(ii) If γ is exceptional, then γ is time minimal with respect to all solutions of (5.1) contained in a sufficiently small C^0-neighborhood of γ.

(iii) If γ is hyperbolic, then γ is time optimal with respect to all solutions contained in a sufficiently small C^0-neighborhood of γ *until the first conjugate point*. This point can be computed by integrating the linear differential equation (5.5), which is Jacobi's equation associated with γ. This equation can be found by constructing the model. From [2], this construction requires two nonlinear operations: the integrations of the reference trajectory, which has to be identified to $t \to (t,0,0)$, and of the vector field Y, identified to $\frac{\partial}{\partial z}$.

5.4. Conjugate points and the synthesis problem: Intrinsic computation. In the classical calculus of variations, the concept of conjugate point is deeply connected with the concept of extremal field (see [9]). This was used in [22] to define a concept of conjugate point along a reference hyperbolic trajectory in the time-optimal control problem. We briefly recall these results and their connection with our previous analysis.

5.4.1. Preliminaries. Consider a control system in $\mathbf{R}^3$, $\dot v = X + uY$, where $|u| \le M$ and $0 < M \le +\infty$. (Our analysis can be straightforwardly extended to the n-dimensional case.) Recall that $\hat S = X - (D'D)Y$ is the vector field whose nonperiodic trajectories are (H0)–(H3) singular extremals. Let γ be such a reference trajectory defined on $[0,T]$ and corresponding to a control taking its values in $]-M,+M[$, and let us assume that γ is hyperbolic. Let $V(t), t \in [0,T]$ be the solution of the *variational equation*

$$\delta\dot v(t) = \frac{\partial \hat S}{\partial v}(y(t))\delta v(t) \tag{5.6}$$

with $V(0) = Y(\gamma(0))$.

Let $\varepsilon, \varepsilon' = \pm 1$ and g be the mapping $(t_1,t_2,t_3,\varepsilon,\varepsilon') \to \exp\, t_3(X+\varepsilon' MY).\exp\, t_2\hat S.\exp\, t_1(X+\varepsilon MY)(\gamma(0))$, and let $\mathcal{F}$ be its image for $t_2 \in [0,T]$ and t_1, $t_3 \ge 0$, sufficiently small. If $\det\,(V(\gamma(t)), Y(\gamma(t)), \hat S(\gamma(t)))$ is never vanishing on $]0,T]$, then $\mathcal{F}$ is a field about the arc γ in the following sense. There exists a C^0-neighborhood of γ, U, such that every point of U is the image of only one $(t_1,t_2,t_3,\varepsilon,\varepsilon')$. If $M < +\infty$, Moyer proved in [22] that $\mathcal{F}$ is an *optimal field*, i.e., every arc of the field is time optimal with respect to C^0-neighboring trajectories, and from [2] this result is still valid if $M = +\infty$. *In other words, we have constructed the time-optimal synthesis in a neighborhood of the reference trajectory.*

Let us denote by t_{1c} the first $0 < t \le T$ such that $\det\,((V(\gamma(t)), Y(\gamma(t)), \hat S(\gamma(t)))$ vanishes. Next, we compare t'_{1c} with t_{1c} defined in (5.5).

LEMMA 5.9. *We have the following*:

(i) $V(t) \in \operatorname{Span}\{Y(\gamma(t)), [X,Y](\gamma(t))\}$,

(ii) $\det\,(V(t),\, Y(\gamma(t)),\, \hat S(\gamma(t))) = 0$ *for* $t \in]0,T]$ *if and only if* $v(t)$ *and* $Y(\gamma(t))$ *are collinear.*

Proof. By construction, $V(t)$ is the derivative at $\varepsilon = 0$ of the curve $\varepsilon \to \exp\, t\hat S.\exp\, \varepsilon Y(\gamma(0))$ which can be written as $\varepsilon \to \exp\, t\hat S.\exp\, \varepsilon Y.\exp -t\hat S(\gamma(t))$. Now, from the ad-formula, we have for small t

$$V(t) = \sum_{n \geq 0} (-1)^n \frac{t^n}{n!} \mathrm{ad}^n \, \hat{S}(Y)(\gamma(t)),$$

and since γ is a singular arc and X, $[X, Y]$ are linearly independent, we have

$$\mathrm{Span}\,\{\mathrm{ad}^n \, \hat{S}\,(Y);\; n \geq 0\}_{|\gamma} = \mathrm{Span}\,\{Y, [\hat{S}, Y]\}_{|\gamma}.$$

Hence, since Span $\{Y, [\hat{S}, Y]\}_{|\gamma}$ = Span $\{Y, [X, Y]\}_{|\gamma}$, we get $V(t) \in$ Span $\{Y(\gamma(t)), [X, Y]\,(\gamma(t))\}$ for small t and everywhere by analycity. This proves (i). Now, in the hyperbolic case det $(Y, [X, Y], X)$ never vanishes along γ, and then (i) implies (ii).

LEMMA 5.10. $t_{1c} = t'_{1c}$.

Proof. To compute t'_{1c}, one may assume system (5.1) written in the normal form of [2]:

$$X = (1 + Q_1)\frac{\partial}{\partial x} + (z + Q_2)\frac{\partial}{\partial y}, \qquad Y = \frac{\partial}{\partial z},$$

where $Q_i \in (\mathbf{R}[x])[y, z]$ and $\delta^\circ Q$ in $y, z \geq 2$, γ being identified to $t \to (t, 0, 0)$ and corresponding to the zero-control. By computing we get

$$\begin{aligned}
[X, Y] &= -\frac{\partial Q_1}{\partial z}\frac{\partial}{\partial x} - \left(1 + \frac{\partial Q_2}{\partial z}\right)\frac{\partial}{\partial y},\\
[Y, [X, Y]] &= -\frac{\partial^2 Q_1}{\partial z^2}\frac{\partial}{\partial x} - \frac{\partial^2 Q_2}{\partial z^2}\frac{\partial}{\partial y},\\
[X, [X, Y]] &= \chi_1 \frac{\partial}{\partial x} + \chi_2 \frac{\partial}{\partial y},
\end{aligned}$$

where

$$\begin{aligned}
\chi_1 &= \frac{\partial Q_1}{\partial x}\frac{\partial Q_1}{\partial z} + \frac{\partial Q_1}{\partial y}\left(1 + \frac{\partial Q_2}{\partial_z}\right) - \frac{\partial^2 Q_1}{\partial x \partial z}(1 + Q_1) - \frac{\partial^2 Q_1}{\partial y \partial z}(z + Q_2),\\
\chi_2 &= \frac{\partial Q_2}{\partial x}\frac{\partial Q_1}{\partial z} + \frac{\partial Q_2}{\partial y}\left(1 + \frac{\partial Q_2}{\partial z}\right) - \frac{\partial^2 Q_2}{\partial x \partial z}(1 + Q_1) - \frac{\partial^2 Q_2}{\partial y \partial z}(z + Q_2).
\end{aligned}$$

Then

$$\begin{aligned}
D = \det(Y, [X, Y], [Y, [X, Y]]) &= \frac{\partial Q_1}{\partial z}\frac{\partial^2 Q_2}{\partial z^2} - \left(1 + \frac{\partial Q_2}{\partial z}\right)\frac{\partial^2 Q_1}{\partial z^2},\\
D' = \det(Y, [X, Y], [X, [X, Y]]) &= \chi_1\left(1 + \frac{\partial Q_2}{\partial z}\right) - \chi_2 \frac{\partial Q_1}{\partial z}.
\end{aligned}$$

Since $\gamma : t \to (t, 0, 0)$, to compute the variational equation of $\hat{S} = X + \hat{u}Y$, $\hat{u} = -D'/D$ along γ, we need only consider the terms in D and D' which are at most linear in y and z. If we set $Q_1 = a(x)z^2 + 2b(x)yz + c(x)z^2 + o_x(y, z)^2$ and $Q_2 = \bar{a}(x)z^2 + 2\bar{b}(x)yz + \bar{c}(x)z^2 + o_x(y, z)^2$, the relevant terms in $\frac{\partial \hat{u}}{\partial v}$ are given by

$$\frac{cy - a'z - b'y}{[-a(1 + 2\bar{a}z + 2\bar{b}z) + \bar{a}(2az + 2bz)]}.$$

Observe that since the numerator is without a constant term, we can take $\bar{a} = \bar{b} = 0$, i.e., one can assume $Q_2 = 0$, and we have only to compute the Jacobian matrix of $\psi = a^{-1}(cy - a'z - b'y)$. Hence we have

$$\frac{\partial\psi}{\partial x} = 0, \quad \frac{\partial\psi}{\partial y} = \frac{c - b'}{a}, \quad \frac{\partial\psi}{\partial z} = -\frac{a'}{a},$$

and the variational equation along γ is

$$\dot{\delta x} = 0, \quad \dot{\delta y} = \delta z, \quad \dot{\delta z} = \frac{c - \dot{b}}{a}\delta y - \frac{\dot{a}}{a}\delta z. \tag{5.7}$$

On the other hand, the Euler–Lagrange equation corresponding to $L(t, \varphi_2, \dot{\varphi}_2) = a(t)\dot{\varphi}_2^2 + 2b(t)\varphi_2\dot{\varphi}_2 + c(t)\varphi_2^2$ is

$$a\,\ddot{\varphi}_2 + (\dot{b} - c)\varphi_2 + \dot{a}\,\dot{\varphi}_2 = 0, \tag{5.8}$$

which is equivalent to the two last equations of (5.7). Therefore $V(t)$ is collinear to $Y(\gamma(t))$ at time t'_{1c} if and only if there exists a nontrivial solution φ_2 of (5.8), with $\varphi_2(0) = \varphi_2(t'_{1c}) = 0$. Hence, we have proved $t_{1c} = t'_{1c}$.

5.4.2. Curvature. Consider the system

$$\dot{\delta y} = \delta z, \qquad \dot{\delta z} = \frac{c - \dot{b}}{a}\delta y - \frac{\dot{a}}{a}\delta z.$$

It can be written as the second-order differential equation

$$\ddot{\delta y} + \frac{\dot{a}}{a}\,\dot{\delta y} + \frac{\dot{b} - c}{a}\delta y = 0.$$

Every equation of the form

$$\ddot{\delta y} + A\,\dot{\delta y} + B\,\delta y = 0$$

can be transformed into

$$\ddot{Y} + KY = 0$$

if we set $\delta y = CY$, where $C = \exp \int_0^t -\frac{A(s)}{2}\,ds$ and K is given by

$$K = \ddot{C} + A\dot{C} + BC.$$

Computing with $A = \frac{\dot{a}}{a}$, $B = \frac{\dot{b} - c}{a}$, and $a < 0$, we get $C = 1/\sqrt{|a|}$.

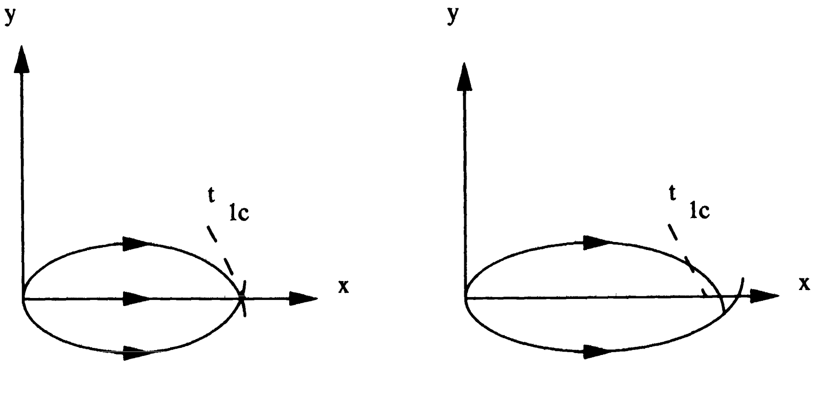
The mapping K defined on $D''D > 0$ corresponds to the concept of *curvature* in Riemannian geometry.

5.4.3. Geometric interpretation. First, let us assume that system (5.1) coincides with the model

$$L(t, y, z)\frac{\partial}{\partial x} + z\frac{\partial}{\partial y} + u\frac{\partial}{\partial z}$$

and the associated reduced system defined in Definition 3.6 is then

$$\dot{x} = 1 + L(t, y, z), \qquad \dot{y} = z, \tag{5.9}$$



(i) (ii)

FIG. 14.

where z is the control variable. By definition of t_{1c}, there exists a curve $\bar{y}$ such that $\dot{\bar{y}}(0) = 1$, $\bar{y}(0) = \bar{y}(t_{1c}) = 0$, $y(t) \neq 0$ on $]0, t_{1c}[$, and $\int_0^{t_{1c}} L(t, \bar{y}, \bar{y})\,dt = 0$. Hence the corresponding solution starting from (0, 0) satisfies $\bar{x}(t_{1c}) = t_{1c}$, and $(\bar{x}, \bar{y})$ intersects $(]0, t_{1c}], 0)$ only at $(t_{1c}, 0)$.

Let $\varepsilon \in \mathbf{R}$ and $\bar{x}_\varepsilon$ be the solutions of (5.9) starting from 0 and corresponding to the controls $z = \varepsilon \bar{y}$. From our previous analysis the family of curves $(\bar{x}_\varepsilon, \varepsilon \bar{y})$ intersects $(]0, t_{1c}], 0)$ only at $(t_{1c}, 0)$ (see Fig. 14(i)), and as in [9] one can show that for the reduced system associated with (5.1), $(t_{1c}, 0)$ is the limiting point of the intersections of the projection of the extremals on the reduced space with the projection of the reference extremal γ (Y can be identified to $\frac{\partial}{\partial z}$ and γ to $t \to (t, 0, 0)$, the reduced space being the (x, y)-space); see Fig. 14(ii).

5.5. Focal points. When we deal with optimal control problems where the terminal manifold is not necessarily a point, the concept of conjugate point has to be generalized to the concept of a *focal point*. To make the application to the batch reactor problem, throughout this section we shall assume that the terminal manifold N is of codimension one and that we are in the flat case, Y tangent everywhere to N.

5.5.1. Generalities. We consider system (5.1) in $\mathbf{R}^3$, with $|u| \leq 1$. The terminal manifold N is assumed to be a regular submanifold of codimension one, its tangent space being given by Span $\{Y, W\}$, where W is a vector field. Let γ be a reference singular (H0)–(H3)-extremal, *hyperbolic*, defined on $[T, 0]$, $T < 0$, and corresponding to an admissible control taking its values in $]-1, +1[$. Let us assume that $\gamma(0) \in N$ and γ satisfies the transversality condition, which can be expressed as follows: $\gamma(0) \in L = \{v \in N;\ \det\,(Y, W, [X, Y])(v) = 0\}$.

We will assume that L is a simple curve. *Now, to define the concept of a focal point along* γ, *we must know the time-optimal synthesis function near* $\gamma(0)$. Hence, we shall assume that γ is time optimal on $[t, 0]$ for the optimal problem with terminal condition on N for t small and the optimal synthesis given in a neighborhood of $\gamma(0)$ by Fig. 15; i.e., the surface formed by the singular arcs arriving at L divides the space into two domains, one in which the optimal feedback is $+1$, and one in which it is -1, the optimal feedback in the surface being the singular control $\hat{u}$. (For a method characterizing such a synthesis, simply see §4.)

DEFINITION 5.11. *Let $V'(t)$ be the solution of the variational equation*

$$\dot{\delta v}(t) = \frac{\partial \hat{S}}{\partial v}(\gamma(t))\delta v(t),$$

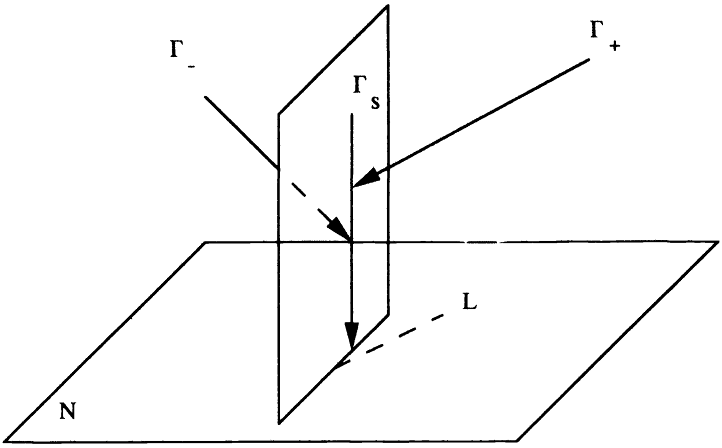


FIG. 15.

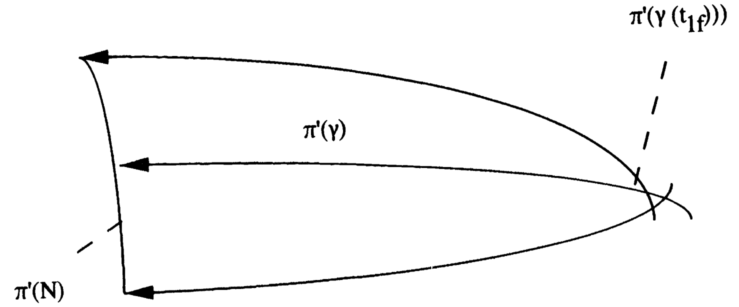

FIG. 16.

with $V'(0) = Z$ *unit tangent vector to* L *at* $\gamma(0)$. *The point* $\gamma(t_{1f})$ *with* $T \le t_{1f} < 0$ *will be called the* (*first*) *focal point about* γ *if* t_{1f} *is the first time* $t < 0$ *such that* det $(V'(t), Y(\gamma(t)), \hat{S}(\gamma(t))) = 0$.

LEMMA 5.12. $V'(t) \in \text{Span}\,\{Y(\gamma(t)), [X,Y](\gamma(t))\}$.

Proof. The vector Z can be written $\lambda_1 Y(\gamma(0)) + \lambda_2[\hat{S},Y](\gamma(0))$, with $\lambda_1, \lambda_2 \in \mathbf{R}$. By definition

$$V'(t) = \frac{d}{d\varepsilon}_{|\varepsilon=0}[\exp t\hat{S}.\exp \varepsilon Z(\gamma(0))], \qquad t < 0$$

and from the ad-formula, the second member of the previous equation belongs to Span $\{\text{ad}^k\hat{S}(Y)(\gamma(t)); k \in \mathbf{N}\}$. This space coincides with Span $\{Y(\gamma(t)), [X,Y](\gamma(t))\}$.

5.5.2. Geometric interpretation. Let $Y = \frac{\partial}{\partial z}$, and let us consider the reduced system. If π' is the projection $(x,y,z) \to (x,y)$, since Y is tangent to the terminal manifold we have the interpretation for the concept of focal points in terms of the behaviors of the projected singular extremals in Fig. 16.

6. Application to the time-optimal control for batch reactors. Now we will compute the optimal synthesis for the problem $\mathcal{P}$ defined in §2 for a sequence of two reactions $X \to Y \to Z$ and where the terminal condition belongs to $N = \{(x,y); y/x = k\}$, k being given, where x and y are the respective (normalized) concentrations of species X and Y. System

(2.3) can be written

$$\frac{dx}{dt} = -vx, \quad \frac{dy}{dt} = vx - \beta v^{\alpha} y, \quad \frac{dv}{dt} = h(v)u, \tag{6.1}$$

where $v = A_1 e^{-E_1/RT}$, $0 < v < A_1$, $h(v) = \frac{R}{E_1} v \ln^2(v/A_1)$, $\alpha = E_2/E_1$, $\beta = A_2/A_1^{\alpha}$, and $w = (x, y, v) \in P$, the physical space defined by $0 < x \leq 1$, $y \geq 0$, $x + y \leq 1$, $0 < v < A_1$, and $y/x < k$.

6.1. Computations. The first step in our analysis is to compute the singular extremals. Using 3.2, we get the following lemma.

LEMMA 6.1. *The singular extremals of order* 2 *for system* (2.3), *written as* $((x, v), (p, \lambda), u) \in \mathbf{R}^n \times \mathbf{R} \times \mathbf{R}^n \times \mathbf{R} \times \mathbf{R}$, *are the solutions of*

$$\begin{aligned} \frac{dx}{dt} &= K(v)x, \quad \frac{dp}{dt} = -pM(v), \quad \frac{dv}{dt} = h(v)\hat{u}(x,p), \\ \hat{u}(x,p) &= \frac{p[M'(v), M(v)]x}{pM''(v)xh(v)}, \qquad \lambda = 0, \end{aligned} \tag{6.2}$$

contained in $\Sigma' = \{(x,p); pM'(v)x = 0\}$. (*Here p is a row vector, M' and M'' are the first and second derivative of M with respect to v, and* $[M', M] = MM' - M'M$.)

PROPOSITION 6.2. *Consider system* (6.1). *If* $\alpha \neq 1$, *all the singular extremals* $w(.)$ *in the physical space p are hyperbolic and the solutions of*

$$\frac{dx}{dt} = -vx, \quad \frac{dy}{dt} = vx - \beta v^{\alpha} y, \quad \frac{dv}{dt} = h(v)\hat{u} \tag{6.3}$$

restricted to P, where the singular control is $\hat{u} = -\dfrac{v^2 x}{h(v)y}$.

Proof. For a system in $\mathbf{R}^3$, $\hat{u}$ is given by $-D'/D$ and the hyperbolic trajectories are contained in $DD'' > 0$, where D, D', and D'' are defined in §5.2. By computing in our case, we get $D = h^4 \alpha(\alpha - 1)\beta v^{\alpha-2} xy$, $D' = h^3 \beta(\alpha - 1)v^{\alpha} x^2$, and $D'' = h^2 \beta v^{\alpha} xy(\alpha - 1)$. This proves the proposition.

6.2. Projected system. System (5.3) is left invariant by the transformations $(x, y, v) \to (\lambda x, \lambda y, v)$, $\lambda \in \mathbf{R} \backslash \{0\}$. Hence it can be projected onto $\mathbf{P}^1 \times \mathbf{R}$, where $\mathbf{P}^1$ = one-dimensional projective space. More precisely, since x never vanishes in the physical space, in the coordinates $(x, z = y/x, v)$ it becomes

$$\frac{dx}{dt} = -vx, \quad \frac{dz}{dt} = v - \beta v^{\alpha} z + vz, \quad \frac{dv}{dt} = h(v)u. \tag{6.4}$$

The system

$$\frac{dz}{dt} = v - \beta v^{\alpha} z + vz, \qquad \frac{dv}{dt} = h(v)u \tag{6.5}$$

is called the *projected system.*

Now, we can project differential equation (6.3) onto

$$\frac{dz}{dt} = v - \beta v^{\alpha} z + vz, \qquad \frac{dv}{dt} = -\frac{v^2}{\alpha z}. \tag{6.6}$$

But from §3.5, not every solution of this equation corresponds to a singular extremal of the projected system. Indeed, let (X, Y) be a system on $\mathbf{R}^2$. The singular extremals are contained in the set

$$S = \{x;\ \det(Y(x), [X, Y](x)) = 0\},$$

the singular control being given by $\hat{u}$. By computing for the planar system (6.5) we get the following lemma.

LEMMA 6.3. *The singular extremals for system* (6.5) *are contained in* $S = \{(z,v);\ z(\alpha\beta v^{\alpha-1}-1) = 1\}$, *and the singular control is given by* $\hat{u} = -(v^2/h(v)\alpha z)$. *The differential equation describing the evolution on a singular arc is*

$$\frac{dv}{dt} = \frac{v^2}{\alpha}(1-\alpha\beta v^{\alpha-1}). \tag{6.7}$$

6.3. Conjugate points. From now on we shall assume $\alpha > 1$, which is the physical interesting situation. All the singular trajectories satisfy (H0)–(H3) and are hyperbolic, and we have to compute the first conjugate point along a reference singular trajectory γ, using the algorithm in §5.4. The variational equation associated with (6.3) is

$$\begin{aligned} \dot{\delta x} &= -v\delta x - x\delta v, \\ \dot{\delta z} &= v(1-\beta v^{\alpha-1})\delta z + \psi(z,v)\delta v, \\ \dot{\delta v} &= \frac{v^2}{\alpha z^2}\delta z - \frac{2v}{\alpha z}\delta v, \end{aligned} \tag{6.8}$$

where $\psi(z,v) = 1 + z(1-\alpha\beta v^{\alpha-1})$ and $\psi = 0$ is the set S. Let $Q = S \times \mathbf{R}$ and $G = \{(x,z,v);\ \dot{z} = 0\}$.

To compute the conjugate points, we must integrate (6.8) with the initial condition $\delta x(0) = \delta z(0) = 0$ and $\delta v(0) = 1$. We have to distinguish two cases.

LEMMA 6.4. *A singular trajectory in* $P \cap Q$ *is without conjugate points.*

Proof. We integrate (6.8) with the initial condition (0,0,1) and $\psi = 0$. Hence we have

$$\delta z = 0, \qquad \delta v = \exp \int_0^t -\frac{2v}{\alpha z}\, ds,$$

and clearly $\delta x(t) < 0$ for all $t > 0$. Therefore the condition $\delta x(t_{1c}) = 0$ cannot be satisfied.

6.3.1. Singular trajectories not contained in $P \cap Q$. Let us write (6.3) as $\dot{w} = X + uY$, and let us denote by π the projection $(x,z,v) \to (z,v)$, X^π and Y^π being the vector fields $d\pi(X)$ and $d\pi(Y)$, respectively. Let γ be a singular trajectory in $P \backslash Q$ and $V(t)$ be the solution of the variational equation along γ, with $V(0) = Y(\gamma(0))$. From Lemma 5.9, $V(t)$ can be written $\lambda_1(t)Y(\gamma(t)) + \lambda_2(t)[X,Y](\gamma(t))$, and its projection on the space (z,v) is

$$d\pi(V(t)) = \lambda_1(t)Y^\pi(\pi(\gamma(t)) + \lambda_2(t)[X^\pi, Y^\pi](\pi(\gamma(t))).$$

Now, t_{1c} is the conjugate time if it is the first t such that $\lambda_2(t) = 0$. Since on $P \backslash Q$, $V(t)$ is collinear to $Y(\gamma(t))$ if and only if $d\pi(V(t))$ is collinear to $Y^\pi(\gamma(t))$, we have proved the following lemma.

LEMMA 6.5. *The time* t_{1c} *is the conjugate time if and only if* t_{1c} *is the first t such that the solution of*

$$\begin{aligned} \dot{\delta z} &= v(1-\beta v^{\alpha-1})\delta z + \psi(z,v)\delta v, \\ \dot{\delta v} &= \frac{v^2}{\alpha z^2}\delta z - \frac{2v}{\alpha z}\delta v \end{aligned} \tag{6.9}$$

passing through (0,1) *at* $t = 0$ *is such that* $\delta z(t_{1c}) = 0$.

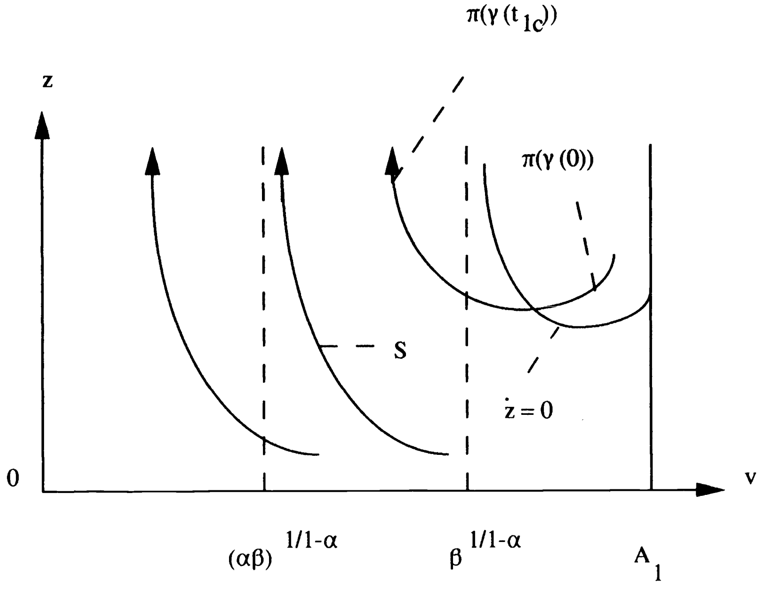

FIG. 17.

6.3.2. Computations. By setting $J = \delta z/\psi(z,v)v$, equation (6.9) can be written in the canonical form $\ddot{J} + (K o \gamma)J = 0$, where the curvature is

$$K = \frac{(\alpha - 1)\beta v^{\alpha+1}}{\alpha z}.$$

From Sturm's theorem [15], we must find L such that $0 < L < K$ to guarantee the existence of a conjugate time on $[0, \pi/\sqrt{L}]$. Since along a singular trajectory γ in P, $z(t) \longrightarrow +\infty$ when $t \longrightarrow +\infty$, such a lower bound $L > 0$ doesn't exist in our case and we have to use numerical simulations to compute conjugate points. If $\beta^{1/(1-\alpha)} < A_1$, they show the existence of conjugate point for singular arcs such that $\gamma(0) \in \{\dot{z} < 0\}$ (see Fig. 17).

6.4. Optimal synthesis.

6.4.1. Preliminaries. From §3.5, to solve problem $\mathcal{P}$ it is sufficient to solve the projected problem $\mathcal{P}'$: minimize the time duration to reach the target $N = \{(z,v);\ z = k,\ k \text{ fixed}\}$ for the solution of

$$\frac{dz}{dt} = v - \beta v^{\alpha} z + vz, \qquad \frac{dv}{dt} = -\frac{v^2}{\alpha z},$$

where $u \in [u_-, u_+]$. Moreover we shall assume $u_- < 0 < u_+$, $\alpha > 1$, $A_1 > \beta^{1/(1-\alpha)}$, and $-v_1^2/h(v_1)\alpha k \in]u_-, u_+[$, where v_1 is defined as the v-coordinate of $P_1 = (v_1, k)$ intersection of S with N. (The other cases can be easily deduced from our analysis.)

6.4.2. Singular arc. A singular trajectory belongs to the set $S = \{(z,v);\ z(\alpha\beta v^{\alpha-1} - 1) = 1\}$, and the singular control is defined by $\hat{u} = -v^2/h(v)\alpha z$ and has to belong to $[u_-, u_+]$ to be admissible. By computing, we get $\hat{u} < 0$ and $\frac{\partial \hat{u}}{\partial v} < 0$. Moreover v decreases along a singular arc and when $v \longrightarrow A_1^-$, $\hat{u} \longrightarrow -\infty$. Since at $P_1 = S \cap N$, $\hat{u}$ is admissible by hypothesis we have Fig. 18, where P_2 is the unique point such that $\hat{u} = u_-$ and Γ_s denotes the maximal admissible singular arc.

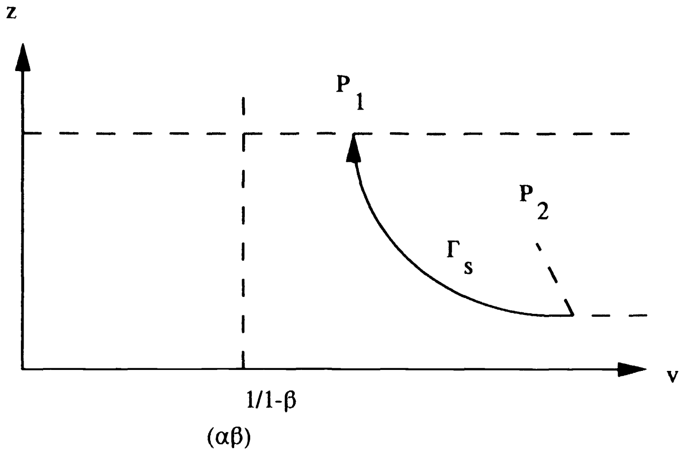

FIG. 18.

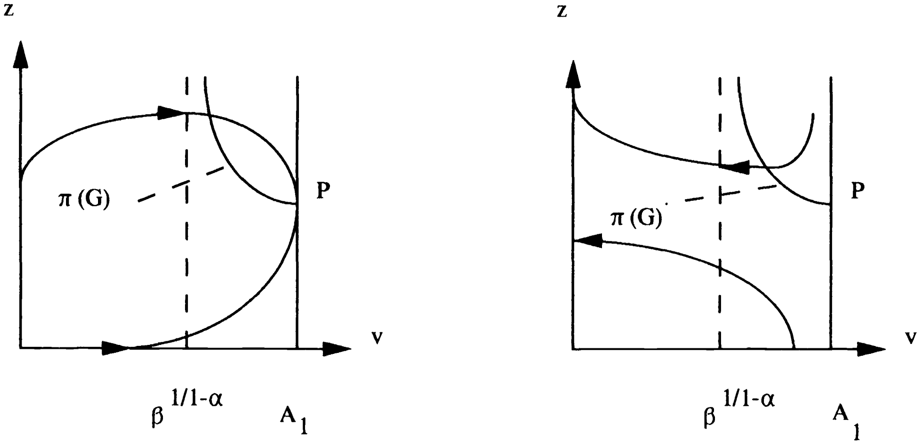

FIG. 19.

6.4.3. Regular arcs. Now, we have to analyze the behaviors of trajectories corresponding to the constant control $u = u_-$ or u_+. First, observe that $h(v) > 0$ if $0 < v < A_1$. Hence, the sign of $\dot{v}$ is given by u_- or u_+. Now, $\dot{z}$ vanishes for $z = (\beta v^{\alpha-1} - 1)^{-1}$, whose graph is denoted by $\pi(G)$. The singular points of the vector fields associated with u_- and u_+ in $0 \leq v \leq A_1$ are the points of the line $v = 0$ and the point $P = ((\beta A_1^{\alpha-1} - 1), A_1)$, which belongs by assumption to $z > 0$. A straightforward analysis gives the phase portraits in Fig. 19.

6.4.4. Switching function. One major problem in optimal control is *estimating the number of switchings* of an optimal control. In our case, it is possible by using the following analysis. The adjoint equations associated with the system, with $p = (p_1, p_2)$, are

$$\frac{dp_1}{dt} = p_1 v(\beta v^{\alpha-1} - 1), \qquad \frac{dp_2}{dt} = p_1 v(\alpha\beta v^{\alpha-1} - 1 - z) - p_2 \frac{dh(v)}{dv} u.$$

Let (γ, p, u) be a smooth extremal defined on $[0, T]$, p being nonzero by assumption. The switching function $\Phi(t) = p_2(t)h(v(t))$ evaluated along this extremal satisfies, from (3.9),

$$\dot{\Phi}(t) = p_1 h(v)[z(\alpha\beta v^{\alpha-1} - 1) - 1],$$
$$\ddot{\Phi}(t) = p_1 h(v)[\beta v^{\alpha}(\alpha - 1) + u\alpha(\alpha - 1)\beta v^{\alpha-2} z h(v)] + u\frac{dh}{dv}(v)\dot{\Phi}.$$

The set $\dot{\Phi}(t) = 0$ plays an important role when the switching points are computed. Observe that if p_1 is nonzero, its projection on the state space is the curve S. We have the following lemma.

LEMMA 6.6. *Let us assume* $\Phi(0) = \Phi(T) = 0$. *Then the extremal* γ *meets* S *for a* $t \in]0, T[$.

Proof. By definition p never vanishes and $p_2(0) = 0$. Now, the sign of p_1 is constant on $[0, T]$ and p_1 never vanishes. Since $\Phi(0) = \Phi(T)$, then there exists $t \in]0, T[$ such that $\dot{\Phi}(t) = 0$. Since p_1 never vanishes, at t we have $z(\alpha\beta v^{\alpha-1} - 1) = 1$.

LEMMA 6.7. *Let us assume that* (γ, p, u) *is such that* $u = u_+, p_1 > 0$ *and* $\Phi(T) = 0$. *Then* $\Phi(0)$ *is nonzero.*

Proof. Let $\varphi(t) = \dot{\Phi}(t)/h(v(t))$ evaluated along the given extremal. We have

$$\dot{\varphi}(t) = p_1[\beta v^{\alpha}(\alpha - 1) + u_+\alpha(\alpha - 1)\beta v^{\alpha-2} z h(v)].$$

Hence, sign $\dot{\varphi}$ = sign $p_1 > 0$ and φ is a strictly increasing function. Now since (γ, p, u_+) is an extremal, if T is a switching time, from §3.6 we must have $\dot{\Phi}(T) \le 0$. Hence $\varphi(0) < \varphi(T) \le 0$. Let us assume $\Phi(0) = 0$; then again we must have $\dot{\Phi}(0) \ge 0$. This contradicts $\varphi(0) = \dot{\Phi}(0)/h(v(0)) < 0$.

6.4.5. Synthesis. Now, we can show the optimal synthesis in Fig. 20.

First, observe that by [19, Thm. 4, p. 259], there exists an optimal controller in the family of all measurable mappings with values in $[u_-, u_+]$, provided that the system is restrained to the compact set $0 \le z \le k$, $0 \le v \le A_1$, and the target is the compact set $z = k$ and $0 \le v \le A_1$.

To compute the synthesis we proceed as follows. First, we use the local classification in §4 to obtain the synthesis function near the target. We are in the flat case. The two singularities of the analysis are at P_1, where an optimal singular arc meets the target, and the point P_3, where both are Γ_+ and Γ_- are tangent to the terminal manifold, the respective synthesis being given by Propositions 4.13 and 4.16.

Now, from the analysis in §4, at the terminal point, the adjoint variable can be taken as $p = (1, 0)$. Since we are in the flat case, all the points of N are virtual switching points. Hence from Lemma 6.7 an extremal arc Γ_+ hitting the target is not allowed to switch at the initial point, and from Lemma 6.6 an extremal arc Γ_- hitting the target has to meet S to switch at the initial time. The point $P_2 = (v_2, *)$ is the point on S such that an arc Γ_- is tangent to S, and if $v > v_2$, then $\hat{u} < u_-$. This will cause the existence of optimal laws with two switchings, one on the singular arc Γ_s and the other on a curve C. As in Lemma 4.2, one can show that this curve cannot be an arc Γ_- and is in fact contained strictly in the acute domain limited by S and the arc Γ_- passing through P_2.

The optimal synthesis for the original problem $\mathcal{P}$ is obtained by adding the x-variable. Observe that it is without a conjugate point, since a singular arc in $\mathbf{R}^2$ is without a conjugate point, and this is in accordance with the analysis of §6.3.

NEUMANN BOUNDARY VALUE PROBLEMS FOR SECOND-ORDER ORDINARY DIFFERENTIAL EQUATIONS ACROSS RESONANCE*

WANG HUAIZHONG† AND LI YONG†

Abstract. There have been some applications of optimal control theory to boundary value problems for ordinary differential equations. Among previous works, the best lengths of intervals on which the boundary value problem admits a solution are estimated by Pontryagin's maximum principle. Hence such approaches are local and the presented conditions are actually not across points of resonance as in the Lazer–Leach condition. Here we consider the existence–uniqueness problem in a class of Neumann boundary value problems for second-order ordinary differential equations probably across several points of resonance. By the optimal control theory method and a careful analysis, we obtain some global optimality results about the existence and uniqueness of solutions for boundary value problems.

Key words. optimal control, Neumann boundary value problems, existence and uniqueness, across points of resonance

AMS subject classifications. 34B, 49B, 49K

1. Introduction. As is well known, the Neumann condition is one of the basic boundary conditions appearing in mathematical physics (for example, equilibrium problems concerning beams, columns, or strings; fluid flow problems; and heat transfer problems). This kind of boundary value problems (BVP) has the following standard form:

$$y'' + f(t, y, y') = 0, \quad y'(a) = A, \quad y'(b) = B, \tag{p}$$

where $A,\ B \in R^n$, $f : [a, b] \times R^n \times R^n \to R^n$. The Neumann BVP (p) differs from a corresponding initial value problem or Dirichlet boundary value problem in that a Lipschitz condition for f does not guarantee the existence nor the uniqueness of solutions even for the simple $f \equiv f(t)$ unless $\int_a^b f(s)\, ds = B - A$. Furthermore, Green's function of the problem $y'' = 0$, $y'(a) = 0$, $y'(b) = 0$ does not exist. This shows that one cannot utilize Green's function in reformulating (p) as an integral equation, unlike the Dirichlet boundary value problem. Therefore, it is more difficult to find general conditions for existence and uniqueness. Under suitable monotonicity conditions or nonresonance conditions, some nice existence or uniqueness theorems or methods for (p) have been presented (see, for example, [1]–[9], [16]–[18], [23], [24], and [26]).

In this paper we are concerned with the following Neumann BVP:

$$y'' + f(t, y) = 0, \tag{1.1}$$

$$y'(0) = A, \qquad y'(1) = B, \tag{1.2}$$

where $A,\ B \in R$ and $f : [0, 1] \times R \to R$ is continuous and satisfies some additional conditions.

In general, the set $\{n^2\pi^2\}_0^\infty$ is called the set of points of resonance for BVP (1.1)–(1.2). If we assume that $f(t, y)$ is continuously differentiable with respect to y, then applying previous works to BVP (1.1)–(1.2), the results that we can obtain are only the following:

(i) If there is an $a > 0$ such that

$$-f'_y(t, y) \left(f'_y = \frac{\partial f}{\partial y} \right) \ge \alpha \quad \text{on } [0, 1] \times R,$$

then BVP (1.1)–(1.2) has a unique solution.

* Received by the editors March 10, 1993; accepted for publication (in revised form) April 17, 1994.

† Department of Mathematics, Jilin University, Changchun 130023, People's Republic of China.

(ii) If there are $\lambda, \mu > 0$ such that

$$N^2\pi^2 < \lambda \leq f'_y(t,y) \leq \mu < (N+1)^2\pi^2 \quad \text{on } [0,1] \times R, \tag{1.3}$$

where N is some nonnegative integer, then BVP (1.1) – (1.2) has a unique solution.

The above condition (1.3) is the usual Lazer–Leach-type condition (see [17]). However, if for some $B > \pi^2$

$$0 \leq f'_y(x,y) \leq B \quad \text{on}, [0,1] \times R, \tag{1.4}$$

then when does BVP (1.1) – (1.2) have a unique solution? The condition (1.4) is usually called one crossing points of resonance.

In this paper, by the optimal control theory method, we prove two optimality results on the existence and uniqueness of BVP (1.1) – (1.2). Our main result is the following theorem.

THEOREM A. *Assume that the following conditions are fulfilled*:

(i) $f(t,y)$ *and* $f_y(t,y)$ *are continuous on* $[0,1] \times R$.

(ii) *For some* $B \geq \pi^2$,

$$0 \leq f_y(t,y) \leq \beta(t) \leq B \quad \textit{on}\, [0,1] \times R,$$

where $\beta \in L[0,1]$ *and satisfies* $\int_0^1 \beta(t)\, dt < B\alpha$. *Here* α *is the minimal positive root of the equation*

$$\cos\left(\sqrt{B}\frac{x}{2}\right) = \frac{1}{2}\sqrt{B}(1-x)\, \sin\left(\sqrt{B}\frac{x}{2}\right).$$

(iii) $\int_0^1 f(t,0)\, \mathrm{d}t = 0$ *and*

$$\text{meas}\, \{t \in [0,1],\ f_y(t,x(t)) > 0\} > 0,$$

for each $x \in C([0,1],R)$.

Then BVP (1.1) – (1.2) *has a unique solution.*

Here the optimality means that given $B \geq \pi^2$, there exists a $u \in C([0,1],R)$ with

$$0 \leq u(t) \leq B \quad \text{for}\, t \in [0,1], \qquad \int_0^t u(t)\, \mathrm{d}t > B\alpha$$

such that the BVP

$$y'' + u(t)y = 0, \qquad y'(0) = y'(1) = 0$$

has nontrivial solutions.

It should be pointed out that Mawhin, Ward, and Willem [19] have presented a sufficient and necessary condition of solvability for the Neumann problem relative to semilinear elliptic equations across resonance by means of the variational method.

Some interesting applications of the control theory method to several BVPs for ordinary differential equations have been presented by the authors of [8], [11]–[15], [20]–[22], and [25]. However, all of these papers do not deal with the Neumann BVPs, and the conditions of the theorems established in the papers are all nonresonant.

The plan of this paper is the following: §2 deals with an optimal control problem for a linear BVP. There, using Pontryagin's maximum principle, we prove the existence of the optimal control for the problem. In particular, we find an explicit expression of the optimal control, which is vital to our discussion. Finally in §3, applying the results of §2 and Schauder's fixed-point theorem, we give the proofs of Theorem A and some other results.

2. Linear problem. Consider the following linear BVP:

$$y'' + u(t)y = 0, \qquad y'(0) = y'(1) = 0, \tag{2.1}$$

where $u \in L[0, 1]$ and satisfies $0 \leq u(t) \leq B$, where $B \geq \pi^2$.

Choose a suitable admissible set Ω as follows:

$$\Omega = \{u \in L[0, 1] : 0 \leq u(t) \leq B,\ \text{meas}\,\{t \in [0, 1] : u(t) > 0\} > 0 \\ \text{and for } u = u(t),\ \text{BVP (2.1) has nontrivial solutions}\}.$$

We are to seek a function $u^* \in \Omega$ such that $u^*(t)$ minimizes the functional $J[u]$ defined by

$$J[u] = \int_0^1 u(t)\,\mathrm{d}t, \qquad u \in \Omega;$$

that is,

$$J[u^*] = \min_{\Omega} J[u]. \tag{2.2}$$

Thus the problem (2.1) – (2.2) is an optimal control problem.

We need the following lemmas.

LEMMA 1. *Problem* (2.1) – (2.2) *has a solution*; *that is*, *the optimal control function exists*.

Proof. Since $u(t) \equiv \pi^2 \in \Omega$, Ω is not empty. Obviously,

$$\mu_0 = \inf_{\Omega} J[u] \in [0, B].$$

Hence there exists a minimizing sequence $\{u_n(t)\} \subset \Omega$ such that

$$J[u_n] \to \mu_0 (n \to \infty).$$

For each $u = u_n(t)$, BVP (2.1) has a solution $y_n(t)$ with

$$\|y_n\| = \max_{[0,1]} |y_n(t)| + \max_{[0,1]} |y_n'(t)| = 1$$

by the definition of Ω. Then $\{y_n''(t)\}$ is uniformly essentially bounded on [0,1]. These imply that $\{y_n(t)\}$ and $\{y_n'(t)\}$ are uniformly bounded and equicontinuous on [0,1]. By the Arzela–Ascoli theorem, passing to a subsequence if necessary, we may assume

$$y_n \to y_0, \quad y_n' \to z_0 \quad (n \to \infty)$$

uniformly on [0,1] for suitable $y_0, z_0 \in C([0, 1], R)$. Since $\{u_n\} \subset L^2[0, 1]$ and is uniformly bounded on [0,1], we may assume that $u_n(t)$ is weakly convergent to $u^* \in L^2[0, 1]$ as $n \to \infty$. By the Hahn–Banach theorem, we see $u^* \in [0, B]$. Consequently,

$$y_0(t) = y_0(0) + \int_0^t z_0(s)\,\mathrm{d}s,$$
$$z_0(t) = z_0(0) + \int_0^t [-u^*(s)y_0(s)]\,\mathrm{d}s$$

for $t \in [0, 1]$. Obviously,

$$y_0'(0) = y_0'(1) = 0, \qquad \|y_0\| = 1. \tag{2.3}$$

These imply that $y_0(t)$ is a solution of BVP (2.1) for $u = u^*(t)$. Note that for each n,

$$\operatorname{meas}\{t \in [0,1] : u_n(t) > 0\} > 0.$$

Therefore, for each n, $y_n(t)$ has a zero in [0,1], which shows that $y_0(t)$ has a zero in [0,1]. From this, (2.3), and the uniqueness for initial value problems it follows that

$$\operatorname{meas}\{t \in [0,1] : u^*(t) > 0\} > 0.$$

To summarize, we have that $u^* \in \Omega$, which completes the proof of the lemma.

LEMMA 2. *Let $u_1 \in \Omega$. If the BVP*

$$y'' + u_1(t)y = 0, \qquad y'(0) = y'(1) = 0$$

has a nontrivial solution $y_1(t)$ such that for some $t_1 \in (0,1)$, $y_1'(t_1) = 0$, then there exists a $u_2 \in \Omega$ such that the BVP

$$y'' + u_2(t)y = 0, \qquad y'(0) = y'(1) = 0$$

has a nontrivial solution $y_2(t)$ with

$$\begin{aligned} |y_2'(t)| &> 0 \quad \text{on } (0,1) \text{ and} \\ \int_0^1 u_2(t)\,\mathrm{d}t &< \int_0^1 u_1(t)\,\mathrm{d}t. \end{aligned} \tag{2.4}$$

Proof. Since $u_1 \in \Omega$, we have

$$\operatorname{meas}\{t \in [0,1] : u_1(t) > 0\} > 0.$$

Hence it is easy to prove that $y_1(t)$ has a zero t_2 in (0,1). By the uniqueness of initial value problems, we get $y_1'(t_2) \neq 0$. Note that $t_1 \in (0,1)$ and $y_1'(t_1) = 0$. Therefore, there exists $[a,b] \subset [0,1]$ such that

$$0 < b - a < 1, \quad t_2 \in (a,b), \quad y_1'(a) = y_1'(b) = 0,$$

and

$$|y_1'(t)| > 0 \quad \text{on } (a,b).$$

Set $t = (b-a)s + a$. Then $y_2(s) = y_1((b-a)s + a)$ is a nontrivial solution of the BVP

$$\begin{aligned} &\frac{\mathrm{d}^2y}{\mathrm{d}s^2} + (b-a)^2 u_1((b-a)s + a)y = 0, \\ &y'(0) = y'(1) = 0. \end{aligned}$$

Take $u_2(s) = (b-a)^s u_1((b-a)s + a)$. Then

$$\int_0^1 u_2(t)\,\mathrm{d}t = (b-a)\int_a^b u_1(t)\,\mathrm{d}t < \int_0^1 u_1(t)\,\mathrm{d}t,$$

which completes the proof.

By Lemma 2, we get the following lemma.

LEMMA 3. *If $u^*(t)$ is an optimal control of problem* (2.1)–(2.2), *then for $u = u^*(t)$ every nontrivial solution $y^*(t)$ of BVP* (2.1) *satisfies*

$$y^{*'}(t) \neq 0 \quad \text{on } (0,1).$$

The main result of this section is the following.

THEOREM 1. *Let $B > \pi^2$. Then the problem* (2.1) – (2.2) *has a unique optimal control $u^* \in \Omega$. In addition, $u^*(t)$ has the following form*:

$$u^*(t) = \begin{cases} B, & 0 \le t \le \frac{1}{2}\alpha, \\ 0, & \frac{1}{2}\alpha < t < 1 - \frac{1}{2}\alpha, \\ B, & 1 - \frac{1}{2}\alpha \le t \le 1, \end{cases}$$

where $\alpha = \alpha(B)$ is the minimal positive root of the equation

$$\cos\left(\sqrt{B}\,\frac{x}{2}\right) = \frac{1}{2}\sqrt{B}(1-x)\,\sin\left(\sqrt{B}\,\frac{x}{2}\right) \tag{2.5}$$

and

$$\mu_0 = J[u^*] = B\alpha(B).$$

Proof. By Lemma 1, problem (2.1) – (2.2) has an optimal control $u^* \in \Omega$. Set $y_1 = y$, $y' = y_2$, and $u = u^*$. Then (2.1) turns into the system

$$y_1' = y_2, \qquad y_2' = -u^* y_1, \qquad y_2(0) = y_2(1) = 0.$$

According to Pontryagin's maximum principle, the Hamilton function of the system reads as follows:

$$H = -u^* + \lambda_1 y_2 + \lambda_2(-u^* y_1),$$

where $\lambda_1(t)$ and $\lambda_2(t)$ satisfy

$$\begin{gathered} \lambda_1' = n^* \lambda_2, \qquad \lambda_2' = -\lambda_1, \\ \lambda_2'(0) - \lambda_1(0) = 0, \qquad \lambda_2'(1) = \lambda_1(1) = 0. \end{gathered} \tag{2.6}$$

Hence $u^*(t)$ satisfies the following:

$$u^*(t) = \begin{cases} 0, & 1 + \lambda_2(t) y_1(t) > 0, \\ B, & 1 + \lambda_2(t) y_1(t) < 0. \end{cases} \tag{2.7}$$

By (2.6), $\lambda_2(t)$ and $y_1(t)$ are solutions of BVP (2.1) for $u = u^*$. Therefore, they are linearly dependent. Thus we can assume that for some constant c,

$$\lambda_2(t) = c y_1(t) \quad \text{on } [0, 1],$$

which implies

$$1 + \lambda_2(t) y_1(t) = 1 + c y_1^2(t) = 1 + c y^2(t).$$

Since $u^*(t)$ is an optimal control, it follows from Lemma 3 that

$$y_1'(t) \ne 0 \quad \text{on } (0, 1). \tag{2.8}$$

Hence $y_1(t)$ is increasing or decreasing on (0,1). Since $u^*(t) \ge 0$ and $y_1'(0) = y_1'(1) = 0$, $y_1(t)$ has a unique zero in (0,1). By (2.7), we get $u^*(t) = 0$ on a interval near the zero, and consequently,

$$y_1(t) = lt + m \tag{2.9}$$

on the interval satisfying $u^*(t) = 0$, where l and m are suitable constants. From

$$\text{meas}\,\{t \in [0,1] : u^*(t) > 0\} > 0,$$

the monotonicity of $y_1(t)$, and (2.7), (2.9), it follows that there exist $t_1, t_2 \in [0,1]$ such that

$$u^*(t) = \begin{cases} B, & 0 \le t \le t_1, \\ 0, & t_1 \le t \le t_2, \\ B, & t_2 \le t \le 1. \end{cases}$$

Noting (2.9) and

$$y_1'(0) = y_1'(1) = 0,$$

we get

$$0 < t_1 < t_2 < 1.$$

Hence

$$y_1(t) = \begin{cases} k_1 \cos(\sqrt{B}t), & 0 \le t \le t_1, \\ lt + m, & t_1 < t < t_2, \\ k_2 \cos(\sqrt{B}(1-t)), & t_2 \le t \le 1, \end{cases} \tag{2.10}$$

where k_1, k_2, l, and m are suitable constants and $k_1, k_2 \neq 0$. From the continuous differentiability of $y_1(t)$ on [0,1] and (2.10), we have

$$k_1 \cos(\sqrt{B}t_1) = lt_1 + m, \tag{2.11a}$$

$$-k_1\sqrt{B} \sin(\sqrt{B}t_1) = l, \tag{2.11b}$$

$$lt_2 + m = k_2 \cos(\sqrt{B}(1-t_2)), \tag{2.11c}$$

$$l = k_2\sqrt{B} \sin(\sqrt{B}(1-t_2)). \tag{2.11d}$$

By (2.7), we see

$$1 + c[y_1(t_1)]^2 = 1 + c[y_1(t_2)]^2 = 0,$$

which shows

$$y_1(t_1) = -y_1(t_2) = \sqrt{-\frac{1}{c}}\,\text{sgn}\,(y_1(0)).$$

See Fig. 1.
Thus,

$$lt_1 + m = -(lt_2 + m);$$

that is,

$$l(t_1 + t_2) + 2m = 0. \tag{2.12}$$

Note

$$H(y_1(t), y_2(t), \lambda_1(t), \lambda_2(t), u^*(t)) = \begin{cases} -B(1 + ck_1^2), & 0 \le t \le t_1, \\ -cl^2, & t_1 \le t \le t_2, \\ -B(1 + ck_2^2), & t_2 \le t \le 1, \end{cases}$$

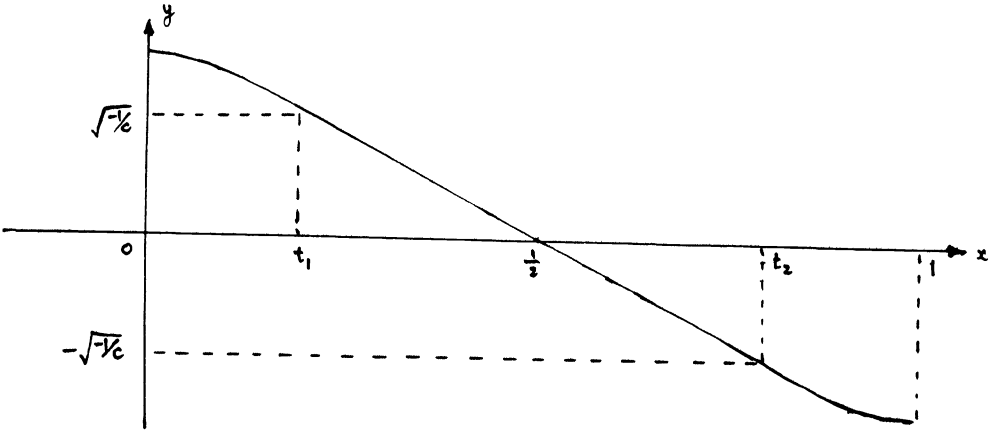

FIG. 1. $\mathbf{y}_1(0) > 0$.

by (2.6), (2.10), and

$$H = -u^* + \lambda_1 y_2 + \lambda_2[-u^* y_1] = \begin{cases} -B - \lambda_2' y_2 - Bcy_1^2, & 0 \le t \le t_1, \\ -\lambda_2' y_2, & t_1 \le t \le t_2, \\ -B - \lambda_2' y_2 - Bcy_1^2, & t_2 \le t \le 1. \end{cases}$$

By Pontryagin's maximum principle,

$$H(y_1, y_2, \lambda_1, \lambda_2, u^*) \equiv \text{const},$$

and hence $k_1^2 = k_2^2$. The monotonicity of $y_1(t)$ and (2.10) yield $k_1 = -k_2$. Since $y_1(t_1) = -y(t_2)$, we have

$$\cos(\sqrt{B} t_1) = \cos(\sqrt{B}(1 - t_2)).$$

By the monotonicity of $y_1(t)$, the arguments $\sqrt{B} t_1$ and $\sqrt{B}(1 - t_2)$ are smaller than $\frac{\pi}{2}$. Thus we get

$$t_1 = 1 - t_2. \tag{2.13}$$

Thus, we need only to study (2.11a), (2.11b), and (2.12) with unknown variables k_1, l, and m. Because $k_1 \neq 0$, the following equality holds certainly:

$$\begin{vmatrix} \cos(\sqrt{B} t_1) & -t_1 & -1 \\ -\sqrt{B} \sin(\sqrt{B} t_1) & -1 & 0 \\ 0 & t_1 + t_2 & 2 \end{vmatrix} = 0.$$

Simplifying it, we get

$$(t_2 - t_1)\sqrt{B} \sin(\sqrt{B} t_1) = 2\cos(\sqrt{B} t_1). \tag{2.14}$$

Set $t_1 = \frac{1}{2}\alpha$. Then $t_2 - t_1 = 1 - \alpha$. Hence, (2.14) turns into

$$\cos\left(\sqrt{B}\frac{\alpha}{2}\right) = \frac{1}{2}(1 - \alpha)\sqrt{B} \sin\left(\sqrt{B}\frac{\alpha}{2}\right). \tag{2.15}$$

Since $u^*(t)$ is an optimal control, α is the minimal positive root of (2.15). Furthermore,

$$\begin{aligned}\int_0^1 u^*(t)\,\mathrm{d}t &= B(t_1 + (1-t_2)) \\ &= B\alpha = \mu_0.\end{aligned}$$

The proof of the theorem is complete.

