

Let $f : \mathbb{R}^n \to \mathbb{R}$ be a nonnecessarily convex and lower semicontinuous function that satisfies the following growth conditions:

$$\text{(F)} \qquad \begin{aligned} c_1|\xi|^p - c_2 \leq f(\xi) \quad & \forall \xi \in \mathbb{R}^n \quad \text{if } p > 1, \\ \psi(|\xi|) - c_2 \leq f(\xi) \quad & \forall \xi \in \mathbb{R}^n \quad \text{if } p = 1, \end{aligned}$$

where c_1 and c_2 are real positive constants and $\psi : [0,+\infty) \to [0,+\infty)$ is a convex and lower semicontinuous function such that $\lim_{r\to+\infty} \frac{\psi(r)}{r} = +\infty$.

Given a function f, we denote by f^{**} its bipolar function.

LEMMA 2.1 (see, for instance, [6, Prop. I.4.1]). *Let $f : \mathbb{R}^n \to \mathbb{R}$ be a lower semicontinuous function. Then f^{**} is the greatest lower semicontinuous and convex function not greater than f.*

Let us consider the set

$$E = \{\xi \in \mathbb{R}^n \ : \ f^{**}(\xi) < f(\xi)\}. \tag{2.1}$$

In the following, we shall assume that $E = \bigcup_{i\in\mathbb{N}} A_i$ and f^{**} is affine on every A_i, where A_i is a convex open and bounded subset of $\mathbb{R}^n$.

Notice that, while the hypothesis on the structure of E is quite natural, the hypothesis on the form of f^{**} on every A_i is a technical hypothesis, which is automatically satisfied only in the scalar case (i.e., when $n = 1$). On the contrary, when n is strictly greater than one, this hypothesis is not always fulfilled.

LEMMA 2.2. *Let A be a simplex in $\mathbb{R}^n$, $I \subseteq [0,T]$ be a measurable set, $u' : [0,T] \to A$ be a measurable function, and η be a fixed vector in $\mathbb{R}^n$. Then there exists a measurable function, $\omega : [0,T] \to \operatorname{extr} A$ depending on u', A, and η, such that*

$$\int_I \omega(s)\,ds = \int_I u'(s)\,ds, \tag{2.2}$$

$$\forall t \in [0,T] \quad \int_0^t [\omega(s)\cdot\eta\chi_I(s)]\,ds \geq \int_0^t [u'(s)\cdot\eta\chi_I(s)]\,ds. \tag{2.3}$$

Proof. Let $v_0,\dots,v_n$ be the $n+1$ vertices of the simplex A; then $u'(s) = p_0(s)v_0 + \cdots + p_n(s)v_n$ for a proper choice of $p_0,\dots,p_n : [0,T] \to [0,1]$ with $p_0(s) + \cdots + p_n(s) \equiv 1$. Moreover, for every $i = 0,\dots,\ n$, let us define $a_i := v_i\cdot\eta$. Without loss of generality, we may assume that $a_0 > \cdots > a_n$.

We shall prove that there exists a measurable partition $E_0,\dots,E_n$ of I such that

$$\operatorname{meas}(E_i) = \int_I p_i(s)\,ds \quad \forall\ i = 0,\dots,n, \tag{2.4}$$

$$\int_0^t \sum_{i=0}^n a_i p_i(s)\chi_I(s)\,ds \leq \int_0^t \sum_{i=0}^n a_i\chi_{E_i}(s)\,ds \quad \forall t \in [0,T]. \tag{2.5}$$

It is clear that, setting $\omega(s) = \sum_{i=0}^n v_i\chi_{E_i}(s)$, (2.2) and (2.3) follow from (2.4) and (2.5). In order to prove (2.4) and (2.5), we proceed by induction. When $n = 0$, we have that $p_0(s) \equiv 1$; and if we set $E_0 = I$, the thesis is trivially satisfied. Let us assume now that $n > 0$. Let $0 = t_0 < t_1 < \cdots < t_{n+1} = T$ be a partition of $[0,T]$ such that

$$\int_{t_i}^{t_{i+1}} \chi_I(s)\,ds = \int_I p_i(s)\,ds \quad \forall\ i = 0,\dots,n.$$

Such partition exists since $p_0(s) + \cdots + p_n(s) \equiv 1$. Let us define

$$E_0 = [t_0,t_1] \cap I, \quad \text{and} \quad E_i = (t_i,t_{i+1}] \cap I \quad \forall\ i = 0,\dots,n.$$

First, by the very definition of E_i, (2.4) trivially holds. In order to prove (2.5), we proceed as follows.

Let us define

$$\tilde{E}_i = E_i, \quad \tilde{p}_i = p_i \quad \forall i = 0,\dots,n-2,$$
$$\tilde{E}_{n-1} = E_{n-1} \cup E_n, \qquad \tilde{p}_{n-1} = p_{n-1} + p_n.$$

Clearly, $\bigcup_{i=0}^{n-1} \tilde{E}_i = I$, $\sum_{i=0}^{n-1} \tilde{p}_i = 1$, and (2.4) is satisfied by $\tilde{E}_i$ and $\tilde{p}_i$ for $i =$

$0, \ldots, n-1$. Moreover, the hypothesis of induction assures that

$$\int_0^t \sum_{i=0}^{n-1} a_i \chi_{\tilde{E}_i}(s)\, ds \geq \int_0^t \sum_{i=0}^{n-1} a_i \tilde{p}_i(s) \chi_I(s)\, ds. \tag{2.6}$$

Assume that $t \leq t_n$. We observe that, in this case, $E_n \cap [0,t] = \emptyset$; hence for every $i = 0, \ldots, n-1$ we have that $E_i \cap [0,t] = \tilde{E}_i \cap [0,t]$. Then, by (2.6), it follows that

$$\begin{aligned}\int_0^t \sum_{i=0}^{n} a_i \chi_{E_i}(s)\, ds &= \int_0^t \sum_{i=0}^{n-1} a_i \chi_{E_i}(s)\, ds \\ &= \int_0^t \sum_{i=0}^{n-1} a_i \chi_{\tilde{E}_i}(s)\, ds \geq \int_0^t \sum_{i=0}^{n-1} a_i \tilde{p}_i(s) \chi_I(s)\, ds \\ &\geq \int_0^t \sum_{i=0}^{n} a_i p_i(s) \chi_I(s)\, ds.\end{aligned}$$

Assume now that $t_n < t \leq T$. Then

$$\begin{aligned}\int_0^t \sum_{i=0}^{n} a_i \chi_{E_i}(s)\, ds &= \sum_{i=0}^{n-1} a_i \operatorname{meas}(E_i) + \int_{t_n}^t a_n \chi_{E_n}(s)\, ds \\ &= \sum_{i=0}^{n-1} a_i \int_0^T p_i(s) \chi_I(s)\, ds + \int_{t_n}^t a_n \chi_{E_n}(s)\, ds \\ &\geq \int_0^t \sum_{i=0}^{n-1} a_i p_i(s) \chi_I(s)\, ds + a_n \left[\int_t^T \sum_{i=0}^{n-1} p_i(s) \chi_I(s)\, ds + \int_0^t \chi_{E_n}(s)\, ds \right] \\ &= \int_0^t \sum_{i=0}^{n-1} a_i p_i(s) \chi_I(s)\, ds + a_n \left[\int_{t_n}^T \sum_{i=0}^{n-1} p_i(s) \chi_I(s)\, ds + \int_{t_n}^t p_n(s) \chi_I(s)\, ds \right] \\ &= \int_0^t \sum_{i=0}^{n-1} a_i p_i(s) \chi_I(s)\, ds + a_n \operatorname{meas}(E_n) - a_n \int_t^T p_n(s) \chi_I(s)\, ds \\ &= \int_0^t \sum_{i=0}^{n-1} a_i p_i(s) \chi_I(s)\, ds + \int_0^t a_n p_n(s) \chi_I(s)\, ds = \int_0^t \sum_{i=0}^{n} a_i p_i(s) \chi_I(s)\, ds.\end{aligned}$$

Hence, also (2.5) holds and the lemma is proved. □

LEMMA 2.3. *Let A be an open convex bounded subset of $\mathbb{R}^n$. Then A can be covered by a countable family of simplexes whose vertices are contained in the boundary of A.*

Proof. Let $x_1, \ldots, x_{n+1}$ be $n+1$ points of the boundary ∂A of A, such that they generate a closed $(n+1)$-dimensional simplex denoted by S_1. We denote by F_i (for $i = 1, \ldots, n+1$) the face generated by

$$\{x_1, \ldots, \check{x}_i, \ldots, x_{n+1}\}$$

and let q_i be a point of F_i such that

$$d(q_i, \partial A) = \max\{d(x, \partial A) : x \in F_i\}.$$

Moreover, let ν_i be the external half-line normal to F_i at the point q_i and let $x_{1,i}$ be its intersection with ∂A. Let $T_{1,i}$ $(i = 1, \ldots, n+1)$ be the closed $(n+1)$-dimensional simplex generated by

$$\{x_1, \dots, x_{i-1}, x_{1,i}, x_{i+1}, \dots, x_{n+1}\},$$

and set

$$S_2 = S_1 \cup \bigcup_{i=1}^{n+1} T_{1,i}.$$

Recursevely, one obtains an increasing family of convex polygons whose vertices lie in ∂A; moreover, each S_{j+1} is obtained by adding to S_j a finite union of $(n+1)$-simplexes $T_{j,k}$ $(1 \leq k \leq k(j) < +\infty)$ with vertices in ∂A. We claim that

$$A \subset \bigcup_j S_j.$$

Clearly, it is enough to prove that

$$\lim_j \max_{x \in \partial S_j} d(x, \partial A) = 0. \tag{2.7}$$

In order to prove (2.7), let us remark that, if it does not hold, there exists $d_0 > 0$ such that

$$\max_{x \in \partial S_j} d(x, \partial A) \geq d_0$$

for each $j \in \mathbb{N}$. It follows that, by construction,

$$\max_{x \in \partial T_{j,k}} d(x, \partial A) \geq d_0$$

for each $j \in \mathbb{N}$ and $k \leq k(j)$, so that the "heights" of the simplexes $T_{j,k}$ (and hence their volumes) are bounded below by a positive constant, a contradiction, the set A being bounded. □

3. Main results.

THEOREM 3.1. *Let A be an open convex and bounded subset of $\mathbb{R}^n$, I a measurable subset of $[0,T]$, $u' : I \longrightarrow A$ a measurable function, and η an arbitrary vector in $\mathbb{R}^n$. Then there exists a function $\omega : I \longrightarrow \partial A$, depending on u', A, and η, such that*

$$\int_I \omega(s)\, ds = \int_I u'(s)\, ds, \tag{3.1}$$

$$\forall t \in [0,T] \qquad \int_0^t [\omega(s) \cdot \eta\chi_I(s)]\, ds \geq \int_0^t [u'(s) \cdot \eta\chi_I(s)]\, ds. \tag{3.2}$$

COROLLARY 3.2. *Assume that A, I, u', ω, and η are as in the previous theorem. Assume that $f : \mathbb{R}^n \longrightarrow \mathbb{R}$ is lower semicontinuous, f^{**} is affine on A, and $f(\xi) = f^{**}(\xi)$ when $\xi \in \partial A$. Then*

$$\int_I f^{**}(u'(s))\, ds = \int_I f(\omega(s))\, ds. \tag{3.3}$$

Proof. Since f^{**} is affine on A, there exist two vectors v_1 and v_2 such that

$$f^{**}(\xi) = v_1 \cdot \xi + v_2 \quad \forall \xi \in A;$$

hence, by (2.2) of Lemma 2.2, it easily follows that

$$\int_I f^{**}(u'(s))\, ds = \int_I f^{**}(\omega(s))\, ds.$$

Finally, recalling that ω takes values in ∂A and f^{**} coincides with f on ∂A, (2.4) follows. □

Proof of Theorem 3.1. By Lemma 2.3 $A = \bigcup_{j\in\mathbb{N}} S_j$, where S_j is a simplex contained in $\mathbb{R}^n$ whose vertices belongs to ∂A. Let us set, for every $j \in \mathbb{N}$, $I_j := (u')^{-1}(S_j) \cap I$ and $u'_j := u'\chi_{I_j} : I_j \to S_j$. Applying Lemma 2.2 to u'_j in I_j, we obtain a function $\omega_j : I_j \to \operatorname{extr} S_j \subset \partial A$, which satisfies (2.2) and (2.3). Hence, defining $\omega(s) := \sum_{j\in\mathbb{N}} \omega_j(s)$, it is clear that ω takes values in ∂A and satisfies (3.1) and (3.2). □

4. Applications. We consider the following minimum problem with obstacle

$$\min_{\substack{u\in K\\ u(t)\notin\Gamma}} \int_0^T f(u'(t))\,dt.$$

As we have already announced in the introduction, our main goal is to prove the existence of a solution for this minimum problem.

THEOREM 4.1. *Let $\Gamma \subset \mathbb{R}^n$, $K \subset W^{1,p}([0,T],\mathbb{R}^n)$, $f : \mathbb{R}^n \to \mathbb{R}$ be as in* §2. *Assume further that $f^{**}(0) = f(0)$. Then the problem*

$$\text{(P)} \qquad \min\left\{\int_0^T f(u'(s))\,ds \;:\; u\in K,\, u(t)\notin\Gamma\right\}$$

admits at least one solution.

Proof. Assume, for the sake of simplicity, that the set defined by

$$\{\xi\in\mathbb{R}^n : f^{**}(\xi) < f(\xi)\}$$

coincides with a simplex E on which f^{**} is affine; by the remark following Lemma 2.1 and by Lemmas 2.3 and 2.2, this is not restrictive. Assume further that $n = 2$, the general case being similar. Let p_i $(i = 1,\dots,m)$ be the vertices of Γ; by G_i we denote the relative interior of the side $\overline{p_ip_{i+1}}$ and by ν_i their external normal vector. The set Γ being open, there exists a solution $\tilde u$ to the associated relaxed problem

$$\min\left\{\int_0^T f^{**}(u'(s))\,ds \quad : \quad u\in K, u(t)\notin\Gamma\right\}.$$

Since the measure of the interval $[0,T]$ is finite, for each vertex p_i there exists an external half-line L_i containing p_i such that, setting $N = \{t : \tilde u(t) \in L_i \setminus \{p_i\}\}$, we have $\operatorname{meas}(N) = 0$.

Fix G_i and consider the "external" unbounded set O_i defined by the interior of the region delimited by the half-lines L_i, L_{i+1} and the side G_i, jointly with the side G_i itself.

Clearly, each O_i is open in the relative topology of $\mathbb{R}^2\setminus\Gamma$; moreover, the solution $\tilde u$ does not belong to Γ. Hence, the inverse image of $\mathcal{O} = \bigcup_i O_i$ under $\tilde u$ is a countable union of relative open intervals (α_j,β_j) of $[0,T]$: for every $j\in\mathbb{N}$ let $i(j)$ be such that

$$\tilde u(\alpha_j,\beta_j) \subset O_{i(j)}.$$

Let us define by $\mathcal{K}$ the subset of $[0,T]$ where $f\circ\tilde u'$ does not coincide with $f^{**}\circ\tilde u'$, i.e.,

$$\mathcal{K} = (\tilde u')^{-1}(E) = \{t : f^{**}(\tilde u'(t)) \neq f(\tilde u'(t))\};$$

and set, for each $j\in\mathbb{N}$,

$$\mathcal{S}_j = (\alpha_j,\beta_j)\cap\mathcal{K}.$$

Now, for each j, $\tilde{u}'(\mathcal{S}_j) \subset E$, on which f^{**} is affine; by Corollary 3.2 there exists a measurable function

$$\sigma_j : \mathcal{S}_j \to \mathbb{R}^2$$

with values in ∂E (on which $f^{**} = f$) satisfying

$$\int_{\mathcal{S}_j} \sigma_j(t)\,dt = \int_{\mathcal{S}_j} \tilde{u}'(t)\,dt, \tag{4.1}$$

$$\forall t \in [\alpha_j, \beta_j] \qquad \int_0^t \sigma_j(s) \cdot \nu_{i(j)} \chi_{\mathcal{S}_j}(s)\,ds \geq \int_0^t \tilde{u}'(s) \cdot \nu_{i(j)} \chi_{\mathcal{S}_j}(s)\,ds, \tag{4.2}$$

$$\int_{\mathcal{S}_j} f(\sigma_j(t))\,dt = \int_{\mathcal{S}_j} f^{**}(\tilde{u}'(t))\,dt. \tag{4.3}$$

Let $\bar{u}' : [0,T] \to \mathbb{R}^2$ be the measurable function defined by

$$\bar{u}' = \tilde{u}' \chi_{[0,T] \setminus \bigcup_j \mathcal{S}_j} + \sum_{j \in \mathbb{N}} \sigma_j \chi_{\mathcal{S}_j}.$$

The growth conditions on f and relation (4.1) show, together with Vitali's convergence theorem, that $\bar{u}' \in L^p$. Let $\bar{u}$ be the function defined by

$$\bar{u}(t) = a + \int_0^t \bar{u}'(s)\,ds.$$

We claim that $\bar{u}$ is a solution to (P).

Clearly, by (4.1) and the definition of $\bar{u}$ we have

$$\bar{u}(0) = \tilde{u}(0), \qquad \bar{u}(T) = \tilde{u}(T).$$

In order to prove that

$$\int_0^T f(\bar{u}'(t))\,dt = \int_0^T f^{**}(\tilde{u}'(t))\,dt = \min_{\substack{u \in K \\ u(t) \notin \Gamma}} \int_0^T f^{**}(u'(t))\,dt \tag{4.4}$$

we first remark that $[0,T]$ can be partitioned as a disjoint union of four measurable subsets N, D_1, D_2, D_3 where

$$D_1 = \bigcup_j \mathcal{S}_j = \tilde{u}^{-1}(\mathcal{O}) \cap \mathcal{K}, \qquad D_2 = \tilde{u}^{-1}(\mathcal{O}) \cap ([0,T] \setminus \mathcal{K}), \qquad D_3 = \tilde{u}^{-1}(\{p_1, \ldots, p_m\}).$$

By (4.3) we have

$$\int_{D_1} f(\bar{u}'(t))\,dt = \int_{D_1} f^{**}(\tilde{u}'(t))\,dt; \tag{4.5}$$

by the very definitions of $\bar{u}$ and $\mathcal{K}$ we have

$$\text{for a.e. t} \in [0,T] \setminus \mathcal{K} \qquad f(\bar{u}'(t)) = f(\tilde{u}'(t)) = f^{**}(\tilde{u}'(t))$$

so that in particular

$$\int_{D_2} f(\bar{u}'(t))\,dt = \int_{D_2} f^{**}(\tilde{u}'(t))\,dt. \tag{4.6}$$

Finally, by [7, Lemma 7.7], on $\tilde{u}^{-1}(\{p_1,\dots,p_m\}) = D_3$ we have $\tilde{u}' = 0$ a.e.; since by the very definition $\bar{u}' = 0$ on D_3 and by our assumption $f^{**}(0) = f(0)$

$$\text{for a.e. t} \in D_3 \qquad f(\bar{u}'(t)) = f(0) = f^{**}(0) = f^{**}(\tilde{u}'(t))$$

so that

$$\int_{D_3} f(\bar{u}'(t))\,dt = \int_{D_3} f^{**}(\tilde{u}'(t))\,dt. \tag{4.7}$$

Taking into account that N has measure zero, equalities (4.5), (4.6), and (4.7) together give (4.4).

At this stage we only need to show that

$$\forall t \in [0,T]: \quad \bar{u}(t) \notin \Gamma.$$

Fix t in $[0,T]$: either there exists $j_0 \in \mathbb{N}$ such that $t \in (\alpha_{j_0}, \beta_{j_0})$ or t does not belong to $\tilde{u}^{-1}(\mathcal{O})$. In the first case let $i \in \mathbb{N}$ be such that $\tilde{u}(\alpha_{j_0}, \beta_{j_0}) \subset O_i$; in order to prove that $\bar{u}(t) \notin \Gamma$ it is enough to show that

$$\bar{u}(t) \cdot \nu_i \geq \tilde{u}(t) \cdot \nu_i. \tag{4.8}$$

Since $\tilde{u}' = \bar{u}'$ on $[0,T] \setminus \bigcup_j \mathcal{S}_j$ then by (4.1) and (4.2) we have

$$\begin{aligned}
(\bar{u}(t) - \tilde{u}(t)) \cdot \nu_i &= \int_0^t (\bar{u}'(s) - \tilde{u}'(s)) \cdot \nu_i\,ds \\
&= \int_0^t (\bar{u}'(s) - \tilde{u}'(s)) \cdot \nu_i \chi_{\cup_j \mathcal{S}_j}(s)\,ds \\
&= \sum_{\{j:\mathcal{S}_j \subset [0,t]\}} \int_{\mathcal{S}_j} (\sigma_j(s) - \tilde{u}'(s)) \cdot \nu_i\,ds \\
&\quad + \int_0^t (\sigma_{j_0}(s) - \tilde{u}'(s)) \cdot \nu_i \chi_{\mathcal{S}_{j_0}}(s)\,ds \\
&= \int_0^t (\sigma_{j_0}(s) - \tilde{u}'(s)) \cdot \nu_i \chi_{\mathcal{S}_{j_0}}(s)\,ds \geq 0,
\end{aligned}$$

which proves (4.8).

In the second case ($t \notin \tilde{u}^{-1}(\mathcal{O})$) there is no interval (α_j, β_j) containing t. It follows that for each j in $\mathbb{N}$ either $\mathcal{S}_j \subset [0,t]$ or $\mathcal{S}_j \cap [0,t] = \emptyset$. As a consequence we have

$$\begin{aligned}
\bar{u}(t) - \tilde{u}(t) &= \int_0^t \bar{u}'(s) - \tilde{u}'(s)\,ds \\
&= \int_0^t (\bar{u}'(s) - \tilde{u}'(s))\chi_{\cup_j \mathcal{S}_j}(s)\,ds \\
&= \sum_{\{j:\mathcal{S}_j \subset [0,t]\}} \int_{\mathcal{S}_j} \sigma_j(s) - \tilde{u}'(s)\,ds.
\end{aligned}$$

Equality (4.1) yields $\bar{u}(t) = \tilde{u}(t)$; in particular $\bar{u}(t) \notin \Gamma$, the conclusion follows. □

As a consequence of the proof of the above theorem, we have the following result, with no assumption on the bipolar of f in 0.

THEOREM 4.2. *Let $\Gamma \subset \mathbb{R}^n$ be an open half-space, $K \subset W^{1,p}([0,T],\mathbb{R}^n)$, $f : \mathbb{R}^n \to \mathbb{R}$ be as in §2. Then the problem*

$$\min\left\{\int_0^T f(u'(s))\,ds \;:\; u \in K,\, u(t) \notin \Gamma\right\}$$

admits at least one solution.

Acknowledgments. We wish to thank Professor Arrigo Cellina for suggesting this problem and for his helpful advice. The authors are grateful to the Laboratoire d'Analyse Numérique of Paris VI for its hospitality and to the Consiglio Nazionale delle Ricerche, who gave them the opportunity to stay in Paris. We are indebted to the unknown referees for kind remarks that improved the presentation of the paper.

THE GLOBAL CONTROL OF NONLINEAR DIFFUSION EQUATIONS*

J. E. RUBIO[†]

Abstract. The boundary control of a nonlinear difussion equation with an integral performance criterion and a fixed final state is considered. By means of a process of embedding used by the author and others for finite-dimensional systems, this problem is replaced by one in which a linear form is minimized over a set of pairs of positive measures satisfying linear constraints. The advantages of this formulation are: (i) There is an automatic existence theory. (ii) There exists the possibility of using linear functional analysis to develop the theory. (iii) The minimization is global. The final state is only reached, however, in an asymptotic fashion, as the number of constraints being considered tends to infinity. A theory of controllability and reachability is developed, as well as a computational method using an infinite-dimensional simplex method. An example is given.

Key words. nonlinear difussion, optimization, measure theory, simplex, reachability, global optimization

1. Introduction.

In this paper we study the control of nonlinear diffusion equations by means of an approach that has proved useful in the analysis of the control of nonlinear ordinary differential equations [1] and linear partial differential equations [1], [2], [3]; lately we have extended it to the control of nonlinear diffusion equations with a small nonlinearity [4]. No such assumption, of "small" nonlinearities, will be made in this paper; we deal here with *fully nonlinear* diffusion.

The main approach that is used here is based on an idea of Young [5], consisting of the replacement of classical variational problems by problems in measure spaces; he mentions the possibility of treating these problems using the tools of linear analysis. The extension of these ideas to optimal control problems and the realization that one is dealing with fully linear problems—even if the original problems were nonlinear in the usual sense—are due to us ([1], [6],[7]); it appears we were the first, in [6], to develop linear programs whose solution would give rise to solutions of nonlinear optimal control problems. The reader can consult the review paper [8] for a full bibliography and a historical analysis of these matters.

The present work is not significantly related to our earlier ones [6], [7], [1, Chap. 7], which proved to give rise to unsuitable finite-dimensional approximations and which could not be used to study controllability in any depth; see [1, Chap. 6, §1], for an analysis of this problem.

We should mention also that independently of our work there has been much research on dual methods, especially by the Leipzig school [9]–[12], and by the group at Imperial College [13]. There has also been some exciting work, mainly on the dual approach, by workers involved in stochastic matters; see, for instance, [14]–[16].

In this paper we consider a nonlinear diffusion equation with a boundary control, through which we wish to minimize an integral performance criterion, given that the terminal state should be fixed. We first write some well-known integral relationships satisfied by the solution to this equation and then proceed to transform the problem; instead of minimizing over a set of admissible trajectory-control pairs, we find that it

*Received by the editors December 2, 1991; accepted for publication (in revised form) September 29, 1993.

[†]University of Leeds, Leeds LS2 9JT, England, United Kingdom.

is possible to minimize over a product of two measure spaces. The advantages of the new formulation are:

(i) An automatic existence theory—there always is a minimizer for our measure-theoretical problem.

(ii) The new problem is linear, and then one can use the whole paraphernalia of linear analysis for dealing with such a problem.

(iii) Also, our minimization is *global*—the value reached, say, numerically is close to what one could reasonably call the global infimum of the problem.

The price to pay for these advantages is that the final state is reached only asymptotically—that is, as the number of (linear) constraints associated with the measure-theoretical problem tends to infinity; the situation is similar to our results in the finite-dimensional case; see [1, Chap. 4].

Our main achievement in the first part of the paper—that is, §§2–4—is the construction of a framework for the treatment of nonlinear partial differential equations; in §§2 and 3 by developing the embedding process in Sobolev spaces; and in §4 by developing our main result on approximation, Theorem 1. Our intention here is to repeat in this context what we have achieved with our work in [1] in the case of finite-dimensional systems: to develop a frame of reference on which applications could be based, as has happened in [11], [12].

We present in the rest of the paper two applications of our theory: a reachability and controllability theory for these equations in which we introduce the concept of *asymptotic reachability* and develop a sufficient condition for a state to be asymptotically reachable and a computational method in which we treat the semi-infinite linear-programming problem developed in the paper by means of an infinite-dimensional simplex method; nearly optimal controls can be constructed in this manner.

2. The equations. Consider a boundary control problem. We follow the notation in [17] and [18] and take D, a bounded domain in $\mathbf{R}^n$ with smooth boundary ∂D and T, a positive real number, and define

$$\begin{aligned} &Q_T := D \times (0,T),\\ &\Gamma_T := \partial D \times (0,T),\\ &D_0 := D \times \{0\},\\ &D_T := D \times \{T\}. \end{aligned}$$

We also choose some functions

$$\begin{aligned} &k : \bar{Q}_T \to \mathbf{R}, k \in C^1(\bar{Q}_T);\\ &f : \mathbf{R} \times \mathbf{R}^n \times \bar{Q}_T \to \mathbf{R}, f \in C(\mathbf{R} \times \mathbf{R}^n \times \bar{Q}_T); \end{aligned}$$

a function is said to be differentiable in the closure of a domain if it is uniformly differentiable in the domain itself. Consider the nonlinear diffusion equation

$$u_t(x,t) - \operatorname{div}(k(x,t)\nabla u(x,t)) = f(u(x,t), \nabla u(x,t), x, t), \tag{2.1}$$

for $(x,t) \in Q_T$, with the initial condition

$$u(x,0) = 0, \qquad x \in D, \tag{2.2}$$

and the boundary condition

$$\nabla u \cdot n|_{\Gamma_T} = v; \tag{2.3}$$

here n is the outward normal, and the function $(s,t) \in \Gamma_T \to v(s,t) \in V \subset \mathbf{R}$ is the *control function*, taking values in a *bounded* control set V. This form appears to be as general as it can be made while retaining the possibility of weak solutions and of boundary control by means of heat flow [19], [20].

A pair (u, v) of trajectory function u and control function v is said to be *admissible* if

(i) The function $(x,t) \to u(x,t)$ is a classical solution of (2.1), that is, it is in $C^{2,1}(Q_T) \cap C(Q_T \cup \Gamma_T \cup \bar{D}_0)$ and satisfies (2.1), (2.2), and (2.3).

(ii) The control function is continuous in Γ_T.

(iii) The terminal relationship

$$u(\cdot, T) = g \tag{2.4}$$

is satisfied; g is a given continuous function on D_T.

Conditions for the existence of a classical solution of (2.1)–(2.3) can be found in the literature [17, Chap. VI], [18, Chap. V, VI].

The set of admissible pairs for this problem will be denoted by $\mathcal{F}$ and assumed to be nonempty, at least until §5, where we will be concerned with controllability.

We make the further point that, since the control set V is bounded, that is, there is a constant M_V so that $|v(s,t)| \leq M_V, (s,t) \in \Gamma_T$, there are *bounded* sets $A \subset \mathbf{R}$ and $B \subset \mathbf{R^n}$ so that (see [18])

$$u(x,t) \in A, \quad \nabla u(x,t) \in B \qquad \forall (x,t) \in \bar{Q}_T. \tag{2.5}$$

We must be *very careful* here, since there are many sets A and B which satisfy (2.5); we must choose from those the *minimum sets*, that is, either the intersections $\cap A$ and $\cap B$ of all sets satisfying (2.5) or subsets of them. Thus, every point in our set A (respectively B) will be a state (respectively, a gradient of a state) that can be reached by an admissible control inside the time interval $[0, T]$. This property will, of course, be needed in our proofs on approximation later.

The optimization problem associated with this equation is as follows. Let f_0, f_1 be continuous, nonnegative, real-valued functions on $\mathbf{R}^{2n+2}$, $\mathbf{R}^{n+1}$, respectively; further, we assume that there are constants $h', h'' > 0$ so that

$$f_0(u,w,x,t) \leq h'|u| + h''\|w\|_E, \qquad (u,w,x,t) \in A \times B \times \bar{Q}_T,$$

with the norm the euclidean norm in $\mathbf{R^n}$. Then we wish to find a minimizing pair in $\mathcal{F}$ for the functional

$$J(u,v) := \int_{Q_T} f_0(u(x,t), \nabla u(x,t), x, t)\, dxdt + \int_{\Gamma_T} f_1(v(s,t), s, t)\, dsdt. \tag{2.6}$$

We transform now this problem, with a view at generalization. Let ψ be in $C^1(\bar{Q}_T)$. Then one can show [17], [18] that the classical solution of (2.1)–(2.3), if it exists, satisfies the integral relation

$$\int_{Q_T} [u\psi_t - k\nabla u \nabla \psi + f\psi]\, dxdt = -\int_{\Gamma_T} k\psi v\, dsdt + \int_{D_T} g\psi\, dx, \tag{2.7}$$

for all $\psi \in C^1(\bar{Q}_T)$. We proceed in the next section to transform this problem.

3. Metamorphosis. In general, the minimization of the functional (2.6) over the set $\mathcal{F}$ is not possible—the infimum is not attained at any admissible pair; it is not possible, for instance, to write necessary conditions for this problem. We proceed then to transform it, realizing that a solution of (2.1)–(2.3) defines a linear, bounded, positive functional

$$u(\cdot,\cdot) : F \longrightarrow \int_{Q_T} F(u(x,t), \nabla u(x,t), x, t)\, dxdt$$

in the space $C(\Omega)$ of continuous real-valued functions F, with $\Omega := A \times B \times Q_T$. Also, a control v defines a linear, bounded, positive functional

$$v(\cdot,\cdot) : G \longrightarrow \int_{\Gamma_T} G(v(s,t), s, t)\, dsdt$$

in the space $C(\omega)$ of continuous functions G, $\omega := V \times \Gamma_T$.

By Riesz's theorem, an admissible pair (u, v) defines two Radon measures μ and ν, the first on Ω, the second on ω, so that (2.7) becomes

$$\int_\Omega F_\psi\, d\mu + \int_\omega G_\psi\, d\nu = \int_{D_T} g\psi\, dx := \alpha_\psi, \quad \forall \psi \in C^1(\bar{Q}_T), \tag{3.1}$$

where

$$F_\psi(u, w, x, t) := u\psi_t(x,t) - k(x,t) w \nabla\psi(x,t) + f(u, w, x, t)\psi(x,t), \tag{3.2a}$$

$$G_\psi(v, s, t) := k\psi(x|_{\partial D}, t)v. \tag{3.2b}$$

Thus, the minimization of the functional (2.6) over $\mathcal{F}$ is equivalent to the minimization of

$$I(\mu, \nu) = \mu(f_0) + \nu(f_1), \tag{3.3}$$

where we have written $\mu(f)$ for $\int_\Omega f\, d\mu$ and $\nu(g)$ for $\int_\omega f\, d\nu$, over the set of measures (μ, ν) corresponding to admissible pairs, which satisfy

$$\mu(F_\psi) + \nu(G_\psi) = \alpha_\psi \quad \forall \psi \in C^1(\bar{Q}_T). \tag{3.4}$$

So far, we have not achieved anything new. We consider the extension of our problem; we shall consider the minimization of (3.3) over the set S of all pairs of measures (μ, ν) in $\mathcal{M}^+(\Omega) \times \mathcal{M}^+(\omega)$ satisfying (3.4) plus the extra condition, satisfied of course by the admissible pairs, that these measures project on the (x, t) or (s, t) spaces as the respective Lebesgue measures. (See [1, Chap. 1], for a further discussion of this point.) Thus, if a function $\xi : \Omega \longrightarrow \mathbf{R}$ depends only on (x, t),

$$\mu(\xi) = a_\xi, \tag{3.5a}$$

the Lebesgue integral of ξ over Q_T. Also, if a function $\zeta : \omega \longrightarrow \mathbf{R}$ depends only on (s, t),

$$\nu(\zeta) = b_\zeta, \tag{3.5b}$$

the Lebesgue integral of ζ over Γ_T. Note that (3.5) imply that, writing 1_Ω and 1_ω for the characteristic functions of Ω and ω and L' and L'' for the Lebesgue measures of D and ∂D, respectively,

$$\mu(1_\Omega) = TL', \qquad \nu(1_\omega) = TL''. \tag{3.6}$$

Even if these equalities are a consequence of the equalities (3.5), they may be used to advantage when only a finite number of these are employed, as will be the case in our main approximation scheme.

In the next section we analyze this new optimization problem. We show that it always has at least one optimizer and that—this is most important—admissible trajectory-control pairs that are nearly minimizing for the original problem can be obtained from this construction.

4. Existence and approximation. The proof of the existence of an optimal measure for the functional I defined in (3.3) on the set S of measures in $\mathcal{M}^+(\Omega) \times \mathcal{M}^+(\omega)$ satisfying (3.4)–(3.5) is quite simple, being based on simple compactness properties of the weak*-topology. The proof of the following Proposition is much like that of Theorem II.1 in [1, Chap. 2], and is therefore omitted.

PROPOSITION 1. *There exists an optimal pair* $(\mu^*, \nu^*) \in S$ *that minimizes the functional* I.

The proof of the following proposition, which will be necessary later to prove our main theorem of approximation, can be found in detail in [7, Prop. 2], and will also be omitted; see also [2]. Note that the function $u \to \nabla u$ as a mapping from $H_1(Q_T) \to \{L_2(Q_T)\}^n$ is continuous.

PROPOSITION 2. *The set* $S_1 \subset S$ *of measures* (u, v) *that are piecewise-constant functions on* Ω *and* ω*, respectively and satisfy* (3.4)–(3.5) *is weakly*-dense in* S.

We start now the arduous process of approximation—that is, of building a framework, based on approximation to our main weak problem, so as to construct admissible pairs that nearly minimize the functional (2.6). The first of such constructions involves the possibility of approximating the set S. Let $\{\psi_i, i = 1, 2, \ldots\}$ be a set of functions that is *total* in $C^1(\bar{Q}_T)$, that is, so that, given $\psi \in C^1(\bar{Q}_T)$ and $\epsilon > 0$, there is an integer $N > 0$ and scalars $\alpha_i, i = 1, \ldots, N$, so that

$$\max_{\bar{Q}_T} \left| \psi - \sum_{i=1}^{N} \alpha_i \psi_i \right| < \epsilon,$$

$$\max_{\bar{Q}_T} \left| \psi_t - \sum_{i=1}^{N} \alpha_i \psi_{it} \right| < \epsilon,$$

$$\max_{\bar{Q}_T} \left\| \nabla\psi - \sum_{i=1}^{N} \alpha_i \nabla\psi_i \right\|_E < \epsilon;$$

we shall write

$$F_i := F_{\psi_i}, \qquad G_i := G_{\psi_i}, \qquad \alpha_i := \alpha_{\psi_i}, \qquad \forall i.$$

Further, we shall also take sets of functions $\{\xi_j, j = 1, 2, \ldots\}$ and $\{\zeta_k, k = 1, 2, \ldots\}$ that are total in the respective subspaces of $C(\Omega)$ and $C(\omega)$, writing a_j for a_{ξ_j} and b_k for b_{ζ_k}. We have then our first result of approximation; the proof is much like that of Proposition III.1 in [1, Chap. 3], and will be omitted.

PROPOSITION 3. *Let* M_1*,* M_2*, and* M_3 *be positive integers. Consider the problem of minimizing*

$$(\mu, \nu) \to \mu(f_0) + \nu(f_1) \tag{4.1a}$$

over the set $S(M_1, M_2, M_3)$ of measures in $\mathcal{M}^+(\Omega) \times \mathcal{M}^+(\omega)$ satisfying $\mu(1_\Omega) = TL'$, $\nu(1_\omega) = TL''$, and

$$\begin{aligned} \mu(F_i) + \nu(G_i) &= \alpha_i, & i &= 1, 2, \dots, M_1; \\ \mu(\xi_j) &= a_j, & j &= 1, 2, \dots, M_2; \\ \nu(\zeta_k) &= b_k, & k &= 1, 2, \dots, M_3. \end{aligned} \tag{4.1b}$$

Then, as $M_1, M_2, M_3 \to \infty$,

$$\inf_{S(M_1, M_2, M_3)} [\mu(f_0) + \nu(f_1)] \to \inf_S [\mu(f_0) + \nu(f_1)]. \tag{4.2}$$

We note that

$$\inf_S I \leq \inf_{\mathcal{F}} J$$

and that this may be a strict inequality; see [1, Chaps. 1 and 4], for a discussion of this point.

We have reached the main point of this section. How do we construct suboptimal pairs of trajectories and controls for the functional (2.6)? We shall proceed in several steps:

(i) First we shall obtain optimal measures (μ^*, ν^*) for a problem such as the one in Proposition 3. The existence of such a minimizer follows from the same simple considerations as the existence theorem given in Proposition 1.

(ii) We then obtain a (weak*) approximation to (μ^*, ν^*) by a set of two piecewise-constant functions (u, v) by means of the results given in Proposition 2.

(iii) The control function v obtained above is in $L_2(\Gamma_T)$, that is, for each $t \in (0, T)$, $v(\cdot, t) \in L_2(\partial D)$, since it is piecewise constant and the set Q_T is bounded. It can serve then as boundary function for a *weak solution* of the system (2.1)–(2.3), to be denoted by u_v. This solution will be in $H^1(Q_T)$. Conditions as to the existence of such weak solutions are given in [17], [18].

(iv) Borrowing the term from Rudolph [12], we shall call the pair (u_v, v) of trajectory and control functions *asymptotically admissible* if:

  (a) The control function $v \in L_2(Q_T)$ and $v(s, t) \in V$.

  (b) The trajectory u_v is the weak solution of (2.1)–(2.3) corresponding to the admissible control $v \in L_2(Q_T)$.

  (c) The trajectory function satisfies the constraint (2.7).

  (d) The final value $u_v(\cdot, T)$ of the trajectory function tends in $L_2(D_T)$ to the prescribed function g in (2.4) as $M_1, M_2, M_3 \to \infty$.

(v) We shall prove below that if the numbers M_1, M_2, M_3, are sufficiently large and the weak*-approximation in step (ii) above sufficiently good, then the value at the pair (u_v, v) of the functional J defined by (2.6), $J(u_v, v)$, is close to the $\inf_S I$ and thus is a good suboptimal pair. Note that no use is made of the trajectory u, obtained in step (ii) together with the control v.

We proceed to prove all this.

THEOREM 1. *Let (u_v, v) be the pair constructed as explained above. Then, under the appropriate conditions on the approximations involved,*

(i) *The pair (u_v, v) is asymptotically admissible.*

(ii) *As M_1, M_2, M_3 tend to ∞,*

$$J(u_v, v) \to \inf_S I(\mu, \nu).$$

Proof. (i) Fix $M_1 > 0$ and write $\epsilon := 1/M_1$. Fix also the values of M_2 and M_3. Let (μ^*, ν^*) be the minimizer for the functional (4.1a) over the set $S(M_1, M_2, M_3)$; its existence can be proven by the same arguments used in proving Proposition 1 (see [1, Chap. 3 and 4]).

By Proposition 2, we can find a pair $(u, v) \in S_1$ so that

$$|\{\mu_u(f_0) + \nu_v(f_1)\} - \{\mu^*(f_0) + \nu^*(f_1)\}| < \epsilon; \tag{4.3a}$$

$$|\mu_u(F_i) + \nu_v(G_i) - \alpha_i| < \epsilon, \qquad i = 1, \ldots, M_1. \tag{4.3b}$$

Here we have written (μ_u, ν_v) for the measure in $\mathcal{M}^+(\Omega) \times \mathcal{M}^+(\omega)$ generated by the pair trajectory-control (u, v). We note, further, that these measures satisfy automatically the rest of the relations in (4.1b).

(ii) We proceed to prove now that the pair (u_v, v) defined above is asymptotically admissible; we only have to prove the contention in (iv)(d) above, on the final value $u_v(\cdot, T)$, since the rest of the requirements in (iv) are trivially satisfied. Choose the functions $\psi_i \in C^1(\bar{Q}_T), i = 1, \ldots, M_1$, of the form $\psi_i = \varphi_i + \chi_i$, so that, for $i = 1, \ldots, M_1$

(a) The function $\chi_i \in C^1(\bar{Q}_T)$ is chosen so that the Lebegue measure of the support of χ_i in $\bar{Q}_T$ is not higher than a number $\epsilon' > 0$ to be chosen below and so that the maximum of the numbers

$$|\chi_i(x,t)|, \qquad |\chi_{it}(x,t)|, \qquad \|\nabla\chi_i(x,t)\|_E, \qquad (t,x) \in \bar{Q}_T,$$

is not larger than a number $\varsigma > 0$, to be defined. Then, since $F_{\chi_i} = u\chi_{it} - k\nabla u \nabla \chi_i + f\chi_i$ and putting $k_{\max}$ and $f_{\max}$ for the maximum values of k and f over their respective domains, we can choose ς so that

$$|F_{\chi_i}(x,t)| \leq \varsigma[\operatorname{diam} A + k_{\max} \operatorname{diam} B + +f_{\max}] < 1.$$

We shall call $\theta_i := F_{\chi_i}$, so that $|\theta_i| < 1$ on Ω, and the Lebesgue measure of the support of θ_i is less than $\epsilon' \cdot \operatorname{meas} A \cdot \operatorname{meas} B$, which can be made less than ϵ by choosing ϵ' accordingly.

(b) The function $\varphi_i \in C^1(\bar{Q}_T)$ is chosen so that $\varphi_i(x, T) = 0$ on D and so that

$$\mu_u(F_{\varphi_i}) + \nu_v(G_{\varphi_i}) < \epsilon. \tag{4.4}$$

This is possible since the pair (μ^*, ν^*) assigns to the pair $(F_{\varphi_i}, G_{\varphi_i})$ a value near $\int_{D_T} g\varphi_i \, dx = 0$, by (4.3b); note that the functions F_ψ, G_ψ and the integral $\int_{D_T} g\psi \, dx$ are linear in the function ψ and that the set $\{\psi_j\}$ is total, so that the functions φ_i are linear combinations of these functions. The relation (4.4) follows then from Proposition 2.

Thus, we have

$$F_i = F_{\varphi_i} + \theta_i,$$

with $\varphi_i \in C^1(\bar{Q}_T)$, $\varphi_i(x,T) = 0$, and $|\theta_i| < 1$ on Ω, with the Lebesgue measure of $\operatorname{supp} \theta_i < \epsilon, i = 1, \ldots, M_1$, and (4.4) is satisfied.

Now we obtain the weak trajectory u_v corresponding to the control v, as explained above. Then, writing μ_{u_v} for the measure corresponding to this trajectory function u_v,

$$\mu_{u_v}(F_i) + \nu_v(G_i) = \int_{D_T} u_v(\cdot, T)\psi_i \, dx, \qquad i = 1, \ldots, M_1, \tag{4.5}$$

by definition of a weak solution. But the pair (μ^*, ν^*) satisfies (4.1):

$$\mu^*(F_i) + \nu^*(G_i) = \int_{D_T} g\psi_i \, dx, \qquad i = 1, \ldots, M_1. \tag{4.6}$$

Then

$$\begin{aligned} |\int_{D_T} (u_v(\cdot, T) - g)\psi_i \, dx| &= |(\mu^* - \mu_{u_v})(F_i) + (\nu^* - \nu_v)(G_i)| \\ &\le |\mu_u(F_i) + \nu_v(G_i) - \alpha_i)| + |(\mu_u - \mu_{u_v})(F_i)| \\ &\le 3\epsilon, \qquad i = 1, \ldots, M_1, \end{aligned} \tag{4.7}$$

by (4.3b) and

$$|(\mu_u - \mu_{u_v})(F_i)| \le |(\mu_u - \mu_{u_v})(F_{\varphi_i})| + |(\mu_u - \mu_{u_v})(\theta_i)| \le 2\epsilon, \tag{4.8}$$

because of (4.4) and the fact that

$$\mu_{u_v}(F_{\varphi_i}) + \nu_v(G_{\varphi_i}) = 0.$$

It follows from (4.7) that as $M_1 \to \infty$,

$$\|u_v(\cdot, T) - g\|_{L_2} \to 0;$$

the proof is as in [1, p. 47]. Note that we need also $M_2, M_3 \to \infty$, a requirement of the proof of Proposition 2 in [2].

(iii) The second contention of the theorem follows from the fact that

$$\begin{aligned} |J(u_v, v) - (\mu^*(f_0) + \nu^*(f_1))| &\le |J(u_v, v) - (\mu_u(f_0) + \nu_v(f_1))| \\ &+ |(\mu_u(f_0) + \nu_v(f_1)) - (\mu^*(f_0) + \nu^*(f_1))| \le 2\epsilon, \end{aligned}$$

by (4.3a) and the fact that

$$J(u_v, v) - (\mu_u(f_0) + \nu_v(f_1)) = (\mu_{u_v} - \mu_u)(f_0), \tag{4.9}$$

since

(a) The function f_0 satisfies the condition $f_0(u, w, x, t) \le h'|u| + h''\|w\|_E$ on Ω, so that

$$|(\mu_{u_v} - \mu_u)(f_0)| \le |(\mu_{u_v} - \mu_u)|(h'\vartheta + +h''\|\sigma\|_E), \tag{4.10}$$

where $\vartheta(u, w, x, t) := u, \sigma(u, w, x, t) := w, (u, w, x, t) \in \Omega$. We are assuming, without loss of generality, that $u \ge 0$ on Ω.

(b) Further, choose $\psi \in C^1(\bar{Q}_T)$ of the form

$$\psi = \sum_{i=1}^{K} \beta_i \psi_i, \qquad \sum_{i=1}^{K} |\beta_i| \le \lambda, \tag{4.11}$$

with K a fixed integer not higher than M_1 and

$$\lambda \le \max\left(\frac{1}{16h'}, \frac{1}{16h''}\right).$$

Then, by (4.8),

$$|(\mu_{u_v} - \mu_u)(F_\psi)| \leq 2\lambda\epsilon.$$

Further, choose the coefficients $\beta_i, i = 1, \ldots, K$, so that

$$\vartheta(|\psi_t| - 1) \leq \epsilon'/3 \quad |k|\,\|\nabla\psi\|_E \leq \epsilon'/3 \quad |f\psi| \leq \epsilon'/3,$$

which implies

$$|\theta(\psi_t - 1) + k\sigma\nabla\psi - f\psi| \leq \epsilon',$$

on Ω; the number ϵ' will be determined below. Then

$$\begin{aligned} |(\mu_{u_v} - \mu_u)\vartheta| &\leq |(\mu_{u_v} - \mu_u)(\vartheta\psi_t - k\sigma\nabla\psi)| \\ &\quad + |(\mu_{u_v} - \mu_u)(\vartheta(\psi_t - 1) + k\sigma\nabla\psi - f\psi)| \\ &\leq 2\lambda\epsilon + \epsilon' L(Q_T) \leq \epsilon/4h', \end{aligned} \tag{4.12}$$

if we take $\epsilon' \leq \epsilon/8L(Q_T)h'$; as above, $L(Q_T)$ is the Lebesgue measure of the domain Q_T.

Note that (4.12) could have been proved for the negative $\mu_u - \mu_{u_v}$ of the measure for which it was actually proved, so that, finally,

$$|(\mu_u - \mu_{u_v})|(\vartheta) \leq \epsilon/2h'.$$

Similarly, we can prove that

$$|(\mu_{u_v} - \mu_u)|\,\|\sigma\|_E \leq \epsilon/2h'',$$

so that, by (4.10),

$$|(\mu_{u_v} - \mu_u)(f_0)| \leq \epsilon.$$

The second contention of the theorem follows. □

Remark. Note that it is not necessary to include in our set of equations (4.1) relationships reflecting equations of the form $\int_{Q_T}(u\Delta\psi + w\nabla\psi)\,dxdt = 0$, for $\psi_n = 0$ on Γ_T, relating w to ∇u; one can show, by methods similar to those used in the proof above, that the function $(x,t) \to w(x,t)$ tends in $\{\mathrm{L}_2(Q_T)^n\}$ to $(x,t) \to \nabla u_v(x,t)$, as M_1, M_2, M_3 tend to ∞.

In the next two sections we present applications of this theory, first to matters on controllablity and reachability and then to matters computational.

5. Controllability and reachability. The—apparently—nonlinear control and dynamical problem (2.1)–(2.4) has many facets that one could explore using the *linear* theory that we have developed. In this Section we examine reachability and controllability. A good review paper on the reachability and controllability of distributed systems is [21], where the concepts of approximate and exact reachability and controllability are defined and illustrated. The most interesting development on nonlinear controllability has been by Henry [22]; his approach has been developed further by Zhou in [23] and [24]. This method has been applied to equations simpler than ours and is based on the development of an associated linear system, whose controllability can be studied in the usual way. It is not related to our approach, even if some results are not dissimilar.

According to our results in the previous section, we are entitled to make the following definition.

DEFINITION. *The state g is said to be* asymptotically reachable *(from the origin, by the system* (2.1)–(2.3)*) if there is an integer $N > 0$ so that the system* (4.1b) *has a solution in $\mathcal{M}^+(\Omega) \times \mathcal{M}^+(\omega)$ for all integers M_1, M_2, M_3 that are larger than N.*

In other words, according to our results on approximation, if a state g is asymptotically reachable one can, given $\epsilon > 0$, find a control v_ϵ that generates a *weak solution* u_{v_ϵ} so that the $L_2(D_T)$-norm of the difference $u_{v_\epsilon}(T) - g$ is not higher than ϵ. This of course does not mean that there is a control by means of which the state g can be reached exactly, so this is a weaker concept than that of exact reachability. It is just as strong as approximate reachability—a concept based on the classical solutions—for systems for which these and weak solutions coincide.

It is an open problem whether one can find a control to reach exactly a state g based on the construction of the family of controls $\{v_\epsilon, \epsilon > 0\}$. Our philosophy is that it is sufficient for any foreseeable application to have the possiblity of reaching a final state as closely as necessary. The mathematical problem, essentially that of exact controllability, remains. It does not appear that our methods can throw any new light on this problem.

We shall follow the mathematical structure developed in [1, Chap. 6], and applied there to finite-dimensional systems. Consider then the real vector space $\mathcal{L}$ of pairs (f, h) of continuous functions $f : \Omega \to \mathbf{R}$ and $h : \omega \to \mathbf{R}$. The linear operations are defined as follows:

$$\lambda(f,h) := (\lambda f, \lambda h), \qquad (f,h) + (v,w) := (f+v, h+w),$$

for all real λ and appropriate functions v and w.

Further, we define an *ordering* on the space $\mathcal{L}$ by defining its positive cone, $\mathcal{C}$:

$$\mathcal{C} = \{(f,h) \in \mathcal{L} : (f,h) \geq 0\} = \{(f,h) \in \mathcal{L} : f \geq 0 \,\text{on}\, \Omega, h \geq 0 \,\text{on}\, \omega\}.$$

It is trivial to show that this defines an ordering compatible with the linear structure. It is also compatible with the topological structure generated by the uniform norm

$$||(f,h)|| = \sup_{\Omega} |f| + \sup_{\omega} |h|.$$

Thus, the space $\mathcal{L}$ is an *ordered topological vector space*, and we can apply to our problem of existence a particular theorem, due to Schaefer [25, Thm. 5.4]. To do this, consider the functional Υ defined by the equalities (4.1b) on the subspace $\mathcal{E}$ of $\mathcal{L}$ spanned by the functions appearing in (4.1b), that is,

$$\text{(5.1)} \quad \mathcal{E} := \left\{ (f,h) \in \mathcal{L} : (f,h) = \sum_{i=1}^{M_1} A_i(F_i, G_i) + \sum_{j=1}^{M_2} B_j(\xi_j, 0) + \sum_{k=1}^{M_3} C_k(0, \zeta_k) \right\},$$

for real numbers A_i, B_j, C_k. Then, according to our results in [1, Chap. 6]—a trivial development of Schaefer's results [25]—we have the following proposition.

PROPOSITION 4. *The functional Υ defined by the equalities* (4.1b) *on the subspace $\mathcal{E}$ can be extended to the whole of the linear space $\mathcal{L}$ as a positive functional if and only if the functional Υ is bounded above on $\mathcal{E} \cap (\mathcal{V} - \mathcal{C})$, where $\mathcal{V}$ is a suitable neighborhood of zero in $\mathcal{L}$. Further, this is true if and only if the functional Υ is bounded above on the subset U of $\mathbf{R}^{M_1+M_2+M_3}$ defined by*

$$U := \Big\{ \{A_i, i = 1, \ldots, M_1, B_j, j = 1, \ldots, M_2, C_k, k = 1, \ldots, M_3\} :$$

$$\left.\sum_{i=1}^{M_1} A_i(F_i,G_i)+\sum_{j=1}^{M_2} B_j(\xi_j,0)+\sum_{k=1}^{M_3} C_k(0,\zeta_k)<1\right\}$$

$$=\left\{\{A_i, i=1,\dots,M_1, B_j, j=1,\dots,M_2, C_k, k=1,\dots,M_3\}:\right.$$

$$\left.\sum_{i=1}^{M_1} A_i(F_i+G_i)+\sum_{j=1}^{M_2} B_j\xi_j+\sum_{k=1}^{M_3} C_k\zeta_k<1 \quad \text{on} \quad \Omega\times\omega\right\}; \tag{5.2}$$

that is, the state g is asymptotically reachable by the system (2.1)–(2.3) *if and only if there is a constant D so that*

$$\{A_i, i=1,\dots,M_1, B_j, j=1,\dots,M_2, C_k, k=1,\dots,M_3\}\in U$$

$$\Rightarrow \sum_{i=1}^{M_1} A_i\alpha_i+\sum_{j=1}^{M_2} B_j a_j+\sum_{k=1}^{M_3} C_k b_k<D. \tag{5.3}$$

Proof. The firt part follows directly from [25, Thm. 5.4]. The second part follows from simply writing down the form of a neighbourhood $\mathcal{V}$; take $\epsilon>0$ and then define the neighborhood $\mathcal{V}_\epsilon$ by

$$(f,h)\in\mathcal{V}_\epsilon \Rightarrow \sup_{\Omega}|f|+\sup_{\omega}|h|<\epsilon,$$

so that

$$\mathcal{V}_\epsilon-\mathcal{C}=\{(f,h)\in\mathcal{L}: f+h<\alpha \quad \text{on} \quad \omega\times\Omega\}, \tag{5.4}$$

for some scalar α. The expression (5.2) follows by simply normalizing as in Proposition VI.3 in [1], and (5.3) follows fom the definition of the functional Υ.

Finally, we can develop our main result of this section.

(i) The set $U\subset\mathbf{R}^{\mathbf{M_1+M_2+M_3}}$ is a convex set that contains the origin. It will normally be unbounded.

(ii) The expression (5.3) defines a hyperplane Π in $\mathbf{R}^{\mathbf{M_1+M_2+M_3}}$ by

$$\sum_{i=1}^{M_1} A_i\alpha_i+\sum_{j=1}^{M_2} B_j a_j+\sum_{k=1}^{M_3} C_k b_k=D. \tag{5.5}$$

Proposition 4 says that (4.1b) has a solution in $\mathcal{M}^+(\Omega)\times\mathcal{M}^+(\omega)$ if and only if the set U is wholly at one side of the hyperplane Π.

(iii) We shall make some assumptions now as to the nature of the functions $\xi_j, j=1,\dots,M_2; \zeta_k, k=1,\dots,M_3$. First, we shall partition the (x,t) and (s,t) spaces and define them as the characteristic functions of the sets in the partitions. Of course, they will not be continuous but can be chosen as lower-semicontinuous, and our arguments above follow without much change; see [1, Chap. 5] for a discussion of this and related problems. Then we shall assume, without loss of generality, that these partitions have been chosen so that $M_1=M_2=M_3\equiv M$.

(iv) Put now $A_i=B_i=C_i\equiv 0 \ \ \forall i\neq\ell$. What does the set U and the hyperplane Π look like, in this subspace with variables A_ℓ, B_ℓ, C_ℓ? Let

$$\begin{aligned}
\mathcal{G}'_\ell &:= \{((x,t),(s,t))\in\Omega\times\omega:\xi_\ell=1,(F_\ell+G_\ell)>0)\},\\
\mathcal{H}'_\ell &:= \{((x,t),(s,t))\in\Omega\times\omega:\xi_\ell=1,(F_\ell+G_\ell)<0)\},\\
\mathcal{G}''_\ell &:= \{((x,t),(s,t))\in\Omega\times\omega:\zeta_\ell=1,(F_\ell+G_\ell)>0\},\\
\mathcal{H}''_\ell &:= \{((x,t),(s,t))\in\Omega\times\omega:\zeta_\ell=1,(F_\ell+G_\ell)<0)\}
\end{aligned} \tag{5.6}$$

and

$$\begin{aligned}
r'_\ell &:= \inf_{\mathcal{G}'_\ell}(1/(F_\ell + G_\ell)),\\
s'_\ell &:= \sup_{\mathcal{H}'_\ell}(1/(F_\ell + G_\ell)),\\
r''_\ell &:= \inf_{\mathcal{G}''_\ell}(1/(F_\ell + G_\ell)),\\
s''_\ell &:= \sup_{\mathcal{H}''_\ell}(1/(F_\ell + G_\ell)).
\end{aligned}\tag{5.7}$$

In the (A_ℓ, B_ℓ) plane, U projects as a set bounded by two straight lines, one from the point P_ℓ of coordinates $A_\ell = 0, B_\ell = 1$ to the point with coordinates $A_\ell = r'_\ell, B_\ell = 0$ and another from the same point P_ℓ to the point with coordinates $A_\ell = s'_\ell, B_\ell = 0$.

In the (A_ℓ, C_ℓ) plane, U projects as a set bounded by two straight lines, one from the point Q_ℓ of coordinates $A_\ell = 0, C_\ell = 1$ to the point with coordinates $A_\ell = r''_\ell, B_\ell = 0$ and another from the same point Q_ℓ to the point with coordinates $A_\ell = s''_\ell, B_\ell = 0$.

The hyperplane Π projects as lines in the (A_ℓ, B_ℓ) and (A_ℓ, C_ℓ) planes. Consider lines parallel to these but passing through the points P_ℓ and Q_ℓ respectively. They cut the A_ℓ axis at the points

$$A'_\ell = \frac{a_\ell}{\alpha_\ell}, \qquad A''_\ell = \frac{b_\ell}{\alpha_\ell},\tag{5.8}$$

respectively. We have thus our main theorem.

Theorem 2. *The system* (4.1b) *has a solution in* $\mathcal{M}^+(\Omega) \times \mathcal{M}^+(\omega)$ *if*

$$\begin{gathered}
A'_\ell > r'_\ell \quad \text{if} \quad A'_\ell > 0, \quad A'_\ell < s'_\ell, \quad \text{if} \quad A'_\ell < 0\\
A''_\ell > r''_\ell \quad \text{if} \quad A''_\ell > 0, \quad A''_\ell < s''_\ell, \quad \text{if} \quad A''_\ell < 0,\\
\forall \ell = 1, \dots, M.
\end{gathered}\tag{5.9}$$

Proof. It follows from the remarks above and the convexity of the set U. □

Corollary 1. *The state g is asymptotically reachable if and only if there is an integer $N > 0$ so that the conditions* (5.9) *of Theorem* 2 *are true for all $M > N$.*

What can go wrong? We can always satisfy (5.9) by making α_ℓ sufficiently small, unless $r'_\ell, r''_\ell, |s'_\ell|, |s_\ell|''$ are actually ∞ for some values of ℓ—because the function $F_\ell + G_\ell$ does not take the appropriate sign on the appropriate subset of $\Omega \times \omega$—or because they tend to ∞ as $M \to \infty$. We shall examine these possibilities further below.

We introduce now a concept of *controllability.* Since the control set is bounded, the trajectories will be in a bounded set A; see (2.5). Thus we cannot hope to reach the whole of the state space and should be content with the following.

Definition. *A system such as* (2.1)–(2.3) *is* asymptotically controllable *if there is a ball centered at the origin in $L_2(D_T)$ so that every state $g \in C(D_T)$ in this ball can be reached asymptotically.*

We have then the following corollary.

Corollary 2. *There is a control set $V \subset \mathbf{R}$ so that the system* (2.1)–(2.3) *is asymptotically controllable. This control set is defined in general in the paragraph after* (2.3).

Proof. If the quantities (5.7) stay bounded as $M \to \infty$, we can choose the moments α_ℓ sufficiently small so that the inequalities of Theorem 2 are satisfied. Consider the first quantity in (5.7). It follows from (3.1) and (3.2) that

$$F_\ell + G_\ell = u\psi_\ell - kw\nabla\psi_\ell + f\psi_\ell + k\psi_\ell|_{\Gamma_T} v;$$

provided that ψ_ℓ is nonzero on Γ_T, we can choose V so that this function takes positive values on $\mathcal{G}'_\ell$, bounded away from zero, for all values of the index ℓ; similarly for the other functions and sets in (5.6), (5.7). For such a control set V the system (2.1)–(2.3) is asymptotically controllable. □

6. Numerical results. The system (4.1) is a semi-infinite linear-programming problem, since the unknown is in $\mathcal{M}^+(\Omega) \times \mathcal{M}^+(\omega)$ but there are only a finite number of constraints. There are several methods for treating numerically such problems [26], [27], even though it appears that only Rudolph's [11], [12], [28], [29] and Hoffman-Klostermair's [30] methods can be assured to converge to the global minimizer; these are simplex methods working in infinite dimensions. We have chosen here Rudolph's method, partly because its author has been very successful in using our finite-dimensional framework for the estimation of optimal controls [11], [12].

To solve these problems we could work in $\mathcal{M}^+(\Omega \cup \omega)$, and indeed this is the most convenient way for work involving discretized approximations; we have done just that in a paper involving the control of variational inequalities, to be published elsewhere. Here, however, it is more convenient to work in $\mathcal{M}^+(\Omega \times \omega)$, identifying $(\mu, \nu) \to \mu \times \nu$, so that

$$\mu \times \nu(f+g) = \mu(f) + \nu(g), \qquad f \in C(\Omega), g \in C(\omega);$$

note that the Lebesgue measures L', L'' are equal to unity and $T = 1$. Also, the conditions (3.6) take the form

$$\mu \times \nu(1_{\Omega\times\omega}) = T = 1.$$

We have added this equality to our constraints because it improved the accuracy of the computation.

The system we have chosen is

$$\begin{aligned} u_t(x,t) - \operatorname{div}\left(\frac{x^2}{1+t^2}\nabla u(x,t)\right) &= \frac{\|\nabla u(x,t)\|_E^2 + 1}{1 + x^2 + u(x,t)^2}, \\ u_x(0,t) = 0, \quad u_x(1,t) &= v(t), \\ t \in (0,1), \quad x &\in (0,1); \end{aligned} \tag{6.1}$$

that is, $k(x,t) := x^2/(1+t^2)$, $f(u,w,x,t) := (\|w\|_E^2 + 1)/(1+x^2+u^2)$. We have taken $V = [-10, 10]$, $g(x) = 0.075$, $x \in [0,1]$; and we wish to minimize

$$J(u,v) = \int_{Q_T} \frac{u(x,t)^2 + \|\nabla u(x,t)\|_E^2}{1 + \sin^2(tu(t,x))}\, dt;$$

that is, $f_0(x,w,x,t) := (u^2 + \|w\|_E^2)/(1 + \sin^2(tu))$, and $f_1 \equiv 0$. The boundary ∂D is composed of two points only, of which only one, the one at $x = 1$, plays an active role, the control being the heat flow at that point.

The functions ψ in (3.2) were chosen of the form $\psi(x,t) = t^p \cos(\ell\pi x) + q(t)$ or $\psi(x,t) = t^p \sin(h\pi x) + q(t)$; the functions q are test functions introduced to improve the behaviour at $x = 1$ for the determination of an initial solution, as explained below. Ten such functions ψ were chosen, with values of $p = 1, 2$ and $\ell = 1, 2, 3$, $h = 1, 2$. The 16 functions ξ were chosen by dividing the square $[0,1] \times [0,1]$ into 16 equal squares, the functions ξ being the characteristic functions of the individual squares. The condition (3.5b) for the functions ζ is satisfied automatically—thus the advantage of this formulation based on product measures. Thus the total number of constraints m equals $m = 1 + 10 + 16 = 27$. The computational method consists of three steps:

(i) The most difficult problem encountered was that of finding an initial solution from which, in part (ii) of the method, one can iterate toward the minimum. This was done here by means of a finite-dimensional linear program, obtained by discretizing all the variables of the problem. It was necessary to find an initial solution by first solving for some of the parameters, thus the need of the functions q introduced above, because the (rather rough) discretization tended to make the problem unfeasible. Then a finite-dimensional simplex program was run, of rather small size, with 677 variables and, of course, 27 constraints. Only the first phase—the one that produces a feasible solution—was run. It is usual in these problems to use a discretized solution as an initial one; see [11], [12], [26, Chap. 5, 6].

(ii) Then the simplex algorithm of Rudolph was run using the output of step (i) as initial solution, and after 87 iterations it converged to a value of 0.202247; it had started with a value of 1.93919. This is a numerical estimation of the *global minimum*.

(iii) Once the optimization is performed, a nearly-optimal control v can be constructed; the method is shown in detail in [1, Chap. 5]. The graph of the resulting control is shown in Fig. 1.

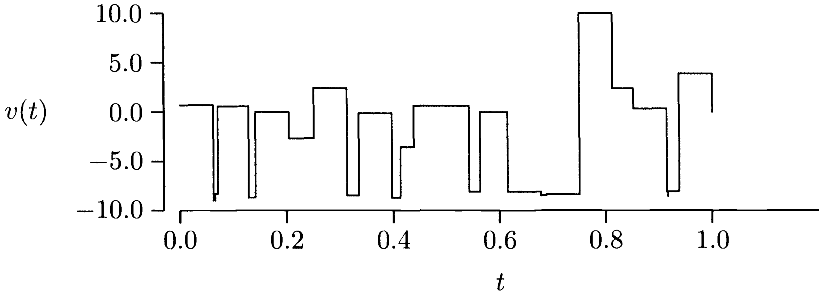

FIG. 1. *Graph of the nearly-optimal control v. Note that the control set is $V = [-10, 10]$.*

We mention, finally, that our approach can be applied to other nonlinear partial differential equations and to variational inequalities.

ASYMPTOTICAL STUDY OF PARAMETER TRACKING ALGORITHMS*

BERNARD DELYON† AND ANATOLI JUDITSKY†

Abstract. This paper addresses the problem of tracking random drifting parameters of a linear regression system. The asymptotic properties of several estimation algorithms in the limit of slow drift are studied. The basic tool is the central limit theorem for a class of stochastic difference equations established under weak conditions on disturbances and observations. The estimates of the rate of convergence obtained in the paper allow the asymptotically optimal algorithms to be developed.

Key words. tracking algorithms, stochastic averaging, normal approximation

AMS subject classifications. 93E10, 93E11, 62L20, 60G35

1. Introduction. In this paper we consider the system of the form

$$y_t = \theta_{t-1}^T \varphi_t + e_t,$$

where e_t is a random noise, $\varphi_t \in \mathbf{R}^N, y_t \in \mathbf{R}$ are observed input and output, and θ_t is an unknown time-varying parameter vector. We assume that θ_t is random and varies slowly, i.e.,

$$\theta_t = \theta_{t-1} + \gamma w_t, \tag{1}$$

where γ is a small parameter.

To estimate the time-varying parameter θ_t in many cases the following general-form identification algorithm can be used (see [11] for a recent review):

$$\hat{\theta}_t = \hat{\theta}_{t-1} + \mu L_t(y_t - \varphi_t^T \hat{\theta}_{t-1}), \qquad \hat{\theta}_t \in \mathbf{R}^N. \tag{2}$$

The way in which the vector gain L_t is updated is characteristic for each particular method. Here μ is a small positive real number. Our paper is devoted essentially to the asymptotical (as $\mu \to 0$ and $\gamma \to 0$) study of the stationary law of the error $\hat{\theta}_t - \theta_t$ of the algorithm. More precisely, our objectives are to show that for a variety of methods the distribution of the error converges to the normal law and to develop asymptotically optimal versions of the algorithms.

Let $\Gamma = \Gamma^T > 0$. In what follows we consider the following gain constructions:

1. Widrow's least mean squares algorithm (LMS):

$$L_t = \Gamma \varphi_t \quad \text{or} \quad L_t = \frac{\Gamma \varphi_t}{1 + \mu \varphi_t^T \Gamma \varphi_t}.$$

2. Normalized least mean squares algorithm (NLMS):

$$L_t = \Gamma \varphi_t / (1 + |\varphi_t|^2).$$

3. Recursive least squares "forgetting factor" algorithm (RLS):

$$\begin{aligned} R_t &= (1-\mu) R_{t-1} + \mu \varphi_t \varphi_t^T, \quad R_0 = \varrho I, \ \varrho > 0, \\ L_t &= R_t^{-1} \varphi_t. \end{aligned}$$

* Received by the editors October 21, 1992; accepted for publication (in revised form) October 15, 1993.

† Institute de Recherche en Informatique et Systèmes Aleatoires, Campus de Beaulieu, 35042 Rennes, France (Delyon@irisa.fr and Anatoli.Iouditski@irisa.fr).

4. "Stabilized" least squares (LS) algorithm:

$$\begin{aligned} L_t &= \Gamma_t \varphi_t, \\ \Gamma_t &= (\mu \rho^{-1} R_t + \Gamma^{-1})^{-1}, \\ R_t &= (1-\rho) R_{t-1} + \rho \varphi_t \varphi_t^T \,, \qquad R_0 = 0, \quad \text{where } 0 < \rho < 1. \end{aligned}$$

Comment. The algorithms above are well known (cf. [11]) except, probably, the stabilized LS. This method was designed as a regularized version of both LMS and forgetting factor algorithms (see [7] for details).

The main theoretical issue of the paper is the central limit theorem (CLT) for the stochastic difference equations developed in §2. It provides an *infinite horizon* approximation for the asymptotic distribution of the error $\hat{\theta}_t - \theta_t$ of equation (2) assuming the stationarity of the sequence (φ_t, e_t, w_t). Next we provide a guide to the application of this result to estimation algorithms. In §3 we consider the algorithms described above and develop conditions of the CLT and expressions for the asymptotic error covariance.

2. Main Result.

2.1. CLT for the stationary case. As usual, we suppose we have a probability space $\{\Omega, \mathcal{F}, P\}$. Let us consider a process (Δ_t), $\Delta_t \in \mathbf{R}^N$, which is generated with the following equation:

$$\Delta_t = (I - \mu P_t)\Delta_{t-1} + \mu \zeta_t \qquad \Delta_0 \in \mathbf{R}^N, \tag{3}$$

where $\mu \leq \mu_0$ is a scalar coefficient, and (P_t) and (ζ_t) are random processes valued in $\mathbf{R}^{N\times N}$ and $\mathbf{R}^N$, respectively. We are going to prove the CLT for the solution Δ_t of (3) which will be quite useful in the study of the estimation algorithms. Let us allow the processes P_t and ζ_t to depend on μ, and P_t can be decomposed in the following way:

$$P_t = P_t^0 + P_t', \tag{4}$$

$$\zeta_t = \zeta_t^0 + \zeta_t', \tag{5}$$

where P_t^0 and ζ_t^0 do not depend on μ. Suppose that there exists a strictly stationary process (X_t) and $\mathcal{F}_t = \sigma\{\dots, X_t\}$ such that $P_t^0, \zeta_t^0, P_t', \zeta_t' \in \mathcal{F}_t$ (for example, in the state-space model X_t contains all the past "innovations"). Consider the following assumptions:

[A1] $P_t^0 = (P_t^0)^T \geq 0$, $EP_1^0 > 0$, $E|P_1^0|^2 < \infty$.

[A2] (P_t^0) and (ζ_t^0) are strictly stationary ergodic processes.

[A3] $\sum_{s=0}^{\infty} (E|E(\zeta_s^0|\mathcal{F}_0)|^2)^{1/2} < \infty$.

[A4] $\lim_{\mu\to 0} \mu^{-1/2} \sup_t E(|\zeta_t'|) = 0$.

[A5] There exists a stationary ergodic process p_t' which satisfies

$$\begin{aligned} &|P_t'| \leq p_t', \\ &\lim_{\mu_0 \to 0} E\left(\sup_{\mu\leq\mu_0} [p_t']^2\right) = 0, \quad t \geq 0, \\ &E([p_t']^2) < \infty, \quad \mu \leq \mu_0. \end{aligned}$$

THEOREM 1. *Let assumptions* [A1]–[A5] *hold. Then for system* (3) *with any initial condition* Δ_0

$$\lim_{\mu\to 0} \lim_{t\to\infty} \mu^{-1/2} \Delta_t = \mathcal{N}(0, V) \quad \textit{in distribution,} \tag{6}$$

i.e., $\mu^{-1/2}\Delta_t$ *converges in distribution to the Gaussian random variable with zero mean and covariance* V. *Here* V *is a solution of the Lyapunov equation*

$$BV + VB = S_0, \tag{7}$$

where $B = EP_1^0$ *and*

$$S_0 = E\zeta_0^0\zeta_0^{0T} + \sum_{i=1}^{\infty} E\zeta_0^0\zeta_i^{0T} + E\zeta_i^0\zeta_0^{0T}. \tag{8}$$

Note that assumptions [A2] and [A3] guarantee the existence of $S_0 < \infty$. The precise sense of the limit above is

$$\lim_{\mu\to 0}\limsup_{t\to\infty} |E[f(\mu^{-1/2}\Delta_t)] - E[f(\mathcal{N}(0, V))]| = 0$$

for any bounded continuous function f.

The proof of Theorem 1 is postponed until §4 below.

Comment. We should note that the assertions of the theorem above provide an infinite horizon approximation. We emphasize the difference with respect to the standard results on weak approximation, when the weak convergence on the finite interval of order γ^{-1} is usually shown. Let us compare Theorem 1 with the analogous results of Theorem 4.15, Part 2 of [1] or the corresponding result in [9]. In fact, those results implicitly require that the trajectories (Δ_t) of equation (3) are bounded. Furthermore, the condition on the dependence in the input sequence (P_t) in Theorem 1 is more explicit and less restrictive than those, for instance, of Theorem 4.15, Part 2 in [1] since only ergodicity is required.

Compared with results obtained in [4], [18], [12]–[14] this paper does not consider moments of $\hat{\theta}_t - \theta_t$ (which may as well be infinite) but investigates the limit in law of this process. The notable advantage of this approach is the weakness of the assumptions made in the theorem. It should be noted that the assertion of the theorem does not imply the convergence of the distribution of $\mu^{-1/2}\Delta_t$ to any limit as $t \to \infty$ for fixed μ. It only means that the distance between the distributions of $\mu^{-1/2}\Delta_t$ and the Gaussian distribution converges to 0 as $\mu \to 0$.

Discussion. Let us consider assumptions of the result above. They are quite simple, and only assumption [A3] needs to be clarified. Note that this condition is usual when proving the CLT for the stationary processes. It is satisfied if, for instance, ζ_t^0 is a martingale-difference process with $E|\zeta_1^0|^2 < \infty$. Let ζ_t^0 be defined by the equation

$$\zeta_t^0 = G\zeta_{t-1}^0 + \xi_t, \quad \zeta_0^0 \in \mathbf{R}^N,$$

where $G \in \mathbf{R}^{N\times N}$. If G is stable (i.e., $|\lambda_{\max}(G)| \le \rho < 1$) and ξ_t is a martingale-difference with $E|\xi|^2 \le \infty$, then $E|E(\zeta_t^0|\mathcal{F}_0)|^2 \le K\rho^t$ and assumption [A3] holds.

We can also translate assumption [A3] into usual mixing conditions on the sequences (ζ_t^0) and (w_t).

Let us recall the definitions of the three mixing coefficients $\phi(k)$, $\alpha(k)$, and $\rho(k)$ (cf. [6]). Consider the sequence (x_t) with $Ex_i = 0$.

1. The uniformly strong mixing coefficient

$$\phi(k) = \sup |P(B|A) - P(B)|, \quad t, k \ge 1, \quad P(A) > 0$$

where the supremum is taken over all sets $A \in \mathcal{M}_t = \sigma\{\ldots, x_{t-1}, x_t\}$ and $B \in \mathcal{M}^{t+k} = \sigma\{x_{t+k}, x_{t+k+1}, \ldots\}$.

2. The strong mixing coefficient

$$\alpha(k) = \sup_{A \in \mathcal{M}_t, B \in \mathcal{M}^{t+k}} |P(AB) - P(A)P(B)|, \quad t, k \geq 1.$$

3. The coefficient of the maximum correlation

$$\rho(k) = \sup \operatorname{cov}(z', z''), \quad t, k \geq 1,$$

where the supremum is taken over all random variables z' and z'' with the bounded second moment such that z' is $\mathcal{M}_t$-measurable and z'' is $\mathcal{M}^{t+k}$-measurable.

LEMMA 1. *The following inequalities hold:*

$$||E(x_{t+k}|\mathcal{M}_t)||_p \leq 2\phi(k)^{1/p} \sup_t ||x_t||_p, \quad p \geq 2;$$

$$||E(x_{t+k}|\mathcal{M}_t)||_p \leq 8\alpha(k)^{1/p-1/q} \sup_t ||x_t||_p, \quad p > 1, \ q \geq p;$$

$$||E(x_{t+k}|\mathcal{M}_t)||_2 \leq \rho(k)^{1/2}.$$

Proof. The proof follows immediately from the classical mixing inequalities (see, for instance, appendix III of [5]). □

2.2. Extension to the Markov case. We use the following propositions to obtain some further generalizations for the the case of Markov processes (P_t) and (ζ_t). By using Proposition 1 below, we can identify the process (P_t, ζ_t) with the stationary sequence $(\bar{P}_t, \bar{\zeta}_t)$ with probability $1 - \epsilon$ for arbitrary $\epsilon > 0$ and $t \geq n(\epsilon)$. The sequence $\bar{\Delta}_t$ obtained from $(\bar{P}_t, \bar{\zeta}_t)_{t \geq n}$ with $\bar{\Delta}_{n(\epsilon)} = \Delta_{n(\epsilon)}$ satisfies (6) and

$$P(\bar{\Delta}_t = \Delta_t, t \geq n(\epsilon)) \geq 1 - \epsilon.$$

The result is now immediate since ϵ is arbitrary (the dependence of $n(\epsilon)$ on μ does not interfere due to the order of the limits in the statement of Theorem 1).

The following proposition shows how trajectories of certain Markov chains may be identified, up to a change of probability space, with those of a stationary Markov chain with same transition probability.

PROPOSITION 1. *Let $\Pi(x, dy)$ be a transition probability on some measurable space S, with invariant measure π, such that for any initial probability measure ν on S,*

$$\lim_{t \to \infty} ||\nu \Pi^t - \pi|| = 0$$

($||\nu||$ denotes the total variation of measure ν). Then for any distribution ν and any $\epsilon > 0$, there exist a (deterministic) time T and two Markov chains X_t and Y_t with transition probability Π, and initial distributions ν and π, respectively, such that

$$P(X_t = Y_t, \ t \geq T) > 1 - \epsilon.$$

Proof. We first recall a useful result [3]: Let X be a Polish space and $M(X)$ be the set of probability measures on X. There exists a Borel function

$$\rho : M(X) \times [0, 1] \longrightarrow X$$

such that if U is a uniform right variable (r.v.) on $[0, 1]$ the distribution of $\rho(m, U)$ is m for any probability measure $m \in M(X)$.

Using this result, we can build a realization of any Markov chain on the probability space $[0,1]^N$ by defining $X_n = \rho(P_n(X_{n-1}, dy), U_n)$ where $P_n(x, dy)$ is the transition probability at time n and U_n is an independently and identically distributed (i.i.d.) sequence of r.v. uniformly distributed on $[0,1]$. This is the mechanism we use in the upcoming sections in order to avoid the construction of trajectory spaces (we will need two functions ρ: one corresponding to $X = S$ and the other to $X = S \times S$).

Consider a realization Z_t of the Markov chain with initial distribution ν. From the assumptions, we can find a time T such that

$$||\nu\Pi^T - \pi|| < 1 - \epsilon,$$

and this implies the existence of a random variable Y_T with distribution π such that

$$P(Z_T = Y_T) > 1 - \epsilon.$$

By running (as explained before) the chain on $S \times S$ with transition probability

$$\Psi(x, x', dy, dy') = I(x = x')\Pi(x, dy)\delta_y(y') + I(x \neq x')\Pi(x, dy)\Pi(x', dy')$$

and starting with (Z_T, Y_T), we obtain a process (X_t, Y_t) defined for $t \geq T$. Then setting $X_t = Z_t$ for $t < T$, we get the desired assertion. □

Consider the following assumption:

[A6] There exist a measure ϕ and a measurable set A such that for any ϕ-positive set B

$$\inf_{x \in A} P_x(X_n \in B \text{ for some } n \leq n_0) > 0 \quad \text{for some } n_0 = n_0(B)$$

and the chain X_n is aperiodic. Furthermore, there exist a measurable non-negative function g and a positive real number ϵ such that

$$\begin{aligned} &\textstyle\int g(y)\Pi(x, dy) \leq g(x) - \epsilon \quad \text{for any } x \in A^c, \\ &\textstyle\sup_{x \in A} \int g(y)\Pi(x, dy) < \infty. \end{aligned} \tag{9}$$

The condition required in the settings of Proposition 1 may be easily checked through the following result (cf. Theorems 4.6 and 5.2 in [16]).

PROPOSITION 2. *Let X_n be a Markov chain with transition probability* $\Pi(x, B)$ ($x \in \mathbf{R}^N$, $B \subset \mathbf{R}^N$). *If assumption* [A6] *holds, then the chain is positive Harris-recurrent* (*ergodic*), *it has a unique invariant probability measure π. In particular,*

$$\lim_{n \to \infty} ||\lambda\Pi^n - \pi|| = 0$$

for any initial distribution λ.

Example. Consider the process (φ_t), $\varphi_t \in \mathbf{R}^N$ defined by the equation

$$\varphi_t = G\varphi_{t-1} + F\xi_t, \quad \varphi_0 \in \mathbf{R}^N,$$

where $G \in \mathbf{R}^{N \times N}$, and (ξ_t) is a sequence of independent and identically distributed random variables with, say, $E\xi_1 = 0$, $E|\xi_1|^2 < \infty$. If the matrix G is stable then by the Lyapunov theorem we conclude that there are matrices $W = W^T > 0$ and $U > 0$ such that $W = G^T W G + U$. Thus we obtain for the function $v_t = \varphi_t^T W \varphi_t$

$$\begin{aligned} E(v_t|\mathcal{F}_{t-1}) &= v_{t-1} - \varphi_t^T U \varphi_t + \xi_t^T F^T W F \xi_t \\ &\leq (1 - \alpha)v_{t-1} + \operatorname{trace}(F^T W F E\xi_t\xi_t^T) \end{aligned} \tag{10}$$

for some $\alpha > 0$. Set $A = \{x \in \mathbf{R}^N : |x| \leq R\}$. From (10) we conclude that there is some $R < \infty$ that the inequalities in (9) hold. Suppose that the distribution of ξ_t has an absolutely continuous on $\mathbf{R}^N$ component with respect to the Lebesgue measure. If the pair of matrices (G, F) is controllable, then it can be easily verified that $\Pi^N(x, dy)$ has a positive continuous component on A, thus assumption [A6] holds. More results may be found in [17, Chap. 6] for the convergence of $\Pi^n(x, \cdot)$ to π and in [19] about the second assertion of the proposition.

When summing up the above arguments we obtain the following result.

THEOREM 2. *Suppose that a Markov chain* (ξ_t) *satisfies assumption* [A6]. *This implies the existence of the invariant probability* $\pi(\cdot)$. *Let* Δ_t *be defined by equation* (3), *where* $P_t = P_t(\xi)$ *and* $\zeta_t = \zeta_t(\xi)$. *Suppose that* P_t *can be decomposed as in* (5). *Furthermore, assumptions* [A1], [A3]–[A5] *hold for the invariant measure* π. *Then* $\lim_{\mu\to 0}\lim_{t\to\infty}\mu^{-1/2}\Delta_t = \mathcal{N}(0, V)$ *in distribution, i.e.,* $\mu^{-1/2}\Delta_t$ *converges in distribution to the Gaussian random variable with zero mean and covariance* V. *Here* V *is a solution of the Lyapunov equation* (7).

2.3. Application guide for Theorem 1. Equation (2) leads to the following recursion on the estimation error $\delta_t = \theta_t - \hat{\theta}_t$:

$$\delta_t = (I - \mu L_t \varphi_t^T)\delta_{t-1} + \mu L_t e_t - \gamma w_t. \tag{11}$$

Set

$$\begin{aligned} \delta_t^{(1)} &= (I - \mu L_t \varphi_t^T)\delta_{t-1}^{(1)} + \sqrt{\mu} L_t e_t, \quad \delta_0^{(1)} = \delta_0, \\ \delta_t^{(2)} &= (I - \mu L_t \varphi_t^T)\delta_{t-1}^{(2)} - \sqrt{\mu} w_t, \quad \delta_0^{(2)} = 0, \\ \Delta_t^T &= \sqrt{\mu}(\delta_t^{(1)}, \delta_t^{(2)})^T. \end{aligned}$$

Then

$$\delta_t = \sqrt{\mu}\delta_t^{(1)} + \frac{\gamma}{\sqrt{\mu}}\delta_t^{(2)}, \tag{12}$$

and equation (3) is equivalent to (11) if we put

$$P_t = \begin{pmatrix} L_t \varphi_t^T & 0 \\ 0 & L_t \varphi_t^T \end{pmatrix}, \tag{13}$$

$$\zeta_t = \begin{pmatrix} L_t e_t \\ -w_t \end{pmatrix}. \tag{14}$$

Thus, as μ tends to zero, δ is supplied by equation (12) where the vector $(\delta^{(1)}, \delta^{(2)})$ is approximated (independently of γ) by a Gaussian vector with known covariance matrix of order one. These arguments are well known when dealing with the moment bounds for δ_t (cf. [15], [13], etc.), but to the best of our knowledge, are somewhat new when considering the distributions. Note that the optimal choice of the gain coefficient is $\mu = \gamma$ (we can attribute the coefficient of order of magnitude one to the gain matrix Γ). Yet, the degenerate case ($\mu = o(\gamma)$ or $\gamma = o(\mu)$) is interesting from the practical point of view, since the scale parameter γ of the disturbance is often unknown and is extremely hard to extract from data. We introduce the following useful notation.

DEFINITION 1. *Let*

$$\delta_t = \sqrt{\mu}\delta_t^{(1)} + \frac{\gamma}{\sqrt{\mu}}\delta_t^{(2)},$$

where $\delta_t^{(1)}$ *and* $\delta_t^{(2)}$ *are two random processes which depend on parameter* μ *only. If* $(\delta_t^{(1)}, \delta_t^{(2)})$ *converges in distribution to the Gaussian random variable* $N(0, V)$, *where*

$$V = \begin{pmatrix} V_1 & 0 \\ 0 & V_2 \end{pmatrix},$$

then we will write $\delta_t \asymp N(0, \mu V_1 + \frac{\gamma^2}{\mu} V_2)$.

In particular

(i) if $\gamma = o(\mu)$ then $\lim_{\mu\to 0}\lim_{t\to\infty} \mu^{-1/2}\delta_t = \mathcal{N}(0, V_1)$ in distribution;

(ii) if $\mu = o(\gamma)$ then $\lim_{\mu\to 0}\lim_{t\to\infty} \frac{\sqrt{\mu}}{\gamma}\delta_t = \mathcal{N}(0, V_2)$ in distribution;

(iii) if $\mu = \gamma$ then $\lim_{\mu\to 0}\lim_{t\to\infty} \gamma^{-1/2}\delta_t = \mathcal{N}(0, V_1 + V_2)$ in distribution.

3. Algorithms study. To simplify the presentation we will require the disturbances e_t and w_t to be martingale-difference processes. This condition is more restrictive than assumption [A3] on ζ_t in (14). Note that in a variety of cases some more general assumptions on the dependence in (e_t), (w_t), and (φ_t) would be sufficient for ζ_t in (14) to verify assumption [A3] of Theorems 1 and 2. We will consider only the stationary case. The implication for the Markov case is then straightforward through Theorem 2 if assumption [A6] holds for the Markov process (φ_t, e_t, w_t).

Denote $\mathcal{F}'_t = \sigma\{\dots, \varphi_{t+1}, e_t, w_t\}$ and by $\mathcal{G}'$ the σ-algebra of invariant sets of the sequence (φ_t, e_t, w_t). Consider the following assumptions:

[B1] (φ_t, e_t, w_t) is a strictly stationary ergodic sequence; $E(e_t|\mathcal{F}'_{t-1}) = 0$, $E(w_t|\mathcal{F}'_{t-1}) = 0$, $Ee_t^4 < \infty$, $E(e^2|\mathcal{F}'_{t-1}) = \sigma_e^2$, $E(w_t w_t^T|\mathcal{F}'_{t-1}) = R_w$, and $E(w_t e_t|\mathcal{F}'_{t-1}) = 0$.

[B2] $E|\varphi_t|^4 < \infty$ and $E\varphi_t\varphi_t^T > 0$.

[B3] $\Gamma = \Gamma^T > 0$.

3.1. Widrow's algorithm (LMS). Let us consider the following algorithm [20]:

$$\hat\theta_t = \hat\theta_{t-1} + \mu\Gamma\varphi_t(y_t - \varphi_t^T\hat\theta_{t-1}). \tag{15}$$

We will also consider a slightly different version of this method:

$$\hat\theta_t = \hat\theta_{t-1} + \mu\Gamma\frac{\varphi_t}{1 + \mu\varphi_t^T\Gamma\varphi_t}(y_t - \varphi_t^T\hat\theta_{t-1}). \tag{16}$$

Let $D = E\varphi_1\varphi_1^T$. Consider the following Lyapunov equations with respect to the matrix V_i:

$$\Gamma D V_1 + V_1 D \Gamma = \sigma_e^2 \Gamma D \Gamma, \tag{17}$$

and

$$\Gamma D V_2 + V_2 D \Gamma = R_w. \tag{18}$$

THEOREM 3. *Let assumptions* [B1]–[B3] *hold true. Consider algorithm* (15) *or* (16) (*in this case we require, in addition,* $E|\varphi_t|^8 < \infty$) *with arbitrary initial condition* $\hat\theta_0$. *Then using the notation of Definition* 1 *we have*

$$\hat{\theta}_t - \theta_t \asymp \mathcal{N}(0, \mu V_1 + V_2\gamma^2/\mu).$$

The correspondent result on L_2 convergence of the Widrow algorithm has been obtained by Macchi and Eweda [15] under condition of m-dependence of regressors φ_t.

Proof. Denote

$$\delta_t = \Gamma^{-1/2}(\hat{\theta}_t - \theta_t),\ \bar{\varphi}_t = \Gamma^{1/2}\varphi_t,\ \bar{w}_t = \Gamma^{-1/2}w_t, \tag{19}$$

$$P_t^0 = \bar{\varphi}_t\bar{\varphi}_t^T, \qquad \zeta_t^0 = \begin{pmatrix} \bar{\varphi}_t e_t \\ \bar{w}_t \end{pmatrix},$$
$$P_t^1 = \frac{\bar{\varphi}_t\bar{\varphi}_t^T}{1+\mu|\bar{\varphi}_t|^2}, \qquad \zeta_t^1 = \begin{pmatrix} \frac{\bar{\varphi}_t e_t}{1+\mu|\bar{\varphi}_t|^2} \\ \bar{w}_t \end{pmatrix}.$$

Using these notations we obtain the transformed error δ_t of algorithms (15) or (16):

$$\delta_t = \sqrt{\mu}\delta_t^{(1)} + \delta_t^{(2)}\gamma/\sqrt{\mu},$$

where the vector $\Delta_t = \sqrt{\mu}(\delta_t^{(1)}, \delta_t^{(2)})$ is defined by the following equation:

$$\Delta_t = (I - \mu P_t)\Delta_{t-1} + \mu\zeta_t \tag{20}$$

with

$$P_t = \begin{pmatrix} P_t^i & 0 \\ 0 & P_t^i \end{pmatrix},$$
$$\zeta_t = \zeta_t^i.$$

We choose i=0 or i=1 for algorithms (15) or (16), respectively. The processes P_t^0, ζ_t^0 verify [A1]–[A5] of Theorem 1, thus the assertion of the theorem is immediate for algorithm (15). Next note that P_t^1 can be decomposed in the following way: $P_t^1 = P_t^0 + P_t'$, where

$$P_t' = -\mu\frac{|\bar{\varphi}_t|^2\bar{\varphi}_t\bar{\varphi}_t^T}{1+\mu|\bar{\varphi}_t|^2}.$$

One can easily verify that assumption [A5] holds true. Furthermore,

$$E|\zeta_t^1 - \zeta_t^0| \leq \mu E(|\bar{\varphi}_t|^3)\sigma_e,$$

which implies the limit in [A4]. Then Theorem 1 implies the assertion of the theorem for algorithm (16). □

To accomplish the asymptotic study of the Widrow algorithm, we develop its optimal version. Let $\mu = \gamma$. Then

$$\gamma^{-1/2}(\hat{\theta}_t - \theta_t) \xrightarrow{D} \mathcal{N}(0, V_3),$$

where $V_3 = V_1 + V_2$ is the solution of the following equation:

$$\Gamma D V_3 + V_3 D\Gamma = \sigma_e^2\Gamma D\Gamma + R_w. \tag{21}$$

We readily get the following corollary.

COROLLARY 1. *Consider a gain matrix* Γ^* *satisfying*

$$\Gamma^* D \Gamma^* = \frac{R_w}{\sigma_e^2}.$$

Then for any choice of Γ *admissible with respect to Theorem* 1

$$V(\Gamma) \geq V(\Gamma^*) = \sigma_e^2 \Gamma^*,$$

where $V(\Gamma)$ *is the solution of equation* (21) *with the fixed matrix* Γ.

The proof of the corollary can be found in [8]. We just remark here that $V(\Gamma^*)$ is given by

$$V(\Gamma^*) = \sigma_e D^{-1/2}(D^{1/2} R_w D^{1/2})^{1/2} D^{-1/2}. \tag{22}$$

Note that if the disturbances e_t and w_t have conditional Gaussian distribution, then this value of the error covariance is the least achievable by any estimation algorithm (see the lower bound in [8]).

3.2. Normalized algorithm (NLMS). Let us consider the following algorithm:

$$\hat{\theta}_t = \hat{\theta}_{t-1} + \mu \Gamma \frac{\varphi_t}{1 + |\varphi_t|^2}(y_t - \varphi_t^T \hat{\theta}_{t-1}). \tag{23}$$

It was introduced in the literature (see, for instance, [13]) as a stable modification of the usual LMS algorithm. The L_p stability of the method has been shown in [13] and some estimates of the rate of convergence have been established.

With a slight abuse of notation we denote $D = E\varphi_t \varphi_t^T (1 + |\varphi_t|^2)^{-1}$ and $G = E\varphi_t \varphi_t^T (1 + |\varphi_t|^2)^{-2}$. Note that if assumption [B2] holds then $D > 0$ and $G > 0$. Consider the following Lyapunov equations with respect to the matrix V_i:

$$\Gamma D V_1 + V_1 D \Gamma = \sigma_e^2 \Gamma G \Gamma,$$
$$\Gamma D V_2 + V_2 D \Gamma = R_w.$$

THEOREM 4. *Let assumptions* [B1]–[B3] *hold true. Consider algorithm* (23) *with arbitrary initial condition* $\hat{\theta}_0$. *Then*

$$\hat{\theta}_t - \theta_t \asymp \mathcal{N}(0, \mu V_1 + V_2 \gamma^2 / \mu).$$

The proof of the theorem is analogous to that of Theorem 3.

3.3. Forgetting factor algorithm (RSL). Consider the following equation for the estimate $\hat{\theta}_t$:

$$\begin{aligned} \hat{\theta}_t &= \hat{\theta}_{t-1} + \mu R_t^{-1} \varphi_t (y_t - \hat{\theta}_{t-1}^T \varphi_t), \\ R_t &= (1 - \mu) R_{t-1} + \mu \varphi_t \varphi_t^T, \quad R_0 = \varrho I \end{aligned} \tag{24}$$

with $\varrho > 0$. Denote $D = E\varphi_t \varphi_t^T$. Define

$$V_1 = \sigma_e^2 D^{-1}/2,$$
$$V_2 = R_w/2$$

THEOREM 5. *Let assumptions* [B1] *and* [B2] *hold true. Consider algorithm* (24) *with arbitrary initial condition* $\hat{\theta}_0$. *Then*

$$\hat{\theta}_t - \theta_t \asymp \mathcal{N}(0, \mu V_1 + V_2\gamma^2/\mu).$$

The sufficient conditions of L_p stability of the method were provided in [4] and [18] along with some estimates of the rate of convergence. We need the following simple lemma.

LEMMA 2. *Suppose that* (φ_t) *is an ergodic stationary process* $\mathbf{R}^N$*-valued,* $E\varphi_t\varphi_t^T = D$, *and* $E|\varphi_t|^4 < \infty$. *Let* R_t *be defined by the equation*

$$R_t = (1-\mu)R_{t-1} + \mu\varphi_t\varphi_t^T, \quad R_0 = \varrho I > 0.$$

Then $\sup_{0<\mu<1}\sup_t E|R_t - D|^2 < \infty$, *and* $\lim_{\mu\to 0}\lim_{t\to\infty} E|R_t - D|^2 = 0$.

Proof. Denote $\Delta_t = R_t - D$. Then we have for Δ_t the following equation:

$$\Delta_t = (1-\mu)\Delta_{t-1} + \mu(\varphi_t\varphi_t^T - D). \tag{25}$$

Note that for any $x, y \in \mathbf{R}$ $2|xy| \le \alpha x^2 + \alpha^{-1}y^2$. If we take $\alpha = 1-\mu$ then we obtain from (25)

$$\begin{aligned} E|\Delta_t|^2 &\le (1-\mu)^2(1+\mu)E|\Delta_{t-1}|^2 + \mu^2(1+\mu^{-1})E|\varphi_t\varphi_t^T - D|^2 \\ &\le (1-\mu)E|\Delta_{t-1}|^2 + K\mu(E|\varphi|^4 + 1), \end{aligned}$$

which implies the first assertion of the lemma.

Let us fix some integer $l > 0$. For $t \ge l$ we have

$$\begin{aligned} |\Delta_t|^2 &= \mathrm{trace}\Delta_t\Delta_t^T \\ &= (1-\mu)^2|\Delta_{t-1}|^2 + \mu^2|\varphi_t\varphi_t^T - D|^2 + 2\mu(1-\mu)\mathrm{trace}(\Delta_{t-1}(\varphi_t\varphi_t^T - D)) \\ &\le (1-\mu)^2|\Delta_{t-1}|^2 + 2\mu^2(|\varphi_t|^4 + |D|^2) \\ &\quad +2\mu(1-\mu)\mathrm{trace}(\Delta_{t-l}(\varphi_t\varphi_t^T - D)) + 2\mu(1-\mu)|\Delta_t - \Delta_{t-l}||\varphi_t\varphi_t^T - D|. \end{aligned} \tag{26}$$

It follows from the stationarity and ergodicity of (φ_t) (and the Levy theorem) that there is $\epsilon(t)$ ($\epsilon(t) \to 0$ as $t \to \infty$) such that $E|E(\varphi_t\varphi_t^T - D|\mathcal{F}_0)|^2 \le \epsilon(t)$. Here, as usual, $\mathcal{F}_t = \sigma\{\dots, \varphi_t\}$. Therefore,

$$|E\Delta_{t-l}(\varphi_t\varphi_t^T - D)|^2 \le E|\Delta_{t-l}|^2 E|E(\varphi_t\varphi_t^T - D|\mathcal{F}_{t-l})|^2 \le K\epsilon(l).$$

On the other hand, we easily derive that $E|\Delta_t - \Delta_{t-l}|^2 \le Kl\mu$. Summing up, we have for $t \ge l$ from (26)

$$E|\Delta_t|^2 \le (1-\mu)^2 E|\Delta_{t-1}|^2 + K\mu(\epsilon(l)^{1/2} + (l+1)\mu).$$

Choosing $l = \mu^{-1/2}$, we get for any $t \ge l$

$$E|\Delta_t|^2 \le K(1-\mu)^t + o(1),$$

which implies the second assertion of the lemma. □

Proof of Theorem 5. For the sake of conciseness we consider only the case $\mu = \gamma$. Denote $x_t = R_t(\hat{\theta}_t - \theta_t)$. Then we obtain for x_t the following equation (cf. [2]):

$$x_t = (1-\gamma)x_{t-1} + \gamma\varphi_t e_t + \gamma R_t w_t.$$

This equation can be decomposed in the following way:

$$x_t = \bar{x}_t + \bar{\delta}_t,$$

where

$$\bar{\delta}_t = (1-\gamma)\bar{\delta}_{t-1} + \gamma(R_t - D)w_t,\ \bar{\delta}_0 = 0,$$
$$\bar{x}_t = (1-\gamma)\bar{x}_{t-1} + \gamma\varphi_t e_t + \gamma D w_t,\ \bar{x}_0 = x_0.$$

It follows from Lemma 2 that all conditions of Theorem 1 are satisfied for the process $(\bar{x}_t)$, thus

$$\lim_{\gamma\to 0}\lim_{t\to\infty} \gamma^{-1/2}\bar{x}_t = \mathcal{N}(0,\bar{V}) \text{ in distribution},$$

where the covariance matrix $\bar{V} = \sigma_e^2 D + DR_w D$. Since $(R_t - D)w_t$ is a martingale-difference, we get for $\bar{\delta}_t$

$$E|\bar{\delta}_t|^2 \leq (1-\gamma)^2 E|\bar{\delta}_{t-1}|^2 + \gamma^2|R_w|E|R_t - D|^2 = o(\gamma).$$

Thus $\lim_{\gamma\to 0}\lim_{t\to\infty}\gamma^{-1/2}|\bar{\delta}_t| = 0$. From Lemma 2 we conclude that for any $0 < \varepsilon \leq 1/2$ there is $\mu(\varepsilon)$ such that $P(|R_t - D| > \varepsilon) < \varepsilon$ as soon as $\mu \leq \mu(\varepsilon)$. Thus $P(|R_t^{-1} - D^{-1}| > 2\lambda_{\min}^{-1}(D)\varepsilon) < \varepsilon$. This implies that $\lim_{\gamma\to 0}\lim_{t\to\infty}\gamma^{-1/2}(R_t^{-1}x_t - D^{-1}x_t) = 0$ and $\gamma^{-1/2}(\hat{\theta}_t - \theta_t) \sim D^{-1}x_t$. □

Note that if $\mu = \gamma$ then the normalized error covariance matrix $V = (\sigma_e^2 D^{-1} + R_w)/2$ differs from the optimal value in (22). This reflects the fact that the forgetting factor method usually used is not optimal.

3.4. Stabilized LS. Consider the following equations:

$$\hat{\theta}_t = \hat{\theta}_{t-1} + \mu\Gamma_t\varphi_t(y_t - \varphi_t^T\hat{\theta}_{t-1}), \tag{27}$$

$$\Gamma_t = (\mu\rho^{-1}R_t + \Gamma^{-1})^{-1},\ \Gamma = \Gamma^T > 0, \tag{28}$$

$$R_t = (1-\rho)R_{t-1} + \rho\varphi_t\varphi_t^T, \quad R_0 = 0. \tag{29}$$

Here $0 < \rho < 1$ and $\mu > 0$ are the algorithm parameters. As $\mu \to 0$ equations (27)–(29) can be seen as a regularized version of the LMS algorithm (15) with the constant gain Γ, as well as a regularized version of the forgetting factor method. The amazing property of this method is its L_p-stability for any choice of parameters μ and ρ under some excitation condition (cf. [7]).

THEOREM 6. *Let assumptions* [B1]–[B3] *hold true. Consider algorithm* (27)–(29) *with arbitrary initial condition* $\hat{\theta}_0$. *Then*

$$\hat{\theta}_t - \theta_t \asymp \mathcal{N}(0, \mu V_1 + V_2\gamma^2/\mu)$$

where the matrices V_1 *and* V_2 *are defined in* (17) *and* (18).

Proof. If we set $P_t^0 = \Gamma$, then $\Gamma_t = P_t^0 + P_t'$, where

$$P_t' = -\Gamma(\Gamma + \mu^{-1}\rho R_t^{-1})^{-1}\Gamma,$$

and

$$|P_t'| \leq |\Gamma|^2|(\Gamma + \mu^{-1}\rho R_t^{-1})^{-1}| \leq |\Gamma|^2\mu\rho^{-1}|R_t|.$$

Let us introduce the "stationary version" of the sequence (R_t):

$$S_0 = \rho \sum_{j=-\infty}^{0} (1-\rho)^{-j} \varphi_j \varphi_j^T,$$
$$S_t = (1-\rho) S_{t-1} + \rho \varphi_t \varphi_t^T.$$

Note that

$$S_t - R_t = (1-\rho)(S_{t-1} - R_{t-1})$$

and $R_0 = 0$ implies $R_t \leq S_t$; thus the choice

$$p_t' = |\Gamma|^2 \mu \rho^{-1} |S_t|$$

satisfies assumption [A5]. The rest of the proof can be carried out along the same lines as the proof of Theorem 3. □

Since the expression for the asymptotic error covariance is the same as in Theorem 3, Corollary 1 remains valid for algorithm (27)–(29).

4. Proof of Theorem 1. The proof of the theorem consists of the following parts. First we show that the matrix product $\prod_{i=k}^{t}(I - \mu P_i)$ is exponentially stable as $t \to \infty$ (Lemma 4). Using this fact, we prove that the process (Δ_t) is asymptotically equivalent to $(\bar{\Delta}_t)$ defined by equation (3) with ζ_t substituted with some martingale-difference process ξ_t (Proposition 3). Next we show that the distribution of $\mu^{-1/2}\bar{\Delta}_t$ is tight (Proposition 4). Next we provide the linear approximation Δ_t' of Δ_t (Lemma 6), which makes it possible to accomplish the proof by using the classical CLT for martingales (Propositions 5 and 6).

LEMMA 3. *For any sequence of symmetric matrices $(Q_i)_{i=1,\dots,n}$, the following inequality holds*:

$$\log\left(\left|\prod_{i=1}^{n}(I - Q_i)\right|\right) \leq -\min\left(\lambda_{\min}\left(\sum_{i=1}^{n} Q_i\right), \frac{1}{2}\right) + \frac{n}{2}\log\left(1 + K(n)\max_i |Q_i|^2\right),$$

where $\lambda_{\min}(P)$ stands for the smallest eigenvalue of P and $K(n)$ is a constant depending only on n.

Proof. For any unit vector X, one has

$$X^T\left(\prod_{i=1}^{n}(I - Q_i)\right)^T \prod_{i=1}^{n}(I - Q_i)X = 1 - 2X^T\left(\sum_{i=1}^{n} Q_i\right)X + X^T \sum_l \Pi_l X,$$

where each Π_l is a product of matrices Q_i with more than 2 and less than $2n$ terms. Putting $q = \max|Q_i|$ and $\lambda = \lambda_{\min}(\sum Q_i)$, we then have

$$\begin{aligned}
\left|\prod_{i=1}^{n}(I - Q_i)\right|^2 &\leq 1 - 2\lambda + K(n)(q^2 + q^{2n}) \\
&\leq 1 - 2\min(\lambda, 1/2) + K(n)(q^2 + q^{2n}) \\
&\leq (1 - \min(\lambda, 1/2))^2 + K(n)(q^2 + q^{2n}) \\
&\leq (1 - \min(\lambda, 1/2))^2(1 + 4K(n)(q^2 + q^{2n})) \\
&\leq (1 - \min(\lambda, 1/2))^2(1 + K'(n)q^2)^n,
\end{aligned}$$

and finally

$$\log \left| \prod_{i=1}^{n} (I - Q_i) \right| \leq -\min(\lambda, 1/2) + \frac{n}{2} \log(1 + K'(n)q^2). \qquad \square$$

Denote

$$\pi_{j,t} = \prod_{i=j}^{t} (I - \mu P_i).$$

LEMMA 4. *Let conditions* [A1], [A2], *and* [A5] *be satisfied, then there exist* μ_0, α_0, *and a stationary random process* $C_s(\omega)$ *such that for any* T

$$\sup_{t>T, \mu\leq\mu_0} (1 - \alpha_0\mu)^{T-t} \pi_{T,t} < C_T(\omega) < \infty \ \ a.s.,$$
$$\sup_{t<T, \mu\leq\mu_0} (1 - \alpha_0\mu)^{t-T} \pi_{t,T} < C_T(\omega) < \infty \ \ a.s..$$

Proof. Note that the second assertion is a consequence of the first used backwards in time (we define the constant $C_T(\omega)$ as the maximum of the backward-forward constants). Let us prove the first one. Consider the case $T = 1$. Note that we have the estimate

$$\log(1 - \alpha\mu)^{1-t} \left| \prod_{i=1}^{t} (I - \mu P_i) \right| \leq t\alpha\mu + \sum_{k=0}^{t/n} \log \left| \prod_{i=kn+1}^{(k+1)n} (I - \mu P_i) \right|.$$

On the other hand, by Lemma 3 we get

$$\begin{aligned}
&(1/\mu) \log \left(\left| \prod_{i=s+1}^{s+n} (I - \mu P_i) \right| \right) \\
&\leq -(1/\mu) \min \left(\lambda_{\min} \left(\mu \sum_{i=s+1}^{s+n} P_i \right), 1/2 \right) + (n/2\mu) \log \left(1 + K(n)\mu^2 \sum_{i=s+1}^{s+n} |P_i|^2 \right) \\
&\leq -\min \left(\lambda_{\min} \left(\sum_{i=s+1}^{s+n} P_i \right), 1/(2\mu) \right) + nK\mu/2 \sum_{i=s+1}^{s+n} |P_i|^2 \\
&\leq -\min \left(\min_{\mu<\mu_0} \lambda_{\min} \left(\sum_{i=s+1}^{s+n} P_i \right), 1/(2\mu_0) \right) + nK\mu_0 \max_{\mu<\mu_0} \left(\sum_{i=s+1}^{s+n} |P_i|^2 \right) /2.
\end{aligned}$$

The bound

$$\begin{aligned}
\lambda_{\min} \left(\sum P_i \right) &\geq \lambda_{\min} \left(\sum P_i^0 + P_i' \right) \\
&\geq \lambda_{\min} \left(\sum P_i^0 \right) - \sum p_i'
\end{aligned}$$
$$\min \left(\lambda_{\min} \left(\sum P_i \right), 1/(2\mu_0) \right) \geq \min \left(\lambda_{\min} \left(\sum P_i^0 \right), 1/(2\mu_0) \right) - \sum p_i'$$

leads to

$$\frac{1}{\mu} \log \left(\left| \prod_{i=s+1}^{s+n} (I - \mu P_i) \right| \right)$$

$$\begin{aligned}&\leq -\min\left(\lambda_{\min}\left(\sum_{i=s+1}^{s+n} P_i^0\right), 1/(2\mu_0)\right) + \sum_{i=s+1}^{s+n} p_i' + (n/2)K\mu_0 \max_{\mu<\mu_0}\left(\sum_{i=s+1}^{s+n} |P_i|^2\right)/2\\ &\leq -\min\left(\lambda_{\min}\left(\sum_{i=s+1}^{s+n} P_i^0\right), 1/(2\mu_0)\right) + \sum_{i=s+1}^{s+n} p_i' + nK\mu_0 \max_{\mu<\mu_0}\left(\sum_{i=s+1}^{s+n} (|P_i^0|^2 + [p_i']^2)\right)\\ &\triangleq K_s(\omega)\end{aligned}$$

where K_s is a sum of stationary ergodic processes. If n has been chosen large enough and μ_0 small enough, then $E[K_s] < 0$. Indeed,

$$\begin{aligned}E[K_s] \leq -E\left[\min\left(\lambda_{\min}\left(\sum P_i^0\right), 1/(2\mu_0)\right)\right] + nE\left[\max_{\mu<\mu_0} p_i'\right]\\ + K\mu_0 n^2\left(E|P_1^0|^2 + E\left[\max_{\mu<\mu_0} |p_1'|\right]^2\right),\end{aligned}$$

where the right-hand side is negative for μ_0 small enough due to the uniform (in μ) bound of p_i' in assumption [A5]. Finally we have

$$\begin{aligned}\log(1-\alpha\mu)^{1-t}\left|\prod_{i=1}^{t}(I-\mu P_i)\right| &\leq t\alpha\mu + \sum_{k=0}^{t/n}\mu K_{kn}\\ &\leq \mu_0 \max_t\left(t\left(\alpha + 1/t\sum_{k=0}^{t/n} K_{kn}\right)\right) \triangleq C_1(\omega).\end{aligned}$$

By the ergodic theorem we conclude that as α is small enough the expression inside the max tends to $-\infty$ as t tends to ∞, which implies the lemma in the case $T = 1$. A shift of indices immediately gives the result for other values of T. □

Let us now make the reduction.

PROPOSITION 3. *The ζ_t^0 process may be written as*

$$\zeta_t^0 = \xi_t - \nu_t + \nu_{t-1} \tag{30}$$

where ξ_t is a stationary martingale-difference process with $E\xi_0\xi_0^T = S_0$, and the process $\bar{\Delta}_t$ defined by

$$\bar{\Delta}_t = (I - \mu P_t)\bar{\Delta}_{t-1} + \mu\xi_t\ , \quad \bar{\Delta}_0 = \Delta_0 \tag{31}$$

satisfies

$$\lim_{\mu\to 0}\lim_{t\to\infty} \mu^{-1/2}(\Delta_t - \bar{\Delta}_t) = 0 \quad \textit{in probability.} \tag{32}$$

This limit is to be taken in the sense explained after Theorem 1.

Proof. Let $C = \sum_{s=0}^{\infty}(E|E(\zeta_s^0|\mathcal{F}_0)|^2)^{1/2}$. If

$$\xi_t = \sum_{s\geq 0} E(\zeta_{t+s}^0|\mathcal{F}_t) - E(\zeta_{t+s}^0|\mathcal{F}_{t-1}), \quad \nu_t = \sum_{s\geq 1} E(\zeta_{t+s}^0|\mathcal{F}_t),$$

then $\zeta_t^0 = \xi_t - \nu_t + \nu_{t-1}$, ξ_t is a martingale-difference and

$$E|\xi_t|^2 \leq 4C^2, \quad E|\nu_t|^2 \leq C^2$$

(this well-known result (see, for example, [5]) is an immediate consequence of the Minkowski inequality), and one easily checks that

$$E\zeta_0^0\zeta_0^{0T} + \sum_{i=1}^{\infty} E\zeta_0^0\zeta_i^{0T} + E\zeta_i^0\zeta_0^{0T} = E\xi_0\xi_0^T.$$

We consider the process $\Delta_t' = \Delta_t - \bar{\Delta}_t$ as follows:

$$\begin{aligned}
\Delta_t' &= (I - \mu P_t)\Delta_{t-1}' + \mu(-\nu_t + \nu_{t-1} + \zeta_j') \\
&= \sum_{j=1}^{t} \pi_{j+1,t}\mu(-\nu_j + \nu_{j-1} + \zeta_j') \qquad (\pi_{t+1,t} = I) \\
&= \mu \sum_{j=2}^{t} (\pi_{j+1,t} - \pi_{j,t})\nu_{j-1} + \pi_{2,t}\mu\nu_0 - \mu\nu_t + \mu \sum_{j=1}^{t} \pi_{j+1,t}\zeta_j' \\
&= \mu \sum_{j=2}^{t} (\mu P_j)\pi_{j+1,t}\nu_{j-1} + \pi_{2,t}\mu\nu_0 - \mu\nu_t + \mu \sum_{j=1}^{t} \pi_{j+1,t}\zeta_j' \\
|\Delta_t'| &\le C_t\mu \sum_{j=1}^{t+1} (1 - \alpha_0\mu)^{t-j-1}(\mu(1 + |P_j|)|\nu_{j-1}| + |\zeta_j'|) \\
&= \mu^{1/2} C_t(\omega) X_t(\mu)
\end{aligned}$$

with $E[X_t(\mu)] < \eta(\mu)$, $\eta(\mu) \to 0$ as $\mu \to 0$. Finally, for any $\epsilon > 0$,

$$\begin{aligned}
P(\mu^{-1/2}|\Delta_t'| > \epsilon) &= P(C_t(\omega)X_t(\mu) > \epsilon) \\
&= P(C_t(\omega) > A) + P(X_t(\mu) > \epsilon/A) \quad \text{for any } A \\
&= P(C_t(\omega) > \eta(\mu)^{-1/2}) + P(X_t(\mu) > \epsilon\eta(\mu)^{1/2}) \\
&= P(C_1(\omega) > \eta(\mu)^{-1/2}) + \eta(\mu)^{1/2}/\epsilon.
\end{aligned}$$

This last quantity is now independent of t and tends to 0 as $\mu \to 0$. □

It remains to prove that

$$\lim_{\mu \to 0} \lim_{t \to \infty} \mu^{-1/2}\bar{\Delta}_t = \mathcal{N}(0, V) \quad \text{in distribution.}$$

We recall that the process $\bar{\Delta}_t$ is defined by

$$\bar{\Delta}_t = (I - \mu P_t)\bar{\Delta}_{t-1} + \mu\xi_t, \quad \bar{\Delta}_0 = \Delta_0,$$

and ξ_t is a stationary martingale-difference process independent of μ with $E\xi_0\xi_0^T = S_0$.

PROPOSITION 4. *The process* $(\mu^{-1/2}\bar{\Delta}_t)$ *is tight in the sense that for some* $\mu' > 0$ *the following is true: for any* $\epsilon > 0$ *there exists* R *such that*

$$P(\mu^{-1/2}|\bar{\Delta}_t| > R(1 + |\bar{\Delta}_0|) < \epsilon$$

for all $\mu \le \mu'$ *and* $t \ge (\alpha_0\mu)^{-1}\ln\mu^{-1}$ (*here* α_0 *was defined in Lemma* 4).

Proof. From equation (3) we get

$$\bar{\Delta}_t = \pi_{1,t}\bar{\Delta}_0 + \sum_{j=1}^{t} \pi_{j+1,t}\mu\xi_j = I_t^{(1)} + I_t^{(2)}$$

(we set $\pi_{t+1,t} = I$). From Lemma 4 we derive that

$$|\pi_{1,t}\bar{\Delta}_0| \le C_1(\omega)(1-\alpha_0\mu)^t|\bar{\Delta}_0| \le C_1(\omega)e^{-\alpha_0\mu t}|\bar{\Delta}_0|$$

with $C_1(\omega) < \infty$ almost surely. This implies that for any $\epsilon > 0$ there is R such that

$$P(C_1(\omega)e^{-\alpha_0\mu t}|\bar{\Delta}_0| > R\mu^{1/2}) \le \epsilon$$

as soon as $t > (\alpha_0\mu)^{-1}\ln\mu^{-1}$; thus $\mu^{-1/2}I_t^{(1)}$ is tight. Let us take $\alpha = \alpha_0/2$. Summing by parts, we have

$$\begin{aligned} I_t^{(2)} &= \sum_{j=1}^{t} \pi_{j+1,t}(1-\alpha\mu)^{-(t-j)}\mu\left((1-\alpha\mu)^{t-j}\xi_j\right) \\ &= \sum_{j=1}^{t-1} \mu(P_{j+1}-\alpha I)\pi_{j+2,t}(1-\alpha\mu)^{-(t-j)}\mu \sum_{i=j+1}^{t}(1-\alpha\mu)^{t-i}\xi_i \\ &\quad + \mu\pi_{2,t}(1-\alpha\mu)^{1-t}\sum_{j=1}^{t}(1-\alpha\mu)^{t-j}\xi_j = r_t^{(1)} + r_t^{(2)}. \end{aligned}$$

The preceding lemma implies that for $\alpha = \alpha_0/2$ the random process

$$\max_{s>0}\{|\pi_{t-s,t}|(1-\alpha\mu)^{-2s}\} \tag{33}$$

may be bounded by a stationary process $C_t'(\omega)$ a.s. finite. Note that

$$E\left|\mu\sum_{i=1}^{t}(1-\alpha\mu)^{t-i}\xi_i\right| \le \mu E\left[\left|\sum_{i=1}^{t}(1-\alpha\mu)^{t-i}\xi_i\right|^2\right]^{1/2} \le K\mu^{1/2},$$

thus

$$|r_t^{(2)}| \le C_t'(\omega)(1-\alpha\mu)^t\mu^{1/2}C_1(\omega)$$

with $EC_1(\omega) < \infty$; $\mu^{-1/2}r_t^{(2)}$ is tight. $r_t^{(1)}$ satisfies the bound

$$|r_t^{(1)}| \le C_t'(\omega)\mu^{3/2}\sum_{j=1}^{t-1}(1-\alpha\mu)^{t-j}C_{j,t}(\omega),$$

where

$$C_{j,t}(\omega) = (|P_{j+1}| + \alpha)\mu^{1/2}\left|\sum_{i=j+1}^{t}(1-\alpha\mu)^{t-i}\xi_i\right|$$

and

$$EC_{j,t}(\omega) \le 4E(|P_{j+1}|^2 + \alpha^2) + 2\mu E\left|\sum_{i=j+1}^{t}(1-\alpha\mu)^{t-i}\xi_i\right|^2 \le K.$$

Hence, we get for $r_t^{(1)}$

$$|r_t^{(1)}| \le \alpha^{-1}\mu^{1/2}C_t'(\omega)C_t''(\omega)$$

where C_t' is a finite stationary process independent of μ, and $E(C_t'')$ is bounded independently of μ. Therefore $\mu^{-1/2}r_t^{(1)}$ is tight. □

LEMMA 5. *There is $\mu' > 0$ and K such that for any $\mu \le \mu'$ and $n \ge 1$*

$$E\left(\sup_{t\le n}\ln(|\bar{\Delta}_t|^2+1)1_{|\bar{\Delta}_0|\le R}\right) \le \ln(R^2+1) + K\mu(n^{1/2}+\mu n).$$

Proof. From equation (3) we get for the probe function $U_t = |\bar{\Delta}_t|^2$

$$\begin{aligned} U_t &\le \bar{\Delta}_{t-1}^T(I-\mu P_t)^T(I-\mu P_t)\bar{\Delta}_{t-1} + 2\mu\bar{\Delta}_{t-1}^T(I-\mu P_t)^T\xi_t + \mu^2|\xi_t|^2 \\ &\le U_{t-1} + 2\mu\xi_t^T\bar{\Delta}_{t-1} + K\mu^2(|\bar{\Delta}_{t-1}|^2|P_t|^2 + |\xi_t|^2). \end{aligned}$$

Denote $l_t = \ln(U_t+1)$. Due to the concavity of the function $\ln(x)$ we get

$$\begin{aligned} l_t &\le l_{t-1} + (U_{t-1}+1)^{-1}\left(2\mu\xi_t^T\bar{\Delta}_{t-1} + K\mu^2(U_{t-1}|P_t|^2 + |\xi_t|^2)\right) \\ &\le l_0 + 2\mu\left|\sum_{i=1}^t \frac{\xi_i^T\bar{\Delta}_{i-1}}{|\bar{\Delta}_{i-1}|^2+1}\right| + K\mu^2\sum_{i=1}^t(|P_i|^2+|\xi_i|^2) \\ &= l_0 + I_t^{(1)} + I_t^{(2)}. \end{aligned} \tag{34}$$

We conclude from the Doob inequality that

$$E\left(\sup_{t\le n} I_t^{(1)}\right) \le \mu C K n^{1/2}$$

and

$$E\left(\sup_{t\le n} I_t^{(2)}\right) = K\mu^2\sum_{i=1}^n(E|P_i|^2 + E|\xi_i|^2) \le K\mu^2 n.$$

Summing up we obtain the desired lemma. □

Denote $L_t = P_t^0 - B$. Let us define for any $t \ge 0$ and $R_0 < \infty$ a random time

$$\sigma'(s) = \inf\{t \ge s : |\bar{\Delta}_t| > \mu^{1/2}R_0\}. \tag{35}$$

We denote $\sigma'(0) = \sigma$. Set

$$m(\varepsilon) = \min\{l \ge 0 : |(I-\mu B)^l| \le \varepsilon\}. \tag{36}$$

Assumption [A1] implies that there exist μ' and $K(\varepsilon) < \infty$ such that

$$m(\varepsilon) \le K(\varepsilon)\mu^{-1} \tag{37}$$

for any $\mu \le \mu'$. Let us consider a new process (Δ_t') along with $(\bar{\Delta}_t)$. We define it by the equation

$$\begin{aligned} \Delta_t' &= (I-\mu B)\Delta_{t-1}' + \mu\xi_t, \quad t \ge 1, \\ \Delta_0' &= \bar{\Delta}_0. \end{aligned} \tag{38}$$

LEMMA 6. *For any $\delta > 0$ there exists $\mu_0(\varepsilon, \delta)$ such that*

$$P(\mu^{-1/2}|\Delta'_{m(\varepsilon)} - \bar{\Delta}_{m(\varepsilon)}| > \delta) < \delta + P\{\sigma < m(\varepsilon)\}$$

for any $\mu \leq \mu_0(\varepsilon, \delta, R_0)$.

Proof. We have the following equation for the difference:

$$\delta'_t = \bar{\Delta}_t - \Delta'_t = (I - \mu B)\delta'_{t-1} - \mu L_t \bar{\Delta}_{t-1} - \mu P'_t \bar{\Delta}_{t-1}, \quad \delta'_0 = 0.$$

Denote $v = \min(\sigma, m(\varepsilon))$. We have for δ'_v the decomposition

$$\begin{aligned} \delta'_v &= -\mu \sum_{i=1}^{v} (I - \mu B)^{v-i}(L_i \bar{\Delta}_{i-1} + \mu P'_i \bar{\Delta}_{i-1}) \\ &= -\mu \sum_{i=l}^{v} (I - \mu B)^{v-i} E(L_i|\mathcal{F}_{i-l})\bar{\Delta}_{i-l} \\ &\quad -\mu \sum_{i=l}^{v} (I - \mu B)^{v-i}(L_i - E(L_i|\mathcal{F}_{i-l}))\bar{\Delta}_{i-l} \\ &\quad -\mu \sum_{i=l}^{v} (I - \mu B)^{v-i} L_i(\bar{\Delta}_{i-1} - \bar{\Delta}_{i-l}) \\ &\quad -\mu \sum_{i=1}^{l-1} (I - \mu B)^{v-i} L_i \bar{\Delta}_{i-1} - \mu \sum_{i=1}^{v} (I - \mu B)^{v-i} P'_i \bar{\Delta}_{i-1} = \sum_{j=1}^{5} I_v^{(j)}. \end{aligned} \tag{39}$$

Let us estimate the first term in (39):

$$\begin{aligned} E|I_v^{(1)}| &\leq K\mu \sum_{i=1}^{m(\varepsilon)} E|E(L_i|\mathcal{F}_{i-l})|\mu^{1/2}R_0 \leq K\mu m(\varepsilon) E|E(L_l|\mathcal{F}_0)|\mu^{1/2}R_0 \\ &\leq K(\epsilon)\epsilon(l) R_0 \mu^{1/2}, \end{aligned}$$

where $K(\epsilon) < \infty$ is defined in (37) and $\epsilon(l)$ is a sequence which tends to 0. From assumption [A5] we derive the estimate for $I_v^{(5)}$:

$$E|I_v^{(5)}| \leq K\mu \sum_{i=1}^{m(\varepsilon)} E|P'_t|\mu^{1/2}R_0 \leq K(\epsilon) R_0 E|p'_1|\mu^{1/2} = \epsilon'(\mu)\mu^{1/2}$$

with $\epsilon'(\mu) \to 0$ as $\mu \to 0$. Next we have for $I_v^{(4)}$

$$\begin{aligned} E|I_v^{(4)}|^2 &\leq K(l+1)\mu^2 E|L_i|^2 \mu R_0^2 \\ &\leq K(l+1)\mu^2 R_0^2. \end{aligned}$$

Note that

$$\begin{aligned} &\bar{\Delta}_{i-1} 1_{i-1<\sigma} - \bar{\Delta}_{i-l} 1_{i-l<\sigma} \\ &= \sum_{k=1}^{l-1} (\bar{\Delta}_{i-k} - \bar{\Delta}_{i-k-1}) 1_{i-k-1<\sigma} - \sum_{k=1}^{l-1} \bar{\Delta}_{i-k} 1_{i-k=\sigma}. \end{aligned}$$

Then we get for $|I_v^{(3)}|$

$$|I_v^{(3)}| \le \mu \sum_{k=1}^{l-1} \sum_{i=1}^{m(\varepsilon)} |L_i||\bar{\Delta}_{i-k} - \bar{\Delta}_{i-k-1}| 1_{i-k-1<\sigma} + \mu \sum_{k=1}^{l-1} \sum_{i=1}^{m(\varepsilon)} |\bar{\Delta}_{i-k}||L_i| 1_{i-k=\sigma}$$

$$\le \mu \sum_{k=1}^{l-1} \sum_{i=1}^{m(\varepsilon)} |L_i||\bar{\Delta}_{i-k} - \bar{\Delta}_{i-k-1}| 1_{i-k-1<\sigma} + \mu|\bar{\Delta}_\sigma| \sum_{k=1}^{l-1} |L_{\sigma+k}| 1_{\sigma+k\le m(\varepsilon)}. \tag{40}$$

Note that

$$E\left(\sup_{i\le m(\varepsilon)} \mu|P_i|\right)^2 \le \mu^2 \sum_{i=1}^{m(\varepsilon)} E|P_i|^2 \le K\,K(\varepsilon)\mu,$$

and $E(\sup_{i\le m(\varepsilon)} \mu|\xi_i|)^2 \le K\,K(\varepsilon)\mu$. Thus

$$(E|\bar{\Delta}_\sigma|^2)^{1/2} \le R_0\mu^{1/2} + K\,K(\varepsilon)\mu^{1/2}(1+\mu^{1/2}).$$

Furthermore,

$$(E|\bar{\Delta}_i - \bar{\Delta}_{i-1}|^2 1_{i-1<\sigma})^{1/2} \le K\mu.$$

Summing up, we obtain from (40)

$$E|I_v^{(3)}| \le \mu K\,K(\varepsilon)(l-1).$$

For $I_v^{(2)}$ we obtain in the same way

$$E|I_v^{(2)}|^2 \le Kl\mu R_0^2.$$

If we take $l = \mu^{-1/4}$, then

$$E|\delta'_v| \le K(\mu^{1/2}(\epsilon(l) + \epsilon'(\mu)) + \mu l) = o(\mu^{1/2})$$

for $\mu \le \mu_0$. Meanwhile, for any $\delta > 0$ we have

$$\begin{aligned}
&P(|\mu^{-1/2}|\delta'_{m(\varepsilon)}| > \delta) \\
&= P(\{|\mu^{-1/2}|\delta'_{m(\varepsilon)}| > \delta\} \cap \{\sigma \ge m(\varepsilon)\}) + P(\{|\mu^{-1/2}|\delta'_{m(\varepsilon)}| > \delta\} \cap \{\sigma < m(\varepsilon)\}) \\
&\le P(\{|\mu^{-1/2}|\delta'_v| > \delta\} \cap \{\sigma \ge m(\varepsilon)\}) + P(\sigma < m(\varepsilon)) \\
&\le \delta^{-1}o(1) + P(\sigma < m(\varepsilon)) \le \delta + P(\sigma < m(\varepsilon))
\end{aligned}$$

for suficiently small μ. □

We must show that $\mu^{-1/2}\Delta'_{m(\varepsilon)}$ converges in distribution to the Gaussian random variable as $\mu \to 0$.

LEMMA 7.

$$\mu \sum_{i=1}^{m(\varepsilon)} (I-\mu B)^{m(\varepsilon)-i} \xi_i \xi_i^T (I-\mu B)^{m(\varepsilon)-i} \xrightarrow{P} V \tag{41}$$

as $\mu \to 0$. Here $V = V^T > 0$ is a unique solution of the Lyapunov equation (7).

Proof. Let us fix μ small enough. Denote $g_i = \xi_i \xi_i^T - S_0$ and

$$\epsilon(i) = \frac{1}{i} \sum_{j=1}^{i} g_{-j}.$$

The ergodicity of the sequence (ξ_i) implies that $\epsilon(i) \to 0$ a.s. The distribution of the sum in the left side of (41) coincides with that of $I_{m(\varepsilon)} + V_{m(\varepsilon)}$, where

$$V_{m(\varepsilon)} = \mu \sum_{i=1}^{m(\varepsilon)} (I - \mu B)^{m(\varepsilon)-i} S_0 (I - \mu B)^{m(\varepsilon)-i}$$

and

$$\begin{aligned} I_{m(\varepsilon)} &= \mu \sum_{i=1}^{m(\varepsilon)} (I - \mu B)^{i-1} (\xi_{-i} \xi_{-i}^T - S_0)(I - \mu B)^{i-1} \\ &= \mu \sum_{i=1}^{m(\varepsilon)} (I - \mu B)^{i-1} g_{-i} (I - \mu B)^{-1} i. \end{aligned}$$

Summing by parts we get

$$\begin{aligned} I_{m(\varepsilon)} = {} & \mu m(\varepsilon)(I - \mu B)^{m(\varepsilon)} \epsilon(m(\varepsilon))(I - \mu B)^{m(\varepsilon)} \\ & + \mu \sum_{i=1}^{m(\varepsilon)-1} i(I - \mu B)^{i-1} \epsilon(i)(I - \mu B)^{i-1} - i(I - \mu B)^{i} \epsilon(i)(I - \mu B)^{i}. \end{aligned}$$

Since $\epsilon(t) \to 0$, for any $\epsilon' > 0$ one can choose t_0 such that $\epsilon(t) \leq \epsilon'$ for all $t \geq t_0$ (note that t_0 does not depend on μ). Thus from the definition of $m(\varepsilon)$ in (36) we have

$$\begin{aligned} |I_{m(\varepsilon)}| &\leq K(\varepsilon)\varepsilon^2 |\epsilon(m(\varepsilon))| + K\mu^2 \sum_{i=0}^{m(\varepsilon)} (1 - \alpha\mu)^{2i} i |\epsilon(i)| \\ &\leq K(\varepsilon)\varepsilon^2 |\epsilon(m(\varepsilon))| + K t_0 \mu^2 \sum_{i=0}^{t_0} (1 - \alpha\mu)^{2i} |\epsilon(i)| \\ &\quad + K\epsilon' \mu^2 \sum_{i=0}^{\infty} i(1 - \alpha\mu)^{2i}. \qquad (42) \end{aligned}$$

For the first term in (42) we have immediately $\varepsilon^2 |\epsilon(m(\varepsilon))| \xrightarrow{P} 0$ as $\mu \to 0$. Since the random time t_0 is independent of μ, we get that

$$K t_0 \mu^2 \sum_{i=0}^{t_0} (1 - \alpha\mu)^{2i} |\epsilon(i)| \xrightarrow{P} 0$$

as $\mu \to 0$. For the last term in (42) we derive

$$K\epsilon\mu^2 \sum_{i=0}^{\infty} (1 - \alpha\mu)^{2i} i \leq K\epsilon \int_0^{\infty} e^{-2\alpha t} t dt \leq K\epsilon.$$

Summing up, we obtain from (42) that $|I_{m(\varepsilon)}| \xrightarrow{P} 0$. Now it suffices to prove that $V_{m(\varepsilon)} \to V$. Note that V_t adheres to the following recursive equation:

$$V_t = (I - \mu B)V_{t-1}(I - \mu B) + \mu S_\mu, \quad V_0 = 0.$$

Let V be a solution of the Lyapunov equation (7). Then for the difference $U_t = V_t - V$ we obtain

$$U_t = (I - \mu B)U_{t-1}(I - \mu B) + \mu^2 BVB.$$

From the stability of matrix $(I - \mu B)$ we conclude that

$$|U_{m(\varepsilon)}| \leq K(1 - \mu\alpha)^{2m(\varepsilon)} + Ko(\mu) = o(\mu)$$

as $\mu \to 0$. □

PROPOSITION 5. *Let the process* (Δ'_t) *be defined by the equation*

$$\Delta'_t = (I - \mu B)\Delta'_{t-1} + \mu\xi_t, \quad t \geq 1.$$

Moreover, for any $\epsilon_1 > 0$ *there exists* $R_1 < \infty$ *such that the initial condition* $\Delta'_0 = \bar{\Delta}_0(\mu)$ *satisfies*

$$P(|\Delta'_0| > R_1\mu^{1/2}) \leq \epsilon_1$$

for any $\varepsilon > 0$, *and*

$$\lim_{\mu \to 0} |Ef(\mu^{-1/2}\Delta'_{m(\varepsilon)}) - Ef(\mathcal{N}(0, V))| \leq \epsilon\|f\|_\infty$$

for any continuous f.

Proof. Note that

$$\Delta'_{m(\varepsilon)} = (I - \mu B)^{m(\varepsilon)}\Delta'_0 + \mu \sum_{i=1}^{m(\varepsilon)} (I - \mu B)^{m(\varepsilon)-i}\xi_i = I^{(1)}_{m(\varepsilon)} + I^{(2)}_{m(\varepsilon)}. \tag{43}$$

Recall that we have chosen $m(\varepsilon)$ in (36) such that $|(I - \mu B)^{m(\varepsilon)}| \leq \varepsilon$. Thus

$$|I^{(1)}_{m(\epsilon)}| \leq \varepsilon|\Delta'_0|,$$

and we have for the first term in (43)

$$P(|I^{(1)}_{m(\varepsilon)}| > \varepsilon R_1\mu^{1/2}) \leq P(|\Delta'_0| > R_1\mu^{1/2}) < \epsilon_1.$$

Next we apply the CLT for martingales to the second term. It states that $\mu^{-1/2}I^{(2)}_{m(\varepsilon)} \xrightarrow{D} \mathcal{N}(0, V)$ if condition (41) is satisfied along with the Lindeberg conditions [10, Thm. 5.4]:

$$\sum_{i=1}^{m(\varepsilon)} \mu|(I - \mu B)^{m(\varepsilon)-i}\xi_i|^2 1_{\sqrt{\mu}|(I-\mu B)^{m(\varepsilon)-i}\xi_i|>\delta} \xrightarrow{P} 0 \quad \text{for any } \delta > 0. \tag{44}$$

Condition (44) is satisfied since (ξ_i) is a strictly stationary sequence, and for some $\alpha > 0$

$$\begin{aligned} &E\left(\sum_{i=1}^{m(\varepsilon)} \mu|(I - \mu B)^{m(\varepsilon)-i}\xi_i|^2 1_{|(I-\mu B)^{m(\varepsilon)-i}\xi_i|>\delta\mu^{-1/2}}\right) \\ &\leq K \sum_{i=1}^{m(\varepsilon)} \mu(1 - \mu\alpha)^{2(m(\varepsilon)-i)} E(|\xi_i|^2 1_{K(I-\mu\alpha)^{m(\varepsilon)-i}|\xi_i|>\delta\mu^{-1/2}}) \\ &\leq KE|\xi_1|^2 1_{|\xi_1|>K\delta\mu^{-1/2}} \to 0 \end{aligned}$$

as $\mu \to 0$. Along with lemma 7 it implies the desired statement. □

The following proposition completes the proof of the theorem.

PROPOSITION 6.

$$\lim_{\mu\to 0}\lim_{t\to\infty} \mu^{-1/2}\bar\Delta_t = \mathcal{N}(0,V) \textit{ in distribution.}$$

Proof. Let us fix any $\delta > 0$. From Proposition 4 we conclude that there is $R < \infty$ such that $P(|\bar\Delta_{t_0}| \le \mu^{1/2}R) \ge 1-\delta$ for all $t_0 \ge (\alpha_0\mu)^{-1}\ln\mu^{-1}$. Let us choose $m(\varepsilon)$ to satisfy (36) with $\varepsilon = \delta/R$ (recall that the estimate (37) implies that $m(\varepsilon) \le K(\varepsilon)\mu^{-1}$ for some $K(\varepsilon) < \infty$). Denote

$$A = \left\{ \sup_{t_0\le t\le t_0+m(\varepsilon)} |\bar\Delta_t| 1_{|\bar\Delta_{t_0}|\le\mu^{1/2}R} \le \mu^{1/2}R_0 \right\}$$

and $B = \{|\bar\Delta_{t_0}| \le \mu^{1/2}R\}$. Lemma 5 implies that

$$\begin{aligned} 1-P(A) = P(A^c) &\le (\log\mu R_0^2+1)^{-1}\left[E\log(\mu R^2+1) + K\mu(m(\varepsilon))^{1/2} + \mu m(\varepsilon))\right] \\ &\le (\log\mu R_0^2+1)^{-1}(\log(\mu R^2+1) + (K(\delta/R)+1)\mu^{1/2}). \end{aligned}$$

Thus, one can choose $R_0 < \infty$ such that $P(A) \ge 1-\delta$. Note then that

$$\left\{ \sup_{t_0\le t\le t_0+m(\varepsilon)} |\bar\Delta_t| \le \mu^{1/2}R_0 \right\} \supseteq A\cap B.$$

Therefore,

$$P\left(\sup_{t_0\le t\le t_0+m(\varepsilon)} |\bar\Delta_t| \le \mu^{1/2}R_0 \right) \ge P(A\cap B) \ge 1-2\delta$$

or

$$P(\sigma'(t_0) < t_0 + m(\varepsilon)) < 2\delta \tag{45}$$

where $\sigma'(t)$ is defined in (35). Let us consider along with $\bar\Delta_t$ a random process Δ'_t defined by the equation

$$\begin{aligned} &\Delta'_t = (I-\mu B)\Delta'_{t-1} - \mu\xi_t \quad \text{for } t > t_0, \\ &\Delta'_t = \bar\Delta_t \quad \text{for } 0 \le t \le t_0. \end{aligned}$$

Then Lemma 6, along with the bound (45), implies that

$$P(\mu^{-1/2}|\Delta'_{t_0+m(\varepsilon)} - \bar\Delta_{t_0+m(\varepsilon)}| > \delta) < 3\delta$$

for all $\mu \le \mu_0$ small enough. On the other hand, all the conditions of Proposition 5 are fulfilled, thus $\Delta'_{t_0+m(\varepsilon)} \sim \mathcal{N}(0,V)$, which results, in turn, in $\bar\Delta_{t_0+m(\varepsilon)} \sim \mathcal{N}(0,V)$.

To conclude the proof, we note that the time $t_0 \ge (\alpha_0\mu)^{-1}\ln\mu^{-1}$and $\delta > 0$ have been arbitrarily chosen. □

JACK WARGA: IN APPRECIATION

The Editorial Board of the *SIAM Journal on Control and Optimization* (SICON) and members of the SIAM community take great pleasure in honoring Professor Jack Warga on the occasion of his retirement as Professor of Mathematics at Northeastern University. Jack's dedication to SICON, especially in its early formative years, was crucial to the establishment of the journal as one of the preeminent publications in the fields of control theory and optimization. In addition, his many contributions to mathematical analysis and optimal control theory have proved to be fundamental for subsequent developments in these important fields.

Jack Warga was born in Warsaw, Poland, on December 5, 1922. He received a B.A. degree in physics from Carleton College in 1944 and a Ph.D. degree in mathematics from New York University in 1950. From 1951 to 1956 he was employed as a mathematical and computing analyst by Reeves Instrument Corporation, New York, New York, Republic Aviation Corporation, Farmingdale, New York, and the ElectroData Division of Burroughs Corporation, Pasadena, California. He was a mathematical analyst and later Manager of the Mathematics Department of Avco Research and Development Division, Wilmington, Massachusetts, from 1957 to 1966. From 1966 until his retirement in July 1993, he was Professor of Mathematics at Northeastern University, Boston, Massachusetts. In addition, Professor Warga held a Weizmann Memorial Fellowship at the Weizmann Institute of Science, Rehovot, Israel, during 1956 and 1957, and spent his sabbatical leave there in 1973. During 1981 he was on sabbatical at Tel Aviv University, Tel Aviv, Israel. He has been an invited speaker at numerous conferences and workshops in the United States, Canada, Italy, and Israel.

Jack Warga joined the editorial board of SICON in 1964, the second year of publication of the journal (then called the *SIAM Journal on Control*), and served with distinction in various capacities for over 25 years. He was Co-Managing Editor with Lucien W. Neustadt from late 1967 until the end of 1969 and Associate Managing Editor from 1969 to 1972, sharing those duties with Leonard D. Berkovitz from 1970 to 1972. For six years, from 1973 through 1978, Jack served as Managing Editor of the journal.

A pioneering researcher in mathematical control theory, Professor Warga's work covers a board spectrum of problems in the field. He has contributed to the theory of necessary conditions for optimal control problems, especially the theory of relaxed controls. Much of this effort is summarized in his book [24], in which the inherent convexity of relaxed controls is exploited in order to address existence questions, as well as to derive strong-variation necessary conditions. In later work he developed a theory of generalized differentiation for nonsmooth functions as well as necessary optimality and controllability conditions for optimization and optimal control problems [26]–[29], [35], [36], [40], [43], [44], [54] , [57]. Among Jack's other significant contributions are those that address higher-order necessary conditions [32]–[34], [39], [47]–[49], [52], iterative computational techniques [2], [6], [42], [46], and related functional analytic issues [41], [61], [62].

In his service to SICON, as well as in his research, Jack is known for his high standards of scholarship, personal integrity, and helpfulness to fellow researchers. Especially noteworthy is his personal concern for young researchers; he has provided guidance and encouragement with extraordinary patience and kindness to many. Over the past 30 years he has worked extensively and anonymously for human rights for scientists throughout the world. He is truly beloved by his students and colleagues for his humble manner and exceptional generosity.

The editorial board is honored to join Jack Warga's many friends and admirers in formally recognizing his many contributions to mathematics and his outstanding service to SIAM and the mathematical community at large.

$\mathbf{H}^\infty$ OPTIMAL SENSITIVITY FOR A CLASS OF INFINITE-DIMENSIONAL SYSTEMS*

HONG YANG†

Abstract. The computation of the $\mathbf{H}^\infty$ optimal weighted pure and mixed sensitivities for a class of infinite-dimensional systems is studied by characterizing certain wandering subspaces of some related Kreĭn spaces. The new characterizations can be used to obtain explicit bases for those subspaces. Explicit formulas for the optimal sensitivity for some infinite-dimensional systems can be obtained from these bases. The new characterizations can also be used to obtain fast algorithms for computing the $\mathbf{H}^\infty$ optimal performance for pure and mixed sensitivity problems. The results are applied to obtain an explicit optimal sensitivity formula for a class of infinite-dimensional systems that generalizes a known result.

Key words. $\mathbf{H}^\infty$ optimal sensitivity, infinite-dimensional systems, Kreĭn space

AMS subject classifications. 93B28, 93B35, 93B36

1. Introduction.

We study the computation of $\mathbf{H}^\infty$ optimal weighted pure and mixed sensitivities for a class of infinite-dimensional systems. In the standard frequency domain approach for $\mathbf{H}^\infty$ control, it is has been shown that for a quite general class of systems, the original $\mathbf{H}^\infty$ sensitivity minimization problem is associated with a self-adjoint operator. For the scalar (single-input/single-output) systems, in the case when the norm of this operator is given by its largest eigenvalue, the minimal pure sensitivity is unique and can be found by means of Sarason's Theorem [16, Prop. 5.1, p. 188]. In this case Sarason's Theorem can also be used to obtain the unique minimal mixed sensitivity [4]. In the case when the norm of this operator is given by its essential spectral radius, the optimal sensitivity may not be unique. Using the Kreĭn space approach developed by Ball and Helton [1], [17] and [4] studied the parameterization of optimal pure and mixed sensitivities in the nonunique case respectively. In this approach, one needs to compute the bases for certain subspaces of some related Kreĭn spaces. Although [17] and [4] gave abstract formulas for computing such bases, for the infinite-dimensional systems, the actual computation using those formulas involves computing an inverse image of an infinite-dimensional operator, an image of an infinite-dimensional operator, and the norm of an inverse image of the square root of an infinite-dimensional operator. Explicitly carrying out these operations is difficult if not impossible. In the matrix (multi-input/multi-output) case, even when the norm of the related self-adjoint operator is given by its largest eigenvalue, the optimal pure sensitivity may not be unique [10]. Intuitively speaking, this is because in the matrix case we only minimize the largest singular value of a matrix and there is some leeway left for the smaller singular values. In the scalar case there is no such leeway.

We begin with the mixed sensitivity case; by studying the actions of various shift operators on the elements of the related subspace, we observe some "symmetry" properties and obtain a new characterization for the subspace. The pure sensitivity case can be treated as a special case. The characterizations enable us to compute explicitly

† Program in Applied and Computational Mathematics and Department of Electrical Engineering, Princeton University, Princeton, New Jersey 08544. Current address: Department of Chemical Engineering, Princeton University, Princeton, New Jersey 08544 (hyang@titan.princeton.edu).

the bases for the related subspaces. These bases in turn give us parameterizations of all optimal pure and mixed sensitivities respectively.

The paper is organized as follows: Notation is introduced in the next section. Computation of optimal mixed sensitivity is considered in §3, and the special case of optimal pure sensitivity is considered in §3.1. In §4 the results are applied to a class of infinite-dimensional systems to obtain an explicit optimal sensitivity formula that generalizes some known results. Some concluding remarks are made in §5.

2. Notation. In this paper we shall work on the Hardy spaces on the unit disc in order to apply more directly the mathematical literature, except for §4, where examples are computed on the Hardy spaces on the right half plane. We shall use s and z to denote the complex variables in the right half plane and the unit disc $\mathbf{D}$ respectively. Basic definitions and facts used in this paper about Hardy spaces and Kreĭn spaces can be found in [12] and [2] respectively.

$\mathbf{H}^2$, $\mathbf{H}^\infty$, $\mathbf{L}^2$, $\mathbf{L}^\infty$: Hardy spaces and Lebesgue spaces.

$\mathbf{H}^2_-$: the orthogonal complement of $\mathbf{H}^2$ in $\mathbf{L}^2$, i.e., $\mathbf{L}^2 = \mathbf{H}^2 \oplus \mathbf{H}^2_-$.

$B_{\mathbf{H}^\infty} := \{\phi \in \mathbf{H}^\infty, \|\phi\|_\infty \leq 1\}$, the unit ball of $\mathbf{H}^\infty$.

$\mathbf{H}^2(0) := \{h \in \mathbf{H}^2, h(0) = 0\}$.

Π_+: the orthogonal projection $\mathbf{L}^2 \to \mathbf{H}^2$.

Π_-: the orthogonal projection $\mathbf{L}^2 \to \mathbf{H}^2_-$.

$x^*(z)$, $x^*(s)$: the involutions of $x(z)$ and $x(s)$ respectively, i.e., $x^*(z) := \bar{x}(\frac{1}{\bar{z}})$ and $x^*(s) := \bar{x}(-\bar{s})$. Here the bar denotes the complex conjugate. Note: when "*" is applied to an operator, it denotes the adjoint.

$F^{(*)} := F^*F$, where F can be an operator or a function.

$\mathbf{K}_1$: the Kreĭn space $\mathbf{L}^2 \oplus \mathbf{H}^2$ with indefinite inner product

$$\left[\begin{pmatrix} u_1 \\ v_1 \end{pmatrix}, \begin{pmatrix} u_2 \\ v_2 \end{pmatrix}\right] = \langle u_1, u_2\rangle_{\mathbf{L}^2} - \langle v_1, v_2\rangle_{\mathbf{H}^2}.$$

$\mathbf{K}_2$: the Kreĭn space $\mathbf{L}^2 \oplus \mathbf{H}^2 \oplus \mathbf{H}^2$ with indefinite inner product

$$\left[\begin{pmatrix} u_1 \\ v_1 \\ w_1 \end{pmatrix}, \begin{pmatrix} u_2 \\ v_2 \\ w_2 \end{pmatrix}\right] = \langle u_1, u_2\rangle_{\mathbf{L}^2} + \langle v_1, v_2\rangle_{\mathbf{H}^2} - \langle w_1, w_2\rangle_{\mathbf{H}^2}.$$

$M^{[\perp]}$: orthogonal companion of M with respect to the indefinite inner product $[\cdot,\cdot]$.

s_1: the bilateral shift operator on $\mathbf{L}^2$.

s_2: the unilateral shift operator on $\mathbf{H}^2$.

S_1: shift operator on $\mathbf{K}_1$ defined as $S_1 \begin{pmatrix} u \\ v \end{pmatrix} := \begin{pmatrix} s_1 u \\ s_2 v \end{pmatrix}$.

S_2: shift operator on $\mathbf{K}_2$ defined as $S_2 \begin{pmatrix} u \\ v \\ w \end{pmatrix} := \begin{pmatrix} s_1 u \\ s_2 v \\ s_2 w \end{pmatrix}$.

$\mathcal{G}(\mathcal{X})$: the graph of $\mathcal{X}$, i.e., if $\mathcal{X} : H_1 \to H_2$, then

$$\mathcal{G}(\mathcal{X}) = \left\{\begin{pmatrix} h_1 \\ \mathcal{X}(h_1) \end{pmatrix} : h_1 \in H_1\right\} \subset H_1 \oplus H_2.$$

3. Optimal sensitivities. We begin with the mixed sensitivity case. It is well known [14], [6], [4] that for a very general class of infinite-dimensional systems (includes systems with infinite-dimensional inner part and finite-dimensional outer part and finite-dimensional weights), minimizing the mixed sensitivity in $\mathbf{H}^\infty$ norm is equivalent to the following problem:

Given matrices $G \in \mathbf{L}^\infty$ and $F \in \mathbf{H}^\infty$, find all $Z_o \in \mathbf{H}^\infty$ such that

$$\left\| \begin{pmatrix} G - Z_o \\ F \end{pmatrix} \right\|_\infty = \mu_o = \min_{Z \in \mathbf{H}^\infty} \left\| \begin{pmatrix} G - Z \\ F \end{pmatrix} \right\|_\infty . \tag{1}$$

It has been shown (see [8], [7], [11], [6], and the references therein) that the *optimal performance* μ_o can be computed in the case when $G = m^* W$ and F rational, where m is arbitrary inner and W is rational. In this paper, we shall assume that the optimal performance μ_o is known. Define $\tilde{G} = \frac{1}{\mu_o} G, \tilde{F} = \frac{1}{\mu_o} F$; then the above problem is equivalent to:

Given matrices $\tilde{G} \in \mathbf{L}^\infty$ and $\tilde{F} \in \mathbf{H}^\infty$, find all $\tilde{Z}_o \in \mathbf{H}^\infty$ such that

$$\left\| \begin{pmatrix} \tilde{G} - \tilde{Z}_o \\ \tilde{F} \end{pmatrix} \right\|_\infty = 1 = \min_{\tilde{Z} \in \mathbf{H}^\infty} \left\| \begin{pmatrix} \tilde{G} - \tilde{Z} \\ \tilde{F} \end{pmatrix} \right\|_\infty ,$$

where $\tilde{Z}$ is related to Z by $Z = \mu_o \tilde{Z}$. In the following, we shall assume $\mu_o = 1$.

For $\binom{G}{F} \in \mathbf{L}^\infty \oplus \mathbf{H}^\infty$, define an operator

$$\mathcal{A} = \mathcal{A}(G, F) : \mathbf{H}^2 \to \mathbf{H}^2_- \oplus \mathbf{H}^2 \quad (\mathcal{A}h = (\Pi_- Gh \quad \Pi_+ Fh)) .$$

Since we assume $\mu_o^2 = 1$, we have [13]

$$\|\mathcal{A}^{(*)}\| = \mu_o^2 = 1.$$

Note that modifying G by adding an $\mathbf{H}^\infty$ function does not change the operator $\mathcal{A}$; and conversely, for any $\Phi \in \mathbf{L}^\infty$ such that $\mathcal{A}(G, F) = \mathcal{A}(\Phi, F)$, we have

$$\min_{Z \in \mathbf{H}^\infty} \|G - \Phi - Z\|_\infty = \|\mathcal{A}(G - \Phi, 0)\| = \|\mathcal{A}(G, F) - \mathcal{A}(\Phi, F)\| = 0,$$

which means that $G - \Phi \in \mathbf{H}^\infty$. We see that the problem (1) is equivalent to finding all $\Phi \in \mathbf{L}^\infty$ such that $\mathcal{A}(G, F) = \mathcal{A}(\Phi, F)$ and $\left\| \binom{\Phi}{F} \right\|_\infty = 1$. We shall call each such Φ a minimal symbol of $\mathcal{A}(G, F)$. From $\Phi = G - Z_o$ we get $Z_o = G - \Phi$.

It is easy to see that the adjoint operator of $\mathcal{A}$ is

$$\mathcal{A}^* : \mathbf{H}^2_- \oplus \mathbf{H}^2 \to \mathbf{H}^2, \quad \mathcal{A}^* \begin{pmatrix} h_- \\ h \end{pmatrix} = (\Pi_+ G^* \quad \Pi_+ F^*) \begin{pmatrix} h_- \\ h \end{pmatrix}$$
$$= \Pi_+ G^* h_- + \Pi_+ F^* h.$$

The graph of $\mathcal{A}^*$ is

$$\mathcal{G}(\mathcal{A}^*) = \left\{ \begin{pmatrix} h_- \\ h \\ \Pi_+ G^* h_- + \Pi_+ F^* h \end{pmatrix} : h_- \in \mathbf{H}^2_-, h \in \mathbf{H}^2 \right\} .$$

Let

$$\mathcal{M}_2 = \mathcal{G}(\mathcal{A}^*)^{[\perp]}.$$

Corresponding to Lemma 3 and Lemma 2 in [10] for the pure sensitivity case, we have the following lemma.

LEMMA 3.1. *A subspace $\mathcal{N}_2$ of $\mathbf{K}_2$ is maximal negative if and only if it is the graph of a contraction $\mathcal{C} : \mathbf{H}^2 \to \mathbf{L}^2 \oplus \mathbf{H}^2$, i.e.,*

$$\mathcal{N}_2 = \left\{ \begin{pmatrix} \mathcal{C}(x) \\ x \end{pmatrix} : x \in \mathbf{H}^2 \right\},$$

where $\|\mathcal{C}\| \leq 1$.

LEMMA 3.2. *If $\mathcal{N}_2$ is the graph of a bounded linear operator $\mathbf{H}^2 \to \mathbf{L}^2 \oplus \mathbf{H}^2$, then $\mathcal{N}_2$ is S_2-invariant if and only if*

$$\mathcal{N}_2 = \left\{ \begin{pmatrix} \Phi_1 x \\ \Phi_2 x \\ x \end{pmatrix} : x \in \mathbf{H}^2 \right\}$$

for some $\Phi_1 \in \mathbf{L}^\infty$ and some $\Phi_2 \in \mathbf{H}^\infty$.

From Lemmas 3.1 and 3.2 we see that for any S_2-invariant maximal negative subspace $\mathcal{N}_2$, there are two matrices $\Phi_1 \in \mathbf{L}^\infty$ and $\Phi_2 \in \mathbf{H}^\infty$ associated with it. Further, we have the following lemma.

LEMMA 3.3. *For an S_2-invariant maximal negative subspace $\mathcal{N}_2$, $\mathcal{N}_2 \subset \mathcal{M}_2$ if and only if*

$$\mathcal{H}_{\Phi_1} = \mathcal{H}_G \quad \textit{and} \quad \Phi_2 = F.$$

Proof. Since $\mathcal{N}_2$ is maximal negative and S_2-invariant, by Lemmas 3.1 and 3.2, there are two matrices $\Phi_1 \in \mathbf{L}^\infty$ and $\Phi_2 \in \mathbf{H}^\infty$ such that

$$\mathcal{N}_2 = \left\{ \begin{pmatrix} \Phi_1 x \\ \Phi_2 x \\ x \end{pmatrix} : x \in \mathbf{H}^2 \right\}.$$

Further, $\mathcal{N}_2 \subset \mathcal{M}_2$ if and only if for any $x \in \mathbf{H}^2, y_- \in \mathbf{H}^2_-$, and $y \in \mathbf{H}^2$,

$$\begin{aligned}
0 &= \left[\begin{pmatrix} \Phi_1 x \\ \Phi_2 x \\ x \end{pmatrix}, \begin{pmatrix} y_- \\ y \\ \mathcal{H}_G^* y_- + \mathcal{T}_F^* y \end{pmatrix} \right] \\
&= \langle \Phi_1 x, y_- \rangle + \langle \Phi_2 x, y \rangle - \langle x, \mathcal{H}_G^* y_- + \mathcal{T}_F^* y \rangle \\
&= \langle \Pi_- \Phi_1 x, y_- \rangle + \langle \Phi_2 x, y \rangle - \langle x, \mathcal{H}_G^* y_- \rangle - \langle x, \mathcal{T}_F^* y \rangle \\
&= \langle \Pi_- \Phi_1 x, y_- \rangle + \langle \Phi_2 x, y \rangle - \langle x, \Pi_+ G^* y_- \rangle - \langle x, \Pi_+ F^* y \rangle \\
&= \langle \Pi_- \Phi_1 x, y_- \rangle + \langle \Phi_2 x, y \rangle - \langle x, G^* y_- \rangle - \langle x, F^* y \rangle \\
&= \langle \Pi_- \Phi_1 x, y_- \rangle + \langle \Phi_2 x, y \rangle - \langle G x, y_- \rangle - \langle F x, y \rangle \\
&= \langle \Pi_- \Phi_1 x, y_- \rangle + \langle \Phi_2 x, y \rangle - \langle \Pi_- G x, y_- \rangle - \langle F x, y \rangle \\
&= \langle \Pi_- \Phi_1 x - \Pi_- G x, y_- \rangle + \langle \Phi_2 x - F x, y \rangle.
\end{aligned}$$

This means $\mathcal{H}_{\Phi_1} = \mathcal{H}_G$ and $\Phi_2 = F$. □

Remark 1. From $\mathcal{H}_{\Phi_1} = \mathcal{H}_G$ and $\Phi_2 = F$ we can infer that $\mathcal{A}(\Phi_1, F) = \mathcal{A}(G, F)$, which in turn means $G - \Phi_1 \in \mathbf{H}^\infty$.

For clarity we summarize the above three lemmas in the following theorem.

THEOREM 3.4. *$\mathcal{N}_2$ is a maximal negative S_2-invariant subspace and $\mathcal{N}_2 \subset \mathcal{M}_2$ if and only if $\mathcal{N}_2$ is the graph of a multiplication operator $(\Phi_1 \quad F)^{\mathsf{T}} : \mathbf{H}^2 \to \mathbf{L}^2 \oplus \mathbf{H}^2$, where $\Phi_1 \in \mathbf{L}^\infty$ and*

$$\mathcal{A}(\Phi_1, F) = \mathcal{A}(G, F) \quad \textit{and} \quad \left\| \begin{pmatrix} \Phi_1 \\ F \end{pmatrix} \right\|_\infty \leq 1.$$

The above theorem characterizes the optimal mixed sensitivity in terms of S_2-invariant maximal-negative subspaces of $\mathcal{M}_2$. By Ball–Helton's Theorem [1], the S_2-invariant maximal-negative subspaces of $\mathcal{M}_2$ can be determined by the following wandering subspace:

$$\mathbf{L}_2 := \mathcal{M}_2 \cap (S_2\mathcal{M}_2)^{[\perp]}.$$

It is shown in [4] (see also [17]) that for $\|\mathcal{A}\| < 1$, $\dim \mathbf{L}_2 = 2$ and there exist

$$x_1 = \begin{pmatrix} p_1 \\ Fr_1 \\ r_1 \end{pmatrix} \in \mathbf{L}_2, \qquad x_2 = \begin{pmatrix} p_2 \\ Fr_2 \\ r_2 \end{pmatrix} \in \mathbf{L}_2$$

such that $[x_1, x_1] = 1, [x_2, x_2] = -1$, and $[x_1, x_2] = 0$ and that the suboptimal symbols Φ such that $\mathcal{A}(G, F) = \mathcal{A}(\Phi, F)$ and $\|(\begin{smallmatrix} \Phi \\ F \end{smallmatrix})\|_\infty < 1$ is parameterized by the formula

$$\Phi = \frac{p_1\phi + p_2}{r_1\phi + r_2}, \quad \phi \in B_{\mathbf{H}^\infty}.$$

In the optimal case, for $\|\mathcal{A}\| = 1$, consider $\tilde{\mathcal{A}} := \frac{1}{\mu}\mathcal{A}$ for $\mu > 1$; then $\|\tilde{\mathcal{A}}\| < 1$. The corresponding $\tilde{r}_2$ is such that

$$\sup_{\mu > 1} |\tilde{r}_2(z)| < \infty \quad \text{for some } z \in \mathbf{D}$$

if and only if the symbol for $\mathcal{A}$ in $B_{\mathbf{L}^\infty}$ is nonunique. In this case there is a sequence $\{\mu_n\}$ such that $1 < \mu_n \to 1$ and the corresponding $\tilde{p}_1, \tilde{r}_1, \tilde{p}_2, \tilde{r}_2$ converge to p_1, r_1, p_2, r_2 respectively and the optimal symbols (minimal symbols) Φ such that $\mathcal{A}(G, F) = \mathcal{A}(\Phi, F)$ and $\|(\begin{smallmatrix} \Phi \\ F \end{smallmatrix})\|_\infty = 1$ is parameterized by

$$\Phi = \frac{p_1\phi + p_2}{r_1\phi + r_2}, \quad \phi \in B_{\mathbf{H}^\infty}.$$

Now we see that in order to compute explicitly the optimal mixed sensitivity we need to find a base for the wandering subspace $\mathbf{L}_2$.

Remark 2. In [4], abstract formulas similar to those of [17] were derived for a base of $\mathbf{L}_2$. As the formulas in [17], for infinite-dimensional systems, those formulas contain an inverse image of an infinite-dimensional operator, an image of an infinite-dimensional operator, and the norm of an inverse image of the square root of an infinite-dimensional operator.

In order to find a base for the subspace $\mathbf{L}_2$ explicitly, we study $\mathbf{L}_2$ and derive some new characterizations for $\mathbf{L}_2$ in the following. Since $\mathbf{L}_2 := \mathcal{M}_2 \cap (S_2\mathcal{M}_2)^{[\perp]}$, we begin with a characterization of the subspace $\mathcal{M}_2$.

PROPOSITION 3.5. *$(p \quad q \quad r)^{\mathsf{T}} \in \mathcal{M}_2$ if and only if $p - Gr \in \mathbf{H}^2$ and $q - Fr \in \mathbf{H}^2_-$. If $F \in \mathbf{H}^\infty$, $(p \quad q \quad r)^{\mathsf{T}} \in \mathcal{M}_2$ if and only if $p - Gr \in \mathbf{H}^2$ and $q = Fr$.*

Proof. By the definition of $\mathcal{M}_2$, we have

$$\begin{aligned}\left[\begin{pmatrix} p \\ q \\ r \end{pmatrix}, \begin{pmatrix} h_- \\ h \\ \Pi_+ G^* h_- + \Pi_+ F^* h \end{pmatrix}\right] &= \langle p, h_-\rangle_{\mathbf{L}^2} + \langle q, h\rangle_{\mathbf{H}^2} - \langle r, \Pi_+ G^* h_- + \Pi_+ F^* h\rangle_{\mathbf{H}^2} \\ &= \langle p, h_-\rangle_{\mathbf{L}^2} + \langle q, h\rangle_{\mathbf{H}^2} - \langle r, G^* h_- + F^* h\rangle_{\mathbf{L}^2} \\ &= \langle p, h_-\rangle_{\mathbf{L}^2} + \langle q, h\rangle_{\mathbf{H}^2} - \langle Gr, h_-\rangle_{\mathbf{L}^2} - \langle Fr, h\rangle_{\mathbf{L}^2} \\ &= \langle p - Gr, h_-\rangle_{\mathbf{L}^2} + \langle q - Fr, h\rangle_{\mathbf{L}^2} = 0\end{aligned}$$

for any $h_- \in \mathbf{H}^2_-$ and $h \in \mathbf{H}^2$. This is true if and only if $p - Gr \in \mathbf{H}^2$ and $q - Fr \in \mathbf{H}^2_-$.

If $F \in \mathbf{H}^\infty$, then $q - Fr \in \mathbf{H}^2$, and this is true if and only if $q - Fr = 0$, i.e., $q = Fr$. □

Remark 3. From Proposition 3.5 we see that for any $h \in \mathbf{H}^2$, $(h \quad 0 \quad 0)^\top \in \mathcal{M}_2$. Also $(\Pi_- Gr \quad Fr \quad r)^\top \in \mathcal{M}_2$.

Remark 4. For $F \in \mathbf{H}^\infty$, $\mathcal{M}_2$ is S_2-invariant, i.e., $S_2\mathcal{M}_2 \subset \mathcal{M}_2$. In fact, for $(u \quad v \quad w)^\top \in S_2\mathcal{M}_2$, by Lemma 3.6 we have

$$\begin{pmatrix} u \\ v \\ w \end{pmatrix} = S_2 \begin{pmatrix} Gx + y \\ Fx \\ x \end{pmatrix} = \begin{pmatrix} s_1 Gx + s_1 y \\ s_2 Fx \\ s_2 x \end{pmatrix} = \begin{pmatrix} Gs_2 x + s_1 y \\ Fs_2 x \\ s_2 x \end{pmatrix}. \tag{2}$$

By Proposition 3.5, we see that the right-hand side of (2) is in $\mathcal{M}_2$. Therefore $S_2\mathcal{M}_2 \subset \mathcal{M}_2$.

We shall use the following lemma that deals with the commuting properties of the shifts s_1 and s_2 with multiplication operators.

LEMMA 3.6. *For any* $A \in \mathbf{L}^\infty$,

$$As_2 = s_1 A \quad on \quad \mathbf{H}^2.$$

In particular, if $A \in \mathbf{H}^\infty$,

$$As_2 = s_2 A \quad on \quad \mathbf{H}^2.$$

Proof. Immediate from the definitions of the shifts s_1 and s_2. □

Using Proposition 3.5, we can prove the following characterization of $\mathbf{L}_2$. We adopt the proof provided by one referee of the paper. The original proof is much more complicated.

THEOREM 3.7. *For* $F \in \mathbf{H}^\infty$, $(p \quad Fr \quad r)^\top \in \mathbf{L}_2 = \mathcal{M}_2 \cap (S_2\mathcal{M}_2)^{[\perp]}$ *if and only if*

$$p^*, \quad p - Gr, \quad (1 - F^{(*)})r^* - Gp^* \in \mathbf{H}^2.$$

Proof. Noting that $F \in \mathbf{H}^\infty$, by Proposition 3.5, we have

$$\mathcal{M}_2 = \left\{ \begin{pmatrix} Gx + y \\ Fx \\ x \end{pmatrix} : x, y \in \mathbf{H}^2 \right\}.$$

Then $(p \quad Fr \quad r)^\top \in (S_2\mathcal{M}_2)^{[\perp]}$ if and only if for any $x, y \in \mathbf{H}^2$,

$$\left[\begin{pmatrix} p \\ Fr \\ r \end{pmatrix}, S_2 \begin{pmatrix} Gx + y \\ Fx \\ x \end{pmatrix}\right] = 0.$$

By Lemma 3.6, for any $x, y \in \mathbf{H}^2$, we have

$$\begin{aligned} 0 &= \left[\begin{pmatrix} p \\ Fr \\ r \end{pmatrix}, S_2 \begin{pmatrix} Gx + y \\ Fx \\ x \end{pmatrix} \right] \\ &= \langle p, s_1 Gx + s_1 y \rangle + \langle Fr, s_2 Fx \rangle - \langle r, s_2 x \rangle \\ &= \langle p, G s_2 x \rangle + \langle Fr, F s_2 x \rangle - \langle r, s_2 x \rangle + \langle p, s_1 y \rangle \\ &= \langle G^* p - F^{(*)} r - r, s_2 x \rangle + \langle p, s_1 y \rangle. \end{aligned}$$

This means that $Gp - F^{(*)}r - r^* = (G^*p - F^{(*)}r - r)^* \in \mathbf{H}^2$ and $p^* \in \mathbf{H}^2$. The theorem follows. □

Two immediate corollaries of Theorem 3.7 are in order.

COROLLARY 3.8.

$$\begin{pmatrix} (1 - F^{(*)})r^* \\ Fp^* \\ p^* \end{pmatrix} \in \mathbf{L}_2 = (S_2 \mathcal{M}_2)^{[\perp]} \cap \mathcal{M}_2$$

if and only if $(1 - F^{(*)})r^* - Gp^*$, $(1 - F^{(*)})(p - Gr) \in \mathbf{H}^2$.

Remark 5. We note that

$$\begin{aligned} &\left[\begin{pmatrix} p \\ Fr \\ r \end{pmatrix}, \begin{pmatrix} (1 - F^{(*)})r^* \\ Fp^* \\ p^* \end{pmatrix} \right] \\ &\quad = \langle p, (1 - F^{(*)})r^* \rangle + \langle Fr, Fp^* \rangle - \langle r, p^* \rangle \\ &\quad = \langle p, r^* \rangle - \langle p, F^{(*)} r^* \rangle + \langle F^{(*)} r, p^* \rangle - \langle r, p^* \rangle \\ &\quad = 0. \end{aligned}$$

If $1 - F^{(*)}$ has spectral factorization $F_s^{(*)}$, i.e., $1 - F^{(*)} = F_s^{(*)}$ with $F_s \in \mathbf{H}^\infty$, then we have the following corollary.

COROLLARY 3.9.

$$\begin{pmatrix} F_s^* r^* \\ Fr \\ r \end{pmatrix} \in \mathbf{L}_2 = (S_2 \mathcal{M}_2)^{[\perp]} \cap \mathcal{M}_2$$

if and only if $F_s^* r^* - Gr \in \mathbf{H}^2$.

Proof. From Theorem 3.7, $(F_s^* r^* \quad Fr \quad r)^\top \in \mathbf{L}_2$ if and only if

$$\begin{aligned} F_s(F_s^* r^* - Gr) = (1 - F^{(*)})r^* - G F_s r &\in \mathbf{H}^2, \\ F_s^* r^* - Gr &\in \mathbf{H}^2. \end{aligned}$$

But $F_s \in \mathbf{H}^\infty$, so we only need $F_s^* r^* - Gr \in \mathbf{H}^2$. □

Remark 6. We note that

$$\begin{aligned} \left[\begin{pmatrix} F_s^* r^* \\ Fr \\ r \end{pmatrix}, \begin{pmatrix} F_s^* r^* \\ Fr \\ r \end{pmatrix} \right] &= \langle F_s^* r^*, F_s^* r^* \rangle + \langle Fr, Fr \rangle - \langle r, r \rangle \\ &= \langle (1 - F^{(*)}) r^*, r^* \rangle - \langle (1 - F^{(*)}) r, r \rangle = 0. \end{aligned}$$

In view of Corollaries 3.8 and 3.9 and Remarks 5 and 6, when we find a base $\{x_1^0, x_2^0\}$ for $\mathbf{L}_2$ such that $[x_1^0, x_1^0] = [x_2^0, x_2^0] = 0$, since $\mathbf{L}_2$ is not neutral, we have $[x_1^0, x_2^0] \neq 0$. We can define

$$x_1 = \frac{1}{2[x_1^0, x_2^0]} x_1^0 + x_2^0, \qquad x_2 = -\frac{1}{2[x_1^0, x_2^0]} x_1^0 + x_2^0;$$

then $\{x_1, x_2\}$ form a base for $\mathbf{L}_2$ and $[x_1, x_1] = 1, [x_2, x_2] = -1$, and $[x_1, x_2] = 0$.

3.1. Special case: optimal pure sensitivity. As a special case, let us look at the problem of minimizing the pure weighted sensitivity in the $\mathbf{H}^\infty$ norm, which is cast as the following Nehari problem [5], [19]:

Given a matrix $G \in \mathbf{L}^\infty$, find all $Z_o \in \mathbf{H}^\infty$ such that

$$\|G - Z_o\|_\infty = \mu_o = \min_{Z \in \mathbf{H}^\infty} \|G - Z\|_\infty .$$

This problem can be treated as a special case of the mixed sensitivity case with $F = 0$. As in the mixed sensitivity case, we may assume without loss of generality that $\mu_o = 1$.

The operator $\mathcal{A}$ becomes a Hankel operator

$$\mathcal{H}_G : \mathbf{H}^2 \to \mathbf{H}^2_- \qquad (\mathcal{H}_G(h) = \Pi_- Gh) .$$

We want to find all $\Phi \in \mathbf{L}^\infty$ such that $\mathcal{H}_G = \mathcal{H}_\Phi$ and $\|\Phi\|_\infty = 1$. Then $Z_o = G - \Phi$. The graph of $\mathcal{H}_G^*$ is

$$\mathcal{G}(\mathcal{H}_G^*) = \left\{ \begin{pmatrix} y \\ \mathcal{H}_G^* y \end{pmatrix} : y \in \mathbf{H}^2_- \right\} .$$

To simplify the notation, we define

$$\mathcal{M}_1 := \mathcal{G}(\mathcal{H}_G^*)^{[\perp]} .$$

From Theorem 3.4 we know that to find the optimal sensitivity is the same as to characterize the set of all S_1-invariant maximal-negative subspaces of $\mathcal{M}_1$. In order to do so, we need to find a base for the subspace [17], [10]

$$\mathbf{L}_1 := \mathcal{M}_1 \cap (S_1 \mathcal{M}_1)^{[\perp]} .$$

Remark 7. Abstract formulas were derived in [17] for a base of $\mathbf{L}_1$. For infinite-dimensional systems, those formulas contain an inverse image of an infinite-dimensional operator, an image of an infinite-dimensional operator, and the norm of an inverse image of the square root of an infinite-dimensional operator. In the finite-dimensional case, an algorithm was given for computing a base of $\mathbf{L}_1$ [10].

By letting $F = 0$ in Theorem 3.7, we have the following corresponding theorem for the pure sensitivity case.

THEOREM 3.10. $\binom{p}{r} \in \mathbf{L}_1$ *if and only if* $p^*, p - Gr, r^* - Gp^* \in \mathbf{H}^2$.

Theorem 3.10 has the following immediate corollaries:

COROLLARY 3.11. $\binom{p}{r} \in \mathbf{L}_1$ *if and only if* $(r^* \quad p^*)^\top \in \mathbf{L}_1$.

COROLLARY 3.12. $(\pm r^* \quad r)^\top \in \mathbf{L}_1$ *if and only if* $r^* \mp Gr \in \mathbf{H}^2$.

Finding a base for the wandering subspaces $\mathbf{L}_1$ or $\mathbf{L}_2$ analytically is in general very difficult. Yang and Orszag [18] proposed a numerical method to find their approximations. Nevertheless, in the next section, we shall show that in some special cases, we can use Theorem 3.10 to construct explicitly a base for the wandering subspaces $\mathbf{L}_1$ and therefore obtain explicit formulas for the optimal sensitivity.

4. Example. In this section, we shall work on the Hardy spaces on the right half plane. Because our results in the previous sections are on the Hardy spaces on the unit disc and $A(z)$ is in $\mathbf{H}^2$ of the unit disc if and only if $A\left(\frac{s-1}{s+1}\right) = (1+s)B(s)$ for some $B(s)$ in $\mathbf{H}^2$ of the right half plane [12, Theorem, p. 130], we find it convenient to still write $A \in \mathbf{H}^2$ when we actually mean $\frac{1}{1+s}A \in \mathbf{H}^2$.

The purpose of this section is to use the results developed in the previous sections to solve the sensitivity minimization problem for $G = m^* \frac{a+s}{b+s}$, where m is an inner function. This corresponds to the problem of pure sensitivity minimization for the plant $P = m$ and weight $W = \frac{a+s}{b+s}$ [5]. We want to find *all* $Z_{\text{o}} \in \mathbf{H}^\infty$ such that

$$\text{(3)} \qquad \|G - Z_{\text{o}}\|_\infty = \mu_{\text{o}} = \inf_{Z \in \mathbf{H}^\infty} \|G - Z\|_\infty = \|\mathcal{H}_G\|,$$

or equivalently, find *all* $\Phi \in \mathbf{L}^\infty$ such that $\mathcal{H}_\Phi = \mathcal{H}_G$ and $\|\Phi\|_\infty = \mu_{\text{o}}$.

Setting $Z = 0$ in (3) we see that

$$\mu_{\text{o}} \le \|G\|_\infty = \sqrt{\sup_{\omega \in \mathbb{R}} \left\{ \frac{a^2 + \omega^2}{b^2 + \omega^2} \right\}} = \begin{cases} \frac{a}{b}, & a > b, \\ 1, & a \le b. \end{cases}$$

It is standard [15], [9] that the essential spectrum of $\mathcal{H}_G^{(*)}$ is

$$\sigma_{\text{e}}(\mathcal{H}_G^{(*)}) = \left\{ \frac{a^2 + \omega^2}{b^2 + \omega^2} : j\omega \in \sigma_{\text{e}}(m) \right\},$$

where $\sigma_{\text{e}}(m)$ denotes the set of imaginary points which are essential singularities of m. Let

$$\text{(4)} \qquad \rho_{\text{e}} = \sup \left\{ \frac{a^2 + \omega^2}{b^2 + \omega^2} : j\omega \in \sigma_{\text{e}}(m) \right\}$$

be the essential spectral radius of $\mathcal{H}_G^{(*)}$. Noting that $\mu_{\text{o}} = \|\mathcal{H}_G\|$, we have $\mu_{\text{o}}^2 = \|\mathcal{H}_G^{(*)}\|$; thus, μ_{o} is given by the norm of a self-adjoint operator, whose spectrum contains only eigenvalues $\sigma_p(\mathcal{H}_G^{(*)})$ and essential spectrum $\sigma_{\text{e}}(\mathcal{H}_G^{(*)})$. We have $\mu_{\text{o}}^2 = \|\mathcal{H}_G^{(*)}\| = \sup\{\sigma_{\text{e}}(\mathcal{H}_G^{(*)}) \cup \sigma_{\text{e}}(\mathcal{H}_G^{(*)})\} \ge \rho_{\text{e}}$.

We shall consider the case when $a \le b$ and m has an essential singularity at infinity. In this case we see that $1 = \rho_{\text{e}} \le \mu_{\text{o}}^2 \le 1$, so $\mu_{\text{o}} = 1$.

Case I: $a = b$. Take $G = \frac{m^*}{\mu}$. For $\mu > 1$, using Theorem 3.10 we see that

$$\begin{cases} p_1 = 1, \\ r_1 = \frac{m}{\mu}; \end{cases} \qquad \begin{cases} p_2 = \frac{m^*}{\mu}, \\ r_2 = 1 \end{cases}$$

is a base for $\mathbf{L}_1$ and

$$\left[\begin{pmatrix} p_1 \\ r_1 \end{pmatrix}, \begin{pmatrix} p_1 \\ r_1 \end{pmatrix} \right] = \frac{\mu^2 - 1}{\mu^2} > 0, \quad \left[\begin{pmatrix} p_2 \\ r_2 \end{pmatrix}, \begin{pmatrix} p_2 \\ r_2 \end{pmatrix} \right] = \frac{1 - \mu^2}{\mu^2} < 0.$$

Let $x_1 = \frac{\mu}{\sqrt{\mu^2 - 1}}(p_1 \quad r_1)^{\mathrm{T}}$, $x_2 = \frac{\mu}{\sqrt{\mu^2-1}}(p_2 \quad r_2)^{\mathrm{T}}$. Then $[x_1, x_1] = 1$, $[x_2, x_2] = -1$, and $[x_1, x_2] = 0$. It is easy to see that

$$\frac{\mu}{\sqrt{\mu^2 - 1}} r_2 \to \infty$$

as $\mu \to 1$. Thus in this case the minimal symbol is unique. It is easy to see that the unique symbol is $\Phi = m^*$.

Case II: $a < b$. Take $G = \frac{m^*}{\mu}\frac{a+s}{b+s}$. For $\binom{p}{r} \in \mathbf{L}_1$, the trick is to assume that

$$p = P_1 m^* + P_2, \quad r = R_1 m + R_2,$$

where P_1, P_2, R_1, R_2 are rational functions to be computed later.

We have

$$p - G_\mu r = m^* \left(P_1 - \frac{1}{\mu}\frac{a+s}{b+s} R_2 \right) + P_2 - \frac{1}{\mu}\frac{a+s}{b+s} R_1,$$

$$r^* - G_\mu p^* = m^* \left(R_1^* - \frac{1}{\mu}\frac{a+s}{b+s} P_2^* \right) + R_2^* - \frac{1}{\mu}\frac{a+s}{b+s} P_1^*.$$

By Theorem 3.10 , in order for $\binom{p}{r} \in \mathbf{L}_1$, we require that $p - G_\mu r \in \mathbf{H}^2$, $r^* - G_\mu p^* \in \mathbf{H}^2$, $p^* \in \mathbf{H}^2$, and $r \in \mathbf{H}^2$. Using these constraints we see that

$$\begin{cases} P_1 - \frac{1}{\mu}\frac{a+s}{b+s} R_2 & = & 0, \\ P_2 - \frac{1}{\mu}\frac{a+s}{b+s} R_1 & \in & \mathbf{H}^2; \end{cases} \quad \begin{cases} R_1^* - \frac{1}{\mu}\frac{a+s}{b+s} P_2^* & = & 0, \\ R_2^* - \frac{1}{\mu}\frac{a+s}{b+s} P_1^* & \in & \mathbf{H}^2. \end{cases}$$

These conditions in turn yield

$$(5) \qquad \begin{cases} P_2 \left(1 - \frac{1}{\mu^2}\frac{a^2 - s^2}{b^2 - s^2} \right) & \in & \mathbf{H}^2, \\ R_2^* \left(1 - \frac{1}{\mu^2}\frac{a^2 - s^2}{b^2 - s^2} \right) & \in & \mathbf{H}^2. \end{cases}$$

For $\mu > 1$, define $B_\mu^2 := \mu^2 b^2 - a^2 > 0$. Then condition (5) becomes

$$\begin{cases} P_2 \frac{B_\mu^2 - (\mu^2 - 1)s^2}{\mu^2 (b^2 - s^2)} & = & P_2 \frac{(B_\mu - \sqrt{\mu^2 - 1s})(B_\mu + \sqrt{\mu^2 - 1s})}{\mu^2 (b^2 - s^2)} & \in \mathbf{H}^2, \\ R_2^* \frac{B_\mu^2 - (\mu^2 - 1)s^2}{\mu^2 (b^2 - s^2)} & = & R_2^* \frac{(B_\mu - \sqrt{\mu^2 - 1s})(B_\mu + \sqrt{\mu^2 - 1s})}{\mu^2 (b^2 - s^2)} & \in \mathbf{H}^2. \end{cases}$$

Since we require that $p^* \in \mathbf{H}^2$ and $r \in \mathbf{H}^2$, we see that we have the following solutions for $\binom{p}{r}$:

$$\begin{cases} p_1 & = & \alpha_1 \frac{1}{\mu} \frac{a+s}{B_\mu - \sqrt{\mu^2 - 1s}} m^* + \beta_1 \frac{b-s}{B_\mu - \sqrt{\mu^2 - 1s}}, \\ r_1 & = & \beta_1 \frac{1}{\mu} \frac{a-s}{B_\mu - \sqrt{\mu^2 - 1s}} m + \alpha_1 \frac{b+s}{B_\mu - \sqrt{\mu^2 - 1s}}; \end{cases} \quad \begin{bmatrix} P_2 & = & \beta_1 \frac{b-s}{B_\mu - \sqrt{\mu^2 - 1s}} \\ R_2^* & = & \bar{\alpha}_1 \frac{b-s}{B_\mu + \sqrt{\mu^2 - 1s}} \end{bmatrix};$$

$$\begin{cases} p_2 & = & \alpha_2 \frac{1}{\mu} \frac{a+s}{B_\mu + \sqrt{\mu^2 - 1s}} m^* + \beta_2 \frac{b-s}{B_\mu + \sqrt{\mu^2 - 1s}}, \\ r_2 & = & \beta_2 \frac{1}{\mu} \frac{a-s}{B_\mu + \sqrt{\mu^2 - 1s}} m + \alpha_2 \frac{b+s}{B_\mu + \sqrt{\mu^2 - 1s}}; \end{cases} \quad \begin{bmatrix} P_2 & = & \beta_2 \frac{b-s}{B_\mu + \sqrt{\mu^2 - 1s}} \\ R_2^* & = & \bar{\alpha}_2 \frac{b-s}{B_\mu - \sqrt{\mu^2 - 1s}} \end{bmatrix}$$

where the coefficients $\alpha_1, \beta_1, \alpha_2, \beta_2$ satisfy the following interpolation conditions:

$$(6) \qquad \beta_1 (a - C_\mu) m (C_\mu) + \alpha_1 \mu (b + C_\mu) = 0,$$

$$(7) \qquad \alpha_2 (a - C_\mu) m^* (-C_\mu) + \beta_2 \mu (b + C_\mu) = 0,$$

where $C_\mu = \frac{B_\mu}{\sqrt{\mu^2 - 1}}$.

By Theorem 3.10,

$$\begin{pmatrix} p_1 \\ r_1 \end{pmatrix} \in \mathbf{L}_1, \qquad \begin{pmatrix} p_2 \\ r_2 \end{pmatrix} \in \mathbf{L}_1.$$

Since $\dim \mathbf{L}_1 = 2$, $(p_1 \quad r_1)^\top$ and $(p_2 \quad r_2)^\top$ form a base for $\mathbf{L}_1$.

Noting that C_μ is real for $\mu > 1$, we have $m^*(-C_\mu) = \bar{m}(C_\mu)$. From (6) and (7) we can let $\beta_1 = \bar{\alpha}_2$ and $\alpha_1 = \bar{\beta}_2$. This gives us

$$\begin{cases} p_1^* = r_2, \\ r_1^* = p_2. \end{cases}$$

Thus $[(p_1 \quad r_1)^\top, (p_2 \quad r_2)^\top] = \langle p_1, p_2\rangle - \langle r_1, r_2\rangle = \langle 1, p_1^* p_2 - r_1^* r_2\rangle = 0$.

Letting $\beta_1 = \alpha_2 = 1$, we have

$$\begin{cases} p_1 = \frac{1}{\mu\sqrt{\mu^2-1}(C_\mu - s)}\left[\frac{F_\mu m(C_\mu)}{\mu}(a+s)m^* + \mu(b-s)\right], \\ r_1 = \frac{1}{\mu\sqrt{\mu^2-1}(C_\mu - s)}\left[(a-s)m + F_\mu m(C_\mu)(b+s)\right]; \end{cases}$$

$$\begin{cases} p_2 = \frac{1}{\mu\sqrt{\mu^2-1}(C_\mu + s)}\left[(a+s)m^* + F_\mu m^*(-C_\mu)(b-s)\right], \\ r_2 = \frac{1}{\mu\sqrt{\mu^2-1}(C_\mu + s)}\left[\frac{F_\mu m^*(-C_\mu)}{\mu}(a-s)m + \mu(b+s)\right], \end{cases}$$

where $F_\mu = \frac{C_\mu - a}{C_\mu + b}$.

One can compute that

$$p_1 p_1^* - r_1 r_1^* = \frac{\mu^2 - F_\mu^2 |m(C_\mu)|^2}{\mu^4}.$$

Thus

$$\begin{aligned}\left[\begin{pmatrix} p_1 \\ r_1 \end{pmatrix}, \begin{pmatrix} p_1 \\ r_1 \end{pmatrix}\right] &= \langle p_1, p_1\rangle - \langle r_1, r_1\rangle \\ &= \langle p_1 p_1^* - r_1 r_1^*, 1\rangle \\ &= \frac{\mu^2 - F_\mu^2 |m(C_\mu)|^2}{\mu^4} > 0.\end{aligned}$$

Define

$$x_1 = \frac{\mu^2}{\sqrt{\mu^2 - F_\mu^2 |m(C_\mu)|^2}}\begin{pmatrix} p_1 \\ r_1 \end{pmatrix} \quad \text{and} \quad x_2 = \frac{\mu^2}{\sqrt{\mu^2 - F_\mu^2 |m(C_\mu)|^2}}\begin{pmatrix} r_1^* \\ p_1^* \end{pmatrix}.$$

Then $[x_1, x_1] = 1$, $[x_2, x_2] = -1$, and $[x_1, x_2] = 0$.

Next let us look at

$$S_\mu(s) := \frac{\mu^2}{\sqrt{\mu^2 - F_\mu^2 |m(C_\mu)|^2}} r_2 = \frac{F_\mu m^*(-C_\mu)(a-s)m + \mu^2(b+s)}{\sqrt{\mu^2 - F_\mu^2 |m(C_\mu)|^2}\,\mu(B_\mu + \sqrt{\mu^2-1}s)}.$$

For any real number sequence $\{y_n\}$ such that $y_n \to \infty$, if $m(y_n) \to M$, then $|M| \le 1$ since $|m(y_n)| \le 1$. We shall further see that $|M| < 1$. In fact, if there exists $y_n \to \infty$ and $m(y_n) \to M$ and $|M| = 1$, then for any $s \in \mathbb{C}^+$,

$$\sup_{\mu > 1} |S_\mu(s)| = +\infty;$$

we should have a unique optimal sensitivity (minimal symbol). We see that

$$\Phi_1 = \frac{(b-s)\bar{M} + (a+s)m^*}{(a-s)m\bar{M} + (b+s)},$$

being a cluster point of $(\Phi_\mu)_{\mu>1}$ relative to the weak-star topology of $\mathbf{L}^\infty$, should be a minimal symbol for $\mathcal{H}_G$; but since $a \neq b$,

$$\Phi_2 = \frac{a+s}{b+s} m^*$$

is clearly another minimal symbol for $\mathcal{H}_G$, which contradicts the assertion that $\mathcal{H}_G$ has a unique minimal symbol.

We now have $|M| < 1$. Then

$$\sup_{\mu>1} |S_\mu(1)| < +\infty$$

and we have nonunique optimal sensitivities (minimal symbols). Since $|m(s)| \leq 1$ for $s \in \mathbb{C}^+$, there exists a sequence $\{y_n\}$ such that $m(y_n) \to M$ and from the above discussion we know that $|M| < 1$. Let $\mu \to 1$; we get the parameterization of the minimal symbols as

$$\Phi = \frac{[M(a+s)m^* + (b-s)]\,\phi_1 + (a+s)m^* + \bar{M}(b-s)}{[(a-s)m + M(b+s)]\,\phi_1 + \bar{M}(a-s)m + (b+s)} \tag{8}$$

for any $\phi_1 \in B_{\mathbf{H}^\infty}$.

Since

$$\phi = \mathcal{F}(\phi_1) := \frac{\phi_1 + \bar{M}}{1 + M\phi_1}$$

is a bijection from $B_{\mathbf{H}^\infty}$ to $B_{\mathbf{H}^\infty}$ for $|M| < 1$, we see from (8) that

$$\Phi = \frac{(b-s)\phi + (a+s)m^*}{(a-s)m\phi + (b+s)} = m^* \frac{(b-s)m\phi + (a+s)}{(a-s)m\phi + (b+s)}$$

for any $\phi \in B_{\mathbf{H}^\infty}$.

We summarize the results in the following theorem.

THEOREM 4.1. *Let $G = m^* \frac{a+s}{b+s}$ with $b \geq a \geq 0$ and m an inner function with an essential singularity at infinity. Then $\mu_o = 1$ and the $\mathbf{H}^\infty$ optimal sensitivity is parameterized by the formula*

$$\Phi = m^* \frac{(b-s)m\phi + (a+s)}{(a-s)m\phi + (b+s)}, \quad \phi \in B_{\mathbf{H}^\infty}.$$

Remark 8. The above formula is a generalization of a result in [3] that shows that for a pure delay system e^{-ds}, i.e., $m = e^{-ds}$, with weight $W = \frac{a+s}{b+s}$, $a < b$, the optimal pure weighted sensitivity can be parameterized as

$$\Phi = e^{ds} \frac{(b-s)e^{-ds}\phi + (a+s)}{(a-s)e^{-ds}\phi + (b+s)}$$

for any $\phi \in B_{\mathbf{H}^\infty}$.

We remark that for other cases such as the inner function m that has finite essential singularities on the imaginary axis or $a > b$, the optimal sensitivity can also be computed by the present method.

5. Conclusions. Based on some well-known results, we have considered the explicit computation of $\mathbf{H}^\infty$ optimal pure and mixed sensitivities for a class of infinite-dimensional systems by studying certain subspaces of some related Kreĭn spaces. We have given some new characterizations for those subspaces. The pure sensitivity case can be treated as a special case of the mixed sensitivity case.

Our new characterizations are particularly useful both from theoretical and practical points of view. They can be used in the theoretical analysis of the optimal compensators as well as convergence analysis for numerical algorithms since from these new characterizations, explicit $\mathbf{H}^\infty$ optimal weighted pure and mixed sensitivities for a class of infinite-dimensional systems can be obtained as we showed in a simple example that generalized a known result. Practically, they can be used to obtain fast and stable algorithms for computing the $\mathbf{H}^\infty$ optimal performances [18]. In addition, we believe that they can also be used to develop numerically efficient algorithms for computing the suboptimal compensators and spectral factorizations for both irrational and rational systems and that the results can be extended to treat the multivariable systems. An added advantage is that the mathematics used in the paper is no more advanced than that used in the analysis of rational systems [10]. One area of further research is to obtain explicit optimal sensitivity formulas for more general systems and weights.

Acknowledgments. The author thanks the anonymous referees for their valuable suggestions and correction of errors. The proof of Theorem 3.7 was greatly simplified by one of the referees.

ZEROS OF SPECTRAL FACTORS, THE GEOMETRY OF SPLITTING SUBSPACES, AND THE ALGEBRAIC RICCATI INEQUALITY*

ANDERS LINDQUIST[†], GYÖRGY MICHALETZKY[‡], AND GIORGIO PICCI[§]

Abstract. In this paper it is shown how the zero dynamics of (not necessarily square) spectral factors relate to the splitting subspace geometry of stationary stochastic models and to the corresponding algebraic Riccati inequality. The notion of *output-induced subspace* of a minimal Markovian splitting subspace, which is the stochastic analogue of the *supremal output-nulling subspace* in geometric control theory, is introduced. Through this concept, the analysis can be made coordinate-free and straightforward geometric methods can be applied. It is shown how the zero structure of the family of spectral factors relates to the geometric structure of the family of minimal Markovian splitting subspaces in the sense that the relationship between the zeros of different spectral factors is reflected in the partial ordering of minimal splitting subspaces. Finally, the well-known characterization of the solutions of the algebraic Riccati equation is generalized in terms of Lagrangian subspaces invariant under the corresponding Hamiltonian to the larger solution set of the algebraic Riccati inequality.

Key words. zero dynamics, Markovian splitting subspaces, minimal spectral factors, matrix Riccati inequality, algebraic Riccati equation, geometric control theory

AMS subject classifications. 93E03, 93B27, 60G10

1. Introduction.

By now it should be fairly well known that there is a one-to-one correspondence between each pair of the following three fundamental areas of systems theory.

(i) *Minimal spectral factorization* of a rational (full-rank) $m \times m$ spectral density matrix Φ. The problem is to find *all* (square *and* rectangular) rational functions

$$W(s) = C\,(sI - A)^{-1}\,B + D \tag{1.1}$$

(where prime denotes transposition) with poles in the open left half plane, satisfying the factorization equation

$$W(s)W(-s)' = \Phi(s) \tag{1.2}$$

and being *minimal* in the sense that the McMillan degree of W is exactly half of that of Φ. The class of all such minimal spectral factors, each defined modulo right multiplication by a constant orthogonal matrix, will be denoted by $\mathcal{W}$. The subclass of *square* spectral factors will be denoted $\mathcal{W}_0$. Throughout this paper we shall always consider representations for which $(A,\ B,\ C)$ is a minimal triplet and $[\begin{smallmatrix}B\\D\end{smallmatrix}]$ has independent columns. This results in no loss of generality [16].

(ii) Finding all symmetric solutions of the *algebraic Riccati inequality*

$$\Lambda(P) \leq 0, \tag{1.3}$$

* Received by the editors October 15, 1992; accepted for publication (in revised form) October 19, 1993. This work was partially supported by the Swedish Board for Technical Development, the Göran Gustafsson Foundation, LADSEB-CNR, and OTKA grant 2042.

where $\Lambda : \mathbb{R}^{n\times n} \longrightarrow \mathbb{R}^{n\times n}$ is given by

$$\Lambda(P) = AP + PA' + (\bar{C} - CP)'R^{-1}(\bar{C} - CP), \tag{1.4}$$

the matrices $A \in \mathbb{R}^{n\times n}, C, \bar{C} \in \mathbb{R}^{m\times n}$, and $R \in \mathbb{R}^{m\times m}$ being defined through a minimal realization

$$\Phi_+(s) = C(sI - A)^{-1}\bar{C}' + \frac{1}{2}R \tag{1.5}$$

of the positive real part Φ_+ of the spectral density Φ, i.e., the rational matrix function Φ_+ satisfying

$$\Phi(s) = \Phi_+(s) + \Phi_+(-s)' \tag{1.6}$$

and having all its poles in the open left half plane. Here we assume that $R := \Phi(\infty) > 0$.

Let us denote by $\mathcal{P}$ the solution set of (1.3). Then each $P \in \mathcal{P}$ corresponds to a spectral factor (1.1) whose B- and D-matrices are determined by a full-rank matrix factorization of the type

$$\begin{bmatrix} B \\ D \end{bmatrix} [B', D'] = \begin{bmatrix} -AP - PA' & \bar{C}' - PC' \\ \bar{C} - CP & R \end{bmatrix}. \tag{1.7}$$

Obviously the correspondence is one-to-one modulo trivial coordinate transformations [1], [9].

(iii) Describing all *minimal stochastic realizations* of an m-dimensional stationary-increments process $\{y(t); t \in \mathbb{R}\}$ having the (incremental) spectral density Φ. Each stochastic realization is obtained by passing a suitable "white noise" through a filter

$$\xrightarrow{dw} \boxed{W} \xrightarrow{dy} \tag{1.8}$$

having an $m \times p$ minimal spectral factor as its transfer function, thus yielding a linear dynamical model

$$(\Sigma) \quad \begin{cases} dx = Axdt + Bdw, \\ dy = Cxdt + Ddw \end{cases} \tag{1.9}$$

for dy, defined on the whole real line. More precisely, w is a vector Wiener process on $\mathbb{R}$ of a dimension p equal to the number of columns of W. The system Σ is in statistical steady state so that the n-dimensional state process x and the increments of the m-dimensional output process y are jointly stationary. The model Σ is a *minimal* stochastic realization in the sense that there is no other representation of dy of type (1.9) with a state process with fewer components.

In regard to topic (iii), it is actually more natural to consider a coordinate-free representation by assigning to each model Σ the n-dimensional space

$$X = \{a'x(0)\,|a \in \mathbb{R}^n\} \tag{1.10}$$

of random variables. This space is the subspace of an *ambient space* H of the model (1.9), defined as the closure of the linear hull of the following random variables $\{w_i(t) - w_i(\tau);\ i = 1, 2, \dots,\ p;\ t, \tau \in \mathbb{R}\}$ in the topology of the inner product

$$\langle \xi, \eta \rangle = E\{\xi\eta\}, \tag{1.11}$$

where $E\{\cdot\}$ stands for mathematical expectation. The ambient space H is naturally equipped with the shift induced by dw, i.e., the strongly continuous group of unitary operators $\{U_t;\ t \in \mathbb{R}\}$ on H such that $U_t\left[w_i(\tau) - w_i(\sigma)\right] = w_i(\tau + t) - w_i(\sigma + t)$ for all $i = 1, 2, \ldots, p$ and $t, \tau, \sigma \in \mathbb{R}$. All random variables of Σ belong to H, and moreover the processes x and dy are stationary with respect to $\{U_t\}$, i.e., $U_t x_i(\tau) = x_i(\tau + t)$ for all $i = 1, 2, \ldots, n$ and $t, \tau \in \mathbb{R}$ and $U_t\left[y_i(\tau) - y_i(\sigma)\right] = y_i(\tau + t) - y_i(\sigma + t)$ for all $i = 1, 2, \ldots, m$ and $t, \tau, \sigma \in \mathbb{R}$. Minimality of Σ corresponds to minimality of the subspace X in the sense of subspace inclusion and, hence, also in the sense of dimension [16].

Defining the *past* and *future output spaces* as

$$H^- = \text{closure}\left\{a'\left[y(t) - y(s)\right] \middle| a \in \mathbb{R}^m, t, s \leq 0\right\}$$

and

$$H^+ = \text{closure}\left\{a'\left[y(t) - y(s)\right] \middle| a \in \mathbb{R}^m, t, s \geq 0\right\}$$

respectively, it is easy to show and well established in the literature [15], [16], [6] that each X, defined as in (1.10), is a *minimal Markovian splitting subspace* for H^- and H^+, i.e., in particular renders H^- and H^+ conditionally orthogonal given X. Moreover, this property captures the concept of stochastic state space model of dy in a coordinate-free way. Given any X together with its ambient space H, equipped with a shift, we can construct the model Σ modulo the choice of coordinates in the state space [16].

Modulo coordinate-transformations, there is a one-to-one correspondence between the family $\mathcal{X}$ of minimal Markovian splitting subspaces and the solution set $\mathcal{P}$ of the algebraic Riccati inequality (1.3) under which

$$P = E\left\{x(0)x(0)'\right\} \tag{1.12}$$

is the state covariance. Under this correspondence the subset $\mathcal{P}_0 \subset \mathcal{P}$ of solutions of the *algebraic Riccati equation*

$$\Lambda(P) = 0 \tag{1.13}$$

corresponds to the subclass $\mathcal{X}_0 \subset \mathcal{X}$ of stochastic realizations such that [1]

$$X \subset H_0 := H^- \vee H^+, \tag{1.14}$$

i.e., *internal* realizations constructed by using only random quantities contained in the subspace

$$H_0 = \text{closure}\{a'[y(t) - y(s)] | a \in \mathbb{R}^n\}$$

spanned by the output. Under the correspondence mentioned above, $\mathcal{X}_0$ and $\mathcal{P}_0$ correspond to $\mathcal{W}_0 \subset \mathcal{W}$, the subclass of square spectral factors.

Although the structure of the solution set of the algebraic Riccati equation (1.13) is by now fairly well established [27], [20], [26], [13], it is fair to say that the structure of the complete solution set $\mathcal{P}$ of the algebraic Riccati inequality (1.3) is far less

[1] In the upcoming sections, given two subspaces A and B, we shall write $A \vee B$ to denote the closure of $\{\alpha + \beta | \alpha \in A, \beta \in B\}$. To stress that the sum is direct we write instead $A + B$ or, if it is an orthogonal direct sum, $A \oplus B$.

understood; and, except for [10], [16], and [25], little seems to have appeared in the literature since the monograph [9]. We stress that the algebraic Riccati inequality and the set $\mathcal{P}$ are important in many areas of systems and control, including dissipative systems and H^∞ control.

In this respect, one purpose of this paper is to provide new results on the structure of $\mathcal{P}$ and new concepts for the study and classification of this set based on the *zero structure* of the family $\mathcal{W}$ of minimal spectral factors W. The work reported here is a continuation and a deepening of the results presented in [16] and [19]. In particular it was shown in [16] that

1. The set $\mathcal{P}$ (which is bounded and convex) has *facets*, each of which is uniquely defined by a pair of solutions of the algebraic Riccati equation (1.13). For each $P \in \mathcal{P}$ there is a minimal facet $[P_{0-}, P_{0+}]$ containing P, called the *tightest local frame* of P, defined as the set of all solutions Q of the algebraic Riccati inequality (1.3) satisfying the relation $P_{0-} \leq Q \leq P_{0+}$, where

$$P_{0-} := \sup \{P_0 \in \mathcal{P}_0 \mid P_0 \leq P\},$$

$$P_{0+} := \inf \{P_0 \in \mathcal{P}_0 \mid P \leq P_0\}.$$

Here, for any $P_1, P_2 \in \mathcal{P}$, $P_1 \leq P_2$ means that $P_2 - P_1$ is nonnegative definite. The tightest bounds of P, i.e., P_{0-} and P_{0+}, can be computed as the limit solutions of the matrix Riccati differential equation $\dot{\Pi} = \Lambda(\Pi)$, with initial condition $\Pi(0) = P$, as t tends to $-\infty$ and ∞ respectively.

2. The *open tightest frame* (P_{0-}, P_{0+}) of $P \in \mathcal{P}$, consisting of all $Q \in [P_{0-}, P_{0+}]$ having P_{0-} and P_{0+} as tight bounds, can be characterized in terms of the *zeros* of the corresponding minimal spectral factor W. If (W_{0-}, W_{0+}) is the pair of square minimal spectral factors corresponding to P_{0-} and P_{0+}, then the zeros of W are precisely the common zeros of W_{0-} and W_{0+}.

In this paper we greatly expand on the above characterization of facets and tight frames providing necessary and sufficient conditions in terms of zeros (or, better, the *zero dynamics*) of spectral factors. To this end, in §2, we first provide a geometric characterization of the zero dynamics in the stochastic framework (Theorem 2.9). In particular, we demonstrate how the zero structure of each W can be recovered directly from the corresponding *output-induced subspace* $X \cap H_0$ and a related compressed shift. We introduce a dual control problem and show that its maximal output-nulling subspace consists of precisely those $a \in \mathbb{R}^n$ for which $a'x(0) \in X \cap H_0$ and that these a are also the zero directions of W. In this way we not only provide the appropriate connection to geometric control theory [3], [28] but also obtain elegant coordinate-free proofs of the main theorems of §§2 and 3.

Next, in §3, we analyze the relation between partial ordering of minimal splitting subspaces and zeros and characterize the ordering in terms of invariant subspaces for the zero dynamics and right half-plane zeros. The results on ordering are very intuitive and are in agreement with some early observations of Anderson [2] and Robinson [23]. The characterizations in terms of invariant subspaces extend those known thus far for square spectral factors and the algebraic Riccati equation, as for example reported in the survey of Kucera [13].

Thus far all results are coordinate-free. Then, in §4, we introduce coordinates and translate the geometric characterizations of §§2 and 3 in terms of covariances and solutions of the algebraic Riccati inequality. Through this analysis we also obtain a natural generalization of the well-known characterization (Potter [22], MacFarlane

[17]; also see [26]) of $\mathcal{P}$ in terms of the n-dimensional Lagrangian subspaces $\mathcal{L} \subset \mathbb{R}^{2n}$, invariant under multiplication by the Hamiltonian $\mathcal{H}$ corresponding to Φ. In fact, in §5, we show that the $\mathcal{H}$-invariant isotropic subspaces $\mathcal{L}$ of dimension $k \leq n$ are in one-to-one correspondence with the facets of $\mathcal{P}$ whose elements P have identical zero structure. Under this correspondence

$$\mathcal{L} = \begin{bmatrix} I \\ P \end{bmatrix} \mathcal{V}^*, \tag{1.15}$$

where $\mathcal{V}^* \subset \mathbb{R}^n$ is the space on which the zero dynamics of W is defined and which corresponds in $\mathcal{X}$ to the output-induced subspace $X \cap H_0$ of X.

We make extensive cross reference between the three frameworks of $\mathcal{P}, \mathcal{X}$, and $\mathcal{W}$; and there are some very good reasons for this. The geometric splitting subspace theory provides a very natural setting also for analyzing the algebraic Riccati inequality. In fact, several geometric results that are linked to such concepts as *splitting* and *internal subspace* have less obvious counterparts in the $\mathcal{P}$-setting and could easily have been overlooked had it not been for the interaction with the geometry of splitting subspaces.

2. Zero dynamics and splitting subspaces. It is well known by now that the poles of a spectral factor W can be expressed in terms of the shift $\{U_t\}$ and the corresponding splitting subspace X [16]. In fact, the compressed forward shift on X,

$$U_t(X) := E^X U_t \,|_X \quad \text{for} \quad t \geq 0 \tag{2.1}$$

(where E^X is the orthogonal projector onto X), is a strongly continuous and uniformly bounded semigroup so that

$$U_{t+\tau}(X) = U_t(X) U_\tau(X); \tag{2.2}$$

and therefore there is an operator $F : X \to X$ such that

$$U_t(X) = e^{Ft}. \tag{2.3}$$

Then it can be shown that

$$\{\text{poles of } W\} = \sigma(F), \tag{2.4}$$

i.e., the poles of W are precisely the eigenvalues of F. To see this, take $a \in \mathbb{R}^n$ and integrate (1.9) to obtain

$$a'x(t) = a'e^{At}x(0) + \int_0^t a'e^{A(t-s)}B\,dw(s), \tag{2.5}$$

the last term of which is orthogonal to X. Consequently, $E^X U_t a'x(0) = a'e^{At}x(0)$, i.e., $e^{Ft}a'x(0) = a'e^{At}x(0)$, showing that A' is in fact a matrix representation of F.

The basic question that we shall address in this section is the following. Is there an analogous geometric characterization of the *zeros* of W in terms of $\{U_t\}$ and X? As we shall see, the answer to this question is yes.

To simplify matters, in this paper we shall make the blanket assumption that the spectral density Φ is *coercive*, i.e., Φ has no zeros on the imaginary axis or at infinity. In particular this implies that

$$R := \Phi(\infty) > 0 \tag{2.6}$$

so that all minimal spectral factors W are of dimension $p \times m$ with $p \geq m$ and of full rank m almost everywhere in the complex plane and, hence, right invertible. Let

$$\left\{ \begin{array}{l} \dot{x} = Ax + Bu, \\ y = Cx + Du \end{array} \right. \tag{2.7}$$

be a minimal realization of W. Recall [7] that a complex number λ is called a *right zero* of W (or, equivalently, of the state-space system (2.7)) if, for some $\left[\begin{smallmatrix} x_0 \\ u_0 \end{smallmatrix}\right] \neq 0$, $u(t) = u_0 e^{\lambda t}$, $x(t) = x_0 e^{\lambda t}$ satisfy (2.7) while at the same time keeping the output $y(t)$ (identically) zero for all $t \in \mathbb{R}$.

It is well known and trivial to check that $\lambda \in \mathbb{C}$ is a right zero of W if and only if there are nonzero solutions of [2]

$$\begin{bmatrix} A - \lambda I & B \\ C & D \end{bmatrix} \begin{bmatrix} x_0 \\ u_0 \end{bmatrix} = 0. \tag{2.8}$$

More generally it can be shown [28] that constraining the dynamic variables x and u in (2.7) to yield an identically zero output $y \equiv 0$ requires confining, for all times $t \in \mathbb{R}$, the state $x(t)$ of the system (2.7) to a particular subspace $\mathcal{V}^* = \mathcal{V}^*(A, B, C, D) \subset \mathbb{R}^n$ called the *maximal output nulling subspace* of the system (2.7). The inputs u that keep $x(t)$ in $\mathcal{V}^*$ for all $t \in \mathbb{R}$ can be generated by suitable linear state feedback laws

$$u = Kx + Lv, \quad x \in \mathcal{V}^*, \tag{2.9}$$

where L is such that $\operatorname{Im} BL \subset \mathcal{V}^*$, $DL = 0$ and v is an unconstrained input function. Any K achieving this is called a *friend* of $\mathcal{V}^*$ [28]. It can be shown that $\mathcal{V}^*$ is actually the largest subspace $\mathcal{V} \subset \mathbb{R}^n$ for which there is a feedback matrix K such that

$$(A + BK)\mathcal{V} \subset \mathcal{V} \subset \ker(C + DK). \tag{2.10}$$

It follows from the discussion above that all x_0 solving (2.8) belong to $\mathcal{V}^*(A, B, C, D)$. Conversely, the subspace $\mathcal{V}^*$ can be associated to the right zeros of (2.7) in the following sense. If K is a friend of $\mathcal{V}^*$ and u is generated by a feedback law (2.9), all solutions of

$$\dot{x} = (A + BK)x + BLv, \quad x(0) \in \mathcal{V}^*, \tag{2.11}$$

belong to $\mathcal{V}^*$ for all times t and all inputs v. Pick λ_0 in the spectrum of $(A + BK)|_{\mathcal{V}^*}$, let x_0 be the corresponding eigenvector, and set $u_0 := Kx_0$. Then it is trivial to check that $\left[\begin{smallmatrix} x_0 \\ u_0 \end{smallmatrix}\right]$ solves (2.8) for $\lambda = \lambda_0$, and hence λ_0 is a right zero of (2.7). Those zeros that are reachable modes for the system (2.11) can actually be moved arbitrarily in the complex plane by a suitable choice of v. Those that are *not* reachable are fixed and are called *invariant zeros* of W. They are in fact even independent of the particular choice of the matrix K [28]. The *maximal reachability subspace* $\mathcal{R}^*(A, B, C, D)$ of W is precisely the maximal subspace of $\mathcal{V}^*$ that is reachable by inputs produced by feedback laws of the form (2.9). If $\mathcal{R}^*(A, B, C, D) = 0$, then all zeros are invariant.

In our setup the spectral factors W are most naturally viewed as operators acting on input functions from the left, and it is more appropriate to consider *left zeros* instead. These are defined simply as the right zeros of the transpose W'. Given a

[2] Note that there are infinitely many λ for which the matrix in (2.8) has a nonzero kernel when $p > m$, and hence there are infinitely many right zeros in this case.

minimal realization of W as in (2.7), a complex number λ is then a left zero of W if and only if there is a nonzero vector $\left[\begin{smallmatrix} z_0 \\ u_0 \end{smallmatrix}\right]$ that solves

$$\begin{bmatrix} A' - \lambda I & C' \\ B' & D' \end{bmatrix} \begin{bmatrix} z_0 \\ u_0 \end{bmatrix} = 0. \tag{2.12}$$

It is easy to show that the vectors z_0 solving (2.12) for some λ form a subspace $\mathcal{V} \subset \mathbb{R}^n$ that is (A', C')-invariant and output-nulling. In fact, $\mathcal{V}$ is a subspace of the *maximal output nulling subspace* $\mathcal{V}^* := \mathcal{V}^*(A', C', B', D')$ of the *dual* system

$$(\Sigma') \quad \begin{cases} \dot{z} = A'z + C'u, \\ v = B'z + D'u \end{cases} \tag{2.13}$$

corresponding to W'. We note that the maximal reachability subspace of Σ', i.e., the subspace $\mathcal{R}^*(A', C', B', D')$ is just the zero space, since W' is left invertible [12] (Theorem 3.36). In other words, the left zeros of W are all invariant.

Now, since $\mathcal{R}^*(A', C', B', D') = 0$, it can be shown that there is a friend K', whose restriction to $\mathcal{V}^*$ is unique, making $\mathcal{V}^*$ $(A' + C'K')$-invariant. The autonomous system

$$\dot{z}(t) = (A' + C'K')z(t), \qquad z(0) \in \mathcal{V}^*, \tag{2.14}$$

with state space $\mathcal{V}^*$, will be called the (left) *zero dynamics* of Σ (or of W) [4], [21]. The eigenvalues of the feedback matrix $(A' + C'K')|_{\mathcal{V}^*}$ are the (*left*) *zeros* of W. As we have pointed out above, all left zeros are invariant. Clearly the invariant zeros of W are the same from the left and from the right. There are, however, noninvariant right zeros of W that are not left zeros (since, in general, $\mathcal{R}^*(A, B, C, D) \neq 0$). From now on we shall only consider left zeros and left zero dynamics, and therefore we shall drop the attribute "left."

Note that the zero dynamics of W is naturally defined only modulo similarity, i.e., modulo coordinate transformations in the state space of minimal realizations (1.1) of W. The vector space $\mathcal{V}^* := \mathcal{V}^*(A', C', B', D')$ will be called the space of *zero directions* of W.

For later reference we shall now explicitly compute the zero dynamics of W for the special case under consideration. To this end, it is convenient to write the system (1.9) in standard form taking

$$\begin{bmatrix} B \\ D \end{bmatrix} = \begin{bmatrix} B_1 & B_2 \\ R^{1/2} & 0 \end{bmatrix}, \tag{2.15}$$

where $R = DD'$ and $R^{1/2}$ is the symmetric square root of R. This can be achieved by an orthogonal coordinate transformation in input space, which of course will not affect the zeros of the spectral factor W. Eliminating the noise dw_1 in

$$(\Sigma) \quad \begin{cases} dx = Axdt + B_1 dw_1 + B_2 dw_2, \\ dy = Cxdt + R^{1/2} dw_1 \end{cases} \tag{2.16}$$

produces a state representation

$$dx = \Gamma x dt + B_1 R^{-1/2} dy + B_2 dw_2 \tag{2.17}$$

in feedback form where Γ is the feedback matrix

$$\Gamma = A - B_1 R^{-1/2} C. \tag{2.18}$$

Let us return to the dual control system (2.13). Then, setting the output v equal to zero yields

$$\left\{\begin{array}{l} \dot{z} = A'z + C'u, \\ 0 = B_1'z + R^{1/2}u, \\ 0 = B_2'z \end{array}\right. \tag{2.19}$$

or, eliminating the control u,

$$\left\{\begin{array}{l} \dot{z} = \Gamma'z, \\ B_2'z = 0. \end{array}\right. \tag{2.20}$$

Consequently, the maximal output-nulling subspace $\mathcal{V}^*$ is precisely

$$\mathcal{V}^* = \langle \Gamma \mid B_2 \rangle^{\perp}, \tag{2.21}$$

i.e., the orthogonal complement of the reachability space

$$\langle \Gamma \mid B_2 \rangle = \operatorname{Im}(B_2, \Gamma B_2, \Gamma^2 B_2, \ldots) \tag{2.22}$$

in $\mathbb{R}^n$. Now, it follows from the discussion above that the invariant zeros of W are precisely the eigenvalues of $\Gamma'|_{\mathcal{V}^*}$, for the maximal reachability space $\mathcal{R}^*$ of the autonomous dynamics (2.20) is zero. Consequently, $\Gamma'|_{\mathcal{V}^*}$ is the generator of the zero dynamics of W. In particular

$$\{\text{zeros of } W\} = \sigma\{\Gamma'|_{\mathcal{V}^*}\}. \tag{2.23}$$

Next we turn to the stochastic version of this theory. For this we need the following definition.

DEFINITION 2.1. *Let X be a Markovian splitting subspace. A subspace $Y \subset X$ is called output induced if*

(i) $Y \subset H_0$;

(ii) $U_t Y \subset Y \vee H^+_{[0,t]}$ *for* $t \geq 0$,

where $H^+_{[0,t]}$ is the subspace spanned by the output dy on the finite interval $[0,t]$,, i.e.,

$$H^+_{[0,t]} = \text{closure}\,\{a'\,[y(\tau) - y(s)]\,|a \in \mathbb{R}^m, \tau, s \in [0,t]\,\};$$

(iii) $U_t Y \subset Y \vee H^-_{[t,0]}$ *for* $t \leq 0$,

where $H^-_{[t,0]}$ is spanned by the output on $[t,0]$.

The following proposition, the proof of which will be postponed to the appendix, establishes the fact that an output-induced subspace is actually a stochastic counterpart of an (A,B)-invariant subspace in geometric control theory.

PROPOSITION 2.1. *Let $Y \subset X \cap H_0$ be output-induced. Then*

$$FY \subset Y \vee \operatorname{Im} N \tag{2.24}$$

where the linear operators $F: X \to X$ and $N: \mathbb{R}^m \to X$ are defined by (2.3) *and*

$$Na = \lim_{h \downarrow 0} \frac{1}{h} E^X a'[y(h) - y(0)], \tag{2.25}$$

respectively.

As we have already noted above, F has the matrix representation A' in the basis in X consisting of the components of $x(0)$. Moreover, it was proven in [14] that

$$Cx(0) = \lim_{h\downarrow 0} \frac{1}{h} E^X[y(h) - y(0)] \tag{2.26}$$

and consequently $Na = a'Cx(0)$, i.e., N has the matrix representation C' in the basis $x(0)$. Therefore, condition (2.24) is equivalent to (A', C')-invariance of the representative of Y in the aforementioned coordinate system. To make this correspondence more precise we shall consider next the problem of finding the *maximal* output-induced subspace of a given minimal Markovian splitting subspace.

THEOREM 2.2. *Let X be a minimal Markovian splitting subspace. Then there is a maximal output-induced subspace of X, namely, $Y^* := X \cap H_0$. The subspace Y^* is maximal in the sense that $Y \subset Y^*$ for any other output-induced subspace Y of X.*

There is a close connection between the concept of maximal output-induced subspace of a minimal Markovian splitting subspace and the zero dynamics of the corresponding minimal spectral factor. This connection is best understood by regarding the realization (1.9).

LEMMA 2.3. *Let $X \in \mathcal{X}$, and let* (1.9) *be a corresponding minimal realization. Then*

$$X \cap H_0 = \{a'x(0) | \, a \in \mathcal{V}^*(A', C', B', D')\}.$$

Proof. First take $\xi \in X \cap H_0$. Then ξ has a representation $\xi = a'x(0)$ where $a \in \mathbb{R}^n$. We shall prove that $a \in \mathcal{V}^* := \mathcal{V}^*(A', C', B', D')$. We immediately see that

$$\xi = a'x(0) = \int_{-\infty}^{0} a'e^{-At}B\,dw(t). \tag{2.27}$$

On the other hand, since $\xi \in H_0$, there is a representation

$$\xi = \int_{-\infty}^{\infty} \hat{u}(i\omega)'\,d\hat{y}(i\omega), \tag{2.28}$$

where $\hat{u}$ is a vector function on the imaginary axis that is L_2 with respect to the matrix measure $\frac{1}{2\pi}\Phi(i\omega)d\omega$ and $d\hat{y}$ is the spectral measure [24] of the process dy, i.e.,

$$y(t) - y(s) = \int_{-\infty}^{\infty} \frac{e^{i\omega t} - e^{i\omega s}}{i\omega} d\hat{y}.$$

This spectral measure may be written

$$d\hat{y} = Wd\hat{w}$$

in terms of the spectral factor (1.1), the transfer function of (1.9), and the spectral measure $d\hat{w}$ of the generating noise dw of (1.9). Consequently,

$$\xi = \int_{-\infty}^{\infty} \hat{u}(i\omega)'W(i\omega)d\hat{w}(i\omega), \tag{2.29}$$

where $\hat{f} := W'\hat{u}$ is an L_2 function on the imaginary axis with inverse Fourier transform

$$f(t) = \int_{-\infty}^{t} B'e^{A'(t-s)}C'u(s)\,ds + D'u(t), \tag{2.30}$$

where u is the inverse Fourier transform of $\hat{u}$ in the L_2 sense. (To see that $\hat{u}$ is L_2 note that $\Phi(\infty)$ is nonsingular by assumption.) Then (2.29) may be written

$$\xi = \int_{-\infty}^{\infty} f(-t)'\, dw(t) \tag{2.31}$$

in the time domain [24], [15], and, in view of (2.27), we must have

$$f(t) = \begin{cases} B'e^{A't}a & \text{for } t \geq 0, \\ 0 & \text{for } t \leq 0. \end{cases} \tag{2.32}$$

Hence, if we set

$$v(t) := B'\left\{e^{A't}(-a) + \int_{-\infty}^{t} e^{A'(t-s)}C'u(s)\, ds\right\} + D'u(t) \tag{2.33}$$

$$= B'\left\{e^{A't}[-a + \bar{z}(0)] + \int_{0}^{t} e^{A'(t-s)}C'u(s)\, ds\right\} + D'u(t), \tag{2.34}$$

where

$$\bar{z}(0) = \int_{-\infty}^{0} e^{-A's}C'u(s)\, ds,$$

it is seen from (2.32) that $v(t) = 0$ for $t \geq 0$, and hence u is an output-nulling input for the dual control system

$$(\Sigma') \quad \begin{cases} \dot{z} = A'z + C'u, \\ v = B'z + D'u \end{cases} \tag{2.35}$$

initiated at $z(0) = -a + \bar{z}(0)$. Therefore $-a + \bar{z}(0) \in \mathcal{V}^*$. On the other hand, (2.30) and (2.32) show that the output of Σ' with control u and initial condition $z(-\infty) = 0$ is identically zero on the negative real axis. Therefore the corresponding state trajectory

$$\bar{z}(t) = \int_{-\infty}^{t} e^{A'(t-s)}C'u(s)\, ds$$

belongs to $\mathcal{V}^*$ for $t \leq 0$. Hence, in particular, $\bar{z}(0) \in \mathcal{V}^*$, and consequently $a \in \mathcal{V}^*$ as claimed.

To prove the converse statement, we first note that the coercivity of Φ ensures that $\Gamma'|_{\mathcal{V}^*}$ has no eigenvalues on the imaginary axis, since the zeros of a minimal spectral factor W are also zeros of the spectral density Φ. Therefore $\mathcal{V}^*$ can be decomposed into a direct sum

$$\mathcal{V}^* = \mathcal{V}^*_- \dotplus \mathcal{V}^*_+, \tag{2.36}$$

where $\mathcal{V}^*_-$ is the sum of the generalized eigenspaces corresponding to eigenvalues of $\Gamma'|_{\mathcal{V}^*}$ with negative real part and $\mathcal{V}^*_+$ is the corresponding subspace for eigenvalues with positive real parts. Both $\mathcal{V}^*_-$ and $\mathcal{V}^*_+$ are of course invariant for Γ'. We want to prove that, if $a \in \mathcal{V}^*$, then $a'x(0) \in X \cap H_0$. To this end, take $a \in \mathcal{V}^*$ and let $a = a_- + a_+$ where $a_- \in \mathcal{V}^*_-$ and $a_+ \in \mathcal{V}^*_+$. Since, in view of (2.21), $\mathcal{V}^* \perp \operatorname{Im} B_2$, (2.17) yields

$$d(a'x) = a'\Gamma x dt + a'B_1R^{-1/2}dy \tag{2.37}$$

for any $a \in \mathcal{V}^*$. Therefore, by choosing a basis in $\mathcal{V}^*$ consistent with the direct sum decomposition (2.36) , (2.37) produces two equations relative to $\mathcal{V}^*_-$ and $\mathcal{V}^*_+$, which by Γ-invariance can be integrated separately on the negative and positive time axis respectively. It then follows that

$$a'_- x(0) = \int_{-\infty}^{0} a'_- e^{-\Gamma t} B_1 R^{-1/2} dy(t) \quad \text{for} \quad a_- \in \mathcal{V}^*_- \tag{2.38}$$

and

$$a'_+ x(0) = \int_{0}^{\infty} a'_+ e^{-\Gamma t} B_1 R^{-1/2} dy(t) \quad \text{for} \quad a_+ \in \mathcal{V}^*_+, \tag{2.39}$$

and hence $a'_- x(0) \in X \cap H^-$ and $a'_+ x(0) \in X \cap H^+$ so that $a'x(0) \in X \cap H_0$, proving the lemma. □

Remark. Note that the basic idea of this construction is that $\mathcal{V}^*$ acts dually in the model (1.9) as a maximal "exogenous-noise-nulling" subspace in the sense that multiplying (1.9) by an $a \in \mathcal{V}^*$ removes the influence of the noninternal components of the input noise dw. An alternative and perhaps more elegant way of seeing this is to consider the adjoint control system

$$(\Sigma^*) \quad \left\{ \begin{array}{l} \dot{z} = -A'z + C'u, \\ v = -B'z + D'u \end{array} \right. \tag{2.40}$$

with transfer function $W^*(s) = W(-s)$, instead of the dual system Σ' defined by (2.13). Clearly Σ^* and Σ' have the same output-nulling subspaces $\mathcal{V}$ and, in particular, the same $\mathcal{V}^*$. (In fact, by a computation similar to the one given above for Σ', we see that the generator of the zero dynamics of Σ^* is $-\Gamma'|_{\mathcal{V}^*}$.) The study of linear functionals $a'x(0)$ of the state at time zero leads naturally to considering the adjoint system Σ^*. Given the stochastic system (1.9), differentiating the bilinear form $z'x$ yields

$$d(z'x) = z'dx + \dot{z}'xdt \tag{2.41}$$
$$= u'dy - v'dw, \tag{2.42}$$

showing that the exogenous noise is blocked out if $z(0) \in \mathcal{V}^*$, i.e., $v = 0$. Then

$$d(z'x) = u'dy$$

can be integrated to establish that $z(0)'x(0) \in X \cap H_0$.

The same idea is used in the following proof.

Proof of Theorem 2.2. Let $\xi \in X \cap H_0$. Then, by Lemma 2.3, $\xi = a'x(0)$ where $a \in \mathcal{V}^*$. Consequently, integrating (2.17) and noting that $\mathcal{V}^* \perp \mathrm{Im} B_2$, we obtain

$$a'x(t) = a'e^{\Gamma t}x(0) + \int_0^t a'e^{\Gamma(t-s)} B_1 R^{-1/2}\, dy(s). \tag{2.43}$$

Since $\mathcal{V}^*$ is Γ'-invariant, $e^{\Gamma' t} a \in \mathcal{V}^*$ and hence the first term in the sum (2.43) belongs to $X \cap H_0$ (Lemma 2.3). Consequently, $X \cap H_0$ satisfies the conditions of Definition 2.1 and is thus output-induced. Since all output-induced subspaces are contained in $X \cap H_0$, it must be maximal. □

The fact that the zero dynamics of W is autonomous is reflected in the following lemma, which will be proved in the appendix.

LEMMA 2.4. *Under the coercivity assumption above, $X \cap H^+_{[0,t]} = 0$ for $t \geq 0$ and $X \cap H^-_{[t,0]} = 0$ for $t \leq 0$ so that the vector sums are direct in* (ii) *and* (iii) *of Definition* 2.1.

In view of Lemma 2.4, an equivalent way of stating Theorem 2.2 is to say that

$$U_t \{X \cap H_0\} \subset X \cap H_0 + H^+_{[0,t]} \quad \text{for} \quad t \geq 0 \tag{2.44}$$

and

$$U_t \{X \cap H_0\} \subset X \cap H_0 + H^-_{[t,0]} \quad \text{for} \quad t \leq 0. \tag{2.45}$$

Note that the direct sum property in Lemma 2.4 is lost as $t \to \infty$, since H^- and H^+ in general have nontrivial intersections with $X \cap H_0$, namely, $X \cap H^-$ and $X \cap H^+$ respectively.

Now, in view of (2.44) and (2.45), there are *oblique* time-varying projectors

$$\pi_t : (X \cap H_0) + H^+_{[0,t]} \to X \cap H_0$$

and

$$\bar{\pi}_t : (X \cap H_0) + H^-_{[-t,0]} \to X \cap H_0,$$

the first being the projection onto $X \cap H_0$ parallel to $H^+_{[0,t]}$ and the second projection onto $X \cap H_0$ parallel to $H^-_{[-t,0]}$. The projectors play the role of feedback in geometric control theory in confining the motion of the state to the subspace $X \cap H_0$. Accordingly, we form the compressed shift operators $V_t(X)$ and $\bar{V}_t(X)$ on $X \cap H_0$ by the relations

$$V_t(X)\xi = \pi_t U_t \xi \tag{2.46}$$

and

$$\bar{V}_t(X)\xi = \bar{\pi}_t U_t^* \xi. \tag{2.47}$$

LEMMA 2.5. *The families $\{V_t(X);\ t \geq 0\}$ and $\{\bar{V}_t(X); t \geq 0\}$ of linear operators are strongly continuous semigroups on $X \cap H_0$.*

Proof. Let $\xi \in X \cap H_0$, and form

$$\begin{aligned} V_t(X)V_s(X) &= \pi_t U_t \pi_s U_s \xi && (2.48)\\ &= \pi_{t+s} U_t \pi_s U_s \xi && (2.49)\\ &= V_{t+s}(X)\xi - \pi_{t+s} U_t (1 - \pi_s) U_s \xi, && (2.50) \end{aligned}$$

where we have used the fact that $\pi_{t+s}|_{X \cap H_0 + H^+_{[0,t]}} = \pi_t$ for $s \geq 0$. But $(1 - \pi_s)U_s\xi \in H^+_{[0,t]}$, and hence

$$U_t(1 - \pi_s)U_s\xi \in H^+_{[0,t+s]};$$

therefore the last term in (2.50) equals zero, establishing the semigroup property for $\{V_t(X);\ t \geq 0\}$. To prove strong continuity, note that, if $t \leq T$, $V_t(X)\xi = \pi_t U_t \xi = \pi_T U_t \xi$, which tends to ξ as $t \to 0$. The rest follows from a symmetric argument. □

Consequently there are infinitesimal generators, i.e., operators $G, \bar{G} : X \cap H_0 \to X \cap H_0$ such that

$$V_t(X) = e^{Gt} \tag{2.51}$$

and

$$\bar{V}_t(X) = e^{\bar{G}t}. \tag{2.52}$$

LEMMA 2.6. *For each $t \geq 0$,*

$$\bar{V}_t(X) = V_t(X)^{-1}; \tag{2.53}$$

i.e., in particular,

$$\bar{G} = -G. \tag{2.54}$$

Proof. Let $\xi \in X \cap H_0$. Then

$$\begin{aligned} \bar{V}_t(X)V_t(X)\xi &= \bar{\pi}_t U_t^* \pi_t U_t \xi & (2.55)\\ &= \xi - \bar{\pi}_t U_t^*(1 - \pi_t)U_t\xi. & (2.56) \end{aligned}$$

Since $(1 - \pi_t)U_t\xi \in H^+_{[0,t]}$, we have

$$U_t^*(1 - \pi_t)U_t\xi \in H^-_{[-t,0]},$$

and therefore the last term of (2.56) is zero. □

Consequently, we may define $V_t(X)$ also for negative t. In fact, setting

$$V_t(X) = \bar{V}_{-t}(X)$$

is equivalent to defining $V_t(X)$ for all $t \in \mathbb{R}$ by means of (2.46) with $\pi_{-t} = \bar{\pi}_t$ for $t \leq 0$. Hence the family of operators $\{V_t(X);\ t \in \mathbb{R}\}$ is actually a *group.*

The following proposition characterizes the output-induced subspaces of X as the invariant subspaces for the group $\{V_t(X);\ t \in \mathbb{R}\}$.

PROPOSITION 2.7. *The output-induced subspaces of X are precisely the G-invariant subspaces of $X \cap H_0$.*

Proof. First suppose that $Y \subset X$ is output-induced. Then

$$U_tY \subset Y + H^+_{[0,t]} \quad \text{for} \quad t \geq 0, \tag{2.57}$$

so applying the projection π_t to both sides we see that $e^{Gt}Y \subset Y$. Conversely, suppose that $Y \subset X \cap H_0$ is e^{Gt}-invariant. From (2.44) we have that

$$U_tY \subset X \cap H_0 + H^+_{[0,t]} \quad \text{for} \quad t \geq 0. \tag{2.58}$$

We want to show that $X \cap H_0$ in (2.58) can be exchanged for Y so that (2.57) is obtained. However, this is obvious by applying the projector π_t to (2.58) and noting that, by assumption, $e^{Gt}Y \subset Y$. Trivially, the corresponding statement for $t \leq 0$ follows from (2.45) by an analogous argument. □

We shall identify two particularly important G-invariant subspaces of $X \cap H_0$, namely, the *past-output-induced* subspace $X \cap H^-$ and the the *future-output-induced* subspace $X \cap H^+$. In fact, suppose that $\xi \in X \cap H^-$ and $t \geq 0$. Then $U_t^* \xi \in H^-$ and

$$(1 - \bar{\pi}_t) U_t^* \xi \in H^-_{[-t,0]} \subset H^-,$$

and hence

$$e^{-Gt}\xi = \bar{V}_t(X \cap H_0)\xi = \bar{\pi}_t U_t^* \xi \in X \cap H^-,$$

because the range of $\bar{\pi}_t$ is contained in X. Therefore $X \cap H^-$ is G-invariant. A symmetric argument shows that $X \cap H^+$ is also G-invariant. Consequently, by Proposition 2.7, $X \cap H^-$ and $X \cap H^+$ are output-induced subspaces of X.

Coercivity also implies that $H^- \cap H^+ = 0$ [14] so that the sum

$$H_0 = H^- + H^+ \tag{2.59}$$

is direct. The following lemma states in particular that the maximal output-induced subspace can be represented as a direct sum of $X \cap H^-$ and $X \cap H^+$.

LEMMA 2.8. *Let H^-, H^+, H_0 be defined as in* §1, *and let X be a splitting subspace. Then*

$$X \cap H_0 = \left(X \cap H^-\right) + \left(X \cap H^+\right) \tag{2.60}$$

where the sum is direct.

For the proof let us first recall that a Markovian splitting subspace can be uniquely represented as the intersection

$$X = S \cap \bar{S} \tag{2.61}$$

of a pair $(S, \bar{S})$ of subspaces of the ambient subspace H that satisfy

$$S \supset H^- \quad \text{and} \quad \bar{S} \supset H^+, \tag{2.62}$$

the invariance properties

$$U_t^* S \subset S \quad \text{and} \quad U_t \bar{S} \subset \bar{S} \quad \text{for all} \quad t \geq 0, \tag{2.63}$$

and intersect perpendicularly in the sense that

$$H = S^\perp \oplus X \oplus \bar{S}^\perp, \tag{2.64}$$

where $S^\perp$ and $\bar{S}^\perp$ are the orthogonal complements in H of S and $\bar{S}$ respectively (see, e.g., [16]). We shall write $X \sim (S, \bar{S})$ to refer to this representation. The class $\mathcal{X}$ of minimal Markovian splitting subspaces consists precisely of the $X \sim \left(S, \bar{S}\right)$ that are *observable*, i.e.,

$$\bar{S} = H^+ \vee S^\perp, \tag{2.65}$$

and *constructible*, i.e.,

$$S = H^- \vee \bar{S}^\perp \tag{2.66}$$

(see [16]).

Proof of Lemma 2.8. Since $X \cap H^- \subset X \cap H_0$ and $X \cap H^+ \subset X \cap H_0$, it trivially holds that

$$X \cap H_0 \supset (X \cap H^-) \vee (X \cap H^+)\,. \tag{2.67}$$

Since $H_0 = H^- + H^+$ is a direct sum, so is that of (2.67). Hence it just remains to show that the converse inclusion holds. To this end suppose that $\lambda \in X \cap H_0$. Since $\lambda \in H_0 = H^- + H^+$, there are unique $\alpha \in H^-$ and $\beta \in H^+$ such that

$$\lambda = \alpha + \beta.$$

Then, since $\lambda \in X \subset \bar{S}$ and $\beta \in H^+ \subset \bar{S}$, we have $\alpha = \lambda - \beta \in \bar{S}$, and hence

$$\alpha \in \bar{S} \cap H^- = \bar{S} \cap S \cap H^- = X \cap H^-$$

Then $\beta = \lambda - \alpha \in X$, i.e., $\beta \in X \cap H^+$. This completes the proof of the lemma.
□

Remark. The fact that $X \cap H^-$ and $X \cap H^+$ are output-induced can be seen from first principles using Lemma 2.8. In fact, from (2.61), we see that $X \cap H^- = \bar{S} \cap H^-$, and hence

$$U_t\left\{X \cap H^-\right\} \subset \bar{S} \cap \left(H^- + H^+_{[0,t]}\right) \tag{2.68}$$

$$= \bar{S} \cap H^- + H^+_{[0,t]}. \tag{2.69}$$

Here the first inclusion follows from the U_t-invariance (2.63) of $\bar{S}$ and the second equality from Lemma 2.8, noting that $\bar{S} \sim (H, \bar{S})$ is a splitting subspace and $\bar{S} \supset H^+_{[0,t]}$. This shows that $X \cap H^-$ satisfies condition (ii) of Definition 2.1. A symmetric argument proves condition (iii), while condition (i) is trivially satisfied. Hence $X \cap H^-$ is output-induced. In the same way we show that $X \cap H^+$ is output-induced.

The following theorem is one of the main results of this paper, tying together the geometry of minimal Markovian splitting subspaces to the zero dynamics of minimal spectral factors.

THEOREM 2.9. *Let X be a minimal Markovian splitting subspace, and let W be the corresponding spectral factor. Then the group $\{V_t(X);\ t \in \mathbb{R}\}$ acting on the maximal output-induced subspace $X \cap H_0$, of X, is isomorphic to the zero dynamics* (2.14) *of W in the sense that the linear bijective map $T : \mathcal{V}^*(A', C', B', D') \to X \cap H_0$, defined by $Ta = a'x(0)$, makes the following diagram commutative:*

$$\begin{tikzcd} X \cap H_O \arrow[r, "V_t(X)"] & X \cap H_0 \\ \mathcal{V}^* \arrow[u, "T"] \arrow[r, "e^{(A'+C'K')t}"] & \mathcal{V}^* \arrow[u, "T"'] \end{tikzcd}$$

In particular,

$$\{\text{zeros of } W\} = \sigma(G), \tag{2.70}$$

where $\sigma(G)$ is the spectrum of the infinitesimal generator of the group $\{V_t(X);\ t \in \mathbb{R}\}$. The restricted groups $V_t^-(X) := V_t(X)|_{X \cap H^-}$ and $V_t^+(X) := V_t(X)|_{X \cap H^+}$, $t \in \mathbb{R}$, describe the asymptotically stable and antistable zero dynamics of W, the respective generators

$$G_s = G|_{X \cap H^-} \quad \text{and} \quad G_u = G|_{X \cap H^+}$$

having spectra $\sigma(G_s)$ and $\sigma(G_u)$ coinciding with the zeros of W with respectively negative and positive real parts.

Hence, in particular, $\dim(X \cap H_0)$, $\dim(X \cap H^-)$, and $\dim(X \cap H^+)$ are respectively the total number of zeros of W, the number zeros in the open left half plane (*stable zeros*), and the number of zeros in the open right half plane (*antistable zeros*). (The last statement is actually a splitting subspace version of Theorem 4.1 in [11] (see also [1]) as we shall see in §4 upon introducing state covariances.) If X is internal and $\dim X = n$, then there are exactly n zeros. If $X \cap H_0 = 0$, there are no zeros.

We shall call G the *generator of the zero dynamics* of X. Since in this paper we consider the special case when R is nonsingular, we may, as we have already pointed out, write the zero dynamics (2.14) as

$$\dot{z} = \Gamma' z, \quad z \in \mathcal{V}^*, \tag{2.71}$$

where Γ is defined by (2.18). By Lemma 2.3, the map T in the commutative diagram of Theorem 2.9 assigns the value $a'x(0) \in X \cap H_0$ to each $a \in \mathcal{V}^*$, i.e.,

$$T : a \to a'x(0). \tag{2.72}$$

Proof. Take $a \in \mathcal{V}^*$ so that $a'x(0) \in X \cap H_0$. Then (2.43) holds. From this sum with the first term in $X \cap H_0$ and the second in $H^+_{[0,t]}$ for $t \geq 0$, we obtain

$$\pi_t U_t a'x(0) = \pi_t a'x(t) = a'e^{\Gamma t}x(0)$$

for $t \geq 0$, i.e.,

$$e^{Gt}a'x(0) = a'e^{\Gamma t}x(0).$$

Hence $G\,[a'x(0)] = a'\Gamma x(0)$, i.e., $GTa = T\Gamma' a$, proving the similarity

$$G = T\Gamma'|_{\mathcal{V}^*}T^{-1}. \tag{2.73}$$

Moreover, note that (2.38) and (2.39) imply that

$$T\mathcal{V}^*_- \subset X \cap H^- \quad \text{and} \quad T\mathcal{V}^*_+ \subset X \cap H^+.$$

However, since, by Lemma 2.8 and (2.36) the two vector sums

$$T\mathcal{V}^* = T\mathcal{V}^*_- + T\mathcal{V}^*_+$$

and

$$X \cap H_0 = X \cap H^- + X \cap H^+$$

are direct and $T\mathcal{V}^* = X \cap H_0$ (Lemma 2.3), it must hold that

$$T\mathcal{V}^*_- = X \cap H^- \quad \text{and} \quad T\mathcal{V}^*_+ = X \cap H^+. \tag{2.74}$$

Then, by retracing the first part of the proof with $\mathcal{V}^*$ replaced by $\mathcal{V}^*_-$ and $\mathcal{V}^*_+$, we establish the similarity relations

$$G_s = T\Gamma'|_{\mathcal{V}^*_-}T^{-1} \quad \text{and} \quad G_u = T\Gamma'|_{\mathcal{V}^*_+}T^{-1},$$

which clearly shows that G_s is stable and G_u is antistable. This completes the proof of the theorem. □

Next we shall derive some representation formulas for the restrictions of the group $\{V_t(X);\ t \in \mathbb{R}\}$ to the complementary invariant subspaces $X \cap H^-$ and $X \cap H^+$. These relations are connected to the generalization to the Riccati inequality of certain projection results concerning the algebraic Riccati equation due to Willems [27]. This will be discussed in §5.

Because of the direct sum decomposition (2.59), any $\eta \in H_0$ has a unique decomposition

$$\eta = \pi_- \eta + \pi_+ \eta \tag{2.75}$$

where $\pi_- : H_0 \to H^-$ is the projection on H^- along H^+ and $\pi_+ : H_0 \to H^+$ is the projection on H^+ along H^-.

LEMMA 2.10. *Let $t \geq 0$. Then if $\xi \in X \cap H^-$, we have $\pi_- U_t \xi \in X \cap H^-$; and, dually, if $\xi \in X \cap H^+ m$ it follows that $\pi_+ U_t^* \xi \in X \cap H^+$. Moreover, the restrictions of $V_t(X)$ to the complementary invariant subspaces $X \cap H^-$ and $X \cap H^+$ coincide with the above compressed shifts $\pi_- U_t : X \cap H^- \to X \cap H^-$ and $\pi_+ U_t^* : X \cap H^+ \to X \cap H^+$ respectively, i.e.,*

$$V_t^-(X) := V_t(X)|_{X \cap H^-} = \pi_- U_t\, |_{X \cap H^-}$$

and

$$V_{-t}^+(X) := V_{-t}(X)|_{X \cap H^+} = \pi_+ U_t^*\, |_{X \cap H^+}.$$

Proof. Let $t \geq 0$, and take $\xi \in X \cap H^-$. Since $X \cap H^-$ is output-induced (see, e.g., the remark before Theorem 2.9),

$$U_t \xi \in X \cap H^- + H^+_{[0,t]}.$$

Therefore, since $X \cap H^- \subset H^-$ and $H^+_{[0,t]} \subset H^+$, we have

$$\pi_- U_t \xi = \pi_t U_t \xi = V_t(X) \xi.$$

The $(\pi_- U_t)$-invariance of $X \cap H^-$ now follows from the $V_t(X)$-invariance. A symmetric result yields the corresponding result for $X \cap H^+$. □

3. Zeros and ordering. In this section we shall study the zero structure of the family of all minimal (analytic) spectral factors by using a partial ordering of the family $\mathcal{X}$ of all minimal Markovian splitting subspaces that are defined in some common probabilistic setting. Such a setting can be described by a sufficiently large common Hilbert space $\hat{H}$ containing H_0. It can be shown [16, §§5.2 and 5.3] that it suffices to take $\hat{H}$ to be of the form

$$\hat{H} = H_0 \oplus H\,(d\eta)\,,$$

where $d\eta$ is some n-dimensional Wiener process independent of dy and $H(d\eta)$ is the space generated by the increments of the components of η. The Hilbert space $\hat{H}$ is endowed with a shift $\{\hat{U}_t; t \in \mathbb{R}\}$, namely, the one induced by $(dy, d\eta)$; and the ambient space of each minimal X in this setting is a doubly invariant subspace of $\hat{H}$ containing H_0. The shift $\{U_t\}$ corresponding to $X \in \mathcal{X}$ is just the restriction of $\{\hat{U}_t\}$ to its ambient space H. Recall that the ambient space H has a representation $H(dw)$, where the Wiener process dw may be identified with the driving noise of a minimal stochastic realization (1.9) corresponding to X.

In [16] we introduced a partial order of $\mathcal{X}$ defined as follows. Given two minimal Markovian splitting subspaces, X_1 and X_2, we say that $X_1 \leq X_2$ if

$$||E^{X_1}\lambda|| \leq ||E^{X_2}\lambda|| \quad \text{for all } \lambda \in H^+$$

or, equivalently,

$$||E^{X_2}\lambda|| \leq ||E^{X_1}\lambda|| \quad \text{for all } \lambda \in H^-.$$

With the above choice of Hilbert space $\hat{H}$, it can be shown that $\leq$ is a bona fide partial ordering relation of $\mathcal{X}$; i.e., in particular, $X_1 \leq X_2$ and $X_2 \leq X_1$ imply that $X_1 = X_2$. Moreover, $\mathcal{X}$ has a maximal and a minimal element, X_+ and X_-, in this ordering, i.e.,

$$X_- \leq X \leq X_+ \tag{3.1}$$

for each $X \in \mathcal{X}$, where $X_- := E^{H^-}H^+$ and $X_+ := E^{H^+}H^-$ are respectively the forward and the backward predictor spaces. Clearly both X_- and X_+ belong to $\mathcal{X}_0$.

It can be seen from (3.1) that any $X \in \mathcal{X}$ is bounded from below and from above by elements in $\mathcal{X}_0$, namely, by X_- and X_+ respectively. In this context, a relevant question is whether these internal bounds could be tightened. In [16] it was shown that, for each $X \in \mathcal{X}$, there are unique $X_{0-}, X_{0+} \in \mathcal{X}_0$ so that

$$X_1 \leq X_{0-} \leq X \leq X_{0+} \leq X_2$$

for all $X_1, X_2 \in \mathcal{X}_0$ such that $X_1 \leq X \leq X_2$. In other words

$$X_{0-} = \max\{X_0 \in \mathcal{X}_0 \mid X_0 \leq X\},$$

$$X_{0+} = \min\{X_0 \in \mathcal{X}_0 \mid X \leq X_0\}$$

are unique, and we call them the *tightest internal bounds* of X.

At several instances that follow we shall consider a restriction of some linear operator to an invariant subspace. Whenever such a restriction occurs, the invariance is automatically implied and will not be stated explicitly.

LEMMA 3.1. *Let* $X_1, X_2 \in \mathcal{X}$, *and suppose that* $X_1 \leq X_2$. *Then*

(i) $X_1 \cap H^+ \subset X_2 \cap H^+$ and $X_2 \cap H^- \subset X_1 \cap H^-$;

(ii) $V_t^-(X_1)|_{X_2 \cap H^-} = V_t^-(X_2), \quad t \in \mathbb{R}$;

(iii) $V_t^+(X_2)|_{X_1 \cap H^+} = V_t^+(X_1), \quad t \in \mathbb{R}$.

Proof. (i) Recall that if $X \sim (S, \bar{S})$ is a minimal Markovian splitting subspace then the corresponding tightest lower internal bound $X_{0-} \sim (S_{0-}, \bar{S}_{0-})$ has the property that $S_{0-} = S \cap H_0$ (Theorem 6.11 in [16]). Now, if $X_1 \leq X_2$, then, with self-explanatory notation, $(X_1)_{0-} \leq X_1 \leq X_2$, and consequently $(X_1)_{0-} \leq (X_2)_{0-}$ or, equivalently, $S_1 \cap H_0 \subset S_2 \cap H_0$, which implies that $S_1 \cap H^+ \subset S_2 \cap H^+$. But, in view of (2.61) and (2.62), this is equivalent to $X_1 \cap H^+ \subset X_2 \cap H^+$. A symmetric argument yields $X_2 \cap H^- \subset X_1 \cap H^-$.

(ii) First take $t \geq 0$. Then, by Lemma 2.10,

$$V_t^-(X) = \pi_- U_t|_{X \cap H^-}$$

for any $X \in \mathcal{X}$, where $\pi_- : H_0 \to H^-$ is the oblique projection parallel to H^+. Therefore, since $X_2 \cap H^- \subset X_1 \cap H^-$ and these spaces are both invariant for the compressed shift $\pi_- U_t$ (Lemma 2.10),

$$V_t^-(X_1)|_{X_2 \cap H^-} = V_t^-(X_2) \tag{3.2}$$

for $t \geq 0$. However, for any $X \in \mathcal{X}$,

$$V_t^-(X) = V_t(X)|_{X \cap H^-}$$

for all $t \in \mathbb{R}$, and hence (3.2) may be written

$$V_t(X_1)|_{X_2 \cap H^-} = V_t(X_2)|_{X_2 \cap H^-} \quad \text{for} \quad t \geq 0,$$

which is a statement about groups and consequently holds for all $t \in \mathbb{R}$.

(iii) The proof follows from a symmetric argument to that used to prove (ii), first proving the the statement for $t \leq 0$ and then invoking the group property. □

COROLLARY 3.2. *Let $X \in \mathcal{X}$. Then*

$$V_t^-(X) = V_t^-(X_-)|_{X \cap H^-} = V_t(X_-)|_{X \cap H^-} \tag{3.3}$$

and

$$V_t^+(X) = V_t^+(X_+)|_{X \cap H^+} = V_t(X_+)|_{X \cap H^+}. \tag{3.4}$$

Proof. To prove (3.3) just take $X_1 = X_-$ and $X_2 = X$ in Lemma 3.1 and then observe that $V_t^-(X_-) = V_t(X_-)$. A symmetric argument yields (3.4). □

We see from this lemma that if W, W_-, and W_+ are the spectral factors of X, X_-, and X_+ respectively, then the stable zeros W are also zeros of W_- and the antistable zeros of W are zeros of W_+. We also see that W_- is the minimum phase spectral factor, all its zeros being stable, and that W_+ is the maximum phase spectral factor with only antistable zeros.

Lemma 3.1 with Corollary 3.2 has a number of other important consequences that will be discussed later. Before turning to this, however, we shall complete the analysis of the relation between subspace inclusion of the type exhibited in statement (i) of Lemma 3.1.

LEMMA 3.3. *Let $X_1, X_2 \in \mathcal{X}_0$. Then, for each $X \in \mathcal{X}$,*

(i) $X_1 \leq X \Longleftrightarrow X_1 \cap H^+ \subset X \cap H^+$,

(ii) $X \leq X_2 \Longleftrightarrow X_2 \cap H^- \subset X \cap H^-$.

Moreover, $X_1 = X_{0-}$ if and only if $X_1 \cap H^+ = X \cap H^+$ and $X_2 = X_{0+}$ if and only if $X_2 \cap H^- = X \cap H^-$.

Proof. We begin by proving (i). In view of Lemma 3.1, it remains to prove that $X_1 \cap H^+ \subset X \cap H^+$ implies that $X_1 \leq X$, which, by Theorem 6.8(ii) in [16], is equivalent to $S_1 \subset S$. This in turn is certainly implied by $S_1 \subset S \cap H_0$.

Now, for any splitting subspace $X \sim (S, \bar{S})$, S is itself a splitting subspace, namely, $S \sim (S, H)$; and consequently Lemma 2.8 implies that

$$S \cap H_0 = H^- + X \cap H^+, \tag{3.5}$$

because, by (2.61) and (2.62), $S \cap H^- = H^-$ and $S \cap H^+ = S \cap \bar{S} \cap H^+ = X \cap H^+$.

Then, by (3.5), $X_1 \cap H^+ \subset X \cap H^+$ implies that $S_1 = S_1 \cap H_0 \subset S \cap H_0$, proving (i). A completely symmetric argument yields (ii). By Theorem 6.11 in [16], $X_1 = X_{0-}$ is equivalent to $S_1 = S \cap H_0$. This implies that $S_1 \cap H^+ = S \cap H^+$, i.e.,

$$X_1 \cap H^+ = X \cap H^+. \tag{3.6}$$

On the other hand, there is only one $X_1 \in \mathcal{X}_0$ satisfying (3.6), because (3.6) and

$$S_1 = H^- + X_1 \cap H^+$$

determine S_1 uniquely and for minimal Markovian splitting subspaces there is a one-to-one correspondence between X and S as can be seen from (2.65). Hence we have shown that (3.6) is equivalent to $X_1 = X_{0-}$. In the same way we show that

$$X_2 \cap H^- = X \cap H^-$$

is equivalent to $X_2 = X_{0+}$. □

THEOREM 3.4. *Let $X_1, X_2 \in \mathcal{X}_0$, and suppose $X_1 \le X_2$. Then:*

(i) *For each $X \in \mathcal{X}$,*

$$X_1 \le X \le X_2 \Longleftrightarrow X_1 \cap X_2 \subset X.$$

Moreover, $X_1 = X_{0-}$ if and only if $X_1 \cap X_2 = X \cap X_2$ and $X_2 = X_{0+}$ if and only if $X_1 \cap X_2 = X \cap X_1$.

(ii) *If $X_1 \cap X_2 \subset X$, then $X_1 \cap X_2$ is a $V_t(X)$-invariant subspace for each $t \in \mathbb{R}$, i.e.,*

$$G[X_1 \cap X_2] \subset X_1 \cap X_2. \tag{3.7}$$

Conversely, any G-invariant subspace $Z \subset X \cap H_0$ takes the form $Z = X_1 \cap X_2$ for some unique $X_1, X_2 \in \mathcal{X}_0$ such that $X_1 \le X \le X_2$.

The proof of this theorem is rather long and technical. For this reason we shall first give some interpretations of the results stated so far and postpone the proof of Theorem 3.4 to the end of the section.

COROLLARY 3.5. *Let at least one of $X_1, X_2 \in \mathcal{X}$ be internal, and suppose that $X_1 \le X_2$. Then*

$$V_t(X_1)|_{X_1 \cap X_2} = V_t(X_2)|_{X_1 \cap X_2} \tag{3.8}$$

for all $t \in \mathbb{R}$.

Proof. We want to prove that, for any $\lambda \in X_1 \cap X_2$,

$$V_t(X_1)\xi = V_t(X_2)\xi$$

for all $t \in \mathbb{R}$. To this end, first suppose that $t \ge 0$ and set $\xi_i := V_t(X_i)$, $i = 1, 2$. Then $\xi_i = \pi_t^{(i)} U_t \lambda$, where, for each $i = 1, 2$,

$$\pi_t^{(i)} : X_i \cap H_0 + H^+_{[0,t]} \to X_i \cap H_0$$

is the oblique projector onto $X_i \cap H_0$ parallel to $H^+_{[0,t]}$. Hence there are $\eta_1, \eta_2 \in H^+_{[0,t]}$ such that

$$U_t \lambda = \xi_1 + \eta_1 = \xi_2 + \eta_2.$$

Now, applying the invariance result of Theorem 3.4 twice, first taking $X = X_1$ and then $X = X_2$, we see that both ξ_1 and ξ_2 must belong to $X_1 \cap X_2$. But

$$X_1 \cap X_2 + H^+_{[0,t]}$$

is a direct sum (Lemma 2.3); and hence we must have $\xi_1 = \xi_2$ (and $\eta_1 = \eta_2$), establishing (3.8) for $t \geq 0$. Because of the group property, (3.8) actually holds for all $t \in \mathbb{R}$. □

Recalling the characterization of Proposition 2.7 of output-induced subspaces of $X \in \mathcal{X}$, we immediately have the following important corollary of Theorem 3.4.

COROLLARY 3.6. *The output-induced subspaces $Y \subset X \in \mathcal{X}$ are precisely the subspaces of the form $Y = X_1 \cap X_2$ where $X_1, X_2 \in \mathcal{X}_0$ are internal bounds of X, i.e., $X_1 \leq X \leq X_2$.*

As an illustration of Corollary 3.6 we shall give representations of the output-induced subspaces $X \cap H_0$, $X \cap H^-$, and $X \cap H^+$ as intersections of internal minimal Markovian splitting subspaces. As we have already seen, these output-induced subspaces are of special importance in the classification of the zero structure of minimal spectral factors.

PROPOSITION 3.7. *Let $X \in \mathcal{X}$ have tightest internal bounds X_{0-} and X_{0+}. Then*

(i) $X \cap H^- = X \cap X_- = X_{0+} \cap X_-$,

(ii) $X \cap H^+ = X \cap X_+ = X_{0-} \cap X_+$,

(iii) $X \cap H_0 = X \cap X_{0-} = X \cap X_{0+} = X_{0-} \cap X_{0+}$.

Proof. In view of the last statement of Theorem 3.4(i), it only remains to prove that

$$X \cap H^- = X \cap X_-, \tag{3.9}$$

$$X \cap H^+ = X \cap X_+, \tag{3.10}$$

and

$$X \cap H_0 = X_{0-} \cap X_{0+}. \tag{3.11}$$

Taking $X_1 = X_-$ and $X_2 = X$ in Lemma 3.1(i) and recalling that $X_- \subset H^-$, we see that $X \cap H^- \subset X_- \cap H^- \subset X_-$ and, hence, $X \cap H^- \subset X \cap X_-$. Trivially, $X_- \subset H^-$ also implies that $X \cap X_- \subset X \cap H^-$, and hence (3.9) follows. Relation (3.10) follows by symmetry. To prove (3.11), let $X \sim (S, \bar{S})$. Then, by Theorem 6.11 in [16], $S_{0-} = S \cap H_0$ and $\bar{S}_{0+} = \bar{S} \cap H_0$. Hence

$$X_{0-} \cap X_{0+} = S_{0-} \cap \bar{S}_{0+} = S \cap \bar{S} \cap H_0 = X \cap H_0$$

because $X_{0-} \leq X_{0+}$ and hence $S_{0-} \subset S_{0+}$ and $\bar{S}_{0+} \subset \bar{S}_{0-}$. □

Recall that the group $\{V_t(X)\}$ acting on the maximal output-induced subspace $X \cap H_0$ can be identified with the *zero dynamics* of the minimal spectral factor W corresponding to X because of the isomorphism of Theorem 2.9. Similarly the groups $\{V_t^-(X)\}$ and $\{V_t^+(X)\}$ on $X \cap H^-$ and $X \cap H^+$ respectively can be identified with the *stable*, respectively, the *antistable*, *zero dynamics* of W. The partial ordering of minimal Markovian splitting subspaces induces a partial ordering of the stable and antistable zero dynamics of the corresponding spectral factors. We shall say that $\{V_t^-(X_1)\}$ acting on $X_1 \cap H^-$ is a *restriction* of $\{V_t^-(X_2)\}$ acting on $X_2 \cap H^-$ if

$$X_1 \cap H^- \subset X_2 \cap H^-$$

and

$$V_t^-(X_1) = V_t^-(X_2)|_{X_1 \cap H^-}.$$

In the same way we can define restrictions of antistable zero dynamics. Clearly restriction is a partial-order relation.

THEOREM 3.8. *Let $X_1, X_2 \in \mathcal{X}$ with at least one of them be internal, and let W_1 and W_2 be the corresponding minimal spectral factors. Then if $X_1 \leq X_2$:*

(i) *The stable zero dynamics of W_2 is a restriction of the stable zero dynamics W_1. In particular, all stable zeros of W_2 are zeros of W_1.*

(ii) *The antistable zero dynamics of W_1 is a restriction of the antistable zero dynamics W_2. In particular, all antistable zeros of W_1 are zeros of W_2.*

(iii) *The zero dynamics of W_1 and W_2 coincide on the intersection $X_1 \cap X_2$ (i.e., a relation such as* (3.8) *holds).*

Proof. Statements (i) and (ii) are just restatements of (ii) and (iii) of Lemma 3.1, while statement (iii) is a reformulation of Corollary 3.5. □

COROLLARY 3.9. *Let X_{0-} and X_{0+} be the tightest internal bounds of $X \in \mathcal{X}$, and let W_{0-}, W_{0+}, and W be the corresponding minimal spectral factors. Then the zeros of W are precisely the common zeros of W_{0-} and W_{0+}.*

Proof. This follows immediately from Proposition 3.7(iii) and Theorem 3.8(iii). □

From Corollary 3.9 we see that if X_- and X_+ are the tightest internal bounds of X, which in fact is the "generic" situation, then the corresponding spectral factor has no zeros. In fact, W_- and W_+ have no common zero. The other extreme is the situation when X is internal so that $X_{0-} = X = X_{0+}$. Then W has n zeros.

The following corollary of Theorem 3.4 is a splitting-subspace version of an invariance result, due to Willems [27], formulated in the context of the algebraic Riccati equation. It will be used in §5.

COROLLARY 3.10. *Let G_+ be the zero generator of X_+. Then there is a one-to-one correspondence between G_+-invariant subspaces $Z \subset X_+$ and $X \in \mathcal{X}_0$ under which $Z = X \cap X_+$ and $X \sim (S, \bar{S})$ where*

$$S = H^- + Z \quad \text{and} \quad \bar{S} = H^+ \vee S^\perp.$$

Similarly, if G_- is the zero generator of X_-, there is a one-to-one correspondence between G_--invariant subspaces $Z \subset X_-$ and $X \in \mathcal{X}_0$ under which $Z = X \cap X_-$ and $X \sim (S, \bar{S})$ where

$$\bar{S} = H^+ + Z \quad \text{and} \quad S = H^+ \vee \bar{S}^\perp.$$

Proof of Theorem 3.4(i). ($\Rightarrow$) We first prove that if $X_1 \leq X_2$ and X_1, X_2 are internal, then

$$X_1 \cap X_2 = (X_1 \cap X_2 \cap H^-) + (X_1 \cap X_2 \cap H^+). \tag{3.12}$$

The inclusion $\supset$ is trivial, and we use the procedure of the proof of Lemma 2.8 to prove the converse. To this end, take $\lambda \in X_1 \cap X_2$. Then, by Lemma 2.8,

$$\lambda = X_2 \cap \left[(X_1 \cap H^-) + (X_1 \cap H^+)\right].$$

Set $\lambda = \alpha + \beta$ where $\alpha \in X_1 \cap H^-$ and $\beta \in X_1 \cap H^+$. But since $S_1 \subset S_2$ (see proof of Lemma 3.3),

$$X_1 \cap H^+ = S_1 \cap H^+ \subset S_2 \cap H^+ = X_2 \cap H^+ \subset X_2,$$

and therefore $\beta \in X_2$. Hence $\alpha = \lambda - \beta \in X_2$ so that $\alpha \in X_1 \cap X_2 \cap H^-$ and $\beta \in X_1 \cap X_2 \cap H^+$, as required. This proves (3.12). Now if $X_1 \leq X \leq X_2$, then by Lemma 3.3, $X_2 \cap H^- \subset X \cap H^-$, and therefore

$$X_1 \cap X_2 \cap H^- \subset X_1 \cap X \cap H^- = \bar{S}_1 \cap \bar{S} \cap H^-,$$

where we also have used (2.61) and (2.62). But

$$\bar{S} \cap H^- \subset \bar{S} \cap H_0 = \bar{S}_{0+}$$

by Theorem 6.11 in [16], and since $X_1 \leq X_{0+}$, it follows that $\bar{S}_{0+} \subset \bar{S}_1$. Hence

$$X_1 \cap X_2 \cap H^- \subset \bar{S} \cap H^- = X \cap H^-.$$

In the same way we show that

$$X_1 \cap X_2 \cap H^+ \subset X \cap H^+,$$

and therefore (3.12) and Lemma 2.8 imply that

$$X_1 \cap X_2 \subset X \cap H_0 \subset X.$$

($\Leftarrow$) Next suppose that $X_1 \cap X_2 \subset X$. Then

$$X_1 \cap X_2 \cap H^+ \subset X \cap H^+.$$

But $X_1 \cap X_2 \cap H^+ = S_1 \cap S_2 \cap H^+$, which in view of the fact that $X_1 \leq X_2$ and hence $S_1 \subset S_2$ (see, e.g., (3.5) and Lemma 3.3) is the same as $S_1 \cap H^+$. Since $S_1 \cap H^+ = X_1 \cap H^+$, we have

$$X_1 \cap H^+ \subset X \cap H^+,$$

which, by Lemma 3.3, is equivalent to $X_1 \leq X$. In the same way we show that $X \leq X_2$.

We turn next to the second statement of the theorem, concerning tight internal bounds. Since $X_1 \leq X_2$ and X_1 and X_2 are internal, $S_1 \subset S_2$ and $\bar{S}_2 \subset \bar{S}_1$ (Theorem 6.8 in [16]). Hence, in view of (2.61),

$$X_1 \cap X_2 = S_1 \cap \bar{S}_2.$$

Now $S_1 = S \cap H_0$ if and only if $X_1 = X_{0-}$ (Theorem 6.11 in [16]), in which case

$$X_1 \cap X_2 = S \cap \bar{S}_2 = X \cap \bar{S}_2.$$

But since $X_1 \cap X_2 \subset S_2$, this is the same as

$$X_1 \cap X_2 = X \cap \bar{S}_2 \cap S_2 = X \cap X_2.$$

The rest follows analogously. □

Proof of Theorem 3.4(ii). First suppose that $\xi \in X_1 \cap X_2 \subset X$, and let $t \geq 0$. Then, for $i = 1, 2$, $U_t\xi \in \bar{S}_i$; and therefore, since

$$(1 - \pi_t)U_t\xi \in H^+_{[0,t]} \subset \bar{S}_i$$

we have $\pi_t U_t \xi \in \bar{S}_i$, i.e.,

$$V_t(X \cap H_0)\xi \in \bar{S}_i \quad \text{for} \quad i = 1, 2. \tag{3.13}$$

A symmetric argument yields

$$\bar{V}_t(X \cap H_0)\xi \in S_i \quad \text{for} \quad i = 1, 2. \tag{3.14}$$

Now from (3.13) and (3.14) we have $G\xi \in \bar{S}_1 \cap \bar{S}_2$ and $\bar{G}\xi \in S_1 \cap S_2$. But the group property of Theorem 2.9 implies that $\bar{G} = -G$, so therefore

$$G\xi \in S_1 \cap S_2 \cap \bar{S}_1 \cap \bar{S}_2 = X_1 \cap X_2,$$

proving the invariance property (3.7).

Finally, we prove the converse statement on G-invariance. Thus, suppose that $Z \subset X \cap H_0$ is G-invariant. Then in view of the decomposition (2.60) of Lemma 2.8 and the fact that both $X \cap H^-$ and $X \cap H^+$ are G-invariant, there is a decomposition

$$Z = Z_s + Z_u \tag{3.15}$$

such that $Z_s \subset X \cap H^-$ is G_s-invariant and $Z_u \subset X \cap H^+$ is G_u-invariant (Theorem 2.9).

We show first that there is a one-to-one correspondence between G_u-invariant subspaces $Z_u \subset X \cap H^+$ and splitting subspaces $X_u \in \mathcal{X}_0$ such that $X_u \leq X$, under which $Z_u = X_u \cap H^+$ and $S_u = H^- + Z_u$. To this end, take $t \geq 0$ and recall that $e^{G_u} Z_u = \pi_+ U_t^* Z_u$; and therefore, since $(1 - \pi_+)U_t^* Z_u \subset H^-$, it follows that $G_u Z_u \subset Z_u$ is equivalent to

$$U_t^* \left(H^- + Z_u\right) \subset \left(H^- + Z_u\right),$$

because $U_t^* H^- \subset H^-$. Set $S_u := H^- + Z_u$ and $\bar{S}_u := H^+ \vee Z_u{}^\perp$. Then $X_u \sim (S_u, \bar{S}_u)$ belongs to $\mathcal{X}_0$. (See the discussion in §2 and [15] or [16].) Since $S_u \sim (S_u, H_0)$ is itself a splitting subspace, Lemma 2.8 yields

$$S_u = H^- + \left(X_u \cap H^+\right) \tag{3.16}$$

for $S_u \cap H^- = H^-$ and $S_u \cap H^+ = X_u \cap H^+$. Hence we must have

$$Z_u = X_u \cap H^+;$$

and since $Z_u \subset X$, we have $X_u \cap H^+ \subset X \cap H^+$, from which we see that $X_u \leq X$ (Lemma 3.3). Consequently we have established the required one-to-one correspondence between G_u-invariant $Z_u \subset X \cap H^+$ and $X_u \in \mathcal{X}_0$ such that $X_u \leq X$.

In the same way we prove the symmetric statement that there is a one-to-one correspondence between G_s-invariant subspaces $Z_s \subset X \cap H^-$ and $X_s \in \mathcal{X}_0$ such that $X_s \geq X$, under which $Z_s = X_s \cap H^-$ and $S_s = H^+ + Z_s$.

Now, returning to the decomposition (3.15), we have shown that there are splitting subspaces $X_1, X_2 \in \mathcal{X}_0$ such that $X_1 \leq X \leq X_2$ and

$$Z = \left(X_1 \cap H^-\right) + \left(X_2 \cap H^+\right).$$

Let $\tilde{X}$ be an abitrary element in $\mathcal{X}$ having X_1 and X_2 as tightest internal bounds. Then by Lemma 3.3,

$$Z = \left(\tilde{X} \cap H^-\right) + \left(\tilde{X} \cap H^+\right),$$

i.e., $Z = \tilde{X} \cap H_0$ (Lemma 2.8). Proposition 3.7(iii) then yields $Z = X_1 \cap X_2$, proving the last statement of the theorem. □

COROLLARY 3.11. *Let $X \in \mathcal{X}$ and $X_0 \in \mathcal{X}_0$ be arbitrary, and let G be the zero generator of X. Then*

$$G\left[X \cap X_0\right] \subset X \cap X_0.$$

Conversely, any G-invariant subspace Z can be written $Z = \tilde{X} \cap X_0$ where $\tilde{X} \in \mathcal{X}$, $X_0 \in \mathcal{X}_0$, and X_0 is either the tightest upper or tightest lower internal bound of $\tilde{X}$.

Proof. Take $\xi \in X \cap X_0$ and $t \geq 0$. Then by the same procedure as in the proof of Theorem 3.4, $V_t(X \cap H_0)\xi \in \bar{S}_0$ and $\bar{V}_t(X \cap H_0)\xi \in S_0$, i.e., $G\xi \in \bar{S}_0$ and $-G\xi \in S_0$, and consequently $G\xi \in S_0 \cap \bar{S}_0 = X_0$. But, by definition, $G\xi \in X \cap H_0 \subset X$, and therefore $G\xi \in X \cap X_0$. This proves the required invariance. The inverse statement follows from the proof of Theorem 3.4. In fact, Z can be written as $Z = X_1 \cap X_2$ where X_1 and X_2 are tight internal bounds of $\tilde{X} \in \mathcal{X}$. Then from the last statement of Theorem 3.4(i), $Z = \tilde{X} \cap X_1 = \tilde{X} \cap X_2$. □

Proof of Corollary 3.10. Just noting that $G_s = G_-$ for $X = X_-$, $G_u = G_+$ for $X = X_+$, and $X_- \leq X \leq X_+$, the statements of the corollary are seen to be special cases of the corresponding results in the proof of Theorem 3.4. □

4. Introducing coordinates.

In this section we shall, among other things, reformulate the geometric results of §3 in the dual deterministic setting of linear functionals of the state at time zero. This will lead to characterizations in terms of state covariances and will facilitate the application of some of these results to the algebraic Riccati inequality in §5.

To this end, we shall now equip each $X \in \mathcal{X}$ with a basis chosen uniformly over the family $\mathcal{X}$, in a way first suggested in [5]. Let $\{\xi_1, \xi_2, \dots, \xi_n\}$ be an arbitrary basis in X_+. Such a basis corresponds to a model (1.1) with a state process $\{x_+(t); t \in \mathbb{R}\}$ such that

$$x_+(0) = \begin{bmatrix} \xi_1 \\ \xi_2 \\ \vdots \\ \xi_n \end{bmatrix}.$$

(See, e.g., [16] for the construction.) Now, for an arbitrary $X \in \mathcal{X}$, we define

$$x_k(0) = E^X \xi_k, \qquad k = 1, 2, \dots. \tag{4.1}$$

This can be seen to be a basis in X, and $x(0)$ is the state vector at zero of a model (1.1) having the same A and C matrices as that of $x_+(0)$.

There are several reasons why this construction is the right one. First, if for each $X \in \mathcal{X}$ we define the state covariance

$$P = E\{x(0)x(0)'\}, \tag{4.2}$$

then it was shown in [16] that

$$X_1 \leq X_2 \iff P_1 \leq P_2 \tag{4.3}$$

(where, as before, $P_1 \leq P_2$ means that $P_2 - P_1$ it positive semidefinite). In particular, (3.1) corresponds to

$$P_- \leq P \leq P_+, \tag{4.4}$$

$\mathcal{X}$ to the solution set $\mathcal{P}$ of the algebraic Riccati inequality $\Lambda(P) \leq 0$, and $\mathcal{X}_0$ to the subfamily $\mathcal{P}_0$ of solutions of the algebraic Riccati equation $\Lambda(P) = 0$, thus connecting the geometric theory of stochastic realization with that of Anderson [1] and Faurre et al. [9].

Secondly, the above family of bases is consistent in the sense that representations coincide on intersecting splitting subspaces as explained in the following lemma.

LEMMA 4.1. *Let $X_1, X_2 \in \mathcal{X}$. Then if $\lambda \in X_1 \cap X_2$, there is a unique $a \in \mathbb{R}^n$ such that*

$$\lambda = a'x_1(0) = a'x_2(0)$$

where $x_1(0)$ and $x_2(0)$ are bases of X_1 and X_2 respectively constructed as in (4.1).

Proof. Suppose that $\lambda = a_1'x_1(0) = a_2'x_2(0)$. Then by Theorem 6.12 in [16],

$$E^{X-}\lambda = a_1'x_-(0) = a_2'x_-(0);$$

and hence we must have $a_1 = a_2$, as claimed. □

Next we shall give a result that will be instrumental in establishing the correspondence between families of output-induced subspaces and covariance matrices P. To this end, given $X \in \mathcal{X}$ and the corresponding basis (4.1), define the linear map $T : \mathbb{R}^n \to X$ as

$$Ta = a'x(0). \tag{4.5}$$

This is a natural extension to $\mathbb{R}^n$ of the map T defined in §2. Clearly T is a bijection, and in view of Lemma 4.1,

$$T_1^{-1}|_{X_1 \cap X_2} = T_2^{-1}|_{X_1 \cap X_2} \tag{4.6}$$

if T_1 corresponds to X_1 and T_2 corresponds to X_2; hence, with some care, we may simply write T^{-1} whenever there is no risk for misunderstanding.

LEMMA 4.2. *Let $X_1, X_2 \in \mathcal{X}$ and $X_1 \leq X_2$, and let at least one of X_1 and X_2 be internal. Then*

$$T^{-1}(X_1 \cap X_2) = \ker(P_2 - P_1)$$

where P_1 and P_2 are the covariances corresponding to X_1 and X_2 respectively.

Proof. Let $\lambda \in X_1 \cap X_2$ and $T^{-1}(\lambda) = a$. Then $a'x_1(0) = a'x_2(0)$, and therefore

$$a'(P_2 - P_1)a = 0, \tag{4.7}$$

and therefore $a \in \ker(P_2 - P_1)$. Conversely, suppose that

$$a \in \ker(P_2 - P_1). \tag{4.8}$$

Since $X_1 \leq X_2$ and at least one of X_1 and X_2 is internal,

$$a'x_1(0) = E^{X_1}a'x_2(0)$$

(Proposition 6.12 in [16]), i.e., $[a'x_2(0) - a'x_1(0)] \perp a'x_1(0)$. Therefore, since

$$a'x_2(0) = [a'x_2(0) - a'x_1(0)] + a'x_1(0),$$

we have

$$E\left|a'x_2(0) - a'x_1(0)\right|^2 = a'(P_2 - P_1)a.$$

Consequently, by (4.8), $a'x_2(0) = a'x_1(0) \in X_1 \cap X_2$, i.e., $a \in T^{-1}(X_1 \cap X_2)$. □

We are now in a position to reformulate the first part of Theorem 3.4 in terms of covariances, thus obtaining an amplification of Theorem 9.1 and Lemma 9.3 in [16]. In the parameterization $\mathcal{P}$ of $\mathcal{X}$ the tightest internal bounds X_{0-} and X_{0+} of $X \in \mathcal{X}$ will be denoted P_{0-} and P_{0+} respectively. Recall that (P_{0-}, P_{0+}) denotes the *open tightest frame* of P, i.e., the set of all $P \in \mathcal{P}$ having P_{0-} and P_{0+} as their tightest upper and lower bounds in $\mathcal{P}_0$.

THEOREM 4.3. *Let $P_1, P_2 \in \mathcal{P}_0$ and $P \in \mathcal{P}$. Then*

(i) $P_1 \leq P \leq P_2 \Longleftrightarrow \ker(P_2 - P_1) \subset \ker(P_2 - P)$
with $\ker(P_2 - P_1) = \ker(P_2 - P)$ *if and only if* $P_1 = P_{0-}$; *and*

(ii) $P_1 \leq P \leq P_2 \Longleftrightarrow \ker(P_2 - P_1) \subset \ker(P - P_1)$
with $\ker(P_2 - P_1) = \ker(P - P_1)$ *if and only if* $P_2 = P_{0+}$.

Proof. Let $T : \mathbb{R}^n \to X$ be the bijection defined above, i.e., $T(a) = a'x(0)$. If $X_1 \leq X \leq X_2$, then $X_1 \cap X_2 \subset X$ by Theorem 3.4. Hence Lemma 4.2 can be applied with the same T^{-1} so that $X_1 \cap X_2$, $X \cap X_2$, and $X \cap X_1$ correspond to $\ker(P_2 - P_1)$, $\ker(P_2 - P)$, and $\ker(P - P_1)$ respectively under the bijection. Therefore,

$$\ker(P_2 - P_1) \subset \ker(P_2 - P) \cap \ker(P - P_1). \tag{4.9}$$

Also $X_2 = X_{0+}$ if and only if $X_1 \cap X_2 = X \cap X_2$, i.e., $\ker(P_2 - P_1) = \ker(P_2 - P)$. To prove the converse statement observe that any element $\xi \in X_1 \cap X_2$ can be written in the form $\xi = a'x_1(0) = a'x_2(0)$, where $a \in \ker(P_2 - P_1)$. So if $\ker(P_2 - P_1) \subset \ker(P_2 - P)$, then $a \in \ker(P_2 - P)$, i.e., $a'x_2(0) = a'x(0)$; therefore $\xi \in X$, which implies that $X_1 \cap X_2 \subset X$, which is equivalent to $X_1 \leq X \leq X_2$ by Theorem 3.4. This proves (i). Statement (ii) is proved in the same way. □

We shall now provide an explicit representation of $\mathcal{V}^*$ and its Γ'-invariant subspaces $\mathcal{V}$ in terms of covariance matrices.

As pointed out in §1, the set $\mathcal{P}$ is a parametrization of the family $\mathcal{X}$ of minimal Markovian splitting subspaces. In fact, a uniform choice of bases produces a unique state process x for each $X \in \mathcal{X}$ and hence a unique $P := E\{x(0)x(0)'\}$. Modulo orthogonal transformations in the input space, there is a unique minimal stochastic realization (1.9) corresponding to x that may be written in standard form

$$(\Sigma) \quad \begin{cases} dx = Axdt + B_1dw_1 + B_2dw_2, \\ dy = Cxdt + R^{1/2}dw_1. \end{cases} \tag{4.10}$$

A uniform choice of bases also fixes the matrices A and C to be the same for all $X \in \mathcal{X}$. Conversely, for each $P \in \mathcal{P}$, we have a minimal spectral factor

$$W(s) = C(sI - A)^{-1}(B_1, B_2) + (R^{1/2}, 0)$$

where

$$B_1 = (\bar{C} - CP)'R^{-1/2} \tag{4.11}$$

and B_2 is a full-rank factor of $-\Lambda(P)$, i.e.,

$$\Lambda(P) = -B_2 B_2', \tag{4.12}$$

and (in a suitable Hilbert space $\hat{H}$ as discussed in the beginning of §3) a unique stochastic realization (4.10), in turn defining a unique X.

Moreover, the uniform choice of bases associates to each $X \in \mathcal{X}$ a maximal output-nulling subspace $\mathcal{V}^* = \mathcal{V}^*(A', C', B', D')$ of the dual system (2.13) and a feedback matrix

$$\Gamma = A - B_1 R^{-1/2} C'. \tag{4.13}$$

We recall that $\mathcal{V}^* = \langle \Gamma \mid B_2 \rangle^{\perp}$. As explained in the proof of Lemma 2.3, (2.36), $\mathcal{V}^*$ can be decomposed into a direct sum

$$\mathcal{V}^* = \mathcal{V}^*_- + \mathcal{V}^*_+$$

of Γ'-invariant subspaces, $\mathcal{V}^*_-$ and $\mathcal{V}^*_+$, coresponding to the stable and the antistable modes of $\Gamma' \,|_{\mathcal{V}^*}$ respectively.

LEMMA 4.4. *Let $P \in \mathcal{P}$, and let $\mathcal{V}^*$ be the corresponding output-nulling subspace. Then*

(i) $\mathcal{V}^* = \ker(P - P_{0-}) = \ker(P_{0+} - P) = \ker(P_{0+} - P_{0-})$,
(ii) $\mathcal{V}^*_- = \ker(P - P_-) = \ker(P_{0+} - P_-)$,
(iii) $\mathcal{V}^*_+ = \ker(P_+ - P) = \ker(P_+ - P_{0-})$.

Proof. In view of Lemma 2.3 and (2.74), $\mathcal{V}^* = T^{-1}(X \cap H_0)$, $\mathcal{V}^*_- = T^{-1}(X \cap H^-)$, and $\mathcal{V}^*_+ = T^{-1}(X \cap H^+)$. Then applying Lemma 4.2 to Proposition 3.7 yields the desired result. □

Consider two covariance matrices P_1 and P_2 in $\mathcal{P}$ such that $P_1 \leq P_2$. We shall next establish the relation between the corresponding pairs of output-nulling subspaces $(\mathcal{V}^*_-)_1$, $(\mathcal{V}^*_+)_1$ and $(\mathcal{V}^*_-)_2$, $(\mathcal{V}^*_+)_2$ and the corresponding feedback matrices (4.13), Γ_1 and Γ_2. The following chain of results provides dual versions of Lemma 3.1, Corollary 3.2, and Lemma 3.3 in §3.

LEMMA 4.5. *Let at least one of $P_1, P_2 \in \mathcal{P}$ belong to $\mathcal{P}_0$, and suppose that $P_1 \leq P_2$. Then*

(i) $(\mathcal{V}^*_+)_1 \subset (\mathcal{V}^*_+)_2$ and $(\mathcal{V}^*_-)_2 \subset (\mathcal{V}^*_-)_1$,
(ii) $\Gamma'_1 \,|_{(\mathcal{V}^*_-)_2} = \Gamma'_2 \,|_{(\mathcal{V}^*_-)_2}$,
(iii) $\Gamma'_1 \,|_{(\mathcal{V}^*_+)_1} = \Gamma'_2 \,|_{(\mathcal{V}^*_+)_1}$.

Proof. The proof follows directly by applying Proposition 3.7 and Lemma 4.2 to Lemma 3.1. □

The following corollary illustrates the role of $\mathcal{V}^*_-$ and $\mathcal{V}^*_+$ as the stable and unstable Γ'-invariant subspaces of $\mathcal{V}^*$.

COROLLARY 4.6. *Let $P \in \mathcal{P}$, and let Γ be the corresponding feedback matrix* (4.13). *Then*

$$\Gamma' \,|_{\mathcal{V}^*_-} = \Gamma'_- \,|_{\mathcal{V}^*_-} \quad \text{and} \quad \Gamma' \,|_{\mathcal{V}^*_+} = \Gamma'_+ \,|_{\mathcal{V}^*_+},$$

where Γ_- and Γ_+ are the feedback matrices corresponding to P_- and P_+ respectively.

Proof. Take $P_1 = P_-$ and $P_2 = P$ in Lemma 4.5(ii) to prove (i). The second statement follows by setting $P_1 = P_+$ and $P_2 = P$ in Lemma 4.5(iii). □

LEMMA 4.7. *Let $P_1, P_2 \in \mathcal{P}_0$. Then for each $P \in \mathcal{P}$,*

(i) $P_1 \leq P \iff \ker(P_+ - P_1) \subset \ker(P_+ - P)$
with $\ker(P_+ - P_1) = \ker(P_+ - P)$ *if and only if* $P_1 = P_{0-}$; *and*
(ii) $P \leq P_2 \iff \ker(P_2 - P_-) \subset \ker(P - P_-)$
with $\ker(P_2 - P_-) = \ker(P - P_-)$ *if and only if* $P_2 = P_{0+}$.

In other words,
(i) $P_1 \leq P \iff (\mathcal{V}_+^*)_1 \subset \mathcal{V}_+^*$
with $(\mathcal{V}_+^*)_1 = \mathcal{V}_+^*$ *if and only if* $P_1 = P_{0-}$; *and*
(ii) $P \leq P_2 \iff (\mathcal{V}_-^*)_2 \subset \mathcal{V}_-^*$
with $(\mathcal{V}_-^*)_2 = \mathcal{V}_-^*$ *if and only if* $X_2 = X_{0+}$.

Proof. Follows immediately from Lemma 3.3. It is also a simple corollary of Theorem 4.3. □

The following theorem gives, for an arbitrary $P \in \mathcal{V}$, a complete characterization of all Γ'-invariant subspaces in $\mathcal{V}$, i.e., the output-nulling subspaces of the dual control system (2.13).

THEOREM 4.8. *Let* Γ *be the feedback matrix* (4.13) *corresponding to* $P \in \mathcal{P}$. *Then if* $P_1, P_2 \in \mathcal{P}_0$ *and* $P_1 \leq P \leq P_2$, *the subspace*

$$\ker(P_2 - P_1)$$

is Γ'*-invariant. Conversely, any* Γ'*-invariant subspace* $\mathcal{V} \subset \mathcal{V}^*$ *has a representation*

$$\mathcal{V} = \ker(P_2 - P_1)$$

for some $P_1, P_2 \in \mathcal{P}_0$ *such that* $P_1 \leq P \leq P_2$.

Proof. Follows by applying Lemma 4.2 to Theorem 3.4. □

Concerning Theorem 3.4, of which Theorem 4.8 is an isomorphic version, we may add that, thanks to Lemma 4.2, a simpler and more transparent proof of the invariances can be given. For example, to prove the G-invariance of $X_1 \cap X_2$ in Theorem 3.4, take $\xi \in X_1 \cap X_2$. Then, by Lemma 4.1, there is an $a \in \mathbb{R}^n$ such that

$$\xi = a'x_1(0) = a'x_2(0).$$

Since X_1 and X_2 are internal, the corresponding B_2-matrices are zero; i.e., for $t \geq 0$ and $i = 1, 2$,

$$U_t\xi = a'e^{\Gamma_i t}x_i(0) + \int_0^t a'e^{\Gamma_i(t-s)}(B_1)_i R^{-1/2}\,dy(s),$$

and therefore

$$e^{Gt}\xi = \pi_t U_t \xi = a'e^{\Gamma_1 t}x_1(0) = a'e^{\Gamma_2 t}x_2(0) \in X_1 \cap X_2.$$

Consequently $X_1 \cap X_2$ is G-invariant.

In the same way as above we obtain from Corollary 3.5 the following result characterizing intersecting zero dynamics.

LEMMA 4.9. *Let at least one of* $P_1, P_2 \in \mathcal{P}$ *belong to* $\mathcal{P}_0$, *and suppose that* $P_1 \leq P_2$. *Then*

$$\Gamma_1' \,|_{\ker(P_2 - P_1)} = \Gamma_2' \,|_{\ker(P_2 - P_1)}.$$

An important consequence of this lemma and the fact that $\mathcal{V}^*$ is constant over the open tightest frame (P_{0-}, P_{0+}) (Lemma 4.4) is that the zero dynamics is the same for all $P \in (P_{0-}, P_{0+})$. In fact, by Lemma 4.9,

$$\Gamma_{0-}' \,|_{\ker(P - P_{0-})} = \Gamma' \,|_{\ker(P - P_{0-})}$$

and, by Lemma 4.4, $\ker(P - P_{0-}) = \ker(P_{0+} - P_{0-})$.

The next proposition, which is due to Molinari [20] (also see [16, Lemma 10.2]), also belongs to the general area of invariance results described in this section and corresponds to Corollary 3.11.

PROPOSITION 4.10. *Let $P \in \mathcal{P}$ and $P_0 \in \mathcal{P}_0$ be arbitrary. Then all subspaces of the form*

$$\mathcal{V} = \ker(P - P_0)$$

are Γ'-invariant subspaces of $\mathcal{V}^*$.

5. Invariant subspaces and the algebraic Riccati inequality. In this section we shall generalize the well-known Potter-MacFarlane characterization of the (symmetric) solutions of the algebraic Riccati equation

$$\Lambda(P) = 0, \tag{5.1}$$

in terms of subspaces invariant under the Hamiltonian matrix, to the algebraic Riccati inequality

$$\Lambda(P) \leq 0. \tag{5.2}$$

Setting

$$F := A - \bar{C}' R^{-1} C, \tag{5.3}$$

we may write

$$\Lambda(P) = FP + PF' + PC'R^{-1}CP + \bar{C}'R^{-1}\bar{C}, \tag{5.4}$$

which corresponds to the *Hamiltonian* matrix

$$\mathcal{H} = \begin{bmatrix} F' & C'R^{-1}C \\ -\bar{C}'R^{-1}\bar{C} & -F \end{bmatrix}. \tag{5.5}$$

It is well known [17], [22], [18] that the solution set $\mathcal{P}_0$ of the algebraic Riccati equation is in a one-to-one correspondence with the class of Lagrangian $\mathcal{H}$-invariant subspaces $\mathcal{L}$ of $\mathbb{R}^{2n}$. Recall that a subspace $\mathcal{L}$ is Lagrangian if it is *isotropic* in the sense that if $x, y \in \mathcal{L}$, then

$$x' \begin{bmatrix} 0 & I \\ -I & 0 \end{bmatrix} y = 0 \tag{5.6}$$

and it is of maximal dimension n. Under this correspondence $\mathcal{L} = \operatorname{Im}\left[\begin{smallmatrix} I \\ P \end{smallmatrix}\right]$. The purpose of this section is to show that a similar correspondence holds for the solution set $\mathcal{P}$ of the algebraic Riccati inequality (5.2) and that this correspondence is related to the zero structure described above. In this respect a crucial observation is the following.

PROPOSITION 5.1. *Let $P \in \mathcal{P}$, and let $\mathcal{V}^*$ be the maximal output-nulling subspace of the corresponding dual system* (2.13). *Then $\mathcal{V}^*$ is the largest Γ'-invariant subspace of $\mathbb{R}^n$ such that*

$$\Lambda(P)\,|_{\mathcal{V}^*} = 0 \tag{5.7}$$

where Γ *is defined by* (2.18) *or, equivalently,*

$$\Gamma = F + PC^{'}R^{-1}C. \tag{5.8}$$

Proof. In view of (2.21), $\mathcal{V}^*$ is the largest $\Gamma^{'}$-invariant subspace orthogonal to the columns of B_2; and consequently, since $\Lambda(P) = -B_2B_2^{'}$, $\mathcal{V}^*$ is the largest $\Gamma^{'}$-invariant subspace for which (5.7) holds. □

Now, recall from §4 that to each $P \in \mathcal{P}$ there is a direct-sum decomposition

$$\ker(P - P_-) + \ker(P_+ - P) = \ker(P_{0+} - P_{0-}) \tag{5.9}$$

where P_{0-}, $P_{0+} \in \mathcal{P}_0$ are the tightest lower and upper internal bounds of P. In view of Lemma 4.4, this is equivalent to

$$\mathcal{V}^* = \mathcal{V}_-^* + \mathcal{V}_+^*. \tag{5.10}$$

As we have seen in §4 $\mathcal{V}_-^*$ is $\Gamma^{'}_-$-invariant and $\mathcal{V}_+^*$ is $\Gamma^{'}_+$-invariant. Moreover, if $a \in \mathcal{V}_-^*$ and $b \in \mathcal{V}_+^*$, then $a^{'}(P_+ - P)b = a^{'}(P - P_-)b = 0$ and, consequently, $\mathcal{V}_-^*$ and $\mathcal{V}_+^*$ are $(P_+ - P_-)$-orthogonal, i.e.,

$$a'(P_+ - P_-)b = 0 \quad \text{for all } a \in \mathcal{V}_-^*, b \in \mathcal{V}_+^*. \tag{5.11}$$

In §4 (Lemma 4.4) we saw that $\mathcal{V}_-^* = \ker(P_{0+} - P_-)$ and $\mathcal{V}_+^* = \ker(P_+ - P_{0-})$, so decomposition (5.9) may also be written

$$\ker(P_{0+} - P_-) + \ker(P_+ - P_{0-}) = \ker(P_{0+} - P_{0-}), \tag{5.12}$$

only involving covariance matrices belonging to $\mathcal{P}_0$.

If P is a solution of the algebraic Riccati equation (5.1), i.e., $P \in \mathcal{P}_0$, then $P = P_{0-} = P_{0+}$ and both (5.9) and (5.12) reduce to the $(P_+ - P_-)$-orthogonal decomposition

$$\ker(P - P_-) + \ker(P_+ - P) = \mathbb{R}^n \tag{5.13}$$

of the whole $\mathbb{R}^n$. This corresponds to the situation studied by J. C. Willems [27]. To set up notation and make contact with the gemetric theory of splitting subspaces we shall here restate Willems's result.

To this end, let $X \in \mathcal{X}_0$ and consider the stochastic version of (5.13), namely,

$$X = X \cap X_- + X \cap X_+, \tag{5.14}$$

obtained via Lemma 4.2 or directly from Lemma 2.8 and Proposition 3.7. Applying the projectors π_- and π_+ of (2.75) to (5.14) shows that

$$\pi_- X = X \cap X_- \quad \text{and} \quad \pi_+ X = X \cap X_+,$$

which can be translated into $\mathbb{R}^n$ via the bijective map $T : \mathbb{R}^n \to X$ of (4.5) to yield

$$\operatorname{Im}\Pi_- = \ker(P - P_-) \quad \text{and} \quad \operatorname{Im}\Pi_+ = \ker(P_+ - P).$$

Here $\Pi_- : \mathbb{R}^n \to \mathbb{R}^n$ and $\Pi_+ : \mathbb{R}^n \to \mathbb{R}^n$ are complementary projection operators defined as $\Pi_- = T^{-1}\pi_-|_X T$ and $\Pi_+ = T^{-1}\pi_+|_X T$ respectively. Now take $a \in \mathbb{R}^n$

and form the projections $a_- := \Pi_- a$ and $a_+ := \Pi_+ a$. From (5.13) we see that $a = a_- + a_+$, $Pa_- = P_- a_-$, and $Pa_+ = P_+ a_+$ so that $Pa = P_- \Pi_- a + P_+ \Pi_+ a$ for all $a \in \mathbb{R}^n$. Consequently,

$$P = P_- \Pi_- + P_+ \Pi_+.$$

LEMMA 5.2. (J. C. Willems). *Let Γ_- and Γ_+ be the feedback matrices, given by* (4.13) *and* (4.11)*, corresponding to P_- and P_+ respectively. Then:*

(i) *There is a one to one correspondence between Γ_-'-invariant subspaces $\mathcal{V}_- \subset \mathbb{R}^n$ and $P \in \mathcal{P}_0$ under which*

$$\mathcal{V}_- = \ker(P - P_-) \tag{5.15}$$

and

$$P = P_- \Pi_- + P_+(I - \Pi_-), \tag{5.16}$$

where Π_- is the $(P_+ - P_-)$-orthogonal projector of $\mathbb{R}^n$ onto $\mathcal{V}_-$.

(ii) *Dually, there is a one-to-one correspondence between Γ_+'-invariant subspaces $\mathcal{V}_+ \subset \mathbb{R}^n$ and $P \in \mathcal{P}_0$ under which*

$$\mathcal{V}_+ = \ker(P_+ - P) \tag{5.17}$$

and

$$P = P_-(I - \Pi_+) + P_+ \Pi_+, \tag{5.18}$$

where Π_+ is the $(P_+ - P_-)$-orthogonal projector of $\mathbb{R}^n$ onto $\mathcal{V}_+$.

Proof. By Lemma 4.2, $\mathcal{V}_-$ corresponds to $Z = X \cap X_-$ and $\mathcal{V}_+$ to $Z = X \cap X_+$ in Corollary 3.10. Moreover, Γ_- and Γ_+ correspond to G_- and G_+ respectively, and therefore the lemma follows. □

In summary, by Lemma 5.2, any $P \in \mathcal{P}_0$ corresponds to two subspaces, $\mathcal{V}_-^* = \ker(P - P_-)$, invariant for Γ_-', and $\mathcal{V}_+^* = \ker(P_+ - P)$, invariant for Γ_+', which by (5.13) are complementary, i.e., sum to all of $\mathbb{R}^n$. If $P \in \mathcal{P}$ does not belong to $\mathcal{P}_0$, however, (5.13) is replaced by (5.9). Therefore, if we insist on representing the invariant subspaces $\mathcal{V}_-^*$ and $\mathcal{V}_+^*$ in terms of solutions of the algebraic Riccati equation, as stated in Lemma 5.2, then there will still be representations of the type $\mathcal{V}_-^* = \ker(P_0 - P_-)$ and $\mathcal{V}_+^* = \ker(P_+ - P_0)$, but now we can no longer use the same P_0. Formula (5.12) is precisely a manifestation of this fact.

The following notation will be used in the sequel. If $\mathcal{L}$ is a k-dimensional subspace of $\mathbb{R}^{2n}$ with basis matrix $L \in \mathbb{R}^{2n \times k}$, define $\tau(\mathcal{L})$ to be the subspace in $\mathbb{R}^n$ spanned by the truncated matrix obtained by removing the bottom n rows of L.

We are now in a position to state the main result of this section.

THEOREM 5.3. *Let $\mathcal{P}$ be the solution set of the matrix Riccati inequality* (5.2)*, and let $\mathcal{H}$ be the Hamiltonian matrix* (5.5)*. Then there is a one-to-one correspondence between the isotropic $\mathcal{H}$-invariant subspaces $\mathcal{L} \subset \mathbb{R}^{2n}$ of dimension $k \leq n$ and the family of open tightest frames (P_{0-}, P_{0+}) of $\mathcal{P}$. Under this correspondence*

$$\mathcal{L} = \begin{bmatrix} I \\ P \end{bmatrix} \mathcal{V}^* \tag{5.19}$$

for any $P \in (P_{0-}, P_{0+})$, where $\mathcal{V}^* \subset \mathbb{R}^n$ is the subspace of zero directions

$$\mathcal{V}^* = \ker(P_{0+} - P_{0-}) \tag{5.20}$$

and $k = \dim \mathcal{L}$ is the number of zeros of the spectral factor W corresponding to P. Conversely, given any isotropic $\mathcal{H}$-invariant subspace $\mathcal{L} \subset \mathbb{R}^{2n}$ of dimension $k \leq n$, the matrices P_{0-} and P_{0+} are obtained from Lemma 5.2, formulas (5.16) and (5.18), as the elements in $\mathcal{P}_0$ corresponding to the invariant subspaces $\mathcal{V}_- = \tau(\mathcal{L}_-)$ and $\mathcal{V}_+ = \tau(\mathcal{L}_+)$, where $\mathcal{L}_-$ and $\mathcal{L}_+$ are the subspaces of $\mathcal{L}$ consisting of sums of stable and antistable eigenspaces of $\mathcal{H}$.

Proof. First suppose that $P \in \mathcal{P}$ has the tightest local frame (P_{0-}, P_{0+}), and define $\mathcal{L}$ by (5.19) and (5.20). Clearly, (5.19) is independent of the choice of $P \in (P_{0-}, P_{0+})$. In fact, if $P_1, P_2 \in (P_{0-}, P_{0+})$, then by Lemma 4.4, $\mathcal{V}^* = \ker(P_1 - P_{0-}) = \ker(P_2 - P_{0-})$, and hence it follows that $(P_2 - P_1)a = 0$ for all $a \in \mathcal{V}^*$. Now a straightforward calculation, using (5.4) and the fact that $\Lambda(P)\mathcal{V}^* = 0$ (Proposition 5.1), shows that

$$\mathcal{H}\mathcal{L} = \begin{bmatrix} I \\ P \end{bmatrix} \Gamma' \mathcal{V}^*.$$

Since $\Gamma' \mathcal{V}^* \subset \mathcal{V}^*$, this yields $\mathcal{H}\mathcal{L} \subset \mathcal{L}$ as claimed. The fact that $P' = P$ ensures that $\mathcal{L}$ is isotropic.

Conversely, suppose that $\mathcal{L} \subset \mathbb{R}^{2n}$ is any $\mathcal{H}$-invariant isotropic subspace of dimension $k \leq n$. Then $\mathcal{L}$ is a direct sum of generalized eigenspaces of $\mathcal{H}$; and since these eigenspaces are contained in either $\operatorname{Im}\left[\begin{smallmatrix} I \\ P_- \end{smallmatrix}\right]$ or $\operatorname{Im}\left[\begin{smallmatrix} I \\ P_+ \end{smallmatrix}\right]$ (for $\mathbb{R}^{2n}$ is a direct sum of these subspaces), we have the direct sum decomposition

$$\mathcal{L} = \mathcal{L}_- + \mathcal{L}_+ \tag{5.21}$$

where $\mathcal{L}_- := \mathcal{L} \cap \operatorname{Im}\left[\begin{smallmatrix} I \\ P_- \end{smallmatrix}\right]$ and $\mathcal{L}_+ := \mathcal{L} \cap \operatorname{Im}\left[\begin{smallmatrix} I \\ P_+ \end{smallmatrix}\right]$ are both $\mathcal{H}$-invariant, because $\operatorname{Im}\left[\begin{smallmatrix} I \\ P_- \end{smallmatrix}\right]$ and $\operatorname{Im}\left[\begin{smallmatrix} I \\ P_+ \end{smallmatrix}\right]$ are. Therefore, there are full-rank matrices M_- and M_+ such that

$$\mathcal{L}_- = \operatorname{Im} \begin{bmatrix} I \\ P_- \end{bmatrix} M_- \quad \text{and} \quad \mathcal{L}_+ = \operatorname{Im} \begin{bmatrix} I \\ P_+ \end{bmatrix} M_+. \tag{5.22}$$

But $\operatorname{Im}\left[\begin{smallmatrix} I \\ P_- \end{smallmatrix}\right]$ is $\mathcal{H}$-invariant and

$$\mathcal{H} \begin{bmatrix} I \\ P_- \end{bmatrix} = \begin{bmatrix} I \\ P_- \end{bmatrix} \Gamma'_-,$$

and consequently

$$\mathcal{H} \begin{bmatrix} I \\ P_- \end{bmatrix} M_- = \begin{bmatrix} I \\ P_- \end{bmatrix} \Gamma'_- M_-.$$

Therefore, since $\mathcal{L}_-$, represented by (5.22), is $\mathcal{H}$-invariant, $\operatorname{Im} M_-$ must be Γ'_--invariant. In the same way we show that $\operatorname{Im} M_+$ is Γ'_+- invariant. Consequently, it follows from Lemma 5.2 that there are unique $P_{0-}, P_{0+} \in \mathcal{P}_0$ so that

$$\mathcal{V}_- := \operatorname{Im} M_- = \ker(P_{0+} - P_-) \tag{5.23}$$

and

$$\mathcal{V}_+ := \operatorname{Im} M_+ = \ker(P_+ - P_{0-}). \tag{5.24}$$

It remains to show that $P_{0-} \leq P_{0+}$ so that (P_{0-}, P_{0+}) may form a tightest local frame and we may identify $\mathcal{V}_-$ and $\mathcal{V}_+$ with $\mathcal{V}_-^*$ and $\mathcal{V}_+^*$ respectively. To this end, note that since

$$\mathcal{L} = \operatorname{Im} \begin{bmatrix} M_- & M_+ \\ P_-M_- & P_+M_+ \end{bmatrix}$$

is isotropic,

$$\begin{bmatrix} M_- & M_+ \\ P_-M_- & P_+M_+ \end{bmatrix}' \begin{bmatrix} 0 & I \\ -I & 0 \end{bmatrix} \begin{bmatrix} M_- & M_+ \\ P_-M_- & P_+M_+ \end{bmatrix} = 0,$$

i.e.,

$$M_-'(P_+ - P_-)M_+ = 0.$$

Consequently, $\mathcal{V}_-$ and $\mathcal{V}_+$ are $(P_+ - P_-)$-orthogonal. In other words,

$$\mathcal{V}_+ \subset (\mathcal{V}_-)^\circ \tag{5.25}$$

where $^\circ$ denotes the $(P_+ - P_-)$-orthogonal complement in $\mathbb{R}^n$. Now, in view of (5.23) and decomposition (5.13),

$$(\mathcal{V}_-)^\circ = \ker(P_+ - P_{0+}). \tag{5.26}$$

Therefore,

$$\ker(P_+ - P_{0-}) = \mathcal{V}_+ \subset (\mathcal{V}_-)^\circ = \ker(P_+ - P_{0+}),$$

so it follows from Lemma 4.7 that $P_{0-} \leq P_{0+}$, as claimed.

Now, let $P \in \mathcal{P}$ be an arbitrary element in the open tightest frame (P_{0-}, P_{0+}). Then by (5.12), (5.23), and (5.24),

$$\mathcal{V} := \mathcal{V}_- + \mathcal{V}_+ = \ker(P_{0+} - P_{0-}),$$

and hence, by Lemma 4.4, $\mathcal{V} = \mathcal{V}^*$, the space of zero directions corresponding to P. Moreover, $\mathcal{V}_-$ and $\mathcal{V}_+$ are actually $\mathcal{V}_-^*$ respectively $\mathcal{V}_+^*$. □

Theorem 5.3 is a generalization of the well-known result linking solutions in $\mathcal{P}_0$ to $\mathcal{H}$-invariant Lagrangian subspaces [17], [22], [18], in which special situation the equivalence classes of Theorem 5.3 are singletons and the invariant subspaces are n-dimensional. The fewer zeros that the spectral factor corresponding to P has, the larger is the equivalence class (the tightest local frame) and the smaller is the dimension of the invariant subspace $\mathcal{L}$.

Appendix. In this appendix we shall give the proofs deferred from §2.

Proof of Proposition 2.1. Suppose that

$$U_tY \subset Y \vee H^+_{[0,t]}. \tag{A.1}$$

Let $\xi \in Y$. Then

$$U_t\xi = \lambda_t + \eta_t \tag{A.2}$$

where $\lambda_t \in Y$ and $\eta_t \in H^+_{[0,t]}$. Since $Y \subset X \cap H_0$, we must have $\lambda_t = e^{Gt}\xi$; and therefore, applying the orthogonal projector E^X to (A.2), we obtain

$$e^{Ft}\xi = e^{Gt}\xi + E^X\eta_t. \tag{A.3}$$

Hence, for $t > 0$,

$$\frac{1}{t}(e^{Ft} - I)\xi = \frac{1}{t}(e^{Gt} - I)\xi + \frac{1}{t}E^X\eta_t, \tag{A.4}$$

and consequently

$$\lim_{t\downarrow 0} \frac{1}{t}E^X\eta_t \tag{A.5}$$

exists and, by the definition (2.25) of the operator N, must belong to $\operatorname{Im} N$. Therefore, since $e^{Gt}\xi \in Y$ (Proposition 2.7), we have $\xi \in Y \vee \operatorname{Im} N$, i.e.,

$$FY \subset Y \vee \operatorname{Im} N \tag{A.6}$$

as claimed. □

Remark. Let $\nu \in \operatorname{Im} N$ be the limit (A.5). Then, from (A.5), we see that

$$\nu = (F - G)\xi$$

is a linear function of ξ, and therefore there is a map $L : Y \to \mathbb{R}^m$ such that $\nu = NL\xi$; consequently,

$$G = F - NL.$$

Proof of Lemma 2.4. If $\xi \in X \cap H_0$, then $\xi = a'x(0)$ with $a \in \mathcal{V}^*$. Therefore it follows immediately from (2.43) and the fact that $\mathcal{V}^*$ is Γ'-invariant that for $t \geq 0$,

$$U_t\xi \in X \cap H_0 \vee H^+_{[0,t]}$$

and

$$U_t^*\xi \in X \cap H_0 \vee H^-_{[-t,0]},$$

so it only remains to show that these vector sums are direct, i.e., that $X \cap H^+_{[0,t]} = 0$ and $X \cap H^-_{[-t,0]} = 0$.

By stationarity $X \cap H^-_{[-t,0]} = 0$ if and only if $(U_tX) \cap H^+_{[0,t]} = 0$. To prove the latter, suppose $\eta \in (U_tX) \cap H^+_{[0,t]}$. We want to prove that η must be zero. To this end, note that

$$\hat{\eta} := E^{H^+_{[0,t]}}\eta = \eta. \tag{A.7}$$

Now there is an $a \in \mathbb{R}^n$ such that $\eta = a'x(t)$ and hence

$$\hat{\eta} = a'\hat{x}(t),$$

where $\hat{x}(t)$ is the Kalman-filter estimate. It is well known that $\Pi(t) := E\{\hat{x}(t)\hat{x}(t)'\}$ satisfies the Riccati differential equation

$$\dot{\Pi} = \Lambda(\Pi), \quad \Pi(0) = 0,$$

which has the limit P_- as $t \to \infty$; see, e.g., [9] or [16]. It is now easy to see that $Q := P_- - \Pi$ satisfies the homogeneous Riccati equation

$$\dot{Q} = \Gamma_- Q + Q\Gamma_-' - QC'R^{-1}CQ, \quad Q(0) = P_- > 0.$$

Since $Q(0) > 0$, $M(t) = Q(t)^{-1}$ exists on some finite interval $[0, t_1]$ and it is readily seen that it satisfies the Lyapunov differential equation

$$\dot{M} = -M\Gamma_- - \Gamma_-' M + C'R^{-1}C, \quad M(0) = P_-^{-1} > 0$$

there. Integrating we obtain

$$M(t) = e^{-\Gamma_-' t} M(0) e^{-\Gamma_- t} + \int_0^t e^{-\Gamma_-'(t-s)} C'R^{-1}C e^{-\Gamma_-(t-s)} \, ds$$

where the first term is positive definite and the second nonnegative definite. Consequently, $M(t) > 0$ for all finite t and hence $Q(t) > 0$ for all finite t.

Now, from (A.7) we have that

$$a' \left[P - \Pi(t) \right] a = 0.$$

But $P - \Pi(t) \geq P_- - \Pi(t) = Q > 0$. Hence $a = 0$, and therefore $\eta = 0$. The proof that $X \cap H_{[0,t]}^+ = 0$ follows from a symmetric argument. □

A GLOBALLY CONVERGENT SUCCESSIVE APPROXIMATION METHOD FOR SEVERELY NONSMOOTH EQUATIONS*

LIQUN QI† AND XIAOJUN CHEN†

Abstract. This paper presents a globally convergent successive approximation method for solving $F(x) = 0$ where F is a continuous function. At each step of the method, F is approximated by a smooth function f_k, with $\|f_k - F\| \to 0$ as $k \to \infty$. The direction $-f_k'(x_k)^{-1}F(x_k)$ is then used in a line search on a sum of squares objective. The approximate function f_k can be constructed for nonsmooth equations arising from variational inequalities, maximal monotone operator problems, nonlinear complementarity problems, and nonsmooth partial differential equations. Numerical examples are given to illustrate the method.

Key words. global convergence, successive approximation, integration convolution

AMS subject classifications. 90C30, 90C33

1. Introduction.

Let $F : R^n \to R^n$ be a continuous but not necessarily differentiable function. We consider the system of nonlinear equations

$$F(x) = 0, \qquad x \in R^n. \tag{1}$$

The recent literature of such nonsmooth equations includes [1]–[3], [6]–[8], [10]–[13], [15], [17], [19], [21].

If F is smooth, a popular method for solving (1) is the damped Newton method [4], [9]

$$\left\{ \begin{array}{ll} \text{Solve} & F(x_k) + F'(x_k)d = 0 \text{ to get } d_k \\ \text{Set} & x_{k+1} = x_k + \alpha_k d_k, \end{array} \right. \tag{2}$$

where the step size α_k in $(0, 1]$ is chosen by a line search.

Han, Pang, and Rangaraj [6] generalized the damped Newton method to solve the nonsmooth equation (1) using the idea of an "iteration function." Let $\theta : R^n \to R_+$ be defined by

$$\theta(x) = \frac{1}{2}F(x)^T F(x).$$

Damped Newton method with iteration function (IF). Let $\rho, \sigma \in (0, 1)$ be given. Let $G : R^{n\times n} \to R^n$ be a given iteration function. Let $x_0 \in R^n$ be arbitrary. Set $k = 0$.

$$\left\{ \begin{array}{ll} \text{Solve} & F(x_k) + G'(x_k, d) = 0 \text{ to get } d_k \\ \text{Set} & x_{k+1} = x_k + \rho^{m_k} d_k, \end{array} \right.$$

where m_k is the smallest nonnegative integer m such that

$$\theta(x_k + \rho^m d_k) - \theta(x_k) \le -2\sigma\rho^m\theta(x_k).$$

Global convergence was established in [6] under four assumptions on G and $F^T G$. In general, $G(x, \cdot)$ is nonlinear. This implies that a system of nonlinear equations (generally easier than (1)) is solved at each step in the above method.

Recently, Gabriel and Pang [7] proposed a trust region algorithm using iteration functions. They also required certain assumptions on the iteration functions to establish convergence of their algorithm. Poliquin and Qi [14] proved that, in the case of nonsmooth optimization, the assumptions on the iteration functions actually implied restrictions on the original function. There are other globally convergent methods for nonsmooth equations [10]–[13], [20]. These methods either assume conditions much stronger than continuity or only work for some special problems.

In this paper, we introduce a successive approximation method. Let $||\cdot||$ denote the Euclidean norm. At the kth step, we approximate F by a smooth function f_k such that $F = f_k + g_k$, where

$$||g_k|| \equiv \sup\{||g_k(x)|| : x \in R^n\} \le \alpha ||F(x_k)||$$

and $\alpha \in (0,1)$ is a fixed constant. The algorithm uses $f'_k(x_k)$, wherever a derivative of F at x_k is needed.

There are two outstanding advantages of the new algorithm over existing methods. The first advantage is that a linear approximation is made at each step, so the subproblem is a system of linear equations. Known globally convergent methods for solving nonsmooth equations do not have this feature. The second advantage is that the conditions required to establish convergence and implement the new algorithm are very general. We establish global convergence of this algorithm under the following assumptions on F: continuity of F, boundedness of a level set, and nonsingularity of f'_k at x_k for all k and at x^*, an accumulation point of $\{x_k\}$. To implement our algorithm we require F to be locally Lipschitzian. Under these assumptions, we may construct f_k with the desired accuracy. The basic tool is the integration convolution. In some special cases, we have other ways to construct f_k.

Although we discuss the linear convergence of this algorithm in §3, we do not intend to pursue a higher rate of convergence for this method. There are already several superlinearly convergent methods [10], [11], [19–21] and a superlinear convergence theory [13], [15] for solving nonsmooth equations. One may construct a hybrid algorithm that is globally and superlinearly convergent using the new algorithm and a known superlinearly convergent algorithm with the methodology proposed in [15]. We do not go into the details of such a construction. The merit of our algorithm is that it may solve some severely nonsmooth equations, such as nonsmooth equations arising from the variational inequality problem for a general convex set and from the maximal monotone operator problem (see §5).

In §2 we describe the successive approximation method and prove its global convergence.

In §3 we consider the rate of convergence.

In §4 we discuss how to construct a successive approximation function for a nonsmooth function F using integration convolution.

In §5 we investigate some applications of our algorithm.

In §6 we give numerical results with the successive approximation method.

2. Method and global convergence.

DEFINITION 1. *Let $\alpha \in (0,1)$ be a constant. At the* kth *step of the iteration methods described in this and the next sections, we call*

$$F = f_k + g_k$$

a normal decomposition of F, *if* f_k *is smooth and* $\|g_k\| \leq \alpha\|F(x_k)\|$, *whenever* $F(x_k) \neq 0$.

We shall give some examples of normal decompositions in §5.

Let

$$\theta(x) = \frac{1}{2}F(x)^T F(x)$$

and

$$\theta_k(x) = \frac{1}{2}f_k(x)^T f_k(x).$$

Our method can be described as follows.

The successive approximation method (SAM). Given $\rho, \alpha \in (0,1)$, an initial vector $x_0 \in R^n$ and a normal decomposition $F = f_0 + g_0$ with $\|g_0\| \leq \frac{\alpha}{2}\|F(x_0)\|$, let $0 < \sigma < 1 - \alpha$. For $k \geq 0$:

1. Solve $F(x_k) + f'_k(x_k)d = 0$ to get d_k.

2. Set $x_{k+1} = x_k + \rho^{m_k}d_k$, where m_k is the smallest nonnegative integer m such that

$$\theta_k(x_k + \rho^m d_k) - \theta_k(x_k) \leq -2\sigma\rho^m\theta(x^k).$$

3. If $F(x_{k+1}) = 0$, stop. If $\|g_k\| < \alpha\|F(x_{k+1})\|$, we let $f_{k+1} = f_k$ and $g_{k+1} = g_k$. Otherwise, we construct a new normal decomposition

$$F = f_{k+1} + g_{k+1},$$

with $\|g_{k+1}\| \leq \min\{\frac{\alpha}{2}\|F(x_{k+1})\|, \frac{1}{2}\|g_k\|\}$.

Assumption 1. The level set

$$D_0 = \{x \in R^n : \theta(x) \leq (1+\alpha)^2\theta(x_0)\}$$

is bounded.

Assumption 2. $f'_k(x_k)$ are nonsingular for all k.