LEMMA 4. *Let $B > \pi^2$. Then $\alpha(B)$ and $B\alpha(B)$ are strictly decreasing, where $\alpha(B)$ is the minimal positive root of* (2.5).

Proof. By Theorem 1, for $B > \pi^2$, $\alpha(B)$ is well defined and satisfies (2.15). Set

$$F(B,\alpha) = \cos\left(\sqrt{B}\,\frac{\alpha}{2}\right) - \frac{1}{2}(1-\alpha)\sqrt{B}\,\sin\left(\sqrt{B}\,\frac{\alpha}{2}\right).$$

Then if (2.15) holds,

$$\begin{aligned}\frac{\partial F}{\partial \alpha} &= -\frac{1}{4}(1-\alpha)B\cos\left(\sqrt{B}\,\frac{\alpha}{2}\right) \\ &= -\frac{1}{8}(1-\alpha)^2 B\sqrt{B}\,\sin\left(\sqrt{B}\,\frac{\alpha}{2}\right), \\ \frac{\partial F}{\partial B} &= -\frac{1}{4\sqrt{B}}\sin\left(\sqrt{B}\,\frac{\alpha}{2}\right) - \frac{1}{8}\alpha(1-\alpha)\cos\left(\sqrt{B}\,\frac{\alpha}{2}\right) \\ &= -\left[\frac{1}{4\sqrt{B}} + \frac{1}{16}\alpha(1-\alpha)^2\sqrt{B}\right]\sin\left(\sqrt{B}\,\frac{\alpha}{2}\right).\end{aligned}$$

Hence,

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}B}\alpha &= -\frac{4+\alpha(1-\alpha)^2 B}{2(1-\alpha)^2 B^2} < 0, \\ \frac{\mathrm{d}}{\mathrm{d}B}(B\alpha(B)) &= \alpha(B) + B\frac{\mathrm{d}}{\mathrm{d}\alpha}\alpha(B) = -\frac{4-\alpha(1-\alpha)^2 B}{2(1-\alpha)^2 B}.\end{aligned}$$

It suffices to prove $4 - \alpha(1-\alpha)^2 B > 0$. Note that

$$B\alpha \le \pi^2, \qquad \alpha \le 1.$$

Therefore, by (2.15), we get

$$\frac{4}{\alpha(1-\alpha)B} = \frac{\mathrm{tg}\left(\sqrt{B}\,\frac{\alpha}{2}\right)}{\sqrt{B}\,\frac{\alpha}{2}} > 1,$$

since $0 < \frac{\sqrt{B\alpha}}{2} \le \frac{\pi}{2}$. This completes the proof.

LEMMA 5. $B\alpha(B) \searrow 4$ (*as* $B \to \infty$).

Proof. Equation (2.15) yields

$$\mathrm{tg}\left(\sqrt{B}\,\frac{\alpha}{2}\right) = \frac{1}{\frac{1}{2}(1-\alpha)\sqrt{B}}. \tag{2.16}$$

Since

$$B\alpha \le \pi^2 \quad \text{for all } B > \pi^2,$$

we have

$$\alpha(B) \to 0 \qquad (B \to \infty),$$

which implies (by (2.16))

$$\operatorname{tg}\left(\sqrt{B}\,\frac{\alpha}{2}\right) \to 0 \qquad (B \to \infty).$$

Because

$$B\frac{\alpha^2}{4} = (B\alpha)\,\frac{\alpha}{4} \le \frac{\pi^2}{4}\alpha \to 0 \qquad (B \to \infty),$$

multiplying (2.16) by $2\sqrt{B}$ yields

$$B\alpha \cdot \frac{\operatorname{tg}\left(\sqrt{B}\,\frac{\alpha}{2}\right)}{\frac{\alpha}{2}\sqrt{B}} = \frac{4}{1-\alpha}.$$

Letting $B \to \infty$ in this equality, we get the desired conclusion.

As applications, we have the following theorems.

THEOREM 2. *Let $B > \pi^2$, and let $b, f : [0, 1] \to R$ be continuous functions such that*

$$0 \le b(t) \le B, \qquad b(t) \not\equiv 0 \quad \text{on } [0,1], \qquad \int_0^1 b(t)\,\mathrm{d}t < B\alpha(B),$$

where $\alpha(B)$ is the minimal positive root of (2.5). *Then for each $A, B \in R$, the BVP*

$$y'' + b(t)y = f(t), \qquad y'(0) = A, \qquad y'(1) = B \tag{2.17}$$

has a unique solution.

Proof. By Theorem 1, it is obvious that the BVP

$$y'' + b(t)y = 0, \qquad y'(0) = 0, \qquad y'(1) = 0$$

has at most one solution. Since the equation is linear, the uniqueness implies the existence. The proof is complete.

THEOREM 3. *Let $b \in L^\infty[0, 2\pi]$ such that*

$$b(t) \ge 0 \quad \text{on } [0,1],$$

$$\operatorname{meas}\{t \in [0,1] : b(t) > 0\} > 0,$$

and

$$\int_0^1 b(t)\,\mathrm{d}t \le 4.$$

Then for each $f \in L[0,1]$, the BVP (2.17) *has a unique solution.*

Proof. The proof follows from Theorem 1 and Lemmas 4 and 5.

Remark 1. From Theorem 3 we can obtain the following conclusion.

If $b \ge 0$ on $[0, 1]$, $b(t) > 0$ on a set of positive measure, and $b \in L^\infty[0, 1]$, then in order that there exist a nontrivial solution of the Neumann problem

$$y'' + b(y)y = 0 \quad \text{a.e.}, \qquad y'(0) = y'(1) = 0,$$

it is necessary that

$$\int_0^1 b(t)\,\mathrm{d}t > 4. \tag{2.18}$$

For the Dirichlet problem

$$y'' + b(t) = 0 \quad \text{a.e.}, \qquad y(0) = y(1) = 0,$$

there is also the same conclusion, which is the classic Hartman – Wintner criterion [10].

3. Nonlinear equations. In this section, we shall give some applications of Theorems 2 and 3. First we prove Theorem A. Without loss of generality, let $A = B = 0$. We first prove uniqueness. Let $y_1(t)$ and $y_2(t)$ be any two solutions of BVP (1.1) – (1.2). Then $y = y_1(t) - y_2(t)$ is a solution of the BVP

$$\begin{aligned} y'' &+ \int_0^1 f_y(t, y_2 + \theta y)\,\mathrm{d}\theta y = 0, \\ y'(0) &= y'(1) = 0. \end{aligned} \tag{3.1}$$

From condition (ii) it follows that

$$0 \le \int_0^1 f_y(t, y_2 + \theta y)\,\mathrm{d}\theta \le \beta(t) \le B \quad \text{on } \{0, 1],$$

$$\text{meas}\,\{t \in [0, 1] : \int_0^1 f_y(t, y_2 + \theta y)\,\mathrm{d}\theta > 0\} > 0.$$

Hence by Theorem 2, $y(t) \equiv 0$ on [0, 1].

Now we prove existence. Rewrite (1.1) as follows:

$$y'' + b(t, y)y = -f(t, 0),$$

where $b(t, y) = \int_0^1 f_y(t, \theta y)\,\mathrm{d}\theta$. Set

$$X = \{y \in C^1([0, 1], R) : y'(0) = y'(1) = 0\}$$

with the norm $\|\cdot\|$ defined by

$$\|y\| = \max_{[0,1]} |y(t)| + \max_{[0,1]} |y'(t)| \quad \text{for each } y \in X.$$

Define an operator $T : X \to X$ by

$$Tx = y_x,$$

where $y_x(t)$ is a solution of the BVP

$$y'' + b(t, x)y = -f(t, 0), \qquad y'(0) = y'(1) = 0. \tag{3.2}$$

By virtue of Theorem 2, BVP (3.2) has a unique solution, and hence T is well defined on X.

We claim that there is $M > 0$ such that

$$\|Tx\| \le M \quad \text{for all } x \in X.$$

In fact, if not, there would exist a sequence $\{x_n(t)\} \subset X$ such that $\|y_{x_n}\| \to \infty\,(n \to \infty)$. Since

$$0 \le b(t, x_n) \le \beta(t) \quad \text{on } [0,1],$$

passing to a subsequence if necessary, we may assume that $b(t, x_n)$ is weakly convergent to $b_0 \in L^2[0,1]$. Because the set

$$S = \{u \in L^2[0,1] : 0 \le u(t) \le \beta(t) \quad \text{on } [0,1]\}$$

is bounded convex closed in $L^2[0,1]$, by the Hahn–Banach theorem, we see $b_0 \in S$. By (3.2) and the Arzela–Ascoli theorem, passing a subsequence, we may assume that

$$y_n = y_{x_n}/\|y_{x_n}\| \to y_0, y'_{z_n}/\|y_{x_n}\| \to z_0 \quad \text{in } C([0,1], R).$$

Note that for each n,

$$\begin{aligned} y_n(t) &= y_n(0) + \int_0^t y'_n(s)\,\mathrm{d}s, \\ y'_n(t) &= -\int_0^t b(s, x_n) y_n(s)\,\mathrm{d}s - \frac{1}{\|y_{x_n}\|}\int_0^t f(s,0)\,\mathrm{d}s, \end{aligned} \tag{3.3}$$

for all $t \in [0,1]$. Letting $n \to \infty$ in (3.3) by Lebesgue's dominant convergence theorem, we get

$$\begin{aligned} y_0(t) &= y_0(0) + \int_0^t z_0(s)\,\mathrm{d}s, \\ z_0(t) &= -\int_0^t b_0(s) y_0(s)\,\mathrm{d}s \end{aligned}$$

for all $t \in [0,1]$.

Note that $\|y_0\| = 1$. These show that $y_0(t)$ is a nontrivial solution of the BVP

$$y'' + b_0(t)y = 0, \qquad y'(0) = y'(1) = 0.$$

Since for each n

$$\text{meas}\,\{t \in [0,1] : b(t, x_n) > 0\} > 0,$$

$$\int_0^1 b(t, x_n(t)) y_{x_n}(t)\,\mathrm{d}t = -\int_0^1 f(t,0)\,\mathrm{d}t = 0 \quad \text{(by (iii))},$$

$y_{x_n}(t)$ has a zero in [0,1], and hence so does $y_0(t)$. This, combined with $\|y_0\| = 1$, implies that

$$\text{meas}\,\{t \in [0,1] : b_0(t) > 0\} > 0, \tag{3.4}$$

but by (ii) and (3.4), the BVP

$$y'' + b_0(t)y = 0, \qquad y'(0) = y'(1) = 0$$

has only the zero solution, which contradicts $\|y_0\| = 1$. Hence the claim holds.

Given any $\{x_n\} \subset X$ such that $x_n \to x_0 \in X$, by definition we know that

$$y''_{x_n} + b(t, x_n) y_{x_n} = -f(t,0), \qquad y'_{x_n}(0) = y'_{x_n}(1) = 0,$$

and

$$y''_{x_0} + b(t, x_0) y_{x_0} = -f(t,0), \qquad y'_{x_0}(0) = y'_{x_0}(1) = 0.$$

Hence, setting $w_n = y_{x_n} - y_{x_0}$, we have

$$w''_n + b(t, x_n) y_{x_n} - b(t, x_0) y_{x_0} = 0, \qquad w'_n(0) = w'_n(1) = 0. \tag{3.5}$$

Thus

$$w''_n + [b(t, x_n) - b(t, x_0)] y_{x_n} + b(t, x_0) w_n = 0 \quad \text{on } [0,1]. \tag{3.6}$$

We claim that

$$w_n \to 0 \quad \text{in} \, C^1([0,1], R). \tag{3.7}$$

If not, then there would be an $m > 0$ such that

$$\overline{\lim_{n\to\infty}} \|w_n\| \geq m.$$

Applying the Arzela–Ascoli theorem and passing to a subsequence if necessary, by the above claim, we may assume that

$$w_n \to w_0 (n \to \infty) \quad \text{in} \, X. \tag{3.8}$$

Note that

$$\frac{w''_n}{\|w_n\|} + b(t, x_0) \frac{w_n}{\|w_n\|} + [b(t, x_n) - b(t, x_0)] \frac{y_{x_n}}{\|w_n\|} = 0 \quad \text{on } [0,1] \tag{3.9}$$

and that

$$\begin{aligned} \frac{w_n}{\|w_n\|} - \frac{w_0}{\|w_0\|} = \frac{w_n - w_0}{\|w_n\|} + \frac{w_0(\|w_0\| - \|w_n\|)}{\|w_n\|\|w_0\|} \to 0 \\ (n \to \infty \, \text{by} \, (3.8)) \, \text{in} \, X. \end{aligned} \tag{3.10}$$

From (3.9), (3.10) it follows that

$$\begin{aligned} \frac{w_0(t)}{\|w_0\|} &= \frac{w_0(0)}{\|w_0\|} + \int_0^t \frac{w'_0(s)}{\|w_0\|} \, ds, \\ \frac{w'_0(t)}{\|w_0\|} &= -\int_0^t b(s, x_0) \frac{w_0(s)}{\|w_0\|} \, ds \quad \text{on } [0,1]. \end{aligned}$$

This shows that $\frac{w_0(t)}{\|w_0\|}$ is a nontrivial solution of the BVP

$$y'' + b(t, x_0) y = 0, \qquad y'(0) = y'(1) = 0. \tag{3.11}$$

On the other hand, by Theorem 2, the BVP (3.11) has only a zero solution, which leads to a contradiction. Hence, the claim is proved.

From two claims and the Arzela–Ascoli theorem, it follows that $T : X \rightarrow X$ is completely continuous and TX is bounded. According to Schauder's fixed-point theorem, T has a fixed point $y(t)$ in X; that is, BVP (3.1) – (3.2) has a solution $y(t)$. This completes the proof of the theorem.

Remark 2. We can remove (iii) by assuming the following condition:

(iii)′ There exists $\eta \in L^1[0, 1]$ such that

$$0 \leq \eta(t) \leq f_y(t, y) \quad \text{on } [0, 1] \times R$$

and

$$\text{meas}\, \{t \in [0, 1] : \eta(t) > 0\} > 0.$$

This is also available for the following theorem.

Using Theorem 3, we can prove the following theorem.

THEOREM B. *Assume that f satisfies conditions* (i) *and* (iii) *and*

$$0 \leq f_y(t, y) \leq \beta(t) \quad \textit{on } [0, 1] \times R,$$

where $\beta \in L^1[0, 1]$ and satisfies $\int_0^1 \beta(t)\, dt \leq 4$. Then BVP (1.1) – (1.2) *has a unique solution.*

EQUIVALENT CONDITIONS FOR THE SOLVABILITY OF THE NONSTANDARD LQ-PROBLEM FOR PRITCHARD–SALAMON SYSTEMS*

BERT VAN KEULEN†

Abstract. Equivalent conditions are presented for the solvability of the infinite-horizon LQ-problem with stability for a class of infinite-dimensional systems with unbounded input and output operators. In particular, these equivalent conditions are given in terms of a Riccati equation and a frequency domain inequality just as in the finite-dimensional case.

Key words. infinite-dimensional systems, linear quadratic control, unbounded input and output operators, Pritchard–Salamon systems

AMS subject classifications. 93C25, 49J27

1. Introduction.

The linear quadratic control problem (LQ-problem) has received a lot of attention in the area of mathematical systems theory. Many interesting system theoretical problems can be formulated in this framework, for instance, questions arising in optimal control, identification theory, and robust stability theory (Kalman–Yakubovich–Popov Lemma, Bounded Real Lemma and so on; see, e.g., the expository paper by Willems [22]). Moreover, the recent results in the area of H_∞-control owe much to the LQ-theory.

The first solutions for the LQ-problem were obtained for the case that the cost criterion is positive definite (sometimes called the *standard* case):

$$J(x_0, u(\cdot)) = \int_0^\infty (\|Cx(t)\|_Y^2 + \|R^{1/2}u(t)\|_U^2)\, dt.$$

However, for many applications a more general formulation is needed. In [22], the LQ-problem is treated for finite-dimensional systems in its most general form; that is, the cost criterion is not necessarily positive definite. In particular, we refer to [22, Thm. 5], which shows the equivalence of the solvability of the LQ-problem with stability to the existence of a solution to a *nonstandard* Riccati equation and a frequency domain inequality.

The system theoretical questions mentioned above are, of course, also interesting for infinite-dimensional systems, and the corresponding LQ-problems can be formulated in a similar way. In fact, much attention has been devoted to the standard LQ-problem for infinite-dimensional systems. In [4], [1] (and references therein) the case is treated where the input and output operators are bounded, and in [10], [15], [11] (and references therein) the unbounded case is considered. The nonstandard problem, however, has received less attention. In [25] the bounded input/output case is treated assuming that the generator of the semigroup of the system is bounded, and in [21] and [12], [13] this result is extended to unbounded generators. These authors have obtained a complete generalization of the aforementioned result in [22] for their classes of systems. It is the purpose of this paper to do the same for a class of unbounded input/output systems (the Pritchard–Salamon class introduced in [15]).

We shall consider nonstandard cost functions of the form

$$J(x_0,u(\cdot)) = \int_0^\infty (\|C_1x(t)\|_{Y_1}^2 - \|C_2x(t)\|_{Y_2}^2 + \langle Lx(t),u(t)\rangle_U + \|R^{1/2}u(t)\|_U^2)\,dt,$$

where C_1, C_2, and L are unbounded output operators that are "admissible" in the sense of Pritchard and Salamon in [15]. In the paper [15] Pritchard and Salamon present a general framework to model a large class of systems with unbounded control and observation operators (it extends the class of bounded input/output semigroup control systems). Their class of systems includes many delay systems: neutral systems with output delays [16] (see also §4) and retarded systems with delays in input and output [15], [19]. Furthermore, the Pritchard–Salamon class includes a class of parabolic PDE systems with unbounded control and observation [15] (see also §4). In [15] it is shown that certain hyperbolic PDE systems also fall into the Pritchard–Salamon framework, but generally these are only exponentially stabilizable if there is some internal damping (in this paper exponential stabilizability will be a standing assumption). In [2] it is shown that the Euler–Bernoulli beam with Kelvin–Voigt damping (see also §4) fits into the Pritchard–Salamon class, but usually one does not call this a hyperbolic system.

It should be noted that the *standard LQ*-problem can be treated for many PDE systems that do not fit into the Pritchard–Salamon class (see [10], [11] and references therein). However, usually one has to distinguish several cases (essentially the parabolic and the hyperbolic cases). In the Pritchard–Salamon framework it is possible to treat delay systems and PDE systems at the same time, at the expense of the allowed amount of input/output unboundedness for PDE systems. It can be argued that the strength of the Pritchard–Salamon class lies in the fact that it contains so many delay systems; a weak point is that not so many PDE systems fit in. In any case, this paper contains the *first generalization of the nonstandard LQ-problem to infinite-dimensional systems with unbounded inputs and outputs*; all the above-mentioned examples can now be accommodated.

In §2 we give some preliminary results, some of which are known (stated with references) and some of which are new. In particular, we refer to [3] where many system theoretic results were obtained for the Pritchard–Salamon class, including some that made this paper possible. After the introduction of the Pritchard–Salamon class, some perturbation theory is given and we show how preliminary (unbounded) feedbacks can be handled. Then we derive an interesting formula that shows how the "unbounded part" of a Pritchard–Salamon system (i.e., unbounded with respect to the larger state space) can be expressed as "something bounded." Section 2 is concluded with some frequency domain results for Pritchard–Salamon systems and a quotation of the main result in [13], which is the generalization of [22, Theorem 5] to the class of infinite-dimensional systems with bounded input and output operators. Our main result, which is a generalization of this result to the Pritchard–Salamon class, is given in §3. In the proof of the main result we apply some preliminary (unbounded) feedback in order to take care of the "cross term" in the LQ-cost criterion. Furthermore, we use the formula for the "unbounded part" given in §2 so that the LQ-result for the bounded input/output case in [13] can be used. Finally, in §4 we shall treat several examples of the theory presented in this paper and give some conclusions.

2. Preliminary results.

We consider the same class of systems as in [15], [16], [19], and [3]. Let W and V be real Hilbert spaces satisfying

$$W \hookrightarrow V, \tag{2.1}$$

where by $\hookrightarrow$ we mean that $W \subset V$ and the canonical injection $W \to V$, $x \mapsto x$ is continuous and W is dense in V. We consider C_0-semigroups $S(\cdot)$ on V that restrict to C_0-semigroups on W (we note that the growth bounds of $S(\cdot)$ on W and V need not be the same, as shown in [3]). The infinitesimal generators of $S(\cdot)$ on V and W will be denoted by A^V and A^W, respectively. We note that A^W is the part of A^V in W so that $D(A^W) = \{x \in D(A^V) \cap W \mid A^V x \in W\}$ and $A^W x = A^V x$ for all $x \in D(A^W)$ (see [14, §4.5]). Using $W \hookrightarrow V$, it is not difficult to show that in fact

$$D(A^W) \hookrightarrow D(A^V).$$

Hilbert adjoints of linear operators are denoted by $*$.

The following definition can be found in [15] and [3]. It was first stated in [15], but we use the formulation of [3].

DEFINITION 2.1. *Let U and Y be Hilbert spaces.*

1. *An operator $B \in \mathcal{L}(U, V)$ is called an admissible input operator if there exist $t_1 > 0$ and $\alpha > 0$ such that*

$$\int_0^{t_1} S(t_1 - s)Bu(s)\,ds \in W \tag{2.2}$$

and

$$\left\| \int_0^{t_1} S(t_1 - s)Bu(s)\,ds \right\|_W \leq \alpha \|u(\cdot)\|_{L_2(0,t_1;U)} \tag{2.3}$$

for all $u(\cdot) \in L_2(0, t_1; U)$.

2. *An operator $C \in \mathcal{L}(W, Y)$ is called an admissible output operator for $S(\cdot)$ if there exist $t_1 > 0$ and $\alpha > 0$ such that*

$$\|CS(\cdot)x\|_{L_2(0,t_1;Y)} \leq \alpha \|x\|_V \text{ for all } x \in W. \tag{2.4}$$

3. *Let $B \in \mathcal{L}(U, V)$ and $C \in \mathcal{L}(W, Y)$ be admissible input and output operators, respectively. The system $\Sigma(S(\cdot), B, C, D)$ given by*

$$\begin{aligned} x(t) &= S(t)x_0 + \int_0^t S(t - s)Bu(s)\,ds, \\ y(t) &= Cx(t) + Du(t), \end{aligned} \tag{2.5}$$

where $x_0 \in V, t \geq 0$, and $u(\cdot) \in L_2^{\text{loc}}(0, \infty; U)$ is called a Pritchard–Salamon system.

Remark 2.2. As is mentioned in [3], if the statements (2.3) and (2.4) hold for some t_1 and α, then they hold for any $t_1 > 0$ and some $\alpha > 0$, α depending on t_1.

If $x_0 \in W$, then $x(t)$ defined by (2.5) is continuous with respect to the topology on W and the controllability map $\mathcal{C}$ from $L_2(0, T; U)$ to W given by

$$\mathcal{C}u(\cdot) = \int_0^T S(T - \tau)Bu(\tau)\,d\tau$$

satisfies $\mathcal{C} \in \mathcal{L}(L_2(0, T; U), W)$.

Furthermore, (2.4) implies that the linear map from W to $L_2(0, T; Y)$, $x \mapsto CS(\cdot)x$ has a unique bounded extension from V to $L_2(0, T; Y)$, which will be denoted by $x \mapsto \overline{CS}(\cdot)x$ for $x \in V$. Hence, the ouput $y(\cdot) \in L_2(0,T;Y)$ in (2.5) should be interpreted as

$$y(\cdot) = \overline{CS}(\cdot)x_0 + C\int_0^{\cdot} S(\cdot - s)Bu(s)\,ds.$$

Finally, we note that if $W = V$, then $B \in \mathcal{L}(U,V)$ and $C \in \mathcal{L}(W,Y)$ are automatically admissible (this is the so-called "bounded input/output case").

In the following lemma we state some perturbation results that follow from [3]. In the last part of the lemma we shall use the additional assumption that

$$D(A^V) \hookrightarrow W. \tag{2.6}$$

Here $D(A^V)$ is the Hilbert space with the inner product given by

$$\langle x,y\rangle_{D(A^V)} := \langle x,y\rangle_V + \langle A^V x, A^V y\rangle_V. \tag{2.7}$$

We note that this assumption is not very restrictive, as explained in [15].

LEMMA 2.3. *Let $\Sigma(S(\cdot),B,C,D)$ be a Pritchard–Salamon system of the form* (2.5), *and let $F \in \mathcal{L}(W,U)$ be an admissible output operator for this system. Then there exists a unique C_0-semigroup $S_{BF}(\cdot)$ on V that restricts to a C_0-semigroup on W such that $\Sigma(S_{BF}(\cdot),B,C,\ D)$ is a Pritchard–Salamon system and*

$$S_{BF}(t)x = S(t)x + \int_0^t S(t-s)B\overline{FS}_{BF}(s)x\,ds \text{ for all } x \in V. \tag{2.8}$$

Furthermore,

$$S_{BF}(t)x = S(t)x + \int_0^t S_{BF}(t-s)B\overline{FS}(s)x\,ds \text{ for all } x \in V \tag{2.9}$$

and

$$D(A^V_{BF}) = D(A^V) \quad \text{with equivalent graph norms,}$$

$$D(A^W_{BF}) = \{x \in D(A^V) \cap W) \mid A^V_{BF}x \in W\},$$

$$A^V_{BF}x = A^V x + \overline{BF(\sigma I - A^W)^{-1}}(\sigma I - A^V)x \text{ for all } x \in D(A^V),$$

where σ is any number with real part larger than the growth bounds of $S(\cdot)$ and $S_{BF}(\cdot)$ on W and V. If, in addition, assumption (2.6) *is satisfied, there holds*

$$A^V_{BF}x = (A^V + BF)x \text{ for all } x \in D(A^V).$$

Proof. Almost all of the results in this lemma can be found in [3]. Here we prove that the graph norms of $D(A^V)$ and $D(A^V_{BF})$ are equivalent and we derive the expressions for A^V_{BF}.

As explained in [3], we can apply the Laplace transform to (2.8) and (2.9) to obtain for all $x \in V$

$$(\sigma I - A^V_{BF})^{-1}x = (\sigma I - A^V)^{-1}x + (\sigma I - A^V)^{-1}\overline{BF(\sigma I - A^W_{BF})^{-1}}x$$

and

$$(\sigma I - A^V)^{-1}x = (\sigma I - A^V_{BF})^{-1}x - (\sigma I - A^V_{BF})^{-1}B\overline{F(\sigma I - A^W)^{-1}}x,$$

where σ is any number with real part larger than the growth bounds of $S(\cdot)$ and $S_{BF}(\cdot)$ on W and V. Defining $T_1 := I + B\overline{F(\sigma I - A^W_{BF})^{-1}} \in \mathcal{L}(V)$ and $T_2 := I - B\overline{F(\sigma I - A^W)^{-1}} \in \mathcal{L}(V)$, we can reformulate the above equations as $(\sigma I - A^V)x = T_1(\sigma I - A^V_{BF})x$ and $(\sigma I - A^V_{BF})x = T_2(\sigma I - A^V)x$, for all $x \in D(A^V) = D(A^V_{BF})$. Since $T_1, T_2 \in \mathcal{L}(V)$, it follows that the graph norms of $D(A^V)$ and $D(A^V_{BF})$ are equivalent. Manipulation of the last equation shows that $A^V_{BF}x = A^Vx + B\overline{F(\sigma I - A^W)^{-1}}(\sigma I - A^V)x$ for all $x \in D(A^V)$. Finally, we prove that if (2.6) is satisfied, it follows that for all $x \in D(A^V)$

$$\overline{F(\sigma I - A^W)^{-1}}(\sigma I - A^V)x = Fx \tag{2.10}$$

(note that this expression is valid for $x \in D(A^W)$). Since $W \hookrightarrow V$, we have $D(A^W) \hookrightarrow D(A^V)$; and because (2.10) is satisfied for all $x \in D(A^W)$, the result follows by taking a sequence $x_n \in D(A^W)$ converging to x in the topology of $D(A^V)$. □

Remark 2.4. We note that if $F \in \mathcal{L}(V, U)$, then F is an admissible output operator. We call the pair (A^V, B) *exponentially stabilizable on* V if there exists some $F \in \mathcal{L}(V, U)$ such that $S_{BF}(\cdot)$ is exponentially stable on V (this corresponds with the usual definition of exponential stabilizability on the Hilbert space V). Using the perturbation results of Lemma 2.3 and [6, Cor. 1], it is not difficult to show (see [3]) that the following two conditions are equivalent:

1. there exists an admissible output operator $F_1 \in \mathcal{L}(W, U)$ such that $S_{BF_1}(\cdot)$ is exponentially stable on V;
2. (A^V, B) is exponentially stabilizable on V.

Finally, we mention that if assumption (2.6) holds, condition (2.3) is implied by (2.2) (see [23]).

Using the perturbation results in Lemma 2.3, we can now make sense of a preliminary feedback "$u = Fx + v$" in system (2.5), where F is an admissible output operator. We note that if F is bounded (i.e., $F \in \mathcal{L}(V, U)$), this type of result can be found in [14].

LEMMA 2.5. *Let $\Sigma(S(\cdot), B, C, D)$ be a Pritchard-Salamon system of the form (2.5), and let $F \in \mathcal{L}(W, U)$ be an admissible output operator for this system.*

1. *Suppose that $v(\cdot) \in L_2^{\text{loc}}(0, \infty; U)$, and define*

$$x_F(t) := S_{BF}(t)x_0 + \int_0^t S_{BF}(t - s)Bv(s)\, ds \tag{2.11}$$

and

$$u(t) := Fx_F(t) + v(t). \tag{2.12}$$

Then $u(\cdot) \in L_2^{\text{loc}}(0, \infty; U)$ and $x(t)$ given by

$$x(t) = S(t)x_0 + \int_0^t S(t - s)Bu(s)\, ds \tag{2.13}$$

satisfies

$$x(t) = x_F(t) \textit{ for all } t \geq 0 \textit{ and } Cx(t) = Cx_F(t) \textit{ for a.e. } t \geq 0. \tag{2.14}$$

2. *Suppose that* $u(\cdot) \in L_2^{\text{loc}}(0,\infty;U)$, *and define* $x(\cdot)$ *by* (2.13) *and* $v(\cdot)$ *by*

$$v(t) := -Fx(t) + u(t). \tag{2.15}$$

Then $v(\cdot) \in L_2^{\text{loc}}(0,\infty;U)$ *and* $x_F(t)$ *given by* (2.11) *satisfies*

$$x(t) = x_F(t) \text{ for all } t \geq 0 \text{ and } Cx(t) = Cx_F(t) \text{ for a.e. } t \geq 0. \tag{2.16}$$

3. *Let* $v(\cdot) \in L_2^{\text{loc}}(0,\infty;U)$, *and define* $x_F(\cdot)$ *as in* (2.11) *and* $u(\cdot)$ *as in* (2.12) *i.e.,* $u(t) = Fx_F(t) + v(t)$. *Then* $v(\cdot)$ *satisfies* (2.15), *i.e.,* $v(t) = -Fx(t) + u(t)$. *Conversely, let* $u(\cdot) \in L_2^{\text{loc}}(0,\infty;U)$ *and define* $x(\cdot)$ *as in* (2.13) *and* $v(\cdot)$ *as in* (2.15). *Then* $u(\cdot)$ *satisfies* (2.12).

Proof. Proof of 1. The expression $Fx_F(\cdot)$ in $u(\cdot) := Fx_F(\cdot) + v(\cdot)$ should be interpreted as explained in Remark 2.2:

$$u(\cdot) = \overline{FS}_{BF}(\cdot)x_0 + F\int_0^{\cdot} S_{BF}(\cdot - s)Bv(s)\,ds + v(\cdot) \in L_2^{\text{loc}}(0,\infty;U),$$

where we note that F is an admissible output operator for $S_{BF}(\cdot)$ (see Lemma 2.3). Substituting $u(\cdot)$ in (2.13) gives

$$\begin{aligned} x(t) = S(t)x_0 &+ \int_0^t S(t-s)B\overline{FS}_{BF}(s)x\,ds + \int_0^t S(t-s)Bv(s)\,ds \\ &+ \int_0^t S(t-s)BF\left[\int_0^s S_{BF}(s-\tau)Bv(\tau)\,d\tau\right]ds. \end{aligned} \tag{2.17}$$

It follows from Lemma 2.3 that the two terms of $x_F(t)$ in (2.11) can be reformulated as

$$S_{BF}(t)x_0 = S(t)x_0 + \int_0^t S_{BF}(t-s)B\overline{FS}(s)x\,ds$$

and

$$\int_0^t S_{BF}(t-s)Bv(s)\,ds = \int_0^t S(t-s)Bv(s)\,ds$$

$$+\int_0^t\left[\int_0^{t-s} S(t-s-\sigma)B\overline{FS}_{BF}(\sigma)Bv(s)\,d\sigma\right]ds.$$

Comparing this with (2.17), we see that to prove that $x(t) = x_F(t)$, we only have to show that

$$\begin{aligned} &\int_0^t S(t-s)BF\left[\int_0^s S_{BF}(s-\tau)Bv(\tau)\,d\tau\right]ds \\ &\quad = \int_0^t\left[\int_0^{t-s} S(t-s-\sigma)B\overline{FS}_{BF}(\sigma)Bv(s)\,d\sigma\right]ds. \end{aligned} \tag{2.18}$$

This means that we have to somehow "get F inside the integral" (the other operators cause no problems, since they are bounded). It follows from [3] that if $v(\cdot)$ is a *step function*, we have

$$F\int_0^s S_{BF}(s-\tau)Bv(\tau)\,d\tau = \int_0^s \overline{FS}_{BF}(s-\tau)Bv(\tau)\,d\tau. \tag{2.19}$$

We note that in [15] a similar result was proved under the extra assumption that (2.6) is satisfied. Using (2.19) and Fubini's Theorem to interchange the integrals, it is straightforward to show that (2.18) is satisfied if $v(\cdot)$ is a step function. The general case can be obtained by introducing sequences $v_n(\cdot)$ on arbitrary intervals $[0, T]$ that converge to $v(\cdot)$ on these intervals in the $L_2(0, T; U)$-norm. Of course the admissibility of B and C should be used. We omit the details and refer to [15, Lem. 2.5] for a similar result that was proved using somewhat different arguments.

Finally, we sketch the proof of the second part of (2.14). This seems to follow trivially from the first part of (2.14). However, $Cx(t) = Cx_F(t)$ should be interpreted in the sense of Remark 2.2, i.e., in the L_2-sense. It is easy to see that $Cx(t) = Cx_F(t)$ holds if $x_0 \in W$. The general result can be obtained by introducing a sequence $x_{0n} \in W$ converging to x_0 as $n \to \infty$ and using the admissibility of B and C. We omit the details.

Proof of 2. Again, using the interpretation of Remark 2.2, we have

$$v(t) = -\overline{FS}(t)x_0 - F\int_0^t S(t-s)Bu(s)\,ds + u(t).$$

The rest of the proof of 2 is similar to the proof of 1 and, therefore, is deleted.

Proof of 3. This follows immediately from 1 and 2. □

In the following lemma we give a Lyapunov type result for systems of the form (2.5) where $S(\cdot)$ is exponentially stable on V. This result (which is also more or less given in [5]) could be considered as a special case of the results in [15], but for reasons of completeness we give a short proof.

LEMMA 2.6. *Let $S(\cdot)$ be a C_0-semigroup on W and V, and suppose that $S(\cdot)$ is exponentially stable on V. Suppose that assumption* (2.6) *holds. Let $C \in \mathcal{L}(W, Y)$ be an admissible output operator for $S(\cdot)$. Then the operator $\mathcal{C}^\infty$ defined on W by*

$$\mathcal{C}^\infty x := CS(\cdot)x \text{ for } x \in W \tag{2.20}$$

has a unique bounded extension on V (denoted by the same symbol) such that

$$\mathcal{C}^\infty \in \mathcal{L}(V, L_2(0, \infty; Y)). \tag{2.21}$$

Furthermore, the nonnegative definite operator $X \in \mathcal{L}(V)$ defined by

$$X := (\mathcal{C}^\infty)^*\mathcal{C}^\infty \tag{2.22}$$

satisfies

$$\langle A^V x, Xy\rangle_V + \langle x, XA^V y\rangle_V + \langle Cx, Cy\rangle_Y = 0 \tag{2.23}$$

for all $x, y \in D(A^V)$.

Proof. It follows from [15, Rem. 3.5(i)], that there exists some $c > 0$ such that for all $x \in W$,

$$\|CS(\cdot)x\|_{L_2(0,\infty;Y)} \le c\|x\|_V. \tag{2.24}$$

Therefore, $\mathcal{C}^\infty \in \mathcal{L}(V, L_2(0, \infty; Y))$ (cf. also Remark 2.2).

Now let $x, y \in D(A^W)$ and define the function

$$f(t) := \langle CS(t)x, CS(t)y\rangle_Y.$$

Then $f(\cdot)$ is defined for all t and it is differentiable; there holds

$$\dot{f}(t) = \langle CS(t)A^W x, CS(t)y\rangle_Y + \langle CS(t)x, CS(t)A^W y\rangle_Y. \tag{2.25}$$

For all $x \in D(A^W)$ we have

$$\|CS(t)x\|_Y \leq \|C\|\|S(t)x\|_W \leq \text{const}\|S(t)x\|_{D(A^V)},$$

where we have used assumption (2.6). Furthermore, for all $x \in D(A^W)$

$$\|S(t)x\|_{D(A^V)} \to 0 \text{ as } t \to \infty,$$

because $S(\cdot)$ is exponentially stable on V and therefore also on $D(A^V)$ (see, e.g., [19]). Therefore, we conclude that $f(t) \to 0$ as $t \to \infty$. Now integrating (2.25) from 0 to T gives

$$f(T) - f(0) = \int_0^T (\langle CS(t)A^W x, CS(t)y\rangle_Y + \langle CS(t)x, CS(t)A^W y\rangle_Y)\, dt.$$

Since $CS(\cdot)x \in L_2(0,\infty;Y)$ for all $x \in W$ (see (2.24)), we can take the limit as $T \to \infty$ to obtain

$$\int_0^\infty (\langle CS(t)A^W x, CS(t)y\rangle_Y + \langle CS(t)x, CS(t)A^W y\rangle_Y)\, dt = -\langle Cx, Cy\rangle_Y.$$

Since $x, y \in D(A^W)$ were arbitrary, we can use (2.20) and the fact that $A^W x = A^V x$ for all $x \in D(A^W)$ to conclude that for all $x, y \in D(A^W)$

$$\langle \mathcal{C}^\infty A^V x, \mathcal{C}^\infty y\rangle_{L_2(0,\infty;Y)} + \langle \mathcal{C}^\infty x, \mathcal{C}^\infty A^V y\rangle_{L_2(0,\infty;Y)} = -\langle Cx, Cy\rangle_Y. \tag{2.26}$$

Using the fact that $D(A^W) \hookrightarrow D(A^V)$ and the assumption that $D(A^V) \hookrightarrow W$, we can extend (2.26) to all $x, y \in D(A^V)$ by choosing sequences $x_n, y_n \in D(A^W)$ that converge to $x, y \in D(A^V)$. Finally, it is clear then that X defined by (2.22) satisfies (2.23). □

We are interested in LQ-problems with stability. We shall try to find controllers that stabilize the state $x(\cdot)$ in (2.5) in the sense that $x(\cdot) \in L_2(0,\infty;V)$. In the next lemma we shall show that, under certain conditions, in this case $y(\cdot) \in L_2(0,\infty;Y)$. This is not obvious in the general case because the growth constant of $S(\cdot)$ on W need not equal the growth constant on V (see [3]) and so we cannot conclude that $x(\cdot) \in L_2(0,\infty;W)$ in general. One required condition is that the pair (A^V, B) must be exponentially stabilizable on V. In this case, it is easy to see that the set U_{adm} defined by

$$U_{\text{adm}} := \{u(\cdot) \in L_2(0,\infty;U) \text{ such that } x(\cdot) \text{ given by}$$
$$(2.5) \text{ satisfies } x(\cdot) \in L_2(0,\infty;V)\}$$

is nonempty.

LEMMA 2.7. *Let $\Sigma(S(\cdot),B,C,D)$ be a Pritchard–Salamon system of the form* (2.5), *and suppose that (A^V,B) is exponentially stabilizable on V. Furthermore, suppose that assumption* (2.6) *is satisfied. For all $u(\cdot) \in U_{\text{adm}}$ it follows that $y(\cdot)$ given by* (2.5) *is in $L_2(0,\infty;Y)$ and if $x_0 = 0$ there holds*

$$\|y(\cdot)\|_{L_2(0,\infty;Y)} \leq \text{const}(\|u(\cdot)\|_{L_2(0,\infty;U)} + \|x(\cdot)\|_{L_2(0,\infty;V)}). \tag{2.27}$$

Proof. If C were an element of $\mathcal{L}(V,Y)$, the fact that $x(\cdot) \in L_2(0,\infty;V)$ would immediately imply the lemma. However, we only know that $C \in \mathcal{L}(W,Y)$ is admissible and so we have to do some work to establish the result.

Since (A^V, B) is exponentially stabilizable on V, there exists an $F \in \mathcal{L}(V,U)$ such that $S_{BF}(\cdot)$ is stable on V. Furthermore, it follows from assumption (2.6) and Lemma 2.3 that $D(A^V_{BF}) \hookrightarrow W$. Using Lemma 2.6 it follows that there exists a nonnegative definite $X_F \in \mathcal{L}(V)$ such that for all $x, y \in D(A^V) = D(A^V_{BF})$

$$\langle A^V_{BF}x, X_F y\rangle_V + \langle x, X_F A^V_{BF} y\rangle_V + \langle Cx, Cy\rangle_Y = 0.$$

Because of (2.6), Lemma 2.3 implies that $A^V_{BF} = A^V + BF$ on its domain and so the above formula can be expressed as

$$\langle A^V x, X_F y\rangle_V + \langle x, X_F A^V y\rangle_V = -\langle Cx, Cy\rangle_Y$$

$$- \langle (X_F BF + F^* B^* X_F)x, y\rangle_V \text{ for all } x, y \in D(A^V) = D(A^V_{BF}). \tag{2.28}$$

Now consider the system (2.5) and suppose that $u(\cdot) \in U_{\text{adm}}$. Let $u_n(\cdot) \in C^1(0,\infty;U)$ be such that $u_n(\cdot) \to u(\cdot)$ (in the L_2-norm) and $x_{0n} \in D(A^V)$ be such that $x_{0n} \to x_0$ (in the norm on V). Let $x_n(\cdot)$ be given by

$$x_n(t) = S(t)x_{0n} + \int_0^t S(t-s)Bu_n(s)\,ds.$$

It follows from known results (see, e.g., [8, App. A.3, A.6]) that $x_n(\cdot)$ is continuously differentiable, $x_n(t) \in D(A^V)$ for all $t \geq 0$,

$$\dot{x}_n(t) = A^V x_n(t) + Bu_n(t) \text{ for all } t \geq 0, \tag{2.29}$$

and for all $T > 0$

$$\|x_n(\cdot) - x(\cdot)\|_{L_2(0,T;V)} \to 0 \text{ and } \|x_n(T) - x(T)\|_V \to 0 \text{ as } n \to \infty. \tag{2.30}$$

Furthermore,

$$\|Cx_n(\cdot) - Cx(\cdot)\|_{L_2(0,T;Y)} \leq \|\overline{CS}(\cdot)(x_{0n} - x_0)\|_{L_2(0,T;Y)}$$

$$+ \left\| C \int_0^{\cdot} S(\cdot - s)B(u_n(s) - u(s))\,ds \right\|_{L_2(0,T;Y)}.$$

Hence, the fact that B and C are both admissible implies that

$$\|Cx_n(\cdot) - Cx(\cdot)\|_{L_2(0,T;Y)} \to 0 \text{ as } n \to \infty. \tag{2.31}$$

Now using (2.28) and (2.29), it is straightforward to show that

$$\frac{d}{dt}\langle x_n(t), X_F x_n(t)\rangle_V = -\langle Cx_n(t), Cx_n(t)\rangle_Y$$

$$- \langle (X_F BF + F^* B^* X_F)x_n(t), x_n(t)\rangle_V + 2\langle Bu_n(t), X_F x_n(t)\rangle_V. \tag{2.32}$$

Integrating (2.32) from 0 to T gives

$$\langle x_n(T), X_F x_n(T)\rangle_V - \langle x_{0n}, X_F x_{0n}\rangle_V + \int_0^T \|Cx_n(t)\|_Y^2\, dt$$

$$= \int_0^T (\langle -(X_F BF + F^* B^* X_F)x_n(t), x_n(t)\rangle_V + 2\langle Bu_n(t), X_F x_n(t)\rangle_V)\, dt.$$

Now we wish to take the limit as $n \to \infty$. Since $X_F \in \mathcal{L}(V), B \in \mathcal{L}(U,V)$, and $F \in \mathcal{L}(V,U)$, the only difficult part is the term $\langle Cx_n(t), Cx_n(t)\rangle_Y$, but this was already dealt with in (2.31). So using (2.30)–(2.31) we obtain

$$\langle x(T), X_F x(T)\rangle_V - \langle x_0, X_F x_0\rangle_V + \int_0^T \|Cx(t)\|_Y^2\, dt$$

$$= \int_0^T (\langle -(X_F BF + F^* B^* X_F)x(t), x(t)\rangle_V + 2\langle Bu(t), X_F x(t)\rangle_V)\, dt.$$

Since X_F is nonnegative definite, $u(\cdot) \in L_2(0,\infty;U)$, and $x(\cdot) \in L_2(0,\infty;V)$, the last equation implies that $Cx(\cdot) \in L_2(0,\infty;Y)$ and therefore $y(\cdot) \in L_2(0,\infty;Y)$. Furthermore, we have that $\|x(T)\|_V \to 0$ as $T \to \infty$ (see, e.g., [8]) and so, using the fact that $u(\cdot) \in L_2(0,\infty;U)$ and $x(\cdot) \in L_2(0,\infty;V)$, we may let $T \to \infty$ to obtain

$$\int_0^\infty \|Cx(t)\|_Y^2\, dt = \langle x_0, X_F x_0\rangle_V$$

$$+ \int_0^\infty (\langle -(X_F BF + F^* B^* X_F)x(t), x(t)\rangle_V + 2\langle Bu(t), X_F x(t)\rangle_V)\, dt. \tag{2.33}$$

Finally, it is clear that if $x_0 = 0$, then (2.27) follows from (2.33). □

Remark 2.8. The fact that $y(\cdot) \in L_2(0,\infty;Y)$ in Lemma 2.7 also follows from very general results in [24]. However, the direct proof that is given here provides us with formula (2.33), which will play an important role in our treatment of the *LQ*-problem. In fact, it shows how we can transform the "unbounded part" with $Cx(\cdot)$ into "something bounded."

In this paper we shall also be interested in frequency domain results. In the following, the complexification of a real Hilbert space H is denoted by the same symbol.

Suppose that H is some Hilbert space, and let $x(\cdot) \in L_2(0,\infty;H)$. The Fourier transform of $x(\cdot)$ denoted by $\hat{x}(\cdot)$ is defined by

$$\hat{x}(i\omega) = \underset{T\to\infty}{\text{l.i.m.}} \int_0^T \exp(-i\omega t)x(t)\, dt,$$

where l.i.m. stands for limit in (quadratic) mean. It is well known (Plancherel's Theorem; see, e.g., [18, §4.8]) that now the function determined by $\omega \mapsto \hat{x}(i\omega)$ is an element of $L_2(\mathbb{R}, H)$ and

$$\|x(\cdot)\|_{L_2(0,\infty;H)}^2 = (1/2\pi)\|\hat{x}(\cdot)\|_{L_2(\mathbb{R};H)}^2.$$

Furthermore, we define the Laplace transform $\hat{x}(\cdot)$ of $x(\cdot)$ by

$$\hat{x}(s) = \int_0^\infty \exp(-st)x(t)dt,\ \mathrm{Re}(s) > 0,$$

and we recall that $\hat{x}(s)$ converges to $\hat{x}(i\omega)$ a.e. on the imaginary axis (see again [18]).

In the next two lemmas we calculate a frequency domain representation of a Pritchard–Salamon system. If $S(\cdot)$ is exponentially stable on V, we find an expression for its transfer function on $\mathbb{C}^+$ and prove that it is in $H^\infty(\mathbb{C}^+)$. A particular difficulty here is that $S(\cdot)$ need not be stable on W and that $\widehat{Cx}(i\omega) = C\hat{x}(i\omega)$ is not immediate because in general $C \notin \mathcal{L}(V, Y)$. Some of the arguments in the proofs that are given here can also be found in [24].

LEMMA 2.9. *Let $\Sigma(S(\cdot), B, C, D)$ be a Pritchard–Salamon system of the form* (2.5)*, and suppose that $S(\cdot)$ is exponentially stable on V. Furthermore, suppose that assumption* (2.6) *is satisfied.*

Then $G(s)$ defined by

$$G(s) := C(sI - A^V)^{-1}B + D \tag{2.34}$$

is well defined for all $\mathrm{Re}(s) \geq 0$ *and*

$$G(s) \in H^\infty(\mathbb{C}^+, \mathcal{L}(U, Y)). \tag{2.35}$$

Furthermore, if $u(\cdot) \in L_2(0, \infty; U)$, then $u(\cdot) \in U_{\mathrm{adm}}$; and if $x_0 = 0$ there holds

$$\hat{y}(s) = G(s)\hat{u}(s) \text{ for all } s \in \mathbb{C}^+ \tag{2.36}$$

and

$$\hat{y}(i\omega) = G(i\omega)\hat{u}(i\omega) \text{ for a.e. } \omega \in \mathbb{R}. \tag{2.37}$$

Proof. First of all we show that $G(s)$ is well defined for all s with $\mathrm{Re}(s) \geq 0$ and holomorphic on $\mathrm{Re}(s) \geq 0$ w.r.t. the topology of $\mathcal{L}(U, Y)$. Using the fact that $S(\cdot)$ is exponentially stable on V, the resolvent identity for $(sI - A^V)^{-1}$ gives

$$(sI - A^V)^{-1} = (\alpha I - A^V)^{-1} + (\alpha - s)(\alpha I - A^V)^{-1}(sI - A^V)^{-1} \tag{2.38}$$

for $\alpha, s \in \mathrm{Re}(s) \geq 0$. We know that $(sI - A^V)^{-1}$ is holomorphic on $\mathrm{Re}(s) \geq 0$ (w.r.t. the topology of $\mathcal{L}(V)$) and that $(\alpha I - A^V)^{-1} \in \mathcal{L}(V, W)$ for $\mathrm{Re}(\alpha) \geq 0$ (use the fact that $(\alpha I - A^V)^{-1} \in \mathcal{L}(V, D(A^V))$ and $D(A^V) \hookrightarrow W$). Hence we can conclude from (2.38) that $(sI - A^V)^{-1} \in \mathcal{L}(V, W)$ on $\mathrm{Re}(s) \geq 0$ and $(sI - A^V)^{-1}$ is holomorphic on $\mathrm{Re}(s) \geq 0$ w.r.t. the topology of $\mathcal{L}(V, W)$. Therefore, $G(s) = C(sI - A^V)^{-1}B + D$ is well defined ($(sI - A^V)^{-1}B$ maps into W) and holomorphic on $\mathrm{Re}(s) \geq 0$ w.r.t. the topology of $\mathcal{L}(U, Y)$.

Next we show (2.35) and (2.36): consider (2.5) with $x_0 = 0$. Since $S(\cdot)$ is exponentially stable on V, we know that for all $u(\cdot) \in L_2(0, \infty; U)$ we have $x(\cdot) \in L_2(0, \infty; V)$ and

$$\|x(\cdot)\|_{L_2(0,\infty;V)} \leq \text{const}\, \|u(\cdot)\|_{L_2(0,\infty;U)} \tag{2.39}$$

(this is well known; see, e.g., [8]). Hence, it follows from Lemma 2.7 that there exists some $c > 0$ such that for all $u(\cdot) \in L_2(0, \infty; U)$ there holds

$$\|y(\cdot)\|_{L_2(0,\infty;Y)} \leq c\, \|u(\cdot)\|_{L_2(0,\infty;U)}, \tag{2.40}$$

so the map from $u(\cdot) \in L_2(0,\infty;U)$ to $y(\cdot) \in L_2(0,\infty;Y)$ is linear and bounded. It is easy to see that this map is also shift invariant and so it follows from a well-known result (see, e.g., [7]) that there exists a (transfer) function $\tilde{G} : \mathbb{C}^+ \rightarrow \mathcal{L}(U,Y)$ such that

$$\hat{y}(s) = \tilde{G}(s)\hat{u}(s) \text{ for all } s \in \mathbb{C}^+ \tag{2.41}$$

and

$$\tilde{G}(\cdot) \in H^\infty(\mathbb{C}^+, \mathcal{L}(U,Y)). \tag{2.42}$$

The next step is to show that $\tilde{G}(s) = C(sI - A^V)^{-1}B + D$ on $\mathbb{C}^+$. We know that for $\text{Re}(s)$ large enough there holds

$$\tilde{G}(s) = C(sI - A^V)^{-1}B + D \tag{2.43}$$

(see, e.g., [3]). We have seen above that $G(s) = C(sI - A^V)^{-1}B + D$ is holomorphic on $\mathbb{C}^+$ w.r.t. the topology of $\mathcal{L}(U,Y)$. Since also $\tilde{G}(s)$ is holomorphic on $\mathbb{C}^+$ w.r.t. the topology of $\mathcal{L}(U,Y)$, we conclude (2.35) and (2.36).

Finally we show (2.37). Because $\hat{u}(\cdot) \in H_2(\mathbb{C}^+,U)$ and $\hat{y}(\cdot) \in H_2(\mathbb{C}^+,Y)$, it follows from Fatou's Theorem (see, e.g., [18, §4.6]) that for a.e. $\omega \in \mathbb{R}$,

$$\lim_{\epsilon \downarrow 0} \|\hat{u}(i\omega + \epsilon) - \hat{u}(i\omega)\|_U = 0 \text{ and } \lim_{\epsilon \downarrow 0} \|\hat{y}(i\omega + \epsilon) - \hat{y}(i\omega)\|_Y = 0. \tag{2.44}$$

(2.37) now follows from (2.36), (2.44), and the fact that $G(s)$ is holomorphic on $\text{Re}(s) \geq 0$ w.r.t. the topology on $\mathcal{L}(U,Y)$. □

Now we derive a frequency domain representation of (2.5), using Lemma 2.9.

LEMMA 2.10. *Let $\Sigma(S(\cdot),B,C,D)$ be a Pritchard–Salamon system of the form* (2.5)*, and suppose that (A^V,B) is exponentially stabilizable on V. Furthermore, suppose that assumption* (2.6) *is satisfied. If $u(\cdot) \in U_{\text{adm}}$ and $x_0 = 0$, then*

$$\hat{x}(i\omega) \in D(A^V) \textit{ for a.e. } \omega \in \mathbb{R}, \tag{2.45}$$

$$i\omega\hat{x}(i\omega) = A^V\hat{x}(i\omega) + B\hat{u}(i\omega) \textit{ for a.e. } \omega \in \mathbb{R}, \tag{2.46}$$

and

$$\hat{y}(i\omega) = C\hat{x}(i\omega) + D\hat{u}(i\omega) \textit{ for a.e. } \omega \in \mathbb{R}. \tag{2.47}$$

Proof. Since $u(\cdot) \in U_{\text{adm}}$ and (A^V,B) is exponentially stabilizable on V, we can use the perturbation results of Lemma 2.3 to infer that

$$x(t) = \int_0^t S_{BF}(t-s)B(u(s) - Fx(s))\,ds,$$

where $F \in \mathcal{L}(V,U)$ is such that $S_{BF}(\cdot)$ is exponentially stable on V.

We know that $x(\cdot) \in L_2(0,\infty;V)$ and

$$\hat{x}(i\omega) = (i\omega I - A^V_{BF})^{-1}B(\hat{u}(i\omega) - F\hat{x}(i\omega)) \text{ for a.e. } \omega \in \mathbb{R} \tag{2.48}$$

(see also Lemma 2.9). Now (2.45) and (2.46) follow from (2.48) and Lemma 2.3.