LEMMA 1. *Suppose that* $F(x_k) \neq 0$ *and* $F = f_k + g_k$ *is a normal decomposition of* F. *Then there exists a scalar* $t_k \in (0,1]$ *such that for all* $t \in (0, t_k]$

$$\theta_k(x_k + td_k) - \theta_k(x_k) \leq -2\sigma t\theta(x_k). \tag{3}$$

Proof. Notice that $\theta'_k(x_k) = f'_k(x_k)^T f_k(x_k)$ and $f'_k(x_k)d_k = -F(x_k)$. We have

$$\begin{aligned}\theta_k(x_k + td_k) - \theta_k(x_k) &= \frac{1}{2}(f_k(x_k + td_k)^T f_k(x_k + td_k) - f_k(x_k)^T f_k(x_k)) \\ &= td_k^T f'_k(x_k)^T f_k(x_k) + o(t) \\ &= -tF(x_k)^T F(x_k) + tF(x_k)^T g_k(x_k) + o(t).\end{aligned}$$

Since $\|g_k\| < \alpha\|F(x_k)\|$,

$$\begin{aligned}\theta_k(x_k + td_k) - \theta_k(x_k) &\leq -2t\theta(x_k) + t\|F(x_k)\|\|g_k(x_k)\| + o(t) \\ &< -2t\theta(x_k) + t\alpha\|F(x_k)\|\|F(x_k)\| + o(t) \\ &= -2t(1-\alpha)\theta(x_k) + o(t).\end{aligned}$$

Since $\sigma < 1 - \alpha$, there exists $t_k \in (0,1]$ such that for all $t \in (0, t_k]$, (3) holds. □

Lemma 1 indicates that the SAM is well defined under Assumption 2.

THEOREM 1. *Suppose that Assumptions* 1 *and* 2 *hold. Then the* SAM *is well defined and for all k*

$$x_k \in D_0. \tag{4}$$

Let $\{x_k\}$ be a sequence produced by the SAM. *If furthermore for an accumulation point x^* of $\{x_k\}, f_k'(x^*)$ is nonsingular for all large k, then*

$$\lim_{k\to\infty} F(x_k) = 0 \tag{5}$$

and

$$F(\tilde{x}) = 0$$

for all accumulation points $\tilde{x}$ of $\{x_k\}$.

Proof. Without loss of generality, we may assume that F is not smooth. Hence $\|g_k\| > 0$ for any k.

By Lemma 1, the SAM is well defined. We now prove (4). Without loss of generality, we assume that $F(x_k) \neq 0$ for all k. Let $K = \{0\} \cup \{k : \|g_{k-1}\| \geq \alpha\|F(x_k)\|\}$. Assume that K consists of $k_0 = 0 < k_1 < k_2 < \cdots$. Let k be an arbitrary nonnegative integer. Let k_j be the largest number in K such that $k_j \leq k$. Then

$$f_k = f_{k_j}, \qquad g_k = g_{k_j},$$

and

$$\begin{aligned}
\|F(x_k)\| &= \|f_k(x_k) + g_k(x_k)\| \\
&= \|f_{k_j}(x_k) + g_{k_j}(x_k)\| \\
&\leq \|f_{k_j}(x_k)\| + \|g_{k_j}(x_k)\| \\
&\leq \|f_{k_j}(x_{k_j})\| + \|g_{k_j}\| \\
&= \|F(x_{k_j}) - g_{k_j}(x_{k_j})\| + \|g_{k_j}\| \\
&\leq \|F(x_{k_j})\| + \|g_{k_j}(x_{k_j})\| + \|g_{k_j}\| \\
&\leq \|F(x_{k_j})\| + 2\|g_{k_j}\|.
\end{aligned}$$

If $j = 0$, then $\|F(x_k)\| \leq \|F(x_0)\| + \alpha\|F(x_0)\|$, since $\|g_0\| \leq \frac{\alpha}{2}\|F(x_0)\|$. If $j \geq 1$, then

$$\begin{aligned}
\|F(x_k)\| &\leq \|F(x_{k_j})\| + 2\|g_{k_j}\| \leq \frac{1}{\alpha}\|g_{k_j-1}\| + \|g_{k_{j-1}}\| \\
&\leq \left(\frac{1}{\alpha} + 1\right)\frac{1}{2^{j-1}}\|g_0\| \leq (1+\alpha)\frac{1}{2^{j-1}}\|F(x_0)\|.
\end{aligned} \tag{6}$$

In both cases it follows that $\theta(x_k) \leq (1+\alpha)^2\theta(x_0)$. This implies that (4) holds.

We now prove the second part of the theorem. If K is infinite, then for any $k \geq 0$ there exists $k_j \in K$, the largest number in K such that $k_j \leq k$ and (6) holds. The limit in the right-hand side of (6) is zero. This proves (5).

Hence, to prove (5), it suffices to prove that K is infinite. Suppose K is finite and assume $\hat{k} > k$ for all $k \in K$. Then $\|g_{\hat{k}}\| < \alpha\|F(x_k)\|$ for $k \geq \hat{k}$. Hence for all $k \geq \hat{k}$,

$$f_k \equiv f_{\hat{k}}, \quad g_k \equiv g_{\hat{k}}, \tag{7}$$

and

$$\theta(x_k) = \frac{1}{2}\|F(x_k)\|^2 > \frac{1}{2\alpha^2}\|g_{\hat{k}}\|^2 \equiv \hat{\epsilon} > 0. \tag{8}$$

Suppose that K_0 is a subsequence of $\{0, 1, \ldots\}$ such that $\{x_k : k \in K_0\}$ converges to x^*. By (7) and the condition of this theorem, $f'_{\hat{k}}(x^*)$ is nonsingular. Since $\lim_{k\to\infty, k\in K_0} x_k = x^*$ and $f'_{\hat{k}}(\cdot)$ is a continuous function, $\{\|f'_{\hat{k}}(x_k)^{-1}\| : k \in K_0\}$ is uniformly bounded. Therefore, there exists $L > 0$ such that $\|d_k\| = \|f'_{\hat{k}}(x_k)^{-1}F(x_k)\| \leq L$ for all $k \geq \hat{k}$, $k \in K_0$. Since $\theta'_{\hat{k}}(\cdot)$ is continuous, we have $\delta > 0$ such that for all x satisfying $\|x - x^*\| \leq \delta$

$$\|\theta'_{\hat{k}}(x) - \theta'_{\hat{k}}(x^*)\| \leq \frac{1 - \sigma - \alpha}{L}\hat{\epsilon}. \tag{9}$$

Since $\lim_{k\to\infty, k\in K_0} x_k = x^*$, we have $\bar{k} > \hat{k}$ such that for all $k > \bar{k}$, $k \in K_0$

$$\|x_k - x^*\| \leq \frac{\delta}{2}. \tag{10}$$

Let $t^* \in (0, 1)$ be such that

$$t^* L < \frac{\delta}{2}. \tag{11}$$

By (10) and (11), for all $k > \bar{k}$, $k \in K_0$, $t \in (0, t^*]$, and $\eta \in (0, 1)$, we have

$$\|x_k + \eta t d_k - x^*\| \leq \delta. \tag{12}$$

Now by (9) and (12), for all $k > \bar{k}, k \in K_0$, and $t \in (0, t^*]$, we have

$$\begin{aligned}
&|\ \theta_{\hat{k}}(x_k + td_k) - \theta_{\hat{k}}(x_k) - td_k^T\theta'_{\hat{k}}(x^*)\ | \\
&\leq t\|d_k\| \int_0^1 \|\theta'_{\hat{k}}(x_k + \eta t d_k) - \theta'_{\hat{k}}(x^*)\| d\eta \\
&\leq t(1 - \sigma - \alpha)\hat{\epsilon}.
\end{aligned} \tag{13}$$

Therefore, for all $k \geq \bar{k}, k \in K_0$, and $t \in (0, t^*]$,

$$\begin{aligned}
&\theta_{\hat{k}}(x_k + td_k) - \theta_{\hat{k}}(x_k) \\
&\quad \leq td_k^T\theta'_{\hat{k}}(x^*) + t(1 - \sigma - \alpha)\hat{\epsilon} \\
&\quad \leq td_k^T\theta'_{\hat{k}}(x_k) + t\|d_k\|\|\theta'_{\hat{k}}(x^*) - \theta'_{\hat{k}}(x_k)\| + t(1 - \sigma - \alpha)\hat{\epsilon} \\
&\quad \leq td_k^T\theta'_{\hat{k}}(x_k) + tL\frac{1 - \sigma - \alpha}{L}\hat{\epsilon} + t(1 - \sigma - \alpha)\hat{\epsilon} \\
&\quad \leq td_k^T f'_{\hat{k}}(x_k)^T f_{\hat{k}}(x_k) + 2t(1 - \sigma - \alpha)\hat{\epsilon} \\
&\quad = -tF(x_k)^T f_{\hat{k}}(x_k) + 2t(1 - \sigma - \alpha)\hat{\epsilon} \\
&\quad = -2t\theta(x_k) + tF(x_k)^T g_{\hat{k}}(x_k) + 2t(1 - \sigma - \alpha)\hat{\epsilon} \\
&\quad \leq -2t\theta(x_k) + t\|F(x_k)\|\|g_{\hat{k}}\| + 2t(1 - \sigma - \alpha)\theta(x_k) \\
&\quad \leq -2t\theta(x_k) + 2t\alpha\theta(x_k) + 2t(1 - \sigma - \alpha)\theta(x_k) \\
&\quad = -2t\sigma\theta(x_k).
\end{aligned}$$

This implies that for all $k \geq \bar{k}$, $k \in K_0$, we have $\rho^{m_k - 1} \geq t^*$, i.e.,

$$\rho^{m_k} \geq \rho t^*. \tag{14}$$

By (8), (14), and the construction of our algorithm, for all $k \geq \bar{k}, k \in K_0$

$$\theta_{\hat{k}}(x_{k+1}) - \theta_{\hat{k}}(x_k) \leq -2\sigma\rho^{m_k}\theta(x_k) \leq -2\rho t^*\sigma\hat{\epsilon} < 0.$$

However, by (7) and the construction of our algorithm, $\theta_{\hat{k}}(x_k)$ is nonincreasing for $k \geq \bar{k}$. This implies $\theta_{\hat{k}}(x_k) \to -\infty$ as $k \to \infty$. This contradicts the fact that $\theta_{\hat{k}}(x_k) \geq 0$ for all k. Hence, K cannot be finite. This proves (5). The final conclusion of this theorem simply follows (5) and the continuity of F. □

Remark 1. We may inductively apply the proof of Lemma 1 and the first part of Theorem 1 to prove (3) and (4). In this way, we may reduce Assumption 2 to "$f'_k(x_k)$ are nonsingular for all k satisfying $x_k \in D_0$."

Remark 2. In [17] trust region methods using the decomposition of F for nonsmooth equations were presented. In the second one, successive approximation was used and $F(x_k)$ and $F'(x_k)$ used in classical trust region methods were replaced by $f(x_k)$ and $f'(x_k)$, respectively. If we use successive approximation and replace all $F(x_k)$ in the SAM by $f_k(x_k)$, then we can also prove the global convergence with the technique of [17].

3. Convergence rate. In order to give a convergence rate, we consider a modification of the SAM.

Modified SAM (MSAM). Given $\rho, \alpha \in (0,1)$, $c \in (0, \frac{1}{1+\alpha})$, an initial vector $x_0 \in R^n$, and a normal decomposition $F = f_0 + g_0$ with $\|g_0\| \leq \frac{\alpha}{2}\|F(x_0)\|$, let $0 < \sigma < 1 - \alpha$. For $k \geq 0$:

1. Solve $F(x_k) + f'_k(x_k)d = 0$ to get d_k.
If

$$\frac{\|F(x_k + d_k)\|}{\|F(x_k)\|} \leq c, \tag{15}$$

we let $x_{k+1} = x_k + d_k$, $f_{k+1} = f_k$, and $g_{k+1} = g_k$. Otherwise, we do Steps 2 and 3 of the SAM.

THEOREM 2. *Theorem* 1 *holds for the* MSAM.

Proof. Let K be the set of k such that (15) holds. If K is finite, then the MSAM is essentially the same as the SAM. Hence Theorem 1 holds in this case. Suppose now K is infinite. Let k_i and k_{i+1} be two consecutive numbers in K. If $k_{i+1} = k_i + 1$, then

$$||F(x_{k_{i+1}})|| \leq c||F(x_{k_i})||.$$

Otherwise, with an argument similar to the first part of the proof of Theorem 1, for any k satisfying $k_i + 1 \leq k \leq k_{i+1}$

$$||F(x_k)|| \leq (1+\alpha)||F(x_{k_i+1})||.$$

Hence, for any k satisfying $k_i + 1 \leq k \leq k_{i+1}$,

$$\begin{aligned} ||F(x_k)|| &\leq c(1+\alpha)||F(x_{k_i})|| \\ &= c_1||F(x_{k_i})|| \leq c_1^i||F(x_{k_1})||, \end{aligned}$$

where $c_1 = c(1+\alpha) \in (0,1)$. This shows that (5) holds. Then the conclusion follows. □

The proof of Theorem 2 shows that the MSAM is globally convergent and the norm $||F(x_{k_i})||$ reduces linearly in i if (15) holds infinitely many times. In the following theorem, we show that under some conditions the linear convergence rate can be realized and that $F = f_k + g_k$ need not be a normal decomposition any more for all large k.

THEOREM 3. *Suppose that the conditions of Theorem* 1 *hold and that x^* is an accumulation point of $\{x_k\}$ generated by the* MSAM. *Suppose that there exist a positive integer $\hat{k}$ and positive numbers r, l_1, l_2, and β such that $x_{\hat{k}} \in S(x^*, r)$ and for all $x, y \in S(x^*, r)$*

$$\|f'_{\hat{k}}(x) - f'_{\hat{k}}(x^*)\| \le l_1\|x - x^*\|,$$

$$\beta \ge \|f'_{\hat{k}}(x^*)^{-1}\|,$$

$$\|g_{\hat{k}}(x) - g_{\hat{k}}(y)\| \le l_2\|x - y\|,$$

and

$$\beta l_1 r < 1, \qquad \frac{\beta}{1 - \beta l_1 r}(2l_1 r + l_2) \le c.$$

Then for all $k \ge \hat{k}$, $f_k = f_{\hat{k}}, g_k = g_{\hat{k}}$, and

$$\|x_{k+1} - x^*\| \le c\|x_k - x^*\|. \tag{16}$$

Furthermore, for all $k \ge \hat{k}$, (15) *also holds.*

Proof. By Theorem 2, $F(x^*) = 0$. For any $x \in S(x^*, r)$, we have

$$\|f'_{\hat{k}}(x) - f'_{\hat{k}}(x^*)\| \le l_1 r.$$

By the Perturbation Lemma, for all $x \in S(x^*, r)$,

$$\|f'_{\hat{k}}(x)^{-1}\| \le \frac{\beta}{1 - l_1 r\beta} =: \beta_1.$$

Let $\bar{x}_{\hat{k}+1} = x_{\hat{k}} + d_{\hat{k}}$. Then from $x_{\hat{k}} \in S(x^*, r)$, we have

$$\begin{aligned}
&\|\bar{x}_{\hat{k}+1} - x^*\| \\
&\quad = \|x_{\hat{k}} - x^* - f'_{\hat{k}}(x_{\hat{k}})^{-1}(F(x_{\hat{k}}) - F(x^*))\| \\
&\quad = \left\| f'_{\hat{k}}(x_{\hat{k}})^{-1}\left(\int_0^1 (f'_{\hat{k}}(x^*) - f'_{\hat{k}}(x_{\hat{k}} + t(x^* - x_{\hat{k}})))(x_{\hat{k}} - x^*)dt \right.\right. \\
&\qquad\qquad \left.\left. + (f'_{\hat{k}}(x_{\hat{k}}) - f'_{\hat{k}}(x^*))(x_{\hat{k}} - x^*) - (g_{\hat{k}}(x_{\hat{k}}) - g_{\hat{k}}(x^*))\right)\right\| \\
&\quad \le \beta_1 \left(\int_0^1 l_1(1-t)\|x_{\hat{k}} - x^*\|^2\,dt + l_1\|x_{\hat{k}} - x^*\|^2 + l_2\|x_{\hat{k}} - x^*\|\right) \qquad (17) \\
&\quad \le \beta_1 \left(l_1\left(\frac{1}{2} + 1\right)\|x_{\hat{k}} - x^*\| + l_2\right)\|x_{\hat{k}} - x^*\| \\
&\quad \le \beta_1 \left(\frac{3}{2}l_1 r + l_2\right)\|x_{\hat{k}} - x^*\| \\
&\quad \le c\|x_{\hat{k}} - x^*\|.
\end{aligned}$$

This implies $\bar{x}_{\hat{k}+1} \in S(x^*, r)$.

Furthermore,

$$\begin{aligned}
\|F(\bar{x}_{\hat{k}+1})\| &= \|F(\bar{x}_{\hat{k}+1}) - f'_{\hat{k}}(x_{\hat{k}})(\bar{x}_{\hat{k}+1} - x_{\hat{k}}) - F(x_{\hat{k}})\| \\
&\le \left\| \int_0^1 (f'_{\hat{k}}(x_{\hat{k}} + t(\bar{x}_{\hat{k}+1} - x_{\hat{k}})) - f'_{\hat{k}}(x^*))(\bar{x}_{\hat{k}+1} - x_{\hat{k}})\, dt \right\| \\
&\quad + \|(f'_{\hat{k}}(x^*) - f'_{\hat{k}}(x_{\hat{k}}))(\bar{x}_{\hat{k}+1} - x_{\hat{k}})\| + \|g_{\hat{k}}(\bar{x}_{\hat{k}+1}) - g_{\hat{k}}(x_{\hat{k}})\| \\
&\le 2l_1 r \|\bar{x}_{\hat{k}+1} - x_{\hat{k}}\| + l_2 \|\bar{x}_{\hat{k}+1} - x_{\hat{k}}\| \\
&= (2l_1 r + l_2)\|f'_{\hat{k}}(x_{\hat{k}})^{-1} F(x_{\hat{k}})\| \\
&\le c\|F(x_{\hat{k}})\|.
\end{aligned}$$

Therefore, we have $x_{\hat{k}+1} = \bar{x}_{\hat{k}+1}$. So that $f_{\hat{k}+1} = f_{\hat{k}}$ and $g_{\hat{k}+1} = g_{\hat{k}}$. Repeating the proof with $\hat{k} := \hat{k} + 1$, we obtain (15) and (16). □

Remark 3. If F is smooth, then $g = 0$ and $l_2 = 0$. Then the quadratic rate of convergence of the Damped Newton method is recovered by (17).

4. Approximation using convolution. In this and the next two sections, we use x_i to represent the ith component of a vector x and x^k to represent a vector.

Without loss of generality, we may assume that $F : R^n \to R^n$ is bounded and uniformly continuous. If F is continuous but not bounded and not uniformly continuous, let the level set D_0 be defined as in §2. By Assumption 1, there is $r_0 > 0$ such that $D_0 \subseteq S(0, r_0)$. Define $F_0 : R^n \to R^n$ by

$$F_0(x) = \begin{cases} F(x) & \text{if } ||x|| \le r_0, \\ F(r_0 \frac{x}{||x||}) & \text{if } ||x|| > r_0. \end{cases}$$

Then (1) is equivalent to

$$F_0(x) = 0,$$

while F_0 is bounded and uniformly continuous. Hence, we assume that F is bounded and uniformly continuous. Let M be a bound of $||F||$.

Let $\omega : R_+ \to R_+$ be the modulus of continuity of F defined by

$$\omega(t) = \sup\{||F(x) - F(y)|| \mid ||x - y|| \le t\}.$$

Then ω is a continuous nondecreasing function [9], $\omega(0) = 0$, and for any x and y in R^n we have

$$||F(x) - F(y)|| \le \omega(||x - y||).$$

We call $\Phi : R^n \to R_+$ a kernel function if

$$\int_{R^n} \Phi(x)dx = 1.$$

If Φ is a kernel function, then $\Phi_\lambda : R^n \to R_+$, defined by

$$\Phi_\lambda(x) = \lambda^n \Phi(\lambda x),$$

where λ is a positive number, is also a kernel function. If Φ is smooth, then Φ_λ is also smooth. If $\phi : R \to R_+$ is a one-dimensional (smooth) kernel function, then $\Phi : R^n \to R_+$, defined by

$$\Phi(x) = \phi(x_1)\phi(x_2)\ldots\phi(x_n), \tag{18}$$

is an n-dimensional (smooth) kernel function. Two famous one-dimensional smooth kernel functions are

$$\phi(t) = \frac{1}{\pi} \cdot \frac{1}{1+t^2} \quad \text{(Cauchy kernel)}$$

and

$$\phi(t) = \frac{1}{\sqrt{\pi}} \cdot e^{-t^2} \quad \text{(Weierstrass kernel)}$$

(see Shapiro [24]).

Suppose now that $\Phi : R^n \to R_+$ is a smooth kernel function. For any $\lambda > 0$, define $F_\lambda : R^n \to R^n$ by

$$F_\lambda(x) = \int_{R^n} F(x-y)\Phi_\lambda(y)dy = \int_{R^n} F(y)\Phi_\lambda(x-y)dy.$$

According to [5], [23], [25], F_λ is a smooth function and

$$\nabla F_\lambda(x) = \int_{R^n} F(y) \nabla \Phi_\lambda(x-y)dy.$$

Furthermore, for any x in R^n,

$$\begin{aligned}||F(x) - F_\lambda(x)|| &= ||\int_{R^n} [F(x) - F(x-y)]\Phi_\lambda(y)dy|| \\ &\leq \int_{R^n} ||F(x) - F(x-y)||\Phi_\lambda(y)dy.\end{aligned}$$

For any $\epsilon > 0$, let $\delta > 0$ and $r > 0$ be such that

$$\int_{||x||>r} \Phi(x)dx \leq \frac{\epsilon}{4M} \tag{19}$$

and

$$\omega(\delta) \leq \frac{\epsilon}{2}. \tag{20}$$

For any $\lambda > \frac{r}{\delta}$, we have

$$\begin{aligned}||F(x) - F_\lambda(x)|| &\leq \int_{R^n} ||F(x) - F(x-y)||\Phi_\lambda(y)dy \\ &\leq \int_{||y||\leq\delta} ||F(x) - F(x-y)||\Phi_\lambda(y)dy + \int_{||y||>\delta} ||F(x) \\ &\qquad - F(x-y)||\Phi_\lambda(y)dy\end{aligned}$$

$$
\begin{aligned}
&\leq \omega(\delta)\int_{||y||\leq\delta}\Phi_\lambda(y)dy+2M\int_{||y||>\delta}\Phi_\lambda(y)dy\\
&\leq \frac{\epsilon}{2}+2M\int_{||y||>\delta}\lambda^n\Phi(\lambda y)dy\\
&= \frac{\epsilon}{2}+2M\int_{||z||>\lambda\delta}\Phi(z)dz \qquad (21)\\
&\leq \frac{\epsilon}{2}+2M\int_{||z||>r}\Phi(z)dz\leq\epsilon.
\end{aligned}
$$

Therefore, in §2, if $F(x_k)\neq 0$, we may choose $\epsilon=\alpha||F(x_k)||$ and construct $f_k\equiv F_\lambda$ for $\lambda>r/\delta$. Then $||g_k||=||F-F_\lambda||\leq\epsilon=\alpha||F(x_k)||$, i.e., we have the normal decomposition required in §2.

To construct F_λ satisfying (21), we need to know $r>0$ and $\delta>0$ such that (19) and (20) hold. If Φ is constructed by (18), then it is not very difficult to choose r. Actually, if (18) holds, then we only need r to satisfy

$$\int_{|t|\geq\frac{r}{\sqrt{n}}}\phi(t)dt\leq(\frac{\epsilon}{4M})^{\frac{1}{n}}.$$

On the other hand, if F is globally Lipschitzian with constant L_0, then $\omega(\delta)\leq L_0\delta$. We may let $\delta=\frac{\epsilon}{2L_0}$. Then (20) will be satisfied. In §5, we will give examples of such applications.

If F is locally Lipschitzian, by the construction of F_0 at the beginning of this section, F_0 is always globally Lipschitzian. Hence our method can be implemented as long as F is locally Lipschitzian.

5. Applications of the successive approximation method.

In this section, we discuss some applications of the successive approximation method. The first two examples have appeared in the literature such as [13].

5.1. The variational inequality problem.

Let C be a closed convex subset of R^n and $\phi: C\to R^n$ be a once continuously differentiable function defined on the open set $D\subseteq R^n$ containing C. This problem, which we denote VI(C,ϕ), is to find a vector $x^*\in C$ such that

$$(x-x^*)^T\phi(x^*)\geq 0,\quad \text{for all } x\in C.$$

The system is equivalent to a system of nonsmooth equations in R^n

$$F(x)\equiv x-\Pi_C(x-\phi(x))=0, \qquad (22)$$

where $\Pi_C(y)$ denotes the projection of y on C. The nonsmoothness of the function F is the consequence of the projection operator $\Pi_C(\cdot)$ (see [13]). When C is a polyhedral set, this operator possesses some B-differentiability properties that can be put to use algorithmically (see [10]). However, it is not easy to establish these properties when C is a general convex set.

Since the projection operator is Lipschitzian with modulus 1, we can use the tool of integration convolution stated in §4 to solve the nonsmooth equations (22) by the successive approximation method.

5.2. The maximal monotone operator problem. Let $T : R^n \to R^n$ be a set-valued maximal monotone operator. An important problem is to find $x \in R^n$ such that

$$0 \in T(x). \tag{23}$$

According to the theory of the maximal monotone operator, the resolvent of T, namely, $P_\mu = (I + \mu T)^{-1}$, where I is the identity operator and μ is a positive number, is always single-valued and nonexpansive (hence globally Lipschitzian) [13]. Moreover, the solution of (23) is equivalent to that of the nonsmooth equation (1) where

$$F(x) = x - P_\mu(x).$$

Since P_μ, and therefore F, is globally Lipschitzian, we can use the tool of integration convolution to approximate F and solve the equation by the successive approximation method.

5.3. LC^1 optimization. Consider

$$\min_x \psi(x), \tag{24}$$

where $\psi : R^n \to R$ is a continuously differentiable function. Let $F = \psi'$. Then we may solve

$$F(x) = 0 \tag{25}$$

to find the stationary points of (24). If F is locally Lipschitzian, then ψ is called an LC^1 function and (24) is called an LC^1 optimization problem. There are many examples of LC^1 optimization problems [16], [18]. For example, if $\psi = \psi_1 - \psi_2$, ψ_1, and ψ_2 are conjugate functions of extended-valued strongly convex functions φ_1 and φ_2, then ψ_1', ψ_2', and F are globally Lipschitzian; see Theorem 2.5 of [16]. Actually, we have

$$\begin{aligned} \psi_i(x) = {} & \max_z\{x^T z - \varphi_i(z)\}, \\ Q_i(x) \equiv {} & \psi_i'(x) = \operatorname{argmax}_z\{x^T z - \varphi_i(z)\} \end{aligned} \tag{26}$$

for $i = 1, 2$ [22] and

$$F(x) \equiv Q_1(x) - Q_2(x). \tag{27}$$

If φ_1 and φ_2 are extended-valued convex quadratic functions, then we can rewrite (26) as

$$Q_i(x) = \operatorname{argmax}_z\{x^T z - \frac{1}{2} z^T H_i z : A_i z \leq b^i\}, \tag{28}$$

where $H_i \in R^{n\times n}$ is symmetric and positive definite, $A_i \in R^{m\times n}$, and $b^i \in R^m$ for $i = 1, 2$. In §6, we will give a numerical example where F is defined by (27) and (28).

5.4. The nonlinear complementarity problem. We consider the nonlinear complementarity problem of finding x such that

$$p(x) \geq 0, \qquad q(x) \geq 0, \qquad p(x)^T q(x) = 0,$$

where $p, q : R^n \to R^n$ are continuously differentiable. This problem can be formulated as a system of nonsmooth equations (1) with

$$F(x) = \min(p(x), q(x)) \tag{29}$$

(see [13]). Now, we give a normal decomposition of F defined by (29). This is simpler than the convolution approximation proposed in the general case.

Let $\alpha \in (0,1)$ be a constant and

$$\epsilon_k = \frac{4\alpha}{\sqrt{n}} \|F(x^k)\| \neq 0.$$

Let

$$(\hat{f}_k(x))_i = \frac{q_i(x) - p_i(x) + 2\epsilon_k}{4\epsilon_k} p_i(x) + \frac{p_i(x) - q_i(x) + 2\epsilon_k}{4\epsilon_k} q_i(x) - \frac{\epsilon_k}{4},$$

$$(\hat{g}_k(x))_i = \frac{1}{4\epsilon_k}(\mid p_i(x) - q_i(x) \mid - \epsilon_k)^2,$$

$$(f_k(x))_i = \begin{cases} F_i(x) & \text{if } \mid p_i(x) - q_i(x) \mid > \epsilon_k, \\ (\hat{f}_k(x))_i & \text{if } \mid p_i(x) - q_i(x) \mid \leq \epsilon_k, \end{cases}$$

$$(g_k(x))_i = \begin{cases} 0 & \text{if } \mid p_i(x) - q_i(x) \mid > \epsilon_k, \\ (\hat{g}_k(x))_i & \text{if } \mid p_i(x) - q_i(x) \mid \leq \epsilon_k, \end{cases}$$

$$\text{for } i = 1, 2, \ldots, n.$$

Then it is easy to verify that

$$F(x) = \min(p(x), q(x)) = f_k(x) + g_k(x), \qquad x \in R^n;$$

f_k is continuously differentiable, g_k is continuous and $\|g_k\| \leq \sqrt{n}\|g_k\|_\infty \leq \sqrt{n}\frac{\epsilon_k}{4} = \alpha\|F(x^k)\|$.

5.5. A piecewise smooth function. Consider

$$F(x) = Ax + \psi(x), \tag{30}$$

where $A : R^n \to R^n$ is a matrix and ψ is a diagonal continuous function, that is, $\psi_i(x) = \phi_i(x_i)$, $i = 1, 2, \ldots, n$. See [9]. Such a system arises from nonsmooth partial differential equations. In a general case, ϕ_i is defined as a piecewise smooth function:

$$\phi_i(x_i) = \begin{cases} u_i(x_i) & \text{if } x_i \geq a_i, \\ v_i(x_i) & \text{if } x_i < a_i, \end{cases}$$

where u_i and v_i are smooth functions with $u_i(a_i) = v_i(a_i)$ and a_i are constants, $i = 1, 2, \ldots, n$.

If $u_i'(a_i) > v_i'(a_i)$, we may replace F_i by $-F_i$. Hence, we may assume that for all i, $u_i'(a_i) \leq v_i'(a_i)$. Let

$$p_i(x) = \begin{cases} (Ax)_i + u_i(x_i) & \text{if } x_i \geq a_i, \\ (Ax)_i + v_i(x_i) + (v_i'(a_i) - u_i'(a_i))(a_i - x_i) & \text{if } x_i < a_i \end{cases}$$

and

$$q_i(x) = \begin{cases} (Ax)_i + u_i(x_i) + (v_i'(a_i) - u_i'(a_i))(x_i - a_i) & \text{if } x_i \geq a_i, \\ (Ax)_i + v_i(x_i) & \text{if } x_i < a_i. \end{cases}$$

Then p, q are smooth functions and

$$F(x) = \min(p(x), q(x))$$

is equivalent to (30).

Now, we can give a normal decomposition of F as in §5.4.

6. Numerical experiments. In this section, we give some computation results to illustrate the SAM and MSAM. The first example is from §5.3.

Example 1. Let

$$Z_1 = \{z \in R^n \ : \ A_1 z \leq b_1\} \quad \text{and} \quad Z_2 = \{z \in R^n \ : \ A_2 z \leq b_2\}$$

be nonempty convex polyhedra in R^n. Let

$$Q_1(x) = \arg\max_{z \in Z_1} \ x^T z - \frac{1}{2} z^T H_1 z$$

and

$$Q_2(x) = \arg\max_{z \in Z_2} \ x^T z - \frac{1}{2} z^T H_2 z,$$

where $H_i \in R^{n \times n}$ are symmetric and positive definite, $A_i \in R^{m \times n}$, and $b_i \in R^m$ for $i = 1, 2$.

We consider the nonsmooth equations

$$F(x) \equiv Q_1(x) - Q_2(x) + Px + c_0 = 0,$$

where P is an $n \times n$ nonsingular matrix and c_0 is a fixed vector in R^n.

PROPOSITION 1. *Let*

$$\psi(x) = \max_z \left\{ x^T z - \frac{1}{2} z^T H z : Az \leq b \right\},$$

where $H \in R^{n \times n}$ is symmetric and positive definite, $A \in R^{m \times n}$, and $b \in R^m$. Assume that $\{z : Az \leq b\}$ is not empty. Then

$$||\psi'(x) - \psi'(y)|| \leq ||H^{-1}|| ||x - y||.$$

Proof. By Theorem 26.3 of [22], ψ is continuously differentiable and $\psi'(x) = Q(x)$ =argmax$_z\{x^T z - \frac{1}{2} z^T H z : Az \leq b\}$. Moreover

$$\varphi(z) = \begin{cases} \frac{1}{2} z^T H z & \text{if } Az \leq b, \\ +\infty & \text{otherwise} \end{cases}$$

is the conjugate function of ψ and φ is a strongly convex function, that is,

$$t\varphi(\bar{z}) + (1-t)\varphi(\hat{z}) - \varphi(t\bar{z} + (1-t)\hat{z}) \geq ct(1-t)||\bar{z} - \hat{z}||^2,$$

TABLE 1

x_0	(7.0764, 4.4550, 7.1401, 2.1182)
$\|\|x_{68} - x^*\|\|$	1.0383882×10^{-7}
$\|\|F(x_{68})\|\|$	7.5659260×10^{-7}
Test Problem 2	
x^*	(4.7545, 10.5370, 1.3704, 5.0524)
$Q_1(x^*)$	(0.7643, 2.9602, 0.0000, 1.0998)
$Q_2(x^*)$	(1.0000, 1.5613, 1.0000, 1.0000)
c_0	(−45.9436, −96.0082, −26.2708, −47.1997)
x_0	(12.8565, 11.5656, 8.4323, 14.7801)
$\|\|x_{81} - x^*\|\|$	1.0267013×10^{-7}
$\|\|F(x_{81})\|\|$	7.1972663×10^{-7}
Test Problem 3	
x^*	(−4.7545, −1.0537, −1.3704, −0.5052)
$Q_1(x^*)$	(0.0000, 0.0000, 0.0000, 0.0000)
$Q_2(x^*)$	(1.0000, 1.0000, 1.0000, 1.0000)
c_0	(36.3344, 15.6718, 14.8669, 8.6836)
x_0	(−2.0265, 7.9727, 5.7637, 3.0629)
$\|\|x_{144} - x^*\|\|$	1.3155275×10^{-7}
$\|\|F(x_{144})\|\|$	8.8361463×10^{-7}

where $c = \frac{1}{2||H^{-1}||}$. Let $\hat{z} = \psi'(x)$ and $\bar{z} = \psi'(y)$. By Theorem 23.5 of [22], $x \in \partial\varphi(\hat{z})$ and $y \in \partial\varphi(\bar{z})$. Hence, for any $t \in (0,1)$,

$$\begin{aligned} \varphi(\bar{z}) - \varphi(\hat{z}) &\geq [\varphi(\hat{z} + t(\bar{z} - \hat{z})) - \varphi(\hat{z})]/t + c(1-t)||\bar{z} - \hat{z}||^2 \\ &\geq x^T(\bar{z} - \hat{z}) + c(1-t)||\bar{z} - \hat{z}||^2, \end{aligned}$$

where the second inequality holds because of the basic property of subgradients. Let $t \to 0$; we have

$$\varphi(\bar{z}) - \varphi(\hat{z}) \geq x^T(\bar{z} - \hat{z}) + c||\bar{z} - \hat{z}||^2. \tag{31}$$

Similarly, we have

$$\varphi(\hat{z}) - \varphi(\bar{z}) \geq y^T(\hat{z} - \bar{z}) + c||\hat{z} - \bar{z}||^2. \tag{32}$$

Addition of (31) and (32) shows that

$$(y - x)^T(\bar{z} - \hat{z}) \geq 2c||\bar{z} - \hat{z}||^2.$$

Hence,

$$2c||\bar{z} - \hat{z}||^2 \leq ||\bar{z} - \hat{z}|| \cdot ||y - x||.$$

Therefore,

$$||\psi'(x) - \psi'(y)|| = ||\hat{z} - \bar{z}|| \leq \frac{1}{2c}||x - y||. \qquad \square$$

TABLE 2

SAM	$130(x^{**})$ 15×10^{-7}	$14(x^*)$ 13×10^{-7}	$29(x^{**})$ 25×10^{-7}	$18(x^{**})$ 7×10^{-7}
MSAM	$4(x^{**})$ 17×10^{-7}	$5(x^*)$ 6×10^{-7}	$8(x^{**})$ 0.1×10^{-7}	$13(x^{**})$ 5×10^{-7}

Proposition 1 can be generalized to the case that φ is locally strongly convex. See [16]. By Proposition 1, F is globally Lipschitzian with modulus $L_0 = ||H_1^{-1}|| + ||H_2^{-1}|| + ||P||$ and $||F(x)|| \leq L_0||x|| + ||F(0)||$. If we take the transformation mentioned in the beginning of §4, then $||F|| \leq L_0 r_0 + ||F(0)|| =: M$. Hence we can give a normal decomposition of F using the convolution discussed in §4. Let

$$f_k(x) = \int_{R^n} F(y)\Phi_{\lambda_k}(x-y)dy,$$

where $\Phi_{\lambda_k}(x) = \lambda_k^n \Phi(\lambda_k x)$

$$\Phi(x) = \phi(x_1)\dots\phi(x_n).$$

We use the Cauchy kernel function stated in §4. At the kth step, let $\epsilon = \alpha||F(x^k)||$ and $\lambda_k \geq \frac{2L_0\sqrt{n}}{\epsilon}\tan(\frac{\pi}{2}(1-(\frac{\epsilon}{4M})^{\frac{1}{n}}))$. Then we have $||F(x) - f_k(x)|| \leq \epsilon = \alpha||F(x^k)||$. We solve the system of linear equations

$$\nabla f_k(x^k)d = -F(x^k),$$

where

$$\nabla f_k(x^k) = \int_{R^n} F(y) \nabla \Phi_{\lambda_k}(x^k - y)dy.$$

Let $F(x) = (F_1(x), \dots, F_n(x))^T, \beta_{k,i}(x) = \lambda_k^{n+1}\phi(\lambda_k x_1)\dots\phi'(\lambda_k x_i)\dots\phi(\lambda_k x_n)$, and $\nabla f_k(x^k) = (J_{ij}(x^k))$. Then

$$J_{ij}(x^k) = \int_{R^n} F_i(y)\beta_{k,j}(x^k - y)dy.$$

Obviously, F is nondifferentiable at x if for one $i = 1$ or 2, $Q_i(x)$ is on the boundary of Z_i. We test the algorithm SAM with a four-dimensional problem where

$$P = \begin{pmatrix} 7.0022 & 0.9018 & 0.6111 & 0.5042 \\ 0.9018 & 7.9745 & 1.0961 & 0.9506 \\ 0.6111 & 1.0961 & 6.9120 & 0.6618 \\ 0.5042 & 0.9506 & 0.6618 & 6.6859 \end{pmatrix},$$

$$H_1 = \begin{pmatrix} 2.0022 & 0.9018 & 0.6111 & 0.5042 \\ 0.9018 & 0.2974 & 1.0961 & 0.9506 \\ 0.6111 & 1.0961 & 1.9120 & 0.6618 \\ 0.5042 & 0.9506 & 0.6618 & 1.6850 \end{pmatrix},$$

$$H_2 = \begin{pmatrix} 2.9174 & 1.4182 & 0.4576 & 1.0221 \\ 1.4182 & 4.4486 & 0.7656 & 1.4075 \\ 0.4576 & 0.7656 & 3.0682 & 0.8975 \\ 1.0221 & 1.4075 & 0.8975 & 3.6760 \end{pmatrix}$$

are randomly generated. Let

$$Z_1 = \{z \in R^4 : z_i \geq 0, i = 1, 2, 3, 4\}$$

and

$$Z_2 = \{z \in R^4 : z_i \geq 1, i = 1, 2, 3, 4\}.$$

We randomly generate x^* and choose c_0 such that x^* is a solution of $F(x) = 0$ and F is nondifferentiable at the solution x^*, i.e., $Q_1(x^*)$ or $Q_2(x^*)$ is on the boundary of Z_1 or Z_2, respectively.

The Monte-Carlo method is used to calculate the integral numerically. Numerical results are shown in Table 1 with random initial points.

Example 2. We consider the following degenerate nonlinear complementarity problem [8]:

$$x \geq 0, \quad p(x) \geq 0, \quad x^T p(x) = 0, \quad x \in R^4$$

where $p : R^4 \to R^4$ is given by

$$p(x) = \begin{pmatrix} 3x_1^2 + 2x_1x_2 + 2x_2^2 + x_3 + 3x_4 - 6 \\ 2x_1^2 + x_1 + x_2^2 + 10x_3 + 2x_4 - 2 \\ 3x_1^2 + x_1x_2 + 2x_2^2 + 2x_3 + 9x_4 - 9 \\ x_1^2 + 3x_2^2 + 2x_3 + 3x_4 - 3 \end{pmatrix}.$$

This problem has two solutions:

$$x^* = (1, 0, 3, 0) \quad \text{and} \quad x^{**} = (\sqrt{6}/2, 0, 0, 0.5) \simeq (1.224745, 0, 0, 0.5).$$

Formulate this problem as $F(x) = 0$ with F defined by (29); then $F(x)$ is differentiable at x^* but nondifferentiable at x^{**}.

Using the Newton line-search method with iteration function method (IF), we quote the particular definition of iteration function $G(\cdot, \cdot)$ given in [6]:

$$G_i(x, d) = \begin{cases} d_i & \text{if } x_i < p_i(x), p_i(x) \geq 0, \\ \nabla p_i(x)^T d & \text{if } x_i > p_i(x), x_i \geq 0, \\ \min(d_i, \nabla p_i^T d) & \text{otherwise.} \end{cases}$$

The computational results by the IF, the SAM, and the MSAM are shown in Table 2. We used single precision. We choose $c = \frac{1}{1+\alpha}$ in the MSAM.

We see that these three methods are globally convergent. The final iteration numbers of the SAM and MSAM are comparable with those of the IF. The SAM and MSAM are further featured by less work at each iteration (the SAM and MSAM only needs to solve a linear system of equations at each step). We can construct approximation functions for any locally Lipschitzian function, but until now generally we do not know how to construct iteration functions in this case. Therefore, the successive approximation method is more general.

Acknowledgments. We are thankful to Professor Olvi Mangasarian, Dr. Rob Womersley, three referees and Mr. Houyuan Jiang for their comments. We are grateful to Professor Carl de Boor for his suggestion on convolution, which upgraded this paper.

OPTIMAL SUPERVISORY CONTROL OF DISCRETE EVENT DYNAMICAL SYSTEMS*

RATNESH KUMAR† AND VIJAY K. GARG‡

Abstract. The notion of optimal supervisory control of discrete event dynamical systems (DEDSs) is formalized in the framework of Ramadge and Wonham. A DEDS is modeled as a state machine and is controlled by disabling some of its transitions. Two types of cost functions are defined: a cost of control function corresponding to disabling transitions in the state machine, and a penalty of control function corresponding to reaching some undesired states or not reaching some desired states in the controlled system. The control objective is to design an *optimal* control mechanism, if it exists, so that the *net* cost is minimized. Since a DEDS is represented as a state machine—a directed graph—network flow techniques are naturally applied for designing optimal supervisors. It is also shown that our techniques can be used to solve supervisory control problems under complete as well as partial observation. In particular, for the first time, techniques for computing the supremal controllable and normal sublanguage and the infimal controllable and normal/observable superlanguage without having to perform alternate computations of controllable and normal/observable languages are obtained.

Key words. discrete event dynamical systems, supervisory control, automata theory, optimal control, max-flow min-cut

1. Introduction.

Research of the supervisory control of a discrete event dynamical system (DEDS) was pioneered by Ramadge and Wonham [23]. In [23], a DEDS, also called plant, is modeled as a state machine (SM) and the behavior of a DEDS is described by the language accepted by the corresponding SM. A controller or a supervisor, based on its observation of the past behavior of the plant, determines the transitions to be disabled in the plant, so that some desired qualitative control objective is achieved. Usually, the control objective is to restrict the plant behavior such that it remains confined within a specific range [24]. In some other cases, the control objective is to design a supervisor so that the closed-loop behavior *eventually* remains confined to a prescribed range [3], [18], [12]. Recently, there has also been some work in which the control objective is to restrict the plant behavior so that a certain cost function defined along the trajectory of the system is optimized [20], [19], [2], [26], [10].

In [20], [19], a cost function is defined on the set of transitions and the control objective is to restrict the plant behavior in such a way that after starting from a *given* initial state the plant reaches one of the accepting states along a trajectory of optimal cost. Authors provide an efficient heuristic search-based algorithm to solve the problem. In [2] also, a cost function is defined on the set of transitions and the control objective is to restrict the plant behavior so that after starting from *any* state the plant reaches one of the accepting states along a trajectory of optimal cost. [26], two types of costs, a control cost and a path cost, are defined on the graph representing a plant. The control objective is to determine that subgraph of the plant graph for which the maximum of the total cost along all its trajectories is minimal. The notions of cost of control and penalty of control considered in our paper are somewhat similar to that of control cost and path cost in [26]. However, our control objective is to determine a *state-feedback* supervisor so that the net cost of disabling transitions, that of reaching undesired states, and that of not reaching desired states is minimized. Thus our control objective is different from that considered in [26].

In this paper, we consider two types of cost functions: (i) A positive *cost of control* function is defined on the set of transitions corresponding to the cost of disabling a transition; if a certain transition such as arrival of a customer in a queue is disabled by a supervisor at a certain point, then its cost of control is added to the net cost, otherwise—if the transition is not disabled—no cost is added to the net cost. (ii) A *penalty of control* function is defined on the set of states corresponding to their reachability in the controlled system. The penalty of control takes a negative or positive value depending on whether the state is desired or undesired. If a state is desired—e.g., working or idle state of a machine—then a negative penalty is associated with it. If such a state remains unreachable in the controlled plant, then a positive cost equal in magnitude to its penalty of control is added to the net cost, otherwise—if the state is reachable—no cost is added to the net cost. On the other hand, if a state is undesired—e.g., over/underflow of a buffer—then a positive penalty is associated with it. If such a state can be reached in the controlled plant, then a cost equal to its penalty of control is added to the net cost, otherwise—if it remains unreachable—no cost is added to the net cost. The optimal control problem is to determine a state-feedback supervisor for which the net cost is minimized. State-feedback supervisors [8], [21], [13], [6] exercise control based on the state of the plant rather than the sequence of events executed by it. However, this does not result in any loss of generality, since a "string-feedback" supervision is equivalent to a state-feedback supervision on a suitably refined [7] model of a plant.

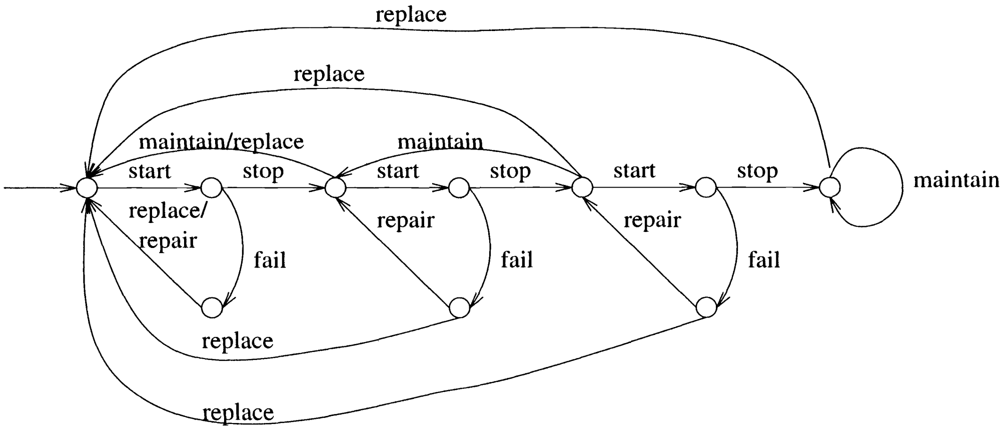

FIG. 1. *Diagram for machine* P *of Example* 1 *with* $N = 4$.

Example 1. Consider for example a machine P shown in Fig. 1. (For clarity, the state labels have been omitted.) Initially P is in the "first idle" state (i.e., idle and unused state). When event "start" is executed, it goes to the "first working" state. In the "kth working" state, where $1 \leq k < N$, the machine may either "fail," in which case it goes to the "kth broken" state; or it may complete its operation, execute "stop," and go to the "$(k+1)$th idle" state. In the "kth broken" state, the machine is either "repaired," in which case it goes back to the "kth idle" state; or it is "replaced," in which case it goes to the "first idle" state. In the "kth idle" state, either the event "start" is executed, which sends the machine to the "kth working" state; or "replace" is executed, which sends the machine to the "first idle" state; or "maintain" is executed, which sends the machine to the "$(\max\{1, 2k - N\})$th idle" state. Thus, in the "Nth idle" state, execution of the "maintain" event does not result in a change in state. Note that the function $\max\{1, 2k - N\}$ is chosen only for an illustration; in general, it is an increasing function of k taking values smaller than k except at $k = 1$ and $k = N$, where it equals k. An optimal control policy is needed to decide (i) whether to repair or replace the machine in a broken state and (ii) whether to operate or maintain or replace the machine in an idle state. An optimal control policy evidently depends on the cost of replacement of machine, cost of repair in the kth broken state, cost of maintenance in the kth idle state, payoff of operating the machine in the kth idle state, penalty of being in a broken state, payoff of being in an idle or a working state, etc.

Our setting is similar to that considered in [27], in which appropriate cost and penalty functions were defined on a suitably refined model of a given plant and the dynamic programming algorithm was used to determine the *existence* of a supervisor for a given control problem. The computational complexity of the dynamic programming algorithm was used to determine the computational complexity of the supervisory control problem thus solved. However, no technique for the *synthesis* of a supervisor, if it exists, was given in that reference. Our approach to optimal supervisory control differs from that considered in [27] in two ways. First, we show that an optimal supervisory control problem of the type described above can be solved using network flow algorithms. Thus a more general algorithm such as dynamic programming can also be used, although this will result in an *increase* in computational complexity. Second, we show that our techniques are equally applicable for the synthesis of supervisors, whenever they exist.

The motivation of formulating an optimal supervisory control problem is twofold: first, to introduce a formal framework for optimal supervisory control in which the control objective is to optimize a suitably defined cost and penalty of exercising controls; and second, to present a unified technique for supervisory synthesis under complete as well as partial observation. In particular, we obtain techniques for computing the supremal controllable and normal sublanguage [22], [16], [1], [11], [4], the infimal controllable and normal superlanguage [14], and the infimal controllable and observable superlanguage [16], [5], [25], [9] *without* having to perform alternate computations of controllable and normal/observable languages as is done in [4] (also refer to Remark 3). Our techniques also illustrate that a supervisory control problem under complete or partial observation can be solved using a state-feedback type of control on a suitably refined state machine representation of the plant. We provide techniques to obtain the appropriate refinements.

In §2, we introduce our notation and formally describe the optimal supervisory control problem under complete as well as partial state observation. In §3, we show how the network flow algorithms can be used to solve the optimal supervisory control problems. In §4, we show that by appropriately defining the cost and penalty functions, our techniques can be used to solve the supervisory control problem under complete as well as partial observation.

2. Notation and problem formulation. A discrete event dynamical system to be controlled, called plant, is modeled as a state machine [7] and denoted as a 4-tuple $G := (X, \Sigma, \delta, x_0)$, where X denotes the set of states, Σ denotes the finite set of *events*, $\delta : X \times \Sigma \rightarrow X$ denotes the partial deterministic state transition function, and $x_0 \in X$ denotes the initial state. A triple $(x_1, \sigma, x_2) \in X \times \Sigma \times X$, such that $\delta(x_1, \sigma) = x_2$, is called a *transition* in G. The behavior of G is described by the language $L(G)$:

$$L(G) := \{s \in \Sigma^\star \mid \delta(x_0, s) \text{ is defined}\},$$

where $\Sigma^\star$ denotes the set of finite sequences of events belonging to Σ, including the zero-length sequence ϵ; the transition function is extended in a natural way to $\delta : X \times \Sigma^\star \rightarrow X$.

In general, a supervisor or a controller determines the set of events to be disabled after each transition, based on the record of observed states and events. We consider a supervisor, denoted S, to be a map $S : X \rightarrow 2^\Sigma$ that determines the set of events $S(x) \subseteq \Sigma$ to be disabled at each state $x \in X$. Events not belonging to the set $S(x)$ remain enabled at x. A supervisor as defined above is called a state-feedback [21], [13], [12], as it exercises control based on the state of G (and not based on the record of observed states and events). As is shown below, this does not result in any loss of generality, as a more general supervisor, which exercises control based on the observed sequence of events, can equivalently be viewed as a state-feedback supervisor on a suitably refined model of the plant. Readers are referred to [24] for a more general definition of a supervisor. The controlled plant, denoted G_S, is another state machine given as the 4-tuple $G_S := (X, \Sigma, \delta_S, x_0)$, where X, Σ, x_0 are as defined above and δ_S denotes the state transition function of the controlled plant G_S:

$$\forall x \in X, \sigma \in \Sigma : \delta_S(x, \sigma) := \begin{cases} \delta(x, \sigma) & \text{if } \sigma \notin S(x), \\ \text{undefined} & \text{otherwise.} \end{cases}$$

The behavior of the closed-loop system is described by the language $L(G_S)$ generated by the controlled plant. It is clear that $L(G_S) \subseteq L(G)$.

Next we formally describe the problem of optimal supervisory control. Let $c : X \times \Sigma \rightarrow \mathcal{R}^+$ denote a cost of control function, where $\mathcal{R}^+$ denotes the set of strictly positive reals, including infinity. The cost $c(x, \sigma)$ represents the cost of disabling the event $\sigma \in \Sigma$ at the state $x \in X$.

We assume for simplicity that the cost of control is a "one-time" cost. A justification for this simplifying assumption is the following: In G_S, a certain state may be visited either only once (if it is not a node on any cycle in the graph of G_S) or an unbounded number of times (otherwise). If a state is visited only once, then the corresponding transitions are controlled only once. Hence, in this case, the cost of control ought to be one-time. On the other hand, if a state is visited an unbounded number of times, then the corresponding transitions are controlled each time the state is visited. However, due to the state-feedback nature of supervision, the *same* control is exercised on each occasion. Hence, in this case, the cost of controlling such transitions can be associated with the first time the control is exercised. The one-time cost of control assumption can also be interpreted as follows: A transition once disabled/enabled at the corresponding state remains disabled/enabled in that state so that on subsequent visits to that state no cost is incurred in disabling/enabling that transition. Alternatively, the cost of control is primarily of setting up a control mechanism—a switch, for example—and the cost of engaging or disengaging the switch is small compared to its one-time setup cost. In each case, the assumption of state-feedback supervision is crucial.

Next, a penalty of control function $p : X \to \mathcal{R}$ is defined on the state set, where $\mathcal{R}$ denotes the set of reals, including positive and negative infinity. It corresponds to the penalty associated with reachability of a certain state in the controlled plant. The penalty function may take a positive or negative value depending on whether the corresponding state is undesired or desired. Given a state $x \in X$, if $p(x) < 0$, then x is a desired state and it should remain reachable in the controlled plant. In case x is unreachable in the controlled plant, a positive cost equal to $-p(x)$ is added to the net cost as a penalty, else no cost is added to the net cost. Similarly, if $p(x) > 0$ for some $x \in X$, then x is an undesired state and it should remain unreachable in the controlled plant. In case x is reachable in the controlled plant, a cost equal to $p(x)$ is added to the net cost as a penalty, else no cost is added to the net cost.

We assume for simplicity, as above for the cost of control, that the penalty of control is a one-time penalty; i.e., the penalty of reaching an undesired state does not depend on the number of times that state is visited. The justification for this simplified assumption is similar to that given above for the one-time cost of control assumption.

Remark 1. If $c(\cdot, \sigma) = \infty$ for an event $\sigma \in \Sigma$, then σ should not be disabled by any supervisor at any state of G. Thus an infinite cost of control of an event captures the notion of *uncontrollable* events [23], [24]. The notion of desired or *target* behavior can be captured by defining the penalty function to be infinity for those states that are reachable by the strings in the undesired behavior, and any fixed negative real for those states that are reachable by strings in the desired behavior. However, this requires that the state machine G be refined [7], [11] with respect to the given target behavior, so that the states corresponding to the desired and undesired behavior can be uniquely identified, and the penalty function is unambiguously defined. This is explained formally in §4.

With the above definitions of the cost and penalty of control functions we can define the optimal supervisory control problem.

DEFINITION 1. For any supervisor $S : X \to 2^{\Sigma}$, the *net cost* of using S, denoted $C(S)$, is defined to be

$$C(S) := \sum_{x \in \mathrm{Re}(G_S)} \left[\sum_{\sigma \in S(x)} c(x, \sigma) \right] + \sum_{\substack{x \in \mathrm{Re}(G_S), \\ p(x) > 0}} p(x) + \sum_{\substack{x \notin \mathrm{Re}(G_S), \\ p(x) < 0}} -p(x),$$

where $\mathrm{Re}(G_S)$ is the set of reachable states[1] in G_S.

Thus the net cost of control of using S consists of the sum of three terms: (i) The first term corresponds to the cost of disabling the events by S. $\sum_{\sigma \in S(x)} c(x, \sigma)$ is the total cost of disabling events at state $x \in X$. Thus $\sum_{x \in \mathrm{Re}(G_S)} \sum_{\sigma \in S(x)} c(x, \sigma)$ is the total cost of disabling the events by S. (ii) The second term, $\sum_{x \in \mathrm{Re}(G_S), p(x) > 0} p(x)$, denotes the penalty of reaching undesired states. (iii) Finally, the third term $\sum_{x \notin \mathrm{Re}(G_S), p(x) < 0} -p(x)$, denotes the penalty of not reaching the desired states.

[1] Given a state machine $V := (Q, \Sigma, \rho, q_0)$, the set of reachable states $\mathrm{Re}(V)$ is recursively defined as: (i) $q_0 \in \mathrm{Re}(V)$; and (ii) $q \in \mathrm{Re}(V), \exists \sigma \in \Sigma : \rho(q, \sigma)$ is defined $\Rightarrow \rho(q, \sigma) \in \mathrm{Re}(V)$.

Optimal supervisory control problem 1 (OSCP1). Let a plant $G := (X, \Sigma, \delta, x_0)$, a cost of control function $c : X \times \Sigma \to \mathcal{R}^+$, and a penalty of control function $p : X \to \mathcal{R}$ be given. Design a supervisor $S : X \to 2^\Sigma$ such that the net cost is minimized, i.e., determine

$$\arg\left\{\min_S C(S)\right\}.$$

2.1. Partial state observation. In OSCP1, a supervisor while deciding its control actions assumes that a complete state information of G is available. We pose another optimal supervisory control problem in which a complete state information is not available, and there exists a mask $\Psi : X \to Y$ defined from the state space X to an observation space Y such that for each $x \in X$, $\Psi(x) \in Y$ is the state value observed by a supervisor. A supervisor in this case is given by a map $S' : Y \to 2^\Sigma$. Since a supervisor takes a control action based on observing a state $y \in Y$, given any $y \in Y$, the same control action is taken at all states in the set $\Psi^{-1}(y) := \{x \in X \mid \Psi(x) = y\}$. Thus corresponding to a supervisor $S' : Y \to 2^\Sigma$, we can equivalently define a supervisor $S : X \to 2^\Sigma$ with the constraint C1:

$$\textbf{C1: } \forall x_1, x_2 \in X : \Psi(x_1) = \Psi(x_2) \Rightarrow S(x_1) = S(x_2).$$

Optimal supervisory control problem 2 (OSCP2). Let a plant $G := (X, \Sigma, \delta, x_0)$, a cost of control function $c : X \times \Sigma \to \mathcal{R}^+$, a penalty of control function $p : X \to \mathcal{R}$, and a mask $\Psi : X \to Y$ be given. Design a supervisor $S' : Y \to 2^\Sigma$ (equivalently a supervisor $S : X \to 2^\Sigma$ satisfying C1) such that the net cost is minimized; i.e., determine

$$\arg\left\{\min_{S:\text{ C1 holds}} C(S)\right\}.$$

Remark 2. The difference between OSCP1 and OSCP2 is that, in OSCP2, the minimization is performed over all supervisors that also satisfy the constraint C1, whereas no such constraint exists in OSCP1. It is easily seen that given an instance of OSCP1, it can be reduced to an instance of OSCP2 by setting the mask function to be the identity function. We show in the next section that given an instance of OSCP2, it can be reduced to an instance of OSCP1 by suitably modifying the cost of control function and the graph representing the plant. Thus the two formulations are reducible to each other.

In the formulation of OSCP2, a state-based mask function is used. This is in contrast to the setting of supervisory control, where usually an event-based mask is used. However, an event-based mask can be used to obtain a state-based mask by first constructing a state estimator, as in [17], and next identifying all the states with identical state estimates to have equal mask value. Thus it is possible to reduce an optimal control problem under partial observation of events to one under partial observation of states.

3. Solution using network flow algorithm. In this section we provide a solution to the optimal supervisory control problems introduced in §2. The problem is to determine for each transition in the state machine G whether to disable or enable it, so that the net cost is minimized. We show that this problem is equivalent to determining an optimal partition of the state space X into the set of states that remain reachable in the controlled plant and the set of remaining unreachable states. The desired optimal partition is determined using the max-flow min-cut theorem [15], a technique for optimal partitioning of directed graphs.

3.1. Max-flow min-cut theorem. Interested readers are referred to [15] for a formal and elaborate description of the max-flow min-cut theorem. Informally described, in its simplest form, a *flow network* is represented as a weighted directed graph having a single *source* node from where the flow starts and a single *terminal* node where the flow terminates. The weights on the directed edges of the graph represent the maximum flow capacities of the corresponding edges (the minimum capacity is zero unless specified). Formally, we have the following definition.

DEFINITION 2. A *flow network* N is a weighted directed graph described by a triple $N = (V, E, u)$, where V denotes the set of vertices or nodes of N, $E \subseteq V^2$—subset of *ordered* pairs of V^2—denotes the set of directed edges or links of N, and $u : E \rightarrow \mathcal{R}^+$ denotes the maximum capacity function of links. V contains two special nodes s and t, the source node and the terminal node respectively.

The basic flow optimization problem is to determine for a given flow network a flow of maximum value between its source and terminal nodes subject to the edge capacity constraints, where a flow and its value are defined as follows.

DEFINITION 3. A *flow* for a network N is a map $f : E \rightarrow \mathcal{R}^+$ such that

1. $\forall e \in E : f(e) \leq u(e)$,
2. $\sum_{v\in V:(s,v)\in E} f((s,v)) = \sum_{v'\in V:(v',t)\in E} f((v',t))$, and
3. $\forall v \in V, v \neq s, v \neq t : \sum_{v'\in V:(v,v')\in E} f((v,v')) = \sum_{v''\in V:(v'',v)\in E} f((v'',v))$.

$\sum_{v\in V:(s,v)\in E} f((s,v)) = \sum_{v'\in V:(v',t)\in E} f((v',t))$ is called the *value* of f. A *max-flow* is a flow of maximum (flow) value. Thus a flow is an assignment of a positive number to each edge in the flow network that corresponds to the amount of flow on that edge, satisfying three constraints. First, the amount of flow through each edge is no greater than its capacity; second, the net flow out of the source node equals the net flow into the terminal node; and finally, the net flow out of the intermediate nodes is zero. The value of a flow equals the net flow out of the source node (equivalently, the net flow into the terminal node).

DEFINITION 4. A *cut* of a network N is a partition of V such that s and t are in different partitions. Let $V_s \subseteq V$ and $V_t := V - V_s$ denote the partitions of a cut such that $s \in V_s$ and $t \in V_t$. Then the *capacity* of this cut is defined as

$$\sum_{(i,j)\in(V_s\times V_t)\cap E} u((i,j)).$$

A *min-cut* is a cut of minimum capacity. Thus any partition of the nodes in N such that the source node and the terminal node belong to different partitions is called a cut. The capacity of a cut equals the sum of capacity of those edges that emerge out of a node contained in the partition containing the source node and terminate at a node contained in the partition containing the terminal node.

THEOREM 1. (max-flow min-cut) [15]. The value of a max-flow of a flow network equals the capacity of a min-cut of that network.

Algorithms for computing a max-flow can be found in [15]. In this paper, we are interested in computing a cost-minimizing supervisor. This is shown to be equivalent to determining a min-cut for a suitably defined flow network, which in view of Theorem 1 can be computed using any of the max-flow computations.

3.2. Solution of OSCP1. In this subsection we provide a solution for the OSCP1 using the network flow technique discussed in the previous subsection. It is clear that each supervisor $S : X \rightarrow 2^{\Sigma}$ partitions the state space X into $\mathrm{Re}(G_S) \cup (X - \mathrm{Re}(G_S))$, the sets of reachable and unreachable states in the controlled plant G_S. We define a supervisor to be parsimonious if and only if it disables those transitions that are defined from a state in $\mathrm{Re}(G_S)$ to a state in $X-$ $\mathrm{Re}(G_S)$. Formally, consider the following definition.

DEFINITION 5. A supervisor $S : X \rightarrow 2^{\Sigma}$ is said to be *parsimonious* if and only if for each state $x \in X$ and event $\sigma \in \Sigma$:

$$\sigma \in S(x) \Leftrightarrow [x \in \mathrm{Re}(G_S),\ \delta(x, \sigma) \notin \mathrm{Re}(G_S)].$$

We prove that parsimonicity is a necessary condition for optimality of a supervisor.

LEMMA 1. If S is an optimal supervisor, then S is parsimonious.

Proof. Assume for the sake of contradiction that S is optimal but not parsimonious. Then there exist an event $\sigma \in \Sigma$ and states $x_1, x_2 \in \mathrm{Re}(G_S)$ such that $\delta(x_1, \sigma) = x_2$ and $\sigma \in S(x_1)$, i.e., σ is disabled at x_1. Consider a supervisor S' that exercises the same control action as S does, except that at state x_1 it does not disable the event σ, i.e., $\sigma \notin S'(x_1)$. Then $C(S') = C(S) - c(x_1, \sigma) < C(S)$, for $c(x_1, \sigma) > 0$. Thus we obtain a contradiction to the optimality of S. □

The following is an immediate corollary of Lemma 1.

COROLLARY 1. OSCP1 is equivalent to determining

$$\arg \left\{ \min_{S:S \text{ parsimonious}} C(S) \right\}.$$

Proof. The proof follows from the fact that parsimonicity is a necessary condition for optimality, and the definition of OSCP1. □

In the next theorem we provide a technique for solving the OSCP1 using the max-flow min-cut theorem. First we define a flow network N_G corresponding to the state machine G, the cost of control function c, and the penalty of control function p as follows.

DEFINITION 6. Given a SM $G := (X, \Sigma, \delta, x_0)$ with cost of control function $c : X \times \Sigma \rightarrow \mathcal{R}^+$ and penalty of control function $p : X \rightarrow \mathcal{R}$, a flow network, denoted N_G, is defined to be $N_G := (V_G, E_G, u_G)$, where

1. $V_G := X \cup \{s, t\}$ with $s, t \notin X$,
2. $E_G := \{(x_1, x_2) \in X \times X \mid \exists \sigma \in \Sigma \text{ s.t. } \delta(x_1, \sigma) = x_2\}$
   $\cup \{(x, t) \in X \times \{t\} \mid p(x) > 0\}$
   $\cup \{(s, x) \in \{s\} \times X \mid p(x) < 0\}$,
3. $\forall (x_1, x_2) \in E_G \cap (X \times X) : u_G((x_1, x_2)) := \sum_{\sigma \in \Sigma : \delta(x_1, \sigma) = x_2} c(x_1, \sigma)$
   $\forall x \in X \text{ s.t. } p(x) > 0 : u_G((x, t)) := p(x)$
   $\forall x \in X \text{ s.t. } p(x) < 0 : u_G((s, x)) := -p(x)$.

Thus the node set of N_G is obtained by adding to the state set X of G two extra nodes s and t—the source and the terminal node, respectively. The edge set of N_G consists of: (i) An edge from $x_1 \in X$ to $x_2 \in X$ if there exists a transition from x_1 to x_2 in G. The capacity of such an edge equals the sum of cost of disabling each transition from x_1 to x_2. (ii) An edge from each $x \in X$ for which $p(x) > 0$ to the terminal node t, with capacity $p(x)$. (iii) An edge from the source node s to each $x \in X$ for which $p(x) < 0$, with capacity $-p(x)$.

Example 2. Consider the plant G shown in Fig. 2, with the state set $X = \{1, 2\}$, the event set $\Sigma = \{a, b\}$, the initial state $x_0 = 1$, and the transition function $\delta(1, a) =$

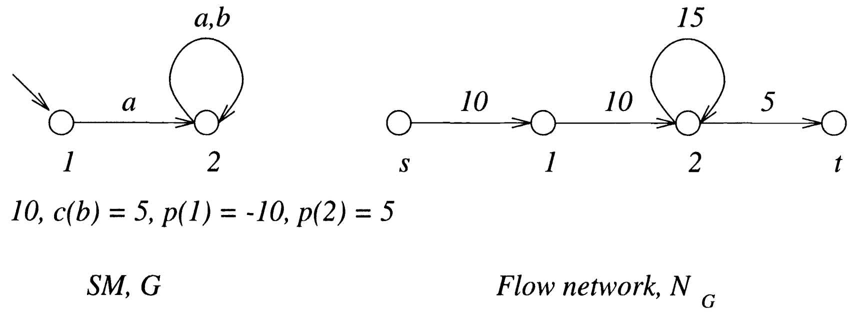

FIG. 2. *Diagram illustrating construction of N_G.*

$2, \delta(2,a) = \delta(2,b) = 2$. Then $L(G) = \overline{a(a+b)^\star}$. Let the cost of control function be defined as $c(a) = 10$ and $c(b) = 5$ and the penalty of control function be defined as $p(1) = -10$ and $p(2) = 5$. Then the flow network N_G, corresponding to the plant G, obtained using Definition 6 is shown in Fig. 2.

DEFINITION 7. Given a supervisor $S : X \to 2^\Sigma$, the cut of flow network N_G induced by S is defined to be $[\mathrm{Re}(G_S) \cup \{s\}] \cup [(X - \mathrm{Re}(G_S)) \cup \{t\}]$. Given a cut $V_s \cup (V_G - V_s)$ of N_G, where $V_s \subseteq V_G$, $s \in V_s$, and $t \notin V_s$, the parsimonious supervisor $S : X \to 2^\Sigma$ induced by the cut is defined to be: for each $x \in X$ and $\sigma \in \Sigma$, $\sigma \in S(x)$ if and only if $x \in V_s$ and $\delta(x,\sigma) \notin V_s$.

THEOREM 2. (Solution of OSCP1). The supervisor induced by a min-cut of N_G is a solution of OSCP1.

We prove a lemma before proving Theorem 2.

LEMMA 2. If S is a parsimonious supervisor, then $C(S)$ equals the capacity of the cut of N_G induced by S.

Proof. Consider the cut $[\mathrm{Re}(G_S) \cup \{s\}] \cup [(X - \mathrm{Re}(G_S)) \cup \{t\})$ induced by S. The capacity of this cut is given by the sum of capacities of all the edges that originate from a node in the set $\mathrm{Re}(G_S) \cup \{s\}$ and terminate at a node in the set $(X - \mathrm{Re}(G_S)) \cup \{t\}$. Let the set of such edges be denoted as E_S, i.e.,

$$E_S := \{(x_1, x_2) \in E_G \mid x_1 \in \mathrm{Re}(G_S) \cup \{s\} \text{ and } x_2 \in (X - \mathrm{Re}(G_S)) \cup \{t\}\}.$$

Then the capacity of the cut of N_G induced by S equals $\sum_{e \in E_S} u_G(e)$. We note that

$$\begin{aligned} E_S = \{(x_1, x_2) &\in \mathrm{Re}(G_S) \times (X - \mathrm{Re}(G_S)) \mid \exists \sigma \in \Sigma \text{ s.t. } \delta(x_1,\sigma) = x_2\} \\ &\cup \{(x,t) \mid x \in \mathrm{Re}(G_S), p(x) > 0\} \\ &\cup \{(s,x) \mid x \notin \mathrm{Re}(G_S), p(x) < 0\}. \end{aligned}$$

Hence

$$\begin{aligned} \sum_{e \in E_S} u_G(e) = &\sum_{x \in \mathrm{Re}(G_S)} \left[\sum_{\sigma \in \Sigma : \delta(x,\sigma) \in X - \mathrm{Re}(G_S)} c(x,\sigma) \right] \\ &+ \sum_{x \in \mathrm{Re}(G_S) : p(x) > 0} p(x) + \sum_{x \notin \mathrm{Re}(G_S) : p(x) < 0} -p(x). \end{aligned}$$

Since S is parsimonious, for each $x \in \mathrm{Re}(G_S)$ the set $\{\sigma \in \Sigma \mid \delta(x,\sigma) \in X - \mathrm{Re}(G_S)\} = \{\sigma \in \Sigma \mid \sigma \in S(x)\}$. Hence $\sum_{e \in E_S} u_G(e) = C(S)$. □

Proof of Theorem 2. Consider the parsimonious supervisor S induced by a min-cut of N_G. Then, from the result of Lemma 2, we obtain that $C(S)$ equals the capacity of min-cut of N_G. In view of Corollary 1, in order to prove the optimality of S it suffices to show that if S' is any other parsimonious supervisor, then $C(S') \geq C(S)$. Since S' is also parsimonious, it follows from Lemma 2 that $C(S')$ equals the capacity of cut of N_G induced by S', which is greater than or equal to the capacity of the min-cut (by definition of min-cut). Since $C(S)$ equals the capacity of the min-cut (by construction of S), we obtain the desired inequality: $C(S') \geq C(S)$. □

3.3. Solution of OSCP2. In this subsection we provide a solution for OSCP2. In this setting, given a plant G, a cost of control function c, a penalty of control function p, and an observation mask Ψ, the control objective is to determine an optimal supervisor $S : X \to 2^{\Sigma}$ satisfying the constraint C1. The constraint C1 can be satisfied by making a few modifications in G and in the cost of control function c as described below. First, we modify the state machine G; the modified state machine is denoted as G'.

DEFINITION 8. Given $G = (X, \Sigma, \delta, x_0)$, the modified state machine G' corresponding to the constraint C1 is the quadruple $G' = (X, \Sigma', \delta', x_0)$, where

1. $\Sigma' := \Sigma \cup \{\theta\}$ with $\theta \notin \Sigma$,
2. $\forall x \in X, \forall \sigma' \in \Sigma' : \delta'(x, \sigma') := \delta(x, \sigma')$ if $\sigma' \neq \theta$, and
3. $\forall \sigma \in \Sigma, x_1, x_2 \in X$ s.t. $\Psi(x_1) = \Psi(x_2), \delta(x_1, \sigma) \neq \delta(x_2, \sigma)$:
$\delta'(\delta(x_1, \sigma), \theta) := \delta(x_2, \sigma)$ and $\delta'(\delta(x_2, \sigma), \theta) := \delta(x_1, \sigma)$.

Thus G' is obtained by adding in G, an oppositely directed pair of transitions labeled θ, between the pair of states reached by executing a common event from a pair of states that look alike under Ψ. No such transition is added if the *same* state is reached after executing a common event from a pair of states that look alike under Ψ.

Next, the cost of control function $c : X \times \Sigma \to \mathcal{R}^+$ is extended to $c' : X \times \Sigma' \to \mathcal{R}^+$ as

$$\forall x \in X, \sigma' \in \Sigma' : c'(x, \sigma') := \begin{cases} c(x, \sigma') & \text{if } \sigma' \in \Sigma, \\ \infty & \text{if } \sigma' = \theta. \end{cases}$$

Thus the cost of control function c' is the extension of c obtained by assigning the cost of disabling the event θ to be infinity. For simplicity of notation, let OSCP1 with respect to G', with cost of control c' and penalty of control p be denoted as OSCP1$'$.

THEOREM 3. (Solution of OSCP2). *OSCP2 is equivalent to OSCP1$'$.*

We prove a few lemmas before proving Theorem 3.

LEMMA 3. If S is parsimonious, then S disables transitions leading from states in Re(G_S) into a state $x \in X$ if and only if it disables all transitions from states in Re(G_S) leading into x.

Proof. if and only if it disables a transition that the set $X - Re(G_S)$. Hence, S does not disable a self-loop. Also, if If S disables some transitions but not all transitions from states in Re(G_S) leading into a state $x \in X$, then x remains reachable in G_S, i.e., $x \in$ Re(G_S), which contradicts that S is parsimonious. □

LEMMA 4. There exists a solution $S : X \to 2^{\Sigma'}$ of OSCP1$'$ such that

1. S never disables the event θ, and
2. S satisfies constraint C1.

Proof. 1. Let $S : X \to 2^{\Sigma'}$ be a solution of OSCP1$'$. If $C(S) < \infty$, then it is clear that S never disables the event θ. Next consider the case when $C(S) = \infty$. If S ever disables the event θ, then consider a supervisor S' that takes the same control action as S does, except that it never disables the event θ. Then by optimality of S, $C(S') \geq C(S) = \infty$, which implies that $C(S') = \infty$. Hence S' is optimal, and it never disables the event θ.

2. Let $S : X \to 2^{\Sigma'}$ be a solution of OSCP1$'$. We show that if $x_1, x_2 \in \text{Re}(G_S)$ are such that $\Psi(x_1) = \Psi(x_2)$, then $S(x_1) = S(x_2)$. In other words, if an event $\sigma \in \Sigma$ is defined at such a pair of states $x_1, x_2 \in \text{Re}(G_S)$, then either σ is disabled at both x_1 and x_2 or it is disabled at neither of x_1 and x_2. Consider such a pair of states $x_1, x_2 \in \text{Re}(G_S)$ and an event $\sigma \in \Sigma$. Then either $\delta(x_1, \sigma) = \delta(x_2, \sigma)$ or $\delta(x_1, \sigma) \neq \delta(x_2, \sigma)$. If $\delta(x_1, \sigma) = \delta(x_2, \sigma)$, then S disables the event σ at both the states or at neither of the states. This follows from the fact that any optimal supervisor is also parsimonious (Lemma 1), and any parsimonious supervisor disables either all transitions leading into a state or none of them (Lemma 3). Thus constraint C1 is satisfied in this case. If $\delta(x_1, \sigma) \neq \delta(x_2, \sigma)$, then according to the construction of G' these states are connected by a pair of oppositely directed transitions labeled θ. Since S never disables the event θ (from part 1), the states $\delta(x_1, \sigma)$ and $\delta(x_2, \sigma)$ do not belong to separate partitions induced by S. Suppose that they both are in $\text{Re}(G_S)$; then due to parsimonicity of S, σ is enabled at both x_1 and x_2. On the other hand, if they both are in $X-$ $\text{Re}(G_S)$, then clearly, σ is disabled at x_1 and x_2. □

Proof of Theorem 3. We first show that if $S : X \to 2^{\Sigma'}$ is a solution of OSCP1$'$, then it is also a solution for OSCP2. In view of Lemma 4, it can be assumed, without loss of generality, that S never disables the event θ and satisfies C1. Since S never disables the event θ and satisfies C1, it can be viewed as a map $S : X \to 2^{\Sigma}$ satisfying C1; and hence it can also be used as a supervisor under partial state observation. Assume for the sake of contradiction that S is not a solution of OSCP2. Let $S' : X \to 2^{\Sigma}$ with $S' \neq S$ be a solution of OSCP2; then we must have $C(S') < C(S)$, where S, S' are treated as *feasible* solutions of OSCP2. Let $C'(S), C'(S')$ denote the net costs of using S and S' respectively, when S, S' are treated as *feasible* solutions of OSCP1$'$. Since (i) S and S' do not disable the event θ and (ii) for each $x \in X$ and $\sigma \in \Sigma$, $c'(x, \sigma) = c(x, \sigma)$, we have $C'(S) = C(S)$ and $C'(S') = C(S')$. Since $C(S') < C(S)$, we obtain $C'(S') < C'(S)$. This contradicts the optimality of S (treated as a solution of OSCP1$'$).

Next we show that if $S : X \to 2^{\Sigma}$ is a solution of OSCP2, then it is also a solution of OSCP1$'$. It is clear that S can also be viewed as a map $S : X \to 2^{\Sigma'}$. Assume for the sake of contradiction that S is not a solution for OSCP1$'$. Let $S' : X \to 2^{\Sigma'}$ with $S' \neq S$ be a solution of OSCP1$'$; then we must have $C'(S') < C'(S)$. Also, from Lemma 4, S' never disables the event θ and satisfies C1. Thus S' can be used as a supervisor under partial state observation. As above, $C'(S) = C(S)$ and $C'(S') = C(S')$. However, since $C'(S') < C'(S)$, we obtain $C(S') < C(S)$. This is a contradiction to the optimality of S (treated as a solution of OSCP2). □

4. Applications to supervisory control.

It is clear from Theorem 3 that an instance of OSCP2 can be reduced to an instance of OSCP1 by suitably modifying the graph of the plant and the cost of control function. We show in this section that supervisory control problems under complete as well as partial observation can also be reduced to instances of OSCP1. We begin with the problem of computing the supervisors under complete observation, which requires computation of supremal controllable sublanguage and infimal controllable superlanguage.

4.1. Computations related to controllability of DEDSs.

We first consider the computation of supremal controllable sublanguage: Given a desired prefix closed behavior $K \subseteq L(G)$, compute the *supremal* sublanguage $K^{\uparrow} \subseteq K$ such that it is *controllable* [23], i.e., $K^{\uparrow}\Sigma_u \cap L(G) \subseteq K^{\uparrow}$, where $\Sigma_u \subseteq \Sigma$ denotes the set of uncontrollable events. A closed-form expression for $K^{\uparrow}$ is given in [1], and an optimal algorithm for computing $K^{\uparrow}$ is given in [11].

In order to reduce the problem of computing $K^{\uparrow}$ to an instance of OSCP1, we refine G with respect to K so that the states corresponding to strings in K are uniquely identified. This is done as follows. Let $V := (Q, \Sigma, \rho, q_0)$ be a trim deterministic state machine that generates K. The graph of V is made "complete" by adding a dump state d to its state set. If a certain event σ is not defined at some state $q \in Q$, then a transition labeled σ from the state q to the dump state d is added. Also, execution of any event in the dump state leaves the system in that state. Formally, the *completion* of V is another state machine $V' := (Q', \Sigma, \rho', q_0)$, where $Q' := Q \cup \{d\}$ with $d \notin Q$ and

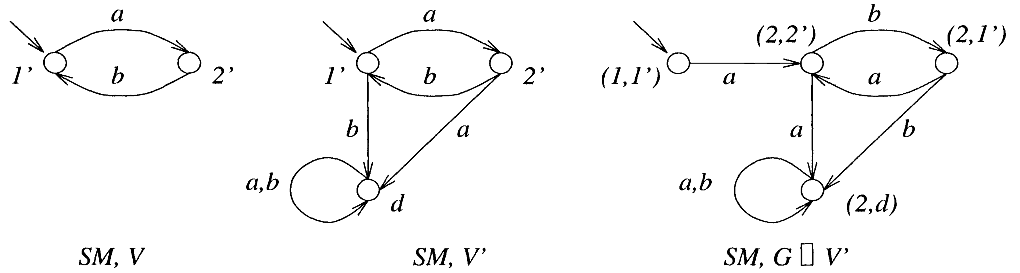
$$\forall q' \in Q', \sigma \in \Sigma : \rho'(q', \sigma) := \begin{cases} \rho(q', \sigma) & \text{if } q' \in Q \text{ and } \rho(q', \sigma) \text{ is defined,} \\ d & \text{otherwise.} \end{cases}$$

It is clear that $L(V') = \Sigma^\star$. Consider the synchronous composition [8], [11] of G and V': $G \Box V' := (X \times Q', \Sigma, \alpha, (x_0, q_0))$, where

$$\forall x \in X, q' \in Q', \sigma \in \Sigma : \alpha((x, q'), \sigma) := \begin{cases} (\delta(x, \sigma), \rho'(q', \sigma)) & \text{if } \delta(x, \sigma), \rho'(q', \sigma) \text{ ,} \\ & \text{are defined,} \\ \text{undefined} & \text{otherwise.} \end{cases}$$

It is easily shown that $L(G \Box V') = L(G) \cap L(V') = L(G) \cap \Sigma^\star = L(G)$. $G \Box V'$ is called *refinement* of G with respect to K. Note that the first coordinate of a state in $G \Box V'$ corresponds to a state of G and the second coordinate to a state of V'.

Example 3. Let G be the plant as in Example 2 and the target language K be given by $K = \overline{(ab)^\star} \subseteq L(G) = \overline{a(a+b)^\star}$. The generator V for the language K is shown in Fig. 3, with the state set $Q = \{1', 2'\}$, the initial state $q_0 = 1'$, and the transition function $\rho(1', a) = 2', \rho(2', b) = a$. The state machine V' obtained by



SM, V SM, V' SM, G □ V'

FIG. 3. *Diagram illustrating construction of* $G \Box V'$.

completing the graph of V and the state machine $G \Box V'$ obtained by synchronous composition of G and V' are both shown in Fig. 3. Note that $L(V') = (a+b)^\star = \Sigma^*$ and $L(G \Box V') = \overline{a(a+b)^\star} = L(G)$.

LEMMA 5. Given a string $s \in \Sigma^\star$, $s \in L(G) - K$ if and only if the second coordinate of the state reached by executing s in $G \Box V'$ is d.

Proof. The proof is straightforward. □

Example 4. Consider the state machine $G \Box V'$ of Example 3. Then the strings, the execution of which take to the state $(2, d)$, belong to $L(G) - K = \overline{a(a+b)^*} - \overline{(ab)^*}$.

Also, the strings, the execution of which take to states $(1, 1')$ or $(2, 2')$ or $(2, 1')$, belong to the language $K = \overline{(ab)^*}$.

The result of Lemma 5 can be used to identify unambiguously the desired and undesired states in $G\Box V'$. The next lemma proves that it is also possible to obtain the generator for $K^\uparrow$ by partitioning the graph of $G\Box V'$ into sets of reachable and unreachable states.

LEMMA 6. [11, Prop. 3.6]. Let $s, t \in K$ be such that $\alpha((x_0, q_0), s) = \alpha((x_0, q_)), t)$; then $s \in K^\uparrow$ if and only if $t \in K^\uparrow$.

Based on the result of Lemma 5, we define a penalty of control function $p : X \times Q' \to \mathcal{R}$ for $G\Box V'$ as

$$(1) \qquad \forall (x, q') \in X \times Q' : p((x, q')) := \begin{cases} \infty & \text{if } q' = d, \\ -p_0 & \text{otherwise,} \end{cases}$$

where $p_0 \in \mathcal{R}^+$ is any positive real. Since the penalty of control of a state in $G\Box V'$ with second coordinate d is infinity, it should remain unreachable in an optimally controlled plant; and since the penalty of control of all other states is $-p_0$, as many such states as possible should remain reachable in an optimally controlled plant.

Example 5. Consider the state machine $G\Box V'$ of Example 3. Then in order to compute the supremal controllable sublanguage of $K = \overline{(ab)^*}$ with respect to G of Example 2, we define the penalty of control function as $p[(2, d)] = \infty, p[(1, 1')] = p[(2, 2')] = p[(2, 1')] = -p_0$.

Next we define a cost of control function $c : X \times \Sigma \to \mathcal{R}^+$ as

$$(2) \qquad \forall x \in X, \sigma \in \Sigma : c(x, \sigma) := \begin{cases} \infty & \text{if } \sigma \in \Sigma_u, \\ \frac{p_0}{|e|+1} & \text{otherwise,} \end{cases}$$

where $|e|$ denotes the total number of transitions in the graph of $G\Box V'$. Since the cost of control of an uncontrollable event is infinity, it should not be disabled by an optimal supervisor; and since the cost of control of a controllable event is $\frac{p_0}{|e|+1}$, as few such events as possible should be disabled. With the above definitions of cost and penalty of control functions, we prove in the following theorem that the computation of $K^\uparrow$ can be posed as an instance of OSCP1.

THEOREM 4. If $K^\uparrow \neq \emptyset$, then $K^\uparrow$ equals the language generated by $G\Box V'$ under the control of a solution of OSCP1 with respect to $G\Box V'$, with cost of control of function as in equation 2 and penalty of control function as in equation 1.

Proof. Let $S : X \times Q' \to 2^\Sigma$ be the parsimonious supervisor induced by the partition of $G\Box V'$ into the set of states that correspond to the supremal controllable sublanguage and the set of remaining states, i.e., S disables those transitions that are defined from states corresponding to the supremal controllable sublanguage to the set of remaining states. That such a partition exists follows from Lemma 6 and the fact that $K^\uparrow \neq \emptyset$. It is clear that S does not disable any uncontrollable events (otherwise the controlled system behavior is not a controllable language), and no state with second coordinate d remains reachable under the control of S (otherwise the controlled system behavior is not a sublanguage of K). Hence $C(S) < \infty$. Let $S' : X \times Q' \to 2^\Sigma$ be a solution of OSCP1. Then it follows from the optimality of S' that $C(S') \leq C(S) < \infty$. Thus S' does not disable any uncontrollable event and no state with second coordinate d remains reachable in the controlled system (otherwise $C(S') = \infty$). Since S' does not disable any of the uncontrollable events, the controlled system behavior under its control is controllable [11, Lemma 2.7]. Also, since no state with second coordinate d remains reachable under the control of S', the controlled system behavior under the control of S' is a sublanguage of K. Assume for contradiction that the controlled system behavior under the control of S' is not the supremal controllable sublanguage of K. So there exists at least one state with second coordinate unequal to d such that it is reachable under the control of S and unreachable under the control of S'. Hence $C(S') - C(S) \geq p_0 - n\frac{p_0}{|e|+1}$, where n is the difference between the number of controllable transitions disabled by S and the number of controllable transitions disabled by S'. Since $n \leq |e|$, the total number of transitions in $G\Box V'$, $n\frac{p_0}{|e|+1} < p_0$. In other words, $C(S') - C(S) > 0$. This is a contradiction to the optimality of S'. □

Next we consider the problem of computing the infimal controllable superlanguage: Given a desired prefix closed behavior $K \subseteq L(G)$, compute the *infimal* superlanguage $K^{\downarrow} \supseteq K$ such that it is *controllable*. A closed-form expression for $K^{\downarrow}$ and an algorithm for computing it is given in [14]. We use the same notation as above. The following modification is made to the penalty of control function:

$$(3) \qquad \forall (x,q') \in X \times Q' : p((x,q')) := \begin{cases} p_0 & \text{if } q' = d, \\ -\infty & \text{otherwise} \end{cases}$$

Since penalty of control of a state with second coordinate d is p_0, as few such states as possible should remain reachable in the controlled system; and since the penalty of control of a state with second coordinate unequal to d is $-\infty$, all such states should remain reachable in the controlled system.

Example 6. Consider the state machine $G\Box V'$ of Example 3. Then in order to compute the infimal controllable superlanguage of $K = \overline{(ab)^*}$ with respect to G of Example 2, we define the penalty of control function as $p[(2,d)] = p_0, p[(1,1')] = p[(2,2')] = p[(2,1')] = -\infty$.

With the above modification in the penalty function, we prove in the following theorem that the computation of $K^{\downarrow}$ can be posed as an instance of OSCP1.

THEOREM 5. $K^{\downarrow}$ equals the language generated by $G\Box V'$ under the control of a solution of OSCP1 with respect to $G\Box V'$, with cost of control function as in equation 2 and penalty of control function as in equation 3.

Proof. The proof is similar to that of Theorem 4. □

4.2. Computations related to observability of DEDSs. Suppose that the supervisor's observation of events is filtered through a mask of the type $M : \Sigma \rightarrow \Lambda \cup \{\epsilon\}$. Computation of a supervisor under such a partial observation requires computation of languages such as supremal normal sublanguage, infimal normal/observable superlanguage, supremal controllable and normal sublanguage, infimal controllable and normal/observable superlanguage, etc. We show that each of these computations can be reduced to instances of OSCP1. Our techniques illustrate how supervisory control under partial observation can be solved using a state-feedback type control on a suitably refined state machine representation of the plant.

We first consider the problem of computing the supremal normal sublanguage: Given a desired prefix closed language $K \subseteq L(G)$, compute the *supremal* sublanguage $K^{\circ} \subseteq K$, such that it is *normal*, i.e., $M^{-1}(M(K^{\circ})) \cap L(G) \subseteq K^{\circ}$. The existence of K° is shown in [16], and a closed form expression for K° is given in [1], [11]. We first refine the state machine G with respect to V (the generator for K) and mask function M so that the states corresponding to K° are uniquely identified. We begin by constructing the machine $G_1 := G\Box V'$. Recall that $L(G_1) = L(G)$. Using G_1 we construct a machine that generates the language $M^{-1}M(L(G_1))$ by employing the following algorithm:

ALGORITHM 1.

1. Replace each transition $\sigma \in \Sigma$ in G_1 by the transition $M(\sigma) \in \Lambda \cup \{\epsilon\}$. Call this machine G_2; clearly, $L(G_2) = M(L(G_1))$.
2. Construct a deterministic machine G_3 that is language equivalent to G_2 [7]. Then the state space of G_3 is $2^{X\times Q'}$ and $L(G_3) = L(G_2) = M(L(G_1))$.
3. Replace each transition $\lambda \in \Lambda$ in machine G_3 by the events in the set $M^{-1}(\lambda) := \{\sigma \in \Sigma \mid M(\sigma) = \lambda\}$. Also, at each state in G_3, add self-loops corresponding to the events in the set $M^{-1}(\epsilon) = \{\sigma \in \Sigma \mid M(\sigma) = \epsilon\}$. Call this machine G_4; clearly, $L(G_4) = M^{-1}(L(G_3)) = M^{-1}(L(G_2)) = M^{-1}M(L(G_1))$.

G_4 has a nice property that if two strings $s, t \in L(G_4)$ are such that $M(s) = M(t)$, then the state reached by executing them are the same. This follows from the observations that (i) the state reached by executing s in G_4 is the same as that reached by executing $M(s)$ in G_3 (by construction); (ii) since $M(s) = M(t)$ and G_3 is deterministic, the same state is reached by executing $M(t)$ in G_3; and (iii) by construction, this is the state reached by t in G_4. We exploit the above property of G_4 in identifying the states corresponding to the strings in the language K°. This, however, requires the construction of machine $G_5 := G_1 \Box G_4$, for which it is clear that $L(G_5) = L(G_1) \cap L(G_4) = L(G) \cap M^{-1}M(L(G)) = L(G)$ and the state space of G_5 equals $X \times Q' \times 2^{X\times Q'}$. Construction of state machines G_1 through G_5, their state spaces, and their languages are summarized in Table 1.

TABLE 1
Various machines used for computation of K°

SM	Construction	State space	Language
G_1	$G\Box V'$	$X \times Q'$	$L(G)$
G_2	$M(G_1)$	$X \times Q'$	$M(L(G))$
G_3	$det(G_2)$	$2^{X\times Q'}$	$M(L(G))$
G_4	$M^{-1}(G_3)$	$2^{X\times Q'}$	$M^{-1}(M(L(G))$
G_5	$G_1\Box G_4$	$X \times Q' \times 2^{X\times Q'}$	$L(G)$

Note that in Table 1 and Fig. 4, we have used the notation (i) $M(G_1)$ to represent that G_2 is obtained by "masking" the transitions of G_1, (ii) $\det(G_2)$ to represent that G_3 is obtained by "determinizing" G_2, and (iii) $M^{-1}(G_3)$ to represent that G_4 is obtained by "unmasking" the transitions of G_3.

Example 7. Consider the state machine $G_1 = G\Box V'$ of Example 3. Let the mask $M : \Sigma = \{a, b\} \to \{\lambda\}$ be defined as $M(a) = M(b) = \lambda$. Then the state machines G_2, G_3, G_4, and G_5 obtained by using Algorithm 1 are shown in Fig. 4.

We use $r = ((x, q'), \{(x_1, q_1'), (x_2, q_2'), \ldots, (x_r, q_r')\}) \in X \times Q' \times 2^{X\times Q'}$ to denote a typical state of G_5, where $(x, q') \in X\times Q'$ and $\{(x_1, q_1'), (x_2, q_2'), \ldots, (x_r, q_r')\} \in 2^{X\times Q'}$. We call $r' := (x, q')$ the G_1 part of r and $R := \{(x_1, q_1'), (x_2, q_2'), \ldots, (x_r, q_r')\}$ the G_4 part of r. We prove in the next lemma that if r_1 and r_2 are two states of G_5 with identical G_4 part, then corresponding to each string, the execution of which takes to the state r_1, there exists another string, the execution of which takes to the state r_2, such that it looks like the former string. We call such a pair of states to be a matching pair. Formally, consider the following definition.

FIG. 4. *Diagram illustrating construction of* G_2, G_3, G_4, G_5.

DEFINITION 9. Let $r_1 = (r_1', R_1)$ and $r_2 = (r_2', R_2) \in X \times Q' \times 2^{X \times Q'}$ be such that $R_1 = R_2$. Then the pair r_1 and r_2 of states is called a *matching* pair of states.

Example 8. Consider the SM G_5 of Example 7. The states $3'' = (2,1'), \{(2,1'), (2,d)\}$ and $5'' = (2,d), \{(2,1'), (2,d)\}$ constitute a matching pair of states. Similarly, the pair of states $4'' = (2,2'), \{(2,2'), (2,d)\}$ and $6'' = (2,d), \{(2,2'), (2,d)\}$ is another matching pair of states.

LEMMA 7. Let $r_1, r_2 \in X \times Q' \times 2^{X \times Q'}$ be a matching pair of states. Then given a string s, the execution of which takes to r_1, there exists a string t, the execution of which takes to r_2, such that $M(s) = M(t)$.

Proof. First note that $r = (r', R)$ is a reachable state of G_5 if and only if $r' \in R$, i.e., if and only if the G_1 part of r is an element of the G_4 part of r. This follows from (i) if $s \in L(G_5)$ is a string, the execution of which takes to r, then the execution of s takes to the state r' in G_1 and to the state R in G_4, and (ii) the execution of s takes to the state $R = \{(x_1, q_1'), (x_2, q_2'), \ldots, (x_r, q_r')\}$ in G_4 implies that there exists a state $(x_j, q_j') \in R$ such that the execution of s takes to the state (x_j, q_j') in G_1.

Consider then the states $r_1, r_2 \in X \times Q' \times 2^{X \times Q'}$ such that $R_1 = R_2 := R$. Then $r_1 = (r_1', R)$ and $r_2 = (r_2', R)$. It follows from the discussion in the preceding paragraph that $r_1' \in R$ and $r_2' \in R$. Let $s \in L(G_5)$ be a string, the execution of which takes to state r_1 in G_5; then the execution of s takes to the state r_1' in G_1 and to the state R in G_4. Since both the states $r_1', r_2' \in R$, there exists at least one string t, the execution of which takes to state r_2' in G_1 and to state R in G_4, such that

$M(t) = M(s)$. This follows from: (i) states r'_1 and r'_2 of G_2 belong to the same state R of G_3 if and only if there exists a string in $L(G_3) = L(G_2) \subseteq \Lambda^\star$, the execution of which takes to state R in G_3 and the execution of it takes to both states r'_1, r'_2 in G_2 (note that G_2 is a nondeterministic machine in general); and (ii) a string, the execution of which takes to the states r'_1, r'_2 in G_2, corresponds to two different strings in $L(G_1)$ having the same mask value. □

The result of Lemma 7 can be used to identify the strings in K°. Note that a string $s \in K - K^\circ$ if and only if there exists a string $t \in L(G) - K$ such that $M(t) = M(s)$. A state $r = (r', R)$ in G_5 corresponds to strings in $L(G) - K$ if and only if $r' = (x, d)$ for some $x \in X$. Thus strings in K and those in $L(G) - K$ can easily be identified in G_5. Let r_1 and r_2 be a matching pair of states in G_5, with $R_1 = R_2 := R$, such that the second coordinate of r'_1 does not equal d whereas the second coordinate of r'_2 equals d. Then as discussed above, strings leading to r_1 belong to K and those leading to r_2 are in $L(G) - K$. Moreover, strings leading to r_1 are in $K - K^\circ$. This follows from Lemma 7, which asserts that corresponding to each string that leads to r_1 (i.e., the string is in K), there exists a string leading to r_2 (i.e., this string is in $L(G) - K$) such that it looks like the former string. Thus states corresponding to $K - K^\circ$ can also be identified in G_5 by first identifying all those matching pair of states for which exactly one of the states in each pair has its second coordinate of the G_1 part equal to d and then, among these matching pair of states, determining those states for which the second coordinate of the G_1 part does not equal d. Hence it is possible to obtain the generator for K° by partitioning the graph of G_5 into the set of reachable and unreachable states. Finally, we pose the problem of computing the supremal normal sublanguage as an instance of OSCP1 with respect to the machine obtained by adding an equally directed pair of transitions labeled θ between each matching pair of states in G_5. We call the machine thus obtained G'_5.

Define the following cost of control function for G'_5:

$$(4) \qquad \forall r \in X \times Q' \times 2^{X \times Q'}, \sigma' \in \Sigma \cup \{\theta\} : c(r, \sigma') := \begin{cases} \infty & \text{if } \sigma' = \theta, \\ \frac{p_0}{|e|+1} & \text{otherwise,} \end{cases}$$

where $|e|$ denotes the total number of transitions in G'_5. The cost of control function for the event θ is infinity. Such a cost of control function ensures that the matching pair of states remains in the same partition of states induced by an optimal supervisor. Define the following penalty of control function on G'_5:

$$(5) \qquad \forall r = (r', R) \in X \times Q' \times 2^{X \times Q'} : p(r) := \begin{cases} \infty & \text{if } r' \in X \times \{d\}, \\ -p_0 & \text{otherwise.} \end{cases}$$

Thus the penalty of control is positive infinity whenever a state corresponds to strings in $L(G) - K$. Such states are undesired and should remain unreachable in the controlled plant under an optimal supervision. Other states have a negative penalty of control, $-p_0$, implying that such states are desired, and as many of them as possible should remain reachable in the controlled plant.

Example 9. Consider the state machine G_5 of Example 7. Then in order to compute the supremal normal sublanguage of the language $K = \overline{(ab)^*}$ with respect to plant G of Example 2 and mask $M(a) = M(b) = \lambda$, G'_5 is constructed by adding, in G_5, a pair of oppositely directed transitions labeled θ between both the pair of matching states, namely, between $3''$ and $5''$, and between $4''$ and $6''$. The cost of disabling θ is assigned to be infinity. Finally, the penalty of control function is defined to be infinity for the states $5''$ and $6''$ and $-p_0$ for the remaining states, $1'', 2'', 3''$, and $4''$. Note that the states $5''$ and $6''$ are such that for them the second part of the G_1 part equals d.

THEOREM 6. If $K^\circ \neq \emptyset$, then K° equals the controlled plant behavior of G'_5 under the control of a solution of OSCP1 with respect to G'_5, with a cost of control function as in equation 4 and penalty of control function as in equation 5.

Proof. The proof proceeds similarly to that of Theorem 4. The key to the proof is that each matching pair of states belong to the same partition induced by an optimal supervisor. □

It can be shown that the cost of control function in equation 4 can be modified slightly to compute the supremal controllable and normal sublanguage of K:

$$(6)\quad \forall r \in X \times Q' \times 2^{X \times Q'}, \sigma' \in \Sigma \cup \{\theta\} : c(r, \sigma') := \begin{cases} \infty & \text{if } \sigma' \in \Sigma_u \cup \{\theta\}, \\ \frac{p_0}{|e|+1} & \text{otherwise.} \end{cases}$$

Also, the penalty of control function in equation 5 can be replaced by the following penalty of control function to compute the infimal controllable and normal superlanguage of K:

$$(7)\qquad \forall r = (r', R) \in X \times Q' \times 2^{X \times Q'} : p(r) := \begin{cases} p_0 & \text{if } r' \in X \times \{d\}, \\ -\infty & \text{otherwise.} \end{cases}$$

THEOREM 7. If the supremal controllable and normal sublanguage of K is nonempty, then it equals the controlled plant behavior of G'_5 under the control of a solution of OSCP1 with respect to G'_5, with cost of control function as in equation 6 and penalty of control function as in equation 5. Furthermore, if instead penalty of control function as in equation 7 is used, then the controlled plant behavior equals the infimal controllable and normal superlanguage of K.

Proof. The proof is similar to that of Theorem 4. □

Finally we show that the computation of the *infimal observable* superlanguage of K can be posed as an instance of OSCP2. Refer to [16] for a detailed discussion of observable languages and their properties. It is shown in [16] that the infimal observable superlanguage of a prefix closed language exists, and a closed-form expression for computing it is obtained in [25], [9]. Observability of a language K requires that whenever a pair of strings belonging to K and having the same mask value are extended by a common event, either both the resulting strings belong to K or do not belong to K. This condition is needed so that the supervisor can take the same control action after execution of a pair of strings that have the same mask value. If K does not satisfy this property, then the infimal observable superlanguage of K is computed, which satisfies such a property.

The notion of pairs of strings in K with the same mask value is captured by the matching pair of states having the second coordinate of the G_1 part unequal to d. Let $r_1, r_2 \in X \times Q' \times 2^{X \times Q'}$ be a matching pair of states so that the second coordinate of the G_1 part of both the states is unequal to d. Since r_1 and r_2 is a matching pair of states, Lemma 7 implies that, corresponding to each string that leads to the state r_1, there exists a string having the same mask value as of the former string, such that it leads to the state r_2, and vice versa. Since the supervisor must take the same control action after the execution of a pair of strings that have the same mask value, an event is enabled at state r_1 if and only if it is enabled at r_2. This constraint is similar to the constraint C1 and can be captured by defining a mask function Ψ on the state space of G_5 as follows:

$$(8)\quad \forall r_1 = (r'_1, R_1), r_2 = (r'_2, R_2) \in X \times Q' \times 2^{X \times Q'} : \Psi(r_1) = \Psi(r_2) \Leftrightarrow R_1 = R_2.$$

Thus two states in state space of G_5 have the same mask value if and only if they constitute a matching pair. Hence, according to constraint C1 of OSCP2, it is ensured that the same control action is taken at any matching pair of states. Next the cost of control function is defined as

$$(9) \qquad \forall r \in X \times Q' \times 2^{X \times Q'}, \sigma \in \Sigma : c(r, \sigma) := \frac{p_0}{|e| + 1}$$

where $|e|$ denotes the number of transitions in G_5.

THEOREM 8. The infimal observable superlanguage of K equals the controlled plant behavior of G_5 under the control of a solution of OSCP2 with respect to G_5, with cost of control function as in equation 9, penalty of control function as in equation 7, and state mask function Ψ as in equation 8. Furthermore, if the cost of control function is modified so that $c(\cdot, \sigma) = \infty$ whenever $\sigma \in \Sigma_u$, then the controlled plant behavior equals the infimal controllable and observable superlanguage of K.

Proof. The proof is similar to that of Theorem 4. □

Example 10. Consider the state machine G_5 of Example 7. Then in order to compute the infimal observable superlanguage of the language $K = \overline{(ab)^*}$ with respect to the plant G of Example 2 and mask $M(a) = M(b) = \lambda$, we define the mask Ψ on the state space G_5 such that $\Psi(3'') = \Psi(5'')$ and $\Psi(4'') = \Psi(6'')$. Next the penalty of control function is defined to be negative infinity for the states 1", 2", 3", and 4". The penalty of control for the states 5" and 6" is defined to be p_0.

Remark 3. An advantage of using the above techniques to compute controllable and normal/observable sublanguages/superlanguages is that they do not require alternate computations of controllable and normal/observable sublanguages/superlanguages as they do in [4]. Note that if M is a *projection* type mask, then the formula in [1] can be used to compute the supremal controllable and normal sublanguage without having to perform alternate computations of supremal controllable and supremal normal sublanguages. However, if the mask is nonprojection type, then no such formula is known, and techniques developed above can be used. reduction of the overall computational complexity.

In case M is a nonprojection type mask, the fact that a computation of supremal controllable sublanguage followed by a computation of supremal normal sublanguage does not necessarily yield the supremal controllable and normal sublanguage can be illustrated as follows. Suppose $\Sigma = \{a, b, c, u\}, \Sigma_u = \{u\}, M(b) = M(c) = M(u) \neq \epsilon$, $K = \{\epsilon, a, au\}$, and $L(G) = \{\epsilon, a, au, ab, ac, acu\}$. Clearly K is controllable, i.e., $K^\uparrow = K$; and K is not normal, as $au \in K, ab \in L(G) - K$ and $M(au) = M(ab)$, i.e., $K^\circ \neq K$. It is easily seen that $K^\circ = \{\epsilon, a\}$. Then K° is not controllable, as $a \in K^\circ, u \in \Sigma_u$, and $au \in L(P) - K^\circ$. Thus $(K^\uparrow)^\circ = K^\circ$ does not equal the supremal controllable and normal sublanguage of K. On the other hand, if we let $\hat{K} = \{\epsilon, a, au, ab, ac\}$, then $\hat{K}$ is normal, i.e., $\hat{K}^\circ = \hat{K}$; and $\hat{K}$ is not controllable, i.e., $\hat{K}^\uparrow \neq \hat{K}$, as $ac \in \hat{K}, u \in \Sigma_u$, and $acu \in L(G) - \hat{K}$. It is easily seen that $\hat{K}^\uparrow = \{\epsilon, a, au, ab\}$. Then $\hat{K}^\uparrow$ is not normal, as $ab \in \hat{K}^\uparrow, ac \in L(G) - \hat{K}^\uparrow$, and $M(ab) = M(ac)$. Thus $(\hat{K}^\circ)^\uparrow = \hat{K}^\uparrow$ does not equal the supremal controllable and normal sublanguage of $\hat{K}$. Also, note that the formula for computing the supremal controllable and normal sublanguage given in [1, Thm. 4] is only applicable in a setting where, whenever a controllable and an uncontrollable events have "nonepsilon" mask values, then their mask values are different; so that the set of "masked uncontrollable" events is unambiguously identified. Since $u \in \Sigma_u$ and $b, c \in \Sigma - \Sigma_u$ are such that $M(b) = M(c) = M(u) \neq \epsilon$, the formula of [1, Theorem 4] is not applicable here.

5. Conclusion. We introduced the problem of optimal supervisory control for DEDS by introducing the notions of cost and penalty of using a controller. Cost of control is incurred when an event is disabled by a controller, and penalty of control is incurred whenever undesired states remain reachable or desired states remain unreachable in the controlled plant. The control objective is to optimize the net cost of control. This is formulated as OSCP1 for the case of complete state observation and OSCP2 for the case of incomplete state observation. We show that a solution to OSCP1 can be obtained as a min-cut of an associated flow network and a solution for OSCP2 is obtained by reducing an instance of OSCP2 to an instance of OSCP1. We show that supervisory control problems under complete as well as partial observations can be reduced to instances of OSCP1. In particular, we provide techniques for the computation of supremal controllable and normal sublanguage and infimal controllable and normal/observable superlanguage without having to perform alternate computations of controllable and normal/observable languages until a fixed point is reached. Thus, the above theory serves as a unified computational framework for supervisory control problems.

We did not comment on the computational complexity of any of the algorithms derived in this paper. However, since (i) all the algorithms developed in this paper are instances of OSCP1 and (ii) OSCP1 is solved using the max-flow min-cut computation, the computational complexity of any of the algorithms presented in this paper can be obtained from that of the max-flow min-cut computation, which is $O(|v| \cdot |e| \log(|v|^2/|e|))$, where $|v|$ denotes the number of vertices and $|e|$ denotes the number of edges in the underlying flow network. Note that we are not suggesting that the computation of a supervisor under partial observation can be performed in a polynomial time; as in case of partial observation, OSCP1 is solved with respect to a state machine having its state space as the *power set* of the state space of the plant composed with the generator of the desired behavior. like to thank anonymous reviewers for their helpful comments.

UNIFORM STABILIZATION OF A HYBRID SYSTEM OF ELASTICITY*

BOPENG RAO†

Abstract. The problem of boundary feedback stabilization of a Euler–Bernoulli beam with an endmass is considered. Using a method of compact perturbation, the lack of uniform stabilization is proved in the case of a clamped beam with the usual boundary feedbacks applied to the end with the mass. Next, the uniform stabilization when the usual boundary feedbacks are applied to the end without the mass is proved. Also the uniform decay of energy by means of higher-order feedbacks applied to the end with the mass is established.

Key words. hybrid system, lack of uniform stabilization, compact perturbation, higher-order feedbacks, boundary multipliers, uniform decay of energy

1. Introduction. The purpose of this work (the results of which were announced in Rao [14]) is to study the boundary feedback stabilization of the well-known SCOLE model. Consisting of an elastic beam, linked to a rigid antenna, this dynamical system can be described by the Euler–Bernoulli equation for the vibrations of the elastic beam and the Newton–Euler rigid-body equations for the oscillations of the antenna

$$\begin{cases} y_{tt} + y_{xxxx} = 0, \\ \mu_1 y_{tt}(1,t) - y_{xxx}(1,t) = L_1(y, y_t), \\ \mu_2 y_{xtt}(1,t) + y_{xx}(1,t) = L_2(y, y_t) \end{cases}$$

where L_1, L_2 denote linear boundary feedbacks acting on the antenna and where μ_1, μ_2 are positive constants. This system is composed of one partial differential equation and two ordinary differential equations and called a hybrid system. For further descriptions concerning the physical structure of the system, we refer to Littman–Markus [10]. Our goal is to choose suitable boundary damping at the end $x = 0$ and boundary feedbacks L_1, L_2 applied to the end $x = 1$ such that the hybrid system can be stabilized uniformly.

In one specific case, Littman–Markus [9] proved the strong stabilization together with the lack of uniform stabilization. Lack of uniform stabilization for hybrid systems was also observed in the string/mass model (cf. Lee–You [7]). However, to the author's knowledge, there is no positive result in the literature concerning uniform stabilization of hybrid systems.

Using an energy multipliers method (cf. Rao [13]), we recently obtained the uniform stabilization for a string/mass model. The idea of the proof is to apply the usual boundary feedbacks to the end of the string without the mass.

Let us outline briefly the content of this work. In §2, using a method of compact perturbation, we prove the lack of uniform stabilization in the case of a clamped beam with the usual boundary feedbacks L_1, L_2. Thus we generalize the result of Littman–Markus mentioned above. In §3, we consider a beam with usual boundary feedbacks applied to the end without the mass. We first formulate the problem by means of the semigroup approach. Next we prove that, in that case, the usual boundary feedbacks are sufficient to obtain uniform exponential decay. Section 4 is devoted to the study of the clamped beam. We establish the uniform exponential decay of energy by higher-order feedbacks applied to the end with the mass.

2. Lack of uniform stabilization. We first consider the dynamical system of the SCOLE model in the case of a clamped beam

$$(2.1)\qquad \begin{cases} y_{tt} + y_{xxxx} = 0, & t > 0, \quad 0 < x < 1, \\ y(0,t) = y_x(0,t) = 0, & t > 0, \\ \mu_1 y_{tt}(1,t) - y_{xxx}(1,t) = L_1(y, y_t), & t > 0, \\ \mu_2 y_{xtt}(1,t) + y_{xx}(1,t) = L_2(y, y_t), & t > 0. \end{cases}$$

We prove the lack of uniform stabilization for the usual boundary feedbacks

$$(2.2)\qquad \begin{cases} L_1(y, y_t) = -\delta_{11} y(1,t) - \delta_{12} y_x(1,t) - \nu_{11} y_t(1,t) - \nu_{12} y_{xt}(1,t), \\ L_2(y, y_t) = -\delta_{21} y(1,t) - \delta_{22} y_x(1,t) - \nu_{21} y_t(1,t) - \nu_{22} y_{xt}(1,t), \end{cases}$$

where the coefficients δ_{ij}, ν_{ij} are real numbers.

Let y be a smooth solution of the system (2.1) – (2.2). After a procedure of Slemrod [18], we introduce the auxiliary functions:

$$z(x,t) = y_t(x,t), \quad \xi(t) = y_t(1,t), \quad \eta(t) = y_{xt}(1,t), \quad u(t) = (y(t), z(t), \xi(t), \eta(t)).$$

Then we can write formally the hybrid system (2.1) – (2.2) into the following form:

$$(2.3)\qquad \begin{aligned} &(y_t(t),\, z_t(t),\, \xi_t(t),\, \eta_t(t)) + \left(-z(t),\, y_{xxxx}(t), -\frac{1}{\mu_1} y_{xxx}(1,t),\, \frac{1}{\mu_2} y_{xx}(1,t)\right) \\ &\quad = (0,\, 0,\, L_1(y, y_t),\, L_2(y, y_t)). \end{aligned}$$

Now let us introduce the energy space E

$$E = \{(y, z, \xi, \eta) \in H^2(0,1) \times L^2(0,1) \times \mathbb{R} \times \mathbb{R} \text{ such that } y(0) = y_x(0) = 0\}.$$

For any $u = (y, z, \xi, \eta) \in E$ and any $\tilde{u} = (\tilde{y}, \tilde{z}, \tilde{\xi}, \tilde{\eta}) \in E$, we define the inner product

$$\langle u, \tilde{u} \rangle = \langle (y, z, \xi, \eta), (\tilde{y}, \tilde{z}, \tilde{\xi}, \tilde{\eta}) \rangle = \int_0^1 (y_{xx}\tilde{y}_{xx} + z\tilde{z})\, dx + \mu_1 \xi\tilde{\xi} + \mu_2 \eta\tilde{\eta}.$$

Next we define the unbounded operator A and the linear operators B, $\tilde{B}$:

$$(2.4)\quad D(A) = \left(\begin{array}{l} u = (y, z, \xi, \eta) \in H^4(0,1) \times H^2(0,1) \times \mathbb{R} \times \mathbb{R} \text{ such that} \\ y(0) = y_x(0) = z(0) = z_x(0) = 0 \quad \text{and} \quad \xi = z(1),\, \eta = z_x(1) \end{array} \right),$$

$$(2.5)\qquad Au = (-z, y_{xxxx}, -\frac{1}{\mu_1} y_{xxx}(1), \frac{1}{\mu_2} y_{xx}(1)) \quad \forall\, u = (y, z, \xi, \eta) \in D(A),$$

$$(2.6)\qquad Bu = (0, 0, b_{11} + b_{12}, b_{21} + b_{22}) \quad \forall\, u = (y, z, \xi, \eta) \in E,$$

$$(2.7)\qquad \tilde{B}u = (0, 0, b_{11} - b_{12}, b_{21} - b_{22}) \quad \forall\, u = (y, z, \xi, \eta) \in E,$$

where we have posed

$$(2.8)\qquad \begin{cases} b_{11} = \dfrac{1}{\mu_1}(\delta_{11} y(1) + \delta_{12} y_x(1)), & b_{12} = \dfrac{1}{\mu_1}(\nu_{11}\xi + \nu_{12}\eta), \\ b_{21} = \dfrac{1}{\mu_2}(\delta_{21} y(1) + \delta_{22} y_x(1)), & b_{22} = \dfrac{1}{\mu_2}(\nu_{21}\xi + \nu_{22}\eta). \end{cases}$$

With these notations we can formulate the system (2.3) into the following abstract form:

$$\frac{d}{dt}u(t) + (A+B)u(t) = 0, \qquad u(0) = u_0. \tag{2.9}$$

THEOREM 2.1. *For any real constants δ_{ij} and ν_{ij}, the equation* (2.9) *is not uniformly stable on the energy space E.*

Proof. It has been shown in Littman–Markus [9] that the operator A defined by (2.4)–(2.5) is maximal monotone and satisfies the property $A^* = -A$; hence it generates a group $S_0(t)$ of isometries on the energy space E.

Let $S(t)$ and $\tilde{S}(t)$ denote the groups generated, respectively, by $A+B$ and $A+\tilde{B}$. From the definitions (2.6)–(2.8) and Sobolev's embedding, it follows that the operators B and $\tilde{B}$ are continuous and of finite rank, therefore compact. Using a classical result of compact perturbation (cf. Russell [17, Prop. 1.1]), we deduce that there exist no positive constants $0 \le \gamma < 1$ and $t_0 > 0$ such that

$$\|S(t_0)\| \le \gamma \quad \text{and} \quad \|\tilde{S}(-t_0)\| \le \gamma. \tag{2.10}$$

Given $\mu_0 \in D(A)$, $u(t) = S(t)u_0 = (y(t), z(t), \xi(t), \eta(t))$ is the solution of the equation (2.9). We define

$$\tilde{y}(x,t) = y(x,-t), \quad \tilde{z}(x,t) = -z(x,-t), \quad \tilde{\xi}(t) = -\xi(-t),$$
$$\tilde{\eta}(t) = -\eta(-t), \quad \tilde{u}(t) = (\tilde{y}(t), \tilde{z}(t), \tilde{\xi}(t), \tilde{\eta}(t)).$$

Then we have $\|\tilde{u}(-t)\| = \|u(t)\|$ for all $t \in \mathbb{R}$.

On the other hand, a straightforward computation shows that $\tilde{u}(t) = \tilde{S}(t)\tilde{u}(0)$. It follows that

$$\|\tilde{S}(-t)\| = \|S(t)\| \quad \forall t \in \mathbb{R},$$

which together with (2.10) achieves the proof of Theorem 2.1. □

Remark 2.1. The proof of Theorem 2.1 is a direct application of the classical result of compact perturbation. In fact, there are several recent more general results that allow us to conclude that the semigroup $S(t)$ is not exponentially stable (cf. Curtain [4], Jacobson [5], and Rebarber [16]).

Remark 2.2. In the specific case of boundary feedbacks L_1, L_2 of the form

$$L_1(y, y_t) = -y_t(1,t), \qquad L_2(y, y_t) = -y_{xt}(1,t),$$

Theorem 2.1 was proved by Littman–Markus [9]. Their method is constructive and based on the asymptotic estimation of the eigenvalues of the operator $A+B$. Here our method is very simple and can be easily applied to other cases, in particular to some plate models (cf. Markus–You [11]) where the estimation of the eigenvalues seems to be impossible.

3. Uniform stabilization by passive boundary damping. In this section, we consider an elastic beam with usual boundary feedbacks applied to the end without the mass. By means of multipliers method, we establish the uniform decay of energy for that case. Let us consider the following hybrid system:

$$y_{tt} + y_{xxxx} = 0, \tag{3.1}$$

$$\alpha_1 y(0,t) + y_{xxx}(0,t) + \beta_{11} y_t(0,t) + 2\beta_{12} y_{xt}(0,t) = 0, \tag{3.2}$$

$$\alpha_2 y_x(0,t) - y_{xx}(0,t) + 2\beta_{21} y_t(0,t) + \beta_{22} y_{xt}(0,t) = 0, \tag{3.3}$$

$$\mu_1 y_{tt}(1,t) - y_{xxx}(1,t) = 0, \tag{3.4}$$

$$\mu_2 y_{xtt}(1,t) + y_{xx}(1,t) = 0, \tag{3.5}$$

where α_1, α_2 are positive constants.

Let y be a smooth solution of the system (3.1)–(3.5). We define the associated energy $E(t)$ by

(3.6)

$$E(t) = \frac{1}{2}\left\{ \int_0^1 (y_t^2 + y_{xx}^2)\,dx + \alpha_1 y^2(0,t) + \alpha_2 y_x^2(0,t) + \mu_1 y_t^2(1,t) + \mu_2 y_{xt}^2(1,t) \right\}.$$

A straightforward computation gives (at least formally)

$$\frac{d}{dt}E(t) = -(\beta_{11} y_t^2(0,t) + 2(\beta_{12} + \beta_{21}) y_t(0,t) y_{xt}(0,t) + \beta_{22} y_{xt}^2(0,t)). \tag{3.7}$$

Assume that the boundary damping coefficients β_{ij} satisfy the following conditions:

$$\beta_{11} > 0, \quad \beta_{22} > 0, \quad \beta_{11}\beta_{22} > (\beta_{12} + \beta_{21})^2. \tag{3.8}$$

Then there exists a constant $\beta_0 > 0$ such that

$$\frac{d}{dt}E(t) \geq -\beta_0 (y_t^2(0,t) + y_{xt}^2(0,t)). \tag{3.9}$$

Now let us introduce the energy space

$$E = \{(y, z, \xi, \eta) \in H^2(0,1) \times L^2(0,1) \times \mathbb{R} \times \mathbb{R}\}. \tag{3.10}$$

For all $u = (y, z, \xi, \eta) \in E$ and all $\tilde{u} = (\tilde{y}, \tilde{z}, \tilde{\xi}, \tilde{\eta}) \in E$, we define the inner product

$$\langle u, \tilde{u} \rangle = \int_0^1 (y_{xx}\tilde{y}_{xx} + z\tilde{z})\,dx + \alpha_1 y(0)\tilde{y}(0) + \alpha_2 y_x(0)\tilde{y}_x(0) + \mu_1 \xi\tilde{\xi} + \mu_2 \eta\tilde{\eta}. \tag{3.11}$$

Next we define the unbounded operator A as follows:

(3.12)

$$D(A) = \left(\begin{array}{c} (y, z, \xi, \eta) \in H^4(0,1) \times H^2(0,1) \times \mathbb{R}^2 \text{ such that } \xi = z(1), \quad \eta = z_x(1) \\ \alpha_1 y(0) + y_{xxx}(0) + \beta_{11} z(0) + 2\beta_{12} z_x(0) = 0 \\ \alpha_2 y_x(0) - y_{xx}(0) + 2\beta_{21} z(0) + \beta_{22} z_x(0) = 0 \end{array} \right),$$

$$Au = \left(-z, y_{xxxx}, -\frac{1}{\mu_1} y_{xxx}(1), \frac{1}{\mu_2} y_{xx}(1) \right) \quad \forall\, u = (y, z, \xi, \eta) \in D(A). \tag{3.13}$$

Then by setting

$$z(x,t) = y_t(x,t), \quad \xi(t) = y_t(1,t), \quad \eta(t) = y_{xt}(1,t), \quad u(t) = (y(t), z(t), \xi(t), \eta(t)),$$

we can write the hybrid system (3.1) – (3.5) into the following abstract form:

$$\frac{d}{dt}u(t) + Au(t) = 0, \qquad u(0) = u_0. \tag{3.14}$$

Under the conditions (3.8), it is easy to prove that A is a maximal monotone operator, hence it generates a semigroup of contractions $S(t)$ on the space E. Moreover by the classical Hille–Yosida theorem (cf. Brezis [1, p. 105], and Pazy [12, p. 14]), we have the following results.

PROPOSITION 3.1. *Assume that the conditions* (3.8) *hold.*

(i) *For any initial data* $u_0 \in D(A)$, *the equation* (3.14) *admits a unique strong solution* $u(t) = (y(t), z(t), \xi(t), \eta(t)) \in D(A)$ *such that*

$$y(t) \in C^0([0,+\infty[; H^4(0,1)) \cap C^1([0,+\infty[; H^2(0,1)) \cap C^2([0,+\infty[; L^2(0,1)), \tag{3.15}$$

$$y(1,t) \in C^2([0,+\infty[; \mathbb{R}), \qquad y_x(1,t) \in C^2([0,+\infty[; \mathbb{R}). \tag{3.16}$$

(ii) *For any initial data* $u_0 \in E$, *the equation* (3.14) *admits a unique weak solution* $u(t) = S(t)u_0 = (y(t), z(t), \xi(t), \eta(t)) \in E$ *such that*

$$y(t) \in C^0([0,+\infty[; H^2(0,1)) \cap C^1([0,+\infty[; L^2(0,1)). \tag{3.17}$$

$$y(1,t) \in C^1([0,+\infty[; \mathbb{R}), \qquad y_x(1,t) \in C^1([0,+\infty[; \mathbb{R}). \tag{3.18}$$

Notice that for a general function $y(x,t)$ possessing only the smoothness property (3.15), the trace functions $y_{tt}(1,t)$ and $y_{xtt}(1,t)$ don't make sense. Here they are defined by means of the equations

$$y_{tt}(1,t) = \frac{1}{\mu_1} y_{xxx}(1,t) \qquad y_{xtt}(1,t) = -\frac{1}{\mu_2} y_{xx}(1,t).$$

From (3.15), we see that the right-hand sides of these equations are continuous functions.

Because the domain $D(A)$ is dense in E and because $S(t)$ is a semigroup of contractions on the space E, we assume in this section systematically the smoothness properties (3.15) – (3.16). All the results of decay estimates established for strong solutions can be extended to the case of weak solutions by a standard argument of density and contraction property.

Now let y be a smooth solution of (3.1) – (3.5). We define the following functionals:

$$\rho_1(t) = 4\int_0^1 (x-1) y_t y_x - 5\int_0^1 y_t y \, dx, \tag{3.19}$$

$$\rho_2(t) = y_x(0,t)\left\{\int_0^1 y_t(C_0 x + 4) + \mu_1(C_0 + 4) y_t(1,t) + \mu_2 C_0 y_{xt}(1,t)\right\}, \tag{3.20}$$

$$\rho_3(t) = 5y(0,t)\left\{2\int_0^1 y_t \, dx + 2\mu_1 y_t(1,t) + \beta_{11} y(0,t) + 2\beta_{12} y_x(0,t)\right\}, \tag{3.21}$$

$$\rho_4(t) = -5\mu_1 y_t(1,t) y(1,t) - \mu_2 y_{xt}(1,t) y_x(1,t), \tag{3.22}$$

$$\rho(t) = \rho_1(t) + \rho_2(t) + \rho_3(t) + \rho_4(t). \tag{3.23}$$

The constant C_0 will be determined later (see (3.39)).

PROPOSITION 3.2. *Assume that the conditions* (3.8) *hold. Then there exist positive constants* C_1, C_2, *and* θ *such that the following estimates hold*

$$|\rho(t)| \leq C_1 E(t) \quad \forall t \geq 0, \tag{3.24}$$

$$\frac{d}{dt}\rho(t) \leq -\theta E(t) + C_2(y_t^2(0,t) + y_{xt}^2(0,t)) \quad \forall t \geq 0 \tag{3.25}$$

for all solutions y *of the system* (3.1) – (3.5).

Proof. First using the Cauchy–Schwartz inequality, a straightforward computation gives

$$\begin{aligned}
&|\rho_1(t)| \leq 5\int_0^1 (y_t^2 + y^2 + y_x^2)\,dx,\\
&|\rho_2(t)| \leq (C_0+4)(1+\mu_1+\mu_2)\left(y_x^2(0,t) + y_t^2(1,t) + y_{xt}^2(1,t) + \int_0^1 y_t^2\,dx\right),\\
&|\rho_3(t)| \leq 10(1+\mu_1+\beta_{11}+|\beta_{12}|)\left(y^2(0,t) + y_x^2(0,t) + y_t^2(1,t) + \int_0^1 y_t^2\,dx\right),\\
&|\rho_4(t)| \leq 3(\mu_1+\mu_2)(y_t^2(1,t) + y_{xt}^2(1,t) + y^2(1,t) + y_x^2(1,t)).
\end{aligned}$$

Now let $\gamma > 0$ denote the largest constant such that

$$y^2(1) + y_x^2(1) + \int_0^1 (y^2 + y_x^2)\,dx \leq \gamma\left(y^2(0) + y_x^2(0) + \int_0^1 y_{xx}^2\,dx\right)$$

for all functions $y \in H^2(0,1)$. Combining the above estimates gives the estimate (3.24).

The estimate (3.25) is more difficult to establish. For the sake of clarity, we divide the proof into five steps.

Step 1. *Calculation of the derivative of* $\rho_1(t)$. Using the equation (3.1), a simple calculation gives

$$\begin{aligned}
\frac{d}{dt}\rho_1(t) = &-\int_0^1 \{7y_t^2 + y_{xx}^2\}\,dx + 2y_t^2(0,t) + 2y_{xx}^2(0,t)\\
&- 4y_{xxx}(0,t)y_x(0,t) - y_{xx}(1,t)y_x(1,t) + y_{xx}(0,t)y_x(0,t)\\
&+ 5y_{xxx}(1,t)y(1,t) - 5y_{xxx}(0,t)y(0,t).
\end{aligned} \tag{3.26}$$

Step 2. *Estimate for the derivative of* $\rho_2(t)$. It follows from the equation (3.1) that

(3.27)

$$\begin{aligned}
\frac{d}{dt}\rho_2(t) = &\; y_{xt}(0,t)\left\{\int_0^1 (C_0x+4)y_t\,dx + \mu_1(C_0+4)y_t(1,t) + \mu_2 C_0 y_{xt}(1,t)\right\}\\
&+ y_x(0,t)\left\{-\int_0^1 (C_0x+4)y_{xxxx}\,dx + \mu_1(C_0+4)y_{tt}(1,t) + \mu_2 C_0 y_{xtt}(1,t)\right\}.
\end{aligned}$$

Using the boundary conditions (3.4) – (3.5), we calculate

$$
\begin{aligned}
&-\int_0^1 (C_0x+4)y_{xxxx}\,dx\\
&= 4y_{xxx}(0,t)-(C_0+4)y_{xxx}(1,t)+C_0y_{xx}(1,t)-C_0y_{xx}(0,t)\\
&= 4y_{xxx}(0,t)-(C_0+4)\mu_1y_{tt}(1,t)-C_0\mu_2y_{xtt}(1,t)-C_0y_{xx}(0,t).
\end{aligned}
\tag{3.28}
$$

Inserting (3.28) into (3.27) gives

$$
\begin{aligned}
\frac{d}{dt}\rho_2(t) &= 4y_x(0,t)y_{xxx}(0,t)-C_0y_x(0,t)y_{xx}(0,t)\\
&\quad + y_{xt}(0,t)\left\{\int_0^1 (C_0x+4)y_t\,dx+\mu_1(C_0+4)y_t(1,t)+\mu_2C_0y_{xt}(1,t)\right\}.
\end{aligned}
\tag{3.29}
$$

Using the Cauchy–Schwartz inequality, we get

$$
\begin{aligned}
&y_{xt}(0,t)\left\{\int_0^1 (C_0x+4)y_t\,dx+\mu_1(C_0+4)y_t(1,t)+\mu_2C_0y_{xt}(1,t)\right\}\\
&\le Cy_{xt}^2(0,t)+\frac{1}{4}\left\{\int_0^1 y_t^2\,dx+\mu_1y_t^2(1,t)+\mu_2y_{xt}^2(1,t)\right\}.
\end{aligned}
\tag{3.30}
$$

Inserting (3.30) into (3.29) gives

$$
\begin{aligned}
\frac{d}{dt}\rho_2(t) &\le 4y_{xxx}(0,t)y_x(0,t)-C_0y_{xx}(0,t)y_x(0,t)\\
&\quad + Cy_{xt}^2(0,t)+\frac{1}{4}\left\{\int_0^1 y_t^2\,dx+\mu_1y_t^2(1,t)+\mu_2y_{xt}^2(1,t)\right\}.
\end{aligned}
\tag{3.31}
$$

Step 3. *Estimate for the derivative of* $\rho_3(t)$. Using the equation (3.1), we have

$$
\begin{aligned}
\frac{d}{dt}\rho_3(t) &= 5y_t(0,t)\left\{2\int_0^1 y_t\,dx+2\mu_1y_t(1,t)+\beta_{11}y(0,t)+2\beta_{12}y_x(0,t)\right\}\\
&\quad + 5y(0,t)\left\{-2\int_0^1 y_{xxxx}\,dx+2\mu_1y_{tt}(1,t)+\beta_{11}y_t(0,t)+2\beta_{12}y_{xt}(0,t)\right\}.
\end{aligned}
\tag{3.32}
$$

By the boundary conditions (3.2) and (3.4), we obtain

$$
\begin{aligned}
-2\int_0^1 y_{xxxx}\,dx &= 2y_{xxx}(0,t)-2y_{xxx}(1,t)\\
&= y_{xxx}(0,t)-\alpha_1y(0,t)-\beta_{11}y_t(0,t)-\beta_{12}y_{xt}(0,t)-2\mu_1y_{tt}(1,t).
\end{aligned}
$$

Inserting the above relation into (3.32), we get

(3.33)

$$\frac{d}{dt}\rho_3(t) = 5y(0,t)y_{xxx}(0,t) - 5\alpha_1 y^2(0,t) + 5y_t(0,t)\left\{2\int_0^1 y_t\,dx + 2\mu_1 y_t(1,t) + \beta_{11}y(0,t) + 2\beta_{12}y_x(0,t)\right\}.$$

Using the Cauchy–Schwartz inequality, we can find a positive constant C such that

$$5y_t(0,t)\left\{2\int_0^1 y_t\,dx + 2\mu_1 y_t(1,t) + \beta_{11}y(0,t) + 2\beta_{12}y_x(0,t)\right\} \le \frac{9\alpha_1}{2}y^2(0,t) + \frac{3\alpha_2^2}{2}y_x^2(0,t) + Cy_t^2(0,t) + \frac{1}{4}\left(\int_0^1 y_t^2\,dx + \mu_1 y_t^2(1,t)\right).$$

Inserting the above estimate into (3.33) gives

$$\frac{d}{dt}\rho_3(t) \le \frac{1}{4}\left(\int_0^1 y_t^2\,dx + \mu_1 y_t^2(1,t)\right) + 5(y_{xxx}y)(0,t) - \frac{\alpha_1}{2}y^2(0,t) + \frac{3\alpha_2^2}{2}y_x^2(0,t) + Cy_t^2(0,t). \tag{3.34}$$

Step 4. *Calculation of the derivative of* $\rho_4(t)$. Using the boundary conditions (3.4) – (3.5) we calculate

$$\begin{aligned}\frac{d}{dt}\rho_4(t) &= -5\mu_1 y_t^2(1,t) - 5\mu_1 y_{tt}(1,t)y(1,t) - \mu_2 y_{xt}^2(1,t) - \mu_2 y_{xtt}(1,t)y_x(1,t)\\ &= -5\mu_1 y_t^2(1,t) - 5y_{xxx}(1,t)y(1,t) - \mu_2 y_{xt}^2(1,t) + y_{xx}(1,t)y_x(1,t).\end{aligned} \tag{3.35}$$

Step 5. *Estimate for the derivative of* $\rho(t)$. Combining (3.26), (3.31), (3.34), and (3.35), we get

$$\begin{aligned}\frac{d}{dt}\rho(t) \le{}& -\frac{1}{2}\left\{\int_0^1 (y_t^2 + y_{xx}^2)\,dx + \alpha_1 y^2(0,t) + \mu_1 y_t^2(1,t) + \mu_2 y_{xt}^2(1,t)\right\}\\ &+ C(y_t^2(0,t) + y_{xt}^2(0,t)) + \frac{3\alpha_2^2}{2}y_x^2(0,t) + 2y_{xx}^2(0,t)\\ &- (C_0 - 1)y_{xx}(0,t)y_x(0,t).\end{aligned} \tag{3.36}$$

On the other hand, by the boundary condition (3.3), we have

$$\alpha_2^2 y_x^2(0,t) - 2\alpha_2(y_x y_{xx})(0,t) + y_{xx}^2(0,t) \le 5\beta_{21}^2 y_t^2(0,t) + 5\beta_{22}^2 y_{xt}^2(0,t). \tag{3.37}$$

Plugging (3.37) into (3.36) gives

(3.38)

$$\frac{d}{dt}\rho(t) \le C_2(y_t^2(0,t) + y_{xt}^2(0,t)) - (C_0 - 4\alpha_2 - 1)y_{xx}(0,t)y_x(0,t) -\frac{1}{2}\left\{\int_0^1 (y_t^2 + y_{xx}^2)\,dx + \alpha_1 y^2(0,t) + \alpha_2^2 y_x^2(0,t) + \mu_1 y_t^2(1,t) + \mu_2 y_{xt}^2(1,t)\right\}.$$

Now, by choosing

$$C_0 = 4\alpha_2 + 1, \qquad \theta = \min\{1,\, \alpha_2\}, \tag{3.39}$$

in (3.38), we obtain

$$\frac{d}{dt}\rho(t) \leq -\theta E(t) + C_2(y_t^2(0,t) + y_{xt}^2(0,t)).$$

The proof of Proposition 3.1 is thus complete. □

Now we proceed as in Komornik–Zuazua [6]. Starting from the estimates (3.24) – (3.25), we can establish the following uniform decay of energy.

THEOREM 3.3. *Assume that the conditions* (3.8) *hold. Then given any* $M > 1$, *there exists a positive constant* ω *such that*

$$E(t) \leq ME(0)\exp(-\omega t) \quad \forall t \geq 0, \tag{3.40}$$

for all solutions y *of the system* (3.1) – (3.5).

Proof. First for $\varepsilon > 0$, we introduce the perturbed energy

$$E_\varepsilon(t) = E(t) + \varepsilon\rho(t).$$

Then given any $M > 1$, using the estimate (3.24), we prove the following inequalities:

$$M^{-1/2}E_\varepsilon(t) \leq E(t) \leq M^{1/2}E_\varepsilon(t) \quad \forall t \geq 0, \tag{3.41}$$

provided $\varepsilon > 0$ is small enough.

Next using (3.9) and (3.25), we have

$$\frac{d}{dt}E_\varepsilon(t) = \frac{d}{dt}E(t) + \varepsilon\frac{d}{dt}\rho(t) \leq -\theta\varepsilon E(t) + (\varepsilon C_2 - \beta_0)(y_{xt}^2(0,t) + y_{xxt}^2(0,t)).$$

Then for $\varepsilon > 0$ small enough, we deduce that

$$\frac{d}{dt}E_\varepsilon(t) \leq -\theta\varepsilon E(t) \leq -\theta\varepsilon M^{-1/2}E_\varepsilon(t).$$

Solving the above differential inequality, we obtain

$$E_\varepsilon(t) \leq E_\varepsilon(0)\exp(-\varepsilon M^{-1/2}t) = E_\varepsilon(0)\exp(-\omega t) \quad \forall t \geq 0,$$

which together with (3.41) implies that

$$E(t) \leq ME(0)\exp(-\omega t) \quad \forall t \geq 0.$$

The proof of Theorem 3.3 is complete. □

Remark 3.1. The conditions (3.8) are by no means optimal in the sense that only one moment control $y_{xt}(0,t)$ or only one force control $y_t(0,t)$ suffices for obtaining the uniform decay of energy. In fact, instead of the boundary feedbacks (3.2) – (3.3), we can consider the following ones:

$$y(0,t) = 0, \qquad y_x(0,t) - y_{xx}(0,t) + \beta y_{xt}(0,t) = 0, \tag{3.42}$$

$$y(0,t) + y_{xxx}(0,t) + \beta y_t(0,t) = 0, \qquad y_x(0,t) = 0. \tag{3.43}$$

For these two cases, the uniform exponential decay of (3.40) remains true for $\beta > 0$ (cf. Rao [15]).

Notice that the boundary feedbacks (3.2) – (3.3), (3.42), and (3.43) can be realized by means of passive mechanical systems of springs-dampers similar to those used in Chen et al. [3].

4. Uniform stabilization by higher-order feedbacks. In this section, we carry out a study of uniform stabilization for a clamped beam. In view of the negative result of Theorem 2.1, we have to choose suitable boundary feedbacks L_1, L_2 and energy space such that not only the boundary feedbacks L_1, L_2 are noncompact but also the problem is well posed. Here, as an example, we propose the following boundary feedbacks:

$$L_1(y, y_t) = y_{xxxt}(1,t), \qquad L_2(y, y_t) = -y_{xxt}(1,t).$$

To make our computations as clear as possible, we assume, without loss of generality, the constants μ_1 and μ_2 are equal to one (because $\mu_1 > 0$, $\mu_2 > 0$), and then we obtain the following hybrid system:

$$(4.1) \qquad \begin{cases} y_{tt} + y_{xxxx} = 0, & t > 0, \quad 0 < x < 1, \\ y(0,t) = y_x(0,t) = 0, & t > 0, \\ y_{tt}(1,t) - y_{xxx}(1,t) = y_{xxxt}(1,t), & t > 0, \\ y_{xtt}(1,t) + y_{xx}(1,t) = -y_{xxt}(1,t), & t > 0. \end{cases}$$

Because of the presence of the higher-order feedbacks such as $y_{xxxt}(1,t)$ and $-y_{xxt}(1,t)$ in the system (4.1), for the well-posedness of the problem, we choose the following more smooth energy space:

$$(4.2)\ E = \{(y,z) \in H^4(0,1) \times H^2(0,1) \text{ such that } y(0) = y_x(0) = z(0) = z_x(0) = 0\}.$$

For any $u = (y,z) \in E$ and any $\tilde{u} = (\tilde{y}, \tilde{z}) \in E$, we define the inner product by

$$(4.3) \qquad \langle u, \tilde{u} \rangle = \int_0^1 \{y_{xxxx}\tilde{y}_{xxxx} + z_{xx}\tilde{z}_{xx}\}\, dx + y_{xx}(1)\tilde{y}_{xx}(1) + y_{xxx}(1)\tilde{y}_{xxx}(1).$$

Next we define the unbounded operator A:

$$(4.4) \quad D(A) = \begin{pmatrix} u = (y,z) \in H^6(0,1) \times H^4(0,1) \text{ such that} \\ y(0) = y_x(0) = z(0) = z_x(0) = 0,\ y_{xxxx}(0) = y_{xxxxx}(0) = 0 \\ y_{xxxxx}(1) + y_{xxx}(1) = -z_{xxx}(1),\ y_{xxxxxx}(1) - y_{xx}(1) = z_{xx}(1) \end{pmatrix},$$

$$(4.5) \qquad Au = (-z,\ y_{xxxx}) \quad \forall\, u = (y,z) \in D(A).$$

PROPOSITION 4.1. *The operator A defined by* (4.4)–(4.5) *is maximal monotone on the Hilbert space E defined by* (4.2)–(4.3).

Proof. First for any $u = (y,z) \in D(A)$, by the definitions (4.3) and (4.5) and integration by parts, we have

$$(4.6) \qquad \begin{aligned} \langle Au, u \rangle &= z_{xx}(1)(y_{xxxxxx}(1) - y_{xx}(1)) - z_{xxx}(1)(y_{xxxxx}(1) + y_{xxx}(1)) \\ &= z_{xx}^2(1) + z_{xxx}^2(1) \geq 0. \end{aligned}$$

The last equality follows from the boundary conditions at $x = 1$ for $u \in D(A)$.

We next verify the range condition

$$(4.7) \qquad R(I + A) = E.$$

Let $u_0 = (y_0, z_0) \in E$, we have to solve the equation

$$u \in D(A) \quad \text{such that } u + Au = u_0,$$

which means that

$$(4.8)\qquad \begin{cases} y - z = y_0, \quad z - y_{xxxx} = z_0, \\ y(0) = y_x(0) = z(0) = z_x(0) = 0, \\ y_{xxxx}(0) = y_{xxxxx}(0) = 0, \\ y_{xxxx}(1) + y_{xxx}(1) = -z_{xxx}(1), \\ y_{xxxxx}(1) - y_{xx}(1) = z_{xx}(1). \end{cases}$$

Eliminating the unknown z in (4.8), we obtain

$$(4.9)\qquad \begin{cases} y + y_{xxxx} = y_0 + z_0 \in H^2(0,1), \\ y(0) = y_x(0) = 0, \\ 2y_{xxx}(1) + y_{xxxx}(1) = y_{0xxx}(1), \\ 2y_{xx}(1) - y_{xxxxx}(1) = y_{0xx}(1). \end{cases}$$

Next, we replace $y_{xxxx}(1)$ and $y_{xxxxx}(1)$ in (4.9) by their expressions

$$y_{xxxx}(1) = y_0(1) + z_0(1) - y(1), \qquad y_{xxxxx}(1) = y_{0x}(1) + z_{0x}(1) - y_x(1)$$

so that we get

$$(4.10)\qquad \begin{cases} y + y_{xxxx} = y_0 + z_0 \in H^2(0,1), \\ y(0) = y_x(0) = 0, \\ y(1) - 2y_{xxx}(1) = y_0(1) - y_{0xxx}(1) + z_0(1), \\ y_x(1) + 2y_{xx}(1) = y_{0x}(1) + y_{0xx}(1) + z_{0x}(1). \end{cases}$$

Now let us denote by V the subspace $V = \{y \in H^2(\omega) : y(0) = y_x(0) = 0\}$. We introduce the bilinear continuous operator $a(\cdot,\cdot)$ in $V \times V$

$$a(y,\varphi) = \int_0^1 (y\varphi + y_{xx}\varphi_{xx})\,dx + \frac{1}{2}y(1)\varphi(1) + \frac{1}{2}y_x(1)\varphi_x(1) \quad \forall y, \varphi \in V.$$

For any $\varphi \in V$, we define the linear continuous operator f by the following way

$$\begin{aligned} f(\varphi) &= \int_0^1 (y_0 + z_0)\varphi\,dx + \frac{1}{2}(y_0(1) - y_{0xxx}(1) + z_0(1))\varphi(1) \\ &\quad + \frac{1}{2}(y_{0x}(1) + y_{0xx}(1) + z_{0x}(1))\varphi_x(1). \end{aligned}$$

It is clear that $a(\cdot,\cdot)$ is V-elliptic in $V \times V$. We therefore deduce from the Lax–Milgram theorem (cf. Lions–Magenes [8, p. 216]) that there exists a unique function $y \in V$ such that

$$(4.11)\qquad a(y,\varphi) = f(\varphi) \quad \forall \varphi \in V,$$

which implies in particular that

$$y + y_{xxxx} = y_0 + z_0 \quad \text{in } \mathcal{D}'.$$

Because $y_0 + z_0 \in V$, we obtain that

$$y_{xxxx} = y_0 + z_0 - y \in V,$$

which means precisely that $y \in H^6(0,1)$. Now, given this regularity, when interpreting the equation (4.11) we find that y is the solution of the equation (4.10). Moreover, we have

$$\begin{cases} y_{xxxx}(0) = y_0(0) + z_0(0) - y(0) = 0, \\ y_{xxxxx}(0) = y_{0x}(0) + z_{0x}(0) - y_x(0) = 0. \end{cases}$$

This proves the range condition (4.7). Proposition 4.1 is thus proved. □

Now letting $z = y_t$, we can write the hybrid system (4.1) in the following abstract form:

$$\frac{d}{dt}u(t) + Au(t) = 0, \qquad u(0) = u_0. \tag{4.12}$$

We have the following well-posed theorem.

THEOREM 4.2. (i) *For any initial data* $u_0 = (y_0, z_0) \in D(A)$, *the equation* (4.12) *admits a unique strong solution* u *such that*

$$u(t) = (y(t), z(t)) \in D(A) \quad \forall t \geq 0, \tag{4.13}$$

$$y(t) \in C^2([0,+\infty[; H^2(0,1)) \cap C^1([0,+\infty[; H^4(0,1)) \cap C^0([0,+\infty[; H^6(0,1)). \tag{4.14}$$

(ii) *For any initial data* $u_0 = (y_0, z_0) \in E$, *the equation* (4.12) *admits a unique weak solution* $u(t) = (y(t), z(t))$ *such that*

$$u(t) = S(t)u_0 = (y(t), z(t)) \in E \quad \forall t \geq 0, \tag{4.15}$$

$$y(t) \in C^1([0,+\infty[; H^2(0,1)) \cap C^0([0,+\infty[; H^4(0,1)). \tag{4.16}$$

where $S(t)$ *denotes the strongly continuous semigroup of contractions on* E *generated by the maximal monotone operator* A.

Proof. Because the operator A is maximal monotone on the Hilbert space E, by the classical linear semigroup theory (cf. Brezis [1, p. 105] and Pazy [12, p. 14]), we know that for any $u_0 \in D(A)$ the equation (4.15) has a unique strong solution u such that

$$u(t) = (y(t), z(t)) \in C^1([0,+\infty[; E) \cap C^0([0,+\infty[; D(A)).$$

This means that

$$y(t) \in C^1([0,+\infty[; H^4(0,1)) \cap C^0([0,+\infty[; H^6(0,1)),$$

$$y_t(t) = z(t) \in C^1([0,+\infty[; H^2(0,1)) \cap C^0([0,+\infty[; H^4(0,1)).$$

The last two conditions, together with Sobolev's embeddings imply that

$$y(t) \in C^2([0,+\infty[; H^2(0,1)).$$

This proves the condition (4.14).

Now let $u_0 \in E$. Then by the denseness of $D(A)$ in E and the contraction of the semigroup $S(t)$, we know that the weak solution u given by $u(t) = S(t)u_0$ satisfies

$$u(t) = (y(t), z(t)) \in C^0([0,+\infty[; E),$$

which means that

$$y(t) \in C^0([0,+\infty[; H^4(0,1)), \qquad y_t(t) = z(t) \in C^0([0,+\infty[; H^2(0,1)).$$

Using Sobolev's embeddings, the above conditions imply that

$$y(t) \in C^1([0,+\infty[; H^2(0,1)).$$

The proof of Theorem 4.2 is thus complete. □

Now let $u(t) = (y(t), z(t))$ be a smooth solution of the system (4.12). We introduce the associated energy

$$E(t) = \frac{1}{2}\|u(t)\|^2 = \frac{1}{2}\left\{\int_0^1 (y_{xxt}^2 + y_{xxxx}^2)\,dx + y_{xx}^2(1,t) + y_{xxx}^2(1,t)\right\}. \tag{4.17}$$

Using (4.6) and (4.12), we calculate the derivative of the energy

$$\frac{d}{dt}E(t) = -\langle Au(t), u(t)\rangle = -(z_{xx}^2(1,t) + z_{xxx}^2(1,t)). \tag{4.18}$$

Using the relation $z = y_t$, it follows from (4.18) that

$$\frac{d}{dt}E(t) = -(y_{xxt}^2(1,t) + y_{xxxt}^2(1,t)) \leq 0. \tag{4.19}$$

Remark 4.1. The expression (4.19) shows that the energy $E(t)$ is nonincreasing and therefore defines a Lyapunov function. This justifies the introduction of the inner product (4.3).

Now let y be a solution of (4.1). We define the following functionals:

$$\begin{cases} \rho_1(t) = 2\int_0^1 x y_{tt} y_{tx}\,dx, \\ \rho_2(t) = 2(y_{xt}(1,t)y_{xx}(1,t) - y_t(1,t)y_{xxx}(1,t)), \\ \rho(t) = \rho_1(t) + \rho_2(t). \end{cases} \tag{4.20}$$

PROPOSITION 4.3. *There exist positive constants* C_1, C_2 *such that*

$$|\rho(t)| \leq C_1 E(t) \quad \forall t \geq 0, \tag{4.21}$$

$$\frac{d}{dt}\rho(t) \leq -E(t) + C_2(y_{xxt}^2(1,t) + y_{xxxt}^2(1,t)) \quad \forall t \geq 0 \tag{4.22}$$

for all solutions y *of the system* (4.1).

Proof. The estimate (4.21) is a direct application of the Cauchy–Schwartz inequality. In fact, we have

$$|\rho(t)| \leq 2(1+\lambda)E(t),$$

where $\lambda > 0$ is the largest constant such that

$$y^2(1) + y_x^2(1) + \int_0^1 y_x^2\,dx \leq \lambda\int_0^1 y_{xx}^2\,dx$$

for all functions $y \in H^2(0,1) : y(0) = y_x(0) = 0$.

The proof of the estimate (4.22) is more complicated. First by a straightforward computation, we have

$$\begin{aligned} \frac{d}{dt}\rho_1(t) = {} & -3\int_0^1 y_{xx}^2\,dx - \int_0^1 y_{xxxx}^2\,dx + y_{xxt}^2(1,t) + y_{tt}^2(1,t) \\ & - 2y_{xt}(1,t)y_{xxxt}(1,t) + 2y_{xt}(1,t)y_{xxt}(1,t), \end{aligned} \tag{4.23}$$

$$\begin{aligned}\frac{d}{dt}\rho_2(t) &= 2y_{xtt}(1,t)y_{xx}(1,t) + 2y_{xt}(1,t)y_{xxt}(1,t)\\ &\quad - 2y_{tt}(1,t)y_{xxx}(1,t) - 2y_t(1,t)y_{xxxt}(1,t).\end{aligned} \tag{4.24}$$

Combining (4.23), (4.24), and the boundary conditions at the end $x = 1$, we obtain

$$\begin{aligned}\frac{d}{dt}\rho(t) &\leq -2E(t) + (y_{xtt}(1,t) + y_{xx}(1,t))^2 + (y_{tt}(1,t) - y_{xxx}(1,t))^2\\ &\quad + y_{xxt}^2(1,t) - 2y_t(1,t)y_{xxxt}(1,t) + 2y_{xt}(1,t)(2y_{xxt}(1,t) - y_{xxxt}(1,t))\\ &= -2E(t) + 2y_{xxt}^2(1,t) + y_{xxxt}^2(1,t)\\ &\quad - 2y_t(1,t)y_{xxxt}(1,t) + 2y_{xt}(1,t)(2y_{xxt}(1,t) - y_{xxxt}(1,t)).\end{aligned} \tag{4.25}$$

Let $\sigma > 0$ denote the largest constant such that

$$y^2(1) + y_x^2(1) \leq \frac{\sigma}{2}\int_0^1 y_{xx}^2\,dx,$$

for all functions $y \in H^2(0,1) : y(0) = y_x(0) = 0$. It follows that

$$y_t^2(1,t) + y_{xt}^2(1,t) \leq \frac{\sigma}{2}\int_0^1 y_{txx}^2\,dx \leq \sigma E(t) \quad \forall t \geq 0.$$

Applying Young's inequality, it follows that

$$\begin{aligned}&-2y_t(1,t)y_{xxxt}(1,t) + 2y_{xt}(1,t)(2y_{xxt}(1,t) - y_{xxxt}(1,t))\\ &\quad \leq E(t) + 6\sigma(y_{xxt}^2(1,t) + y_{xxxt}^2(1,t)).\end{aligned} \tag{4.26}$$

Inserting (4.26) into (4.25) gives

$$\frac{d}{dt}\rho(t) \leq -E(t) + 2(1 + 3\sigma)(y_{xxt}^2(1,t) + y_{xxxt}^2(1,t)).$$

The proof of Proposition 4.3 is thus complete. □

Remark 4.2. We see that the first functional $\rho_1(t)$ is defined by means of the well-known classical multiplier xy_{tx} (cf. Chen et al. [2]) and the second one $\rho_2(t)$ designates the two *boundary multipliers*: $y_{xx}(1,t)$ and $y_{xxx}(1,t)$. The idea of the proof of the estimate (4.22) is to construct a suitable functional $\rho_2(t)$ such that all the boundary terms can be absorbed by the dissipative boundary damping.

THEOREM 4.4. *Given any* $M > 1$, *there exists a positive constant* ω *such that*

$$E(t) \leq ME(0)\exp(-\omega t) \quad \forall t \geq 0, \tag{4.27}$$

for all solutions y *of the hybrid system* (4.1).

The proof is a slight modification of that one of Theorem 3.3. Therefore, we omit the details.

Acknowledgment. The author would like to thank Professor F. Conrad for helpful discussions and the anonymous referees for the corrections and suggestions.

SYSTEM EQUIVALENCE FOR PERIODIC MODELS AND SYSTEMS*

OSVALDO M. GRASSELLI[†], SAURO LONGHI[‡], AND ANTONIO TORNAMBÈ[†]

Abstract. In this paper, the problem of obtaining a periodic description in state-space form of a linear process which can be modeled by linear difference equations with periodic coefficients is considered. On the basis of a polynomial time-invariant description of a linear periodic process, system equivalence between two such processes is introduced and studied. For a given periodic causal process, under an additional assumption, a periodic state-space description is found which is system equivalent to it. It is shown that the order, the characteristic multipliers, and the stacked transfer matrix at any initial time of the periodic system thus obtained coincide with those of the original periodic process, and that the asymptotic stability, the reachability, the observability, the controllability, the reconstructibility, the stabilizability, the detectability, and even the Jordan form of the monodromy matrix of such a system are determined by the original periodic model, as well as the existence of a solution of the robust tracking and regulation problem.

Key words. periodic systems, discrete-time systems, periodic models, system equivalence, realization theory

1. Introduction.

For processes which can be modeled by linear difference (or differential) equations with constant coefficients, Rosenbrock [28] introduced the polynomial matrix description in the form of the following pair of vector equations:

$$T(\delta)\xi = U(\delta)u, \tag{1}$$

$$y = V(\delta)\xi + W(\delta)u, \tag{2}$$

where $T(\delta), U(\delta), V(\delta)$, and $W(\delta)$ are polynomial matrices in δ, which for difference equations has the meaning of the one-step forward-shift operator. He showed that under the polynomial transformations on (1), (2) that he called strict system equivalence, if $T(\delta)$ is square, $\det T(\delta) \neq 0$ (and has a degree equal to the dimension of $T(\delta)$), and the input-output transfer matrix corresponding to (1), (2) is proper, then it is possible to obtain a description of the same process in state-space form, i.e., in the case of difference equations, of the type

$$x(k+1) = A\,x(k) + B\,u(k), \tag{3}$$

$$y(k) = C\,x(k) + D\,u(k). \tag{4}$$

Since then, several authors have studied the polynomial matrix description (1), (2) and the procedures for the computation of a state-space realization (3), (4) strictly system equivalent to (1), (2) (see, e.g., [4], [5], [8], [18], [19], [24], [26], [30]).

The same kind of problem seems to be of real interest for processes which can be modeled by linear difference equations with periodic coefficients (whose period will be denoted by ω) of the following form:

$$\sum_{i=0}^{r} T_i(k)\xi(k+i) = \sum_{i=0}^{r} U_i(k)u(k+i), \tag{5}$$

$$y(k) = \sum_{i=0}^{r} V_i(k)\xi(k+i) + \sum_{i=0}^{r} W_i(k)u(k+i) \tag{6}$$

for some integer $r \geq 0$, where $k \in \mathbf{Z}, \xi(k+i) \in \mathbf{R}^m$ is the vector of the internal variables or pseudostate, $u(k+i) \in \mathbf{R}^p$ is the input, $y(k) \in \mathbf{R}^q$ is the output, $T_i(k)$, $U_i(k)$, $V_i(k)$, and $W_i(k)$ $(i = 0, \ldots, r)$ are real periodic matrices of period ω (briefly ω-periodic), and the $T_i(k)$, $i = 0, \ldots, r$, are possibly square. Equations (5), (6) are termed the *model* of the process under consideration.

The interest in obtaining a description of such a process in state-space form is motivated by the large variety of processes which can be modeled by linear equations with periodic coefficients and the resulting attention devoted to linear periodic systems [1], [2], [23], [27], specifically to discrete-time ones (see, e.g., [3], [9], [13], [14], [29]), for which a control theory (based on a state-space description) is developing, including eigenvalue assignment, state and output dead-beat control, disturbance localization, model matching, robust tracking and regulation, and block decoupling [6], [10], [11], [12], [15], [16], [21], [22], [25].

In this paper, the problem of obtaining a state-space description of the periodic process (5), (6) is faced. In §2 a polynomial time-invariant characterization of such a process and some related notions are introduced, including the order of such a model (i.e., the number of arbitrary and independent initial conditions needed for uniquely solving (5) for a given function $u(\cdot)$), as well as some conditions which are to be satisfied so that the process is causal. In §3, system equivalence between two models of the form (5), (6) is introduced, and the properties which are invariant under it are analysed. In §4, a periodic system which is system equivalent to a causal periodic model (5), (6) is found under an additional assumption on the model.

Henceforth, the identity matrix of dimension ν will be denoted either by I_ν, or simply by I; Δ will denote the ω-steps forward-shift operator, Δ^{-1} will denote its inverse; the following notation will be used also. Let $R_\nu(\Delta)$, $\nu \in \mathbf{Z}^+$, be defined by

$$R_\nu(\Delta) := \begin{bmatrix} 0 & I_{(\omega-1)\nu} \\ \Delta I_\nu & 0 \end{bmatrix}. \tag{7}$$

Let a vector function $z(t) \in \mathbf{R}^\nu$ be given with $t \in \mathbf{Z}$; for any $k \in \mathbf{Z}$, the *ω-stacked form of $z(t)$ at (the initial) time k* is defined by

$$z_k(h) := \left[z^T(k+h\omega)\ z^T(k+h\omega+1)\ \ldots\ z^T(k+h\omega+\omega-1)\right]^T, \quad h \in \mathbf{Z}.$$

The vector $z_k(h)$ can be considered a function either of k or of h; in the following, whenever the operator $R_\nu(\Delta)$ will be applied to $z_k(h)$, the operator Δ will have the meaning of an ω-steps forward-shift in the k variable, or, equivalently, a one-step forward-shift in the h variable. Let an ω-periodic matrix $F(t) \in \mathbf{R}^{\nu\times\mu}$ be given, with $t \in \mathbf{Z}$, representing the linear map $z(t) = F(t)w(t)$. For any $k \in \mathbf{Z}$, the *ω-stacked form of $F(t)$ at (the initial) time k* is defined by $\mathcal{F}_k := \operatorname{diag}\{F(k), F(k+1), \ldots, F(k+\omega-1)\}$, and represents the induced linear map between the ω-stacked forms at time k of the vector functions $z(t)$ and $w(t)$, i.e., $z_k(h) = \mathcal{F}_k w_k(h), h \in \mathbf{Z}$.

The following lemma can be easily proved, taking into account that $\Delta F(k)\Delta^{-1} = F(k+\omega)$ and $\Delta^{-1}F(k+\omega-1)\Delta = F(k-1)$.

LEMMA 1.1. *For any vector function $z(t) \in \mathbf{R}^\nu$ and ω-periodic matrix $F(t) \in \mathbf{R}^{\nu\times\mu}$ $(t \in \mathbf{Z})$, and for any $k \in \mathbf{Z}$, the following identities hold:*

$$R_\nu^{j\omega+i}(\Delta)z_k(h) = z_{k+j\omega+i}(h) = z_{k+i}(h+j) \quad \forall i,j \in \mathbf{Z}; \tag{8}$$

$$R_\nu^{j\omega+i}(\Delta)\mathcal{F}_k R_\mu^{-(j\omega+i)}(\Delta) = \mathcal{F}_{k+j\omega+i} = \mathcal{F}_{k+i} \quad \forall i,j \in \mathbf{Z}. \tag{9}$$

Identity (9) *still holds with* Δ *replaced by a scalar complex variable.*

2. A time-invariant characterization of ω-periodic models and systems. By introducing the ω-stacked forms $\xi_{k_0}(h)$, $u_{k_0}(h)$, and $y_{k_0}(h)$ at time k_0 of vectors $\xi(k), u(k), y(k)$, and the ω-stacked forms $\mathcal{T}_{i,k_0}, \mathcal{U}_{i,k_0}, \mathcal{V}_{i,k_0}$, and $\mathcal{W}_{i,k_0}$ at time k_0 of matrices $T_i(k), U_i(k)$, $V_i(k), W_i(k), i = 0, \ldots, r$, and taking (8) into account, model (5), (6) can be expressed in the following form, which is called the *ω-stacked form at time k_0 of model* (5), (6) (briefly, the *ω-stacked model at time k_0*):

$$\mathcal{T}_{k_0}(\Delta)\xi_{k_0}(h) = \mathcal{U}_{k_0}(\Delta)u_{k_0}(h), \tag{10}$$

$$y_{k_0}(h) = \mathcal{V}_{k_0}(\Delta)\xi_{k_0}(h) + \mathcal{W}_{k_0}(\Delta)u_{k_0}(h), \tag{11}$$

where $\mathcal{T}_{k_0}(\Delta) := \sum_{i=0}^{r} \mathcal{T}_{i,k_0} R_m^i(\Delta)$, $\mathcal{U}_{k_0}(\Delta) := \sum_{i=0}^{r} \mathcal{U}_{i,k_0} R_p^i(\Delta)$, $\mathcal{V}_{k_0}(\Delta) : = \sum_{i=0}^{r} \mathcal{V}_{i,k_0} R_m^i(\Delta)$, $\mathcal{W}_{k_0}(\Delta) := \sum_{i=0}^{r} \mathcal{W}_{i,k_0} R_p^i(\Delta)$. Since the matrices $\mathcal{T}_{k_0}(\Delta)$, $\mathcal{U}_{k_0}(\Delta), \mathcal{V}_{k_0}(\Delta), \mathcal{W}_{k_0}(\Delta)$ are polynomial in Δ with constant coefficients, it seems natural to associate the following matrix with (10), (11):

$$S_{k_0}^M(\Delta) := \begin{bmatrix} -\mathcal{T}_{k_0}(\Delta) & \mathcal{U}_{k_0}(\Delta) \\ \mathcal{V}_{k_0}(\Delta) & \mathcal{W}_{k_0}(\Delta) \end{bmatrix}, \tag{12}$$

which is termed the *ω-stacked system matrix at time k_0 of model* (5), (6), thus extending the time-invariant Rosenbrock system matrix [28]. For the computation of the solutions of (10), (11), the following three types of elementary operations on the scalar rows of (10) can be useful, as for $\omega = 1$ [28]: (i) multiply any row by a nonzero real constant α; (ii) interchange rows i and j; (iii) add a multiple, by a polynomial $\beta(\Delta)$ in Δ with real coefficients, of row j to row i. On this basis, the next proposition can be easily proved, thus justifying the following assumption.

Assumption 2.1. The polynomial matrix $\mathcal{T}_{k_0}(\Delta)$ is square and nonsingular.

PROPOSITION 2.2. *If Assumption* 2.1 *does not hold, then one* (*or more*) *of the following situations occurs for equation* (10):

(α) *by a finite sequence of elementary operations of the types* (i), (ii), *and* (iii) *on the rows of equation* (10), *one of the scalar rows of the transformed equation of* (10) *can be reduced to the trivial identity* $0 = 0$;

(β) *there exists an ω-stacked input function $u_{k_0}(\cdot)$ for which* (10) *admits no solution for $h \geq 0$*;

(γ) *there exist solutions of* (10) *for $h \geq 0$ and for any $u_{k_0}(\cdot)$, but they depend on an infinite number of arbitrary and independent initial conditions.*

If Assumption 2.1 *holds, then, for each input function $u(\cdot)$, there exist solutions $\xi_{k_0}(\cdot), y_{k_0}(\cdot)$ of* (10), (11) *for $h \geq 0$, and they depend on arbitrary and independent initial conditions whose number is equal to the degree of* $\det\mathcal{T}_{k_0}(\Delta)$.

Relation (9) yields the following lemma about the dependence on k_0 of the matrices in (10), (11).

LEMMA 2.3. *If $\mathcal{T}_{k_0}(\Delta)$ is square, then the following identities hold*:

$$\mathcal{T}_{k_0+1}(\Delta) = R_m(\Delta)\mathcal{T}_{k_0}(\Delta)R_m^{-1}(\Delta), \quad \det\mathcal{T}_{k_0+1}(\Delta) = \det\mathcal{T}_{k_0}(\Delta), \tag{13}$$

$$\mathcal{U}_{k_0+1}(\Delta) = R_m(\Delta)\mathcal{U}_{k_0}(\Delta)R_p^{-1}(\Delta), \quad \mathcal{V}_{k_0+1}(\Delta) = R_q(\Delta)\mathcal{V}_{k_0}(\Delta)R_m^{-1}(\Delta), \tag{14}$$

$$\mathcal{W}_{k_0+1}(\Delta) = R_q(\Delta)\mathcal{W}_{k_0}(\Delta)R_p^{-1}(\Delta). \tag{15}$$

If Assumption 2.1 *holds for $k_0 = \overline{k}_0 \in \mathbf{Z}$, then it holds for any $k_0 \in \mathbf{Z}$, and the degree of* $\det\mathcal{T}_{k_0}(\Delta)$ *is independent of the initial time k_0.*

Hereafter, in view of Proposition 2.2, Assumption 2.1 will be assumed to hold; then, by virtue of Lemma 2.3, the degree of $\det \mathcal{T}_{k_0}(\Delta)$ for an arbitrary $k_0 \in \mathbf{Z}$ will be called the *order of model* (5), (6).

Now, consider a linear ω-periodic *model in state-space form*, i.e., a linear *system* described by:

$$x(k+1) = A(k)\,x(k) + B(k)\,u(k), \tag{16}$$

$$y(k) = C(k)\,x(k) + D(k)\,u(k), \tag{17}$$

where $k \in \mathbf{Z}$, $x(k) \in \mathbf{R}^n$ is the state, $u(k) \in \mathbf{R}^p$, $y(k) \in \mathbf{R}^q$, and $A(\cdot), B(\cdot), C(\cdot), D(\cdot)$ are real ω-periodic matrices. For this special case of an ω-periodic model, equations (10), (11) reduce to

$$R_n(\Delta)\,x_{k_0}(h) = \mathcal{A}_{k_0}\,x_{k_0}(h) + \mathcal{B}_{k_0}\,u_{k_0}(h), \tag{18}$$

$$y_{k_0}(h) = \mathcal{C}_{k_0}\,x_{k_0}(h) + \mathcal{D}_{k_0}\,u_{k_0}(h) \tag{19}$$

(where $x_{k_0}(h)$, $\mathcal{A}_{k_0}, \mathcal{B}_{k_0}, \mathcal{C}_{k_0}$, and $\mathcal{D}_{k_0}$ are the ω-stacked forms at time k_0 of $x(k)$, $A(k), B(k), C(k)$, and $D(k)$, respectively), which are termed the *ω-stacked form at time k_0 of system* (16), (17) (briefly, the *ω-stacked system at time k_0*). The stacked forms $\mathcal{A}_{k_0}$, $\mathcal{B}_{k_0}$, $\mathcal{C}_{k_0}$, $\mathcal{D}_{k_0}$ allow the notions of invariant zero, input (output) decoupling zero, and characteristic multiplier to be characterized and studied in a direct way for the ω-periodic system (16), (17) [13]. This is achieved through the matrix obtained by substituting the operator Δ by the complex variable z in

$$S^S_{k_0}(\Delta) := \begin{bmatrix} \mathcal{A}_{k_0} - R_n(\Delta) & \mathcal{B}_{k_0} \\ \mathcal{C}_{k_0} & \mathcal{D}_{k_0} \end{bmatrix}, \tag{20}$$

which from now on will be called the *ω-stacked system matrix at time k_0 of system* (16), (17).

Notice that, under Assumption 2.1, the roots of the equation $\det\mathcal{T}_{k_0}(z) = 0$ coincide with the values of z, for which there exists a nonzero solution of (5) for $u(\cdot) = 0$, satisfying the following:

$$\xi(k_0 + h\omega + \ell) = z^h \xi(k_0 + \ell) \quad \forall h \in \mathbf{Z}^+, \ell = 0, 1, \dots, \omega - 1; \tag{21}$$

therefore, such values play the same role for model (5), (6) that is played by the roots of the equation $\det[R_n(z) - \mathcal{A}_{k_0}] = 0$ for system (16), (17). In view of the results in [13], it seems natural to call *eigenvalues* or *characteristic multipliers of model* (5), (6) *at time* k_0, under Assumption 2.1, the zeros of the polynomial $\det\mathcal{T}_{k_0}(z)$ (and *characteristic polynomial of model* (5), (6) *at time* k_0 such a polynomial) with corresponding *ordered sets of structural indices* defined at the same time as their nondecreasing sequences of multiplicities as zeros of the invariant polynomials of $\mathcal{T}_{k_0}(z)$. In a similar way, under the same Assumption 2.1, the *invariant zeros*, *input decoupling zeros*, and *output decoupling zeros of model* (5), (6) *at time* k_0 are defined to be the zeros of the invariant polynomials of $S^M_{k_0}(z)$, $[-\mathcal{T}_{k_0}(z) \;\; \mathcal{U}_{k_0}(z)]$, $[-\mathcal{T}^T_{k_0}(z) \;\; \mathcal{V}^T_{k_0}(z)]^T$, respectively, with *ordered sets of structural indices* defined at the same time as their nondecreasing sequences of multiplicities as zeros of such polynomials.

The following proposition extends some results of [13] about system (16), (17) to model (5), (6); it can be proved on the basis of Lemmas 1.1 and 2.3 in a way similar to Theorem 3.4 in [13].

PROPOSITION 2.4. *Identities* (13)–(15) *still hold with* Δ *replaced by a scalar complex variable. Under Assumption* 2.1, *the rank of* $S^M_{k_0}(\Delta)$, *the nonzero invariant* *zeros, the nonzero input (output) decoupling zeros of model* (5), (6) *at time* k_0*, their ordered sets of structural indices, the whole characteristic polynomial of model* (5), (6) *at time* k_0*, and the ordered sets of structural indices of the nonzero characteristic multipliers are independent of* k_0.

Note that, under Assumption 2.1 for a fixed initial time k_0, the application of the z-transform to both sides of (10), (11), with zero initial conditions, yields $y_{k_0}(z) = G^M_{k_0}(z)\, u_{k_0}(z)$, where $G^M_{k_0}(z) := \mathcal{V}_{k_0}(z)\mathcal{T}^{-1}_{k_0}(z)\mathcal{U}_{k_0}(z) + \mathcal{W}_{k_0}(z)$ is called the *ω-stacked transfer matrix of model* (5), (6) *at* (*the initial*) *time* k_0. Proposition 2.4 yields

$$G^M_{k_0+1}(z) = R_q(z)G^M_{k_0}(z)R_p^{-1}(z) \quad \forall z \in \mathbf{C} \quad \forall k_0 \in \mathbf{Z}, \tag{22}$$

thus extending a similar relation for the ω-stacked transfer matrix of system (16), (17) [13]. By (22), if the transmission zeros and the poles of model (5), (6) at time k_0 and their ordered sets of structural indices are defined through the Smith–MacMillan form of $G^M_{k_0}(z)$, as in [13] those of system (16), (17), then by the same proofs as in [13] it is readily shown that the nonzero transmission zeros and poles of model (5), (6) and their ordered sets of structural indices are independent of time.

If $y_a(k)$ and $y_b(k)$ denote the output solutions of (5), (6) at time $k \geq k_0$ corresponding to given input functions $u_a(\cdot)$ and $u_b(\cdot)$, respectively, and to the same initial time k_0 and initial conditions, then model (5), (6) is said to be *causal* if $y_a(k) = y_b(k)$ for all the input functions $u_a(\cdot), u_b(\cdot)$ such that $u_a(t)|_{[k_0,k]} = u_b(t)|_{[k_0,k]}$, for all the initial conditions, for all $k \in \mathbf{Z}$, $k \geq k_0$, and for all $k_0 \in \mathbf{Z}$.

The proof of the following proposition is given in the appendix. A result similar to its first part was given in [20].

PROPOSITION 2.5. *Under Assumption* 2.1, *the ω-periodic model* (5), (6) *is causal only if, for all* $k_0 \in \mathbf{Z}$, *the corresponding ω-stacked model* (10), (11) *at time* k_0 *satisfies the following conditions*:

(i) $G^M_{k_0}(z)$ *is a proper rational matrix*;

(ii) *if* $G^M_{k_0}(z)$ *is rewritten as* $G^M_{k_0}(z) = F_{k_0}(z) + Q_{k_0}$ *with* $F_{k_0}(z)$ *strictly proper and* Q_{k_0} *constant, and* Q_{k_0} *is decomposed into blocks of dimensions* $q \times p$, *then* Q_{k_0} *is lower block triangular.*

If conditions (i) *and* (ii) *hold for* $k_0 = \bar{k}_0, \bar{k}_0 \in \mathbf{Z}$, *then* (i) *and* (ii) *hold for all* $k_0 \in \mathbf{Z}$.

3. System equivalence.

By formally using the same definition as the one introduced by Rosenbrock [28] for the time-invariant case, two $(m\omega + q\omega) \times (m\omega + p\omega)$ polynomial system matrices $S^1(\Delta)$ and $S^2(\Delta)$ with real coefficients are said to be *strictly system equivalent* if a relation of the following form holds:

$$S^2(\Delta) = \begin{bmatrix} M(\Delta) & 0 \\ Y(\Delta) & I_{q\omega} \end{bmatrix} S^1(\Delta) \begin{bmatrix} N(\Delta) & X(\Delta) \\ 0 & I_{p\omega} \end{bmatrix}, \tag{23}$$

where $M(\Delta), N(\Delta), X(\Delta)$, and $Y(\Delta)$ are polynomial matrices in Δ with real coefficients, and $M(\Delta), N(\Delta)$ are square and unimodular. It is stressed that strict system equivalence is an equivalence relation [28]. In addition, for the same reason as in [28] for the case $\omega = 1$, the following extra operations can be considered on the ω-stacked form (10), (11) at time k_0 of model (5), (6):

(a) for each $l = 0, \ldots, \omega - 1$, add to the vector component $\xi(k_0 + h\omega + l)$ of $\xi_{k_0}(h)$, ν scalar components, $\nu \geq 0$, which are defined to be equal to zero for each $h \geq 0$;

(b) for each $l = 0, \ldots, \omega - 1$, remove from the vector component $\xi(k_0 + h\omega + l)$ of $\xi_{k_0}(h)$, ν scalar components, $0 \leq \nu \leq m$, if they are equal to zero for each $\ell = 0, \ldots, \omega - 1$, for each $h \geq 0$, for all input functions $u(\cdot)$, and for all initial conditions.

The ω-stacked system matrix at time k_0, obtained from (10), (11) after an operation of type (a) has been carried out, is strictly system equivalent to the following one:

$$S_{k_0}^{ME}(\Delta) = \left[\begin{array}{cc|c} -I_{\nu\omega} & 0 & 0 \\ 0 & -\mathcal{T}_{k_0}(\Delta) & \mathcal{U}_{k_0}(\Delta) \\ \hline 0 & \mathcal{V}_{k_0}(\Delta) & \mathcal{W}_{k_0}(\Delta) \end{array}\right]. \tag{24}$$

A similar characterization of operation (b) holds. Then, two ω-periodic models of type (5), (6) satisfying Assumption 2.1 and having inputs and outputs of the same dimensions p and q, respectively, pseudostates of dimensions $m_i, i = 1, 2$, and corresponding ω-stacked models $\mathcal{M}_{k_0}^i$ of the form (10), (11), $i = 1, 2$, at the same time k_0, are said to be *system equivalent at time* k_0 if there exist an operation of type (a) or (b) to be carried out on $\mathcal{M}_{k_0}^1$ and an operation of type (a) or (b) to be carried out on $\mathcal{M}_{k_0}^2$ such that the ω-stacked system matrices at time k_0 associated with the resulting ω-stacked models at time k_0 are strictly system equivalent. For the proof of the following proposition see the appendix.

PROPOSITION 3.1. *The relation of system equivalence at time* k_0 *between two* ω*-periodic models of type* (5), (6) *is an equivalence relation.*

Remark 3.2. The solutions for $k \geq k_0$ of two ω-periodic models which are system equivalent at time k_0 are biuniquely related in the pseudostate, and are exactly the same in the output.

Such a statement is more deeply specified and clarified by the following proposition (which follows from well-known time invariant results [28], Lemma 2.3, relation (22), and Proposition 2.4) and by the subsequent remark.

PROPOSITION 3.3. *Given two* ω*-periodic models* $\mathcal{M}_1$ *and* $\mathcal{M}_2$ *of type* (5), (6) *satisfying Assumption* 2.1 *and having inputs and outputs of the same dimensions* p *and* q*, respectively, pseudostates of dimensions* $m_i, i = 1, 2$*, and the following* ω*-stacked system matrices at time* k_0:

$$S_{k_0,i}^{M}(\Delta) = \begin{bmatrix} -\mathcal{T}_{k_0,i}(\Delta) & \mathcal{U}_{k_0,i}(\Delta) \\ \mathcal{V}_{k_0,i}(\Delta) & \mathcal{W}_{k_0,i}(\Delta) \end{bmatrix}, \quad i = 1, 2, \tag{25}$$

if $\mathcal{M}_1$ *and* $\mathcal{M}_2$ *are system equivalent at time* k_0*, then*: (i) *the matrices in each of the pairs* $(S_{k_0,1}^M(z), S_{k_0,2}^M(z))$, $(\mathcal{T}_{k_0,1}(z), \mathcal{T}_{k_0,2}(z))$, $([-\mathcal{T}_{k_0,1}(z) \ \mathcal{U}_{k_0,1}(z)], [-\mathcal{T}_{k_0,2}(z) \ \mathcal{U}_{k_0,2}(z)])$, $([-\mathcal{T}_{k_0,1}^T(z) \ \mathcal{V}_{k_0,1}^T(z)]^T, [-\mathcal{T}_{k_0,2}^T(z) \ \mathcal{V}_{k_0,2}^T(z)]^T)$, *have the same Smith form, apart from some unit invariant polynomials, equal in number to* $\omega|m_1 - m_2|$; (ii) *the orders of* $\mathcal{M}_1$ *and* $\mathcal{M}_2$ *coincide*; (iii) *the* ω*-stacked transfer matrices of* $\mathcal{M}_1$ *and* $\mathcal{M}_2$ *at any initial time coincide*; (iv) $\mathcal{M}_1$ *and* $\mathcal{M}_2$ *have the same nonzero invariant zeros, nonzero input* (*output*) *decoupling zeros at all times, the same corresponding ordered sets of structural indices* (*apart from* $\omega|m_1 - m_2|$ *null structural indices*)*, the same characteristic multipliers at all times, and the same ordered sets of structural indices of their nonzero characteristic multipliers* (*apart from* $\omega|m_1 - m_2|$ *null structural indices*).

Remark 3.4. By Proposition 3.3, if a system $\mathcal{M}_2$ of the form (16), (17) is system equivalent at time k_0 to a given model $\mathcal{M}_1$, then all the features of $\mathcal{M}_2$ that are listed in items (ii), (iii), and (iv) of Proposition 3.3 are specified by the original model $\mathcal{M}_1$. Hence, such a system $\mathcal{M}_2$ is controllable (respectively, reconstructible) if and only if $\mathcal{M}_1$ has no nonzero input (respectively, output) decoupling zeros; it is stabilizable (respectively, detectable), if and only if $\mathcal{M}_1$ has no input (respectively, output) decoupling zeros outside the open disk of unit radius; it is reachable (respectively, observable) at time k_0 if and only if $\mathcal{M}_1$ has no input (respectively, output) decoupling zeros at time k_0 [13]. Moreover, the order, the ω-stacked transfer matrix at any time k_0, the asymptotic stability [7], the rate of convergence of the free motions, all the characteristic multipliers of system $\mathcal{M}_2$, and even the number and the dimensions of the Jordan blocks corresponding to each nonzero characteristic multiplier in the Jordan form of the monodromy matrix of system $\mathcal{M}_2$ (denoted later on by $E^S_{k_0}$) [13] at any time k_0 are determined by the properties of the original model $\mathcal{M}_1$. In addition, $S^M_{k_0,2}(z)$ has full row-rank for any $k_0 \in \mathbf{Z}$ and for any nonzero $z \in \mathbf{C}$ if and only if $S^M_{k_0,1}(z)$ has full row-rank (it is recalled that such a condition on the ω-stacked system matrix $S^M_{k_0,2}(z)$ of the ω-periodic system $\mathcal{M}_2$ described by equations of the form (16), (17) is necessary and sufficient, together with stabilizability and detectability, for the existence of a solution of the robust tracking and regulation problem when the ω-stacked forms of reference signals and disturbance functions have a time dependence of the form z^h [16]).

In view of the above discussion, it seems reasonable to look for an ω-periodic system of the form (16), (17) that is system equivalent at time k_0 to the given ω-periodic model (5), (6). The following section is devoted to this.

4. State-space representation for periodic models. For the ω-periodic model (5), (6) and its corresponding ω-stacked form at time k_0 (10), (11), if Assumption 2.1 holds, its ω-stacked transfer matrix $G^M_{k_0}(z)$ is proper, and its order $\overline{n}$ is less than or equal to $m\omega$, possibly after a preliminary operation of the type (a) has been carried out on (10), (11), then $S^M_{k_0}(\Delta)$ is strictly system equivalent to the following matrix [28]:

$$\left[\begin{array}{cc|c} -I_{m\omega-\overline{n}} & 0 & 0 \\ 0 & E_{k_0} - \Delta I_{\overline{n}} & J_{k_0} \\ \hline 0 & L_{k_0} & P_{k_0} \end{array}\right] =: S^{Ma}_{k_0}(\Delta) \tag{26}$$

(with $E_{k_0}, J_{k_0}, L_{k_0}$, and P_{k_0} being constant matrices), which will be called a *normal system matrix associated with* (10), (11).

The property stated by the following lemma will be used constructively to find a representation in the state-space form (16), (17) that is system equivalent at time k_0 to a given model of a periodic process having the form (5), (6).

LEMMA 4.1. *For the ω-periodic model* (5), (6), *if Assumption* 2.1 *holds, its ω-stacked transfer matrix $G^M_{\overline{k}_0}(z)$ satisfies conditions* (i) *and* (ii) *of Proposition* 2.5, *and* $\det\mathcal{T}_{\overline{k}_0}(z)|_{z=0} \neq 0$ *for some time $\overline{k}_0$, then for a normal system matrix $S^{Ma}_{k_0}(\Delta)$ of the form* (26) *associated with its ω-stacked model* (10), (11) *at any time k_0, the following properties hold:* (i) *matrix E_{k_0} is nonsingular;* (ii) *the matrix $H_{k_0} := P_{k_0} - L_{k_0}(E_{k_0})^{-1}J_{k_0}$ is upper block triangular if it is partitioned into blocks of dimensions $q \times p$.*

Proof. By (13) and Propositions 2.4 and 2.5, the same hypotheses of the lemma hold at all $k_0 \in \mathbf{Z}$. Then, for an arbitrary $k_0 \in \mathbf{Z}$, by (23) and (24) the following relation holds:

$$\det\mathcal{T}_{k_0}(\Delta) = c\det(\Delta I - E_{k_0}) \tag{27}$$

with $c \in \mathbf{R}$ being a nonzero constant, thus yielding (i). In addition, well-known time-invariant results [28] imply that

$$G^M_{k_0}(z) = L_{k_0}(zI - E_{k_0})^{-1}J_{k_0} + P_{k_0}. \tag{28}$$

Property (i) and relation (28) imply that $G^M_{k_0}(z)$ is analytic at $z = 0$; therefore, $G^M_{k_0}(z)$ can be expressed by means of a McLaurin series as $G^M_{k_0}(z) = \sum_{i=0}^{+\infty} G^{M,i}_{k_0} z^i$, whence (28) and the definition of H_{k_0} yield $H_{k_0} = G^M_{k_0}(0) = G^{M,0}_{k_0}$.

Now, let matrices $G^{M,i}_{k_0}$ be partitioned as follows in the same way as H_{k_0}:

(29)

$$G^{M,i}_{k_0} = \begin{bmatrix} G^{M,i}_{k_0,00} & G^{M,i}_{k_0,01} & \cdots & G^{M,i}_{k_0,0,j-1} & \cdots & G^{M,i}_{k_0,0,\omega-2} & G^{M,i}_{k_0,0,\omega-1} \\ G^{M,i}_{k_0,10} & G^{M,i}_{k_0,11} & \cdots & G^{M,i}_{k_0,1,j-1} & \cdots & G^{M,i}_{k_0,1,\omega-2} & G^{M,i}_{k_0,1,\omega-1} \\ \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\ G^{M,i}_{k_0,j0} & G^{M,i}_{k_0,j1} & \cdots & G^{M,i}_{k_0,j,j-1} & \cdots & G^{M,i}_{k_0,j,\omega-2} & G^{M,i}_{k_0,j,\omega-1} \\ G^{M,i}_{k_0,j+1,0} & G^{M,i}_{k_0,j+1,1} & \cdots & G^{M,i}_{k_0,j+1,j-1} & \cdots & G^{M,i}_{k_0,j+1,\omega-2} & G^{M,i}_{k_0,j+1,\omega-1} \\ \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\ G^{M,i}_{k_0,\omega-1,0} & G^{M,i}_{k_0,\omega-1,1} & \cdots & G^{M,i}_{k_0,\omega-1,j-1} & \cdots & G^{M,i}_{k_0,\omega-1,\omega-2} & G^{M,i}_{k_0,\omega-1,\omega-1} \end{bmatrix}.$$

By the arbitrariness of k_0, relation (22), and the McLaurin series expansion of $G^M_{k_0}(z)$ imply that

(30)

$$G^M_{k_0+1}(z) = \sum_{i=0}^{+\infty} G^{M,i}_{k_0+1} z^i = R_q(z) G^M_{k_0}(z) R_p^{-1}(z) = \sum_{i=0}^{+\infty} R_q(z) G^{M,i}_{k_0} R_p^{-1}(z) z^i$$

$$= \sum_{i=0}^{+\infty} \begin{bmatrix} G^{M,i}_{k_0,11} & \cdots & G^{M,i}_{k_0,1,j-1} & \cdots & G^{M,i}_{k_0,1,\omega-2} & G^{M,i}_{k_0,1,\omega-1} & z^{-1} G^{M,i}_{k_0,10} \\ \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\ G^{M,i}_{k_0,j1} & \cdots & G^{M,i}_{k_0,j,j-1} & \cdots & G^{M,i}_{k_0,j,\omega-2} & G^{M,i}_{k_0,j,\omega-1} & z^{-1} G^{M,i}_{k_0,j0} \\ G^{M,i}_{k_0,j+1,1} & \cdots & G^{M,i}_{k_0,j+1,j-1} & \cdots & G^{M,i}_{k_0,j+1,\omega-2} & G^{M,i}_{k_0,j+1,\omega-1} & z^{-1} G^{M,i}_{k_0,j+1,0} \\ \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\ G^{M,i}_{k_0,\omega-1,1} & \cdots & G^{M,i}_{k_0,\omega-1,j-1} & \cdots & G^{M,i}_{k_0,\omega-1,\omega-2} & G^{M,i}_{k_0,\omega-1,\omega-1} & z^{-1} G^{M,i}_{k_0,\omega-1,0} \\ z G^{M,i}_{k_0,0,1} & \cdots & z G^{M,i}_{k_0,0,j-1} & \cdots & z G^{M,i}_{k_0,0,\omega-2} & z G^{M,i}_{k_0,0,\omega-1} & G^{M,i}_{k_0,0,0} \end{bmatrix} z^i.$$

Let matrices $G^{M,i}_{k_0+1}$ be partitioned in the same way as $G^{M,i}_{k_0}$ in (29). By computing $G^{M,0}_{k_0+1}$ with the help of (30), we have $G^{M,0}_{k_0+1,\omega-1,\ell} = 0$, $\ell = 0, \dots, \omega - 2$; whence, by the arbitrariness of k_0, we have $G^{M,0}_{k_0,\omega-1,\ell} = 0$, $\ell = 0, \dots, \omega - 2$.

Now, the proof can be carried out by induction by showing that

$$(31) \qquad G^{M,0}_{k_0,j,\ell} = 0,\ j = \bar{j} - 1, \dots, \omega - 1,\ \ell = 0, \dots, j - 1$$

under the inductive assumption that

$$(32) \qquad G^{M,0}_{k_0,j,\ell} = 0,\ j = \bar{j}, \dots, \omega - 1,\ \ell = 0, \dots, j - 1$$

for $\bar{j} \le \omega - 1$, satisfying $\bar{j} \ge 2$. In fact, with the help of (30) it is readily seen that (32) implies (31) written with $k_0 + 1$ instead of k_0, and this proves (31) by the arbitrariness of k_0. Since (31) coincides with property (ii) for $\bar{j} = 2$, this completes the proof. □

Remark 4.2. In the special case of the state-space model (16), (17), $S^S_{k_0}(\Delta)$ is strictly system equivalent to (26) with $m = \bar{n} = n$. It is stressed that in this case the quadruplet $(E_{k_0}, J_{k_0}, L_{k_0}, P_{k_0})$ can be shown to coincide [17] within a coordinate transformation with the quadruplet $(E^S_{k_0}, J^S_{k_0}, L^S_{k_0}, P^S_{k_0})$ characterizing the time-invariant *associated system* (or *lifted representation*) *at time* k_0 *of system* (16), (17) [13], [16], [23]. $E^S_{k_0}$ is the monodromy matrix at time k_0 of system (16), (17), expressed by

$$E^S_{k_0} := A(k_0 + \omega - 1)A(k_0 + \omega - 2) \cdots A(k_0), \tag{33}$$

so that the characteristic multipliers, the invariant zeros, the input (output) decoupling zeros at time k_0, the corresponding ordered sets of structural indices, and the ω-stacked transfer matrix at time k_0 of system (16), (17) can be equivalently defined in terms of these quadruplets instead of the ω-stacked system (18), (19) at time k_0 [13]. Note that in the same case of system (16), (17), the hypothesis of nonsingularity of $R_n(0) - \mathcal{A}_{\overline{k}_0}$ means the nonsingularity of the monodromy matrix $E^S_{k_0}$, i.e., that of $A(k)$ for all $k \in \mathbf{Z}$, which implies the time reversibility of the causal system (16), (17), i.e., its state $x(k)$ and its output $y(k)$ at any time $k < k_0$ can be uniquely computed from the knowledge of the state $x(k_0)$ at time k_0, and of the values $u(j)$ of the input function at times $j < k_0$. This, together with the causality of system (16), (17), is easily seen to imply condition (ii) of Lemma 4.1.

Under the following assumption (which implies Assumption 2.1), the necessary and sufficient conditions will now be given for the existence of a periodic system of the form (16), (17) that is system equivalent at time k_0 to a given periodic model (5), (6).

Assumption 4.3. The polynomial matrix $\mathcal{T}_{k_0}(\Delta)$ is square and $\mathcal{T}_{k_0}(z)|_{z=0}$ is nonsingular.

By Proposition 2.4, if Assumption 4.3 holds for $k_0 = \overline{k}_0 \in \mathbf{Z}$, then it holds for any $k_0 \in \mathbf{Z}$ (as well as the pair of conditions (i) and (ii) of Proposition 2.5).

THEOREM 4.4. *For the ω-periodic model* (5), (6) *and its corresponding ω-stacked form* (10), (11) *at time k_0, under Assumption* 4.3, *there exists an ω-periodic system of the form* (16), (17) *which is system equivalent at time k_0 to the model* (5), (6), *if and only if its ω-stacked transfer matrix $G^M_{k_0}(z)$ is proper and satisfies condition* (ii) *of Proposition* 2.5.

Proof. Necessity. If model (5), (6) is system equivalent at time k_0 to system (16), (17), then it satisfies conditions (i) and (ii) of Proposition 2.5 by Theorem 3.1 in [13] and Proposition 3.3.

Sufficiency. Denote by $\mathcal{M}$ the given ω-periodic model (5), (6), and by n its order. Denote by $\overline{\mathcal{M}}$ the ω-periodic model—which is system equivalent to $\mathcal{M}$ at time k_0—whose ω-stacked form at time k_0 is obtained from the ω-stacked form (10), (11) at time k_0 of $\mathcal{M}$ through an operation of type (a) with $\nu := n - m$ if $m \leq n$, and with $\nu := 0$ if $m > n$. Denote by $\overline{\mathcal{T}}_{k_0}(\Delta)$ the $(\overline{m}\omega) \times (\overline{m}\omega)$ matrix thus obtained from $\mathcal{T}_{k_0}(\Delta)$ with $\overline{m} := m + \nu \geq n$, and denote by $\overline{S}^M_{k_0}(\Delta)$ the ω-stacked system matrix at time k_0 associated with $\overline{\mathcal{M}}$. The definition of operation (a) yields $\det\mathcal{T}_{k_0}(\Delta) = \det\overline{\mathcal{T}}_{k_0}(\Delta)$, thus implying that the degree of $\det\overline{\mathcal{T}}_{k_0}(\Delta)$ is equal to n and that $\overline{\mathcal{T}}_{k_0}(z)|_{z=0}$ is nonsingular; in addition, by Proposition 3.3, the ω-stacked transfer matrix of $\overline{\mathcal{M}}$ at time k_0 coincides with $G^M_{k_0}(z)$.

The hypotheses on $\overline{\mathcal{M}}$ guarantee that $\overline{S}^M_{k_0}(\Delta)$ is strictly system equivalent to a matrix $S^{Ma}_{k_0}(\Delta)$ of the form (26) [28], with n instead of $\overline{n}$, and E_{k_0} nonsingular by Lemma 4.1. Let J_{k_0}, L_{k_0}, and P_{k_0} be partitioned into blocks of dimensions $n \times p$, $q \times n$, and $q \times p$, respectively, as follows:

$$J_{k_0} = [\, J_{k_0,0} \quad J_{k_0,1} \quad \cdots \quad J_{k_0,\omega-1} \,], \tag{34}$$

$$(35)\qquad P_{k_0} = \begin{bmatrix} P_{k_0,0,0} & 0 & 0 & \dots & 0 \\ P_{k_0,1,0} & P_{k_0,1,1} & 0 & \dots & 0 \\ \dots & \dots & \dots & \dots & \dots \\ P_{k_0,\omega-1,0} & P_{k_0,\omega-1,1} & P_{k_0,\omega-1,2} & \dots & P_{k_0,\omega-1,\omega-1} \end{bmatrix},$$

$$(36)\qquad L_{k_0} = \begin{bmatrix} L_{k_0,0} \\ L_{k_0,1} \\ \dots \\ L_{k_0,\omega-1} \end{bmatrix},$$

where the zero blocks in P_{k_0} are yielded by condition (ii) of Proposition 2.5, and by Proposition 3.3.

By virtue of property (ii) of Lemma 4.1, it is easy to check that

$$(37)\qquad \begin{bmatrix} \hat{M}(\Delta) & 0 \\ \hat{Y}(\Delta) & I_{q\omega} \end{bmatrix} S_{k_0}^{Ma}(\Delta) \begin{bmatrix} \hat{N}(\Delta) & \hat{X}(\Delta) \\ 0 & I_{p\omega} \end{bmatrix} = \hat{S}_{k_0}^{M}(\Delta)$$

with

(38)

$$\hat{S}_{k_0}^{M}(\Delta) = \left[\begin{array}{cc|c} -I_{\omega(\overline{m}-n)} & 0 & 0 \\ 0 & \mathrm{diag}\{A_0,\dots,A_{\omega-1}\} - R_n(\Delta) & \mathrm{diag}\{B_0,\dots,B_{\omega-1}\} \\ \hline 0 & \mathrm{diag}\{C_0,\dots,C_{\omega-1}\} & \mathrm{diag}\{D_0,\dots,D_{\omega-1}\} \end{array}\right],$$

$$(39)\quad \hat{M}(\Delta) = \begin{bmatrix} I_{\omega(\overline{m}-n)} & 0 & 0 & \dots & 0 & 0 \\ 0 & -I_n & 0 & \dots & 0 & 0 \\ 0 & 0 & -I_n & \dots & 0 & 0 \\ \dots & \dots & \dots & \dots & \dots & \dots \\ 0 & 0 & 0 & \dots & -I_n & 0 \\ 0 & E_{k_0} & E_{k_0} & \dots & E_{k_0} & I_n \end{bmatrix},$$

$$(40)\quad \hat{Y}(\Delta) = \begin{bmatrix} 0 & 0 & 0 & \dots & 0 & 0 \\ 0 & L_{k_0,1} & 0 & \dots & 0 & 0 \\ 0 & L_{k_0,2} & L_{k_0,2} & \dots & 0 & 0 \\ \dots & \dots & \dots & \dots & \dots & \dots \\ 0 & L_{k_0,\omega-1} & L_{k_0,\omega-1} & \dots & L_{k_0,\omega-1} & 0 \end{bmatrix},$$

$$(41)\quad \hat{N}(\Delta) = \begin{bmatrix} I_{\omega(\overline{m}-n)} & 0 & 0 & 0 & \dots & 0 & 0 \\ 0 & I_n & -I_n & 0 & \dots & 0 & 0 \\ 0 & 0 & I_n & -I_n & \dots & 0 & 0 \\ \dots & \dots & \dots & \dots & \dots & \dots & \dots \\ 0 & 0 & 0 & 0 & \dots & I_n & -I_n \\ 0 & I_n & 0 & 0 & \dots & 0 & 0 \end{bmatrix},$$

$$(42)\quad \hat{X}(\Delta) = \begin{bmatrix} 0 & 0 & \dots & 0 & 0 \\ (E_{k_0})^{-1}J_{k_0,0} & 0 & \dots & 0 & 0 \\ 0 & (E_{k_0})^{-1}J_{k_0,1} & \dots & 0 & 0 \\ \dots & \dots & \dots & \dots & \dots \\ 0 & 0 & \dots & (E_{k_0})^{-1}J_{k_0,\omega-2} & 0 \\ 0 & 0 & \dots & 0 & 0 \end{bmatrix},$$

where

$$(43)\qquad A_i := I_n,\ i = 0,\dots,\omega-2,\ A_{\omega-1} := E_{k_0},$$

$$(44)\qquad B_i := (E_{k_0})^{-1}J_{k_0,i},\ i = 0,\dots,\omega-2,\ B_{\omega-1} := J_{k_0,\omega-1},$$

$$C_i := L_{k_0,i},\ i = 0, \dots, \omega - 1, \tag{45}$$

$$D_i := P_{k_0,ii},\ i = 0, \dots, \omega - 1, \tag{46}$$

and the block columns (respectively, rows) of $\hat{M}(\Delta)$ and $\hat{Y}(\Delta)$ (respectively, $\hat{N}(\Delta)$ and $\hat{X}(\Delta)$) in the same position have the same number of scalar columns (respectively, rows).

Since (38) exhibits a structure of the same form as (24) with $\nu = \overline{m} - n$, a suitable transformation of strict system equivalence on $\hat{S}^M_{k_0}(\Delta)$, followed by an operation of type (b) with $\nu = \overline{m} - n$, allow us to obtain the matrix $S^S_{k_0}(\Delta)$ defined by (20) with

$$A(k_0 + i + h\omega) := A_i, i = 0, \dots, \omega - 1 \quad \forall h \in \mathbf{Z}, \tag{47}$$

$$B(k_0 + i + h\omega) := B_i, i = 0, \dots, \omega - 1 \quad \forall h \in \mathbf{Z}, \tag{48}$$

$$C(k_0 + i + h\omega) := C_i, i = 0, \dots, \omega - 1 \quad \forall h \in \mathbf{Z}, \tag{49}$$

$$D(k_0 + i + h\omega) := D_i, i = 0, \dots, \omega - 1 \quad \forall h \in \mathbf{Z}. \tag{50}$$

Thus system (16), (17), with $A(k), B(k), C(k)$, and $D(k)$ defined by (47)–(50), is system equivalent at time k_0 to the original model (5), (6) by construction. □

Remark 4.5. The constructive procedure provided by the sufficiency proof of Theorem 4.4 gives rise, under Assumption 4.3 and conditions (i) and (ii) of Proposition 2.5, to an ω-periodic system (16), (17) which is time reversible, since $A(k)$ is nonsingular for all $k \in \mathbf{Z}$ because of the assumption $\det \mathcal{T}_{k_0}(z)|_{z=0} \neq 0$ by Proposition 3.3. It is stressed that many properties and features of the ω-periodic system (16), (17) thus found are determined by the original model (5), (6) (see Remark 3.4). In addition, by Assumption 4.3, model (5), (6) and, hence, system (16), (17) have no null characteristic multiplier; thus, they have no null input decoupling zero and output decoupling zero [13], and, therefore, system (16), (17) is reachable (respectively, observable) at all times, or is not, according to the properties of model (5), (6) and irrespective of the time k_0 used in the procedure.

Remark 4.6. If a larger equivalence relation is introduced between two ω-periodic models, in which it is allowed to add to the original model of the form (5), (6) some further pseudostate components in order to store the input values, then for this new equivalence relation a theorem wholly similar to Theorem 4.4 can be obtained by merely substituting Assumption 4.3 with the weaker Assumption 2.1 [17]. In this way, under no assumption about time reversibility, an ω-periodic system can be found such that its ω-stacked transfer matrix at any initial time, its output solutions at any initial time, its nonzero characteristic multipliers at any time, and its nonzero input (output) decoupling zeros at any time are still the same as those of the original model, as well as the corresponding ordered sets of structural indices (apart from some null structural indices), although their orders do not coincide, in general. Therefore, the asymptotic stability and the rate of convergence of the free motions, the controllability, the reconstructibility, the stabilizability, the detectability, and even the number and the dimensions of the Jordan blocks corresponding to each nonzero characteristic multiplier in the Jordan form of the monodromy matrix of such a system at any time k_0 are still determined by the properties of the original model, as well as the existence of a solution of the robust tracking and regulation problem [17].

5. Conclusions.

In this paper a polynomial time-invariant description of a discrete-time linear periodic process has been used in order to obtain a representation of it in state-space form.

A solution of this problem has been proposed within the class of models which are system equivalent at time k_0 to the given one, under an assumption on the latter implying the time reversibility of the corresponding state-space representation. It has been shown that the order, the characteristic multipliers, and the stacked transfer matrix at any initial time of the periodic system thus obtained coincide with those of the original periodic model, and that the asymptotic stability, the reachability, the observability, the controllability, the reconstructibility, the stabilizability, the detectability, and even the Jordan form of the monodromy matrix of such a system at any initial time are determined by the original periodic model, as well as the existence of a solution of the robust tracking and regulation problem.

A. Appendix.

Proof of Proposition 2.5. Item (i) trivially follows by contradiction from causality, taking into account that the ω-stacked model (10), (11) is just a compact description of the original periodic model (5), (6). For item (ii), call $\bar{h}$ the maximum degree in Δ among all the elements of $\mathcal{U}_{k_0}(\Delta)$ and $\mathcal{W}_{k_0}(\Delta)$, assume $u_{k_0}(h) = 0$ for all $h \neq \bar{h}$, and assume all the initial conditions of $\xi_{k_0}(h)$ to be zero, so that item (i) and the application of the z-transform to (10), (11) show that $y_{k_0}(\bar{h}) = Q_{k_0} u_{k_0}(\bar{h})$. Then, item (ii) follows by contradiction, since otherwise $y(k_0 + \bar{h}\omega + i)$ should depend on $u(k_0 + \bar{h}\omega + j)$ for some $i, j \in [0, \omega - 1], i < j$, thus preventing the model to be causal.

Now, let (i) and (ii) hold for $k_0 = \bar{k}_0$, and $G^M_{\bar{k}_0}(z)$ be partitioned as follows:

$$G^M_{\bar{k}_0}(z) := \begin{bmatrix} G_{11}(z) & G_{12}(z) \\ G_{21}(z) & G_{22}(z) \end{bmatrix}, \tag{51}$$

where $G_{11}(z)$ has dimensions $q \times p$ and is proper, $G_{12}(z)$ has dimensions $q \times (\omega - 1)p$ and is strictly proper, $G_{21}(z)$ has dimensions $(\omega - 1)q \times p$ and is proper, $G_{22}(z)$ has dimensions $(\omega - 1)q \times (\omega - 1)p$ and is proper, and item (ii), rewritten for $G_{22}(z)$ instead of $G^M_{\bar{k}_0}(z)$, holds. Then relation (22) yields

$$G^M_{\bar{k}_0+1}(z) := \begin{bmatrix} G_{22}(z) & z^{-1}G_{21}(z) \\ zG_{12}(z) & G_{11}(z) \end{bmatrix}, \tag{52}$$

thus proving (i) and (ii) for $k_0 = \bar{k}_0 + 1$. The proof is completed recursively by virtue of the ω-periodicity. □

Proof of Proposition 3.1. The reflexivity and symmetry properties are obvious. For transitivity, given three ω-periodic models $\mathcal{M}_i, i = 1, 2, 3$, having inputs and outputs of the same dimensions p and q, respectively, and having ω-stacked models $\mathcal{M}^i_{k_0}$ and ω-stacked pseudo-states $\xi^i_{k_0}(h)$ at time k_0, $i = 1, 2, 3$, assume that the pairs $\mathcal{M}_1$ and $\mathcal{M}_2$ and, respectively, $\mathcal{M}_2$ and $\mathcal{M}_3$, are system equivalent at time k_0. That is, let $\overline{\mathcal{M}}^1_{k_0}$ and $\overline{\mathcal{M}}^2_{k_0}$ (respectively, $\tilde{\mathcal{M}}^2_{k_0}$ and $\tilde{\mathcal{M}}^3_{k_0}$) be the ω-stacked models at time k_0 obtained after operations of type (a) or (b) are accomplished on $\mathcal{M}^1_{k_0}$ and $\mathcal{M}^2_{k_0}$ (respectively, $\mathcal{M}^2_{k_0}$ and $\mathcal{M}^3_{k_0}$), such that their two corresponding ω-stacked system matrices at time k_0 are strictly system equivalent. Let $\bar{\xi}^i_{k_0}(h), i = 1, 2,$ (respectively, $\tilde{\xi}^i_{k_0}(h), i = 2, 3$), be their ω-stacked pseudo-states, and let $\bar{\nu}_i \gtrless 0, i = 1, 2,$ (respectively, $\tilde{\nu}_i \gtrless 0, i = 2, 3$), be the number of zero scalar components added to or removed from each of the ω vector components of $\xi^i_{k_0}(h)$ for obtaining $\bar{\xi}^i_{k_0}(h)$ (respectively, $\tilde{\xi}^i_{k_0}(h)$), where $\bar{\nu}_i$ (respectively, $\tilde{\nu}_i$) is defined to be < 0 if $|\bar{\nu}_i|$ (respectively, $|\tilde{\nu}_i|$) scalar components are removed. Without loss of generality assume that $\overline{\nu}_2 \geq \tilde{\nu}_2$ (otherwise the ordering of the $\mathcal{M}_i$ could be reversed). Make two operations of type (a) on both $\tilde{\mathcal{M}}^2_{k_0}$ and $\tilde{\mathcal{M}}^3_{k_0}$ by adding the same number $\overline{\nu}_2 - \tilde{\nu}_2$ of scalar components to each of the ω vector components of $\tilde{\xi}^2_{k_0}(h)$ and $\tilde{\xi}^3_{k_0}(h)$, and denote by $\hat{\mathcal{M}}^2_{k_0}$ and $\hat{\mathcal{M}}^3_{k_0}$ the ω-stacked models at time k_0 thus obtained from $\tilde{\mathcal{M}}^2_{k_0}$ and $\tilde{\mathcal{M}}^3_{k_0}$, respectively. The proposition follows from the transitivity property of strict system equivalence by noting that $\hat{\mathcal{M}}^2_{k_0} = \overline{\mathcal{M}}^2_{k_0}$ and that the ω-stacked system matrices at time k_0 associated with $\hat{\mathcal{M}}^2_{k_0}$ and $\hat{\mathcal{M}}^3_{k_0}$ are strictly system equivalent, as well as those of $\overline{\mathcal{M}}^1_{k_0}$ and $\overline{\mathcal{M}}^2_{k_0}$. □

SUPERVISORY CONTROL OF NONDETERMINISTIC SYSTEMS WITH DRIVEN EVENTS VIA PRIORITIZED SYNCHRONIZATION AND TRAJECTORY MODELS*

MARK A. SHAYMAN[†] AND RATNESH KUMAR[‡]

Abstract. The supervisory control of nondeterministic discrete event dynamical systems (DEDSs) with driven events in the setting of *prioritized synchronization* and *trajectory models* introduced by Heymann are studied. Prioritized synchronization captures the notions of controllable, uncontrollable, and driven events in a natural way, and the authors use it for constructing supervisory controllers. The trajectory model is used for characterizing the behavior of nondeterministic DEDSs since it is a sufficiently detailed model (in contrast to the less detailed language or failures models), and serves as a *language congruence* with respect to the operation of prioritized synchronization. Results concerning controllability and observability in this general setting are obtained.

Key words. discrete event systems, supervisory control, nondeterministic automata, driven events, prioritized synchronization, trajectory models

1. Introduction.

Supervisory control of discrete event dynamical systems (DEDSs) was introduced by Ramadge and Wonham [23]. In this approach, the behavior of a DEDS, called the plant, is described by its language, that is the collection of all possible sequences of events (traces) that it can generate. The task is to design a controller, called a supervisor, which, based on the observation of the sequence of events, disables some of the *controllable* events so that the language generated by the controlled plant either equals a prespecified desired language, called a target language, or remains confined to a prespecified range of languages. Various extensions of this basic problem such as control under partial observation, decentralized and modular control, hierarchical control, and optimal control have also been studied. Refer to [24] and references therein for an overview of research in this area (up to 1989).

Most of the research on supervisory control of DEDSs assumes that the plant can be modeled as a *deterministic* system [10]. In other words, given a state of the system and an event that occurs in that state, the state reached after the occurrence of the event is uniquely known. Such an assumption is not satisfied whenever unmodeled dynamics, partial observation, or inherent nondeterminism are present. Hence the assumption of a deterministic plant is quite strong. In this paper, we relax this assumption and consider the control of a *nondeterministic* plant [10], [17], [18], [9], [11], [7].

A *modeling framework* m over a finite event set Σ is an equivalence relation on all DEDSs representable as state machines with arbitrary state space (finite or denumerable) having ϵ-transitions and event set Σ. We identify m with the projection π_m, which maps each state machine $\mathcal{P}$ to its equivalence class or *model* $\pi_m(\mathcal{P})$. If

the equivalence class of $\mathcal{P}$ is uniquely characterized by an attribute, is common to its members, we will freely identify $\pi_m(\mathcal{P})$ with this attribute.

We say that a modeling framework π_m is *more detailed* than another modeling framework π_n if the equivalence relation π_m *refines* the equivalence relation π_n. Obviously, it is desirable to use the least detailed modeling framework which is sufficient for the design task at hand. A complex system is generally synthesized by combining simpler systems using various types of interconnections. Since specifications for the logical behavior of a DEDS are typically given in terms of the *language* of the system, a basic requirement is that the modeling framework should contain sufficient detail so that if the models for each subsystem are known, then the language of the interconnected system is uniquely determined. A modeling framework with such a property for a given class of admissible interconnections is referred to as a *language congruence* [7].

The language modeling framework associates with a system its language, the collection of all possible finite traces which are executable. Thus, the language model of a system is a subset of Σ^*, the set of all finite sequences of events in Σ including ϵ, the zero-length sequence. For deterministic systems and deterministic operators such as *strict synchronous composition* (SSC), the language modeling framework is a language congruence. If operators which introduce nondeterminism (e.g., internal choice, event internalization) are admissible, then the language modeling framework is no longer a language congruence and a more detailed modeling framework such as the *failures model* introduced by Hoare [9] must be used to have a language congruence. The failures model consists of the set of all *failures* of the system—pairs (s, Σ') where s is a trace and $\Sigma' \subseteq \Sigma$ is a refusal set with the property that if the environment restricts the possible events to Σ', the system can deadlock following execution of s. Thus, a failures model is a subset of $\Sigma^* \times 2^{\Sigma}$.[1]

In the work of Kumar, Garg, and Marcus [14], control design is accomplished by constructing a supervisor which operates in strict synchronization with the plant. In the work of Balemi et al. [3], the set of events Σ is partitioned into two disjoint subsets: *commands*, which are generated by the supervisor and sent to the plant, and *responses*, which are generated by the plant and sent to the supervisor. It is required that the plant and supervisor be *mutually receptive*, which means that the plant executes every command generated by the supervisor and the supervisor executes every response generated by the plant. Thus, this design also requires that every event be executed synchronously.

There are several reasons for considering control designs which do not require complete synchronization between the plant and supervisor. Uncontrollable events are generated spontaneously by the plant, and the supervisor is not permitted to interfere with their execution. Consequently, there is no a priori reason to assume that the supervisor needs to "track" every such event by undergoing a transition synchronously with the plant. Also, certain uncontrollable events in the plant may not be sensed and hence are invisible to the supervisor. It is unrealistic to require the supervisor to execute such events synchronously.

In many applications, it is not realistic to expect (or require) the plant to respond synchronously to every event generated by the supervisor. (Such events are referred to as *forcible* [6], *driven* [7], or *command* [3] events in the literature.) By permitting the supervisor to place commands which are not executed by the plant, nondeterminism in the plant may be resolved and performance improved. For example, not every piece

[1] For simplicity, we ignore the possibility of divergence.

of equipment in a factory will trigger an alarm upon breakdown. Breakdown may only be discovered when an action is requested by the supervisor and not executed by the plant. Thus, the unsensed state of the plant is determined by a synchronization failure.

Another motivation for relaxing the requirement of strict synchronization comes from systems in which a single supervisor controls more than one plant. For example, in a walking machine, there could be separate modules (viewed here as plants), which perform motion control and vision control, respectively. At a higher level, there could be a single supervisor which controls and coordinates the two modules. Some of the commands issued by the supervisor may apply to both the modules, while others may be relevant to only one of them and should be ignored by the other.

Heymann [7] has proposed a type of interconnection, called *prioritized synchronous composition* (PSC), which relaxes the synchronization requirements on the plant and supervisor. Each process in a PSC interconnection is assigned a *priority set* of events. For an event to be enabled in the interconnected system, it must be enabled in all processes whose priority sets contain that event. Also, when an enabled event occurs, it occurs in each subsystem in which the event is enabled. In the context of supervisory control, the priority set of the plant contains the controllable and uncontrollable events, while the priority set of the supervisor contains the controllable and driven events. Thus, controllable events require the participation of both plant and supervisor; uncontrollable events require the participation of the plant and will occur synchronously in the supervisor whenever possible; driven events require the participation of the supervisor and will occur synchronously in the plant whenever possible.

It is important to distinguish between PSC and other types of parallel composition in the literature. For example, Hoare [9] defines a concurrent composition operator in which each process has its own event set and the processes synchronize on the events in the intersection of their event sets. This is generalized to trace-dependent event sets, called event-control sets, by Inan and Varaiya [11]. The key difference between concurrent composition and PSC is that in PSC, although a process cannot block events which are outside its priority set, it may be able to execute these events and, whenever possible, will execute these events synchronously when they occur in the other process.[2]

It is shown in [7, Ex. 7] that two systems with the same failures model may yield different languages when composed in prioritized synchronization with a fixed system. Thus, if PSC is included as an admissible interconnection operator, a more detailed modeling framework than the failures model is required to serve as a language congruence. One such modeling framework, called the *trajectory model*, is proposed by Heymann [7] and Heymann and Meyer [8].[3] The trajectory model of a system consists of the set of all *trajectories* or *refusal-traces*—finite sequences of the type $\Sigma_0(\sigma_1, \Sigma_1)\cdots(\sigma_k, \Sigma_k)$, where $\sigma_1 \cdots \sigma_k$ is the trace executed by the system, while

[2] If applied to so-called *improper* processes, the parallel operator defined by Inan [12] can be viewed as a generalized form of PSC, but only in the deterministic setting. However, when supervisory control is considered in this reference, the assumption is made that the plant is proper and has a constant event control set. This assumption excludes driven events.

[3] The trajectory model is similar to the *failure-trace model* (also called the refusal-testing model) of Phillips [20], but differs from this model in its treatment of silent transitions (transitions labeled with ϵ). The trajectory model treats silent transitions in a way that is consistent with the failures model. While more detailed than the failures model, the failure-trace model is less detailed than the ready-trace model [21], [1], and hence less detailed than the bisimulation model [19], [18]. Comparison of various semantics for nondeterministic systems can be found in [27], [2].

$\Sigma_j \subseteq \Sigma$ $(j = 0, \dots, k)$ is a refusal set, a set of events which can result in deadlock if presented to the system by the environment at the indicated point in the refusal-trace. Thus, a trajectory model is a subset of $2^{\Sigma} \times (\Sigma \times 2^{\Sigma})^*$ and refines the failures model by including the intermediate refusal sets.

Although we use the trajectory model for describing the behavior of a nondeterministic plant, it is assumed that the desired specification is given only in terms of a language model (as in [23]), and not in terms of a trajectory model. This is a reasonable assumption, for in most applications, we are only interested in the sequences of events that a system can execute, and not in the events that the system may "refuse" to execute after execution of a certain event in a certain event sequence. Hence we address the following supervisory control problem:

> Given (i) a partition $\Sigma = \Sigma_c \cup \Sigma_u \cup \Sigma_d$ of the event set into subsets of controllable, uncontrollable, and driven events, (ii) a nondeterministic plant with trajectory model $P \subseteq 2^{\Sigma} \times (\Sigma \times 2^{\Sigma})^*$ whose priority set is $A = \Sigma_c \cup \Sigma_u$, and (iii) a (prefix-closed) target language $K \subseteq \Sigma^*$, design a supervisor—another trajectory model, denoted $S \subseteq 2^{\Sigma} \times (\Sigma \times 2^{\Sigma})^*$—whose priority set is $B = \Sigma_c \cup \Sigma_d$ such that the language of the PSC of P and S equals K.

The interconnection of the plant and the supervisor by PSC results in the disabling of some of the controllable events and the forcing of some of the driven events, while never preventing any of the uncontrollable events from occurring in the plant. Thus we investigate the supervisory control of DEDSs in the general setting of trajectory models and PSC, as opposed to language models and SSC studied by Kumar, Garg, and Marcus [14].

We obtain a necessary and sufficient condition for the existence of a supervisor for the general problem with driven events, and also provide a technique for synthesizing a supervisor. For ease of implementation, we design supervisors which are deterministic. We also address the control problem when some of the uncontrollable events are not observed by the supervisor. While the primary goal of this paper is to obtain necessary and sufficient conditions for the control of nondeterministic systems with driven events, a secondary goal is to provide a rigorous mathematical foundation for the theory of trajectory models and PSC.

The organization of this paper is as follows. In §2, an example is presented that motivates the design techniques to be developed in the remainder of the paper. In §3, the trajectory model of a nondeterministic state machine (NSM) with ϵ-moves is defined and its properties derived from those of NSMs. An algorithm for constructing a canonical NSM from a given trajectory model is presented and its correctness is proven. In §4, the PSC of NSMs is defined, and it is shown that this induces a PSC operation on trajectory models. It is also proven that the trajectory modeling framework is a language congruence relative to PSC. Properties of the PSC of trajectory models are described in §5, and the technique of *augmentation* is introduced. In §6, the supervisory control problem with driven events under both complete and partial observation is solved, and the results are applied to obtain a control design for the example system from §2.

An abbreviated version of this paper appeared in [25]. Extensions of many of the results to include nonclosed specifications and marking can be found in [15].

2. Motivating example.

In this section, we describe an example that motivates the results described in this paper. Figure 1(a) gives a deterministic model for a plant that processes a single type of part. Event α represents inputting a part. Event

β_1 represents successful completion and outputting of the part. Event β_2 represents completion and outputting of the part, but accompanied by an undetectable misalignment of an internal mechanism. If this has occurred, another part may be input, but this event α can be followed by an event λ that represents jamming of the machine. When this occurs, further processing is impossible. The event μ represents realignment of the misaligned internal mechanism. Since the misalignment of the internal mechanism is undetectable, the observation mask $M(\cdot)$ identifies the events β_1 and β_2, i.e., $M(\beta_1) = M(\beta_2) := \beta$. It is assumed that α is controllable and that $\beta_1, \beta_2, \lambda$ are uncontrollable. A natural performance specification is that λ should never occur and that the closed-loop generated language should include $(\alpha(\beta_1 + \beta_2\mu))^*$, i.e., cyclic operation should be possible.

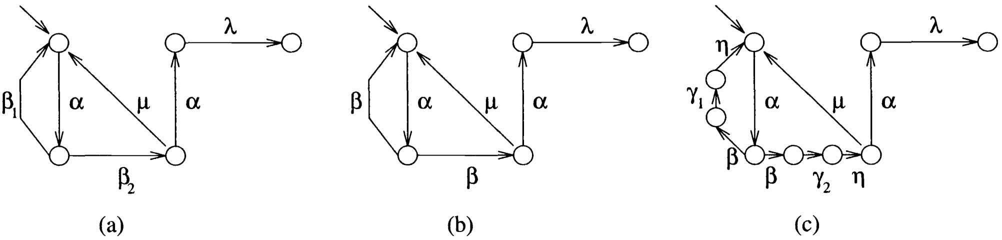

FIG. 1. *Diagram illustrating example of* §2.

Let us regard μ as a controllable event and consider whether the specifications can be met by a supervisor S of the Ramadge–Wonham type that is consistent with the observation mask. Since λ is uncontrollable, such a supervisor would need to disable α following any occurrence of β_2. Since the mask identifies β_1 and β_2, the supervisor must also disable α following β_1. Consequently, the generated closed-loop language imposed by any such supervisor is contained in $pr((\alpha\beta_2\mu)^*\alpha\beta_1)$ and thus fails to meet the lower-bound specification. ($pr(\cdot)$ denotes the prefix-closure operation.)

The design problem is also unsolvable using a forcing supervisor of the type considered by Golaszewski and Ramadge [6]. If such a supervisor forces μ following β_2, it must also force μ following β_1. Since the plant cannot execute μ after β_1, the controlled system would deadlock after the first occurrence of β_1. Thus, the lower-bound specification is not satisfied.

We could transform the partially observed deterministic system by identifying the events β_1, β_2 in the plant model and representing both of these events by their common mask value β. This yields the completely observed nondeterministic model depicted in Fig. 1(b). However, this results in a loss of information. In the first model, β_1, β_2 are indistinguishable only from the viewpoint of observation, while in the second model, they are indistinguishable for specification and control, as well as for observation. Since β_1, β_2 are uncontrollable, it is irrelevant whether they are distinguishable for the purpose of control. However, to be able to translate the original lower-bound specification into a corresponding specification on the transformed system, it is important that the events remain distinguishable from the viewpoint of specification. This can be accomplished by replacing β_1, β_2 by the three-event sequences $\beta\gamma_1\eta$, $\beta\gamma_2\eta$, respectively, where γ_1, γ_2 are completely unobservable, i.e., have mask value ϵ. If $M'(\cdot)$ denotes the mask for the transformed system, then $M'(\beta\gamma_1\eta) = M'(\beta)M'(\eta) = M'(\beta\gamma_2\eta)$. Thus, the substitution preserves the modeling assumption that the events β_1, β_2 have the same mask value. On the other hand, since γ_1, γ_2 are distinct event labels, the distinguishability of β_1, β_2 for the purpose of specification is also preserved. To model the uncontrollability of β_1, β_2, we designate β, γ_1, γ_2, η to be uncontrollable events. The "sandwiching" of the unobservable event γ_i between the observable events β, η reflects the fact that in the original model, the occurrence of β_i is known to the supervisor even though the supervisor cannot determine which of β_1, β_2 has occurred. With the new model, the supervisor knows that neither of the pair γ_1, γ_2 has occurred if β has not been observed. Similarly, it knows that one of the pair has occurred if η has been observed.

The substituted events can also be given a physical interpretation. β represents commenced processing of a part with or without internal undetectable misalignment. γ_1 and γ_2 represent the registering of faultless processing and of faulty processing, respectively. These are internal events that are modeled but whose occurrence is unobservable to an external process such as a supervisor. η represents the completion of processing and outputting of the part.

The transformed system is shown in Fig. 1(c). It is a partially observed nondeterministic system in which the mask is a natural projection and the unobservable events are uncontrollable. We will treat μ as a driven event rather than a controllable event as would be done in the Ramadge–Wonham theory. In the context of PSC-based control design, this allows for the possibility that the plant may refuse a request from the supervisor to execute this event. Using the results of §6, we will construct a PSC-based supervisor that meets the control specifications. (See Example 5.) The flexibility obtained by permitting the plant to refuse a supervisor-initiated event is an essential feature of the successful control design.

3. Trajectory model.

A plant, or a DEDS to be controlled, is modeled as an NSM with ϵ-moves. Letting $\mathcal{P}$ denote an NSM, it is defined to be the four tuple [10]: $\mathcal{P} := (X_{\mathcal{P}}, \Sigma, \delta_{\mathcal{P}}, x^0_{\mathcal{P}})$, where $X_{\mathcal{P}}$ denotes the state space of $\mathcal{P}$, Σ denotes the event set of $\mathcal{P}$, $\delta_{\mathcal{P}} : X_P \times \Sigma \cup \{\epsilon\} \to 2^{X_{\mathcal{P}}}$ denotes the nondeterministic[4] transition function of $\mathcal{P}$, and $x^0_{\mathcal{P}} \in X_{\mathcal{P}}$ denotes the initial state of $\mathcal{P}$. A triple $(x_1, \sigma, x_2) \in X_{\mathcal{P}} \times (\Sigma \cup \{\epsilon\}) \times X_{\mathcal{P}}$ is called a transition in $\mathcal{P}$ if $x_2 \in \delta_{\mathcal{P}}(x_1, \sigma)$. A transition (x_1, ϵ, x_2) is referred to as a *silent* transition. We assume that the plant NSM is finitely branching and cannot undergo an unbounded sequence of silent transitions.

3.1. Language model of a nondeterministic state machine.

As mentioned in §1, although trajectory models are used for describing the behaviors of nondeterministic systems, language or trace models are used for describing the desired or target specifications. Hence in this section we define the language model of an NSM $\mathcal{P}$. We first define the ϵ-closure of a state, which is the set of states reached by executing a finite sequence of silent transitions.

DEFINITION 1. *The* ϵ-closure *map,* $\epsilon^*_{\mathcal{P}} : X_{\mathcal{P}} \to 2^{X_{\mathcal{P}}}$, *is recursively defined to be*:

- $\forall x \in X_{\mathcal{P}} : \begin{cases} x \in \epsilon^*_{\mathcal{P}}(x), \\ x' \in \epsilon^*_{\mathcal{P}}(x) \Rightarrow \delta_{\mathcal{P}}(x', \epsilon) \subseteq \epsilon^*_{\mathcal{P}}(x). \end{cases}$

Using the definition of ϵ-closure, we extend the definition of the transition function from events to traces as follows.

DEFINITION 2. *The extension of the transition function to traces, denoted* $\delta^*_{\mathcal{P}} : X_{\mathcal{P}} \times \Sigma^* \to 2^{X_{\mathcal{P}}}$, *is defined inductively on the length of the traces as*:

- $\forall x \in X_{\mathcal{P}} : \begin{cases} \delta^*_{\mathcal{P}}(x, \epsilon) := \epsilon^*_{\mathcal{P}}(x), \\ \forall s \in \Sigma^*, \sigma \in \Sigma : \delta^*_{\mathcal{P}}(x, s\sigma) := \epsilon^*_{\mathcal{P}}(\delta_{\mathcal{P}}(\delta^*_{\mathcal{P}}(x, s), \sigma)), \end{cases}$

[4] The transition function $\delta_{\mathcal{P}}(\cdot, \cdot)$ is deterministic if and only if it is of the type $\delta_{\mathcal{P}} : X_{\mathcal{P}} \times \Sigma \to X_{\mathcal{P}}$, in which (i) there are no transitions labeled ϵ, and (ii) given a state and an event, either a unique state is reached upon execution of that event in that state, or that event is undefined in that state.

where in the last equality, the transition map is extended to $\delta_{\mathcal{P}} : 2^{X_{\mathcal{P}}} \times \Sigma \cup \{\epsilon\} \rightarrow 2^{X_{\mathcal{P}}}$, and the ϵ-closure map is extended to $\epsilon^*_{\mathcal{P}} : 2^{X_{\mathcal{P}}} \rightarrow 2^{X_{\mathcal{P}}}$ in the natural way. The set of states reached by executing a trace $s \in \Sigma^*$ from a state $x \in X_{\mathcal{P}}$ is given by the set $\delta^*_{\mathcal{P}}(x, s)$. It is clear that if $\mathcal{P}$ is deterministic, then the extension of the transition function to traces is also a deterministic partial map $\delta^*_{\mathcal{P}} : X_{\mathcal{P}} \times \Sigma^* \rightarrow X_{\mathcal{P}}$. (It is a partial map since it is generally defined only on a subset of $X_{\mathcal{P}} \times \Sigma^*$.)

The preceding definition can be used to obtain the language or trace model for the plant $\mathcal{P}$, denoted $L(\mathcal{P}) \subseteq \Sigma^*$, as follows:

- $L(\mathcal{P}) := \{s \in \Sigma^* \mid \delta^*_{\mathcal{P}}(x^0_{\mathcal{P}}, s) \neq \emptyset\}$.

3.2. Trajectory model of a nondeterministic state machine. As discussed in §1, language models are not adequate for characterizing the behavior of nondeterministic systems. Hence, we next define the trajectory model for an NSM $\mathcal{P}$. We first need to define the refusal map, and extend the transition function from events to refusal-traces.

DEFINITION 3. *The* refusal *map, $\Re_{\mathcal{P}} : X_{\mathcal{P}} \rightarrow 2^{\Sigma}$, is defined as*:

- $\forall x \in X_{\mathcal{P}} : \Re_{\mathcal{P}}(x) := \{\sigma \in \Sigma \mid \delta_{\mathcal{P}}(x', \sigma) = \emptyset, \forall x' \in \epsilon^*_{\mathcal{P}}(x)\}$.

Thus the refusal map defines, at each state, a set of events such that the system "refuses" to execute any of the events belonging to that set at that state. An event $\sigma \in \Sigma$ belongs to the refusal set of a state $x \in X_{\mathcal{P}}$ if and only if it is undefined at each state belonging to the ϵ-closure of x. Figure 2 depicts several NSMs defined over the event set $\{a, b\}$; each of the states is labeled with its refusal event set.

DEFINITION 4. *The extension of the transition function to refusal-traces, denoted $\delta^T_{\mathcal{P}} : X_{\mathcal{P}} \times (2^{\Sigma} \times (\Sigma \times 2^{\Sigma})^*) \rightarrow 2^{X_{\mathcal{P}}}$, is defined inductively on the length of the refusal-traces as*:

$$\bullet\ \forall x \in X_{\mathcal{P}} : \begin{cases} \forall \Sigma' \subseteq \Sigma : \delta^T_{\mathcal{P}}(x, \Sigma') := \{x' \in \epsilon^*_{\mathcal{P}}(x) \mid \Sigma' \subseteq \Re_{\mathcal{P}}(x')\}, \\ \forall e \in 2^{\Sigma} \times (\Sigma \times 2^{\Sigma})^*, \sigma \in \Sigma, \Sigma' \subseteq \Sigma : \\ \delta^T_{\mathcal{P}}(x, e(\sigma, \Sigma')) := \{x' \in \epsilon^*_{\mathcal{P}}(\delta_{\mathcal{P}}(\delta^T_{\mathcal{P}}(x, e), \sigma)) \mid \Sigma' \subseteq \Re_{\mathcal{P}}(x')\}. \end{cases}$$

A state $x' \in X_{\mathcal{P}}$ is reached by executing a "zero-length" refusal-trace $\Sigma' \subseteq \Sigma$ from a state $x \in X_{\mathcal{P}}$ if (i) x' belongs to the ϵ-closure of x, and (ii) the refusal set of x' contains Σ'. A state $x' \in X_{\mathcal{P}}$ is reached by executing a refusal-trace $e(\sigma, \Sigma') \in 2^{\Sigma} \times (\Sigma \times 2^{\Sigma})^*$ from a state $x \in X_{\mathcal{P}}$ if (i) x' belongs to the ϵ-closure of a state reached by executing the event σ from a state reached after executing the refusal-trace e from x, and (ii) the refusal set of x' contains Σ'. It is clear that if $\mathcal{P}$ is deterministic, then the extension of the transition function to refusal-traces is also a deterministic partial map $\delta^T_{\mathcal{P}} : X_{\mathcal{P}} \times (2^{\Sigma} \times (\Sigma \times 2^{\Sigma})^*) \rightarrow X_{\mathcal{P}}$. Based on the above extension of the transition function from events to refusal-traces, we define the trajectory model of the plant $\mathcal{P}$, which we denote as $T(\mathcal{P})$:

- $T(\mathcal{P}) := \{e \in 2^{\Sigma} \times (\Sigma \times 2^{\Sigma})^* \mid \delta^T_{\mathcal{P}}(x^0_{\mathcal{P}}, e) \neq \emptyset\}$.

We refer to the elements of this set as the *refusal-traces* or *trajectories* of $\mathcal{P}$.

Remark 1. There is a subtle but important difference in the meaning of the refusal sets in a trajectory model as opposed to those in an NSM. In the NSM, $\Re_{\mathcal{P}}(x)$ represents events that *must* be refused at the state x if offered by the environment. In contrast, the refusal set $\Sigma_i(e)$ in the refusal-trace e represents a set of events which *can* be refused if offered by the environment following execution of the previous fragment of the refusal-trace. The reason for this is that the *refusal-trace fragment* does not uniquely determine the state of the NSM due to nondeterminism. (Refer to Algorithm 1.)

Let $e = \Sigma_0(e)(\sigma_1(e), \Sigma_1(e)) \cdots (\sigma_n(e), \Sigma_n(e)) \in 2^{\Sigma} \times (\Sigma \times 2^{\Sigma})^*$ be a refusal-trace, where $n \in \mathcal{N}$, $\Sigma_i(e) \subseteq \Sigma$ and $\sigma_i(e) \in \Sigma$ for each $i \leq n$. We call n the length of e, and denote it as $|e| = n$. $\Sigma_i(e)$ is called the ith refusal set of e, and $\sigma_i(e)$ the ith event of e. For each $i \leq |e|$, we use e^i to denote the prefix of length i of e, i.e., $e^i := \Sigma_0(e) \cdots (\sigma_i(e), \Sigma_i(e))$. The notation $pr(e) \subseteq 2^\Sigma \times (\Sigma \times 2^\Sigma)^*$ is used to denote the set of all prefixes of e. Let $e, f \in 2^\Sigma \times (\Sigma \times 2^\Sigma)^*$ be refusal-traces. If f is a prefix of e, we indicate this by the notation $f \leq e$. We say that f is *dominated* by e, denoted $f \sqsubseteq e$, if $|f| = |e| := n$, $\sigma_i(f) = \sigma_i(e)$, and $\Sigma_i(f) \subseteq \Sigma_i(e)$ for each $i \leq n$. The notation $\text{dom}(e) \subseteq 2^\Sigma \times (\Sigma \times 2^\Sigma)^*$ is used to denote the set of all refusal-traces dominated by e.

Example 1. Consider a system $\mathcal{P}$ that deadlocks, i.e., cannot execute any transition, at its initial state. Then $T(\mathcal{P}) = \{\Sigma' \mid \Sigma' \subseteq \Sigma\}$, i.e., the trajectory model of $\mathcal{P}$ consists of all zero-length refusal-traces. We use $\Delta_\Sigma := \{\Sigma' \mid \Sigma' \subseteq \Sigma\}$ to denote the trajectory model of the *deadlock* system. Given $\sigma \in \Sigma$ and a trajectory model $P \subseteq 2^\Sigma \times (\Sigma \times 2^\Sigma)^*$, we use $\sigma \rightarrow P$ to denote the system that first executes the event σ and then follows with a refusal-trace in P. In other words, $\sigma \rightarrow P := pr\{\Sigma'(\sigma, e) \mid \Sigma' \subseteq \Sigma - \{\sigma\}, e \in P\}$. $\sigma \rightarrow P$ is called the *σ-prefix* operation on the trajectory model P. Given trajectory models $P_1, P_2 \subseteq 2^\Sigma \times (\Sigma \times 2^\Sigma)^*$, and $\sigma_1, \sigma_2 \in \Sigma$ with $\sigma_1 \neq \sigma_2$, the *external choice* between the trajectory models $\sigma_1 \rightarrow P_1$ and $\sigma_2 \rightarrow P_2$, denoted $(\sigma_1 \rightarrow P_1) + (\sigma_2 \rightarrow P_2)$, is defined to be the trajectory model:

$$(\sigma_1 \rightarrow P_1) + (\sigma_2 \rightarrow P_2) := \{e \in (\sigma_1 \rightarrow P_1) \cup (\sigma_2 \rightarrow P_2) \mid e^0 \in (\sigma_1 \rightarrow P_1) \cap (\sigma_2 \rightarrow P_2)\}.$$

This is a system which initially makes a deterministic choice between σ_1 and σ_2. If σ_i is executed, then the remainder of the refusal-trace is in P_i. The notation $P_1 \oplus P_2$ denotes the system that nondeterministically chooses to execute refusal-traces either in P_1 or in P_2. $P_1 \oplus P_2$ is called the *internal choice* between P_1 and P_2, and $P_1 \oplus P_2 := P_1 \cup P_2$.

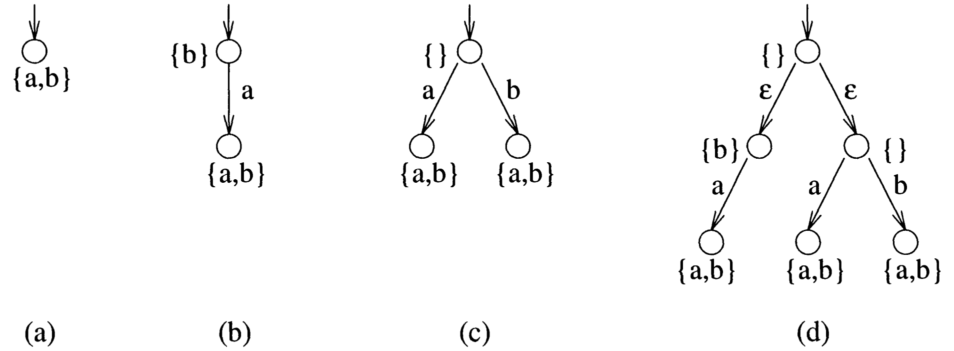

FIG. 2. *Diagram illustrating Example* 1.

Figures 2(a)–(d) depict NSMs defined over the event set $\{a, b\}$; each of the states is labeled with the set of events that are refused at that state. Figure 2(a) depicts an NSM that deadlocks. Hence its trajectory model is $\Delta_{\{a,b\}}$. Figure 2(b) depicts an NSM that initially executes the event a and then deadlocks. Hence its trajectory model is $a \rightarrow \Delta_{\{a,b\}}$. Figure 2(c) depicts an NSM that initially makes a deterministic choice between the events a and b and deadlocks after executing either of the events. Hence its trajectory model is given by $(a \rightarrow \Delta_{\{a,b\}}) + (b \rightarrow \Delta_{\{a,b\}})$. Figure 2(d) depicts an NSM that initially makes a nondeterministic choice between the systems of Figs. 2(b) and (c). Hence its trajectory model is $(a \rightarrow \Delta_{\{a,b\}}) \oplus [(a \rightarrow \Delta_{\{a,b\}}) + (b \rightarrow \Delta_{\{a,b\}})]$.

It follows from the definition of the trajectory model $T(\mathcal{P})$ that it satisfies the following five properties, denoted (T1), (T2), (T3), (T4), and (T5).

PROPOSITION 1. *The trajectory model $T(\mathcal{P})$ of an NSM $\mathcal{P}$ satisfies the following properties:*

(T1) (*nonemptiness*): $\emptyset \in T(\mathcal{P}) \Rightarrow T(\mathcal{P}) \neq \emptyset$;

(T2) (*prefix closure*): $\forall e \in T(\mathcal{P}), f \in 2^\Sigma \times (\Sigma \times 2^\Sigma)^* : f < e \Rightarrow f \in T(\mathcal{P})$;

(T3) (*dominance closure*): $\forall e \in T(\mathcal{P}), f \in 2^\Sigma \times (\Sigma \times 2^\Sigma)^* : f \sqsubset e \Rightarrow f \in T(\mathcal{P})$;

(T4) (*refusal of infeasible*): $\forall e \in T(\mathcal{P}), i \leq |e|, \sigma \in \Sigma : e^i(\sigma, \emptyset) \notin T(\mathcal{P}) \Rightarrow e^{i-1}(\sigma_i(e), \Sigma_i(e) \cup \{\sigma\}) \dots (\sigma_{|e|}, \Sigma_{|e|}) \in T(\mathcal{P})$;

(T5) (*persistence of refused*): $\forall e \in T(\mathcal{P}), i \leq |e|, \sigma \in \Sigma : \sigma \in \Sigma_i(e) \Rightarrow \sigma_{i+1}(e) \neq \sigma$.

Proof. (T1), (T2), and (T5) follow immediately from the definition of the trajectory model. To prove (T3), we note that a straightforward induction on length of refusal-traces shows that if $f \sqsubset e$, then $\delta^T_{\mathcal{P}}(x^0_{\mathcal{P}}, e) \subseteq \delta^T_{\mathcal{P}}(x^0_{\mathcal{P}}, f)$, which immediately yields (T3). It remains to prove (T4). Fix i, and suppose that $e^i(\sigma, \emptyset) \notin T(\mathcal{P})$. Then $\delta_{\mathcal{P}}(\delta^T_{\mathcal{P}}(x^0_{\mathcal{P}}, e^i), \sigma) = \emptyset$. Since $\epsilon^*_{\mathcal{P}}(\delta^T_{\mathcal{P}}(x^0_{\mathcal{P}}, e^i)) = \delta^T_{\mathcal{P}}(x^0_{\mathcal{P}}, e^i)$, this implies that $\sigma \in \Re_{\mathcal{P}}(x)$ for all $x \in \delta^T_{\mathcal{P}}(x^0_{\mathcal{P}}, e^i)$. It follows immediately that if $\bar{e}$ is obtained from e by replacing $\Sigma_i(e)$ with $\Sigma_i(e) \cup \{\sigma\}$, then $\delta^T_{\mathcal{P}}(x^0_{\mathcal{P}}, \bar{e}) = \delta^T_{\mathcal{P}}(x^0_{\mathcal{P}}, e)$, which implies that $\bar{e} \in T(\mathcal{P})$. □

Remark 2. In contrast to [8] where the properties of the trajectory model are defined axiomatically, we regard the NSM as the fundamental object and *derive* the properties of the trajectory model from the properties of NSMs.

3.3. Construction of canonical nondeterministic state machine. In this section we develop an algorithm for constructing a canonical nondeterministic state machine for any given set of refusal-traces satisfying (T1)–(T5).

DEFINITION 5. *Let $P \subseteq 2^\Sigma \times (\Sigma \times 2^\Sigma)^*$ be a refusal-trace set satisfying* (T1)–(T5). *If $e \in P$ is any refusal-trace which has the property that for each $i \leq |e|$, $\sigma \in \Sigma_i(e)$ whenever $e^i(\sigma, \emptyset) \notin P$, then we say that e is* saturated. *The* saturated trajectory model, *denoted P_{sat}, of P is defined to be*: $P_{\text{sat}} := \{e \in P \mid e$ *is saturated*$\}$.

It is easy to see that a prefix of a saturated refusal-trace is also saturated, and each refusal-trace of P is dominated by a saturated refusal-trace of P, so $\text{dom}(P_{\text{sat}}) = P$. Thus P_{sat} is equivalent in detail of description to P. So, we use the set of saturated refusal-traces for the construction of the canonical nondeterministic state machine. Given a finite number of event sets $\Sigma_1, \dots, \Sigma_n \subseteq \Sigma$ for some $n \in \mathcal{N}$, we use the notation $\min(\Sigma_1, \dots, \Sigma_n)$ to denote the collection of minimal sets from among the given n sets, i.e.,

- $\min(\Sigma_1, \dots, \Sigma_n) := \{\Sigma_i, 1 \leq i \leq n \mid \nexists j$ such that $1 \leq j \leq n; j \neq i; \Sigma_j \subset \Sigma_i\}$.

LEMMA 1. *Let $P \subseteq 2^\Sigma \times (\Sigma \times 2^\Sigma)^*$ satisfy* (T1)–(T5).

1. *P_{sat} contains a unique minimal zero-length refusal-trace $\Sigma^0_{\min} := \{\sigma' \in \Sigma \mid \sigma' \notin L(P)\}$.*
2. *If $e \in P_{\text{sat}}$ and $e(\sigma, \emptyset) \in P$, then the family $\{\Sigma' \subseteq \Sigma \mid e(\sigma, \Sigma') \in P_{\text{sat}}\}$ has a unique minimal element given by $\Sigma^{(e,\sigma)}_{\min} := \{\sigma' \in \Sigma \mid e(\sigma, \emptyset)(\sigma', \emptyset) \notin P\}$.*

Proof. The proof of the first part is similar to that of the second part, so we include only the latter. Since $e(\sigma, \emptyset) \in P$, repeated application of (T4) yields $e(\sigma, \Sigma^{(e,\sigma)}_{\min}) \in P$. Since e is saturated, in order to show that $e(\sigma, \Sigma^{(e,\sigma)}_{\min})$ is saturated, it suffices to show that if $e(\sigma, \Sigma^{(e,\sigma)}_{\min})(\sigma', \emptyset) \notin P$, then $\sigma' \in \Sigma^{(e,\sigma)}_{\min}$. Suppose $\sigma' \notin \Sigma^{(e,\sigma)}_{\min}$. Then $e(\sigma, \emptyset)(\sigma', \emptyset) \in P$. By repeated application of T4, it follows that $e(\sigma, \Sigma^{(e,\sigma)}_{\min})(\sigma', \emptyset) \in P$, which is a contradiction. Thus, $e(\sigma, \Sigma^{(e,\sigma)}_{\min}) \in P_{\text{sat}}$.

Finally, suppose $e(\sigma, \Sigma') \in P_{\rm sat}$ and $\sigma' \in \Sigma_{\min}^{(e,\sigma)}$, i.e., $e(\sigma, \emptyset)(\sigma', \emptyset) \notin P$. By (T3), it follows that $e(\sigma, \Sigma')(\sigma', \emptyset) \notin P$. Since $e(\sigma, \Sigma')$ is saturated, $\sigma' \in \Sigma'$, so $\Sigma_{\min}^{(e,\sigma)} \subseteq \Sigma'$. □

ALGORITHM 1. *Given* $P \subseteq 2^\Sigma \times (\Sigma \times 2^\Sigma)^*$ *satisfying* (T1)–(T5), *construct a nondeterministic state machine (with* ϵ*-moves)* $\mathcal{P} := (X_\mathcal{P}, \Sigma, \delta_\mathcal{P}, x_\mathcal{P}^0)$, *where*

- $X_\mathcal{P} := P_{\rm sat}$ *is the state space of* $\mathcal{P}$,
- $x_\mathcal{P}^0 := \Sigma_{\min}^0$ *is the initial state of* $\mathcal{P}$,
- $\delta_\mathcal{P} : X_\mathcal{P} \times \Sigma \cup \{\epsilon\} \to 2^{X_\mathcal{P}}$ *is the transition function of* $\mathcal{P}$ *defined as:*

(1) $\forall e \in P_{\rm sat}$, $\sigma \in \Sigma$:

$$\delta_\mathcal{P}(e, \sigma) := \begin{cases} e(\sigma, \Sigma_{\min}^{(e,\sigma)}) & \text{if } e(\sigma, \emptyset) \in P \\ \emptyset & \text{otherwise,} \end{cases}$$

(2(a)) $\forall \Sigma' \subseteq \Sigma$ *such that* $\Sigma' \in P_{\rm sat}$:

$$\delta_\mathcal{P}(\Sigma', \epsilon) := \min(\{\Sigma'' \subseteq \Sigma | \; \Sigma'' \in P_{\rm sat}, \; \Sigma' \subset \Sigma''\}),$$

(2(b)) $\forall e \in 2^\Sigma \times (\Sigma \times 2^\Sigma)^*, \sigma \in \Sigma, \Sigma' \subseteq \Sigma$ *such that* $e(\sigma, \Sigma') \in P_{\rm sat}$:

$$\delta_\mathcal{P}(e(\sigma, \Sigma'), \epsilon) := \{e(\sigma, \Sigma'') \,|\, \Sigma'' \in \min(\{\hat\Sigma \subseteq \Sigma \,|\, e(\sigma, \hat\Sigma) \in P_{\rm sat}, \Sigma' \subset \hat\Sigma\})\}.$$

Algorithm 1 provides a procedure for constructing a canonical NSM $\mathcal{P}$ for a given set of refusal-traces P satisfying (T1)–(T5). The state space of $\mathcal{P}$ equals $P_{\rm sat}$, the set of saturated refusal-traces of P, and the initial state of $\mathcal{P}$ is the minimal zero-length saturated refusal-trace $\Sigma_{\min}^0$ of P. The state reached by executing a nonepsilon event $\sigma \in \Sigma$ from a state $e \in P_{\rm sat}$ equals the minimal saturated refusal-trace of the type $e(\sigma, \Sigma')$ dominating $e(\sigma, \emptyset)$. The set of states reached by executing an epsilon transition from a zero-length refusal-trace $\Sigma' \in P_{\rm sat} = X_\mathcal{P}$ equals the minimal elements of the set of zero-length saturated refusal-traces dominating Σ'. Also, the set of states reached by executing an epsilon transition from a refusal-trace $e(\sigma, \Sigma') \in P_{\rm sat} = X_\mathcal{P}$ equals the set of saturated refusal-traces of the type $e(\sigma, \Sigma'')$ dominating $e(\sigma, \Sigma')$ with Σ'' minimal. Note that the canonical NSM constructed using Algorithm 1 has as many states as the number of saturated refusal-traces.

Remark 3. A construction which bears some similarity to Algorithm 1 was informally described in [8, Alg. 12.1]. However, a proof showing that the trajectory model of the canonical NSM equals P was omitted in that reference. There is also an important difference between the two algorithms. The construction in [8, Alg. 12.1] is based on prefixes of dominant refusal-traces, i.e., refusal-traces which are maximal with respect to $\sqsubseteq$ partial order. In contrast, Algorithm 1 is based on saturated refusal-traces. The use of saturated refusal-traces for the states has the advantage of avoiding the need to introduce certain "auxiliary states," which is the case when prefixes of dominant refusal-traces are used. This advantage arises because the saturated refusal-traces satisfy the properties described in Lemma 1.

Example 2. The trajectory model of the NSM shown in Fig. 2(d) is $P := pr(\mathrm{dom}(P'))$, where $P' := \{\{b\}(a, \{a, b\}), \; \emptyset(b, \{a, b\})\}$. Since P is obtained as the trajectory model of an NSM, it follows from Proposition 1 that P satisfies (T1)–(T5). Consequently, Algorithm 1 may be applied to obtain the canonical NSM $\mathcal{P}$ with trajectory model P. The state space of $\mathcal{P}$ is the set of saturated refusal-traces

$$P_{\rm sat} = pr(\{\emptyset(a, \{a, b\}), \; \{b\}(a, \{a, b\}), \; \emptyset(b, \{a, b\})\}),$$

which contains five elements. The canonical NSM $\mathcal{P}$ with these five states is depicted in Fig. 3(a). Each node is labeled with the name of the state—a saturated refusal-trace—that it represents. The NSM depicted in Fig. 3(b) with four states also has the same trajectory model.

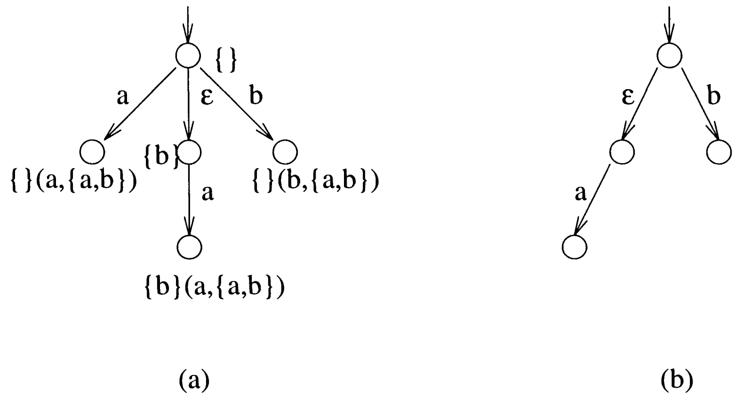

FIG. 3. *Diagram illustrating Example* 2.

The equality of the *failures* models of the two NSMs shown in Figs. 3(a) and (b) and the NSM shown in Fig. 2(d) is an instance of a basic property of the failures model concerning the operations of external choice and event concealment [9, Law L10, p. 113]. Since the three NSMs have identical trajectory models, the additional detail present in the trajectory model still does not distinguish among the three systems. However, the failure-trace model of Phillips does distinguish between the systems analogous to those in Figs. 2(d) and 3(b) with τ in place of ϵ [20, Ex. 3, p. 250].

We now prove the correctness of Algorithm 1, i.e., that the trajectory model of the canonical NSM $\mathcal{P}$ equals P.

PROPOSITION 2. *Let* $P \subseteq 2^\Sigma \times (\Sigma \times 2^\Sigma)^*$ *satisfy* (T1)–(T5). *Then* $T(\mathcal{P}) = P$, *where* $\mathcal{P}$ *is as constructed in Algorithm* 1.

Proof. We begin by showing that

$$(1) \qquad \forall\, e = \bar{e}(\sigma, \Sigma') \in P_{\text{sat}}, \quad \Re_{\mathcal{P}}(e) = \Sigma'.$$

It follows from the definition of $\delta_{\mathcal{P}}$ that $\sigma' \in \Re_{\mathcal{P}}(e)$ if and only if for each $f = \bar{e}(\sigma, \Sigma'') \in P_{\text{sat}}$ such that $\Sigma' \subseteq \Sigma''$, $f(\sigma', \emptyset) \notin P$. If $\sigma' \in \Sigma'$, then $\sigma' \in \Sigma''$ for all such Σ''. By T5, $f(\sigma', \emptyset) \notin P$, so $\sigma' \in \Re_{\mathcal{P}}(e)$. Thus, $\Sigma' \subseteq \Re_{\mathcal{P}}(e)$. On the other hand, if $\sigma' \notin \Sigma'$, then since $e \in P_{\text{sat}}$, it follows that $e(\sigma', \emptyset) \in P$, so $\sigma' \notin \Re_{\mathcal{P}}(e)$. Thus, $\Re_{\mathcal{P}}(e) \subseteq \Sigma'$, proving (1).

Next, we claim that

$$(2) \qquad \delta^T_{\mathcal{P}}(x^0_{\mathcal{P}}, e) = \{f \in P_{\text{sat}} \mid e \sqsubseteq f\} \quad \forall\, e \in 2^\Sigma \times (\Sigma \times 2^\Sigma)^*.$$

We prove (2) by induction on $|e|$. Let $e = \Sigma' \subseteq \Sigma$, a zero-length refusal-trace. Using the definition of $\delta_{\mathcal{P}}$ and (1) gives $\delta^T_{\mathcal{P}}(x^0_{\mathcal{P}}, \Sigma') = \{\Sigma'' \in \epsilon^*_{\mathcal{P}}(x^0_{\mathcal{P}}) \mid \Sigma' \subseteq \Re_{\mathcal{P}}(\Sigma'')\} = \{\Sigma'' \in P_{\text{sat}} \mid \Sigma' \subseteq \Sigma''\}$. This establishes (2) in the zero-length case.

For the induction step, let $e = \bar{e}(\sigma, \Sigma') \in 2^\Sigma \times (\Sigma \times 2^\Sigma)^*$. Using the induction hypothesis on $\bar{e}$, (1), and the fact that P_{sat} is prefix-closed gives

$$\delta^T_{\mathcal{P}}(x^0_{\mathcal{P}}, e) = \{f \in \epsilon^*_{\mathcal{P}}(\delta_{\mathcal{P}}(\delta^T_{\mathcal{P}}(x^0_{\mathcal{P}}, \bar{e}), \sigma)) \mid \Sigma' \subseteq \Re_{\mathcal{P}}(f)\}$$

$$\begin{aligned}
&= \{f \in \epsilon^*_{\mathcal{P}}(\delta_{\mathcal{P}}(\{\bar{f} \in P_{\text{sat}} |\, \bar{e} \sqsubseteq \bar{f}\}, \sigma)) |\, \Sigma' \subseteq \Re_{\mathcal{P}}(f)\} \\
&= \{\bar{f}(\sigma, \Sigma'') \in P_{\text{sat}} |\, \bar{e} \sqsubseteq \bar{f},\ \Sigma' \subseteq \Sigma''\} \\
&= \{f \in P_{\text{sat}} |\, e \sqsubseteq f\}.
\end{aligned}$$

This completes the induction step and establishes (2).

If $e \in P_{\text{sat}}$, (2) implies that $e \in \delta^T_{\mathcal{P}}(x^0_{\mathcal{P}}, e)$. Thus, $\delta^T_{\mathcal{P}}(x^0_{\mathcal{P}}, e)$ is nonempty, so $e \in T(\mathcal{P})$. Hence $P_{\text{sat}} \subseteq T(\mathcal{P})$. Since every refusal-trace in P is dominated by a saturated refusal-trace and $T(\mathcal{P})$ satisfies (T3), this implies that $P \subseteq T(\mathcal{P})$.

On the other hand, if $e \in T(\mathcal{P})$, then $\delta^T_{\mathcal{P}}(x^0_{\mathcal{P}}, e)$ is nonempty, so there exists $f \in P_{\text{sat}}$ which dominates e. Since P satisfies (T3), this implies that $e \in P$, so $T(\mathcal{P}) \subseteq P$, which completes the proof. □

The following result is an immediate consequence of the proof of Proposition 2.

COROLLARY 1. *If P is a trajectory model with canonical* NSM *$\mathcal{P}$, then for each $e \in P$, $\delta^T_{\mathcal{P}}(x^0_{\mathcal{P}}, e) = \{f \in P_{sat} |\, e \sqsubseteq f\}$.*

The following result is an immediate consequence of Propositions 1 and 2.

THEOREM 1. *Let $P \subseteq 2^\Sigma \times (\Sigma \times 2^\Sigma)^*$. Then P is the trajectory model of a nondeterministic state machine (with ϵ-moves) if and only if P satisfies properties* (T1)–(T5).

3.4. Deterministic trajectory models. Recall that a state machine $\mathcal{P}$ is deterministic if and only if its transition function is a partial map $\delta_{\mathcal{P}} : X_{\mathcal{P}} \times \Sigma \to X_{\mathcal{P}}$, i.e., there are no ϵ-transitions and $\delta_{\mathcal{P}}(x, \sigma)$ is either empty or contains exactly one element.

DEFINITION 6. *$P \subseteq 2^\Sigma \times (\Sigma \times 2^\Sigma)^*$ is called a* deterministic trajectory model *if and only if there exists a deterministic state machine $\mathcal{P}$ such that $T(\mathcal{P}) = P$.*

For any NSM $\mathcal{P}$, the language model can be obtained from the trajectory model via the trace map defined below. In the special case when the system $\mathcal{P}$ is deterministic, the trajectory model can be recovered from the language model via the inverse operation of the trace map, called the trajectory map, also defined below. Consequently, for deterministic systems, the language model is equivalent in detail of description to the trajectory model.

DEFINITION 7. *The* trace *map from refusal-traces to traces, denoted $tr : 2^\Sigma \times (\Sigma \times 2^\Sigma)^* \to \Sigma^*$, is defined inductively on the length of the refusal-traces as*:

- $\forall \Sigma' \subseteq \Sigma : tr(\Sigma') := \epsilon$,
- $\forall e \in 2^\Sigma \times (\Sigma \times 2^\Sigma)^*, \sigma \in \Sigma, \Sigma' \subseteq \Sigma : tr(e(\sigma, \Sigma')) := tr(e)\sigma$.

It is clear that $tr(T(\mathcal{P})) = L(\mathcal{P})$, where the trace operator is extended to the set of trajectory models in the natural way. Given a trajectory model $P \subseteq 2^\Sigma \times (\Sigma \times 2^\Sigma)^*$, we use $L(P) := tr(P)$ to denote the language model associated with P.

DEFINITION 8. *Let $K \subseteq \Sigma^*$ be a nonempty prefix-closed language. The* trajectory *map from traces to refusal-traces for the language model K, denoted $trj_K : K \to 2^\Sigma \times (\Sigma \times 2^\Sigma)^*$, is defined inductively on the length of traces of K as*:

- $trj_K(\epsilon) := \{\sigma \in \Sigma \mid \sigma \notin K\}$,
- $\forall s \in K, \sigma \in \Sigma$ *s.t.* $s\sigma \in K : trj_K(s\sigma) := trj_K(s)(\sigma, \{\sigma' \in \Sigma \mid s\sigma\sigma' \notin K\})$.

LEMMA 2. *Let $\mathcal{P}$ be an* NSM *with language model $K := L(\mathcal{P})$. Then*

(1) *$trj_K(K) \subseteq T(\mathcal{P})$,*

(2) *If $\mathcal{P}$ is deterministic, then $trj_K(K) = (T(\mathcal{P}))_{\text{sat}}$.*

Proof. Let $s \in K$ be a trace of length r. If $r = 0$, then $s = \epsilon$; otherwise, let $s = \sigma_1\sigma_2, \ldots, \sigma_r$. Let s^i denote the length-i prefix of s, and define $\hat{\Sigma}_i = \{\sigma \in \Sigma |\, s^i\sigma \notin K\}$.

Set

$$e := trj_K(s) = \hat{\Sigma}_0(\sigma_1, \hat{\Sigma}_1) \cdots (\sigma_r, \hat{\Sigma}_r).$$

Since $s \in L(\mathcal{P}) = L(T(\mathcal{P}))$, it follows from (T3) that the refusal-trace $\emptyset(\sigma_1, \emptyset) \cdots (\sigma_r, \emptyset) \in T(\mathcal{P})$. By repeated application of (T4), this implies that $e \in T(\mathcal{P})$, proving the first part.

Now assume that $\mathcal{P}$ is deterministic. To prove the second part, it suffices to show that e is the unique refusal-trace in $(T(\mathcal{P}))_{\text{sat}}$ with $tr(e) = s$. Also, since there must exist a saturated refusal-trace with trace s, it suffices to show that if $f \in (T(\mathcal{P}))_{\text{sat}}$ with $tr(f) = s$, then $f = e$. We use induction on $r = |e|$ to prove this together with the assertion that

$$\delta^T_{\mathcal{P}}(x^0_{\mathcal{P}}, e) = \delta^*_{\mathcal{P}}(x^0_{\mathcal{P}}, tr(e)). \tag{3}$$

Note that since $\mathcal{P}$ is deterministic, $\epsilon^*_{\mathcal{P}}(x) = x$, and given any $s \in K$, there exists a unique $x_s \in \delta^*_{\mathcal{P}}(x^0_{\mathcal{P}}, s)$. Furthermore, $\Re_{\mathcal{P}}(x_s) = \{\sigma \in \Sigma \mid s\sigma \notin K\}$.

If $r = 0$, then $f = \Sigma_0$ with $\Sigma_0 \subseteq \Re_{\mathcal{P}}(x^0_{\mathcal{P}}) = \hat{\Sigma}_0$. Since f is saturated, $\hat{\Sigma}_0 \subseteq \Sigma_0$, so $f = e$. Also, $\delta^T_{\mathcal{P}}(x^0_{\mathcal{P}}, e) = x^0_{\mathcal{P}} = \delta^*_{\mathcal{P}}(x^0_{\mathcal{P}}, \epsilon) = \delta^*_{\mathcal{P}}(x^0_{\mathcal{P}}, tr(e))$ as required.

For the induction step, express e and f as $e = \bar{e}(\sigma_r, \hat{\Sigma}_r)$, $f = \bar{f}(\sigma_r, \Sigma_r)$. Since the prefix of a saturated refusal-trace is saturated, $\bar{f} \in (T(\mathcal{P}))_{\text{sat}}$. Therefore, by induction hypothesis, we may assume that $\bar{f} = \bar{e}$. Using (3) applied to $\bar{e}$, it follows that

$$\begin{align}
\delta^T_{\mathcal{P}}(x^0_{\mathcal{P}}, f) &= \{x \in \epsilon^*_{\mathcal{P}}(\delta_{\mathcal{P}}(\delta^T_{\mathcal{P}}(x^0_{\mathcal{P}}, \bar{e}), \sigma_r)) \mid \Sigma_r \subseteq \Re_{\mathcal{P}}(x)\} \tag{4}\\
&= \{x \in \delta_{\mathcal{P}}(\delta^*_{\mathcal{P}}(x^0_{\mathcal{P}}, tr(\bar{e})), \sigma_r) \mid \Sigma_r \subseteq \Re_{\mathcal{P}}(x)\} \tag{5}\\
&= \{x \in \delta^*_{\mathcal{P}}(x^0_{\mathcal{P}}, tr(e)) \mid \Sigma_r \subseteq \Re_{\mathcal{P}}(x)\} \tag{6}\\
&= \begin{cases} x_s & \text{if } \Sigma_r \subseteq \Re_{\mathcal{P}}(x_s), \\ \emptyset & \text{otherwise.} \end{cases} \tag{7}
\end{align}$$

Since f is a refusal-trace of $\mathcal{P}$, $\delta^T_{\mathcal{P}}(x^0_{\mathcal{P}}, f)$ is nonempty, so $\Sigma_r \subseteq \Re_{\mathcal{P}}(x_s) = \hat{\Sigma}_r$. Since f is saturated, $\hat{\Sigma}_r \subseteq \Sigma_r$, so $f = e$. Also, by replacing f by e and Σ_r by $\hat{\Sigma}_r$ in equalities (4)–(7), we get $\delta^T_{\mathcal{P}}(x^0_{\mathcal{P}}, e) = x_s = \delta^*_{\mathcal{P}}(x^0_{\mathcal{P}}, tr(e))$. This completes the induction step. □

PROPOSITION 3. *Let $K \subseteq \Sigma^*$ be a nonempty prefixed-closed language, and let* $\det(K) := \operatorname{dom}(trj_K(K))$. *Then*

(1) $\det(K)$ *is a deterministic trajectory model.*

(2) *If P is any trajectory model with $L(P) = K$, then* $\det(K) \subseteq P$, *with equality if and only if P is deterministic.*

Proof. By a standard result, there exists a deterministic state machine $\mathcal{Q}$ such that $L(\mathcal{Q}) = K$. Setting $Q = T(\mathcal{Q})$ gives $L(Q) = K$. Since $\mathcal{Q}$ is deterministic, it follows from Lemma 2 that $trj_K(K) = (T(\mathcal{Q}))_{\text{sat}}$, which implies that $\det(K) = \operatorname{dom}((T(\mathcal{Q}))_{\text{sat}}) = Q$. Thus, $\det(K)$ is a deterministic trajectory model.

Let P be any trajectory model with $L(P) = K$. Then there exists a state machine $\mathcal{P}$ such that $T(\mathcal{P}) = P$. By Lemma 2, $trj_K(K) \subseteq P$, so $\det(K) \subseteq P$. If P is deterministic, then we can take $\mathcal{P}$ to be deterministic, so Lemma 2 implies that $trj_K(K) = (T(\mathcal{P}))_{\text{sat}}$, and hence $\det(K) = P$. On the other hand, if $\det(K) = P$, then P is deterministic by the first part. □

Remark 4. It follows from Proposition 3 that, given a nonempty prefix-closed language K, there is a unique deterministic trajectory model with language K. Furthermore, this trajectory model $\det(K)$ can be constructed from K by applying the map $trj_K(\cdot)$ and taking dominance closure. This trajectory model is the unique minimal element (with respect to inclusion) of the family of trajectory models having language K.

4. Prioritized synchronous composition. In this section, we define the PSC of two NSMs (with ϵ-moves), which induces a PSC operation on trajectory models. We also prove that the trajectory modeling framework is a language congruence with respect to PSC. Our definition of the PSC of NSMs is more general than the one in [7], since the silent transitions, i.e., transitions labeled ϵ, were not included. As discussed in §1, a priority set is associated with a system. This means that for an event which belongs to the priority set of a system to occur in the PSC with another system, the former system must participate.

DEFINITION 9. *Let $\mathcal{P} = (X_\mathcal{P}, \Sigma, \delta_\mathcal{P}, x^0_\mathcal{P})$ and $\mathcal{Q} = (X_\mathcal{Q}, \Sigma, \delta_\mathcal{Q}, x^0_\mathcal{Q})$ be two* NSM*s (with ϵ-moves). Let $A, B \subseteq \Sigma$ be the priority sets of $\mathcal{P}, \mathcal{Q}$, respectively. Then the* PSC *of $\mathcal{P}$ and $\mathcal{Q}$, denoted $\mathcal{P}\ {}_A\|_B\ \mathcal{Q}$, is another* NSM *defined as: $\mathcal{P}\ {}_A\|_B\ \mathcal{Q} := \mathcal{R} := (X_\mathcal{R}, \Sigma, \delta_\mathcal{R}, x^0_\mathcal{R})$, where $X_\mathcal{R} := X_\mathcal{P} \times X_\mathcal{Q}, x^0_\mathcal{R} := (x^0_\mathcal{P}, x^0_\mathcal{Q})$, and the transition function $\delta_\mathcal{R} : X_\mathcal{R} \times \Sigma \cup \{\epsilon\} \to 2^{X_\mathcal{R}}$ is defined as:*

- $\forall x_r = (x_p, x_q) \in X_\mathcal{R}$,

$$\forall \sigma \in \Sigma : \delta_\mathcal{R}(x_r, \sigma) := \begin{cases} \delta_\mathcal{P}(x_p, \sigma) \times \delta_\mathcal{Q}(x_q, \sigma) & \textit{if } \delta_\mathcal{P}(x_p, \sigma) \neq \emptyset, \delta_\mathcal{Q}(x_q, \sigma) \neq \emptyset, \\ \delta_\mathcal{P}(x_p, \sigma) \times \{x_q\} & \textit{if } \delta_\mathcal{P}(x_p, \sigma) \neq \emptyset, \sigma \in \Re_\mathcal{Q}(x_q), \sigma \notin B, \\ \{x_p\} \times \delta_\mathcal{Q}(x_q, \sigma) & \textit{if } \delta_\mathcal{Q}(x_q, \sigma) \neq \emptyset, \sigma \in \Re_\mathcal{P}(x_p), \sigma \notin A, \\ \emptyset & \textit{otherwise,} \end{cases}$$

$$\delta_\mathcal{R}(x_r, \epsilon) := [\delta_\mathcal{P}(x_p, \epsilon) \cup \{x_p\}] \times [\delta_\mathcal{Q}(x_q, \epsilon) \cup \{x_q\}] - \{(x_p, x_q)\}.$$

Thus, if an event is executable in the current states of both $\mathcal{P}$ and $\mathcal{Q}$, then it can be executed in $\mathcal{R}$, in which case both $\mathcal{P}$ and $\mathcal{Q}$ change their states synchronously according to their respective transitions. An event can be executed asynchronously by one of the systems if it is executable by that system and is not in the priority set of and cannot be executed in any state in the ϵ-closure of the current state of the other system. In this case, a state transition occurs in one system while no state change occurs in the other system. The silent transitions, i.e., those labeled by ϵ, can occur either synchronously or asynchronously. It is clear that an event in $A \cap B$ occurs only synchronously. Such synchronous execution is not required for events that do not belong to $A \cap B$. However, if an event that does not belong to $A \cap B$ is defined at states $x_p \in X_\mathcal{P}$ and $x_q \in X_\mathcal{Q}$, then it occurs synchronously at state $x_r = (x_p, x_q) \in X_\mathcal{R}$. Synchronous execution of such events is called *broadcast synchronization.*

Remark 5. If $A = B = \Sigma$, then an event is executable in the composed system if and only if it is executable in both systems. Thus this case corresponds to SSC. In contrast, if $A = B = \emptyset$, then an event is executable in the composed system if and only if it is executable in either of the systems.[5] This corresponds to an interleaving composition of the systems modified by the requirement that events which are executable by both systems are executed synchronously.

If $\mathcal{P}$ represents an uncontrolled plant, $\mathcal{Q}$ a supervisor, and $\mathcal{P}\ {}_A\|_B\ \mathcal{Q}$ the controlled plant or the closed-loop system, then (i) $A \cap B$ is the set of strict synchronization events and can be used to represent the set of *controllable* events; (ii) $A - B$ is the

[5] If an event is executable in the current state of one system but not in the current state of the other system, yet is executable in the second system following a silent transition, the event cannot occur in the composed system until the silent transition has occurred.

set of priority events only of $\mathcal{P}$ and can be used to represent the set of *uncontrollable* events; (iii) $B - A$ is the set of priority events only of $\mathcal{Q}$ and can be used to represent the set of *driven* events; (iv) $\Sigma - (A \cup B)$ is assumed to be empty, because events in $\Sigma - A \cup B$ belong neither to the priority set of the plant nor to that of the supervisor.

To simplify future notation, we define for any sets $\Sigma', \Sigma_1, \Sigma_2, \Sigma'' \subseteq \Sigma$:

- $\Sigma' \,_{\Sigma_1}\!\bigotimes_{\Sigma_2} \Sigma'' := (\Sigma' \cap \Sigma'') \cup (\Sigma' \cap \Sigma_1) \cup (\Sigma'' \cap \Sigma_2)$.

The following lemma gives two useful properties of the PSC of NSMs. It is a straightforward consequence of the definition of PSC.

LEMMA 3. *If* $\mathcal{R} = \mathcal{P} \,_A\|_B\, \mathcal{Q}$ *and* $x_r = (x_p, x_q) \in X_{\mathcal{R}}$*, then*

(1) $\epsilon^*_{\mathcal{R}}(x_r) = \epsilon^*_{\mathcal{P}}(x_p) \times \epsilon^*_{\mathcal{Q}}(x_q)$,

(2) $\Re_{\mathcal{R}}(x_r) = \Re_{\mathcal{P}}(x_p) \,_A\!\bigotimes_B \Re_{\mathcal{Q}}(x_q)$.

In other words, a state $x'_r = (x'_p, x'_q) \in X_{\mathcal{R}}$ belongs to the ϵ-closure of $x_r = (x_p, x_q)$ if and only if x'_p (respectively, x'_q) belongs to ϵ-closure of x_p (respectively, x_q). Also, an event is refused in $\mathcal{P} \,_A\|_B\, \mathcal{Q}$ if and only if either it is refused in both $\mathcal{P}$ and $\mathcal{Q}$, or it belongs to the priority set of $\mathcal{P}$ and is refused in $\mathcal{P}$, or it belongs to the priority set of $\mathcal{Q}$ and is refused in $\mathcal{Q}$.

We next consider the trajectory model of the PSC of two systems, and obtain its relationship to the trajectory models of the component systems. Using the definition of $\mathcal{P} \,_A\|_B\, \mathcal{Q}$ and that of its refusal map $\Re_{\mathcal{P} \,_A\|_B\, \mathcal{Q}}$, the trajectory model $T(\mathcal{P} \,_A\|_B\, \mathcal{Q})$ is easily obtained from its definition developed in the previous section. To obtain the relationship between $T(\mathcal{P})$, $T(\mathcal{Q})$, and $T(\mathcal{P} \,_A\|_B\, \mathcal{Q})$, we first define the PSC of a pair of refusal-traces.

DEFINITION 10. *Let* $e_p \in T(\mathcal{P})$ *and* $e_q \in T(\mathcal{Q})$*. Then the* PSC *of* e_p *and* e_q *(with respect to* $T(\mathcal{P})$ *and* $T(\mathcal{Q})$*), denoted* $e_p \,_A\|_B\, e_q$*, is defined inductively on* $|e_p| + |e_q|$ *as follows:*

- $\forall \Sigma_p, \Sigma_q \subseteq \Sigma$ *s.t.* $\Sigma_p \in T(\mathcal{P}), \Sigma_q \in T(\mathcal{Q})$:

$$\Sigma_p \,_A\|_B\, \Sigma_q := \{\Sigma' \subseteq \Sigma_p \,_A\!\bigotimes_B \Sigma_q\},$$

- $\forall e_p \in T(\mathcal{P}); e_q \in T(\mathcal{Q}); \sigma_p, \sigma_q \in \Sigma; \Sigma_p, \Sigma_q \subseteq \Sigma$ *s.t.* $e_p(\sigma_p, \Sigma_p) \in T(\mathcal{P}), e_q(\sigma_q, \Sigma_q) \in T(\mathcal{Q})$:

$$e_p(\sigma_p, \Sigma_p) \,_A\|_B\, e_q(\sigma_q, \Sigma_q) := T_1 \cup T_2 \cup T_3,$$

where

$$T_1 := \begin{cases} \{e(\sigma_p, \Sigma') \mid e \in e_p \,_A\|_B\, e_q(\sigma_q, \Sigma_q); \Sigma' \subseteq \Sigma_p \,_A\!\bigotimes_B \Sigma_q\} & \textit{if } \sigma_p \notin B \textit{ and } \\ & \quad e_q(\sigma_q, \Sigma_q)(\sigma_p, \emptyset) \notin T(\mathcal{Q}), \\ \emptyset & \textit{otherwise}; \end{cases}$$

$$T_2 := \begin{cases} \{e(\sigma_q, \Sigma') \mid e \in e_p(\sigma_p, \Sigma_p) \,_A\|_B\, e_q; \Sigma' \subseteq \Sigma_p \,_A\!\bigotimes_B \Sigma_q\} & \textit{if } \sigma_q \notin A \textit{ and } \\ & \quad e_p(\sigma_p, \Sigma_p)(\sigma_q, \emptyset) \notin T(\mathcal{P}), \\ \emptyset & \textit{otherwise}; \end{cases}$$

$$T_3 := \begin{cases} \{e(\sigma, \Sigma') \mid e \in e_p \,_A\|_B\, e_q; \Sigma' \subseteq \Sigma_p \,_A\!\bigotimes_B \Sigma_q\} & \textit{if } \sigma_p = \sigma_q := \sigma, \\ \emptyset & \textit{otherwise}. \end{cases}$$

It should be noted that $e_p \,_A\|_B\, e_q$ is a set of refusal-traces that depends on $T(\mathcal{P}), T(\mathcal{Q})$ as well as on the particular refusal-traces e_p, e_q. The dependence on $T(\mathcal{P}), T(\mathcal{Q})$ is not explicitly indicated in the notation.

The PSC of two zero-length refusal-traces $\Sigma_p \in T(\mathcal{P})$ and $\Sigma_q \in T(\mathcal{Q})$, which correspond to initial refusal sets of $T(\mathcal{P})$ and $T(\mathcal{Q})$, respectively, is obtained by computing $\Sigma_p \,{}_A\!\bigotimes_B\, \Sigma_q$, which corresponds to an initial refusal set of $T(\mathcal{P} \,{}_A\|_B\, \mathcal{Q})$. Next, the PSC of two refusal-traces $e_p(\sigma_p, \Sigma_p) \in T(\mathcal{P})$ and $e_q(\sigma_q, \Sigma_q) \in T(\mathcal{Q})$ is obtained by considering these three possible cases: (i) a refusal-trace belonging to $e_p \,{}_A\|_B\, e_q(\sigma_q, \Sigma_q)$ has already been executed in the composed system, and at this point σ_p is executable in $\mathcal{P}$ (indicated by $e_p(\sigma_p, \Sigma_p) \in T(\mathcal{P})$), the occurrence of σ_p cannot be blocked by $\mathcal{Q}$ (indicated by $\sigma_p \notin B$), and $\mathcal{Q}$ cannot participate in the occurrence of σ_p (indicated by $e_q(\sigma_q, \Sigma_q)(\sigma_p, \emptyset) \notin T(\mathcal{Q})$); (ii) a refusal-trace belonging to $e_p(\sigma_p, \Sigma_p) \,{}_A\|_B\, e_q$ has already been executed in the composed system, and at this point σ_q is executable in $\mathcal{Q}$, and $\mathcal{P}$ can neither block the occurrence of σ_q, nor can it participate in the occurrence of σ_q; (iii) $\sigma_p = \sigma_q := \sigma$; a refusal-trace belonging to $e_p \,{}_A\|_B\, e_q$ has already been executed in the composed system, and at this point σ is executable in both $\mathcal{P}$ and $\mathcal{Q}$.

Remark 6. It is clear from Definition 10 that if $A = B = \Sigma$, which corresponds to the case of SSC, then the sets $T_1 = T_2 = \emptyset$ since the conditions "$\sigma_p \notin B$" and "$\sigma_q \notin A$" both evaluate to "false." Hence the PSC of $e_p(\sigma_p, \Sigma_p) \in T(\mathcal{P})$ and $e_q(\sigma_q, \Sigma_q) \in T(\mathcal{Q})$ is nonempty if and only if the set T_3 is nonempty, which requires that $\sigma_p = \sigma_q$. Using induction, it can be easily concluded that the SSC of refusal-traces $e_p \in T(\mathcal{P})$ and $e_q \in T(\mathcal{Q})$ is a nonempty set if and only if $tr(e_p) = tr(e_q)$, in which case, $tr(e_p \,{}_\Sigma\|_\Sigma\, e_q) = tr(e_p) = tr(e_q)$, and for each $i \leq |e_p| = |e_q|$, the ith refusal set of any trace in $e_p \,{}_\Sigma\|_\Sigma\, e_q$ is any subset of the union of the ith refusal set of e_p and the ith refusal set of e_q, since $\Sigma_i(e_p) \,{}_\Sigma\!\bigotimes_\Sigma\, \Sigma_i(e_q) = \Sigma_i(e_p) \cup \Sigma_i(e_q)$.

We can extend the definition of the PSC of a pair of refusal-traces to the PSC of the trajectory models. With a slight abuse of notation, we use the same symbol ${}_A\|_B$ for the PSC of the NSMs $\mathcal{P}, \mathcal{Q}$ and for the PSC of their corresponding trajectory models $T(\mathcal{P}), T(\mathcal{Q})$.

DEFINITION 11. *The* PSC *of the trajectory models* $T(\mathcal{P}), T(\mathcal{Q})$ *is defined to be*

- $T(\mathcal{P}) \,{}_A\|_B\, T(\mathcal{Q}) := \bigcup_{e_p \in T(\mathcal{P}), e_q \in T(\mathcal{Q})} e_p \,{}_A\|_B\, e_q$.

The following result shows that the trajectory model of the PSC of NSMs is the PSC of their corresponding trajectory models. Equivalently, it states that the PSC operation on NSMs induces a PSC operation on trajectory models, and the induced operation is precisely the one described in Definition 11.

THEOREM 2. *For any* NSM*s* $\mathcal{P}, \mathcal{Q}$, $T(\mathcal{P} \,{}_A\|_B\, \mathcal{Q}) = T(\mathcal{P}) \,{}_A\|_B\, T(\mathcal{Q})$.

Proof. Refer to Appendix A. □

COROLLARY 2. *The trajectory model is a language congruence with respect to the operation of* PSC.

Proof. Let $\mathcal{P}_1, \mathcal{P}_2, \mathcal{Q}_1, \mathcal{Q}_2$ be NSMs with $T(\mathcal{P}_1) = T(\mathcal{P}_2)$ and $T(\mathcal{Q}_1) = T(\mathcal{Q}_2)$. Theorem 2 implies that $T(\mathcal{P}_1 \,{}_A\|_B\, \mathcal{Q}_1) = T(\mathcal{P}_2 \,{}_A\|_B\, \mathcal{Q}_2)$. Hence $L(\mathcal{P}_1 \,{}_A\|_B\, \mathcal{Q}_1) = L(T(\mathcal{P}_1 \,{}_A\|_B\, \mathcal{Q}_1)) = L(T(\mathcal{P}_2 \,{}_A\|_B\, \mathcal{Q}_2)) = L(\mathcal{P}_2 \,{}_A\|_B\, \mathcal{Q}_2)$. □

We will need the following result which shows that PSC of trajectory models preserves determinism.

COROLLARY 3. *If* P *and* Q *are deterministic trajectory models, then so is* $P \,{}_A\|_B\, Q$.

Proof. By definition, there exist deterministic state machines $\mathcal{P}, \mathcal{Q}$ such that $T(\mathcal{P}) = P$, $T(\mathcal{Q}) = Q$. From Definition 9, it is clear that $\mathcal{P} \,{}_A\|_B\, \mathcal{Q}$ is deterministic. Since Theorem 2 implies that $P \,{}_A\|_B\, Q = T(\mathcal{P} \,{}_A\|_B\, \mathcal{Q})$, we conclude that $P \,{}_A\|_B\, Q$ is deterministic. □

Remark 7. Theorem 2 shows that the trajectory model of $\mathcal{P} \,{}_A\|_B\, \mathcal{Q}$ can be described using only $T(\mathcal{P})$ and $T(\mathcal{Q})$, and not $\mathcal{P}, \mathcal{Q}$ directly. This is in contrast to the situation with the failures model. Theorem 2 and Corollary 2 both fail if the trajectory model is replaced with the failures model. The equality of failures models does not necessarily imply the equality of failures models, or even language models, under prioritized synchronous composition with a fixed system [7, Ex. 7]. The result in Corollary 2 was mentioned without proof in [7], [8]. However, its rigorous demonstration depends on the precise definitions given above for the PSC of NSMs (with ϵ-moves) as well as for the trajectory model of an NSM.

5. Properties of prioritized synchronous composition. In this section we describe some of the properties of the PSC of two or more trajectory models, which are used in §6 for the synthesis of supervisors which control the behavior of nondeterministic plants via PSC.

5.1. Associativity. We begin by providing a proof for the following result which is stated without proof as part of [8, Thm. 13.4].

THEOREM 3. *For any trajectory models P, Q, R and priority sets $A, B, C \subseteq \Sigma$*

$$(P\, {}_A\|_B\, Q)\, {}_{A\cup B}\|_C\, R = P\, {}_A\|_{B\cup C}\, (Q\, {}_B\|_C\, R).$$

Proof. Refer to Appendix A. □

This can be interpreted as an associative property as follows. Let P, Q denote trajectory models with event set Σ, and let A, B be subsets of Σ. We refer to the pairs (P, A), (Q, B) as *prioritized systems*, and define their *synchronous composition* to be the prioritized system

- $(P, A) \parallel (Q, B) := (P\, {}_A\|_B\, Q,\ A \cup B)$.

Then Theorem 3 asserts that $[(P, A) \parallel (Q, B)] \parallel (R, C) = (P, A) \parallel [(Q, B) \parallel (R, C)]$. Thus, the result is simply the associative property for the synchronous composition of prioritized systems.

5.2. Augmentation and prioritized synchronous composition. We define augmentation of both NSMs and trajectory models, and show that the prioritized synchronous composition of two trajectory models is identical to *strict* synchronous composition of their augmentations, provided the two priority sets exhaust the set of events.

Let $\mathcal{P}$ be an NSM with event set Σ, and let $D \subseteq \Sigma$. We denote by $\mathcal{D}$ the deterministic state machine with one state and self-loops labeled by every event in D. The *augmentation of $\mathcal{P}$ by D*, denoted $\mathcal{P}^D$, is defined to be the NSM $\mathcal{P}^D := \mathcal{P}\, {}_\emptyset\|_\emptyset\, \mathcal{D}$. The state space of $\mathcal{P}^D$ can be identified with the state space of $\mathcal{P}$, and $\mathcal{P}^D$ is then obtained from $\mathcal{P}$ by adding self-loops at each $x \in X_{\mathcal{P}}$ labeled by every event in $D \cap \Re_{\mathcal{P}}(x)$. It is clear that $\mathcal{P}^D$ is deterministic whenever $\mathcal{P}$ is deterministic.

If P is a trajectory model, the *augmentation of P by D*, denoted P^D, is defined to be the trajectory model $P^D := P\, {}_\emptyset\|_\emptyset\, \det(D^*)$. Note that since both priority sets are empty, P^D represents interleaving of P and $\det(D^*)$ except that the broadcast synchronization requirement means that events in D which can also occur in P occur synchronously in both P and $\det(D^*)$.

Remark 8. Since $\det(D^*)$ can always execute every event in D and can never execute any event in $\Sigma - D$, it follows that for any $A \subseteq \Sigma - D$ and any $B \subseteq D$,

$$P^D := P\, {}_\emptyset\|_\emptyset\, \det(D^*) = P\, {}_A\|_B\, \det(D^*).$$

It follows from Theorem 2 that given an NSM $\mathcal{P}$ and an event set $D \subseteq \Sigma$, $T(\mathcal{P}^D) = [T(\mathcal{P})]^D$, and it follows from Corollary 3 that if P is a deterministic trajectory model, then so is its augmentation P^D.

The following result shows that augmentation can be used to reduce prioritized synchronous composition to strict synchronization.

PROPOSITION 4. *If* $A \cup B = \Sigma$, *then* $P\ {}_A\|_B\ Q = P^{B-A}\ {}_\Sigma\|_B\ Q = P^{B-A}\ {}_\Sigma\|_\Sigma\ Q^{A-B}$.

Proof. It suffices to prove the first equality since the second equality follows from symmetry and a second application of the first equality. Using Remark 8 and Theorem 3 gives

$$\begin{aligned} P^{B-A}\ {}_\Sigma\|_B\ Q &= (P\ {}_A\|_{B-A}\ \det((B-A)^*))\ {}_\Sigma\|_B\ Q \\ &= \det((B-A)^*)\ {}_{B-A}\|_\Sigma\ (P\ {}_A\|_B\ Q) \\ &= P\ {}_A\|_B\ Q. \end{aligned}$$

The final equality is an easy consequence of two facts: the priority set of $P\ {}_A\|_B\ Q$ is Σ, so $\det((B-A)^*)$ cannot execute any events which do not occur in $P\ {}_A\|_B\ Q$; $\det((B-A)^*)$ can alway execute each event in its priority set, so it cannot block any events in $P\ {}_A\|_B\ Q$. □

6. Supervisory control with driven events.

In this section, we derive results concerning supervisory control by prioritized synchronous composition in the presence of driven events.

6.1. Control under complete observability.

We begin with a result which shows that in a prioritized synchronous composition, a deterministic system participates in every event of any refusal-trace whose trace belongs to its language.

LEMMA 4. *Let* P, Q *be trajectory models with* Q *deterministic. If* $e \in e_p\ {}_A\|_B\ e_q \subseteq P\ {}_A\|_B\ Q$ *with* $tr(e) \in L(Q)$, *then* $tr(e) = tr(e_q)$.

Proof. The result follows as a special case of Lemma 5 below. □

The following result gives necessary and sufficient conditions for a given (prefix-closed) language to be realizable as the closed-loop language for a plant supervised by prioritized synchronous composition. The basic assumption is that every event in Σ belongs to the priority set A of the plant P or the priority set B of the supervisor. The interpretation is that Σ is partitioned into disjoint subsets Σ_c, Σ_u and Σ_d consisting of the controllable, uncontrollable, and driven events, and $A = \Sigma_c \cup \Sigma_u$ while $B = \Sigma_c \cup \Sigma_d$.

THEOREM 4. *Let* P *be a trajectory model,* $A \cup B = \Sigma$, *and let* K *be a nonempty prefix-closed sublanguage of* $L(P^{B-A})$. *Then there exists a trajectory model* S *such that* $L(P\ {}_A\|_B\ S) = K$ *if and only if*

$$K(A-B) \cap L(P^{B-A}) \subseteq K, \tag{8}$$

in which case S *can be chosen to be the deterministic trajectory model* $\det(K)$.

Proof. We begin with sufficiency. Suppose that equation (8) holds. Since K is a nonempty prefix-closed sublanguage of $L(P^{B-A})$, there exists a trajectory model S such that $L(P^{B-A}) \cap L(S) = K$. Without loss of generality, we may assume that S is deterministic. (In particular, we can choose $S = \det(K)$.)

We claim that

$$L(P^{B-A}) \cap L(S^{A-B}) = K. \tag{9}$$

Obviously, $K = L(P^{B-A}) \cap L(S) \subseteq L(P^{B-A}) \cap L(S^{A-B})$. We establish the reverse inclusion by contradiction. Suppose $L(P^{B-A}) \cap L(S^{A-B})$ strictly contains K. Let $t = s\sigma$ be a minimal length trace in $L(P^{B-A}) \cap L(S^{A-B}) - K$. Then $s \in K = L(P^{B-A}) \cap L(S)$. Since $s\sigma \in L(S^{A-B})$, there exists $g = \bar{g}(\sigma, \emptyset) \in S^{A-B}$ such that $tr(\bar{g}) = s$. Hence, there exist $e = \bar{e}(\sigma', \Sigma') \in S$, $f = \bar{f}(\sigma'', \Sigma'') \in \det((A-B)^*)$

such that $g \in e\,{}_{\emptyset}\|_{\emptyset}\, f$. First suppose $\sigma \notin A - B$. Then $\sigma \neq \sigma''$, so $\sigma = \sigma'$ and $\bar{g} \in \bar{e}\,{}_{\emptyset}\|_{\emptyset}\, f$. Since S is deterministic and $tr(\bar{g}) = s \in L(S)$, it follows from Lemma 4 that $tr(\bar{g}) = tr(\bar{e})$. Thus, $s\sigma = tr(g) = tr(e) \in L(S)$, which implies that $t \in K$, a contradiction. On the other hand, if $\sigma \in A - B$, then it follows from (8) that $t \in K$, again a contradiction. Thus, (9) holds.

Using Proposition 4, we get $K = L(P^{B-A}) \cap L(S^{A-B}) = L(P^{B-A}\,{}_{\Sigma}\|_{\Sigma}\, S^{A-B}) = L(P\,{}_{A}\|_{B}\, S)$, showing that S solves the supervisory control problem.

Conversely, suppose there exists a trajectory model S such that $L(P\,{}_{A}\|_{B}\, S) = K$. Then (9) holds. Let $t = s\sigma \in K(A - B) \cap L(P^{B-A})$. Since $s \in K \subseteq L(S^{A-B})$ and $\sigma \in A - B$, it follows that $s\sigma \in L(S^{A-B})$. Thus, $t \in L(P^{B-A}) \cap L(S^{A-B}) = K$, so (8) holds. □

Remark 9. Theorem 4 states that K is realizable as the closed-loop language if and only if it is controllable (in the sense of Ramadge and Wonham [24]) *with respect to the language of the augmented plant,* $L(P^{B-A})$, which depends on the trajectory model P—not simply on $L(P)$. Knowledge of $L(P)$ is not sufficient to determine if the supervisory control problem is solvable for a given target language K. This is illustrated by the following example.

Example 3. We consider a very simple air traffic control problem. The plant represents the aircraft and pilot, while the supervisor represents the air traffic controller. Let $\Sigma = \{a, b\}$ where $a \in \Sigma_u$ represents a flight maneuver, while $b \in \Sigma_d$ represents a command from the tower not to execute the flight maneuver. The execution of b by the supervisor indicates that the command has been broadcasted, whereas the execution of b by the plant indicates that the command has been received.

We consider two alternative trajectory models for the plant:

$$P_1 = (a \rightarrow \Delta_\Sigma) + (b \rightarrow \Delta_\Sigma), \quad P_2 = P_1 \oplus (a \rightarrow \Delta_\Sigma).$$

NSMs with trajectory models P_1 and P_2 are depicted in Figs. 2(c) and (d), respectively. In P_1, the pilot can initially execute the maneuver or receive the command not to do so. However, in P_2 there is an initial nondeterministic choice between P_1 and the trajectory model $(a \rightarrow \Delta_\Sigma)$ in which the maneuver is possible but the command cannot be received. Thus, P_2 models the possibility of aircraft radio receiver failure. Note that $L(P_1) = L(P_2)$. However, it can be verified that $L(P_1^{B-A}) = (a + \epsilon)b^*$, while $L(P_2^{B-A}) = b^*(a + \epsilon)b^*$. Suppose that the target language K is not completely specified but is required to contain the trace b and not contain any trace in which the event a occurs after the event b has occurred. In other words, the tower should be initially able to broadcast the command b, and if the command has been broadcasted, the pilot must not be able to execute the maneuver a.

The supervisory control problem is clearly solvable for the plant model P_1. For example, if we choose $S = P_1$, then $P_1\,{}_{A}\|_{B}\, S = P_1$, so the closed-loop language is $L(P_1) = \{\epsilon, a, b\}$, which meets the specifications for K. On the other hand, the supervisory control problem is not solvable for the plant model P_2. For any target language K which satisfies the specifications, we have $ba \in K(A - B) \cap L(P_2^{B-A}) - K$. It follows from Theorem 4 that there is no supervisor S such that $L(P_2\,{}_{A}\|_{B}\, S) = K$.

It is worth noting that if P_2 is the correct plant model, i.e., receiver failure can occur, then the supervisory control problem can be made solvable by changing the protocol between the pilot and tower. If the pilot is required to obtain clearance from the tower in order to execute maneuver a, then a becomes a controllable event and it is then trivial to construct a supervisor that meets the specifications.

When there are no driven events, then $A = \Sigma_c \cup \Sigma_u = \Sigma$ and $B = \Sigma_c$. In this case Theorem 4 specializes to give the following corollary.

COROLLARY 4. *Let K be a nonempty prefix-closed sublanguage of $L(P)$. Then the following are equivalent:*

(1) *There exists a trajectory model S such that $L(P\,_{\Sigma}\|_{\Sigma_c}\,S) = K$.*

(2) $L(P\,_{\Sigma}\|_{\Sigma_c}\,\det(K)) = K$.

(3) $K\Sigma_u \cap L(P) \subseteq K$.

Remark 10. Corollary 4 shows that when there are no driven events, the necessary and sufficient conditions for supervisory control by prioritized synchronous composition are the same as those in the Ramadge–Wonham framework [23]. The equivalence of the first and second conditions of Corollary 4 was stated without proof in [7, Thm. 1] and [8, Thm. 14.2]. The equivalence of the first and third conditions of Corollary 4 was stated in [8, Thm. 14.1] accompanied by an incomplete proof.

Remark 11. The proof of Theorem 4 shows that if K satisfies condition (8) and N is any prefix-closed sublanguage of Σ^* with $L(P^{B-A}) \cap N = K$, then the deterministic supervisor $S := \det(N)$ results in K as the closed-loop language $L(P\,_A\|_B\,S)$. Since $K \subseteq N$, it follows from Lemma 4 that every event executed by the closed-loop system occurs in S. In particular, every uncontrollable event is executed by the supervisor even though such events do not belong to its priority set. This behavior is induced by the broadcast synchronization requirement in prioritized synchronous composition.

It is interesting to specialize this observation to the case where there are no driven events. Since $A = \Sigma$, the plant also participates in every event. Thus, the plant and supervisor function as though they are connected by *strict synchronization* rather than by prioritized synchronous composition. In particular, this is the case when the supervisor is chosen to be $\det(K)$. The determinism of S is essential here. If S is a nondeterministic trajectory model with $L(S) = N$, there is no guarantee that the closed-loop language will be K. This is demonstrated by the next example.

Example 4. Let $\Sigma = \{a,b\}$, $\Sigma_c = \{a\}$, $\Sigma_u = \{b\}$, $P = (a \to \Delta_\Sigma) + (b \to (a \to \Delta_\Sigma))$, $S = (a \to \Delta_\Sigma) \oplus (b \to \Delta_\Sigma)$. Then $L(P) = \{\epsilon, a, b, ba\}$, $L(S) = \{\epsilon, a, b\}$. Let $K = L(S)$. Then K satisfies the controllability condition (the third condition of Corollary 4) as well as $L(P) \cap L(S) = K$. A straightforward calculation shows that $P\,_{\Sigma}\|_{\Sigma_c}\,S = ((a \to \Delta_\Sigma) + (b \to (a \to \Delta_\Sigma))) \oplus (b \to \Delta_\Sigma)$. Thus, $L(P\,_{\Sigma}\|_{\Sigma_c}\,S) = \{\epsilon, a, b, ba\} = L(P) \neq K$. What happens is that since S is nondeterministic, the event b can be executed as the initial event solely in P even though $b \in L(S)$. (This cannot happen for deterministic S by Lemma 4.) Thus, strict synchronization is lost. This permits a trace of $P\,_{\Sigma}\|_{\Sigma_c}\,S$, which is not a trace of S.

6.2. Control under restricted unobservability. We continue to assume that $A \cup B = \Sigma$, where $A = \Sigma_c \cup \Sigma_u$ and $B = \Sigma_c \cup \Sigma_d$. In the closed-loop system $P\,_A\|_B\,S$, the events in $A - B$, i.e., the uncontrollable events, are generated by the plant P and are broadcast to the supervisor S, where they are synchronously executed whenever enabled. It may happen that information about the occurrence of certain uncontrollable events is unavailable for broadcasting due to lack of sensors, or it may be desirable to implement a simplified supervisor which ignores such information. This suggests a generalization of prioritized synchronous composition in which the broadcast synchronization requirement is disregarded for a specified subset $\Gamma \subseteq A - B$ of uncontrollable events. Since events in $A - B$ cannot occur spontaneously in S, this effectively prevents S from ever executing the events in Γ. Thus, instead of modifying the definition of prioritized synchronous composition, it is equivalent to restrict the admissible supervisors to those which do not execute events in Γ.

Let $\Pi_\Gamma : \Sigma \to \Sigma$ denote the natural projection defined by

- $\forall \sigma \in \Sigma : \Pi_\Gamma(\sigma) := \begin{cases} \epsilon & \text{for } \sigma \in \Gamma, \\ \sigma & \text{for } \sigma \in \Sigma - \Gamma. \end{cases}$

$\Pi_\Gamma(\cdot)$ extends to a map on Σ^* in the obvious way. We define the *restricted supervisory control problem* (RSCP) to be as follows: Given a prefix-closed sublanguage K of $L(P^{B-A})$ and $\Gamma \subseteq A - B$, determine if there exists a supervisor S such that

- $L(P\,{}_A\|_B\, S) = K$ and $\Pi_\Gamma(L(S)) = L(S)$.

Remark 12. There are two different ways to model an uncontrollable event in the plant which is unobservable to the supervisor. It can be completely suppressed and treated as an ϵ-event in P. Alternatively, it can be treated as a labeled event $\sigma \in \Sigma$ in the plant which does not label any transitions in the supervisor. The advantage of the second approach (which is the one taken in the RSCP) is that such an event can be included in the performance specifications, i.e., in the target language K. Hence, even though it is unobservable to the supervisor, its occurrence in the closed-loop system can be controlled—albeit subject to the conditions that must be satisfied by K for the solvability of the RSCP.

The next result generalizes Lemma 4 to the case where certain events in $A - B$ are not present in the second system Q.

LEMMA 5. *Let* $\Gamma \subseteq A-B$, *and* P, Q *be trajectory models with* Q *deterministic and satisfying* $\Pi_\Gamma(L(Q)) = L(Q)$. *If* $e \in e_p\,{}_A\|_B\, e_q \subseteq P\,{}_A\|_B\, Q$ *with* $\Pi_\Gamma(tr(e)) \in L(Q)$, *then* $\Pi_\Gamma(tr(e)) = tr(e_q)$.

Proof. The proof is by induction on $|e|$. The assertion holds trivially when $|e| = 0$. For the induction step, write $e = \bar{e}(\sigma, \Sigma')$ and let $\bar{e}_p$, $\bar{e}_q$ denote the prefixes of e_p, e_q obtained by deleting the final event and refusal set from each refusal-trace.

If σ occurs synchronously in both P and Q, then $\bar{e} \in \bar{e}_p\,{}_A\|_B\, \bar{e}_q$. Then $\sigma \notin \Gamma$, so $\Pi_\Gamma(tr(e)) = \Pi_\Gamma(tr(\bar{e}))\sigma$. Since $L(Q)$ is prefix-closed, $\Pi_\Gamma(tr(\bar{e})) \in L(Q)$. Applying the induction hypothesis gives $\Pi_\Gamma(tr(\bar{e})) = tr(\bar{e}_q)$. Thus, $\Pi_\Gamma(tr(e)) = \Pi_\Gamma(tr(\bar{e}))\sigma = tr(\bar{e}_q)\sigma = tr(e_q)$. The same argument applies in the case where $\bar{e} \in e_p\,{}_A\|_B\, \bar{e}_q$, i.e., when σ occurs only in Q.

Suppose $\bar{e} \in \bar{e}_p\,{}_A\|_B\, e_q$, i.e., σ occurs only in P. If $\sigma \in \Gamma$, then $\Pi_\Gamma(tr(e)) = \Pi_\Gamma(tr(\bar{e})) = tr(e_q)$, where the second equality follows from the induction hypothesis. Now suppose that $\sigma \notin \Gamma$. Since σ occurs only in P, it follows that $e_q(\sigma, \emptyset) \notin Q$. Since Q is deterministic, Proposition 3 implies that $tr(e_q)\sigma \notin L(Q)$. Since $L(Q)$ is prefix-closed, $\Pi_\Gamma(tr(\bar{e})) \in L(Q)$. Using the induction hypothesis, we have $tr(e_q)\sigma = \Pi_\Gamma(tr(\bar{e}))\sigma = \Pi_\Gamma(tr(e)) \in L(Q)$, a contradiction. Thus, this final case cannot occur. □

For the standard supervisory control problem with partial observations (and no driven events), a target language K is obtainable as the language of the closed-loop system if and only if K is controllable and observable relative to the language of the plant [16], [5]. The following result shows that in the presence of driven events, the RSCP is solvable if and only if K is controllable and observable *relative to the language of the augmented plant.*

THEOREM 5. *Let* $A \cup B = \Sigma$, $\Gamma \subseteq A - B$, *and let* K *be a nonempty prefix-closed sublanguage of* $L(P^{B-A})$. *Then there exists a trajectory model* S *such that*

$$(10) \qquad L(P\,{}_A\|_B\, S) = K, \qquad \Pi_\Gamma(L(S)) = L(S)$$

if and only if the following two conditions are satisfied:

$$(11) \qquad K(A-B) \cap L(P^{B-A}) \subseteq K,$$

$$(12) \qquad \forall \bar{s}, \bar{t} \in K, \sigma \in \Sigma : \Pi_\Gamma(\bar{s}) = \Pi_\Gamma(\bar{t}), \bar{s}\sigma \in K,\ \bar{t}\sigma \in L(P^{B-A}) \Rightarrow \bar{t}\sigma \in K.$$

In this case, S can be chosen to be the deterministic trajectory model $\det(\Pi_\Gamma(K))$.

Proof. We first show the necessity of the controllability condition (11) and observability condition (12). Suppose there exists a trajectory model S such that (10) is satisfied. Then (11) follows from Theorem 4. Let $\bar{s}$, $\bar{t} \in K$ with $\Pi_\Gamma(\bar{s}) = \Pi_\Gamma(\bar{t})$, and suppose that $\bar{s}\sigma \in K$, $\bar{t}\sigma \in L(P^{B-A})$. We need to show that $\bar{t}\sigma \in K$. Since $L(P^{B-A}) \cap L(S^{A-B}) = K$, it suffices to show that $\bar{t}\sigma \in L(S^{A-B})$. Since K is controllable, it suffices to consider $\sigma \in B$. Note that $S^{A-B} = (S^{A-B-\Gamma})^\Gamma$. Also, since $\Pi_\Gamma(L(S)) = L(S)$, events in Γ are never executed in S. Hence $\Pi_\Gamma(L(S^{A-B-\Gamma})) = L(S^{A-B-\Gamma})$. In other words, events in Γ are never executed in $S^{A-B-\Gamma}$. Hence the language $L(S^{A-B}) = L((S^{A-B-\Gamma})^\Gamma)$ is obtained by pure interleaving of the languages $L(S^{A-B-\Gamma})$ and $L(\det(\Gamma^*)) = \Gamma^*$. Since the trace $\bar{s}\sigma \in L(S^{A-B})$, we have $\Pi_\Gamma(\bar{s}\sigma) \in L(S^{A-B-\Gamma})$. Also, since $\Pi_\Gamma(\bar{s}\sigma) = \Pi_\Gamma(\bar{s})\sigma = \Pi_\Gamma(\bar{t})\sigma = \Pi_\Gamma(\bar{t}\sigma)$, we have $\Pi_\Gamma(\bar{t}\sigma) \in L(S^{A-B-\Gamma})$. Since $\bar{t}\sigma$ is a pure interleaving of $\Pi_\Gamma(\bar{t}\sigma) \in L(S^{A-B-\Gamma})$ and a trace in Γ^*, $\bar{t}\sigma \in L(S^{A-B})$. This establishes (12) and completes the proof of necessity.

To prove sufficiency, suppose that (11) and (12) both hold. Let $S = \det(\Pi_\Gamma(K))$. By Proposition 4, it is equivalent to prove $L(P^{B-A}\,{}_\Sigma\|_B\, S) = K$. Given any $t \in K$, there exists $e \in P^{B-A}$ with $tr(e) = t$ and there exists $f \in S$ with $tr(f) = \Pi_\Gamma(t)$. Since $\Gamma \cap B = \emptyset$ and S can never execute an event in Γ, it follows that $e\,{}_\Sigma\|_B\, f$ is nonempty and every refusal-trace which it contains has trace t. Thus, $K \subseteq L(P^{B-A}\,{}_\Sigma\|_B\, S)$.

It remains to prove

$$L(P^{B-A}\,{}_\Sigma\|_B\, S) \subseteq K. \tag{13}$$

We establish (13) by contradiction. Let $g = \bar{g}(\sigma, \Sigma') \in P^{B-A}\,{}_\Sigma\|_B\, S$ and suppose g has minimal length among the refusal-traces of $P^{B-A}\,{}_\Sigma\|_B\, S$, whose traces are not in K. Let $\bar{t}$ and $t = \bar{t}\sigma$ denote the traces of $\bar{g}$ and g, respectively. Then $t \notin K$ and

$$\bar{t} \in K, \quad t \in L(P^{B-A}), \tag{14}$$

where the final membership follows from the fact that the priority set of P^{B-A} is Σ.

If $\sigma \in A - B$, then it follows from (11) that $t \in K$, contrary to assumption. Thus, without loss of generality, we may assume that $\sigma \in B$. Since $\bar{r} := \Pi_\Gamma(\bar{t}) \in \Pi_\Gamma(K) = L(S)$, it follows from Lemma 5 that S executes every event in $\bar{r}$ while $P^{B-A}\,{}_\Sigma\|_B\, S$ executes the refusal-trace $\bar{g}$. Since $\sigma \in B$, the final event in g must occur synchronously in P^{B-A} and S. This implies that $\bar{r}\sigma \in L(S) = \Pi_\Gamma(K)$. Thus, there exists $s \in K$ such that $\Pi_\Gamma(s) = \bar{r}\sigma$. Since the last observable event in s is σ, by replacing s with a prefix if necessary, we may assume that $s = \bar{s}\sigma$. Then

$$\bar{s} \in K, \quad \Pi_\Gamma(\bar{s}) = \bar{r} = \Pi_\Gamma(\bar{t}). \tag{15}$$

From (14), (15), and the observability assumption it follows that $t \in K$, contrary to assumption. This establishes (13) and completes the proof of sufficiency. □

Remark 13. It follows from Lemma 5 that if $S := \det(\Pi_\Gamma(K))$ is used to solve the RSCP, then every event in $\Sigma - \Gamma$ which occurs in the closed-loop system is executed by the supervisor. The events in Γ are not observed by the supervisor and are executed only by the plant.

With Theorem 5 in hand, we can obtain a successful control design for the example presented in §2. Recall that for the given partially observed plant, there is no supervisor of the Ramadge–Wonham type that is consistent with the observation mask and satisfies the upper-bound specification of preventing jamming and the lower-bound specification of permitting cyclic operation.

Example 5. Let $\mathcal{P}$ denote the open-loop NSM described in §2 and depicted in Fig. 1(c). $\mathcal{P}$ is partially observed with a natural projection mask corresponding to $\Gamma = \{\gamma_1, \gamma_2\}$. The partition of the event set Σ into subsets of controllable, uncontrollable, and driven events is given by $\Sigma_c = \{\alpha\}$, $\Sigma_u = \{\beta, \gamma_1, \gamma_2, \eta, \lambda\}$, $\Sigma_d = \{\mu\}$. Thus, in a PSC-based control design, the priority sets of the plant and supervisor are $A = \{\alpha, \beta, \gamma_1, \gamma_2, \eta, \lambda\}$ and $B = \{\alpha, \mu\}$, respectively.

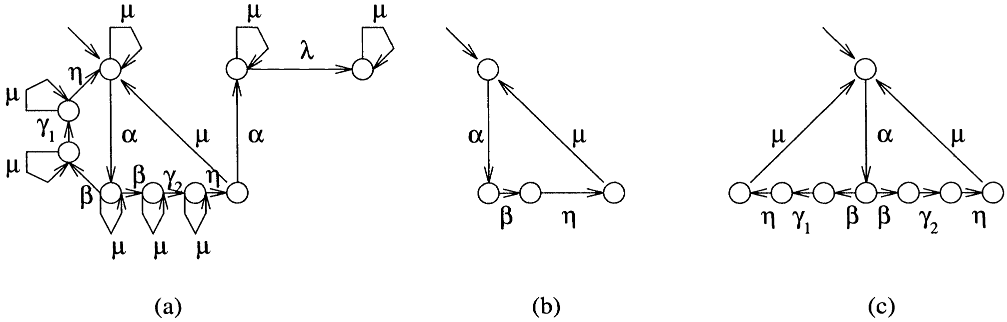

FIG. 4. *Diagram illustrating Example* 5.

The augmented plant $\mathcal{P}^{B-A}$ is shown in Fig. 4(a). The requirement that the jamming event λ never occur in the closed-loop system is represented by the specification $L(P\,_A\|_B\, S) \subseteq K$, where P is the trajectory model of $\mathcal{P}$, S is the trajectory model of a supervisor, and $K := \{s \in L(P^{B-A}) \mid \text{no event in } s \text{ is } \lambda\}$. Since $s := \alpha\beta\gamma_2\eta\alpha \in K$, $s\lambda \in L(P^{B-A}) - K$, and $\lambda \in A - B = \Sigma_u$, K is not controllable with respect to $A - B$ and $L(P^{B-A})$, and a straightforward calculation yields

$$K^{\uparrow} = pr((\mu^*\alpha\mu^*\beta\mu^*(\gamma_1\mu^*\eta + \gamma_2\mu^*\eta\mu))^*)$$

as the supremal controllable sublanguage [22]. However, $K^{\uparrow}$ is not observable relative to the augmented plant language $L(P^{B-A})$ and mask $\Pi_\Gamma(\cdot)$. In particular, if $\bar{t} \in (\mu^*\alpha\mu^*\beta\mu^*(\gamma_1\mu^*\eta + \gamma_2\mu^*\eta\mu))^*\mu^*\alpha\mu^*\beta\mu^*\gamma_2\mu^*\eta \subset K^{\uparrow}$, then $\bar{t}\alpha \in L(P^{B-A}) - K^{\uparrow}$, and $\exists \bar{s} \in (\mu^*\alpha\mu^*\beta\mu^*(\gamma_1\mu^*\eta + \gamma_2\mu^*\eta\mu))^*\mu^*\alpha\mu^*\beta\mu^*\gamma_1\mu^*\eta \subset K^{\uparrow}$ such that $\Pi_\Gamma(\bar{s}) = \Pi_\Gamma(\bar{t})$ and $\bar{s}\alpha \in K^{\uparrow}$.

It is easy to see that the supremal normal sublanguage [16], [4] of $K^{\uparrow}$ is given by

$$\hat{K} = pr((\mu^*\alpha\mu^*\beta\mu^*(\gamma_1 + \gamma_2)\mu^*\eta\mu)^*).$$

Since $\hat{K}$ is obtained from $K^{\uparrow}$ by disabling certain occurrences of the controllable event α, it is controllable. The fact that $\hat{K}$ is controllable also follows from the fact that it equals the closed and observable sublanguage of $K^{\uparrow}$, computed using the formula given in [13, Eq. 10], and the fact that controllability is preserved under such a computation [13, Thm. 5]. Since normality implies observability [16], it follows from Thm. 5 that $\hat{K}$ can be obtained as the closed-loop language by using an appropriate PSC-based supervisor, one choice being $S := \det(\Pi_\Gamma(\hat{K}))$.

While the supervisor $S = \det(\Pi_\Gamma(\hat{K}))$ is minimally restrictive, it possesses an undesirable trait: S can execute arbitrarily long sequences of the driven event μ. Since the plant can never execute more than one μ in succession, all but at most one of a sequence of μ's requested by the supervisor will be refused by the plant. We can remove this redundancy by replacing $\hat{K}$ by the sublanguage $\hat{K}' := pr((\alpha\beta(\gamma_1 + \gamma_2)\eta\mu)^*)$. $\hat{K}'$ is obtained by removing the self-loops on μ from $\hat{K}$, and is also both controllable and observable. By Theorem 5, the PSC-based supervisor $S' := \det(\Pi_\Gamma(\hat{K}'))$ will impose $\hat{K}'$ as the closed-loop language. A minimal state machine realization $\S'$ for the deterministic trajectory model S' is shown in Fig. 4(b), and the resulting closed-loop NSM $\mathcal{P}\ {}_A\|_B\ \S'$ is depicted in Fig. 4(c). The closed-loop language $\hat{K}'$ does not contain λ yet permits γ_1 and γ_2 to be executed arbitrarily many times. Hence, the dual objectives of preventing jamming and permitting cyclic operation are met.

The supervisor $\S'$ implements the following control strategy: $\S'$ tracks the inputting, commencement of processing, and completion/outputting of each part by executing α, β and η synchronously with $\mathcal{P}$. Between the synchronous executions of β and η, the plant executes either γ_1 or γ_2 without the participation or knowledge of the supervisor. Following the synchronous execution of η, the supervisor requests execution of the realignment event μ. If the mechanism is misaligned, i.e., γ_2 has preceded η, then the plant executes μ synchronously with the supervisor. This corrects the alignment and returns the plant to its initial state. On the other hand, if misalignment has not occurred, i.e., γ_1 has preceded η, then the plant refuses μ and this event occurs solely in the supervisor. The possibility that the plant can refuse an event offered by the supervisor is an essential feature of this control design.

7. Conclusion. In this paper we have studied the supervisory control of nondeterministic plants in the presence of driven events under complete as well as partial observation. We have shown that prioritized synchronous composition is an adequate control mechanism for this purpose. The trajectory model, used for describing the behavior of nondeterministic systems, is shown to be a language congruence with respect to prioritized synchronous composition. Hence it is quite useful for describing the behaviors of nondeterministic systems which may be controlled via PSC. It is shown that the supervisory control problem with driven events is solvable if and only if the target language is controllable and observable with respect to the language of the plant augmented by the set of driven events. In case the languages involved are regular, one way to perform the test for controllability/observability is to construct a deterministic system and language equivalent to the augmented plant, and apply a known test for controllability/observability [23], [14], [26]. However, it can be shown that by modifying the algorithms in these references, the tests can be performed without having to do such a nondeterministic to deterministic conversion. Hence it is possible to obtain algorithms of polynomial complexity (polynomial in the product of the number of states in the given plant NSM and that in the deterministic generator of the desired language) for testing controllability/observability. Due to the augmentation, the solvability depends on the trajectory model of the plant—not simply on its language. We have also described the associativity and augmentation properties of PSC, which are useful in the analysis of supervisory control.

Appendix A. Proof of Theorems 2 and 3.

Proof of Theorem 2. Let $\mathcal{R} = \mathcal{P}\ {}_A\|_B\ \mathcal{Q}$. First, we show that

$$T(\mathcal{R}) \subseteq T(\mathcal{P})\ {}_A\|_B\ T(\mathcal{Q}). \tag{16}$$

We prove by induction on length of refusal-trace that if $e \in T(\mathcal{R})$ and $x_r = (x_p, x_q) \in \delta^T_{\mathcal{R}}(x^0_{\mathcal{R}}, e)$, then there exist $e_p \in T(\mathcal{P})$, $e_q \in T(\mathcal{Q})$ such that

(i) the final refusal sets of e_p, e_q are $\Re_{\mathcal{P}}(x_p)$, $\Re_{\mathcal{Q}}(x_q)$, respectively;

(ii) $e \in e_p\ {}_A\|_B\ e_q$;

(iii) $x_r \in \delta^T_{\mathcal{P}}(x^0_{\mathcal{P}}, e_p) \times \delta^T_{\mathcal{Q}}(x^0_{\mathcal{Q}}, e_q)$.