In Lemma 2.7 we saw that $y(\cdot) \in L_2(0,\infty;Y)$. We have $y(t) = Cx(t) + Du(t)$ and so Lemma 2.9 tells us that

$$\text{(2.49)} \quad \hat{y}(i\omega) = C(i\omega I - A^V_{BF})^{-1}B(\hat{u}(i\omega) - F\hat{x}(i\omega)) + D\hat{u}(i\omega) \text{ for a.e. } \omega \in \mathbb{R}.$$

The combination of (2.48) and (2.49) gives (2.47). □

The next lemma is a crucial result for the theory of optimal control. The result follows immediately from [11, Thm. 1.1].

LEMMA 2.11. *Let H be a real Hilbert space, let $T \in \mathcal{L}(H)$ be coercive, and let y be an arbitrary element of H. Then there exists a unique $x^* \in H$ such that*

$$\text{(2.50)} \qquad \langle Tx, x\rangle_H + \langle x, y\rangle_H \geq \langle Tx^*, x^*\rangle_H + \langle x^*, y\rangle_H \textit{ for all } x \in H.$$

The last lemma of this section deals with the optimal control problem for infinite-dimensional systems with bounded input and output operators. It is a complete generalization of the finite-dimensional result in [22]. The lemma is proved in full detail in [12], [13]. In the next section, we shall generalize this result to systems in the Pritchard–Salamon class.

LEMMA 2.12. *Let A be the infinitesimal generator of a semigroup $S(\cdot)$ on a real Hilbert space H; let $B \in \mathcal{L}(U,H)$, where U is another Hilbert space; and suppose that (A,B) is exponentially stabilizable. Furthermore, let $Q = Q^* \in \mathcal{L}(H)$, $L \in \mathcal{L}(H,U)$, and $R = R^* \in \mathcal{L}(U)$, with R coercive. For all $(x,u) \in H \times U$ we define the quadratic form*

$$\text{(2.51)} \qquad \mathcal{F}(x,u) := \langle Qx, x\rangle_H + 2\langle Lx, u\rangle_U + \langle Ru, u\rangle_U.$$

Consider the system

$$\text{(2.52)} \qquad x(t) = S(t)x_0 + \int_0^t S(t-s)Bu(s)\,ds, \; x_0 \in H, \; t \geq 0.$$

Define

$$U_{\text{adm}} := \{u(\cdot) \in L_2(0,\infty;U) \textit{ such that } x(\cdot) \textit{ given by } (2.52)$$

$$\text{(2.53)} \qquad \textit{satisfies } x(\cdot) \in L_2(0,\infty;H)\}.$$

For all $u(\cdot) \in U_{\text{adm}}$ define the cost functional

$$\text{(2.54)} \qquad J(x_0, u(\cdot)) := \int_0^\infty \mathcal{F}(x(t), u(t))\,dt.$$

Now the following are equivalent:

1. *For all $x_0 \in H$ there exists a unique $\bar{u}(\cdot) \in L_2(0,\infty;U)$ such that*

$$\text{(2.55)} \qquad \inf_{u(\cdot)\in U_{\text{adm}}} J(x_0,u(\cdot)) = \min_{u(\cdot)\in U_{\text{adm}}} J(x_0,u(\cdot)) = J(x_0,\bar{u}(\cdot)).$$

2. *There exists a selfadjoint $X \in \mathcal{L}(H)$ such that for all $x, y \in D(A)$*

$$\langle Ax, Xy\rangle_H + \langle Xx, Ay\rangle_H$$

$$\text{(2.56)} \qquad - \langle (B^*X + L)^*R^{-1}(B^*X + L)x, y\rangle_H + \langle Qx, y\rangle_H = 0$$

and $A - BR^{-1}(B^*X + L)$ is the infinitesimal generator of an exponentially stable semigroup.

3. *There exists an* $\epsilon > 0$ *such that for all* $(\omega, x, u) \in \mathbb{R} \times D(A) \times U$ *that satisfy* $i\omega x = Ax + Bu$ *there holds*

$$\mathcal{F}(x,u) \geq \epsilon(\|x\|_H^2 + \|u\|_U^2). \tag{2.57}$$

Furthermore, if one of these conditions holds, the minimizing $\bar{u}(\cdot)$ *in* (2.55) *can be given in feedback form:*

$$\bar{u}(\cdot) = -R^{-1}(B^*X + L)x(\cdot), \tag{2.58}$$

and

$$\inf_{u(\cdot)\in U_{\text{adm}}} J(x_0, u(\cdot)) = J(x_0, \bar{u}(\cdot)) = \langle x_0, Xx_0\rangle_H. \tag{2.59}$$

Finally, if the X *in* 2 *exists, it is unique.*

3. Problem formulation and main result. The purpose of this section is to find a generalization of Lemma 2.12 to the class of systems as presented in §2. So let W and V be two Hilbert spaces that satisfy (2.1), and suppose that we have a C_0-semigroup $S(\cdot)$ on both spaces. Furthermore, let U, Y_1, and Y_2 be Hilbert spaces (as before U will play the role of the input space, Y_1 and Y_2 will be output spaces). Let $B \in \mathcal{L}(U, V)$ be an admissible input operator and $C_1 \in \mathcal{L}(W, Y_1), C_2 \in \mathcal{L}(W, Y_2)$, and $L \in \mathcal{L}(W, U)$ be admissible output operators.

For all $(x, u) \in W \times U$ we define the quadratic form

$$\mathcal{F}(x,u) := \langle C_1x, C_1x\rangle_{Y_1} - \langle C_2x, C_2x\rangle_{Y_2} + 2\langle Lx, u\rangle_U + \langle Ru, u\rangle_U, \tag{3.1}$$

where $R = R^* \in \mathcal{L}(U)$ is coercive. In the quadratic form $\langle Qx, x\rangle_H$ in (2.51), Q could have been expressed as $Q = C_1^*C_1 - C_2^*C_2$ for some $C_1 \in \mathcal{L}(H, Y)$ and $C_2 \in \mathcal{L}(H, Y)$ (use $Q = \text{const}I - (\text{const}I - Q)$ with const large enough). Therefore, (3.1) represents an appropriate generalization of (2.51). It may not be the most general quadratic criterion for Pritchard–Salamon systems, but it does contain the interesting applications (see Remark 3.3).

Our system is given by

$$x(t) = S(t)x_0 + \int_0^t S(t-s)Bu(s)\,ds, \tag{3.2}$$

where $x_0 \in V$ and $t \geq 0$; and we assume that

$$(A^V, B) \text{ is exponentially stabilizable on } V. \tag{3.3}$$

We define the class of admissible inputs as

$$U_{\text{adm}} := \{u(\cdot) \in L_2(0,\infty; U) \text{ such that } x(\cdot) \text{ given by (3.2)}$$

$$\text{satisfies } x(\cdot) \in L_2(0,\infty; V)\}. \tag{3.4}$$

From Lemma 2.7 it follows that for all $u(\cdot) \in U_{\text{adm}}$, the cost functional $J(x_0, u(\cdot))$ defined by

$$J(x_0, u(\cdot)) := \int_0^\infty \mathcal{F}(x(t), u(t))\,dt \tag{3.5}$$

is finite. Note that $\mathcal{F}(x(t), u(t))$ should not be interpreted pointwise but as explained in Remark 2.2:

$$\int_0^\infty \mathcal{F}(x(t), u(t))\,dt = \|C_1 x(\cdot)\|^2_{L_2(0,\infty;Y_1)} - \|C_2 x(\cdot)\|^2_{L_2(0,\infty;Y_2)}$$

$$+\, 2\langle Lx(\cdot), u(\cdot)\rangle_{L_2(0,\infty;U)} + \langle Ru(\cdot), u(\cdot)\rangle_{L_2(0,\infty;U)}. \tag{3.6}$$

The following result is a complete generalization of Lemma 2.12.

THEOREM 3.1. *Suppose that we have a Pritchard–Salamon system of the form* (3.2) *that satisfies the assumptions* (2.6) *and* (3.3). *Furthermore, let $\mathcal{F}$ be defined as in* (3.1). *The following three conditions are equivalent:*

1. *For all $x_0 \in V$ there exists a unique $\bar{u}(\cdot) \in L_2(0,\infty;U)$ such that*

$$\inf_{u(\cdot)\in U_{\mathrm{adm}}} J(x_0, u(\cdot)) = \min_{u(\cdot)\in U_{\mathrm{adm}}} J(x_0, u(\cdot)) = J(x_0, \bar{u}(\cdot)). \tag{3.7}$$

2. *There exists a selfadjoint $X \in \mathcal{L}(V)$ such that for all $x, y \in D(A^V)$*

$$\langle (A^V - BR^{-1}L)x, Xy\rangle_V + \langle Xx, (A^V - BR^{-1}L)y\rangle_V$$

$$-\langle XBR^{-1}B^*Xx, y\rangle_V - \langle R^{-1}Lx, Ly\rangle_U$$

$$+\, \langle C_1 x, C_1 y\rangle_{Y_1} - \langle C_2 x, C_2 y\rangle_{Y_2} = 0 \tag{3.8}$$

and $A^V - BR^{-1}(B^*X + L)$ is the generator of a C_0-semigroup, exponentially stable on V.

3. *There exists an $\epsilon > 0$ such that for all $(\omega, x, u) \in \mathbb{R} \times D(A^V) \times U$ that satisfy $i\omega x = A^V x + Bu$ there holds*

$$\mathcal{F}(x, u) \geq \epsilon(\|x\|^2_V + \|u\|^2_U). \tag{3.9}$$

Furthermore, if one of these conditions holds, the minimizing $\bar{u}(\cdot)$ in (3.7) *can be given in feedback form:*

$$\bar{u}(\cdot) = -R^{-1}(B^*X + L)x(\cdot), \tag{3.10}$$

and

$$\inf_{u(\cdot)\in U_{\mathrm{adm}}} J(x_0, u(\cdot)) = J(x_0, \bar{u}(\cdot)) = \langle x_0, Xx_0\rangle_V. \tag{3.11}$$

Finally, if the X in (3.8) *exists, it is unique.*

Remark 3.2. In [15] the authors assume the existence of a third Hilbert space H such that $W \hookrightarrow H \hookrightarrow V$ and $S(\cdot)$ is also a C_0-semigroup on H. In applications H is often the actual state-space so that $B \in \mathcal{L}(U, V)$ and $C \in \mathcal{L}(W, Y)$ are both unbounded with respect to this state-space (see [15]). The role of H is not important in the derivation of Theorem 3.1 because we consider the LQ-problem with initial conditions in V and with stability on V, just as in [15]. Identifying H with its dual we can use H as a pivot space, in order to obtain a "strong form" of the Riccati equation, also just as in [15]:

Using $H = H'$ as a pivot space we have $D(A^V) \hookrightarrow W \hookrightarrow H \hookrightarrow V$ and $V' \hookrightarrow H \hookrightarrow W' \hookrightarrow (D(A^V))'$. We let $i : V \to V'$ denote the canonical isometric isomorphism, and the duality pairing of V is denoted by $\langle \cdot, \cdot \rangle_{V,V'}$. Furthermore, we identify $U = U'$, $Y_1 = Y_1'$, and $Y_2 = Y_2'$. Then $X \in \mathcal{L}(V)$ satisfies (3.8) if and only if $\tilde{X} = iX \in \mathcal{L}(V, V')$ satisfies the equation

$$\langle (A^V - BR^{-1}L)x, \tilde{X}y \rangle_{V,V'} + \langle x, \tilde{X}(A^V - BR^{-1}L)y \rangle_{V,V'}$$

$$- \langle x, \tilde{X}BR^{-1}B'\tilde{X}y \rangle_{V,V'} - \langle R^{-1}Lx, Ly \rangle_U$$

$$+ \langle C_1 x, C_1 y \rangle_{Y_1} - \langle C_2 x, C_2 y \rangle_{Y_2} = 0 \text{ for all } x, y \in D(A^V). \tag{3.12}$$

Equation (3.12) can in turn be reformulated as

$$\Big((A^V - BR^{-1}L)'\tilde{X} + \tilde{X}(A^V - BR^{-1}L)$$

$$- \tilde{X}BR^{-1}B'\tilde{X} - L'R^{-1}L + C_1'C_1 - C_2'C_2 \Big) x = 0 \tag{3.13}$$

in $(D(A^V))'$ for all $x \in D(A^V)$. Here $(A^V - BR^{-1}L)' \in \mathcal{L}(V', (D(A^V))')$ can be considered as the dual of the bounded linear operator $(A^V - BR^{-1}L) \in \mathcal{L}(D(A^V), V)$, as explained in [15]. Of course, the other statements of the theorem can be reformulated in terms of $\tilde{X}$ in the obvious way.

Finally, we note that because of $H \hookrightarrow V$, $V' \hookrightarrow H$, and the fact that $\tilde{X} \in \mathcal{L}(V, V')$, there holds $\tilde{X} \in \mathcal{L}(H)$ and that for all $x_0 \in H$ we have

$$\inf_{u(\cdot) \in U_{\mathrm{adm}}} J(x_0, u(\cdot)) = \langle x_0, Xx_0 \rangle_V = \langle x_0, \tilde{X}x_0 \rangle_{V,V'} = \langle x_0, \tilde{X}x_0 \rangle_H.$$

Remark 3.3. The first results for the infinite-dimensional LQ-problem were obtained for the case that $L = 0$ and $C_2 = 0$ assuming some exponential detectability condition for C_1 (see, e.g., [4], [1], [11] and references therein). It is not difficult to show that if in our setting $L = 0$ and $C_2 = 0$, then the frequency domain inequality is *implied* by the assumption that there exists a $G \in \mathcal{L}(Y_1, V)$ such that $S_{GC_1}(\cdot)$ is exponentially stable on V. In fact, if the system is finite dimensional, then the frequency domain inequality is in this case equivalent to the statement that the poles of A on the imaginary axis are detectable by C_1 (this is, for instance, the case if $\sigma(A) \cap i\mathbb{R} = \emptyset$). Thus, the frequency domain inequality is much weaker than the exponential detectability assumption. It is straightforward to show that if

$$\sup_{\omega \in \mathbb{R}} \|(i\omega I - A^V)^{-1}\|_{\mathcal{L}(V)} < \infty, \tag{3.14}$$

then the frequency domain condition of item 3 is equivalent to the condition that for all $\omega \in \mathbb{R}$ and all $u \in U$

$$\mathcal{F}((i\omega I - A^V)^{-1}Bu, u) \geq \epsilon_1 \|u\|_U^2 \tag{3.15}$$

for some $\epsilon_1 > 0$. It follows that if $L = 0, C_1 = 0, R = I$, and $S(\cdot)$ is exponentially stable on V, then Theorem 3.1 corresponds to the *bounded real lemma* (this was also considered in [17] for the Pritchard–Salamon class) and if $C_1 = C_2 = 0, R = D + D^*$ it corresponds to the *positive real lemma.*

In the case that $C_2 = 0, R = D_{12}^* D_{12}$, and $L = D_{12}^* C_1$, the frequency domain inequality in (3.9) corresponds to the "invariant zeros condition" related to the H_∞-control problem with state-feedback in [8]. Theorem 3.1 can be used to extend the results in [8] to the Pritchard–Salamon class (see [9]).

Remark 3.4. Theorem 3.1 is a considerable extension of existing results about LQ-theory for systems in the Pritchard–Salamon class:

In [15] the authors consider the infinite horizon LQ-problem (without a priori stability requirements on the state $x(\cdot)$) for the special case that $C_2 = 0$ and $L = 0$, and they prove that the cost can be made finite for any initial condition if and only if there exists a nonnegative solution $\tilde{X} \in \mathcal{L}(V, V')$ to the corresponding Riccati equation (see Remark 3.2 and (3.8) with $C_2 = L = 0$). The result in Theorem 3.1 is different because we always assume that the control is such that $x(\cdot) \in L_2(0, \infty; V)$. However, under some additional detectability assumption it is proved in [15] that their optimal control given by $\bar{u}(\cdot) = -R^{-1}B'\tilde{X}x(\cdot)$ is exponentially stabilizing on V. This result corresponds to the equivalence between 1 and 2 in Theorem 3.1 with $C_2 = 0$ and $L = 0$.

In [17], the equivalence between 1, 2, and 3 is proved for the special case that $C_1 = 0, L = 0$, and $S(\cdot)$ is exponentially stable on V and W.

Proof. We shall prove the implications 1 ⇒ 2, 2 ⇒ 3, and 3 ⇒ 1.

Proof of 1 ⇒ 2. We first assume that $L = 0$ (later we remove this extra assumption by applying some preliminary feedback). The idea is to use Lemma 2.7 and in particular, formula (2.33), to transform the criterion (3.5) in such a way that the new criterion can be treated using Lemma 2.12. Since (A^V, B) is exponentially stabilizable on V, there exists some $\bar{F} \in \mathcal{L}(V, U)$ such that $S_{B\bar{F}}(\cdot)$ is exponentially stable on V. Using Lemma 2.6 it follows that there exist nonnegative definite operators $X_1, X_2 \in \mathcal{L}(V)$ such that for all $x, y \in D(A^V) = D(A^V_{B\bar{F}})$

$$\begin{aligned}&\langle A^V x, X_1 y\rangle_V + \langle x, X_1 A^V y\rangle_V \\ &= -\langle C_1 x, C_1 y\rangle_{Y_1} - \langle (X_1 B\bar{F} + \bar{F}^* B^* X_1)x, y\rangle_V \end{aligned} \tag{3.16}$$

and

$$\begin{aligned}&\langle A^V x, X_2 y\rangle_V + \langle x, X_2 A^V y\rangle_V \\ &= -\langle C_2 x, C_2 y\rangle_{Y_2} - \langle (X_2 B\bar{F} + \bar{F}^* B^* X_2)x, y\rangle_V. \end{aligned} \tag{3.17}$$

Since we assume that $L = 0$, we have

$$J(x_0, u(\cdot)) = \int_0^\infty \left(\|C_1 x(t)\|^2_{Y_1} - \|C_2 x(t)\|^2_{Y_2} + \left\| R^{\frac{1}{2}} u(t) \right\|^2_U \right) dt.$$

Hence, we can use formula (2.33) in the proof of Lemma 2.7 to infer that

$$J(x_0, u(\cdot)) = \langle x_0, (X_1 - X_2)x_0\rangle_V$$

$$+ \int_0^\infty \Big(\langle ((X_2 - X_1)B\bar{F} + \bar{F}^* B^* (X_2 - X_1))x(t), x(t)\rangle_V$$

$$+ 2\langle B^*(X_1 - X_2)x(t), u(t)\rangle_U + \left\|R^{\frac{1}{2}}u(t)\right\|_U^2 \Bigg) dt. \tag{3.18}$$

Note that the integral term is as in Lemma 2.12 (formulas (2.51) and (2.54)), with Q replaced by $(X_2 - X_1)B\bar{F} + \bar{F}^*B^*(X_2 - X_1)$ and L replaced by $B^*(X_1 - X_2)$. Hence, because of our assumption (1), we can apply this lemma on V and infer the existence of a selfadjoint $X_3 \in \mathcal{L}(V)$ such that for all $x, y \in D(A^V)$

$$\langle A^V x, X_3 y\rangle_V + \langle X_3 x, A^V y\rangle_V$$

$$-\langle (X_3 + X_1 - X_2)BR^{-1}B^*(X_3 + X_1 - X_2)x, y\rangle_V$$

$$+ \langle ((X_2 - X_1)B\bar{F} + \bar{F}^*B^*(X_2 - X_1))x, y\rangle_V = 0 \tag{3.19}$$

and $A^V - BR^{-1}B^*(X_3 + X_1 - X_2)$ is the infinitesimal generator of an exponentially stable semigroup on V. Combining (3.16), (3.17), and (3.19), with $X := X_3 + X_1 - X_2$, we conclude that $X \in \mathcal{L}(V)$ is selfadjoint and satisfies

$$\langle A^V x, Xy\rangle_V + \langle Xx, A^V y\rangle_V - \langle XBR^{-1}B^*Xx, y\rangle_V$$

$$+ \langle C_1 x, C_1 y\rangle_{Y_1} - \langle C_2 x, C_2 y\rangle_{Y_2} = 0 \tag{3.20}$$

for all $x, y \in D(A^V)$ and $A^V - BR^{-1}B^*X$ is the generator of an exponentially stable semigroup on V. We note that (3.20) is just (3.8) with $L = 0$.

Next we show how to reduce the general case to the case where $L = 0$. We remove the "cross term" of the cost criterion by applying the preliminary feedback

$$u(\cdot) = Fx(\cdot) + v(\cdot), \tag{3.21}$$

where $F \in \mathcal{L}(W, U)$ is given by

$$F = -R^{-1}L. \tag{3.22}$$

To make this more precise we note that F given by (3.22) is an admissible output operator because L is, and we define the transformed system

$$x_F(t) = S_{BF}(t)x_0 + \int_0^t S_{BF}(t-s)Bv(s)\, ds \tag{3.23}$$

just as in Lemma 2.5. It follows from Lemma 2.3 that C_1, C_2, and L are admissible output operators for this transformed system as well. Furthermore, it follows from Remark 2.4 that (A^V_{BF}, B) is exponentially stabilizable on V and Lemma 2.3 shows that $D(A^V_{BF}) \hookrightarrow V$. Hence, the transformed system also satisfies the a priori assumptions of Theorem 3.1. We define the class of admissible inputs for this system as

$$\bar{U}_{\mathrm{adm}} := \{v(\cdot) \in L_2(0, \infty; U) \text{ such that } x_F(\cdot) \text{ given by (3.23)}$$

$$\text{satisfies } x_F(\cdot) \in L_2(0, \infty; V)\}. \tag{3.24}$$

Using the perturbation results in Lemma 2.5, we see that if $u(\cdot)$ and $v(\cdot)$ are related by (3.21) (or, more specifically, by (2.12) and (2.15)), we have $x(\cdot) = x_F(\cdot)$, $u(\cdot) = Fx_F(\cdot) + v(\cdot)$, and $v(\cdot) = -Fx(\cdot) + u(\cdot)$. Hence, we conclude that $u(\cdot) \in U_{\text{adm}}$ if and only if $v(\cdot) \in \bar{U}_{\text{adm}}$. Next, for all $v(\cdot) \in \bar{U}_{\text{adm}}$, we define the transformed cost function

$$J_F(x_0, v(\cdot)) := \int_0^\infty \mathcal{F}_F(x_F(t), v(t))\, dt,$$

where for $x \in W$ and $v \in U$ we have

$$\mathcal{F}_F(x, v) = \mathcal{F}(x, Fx + v) = \langle C_1 x, C_1 x\rangle_{Y_1} - \langle C_2 x, C_2 x\rangle_{Y_2}$$

$$+2\langle Lx, Fx + v\rangle_U + \langle R(Fx + v), (Fx + v)\rangle_U,$$

so because of $F = -R^{-1}L$, we have

$$\mathcal{F}_F(x, v) =$$

$$\langle C_1 x, C_1 x\rangle_{Y_1} - \langle C_2 x, C_2 x\rangle_{Y_2} - \langle R^{-\frac{1}{2}} Lx, R^{-\frac{1}{2}} Lx\rangle_U + \langle Rv, v\rangle_U.$$

Note that the transformed cost function has the same form as in (3.5), with $L = 0$ and $\langle C_2 x, C_2 x\rangle_{Y_2}$ replaced by $\langle C_2 x, C_2 x\rangle_{Y_2} + \langle R^{-\frac{1}{2}} Lx\ , R^{-\frac{1}{2}} Lx\rangle_U$. Using Lemma 2.5 and the above, we have

$$J(x_0, u(\cdot)) = J_F(x_0, v(\cdot)).$$

Now 1 implies that there exists a unique $\bar{v}(\cdot) \in L_2(0, \infty; U)$ such that

$$\inf_{v(\cdot)\in\bar{U}_{\text{adm}}} J_F(x_0, v(\cdot)) = \min_{v(\cdot)\in\bar{U}_{\text{adm}}} J_F(x_0, v(\cdot)) = J_F(x_0, \bar{v}(\cdot)). \tag{3.25}$$

We have proved the implication 1 ⇒ 2 under the assumption that there is no "cross term" (i.e., $L = 0$), so we conclude from (3.25) that there exists a selfadjoint $X \in \mathcal{L}(V)$ such that for all $x, y \in D(A^V_{BF}) = D(A^V)$, we have

$$\langle A^V_{BF} x, Xy\rangle_V + \langle Xx, A^V_{BF} y\rangle_V - \langle XBR^{-1}B^* Xx, y\rangle_V$$

$$+ \langle C_1 x, C_1 y\rangle_{Y_1} - \langle C_2 x, C_2 y\rangle_{Y_2} - \langle R^{-\frac{1}{2}} Lx, R^{-\frac{1}{2}} Lx\rangle_U = 0 \tag{3.26}$$

and $A^V_{BF} - BR^{-1}B^* X$ is the generator of an exponentially stable semigroup on V.

Since $A^V_{BF} = A^V - BR^{-1}L$, we have proved 2.

Proof of 2 ⇒ 3. Using 2, it is straightforward to show that for all $(\omega, x, u) \in \mathbb{R} \times D(A^V) \times U$ that satisfy $i\omega x = A^V x + Bu$ there holds

$$\mathcal{F}(x, u) = \left\| R^{\frac{1}{2}}(u + R^{-1}(B^* X + L)x)\right\|_U^2. \tag{3.27}$$

Now since $A^V - BR^{-1}(B^* X + L)$ is the generator of an exponentially stable semigroup on V, we see that for all $(\omega, x, u) \in \mathbb{R} \times D(A^V) \times U$ that satisfy $i\omega x = A^V x + Bu$ there holds

$$x = (i\omega I - A^V + BR^{-1}(B^* X + L))^{-1} B(u + R^{-1}(B^* X + L)x) \tag{3.28}$$

and so

$$\|x\|_V \leq c_1 \left\|u + R^{-1}(B^*X + L)x\right\|_U \tag{3.29}$$

for some $c_1 > 0$. Combination of (3.27) and (3.29) (using the fact that R is coercive) implies the existence of some $\epsilon_1 > 0$ such that for all $(\omega, x, u) \in \mathbb{R} \times D(A^V) \times U$ that satisfy $i\omega x = A^V x + Bu$,

$$\mathcal{F}(x,u) \geq \epsilon_1 \|x\|_V^2 . \tag{3.30}$$

For $u \in U$ and $x \in W$ we have

$$u = u + R^{-1}(B^*X + L)x - R^{-1}(B^*X + L)x$$

so that

$$\|u\|_U \leq \left\|R^{-1}(B^*X + L)x\right\|_U + \left\|u + R^{-1}(B^*X + L)x\right\|_U . \tag{3.31}$$

Since $A^V - BR^{-1}(B^*X + L)$ is the generator of an exponentially stable semigroup on V and L is an admissible output operator, we conclude from (3.28) and Lemma 2.9, formula (2.35), that for all $(\omega, x, u) \in \mathbb{R} \times D(A^V) \times U$ that satisfy $i\omega x = A^V x + Bu$ there holds

$$\|Lx\|_U \leq c_2 \left\|u + R^{-1}(B^*X + L)x\right\|_U \tag{3.32}$$

for some $c_2 > 0$. Since $R^{-1}B^*X \in \mathcal{L}(V, U)$, the combination of (3.31) and (3.32) gives

$$\|u\|_U \leq c_3(\|x\|_V + \left\|u + R^{-1}(B^*X + L)x\right\|_U)$$

for some $c_3 > 0$. We can combine this with (3.29) to obtain

$$\|u\|_U \leq c_4 \left\|u + R^{-1}(B^*X + L)x\right\|_U \tag{3.33}$$

for some $c_4 > 0$.

Finally, (3.33), (3.27), and the fact that R is coercive imply the existence of some $\epsilon_2 > 0$ such that

$$\mathcal{F}(x,u) \geq \epsilon_2 \|u\|_U^2 . \tag{3.34}$$

Now 3 follows from (3.30) and (3.34).

Proof of 3 ⇒ 1. The idea is to apply Lemma 2.11 (a similar procedure is used in [12] and [21] for the bounded case). Let $x_0 \in V$ be given. We define

$$H := \Bigg\{ (x(\cdot), u(\cdot)) \in L_2(0,\infty; V) \times L_2(0,\infty; U) \text{ such that}$$

$$u(\cdot) \in U_{\text{adm}} \text{ and } x(t) = S(t)x_0 + \int_0^t S(t-s)Bu(s)\,ds \Bigg\} \tag{3.35}$$

and

$$H_0 := \Bigg\{ (x(\cdot), u(\cdot)) \in L_2(0,\infty; V) \times L_2(0,\infty; U) \text{ such that}$$

$$u(\cdot) \in U_{\text{adm}} \text{ and } x(t) = \int_0^t S(t-s)Bu(s)\,ds \Big\}. \tag{3.36}$$

It is straightforward to show that H_0 is a closed subspace of $L_2(0,\infty;V) \times L_2(0,\infty;U)$ and so H_0 is a Hilbert space (with the obvious inner product determined by the inner products of $L_2(0,\infty;V)$ and $L_2(0,\infty;U)$). Since (A^V, B) is exponentially stabilizable on V, there exists an $F \in \mathcal{L}(V,U)$ such that $S_{BF}(\cdot)$ is exponentially stable on V. We define

$$(x_0(\cdot), u_0(\cdot)) := (S_{BF}(\cdot)x_0, FS_{BF}(\cdot)x_0).$$

Using the perturbation results of Lemma 2.3, it is easy to see that $(x_0(\cdot), u_0(\cdot)) \in H$ and that $H = H_0 + (x_0(\cdot), u_0(\cdot))$ and we have

$$\inf_{u(\cdot)\in U_{\text{adm}}} J(x_0, u(\cdot)) = \inf_{(x(\cdot),u(\cdot))\in H} \int_0^\infty \mathcal{F}(x(t), u(t))\,dt$$

$$= \inf_{(x(\cdot),u(\cdot))\in H_0} \int_0^\infty \mathcal{F}(x(t)+x_0(t), u(t)+u_0(t))\,dt. \tag{3.37}$$

Now for $(x(\cdot), u(\cdot)) \in H_0$ we have

$$\begin{aligned}
&\int_0^\infty \mathcal{F}(x(t)+x_0(t), u(t)+u_0(t))\,dt \\
&\quad= \int_0^\infty (\|C_1x(t) + C_1x_0(t)\|_{Y_1}^2 - \|C_2x(t) + C_2x_0(t)\|_{Y_2}^2 \\
&\qquad + 2\langle L(x(t)+x_0(t)), u(t)+u_0(t)\rangle_U + \langle R(u(t)+u_0(t)), u(t)+u_0(t)\rangle_U)dt \\
&\quad= \int_0^\infty \mathcal{F}(x(t), u(t)) + 2\langle C_1x(\cdot), C_1x_0(\cdot)\rangle_{L_2(0,\infty;Y_1)} \\
&\qquad -2\langle C_2x(\cdot), C_2x_0(\cdot)\rangle_{L_2(0,\infty;Y_2)} + 2\langle Lx(\cdot), u_0(\cdot)\rangle_{L_2(0,\infty;U)} \\
&\qquad +2\langle Lx_0(\cdot), u(\cdot)\rangle_{L_2(0,\infty;U)} + 2\langle Ru(\cdot), u_0(\cdot)\rangle_{L_2(0,\infty;U)} + c
\end{aligned} \tag{3.38}$$

for some $c \in \mathbb{R}$. Next we infer that there exists a selfadjoint operator $T \in \mathcal{L}(H_0)$ and some element $y \in H_0$ such that (3.38) can be reformulated as

$$\int_0^\infty \mathcal{F}(x(t)+x_0(t), u(t)+u_0(t))\,dt = \langle Tx, x\rangle_{H_0} + \langle x, y\rangle_{H_0} + c, \tag{3.39}$$

where $x := (x(\cdot), u(\cdot)) \in H_0$. Indeed, it follows from Lemma 2.7 that for any admissible $C \in \mathcal{L}(W,Y)$ the map from H_0 to $L_2(0,\infty;Y)$ determined by $(x(\cdot), u(\cdot)) \mapsto Cx(\cdot)$ is linear and bounded. Since C_1, C_2, and L are admissible output operators and R is bounded, it is straightforward to conclude from (3.6) that we have a selfadjoint operator $T \in \mathcal{L}(H_0)$, such that for all $x := (x(\cdot), u(\cdot)) \in H_0$ there holds

$$\int_0^\infty \mathcal{F}(x(t), u(t)) = \langle Tx, x\rangle_{H_0}. \tag{3.40}$$

Similarly, one can show that in (3.38),

$$2\langle C_1x(\cdot), C_1x_0(\cdot)\rangle_{L_2(0,\infty;Y_1)} - 2\langle C_2x(\cdot), C_2x_0(\cdot)\rangle_{L_2(0,\infty;Y_2)}$$

$$+ 2\langle Lx(\cdot), u_0(\cdot)\rangle_{L_2(0,\infty;U)} + 2\langle Lx_0(\cdot), u(\cdot)\rangle_{L_2(0,\infty;U)}$$

$$+ 2\langle Ru(\cdot), u_0(\cdot)\rangle_{L_2(0,\infty;U)}$$

is equal to $\langle x, y\rangle_{H_0}$ for some $y \in H_0$. Hence we have (3.39).

It follows from (3.37) and the above that

$$\inf_{u(\cdot)\in U_{\text{adm}}} J(x_0, u(\cdot)) = \inf_{x\in H_0} \langle Tx, x\rangle_{H_0} + \langle x, y\rangle_{H_0} + c. \tag{3.41}$$

To apply Lemma 2.11, we still have to show that T in (3.40) is coercive (of course using the frequency domain inequality of 3). Both components of $(x(\cdot), u(\cdot)) \in H_0$ are Fourier transformable, and it follows from Lemma 2.10 that $\hat{x}(i\omega) \in D(A^V)$ for a.e. $\omega \in \mathbb{R}$ and

$$\begin{aligned} i\omega\hat{x}(i\omega) &= A^V\hat{x}(i\omega) + B\hat{u}(i\omega), \\ \widehat{Cx}(i\omega) &= C\hat{x}(i\omega) \end{aligned}$$

for a.e. $\omega \in \mathbb{R}$, for any admissible $C \in \mathcal{L}(W, Y)$. Hence, for all $x = (x(\cdot), u(\cdot))\in H_0$ we have

$$\langle Tx, x\rangle_{H_0} = \int_0^\infty \mathcal{F}(x(t), u(t))\, dt$$

$$= \frac{1}{2\pi}\int_{-\infty}^{\infty} \mathcal{F}(\hat{x}(i\omega), \hat{u}(i\omega))\, d\omega \qquad \text{(Plancherel's Theorem, see [18, §4.8])}$$

$$\geq \epsilon\frac{1}{2\pi}\int_{-\infty}^{\infty} (\|\hat{x}(i\omega)\|_V^2 + \|\hat{u}(i\omega)\|_U^2)\, d\omega \qquad \text{(using 3)}$$

$$= \epsilon\int_0^\infty (\|x(t)\|_V^2 + \|u(t)\|_U^2)\, dt \qquad \text{(again using Plancherel's Theorem)}$$

$$= \epsilon\, \|(x(\cdot), u(\cdot))\|_{H_0}^2 = \epsilon\, \|x\|_{H_0}^2 .$$

This proves that T is coercive and so Lemma 2.11 implies 1.

Finally, it follows from Lemma 2.12 and the above that the optimal control $\bar{u}(\cdot)$ is given by the state-feedback $\bar{u}(\cdot) = -R^{-1}(B^*X + L)x(\cdot)$ (cf. Lemma 2.3) and that (3.11) is satisfied. The uniqueness of X also follows from that above and Lemma 2.12. □

4. Examples and conclusions. We have solved the nonstandard LQ-problem with stability for the Pritchard–Salamon class. This represents a considerable extension of existing LQ-results for this class in [15] and [17]. As explained in the introduction, many interesting system theoretical problems can be formulated in the nonstandard LQ-framework, for instance, questions arising in optimal control, identification theory, and robust stability theory (see Willems [22]) and so Theorem 3.1 is an important result. Also the solution to the H_∞-control problem for Pritchard–Salamon systems can be solved using Theorem 3.1. In particular, if $C_2 = 0, R = D_{12}^*D_{12}$, and

$L = D_{12}^* C_1$, the frequency domain inequality corresponds to the "invariant zeros condition" in [9, Theorems 4.4, 5.4].

Upon the request of one reviewer we shall now discuss some examples of the theory presented in this paper, in the sense that we shall consider some nonstandard LQ-problems for systems in the Pritchard–Salamon class that are not covered by the bounded theory in [12], [13], [21]. As pointed out in [15], [16] and the introduction, the Pritchard–Salamon class contains many delay systems and several PDE systems. Since the strength of the Pritchard–Salamon class lies in the fact that so many delay systems fit in, we shall extensively treat a delay example, briefly discuss a parabolic PDE example, and make some comments about a flexible beam example.

4.1. Delay systems. The following neutral system with output delays is treated in [15] (for more general delay systems in the Pritchard–Salamon class, like retarded and neutral systems with delays in both the input and the output, we refer to [16], [19]). Consider the system given by

$$(4.1) \qquad \begin{cases} \dfrac{d}{dt}(z(t) - Mz_t) & = & \bar{L}z_t + \bar{B}u(t), \\ y(t) & = & \bar{C}z_t, \end{cases}$$

where $z(t) \in \mathbb{R}^n$; $u(t) \in \mathbb{R}^m$; $y(t) \in \mathbb{R}^p$; z_t is the solution segment defined by

$$z_t(\tau) = z(t+\tau)\ , \quad -h \leq \tau \leq 0\ , \quad h > 0;$$

and $\bar{B} \in \mathbb{R}^{n \times m}$ and $\bar{L}, M, \bar{C}$ are bounded linear functionals from $C(-h, 0\ ;\mathbb{R}^n)$ into $\mathbb{R}^n$ and $\mathbb{R}^p$, respectively. Under some conditions (see [15, Exe. 4.1]), the system given by (4.1) has a unique solution $z(t)$; $t \geq -h$, for every input $u(\cdot) \in L_2^{\mathrm{loc}}(0, \infty; \mathbb{R}^m)$ and every initial condition satisfying

$$\lim_{t \downarrow 0}(z(t) - Mz_t) = \eta_0, \qquad z(\tau) = \phi_0(\tau), \quad -h < \tau < 0,$$

where $x_0 = (\eta_0, \phi_0) \in M_2 = \mathbb{R}^n \times L_2(-h, 0\ ;\mathbb{R}^n)$. Moreover, the evolution of the state

$$x(t) = (z(t) - Mz_t, z_t) \in M_2$$

of the system can be described by

$$(4.2) \qquad x(t) = S(t)x_0 + \int_0^t S(t-s)Bu(s)\,ds,$$

where $B \in \mathcal{L}(\mathbb{R}^m, M_2)$ maps $u \in \mathbb{R}^m$ into the pair $Bu = (\bar{B}u, 0)$ and $S(t) \in \mathcal{L}(M_2)$ is the C_0-semigroup generated by the operator A given by

$$(4.3) \qquad \begin{array}{rcl} D(A) & = & \{x = (\eta, \phi) \in M_2 \mid \phi \in W^{1,2}, \eta = \phi(0) - M\phi\}, \\ Ax & = & (\bar{L}\phi, \dot{\phi}). \end{array}$$

Here $W^{1,2}$ denotes the Sobolev space $W^{1,2}(-h, 0\ ;\mathbb{R}^n)$ of absolute continuous functions in $L_2(-h, 0\ ;\mathbb{R}^n)$ whose derivative is in $L_2(-h, 0\ ;\mathbb{R}^n)$.

Now $D(A)$ can be considered as a Hilbert space by choosing the inner product

$$\langle(\eta, \phi), (\bar{\eta}, \bar{\phi})\rangle_{D(A)} = \langle\phi, \bar{\phi}\rangle_{W^{1,2}},$$

and it follows that $S(\cdot)$ restricts to a C_0-semigroup on $D(A)$.

The output $y(t) = \bar{C}z_t$ of the system may formally be described by

$$y(t) = Cx(t) = C\left(z(t) - Mz_t, z_t\right),$$

where the output operator C is given by

$$C : D(A) \to \mathbb{R}^p, \quad Cx = C(\eta, \phi) = \bar{C}\phi. \tag{4.4}$$

We recall that by assumption $\bar{C}$ is a bounded linear map from $C(-h, 0\,; \mathbb{R}^n)$ to $\mathbb{R}^p$ so that $C \in \mathcal{L}(D(A), \mathbb{R}^p)$ but in general $C \notin \mathcal{L}(M_2, \mathbb{R}^p)$. Using the fact that $S(\cdot)$ restricts to a C_0-semigroup on $D(A)$, a natural choice for W and V is $W = D(A)$ and $V = M_2$, because then $C \in \mathcal{L}(W, \mathbb{R}^p)$ and $B \in \mathcal{L}(\mathbb{R}^m, V)$ and we can choose $U = \mathbb{R}^m$ and $Y = \mathbb{R}^p$. We note that the operator A from $D(A) \subset V$ to V should in fact be denoted by A^V and that the generator of the restriction of $S(\cdot)$ to $W = D(A^V)$ is denoted by A^W (cf. the beginning of §2). In [15] it is explained that now B and C are both admissible in the sense of Definition 2.1, so that the neutral functional differential equation described above can indeed be modeled as a Pritchard–Salamon system $\Sigma(S(\cdot), B, C, 0)$.

Below we shall consider a certain nonstandard LQ-problem for delay systems of the above type, but first we shall discuss the two a priori assumptions of Theorem 3.1, namely (2.6) and (3.3). First of all, we note that condition (2.6) is trivially satisfied because of $W = D(A^V)$. In order to deal with assumption (3.3), we assume in the sequel that $M : C(-h, 0; \mathbb{R}^n) \to \mathbb{R}^n$ has the particular form

$$M\phi = \sum_{j=1}^{\infty} A_{-j}\phi(-h_j) + \int_{-h}^{0} A_{-\infty}(\tau)\phi(\tau)\, d\tau \quad \text{for} \quad \phi \in C(-h, 0; \mathbb{R}^n), \tag{4.5}$$

where $0 < h_j \leq h$, $A_{-j} \in \mathbb{R}^{n \times n}$ for $j \in \mathbb{N}$, $A_{-\infty}(\cdot) \in L_1(-h, 0; \mathbb{R}^{n\times n})$, and $\sum_{j=1}^{\infty} \|A_{-j}\| < \infty$. Furthermore, we assume that

$$\sup\left\{ \mathrm{Re}\lambda : \det\left[I - \sum_{j=1}^{\infty} A_{-j}\exp(-\lambda h_j) \right] = 0 \right\} < 0. \tag{4.6}$$

It is explained in [15] that under the above two assumptions the pair (A^V, B) is exponentially stabilizable on V if and only if

$$\mathrm{rank}\, [\Delta(\lambda), \bar{B}] = n \text{ for all } \lambda \in \mathbb{C} \text{ with } \mathrm{Re}(\lambda) \geq 0, \tag{4.7}$$

where $\Delta(\lambda) = \lambda[I - M(\exp(\lambda \cdot))] - \bar{L}(\exp(\lambda \cdot))$. Now suppose that we have two admissible output operators that have the same form as C:

$$C_1 : D(A^V) \to \mathbb{R}^{p_1}, \quad C_1 x = C_1(\eta, \phi) = \bar{C}_1\phi \tag{4.8}$$

and

$$C_2 : D(A^V) \to \mathbb{R}^{p_2}, \quad C_2 x = C_2(\eta, \phi) = \bar{C}_2\phi, \tag{4.9}$$

where $\bar{C}_1$ and $\bar{C}_1$ are bounded linear functionals from $C(-h, 0; \mathbb{R}^n)$ into $\mathbb{R}^{p_1}$ and $\mathbb{R}^{p_2}$, respectively. We introduce the nonstandard cost function

$$J(x_0, u(\cdot)) := \int_0^{\infty} \mathcal{F}(x(t), u(t))\, dt, \tag{4.10}$$

where

$$\mathcal{F}(x,u) := \langle C_1x, C_1x\rangle_{\mathbb{R}^{p_1}} - \langle C_2x, C_2x\rangle_{\mathbb{R}^{p_2}} + \langle u,u\rangle_{\mathbb{R}^m}. \tag{4.11}$$

The state of the system is given by (4.2), and the cost function can also be written as

$$J(x_0,u(\cdot)) = \int_0^\infty \left(\|y_1(t)\|^2_{\mathbb{R}^{p_1}} - \|y_2(t)\|^2_{\mathbb{R}^{p_2}} + \|u(t)\|^2_{\mathbb{R}^m}\right) dt,$$

where

$$y_1(t) = C_1x(t) \text{ and } y_2(t) = C_2x(t).$$

The following result is an immediate consequence of Theorem 3.1.

THEOREM 4.1. *Let $S(\cdot), B, C_1$, and C_2 be given as above (with M satisfying* (4.5) *and* (4.6)); *and let $J(x_0,u(\cdot))$ be given by* (4.10). *Furthermore, suppose that the stabilizability condition* (4.7) *is satisfied and define U_{adm} according to* (3.4). *Then the following are equivalent.*

1. *For all $x_0 \in V$ there exists a unique $\bar{u}(\cdot) \in L_2(0,\infty;U)$ such that*

$$\inf_{u(\cdot)\in U_{\text{adm}}} J(x_0,u(\cdot)) = \min_{u(\cdot)\in U_{\text{adm}}} J(x_0,u(\cdot)) = J(x_0,\bar{u}(\cdot)). \tag{4.12}$$

2. *There exists a selfadjoint $X \in \mathcal{L}(V)$ such that for all $x,y \in D(A^V)$*

$$\langle A^Vx, Xy\rangle_V + \langle Xx, A^Vy\rangle_V - \langle XBB^*Xx,y\rangle_V$$

$$+ \langle C_1x, C_1y\rangle_{\mathbb{R}^{p_1}} - \langle C_2x, C_2y\rangle_{\mathbb{R}^{p_2}} = 0 \tag{4.13}$$

and $A^V - BB^*X$ is the generator of a C_0-semigroup, exponentially stable on V.

3. *There exists an $\epsilon > 0$ such that for all $(\omega,x,u) \in \mathbb{R}\times D(A^V)\times U$ that satisfy $i\omega x = A^Vx + Bu$ there holds*

$$\|C_1x\|^2_{\mathbb{C}^{p_1}} - \|C_2x\|^2_{\mathbb{C}^{p_2}} + \|u\|^2_{\mathbb{C}^m} \geq \epsilon(\|x\|^2_V + \|u\|^2_{\mathbb{C}^m}). \tag{4.14}$$

Furthermore, if one of these conditions holds, the minimizing $\bar{u}(\cdot)$ in (3.7) *can be given in feedback form*

$$\bar{u}(\cdot) = -B^*Xx(\cdot) \tag{4.15}$$

and

$$\inf_{u(\cdot)\in U_{\text{adm}}} J(x_0,u(\cdot)) = J(x_0,\bar{u}(\cdot)) = \langle x_0, Xx_0\rangle_V. \tag{4.16}$$

Finally, if the X in (3.8) *exists, it is unique.*

Remark 4.2. As explained in Remark 3.3, if

$$\sup_{\omega\in\mathbb{R}} \|(i\omega I - A^V)^{-1}\|_{\mathcal{L}(V)} < \infty, \tag{4.17}$$

then the frequency domain condition of item 3 is equivalent to the condition that for all $\omega \in \mathbb{R}$ and all $u \in \mathbb{C}^m$

$$\mathcal{F}((i\omega I - A^V)^{-1}Bu, u)$$

$$= \|C_1(i\omega I - A^V)^{-1}Bu\|^2_{\mathbb{C}^{p_1}} - \|C_2(i\omega I - A^V)^{-1}Bu\|^2_{\mathbb{C}^{p_2}} + \|u\|^2_{\mathbb{C}^m} \geq \epsilon_1 \|u\|^2_{\mathbb{C}^m}$$

(we note that for our delay system (4.17) will generically hold; in fact, stabilizability of the delay system implies that there are finitely many unstable poles; see [2]). Hence, defining the transfer functions

$$G_1(s) := C_1(sI - A^V)^{-1}B \text{ and } G_2(s) := C_2(sI - A^V)^{-1}B,$$

it follows that the frequency domain condition of item 3 is in this case equivalent to the condition that for all $\omega \in \mathbb{R}$

$$(G_1(i\omega))^*G_1(i\omega) - (G_2(i\omega))^*G_2(i\omega) \geq (\epsilon_1 - 1)I$$

for some $\epsilon_1 > 0$. Hence, the solvability of the LQ-problem depends on a trade-off between the "sizes" of G_1 and G_2 on the imaginary axis.

Finally, we note that if (4.17) holds and $C_2 = 0$, then the frequency domain condition is automatically satisfied (this corresponds to the *standard* LQ-problem, except that here there is no exponential detectability assumption on C_1).

4.2. Parabolic PDEs. Next, we discuss a nonstandard LQ-problem for the class of parabolic PDE systems given in [15].

Let A be a selfadjoint operator on a separable Hilbert space H, and suppose that it has compact resolvent and that its spectrum consists of strictly decreasing real eigenvalues λ_n, $n \in \mathbb{N}$, with eigenvectors $\phi_n \in H$, $\|\phi_n\|_H = 1$. In this case $\{\phi_n, n \in \mathbb{N}\}$ forms an orthonormal basis of H so that for all $x \in H$,

$$\sum_{n=0}^{\infty} \langle x, \phi_n \rangle_H^2 < \infty \quad \text{and} \quad x = \sum_{n=0}^{\infty} \langle x, \phi_n \rangle_H \phi_n.$$

A can be represented as

$$\begin{aligned} D(A) &= \left\{ x \in H \mid \sum_{n=0}^{\infty} \lambda_n^2 \langle x, \phi_n \rangle_H^2 < \infty \right\}, \\ Ax &= \sum_{n=0}^{\infty} \lambda_n \langle x, \phi_n \rangle_H \phi_n, \end{aligned} \tag{4.18}$$

and the C_0-semigroup $S(\cdot)$ generated by A is given by

$$S(t)x = \sum_{n=0}^{\infty} \exp(\lambda_n t) \langle x, \phi_n \rangle_H \phi_n. \tag{4.19}$$

Now let β_n and γ_n be positive sequences satisfying $0 < \beta_n \leq 1 \leq \gamma_n < \infty$ and suppose that W and V are determined by

$$W = \left\{ x \in H \mid \sum_{n=0}^{\infty} \gamma_n \langle x, \phi_n \rangle_H^2 < \infty \right\},$$

$$V' = \left\{ x \in H \mid \sum_{n=0}^{\infty} \beta_n^{-1} \langle x, \phi_n \rangle_H^2 < \infty \right\},$$

with the obvious inner products. Here we assume that H is identified with its dual so that $V' \subset H = H' \subset V$. This means that V can be represented as a space of sequences

$$V = \left\{ x \in \mathbb{R}^{\mathbb{N}} \mid \sum_{n=0}^{\infty} \beta_n x_n^2 < \infty \right\},$$

and the injection $H \subset V$ is given by identifying $x \in H$ with the sequence $\{\langle x, \phi_n \rangle_H \ , n \in \mathbb{N}\}$. Finally, let $B \in \mathcal{L}(\mathbb{R}, V)$ and $C \in \mathcal{L}(W, \mathbb{R})$ be given by

$$Bu = \{b_n u, n \in \mathbb{N}\} \quad \text{and} \quad Cx = \sum_{n=0}^{\infty} c_n \langle x, \phi_n \rangle_H,$$

where the sequences $\{b_n, n \in \mathbb{N}\}$ and $\{c_n, n \in \mathbb{N}\}$ are such that

$$\sum_{n=0}^{\infty} \beta_n b_n^2 < \infty \quad \text{and} \quad \sum_{n=0}^{\infty} \gamma_n^{-1} c_n^2 < \infty. \tag{4.20}$$

It is not difficult to show that B and C are admissible with respect to (W, V) in the sense of Definition 2.1 if

$$\sum_{n=n_0}^{\infty} \frac{\gamma_n b_n^2}{|\lambda_n|} < \infty \quad \text{and} \quad \sum_{n=n_0}^{\infty} \frac{c_n^2}{\beta_n |\lambda_n|} < \infty, \tag{4.21}$$

where $n_0 = 1+\max\{n \in \mathbb{N} \mid \lambda_n \geq 0\}$. Furthermore, given sequences $b_n, c_n, \lambda_n \in \mathbb{R}$ such that λ_n is strictly decreasing and $\lambda_n \downarrow -\infty$, there exist sequences β_n, γ_n such that the inequalities (4.20)–(4.21) are satisfied if and only if

$$\sum_{n=n_0}^{\infty} \frac{b_n c_n}{|\lambda_n|^{1/2}} < \infty \tag{4.22}$$

(see [15, Lemma 4.4]). This last result particularly shows that B and C cannot be "too unbounded" with respect to H. Furthermore, it shows that B can be "more unbounded" as long as C is "less unbounded" and vice versa. We mention that in addition to (2.3)–(2.4), the condition $D(A^V) \hookrightarrow W$ is also satisfied provided that γ_n, β_n are chosen appropriately. Hence, this class of parabolic systems fits into the Pritchard–Salamon framework. A particular example of this class of parabolic systems is given by the PDE model for the temperature distribution of a heated rod with boundary heat control:

$$\begin{cases} \dfrac{\partial z}{\partial t}(\xi, t) = \dfrac{\partial^2 z}{\partial \xi^2}(\xi, t), & t > 0, \quad 0 < \xi < 1; \\[2ex] \dfrac{\partial z}{\partial \xi}(0, t) = u(t), \quad \dfrac{\partial z}{\partial \xi}(1, t) = 0, & t > 0; \\[2ex] y(t) = \int_0^t c(\xi) z(\xi, t)\, d\xi, & t > 0; \\[2ex] z(\xi, 0) = z_0(\xi), & 0 < \xi < 1 \text{ (intitial condition)}, \end{cases} \tag{4.23}$$

where $c(\cdot) \in L_2(0,1)$ (the output $y(t)$ is some averaged measurement of the temperature). Formally, the PDE may be expressed as

$$\frac{\partial z}{\partial t}(\xi, t) = \frac{\partial^2 z}{\partial \xi^2}(\xi, t) - \delta_0 u(t),$$

where δ_0 denotes the Dirac delta impulse at $\xi = 0$ (actually, this can be done in a rigorous way, using distribution theory; see Salamon [20]). Choosing the state-space $H = L_2(0,1)$ with the state function

$$x(t) = z(t,\xi), \qquad t > 0, \quad 0 < \xi < 1,$$

the PDE can be modeled as a system of the form (2.5) with $D = 0$, i.e.,

$$\begin{cases} x(t) &=& S(t)x_0 + \int_0^t S(t-s)Bu(s)\,ds, \\ y(t) &=& Cx(t). \end{cases}$$

Here $S(\cdot)$ is a C_0-semigroup on H and its infinitesimal generator A, the input operator B, and the output operator C are defined by

$$D(A) = \left\{ x \in H \mid x, \frac{dx}{d\xi} \text{ are absolutely continuous }, \right.$$
$$\left. \frac{d^2x}{d\xi^2} \in H, \text{ and } \frac{dx}{d\xi}(0) = \frac{dx}{d\xi}(1) = 0 \right\},$$

$$Ax = \frac{d^2x}{d\xi^2},$$

$$Bu = -\delta_0 u,$$

$$Cx = \langle c(\cdot), x(\cdot)\rangle_H.$$

It follows that A is indeed selfadjoint, that it has compact resolvent, and that it is of the form (4.18), where $\lambda_0 = 0$, $\phi_0 = 1$ and $\lambda_n = -n^2\pi^2$, $\phi_n(\xi) = \sqrt{2}\cos(n\pi\xi)$ for $n \geq 1$. Furthermore, we get $c_n = \langle c(\cdot), \phi_n\rangle_H, n \in \mathbb{N}$, and $b_0 = -1$, $b_n = -\sqrt{2}$ for $n \geq 1$ and condition (4.22) is satisfied if and only if

$$\sum_{n=1}^{\infty} \frac{|c_n|}{n} < \infty. \tag{4.24}$$

Since $c(\cdot) \in H$, we have $\sum_{n=1}^{\infty} c_n^2 < \infty$ and so condition (4.24) is satisfied. In fact, we can choose the sequences γ_n and β_n by $\gamma_n = 1$ and $\beta_n = n^{-2}$, $n \geq 1$. This corresponds to the choice $W = H$ and $V' = W^{1,2}(0,1)$ (the Sobolev space of absolute continuous functions in $L_2(0,1)$ whose derivative is in $L_2(0,1)$).

Now it is of course possible to set up a nonstandard LQ-problem for the above described abstract parabolic systems. The system is given by

$$x(t) = S(t)x_0 + \int_0^t S(t-s)Bu(s)\,ds,$$

and one can choose output operators C_1, C_2, and L with the same admissiblity properties as the output operator C above and construct a cost function of the form

$$J(x_0, u(\cdot)) = \int_0^\infty ((C_1x(t))^2 - (C_2x(t))^2 + Lx(t)u(t) + r(u(t))^2)\,dt.$$

If $b_n \neq 0$ for $n = 1, \dots, n_0 - 1$, the pair (A^V, B) is exponentially stabilizable (see [15]) and so in this case Theorem 3.1 is applicable. In order to make this very general result a bit more explicit we consider the special case of the PDE in (4.23) and we choose the output operators $C_1, C_2 \in \mathcal{L}(W, \mathbb{R})$ as follows:

$$\begin{aligned} C_1x &= K\langle\phi_0(\cdot), x(\cdot)\rangle_H \text{ for some } K \in \mathbb{R}, \\ C_2x &= \langle c(\cdot), x(\cdot)\rangle_H \text{ for some } c(\cdot) \in H \end{aligned}$$

(we take $L = 0$). It follows from the above that with $\gamma_n = 1$ for $n \geq 0$, $\beta_0 = 1$, and $\beta_n = 1/n^2$ for $n \geq 1$ we have a stabilizable Pritchard–Salamon system that satisfies assumption (2.6) and C_1 and C_2 are admissible output operators (recall that $\lambda_0 = 0$, $\phi_0 = 1$; $\lambda_n = -n^2\pi^2$, $\phi_n(\xi) = \sqrt{2}\cos(n\pi\xi)$ for $n \geq 1$; $b_0 = -1$, $b_n = -\sqrt{2}$ for $n \geq 1$, and $c_n = \langle c(\cdot), \phi_n\rangle_H$ for $n \geq 0$). The nonstandard LQ-cost function is given by

$$J(x_0, u(\cdot)) = \int_0^\infty ((C_1x(t))^2 - (C_2x(t))^2 + r(u(t))^2)\,dt.$$

Now let us consider the frequency domain condition of Theorem 3.1 for the problem:

- There exists an $\epsilon > 0$ such that for all $(\omega, x, u) \in \mathbb{R} \times D(A^V) \times \mathbb{C}$ that satisfy $i\omega x = A^V x + Bu$ there holds

$$|C_1x|^2 - |C_2x|^2 + r|u|^2 \geq \epsilon(\|x\|_V^2 + |u|^2). \tag{4.25}$$

The expression $i\omega x = A^V x + Bu$ can be reformulated componentwise as

$$i\omega x_n = (A^V x)_n + (Bu)_n = \lambda_n x_n + b_n u \text{ for all } n \geq 0,$$

and due to the fact that $\lambda_0 = 0$ we need to consider two cases:

$$\omega = 0 \Rightarrow \begin{cases} x_0 \text{ is arbitrary, } x_n = 0 \text{ for } n \geq 1,\ u = 0; \\ \|x\|_V^2 = |x_0|^2; \\ C_1x = Kx_0; \\ C_2x = c_0x_0. \end{cases}$$

and

$$\omega \neq 0 \Rightarrow \begin{cases} x_n = \dfrac{b_n u}{i\omega - \lambda_n} \text{ for } n \geq 0, u \text{ arbitrary}, \\ \|x\|_V^2 = \dfrac{|u|^2}{\omega^2} + \displaystyle\sum_{n=1}^\infty \dfrac{2|u|^2}{n^2(\omega^2 + \lambda_n^2)}, \\ C_1x = Kx_0 = \dfrac{Ku}{i\omega}, \\ C_2x = \langle c(\cdot), x(\cdot)\rangle = \displaystyle\sum_{n=0}^\infty \dfrac{c_n b_n u}{i\omega - \lambda_n} \text{ for } n \geq 0. \end{cases}$$

It follows that a necessary condition for the frequency domain inequality to hold is that $|K| > |c_0|$ (due to the case $\omega = 0$). Sufficient conditions on c_n for the frequency domain inequality to hold may now be obtained by estimating $|C_2 x|$.

Hence, just as in the delay example, Theorem 3.1 is applicable and the frequency domain inequality is the condition that is most easy to verify.

4.3. A beam example. Finally, we discuss the applicability of Theorem 3.1 to a flexible beam example. In [2] an example is given of an Euler–Bernoulli beam with Kelvin–Voigt damping that can be modeled as a Pritchard–Salamon system (it is in fact a simple model for a satellite). The corresponding PDE is given by

$$\begin{cases} \dfrac{\partial^2 w}{\partial t^2}(\xi,t) + \alpha_1 A \dfrac{\partial w}{\partial t}(\xi,t) + \alpha_2 A w(\xi,t) = \dfrac{1}{\rho a}(\delta_0 u_1(t) - \delta_0' u_2(t)),\ t \geq 0, -1 < \xi < 1; \\ \dfrac{\partial^2 w}{\partial \xi^2}(-1,t) = 0 = \dfrac{\partial^2 w}{\partial \xi^2}(1,t) \text{ for } t \geq 0; \\ \dfrac{\partial^3 w}{\partial \xi^3}(-1,t) = 0 = \dfrac{\partial^3 w}{\partial \xi^3}(1,t) \text{ for } t \geq 0; \\ y_1(t) = w(0,t),\ y_2(t) = \dfrac{\partial w}{\partial \xi}(0,t) \text{ for } t \geq 0, \end{cases}$$

where α_1 and α_2 are the damping and stiffness coefficients, ρa is the mass per unit length, and A is the selfadjoint positive operator from $D(A) \subset L_2(-1,1)$ to $L_2(-1,1)$ given by

$$\begin{aligned} D(A) &= \{h \in L_2(-1,1) \mid h', h'', h''', h'''' \in L_2(-1,1) \\ &\qquad h''(-1) = h''(1) = 0,\ h'''(-1) = h'''(1) = 0\}, \\ Ah &= \frac{d^4 h}{d\xi^4}. \end{aligned}$$

Choosing the state $x(t) = (w(\cdot,t), \frac{\partial w}{\partial t}(\cdot,t)) \in D(A^{1/2}) \times L_2(-1,1)$, this PDE can be reformulated as a Pritchard-Salamon system of the form (2.5). For the details we refer to [2]; important elements are the spectral analysis of the system operator $\left(\begin{smallmatrix} 0 & I \\ -\alpha_2 A & -\alpha_1 A \end{smallmatrix}\right)$ and the use of scaled Hilbert spaces, just as in the parabolic PDE example. Furthermore, it is straightforward to formulate nonstandard LQ-problems for this example by choosing appropriate admissible output operators C_1, C_2, and L just as in the delay example and the parabolic PDE example, so we need not pursue this issue any further.

Acknowledgment. I thank the authors of [3] and Martin Weiss for some interesting and helpful discussions.

EXACT CONTROLLABILITY AND STABILIZATION OF A VIBRATING STRING WITH AN INTERIOR POINT MASS*

SCOTT HANSEN[†] AND ENRIQUE ZUAZUA[‡]

Abstract. In this article we examine the problems of boundary control and stabilization for a one-dimensional wave equation with interior point masses. We show that singularities in waves are "smoothed one order" as they cross a point mass. Thus in the case of one interior point mass, with, e.g., L^2-Dirichlet control at the left end, the most general reachable space (from 0) that one can expect is $L^2 \times H^{-1}$ to the left of the mass and $H^1 \times L^2$ to the right of the mass. We show that this is in fact the optimal result (modulo certain compatibility conditions). Several related results for both control and stabilization of such systems are also given.

Key words. boundary control, hyperbolic system, hybrid system, vibrating network

AMS subject classifications. 35P10, 35P20, 35L20, 73K03, 93C20

1. Introduction and main results.

In recent years there has been much interest in the topic of control and stabilization of so called "hybrid systems" in which the dynamics of elastic systems and possibly rigid structures are related through some form of coupling. For example, see [1] for serially connected beams, [8]–[10] for beams with end masses, and [4], [12], [14] for networks of strings and beams.

In this article we examine a simple model for an elastic string involving an interior point mass. We obtain a precise description of the space of exact controllability when control is active at one or both ends of the string and also describe the best possible stabilization results via velocity feedback at one or both ends. We refer to [14] for a discussion on the modeling and well-posedness of networks of strings containing, in particular, point masses. Approximate controllability results for these networks were announced in [13].

It will be convenient to regard the string-mass system as two separate strings in which one end of each string is attached to a common point mass. Thus assume the first string occupies $\Omega_1 = (-\ell_1, 0) \subset \mathbb{R}$ and the second one $\Omega_2 = (0, \ell_2) \subset \mathbb{R}$, where ℓ_1 and ℓ_2 are positive.

For simplicity of the exposition we suppose both strings to be homogeneous. The deformations of the first and second string will be described respectively by the functions

$$\begin{aligned} u &= u(x,t), \quad x \in \Omega_1, \quad t > 0, \\ v &= v(x,t), \quad x \in \Omega_2, \quad t > 0. \end{aligned}$$

The position of the mass (which is attached to the strings at the point $x = 0$) is described by the function $z = z(t)$ for $t > 0$.

To fix ideas we suppose that the strings satisfy Dirichlet boundary conditions at the end points ($x = -\ell_1, \ell_2$). Then the equations modeling the dynamics of this system in the absence of controls are as follows:

$$\left\{\begin{array}{ll} \rho_1 u_{tt} = \sigma_1 u_{xx}, & x \in \Omega_1,\ t > 0, \\ \rho_2 v_{tt} = \sigma_2 v_{xx}, & x \in \Omega_2,\ t > 0, \\ M z_{tt}(t) + \sigma_1 u_x(0,t) - \sigma_2 v_x(0,t) = 0, & t > 0, \\ u(-\ell_1, t) = v(\ell_2, t) = 0, & t > 0, \\ u(0,t) = v(0,t) = z(t), & t > 0. \end{array}\right. \tag{1.1}$$

The constants $\rho_1 > 0$ and $\rho_2 > 0$ represent the density of each string and $M > 0$ represents the mass of the point mass. The tensions in each string are assumed positive and denoted by σ_1 and σ_2. If the only forces acting on the point mass are those of the strings then $\sigma_1 = \sigma_2$; however, if an external force is present (for example, gravity acting along the x-axis) then the two tensions will be different.

Note that when $M = 0$, system (1.1) describes the motion of a string with a piecewise constant wave speed.

Of course, in order to determine the solution of (1.1) in a unique way we have to add some initial conditions at time $t = 0$ that will be represented by

$$\left\{\begin{array}{ll} u(x,0) = u^0(x), \quad u_t(x,0) = u^1(x), & x \in \Omega_1, \\ v(x,0) = v^0(x), \quad v_t(x,0) = v^1(x), & x \in \Omega_2, \\ z(0) = z^0, \quad z_t(0) = z^1. & \end{array}\right. \tag{1.2}$$

As usual, depending on the regularity properties and the compatibility conditions these initial data satisfy, we may expect a different degree of regularity of solutions.

Let us introduce the energy

$$\begin{aligned} E_M(t) = \frac{1}{2} \int_{-\ell_1}^{0} [\rho_1 |u_t(x,t)|^2 + \sigma_1 |u_x(x,t)|^2]\, dx + \frac{M}{2} |z_t(t)|^2 \\ + \frac{1}{2} \int_0^{\ell_2} [\rho_2 |v_t(x,t)|^2 + \sigma_2 |v_x(x,t)|^2] dx. \end{aligned} \tag{1.3}$$

In the absence of controls, i.e., for solutions of (1.1), this energy is constant in time.

We are interested in the controllability properties of this system when control is active at one or both of the end points of the string-mass system. We will discuss these control problems from two different point of views. The first consists of finding suitable observability estimates and then applying Hilbert's uniqueness method (HUM) (cf. J. L. Lions [6], [7]) and the other is based on the use of nonharmonic Fourier series and moment problems (cf. D. L. Russell [11]).

We will see that the presence of the point mass introduces some important changes in the behavior of the system with respect to the observability properties.

Let us recall what one has concerning the observability of (1.1) in the absence of the mass (i.e., when $M = 0$):

(a) If $T > \ell_1 \sqrt{\rho_1/\sigma_1} + \ell_2 \sqrt{\rho_2/\sigma_2}$ there exists $C(T) > 0$ such that

$$E_0(0) \le C \int_0^T [\,|u_x(-\ell_1, t)|^2 + |v_x(\ell_2, t)|^2] dt. \tag{1.4}$$

(b) If $T > 2(\ell_1\sqrt{\rho_1/\sigma_1} + \ell_2\sqrt{\rho_2/\sigma_2})$ there exists $C(T) > 0$ such that

$$E_0(0) \leq C \int_0^T |v_x(\ell_2, t)|^2 dt. \tag{1.5}$$

We will see that an estimate of the form (1.4) holds[1] for any $M > 0$ but only if $T > 2\max(\ell_1\sqrt{\rho_1/\sigma_1}, \ell_2\sqrt{\rho_2/\sigma_2})$. Thus when controlling at both extremes $x = -\ell_1, \ell_2$ we will get the analogue of the results one can prove (see Theorem 3.1) for two serially connected strings without the point mass but only for $T > 2\max(\ell_1\sqrt{\rho_1/\sigma_1}, \ell_2\sqrt{\rho_2/\sigma_2})$.

However, we will see that the observability inequality (1.5) does not hold when $M > 0$, no matter how large T is. By an explicit computation (see Proposition 2.5) one sees that when a wave starting from initial data

$$\begin{cases} u^0 = \varphi^0 \in H_0^1(\Omega_1), & v^0 = 0, \\ u^1 = \varphi^1 \in L^2(\Omega_1), & v^1 = 0, \\ z^0 = z^1 = 0 & \end{cases}$$

crosses the point mass, part of the wave is reflected off the point mass and part is transmitted. The part which is reflected keeps the same regularity as the initial data, but the part that crosses the mass is regularized by one degree (i.e., $v(\cdot, t) \in H^2(\Omega_2)$ for all $t > 0$). Of course this is due to the presence of the mass and does not occur when $M = 0$.

This phenomena explains why, if we want to observe the initial energy of the solution (in this case the H^1-norm of φ), we need an estimate on $v_{xt}(\ell_2, t)$ in $L^2(0, T)$ and not only on $v_x(\ell_2, t)$.

When $M > 0$ and $T > 2(\ell_1\sqrt{\rho_1/\sigma_1} + \ell_2\sqrt{\rho_2/\sigma_2})$ we are able to prove that

$$E_M(0) + ||v_{xx}(\cdot, 0)||^2_{L^2(\Omega_1)} + ||v_{xt}(\cdot, 0)||^2_{L^2(\Omega_2)} \leq C \int_0^T |v_{xt}(\ell_2, t)|^2 dt \tag{1.6}$$

and this inequality is sharp in the sense that the reverse one holds for all $T > 0$.

As a consequence of (1.6) we deduce that when controlling from only the end $x = \ell_2$ with $L^2(0, T)$ controls, the controllability is achieved in a space smaller than the usual one (the one we have for $M = 0$) since the components corresponding to the first string are of one more degree of regularity. The well-posedness of the system (1.1) in this asymmetric space is due to the presence of the point mass and does not hold when $M = 0$.

It is also interesting to understand this phenomena from the point of view of nonharmonic Fourier series. Let us consider, for simplicity, the case $\rho_1 = \rho_2 = \ell_1 = \ell_2 = \sigma_1 = \sigma_2 = 1$. By a careful study of the spectrum of the elliptic operator involved in system (1.1) we can see that $v_x(\ell_2, t)$ is given by the nonharmonic Fourier series

$$v_x(1, t) = a_0 e^{-i\omega_0 t} + b_0 e^{i\omega_0 t} + \sum_{k \in \mathbb{Z}\setminus\{0\}} (a_k e^{ik\pi t} + b_k e^{i\omega_k t}), \tag{1.7}$$

[1] That an estimate of this type can be obtained was mentioned by Schmidt [13]; however, the optimality of T is much more subtle and was unknown at that time.

where a_k and b_k are complex numbers related to the Fourier coefficients of the initial data and $(i\omega_k)$ is a sequence of eigenvalues such that

$$\left\{\begin{array}{l} |\omega_k - k\pi| \to 0 \text{ as } |k| \to \infty, \\ \omega_k \neq k\pi, \quad \forall k \in \mathbb{Z}. \end{array}\right. \tag{1.8}$$

When $M = 0$ this second sequence $(\omega_k) \cup -\omega_0$ of eigenvalues becomes $(k\pi + \frac{\pi}{2})_{k\in\mathbb{Z}}$ and $v_x(1,t)$ is given by a (harmonic) Fourier series involving the exponentials $(e^{ik\pi t/2})_{k\in\mathbb{Z}}$, which are orthogonal on $L^2(0,4)$.

In terms of (1.7) the inequality (1.5) (which we already mentioned does not hold when $M > 0$) would be equivalent to

$$\sum_{k=-\infty}^{\infty} [\,|a_k|^2 + |b_k|^2] \le C \int_0^T |v_x(1,t)|^2 dt, \tag{1.9}$$

for $T > 4$. However, all results concerning inequality (1.9) for nonharmonic Fourier series existing in the literature require an asymptotic spectral gap (cf. [2], [3], and [16]) that, in view of (1.8), does not hold in our case. Instead of (1.9), employing a result of D. Ullrich [15], we get the following weaker version of (1.9):

$$\sum_{k=-\infty}^{\infty} [\,|a_k + b_k|^2 + (w_k - k\pi)^2 |a_k - b_k|^2] \le C \int_0^T |v_x(1,t)|^2 dt, \tag{1.10}$$

which holds for $T \ge 4$, and is just the Fourier version of the observability inequality (1.6).

When controlling at both extremes $x = -\ell_1, \ell_2$ but with

$$\ell_1 \sqrt{\frac{\rho_1}{\sigma_1}} + \ell_2 \sqrt{\frac{\rho_2}{\sigma_2}} < T < 2\max\left(\ell_1 \sqrt{\frac{\rho_1}{\sigma_1}}, \ell_2 \sqrt{\frac{\rho_2}{\sigma_2}}\right) \tag{1.11}$$

(which is only possible if $\ell_1\sqrt{\rho_1/\sigma_1} \neq \ell_2\sqrt{\rho_2/\sigma_2}$), we again obtain, as above, an asymmetric controllability space since the solution components corresponding the string with the longest propagation time has one more degree of regularity over a portion of that string. Thus we also obtain controls with different regularities, namely, the control on the side of the mass with the smoother solution belongs to $H_0^1(0,T)$ and the control at the other end belongs to $L^2(0,T)$. Therefore, even if we control at both ends when T satisfies (1.11), this phenomena in which the controllability space is asymmetric appears.

We will also briefly discuss the stabilization problem concernings two different situations. First we prove that by introducing boundary damping at both extremes $x = -\ell_1, \ell_2$ the energy of solutions decays exponentially uniformly. Moreover trajectories converge exponentially to a constant equilibrium that can be determined in terms of the initial data. We then consider the case where the boundary damping acts only at one extreme point. In this case the energy of every solution converges to zero but there is not a uniform exponential decay since a sequence of eigenvalues of the system approaches the imaginary axis. This phenomena is similar to that founded by E. B. Lee and Y. C. You [5] and W. Littman and L. Markus [10] when studying the stability properties of strings and beams damped at one extreme through a point mass.

This paper will be devoted to the particular case of two homogeneous strings with a point mass, but the techniques and ideas involved are rather general and may be used to discuss nonhomogeneous strings, other boundary conditions at the extremes, other dynamics at the point mass, and other situations where more than two strings and one mass are present. A more detailed discussion of some of these extensions will be given in the last section.

The rest of the paper is organized as follows. In §2 we give some preliminary results concerning the existence, regularity, and uniqueness of solutions of both the uncontrolled and the controlled system. In §3 we examine the controllability problem for the case where the control acts at both extremes. In §4, using energy methods we prove estimate (1.7) and its consequence concerning controllability. In §5 we carefully analyze the problem of controlling from only one extreme by means of moment problems and nonharmonic Fourier series. In particular we discuss and prove inequality (1.10). In §6 we discuss the boundary-stabilization problem. Finally, in §7, we give some extensions of our main results.

Throughout this paper C will denote a positive constant that may vary from line to line. We will make explicit the dependence of these constants with respect to the various parameters of the problem only when this becomes necessary.

2. Existence, uniqueness and regularity of solutions. In this section we give some preliminary results concerning the existence, uniqueness, and regularity of solutions. First we consider the system (1.1) without controls and then the case of nonhomogeneous boundary conditions.

2.1. Homogeneous boundary conditions. Let us introduce the vector spaces

$$\begin{aligned}\vartheta_1 &= \{\varphi \in H^1(\Omega_1) : \varphi(-\ell_1) = 0\},\\ \vartheta_2 &= \{\psi \in H^1(\Omega_2) : \psi(\ell_2) = 0\},\\ \vartheta &= \{(\varphi, \psi) \in \vartheta_1 \times \vartheta_2 : \varphi(0) = \psi(0)\}\end{aligned}$$

endowed with the norms

$$\begin{aligned}||\varphi||^2_{\vartheta_i} &= \int\limits_{\Omega_i} |\varphi_x(x)|^2\,dx, \qquad i = 1, 2,\\ ||(\varphi, \psi)||^2_{\vartheta} &= ||\varphi||^2_{\vartheta_1} + ||\psi||^2_{\vartheta_2}.\end{aligned}$$

Note that the space ϑ is algebraically and topologically equivalent to $H^1_0(-\ell_1, \ell_2)$. However, since we are considering a system made of two different strings it is convenient to think of ϑ as a subspace of $\vartheta_1 \times \vartheta_2$.

Let us also consider the following closed subspace of $\vartheta \times \mathbb{R}$:

$$W_1 = \{(\varphi, \psi, z) \in \vartheta \times \mathbb{R} : \varphi(0) = \psi(0) = z\},$$

which is densely and continuously embedded in the space

$$W_0 = L^2(\Omega_1) \times L^2(\Omega_2) \times \mathbb{R}.$$

Define the Hilbert space $\mathcal{H}$ by

$$\mathcal{H} = W_1 \times W_0$$

with the product topology. In terms of the vector-valued function

$$y = (u, v, z, \dot{u}, \dot{v}, \dot{z})^t$$

(the superscript ^{t} denotes transposition), we may define an unbounded operator $\mathcal{A}$ on $\mathcal{H}$ by

$$\mathcal{A}y = \begin{pmatrix} 0 & I \\ A & 0 \end{pmatrix} y; \quad A = \begin{pmatrix} \frac{\sigma_1}{\rho_1} d^2 & 0 & 0 \\ 0 & \frac{\sigma_2}{\rho_2} d^2 & 0 \\ \frac{-\sigma_1}{M} d\delta_0 & \frac{\sigma_2}{M} d\delta_0 & 0 \end{pmatrix},$$

where d denotes the (distributional) derivative operator and δ_0 denotes the Dirac delta function with mass at $x = 0$. The domain of $\mathcal{A}$ is given by

$$D(\mathcal{A}) = \{ y \in \mathcal{H} : u \in H^2(\Omega_1), v \in H^2(\Omega_2), (\dot{u}, \dot{v}, \dot{z}) \in W_1 \}.$$

When $\mathcal{D}(\mathcal{A})$ is endowed with the graph-norm topology

$$||y||_{\mathcal{D}(\mathcal{A})} = \{||y||^2_{\mathcal{H}} + ||\mathcal{A}y||^2_{\mathcal{H}}\}^{1/2}$$

it becomes a Hilbert space with dense and continuous embedding in $\mathcal{H}$.

System (1.1)–(1.2) can be written as

$$\text{(2.1)} \qquad \frac{dy}{dt} = \mathcal{A}y, \qquad y(0) = y^0 = (u^0, v^0, z^0, u^1, v^1, z^1)^t.$$

It is easy to see that $\mathcal{A}$ is skew adjoint and m-dissipative on $\mathcal{H}$ and therefore generates a strongly continuous group of isometries on $\mathcal{H}$. Therefore we have the following existence and uniqueness result for (1.1)–(1.2).

PROPOSITION 2.1. (i) *For every* $y^0 = (u^0, v^0, z^0, u^1, v^1, z^1)^t \in \mathcal{H}$ *there exists a unique solution of* (1.1)–(1.2) *in the class*

$$\text{(2.2)} \qquad (u, v, z) \in C([0,T]; W_1) \cap C^1([0,T]; W_0).$$

Furthermore, the energy E_M *remains constant along this solution trajectory.*

(ii) *If* $y^0 \in \mathcal{D}(\mathcal{A})$ *then the corresponding solution has the following additional regularity:*

$$\text{(2.3)} \qquad \begin{cases} u \in C([0,T]; H^2(\Omega_1) \cap C^1([0,T]; H^1(\Omega_1)), \\ v \in C([0,T]; H^2(\Omega_2) \cap C^1([0,T]; H^1(\Omega_2)). \end{cases}$$

Let us denote those solutions satisfying (2.2) by finite-energy solutions.

We can also prove the following regularity result for finite-energy solutions.

PROPOSITION 2.2. *For every* $T > 0$ *there exists some constant* $C(T) > 0$ *such that the following inequality holds for every finite-energy solution:*

$$\text{(2.4)} \qquad \int_0^T [\,|u_x(-\ell_1, t)|^2 + |v_x(\ell_2, t)|^2]dt \leq CE_M(0).$$

Proof. It is well known by now (cf. [7]) that this estimate is of local nature. Therefore it does not depend on whether there is a point mass on the string. However, we have to use the conservation of the energy $E_M(t)$ in (1.3) to obtain the upper bound in terms of the initial energy. $\square$

It is also convenient to consider system (1.1) in the presence of some external distributed force:

$$
\begin{cases}
\rho_1 u_{tt} = \sigma_1 u_{xx} + f(x,t), & x \in \Omega_1,\ 0 < t < T, \\
\rho_2 v_{tt} = \sigma_2 v_{xx} + g(x,t), & x \in \Omega_2,\ 0 < t < T, \\
M z_{tt}(t) + \sigma_1 u_x(0,t) - \sigma_2 v_x(0,t) = h(t), & 0 < t < T, \\
u(0,t) = v(0,t) = z(t), & 0 < t < T, \\
u(-\ell_1, t) = v(\ell_2, t) = 0, & 0 < t < T.
\end{cases}
\tag{2.5}
$$

By standard semigroup methods we have the following proposition.

PROPOSITION 2.3. *For every $y^0 \in \mathcal{H}$ and $(f,g,h) \in L^1(0,T;W_0)$ there exists a unique finite-energy solution of (2.5), (1.2) in the class (2.2). Moreover, there exists a constant $C > 0$ such that*

$$
\int_0^T \left[|u_x(-\ell_1,t)|^2 + |v_x(\ell_2,t)|^2 \right] dt \le C \Big[||y^0||^2_{\mathcal{H}} + ||f||^2_{L^1(0,T;L^2(\Omega_1))} + ||g||^2_{L^1(0,T;L^2(\Omega_2))} + ||h||^2_{L^1(0,T)} \Big].
\tag{2.6}
$$

We will also need the following result.

PROPOSITION 2.4. *Suppose that $y^0 = 0$ and*

$$
f = \frac{\partial F}{\partial t}, \quad g = \frac{\partial G}{\partial t}, \quad h = \frac{dH}{dt},
$$

where $(F,G,H) \in L^1(0,T;W_1)$. Then the solution (u,v,z) of (2.5), (1.2) is such that

$$
(u,v,z) = (U_t, V_t, Z_t)
$$

with

$$
(U,V,Z,U_t,V_t,Z_t)^t \in C([0,T];D(\mathcal{A}))
$$

and therefore, in particular,

$$
\begin{cases}
(u,v,z) \in C([0,T];W_1), \\
(u_t,v_t,z_t) \in C([0,T];W_0) + L^1(0,T;W_1), \\
(U,V) \in C([0,T];H^2(\Omega_1) \times H^2(\Omega_2)).
\end{cases}
\tag{2.7}
$$

Moreover, there exists a constant $C > 0$ such that

$$
\int_0^T [\,|u_x(-\ell_1,t)|^2 + |v_x(\ell_2,t)|^2] dt \le C||(F,G,H)||^2_{L^1(0,T;W_1)}.
\tag{2.8}
$$

Proof. We have $(u,v,z) = (U_t,V_t,Z_t)$ where (U,V,Z) is the solution of (2.5), (1.2) with zero initial data and $(f,g,h) = (F,G,H)$. We have

$$
(U,V,Z,U_t,V_t,Z_t)^t \in C([0,T];D(\mathcal{A})),
$$

and therefore (2.7) holds.

The regularity property (2.8) is more subtle and can be proved proceeding as in [7, Chap. I, Thm. 4.2, p. 46]. □

Let us now study the regularity of solutions where the initial data belong to a space where the regularity is not the same in each of the strings. More precisely, let us consider initial data

$$
y^0 \in \mathcal{H}
\tag{2.9}
$$

such that

$$u^0 \in H^2(\Omega_1), \quad u^1 \in \vartheta_1, \quad u^1(0) = z^1. \tag{2.10}$$

Of course, (2.9)–(2.10) do not imply that $y^0 \in D(\mathcal{A})$ and therefore we cannot apply the regularity Proposition 2.1(ii) provides. However, we can prove the following result.

PROPOSITION 2.5. *Suppose that the initial data y^0 satisfies* (2.9)–(2.10). *Then the solution of* (1.1)–(1.2) *is such that, in addition to* (2.2), *we have*

$$u \in C([0,T]; H^2(\Omega_1)) \cap C^1([0,T]; \vartheta_1). \tag{2.11}$$

Moreover, there exists $C > 0$ such that

$$||u||^2_{L^\infty(0,T;H^2(\Omega_1))} + ||u_t||^2_{L^\infty(0,T;\vartheta_1)} \leq C[E_M(0) + ||u^0||^2_{H^2(\Omega_1)} + ||u^1||^2_{\vartheta_1}] \tag{2.12}$$

for every solution with initial data satisfying (2.9)–(2.10).

Proof. It is sufficient to prove the existence of some $\tau > 0$ and $C > 0$ such that (2.11) and (2.12) hold in the time interval $[0, \tau]$. By scaling the spatial variable in Ω_1 and changing the time scale we may assume $\ell_1 = 1$ and in the wave equation u satisfies, $\rho_1 = \sigma_1 = 1$. Likewise, by changing the length of the second string we may assume $\rho_2 = \sigma_2 = 1$ in the wave equation v satisfies. However, the conditions at the point mass change and we are led to consider the following system:

$$\begin{cases} u_{tt} = u_{xx}, & -1 < x < 0, \quad 0 < t < T, \\ v_{tt} = v_{xx}, & 0 < x < \ell, \quad 0 < t < T, \\ mz_{tt}(t) + u_x(0,t) - \gamma v_x(0,t) = 0, & 0 < t < T, \\ u(-1,t) = v(\ell,t) = 0, & 0 < t < T, \\ u(0,t) = v(0,t) = z(t), & 0 < t < T, \end{cases}$$

with $\gamma > 0$ and $m > 0$, ℓ being the length of the second string.

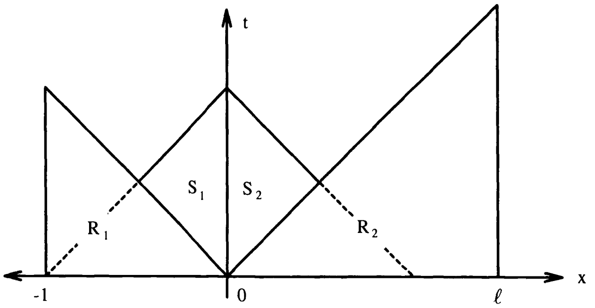

FIG. 1.

The value of u and v in the regions

$$R_1 = \{(x,t) \in (-1,0) \times (0,1) : t < -x\},$$
$$R_2 = \{(x,t) \in (0,\ell) \times (0,\ell) : t < x\},$$

respectively, does not depend on the point mass because of the finite speed of propagation (see Fig. 1).

Therefore, in R_1 and R_2, u and v remain as smooth as in the absence of mass. In particular $u \in C([0,1]; H^2(R_1(t)) \cap C^1([0,1]; H^1(R_1(t)))$ where $R_1(t) = (-1, -t)$. Moreover

$$||u||_{L^\infty(0,1;H^2(R_1(t)))} + ||u_t||_{L^\infty(0,1;H^1(R_1(t)))} \leq C\left[||u^0||_{H^2(-1,0)} + ||u^1||_{H^1(-1,0)}\right].$$

Let us compute u and v in S_1 and S_2, respectively, where

$$S_1 = \left\{(x,t) \in \left(-\frac{\mu}{2},0\right) \times (0,\mu) : |2t-\mu| < \mu + 2x\right\},$$
$$S_2 = \left\{(x,t) \in \left(0,\frac{\mu}{2}\right) \times (0,\mu) : |2t-\mu| < \mu - 2x\right\},$$

with $\mu = \min(\ell, 1)$ ($\mu = 1$ in Fig. 1).

We have from D'Alembert's formula

$$u(x,t) = \frac{1}{2}[z(t-x) + z(t+x)] + \frac{1}{2}\int_{t-x}^{t+x} u_x(0,s)ds \quad \text{in } S_1, \tag{2.13}$$

$$v(x,t) = \frac{1}{2}[z(t-x) + z(t+x)] + \frac{1}{2\gamma}\int_{t-x}^{t+x} [u_x(0,s) + mz''(s)]ds \quad \text{in } S_2. \tag{2.14}$$

Likewise for $(x.t)$ in R_1 and R_2, u and v, respectively, are given in terms of the initial data by D'Alembert's formula. By Proposition 2.1 we know that the solution is continuous, in particular, along the rays $t = |x|$, $(-\mu/2 < x < \mu/2)$. Imposing continuity in the expressions for u and v along these rays leads to

$$z_t(t) + \frac{(1+\gamma)}{m} z(t) = z^1 + \frac{1}{m}[L(t) + \gamma R(t)], \quad z(0) = z^0 \tag{2.15}$$

and

$$u_x(0,t) = z_t(t) + u_x^0(-t) - u^1(-t), \tag{2.16}$$

where

$$L(t) = u^0(t) - \int_0^{-t} u^1(s)ds; \quad R(t) = v^0(t) + \int_0^t v^1(s)ds. \tag{2.17}$$

From the conditions the initial data satisfy we deduce from (2.17) that L and R belong to $H^1(0,\mu)$. It thus follows from (2.15) that $z = z(t)$ belongs to $H^2(0,\mu)$. Then, from (2.10) and (2.16) we deduce that $u_x(0,t) \in H^1(0,\mu)$.

Now, from (2.13) we easily deduce that

$$u \in C\left(\left[0,\frac{\mu}{2}\right]; H^2(-t,0)\right) \cap C^1\left(\left[0,\frac{\mu}{2}\right]; H^1(-t,0)\right). \tag{2.18}$$

Finally, it is easy to check that the expressions we have for u in R_1 (as a solution of the wave equation) and in S_1 (by (2.13)) are such that u_x and u_t are continuous across $x = -t$. This concludes the proof of the proposition. □

Remark 2.1. It is obvious from the proof of this proposition that we cannot replace in the hypothesis (2.10) and in the conclusions (2.11)–(2.12) the space $H^2(-1,0) \times H^1(-1,0)$ by any $H^s(-1,0) \times H^{s-1}(-1,0)$ with $s > 2$. In other words, the most extra regularity degree we may keep in one of the strings is one.

2.2. Nonhomogeneous boundary data. In this section we prove the existence and uniqueness of weak solutions when we introduce $L^2(0,T)$-Dirichlet controls at the extreme points $x = -\ell_1, \ell_2$.

Let us consider the system

$$
(2.19)\qquad \begin{cases}
\rho_1 u_{tt} = \sigma_1 u_{xx}, & x \in \Omega_1,\ 0 < t < T,\\
\rho_2 v_{tt} = \sigma_2 v_{xx}, & x \in \Omega_2,\ 0 < t < T,\\
M z_{tt}(t) + \sigma_1 u_x(0,t) - \sigma_2 v_x(0,t) = 0, & 0 < t < T,\\
u(0,t) = v(0,t) = z(t), & 0 < t < T,\\
u(-\ell_1, t) = p(t), & 0 < t < T,\\
v(\ell_2, t) = q(t), & 0 < t < T,\\
u(x,0) = u^0(x), \quad u_t(x,0) = u^1(x), & x \in \Omega_1,\\
v(x,0) = v^0(x), \quad v_t(x,0) = v^1(x), & x \in \Omega_2,\\
z(0) = z^0, \quad z_t(0) = z^1,
\end{cases}
$$

with $p, q \in L^2(0,T)$, $u^0 \in L^2(\Omega_1)$, $v^0 \in L^2(\Omega_2)$, the initial velocity u^1 and v^1 belonging, respectively, to the dual spaces ϑ_1' and ϑ_2' and $z^0, z^1 \in \mathbb{R}$.

The solution (u, v, z) of (2.19) has to be understood in the sense of transposition. Let us give its precise definition. For that, consider the following system with homogeneous boundary conditions:

$$
(2.20)\qquad \begin{cases}
\rho_1 \varphi_{tt} = \sigma_1 \varphi_{xx} + f, & x \in \Omega_1, \quad 0 < t < T,\\
\rho_2 \psi_{tt} = \sigma_2 \psi_{xx} + g, & x \in \Omega_2, \quad 0 < t < T,\\
M \zeta_{tt}(t) + \sigma_1 \varphi_x(0,t) - \sigma_2 \psi_x(0,t) = h(t), & 0 < t < T,\\
\varphi(-\ell_1, t) = \psi(\ell_2, t) = 0, & 0 < t < T,\\
\varphi(0,t) = \psi(0,t) = \zeta(t), & 0 < t < T,\\
\varphi(x,T) = \varphi_t(x,T) = 0, & x \in \Omega_1,\\
\psi(x,T) = \psi_t(x,T) = 0, & x \in \Omega_2,\\
\zeta(T) = \zeta_t(T) = 0.
\end{cases}
$$

For every $(f, g, h) \in L^1(0,T; W_0)$, in view of the time-reversibility of the system and as a consequence of Proposition 2.3, system (2.20) has a unique solution

$$
(2.21)\qquad \begin{cases}
(\varphi, \psi, \zeta) \in C([0,T]; W_1),\\
(\varphi_t, \psi_t, \zeta_t) \in C([0,T]; W_0)
\end{cases}
$$

satisfying

$$
(2.22)\qquad \int_0^T [\,|\varphi_x(-\ell_1, t)|^2 + |\psi_x(\ell_2, t)|^2] dt \le C ||(f, g, h)||^2_{L^1(0,T;W_0)}.
$$

Multiplying by φ and ψ in the equations satisfied by u and v in (2.19) and integrating formally by parts with respect to x and t, we obtain the following identity:

$$\begin{aligned}\int_0^T\int_{-\ell_1}^0 ufdxdt+\int_0^T\int_0^{\ell_2} vgdxdt+\int_0^T zhdt &= -\rho_1\int_{-\ell_1}^0 u^0\varphi_t(x,0)dx\\ &-\rho_2\int_0^{\ell_2} v^0\psi_t(x,0)dx+\rho_1\langle u^1,\varphi(\cdot,0)\rangle_{\Omega_1}+\rho_2\langle v^1,\psi(\cdot,0)\rangle_{\Omega_2}\\ &+\sigma_1\int_0^T p(t)\varphi_x(-\ell_1,t)dt-\sigma_2\int_0^T q(t)\psi_x(\ell_2,t)dt+Mz^1\zeta(0)-Mz^0\zeta_t(0).\end{aligned}\tag{2.23}$$

We adopt this identity as the definition for weak solutions of (2.19) in the sense of transposition, i.e., (u,v,z) is said to be weak solution of (2.19) (in the sense of transposition) if (2.23) holds for every $(f,g,h)\in L^1(0,T;W_0)$.

In (2.23) observe that the initial velocities (u^1,v^1,z^1) are applied (in the sense of the duality in W_1) to the elements $(\varphi(\cdot,0),\psi(\cdot,0),\zeta(0))$ of W_1. Therefore two initial data that coincide in $W_0\times W_1'$ (note that W_1' is a quotient space of $(\vartheta_1\times\vartheta_2\times\mathbb{R})'$) give rise to the same solution.

We have the following result.

PROPOSITION 2.6. *For every $p,q\in L^2(0,T)$, $(u^0,v^0)\in L^2(\Omega_1)\times L^2(\Omega_2)$, $(u^1,v^1)\in(\vartheta_1'\times\vartheta_2')$, and $z^0,z^1\in\mathbb{R}$ there exists a solution (in the sense of transposition) of* (2.19) *in the class*

$$(u,v,z)\in C([0,T];W_0),\tag{2.24}$$

$$(u_t,v_t,z_t)\in C([0,T];\vartheta_1'\times\vartheta_2'\times\mathbb{R}).\tag{2.25}$$

Moreover, there is a one-to-one correspondence between the initial data as elements of the quotient space $W_0\times W_1'$ and the solutions of (2.19) *in the class* (2.24)–(2.25).

Proof. In view of Proposition 2.3, the right-hand side of (2.23) defines a linear and continuous form on $(f,g,h)\in L^1(0,T;W_0)$. Therefore, there exists a unique

$$(u,v,z)\in L^\infty(0,T;W_0)\tag{2.26}$$

satisfying (2.23). Furthermore, there exists $C>0$ such that

$$\begin{aligned}||(u,v,z)||_{L^\infty(0,T;W_0)}\le C\{&||p||_{L^2(0,T)}+||q||_{L^2(0,T)}+||u^0||_{L^2(\Omega_1)}\\ &+||v^0||_{L^2(\Omega_2)}+||u^1||_{\vartheta_1'}+||v^1||_{\vartheta_2'}+|z^0|+|z^1|\}.\end{aligned}\tag{2.27}$$

When the data are smooth, the solution of (2.19) satisfies (2.24). By a density argument using (2.27), we deduce that (2.24) holds for our weak solution.

Suppose now that

$$(f,g,h)=\left(\frac{\partial F}{\partial t},\frac{\partial G}{\partial t},\frac{dH}{dt}\right)$$

with $(F,G,H)\in\mathcal{D}((0,T);W_1)$ (C^∞ and compactly supported with respect to time). In this case the solution of (2.20) can be written as

$$(\varphi,\psi,\zeta)=\left(\frac{\partial\Phi}{\partial t},\frac{\partial\Psi}{\partial t},\frac{d\Sigma}{dt}\right),$$

where (Φ,Ψ,Σ) is the solution of (2.20) with data (F,G,H) instead of (f,g,h).

In view of Proposition 2.4 we have

$$\begin{aligned}(2.28)\quad &||\varphi_x(-\ell_1,t)||_{L^2(0,T)} + ||\psi_x(\ell_2,t)||_{L^2(0,T)} + ||\varphi(\cdot,0)||_{\vartheta_1} + ||\psi(\cdot,0)||_{\vartheta_2} + |\zeta(0)|\\ &\leq C||(F,G,H)||_{L^1(0,T,W_1)}.\end{aligned}$$

On the other hand,

$$\begin{aligned}\rho_1\varphi_t(x,0) &= \rho_1\Phi_{tt}(x,0) = \sigma_1\Phi_{xx}(x,0) + F(x,0) = \sigma_1\Phi_{xx}(x,0) \in L^2(\Omega_1),\\ \rho_2\psi_t(x,0) &= \rho_2\Psi_{tt}(x,0) = \sigma_2\Psi_{xx}(x,0) + G(x,0) = \sigma_2\Psi_{xx}(x,0) \in L^2(\Omega_2),\\ M\zeta_t(0) &= M\Sigma_{tt}(0) = -\sigma_2\Phi_x(0,0) + \sigma_2\Psi_x(0,0) \in \mathbb{R}\end{aligned}$$

with the bound

$$(2.29)\qquad ||(\varphi_t(\cdot,0),\psi_t(\cdot,0),\zeta_t(0))||_{W_0} \leq C||(F,G,H)||_{L^1(0,T;W_1)}.$$

As a consequence of (2.28)–(2.29) we deduce that

$$(u,v,z) \in W^{1,\infty}(0,T;(\vartheta_1)' \times (\vartheta_2)' \times \mathbb{R}).$$

The continuity in time of (u_t,v_t,z_t) with values in $(\vartheta_1)' \times (\vartheta_2)' \times \mathbb{R}$ can be proved again by density. □

Let us finally consider these weak solutions when the initial and boundary data corresponding to the first string have one more degree of regularity, i.e.,

$$(2.30)\quad p \in H^1(0,T),\ u^0 \in H^1(-\ell_1,0),\ u^1 \in L^2(\Omega_1),\ u^0(0) = z^0,\ p(0) = u^0(-\ell_1).$$

We have the following result.

PROPOSITION 2.7. *Suppose that the initial and boundary data in Proposition* 2.6 *satisfy the further regularity and compatibility conditions* (2.30). *Then, in addition to* (2.24)–(2.25) *we have*

$$(2.31)\qquad u \in C([0,T];H^1(\Omega_1)) \cap C^1([0,T];L^2(\Omega_1)).$$

Furthermore, $u_x(-\ell_1,t) \in L^2(0,T)$ *and there exists some* $C>0$ *such that*

$$\begin{aligned}(2.32)\quad \int_0^T |u_x(-\ell_1,t)|^2 dt \leq C\Big[&||q||^2_{L^2(0,T)} + ||p||^2_{H^1(0,T)} + ||u^0||^2_{H^1(\Omega_1)} + ||u^1||^2_{L^2(\Omega_1)}\\ &+||v^0||^2_{L^2(\Omega_2)} + ||v^1||^2_{(\vartheta_2)'} + |z^0|^2 + |z^1|^2\Big]\end{aligned}$$

Proof. The proof of (2.31) can be carried out in the same way as in Proposition 2.5. Indeed, in R_1 (see Fig. 1), the presence the nonhomogeneous boundary condition does not change the regularity of the solution, which matches that of the initial data. Thus (2.31) holds when restricted to R_1. When studying the regularity of the solution in S_1, the argument is the same as in Proposition 2.5, although since the regularities of the initial data are one degree less, the formulas (2.13)–(2.17) (which no longer have a pointwise interpretation) need to be justified by a density argument.

The regularity property (2.32) is a direct consequence of (2.31) and the local nature of the wave equation. More precisely, the trace regularity

$$(2.33)\qquad \int_0^T |u_x(-\ell_1,t)|^2\,dt \leq C\int_0^T ||u(\cdot,t)||^2_{H^1(\Omega_1)} + ||u_t(\cdot,t)||^2_{L^2(\Omega_1)}\,dt$$

is local and does not depend at all upon whether there is a point mass. Since u has the regularity in (2.31) it follows that the solution map $(p, q, u^0, v^0, z^0, u^1, v^1, z^1) \mapsto u$ is continuous from the space it is defined (with norm defined by the right hand side of (2.32)) into the space in (2.31). Thus

$$\int_0^T \|u(\cdot,t)\|^2_{H^1(\Omega_1)} + \|u_t(\cdot,t)\|^2_{L^2(\Omega_1)}\,dt \le C\Big[\|q\|^2_{L^2(0,T)} + \|p\|^2_{H^1(0,T)} + \|u^0\|^2_{H^1(\Omega_1)}$$
$$+\|u^1\|^2_{L^2(\Omega_1)} + \|v^0\|^2_{L^2(\Omega_2)} + \|v^1\|^2_{(\vartheta_2)'} + |z^0|^2 + |z^1|^2\Big]$$

holds and (2.32) follows. □

3. Control at both extremes. In this section we consider the problem of controlling our system from both ends $x = -\ell_1, \ell_2$. The system now reads

$$(3.1)\qquad \begin{cases} \rho_1 u_{tt} = \sigma_1 u_{xx}, & x \in \Omega_1,\ 0 < t < T,\\ \rho_2 v_{tt} = \sigma_2 v_{xx}, & x \in \Omega_2,\ 0 < t < T,\\ Mz_{tt}(t) + \sigma_1 u_x(0,t) - \sigma_2 v_x(0,t) = 0, & 0 < t < T,\\ u(-\ell_1, t) = p(t), & 0 < t < T,\\ v(\ell_2, t) = q(t), & 0 < t < T,\\ u(0,t) = v(0,t) = z(t), & 0 < t < T,\\ u(x,0) = u^0(x), \quad u_t(x,0) = u^1(x), & x \in \Omega_1,\\ v(x,0) = v^0(x), \quad v_t(x,0) = v^1(x), & x \in \Omega_2,\\ z(0) = z^0, \quad z_t(0) = z^1. \end{cases}$$

We have the following results.

THEOREM 3.1. *Suppose that $T > 2\max(\ell_1\sqrt{\rho_1/\sigma_1}, \ell_2\sqrt{\rho_2/\sigma_2})$. Then, for every*

$$(3.2)\qquad \begin{cases} (u^0, v^0, z^0) \in W_0,\\ (u^1, v^1, z^1) \in (\vartheta_1)' \times (\vartheta_2)' \times \mathbb{R}, \end{cases}$$

there exist controls $p, q \in L^2(0,T)$ such that the solution of (3.1) *satisfies*

$$(3.3)\qquad \begin{cases} u(x,T) = u_t(x,T) = 0, & x \in \Omega_1,\\ v(x,T) = v_t(x,T) = 0, & x \in \Omega_2,\\ z(T) = z_t(T) = 0. \end{cases}$$

Remark 3.1. Concerning Theorem 3.1 we have the following:

(1) As a consequence of Proposition 2.6 the solution of (3.1) (which is defined by transposition) satisfies (2.24)–(2.25).

(2) Due to the linearity and time-reversibility of system (3.1), we deduce that for any initial data as in (3.2) and final data $(\tilde{u}^0, \tilde{v}^0, \tilde{z}^0, \tilde{u}^1, \tilde{v}^1, \tilde{z}^1)$ satisfying the same properties, there exist controls $p, q \in L^2(0,T)$ such that the solution of (3.1) satisfies

$$(3.4)\qquad \begin{cases} u(x,T) = \tilde{u}^0(x), \quad u_t(x,T) = \tilde{u}^1(x), & x \in \Omega_1,\\ v(x,T) = \tilde{v}^0(x), \quad v_t(x,T) = \tilde{v}^1(x), & x \in \Omega_2,\\ z(T) = \tilde{z}^0, \quad z_t(T) = \tilde{z}^1. \end{cases}$$

(3) The controllability space (3.2) is that same as what one obtains when $M = 0$; however, the control time is strictly larger when $\ell_1\sqrt{\rho_1/\sigma_1} \neq \ell_2\sqrt{\rho_2/\sigma_2}$.

THEOREM 3.2. *Suppose that* $T > \ell_1\sqrt{\rho_1/\sigma_1}+\ell_2\sqrt{\rho_2/\sigma_2}$ *and for instance,* $\ell_1\sqrt{\rho_1/\sigma_1} > \ell_2\sqrt{\rho_2/\sigma_2}$. *Then, for every initial data as in* (3.2) *satisfying the additional regularity and compatibility properties*

$$u^0 \in \vartheta_1,\ u^1 \in L^2(\Omega_1),\ u^0(0) = z^0 \tag{3.5}$$

there exist controls $p \in H_0^1(0,T)$ *and* $q \in L^2(0,T)$ *such that the solution of* (3.1) *satisfies* (3.3).

Remark 3.2. Concerning Theorem 3.2 we have the following:

(1) In addition to satisfying (2.24)–(2.25), by Proposition 2.7 the solution of (3.1) also satisfies (2.31).

(2) Due to the linearity, time-reversibility, and well-posedness of the system in the (asymmetric) space (3.2), (3.5), as a consequence of Theorem 3.2, we deduce that we can drive system (3.1) from any initial state in the class (3.2), (3.5) to any terminal state in the same class.

(3) The control time we obtain is the same as in the absence of the mass ($M = 0$). However we only get controllability in the space (3.2) when $T > 2\max\left(\ell_1\sqrt{\rho_1/\sigma_1},\ \ell_2\sqrt{\rho_2/\sigma_2}\right)$.

The proof of Theorem 3.2 will be given at the end of §4.

Applying Lions' HUM (see below), Theorem 3.1 is a direct consequence of the following observability result for solution of the uncontrolled problem:

$$\begin{cases} \rho_1\varphi_{tt} = \sigma_1\varphi_{xx}, & x \in \Omega_1, \quad 0 < t < T, \\ \rho_2\psi_{tt} = \sigma_2\psi_{xx}, & x \in \Omega_2, \quad 0 < t < T, \\ M\zeta_{tt}(t) + \sigma_1\varphi_x(0,t) - \sigma_2\psi_x(0,t) = 0, & 0 < t < T, \\ \varphi(-\ell_1,t) = \psi(\ell_2,t) = 0, & 0 < t < T, \\ \varphi(0,t) = \psi(0,t) = \zeta(t), & 0 < t < T. \end{cases} \tag{3.6}$$

PROPOSITION 3.3. *Let* $T_0 = 2\max(\ell_1\sqrt{\rho_1/\sigma_1}, \ell_2\sqrt{\rho_2/\sigma_2})$ *and suppose that* $T > T_0$. *Then*

(3.7)
$$(T - T_0)\,E_M(0) \le \left(\frac{\max(\ell_1,\ell_2)}{2} + \frac{M}{2(\rho_1+\rho_2)}\right)\int_0^T [\sigma_1|\varphi_x(-1,t)|^2 + \sigma_2|\psi_x(1,t)|^2]dt$$

for every finite-energy solution of (3.6).

Proof of Proposition 3.3. We proceed in several steps.

Step 1. Consider the x-dependent energy:

$$e_1(x) = \frac{1}{2}\int_{(x+\ell_1)\tau_1}^{T-(x+\ell_1)\tau_1} \left[\rho_1|\varphi_t(x,t)|^2 + \sigma_1|\varphi_x(x,t)|^2\right] dt, \quad -\ell_1 \le x \le 0, \tag{3.8}$$

where $\tau_1 = \sqrt{\rho_1/\sigma_1}$. It is easy to check that $e_1(\cdot)$ is nonincreasing. Thus

$$e_1(x) \le e_1(-\ell_1) = \frac{\sigma_1}{2}\int_0^T |\varphi_x(-\ell_1,t)|^2 dt, \quad -\ell_1 \le x \le 0. \tag{3.9}$$

Step 2. Consider

$$e_2(x) = \frac{1}{2} \int_{(\ell_2 - x)\tau_2}^{T-(\ell_2-x)\tau_2} \left[\rho_2 |\psi_t(x,t)|^2 + \sigma_2 |\psi_x(x,t)|^2\right] dt, \quad 0 \le x \le \ell_2, \tag{3.10}$$

where $\tau_2 = \sqrt{(\rho_2/\sigma_2)}$. This energy is nondecreasing and therefore

$$e_2(x) \le e_2(\ell_2) = \frac{\sigma_2}{2} \int_0^T |\psi_x(\ell_2, t)|^2 dt, \quad 0 \le x \le \ell_2. \tag{3.11}$$

Step 3. From (3.9), (3.11) we deduce in particular that

$$\int_\mu^{T-\mu} \int_{-\ell_1}^{0} \left[\rho_1 |\varphi_t(x,t)|^2 + \sigma_1 |\varphi_x(x,t)|^2\right] dxdt + \int_\mu^{T-\mu} \int_0^{\ell_2} \left[\rho_2 |\psi_t(x,t)|^2 + \sigma_2 |\psi_x(x,t)|^2\right] dxdt$$

$$\le \max(\ell_1, \ell_2) \int_0^T \left[\sigma_1 |\varphi_x(-\ell_1, t)|^2 + \sigma_2 |\psi_x(\ell_2, t)|^2\right] dt,$$

where $\mu = \max(\tau_1 \ell_1, \tau_2 \ell_2)$.

Moreover, since $\varphi(0,t) = \psi(0,t) = \zeta(t)$, we have

$$M \int_\mu^{T-\mu} |\zeta_t(t)|^2 dt \le M(r\frac{e_1(0)}{\rho_1} + (2-r)\frac{e_2(0)}{\rho_2}) \,|_{r=\frac{2\rho_1}{\rho_1+\rho_2}}$$

$$\le \frac{M}{\rho_1 + \rho_2} \int_0^T [\sigma_1 |\varphi_x(-1,t)|^2 + \sigma_2 |\psi_x(1,t)|^2] dt.$$

Thus

$$(T - 2\mu) E_M(0) = \int_\mu^{T-\mu} E_M(t) dt$$

$$\le \left(\frac{\max(\ell_1, \ell_2)}{2} + \frac{M}{2(\rho_1 + \rho_2)}\right) \int_0^T [\sigma_1 |\varphi_x(-\ell_1, t)|^2 + \sigma_2 |\psi_x(\ell_2, t)|^2] dt,$$

which is precisely (3.7). □

Remark 3.3. (1) Inequality (3.7) provides explicit constants. In particular, we have explicitly the dependence of the observability constant with respect to the mass. As $M \to 0$ we obtain the usual constant one has for a wave equation with piecewise constant coefficients.

(2) The reverse inequality of (3.7) has been proved in Proposition 2.2.

End of Proof of Theorem 3.1: *Application of HUM.* For any $(\varphi^0, \psi^0, \zeta^0, \varphi^1, \psi^1, \zeta^1)^t \in \mathcal{H}$ we define

$$\Lambda(\varphi^0, \psi^0, \zeta^0, \varphi^1, \psi^1, \zeta^1) = (u_t(0), v_t(0), z_t(0), -u(0), -v(0), -z(0)) \in \mathcal{H}' \text{ (dual of } \mathcal{H}), \tag{3.12}$$

where (u, v, z) is the solution of

$$(3.13) \qquad \begin{cases} \rho_1 u_{tt} = \sigma_1 u_{xx}, & x \in \Omega_1,\ 0 < t < T, \\ \rho_2 v_{tt} = \sigma_2 v_{xx}, & x \in \Omega_2,\ 0 < t < T, \\ M z_{tt}(t) + \sigma_1 u_x(0,t) - \sigma_2 v_x(0,t) = 0, & 0 < t < T, \\ u(-\ell_1, t) = -\varphi_x(-\ell_1, t), & 0 < t < T, \\ v(\ell_2, t) = \psi_x(\ell_2, t), & 0 < t < T, \\ u(0,t) = v(0,t) = z(t), & 0 < t < T, \\ u(x,T) = u_t(x,T) = 0, & x \in \Omega_1, \\ v(x,T) = v_t(x,T) = 0, & x \in \Omega_2, \\ z(T) = z_t(T) = 0, & \end{cases}$$

and $(\varphi, \psi, \zeta, \dot{\varphi}, \dot{\psi}, \dot{\zeta})^t$ is the solution of (2.1) with $y^0 = (\varphi^0, \psi^0, \zeta^0, \varphi^1, \psi^1, \zeta^1)^t$.

In view of Proposition 2.2 we have

$$\varphi_x(-\ell_1, \cdot), \psi_x(\ell_2, \cdot) \in L^2(0,T)$$

and as a consequence of Proposition 2.6, (u, v, z) satisfies (2.24)–(2.25). In particular, $(u_t(0), v_t(0), z_t(0), -u(0), -v(0), -z(0))$ is well defined as an element of $\mathcal{H}'$.

Thus $\Lambda : \mathcal{H} \to \mathcal{H}'$ is continuous and linear.