Consider a zero-length refusal-trace $e = \Sigma' \in T(\mathcal{R})$. Then there exists $x_r = (x_p, x_q) \in \epsilon^*_{\mathcal{R}}(x^0_{\mathcal{R}})$ such that $\Sigma' \subseteq \Re_{\mathcal{R}}(x_r)$. Lemma 3 implies that $x_p \in \epsilon^*_{\mathcal{P}}(x^0_{\mathcal{P}})$, $x_q \in$

$\epsilon^*_{\mathcal{Q}}(x^0_{\mathcal{Q}})$, $\Sigma' \subseteq \Re_{\mathcal{P}}(x_p) \, {}_A\!\bigotimes_B \Re_{\mathcal{Q}}(x_q)$. Setting $e_p = \Re_{\mathcal{P}}(x_p)$, $e_q = \Re_{\mathcal{Q}}(x_q)$, it follows that (i), (ii), (iii) are satisfied.

For the induction step, consider a refusal-trace $e = \bar{e}(\sigma, \Sigma') \in T(\mathcal{R})$. Then there exist $\bar{x}_r = (\bar{x}_p, \bar{x}_q) \in \delta^T_{\mathcal{R}}(x^0_{\mathcal{R}}, \bar{e})$, $x'_r = (x'_p, x'_q) \in \delta_{\mathcal{R}}(\bar{x}_r, \sigma)$, $x_r = (x_p, x_q) \in \epsilon^*_{\mathcal{R}}(x'_r)$ such that $\Sigma' \subseteq \Re_{\mathcal{R}}(x_r)$. By induction hypothesis, there exist $\bar{e}_p \in T(\mathcal{P})$, $\bar{e}_q \in T(\mathcal{Q})$ with final refusal sets $\Re_{\mathcal{P}}(\bar{x}_p)$, $\Re_{\mathcal{Q}}(\bar{x}_q)$, respectively, such that $\bar{e} \in \bar{e}_p \, {}_A\|_B \, \bar{e}_q, \bar{x}_p \in \delta^T_{\mathcal{P}}(x^0_{\mathcal{P}}, \bar{e}_p), \bar{x}_q \in \delta^T_{\mathcal{Q}}(x^0_{\mathcal{Q}}, \bar{e}_q)$. Since σ is executable in $\bar{x}_r$, it follows from Definition 9 that there are three cases:

(a) $\delta_{\mathcal{P}}(\bar{x}_p, \sigma) \neq \emptyset$, $\delta_{\mathcal{Q}}(\bar{x}_q, \sigma) \neq \emptyset$;
(b) $\delta_{\mathcal{P}}(\bar{x}_p, \sigma) \neq \emptyset$, $\sigma \in \Re_{\mathcal{Q}}(\bar{x}_q)$, $\sigma \notin B$;
(c) $\delta_{Q}(\bar{x}_q, \sigma) \neq \emptyset$, $\sigma \in \Re_{\mathcal{P}}(\bar{x}_p)$, $\sigma \notin A$.

By symmetry, it suffices to consider cases (a) and (b).

In case (a), $x'_p \in \delta_{\mathcal{P}}(\bar{x}_p, \sigma)$, $x'_q \in \delta_{\mathcal{Q}}(\bar{x}_q, \sigma)$. Setting $e_p = \bar{e}_p(\sigma, \Re_{\mathcal{P}}(x_p))$, $e_q = \bar{e}_q(\sigma, \Re_{\mathcal{Q}}(x_q))$, and using the fact that

$$(17) \qquad \Sigma' \subseteq \Re_{\mathcal{R}}(x_r) = \Re_{\mathcal{P}}(x_p) \, {}_A\!\bigotimes_B \Re_{\mathcal{Q}}(x_q),$$

it follows easily that $e_p \in T(\mathcal{P})$, $e_q \in T(\mathcal{Q})$, and conditions (i), (ii), (iii) are satisfied.

In case (b), $x'_p \in \delta_{\mathcal{P}}(\bar{x}_p, \sigma)$, $x'_q = \bar{x}_q$. Set $e_p = \bar{e}_p(\sigma, \Re_{\mathcal{P}}(x_p))$ and let e_q be the refusal-trace obtained from $\bar{e}_q$ by replacing its final refusal set $\Re_{\mathcal{Q}}(\bar{x}_q)$ with the set $\Re_{\mathcal{Q}}(x_q)$. (Since $x_q \in \epsilon^*_{\mathcal{Q}}(\bar{x}_q)$, the new final refusal set will contain the old final refusal set.) Then $e_p \in T(\mathcal{P})$, $e_q \in T(\mathcal{Q})$ and conditions (i), (iii) are clearly satisfied. It follows from Definition 10 that $\bar{e} \in \bar{e}_p \, {}_A\|_B \, \bar{e}_q \subseteq \bar{e}_p \, {}_A\|_B \, e_q$. Since $\sigma \in \Re_{\mathcal{Q}}(\bar{x}_q) \subseteq \Re_{\mathcal{Q}}(x_q)$, it follows from property (T5) that $e_q(\sigma, \emptyset) \notin T(\mathcal{Q})$. Since $\sigma \notin B$ and (17) holds, it follows from Definition 10 that condition (ii) is satisfied. This completes the induction step and establishes (16).

It remains to show that

$$(18) \qquad T(\mathcal{P}) \, {}_A\|_B \, T(\mathcal{Q}) \subseteq T(\mathcal{R}).$$

We prove by induction on $|e_p| + |e_q|$ that if $e \in e_p \, {}_A\|_B \, e_q$ with $e_p \in T(\mathcal{P})$, $e_q \in T(\mathcal{Q})$, then

$$(19) \qquad \delta^T_{\mathcal{P}}(x^0_{\mathcal{P}}, e_p) \times \delta^T_{\mathcal{Q}}(x^0_{\mathcal{Q}}, e_q) \subseteq \delta^T_{\mathcal{R}}(x^0_{\mathcal{R}}, e).$$

Since the set on the left side is nonempty by assumption, this implies that the set on the right side is nonempty, i.e., that $e \in T(\mathcal{R})$.

Let $e_p = \Sigma_p$, $e_q = \Sigma_q$ be zero-length refusal-traces of $\mathcal{P}$, $\mathcal{Q}$, respectively, and let $x_p \in \delta^T_{\mathcal{P}}(x^0_{\mathcal{P}}, \Sigma_p)$, $x_q \in \delta^T_{\mathcal{Q}}(x^0_{\mathcal{Q}}, \Sigma_q)$. Then $x_p \in \epsilon^*_{\mathcal{P}}(x^0_{\mathcal{P}}), x_q \in \epsilon^*_{\mathcal{Q}}(x^0_{\mathcal{Q}}), \Sigma_p \subseteq \Re_{\mathcal{P}}(x_p), \Sigma_q \subseteq \Re_{\mathcal{Q}}(x_q)$. Let $x_r = (x_p, x_q)$. Then $x_r \in \epsilon^*_{\mathcal{R}}(x^0_{\mathcal{R}})$. It follows from Definition 10 and Lemma 3 that $e = \Sigma'$ with $\Sigma' \subseteq \Sigma_p \, {}_A\!\bigotimes_B \Sigma_q \subseteq \Re_{\mathcal{P}}(x_p) \, {}_A\!\bigotimes_B \Re_{\mathcal{Q}}(x_q) = \Re_{\mathcal{R}}(x_r)$. This shows that $x_r \in \delta^T_{\mathcal{R}}(x^0_{\mathcal{R}}, \Sigma')$, so (19) holds in the zero-length case.

For the induction step, write $e_p = \bar{e}_p(\sigma_p, \Sigma_p)$, $e_q = \bar{e}_q(\sigma_q, \Sigma_q)$, and suppose $e = \bar{e}(\sigma, \Sigma') \in e_p \, {}_A\|_B \, e_q$. It follows from Definition 10 that there are three cases to consider:

(d) $\sigma = \sigma_p = \sigma_q$, $\bar{e} \in \bar{e}_p \, {}_A\|_B \, \bar{e}_q$, $\Sigma' \subseteq \Sigma_p \, {}_A\!\bigotimes_B \Sigma_q$;
(e) $\sigma = \sigma_p$, $\sigma \notin B$, $e_q(\sigma, \emptyset) \notin T(\mathcal{Q})$, $\bar{e} \in \bar{e}_p \, {}_A\|_B \, e_q$, $\Sigma' \subseteq \Sigma_p \, {}_A\!\bigotimes_B \Sigma_q$;
(f) $\sigma = \sigma_q$, $\sigma \notin A$, $e_p(\sigma, \emptyset) \notin T(\mathcal{P})$, $\bar{e} \in e_p \, {}_A\|_B \, \bar{e}_q$, $\Sigma' \subseteq \Sigma_p \, {}_A\!\bigotimes_B \Sigma_q$.

By symmetry, it suffices to consider cases (d), (e).

For case (d), let $x_r = (x_p, x_q) \in \delta^T_{\mathcal{P}}(x^0_{\mathcal{P}}, e_p) \times \delta^T_{\mathcal{Q}}(x^0_{\mathcal{Q}}, e_q)$. Then $\Sigma_p \subseteq \Re_{\mathcal{P}}(x_p)$, $\Sigma_q \subseteq \Re_{\mathcal{Q}}(x_q)$, so

$$(20) \qquad \Sigma' \subseteq \Sigma_p \, {}_A\!\bigotimes_B \Sigma_q \subseteq \Re_{\mathcal{P}}(x_p) \, {}_A\!\bigotimes_B \Re_{\mathcal{Q}}(x_q)) = \Re_{\mathcal{R}}(x_r).$$

Since $x_p \in \delta^T_{\mathcal{P}}(x^0_{\mathcal{P}}, e_p)$, $x_q \in \delta^T_{\mathcal{Q}}(x^0_{\mathcal{Q}}, e_q)$, there exist $\bar{x}_p \in \delta^T_{\mathcal{P}}(x^0_{\mathcal{P}}, \bar{e}_p)$, $\bar{x}_q \in \delta^T_{\mathcal{Q}}(x^0_{\mathcal{Q}}, \bar{e}_q)$, $x'_p \in \delta_{\mathcal{P}}(\bar{x}_{\mathcal{P}}, \sigma)$, $x'_q \in \delta_{\mathcal{Q}}(\bar{x}_{\mathcal{Q}}, \sigma)$ such that $x_p \in \epsilon^*_{\mathcal{P}}(x'_p)$, $x_q \in \epsilon^*_{\mathcal{Q}}(x'_q)$. Let $\bar{x}_r = (\bar{x}_p, \bar{x}_q)$. It follows from Definition 9 that $(x'_p, x'_q) \in \delta_R(\bar{x}_r, \sigma)$, while by induction hypothesis we may assume that $\bar{x}_r \in \delta^T_{\mathcal{R}}(x^0_{\mathcal{R}}, \bar{e})$. Then

$$x_r \in \epsilon^*_{\mathcal{R}}((x'_p, x'_q)) \subseteq \epsilon^*_{\mathcal{R}}(\delta_{\mathcal{R}}(\bar{x}_r, \sigma)) \subseteq \epsilon^*_{\mathcal{R}}(\delta_{\mathcal{R}}(\delta^T_{\mathcal{R}}(x^0_{\mathcal{R}}, \bar{e}), \sigma)). \tag{21}$$

We conclude from (20) and (21) that $x_r \in \delta^T_{\mathcal{R}}(x^0_{\mathcal{R}}, e)$ as required.

For case (e), let $x_r = (x_p, x_q) \in \delta^T_{\mathcal{P}}(x^0_{\mathcal{P}}, e_p) \times \delta^T_{\mathcal{Q}}(x^0_{\mathcal{Q}}, e_q)$. The inclusions given by (20) hold as in the previous case. Since $x_p \in \delta^T_{\mathcal{P}}(x^0_{\mathcal{P}}, e_p)$, there exist $\bar{x}_p \in \delta^T_{\mathcal{P}}(x^0_{\mathcal{P}}, \bar{e}_p)$ and $x'_p \in \delta_{\mathcal{P}}(\bar{x}_{\mathcal{P}}, \sigma)$ such that $x_p \in \epsilon^*_{\mathcal{P}}(x'_p)$. Let $\bar{x}_r = (\bar{x}_p, x_q)$. We have $\delta_{\mathcal{Q}}(\epsilon^*_{\mathcal{Q}}(x_q), \sigma) \subseteq \delta_{\mathcal{Q}}(\delta^T_{\mathcal{Q}}(x^0_{\mathcal{Q}}, e_q), \sigma) = \emptyset$, where the final equality follows from the assumption that $e_q(\sigma, \emptyset) \notin T(\mathcal{Q})$. This implies that $\sigma \in \mathfrak{R}_{\mathcal{Q}}(x_q)$. It then follows from Definition 9 that $(x'_p, x_q) \in \delta_{\mathcal{R}}(\bar{x}_r, \sigma)$, while by induction hypothesis, we may assume that $\bar{x}_r \in \delta^T_{\mathcal{R}}(x^0_{\mathcal{R}}, \bar{e})$. Then

$$x_r \in \epsilon^*_{\mathcal{R}}((x'_p, x_q)) \subseteq \epsilon^*_{\mathcal{R}}(\delta_{\mathcal{R}}(\bar{x}_r, \sigma)) \subseteq \epsilon^*_{\mathcal{R}}(\delta_{\mathcal{R}}(\delta^T_{\mathcal{R}}(x^0_{\mathcal{R}}, \bar{e}), \sigma)). \tag{22}$$

We conclude from (20) and (22) that $x_r \in \delta^T_{\mathcal{R}}(x^0_{\mathcal{R}}, e)$ as required. This completes the induction step and establishes (18). □

The following result was proved in the course of the proof of Theorem 2.

COROLLARY 5. *For* NSM*s* $\mathcal{P}, \mathcal{Q}$ *and* $A, B \subseteq \Sigma$, *let* $\mathcal{R} := \mathcal{P}\ {}_A\|_B\ \mathcal{Q}$. *Then*

(1) *for each* $e \in T(\mathcal{R})$ *and* $x_r = (x_p, x_q) \in \delta^T_{\mathcal{R}}(x^0_{\mathcal{R}}, e)$, *there exists* $e_p \in T(\mathcal{P})$ *and* $e_q \in T(\mathcal{Q})$ *such that* $\Sigma_{|e_p|}(e_p) = \mathfrak{R}_{\mathcal{P}}(x_p), \Sigma_{|e_q|}(e_q) = \mathfrak{R}_{\mathcal{Q}}(x_q)$, $e \in e_p\ {}_A\|_B\ e_q$, *and* $x_r \in \delta^T_{\mathcal{P}}(x^0_{\mathcal{P}}, e_p) \times \delta^T_{\mathcal{Q}}(x^0_{\mathcal{Q}}, e_q)$;

(2) *for each* $e_p \in T(\mathcal{P}), e_q \in T(\mathcal{Q})$ *and* $e \in e_p\ {}_A\|_B\ e_q$; $\delta^T_{\mathcal{P}}(x^0_{\mathcal{P}}, e_p) \times \delta^T_{\mathcal{Q}}(x^0_{\mathcal{Q}}, e_q) \subseteq \delta^T_{\mathcal{R}}(x^0_{\mathcal{R}}, e)$.

In order to prove Theorem 3 we will use the following result which gives a monotonicity property of the PSC of refusal-traces with respect to the dominance partial order.

LEMMA 6. *Let* P, Q *be trajectory models,* $A, B \subseteq \Sigma$, $f_p, e_p \in P$, $f_q, e_q \in Q$, *with* $f_p \sqsubseteq e_p$, $f_q \sqsubseteq e_q$. *Then* $f_p\ {}_A\|_B\ f_q \subseteq e_p\ {}_A\|_B\ e_q$.

Proof. The proof is by induction on the sum of refusal-trace lengths $|e_p| + |e_q|$. If $|e_p| + |e_q| = 0$, then $f_p = \hat{\Sigma}_p$, $e_p = \Sigma_p$, $f_q = \hat{\Sigma}_q$, $e_q = \Sigma_q$ with $\hat{\Sigma}_p \subseteq \Sigma_p$, $\hat{\Sigma}_q \subseteq \Sigma_q$. Let $f \in f_p\ {}_A\|_B\ f_q$. Then $f = \Sigma' \subseteq \hat{\Sigma}_p\ {}_A\bigotimes_B\ \hat{\Sigma}_q \subseteq \Sigma_p\ {}_A\bigotimes_B\ \Sigma_q$. Thus, $f \in e_p\ {}_A\|_B\ e_q$.

For the induction step, write $f_p = \bar{f}_p(\sigma_p, \hat{\Sigma}_p)$, $e_p = \bar{e}_p(\sigma_p, \Sigma_p)$, $f_q = \bar{f}_q(\sigma_q, \hat{\Sigma}_q)$, $e_q = \bar{e}_q(\sigma_q, \Sigma_q)$ with $\bar{f}_p \sqsubseteq \bar{e}_p$, $\hat{\Sigma}_p \subseteq \Sigma_p$, $\bar{f}_q \sqsubseteq \bar{e}_q$, $\hat{\Sigma}_q \subseteq \Sigma_q$. Let $f = \bar{f}(\sigma, \Sigma') \in f_p\ {}_A\|_B\ f_q$. There are three cases to consider. (1) Suppose $\bar{f} \in \bar{f}_p\ {}_A\|_B\ \bar{f}_q$, $\sigma = \sigma_p = \sigma_q$, $\Sigma' \subseteq \hat{\Sigma}_p\ {}_A\bigotimes_B\ \hat{\Sigma}_q$. By the induction hypothesis, $\bar{f} \in \bar{e}_p\ {}_A\|_B\ \bar{e}_q$. Since $\Sigma' \subseteq \hat{\Sigma}_p\ {}_A\bigotimes_B\ \hat{\Sigma}_q \subseteq \Sigma_p\ {}_A\bigotimes_B\ \Sigma_q$, this implies that $f \in e_p\ {}_A\|_B\ e_q$. (2) Suppose $\bar{f} \in \bar{f}_p\ {}_A\|_B\ f_q$, $\sigma = \sigma_p \notin B$, $f_q(\sigma, \emptyset) \notin Q$, $\Sigma' \subseteq \hat{\Sigma}_p\ {}_A\bigotimes_B\ \hat{\Sigma}_q$. By induction hypothesis, $\bar{f} \in \bar{e}_p\ {}_A\|_B\ e_q$. Also, $e_q(\sigma, \emptyset) \notin Q$, since otherwise (T3) would imply that $f_q(\sigma, \emptyset) \in Q$, a contradiction. Since $\Sigma' \subseteq \hat{\Sigma}_p\ {}_A\bigotimes_B\ \hat{\Sigma}_q \subseteq \Sigma_p\ {}_A\bigotimes_B\ \Sigma_q$, this implies that $f \in e_p\ {}_A\|_B\ e_q$. (3) Suppose $\bar{f} \in f_p\ {}_A\|_B\ \bar{f}_q$, $\sigma = \sigma_q \notin A$, $f_p(\sigma, \emptyset) \notin P$, $\Sigma' \subseteq \hat{\Sigma}_p\ {}_A\bigotimes_B\ \hat{\Sigma}_q$. This case is analogous to case (2). Hence, the induction step is complete. □

Proof of Theorem 3. By symmetry, it suffices to prove the inclusion

$$(P\ {}_A\|_B\ Q)\ {}_{A \cup B}\|_C\ R \subseteq P\ {}_A\|_{B \cup C}\ (Q\ {}_B\|_C\ R).$$

By Lemma 6, it suffices to show that if e_p, e_q, e_r are *saturated* refusal-traces of P, Q, R respectively, then $(e_p\;{}_A\|_B\;e_q)\;{}_{A\cup B}\|_C\;e_r \subseteq P\;{}_A\|_{B\cup C}\;(Q\;{}_B\|_C\;R)$. To prove this, we show by induction on the sum of the lengths $|e_p| + |e_q| + |e_r|$ that

$$(e_p\;{}_A\|_B\;e_q)\;{}_{A\cup B}\|_C\;e_r \subseteq e_p\;{}_A\|_{B\cup C}\;(e_q\;{}_B\|_C\;e_r). \tag{23}$$

For future reference, we note that the following identity holds:

$$\begin{aligned}(\Sigma_p\;{}_A\!\bigotimes_B\Sigma_q)\;{}_{A\cup B}\!\bigotimes_C\Sigma_r &= (\Sigma_p\cap\Sigma_q\cap\Sigma_r)\cup(\Sigma_p\cap A)\cup(\Sigma_q\cap B)\cup(\Sigma_r\cap C)\\ &= \Sigma_p\;{}_A\!\bigotimes_{B\cup C}(\Sigma_q\;{}_B\!\bigotimes_C\Sigma_r) := \hat\Sigma\end{aligned} \tag{24}$$

If $e_p = \Sigma_p$, $e_q = \Sigma_q$, $e_r = \Sigma_r$ each have zero-length, then $(e_p\;{}_A\|_B\;e_q)\;{}_{A\cup B}\|_C\;e_r$ consists of all subsets of $(\Sigma_p\;{}_A\!\bigotimes_B\Sigma_q)\;{}_{A\cup B}\!\bigotimes_C\Sigma_r$, while $e_p\;{}_A\|_{B\cup C}\;(e_q\;{}_B\|_C\;e_r)$ consists of all subsets of $\Sigma_p\;{}_A\!\bigotimes_{B\cup C}(\Sigma_q\;{}_B\!\bigotimes_C\Sigma_r)$. Thus, (23) follows from (24).

For the induction step, let $e_p = \bar e_p(\sigma_p, \Sigma_p)$, $e_q = \bar e_q(\sigma_q, \Sigma_q)$, $e_r = \bar e_r(\sigma_r, \Sigma_r)$. $\bar e_p$, $\bar e_q$, $\bar e_r$ are saturated since they are prefixes of saturated refusal-traces. Let $f \in e_p\;{}_A\|_B\;e_q$ and let $h \in f\;{}_{A\cup B}\|_C\;e_r \subseteq (e_p\;{}_A\|_B\;e_q)\;{}_{A\cup B}\|_C\;e_r$. Let $h = \bar h(\sigma, \hat\Sigma)$. (There is no loss of generality in taking the final refusal set of h to be the maximal set $\hat\Sigma$.) To establish the induction step, we consider several cases. (Some cases will not apply if at least one of the refusal-traces e_p, e_q, e_r has zero-length.)

(1) $\bar h \in f\;{}_{A\cup B}\|_C\;\bar e_r, \sigma \notin A\cup B$, $f(\sigma,\emptyset) \notin P\;{}_A\|_B\;Q$, $\sigma = \sigma_r$. (This is when the final event in h occurs in R but not in $P\;{}_A\|_B\;Q$.)

(2a) $\bar h \in \bar f\;{}_{A\cup B}\|_C\;e_r$, $\sigma \notin C$, $e_r(\sigma,\emptyset) \notin R$, $\sigma = \sigma_p$, $\bar f \in \bar e_p\;{}_A\|_B\;e_q$, $\sigma \notin B$, $e_q(\sigma,\emptyset) \notin Q$. (This is when the final event in h occurs in $P\;{}_A\|_B\;Q$ but not in R, and within $P\;{}_A\|_B\;Q$, it occurs in P but not in Q.)

(2b) $\bar h \in \bar f\;{}_{A\cup B}\|_C\;e_r$, $\sigma \notin C$, $e_r(\sigma,\emptyset) \notin R$, $\sigma = \sigma_q$, $\bar f \in e_p\;{}_A\|_B\;\bar e_q$, $\sigma \notin A$, $e_p(\sigma,\emptyset) \notin P$. (This is when the final event in h occurs in $P\;{}_A\|_B\;Q$ but not in R, and within $P\;{}_A\|_B\;Q$, it occurs in Q but not in P.)

(2c) $\bar h \in \bar f\;{}_{A\cup B}\|_C\;e_r$, $\sigma \notin C$, $e_r(\sigma,\emptyset) \notin R$, $\sigma = \sigma_p = \sigma_q$, $\bar f \in \bar e_p\;{}_A\|_B\;\bar e_q$. (This is when the final event in h occurs in $P\;{}_A\|_B\;Q$ but not in R, and within $P\;{}_A\|_B\;Q$, it occurs in both P and Q.)

(3a) $\bar h \in \bar f\;{}_{A\cup B}\|_C\;\bar e_r$, $\sigma = \sigma_p = \sigma_r$, $\bar f \in \bar e_p\;{}_A\|_B\;e_q$, $\sigma \notin B$, $e_q(\sigma,\emptyset) \notin Q$. (This is when the final event in h occurs in $P\;{}_A\|_B\;Q$ and in R, and within $P\;{}_A\|_B\;Q$, it occurs in P but not in Q.)

(3b) $\bar h \in \bar f\;{}_{A\cup B}\|_C\;\bar e_r$, $\sigma = \sigma_q = \sigma_r$, $\bar f \in e_p\;{}_A\|_B\;\bar e_q$, $\sigma \notin A$, $e_p(\sigma,\emptyset) \notin P$. (This is when the final event in h occurs in $P\;{}_A\|_B\;Q$ and in R, and within $P\;{}_A\|_B\;Q$, it occurs in Q but not in P.)

(3c) $\bar h \in \bar f\;{}_{A\cup B}\|_C\;\bar e_r$, $\sigma = \sigma_p = \sigma_q = \sigma_r$, $\bar f \in \bar e_p\;{}_A\|_B\;\bar e_q$. (This is when the final event in h occurs in $P\;{}_A\|_B\;Q$ and in R, and within $P\;{}_A\|_B\;Q$, it occurs in both P and Q.)

We include a detailed proof for case (2a). The other cases are proven in a similar manner and are left to the reader. Under the assumptions of (2a),

$$\bar h \in \bar f\;{}_{A\cup B}\|_C\;e_r \subseteq (\bar e_p\;{}_A\|_B\;e_q)\;{}_{A\cup B}\|_C\;e_r \subseteq \bar e_p\;{}_A\|_{B\cup C}\;(e_q\;{}_B\|_C\;e_r),$$

where the last inclusion is the induction hypothesis. Thus, there exists

$$g = \bar g(\sigma', \Sigma_q\;{}_B\!\bigotimes_C\Sigma_r) \in e_q\;{}_B\|_C\;e_r$$

with $\sigma' \in \{\sigma_q, \sigma_r\}$ such that $\bar h \in \bar e_p\;{}_A\|_{B\cup C}\;g$. (By Lemma 6, there is no loss of generality in taking the final refusal set of g to be the maximal set $\Sigma_q\;{}_B\!\bigotimes_C\Sigma_r$.)

Since $e_q(\sigma,\emptyset) \notin Q$ and $e_r(\sigma,\emptyset) \notin R$, it follows from the assumption that e_q and e_r are saturated such that $\sigma \in \Sigma_q$ and $\sigma \in \Sigma_r$. Thus, $\sigma \in \Sigma_q \cap \Sigma_r \subseteq \Sigma_q\, {}_B\!\bigotimes_C \Sigma_r$. By (T5), $g(\sigma,\emptyset) \notin Q\, {}_B\|_C\, R$. This together with $\sigma \notin B \cup C$, implies that

$$h = \bar{h}(\sigma,\hat{\Sigma}) = \bar{h}(\sigma, \Sigma_p\, {}_A\!\bigotimes_{B\cup C}(\Sigma_q\, {}_B\!\bigotimes_C \Sigma_r)) \in e_p\, {}_A\|_{B\cup C}\, g \subseteq e_p\, {}_A\|_{B\cup C}\, (e_q\, {}_B\|_C\, e_r),$$

completing the induction step. □

RISK-SENSITIVE PRODUCTION PLANNING OF STOCHASTIC MANUFACTURING SYSTEMS: A SINGULAR PERTURBATION APPROACH*

QING ZHANG†

Abstract. This paper is concerned with robust production planning of a stochastic manufacturing system in which the rate of machine breakdown and repair is much larger than the rate of fluctuation in demand. It is shown that the risk-sensitive production planning problem can be approximated by a limiting problem in which the stochastic machine availability process is replaced by its mean availability. The value function of the limiting problem is shown to be the only viscosity solution to the Isaacs equation associated with a zero-sum, two-player differential game. Near-optimal production plans are constructed from near-optimal controls of the limiting problem. Finally, these results are extended to problems with state constraints.

Key words. stochastic manufacturing systems, risk-sensitive control, differential games, Isaacs equations, viscosity solutions, near-optimal production planning

AMS subject classifications. 93E20, 90B30

1. Introduction.

Most manufacturing systems are large complex systems. Because of the large size of these systems, exact optimal policies for running them are quite difficult to obtain, both theoretically and computationally. One way to cope with these complexities is to develop methods of hierarchical controls for these systems. The idea of hierarchical control is to reduce the overall complex problem into manageable approximate problems or subproblems, solve these problems, and construct a solution for the original problem from solutions of these simpler problems. Development of such approaches for large complex systems has been identified as a particularly fruitful research area by the Committee on the Next Decade in Operations Research [3] as well as by the Panel on Future Directions in Control Theory [7]. A great deal of research in hierarchical control has been conducted by researchers in the areas of operations research, operations management, system theory, and control theory. Related literature can be found in recent papers by Rogers et al. [16], Saksena, O'Reilly, and Kokotovic [17], Gershwin [11], Lehoczky et al. [15], Soner [24], and the book by Sethi and Zhang [19].

An interesting approach in hierarchical control is the singular perturbation method. To illustrate this approach, let us consider a manufacturing system which consists of machines that are subject to breakdown and repair and which faces an uncertain demand. The objective of the system is to obtain the rate of production over time in order to meet the demand at the minimum expected discounted cost of production and inventory/shortages over the infinite horizon. Because of the uncertainties in machine availability and product demand, the exact optimal solution of such a problem is very difficult to obtain. To reduce the complexity, we consider the case in which the rate at which the machine breakdown and repair events occur is much larger than the rate of fluctuation in demand. The idea of a singular perturbation approach is to derive a limiting control problem, which is easier to solve than the original problem. This limiting problem is obtained by replacing the stochastic machine availability

process by the average total capacity of machines and by appropriately modifying the objective function. From its optimal control, one constructs an approximate optimal control of the original, more complex, problem. Research along this line can be found in Lehoczky et al. [15], Soner [24], Sethi and Zhang [20], [19], and Sethi, Zhang, and Zhou [21].

In this paper, we consider robust production plans of stochastic manufacturing systems with a risk-sensitive cost function (cf. Whittle [25]). This consideration is motivated by the following observations. First, since most manufacturing systems are large complex systems, it is very difficult to establish accurate mathematical models to describe them. Modeling errors are inevitable. Second, in practice, an optimal policy for a subdivision of a big corporation is usually not an optimal policy for the whole corporation. Therefore, optimal solutions with actual cost criteria may not be desirable in many real problems. An alternative approach is to consider robust controls. The design of robust controls emphasizes system stability rather than optimality. In some manufacturing systems, it is more desirable to consider controls that are robust enough to attenuate uncertain disturbances, which include modeling errors, and therefore to achieve the system stability. Robust control design is particularly important in manufacturing systems with unfavorable disturbances. There are two kinds of system disturbances in the system under consideration: (1) unfavorable internal disturbances—usually associated with unfavorable machine capacity fluctuations; (2) unfavorable external disturbances—usually associated with unfavorable fluctuations in demand.

The basic idea of the risk-sensitive control is to consider a risk-sensitive cost function that penalizes heavily on costs associated with large state trajectories and controls. Related literature on risk-sensitive control can be found, for example, in Whittle [25], Fleming and McEneaney [8], [9], James [14], and Glover and Doyle [12].

In [8], [14], risk-sensitive control problems of controlled diffusions are considered. Using the associated dynamic programming equations, the authors show that as the system noise goes to zero, the value function of the risk-sensitive control problem converges to the value function of a differential game problem. Then, a near-optimal policy for the differential game problem can be shown to be a near-optimal control for the risk-sensitive control problem. In this paper, we consider the risk-sensitive control of the manufacturing systems with stochastic production capacity and stochastic product demand. As the rate of fluctuation of the production capacity process goes to infinity, we show that the risk-sensitive control problem can be approximated by a limiting problem in which the stochastic capacity process can be averaged out and replaced by its average. We also show that the value function of the limiting problem satisfies the Isaacs equation of a zero-sum, two-player differential game. Then, we use a near-optimal control of the limiting problem to construct a near-optimal control for the original risk-sensitive control problem. In this paper, the machine capacity process will be assumed to be a finite state (jump) Markov chain. Our formulation is similar to that of [8], [14]. Because of the presence of the jump Markov disturbance processes, the dynamic programming approach used in [8], [14] will not work in our problem. To obtain the desired results, we first prove an asymptotic property of the machine capacity process (Lemma 3.1). Then, we use a combination of a probabilistic approach and a weak convergence approach to derive the convergence of the associated value functions (Theorems 4.1, 5.1, and 6.1) to the value function of a limiting problem. We show that the value function of the limiting problem is the only viscosity solution to the associated Isaacs equation (Theorem 5.2).

The plan of the paper is as follows. In the next section, we consider a relatively simple model of manufacturing systems. We formulate the risk-sensitive control problem and make some assumptions on the cost function and stochastic processes of the system. In §3, we give asymptotic estimates on the machine capacity process. Then, in §4 and §5, we show that the value function of the risk-sensitive control problem converges to the value function of a limiting problem that has a differential game interpretation. In §6, we construct near-optimal production plans for the original problem. In §7, we extend the results to a class of manufacturing systems with internal buffers. We present only the results obtained by considering a two-machine flowshop for simplicity in exposition. Finally, we conclude the paper by making some remarks.

2. Problem formulation. We consider a manufacturing system that produces n_0 distinct part types using m identical machines. Let $u_t \in R^{n_0}$ denote the vector of production rates, $x_t \in R^{n_0}$ denote the vector of total inventories/backlogs, and $z_t \in R^{n_0}$ denote the vector of demand rates. They satisfy the following system equation:

$$\dot{x}_t = u_t - z_t,\ x_0 = a \in R^{n_0}\ (a \text{ is given}). \tag{2.1}$$

We consider the manufacturing system that consists of machines that are subject to breakdown and repair. Let $\mathcal{M} = \{0, 1, \ldots, m\}$ denote the set of machine capacity states and let a random process $\alpha(\varepsilon, t) \in \mathcal{M}$, defined on a standard probability space $(\Omega, \mathcal{F}, P)$, denote the total capacity process for the manufacturing system, where ε is a small parameter to be specified later in this section. Since only a finite amount of production capacity is available at any given time t, it would impose an upper bound on the production rate u_t. For example, in the one-dimensional case ($n_0 = 1$), the production constraint is $0 \le u_t \le \alpha(\varepsilon, t)$.

We consider the risk sensitive cost function $J^{\varepsilon,\sqrt{\varepsilon}}(u.)$ defined by

$$J^{\varepsilon,\sqrt{\varepsilon}}(u.) = \sqrt{\varepsilon}\log E\left[\exp\left\{\frac{1}{\sqrt{\varepsilon}}\int_0^\infty e^{-\rho t}[h(x_t) + c(u_t)]dt\right\}\right], \tag{2.2}$$

where h is the inventory/backlog cost, c is the production cost, and $\rho > 0$ is the discount rate. The problem is to find an admissible control $u.$ (to be precisely defined later in this section) that minimizes $J^{\varepsilon,\sqrt{\varepsilon}}(u.)$.

In the above problem, we choose the risk-sensitivity parameter $\sqrt{\varepsilon} > 0$. This type of risk-sensitive control problem is classified as a risk-averse problem (cf. [25]). The cost function in (2.2) emphasizes the stability of the system since it penalizes heavily on large trajectory x_t and large control u_t when ε is small.

Notation. We make use of the following notation in this paper:

χ_D	the indicator function of any set D;
$O(y)$	a function of y such that $\sup_y \lvert O(y)\rvert/\lvert y\rvert < \infty$;
A'	the transpose of any matrix (or vector) A;
$\lVert\xi\rVert_\infty$	ess sup$\lvert\xi\rvert$ of any random variable ξ;
$f_x(x)$	the derivative of f at x;
$f_{x^+}(x)$	the right-hand derivative of f at x;
$C, C_0, C_1, \ldots$	multiplicative constants;
$k_h, k_0, k_1, \ldots$	exponential constants.

We now specify the production (or control) constraints. For each $i \in \mathcal{M} = \{0, 1, 2, \ldots, m\}$, let

$$\mathcal{U}(i) = \{l = (l_1, \ldots, l_{n_0}) \geq 0 : p \cdot l \leq i\} \subset R^{n_0}, \tag{2.3}$$

where $p = (p_1, \ldots, p_{n_0}) \geq 0$ are given constants with p_i representing the amount of capacity needed to produce part type i at rate 1. With this definition, the production constraint at time t is $u_t \in \mathcal{U}(\alpha(\varepsilon, t))$.

We make the following assumptions on the functions h and c and the random processes $\alpha(\varepsilon, t)$ and z_t.

(A1) h and c are convex functions. There exist constants C_0 and $k_h > 0$ such that for all x, x', u, and u',

$$\begin{aligned} &0 \leq h(x) \leq C_0(1 + |x|^{k_h}), \\ &|h(x) - h(x')| \leq C_0(1 + |x|^{k_h} + |x'|^{k_h})|x - x'|, \\ \text{and} \quad &|c(u) - c(u')| \leq C_0|u - u'|. \end{aligned}$$

(A2) Let $\varepsilon > 0$ denote a small parameter. The machine capacity process $\alpha(\varepsilon, t) \in \mathcal{M}$ is a finite-state Markov process governed by a generator $Q = Q^{(1)} + \varepsilon^{-1}Q^{(2)}$, where $Q^{(l)}$ is an $(m+1) \times (m+1)$ matrix such that $Q^{(l)} = (q_{ij}^{(l)})$ with $q_{ij}^{(l)} \geq 0$ if $i \neq j$ and $q_{ii}^{(l)} = -\sum_{j \neq i} q_{ij}^{(l)}$ for $l = 1, 2$. Moreover, $Q^{(2)}$ is irreducible.

(A3) The demand rate z_t is a bounded process which is independent of $\alpha(\varepsilon, t)$.

Remark 2.1. Assumptions (A1) and (A2) are used in [15], [20], [21], [22], [23], [27]. Soner [24] considers a model in which Q depends on the control variables. However, due to the jump Markov property of the machine capacity process, the viscosity solution method used in [24] will not work for the risk-sensitive control problem under consideration.

DEFINITION 2.1. *We say that a control* $u. = \{u_t : t \geq 0\}$ *is* admissible *if* u_t *is a* $\sigma\{\alpha(\varepsilon, s), z_s : s \leq t\}$ *adapted measurable process and* $u_t \in \mathcal{U}(\alpha(\varepsilon, t))$ *for all* $t \geq 0$. *We use* $\mathcal{A}^\varepsilon$ *to denote the set of all admissible controls. Then our control problem can be written as follows*:

$$\mathcal{P}^{\varepsilon,\sqrt{\varepsilon}} : \begin{cases} \text{min.} & J^{\varepsilon,\sqrt{\varepsilon}}(u.) \\ & = \sqrt{\varepsilon} \log E\left[\exp\left\{\dfrac{1}{\sqrt{\varepsilon}} \displaystyle\int_0^\infty e^{-\rho t}[h(x_t) + c(u_t)]dt\right\}\right], \\ \text{s.t.} & \dot{x}_t = u_t - z_t, \ x_0 = a, \ u. \in \mathcal{A}^\varepsilon, \\ \text{value fn.} & v^{\varepsilon,\sqrt{\varepsilon}} = \inf\limits_{u. \in \mathcal{A}^\varepsilon} J^{\varepsilon,\sqrt{\varepsilon}}(u.). \end{cases} \tag{2.4}$$

Let $\nu = (\nu_0, \nu_1, \ldots, \nu_m)'$ denote the equilibrium distribution of $Q^{(2)}$. That is, ν is the only positive solution to

$$\nu' Q^{(2)} = 0 \text{ and } \sum_{i=0}^{m} \nu_i = 1.$$

Intuitively, the machine capacity process $\alpha(\varepsilon, t)$ "converges" weakly to its equilibrium distribution as ε tends to zero. This property suggests that the problem $\mathcal{P}^{\varepsilon,\sqrt{\varepsilon}}$

can be approximated by a problem in which the stochastic machine availability is replaced by its equilibrium distribution.

Let $\mathcal{Z}_t$ denote the σ-algebra generated by z_s, $s \le t$, i.e., $\mathcal{Z}_t = \sigma\{z_s : s \le t\}$. As in [21], we consider the following control space:

$$\mathcal{A}^0 = \{U. = (u^0_\cdot, u^1_\cdot, \dots, u^m_\cdot) : u^i_t \in \mathcal{U}(i), \text{ and } U_t \text{ is a } \mathcal{Z}_t \text{ adapted process}\}.$$

We also consider two control problems $\mathcal{P}^{0,\sqrt{\varepsilon}}$ and $\mathcal{P}^{0,0}$ defined as follows:

$$(2.5)\quad \mathcal{P}^{0,\sqrt{\varepsilon}}: \begin{cases} \text{min.} & J^{0,\sqrt{\varepsilon}}(U.) \\ & = \sqrt{\varepsilon}\log\left[E\exp\left\{\frac{1}{\sqrt{\varepsilon}}\int_0^\infty e^{-\rho t}\left[h(x_t)+\sum_{i=0}^m \nu_i c(u^i_t)\right]dt\right\}\right], \\ \text{s.t.} & \dot{x}_t = \sum_{i=0}^m \nu_i u^i_t - z_t,\ x_0 = a,\ U. = (u^0_\cdot, \dots, u^m_\cdot) \in \mathcal{A}^0, \\ \text{value fn.} & v^{0,\sqrt{\varepsilon}} = \inf_{U.\in\mathcal{A}^0} J^{0,\sqrt{\varepsilon}}(U.), \end{cases}$$

and

$$(2.6)\quad \mathcal{P}^{0,0}: \begin{cases} \text{min.} & J^{0,0}(U.) = \left\|\int_0^\infty e^{-\rho t}\left[h(x_t)+\sum_{i=0}^m \nu_i c(u^i_t)\right]dt\right\|_\infty, \\ \text{s.t.} & \dot{x}_t = \sum_{i=0}^m \nu_i u^i_t - z_t,\ x_0 = a,\ U. = (u^0_\cdot, \dots, u^m_\cdot) \in \mathcal{A}^0, \\ \text{value fn.} & v^{0,0} = \inf_{U.\in\mathcal{A}^0} J^{0,0}(U.). \end{cases}$$

We will show that, when ε is small, $\mathcal{P}^{\varepsilon,\sqrt{\varepsilon}}$ can be approximated by $\mathcal{P}^{0,\sqrt{\varepsilon}}$, and $\mathcal{P}^{0,\sqrt{\varepsilon}}$ can be approximated further by $\mathcal{P}^{0,0}$. Therefore, $\mathcal{P}^{\varepsilon,\sqrt{\varepsilon}}$ can be approximated by $\mathcal{P}^{0,0}$. Then, a near optimal control for $\mathcal{P}^{0,0}$ will be used to construct controls for $\mathcal{P}^{\varepsilon,\sqrt{\varepsilon}}$ that are nearly optimal.

3. Asymptotic properties of $\alpha(\varepsilon, t)$.

In this section, we consider an asymptotic property of the process $\alpha(\varepsilon, t)$, which plays a very important role in this paper.

LEMMA 3.1. *For each $N_0 > 0$, there exist constants $\varepsilon_0 > 0$ and C such that for $0 < \varepsilon \le \varepsilon_0$, $i \in \mathcal{M}$, $t \ge 0$, and for any $\mathcal{Z}_t$ adapted process $\beta(t)$, $|\beta(t)| \le N_0$ a.s.,*

$$(3.1)\qquad E\left[\exp\left\{\frac{1}{\sqrt{\varepsilon}(t+1)^{\frac{3}{2}}}\left|\int_0^t (\chi_{\{\alpha(\varepsilon,s)=i\}} - \nu_i)\beta(s)ds\right|\right\}\middle|\mathcal{Z}_t\right] \le C, \text{ a.s.}$$

Proof. In view of Lemma A.2, it suffices to show that for any deterministic $\beta(t)$, $|\beta(t)| \le N_0$,

$$(3.2)\qquad E\exp\left\{\frac{1}{\sqrt{\varepsilon}(t+1)^{\frac{3}{2}}}\left|\int_0^t (\chi_{\{\alpha(\varepsilon,s)=i\}} - \nu_i)\beta(s)ds\right|\right\} \le C.$$

We let

$$\lambda(t) = (\chi_{\{\alpha(\varepsilon,t)=0\}}, \dots, \chi_{\{\alpha(\varepsilon,t)=m\}})'$$
$$\text{and}\quad w(t) = \lambda(t) - \lambda(0) - \int_0^t Q'\lambda(s)ds,$$

where $Q = Q^{(1)} + \varepsilon^{-1}Q^{(2)}$ is the generator of the process $\alpha(\varepsilon, t)$. Then, it is well known (cf. [5]) that $w(t) = (w_0(t), \ldots, w_m(t))'$ is a $\sigma\{\alpha(\varepsilon, s) : s \leq t\}$ martingale and

$$\lambda(t) = e^{Q't}\lambda(0) + \int_0^t e^{Q'(t-s)}dw(s). \tag{3.3}$$

Let

$$\bar{P} = \begin{pmatrix} \nu_0 & \cdots & \nu_0 \\ \vdots & \cdots & \vdots \\ \nu_m & \cdots & \nu_m \end{pmatrix}$$

and let $\Phi(t) = e^{Q't} - \bar{P}$. Then, $\Phi(t)$ is deterministic and by Lemma A.1

$$\Phi(t) = O(\varepsilon + e^{-k_0 t/\varepsilon}). \tag{3.4}$$

Moreover, since $\bar{P}\lambda(t) = \bar{P}\lambda(0) = \nu$ and $\bar{P}Q' = 0$,

$$\bar{P}w(t) = \bar{P}\left[\lambda(t) - \lambda(0) - \int_0^t Q'\lambda(s)ds\right] = \nu - \nu - \int_0^t \bar{P}Q'\lambda(s)ds = 0.$$

We combine (3.3) and the definition of $\Phi(t)$ to obtain

$$\begin{aligned} \lambda(t) - \nu = &\ \Phi(t)\lambda(0) + \int_0^t (\Phi(t-s) + \bar{P})dw(s) \\ = &\ \Phi(t)\lambda(0) + \int_0^t \Phi(t-s)dw(s). \end{aligned}$$

By integrating $(\lambda(s) - \nu)\beta(s)$ over $[0, t]$ and exchanging orders of integration, we have

$$\int_0^t (\lambda(s) - \nu)\beta(s)ds = \lambda(0)\int_0^t \Phi(s)\beta(s)ds + \int_0^t \left\{\int_s^t \Phi(r-s)\beta(r)dr\right\} dw(s).$$

Recall that $\beta(t)$ is assumed to be deterministic at the beginning of the proof. Both $\int_0^t \Phi(s)\beta(s)ds$ and $\int_s^t \Phi(r-s)\beta(r)dr$ are deterministic. Moreover,

$$\frac{1}{t+1}\int_0^t \Phi(s)\beta(s)ds = \frac{1}{t+1}\int_0^t O(\varepsilon + e^{-k_0 s/\varepsilon})ds = O(\varepsilon),$$

$$\frac{1}{t+1}\int_s^t \Phi(r-s)\beta(r)dr = \frac{1}{t+1}\int_s^t O(\varepsilon + e^{-k_0(r-s)/\varepsilon})dr = O(\varepsilon),$$

where $O(1)$ is deterministic and is independent of s and t. Thus,

$$\frac{1}{t+1}\int_0^t (\lambda(s) - \nu)\beta(s)ds = \varepsilon O(1) + \varepsilon\int_0^t O(1)dw(s). \tag{3.5}$$

Therefore,

$$\begin{aligned} &E\exp\left\{\frac{1}{\sqrt{\varepsilon}(t+1)^{\frac{3}{2}}}\left|\int_0^t (\lambda(s) - \nu)\beta(s)ds\right|\right\} \\ &\quad = \exp\frac{\sqrt{\varepsilon}O(1)}{\sqrt{t+1}} E\exp\left\{\frac{\sqrt{\varepsilon}}{\sqrt{t+1}}\left|\int_0^t O(1)dw(s)\right|\right\}. \end{aligned} \tag{3.6}$$

Recall that $w(t) = (w_0(t), \ldots, w_m(t))'$. It suffices to show that, for ε_0 small enough and for each $i \in \mathcal{M}$,

$$E \exp\left\{ \frac{\sqrt{\varepsilon}}{\sqrt{t+1}} \left| \int_0^t b(s,t) dw_i(s) \right| \right\} \leq C \tag{3.7}$$

for all bounded measurable functions $|b(s,t)| \leq N_1$ (for some fixed N_1) and $t \geq 0$. Now, for each $t_0 \geq 0$, let $b_0(s) = b(s, t_0)$. Then, by Lemma A.3,

$$\begin{aligned} & E \exp\left\{ \frac{\sqrt{\varepsilon}}{\sqrt{t+1}} \left| \int_0^t b_0(s) dw_i(s) \right| \right\} \\ & \leq e + (e-1) \sum_{j=1}^{\infty} e^j P\left(\frac{\sqrt{\varepsilon}}{\sqrt{t+1}} \left| \int_0^t b_0(s) dw_i(s) \right| \geq j \right). \end{aligned} \tag{3.8}$$

Now, we estimate

$$P\left(\frac{\sqrt{\varepsilon}}{\sqrt{t+1}} \left| \int_0^t b_0(s) dw_i(s) \right| \geq j \right).$$

Let $p(t) = \int_0^t b_0(s) dw_i(s)$. Then $p(t)$ is a local martingale. Let $q(\cdot)$ denote the only solution to the equation (cf. [4])

$$q(t) = 1 + \zeta \int_0^t q(s^-) dp(s),$$

where $q(s^-)$ is the left-hand limit of q at s and ζ is a positive constant to be determined later. Then, it is shown in [22] that

(1) $Eq(t) \leq 1$ for all $t \geq 0$;

(2) $q(t) = e^{\zeta p(t)} \prod_{s \leq t} (1 + \zeta \Delta p(s)) e^{-\zeta \Delta p(s)}$, where $\Delta p(s) := p(s) - p(s^-)$, $|\Delta p(s)| \leq N_1$;

(3) $q(t) \geq \exp\{\zeta p(t) - k_1 \zeta^2 N(t)\}$ for $0 < \zeta \leq \zeta_0$, $t > 0$, where k_1 and ζ_0 are positive constants and $N(t)$ is the number of jumps of $p(s)$ in $s \in [0,t]$. Therefore,

$$\begin{aligned} & P\left(\frac{\sqrt{\varepsilon}}{\sqrt{t+1}} \left| \int_0^t b_0(s) dw_i(s) \right| \geq j \right) \\ = \; & P\left(|p(t)| \geq \frac{j\sqrt{t+1}}{\sqrt{\varepsilon}} \right) \\ \leq \; & P\left(p(t) \geq \frac{j\sqrt{t+1}}{\sqrt{\varepsilon}} \right) + P\left(p(t) \leq -\frac{j\sqrt{t+1}}{\sqrt{\varepsilon}} \right). \end{aligned}$$

We first consider $P\left(p(t) \geq j\zeta\sqrt{t+1}/\sqrt{\varepsilon}\right)$. Let $a_j = j(t+1)/(8k_1\varepsilon)$. Then,

$$\begin{aligned} & P\left(p(t) \geq \frac{j\sqrt{t+1}}{\sqrt{\varepsilon}} \right) \\ & \leq P\left(q(t) \geq \exp\left\{ \frac{j\zeta\sqrt{t+1}}{\sqrt{\varepsilon}} - k_1\zeta^2 N(t) \right\} \right) \\ & \leq P\left(q(t) \geq \exp\left\{ \frac{j\zeta\sqrt{t+1}}{\sqrt{\varepsilon}} - k_1\zeta^2 N(t) \right\}, N(t) \leq a_j \right) + P(N(t) \geq a_j) \\ & \leq P\left(q(t) \geq \exp\left(\frac{j\zeta\sqrt{t+1}}{\sqrt{\varepsilon}} - k_1\zeta^2 a_j \right) \right) + P(N(t) \geq a_j) \\ & \leq \exp\left(-\frac{j\zeta\sqrt{t+1}}{\sqrt{\varepsilon}} + k_1\zeta^2 a_j \right) + P(N(t) \geq a_j). \end{aligned}$$

Now if we take $\zeta = 4\sqrt{\varepsilon}/\sqrt{t+1}$, then

$$\exp\left(-\frac{j\zeta\sqrt{t+1}}{\sqrt{\varepsilon}} + k_1\zeta^2 a_j\right) = e^{-2j}.$$

As in [22], we can show that for ε small enough,

$$P(N(t) \geq a_j) \leq 2\gamma^{a_j-1} \quad \text{for } j \geq j_0,$$

where $\gamma = 8ek_1/j_0 \in (0,1)$ and $j_0 > \max\{1, 8ek_1\}$. Thus,

$$P\left(p(t) \geq \frac{j\sqrt{t+1}}{\sqrt{\varepsilon}}\right) \leq \begin{cases} e^{-2j} + 2\gamma^{a_j-1} & \text{if } j \geq j_0, \\ 1 + e^{-2} & \text{if } j < j_0. \end{cases}$$

Repeating the same argument for the martingale $(-p(t))$ we get

$$P\left(p(t) \leq -\frac{j\sqrt{t+1}}{\sqrt{\varepsilon}}\right) \leq \begin{cases} e^{-2j} + 2\gamma^{a_j-1} & \text{if } j \geq j_0, \\ 1 + e^{-2} & \text{if } j < j_0. \end{cases}$$

Combining the above two inequalities we obtain

$$P\left(\frac{\sqrt{\varepsilon}}{\sqrt{t+1}}\left|\int_0^t b_0(s)dw_i(s)\right| \geq j\right) \leq \begin{cases} 2(e^{-2j} + 2\gamma^{a_j-1}) & \text{if } j \geq j_0, \\ 2(1 + e^{-2}) & \text{if } j < j_0. \end{cases}$$

Then, by (3.8),

$$E\exp\left\{\frac{\sqrt{\varepsilon}}{\sqrt{t+1}}\left|\int_0^t b(s,t)dw_i(s)\right|\right\} \leq C_1 + (e-1)\sum_{j=1}^{\infty} 2e^j(e^{-2j} + 2\gamma^{a_j-1}),$$

where $C_1 = e + 2j_0(e-1)(1+e^{-2})$. Now, we choose ε_0 small enough such that $e\gamma^{1/(8k_1\varepsilon_0)} \leq 1/2$. Then,

$$E\exp\left\{\frac{\sqrt{\varepsilon}}{\sqrt{t+1}}\left|\int_0^t b(s,t_0)dw_i(s)\right|\right\} \leq C_1 + 2 + 4(e-1)\gamma^{-1}.$$

Since t_0 is arbitrary, we may take $t_0 = t$ in the above inequality. Then,

$$E\exp\left\{\frac{\sqrt{\varepsilon}}{\sqrt{t+1}}\left|\int_0^t b(s,t)dw_i(s)\right|\right\} \leq C_1 + 2 + 4(e-1)\gamma^{-1}.$$

Combining this inequality with (3.6), we obtain

$$E\exp\left\{\frac{1}{\sqrt{\varepsilon}(t+1)^{\frac{3}{2}}}\left|\int_0^t (\lambda(s)-\nu)\beta(s)ds\right|\right\} \leq C \text{ for some constant } C.$$

This completes the proof of the lemma. □

COROLLARY 3.1. *In the above lemma, if* $Q^{(1)} = 0$, *i.e.*, $Q = \varepsilon^{-1}Q^{(2)}$, *then we have the following stronger estimate*:

$$E\left[\exp\left\{\frac{1}{\sqrt{\varepsilon}\sqrt{t+1}}\left|\int_0^t (\chi_{\{\alpha(\varepsilon,s)=i\}} - \nu_i)\beta(s)ds\right|\right\}\middle|\mathcal{Z}_t\right] \leq C, \ a.s. \tag{3.9}$$

Proof. If $Q^{(1)} = 0$, then Lemma A.1 becomes

$$|P(\alpha(\varepsilon, t) = i) - \nu_i| \leq Ce^{-k_0 t/\varepsilon};$$

see [20] for details. Thus, equation (3.5) can be replaced by

$$\int_0^t (\lambda(s) - \nu)\beta(s)ds = \varepsilon O(1) + \varepsilon \int_0^t O(1)dw(s).$$

The remaining proof of the corollary follows exactly as the rest of the proof of Lemma 3.1. □

COROLLARY 3.2. *For each $N_0 > 0$ and $0 < \delta < 1/2$, there exist constants $\varepsilon_0 > 0$ and C such that for $0 < \varepsilon \leq \varepsilon_0$, $i \in \mathcal{M}$, $t \geq 0$, and for any $\mathcal{Z}_t$ adapted process $\beta(t)$, $|\beta(t)| \leq N_0$,*

$$P\left(\left|\int_0^t (\chi_{\{\alpha(\varepsilon,s)=i\}} - \nu_i)\beta(s)ds\right| \geq \varepsilon^{\frac{1}{2}-\delta}\right) \leq C\exp\left\{-\frac{1}{\varepsilon^\delta (t+1)^{\frac{3}{2}}}\right\}. \tag{3.10}$$

Moreover, if $Q^{(1)} = 0$, then

$$P\left(\left|\int_0^t (\chi_{\{\alpha(\varepsilon,s)=i\}} - \nu_i)\beta(s)ds\right| \geq \varepsilon^{\frac{1}{2}-\delta}\right) \leq C\exp\left\{-\frac{1}{\varepsilon^\delta \sqrt{t+1}}\right\}. \tag{3.11}$$

Proof. Note in view of Lemma 3.1 that

$$\begin{aligned} & P\left(\left|\int_0^t (\chi_{\{\alpha(\varepsilon,s)=i\}} - \nu_i)\beta(s)ds\right| \geq \varepsilon^{\frac{1}{2}-\delta}\right) \\ = \; & P\left(\exp\left\{\frac{1}{\sqrt{\varepsilon}(t+1)^{\frac{3}{2}}}\left|\int_0^t (\chi_{\{\alpha(\varepsilon,s)=i\}} - \nu_i)\beta(s)ds\right|\right\} \geq \exp\left\{\frac{\varepsilon^{\frac{1}{2}-\delta}}{\sqrt{\varepsilon}(t+1)^{\frac{3}{2}}}\right\}\right) \\ \leq \; & C\exp\left\{-\frac{1}{\varepsilon^\delta (t+1)^{\frac{3}{2}}}\right\}. \end{aligned}$$

This proves (3.10). Similarly, (3.11) follows from Corollary 3.1. □

To conclude this section, we give a corollary that will be needed in §7.

COROLLARY 3.3. *Let $D(\varepsilon) = \{|\int_0^t (\chi_{\{\alpha(\varepsilon,s)=i\}} - \nu_i)\beta(s)ds| \geq \sqrt[4]{\varepsilon}\}$. Then, there exist $k > 0$ and C such that*

$$E\exp\left\{\frac{k}{\sqrt[4]{\varepsilon}}e^{-\rho t/2}\chi_{D(\varepsilon)}\right\} \leq C.$$

Proof. Note that

$$\exp\left\{\frac{k}{\sqrt[4]{\varepsilon}}e^{-\rho t/2}\chi_{D(\varepsilon)}\right\} \leq 1 + \left[\exp\left\{\frac{k}{\sqrt[4]{\varepsilon}}e^{-\rho t/2}\right\}\right]\chi_{D(\varepsilon)}. \tag{3.12}$$

By Corollary 3.2,

$$P(D(\varepsilon)) \leq C\exp\left\{-\frac{1}{\sqrt[4]{\varepsilon}(t+1)^{\frac{3}{2}}}\right\}. \tag{3.13}$$

Combine (3.12) and (3.13) to obtain

$$\begin{aligned} E\exp\left\{\frac{k}{\sqrt[4]{\varepsilon}}e^{-\rho t/2}\chi_{D(\varepsilon)}\right\} & \leq 1 + \exp\left\{\frac{k}{\sqrt[4]{\varepsilon}}e^{-\rho t/2}\right\}P(D(\varepsilon)) \\ & \leq 1 + C\exp\left\{\frac{k}{\sqrt[4]{\varepsilon}}e^{-\rho t/2}\right\}\exp\left\{-\frac{1}{\sqrt[4]{\varepsilon}(t+1)^{\frac{3}{2}}}\right\} \\ & = 1 + C\exp\left[\frac{k}{\sqrt[4]{\varepsilon}}e^{-\rho t/2} - \frac{1}{\sqrt[4]{\varepsilon}(t+1)^{\frac{3}{2}}}\right]. \end{aligned}$$

We now choose $k > 0$ and small enough such that

$$\frac{k}{\sqrt[4]{\varepsilon}} e^{-\rho t/2} \le \frac{1}{\sqrt[4]{\varepsilon}(t+1)^{\frac{3}{2}}}.$$

Then, for k small enough, we have

$$E \exp\left\{ \frac{k}{\sqrt[4]{\varepsilon}} e^{-\rho t/2} \chi_{D(\varepsilon)} \right\} \le 1 + C. \qquad \square$$

4. Asymptotic properties of the value functions. In this section, we study the asymptotic property of the value function $v^{\varepsilon,\sqrt{\varepsilon}}$. The next theorem shows that the value function $v^{\varepsilon,\sqrt{\varepsilon}}$ of $\mathcal{P}^{\varepsilon,\sqrt{\varepsilon}}$ can be approximated by the value function $v^{0,\sqrt{\varepsilon}}$ of $\mathcal{P}^{0,\sqrt{\varepsilon}}$.

THEOREM 4.1. *There exist constants $\varepsilon_0 > 0$ and C such that, for $0 < \varepsilon \le \varepsilon_0$,*

$$|v^{\varepsilon,\sqrt{\varepsilon}} - v^{0,\sqrt{\varepsilon}}| \le C\sqrt{\varepsilon}.$$

Proof. We first show that $v^{\varepsilon,\sqrt{\varepsilon}} \le v^{0,\sqrt{\varepsilon}} + C\sqrt{\varepsilon}$. For any given $\bar{U}_\cdot = (u^0_\cdot, \dots, u^m_\cdot) \in \mathcal{A}^0$, we construct a control $u^\varepsilon_t = \sum_{i=0}^m \chi_{\{\alpha(\varepsilon,t)=i\}} u^i_t$. Then, obviously, $u^\varepsilon_\cdot \in \mathcal{A}^\varepsilon$. Moreover, let $x_\cdot$ and $\bar{x}_\cdot$ denote, respectively, the corresponding states of the systems $\mathcal{P}^{\varepsilon,\sqrt{\varepsilon}}$ and $\mathcal{P}^{0,\sqrt{\varepsilon}}$ with the same initial value a, i.e.,

$$\dot{x}_t = u^\varepsilon_t - z_t, \; x_0 = a, \tag{4.1}$$

$$\dot{\bar{x}}_t = \sum_{i=0}^m \nu_i u^i_t - z_t, \; \bar{x}_0 = a. \tag{4.2}$$

Note that $c(u^\varepsilon_t) = \sum_{i=0}^m \chi_{\{\alpha(\varepsilon,t)=i\}} c(u^i_t)$. Then,

$$\begin{aligned}
&J^{\varepsilon,\sqrt{\varepsilon}}(u^\varepsilon_\cdot)\\
&= \sqrt{\varepsilon} \log E \left\{ \exp\left\{ \frac{1}{\sqrt{\varepsilon}} \int_0^\infty e^{-\rho t}[h(x_t) + c(u^\varepsilon_t)]dt \right\} \right\}\\
&= \sqrt{\varepsilon} \log E \left\{ \exp\left\{ \frac{1}{\sqrt{\varepsilon}} \int_0^\infty e^{-\rho t} \left[h(x_t) + \sum_{i=0}^m \chi_{\{\alpha(\varepsilon,t)=i\}} c(u^i_t) \right] dt \right\} \right\}\\
&= \sqrt{\varepsilon} \log E \left\{ \left(\exp\left\{ \frac{1}{\sqrt{\varepsilon}} \int_0^\infty e^{-\rho t} \left[h(\bar{x}_t) + \sum_{i=0}^m \nu_i c(u^i_t) \right] dt \right\} \right) \cdot I(\varepsilon) \right\},
\end{aligned}$$

where

$$I(\varepsilon) = \exp\left\{ \frac{1}{\sqrt{\varepsilon}} \int_0^\infty e^{-\rho t} \left[h(x_t) - h(\bar{x}_t) + \sum_{i=0}^m (\chi_{\{\alpha(\varepsilon,t)=i\}} - \nu_i) c(u^i_t) \right] dt \right\}.$$

Recall that $\bar{x}_t$ and $\bar{U}_t$ are $\mathcal{Z}_t$ adapted. Thus,

$$\begin{aligned}
&J^{\varepsilon,\sqrt{\varepsilon}}(u^\varepsilon_\cdot)\\
&= \sqrt{\varepsilon} \log E \left\{ E \left[\left(\exp\left\{ \frac{1}{\sqrt{\varepsilon}} \int_0^\infty e^{-\rho t} \left[h(\bar{x}_t) + \sum_{i=0}^m \nu_i c(u^i_t) \right] dt \right\} \right) \cdot I(\varepsilon) \middle| \mathcal{Z}_t \right] \right\}\\
&= \sqrt{\varepsilon} \log E \left\{ \left(\exp\left\{ \frac{1}{\sqrt{\varepsilon}} \int_0^\infty e^{-\rho t} \left[h(\bar{x}_t) + \sum_{i=0}^m \nu_i c(u^i_t) \right] dt \right\} \right) \cdot E[I(\varepsilon)|\mathcal{Z}_t] \right\}.
\end{aligned} \tag{4.3}$$

We now estimate $E[I(\varepsilon)|\mathcal{Z}_t]$. Note that by Assumption (A1) and the fact that $|x_t| + |\bar{x}_t| = O(1+t)$,

$$
\begin{aligned}
|h(x_t) - h(\bar{x}_t)| &\le C_0(1 + |x_t|^{k_h} + |\bar{x}_t|^{k_h})|x_t - \bar{x}_t| \\
&\le C_2(1 + t^{k_h})|x_t - \bar{x}_t| \\
&= C_2(1 + t^{k_h})\left|\int_0^t \sum_{i=0}^m (\chi_{\{\alpha(\varepsilon,s)=i\}} - \nu_i)u_s^i ds\right| \qquad (4.4) \\
&\le C_2(1 + t^{k_h})\sum_{i=0}^m \left|\int_0^t (\chi_{\{\alpha(\varepsilon,s)=i\}} - \nu_i)u_s^i ds\right|.
\end{aligned}
$$

Note also that, by integration by parts,

$$
\begin{aligned}
&\left|\int_0^\infty e^{-\rho t}\sum_{i=0}^m (\chi_{\{\alpha(\varepsilon,t)=i\}} - \nu_i)c(u_t^i)dt\right| \\
&= \left|\rho\int_0^\infty e^{-\rho t}\left(\sum_{i=0}^m \int_0^t (\chi_{\{\alpha(\varepsilon,s)=i\}} - \nu_i)c(u_s^i)ds\right)dt\right| \qquad (4.5) \\
&\le \rho\int_0^\infty e^{-\rho t}\sum_{i=0}^m \left|\int_0^t (\chi_{\{\alpha(\varepsilon,s)=i\}} - \nu_i)c(u_s^i)ds\right| dt.
\end{aligned}
$$

Combining (4.3), (4.4), and (4.5), we obtain

$$
\begin{aligned}
I(\varepsilon) \le \exp\left\{\frac{1}{\sqrt{\varepsilon}}\int_0^\infty e^{-\rho t}\right. & \left[C_2(1 + t^{k_h})\sum_{i=0}^m \left|\int_0^t (\chi_{\{\alpha(\varepsilon,s)=i\}} - \nu_i)u_s^i ds\right|\right. \\
&\left.\left. + \rho\sum_{i=0}^m \left|\int_0^t (\chi_{\{\alpha(\varepsilon,s)=i\}} - \nu_i)c(u_s^i)ds\right|\right]\right\}.
\end{aligned}
$$

By Jensen's inequality and the convexity of e^x,

$$
\exp\int_0^\infty e^{-\rho t}\gamma_t dt \le \frac{\rho}{2}\int_0^\infty e^{-\rho t/2}\exp\left[\frac{2}{\rho}e^{-\rho t/2}\gamma_t\right\} dt \qquad (4.6)
$$

for any function γ_t. Taking

$$
\begin{aligned}
\gamma_t = \frac{1}{\sqrt{\varepsilon}}&\left[C_2(1 + t^{k_h})\sum_{i=0}^m \left|\int_0^t (\chi_{\{\alpha(\varepsilon,s)=i\}} - \nu_i)u_s^i ds\right|\right. \\
&\left. + \rho\sum_{i=0}^m \left|\int_0^t (\chi_{\{\alpha(\varepsilon,s)=i\}} - \nu_i)c(u_s^i)ds\right|\right]
\end{aligned}
$$

in (4.6), we get

$$
\begin{aligned}
I(\varepsilon) \le \frac{\rho}{2}\int_0^\infty e^{-\rho t/2}\exp\left\{\frac{2}{\rho\sqrt{\varepsilon}}e^{-\rho t/2}\right. & \left[C_2(1 + t^{k_h})\sum_{i=0}^m \left|\int_0^t (\chi_{\{\alpha(\varepsilon,s)=i\}} - \nu_i)u_s^i ds\right|\right. \\
&\left.\left. + \rho\sum_{i=0}^m \left|\int_0^t (\chi_{\{\alpha(\varepsilon,s)=i\}} - \nu_i)c(u_s^i)ds\right|\right]\right\} dt.
\end{aligned}
$$

Note that there exists $k_2 > 0$ such that, for all $t \geq 0$,

$$\frac{2}{\rho}e^{-\rho t/2}C_2(1+t^{k_h})(t+1)^{\frac{3}{2}} \leq k_2$$

and

$$\frac{2}{\rho}e^{-\rho t/2}\rho(t+1)^{\frac{3}{2}} \leq k_2.$$

This implies that

(4.7)

$$\begin{aligned}I(\varepsilon) \leq \frac{\rho}{2}\int_0^\infty e^{-\rho t/2}\exp\Bigg\{\frac{k_2}{\sqrt{\varepsilon}(t+1)^{\frac{3}{2}}}\sum_{i=0}^m\Bigg[&\left|\int_0^t(\chi_{\{\alpha(\varepsilon,s)=i\}}-\nu_i)u_s^i ds\right| \\ &+\left|\int_0^t(\chi_{\{\alpha(\varepsilon,s)=i\}}-\nu_i)c(u_s^i)ds\right|\Bigg]\Bigg\}dt.\end{aligned}$$

Moreover, observe that

$$\begin{aligned}&E\Bigg[\exp\Bigg\{\frac{k_2}{\sqrt{\varepsilon}(t+1)^{\frac{3}{2}}}\sum_{i=0}^m\Bigg[\left|\int_0^t(\chi_{\{\alpha(\varepsilon,s)=i\}}-\nu_i)u_s^i ds\right| \\ &\qquad\qquad +\left|\int_0^t(\chi_{\{\alpha(\varepsilon,s)=i\}}-\nu_i)c(u_s^i)ds\right|\Bigg]\Bigg\}dt \mid \mathcal{Z}_t\Bigg] \\ \leq\ &\left[\prod_{i=0}^m E\left[\exp\left\{\frac{2(m+1)k_2}{\sqrt{\varepsilon}(t+1)^{\frac{3}{2}}}\left|\int_0^t(\chi_{\{\alpha(\varepsilon,s)=i\}}-\nu_i)u_s^i ds\right|\right\}\Bigg|\ \mathcal{Z}_t\right]\right]^{\frac{1}{2(m+1)}} \\ &\cdot\left[\prod_{i=0}^m E\left[\exp\left\{\frac{2(m+1)k_2}{\sqrt{\varepsilon}(t+1)^{\frac{3}{2}}}\left|\int_0^t(\chi_{\{\alpha(\varepsilon,s)=i\}}-\nu_i)c(u_s^i)ds\right|\right\}\Bigg|\ \mathcal{Z}_t\right]\right]^{\frac{1}{2(m+1)}} \\ \leq\ &[C_3^{2(m+1)}]^{\frac{1}{2(m+1)}} \quad \text{a.s.} \\ =\ &C_3.\end{aligned}$$

In view of (4.7), we have

$$E[I(\varepsilon)|\mathcal{Z}_t] \leq \frac{\rho}{2}\int_0^\infty e^{-\rho t/2}C_3 dt = C_3.$$

Using this inequality in (4.3) we obtain

$$\begin{aligned}&J^{\varepsilon,\sqrt{\varepsilon}}(u_\cdot^\varepsilon) \\ &\leq \sqrt{\varepsilon}\log E\left[C_3\exp\left\{\frac{1}{\sqrt{\varepsilon}}\int_0^\infty e^{-\rho t}\left[h(\bar{x}_t)+\sum_{i=0}^m \nu_i c(u_t^i)\right]dt\right\}\right] \\ &= \sqrt{\varepsilon}\log C_3 + \sqrt{\varepsilon}\log E\left[\exp\left\{\frac{1}{\sqrt{\varepsilon}}\int_0^\infty e^{-\rho t}\left[h(\bar{x}_t)+\sum_{i=0}^m \nu_i c(u_t^i)\right]dt\right\}\right] \\ &= \sqrt{\varepsilon}\log C_3 + J^{0,\sqrt{\varepsilon}}(\bar{U}_\cdot).\end{aligned} \tag{4.8}$$

Since $\bar{U}. \in \mathcal{A}^0$ is arbitrary we have

$$v^{\varepsilon,\sqrt{\varepsilon}} \leq v^{0,\sqrt{\varepsilon}} + \sqrt{\varepsilon} \log C_3. \tag{4.9}$$

Now it suffices to show the opposite inequality, i.e.,

$$v^{\varepsilon,\sqrt{\varepsilon}} \geq v^{0,\sqrt{\varepsilon}} - C\sqrt{\varepsilon}. \tag{4.10}$$

The proof of this part is similar to that of [20]. We provide the proof in the appendix for the sake of completeness.

Combining (4.9) and (4.10), we conclude

$$|v^{\varepsilon,\sqrt{\varepsilon}} - v^{0,\sqrt{\varepsilon}}| \leq C\sqrt{\varepsilon}. \qquad \square$$

COROLLARY 4.1. *Let $\bar{U}. = (u_.^0, \ldots, u_.^m) \in \mathcal{A}^0$ be an $\sqrt{\varepsilon}$-optimal (stochastic open loop) control for $\mathcal{P}^{0,\sqrt{\varepsilon}}$. Then, $u_t^\varepsilon := \sum_{i=0}^m \chi_{\{\alpha(\varepsilon,t)=i\}} u_t^i \in \mathcal{A}^\varepsilon$ is an asymptotically optimal (stochastic open loop) control for $\mathcal{P}^{\varepsilon,\sqrt{\varepsilon}}$, i.e.,*

$$|J^{\varepsilon,\sqrt{\varepsilon}}(u_.^\varepsilon) - v^{\varepsilon,\sqrt{\varepsilon}}| \leq C\sqrt{\varepsilon}.$$

Proof. By (4.8) and the choice of $\bar{U}. \in \mathcal{A}^0$ ($\sqrt{\varepsilon}$-optimal), we have

$$\begin{aligned} 0 &\leq J^{\varepsilon,\sqrt{\varepsilon}}(u_.^\varepsilon) - v^{\varepsilon,\sqrt{\varepsilon}} \\ &\leq [J^{\varepsilon,\sqrt{\varepsilon}}(u_.^\varepsilon) - J^{0,\sqrt{\varepsilon}}(\bar{U}.)] + [J^{0,\sqrt{\varepsilon}}(\bar{U}.) - v^{0,\sqrt{\varepsilon}}] + [v^{0,\sqrt{\varepsilon}} - v^{\varepsilon,\sqrt{\varepsilon}}] \\ &\leq C\sqrt{\varepsilon} + \sqrt{\varepsilon} + C\sqrt{\varepsilon}. \qquad \square \end{aligned}$$

5. Averaged problems. In this section we show that $\mathcal{P}^{0,\sqrt{\varepsilon}}$ can be approximated by $\mathcal{P}^{0,0}$, and the value function of $\mathcal{P}^{0,0}$ is a viscosity solution to the Isaacs equation of a zero sum, two-player differential game. To simplify the notation, we take $\delta = \sqrt{\varepsilon}$ and consider the following control problem $\mathcal{P}^{0,\delta}$:

$$\mathcal{P}^{0,\delta}: \begin{cases} \text{min.} & J^{0,\delta}(U.) \\ & = \delta \log E\left[\exp\left\{\dfrac{1}{\delta}\displaystyle\int_0^\infty e^{-\rho t}\left[h(x_t) + \sum_{i=0}^m \nu_i c(u_t^i)\right] dt\right\}\right], \\ \text{s.t.} & \dot{x}_t = \displaystyle\sum_{i=0}^m \nu_i u_t^i - z_t,\ x_0 = a,\ U. = (u_.^0, \ldots, u_.^m) \in \mathcal{A}^0, \\ \text{value fn.} & v^{0,\delta} = \displaystyle\inf_{U. \in \mathcal{A}^0} J^{0,\delta}(U.). \end{cases} \tag{5.1}$$

Then, we have the following theorem.

THEOREM 5.1. *$v^{0,\delta}$ is a monotone increasing function of $\delta > 0$ and*

$$\lim_{\delta \to 0} v^{0,\delta} = v^{0,0}.$$

Proof. First of all, note that $J^{0,\delta}(U.) \leq J^{0,0}(U.)$ for all $\delta > 0$ and $U. \in \mathcal{A}^0$. This implies

$$v^{0,\delta} \leq v^{0,0}. \tag{5.2}$$

By Lemma A.4, for each $U_\cdot \in \mathcal{A}^0$,

$$J^{0,\delta}(U_\cdot) \uparrow J^{0,0}(U_\cdot) \text{ as } \delta \downarrow 0. \tag{5.3}$$

Now, for any given $\delta > 0$, let $U_\cdot^\delta = (u_\cdot^{0\delta}, u_\cdot^{1\delta}, \dots, u_\cdot^{m\delta}) \in \mathcal{A}^0$ denote a δ-optimal control for problem $\mathcal{P}^{0,\delta}$, i.e.,

$$v^{0,\delta} \le J^{0,\delta}(U_\cdot^\delta) \le v^{0,\delta} + \delta.$$

Combining these two inequalities and (5.2), we obtain

$$\limsup_{\delta\to 0} J^{0,\delta}(U_\cdot^\delta) \le \limsup_{\delta\to 0} v^{0,\delta} \le v^{0,0}. \tag{5.4}$$

Let $\delta_1 > \delta > 0$. Then, again by Lemma A.4,

$$J^{0,\delta}(U_\cdot^\delta) \ge J^{0,\delta_1}(U_\cdot^\delta). \tag{5.5}$$

We now show that there exists a sequence of δ such that $\{U_\cdot^\delta\}$ converges weakly to a control $U_\cdot^* \in \mathcal{A}^0$. To this end, we consider the following functional space.

$$\begin{aligned}\mathcal{H}_N = \quad & \{f(t) = f(t)(\omega) \in R^1 : \text{ measurable functions on } [0,N] \times \Omega,\\ & f(t) \text{ is } \mathcal{Z}_t \text{ adapted and } \langle f, f\rangle_N < \infty\},\end{aligned}$$

where $N = 1, 2, \dots$, and $\langle f, g\rangle_N := E\int_0^N f(t)g(t)dt$ for any measurable functions f and g on $[0,N] \times \Omega$. Then, it is easy to check that $\mathcal{H}_N$ is a Hilbert space with the inner product $\langle f, g\rangle_N$.

By [26, Thm. 1, p. 126], for each fixed N there exists a sequence of $\delta \to 0$ such that $U_\cdot^\delta \longrightarrow U_\cdot^* \in \mathcal{H}_N$ weakly. By using the Cauchy diagonalization method, we can show that there exists a further subsequence of $\delta \to 0$ (still denoted by δ) and a measurable $U_t^* = (u_t^{0*}, u_t^{1*}, \dots, u_t^{m*})$ for all $t \ge 0$ such that $U_\cdot^* \in \mathcal{H}_N$ for each N and

$$U_\cdot^\delta \longrightarrow U_\cdot^* \in \mathcal{H}_N \text{ weakly on } \mathcal{H}_N \text{ for each } N.$$

This means, in particular, for all bounded measurable and $\mathcal{Z}_t$ adapted functions $f(t)$ on $[0, \infty) \times \Omega$ and for any $t \ge 0$,

$$E\int_0^t f(s)U_s^\delta ds \longrightarrow E\int_0^t f(s)U_s^* ds. \tag{5.6}$$

We now show that $U_\cdot^* \in \mathcal{A}^0$. Since $U_\cdot^* \in \mathcal{H}_N$, U_t^* is $\mathcal{Z}_t$ adapted. It suffices to show that $u_s^{i*} \in \mathcal{U}(i)$ a.s. If not, then for some $\eta > 0$, the set $D_0 = \{(s,\omega) : p \cdot u_s^{i*} > i + \eta\}$ has a positive measure, i.e., $(l \times P)(D_0) > 0$, where l denotes the Lebesgue measure. Now, let $f(t) = E[\chi_{D_0}|\mathcal{Z}_t]p$, where $p \in R^{n_0}$ is the vector used in defining $\mathcal{U}(i)$. Then,

$$E\int_0^t f(s)p \cdot u_s^{i\delta} ds = E\int_0^t \chi_{D_0} p \cdot u_s^{i\delta} ds \to E\int_0^t \chi_{D_0} p \cdot u_s^{i*} ds, \text{ as } \delta \to 0. \tag{5.7}$$

On the other hand,

$$E\int_0^t \chi_{D_0} p \cdot u_s^{i\delta} ds \le iE\int_0^t \chi_{D_0} ds = i(l \times P)(D_0)$$

and

$$E\int_0^t \chi_{D_0} p\cdot u_s^{i*} ds \geq (i+\eta) E\int_0^t \chi_{D_0} ds = (i+\eta)(l\times P)(D_0).$$

This contradicts (5.7). Hence, $U^*_\cdot \in \mathcal{A}^0$.

Let x_t^* denote the trajectory of $\mathcal{P}^{0,0}$ under control $U^*_\cdot$. Recall the convexities of h and c to obtain

$$\begin{aligned} & h(x_t) \geq h(x_t^*) + h_{x^+}(x_t^*)(x_t - x_t^*) \\ \text{and}\quad & c(u_t^{i\delta}) \geq c(u_t^{i*}) + c_{u^+}(u_t^{i*})(u_t^{i\delta} - u_t^{i*}), \end{aligned}$$

where h_{x^+} and c_{u^+} denote the right-hand derivatives of h and c. Then,

$$\begin{aligned} J^{0,\delta_1}(U^\delta_\cdot) &= \delta_1 \log E \exp\left\{ \frac{1}{\delta_1}\int_0^\infty e^{-\rho t}\left[h(x_t) + \sum_{i=0}^m \nu_i c(u_t^{i\delta})\right] dt\right\} \\ &\geq \delta_1 \log E\left[\left(\exp\left\{ \frac{1}{\delta_1}\int_0^\infty e^{-\rho t}\left[h(x_t^*) + \sum_{i=0}^m \nu_i c(u_t^{i*})\right] dt\right\}\right) R(\delta,\delta_1)\right], \end{aligned}$$

where

$$R(\delta,\delta_1) = \exp \frac{1}{\delta_1}\int_0^\infty e^{-\rho t}\left[h_{x^+}(x_t^*)(x_t - x_t^*) + \sum_{i=0}^m \nu_i c_{u^+}(u_t^{i*})(u_t^{i\delta} - u_t^{i*})\right] dt.$$

For each $\eta > 0$, let

$$D = \left\{ \int_0^\infty e^{-\rho t}\left[h(x_t^*) + \sum_{i=0}^m \nu_i c(u_t^{i*})\right] dt \geq J^{0,0}(U^*_\cdot) - \eta\right\}.$$

Then, $P(D) > 0$. Moreover,

$$\begin{aligned} J^{0,\delta_1}(U^\delta_\cdot) &\geq \delta_1 \log E\left[\chi_D \left[\exp\frac{1}{\delta_1}(J^{0,0}(U^*_\cdot) - \eta)\right] R(\delta,\delta_1)\right] \\ &= J^{0,0}(U^*_\cdot) - \eta + \delta_1 \log E\{\chi_D R(\delta,\delta_1)\}. \end{aligned}$$

We now show that

$$\liminf_{\delta\to 0}\, [\log E\{\chi_D R(\delta,\delta_1)\}] \geq \log P(D). \tag{5.8}$$

To this end, we observe in view of assumption (A1) that

$$\begin{aligned} & h_{x^+}(x_t^*) = O(1 + |x_t^*|^{k_h}) = O(1 + t^{k_h}), \\ & x_t - x_t^* = O(1+t), \\ \text{and}\quad & c_{u^+}(u_t^{i*})(u_t^{i\delta} - u_t^{i*}) = O(1). \end{aligned}$$

These imply, for any N,

$$\begin{aligned} & E\chi_D \int_N^\infty e^{-\rho t}\left[h_{x^+}(x_t^*)(x_t - x_t^*) + \sum_{i=0}^m \nu_i c_{u^+}(u_t^{i*})(u_t^{i\delta} - u_t^{i*})\right] dt \\ & \leq \int_N^\infty e^{-\rho t} O(1)[(1+t^{k_h})(1+t) + 1] dt \\ & \to 0 \quad \text{as } N\to\infty. \end{aligned} \tag{5.9}$$

Moreover, in view of the convergence of $U_\cdot^\delta \to U_\cdot^*$,

$$(5.10)\quad \begin{aligned} &E\chi_D \int_0^N e^{-\rho t}\left[h_{x^+}(x_t^*)(x_t - x_t^*) + \sum_{i=0}^m \nu_i c_{u^+}(u_t^{i*})(u_t^{i\delta} - u_t^{i*})\right] dt \\ &= E\int_0^N e^{-\rho t}(E[\chi_D|\mathcal{Z}_t])\left[h_{x^+}(x_t^*)(x_t - x_t^*)\right. \\ &\qquad \left. + \sum_{i=0}^m \nu_i c_{u^+}(u_t^{i*})(u_t^{i\delta} - u_t^{i*})\right] dt \to 0, \text{ as } \delta \to 0. \end{aligned}$$

Combining (5.9) and (5.10), we obtain

$$E\left[\chi_D \int_0^\infty e^{-\rho t}\left[h_{x^+}(x_t^*)(x_t - x_t^*) + \sum_{i=0}^m \nu_i c_{u^+}(u_t^{i*})(u_t^{i\delta} - u_t^{i*})\right]\right] dt \to 0.$$

Now, by Jensen's inequality, we have

$$\begin{aligned} &E\{\chi_D R(\delta, \delta_1)\} \\ &\geq P(D) \exp \frac{1}{\delta_1 P(D)} E\left[\chi_D \int_0^\infty e^{-\rho t}\left[h_{x^+}(x_t^*)(x_t - x_t^*)\right.\right. \\ &\qquad \left.\left. + \sum_{i=0}^m \nu_i c_{u^+}(u_t^{i*})(u_t^{i\delta} - u_t^{i*})\right] dt\right]. \end{aligned}$$

Then, (5.8) follows from the fact that

$$\begin{aligned} &\liminf_{\delta\to 0}\left[\log E\{\chi_D R(\delta, \delta_1)\}\right] \\ &\geq \log P(D) + \frac{1}{\delta_1 P(D)} E\left[\chi_D \int_0^\infty e^{-\rho t}\left[h_{x^+}(x_t^*)(x_t - x_t^*)\right.\right. \\ &\qquad \left.\left. + \sum_{i=0}^m \nu_i c_{u^+}(u_t^{i*})(u_t^{i\delta} - u_t^{i*})\right] dt\right] \to \log P(D) \end{aligned}$$

as $\delta \to 0$. Therefore,

$$\liminf_{\delta\to 0} J^{0,\delta_1}(U_\cdot^\delta) \geq J^{0,0}(U_\cdot^*) - \eta + \delta_1 \log P(D).$$

Since η is arbitrary, we have

$$\liminf_{\delta\to 0} J^{0,\delta_1}(U_\cdot^\delta) \geq J^{0,0}(U_\cdot^*) + \delta_1 \log P(D).$$

In view of the monotonicity of $J^{0,\delta}$, we obtain

$$\liminf_{\delta\to 0} J^{0,\delta}(U_\cdot^\delta) \geq \liminf_{\delta\to 0} J^{0,\delta_1}(U_\cdot^\delta) \geq J^{0,0}(U_\cdot^*) + \delta_1 \log P(D) \geq v^{0,0} + \delta_1 \log P(D).$$

Sending $\delta_1 \to 0$, we have $\liminf_{\delta\to 0} J^{0,\delta}(U_\cdot^\delta) \geq v^{0,0}$. Combining this inequality and (5.4), we obtain

$$\lim_{\delta\to 0} J^{0,\delta}(U_\cdot^\delta) = v^{0,0}.$$

Finally, since $J^{0,\delta}(U^{\delta}_{\cdot}) - \delta \le v^{0,0} \le J^{0,\delta}(U^{\delta}_{\cdot})$,

$$\lim_{\delta\to 0} v^{0,\delta} = v^{0,0}.$$

This completes the proof. □

Remark 5.1. Theorem 5.1 says that the risk-sensitive control problem $\mathcal{P}^{0,\delta}$ can be approximated by the limiting problem $\mathcal{P}^{0,0}$. This result can be easily extended to any linear systems with convex costs and compact control spaces.

Remark 5.2. A related result on the connection of risk-sensitive control and differential games is given in Barron and Jensen [2] in the context of financial economics.

In the next theorem, we will show that the value function of $\mathcal{P}^{0,0}$ satisfies the Isaacs equation of a zero-sum, two-player differential game. The advantage of considering $\mathcal{P}^{0,0}$ instead of $\mathcal{P}^{0,\delta}$ is that the theory of differential games (cf. Basar and Bernhard [1]) can be used to obtain an optimal control for $\mathcal{P}^{0,0}$, and such optimal control is independent of the choice of $\delta(=\sqrt{\varepsilon})$.

We write $v^{0,0}(x)$ as the value function of $\mathcal{P}^{0,0}$ with the initial value $x_0 = x$. Note that $\|\xi\|_\infty = \inf_{P(F)=0} \sup_{\omega\in\Omega-F} |\xi(\omega)|$ for any random variable ξ. It is not difficult to show that $0 \le v^{0,0}(x) \le C(1+|x|^{k_h})$ and $v^{0,0}(x)$ is convex and locally Lipschitz; see [20] for details of the proof.

Let $\Gamma_u = \{U = (u^0, u^1, \ldots, u^m) \in R^{n_0\times(m+1)}$ such that $u^i \in \mathcal{U}(i)\}$, and let Γ_z denote a compact subset of R^{n_0}. We consider functions $z_t \in \Gamma_z$ $(t \ge 0)$ that are right continuous and have left-hand limits. Let $\mathcal{Z}$ denote the metric space of such functions that is equipped with the Skorohod topology $d(\cdot,\cdot)$.

We make another assumption on the probability distribution of the demand process $z_t = z_t(\omega)$.

(A4) $z_{\cdot}(\omega) \in \Gamma_z$ a.s., and for each $z_{\cdot}^0 \in \mathcal{Z}$ and any $\delta_0 > 0$,

$$P(d(z_{\cdot}(\omega), z_{\cdot}^0) \le \delta_0) > 0.$$

Assumption (A4) says that the probability of $z_{\cdot}$ is continuously distributed on $\mathcal{Z}$. An immediate example that satisfies assumption (A4) can be given as a finite state Markov chain.

Note that under assumption (A4),

$$\operatorname*{ess\,sup}_{\omega\in\Omega} F(z_{\cdot}(\omega)) = \sup_{z_{\cdot}\in\mathcal{Z}} F(z_{\cdot})$$

for any continuous function $F(z_{\cdot})$ on $\mathcal{Z}$. It can be shown that

$$\int_0^\infty e^{-\rho t}\left[h(x_t) + \sum_{i=0}^m \nu_i c(u_t^i)\right] dt$$

is continuous on $\mathcal{Z}$ for each given $U_{\cdot} \in \mathcal{A}^0$. Therefore,

$$J^{0,0}(U_{\cdot}) = \sup_{z_{\cdot}\in\mathcal{Z}} \int_0^\infty e^{-\rho t}\left[h(x_t) + \sum_{i=0}^m \nu_i c(u_t^i)\right] dt.$$

THEOREM 5.2. *Assume* (A1) *and* (A4). *Then,* $v^{0,0}(x)$ *is the only viscosity solu-*

tion (*see Fleming and Soner* [10] *for definitions*) *to the following Isaacs equation*:

$$
(5.11)\qquad
\begin{aligned}
\rho v^{0,0}(x) &= \min_{U\in\Gamma_u}\max_{z\in\Gamma_z}\left\{\left(\sum_{i=0}^{m}\nu_i u^i - z\right)v_x^{0,0}(x) + h(x) + \sum_{i=0}^{m}\nu_i c(u^i)\right\}\\
&= \max_{z\in\Gamma_z}\min_{U\in\Gamma_u}\left\{\left(\sum_{i=0}^{m}\nu_i u^i - z\right)v_x^{0,0}(x) + h(x) + \sum_{i=0}^{m}\nu_i c(u^i)\right\}.
\end{aligned}
$$

Proof. First of all, note that

$$
\min_{U\in\Gamma_u}\max_{z\in\Gamma_z}\left[\left(\sum_{i=0}^{m}\nu_i u^i - z\right)p + h(x) + \sum_{i=0}^{m}\nu_i c(u^i)\right]
$$

is Lipschitz in p. The uniqueness of viscosity solution follows from Ishii [13, Thm. 1.6, p. 731]. It remains to show that $v^{0,0}$ is a viscosity solution to (5.11). The proof of this part is similar to that of Evans and Souganidis [6]. We only sketch the proof below. Let $x_0 \in R^{n_0}$ and let $\phi(x) \in C^1$ such that $v(x) - \phi(x)$ has a local maximum at $x = x_0$. Then, by using the Dynkin formula, we can show that for $\theta > 0$ small enough,

$$
(5.12)\qquad e^{-\rho\theta}v^{0,0}(x_\theta)-v^{0,0}(x_0) \le \int_0^\theta e^{-\rho t}\left[-\rho v^{0,0}(x_t)+\left(\sum_{i=0}^{m}\nu_i u_t^i - z_t\right)\phi_x(x_t)\right]dt.
$$

On the other hand, it can be shown that

$$
(5.13)\qquad v^{0,0}(x) \le \left\|\int_0^\theta e^{-\rho t}\left[h(x_t)+\sum_{i=0}^{m}\nu_i c(u_t^i)\right]dt\right\|_\infty + e^{-\rho\theta}\|v^{0,0}(x_\theta)\|_\infty.
$$

Combine (5.12) and (5.13) to obtain

$$
(5.14)\qquad
\begin{aligned}
&\left\|\int_0^\theta e^{-\rho t}\left[h(x_t)+\sum_{i=0}^{m}\nu_i c(u_t^i)\right]dt\right\|_\infty\\
&+\sup_{z.}\int_0^\theta e^{-\rho t}\left[-\rho v^{0,0}(x_t)+\left(\sum_{i=0}^{m}\nu_i u_t^i - z_t\right)\phi_x(x_t)\right]dt \ge 0.
\end{aligned}
$$

Let $\bar{x}_t = x_0+\int_0^t(\sum_{i=0}^m \nu_i u_s^i - z_0)ds$. Then $|x_t-\bar{x}_t| \le Ct$ for some C. This implies, by assumption (A1) as $\theta \to 0$,

$$
\frac{1}{\theta}\left\{\left\|\int_0^\theta e^{-\rho t}\left[h(x_t)+\sum_{i=0}^{m}\nu_i c(u_t^i)\right]dt\right\|_\infty - \int_0^\theta e^{-\rho t}\left[h(\bar{x}_t)+\sum_{i=0}^{m}\nu_i c(u_t^i)\right]dt\right\} \to 0.
$$

Using this fact together with (5.14) we can show

$$
\rho v^{0,0}(x_0) \le \min_{U\in\Gamma_u}\max_{z\in\Gamma_z}\left[\left(\sum_{i=0}^{m}\nu_i u^i - z\right)\phi_x(x_0) + h(x_0) + \sum_{i=0}^{m}\nu_i c(u^i)\right].
$$

Thus, $v^{0,0}$ is a viscosity subsolution.

Similarly, we can show $v^{0,0}$ is a viscosity supersolution. Therefore, $v^{0,0}$ is a viscosity solution to the Isaacs equation (5.11). □

6. Asymptotically optimal controls. In this section we state and prove our main results, which are summarized in the next theorem.

THEOREM 6.1. *Under assumptions* (A1)–(A3), *the following hold.*

(1) (convergence).

$$\lim_{\varepsilon\to 0} v^{\varepsilon,\sqrt{\varepsilon}} = v^{0,0}. \tag{6.1}$$

(2) (stochastic open loop control). *Let* $U_{\cdot} = (u_{\cdot}^0, \dots, u_{\cdot}^m) \in \mathcal{A}^0$ *denote a stochastic open loop* ε'*-optimal control for* $\mathcal{P}^{0,0}$, *i.e.,*

$$0 \le J^{0,0}(U_{\cdot}) - v^{0,0} \le \varepsilon'.$$

Let $u_t^\varepsilon = \sum_{i=0}^m \chi_{\{\alpha(\varepsilon,t)=i\}} u_t^i$. *Then,* $u_{\cdot}^\varepsilon \in \mathcal{A}^\varepsilon$ *and*

$$\limsup_{\varepsilon\to 0} |J^{\varepsilon,\sqrt{\varepsilon}}(u_{\cdot}^\varepsilon) - v^{\varepsilon,\sqrt{\varepsilon}}| \le \varepsilon'. \tag{6.2}$$

(3) (feedback control). *Let* $U_{\cdot} = U(z_{\cdot}, x_{\cdot}) = (u^0(z_{\cdot}, x_{\cdot}), \dots, u^m(z_{\cdot}, x_{\cdot}))$ *denote a feedback* ε'*-optimal control for* $\mathcal{P}^{0,0}$, *i.e.,* $0 \le J^{0,0}(U_{\cdot}) - v^{0,0} \le \varepsilon'$. *Let*

$$u_{\cdot}^\varepsilon = u^\varepsilon(\alpha(\varepsilon,\cdot), z_{\cdot}, x_{\cdot}) = \sum_{i=0}^m \chi_{\{\alpha(\varepsilon,\cdot)=i\}} u^i(z_{\cdot}, x_{\cdot}).$$

Assume that $U(z,x)$ *is locally Lipschitz in* x, *i.e., for some* $k_5 > 0$,

$$|U(z,x) - U(z,x')| \le C(1 + |x|^{k_5} + |x'|^{k_5})|x - x'|.$$

Then, $u_{\cdot}^\varepsilon = u^\varepsilon(\alpha(\varepsilon,\cdot), z_{\cdot}, x_{\cdot}) \in \mathcal{A}^\varepsilon$ *and*

$$\limsup_{\varepsilon\to 0} |J^{\varepsilon,\sqrt{\varepsilon}}(u_{\cdot}^\varepsilon) - v^{\varepsilon,\sqrt{\varepsilon}}| \le \varepsilon'. \tag{6.3}$$

Proof. Note that, by Theorems 4.1 and 5.1,

$$\begin{aligned} |v^{\varepsilon,\sqrt{\varepsilon}} - v^{0,0}| &\le |v^{\varepsilon,\sqrt{\varepsilon}} - v^{0,\sqrt{\varepsilon}}| + |v^{0,\sqrt{\varepsilon}} - v^{0,0}| \\ &\le C\sqrt{\varepsilon} + |v^{0,\sqrt{\varepsilon}} - v^{0,0}| \to 0 \text{ as } \varepsilon \to 0. \end{aligned}$$

Thus, $\lim_{\varepsilon\to 0} v^{\varepsilon,\sqrt{\varepsilon}} = v^{0,0}$. (1) holds.

To show (2), we first observe that

$$\begin{aligned} &|J^{\varepsilon,\sqrt{\varepsilon}}(u_{\cdot}^\varepsilon) - v^{\varepsilon,\sqrt{\varepsilon}}| \\ &= J^{\varepsilon,\sqrt{\varepsilon}}(u_{\cdot}^\varepsilon) - v^{\varepsilon,\sqrt{\varepsilon}} \\ &= (J^{\varepsilon,\sqrt{\varepsilon}}(u_{\cdot}^\varepsilon) - J^{0,\sqrt{\varepsilon}}(U_{\cdot})) + (J^{0,\sqrt{\varepsilon}}(U_{\cdot}) - J^{0,0}(U_{\cdot})) \\ &\quad + (J^{0,0}(U_{\cdot}) - v^{0,0}) + (v^{0,0} - v^{\varepsilon,\sqrt{\varepsilon}}). \end{aligned} \tag{6.4}$$

Note that

$$\begin{aligned} &J^{\varepsilon,\sqrt{\varepsilon}}(u_{\cdot}^\varepsilon) - J^{0,\sqrt{\varepsilon}}(U_{\cdot}) \le C\sqrt{\varepsilon} \text{ (by (4.8))}, \\ &J^{0,\sqrt{\varepsilon}}(U_{\cdot}) - J^{0,0}(U_{\cdot}) \to 0 \text{ as } \varepsilon \to 0 \text{ (by Lemma A.4)}, \\ \text{and}\quad &v^{\varepsilon,\sqrt{\varepsilon}} - v^{0,0} \to 0 \text{ (by (1) of this theorem)}. \end{aligned}$$

Then, (6.4) yields

$$\begin{aligned}&\limsup_{\varepsilon\to 0} |J^{\varepsilon,\sqrt{\varepsilon}}(u^\varepsilon_\cdot) - v^{\varepsilon,\sqrt{\varepsilon}}|\\ &\quad\le \limsup_{\varepsilon\to 0}[C\sqrt{\varepsilon} + (J^{0,\sqrt{\varepsilon}}(U_\cdot) - J^{0,0}(U_\cdot)) + \varepsilon' + (v^{0,0} - v^{\varepsilon,\sqrt{\varepsilon}})] = \varepsilon'.\end{aligned}$$

This implies (2).

We now show (3). In view of (6.4), it suffices to show that

$$\limsup_{\varepsilon\to 0}[J^{\varepsilon,\sqrt{\varepsilon}}(u^\varepsilon(\alpha(\varepsilon,\cdot),z_\cdot,x_\cdot)) - J^{0,\sqrt{\varepsilon}}(U(z_\cdot,\bar{x}_\cdot))] \le 0, \tag{6.5}$$

where x_t and $\bar{x}_t$ are the trajectories of systems $\mathcal{P}^{\varepsilon,\sqrt{\varepsilon}}$ and $\mathcal{P}^{0,\sqrt{\varepsilon}}$ under the controls $u^\varepsilon_\cdot = u^\varepsilon(\alpha(\varepsilon,\cdot),z_\cdot,x_\cdot)$ and $U_\cdot = U(z_\cdot,\bar{x}_\cdot)$, respectively. We can show, by the local Lipschitz property of $U(z,\cdot)$, that, for some k_6 and C_4,

$$|x_t - \bar{x}_t| \le R(t) + C_4\int_0^t (1+s^{k_6})|x_s - \bar{x}_s|ds, \tag{6.6}$$

where $R(t) = |\int_0^t \sum_{i=0}^m (\chi_{\{\alpha(\varepsilon,s)=i\}} - \nu_i)u^i(z_s,\bar{x}_s)ds|$. By Gronwall's inequality,

$$|x_t - \bar{x}_t| \le R(t) + C_4\int_0^t (1+s^{k_6})R(s)\exp\left\{C_4\int_s^t (1+r^{k_6})dr\right\}ds.$$

Let T be any fixed number. Then, for $0\le t\le T$ and some C_5,

$$|x_t - \bar{x}_t| \le R(t) + C_5\int_0^t R(s)ds.$$

Note that $|x_t| \le C_6(1+t)$ for some constant C_6. Thus, for all $t\ge 0$,

$$h(x_t) \le C_0(1+|x_t|^{k_h}) \le C_7(1+t^{k_h}).$$

We have

$$\begin{aligned}\int_0^\infty e^{-\rho t}h(x_t)dt \le\ & \int_0^\infty e^{-\rho t}h(\bar{x}_t)dt + C_8\int_0^T e^{-\rho t}(1+t^{k_h})|x_t - \bar{x}_t|dt\\ & + C_7\int_T^\infty e^{-\rho t}(1+t^{k_h})dt.\end{aligned} \tag{6.7}$$

Now, (6.6) implies

$$\begin{aligned}&C_8\int_0^T e^{-\rho t}(1+t^{k_h})|x_t - \bar{x}_t|dt\\ &\le C_9\int_0^T e^{-\rho t}\left[R(t) + C_5\int_0^t R(s)ds\right]dt\\ &= C_{10}\left\{\int_0^T e^{-\rho t}R(t)dt + \frac{1}{\rho}\int_0^T e^{-\rho t}R(t)dt - \frac{e^{-\rho T}}{\rho}\int_0^T R(t)dt\right\}\\ &\le C_{11}\int_0^T e^{-\rho t}R(t)dt.\end{aligned} \tag{6.8}$$

Combine (6.7) and (6.8) to obtain

$$\begin{aligned}(6.9)\qquad &\int_0^\infty e^{-\rho t}h(x_t)dt\\ &\leq \int_0^\infty e^{-\rho t}h(\bar{x}_t)dt + C_{11}\int_0^T e^{-\rho t}R(t)dt + C_7\int_T^\infty e^{-\rho t}(1+t^{k_h})dt.\end{aligned}$$

Let $R_1(\varepsilon) = \int_0^\infty e^{-\rho t}\sum_{i=0}^m (\chi_{\{\alpha(\varepsilon,t)=i\}} - \nu_i)c(u^i(z_t,\bar{x}_t))dt$. Then,

$$\begin{aligned}&\int_0^\infty e^{-\rho t}c(u^\varepsilon(\alpha(\varepsilon,t),z_t,x_t))dt\\ &= \int_0^\infty e^{-\rho t}\sum_{i=0}^m \chi_{\{\alpha(\varepsilon,t)=i\}}c(u^i(z_t,x_t))dt\\ &\leq \int_0^\infty e^{-\rho t}\sum_{i=0}^m \nu_i c(u^i(z_t,\bar{x}_t))dt + R_1(\varepsilon)\\ &+\int_0^T e^{-\rho t}\sum_{i=0}^m \chi_{\{\alpha(\varepsilon,t)=i\}}[c(u^i(z_t,x_t)) - c(u^i(z_t,\bar{x}_t))]dt \quad + C_{11}\int_T^\infty e^{-\rho t}dt\end{aligned}$$

for any fixed T and some constant C_{11}. Note, by the local Lipschitz property of U., that

$$\begin{aligned}\int_0^T e^{-\rho t}\sum_{i=0}^m \chi_{\{\alpha(\varepsilon,t)=i\}}[c(u^i(z_t,x_t)) - c(u^i(z_t,\bar{x}_t))]dt &\leq C_{13}\int_0^T e^{-\rho t}|x_t-\bar{x}_t|dt\\ &\leq C_{14}\int_0^T e^{-\rho t}R(t)dt.\end{aligned}$$

This yields

$$\begin{aligned}(6.10)\quad \int_0^\infty e^{-\rho t}c(u^\varepsilon(\alpha(\varepsilon,t),z_t,x_t))dt &\leq \int_0^\infty e^{-\rho t}\sum_{i=0}^m \nu_i c(u^i(z_t,\bar{x}_t))dt + R_1(\varepsilon)\\ &+C_{14}\int_0^T e^{-\rho t}R(t)dt + C_{12}\int_T^\infty e^{-\rho t}dt.\end{aligned}$$

Let

$$\begin{aligned}I_2(\varepsilon) = \exp\frac{1}{\sqrt{\varepsilon}}\Bigg[&(C_{11}+C_{14})\int_0^T e^{-\rho t}R(t)dt\\ &+(C_7+C_{12})\int_T^\infty e^{-\rho t}(1+t^{k_h})dt + R_1(\varepsilon)\Bigg].\end{aligned}$$

Then, by combining (6.9) and (6.10), we have

$$\begin{aligned}&\int_0^\infty e^{-\rho t}h(x_t)dt + \int_0^\infty e^{-\rho t}c(u^\varepsilon(\alpha(\varepsilon,t),z_t,x_t))dt\\ &\leq I_2(\varepsilon) + \int_0^\infty e^{-\rho t}h(\bar{x}_t)dt + \int_0^\infty e^{-\rho t}\sum_{i=0}^m \nu_i c(u^i(z_t,\bar{x}_t))dt.\end{aligned}$$

Moreover,

$$
\begin{aligned}
E[I_2(\varepsilon)|\mathcal{Z}_t] \le & \exp\left\{\frac{(C_7+C_{12})}{\sqrt{\varepsilon}}\int_T^\infty e^{-\rho t}(1+t^{k_h})dt\right\} \\
& \cdot\left(E\left[\exp\left\{\frac{2(C_{11}+C_{14})}{\sqrt{\varepsilon}}\int_0^T e^{-\rho t}R(t)dt\right\}\middle|\mathcal{Z}_t\right]\right)^{\frac{1}{2}} \\
& \cdot\left(E\left[\exp\left\{\frac{2}{\sqrt{\varepsilon}}R_1(\varepsilon)\right\}\middle|\mathcal{Z}_t\right]\right)^{\frac{1}{2}}.
\end{aligned}
$$

Similarly, as in §4, we can show that, for some C_{15},

$$
\left(E\left[\exp\left\{\frac{2(C_{11}+C_{14})}{\sqrt{\varepsilon}}\int_0^T e^{-\rho t}R(t)dt\right\}\middle|\mathcal{Z}_t\right]\right)^{\frac{1}{2}} \le C_{15},
$$
$$
\text{and } \left(E\left[\exp\left\{\frac{2}{\sqrt{\varepsilon}}R_1(\varepsilon)\right\}\middle|\mathcal{Z}_t\right]\right)^{\frac{1}{2}} \le C_{15}.
$$

Therefore,

$$
E[I_2(\varepsilon)|\mathcal{Z}_t] \le C_{15}^2 \exp\frac{(C_7+C_{12})}{\sqrt{\varepsilon}}\int_T^\infty e^{-\rho t}(1+t^{k_h})dt.
$$

Now, we have

$$
\begin{aligned}
& J^{\varepsilon,\sqrt{\varepsilon}}(u^\varepsilon_\cdot) \\
&= \sqrt{\varepsilon}\log E\exp\left\{\frac{1}{\sqrt{\varepsilon}}\int_0^\infty e^{-\rho t}[h(x_t)+c(u^\varepsilon_t)]dt\right\} \\
&\le \sqrt{\varepsilon}\log E\left\{\left(\exp\left\{\frac{1}{\sqrt{\varepsilon}}\int_0^\infty e^{-\rho t}\left(h(\bar{x}_t)+\sum_{i=0}^m \nu_i c(u^i_t)\right)dt\right\}\right)\cdot I_2(\varepsilon)\right\} \\
&= \sqrt{\varepsilon}\log E\left\{\left(\exp\left\{\frac{1}{\sqrt{\varepsilon}}\int_0^\infty e^{-\rho t}\left(h(\bar{x}_t)+\sum_{i=0}^m \nu_i c(u^i_t)\right)dt\right\}\right)\cdot E[I_2(\varepsilon)|\mathcal{Z}_t]\right\} \\
&\le \sqrt{\varepsilon}\log E\left\{\exp\left\{\frac{1}{\sqrt{\varepsilon}}\int_0^\infty e^{-\rho t}\left(h(\bar{x}_t)+\sum_{i=0}^m \nu_i c(u^i_t)\right)dt\right\}\right\} \\
&\quad + \sqrt{\varepsilon}\log C_{15}^2 + (C_7+C_{12})\int_T^\infty e^{-\rho t}(1+t^{k_h})dt \\
&= J^{0,\sqrt{\varepsilon}}(U_\cdot) + \sqrt{\varepsilon}\log C_{15}^2 + (C_7+C_{12})\int_T^\infty e^{-\rho t}(1+t^{k_h})dt.
\end{aligned}
$$

Thus, for any fixed $0 < T < \infty$,

$$
\begin{aligned}
& \limsup_{\varepsilon\to 0}[J^{\varepsilon,\sqrt{\varepsilon}}(u^\varepsilon(\alpha(\varepsilon,\cdot),z_\cdot,x_\cdot)) - J^{0,\sqrt{\varepsilon}}(U(z_\cdot,\bar{x}_\cdot))] \\
& \le \ (C_7+C_{12})\int_T^\infty e^{-\rho t}(1+t^{k_h})dt
\end{aligned}
$$

which converges to 0 as $T \to \infty$. Therefore,

$$
\limsup_{\varepsilon\to 0}[J^{\varepsilon,\sqrt{\varepsilon}}(u^\varepsilon(\alpha(\varepsilon,\cdot),z_\cdot,x_\cdot)) - J^{0,\sqrt{\varepsilon}}(U(z_\cdot,x_\cdot))] \le 0.
$$

This completes the proof. □

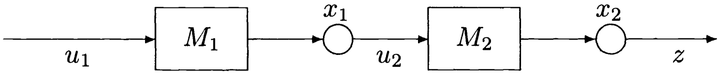

FIG. 1. *A manufacturing system with two machines in tandem.*

7. Extensions to problems with state constraints. In this section, we extend the results in the previous sections to incorporate problems of manufacturing systems with state constraints. These constraints are inherent in systems with internal buffers, i.e., buffers between any two machines, as the inventories in each of them cannot be allowed to become negative. These state constraints cause great difficulty to the analysis. In fact, if we follow Theorem 6.1 to construct a control for the original problem from a near optimal control for the limiting problem, then we find that the constructed control may not even be admissible, i.e., the corresponding trajectory may not satisfy the state constraints. In [22], a method of "lifting" and "modification" is introduced to overcome the difficulty. The basic idea behind it is as follows: First, we modify a given near optimal control of the limiting problem by increasing the inventory in the buffer by a small amount. Then, we use this resulting control to construct a "control" for the original problem in the same way as in Theorem 6.1. The constructed control is not necessarily admissible for the original problem, so we modify it whenever the state constraints are violated.

In this section, we only consider the risk-sensitive control problem of manufacturing systems with two tandem machines and an internal buffer. For risk-sensitive controls with more general manufacturing systems, the results can be extended similarly; see Remark 7.2.

We consider a manufacturing system with two machines arranged in tandem (see Fig. 1). Each machine has a finite number of states resulting in a finite state machine capacity process denoted by $\alpha(\varepsilon,t) = (\alpha_1(\varepsilon,t), \alpha_2(\varepsilon,t))$.

We use $u_1(t)$ and $u_2(t)$ to denote the input rates to the first and second machines, respectively. We denote the number of parts in the buffer between the first and second machine as $x_1(t) \geq 0$ and the difference between cumulative production and cumulative demand, called surplus, as $x_2(t)$. Then, the system can be written as follows:

$$\begin{cases} \dot{x}_1(t) = u_1(t) - u_2(t), & x_1(0) = a_1, \\ \dot{x}_2(t) = u_2(t) - z_t, & x_2(0) = a_2, \end{cases}$$

where

$$x_1(t) \geq 0,\ 0 \leq u_j(t) \leq \alpha_j(\varepsilon,t),\ t \geq 0,\ j = 1,2. \tag{7.1}$$

Let $S = [0,\infty) \times R^1 \subset R^2$ denote the state constraint domain.

DEFINITION 7.1. *A control* $u_t = (u_1(t), u_2(t))$ *is* admissible *with respect to the initial state value* $a = (a_1, a_2) \in S$ *if* (i) $u(t)$ *is adapted to* $\sigma\{\alpha(\varepsilon,s), z_s : 0 \leq s \leq t\}$, (ii) $0 \leq u_j(t) \leq \alpha_j(\varepsilon,t)$ for $t \geq 0$ and $j = 1,2$, and (iii) *the corresponding state*

$$x_t = (x_1(t), x_2(t)) \in S\, for\ \ all\, t \geq 0. \tag{7.2}$$

We use $\mathcal{A}^\varepsilon$ to denote the set of admissible controls.

The problem is to find an admissible control $u(t)$ that minimizes the risk-sensitive cost function

$$J^{\varepsilon,\sqrt[4]{\varepsilon}}(u.) = \sqrt[4]{\varepsilon}\log E\left[\exp\left\{\frac{1}{\sqrt[4]{\varepsilon}}\int_0^\infty e^{-\rho t}[h(x_t)+c(u_t)]dt\right\}\right].$$

Note that the risk-sensitive parameter in the above cost function is chosen to be $\sqrt[4]{\varepsilon}$ rather than $\sqrt{\varepsilon}$. This is because a certain degree of sharpness in estimation is lost due to the presence of state constraints. We refer the reader to [22] for more discussion on this point.

We use $\mathcal{M} = \{\alpha^0,\ldots,\alpha^m\}$ to denote the machine capacity process, where $\alpha^i = (\alpha_1^i,\alpha_2^i)$ with α_j^i denoting the capacity of the jth machine in state i for $j = 1,2$.

We use $\mathcal{P}^{\varepsilon,\sqrt[4]{\varepsilon}}$ to denote our control problem, i.e.,

$$(7.3)\quad \mathcal{P}^{\varepsilon,\sqrt[4]{\varepsilon}}:\begin{cases}\text{min.} & J^{\varepsilon,\sqrt[4]{\varepsilon}}(u.)\\ & = \sqrt[4]{\varepsilon}\log E\left[\exp\left\{\frac{1}{\sqrt[4]{\varepsilon}}\int_0^\infty e^{-\rho t}[h(x_t)+c(u_t)]dt\right\}\right],\\ \text{s.t.} & \begin{cases}\dot{x}_1(t) = u_1(t)-u_2(t), & x_1(0)=a_1,\\ \dot{x}_2(t) = u_2(t)-z_t, & x_2(0)=a_2,\ u.\in\mathcal{A}^\varepsilon\end{cases}\\ \text{value fn.} & v^{\varepsilon,\sqrt[4]{\varepsilon}} = \inf\limits_{u.\in\mathcal{A}^\varepsilon} J^{\varepsilon,\sqrt[4]{\varepsilon}}(u.).\end{cases}$$

Similarly, as in §2, we define $\mathcal{A}^0$ as a set of the following $\mathcal{Z}_t$ adapted controls $U.$.

$$U. = (u^0(\cdot),\ldots,u^m(\cdot)) = ((u_1^0(\cdot),u_2^0(\cdot)),\ldots,(u_1^m(\cdot),u_2^m(\cdot)))$$

such that $0 \le u_j^i(t) \le \alpha_j^i$ for all $t \ge 0$, $j = 1,2$, and $i = 0,1,\ldots,m$, and the corresponding solutions $x. = (x_1(\cdot),x_2(\cdot))$ of the following system:

$$(7.4)\quad \begin{cases}\dot{x}_1(t) &= \sum\limits_{i=0}^m \nu_i u_1^i(t) - \sum\limits_{i=0}^m \nu_i u_2^i(t), & x_1(0)=a_1,\\ \dot{x}_2(t) &= \sum\limits_{i=0}^m \nu_i u_2^i(t) - z_t, & x_2(t)=a_2,\end{cases}$$

satisfy $x_t \in S$ for all $t \ge 0$.

We use $\mathcal{P}^{0,0}$ to denote the limiting problem.

$$\mathcal{P}^{0,0}:\begin{cases}\text{min.} & J^{0,0}(U.) = \left\|\int_0^\infty e^{-\rho t}\left[h(x(t)) + \sum\limits_{i=0}^m \nu_i c(u^i(t))\right]dt\right\|_\infty,\\ \text{s.t.} & \begin{cases}\dot{x}_1(t) = \sum\limits_{i=0}^m \nu_i u_1^i(t) - \sum\limits_{i=0}^m \nu_i u_2^i(t), & x_1(0)=a_1,\\ \dot{x}_2(t) = \sum\limits_{i=0}^m \nu_i u_2^i(t) - z_t, & x_2(0)=a_2,\\ U.\in\mathcal{A}^0,\end{cases}\\ \text{vaule fn.} & v^{0,0} = \inf\limits_{U.\in\mathcal{A}^0} J^{0,0}(U.).\end{cases}$$

Next, we describe the flow of constructing an asymptotic optimal control $u^\varepsilon_\cdot \in \mathcal{A}^\varepsilon$ of the original problem $\mathcal{P}^{\varepsilon,\sqrt[4]{\varepsilon}}$ beginning with a near optimal control $\bar{U}_\cdot \in \mathcal{A}^0$ of the problem $\mathcal{P}^{0,0}$.

Construction of nearly optimal controls. Let $\bar{U}_\cdot = (u^0(\cdot), \dots, u^m(\cdot)) \in \mathcal{A}^0$, where $u^j(t) = (u_1^j(t), u_2^j(t))$, be an ε'-optimal control for $\mathcal{P}^{0,0}$, and let

$$t^* = \inf\left\{t : \int_0^t \left[\sum_{i=0}^m \nu_i(\alpha_1^i - u_1^i(s) + u_2^i(s))\right] ds \geq \sqrt[4]{\varepsilon}\right\}.$$

We define another control process $\tilde{U}_t = (\tilde{u}^0(\cdot), \dots, \tilde{u}^m(\cdot)) \in \mathcal{A}^0$ as follows: for $j = 0, 1, \dots, m$,

$$\tilde{u}^i(t) = (\tilde{u}_1^i(t), \tilde{u}_2^i(t)) = \begin{cases} (\alpha_1^i, 0) & \text{if } t < t^*, \\ (u_1^i(t), u_2^i(t)) & \text{if } t \geq t^*. \end{cases} \tag{7.5}$$

Let

$$w(t) = (w_1(t), w_2(t)) = \sum_{i=0}^m \chi_{\{\alpha(\varepsilon,t)=\alpha^i\}}(\tilde{u}_1^i(t), \tilde{u}_2^i(t)), \tag{7.6}$$

and let $y(t) = (y_1(t), y_2(t))$ be the corresponding trajectory defined as

$$\begin{cases} y_1(t) = a_1 + \displaystyle\int_0^t (w_1(s) - w_2(s))ds, \\ y_2(t) = a_2 + \displaystyle\int_0^t (w_2(s) - z_s)ds. \end{cases}$$

Note that $w(t)$ satisfies the machine capacity constraints. However, it does not necessarily satisfy the state constraints, i.e., $y(t)$ may not be in S for some $t \geq 0$. To obtain an admissible control for $\mathcal{P}^{\varepsilon,\sqrt[4]{\varepsilon}}$, we need to modify $w(t)$ so that the state trajectory stays in S. We define

$$u_t^\varepsilon = w(t)\chi_{\{y_1(t)\geq 0\}}. \tag{7.7}$$

Then, $u^\varepsilon_\cdot \in \mathcal{A}^\varepsilon$. Moreover, we have the following theorem.

THEOREM 7.1. *Let $\bar{U}_\cdot \in \mathcal{A}^0$ be an open loop ε'-optimal for $\mathcal{P}^{0,0}$. Then, for the control $u^\varepsilon_\cdot \in \mathcal{A}^\varepsilon$ constructed above, there exist constants ε_0 and C such that, for all $0 < \varepsilon \leq \varepsilon_0$,*

$$\limsup_{\varepsilon\to 0} |J^{\varepsilon,\sqrt{\varepsilon}}(u^\varepsilon_\cdot) - v^{\varepsilon,\sqrt{\varepsilon}}| \leq C\varepsilon'. \tag{7.8}$$

Proof. We only sketch the proof as follows. We can define $\mathcal{P}^{0,\sqrt[4]{\varepsilon}}$, $J^{0,\sqrt[4]{\varepsilon}}$, and $v^{0,\sqrt[4]{\varepsilon}}$ similar to their definitions in previous sections.

Step 1. Following the proof of Theorem 4.1 and [22], we can show

$$J^{\varepsilon,\sqrt[4]{\varepsilon}}(u^\varepsilon_\cdot) \leq J^{0,\sqrt[4]{\varepsilon}}(\bar{U}_\cdot) + C\sqrt[4]{\varepsilon}.$$

In this step, Corollary 3.3 must be used to replace Corollary 3.2, which was used in [22].

Step 2. We can show as in the second part of the proof of Theorem 4.1 that

$$v^{\varepsilon,\sqrt[4]{\varepsilon}} \geq v^{0,\sqrt[4]{\varepsilon}} - C\sqrt[4]{\varepsilon}.$$

Step 3. We then check that Theorem 5.1 holds even with the presence of the state constraints.

Step 4. An estimate similar to the one in (6.4) can be obtained. Finally, (7.8) follows from the proof of Theorem 6.1. □

Remark 7.1. Note that only the construction of open loop controls is discussed in the above theorem. In fact, construction of feedback controls is much more difficult in the presence of state constraints. The reader is referred to [18] for some discussions on feedback controls.

Remark 7.2. As we mentioned, Theorem 7.1 can actually be extended to incorporate flowshops that consist of more than two machines (cf. [22]), or even more general jobshops that are formulated in [23]. The proofs are similar to the ones we sketched above. Since the procedures are much more involved, the statements, proofs, and results are omitted.

8. Concluding remarks. In this paper, we have carried out an asymptotic analysis of risk-sensitive production of stochastic manufacturing systems as the rates of machines breakdown and repairs become arbitrarily large. Based on this analysis we have constructed open loop and feedback production rate decisions for the original problem $\mathcal{P}^{\varepsilon,\sqrt{\varepsilon}}$ from a near-optimal control of the limit problem $\mathcal{P}^{0,0}$. We have shown that the constructed production decisions are asymptotically optimal as the fluctuation rate of the machine capacities goes to infinity, i.e., $\varepsilon \to 0$.

9. Appendix. In this section, we give five lemmas that are needed in the previous sections and the second part of the proof of Theorem 4.1.

LEMMA A.1. *There exist constants C and $k_0 > 0$ such that for all $t \geq 0$,*

$$|P(\alpha(\varepsilon,t)=i) - \nu_i| \leq C(\varepsilon + e^{-k_0 t/\varepsilon})\ \forall i \in \mathcal{M}.$$

Proof. We refer the reader to [20] for the proof. □

LEMMA A.2. *Let $\mathcal{Y} = \{y(\cdot) : [0,\infty) \to R^1, |y(t)| \leq N_0$ a.s.$\}$ and let*

$$f(t, y(\cdot), \alpha(\varepsilon,\cdot)) = \exp\left\{\frac{1}{\sqrt{\varepsilon}(t+1)^{\frac{3}{2}}}\left|\int_0^t (\chi_{\{\alpha(\varepsilon,t)=i\}} - \nu_i) y(s) ds\right|\right\}.$$

For each $y(\cdot) \in \mathcal{Y}$, define

$$\Psi_t(y(\cdot)) = Ef(t, y(\cdot), \alpha(\varepsilon,\cdot)).$$

Then, for any $\mathcal{Z}_t$ adapted process $\beta(\cdot) \in \mathcal{Y}$ a.s.,

$$\Psi_t(\beta(\cdot)) = E[f(t,\beta(\cdot),\alpha(\varepsilon,\cdot))|\mathcal{Z}_t] \text{ a.s.}$$

Proof. The proof is similar to the proof of [4, Lem. 14.18]. □

LEMMA A.3. *Let ξ denote a nonnegative random variable. Then,*

$$Ee^{\xi} \leq e + (e-1)\sum_{j=1}^{\infty} e^j P(\xi \geq j).$$

Proof. The proof is given as follows:

$$\begin{aligned}
Ee^{\xi} =&\sum_{j=0}^{\infty}\int_{\{j\leq\xi<j+1\}} e^{\xi}dP\\
\leq&\sum_{j=0}^{\infty}\int_{\{j\leq\xi<j+1\}} e^{j+1}dP\\
=&\sum_{j=0}^{\infty} e^{j+1}P(j\leq\xi<j+1)\\
=&\sum_{j=0}^{\infty} e^{j+1}[P(\xi\geq j)-P(\xi\geq j+1)]\\
\leq&\ \ e+(e-1)\sum_{j=1}^{\infty} e^{j}P(\xi\geq j). \qquad \square
\end{aligned}$$

LEMMA A.4. *Let ξ denote a nonnegative random variable such that $||\xi||_\infty < \infty$, where $||\xi||_\infty := \text{esssup}|\xi|$. Then, $\phi(x) := x^{-1}\log Ee^{x\xi}$ is a monotone increasing* function on $(0,\infty)$ and

$$\lim_{x\to\infty}\phi(x)=||\xi||_\infty.$$

Proof. First of all,

$$\phi'(x)=-\frac{1}{x^2}\log Ee^{x\xi}+\frac{1}{x}\frac{E\xi e^{x\xi}}{Ee^{x\xi}}=\frac{1}{x^2}\left[-\log Ee^{x\xi}+x\frac{E\xi e^{x\xi}}{Ee^{x\xi}}\right].$$

Let

$$\psi(x)=-\log Ee^{x\xi}+x\frac{E\xi e^{x\xi}}{Ee^{x\xi}}.$$

Then, $\phi'(x)=\frac{1}{x^2}\psi(x)$. Note that $\psi(0)=0$ and

$$\begin{aligned}
\psi'(x)=&-\frac{E\xi e^{x\xi}}{Ee^{x\xi}}+\frac{E\xi e^{x\xi}}{Ee^{x\xi}}+x\frac{E\xi^2e^{x\xi}Ee^{x\xi}-(E\xi e^{x\xi})^2}{(Ee^{x\xi})^2}\\
=&\,x\left(\frac{E\xi^2e^{x\xi}Ee^{x\xi}-(E\xi e^{x\xi})^2}{(Ee^{x\xi})^2}\right)\geq 0.
\end{aligned}$$

Therefore, $\psi(x)\geq 0$ for all $x\in(0,\infty)$. This implies $\phi'(x)\geq 0$ for all $x\in(0,\infty)$. Thus, $\phi(x)$ is a monotone increasing function.

To see the limit of $\phi(x)$ as $x\to\infty$, we observe that

$$\phi(x)\leq\frac{1}{x}\log Ee^{x||\xi||_\infty}=||\xi||_\infty<\infty.$$

This implies that $\lim_{x\to\infty}\phi(x)$ exists. Now, for any $\eta>0$, let $D=\{\xi\geq||\xi||_\infty-\eta\}$. Then $P(D)>0$.

$$\begin{aligned}
\phi(x)\geq&\frac{1}{x}\log E\chi_De^{x(||\xi||_\infty-\eta)}\\
=&\frac{1}{x}\log e^{x(||\xi||_\infty-\eta)}+\frac{1}{x}\log E\chi_D\\
=&\,||\xi||_\infty-\eta+\frac{1}{x}\log P(D).
\end{aligned}$$

Thus,

$$\|\xi\|_\infty \geq \lim_{x\to\infty} \phi(x) \geq \|\xi\|_\infty - \eta.$$

Since η is arbitrary, $\lim_{x\to\infty} \phi(x) = \|\xi\|_\infty$. □

LEMMA A.5. *Let $\beta(t)$ denote a $\sigma\{\alpha(\varepsilon, s), z_s : s \leq t\}$ adapted process. Then $E[\beta(t)|\mathcal{Z}_t] = E[\beta(t)| \vee_{t\geq 0} \mathcal{Z}_t]$. In particular, $E[\beta(t)|\mathcal{Z}_t] = E[\beta(t)|\mathcal{Z}_{t'}]$ for all $t' \geq t$.*

Proof. We refer the reader to [20] for the proof. □

Proof of Theorem 4.1 (*cont.*). To show (4.10), we first show that for any control $u^\varepsilon_\cdot \in \mathcal{A}^\varepsilon$, there exists a control $U_\cdot = (u^0_\cdot, \dots, u^m_\cdot) \in \mathcal{A}^0$ such that $|E[u^\varepsilon_t|\mathcal{Z}_t] - \sum_{i=0}^m \nu_i u^i_t|$ is small. In fact, for each $i \in \mathcal{M}$, let $u^i_t = E[u^\varepsilon_t|\alpha(\varepsilon, t) = i, \mathcal{Z}_t]$. Then $U_\cdot = (u^0_\cdot, \dots, u^m_\cdot) \in \mathcal{A}^0$. Moreover, note that u^i_t is $\mathcal{Z}_t$ adapted and $\mathcal{Z}_t$ is independent of $\alpha(\varepsilon, t)$.

$$\begin{aligned}
E[u^\varepsilon_t|\mathcal{Z}_t] &= E\left\{\sum_{i=0}^m \chi_{\{\alpha(\varepsilon,t)=i\}} u^\varepsilon_t \middle| \mathcal{Z}_t\right\}\\
&= E\left\{\sum_{i=0}^m \chi_{\{\alpha(\varepsilon,t)=i\}} E[u^\varepsilon_t|\alpha(\varepsilon,t), \mathcal{Z}_t] \middle| \mathcal{Z}_t\right\}\\
&= E\left\{\sum_{i=0}^m \chi_{\{\alpha(\varepsilon,t)=i\}} E[u^\varepsilon_t|\alpha(\varepsilon,t) = i, \mathcal{Z}_t] \middle| \mathcal{Z}_t\right\}\\
&= \sum_{i=0}^m E[\chi_{\{\alpha(\varepsilon,t)=i\}}|\mathcal{Z}_t] E[u^\varepsilon_t|\alpha(\varepsilon,t) = i, \mathcal{Z}_t]\\
&= \sum_{i=0}^m P(\alpha(\varepsilon,t) = i) E[u^\varepsilon_t|\alpha(\varepsilon,t) = i, \mathcal{Z}_t]\\
&= \sum_{i=0}^m P(\alpha(\varepsilon,t) = i) u^i_t.
\end{aligned}$$

By Lemma A.1,

$$\begin{aligned}
E[u^\varepsilon_t|\mathcal{Z}_t] &= \sum_{i=0}^m \nu_i u^i_t + \sum_{i=0}^m (P(\alpha(\varepsilon,t) = i) - \nu_i) u^i_t\\
&= \sum_{i=0}^m \nu_i u^i_t + O(\varepsilon + e^{-k_0 t/\varepsilon}).
\end{aligned} \tag{9.1}$$

We repeat the above argument with u^ε_t replaced by $c(u^\varepsilon_t)$. Then,

$$E[c(u^\varepsilon_t)|\mathcal{Z}_t] = \sum_{i=0}^m P(\alpha(\varepsilon,t) = i) E[c(u^\varepsilon_t)|\alpha(\varepsilon,t) = i, \mathcal{Z}_t].$$

Now, by the convexity of $c(u)$, we have

$$E[c(u^\varepsilon_t)|\alpha(\varepsilon,t) = i, \mathcal{Z}_t] \geq c(E[u^\varepsilon_t|\alpha(\varepsilon,t) = i, \mathcal{Z}_t]) = c(u^i_t).$$

Thus,

$$\begin{aligned}
E[c(u^\varepsilon_t)|\mathcal{Z}_t] &\geq \sum_{i=0}^m P(\alpha(\varepsilon,t) = i) c(u^i_t)\\
&= \sum_{i=0}^m \nu_i c(u^i_t) + O(\varepsilon + e^{-k_0 t/\varepsilon}).
\end{aligned} \tag{9.2}$$

Let $x.$ and $\bar{x}.$ be corresponding state trajectories under controls $u^\varepsilon_\cdot$ and $U.$, respectively. Then, by Lemma A.5,

$$\begin{aligned} E[x_t|\mathcal{Z}_t] &= x + \int_0^t [E[u^\varepsilon_s|\mathcal{Z}_s] - z_s]ds \\ \bar{x}_t \quad &= x + \int_0^t \left[\sum_{i=0}^m \nu_i u^i_s - z_s\right] ds. \end{aligned}$$

Subtracting the above two equations, we have

$$E[x_t|\mathcal{Z}_t] - \bar{x}_t = \int_0^t \left[E[u^\varepsilon_s|\mathcal{Z}_s] - \sum_{i=0}^m \nu_i u^i_t\right] ds. \tag{9.3}$$

Then, applying (9.1), we obtain

$$|E[x_t|\mathcal{Z}_t] - \bar{x}_t| = O(\varepsilon(1+t)).$$

Now, by the convex and locally Lipschitz assumptions on h,

$$\begin{aligned} J^{\varepsilon,\sqrt{\varepsilon}}(u^\varepsilon_\cdot) &= \sqrt{\varepsilon}\log E\left\{E\left[\exp\left\{\frac{1}{\sqrt{\varepsilon}}\int_0^\infty e^{-\rho t}[h(x_t) + c(u^\varepsilon_t)]dt\right\}\middle|\mathcal{Z}_t\right]\right\} \\ &\geq \sqrt{\varepsilon}\log E\left\{\exp\left\{\frac{1}{\sqrt{\varepsilon}}\int_0^\infty e^{-\rho t}[h(E[x_t|\mathcal{Z}_t]) + E[c(u^\varepsilon_t)|\mathcal{Z}_t]]dt\right\}\right\} \\ &= \sqrt{\varepsilon}\log E\left\{\exp\left\{\frac{1}{\sqrt{\varepsilon}}\int_0^\infty e^{-\rho t}\left[h(\bar{x}_t) + \sum_{i=0}^m \nu_i c(u^i_t)\right]dt\right\}\cdot I_1(\varepsilon)\right\}, \end{aligned}$$

where

$$I_1(\varepsilon) = \exp\frac{1}{\sqrt{\varepsilon}}\int_0^\infty e^{-\rho t}\left[h(E[x_t|\mathcal{Z}_t]) - h(\bar{x}_t) + E[c(u^\varepsilon_t)|\mathcal{Z}_t] - \sum_{i=0}^m \nu_i c(u^i_t)\right] dt.$$

Combining (9.2) and (9.3), we obtain

$$\begin{aligned} I_1(\varepsilon) &\geq \exp\frac{-k_3}{\sqrt{\varepsilon}}\int_0^\infty e^{-\rho t}\left[\varepsilon(1+t^{k_h})(1+t) + \varepsilon + \exp\left\{-\frac{k_0 t}{\varepsilon}\right\}\right] dt \\ &\geq \exp\{-k_4\sqrt{\varepsilon}\} \end{aligned}$$

for some $k_3 > 0$ and $k_4 > 0$. Therefore,

$$\begin{aligned} J^{\varepsilon,\sqrt{\varepsilon}}(u^\varepsilon_\cdot) &\geq \sqrt{\varepsilon}\log\exp\{-k_4\sqrt{\varepsilon}\} + J^{0,\sqrt{\varepsilon}}(U.) \\ &= -k_4\varepsilon + J^{0,\sqrt{\varepsilon}}(U.). \qquad \square \end{aligned}$$

MULTILEVEL HIERARCHICAL DECISION MAKING IN STOCHASTIC MARKETING–PRODUCTION SYSTEMS*

S. P. SETHI† AND Q. ZHANG†

Abstract. This paper presents an asymptotic analysis of hierarchical marketing–production systems with stochastic demand and stochastic production capacity modelled as finite state Markov processes. The decision variables used are advertising and production rates which influence capacity, demand, and inventory levels. The objective of this paper is to maximize the expected total discounted profit over an infinite horizon. The authors are interested in situations in which the rate of change in capacity states is an order of magnitude different from the rate of change in demand states. These give rise to upper-level problems in which the stochastic capacity is replaced by the average capacity and/or the random demand is replaced by the average demand. Controls for the corresponding lower-level problems in different cases can be constructed from nearly optimal controls of the upper-level problems in a way that guarantees their asymptotic optimality.

Key words. stochastic manufacturing systems, marketing–production planning, hierarchical control, Markov processes, dynamic programming, viscosity solutions

1. Introduction. One of the most important methods for dealing with optimization of large complex systems is that of hierarchical decomposition. The idea is to reduce the overall complex problem into manageable approximate problems or subproblems, solve these problems, and construct a solution of the original problem from solutions of these simpler problems. Development of such approaches for large complex systems has been identified as a particularly fruitful research area by the Committee on the Next Decade in Operations Research [6] and by the Panel on Future Directions in Control Theory [11].

Most manufacturing firms are large complex systems characterized by several decision subsystems such as finance, personnel, marketing, and operations. Furthermore, they may have a number of plants and warehouses and produce a large number of different products using a wide variety of machines and equipment. Moreover, these systems are subject to discrete events such as construction of new facilities; purchase of new equipment and scrappage of old; machine setups, failures, and repairs; and new product introductions. These events could be deterministic or stochastic. Management must recognize and react to these events. Because of the large size of these systems and the presence of these events, obtaining exact optimal policies to run these systems is nearly impossible both theoretically and computationally.

In practice, therefore, these systems, largely due to their complexity, are managed in a hierarchical fashion. In this context, Herbert Simon [29] writes, "My thesis has been that one path to the construction of a nontrivial theory of complex systems is by way of a theory of hierarchy. Empirically, a large proportion of the complex systems we observe in nature exhibit hierarchic structure." The literature provides little additional justification beyond the fact that these systems are complex for the practice of treating them hierarchically, especially when the environment is uncertain.

There are several different and not mutually exclusive ways to reduce the complexity. These include decomposing the problem into problems of smaller subsystems with a proper coordinating mechanism; aggregating products and subsequently disaggregating them; replacing random processes with their averages and possibly other moments; and so on. For further details on hierarchical approaches in production planning systems and their importance in practice, we refer the reader to the surveys of the literature by Libosvar [18], Bitran and Tirupati [4], and Sethi and Zhang [22], [24], books by Stadtler [33], Switalski [34], and Sethi and Zhang [26], and a bibliography compiled by Bukh [5].

In this paper, we focus on the problem of a profit-maximizing manufacturing firm that must decide over time on the rate of promotional expenditures that create additional demand for its products and the rate of production to meet the demand. Problems incorporating promotional and production decisions have also been addressed by Abad [1], Sogomonian and Tang [30], and Sethi and Zhang [23]. Sethi, Taksar, and Zhang [21] treat a problem dealing with capacity expansion decisions along with production decisions and Zhou and Sethi [36] consider a problem with with production and personnel decisions.

The problem under consideration, termed the global problem, is formulated as a dynamic stochastic optimization problem with finite state Markovian demand and production capacity processes that depend, respectively, on the advertising and the production rates over time. In general, such problems are intractable. Either because of this intractability or because of some organizational considerations, such as the presence of a hierarchical structure within the firm, in practice the advertising and production planning decisions are made at different levels of the organization; see Meal [19] or Kistner and Switalski [16]. The former decisions are usually medium- or long-term decisions and are in the domain of marketing management. The latter are short- to medium-term decisions and are usually the concern of operations management. The two-level decision-making procedure works roughly as follows. Marketing (the upper level) bases its promotional decisions on some aggregated, rather than detailed, information from the shop floor. Subsequently, operations management (the lower level) makes production planning decisions given the advertising decisions already made at the upper level.

An important and obvious question that arises is whether there is a two-level decision procedure, such as the above, that is simpler than solving the global problem and is, at the same time, a good approximation of the optimal solution of the global problem. That such a procedure is usually simpler has been discussed in the literature; see Meal [19], for example. The theory developed in this paper answers the second part of the question in the affirmative under reasonable assumptions.

We shall develop several different two-level procedures, such as the above, that are simpler than solving the global problem and are, at the same time, good approximations of the optimal solution of the global problem. One such two-level procedure can be described as follows. The upper level solves a limiting problem obtained by replacing random capacities by their averages. The solution of this limiting problem yields an advertising decision as well as an average production plan. The upper level implements the advertising decision and informs the lower level of it. It is clear that the average production plan is not feasible for the global problem. However, one could construct a feasible production plan from it at the lower level that takes into account the stochastic demand resulting from the upper level's advertising decision. We are able to prove that the two-level decision procedure provides an asymptotic optimal solution to the global problem as the rates of transition between the various possible capacity states become very large in comparison to those between the demand states. The striking novelty of our approach is that this can be done without solving for the optimal solution, which, as stated earlier, is an insurmountable task.

It is important to note that the model we formulate is sufficiently rich and representative to illustrate the idea of asymptotic optimality in hierarchical manufacturing organizations in which medium-term and short-term decisions are made by different organizational units. Moreover, the processes taking place in the short term are much faster than those in the medium term. By a fast-changing process, we mean a process that is changing so rapidly that from any initial condition, it reaches its stationary distribution in a time during which there are few, if any, fluctuations in the other processes. The reader is referred to Lehoczky et al. [17, pp. 597 and 605] and Gershwin [14], [15] for further details on this point.

So far in our discussion, we have assumed that the capacity process is much faster than the demand process. In other words, the mean times between changes in capacity states is much smaller than those between changes in demand states. In the cases when the opposite might hold, a proper hierarchy would have operations management at the upper level and marketing at the lower level. In this paper we treat all possible hierarchies, including the case when capacity and demand processes have comparable frequencies with both of them being faster than the discounting process.

The model developed here represents an extension of preceding papers by Soner [31] and Sethi and Zhang [25] in the sense that it incorporates the possibility of influencing demand using advertising. In more general terms, the model has *two* explicit decision-making levels not present in the other two papers.

Furthermore, the results provide a rigorous theoretical justification, although in the case of a mathematically tractable model, for the common practice of hierarchical decision making as elaborated in the classical work of Anthony [2]. More importantly, they elicit deep insights into the structure of hierarchy and suggest near-optimal procedures of hierarchical decision making in more general contexts. Also, by establishing a criterion for determining the quality of hierarchical solutions, these results and further research could identify existing "right" and "wrong" practices. Viewed in this way, the results may have profound implications for the design of hierarchical structures within manufacturing organizations.

Finally, our model contains two parameters signifying the orders of magnitude associated with the rates of change of the capacity process and the demand process. We deal with cases in which only one of the two parameters is small and cases in which both parameters are small. In the latter cases, the arguments used in [25] to obtain the limiting problem in a single parameter case do not work because the two parameters in our problem may converge to zero at different rates. Thus, we need to modify the method used in [25] to suit our situation. In the former cases, the presence of the two parameters implies a number of different limiting problems. When one parameter is fixed while the other is small, the associated limiting problem involves a stochastic process associated with the fixed parameter. While this does not complicate the asymptotic analysis of (partial) open-loop controls, it requires additional care in dealing with feedback controls. Specifically, the uniqueness of a solution for such a stochastic limiting problem needs to be specified via a solution to an associated martingale problem. Consequently, various concepts in probability and stochastic processes such as tightness, convergence in distribution, Skorohod's representation, and weak convergence in the space of square integrable functions are used for obtaining the desired asymptotic optimality results.

The plan of the paper is as follows. In §2, we formulate the model of the marketing–production system under consideration and the related global stochastic optimization problem. Also developed are possible hierarchies and relevant limiting problems. In §3, we discuss some elementary properties of the associated value functions and show that the value function of our problem converges to the value functions of appropriate limiting problems. In §4, we study the asymptotic behavior of the capacity and demand processes. Then, in §5, we provide a construction of the asymptotically optimal open-loop controls. Asymptotically optimal feedback controls are studied in §6. Finally, §7 concludes the paper.

2. Problem formulation and possible hierarchies.

In §2.1 we develop the marketing–production problem under consideration. The stochastic processes and control variables involved in the problem will be specified precisely in §2.2. In §2.3, we develop possible hierarchies by specifying three different limiting problems.

2.1. The marketing–production problem.

Let us consider a marketing–production system that produces n distinct product types using a random production capacity $\alpha(\varepsilon, t) \in R^1$ (parameter ε to be specified later). Let $\mathbf{u}_t \in R^n$ denote the production rate. Clearly $\mathbf{u}_t \geq 0$ and, in addition, $\mathbf{u}_t$ will be subject to the available production capacity $\alpha(\varepsilon, t)$ in a way defined later. With the total surplus $\mathbf{x}_t \in R^n$ and a stochastic demand rate $\mathbf{z}(\delta, t) \in R^n$ (parameter δ to be specified later), the system dynamic is

$$\dot{\mathbf{x}}_t = \mathbf{u}_t - \mathbf{z}(\delta, t), \ \mathbf{x}_0 = \mathbf{x}, \tag{2.1}$$

where $\mathbf{x} \in R^n$ is the initial surplus. Note that surplus represents inventories when positive and shortages when negative. Here and elsewhere we use boldface letters to represent vectors.

We consider the profit functional J defined by

$$J(\mathbf{x}, \alpha, \mathbf{z}, \mathbf{u}., \mathbf{w}.) = E\left[\int_0^\infty e^{-\rho t} G(\mathbf{x}_t, \mathbf{z}(\delta, t), \mathbf{u}_t, \mathbf{w}_t) dt\right], \tag{2.2}$$

where $\rho > 0$ is the discount rate; $\mathbf{w}_t \in R^{n_1}$ is the rate of advertising; G is the net income function of $\mathbf{x}, \mathbf{z}, \mathbf{u}$, and $\mathbf{w}$; and $\mathbf{x}$, α, and $\mathbf{z}$ are the initial surplus, the initial capacity, and the initial demand, respectively. The problem is to find a control $(\mathbf{u}_t, \mathbf{w}_t)$, $t \geq 0$, that maximizes $J(\mathbf{x}, \alpha, \mathbf{z}, \mathbf{u}., \mathbf{w}.)$.

Example 2.1. Let $x_t \in R^1$ denote the total surplus at time t, $u_t \in R^1$ denote the production rate, $w_t \in R^1$ denote the advertising rate, and $z(\delta, t) \in R^1$ denote the demand rate. These variables satisfy (2.1). The decision variables u_t and w_t satisfy the constraints $0 \leq u_t \leq \alpha(\varepsilon, t)$, $0 \leq w_t \leq K < \infty$, where K represents an upper bound on the advertising rate. The objective is to choose admissible decision $(u., w.)$ to maximize the expected total discounted profit

$$J(x, \alpha, z, u., w.) = E\int_0^\infty e^{-\rho t}[\pi z(\delta, t) - (h_1(x_t) + cu_t + w_t)]dt,$$

where π is the revenue per unit sale, $h_1(\cdot)$ is the inventory/shortage cost function, and $c < \pi$ is the unit production cost. See Sethi [20] and Feichtinger, Hartl, and Sethi [10] for surveys on dynamic optimal control models in advertising.

We now specify the production and advertising constraints. For each possible capacity state i, let

$$\mathcal{U}_i = \{\mathbf{u} = (u_1, \ldots, u_n) \geq 0 : \mathbf{p} \cdot \mathbf{u} \leq i\} \subset R^n, \tag{2.3}$$

where $\mathbf{p} = (p_1, \ldots, p_n) \geq 0$ is a given constant vector with p_j representing the amount of capacity needed to produce product type j at rate 1. Let $\mathcal{W}$ denote a convex compact subset of the positive orthant of R^{n_1}. With this definition, the advertising and production constraints at time t, respectively, are

$$\mathbf{w}_t \in \mathcal{W} \text{ and } \mathbf{u}_t \in \mathcal{U}_{\alpha(\varepsilon,t)}.$$

2.2. Specification of capacity and demand processes. Our purpose in this section is to specify precisely the joint process $(\alpha(\varepsilon,t), \mathbf{z}(\delta,t))$ as a Markov process constructed from an infinitesimal generator that depends on production and advertising rates.

We begin with a standard probability space $(\Omega, \mathcal{F}, P)$. Let $\mathcal{Z} = \{\mathbf{z}^0, \mathbf{z}^1, \ldots, \mathbf{z}^d\}$ denote the set of demand states and let $\mathbf{w}_t \in R^{n_1}$, $\mathbf{w}_t \geq 0$, $\mathbf{w}_t$ bounded, denote the advertising rate at time t. We shall assume that the demand process $\mathbf{z}(\delta,t)$ takes values in $\mathcal{Z}$ and that transitions between the demand states depend on the rate of advertising. Assume that the random process $\alpha(\varepsilon,t) \in \mathcal{M} = \{0, 1, \ldots, m\}$, and that the transitions between the capacity states may depend on the production rate.

The dependence of $\alpha(\varepsilon,t)$ on the production rate will be given by a generator $\varepsilon^{-1}Q^m(\mathbf{u})$, $\varepsilon > 0$, where $Q^m(\mathbf{u})$ is an $(m+1) \times (m+1)$-matrix such that $Q^m(\mathbf{u}) = \{q^m_{ij}(\mathbf{u})\}$ with $q^m_{ij}(\mathbf{u}) \geq 0$ if $i \neq j$ and $q^m_{ii}(\mathbf{u}) = -\sum_{j \neq i} q^m_{ij}(\mathbf{u})$. To model the dependence of $\mathbf{z}(\delta,t)$ on the advertising decision, we let $\delta > 0$ and $\mathbf{z}(\delta,t) \in \mathcal{Z}$ be governed by a generator $\delta^{-1}Q^d(\mathbf{w})$. Here $Q^d(\mathbf{w})$ is a $(d+1) \times (d+1)$-matrix such that $Q^d(\mathbf{w}) = \{q^d_{ij}(\mathbf{w})\}$ with $q^d_{ij}(\mathbf{w}) \geq 0$ if $i \neq j$ and $q^d_{ii}(\mathbf{w}) = -\sum_{j \neq i} q^d_{ij}(\mathbf{w})$.

Next, we define the average distributions associated with the generators. For this purpose, let

$$\begin{aligned} &\Gamma^m = \{U = (\mathbf{u}^0, \mathbf{u}^1, \ldots, \mathbf{u}^m) : \text{ such that } \mathbf{u}^i \in \mathcal{U}_i\} \\ \text{and}\quad &\Gamma^d = \{W = (\mathbf{w}^0, \mathbf{w}^1, \ldots, \mathbf{w}^d) : \text{ such that } \mathbf{w}^i \in \mathcal{W}\}. \end{aligned} \tag{2.4}$$

We define two matrices $\bar{Q}^m(U)$ and $\bar{Q}^d(W)$ as functions of $(U, W) \in \Gamma^m \times \Gamma^d$:

$$\bar{Q}^m(U) = \begin{pmatrix} q^m_{00}(\mathbf{u}^0) & q^m_{01}(\mathbf{u}^0) & \cdots & q^m_{0m}(\mathbf{u}^0) \\ q^m_{10}(\mathbf{u}^1) & q^m_{11}(\mathbf{u}^1) & \cdots & q^m_{0m}(\mathbf{u}^1) \\ \vdots & \vdots & \cdots & \vdots \\ q^m_{m0}(\mathbf{u}^m) & q^m_{m1}(\mathbf{u}^m) & \cdots & q^m_{mm}(\mathbf{u}^m) \end{pmatrix},$$

$$\bar{Q}^d(W) = \begin{pmatrix} q^d_{00}(\mathbf{w}^0) & q^d_{01}(\mathbf{w}^0) & \cdots & q^d_{0d}(\mathbf{w}^0) \\ q^d_{10}(\mathbf{w}^1) & q^d_{11}(\mathbf{w}^1) & \cdots & q^d_{1d}(\mathbf{w}^1) \\ \vdots & \vdots & \cdots & \vdots \\ q^d_{d0}(\mathbf{w}^d) & q^d_{d1}(\mathbf{w}^d) & \cdots & q^d_{dd}(\mathbf{w}^d) \end{pmatrix}.$$

For each $U \in \Gamma^m$ and $W \in \Gamma^d$, let

$$\begin{aligned} \boldsymbol{\nu}^m(U) &= (\nu_0^m(U), \nu_1^m(U), \dots, \nu_m^m(U)), \\ \text{and} \quad \boldsymbol{\nu}^d(W) &= (\nu_0^d(W), \nu_1^d(W), \dots, \nu_d^d(W)) \end{aligned}$$

denote nonnegative solutions, respectively, to

$$\begin{aligned} &\boldsymbol{\nu}^m(U)\bar{Q}^m(U) = 0 \text{ and } \textstyle\sum_{i=0}^m \nu_i^m(U) = 1, \\ \text{and} \quad &\boldsymbol{\nu}^d(W)\bar{Q}^d(W) = 0 \text{ and } \textstyle\sum_{i=0}^d \nu_i^d(W) = 1. \end{aligned} \tag{2.5}$$

The vectors $\boldsymbol{\nu}^m(U)$ and $\boldsymbol{\nu}^d(W)$ will be called the average distributions of $\bar{Q}^m(U)$ and $\bar{Q}^d(W)$ for any given $U \in \Gamma^m$ and $W \in \Gamma^d$, respectively.

We make the following assumptions on the function G and the generators $Q^m(\mathbf{u})$ and $Q^d(\mathbf{w})$.

(A1) There exists a constant c_g, such that for all $\mathbf{x}, \mathbf{x}', \mathbf{u}, \mathbf{u}', \mathbf{w}$, and $\mathbf{w}'$, we have

$$\begin{aligned} &0 \le G(\mathbf{x}, \mathbf{z}, \mathbf{u}, \mathbf{w}) \le c_g(1 + |\mathbf{x}|), \\ &|G(\mathbf{x}, \mathbf{z}, \mathbf{u}, \mathbf{w}) - G(\mathbf{x}', \mathbf{z}, \mathbf{u}', \mathbf{w}')| \\ &\quad \le c_g(1 + |\mathbf{x}| + |\mathbf{x}'|)|\mathbf{x} - \mathbf{x}'| + c_g|\mathbf{u} - \mathbf{u}'| + c_g|\mathbf{w} - \mathbf{w}'|. \end{aligned}$$

(A2) $Q^m(\mathbf{u})$ and $Q^d(\mathbf{w})$ are continuous functions of $\mathbf{u}$ and $\mathbf{w}$. Moreover, for each $U \in \Gamma^m$ and $W \in \Gamma_d$, the systems of equations (2.5) have unique nonnegative solutions $\boldsymbol{\nu}^m(U)$ and $\boldsymbol{\nu}^d(W)$, which are assumed to be continuous with respect to $U \in \Gamma^m$ and $W \in \Gamma^d$. Furthermore, there exist $U \in \Gamma^m$ and $W \in \Gamma^d$ such that $\bar{Q}^m(U)$ and $\bar{Q}^d(W)$ are both irreducible.

We give two examples in which assumption (A2) holds.

Example 2.2. $Q^m(\mathbf{u}) = Q^m$ and $Q^d(\mathbf{w}) = Q^d$, where Q^m and Q^d are constant irreducible matrices. In this case, $\boldsymbol{\nu}^m(U) = \boldsymbol{\nu}^m$ and $\boldsymbol{\nu}^d(W) = \boldsymbol{\nu}^d$ are the familiar equilibrium distributions.

Example 2.3. Let $Q^m(\mathbf{u})$ and $Q^d(\mathbf{w})$ denote generators of birth–death processes, i.e.,

$$Q^m(\mathbf{u}) = \begin{pmatrix} -\mu_0 & \mu_0 & 0 & 0 & \cdots & 0 \\ \lambda_1(\mathbf{u}) & -(\lambda_1(\mathbf{u}) + \mu_1) & \mu_1 & 0 & \cdots & 0 \\ 0 & \lambda_2(\mathbf{u}) & -(\lambda_2(\mathbf{u}) + \mu_2) & \mu_2 & \cdots & 0 \\ \vdots & \vdots & \vdots & \vdots & \cdots & \vdots \\ 0 & 0 & 0 & \cdots & \lambda_m(\mathbf{u}) & -\lambda_m(\mathbf{u}) \end{pmatrix},$$

$$Q^d(\mathbf{w}) =$$

$$\begin{pmatrix} -\bar{\mu}_0(\mathbf{w}) & \bar{\mu}_0(\mathbf{w}) & 0 & 0 & \cdots & 0 \\ \bar{\lambda}_1(\mathbf{w}) & -(\bar{\lambda}_1(\mathbf{w}) + \bar{\mu}_1(\mathbf{w})) & \bar{\mu}_1(\mathbf{w}) & 0 & \cdots & 0 \\ 0 & \bar{\lambda}_2(\mathbf{w}) & -(\bar{\lambda}_2(\mathbf{w}) + \bar{\mu}_2(\mathbf{w})) & \bar{\mu}_2(\mathbf{w}) & \cdots & 0 \\ \vdots & \vdots & \vdots & \vdots & \cdots & \vdots \\ 0 & 0 & 0 & \cdots & \bar{\lambda}_d(\mathbf{w}) & -\bar{\lambda}_d(\mathbf{w}) \end{pmatrix}.$$

We assume that $\mu_i > 0$, $\bar{\lambda}_i > 0$, and that $\lambda_i(\mathbf{u}) \geq 0$ and $\bar{\mu}_i(\mathbf{w})$ are continuous in $\mathbf{u}, \mathbf{w}$. Thus, for any given $U \in \Gamma$ and $W \in \Gamma^d$, we have

$$\bar{Q}^m(U) = \begin{pmatrix} -\mu_0 & \mu_0 & 0 & 0 & \cdots & 0 \\ \lambda_1(\mathbf{u}^1) & -\lambda_1(\mathbf{u}^1) - \mu_1 & \mu_1 & 0 & \cdots & 0 \\ 0 & \lambda_2(\mathbf{u}^2) & -\lambda_2(\mathbf{u}^2) - \mu_2 & \mu_2 & \cdots & 0 \\ \vdots & \vdots & \vdots & \vdots & \cdots & \vdots \\ 0 & 0 & 0 & \cdots & \lambda_m(\mathbf{u}^m) & -\lambda_m(\mathbf{u}^m) \end{pmatrix},$$

$$\bar{Q}^d(\mathbf{w}) =$$

$$\begin{pmatrix} -\bar{\mu}_0(\mathbf{w}^0) & \bar{\mu}_0(\mathbf{w}^0) & 0 & 0 & \cdots & 0 \\ \bar{\lambda}_1(\mathbf{w}^1) & -\bar{\lambda}_1(\mathbf{w}^1) - \bar{\mu}_1(\mathbf{w}^1) & \bar{\mu}_1(\mathbf{w}^1) & 0 & \cdots & 0 \\ 0 & \bar{\lambda}_2 & -\bar{\lambda}_2(\mathbf{w}^2) - \bar{\mu}_2(\mathbf{w}^2) & \bar{\mu}_2(\mathbf{w}^2) & \cdots & 0 \\ \vdots & \vdots & \vdots & \vdots & \cdots & \vdots \\ 0 & 0 & 0 & \cdots & \bar{\lambda}_d(\mathbf{w}^d) & -\bar{\lambda}_d(\mathbf{w}^d) \end{pmatrix}.$$

The average distributions $\boldsymbol{\nu}^m(U)$ and $\boldsymbol{\nu}^d(W)$ are given as follows:

$$\nu_0^m(U) = \frac{\lambda_1(\mathbf{u}^1) \cdots \lambda_m(\mathbf{u}^m)}{\lambda_1(\mathbf{u}^1) \cdots \lambda_m(\mathbf{u}^m) + \mu_0 \lambda_2(\mathbf{u}^2) \cdots \lambda_m(\mathbf{u}^m) + \cdots + \mu_0 \cdots \mu_{m-1}},$$

and for $i \geq 1$,

$$\nu_i^m(U) = \nu_0^m(U) \frac{\mu_0 \cdots \mu_{i-1}}{\lambda_1(\mathbf{u}^1) \cdots \lambda_m(\mathbf{u}^m)};$$

$$\nu_0^d(W) =$$

$$\frac{\bar{\lambda}_1(\mathbf{w}^1) \cdots \bar{\lambda}_d(\mathbf{w}^d)}{\bar{\lambda}_1(\mathbf{w}^1) \cdots \bar{\lambda}_d(\mathbf{w}^d) + \bar{\mu}_0(\mathbf{w}^0) \bar{\lambda}_2(\mathbf{w}^2) \cdots \bar{\lambda}_d(\mathbf{w}^d) + \cdots + \bar{\mu}_0(\mathbf{w}^0) \cdots \bar{\mu}_{d-1}(\mathbf{w}^{d-1})},$$

and for $i \geq 1$,

$$\nu_i^d(W) = \nu_0^d(W) \frac{\bar{\mu}_0(\mathbf{w}^0) \cdots \bar{\mu}_{i-1}(\mathbf{w}^{i-1})}{\bar{\lambda}_1(\mathbf{w}^1) \cdots \bar{\lambda}_d(\mathbf{w}^d)}.$$

Note that $Q^m(\mathbf{u})$ in the example could be thought of as a production capacity process consisting of m identical machines of unit capacity each. The state $i \in \mathcal{M}$ would correspond to the situation when i machines are up and $(m - i)$ machines are down. The machine breakdown rate depends on the production rate $\mathbf{u}$, whereas their repair rates are independent of it.

Let us now return to the general setup. Since $Q^m(\mathbf{u})$ and $Q^d(\mathbf{w})$ depend on the control variables of the system under consideration, the processes $\alpha(\varepsilon, t)$ and $\mathbf{z}(\delta, t)$ need to be defined simultaneously by using the piecewise-deterministic process approach introduced by Davis [8]. To this end, we need to define the generator of the joint process $(\alpha(\varepsilon, t), \mathbf{z}(\delta, t))$.