Using the transposition formula and Proposition 3.3 one obtains

$$\begin{aligned} \langle \Lambda(\varphi^0, \psi^0, \zeta^0, \varphi^1, \psi^1, \zeta^1), (\varphi^0, \psi^0, \zeta^0, \varphi^1, \psi^1, \zeta^1) \rangle &= \int_0^T \left[|\psi_x(\ell_2, t)|^2 + |\varphi_x(-\ell_1, t)^2 \right] dt \\ &\geq C E_M(0). \end{aligned}$$

Taking into account that $(E_M(0))^{1/2}$ is equivalent to the norm of $(\varphi^0, \psi^0, \zeta^0, \varphi^1, \psi^1, \zeta^1)$ in $\mathcal{H}$, we conclude that $\Lambda : \mathcal{H} \to \mathcal{H}'$ is an isomorphism.

Given any $(u^0, v^0, z^0) \in W_0$ and any $(u^1, v^1, z^1) \in \vartheta_1' \times \vartheta_2' \times \mathbb{R}$, we have $(u^1, v^1, z^1) \in W_1'$ and therefore the equation

$$\Lambda(\varphi^0, \psi^0, \zeta^0, \varphi^1, \psi^1, \zeta^1) = (u^1, v^1, z^1, -u^0, -v^0, -z^0)$$

admits a unique solution $(\varphi^0, \psi^0, \zeta^0, \varphi^1, \psi^1, \zeta^1) \in \mathcal{H}$, but this is equivalent to the fact that the solution of (3.13) satisfies

$$\begin{cases} u(x,0) = u^0(x), \quad u_t(x,0) = u^1(x), & x \in \Omega_1, \\ v(x,0) = v^0(x), \quad v_t(x,0) = v^1(x), & x \in \Omega_2, \\ z(0) = z^0, \quad z_t(0) = z^1. & \end{cases}$$

This concludes the proof of Theorem 3.1. □

4. Control at one extreme. In this section we consider the problem of controlling our system from only one extreme-point, for instance, $x = \ell_2$. The system now reads

$$\left\{\begin{array}{ll} \rho_1 u_{tt} = \sigma_1 u_{xx}, & x \in \Omega_1,\ 0<t<T, \\ \rho_2 v_{tt} = \sigma_2 v_{xx}, & x \in \Omega_2,\ 0<t<T, \\ M z_{tt}(t) + \sigma_1 u_x(0,t) - \sigma_2 v_x(0,t) = 0, & 0<t<T, \\ u(0,t) = v(0,t) = z(t), & 0<t<T, \\ u(-\ell_1, t) = 0, & 0<t<T, \\ v(\ell_2, t) = q(t), & 0<t<T, \\ u(x,0) = u^0(x), \quad u_t(x,0) = u^1(x), & x \in \Omega_1, \\ v(x,0) = v^0(x), \quad v_t(x,0) = v^1(x), & x \in \Omega_2, \\ z(0) = z^0, \quad z_t(0) = z^1. & \end{array}\right. \tag{4.1}$$

We have the following result.

THEOREM 4.1. *Suppose that* $T > 2(\ell_1\sqrt{\rho_1/\sigma_1} + \ell_2\sqrt{\rho_2/\sigma_2})$. *Then, for every*

$$\left\{\begin{array}{l} (u^0, u^1) \in \vartheta_1 \times L^2(\Omega_1), \\ (v^0, v^1) \in L^2(\Omega_2) \times (\vartheta_2)', \\ (z^0, z^1) \in \mathbb{R}^2, \end{array}\right. \tag{4.2}$$

such that

$$u^0(0) = z^0 \tag{4.3}$$

there exists a control function $q \in L^2(0,T)$ *such that the solution of* (4.1) *satisfies* (3.3).

Remark 4.1. (1) As a consequence of Proposition 2.6 the solution of (4.1) satisfies (2.24)–(2.25). Furthermore, by Proposition 2.7, it also satisfies (2.31).

(2) Due to the linearity, time-reversibility, and well-posedness of the system in the (asymmetric) space (4.2)–(4.3), as a consequence of Theorem 4.1, we deduce that we can drive system (4.1) from any initial state to any final state in the class (4.2)–(4.3).

(3) The control time we obtain is the same as for the case $M = 0$. However, notice that, when $M = 0$, the controllable space is larger and is given by (3.2). The controllable space we obtain for $M > 0$ is the optimal one.

By HUM (see the proof of Theorem 3.1 for more details), Theorem 4.1 is equivalent to the following observability result for the solutions of the uncontrolled problem (3.6).

PROPOSITION 4.2. *Suppose that* $T > 2\left(\ell_1\sqrt{\rho_1/\sigma_1} + \ell_2\sqrt{\rho_2/\sigma_2}\right)$. *Then there exists* $C = C(T) > 0$ *such that the following holds for every finite-energy solution of* (3.6):

$$\begin{aligned} &||\varphi(\cdot,0)||^2_{L^2(\Omega_1)} + ||\varphi_t(\cdot,0)||^2_{(\vartheta_1)'} + ||\psi(\cdot,0)||^2_{\vartheta_2} + ||\psi_t(\cdot,0)||^2_{L^2(\Omega_2)} \\ &\qquad + |\zeta(0)|^2 + |\zeta_t(0)|^2 \le C\int_0^T |\psi_x(\ell_2,t)|^2 dt. \end{aligned} \tag{4.4}$$

Remark 4.2. This inequality is sharp in the sense that, as pointed out in Proposition 2.7, the reverse holds for all $T > 0$. As a consequence of this double inequality we deduce that the controllable space (4.2)–(4.3) is the optimal one.

Proof. However, first note that by rescaling the spatial variables and renaming the densities ρ_1 and ρ_2 we can obtain the system (4.1) with $\ell_1 = \ell_2 = 1$. Thus it will suffice to prove Proposition 4.2 for the case $\Omega_1 = (-1,0)$ and $\Omega_2 = (0,1)$.

We proceed in several steps.

Step 1. Consider the space-dependent energy $e_2(\cdot)$ defined in (3.10). Since it is nondecreasing we have

$$e_2(x) \le e_2(1) = \frac{\sigma_2}{2}\int_0^T |\psi_x(1,t)|^2 dt, \quad 0 \le x \le 1.$$

This implies, in particular, that

$$\int_{\tau_2}^{T-\tau_2}\int_0^1 \left[\rho_2|\psi_t(x,t)|^2 + \sigma_2|\psi_x(x,t)|^2\right] dxdt \le \sigma_2 \int_0^T |\psi_x(1,t)|^2 dt, \tag{4.5}$$

where $\tau_2 = \sqrt{\rho_2/\sigma_2}$. Taking into account that $\psi(1,t) = 0$ for $\tau_2 \le t \le T - \tau_2$ from Poincaré's inequality and (4.5) we deduce that

$$\int_{\tau_2}^{T-\tau_2} |\psi(0,t)|^2 dt \le C\int_0^T |\psi_x(1,t)|^2 dt$$

and therefore, since $\varphi(0,t) = \psi(0,t) = \zeta(t)$,

$$\int_{\tau_2}^{T-\tau_2} \left[\, |\varphi(0,t)|^2 + |\zeta(t)|^2\right] dt \le C\int_0^T |\psi_x(1,t)|^2 dt. \tag{4.6}$$

On the other hand, since $e_2(0) \le e_2(1)$ we have

$$\int_{\tau_2}^{T-\tau_2} \left[\rho_2|\psi_t(0,t)|^2 + \sigma_2|\psi_x(0,t)|^2\right] dt \le \sigma_2\int_0^T |\psi_x(1,t)|^2 dt \tag{4.7}$$

and therefore, since $\zeta(t) = \psi(0,t)$,

$$\int_{\tau_2}^{T-\tau_2} \rho_2|\zeta_t(t)|^2 dt \le \sigma_2\int_0^T |\psi_x(1,t)|^2 dt. \tag{4.8}$$

Furthermore, since $\sigma_1\varphi_x(0,t) = -M\zeta_{tt}(t) + \sigma_2\psi_x(0,t)$, in view of (4.7)–(4.8) we have

$$\|\varphi_x(0,t)\|^2_{H^{-1}(\tau_2,T-\tau_2)} \le C\int_0^T |\psi_x(1,t)|^2 dt. \tag{4.9}$$

Step 2. As a consequence of (4.6) and (4.9) we have

$$\|\varphi(0,t)\|^2_{L^2(\tau_2,T-\tau_2)} + \|\varphi_x(0,t)\|^2_{H^{-1}(\tau_2,T-\tau_2)} \le C\int_0^T |\psi_x(1,t)|^2 dt. \tag{4.10}$$

The well-posedness of the one-dimensional wave equation as an evolution in x-variable allows us to prove that (see [17], [18] for details)

$$\int_{-1}^{0}\int_{\tau_2-\tau_1 x}^{T-\tau_2+\tau_1 x} |\varphi(x,t)|^2 dtdx \le C\left[\|\varphi(0,t)\|^2_{L^2(\tau_2,T-\tau_2)} + \|\varphi_x(0,t)\|^2_{H^{-1}(\tau_2,T-\tau_2)}\right], \tag{4.11}$$

where $\tau_1 = \sqrt{\rho_1/\sigma_1}$. Combining (4.10) and (4.11), we deduce that

$$\int_{\tau_2+\tau_1}^{T-(\tau_2+\tau_1)}\int_{1}^{0} |\varphi(x,t)|^2 dxdt \le C\int_{0}^{T} |\varphi_x(1,t)|^2 dt. \tag{4.12}$$

Step 3. Set $\mu = \tau_1+\tau_2$ and let $\varepsilon > 0$ be such that

$$T - 2\varepsilon > 2\mu \tag{4.13}$$

and $\eta = \eta(t) \in C^1(\mu, T-\mu)$ such that

$$\begin{cases} 0 \le \eta(t) \le 1, \quad \mu \le t \le T-\mu, \\ \eta(\mu) = \eta(t-\mu) = 0, \\ \eta(t) = 1, \quad \mu+\varepsilon \le t \le T-\mu-\varepsilon, \\ \frac{|\eta_t|^2}{\eta} \in L^\infty(\mu, T-\mu). \end{cases} \tag{4.14}$$

Let us introduce the function $\phi = \phi(x,t)$ such that

$$\begin{cases} -\phi_{xx} = \varphi, \quad -1 < x < 0, \quad \mu \le t \le T-\mu, \\ \phi(-1,t) = \phi_x(0,t) = 0, \quad \mu \le t \le T-\mu. \end{cases} \tag{4.15}$$

We have

$$-\int_{-1}^{0} \varphi_{xx}(x,t)\phi(x,t)dx = \int_{-1}^{0} |\varphi(x,t)|^2 dx - \varphi_x(0,t)\phi(0,t), \quad \mu \le t \le T-\mu \tag{4.16}$$

and

$$\int_{-1}^{0} \varphi_t(x,t)\phi_t(x,t)dx = \int_{-1}^{0} |\phi_{tx}(x,t)|^2 dx = \|\varphi_t(\cdot,t)\|^2_{(\vartheta_1)'}, \quad \mu \le t \le T-\mu. \tag{4.17}$$

We multiply by $\phi\eta$ the equation satisfied by φ and integrate in the region $(x,t) \in \Omega_1 \times (\mu, T-\mu)$ to get, in view of (4.16)–(4.17),

$$\begin{aligned} \rho_1 \int_{\mu}^{T-\mu} \|\varphi_t(\cdot,t)\|^2_{\vartheta_1'}\eta(t)dt = &-\rho_1 \int_{\mu}^{T-\mu}\int_{-1}^{0} \varphi_t\phi\eta_t dxdt + \sigma_1 \int_{\mu}^{T-\mu}\int_{-1}^{0} |\varphi|^2\eta dxdt \\ &- \sigma_1 \int_{\mu}^{T-\mu} \varphi_x(0,t)\phi(0,t)\eta(t)dt. \end{aligned} \tag{4.18}$$

On the other hand,

$$\left|\int_\mu^{T-\mu}\int_{-1}^{0}\varphi_t\phi\eta_t dxdt\right| \le \frac{1}{2}\int_\mu^{T-\mu}\|\varphi_t(\cdot,t)\|^2_{\vartheta_1'}\eta(t)dt + \frac{1}{2}\int_\mu^{T-\mu}\|\phi(\cdot,t)\|^2_{\vartheta_1}\frac{|\eta_t|^2}{\eta}dt. \tag{4.19}$$

Note that

$$\|\phi(\cdot,t)\|_{\vartheta_1} = \|\varphi(\cdot,t)\|_{\vartheta_1'} \le C\|\varphi(\cdot,t)\|_{L^2(\Omega_1)}, \quad \mu \le t \le T-\mu. \tag{4.20}$$

Combining (4.18)–(4.20) we deduce that

$$\int_\mu^{T-\mu}\|\varphi_t(\cdot,t)\|^2_{\vartheta_1'}\eta(t)dt \le C_1\left\{\int_\mu^{T-\mu}\int_{-1}^{0}\varphi^2 dxdt + \sigma_1\left|\int_\mu^{T-\mu}\varphi_x(0,t)\phi(0,t)\eta(t)dt\right|\right\}. \tag{4.21}$$

Since $\sigma_1\varphi_x(0,t) = \sigma_2\psi_x(0,t) - M\zeta_{tt}(t)$, we have

$$\begin{aligned}\sigma_1\int_\mu^{T-\mu}\varphi_x(0,t)\phi(0,t)\eta(t)dt &= \sigma_2\int_\mu^{T-\mu}\psi_x(0,t)\phi(0,t)\eta(t)dt\\ &\quad - M\int_\mu^{T-\mu}\zeta_{tt}(t)\phi(0,t)\eta(t)dt.\end{aligned} \tag{4.22}$$

On the other hand,

$$\int_\mu^{T-\mu}\zeta_{tt}(t)\phi(0,t)\eta(t)dt = -\int_\mu^{T-\mu}\zeta_t(t)\phi_t(0,t)\eta(t)dt - \int_\mu^{T-\mu}\zeta_t(t)\phi(0,t)\eta_t(t)dt. \tag{4.23}$$

Now, observe that

$$|\phi_t(0,t)| \le C\|\phi_t(\cdot,t)\|_{\vartheta_1} \le C\|\varphi_t(\cdot,t)\|_{\vartheta_1'} \quad \mu \le t \le T-\mu.$$

Therefore, there exists $C>0$ such that

$$\left|\int_\mu^{T-\mu}\zeta_t(t)\phi_t(0,t)\eta(t)dt\right| \le \frac{1}{2}\int_\mu^{T-\mu}\|\varphi_t(\cdot,t)\|^2_{\vartheta_1'}\eta(t)dt + C\int_\mu^{T-\mu}|\zeta_t(t)|^2dt. \tag{4.24}$$

Moreover

$$|\phi(0,t)| \le C\|\phi(\cdot,t)\|_{\vartheta_1} \le C\|\varphi(\cdot,t)\|_{L^2(-1,0)}$$

and thus

$$\left|\int_\mu^{T-\mu}\zeta_t(t)\phi(0,t)\eta_t dt\right| \le C\left\{\int_\mu^{T-\mu}\int_{-1}^{0}\varphi^2 dxdt + \int_\mu^{T-\mu}|\zeta_t(t)|^2dt\right\} \tag{4.25}$$

and

$$\left|\int_\mu^{T-\mu}\psi_x(0,t)\phi(0,t)\eta dt\right| \le C\left\{\int_\mu^{T-\mu}\int_{-1}^{0}\varphi^2 dxdt + \int_\mu^{T-\mu}|\psi_x(0,t)|^2dt\right\}. \tag{4.26}$$

Combining (4.21)–(4.26) with $\varepsilon > 0$ small enough, we deduce that

$$\begin{aligned}\int_{\mu+\varepsilon}^{T-\mu-\varepsilon} \|\varphi_t(\cdot,t)\|^2_{\vartheta_1'} dt &\leq \int_{\mu}^{T-\mu} \|\varphi_t(\cdot,t)\|^2_{\vartheta_1'} \eta(t) dt \\ &\leq C\left\{ \int_{\mu}^{T-\mu}\int_{-1}^{0} \varphi^2 dx dt + \int_{\mu}^{T-\mu} [\,|\zeta_t(t)|^2 + |\psi_x(0,t)|^2] dt \right\}.\end{aligned} \tag{4.27}$$

Step 4. As a consequence of (4.5), (4.6), (4.8), (4.12), and (4.27) we have

$$\begin{aligned}\int_{\mu+\varepsilon}^{T-\mu-\varepsilon} \left[\int_{-1}^{0} \varphi^2 dx + \|\varphi_t(\cdot,t)\|^2_{\vartheta_1'} + \int_0^1 \left[\,|\psi_x|^2 + |\psi_t|^2\right] dx + |\zeta(t)|^2 + |\zeta_t(t)|^2 \right] dt \\ \leq C \int_0^T |\psi_x(1,t)|^2 dt.\end{aligned} \tag{4.28}$$

Recall that, in virtue of Proposition 2.7, system (3.6) is well posed in the space

$$\begin{cases} \varphi \in L^2(-1,0), & \varphi_t \in \vartheta_1', \\ \psi \in \vartheta_2, & \psi_t \in L^2(0,1), \\ \zeta, \zeta_t \in \mathbb{R} \end{cases}$$

with compatibility condition

$$\psi(0) = \zeta.$$

Therefore, (4.4) is an immediate consequence of (4.28) and the time-reversibility of system (3.6). □

We are now in a position to prove Theorem 3.2.

Proof of Theorem 3.2. Theorem 3.2 is a direct consequence by HUM (see proof of Theorem 3.1) of the following observability result for the uncontrolled problem (3.6).

PROPOSITION 4.3. *Suppose that* $T > \ell_1\sqrt{\rho_1/\sigma_1} + \ell_2\sqrt{\rho_2/\sigma_2}$ *and* $\ell_1\sqrt{\rho_1/\sigma_1} > \ell_2\sqrt{\rho_2/\sigma_2}$. *Then there exists* $C(T) > 0$ *such that the following holds for every finite energy solution of* (3.6):

$$\begin{aligned}\|\varphi(\cdot,0)\|^2_{L^2(\Omega_1)} + \|\varphi_t(\cdot,0)\|^2_{(\vartheta_1)'} + \|\psi(\cdot,0)\|^2_{\vartheta_2} + \|\psi_t(\cdot,0)\|^2_{L^2(\Omega_2)} \\ + |\xi(0)|^2 + |\xi_t(0)|^2 \leq C\left[\|\varphi_x(-\ell_1,t)\|^2_{H^{-1}(0,T)} + \|\psi_x(\ell_2,t)\|^2_{L^2(0,T)}\right].\end{aligned} \tag{4.29}$$

Proof of Proposition 4.3. As in the proof of Proposition 4.2 we assume that $\ell_1 = \ell_2 = 1$ without loss of generality.

Let τ_1 and τ_2 be the same as in the proof of Proposition 4.2 and let $\mu = \frac{\tau_1+\tau_2}{2}$. For any sufficiently small $\varepsilon > 0$ we have

$$\begin{aligned}\int_{\mu+\varepsilon}^{T-\mu-\varepsilon} \left[\|\varphi(\cdot,t)\|^2_{L^2\left(-1,\frac{\tau_2-\tau_1}{2\tau_1}\right)} + \|\varphi_t(\cdot,t)\|^2_{H^{-1}\left(-1,\frac{\tau_2-\tau_1}{2\tau_1}\right)}\right] dt \\ \leq C\|\varphi_x(-1,t)\|^2_{H^{-1}(0,T)}\end{aligned} \tag{4.30}$$

and

$$\begin{aligned}
&\int_{\mu+\varepsilon}^{T-\mu-\varepsilon} \left[||\varphi(\cdot,t)||^2_{L^2\left(\frac{\tau_2-\tau_1}{2\tau_1},0\right)} + ||\varphi_t(\cdot,t)||^2_{\left(H^1\left(\frac{\tau_2-\tau_1}{2\tau_1},0\right)\right)'} \right] dt \\
&\quad + \int_{\mu+\varepsilon}^{T-\mu-\varepsilon} \int_0^1 [|\psi_t(x,t)|^2 + |\psi_x(x,t)|^2] dx dt + \int_{\mu+\varepsilon}^{T-\mu-\varepsilon} [|\xi(t)|^2 + |\xi_t(t)|^2] dt \\
&\quad \leq C \int_0^T |\psi_x(1,t)|^2 dt.
\end{aligned} \tag{4.31}$$

The inequality (4.30) is a standard estimate that holds for the wave equation (which we may apply here due to the finite speed of propagation) while (4.31) is proved in the same way that (4.28) was.

Since

$$\int_{\mu+\varepsilon}^{T-\mu-\varepsilon} ||\varphi_t(\cdot,t)||^2_{(\vartheta_1)'} \leq C \int_{\mu+\varepsilon}^{T-\mu-\varepsilon} \left[||\varphi_t(\cdot,t)||^2_{H^{-1}\left(-1,\frac{\tau_2-\tau_1}{2\tau_1}\right)} + ||\varphi_t(\cdot,t)||^2_{\left(H^1\left(\frac{\tau_2-\tau_1}{2\tau_1},0\right)\right)'} \right] dt,$$

the inequalities (4.30) and (4.31) can be combined and we deduce easily (4.29) as in Step 4 of the proof of Proposition 4.2. □

5. Representation of controllability spaces by Fourier series.

In this section we give a characterization of the controllable and observable spaces for (4.1) in terms of nonharmonic Fourier series. For simplicity, we limit our analysis to the case where

$$\ell_1 = \ell_2 = \sigma_1 = \sigma_2 = \rho_1 = \rho_2 = 1, \tag{5.1}$$

although a similar analysis is valid, for example, when the above parameters are rational.

5.1. Spectral analysis.

We begin with a spectral analysis of the operator $\mathcal{A}$ in (2.1). Since $\mathcal{A}$ is skew adjoint with compact inverse, $\sigma(\mathcal{A})$ consists of a discrete sequence of imaginary eigenvalues. We seek nontrivial solutions y for

$$\mathcal{A}y = i\omega y, \quad \omega \in \mathbb{R}. \tag{5.2}$$

We obtain nontrivial solutions only when $\omega \in S_1 \cup S_2$, where

$$\begin{cases} S_1 = (k\pi)_{k\in\mathbb{Z}\setminus\{0\}}, \\ S_2 = (\omega_k)_{k=0^-,0^+,\pm1,\pm2,\ldots}, \end{cases} \tag{5.3}$$

where $\omega_{0^+} = -\omega_{0^-}$ and for $k \in \mathbb{N}$, $\omega_k = -\omega_{-k}$, where ω_{k-1} is the kth positive root of

$$M\omega = 2\cot\omega. \tag{5.4}$$

It is easy to see from (5.4) that $|\omega_k - k\pi| \to 0$ as $k \to \infty$. In fact, if we let

$$\delta_k = \omega_k - k\pi, \quad k \in \mathbb{N}, \tag{5.5}$$

a simple calculation using Taylor's formula applied to (5.4) gives

$$\delta_k = \frac{2}{Mk\pi} + \mathcal{O}(k^{-2}) \quad \text{as } k \to \infty. \tag{5.6}$$

The eigenfunctions of $\mathcal{A}$ corresponding to the eigenvalue ω are given by

$$\varphi_\omega(x) = \begin{pmatrix} U_\omega \\ V_\omega \\ Z_\omega \\ \dot{U}_\omega \\ \dot{V}_\omega \\ \dot{Z}_\omega \end{pmatrix} = \begin{pmatrix} \frac{a}{\omega} \sin \omega(x+1) \\ \frac{1}{\omega} \sin \omega(x-1) \\ -\frac{(1-a)}{M\omega^2} \cos \omega \\ ia \sin \omega(x+1) \\ i \sin \omega(x-1) \\ -\frac{i(1-a)}{M\omega} \cos \omega \end{pmatrix}, \tag{5.7}$$

where $a = 1$ when $\omega \in S_1$ and $a = -1$ when $\omega \in S_2$.

Under the above normalization there exist positive constants C_1, C_2 for which

$$C_1 \leq \|\varphi_\omega\|_{\mathcal{H}} \leq C_2 \quad \forall \omega \in \sigma(\mathcal{A}). \tag{5.8}$$

Remark 5.1. The form of the eigenfunctions in (5.7) shows that each spectral class, S_1 and S_2, has its own physical significance; namely, if $\omega \in S_1$ then φ_ω describes a sinusoidal motion of the string which does not move the mass, while if $\omega \in S_2$ then φ_ω describes an even, piecewise sinusoidal motion of the string with a jump in the spatial derivative at the point mass. It is insightful to note that, although $(\varphi_\omega)_{i\omega \in \sigma(\mathcal{A})}$ forms an orthogonal set, $\|V_{k\pi} - V_{\omega_k}\|_{H^1(\Omega_2)} + \|\dot{V}_{k\pi} - \dot{V}_{\omega_k}\|_{L^2(\Omega_2)} \to 0$ as $k \to \infty$. It thus becomes increasingly difficult to distinguish such consecutive modes (as the frequency gets large) by only observing the v (or only the w) portion of the state. This explains why, in terms of the eigenfunctions, we obtain an asymmetric observability (and hence also controllability) space when we only observe (or control) at an endpoint.

5.2. Reduction to moment problem. Let us consider a general class of control problems which will include the problem (4.1).

Let $b \in \mathcal{D}(\mathcal{A})'$ and consider the system

$$\dot{y} = \mathcal{A}y + bg(t), \quad y(0) = 0, \tag{5.9}$$

where $g \in L^2(0,T)$. A unique mild solution $y \in C([0,T]; D(\mathcal{A})')$ is given by

$$y(t) = \Phi_t g, \tag{5.10}$$

where for $0 \leq t \leq T$, $\Phi_t : L^2(0,T) \to \mathcal{D}(\mathcal{A})'$ is given by

$$\Phi_t h = \int_0^t e^{\mathcal{A}(t-s)} bh(s) ds. \tag{5.11}$$

This notion of mild solution coincides with that of the weak solutions in the sense of transposition introduced in §2. (Note that $\mathcal{D}(\mathcal{A})' = W_0 \times W_1'$.) We adopt here this notation and terminology of the theory of semigroups for the sake of clarity and brevity.

The central problem for controllability of (5.9) is to determine the range of Φ_t. By integrating (5.10) against φ_ω we obtain the modal solutions

$$y_\omega(t) = \int_0^t e^{i\omega(t-s)} b_\omega g(s) ds, \quad \omega \in S_1 \cup S_2, \tag{5.12}$$

where

$$y_\omega(t) = (y(t), \varphi_\omega), \quad b_\omega = (b, \varphi_w),$$

and $(\cdot,\cdot)$ denotes the duality pairing of $\mathcal{D}(\mathcal{A})'$ and $\mathcal{D}(\mathcal{A})$ relative to $\langle\cdot,\cdot\rangle_{\mathcal{H}}$. Thus $x = \sum_{\omega\in\sigma(\mathcal{A})} x_\omega \varphi_\omega \in \mathcal{R}(\Phi_T)$ if and only if there exist $g \in L^2(0,T)$ for which

$$x_\omega = \int_0^T e^{i\omega s} b_w g(s) ds \quad \forall \omega \in S_1 \cup S_2. \tag{5.13}$$

Hence the problem of determining $\mathcal{R}(\Phi_T)$ has been replaced by one of determining the moment space (i.e., the sequences (x_ω) associated with some $g \in L^2(0,T)$ in (5.13)) of the moment problem (5.13).

5.3. Some general results on moment problems. Before determining the moment space of (5.13) we first give some background and some results of independent interest.

A Riesz basis for a Hilbert space X is the image of an orthonormal basis through a bounded, invertible operator $B : X \to X$.

The following is due to Ullrich [15].

THEOREM 5.1. *Let $(\sigma_n)_{n\in\mathbb{Z}}$ be a sequence of distinct, noninteger, complex numbers with* $\lim_{|n|\to\infty} |\sigma_n - n| = 0$. *Then*

$$(e^{int})_{n\in\mathbb{Z}} \cup \left(\frac{e^{int} - e^{i\sigma_n t}}{n - \sigma_n}\right)_{n\in\mathbb{Z}} \tag{5.14}$$

forms a Riesz basis for $L^2(0,4\pi)$.

COROLLARY 5.2. *For each $T \geq 4\pi$ the moment problem*

$$\int_0^T e^{int} f(t)\, dt = a_n, \quad \int_0^T e^{i\sigma_n t} f(t)\, dt = b_n; \quad n \in \mathbb{Z}, \tag{5.15}$$

has a solution $f \in L^2(0,T)$ if and only if

$$\left(\frac{a_n - b_n}{n - w_n}\right) \in \ell^2, \quad (a_n) \in \ell^2, \quad (b_n) \in \ell^2. \tag{5.16}$$

Proof. It is obvious that if the result is true when $T = 4\pi$, then it is true for $T > 4\pi$. Hence we may assume $T = 4\pi$. By Theorem 5.1 we know that

$$\int_0^T e^{int} f(t) dt = c_k, \quad \int_0^T \frac{e^{int} - e^{i\sigma_n t}}{n - \sigma_n} f(t)\, dt = d_k \tag{5.17}$$

has a solution if and only if $(c_k) \in \ell^2$ and $(d_k) \in \ell^2$. Putting $a_n = c_n - d_n(n - \sigma_n)$ and $b_n = c_n$, $n \in \mathbb{Z}$ we recover (5.15).

Since

$$(c_n) \in \ell^2 \text{ and } (d_n) \in \ell^2 \Leftrightarrow \text{(5.16) holds}$$

the result holds. $\square$

When applied to the moment problem (5.13), Corollary 5.2 completely describes the moment space. However it will be more convenient to use a dual version of Corollary 5.2, which we give below after we develop some notation.

Let

$$\mathcal{M} = \{(a_n) \cup (b_n) : (a_n), (b_n) \text{ satisfy (5.16)}\}.$$

Then $\mathcal{M}$ becomes a Hilbert space when endowed with the inner product

$$(5.18)\quad \langle (a_n)\cup(b_n),(\hat{a}_n)\cup(\hat{b}_n)\rangle_{\mathcal{M}} = \langle (a_n),(\hat{a}_n)\rangle_{\ell^2} + \left\langle \left(\frac{a_n-b_n}{\sigma_n-n}\right), \left(\frac{\hat{a}_n-\hat{b}_n}{\sigma_n-n}\right)\right\rangle_{\ell^2}.$$

One easily computes $\mathcal{M}'$, the dual space of $\mathcal{M}$ relative to the ℓ^2 inner product, to be the Hilbert space of sequences $(c_k)_{k\in\mathbb{Z}} \cup (d_k)_{k\in\mathbb{Z}}$ with $(c_k+d_k)\in\ell^2$ and $([\sigma_k-k][c_k-d_k])\in\ell^2$ with corresponding scalar product given by

$$(5.19)\quad \begin{aligned}\langle (c_k)\cup(d_k),(\hat{c}_k)\cup(\hat{d}_k)\rangle_{\mathcal{M}'} &= \langle([\sigma_k-k][c_k-d_k]),([\sigma_k-k][\hat{c}_k-\hat{d}_k])\rangle_{\ell^2}\\ &\quad+\langle(c_k+d_k),(\hat{c}_k+\hat{d}_k)\rangle_{\ell^2}.\end{aligned}$$

COROLLARY 5.3. *For any $T>0$ there exists $M>0$ such that for any $N\in\mathbb{N}$*

$$(5.20)\quad \int_0^T\left|\sum_{k=-N}^{N} a_k e^{ikt}+b_k e^{i\sigma_k t}\right|^2 dt \le M\|(a_k)\cup(b_k)\|^2_{\mathcal{M}'}.$$

Furthermore, there exists $m>0$ such that for any $N\in\mathbb{N}$

$$(5.21)\quad \int_0^{4\pi}\left|\sum_{k=-N}^{N} a_k e^{ikt}+b_k e^{i\sigma_k t}\right|^2 dt \ge m\|(a_k)\cup(b_k)\|^2_{\mathcal{M}'}.$$

Proof. Let $\mathcal{C}_T : L^2(0,T)\to\mathcal{M}$ by

$$\mathcal{C}_T f = (a_k)\cup(b_k):\ (5.15)\text{ holds.}$$

By Theorem 5.1 and the proof of Corollary 5.2, $\mathcal{C}_T$ is continuous for all $T>0$ and becomes onto when $T\ge 4\pi$. Equation (5.20) is simply the statement that $\mathcal{C}_T^*$ is continuous for $T>0$ while (5.21) states that $\mathcal{C}_T^*$ is bounded away from zero for $T\ge 4\pi$. □

5.4. Fourier description of observable space. We close this section with a description of the observable space in terms of nonharmonic Fourier series. In particular, we obtain a slight improvement of Theorem 4.1 for the case where (5.1) holds and also examine the dependence of the observability in terms of the frequency of the initial data.

PROPOSITION 5.4. *Assume* (5.1) *and let $y=(u,v,z,\dot{u},\dot{v},\dot{z})^t$ be a finite-energy solution of* (2.1) *with*

$$y^0=\sum_{k\in\mathbb{Z}\setminus\{0\}} a_k\varphi_{k\pi}+\sum_{\omega_k\in S_2} b_k\varphi_{\omega_k}.$$

Then for any $T>0$ there exists $C>0$ for which

$$(5.22)\quad \int_0^T |v_x(1,t)|^2dt \le C\left(b_{0^-}^2+b_{0^+}^2+\sum_{k\in\mathbb{Z}\setminus\{0\}}\delta_k^2(b_k-a_k)^2+(b_k+a_k)^2\right).$$

Furthermore, there exists $c>0$ for which

$$(5.23)\quad \int_0^4 |v_x(1,t)|^2dt \ge c\left(b_{0^-}^2+b_{0^+}^2+\sum_{k\in\mathbb{Z}\setminus\{0\}}\delta_k^2(b_k-a_k)^2+(b_k+a_k)^2\right).$$

In particular, Theorem 4.1 *and Proposition* 4.2 *remain true when* $T = 4$ *and* (5.1) *holds.*

Proof. For $h = (u, v, z, \dot{u}, \dot{v}, \dot{z})^t \in \mathcal{D}(\mathcal{A})$ define $b^* : \mathcal{D}(\mathcal{A}) \to \mathbb{R}$ by

$$b^* h = v_x(1).$$

Then b can be viewed as an element of $\mathcal{D}(\mathcal{A})'$ and we are in the setting of (5.9). Under the normalization of the eigenfunctions taken in (5.7) we have

$$b^* \varphi_w = 1 \quad \forall w \in S_1 \cup S_2.$$

It follows that for $T > 0$

$$\int_0^T |b^* y|^2 dt = \int_0^T \left| \sum_{k \in \mathbb{Z} \setminus \{0\}} a_k e^{ik\pi t} + \sum_{\omega_k \in S_2} b_k e^{i\omega_k t} \right|^2 dt. \tag{5.24}$$

A Riesz basis of exponentials $(e^{ir_k t})_{k \in \mathbb{Z}}$ is stable with respect to the perturbation $r_0 \to \tilde{r}_0$ provided $r_0 \neq r_k, k = \pm 1, \pm 2, \ldots$, (see [16]). Therefore Theorem 5.1 and its corollaries remain true when the exponential 1 is replaced by $\exp t\omega_{0-}$. Thus (5.22) and (5.23) follow from (5.24) and Corollary 5.3.

Define E as the completion of $\mathcal{H}$ with respect to the norm

$$\left\| \sum_{k \in \mathbb{Z} \setminus \{0\}} a_k \varphi_{k\pi} + \sum_{\omega_k \in S_2} b_k \varphi_{\omega_k} \right\|_E = \|(a_k) \cup (b_k)\|_{\mathcal{M}'}. \tag{5.25}$$

Corollary 5.3 and (5.22) show that the map $E \to \mathbb{R}$ defined by

$$y^0 \to \left(\int_0^T |b^* y|^2 dt \right)^{1/2}$$

defines a norm on E for any $T \geq 4$. By Proposition 4.2, an equivalent norm on E is given by the left side of (4.4). It thus follows that the inequality (4.4) remains valid when ((5.1) holds and) $T \geq 4$. Consequently Theorem 4.1 remains true when ((5.1) holds and) $T \geq 4$. □

Let us now give a characterization of the observable space E defined in (5.25) in terms of the eigenfunctions.

Let $p_0 = \phi_{\omega_{0-}}$, $q_0 = \phi_{\omega_{0+}}$ and for $k \in \mathbb{Z} \setminus \{0\}$ define

$$p_k = \frac{\varphi_{k\pi} + \varphi_{\omega_k}}{2}, \quad q_k = \frac{\varphi_{k\pi} - \varphi_{\omega_k}}{2\delta_k}.$$

LEMMA 5.5. $(p_k)_{k \in \mathbb{Z}} \cup (q_k)_{k \in \mathbb{Z}}$ *forms a Riesz basis for the space* E *defined by* (5.25). *In particular,*

$$E = \left\{ \sum_{k \in \mathbb{Z}} c_k p_k + d_k q_k : (c_k) \in \ell^2, (d_k) \in \ell^2 \right\}.$$

Proof. From (5.6) and (5.19), an equivalent representation for $\mathcal{M}'$ as it applies to our problem is

$$\mathcal{M}' = \left\{ (a_k) \cup (b_k) : b_{0+}^2 + b_{0-}^2 + \sum_{k \in \mathbb{Z} \setminus \{0\}} ((a_k - b_k)\delta_k)^2 + (a_k + b_k)^2 < \infty \right\}.$$

Thus the topology obtained by making $(p_k) \cup (q_k)$ form an orthonormal basis must also be equivalent to the natural one given by (5.25). □

We can now easily prove the following result, which describes the dependence of the observability upon the frequency.

PROPOSITION 5.6. *Assume* (5.1) *and let* $y = (u, v, z, \dot{u}, \dot{v}, \dot{z})^t$ *be a solution of* (2.1) *with*

$$y^0 = \sum_{k=-N}^{N} c_k p_k + d_k q_k.$$

Then there exists $C > 0$ *independent of* $N > 0$ *for which*

$$\left(\int_0^4 |v_x(1,t)|^2 dt \right)^{1/2} \geq \frac{C}{N} \|y^0\|_{\mathcal{H}}. \tag{5.26}$$

Furthermore, the bound is sharp in the sense that if $y^0 = q_N$ *then the inequality in* (5.26) *is reversible for some larger value of* C.

Proof. First note that $(p_k) \cup (q_k)$ form an orthogonal system on $\mathcal{H}$. In particular,

$$\|y^0\|^2_{\mathcal{H}} \leq C_1 \sum_{k=-N}^{N} |c_k|^2 + \frac{|d_k|^2}{\delta_k^2}, \tag{5.27}$$

where C_1 is independent of N. By Proposition 5.4 and Lemma 5.5 there exists $C_2 > 0$, independent of N for which

$$\int_0^4 |v_x(1,t)|^2 dt \geq C_2 \sum_{k=-N, k\neq 0}^{N} |c_k|^2 + |d_k|^2. \tag{5.28}$$

Let $\Delta_N = \min\{1, \delta_1^2, \delta_2^2, \ldots \delta_N^2\}$. Since

$$\sum_{k=-N}^{N} |c_k|^2 + |d_k|^2 \geq \Delta_N \sum_{k=-N}^{N} |c_k|^2 + \frac{|d_k|^2}{\delta_k^2}, \tag{5.29}$$

(5.26) follows from (5.6). To show the optimality, it is enough to see that all the inequalities are reversible when $y^0 = q_N$. For (5.27) this is obvious, for (5.28) the reversibility follows from Lemma 5.5, and for (5.29) we have equality for N sufficiently large by (5.6). Thus the reverse inequality of (5.26) holds for all N by making C sufficiently large. □

Remark 5.2. In the previous proof, the constants C_1 and C_2 can be shown to be independent of M for $M \in (1, \infty)$. Thus (5.29) shows that the constant C in the statement of Proposition 5.6 is proportional to $\Delta_N^{1/2}$, i.e., to M^{-1} as $M \to \infty$. Thus for solutions of a fixed energy level, the frequencies one can observe above a certain threshhold level vary inversely with the mass. As $M \to 0$, the numbers Δ_N in (5.29) approach 1 for all N, but not uniformly. Thus as $M \to 0$, for fixed N, we obtain the same observability constant as with the string without a point mass.

6. Some results on boundary stabilization. In this section we examine the problem of stabilization by velocity feedback at one or both ends. Thus we will be interested in the decay properties of solutions of the system

$$\tag{6.1}\begin{cases} \rho_1 u_{tt} = \sigma_1 u_{xx}, & x \in \Omega_1,\ t > 0, \\ \rho_2 v_{tt} = \sigma_2 v_{xx}, & x \in \Omega_2,\ t > 0, \\ M z_{tt}(t) + \sigma_1 u_x(0,t) - \sigma_2 v_x(0,t) = 0, & t > 0, \\ u(0,t) = v(0,t) = z(t), & t > 0, \\ u(x,0) = u^0(x),\ u_t(x,0) = u^1(x), & x \in \Omega_1, \\ v(x,0) = v^0(x),\ v_t(x,0) = v^1(x), & x \in \Omega_2, \\ z(0) = z^0,\ z_t(0) = z^1 \end{cases}$$

under the following two types of boundary conditions:

$$\tag{6.2}\begin{cases} u(-\ell_1, t) = 0, & t > 0, \\ \sigma_2 v_x(\ell_2, t) + \gamma v_t(\ell_2, t) = 0, & t > 0 \end{cases}$$

and

$$\tag{6.3}\begin{cases} \sigma_1 u_x(-\ell_1, t) - \gamma u_t(-\ell_1, t) = 0, & t > 0, \\ \sigma_2 v_x(\ell_2, t) + \gamma v_t(\ell_2, t) = 0, & t > 0, \end{cases}$$

where γ is positive.

In (6.2) we are introducing some damping on the system at the extreme-point $x = \ell_2$ and in (6.3) at both extremes $x = -\ell_1, \ell_2$.

The effect of the damping can be seen by noting that (formally) the energy of solutions of (6.1)–(6.2) and (6.1), (6.3) satisfies

$$\frac{dE_M}{dt}(t) = -\gamma |v_t(\ell_2, t)|^2$$

and

$$\frac{dE_M}{dt}(t) = -\gamma [\, |u_t(-\ell_1, t)|^2 + |v_t(\ell_2, t)|^2],$$

respectively.

Standard semigroup theory allows us to prove the following two facts:

(i) If $y^0 = (u^0, v^0, z^0, u^1, v^1, z^1)^t$ and

$$\tag{6.4}\begin{cases} y^0 \in H^1(\Omega_1) \times H^1(\Omega_2) \times \mathbb{R} \times L^2(\Omega_1) \times L^2(\Omega_2) \times \mathbb{R}, \\ u^0(0) = v^0(0) = z^0 \quad (u^0(-\ell_1) = 0 \text{ in case of (6.2) }), \end{cases}$$

then (6.1)–(6.2) and (6.1), (6.3) have a unique solution in the class

$$\tag{6.5}\begin{cases} (u, v, z) \in C([0, \infty); H^1(\Omega_1) \times H^1(\Omega_2) \times \mathbb{R}), \\ (u_t, v_t, z_t) \in C([0, \infty); L^2(\Omega_1) \times L^2(\Omega_2) \times \mathbb{R}) \end{cases}$$

and the following energy identities hold:

$$\tag{6.6}\begin{cases} \text{(i) } E_M(t_2) - E_M(t_1) = -\gamma \int_{t_1}^{t_2} |v_t(\ell_2, t)|^2 dt \quad \text{(for (6.1)–(6.2))}, \\ \text{(ii) } E_M(t_2) - E_M(t_1) = -\gamma \int_{t_1}^{t_2} [\, |u_t(-\ell_1, t)|^2 + |v_t(\ell_2, t)|^2] dt \quad \text{(for (6.1), (6.3))}. \end{cases}$$

(ii) If the initial data satisfy the following additional regularity and compatibility conditions:

$$\tag{6.7}\begin{cases} (u^0, v^0) \in H^2(\Omega_1) \times H^2(\Omega_2); \quad (u^1, v^1) \in H^1(\Omega_1) \times H^1(\Omega_2), \\ u^1(0) = v^1(0) = z^1, \\ \sigma_2 v_x^0(\ell_2) + \gamma v^1(\ell_2) = 0, \\ u^1(-\ell_1) = 0 \quad (\text{for (6.1)–(6.2)}), \\ \sigma_1 u_x^0(-\ell_1) - \gamma u^1(-\ell_1) = 0 \text{ (for (6.1), (6.3))}, \end{cases}$$

then the solutions have the following added regularity:

$$\tag{6.8}\begin{cases} (u, v) \in C([0, \infty); H^2(\Omega_1) \times H^2(\Omega_2)), \\ (u_t, v_t) \in C([0, \infty); H^1(\Omega_1) \times H^1(\Omega_2)), \\ z \in C^2([0, \infty); \mathbb{R}). \end{cases}$$

In what follows, solutions in the class (6.5) will be referred to as finite-energy solutions and those in (6.8) as smooth solutions.

There is an important difference between boundary conditions (6.2) and (6.3). For solutions of (6.1)–(6.2) the energy E_M is coercive and thus the only equilibrium configuration is the zero one. However in the system (6.1), (6.3) the energy is not coercive and for every real constant k, $(u, v, z) = (k, k, k)$ defines a solution.

In both systems we may expect the energy to decay to zero and this is the case. However, in system (6.1)–(6.3) additional work is required to show that every solution converges to an equilibrium.

There is another important difference between system (6.1)–(6.2) and (6.1), (6.3). In (6.1), (6.3) we will prove a uniform exponential decay of the energy; however, we will see that this does not hold for the system (6.1)–(6.2) since the system possesses a sequence of eigenfrequencies that approach the imaginary axis.

We have divided this section in three parts. In the first one we show that the energy of solutions of (6.1)–(6.2) converges to zero. In the second one we prove the uniform exponential decay of energy of solutions of (6.1), (6.3) and the fact that every trajectory converges toward an equilibrium. In the last part we study the spectral properties of system (6.1)–(6.2) and prove the nonuniform decay of energy.

6.1 Strong convergence to the equilibrium for (6.1)–(6.2). We have the following result.

THEOREM 6.1. *Every trajectory associated with a finite-energy solution of* (6.1)–(6.2) *converges strongly to zero in the finite-energy space* (6.4).

Proof. It is sufficient to prove that

$$\tag{6.9} E_M(t) \to 0 \text{ as } t \to \infty.$$

First observe that due to the density of the data satisfying (6.7) in the finite-energy space (6.4), the decreasing character of the energy (as in (6.6)) and the linearity of the system, if (6.9) holds for all smooth solutions then it also holds for all finite-energy solutions. Thus we will need to consider only smooth solutions.

Next we observe that $(u_t, v_t, z_t, u_{tt}, v_{tt}, z_{tt})$ is a solution (6.1)–(6.2) with the initial data $(u^1, v^1, z^1, \rho_1^{-1}\sigma_1 u_{xx}^0, \rho_2^{-1}\sigma_2 v_{xx}^0, M^{-1}(\sigma_2 v_x^0 - \sigma_1 u_x^0))$ which satisfies the compatibility condition $u^1(0) = v^1(0) = z^1$. Thus the trajectory $(u_t, v_t, z_t, u_{tt}, v_{tt}, z_{tt})$ is a finite energy solution and hence due to the fact that this energy is nonincreasing we deduce that

$$(u_t, v_t, z_t) \in L^\infty(0,\infty; H^1(\Omega_1) \times H^1(\Omega_2) \times \mathbb{R}),$$
$$(u_{tt}, v_{tt}, z_{tt}) \in L^\infty(0,\infty; L^2(\Omega_1) \times L^2(\Omega_2), \times\mathbb{R}),$$

and then by elliptic regularity that

$$(u,v) \in L^\infty(0,\infty; H^2(\Omega_1) \times H^2(\Omega_2)).$$

This shows that trajectories

$$\{(u(t), v(t), z(t), u_t(t), v_t(t), z_t(t))\}_{t\geq 0}$$

are relatively compact in the finite-energy space. Let ω be its ω-limit set with respect to the strong topology of the finite-energy space.

Since the energy E_M is a Lyapunov function, by LaSalle's invariance principle we deduce that ω is reduced to states for which the corresponding solution has constant energy for all $t > 0$. It is easy to see that the only solution satisfying this property is the zero solution. This shows that $\omega = \{0\}$ and concludes the proof. □

6.2. Uniform exponential decay for (6.1), (6.3). We have the following result.

THEOREM 6.2. *There exist $C > 0$ and $\omega_0 > 0$ such that*

$$E_M(t) \leq C E_M(0) e^{-\omega_0 t} \quad \forall t > 0 \tag{6.10}$$

holds for every finite-energy solution of (6.1), (6.3).

Moreover,

(6.11)
$$\begin{cases} \|(u(\cdot,t) - k)\|^2_{H^1(\Omega_1)} + \|(v(\cdot,t) - k)\|^2_{H^1(\Omega_2)} + |z(t) - k|^2 \leq C E_M(0) e^{-\omega_0 t} \\ \text{with } k \in \mathbb{R} \text{ such that } 2\gamma k = \int\limits_{-\ell_1}^{0} u^1 dx + \int\limits_{0}^{\ell_2} v^1 dx + M z^1 + \gamma u^0(-\ell_1) + \gamma v^0(\ell_2). \end{cases}$$

Proof. It is sufficient to prove the result for smooth solutions. Let us first prove (6.10).

We have

$$E_M(T) - E_M(0) = -\gamma \int\limits_0^T [\,|u_t(-\ell_1,t)|^2 + |v_t(\ell_2,t)|^2]dt \quad \forall T > 0. \tag{6.12}$$

Therefore it is sufficient to prove the existence of $C > 0$ and $T > 0$ such that

$$E_M(T) \leq C \int\limits_0^T [\,|u_t(-\ell_1,t)|^2 + |v_t(\ell_2,t)|^2]dt \tag{6.13}$$

for every smooth solution. Indeed from (6.12) and (6.13), (6.10) holds easily by using the semigroup property.

On the other hand, (6.13) can be proved the same way as we proved inequality (3.7) in Proposition 3.3.

Let us now prove (6.11). By differentiating the quantity

$$I(t) = \int\limits_{-\ell_1}^{0} \rho_1 u_t(x,t)dx + \int\limits_{0}^{\ell_2} \rho_2 v_t(x,t)dx + M z_t(t) + \gamma u(-\ell_1,t) + \gamma v(\ell_2,t) \tag{6.14}$$

and using (6.1), (6.3), one sees that $I(t)$ remains constant in time.

Given a solution of (6.1), (6.3) we decompose it as follows:

$$(u, v, z, u_t, v_t, z_t) = (\tilde{u}, \tilde{v}, \tilde{z}, u_t, v_t, z_t) + (\bar{u}, \bar{v}, \bar{z}, 0, 0, 0), \tag{6.15}$$

where

$$\bar{u} = \bar{v} = \bar{z} = k \quad \text{and} \quad \tilde{u} = u - k, \quad \tilde{v} = v - k, \quad \tilde{z} = z - k \tag{6.16}$$

with k a constant such that

$$2\gamma k = I(0). \tag{6.17}$$

Clearly $(\bar{u}, \bar{v}, \bar{z})$ is a stationary solution of (6.1), (6.3). On the other hand, the quantity $I(t)$ associated with $(\tilde{u}, \tilde{v}, \tilde{z}, u_t, v_t, z_t)$ is identically zero. It is easy to check that $E_M(\cdot)$ is coercive over the subspace of the finite-energy space in which $I = 0$. From (6.10) we then deduce that the component $(\tilde{u}, \tilde{v}, \tilde{z}, u_t, v_t, z_t)$ of our solutions decays exponentially to zero in the energy space, i.e., (6.11) holds. □

6.3. Nonuniform energy decay. Let $\mathcal{A}$ be the differential operator in (2.1), however, on the space

$$\widetilde{\mathcal{H}} = \widetilde{W_1} \times W_0, \tag{6.18}$$

where

$$\widetilde{W_1} = \{(u, v, z) \in H^1(\Omega_1) \times H^1(\Omega_2) \times \mathbb{R} : u(-\ell_1) = 0, \ u(0) = v(0) = z\} \tag{6.19}$$

with domain

(6.20)

$$\widetilde{\mathcal{D}}(\mathcal{A}) = \{y \in \widetilde{\mathcal{H}} : u \in H^2(\Omega_1), v \in H^2(\Omega_2), \ (\dot{u}, \dot{v}, \dot{z}) \in \widetilde{W_1} : \sigma_2 v_x(\ell_2) + \gamma \dot{v}(\ell_2) = 0\}.$$

We have the following result, which describes the amount of damping in (6.1)–(6.2), in terms of $\sigma(\mathcal{A})$.

THEOREM 6.3. *Let $\mathcal{A}$ be defined by (6.18)–(6.20), with $\gamma > 0$. Then there exists a sequence $(s_k)_{k\in\mathbb{Z}} \subset \sigma(\mathcal{A})$ for which*

(i) $\left| \sqrt{\dfrac{\sigma_1}{\rho_1}} \dfrac{k\pi}{\ell_1} - \operatorname{Im} s_k \right| \to 0$ *as* $|k| \to \infty$

(ii) *there exists c_1, $c_2 > 0$ for which* $-\dfrac{c_1}{k^2} > \operatorname{Re} s_k > -\dfrac{c_2}{|k|} \quad \forall k \in \mathbb{Z}.$

If $\lambda \in \sigma(\mathcal{A}) \setminus \{(s_k)\}$ then there exists $c_3 > 0$ for which $\operatorname{Re} \lambda < -c_3$.

Remark 6.1. The second inequality of (ii) implies that the energy of solutions does not decay uniformly to zero in bounded sets of $\mathcal{H}$. But as a consequence of a general result due to W. Littman and L. Markus [8], in view of the first inequality of (ii), one can obtain uniform polynomial decay rates of energy for solutions with initial data belonging to a bounded set of the domain of some power of $\mathcal{A}$.

Proof. We assume without loss of generality (by rescaling) that $\ell_1 = \ell_2 = 1$.

We seek nontrivial solutions of

$$\mathcal{A}y = i\omega y. \tag{6.21}$$

Let

$$\alpha = \sqrt{\frac{\sigma_1}{\rho_1}}, \quad \beta = \sqrt{\frac{\sigma_2}{\rho_2}}.$$

Using (6.21) and the boundary conditions, one can easily calculate

$$\text{(6.22)} \qquad \begin{cases} u = a\sin\dfrac{\omega}{\alpha}(x+1), \\ v = b\psi_\omega(x); \quad \psi_\omega(x) = \dfrac{\gamma}{\rho_2}\sin\dfrac{\omega}{\beta}(x-1) + i\beta\cos\dfrac{\omega}{\beta}(x-1), \\ z = \dfrac{a\sigma_1}{M\alpha\omega}\cos\dfrac{\omega}{\alpha} - \dfrac{b\sigma_2}{M\omega^2}\dfrac{d\psi_\omega}{dx}(0), \end{cases}$$

where a, b, ω are to be determined. The boundary conditions in (6.19) imply that

$$\text{(6.23)} \qquad a\sin\frac{\omega}{\alpha} = b\psi_\omega(0) = z.$$

The possibility that $z = 0$ leads to only trivial solutions. Thus we may set $a = \psi_\omega(0)$, $b = \sin\omega/\alpha$, and obtain from (6.23)

$$\text{(6.24)} \qquad M\omega = \frac{\sigma_1\cos\omega/\alpha}{\alpha\sin\omega/\alpha} - h(\omega); \quad h(\omega) = \frac{\sigma_2}{\omega\psi_\omega(0)}\frac{d\psi_\omega}{dx}(0).$$

Now there are three separate cases to consider:

$$\gamma < \sqrt{\rho_2\sigma_2}, \quad \gamma = \sqrt{\rho_2\sigma_2}, \quad \gamma > \sqrt{\rho_2\sigma_2}.$$

In each case the result is the same and the idea is the same. Thus let us consider only the first case, $\gamma < \sqrt{\rho_2\sigma_2}$.

Let $\mathbb{K}$ denote the roots of $\psi_\omega(0) = 0$. A simple calculation shows

$$\text{(6.25)} \qquad \mathbb{K} = \left\{\beta\left(k\pi + \frac{\pi}{2} + i\tanh^{-1}\frac{\gamma}{\beta\rho_2}\right)\right\}_{k\in\mathbb{Z}}.$$

For $S \subset \mathbb{C}$, define

$$N_\delta(S) = \{\lambda \in \mathbb{C} : \operatorname{dist}(\lambda, S) < \delta\}.$$

From (6.25) it follows that $N_{\delta_0}(\mathbb{K}) \cap N_{\delta_0}(\alpha\pi\mathbb{Z}) = \emptyset$ for δ_0 small enough. Furthermore, since $h(\omega)$ and $\cot\omega/\alpha$ are periodic and analytic outside $N_{\delta_0}(\mathbb{K})$ and, respectively, $N_{\delta_0}(\alpha\pi\mathbb{Z})$, $h(\omega)$ is uniformly bounded in $N_{\delta_0}(\alpha\pi\mathbb{Z})$ and $\cot\omega/\alpha$ is uniformly bounded in $N_{\delta_0}(\mathbb{K})$. Since the moduli of both sides of (6.24) are the same, it follows that for any $\varepsilon > 0$, only finitely many eigenvalues lie outside $N_\varepsilon(\alpha\pi\mathbb{Z}) \cup N_\varepsilon(\mathbb{K})$. Rouché's theorem can be used to show that for any $\varepsilon > 0$ if $|\omega|$ is sufficiently large, there is a unique root of (6.24) in each component of $N_\varepsilon(\alpha\pi\mathbb{Z})$ and $N_\varepsilon(\mathbb{K})$. (See [8] for an example of this calculation.)

A simple calculation shows that $\operatorname{Im} h(\omega) < -a < 0$ for all $\omega \in \mathbb{R}$. Since $h(\omega)$ is periodic and analytic in a neighborhood of the real axis, we may assume there exist positive numbers a_0 and l for which

$$\text{(6.26)} \qquad \operatorname{Im}\, h(\omega) < -a_0 \quad \forall\omega \in \mathbb{C} : |\operatorname{Im}\,\omega| \le l.$$

Let $\alpha k\pi + s + i\tau$ denote a root of (6.24) in $N_\varepsilon(\alpha\pi\mathbb{Z})$. By setting the imaginary parts of (6.24) equal and then using (6.26), we find that for ε sufficiently small (and hence $|k|$ sufficiently large) we have

$$\text{(6.27)} \qquad \left(\tau - \frac{\sigma_1}{2a_0}\right)^2 + s^2 < \frac{\sigma_1^2}{4a_0^2}.$$

Thus for $|\omega|$ sufficiently large, these roots lie in disks of radii $\sigma_1/2a_0$ tangent to the real axis at the points in $\{\alpha\pi\mathbb{Z}\}$.

Due to the upperbound on $|h(\omega)|$ in $N_{\delta_0}(\alpha\pi\mathbb{Z})$, since the moduli of both sides of (6.24) are the same, for $|\omega|$ sufficiently large we must have

$$\frac{M}{2}|\omega| < \left|\frac{\sigma_1}{\alpha}\cot\frac{\omega}{\alpha}\right| < 2M|\omega|. \tag{6.28}$$

Since $\cot\omega/\alpha$ is periodic and has a first-order pole at 0, (6.28) implies there exists c_1, $c_2 > 0$, and $k \in \mathbb{Z}$ for which

$$\frac{c_1}{|\omega|} < |\omega - \alpha k\pi| < \frac{c_2}{|\omega|}, \quad |\omega| \text{ sufficiently large.} \tag{6.29}$$

Intersecting the sets described by (6.27) and (6.29) and recalling (6.21), we obtain (i) and (ii). For any other roots of (6.24), either $\omega \in N_{\delta_0}(\mathbb{K})$ or ω is one of the finitely many outside of both $N_{\delta_0}(\mathbb{K})$ and $N_\varepsilon(\alpha k\mathbb{Z})$. In either case, by (6.25) and the dissipativity of $\mathcal{A}$ we have Im $\omega >$ const > 0. Thus Re $\lambda =$ Re $i\omega < -c_3 < 0$. ||

7. Extensions. In this final section we discuss two important generalizations of the results in the previous sections. First we consider a string with n point masses and describe the manner in which the previous results extend to this case. Second we analyze again the one-mass problem, but this time with a string having spatially varying coefficients.

7.1. n masses. All the regularity results carry over to strings with n masses due to the local nature of these results. In particular Proposition 2.5 and the remark that follows it imply that the degree of regularity of a travelling wave solution increases exactly one order as it crosses each mass. (Of course, part of the wave is *reflected* at each mass point with no increase in regularity.) Furthermore, the method used to prove controllability (Theorem 4.1) relies only upon the regularity result (Proposition 2.7) and the use of characteristics (as in construction of the energy functions e_1 and e_2 in (3.7) and (3.9)) and hence applies equally well to strings with n masses. As such, analogous controllability and observability results hold for strings with n masses. For example, if we consider the problem of Dirichlet control of the rightmost end of the string, which has $n - 1$ masses (and n intervals), the control space one obtains is the same on the first (farthest right) interval as in Theorem 4.1. For each successive interval the regularity increases one order, i.e., on the kth interval I_k (from the right), the position of the string (respectively, velocity) is in $H^{k-1}(I_k)$ (respectively, $H^{k-2}(I_k)$). In addition, boundary conditions and compatibility conditions up to the proper order for that interval must be imposed to obtain a well-posed system. A detailed examination of this problem is beyond the scope of this paper, however.

7.2. Variable coefficients. All the results of the previous sections remain valid for strings with spatially variable coefficients. To see this, let us consider the following system:

$$\left\{\begin{array}{lll} \rho(x)w_{tt}(x,t) - \frac{\partial}{\partial x}(\sigma(x)w_x(x,t)) = 0, & x \in \Omega, & t > 0, \\ Mz_{tt}(t) = \sigma(0^+)w_x(0^+,t) - \sigma(0^-)w_x(0^-,t), & t > 0, & \\ w(0^-,t) = w(0^+,t) = z(t), & t > 0, & \\ w(-1,t) = 0, \quad w(1,t) = q(t), & t > 0, & \\ w(x,0) = w^0(x), \quad w_t(x,0) = w^1(x), & x \in \Omega, & \\ z(0) = z^0, \quad z_t(0) = z^1, & & \end{array}\right. \tag{7.1}$$

where $\Omega = (-1,0)\cup(0,1)$ and the notation 0^+, 0^- refers to right- and left-hand limits at 0.

We have the following result.

THEOREM 7.1. *Suppose that $\rho, \sigma \in H^2((-1,0)\cup(0,1))$ and that both functions are bounded below by a positive constant. Then, if*

$$T > 2\int_{-1}^{1}\left(\frac{\rho(\tau)}{\sigma(\tau)}\right)^{1/2} d\tau,$$

the conclusion of Theorem 4.1 *holds.*

Sketch of proof. Let us introduce the following change of variables:

$$\begin{aligned}
&s = \int_0^x \rho(\tau)^{1/2}\sigma(\tau)^{-1/2} d\tau,\\
&\tilde{\Omega} = (-\ell_1, 0)\cup(0,\ell_2); \quad \ell_1 = -s(-1), \quad \ell_2 = s(1),\\
&b(s) = \rho(x)^{-1}\frac{d}{dx}\sqrt{\rho(x)\sigma(x)}\ |_{x=x(s)},\\
&\tilde{w}(s,t) = \exp\left(\int_0^s b(r)/2\, dr\right) w(x(s),t),\\
&a = \sqrt{\rho(0^+)\sigma(0^+)}\frac{b(0^+)}{2} - \sqrt{\rho(0^-)\sigma(0^-)}\frac{b(0^-)}{2}.
\end{aligned}$$

Then (7.1), in the absence of control ($q = 0$), becomes

$$(7.2)\quad \begin{cases}
\tilde{w}_{tt} - \left[\tilde{w}_{ss} - \left(\frac{b'(s)}{2} + \frac{b^2(s)}{4}\right)\tilde{w}\right] = 0, & s \in \tilde{\Omega},\ t > 0,\\
Mz_{tt}(t) + az(t) = \sqrt{\rho(0^+)\sigma(0^+)}\tilde{w}_s(0^+,t) & \\
\qquad -\sqrt{\rho(0^-)\sigma(0^-)}\tilde{w}_s(0^-,t), & t > 0,\\
\tilde{w}(0^-,t) = \tilde{w}(0^+,t) = z(t), & t > 0,\\
\tilde{w}(-\ell_1,t) = 0 = \tilde{w}(\ell_2,t), & t > 0,\\
\tilde{w}(s,0) = \exp\int_0^s b(r)/2\, dr w^0(x(s)), & s \in \tilde{\Omega},\\
\tilde{w}_t(s,0) = \exp\int_0^s b(r)/2\, dr w^1(x(s)), & s \in \tilde{\Omega},\\
z(0) = z^0, \quad z_t(0) = z^1. &
\end{cases}$$

Therefore, it is sufficient to prove the controllability of this system at time $T > 2(\ell_1 + \ell_2)$ with a control at the right end $x = \ell_2$.

First let us examine the system (7.2), but without the potential term. This is equivalent to

$$(7.3)\quad \begin{cases}
w_{tt} - w_{xx} = 0, & x \in \tilde{\Omega},\ t > 0,\\
Mz_{tt}(t) + az(t) = \gamma w_x(0^+,t) - w_x(0^-,t), & t > 0,\\
w(0^-,t) = w(0^+,t) = z(t), & t > 0,\\
w(-\ell_1,t) = 0 = w(\ell_2,t), & t > 0,\\
w(x,0) = w^0(x), \quad w_t(x,0) = w^1(x), & x \in \tilde{\Omega},\\
z(0) = z^0, \quad z_t(0) = z^1. &
\end{cases}$$

We assume $M, \gamma, \ell_1, \ell_2$ to be arbitrary positive numbers, and a is assumed only to be real. One can check that the proof of Proposition 2.5 remains valid for the system (7.3); when $Mz_{tt} + az$ replaces Mz_{tt} in (2.14) one still obtains (2.18). It hence follows that all regularity results, in particular Proposition 2.7, remain valid for (7.3).

Finally, the assumptions on the coefficients imply the potential $(\frac{b'(s)}{2} + \frac{b^2(s)}{4})$ remains in $L^2(\widetilde{\Omega})$. We can thus write the solution of (7.2) in terms of an integral equation given by the variation of constants formula for (7.3) and for small enough t determine a fixed point having the same regularity as the solution of (7.3) with initial data as in the hypothesis of Proposition 2.7. The remaining parts of the proof of Theorem 4.1 only rely upon the use of characteristics, and hence can be done directly for the variable coefficient problem (7.1). □

OPTIMAL STOPPING OF A DISCRETE MARKOV PROCESS BY TWO DECISION MAKERS*

KRZYSZTOF SZAJOWSKI†

Abstract. In this paper a problem of optimal stopping of the discrete time Markov process by two decision makers in a competitive situation is considered. The zero-sum game approach is adopted. The gain function depends on the states chosen by both decision makers. The random assignment mechanism is used when both want to accept the realization of the Markov process at the same moment. The construction of the value function and the optimal strategies for the players are given. Examples related to the generalization of the best choice problem are solved.

Key words. optimal stopping problem, game variant, Markov process, random priority, secretary problem, zero-sum two-person game

AMS subject classifications. 60G40, 90D15

1. Introduction.

This paper deals with a class of the following two-person decision problems. Let $(X_n, \mathcal{F}_n, \mathbf{P}_x)_{n=0}^N$ be a homogeneous Markov process defined on probability space $(\Omega, \mathcal{F}, \mathbf{P})$ with fixed state space $(\mathbb{E}, \mathcal{B})$. The decision makers, henceforth called Player 1 and Player 2, observe the process sequentially. They want to accept the most profitable state of the process from their point of view.

We adopt the zero-sum game model for the problem. In view of this approach, the preferences of each player are described by gain function $f : \mathbb{E} \times \mathbb{E} \rightarrow \Re$. The function depends on the state chosen by both players. It would be natural to consider the stopping times with respect to $(\mathcal{F}_n)_{n=0}^N$ as the strategies of the player if the players could obtain the state which they want. Since there is only one random sequence $(X_n)_{n=0}^N$ on a trial, at each moment n only one player can obtain realization x_n of X_n. The problem of assigning an object to the players when both want to accept the same one at the same moment is solved by adopting the random mechanism; i.e., a lottery chooses the player who benefits. The player chosen by the lottery obtains realization x_n, and the player thus deprived of the acceptance of x_n at $n < N$ may select any later realization. The realization can be accepted only when it appears. No recall is allowed. We can think about the decision process as an investigation of objects with characteristics described by the Markov process. Both players together can accept at most two objects.

The above-described decision model is a generalization of the problems considered by the author in [20] and by Radzik and the author in [13]. The related questions, when Player 1 has permanent priority, have been considered by many authors in the zero-sum game or the non–zero-sum game setting. One can mention, for example, the recent papers of Ano [1], Enns and Ferenstein [4], Ferenstein [5], and Sakaguchi [16]. Many papers on the subject were inspired by the secretary problem (see T. S. Ferguson [6] for an extensive bibliography on the problem). Sakaguchi [16] considered the non–zero-sum two-person game related to the full-information best-choice problem with random priority. The review of the related models can be found in [20].

In this paper a formal model of the random priority is derived. The lottery is taken into account in the sets of the strategies of the players. The most interesting

† Institute of Mathematics, Technical University of Wrocław, Wybrzeże Wyspiańskiego 27, PL-50-370 Wrocław, Poland (szajow@im.pwr.wroc.pl).

question concerns the influence of the level of priority on the value of the problem or the probability of obtaining the required state of the process (or, in other words, the required object). The tip of the problem is shown by the examples. The random-priority game approach to the generalized secretary problem is considered. At first, random priority is added to the problem of choosing the best or the second best (BOS) but a better one than that of an applicant who is chosen by the opponent (the game considered in [20]). The dependence of the value, the strategies, and the probability of obtaining the required object by Player 1 on the priority is investigated. The second example tries to answer the question of what is the relation between the priority level and the aims of the players. The simplest problem with asymmetric aims of the players is considered. The first player's aim is to choose the best applicant (BA), and the second player wants to accept the BOS but a better one than the opponent. The numerical solution provides that the game is fair when Player 1 has priority $p \cong 0.7579$ (in the limiting case when $N \to \infty$).

The organization of the paper is as follows. In §2, the formal model is formulated in a rigorous way, and the general solution of the problem is given. The ideas used by Yasuda [21] and in [20] are employed. In §§3 and 4, the above-mentioned examples are solved. Section 5 contains some final remarks. Among other things, the probabilities of the success in the considered games are given.

2. Random priority and stopping the Markov process. Let a homogeneous Markov chain $(X_n, \mathcal{F}_n, \mathbf{P}_x)_{n=0}^N$ be defined on a probability space $(\Omega, \mathcal{F}, \mathbf{P})$ with a state space $(I\!\!E, \mathcal{B})$, and let $f : I\!\!E \times I\!\!E \to \Re$ be a $\mathcal{B} \times \mathcal{B}$ real-valued measurable function. Horizon N is finite. The players observe the Markov chain, and they try to accept the "best realization" according to function f and a possible selection of another player. Each realization x_n of X_n can be accepted by only one player, and each player can accept at most one realization. If the players have not accepted previous realizations, they evaluate the state of the Markov chain at instant n and have two options: either to accept the observed state of the process at moment n or to reject it. If both players want to accept the same realization, the following random priority mechanism is applied. Let $\xi_1, \xi_2, \dots, \xi_N$ be a sequence of independently and identically distributed random variables with the uniform distribution on $[0, 1]$, and let $\alpha = (\alpha_1, \alpha_2, \dots, \alpha_N)$ be a given vector of real numbers, $\alpha_i \in [0, 1]$. When both players want to accept realization x_n of X_n, then Player 1 obtains x_n if $\xi_n \leq \alpha_n$; otherwise Player 2 benefits. If Player 1 rejects the applicant, then Player 2 turns to exercise one of his options, which also consists of accepting the observed state of the Markov chain or rejecting it. If one of the players accepts realization x_n of X_n, then the other one is informed about it and he continues to play alone. If, in the above decision process, Player 1 and Player 2 have accepted states x and y, respectively, then Player 2 pays $f(x, y)$ to Player 1. When only Player 1 (Player 2) accepts state x (y), then Player 1 obtains $f_1(x) = \sup_{y \in I\!\!E} f(x, y)$ ($f_2(y) = \inf_{x \in I\!\!E} f(x, y)$) by assumption. If both players finish the decision process without any accepted state, then they gain 0.

Let $\mathcal{S}^N$ be the aggregation of Markov times with respect to $(\mathcal{F}_n)_{n=0}^N$. We admit that $\mathbf{P}_x(\tau \leq N) < 1$ for some $\tau \in \mathcal{S}^N$ (i.e., there is a positive probability that the Markov chain will not be stopped). The elements of $\mathcal{S}^N$ are possible strategies for the players with the restriction that Player 2 cannot stop at the same moment as Player 1. If the players declare willingness to accept the same object, the random device decides which player is endowed. Let us formalize these considerations. Denote $\mathcal{S}_k^N = \{\tau \in \mathcal{S}^N : \tau \geq k\}$. Let Λ_k^N and M_k^N be copies of $\mathcal{S}_k^N$ ($\mathcal{S}^N = \mathcal{S}_0^N$). One can define the set of strategies $\tilde{\Lambda}^N = \{(\lambda, \{\sigma_n^1\}) : \lambda \in \Lambda^N, \sigma_n^1 \in \Lambda_{n+1}^N \text{ for every } n\}$ and $\tilde{M}^N = \{(\mu, \{\sigma_n^2\}) : \mu \in M^N, \sigma_n^2 \in M_{n+1}^N \text{ for every } n\}$ for Players 1 and 2, respectively. Denote $\tilde{\mathcal{F}}_n = \sigma(\mathcal{F}_n, \xi_1, \xi_2, \ldots, \xi_n)$ and let $\tilde{\mathcal{S}}^N$ be the set of stopping times with respect to $(\tilde{\mathcal{F}}_n)_{n=0}^N$. Define $\tau_1 = \lambda \mathbb{I}_{\{\lambda<\mu\}} + (\lambda \mathbb{I}_{\{\xi_\lambda \le \alpha_\lambda\}} + \sigma_\mu^1 \mathbb{I}_{\{\xi_\lambda > \alpha_\lambda\}}) \mathbb{I}_{\{\lambda=\mu\}} + \sigma_\mu^1 \mathbb{I}_{\{\lambda>\mu\}}$ and $\tau_2 = \mu \mathbb{I}_{\{\lambda>\mu\}} + (\mu \mathbb{I}_{\{\xi_\mu > \alpha_\mu\}} + \sigma_\lambda^2 \mathbb{I}_{\{\xi_\mu \le \alpha_\mu\}}) \mathbb{I}_{\{\lambda=\mu\}} + \sigma_\lambda^2 \mathbb{I}_{\{\lambda \le \mu\}}$.

LEMMA 2.1. *Random variables τ_1 and τ_2 are Markov times with respect to $(\tilde{\mathcal{F}}_n)_{n=0}^N$ and $\tau_1 \neq \tau_2$.*

Proof. We have

$$\{\tau_1 = n\} = \{\lambda = n, \mu \ge n\} \cup \bigcup_{i=0}^{n-1} \{\mu = i, \sigma_i^1 = n\}$$
$$\cup \{\mu = n, \lambda = n, \xi_n \le \alpha_n\} \in \tilde{\mathcal{F}}_n \text{ for every } n$$

and

$$\{\tau_2 = n\} = \{\mu = n, \lambda > n\} \cup \bigcup_{i=0}^{n} \{\lambda = i, \sigma_i^2 = n\}$$
$$\cup \{\mu = n, \lambda = n, \xi_n \le \alpha_n\} \in \tilde{\mathcal{F}}_n \text{ for every } n;$$

hence τ_1 and τ_2 are Markov times and $\tau_1 \neq \tau_2$. □

Let $E_x f_1^+(X_n) < \infty$ and $E_x f_2^-(X_m) < \infty$ for $n, m = 0, 1, \ldots, N$ and $x \in \mathbb{E}$. Let $s \in \tilde{\Lambda}^N$ and $t \in \tilde{M}^N$. Define $\tilde{R}(x, s, t) = E_x f(X_{\tau_1}, X_{\tau_2})$ as the expected gain of Player 1. In this way the normal form of the game $(\tilde{\Lambda}^N, \tilde{M}^N, \tilde{R}(x, s, t))$ is defined. This game is denoted by $\mathcal{G}$. The game $\mathcal{G}$ is a model of the considered bilateral stopping problem for the Markov process.

DEFINITION 2.2. *Pair (s^*, t^*), $s^* \in \tilde{\Lambda}^N$, $t^* \in \tilde{M}^N$, is an equilibrium point in the game $\mathcal{G}$ if for every $x \in \mathbb{E}$, $s \in \tilde{\Lambda}^N$, and $t \in \tilde{M}^N$ we have*

$$\tilde{R}(x, s, t^*) \le \tilde{R}(x, s^*, t^*) \le \tilde{R}(x, s^*, t).$$

The aim is to construct the equilibrium pair (s^*, t^*). The following approach is proposed. When one of the players accepts realization x_n at moment n, the second player will try to maximize his gain without any disturbance from another player. It means that if there is no acceptance of states until moment n, the players must take into account the potential danger from a future decision of the opponent before accepting or rejecting realization x_n of X_n. To this end, they consider the following auxiliary game $\mathcal{G}_a$.

Define $s_0(x, y) = S_0(x, y) = f(x, y)$ and

$$s_n(x, y) = \inf_{\tau \in \mathcal{S}^n} E_y f(x, X_\tau),$$
$$S_n(x, y) = \sup_{\tau \in \mathcal{S}^n} E_x f(X_\tau, y)$$

for all $x, y \in \mathbb{E}$, $n = 1, 2, \ldots, N$. By the theory of optimal stopping for the Markov processes [17], the function $s_n(x, y)$ $(S_n(x, y))$ can be constructed by the recursive procedure as $s_n(x, y) = Q_{\min}^n f(x, y)$ $(S_n(x, y) = Q_{\max}^n f(x, y))$, where $Q_{\min} f(x, y) = f(x, y) \wedge T_2 f(x, y)$ $(Q_{\max} f(x, y) = f(x, y) \vee T_1 f(x, y))$ and $T_2 f(x, y) = E_y f(x, X_1)$ $(T_1 f(x, y) = E_x f(x, y))$. ($\wedge$ and $\vee$ denote minimum and maximum, respectively.) Operations $\wedge$ and T_2 ($\vee$ and T_1) preserve measurability. This can be proved in a standard way. Hence $s_n(x,y)$ $(S_n(x,y))$ are $\mathcal{B}\otimes\mathcal{B}$ measurable (cf. [3]). If Player 1 is the first to accept x at moment n, then his expected gain is

$$h(n,x) = E_x s_{N-n-1}(x, X_1) \tag{1}$$

for $n = 0, 1, \ldots, N-1$ and $h(N,x) = f_1(x)$. When Player 2 is the first, then the expected gain of Player 1 is

$$H(n,x) = E_x S_{N-n-1}(X_1, x) \tag{2}$$

for $n = 0, 1, \ldots, N-1$ and $H(N,x) = f_2(x)$. Functions $h(n,x)$ and $H(n,x)$ are well defined. They are $\mathcal{B}$-measurable of the second variable; $h(n, X_1)$ and $H(n, X_1)$ are integrable with respect to $\mathbf{P}_x$. Let Λ^N and M^N be sets of strategies in $\mathcal{G}_a$ for Player 1 and Player 2, respectively. For $\lambda \in \Lambda^N$ and $\mu \in M^N$, define the payoff function

$$r(\lambda,\mu) = \begin{cases} h(\lambda, X_\lambda)(\mathbb{I}_{\{\lambda<\mu\}} + \mathbb{I}_{\{\lambda=\mu,\xi_\lambda\le\alpha_\lambda\}}) & \\ \quad +H(\mu, X_\mu)(\mathbb{I}_{\{\lambda>\mu\}} + \mathbb{I}_{\{\lambda=\mu,\xi_\mu>\alpha_\mu\}}) & \text{if } \lambda \le N \text{ or } \mu \le N, \\ 0 & \text{otherwise,} \end{cases} \tag{3}$$

where $\mathbb{I}_A$ is a characteristic function of set A. As a solution of the game we search for equilibrium pair (λ^*, μ^*) such that

$$R(x, \lambda, \mu^*) \le R(x, \lambda^*, \mu^*) \le R(x, \lambda^*, \mu) \qquad \text{for all } x \in \mathbb{E}, \tag{4}$$

where $R(x,\lambda,\mu) = E_x r(\lambda,\mu)$. By (3) we can observe that $\mathcal{G}_a$ with the sets of strategies Λ^N and M^N is equivalent to Neveu's stopping problem [12] considered by Yasuda [21] if the sets of strategies are extended to the set of stopping times not greater than $N+1$ and the payoff function is (3). Because the Markov process is observed here, one can define a sequence $v_n(x)$, $n = 0, 1, \ldots, N+1$, on $\mathbb{E}$ by setting $v_{N+1}(x) = 0$ and

$$v_n(x) = \operatorname{val}\begin{bmatrix} h(n,x)\alpha_n + (1-\alpha_n)H(n,x) & h(n,x) \\ H(n,x) & Tv_{n+1}(x) \end{bmatrix} \tag{5}$$

for $n = 0, 1, \ldots, N$, where $Tv_\cdot(x) = E_x v_\cdot(X_1)$ and val A denotes a value of the two-person zero-sum game with payoff matrix A (see [10], [21]).

To prove the correctness of the construction let us observe that the payoff matrix in (5) has the form

$$A = \begin{array}{cc} & \begin{array}{cc} \text{zall s} & \text{f} \end{array} \\ \begin{array}{c} \text{s} \\ \text{f} \end{array} & \begin{bmatrix} (a-b)\alpha + b & a \\ b & c \end{bmatrix} \end{array}, \tag{6}$$

where a, b, c, and α are real numbers and $\alpha \in [0,1]$. By direct checking we have the following lemma.

LEMMA 2.3. *The two-person zero-sum game with payoff matrix A given by* (6) *has an equilibrium point (ϵ, δ) in pure strategies, where*

$$(\epsilon,\delta) = \begin{cases} (s,s) & \text{if } a \ge b, \\ (s,f) & \text{if } c \le a < b, \\ (f,s) & \text{if } a < b \le c, \\ (f,f) & \text{if } a < c < b. \end{cases}$$

Notice that v_{N+1} is measurable. Let us assume that functions v_i, $i = N, N-1, \dots, n+1$, are measurable. Denote

$$\begin{aligned}
A_n^{\mathrm{ss}} &= \{x \in \mathbb{E} : h(n,x) \geq H(n,x)\},\\
A_n^{\mathrm{sf}} &= \{x \in \mathbb{E} : h(n,x) < H(n,x), h(n,x) \geq Tv_{n+1}(x)\},\\
A_n^{\mathrm{fs}} &= \{x \in \mathbb{E} : h(n,x) < H(n,x), H(n,x) \leq Tv_{n+1}(x)\},
\end{aligned}$$

and

$$A_n^{\mathrm{ff}} = \mathbb{E} \setminus (A_n^{\mathrm{ss}} \cup A_n^{\mathrm{sf}} \cup A_n^{\mathrm{fs}}).$$

By sets $A_n^{\mathrm{ss}}, A_n^{\mathrm{sf}}$, and $A_n^{\mathrm{fs}} \in \mathcal{B}$ and Lemma 2.3 we have

$$\begin{aligned}
v_n(x) = {} & [(h(n,x) - H(n,x))\alpha_n + H(n,x)]\mathbb{I}_{A_n^{\mathrm{ss}}}(x) + h(n,x)\mathbb{I}_{A_n^{\mathrm{sf}}}(x)\\
& + H(n,x)\mathbb{I}_{A_n^{\mathrm{fs}}(x)} + Tv_{n+1}(x)\mathbb{I}_{A_n^{\mathrm{ff}}(x)};
\end{aligned}$$

hence $v_n(x)$ is $\mathcal{B}$-measurable.

Define $\lambda^* = \inf_n\{X_n \in A_n^{\mathrm{ss}} \cup A_n^{\mathrm{sf}}\}$ and $\mu^* = \inf_n\{X_n \in A_n^{\mathrm{ss}} \cup A_n^{\mathrm{fs}}\}$.

THEOREM 2.4. *Game $\mathcal{G}_a$ with payoff function* (3) *and sets of strategies Λ^N and M^N for Players* 1 *and* 2, *respectively, has a solution. Pair (λ^*, μ^*) is the equilibrium point and $v_0(x)$ is the value of the game.*

Proof. The theorem follows from the results in [21]. The form of the equilibrium point is obtained by Lemma 2.3. □

Let us construct an equilibrium pair for game $\mathcal{G}$. Define (see [3])

$$\sigma_n^{1^*} = \inf\{m > n : S_{N-m}(X_m, X_n) = f(X_m, X_n)\}, \tag{7}$$

$$\sigma_n^{2^*} = \inf\{m > n : s_{N-m}(X_n, X_m) = f(X_n, X_m)\}. \tag{8}$$

Let (λ^*, μ^*) be an equilibrium point in $\mathcal{G}_a$.

THEOREM 2.5. *Game $\mathcal{G}$ has a solution. Pair (s^*, t^*) such that $s^* = (\lambda^*, \{\sigma_n^{1^*}\})$ and $t^* = (\mu^*, \{\sigma_n^{2^*}\})$ is the equilibrium point. The value of the game is $v_0(x)$.*

Proof. Let

$$\tau_1^* = \lambda^* \mathbb{I}_{\{\lambda^* < \mu^*\}} + (\lambda^* \mathbb{I}_{\{\xi_{\lambda^*} \leq \alpha_{\mu^*}\}} + \sigma_{\mu^*}^{1^*} \mathbb{I}_{\{\xi_{\lambda^*} > \alpha_{\lambda^*}\}})\mathbb{I}_{\{\lambda^* = \mu^*\}} + \sigma_{\mu^*}^{1^*} \mathbb{I}_{\{\lambda^* > \mu^*\}}$$

and

$$\tau_2^* = \mu^* \mathbb{I}_{\{\lambda^* > \mu^*\}} + (\mu^* \mathbb{I}_{\{\xi_{\lambda^*} > \alpha_{\lambda^*}\}} + \sigma_{\lambda^*}^{2^*} \mathbb{I}_{\{\xi_{\lambda^*} \leq \alpha_{\lambda^*}\}})\mathbb{I}_{\{\lambda^* = \mu^*\}} + \sigma_{\lambda^*}^{2^*} \mathbb{I}_{\{\lambda^* < \mu^*\}}.$$

We obtain by the properties of conditional expectation and by (7) and (8)

$$\begin{aligned}
\tilde{R}(x, s^*, t^*) = E_x f(X_{\tau_1^*}, X_{\tau_2^*}) = {} & E_x[\mathbb{I}_{\{\lambda^* < \mu^*\} \cup \{\lambda^* = \mu^*, \xi_{\lambda^*} \leq \alpha_{\mu^*}\}} f(X_{\lambda^*}, X_{\sigma_{\lambda^*}^{2*}})\\
& + \mathbb{I}_{\{\lambda^* > \mu^*\} \cup \{\lambda^* = \mu^*, \xi_{\lambda^*} > \alpha_{\lambda^*}\}} f(X_{\sigma_{\mu^*}^{1*}}, X_{\mu^*})]\\
= {} & E_x \mathbb{I}_{\{\lambda^* < \mu^*\} \cup \{\lambda^* = \mu^*, \xi_{\lambda^*} \leq \alpha_{\mu^*}\}} E_{X_{\lambda^*}} f(X_{\lambda^*}, X_{\sigma_{\lambda^*}^{2*}})\\
& + E_x \mathbb{I}_{\{\lambda^* > \mu^*\} \cup \{\lambda^* = \mu^*, \xi_{\lambda^*} > \alpha_{\lambda^*}\}} E_{X_{\mu^*}} f(X_{\sigma_{\mu^*}^{1*}}, X_{\mu^*})\\
= {} & R(x, \lambda^*, \mu^*).
\end{aligned}$$

Let $t = (\mu, \{\sigma_n^2\}) \in \tilde{M}^N$. We obtain

$$\tilde{R}(x, s^*, t^*) = R(x, \lambda^*, \mu^*) \leq R(x, \lambda^*, \mu)$$

$$\begin{aligned}
&= E_x[\mathbb{I}_{\{\lambda^*<\mu\}\cup\{\lambda^*=\mu,\xi_{\lambda^*}\le\alpha_\mu\}} h(\lambda^*, X_{\lambda^*}) \\
&\qquad + \mathbb{I}_{\{\lambda^*>\mu\}\cup\{\lambda^*=\mu,\xi_{\lambda^*}>\alpha_{\lambda^*}\}} H(\mu, X_\mu)] \\
&= E_x[\mathbb{I}_{\{\lambda^*<\mu\}\cup\{\lambda^*=\mu,\xi_{\lambda^*}\le\alpha_\mu\}} E_{X_{\lambda^*}} f(X_{\lambda^*}, X_{\sigma^{2*}_{\lambda^*}}) \\
&\qquad + \mathbb{I}_{\{\lambda^*>\mu\}\cup\{\lambda^*=\mu,\xi_{\lambda^*}>\alpha_{\lambda^*}\}} H(\mu, X_\mu)] \\
&\le E_x[\mathbb{I}_{\{\lambda^*<\mu\}\cup\{\lambda^*=\mu,\xi_{\lambda^*}\le\alpha_\mu\}} E_{X_{\lambda^*}} f(X_{\lambda^*}, X_{\sigma^2_{\lambda^*}}) \\
&\qquad + \mathbb{I}_{\{\lambda^*>\mu\}\cup\{\lambda^*=\mu,\xi_{\lambda^*}>\alpha_{\lambda^*}\}} E_{X_\mu} f(X_{\sigma^{1*}_\mu}, X_\mu)] \\
&= E_x[\mathbb{I}_{\{\lambda^*<\mu\}\cup\{\lambda^*=\mu,\xi_{\lambda^*}\le\alpha_\mu\}} f(X_{\lambda^*}, X_{\sigma^2_{\lambda^*}}) \\
&\qquad + \mathbb{I}_{\{\lambda^*>\mu\}\cup\{\lambda^*=\mu,\xi_{\lambda^*}>\alpha_{\lambda^*}\}} f(X_{\sigma^{1*}_\mu}, X_\mu)] \\
&= E_x f(X_{s^*}, X_t) = \tilde{R}(x, s^*, t)
\end{aligned}$$

Similarly one can show that for every $s \in \tilde{\Lambda}^N$ we have $\tilde{R}(x,s,t^*) \le \tilde{R}(x,s^*,t^*)$. Hence (s^*,t^*) is the equilibrium pair for $\mathcal{G}$. □

3. Random priority in choosing BOS but a better one than the opponent. Let us formulate the problem. Two employers, Player 1 and Player 2, are to view a group of N applicants for vacancies in their enterprises sequentially. Each of the applicant has some characteristic unknown to the employer. Let $\mathbb{K} = \{x_1, x_2, \ldots, x_N\}$ be the set of characteristics, assuming that the values are different. The employer observes a permutation $\eta_1, \eta_2, \ldots, \eta_N$ of the elements of $\mathbb{K}$ sequentially. We assume that all permutations are equally likely. Let Z_k denote the absolute rank of the object with the characteristics η_k, i.e.,

$$Z_k = \min\left\{ r : \eta_k = \bigwedge_{1\le i_1<\cdots<i_r\le N} \; \bigvee_{1\le j\le r} \eta_{i_j} \right\},$$

($\bigwedge$ and $\bigvee$ denote minimum and maximum, respectively.) The object with the smallest characteristics has the rank 1. The decisions of the employer at each time n are based on the relative ranks $Y_1, Y_2, \ldots, Y_N$ of the applicants and the previous decisions of the opponent, where

$$Y_k = \min\left\{ r : \eta_k = \bigwedge_{1\le i_1<\cdots<i_r\le k} \; \bigvee_{1\le j\le r} \eta_{i_j} \right\}.$$

The random priority assignment model is applied when both players want to accept the same applicant. We assume that $\alpha_n = p$, $p \in [0,1]$ for every n. If the applicant is viewed, the employer must either accept or reject her. Once accepted, the applicant cannot be rejected; once rejected, the applicant cannot be reconsidered. Each employer can accept at most one applicant. The aim of the players is to accept BOS but a better one than that chosen by the opponent. Both players together can accept at most two objects. It makes the problem resemble the optimal double stop of the Markov process (cf. [9], [18], [3]). It is a generalization of the best-choice problem. Excellent reviews of the extensions and modifications of the best-choice problem or the secretary problem are given by Gilbert and Mosteller [8], Freeman [7], and Rose [15]. The review of the game extensions of the problem are mentioned in [20]. We adopt the following payoff function here. The player obtains $+1$ from the other if he has chosen the required applicant, -1 when the opponent has done so, and 0 otherwise.

Let us describe the mathematical model of the problem. With sequential observation of the applicants we connect the probability space $(\Omega, \mathcal{F}, \mathbf{P})$. The elementary events are a permutation of the elements of $I\!\!K$, and the probability measure $\mathbf{P}$ is the uniform probability on Ω. The observable sequence of relative ranks Y_k, $k = 1, 2, \ldots, N$, defines a sequence of σ-fields $\mathcal{F}_k = \sigma(Y_1, \ldots, Y_k)$, $k = 1, 2, \ldots, N$. The random variables Y_k are independent and $\mathbf{P}(Y_k = i) = 1/k$. Denote by $\mathcal{S}^N$, the set of all Markov times τ with respect to the σ-fields $\{\mathcal{F}_k\}_{k=1}^N$. The problem considered can be formulated as follows. For $s \in \tilde{\Lambda}^N$ and $t \in \tilde{M}^N$ denote $A_i = \{\omega : X_{\tau_i} = 1\} \cup \{\omega : X_{\tau_i} = 2, X_{\tau_j} \neq 1\}$. Define the payoff function $g(s,t) = I\!\!I_{A_1} - I\!\!I_{A_2}$ and the expected payoff $G(s,t) = Eg(s,t)$. We are looking for (s^*, t^*) such that for every $s \in \tilde{\Lambda}^N$ and $t \in \tilde{M}^N$

$$G(s, t^*) \leq G(s^*, t^*) \leq G(s^*, t).$$

It is obvious that the essential decisions of the players can be made when applicants with relative rank 1 or 2 have appeared. We will call them candidates. For further consideration it is convenient to define the following random sequence $(W_k)_{k=1}^N$. Let $W_1 = (1, Y_1) = (1,1)$, $\rho_1 = 1$. Define

$$\rho_t = \inf\{r > \rho_{t-1} : Y_r \in \{1,2\}\}, \qquad t > 1,$$

$(\inf \emptyset = \infty)$ and $W_t = (\rho_t, Y_{\rho_t})$. If $\rho_t = \infty$, then we put $W_t = (\infty, \infty)$. The Markov chain $(W_t, \mathcal{G}_t, \mathbf{P}_{(1,1)})_{t=1}^N$ with state space $I\!\!E = \{(s,l) : l \in \{1,2\}, s = 1, 2, \ldots, N\} \cup \{(\infty, \infty)\}$ and $\mathcal{G}_t = \sigma(W_1, W_2, \ldots, W_t)$ is homogeneous. The one-step transition probabilities are the following:

$$\begin{aligned} p(r,s) &= \mathbf{P}\{W_{t+1} = (s, l_s) \mid W_t = (r, l_r)\} \\ &= \begin{cases} \frac{1}{2} & \text{if } r = 1,\ s = 2, \\ \frac{r(r-1)}{s(s-1)(s-2)} & \text{if } 2 \leq r < s, \\ 0 & \text{if } r \geq s \text{ or } (r = 1,\ s \neq 2), \end{cases} \end{aligned} \tag{9}$$

$p(\infty, \infty) = 1$, $p(r, \infty) = 1 - 2\sum_{s=r+1}^N p(r,s)$ for $l_s, l_r \in \{1,2\}$ and $1 \leq r \leq s \leq N$. We will call this Markov chain the auxiliary Markov chain (AMC).

The solution of the two-decision-makers problem will partially use the solution of the problem of choosing BOS (see [8], [2], [14]). The problem can be treated as an optimal stopping problem for AMC with the following payoff function:

$$f_{\mathrm{BOS}}(r, l_r) = \begin{cases} \frac{r(2N-r-1)}{N(N-1)} & \text{if} \quad l_r = 1, \\ \frac{r(r-1)}{N(N-1)} & \text{if} \quad l_r = 2. \end{cases} \tag{10}$$

Let $\mathcal{T}^N = \{\tau \in \mathcal{S}^N : \tau = r \Rightarrow Y_r \in \{1,2\}\}$. It is a set of stopping times with respect to $\mathcal{G}_t$, $t = 1, 2, \ldots, N$. We search $\tau^* \in \mathcal{S}^N$ such that

$$\mathbf{P}\{Z_{\tau^*} \in \{1,2\}\} = \sup_{\tau \in \mathcal{S}^N} \mathbf{P}\{Z_\tau \in \{1,2\}\} = \sup_{\sigma \in \mathcal{T}^N} E_{(1,1)} f_{\mathrm{BOS}}(W_\sigma).$$

Denote $\Gamma(r,s) = \{(t, l_t) : t > r,\ l_t = 1\} \cup \{(t, l_t) : t > s,\ l_t = 2\}$. Let $r < s$ and $c(r,s) = E_{(r,l_r)} f_{\mathrm{BOS}}(W_\sigma)$, where $\sigma = \inf\{t : W_t \in \Gamma(r,s)\}$. Denote $c(r) = E_{(r,l_r)} f_{\mathrm{BOS}}(W_{\sigma_1}) = 2\frac{r(N-r)}{N(N-1)}$, where $\sigma_1 = \inf\{t : W_t \in \Gamma(r,r)\}$. We have

$$c(r,s) = \frac{r}{N(N-1)} \sum_{i=r+1}^{s-1} \frac{2N-i-1}{i-1} + \frac{r}{s-1} c(s-1) \tag{11}$$

for $r < s$, $r, s = 1, 2, \ldots, N$ ($\sum_r^s = 0$ if $s < r$). Define $r_a = \inf\{1 \leq r \leq N : f_{\mathrm{BOS}}(r,2) \geq c(r,r)\}$ and $r_b = \inf\{1 \leq r \leq r_a : f_{\mathrm{BOS}}(r,1) \geq c(r,r_a)\}$. Denote

$$\tilde{c}_{\mathrm{BOS}}(r,l_r) = \sup_{\tau \in \mathcal{S}_{r+1}^N} \mathbf{P}\{Z_\tau \in \{1,2\} \mid Y_r = l_r\}.$$

We have

$$\tilde{c}_{\mathrm{BOS}}(r,l_r) = \tilde{c}_{\mathrm{BOS}}(r) = \begin{cases} c(r) & \text{if } r_a \leq r \leq N, \\ c(r,r_a) & \text{if } r_b \leq r < r_a, \\ c(r_b-1,r_a) & \text{if } 1 \leq r < r_b. \end{cases} \tag{12}$$

The optimal stopping time for the one-decision-maker problem of choosing BOS is $\sigma^* = \inf\{t : W_t \in \Gamma(r_b, r_a)\} \in \mathcal{T}^N$ or $\tau^* = \inf\{r : (r, Y_r) \in \Gamma(r_b, r_a)\} \in \mathcal{S}^N$. We have $a = \lim_{N\to\infty} \frac{r_a}{N} = \frac{2}{3}$, $b = \lim_{N\to\infty} \frac{r_b}{N} \cong 0.3470$ and $\lim_{N\to\infty} \tilde{c}_{\mathrm{BOS}}(1) \cong 0.5736$ (cf. [11], [2], [19]).

To solve the two-person competitive stopping problem described at the beginning of the section let us perform a strategy of the players when one of them accepts some observation at moment r with relative rank $Y_r = l_r$. It is enough to focus our attention on a situation when Player 1 has accepted and Player 2 is alone in the remaining decision process. Player 2 will use a strategy $\sigma_r^{2^*} = \varsigma^*(r,l_r)$. The strategy $\varsigma^*(r,l_r)$ is such that

$$h(r,l_r) = E_{(r,l_r)} g((r,\sigma_\mu^1),(\mu,\varsigma^*(r,l_r))) = \inf_{\sigma \in \mathcal{S}_{r+1}^N} E_{(r,l_r)} g((r,\sigma_\mu^1),(\mu,\sigma)), \tag{13}$$

where the expectation is taken with respect to $\mathbf{P}_{(r,l_r)}$ of AMC. To perform strategy $\varsigma^*(r,l_r)$ let us consider the possible essential situations. Let $W_t = (r,l_r)$. Since Player 2 minimizes his expected loss (cf. (13)), he can do so by stopping on some object with relative rank 1 or 2. If $l_r = 1$, then he cannot change the payoff by stopping on the objects with relative rank 2 before another one having relative rank 1 has appeared. Let $W_s = (m,1)$ and $W_u = (n,2)$ for $u = t+1, t+2, \ldots, s-1$. Player 1 can be the winner in this case if $W_{s+1} = (\infty,\infty)$ and Player 2 does not accept the mth object. We see that it is the first moment after the acceptance decision of Player 1 when Player 2 can change the gain of Player 1. We want to know if it is optimal for Player 2 to stop at $(m,1)$. If he stops, he has -1 with the probability $f_{\mathrm{BOS}}(m,1)$ (see (10)). When he passes over and will behave optimally in the future, he has -1 with probability $\tilde{c}_{\mathrm{BOS}}(m)$. Since he minimizes his loss, his optimal strategy in $(m,1)$ is the same as in the previously mentioned one-player problem. If it happens that $n < m < r_b$, then according to the optimal strategy in the problem of one player choosing BOS, the mth object will not be accepted and Player 2 will behave according to σ^*. It means Player 1 will have $+1$ if the nth object is the best or it happens that his candidate is the absolute second and the best one will not be chosen by Player 2 (because she has appeared before r_b). If $l_r = 2$, then the optimal behaviour of Player 2 is to use the optimal strategy for the problem of one player choosing BOS. Hence, by (9), (12), and (10) we have

$$\begin{aligned} h_1(r,l_r) &= \mathbf{P}\{A_1 \mid \tau_1 = r, \tau_2 > \tau_1, Y_r = l_r\} \\ &= \begin{cases} \frac{r}{N} + \begin{cases} 0 & \text{if } r \geq r_b \\ \sum_{s=r+1}^{r_b-1} \frac{r}{s(s-1)} \frac{s(s-1)}{N(N-1)} & \text{if } r < r_b \end{cases} & \text{for } l_r = 1, \\ \frac{r(r-1)}{N(N-1)} & \text{for } l_r = 2 \end{cases} \end{aligned}$$

and

$$h_2(r,l_r) = \mathbf{P}\{A_2 \mid \tau_1 = r, \tau_2 > \tau_1, Y_r = l_r\}$$
$$= \begin{cases} \sum_{s=r+1}^{N} \frac{r}{s(s-1)} \max\left\{\frac{s(2N-s-1)}{N(N-1)}, \tilde{c}_{\mathrm{BOS}}(s)\right\} & \text{if } l_r = 1, \\ \tilde{c}_{\mathrm{BOS}}(r) & \text{if } l_r = 2, \end{cases}$$

where $\sigma_n^{i^*} = \varsigma^*(n, Y_n)$, $s = (\lambda, \{\sigma_n^{1^*}\})$, and $t = (\mu, \{\sigma_n^{2^*}\})$. The optimal strategy ς^*, after the first acceptance has been made at moment r on $Y_r = l_r$, has the form

$$\varsigma^*(r,l_r) = \begin{cases} \begin{cases} \vartheta_r & \text{if } \vartheta_r \geq r_b \\ \sigma^*_{\vartheta_r} & \text{if } \vartheta_r < r_b \end{cases} & \text{for } l_r = 1, \\ \sigma_r^* & \text{for } l_r = 2, \end{cases} \tag{14}$$

where $\vartheta_r = \inf\{s > r : Y_s = 1\}$ and $\sigma_r^* = \inf\{s > r : (s, Y_s) \in \Gamma(r_b, r_a)\}$.

Let us consider the auxiliary game described in §2. The above comments and the solution of the problem of one player choosing BOS suggest that it is enough to consider AMC. We will use it for further calculations. For presentation of strategies the sequence of relative ranks $(Y_n)_{n=1}^N$ is more convenient. To avoid some misunderstanding the arguments of the functions h, H, and v are the moment n and the relative rank Y_n as well as the state of process W_t. We have also $h(r,l_r) = -H(r,l_r) = h_1(r,l_r) - h_2(r,l_r)$. By backward induction we construct the strategies and the value of the game. The results of this calculation and consideration can be presented as follows.

Denote for $p \in [.5, 1]$

$$\begin{aligned} w(r,s,t,u;p) = &\sum_{j=r+1}^{s-1} p(r,j)[H(j,1) + w(j,s,t,u;p)] \\ &+ \sum_{j=s}^{t-1} p(r,j)[h(j,1)(2p-1) + w(j,j+1,t,u;p)] \\ &+ \sum_{j=t}^{u-1} p(r,j)[h(j,1)(2p-1) + H(j,2)] \\ &+ (2p-1)\sum_{j=u}^{N} p(r,j)[h(j,1) + h(j,2)] \end{aligned}$$

and $B_{st}(k) = \{(r,l_r) : s \leq r \leq t,\ l_r = k\}$. Solving (5) recursively we have $r_a = \min\{1 \leq r \leq N : h(r,2) \geq 0\}$ and obtain that there exist $r_{\alpha(p)} = \min\{r < r_a : H(r,2) \leq \tilde{v}(r;p)\}$, $r_\gamma = \min\{r < r_{\alpha(p)} : h(r,1) \geq 0\}$, and $r_{\beta(p)} = \min\{r < r_\gamma : H(r,1) \leq \tilde{v}(r;p)\}$ such that

$$v(r,l_r;p) = \begin{cases} h(r,l_r)(2p-1) & \text{if } (r,l_r) \in B_{r_\gamma N}(1) \cup B_{r_a N}(2), \\ H(r,l_r) & \text{if } (r,l_r) \in B_{r_{\beta(p)} r_\gamma - 1}(1) \cup B_{r_{\alpha(p)} r_a - 1}(2), \\ \tilde{v}(r;p) & \text{if } (r,l_r) \in B_{1 r_{\beta(p)} - 1}(1) \cup B_{1 r_{\alpha(p)} - 1}(2), \end{cases} \tag{15}$$

where

$$\tilde{v}(r;p) = \tilde{v}(r,l_r;p) = Tv(r,l_r;p) = \begin{cases} w(r,r+1,r+1,r+1;p) & \textit{if } r_a \leq r \leq N, \\ w(r,r+1,r+1,r_a;p) & \textit{if } r_{\alpha(p)} \leq r < r_a, \\ w(r,r+1,r_{\alpha(p)},r_a;p) & \textit{if } r_\gamma \leq r < r_{\alpha(p)}, \\ w(r,r_\gamma,r_{\alpha(p)},r_a;p) & \textit{if } r_{\beta(p)} \leq r < r_\gamma, \\ w(r_{\beta(p)},r_\gamma,r_{\alpha(p)},r_a;p) & \textit{if } 1 \leq r < r_{\beta(p)}. \end{cases} \tag{16}$$

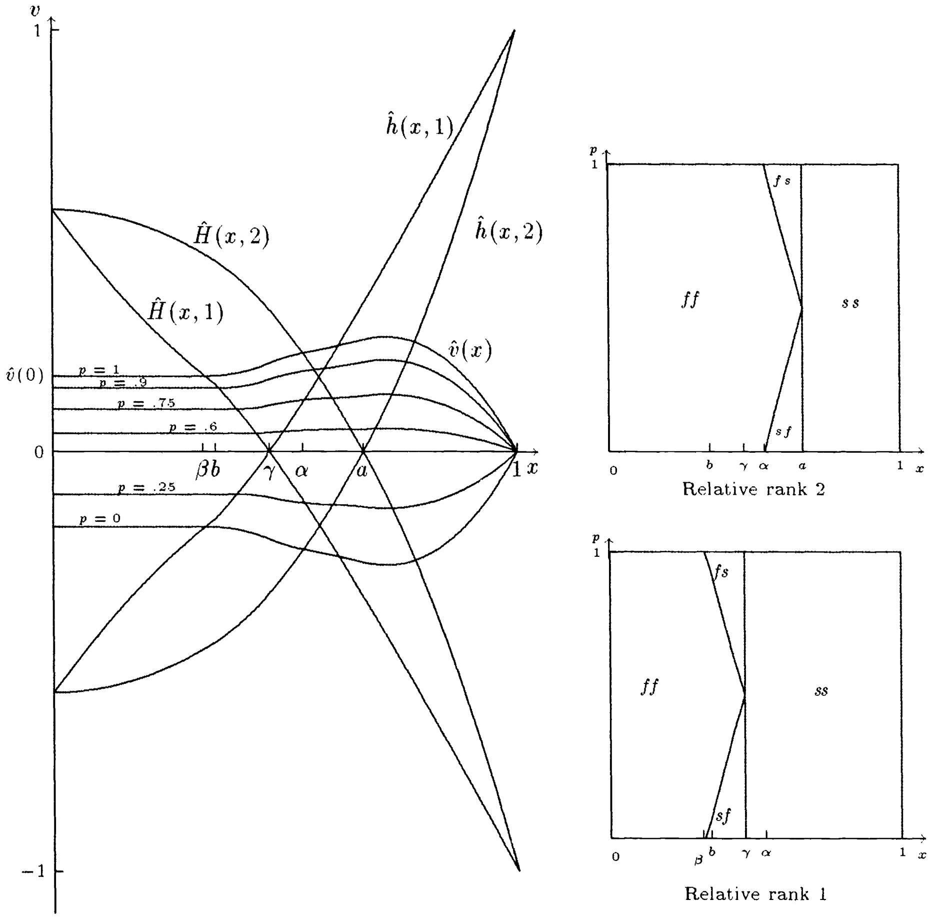

FIG. 1. *The gain functions, the value function, and strategies of the first stop in the* BOS *vs.* BOS *game.*

The optimal first-stop strategy is given by the sets (see §2 and Fig. 1) $A_t^{ss} = B_{r_\gamma N}(1) \cup B_{r_a N}(2)$, $A_t^{fs} = B_{r_{\beta(p)} r_\gamma}(1) \cup B_{r_{\alpha(p)} r_a}(2)$, $A_t^{ff} = I\!\!E \setminus (A_t^{ss} \cup A_t^{fs})$, $t = 1, 2, \ldots, N$.

The above solution was obtained in the following way. Let us assume $p \in [0.5, 1]$. For $n = N$ we have that ss is an equilibrium point. Assume for induction that ss is the equilibrium for $n, n+1, \ldots, N$ and $l_n = 1, 2$. It is not easy to check whether this assumption implies that ss is the equilibrium at $n-1$ and $l_{n-1} = 1, 2$. Instead of looking for a solution for every N, we will be content with the limit of the value of the game and the asymptotic behavior of the equilibrium strategies. By monotonicity of $h(r, l_r)$ and $H(r, l_r)$ on r this approach gives the solution for large N. To this end we find the limit of functions $h(r, l_r)$, $H(r, i_r)$ and under the induction assumption the limit of $\tilde{v}(r, l_r; p)$ when $N \to \infty$ in such a way that $\frac{r}{N} \to x$. Let us denote these

TABLE 1
The value of the game BOS *vs.* BOS *and decision point as a function of priority.*

Priority p	$\alpha(p)$	$\beta(p)$	Value of the game
1.00	0.5365	0.3263	0.1789
0.95	0.5485	0.3421	0.1651
0.90	0.5608	0.3557	0.1505
0.85	0.5736	0.3682	0.1350
0.80	0.5866	0.3809	0.1186
0.75	0.5998	0.3940	0.1013
0.70	0.6131	0.4073	0.0831
0.65	0.6266	0.4209	0.0639
0.60	0.6400	0.4349	0.0436
0.55	0.6534	0.4493	0.0223
0.50	0.6667	0.4639	0

limits by $\hat{h}(x,l)$, $\hat{H}(x,l)$, and $\hat{v}(x,l)$, respectively. Next, we are looking for x_{ss} such that the strategy ss is the equilibrium for the game

$$\begin{array}{c|cc} & \text{s} & \text{f} \\ \hline \text{s} & \hat{h}(x,l)(2p-1) & \hat{h}(x,l) \\ \text{f} & \hat{H}(x,l) & \hat{v}(x,l) \end{array} \tag{17}$$

for every $x \in [x_{ss}, 1]$, $l = 1, 2$. In the presence of the above, the value x_{ss} is the value of x nearest to 1 at which the equilibrium will change to the other one. We have $x_{ss} = a$. One can show that if $\epsilon > 0$ is small enough, then for $x \in (x_{ss} - \epsilon, x_{ss})$ the equilibrium point is ss at $(x,1)$ and fs at $(x,2)$. We can also say, by the above consideration, that for large N there exists r_{ss} such that for every $r \geq r_{ss}$ and $l = 1,2$ the equilibrium is ss and for $r = r_{ss} - 1$ at one of the state $(r_{ss} - 1, 1)$ or $(r_{ss} - 1, 2)$ the strategy ss is not the equilibrium. One can check that for $p \in (0.5, 1]$ we have that at $(r_{ss} - 1, 2)$ the strategy fs is the equilibrium strategy and at the state $(r_{ss} - 1, 1)$ the strategy ss is the equilibrium. Let us assume for backward induction that for $r, r+1, \ldots, r_{ss} - 1$ the equilibrium strategies are the same. By analysis of (17) for $x < x_{ss}$ similarly as for $x \in [x_{ss}, 1]$, one can find $x_{fs} \leq x_{ss}$ such that for $x \in [x_{fs}, x_{ss})$ at the state $(x, 1)$ the equilibrium is ss and at $(x, 2)$ the equilibrium is fs. When we iterate the above consideration up to $r = 1$ (or $x = 0$ in limit case), the construction of the strategy and the value of the game will be finished. The strategy is presented by constants $\beta(p)$, γ, $\alpha(p)$, and a. The numeric value of $\gamma \cong 0.4639$ and $a = \frac{2}{3}$. The parameters α and β depend on the value of the priority parameter p, and some values of p are given in Table 1 (see also Fig. 1). The value of the game also depends on p (see Table 1 and Fig. 1). By asymmetry of the problem with respect to $p = 0.5$ we have that the value of the problem fulfills the relation $\tilde{v}(r;p) = -\tilde{v}(r; 1-p)$. We have also following relations between stopping sets for equilibrium strategies. We have that A^{fs} for p and A^{sf} for $1-p$ are equal.

The analytical description of the value function follows.