First of all, note that the state space of $(\alpha(\varepsilon,t),\mathbf{z}(\delta,t))$ is given by

$$\mathcal{M}\times\mathcal{Z}=\{(0,\mathbf{z}^0),\dots,(0,\mathbf{z}^d),(1,\mathbf{z}^0),\dots,(1,\mathbf{z}^d),\dots,(m,\mathbf{z}^0),\dots,(m,\mathbf{z}^d)\}.$$

For ease of notation, we represent $\mathcal{M}\times\mathcal{Z}$ by the set

$$\{(00),\dots,(0d),(10),\dots,(1d),\dots,(m0),\dots,(md)\}$$

such that (ij) corresponds to $(i,\mathbf{z}^j)$.

We define an $[(m+1)\times(d+1)]\times[(m+1)\times(d+1)]$-matrix $Q(\mathbf{u},\mathbf{w})$ as follows:

$$Q(\mathbf{u},\mathbf{w})=\frac{1}{\varepsilon}\begin{pmatrix} q^m_{00}(\mathbf{u})I & q^m_{01}(\mathbf{u})I & \cdots & q^m_{0m}(\mathbf{u})I\\ q^m_{10}(\mathbf{u})I & q^m_{11}(\mathbf{u})I & \cdots & q^m_{1m}(\mathbf{u})I\\ \vdots & \vdots & \cdots & \vdots\\ q^m_{m0}(\mathbf{u})I & q^m_{m1}(\mathbf{u})I & \cdots & q^m_{mm}(\mathbf{u})I\end{pmatrix} +\frac{1}{\delta}\begin{pmatrix} Q^d(\mathbf{w}) & 0 & \cdots & 0\\ 0 & Q^d(\mathbf{w}) & \cdots & 0\\ \vdots & \vdots & \cdots & \vdots\\ 0 & 0 & \cdots & Q^d(\mathbf{w})\end{pmatrix},$$

where I is the $(d+1)\times(d+1)$-identity matrix. If we let $q_{(ii')(jj')}(\mathbf{u},\mathbf{w})$ denote the $(ii')(jj')$th entry of $Q(\mathbf{u},\mathbf{w})$, then one can see that

$$q_{(ii')(jj')}(\mathbf{u},\mathbf{w})=\begin{cases}\varepsilon^{-1}q^m_{ii}(\mathbf{u})+\delta^{-1}q^d_{i'i'}(\mathbf{w}) & \text{if } i=j,\ i'=j',\\ \delta^{-1}q^d_{i'j'}(\mathbf{w}) & \text{if } i=j,\ i'\neq j',\\ \varepsilon^{-1}q^m_{ij}(\mathbf{u}) & \text{if } i\neq j,\ i'=j',\\ 0 & \text{if } i\neq j,\ i'\neq j'.\end{cases}$$

We can also define a matrix $\bar{Q}(U,W)$ as follows:

$$\bar{Q}(U,W)=\frac{1}{\varepsilon}\begin{pmatrix} q^m_{00}(\mathbf{u}^0)I & q^m_{01}(\mathbf{u}^0)I & \cdots & q^m_{0m}(\mathbf{u}^0)I\\ q^m_{10}(\mathbf{u}^1)I & q^m_{11}(\mathbf{u}^1)I & \cdots & q^m_{1m}(\mathbf{u}^1)I\\ \vdots & \vdots & \cdots & \vdots\\ q^m_{m0}(\mathbf{u}^m)I & q^m_{m1}(\mathbf{u}^m)I & \cdots & q^m_{mm}(\mathbf{u}^m)I\end{pmatrix} +\frac{1}{\delta}\begin{pmatrix} \bar{Q}^d(W) & 0 & \cdots & 0\\ 0 & \bar{Q}^d(W) & \cdots & 0\\ \vdots & \vdots & \cdots & \vdots\\ 0 & 0 & \cdots & \bar{Q}^d(W)\end{pmatrix}. \tag{2.6}$$

It can be shown that if $\bar{Q}^m(U)$ and $\bar{Q}^d(W)$ are irreducible for some U and W, respectively, then $\bar{Q}(U,W)$ is also irreducible for some (U,W).

With $\bar{Q}(U, W)$ thus specified, we can construct the desired Markov process $(\alpha(\varepsilon, t), \mathbf{z}(\delta, t))$ by the same approach used in [25]. Moreover, the process

$$(2.7)\quad f(\alpha(\varepsilon,t),\mathbf{z}(\delta,t)) - f(\alpha(\varepsilon,s),\mathbf{z}(\delta,s)) - \int_s^t Q(\mathbf{u}_r,\mathbf{w}_r) f(\alpha(\varepsilon,r),\mathbf{z}(\delta,r))dr$$

is a martingale for any bounded function f on $\mathcal{M} \times \mathcal{Z}$.

2.3. Possible hierarchies and associated problems. In this section, we shall state precisely the various optimization problems that will be studied in this paper. These problems arise in the process of specifying various possible hierarchies that are involved.

We begin with a precise statement of the marketing–production problem developed in §§2.1 and 2.2.

DEFINITION 2.1. *We say that a control* $(\mathbf{u}.,\mathbf{w}.) = \{(\mathbf{u}_t,\mathbf{w}_t) : t \geq 0\}$ *is* admissible *if* $(\mathbf{u}.,\mathbf{w}.)$ *is right-continuous having left-hand limit* (RCLL), *is* $\sigma\{(\alpha(\varepsilon,s),\mathbf{z}(\delta,s)) : s \leq t\}$ *adapted, and satisfies* $\mathbf{u}_t \in \mathcal{U}_{\alpha(\varepsilon,t)}$ *and* $\mathbf{w}_t \in \mathcal{W}$ *for all* $t \geq 0$. *We use* $\mathcal{A}^{\varepsilon,\delta}$ *to denote the set of all admissible controls. Then our control problem can be written as follows*:

$$(2.8)\ \mathcal{P}^{\varepsilon,\delta} : \begin{cases} \text{max.} & J^{\varepsilon,\delta}(\mathbf{x},\alpha,\mathbf{z},\mathbf{u}.,\mathbf{w}.) = E\displaystyle\int_0^\infty e^{-\rho t} G(\mathbf{x}_t,\mathbf{z}(\delta,t),\mathbf{u}_t,\mathbf{w}_t)dt \\ \text{s.t.} & \begin{cases} \dot{\mathbf{x}}_t = \mathbf{u}_t - \mathbf{z}(\delta,t), \ \mathbf{x}_0 = \mathbf{x}, \\ (\alpha(\varepsilon,t),\mathbf{z}(\delta,t)) \sim \bar{Q}(\mathbf{u}_t,\mathbf{w}_t), \\ (\alpha(\varepsilon,0),\mathbf{z}(\delta,0)) = (\alpha,\mathbf{z}), \\ (\mathbf{u}.,\mathbf{w}.) \in \mathcal{A}^{\varepsilon,\delta}, \end{cases} \\ \text{value fn.} & v^{\varepsilon,\delta}(\mathbf{x},\alpha,\mathbf{z}) = \displaystyle\sup_{(\mathbf{u}.,\mathbf{w}.)\in\mathcal{A}^{\varepsilon,\delta}} J^{\varepsilon,\delta}(\mathbf{x},\alpha,\mathbf{z},\mathbf{u}.,\mathbf{w}.), \end{cases}$$

where by $(\alpha(\varepsilon,t),\mathbf{z}(\delta,t)) \sim \bar{Q}(\mathbf{u}_t,\mathbf{w}_t)$, *we mean that the Markov process* $(\alpha(\varepsilon,t),\mathbf{z}(\delta,t))$ *has the generator* $\bar{Q}(\mathbf{u}_t,\mathbf{w}_t)$.

We use $\mathcal{A}^{0,0}$, $\mathcal{A}^{\varepsilon,0}$, and $\mathcal{A}^{0,\delta}$ to denote the admissible control spaces

$$\mathcal{A}^{0,0} = \{(U_t,W_t) \in \Gamma^m \times \Gamma^d : (U_t,W_t) \text{ is deterministic and RCLL}\},$$
$$\mathcal{A}^{\varepsilon,0} = \{(\mathbf{u}_t,W_t) \in \mathcal{U}_{\alpha(\varepsilon,t)} \times \Gamma^d : (\mathbf{u}_t,W_t) \text{ is } \sigma\{\alpha(\varepsilon,s) : s \leq t\} \text{ adapted and RCLL}\},$$
$$\mathcal{A}^{0,\delta} = \{(U_t,\mathbf{w}_t) \in \Gamma^m \times \mathcal{W} : (U_t,\mathbf{w}_t) \text{ is } \sigma\{\mathbf{z}(\delta,s) : s \leq t\} \text{ adapted and RCLL}\},$$

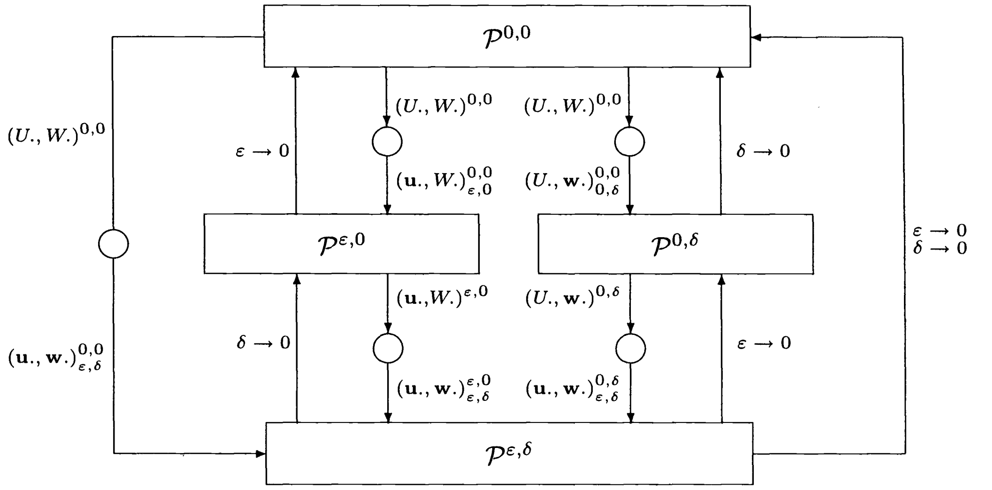
respectively, for the optimal control problems $\mathcal{P}^{0,0}, \mathcal{P}^{\varepsilon,0}$, and $\mathcal{P}^{0,\delta}$ given below:

$$(2.9)\qquad \mathcal{P}^{\varepsilon,0}: \begin{cases} \text{max.} & J^{\varepsilon,0}(\mathbf{x}, \alpha, \mathbf{u}., W.) \\ & \quad = \displaystyle\int_0^\infty e^{-\rho t} \sum_{j=0}^{d} \nu_j^d(W_t) G(\mathbf{x}_t, \mathbf{z}^j, \mathbf{u}_t, \mathbf{w}_t^j)\, dt \\ \text{s.t.} & \begin{cases} \dot{\mathbf{x}}_t = \mathbf{u}_t - \displaystyle\sum_{j=0}^{d} \nu_j^d(W_t)\mathbf{z}^j, & \mathbf{x}_0 = \mathbf{x}, \\ \alpha(\varepsilon, t) \sim \dfrac{1}{\varepsilon} Q^m(\mathbf{u}_t), & \alpha(\varepsilon, 0) = \alpha, \\ (\mathbf{u}., W.) \in \mathcal{A}^{\varepsilon,0}, \end{cases} \\ \text{value fn.} & v^{\varepsilon,0}(\mathbf{x}, \alpha) = \displaystyle\sup_{(\mathbf{u}., W.) \in \mathcal{A}^{\varepsilon,0}} J^{\varepsilon,0}(\mathbf{x}, \alpha, \mathbf{u}., W.); \end{cases}$$

$$(2.10)\qquad \mathcal{P}^{0,\delta}: \begin{cases} \text{max.} & J^{0,\delta}(\mathbf{x}, \mathbf{z}, U., \mathbf{w}.) \\ & \quad = \displaystyle\int_0^\infty e^{-\rho t} \sum_{i=0}^{m} \nu_i^m(U_t) G(\mathbf{x}_t, \mathbf{z}(\delta, t), \mathbf{u}_t^i, \mathbf{w}_t)\, dt \\ \text{s.t.} & \begin{cases} \dot{\mathbf{x}}_t = \displaystyle\sum_{i=0}^{m} \nu_i^m(U_t)\mathbf{u}_t^i - \mathbf{z}(\delta, t), & \mathbf{x}_0 = \mathbf{x}, \\ \mathbf{z}(\delta, t) \sim \dfrac{1}{\delta} Q^d(\mathbf{w}_t), & \mathbf{z}(\delta, 0) = \mathbf{z}, \\ (U., \mathbf{w}.) \in \mathcal{A}^{0,\delta}, \end{cases} \\ \text{value fn.} & v^{0,\delta}(\mathbf{x}, \mathbf{z}) = \displaystyle\sup_{(U., \mathbf{w}.) \in \mathcal{A}^{0,\delta}} J^{0,\delta}(\mathbf{x}, \mathbf{z}, U., \mathbf{w}.); \end{cases}$$

$$(2.11)\qquad \mathcal{P}^{0,0}: \begin{cases} \text{max.} & J^{0,0}(\mathbf{x}, U., W.) \\ & \quad = \displaystyle\int_0^\infty e^{-\rho t} \sum_{i=0, j=0}^{m,d} \nu_i^m(U_t)\nu_j^d(W_t) G(\mathbf{x}_t, \mathbf{z}^j, \mathbf{u}_t^i, \mathbf{w}_t^j)\, dt \\ \text{s.t.} & \begin{cases} \dot{\mathbf{x}}_t = \displaystyle\sum_{i=0}^{m} \nu_i^m(U_t)\mathbf{u}_t^i - \sum_{j=0}^{d} \nu_j^d(W_t)\mathbf{z}^j, & \mathbf{x}_0 = \mathbf{x}, \\ (U., W.) \in \mathcal{A}^{0,0}, \end{cases} \\ \text{value fn.} & v^{0,0}(\mathbf{x}) = \displaystyle\sup_{(U., W.) \in \mathcal{A}^{0,0}} J^{0,0}(\mathbf{x}, U., W.). \end{cases}$$

Here we refer to $\mathcal{P}^{0,0}$ as the corporate-level problem, $\mathcal{P}^{\varepsilon,0}$ as the production-level problem, $\mathcal{P}^{0,\delta}$ as the marketing-level problem, and $\mathcal{P}^{\varepsilon,\delta}$ as the operational-level problem. Figure 1 shows the structure of this multilevel hierarchy. Note further that when we consider any two of the above problems (except $\mathcal{P}^{\varepsilon,0}$ vs. $\mathcal{P}^{0,\delta}$), we always use *upper level* to refer to the simpler problem and *lower level* to refer to the other. For example, between $\mathcal{P}^{0,0}$ and $\mathcal{P}^{\varepsilon,0}$, we say $\mathcal{P}^{0,0}$ is the upper-level problem and $\mathcal{P}^{\varepsilon,0}$ is the lower-level problem. The structure of the multilevel hierarchy is shown in Fig. 1, in which we use $(U., W.)^{0,0}$, $(\mathbf{u}., W)^{\varepsilon,0}$, and $(U., \mathbf{w})^{0,\delta}$ to denote near-optimal controls for $\mathcal{P}^{0,0}$, $\mathcal{P}^{\varepsilon,0}$, and $\mathcal{P}^{0,\delta}$, respectively. We also use $(\mathbf{u}., W.)^{0,0}_{\varepsilon,0} \in \mathcal{A}^{\varepsilon,0}$ and $(U., \mathbf{w}.)^{0,0}_{0,\delta} \in \mathcal{A}^{0,\delta}$ to



$\mathcal{P}^{0,0}$
$(U., W.)^{0,0}$
$(U., W.)^{0,0}$
$(U., W.)^{0,0}$
$\varepsilon \to 0$
$\delta \to 0$
$(\mathbf{u}., W.)^{0,0}_{\varepsilon,0}$
$(U., \mathbf{w}.)^{0,0}_{0,\delta}$
$\mathcal{P}^{\varepsilon,0}$
$\mathcal{P}^{0,\delta}$
$\varepsilon \to 0$
$\delta \to 0$
$(\mathbf{u}., W.)^{\varepsilon,0}$
$(U., \mathbf{w}.)^{0,\delta}$
$(\mathbf{u}., \mathbf{w}.)^{0,0}_{\varepsilon,\delta}$
$\delta \to 0$
$\varepsilon \to 0$
$(\mathbf{u}., \mathbf{w}.)^{\varepsilon,0}_{\varepsilon,\delta}$
$(\mathbf{u}., \mathbf{w}.)^{0,\delta}_{\varepsilon,\delta}$
$\mathcal{P}^{\varepsilon,\delta}$

FIG. 1. *Possible multilevel hierarchies.*

denote asymptotic optimal controls constructed from $(U., W.)^{0,0}$ for $\mathcal{P}^{\varepsilon,0}$ and $\mathcal{P}^{0,\delta}$, respectively. Similarly, $(\mathbf{u}., \mathbf{w}.)^{0,0}_{\varepsilon,\delta} \in \mathcal{A}^{\varepsilon,\delta}$, $(\mathbf{u}., \mathbf{w}.)^{\varepsilon,0}_{\varepsilon,\delta} \in \mathcal{A}^{\varepsilon,0}$, and $(\mathbf{u}., \mathbf{w}.)^{0,\delta}_{\varepsilon,\delta} \in \mathcal{A}^{\varepsilon,0}$, are asymptotic optimal controls constructed from $(U., W.)^{0,0}$, $(\mathbf{u}., W)^{\varepsilon,0}$, and $(U., \mathbf{w}.)^{0,\delta}$, respectively, for $\mathcal{P}^{\varepsilon,\delta}$. It should be noted that the construction of asymptotic optimal controls for the lower problems are certainly not unique.

3. Analysis of the value functions. In this section, we first state some elementary properties of the value functions and then study their asymptotic behavior as $\varepsilon \to 0$ and/or $\delta \to 0$.

We begin with the Lipschitz property of the value functions.

THEOREM 3.1. *Let $v(\mathbf{x}, \alpha, \mathbf{z})$ denote any of the four value functions $v^{\varepsilon,\delta}(\mathbf{x}, \alpha, \mathbf{z})$, $v^{\varepsilon,0}(\mathbf{x}, \alpha)$, $v^{0,\delta}(\mathbf{x}, \mathbf{z})$, and $v^{0,0}(\mathbf{x})$. Then for each $(\alpha, \mathbf{z}) \in \mathcal{M} \times \mathcal{Z}$, $v(\mathbf{x}, \alpha, \mathbf{z})$ has at most linear growth and is locally Lipschitz with the Lipschitz constant independent of ε and δ, i.e., for some constant C,*

$$0 \le v(\mathbf{x}, \alpha, \mathbf{z}) \le C(1 + |\mathbf{x}|) \text{ for all } \varepsilon \text{ and } \mathbf{x}, \tag{3.1}$$

and

$$|v(\mathbf{x}_1, \alpha, \mathbf{z}) - v(\mathbf{x}_2, \alpha, \mathbf{z})| \le C(1 + |\mathbf{x}_1| + |\mathbf{x}_2|)|\mathbf{x}_1 - \mathbf{x}_2| \tag{3.2}$$

for all $\mathbf{x}_1$ and $\mathbf{x}_2$.

Proof. The proof is similar to the one in [25, Thm. 3.1]. □

Next, we write Hamilton–Jacobi–Bellman (HJB) equations for the problems defined in the last section and claim that the value functions of the problems satisfy these equations. In writing these equations, however, we note that the notation $f_{\mathbf{x}}$ means the gradient of a function f with respect to $\mathbf{x}$ when it exists. Otherwise, the equations are understood to be in the sense of the viscosity solutions (see, e.g., [13] and [7]).

THEOREM 3.2. *The value functions* $v^{\varepsilon,\delta}(\mathbf{x},\alpha,\mathbf{z})$, $v^{\varepsilon,0}(\mathbf{x},\alpha)$, $v^{0,\delta}(\mathbf{x},\mathbf{z})$, *and* $v^{0,0}(\mathbf{x})$ *are viscosity solutions to the following* HJB *equations, respectively*:

(3.3)
$$\rho v^{\varepsilon,\delta}(\mathbf{x},\alpha,\mathbf{z}) = \max_{(\mathbf{u},\mathbf{w})\in\mathcal{U}_\alpha\times\mathcal{W}}\left\{(\mathbf{u}-\mathbf{z})\cdot v^{\varepsilon,\delta}_{\mathbf{x}}(\mathbf{x},\alpha,\mathbf{z}) + G(\mathbf{x},\mathbf{z},\mathbf{u},\mathbf{w}) \right.$$
$$\left. + \frac{1}{\varepsilon}Q^m(\mathbf{u})v^{\varepsilon,\delta}(\mathbf{x},\cdot,\mathbf{z})(\alpha) + \frac{1}{\delta}Q^d(\mathbf{w})v^{\varepsilon,\delta}(\mathbf{x},\alpha,\cdot)(\mathbf{z})\right\}$$

for any $(\alpha,\mathbf{z})\in\mathcal{M}\times\mathcal{Z}$;

(3.4)
$$\rho v^{\varepsilon,0}(\mathbf{x},\alpha) = \max_{(\mathbf{u},W)\in\mathcal{U}_\alpha\times\Gamma^d}\left\{(\mathbf{u}-\mathbf{z})\cdot v^{\varepsilon,0}_{\mathbf{x}}(\mathbf{x},\alpha) + \sum_{j=0}^{d}\nu^d_j(W)G(\mathbf{x},\mathbf{z}^j,\mathbf{u},\mathbf{w}^j)\right.$$
$$\left. + \frac{1}{\varepsilon}Q^m(\mathbf{u})v^{\varepsilon,0}(\mathbf{x},\cdot)(\alpha)\right\}$$

for any $\alpha\in\mathcal{M}$;

(3.5)
$$\rho v^{0,\delta}(\mathbf{x},\mathbf{z}) = \max_{(U,\mathbf{w})\in\Gamma^m\times\mathcal{W}}\left\{\sum_{i=0}^{m}\nu^m_i(U)(\mathbf{u}^i-\mathbf{z})\cdot v^{0,\delta}_{\mathbf{x}}(\mathbf{x},\mathbf{z})\right.$$
$$\left. + \sum_{i=0}^{m}\nu^m_i(U)G(\mathbf{x},\mathbf{z},\mathbf{u}^i,\mathbf{w}) + \frac{1}{\delta}Q^d(\mathbf{w})v^{0,\delta}(\mathbf{x},\cdot)(\mathbf{z})\right\}$$

for any $\mathbf{z}\in\mathcal{Z}$;

(3.6)
$$\rho v^{0,0}(\mathbf{x}) = \max_{(U,W)\in\Gamma^m\times\Gamma^d}\left\{\left(\sum_{i=0}^{m}\nu^m_i(U)\mathbf{u}^i - \sum_{j=0}^{d}\nu^d_j(W)\mathbf{z}^j\right)\cdot v^{0,0}_{\mathbf{x}}(\mathbf{x})\right.$$
$$\left. + \sum_{i=0,j=0}^{m,d}\nu^m_i(U)\nu^d_j(W)G(\mathbf{x},\mathbf{z}^j,\mathbf{u}^i,\mathbf{w}^j)\right\}.$$

Proof. The proof follows directly from Soner [32]. □

We now examine the asymptotic behavior of the value functions $v^{\varepsilon,\delta}(\mathbf{x},\alpha,\mathbf{z})$, $v^{\varepsilon,0}(\mathbf{x},\alpha)$, and $v^{0,\delta}(\mathbf{x},\mathbf{z})$, as ε goes to 0 and/or δ goes to 0.

THEOREM 3.3. *Under assumptions* (A1) *and* (A2), *the following hold*:

(i) $\lim_{\varepsilon,\delta\to 0} v^{\varepsilon,\delta}(\mathbf{x},\alpha,\mathbf{z}) = v^{0,0}(\mathbf{x})$;

(ii) $\lim_{\delta\to 0} v^{\varepsilon,\delta}(\mathbf{x},\alpha,\mathbf{z}) = v^{\varepsilon,0}(\mathbf{x},\alpha)$;

(iii) $\lim_{\varepsilon\to 0} v^{\varepsilon,\delta}(\mathbf{x},\alpha,\mathbf{z}) = v^{0,\delta}(\mathbf{x},\mathbf{z})$;

(iv) $\lim_{\varepsilon\to 0} v^{\varepsilon,0}(\mathbf{x},\alpha) = v^{0,0}(\mathbf{x})$;

(v) $\lim_{\delta\to 0} v^{0,\delta}(\mathbf{x},\mathbf{z}) = v^{0,0}(\mathbf{x})$.

Proof. We only prove (i), since the proofs for the others are similar. By [25, Thm. 4.1], it is sufficient to show the following: if there exists a sequence $(\varepsilon_l,\delta_l)\to 0$

$(l = 1, 2, \ldots)$ such that $v^{\varepsilon_l,\delta_l}(\mathbf{x}, \alpha, \mathbf{z}) \to v(\mathbf{x}, \alpha, \mathbf{z})$ as $l \to \infty$, then the limit function $v(\mathbf{x}, \alpha, \mathbf{z})$ is independent of $(\alpha, \mathbf{z})$.

If we examine the ratio of ε_l and δ_l, there are only three cases that may occur.

Case (a). $\liminf_{l\to\infty} \varepsilon_l/\delta_l = 0$.

Case (b). $\limsup_{l\to\infty} \varepsilon_l/\delta_l = \infty$.

Case (c). There exist constants c_1 and c_2 such that $0 < c_1 \le \varepsilon_l/\delta_l \le c_2 < \infty$ for all l.

We deal with each of these cases separately. We show that in each case, the limiting function $v(\mathbf{x}, \alpha, \mathbf{z})$ is independent of $(\alpha, \mathbf{z})$.

We consider Case (a) first. Note that Case (a) implies the existence of a further subsequence of $\{l\}$, still denoted by $\{l\}$, such that $\varepsilon_l/\delta_l \to 0$ as $l \to \infty$.

By assumption (A2), there exist $U^0 = (\mathbf{u}^0, \mathbf{u}^1, \ldots, \mathbf{u}^m) \in \Gamma^m$ and $W^0 = (\mathbf{w}^0, \mathbf{w}^1, \ldots, \mathbf{w}^d) \in \Gamma^d$ such that $\bar{Q}^m(U^0)$ and $\bar{Q}^d(W^0)$ are irreducible. Moreover, $\bar{Q}(U^0, W^0)$ defined in (2.6) is also irreducible.

For each fixed $\mathbf{x}$, it follows from Theorem 3.1 that $v^{\varepsilon_l,\delta_l}(\mathbf{x}, \alpha, \mathbf{z})$ is bounded on $(\alpha, \mathbf{z}) \in \mathcal{M} \times \mathcal{Z}$. Moreover, the subgradient $\partial_{\mathbf{x}} v^{\varepsilon_l,\delta_l}(\mathbf{x}, \alpha, \mathbf{z})$ is also a bounded set. Therefore by (3.3), we have

$$\begin{aligned}\rho v^{\varepsilon_l,\delta_l}(\mathbf{x}, i, \mathbf{z}^j) \ge\ & (\mathbf{u}^i - \mathbf{z}^j)\cdot\xi + G(\mathbf{x}, \mathbf{z}^j, \mathbf{u}^i, \mathbf{w}^j) \\ & + \frac{1}{\varepsilon_l}\bar{Q}^m(U^0)v^{\varepsilon_l,\delta_l}(\mathbf{x}, \cdot, \mathbf{z}^j)(i) + \frac{1}{\delta_l}\bar{Q}^d(W^0)v^{\varepsilon_l,\delta_l}(\mathbf{x}, i, \cdot)(\mathbf{z}^j)\end{aligned} \tag{3.7}$$

for all $\xi \in \partial_{\mathbf{x}} v^{\varepsilon_l,\delta_l}(\mathbf{x}, i, \mathbf{z}^j)$. Since $\varepsilon_l/\delta_l \to 0$, it follows that

$$\liminf_{l\to\infty} \bar{Q}^m(U^0)v^{\varepsilon_l,\delta_l}(\mathbf{x}, \cdot, \mathbf{z})(i) \le 0$$

for each $i \in \mathcal{M}$. Since $v^{\varepsilon_l,\delta_l}(\mathbf{x}, i, \mathbf{z}) \to v(\mathbf{x}, i, \mathbf{z})$,

$$\bar{Q}^m(U^0)v(\mathbf{x}, \cdot, \mathbf{z})(i) \le 0. \tag{3.8}$$

This system of inequalities (3.8) implies (cf. [25, Thm. 4.1]) that $v(\mathbf{x}, i, \mathbf{z})$ is independent of i. We may now denote $v(\mathbf{x}, i, \mathbf{z})$ by $v(\mathbf{x}, \mathbf{z})$ with a slight abuse of notation.

We next show that $v(\mathbf{x}, \alpha, \mathbf{z})$ is also independent of $\mathbf{z}$. Indeed, if we multiply the inequality in (3.7) that corresponds to $(\alpha, \mathbf{z}) = (i, \mathbf{z}^j)$ by $\nu_i^m(U^0)$, sum over $i \in \mathcal{M}$, and use the fact that $\sum_{i=0}^m \nu_i^m(U^0)\bar{Q}^m(U^0)v^{\varepsilon,\delta}(\mathbf{x}, \cdot, \mathbf{z}^j)(i) = 0$, then we shall have

$$\begin{aligned}\rho\sum_{i=0}^m \nu_i^m(U^0)v^{\varepsilon_l,\delta_l}(\mathbf{x}, i, \mathbf{z}^j) \ge\ & \sum_{i=0}^m \nu_i^m(U^0)(\mathbf{u}^i - \mathbf{z}^j)\cdot\partial_{\mathbf{x}} v^{\varepsilon_l,\delta_l}(\mathbf{x}, i, \mathbf{z}^j) \\ & + \sum_{i=0}^m \nu_i^m(U^0)G(\mathbf{x}, \mathbf{z}^j, \mathbf{u}^i, \mathbf{w}^j) \\ & + \frac{1}{\delta_l}\bar{Q}^d(W^0)\sum_{i=0}^m \nu_i^m(U^0)v^{\varepsilon_l,\delta_l}(\mathbf{x}, i, \cdot)(\mathbf{z}^j).\end{aligned}$$

Multiplying by δ_l and taking the limit yields

$$\liminf_{l\to\infty} \bar{Q}^d(W^0)\sum_{i=0}^m \nu_i^m(U^0)v^{\varepsilon_l,\delta_l}(\mathbf{x}, i, \cdot)(\mathbf{z}^j) \le 0$$

for each $\mathbf{z}^j \in \mathcal{Z}$. By using $v^{\varepsilon_l,\delta_l}(\mathbf{x}, \alpha, \mathbf{z}) \to v(\mathbf{x}, \mathbf{z})$, we have

$$\bar{Q}^d(W^0)v(\mathbf{x}, \cdot)(\mathbf{z}) \le 0.$$

This implies that $v(\mathbf{x}, \mathbf{z})$ is independent of $\mathbf{z}$. Hence, if Case (a) holds, then $v(\mathbf{x}, \alpha, \mathbf{z})$ is independent of $(\alpha, \mathbf{z})$.

If Case (b) holds, i.e., $\limsup_{l \to \infty} \varepsilon_l/\delta_l = \infty$, then we have $\liminf_{l \to \infty} \delta_l/\varepsilon_l = 0$. If we exchange the role of ε_l and δ_l, then there exists a further subsequence of $\{l\}$ such that $\delta_l/\varepsilon_l \to 0$. We can thus repeat the argument used in Case (a) to show that the limiting function $v(\mathbf{x}, \alpha, \mathbf{z})$ is independent of $(\alpha, \mathbf{z})$, also in Case (b).

Finally, in Case (c), there exists a further subsequence of $\{l\}$, still denoted by $\{l\}$, such that $\varepsilon_l/\delta_l \to a > 0$ as $l \to \infty$. Without loss of generality, we may assume $a = 1$. Then, as in Case (a), we have

$$\bar{Q}(U^0, W^0)v(\mathbf{x}, \cdot, \cdot)(\alpha, \mathbf{z}) \leq 0$$

for all $(\alpha, \mathbf{z}) \in \mathcal{M} \times \mathcal{Z}$. Then by the irreducibility of $\bar{Q}(U^0, W^0)$, we conclude that $v(\mathbf{x}, \alpha, \mathbf{z})$ is independent of $(\alpha, \mathbf{z})$. This completes the proof. □

4. Asymptotic behavior of capacity and demand processes. The purpose of this section is to analyze the asymptotic behavior of the process $(\alpha(\varepsilon, t), \mathbf{z}(\delta, t))$ as $\varepsilon \to 0$ and/or $\delta \to 0$. The analysis will allow us to use optimal controls of lower-level problems for constructing asymptotically optimal controls for the corresponding upper-level problems.

Let χ_D denote the indicator function of set D and let

$$\begin{aligned}
&\psi^\varepsilon(t) = (\chi_{\{\alpha(\varepsilon,t)=0\}}, \ldots, \chi_{\{\alpha(\varepsilon,t)=m\}}),\\
&\psi^\delta(t) = (\chi_{\{\mathbf{z}(\delta,t)=\mathbf{z}^1\}}, \ldots, \chi_{\{\mathbf{z}(\delta,t)=\mathbf{z}^d\}}),\\
\text{and}\quad &\psi^{\varepsilon,\delta}(t) = (\chi_{\{\alpha(\varepsilon,t)=0\}}\psi^\delta(t), \ldots, \chi_{\{\alpha(\varepsilon,t)=m\}}\psi^\delta(t)).
\end{aligned}$$

From (2.7) it is easy to see that

$$\psi^{\varepsilon,\delta}(t) - \psi^{\varepsilon,\delta}(s) - \int_s^t \psi^{\varepsilon,\delta}(r)\bar{Q}(U_r, W_r)dr \tag{4.1}$$

is a martingale. But

$$\begin{aligned}
\psi^{\varepsilon,\delta}(t)\bar{Q}(U_t, W_t) = \frac{1}{\varepsilon}\Big\{ &(q_{00}^m(\mathbf{u}^0)\chi_{\{\alpha(\varepsilon,t)=0\}} + \cdots + q_{m0}^m(\mathbf{u}^m)\chi_{\{\alpha(\varepsilon,t)=m\}})\psi^\delta(t),\\
&\ldots, (q_{0m}^m(\mathbf{u}^0)\chi_{\{\alpha(\varepsilon,t)=0\}} + \cdots + q_{mm}^m(\mathbf{u}^m)\chi_{\{\alpha(\varepsilon,t)=m\}})\psi^\delta(t)\Big\}\\
&+ \frac{1}{\delta}\Big\{\chi_{\{\alpha(\varepsilon,t)=0\}}\psi^\delta(t)\bar{Q}^d(W_t), \ldots, \chi_{\{\alpha(\varepsilon,t)=m\}}\psi^\delta(t)\bar{Q}^d(W_t)\Big\}.
\end{aligned}$$

This implies that for each $i \in \mathcal{M}$,

$$\begin{aligned}
&\chi_{\{\alpha(\varepsilon,t)=i\}}\psi^\delta(t) - \chi_{\{\alpha(\varepsilon,s)=i\}}\psi^\delta(s)\\
&\quad - \int_s^t \{\varepsilon^{-1}[(q_{0i}^m(\mathbf{u}_r^0)\chi_{\{\alpha(\varepsilon,r)=0\}} + \cdots + q_{mi}^m(\mathbf{u}_r^m)\chi_{\{\alpha(\varepsilon,r)=m\}})\psi^\delta(r)]\\
&\qquad + \delta^{-1}\chi_{\{\alpha(\varepsilon,t)=i\}}\psi^\delta(t)\bar{Q}^d(W_r)\}\, dr
\end{aligned}$$

is a martingale. Summing up over $i \in \mathcal{M}$, we conclude that

$$\psi^\delta(t) - \psi^\delta(s) - \int_s^t \frac{1}{\delta}\psi^\delta(r)\bar{Q}^d(W_r)dr \tag{4.2}$$

is a martingale.

Similarly, we can show that

$$\psi^\varepsilon(t) - \psi^\varepsilon(s) - \int_s^t \frac{1}{\varepsilon}\psi^\varepsilon(r)\bar{Q}^m(U_r)dr \tag{4.3}$$

is also a martingale.

Now define $P^{\varepsilon,\delta}(t) = E\psi^{\varepsilon,\delta}(t)$. Then,

$$\begin{aligned}P^{\varepsilon,\delta}(t) = (\,&P((\alpha(\varepsilon,t),\mathbf{z}(\delta,t)) = (0,\mathbf{z}^1)),\dots,P((\alpha(\varepsilon,t),\mathbf{z}(\delta,t)) = (0,\mathbf{z}^d)),\\ &\dots,P((\alpha(\varepsilon,t),\mathbf{z}(\delta,t)) = (m,\mathbf{z}^1)),\dots,P((\alpha(\varepsilon,t),\mathbf{z}(\delta,t)) = (m,\mathbf{z}^d))).\end{aligned}$$

By (4.1), we see that

$$P^{\varepsilon,\delta}(t) = P^{\varepsilon,\delta}(s) + \int_s^t P^{\varepsilon,\delta}(r)\bar{Q}(U_r,W_r)dr. \tag{4.4}$$

Similarly, if we let $P^\varepsilon(t) = E\psi^\varepsilon(t)$ and $P^\delta(t) = E\psi^\delta(t)$ so that

$$\begin{aligned}&P^\varepsilon(t) = (P(\alpha(\varepsilon,t) = 0),\dots,P(\alpha(\varepsilon,t) = m))\\ \text{and}\quad &P^\delta(t) = (P(\mathbf{z}(\delta,t) = \mathbf{z}^1),\dots,P(\mathbf{z}(\delta,t) = \mathbf{z}^d)),\end{aligned}$$

we can derive

$$P^\varepsilon(t) = P^\varepsilon(s) + \int_s^t P^\varepsilon(r)\bar{Q}^m(U_r)dr \text{ and } P^\delta(t) = P^\delta(s) + \int_s^t P^\delta(r)\bar{Q}^d(W_r)dr.$$

Let $\boldsymbol{\nu}^m(t) := \boldsymbol{\nu}^m(U_t)$, $\boldsymbol{\nu}^d(t) := \boldsymbol{\nu}^d(W_t)$, and $\boldsymbol{\nu}(t) := (\nu_0^m(t)\boldsymbol{\nu}^d(t),\dots,\nu_m^m(t)\boldsymbol{\nu}^d(t))$. Let $L^2([s,T])$, $0 \le s \le T$, denote the space of all functions $f : [s,T] \to R^1$ that are square integrable. Then, we have the following two lemmas.

LEMMA 4.1. *For each $s \in [0,T]$, $P^{\varepsilon,\delta}(t)$, $P^\varepsilon(t)$, and $P^\delta(t)$ converge weakly to $\boldsymbol{\nu}(t)$, $\boldsymbol{\nu}^m(t)$, and $\boldsymbol{\nu}^d(t)$ on $L^2([s,T])$, respectively. That is, for each $f(t) \in L^2([0,T])$, we have*

$$\begin{aligned}&\text{(i)}\quad \lim_{\varepsilon\to 0}\int_s^T [P^\varepsilon(t) - \boldsymbol{\nu}^m(t)]f(t)dt = 0;\\ &\text{(ii)}\quad \lim_{\delta\to 0}\int_s^T [P^\delta(t) - \boldsymbol{\nu}^d(t)]f(t)dt = 0;\\ &\text{(iii)}\quad \lim_{\varepsilon,\delta\to 0}\int_s^T [P^{\varepsilon,\delta}(t) - \boldsymbol{\nu}(t)]f(t)dt = 0.\end{aligned}$$

Proof. First of all, (i) and (ii) can be proved as in [25, Lem. 5.1]. Thus we need only to show (iii). Let $(\varepsilon_l,\delta_l,\ l = 1,2,\dots)$ denote a subsequence of $(\varepsilon,\delta) \to 0$. We have the same three possible cases as in Theorem 3.3. We deal with these cases one by one.

If Case (a) holds, then there exists a further subsequence of $\{l\}$, still denoted by $\{l\}$, such that $\varepsilon_l/\delta_l \to 0$ as $l \to \infty$. Note that since $P^{\varepsilon,\delta}(t) \in L^2([0,T])$, there exists (cf. [35, Thm. 1, p. 126]) yet another subsequence of $(\varepsilon_l,\delta_l) \to 0$ such that $\{P^{\varepsilon_l,\delta_l}(t)\}_{[0,T]}$ converges weakly to some

$$P^{0,0}(t) = (p_{00}(t),\dots,p_{0d}(t),\dots,p_{m0}(t),\dots,p_{md}(t)) \in L^2([0,T]),$$

i.e.,

$$\int_0^T [P^{\varepsilon,\delta}(r) - P^{0,0}(r)]f(r)dr \to 0$$

for any $f(\cdot) \in L^2([0,T])$. Moreover, $0 \leq P^{0,0}(t) \leq 1$ and $\sum_{i,j}^{m,d} p_{ij}(t) = 1$ a.e.

Let

$$\tilde{Q}^m(U_t) = \begin{pmatrix} q_{00}^m(\mathbf{u}_t^0)I & q_{01}^m(\mathbf{u}_t^0)I & \cdots & q_{0m}^m(\mathbf{u}_t^0)I \\ q_{10}^m(\mathbf{u}_t^1)I & q_{11}^m(\mathbf{u}_t^1)I & \cdots & q_{1m}^m(\mathbf{u}_t^1)I \\ \vdots & \vdots & \cdots & \vdots \\ q_{m0}^m(\mathbf{u}_t^m)I & q_{m1}^m(\mathbf{u}_t^m)I & \cdots & q_{mm}^m(\mathbf{u}_t^m)I \end{pmatrix}.$$

It is easy to see that $\tilde{Q}^m(U_t) \in L^2([0,T])$. This implies that for $0 \leq s \leq t \leq T$, we have

$$\int_s^t [P^{\varepsilon,\delta}(r) - P^{0,0}(r)]\tilde{Q}^m(U_r)dr \to 0.$$

Thus, by noting (4.4) and the fact that $\varepsilon_l/\delta_l \to 0$, we obtain

$$\int_s^t P^{0,0}(r)\tilde{Q}^m(U_r)dr = 0.$$

Since s and t are arbitrary, it follows immediately that

$$P^{0,0}(t)\tilde{Q}^m(U_t) = 0, \text{ a.e.}$$

From this and the irreducibility of $\bar{Q}^m(U_t)$, which is related to $\tilde{Q}^m(U_t)$, one can conclude

$$\begin{cases} (p_{00}(t), \ldots, p_{m0}(t)) = p_0(t)\boldsymbol{\nu}^m(t), \\ \qquad \cdots \\ (p_{0d}(t), \ldots, p_{md}(t)) = p_d(t)\boldsymbol{\nu}^m(t), \\ \qquad p_0(t) + \cdots + p_d(t) = 1 \end{cases}$$

for some $p_j(t) \geq 0$. By (i) of Lemma 4.1,

$$P(\mathbf{z}(\delta,t) = \mathbf{z}^j) \to \nu_j^d(t).$$

Since

$$P(\mathbf{z}(\delta,t) = \mathbf{z}^j) = P((\alpha(\varepsilon,t), \mathbf{z}(\delta,t)) = (0, \mathbf{z}^j)) + \cdots + P((\alpha(\varepsilon,t), \mathbf{z}(\delta,t)) = (m, \mathbf{z}^j)),$$

it follows that $p_{0j}(t) + \cdots + p_{mj}(t) = \nu_j^d(t)$. This implies $p_j(t) = \nu_j^d(t)$. Thus,

$$p_{ij}(t) = \nu_i^m(t)\nu_j^d(t) \text{ a.e. for all } i,j.$$

Since the weak limit of $P^{\varepsilon,\delta}(t)$ equals $\boldsymbol{\nu}(t)$, which is independent of the choice of the subsequences of $(\varepsilon_l, \delta_l)$, it holds that $P^{\varepsilon,\delta}(t) \to \boldsymbol{\nu}(t)$ weakly.

Similarly, we can show that Lemma 4.1(iii) holds in Case (b) if we reverse the role of ε and δ. Finally, if Case (c) holds, the above argument goes through by noting the irreducibility of $\bar{Q}(U_t, W_t)$. □

LEMMA 4.2. *For any bounded deterministic process $\beta(s)$ and for each $i \in \mathcal{M}$ and $t \geq 0$,*

$$E\left|\int_0^t (\chi_{\{\alpha(\varepsilon,s)=i\}} - \nu_i^m(s))\beta(s)ds\right|^2 \to 0 \text{ as } \varepsilon \to 0,$$

$$E\left|\int_0^t (\chi_{\{\mathbf{z}(\delta,s)=\mathbf{z}^j\}} - \nu_i^d(s))\beta(s)ds\right|^2 \to 0 \text{ as } \delta \to 0.$$

Moreover, for any $0 \leq s \leq T$,

$$P(\alpha(\varepsilon,t) = i|\sigma\{\mathbf{z}(\delta,r) : \, r \leq s\}) \to \nu_j^m(U_t) \textit{weakly on } L^2([s,T]) \textit{as } \varepsilon \to 0 \text{ a.s.},$$
$$P(\mathbf{z}(\delta,t) = \mathbf{z}^j|\sigma\{\alpha(\varepsilon,r) : r \leq s\}) \to \nu_j^d(W_t) \textit{weakly on } L^2([s,T]) \textit{as } \delta \to 0 \text{ a.s.}$$

Proof. The proof is as in [25, Lem. 5.1]. □

5. Asymptotically optimal open-loop controls. In this section, we construct asymptotically optimal open-loop controls for the lower-level problems from optimal controls of the corresponding upper-level problems. Here open-loop controls refer to partially open-loop controls, i.e., controls that respond to the machine state but not to the surplus state. Feedback controls are considered in the next section.

THEOREM 5.1 (open-loop controls; $\mathcal{P}^{\varepsilon,\delta}$ vs. $\mathcal{P}^{0,0}$). *Let $(U_\cdot, W_\cdot) \in \mathcal{A}^{0,0}$ denote an optimal control for the upper-level problem $\mathcal{P}^{0,0}$. Construct*

$$(\mathbf{u}_t^{\varepsilon,\delta}, \mathbf{w}_t^{\varepsilon,\delta}) = \left(\sum_{i=0}^m \chi_{\{\alpha(\varepsilon,t)=i\}}\mathbf{u}_t^i, \sum_{j=0}^d \chi_{\{\mathbf{z}(\delta,t)=\mathbf{z}^j\}}\mathbf{w}_t^j\right).$$

Then, $(\mathbf{u}_\cdot^{\varepsilon,\delta}, \mathbf{w}_\cdot^{\varepsilon,\delta}) \in \mathcal{A}^{\varepsilon,\delta}$. Furthermore, it is asymptotically optimal for the original lower-level problem $\mathcal{P}^{\varepsilon,\delta}$, i.e.,

$$\lim_{\varepsilon,\delta\to 0} |J^{\varepsilon,\delta}(\mathbf{x}, \alpha, \mathbf{z}, \mathbf{u}_\cdot^{\varepsilon,\delta}, \mathbf{w}_\cdot^{\varepsilon,\delta}) - v^{\varepsilon,\delta}(\mathbf{x}, \alpha, \mathbf{z})| = 0.$$

Proof. The proof of this theorem can be given as in [25, Thm. 6.1]. We provide an outline of the proof here, however, for the sake of completeness. From the procedure of constructing piecewise-deterministic processes described in [25], it is not difficult to see that the generators $Q(\mathbf{u}_t^{\varepsilon,\delta}, \mathbf{w}_t^{\varepsilon,\delta})$ and $\bar{Q}(U_t, W_t)$ both generate the same process $(\alpha(\varepsilon,t), \mathbf{z}(\delta,t))$. Thus, $(\mathbf{u}_t^{\varepsilon,\delta}, \mathbf{w}_t^{\varepsilon,\delta}) \in \mathcal{A}^{\varepsilon,\delta}$. Since $\lim_{\varepsilon,\delta\to 0} v^{\varepsilon,\delta}(\mathbf{x}, \alpha, \mathbf{z}) = v^{0,0}(\mathbf{x})$ and $J^{\varepsilon,\delta}(\mathbf{x}, \alpha, \mathbf{z}, \mathbf{u}_\cdot^{\varepsilon,\delta}, \mathbf{w}_\cdot^{\varepsilon,\delta}) \leq v^{\varepsilon,\delta}(\mathbf{x}, \alpha, \mathbf{z})$, it suffices to show that

$$\liminf_{\varepsilon,\delta\to 0} J^{\varepsilon,\delta}(\mathbf{x}, \alpha, \mathbf{z}, \mathbf{u}_\cdot^{\varepsilon,\delta}, \mathbf{w}_\cdot^{\varepsilon,\delta}) \geq v^{0,0}(\mathbf{x}). \tag{5.1}$$

Let $(U_\cdot, W_\cdot) = ((\mathbf{u}_\cdot^0, \ldots, \mathbf{u}_\cdot^m), (\mathbf{w}_\cdot^0, \ldots, \mathbf{w}_\cdot^d)) \in \mathcal{A}^{0,0}$ be an open-loop optimal control for $\mathcal{P}^{0,0}$ and let $(\mathbf{u}_t^{\varepsilon,\delta}, \mathbf{w}_t^{\varepsilon,\delta}) = (\sum_{i=0}^m \chi_{\{\alpha(\varepsilon,t)=i\}}\mathbf{u}_t^i, \sum_{j=0}^d \chi_{\{\mathbf{z}(\delta,t)=\mathbf{z}^j\}}\mathbf{w}^j)$. Let $\mathbf{x}_\cdot$ and $\bar{\mathbf{x}}_\cdot$ denote the corresponding state trajectories of the systems $\mathcal{P}^{\varepsilon,\delta}$ and $\mathcal{P}^{0,0}$ with

TABLE 1
Asymptotically optimal open-loop controls.

Hierarchy: lower vs. upper	Optimal control for upper level	Asymptotically optimal control constructed for lower-level problems
$\mathcal{P}^{\varepsilon,\delta}$ vs. $\mathcal{P}^{0,0}$	$(U_\cdot, W_\cdot) \in \mathcal{A}^{0,0}$	$\left(\sum_{i=0}^{m} \chi_{\{\alpha=i\}}\mathbf{u}_t^i, \sum_{j=0}^{d} \chi_{\{\mathbf{z}=\mathbf{z}^j\}}\mathbf{w}_t^j\right) \in \mathcal{A}^{\varepsilon,\delta}$
$\mathcal{P}^{\varepsilon,\delta}$ vs. $\mathcal{P}^{\varepsilon,0}$	$(\mathbf{u}_\cdot, W_\cdot) \in \mathcal{A}^{\varepsilon,0}$	$\left(\mathbf{u}_t, \sum_{j=0}^{d} \chi_{\{\mathbf{z}=\mathbf{z}^j\}}\mathbf{w}_t^j\right) \in \mathcal{A}^{\varepsilon,\delta}$
$\mathcal{P}^{\varepsilon,\delta}$ vs. $\mathcal{P}^{0,\delta}$	$(U_\cdot, \mathbf{w}_\cdot) \in \mathcal{A}^{0,\delta}$	$\left(\sum_{i=0}^{m} \chi_{\{\alpha=i\}}\mathbf{u}_t^i, \mathbf{w}_t\right) \in \mathcal{A}^{\varepsilon,\delta}$
$\mathcal{P}^{\varepsilon,0}$ vs. $\mathcal{P}^{0,0}$	$(U_\cdot, W_\cdot) \in \mathcal{A}^{0,0}$	$\left(\sum_{i=0}^{m} \chi_{\{\alpha=i\}}\mathbf{u}_t^i, W_t\right) \in \mathcal{A}^{\varepsilon,0}$
$\mathcal{P}^{0,\delta}$ vs. $\mathcal{P}^{0,0}$	$(U_\cdot, W_\cdot) \in \mathcal{A}^{0,0}$	$\left(U_t, \sum_{j=0}^{d} \chi_{\{\mathbf{z}=\mathbf{z}^j\}}\mathbf{w}_t^j\right) \in \mathcal{A}^{0,\delta}$

the same initial $\mathbf{x}$, respectively. Then by Lemma 4.2, we can show that $E|\mathbf{x}_t - \bar{\mathbf{x}}_t| \to 0$ as $\varepsilon, \delta \to 0$.

Moreover, by assumption (A1),

$$\liminf_{\varepsilon,\delta\to 0} E\int_0^\infty e^{-\rho t}[G(\mathbf{x}_t, \mathbf{z}(\delta,t), \mathbf{u}_t^{\varepsilon,\delta}, \mathbf{w}_t^{\varepsilon,\delta}) - G(\bar{\mathbf{x}}_t, \mathbf{z}(\delta,t), \mathbf{u}_t^{\varepsilon,\delta}, \mathbf{w}_t^{\varepsilon,\delta})]dt \geq 0.$$

It follows that

$$\liminf_{\varepsilon,\delta\to 0} J^{\varepsilon,\delta}(\mathbf{x}, \alpha, \mathbf{z}, \mathbf{u}_\cdot^{\varepsilon,\delta}, \mathbf{w}_\cdot^{\varepsilon,\delta}) \geq \liminf_{\varepsilon,\delta\to 0} E\int_0^\infty e^{-\rho t} G(\bar{\mathbf{x}}_t, \mathbf{z}(\delta,t), \mathbf{u}_t^{\varepsilon,\delta}, \mathbf{w}_t^{\varepsilon,\delta})dt.$$

Now, by our construction of $(\mathbf{u}_\cdot^{\varepsilon,\delta}, \mathbf{w}_\cdot^{\varepsilon,\delta})$ and by Lemma 4.1, we have

$$\begin{aligned} & E\int_0^\infty e^{-\rho t} G(\bar{\mathbf{x}}_t, \mathbf{z}(\delta,t), \mathbf{u}_t^{\varepsilon,\delta}, \mathbf{w}_t^{\varepsilon,\delta})dt \\ & \to \int_0^\infty e^{-\rho t}\left(\sum_{i=0,j=0}^{m,d} \nu_i^m(U_t)\nu_j^d(W_t)G(\bar{\mathbf{x}}_t, \mathbf{z}^j, \mathbf{u}_t^i, \mathbf{w}_t^j)\right)dt = v^{0,0}(\mathbf{x}). \end{aligned}$$

This implies (5.1) and completes the proof. □

In Theorem 5.1, the lower-level problem is $\mathcal{P}^{\varepsilon,\delta}$ and the upper-level problem is $\mathcal{P}^{0,0}$. The idea is to construct an asymptotically optimal solution for the lower-level problem from an optimal solution of the upper-level problem. The result is summarized in Table 1 in the $\mathcal{P}^{\varepsilon,\delta}$ vs. $\mathcal{P}^{0,0}$ row, which is the first row. Similar results can be proved in similar ways for other combinations of lower- and upper-level problems. These are also summarized in Table 1 in rows 2–4.

Remark 5.1. Another possible method for obtaining a lower-level decision is to resolve the lower-level problem given the upper-level decision. In view of the results proved in this section, it should be obvious that this method would also provide an asymptotically optimal solution; see also [21].

6. Asymptotically optimal feedback controls. We now consider feedback controls. We begin with the hierarchy $\mathcal{P}^{\varepsilon,\delta}$ vs. $\mathcal{P}^{0,0}$. Let

$$(U(\mathbf{x}), W(\mathbf{x})) = (\mathbf{u}^0(\mathbf{x}), \dots, \mathbf{u}^m(\mathbf{x}), \mathbf{w}^0(\mathbf{x}), \dots, \mathbf{w}^d(\mathbf{x}))$$

denote an optimal feedback control for $\mathcal{P}^{0,0}$. This is obtained by maximizing the right-hand side of (3.6), i.e.,

$$\begin{aligned} &\left(\sum_{i=0}^{m} \nu_i^m(U(\mathbf{x}))\mathbf{u}^i(\mathbf{x}) - \sum_{j=0}^{d} \nu_j^d(W(\mathbf{x}))\mathbf{z}^j\right) \cdot v_{\mathbf{x}}^{0,0}(\mathbf{x}) \\ &\quad + \sum_{i=0,j=0}^{m,d} \nu_i^m(U(\mathbf{x}))\nu_j^d(W(\mathbf{x}))G(\mathbf{x}, \mathbf{z}^j, \mathbf{u}^i(\mathbf{x}), \mathbf{w}^j(\mathbf{x})) \\ &= \max_{(U,W)\in\Gamma^m\times\Gamma^d} \left\{ \left(\sum_{i=0}^{m} \nu_i^m(U)\mathbf{u}^i - \sum_{j=0}^{d} \nu_j^d(W)\mathbf{z}^j\right) \cdot v_{\mathbf{x}}^{0,0}(\mathbf{x}) \right. \\ &\qquad \left. + \sum_{i=0,j=0}^{m,d} \nu_i^m(U)\nu_j^d(W)G(\mathbf{x}, \mathbf{z}^j, \mathbf{u}^i, \mathbf{w}^j) \right\}. \end{aligned} \tag{6.1}$$

We then construct a control

$$\begin{cases} \mathbf{u}(\mathbf{x}, \alpha, \mathbf{z}) = \displaystyle\sum_{i=0}^{m} \chi_{\{\alpha=i\}}\mathbf{u}^i(\mathbf{x}), \\ \mathbf{w}(\mathbf{x}, \alpha, \mathbf{z}) = \displaystyle\sum_{j=0}^{d} \chi_{\{\mathbf{z}=\mathbf{z}^j\}}\mathbf{w}^j(\mathbf{x}), \end{cases} \tag{6.2}$$

which is clearly feasible (satisfies the control constraints) for $\mathcal{P}^{\varepsilon,\delta}$. Moreover, if $(U(\mathbf{x}), W(\mathbf{x}))$ is locally Lipschitz, then the system $\dot{\mathbf{x}}_t = \mathbf{u}(\mathbf{x}_t, \alpha(\varepsilon, t), \mathbf{z}(\delta, t)) - \mathbf{z}(\delta, t)$, $\mathbf{x}_0 = \mathbf{x}$, has a unique solution and, therefore,

$$(\mathbf{u}_t, \mathbf{w}_t) = (\mathbf{u}(\mathbf{x}_t, \alpha(\varepsilon, t), \mathbf{z}(\delta, t)), \mathbf{w}(\mathbf{x}_t, \alpha(\varepsilon, t), \mathbf{z}(\delta, t)))$$

is also admissible for $\mathcal{P}^{\varepsilon,\delta}$. Discussions concerning the existence of such locally Lipschitz feedback controls can be found in [12], [28].

We need an additional assumption to show that $(\mathbf{u}(\mathbf{x}, \alpha, \mathbf{z}), \mathbf{w}(\mathbf{x}, \alpha, \mathbf{z}))$ is asymptotically optimal for $\mathcal{P}^{\varepsilon,\delta}$.

(A3) The following equation has a unique solution:

$$\bar{\mathbf{x}}_t = \mathbf{x} + \int_0^t \left(\sum_{i=0}^{m} \nu_i^m(U(\bar{\mathbf{x}}_r))\mathbf{u}^i(\bar{\mathbf{x}}_r) - \sum_{j=0}^{d} \nu_j^d(W(\bar{\mathbf{x}}_r))\mathbf{z}^j\right) dr, \ \bar{\mathbf{x}}_0 = \mathbf{x}. \tag{6.3}$$

A sufficient condition for this is that $(\boldsymbol{\nu}^m(U), \boldsymbol{\nu}^d(W))$ is locally Lipschitz in (U, W).

THEOREM 6.1 (feedback controls; $\mathcal{P}^{\varepsilon,\delta}$ vs. $\mathcal{P}^{0,0}$). *Assume* (A1)–(A3). *Suppose the feedback control* $(U(\mathbf{x}), W(\mathbf{x})) \in \mathcal{A}^{0,0}$ *is locally Lipschitz. Then, the feedback control constructed in* (6.2) *is asymptotically optimal for* $\mathcal{P}^{\varepsilon,\delta}$, *i.e.*,

$$\lim_{\varepsilon,\delta\to 0} |J^{\varepsilon,\delta}(\mathbf{x}, \alpha, \mathbf{z}, \mathbf{u}(\mathbf{x}_\cdot, \alpha(\varepsilon, \cdot), \mathbf{z}(\delta, \cdot)), \mathbf{w}(\mathbf{x}_\cdot, \alpha(\varepsilon, \cdot), \mathbf{z}(\delta, \cdot))) - v^{\varepsilon,\delta}(\mathbf{x}, \alpha, \mathbf{z})| = 0.$$

Proof. Since $\bar{\mathbf{x}}_t$ is the only solution to (6.3), we can show as in Lemma 4.1 and [25, Lem. 5.2] that

$$\psi^{\varepsilon,\delta}(t) \to \nu_i^m(U(\bar{\mathbf{x}}_t))\nu_j^d(W(\bar{\mathbf{x}}_t)) \text{ as } \varepsilon, \delta \to 0.$$

The rest of the proof follows exactly as in [25, Thm. 6.2]. □

Next we consider the hierarchy $\mathcal{P}^{\varepsilon,\delta}$ vs. $\mathcal{P}^{\varepsilon,0}$, which arises when ε is fixed and δ is small. While asymptotically optimal controls for $\mathcal{P}^{\varepsilon,\delta}$ can be constructed from the optimal control of $\mathcal{P}^{\varepsilon,0}$ in a way similar to that in (6.2), the proof of asymptotic optimality is quite different from that in [25] due to the fact that the limiting problem is no longer deterministic as it is in [25]. The uniqueness of the solution to the limiting problem, therefore, needs to be specified by the probability distribution of the underlying processes.

Let $(\mathbf{u}(\mathbf{x},\alpha), W(\mathbf{x},\alpha)) \in \mathcal{A}^{\varepsilon,0}$ denote an optimal feedback control for $\mathcal{P}^{\varepsilon,0}$ obtained by maximizing the right-hand side of (3.4). We need to make the following assumption:

(A3)$'$ The ordinary differential equation

$$\dot{\bar{\mathbf{x}}}_t = \mathbf{u}(\bar{\mathbf{x}}_t, \bar{\alpha}(\varepsilon,t)) - \sum_{j=0}^{d} \nu_j^d(W(\bar{\mathbf{x}}_t, \bar{\alpha}(\varepsilon,t)))\mathbf{z}^j, \ \bar{\mathbf{x}}_0 = \mathbf{x} \tag{6.4}$$

has a unique solution for any given $\bar{\alpha}(\varepsilon,t)$ generated by $\varepsilon^{-1}\bar{Q}^m(U(\bar{\mathbf{x}}_t))$ and $\alpha(\varepsilon,0) = \alpha$, where

$$U(\mathbf{x}) = (\mathbf{u}(\mathbf{x},0),\ldots,\mathbf{u}(\mathbf{x},m)). \tag{6.5}$$

A sufficient condition for (A3)$'$ is that $(\mathbf{u}(\mathbf{x},\alpha), W(\mathbf{x},\alpha))$ is locally Lipschitz in $\mathbf{x}$ for each α and $\boldsymbol{\nu}^d(W)$ is locally Lipschitz in W.

THEOREM 6.2 (feedback controls; $\mathcal{P}^{\varepsilon,\delta}$ vs. $\mathcal{P}^{\varepsilon,0}$). *Assume* (A1), (A2), *and* (A3)$'$. *Suppose the optimal feedback control* $(\mathbf{u}(\mathbf{x},\alpha), W(\mathbf{x},\alpha)) \in \mathcal{A}^{\varepsilon,0}$ *is locally Lipschitz for each* α. *Let*

$$\begin{cases} \mathbf{u}_t^{\varepsilon,\delta} = \mathbf{u}(\mathbf{x}_t, \alpha(\varepsilon,t), \mathbf{z}(\delta,t)), \\ \mathbf{w}_t^{\varepsilon,\delta} = \displaystyle\sum_{j=0}^{d} \chi_{\{\mathbf{z}(\delta,t)=\mathbf{z}^j\}}\mathbf{w}^j(\mathbf{x}_t, \alpha(\varepsilon,t)). \end{cases} \tag{6.6}$$

Then, the feedback control $(\mathbf{u}_\cdot^{\varepsilon,\delta}, \mathbf{w}_\cdot^{\varepsilon,\delta})$ *is asymptotically optimal for* $\mathcal{P}^{\varepsilon,\delta}$, *i.e.*,

$$\lim_{\delta\to 0} |J^{\varepsilon,\delta}(\mathbf{x},\alpha,\mathbf{z},\mathbf{u}_\cdot^{\varepsilon,\delta},\mathbf{w}_\cdot^{\varepsilon,\delta}) - v^{\varepsilon,\delta}(\mathbf{x},\alpha,\mathbf{z})| = 0.$$

Proof. In view of Theorem 3.3, it is sufficient to prove that

$$\liminf_{\delta\to 0} J^{\varepsilon,\delta}(\mathbf{x},\alpha,\mathbf{z},\mathbf{u}_\cdot^{\varepsilon,\delta},\mathbf{w}_\cdot^{\varepsilon,\delta}) \geq v^{\varepsilon,0}(\mathbf{x},\alpha,\mathbf{z}). \tag{6.7}$$

We divide the proof into four steps. These steps require the concepts of a martingale problem, the tightness of a class of processes, convergence in distribution, and the Skorohod topology. The reader is referred to [9] for details on these concepts.

Step 1. We need to show that $(\bar{\mathbf{x}}_t, \bar{\alpha}(\varepsilon,t))$ stipulated in (A3)$'$ has a uniquely determined distribution. For this purpose, we let A denote the generator defined as follows:

$$Af(\mathbf{x},\alpha) = \left(\mathbf{u}(\mathbf{x},\alpha) - \sum_{j=0}^{d} \nu_j^d(W(\mathbf{x},\alpha))\mathbf{z}^j\right)\frac{\partial}{\partial\mathbf{x}}f(\mathbf{x},\alpha) + \frac{1}{\varepsilon}\bar{Q}^m(U(\mathbf{x}))f(\mathbf{x},\cdot)(\alpha),$$

where $U(\mathbf{x})$ is given as in (6.5). As in [25, Eq. (5)], we can conclude that for $(\bar{\mathbf{x}}_t, \bar{\alpha}(\varepsilon, t))$,

$$f(\bar{\mathbf{x}}_t, \bar{\alpha}(\varepsilon, t)) - f(\mathbf{x}, \alpha) - \int_0^t Af(\bar{\mathbf{x}}_r, \bar{\alpha}(\varepsilon, r))dr \tag{6.8}$$

is a martingale for any continuously differentiable $f(\mathbf{x}, \alpha)$ which vanishes at infinity. Therefore, in order to prove that the probability distribution of $(\bar{\mathbf{x}}_t, \bar{\alpha}(\varepsilon, t))$ is uniquely determined, it is sufficient to show that the martingale problem (6.8) for A has a unique solution.

Indeed, let $(\bar{\mathbf{x}}_t^0, \bar{\alpha}^0(\varepsilon, t))$ denote a stochastic process such that

$$f(\bar{\mathbf{x}}_t^0, \bar{\alpha}^0(\varepsilon, t)) - f(\mathbf{x}, \alpha) - \int_0^t Af(\bar{\mathbf{x}}_r^0, \bar{\alpha}^0(\varepsilon, r))dr$$

is a martingale. For any $\gamma > 0$ and a bounded locally Lipschitz function $g(\mathbf{x}, \alpha)$, let

$$\phi(\mathbf{x}, \alpha) = E\int_0^\infty e^{-\gamma t} g(\bar{\mathbf{x}}_t^0, \bar{\alpha}^0(\varepsilon, t))dt.$$

Then, we can show (cf. [32]) that $\phi(\mathbf{x}, \alpha)$ is locally Lipschitz and is a viscosity solution to the HJB equation $(\gamma - A)\phi = g$. It can be shown (cf. [32]) that such an HJB equation has a unique viscosity solution. This implies, by [9, Eq. (4.29), p. 187], that the martingale problem (6.8) has a unique solution.

Step 2. Consider $(\mathbf{x}_t, \alpha(\varepsilon, t), \mathbf{z}(\delta, t))$ given by

$$\begin{cases} \dot{\mathbf{x}}_t = \mathbf{u}(\mathbf{x}_t, \alpha(\varepsilon, t)) - \mathbf{z}(\delta, t), \ \mathbf{x}_0 = \mathbf{x}, \\ (\alpha(\varepsilon, t), \mathbf{z}(\delta, t)) \sim \bar{Q}(U(\mathbf{x}_t), W(\mathbf{x}_t, \alpha(\varepsilon, t))), \ \alpha(\varepsilon, 0) = \alpha, \ \mathbf{z}(\delta, 0) = \mathbf{z}. \end{cases} \tag{6.9}$$

Let $D([0, T])$ denote the space of functions that are right-continuous having left-hand limits on $[0, T]$. We now prove that $\{(\mathbf{x}_t, \alpha(\varepsilon, t))\}$, as a sequence of processes indexed by $\delta > 0$, is tight on $D([0, T])$.

Since $\mathbf{u}(\mathbf{x}, \alpha)$ and $\mathbf{z}(\delta, t)$ are bounded, it suffices to show that $\{\alpha(\varepsilon, t)\}$ is tight. Note that for any $0 \le t_1 \le t \le t_2 \le T$ and $\eta > 0$,

$$\begin{aligned} &P(|\alpha(\varepsilon, t) - \alpha(\varepsilon, t_1)| \ge \eta, |\alpha(\varepsilon, t_2) - \alpha(\varepsilon, t)| \ge \eta) \\ &\quad \le P(\alpha(\varepsilon, t) \text{ jumps at least twice on } [t_1, t_2]). \end{aligned}$$

Let $0 = \tau_0 < \tau_1 < \tau_2 < \cdots$ denote a sequence of jump times of $\alpha(\varepsilon, t)$. If $t_1 = 0$, then

$$\begin{aligned} &P(\alpha(\varepsilon, t) \text{ jumps at least twice on } [0, t_2]) \\ &\quad \le P(\tau_1 + \tau_2 \le t_2) \\ &\quad \le 2C\int_0^{t_2}\int_0^t dsdt, \text{ for some constant } C \\ &\quad = Ct_2^2. \end{aligned}$$

If $t_1 > 0$, then by shifting the process $\alpha(\varepsilon, t)$ by t_1 units, we can show that

$$P(\alpha(\varepsilon, t) \text{ jumps at least twice on } [t_1, t_2]) \le C(t_2 - t_1)^2.$$

Let $F(t) = \sqrt{C}t$. Then,

$$P(|\alpha(\varepsilon,t) - \alpha(\varepsilon,t_1)| \geq \eta, |\alpha(\varepsilon,t_2) - \alpha(\varepsilon,t)| \geq \eta) \leq (F(t_2) - F(t_1))^2.$$

By the proof of [3, Thm. 15.6, p. 128], we conclude that $\{\alpha(\varepsilon,t)\}$ is tight.

Step 3. Let $(\mathbf{x}_t, \alpha(\varepsilon,t))$ denote a solution to (6.9) and $(\bar{\mathbf{x}}_t, \bar{\alpha}(\varepsilon,t))$ as defined in (A3)$'$. We now show that $(\mathbf{x}_t, \alpha(\varepsilon,t))$ converges in distribution to $(\bar{\mathbf{x}}_t, \bar{\alpha}(\varepsilon,t))$ as $\delta \to 0$.

Since $\{(\mathbf{x}_t, \alpha(\varepsilon,t)\}$ is tight on $D([0,T])$ for each sequence of δ converging to 0, there exists a subsequence, still denoted by δ, and $(\mathbf{x}_t^0, \alpha^0(\varepsilon,t)) \in D([0,T])$, such that $(\mathbf{x}_t, \alpha(\varepsilon,t))$ converges in distribution to $(\mathbf{x}_t^0, \alpha^0(\varepsilon,t))$. Then, by the Skorohod representation theorem [9, Thm. 1.8, p. 102], there exist a probability space $(\hat{\Omega}, \hat{\mathcal{F}}, \hat{P})$ and processes $(\tilde{\mathbf{x}}_t, \tilde{\alpha}(\varepsilon,t)) \in D([0,T])$ and $(\hat{\mathbf{x}}_t, \hat{\alpha}(\varepsilon,t)) \in D([0,T])$ defined on it, such that

$$\hat{P}((\tilde{\mathbf{x}}_t, \tilde{\alpha}(\varepsilon,t)) \in \cdot) = P((\mathbf{x}_t, \alpha(\varepsilon,t)) \in \cdot),$$
$$\hat{P}((\hat{\mathbf{x}}_t, \hat{\alpha}(\varepsilon,t)) \in \cdot) = P((\mathbf{x}_t^0, \alpha^0(\varepsilon,t)) \in \cdot),$$

and

$$(\tilde{\mathbf{x}}_t, \tilde{\alpha}(\varepsilon,t)) \to (\hat{\mathbf{x}}_t, \hat{\alpha}(\varepsilon,t)) \text{ a.s. as } \delta \to 0 \tag{6.10}$$

in the Skorohod topology. Note that $\mathbf{x}_t$ is continuous almost surely. It follows that $\tilde{\mathbf{x}}_t$ is also continuous almost surely, and so is $\hat{\mathbf{x}}_t$. Therefore, (6.10) yields that $\tilde{\mathbf{x}}_t \to \hat{\mathbf{x}}_t$ in the space $C([0,T])$ of continuous functions with the uniform convergence topology.

Since $\tilde{\mathbf{x}}_t$ has the same distribution as $\mathbf{x}_t$, it holds that $\tilde{\mathbf{x}}_t$ is differentiable almost surely. Define

$$\tilde{\mathbf{z}}(\delta,t) = \mathbf{u}(\tilde{\mathbf{x}}_t, \tilde{\alpha}(\varepsilon,t)) - \dot{\tilde{\mathbf{x}}}_t.$$

Then

$$\hat{P}((\tilde{\mathbf{x}}_t, \tilde{\alpha}(\varepsilon,t), \tilde{\mathbf{z}}(\delta,t)) \in \cdot) = P((\mathbf{x}_t, \alpha(\varepsilon,t), \mathbf{z}(\delta,t)) \in \cdot).$$

Moreover, for any f defined on $\mathcal{Z}$,

$$f(\tilde{\mathbf{z}}(\delta,t)) - f(\tilde{\mathbf{z}}(\delta,0)) - \frac{1}{\delta}\int_0^t \bar{Q}^d(W(\tilde{\mathbf{x}}_r, \tilde{\alpha}(\varepsilon,r)))f(\tilde{\mathbf{z}}(\delta,r))dr$$

is a martingale. Then, we can show as in [25, Lem. 5.1] that

$$\tilde{\mathbf{z}}(\delta,t) \to \boldsymbol{\nu}^d(W(\hat{\mathbf{x}}_t, \hat{\alpha}(\varepsilon,t))) \text{ weakly in } L^2([0,T]) \text{ a.s. as } \delta \to 0,$$

i.e.,

$$\int_a^b \chi_{\{\tilde{\mathbf{z}}(\delta,t)=\mathbf{z}^j\}} g(t)dt \to \int_a^b \nu_j^d(W(\hat{\mathbf{x}}_t, \hat{\alpha}(\varepsilon,t)))g(t)dt \text{ a.s.}$$

for all $g \in L^2([0,T])$.

Note that for any continuously differentiable $f(\mathbf{x},\alpha)$,

$$\begin{aligned} f(\tilde{\mathbf{x}}_t, \tilde{\alpha}(\varepsilon,t)) - f(\mathbf{x},\alpha) - \int_0^t & (\mathbf{u}(\tilde{\mathbf{x}}_r, \tilde{\alpha}(\varepsilon,r)) - \tilde{\mathbf{z}}(\delta,r))\frac{\partial}{\partial \mathbf{x}} f(\tilde{\mathbf{x}}_r, \tilde{\alpha}(\varepsilon,r)) \\ & + \frac{1}{\varepsilon}\bar{Q}^m(U(\tilde{\mathbf{x}}_r))f(\tilde{\mathbf{x}}_r, \cdot)(\tilde{\alpha}(\varepsilon,r))dr \end{aligned} \tag{6.11}$$

is a martingale. Recall that $(\tilde{\mathbf{x}}_t, \tilde{\alpha}(\varepsilon, t)) \to (\bar{\mathbf{x}}_t, \bar{\alpha}(\varepsilon, t))$. By sending $\delta \to 0$ in (6.11), we conclude (cf. [9]) that

$$f(\hat{\mathbf{x}}_t, \hat{\alpha}(\varepsilon, t)) - f(\mathbf{x}, \alpha) - \int_0^t \left(\mathbf{u}(\hat{\mathbf{x}}_r, \hat{\alpha}(\varepsilon, r)) - \sum_{j=0}^{d} \nu_j^d(W(\hat{\mathbf{x}}_r, \hat{\alpha}(\varepsilon, r))) \right) \frac{\partial}{\partial \mathbf{x}} f(\hat{\mathbf{x}}_r, \hat{\alpha}(\varepsilon, r))$$
$$+ \frac{1}{\varepsilon} \bar{Q}^m(U(\hat{\mathbf{x}}_r)) f(\hat{\mathbf{x}}_r, \cdot)(\hat{\alpha}(\varepsilon, r)) dr$$

is also a martingale. Therefore, by Step 1, the probability distribution of $(\hat{\mathbf{x}}_t, \hat{\alpha}(\varepsilon, t))$ is uniquely determined by (6.8). Thus, $(\tilde{\mathbf{x}}_t, \tilde{\alpha}(\varepsilon, t))$ converges to $(\hat{\mathbf{x}}_t, \hat{\alpha}(\varepsilon, t))$ in distribution as $\delta \to 0$.

By the above argument, we may assume (by the Skorohod representation) that

$$\begin{aligned} &(\mathbf{x}_t, \alpha(\varepsilon, t)) \to (\bar{\mathbf{x}}_t, \bar{\alpha}(\varepsilon, t)) \text{ a.s. in the Skorohod topology} \\ \text{and} \quad &\mathbf{z}(\delta, t) \to \boldsymbol{\nu}^d(W(\bar{\mathbf{x}}_t, \bar{\alpha}(\varepsilon, t))) \text{ weakly in } L^2([0, T]) \text{ a.s.} \end{aligned} \tag{6.12}$$

Step 4. We can now prove (6.7).

Let

$$\begin{cases} \mathbf{u}_t^{\varepsilon,0} = \mathbf{u}(\bar{\mathbf{x}}_t, \bar{\alpha}(\varepsilon, t)), \\ W_t^{\varepsilon,0} = (\mathbf{w}_t^0, \ldots, \mathbf{w}_t^d) = W(\bar{\mathbf{x}}_t, \bar{\alpha}(\varepsilon, t)). \end{cases}$$

Then, in view of assumption (A1) and a corresponding result in [25, Thm. 6.1], it remains to show that for any fixed $0 < T < \infty$,

$$\begin{aligned} &\liminf_{\delta \to 0} E \int_0^T e^{-\rho t} G(\mathbf{x}_t, \mathbf{z}(\delta, t), \mathbf{u}_t^{\varepsilon,\delta}, \mathbf{w}_t^{\varepsilon,\delta}) dt \\ &\qquad \geq E \int_0^T e^{-\rho t} \sum_{j=0}^{d} \nu_j^d(W(\bar{\mathbf{x}}_t, \bar{\alpha}(\varepsilon, t))) G(\bar{\mathbf{x}}_t, \mathbf{z}^j, \mathbf{u}_t^{\varepsilon,0}, \mathbf{w}_t^{\varepsilon,0}) dt. \end{aligned} \tag{6.13}$$

In fact,

$$\begin{aligned} &E \int_0^T e^{-\rho t} G(\mathbf{x}_t, \mathbf{z}(\delta, t), \mathbf{u}_t^{\varepsilon,\delta}, \mathbf{w}_t^{\varepsilon,\delta}) dt \\ &\quad = E \int_0^T e^{-\rho t} \chi_{\{\mathbf{z}(\delta,t) = \mathbf{z}^j\}} G(\bar{\mathbf{x}}_t, \mathbf{z}^j, \mathbf{u}_t^{\varepsilon,0}, \mathbf{w}_t^j) dt \\ &\qquad + E \int_0^T e^{-\rho t} \sum_{j=0}^{d} \chi_{\{\mathbf{z}(\delta,t) = \mathbf{z}^j\}} [G(\mathbf{x}_t, \mathbf{z}^j, \mathbf{u}_t^{\varepsilon,\delta}, \mathbf{w}^j(\mathbf{x}_t, \alpha(\varepsilon, t), \mathbf{z}(\delta, t))) \\ &\qquad\qquad - G(\bar{\mathbf{x}}_t, \mathbf{z}^j, \mathbf{u}_t^{\varepsilon,0}, \mathbf{w}_t^j)] dt. \end{aligned} \tag{6.14}$$

Since $(\mathbf{x}_t, \alpha(\varepsilon, t))$ converges to $(\bar{\mathbf{x}}_t, \bar{\alpha}(\varepsilon, t))$ almost surely, the second term in the right-hand side of (6.14) goes to 0. By (6.12), the first term goes to

$$E \int_0^T e^{-\rho t} \nu_j^d(W(\bar{\mathbf{x}}_t, \bar{\alpha}(\varepsilon, t))) G(\bar{\mathbf{x}}_t, \mathbf{z}^j, \mathbf{u}_t^{\varepsilon,0}, \mathbf{w}_t^j) dt = v^{\varepsilon,0}(\mathbf{x}, \alpha, \mathbf{z}).$$

This completes the proof. □

In view of Theorems 6.1 and 6.2, summarized, respectively, in rows 1 and 2 of Table 2, the only remaining hierarchies for which asymptotically optimal controls need

TABLE 2
Asymptotically optimal feedback controls.

Hierarchy: lower vs. upper	Optimal control for upper level	Asymptotically optimal control constructed for lower-level problems
$\mathcal{P}^{\varepsilon,\delta}$ vs. $\mathcal{P}^{0,0}$	$(U,W)\in\mathcal{A}^{0,0}$	$\left(\sum_{i=0}^{m}\chi_{\{\alpha=i\}}\mathbf{u}^i(\mathbf{x}),\sum_{j=0}^{d}\chi_{\{\mathbf{z}=\mathbf{z}^j\}}\mathbf{w}^j(\mathbf{x})\right)\in\mathcal{A}^{\varepsilon,\delta}$
$\mathcal{P}^{\varepsilon,\delta}$ vs. $\mathcal{P}^{\varepsilon,0}$	$(\mathbf{u},W)\in\mathcal{A}^{\varepsilon,0}$	$\left(\mathbf{u}(\mathbf{x},\alpha),\sum_{j=0}^{d}\chi_{\{\mathbf{z}=\mathbf{z}^j\}}\mathbf{w}^j(\mathbf{x},\alpha)\right)\in\mathcal{A}^{\varepsilon,\delta}$
$\mathcal{P}^{\varepsilon,\delta}$ vs. $\mathcal{P}^{0,\delta}$	$(U,\mathbf{w})\in\mathcal{A}^{0,\delta}$	$\left(\sum_{i=0}^{m}\chi_{\{\alpha=i\}}\mathbf{u}^i(\mathbf{x},\mathbf{z}),\mathbf{w}(\mathbf{x},\mathbf{z})\right)\in\mathcal{A}^{\varepsilon,\delta}$
$\mathcal{P}^{\varepsilon,0}$ vs. $\mathcal{P}^{0,0}$	$(U,W)\in\mathcal{A}^{0,0}$	$\left(\sum_{i=0}^{m}\chi_{\{\alpha=i\}}\mathbf{u}^i(\mathbf{x}),W(\mathbf{x})\right)\in\mathcal{A}^{\varepsilon,0}$
$\mathcal{P}^{0,\delta}$ vs. $\mathcal{P}^{0,0}$	$(U,W)\in\mathcal{A}^{0,0}$	$\left(U(\mathbf{x}),\sum_{j=0}^{d}\chi_{\{\mathbf{z}=\mathbf{z}^j\}}\mathbf{w}^j(\mathbf{x})\right)\in\mathcal{A}^{0,\delta}$

to be constructed are $\mathcal{P}^{\varepsilon,\delta}$ vs. $\mathcal{P}^{0,\delta}$, $\mathcal{P}^{\varepsilon,0}$ vs. $\mathcal{P}^{0,0}$, and $\mathcal{P}^{0,\delta}$ vs. $\mathcal{P}^{0,0}$. The results for these are shown in Table 2 in rows 3, 4, and 5, respectively. The proof of row 2 is similar to the proof of Theorem 6.2. The proofs of rows 3 and 4 follow from [25, Thm. 6.2].

7. Concluding remarks.

In this paper, we have presented asymptotic optimality results for hierarchical production and advertising planning in a marketing–production system with random capacity and demand. We describe a procedure to construct a control for the given system, derived from the solution to one of the upper-level problems. The upper-level problems happen to be simpler problems obtained by averaging the given stochastic production capacity process and/or averaging the given stochastic demand process. Therefore, by showing that the associated value functions for the lower-level problems converge to the value functions of the upper-level problems, we are able to construct a control for a lower-level problem from the optimal control of the corresponding upper-level problem. It turns out that the controls so constructed are asymptotically optimal as the rates of transition between the capacity states go to infinity and/or the rates of transition between the demand states go to infinity, respectively.

Several open problems remain. Particularly important to us is the extension of these results to marketing–production systems with state constraints such as those with machines in tandem analyzed in Sethi, Zhang, and Zhou [27]. We would also like to obtain the convergence rates of value functions and error estimates of the constructed controls.

ON BANG–BANG CONSTRAINED SOLUTIONS OF A CONTROL SYSTEM*

RAPHAËL CERF[†] AND CARLO MARICONDA[‡]

Abstract. Given $\phi_1, \phi_2 \in L^1([0,T])$ and a function $x \in W^{2,1}([0,T])$ solving the control problem (P) $x''+a_1(t)x'+a_0(t)x \in [\phi_1(t), \phi_2(t)]$ a.e., $x(0) = x_0$, $x(T) = x_1$, $x'(0) = v_0$, $x'(T) = v_1$, there exists a bang–bang solution y to (P) satisfying $y \leq x$; moreover there exists a finite union of intervals E such that $y'' + a_1y' + a_0y = \phi_1\chi_E + \phi_2\chi_{[0,T]\setminus E}$. The reachable set of bang–bang constrained solutions is convex: an application to the calculus of variations.

Key words. bang–bang, linear control system, range of a vector measure, reachable set, calculus of variations

AMS subject classifications. 34H05, 49B10, 93C15

1. Introduction.

We consider the family of bidimensional linear control systems (P) described by a generic second-order equation subject to a scalar control:

$$x''+a_1(t)x'+a_0(t)x \in \Phi(t) = [\phi_1(t), \phi_2(t)],\ (x(0), x'(0), x(T), x'(T)) = (x_0, v_0, x_1, v_1),$$

where $\phi_1 \leq \phi_2 \in L^1([0,T])$ and $a_1, a_0 \in \mathcal{C}([0,T])$, $x_0, v_0, x_1, v_1 \in \mathbb{R}, x \in W^{2,1}([0,T])$.

The function y is said to be a bang–bang solution to (P) if it solves (P) and, moreover,

$$y'' + a_1(t)y' + a_0(t)y \in \text{extr } \Phi(t) = \{\phi_1(t), \phi_2(t)\} \text{ a.e.} \tag{1.1}$$

Existence of bang–bang solutions has been proved, for instance, by Cesari [4, Thm. 16.3]. The purpose of this paper is to prove that, given an arbitrary solution x to (P), there exists a bang–bang solution y such that

$$\forall t \in [0,T] \qquad y(t) \leq x(t) \tag{1.2}$$

and, in addition, $y'' + a_1y' + a_0y$ steers from ϕ_1 to ϕ_2 only a finite number of times.

Motivation of such a problem was to study the reachable set

$$\mathcal{Y}_T^c = \{(y(T), y'(T)) : y \leq c,\ y''+a_1(t)y'+a_0(t)y \in \text{extr } \Phi(t),\ (y(0), y'(0)) = (x_0, v_0)\},$$

where c is an arbitrary function. A consequence of Theorem 3.1 is that $\mathcal{Y}_T^c$ coincides with

$$\mathcal{X}_T^c = \{(y(T), y'(T)) : y \leq c,\ y'' + a_1(t)y' + a_0(t)y \in \Phi(t),\ (y(0), y'(0)) = (x_0, v_0)\}.$$

Notice that $\mathcal{X}_T^c$ is convex, so the above assumption implies that $\mathcal{Y}_T^c$ is convex too. Another motivation arises from nonconvex problems of the calculus of variations (see [1]).

A possible approach in finding bang–bang solutions is to use the Lyapunov Theorem on the range of a vector measure [4, §16.1].

Here, the solution of $x'' + a_1(t)x' + a_0(t)x = \rho(t)$, $x(0) = x'(0) = 0$ is given by

$$x(t) = \int_0^t h(t,s)\rho(s)\,ds,$$

where $h \in \mathcal{C}^1([0,T] \times [0,T])$, and for each $s \in [0,T]$ the function $h_s(.) = h(.,s) \in \mathcal{C}^2([0,T])$ is the solution to the associated homogeneous differential equation satisfying the initial conditions $h_s(s) = 0$, $h_s'(s) = 1$. The Lyapunov Theorem yields the existence of a measurable subset E of $[0,T]$ such that

$$\int_0^T h(T,s)\rho(s)\,ds = \int_0^T h(T,s)(\phi_1(s)\chi_E(s) + \phi_2(s)\chi_{[0,T]\setminus E}(s))\,ds, \tag{1.3}$$

$$\int_0^T \frac{\partial h}{\partial t}(T,s)\rho(s)\,ds = \int_0^T \frac{\partial h}{\partial t}(T,s)(\phi_1(s)\chi_E(s) + \phi_2(s)\chi_{[0,T]\setminus E}(s))\,ds. \tag{1.4}$$

Clearly, by differentiating under the integral sign, the function y defined by

$$y(t) = \int_0^t h(t,s)(\phi_1(s)\chi_E(s) + \phi_2(s)\chi_{[0,T]\setminus E}(s))\,ds \tag{1.5}$$

is a bang–bang solution. However, this approach does not give any information on the behaviour of y with respect to x on $[0,T]$.

Here we prove a new Lyapunov-type theorem concerning the range of a two-dimensional vector measure whose densities are such that their quotient is monotone; in this case, the set E can be chosen in the form $[\alpha,\beta]$. Note that this is not true in general; for instance, there are no $\alpha,\beta \in [0,3\pi]$ satisfying

$$\int_\alpha^\beta \sin t\,dt = \int_0^{3\pi} \sin t\chi_{[0,\pi]\cup[2\pi,3\pi]}(t)\,dt, \qquad \int_\alpha^\beta 1\,dt = \int_0^{3\pi} 1\chi_{[0,\pi]\cup[2\pi,3\pi]}(t)\,dt.$$

In our application, the equalities $h(s,s) = 0$ and $\frac{\partial h}{\partial t}(s,s) = 1$ imply that the monotonicity condition is locally fulfilled; this allows us to build a set E satisfying (1.3)–(1.4) as a finite union of intervals and, in the case where $\phi_1 < \rho < \phi_2$ are continuous, to choose E in such a way that neither 0 nor T belong to its closure.

These facts, together with a decomposition of the kernel $h(t,s)$ into a linear combination of linearly independent functions, are the main tools that we use to show that the bang–bang solution y defined by (1.5) satisfies the inequality $y \leq x$.

As an application, we consider the problem of minimizing the integral functionals

$$I(x,u) = \int_0^T f(t,x(t),u(t))\,dt,$$

where $x : [0,T] \to \mathbb{R}^2$ is such that $x(0)$, $x'(0)$, $x(T)$, $x'(T)$ are fixed and u is a control belonging to $U(t,x) \subset R^2$. The classical approach to obtain existence of a minimum is to impose conditions in order to have the lower semicontinuity of I with respect to u (for instance convexity of $u \mapsto f(t,x,u)$).

Recently, in an effort to provide existence criteria other than convexity in u, some sufficient conditions have been given: for problems of the calculus of variations ($x' = u$ in the above setting) and for maps of the form $f(t,x,x') = g(t,x) + h(t,x')$, existence of solutions has been obtained by requiring that the real map $x \mapsto g(t,x)$ be monotone [5] or, for x in $\mathbb{R}^n$, that the same function be concave [2]. Optimal control problems escaping to convexity conditions have been handled in [6].

It has been proved further in [3] that there exists a dense subset $\mathcal{D}$ of $\mathcal{C}(\mathbb{R})$ such that, for g in it, the problem

$$\text{minimize} \int_0^T g(x(t))\,dt + \int_0^T h(x'(t))\,dt \quad : \quad x(0) = x_0,\, x(T) = x_1$$

admits a solution for every lower semicontinuous h satisfying growth conditions.

Our theorem gives a straightforward generalization of the above result.

2. Assumptions and preliminary results. Let $\phi_1, \phi_2 \in L^1[0,T]$, $\phi_1 \le \phi_2$, and put $\Phi(t) = [\phi_1(t), \phi_2(t)] \subset \mathbb{R}$. We are interested in the solutions of the following control problem.

Problem P.

$$a_1, a_0 \in \mathcal{C}([0,T]), \quad x_0, x_1, v_0, v_1 \in \mathbb{R}, \quad x \in W^{2,1}([0,T]),$$

$$\text{(P)} \qquad x'' + a_1(t)x' + a_0(t)x \in \Phi(t) \text{ a.e.,}$$

$$x(0) = x_0, \quad x'(0) = v_0, \quad x(T) = x_1, \quad x'(T) = v_1.$$

By extr Φ we mean the extreme points of Φ, i.e., extr $\Phi(t) = \{\phi_1(t), \phi_2(t)\}$.

DEFINITION 2.1. *A function $y \in W^{2,1}([0,T])$ is said to be a bang-bang solution to* (P) *if y solves* (P) *and, moreover,*

$$y'' + a_1(t)y' + a_0(t)y \in \text{ extr } \Phi(t) \ a.e.$$

The following representation formula of the solutions to (P) will be used later.

PROPOSITION 2.1. *There exists a function $h \in \mathcal{C}^1([0,T] \times [0,T])$ satisfying Property* S *below such that, for each function $\rho \in L^1([0,T])$, the solution of*

$$(\text{P}_\rho) \qquad x'' + a_1(t)x' + a_0(t)x = \rho(t), \quad x(0) = x'(0) = 0$$

is given by the formula

$$(2.1) \qquad x(t) = \int_0^t h(t,s)\rho(s)\,ds\,.$$

Moreover, for each $s \in [0,T]$, the function $h(.,s)$ is of class $\mathcal{C}^2([0,T])$.

PROPERTY S.

(1) There exist $w_1, w_2 \in \mathcal{C}^2([0,T])$, $z_1, z_2 \in \mathcal{C}^1([0,T])$ such that

$$(2.2) \qquad \forall s,t \in [0,T] \qquad h(t,s) = w_1(t)z_1(s) + w_2(t)z_2(s)$$

$$\text{and} \quad W(w_1, w_2, t) = \det \begin{vmatrix} w_1(t) & w_2(t) \\ w_1'(t) & w_2'(t) \end{vmatrix} \neq 0.$$

For each t_0 in $[0,T]$ there exists $\delta > 0$ such that if we set $I_\delta = [t_0 - \delta, t_0 + \delta] \cap [0,T]$ then:

(2) $\forall s,t \in I_\delta$ $\quad h(t,s) > 0$ if $s < t$, $\quad h(t,s) < 0$ if $t < s$ $\quad$ (whence $h(s,s) = 0$);

(3) $\forall s,t \in I_\delta$ $\quad \frac{\partial h}{\partial t}(t,s) > 0$;

(4) $\forall t \in I_\delta$ $\quad s \mapsto h(t,s)/\frac{\partial h}{\partial t}(t,s)$ is decreasing on I_δ.

Proof of Proposition 2.1. For each $s \in [0,T]$, let $h_s(.) = h(.,s) \in \mathcal{C}^2([0,T])$ be the solution to

$$h_s''(t) + a_1(t)h_s'(t) + a_0(t)h_s(t) = 0, \qquad h_s(s) = 0,\, h_s'(s) = 1.$$

Set $z(t) = \int_0^t h(t,s)\rho(s)\,ds$. Differentiation under the integral sign shows that z is a solution to (P_ρ) whence, by uniqueness, $z = x$.

To prove the second part of the claim, let $w_1, w_2 \in \mathcal{C}^2([0,T])$ be two solutions of the differential equation

$$x'' + a_1(t)x' + a_0(t)x = 0 \tag{2.3}$$

such that their Wronskian

$$W(w_1,w_2,t) = \det\begin{vmatrix} w_1(t) & w_2(t) \\ w_1'(t) & w_2'(t)\end{vmatrix}$$

is nonzero for every t. Such functions exist because the set of the solutions of a second-order linear differential equation is a two-dimensional vector space. Since for each $s \in [0,T]$ the function h_s is a solution to (2.3), there exist z_1, z_2 defined on $[0,T]$ such that

$$\forall s,t \in [0,T] \qquad h_s(t) = w_1(t)z_1(s) + w_2(t)z_2(s). \tag{2.4}$$

Conditions on h_s at s and equation (2.4) yield

$$\begin{cases} h_s(s) = 0 = w_1(s)z_1(s) + w_2(s)z_2(s), \\ h_s'(s) = 1 = w_1'(s)z_1(s) + w_2'(s)z_2(s). \end{cases}$$

Since $W(w_1,w_2,s) \neq 0$ for each s, we find

$$z_1(s) = -\frac{w_2(s)}{W(w_1,w_2,s)}, \quad z_2(s) = \frac{w_1(s)}{W(w_1,w_2,s)},$$

so that $z_1, z_2 \in \mathcal{C}^1([0,T])$; hence $h(t,s) = h_s(t)$ belongs to $\mathcal{C}^1([0,T] \times [0,T])$. By construction

$$\forall s \in [0,T] \qquad h(s,s) = 0 \quad \text{and} \quad \frac{\partial h}{\partial t}(s,s) = 1$$

implying

$$\begin{aligned} \forall s \in [0,T] \qquad \frac{d}{ds}h(s,s) = 0 &\Leftrightarrow \forall s \in [0,T] \qquad \frac{\partial h}{\partial t}(s,s) + \frac{\partial h}{\partial s}(s,s) = 0 \\ &\Leftrightarrow \forall s \in [0,T] \qquad \frac{\partial h}{\partial s}(s,s) = -1. \end{aligned}$$

As a consequence,

$$\forall s \in [0,T] \qquad \frac{\partial}{\partial s}\left(\frac{h}{\frac{\partial h}{\partial t}}\right)(s,s) = -1.$$

By continuity for a fixed t_0 in $[0,T]$, there exists $\delta > 0$ such that

$$\forall s,t \in [t_0 - \delta, t_0 + \delta] \cap [0,T] \qquad \frac{\partial h}{\partial t}(t,s) > 0 \quad \text{and} \quad \frac{\partial}{\partial s}\left(\frac{h}{\frac{\partial h}{\partial t}}\right)(t,s) < 0;$$

for this δ (2), (3), and (4) in Property S are satisfied.

Assume, for instance, $\Phi(t) = [0, \phi(t)]$ and let $\rho \in \mathrm{L}^1([0,T])$ be such that $0 \le \rho \le \phi$. For a solution x to (P_ρ) formula (2.1) yields, in particular,

$$x(T) = \int_0^T h(T,s)\rho(s)\,ds\,, \tag{2.5}$$

$$x'(T) = \int_0^T \frac{\partial h}{\partial t}(T,s)\rho(s)\,ds. \tag{2.6}$$

Let us point out that the classical Lyapunov Theorem on the range of a vector measure [4, §16.1] allows us to find a bang–bang solution. In fact, its application yields the existence of a measurable subset E of $[0,T]$ such that

$$\int_0^T h(T,s)\rho(s)\,ds = \int_0^T h(T,s)\phi(s)\chi_E(s)\,ds\,, \tag{2.7}$$

$$\int_0^T \frac{\partial h}{\partial t}(T,s)\rho(s)\,ds = \int_0^T \frac{\partial h}{\partial t}(T,s)\phi(s)\chi_E(s)\,ds\,, \tag{2.8}$$

so that the function $\bar{x}$ defined by

$$\bar{x}(t) = \int_0^t h(t,s)\phi(s)\chi_E(s)\,ds$$

is, by Proposition 2.1, a bang–bang solution to (P) (with $\phi_1 = 0$, $\phi_2 = \phi$, $x_0 = v_0 = 0$). However, for $0 < t < T$, the Lyapunov Theorem does not give any information on the relative positions of $\bar{x}$ and the original solution x.

The purpose of Proposition 2.2 below is to show that if $s \mapsto \left(h/\frac{\partial h}{\partial t}\right)(t,s)$ is monotone on $[0,T]$ then the measurable subset E can be chosen to be an interval $[\alpha,\beta]$ with $0 \le \alpha \le \beta \le T$. Taking into account Property S (4), this will allow us to define in §3 a bang–bang solution y satisfying $y(t) \le x(t)$ for each t.

In what follows $[a,b]$ is an interval of $\mathbb{R}$; ρ and ϕ are two functions belonging to $L^1([a,b])$ satisfying $0 \le \rho \le \phi$. We say that $r \in \mathbb{R}$ is positive (resp. negative) if $r \ge 0$ (resp. $r \le 0$).

We consider the following hypothesis.

Hypothesis H. The functions f, g belong to $L^\infty([a,b])$ and are positive almost everywhere. Moreover there exists a strictly monotone positive function k such that

$$g(t) = k(t)f(t) \text{ a.e.}$$

We have the following Lyapunov-type result.

PROPOSITION 2.2. *Let f, g satisfy Hypothesis* H. *Then there exist $\alpha, \beta \in \mathbb{R}$ such that, if we put $E = [\alpha,\beta]$, we have*

$$\int_a^b \rho(s)f(s)\,ds = \int_\alpha^\beta \phi(s)f(s)\,ds = \int_a^b \phi(s)f(s)\chi_E(s)\,ds\,, \tag{2.9}$$

$$\int_a^b \rho(s)g(s)\,ds = \int_\alpha^\beta \phi(s)g(s)\,ds = \int_a^b \phi(s)g(s)\chi_E(s)\,ds\,. \tag{2.10}$$

Moreover, α and β are unique if ρ, ϕ, f, g are continuous, and $0 < \rho < \phi$, $f > 0$, $g > 0$.

To prove Proposition 2.2, we need the following fundamental lemma.

LEMMA 2.1. *Assume that f, g satisfy Hypothesis* H *and let $\alpha, \beta \in [a,b]$ be such that*

$$\int_\alpha^b \phi(s)f(s)\,ds = \int_a^b \rho(s)f(s)\,ds, \tag{2.11}$$

$$\int_a^\beta \phi(s)f(s)\,ds = \int_a^b \rho(s)f(s)\,ds. \tag{2.12}$$

Then, if k is increasing, we have

$$\int_\alpha^b \phi(s)g(s)\,ds \geq \int_a^b \rho(s)g(s)\,ds, \tag{2.13}$$

$$\int_a^\beta \phi(s)g(s)\,ds \leq \int_a^b \rho(s)g(s)\,ds. \tag{2.14}$$

If k is decreasing on $[a,b]$, inequalities (2.13) *and* (2.14) *are reversed. Moreover, inequalities* (2.13)–(2.14) *are strict if $0 < \rho < \phi$ and $f > 0$, $g > 0$ a.e.*

Proof of Lemma 2.1. Assume for instance that k is increasing. To prove (2.14) let f_ϕ, f_ρ be the monotone functions defined by

$$f_\phi(t) = \int_a^t \phi(s)f(s)\,ds, \qquad f_\rho(t) = \int_a^t \rho(s)f(s)\,ds.$$

The Lebesgue–Stieltjes formula for integration by parts yields

$$\begin{aligned}\int_a^b \rho(s)g(s)\,ds &= \int_a^b \rho(s)k(s)f(s)\,ds \\ &= \int_a^b k(s)\,df_\rho(s) \\ &= k(b)f_\rho(b) - k(a)f_\rho(a) - \int_a^b f_\rho(s)\,dk(s);\end{aligned}$$

analogously we have

$$\int_a^\beta \phi(s)g(s)\,ds = k(\beta)f_\phi(\beta) - k(a)f_\phi(a) - \int_a^\beta f_\phi(s)\,dk(s).$$

Taking into account that $f_\phi(a) = f_\rho(a) = 0$ and that by (2.12) $f_\rho(b) = f_\phi(\beta)$, we are thus led to show that

$$\int_a^b f_\rho(s)\,dk(s) - \int_a^\beta f_\phi(s)\,dk(s) \leq (k(b) - k(\beta))f_\rho(b). \tag{2.15}$$

By our assumptions we have

$$\forall t \in [a,b] \qquad f_\phi(t) \geq f_\rho(t); \tag{2.16}$$

therefore,

$$\int_a^b f_\rho(s)\,dk(s) - \int_a^\beta f_\phi(s)\,dk(s) \leq \int_\beta^b f_\rho(s)\,dk(s). \tag{2.17}$$

Furthermore, since functions f_ρ and k are increasing we have

$$\int_\beta^b f_\rho(s)\,dk(s) \leq (k(b) - k(\beta))f_\rho(b),$$

which, together with (2.17), gives (2.15).

To prove the final part of the lemma, it is enough to remark that if $f > 0$ and $\rho > 0$ then, by (2.12), $\beta \neq a$; if, moreover, $0 < \rho < \phi$ a.e., then inequality (2.16) is strict for every $t > a$ so that (2.17) is strict too (k being increasing). Similar arguments prove (2.13). ☐

Proof of Proposition 2.2.

(i) *Existence.* (a) Assume first $0 < \rho < \phi$ and $f > 0$, $g > 0$ a.e. Let α_1, α_2, β_1, $\beta_2 \in [a, b]$ be such that

$$\int_{\alpha_1}^{b} \phi(s)f(s)\,ds = \int_a^b \rho(s)f(s)\,ds, \tag{2.18}$$

$$\int_{\alpha_2}^{b} \phi(s)g(s)\,ds = \int_a^b \rho(s)g(s)\,ds, \tag{2.19}$$

$$\int_{a}^{\beta_1} \phi(s)f(s)\,ds = \int_a^b \rho(s)f(s)\,ds, \tag{2.20}$$

$$\int_{a}^{\beta_2} \phi(s)g(s)\,ds = \int_a^b \rho(s)g(s)\,ds. \tag{2.21}$$

Assume for instance that k is decreasing on $[a, b]$. In this situation Lemma 2.1 yields

$$\beta_2 \leq \beta_1, \qquad \alpha_2 \leq \alpha_1. \tag{2.22}$$

The function v defined by

$$v(x) = \int_a^x \phi(s)f(s)\,ds$$

is continuous and increasing with values in $[0, v(b)]$: let v^{-1} denote its inverse function. Set

$$m = \int_a^b \rho(s)f(s)\,ds.$$

Since, by (2.18), $v(b) = v(\alpha_1) + m$, then $v(\alpha) + m \in [0, v(b)]$ if and only if $a \leq \alpha \leq \alpha_1$; this allows us to introduce the continuous function ξ_1 defined by the formula

$$\forall \alpha \in [a, \alpha_1] \qquad \xi_1(\alpha) = v^{-1}(v(\alpha) + m).$$

By definition, we have

$$\forall \alpha \in [a, \alpha_1] \qquad \int_\alpha^{\xi_1(\alpha)} \phi(s)f(s)\,ds = v(\xi_1(\alpha)) - v(\alpha) = m = \int_a^b \rho(s)f(s)\,ds \tag{2.23}$$

so that, by (2.20) and (2.22), we deduce

$$\forall \alpha \in [a, \alpha_1] \qquad \xi_1(\alpha) \geq \beta_1 \geq \beta_2. \tag{2.24}$$

Similarly, (2.21) allows us to define a continuous function $\xi_2 : [\beta_2, b] \to \mathbb{R}$ such that we have

$$\forall \beta \geq \beta_2 \qquad \int_{\xi_2(\beta)}^{\beta} \phi(s)g(s)\,ds = \int_a^b \rho(s)g(s)\,ds, \tag{2.25}$$

from which, together with (2.19) and (2.22), we deduce

$$\forall \beta \geq \beta_2 \qquad \xi_2(\beta) \leq \alpha_2 \leq \alpha_1. \tag{2.26}$$

We deduce from (2.24) and (2.26) that the composed application

$$\xi_2 \circ \xi_1 : [a, \alpha_1] \xrightarrow{\xi_1} [\beta_2, b] \xrightarrow{\xi_2} [a, \alpha_1]$$

is defined and continuous from $[a, \alpha_1]$ into itself and, therefore, admits a fixed point $\bar{\alpha}$. Thus, if we set $\bar{\beta} = \xi_1(\bar{\alpha})$ we have $\bar{\alpha} = \xi_2(\bar{\beta})$. Equalities (2.23) and (2.25) with α, β replaced by $\bar{\alpha}, \bar{\beta}$ yield the conclusion.

(b) Let $\rho_n = \rho + \frac{1}{n}$, $\phi_n = \phi + \frac{2}{n}$, $f_n = f + \frac{1}{n}$ so that $0 < \rho_n < \phi_n$ and $f_n > 0$ a.e., and set $g_n = kf_n$ so that the monotonicity of k implies that $g_n > 0$ a.e. and f_n, g_n satisfy H. By (a) there exist α_n, β_n such that

$$\int_a^b \rho_n(s) f_n(s)\, ds = \int_{\alpha_n}^{\beta_n} \phi_n(s) f_n(s)\, ds, \tag{2.27}$$

$$\int_a^b \rho_n(s) g_n(s)\, ds = \int_{\alpha_n}^{\beta_n} \phi_n(s) g_n(s)\, ds. \tag{2.28}$$

By compactness we may assume $\alpha_n \to \alpha$, $\beta_n \to \beta$. The conclusion follows by passing through the limit in (2.27) and (2.28).

(ii) *Uniqueness.* Assume that $0 < \rho < \phi$, $f > 0$, $g > 0$ are continuous and that, for instance, k is decreasing. By (i(a)) the points α, such that there exists β satisfying (2.11) and (2.12), are the fixed points of the composed map $\xi_2 \circ \xi_1$. By definition the functions ξ_1, ξ_2 are differentiable and we have

$$\forall \alpha \in [a, \alpha_1] \qquad \xi_1'(\alpha) = \frac{v'(\alpha)}{v'(\xi_1(\alpha))} = \frac{\phi(\alpha) f(\alpha)}{\phi(\xi_1(\alpha)) f(\xi_1(\alpha))},$$

$$\forall \beta \in [\beta_2, b] \qquad \xi_2'(\beta) = \frac{\phi(\beta) g(\beta)}{\phi(\xi_2(\beta)) g(\xi_2(\beta))}.$$

To prove the claim we notice that if α satisfies $\xi_2 \circ \xi_1(\alpha) = \alpha$ then

$$(\xi_2 \circ \xi_1)'(\alpha) = \xi_2'(\xi_1(\alpha))\xi_1'(\alpha) = \frac{k(\xi_1(\alpha))}{k(\alpha)}. \tag{2.29}$$

By (2.23) we have $\xi_1(\alpha) > \alpha$ so that the strict monotonicity of k implies $k(\xi_1(\alpha)) < k(\alpha)$ and thus $(\xi_2 \circ \xi_1)'(\alpha) < 1$ whenever $\xi_2 \circ \xi_1(\alpha) = \alpha$. Let $S = \{\alpha \in [a, b] : \xi_2 \circ \xi_1(\alpha) = \alpha\}$. Clearly, S is compact and nonempty by (i); moreover, taking (2.29) into account, for each $\alpha \in S$ there exists η such that

$$\begin{aligned} &\forall t \in]\alpha - \eta, \alpha[\qquad \xi_2 \circ \xi_1(t) > t, \\ &\forall t \in]\alpha, \alpha + \eta[\qquad \xi_2 \circ \xi_1(t) < t. \end{aligned} \tag{2.30}$$

As a consequence, the set S has no accumulation points and is therefore finite.

Let $\alpha_1 = \min S$ and assume $S \neq \{\alpha_1\}$; let $\alpha_2 = \min S \setminus \{\alpha_1\}$. Then by (2.30) there exist $t_1 < t_2 \in [\alpha_1, \alpha_2]$ such that $\xi_2 \circ \xi_1(t_1) < t_1$ and $\xi_2 \circ \xi_1(t_2) > t_2$. Therefore there exists $\bar{t} \in [t_1, t_2]$ such that $\xi_2 \circ \xi_1(\bar{t}) = \bar{t}$, a contradiction. □

3. Main result.

THEOREM 3.1. *Let $x \in W^{2,1}([0,T])$ be a solution to* (P). *Then there exists a bang-bang solution y to* (P) *satisfying*

$$\forall t \in [0, T] \qquad y(t) \le x(t).$$

Moreover, there exists a set E which is a finite union of intervals such that

$$y'' + a_1(t)y' + a_0(t)y = \phi_1(t)\chi_E(t) + \phi_2(t)\chi_{[0,T]\setminus E}(t) \text{ a.e.}$$

COROLLARY 1. *Under the above assumption, there exists a bang–bang solution y satisfying*

$$\forall t \in [0,T] \qquad y(t) \geq x(t).$$

Proof of Corollary 1. Let $-\Phi$ be defined by the equality $(-\Phi)(t) = -\Phi(t)$. Clearly, $\tilde{x} = -x$ solves

$$\tilde{x}'' + a_1(t)\tilde{x}' + a_0(t)\tilde{x} \in -\Phi(t) \text{ a.e.}$$

By Theorem 3.1 there exists a bang–bang solution $\tilde{y}$ satisfying the same boundary conditions as $\tilde{x}$ and satisfying

$$\forall t \in [0,T] \qquad \tilde{y}(t) \leq \tilde{x}(t).$$

Then the function y defined by

$$\forall t \in [0,T] \qquad y(t) = -\tilde{y}(t)$$

is a solution to our problem. □

Proof of Theorem 3.1. Let h be the function defined in Proposition 2.1.

(i) We show that it is not restrictive to assume

$$\Phi(t) = [0, \phi(t)] \quad (\phi \in L^1([0,T]),\ \phi > 0 \text{ a.e.}) \quad \text{and} \quad x_0 = v_0 = 0.$$

In fact, let $\Phi(t) = [\phi_1(t), \phi_2(t)]$ and x satisfy

$$x'' + a_1(t)x' + a_0(t)x \in \Phi(t) \text{ a.e.}$$

Then the function $\tilde{x}$ defined by

$$\tilde{x}(t) = x(t) - x'(0)t - x(0)$$

satisfies $\tilde{x}(0) = \tilde{x}'(0) = 0$ and

$$\tilde{x}'' + a_1(t)\tilde{x}' + a_0(t)\tilde{x} \in [\psi_1(t), \psi_2(t)] \text{ a.e.,}$$

where

$$\psi_1(t) = \phi_1(t) - a_0(t)x'(0)t - a_1(t)x'(0) - a_0(t)x(0),$$
$$\psi_2(t) = \phi_2(t) - a_0(t)x'(0)t - a_1(t)x'(0) - a_0(t)x(0).$$

Moreover, by Proposition 2.1, the function $\bar{x}$ defined by

$$\bar{x}(t) = \tilde{x}(t) - \int_0^t h(t,s)\psi_1(s)\,ds$$

satisfies $\bar{x}(0) = 0$, $\bar{x}'(0) = 0$ and

$$\bar{x}'' + a_1(t)\bar{x}' + a_0(t)\bar{x} \in [0, \psi_2(t) - \psi_1(t)] \text{ a.e.}$$

If we assume that Theorem 3.1 holds for such an interval and initial boundary conditions, there exists a function $\bar{y}$ satisfying

$$\bar{y}(0) = \bar{x}(0), \quad \bar{y}'(0) = \bar{x}'(0), \quad \bar{y}(T) = \bar{x}(T), \quad \bar{y}'(T) = \bar{x}'(T),$$

$$\bar{y}'' + a_1(t)\bar{y}' + a_0(t)\bar{y} \in \{0, \psi_2(t) - \psi_1(t)\} \text{ a.e.,}$$

$$\forall t \in [0,T] \qquad \bar{y}(t) \leq \bar{x}(t).$$

It is now easy to check that the function y defined by

$$y(t) = \bar{y}(t) + \int_0^t h(t,s)\psi_1(s)\,ds + x'(0)t + x(0)$$

is a solution to our problem.

(ii) Assume first that the δ of Property (S) can be chosen in such a way that $I_\delta = [0,T]$. In this case, if we set

$$\rho = x'' + a_1 x' + a_0 x$$

then by Proposition 2.1 we can write

$$x(t) = \int_0^t h(t,s)\rho(s)\,ds, \tag{3.1}$$

where h satisfies Property (S(1)) and, in addition,

$$\forall s,t \in [0,T] \qquad h(t,s) > 0 \text{ if } s < t, \quad h(t,s) < 0 \text{ if } t < s, \tag{3.2}$$

$$\forall s,t \in [0,T] \qquad \frac{\partial h}{\partial t}(t,s) > 0, \tag{3.3}$$

$$\forall t \in [0,T] \qquad s \mapsto h(t,s)/\frac{\partial h}{\partial t}(t,s) \text{ is decreasing on } [0,t]. \tag{3.4}$$

In particular, the functions f and g defined on $[0,T]$ by

$$g(s) = h(T,s), \qquad f(s) = \frac{\partial h}{\partial t}(T,s)$$

verify Hypothesis H with $k(.) = h(T,.)/\frac{\partial h}{\partial t}(T,.)$.

By Proposition 2.1, each bang–bang solution y such that $x(0) = x'(0) = 0$ is given by the formula $y(t) = \int_0^t h(t,s)\nu(s)\,ds$ for some measurable function ν with values in $\{0,\phi(t)\}$.

We are thus led to show that there exists such a ν satisfying

$$\int_0^T h(T,s)\rho(s)\,ds = \int_0^T h(T,s)\nu(s)\,ds, \tag{3.5}$$

$$\int_0^T \frac{\partial h}{\partial t}(T,s)\rho(s)\,ds = \int_0^T \frac{\partial h}{\partial t}(T,s)\nu(s)\,ds, \tag{3.6}$$

and for each t in $[0,T]$,

$$\int_0^t h(t,s)\rho(s)\,ds \geq \int_0^t h(t,s)\nu(s)\,ds. \tag{3.7}$$

(a) Assume $0 < \rho < \phi$ a.e.

By Proposition 2.2 there exist $\alpha, \beta \in [0,T]$ such that

$$\int_0^T h(T,s)\rho(s)\,ds = \int_\alpha^\beta h(T,s)\phi(s)\,ds, \tag{3.8}$$

$$\int_0^T \frac{\partial h}{\partial t}(T,s)\rho(s)\,ds = \int_\alpha^\beta \frac{\partial h}{\partial t}(T,s)\phi(s)\,ds. \tag{3.9}$$

It is clear that if we set

$$\nu(s) = \phi(s)\chi_{[\alpha,\beta]}(s) \tag{3.10}$$

then (3.5) and (3.6) are satisfied. In order to prove (3.7) we first show that under our assumptions on ρ and ϕ we have

$$0 < \alpha < \beta < T. \tag{3.11}$$

Notice first that the equalities $(\alpha, \beta) = (0, T)$ or $\alpha = \beta$ cannot hold otherwise by (3.8), $\rho = \phi$ or $\rho = 0$ a.e., a contradiction. Assume, for instance, $\alpha = 0$ and $\beta < T$, the case $\alpha > 0$ and $\beta = T$ being similar. Under this assumption, equalities (3.8) and (3.9) become

$$\int_0^T h(T,s)\rho(s)\,ds = \int_0^\beta h(T,s)\phi(s)\,ds, \tag{3.12}$$

$$\int_0^T \frac{\partial h}{\partial t}(T,s)\rho(s)\,ds = \int_0^\beta \frac{\partial h}{\partial t}(T,s)\phi(s)\,ds. \tag{3.13}$$

Property (3.4) and the assumption $0 < \rho < \phi$ a.e. allow us to apply Lemma 2.1, from which we deduce

$$\int_0^T h(T,s)\rho(s)\,ds < \int_0^\beta h(T,s)\phi(s)\,ds,$$

contradicting (3.12).

Set $y(t) = \int_0^t h(t,s)\nu(s)\,ds$ so that (3.8) and (3.9) become $y(T) = x(T)$ and $y'(T) = x'(T)$.

The purpose of what follows is to show (3.7), i.e., that $y(t) \leq x(t)$ for each t. We consider the cases $t \in [0, \alpha]$, $t \in [\beta, T]$, $t \in [\alpha, \beta]$ separately.

Inequality (3.7) is trivial if $t \leq \alpha$; in fact we have

$$y(t) = 0 \leq \int_0^t h(t,s)\rho(s)\,ds = x(t),$$

the inequality being strict for $t \in]0, \alpha]$. In particular

$$y(\alpha) < x(\alpha). \tag{3.14}$$

Assume $t \in [\beta, T]$.

Since, taking (3.2) into account, $h(t,s) \leq 0$ whenever $s \geq t$, we have

$$\forall t \geq \beta \qquad \int_t^T h(t,s)\rho(s)\,ds \leq 0 = \int_t^T h(t,s)\nu(s)\,ds \tag{3.15}$$

or, equivalently,

$$\forall t \geq \beta \int_0^T h(t,s)\rho(s)\,ds - \int_0^t h(t,s)\rho(s)\,ds \leq \int_0^T h(t,s)\nu(s)\,ds - \int_0^t h(t,s)\nu(s)\,ds. \tag{3.16}$$

Therefore, in order to prove that $y(t) \leq x(t)$ for $t \in [\beta, T]$ it is enough to show that

$$\forall t \in [\beta, T] \qquad \int_0^T h(t,s)\rho(s)\,ds = \int_0^T h(t,s)\nu(s)\,ds. \tag{3.17}$$

For this purpose, we use Property (S(1)). Equalities (3.8) and (3.9) become

$$\begin{cases} w_1(T)\displaystyle\int_0^T z_1(s)(\rho(s)-\nu(s))\,ds + w_2(T)\int_0^T z_2(s)(\rho(s)-\nu(s))\,ds = 0,\\ w_1'(T)\displaystyle\int_0^T z_1(s)(\rho(s)-\nu(s))\,ds + w_2'(T)\int_0^T z_2(s)(\rho(s)-\nu(s))\,ds = 0.\end{cases}$$

The condition on the Wronskian of w_1, w_2 at T implies

$$\int_0^T z_1(s)(\rho(s)-\nu(s))\,ds = 0, \tag{3.18}$$

$$\int_0^T z_2(s)(\rho(s)-\nu(s))\,ds = 0. \tag{3.19}$$

Multiplying (3.18) by $w_1(t)$, (3.19) by $w_2(t)$, and adding the two equations we obtain

$$\int_0^T (w_1(t)z_1(s)+w_2(t)z_2(s))\rho(s)\,ds = \int_0^T (w_1(t)z_1(s)+w_2(t)z_2(s))\nu(s)\,ds,$$

which, together with Property (S(1)), gives (3.17). Moreover, note that since inequality (3.15) is strict for $t \neq T$,

$$y(\beta) < x(\beta). \tag{3.20}$$

At this stage, we only need to prove that (3.7) holds for $t \in [\alpha, \beta]$.

Assume by contradiction that there exists $t \in [\alpha, \beta]$ such that $x(t) = y(t)$. Let

$$\bar{t} = \sup\{t \in [\alpha,\beta] : x(t) = y(t)\}.$$

Then $\alpha < \bar{t} < \beta$ and, by the very definition of $\bar{t}$, $x(\bar{t}) = y(\bar{t})$ so that

$$y'(\bar{t}) - x'(\bar{t}) = \lim_{t\to\bar{t}^+} \frac{y(t)-x(t)}{t-\bar{t}} \leq 0.$$

It follows that

$$\int_\alpha^{\bar{t}} h(\bar{t},s)\phi(s)\,ds = \int_0^{\bar{t}} h(\bar{t},s)\rho(s)\,ds, \tag{3.21}$$

$$\int_\alpha^{\bar{t}} \frac{\partial h}{\partial t}(\bar{t},s)\phi(s)\,ds \leq \int_0^{\bar{t}} \frac{\partial h}{\partial t}(\bar{t},s)\rho(s)\,ds. \tag{3.22}$$

For each $s \in [0,\bar{t}[$ let $f(s) = h(\bar{t},s)$, $g(s) = \frac{\partial h}{\partial t}(\bar{t},s)$, and $k = g/f$ so that by (3.2)–(3.4) the function k is increasing and $f > 0$, $g > 0$. If we replace (a,b) by $(0,\bar{t})$, Lemma 2.1 together with (3.21) implies that

$$\int_\alpha^{\bar{t}} \frac{\partial h}{\partial t}(\bar{t},s)\phi(s)\,ds > \int_0^{\bar{t}} \frac{\partial h}{\partial t}(\bar{t},s)\rho(s)\,ds,$$

thus contradicting (3.22).

(b) Assume, in general, $0 \leq \rho \leq \phi$ a.e. and let ϕ_n, $\rho_n \in L^1([0,T])$ be such that

$$0 < \rho_n < \phi_n \text{ a.e.} \quad \text{and} \quad \rho_n \to \rho,\ \phi_n \to \phi \text{ in } L^1([0,T])$$

(for instance, $\rho_n = \rho + \frac{1}{n}$, $\phi_n = \phi + \frac{2}{n}$).

Corresponding to each n, there exist α_n, $\beta_n \in [0,T]$ such that, if we set $\nu_n = \phi_n \chi_{[\alpha_n,\beta_n]}$, we have

$$\int_0^T h(T,s)\rho_n(s)\,ds = \int_0^T h(T,s)\nu_n(s)\,ds, \tag{3.23}$$

$$\int_0^T \frac{\partial h}{\partial t}(T,s)\rho_n(s)\,ds = \int_0^T \frac{\partial h}{\partial t}(T,s)\nu_n(s)\,ds, \tag{3.24}$$

and, for each t in $[0,T]$,

$$\int_0^t h(t,s)\rho_n(s)\,ds \geq \int_0^t h(t,s)\nu_n(s)\,ds. \tag{3.25}$$

Because the interval $[0,T]$ is compact, we may assume $\alpha_n \longrightarrow \alpha$, $\beta_n \longrightarrow \beta$ for some $\alpha \leq \beta \in [0,T]$.

Clearly $\nu_n = \phi_n \chi_{[\alpha_n,\beta_n]}$ converges to $\phi\chi_{[\alpha,\beta]}$ in $L^1([0,T])$; therefore, if we pass through the limit in (3.23), (3.24), and (3.25) and we set $\nu = \phi\chi_{[\alpha,\beta]}$, we obtain (3.5), (3.6), and (3.7).

(iii) In the general case, using Property (S) and the compactness of $[a,b]$, there exists a subdivision $a_0 = 0 < a_1 < \cdots < a_l < T = a_{l+1}$ of $[0,T]$ such that, if we put $I_j = [a_j, a_{j+1}]$, we have

- $\forall s,t \in I_j \quad h(t,s) > 0$ if $s < t$, $\quad h(t,s) < 0$ if $t < s$;
- $\forall s,t \in I_j \quad \frac{\partial h}{\partial t}(t,s) > 0$;
- $\forall t \in I_j \quad s \mapsto h(t,s)/\frac{\partial h}{\partial t}(t,s)$ is decreasing on I_j.

By (ii), on each interval I_j there exist α_j, β_j such that the solution y_j to the problem

$$y'' + a_1(t)y' + a_0(t)y = \phi_1(t)\chi_{[a_j,\alpha_j]\cup[\beta_j,b_j]}(t) + \phi_2(t)\chi_{[\alpha_j,\beta_j]}(t) \text{ a.e. on } I_j$$

with the initial conditions

$$y_j(a_j) = x(a_j), \quad y_j'(a_j) = x'(a_j)$$

satisfies the equalities

$$y_j(a_{j+1}) = x(a_{j+1}), \quad y_j'(a_{j+1}) = x'(a_{j+1}),$$

and, moreover, $y_j(t) \leq x(t)$ for each $t \in I_j$.

Clearly the function $y \in W^{2,1}([0,T])$ obtained by glueing together the functions y_j is a solution to our problem. □

Remark 3.1. The proof of Theorem 3.1, part (ii(a)) shows in fact that when $0 < \rho < \phi$, we have $y(t) < x(t)$ on $]0,T[$.

Remark 3.2. With the notations introduced in Proposition 2.1, the proof of Theorem 3.1, part (ii) shows that if $T = \delta$ then, given a solution x to (P), there exists a bang–bang solution $y \leq x$ satisfying

$$\begin{aligned} y'' + a_1(t)y' + a_0(t)y &= \min \Phi(t) \text{ on } [0,\alpha] \cup [\beta,T], \\ y'' + a_1(t)y' + a_0(t)y &= \max \Phi(t) \text{ on } [\alpha,\beta]. \end{aligned}$$

Because the number δ depends only on the function h, it can happen that $\delta = +\infty$.

This is the case when a_1 and a_0 are constant and the equation $\lambda^2 + a_1\lambda + a_0 = 0$ admits two real roots λ_1, λ_2. In fact, under this assumption we have either

$$h(t,s) = \frac{1}{\lambda_2 - \lambda_1}(e^{\lambda_2(t-s)} - e^{\lambda_1(t-s)}) \text{ if } \lambda_1 \neq \lambda_2, \text{ or}$$
$$h(t,s) = (t-s)e^{\lambda(t-s)} \text{ if } \lambda_1 = \lambda_2 = \lambda.$$

4. Applications. Our first application concerns the reachable set of bang–bang constrained solutions. Let c be an arbitrary function defined on $[0,T]$ and consider the reachable sets $\mathcal{X}_T^c$ and $\mathcal{Y}_T^c$ associated with (P) defined by

$$\mathcal{X}_T^c = \{(y(T), y'(T)) : y \leq c,\ y'' + a_1(t)y' + a_0(t)y \in \Phi(t),\ (y(0), y'(0)) = (x_0, v_0)\},$$

$$\mathcal{Y}_T^c = \{(y(T), y'(T)) : y \leq c,\ y'' + a_1(t)y' + a_0(t)y \in \operatorname{extr}\Phi(t),\ (y(0), y'(0)) = (x_0, v_0)\}.$$

Then Theorem 3.1 claims $\mathcal{X}_T^c = \mathcal{Y}_T^c$, whence $\mathcal{Y}_T^c$ is convex.

Finally, we give an application to the calculus of variations.

THEOREM 4.1. *Let a_0, $a_1 \in \mathcal{C}([0,T])$, $\phi_1, \phi_2 \in L^1([0,T])$ verify $\phi_1(t) \leq \phi_2(t)$. Let x_0, v_0, x_1, v_1 be 4 fixed real numbers. Then there exists a dense subset $\mathcal{D}$ of $\mathcal{C}(\mathbb{R})$ for the uniform convergence such that for g in $\mathcal{D}$ the problem*

$$\textit{minimize} \left\{ \int_0^T g(x(t))\,dt + \int_0^T h(\rho(t))\,dt \right\}$$

on the subset of $W^{2,1}([0,T]) \times L^1([0,T])$ of those functions (x, ρ) satisfying

$$(x(0), x'(0), x(T), x'(T)) = (x_0, v_0, x_1, v_1),\ x'' + a_1(t)x' + a_0(t)x = \rho(t) \in [\phi_1(t), \phi_2(t)]$$

admits at least one solution for every lower semicontinuous function h satisfying the growth condition $h(u) \geq c\psi(|u|)$, ψ being lower semicontinuous and convex, $\lim_{r \to +\infty} \psi(r)/r = +\infty$.

Proof. With Theorem 3.1 and the preceding application, the proof is a direct adaptation of the proof given in [3]. □

5. Acknowledgments. We are deeply grateful to Professor Arrigo Cellina for suggesting the problem, for his useful advice, and for carefully reading this paper. We thank Professors Jean-Pierre Aubin and Helena Frankowska who gave us the opportunity to meet together. We are indebted to two anonymous referees for their useful remarks that improved the quality and the presentation of the paper.

DEALING WITH INTEGRAL STATE CONSTRAINTS IN BOUNDARY CONTROL PROBLEMS OF QUASILINEAR ELLIPTIC EQUATIONS*

EDUARDO CASAS† AND LUIS A. FERNÁNDEZ‡

Abstract. This paper deals with state-constrained optimal control problems governed by a quasilinear elliptic equation. These constraints are given in an integral form and depend on the state and its gradient. Equality and inequality constraints are simultaneously considered. Existence of a solution is investigated and some optimality conditions are obtained with the aid of Ekeland's variational principle.

Key words. optimal control, boundary control, quasilinear elliptic operators, optimality conditions, integral state constraints

AMS subject classifications. 49K20, 49J20

1. Introduction.

The main objective of this paper is to derive some necessary conditions satisfied by the optimal controls of a system governed by a quasilinear elliptic equation. Two difficulties arise in obtaining these optimality conditions. The first one is due to the fact that the relation between the control and the state is not differentiable in many cases. When this relation is differentiable, its differential exists in the Gâteaux sense, but we do not know if it is continuously Gâteaux differentiable. The authors have studied these questions in [7], [11], and [18]. The method followed to treat the nondifferentiable cases consists of introducing a family of approximate control problems by perturbing the state equation in such a way that the dependence of the state with respect to the control is now differentiable and then passing to the limit.

The second difficulty is motivated by the presence of equality and inequality integral state constraints. The case of inequality integral state constraints has been considered by several authors, among them Barbu and Precupanu [3], Lasiecka [21], and Mackenroth [24] for control problems governed by linear partial differential equations, and Casas and Fernández [10] for Dirichlet problems associated with quasilinear elliptic equations. Problems with equality and inequality integral constraints on the state have been studied by Chryssoverghi [13] and Tröltzsch [33] for a parabolic semilinear equation. In the framework of the quasilinear equations, when dealing with these state constraints we cannot apply the known multiplier rules like the one of Carathéodory and John (see Mangasarian and Fromovitz [25], McShane [26], Halkin [19], and Pourciau [30]), because it is unknown to us if the functionals involved in the control problem are continuously differentiable or even Frechet differentiable. This lack of Frechet differentiability is motivated by the relationship between the control and the state. Here we are concerned with boundary controls; the reader is referred to [9] for the case of distributed controls.

The plan of the paper is as follows. In the next section we formulate the control problem for a particular quasilinear operator that is essentially the α-Laplacian, $\alpha > 1$.

‡ Departamento de Matemáticas, Estadística y Computación, Facultad de Ciencias, Universidad de Cantabria, 39071 Santander, Spain.

The reason for this choice is twofold: on the one hand, the α-Laplacian is a very important operator because it appears in many physical models (steady laminar flow of non-Newtonian fluids, some reaction-diffusion problems, magnetostatics, glaciology, etc.; see Ames [1], Aris [2], and Pelissier [29]) and it has been extensively studied, being the main example among the quasilinear elliptic equations; on the other hand, this choice avoids technical complications and simplifies the exposition. In §3 we will describe a more general kind of quasilinear elliptic operator, containing the α-Laplacian as a particular case, for which it is possible to extend the results stated in this work; see Remarks 5.2 and 6.1 for more precision. A theorem of existence of solution is proved in §4, and some optimality conditions of Fritz John type are obtained in §§5 and 6 corresponding to the strongly elliptic and degenerate operators, respectively. Finally, in §7 we study control problems submitted only. to inequality state constraints and derive the optimality conditions in a qualified form for almost every problem.

2. Setting of the problem. Let Ω be an open-bounded subset of R^n, $n > 1$, with a Lipschitz boundary Γ; see Nečas [28]. Let us consider the following Neumann problem:

$$(2.1)\qquad \begin{cases} -\operatorname{div}\left\{[k+|\nabla y|]^{\alpha-2}\nabla y\right\}+\lambda y=f & \text{in } \Omega, \\ (k+|\nabla y|)^{\alpha-2}\nabla y\cdot\vec{\nu}=u & \text{on } \Gamma, \end{cases}$$

where k is a nonnegative real number, $\lambda > 0$, $\alpha > 1$, and $\vec{\nu}$ is the unit outward normal vector to Γ.

If we assume on the data (f,u) that $f \in L^p(\Omega)$ with $p > n/\alpha$ and $u \in L^\infty(\Gamma)$, the existence of a unique $y_u \in W^{1,\alpha}(\Omega) \cap L^\infty(\Omega)$ solution of (2.1) can be proved; see Theorem 3.1 below.

Now, if we fix an element $f \in L^p(\Omega)$ with $p > n/\alpha$, the optimal control problem is formulated as follows:

$$(P_\delta)\quad \begin{cases} \text{minimize } \; J(u)=\displaystyle\int_\Omega L(x,y_u(x))dx+\int_\Gamma l(x,y_u(x),u(x))d\sigma(x) \\ \text{such that } \; u\in K \text{ and} \\ G_j(u)=\delta_j, \quad 1\le j\le n_e, \\ G_j(u)\le\delta_j, \quad n_e+1\le j\le n_e+n_i, \end{cases}$$

where $\delta = (\delta_j)_{j=1}^{n_e+n_i} \subset R^{n_e+n_i}$, K is a *weakly closed convex bounded subset of $L^\infty(\Gamma)$,

$$G_j(u)=\int_\Omega g_j(x,y_u(x),\nabla y_u(x))dx,$$

and $L : \Omega \times R \longrightarrow R$, $l : \Gamma \times (R \times R) \longrightarrow R$ and $g_j : \Omega \times (R \times R^n) \longrightarrow R$ are Carathéodory functions of class C^1 with respect to the second and third variables and satisfy

$$(2.2)\qquad l(\cdot,0,0)\in L^1(\Gamma),\; L(\cdot,0),g_j(\cdot,0,0)\in L^1(\Omega),$$

$$\left|\frac{\partial l}{\partial u}(x,y,u)\right| \leq h_1(x)\varphi(|y|+|u|), \tag{2.3}$$

$$\left|\frac{\partial l}{\partial y}(x,y,u)\right| \leq h_2(x)\varphi(|y|+|u|) \tag{2.4}$$

for all $x \in \Gamma$, $y, u \in R$ with $h_1 \in L^1(\Gamma)$ and $h_2 \in L^\tau(\Gamma)$,

$$\left|\frac{\partial L}{\partial y}(x,y)\right| \leq h_3(x)\varphi(|y|), \tag{2.5}$$

$$\left|\frac{\partial g_j}{\partial y}(x,y,\eta)\right| \leq \varphi(|y|)(h_3(x) + |\eta|^{\alpha/\rho}), \tag{2.6}$$

$$\left|\frac{\partial g_j}{\partial \eta_i}(x,y,\eta)\right| \leq \varphi(|y|)(h_4(x) + |\eta|^{\alpha/\theta}), \quad i = 1,\dots,n \tag{2.7}$$

for all $x \in \Omega$, $y \in R$, and $\eta \in R^n$, $1 \leq j \leq n_e + n_i$, with $h_3 \in L^\rho(\Omega)$, $h_4 \in L^\theta(\Omega)$, and $\varphi : R_+ \longrightarrow R_+$ being an increasing function. Initially, the constants τ, ρ, and θ are supposed to be strictly greater than one, later their values will be suitably limited.

The difficulties in deriving the optimality conditions satisfied by a solution of problem (P_δ) depend on the values of k and α in the state equation (2.1). In the next section we will see that the relation between the control and the state is differentiable when $k > 0$ and $\alpha \geq 2$, which will allow us to deduce these conditions in §5. The differentiability in the case $\alpha < 2$ and $k > 0$ is an open problem for us; however, we will obtain the optimality conditions for this case in §5 by introducing a family of approximate problems corresponding to the case $\alpha = 2$ and passing to the limit in the optimality systems of these problems. When $k = 0$ the mapping $u \longrightarrow y_u$ is not necessarily differentiable, as we will prove in the next section. To deal with this case we study the limits of the previous optimality systems when $k \longrightarrow 0$.

3. Sensitivity analysis of quasilinear elliptic equations. It is known that, in order to derive the optimality system satisfied by the solutions of (P_δ), an important question to study is the differentiable character of the relation control-state. In this section, we present a general result about this question concerning the Neumann problem associated with a quasilinear operator in divergence form:

$$\begin{cases} Ay = -\mathrm{div}\,(a(x,\nabla y)) + a_0(x,y) = f & \text{in } \Omega, \\ a(x,\nabla y)\cdot\vec{\nu} = u & \text{on } \Gamma, \end{cases} \tag{3.1}$$

where $a(x,\eta) = (a_1(x,\eta),\dots,a_n(x,\eta))$. On the operator coefficients we will assume the following conditions:

$$\begin{cases} a_j(\cdot,\eta) \text{ is a measurable function in } \Omega, \\ a_j(x,\cdot) \text{ belongs to } C^1(R^n), \qquad j = 1,\dots,n, \end{cases} \tag{3.2}$$

$$\begin{cases} a_0(\cdot,s) \text{ is a measurable function in } \Omega, \\ a_0(x,\cdot) \text{ belongs to } C^1(R), \end{cases} \tag{3.3}$$

$$\sum_{i,j=1}^{n} \frac{\partial a_j}{\partial \eta_i}(x,\eta)\xi_i\xi_j \geq \Lambda_1(k+|\eta|)^{\alpha-2}|\xi|^2, \tag{3.4}$$

$$\sum_{i,j=1}^{n} \left|\frac{\partial a_j}{\partial \eta_i}(x,\eta)\right| \leq \Lambda_2(k+|\eta|)^{\alpha-2}, \tag{3.5}$$

$$\Lambda_3 \leq \frac{\partial a_0}{\partial s}(x,s) \leq h_0(|s|), \tag{3.6}$$

$$a_0(x,0) = a_j(x,0) = 0, \qquad j = 1,\dots,n \tag{3.7}$$

for some $k \geq 0$, some $\alpha \in (1,+\infty)$, some strictly positive constants $\Lambda_1, \Lambda_2, \Lambda_3$, some positive increasing function h_0, all $x \in \Omega$, all $s \in R$, and all $\eta, \xi \in R^n$.

Let us remark that the operator given in (2.1) satisfies these assumptions.

In spite of the general growth condition allowed to the term a_0 (see (3.6)), we can still prove the existence and uniqueness of the solution for (3.1), together with the continuous dependence of this solution with respect to the control u.

THEOREM 3.1. *Under hypotheses* (3.2)–(3.7), *and given* $f \in L^p(\Omega)$ *with* $p > n/\alpha$, *for every* $u \in L^\infty(\Gamma)$ *there exists a unique* $y_u \in W^{1,\alpha}(\Omega) \cap L^\infty(\Omega)$ *solution of the Neumann problem* (3.1). *Moreover, if* $\{u_j\}_{j\in N}$ *is bounded in* $L^\infty(\Gamma)$ *there exists a positive constant* k_1 *independent of* j *such that*

$$\|y_{u_j}\|_{W^{1,\alpha}(\Omega)} + \|y_{u_j}\|_{L^\infty(\Omega)} \leq k_1 \quad \forall j \in N. \tag{3.8}$$

Finally, if $\{u_j\}$ *converges* **weakly towards* u *in* $L^\infty(\Gamma)$, *then* $\{y_{u_j}\}$ *converges to* y_u *strongly in* $W^{1,\alpha}(\Omega)$ *and* **weakly in* $L^\infty(\Omega)$.

Proof. For every natural number m, let us define the function

$$a_0^m(x,s) = \begin{cases} a_0(x,s) & \text{if } |s| \leq m, \\ \Lambda_3(s^{\alpha-1} - m^{\alpha-1}) + a_0(x,m) & \text{if } s > m, \\ \Lambda_3(m^{\alpha-1} - (-s)^{\alpha-1}) + a_0(x,-m) & \text{if } s < -m. \end{cases}$$

Using the hypotheses assumed on a_0, it can be easily verified that a_0^m is a Carathéodory function satisfying

$$|a_0^m(x,s)| \leq \Lambda_3(|s|^{\alpha-1} + m^{\alpha-1}) + h_0(m)m, \tag{3.9}$$

$$(a_0^m(x,s) - a_0^m(x,s'))(s-s') > 0 \quad \text{if } s \neq s', \tag{3.10}$$

$$\begin{cases} a_0^m(x,s)s \geq \Lambda_3 s^2 & \text{if } \alpha \geq 2, \\ a_0^m(x,s)s \geq \Lambda_3(|s|^\alpha - k_2) & \text{if } \alpha < 2 \end{cases} \tag{3.11}$$

for some $k_2 \geq 0$. In fact, when $\alpha < 2$,

$$a_0^m(x,s)s \geq \left\{ \begin{array}{ll} \Lambda_3 s^2 & \text{if } |s| \leq m \\ \Lambda_3|s|^\alpha & \text{if } |s| \geq m \end{array} \right\} \geq \Lambda_3\left(|s|^\alpha - \frac{2-\alpha}{\alpha}\right)$$

for all $x \in \Omega$ and all $s \in R$. Now, let us consider the Neumann problem

$$(3.12)\qquad \begin{cases} -\operatorname{div}(a(x,\nabla y)) + a_0^m(x,y) = f & \text{in } \Omega, \\ a(x,\nabla y)\cdot \vec{\nu} = u & \text{on } \Gamma. \end{cases}$$

By virtue of the corresponding hypotheses on a_j for $j = 1,\dots,n$ and the conditions (3.9)–(3.11), for every $m \in N$, we can apply classical results (see, for instance, Lions [22, Thm. 2.8, p. 183]) to derive the existence of a unique $y_m \in W^{1,\alpha}(\Omega)$ solution of the Neumann problem (3.12). For the boundedness of y_m, let us remark that, if $\alpha > n$, it follows from the Sobolev inclusion $W^{1,\alpha}(\Omega) \subset L^\infty(\Omega)$. If $\alpha \le n$, it can be deduced using Stampacchia's procedure [31], and taking into account the continuous inclusions

$$L^p(\Omega) \subset (W^{1,s}(\Omega))' \quad\text{and}\quad L^\infty(\Gamma) \subset W^{-1/r,r}(\Gamma),$$

where $r = s/(s-1)$ with $r \ge \beta = \alpha/(\alpha-1)$ and $r > n/(\alpha-1)$, because of condition $p > n/\alpha$. Furthermore, there exists a positive constant C independent of m such that

$$\|y_m\|_{W^{1,\alpha}(\Omega)} + \|y_m\|_{L^\infty(\Omega)} \le C.$$

Given $m \ge C$, it follows from its definition that $a_0^m(x,y_m) = a_0(x,y_m)$. Therefore, for every $m \ge C$ the function y_m is a solution of (3.1). On the other hand, the uniqueness of the solution of this problem in $W^{1,\alpha}(\Omega) \cap L^\infty(\Omega)$ is an immediate consequence of the strict monotonicity of A. Finally, the uniform bound (3.8) and the continuous dependence can be obtained by standard arguments. □

Now let us begin the analysis of the differentiability question by showing that the mapping $u \longrightarrow y_u$ is not necessarily differentiable if $k = 0$. Let us take $\alpha = 3$, $\Omega = (-1,+1)^n$, $\lambda = 36$, and $f = 0$ in (2.1). Then it is easy to verify that the associated states to the controls $u_0 = 0$ and $u_t = u_0 + tv$, with $t > 0$ and

$$v(x) = \begin{cases} 1 & \text{if } |x_1| = 1, \\ 0 & \text{otherwise}, \end{cases}$$

are $y_{u_0} = 0$ and

$$y_{u_t}(x) = \begin{cases} \left(|x_1| - 1 + \left(\dfrac{t}{9}\right)^{1/4}\right)^3 & \text{if } |x_1| > 1 - \left(\dfrac{t}{9}\right)^{1/4}, \\ 0 & \text{otherwise}. \end{cases}$$

Thus the nonexistence of the Gâteaux differential of the relation control-state at u_0 in the direction v is a consequence of the following fact:

$$\left\|\frac{y_{u_t} - y_{u_0}}{t}\right\|_{W^{1,1}(\Omega)} = 2^n\left(\frac{1}{36} + \frac{1}{\sqrt{27}t^{1/4}}\right) \longrightarrow +\infty \quad\text{when}\quad t \searrow 0.$$

For $k \ne 0$ we are going to establish that the relationship between the control and the state is Gâteaux differentiable if $\alpha \ge 2$. In this study, some weighted Sobolev spaces appear in a natural form.

DEFINITION 3.1. *Given $y \in W^{1,\alpha}(\Omega)$ and $k \neq 0$, let us define the space $H^y(\Omega)$ as the completion of $C^\infty(\bar{\Omega})$ with respect to the norm*

$$\|z\| = \left(\int_\Omega (k + |\nabla y|)^{\alpha-2} |\nabla z|^2 dx + \int_\Omega |z|^2 dx \right)^{1/2}$$

It may be easily verified that $H^y(\Omega)$ is a Hilbert space with the inner product

$$(z_1, z_2) = \int_\Omega (k + |\nabla y|)^{\alpha-2} \nabla z_1 \nabla z_2 dx + \int_\Omega z_1 z_2 dx.$$

Moreover, we have

$$W^{1,\alpha}(\Omega) \subset H^y(\Omega) \subset H^1(\Omega) \text{ if } \alpha \geq 2,$$

$$H^1(\Omega) \subset H^y(\Omega) \subset W^{1,\alpha}(\Omega) \text{ if } \alpha \leq 2$$

with continuous injections.

More general spaces of this type have been studied by Coffman, Duffin, and Mizel [15], Murthy and Stampacchia [27], and Trudinger [34].

THEOREM 3.2. *Let us suppose $k \neq 0$ and $\alpha \geq 2$. Let $F : L^\infty(\Gamma) \longrightarrow H^1(\Omega)$ be the functional defined by $F(u) = y_u$. Then F is Gâteaux differentiable. Moreover, if $DF(u)v = z$, then z belongs to $H^{y_u}(\Omega)$ and is the unique solution in this space of problem*

$$(3.13) \qquad \begin{cases} -\text{div} \left(\dfrac{\partial a}{\partial \eta}(x, \nabla y_u) \nabla z \right) + \dfrac{\partial a_0}{\partial s}(x, y_u) z = 0 & \text{in } \Omega, \\ \\ \dfrac{\partial a}{\partial \eta}(x, \nabla y_u) \nabla z \cdot \vec{\nu} = v & \text{on } \Gamma. \end{cases}$$

The proof of this theorem is basically the same as the proof of [11, Thm. 3.1] with minor technical changes. Let us remark that the uniqueness of solution of (3.13) in $H^{y_u}(\Omega)$ is a direct consequence of the Lax Milgram theorem applied to the bilinear form

$$B(z_1, z_2) = \int_\Omega \nabla z_1(x)^T \frac{\partial a}{\partial \eta}(x, \nabla y_u(x)) \nabla z_2(x) dx + \int_\Omega \frac{\partial a_0}{\partial s}(x, y_u(x)) z_1(x) z_2(x) dx,$$

which is continuous and coercive on $H^{y_u}(\Omega)$.

4. Existence of a solution for the control problem.

Under an assumption of convexity of l with respect to the last variable, we are going to prove the existence of a solution for the problem (P_δ).

THEOREM 4.1. *Let us assume that L, l and g_j, $1 \leq j \leq n_e + n_i$, are Carathéodory functions in $\Omega \times R$, $\Gamma \times (R \times R)$, and $\Omega \times (R \times R^n)$, respectively, satisfying the following: For every $M > 0$ there exist functions $\psi_M^1 \in L^1(\Gamma)$, $\psi_M^2 \in L^1(\Omega)$, and a constant $C_M > 0$ such that*

$$(4.1) \qquad l(x, y, u) \geq \psi_M^1(x) \quad \forall x \in \Gamma,\ |y|,\ |u| \leq M,$$

$$L(x,y) \geq -\psi_M^2(x) \quad \forall x \in \Omega,\ |y| \leq M, \tag{4.2}$$

$$|g_j(x,y,\eta)| \leq \psi_M^2(x) + C_M|\eta|^\alpha \quad \forall x \in \Omega,\ \eta \in R^n,\ |y| \leq M,\ 1 \leq j \leq n_e + n_i. \tag{4.3}$$

Moreover, let us suppose that $l(x,y,\cdot)$ is convex in u for all $(x,y) \in \Gamma \times R$ and that there exists a feasible control u_0. Then the problem (P_δ) has at least one solution.

Proof. Because of the existence of a feasible control for the problem (P_δ), we can take a minimizing sequence $\{u_k\}_{k=1}^\infty \subset K$ such that every $y_k = y_{u_k}$ satisfies the state constraints. Since K is bounded in $L^\infty(\Gamma)$, with the aid of Theorem 3.1, we can deduce the existence of a subsequence, denoted in the same way, a function $\phi \in L^\alpha(\Omega)$, a constant C, and elements u and $y = y_u$ such that

$$u_k \to u \quad \text{in the }{}^\star\text{weak topology of } L^\infty(\Gamma), \tag{4.4}$$

$$y_k \to y \quad \text{in } W^{1,\alpha}(\Omega), \tag{4.5}$$

$$y_k(x) \to y(x) \ \text{ a.e.}[\sigma]\ x \in \Gamma \quad \text{and} \quad y_k(x) \to y(x) \ \text{ a.e. } x \in \Omega, \tag{4.6}$$

$$\nabla y_k(x) \to \nabla y(x) \ \text{ a.e. } x \in \Omega, \tag{4.7}$$

and

$$\|y_k\|_{L^\infty(\Omega)} \leq C \quad \text{and} \quad |\nabla y_k(x)| \leq \phi(x) \ \text{ a.e. } x \in \Omega \quad \forall k. \tag{4.8}$$

Taking into account that K is *weakly closed in $L^\infty(\Gamma)$, we deduce from (4.4) that $u \in K$. Let us take

$$M = \max\{C, \max_{v \in K} \|v\|_{L^\infty(\Gamma)}\}.$$

Then using the dominated convergence theorem, hypothesis (4.3), and relations (4.6)–(4.8), we get that $G_j(u_k) \to G_j(u)$ for each $j = 1, \ldots, n_e + n_i$. Consequently, u is a feasible control for (P_δ).

On the other hand, thanks to the convexity of l with respect to the last variable, hypotheses (4.1)–(4.2), and convergences (4.4) and (4.6), it follows that (see Cesari [12] or Ekeland and Temam [17])

$$\begin{aligned} J(u) &= \int_\Omega L(x,y(x))dx + \int_\Gamma l(x,y(x),u(x))d\sigma(x) \\ &\leq \liminf_{k\to\infty}\left(\int_\Omega L(x,y_k(x))dx + \int_\Gamma l(x,y_k(x),u_k(x))d\sigma(x)\right) = \inf(P_\delta), \end{aligned}$$

which proves that u is a solution of (P_δ). □

Let us remark that hypothesis (4.3) is satisfied under assumptions (2.2)–(2.7) if $\theta \geq \beta = \alpha/(\alpha-1)$.

5. Optimality conditions: $k > 0$. In this section we are going to deduce the optimality conditions for the problem (P_δ) under the assumption $k > 0$. We will distinguish the cases $\alpha \geq 2$ and $\alpha < 2$.

Hereafter, for the sake of simplicity, let us denote

$$M_k(y)(x) = \frac{(\alpha-2)}{|\nabla y(x)|}[k + |\nabla y(x)|]^{\alpha-3}\nabla y(x)\nabla y(x)^T + [k + |\nabla y(x)|]^{\alpha-2}I, \tag{5.1}$$

where I denotes the identity matrix $n \times n$.

5.1. Case $\alpha \geq 2$. As mentioned in the introduction, since it is unknown to us whether the functions involved in the optimization problem are Frechet differentiable, we cannot apply any known rule of Lagrange multipliers because of the presence of equality constraints; see Pourciau [30] for a discussion of this question and Halkin [19] for a strong result not covering our case.

THEOREM 5.1. *Let us suppose $\alpha \geq 2$, $k > 0$, and that assumptions* (2.2)–(2.7) *are satisfied with $\tau \geq (2n-2)/n$, $\rho \geq (2n)/(n+2)$, and $\theta \geq 2$. Let $\bar{u}$ be a solution of (P_δ). Then there exist real numbers $\bar{\mu}_j$, $j = 0, 1, \dots, n_e + n_i$, and elements $\bar{y} \in W^{1,\alpha}(\Omega) \cap L^\infty(\Omega)$ and $\bar{p} \in H^1(\Omega)$ such that*

$$\bar{\mu}_0 \geq 0 \quad \textit{and} \quad \bar{\mu}_j \geq 0,\ n_e + 1 \leq j \leq n_e + n_i, \tag{5.2}$$

$$\bar{\mu}_0 + \sum_{j=1}^{n_e} |\bar{\mu}_j| + \sum_{j=n_e+1}^{n_e+n_i} \bar{\mu}_j > 0, \tag{5.3}$$

$$\left\{ \begin{aligned} -\text{div}\left\{[k + |\nabla\bar{y}|]^{\alpha-2}\nabla\bar{y}\right\} + \lambda\bar{y} = f \quad & \textit{in } \Omega, \\ (k + |\nabla\bar{y}|)^{\alpha-2}\nabla\bar{y}\cdot\vec{\nu} = \bar{u} \quad & \textit{on } \Gamma, \end{aligned} \right. \tag{5.4}$$

$$\left\{ \begin{aligned} & -\text{div}\left\{M_k(\bar{y})\nabla\bar{p}\right\} + \lambda\bar{p} = \bar{\mu}_0\frac{\partial L}{\partial y}(x,\bar{y}) \\ & + \sum_{j=1}^{n_e+n_i} \bar{\mu}_j \left\{\frac{\partial g_j}{\partial y}(x,\bar{y},\nabla\bar{y}) - \text{div}\left(\frac{\partial g_j}{\partial \eta}(x,\bar{y},\nabla\bar{y})\right)\right\} \quad \textit{in } \Omega, \\ & M_k(\bar{y})\nabla\bar{p}\cdot\vec{\nu} = \bar{\mu}_0\frac{\partial l}{\partial y}(x,\bar{y},\bar{u}) \ \textit{on } \Gamma, \end{aligned} \right. \tag{5.5}$$

with M_k given by (5.1),

$$\bar{\mu}_j\left(\int_\Omega g_j(x,\bar{y}(x),\nabla\bar{y}(x))dx - \delta_j\right) = 0, \quad j > n_e, \tag{5.6}$$

$$\int_\Gamma \left(\bar{p} + \bar{\mu}_0\frac{\partial l}{\partial u}(x,\bar{y},\bar{u})\right)(u - \bar{u})d\sigma(x) \geq 0 \quad \forall u \in K. \tag{5.7}$$

Moreover,

$$\begin{aligned} & \int_\Omega \nabla\bar{p}^T M_k(\bar{y})\nabla\bar{p}dx + \int_\Omega \lambda\bar{p}^2 dx \leq \bar{\mu}_0\left(\int_\Omega \frac{\partial L}{\partial y}(x,\bar{y})\bar{p}dx + \int_\Gamma \frac{\partial l}{\partial y}(x,\bar{y},\bar{u})\bar{p}d\sigma(x)\right) \\ & + \sum_{j=1}^{n_e+n_i} \bar{\mu}_j\left(\int_\Omega \frac{\partial g_j}{\partial y}(x,\bar{y},\nabla\bar{y})\bar{p}dx + \int_\Omega \frac{\partial g_j}{\partial \eta}(x,\bar{y},\nabla\bar{y})\nabla\bar{p}dx\right). \end{aligned} \tag{5.8}$$

Before proving this theorem, let us make some remarks. Since the right-hand side of the partial differential equation in (5.5) involves derivatives of $L^2(\Omega)$-functions and the boundary condition is of Neumann type, the solution of this boundary problem must be intended in a variational sense, i.e., an element $\bar{p} \in H^1(\Omega)$ satisfies (5.5) if and only if for every $\psi \in C^\infty(\bar{\Omega})$ the following identity holds:

$$\int_\Omega \nabla\psi^T M_k(\bar{y})\nabla\bar{p}dx + \int_\Omega \lambda\psi\bar{p}dx = \bar{\mu}_0\left(\int_\Omega \frac{\partial L}{\partial y}(x,\bar{y})\psi dx + \int_\Gamma \frac{\partial l}{\partial y}(x,\bar{y},\bar{u})\psi d\sigma(x)\right)$$

$$+\sum_{j=1}^{n_e+n_i}\bar{\mu}_j\left(\int_\Omega \frac{\partial g_j}{\partial y}(x,\bar{y},\nabla\bar{y})\psi dx + \int_\Omega \frac{\partial g_j}{\partial \eta}(x,\bar{y},\nabla\bar{y})\nabla\psi dx\right).$$

Let us point out that the first integral in the above expression is finite thanks to (5.8).

It is well known that the difficulty with the Neumann problems is the interpretation of the boundary condition; see, for instance, Lions and Magenes [23, Vol. 1] for linear problems and Casas and Fernández [6] for quasilinear elliptic problems.

To illustrate this situation and the previous theorem, let us give an example:

$$(P_\delta)\begin{cases} \text{minimize } J(u) = \dfrac{1}{2}\displaystyle\int_\Omega (y_u(x) - z_d(x))^2 dx \\ \text{such that } 0 \le u(x) \le 1 \text{ a.e. } [\sigma]\ x \in \Gamma \text{ and} \\ G_j(u) = \delta_j, \quad 1 \le j \le n, \end{cases}$$

with

$$G_j(u) = \int_\Omega \frac{\partial y_u}{\partial x_j}(x)dx, \quad j = 1,\dots,n$$

and z_d a given element of $L^2(\Omega)$.

If we assume that problem (P_δ) has a feasible control, the existence of at least one solution $\bar{u}$ follows from Theorem 4.1. Now, applying Theorem 5.1, we deduce the existence of some real numbers $\{\bar{\mu}_j\}_{j=0}^n$ and elements $\bar{y} \in W^{1,\alpha}(\Omega) \cap L^\infty(\Omega)$ and $\bar{p} \in H^1(\Omega)$ such that

$$\bar{\mu}_0 \ge 0 \quad\text{and}\quad \bar{\mu}_0 + \sum_{j=1}^n |\bar{\mu}_j| > 0, \tag{5.9}$$

$$\begin{cases} -\operatorname{div}\{[k+|\nabla\bar{y}|]^{\alpha-2}\nabla\bar{y}\} + \lambda\bar{y} = f & \text{in } \Omega, \\ (k+|\nabla\bar{y}|)^{\alpha-2}\nabla\bar{y}\cdot\vec{\nu} = \bar{u} & \text{on } \Gamma, \end{cases} \tag{5.10}$$

$$\begin{cases} -\operatorname{div}\{M_k(\bar{y})\nabla\bar{p}\} + \lambda\bar{p} = \bar{\mu}_0(\bar{y} - z_d) - \displaystyle\sum_{j=1}^n \bar{\mu}_j\frac{\partial}{\partial x_j} & \text{in } \Omega, \\ M_k(\bar{y})\nabla\bar{p}\cdot\vec{\nu} = 0 \quad \text{on } \Gamma, \end{cases} \tag{5.11}$$

$$\int_\Gamma \bar{p}(u - \bar{u})d\sigma(x) \ge 0 \quad \forall\, 0 \le u(x) \le 1 \text{ a.e. } [\sigma]\ x \in \Gamma. \tag{5.12}$$

According to the preceding comments, the solution of (5.11) must be intended in a variational sense as follows: for every $\psi \in C^\infty(\bar\Omega)$

$$\int_\Omega \nabla\psi^T M_k(\bar y)\nabla\bar p dx + \int_\Omega \lambda\psi\bar p dx = \bar\mu_0 \int_\Omega (\bar y - z_d)\psi dx + \sum_{j=1}^n \bar\mu_j \int_\Omega \frac{\partial\psi}{\partial x_j} dx.$$

As it is classical in control theory, from (5.12) we can deduce a behaviour of bang-bang type of $\bar u$:

$$\bar u(x) = \begin{cases} 1 & \text{if } \bar p(x) < 0, \\ 0 & \text{if } \bar p(x) > 0. \end{cases}$$

Proof of Theorem 5.1. We will follow a penalization method, where the penalty objective function is a slight differentiable modification of the one used by Clarke in [14]. For every $\epsilon > 0$, let us consider the problem

$$(P_{\delta,\epsilon}) \begin{cases} \text{minimize } J_\epsilon(u) \\ \text{such that } u \in K, \end{cases}$$

where

$$J_\epsilon(u) = \left\{ [(J(u) - J(\bar u) + \epsilon)^+]^2 + \sum_{j=1}^{n_e} |G_j(u) - \delta_j|^2 + \sum_{j=n_e+1}^{n_e+n_i} [(G_j(u) - \delta_j)^+]^2 \right\}^{1/2}$$

and $c^+ = \max\{c, 0\}$. It is obvious that (K, d) is a complete metric space, with $d(u,v) = \|u - v\|_{L^\infty(\Gamma)}$, $J_\epsilon : K \longrightarrow R$ is a continuous function, and

$$J_\epsilon(\bar u) = \epsilon \leq \epsilon + \inf_{u\in K} J_\epsilon(u).$$

Then we can apply Ekeland's variational principle [16] to deduce the existence of an element $u_\epsilon \in K$ such that

$$d(u_\epsilon, \bar u) = \|u_\epsilon - \bar u\|_{L^\infty(\Gamma)} \leq \sqrt\epsilon \tag{5.13}$$

and u_ϵ is a solution of problem

$$(Q_{\delta,\epsilon}) \begin{cases} \text{minimize } J_\epsilon(u) + \sqrt\epsilon\|u_\epsilon - u\|_{L^\infty(\Gamma)} \\ \text{such that } u \in K. \end{cases}$$

Since J_ϵ is Gâteaux differentiable in K (note that $J_\epsilon(u) > 0 \ \ \forall u \in K$ because $\bar u$ is a solution of (P_δ)) and $\phi(u) = \|u_\epsilon - u\|_{L^\infty(\Gamma)}$ is a convex function, we obtain (for example, see [4, Lem. 2])

$$J'_\epsilon(u_\epsilon)\cdot(u - u_\epsilon) + \sqrt\epsilon\|u - u_\epsilon\|_{L^\infty(\Gamma)} \geq 0 \quad \forall u \in K. \tag{5.14}$$

Now it is easy to verify that

$$J'_\epsilon(u_\epsilon)\cdot(u - u_\epsilon) = \left(\mu_{0\epsilon}J'(u_\epsilon) + \sum_{j=1}^{n_e+n_i} \mu_{j\epsilon}G'_j(u_\epsilon)\right)\cdot(u - u_\epsilon), \tag{5.15}$$

where

$$\begin{cases} \mu_{0\epsilon} = J_\epsilon(u_\epsilon)^{-1}(J(u_\epsilon) - J(\bar{u}) + \epsilon)^+, \\ \mu_{j\epsilon} = J_\epsilon(u_\epsilon)^{-1}(G_j(u_\epsilon) - \delta_j),\ 1 \le j \le n_e, \\ \mu_{j\epsilon} = J_\epsilon(u_\epsilon)^{-1}(G_j(u_\epsilon) - \delta_j)^+,\ j > n_e. \end{cases}$$

So we have that $\mu_{0\epsilon} \ge 0$ and $\mu_{j\epsilon} \ge 0$ for $j > n_e$; moreover,

$$\sum_{j=0}^{n_e+n_i} \mu_{j\epsilon}^2 = 1. \tag{5.16}$$

On the other hand, let p_ϵ be the unique variational solution in $H^{y_\epsilon}(\Omega)$ of the problem

$$\begin{cases} -\text{div}\,\{M_k(y_\epsilon)\nabla p_\epsilon\} + \lambda p_\epsilon = \mu_{0\epsilon}\dfrac{\partial L}{\partial y}(x, y_\epsilon) \\ \displaystyle + \sum_{j=1}^{n_e+n_i} \mu_{j\epsilon}\left\{\frac{\partial g_j}{\partial y}(x, y_\epsilon, \nabla y_\epsilon) - \text{div}\left(\frac{\partial g_j}{\partial \eta}(x, y_\epsilon, \nabla y_\epsilon)\right)\right\} \quad \text{in } \Omega, \\ M_k(y_\epsilon)\nabla p_\epsilon \cdot \vec{\nu} = \mu_{0\epsilon}\dfrac{\partial l}{\partial y}(x, y_\epsilon, u_\epsilon) \quad \text{on } \Gamma, \end{cases} \tag{5.17}$$

where $y_\epsilon \in W^{1,\alpha}(\Omega) \cap L^\infty(\Omega)$ is the state associated with u_ϵ. Let us note that

$$z \longrightarrow \sum_{j=1}^{n_e+n_i} \mu_{j\epsilon}\left(\int_\Omega \frac{\partial g_j}{\partial y}(x, y_\epsilon, \nabla y_\epsilon)z + \frac{\partial g_j}{\partial \eta}(x, y_\epsilon, \nabla y_\epsilon)\nabla z dx\right)$$

$$+ \mu_{0\epsilon}\left(\int_\Omega \frac{\partial L}{\partial y}(x, y_\epsilon)z dx + \int_\Gamma \frac{\partial l}{\partial y}(x, y_\epsilon, u_\epsilon)z d\sigma(x)\right)$$

defines an element belonging to $(H^1(\Omega))' \subset (H^{y_\epsilon}(\Omega))'$ thanks to the choice of τ, ρ and θ, the Sobolev imbedding theorems, and assumptions (2.4)–(2.7).

Let u be an arbitrary element of K and let us denote $z_\epsilon = DF(u_\epsilon) \cdot (u - u_\epsilon)$, where $F(v) = y_v$; see Theorem 3.2. Then, from conditions (2.3)–(2.7), the identity (5.15), and equations (3.13) and (5.17) we obtain

$$\begin{aligned} J'_\epsilon(u_\epsilon) \cdot (u - u_\epsilon) &= \mu_{0\epsilon}\int_\Omega \frac{\partial L}{\partial y}(x, y_\epsilon)z_\epsilon dx \\ &\quad + \mu_{0\epsilon}\int_\Gamma \left\{\frac{\partial l}{\partial y}(x, y_\epsilon, u_\epsilon)z_\epsilon + \frac{\partial l}{\partial u}(x, y_\epsilon, u_\epsilon)(u - u_\epsilon)\right\} d\sigma(x) \\ &\quad + \sum_{j=1}^{n_e+n_i} \mu_{j\epsilon}\int_\Omega \left\{\frac{\partial g_j}{\partial y}(x, y_\epsilon, \nabla y_\epsilon)z_\epsilon + \frac{\partial g_j}{\partial \eta}(x, y_\epsilon, \nabla y_\epsilon)\nabla z_\epsilon\right\} dx \\ &= \int_\Omega \{\nabla z_\epsilon^T M_k(y_\epsilon)\nabla p_\epsilon + \lambda z_\epsilon p_\epsilon\}\, dx + \int_\Gamma \mu_{0\epsilon}\frac{\partial l}{\partial u}(x, y_\epsilon, u_\epsilon)(u - u_\epsilon)d\sigma(x) \\ &= \int_\Gamma \left(p_\epsilon + \mu_{0\epsilon}\frac{\partial l}{\partial u}(x, y_\epsilon, u_\epsilon)\right)(u - u_\epsilon)d\sigma(x). \end{aligned}$$

From (5.13) it follows that $u_\epsilon \to \bar{u}$ in $L^\infty(\Gamma)$; therefore, $y_\epsilon = y_{u_\epsilon} \to \bar{y} = y_{\bar{u}}$ in $W^{1,\alpha}(\Omega)$. Now, thanks to Theorem 3.1 and (5.16), we deduce the existence of a constant $C > 0$, a function $\phi \in L^\alpha(\Omega)$, and a subsequence, still denoted in the same way, verifying

$$\mu_{j\epsilon} \to \bar{\mu}_j, \quad j = 0, 1, \ldots, n_e + n_i, \tag{5.18}$$

$$y_\epsilon(x) \to \bar{y}(x) \ \text{ a.e.}[\sigma]\ x \in \Gamma \quad \text{and} \quad y_\epsilon(x) \to \bar{y}(x) \ \text{ a.e. } x \in \Omega, \tag{5.19}$$

$$\nabla y_\epsilon(x) \to \nabla \bar{y}(x) \ \text{ a.e. } x \in \Omega, \tag{5.20}$$

and

$$\|y_\epsilon\|_{L^\infty(\Omega)} \le C \quad \text{and} \quad |\nabla y_\epsilon(x)| \le \phi(x) \ \text{ a.e. } x \in \Omega \quad \forall \epsilon. \tag{5.21}$$

With the aid of the previous relations, and taking into account the definitions of $\mu_{j\epsilon}$ and identity (5.16), we can pass to the limit and get (5.2)–(5.4) and (5.6). On the other hand, from hypotheses (2.3)–(2.7) and (5.18)–(5.21), we deduce the convergence of the right-hand terms of (5.17) toward the corresponding terms of (5.5) in $(H^1(\Omega))'$. Utilizing the fact that p_ϵ is the solution of (5.17) and integrating by parts we get

$$C_1 \|p_\epsilon\|^2_{H^1(\Omega)} \le \int_\Omega \nabla p_\epsilon^T M_k(y_\epsilon) \nabla p_\epsilon dx + \lambda \int_\Omega p_\epsilon^2 dx \le C_2 \|p_\epsilon\|_{H^1(\Omega)}, \tag{5.22}$$

where C_1 and C_2 are positive constants. This implies that $\{p_\epsilon\}_\epsilon$ is bounded in $H^1(\Omega)$. Then, we can take a new subsequence, denoted again by $\{p_\epsilon\}_\epsilon$, such that

$$p_\epsilon \to \bar{p} \quad \text{weakly in } H^1(\Omega) \tag{5.23}$$

for a certain element $\bar{p} \in H^1(\Omega)$. By virtue of the expression obtained for the derivate $J'_\epsilon(u_\epsilon) \cdot (u - u_\epsilon)$, we can pass to the limit in (5.14) and derive (5.7).

To finish the proof it is enough to establish that $\bar{p}$ satisfies (5.5) and inequality (5.8). First, we point out that $M_k(y_\epsilon)(x)$ and $M_k(\bar{y})(x)$ are symmetric and positive definite matrices for every $x \in \Omega$. Thus, applying the Cholesky method, we deduce the existence of lower triangular matrices U_ϵ and U with strictly positive elements such that

$$M_k(y_\epsilon)(x) = U_\epsilon(x) U_\epsilon^T(x) \quad \text{and} \quad M_k(\bar{y})(x) = U(x) U^T(x).$$

From (5.22) and the boundedness of $\{p_\epsilon\}_\epsilon$ in $H^1(\Omega)$ it follows that $\{U_\epsilon^T \nabla p_\epsilon\}_\epsilon$ is bounded in $\left(L^2(\Omega)\right)^n$. Furthermore, using (5.21), the expressions of the elements of U_ϵ and U as function of those of $M_k(y_\epsilon)$ and $M_k(\bar{y})$, respectively, and taking a new subsequence, if necessary, we obtain

$$\begin{aligned} \|U_\epsilon(x)\|_s &\le \sqrt{\alpha - 1}(k + |\nabla y_\epsilon(x)|)^{(\alpha-2)/2} \\ &\le \sqrt{\alpha - 1}(k + |\phi(x)|)^{(\alpha-2)/2} \ \text{ a.e. } x \in \Omega \quad \forall \epsilon, \end{aligned} \tag{5.24}$$

and

$$U_\epsilon(x) \longrightarrow U(x) \quad \text{a.e. } x \in \Omega \quad \text{when } \epsilon \to 0, \tag{5.25}$$

where $\|.\|_s$ denotes the spectral matrix norm defined by

$$\|U\|_s = \left(\max_i\{|\gamma_i| : \gamma_i \text{ is an eigenvalue of } U^TU\}\right)^{1/2};$$

see, for instance, Isaacson and Keller [20]. Together with the dominated convergence theorem, this implies that

$$U_\epsilon \to U \quad \text{in } (L^2(\Omega))^{n\times n}.$$

Since $\nabla p_\epsilon \to \nabla \bar{p}$ weakly in $(L^2(\Omega))^n$ as $\epsilon \to 0$, we have that

$$U_\epsilon^T \nabla p_\epsilon \longrightarrow U^T\nabla\bar{p} \quad \text{weakly in } (L^2(\Omega))^n. \tag{5.26}$$

Combining (5.26) with the convergence

$$U_\epsilon^T\nabla\psi \longrightarrow U^T\nabla\psi \quad \text{in } (L^2(\Omega))^n$$

for $\psi \in C^\infty(\bar{\Omega})$ arbitrary, it follows that

$$\begin{aligned}\int_\Omega \nabla\psi^T M_k(y_\epsilon)\nabla p_\epsilon dx &= \int_\Omega [U_\epsilon^T\nabla\psi]^T[U_\epsilon^T\nabla p_\epsilon]dx\\ \longrightarrow \int_\Omega [U^T\nabla\psi]^T[U^T\nabla\bar{p}]dx &= \int_\Omega \nabla\psi^T M_k(\bar{y})\nabla\bar{p}dx,\end{aligned}$$

and therefore $\bar{p}$ is a solution of (5.5). Finally, as a consequence of the previous relations and convergences, hypotheses (2.4)–(2.7), the values of τ, ρ, and θ, and the Sobolev imbedding theorem for $H^1(\Omega)$ we conclude that

$$\begin{aligned}&\int_\Omega \nabla\,\bar{p}^T M_k(\bar{y})\nabla\bar{p}dx + \int_\Omega \lambda\bar{p}^2dx\\
&= \|U^T\nabla\bar{p}\|^2_{L^2(\Omega)} + \lambda\|\bar{p}\|^2_{L^2(\Omega)}\\
&\leq \liminf_{\epsilon\to 0}\left(\|U_\epsilon^T\nabla p_\epsilon\|^2_{L^2(\Omega)} + \lambda\|p_\epsilon\|^2_{L^2(\Omega)}\right)\\
&= \liminf_{\epsilon\to 0}\left(\int_\Omega \nabla p_\epsilon^T M_k(y_\epsilon)\nabla p_\epsilon dx + \lambda\int_\Omega p_\epsilon^2dx\right)\\
&= \liminf_{\epsilon\to 0}\left\{\mu_{0\epsilon}\left(\int_\Omega \frac{\partial L}{\partial y}(x,y_\epsilon)p_\epsilon dx + \int_\Gamma \frac{\partial l}{\partial y}(x,y_\epsilon,u_\epsilon)p_\epsilon d\sigma(x)\right)\right.\\
&\qquad\left. + \sum_{j=1}^{n_e+n_i}\mu_{j\epsilon}\left(\int_\Omega \frac{\partial g_j}{\partial y}(x,y_\epsilon,\nabla y_\epsilon)p_\epsilon dx + \int_\Omega \frac{\partial g_j}{\partial \eta}(x,y_\epsilon,\nabla y_\epsilon)\nabla p_\epsilon dx\right)\right\}\\
&= \bar{\mu}_0\left(\int_\Omega \frac{\partial L}{\partial y}(x,\bar{y})\bar{p}dx + \int_\Gamma \frac{\partial l}{\partial y}(x,\bar{y},\bar{u})\bar{p}d\sigma(x)\right)\\
&\qquad + \sum_{j=1}^{n_e+n_i}\bar{\mu}_j\left(\int_\Omega \frac{\partial g_j}{\partial y}(x,\bar{y},\nabla\bar{y})\bar{p}dx + \int_\Omega \frac{\partial g_j}{\partial\eta}(x,\bar{y},\nabla\bar{y})\nabla\bar{p}dx\right),\end{aligned}$$

or equivalently, $\bar{p}$ satisfies (5.8). □

Remark 5.1. In the absence of equality constraints ($n_e = 0$), we can derive the optimality conditions by a direct application of the abstract Lagrange multiplier rule given in [5, Thm. 5.2], where only Gâteaux differentiability of the functions defining the problem is required. Following this approach we derive the existence of a unique adjoint state $\bar{p} \in H^{\bar{y}}(\Omega)$.

5.2. Case $\alpha < 2$. The goal of this section is to prove the following theorem.

THEOREM 5.2. *Let $\bar{u}$ be a solution of (P_δ), $\alpha < 2$ and $k > 0$. Furthermore, let us assume that $l(x,y,\cdot) : R \longrightarrow R$ is a convex function for all $(x,y) \in \Omega \times R$, $\tau \geq (n\alpha - \alpha)/(n\alpha - n)$, $\rho \geq (\alpha n)/(\alpha n + \alpha - n)$, and $\theta \geq \alpha/(\alpha - 1)$. Then there exist real numbers $\bar{\mu}_j$, $j = 0, 1, \dots, n_e + n_i$, and elements $\bar{y} \in W^{1,\alpha}(\Omega) \cap L^\infty(\Omega)$ and $\bar{p} \in W^{1,\alpha}(\Omega)$ verifying* (5.2)–(5.8).

As we have already mentioned, in this case we do not know if the relation control-state is differentiable. To overcome this difficulty the state equation is perturbed in such a way that this relation again becomes differentiable. So, given $\epsilon > 0$, let us consider the following operator

$$A_\epsilon y = -\text{div}\left\{(\epsilon + [k + |\nabla y|]^{\alpha-2})\nabla y\right\} + \lambda y,$$

which satisfies hypotheses (3.2)–(3.7) with an exponent 2. Therefore the Neumann problem

$$\text{(5.27)} \qquad \begin{cases} A_\epsilon y = f & \text{in } \Omega, \\ \left(\epsilon + [k + |\nabla y|]^{\alpha-2}\right) \nabla y \cdot \vec{\nu} = u & \text{on } \Gamma \end{cases}$$

has a unique solution $y_\epsilon(u) \in H^1(\Omega) \cap L^\infty(\Omega)$ for every $u \in L^\infty(\Gamma)$. Moreover, since we are in the conditions of Theorem 3.2, the mapping $u \longrightarrow y_\epsilon(u)$ is Gâteaux differentiable.

Now associated with the previous Neumann problem we introduce the following family of control problems that approximate (P_δ) in a sense to be specified later:

$$(Q_{\delta,\epsilon}) \begin{cases} \text{minimize } \tilde{J}_\epsilon(u) \\ \text{such that } u \in K \text{ and} \\ G_{j\epsilon}(u) = \delta_{j\epsilon}, \quad 1 \leq j \leq n_e, \\ G_{j\epsilon}(u) \leq \delta_{j\epsilon}, \quad n_e + 1 \leq j \leq n_e + n_i, \end{cases}$$

where

$$\tilde{J}_\epsilon(u) = \int_\Omega L(x, y_\epsilon(u)(x))dx + \int_\Gamma l(x, y_\epsilon(u)(x), u(x))d\sigma(x) + \frac{1}{2}\int_\Gamma |u(x) - \bar{u}(x)|^2 d\sigma(x),$$

$$G_{j\epsilon}(u) = \int_\Omega g_j(x, y_\epsilon(u)(x), \nabla y_\epsilon(u)(x))dx,$$

$\delta_{j\epsilon} = G_{j\epsilon}(\bar{u})$ if $1 \leq j \leq n_e$, and $\delta_{j\epsilon} = \max\{\delta_j, G_{j\epsilon}(\bar{u})\}$ if $j > n_e$.

THEOREM 5.3. *Under the assumptions of Theorem 5.2, for every $\epsilon > 0$ the problem $(Q_{\delta,\epsilon})$ has at least one solution u_ϵ. Moreover there exist real numbers $\mu_{j\epsilon}$, $j = 0, 1, \dots, n_e + n_i$, and elements $y_\epsilon \in H^1(\Omega) \cap L^\infty(\Omega)$ and $p_\epsilon \in H^1(\Omega)$ such that*

$$\text{(5.28)} \qquad \mu_{0\epsilon} \geq 0 \quad \textit{and} \quad \mu_{j\epsilon} \geq 0, \; n_e + 1 \leq j \leq n_e + n_i,$$

$$\text{(5.29)} \qquad \mu_{0\epsilon} + \sum_{j=1}^{n_e} |\mu_{j\epsilon}| + \sum_{j=n_e+1}^{n_e+n_i} \mu_{j\epsilon} > 0,$$

$$(5.30)\qquad \begin{cases} -\mathrm{div}\left\{(\epsilon + [k + |\nabla y_\epsilon|]^{\alpha-2})\nabla y_\epsilon\right\} + \lambda y_\epsilon = f & \textit{in } \Omega \\ \left(\epsilon + [k + |\nabla y_\epsilon|]^{\alpha-2}\right) \nabla y_\epsilon \cdot \vec{\nu} = u_\epsilon & \textit{on } \Gamma, \end{cases}$$

$$(5.31)\qquad \begin{cases} -\mathrm{div}\left\{(\epsilon + M_k(y_\epsilon))\nabla p_\epsilon\right\} + \lambda p_\epsilon = \mu_{0\epsilon}\dfrac{\partial L}{\partial y}(x, y_\epsilon) \\ \quad + \displaystyle\sum_{j=1}^{n_e+n_i} \mu_{j\epsilon}\left\{\frac{\partial g_j}{\partial y}(x, y_\epsilon, \nabla y_\epsilon) - \mathrm{div}\left(\frac{\partial g_j}{\partial \eta}(x, y_\epsilon, \nabla y_\epsilon)\right)\right\} \quad \textit{in } \Omega, \\ (\epsilon + M_k(y_\epsilon))\, \nabla p_\epsilon \cdot \vec{\nu} = \mu_{0\epsilon}\dfrac{\partial l}{\partial y}(x, y_\epsilon, u_\epsilon) \quad \textit{on } \Gamma, \end{cases}$$

with M_k *given by* (5.1),

$$(5.32)\qquad \mu_{j\epsilon}\left(\int_\Omega g_j(x, y_\epsilon(x), \nabla y_\epsilon(x))dx - \delta_{j\epsilon}\right) = 0, \quad j > n_e,$$

$$(5.33)\qquad \int_\Gamma \left(p_\epsilon + \mu_{0\epsilon}\left(\frac{\partial l}{\partial u}(x, y_\epsilon, u_\epsilon) + u_\epsilon - \bar{u}\right)\right)(u - u_\epsilon)d\sigma(x) \geq 0 \quad \forall u \in K.$$

Moreover,

$$(5.34)\qquad \begin{aligned} &\epsilon \int_\Omega |\nabla p_\epsilon|^2 dx + \int_\Omega \nabla p_\epsilon^T M_k(y_\epsilon)\nabla p_\epsilon dx + \int_\Omega \lambda p_\epsilon^2 dx \\ &\leq \mu_{0\epsilon}\left(\int_\Omega \frac{\partial L}{\partial y}(x, y_\epsilon)p_\epsilon dx + \int_\Gamma \frac{\partial l}{\partial y}(x, y_\epsilon, u_\epsilon)p_\epsilon d\sigma(x)\right) \\ &+ \sum_{j=1}^{n_e+n_i} \mu_{j\epsilon}\left(\int_\Omega \frac{\partial g_j}{\partial y}(x, y_\epsilon, \nabla y_\epsilon)p_\epsilon dx + \int_\Omega \frac{\partial g_j}{\partial \eta}(x, y_\epsilon, \nabla y_\epsilon)\nabla p_\epsilon dx\right). \end{aligned}$$

Proof. Because $\bar{u}$ is a feasible control for $(Q_{\delta,\epsilon})$, we are in the conditions of Theorem 4.1; thus we obtain the existence of a solution for $(Q_{\delta,\epsilon})$. The optimality conditions are derived as in Theorem 5.1; see Remark 5.2 below. □

The next result shows in what sense (P_δ) is approximated by the problems $(Q_{\delta,\epsilon})$.

THEOREM 5.4. *Let* u_ϵ *and* y_ϵ *be as they were in the previous theorem and let us denote* $\bar{y} = y_{\bar{u}}$. *Then as* $\epsilon \to 0$ *we have the following convergences*:

$$(5.35)\qquad u_\epsilon \to \bar{u} \quad \textit{in } L^t(\Gamma) \quad \forall\, t < +\infty,$$

$$(5.36)\qquad y_\epsilon \to \bar{y} \quad \textit{in } W^{1,\alpha}(\Omega),$$

$$(5.37)\qquad \tilde{J}_\epsilon(u_\epsilon) \to J(\bar{u}).$$

Moreover, $\{y_\epsilon\}_\epsilon$ *is uniformly bounded in* $L^\infty(\Omega)$.

The proof of this theorem uses the following lemma that can be proved as in [11, §4] (see also [18]) taking into account that the condition $\alpha > n/2$ assumed there can be removed because here the controls are bounded and $f \in L^p(\Omega)$ with $p > n/\alpha$.

LEMMA 5.5. *Let us suppose that* $\{v_\epsilon\}_\epsilon \subset L^\infty(\Gamma)$ *and* $v_\epsilon \to v$ *in the* **weak topology of* $L^\infty(\Gamma)$. *Then* $y_\epsilon(v_\epsilon) \to y_v$ *in* $W^{1,\alpha}(\Omega)$ *and in the* **weak topology of* $L^\infty(\Omega)$.

Proof of Theorem 5.4. Taking in the previous lemma $v_\epsilon = \bar{u}$ for all $\epsilon > 0$, we deduce that $y_\epsilon(\bar{u}) \to \bar{y}$ in $W^{1,\alpha}(\Omega)$. Then we can extract a subsequence of $\{y_\epsilon(\bar{u})\}_\epsilon$, denoted in the same way, such that

$$(5.38)\qquad y_\epsilon(\bar{u})(x) \to \bar{y}(x) \ \text{ a.e.}[\sigma]\ x \in \Gamma \quad \text{and} \quad y_\epsilon(\bar{u})(x) \to \bar{y}(x) \ \text{ a.e. } x \in \Omega,$$

$$\nabla y_\epsilon(\bar{u})(x) \to \nabla \bar{y}(x) \text{ a.e. } x \in \Omega, \tag{5.39}$$

and

$$\|y_\epsilon(\bar{u})\|_{L^\infty(\Omega)} \le C_1 \quad \text{and} \quad |\nabla y_\epsilon(\bar{u})(x)| \le \phi_1(x) \text{ a.e. } x \in \Omega \quad \forall\epsilon \tag{5.40}$$

for some positive constant C_1 and some function $\phi_1 \in L^\alpha(\Omega)$. From (5.38)–(5.40) and hypotheses (2.2), (2.6), and (2.7) it follows that $G_{j\epsilon}(\bar{u}) \to G_j(\bar{u})$ when ϵ tends to 0, which implies that $\delta_{j\epsilon} \to \delta_j$, $1 \le j \le n_e + n_i$.

On the other hand, since K is a *weakly closed bounded subset of $L^\infty(\Gamma)$ we can take another subsequence of $\{u_\epsilon\}_\epsilon$, again denoted in the same way, converging to an element $u \in K$ in the *weak topology of $L^\infty(\Gamma)$. Using Lemma 5.5 once again we deduce, taking a new subsequence if necessary,

$$y_\epsilon \to y_u \quad \text{in } W^{1,\alpha}(\Omega), \tag{5.41}$$

$$y_\epsilon(x) \to y_u(x) \text{ a.e. } [\sigma]\ x \in \Gamma \quad \text{and} \quad y_\epsilon(x) \to y_u(x) \text{ a.e. } x \in \Omega, \tag{5.42}$$

$$\nabla y_\epsilon(x) \to \nabla y_u(x) \text{ a.e. } x \in \Omega, \tag{5.43}$$

and

$$\|y_\epsilon\|_{L^\infty(\Omega)} \le C_2 \quad \text{and} \quad |\nabla y_\epsilon(x)| \le \phi_2(x) \text{ a.e. } x \in \Omega \quad \forall\epsilon \tag{5.44}$$

for some positive constant C_2 and some function $\phi_2 \in L^\alpha(\Omega)$. Arguing as above, we obtain that $G_{j\epsilon}(u_\epsilon) \to G_j(u)$ for every j. Hence u is a feasible control for problem (P_δ).

Hypotheses (2.2)–(2.4) and the convexity of l in the last variable allow us to deduce the lower semicontinuity of $\tilde{J}_\epsilon$ in the *weak topology of $L^\infty(\Gamma)$; see Ekeland and Temam [17]. Now, remembering that u_ϵ is a solution of $(Q_{\delta,\epsilon})$ and $\bar{u}$ is a feasible control for this problem, we obtain

$$\begin{aligned}
&\int_\Omega L(x, y_u)dx + \int_\Gamma l(x, y_u, u)d\sigma(x) + \frac{1}{2}\int_\Gamma (u - \bar{u})^2 d\sigma(x) \\
&\quad \le \liminf_{\epsilon\to 0} \tilde{J}_\epsilon(u_\epsilon) \le \limsup_{\epsilon\to 0} \tilde{J}_\epsilon(u_\epsilon) \le \limsup_{\epsilon\to 0} \tilde{J}_\epsilon(\bar{u}) = J(\bar{u}) \le J(u) \\
&\quad = \int_\Omega L(x, y_u)dx + \int_\Gamma l(x, y_u, u)d\sigma(x),
\end{aligned}$$

which implies that $u = \bar{u}$ and convergence (5.37). Finally, from the relations

$$\begin{aligned}
&\frac{1}{2}\limsup_{\epsilon\to 0} \int_\Gamma (u_\epsilon - \bar{u})^2 d\sigma(x) \\
&\quad \le \limsup_{\epsilon\to 0} \left(\tilde{J}_\epsilon(u_\epsilon) - \int_\Omega L(x, y_\epsilon)dx - \int_\Gamma l(x, y_\epsilon, u_\epsilon)d\sigma(x)\right) \\
&\quad = J(\bar{u}) - \liminf_{\epsilon\to 0} \left\{\int_\Omega L(x, y_\epsilon)dx + \int_\Gamma l(x, y_\epsilon, u_\epsilon)d\sigma(x)\right\} \le J(\bar{u}) - J(u) \le 0,
\end{aligned}$$

we deduce the desired convergence of $\{u_\epsilon\}_\epsilon$ to $\bar{u}$. □

Proof of Theorem 5.2. The idea is to pass to the limit in (5.28)–(5.34). It follows exactly as in Theorem 5.1, except for some peculiarities that can be summarized as follows:

- We can suppose without loss of generality that

$$\omega_\epsilon = \mu_{0\epsilon} + \sum_{j=1}^{n_e} |\mu_{j\epsilon}| + \sum_{j=n_e+1}^{n_e+n_i} \mu_{j\epsilon} = 1.$$

In the other case, it is enough to divide the expressions (5.31)–(5.34) by ω_ϵ and rename $\omega_\epsilon^{-1}p_\epsilon$ and $\omega_\epsilon^{-1}\mu_{j\epsilon}$ as p_ϵ and $\mu_{j\epsilon}$, respectively.

- After Theorems 5.3 and 5.4 and Lemma 5.5, the main question to prove is the boundedness of $\{p_\epsilon\}_\epsilon$ in $W^{1,\alpha}(\Omega)$. First, applying Hölder's inequality, with $q = 2/\alpha$ and $q' = 2/(2-\alpha)$, and thanks to (5.36) we obtain that

$$\begin{aligned}
&\|\nabla p_\epsilon\|^2_{L^\alpha(\Omega)^n} + \|p_\epsilon\|^2_{L^\alpha(\Omega)} \\
&\leq C_1 \left(\int_\Omega [k + |\nabla y_\epsilon|]^{\alpha-2} |\nabla p_\epsilon|^2 dx\right) \left(\int_\Omega [k + |\nabla y_\epsilon|]^\alpha\right)^{(2-\alpha)/\alpha} \\
&\quad + C_2 \int_\Omega |p_\epsilon|^2 dx \leq C_3 \left(\int_\Omega [k + |\nabla y_\epsilon|]^{\alpha-2} |\nabla p_\epsilon|^2 dx + \int_\Omega |p_\epsilon|^2 dx\right).
\end{aligned}$$

On the other hand, from hypotheses (2.4)–(2.7), the values of τ, ρ, and θ, the Sobolev imbedding theorem for $W^{1,\alpha}(\Omega)$, and Lemma 5.5, it follows that the right-hand terms of problem (5.31) define a bounded element of $(W^{1,\alpha}(\Omega))'$. Hence, with the aid of (5.34), we obtain

$$\begin{aligned}
&(\alpha - 1) \int_\Omega [k + |\nabla y_\epsilon|]^{\alpha-2} |\nabla p_\epsilon|^2 dx + \lambda \int_\Omega |p_\epsilon|^2 dx \\
&\leq \mu_{0\epsilon} \left(\int_\Omega \frac{\partial L}{\partial y}(x, y_\epsilon) p_\epsilon dx + \int_\Gamma \frac{\partial l}{\partial y}(x, y_\epsilon, u_\epsilon) p_\epsilon d\sigma(x)\right) \\
&\quad + \sum_{j=1}^{n_e+n_i} \mu_{j\epsilon} \left(\int_\Omega \frac{\partial g_j}{\partial y}(x, y_\epsilon, \nabla y_\epsilon) p_\epsilon dx + \int_\Omega \frac{\partial g_j}{\partial \eta}(x, y_\epsilon, \nabla y_\epsilon) \nabla p_\epsilon dx\right) \\
&\leq C_4 \|p_\epsilon\|_{W^{1,\alpha}(\Omega)} \quad \forall \epsilon > 0.
\end{aligned}$$

- The weak convergence (5.26) can now be derived noting that

$$\|U_\epsilon(x)\|_s \leq C_5 \text{ a.e. } x \in \Omega \quad \forall \epsilon$$

(with the notations established in the proof of Theorem 5.1) and therefore

$$U_\epsilon \rightharpoonup U \quad \text{in } (L^t(\Omega))^{n\times n} \quad \forall\, t < +\infty,$$

in particular, for $t = \alpha/(\alpha - 1)$.

- Finally, let us note that the boundedness of $\epsilon^{1/2}\|\nabla p_\epsilon\|_{L^2(\Omega)^n}$ (that follows from (5.34)) and Hölder's inequality imply that

$$\epsilon \int_\Omega \nabla\psi \nabla p_\epsilon dx \to 0 \quad \forall \psi \in C^\infty(\bar{\Omega}). \qquad \square$$

Remark 5.2. The results stated in Theorems 5.1 and 5.2 can be extended to more general quasilinear elliptic equations such as that given in (3.1), under assumptions

(3.2)–(3.7), following essentially the same argumentation; some technical changes appear in relation to the adjoint state equation. In this framework equation (5.5) and inequality (5.8) become

$$\left\{\begin{array}{l} -\operatorname{div}\left(\left[\dfrac{\partial a}{\partial \eta}(x,\nabla\bar{y})\right]^T \nabla\bar{p}\right)+\dfrac{\partial a_0}{\partial s}(x,\bar{y})\bar{p}=\bar{\mu}_0\dfrac{\partial L}{\partial y}(x,\bar{y}) \\ \quad +\displaystyle\sum_{j=1}^{n_e+n_i}\bar{\mu}_j\left\{\dfrac{\partial g_j}{\partial y}(x,\bar{y},\nabla\bar{y})-\operatorname{div}\left(\dfrac{\partial g_j}{\partial \eta}(x,\bar{y},\nabla\bar{y})\right)\right\} \text{ in } \Omega, \\ \qquad \left(\dfrac{\partial a}{\partial \eta}(x,\nabla\bar{y})\right)^T \nabla\bar{p}\cdot\vec{\nu}=\bar{\mu}_0\dfrac{\partial l}{\partial y}(x,\bar{y},\bar{u}) \quad \text{on } \Gamma, \end{array}\right.$$

and

$$\begin{aligned} &\int_\Omega \nabla\bar{p}^T\frac{\partial a}{\partial \eta}(x,\nabla\bar{y})\nabla\bar{p}dx+\int_\Omega\frac{\partial a_0}{\partial s}(x,\bar{y})\bar{p}^2dx \\ &\le \bar{\mu}_0\left(\int_\Omega\frac{\partial L}{\partial y}(x,\bar{y})\bar{p}dx+\int_\Gamma\frac{\partial l}{\partial y}(x,\bar{y},\bar{u})\bar{p}d\sigma(x)\right) \\ &\quad+\sum_{j=1}^{n_e+n_i}\bar{\mu}_j\left(\int_\Omega\frac{\partial g_j}{\partial y}(x,\bar{y},\nabla\bar{y})\bar{p}dx+\int_\Omega\frac{\partial g_j}{\partial \eta}(x,\bar{y},\nabla\bar{y})\nabla\bar{p}dx\right), \end{aligned}$$

respectively.

6. Optimality conditions: $k = 0$. When $k = 0$ and $\alpha > 2$, the operator of the state equation (2.1) becomes degenerate in the sense that its modulus of ellipticity vanishes in the subset $\{x \in \Omega : \nabla y(x) = 0\}$; when $\alpha < 2$, the operator is singular because that modulus blows up in the same subset. Nevertheless, we can still derive some optimality conditions for (P_δ) with the peculiarity that the adjoint state equation is only satisfied in the subset Ω_0 defined by

$$\Omega_0 = \{x \in \Omega : \nabla\bar{y}(x) \neq 0\},$$

where $\bar{y} = y_{\bar{u}}$ (this is an open set because $\nabla\bar{y}$ is continuous in Ω; see [32]). To do this we introduce a family of approximate problems that belong to the case $k > 0$ and we pass to the limit in their optimality systems making $k \longrightarrow 0$.

We will only deal with the case $\alpha < 2$. For $\alpha > 2$, we can prove that the adjoint states corresponding to the approximate problems converge in $H^1_{\text{loc}}(\Omega_0)$, but not on Γ (even when $\Omega_0 = \Omega$). Therefore, we are not able to derive the condition (5.7) and the optimality conditions obtained lose interest.

THEOREM 6.1. *Let $\bar{u}$ be a solution of (P_δ), $\alpha < 2$ and $k = 0$. Let us assume that $\tau \geq (n\alpha - \alpha)/(n\alpha - n)$, $\rho \geq (\alpha n)/(\alpha n + \alpha - n)$, $\theta \geq \alpha/(\alpha - 1)$, and $l(x, y, \cdot) : R \longrightarrow R$ is a convex function for all $(x, y) \in \Omega \times R$. Then there exist real numbers $\bar{\mu}_j$, $j = 0, 1, \ldots, n_e + n_i$, and elements $\bar{y} \in W^{1,\alpha}(\Omega) \cap L^\infty(\Omega)$ and $\bar{p} \in W^{1,\alpha}(\Omega)$ verifying* (5.2)–(5.4) (*with* $k = 0$), (5.6)–(5.7), *and*

$$\begin{aligned} &-\operatorname{div}\{M_0(\bar{y})\nabla\bar{p}\}+\lambda\bar{p}=\bar{\mu}_0\frac{\partial L}{\partial y}(x,\bar{y}) \\ (6.1)\qquad &+\sum_{j=1}^{n_e+n_i}\bar{\mu}_j\left\{\frac{\partial g_j}{\partial y}(x,\bar{y},\nabla\bar{y})-\operatorname{div}\left(\frac{\partial g_j}{\partial \eta}(x,\bar{y},\nabla\bar{y})\right)\right\} \textit{ in } \Omega_0 \end{aligned}$$

with M_0 given by (5.1).

Sketch of the proof. Given $\epsilon > 0$, let us consider the perturbed operator given by

$$A_\epsilon y = -\mathrm{div}\left\{[\epsilon + |\nabla y|]^{\alpha-2}\nabla y\right\} + \lambda y,$$

and the family of approximate problems $(Q_{\delta,\epsilon})$ of §5.2. The operator A_ϵ now verifies hypotheses (3.2)–(3.7) with exponent α and constant $k = \epsilon$. Consequently, given $u \in L^\infty(\Gamma)$, the Neumann problem

$$\begin{cases} A_\epsilon y = f & \text{in } \Omega, \\ (\epsilon + |\nabla y|)^{\alpha-2}\nabla y \cdot \vec{\nu} = u & \text{on } \Gamma, \end{cases}$$

has a unique solution $y_\epsilon(u) \in W^{1,\alpha}(\Omega) \cap L^\infty(\Omega)$.

Now applying Theorem 5.2 to each control problem $(Q_{\delta,\epsilon})$, we derive a result analogous to that of Theorem 5.3 with $y_\epsilon \in W^{1,\alpha}(\Omega) \cap L^\infty(\Omega)$, $p_\epsilon \in W^{1,\alpha}(\Omega)$, and $k = \epsilon$. Of course, the terms $\epsilon\triangle y_\epsilon$, $\epsilon\nabla y_\epsilon$, $\epsilon\triangle p_\epsilon$, $\epsilon\nabla p_\epsilon$, and $\epsilon\int_\Omega |\nabla p_\epsilon|^2 dx$ do not appear. Furthermore, Lemma 5.5 is still valid (see [8, Lem. 4.5] for the Dirichlet problem), and thus Theorem 5.4 is too.

We can suppose again that

$$\omega_\epsilon = \mu_{0\epsilon} + \sum_{j=1}^{n_e} |\mu_{j\epsilon}| + \sum_{j=n_e+1}^{n_e+n_i} \mu_{j\epsilon} = 1,$$

and pass to the limit as $\epsilon \to 0$ without difficulty in (5.28)–(5.30) and (5.32) to obtain (5.2)–(5.4) (with $k = 0$) and (5.6).

The boundedness of $\{p_\epsilon\}_\epsilon$ in $W^{1,\alpha}(\Omega)$ follows exactly as in the case $\alpha < 2$, $k > 0$. Thus, at least for a subsequence, it follows that

$$p_\epsilon \longrightarrow \bar{p} \quad \text{weakly in } W^{1,\alpha}(\Omega)$$

for a certain element $\bar{p} \in W^{1,\alpha}(\Omega)$.

To establish (6.1), we utilize a regularity result due to Tolksdorf [32]. Thanks to this result, $\bar{y}$ and $y_\epsilon(u)$ belong to $C^{1,t}(\Omega)$ for some $0 < t < 1$. Let Ω' be an open set such that $\Omega' \subset \overline{\Omega'} \subset \Omega_0$. Therefore, there exists $C_1 > 0$ such that

$$(6.2) \qquad |\nabla\bar{y}(x)| > C_1 \quad \forall x \in \overline{\Omega'}.$$

Now, using the estimates given in [32, Thm. 1], we can apply the Ascoli–Arzelá theorem to the family $\{\nabla y_\epsilon\}_\epsilon$ for deriving that $\{\nabla y_\epsilon\}_\epsilon$ is precompact in $C(\overline{\Omega'})^n$. Together with (5.36) this implies the existence of a subsequence, denoted in the same way, such that

$$(6.3) \qquad \nabla y_\epsilon \to \nabla\bar{y} \quad \text{in } C(\overline{\Omega'})^n.$$

From (6.2) and (6.3) it follows that there exists $\epsilon' > 0$ such that

$$(6.4) \qquad |\nabla y_\epsilon(x)| > C_1 \quad \forall x \in \overline{\Omega'} \quad \forall \epsilon < \epsilon'.$$

To deduce (6.1) it is now enough to multiply the equation of (5.31) by $\phi \in D(\Omega_0)$, integrate by parts, and pass to the limit as $\epsilon \to 0$ with the aid of estimate (6.4) for $\Omega' \supset \mathrm{sop}\phi$.

Finally, it is immediate to obtain (5.7) passing to the limit in (5.33). □

Remark 6.1. Theorem 6.1 can be extended to a wider class of quasilinear elliptic equations of the type

$$Ay = -\mathrm{div}\,(a(x, |\nabla y|)\nabla y) + a_0(x, y)$$

with $a : \Omega \times (0, +\infty) \to (0, +\infty)$; see [8] for the Dirichlet problem.

7. A qualification condition for $(\mathbf{P}_\delta)$. In the absence of equality constraints (i.e., $n_e = 0$), it is possible to deduce the previous optimality systems in a qualified form (i.e., with $\bar\mu_0 = 1$) for almost every problem (P_δ).

THEOREM 7.1. *Let us suppose that $n_e = 0$ and Δ is a cube of R^{n_i} such that (P_δ) has at least one solution for every $\delta \in \Delta$. Then, Theorems 5.1, 5.2, and 6.1 remain valid for each solution $\bar u$ of (P_δ) with $\bar\mu_0 = 1$ for almost every $\delta \in \Delta$.*

Proof. The proof is a modified version of Clarke's argument [14, §4]. Let us consider the function $\phi : \Delta \to R$ defined by

$$\phi(\delta) = \inf\{J(u) : u \in K,\quad G_j(u) \le \delta_j,\ 1 \le j \le n_i\} = \inf(P_\delta).$$

It is obvious that $\phi(\delta)$ is decreasing as a function of each component of δ separately and, thus, it is differentiable almost everywhere. Now, let us fix $\delta \in \Delta$ such that there exists $D\phi(\delta)$. Therefore, given a $\bar u$ solution of (P_δ), we can argue as in [14, Thm. 2] to derive the existence of strictly positive constants r and γ such that $\bar u$ is a solution of the following problem:

$$(Q_{\delta,r,\gamma}) \begin{cases} \text{minimize } J(u) + r\displaystyle\sum_{j=1}^{n_i}(G_j(u) - \delta_j)^+ \\ \text{such that } \ u \in K_\gamma, \end{cases}$$

where $K_\gamma = K \cap \{u \in L^\infty(\Gamma) : \|u - \bar u\|_{L^\infty(\Gamma)} \le \gamma\}$. The proof will be completed when we obtain the optimality system for $(Q_{\delta,r,\gamma})$.

In the case $\alpha \ge 2$ and $k \ne 0$, this can be done again using Ekeland's variational principle. To do this, let us introduce the family of problems

$$(Q_{\delta,r,\gamma,s}) \begin{cases} \text{minimize } \ J_s(u) \\ \text{such that } \ u \in K_\gamma, \end{cases}$$

where $s > 1$ and

$$J_s(u) = J(u) + r\sum_{j=1}^{n_i}\left\{\frac{1}{s^s} + [(G_j(u) - \delta_j)^+]^s\right\}^{1/s}.$$

Obviously, K_γ is a complete metric space with $d(u,v) = \|u - v\|_{L^\infty(\Gamma)}$, $J_s : K_\gamma \longrightarrow R$ is a continuous function, and

$$J_s(\bar u) = J(\bar u) + \frac{rn_i}{s} \le \frac{rn_i}{s} + \inf(Q_{\delta,r,\gamma,s}).$$

Hence, applying Ekeland's variational principle [16], we deduce the existence of an element $u_s \in K_\gamma$ such that

$$\|u_s - \bar u\|_{L^\infty(\Gamma)} \le \sqrt{\gamma_s} \tag{7.1}$$

with $\gamma_s = rn_i/s$ and u_s is a solution of problem

$$\begin{cases} \text{minimize } \ J_s(u) + \sqrt{\gamma_s}\|u_s - u\|_{L^\infty(\Gamma)} \\ \text{such that } \ u \in K_\gamma. \end{cases}$$

It follows from (7.1) that the constraint $\|u_s - \bar u\|_{L^\infty(\Gamma)} \le \gamma$ is not active for every $s > (rn_i)/\gamma^2$. Thus we conclude the proof exactly as in the proof of Theorem 5.1, noting that J_s is Gâteaux differentiable,

$$J_s'(u_s)\cdot(u - u_s) = \left(J'(u_s) + \sum_{j=1}^{n_i}\mu_{js}G_j'(u_s)\right)\cdot(u - u_s),$$

where

$$\mu_{js} = r\left\{\frac{1}{s^s} + [(G_j(u_s) - \delta_j)^+]^s\right\}^{(1/s)-1} [(G_j(u_s) - \delta_j)^+]^{s-1} \le r$$

for every $s > 1$ and $1 \le j \le n_i$, and passing to the limit as $s \to +\infty$.

If $\alpha < 2$ we approximate $(Q_{\delta,r,\gamma})$ by problems

$$(Q_{\delta,r,\gamma,\epsilon}) \begin{cases} \text{minimize } \tilde{J}_\epsilon(u) + r\sum_{j=1}^{n_i}(G_j(u) - \delta_j)^+ \\ \text{such that } \ u \in K_\gamma, \end{cases}$$

with $\tilde{J}_\epsilon$ defined as in §5.2 for $k > 0$ and §6 for $k = 0$. Now, $(Q_{\delta,r,\gamma,\epsilon})$ falls into the case $\alpha \ge 2$ and $k \ne 0$. Therefore we can use the results established above in this proof to obtain an optimality system for $(Q_{\delta,r,\gamma,\epsilon})$ with Lagrange multipliers $\mu_{0\epsilon} = 1$ and $\mu_{j\epsilon} \le r$ for all $\epsilon > 0$ and $j = 1, \ldots, n_i$. Finally, we pass to the limit as in the proofs of Theorems 5.2 and 6.1 to derive the desired result. □

Remark 7.1. In case $\alpha \ge 2$ and $n_e = 0$, and under the following Slater-type condition: there exists $u_o \in K$ such that

$$G_j(\bar{u}) + DG_j(\bar{u}) \cdot (u_0 - \bar{u}) < \delta_j, \quad j = 1, \ldots, n_i,$$

we can obtain the optimality conditions in a qualified form by applying [5, Thm. 5.2]; see Remark 5.1.

THE STOCHASTIC MAXIMUM PRINCIPLE FOR LINEAR, CONVEX OPTIMAL CONTROL WITH RANDOM COEFFICIENTS*

ABEL CADENILLAS† AND IOANNIS KARATZAS‡

This paper is dedicated to Professor Herbert Robbins on the occasion of his 80*th birthday.*

Abstract. This paper considers a stochastic control problem with linear dynamics, convex cost criterion, and convex state constraint, in which the control enters both the drift and diffusion coefficients. These coefficients are allowed to be random, and no L^p-bounds are imposed on the control. An explicit solution for the adjoint equation and a global stochastic maximum principle are obtained for this model. This is evidently the first version of the stochastic maximum principle that covers the consumption-investment problem. The mathematical tools are those of stochastic calculus and convex analysis.

When it is assumed, as in other versions of the stochastic maximum principle, that the admissible controls are square-integrable, not only a necessary but also a sufficient condition for optimality is obtained. It is then shown that this particular case of the general model may be applied to solve a variety of problems in stochastic control, including the linear-regulator, predicted-miss, and Beneš problems.

Key words. stochastic maximum principle, convex analysis, stochastic control, backwards stochastic differential equations, adjoint equation, consumption-investment problem

1. The stochastic maximum principle.

1.1. Introduction.

We consider the stochastic differential equation

$$dX_t = f(t, X_t, u_t)dt + g(t, X_t, u_t)dW_t, \tag{1}$$

$$X_0 = x, \tag{2}$$

where W is a Brownian motion on a probability space $(\Omega, \mathcal{F}, P, (\mathcal{F}_t))$, u is a suitable control process adapted to $(\mathcal{F}_t)$, and X is the trajectory of the system controlled by u. We require that X take values in a fixed set V. Our problem is to choose u in such a way as to minimize a functional of the type

$$E\left[\int_0^T L(t, X_t, u_t)dt + \Psi(X_T)\right]. \tag{3}$$

A control process that solves this problem is called *optimal.* In §1, we impose conditions on f, g, L, Ψ, and V to obtain a stochastic maximum principle for our model. Roughly speaking, this principle asserts the following: we assume that $\hat{u}$ is an optimal control, define the *Hamiltonian*

$$H(t, p, q, x, u) = -L(t, x, u) + p \bullet f(t, x, u) + q \bullet g(t, x, u), \tag{4}$$

and consider the solution of the *adjoint equation*

$$dp_t = -H_x(t, p_t, q_t, \hat{X}_t, \hat{u}_t)dt + q_t dW_t, \tag{5}$$

$$p_T = -\Psi_x(\hat{X}_T) \tag{6}$$

for the pair of $(\mathcal{F}_t)$-adapted processes (p, q), where $\hat{X}$ is the trajectory of the system controlled by $\hat{u}$. The stochastic maximum principle states roughly that, under certain conditions on f, g, L, Ψ, and V,

$$\max_u H(t, p_t, q_t, \hat{X}_t, u) = H(t, p_t, q_t, \hat{X}_t, \hat{u}_t), \tag{7}$$

i.e., *that a necessary condition for the optimality of a control is to maximize the Hamiltonian.*

The initial work on the stochastic maximum principle was done by Kushner [31], [32]. Then in the 1970s, Haussmann developed a powerful version of the stochastic maximum principle (see [21] for an account of his theory and references to his previous work [15]–[20] on this subject), and applied it to solve some important problems in stochastic control [18]. The main limitation of Haussmann's theory is that the control does not affect the diffusion coefficient.

Versions of the stochastic maximum principle in which the diffusion coefficient is controlled were developed by Bensoussan [4], Elliott [12], and Peng [34] in a form weaker than (7), and by Arkin and Saksonov [1], Bismut [5], [6], [7], and Saksonov [38] in the strong form (7). The main limitation of these approaches is that they impose L^p-bounds on the controls. Other limitations are that they assume the trajectory to be unconstrained, and the running cost, terminal cost, and/or their derivatives to have polynomial growth. Furthermore, only Arkin and Saksonov [1], Bismut [5], [6], [7], and Saksonov [38] consider the case of random coefficients.

The present paper treats linear systems with random coefficients and with the control affecting the diffusion term. Its two main contributions are the development of a stochastic maximum principle in its strongest form (7) *without imposing L^p-bounds on the controls*, and the explicit solution of the adjoint equation for the resulting model. As pointed out by Whittle [41, p. 183], the solution of the adjoint equation is a difficult problem, and it is one of the two main difficulties that face the stochastic maximum principle (the other being that the principle is not simple when the control affects the diffusion coefficient). An additional contribution of our paper is that it also allows for state-constraints and does not impose polynomial growth conditions on the cost functions or their derivatives. Furthermore, we derive necessary as well as sufficient conditions for optimality, and show that these coincide in the presence of L^2-bounds on the class of admissible controls.

In §2, we apply our version of the stochastic maximum principle to the consumption-investment problem. This important problem could not be covered by any of the previous versions of the stochastic maximum principle. The reasons were multiple: in this problem the optimal control is not square-integrable, the trajectory of the system is constrained, and the running cost, terminal cost, and their derivatives do not necessarily obey global polynomial growth conditions. (In this problem, the typical running cost and/or terminal cost is the negative of the logarithmic function.)

In §3, we make the additional assumption that the controls are square-integrable, and notice that, in this particular case of our general model, a *necessary and sufficient* condition for the optimality of a control is the maximization of the Hamiltonian. We also show that this particular version of our general model may be applied to solve completely other stochastic control problems as well, including the linear-regulator, predicted-miss, and Beneš problems.

After this paper was submitted for publication, Cadenillas and Haussmann [9] generalized some of the results of §1 and §3 to obtain a stochastic maximum principle for a problem in which the control has both absolutely continuous and singular components.

1.2. Notations and assumptions. We suppose that a d-dimensional Brownian motion W is defined on a complete probability space $(\Omega, \mathcal{F}, (\mathcal{F}_t), P)$. Here, $(\mathcal{F}_t)$ is the P-augmentation of the natural filtration $(\mathcal{F}_t^W)$ defined by

$$\mathcal{F}_t^W = \sigma(W(s) : 0 \leq s \leq t) \quad \forall t \in [0, \infty).$$

Let T be a fixed strictly positive real number, U a closed convex subset of $\Re^k$, and let us consider the functions

$$\begin{aligned}
A &: [0,T] \times \Omega \longmapsto \mathcal{L}(\Re^n; \Re^n), \\
B &: [0,T] \times \Omega \longmapsto \mathcal{L}(\Re^k; \Re^n), \\
C &: [0,T] \times \Omega \longmapsto \Re^n, \\
D &: [0,T] \times \Omega \longmapsto \mathcal{L}(\Re^n; \mathcal{L}(\Re^d; \Re^n)), \\
E &: [0,T] \times \Omega \longmapsto \mathcal{L}(\Re^k; \mathcal{L}(\Re^d; \Re^n)), \\
F &: [0,T] \times \Omega \longmapsto \mathcal{L}(\Re^d; \Re^n).
\end{aligned}$$

Here $\mathcal{L}(V; W)$ denotes the space of linear transformations of a vector space V into a vector space W. We shall assume that $A, B, C, D, E,$ and F are all progressively measurable with respect to $(\mathcal{F}_t)$, and bounded uniformly in $(t, \omega) \in [0, \infty) \times \Omega$. Let us now consider the linear stochastic differential equation

$$dX_t = f(t, X_t, u_t)dt + g(t, X_t, u_t)dW_t, \tag{8}$$

$$X_0 = x, \tag{9}$$

where

$$f(t, x, u) = A_t x + B_t u + C_t, \tag{10}$$

$$g(t, x, u) = D_t x + E_t u + F_t. \tag{11}$$

In order that the above stochastic differential equation make sense, we need that

$$P\left\{ \int_0^T |f(t, X_t, u_t)| dt < \infty \right\} = 1 \tag{12}$$

and

$$P\left\{ \int_0^T |g(t, X_t, u_t)|^2 dt < \infty \right\} = 1. \tag{13}$$

A sufficient condition for this to happen is

$$P\left\{ \int_0^T |B_t u_t| dt < \infty, \quad \int_0^T |E_t u_t|^2 dt < \infty \right\} = 1. \tag{14}$$

Corresponding to any $(\mathcal{F}_t)$-adapted control process $u : [0,T] \times \Omega \mapsto U \subset \Re^k$ that is $\mathcal{B}([0,T]) \otimes \mathcal{F}/\mathcal{B}(\Re^k)$-measurable, and satisfies (14), we denote by X^u the solution of the linear stochastic integral equation

$$X_t = x + \int_0^t (A_s X_s + B_s u_s + C_s) ds + \int_0^t (D_s X_s + E_s u_s + F_s) dW_s, \quad 0 \leq t \leq T, \tag{15}$$

and call it the *trajectory of the linear system* (8)–(9) *controlled by* u. Evidently, from the linearity of this system and for any control processes u, v as above, we have for any $\alpha \in [0,1]$

$$X^{\alpha u+(1-\alpha)v} = \alpha X^u + (1-\alpha)X^v, \quad \text{a.s.} \tag{16}$$

We shall restrict the class of admissible control processes u in the following manner.

DEFINITION 1.1 (admissibility). *Let V be a fixed, nonempty, convex subset of $\Re^n$. For any $x \in V$, we shall denote by $\mathcal{U}(x,V)$ the class of* admissible control processes *$u : [0,T] \times \Omega \mapsto U$ that are measurable, adapted to $(\mathcal{F}_t)$, satisfy condition* (14), *and are such that the corresponding trajectory X^u of* (15) *satisfies*

$$X_t^u \in V \quad \forall t \in [0,T] \quad \text{a.s.}$$

Whenever x and V are fixed, we shall denote $\mathcal{U}(x,V)$ by $\mathcal{U}$, without danger of confusion.

Quite obviously from this definition and (16), we have the following remark.

controls is convex.

Let us now consider the measurable functions $\Psi : \Omega \mapsto C^1(V;\Re)$ and $L : [0,T] \times \Omega \mapsto C^{1,1}(V \times U;\Re)$. We assume that Ψ is $\mathcal{F}_T$-measurable, that L is $(\mathcal{F}_t)$-progressively measurable, and that for each $(t,\omega) \in [0,T] \times \Omega$, $L(t,\cdot,\cdot) \in C^{1,1}(V \times U;\Re)$ and $\Psi(\cdot) \in C^1(V;\Re)$ are convex functions. This means that $\forall (t,\omega) \in [0,T] \times \Omega, x \in V, y \in V, u \in U, v \in U, \alpha \in [0,1]$:

$$L(t, \alpha x + (1-\alpha)y, \alpha u + (1-\alpha)v) \leq \alpha L(t,x,u) + (1-\alpha)L(t,y,v),$$

and

$$\Psi(\alpha x + (1-\alpha)y) \leq \alpha\Psi(x) + (1-\alpha)\Psi(y).$$

We say that, for each $(t,\omega) \in [0,T] \times \Omega$, $L(t,\cdot,\cdot)$ is strictly convex or $\Psi(\cdot)$ is strictly convex if the first or the second inequalities, respectively, are strict. We are interested in the functional $J : \mathcal{U} \mapsto \Re$ defined by

$$J(u) = E\left[\int_0^T L(t, X_t, u_t)dt + \Psi(X_T)\right]. \tag{17}$$

The following property is then obvious.

PROPOSITION 1.1. *The functional J is convex. Furthermore, if, for each $(t,\omega) \in [0,T] \times \Omega$, $L(t,\cdot,\cdot)$ or $\Psi(\cdot)$ are strictly convex, then J is strictly convex.*

1.3. The problem. In this section we want to address the following stochastic control problem:

$$\inf_{u \in \mathcal{U}} J(u), \tag{18}$$

where $\mathcal{U}$ and J have been defined in §1.2. That is, we want to select the control $u \in \mathcal{U}$ that minimizes the criterion J.

We are imposing minimal conditions on the admissible controls u in $\mathcal{U}$. Indeed, all the versions of the stochastic maximum principle in which the control enters into the diffusion coefficient (including the ones in [1], [4]–[6], [12], [34], [38]) require at least that the controls be square-integrable. Assuming this technical condition makes the problem much easier, as we shall see in §3.

Furthermore, our objective function is more general than the one considered in Saksonov's linear problem, the linear-regulator problem, the predicted-miss problem, or the consumption-investment problem. Indeed, if L were identically equal to zero, and Ψ were linear and deterministic, then we would be in the linear case studied in [38]. On the other hand, with $V = \Re^n$,

$$L(t,x,u) = x^* M(t) x + u^* N(t) u,$$

and

$$\Psi(x) = x^* \tilde{N} x,$$

where M, N are $(\mathcal{F}_t)$-progressively measurable, $\tilde{N}$ is $\mathcal{F}_T$-measurable, and, for each $(t,\omega) \in [0,T] \times \Omega$, the $n \times n$ matrices $M(t)$ and $\tilde{N}$ are symmetric, nonnegative-definite, and the $k \times k$ matrix $N(t)$ is symmetric and positive-definite, we recover the linear-regulator problem studied, for instance, in [6], [14], and [18]. Instead, if $V = \Re^n$, L were identically equal to zero, and

$$\Psi(x) = (v \bullet x)^2 \quad \text{for some } v \in \Re^n,$$

then our objective function would be the same as the one in the predicted-miss problem studied in [3] and [18]. Finally, in the particular case of $V = (0,\infty)$,

$$L(t,x,u) = L(t,x,(\pi,c)) = -U_1(t,c); \qquad u = (\pi,c) \in \Re^m \times [0,\infty)$$

and

$$\Psi(x) = -U_2(x),$$

where $U_1(t,\cdot)$ and U_2 are strictly concave and strictly increasing functions, we recover the consumption-investment model studied in [24], [27]; we shall study that model in §2.

1.4. The adjoint processes. The purpose of the stochastic maximum principle is to find a necessary condition for the optimality of a control. Thus, let us suppose in this section that $\hat{u}$ is a candidate for optimal control for problem (18) (i.e., that it achieves the infimum there), and denote by $\hat{X}$ the trajectory of the system controlled by $\hat{u}$.

DEFINITION 1.2 (adjoint equation). *The adjoint equation is the backward stochastic differential equation*

$$dp_t = \left[L_x(t, \hat{X}_t, \hat{u}_t) - A_t^* p_t - \sum_{j=1}^{d} D_t^{(j*)} q_t^{(j)} \right] dt + q_t dW_t, \tag{19}$$

$$p_T = -\Psi_x(\hat{X}_T). \tag{20}$$

We want to find a pair of measurable, adapted processes $p : [0,T] \times \Omega \longmapsto \Re^n$, $q : [0,T] \times \Omega \longmapsto \mathcal{L}(\Re^d; \Re^n)$ that solve the adjoint equation. They will be called adjoint processes. In our notation, for each $j \in \{1, 2, \ldots, d\}$, $D_t^{(j)}$ and $q_t^{(j)}$ are $n \times n$ and $n \times 1$ matrices, respectively.

The adaptivity of the processes (p, q) is a very strong requirement. Indeed, without this requirement, it would be very easy to solve the system (19)–(20): we could take q identically equally to zero, and solve the resulting ordinary differential equation with terminal condition. Of course, that *trivial solution* would not be adapted!

Assumption 1.1. In this section, we shall need to assume that

$$E|\Psi_x(\hat{X}_T)|^2 < \infty, \tag{21}$$

and

$$E\int_0^T |L_x(t, \hat{X}_t, \hat{u}_t)|^2 dt < \infty. \tag{22}$$

set of vector-valued processes $p : [0, T] \times \Omega \longmapsto \Re^n$ that are measurable, adapted, and satisfy

$$E\int_0^T |p(t)|^2 dt < \infty. \tag{23}$$

Similarly, $M^2(0, T; \mathcal{L}(\Re^d; \Re^n))$ will denote the set of matrix-valued processes $q : [0, T] \times \Omega \longmapsto \mathcal{L}(\Re^d; \Re^n)$ that are measurable, adapted, and satisfy

$$E\int_0^T |q(t)|^2 dt < \infty. \tag{24}$$

The following existence and uniqueness result is proved in Theorem 3.1 of [33].

THEOREM 1.1. *If assumptions* (21)–(22) *hold, then there exists a unique pair*

$$(p, q) \in M^2(0, T; \Re^n) \times M^2(0, T; \mathcal{L}(\Re^d; \Re^n))$$

that solves the adjoint equation (19)–(20). *Furthermore, the process p satisfies*

$$E\left[\sup_{0 \le t \le T} |p(t)|^2\right] < \infty. \tag{25}$$

From now on, we shall call the pair (p, q) the *adjoint processes.*

1.4.1. Explicit solutions.

Now that we have a result about existence and uniqueness of the adjoint processes, we would like to compute them. Let $\Phi : [0, T] \times \Omega \mapsto \mathcal{L}(\Re^n; \Re^n)$ be the solution of the matrix stochastic integral equation

$$\Phi(t) = I + \int_0^t A(s)\Phi(s)ds + \sum_{j=1}^{d} \int_0^t D^{(j)}(s)\Phi(s)dW_s^{(j)}. \tag{26}$$

From §5.6.D of [25], we know that the stochastic integral equation (26) has a unique, strong solution. According to Exercise 5.6.22 of [25, pp. 362–363], Φ has an inverse, which satisfies

$$\Phi^{-1}(t) = I + \int_0^t \Phi^{-1}(s)\left[\sum_{j=1}^{d}(D^{(j)}(s))^2 - A(s)\right]ds - \sum_{j=1}^{d} \int_0^t \Phi^{-1}(s)D^{(j)}(s)dW_s^j. \tag{27}$$

From Corollary 2.5.12 of [30, p. 86], we also know that $\forall m \in \aleph$:

$$E\left[\sup_{0\le t\le T}|\Phi(t)|^m\right]+E\left[\sup_{0\le t\le T}|\Phi^{-1}(t)|^m\right]<\infty. \tag{28}$$

Equation (27) may also be written as

$$\begin{aligned}\Phi^*(t)^{-1}=I&+\int_0^t\left[\sum_{j=1}^d(D^{(j)}(s)^*)^2-A^*(s)\right]\Phi^*(s)^{-1}ds\\&-\sum_{j=1}^d\int_0^t D^{(j)}(s)^*\Phi^*(s)^{-1}dW_s^{(j)}.\end{aligned}\tag{29}$$

Let $\theta:[0,T]\times\Omega\longmapsto\mathcal{L}(\Re^n;\mathcal{L}(\Re^d;\Re^n))$ be any measurable, adapted process such that

$$P\left\{\sum_{j=1}^d\int_0^T|\theta_s^{(j)}|^2ds<\infty\right\}=1, \tag{30}$$

and let us denote by $Z_\theta:[0,T]\times\Omega\longmapsto\mathcal{L}(\Re^n;\Re^n)$ the solution of the matrix stochastic integral equation

$$Z_\theta(t)=I-\sum_{j=1}^d\int_0^t\theta^{(j)}(s)Z_\theta(s)dW^{(j)}(s). \tag{31}$$

From §5.6.D of [25], we know that the matrix stochastic integral equation (31) has a unique, strong solution.

Also, let γ be a given vector in $\Re^n$ and consider the adapted process $\Phi^*(t)^{-1}Z_\theta(t)\gamma + \tilde{p}(t)$, where $\tilde{p}:[0,T]\times\Omega\longmapsto\Re^n$ is the solution of the integral equation

$$\tilde{p}(t)=\int_0^t\{L_x(s,\hat{X}_s,\hat{u}_s)-A^*(s)\tilde{p}(s)\}ds. \tag{32}$$

We note that for any fixed $\omega\in\Omega$, (32) is an ordinary integral equation.

Applying the integration by parts formula (see, for instance, [25, p. 155]) to each component of the matrix $\Phi^*(t)^{-1}Z_\theta(t)$ we get from (29), (31), and (32):

$$\begin{aligned}&d(\Phi^*(t)^{-1}Z_\theta(t)\gamma+\tilde{p}(t))\\&=\Phi^*(t)^{-1}dZ_\theta(t)\gamma+d\Phi^*(t)^{-1}Z_\theta(t)\gamma+d<\Phi^*(t)^{-1},Z_\theta(t)>\gamma+d\tilde{p}(t)\\&=\Phi^*(t)^{-1}\left\{-\sum_{j=1}^d\theta^{(j)}(t)Z_\theta(t)dW^{(j)}(t)\right\}\gamma\\&\quad+\left\{\left[\sum_{j=1}^d(D^{(j)}(t)^*)^2-A^*(t)\right]\Phi^*(t)^{-1}dt-\sum_{j=1}^d D^{(j)}(t)^*\Phi^*(t)^{-1}dW^{(j)}(t)\right\}Z_\theta(t)\gamma\\&\quad+\sum_{j=1}^d D^{(j)}(t)^*\Phi^*(t)^{-1}\theta^{(j)}(t)Z_\theta(t)dt\bullet\gamma+\{L_x(t,\hat{X}_t,\hat{u}_t)-A^*(t)\tilde{p}(t)\}dt\end{aligned}$$

$$= \left\{ L_x(t,\hat{X}_t,\hat{u}_t) - A^*(t)[\Phi^*(t)^{-1}Z_\theta(t)\gamma + \tilde{p}(t)] \right.$$
$$\left. + \sum_{j=1}^{d} D^{(j)}(t)^*[D^{(j)}(t)^*\Phi^*(t)^{-1}Z_\theta(t) + \Phi^*(t)^{-1}\theta^j(t)Z_\theta(t)]\gamma \right\} dt$$
$$- \sum_{j=1}^{d}[\Phi^*(t)^{-1}\theta^{(j)}(t)Z_\theta(t) + D^{(j)}(t)^*\Phi^*(t)^{-1}Z_\theta(t)]\gamma dW^{(j)}(t).$$

From the above equation, we see that the measurable, adapted processes $p : [0,T] \times \Omega \mapsto \Re^n$ and $q : [0,T] \times \Omega \mapsto \mathcal{L}(\Re^d; \Re^n)$ defined by

$$p(t) := \Phi^*(t)^{-1}Z_\theta(t)\gamma + \tilde{p}(t) \tag{33}$$

and

$$q(t)w := -\sum_{j=1}^{d}[\Phi^*(t)^{-1}\theta^{(j)}(t) + D^{(j)}(t)^*\Phi^*(t)^{-1}]Z_\theta(t)\gamma w_j \quad \forall w \in \Re^d, \tag{34}$$

satisfy equation (19). In order that they also satisfy the terminal condition (20), we have to choose θ and γ so that we have, almost surely,

$$\Phi^*(T)^{-1}Z_\theta(T)\gamma + \tilde{p}(T) = -\Psi_x(\hat{X}_T), \tag{35}$$

or equivalently

$$Z_\theta(T)\gamma = -\Phi^*(T)[\Psi_x(\hat{X}_T) + \tilde{p}(T)]. \tag{36}$$

Taking $t = 0$ in equation (33), we see that γ has a very simple interpretation as the initial condition for the adjoint process p: $\gamma = p(0)$.

To check that such θ and γ indeed exist under appropriate conditions, let us consider the random vector Q defined by

$$Q := -\Phi^*(T)[\Psi_x(\hat{X}_T) + \tilde{p}(T)]. \tag{37}$$

If $P\{Q = 0\} = 1$, we may take $\gamma \equiv 0$ to satisfy equation (36). Thus, if

$$P\{Q = 0\} = 1, \tag{38}$$

a solution of the adjoint equation is given by equations (33)–(34). Let us now consider the nontrivial case in which $P\{Q = 0\} < 1$. According to Assumption 1.1, inequality (28), and Hölder's inequality, we have $E[|Q|] < \infty$. Thus, there exists a progressively measurable process $Y : [0,T] \times \Omega \longmapsto \mathcal{L}(\Re^d; \Re^n)$, with

$$P\left\{ \sum_{j=1}^{d} \int_0^T |Y_s^{(j)}|^2 ds < \infty \right\} = 1, \tag{39}$$

such that we have, almost surely,

$$Q(t) := E[Q|\mathcal{F}_t] = E[Q] + \sum_{j=1}^{d} \int_0^t Y_s^{(j)} dW_s^{(j)} \quad \forall\ 0 \le t \le T. \tag{40}$$

Assuming that

$$P\{(E[Q])^*Q > 0\} = 1 \quad \text{or} \quad P\{(E[Q])^*Q < 0\} = 1, \tag{41}$$

the above equation may be written as

$$Q(t) = E[Q] + \sum_{j=1}^{d} \int_0^t \tilde{Y}_s^{(j)} Q(s) dW_s^{(j)}, \tag{42}$$

where $\tilde{Y} : [0,T] \times \Omega \longmapsto \mathcal{L}(\Re^n; \mathcal{L}(\Re^d; \Re^n))$ is the progressively measurable process defined by

$$\tilde{Y}_s^{(j)} := \frac{Y_s^{(j)}\{\text{sgn}[(EQ)^*Q(s)]\}(EQ)^*}{|(EQ)^*Q(s)|} \quad \forall\ 1 \le j \le d,\ 0 \le s \le T. \tag{43}$$

Let us consider the events $A := \{\omega \in \Omega : (E[Q])^*Q(\omega) > 0\}, B := \{\omega \in \Omega : (E[Q])^*Q(\omega) < 0\}$ so that, according to assumption (41), we have either $P\{A\} = 1$ or $P\{B\} = 1$. Let us suppose that $P\{A\} = 1$. We claim that, under this assumption,

$$(E[Q])^*Q(s) = E[(E[Q])^*Q|\mathcal{F}_s] > 0 \quad \forall\, 0 \le s \le T$$

holds almost surely, so that we have

$$K = K(\omega) := \inf_{0 \le s \le T} (E[Q])^*Q(s)(\omega) > 0$$

for $P-$ a.e. $\omega \in \Omega$. To see this, let $A' := \{\omega \in A : K(\omega) = 0\}$, and suppose that $\sigma(\omega) := \inf\{s \in [0,T] : (E[Q])^*Q(s)(\omega) = 0\} \in [0,T)$. Since $\{((E[Q])^*Q(t), \mathcal{F}_t) : 0 \le t \le T\}$ is a continuous nonnegative martingale, we conclude (see, for instance, [25, Problem 1.3.29]) that $(E[Q])^*Q(\omega) = 0$ holds for $P-$ a.e. $\omega \in A'$. This contradicts $A' \subset A$, unless $P\{A'\} \equiv 0$. Thus, if $P\{A\} = 1$ then

$$|\tilde{Y}_s^{(j)}(\omega)|^2 = \frac{|Y_s^{(j)}(\omega)(E[Q])^*|^2}{|(E[Q])^*Q(s)(\omega)|^2} \le \frac{|E[Q]|^2}{K^2(\omega)} |Y_s^{(j)}(\omega)|^2 < \infty,$$

$0 \le s \le T, j \in \{1, 2, \ldots, d\}$ for $P-$ a.e. $\omega \in \Omega$. The same result (but with a different random variable K) is valid if we assume $P\{B\} = 1$. Therefore, from equations (39) and (43), we obtain

$$P\left\{\sum_{j=1}^{d} \int_0^T |\tilde{Y}_s^{(j)}|^2 ds < \infty\right\} = P\left\{\sum_{j=1}^{d} \int_0^T \frac{|Y_s^{(j)}(EQ)^*|^2}{|(EQ)^*Q(s)|^2} ds < \infty\right\} = 1. \tag{44}$$

On the other hand, equation (31) may be written as

$$Z_\theta(t)\gamma = \gamma - \sum_{j=1}^{d} \int_0^t \theta^{(j)}(s) Z_\theta(s) \gamma dW^{(j)}(s). \tag{45}$$

If we choose

$$\gamma = E[Q], \tag{46}$$

$$\theta = -\tilde{Y}, \tag{47}$$

we see from (42) and (45) that $Z_\theta(t)\gamma = Q(t)$, $\forall\, 0 \le t \le T$. From this and (40), (37), we obtain

$$Z_\theta(T)\gamma = Q(T) = Q = -\Phi^*(T)[\Psi_x(\hat{X}_T) + \tilde{p}(T)],$$

so the vector γ and the vector-valued process θ defined by equations (46)–(47) satisfy the terminal condition (35), or equivalently (36).

Therefore, we have proved the following result.

THEOREM 1.2 (explicit solution of the adjoint equation). *Under Assumption* 1.1, *if either* (38) *or* (41) *holds, then a solution of the adjoint equation is given by equations* (33)–(34).

The explicit solution of the adjoint equation (19)–(20) given by formulae (33)–(34) is one of the contributions of this paper. To apply these formulae, we must check that we have either (38) or (41). We now list some simple sufficient conditions for this to happen.

COROLLARY 1.1. *If one of the following nine possibilities*[1] *holds, then a solution of the adjoint equation is given by equations* (33)–(34):

1. $L_x \equiv 0$, $\Psi_x \equiv 0$;
2. $D \equiv 0$, $A \ge 0$, $L_x \equiv 0$, $\Psi_x > 0$;
3. $D \equiv 0$, $A \ge 0$, $L_x \equiv 0$, $\Psi_x < 0$;
4. $D \equiv 0$, $A \ge 0$, $L_x > 0$, $\Psi_x \equiv 0$;
5. $D \equiv 0$, $A \ge 0$, $L_x < 0$, $\Psi_x \equiv 0$;
6. $n = 1$, $L_x > 0$, $\Psi_x \ge 0$;
7. $n = 1$, $L_x < 0$, $\Psi_x \le 0$;
8. $n = 1$, $L_x \ge 0$, $\Psi_x > 0$;
9. $n = 1$, $L_x \le 0$, $\Psi_x < 0$.

The last condition of the above corollary will be satisfied trivially in the model of §2.

It should be noted that we cannot apply Theorem 1.1 to settle the question of uniqueness for the explicit solution (33)–(34). The problem is that we cannot guarantee that (p, q) defined by (33)–(34) is in $M^2(0,T;\Re^n) \times M^2(0,T;\mathcal{L}(\Re^d;\Re^n))$. Nevertheless, we can note the following remark.

Remark 1.2. If θ given by equation (47) is uniformly bounded in $(t,\omega) \in [0,T] \times \Omega$, then (p, q) defined by equations (33)–(34) is the unique solution of the adjoint equation in the space $M^2(0,T;\Re^n) \times M^2(0,T;\mathcal{L}(\Re^d;\Re^n))$ of Theorem 1.1.

In fact, if θ is uniformly bounded in $(t,\omega) \in [0,T] \times \Omega$ then, according to Corollary 2.5.12 of [30, p. 86], $\forall m \in \aleph$,

$$E\left[\sup_{0\le t\le T} |Z_\theta(t)|^m\right] < \infty. \tag{48}$$

This, combined with equations (28), (22), and (32), guarantees that (p, q) defined by equations (33)–(34) is in $M^2(0,T;\Re^n) \times M^2(0,T;\mathcal{L}(\Re^d;\Re^n))$; and we know from Theorem 1.1 that the solution of the adjoint equation in this space is unique.

Professor Shige Peng remarks (private communication) that it would be of interest to find general conditions guaranteeing the boundedness of the processes $Y, \tilde{Y}$, and θ (in L^∞ or L^p, $p > 2$), preferably *without* invoking Malliavin derivatives or the Clark–Ocone formula of [29].

[1] $A \ge 0$ means that every component of the matrix A is nonnegative. Similarly, if α is a vector, $\alpha > 0$ means that each one of its components is positive, and $\alpha < 0$ means that each one of its components is negative.

Remark: The one-dimensional case. We can be much more explicit if we suppose that the state of the system is one-dimensional, i.e., that $n = 1$. Then, Q is a real-valued random variable,

$$\gamma = E[Q] \in \Re,$$

and

$$\theta_s = -\tilde{Y}_s = -\frac{1}{Q_s} Y_s \in \Re^d.$$

According to §5.6.C of [25],

$$\begin{aligned} \Phi(t) = {} & \exp\left\{ \int_0^t A(s)ds \right\} \\ & \exp\left\{ \sum_{j=1}^d \int_0^t D^{(j)}(s)dW^{(j)}(s) - \frac{1}{2}\sum_{j=1}^d \int_0^t |D^{(j)}(s)|^2 ds \right\} \end{aligned} \tag{49}$$

and

$$Z_\theta(t) = \exp\left\{ -\sum_{j=1}^d \int_0^t \theta^{(j)}(s)dW^{(j)}(s) - \frac{1}{2}\sum_{j=1}^d \int_0^t |\theta^{(j)}(s)|^2 ds \right\}, \tag{50}$$

so

$$\begin{aligned} p(t) = {} & \exp\left\{ -\int_0^t A(s)ds \right\} \\ & \exp\left\{ -\sum_{j=1}^d \int_0^t D^{(j)}(s)dW^{(j)}(s) + \frac{1}{2}\sum_{j=1}^d \int_0^t |D^{(j)}(s)|^2 ds \right\} \\ & \exp\left\{ -\sum_{j=1}^d \int_0^t \theta^{(j)}(s)dW^{(j)}(s) - \frac{1}{2}\sum_{j=1}^d \int_0^t |\theta^{(j)}(s)|^2 ds \right\} \gamma \\ & + \exp\left\{ -\int_0^t A(s)ds \right\} \int_0^t \exp\left\{ \int_0^s A(v)dv \right\} L_x(s, \hat{X}_s, \hat{u}_s)ds \end{aligned} \tag{51}$$

and

$$\begin{aligned} q(t) = {} & -\Phi(t)^{-1}(\theta(t) + D(t))Z_\theta(t)\gamma \\ = {} & -\exp\left\{ -\int_0^t A(s)ds \right\} \\ & \exp\left\{ -\sum_{j=1}^d \int_0^t D^{(j)}(s)dW^{(j)}(s) + \frac{1}{2}\sum_{j=1}^d \int_0^t |D^{(j)}(s)|^2 ds \right\} \\ & \exp\left\{ -\sum_{j=1}^d \int_0^t \theta^{(j)}(s)dW^{(j)}(s) - \frac{1}{2}\sum_{j=1}^d \int_0^t |\theta^{(j)}(s)|^2 ds \right\} [\theta(t) + D(t)]\gamma. \end{aligned} \tag{52}$$

We shall apply the last two formulae to solve the consumption-investment problem in §2. In that model, $D \equiv 0$ and $L_x \equiv 0$.

Remark: A second representation. There exists yet another representation for the adjoint processes. By Itô's formula,

$$\begin{aligned} d(\Phi^*(t)p(t)) &= \Phi^*(t)dp(t) + d\Phi^*(t)p(t) + d < \Phi^*, p > (t) \\ &= \Phi^*(t)\left\{\left[L_x(t,\hat{X}_t,\hat{u}_t) - A_t^* p_t - \sum_{j=1}^{d} D_t^{(j*)} q_t^{(j)}\right] dt + q_t dW_t\right\} \\ &\quad + \left\{\Phi^*(t)A^*(t)dt + \sum_{j=1}^{d} \Phi^*(t)D^{(j*)}(t)dW_t^{(j)}\right\} p(t) \\ &\quad + \sum_{j=1}^{d} \Phi^*(t)D^{(j*)}(t)q^{(j)}(t)dt \\ &= \Phi^*(t)L_x(t,\hat{X}_t,\hat{u}_t)dt + \Phi^*(t)q(t)dW(t) \\ &\quad + \Phi^*(t)\sum_{j=1}^{d} D^{(j*)}(t)p(t)dW^{(j)}(t). \end{aligned} \tag{53}$$

Thus, the process $M : [0,T] \times \Omega \mapsto \Re^n$ defined by

$$M(t) := \Phi^*(t)p(t) - \int_0^t \Phi^*(s)L_x(s,\hat{X}_s,\hat{u}_s)ds, \quad 0 \le t \le T \tag{54}$$

is a local martingale. According to inequality (28), Theorem 1.1, Assumption 1.1, and Hölder's inequality, both terms on the right-hand side are integrable. Thus, $E[\sup_{0 \le t \le T} |M(t)|] < \infty$. This shows that M is a local martingale of class DL, hence a martingale. Thus,

$$\begin{aligned} M(t) &= \Phi^*(t)p(t) - \int_0^t \Phi^*(s)L_x(s,\hat{X}_s,\hat{u}_s)ds \\ &= E\left[\Phi^*(T)p(T) - \int_0^T \Phi^*(s)L_x(s,\hat{X}_s,\hat{u}_s)ds|\mathcal{F}_t\right] \\ &= E\left[-\Phi^*(T)\Psi_x(\hat{X}_T) - \int_0^T \Phi^*(s)L_x(s,\hat{X}_s,\hat{u}_s)ds|\mathcal{F}_t\right], \end{aligned} \tag{55}$$

or equivalently $\forall 0 \le t \le T$,

$$\Phi^*(t)p(t) = -E\left[\Phi^*(T)\Psi_x(\hat{X}_T) + \int_t^T \Phi^*(s)L_x(s,\hat{X}_s,\hat{u}_s)ds|\mathcal{F}_t\right]. \tag{56}$$

This gives a formula to compute p, but we still need a formula to compute q. Suppose that for some $\delta > 0$, we have

$$E|\Psi_x(\hat{X}_T)|^{2+\delta} < \infty \tag{57}$$

and

$$E\int_0^T |L_x(t,\hat{X}_t,\hat{u}_t)|^{2+\delta}dt < \infty. \tag{58}$$

Then equation (55), together with the additional conditions (57)–(58), inequality (28), and Hölder's and Minkowski's inequalities, implies that $E[|M(t)|^2] < \infty$ for every $0 \leq t \leq T$. Applying the theorem on the representation of Brownian, square-integrable martingales as stochastic integrals (see, for instance, [25, p. 182]), we see that there exists an adapted process $\alpha = \{(\alpha_t, \mathcal{F}_t) : 0 \leq t \leq T\}$ such that $\forall 1 \leq j \leq d$, $E[\int_0^T |\alpha_t^{(j)}|^2 dt] < \infty$, and

$$M(t) = \Phi^*(0)p(0) + \sum_{j=1}^{d} \int_0^t \alpha_s^{(j)} dW_s^{(j)}, \quad 0 \leq t \leq T. \tag{59}$$

From the uniqueness of the representation (53), we obtain

$$\Phi^*(t)q(t) + \Phi^*(t)D^*(t)p(t) = \alpha(t). \tag{60}$$

Now, we summarize our results.

THEOREM 1.3. *If the additional conditions* (57)–(58) *hold, then the adjoint processes are given, for any* $0 \leq t \leq T$, *by*

$$p(t) = -\Phi^*(t)^{-1} E\left[\Phi^*(T)\Psi_x(\hat{X}_T) + \int_t^T \Phi^*(s)L_x(s, \hat{X}_s, \hat{u}_s)ds | \mathcal{F}_t\right], \tag{61}$$

$$q(t) = \Phi^*(t)^{-1}\{\alpha(t) - \Phi^*(t)D^*(t)p(t)\}, \tag{62}$$

where $\alpha(\cdot)$ *is the integrand in the stochastic integral representation* (59).

The explicit solution of the adjoint equation given by Theorem 1.3 is due to Arkin and Saksonov [1], [38] under stronger conditions. Theorem 1.3 has two limitations: The first is that to find p we have to compute a conditional expectation, and this is not simple in applications. The second limitation is that the expression (62) for q is not explicit; it requires the determination of the integrand process α in (59).

Other references on the adjoint equation include [13], [17], and [35]. On the other hand, Detemple [10] has studied another class of stochastic equations with terminal conditions and provided some economic interpretations.

1.5. The stochastic maximum principle. From Remark 1.1 and Proposition 1.1, we know that $\mathcal{U}$ is convex and $J : \mathcal{U} \mapsto \Re$ is a convex functional defined on $\mathcal{U}$. Thus, we see that *our stochastic control problem is a particular case of the general problem of minimizing a convex functional.* It is then natural to investigate what information the theory of convex analysis can provide about problem (18); we shall do this in the remainder of this section. All the necessary results from convex analysis can be found, for instance, in Chapters I and II of [11].

DEFINITION 1.3. *The Hamiltonian is the function* $H : [0,T] \times \Re^n \times \mathcal{L}(\Re^d; \Re^n) \times V \times U \longmapsto \Re$ *defined by*

$$\begin{aligned} H(t,p,q,x,u) &= -L(t,x,u) + p \bullet f(t,x,u) + q \bullet g(t,x,u) \\ &= -L(t,x,u) + p \bullet (A_t x + B_t u + C_t) + q \bullet (D_t x + E_t u + F_t), \end{aligned} \tag{63}$$

where (p, q) *are the adjoint variables.*

We see that the backward stochastic differential equation (19)–(20) satisfied by the adjoint processes may be written as (5)–(6).

Let us consider the functionals $J_1 : \mathcal{U} \mapsto \Re$ and $J_2 : \mathcal{U} \mapsto \Re$ defined by

$$J_1(u) = E\int_0^T L(t, X_t^u, u_t)dt, \tag{64}$$

$$J_2(u) = E[\Psi(X_T^u)]. \tag{65}$$

Obviously,

$$J = J_1 + J_2.$$

Furthermore, since $L(t, \cdot, \cdot)$ and $\Psi(\cdot)$ are convex, J_1 and J_2 are both convex. On the other hand, for every $u \in \mathcal{U}$, let X^u be the trajectory of the system controlled by u, and Z^u be the solution of the linear stochastic integral equation

$$Z_t = \int_0^t (A_sZ_s + B_su_s)ds + \int_0^t (D_sZ_s + E_su_s)dW_s, \tag{66}$$

so that $u \mapsto Z^u$ is linear. We note that for every $u, v \in \mathcal{U}$,

$$Z^u - Z^v = X^u - X^v. \tag{67}$$

We need to impose the following assumption about the derivatives of L and Ψ.

Assumption 1.2. Let u and v be admissible controls, with corresponding trajectories X^u and X^v. We shall assume that there exists a random variable $\tilde{Y} : \Omega \longmapsto \Re$ and a measurable process $Y : [0,T] \times \Omega \longmapsto \Re$ such that $E|\tilde{Y}| < \infty$, $E\int_0^T |Y_t|dt < \infty$, and

$$\tilde{Y} \geq Z_T^u \bullet \Psi_x(X_T^v + \rho Z_T^u),$$
$$Y_t \geq Z_t^u \bullet L_x(t, X_t^v + \rho Z_t^u, v_t + \rho u_t) + u_t \bullet L_u(t, X_t^v + \rho Z_t^u, v_t + \rho u_t)$$

for arbitrary $u, v \in \mathcal{U}, \rho \in [0,1]$ that satisfy $X_t^v + \rho Z_t^u \in V$ and $v_t + \rho u_t \in U$.

LEMMA 1.1. *J_1 and J_2 are Gâteaux-differentiable with differentials J_1' and J_2' given by*

$$\langle J_1'(v), u\rangle = E\int_0^T \{Z_t^u \bullet L_x(t, X_t^v, v_t) + u_t \bullet L_u(t, X_t^v, v_t)\}dt \tag{68}$$

$$\langle J_2'(v), u\rangle = E[Z_T^u \bullet \Psi_x(X_T^v)]. \tag{69}$$

Hence $J = J_1 + J_2$ is Gâteaux-differentiable with differential given by

$$\begin{aligned}&\langle J'(v), u\rangle \\ &= E\left[\int_0^T \{Z_t^u \bullet L_x(t, X_t^v, v_t) + u_t \bullet L_u(t, X_t^v, v_t)\}dt + Z_T^u \bullet \Psi_x(X_T^v)\right].\end{aligned} \tag{70}$$

Proof. We start by studying the differentiability of J_2. We want to analyse the limit as $\lambda \downarrow 0$ of

$$\frac{J_2(v + \lambda u) - J_2(v)}{\lambda} = \frac{E[\Psi(X_T^v + \lambda Z_T^u)] - E[\Psi(X_T^v)]}{\lambda}.$$

Since $\Psi : \Omega \mapsto C^1(V; \Re)$ is $\mathcal{F}_T$-measurable, for every λ in the interval $(0,1]$, there exists a $\mathcal{F}_T$-measurable random variable $\theta = \theta(\omega)$ in the interval $[0,1]$ such that

$$\frac{1}{\lambda}[\Psi(X_T^v + \lambda Z_T^u) - \Psi(X_T^v)] = Z_T^u \bullet \Psi_x(X_T^v + \theta\lambda Z_T^u).$$

Thus, for any given $\lambda \in (0,1]$, there exists an $\mathcal{F}_T$-random variable θ with values in $[0,1]$ such that

$$\frac{J_2(v+\lambda u)-J_2(v)}{\lambda} = E[Z_T^u \bullet \Psi_x(X_T^v + \theta\lambda Z_T^u)].$$

Since Ψ and J_2 are convex, the left-hand sides of the above two expressions are nondecreasing functions of λ. Thus, .when $\lambda \downarrow 0$, these expressions possess limits. Since, for each $\omega \in \Omega$, $\Psi(\cdot)$ is a differentiable convex function, $\Psi_x(\cdot)$ is monotone (see [11, Prop. 1.5.5]), i.e.,

$$(x-y)\bullet(\Psi_x(x)-\Psi_x(y)) \geq 0 \quad \forall x,y \in \Re^n.$$

In particular, for any given $0 \leq \alpha < \beta \leq 1$, we can take $x = X_T^v + \beta Z_T^u, y = X_T^v + \alpha Z_T^u$ and obtain

$$Z_T^u \bullet \Psi_x(X_T^v + \beta Z_T^u) \geq Z_T^u \bullet \Psi_x(X_T^v + \alpha Z_T^u).$$

If we consider any sequence (λ_k) such that $\lambda_k \downarrow 0$ as $k \uparrow \infty$, we see then

$$\tilde{Y} \geq Z_T^u \bullet \Psi_x(X_T^v + \theta_k\lambda_k Z_T^u) \downarrow Z_T^u \bullet \Psi_x(X_T^v), \quad \text{a.s.}$$

Applying the monotone convergence theorem, we get

$$\begin{aligned}\lim_{\lambda\downarrow 0}\frac{J_2(v+\lambda u)-J_2(v)}{\lambda} &= \lim_{k\uparrow\infty}\frac{J_2(v+\lambda_k u)-J_2(v)}{\lambda_k}\\ &= \lim_{k\uparrow\infty} E[Z_T^u \bullet \Psi_x(X_T^v + \theta_k\lambda_k Z_T^u)]\\ &= E[Z_T^u \bullet \Psi_x(X_T^v)].\end{aligned}$$

Thus, J_2 is Gâteaux-differentiable with differential J_2' given by

$$\langle J_2'(v), u\rangle = E[Z_T^u \bullet \Psi_x(X_T^v)].$$

Similarly, J_1 is Gâteaux-differentiable with differential J_1' given by (68), and (70) follows. □

Let us now consider the semimartingales p and X^u given by equations (19) and (8). Applying the formula of integration by parts, we get, in conjunction with (8), (19),

$$\begin{aligned} p_t \bullet X_t^u &= p_0 \bullet X_0^u + \int_0^t p_s \bullet dX_s^u + \int_0^t X_s^u \bullet dp_s + \langle p_t, X_t^u\rangle\\ &= p_0 \bullet X_0^u + \int_0^t \Bigg\{ p_s \bullet f(s,X_s^u,u_s) + X_s^u \bullet \Bigg[L_x(s,\hat{X}_s,\hat{u}_s)\\ &\qquad -A_s^* p_s - \sum_{j=1}^d D_s^{(j*)} q_s^{(j)}\Bigg] + q_s \bullet g(s,X_s^u,u_s)\Bigg\} ds\\ &\quad + \int_0^t \{p_s \bullet g(s,X_s^u,u_s) + X_s^u \bullet q_s\} dW_s. \end{aligned} \tag{71}$$

The above equation may be written as

$$R_t^u = p_0 \bullet x + \int_0^t \{p_s \bullet C_s + q_s \bullet F_s\} ds + S_t^u, \tag{72}$$

where we denote $\forall u \in \mathcal{U}, t \in [0,T]$,

$$S_t^u := \int_0^t \{p_s \bullet g(s, X_s^u, u_s) + X_s^u \bullet q_s\} dW_s, \tag{73}$$

$$R_t^u := p_t \bullet X_t^u - \int_0^t \{X_s^u \bullet (L_x(s, \hat{X}_s, \hat{u}_s)) + p_s \bullet B_s u_s + q_s \bullet E_s u_s\} ds. \tag{74}$$

If, for every admissible control u, S^u happens to be not only a local martingale, but also a martingale, then $\forall t \in [0,T]$,

$$E[R_t^u] = E\left[p_0 \bullet x + \int_0^t \{p_s \bullet C_s + q_s \bullet F_s\} ds\right] = E[R_t^{\hat{u}}]. \tag{75}$$

But, in general, S^u is not necessarily a martingale, so we have to consider the following four cases. We shall see later that in the first case we get a necessary condition for optimality of a given control $\hat{u}$, while in the second case we get a sufficient one.

Case 1.1. $\forall u \in \mathcal{U}$,

$$E[R_T^{\hat{u}}] \leq E[R_T^u], \tag{76}$$

or equivalently,

$$\begin{aligned} &E\left[p_T \bullet \hat{X}_T - \int_0^T \{\hat{X}_s \bullet (L_x(s, \hat{X}_s, \hat{u}_s)) + p_s \bullet B_s \hat{u}_s + q_s \bullet E_s \hat{u}_s\} ds\right] \\ &\quad \leq E\left[p_T \bullet X_T^u - \int_0^T \{X_s^u \bullet (L_x(s, \hat{X}_s, \hat{u}_s)) + p_s \bullet B_s u_s + q_s \bullet E_s u_s\} ds\right]. \end{aligned} \tag{77}$$

Case 1.2. $\forall u \in \mathcal{U}$,

$$E[R_T^{\hat{u}}] \geq E[R_T^u], \tag{78}$$

or equivalently,

$$\begin{aligned} &E\left[p_T \bullet \hat{X}_T - \int_0^T \{\hat{X}_s \bullet (L_x(s, \hat{X}_s, \hat{u}_s)) + p_s \bullet B_s \hat{u}_s + q_s \bullet E_s \hat{u}_s\} ds\right] \\ &\quad \geq E\left[p_T \bullet X_T^u - \int_0^T \{X_s^u \bullet (L_x(s, \hat{X}_s, \hat{u}_s)) + p_s \bullet B_s u_s + q_s \bullet E_s u_s\} ds\right]. \end{aligned} \tag{79}$$

Case 1.3. $\forall u \in \mathcal{U}$,

$$E[R_T^{\hat{u}}] = E[R_T^u], \tag{80}$$

or equivalently,

$$\begin{aligned} &E\left[p_T \bullet \hat{X}_T - \int_0^T \{\hat{X}_s \bullet (L_x(s, \hat{X}_s, \hat{u}_s)) + p_s \bullet B_s \hat{u}_s + q_s \bullet E_s \hat{u}_s\} ds\right] \\ &\quad = E\left[p_T \bullet X_T^u - \int_0^T \{X_s^u \bullet (L_x(s, \hat{X}_s, \hat{u}_s)) + p_s \bullet B_s u_s + q_s \bullet E_s u_s\} ds\right]. \end{aligned} \tag{81}$$

Case 1.4. $\exists u, v \in \mathcal{U}$ such that

$$E[R_T^u] < E[R_T^{\hat{u}}] < E[R_T^v]. \tag{82}$$

When we study the consumption-investment problem, we shall check that inequality (79) is satisfied. On the other hand, in the case of the square-integrable controls, we shall see that equation (81) is trivially satisfied. An example of Case 1.4 is given in Appendix B of [8].

Now, we are ready to state and prove the most important result of this paper: our version of the stochastic maximum principle (SMP).

Let us consider the function $\tilde{H} : [0,T] \times \Omega \times U \longmapsto \Re$ defined by

$$\tilde{H}(t,\omega,u) := L(t,\hat{X}_t(\omega),u) - p_t(\omega) \bullet B_t(\omega)u - q_t(\omega) \bullet E_t(\omega)u, \tag{83}$$

and note that $\tilde{H}(t,\omega,\cdot)$ is convex.

PROPOSITION 1.2 (the SMP in integral form). *If Case* 1.1 *holds, then a necessary condition for a control $\hat{u}$ to be optimal for the problem*

$$\min_{u\in\mathcal{U}} E\left[\int_0^T L(t,X_t^u,u_t)dt + \Psi(X_T^u)\right] \tag{84}$$

is that $\forall u \in \mathcal{U}$,

$$E\int_0^T \{\tilde{H}_u(t,\omega,\hat{u}_t(\omega)) \bullet (u_t(\omega) - \hat{u}_t(\omega))\}dt \;\; \geq \;\; 0. \tag{85}$$

On the other hand, if Case 1.2 *holds, then inequality* (85) *is a sufficient condition for a control $\hat{u}$ to be optimal for problem* (84).

Proof. The optimal control problem consists of minimizing $J(u)$ over $u \in \mathcal{U}$, where J is a Gâteaux-differentiable convex functional with derivative given by equation (70). Hence, according to Proposition 2.2.1 of [11, pp. 36–37], a necessary and sufficient condition for $\hat{u}$ to be optimal for problem (84) is

$$\langle J'(\hat{u}), u - \hat{u}\rangle \;\; \geq \;\; 0 \quad \forall u \in \mathcal{U}.$$

Thus, according to (70) and (20), $\hat{u}$ is an optimal control if and only if $\forall u \in \mathcal{U}$,

$$\begin{aligned} & E\left[\int_0^T \{(X_t^u - \hat{X}_t) \bullet L_x(t,\hat{X}_t,\hat{u}_t) + (u_t - \hat{u}_t) \bullet L_u(t,\hat{X}_t,\hat{u}_t)\}dt \right. \\ & \qquad \left. + (X_T^u - \hat{X}_T) \bullet \Psi_x(\hat{X}_T)\right] \\ & = E\left[\int_0^T \{(X_t^u - \hat{X}_t) \bullet L_x(t,\hat{X}_t,\hat{u}_t) + (u_t - \hat{u}_t) \bullet L_u(t,\hat{X}_t,\hat{u}_t)\}dt \right. \\ & \qquad \left. + (\hat{X}_T - X_T^u) \bullet p_T\right] \\ & \geq 0. \end{aligned} \tag{86}$$

In Case 1.1 (see inequality (77)), we see that $\forall u \in \mathcal{U}$,

$$\begin{aligned}
&E\int_0^T \{L_u(t,\hat{X}_t,\hat{u}_t)\bullet(u_t-\hat{u}_t)+p_t\bullet B_t(\hat{u}_t-u_t)+q_t\bullet E_t(\hat{u}_t-u_t)\}dt\\
&=E\left[\int_0^T \{L_u(t,\hat{X}_t,\hat{u}_t)\bullet(u_t-\hat{u}_t)+L_x(t,\hat{X}_t,\hat{u}_t)\bullet(X_t^u-\hat{X}_t)\}dt\right.\\
&\qquad+\int_0^T\{p_t\bullet B_t\hat{u}_t+\hat{X}_t\bullet L_x(t,\hat{X}_t,\hat{u}_t)+q_t\bullet E_t\hat{u}_t\}dt\\
&\qquad\left.-\int_0^T\{p_t\bullet B_tu_t+X_t^u\bullet L_x(t,\hat{X}_t,\hat{u}_t)+q_t\bullet E_tu_t\}dt\right]\\
&\geq E\left[\int_0^T\{(X_t^u-\hat{X}_t)\bullet L_x(t,\hat{X}_t,\hat{u}_t)+(u_t-\hat{u}_t)\bullet L_u(t,\hat{X}_t,\hat{u}_t)\}dt\right.\\
&\qquad\left.+(\hat{X}_T-X_T^u)\bullet p_T\right].
\end{aligned}$$

Thus, in Case 1.1 and in conjunction with (86), a necessary condition for a control $\hat{u}$ to be optimal is that $\forall u \in \mathcal{U}$,

$$(87)\quad E\int_0^T\{L_u(t,\hat{X}_t,\hat{u}_t)\bullet(u_t-\hat{u}_t)+p_t\bullet B_t(\hat{u}_t-u_t)+q_t\bullet E_t(\hat{u}_t-u_t)\}dt\geq 0,$$

which is equivalent to (85).

On the other hand, in Case 1.2, $\forall u \in \mathcal{U}$,

$$\begin{aligned}
&E\int_0^T \{L_u(t,\hat{X}_t,\hat{u}_t)\bullet(u_t-\hat{u}_t)+p_t\bullet B_t(\hat{u}_t-u_t)+q_t\bullet E_t(\hat{u}_t-u_t)\}dt\\
&=E\left[\int_0^T \{L_u(t,\hat{X}_t,\hat{u}_t)\bullet(u_t-\hat{u}_t)+L_x(t,\hat{X}_t,\hat{u}_t)\bullet(X_t^u-\hat{X}_t)\}dt\right.\\
&\qquad+\int_0^T\{p_t\bullet B_t\hat{u}_t+\hat{X}_t\bullet L_x(t,\hat{X}_t,\hat{u}_t)+q_t\bullet E_t\hat{u}_t\}dt\\
&\qquad\left.-\int_0^T\{p_t\bullet B_tu_t+X_t^u\bullet L_x(t,\hat{X}_t,\hat{u}_t)+q_t\bullet E_tu_t\}dt\right]\\
&\leq E\left[\int_0^T\{(X_t^u-\hat{X}_t)\bullet L_x(t,\hat{X}_t,\hat{u}_t)+(u_t-\hat{u}_t)\bullet L_u(t,\hat{X}_t,\hat{u}_t)\}dt\right.\\
&\qquad\left.+(\hat{X}_T-X_T^u)\bullet p_T\right].
\end{aligned}$$

Thus, in Case 1.2, a sufficient condition for a control $\hat{u}$ to be optimal is that (87), or equivalently (85), holds for all $u \in \mathcal{U}$. □

The meaning of inequality (85), or equivalently (87), is very *intriguing*. It is a necessary condition for optimality in Case 1.1, and a sufficient condition for optimality in Case 1.2. Now, we want to rewrite this inequality in a suitable form for applications. This is the objective of the next two theorems.

We should note that for a control $\tilde{v} : [0,T] \times \Omega \longmapsto U$, the statements

$$\min_{u \in U} \tilde{H}(t,\omega,u) = \tilde{H}(t,\omega,\tilde{v}_t(\omega)) \tag{88}$$

and

$$\max_{u \in U} H(t,p_t(\omega),q_t(\omega),\hat{X}_t(\omega),u) = H(t,p_t(\omega),q_t(\omega),\hat{X}_t(\omega),\tilde{v}_t(\omega)) \tag{89}$$

are equivalent (recall the notation of (63), (83)). Furthermore, the theorem of measurable selection (see [39, Thm. 3, p. 220]) guarantees that such $\tilde{v}$ is adapted; nevertheless, it does not guarantee that $X^{\tilde{v}} \in V$.

THEOREM 1.4 (the SMP with state-constraints). *Let us assume that $L(t,x,\cdot) : U \mapsto \Re$ is strictly convex, $\forall (t,\omega,x) \in [0,T] \times \Omega \times V$, and there exists a control $\tilde{v}$ such that*

$$\max_{u \in U} H(t,p_t,q_t,\hat{X}_t,u) = H(t,p_t,q_t,\hat{X}_t,\tilde{v}_t), \qquad X_t^{\tilde{v}} \in V, \tag{90}$$

$Leb \otimes P-$ a.e. on $[0,T] \times \Omega$. If the admissible control $\hat{u}$ satisfies Case 1.1, *then a necessary condition for $\hat{u}$ to be optimal for problem* (84) *is*

$$\hat{u} = \tilde{v}, \quad Leb \otimes P - a.e. \ on \ [0,T] \times \Omega. \tag{91}$$

On the other hand, if the admissible control $\hat{u}$ satisfies Case 1.2 *instead of Case* 1.1, *then equation* (91) *is a sufficient condition for the optimality of $\hat{u}$.*

Proof. Let us first consider the case in which $\hat{u}$ is optimal and satisfies Case 1.1. According to Proposition 1.2, we need to prove that inequality (85) implies that, with $\tilde{v}$ as in the hypothesis of this Theorem, we have (91). Since $\tilde{H}(t,\omega,\cdot)$ is convex and (88) is equivalent to (89), Proposition 2.2.1 of [11, pp. 36–37] shows that $\tilde{v}$ of (90) satisfies

$$\tilde{H}_u(t,\omega,u) \bullet (u - \tilde{v}_t(\omega)) \geq 0 \quad \forall u \in U \tag{92}$$

for $Leb \otimes P-$a.e. $(t,\omega) \in [0,T] \times \Omega$ (with equality if and only if $u = \tilde{v}_t(\omega)$, thanks to the strict convexity of $\tilde{H}(t,\omega,\cdot)$). To prove (91), consider the product set

$$\begin{aligned} A &:= \{(t,\omega) \in [0,T] \times \Omega : \hat{u}_t(\omega) \neq \tilde{v}_t(\omega)\} \\ &= \{(t,\omega) \in [0,T] \times \Omega : \tilde{H}_u(t,\omega,\hat{u}_t(\omega)) \bullet (\hat{u}_t(\omega) - \tilde{v}_t(\omega)) > 0\}, \end{aligned}$$

and suppose that $(Leb \otimes P)\{A\} > 0$. Then

$$E \int_0^T \{\tilde{H}_u(t,\omega,\hat{u}_t(\omega)) \bullet (\tilde{v}_t(\omega) - \hat{u}_t(\omega))\} dt \ < \ 0,$$

contradicting inequality (85). Thus, $(Leb \otimes P)\{A\} = 0$, or equivalently (91), holds.

Now, we consider Case 1.2, and assume that $\hat{u}$ satisfies equation (91). According to Proposition 1.2, we need to prove that inequality (85) holds. If $\hat{u}$ satisfies (91), then for $Leb \otimes P-$ a.e. $(t,\omega) \in [0,T] \times \Omega$,

$$\max_{u \in U} H(t,p_t,q_t,\hat{X}_t,u) = H(t,p_t,q_t,\hat{X}_t,\hat{u}_t)$$

or, equivalently,

$$\min_{u \in U} \tilde{H}(t,\omega,u) = \tilde{H}(t,\omega,\hat{u}_t(\omega)).$$

According to Proposition 2.2.1 of [11, pp. 36–37],

$$\tilde{H}_u(t,\omega,\hat{u}_t(\omega)) \bullet (u - \hat{u}_t(\omega)) \geq 0 \quad \forall u \in U, \tag{93}$$

for $Leb \otimes P-$ a.e. $(t,\omega) \in [0,T] \times \Omega$. Therefore, inequality (85) is valid, and from the second part of Proposition 1.2 the control $\hat{u}$ is optimal for problem (84). □

The admissible controls that maximize the Hamiltonian (i.e., satisfy equation (91)) are called *extremal controls.* Thus, the first part of Theorem 1.4 states that, under Case 1.1, every optimal control is extremal; and the second part states that, under Case 1.2, every extremal control is optimal. We shall apply the second part in the next section to solve the consumption-investment problem.

COROLLARY 1.2 (Case 1.3 and state-constraints). *If Case* 1.3 *holds and, for each* $(t,\omega,x) \in [0,T] \times \Omega \times V$, *the function* $L(t,x,\cdot)$ *is strictly convex, then a necessary and sufficient condition for a control* $\hat{u}$ *to be optimal for problem* (84) *is that*

$$\hat{u} = \tilde{v}, \qquad Leb \otimes P - a.e. \text{ on } [0,T] \times \Omega, \tag{94}$$

where $\tilde{v}$ *is a control that satisfies*

$$\max_{u \in U} H(t,p_t,q_t,\hat{X}_t,u) = H(t,p_t,q_t,\hat{X}_t,\tilde{v}_t), \quad X_t^{\tilde{v}} \in V, \tag{95}$$

$Leb \otimes P-$ *a.e. on* $[0,T] \times \Omega$.

In the next theorem we shall see that, in the case of unconstrained state, it is not necessary to assume *strict* convexity of $L(t,x,\cdot)$.

THEOREM 1.5 (the SMP without state-constraints). *Let us suppose that* $V = \Re^n$. *If Case* 1.1 *holds, then a necessary condition for a control* $\hat{u}$ *to be optimal for problem* (84) *is that,* $Leb \otimes P-$ *a.e. on* $[0,T] \times \Omega$,

$$\max_{u \in U} H(t,p_t,q_t,\hat{X}_t,u) = H(t,p_t,q_t,\hat{X}_t,\hat{u}_t). \tag{96}$$

On the other hand, if Case 1.2 *holds, then equation* (96) *is a sufficient condition for a control* $\hat{u}$ *to be optimal for problem* (84).

Proof. Let us first consider Case 1.1, and assume that $\hat{u}$ is an optimal control for problem (84). Again as before, in order to prove (96), it suffices to show that

$$\tilde{H}_u(t,\omega,\hat{u}_t(\omega)) \bullet (u - \hat{u}_t(\omega)) \geq 0 \quad \forall u \in U \tag{97}$$

for $Leb \otimes P-$ a.e. $(t,\omega) \in [0,T] \times \Omega$. To do this, define for any given $v \in U$:

$$B^v := \{(t,\omega) \in [0,T] \times \Omega : \tilde{H}_u(t,\omega,\hat{u}_t(\omega)) \bullet (v - \hat{u}_t(\omega)) < 0\}.$$

Obviously, for each $t \in [0,T]$, $B_t^v \in \mathcal{F}_t$. Let us consider the control $\check{v} : [0,T] \times \Omega \longmapsto U$ in $\mathcal{U}$, defined by

$$\check{v}(t,\omega) := \begin{cases} v & \text{if } (t,\omega) \in B^v, \\ \hat{u}(t,\omega) & \text{otherwise.} \end{cases}$$

Then $\check{v}$ is adapted and we have

$$E \int_0^T \{\tilde{H}_u(t,\omega,\hat{u}_t(\omega)) \bullet (\check{v}_t(\omega) - \hat{u}_t(\omega))\} dt \; < \; 0,$$

contradicting (85), unless $(Leb \otimes \Pr)\{B^v\} = 0$ for every $v \in U$. Thus, for any given $v \in U$:

$$\tilde{H}_u(t, \omega, \hat{u}_t(\omega)) \bullet (v - \hat{u}_t(\omega)) \geq 0$$

for $Leb \otimes P-$ a.e. $(t, \omega) \in [0,T] \times \Omega$. The stronger result (97) follows from the separability of U, and (96) then follows from Proposition 2.2.1 of [11, pp. 36–37].

Now, we consider Case 1.2. One shows exactly as before that (96) implies (93), and thus the optimality of $\hat{u}$. □

COROLLARY 1.3 (Case 1.3 and no state-constraints). *If Case* 1.3 *holds, and* $V = \Re^n$, *then a necessary and sufficient condition for a control* $\hat{u}$ *to be a solution for problem* (84) *is that*

$$(98) \quad \max_{u \in U} H(t, p_t, q_t, \hat{X}_t, u) = H(t, p_t, q_t, \hat{X}_t, \hat{u}_t), \quad Leb \otimes P - a.e. \text{ on } [0,T] \times \Omega.$$

Our methodology of applying the theory of convex analysis to study the stochastic control problem of this section can provide additional results. To obtain them it is necessary to notice that the problem

$$(99) \qquad \gamma = \min_{u \in \mathcal{U}} J(u)$$

is equivalent to

$$(100) \qquad \gamma = \min_{u \in \mathcal{V}} \tilde{J}(u),$$

where $\mathcal{V} = \{v : [0,T] \times \Omega \longmapsto \Re^k\}$ and $\tilde{J} : \mathcal{V} \longmapsto \bar{\Re}$ is the function defined by

$$\tilde{J}(v) = \begin{cases} J(v) & \text{if } v \in \mathcal{U}, \\ \infty & \text{otherwise.} \end{cases}$$

Obviously, $\tilde{J}$ is also a convex function.

LEMMA 1.2. *The set of optimal controls for problem* (99) *is convex.*

Proof. The set of optimal controls for problem (99) is equal to the set of optimal controls for problem (100). But this latter set of optimal controls is $\{v \in \mathcal{V} : \tilde{J}(v) \leq \gamma\}$, which is convex. This proves the lemma. □

THEOREM 1.6 (uniqueness). *If, for each* $(t, \omega) \in [0,T] \times \Omega$, $L(t, \cdot, \cdot)$ *or* $\Psi(\cdot)$ *are strictly convex, then problem* (99) *has at most one optimal control.*

Proof. Let $u^1 \neq u^2$ be two optimal controls for problem (99). According to Lemma 1.2, $\frac{1}{2}u^1 + \frac{1}{2}u^2$ is also an optimal control.

On the other hand, according to Proposition 1.1, J is strictly convex. Hence, $J(\frac{1}{2}u^1 + \frac{1}{2}u^2) < \frac{1}{2}J(u^1) + \frac{1}{2}J(u^2) = \gamma$, a contradiction. Therefore, $u^1 = u^2$. □

2. The consumption-investment problem.

2.1. The financial market model. We consider a financial market in which $m + 1$ securities (financial assets) are traded continuously. One of them is a pure discount *bond*, with price $P_0(t)$ at time t governed by the equation

$$(101) \qquad dP_0(t) = P_0(t) r(t) dt.$$

There are also m risky assets called *stocks* with prices-per-share $P_i(t)$ at time t governed by the linear stochastic differential equations

$$(102) \qquad dP_i(t) = P_i(t) \left[b_i(t)dt + \sum_{j=1}^{d} \sigma_{ij}(t) dW_j(t) \right], \quad i \in \{1, 2, \ldots, m\}.$$

These equations are driven by a d-dimensional Brownian motion $W = (W_1, \dots, W_d)^*$, whose components model the d independent sources of uncertainty that influence this market.

The probabilistic setting is as follows: the Brownian motion W is defined on the complete probability space $(\Omega, \mathcal{F}, P)$, and we denote by $(\mathcal{F}_t)$ the P-augmentation of the natural filtration $(\mathcal{F}_t^W)$. The coefficients of the model (i.e., the interest rate r, the appreciation rate vector $b = (b_i)_{m\times 1}$, and the volatility matrix $\sigma = (\sigma_{ij})_{m\times d}$) are random processes, progressively measurable with respect to $(\mathcal{F}_t)$ and bounded uniformly in $(t,\omega) \in [0,\infty) \times \Omega$. We suppose that $d \geq m$, and that σ has full row rank. It is also assumed that r and the relative risk process $\hat{\theta} : [0,\infty) \times \Omega \longmapsto \Re^d$ defined by

$$\hat{\theta}(t) = \sigma^*(t)(\sigma(t)\sigma^*(t))^{-1}[b(t) - r(t)1] \tag{103}$$

are bounded.

For any measurable adapted process $\theta : [0,\infty) \times \Omega \longmapsto \Re^d$, which is uniformly bounded in $(t,\omega) \in [0,T] \times \Omega$, we define the exponential martingale Z_θ by $\forall t \in [0,\infty)$,

$$Z_\theta(t) := \exp\left\{ -\sum_{j=1}^{d} \int_0^t \theta^{(j)}(s)dW^{(j)}(s) - \frac{1}{2}\sum_{j=1}^{d}\int_0^t |\theta^{(j)}(s)|^2 ds \right\}. \tag{104}$$

This is the solution of the equation

$$Z_\theta(t) = 1 - \int_0^t Z_\theta(s)\theta^*(s)dW(s). \tag{105}$$

We also define the processes β and ζ_θ by

$$\beta(t) := \exp\left\{ -\int_0^t r(s)ds \right\}, \quad \zeta_\theta(t) := \beta(t)Z_\theta(t). \tag{106}$$

All economic activity is supposed to take place on the finite time-horizon $[0,T]$. For a small investor, a portfolio rule π is a process whose components π_i represent the amount of money invested in the corresponding stock $i \in \{1,2,\dots,m\}$.

NOTATION 2.1. *We denote by $\mathcal{P}$ the set of all processes $\pi : [0,T] \times \Omega \mapsto \Re^m$ that are progressively measurable with respect to $(\mathcal{F}_t)$ and satisfy*

$$P\left\{ \int_0^T |\pi(t)|^2 dt < \infty \right\} = 1. \tag{107}$$

The elements of $\mathcal{P}$ are called portfolio processes.

The consumption rate rule c is the rate at which the small investor withdraws funds for consumption.

NOTATION 2.2. *We denote by $\mathcal{C}$ the set of all processes $c : [0,T] \times \Omega \mapsto [0,\infty)$ that are progressively measurable with respect to $(\mathcal{F}_t)$ and satisfy*

$$P\left\{ \int_0^T c(t)dt < \infty \right\} = 1. \tag{108}$$

The elements of $\mathcal{C}$ are called consumption rate processes.

The wealth process $X = X^{x,\pi,c}$ corresponding to initial capital $x > 0$, portfolio rule π, and consumption rate c then satisfies the equation

$$dX(t) = [r(t)X(t) - c(t)]dt + \pi^*(t)[b(t) - r(t)\mathbf{1}]dt + \pi^*(t)\sigma(t)dW(t) \tag{109}$$

with initial condition

$$X(0) = x. \tag{110}$$

From now on, we are going to consider only the following portfolios and consumption rate processes.

DEFINITION 2.1 (admissibility). *A pair $(\pi, c) \in \mathcal{P} \times \mathcal{C}$ of portfolio and consumption rate process is called admissible for the initial capital $x > 0$ if the corresponding wealth process X given by equations* (109)–(110) *satisfies*

$$P\{X(t) \geq 0 \;\; \forall 0 \leq t \leq T\} = 1. \tag{111}$$

We denote by $\mathcal{A}(x)$ the class of such pairs.

DEFINITION 2.2 (utility function). *A utility function is a function $U \in C^1((0,\infty); \Re)$ that is strictly increasing, strictly concave, and has a derivative $U' : (0,\infty) \mapsto (0,\infty)$ that satisfies $\lim_{c\to\infty} U'(c) = 0$. We shall denote by I the inverse of the strictly decreasing function U'.*

From now on, we are going to consider two fixed utility functions: $U_1(t,\cdot)$ and U_2. That is, for every $t \in [0,T]$, $U_1(t,\cdot)$ is a utility function, and $U_1'(t,\cdot)$ has inverse $I_1(t,\cdot)$.

PROBLEM 2.1. *The optimization problem faced by the small investor is to find a pair $(\pi, c) \in \mathcal{A}(x)$ which achieves the maximum in*

$$\mathcal{V}(x) := \max_{(\pi,c)\in\mathcal{A}(x)} E\left[\int_0^T U_1(t, c(t))dt + U_2(X(T))\right]. \tag{112}$$

The function $\mathcal{V} : (0,\infty) \mapsto \Re$ is called the value function of problem (112).

2.2. Relation between the stochastic maximum principle and the consumption-investment problem. In the notation of §1, let us take $u \equiv (\pi, c)$, $U \equiv \Re^m \times [0,\infty)$, $V \equiv [0,\infty)$, $\mathcal{U} \equiv \mathcal{A}(x)$, $f(t,x,u) \equiv r(t)x - c + \pi^*[b(t) - r(t)\mathbf{1}]$, $g(t,x,u) \equiv \pi^*\sigma(t)$, $L(t,x,u) \equiv -U_1(t,c)$, and $\Psi(x) \equiv -U_2(x)$; we see then that all the assumptions made in §1.2 hold for the model described in §2.1. To apply the general theory of §1, it only remains to check that Assumption 1.2 holds in the financial market model. But since both $U_1(t,\cdot)$ and U_2 are utility functions, $U_1'(t,\cdot)$ and U_2' are both positive and decreasing; in particular, Assumption 1.2 holds for the model described in §2.1. Therefore, *we are in a position to apply the stochastic maximum principle developed in the previous section to solve the consumption-investment problem.*

The Hamiltonian for this problem is

$$H(t,p,q,x,(\pi,c)) = U_1(t,c) + p(r(t)x - c + \pi^*[b(t) - r(t)\mathbf{1}]) + q^*\sigma^*(t)\pi, \tag{113}$$

and the adjoint equation takes the form

$$dp(t) = -r(t)p(t)dt + q(t)dW(t), \tag{114}$$

$$p(T) = U_2'(\hat{X}(T)) \tag{115}$$

for a suitable pair of processes (p, q).

Now we want to solve the adjoint equation. But in order to apply Theorem 1.2, we have to check first that

$$E[\{U_2'(\hat{X}(T))\}^2] < \infty. \tag{116}$$

Since we do not have enough information to check this condition right now, we shall just assume it. We shall justify our approach in the comment that follows equation (126). According to equations (51)–(52), an adapted solution to equation (114) is given by the processes

$$p(t) = \gamma\zeta_\theta(t), \tag{117}$$

$$q(t) = -\gamma\zeta_\theta(t)\theta(t) \tag{118}$$

in the notation of (106), where $\gamma = p(0)$. To satisfy the terminal condition (115), we need to find θ and γ such that

$$\gamma\zeta_\theta(T) = U_2'(\hat{X}(T)). \tag{119}$$

Since U_2 is strictly increasing, the right-hand side is positive. Hence, we require that γ be positive. From equation (119) we obtain

$$\hat{X}(T) = I_2(\gamma\zeta_\theta(T)). \tag{120}$$

From equations (117)–(118), and the fact that γ is a positive constant, condition (79) takes the form

(121)
$$\begin{aligned}E&\left[\zeta_\theta(T)X(T) + \int_0^T \{\zeta_\theta(t)(c(t) - \pi^*(t)[b(t) - r(t)1] + \pi^*(t)\sigma(t)\theta(t))\}dt\right]\\ &\leq E\left[\zeta_\theta(T)\hat{X}(T) + \int_0^T \{\zeta_\theta(t)(\hat{c}(t) - \hat{\pi}^*(t)[b(t) - r(t)1] + \hat{\pi}^*(t)\sigma(t)\theta(t))\}dt\right].\end{aligned}$$

The second part of Theorem 1.4 then leads to the following theorem.

THEOREM 2.1. *Suppose that* $(\hat{\pi}, \hat{c}) \in \mathcal{A}(x)$ *satisfies inequality* (121) *for every* $(\pi, c) \in \mathcal{A}(x)$, *and*

$$(p(t), q(t)) = (\gamma\zeta_\theta(t), -\gamma\zeta_\theta(t)\theta(t))$$

is a solution of the adjoint equation (114)–(115). *If*

(122)
$$\begin{aligned}&\max_{\pi\in\Re^m, c\geq 0}\{U_1(t, c) + \gamma\zeta_\theta(t)(r(t)\hat{X}(t) - c + \pi^*[b(t) - r(t)1]) - \gamma\zeta_\theta(t)\pi^*\sigma(t)\theta(t)\}\\ &\quad = U_1(t, \hat{c}(t)) + \gamma\zeta_\theta(t)(r(t)\hat{X}(t) - \hat{c}(t) + \hat{\pi}^*(t)[b(t) - r(t)1]) - \gamma\zeta_\theta(t)\hat{\pi}^*(t)\sigma(t)\theta(t),\end{aligned}$$

Leb$\otimes$*P*– *a.e., then* $(\hat{\pi}, \hat{c})$ *is optimal for problem* (112). *Here,* $\hat{X}$ *is the wealth process associated with the portfolio process* $\hat{\pi}$ *and consumption rate process* $\hat{c}$.

2.3. The candidates for optimal control. In this subsection, we shall guess the form of the optimal control from Theorem 2.1. The idea is first to find the controls that satisfy condition (122), the so-called *extremal controls*, and then those which also satisfy condition (121).

To find the controls that satisfy condition (122), we differentiate that expression, obtaining

$$U_1'(t,\hat{c}(t)) - \gamma\zeta_\theta(t) = 0, \tag{123}$$

$$\gamma\zeta_\theta(t)[b(t)-r(t)1] - \gamma\zeta_\theta(t)\sigma(t)\theta(t) = 0. \tag{124}$$

From equation (123) we get

$$\hat{c}(t) = I_1(t,\gamma\zeta_\theta(t)), \tag{125}$$

and from equation (124) we get

$$\theta(t) = \sigma^*(t)(\sigma(t)\sigma^*(t))^{-1}[b(t)-r(t)1] =: \hat{\theta}(t). \tag{126}$$

This completes the characterization of the extremal controls; it also shows, in conjunction with (119) and the boundedness of $\hat{\theta}$, that they satisfy (116).

Remark 2.1. The controls that satisfy condition (122) are those controls $(\hat{\pi},\hat{c}) \in \mathcal{A}(x)$ that satisfy equations (120) and (125), with $\theta = \hat{\theta}$ as in (126) and with $\gamma > 0$.

The controls which, in addition, satisfy condition (121) are those controls $(\hat{\pi},\hat{c})$ such that $\forall(\pi,c) \in \mathcal{A}(x)$,

(127)
$$E\left[\zeta(T)X(T) + \int_0^T \zeta(t)c(t)dt\right] \le E\left[\zeta(T)\hat{X}(T) + \int_0^T \zeta(t)\hat{c}(t)dt\right]$$
$$= E\left[\zeta(T)I_2(\gamma\zeta(T)) + \int_0^T \zeta(t)I_1(t,\gamma\zeta(t))dt\right].$$

Here, we denote $\zeta = \zeta_{\hat{\theta}}$, where $\hat{\theta}$ is given by equation (126).

We have easily found the controls that satisfy condition (122), but it remains to find more explicitly the controls that, in addition, satisfy (121), or equivalently (127). To that end, it is convenient to note the following.

LEMMA 2.1. *For every $(\pi,c) \in \mathcal{A}(x)$, the process N defined by*

$$N(t) = \zeta(t)X(t) + \int_0^t \zeta(s)c(s)ds, \quad 0 \le t \le T, \tag{128}$$

is a continuous, nonnegative local martingale, hence a supermartingale. In particular,

$$E\left[\zeta(T)X(T) + \int_0^T \zeta(s)c(s)ds\right] \le x. \tag{129}$$

Proof. According to equations (72)–(74), and (117)–(118),

$$\gamma\zeta(t)X(t) = \gamma x + \int_0^t \{\gamma\zeta(s)(-c(s) + \pi^*(s)[b(s)-r(s)1])$$
$$-\gamma\zeta(s)\theta^*(s)\sigma^*(s)\pi(s)\}ds + S_t^u.$$

From equation (124), we obtain $\zeta(t)X(t) = x - \int_0^t \zeta(s)c(s)ds + \gamma^{-1}S_t^u$, where S^u is a local martingale. □

In the remainder of this subsection, we are going to apply Remark 2.1 and Lemma 2.1 to select (heuristically) a candidate for optimal control, and in the next subsection we are going to prove that our selected candidate is indeed optimal.

From Remark 2.1 and Lemma 2.1, we *conjecture* that the optimal controls $(\hat{\pi}, \hat{c})$ satisfy

$$E\left[\zeta(T)\hat{X}(T) + \int_0^T \zeta(s)\hat{c}(s)ds\right] = x. \tag{130}$$

Let us now assume that

$$E\left[\zeta(T)I_2(y\zeta(T)) + \int_0^T \zeta(s)I_1(s, y\zeta(s))ds\right] < \infty \quad \forall y \in (0,\infty), \tag{131}$$

and define the function $\mathcal{X} : (0,\infty) \longmapsto (0,\infty)$ by

$$\mathcal{X}(y) := E\left[\zeta(T)I_2(y\zeta(T)) + \int_0^T \zeta(s)I_1(s, y\zeta(s))ds\right]. \tag{132}$$

Since $\mathcal{X}$ is strictly decreasing and surjective, it has an inverse $\mathcal{Y} \equiv \mathcal{X}^{-1} : (0,\infty) \longmapsto (0,\infty)$ which is also strictly decreasing. If conjecture (130) is valid, then

$$\hat{\gamma} = \mathcal{Y}(x), \tag{133}$$

and the process $\hat{N}$ defined by

$$\hat{N}(t) := \zeta(t)\hat{X}(t) + \int_0^t \zeta(s)\hat{c}(s)ds$$

will be not only a supermartingale, but also a martingale. In fact, $E[\hat{N}(0)] = x = E[\hat{N}(T)]$. Thus, $\hat{N}(t) = E[\hat{N}(T)|\mathcal{F}_t]$, or equivalently $\forall 0 \le t \le T$,

$$\begin{aligned} \zeta(t)\hat{X}(t) + \textstyle\int_0^t \zeta(s)\hat{c}(s)ds &= E\left[\zeta(T)\hat{X}(T) + \textstyle\int_0^T \zeta(s)\hat{c}(s)ds|\mathcal{F}_t\right] \\ &= E\left[\zeta(T)I_2(\hat{\gamma}\zeta(T)) + \textstyle\int_0^T \zeta(s)I_1(s, \hat{\gamma}\zeta(s))ds|\mathcal{F}_t\right]. \end{aligned} \tag{134}$$

In addition, according to the representation theorem of Brownian martingales as stochastic integrals (see, for instance, [25, §3.4.D]), there exists a progressively measurable process $\psi : [0,T] \times \Omega \mapsto \Re^d$ with

$$P\left\{\int_0^T |\psi(s)|^2 ds < \infty\right\} = 1 \tag{135}$$

and

$$E\left[\zeta(T)I_2(\hat{\gamma}\zeta(T)) + \int_0^T \zeta(s)I_1(s, \hat{\gamma}\zeta(s))ds|\mathcal{F}_t\right] = x + \int_0^t \psi^*(s)dW_s. \tag{136}$$

On the other hand, according to equations (72)–(74),

$$\zeta(t)\hat{X}(t) + \int_0^t \zeta(s)\hat{c}(s)ds = x + \int_0^t \zeta(s)[\sigma^*(s)\hat{\pi}(s) - \hat{X}(s)\hat{\theta}(s)]^* dW(s). \tag{137}$$

Thus, comparing equations (134)–(136) with (137), we see that if conjecture (130) is valid, then the process $\hat{\pi}$ will satisfy

$$\zeta(s)[\sigma^*(s)\hat{\pi}(s) - \hat{X}(s)\hat{\theta}(s)] = \psi(s).$$

2.4. The complete market. In the complete market case ($m = d$), $\sigma(t)$ is a square matrix with inverse $\sigma^{-1}(t)$. This case has the distinctive feature that *every contingent claim is attainable* (see, e.g., [24] or [25, pp. 376–378]).

As suggested heuristically in the previous subsection, let us define the processes $\hat{\pi} : [0,T] \times \Omega \mapsto \Re^m$ and $\hat{c} : [0,T] \times \Omega \mapsto [0,\infty)$ by

$$\hat{\pi}(t) := (\sigma^*(t))^{-1} \left\{ \frac{\psi(t)}{\zeta(t)} + \hat{X}(t)\hat{\theta}(t) \right\}, \tag{138}$$

$$\hat{c}(t) := I_1(t, \hat{\gamma}\zeta(t)), \tag{139}$$

where $\hat{\gamma}$ is defined by (133), ψ is the progressively measurable process defined by (135)–(136), $\hat{\theta}$ is defined by (126), and $\zeta = \zeta_{\hat{\theta}}$.

We see that $\hat{\pi}$ and $\hat{c}$ are progressively measurable and satisfy (107)–(108). Furthermore, according to equations (72)–(74), (138), and (136), the control $(\hat{\pi}, \hat{c})$ determines a trajectory of the system $\hat{X}$ which satisfies

$$\begin{aligned} \zeta(t)\hat{X}(t) + \int_0^t \zeta(s)\hat{c}(s)ds &= x + \int_0^t \zeta(s)[\sigma^*(s)\hat{\pi}(s) - \hat{X}(s)\hat{\theta}(s)]^* dW(s) \\ &= x + \int_0^t \psi^*(s)dW(s) \\ &= E\left[\zeta(T)I_2(\hat{\gamma}\zeta(T)) + \int_0^T \zeta(s)I_1(s, \hat{\gamma}\zeta(s))ds | \mathcal{F}_t\right], \end{aligned} \tag{140}$$

so $\forall t \in [0,T]$,

$$\hat{X}(t) = \frac{1}{\zeta(t)} E\left[\zeta(T)I_2(\mathcal{Y}(x)\zeta(T)) + \int_t^T \zeta(s)I_1(s, \mathcal{Y}(x)\zeta(s))ds | \mathcal{F}_t\right]. \tag{141}$$

Thus, the wealth process determined by $(\hat{\pi}, \hat{c})$ of (138)–(139) never takes negative values, which shows that $(\hat{\pi}, \hat{c})$ is indeed admissible (that is, $(\hat{\pi}, \hat{c}) \in \mathcal{A}(x)$). Furthermore, from equations (140), (132)–(133) we see that

$$E\left[\zeta(T)\hat{X}(T) + \int_0^T \zeta(s)\hat{c}(s)ds\right] = \mathcal{X}(\hat{\gamma}) = \mathcal{X}(\mathcal{Y}(x)) = x.$$

Thus, according to Remark 2.1 and Lemma 2.1, condition (121) is satisfied. From equations (125)–(126), we see that condition (122) is also satisfied by the control $(\hat{\pi}, \hat{c})$ defined by (138)–(139).

According to Theorem 2.1, we have proved the following theorem.

THEOREM 2.2. *Suppose that assumption* (131) *holds, and that we have a complete market* (*i.e.,* $m = d$ *and* $\sigma(t)$ *invertible*). *Then the optimal consumption rate process and the optimal portfolio process are given by equations* (138)–(139). *This consumption-investment policy determines a wealth process* $\hat{X}$ *given by*

$$\hat{X}(t) = \frac{1}{\zeta(t)} E\left[\zeta(T) I_2(\mathcal{Y}(x)\zeta(T)) + \int_t^T \zeta(s) I_1(s, \mathcal{Y}(x)\zeta(s)) ds | \mathcal{F}_t\right] \quad \forall 0 \leq t \leq T. \tag{142}$$

We should also notice that the process described in Theorem 2.2 is the *unique solution* of Problem 2.1 (see equation (112)). In fact, since $U_1(t, \cdot)$ and U_2 are strictly concave functions, we may apply Theorem 1.6.

As in [8], we can obtain more results about the consumption-investment problem. Since those results are not a direct application of Theorem 1.4, we prefer to stop here, and refer the interested reader to [8]. Related optimization problems in financial markets appear in [24]–[28] and [40].

3. The square-integrable controls.

3.1. Introduction. In this section we reduce the class of admissible controls and obtain a stochastic maximum principle which is not only a necessary condition for optimality, but also a sufficient one. We also get some results concerning the existence and uniqueness of optimal controls.

Although all the previous versions of the stochastic maximum principle in which the control enters into the diffusion coefficient require at least that the controls be square-integrable, only one of them (Bismut [6]) supplies both necessary and sufficient conditions for optimality. Since that paper considers only the linear-regulator problem, we extend that work by considering general convex cost functions and allowing state constraints. Other references in which the stochastic maximum principle is also a sufficient condition for optimality are [19] and [21, Chap. 10], but those two references allow neither the diffusion coefficient to be controlled nor random coefficients.

3.2. The problem. We are going to consider a problem similar to the one stated in §1. The difference is that now the set of controls has more *structure*, and the terminal and running costs satisfy an additional condition.

DEFINITION 3.1. $\mathcal{U}^*$ *is the set of controls* $u \in \mathcal{U}$ *that satisfy*

$$\|u\|^2 := E \int_0^T |u_t|^2 dt < \infty. \tag{143}$$

As in the general theory of §1, the trajectory of the system controlled by $u \in \mathcal{U}^*$ satisfies equations (8)–(9). We want to minimize the functional $J : \mathcal{U}^* \longmapsto \Re$ defined by equation (17). That is, we want to select the control $\hat{u} \in \mathcal{U}^*$ that solves the problem

$$\min_{u \in \mathcal{U}^*} J(u). \tag{144}$$

We impose the same assumptions about the coefficients of the system as in §1, but now we take advantage of the restriction stated by equation (143). From Corollary 2.5.10 of [30, p. 85], we know that for every u in $\mathcal{U}^*$

$$E\left[\sup_{0 \leq t \leq T} |X_t^u|^2\right] < \infty. \tag{145}$$

Hence, $\forall u \in \mathcal{U}^*$,

$$E\left[\left(\int_0^T |f(t,X_t^u,u_t)|dt\right)^2\right] = E\left[\left(\int_0^T |A_tX_t^u + B_tu_t + C_t|dt\right)^2\right] \tag{146}$$
$$\leq E\int_0^T |A_tX_t^u + B_tu_t + C_t|^2dt < \infty,$$

and

$$E\int_0^T |g(t,X_t^u,u_t)|^2dt = E\int_0^T |D_tX_t^u + E_tu_t + F_t|^2dt < \infty. \tag{147}$$

We should note that the version of the stochastic maximum principle that we are going to develop in this section cannot be applied to the consumption-investment problem. In fact, conditions (143), (145)–(147) are *not* satisfied by the model of §2.

3.3. Assumptions. When we consider $\mathcal{U}^*$ instead of $\mathcal{U}$ as our set of admissible controls we have, in particular, that equations (146) and (147) hold. Now, we are going to impose an additional assumption.

Assumption 3.1. In addition to Assumptions 1.1 and 1.2 of §1 we shall assume in this section that for every $u, v \in \mathcal{U}^*, \rho \in [0,1]$,

$$E\int_0^T |L_x(t, X_t^v + \rho X_t^u, v_t + \rho u_t)|^2dt < \infty. \tag{148}$$

According to Hölder's inequality and inequalities (143) and (145), a sufficient condition for Assumption 3.1 to hold is that there exists a constant $K \in (0,\infty)$ such that for every $(t,x,u) \in [0,T] \times V \times U$,

$$|\Psi_x(x)|^2 + |L_x(t,x,u)|^2 + |L_u(t,x,u)|^2 \leq K(1+|x|^2+|u|^2). \tag{149}$$

3.4. The adjoint equation. We have already obtained some results about the adjoint equation in §1.4. The following proposition is a consequence of Theorem 1.1.

PROPOSITION 3.1. *Under the assumptions of this section, there is a unique pair of adapted processes (p,q) that satisfies equations* (19)–(20), *as well as conditions* (24)–(25).

3.5. The stochastic maximum principle. The purpose of the stochastic maximum principle is usually to state a necessary condition for the optimality of a given control $\hat{u} \in \mathcal{U}$. Nevertheless, the version of the stochastic maximum principle that we are going to build provides not only a necessary but also a sufficient condition for optimality. Let us suppose that $\hat{u}$ is a fixed control, a candidate to be optimal for the problem (144), and $\hat{X}$ is the corresponding state process. We shall start by studying the process S defined in §1.5.

LEMMA 3.1. *Under the assumptions of this section, for every $u \in \mathcal{U}^*$ the process S^u defined by*

$$S_t^u := \int_0^t \{p_s \bullet g(s,X_s^u,u_s) + X_s^u \bullet q_s\}dW_s, \quad 0 \leq t \leq T \tag{150}$$

is a martingale.

Proof. Obviously, the process S^u is a local martingale, but now we want to prove that S^u is indeed a martingale. For that purpose it is good enough to check that S^u is of class D[0,T], or even the weaker condition $E[\sup_{0\leq t\leq T}|S^u(t)|] < \infty$. According to the Burkholder–Davis–Gundy inequality (see, for instance, [25, Thm. 3.3.28]), to check this weaker condition it is enough to verify that

$$E\left[\left(\int_0^T \{|p_s \bullet g(s, X_s^u, u_s)|^2 + |X_s^u \bullet q_s|^2\} ds\right)^{\frac{1}{2}}\right] < \infty.$$

But this follows from Hölder's inequality, together with inequalities (24)–(25), (145), and (147). Hence, $E[\sup_{0\leq t\leq T}|S^u(t)|] < \infty$, which implies that S^u is indeed a martingale. □

COROLLARY 3.1. $\forall u \in \mathcal{U}^*$,

$$E[R_T^{\hat{u}}] = E[R_T^u]. \tag{151}$$

Proof. This is an immediate consequence of equation (75). □

THEOREM 3.1 (state-constraints). *Suppose that for each $(t, \omega, x) \in [0,T] \times \Omega \times V$, $L(t, x, \cdot)$ is strictly convex. Then, under the assumptions of this section, $\hat{u}$ is a solution of the optimal control problem*

$$\min_{u\in\mathcal{U}^*} E\left[\int_0^T L(t, X_t^u, u_t)dt + \Psi(X_T^u)\right] \tag{152}$$

if and only if

$$\hat{u} = \tilde{v}, \quad Leb \otimes P - a.e. \text{ on } [0,T] \times \Omega, \tag{153}$$

where $\tilde{v}$ is a control that satisfies

$$\max_{u\in U} H(t, p_t, q_t, \hat{X}_t, u) = H(t, p_t, q_t, \hat{X}_t, \tilde{v}_t), \quad X^{\tilde{v}} \in V, \tag{154}$$

$Leb \otimes P - a.e.$ on $[0,T] \times \Omega$.

Proof. This is an immediate consequence of Corollaries 1.2 and 3.1. □

THEOREM 3.2 (no state-constraints). *Suppose that $V = \Re^n$. Then $\hat{u}$ is a solution of the optimal control problem of* (152) *if and only if*

$$\max_{u\in U} H(t, p_t, q_t, \hat{X}_t, u) = H(t, p_t, q_t, \hat{X}_t, \hat{u}_t), \quad Leb \otimes P - a.e. \text{ on } [0,T] \times \Omega. \tag{155}$$

Proof. This is an immediate consequence of Corollaries 1.3 and 3.1. □

An interesting remark about this version of the stochastic maximum principle is that it provides not only a necessary, but also a sufficient condition for optimality. That is, *a control is optimal if and only if it maximizes the Hamiltonian.*

Our method of applying the theory of convex analysis to the stochastic control problem of this paper can also provide the following result about the existence and uniqueness of the optimal control.

THEOREM 3.3. *Let us suppose that there exists a convex function $k : \Re \longmapsto \Re$ such that $\lim_{x\to\infty} k(x) = \infty$ and $\forall (t, \omega, x, u) \in [0,T] \times \Omega \times V \times U$,*

$$L(t, x, u) \geq k(|u|^2).$$

Let us also suppose that the function $\Psi(\cdot)$ is bounded from below by a constant $\eta \in \Re$. Then problem (144) *has at least one solution. It has a unique solution if, for each $(t,\omega) \in [0,T] \times \Omega$, $L(t,\cdot,\cdot)$ or $\Psi(\cdot)$ are strictly convex.*

Proof. Applying Jensen's inequality, $\forall u \in \mathcal{U}^*$,

$$\begin{aligned} J(u) &= E\left[\int_0^T L(t, X_t^u, u_t)dt + \Psi(X_T^u)\right] \\ &\geq E\left[\int_0^T k(|u_t|^2)dt + \eta\right] \geq k(\|u\|^2) + \eta. \end{aligned}$$

Thus J is coercive over $\mathcal{U}^*$, that is, $\lim_{\|u\|\to\infty} J(u) = \infty$. Applying Proposition 2.1.2 of [11, p. 35], we get our result. □

We shall finish this paper by showing that the results of this section can be applied to solve three problems that arise in engineering: the linear-regulator problem, the predicted-miss problem, and the Beneš problem.

3.6. Example 1: The linear regulator.

3.6.1. The model. In the linear-regulator model, $\mathcal{U}$ is the set of controls $u : [0,T] \times \Omega \longmapsto \Re^k$ that are measurable, $(\mathcal{F}_t)$-adapted, and satisfy

$$\|u\|^2 = E\left[\int_0^T |u_t|^2 dt\right] < \infty. \tag{156}$$

Each $u \in \mathcal{U}$ determines a trajectory of the system that is the solution of the linear stochastic differential equation

$$dX_t^u = (A(t)X_t^u + B(t)u_t + C(t))dt + (D(t)X_t^u + E(t)u_t + F(t))dW_t, \tag{157}$$

$$X_0^u = x. \tag{158}$$

We assume that A, B, C, D, E, and F are all progressively measurable with respect to $(\mathcal{F}_t)$, and bounded uniformly in $(t,\omega) \in [0,T] \times \Omega$. We want to minimize the criterion $J : \mathcal{U} \longmapsto \Re$ defined by

$$J(u) = E\left[\int_0^T (X_t^{u*} M(t) X_t^u + u_t^* N(t) u_t)dt + X_T^{u*} \tilde{N} X_T^u\right], \tag{159}$$

where $M : [0,T] \times \Omega \mapsto \mathcal{L}(\Re^n; \Re^n)$ and $N : [0,T] \times \Omega \mapsto \mathcal{L}(\Re^k; \Re^k)$ are $(\mathcal{F}_t)$-progressively measurable, $\tilde{N} : \Omega \mapsto \mathcal{L}(\Re^n; \Re^n)$ is $\mathcal{F}_T$-measurable, and for each $(t,\omega) \in [0,T] \times \Omega$, the $n \times n$ matrices $M(t)$ and $\tilde{N}$ are symmetric, nonnegative definite, and the $k \times k$ matrix $N(t)$ is symmetric and positive definite. We shall also assume that M, N, and $\tilde{N}$ are bounded.

3.6.2. Assumptions. Following the notation of §1, we note that $U \equiv \Re^k$, $V \equiv \Re^n$, $f(t,x,u) \equiv A(t)x + B(t)u + C(t)$, $g(t,x,u) \equiv D(t)x + E(t)u + F(t)$, $L(t,x,u) \equiv x^* M(t) x + u^* N(t) u$, and $\Psi(x) \equiv x^* \tilde{N} x$.

Since we have a stochastic control problem with linear dynamics, convex cost-criterion, and unconstrained state, we may apply the general theory of §1 to solve this problem. In addition, since we are assuming (156), inequalities (145)–(147) are also valid for the linear regulator. Nevertheless, to apply the theory of §3.5, we have to check that Assumption 3.1 also holds in this model. But this is straightforward, applying the sufficient condition (149). *Therefore, we may apply the stochastic maximum principle, as stated in Theorem* 3.2. The details of the application of Theorem 3.2 to solve the linear-regulator problem can be found in Chapter 4 of [8]. The adjoint processes are found to be

$$p(t) = -P(t)\hat{X}(t) - R(t), \tag{160}$$

$$q(t) = -Q(t)\hat{X}(t) - P(t)[D(t)\hat{X}(t) + E(t)\hat{u}(t) + F(t)] - S(t), \tag{161}$$

and the optimal control given by

$$\begin{aligned}\hat{u}(t) = -[N(t) + E^*(t)P(t)E(t)]^{-1}\{&[B^*(t)P(t)\\ &+E^*(t)Q(t) + E^*(t)P(t)D(t)]\hat{X}(t) + B^*(t)R(t)\\ &+E^*(t)(P(t)F(t) + S(t))\},\end{aligned} \tag{162}$$

where $P : [0,T] \times \Omega \longmapsto \mathcal{L}(\Re^n; \Re^n)$, $Q : [0,T] \times \Omega \longmapsto \mathcal{L}(\Re^d; \mathcal{L}(\Re^n; \Re^n))$, are a pair of measurable, adapted processes that solve the backward matrix stochastic differential equation

$$\begin{aligned}dP(t) = &- \{P(t)A(t) + A^*(t)P(t) + D^*(t)P(t)D(t) + D^*(t)Q(t) + Q(t)D(t)\\ &-[D^*(t)P(t)E(t) + P(t)B(t) + Q(t)E(t)][N(t) + E^*(t)P(t)E(t)]^{-1}\\ &[E^*(t)P(t)D(t) + B^*(t)P(t) + E^*(t)Q(t)] + 2M(t)\}\, dt + Q(t)dW(t),\\ P(T) = &\ 2\tilde{N}.\end{aligned}$$

We notice that if we assume that the coefficients of the system are deterministic and take $Q \equiv 0$, we recover the familiar Riccati equation. On the other hand, $R : [0,T] \times \Omega \longmapsto \Re^n$ and $S : [0,T] \times \Omega \longmapsto \mathcal{L}(\Re^d; \Re^n)$ are a pair of measurable, adapted processes that solve the backward matrix stochastic differential equation

$$\begin{aligned}dR(t) = &\{[P(t)B(t) + D^*(t)P(t)E(t) + Q(t)E(t)]\ [N(t) + E^*(t)P(t)E(t)]^{-1}B^*(t)\\ &-A^*(t)\}\ R(t)dt\\ &+\{[(P(t)B(t) + D^*(t)P(t)E(t) + Q(t)E(t))\ (N(t) + E^*(t)P(t)E(t))^{-1}\\ &\quad E^*(t) - D^*(t)]\ [P(t)F(t) + S(t)] - P(t)C(t) - Q(t)F(t)\}\, dt + S(t)dW(t),\\ R(T) = &\ 0.\end{aligned}$$

3.7. Example 2: The predicted-miss problem.

3.7.1. The model. In this model, $\mathcal{U}$ is the set of controls $u : [0,T] \times \Omega \longmapsto [-1,1]^k$ that are measurable and $(\mathcal{F}_t)$-adapted. Each $u \in \mathcal{U}$ determines a trajectory of the system that is the solution of the linear stochastic differential equation

$$dX_t^u = (A(t)X_t^u + B(t)u_t)dt + F(t)dW_t, \tag{163}$$

$$X_0^u = x. \tag{164}$$

We assume that A, B, and F are deterministic, bounded, and measurable.

We want to minimize the criterion $J : \mathcal{U} \longmapsto \Re$ defined by

$$J(u) = E[k(v \bullet X_T^u)], \tag{165}$$

where $v \in \Re^n$ is fixed, and $k : \Re \longmapsto \Re$ is given by $k(y) = y^2$. This means that the controller is trying to drive the final state to the hyperplane $H = \{x \in \Re^n : v \bullet x = 0\}$ using bounded controls.

3.7.2. Assumptions. Following the notation of §1, we note that $U \equiv [-1,1]^k$, $V \equiv \Re^n$, $f(t,x,u) \equiv A(t)x + B(t)u$, $g(t,x,u) \equiv F(t)$, $L(t,x,u) \equiv 0$, and $\Psi(x) \equiv k(v \bullet x)$. We can also note that the trajectory of the system satisfies a linear stochastic differential equation, and that the criterion that we want to minimize is a convex functional. The trajectory of the system is unconstrained. Thus, we may apply the general theory of §1. It is not hard to check that the assumptions made in this section are all satisfied. *Hence, we may apply Theorem* 3.2 *to solve the predicted-miss problem.* The details of the application of Theorem 3.2 to solve this problem can be found in Chapter 5 of [8]. The first component of the adjoint process and the optimal control are found to be

$$p(t) = -2s(t)E[v \bullet \hat{X}_T | \mathcal{F}_t] \tag{166}$$

and

$$\hat{u}(t) = -\text{sgn}\{B^*(t)s(t)\}\text{sgn}\{s(t) \bullet \hat{X}(t)\}, \tag{167}$$

respectively, where $s(t) = \Phi^*(t)^{-1}\Phi^*(T)v$, and $\Phi : [0,T] \mapsto \mathcal{L}(\Re^n; \Re^n)$ is the deterministic solution of $\Phi(t) = I + \int_0^t A(s)\Phi(s)ds$.

3.8. Example 3: The Beneš problem.

3.8.1. The model. In this model, $\mathcal{U}$ is the set of measurable, $(\mathcal{F}_t)$-adapted processes $u : [0,T] \times \Omega \longmapsto U$, where $U := \{v \in \Re^k : |v| \leq 1\}$. Each $u \in \mathcal{U}$ determines a trajectory of the system that satisfies the linear stochastic differential equation

$$dX_t^u = ([H(t) + \gamma(t)I]X_t^u + \beta(t)u_t)dt + \alpha(t)dW_t, \tag{168}$$

$$X_0^u = x. \tag{169}$$

We assume that the function $H : [0,T] \longmapsto \mathcal{L}(\Re^n; \Re^n)$ is bounded, measurable, skew symmetric, and the functions $\alpha : [0,T] \longmapsto \Re$, $\beta : [0,T] \longmapsto \Re$, and $\gamma : [0,T] \longmapsto \Re$ are bounded, measurable, with α, β continuous. We assume, as in [18], [22], and [23], that the dimensions of the Brownian motion, the trajectory of the system, and the control are equal. That is, $d = n = k$. We want to minimize the criterion $J : \mathcal{U} \longmapsto \Re$ defined by

$$J(u) = E\left[\int_0^T l(t, X^u(t))dt + k(X^u(T))\right]. \tag{170}$$

In the above definition, $l : [0,T] \times \Re^n \longmapsto \Re$ is given by

$$l(t,x) = \eta(t)|x|^2,$$

where $\eta : [0,T] \longmapsto [0,\infty)$ is bounded and measurable. On the other hand, $k : \Re^n \longmapsto \Re$ is given by

$$k(y) = |y|^2.$$

This problem was first solved by Beneš [2].

3.8.2. Assumptions. Following the notation of §1, we note that $U \equiv \{v \in \mathcal{R}^k : |v| \leq 1\}$, $V \equiv \Re^n$, $f(t,x,u) \equiv [H(t) + \gamma(t)I]x + \beta(t)u$, $g(t,x,u) \equiv \alpha(t)I$, $L(t,x,u) \equiv l(t,x) = \eta(t)|x|^2$, and $\Psi(x) \equiv k(x) = |x|^2$. Since we have a stochastic control problem with linear dynamics, convex cost criterion, and unconstrained state, we may apply the general theory of §1 to solve this problem. It is not hard to check that all the assumptions made in this section are also satisfied. *Hence, we may apply Theorem* 3.2 *to solve the Beneš problem.* The details of the application of Theorem 3.2 to solve this problem can be found in Chapter 6 of [8]. The first component of the adjoint process is found to satisfy

$$\frac{p(t)}{|p(t)|} = -\frac{\hat{X}(t)}{|\hat{X}(t)|}, \tag{171}$$

and the optimal control is found to be

$$\hat{u}(t) = -\text{sgn}(\beta(t))\frac{\hat{X}(t)}{|\hat{X}(t)|}. \tag{172}$$

Acknowledgments. We are grateful to Professors Ulrich G. Haussmann, Shige Peng, and X. X. Xue for their comments, and to Professor Mark Saksonov for advancing his preprint [38]. The two referees made valuable suggestions that improved the manuscript considerably; we thank both of them.

PERSISTENCY OF EXCITATION IN IDENTIFICATION USING RADIAL BASIS FUNCTION APPROXIMANTS*

A. J. KURDILA†, FRANCIS J. NARCOWICH‡, AND JOSEPH D. WARD‡

Abstract. In this paper, identification algorithms whose convergence and rate of convergence hinge on the regressor vector being persistently exciting are discussed. It is then shown that if the regressor vector is constructed out of radial basis function approximants, it will be persistently exciting, provided a kind of "ergodic" condition is satisfied. In addition, bounds on parameters associated with the persistently exciting regressor vector are provided; these parameters are connected with both the convergence and rates of convergence of the algorithms involved.

Key words. persistency of excitation, identification, radial basis functions

AMS subject classifications. Primary 93B30, 41A30; secondary 93D20, 41A63

1. Introduction.

In applications to neural networks and adaptive control, the use of radial basis function (RBF) approximants has become increasingly popular over the past few years. This popularity can be attributed to several factors. First, because data is collected in control applications in (near) real-time, uniform sampling of trajectories in time naturally leads to scattered data in phase space. The utility of radial basis approximants for scattered data is well documented [2]–[7], [10]–[15], [17]. Second, RBF approximants appear to be particularly well suited to tracking control. Papers by Sanner and Slotine [22]–[24], Tzirkel-Hancock and Fallside [28], and the present authors [8] provide examples in which direct adaptive tracking control using RBFs is achieved. Finally, several papers have appeared in the literature that use RBFs as the foundation of neural network architectures designed for identification and control [1], [9]. The relationship of some of these architectures and classical questions of "hypersurface reconstruction" in approximation theory has been addressed in [16].

Algorithms for handling identification problems have been studied extensively [22]–[25], [28]. In this paper we discuss two such algorithms, a standard least-squares method and a gradient-descent/dead-zone method introduced by Sanner and Slotine [22]–[24], and show that persistency of excitation of the regressor vector employed in each of them is a sufficient condition for them to converge at an exponential rate. (The gradient-descent/dead-zone algorithm always converges whether or not the regressor vector is perisistently exciting [22]–[24].) We then proceed to show that if the regressor vector is constructed out of RBF approximants, it will be persistently exciting, provided a kind of "ergodic" condition is satisfied. Finally, we will provide bounds on the parameters associated with the persistently excited regressor vector; these parameters are associated with convergence and rates of convergence.

The remainder of the paper is organized as follows. To complete the introduction, we will briefly discuss radial basis functions. In §2 we will provide a description of the identification problem and discuss several algorithms for dealing with it. In §3 we will prove the main theorem, Theorem 3.5, alluded to above. In §4 we will obtain bounds on quantities associated with a persistently excited regressor vector.

Radial basis functions. In this paper, we will be concerned with two classes of RBFs. The first class comprises every nonconstant $F(r)$ that can be represented via the formula

$$F(r) = \int_0^\infty e^{-r^2\rho} d\beta(\rho), \tag{1.1}$$

where $d\beta(\rho)$ is a finite, nonnegative Borel measure on $[0,\infty)$ and $r \in [0,\infty)$. (Such functions are closely related to *completely monotonic* functions; see [12], [26], [29].) RBFs have an "order" $m = 0, 1, \ldots$, associated with them. The functions described in (1.1) are "order-0" RBFs, and they include the Gaussian RBFs as well as the inverse multiquadric, $(1+r^2)^{-1/2}$. It should be mentioned that RBFs of the form (1.1) do not exhaust the class of all possible order-0 RBFs, but they do include all of the ones in use.

The second class comprises those order-1 RBFs that can be represented via a formula similar to (1.1). Let $d\eta(\rho)$ be a nonnegative Borel measure on $[0,\infty)$ for which $\int_1^\infty \rho^{-1} d\eta(\rho) < \infty$. All functions of the form

$$F(r) = F(0) + \int_0^\infty \frac{1 - e^{-r^2\rho}}{\rho} d\eta(\rho) \tag{1.2}$$

such that $r^{-1}F'(r)$ is nonconstant are order-1 RBFs that make up the second class. We remark that the case when $r^{-1}F'(r)$ is a constant is degenerate. Also, it should be noted that although the constant $F(0)$ in (1.2) can be arbitrary, it is taken to be nonnegative. The reason for making this assumption involves the invertibility of a certain interpolation matrix [12], [10], [13]–[15]. Finally, it is easy to show that if F is in the first class, then $F(0) - F(r)$ is in the second. On the other hand, there are many order-1 RBFs in the second class that do not arise in this way. Since the only order-0 RBFs considered here are those of the form (1.1), and the only order-1 RBFs are those of the form (1.2), we will simply refer to functions of the first class as "order-0 RBFs," and to those of the second class as "order-1 RBFs." No confusion should result from this minor abuse of terminology.

The most prominent members of the second class that are not in the first are the Hardy multiquadric function, $\sqrt{1+r^2}$, a function studied by Dyn [3], $\log(1+r^2)$, and the distance function r. As was mentioned above in connection with the first class, RBFs of the form (1.2) do not exhaust the class of all possible order-1 RBFs, but they do include all the ones of practical importance. For a complete discussion of the definition, classification, and representation of RBFs, we refer the interested reader to the papers by Powell [17], [18].

Two important features concerning RBFs are the stability of their associated interpolation and least-squares matrices [13], [15], [19], [27], and their ability to provide uniform approximations to smooth functions on compact sets. A typical interpolant/approximant $L(x)$ is formed in the following way. Pick a set of distinct points in $\mathbb{R}^s$, $\Xi := \{\xi_j\}_{j=1}^N$; these are called the *centers*. The function L is then selected from the span of the family $\{F(x - \xi_j)\}_{j=1}^N$, where F is a fixed RBF.

For the case in which one wishes to use RBFs to uniformly approximate a smooth function f defined on a compact set $\Omega \subset \mathbb{R}^s$, one first uniformly approximates f by a band-limited function f_B (see [24] for a discussion). For uniform approximation of f_B with RBFs, one may use a result of Madych and Nelson [11, Thm. 4.4].