Denote

$$\begin{aligned} \hat{w}_1(x_2, y_1, y_2, z; p) &= 2x_2 \ln \frac{x_2}{y_1} + x_2(y_1 - x_2) + x_2[(\ln x_2)^2 - (\ln y_1)^2] \\ &\quad + (2p-1)\left[2x_2 \ln \frac{y_2}{y_1} + x_2(y_1 - y_2) + x_2[(\ln y_2)^2 - (\ln y_1)^2]\right] \\ &\quad + x_2 y_2 \left[(4(2p-1) - 3z + 2\ln z)\left(\frac{1}{y_2} - \frac{1}{z}\right) - (2p-1)\ln \frac{z}{y_2}\right. \end{aligned}$$

$$+ 4(p-1)\left[\frac{\ln y_2}{y_2} - \frac{\ln z}{z}\right] + 2(2p-1)\left(\frac{1}{z} + \frac{\ln z}{z} - \ln ez\right)\Bigg],$$

Let p_0 be the solution of the equation $\hat{h}(b,1) = \hat{w}_1(b,\gamma,\alpha(p),a;p)$ in $[0.5,1]$. Such a solution exists since $\hat{w}_1$ is a nondecreasing function of p and $\hat{h}(b,1) < \hat{w}_1$ for $p = 1$. We have $p_0 \cong 0.9358$, and for $p \in [0.5,1]$ we define

$$\begin{aligned}\hat{w}(x_1,x_2,y_1,y_2,z;p) = & \left[(2 - x_2 + x_1)(x_2 - x_1) + (4 - x_2 + 2\ln x_2)x_1 \ln\frac{x_1}{x_2}\right] I\!I_{\{p>p_0\}} \\ & + 2x_1 \ln\frac{x_2}{y_1} + x_1(y_1 - x_2) + x_1[(\ln x_2)^2 - (\ln y_1)^2] \\ & + (2p-1)\left[2x_1 \ln\frac{y_2}{y_1} + x_1(y_1 - y_2) + x_1[(\ln y_2)^2 - (\ln y_1)^2]\right] \\ & + x_1 y_2 \Bigg[[4(2p-1) - 3z + 2\ln z]\left(\frac{1}{y_2} - \frac{1}{z}\right) - (2p-1)\ln\frac{z}{y_2} \\ & + 4(p-1)\left(\frac{\ln y_2}{y_2} - \frac{\ln z}{z}\right) + 2(2p-1)\left(\frac{1}{z} + \frac{\ln z}{z} - \ln ez\right)\Bigg].\end{aligned}$$

We have

$$(18)\ \hat{v}(x;p) = \lim_{N\to\infty} \tilde{v}(r;p) = \begin{cases} \hat{w}(x,x,x,x,x;p) & \textit{if } a \le x \le 1, \\ \hat{w}(x,x,x,x,a;p) & \textit{if } \alpha(p) \le x < a, \\ \hat{w}(x,x,x,\alpha(p),a;p) & \textit{if } \gamma \le x < \alpha(p), \\ \hat{w}(x,x,\gamma,\alpha(p),a;p) & \textit{if } \max(b,\beta(p) \le x < \gamma, \\ \hat{w}(x,\max(\beta(p),b),\gamma,\alpha,a;p) & \textit{if } \min(\beta(p),b) \le x < b, \\ \hat{w}(\beta,\max(\beta(p),b),\gamma,\alpha,a;p) & \textit{if } 0 \le x < \min(\beta(p),b). \end{cases}$$

So we can formulate the following theorem.

THEOREM 3.1. *In the competitive two-person problem of choosing* BOS *but better than the opponent the asymptotically optimal strategy of the first stop is described by the sets* A_t^{ss}, A_t^{fs}, *and* A_t^{ff}. *The second stop is according to* (14). *The value function of the problem is given by* (15), *the expected value with respect to* $\mathbf{P}_{(r,l_r)}$ *of* AMC *by* (16), *and its limit by* (18).

4. The best vs. the BOS game. Let us consider once more the game investigated in §3, but let us assume that the aim of Player 1 is to accept the BA. The meaning of the most of the denotations is the same as in §3. The changes of notation will be given.

We denote by A_i the random event that the ith player is a winner. For $s \in \tilde{\Lambda}^N$ and $t \in \tilde{M}^N$ we have $A_1 = \{\omega : X_{\tau_1} = 1\}$ and $A_2 = \{\omega : X_{\tau_2} = 1\} \cup \{\omega : X_{\tau_2} = 2,\ X_{\tau_1} \neq 1\}$. The payoff function in this game is $g_1(s,t) = I\!I_{A_1} - I\!I_{A_2}$.

First of all, let us consider the position when one of the players has accepted some object at moment r with the relative rank $Y_r = l_r$. We construct the strategy of the player who has not accepted any state yet. Since the aims of the players are different, we have to consider independently the situations when Player 1 has stopped as the first and when Player 2 has done so. We introduce the useful denotation

$$h_{ik}(r,l_r) = \mathbf{P}(A_k | \tau_i = r, \tau_j > \tau_i, Y_r = l_r)$$

for $k,i,j = 1,2$, $i \neq j$, $r = 1,2,\ldots,N$, $l_r = 1,2$.

Let Player 1 stop the process as the first at the moment r on the object with $Y_r = l_r$. As he wants to accept the object with the absolute rank 1, it is obvious that he will stop on the relatively first object. He will also probably accept, in some circumstances, the relatively second objects to disturb Player 2 in the realization of his aims. We will see that this supposition is true. Player 2 staying alone will use a strategy $\sigma_r^{2^*} = \varsigma^*(r, l_r)$ defined in (14) with $g(s,t) = g_1(s,t)$. Let $W_t = (r, l_r)$. Since Player 2 minimizes his expected loss and he would like to choose the BOS object, he can do so by stopping on some object with relative rank 1 or 2. The optimal strategy ς^* is given by (13). Consequently,

$$h(r, l_r) = h_{11}(r, l_r) - h_{12}(r, l_r),$$

where we have $h_{11}(r, l_r) = \frac{r}{N}$ for $l_r = 1$ and 0; otherwise, $h_{12}(r, l_r) = h_2(r, l_r)$.

Let us assume that Player 2 has stopped the process as the first on some object at moment r with relative rank $Y_r = l_r$. Player 1 will use a strategy $\sigma_r^{1^*} = \delta^*(r, l_r)$. The strategy $\delta^*(r, l_r)$ is such that

$$H(r, l_r) = E_{(r,l_r)} g_1((\lambda, \delta^*(r, l_r)), (r, \sigma_\lambda^2)) = \sup_{\sigma \in \mathcal{S}_{r+1}^N} E_{(r,l_r)} g_1((\lambda, \sigma), (r, \sigma_\lambda^2)).$$

Let $W_t = (r, l_r)$. Since Player 1 maximizes his expected gain and would like to choose the best object, he can do so by stopping on some object with relative rank 1. Denote $\tilde{c}_{\mathrm{BA}}(r) = \sup_{\tau \in \mathcal{S}_{r+1}^N} \mathbf{P}\{Z_\tau = 1 | Y_r = l_r\}$, $r_c = \inf\{1 \le r \le N : \sum_{i=r+1}^N \frac{1}{i-1} \le 1\}$, and $\tau_r^* = \inf\{s > r : Y_s = 1, s \ge r_c\}$. The optimal strategy δ^* of Player 1, after the first acceptance at the moment r on $Y_r = l_r$ by Player 2, has the form

$$\delta^*(r, l_r) = \begin{cases} \begin{cases} \vartheta_r & \text{if } \vartheta_r \ge r_c \\ \tau_{\vartheta_r}^* & \text{if } \vartheta_r < r_c \end{cases} & \text{for } l_r = 1, \\ \tau_r^* & \text{for } l_r = 2, \end{cases} \tag{19}$$

where ϑ_r is the first moment after r when $Y_r = 1$. We have

$$H(r, l_r) = h_{21}(r, l_r) - h_{22}(r, l_r),$$

where

$$h_{21}(r, l_r) = \sum_{s=r+1}^{N} p(r,s) \left[\max\left\{\frac{s}{N}, \tilde{c}_{\mathrm{BA}}(r)\right\} + \tilde{c}_{\mathrm{BA}}(r)\right] = \tilde{c}_{\mathrm{BA}}(r)$$

and

$$\begin{aligned} h_{22}(r, l_r) &= \mathbf{P}\{A_2 \mid \tau_2 = r,\ \tau_1 > \tau_2,\ Y_r = l_r\} \\ &= \begin{cases} \frac{r}{N} + \begin{cases} 0 & \text{if } r \ge r_c \\ \sum_{s=r+1}^{r_c - 1} \frac{r}{s(s-1)} \frac{s(s-1)}{N(N-1)} & \text{if } r < r_c \end{cases} & \text{for } l_r = 1, \\ \frac{r(r-1)}{N(N-1)} & \text{for } l_r = 2 \end{cases} \end{aligned}$$

Denote $h_p(r, l_r) = p h(r, l_r) + (1-p) H(r, l_r)$. Define $r_d = \min\{1 \le r \le N : h(r, 2) \ge H(r, 2)\}$ and $r_\ell = \min\{1 \le r \le r_d : h(r,1) \ge H(r,1)\}$. During the recursive construction of $\tilde{v}(r, l_r; p)$ and the strategy according to Theorems 2.4 and 2.5 (see also (5)) for a large N we get that there exist $r_{\nu(p)} = \min\{r < r_d : H(r,2) \le \tilde{v}(r;p)\}$ and $\tilde{p}_1 = \min\{0 \le p \le 1 : h(\ell, 1) < \tilde{v}(\ell; p)\}$. For $p \ge \tilde{p}_1$ there exists $r_{\kappa(p)} = \min\{r \le r_\ell :$

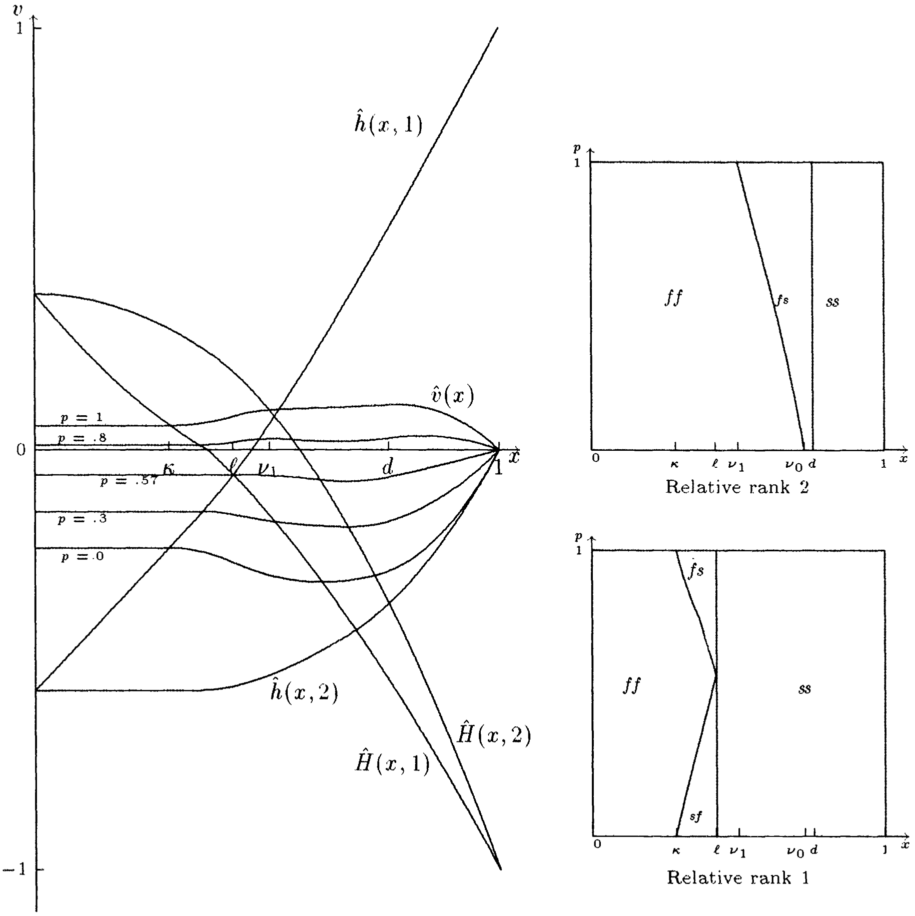

FIG. 2. *The gain function, the value functions, and strategies of the first stop in the random priority game BA vs. BOS but a better one than the opponent.*

$H(r,1) \le \tilde{v}(r;p)\}$, and for $p < \tilde{p}_1$ there exists $r_{\kappa(p)} = \min\{r \le r_\ell : h(r,1) \ge \tilde{v}(r;p)\}$. These points r_d, r_ℓ, $r_{\nu(p)}$, and $r_{\kappa(p)}$ are such that

$$
(20) \qquad v(r,l_r;p) = \begin{cases} h_p(r,l_r) & \textit{if } (r,l_r) \in B_{r_\ell N}(1) \cup B_{r_d N}(2), \\ H(r,l_r) & \textit{if } (r,l_r) \in B_{r_{\nu(p)} r_d - 1}(2), \\ H(r,l_r)\mathbb{I}_{\{p \ge \tilde{p}_1\}} & \\ \quad + h(r,l_r)\mathbb{I}_{\{p < \tilde{p}_1\}} & \textit{if } (r,l_r) \in B_{r_{\kappa(p)} r_\ell - 1}(1), \\ \tilde{v}(r;p) & \textit{if } (r,l_r) \in B_{1 r_{\kappa(p)} - 1}(1) \cup B_{1 r_{\nu(p)} - 1}(2), \end{cases}
$$

where

$$\tilde{v}(r;p) = Tv(r,l_r;p) = \begin{cases} w(r,r+1,r+1,r+1;p) & \text{if } r_d \le r \le N, \\ w(r,r+1,r+1,r_d;p) & \text{if } r_{\nu(p)} \le r < r_d, \\ w(r,r+1,r_{\nu(p)},r_d;p) & \text{if } r_\ell \le r < r_{\nu(p)}, \\ w(r,r_\ell,r_{\nu(p)},r_d;p) & \text{if } r_{\kappa(p)} \le r < r_\ell, \\ w(r_{\kappa(p)},r_\ell,r_{\nu(p)},r_d;p) & \text{if } 1 \le r < r_{\kappa(p)} \end{cases} \tag{21}$$

and

$$\begin{aligned} w(r,s,t,u;p) = {} & \sum_{j=r+1}^{s-1} \frac{r}{j(j-1)}[H(j,1)\mathbb{I}_{\{p\ge\tilde{p}_1\}} + h(j,1)\mathbb{I}_{\{p<\tilde{p}_1\}}] \\ & + \sum_{j=s}^{t-1} \frac{r}{j(j-1)} h_p(j,1) + \sum_{j=t}^{u-1} \frac{r(t-2)}{j(j-1)(j-2)}[h_p(j,1) + H(j,2)] \\ & + \sum_{j=u}^{N} \frac{r(t-2)}{j(j-1)(j-2)}[h_p(j,1) + h_p(j,2)] \end{aligned}$$

for $r \le s \le t \le u$. The optimal first-stop strategy is given by sets $A_t^{ss} = B_{r_\ell N}(1) \cup B_{r_d N}(2)$, $A_t^{fs} = (\mathbb{I}_{\{p\ge\tilde{p}_1\}} B_{r_{\kappa(p)} r_\ell - 1}(1)) \cup B_{r_{\nu(p)} r_d - 1}(2)$, $A_t^{sf} = \mathbb{I}_{\{p<\tilde{p}_1\}} B_{r_{\kappa(p)} r_\ell - 1}(1)$, $A_t^{ff} = \mathbb{E} \setminus (A_t^{ss} \cup A_t^{fs} \cup A_t^{sf})$, $t = 1,2,\dots,N$ (see §§2 and 3 and Fig. 2). Here we adopt the convention that for every set A we have $1 \cdot A = A$ and $0 \cdot A = \emptyset$, where $\emptyset$ is the empty set.

The function $w(r,s,t,u;p)$ also depends on r_b and r_c. Let $r \le s \le r \le t \le u$. When $N \to \infty$ and $\frac{r}{N} \to x_1$, $\frac{s}{N} \to x_2$, $\frac{t}{N} \to y_1$, and $\frac{u}{N} \to y_2$, we get

$$\begin{aligned} \hat{w}(x_1,x_2,y_1,y_2;p) &= \lim_{N\to\infty} w(r,s,t,u;p) \\ &= \hat{w}_{21}(x_1,x_2,y_1,y_2;p)\mathbb{I}_{\{p\ge p_1\}} + \hat{w}_{22}(x_1,x_2,y_1,y_2;p)\mathbb{I}_{\{p<p_1\}}, \end{aligned}$$

where

$$\begin{aligned} \hat{w}_{21}(x_1,x_2,y_1,y_2;p) = x_1 & \left[\left(\ln\frac{x_1}{x_2} - \frac{1}{2}((\ln x_2)^2 - (\ln x_1)^2) \right) \mathbb{I}_{\{x_1>c\}} \right. \\ & \left. - \left(\frac{1}{2} + \ln x_2 + \frac{1}{2}(\ln x_2)^2 \right) \mathbb{I}_{\{x_1\le c\}} \right] \\ & + \frac{x_1 \mathbb{I}_{\{x_1>c\}} + c\mathbb{I}\{x_1 \le c\}}{x_2} \hat{w}_1(x_2,y_1,y_2;p), \end{aligned}$$

$$\begin{aligned} \hat{w}_{22}(x_1,x_2,y_1,y_2;p) = x_1 & \left[\left((\ln x_2)^2 - (\ln x_1)^2 + x_1 - x_2 + 2\ln\frac{x_2}{x_1} \right) \mathbb{I}_{\{x_1>b\}} \right. \\ & + \left((4 - 2b + 2\ln b)\ln\frac{b}{x_1} + (2-b)(x_1-b) \right. \\ & \left. \left. + (\ln x_2)^2 - (\ln b)^2 - x_2 + b + 2\ln\frac{x_2}{b} \right) \mathbb{I}_{\{x_1\le b\}} \right] \\ & + \frac{x_1 \mathbb{I}_{\{x_1>b\}} + b\mathbb{I}_{\{x_1\le b\}}}{x_2} w_1(x_2,y_1,y_2;p), \end{aligned}$$

TABLE 2

and

$$\begin{aligned}\hat{w}_1(x_2,y_1,y_2;p) = x_2 &\left[(3p-1)\ln\frac{y_1}{x_2} + \frac{3p-1}{2}((\ln y_1)^2 - (\ln x_2)^2) - p(y_1 - x_2)\right] \\ &+ x_2 y_1 \left[3(2p-1)\left(\frac{1}{y_1} - \frac{1}{y_2}\right) + (3p-2)\left(\frac{\ln y_1}{y_1} - \frac{\ln y_2}{y_2}\right)\right. \\ &\left. + (1+p)\ln\frac{y_1}{y_2}\right] + y_1^2\left[(p-1)\left(\frac{1}{y_2} - 1\right)\right. \\ &\left. + (4p-2)\left(\frac{\ln y_2}{y_2} + \frac{1}{y_2} - 1\right) - (2p-1)\ln y_2\right].\end{aligned}$$

Parameter p_1 is asymptotic equivalent of $\tilde{p}_1$. The value of p_1 can be determined as the solution of some equation which will be given later.

Let $d = \lim_{N\to\infty} \frac{r_d}{N} \cong 0.7587$ and $\ell = \lim_{N\to\infty} \frac{r_\ell}{N} \cong 0.4237$. We have that $\nu(p) = \lim_{N\to\infty} \frac{r_\nu(p)}{N}$ is the solution of the equation $\hat{w}_1(\nu,\nu,d;p) = \hat{H}(\nu,2)$ in $[\ell,d]$. Now we can determine p_1 as the solution of the equation $\hat{w}_1(\ell,\nu(p),d;p) = \hat{H}(\ell,1)$ with respect to p in $[0,1]$. Such a solution exists since $\hat{w}_1(\ell,\nu(p),d;p)$ is a nondecreasing function of p and $\hat{H}(\ell,\nu(1),d;1) < \hat{w}_1(\ell,\nu(1),d;1)$. We have $p_1 \cong 0.5659$.

Determine $\kappa(p) = \lim_{N\to\infty} \frac{r_{\kappa(p)}}{N}$. The decision point $\kappa(p)$ is the solution of the equation $\hat{w}(\kappa,\ell,\nu(p);p) = \hat{h}(\kappa,1)\mathbb{I}_{\{p<p_1\}} + \hat{H}(\kappa,1)\mathbb{I}_{\{p\geq p_1\}}$. The asymptotic value function (see also Fig. 2 and Table 2) is

$$\text{(22)}\qquad \hat{v}(x;p) = \lim_{N\to\infty} \tilde{v}(r;p) = \begin{cases} \hat{w}(x,x,x,x;p) & \text{if } d \leq x \leq 1, \\ \hat{w}(x,x,x,d;p) & \text{if } \nu(p) \leq x < d, \\ \hat{w}(x,x,\nu(p),d;p) & \text{if } \ell \leq x < \nu(p), \\ \hat{w}(x,\ell,\nu(p),d;p) & \text{if } \kappa(p) \leq x < \ell, \\ \hat{w}(\kappa(p),\ell,\nu(p),d;p) & \text{if } 0 \leq x < \kappa(p). \end{cases}$$

We can formulate the following theorem.

THEOREM 4.1. *For a large N in the competitive two-person problem of choosing the best vs. the BOS applicant but a better one than the opponent, the asymptotically optimal strategy of the first stop is described by the sets A_t^{ss}, A_t^{fs}, A_t^{sf}, and A_t^{ff}. The second stop is according to ς^* given by* (14) *for Player* 2 *and δ^* given by* (19) *for Player* 1. *The value function of the problem is given by* (20), *the expected value with respect to $\mathbf{P}_{(r,l_r)}$ of* AMC *by* (21), *and its limit by* (22).

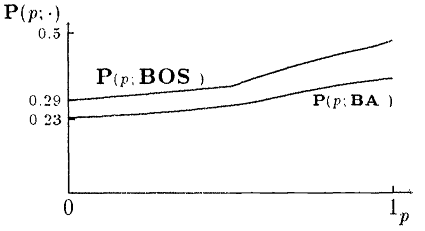

FIG. 3. *The probability of success in the* BOS *vs.* BOS *and* BA *vs.* BOS *games.*

5. Final remarks. The results of §§2 and 3 give an image of the influence of the priority level on the game value. We have naturally realized that the such influence depends also on the definition of the gain function or, in other words, the aims of the players. To compare the role of priority in the two games considered we compare the results obtained. We can observe that the BOS vs. BOS game is fair for $p = 0.5$ (§3) and the BA vs. BOS game is fair for $p \cong 0.7580$. The question is, how much does Player 2 have to reduce his demand concerning the absolute rank of the chosen applicant to recompense the full priority ($p = 1$) of Player 1 looking for the BA?

Finally, let us investigate the probability that Player 1 will be the winner in both examples considered. Let us denote as $\mathbf{P}_N(p; \mathrm{BOS})$ and $\mathbf{P}_N(p; \mathrm{BA})$ the probability of success for Player 1 in the BOS vs. BOS game (§3) and the BA nvs. BOS game (§4), respectively, when the two players adopt the equilibrium strategies and the horizon is N. From the definition of event A_1 and the definition of the equilibrium strategies in the two examples we have

$$\begin{aligned}\mathbf{P}_N(p; \mathrm{BOS}) = &\sum_{j=r_{\beta(p)}+1}^{r_\gamma - 1} \frac{r_{\beta(p)}}{j(j-1)}[\mathbb{I}_{\{p\le 0.5\}} h_1(j,1) + \mathbb{I}_{\{p>0.5\}} h_2(j,1)] \\ &+ \sum_{j=r_\gamma}^{r_{\alpha(p)}-1} \frac{r_{\beta(p)}}{j(j-1)}[ph_1(j,1) + (1-p)h_2(j,1)] \\ &+ \sum_{j=r_{\alpha(p)}}^{r_a - 1} \frac{r_{\beta(p)}(r_{\alpha(p)}-2)}{j(j-1)(j-2)}[\mathbb{I}_{\{p\le 0.5\}} h_1(j,2) \\ &+ \mathbb{I}_{\{p>0.5\}} h_2(j,2) + ph_1(j,1) + (1-p)h_2(j,1)] \\ &+ \sum_{j=r_a}^{N} \sum_{k=1}^{2} \frac{r_{\beta(p)}(r_{\alpha(p)}-2)}{j(j-1)(j-2)}[ph_1(j,k) + (1-p)h_2(j,k)]\end{aligned}$$

and

$$\begin{aligned}\mathbf{P}_N(p; \mathrm{BA}) = &\sum_{j=r_{\kappa(p)}+1}^{r_\ell - 1} \frac{r_{\kappa(p)}}{j(j-1)}[\mathbb{I}_{\{p\le \tilde{p}_1\}} h_{11}(j,1) + \mathbb{I}_{\{p>\tilde{p}_1\}} h_{21}(j,1)] \\ &+ \sum_{j=r_\ell}^{r_{\nu(p)}-1} \frac{r_{\kappa(p)}}{j(j-1)}[ph_{11}(j,1) + (1-p)h_{21}(j,1)]\end{aligned}$$

ON NONLINEAR OPTIMAL CONTROL PROBLEMS WITH STATE CONSTRAINTS*

MONICA MOTTA[†]

Abstract. This paper is concerned with an optimal control problem where the state is constrained to stay either in a smooth open set Ω or in its closure $\overline{\Omega}$. Under a "higher-order" sufficient condition for the viability of Ω and $\overline{\Omega}$, we prove that the optimal cost function v_Ω is the unique continuous constrained solution of the Hamilton–Jacobi–Bellman equation. Furthermore, we show that v_Ω coincides with the optimal cost function $v_{\overline{\Omega}}$ on Ω.

Key words. viscosity solutions, Hamilton–Jacobi–Bellman (HJB) equations, state–space constraints, Lie brackets

AMS subject classifications. 93C10, 49L25

1. Introduction.

This paper studies the value functions of optimal control problems where the state is constrained to stay either in a smooth open set Ω or in its closure $\overline{\Omega}$. We are interested in the continuity properties of the value functions v_Ω and $v_{\overline{\Omega}}$, respectively, in the Hamilton–Jacobi–Bellman (HJB) equation of dynamic programming they satisfy in some weak sense, and in proving that $v_\Omega = v_{\overline{\Omega}}$ on Ω.

These problems were first studied by Soner in [13] in the context of viscosity solutions (see [5], [6], [10]) under the assumption that at each point of $\partial\Omega$ there is a field of the system pointing inward Ω. Clearly this condition ensures the "viability" of the sets Ω and $\overline{\Omega}$ for the system, that is, the existence of controls that do not violate the constraints. Soner proved that $v_{\overline{\Omega}}$ is the unique viscosity solution of the HJB equation with a suitable new boundary condition. This notion of *constrained viscosity solution* was studied by Capuzzo-Dolcetta and P. L. Lions in [4] for more general problems and by Loreti and Tessitore in [12]. Loreti proved in [11], among other things, that $v_\Omega = v_{\overline{\Omega}}$ under Soner's assumption. The goal of this paper is to weaken this assumption and consider a "first-order" sufficient condition for the viability of Ω and $\overline{\Omega}$, that is, a condition involving the derivatives of the fields of the system. This is analogous to the application of "higher-order" controllability conditions to the study of the value function in time-optimal control problems, see, e.g., the survey paper of Stefani [14], Sussmann [15], and Evans and James [7] as well as Bardi and Soravia [1] for the connection with Hamilton–Jacobi equations.

Our condition is that, around the points of $\partial\Omega$ where Soner's assumption is not satisfied, the system is symmetric and there is a Lie bracket between two fields of the system pointing inward Ω.

More precisely, let Ω be an open subset of $\mathbb{R}^n$, let $b(\cdot,\cdot)$ be a continuous function from $\mathbb{R}^n \times U$ into $\mathbb{R}^n$, and let $\sigma(\cdot)$ be a C^1 function from $\mathbb{R}^n$ into $M_{n\times m}$, where $M_{n\times m}$ denotes the vector space of $n \times m$ matrices on $\mathbb{R}$. We consider the trajectories $y_x(\cdot, u)$ which are solutions of the controlled dynamical system

$$\begin{cases} y'(t) = b\big(y(t), u(t)\big), & t > 0, \\ y(0) = x, \end{cases} \tag{1.1}$$

which will be assumed to have the symmetric structure

$$\begin{cases} y'(t) = \sigma(y(t))u(t), & t > 0, \\ y(0) = x, \end{cases} \tag{1.2}$$

around certain points of the boundary, and where the control $u(\cdot)$ is measurable and takes values in a compact subset U of $\mathbb{R}^m$ symmetrical with respect to the origin. Let $\mathcal{A}_x^0$ and $\mathcal{A}_x$ be the sets of the controls under which $y_x(t,u)$ lies in Ω or, respectively, in $\overline{\Omega}$ (bar denotes the closure). Given a discounted cost associated to every control u and x in $\mathbb{R}^n$, we consider either $\mathcal{A}_x^0$ or $\mathcal{A}_x$ as the set of admissible controls, so that we obtain, respectively, the optimal value functions

$$v_\Omega(x) = \inf_{u\in\mathcal{A}_x^0} \int_0^{+\infty} e^{-t} f(y(t),u(t))\,dt, \qquad x \in \Omega, \tag{1.3}$$

or

$$v_{\overline{\Omega}}(x) = \inf_{u\in\mathcal{A}_x} \int_0^{+\infty} e^{-t} f(y(t),u(t))\,dt, \qquad x \in \overline{\Omega}, \tag{1.4}$$

by assuming $\mathcal{A}_x^0$ (and hence $\mathcal{A}_x$) $\neq \emptyset$.

The sufficient condition given in [13] to prove the continuity of $v_{\overline{\Omega}}$ follows:

$$\text{(S)} \qquad \forall x \in \partial\Omega \qquad \exists u(x) \in U: \quad b(x,u(x)) \cdot n(x) < 0,$$

where $n(x)$ is the exterior normal vector to Ω at x. Moreover, [13] introduces the definition of constrained viscosity solution of the HJB equation

$$\text{(HJB)} \qquad v + H(x,Dv) = 0 \qquad x \in \overline{\Omega},$$

where the Hamiltonian is given by

$$H(x,p) = \max_{u\in U}\{-b(x,u)\cdot p - f(x,u)\}, \tag{1.5}$$

that is, a subsolution in Ω which is supersolution in $\overline{\Omega}$, and [13] checks that, under condition (S), $v_{\overline{\Omega}}$ is the unique constrained viscosity solution of the HJB equation.

Here we replace (S) with the following assumption:

(A1) $\forall x \in \partial\Omega$ $\min_{u\in U} b(x,u)\cdot n(x) \leq 0$ and in case $\min_{u\in U} b(x,u)\cdot n(x) = 0$, there is a neighborhood of x where the system takes the form (1.2) and

$$\exists u_1(x), u_2(x) \in U \quad \text{satisfying} \quad [\sigma_1,\sigma_2](x)\cdot n(x) < 0, \tag{1.6}$$

where $\sigma_i(x) := \sigma(x)u_i(x)$ $(i = 1,2)$ and $[h,k]$ denotes the Lie bracket between $h,k \in C^1(\mathbb{R}^n,\mathbb{R}^n)$, i.e., $[h,k](x) := k'(x)h(x) - h'(x)k(x)$.

Note that under such an assumption, the set of all points $x \in \partial\Omega$ which fails to verify (S) has always empty interior, as it is observed in Remark 2.2.

Thus by assuming (A1) and some technical hypotheses stated in (A0) in §2, we prove that v_Ω coincides with $v_{\overline{\Omega}}$ in Ω. Furthermore we check that the value function v_Ω is (bounded and) uniformly continuous (briefly, $v_\Omega \in BUC(\Omega)$), so that it has unique continuous extension $\bar{v}$ on $\overline{\Omega}$, and we characterize $\bar{v}$ as the unique continuous constrained viscosity solution of the HJB equation, therefore extending the main result of [13]. Here we need some results in the theory of discontinuous viscosity solution, see Barles and Perthame [3], Ishii [9], and Bardi and Soravia [2]. Finally by means of an example we show that, unlike assumption (S), (A1) does not guarantee the continuity of $v_{\overline{\Omega}}$ on $\partial\Omega$.

The paper is organized as follows. In §2 we lay down the hypotheses. In §3 it is shown that $v_\Omega \in BUC(\Omega)$. and in §4 we check that $v_\Omega = v_{\overline{\Omega}}$ in Ω. In §5 we prove that $\bar{v}$ is the unique constrained solution of the HJB equation, and in §6 we give an example where $v_{\overline{\Omega}}$ is discontinuous on $\partial\Omega$.

2. Statement of the problem. Throughout this paper we will use (A1) and the following assumptions:

(A0) (i) Ω is a connected, open subset of $\mathbb{R}^n$ with a C^2 compact boundary $\partial\Omega$;

(ii) the controls take values in a compact symmetrical subset of $\mathbb{R}^m$, U;

(iii) $\sigma \in C^1(\mathbb{R}^n, M_{n\times m})$ is bounded and Lipschitz continuous;

(iv) $f \in C(\mathbb{R}^n \times U, \mathbb{R})$ and $b \in C(\mathbb{R}^n \times U, \mathbb{R}^n)$ are bounded and Lipschitz continuous in x, uniformly w.r.t. U, i.e.,

$$(2.1)\qquad \begin{array}{ll} |f(x,u) - f(y,u)| \le L(f)|x-y|, & |f(x,u)| \le K(f) \\ |b(x,u) - b(y,u)| \le L(b)|x-y|, & |b(x,u)| \le K(b) \end{array} \qquad \forall x,y \in \mathbb{R}^n,\ \forall u \in U.$$

For any Lipschitz-continuous (possibly in x, uniformly w.r.t. U) and bounded function g, we call $L(g)$ and $K(g)$ the Lipschitz constant and the bound of g, respectively.

Consider $\mathcal{A}$, the set of all measurable maps of $[0,+\infty)$ into U. For any $u \in \mathcal{A}$ and $x \in \overline{\Omega}$, let $y_x(\cdot,u)$ be the solution of (1.1) with initial data $y_x(0,u) = x$. The associated payoff is

$$(2.2)\qquad J(x,u) = \int_0^{+\infty} e^{-t} f\big(y(t),u(t)\big)\,dt.$$

We allow only the controls which leave $y_x(\cdot,u)$ in Ω (or in $\overline{\Omega}$); thus the sets of admissible controls are

$$\mathcal{A}_x^0 := \big\{u \in \mathcal{A} :\ y_x(t,u) \in \Omega\ \forall t \ge 0\big\} \quad \text{for any } x \in \Omega$$

and

$$\mathcal{A}_x := \big\{u \in \mathcal{A} :\ y_x(t,u) \in \overline{\Omega}\ \forall t \ge 0\big\} \quad \text{for any } x \in \overline{\Omega},$$

respectively. We suppose $\mathcal{A}_x^0 \neq \emptyset$, hence both the optimal value functions v_Ω and $v_{\overline{\Omega}}$ defined in §1 are bounded. Setting $J_t(x,u) := \int_0^t e^{-s} f\big(y(s),u(s)\big)\,ds$ the dynamic programming principle (DPP) assumes for every $t > 0$ the form

$$(2.3)\qquad v_\Omega(x) = \inf_{u\in\mathcal{A}_x^0} \big\{J_t(x,u) + e^{-t} v_\Omega(y(t))\big\} \qquad \forall x \in \Omega$$

and

$$(2.4)\qquad v_{\overline{\Omega}}(x) = \inf_{u\in\mathcal{A}_x} \big\{J_t(x,u) + e^{-t} v_{\overline{\Omega}}(y(t))\big\} \qquad \forall x \in \overline{\Omega},$$

respectively.

Remark 2.1. For the sake of simplicity we assume that the boundary $\partial\Omega$ is compact and that both the functions $b(\cdot,U)$ and $\sigma(\cdot)$ are bounded and Lipschitz continuous, but we could obtain the same results by using a local version of the techniques indicated in this paper.

Remark 2.2. The assumption (A1) implies that the set of the points $x \in \partial\Omega$ for which the Soner's condition (S) fails, i.e., where $\min_{u\in U} b(x,u)\cdot n(x) = 0$, has empty interior.

Proof. Assume (A1) and let us suppose that there exists an open subset Λ of $\mathbb{R}^n$ such that $\partial\Lambda := \Lambda \cap \partial\Omega \neq \emptyset$ and for all $x \in \partial\Lambda$, one has $\min_{u\in U} b(x,u)\cdot n(x) = 0$; hence we can assume that the system has the form (1.2) on Λ. Then we find a contradiction in that for any pair $u_1, u_2 \in U$, the Lie bracket $[\sigma_1, \sigma_2](x)$, where $\sigma_i(x) = \sigma(x)u_i$ $(i = 1, 2)$, is tangent to Ω in x. Indeed, since under our assumption $\forall u \in \mathcal{A}$ the corresponding trajectory $y_x(t, u)$ is in $\partial\Omega$ for all time t small enough, by standard properties of the Lie brackets we have $[\sigma_1, \sigma_2](x) \cdot n(x) = 0$ for all $u_1, u_2 \in U$. Hence (1.6) fails to hold, and that contradicts assumption (A1). □

3. Uniform continuity of the value function v_Ω on Ω.

In this section we prove that the value function v_Ω belongs to $BUC(\Omega)$. First, let us note that, if u is an admissible control for $x_0 \in \Omega$ which leaves $y_{x_0}(t, u)$ either in $\overline{\Omega}$ or in Ω $\forall t > 0$, then u is not necessarily admissible at any point x, regardless of how close that point is to x_0. The following lemma shows a way to modify it, keeping $y_x(\cdot, u)$ in Ω at least on the interval $[0, t^*]$ with $t^* > 0$, independent of x_0 and x, and changing the cost proportionally to $|x - x_0|^{1/2}$.

LEMMA 3.1. *Assume* (A0), (A1). *Then there are some* $t^* > 0$ *and* $L > 0$ *such that for any* $x \in \Omega$ *and* $u \in \mathcal{A}$ *there exists some constant* $\alpha_x > 0$ *such that for all* $\alpha \in [0, \alpha_x]$ *one can determine a control* $\bar{u} \in \mathcal{A}$ *satisfying*

(i) $y_x(t, \bar{u}) \in \overline{\Omega}_\alpha$ $\forall t \in [0, t^*]$;

(ii) $|J_{t^*}(x, \bar{u}) - J_{t^*}(x, u)| \le L\sqrt{\tilde{d}_\alpha}$,

where

$$\Omega_\alpha := \{y \in \Omega : \ \mathrm{dist}(y, \partial\Omega) > \alpha\} \tag{3.1}$$

and

$$\tilde{d}_\alpha := \sup\{\mathrm{dist}(y_x(t, u), \Omega_\alpha) : \quad t \in [0, t^*]\}. \tag{3.2}$$

Proof. First of all, let us observe that under the hypotheses on Ω and $\partial\Omega$ in (A0), there exists some $\hat{\alpha} > 0$ such that for every $\alpha \in [0, \hat{\alpha}]$ the set Ω_α is a nonempty, connected open subset of $\mathbb{R}^n$ with C^2 compact boundary $\partial\Omega_\alpha$. Moreover, the signed distances $d(\cdot) := d(\cdot, \partial\Omega)$ and $d_\alpha(\cdot) := d(\cdot, \partial\Omega_\alpha)$ verify the simple relation

$$d_\alpha(y) = d(y) + \alpha \qquad \forall y \in \mathbb{R}^n. \tag{3.3}$$

The proof of (3.3) follows quite easily, e.g., by the ε-neighborhood theorem in §3 of [8].

Furthermore, we note that $\forall x \in \partial\Omega$ there are $\delta(x) > 0$ and $\xi_0(x) > 0$ such that the signed distance $d(\cdot) = d(\cdot, \partial\Omega)$ can be redefined as a C^2 and negative function inside Ω, verifying, by (A1), either

$$b(y, u(x)) \cdot d'(y) \le -\xi_0(x) < 0 \qquad \forall y \in B(x, \delta(x)), \tag{3.4}$$

if $\min_{u \in U} b(x, u) \cdot n(x) < 0$ and this minimum is attained at $u = u(x)$ or

$$\left.\begin{aligned} b(y, u) &= \sigma(y)u, \\ [\sigma_1, \sigma_2](y) \cdot d'(y) &\le -32\xi_0(x) < 0 \end{aligned}\right. \qquad \forall y \in B(x, \delta(x)), \tag{3.5}$$

with $\sigma_i(y) = \sigma(y)u_i(x)$ $(i = 1, 2)$, if $\min_{u \in U} b(x, u) \cdot n(x) = 0$. By the compactness of $\partial\Omega$, there exist $x_1, \dots, x_R \in \partial\Omega$ such that $\{B(x_j, \delta_j/4) \ : \ j = 1, \dots, R\}$ with $\delta_j = \delta(x_j)$ as an open covering of $\partial\Omega$. By setting

$$\delta := \min\{\delta_j/4 : \ j = 1, \dots, R\}, \quad \xi_0 := \min\{\xi_0(x_j) : \ j = 1, \dots, R\},$$
$$I := \left\{j \in \{1, \dots, R\} : \ \min_{u \in U} b(x_j, u) \cdot n(x_j) = 0\right\},$$

one has for all $x \in B(\partial\Omega, \delta) := \{y \in \mathbb{R}^n \ : \ \operatorname{dist}(y, \partial\Omega) < \delta\}$:

$$\begin{aligned} x &\in B(x_j, \delta_j/2) \quad \text{for some } j, \\ y_x(t,u) &\in B(x_j, \delta_j) \qquad \forall t \in [0, \delta/K(b)] \text{ and } \forall u \in \mathcal{A}. \end{aligned} \tag{3.6}$$

Furthermore, if $j \in \{1, \ldots, R\} \setminus I$, one has

$$b\big(y_x(t,u), u(x_j)\big) \cdot d'\big(y_x(t,u)\big) \le -\xi_0 < 0 \qquad \forall t \in [0, \delta/K(b)] \text{ and } \forall u \in \mathcal{A}; \tag{3.7}$$

otherwise, i.e., if $j \in I$,

$$[\sigma_1, \sigma_2]\big(y_x(t,u)\big) \cdot d'\big(y_x(t,u)\big) \le -32\xi_0 < 0 \qquad \forall t \in [0, \delta/K(b)] \text{ and } \forall u \in \mathcal{A}, \tag{3.8}$$

with $\sigma_i(y) = \sigma(y) u_i(x_j)$ (and $i = 1, 2$) holds.

For any $x \in \Omega$ let us set

$$\alpha_x := \frac{|d(x)| \wedge \delta}{2}, \tag{3.9}$$

where $\forall \nu, \mu \in \mathbb{R}$, $\nu \wedge \mu$ denotes the $\min\{\nu, \mu\}$. Note that, by decreasing δ if necessary, we can assume $\delta \le \hat{\alpha}$, hence $\forall \alpha \in [0, \alpha_x]$, (3.3) holds.

Let $x \in \Omega_\delta$. Then $B(x, \delta/2) \subset \Omega_{\delta/2}$, hence by (3.9) and by a standard estimate it follows that for all $\alpha \in [0, \alpha_x]$, $y_x(t,u) \in \overline{\Omega}_\alpha$ $\forall t \in [0, t^*]$ and $\forall u \in \mathcal{A}$ if $t^* = \delta/2K(b)$. Thus both (i) and (ii) hold by choosing $\bar{u} \equiv u$.

Let $x \in \Omega \cap B(\partial\Omega, \delta)$, so that $x \in B(x_j, \delta_j/2)$ for some $j \in \{1, \ldots, R\}$ and either $j \in \{1, \ldots, R\} \setminus I$, or $j \in I$. Since for all $\alpha \in [0, \alpha_x]$ the signed distance $d_\alpha(\cdot) = d(\cdot, \partial\Omega_\alpha)$ satisfies (3.3), in the first case Soner's condition (S) holds on $\partial\Omega_\alpha \cap B(x, \delta)$ $\forall \alpha \in [0, \alpha_x]$, see (3.7). Thus, analogous to Lemma 3.2 of [13], one can verify that there exist some constants $t^* > 0$ and $L > 0$, independent of x and α, such that $\forall u \in \mathcal{A}$, the control $\bar{u}$ defined by

$$\bar{u}(t) := u(t)\chi_{[0,t_0)}(t) + u(x_j)\chi_{[t_0, t_0 + k\tilde{d}_\alpha]}(t) + u(t - k\tilde{d}_\alpha)\chi_{(t_0 + k\tilde{d}_\alpha, +\infty)}(t), \tag{3.10}$$

with $\tilde{d}_\alpha$ in (3.2), and

$$k := \frac{4}{\xi_0}, \qquad t_0 := \inf\{t \in (0, t^*] \ : \ y_x(t,u) \in \partial\Omega_\alpha\},$$
$$\chi_{\mathcal{I}}(t) := \begin{cases} 1 & t \in \mathcal{I} \\ 0 & t \in \mathbb{R} \setminus \mathcal{I} \end{cases} \qquad \forall \mathcal{I} \subset \mathbb{R},$$

satisfies both (i) and (ii), for we can assume $\tilde{d}_\alpha \le 1$ so that $\tilde{d}_\alpha \le \sqrt{\tilde{d}_\alpha}$ $\forall \alpha \in [0, \alpha_x]$. Otherwise, if $j \in I$, for a fixed $t^* \in (0, \delta/K(b)]$, we set

$$\alpha_i(t) := u_1\big(\chi_{[0, t_i/4)}(t) - \chi_{[t_i/2, 3t_i/4)}(t)\big) + u_2\big(\chi_{[t_i/4, t_i/2)}(t) - \chi_{[3t_i/4, t_i]}(t)\big), \tag{3.11}$$

where $t_i \ge 0$ will be chosen later, $u_h = u_h(x_j)$ $(h = 1, 2)$, and we define $T_0 := 0$, $T_k := \sum_{i=1}^k t_i$. Let some $u \in \mathcal{A}$ and $\alpha \in [0, \alpha_x]$ be fixed. We claim that the control

$$\bar{u}(t) := \sum_{i=1}^{N} \alpha_i(t - T_{i-1})\chi_{[T_{i-1}, T_i)}(t) + u(t - T_N)\chi_{[T_N, +\infty)}(t), \tag{3.12}$$

by choosing convenient values of $t^* > 0$, $t_i = t_i(x,\alpha)$ and $N = N(x,\alpha)$, reaches our goal. We set $y_x(\cdot) := y_x(\cdot,u)$ and $\bar{y}_x(\cdot) := y_x(\cdot,\bar{u})$. Then for $t \geq 0$ we get the estimate

$$\begin{aligned}(3.13)\quad d\big(\bar{y}_x(t+T_N)\big) &= d\big(\bar{y}_x(T_N)\big) + \int_0^t d'\big(\bar{y}_x(s+T_N)\big)\cdot\sigma\big(\bar{y}_x(s+T_N)\big)u(s)\,ds \\ &\leq d\big(\bar{y}_x(T_N)\big) + d\big(y_x(t)\big) - d(x) + \big(L(b)+K(b)\big)\big|\bar{y}_x(T_N)-x\big|L(b)^{-1}\big(e^{L(b)t}-1\big),\end{aligned}$$

by using

$$(3.14)\qquad \big|\bar{y}_x(s+T_N) - y_x(s)\big| \leq \big|\bar{y}_x(T_N) - x\big|e^{L(b)s},$$

which follows by Gronwall's lemma. Furthermore, by $\bar{u}$'s definition (3.12), one has for $k = 1,\ldots,N$

$$\bar{y}_x(T_k) = \bar{y}_x(T_{k-1}) + [\sigma_1,\sigma_2]\big(\bar{y}_x(T_{k-1})\big)\frac{t_k^2}{16} + o(t_k^2),$$

which implies

$$(3.15)\qquad \bar{y}_x(T_k) = x + \sum_{i=1}^{k}[\sigma_1,\sigma_2]\big(\bar{y}_x(T_{i-1})\big)\frac{t_i^2}{16} + \sum_{i=1}^{k}o(t_i^2),$$

and therefore

$$(3.16)\qquad \big|\bar{y}_x(T_N) - x\big| \leq C_1\sum_{i=1}^{N}t_i^2 \qquad \text{with } C_1 > 0 \text{ independent on } x \text{ and } \alpha.$$

By $d(\cdot)$'s expansion around x we obtain

$$d\big(\bar{y}_x(T_k)\big) = d(x) + d'(x)\left\{\sum_{i=1}^{k}[\sigma_1,\sigma_2]\big(\bar{y}_x(T_{i-1})\big)\frac{t_i^2}{16}\right\} + \sum_{i=1}^{k}o(t_i^2),$$

which yields

$$(3.17)\qquad d\big(\bar{y}_x(T_k)\big) \leq d(x) - \xi_0\sum_{i=1}^{k}t_i^2 \qquad \text{for } k = 1,\ldots,N,$$

if $t_i \leq T$ (for a convenient $T > 0$ independent of x and α) for all $i = 1,\ldots,N$ and $T_{N-1} \leq \delta/K(b)$, by (3.6), (3.8), and $d'(\cdot)$'s continuity. Applying these results to the estimate (3.13) and recalling the relation (3.3) between $d(\cdot)$ and $d_\alpha(\cdot)$, we get

$$d_\alpha\big(\bar{y}_x(t+T_N)\big) \leq d_\alpha\big(y_x(t)\big) - \xi_0\sum_{i=1}^{N}t_i^2 + C_2\big(e^{L(b)t}-1\big)\sum_{i=1}^{N}t_i^2$$

for all $t \geq 0$ and for some $C_2 > 0$, i.e., by the definition (3.2) of $\tilde{d}_\alpha$

$$(3.18)\qquad d_\alpha\big(\bar{y}_x(t+T_N)\big) \leq \tilde{d}_\alpha\left(1 - \frac{\xi_0}{2}\sum_{i=1}^{N}k_i\right) \qquad \forall t \in [0, t^* - T_N],$$

if we assume $t^* \leq \frac{\delta}{K(b)} \wedge \frac{1}{L(b)}\ln\big(1 + \frac{\xi_0}{2C_2}\big)$ and

$$(3.19)\qquad t_i := \sqrt{\tilde{d}_\alpha k_i} \qquad \text{for } i = 1,\ldots,N,$$

where $k_1,\ldots,k_N$ are to be chosen (generally depending on x and α). As we will show, verifying theses (i) and (ii) is equivalent to checking that there exist N, $k_1,\ldots,k_N$

such that, first, the estimate (3.17) holds for $t_1, \dots, t_N$ given by (3.19), the following relations

$$\sum_{i=1}^{N} k_i = \frac{4}{\xi_0}, \tag{3.20}$$

and

$$\sum_{i=1}^{N} \sqrt{k_i} \leq C_3 \qquad \text{for some } C_3 \text{ independent of } x \text{ (and } \alpha\text{)}, \tag{3.21}$$

hold; second, $\bar{y}_x(t) \in \overline{\Omega}_\alpha$ for all $t \in [0, T_N]$. Note that the estimate (3.17), decreasing t^* if necessary, is verified. It is important to remark that it is not restrictive to assume

$$d'(y_k) \cdot \sigma(y_k) u_1 \leq 0 \quad \text{and} \quad d'(y_k) \cdot \sigma(y_k) u_2 \leq 0, \tag{3.22}$$

where $y_k := \bar{y}_x(T_k)$ and $k = 0, \dots, N$. Indeed by using the identities $[\sigma_1, \sigma_2] = [-\sigma_2, \sigma_1] = [\sigma_2, -\sigma_1] = [-\sigma_2, -\sigma_1]$, we can modify in the definition (3.11) of α_i with $i = k$ the order of u_1, u_2 and their opposites in a convenient way, so that both (3.22) and (3.15) are true. Then we claim that both

$$d(\bar{y}_x(t)) \leq d(x) + C_4 t^2 \qquad \forall t \in [0, t_1], \tag{3.23}$$

and

$$\begin{aligned} d(\bar{y}_x(t)) &\leq d(\bar{y}_x(T_{k-1})) + C_4 (t - T_{k-1})^2 \\ &\leq d(x) - \xi_0 \sum_{i=1}^{k-1} t_i^2 + C_4 t_k^2 \quad \forall t \in [T_{k-1}, T_k], \end{aligned} \tag{3.24}$$

for $k = 2, \dots, N$ hold. In fact,

$$\begin{aligned} d(\bar{y}_x(t)) &= d(x) + \int_0^t d'(\bar{y}_x(s)) \sigma_1(\bar{y}_x(s))\, ds \\ &\leq d(x) + t d'(x) \sigma_1(x) + L(d'\sigma) \int_0^t |\bar{y}_x(s) - x|\, ds \\ &\underset{(3.22)_1}{\leq} d(x) + C_4' t^2 \qquad \forall t \in \left[0, \frac{t_1}{4}\right]; \\ d(\bar{y}_x(t)) &= d\left(\bar{y}_x\left(\frac{t_1}{4}\right)\right) + \int_{t_1/4}^t d'(\bar{y}_x(s)) \sigma_2(\bar{y}_x(s))\, ds \\ &\leq C_4' \left(\frac{t_1}{4}\right)^2 + \left(t - \frac{t_1}{4}\right) d'(x) \sigma_2(x) + C_4' \left(t - \frac{t_1}{4}\right)^2 + d(x) \\ &\underset{(3.22)_2}{\leq} d(x) + C_4' t^2 \qquad \forall t \in \left[\frac{t_1}{4}, \frac{t_1}{2}\right]; \\ \bar{y}_x(t) &= \bar{y}_x\left(\frac{t_1}{2}\right) - \int_{t_1/2}^t \{\sigma_1(x) + \sigma_1'(x)(\bar{y}_x(s) - x)\}\, ds + o\left(\left(t - \frac{t_1}{2}\right)^2\right) \\ &= x + \frac{t_1}{4}(\sigma_1(x) + \sigma_2(x)) + \frac{1}{2}\left(\frac{t_1}{4}\right)^2 [\sigma_2' \sigma_2 + 2\sigma_2' \sigma_1 + \sigma_1 \sigma_2'] + o(t_1^2) \end{aligned}$$

$$- \left(t - \frac{t_1}{2}\right)\sigma_1(x) - \sigma_1'(x)\int_{t_1/2}^{t} (\bar{y}_x(s) - x)\, ds + o\left(\left(t - \frac{t_1}{2}\right)^2\right)$$
$$\forall t \in \left[\frac{t_1}{2}, \frac{3t_1}{4}\right],$$

and expanding $d(\cdot)$ around x we get

$$d(\bar{y}_x(t)) \leq d(x) + d'(x)\left[\left(\frac{3t_1}{4} - t\right)\sigma_1(x) + \frac{t_1}{4}\sigma_2(x)\right] + C_4''\left[\left(\frac{t_1}{2}\right)^2 + \left(t - \frac{t_1}{2}\right)^2\right]$$
$$\underset{(3.22)}{\leq} d(x) + C_4''t^2 \qquad \forall t \in \left[\frac{t_1}{2}, \frac{3t_1}{4}\right].$$

Furthermore, we have

$$\bar{y}_x(t) = \bar{y}_x\left(\frac{3t_1}{4}\right) - \int_0^t \{\sigma_2(x) + \sigma_2'(x)[\bar{y}_x(s) - x]\}\, ds + o\left(\left(t - \frac{3t_1}{4}\right)^2\right)$$
$$= x + (t_1 - t)\sigma_2(x) + \frac{1}{2}\left(\frac{t_1}{4}\right)^2 (2[\sigma_1, \sigma_2] - \sigma_2'\sigma_1) - \sigma_2'(x)\int_0^t [\bar{y}_x(s) - x]\, ds$$
$$+ o(t_1^2) + o\left(\left(t - \frac{3t_1}{4}\right)^2\right) \qquad \forall t \in \left[\frac{3t_1}{4}, t_1\right],$$

which yields, as before, $d(\bar{y}_x(t)) \leq d(x) + C_4''t^2$ for all $t \in [3t_1/4, t_1]$. Now, by replacing x with y_k for $k = 1, \dots, N$ and choosing $C_4 := \max\{C_4', C_4''\}$ we can conclude that (3.23) and (3.24) hold.

By estimate (3.23), to keep $\bar{y}_x(t)$ in $\overline{\Omega}_\alpha$ for all $t \in [0, t_1]$, it suffices to have

$$k_1 := \frac{4}{\xi_0} \wedge \beta, \qquad \text{with } \beta := \frac{|d_\alpha(x)|}{2C_4\tilde{d}_\alpha}. \tag{3.25}$$

If $4/\xi_0 \leq \beta$, choosing $N = 1$ we have (3.20) and (3.21); otherwise, i.e., if $\beta \in (0, 4/\xi_0)$, we set for $r > 1$

$$k_r := \left(\frac{4}{\xi_0} - \sum_{i=1}^{r-1} k_i\right) \wedge \frac{\xi_0}{C_4}\sum_{i=1}^{r-1} k_i. \tag{3.26}$$

By the estimate (3.24), (3.26) implies that $\bar{y}_x(t) \in \overline{\Omega}_\alpha$ for all $t \in [0, T_r]$. As long as $\sum_{i=1}^r k_i < 4/\xi_0$, k_r is defined by $(3.26)_2$, thus

$$\frac{k_r}{k_{r-1}} = \frac{\xi_0}{C_4}\frac{k_1 + \cdots + k_{r-1}}{k_{r-1}} = 1 + \frac{\xi_0}{C_4} =: a,$$

i.e., we get

$$k_r = a^{r-1}\beta, \qquad \text{where } a > 1 \text{ and } r \geq 1. \tag{3.27}$$

The geometric series $\sum_{r=1}^{+\infty} k_r$ diverges, hence there exists some $N(x, \alpha) \in \mathbb{N}$ such that $\sum_{r=1}^{N} k_r \geq 4/\xi_0$; moreover, we can determine an upper bound $\overline{N}$ for N:

$$\sum_{r=1}^{N} a^{r-1}\beta = \beta\frac{a^N - 1}{a - 1} \geq \frac{4}{\xi_0} \quad \text{for } a^N - 1 \geq \frac{4}{\xi_0}(a - 1)\beta^{-1},$$

i.e.,

$$\overline{N} := \left[\log_a\left(1 + \frac{4}{\xi_0}(a-1)\beta^{-1}\right)\right] + 1, \tag{3.28}$$

where $[\ \cdot\ ]$ represents the integer part. The values $k_1, \dots, k_N$ satisfy (3.20) by construction, hence it remains to check that (3.21) is also true. By (3.28) it follows that

$$\begin{aligned}\sum_{r=1}^{N} \sqrt{k_r} = \sqrt{\beta}\sum_{r=1}^{N}(\sqrt{a})^{r-1} &= \sqrt{\beta}\,\frac{a^{N/2}-1}{\sqrt{a}-1}\\ &\le g_a(\beta) := \frac{\sqrt{a}}{\sqrt{a}-1}\left(\sqrt{\beta + \frac{4}{\xi_0}(a-1)} - \frac{\sqrt{\beta}}{\sqrt{a}}\right),\end{aligned}$$

where

$$\sup_{\beta\in(0,4/\xi_0)} g_a(\beta) = g_a(0) = \frac{2\sqrt{a}}{\sqrt{a}-1}\sqrt{\frac{a-1}{\xi_0}}.$$

At this point, the part (i) of the lemma is proved for all $x \in \Omega$, $\alpha \in [0, \alpha_x]$, and $u \in \mathcal{A}$.