Let the centers $\xi_1, \ldots, \xi_N$ be scattered throughout Ω in a way that makes the quantity

$$d = d(\Xi, \Omega) := \sup_{y\in\Omega} \inf_{x\in\Xi} \|y - x\|_2$$

small. Because Ξ is a subset of Ω, d turns out to be the standard Hausdorff distance between compact sets. Indeed, when the centers are placed at the vertices of an s-cube whose sides have length h, it is easy to show that $d = \frac{1}{2}\sqrt{s}\,h$. The result in [11] is as follows. For certain RBFs F (including Gaussian and multiquadrics) and arbitrary k, there exist coefficients $\{a_j\}$ such that

$$\sup_{x\in\Omega}\left|f_B(x) - \sum_j a_j F(x - x_j)\right| = \mathcal{O}(d^k).$$

Thus, one may uniformly approximate the band-limited function f_B by linear combinations of translates of RBFs. The usual "up-over-and-around" argument then implies that one can uniformly approximate the original function f on Ω by such linear combinations.

2. An identification problem.

Algorithms for handling identification problems have been studied extensively [22]–[25], [28]. In this section, we wish to discuss two such algorithms, a standard least-squares method and a gradient-descent/dead-zone method introduced by Sanner and Slotine [22]–[24]. Specifically, we wish to analyze the problem of trying to determine the functional form of a continuous output funtion $G : \Omega \to \mathbb{R}$, where Ω is a compact subset of the state space, $\mathbb{R}^s$. The information available is the signal $Y(t) = G(x(t))$, where $x(t)$ denotes a continuous function of t taking values in Ω.

To deal with this identification problem, assume that $\mathfrak{W} = \{w_k(x)\}_{k=1}^N$ is a fixed set of continuous functions (RBFs with various centers, for example) defined on the state space. The basis is chosen so that $G(x)$ can be uniformly approximated to within an acceptable level of error by (time-independent) linear combinations of the w_k's. More precisely, given an error-level $\Phi > 0$, we suppose that there exist coefficients c_k^* for which

$$\left\|G(x) - \sum_{k=1}^N c_k^* w_k(x)\right\|_{\infty,\Omega} \leq \Phi,$$

where $\|\cdot\|_{\infty,\Omega}$ denotes the supremum norm in Ω. Whether a given basis provides an acceptable approximation is an issue that must be addressed. For RBFs, we discussed the matter when we reviewed them earlier.

The coefficients c_k^* may not be unique, even if they make $\sum_{k=1}^N c_k^* w_k(x)$ a "best approximant" to $G(x)$, because the unit ball in L^∞ is not strictly convex. Among all sets of coefficients that yield a best approximant, one may uniquely specify a set by imposing the additional requirement that $\sum_k (c_k^*)^2$ be a minimum.

Because knowing $c_1^*, \ldots, c_N^*$ is equivalent to knowing the function G, at least to within the error-level, Φ, our problem amounts to using the available information on $x(t)$ and the signal $Y(t) = G(x(t))$ described above to identify approximately the c_k^*'s. We wish to discuss both continuous and discrete-time methods to identifty these coefficients.

The idea common to all of these methods is to choose time-dependent coefficients $c_k(t)$, $k = 1, \ldots, N$, in such a way that each $c_k(t)$ converges to a neighborhood of the c_k^* as $t \to \infty$. Thus, for large t, the time-dependent approximation to G,

$$\tilde{G}(t,x) = \sum_{k=1}^N c_k(t) w_k(x),$$

will then be sufficiently close to

$$G^*(x) := \sum_k c_k^* w_k(x)$$

to render the same level of approximation to G as G^* itself.

We remark that, to bring the quantity $|Y(t) - \tilde{G}(t, x(t))|$ (the prediction error) to a neighborhood of zero along a particular trajectory, it is *not* necessary to have each $c_j(t)$ converge to a neighborhood of the corresponding c_j^*, at least in the case of the gradient-descent/dead-zone algorithm [22]–[24]. For this algorithm, the convegence of $c_j(t)$ will be an added feature that occurs when the regressors are persistently exciting. See Proposition 2.2 below.

These methods are better formulated with the aid of additional notation, which we now introduce. First of all, let

$$\Delta(x) := G(x) - G^*(x) = G(x) - \sum_{k=1}^{N} c_k^* w_k(x).$$

Our error criterion then becomes

$$\|\Delta\|_{\infty,\Omega} \le \Phi.$$

With a slight abuse of notation, set $\Delta(t) = \Delta(x(t))$. In addition, define the following quantities:

$$w(t) := \begin{pmatrix} w_1(x(t)) \\ \vdots \\ w_N(x(t)) \end{pmatrix}, \qquad c(t) := \begin{pmatrix} c_1(t) \\ \vdots \\ c_N(t) \end{pmatrix}, \qquad c^* := \begin{pmatrix} c_1^* \\ \vdots \\ c_N^* \end{pmatrix}.$$

In this notation, we have $Y(t) = w(t)^T c^* + \Delta(t)$ and $\tilde{G}(t, x(t)) = w(t)^T c(t)$. We now turn to our first identification method.

Least squares. Let $\alpha > 0$ be a positive constant that is at our disposal, and let $c \in \mathbb{R}^N$. The object is to minimize

$$E(t) := \alpha\|c\|^2 + \int_{[0,t]} (w(\tau)^T c - Y(\tau))^2 d\mu(\tau)$$

where $d\mu(\tau) = d\tau$ in the continuous case, and $d\mu(\tau) = \sum_{i=0}^{\infty} \delta(\tau - i) d\tau$ in the discrete case. (We will try to treat the discrete and continuous cases simultaneously when this is possible. Doing so may require that we think of a sequence as a continuous function evaluated at integers.) This is a straightforward task that yields [25, p. 50]

$$c(t) = \left(\alpha I + \int_{[0,t]} w(\tau) w(\tau)^T d\mu(\tau)\right)^{-1} \int_{[0,t]} Y(\tau) w(\tau) d\mu(\tau). \tag{2.1}$$

The parameter error is defined to be $\phi(t) := c(t) - c^*$. If one uses $Y(\tau) = w(\tau)^T c^* + \Delta(t)$, then one may put the last equation in terms of $\phi(t)$,

$$\phi(t) = \left(\alpha I + \int_{[0,t]} w(\tau) w(\tau)^T d\mu(\tau)\right)^{-1} \left(-\alpha c^* + \int_{[0,t]} \Delta(\tau) w(\tau) d\mu(\tau)\right). \tag{2.2}$$

The regressor vector $w(t)$ is *persistently exciting* [25, p. 72] if there exist positive constants δ, α_1, and α_2 such that

$$\alpha_2\|c\|^2 \geq \int_{[t_0,t_0+\delta]} |w(\tau)^T c|^2 d\mu(\tau) \geq \alpha_1\|c\|^2, \tag{2.3}$$

where $\|\cdot\| = \|\cdot\|_2$, holds for every $t_0 \geq 0$ and every constant column vector $c = (c_1 \cdots c_N)^T \in \mathbb{R}^N$. If persistency of excitation holds in the case at hand, then we have the following result.

PROPOSITION 2.1. *In the least-squares algorithm, if the regressor vector $w(t)$ is persistently exciting, then*

$$\limsup_{t\to\infty} \|\phi(t)\| \leq \frac{\sqrt{\alpha_2\delta}\|\Delta\|_{\infty,\Omega}}{\alpha_1} \leq \frac{\sqrt{\alpha_2\delta}\,\Phi}{\alpha_1}. \tag{2.4}$$

Proof. In (2.2), the parameter error has the form $\phi(t) = A(t)^{-1}(-\alpha c^* + v(t))$. The matrix $A(t)$ being inverted in (2.2) is real, self-adjoint, and positive definite. Using (2.3) and $t \geq m\delta$, we may estimate its lowest eigenvalue as $\alpha + m\alpha_1$. Consequently, the norm of its inverse is $(\alpha + m\alpha_1)^{-1}$, and so

$$\|\phi(t)\| \leq (\alpha + m\alpha_1)^{-1}(\alpha\|c^*\| + \|v(t)\|). \tag{2.5}$$

To obtain the norm of $v(t)$, let $b \in \mathbb{R}^N$, and note that

$$b^T v(t) = \int_{[0,t]} \Delta(\tau) b^T w(\tau) d\mu(\tau).$$

Applying Schwarz's inequality, $t \leq (m+1)\delta$, the inequality $|\Delta(\tau)| \leq \|\Delta\|_{\infty,\Omega}$, and (2.3), we arrive at

$$(b^T v(t))^2 \leq (m+1)\delta\|\Delta\|^2_{\infty,\Omega} \int_{[0,(m+1)\delta]} (b^T w(\tau))^2 d\mu(\tau) \leq (m+1)^2\delta\|\Delta\|^2_{\infty,\Omega}\alpha_2\|b\|^2,$$

from which it follows that

$$\|v(t)\| = \left\| \int_{[0,t]} \Delta(\tau) w(\tau) d\mu(\tau) \right\| \leq (m+1)\|\Delta\|_{\infty,\Omega}\sqrt{\alpha_2\delta} \quad \text{if } t \leq (m+1)\delta. \tag{2.6}$$

Combining (2.5) and (2.6) yields

$$\|\phi(t)\| \leq \frac{\alpha\|c^*\| + \sqrt{\alpha_2\delta}\,(m+1)\|\Delta\|_{\infty,\Omega}}{\alpha + m\alpha_1}. \tag{2.7}$$

Letting $t \to \infty$ above yields (2.4). □

We proved above that if the regressor vector $w(t)$ is persistently exciting, then as $t \to \infty$, the parameter error $\phi(t)$ enters a neighborhood of the origin, and $c(t)$ enters a neighborhood of c^*. It is clear that persistency of excitation is crucial to convergence of the method.

We remark that the algorithm treated above is least squares in its "classic" form. In general, one would use a modified, recursive form of the algorithm [25]. Rather than treat one of these, we will turn to the the algorithm below, which is naturally formulated in a recursive way.

Gradient-descent/dead-zone algorithm. Sanner and Slotine [22]–[24] have discussed and analyzed a class of gradient-descent algorithms that employ a dead zone. If $c(t)$ is the parameter vector at time t and $\phi(t)$ is the parameter error, then define the prediction error to be

$$(2.8)\quad \epsilon(t) := \begin{cases} w(t)^T c(t) - Y(t) = w(t)^T \phi(t) - \Delta(t) & \text{(continuous time)}, \\ w(t)^T c(t-1) - Y(t) = w(t)^T \phi(t-1) - \Delta(t) & \text{(discrete time)}, \end{cases}$$

and the dead-zone prediction error to be

$$(2.9)\quad \epsilon_d(t) = \begin{cases} \epsilon(t) - \Phi \operatorname{sgn}(\epsilon(t)) & \text{if } |\epsilon| \geq \Phi, \\ 0 & \text{if } |\epsilon| \leq \Phi. \end{cases}$$

To update $c(t)$, we require that for continuous time,

$$(2.10)\quad \dot{c}(t) = -\eta \epsilon_d(t) w(t),$$

and for discrete time,

$$(2.11)\quad c(t) = c(t-1) - \eta \epsilon_d(t) w(t).$$

Here, η is another positive constant that is at our disposal. Of course, we may replace the left side in each of these equations by $\phi(t) = c(t) - c^*$ because c^* is constant.

For the case in which the basis comprised Gaussians centered on a discrete lattice, both the selection of the error-level Φ and the stability of the algorithm were analyzed in detail in [23], [24]. While more work is required in the error-level selection for the scattered-data case, their stability analysis applies to the case at hand almost verbatim. Here is a brief summary of that analysis.

Choose the function $V(t) := \frac{1}{2}\|\phi(t)\|^2$ as a Lyapunov function. In the continuous case, the derivative of V is negative; indeed, it satisfies

$$(2.12)\quad \dot{V} \leq -\eta \epsilon_d(t)^2.$$

A similar result applies in the discrete case, although the analysis forces a restriction on the constant η. If $0 < \eta < 2(\sum_k \|w_k(x)\|^2_{\infty,\Omega})^{-1}$, then

$$(2.13)\quad V(t) - V(t-1) \leq -\eta \epsilon_d(t)^2.$$

Thus, in either case, $V(t)$ is decreasing, and the algorithm is stable.

An obvious by-product of the analysis is that, in the continuous case, the dead-zone prediction error is square integrable, and, in the discrete case it is square summable. This observation has some important consequences. In the discrete case, $\epsilon_d(t)$ being square summable implies that $\epsilon_d(t) \to 0$ as $t \to \infty$. In the continuous case, the same conclusion can be arrived at if a few mild regularity assumptions are made. Suppose that $x(t)$ has a uniformly bounded, piecewise continuous derivative on $[0, \infty)$, and that $G(x)$ and the basis functions $w_k(x)$ are continuously differentiable on Ω. It easily follows that the continuous-case dead-zone prediction error $\epsilon_d(t)$ is continuous and has a bounded, piecewise continuous derivative $\dot{\epsilon}_d(t)$. Following the argument in

[24, p. 850] then yields that $\epsilon_d(t) \to 0$ as $t \to \infty$. Note that persistency of excitation is *not* required for these convergence results.

As in the least-squares algorithm, persistency of excitation guarantees that the parameter error vector will asymptotically enter a neighborhood of the origin—equivalently, $c(t)$ will asymptotically enter a neighborhood of c^*—with the neighborhood's size being controlled by the level of error, Φ. Indeed, we have this result.

PROPOSITION 2.2. *In the gradient-descent/dead-zone algorithm, if the regressor vector $w(t)$ is persistently exciting, then*

$$\limsup_{t\to\infty} \|\phi(t)\| \le 2\Phi\sqrt{\frac{\delta}{\alpha_1}}. \tag{2.14}$$

Proof. To do the continuous case, integrate (2.10) to get the equation

$$\phi(t') - \phi(t) = -\eta \int_t^{t'} \epsilon_d(\tau) w(\tau) d\tau.$$

Fix t. By multiplying both sides of this equation by $w(t')^T$ and then rearranging and manipulating its terms, we obtain

$$w(t')^T\phi(t) = \epsilon_d(t') + \gamma(t') + \eta\zeta(t'), \tag{2.15}$$

where $\gamma(t') := \epsilon(t') - \epsilon_d(t') + \Delta(t')$ and $\zeta(t') = \int_t^{t'} \epsilon_d(\tau)w(t')^T w(\tau)d\tau$. From (2.8) and (2.9), coupled with $|\Delta(t')| \le \Phi$, we see that

$$|\gamma(t')| \le 2\Phi. \tag{2.16}$$

Let δ be as in (2.3), which holds because $w(t)$ is persistently exciting. Compute the $H = L^2([t, t+\delta])$-norm of both sides, and use the upper estimate on the norm of the right side obtained with the triangle inequality to get

$$\|w(\cdot)^T\phi(t)\|_H \le \|\epsilon_d(\cdot)\|_H + \|\gamma(\cdot)\|_H + \eta\|\zeta(\cdot)\|_H. \tag{2.17}$$

From (2.3), we have that the left side of (2.17) satisfies

$$\|w(t')^T\phi(t)\|_H = \sqrt{\int_t^{t+\delta} (w(t')^T\phi(t))^2 dt'} \ge \sqrt{\alpha_1}\|\phi(t)\|. \tag{2.18}$$

In addition, (2.16) implies that

$$\|\gamma(\cdot)\|_H \le 2\Phi\sqrt{\delta}. \tag{2.19}$$

To estimate $\|\zeta(\cdot)\|_H$, first estimate $\zeta(t')$ using Schwarz's inequality and (2.3) as follows:

$$\begin{aligned}
|\zeta(t')| &\le \sqrt{\int_t^{t'} \epsilon_d(\tau)^2 d\tau}\sqrt{\int_t^{t'} (w(t')^T w(\tau))^2 d\tau} \\
&\le \sqrt{\int_t^{\delta} \epsilon_d(\tau)^2 d\tau}\sqrt{\int_t^{\delta} (w(t')^T w(\tau))^2 d\tau} \\
&\le (\|\epsilon_d(\cdot)\|_H)\,(\sqrt{\alpha_2}\|w(t')\|) \\
&\le \sqrt{\alpha_2}\|\epsilon_d(\cdot)\|_H \left(\sum_k \|w_k(x)\|_{\infty,\Omega}\right),
\end{aligned}$$

where $\|w(x)\|_{\infty,\Omega}$ is finite because the $w_k(x)$'s are continuous on the compact set Ω. From this inequality, we easily get an upper bound on $\|\zeta(\cdot)\|_H$:

$$\|\zeta(\cdot)\|_H \leq \sqrt{\alpha_2\delta}\|\epsilon_d(\cdot)\|_H \left(\sum_k \|w_k(x)\|_{\infty,\Omega}\right). \tag{2.20}$$

Combining (2.18), (2.19), and (2.20) yields

$$\begin{aligned}\|\phi(t)\| \leq & \frac{2\Phi\sqrt{\delta}+[1+\eta\sqrt{\alpha_2\delta}(\sum_k \|w_k(x)\|_{\infty,\Omega})]\|\epsilon_d(\cdot)\|_H}{\sqrt{\alpha_1}} \\ \leq & \frac{2\Phi\sqrt{\delta}+[1+\eta\sqrt{\alpha_2\delta}(\sum_k \|w_k(x)\|_{\infty,\Omega})]\sqrt{\int_t^{t+\delta}\epsilon_d(\tau)^2 d\tau}}{\sqrt{\alpha_1}}.\end{aligned} \tag{2.21}$$

Since, as we mentioned above, $\epsilon_d \in L^2[0,\infty]$, we have that $\int_t^{t+\delta}\epsilon_d(\tau)^2 d\tau \to 0$ as $t \to \infty$. Using this fact and taking the lim sup as $t \to \infty$ in (2.21), we arrive at (2.14). The discrete case differs only in minor ways from the continuous one, so the proof in that case will be omitted. □

In the continuous case, the convergence to such a neighborhood will happen at an exponential rate, at least in the time-regime during which the dead-zone prediction error $\epsilon_d(t)$ is strictly bounded away from 0. The lemmas that follow are aimed toward showing this.

LEMMA 2.3. *If $\epsilon_d(t) \neq 0$, then the function*

$$\sigma(t) := \frac{\epsilon_d(t)}{w(t)^T\phi(t)} \tag{2.22}$$

satisfies the inequality

$$1 \geq \sigma(t) \geq \frac{|\epsilon_d(t)|}{|\epsilon_d(t)|+2\Phi}. \tag{2.23}$$

In particular, if $|\epsilon_d(t)| \geq \Phi/\kappa$, where κ is a positive integer, then

$$1 \geq \sigma(t) \geq \frac{1}{2\kappa+1}. \tag{2.24}$$

Proof. From (2.8) and (2.9), it follows that when $\epsilon_d(t) \neq 0$, we have $|\epsilon(t)| > \Phi$, $\operatorname{sgn}(\epsilon_d) = \operatorname{sgn}(\epsilon)$, and

$$w(t)^T\phi(t) = \epsilon_d(t) + \Delta(t) + \Phi\operatorname{sgn}(\epsilon_d(t)). \tag{2.25}$$

This equation and the inequality $|\Delta(t)| \leq \Phi$ imply that

$$\operatorname{sgn}(\epsilon_d(t))w(t)^T\phi(t) = |\epsilon_d(t)| + (\Phi + \Delta(t)\operatorname{sgn}(\epsilon_d(t))) \geq |\epsilon_d(t)| > 0,$$

so that $w(t)^T\phi(t) \neq 0$ and $\operatorname{sgn}(w(t)^T\phi(t)) = \operatorname{sgn}(\epsilon_d(t))$. Thus, the function $\sigma(t)$ defined in (2.22) is finite and positive. Divide (2.25) by $w(t)^T\phi(t)$ and manipulate the resulting equation as follows:

$$\begin{aligned} 1 =& \sigma(t) + \frac{\Delta(t)+\Phi\operatorname{sgn}(\epsilon_d(t))}{\epsilon_d(t)}\sigma(t), \\ 1 =& \left(1+\frac{\Delta(t)\operatorname{sgn}(\epsilon_d(t))+\Phi\operatorname{sgn}^2(\epsilon_d(t))}{\epsilon_d(t)\operatorname{sgn}(\epsilon_d(t))}\right)\sigma(t), \\ 1 =& \left(1+\frac{\Phi+\Delta(t)\operatorname{sgn}(\epsilon_d(t))}{|\epsilon_d(t)|}\right)\sigma(t).\end{aligned}$$

Using the last equation and the inequality $\Phi \geq |\Delta(t)|$, we easily get (2.23). Inequality (2.24) is a direct consequence of the fact that the term on the right-hand side in (2.23) decreases with decreasing $|\epsilon_d|$. □

As long as we are working with a time interval, starting at $t = 0$, during which $\epsilon_d \neq 0$, we may change the time variable to

$$\tau = \int_0^t \sigma(s)ds. \tag{2.26}$$

The next lemma addresses the persistency of excitation for the regressor vector $w(t(\tau))$.

LEMMA 2.4. *Let $w(t)$ be persistently exciting, so that* (2.3) *holds, and let α_1, α_2, and δ be as in* (2.3). *If $t(\tau_0+\delta)$ is in a time interval $[0, t_\kappa]$ during which $|\epsilon_d(t)| \geq \Phi/\kappa$, then $w(t(\tau))$ satisfies*

$$\underbrace{(2\kappa+1)^{-1}\alpha_1}_{\alpha_1'} \|c\|^2 \leq \int_{\tau_0}^{\tau_0+\delta} |w(t(\tau'))^T c|^2 d\tau' \leq \underbrace{(2\kappa+1)\alpha_2}_{\alpha_2'} \|c\|^2. \tag{2.27}$$

Proof. Suppose that $t_0 \leq t_1 \leq t_\kappa$. Making the change of variables $\tau \longrightarrow t$ in the integral $\int_{\tau_0}^{\tau_1} |w(t(\tau'))^T c|^2 d\tau'$ and using (2.24) in the resulting integral yields

$$(2\kappa+1)^{-1} \int_{t_0}^{t_1} |w(t)^T c|^2 dt \leq \int_{\tau(t_0)}^{\tau(t_1)} |w(t(\tau'))^T c|^2 d\tau' \leq \int_{t_0}^{t_1} |w(t)^T c|^2 dt. \tag{2.28}$$

On the other hand, from (2.24) and (2.26), we see that

$$\frac{1}{2\kappa+1}(t_1 - t_0) \leq \tau(t_1) - \tau(t_0) = \int_{t_0}^{t_1} \sigma(s)ds \leq t_1 - t_0,$$

and so

$$\tau(t_1) - \tau(t_0) \leq t_1 - t_0 \leq (2\kappa+1)(\tau(t_1) - \tau(t_0)). \tag{2.29}$$

Note that the last equation implies that if $\tau(t_1) - \tau(t_0) = \delta$, then

$$\delta \leq t_1 - t_0 \leq (2\kappa+1)\delta.$$

The desired inequality (2.27) is a straightforward consequence of the last inequality, (2.28), and (2.3). □

If we make the change $t \longrightarrow \tau$ in the evolution equation (2.10), then we get a new evolution equation,

$$\frac{d\phi}{d\tau} = -\eta w(t(\tau))w(t(\tau))^T \phi, \tag{2.30}$$

which is prototypical of equations that are guaranteed to be exponentially stable with exponential decay in the norm of the parameter error vector, provided the regressor vector is persistently excited [25, p. 75]. In the case we are dealing with here, equation (2.30) is only valid for τ's that are bounded by $\tau_\kappa = \int_0^{t_\kappa} \sigma(t)dt$. If this is taken into account, one easily sees that the analysis given in [25, §2.5] applies as long as δ is less than τ_κ. More precisely, we have the following result.

PROPOSITION 2.5. *Let α_1, α_2, and δ be as in (2.3), and let t_κ be as in Lemma 2.4. If $\delta < \int_0^{t_\kappa} |\epsilon_d(s)|(|\epsilon_d(s)| + \Phi)^{-1} ds$, then for all $t \leq t_k$ the norm of the parameter error vector $\phi(t)$ satisfies*

$$\|\phi(t)\| \leq \exp\left\{-\alpha_\kappa \left(\int_0^t \frac{|\epsilon_d(s)|}{|\epsilon_d(s)| + \Phi} ds - \delta\right)\right\} \|\phi(0)\|. \tag{2.31}$$

The rate α_κ is given by

$$\alpha_\kappa = \frac{1}{2\delta} \ln \left[\frac{1}{1 - \dfrac{2\eta(2\kappa+1)^{-1}\alpha_1}{(1+\sqrt{s}\,\eta(2\kappa+1)\alpha_2)^2}}\right]. \tag{2.32}$$

Proof. If $\delta < \int_0^{t_\kappa} |\epsilon_d(s)|(|\epsilon_d(s)|+\Phi)^{-1} ds$, then (2.23) implies $\delta < \int_0^{t_\kappa} \sigma(s) ds =: \tau_k$. The argument used to prove [25, Thm. 2.5.3, p. 75] applies to the evolution equation (2.30), provided that $\tau < \tau_\kappa$. Combining [25, Thm. 1.5.2, p. 33] with [25, Thm. 2.5.3, p. 75], with the constants α_1 and α_2 in [25, Eq. 2.5.12] replaced by α_1' and α_2' from Lemma 2.4, yields

$$\|\phi(t(\tau))\| \leq \exp\{-\alpha_\kappa(\tau - \delta)\}\|\phi(0)\|. \tag{2.33}$$

The inequality in (2.31) follows from (2.23) and the definition of $\tau(t)$ given in (2.26). □

In closing our discussion of the gradient-descent/dead-zone algorithm, we wish to point out that, in the discrete case, a similar algorithm was analyzed by N. Sadegh [21], who also obtained an exponential rate of convergence for the associated parameters when the regressor vector is persistently exciting.

One unique feature of the identification algorithms presented above is the central role played by the persistency of excitation of the regressor vector. We now turn to an analysis of conditions sufficient to guarantee persistency of excitation when the basis $\mathfrak{W}$ used to construct the regressor vector w consists of RBFs centered at (possibly) scattered sites.

3. Sufficient conditions for persistency of excitation. We begin by stating a slightly broadened version of the definition of persistency of excitation, one that encompasses the discrete and continuous cases employed in the algorithms analyzed above. Let μ be a positive, Σ-finite Borel measure on $[0,\infty)$. We will say that a continuous, vector-valued function $w : [0,\infty) \longrightarrow \mathbb{R}^N$ is *persistently exciting* [25, p. 72] if there exist positive constants δ, α_1, and α_2 such that

$$\alpha_2\|c\|^2 \geq \int_{t_0}^{t_0+\delta} |w(\tau)^T c|^2 d\mu(\tau) \geq \alpha_1\|c\|^2$$

holds for every $t_0 \geq 0$ and every constant column vector $c = (c_1 \cdots c_N)^T \in \mathbb{R}^N$.

When RBFs are employed in solving the identification problem described in §2, the vector $w(t)$ has the form

$$w(t) = (F(\|x(t) - \xi_1\|) \cdots F(\|x(t) - \xi_N\|))^T, \tag{3.1}$$

where F is the RBF, each ξ_i is a given point in state space, termed a center, and $x(t)$ is the target trajectory. The function $x(t)$ is a continuous map from $[0,\infty)$ into $\mathbb{R}^s$, the state space. Furthermore, we assume that $x(t)$ remains in a bounded subset of $\mathbb{R}^s$. The N centers $\xi_1,\ldots,\xi_N$ are distinct points in $\mathbb{R}^s$. We wish to show that a sufficient condition for w of the form (3.1) to be persistently exciting amounts to an "ergodic" condition on $x(t)$, which we will precisely state in Theorem 3.5 below. We begin by proving three lemmas.

LEMMA 3.1. *Let $c \in \mathbb{R}^N$ and let $x \in \mathbb{R}^s$ be fixed. If $F(r)$ is an order-0 RBF of the form (1.1) or an order-1 RBF of the form (1.2), then*

$$\left|\sum_{j=1}^{N} F(\|x-\xi_j\|)c_j\right|^2 \le \left(\sum_{j=1}^{N} F(\|x-\xi_j\|)^2\right)\|c\|^2 \le \begin{cases} F(0)^2N\|c\|^2 & \text{for order } 0,\\ F(R)^2N\|c\|^2 & \text{for order } 1,\end{cases}$$

where in the order-1 case R is any number larger than the diameter of the set $\{x,\xi_1,\ldots,\xi_N\}$.

Proof. The proof of either inequality begins with an application of Schwarz's inequality. The top inequality then follows from the fact that an order-0 RBF attains its maximum at $r = 0$, and the bottom from the fact that an order-1 RBF is an increasing function of r. □

Remark 3.2. For many different order-0 RBFs, including the Gaussians, bounds not involving N are available. See Corollary 4.2 in §4 below.

LEMMA 3.3. *Let $x_i \in \mathbb{R}^s$ for $i = 1,\ldots,N$. If F is an RBF of the form (1.1) or (1.2), and if*

$$A = A(x_1,\ldots,x_N) = \begin{pmatrix} F(\|x_1-\xi_1\|) & \cdots & F(\|x_1-\xi_N\|)\\ \vdots & \ddots & \vdots\\ F(\|x_N-\xi_1\|) & \cdots & F(\|x_N-\xi_N\|)\end{pmatrix},$$

then there exists a number $\epsilon > 0$ and a number $\theta = \theta(\epsilon,\xi_1,\ldots,\xi_N) > 0$ such that

$$\|Ac\| \ge \theta\|c\|$$

for all $c \in \mathbb{R}^N$ and for every set of x_i's that satisfy $|x_i - \xi_i| \le \epsilon$ for $i = 1,\ldots,N$.

Proof. It is clear that θ^2 is a lower estimate for the smallest eigenvalue $\lambda(x_1,\ldots,x_N)$ of $A(x_1,\ldots,x_N)^T A(x_1,\ldots,x_N)$, whose components are obviously real, continuous functions of the x_i's. One can easily modify a theorem of Rellich [20, p. 40] to show that λ is also a continuous function of the x_i's. Moreover, $\lambda(\xi_1,\ldots,\xi_N) > 0$, because $A(\xi_1,\ldots,\xi_N)$ is invertible [12], [10], [26]. One may therefore choose $\epsilon > 0$ so that

$$\lambda(x_1,\ldots,x_N) > \frac{1}{2}\lambda(\xi_1,\ldots,\xi_N) > 0$$

whenever $|x_i - \xi_i| \le \epsilon$, $i = 1,\ldots,N$. Choosing $\theta = \sqrt{\frac{1}{2}\lambda(\xi_1,\ldots,\xi_N)}$ completes the proof. □

The lemma above is certainly not the best possible, because no estimates on the size of θ are given. In the next section, we shall discuss precise estimates for θ as a function of ϵ and the ξ_i's. For present purposes, this is not necessary.

We point out that if some choice of $\epsilon > 0$ works in Lemma 3.3, every smaller one will work as well. For purposes of the next lemma, we restrict our choice of ϵ so that

$$0 < \epsilon < q := \frac{1}{2} \min_{i \neq j} \|\xi_i - \xi_j\|. \tag{3.2}$$

Our next lemma is crucial to the proof of the main result.

LEMMA 3.4. *Let I be a bounded, μ-measurable subset of $[0,\infty)$, and also let the sets I_i be defined by*

$$I_i = \{t \in I \, : \, \|x(t) - \xi_i\| \leq \epsilon\} \quad \text{with } i = 1, \dots, N,$$

where ϵ is as in (3.2). If $\mu(I_i) \geq \tau_0$ for $i = 1, \dots, N$, then with $\theta > 0$ as in Lemma 3.3,

$$\int_I |w(\tau)^T c|^2 d\mu(\tau) \geq \tau_0 \theta^2 \|c\|^2 \tag{3.3}$$

holds for every constant column vector $c = (c_1 \cdots c_N)^T \in \mathbb{R}^N$.

Proof. The sets I_i are disjoint, because with $\epsilon < q = \frac{1}{2}\min_{i \neq j} \|\xi_i - \xi_j\|$ the balls with center ξ_i and radius ϵ are nonintersecting. Clearly, we thus have that

$$\int_I |w(\tau)^T c|^2 d\mu(\tau) \geq \sum_{i=1}^N \int_{I_i} |w(\tau)^T c|^2 d\mu(\tau). \tag{3.4}$$

Since we have that

$$|w(\tau)^T c|^2 = \left| \sum_{j=1}^N F(\|x(\tau) - \xi_j\|) c_j \right|^2,$$

and since $\tau \in I_i$ implies that $\|x(\tau) - \xi_i\| \leq \epsilon$, we immediately obtain the inequality

$$\begin{aligned} &\max_{|x - \xi_i| \leq \epsilon} \left\{ \left| \sum_{j=1}^N F(\|x - \xi_j\|) c_j \right|^2 \right\} \int_{I_i} d\mu(\tau) \\ &\geq \int_{I_i} |w(\tau)^T c|^2 d\mu(\tau) \geq \min_{|x - \xi_i| \leq \epsilon} \left\{ \left| \sum_{j=1}^N F(\|x - \xi_j\|) c_j \right|^2 \right\} \int_{I_i} d\mu(\tau), \end{aligned}$$

where the maximum and minimum are taken over all x in the ball $\|x - \xi_i\| \leq \epsilon$. The inequality above and the continuity of $|\sum_{j=1}^N F(\|x - \xi_j\|) c_j|^2$ over this compact and connected ball allow application of the intermediate value theorem, from which we may deduce that there exist vectors $x_i \in \mathbb{R}^n$ such that $\|x_i - \xi_i\| \leq \epsilon$ and

$$\int_{I_i} |w(\tau)^T c|^2 \, d\mu(\tau) = \left| \sum_{j=1}^N F(\|x_i - \xi_j\|) c_j \right|^2 \mu(I_i).$$

By assumption, $\mu(I_i) \geq \tau_0$ for $i = 1, \dots, N$, so

$$\int_{I_i} |w(\tau)^T c|^2 \, d\mu(\tau) \geq \left| \sum_{j=1}^N F(\|x_i - \xi_j\|) c_j \right|^2 \tau_0.$$

Inequality (3.4) and the last inequality imply that

$$\int_I |w(\tau)^T c|^2 \, d\mu(\tau) \geq \|Ac\|^2 \tau_0, \tag{3.5}$$

where A is an $N \times N$ matrix with i-j entry $A_{ij} = F(\|x_i - \xi_j\|)$. From the fact that $\|x_i - \xi_i\| \leq \epsilon$, where ϵ has been chosen to satisfy the conditions of Lemma 3.3, and from Lemma 3.3 itself, we have that

$$\|Ac\|^2 \geq \theta^2 \|c\|^2, \tag{3.6}$$

where θ depends upon ϵ and the ξ_i's, but not on the x_i's or c. Using (3.6) to replace the right-hand side of (3.5) yields the desired inequality, (3.3). □

THEOREM 3.5. *Let ϵ be as in Lemma* 3.3, *subject to restriction* (3.2). *In addition, for every $t_0 \geq 0$ and every $\delta > 0$, let*

$$I_i = \{t \in [t_0, t_0 + \delta] \, : \, \|x(t) - \xi_i\| \leq \epsilon\}.$$

If there exists a δ such that $\mu(I_i)$ is bounded below by a positive constant that is independent of t_0 and i, and if $\mu([t_0, t_0 + \delta]) \leq \delta$, then $w(t)$ is persistently exciting.

Proof of Theorem 3.5. Take the interval $I = [t_0, t_0 + \delta]$, and choose ϵ as in (3.2) and Lemma 3.3. By the hypotheses of the theorem, the sets I_i satisfy $\mu(I_i) \geq \tau_0 > 0$, where τ_0 depends upon $\delta, \epsilon, \xi_1, \ldots, \xi_N$, but does not depend on t_0 or i. Consequently, we may apply Lemma 3.3 to get

$$\int_{t_0}^{t_0+\delta} |w(\tau)^T c|^2 \, d\mu(\tau) \geq \alpha_1 \|c\|^2 \quad \text{with } \alpha_1 = \theta^2 \tau_0. \tag{3.7}$$

On the other hand, Lemma 3.1 implies that

$$\int_{t_0}^{t_0+\delta} |w(\tau)^T c|^2 d\mu(\tau) \leq \alpha_2 \|c\|^2 \quad \text{with } \alpha_2 = \begin{cases} F(0)^2 \delta N & \text{for order 0,} \\ F(R)^2 \delta N & \text{for order 1.} \end{cases} \tag{3.8}$$

Here, R is the diameter of the set $\{x(t) \, : \, t \in [0, \infty)\} \cup \{\xi_1, \ldots, \xi_N\}$. (This is a finite number, because the trajectory $x(t)$ is bounded.) Since both α_1 and α_2 are independent of t_0, $w(t)$ is persistently exciting. □

As we mentioned in §1, for the regressor vector to be persistently exciting, Theorem 3.5 requires a kind of ergodic condition. We wish to briefly discuss some consequences of Theorem 3.5 for the continuous and discrete algorithms mentioned in §2.

Continuous algorithms. The theorem essentially requires that in each time interval $[t_0, t_0 + \delta]$, the vector $x(t)$ must visit a sufficiently small ϵ-ball about each ξ_i for a minimum amount of time that is independent of t_0. As a simple example of how these conditions might be met, suppose that $x(t)$ is periodic with period T, and μ is the Lebesgue measure. If in the time interval $[0, T]$ the trajectory $x(t)$ stays within a distance ϵ of each center ξ_i for an amount of time that is at least $\tau_0 > 0$, then $w(t)$ is persistently exciting.

Discrete algorithms and neural networks. The theory derived above yields a strengthened version of certain results of Sanner and Slotine [23] concerning the persistency of excitation of the sequence of hidden layer outputs of a neural network.

The regressor vector $w(\tau)$ defined in (3.1) is called $g(\tau)$ in [23]; the function $F(\|x(\tau) - \xi_j\|)$ represents the jth hidden layer node. In [23], it was shown that by choosing the input function $x : [0, \infty) \to \mathbb{R}^s$ so that for any integer t, $\{x(\tau)\}_{\tau=t}^{\tau=N+t-1} = \{\xi_j\}_1^N$ (equality of sets), the corresponding sequence of hidden layer outputs will be persistently exciting.

To extend these results, first recall that the Hausdorff distance between two compact sets A and B in $\mathbb{R}^s$ is given by

$$d(A, B) = \max_{x \in A, y \in B} \{\operatorname{dist}(x, B),\ \operatorname{dist}(y, A)\},$$

where $\operatorname{dist}(x, B) = \inf_{z \in B} \|x - z\|$. Suppose that the sequence of network inputs satisfies an ergodic condition, namely, the input function $x(\tau)$ should have the property that for any integer t,

$$d(\{x(\tau)\}_{\tau=t}^{\tau=t+N-1}, \{\xi_j\}_1^N) < \epsilon.$$

Using Theorem 3.5 and taking the ϵ there to be the one used in the inequality above, one obtains that the system is still persistently exciting.

4. Estimates on parameters. What the identification algorithms discussed in §2 converge to, and at what rate they converge, depend quantitatively on the parameters δ, α_1, and α_2 that appear in the inequality defining persistency of excitation, (2.3), and indirectly on τ_0 from Lemma 3.4. The parameter δ is a "recurrence time." τ_0 represents the minimum time spent in an ϵ-ball about each of the centers, and is dependent on the system one is working with. On the other hand, from the proof of Theorem 3.5, one sees that the two ratios α_1/τ_0 and α_2/δ are independent of the behavior of $x(t)$; indeed, using the best bounds one can get from Lemmas 3.1–3.4, they have the following form:

$$\frac{\alpha_1}{\tau_0} = \theta(\epsilon, \xi_1, \dots, \xi_N)^2, \tag{4.1}$$

$$\frac{\alpha_2}{\delta} = \sup_{x \in \Omega} \left(\sum_{j=1}^{N} F(\|x - \xi_j\|)^2 \right). \tag{4.2}$$

In this section, we wish to estimate these ratios.

Let us begin with the problem of estimating α_1/τ_0. This problem hinges on the problem mentioned after Lemma 3.3—estimating θ as a function of ϵ and the ξ_i's. Fortunately, this problem was treated in detail in [27]. Since the technicalities involved in it are formidable, we will confine our discussion to the case of Gaussian RBFs,

$$F_\rho(r) = e^{-\rho r^2}, \tag{4.3}$$

where $\rho > 0$ is a parameter that classifies the choice of Gaussian. Concerning these RBFs, the following result holds.

THEOREM 4.1. *Let $\rho > 0$ be fixed, and let s and q be as in* §3; *set $z = \rho q^2$. For the Gaussian* RBF *F_ρ given in* (4.3), *we may take as a lower bound in Lemma* 3.3

$$\theta = \frac{1}{2} C_s z^{-s/2} e^{-\sigma^2/z}, \tag{4.4}$$

where C_s and σ are constants given by

$$\sigma := 12 \left(\frac{\pi \Gamma^2(\frac{s+2}{2})}{9} \right)^{1/(s+1)} \quad \textit{and} \quad C_s := \frac{\sigma^s}{2^{s+1} \Gamma(\frac{s+2}{2})},$$

provided $\epsilon > 0$ *in Lemma* 3.3 *is chosen to satisfy*

$$\epsilon \le \min\left\{q, \frac{q}{2}\frac{C_s e^{-\sigma^2/z}}{z^{1+s/2}}[1+6sf_s(z)]\right\}, \quad \text{where } f_s(z) := \sum_{j=0}^{\infty}(j+3)^s e^{-zj^2}. \tag{4.5}$$

Proof. We will adopt the notation used in Lemma 3.3, and we will follow the pattern of proof used to establish similar results in [27]. To begin, split $A(x_1,\dots,x_N)$ into its symmetric and antisymmetric parts, $A = A_{\text{sym}} + A_{\text{anti}}$. If $c \in \mathbb{R}^N$, then, from standard matrix theory, we have $c^TAc = c^TA_{\text{sym}}c$. Applying the Cauchy–Schwarz inequality results in $\|Ac\|\|c\| \ge c^TA_{\text{sym}}c$. Because the entries of A are real, the minimum of $\|Ac\|/\|c\|$ occurs for $c \in \mathbb{R}^N$. Hence, we obtain the inequality

$$\frac{\|A(x_1,\dots,x_N)c\|}{\|c\|} \ge \min_{\|\alpha\|=1} \alpha^T A_{\text{sym}}(x_1,\dots,x_N)\alpha, \tag{4.6}$$

and our task is reduced to estimating the symmetric quadratic form on the right above.

To estimate this quadratic form, write it as

$$\begin{aligned}\alpha^T A_{\text{sym}}(x_1,\dots,x_N)\alpha =&\alpha^T A_{\text{sym}}(\xi_1,\dots,\xi_N)\alpha\\ &+ [\alpha^T A_{\text{sym}}(x_1,\dots,x_N)\alpha - \alpha^T A_{\text{sym}}(\xi_1,\dots,\xi_N)\alpha]\\ =&I_\rho + J_\rho,\end{aligned}$$

where I_ρ and J_ρ denote the obvious quadratic forms, with the many arguments involved suppressed. From Proposition 3.6(iv) in [27], we have that

$$I_\rho \ge C_s\rho^{-s/2}q^{-s}e^{-\sigma^2q^{-2}\rho^{-1}} = C_s z^{-s/2}e^{-\sigma^2/z}.$$

An estimate for $|J_\rho|$ is given in Proposition 3.12 in [27], provided $\epsilon < q$. The estimate in our setting (where the quantity $\|d_0\|$ in [27] is ϵ here, and the incorrect factor π^s appearing in [27] is omitted here) becomes

$$|J_\rho| \le \rho q\epsilon[1+6sf_s(\rho q^2)] = \frac{z\epsilon}{q}[1+6sf_s(z)], \quad \text{where } f_s(z) := \sum_{j=0}^{\infty}(j+3)^s e^{-zj^2}.$$

Putting the various estimates together yields

$$\begin{aligned}\min_{\|\alpha\|=1} \alpha^T A_{\text{sym}}(x_1,\dots,x_N)\alpha &\ge I_\rho - |J_\rho|\\ &\ge C_s z^{-s/2}e^{-\sigma^2/z} - \frac{z\epsilon}{q}[1+6sf_s(z)].\end{aligned}$$

Picking ϵ so that it satisfies (4.5) results in

$$\min_{\|\alpha\|=1} \alpha^T A_{\text{sym}}(x_1,\dots,x_N)\alpha \ge \frac{1}{2}C_s z^{-s/2}e^{-\sigma^2/z}.$$

The theorem then follows on combining our last estimate with (4.6). □

We now turn to estimates for the ratio α_2/δ. When the RBF is a Gaussian F_ρ, the estimate for α_2/δ used in Theorem 3.5 can be made independent of N. To see why, note that from (4.2) it suffices to show that the vector $w_\rho(x) = (F_\rho(x-\xi_1)\cdots F_\rho(x-\xi_N))^T$ has length independent of x and N. Set

$$S_k(x) := \{\xi_j \mid kq \le \|x-\xi_j\| \le (k+1)q\}.$$

Observe that the cardinality of S_k cannot be any more than the ratio of the volume of the spherical shell with radii $(k-1)q$ and $(k+2)q$ to the volume of a sphere of radius q, because $\|\xi_j - \xi_k\| \ge 2q$. It is easy to see that

$$\operatorname{card}(S_k) \le (k+2)^s - (k-1)^s \le 3s(k+2)^{s-1},$$

where the inequality on the right follows from applying the mean value theorem. In addition, we obviously have

$$\bigcup_{k=0}^{\infty} S_k \supset \{\xi_1, \dots, \xi_N\}.$$

Furthermore, note that if $\xi_j \in S_k$, then

$$F_\rho(\|x-\xi_j\|) = e^{-\rho\|x-\xi_j\|^2} \le e^{-\rho(kq)^2}.$$

We thus have
(4.7)

$$\|w_\rho(x)\|^2 = \sum_{j=1}^{N} F_\rho^2(\|x-\xi_j\|) \le \sum_{k=0}^{\infty} \operatorname{card}(S_k) e^{-2\rho q^2 k^2} \le \sum_{k=0}^{\infty} 3s(k+2)^{s-1} e^{-2\rho q^2 k^2},$$

which gives us the following result.

COROLLARY 4.2. *If* $w_\rho(x) = (F_\rho(x-\xi_1)\cdots F_\rho(x-\xi_N))^T$, *then* $\|w_\rho(x)\|^2 \le 3sf_{s-1}(2\rho q^2)$, *where* f_s *is defined in* (4.5), *and the expression for* α_2/δ *in* (3.8) *may be replaced by*

$$\frac{\alpha_2}{\delta} = 3sf_{s-1}(2\rho q^2). \tag{4.8}$$

Proof. In the proof of Theorem 3.5, instead of using Lemma 3.1, use the expression for $\|w_\rho(x)\|^2$ given in (4.7). In addition, note that since $k+2 < k+3$,

$$\sum_{k=0}^{\infty} 3s(k+2)^{s-1} e^{-2\rho q^2 k^2} \le \sum_{k=0}^{\infty} 3s(k+3)^{s-1} e^{-2\rho q^2 k^2}.$$

Replacing the series on right side of this inequality by $f_{s-1}(2\rho q^2)$, where f_s is given in (4.5), completes the proof. □

Remark 4.3. For many order-0 RBFs, one can use Corollary 4.2 to obtain an upper estimate on α_2. To see this, note that from (1.1) and the expression for w_ρ given above, we have

$$w(x) = (\,F(x-\xi_1) \quad \cdots \quad F(x-\xi_N)\,)^T = \int_0^\infty w_\rho(x) d\beta(\rho).$$

Obviously, from Corollary 4.2, we also have

$$\|w(x)\| \le \int_0^\infty \|w_\rho(x)\| d\beta(\rho) \le \int_0^\infty \sqrt{3sf_{s-1}(2\rho q^2)}\, d\beta(\rho),$$

and so we arrive at

$$\alpha_2 \leq \left(\int_0^\infty \sqrt{3sf_{s-1}(2\rho q^2)}\, d\beta(\rho) \right)^2 \delta, \tag{4.9}$$

which will hold whenever the right side above is finite. Similar, somewhat more complicated results can be derived for α_1; we will not state them here.

Acknowledgments. The authors thank B. J. C. Baxter and the referee for helpful suggestions.

MAXIMIZING ROBUSTNESS IN NONLINEAR ILLPOSED INVERSE PROBLEMS*

KAZUFUMI ITO† AND KARL KUNISCH‡

Abstract. A framework for maximizing the robustness of nonlinear illposed inverse problems by choosing appropriate system inputs is presented. This framework is based on maximizing the lowest eigenvalues of the linearized and regularized nonlinear mapping. Stability and sensitivity of the eigenvalues of the linearization are studied. The results are applied to parameter estimation problems for elliptic partial differential equations. Numerical examples illustrating the results are given.

Key words. nonlinear illposed inverse problems, optimal input, sensitivity measures, regularization

AMS subject classifications. 49B40, 35R25

1. Introduction.

Let Φ_f be a family of nonlinear mappings from a subset of a Hilbert space X into a Hilbert space Y. The problem under investigation in this paper is the choice of an optimal f such that the inversion of Φ_f becomes as stable as possible. The mapping $a \to \Phi_f(a)$ can typically arise as the solution mapping for a partial differential equation with a representing a coefficient or an inhomogeneity of the differential equation. The functional parameter f represents a design parameter that is chosen from a class of admissible input functions. We then study a problem of optimal experimental design: Which is the best choice for the input f for the reconstruction of the coefficient a given knowledge of $\Phi_f(a)$, the state of the differential equation.

A criterion for the selection of the optimal parameter f must be specified. Here we proceed as follows. Let $\Phi'_f(a)$ be the linearization of Φ_f at some reference point $a \in X$; and consider

$$\sup_{f \in \mathcal{F}} \inf_{\substack{h \in V \\ h \neq 0}} \frac{|\Phi'_f(a)h|_Y^2}{|h|_X^2}, \tag{1.1}$$

where $V \subset X$ is a Hilbert space continuously embedded in X. Thus we propose to maximize the lowest singular value of $\Phi'_f(a)$ (considered as unbounded operator between X and Y) as f varies in F. The saddle point problem (1.1) is the focus of attention in this paper.

Let us turn to the infimum problem

$$\inf_{\substack{h \in V \\ h \neq 0}} \frac{|\Phi'_f(a)h|_Y^2}{|h|_X^2} \tag{1.2}$$

in (1.1). Since the focuses of attention are mappings Φ_f that are illposed in the sense of lack of continuous invertibility, one has to guard against the infimum being zero for all $f \in \mathcal{F}$. First, of course, this requires injectivity of $\Phi'_f(a)$ for at least one $f \in \mathcal{F}$.

Second, for (1.2) to be nonzero an estimate of the type

$$(1.3)\qquad |\Phi'_f(a)h|_Y \geq k_f |h|_X, \quad \text{for all } h \in V,$$

is necessary with k_f a positive constant, possibly depending on f. For illposed problems (1.3) is not feasible and the infimum in (1.2), while it may not be attained, will be zero. To overcome this difficulty we need to change the problem formulation in such a way that an estimate of the type (1.3) holds while simultaneously the underlying structure of the inverse problem remains as unchanged as possible.

To be specific, let us consider the problem of estimating the functional coefficient a in

$$(1.4)\qquad \begin{cases} -\text{div}(a \text{ grad } u) &= f \quad \text{in } \Omega, \\ u|\partial\Omega &= 0 \end{cases}$$

given knowledge of $u(a)$, where Ω is a bounded domain in $\mathbf{R}^n, n = 1, 2,$ or 3. In this case $\Phi_f(a) = u(a)$ and the linearization of Φ_f is given by

$$\Phi'_f(a)h = A^{-1} \text{ div}(h \text{ grad } u(a)),$$

where $A(a) : H_0^1(\Omega) \to H^{-1}(\Omega)$ is defined by $A(a)u = -\text{div}(a \text{ grad } u), a(x) \geq \nu > 0$. For the choice $X = Y = L^2(\Omega)$ an estimate of the type (1.3) is impossible. If X and Y are chosen as $L^2(\Omega)$ and $H^1(\Omega)$ respectively and if f satisfies additional assumptions, then for every $K > 0$ there exists $k_f > 0$ such that

$$(1.5)\qquad |\Phi'_f(a)h|_{H^1} \geq k_f |h|^2_{L^2} \quad \text{for all } h \in L^2(\Omega), \text{ with } |h|_{H^1} \leq K$$

[IK1]. While this estimate does not give (1.3) with X, Y replaced by $L^2(\Omega)$ and $H^1(\Omega)$, it indicates what can be achieved by changing the norm in image and preimage space. In passing let us note that in the one-dimensional case (1.5) holds with the constraint $|h|_{H^1} \leq K$ replaced by the assumption that h lies in a subspace of L^2 with codimension 1. To obtain an estimate of the type (1.3) we need to make an additional change in the problem formulation by using a regularization term.

Returning to the general formulation, (1.2) is replaced by

$$(1.6)\qquad \inf_{h\neq 0} \frac{|\Phi'_f(a)h|^2_Y + \beta\tilde{\sigma}(h,h)}{|h|^2_X}$$

where $\tilde{\sigma}$ is a nonnegative Hermitian form on $V \times V$ and β is a small, positive parameter. The original saddle point problem becomes

$$(1.7)\qquad \sup_{f\in\mathcal{F}} \inf_{h\neq 0} \frac{|\Phi'_f(a)h|^2_Y + \beta\tilde{\sigma}(h,h)}{|h|^2_X}.$$

We can now describe our proposal to solve the optimal design problem stated at the beginning of this section: First, find a problem formulation by restricting the class of design functions $\mathcal{F}$ and by appropriate choice of norms for the preimage and the image spaces X and Y of $\Phi'_f(a)$ to make this linearized problem as "well posed as possible." Second, use regularization, if necessary.

Let us turn to (1.7). First, this is a difficult saddle point problem for which questions of existence and differentiability of the infimum problem with respect to f need to be studied. This will be the focus of the present paper. Second, if regularization is used, the question arises whether the infimum is still sufficiently sensitive with respect to different choices of $f \in \mathcal{F}$. We have no analysis to answer this question, but numerical experiments with specific problems suggest a positive answer. Finally, in view of the fact that the mapping Φ_f can be nonlinear, (1.7) is not satisfactory in as far as it requires linearization about a reference parameter, which in practice must be chosen as good approximation to a^*, the unknown preimage of $\Phi_f(a^*)$ and updated by an appropriate iterative procedure.

Let us also mention that this paper is a continuation of our work on optimal design for inverse problems, with the first paper [IK2] focusing on the one-dimensional version of (1.4). By allowing only a restrictive class of inputs $\mathcal{F}$, the analysis of [IK2] does not necessitate the use of a regularization term and the infimum problem can be solved explicitly in specific situations, thus allowing a rather detailed analysis of (1.7) with $\beta = 0$.

While in our analysis we have chosen the lowest singular value of Φ'_f as a measure for distinguishing the behaviour of the inverse of Φ_f as f varies, other criteria may also be of interest. One of them would be the trace of a discretization of $\mathcal{T} = (\Phi'_f(a))^* \Phi'_f(a)$ or the sum of the eigenvalues of $\mathcal{T}$. Different choices will lead to different optimal inputs f. This can be seen, for example, from numerical experiments, where in some cases we calculated the complete spectrum of a discretization of $\mathcal{T}$. Minimizing the lowest singular value represents a conservative measure (robustness). For parameter estimation problems such as (1.4) it requires that the reconstruction of a^* from $u(a^*)$ is uniformly "as well posed as possible" throughout the domain Ω.

The paper is organized in the following way. Section 2 contains a study of the saddle point problem (1.7). In §3 we apply these results to the problem of determining a from $u(a)$, with u the solution of (1.4). Numerical results are given in §4.

2. The general framework. Let V and X be Hilbert spaces with V densely and compactly imbedded in X, such that

$$V \subset X \subset V^*$$

forms a Gelfand triple, with V^* denoting the antidual of V. The norm and the inner product on V are denoted by $\| \cdot \|$ and $\langle\langle \cdot, \cdot \rangle\rangle$ and similarly those on X by $| \cdot |$ and $\langle \cdot, \cdot \rangle$. Further for a bounded linear operator T from V into a Hilbert space Y, we shall write $T \in \mathcal{L}(V, Y)$. By $\sigma(\cdot, \cdot)$ we denote a continuous Hermitian form on $V \times V$. In particular $\sigma(x, y) = \overline{\sigma(y, x)}$ and there exist a constant $c > 0$ such that

$$|\sigma(x, y)| \leq c \, \| x \| \, \| y \| \, .$$

This implies the existence of an operator $\mathcal{N} \in \mathcal{L}(V, V^*)$ with

$$\sigma(x, y) = \langle \mathcal{N} x, y \rangle_{V^*, V} \quad \text{for all } x \text{ and } y \in V,$$

where $\langle \cdot, \cdot \rangle_{V^*, V}$ denotes the antiduality between V^* and V. Since $T \in \mathcal{L}(V, Y)$, it defines a continuous Hermitian form on $V \times V$ via $(x, y) \to \langle Tx, Ty \rangle_Y$.

The operator $\mathcal{T} \in \mathcal{L}(V, V^*)$ representing this form satisfies

$$\langle Tx, Ty \rangle_Y = \langle \mathcal{T} x, y \rangle_{V^*, V} \quad \text{for } x \text{ and } y \in V$$

and is given by $\mathcal{T} = T^* T$, where $T^* \in \mathcal{L}(Y, V^*)$ denotes the adjoint of T. We are now prepared to introduce the Hermitian form $a : V \times V \to C$, which will be the focus of this section. It is defined by

$$a(x, y) = \langle Tx, Ty \rangle_Y + \sigma(x, y),$$

and it will be assumed that

(H1) There exists $\mu > 0$ such that $a(x,x) = |Tx|_Y^2 + \sigma(x,x) \geq \mu \parallel x \parallel^2$ for all $x \in V$.

In the context of the introduction the present formalism will be used with $\mathcal{T} = \Phi'_f(a)$ and with the regularization term given by $\beta\tilde{\sigma}(x,x) = \sigma(x,x)$. Neither $\mathcal{T}$ nor σ separately are assumed to be coercive. Condition (H1) requires strict coercivity of their sum. For $(x,y) \in V \times V$ we have

$$a(x,y) = \langle(\mathcal{T} + \mathcal{N})x, y\rangle_{V^*,V},$$

and by the Lax-Milgram theorem $A := \mathcal{T} + \mathcal{N}$ is an isomorphism of V onto V^*. In the usual way [DL, II p. 369 and III p. 39], A can be considered a closed linear selfadjoint operator in X with domain $D_A = \{x \in X : Ax \in X\} = \{x \in V : y \to a(x,y)$ with $y \in V$, is continuous form X to $C\}$. Alternatively, a can be treated as a densely defined Hermitian closed form in $X \times X$.

Example. As an example for the above formalism we may consider the special case $X = Y = H^0(\Omega)$, $V = H^1(\Omega)$,

$$\sigma(x,y) = \langle\nabla x, \nabla y\rangle_{H^0},$$

where H^i denotes the Sobolev space of order i. If $T \in \mathcal{L}(H^1(\Omega), H^0(\Omega))$ satisfies

$$|Tx|_{H^0} \geq \bar{\mu}|x|_{H^0} \quad \text{for some } \bar{\mu} > 0 \text{ and all } x \in H^1(\Omega)$$

(or if only $|T1|_{L^2} \geq \bar{\mu}$ with 1 the constant function with value 1), then (H1) holds.

LEMMA 2.1. *Let* (H1) *hold. Then the spectrum of the operator A is point spectrum $\sigma_p(A)$ with real eigenvalues λ^i satisfying*

$$0 < \mu \leq \lambda^1 \leq \lambda^2 \leq \cdots,$$

and no finite point of accumulation. The eigenvectors x^n, normalized in X and associated with λ^n, satisfy

$$a(x^n, v) = \lambda^n\langle x^n, v\rangle \quad \textit{for all } v \in V.$$

The eigenvectors form an orthonormal basis for X. For a proof see [DL, III p. 39].

We next introduce a family of operators A_f, and we investigate continuity and differentiability results of their spectrum.

Let $\mathcal{F}$ be a metric space with metric ρ, and for each $f \in \mathcal{F}$ let $T_f \in \mathcal{L}(V,Y)$. Assume that

(H1*) There exists $\mu > 0$ such that $a_f(x,x) = |T_f(x)|_Y^2 + \sigma(x,x) \geq \mu \parallel x \parallel^2$ for all $x \in V$ and $f \in \mathcal{F}$.

We introduce the notation $A_f = T_f^* T_f + \mathcal{N} \in \mathcal{L}(V, V^*)$ and

$$a_f(x,y) = \langle T_f x, T_f y\rangle + \sigma(x,y).$$

Henceforth let $f_0 \in \mathcal{F}$, let $\{f_k\}_{k=1}^{\infty}$ be a sequence in $\mathcal{F}$ with $\lim_{k\to\infty} \rho(f_k, f_0) = 0$, let λ_k^n, x_k^n be the eigenvalues and eigenfunctions of A_{f_k} enumerated as in Lemma 2.1, and similarly let λ_0^n, x_0^n be the eigenvalues and eigenfuctions of A_{f_0}.

By P_k^n we denote the orthogonal (in X) projection from X into the eigenspace M_k^n associated with the eigenvalue λ_k^n. We shall require the following condition:

(H2) $\lim_{k\to\infty} T_{f_k} = T_{f_0}$ in $\mathcal{L}(V,Y)$.

PROPOSITION 2.2. *Let* $\lim_{k\to\infty} \rho(f_k, f_0) = 0$, *and let* (H1*) *and* (H2) *hold. Then*

(i) $\lim_{k\to\infty} \lambda_k^n = \lambda_0^n$ *for every* $n = 1, 2, \ldots.$
(ii) $\lim_{k\to\infty} P_k^n = P_0^n$ *in* $\mathcal{L}(X)$ *for every* $n = 1, 2, \ldots.$
(iii) $\dim M_k^n = \dim M_0^n$ *for every* $k = k(n)$ *sufficiently large and* $n = 1, 2, \ldots.$
(iv) *If* $\dim M_0^n$, *then*

$$\lim_{k\to\infty} x_k^n = x_0^n \quad \text{in } V,$$

where $x_k^n \in M_k^n$ *are eigenfunctions of* A_k^n *for the eigenvalue* λ_k^n *normalized by* $\langle x_0^n, x_k^n\rangle = 1$.

For the proof we refer to results in [K]; see also [C]. Specifically, the densely defined closed symmetric forms a_{f_k} are relatively bounded with respect to the form a_{f_0}. It follows that A_{f_k} converges in X to A_{f_0} in the generalized sense and any finite system of eigenvalues of A_{f_0} is stable [K, pp. 202, 212, 338–340]. In particular this implies (i)–(iii). Next assume that the multiplicity of the eigenvalue λ_0^n is 1. Then $\dim M_k^n = 1$ and $x_k^n = \alpha_k^{-1} P_k^n x_0^n$ for all k sufficiently large, where $\alpha_k = \langle P_k^n x_0^n, x_0^n\rangle$. Since $\lim_{k\to\infty} P_k^n x_0^n = x_0^n$ in X, it follows that $\lim_{k\to\infty} \alpha_k = 1$. We find

$$\lim_{k\to\infty} |x_k^n - x_0^n| = \lim_{k\to\infty} \left|\frac{1-\alpha_k}{\alpha_k} P_k^n x_0^n\right| + \lim_{k\to\infty} |P_k^n x_0^n - x_0^n| = 0$$

and thus $\lim_{k\to\infty} x_k^n = x_0^n$ in X. To show the final assertion of the theorem note that

$$a_{f_k}(x_k^n, x_k^n) = \lambda_k^n \langle x_k^n, x_k^n\rangle. \tag{2.1}$$

Due to (H1*) and (2.1) it follows that $\{x_k^n\}_{k=1}^{\infty}$ is bounded in V. Moreover, taking the limit in (2.1) and by (H2)

$$\begin{aligned}|a_{f_0}(x_0^n, x_0^n) - a_{f_0}(x_k^n, x_k^n)| \le & |a_{f_0}(x_0^n, x_0^n) - a_{f_k}(x_k^n, x_k^n)| \\ & + |a_{f_k}(x_k^n, x_k^n) - a_{f_0}(x_k^n, x_k^n)| \to 0 \quad \text{as } k \to \infty.\end{aligned}$$

Consequently $a_{f_0}(x_k^n, x_k^n) \to a_{f_0}(x_0^n, x_0^n)$ and $x_k^n \to x_0^n$ weakly in V as $k \to \infty$. Since $\sqrt{a_{f_0}(\cdot,\cdot)}$ defines an equivalent norm on V, it follows that $\lim_{k\to\infty} x_k^n = x_0^n$ in V.

Strenghtening (H2) to

(H3i) There exist constants K and $\gamma > 0$ such that $\| T_{f_k} - T_{f_0} \|_{\mathcal{L}(V,Y)} \le K\rho(f_k, f_0)^\gamma$, respectively,

(H3ii) There exist constants K and $\gamma > 0$ such that $|T_{f_k}x - T_{f_0}x|_Y \in K\rho(f_k, f_0)^\gamma |x|_X$ for all $x \in V$, allows us to assert

PROPOSITION 2.3. *Let* $\lim_{k\to\infty} \rho(f_k, f_0) = 0$, *and let* (H1*) *and* (H3i) *hold. Then for every* n *there exists* K_n *such that*

$$\| P_k^n - P_0^n \|_{\mathcal{L}(X)} \le K_n \rho(f_k, f_0)^\gamma$$

and

$$|\lambda_k^n - \lambda_0^n| \le K_n \rho(f_k, f_0)^\gamma.$$

If (H3ii) *holds in place of* (H3i), *then there exists* $\hat{K}$ *independent of* n *such that*

$$|\lambda_k^n - \lambda_0^n| \le \hat{K} \rho(f_k, f_0)^\gamma.$$

For the proof one notes that (H3i) implies the existence of a constant M such that

$$|(a_{f_0} - a_{f_k})(x,x)| \leq M\rho(f_k, f_0)^\gamma \parallel x \parallel^2 \leq \frac{M}{\mu}\rho(f_k, f_0)^\gamma a_0(x,x),$$

for all $x \in V$. The assertion under condition (H3i) then follows from the same results in [K] as cited above. The proof of convergence of the eigenvalues under condition (H3ii) can be based on an argument using the Raleigh quotient representation of eigenvalues or on [K, Thm. V. 4.10]

We turn next to investigating differentiability properties of the lowest eigenvalue–eigenvector pair at a reference value $f_0 \in F$, where F is now assumed to be a normed linear space with norm $|\cdot|_F$. We drop the superscript 1 for the largest eigenvalue–eigenvector pair and assume that the multiplicity of the smallest eigenvalue λ_{f_0} of A_{f_0} is one. Let x_f denote the eigenvectors associated with the lowest eigenvalue λ_f of A_f normalized by

$$\langle x_f, x_{f_0}\rangle = 1, \qquad |x_{f_0}| = 1.$$

For $f \in \mathcal{F}$ we put

$$\mathcal{T}_f = T_f^* T_f \in \mathcal{L}(V, V^*).$$

We shall employ the following hypotheses:

(H2*) The mapping $f \longrightarrow T_f$ from F to $\mathcal{L}(V,Y)$ is continuous at $f_0 \in \mathcal{F}$.

(H4) The mapping $f \longrightarrow \mathcal{T}_f$ from $\mathcal{F}$ into $\mathcal{L}(V,V^*)$ has a Gateaux differential at $f_0 \in \mathcal{F}$ in the direction $f_1 \in F$; i.e., $f_0 + \tau f_1 \in \mathcal{F}$ for $|\tau|$ sufficiently small and there exists $\dot{\mathcal{T}}(f_0, f_1) \in \mathcal{L}(V,V^*)$ such that

$$\dot{\mathcal{T}}(f_0, f_1) = \lim_{\tau \longrightarrow 0} \frac{1}{\tau}[\mathcal{T}_{f_0+\tau f_1} - \mathcal{T}_{f_0}] \quad \text{in } \mathcal{L}(V, V^*).$$

Concerning the terminology of differentiability in infinite-dimensional spaces we follow [W]. The proofs of the subsequent results of this section are given in the appendix.

THEOREM 2.4. *Assume that* (H1*), (H2*), *and* (H4) *hold and that the smallest eigenvalue associated with* A_{f_0} *is simple. Then the mapping* $f \longrightarrow (\lambda_f, x_f)$, *where* λ_f *is the smallest eigenvalue of* A_f *and* x_f *is the corresponding eigenfunction of* A_f *normalized by* $\langle x_{f_0}, x_f\rangle = 1$, *from* F *to* $\mathbf{R} \times V$ *has a Gateaux differential* $(\dot\lambda, \dot x) = (\dot\lambda(f_0, f_1), \dot x(f_0, f_1))$ *at* f_0 *in direction* f_1. *It is the unique solution of*

$$(2.2) \qquad \left\{ \begin{array}{rcl} (A_{f_0} - \lambda_{f_0})\dot x - \dot\lambda x_{f_0} & = & -\dot{\mathcal{T}}(f_0, f_1)x_{f_0}, \\ \langle \dot x, x_{f_0}\rangle_X & = & 0. \end{array} \right.$$

Stronger differentiability assumptions for $f \longrightarrow \mathcal{T}_f$ carry over to improved differentiability properties of $f \longrightarrow (\lambda_f, x_f)$. Throughout the remainder of this section we assume that f_0 is an interior point of $\mathcal{F}$. We shall use the following hypotheses:

(H5) $f \in \mathcal{F} \longrightarrow T_f \in \mathcal{L}(V,V^*)$ has a Gateaux differential at $f_0 \in \mathcal{F}$ in every direction $f_1 \in F$, and $f_1 \longrightarrow \dot{\mathcal{T}}(f_0, f_1)x_{f_0}$ from F to V^* is linear.

(H6) $f \in \mathcal{F} \subset F \longrightarrow \mathcal{T}_f \in \mathcal{L}(V,V^*)$ has a Fréchet derivative at f_0.

With these conditions we obtain the following.

COROLLARY 2.5.

(i) *Let* (H1*), (H2*), (H4), *and* (H5) *hold. Then* $f \to (\lambda_f, x_f)$ *from* $\mathcal{F}$ *to* $\mathbf{R} \times V$ *has a Gateaux derivative at* f_0.

(ii) *Let* (H1*), (H2*), *and* (H6) *hold. Then* $f \to (\lambda_f, x_f)$ *from* F *to* $\mathbf{R} \times V$ *has a Fréchet derivative at* f_0.

The differentiability properties of the higher eigenvalue–eigenvector pairs can be studied with no additional effort. We obtain the following corollary.

COROLLARY 2.6.

(i) *Assume that* (H1*), (H2*), *and* (H4) *hold and that the eigenvalues of* A_{f_0} *are simple. Then the mapping* $\mathcal{F}^n : f \to (\lambda^n_f, x^n_f)$, *where* $\langle x^n_f, x^n_{f_0}\rangle = 1$, *from* F *to* $\mathbf{R} \times V$ *has a Gateaux differential* $(\dot\lambda^n(f_0, f_1), \dot x^n(f_0, f_1))$ *at* f_0 *in direction* f_1. *It is the unique solution of*

$$\begin{aligned}(A_{f_0} - \lambda^n_{f_0})\dot x - \dot\lambda x^n_{f_0} &= -\dot{\mathcal{T}}(f_0, f_1)x^n_{f_0},\\ \langle \dot x, x^n_{f_0}\rangle &= 0.\end{aligned} \tag{2.3}$$

(ii) *If* (H1*), (H2*), (H4), *and* (H5) *hold, then* $\mathcal{F}^n$ *has a Gateaux derivative at* f_0. *If* (H1*), (H2*), *and* (H6) *hold, then* $\mathcal{F}^n$ *has a Fréchet derivative at* f_0.

In the final results of this section we give conditions on

$$f \to T_f \text{ from } \mathcal{F} \subset F \text{ to } \mathcal{L}(V, Y),$$

which imply (H5) and (H6). We shall use the following:

(A1) $f \to T_f$ is continuous and has a Gateaux derivative at the point f_0.

(A2) $f \to T_f$ has a Fréchet derivative depending continuously on f at the point f_0.

LEMMA 2.7. *If* (A1) *holds, then* $f \to \mathcal{T}_f$ *from* F *to* $\mathcal{L}(V, V^*)$ *has a Gateaux derivative at* f_0 *and*

$$\dot{\mathcal{T}}(f_0, f_1) = T^*_{f_0}\dot T(f_0, f_1) + \dot T^*(f_0, f_1)T_{f_0} \tag{2.4}$$

or equivalently

$$\begin{aligned}\langle \dot{\mathcal{T}}(f_0, f_1)\varphi, \psi\rangle_{V^*,V} =& \langle \dot T(f_0, f_1)\varphi, T_{f_0}\psi\rangle_Y\\ &+\langle T_{f_0}\varphi, \dot T(f_0, f_1)\psi\rangle_Y\end{aligned} \tag{2.5}$$

for all $f_1 \in F$ *and* $\varphi, \psi \in V$. *Here* $\dot T(f_0, f_1)$ *denotes the Gateaux differential of* T_f *at* f_0 *in direction* f_1. *In particular,* (H5) *holds.*

LEMMA 2.8. *If* (A2) *holds, then* $f \to \mathcal{T}_f$ *from* F *to* $\mathcal{L}(V, V^*)$ *has a Fréchet derivative at* f_0.

3. Optimal input.

In this section we demonstrate the applicability of the general results of §2 for the linearization $\Phi'(a)$ of the parameter-to-solution mapping $\Phi(a)$ given by the elliptic boundary value problem (1.4).

First we reconsider the saddle point problem (1.7) in the form

$$\sup_{f\in\mathcal{F}} G_f \tag{3.1}$$

where

$$G_f = \inf_{h\neq 0} \frac{|\Phi'_f(a)h|^2_Y + \beta\tilde\sigma(h, h)}{|h|^2_X}.$$

To apply the results of §2 we make the identification $T_f h = \Phi'_f(a)h$ and $\sigma(h_1, h_2) = \beta\tilde{\sigma}(h_1, h_2)$. Let us now assume that $\mathcal{F}$ is compact, that (H1*) holds, that $f \longrightarrow T_f$ from $\mathcal{F}$ to $\mathcal{L}(V, Y)$ is continuous, and that the smallest eigenvalues λ_f of $A_f, f \in \mathcal{F}$, are distinct. In view of the Rayleigh principle [DL]

$$G_f = \lambda_f = a_f(h_f, h_f),$$

where h_f denotes the eigenfunction associated with λ_f. Due to the continuity of $f \longrightarrow \lambda_f$ established in Proposition 2.2, (3.1) has at least one solution $f^* \in \mathcal{F}$. An approximate evalution of G_f can be achieved by Galerkin approximation and solution of the resulting generalized eigenvalue problems. For an approximate solution of (3.1) one can rely on iterative techniques that require a gradient. Sufficient conditions for the existence and characterization of the Gateaux and the Fréchet derivatives of $f \longrightarrow G_f$ were given in Theorem 2.4 and Corollary 2.5.

The following technical lemma will be required later. We denote by 1 the constant function with value 1 as well as the real number 1.

LEMMA 3.1. (i) *Let $\Omega \subset \mathbf{R}^n, n \in \mathbf{N}$, be a domain satisfying the cone property if $n > 1$; and let $l \in H^1(\Omega)^*$ with the property that $l(1) \neq 0$. Then $h \longrightarrow (|\nabla h|^2_{L^2} + |l(h)|^2)^{1/2}$ defines a norm on $H^1(\Omega)$ that is equivalent to the common Hilbert space norm on $H^1(\Omega)$.*

(ii) *Let A be a compact metric space, and let $l_\alpha \in H^1(\Omega)^*$ with the property that $l_\alpha(1) \neq 0$ for all $\alpha \in A$ and such that $\alpha \longrightarrow l_\alpha$ from A to $H^1(\Omega)^*$ is continuous. Then there exists $\kappa > 0$ such that*

$$|\nabla h|^2_{L^2} + |l_\alpha(h)|^2 \geq \kappa |h|^2_{H^1} \quad \textit{for all } \alpha \in A \textit{ and } h \in H^1(\Omega). \tag{3.2}$$

Proof. Part (i) follows from [M, p. 27]. We turn to (ii). If (3.2) was false, then there would exist $\{\alpha_i\}_{i=1}^\infty \subset A$ and $\{h\}_{i=1}^\infty \subset H^1(\Omega)$ with $|h_i|_{H^1} = 1$ such that

$$\lim_{i \to \infty} \left(|\nabla h_i|^2_{L^2} + |l_{\alpha_i}(h_i)|^2\right) = 0. \tag{3.3}$$

Due to compactness of A it can be assumed that $\{\alpha_i\}_{i=1}^\infty$ is convergent with limit α_0. Continuity of $\alpha \longrightarrow l_\alpha$ from A to $H^1(\Omega)^*$ implies that

$$\lim_{i \to \infty} [l_{\alpha_i}(h_i) - l_{\alpha_0}(h_i)] = 0. \tag{3.4}$$

From (3.3) and (3.4) it follows that

$$\lim(|\nabla h_i|^2_{L^2} + |l_{\alpha_0}(h_i)|^2) = 0,$$

which is a contradiction. □

3.1. The one-dimensional case.

Here we consider the two-point boundary value problem

$$\begin{aligned} -(au_x)_x &= f \text{ in } (0,1), \\ u(0) = u(1) &= 0, \end{aligned} \tag{3.5}$$

where $a \in H^1, a(x) \geq \nu > 0$ on $(0,1)$, and $f \in H^{-1}$. In this subsection all function spaces are considered over the interval $(0,1)$. We introduce the operator

$$A(a)u = -(au_x)_x;$$

it is an isomorphism form H_0^1 to H^{-1}. The solution $u = u(a, f)$ to (3.5) is given by $u(a, f) = A^{-1}(a)f$. The mapping $a \rightarrow u(a, f)$ (for $a \geq \nu$) is Fréchet differentiable from H^1 to H_0^1 and the Fréchet derivative at a in the direction $h \in H^1$ is given by

$$u_a(a, f)(h) = A^{-1}(a)D(hDu(a, f)). \tag{3.6}$$

Here D denotes differentiation. Henceforth a will be fixed. In the context of §2 we choose the spaces

$$X = L^2, \qquad V = H^1, \qquad Y = H_0^1, \qquad F = H^{-1}, \tag{3.7}$$

and define the operators

$$T_f h = A^{-1}(a)D(hD(u(a, f))). \tag{3.8}$$

Clearly $T_f \in \mathcal{L}(V, Y)$ for every $f \in \mathcal{F}$. For T_f to be well defined and for the subsequent discussion it suffices to have $a \in L^\infty$ and $a \geq \nu > 0$ a.e. on $(0, 1)$. Above we choose $a \in H^1$ only for the sake of consistency since the variations h of a are taken in $V = H^1$. We further define

$$\sigma(h, \tilde{h}) = \beta\langle h_x, \tilde{h}_x\rangle_{L^2}, \tag{3.9}$$

where β is a small positive parameter. To assertain continuity of the eigenvalues and eigenfunctions of $f \rightarrow A_f$ we verify (H1*) and (H2*). Let us assume that $\hat{f} \neq 0$. Then

$$h \rightarrow \left(|DT_{\hat{f}}h|^2_{L^2} + \beta|Dh|^2_{L^2}\right)^{1/2}$$

defines a norm on H^1 that is equivalent to the usual H^1-norm. This implies the existence of $\mu > 0$ such that

$$a_{\hat{f}}(h, h) = |DT_{\hat{f}}h|^2_{L^2} + \beta|Dh|^2_{L^2} \geq 2\mu|h|^2_{H^1} \quad \text{for all } h \in H^1. \tag{3.10}$$

Using (3.10) and continuity of $f \rightarrow u(f)$ from H^{-1} to H_0^1 it can be shown that there exists a neighborhood $\mathcal{F}$ of $\hat{f}$ in H^{-1}, such that

$$a_f(h, h) \geq \mu|h|^2_{H^1} \quad \text{for all } f \in \mathcal{F}\text{and } h \in H^1, \tag{3.11}$$

and (H1*) holds. Next we show the continuity of the linear mapping $f \rightarrow T_f$ from F to $\mathcal{L}(V, Y)$. Let $M = \| DA^{-1}(a)D \|_{\mathcal{L}(L^2)}$, and let k_1 be the embedding constant from H^1 into L^∞. For $f \in H^{-1} = F$ and $h \in H^1 = V$ we find

$$\begin{aligned} (3.12)\, |T_f h|_{H_0^1} &= |DA^{-1}(a)D(hDu(a, f))|_{L^2} \leq Mk_1|h|_{H^1}|u(a, f)|_{H_0^1} \\ &\leq Mk_1|h|_{H^1}|A^{-1}(a)f|_{H_0^1} \leq Mk_1|h|_{H^1} \parallel A^{-1}(a) \parallel_{\mathcal{L}(H^{-1}, H_0^1)} |f|_{H^{-1}}. \end{aligned}$$

This estimate implies continuity of $f \rightarrow T_f$. In particular (H2*) holds (with $f_0 = \hat{f}$), and Proposition 2.2 is applicable. Moreover, (H3i) holds with $\gamma = 1$. Turning to the differentiability properties of the eigenvalues and eigenfunctions of T_f, we note that $f \rightarrow T_f$ is in $\mathcal{L}(F, \mathcal{L}(V; Y))$. Thus (A2) holds at every $f \in F$ and $f \rightarrow T_f$ has a Fréchet derivative at every $f \in F$. Thus the conclusions of Theorem 2.4 and Corollaries 2.5 and 2.6 are applicable.

Specific examples. We discussed the case where $\mathcal{F}$ is a subset of H^{-1}. Next we turn to the situation that is of practical importance where f varies in a parameterized set.

(i) Let $\epsilon \in (0,1)$ and $\mathcal{F} = [\epsilon, 1-\epsilon] \subset \mathbf{R}$. For $\alpha \in \mathcal{F}$ let δ_α denote the delta impulse at α. For a as above and $\alpha \in \mathcal{F}$ let $u(a, \delta_\alpha) \in W^{1,\infty}$ denote the solution of (3.5) with $f = \delta_\alpha$. The general theory will be applied to the operators

$$h \rightarrow T_{\delta_\alpha}(h) = A^{-1}(a)D(hDu(a, \delta_\alpha)), \quad \alpha \in \mathcal{F},$$

which are elements of $\mathcal{L}(H^1, H_0^1)$, with X, V, Y and σ as in (3.7), (3.9) and $F = \mathbf{R}$. It is simple to argue that $h \rightarrow |T_{\delta_\alpha} h|$ satisfies the assumptions for l_α of Lemma 3.1 with $A = [\epsilon, 1-\epsilon]$. Consequently there exists $\mu > 0$ such that

$$a_{\delta_\alpha}(h,h) \geq \mu |h|^1_{H^1} \quad \text{for all } h \in H^1 \text{ and } \alpha \in \mathcal{F},$$

i.e., (3.11) and hence (H1*) holds. Concerning the continuity assumption (H2), we note that T_{δ_α} is the composition of the mappings $\alpha \rightarrow \delta_\alpha \rightarrow A^{-1}(a)D(hDu(a, \delta_\alpha))$, which is Hölder continuous from $\mathcal{F}$ to $\mathcal{L}(H^1, H_0^1)$ using (3.12). In particular, Proposition 2.2 is applicable. Since $\alpha \rightarrow \delta_\alpha$ is not differentiable from $\mathcal{F} \subset \mathbf{R}$ to H^{-1}, the mapping $\alpha \rightarrow (\lambda_{\delta_\alpha}, h_{\delta_\alpha})$ is not differentiable for $Y = H_0^1$ as output space. In [IK2] we derived an explicit formula for the lowest eigenvalue of $T^*_{\delta_\alpha} T_{\delta_\alpha}$ and we argued directional differentiability of the smallest eigenvalues by means of the explicit representation. If one chooses the output space Y to be L^2, then the continuity assumptions (H1*), (H2*), and (H3i) as well as the differentiability hypothesis (A2) hold. This is a consequence of the fact that $\alpha \rightarrow \delta_\alpha$ is differentiable from $\mathcal{F} \subset \mathbf{R}$ to H^{-2} and of Hölder continuity and continuous differentiability of $\alpha \rightarrow T_{\delta_\alpha}$ from $\mathcal{F}$ to $\mathcal{L}(H^1, L^2)$.

(ii) Again we choose $\epsilon \in (0,1)$ and put $\mathcal{F} = [\epsilon, 1-\epsilon]$. For $\alpha \in \mathcal{F}$ we define

$$\eta_\alpha(x) = \begin{cases} 1 & \text{for } x \in \left[a - \frac{\epsilon}{2}, a + \frac{\epsilon}{2}\right], \\ 0 & \text{otherwise.} \end{cases}$$

The inhomogeneities f in (3.5) are now chosen in the class of functions $\{\eta_\alpha : \alpha \in \mathcal{F}\}$. We define the operators $T_{\eta_\alpha} h = A^{-1}(a)D(hDu(a; \eta_\alpha))$. The spaces X, Y, and V and the form σ are chosen as above and $\beta > 0$. Using Lemma 3.1 one can show that there exists $\mu > 0$ such that

$$a_{\eta_\alpha}(h,h) = \langle T_{\eta_\alpha} h, T_{\eta_\alpha} h \rangle_{L^2} + \beta \langle Dh, Dh \rangle_{L^2} \geq \mu |h|^2_{H^1}$$

for all $h \in H^1$ and $\alpha \in \mathcal{F}$. Thus (H1*) holds and (H2), (H2*), and (H3i) are simple to check. Turning to (H3ii) we choose $\alpha, \tilde{\alpha} \in \mathcal{F}$ and find for all $h \in L^2$

$$\begin{aligned} (3.13) \quad |T_{\eta_\alpha} h - T_{\eta_{\tilde{\alpha}}} h|_{H^1} &\leq M |hDu(a, \eta_\alpha - \eta_{\tilde{\alpha}})|_{L^2} \\ &\leq M |h|_{L^2} |u(a, \eta_\alpha - \eta_{\tilde{\alpha}})|_{W^{1,\infty}} \leq k_2 M |h|_{L^2} |\eta_\alpha - \eta_{\tilde{\alpha}}|_{L^2}, \end{aligned}$$

where k_2 is a constant independent of $\alpha, \tilde{\alpha} \in \mathcal{F}$ and M was defined immediately following (3.11). A short calculation gives $|\eta_\alpha - \eta_{\tilde{\alpha}}|_{L^2} \leq \sqrt{2} |\alpha - \tilde{\alpha}|^{1/2}$. Combining this estimate with (3.13) we have

$$|T_{\eta_\alpha} h - T_{\eta_{\tilde{\alpha}}} h|_{H^1} \leq \sqrt{2} k_2 M |h|_{L^2} |\alpha - \tilde{\alpha}|^{1/2} \quad \text{for all } h \in H^1 \text{ and } \alpha, \tilde{\alpha}, \in \mathcal{F}.$$

This is (H3ii) with $\gamma = \frac{1}{2}$, and hence Proposition 2.3 is applicable. Concerning differentiability we first note that $\alpha \rightarrow \eta_\alpha$ from $\mathcal{F} \subset \mathbf{R} \rightarrow H^{-1}$ is differentiable with the derivative given by $\frac{d}{d\alpha} \eta_\alpha = \delta_{\alpha + \epsilon/2} - \delta_{\alpha - \epsilon/2}$. Moreover, $\alpha \rightarrow T_{\eta_\alpha}$ is differentiable with

$$\frac{d}{d\alpha} T_{\eta_\alpha} = T_{\delta_{\alpha+\epsilon/2} - \delta_{\alpha-\epsilon/2}},$$

and Lemma 2.7 implies

$$\frac{d}{d\alpha}\mathcal{T}_{\eta_\alpha} = \frac{d}{d\alpha}(T^*_{\eta_\alpha} T_{\eta_\alpha}) = T^*_{\eta_\alpha} T_{\delta_{\alpha+\epsilon/2}-\delta_{\alpha-\epsilon/2}} + T^*_{\delta_{\alpha+\epsilon/2}-\delta_{\alpha-\epsilon/2}} T_{\eta_\alpha}.$$

We conclude Fréchet differentiability of the eigenvalues and eigenvectors of A_{η_α} according to Corollaries 2.5 and 2.6.

3.2. The multidimensional case. We turn to

$$(3.14) \qquad \begin{cases} -\mathrm{div}(a \text{ grad } u) = f & \text{in } \Omega, \\ u|\partial\Omega = 0, \end{cases}$$

where Ω is a bounded domain in $\mathbf{R}^n, n \in \{2,3,4\}$, with boundary $\partial\Omega$ of class $C^{1,\delta}$ for some $\delta \in (0,1)$. The choice of n guarantees that $H^1 \subset L^4$. Unless specified otherwise the function spaces in this subsection are considered over the domain Ω. The coefficient a is assumed to satisfy $a \in L^\infty, a(x) \geq \nu > 0$ a.e. on Ω, and $f \in H^{-1}$. Additional regularity for a and f will be required later. The operator $A(a) : H^1_0 \to H^{-1}$ defined by

$$A(a)u = -\mathrm{div}(a \text{ grad } u)$$

is an isomorphism. In particular this implies that (3.14) has a unique solution $u(a,f) = A^{-1}(a)f$. The mapping $a \to u(a,f)$ is Fréchet differentiable from L^∞ to H^{-1} with

$$(3.15) \qquad u_a(a,f)h = A^{-1}(a)\nabla \cdot (h\nabla u(a,f)) \quad \text{for } h \in L^\infty.$$

To extend (3.15) to a continuous linear operator on H^1 additional regularity of $u(a,f)$ is required. For the dimensions under consideration it suffices to require $u(a,f) \in W^{1,4}$. This is implied by the additional assumptions

$$(3.16) \qquad f \in W^{-1,4} = (W_0^{1,4/3})^* \quad \text{and} \quad a \in C^{0,\delta}$$

[A, T]. Henceforth we fix $a \in C^{0,\delta}, a \geq \nu > 0$, and for $f \in W^{-1,4}$ we introduce $T_f : H^1 \to H^1_0$ defined by

$$T_f(h) = A^{-1}(a)\nabla \cdot (h\nabla u(a,f)).$$

Conditions were given in [IK1] that guarantee injectivity of T_f (and $|T_f h|_{H^1_0} \geq \kappa |h|_{L^2}$, where $\kappa > 0$ is uniform with respect to h in bounded subsets of H^1). We shall discuss the "wellposedness" criterion (H1*) and the continuity assumption (H2*) with the choice

$$(3.17) \qquad X = L^2,\ Y = H^1_0,\ V = H^1,\ F = W^{-1,4},\ \sigma(h,\tilde{h}) = \beta\langle\nabla h, \nabla\tilde{h}\rangle_{L^2},$$

and

$$a_f(h,\tilde{h}) = \langle T_f h, T_f \tilde{h}\rangle_{H^1_0} + \beta\langle\nabla h, \nabla\tilde{h}\rangle_{L^2}, \qquad \text{for } h, \tilde{h} \in H^1 \text{ and } f \in F.$$

Let $0 \neq \hat{f} \in F$. Then by Lemma 3.1 there exists $\mu > 0$ such that

$$a_{\hat{f}}(h,h) \geq 2\mu|h|^2_{H^1} \quad \text{for all } h \in H^1.$$

We shall make use of the fact that there exists a constant C such that

$$|u(f)|_{W_0^{1,4}} \leq C|f|_{W^{-1,4}} \text{ for all } f \in W^{-1,4} \tag{3.18}$$

[A, p. 48], [T, p. 179]. Due to (3.18) and the continuous embedding of H^1 into L^2 there exists a neighborhood $\mathcal{F}$ of $\hat{f}$ in $W^{-1,4}$ such that

$$a_f(h,h) \geq \mu |h|^2_{H^1} \quad \text{and} \quad f \in \mathcal{F}. \tag{3.19}$$

This is (H1*). For the following estimate let $M = \| \nabla A^{-1}(a)\nabla \|_{\mathcal{L}(L^2_n)}$, with $L^2_n = \otimes_{i=1}^n L^2$, and let k_2 denote the embedding constant of H^1 into L^4. For $h \in H^1$ we find

$$\begin{aligned} |T_f h|_{H_0^1} &= |\nabla A^{-1}(a)\nabla \cdot (h\nabla u(a,f))|_{L^2} \leq M|h\nabla u(a,f)|_{L^2} \\ &\leq M|h|_{L^4}|\nabla u(a,f)|_{L^4_n} \leq Mk_2|h|_{H^1}|u(a,f)|_{W^{1,4}} \\ &\leq Mk_2C|h|_{H^1}|f|_{W^{-1,4}}. \end{aligned} \tag{3.20}$$

This estimate implies that $f \to T_f \in \mathcal{L}(W^{-1,4}, \mathcal{L}(H^1, H_0^1))$ is Lipschitz continuous. It follows that (H2*), (H3i), and (A2) hold and that Propositions 2.2 and 2.3(i), Theorem 2.4, and Corollaries 2.5 and 2.6 are applicable for the choice of spaces given in (3.7).

Specific example. As in the one-dimensional case we consider a specific situation where f varies in a parametrized set. Let $n = 2$; let Ω be as specified above; and choose $\mathcal{F} = [c,d]$, a compact interval in $\mathbf{R}$. For every $\alpha \in \mathcal{F}$, Γ_α denotes a (nontrivial) Lipschitzian curve in Ω and f_α is given by

$$\langle f_\alpha, \varphi \rangle = \int_{\Gamma_\alpha} \varphi \, ds \quad \text{for all } \varphi \in H_0^1. \tag{3.21}$$

We shall make use of the fact that $(W_0^{1,4/3})^* = W^{-1,4}$, with $W^{-1,4}$ densely injected into H^{-1}. Moreover, if G is a bounded open subset of $\mathbf{R}^n$ with Lipschitz boundary ∂G, then the zero-order trace operator has a unique continuous extension to an operator form $W^{1,4/3}$ onto $W^{1/4,4/3}(\partial\Omega)$ and $W^{1/4,4/3}(\partial\Omega) \subset L^2(\partial\Omega)$. This implies that (3.21) defines an element $f_\alpha \in W^{-1,4}(\Omega)$, and

$$h \to T_{f_\alpha}(h) = \nabla A^{-1}(a)\nabla(h\nabla u(a,f_\alpha))$$

is well defined for all $h \in H^1$. We next give a condition that implies continuity of $\alpha \to f_\alpha$ from $\mathcal{F}$ to $W^{-1,4}$.

> For $\alpha_0 \in (c,d)$ choose $\epsilon = \epsilon(\alpha_0) > 0$ such that $I_{\alpha_0} = [\alpha_0, \alpha_0 + \epsilon] \subset [c,d]$ and define the sets
>
> $$\Omega_\epsilon = \operatorname{int} \bigcup_{\beta \in I_{\alpha_0}} \Gamma_\beta \text{ and } \Omega_\alpha = \operatorname{int} \bigcup_{\beta \in [\alpha_0, \alpha]} \Gamma_\beta, \quad \text{for } \alpha \in I_{\alpha_0}. \tag{3.22}$$
>
> It is assumed that Ω_ϵ and Ω_α are connected domains in $\mathbf{R}^2$ with $\partial\Omega_\alpha$ Lipschitzian for all $\alpha \in I_{\alpha_0}$ and such that the subdomains Ω_α and $\Omega_\epsilon - \Omega_\alpha$ lie on opposite sides of Γ_α and
>
> $$\partial\Omega_\alpha = \Gamma_{\alpha_0} \cup \Gamma_\alpha \cup \tilde{\Gamma}_\alpha,$$

with $\tilde{\Gamma}_\alpha$ consisting of at most two connected smooth components. Let v_α denote the unit normal to Γ_α pointing into $\Omega_\epsilon - \Omega_\alpha$. Assume that v_α defines a vectorfield $v \in W^{1,\infty}(\Omega_\epsilon, \mathbf{R}^n)$ as α varies in I_{α_0} and that it can be extended uniquely to a vectorfield on $\overline{\Omega_\epsilon}$ and that $\alpha \to \alpha_0$ implies $\int_{\Omega_\alpha} dx \to 0$ and $\int_{\tilde{\Gamma}_\alpha} ds \to 0$. Further assume that the analogous construction is possible with I_{α_0} replaced by $[\alpha_0 - \epsilon, \alpha_0]$.

Let $\alpha \to \alpha^0$, and without loss of generality assume that $\alpha \geq \alpha_0$. Then by Green's formula, applied to $v\psi \in W^{1,4/3}(\Omega_\alpha)$, we find for $\psi \in W^{1,4/3}(\Omega)$ and n_α the unit outer normal to Ω_α:

$$\begin{aligned}\int_{\Omega_\alpha} \operatorname{div}(v\psi)\,dx &= \int_{\Gamma_{\alpha_0}} n_\alpha v\psi\,ds + \int_{\Gamma_\alpha} n_\alpha v\psi\,ds + \int_{\tilde{\Gamma}_\alpha} n_\alpha v\psi\,ds \\ &= -\int_{\Gamma_{\alpha_0}} \psi\,ds + \int_{\Gamma_\alpha} \psi\,ds + \int_{\tilde{\Gamma}_\alpha} n_\alpha v\psi\,ds,\end{aligned}$$

and consequently

$$\begin{aligned}|\langle f_{\alpha_0} - f_\alpha, \psi\rangle| &= \left|\int_{\Gamma_{\alpha_0}} \psi\,ds - \int_{\Gamma_\alpha} \psi\,ds\right| \\ &\leq \left|\int_{\Omega_\alpha} \operatorname{div}(v\psi)\,dx\right| + \left|\int_{\tilde{\Gamma}_\alpha} n_\alpha v\psi\,ds\right| \\ &\leq K\left(|\psi|_{W^{1,4/3}}\left(\int_{\Omega_\alpha} dx\right)^{1/4} + \int_{\tilde{\Gamma}_\alpha} |\psi|\,ds\right),\end{aligned}$$

with K a constant independent of $\psi \in W^{1,4/3}$. It follows that

$$\begin{aligned}\left|\int_{\Gamma_{\alpha_0}} \psi\,ds - \int_{\Gamma_\alpha} \psi\,ds\right| &\leq K\left[\left|\int_{\Omega_\alpha} dx\right|^{1/4} |\psi|_{W^{1,4/3}} + \left(\int_{\tilde{\Gamma}_\alpha} ds\right)^{1/2}\left(\int_{\tilde{\Gamma}_\alpha} |\psi|^2\,ds\right)^{1/2}\right] \\ &\leq \tilde{K}\,|\psi|_{W^{1,4/3}(\Omega)}\left[\left(\int_{\Omega_\alpha} dx\right)^{1/4} + \left(\int_{\tilde{\Gamma}_\alpha} ds\right)^{1/2}\right],\end{aligned}$$

with $\tilde{K}$ independent of $\psi \in W^{1,4/3}$. By (3.22) continuity of $\alpha \to f_\alpha$ from $\mathcal{F}$ to $W^{-1,4}$ follows. Together with (3.20) we have

$$\alpha \to T_{f_\alpha} \text{ is continuous from } [c,d] \text{ to } \mathcal{L}(H^1, H_0^1). \tag{3.23}$$

Thus (H2*) holds. To verify (H1*) we note that $l_\alpha(1) \neq 0$ for all $\alpha \in [c,d]$. Together with compactness of $\mathcal{F}$ and (3.23), Lemma 3.1 implies the desired conclusion. Thus Proposition 2.2 can be applied. It implies continuity of the eigenvalues and eigenfuctions of A_{f_α} provided they are distinct. Moreover, since $\mathcal{F}$ is compact, the associated saddle point problem (3.1) has a solution.

Two examples in which (3.22) holds true are given by the domain $\Omega =$ unit ball in $\mathbf{R}^2$, and

(i)

$$\Gamma_\alpha = \left\{\begin{pmatrix} x \\ \alpha \end{pmatrix} : x \in \left[-\frac{1}{2}, \frac{1}{2}\right]\right\}, \qquad \alpha \in \left[-\frac{1}{2}, \frac{1}{2}\right];$$

and

(ii)

$$\Gamma_\alpha = \left\{ \begin{pmatrix} x \\ \alpha(x-\frac{1}{2})(x+\frac{1}{2}) \end{pmatrix} : x \in \left[-\frac{1}{2}, \frac{1}{2} \right] \right\}, \qquad \alpha \in [-2, 2].$$

3.3. The multidimensional case revisited. Once again we consider the problem of the optimal choice of f for the identification of a in (3.14), but now the output space is chosen to be $H^2 \cap H^1_0$ rather than H^1_0. This choice of output space enhances the sensitivity of the parameter-to-solution mapping. We shall consider the maximization of the measure

$$G^\beta_f = \inf_{\substack{h \in H^1 \\ h \neq 0}} \frac{|T_f h|^2_{H^2} + \beta |\nabla h|^2}{|h|^2_{L^2}} \tag{3.24}$$

with $\beta > 0$ (regularized case) and $\beta = 0$ (unregularized case).

Let Ω be a bounded domain in $\mathbf{R}^n$ with Lipschitzian boundary, and fix a such that $A(a) : H^2 \cap H^1_0 \to L^2$ is an isomorphism. Assume further that $\partial\Omega$ is sufficiently regular such that for an appropriately chosen normed linear space F the linear mapping

$$f \to u(a, f)$$

is continuous from F to $W^{1,\infty} \cap W^{2,1+\epsilon}$ with $\epsilon > 0$ if $n = 2$ and from F to $W^{2,n}$ if $n \geq 3$.

Here $u(a, f)$ denotes the solution of (3.14).

It follows that $h \to T_f(h) = A^{-1}(a)\nabla\cdot(h\nabla u(a, f))$ is an element of $\mathcal{L}(H^1, H^2 \cap H^1_0)$ and that there exists a constant C independent of $(h, f) \in H^1 \times F$ such that

$$|T_f(h)|_{H^2 \cap H^1_0} \leq C |h|_{H^1} |f|_F \quad \text{for all } (h, f) \in H^1 \times F. \tag{3.25}$$

In the context of the notation of §2 we take

$$X = L^2, \qquad Y = H^2 \cap H^1_0, \qquad Y = H^1, \qquad \sigma(h, \tilde{h}) = \beta \langle \nabla h, \nabla \tilde{h} \rangle_{L^2}, \tag{3.26}$$

F as specified above and

$$a_f(h, \tilde{h}) = \langle T_f h, T_f \tilde{h} \rangle_{H^2} + \beta \langle \nabla h, \nabla \tilde{h} \rangle_{L^2} \quad \text{for } h, \tilde{h} \in H^1 \text{ and } f \in F. \tag{3.27}$$

First let us argue that (H1*), (H2*), and (A2) hold for an appropriately chosen subset $\mathcal{F} \subset F$, if $\beta > 0$.

Let $0 \neq \hat{f} \in F$. Then by Lemma 3.1 there exists $\mu > 0$ such that

$$a_{\hat{f}}(h, h) \geq 2\mu |h|^2_{H^1} \quad \text{for all } \in H^1,$$

and due to (3.25) and bilinearity of $(h, f) \to T_f h$ there exists a neighborhood $\mathcal{F}$ of $\hat{f}$ such that

$$a_f(h, h) \geq \mu |h|^2_{H^1} \quad \text{for all } (h, f) \in H^1 \times \mathcal{F}.$$

Thus (H1*) is satisfied. As a consequence of (3.25) condition (H2*) holds with f_0 replaced by $\hat{f}$ and hence Propostion 2.2 is applicable. We note that (3.25) also implies (H3i) and (A2) so that, in particular, by Corollary 2.5 Fréchet differentiability of $f \to (\lambda_f, x_f)$ at $\hat{f}$ follows.

Now let us turn to the case $\beta = 0$ in (3.24). This requires the interpretation of T_f as an unbounded operator in L^2. In [IK] sufficient conditions are given that guarantee T_f with dom $T_f = H_0^1 \subset L^2$ and $T_f h = A^{-1}\nabla \cdot (h \nabla u(a,f))$ is a closable operator in L^2 with its closure (which is again denoted by T_f) satisfying

$$|T_f h|_{H^2} \geq 2K |h|_{L^2} \quad \text{for all } h \in \text{ dom } T_f,$$

for a constant $K > 0$ independent of h. Such a sufficient condition is given by assuming that $\Omega \subset \mathbf{R}^n, n \in \{1,2,3\}, \partial\Omega$ is $C^{1,1}$-smooth (if $n = 2,3$), and

$$(3.28) \qquad \begin{cases} u(a,f) \in W^{3,4}(\Omega) \\ \nabla u(x;a,f) \cdot n < 0 \text{ on } \partial\Omega, \\ \text{there exist constants } k_1 \in \mathbf{R} \text{ and } k_2 > 0 \text{ such that} \\ k_1 |\nabla u(x;a,f)|^2 + \Delta u(x;a,f) \geq k_2 \text{ on } \Omega. \end{cases}$$

Let us assume henceforth that the normed linear space F is chosen such that

$$f \longrightarrow u(a,f)$$

is continuous from F to $W^{3,4}$, and let $\hat{f}$ be a reference input for which (3.28) holds. Then the existence of a neighborhood $\mathcal{F}$ of $\hat{f}$ follows, such that T_f is closable for all $f \in \mathcal{F}$ and

$$(3.29) \qquad |T_f h|_{H^2} \geq K|h|_{L^2} \quad \text{for all } (h,f) \in \text{ dom } T_f \times \mathcal{F}.$$

In particular this implies that the measure

$$G_f = \inf_{\substack{h \in \text{ dom } T_f \\ h \neq 0}} \frac{|T_f h|^2_{H^2}}{|h|^2_{L^2}}$$

is nontrivial for all $f \in \mathcal{F}$. We shall argue that $f \longrightarrow G_f$ is upper semicontinuous, so that existence of a solution to

$$\max \ G_f \quad \text{over } f \in \mathcal{F}$$

is guaranteed if $\mathcal{F} \subset F$ is compact. We first show that

$$(3.30) \qquad \lim_{\beta \to 0^+} G_f^\beta = G_f \quad \text{for every } f \in \mathcal{F}.$$

Since $\beta \longrightarrow G_f^\beta$ is monotonically decreasing, $\lim_{\beta \to 0^+} G_f^\beta$ exists. Arguing by contradiction, assume that $\lim_{\beta \to 0^+} G_f^\beta = \mu_0 > G_f$. Since $H^1(\Omega)$ is dense in $L^2(\Omega)$, we find

$$(3.31) \qquad G_f = \inf_{\substack{h \neq 0 \\ h \in H^1}} \frac{|T_f h|^2_{H^2}}{|h|^2_{L^2}}.$$

Hence there exists $\bar{h} \neq 0$ in $H^1(\Omega)$ such that

$$\frac{|T_f \bar{h}|^2_{H^2}}{|\bar{h}|^2_{L^2}} \leq G_f + \delta,$$

where $\delta = \frac{1}{4}(\mu_0 - G_f)$. It follows that

$$G_f^\beta \le \frac{|T_f\bar{h}|^2_{H^1} + \beta|\nabla\bar{h}|^2_{L^2}}{|\bar{h}|^2_{L^2}} \le G_f + 2\delta = \frac{1}{2}(\mu_0 + G_f) \tag{3.32}$$

for all β with $\beta|\nabla\bar{h}|^2_{L^2} \le \delta|\bar{h}|^2_{L^2}$. Taking the limit with respect to β in (3.32) leads to a contradiction, and hence (3.30) holds. To prove upper semicontinuity of $f \to G_f$ let $\{f_n\}_{n=1}^\infty$ be a sequence in $\mathcal{F}$ with $\lim_{n\to\infty} f_n = f$, and let $\eta > 0$ be arbitrary. By (3.30) there exists β_0 such that

$$|G_f^{\beta_0} - G_f| < \eta.$$

Moreover, by Proposition 2.3 there exists N_0 such that

$$|G_{fn}^{\beta_0} - G_f^{\beta_0}| < \eta \quad \text{for all } n \ge N_0.$$

Consequently we have

$$\begin{aligned} G_f - G_{f_n} &\ge G_f - G_f^{\beta_0} + G_f^{\beta_0} - G_{f_n}^{\beta_0} + G_{f_n}^{\beta_0} - G_{f_n} \\ &\ge G_f - G_f^{\beta_0} + G_f^{\beta_0} - G_{f_n}^{\beta_0} \ge -2\eta \end{aligned}$$

for all $n \ge N_0$. Since $\eta > 0$ is arbitrary, upper semicontinuity of $f \to G_f$ follows.

4. Numerical experiments.

We carried out numerical tests to determine the optimal location of the unit impulse δ_α in

$$\begin{cases} -(au_x)_x = & \delta_\alpha \quad \text{in } (0,1), \\ u(0) = u(1) = & 0, \end{cases} \tag{4.1}$$

for the determination of the function $a(x)$. Theoretical aspects for this problem were considered in §3.1, Specific Examples (i). For $\alpha \in (0,1)$ the solution to (4.1) satisfies $u(a, \delta_\alpha) \in W^{1,\infty}$, and therefore $T_{\delta_\alpha} h = A^{-1}(a)D(hDu(a,\delta_\alpha))$ is well defined for $h \in L^2$. The Hermitian forms are given by

$$a_{\delta_\alpha}(h, \tilde{h}) = \langle T_{\delta_\alpha} h, T_{\delta_\alpha} \tilde{h}\rangle_{H_0^1} + \beta\langle h_x, \tilde{h}_x\rangle_{L^2},$$

and the saddle point problems are

$$\sup \inf_{\substack{h\in H^1 \\ h\neq 0}} \frac{a_{\delta_\alpha}(h,h)}{|h|^2_{L^2}}. \tag{4.2}$$

It is known [IK1] that a_{δ_α} does not satisfy (H1) for $\beta = 0$. To discretize these problems we choose subspaces $H^N = \{h^N = \sum_{i=1}^{N/2} h_i B_i^N : h_i\}$, where N is even and B_i^N are piecewise constant functions with value 1 on $\left[\frac{2(i-1)}{N}, \frac{2i}{N}\right]$ and value 0 outside of this interval. For given α and $a > 0$, the approximate solution $u^N(a, \delta_\alpha)$ to (4.1) was determined as the Galerkin solution with respect to the discretization of (4.1) by linear spline functions on the grid $\left\{\frac{i}{N}\right\}_{i=0}^N$. The approximate minimization problems are then given by

$$\min_{\substack{h^N\in H^N \\ h^N\neq 0}} \frac{a_{\delta_\alpha}^N(h^N, h^N)}{|h^N|^2_{L^2}}, \tag{4.3}$$

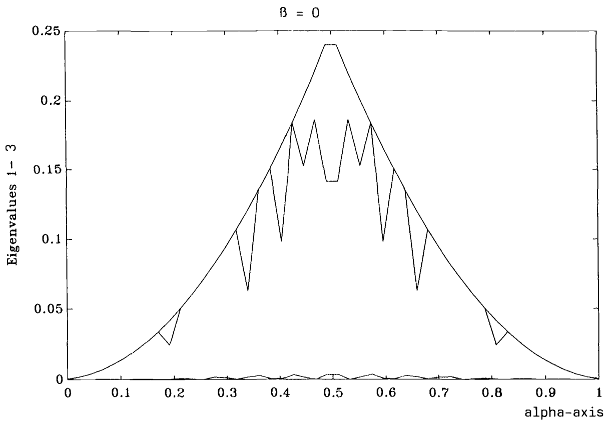

FIG. 1.

where $a^N_{\delta_\alpha}$ is defined like a_{δ_α} with $u(a, \delta_\alpha)$ replaced by $u^N(a, \delta_\alpha)$. The solution to (4.3) is characterized by the smallest eigenvalue of the generalized eigenvalue problem

$$A^N_{\delta_\alpha} \vec{h}^N = Q^N \vec{h}^N, \tag{4.4}$$

and the minimum in (4.3) is assumed at the eigenfunction associated with the smallest eigenvalue. In (4.4), $\vec{h}^N$ denotes the coordinate vector of h^N, and $A^N_{\delta_\alpha}, Q^N$ are the matrix representations of the forms $a^N_{\delta_\alpha}(h^N, \tilde{h}^N)$ and $\langle h^N, \tilde{h}^N \rangle$ on $H^N \times H^N$.

(i) In the first test example we choose $a = 1$. It is simple to see that 0 is an eigenvalue of $T^*_{\delta_\alpha} T_{\delta_\alpha}, \alpha \in (0,1)$, with T_{δ_α} considered as the operator form L^2 to H^1_0. Consequently we expect that for $\beta = 0$ the lowest eigenvalues of $A^N_{\delta_\alpha}, \alpha \in (0,1)$, approximate zero from above. Figure 1 shows the first three eigenvalues of A_{δ_α} as α varies in $(0,1)$ with $\beta = 0$ and $N = 128$. The curves were obtained by solving the generalized eigenvalue problem (4.4) for $\alpha_i = \frac{i}{49}, i = 1, \ldots, 48$. This plot was already analyzed in [IK2] where we noted that the eigenfunctions associated with the lowest eigenvalue approximate the step function in the spectrum of A_{δ_α} (considered as operator in L^2) and the eigenfunctions associated with the second eigenvalue approximate a δ-function. In [IK2] we also showed that the smallest eigenvalues of $T^*_{\delta_\alpha} T_{\delta_\alpha}$ when properly restriced to a subspace of codimension 1 (to eleminate 0 as eigenvalue) are given by

$$\lambda^0(\alpha) = \begin{cases} \alpha^2 & \text{on } \left(0, \frac{1}{2}\right), \\ (1-\alpha)^2 & \text{on } \left(\frac{1}{2}, 1\right). \end{cases}$$

The graph of λ^0 is almost identical with the third eigenvalue of $A_{\delta_\alpha}, \alpha \in (0,1)$, seen in Fig. 1. The elimination of a proper subspace to obtain (H1*) may be impractical in larger problems, and then regularization can be used. In Figs. 2 and 3 we show the results with $\beta = 10^{-4}$ and 10^{-3} respectively. The remaining specifications are those of Fig. 1. It can be observed that the lowest eigenvalue is now bounded away from 0 and that its maximum is attained at (the desired) location $\alpha^* = .5$. A comparison of all eigenvalues of A_{δ_α} with $\beta = 0$ and $\beta > 0$ also shows that regularization spreads the eigenvalues apart.

(ii) For this experiment we choose $a(x) = 1 + x$. It is known from [IK2] that the optimal location for the unit impulse is to the right of .5. Figure 4 depicts the

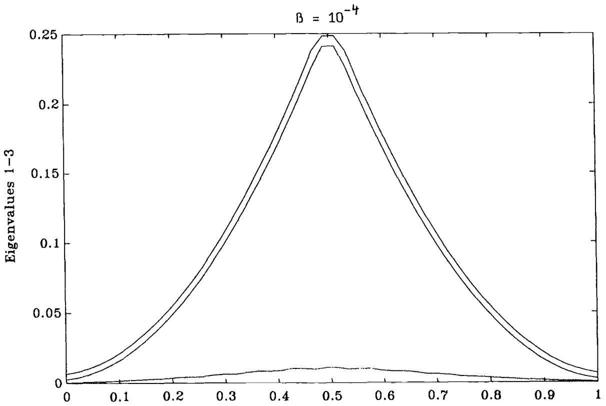

FIG. 2.

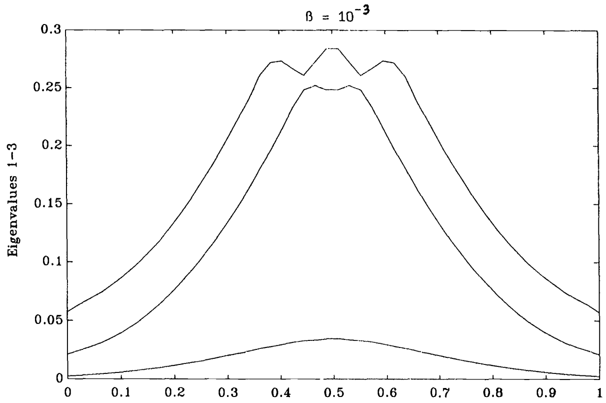

FIG. 3.

lowest eigenvalue of the generalized eigenvalue problem (4.4) for different values of β and for $N = 32$. The abscissa is again the α-axis, and the curves were obtained from results for $\alpha_i = \frac{i}{49}, i = 1, \ldots, 48$. Starting with the lowest curve, the graphs correspond successively to $\beta = 10^{-5}, 5 \times 10^{-5}, 10^{-4}, 5 \times 10^{-4}, 10^{-3}$. If β is sufficiently large, here $\beta \geq 5 \times 10^{-4}$, then we can see that $\alpha^* \approx .531$, which is larger than .5, as desired. The value for the optimal input $\hat{\alpha}$ calculated by restricting $T^*_{\delta_\alpha} T_{\delta_\alpha}$ to a proper subspace, so that (H1*) holds, was found to be $\hat{\alpha} \approx .545$ [IK2, Plot 2]. The zig-zag of the curves corresponding to small β-values is due to the relative distance of the gridpoints $\left\{\frac{i}{N}\right\}_{i=0}^{N}$ of the discretization for u and h and the location for the impulses at $\left\{\frac{j}{49}\right\}_{j=1}^{48}$, with smaller distance giving smaller eigenvalues.

(iii) In the final two plots we compare the eigenfunctions corresponding to the three smallest eigenvalues of the generalized eigenvalues problem (4.4) for $\beta = 0$ and $\beta = 10^{-4}$; see Figs. 5 and 6 respectively. Here $a(x) = 1+x, N = 128$, and $\alpha = \alpha^*$, the optimal input location found in (ii). As expected, the eigenfunctions for $\beta = 10^{-4}$ are much smoother than those for $\beta = 0$. We can also note that the first eigenfunction for $\beta = 10^{-4}$ is a smooth approximation to a multiple of the first eigenfunction for $\beta = 0$, which is almost a step function.

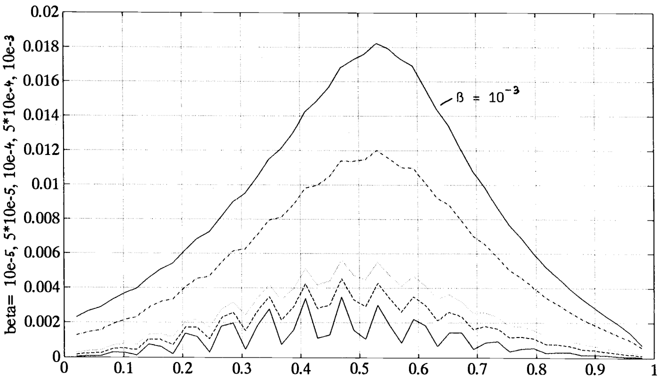

FIG. 4.

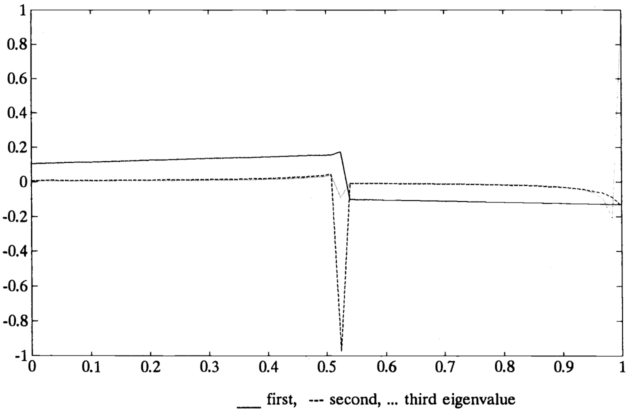

FIG. 5.

5. Appendix. Here we give the proof for the differentiability results of §2. The eigenvectors x_f^n are normalized by $\langle x_f^n, x_{f_0}^n \rangle = 1$ and put $(\lambda_0^n, x_0^n) = (\lambda_{f_0}^n, x_{f_0}^n)$. The superscript $n = 1$ is deleted.

Proof of Theorem 2.4. For simplicity of notation we put $f = f_0 + \tau f_1$ and $(\lambda_0, x_0) = (\lambda_{f_0}, x_{f_0})$. As a consequence of Proposition 2.2 and (H2*) we find

$$(\lambda_f, x_f) \to (\lambda_0, x_0) \quad \text{in } \mathbf{R} \times V, \text{ for } \tau \to 0. \tag{5.1}$$

By Lemma 2.1

$$a_f(x_f, v) = \lambda_f \langle x_f, v \rangle \tag{5.2}$$

and

$$a_{f_0}(x_0, v) = \lambda_0 \langle x_0, v \rangle \quad \text{for all } v \in V. \tag{5.3}$$

Subtracting (5.3) from (5.2) we obtain

$$\begin{aligned} \sigma(x_f - x_0, v) + \langle T_{f_0}(x_f - x_0), T_{f_0} v \rangle_Y - \lambda_0 \langle x_f - x_0, v \rangle_X \\ -(\lambda_f - \lambda_0) \langle x_f, v \rangle_X \\ = -\langle T_f x_f, T_f v \rangle_Y + \langle T_{f_0} x_f, T_{f_0} v \rangle_Y. \end{aligned} \tag{5.4}$$

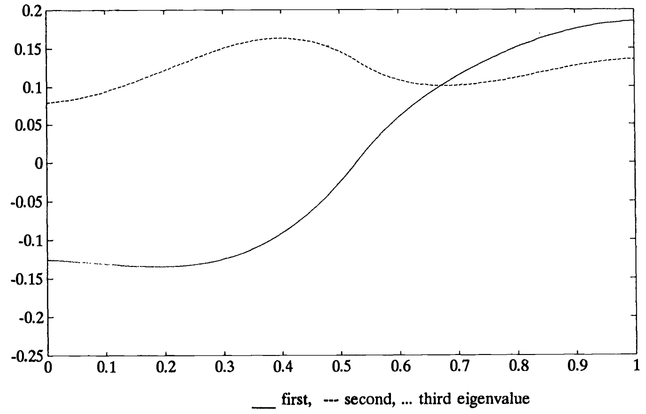

FIG. 6.

The normalizing equation $\langle x_f, x_{f_0}\rangle = 1$ together with (5.4) gives the following system of equations

$$(5.5)\qquad \begin{cases} (A_{f_0} - \lambda_0)(x_f - x_0) - (\lambda_f - \lambda_0)x_f & = -(\mathcal{T}_f x_f - \mathcal{T}_{f_0} x_f), \\ \qquad\qquad < x_f, x_f - x_0 >_X & = 0. \end{cases}$$

Introducting the operaters

$$C(x_f) : V \times \mathbf{R} \to V^* \times \mathbf{R}$$

defined by

$$C(x_f) = \begin{pmatrix} (A_{f_0} - \lambda_0) & -x_f \\ \langle x_0, \cdot\rangle & 0 \end{pmatrix}$$

it can be seen that (5.5) is equivalent to

$$(5.6)\quad C(x_0) = \begin{pmatrix} x_f - x_0 \\ \lambda_f - \lambda_0 \end{pmatrix} = [C(x_0) - C(x_f)] \begin{pmatrix} x_f - x_0 \\ \lambda_f - \lambda_0 \end{pmatrix} - \begin{pmatrix} \mathcal{T}_f x_f - \mathcal{T}_{f_0} x_f \\ 0 \end{pmatrix}.$$

Due to Proposition 2.2 and the special form of $C(x_f)$ we have

$$(5.7)\qquad \| \, C(x_0) - C(x_f) \, \|_{\mathcal{L}(V\times\mathbf{R}, V^*\times\mathbf{R})} \to 0 \quad \text{for } \tau \to 0.$$

It is simple to verify that $C(x_0)$ is injective and surjective. It follows that $C(x_0)$ has a bounded inverse and that (5.6) is equivalent to

$$(5.8)\qquad \left[I + C(x_0)^{-1} M_\tau\right] \begin{pmatrix} x_f - x_0 \\ \lambda_f - \lambda_0 \end{pmatrix} = -C(x_0)^{-1} \begin{pmatrix} \mathcal{T}_f x_f - \mathcal{T}_{f_0} x_f \\ 0 \end{pmatrix},$$

where $M_\tau = C(x_f) - C(x_0) \in \mathcal{L}(V \times \mathbf{R}, V^* \times \mathbf{R})$ and $\| \, M_\tau \, \| \to 0$ with $\tau \to 0$.

From (5.7) there exists $\tau_0 > 0$ and a constant K such that $I + C(x_0)^{-1} M_\tau$ is invertible in $\mathcal{L}(V \times \mathbf{R})$ and

$$(5.9)\qquad \| \, [I + C(x_0)^{-1} M_\tau]^{-1} \, \|_{\mathcal{L}(V\times\mathbf{R})} \le K$$

for all τ with $|\tau| \leq \tau_0$. Therefore, (5.8) is equivalent to

$$(5.10)\qquad \begin{pmatrix} x_f - x_0 \\ \lambda_f - \lambda_0 \end{pmatrix} = -[I + C(x_0)^{-1}M_\tau]^{-1}C(x_0)^{-1}\begin{pmatrix} \mathcal{T}_f x_f - \mathcal{T}_{f_0} x_f \\ 0 \end{pmatrix}.$$

Finally observe that

$$\begin{aligned}(5.11)\quad & \| \ \frac{1}{\tau}[I + C(x_0)^{-1}M_\tau]^{-1}C(x_0)^{-1}\begin{pmatrix} \mathcal{T}_f x_f - \mathcal{T}_{f_0} x_f \\ 0 \end{pmatrix} \\ & \quad -C(x_0)^{-1}\begin{pmatrix} \dot{\mathcal{T}}(f_0, f_1)x_0 \\ 0 \end{pmatrix} \|_{\mathcal{L}(V\times\mathbf{R})} \\ \leq \ & \| \ C(x_0)^{-1}M_\tau[I + C(x_0)^{-1}M_\tau]^{-1}C(x_0)^{-1}\begin{pmatrix} \frac{1}{\tau}(\mathcal{T}_f x_f - \mathcal{T}_{f_0} x_f) \\ 0 \end{pmatrix} \|_{\mathcal{L}(V\times\mathbf{R})} \\ + \ & \| \ C(x_0)^{-1} \|_{\mathcal{L}(V^*\times\mathbf{R}, V\times\mathbf{R})} \, |\frac{1}{\tau}[\mathcal{T}_f x_f - \mathcal{T}_{f_0} x_f] - \dot{\mathcal{T}}(f_0, f_1)x_f|_{V^*} \\ + \ & \| \ C(x_0)^{-1} \|_{\mathcal{L}(V^*\times\mathbf{R}, V\times\mathbf{R})} \, |\dot{\mathcal{T}}(f_0, f_1)(x_f - x_0)|_{V^*}.\end{aligned}$$

Due to (H4), (5.3), and the fact that $\| M_\tau \| \to 0$ for $\tau \to 0$, the first term on the right-hand side of (5.11) converges to zero. The second additive term tends to zero as a consequence of (H4). Finally due to (H4) and Proposition 2.2 the last term converges to zero as well. As a consequence of (5.10) and (5.11) it follows that $f \to (\lambda_f, x_f)$ has a Gateaux differential $(\dot{\lambda}, \dot{x})$ at f_0 in direction f_1. It is given by

$$(5.12)\qquad \begin{pmatrix} \dot{x} \\ \dot{\lambda} \end{pmatrix} = -C(x_0)^{-1}\begin{pmatrix} \dot{\mathcal{T}}(f_0, f_1)x_0 \\ 0 \end{pmatrix}.$$

This is (2.2). Uniqueness of the solution to (2.2) follows from injectivity of $C(x_0)$. □

Proof of Corollary 2.5. (i) We need to argue that $f_1 \to (\dot{\lambda}(f_0, f_1), \dot{x}(f_0, f_1))$ is linear [W]. This is a direct consequence of (H5) and (5.12).

(ii) Due to (5.12) and (H6) the mapping

$$(5.13)\qquad f_1 \to \begin{pmatrix} \dot{x}(f_0, f_1) \\ \dot{\lambda}(f_0, f_1) \end{pmatrix} = -C(x_0)^{-1}\begin{pmatrix} \dot{\mathcal{T}}(f_0, f_1)x_0 \\ 0 \end{pmatrix}$$

is an element of $\mathcal{L}(F; V \times \mathbf{R})$. To show that it satisfies the definition of Fréchet differentiability we estimate

$$(5.14)\qquad \begin{pmatrix} x_f - x_0 \\ \lambda_f - \lambda_0 \end{pmatrix} - (-C(x_0))^{-1}\begin{pmatrix} \dot{\mathcal{T}}(f_0, f_1)x_0 \\ 0 \end{pmatrix},$$

where we put $f = f_0 + f_1$. By Proposition 2.2 we have that

$$(\lambda_f, x_f) \to (\lambda_0, x_0) \quad \text{in } \mathbf{R} \times V \text{ if } |f_1|_F \to 0.$$

As in the proof of Theorem 2.4, $C(x_0)$ is an isomorphism from $V \times \mathbf{R}$ to $V^* \times \mathbf{R}$,

$$M(f) = C(x_f) - C(x_0) \to 0 \quad \text{in } \mathcal{L}(V \times \mathbf{R}, V^* \times \mathbf{R}) \text{ as } f \to f_0 \text{ in } F,$$

and $\| \left(I + C(x_0)^{-1}[C(x_f) - C(x_0)]\right)^{-1} \|_{\mathcal{L}(V\times\mathbf{R})}$ is uniformly bounded for all f sufficiently close to f_0. Returning to (5.14) we find (compare (5.8)

$$\begin{aligned}
&\begin{pmatrix} x_f - x_0 \\ \lambda_f - \lambda_0 \end{pmatrix} + C(x_0)^{-1}\begin{pmatrix} \dot{\mathcal{T}}(f_0, f_1)x_0 \\ 0 \end{pmatrix} \\
&\quad = \left\{-[I + C(x_0)^{-1}M(f)]^{-1} + I\right\} C(x_0)^{-1}\begin{pmatrix} \mathcal{T}_f x_f - \mathcal{T}_{f_0} x_f \\ 0 \end{pmatrix} \\
&\qquad -C(x_0)^{-1}\begin{pmatrix} \mathcal{T}_f x_f - \mathcal{T}_{f_0} x_f - \dot{\mathcal{T}}(f_0, f_1)x_0 \\ 0 \end{pmatrix} \\
&\quad = [I + C(x_0)^{-1}M(f)]^{-1}C(x_0)^{-1}M(f)C(x_0)^{-1}\begin{pmatrix} \mathcal{T}_f x_f - \mathcal{T}_{f_0} x_f \\ 0 \end{pmatrix} \\
&\qquad -C(x_0)^{-1}\begin{pmatrix} \mathcal{T}_f x_f - \mathcal{T}_{f_0} x_f - \dot{\mathcal{T}}(f_0, f_1)x_{f_0} \\ 0 \end{pmatrix}
\end{aligned}$$

and therefore

$$\begin{aligned}
(5.15)\qquad &\left\| \begin{pmatrix} x_f - x_0 \\ \lambda_f - \lambda_0 \end{pmatrix} + C(x_0)^{-1}\begin{pmatrix} \dot{\mathcal{T}}(f_0, f_1)x_0 \\ 0 \end{pmatrix} \right\|_{(V\times\mathbf{R})} \\
&\leq \; c_1 \, \| \, M(f) \, \|_{\mathcal{L}(V\times\mathbf{R}, V^*\times\mathbf{R})} \left\| C(x_0)^{-1}\begin{pmatrix} \mathcal{T}_f x_f - \mathcal{T}_{f_0} x_f \\ 0 \end{pmatrix} \right\|_{\mathcal{L}(V\times\mathbf{R})} \\
&\quad + c_2 \Big(\| \, \mathcal{T}_f - \mathcal{T}_{f_0} - \dot{\mathcal{T}}(f_0, f_1) \, \|_{\mathcal{L}(V,V^*)} \| \, x_f \, \|_V \\
&\quad + \| \, \dot{\mathcal{T}}(f_0, f_1) \, \|_{\mathcal{L}(V,V^*)} \| \, x_f - x_0 \, \|_V \Big),
\end{aligned}$$

where

$$c_1 = \| \, (I + C(x_0)^{-1}M(f))^{-1}C(x_0)^{-1} \, \|_{\mathcal{L}(V^*\times\mathbf{R}, V\times\mathbf{R})}$$

and

$$c_2 = \| \, C(x_0)^{-1} \, \|_{\mathcal{L}(V^*\times\mathbf{R}, V\times\mathbf{R})} \, .$$

Since $M(f) \to 0$ in $\mathcal{L}(V\times\mathbf{R}, V^*\times\mathbf{R})$ and due to (H6) the first term on the right-hand side of (5.15) behaves like $o(|f_1|_F)$. Due to (H6) and Proposition 2.3 the second term behaves like $o(|f_1|_F)$ as well. □

Proof of Corollary 2.6. For the proof it suffices to observe that (λ_f^n, x_f^n), $(\lambda_{f_0}^n, x_{f_0}^n)$ satisfy

$$C(x_{f_0}^n)\begin{pmatrix} x_f^n - x_{f_0}^n \\ \lambda_f^n - \lambda_{f_0}^n \end{pmatrix} = \left[C(x_{f_0}^n) - C(x_f^n)\right]\begin{pmatrix} x_f^n - x_{f_0}^n \\ \lambda_f^n - \lambda_{f_0}^n \end{pmatrix} - \begin{pmatrix} \mathcal{T}_f x_f^n - \mathcal{T}_{f_0} x_f^n \\ 0 \end{pmatrix};$$

compare (5.6), where $C(x_{f_0}^n) : V \times \mathbf{R} \to V^* \times \mathbf{R}$ is given by

$$C(x_f^n) = \begin{pmatrix} A_{f_0} - \lambda_0^n & -x_f^n \\ \langle x_{f_0}^n, \cdot \rangle & 0 \end{pmatrix}.$$

It is simple to check that $C(x_{f_0}^n)$ is an isomorphism. The assertions then follow with the same arguments as for Theorem 2.4 and Corollary 2.5. □

Proof of Lemma 2.7. Let $f_1 \in F$ and $\tau \in \mathbf{R}$, and consider

$$\begin{aligned}
&\left\| \frac{1}{\tau} \left(\mathcal{T}_{f_0+\tau f_1} - \mathcal{T}_{f_0} \right) - \dot{\mathcal{T}}(f_0, f_1) \right\|_{\mathcal{L}(V,V^*)} \\
&\quad = \sup_{|\varphi|_V=|\psi|_V=1} \left| \frac{1}{\tau} \langle T_{f_0+\tau f_1}\varphi, T_{f_0+\tau f_1}\psi \rangle - \frac{1}{\tau} \langle T_{f_0}\varphi, T_{f_0}\psi \rangle \right. \\
&\qquad\qquad \left. - \langle \dot{T}(f_0, f_1)\varphi, T_{f_0}\psi \rangle - \langle T_{f_0}\varphi, \dot{T}(f_0, f_1)\psi \rangle \right| \\
&\quad = \sup_{|\varphi|_V=|\psi|_V=1} \left| \left\langle \frac{1}{\tau} (T_{f_0+\tau f_0}\varphi - T_{f_0}\varphi) - \dot{T}(f_0, f_1)\varphi, T_{f_0+\tau f_1}\psi \right\rangle \right. \\
&\qquad\qquad - \langle \dot{T}(f_0, f_1)\varphi, T_{f_0+\tau f_1}\psi - T_{f_0}\psi \rangle \\
&\qquad\qquad \left. + \left\langle T_{f_0}\varphi, \frac{1}{\tau} (T_{f_0+\tau f_1}\psi - T_{f_0}\psi) - \dot{T}(f_0, f_1)\psi \right\rangle \right|.
\end{aligned}$$

From (A1) the expression on the right-hand side of the last equality converges to zero for $\tau \to 0$. Thus $f \to \mathcal{T}_f$ is Gateaux differentiable at f_0 in every direction $f_1 \in F$. From (2.3) it follows that $f_1 \to \dot{\mathcal{T}}(f_0, f_1)$ is linear, and therefore $f \to \mathcal{T}_f$ has a Gateaux derivative at f_0. □

Proof of Lemma 2.8. From (2.4) it is easily seen that $\dot{\mathcal{T}}(f_0, \cdot) \in \mathcal{L}(F, \mathcal{L}(V, V^*))$. To argue Fréchet differentiability at f_0 it suffices to demonstrate continuity of $f \to \dot{\mathcal{T}}(f, \cdot)$ from F to $\mathcal{L}(F, \mathcal{L}(V, V^*))$ at f_0. For $\hat{f}_0$ in a neighborhood of f_0 we have

$$\begin{aligned}
&\| \dot{\mathcal{T}}(f_0, \cdot) - \dot{\mathcal{T}}(\hat{f}_0, \cdot) \|_{\mathcal{L}(F,\mathcal{L}(V,V^*))} \\
&\quad = \sup_{|f_1|_F=|\varphi|_V=|\psi|_V=1} |\langle \dot{T}(f_0, f_1)\varphi - \dot{T}(\hat{f}_0, f_1)\varphi, T_{f_0}\psi \rangle_Y \\
&\qquad\qquad + \langle \dot{T}(\hat{f}_0, f_1)\varphi, T_{f_0}\psi - T_{\hat{f}_0}\psi \rangle_Y + \langle T_{f_0}\varphi - T_{\hat{f}_0}\varphi, \dot{T}(f_0, f_1)\psi \rangle_Y \\
&\qquad\qquad + \langle T_{\hat{f}_0}\varphi, \dot{T}(f_0, f_1)\psi - \dot{T}(\hat{f}_0, f_1)\psi \rangle_Y |,
\end{aligned}$$

and (A2) implies the claim. □

Acknowledgment. The authors would like to acknowledge the comments of the anonymous referee on an earlier version of this paper. The authors are thankful to M. Jaksche for his help with the MATLAB codes that were used to carry out the computations for this section.

CORRIGENDUM: LAGRANGE MULTIPLIERS IN STOCHASTIC PROGRAMMING*

SJUR DIDRIK FLÅM†

Abstract. This note deals with an error in S. D. Flåm, *SIAM J. Control Optim.*, 30 (1992), pp. 1–10. Using approximate subdifferentials the author corrects that error by deriving a Fritz John optimality condition for abstract programs constrained by cones which may have empty interior.

Key words. Fritz John optimality condition, nonsmooth analysis, approximate subdifferential, compactly Lipschitzian mappings, stochastic programming

AMS subject classifications. 90C30, 49J52, 26A27

1. Introduction. Several scholars, notably M. Ciligot-Travain and L. Thibault, have quickly and kindly pointed out that Theorem 3.2 in [7] concerning the Fritz John (FJ) optimality condition needs further qualification. Also, Glover and Craven [8] provide a counterexample to the theorem. As it stands, the theorem is valid only in finite dimensions (implying that the probability measure should have finite support), and would then result from earlier theorems of Clarke and Hiriart-Urruty [11]. In that context it can also be sharpened by replacing the Clarke subdifferential by the generally tighter approximate subdifferential of Ioffe [13], extensively used by Jourani and Thibault [16], [17] and Glover [9].

The error is that the set $\{\lambda \geq 0 : \rho(\lambda) \leq 1\}$ of multipliers λ used in [7] with $\rho(\cdot)$ stemming from a Clarkson–Rieffel renorming need not be bounded.

Therefore, a primary purpose of this note is to rectify these matters; a secondary aim is to complement the recent results in [8] and [10]. Thus, a new FJ condition is demonstrated in Theorem 2 below, partly motivated by stochastic programming problems, but of independent interest and applicable in other fields as well.

To make the note self-contained, we shall deal with the abstract and generic programming problem

$$\text{(P)} \qquad \text{minimize } f(x) \quad \text{subject to } x \in C \quad \text{and} \quad -g(x) \in K,$$

where $f : X \longrightarrow \mathbb{R}$, $g : X \longrightarrow Y$ are locally Lipschitz functions, X, Y are Banach spaces with Y separable, $C \subset X$ is closed, and $K \subset Y$ is a closed convex cone. In the topological dual space Y' of Y, denote by

$$\Lambda := \{y' \in Y' : \langle y, y' \rangle \geq 0 \quad \text{for all } y \in K\}$$

the positive dual cone of K. The following theorem, recently proven in [6, Thm. 2.6] and [10, Thm. 5], extends a similar result in [8] and serves as a point of reference.

THEOREM 1. *For problem* (P) *assume f is locally Lipschitz and g is locally compactly Lipschitz. Also, assume that K has nonempty interior. Then a necessary condition for x_0 to be a local minimum of* (P) *is that there exists* $\tau_0 \in [0,1]$, $\lambda_0 \in \Lambda$, $\|\lambda_0\| \leq 1$, $(\tau_0, \lambda_0) \neq 0$ *such that*

$$(1.1) \qquad 0 \in \tau_0 \partial_A f(x_0) + (1-\tau_0)\partial_A(\lambda_0 g)(x_0) + N_G(x_0, C), \qquad \langle \lambda_0, g(x_0) \rangle = 0.$$

Here ∂_A denotes the *approximate subdifferential*— developed by Ioffe [13], [14], [15], and Mordukhovich [20]—known to be weak* compact, occasionally nonconvex but always contained, and possibly strictly within the Clarke subdifferential. In (1.1) $N_G(x, C)$ is the normal cone to C at x in the sense that it equals the weak* closure of $\mathbb{R}_+\partial_A d(x, C)$, where

* Received by the editors June 30, 1994; accepted for publication July 26, 1994.

† Economics Department, Bergen University, 5007 Bergen, Norway.

$d(x, C) := \inf\{\|x-c\| : c \in C\}$ is the distance function to C; see [15]. Note that in Theorem 1 and throughout most of the section, the constraint function g must be *locally compactly Lipschitzian*—a notion introduced by Thibault [21], [22].

The assumption $\operatorname{int} K \neq \emptyset$ of Theorem 1 is often unfitting, however, it excludes equality constraints and it is at variance with stochastic programming and other fields where cones K like $L^p(\Omega, \mathbb{R}^m_+)$, $p \in [1, +\infty[$ may naturally arise. Admittedly, progress can sometimes be made without constraint qualifications; see [1] and [3]. However, it appears difficult to obtain results like Theorem 1 for spaces like $Y = L^p(\Omega, \mathbb{R}^m_+)$, $p \in [1, +\infty[$ unless some condition is placed on the criterion f also.

Therefore, we shall impose what we name an FJ *qualification*, motivated as follows. In his proof of the FJ condition, Clarke [2, Thm. 6.1.1] maximized for a real $\varepsilon > 0$ a Lagrangian-type expression over a nonempty weak*-compact set M of multipliers to obtain the desired conclusion by letting $\varepsilon \downarrow 0$. Two things, among others, were important then and in subsequent extensions of Clarke's technique [4], [8], [10] as well. First, in order to work with converging sequences of multipliers, M should be sequentially compact. This is ensured by the separability of Y. Second, limiting multipliers must be nonzero. For this property it suffices that $\operatorname{int} K \neq \emptyset$, but what seems more natural here is to let the entire problem structure, not only K, help in avoiding degenerate multipliers. Therefore we introduce the following.

FRITZ JOHN QUALIFICATION AT A POINT x_0. *There exists a w^*-compact convex set $M \subset \Lambda$ of multipliers such that*

$$\langle \lambda, y\rangle \le 0 \quad \textit{for all } \lambda \in M \Rightarrow -y \in K, \tag{1.2}$$

and such that among all sequences $(\varepsilon, x_\varepsilon, \lambda_\varepsilon, \tau_\varepsilon)$ *(omitting, for notational convenience, reference to the sequence index) satisfying* $\varepsilon \downarrow 0$ *in* $\mathbb{R}$, $x_\varepsilon \rightarrow x_0$ *strongly in* C, $\lambda_\varepsilon \rightarrow \lambda_0$ *weak* in* M, $1 \ge \tau_\varepsilon \rightarrow 0$ *in* $\mathbb{R}$,

$$\langle \lambda_\varepsilon, g(x_\varepsilon)\rangle = \max\{\langle m, g(x_\varepsilon)\rangle : m \in M\} \ge f(x_\varepsilon) - f(x_0) + \varepsilon > 0, \tag{1.3}$$

and

$$0 \in \tau_\varepsilon \partial_A f(x_\varepsilon) + (1-\tau_\varepsilon)\partial_A(\lambda_\varepsilon g)(x_\varepsilon) + \sqrt{\varepsilon} B^* + N_G(x_\varepsilon, C), \tag{1.4}$$

there exists, if any, at least one sequence for which the limiting multiplier λ_0 is nonzero.

We remark that frequently the burden of ensuring $\lambda_0 \neq 0$ is entirely carried by K or Y.

PROPOSITION 1. *The* FJ *qualification is satisfied if one of the conditions below holds*:

(i) $\operatorname{int} K \neq \emptyset$;

(ii) Y *is finite-dimensional*;

(iii) K *is the product of one cone having nonempty interior and another being finite dimensional*;

(iv) *There exists a weak* upper semicontinuous function* $c : \Lambda \rightarrow \mathbb{R}$, *and a number* χ *such that the set*

$$\{\lambda \in \Lambda : \|\lambda\| \le 1 \textit{ and } c(\lambda) \ge \chi\} \tag{1.5}$$

is nonempty, convex, does not contain 0, *and satisfies* (1.2).

Proof. In cases (i), (ii), and (iii), take $M = \{\lambda \in \Lambda : \|\lambda\| \le 1\}$. Then (1.3) implies $\|\lambda_\varepsilon\| = 1$, and any sequence $\{\lambda_\varepsilon\}$ contains a weak*-convergent subsequence with nonzero limit; see [8]. In case (iv), take M to equal the set defined in (1.5). □

Remark. In problem (P) one may accommodate more general sets K than closed convex cones. Also, to satisfy the FJ qualification it suffices that K be epi-Lipschitz-like at $-g(x_0)$. For details see Jourani [9].

2. Main result. We now state the announced result on the FJ condition, quite parallel to Theorem 1 and applicable to stochastic programming.

THEOREM 2. *For problem* (P) *assume f is locally Lipschitz, g is locally compactly Lipschitz, and the* FJ *qualification is satisfied at x_0. Then a necessary condition for x_0 to be a local minimum of* (P) *is that there exists $\tau_0 \in [0,1]$, $\lambda_0 \in M$, not both zero, such that* (1.1) *holds.*

Proof. The argument follows that of [10] with small modifications, but is given for completeness. Define a continuous sublinear function $k : Y \to \mathbb{R}$ by $k(y) = \max\{\langle m, y\rangle : m \in M\}$, where M is the nonempty set defined in the above FJ qualification. For any positive number ε consider the function

$$h_\varepsilon(x) := \max\{f(x) - f(x_0) + \varepsilon,\ k(g(x))\}$$

mapping X into $\mathbb{R}$. Observe that $h_\varepsilon(x) \leq 0$ implies $k(g(x)) \leq 0$; then (1.2) yields $-g(x) \in K$. It follows that $h_\varepsilon(x) > 0$ for all $x \in C$ sufficiently near x_0. Indeed, otherwise there would exist $x \in C$, arbitrarily close to x_0, satisfying $f(x) \leq f(x_0) - \varepsilon$ and $-g(x) \in K$. If so, this contradicts the local optimality of x_0. Now, the fact that $h_\varepsilon(x_0) = \varepsilon$ tells us that x_0 furnishes a local ε-minimum of h_ε, provided that this function is restricted to C. Since h_ε is lower semicontinuous, we may find, by Ekeland's variational principle [5], a point $x_\varepsilon \in C$ within $\sqrt{\varepsilon}$-distance from x_0 such that

$$h_\varepsilon(x_\varepsilon) < h_\varepsilon(x) + \sqrt{\varepsilon}\|x - x_\varepsilon\|$$

for all $x \in C$ different from x_ε and sufficiently close to x_0. In fact, a fortiori h_ε is Lipschitz near x_0 with some modulus L (independent of ε). It follows, therefore, by the exact penalization result of Clarke [2, Prop. 2.4.3], that the function

$$h_\varepsilon(x) + \sqrt{\varepsilon}\|x - x_\varepsilon\| + (L+\varepsilon)d(x, C)$$

attains an unconstrained local minimum at x_ε. Thus, since Fermat's rule applies to ∂_A, we get

$$\begin{aligned} 0 &\in \partial_A[h_\varepsilon(\cdot) + \sqrt{\varepsilon}\| \cdot - x_\varepsilon\| + (L+\varepsilon)d(\cdot, C)](x_\varepsilon) \\ &\subset \partial_A h_\varepsilon(x_\varepsilon) + \sqrt{\varepsilon}B^* + (L+\varepsilon)\partial_A d(x_\varepsilon, C), \end{aligned} \tag{2.6}$$

where B^* denotes the closed unit ball in Y'. We proceed to invoke the following chain rule of Jourani and Thibault [18].

Let $g : X \to Y$ be locally compactly Lipschitzian at x and let $k : Y \to \mathbb{R}$ be locally Lipschitz at $g(x)$. Then kg is locally Lipschitz at x and

$$\partial_A(kg)(x) \subset \bigcup\{\partial_A(\lambda g)(x) : \lambda \in \partial_A k(g(x))\}. \tag{2.7}$$

Letting k and g be as above, this chain rule (2.2) yields

$$\partial_A(kg)(x) \subset \bigcup\{\partial_A(\lambda g)(x) : \lambda \in M,\ \langle \lambda, g(x)\rangle = kg(x)\}. \tag{2.8}$$

The same rule (2.2) also implies that

$$\partial_A h(x) \subset \operatorname{conv}\{\partial_A h_i(x) : h_i(x) = h(x)\}, \tag{2.9}$$

when $h(x) := \max\{h_1(x), h_2(x)\}$ for locally Lipschitz functions $h_i : X \to \mathbb{R}$. For details on these last two assertions see [8]. Employing (2.3)–(2.4) in (2.1) we find $\tau_\varepsilon \in [0,1]$ and $\lambda_\varepsilon \in M$ such that

$$0 \in \tau_\varepsilon \partial_A f(x_\varepsilon) + (1 - \tau_\varepsilon)\partial_A(\lambda_\varepsilon g)(x_\varepsilon) + \sqrt{\varepsilon}B^* + (L+\varepsilon)\partial_A d(x_\varepsilon, C). \tag{2.10}$$

Now let $\varepsilon \downarrow 0$ to have $x_\varepsilon \to x_0$ strongly. We consider two cases.

Case 1. Assume $kg(x_\varepsilon) < f(x_\varepsilon) - f(x_0) + \varepsilon$ for some sequence $\varepsilon \downarrow 0$. Then $h_\varepsilon(x_\varepsilon) = f(x_\varepsilon) - f(x_0) + \varepsilon > 0$, so that $\tau_\varepsilon = 1$ by (2.4), and we may select $\lambda_\varepsilon = 0$ in (2.5). Passing to the limit in (2.5) we obtain (1.1) with $\tau_0 = 1$, $\lambda_0 = 0$.

Case 2. $kg(x_\varepsilon) \geq f(x_\varepsilon) - f(x_0) + \varepsilon > 0$ along every sequence $\varepsilon \downarrow 0$. Associated with any such sequence $\varepsilon \downarrow 0$, there are numbers $\tau_\varepsilon \to \tau_0 \in [0,1]$, and the multipliers $\lambda_\varepsilon \in M$ satisfying $\langle \lambda_\varepsilon, g(x_\varepsilon)\rangle = kg(x_\varepsilon)$ by (2.3). Since M is weak* sequentially compact (because Y is separable, see [12]), we may suppose $\lambda_\varepsilon \to \lambda_0 \in M$. We claim that limiting λ_0 satisfies the complementarity condition in (1.1). In fact, $\langle \lambda_0, g(x_0)\rangle \leq 0$ holds trivially, and the converse inequality follows from two facts: first, $\langle \lambda_\varepsilon, g(x_\varepsilon)\rangle = kg(x_\varepsilon) \to kg(x_0) \geq 0$, because $kg(x_\varepsilon) > 0$, and second, $\langle \lambda_\varepsilon, g(x_\varepsilon)\rangle \to \langle \lambda_0, g(x_0)\rangle$.

Next, for the inclusion in (1.1), observe that the correspondence $(\lambda, x) \to \partial_A(\lambda g)(x)$ has a closed graph in the (weak* × strong) product topology, see [6, Lem. 2.5] or [10].

Therefore, limit (2.5) gives the desired inclusion (1.1). Thus, it remains in this case only to exclude the degenerate outcome $(\tau_0, \lambda_0) = 0$. Clearly, if for some sequence $\varepsilon \downarrow 0$ it holds that $\tau_\varepsilon \to \tau_0 > 0$, then we are done. Otherwise the FJ qualification comes into play, ensuring that some $\lambda_0 \neq 0$. This completes the proof. □

Following [10] we remark that if g is *K-convex* in the sense that

$$\mu_1, \mu_2 \geq 0,\ \mu_1 + \mu_2 = 1 \Rightarrow \mu_1 g(x_1) + \mu_2 g(x_2) - g(\mu_1 x_1 + \mu_2 x_2) \in K \quad \forall x_1,\ x_2 \in X,$$

then the assumption that g is locally compactly Lipschitzian often becomes redundant.

COROLLARY. *For problem* (P) *assume that f, g are locally Lipschitz, g is K-convex, and the* FJ *qualification is satisfied at x_0. If Y has a strictly convex dual norm, then a necessary condition for x_0 to be a local minimum of* (P) *is that there exists $\tau_0 \in [0,1]$, $\lambda_0 \in M$, not both zero, such that* (1.1) *holds.*

THE RENDEZVOUS SEARCH PROBLEM[*]

STEVE ALPERN[†]

Abstract. The author considers the problem faced by two people who are placed randomly in a known search region and move about at unit speed to find each other in the least expected time. This time is called the rendezvous value of the region. It is shown how symmetries in the search region may hinder the process by preventing coordination based on concepts such as north or clockwise. A general formulation of the rendezvous search problem is given for a compact metric space endowed with a group of isometries which represents the spatial uncertainties of the players. These concepts are illustrated by considering upper bounds for various rendezvous values for the circle and an arbitrary metric network. The discrete rendezvous problem on a cycle graph for players restricted to symmetric Markovian strategies is then solved. Finally, the author considers the problem faced by two people on an infinite line who each know the distribution of the distance but not the direction to each other.

Key words. rendezvous, search

AMS subject classifications. 90B40, 90D26

1. Introduction. The purpose of this paper is to introduce and rigorously formulate a new form of cooperative optimal search, which we call the rendezvous search problem. This is the problem faced by two people placed in a known region according to some known distribution who wish to meet in minimum time. They attempt to find each other by moving with speed bounded by one until the first meeting time T, when the distance between them comes within a given detection radius. The least expected meeting time that can be achieved by allowable search strategies is called the rendezvous value R of the search region X. We give a formal definition of the rendezvous search problem, find upper bounds on R for certain regions or classes of regions, and consider a few related problems of rendezvous on the line and on a cycle graph. In addition, we give a number of questions that we hope will stimulate the development of a theory of rendezvous search.

As we shall see, there are in fact several different rendezvous values depending on which search strategies are allowed. We shall be primarily concerned with the symmetric rendezvous value R^s obtained by restricting the two players to using the same mixed search strategy. This corresponds to the case where the players have not previously agreed which role each should take (e.g., wait or search) in the event they become separated, or where, after becoming separated, they both take directions from a controller who does not know their names. Without this restriction we have the asymmetric rendezvous value R^a, which in general is smaller. In addition, the rendezvous value will depend on geometric aspects of the information each player has about his position in a symmetrical region X, which we will formalize by specifying a particular subgroup G of the isomorphism group Γ of the metric space (X, ρ). For example, the players may be lost on a circle, have no common notion of where $\theta = 0$ is, but have a common notion of clockwise (i.e., both know which way is up). In this case a strategy of *head for* $\theta = 0$ would not be allowable, but *go clockwise* would. In other words, the players may have some uncertainty about how to fit the picture of the search region that they see to a map common to both. It is the aim of this paper to formalize these notions of spatial symmetry, to give a rigorous definition of the rendezvous value(s), and to provide some estimates or determinations of R^s in some simple cases. We also suggest some extensions to the theory given here that we hope will stimulate further work on rendezvous search theory.

From a formal point of view rendezvous problems are very close to search games with mobile hiders (also called *princess and monster games*). As proposed in Isaacs's book on

[*] Received by the editors May 12, 1993; accepted for publication (in revised form) November 18, 1993.

[†] Department of Mathematics, London School of Economics, University of London, Houghton Street, London, England WC2A 2AE.

differential games [12], and extensively analyzed in Gal's book on search games [9] and in the literature [1], [2], [3], [4], [11], [10], [6], [13], [17], the latter are zero-sum games where the meeting time T is the payoff to the maximizing hider. One direct comparison is that the value of that game (called the search value) is obviously an upper bound for the rendezvous values. Our work on rendezvous search on the line is also closely related to the work of Beck (e.g., [7], [8]) on the linear search problem.

No introduction to a work on rendezvous search would be complete without reference to the examples and analysis given by Schelling in his book on the strategy of conflict [16]. His paradigm is the problem facing two parachutists who land in a field with various roads, buildings, a river, and a single bridge. He suggests that the essential problem is to find the unique *focal point*, which in this case is generally thought to be the bridge. The implication is that without focal points the problem cannot be formulated, let alone solved. Our perspective is diametrically opposed to Schelling's. We ask how to rendezvous when the search region is homogeneous. The difference in our analysis that enables us to tackle (sometimes) such questions is that while Schelling considered one-shot strategies (go to point x), we consider multistage strategies that continue to search after initial failed attempts to rendezvous. This is not to suggest that focal points are not important in practice—surely they are—but we hope to show that even in the absence of focal points rendezvous search is more than purely random wanderings.

The paper is organized as follows. In §2 we define the rendezvous value for a compact metric space endowed with a given subgroup of its isometries which reflects the players' spatial uncertainties. In §3 we give upper bounds for the rendezvous values of a metric network. In §4 we illustrate the definitions of §2 involving symmetries by considering various rendezvous values for the circle with respect to different isometry groups. Up to this point all the definitions and examples relate to continuous motion in continuous time, which is our main interest. However, interesting search problems can also be formulated on graphs with the players moving in integer time to adjacent nodes of a graph. An outstanding result in this direction is the paper of Anderson and Weber [5], which gives asymptotic results for the symmetric rendezvous value of a complete graph. In §5 we find the symmetric rendezvous value for the cycle graph on m nodes when the players are restricted to symmetric Markovian strategies. This result is a rendezvous version of the elegant analysis of Ruckle for the (zero-sum) search game with the same dynamics [14], [15]. In §6 we consider rendezvous search on the real line, where the players know the distribution of the distance between them but do not know the direction of the other player. These problems are a rendezvous version of the linear search problem [7], [8] mentioned above. We conclude with a short final section on suggestions for further research on rendezvous search.

2. Rendezvous on a compact metric space. In this section we define the rendezvous search problem (and associated values R^s and R^a) for a compact metric space (X, ρ) with a given detection radius δ and a given group G of isometries (distance preserving bijections) of X. Since it is the last of these elements that requires the most motivation, a brief discussion of the isometry group and its connection with spatial symmetries precedes the formal argument. Note that throughout this paper we are assuming that the players can see the whole region X but cannot see the other player. (Without this assumption we have rendezvous search in a maze, which will be the subject of another paper.)

Suppose the search region X is a plane (it's not compact, but that won't matter for this example) with a perfectly straight canal running through it, and a single bridge over the canal. If the water is flowing, then the two players could each determine their exact position on a map common to both. Thus a search strategy could, in principle, depend on the exact point where they are initially placed (where the parachutists land). Now suppose the bridge is not present.

The players can now tell their distance from the canal and which side of the canal they are on (the side from which the river flows right or left). The group G of isometries which describes this lack of information is the real line $\Re$, which acts on the planar region by translations in the direction of the canal. Each real number corresponds to a possible placement of the bridge along the canal. If the canal is the y-axis on the map, then each player's information on landing is his x-coordinate, and his information space $\tilde{X}$ is thus $\Re = X/G = \Re^2/\Re$, where the / indicates the equivalence classes of the set on the left via the action of the group on the right as defined below. Now suppose the river no longer flows. The players now know only their distance to the river, not which side they are on. Their information is now in $\tilde{X} = \Re^+ = [0, \infty)$, which equals X/G, where G now also includes the reflection isometry across the canal. Next, take away the canal. Now the region X is a featureless plane where all points look the same. Let us assume they landed on Earth so they know where up is. Then the relevant isometry group consists of translations and rotations of X, and the information space $\tilde{X}$ is a singleton, meaning no information is obtained upon landing. However, since they agree on up, they can coordinate to the extent of using, say, clockwise spirals in the symmetric game or opposite directional spirals in the asymmetric game. Finally, if we consider two astronauts landing on a planar region of space, perhaps from opposite sides, then they no longer have a common up, and a reflection of the plane must be added to the isometry group G. They can no longer agree on the meaning of clockwise. Note that in both of the last two scenarios the information space $\tilde{X}$ is trivial, but more strategies are available in the former than the latter. To summarize, the given group G represents the players' uncertainty (or information set) when trying to fit their view of the search region and their position on it onto a map common to both. We apologize to mathematicians for this lengthy discussion, but it is possible that these ideas are new to some who could otherwise follow the arguments of the paper.

To begin the formal analysis, we first define the set of paths P that the players may use for searching by $P = \{p : \Re^+ \to X, \rho(p(t_1), p(t_2)) \le |t_1 - t_2|\}$. The subset of paths which start at a point x is denoted by P_x. The *meeting time* $T : P \times P \to \Re^+$ of two paths p, q is defined by

$$T(p, q) = \min\{t : \rho(p(t), q(t)) \le \delta\}, \tag{1}$$

where δ is the given detection radius. We note that in most of our examples the space X is one-dimensional, and we will take $\delta = 0$. The group G induces an equivalence relation on X and P by $x \sim y \Leftrightarrow \exists g \in G,\ g(x) = y$ and $p \sim q \Leftrightarrow \exists g \in G, g(p(t)) \equiv q(t)$. Call the associated sets of equivalence classes $\tilde{X}$ and $\tilde{P}$, and let [ ] denote the equivalence class of an element. A search strategy is a map $s : \tilde{X} \to \tilde{P}$ such that there is some path $p \in s(x)$ with $p(0) = x$, and the set of all search strategies will be denoted by S. It is worth noting two important cases in which this formalism simplifies considerably. If there is no group of isometries given (or formally, if G is just the identity transformation), then a strategy is simply a map $s : X \to P$ satisfying $s(x) \in P_x$. If the group G acts transitively on X ($\forall x, y \in X, \exists g \in G : g(x) = y$), then $\tilde{X}$ is a singleton and $S = \tilde{P}$. The next problem is how to evaluate the (expected) meeting time for pairs of equivalence classes of paths. Let ν denote the Haar measure on G and define

$$\tilde{T}([p], [q]) = \int_G T(gp, q)\, d\nu(g). \tag{2}$$

The reason we must only have G act on one of the paths is that for $g,\ h \in G$, $T(gp, hq) = T(h^{-1}gp, q)$. To obtain the normal form for the search game, assume players are placed in X independently, according to the same measure μ. Then the normal form is given by the function $\hat{T} : S \times S \to \Re$ defined by

$$\hat{T}(s_1, s_2) = \int_{x \in X} \int_{y \in X} \tilde{T}(s_1(x), s_2(y))\, d\mu(x)\, d\mu(y). \tag{3}$$

The symmetric rendezvous search problem is finding the search strategy which, when used by both players, minimizes the expected meeting time. For some search problems (X, G) it may be that when the same path class is chosen by both players, for some choices of g in (2) the players' initial distance is preserved in time (e.g., if both go at speed 1 clockwise on the circle and g is the identity). The result may be an infinite expected meeting time. To get out of this enforced symmetry, the players can choose the same *mixed* strategy, breaking the symmetry by independent randomization. Thus even though this is essentially a one-person decision problem, randomization may be necessary. With this in mind, let S^* denote the set of all mixed search strategies, i.e., the set of all probability Borel measures on S. The topology on S is defined by giving P the topology of uniform convergence on compact sets. We then define the symmetric rendezvous value of the search problem (X, G, δ) by

$$R^s = R^s(X, G, \delta) = \min_{s^* \in S^*} \int_S \int_S \hat{T}(s_1, s_2)\, ds^*(s_1)\, ds^*(s_2). \tag{4}$$

The use of min rather than inf can be justified by observing that the meeting time function T is lower semicontinuous in each variable on the path space P when the latter is given the topology of uniform convergence on compact sets. The full argument is the same as for search games as in [9]. For the asymmetric rendezvous problem there is no need for mixed strategies, so the asymmetric rendezvous value is given by

$$R^a = R^a(X, G, \delta) = \min_{r,s \in S} \hat{T}(r, s). \tag{5}$$