Part (ii) follows easily from (3.14), (3.16), and (3.21). ▯

This technical lemma allows us to obtain the following continuity result.

THEOREM 3.1. *Under assumptions* (A0), (A1), *the value function* v_Ω *belongs to* $BUC(\Omega)$.

Proof. Let x, z be in Ω and $|x - z| < r$ (where $r < 1$). For any $\rho > 0$ by the DPP (2.3) and choosing t^* as in Lemma 3.1, there exists a control $u \in \mathcal{A}_z^0$ such that

$$J_{t^*}(z, u) + e^{-t^*} v_\Omega\left[y_z(t^*)\right] \le v_\Omega(z) + \rho,$$

with $y_z(\cdot) = y_z(\cdot, u)$, holds. Since $u \in \mathcal{A}_z^0$, there is a constant $\bar{\alpha} > 0$ such that $y_z(t) \in \Omega_\alpha$ for all $\alpha \in [0, \bar{\alpha}]$. For any x, choose $\alpha_1 := \alpha_x \wedge \bar{\alpha}$ and let $\bar{u}$ be the control defined in Lemma 3.1, let $\bar{y}_x$ be the corresponding trajectory, and recall that $\tilde{d}_{\alpha_1} = \sup\left\{\operatorname{dist}\left(y_x(t), \overline{\Omega}_{\alpha_1}\right) : t \in [0, t^*]\right\}$, with $y_x(\cdot) = y_x(\cdot, u)$. By standard estimates, $\tilde{d}_{\alpha_1} < A_1 r$ for some $A_1 > 0$. Thus we have

$$\left|J_{t^*}(x, \bar{u}) - J_{t^*}(x, u)\right| \le L\sqrt{A_1 r}$$

and the definition of $\bar{u}$ implies

$$\left|y_x(t^*) - \bar{y}_x(t^*)\right| \le A_2\sqrt{r}, \quad A_2 > 0.$$

Therefore we get

$$\left|\bar{y}_x(t^*) - y_z(t^*)\right| \le A_3\sqrt{r}, \quad A_3 > 0, \tag{3.29}$$

and

$$\left|J_{t^*}(x, \bar{u}) - J_{t^*}(z, u)\right| \le L\sqrt{A_1 r} + \left|J_{t^*}(x, u) - J_{t^*}(z, u)\right| \le A_4\sqrt{r}, \quad A_4 > 0. \tag{3.30}$$

Now we set

$$\omega(r) := \sup\left\{\left|v_\Omega(x) - v_\Omega(z)\right| : \quad x, z \in \Omega \text{ and } |x - z| < r\right\}.$$

Combining these relations and using the DPP (2.3) we have

$$\begin{aligned}v_\Omega(x) - v_\Omega(z) &\le J_{t^*}(x, \bar{u}) - J_{t^*}(z, u) + e^{-t^*}\left[v_\Omega\left(\bar{y}_x(t^*)\right) - v_\Omega\left(y_z(t^*)\right)\right] + \rho\\ &\le A_4\sqrt{r} + e^{-t^*}\omega(A_3\sqrt{r}) + \rho \quad \forall\rho > 0,\end{aligned} \tag{3.31}$$

i.e.,

$$\omega(r) \le A_4\sqrt{r} + e^{-t^*}\omega(A_3\sqrt{r}) \quad \text{where } A_3 > 1 \text{ and } A_4 > 0. \tag{3.32}$$

Since ω is nondecreasing on $(0, +\infty)$, the limit $\omega(+0) \in [0, +\infty)$ exists. By (3.32), we have $\omega(0+) \le e^{-t^*}\omega(0+)$ and conclude that $\omega(0+) = 0$. □

4. Relation between the value functions $v_{\overline{\Omega}}$ and v_Ω. In this section we prove that the value functions $v_{\overline{\Omega}}$ and v_Ω coincide on Ω.

THEOREM 4.1. *Assume* (A0) *and* (A1). *Then*

$$v_\Omega(x) = v_{\overline{\Omega}}(x) \qquad \forall x \in \Omega.$$

Proof. Since $\mathcal{A}_x^0 \subset \mathcal{A}_x$, the inequality $v_\Omega(x) \ge v_{\overline{\Omega}}(x)$ holds by definition. Therefore it is enough to show that $v_\Omega(x) \le v_{\overline{\Omega}}(x)$ $\forall x \in \Omega$. Let $x \in \Omega$ and $\varepsilon > 0$ be fixed. Then there exist some $u \in \mathcal{A}_x$ such that

$$\int_0^{+\infty} e^{-t} f\big(y_x(t), u(t)\big)\, dt \le v_{\overline{\Omega}}(x) + \varepsilon,$$

and some $T > 0$ such that

$$\left| \int_T^{+\infty} e^{-t} f\big(\tilde{y}_x(t), \tilde{u}(t)\big)\, dt \right| \le \varepsilon \quad \forall \tilde{u} \in \mathcal{A},$$

if $y_x(\cdot)$ and $\tilde{y}_x(\cdot)$ denote $y_x(\cdot, u)$ and $y_x(\cdot, \tilde{u})$, respectively. Therefore the inequality

$$v_\Omega(x) - v_{\overline{\Omega}}(x) \le \int_0^T e^{-t}\big\{f\big(\tilde{y}_x(t), \tilde{u}(t)\big) - f\big(y_x(t), u(t)\big)\big\}\, dt + 3\varepsilon \tag{4.1}$$

holds for any $\tilde{u} \in \mathcal{A}_x^0$. Now let us consider some $\alpha \in (0, \alpha_x]$ $(\alpha < 1)$, where α_x is given by Lemma 3.1. By this lemma, there is a control $\tilde{u}_1 \in \mathcal{A}$ satisfying

$$y_x(t, \tilde{u}_1) \in \overline{\Omega}_\alpha \qquad \forall t \in [0, t^*],$$

and (since u is in $\mathcal{A}_x$)

$$\big|J_{t^*}(x, \tilde{u}_1) - J_{t^*}(x, u)\big| \le L\sqrt{\alpha}.$$

Now, if $t^* \ge T$ by choosing $\alpha \le \varepsilon^2/L^2$ and using the estimate (4.1), we can conclude that $v_\Omega(x) - v_{\hat{\Omega}}(x) \le 0$ by the arbitrariness of ε. Otherwise, we set

$$x_1 := y_x(t^*), \qquad \tilde{x}_1 := y_x(t^*, \tilde{u}_1),$$

and call u^{t^*} the control $u^{t^*}(t) = u(t + t^*)$ for all $t \ge 0$. Since $\tilde{x}_1 \in \overline{\Omega}_\alpha$ and $u^{t^*} \in \mathcal{A}_{x_1}$ we can again apply Lemma 3.1 with α replaced by $\alpha/2$ (see the definition (3.9) of α_x) to obtain a control $\bar{u}_2$ analogous to $\tilde{u}_1$, but starting from $\tilde{x}_1$ instead of x. Let M be $[T/t^*] + 1$. For $m \in \{1, \dots, M - 1\}$ we set recursively

$$x_m := y_x(mt^*), \qquad \tilde{x}_m := y_x(mt^*, \tilde{u}_m),$$

where any $\bar{u}_m$ for $m \ge 2$ is determined on the basis of Lemma 3.1 applied to $\tilde{x}_{m-1} \in \overline{\Omega}_{-\alpha/2^{m-2}}$ with α replaced by $\alpha/2^{m-1}$ and $u^{(m-1)t^*} \in \mathcal{A}_{x_{m-1}}$; and $\tilde{u}_m$ is defined by

$$\tilde{u}_m(t) := \tilde{u}_{m-1}(t)\chi_{[0,(m-1)t^*]}(t) + \bar{u}_m(t - (m-1)t^*)\chi_{((m-1)t^*, +\infty)}(t).$$

We claim that for any $m \in \{1, \dots, M - 1\}$

$$|\tilde{x}_m - x_m| \le a\alpha^{2^{-m}} \quad \text{for some } a > 0, \tag{4.2}$$

and

$$(4.3) \qquad \left|J_{(m+1)t^*}(x, \tilde{u}_{m+1}) - J_{(m+1)t^*}(x, u)\right| \leq L_1 \alpha^{2^{-(m+1)}} \quad (L_1 \geq L),$$

hold. For $m = 1$ they follow by Lemma 3.1 and standard estimates, under which we use in particular

$$\operatorname{dist}\big(y_{\tilde{x}_1}(t, u^{t^*}), \Omega\big) \leq \left|y_{\tilde{x}_1}(t, u^{t^*}) - y_{x_1}(t, u^{t^*})\right| \leq L'|\tilde{x}_1 - x_1|,$$
$$\operatorname{dist}\big(y_{\tilde{x}_1}(t, u^{t^*}), \Omega_{\alpha/2}\big) \leq \operatorname{dist}\big(y_{\tilde{x}_1}(t, u^{t^*}), \Omega\big) + \alpha/2, \qquad \alpha \leq \sqrt{\alpha}.$$

By finite induction we can easily verify (4.2) and (4.3) for all m. Now, for any fixed ε it suffices to choose some $\alpha = \alpha_\varepsilon \leq (\varepsilon/L_1)^{2^M}$ and to set $\tilde{u} \equiv \tilde{u}_M$ on $[0, T]$ to have $v_\Omega(x) - v_{\overline{\Omega}}(x) \leq 4\varepsilon$ by inequality (4.1); by the arbitrariness of ε, that concludes the proof. □

5. Constrained viscosity solutions and a comparison result.

We begin recalling the definition of viscosity solution (see [3], [9]) and a comparison theorem in [9]. First of all, for any bounded function $u : E \longrightarrow \mathbb{R}$, $E \subset \mathbb{R}^k$ we define

$$(5.1) \qquad \begin{aligned} u^*(x) &:= \lim_{r \searrow 0} \sup\{u(y) :\ y \in E,\ |x - y| \leq r\} \\ u_*(x) &:= \lim_{r \searrow 0} \inf\{u(y) :\ y \in E,\ |x - y| \leq r\} \end{aligned} \qquad \text{for all } x \in \overline{E}.$$

Throughout this paper we consider the Hamiltonian H defined by (1.5).

DEFINITION 5.1. *We say u is a viscosity subsolution (supersolution) of the Hamilton-Jacobi equation*

$$(5.2) \qquad u(x) + H\big(x, Du(x)\big) = 0$$

on E, if for all $\phi \in C^1(E)$ such that $u^* - \phi$ $(u_* - \phi)$ has a local maximum (minimum) at $x \in E$, we get

$$u^*(x) + H\big(x, \nabla\phi(x)\big) \leq 0 \quad \big(u_*(x) + H\big(x, \nabla\phi(x)\big) \geq 0\big).$$

If u is both subsolution and supersolution, then u is called a viscosity solution. When Ω is an open set and u is subsolution on Ω and supersolution on $\overline{\Omega}$, we say u is a constrained viscosity solution on $\overline{\Omega}$.

THEOREM 5.1. *Let $v_i : \overline{\Omega} \longrightarrow \mathbb{R}$ where $i = 1, 2$ be bounded, v_1 be upper semicontinuous and continuous at each point of $\partial\Omega$, and v_2 be lower semicontinuous. Assume v_1 and v_2 are, respectively, viscosity subsolution in Ω and supersolution in $\overline{\Omega}$ of* (5.2). *Then $v_1 \leq v_2$ in $\overline{\Omega}$.*

Proof. Theorem 5.1 follows as a corollary of Theorem 2.1 in [9] or from Theorem 1.1 in [2] in the unbounded case. □

In a way similar to the one indicated in Theorem 2.1 of [13], but using also Barles and Perthame's and Ishii's arguments on the discontinuous solutions in [3] and in [9], respectively, it is not hard to check the following proposition.

PROPOSITION 5.1. *The value functions $v_{\overline{\Omega}}$ and v_Ω are constrained viscosity solutions of the HJB equation on $\overline{\Omega}$.*

The last result says that under the assumptions of §2, v_Ω is the unique continuous constrained solution of (5.2).

COROLLARY 5.1. *Assume* (A0), (A1). *Then, the unique continuous extension $\bar{v}$ of v_Ω to $\overline{\Omega}$ is the unique continuous constrained solution of the HJB equation* (5.2).

Moreover,

$$\bar{v}(x) = (v_{\overline{\Omega}})_*(x) \quad \textit{for all } x \in \overline{\Omega}. \tag{5.3}$$

Proof. The existence of the unique continuous extension $\bar{v}$ of v_Ω follows by Theorem 3.1, and moreover by Theorem 4.1 in §4 the restriction of $v_{\overline{\Omega}}$ to Ω coincides with the value function v_Ω. Hence the inequality

$$(v_{\overline{\Omega}})_* \leq \bar{v} \leq (v_{\overline{\Omega}})^* \quad \text{on } \partial\Omega$$

is always true, while the relation

$$\bar{v} \leq (v_{\overline{\Omega}})_* \quad \text{on } \partial\Omega$$

follows from the comparison Theorem 5.1 applied to $v_1 = \bar{v}$ and $v_2 = (v_{\overline{\Omega}})_*$. Thus we have verified that (5.3) holds. The uniqueness of the continuous constrained viscosity solution is a consequence of Proposition 5.1 and Theorem 5.1. □

6. An example of discontinuous $v_{\overline{\Omega}}$. Under hypotheses (A0), (A1) in the previous sections, we proved the (uniform) continuity of the value function $v_{\overline{\Omega}}$ only on the open set Ω. In fact, unlike assumption (S), (A1) does not ensure the continuity of $v_{\overline{\Omega}}$ on the whole $\overline{\Omega}$, as shown by the following example.

Consider the control system

$$\begin{cases} y_1'(t) = 2u_1, \\ y_2'(t) = 2(y_1 + y_2)u_2, \end{cases} \tag{6.1}$$

where the state (y_1, y_2) is constrained to stay in the closure of the set Ω defined by

$$\Omega := \{(y_1, y_2) \in \mathbb{R}^2 \ : \ y_1^2 < y_2\}, \tag{6.2}$$

while the control $u = (u_1, u_2)$ takes values on the compact symmetrical w.r.t. 0 subset U of $\mathbb{R}^2$ given by

$$U := \{(1,0), (-1,0), (0,1), (0,-1)\}. \tag{6.3}$$

Let $\psi \in C^\infty(\mathbb{R}^+)$ be a nonincreasing function such that $\psi(r) \equiv 1$ if $0 \leq r \leq 1$ and $\psi(r) \equiv 0$ if $r \geq 2$, and consider

$$J(x,u) := \int_0^{+\infty} e^{-t}\psi(y_{2_x}(t,u))\,dt \tag{6.4}$$

as the associated payoff to be minimized. Thus the value function $v_{\overline{\Omega}}$ is defined by

$$v_{\overline{\Omega}}(x) := \inf_{u \in \mathcal{A}_x} J(x,u) \qquad \forall x = (x_1, x_2) \in \overline{\Omega}, \tag{6.5}$$

where $\mathcal{A}_x$ denotes the set of the admissible controls u such that $y_x(t,u) \in \overline{\Omega}$ $\forall t \in [0, +\infty)$. Note that the admissible vector fields are all tangent only at $(0,0)$ and here there is a Lie bracket pointing inward Ω. Indeed, by setting $u_1 := (1,0)$, $u_2 := (0,1)$, one has $[\sigma_1, \sigma_2](0,0) = (0,4)$, where $\sigma_1(y_1,y_2) = (2,0)$ and $\sigma_2(y_1,y_2) = (0, 2y_1 + 2y_2)$. We shall prove that $v_{\overline{\Omega}}$ is discontinuous at $(0,0)$ by showing that for some $T > 0$: $v_{\overline{\Omega}}(0,\delta) \leq 1 + e^{-T} < 1 = v_{\overline{\Omega}}(0,0)$ $\forall \delta > 0$. To this end, in a similar way to that used in Lemma 3.1, see (3.11), (3.12), for any $\delta > 0$ we define a control $u_\delta \in \mathcal{A}_{(0,\delta)}$ as follows:

$$u_\delta(t) := \sum_{i=1}^{N} \alpha_i(t - T_{i-1})\chi_{[T_{i-1},T_i)}(t) + u_2(t - T_N)\chi_{[T_N,+\infty)}(t), \tag{6.6}$$

where

$$\alpha_i(t) := u_1\big(\chi_{[0,t_i)}(t) - \chi_{[2t_i,3t_i)}(t)\big) + u_2\big(\chi_{[t_i,2t_i)}(t) - \chi_{[3t_i,4t_i]}(t)\big),$$

$$T_0 := 0, \qquad T_i := 4\sum_{j=1}^{i} t_j,$$

and

$$\begin{cases} t_1^2 := \dfrac{\delta}{4}, \\ t_k^2 := \left(\dfrac{1}{4} - \displaystyle\sum_{i=1}^{k-1} t_i^2\right) \wedge \dfrac{1}{2}\displaystyle\sum_{i=1}^{k-1} t_i^2 \quad \forall k > 1, \end{cases} \tag{6.7}$$

while N represents the minimum integer such that the y_2-component of the trajectory $y_{(0,\delta)}(\cdot, u_\delta)$ satisfies $y_2(T_N) \geq 1/2$. It is straightforward to check that at T_k $(k \geq 0)$ one has $y_{(0,\delta)}(T_k, u_\delta) \equiv (0, y_k)$, where y_k is given by

$$y_0 = \delta, \qquad y_k = y_{k-1} + 2t_k(1 - e^{-2t_k}) \quad (k > 0), \tag{6.8}$$

which is equivalent to

$$y_k = \delta + 4\sum_{i=1}^{k} t_i^2 + \sum_{i=1}^{k} o(t_i^2) \quad \text{with } o(t_i^2) := 2t_i(1 - e^{-2t_i}) - 4t_i^2 \quad \forall i, k > 0.$$

Hence it follows that

$$y_k \geq \delta + 2\sum_{i=1}^{k} t_i^2 \qquad \forall t_i \leq \frac{1}{2}.$$

Furthermore as long as $\sum_{i=1}^{k} t_i^2 < 1/4$, t_k^2 is given by

$$t_k^2 = \left(\frac{3}{2}\right)^{k-1} \frac{\delta}{4},$$

we can determine an upper bound $\bar{N}$ for N:

$$\bar{N} := \left[\log_{(3/2)}\left(1 + \frac{1}{2\delta}\right)\right] + 1,$$

where $[\ \cdot\ ]$ represents the integer part. Hence a time sufficient to reach the position $(0, 1/2)$ is given by

$$4\sum_{i=1}^{N} t_i^2 \leq \frac{\sqrt{\delta}}{2}\sum_{i=1}^{N}\left(\sqrt{\frac{3}{2}}\right)^{i-1} = \frac{\sqrt{\delta}}{2}\,\frac{(\sqrt{3/2})^{N-1} - 1}{(\sqrt{3/2}) - 1} \leq \sqrt{3}(2 + \sqrt{6}),$$

and by definition (6.6) of u_δ it follows that

$$v_{\overline{\Omega}}(0, \delta) \leq J\big((0, \delta), u_\delta\big) \leq 1 - e^{-T} \quad \text{if, e.g., } T := \sqrt{3}(2 + \sqrt{6}) + \ln 2 \ \ \forall \delta > 0.$$

Acknowledgments. I thank M. Bardi for helpful discussions and good advice and H. M. Soner for a useful suggestion about the construction of an example of discontinuous $v_{\overline{\Omega}}$. Thanks are also due to the referees for the suggestion of a simplification in the proof of Theorem 3.1.

THE LINEAR-QUADRATIC CONTROL PROBLEM REVISITED*

TOMASZ R. BIELECKI[†]

Abstract. A long-run, average-cost, stochastic, linear-quadratic control problem that incorporates different time scales is considered. The system dynamics and the cost functional are modeled with the help of a locally square-integrable semimartingale process with independent increments and the corresponding predictable quadratic variation process. The solution of the control problem is given in terms of the solution of certain system of algebraic and differential Riccati equations. The model considered here embodies as particular cases the "traditional" continuous-time and discrete-time linear quadratic control problems, and is applicable, for example, to certain hybrid control problems that cannot be treated using existing control methods.

Key words. linear-quadratic control, square-integrable semimartingales, various time scales, hybrid control

AMS subject classifications. 60H30, 93E20

1. Introduction.

In recent years there has been growing interest in developing a unified approach to control and identification problems for both discrete and continuous-time scales. In Middleton and Goodwin (1990), the unified approach to control and estimation is presented via the so-called "generalized transform." In spite of its many advantages, the method is not capable of handling the problems that "live" in continuous and discrete time simultaneously or stochastic control problems involving the continuous-time scale, for example. This paper provides a way of looking at some of these problems via the stochastic calculus for locally square-integrable semimartingales.

In this paper we consider a long-run, average-cost, stochastic, linear-quadratic control problem that incorporates different time scales. The system dynamics and the cost functional are modeled with the help of a locally square-integrable semimartingale process with independent increments and the corresponding predictable quadratic variation process. The situation considered here is not, of course, "the most general" one. But it is general enough to produce as particular cases the traditional continuous-time (e.g., Davis, 1977) and discrete-time (e.g., Hall and Heyde, 1980) linear-quadratic, stochastic control problems with the average cost per unit of time criterion. The results obtained in the paper follow from an application of the powerful general theory of random processes (Dellacherie and Meyer, 1975, 1980, 1983; Jacod, 1979; Jacod and Shiryayev, 1987; Lipster and Shiryayev, 1989; Protter, 1990, among others). We emphasize that the asymptotic results obtained here are essentially due to the strong law of large numbers type property for semimartingales (see Lipster and Shiryayev, 1989, for example). The L^2-ergodic type results for martingales, discussed by Sundar (1989), may be useful in the study of the control problem with the expected long-run average cost, which is not included here.

The solution of the control problem considered in this paper is given in terms of the solution to the system of algebraic and differential Riccati equations (3.1). Theorem 3.1 concerning the existence and uniqueness of the solution for system (3.1) is

* Received by the editors July 9, 1992; accepted for publication (in revised form) March 2, 1994.

[†] Department of Mathematics, Statistics, and Computer Science, University of Illinois at Chicago, Chicago, Illinois 60680.

interesting in itself. At the very least it interprets the relationship between the algebraic Riccati equations corresponding to continuous and discrete time, as indicated in Remark 3.2 and in §6. The "classical" relationship between continuous- and discrete-time Riccati equations resulting from time discretization is reconfirmed by limiting analysis of equations (3.1) (see §6).

We were inspired to consider a control problem incorporating different time scales by some work on the semimartingale regression problem (Christopeit, 1986; LeBreton and Musiela, 1988), where the time scales are modeled in terms of the predictable quadratic variation process of a semimartingale. Control problems involving continuous-time semimartingale dynamics were considered before in Foldes (1990), for example. To the best of our knowledge, linear quadratic (LQ) control problems incorporating both continuous- and discrete-time scales in the system dynamics have not been considered in the literature before.

Although we consider here only the ergodic linear-quadratic control problem, the modeling methodology presented in this paper is applicable to a wider spectrum of control problems. As a direct control application we see an application of our methodology to a class of hybrid control problems which are attracting more and more interest (see, e.g., Elliot and Sworder, 1992). A simple example of a hybrid control problem that can be treated by methods presented in this paper is given in §7. In this paper we treat neither a finite-time horizon problem, nor an infinite-time horizon with a discounted cost criterion. These are for future research.

The paper is organized as follows. In §2 we describe the noise process. Section 3 introduces a system of differential-algebraic Riccati equations that plays a central role in characterization of the optimal controls (as expected). The system of those equations reduces to the well-known algebraic Riccati equations corresponding to the continuous-time or discrete-time linear-quadratic control problems under appropriate parametrization. Section 4 formulates a semimartingale driven linear-quadratic control problem and provides a solution to it. In §5 we point out how our control problem relates to some other problems considered before in the literature. Section 6 contains three limiting results. One of them reconfirms the classical relationship between continuous and discrete Riccati equations resulting from time discretization. Moreover the result indicates that our approach allows for a "partial" time discretization, that is, time discretization with respect to only some of the components of the state vector. The other two limiting results analyze the effect on the control system of vanishing discrete components ($k_3 \to 0$) and continuous components ($k_1 \to 0$), respectively. In §7 we provide a simple but illustrative example of a hybrid control problem and solve it by our method. A few final remarks are formulated in §8.

Much of the notation used in the paper is taken from Jacod and Shiryayev (1987). "T" denotes the transposition of a matrix.

2. The noise process.

In this section we shall describe the noise process $Z \cong \{Z_t, t \geq 0\}$ that will be appearing in the dynamics equation of the control model. We begin with the following assumption about Z.

Assumption A1. Z is an n-dimensional locally square-integrable semimartingale (Jacod and Shiryayev (1987), Def. II.2.27) and a process with independent increments. The underlying stochastic basis is $(\Omega, \mathcal{F}, \mathbf{F}, P)$ and it is supposed to satisfy the usual conditions.

Let J denote the set of fixed times of discontinuity of Z, that is, $J := \{t \geq 0 : P(\Delta Z_t \neq 0) > 0\}$, where $\Delta Z_t := Z_t - Z_{t-}$ is the jump of Z at time t, $(\Delta Z_0 = 0)$. As usual $\{B, C, \nu\}$ will denote a triplet of predictable characteristics of Z with regard to some truncation function h. According to Theorem II.4.15 of Jacod and Shiryayev (1987) we also have, under A1, that the characteristics of Z are deterministic processes and $J = \{t \geq 0 : \nu(\{t\} \times R^n) > 0\}$. We will denote the stochastically continuous and stochastically discontinuous components of Z by $\bar{Z}$, and $\bar{\bar{Z}}$ respectively. This means that

$$\bar{\bar{Z}}_t = \sum_{\substack{0<s\leq t \\ s\in J}} \Delta Z_s \text{ and } \bar{Z}_t = Z_t - \bar{\bar{Z}}_t,\ t \geq 0.$$

From Proposition II.1.16 of Jacod and Shiryayev (1987) we know that J is countable. Denote elements of J by j_n, $n \in I$, where I is a countable index set. Also let $\epsilon_n := \bar{\bar{Z}}_{j_n}$, $n \in I$, so that $\{\epsilon_n\}_{n\in I}$ is the embedded random sequence. Because of the control problem we will treat in §4 we introduce the following two assumptions.

Assumption A2. (a) $I = N^* := \{1, 2, 3, \dots\}$; (b) $j_n = \epsilon n$, $\epsilon > 0$, $n \in N^*$.

Assumption A3. Both $\bar{Z}$ and $\{\epsilon_n\}_{n\in N^*}$ have stationary increments.

Assumption A2(b) is not essential for the control-theoretic considerations to follow. It will be used to simplify the presentation.

We will keep the usual notation for the measure of jumps of $Z : \mu^z$. From the above stated assumptions and the results of Jacod and Shiryayev (1987), Chapters I and II, we infer the following.

PROPOSITION 2.1. *Assume* A1–A3. *Then*

(i) *the canonical decomposition of Z has the form $Z = Z_0 + N_1 + N_2 + N_3 + A$, where $N_1 := Z^c$ is the continuous martingale part of Z, $N_2 := (z1_{J^c} * (\mu^z - \nu)$ is the stochastically continuous jump-martingale part of Z, $N_3 := (z1_J) * (\mu^z - \nu)$ is the stochastically discontinuous jump-martingale part of Z, and $A = B + (z - h(z)) * \nu$ is a deterministic process.*

(ii) *the characteristics of Z are $B_t = bt + (h1_J) * \nu$, $C_t = ct$ and $\nu(\cdot, dt, dz) = dtK_2(dz)1_{J^c}(t) + K_3(dz)1_J(t)$, where $b \in R^n$, $c \in L(R^n, R^n)$ and $c \geq 0$, K_2 and K_3 are positive measures on R^n satisfying $K_i(\{0\}) = 0$, and $k_i := \int |z|^2 K_i(dz) < +\infty$, $i = 2, 3$.*

(iii) *N_1, N_2, and N_3 are independent and their predictable quadratic variation processes are given by*

$$\begin{aligned}
\langle N_1^i, N_1^j \rangle &= C^{ij}, \\
\langle N_2^i, N_2^j \rangle &= (z^i z^j)1_{J^c} * \nu, \\
\langle N_3^i, N_3^j \rangle &= (z^i z^j)1_J * \nu - \sum_{s\leq\cdot} \int z^i \nu(\{s\} \times dz) \int z^j \nu(\{s\} \times dz)
\end{aligned}$$

for $i, j = 1, 2, \dots, n$.

Proof. (i) The result follows from (2.30) and (2.39), Chapter II of Jacod and Shiryayev (1987).

(ii) The result follows from (2.14), (4.16), and the result analogous to Corollary 4.19 of Jacod and Shiryayev (1987) applied to $\bar{Z}$ and $\bar{\bar{Z}}$, respectively.

(iii) This part of the proposition follows from (2.31) and (4.16) of Jacod and Shiryayev (1987), Chapter II. □

As usual, we let $\langle N_1 \rangle :=$ trace C, $\langle N_2 \rangle :=$ trace$(zz^T)1_{J^c} * \nu$ and $\langle N_3 \rangle :=$ trace$(zz^T)1_J * \nu$ denote the scalar predictable quadratic variation processes of N_1, N_2, and N_3, respectively.

Remark 2.1. From now on we will assume (without loss of generality) that $A \equiv 0$

and $Z_0 \equiv 0$.

COROLLARY 2.1. *Under conditions of Proposition* 2.1 *we have*

$$\begin{aligned}\langle N_1\rangle_t &= t \cdot \text{ trace } c,\\ \langle N_2\rangle_t &= t \cdot k_2 \text{ for } t \geq 0, \text{ and}\\ \langle N_3\rangle_t &= n \cdot k_3,\ t \in]\epsilon n, \epsilon(n+1)],\ n \geq 0,\\ \langle N_3\rangle_0 &= 0.\end{aligned}$$

Remark 2.2. In fact, N_1 is a Wiener process.

3. The Riccati equations.

In this section we let $A, B \in L(R^n, R^n)$, $E \in L(R^m, R^n)$, and $F \in L(R^k, R^n)$. Also let $Q_1, Q_2 \in L(R^n, R^n)$, $R_1 \in L(R^m, R^m)$, $R_2 \in L(R^k, R^k)$, and $Q_1, Q_2 \geq 0$, $R_1, R_2 > 0$.

In Definition 3.1 below we recall the concepts of Hurwitz and Schur stability of a matrix, which we shall respectively call c- and d-stability with reference to "continuous" and "discrete" time.

DEFINITION 3.1. *A quadratic matrix M is called d-stable iff its spectrum is contained in an open unit disk. A quadratic matrix N is called c-stable iff its spectrum is contained in the complex left open half-plane.*

DEFINITION 3.2.

(a) *A pair (B, F) is called d-stabilizable iff there exists $H \in L(R^n, R^k)$ so that $B + FH$ is d-stable. A pair (B, F) is said to be d^T-stabilizable iff there exists $H \in L(R^k, R^n)$ so that $B + HF$ is d-stable.*

(b) *A four-tuple (A, E, B, F) is called cd-stabilizable iff there exist $H_1 \in L(R^n, R^m)$ and $H_2 \in L(R^n, R^k)$ so that $\mathcal{A}(H_1, H_2)$ is d-stable, where*

$$\mathcal{A}(H_1, H_2) := e^{A+EH_1} \cdot (B + FH_2).$$

DEFINITION 3.3. *A four-tuple (A, Q_1, B, Q_2) is called cd-detectable iff $(Be^A, \sqrt{B^T e^{A^T} Q_1 e^A B + Q_2})$ is d^T-stabilizable.*

Remark 3.1. Note that if $(e^A, \sqrt{e^{A^T} Q_1 e^A})$ is d^T-stabilizable then $(e^A, \sqrt{Q_1})$, is d^T-stabilizable and consequently $(\sqrt{Q_1}, A)$ is c-detectable, which means that there is a matrix H such that $A^T + \sqrt{Q_1^T}\, H$ is d^T-stable.

Proof. This follows from the fact that $\text{Ker}(\sqrt{M}) = \text{Ker}(M)$ for any symmetric, nonnegative semidefinite matrix M and from Proposition 3.1 in Wonham (1979). □

In what follows we will require more notation. Let $\epsilon > 0$. Let $P_t : [0, \epsilon] \to L_+(R^n, R^n)$ be a continuous function, where "+" denotes nonnegative semidefiniteness. Next define

$$\begin{aligned}\mathcal{P}(\epsilon) &:= \{P_t, t \in [0, \epsilon]\},\\ L_t(\epsilon) &:= -R_1^{-1} E^T P_{\epsilon - t}, \quad L_1(\mathcal{P}(\epsilon), \epsilon) := \int_0^\epsilon L_t(\epsilon)dt,\\ \mathcal{D}_1(\mathcal{P}(\epsilon), \epsilon) &:= \epsilon A + EL_1(\mathcal{P}(\epsilon), \epsilon), \quad \mathcal{D}_{1,t}(\epsilon) := A + EL_t(\epsilon),\\ L_2(\mathcal{P}(\epsilon), \epsilon) &:= -(F^T P_\epsilon F + R_2)^{-1} F^T P_\epsilon B,\\ \mathcal{D}_2(\mathcal{P}(\epsilon), \epsilon) &:= B + FL_2(\mathcal{P}(\epsilon), \epsilon),\\ \mathcal{S}(\mathcal{P}(\epsilon), \epsilon) &:= \int_0^\epsilon e^{\int_s^\epsilon \mathcal{D}^T_{1,\epsilon - t}(\epsilon)dt} [Q_1^T + L^T_{\epsilon - s}(\epsilon) R_1 L_{\epsilon - s}(\epsilon)] e^{\int_s^\epsilon \mathcal{D}^T_{1,\epsilon - t}(\epsilon)dt} ds,\\ \mathcal{B}_{(\mathcal{P}(\epsilon),\epsilon)} &:= \mathcal{D}_2^T(\mathcal{P}(\epsilon), \epsilon)\mathcal{S}(\mathcal{P}(\epsilon), \epsilon)\mathcal{D}_2(\mathcal{P}(\epsilon), \epsilon)) + Q_2 + L_2^T(\mathcal{P}(\epsilon), \epsilon) R_2 L_2(\mathcal{P}(\epsilon), \epsilon),\end{aligned}$$

and

$$\mathcal{A}_{(\mathcal{P}(\epsilon),\epsilon)} : L(R^n, R^n) \to L(R^n, R^n)$$

given by

$$\mathcal{A}_{(\mathcal{P}(\epsilon),\epsilon)}(K) := \mathcal{D}_2^T(\mathcal{P}(\epsilon),\epsilon)e^{\mathcal{D}_1^T(\mathcal{P}(\epsilon),\epsilon)}Ke^{\mathcal{D}_1(\mathcal{P}(\epsilon),\epsilon)}\mathcal{D}_2(\mathcal{P}(\epsilon),\epsilon).$$

Consider the following system of Riccati equations, which we will call a *cd*-Riccati equation:

$$\text{(3.1)} \qquad \begin{cases} \mathcal{A}_{(\mathcal{P}(\epsilon),\epsilon)}(R) + \mathcal{B}_{(\mathcal{P}(\epsilon),\epsilon)} = R, \\ \dot{P}_t = Q_1 + A^T P_t + P_t A - P_t E R_1^{-1} E^T P_t, \\ P_0 = R, \ t \in [0,\epsilon]. \end{cases}$$

Observe that

$$\text{(3.2)} \qquad P_\epsilon = e^{\mathcal{D}_1^T(\mathcal{P}(\epsilon),\epsilon)}Re^{\mathcal{D}_1(\mathcal{P}(\epsilon),\epsilon)} + \mathcal{S}(\mathcal{P}(\epsilon),\epsilon).$$

Therefore the first equation in (3.1) can equivalently be written as

$$\text{(3.3)} \quad (B+FL_2(\mathcal{P}(\epsilon),\epsilon))^T P_\epsilon(B+FL_2(\mathcal{P}(\epsilon),\epsilon))+Q_2+L_2^T(\mathcal{P}(\epsilon),\epsilon)R_2L_2(\mathcal{P}(\epsilon),\epsilon) = R.$$

Remark 3.2.

(a) If we assume that $B = I$, or $B = -I$, $F = 0$, $Q_2 = 0$, and $P_t =$ const, $t \in [0,\epsilon]$, then (3.1) reduces to the following algebraic Riccati equation;

$$\text{(c-ARE)} \qquad \begin{aligned} 0 &= Q_1 + A^T R + RA - RER_1^{-1}E^T R, \\ P_t &= R, \ t \in [0,\epsilon]. \end{aligned}$$

We call the above equation c-ARE because it is related to the continuous-time linear-quadratic control problem (see Davis (1977), p. 185).

(b) If we assume that $A = 0$, $E = 0$, $Q_1 = 0$, and $\epsilon = 1$ then (3.1) reduces to the following algebraic Riccati equation,

$$\text{(d-ARE)} \qquad \begin{aligned} R &= B^T[R - RF(F^T RF + R_2)^{-1}F^T R]B + Q_2, \\ P_t &= R, \ t \in [0,1]. \end{aligned}$$

We call the above equation d-ARE since it is related to the discrete-time linear-quadratic control problem (see Bertsekas (1976), p. 355).

In Theorem 3.1 below we shall consider equations (3.1) for $\epsilon = 1$ only. The result is true for any $\epsilon > 0$, as can be easily deduced from the proof of the theorem. We will use a simplified notation by omitting $\epsilon = 1$ from the above definitions. So, for example, we will write $\mathcal{P}$ instead of $\mathcal{P}(1)$, L_1 instead of $L_1(\mathcal{P}(1),1)$, $\mathcal{A}_\mathcal{P}$ instead $\mathcal{A}_{(\mathcal{P}(1),1)}$, etc.

We note that Theorem 12.2 of Wonham (1979) and Proposition on page 75 of Bertsekas (1977) are special cases of Theorem 3.1.

THEOREM 3.1. *Let* $\epsilon = 1$. *Assume that* (A, E, B, F) *is cd-stabilizable and* (A, Q_1, B, Q_2) *is cd-detectable. Then there exists the unique solution* $(\bar{R}, \bar{\mathcal{P}})$ *to* (3.1) *such that* $\bar{R} \geq 0$, $\bar{P}_t \geq 0$ *for* $t \in [0,1]$, *and* $\mathcal{A}(\bar{L}_1, \bar{L}_2)$ *is d-stable, where* $\bar{L}_i := L_i(\bar{\mathcal{P}})$, $i = 1, 2$.

Proof. See Appendix 1.

4. Linear-quadratic stochastic control problem. We begin with introducing the dynamics of the controlled process first:

$$dx_t = (\widetilde{A}x_{t-} + \widetilde{E}v_{t-})d\langle M\rangle_t + (\widetilde{B}x_{t-} + \widetilde{F}u_{t-})d\langle N\rangle_t$$
$$+ dZ_t,\ x_0 = x,\ t \geq 0, \tag{4.1}$$

where $M = N_1 + N_2$, $N = N_3$. The admissible control processes $u. := \{u_t, t \geq 0\}$ and $v. := \{v_t, t \geq 0\}$ are supposed to satisfy the following conditions:

- They are non-anticipating w.r.t. Z,
- There exists a weak semimartingale solution to (4.1) in the sense of Jacod (1979) Chap. XIV,
- $\lim_{t\to\infty} \frac{\|x_t\|^2}{t} = 0$, a.s.,
- $\overline{\lim}_{t\to\infty} \frac{1}{t}\int_0^t(\|x_s\|^2 + \|u_s\|^2 + \|v_s\|^2)ds < +\infty$, a.s.

The class of admissible controls is denoted by $\mathcal{U}_{ad}$. The cost functional will be given in terms of $(T \geq 0)$

$$\begin{aligned}\mathbf{C}_T(v., u., x) = \int_{0^+}^T &[\langle\widetilde{Q}_1 x_{t-}, x_{t-}\rangle \\ &+ \langle\widetilde{R}_1 v_{t-}, v_{t-}\rangle]d\langle M\rangle_t \\ &+ \int_{0^+}^T [\langle\widetilde{Q}_2 x_{t-}, x_{t-}\rangle \\ &\qquad + \langle\widetilde{R_2} u_{t-}, u_{t-}\rangle]d\langle N\rangle_t.\end{aligned}$$

We want to show the existence and characterization of optimal controls, that is, admissible controls $u^0.$ and $v^0.$ such that for all $v., u. \in \mathcal{U}_{ad}$ and $x \in R^n$ it holds that

$$\mathbf{C}(v^0., u^0., x) \leq \mathbf{C}(v., u., x),$$

where

$$\mathbf{C}(v., u., x) := \overline{\lim_{T\to\infty}} \frac{1}{T}\mathbf{C}_T(v., u., x).$$

In the above description of the control problem we have supposed $\widetilde{A}, \widetilde{B} \in L(R^n, R^n)$, $\widetilde{E} \in L(R^m, R^n)$, $\widetilde{F} \in L(R^k, R^n)$, $\widetilde{Q}_1$ and $\widetilde{Q}_2$ are in $L(R^n, R^n)$, and $\widetilde{Q}_1, \widetilde{Q}_2 \geq 0$, $\widetilde{R}_1 \in L(R^m, R^m)$, $\widetilde{R}_2 \in L(R^k, R^k)$, and $\widetilde{R}_1, \widetilde{R} > 0$. Throughout this section we let $k_1 := k_2 + \text{trace } c$, $A := k_1\widetilde{A}$, $E := k_1\widetilde{E}$, $B := k_3\widetilde{B} + I$, $F := k_3\widetilde{F}$, $Q_1 := k_1\widetilde{Q}_1$, $Q_2 := k_3\widetilde{Q}_2$, $R_1 := k_1\widetilde{R}_1$, and $R_2 := k_3\widetilde{R}_2$. The following assumptions will be used.

Assumption A4. (A, E, B, F) is *cd*-stabilizable.

Assumption A5. (A, Q_1, B, Q_2) is *cd*-detectable.

Fix $\epsilon > 0$. Let $(\bar{\bar{R}}, \bar{\bar{P}})$ denote the solution to (3.1) with t substituted with $k_3 t$ and $\dot{P}_t$ changed to $k_3\dot{P}_{k_3 t}$, $t \in [0, \epsilon]$. Define $\Pi_t : [0, \infty) \to L(R^n, R^n)$ by

$$\Pi_{n+s} = \bar{\bar{P}}_{(\epsilon-s)k_3},\ s \in [0, \epsilon),\ n = 0, 1, 2, \ldots .$$

Remark 4.1. Note that

$$\begin{aligned}\dot{\Pi}_t &= -k_3\dot{\bar{\bar{P}}}_{(\epsilon n-t)k_3} = -Q_1 - A^T\bar{\bar{P}}_{(\epsilon n-t)k_3} - \bar{\bar{P}}_{(\epsilon n-t)k_3}A \\ &\quad + \bar{\bar{P}}_{(\epsilon n-t)k_3}ER_1^{-1}E^T\bar{\bar{P}}_{(\epsilon n-t)}k_3 \\ &= -Q_1 - A^T\Pi_t - \Pi_t A + \Pi_t E R_1^{-1}E^T\Pi_t\end{aligned}$$

for $t \in [\epsilon n, \epsilon(n+1))$, $n = 0, 1, 2, \ldots$.

Also let $\widetilde{P} := \epsilon^{-1}\int_0^1 \Pi_t dt = \epsilon^{-1}\int_0^1 \bar{\bar{P}}_{tk_3} dt$. Define controls $(u^0., v^0.)$ by

$$v_t^0 := \bar{\Lambda}_t x_t,\ u_t^0 := \Lambda_2 x_t, \tag{4.2}$$

where

$$\bar{\Lambda}_t := -R_1^{-1}E^T\Pi_t,\ \Lambda_2 := -(F^T\Pi_0 F + R_2)^{-1}F^T\Pi_0 B$$

for $t \geq 0$.

We will need one more assumption.

Assumption A6. $\int |z|^4 K_2(dz) < +\infty$.

THEOREM 4.1. *Suppose assumptions* A1–A6 *are satisfied. Then we have the following:*

(a) *The definitions* (4.2) *are correct: there exists a unique, strong, semimartingale solution to* (4.1) *with* $(v^0., u^0.)$ *in place of* $(v., u.)$,

(b) *The controls* $(v^0., u^0.)$ *are optimal,*

(c) $\mathbf{C}(v^0., u^0., x) = \epsilon^{-1}$*trace*$(c + k_2 I)\widetilde{P} + \epsilon^{-1}$*trace* $k_3\Pi_0$ *for all* $x \in R^n$.

Proof. (a). It is enough to note that $\langle M\rangle$ and $\langle N\rangle$ are special semimartingales and apply Theorem V.3.7 of Protter (1990).

(b). We will use the standard comparison method.

Step 1. Let us first observe the following:

- For all $x \in R^n$ and $t \geq 0$

$$\min_{v\in R^m}[x^T\Pi_t E v + v^T E^T \Pi_t x + v^T R_1 v] = x^T\Pi_t E R_1^{-1}E^T\Pi_t x = -x^T\Pi_t E\bar{\Lambda}_t x,$$

where the minimum is realized by

$$^0v_t := \bar{\Lambda}_t x;$$

- For each $x \in R^n$

$$\begin{aligned}\min_{u\in R^k}&[u^T F^T\Pi_0 Bx + x^T B^T\Pi_0 F u + u^T F^T \Pi_0 F u + u^T R_2 u]\\ &= x^T B^T \Pi_0 F(F^T\Pi_0 F + R_2)^{-1}F^T\Pi_0 Bx\\ &= x^T\Lambda_2^T(F^T\Pi_0 F + R_2)\Lambda_2 x\end{aligned}$$

and the minimum is realized by

$$^0u := \Lambda_2 x.$$

Step 2. Now let $(v., u.) \in \mathcal{U}_{ad}$ be an arbitrary pair of admissible controls. From Lemma A.3.1 of Appendix 3 it follows that $(v^0., u^0.) \in \mathcal{U}_{ad}$. Consider the function $V : [0,\infty) \times R^n \to R$ given by

$$V(t,x) := x^T\Pi_t x.$$

Upon application of Ito's rule for semimartingales (Jacod and Shiryayev (1987), Thm. I.4.57) to V we obtain, for $t \geq 0$,

(4.3)

$$\begin{aligned}x_t^T\Pi_t x_t - x^T\Pi_0 x = \int_{0+}^t &[x_{s-}^T\Pi_{s-}\widetilde{A}x_{s-}\\ &+ x_{s-}^T\Pi_{s-}\widetilde{E}v_{s-} + x_{s-}^T\widetilde{A}^T\Pi_{s-}x_{s-} + v_{s-}^T\widetilde{E}^T\Pi_{s-}x_{s-}]d\langle M\rangle_s\end{aligned}$$

$$
\begin{aligned}
&+\int_{0+}^{t}[x_{s-}^T\Pi_{s-}\widetilde{B}x_{s-}+x_{s-}^T\Pi_{s-}\widetilde{F}u_{s-}+x_{s-}^T\widetilde{B}^T\Pi_{s-}x_{s-}\\
&\qquad +u_{s-}^T\widetilde{F}^T\Pi_{s-}x_s]d\langle N\rangle_s\\
&+2\int_{0+}^{t}x_{s-}^T\Pi_{s-}dZ_s+\int_{0+}^{t}x_{s-}^Td\Pi_s x_{s-}\\
&+\int_{0+}^{t}\text{trace }\Pi_{s-}c ds\\
&+\sum_{\substack{0<s\le t\\ s\in J^c}}\{x_s^T\Pi_s x_s-x_{s-}^T\Pi_{s-}x_{s-}-\Delta x_s^T\Pi_{s-}x_{s-}\\
&\qquad -x_{s-}^T\Pi_{s-}\Delta x_s-x_{s-}^T\Delta\Pi_s x_s\}\\
&+\sum_{0<\epsilon n\le t}\{(Bx_{\epsilon n-}+Fu_{\epsilon n-}+\Delta N_{\epsilon n})^T\Pi_{\epsilon n}(Bx_{\epsilon n-}+Fu_{\epsilon n-}+\Delta N_{\epsilon n})\\
&\qquad -x_{\epsilon n-}^T\Pi_{\epsilon n-}x_{\epsilon n-}-(Bx_{\epsilon n-}+Fu_{\epsilon n-})^T\Pi_{\epsilon n-}x_{\epsilon n-}\\
&\qquad -x_{\epsilon n-}^T\Pi_{\epsilon n-}(Bx_{\epsilon n-}+Fu_{\epsilon n-})-x_{\epsilon n-}^T\Delta\Pi_{\epsilon n}x_{\epsilon n-}\}\\
&=-\int_{0+}^{t}[x_{s-}^T\widetilde{Q}_1x_{s-}-v_{s-}^T\widetilde{R}_1v_{s-}]d\langle M\rangle_s\\
&+\int_{0+}^{t}[x_{s-}^T\Pi_{s-}\widetilde{E}v_{s-}+v_{s-}^T\widetilde{E}^T\Pi_{s-}x_{s-}+v_{s-}^T\widetilde{R}_1v_{s-}\\
&\qquad +x_{s-}^T\Pi_{s-}\widetilde{E}\widetilde{R}_1^{-1}\widetilde{E}^T\Pi_{s-}x_{s-}]d\langle M\rangle_s\\
&+\sum_{\substack{0<s\le t\\ s\in J^C}}\{x_s^T\Pi_s x_s-x_{s-}^T\Pi_{s-}x_{s-}-\Delta x_s^T\Pi_{s-}x_{s-}\\
&\qquad -x_{s-}^T\Pi_{s-}\Delta x_s\}+\int_{0+}^{t}\text{trace }\Pi_{s-}c\, ds\\
&-\int_{0+}^{t}[x_{s-}^T\widetilde{Q}_2x_{s-}+u_{s-}^T\widetilde{R}_2u_{s-}]d\langle N\rangle_s\\
&+\int_{0+}^{t}[x_{s-}^TB^T\Pi_sFu_{s-}+u_{s-}^TF^T\Pi_sBx_{s-}+u_{s-}^TF^T\Pi_sFu_{s-}\\
&\qquad +u_{s-}^TR_2u_s-x_{s-}^T\Lambda_2^T(F^T\Pi_sF+R_2)\Lambda_2x_s]\frac{d\langle N\rangle_s}{k^3}\\
&+2\int_{0+}^{t}[x_{s-}^TB^T\Pi_s+u_{s-}^TF^T\Pi_s]dN_s+2\int_{0+}^{t}x_{s-}^T\Pi_{s-}dZ_s\\
&+\int_{0+}^{t}dN_s^T\Pi_s dN_s\\
&=\sum_{i=1}^{9}I_t^i,\quad \text{a.s.}
\end{aligned}
$$

Note that from Step 1 it follows that $I_t^2\ge 0$ and $I_t^6\ge 0$, $t\ge 0$. As in Theorem 3.6.1 of Lipster and Shiryayev (1989) we have

$$I_t^3=(z^T\Pi z)1_{J^c}*(\mu^z-\nu)_t+(z^T\Pi z)1_{J^c}*\nu_t$$

and note that in view of A6 the process $\zeta_t := (z^T\Pi z)1_{J^c}*(\mu^z-\nu)_t$ is a locally square-integrable martingale with predictable quadratic variation process

$$\langle\zeta\rangle_t = \int_{0+}^t \int_{R^n} (z^T\Pi_s z)^2 1_{J^c} ds K_2(dz).$$

Taking the above remarks into account we obtain from (4.2) the following, $t \geq 0$,

$$\begin{aligned} x_t^T\Pi_t x_t - x^T\Pi_0 x + \mathbf{C}_t(v., u., x) \\ \geq (z^T\Pi z)1_{J^c} * \nu_t + \int_{0+}^t \text{trace } \Pi_{s-} c \, ds \\ + \int_{0+}^t dN_s^T\Pi_s dN_s + \zeta_t + \rho_t + \xi_t, \text{ a.s.,} \end{aligned} \tag{4.4}$$

where

$$\rho_t := 2\int_{0+}^t [x_{s-}^T B^T\Pi_s + u_{s-}^T F^T\Pi_s] dN_s$$

and $\xi_t := 2\int_{0+}^t x_{s-}^T\Pi_{s-} dz_s$ are locally square-integrable martingales. Since $(\Pi_t)_{t\geq 0}$ is periodic we have $\lim_{t\to\infty} \frac{1}{t}(z^T\Pi z)1_{J^c} * \nu_t = \epsilon^{-1}k_2 \text{trace } \widetilde{P}$ and $\lim_{t\to\infty} \frac{1}{t}\int_{0+}^t \text{trace } \Pi_{s-} c ds = \epsilon^{-1}$ trace $\widetilde{P}c$. Applying ergodic theorem to $\varphi_t := \int_{0+}^t dN_s^T\Pi_s dN_s$ we get $\lim_{t\to\infty}\frac{1}{t}\varphi_t = \epsilon^{-1}k_3$ trace Π_0, a.s. Also, it follows from the results of Lipster and Shiryayev (1989), §2.6, that $\lim_{t\to\infty}\frac{1}{t}\zeta_t = \lim_{t\to\infty}\frac{1}{t}\rho_t = \lim_{t\to\infty}\frac{1}{t}\xi_t = 0$, a.s. Therefore from (4.4) we conclude that

$$\mathbf{C}(v., u., x) \geq \epsilon^{-1}\text{trace } (c + k_2 I)\widetilde{P} + \epsilon^{-1}k\Pi_0, \text{ a.s.} \tag{4.5}$$

Using considerations analogous to the ones above, it is straightforward to show that

$$\mathbf{C}(v^0., u^0., x) = \epsilon^{-1}\text{trace } (c + k_2 I)\widetilde{P} + \epsilon^{-1}k\Pi, \text{ a.s.} \tag{4.6}$$

This concludes the proof of (b).

(c). This result follows from (4.5) and (4.6). ||

5. Some special cases. In this section we will shortly demonstrate that Theorem 4.1 encompasses solutions to some "classical" stochastic linear-quadratic control problems.

Case 1 (continuous time system driven by Wiener process). Using our notation this case corresponds to

$$k_2 = 0, \ k_3 = 0.$$

For a problem of this type see, for example, Davis (1977).

Case 2 (continuous time system driven by Wiener and Poisson processes). This corresponds to

$$k_3 = 0, \ N_2 \text{ equivalent to a Poisson process.}$$

Note that in case of a Poisson process Assumption A6 is automatically satisfied. For a problem of this type see, for example, Wonham (1970).

Case 3 (continuous time system driven by a Poisson process). This case corresponds to

$$c = 0 \text{ and } k_3 = 0, \ N_2 \text{ equivalent to a Poisson process.}$$

For a more general model of this type (including the multiplicative noise components) see, for example, Li and Blankenship (1986).

Case 4 (discrete time system driven by a sequence of independent random variables). In our terminology this case corresponds to

$$c = 0, \quad k_2 = 0.$$

For a problem of this type see, for example, Hall and Heyde (1980).

6. Three limiting results. Let us consider equations (3.1) with $A, B, E, F, Q_1, Q_2, R_1, R_2$ as in §4. We also require that k_3 is changed to ϵk_3 in the definitions of B, F, Q_2, and R_2, that time index t is substituted with $k_3 t$, and that $\dot{P}_t$ is changed to $k_3 \dot{P}_{k_3 t}$.

In this section we shall analyze the behavior of equations (3.1) in the present setting when (i) ϵ tends to 0, (ii) k_3 tends to zero, and (iii) k_1 tends to zero. Note that the first case corresponds to "increasing frequency of the discrete time component." A "classical" prototype of it has been considered before in the context of approximating of a continuous-time linear-quadratic problem with a sequence of discrete-time linear-quadratic problems (see Whittle, 1983, Ex. 1, p. 209, for example). The second case corresponds to vanishing of the discrete-time component, and the third case corresponds to vanishing of the continuous-time component of the system.

Case i. Assume A4 and A5. Also assume that $(A + k_3\widetilde{B}, [E \ F])$ and $(A^T + k_3\widetilde{B}^T, \sqrt{Q_1 + Q_2})$ are c-stabilizable pairs. Denote by $(R(\epsilon, k_1, k_3), \mathcal{P}(\epsilon, k_1, k_3))$ the solution to (3.1). Then, using (3.1)–(3.3) and some algebra, it can be shown that

$$\lim_{\epsilon \to 0} (R(\epsilon, k_1, k), \mathcal{P}(\epsilon, k_1, k)) = (P(0, k_1, k_3), P(0, k_1, k_3)) \ , \tag{6.1}$$

where $P(0, k_1, k_3)$ is the solution to

$$\begin{aligned} Q_1 + Q_2 + (A + k_3\widetilde{B})^T P + P(A + k_3\widetilde{B}) \\ -P[E \ F] \begin{pmatrix} R_1^{-1} & 0 \\ 0 & R_2^{-1} \end{pmatrix} [E \ F]^T P = 0 \ . \end{aligned} \tag{6.2}$$

Example (partial time discretization). Here $n = 2$, $m = k = k_1 = k_3 = 1$. We also let

$$\widetilde{A} = \begin{pmatrix} a & b \\ 0 & 0 \end{pmatrix}, \ \widetilde{E} = \begin{pmatrix} e \\ 0 \end{pmatrix}, \ \widetilde{B} = \begin{pmatrix} 0 & 0 \\ c & d \end{pmatrix}, \ \widetilde{F} = \begin{pmatrix} 0 \\ f \end{pmatrix},$$

$$\widetilde{Q}_1 = \begin{pmatrix} q_1 & 0 \\ 0 & 0 \end{pmatrix}, \ \widetilde{Q}_2 = \begin{pmatrix} 0 & 0 \\ 0 & q_2 \end{pmatrix},$$

$$\widetilde{R}_1 = r_1, \ \widetilde{R}_2 = r_2 \ .$$

This parametrization corresponds, for example, to a partial time discretization, with time step ϵ, of the following control problem (here we are using notation $x(t)$ and $u(t)$ instead of x_t and u_t):

(6.3) Minimize

$$\overline{\lim_{T \to \infty}} \, T^{-1} \int_0^T \left\{ (x_1(t), x_2(t)) \begin{pmatrix} q_1 & 0 \\ 0 & q_2 \end{pmatrix} \begin{pmatrix} x_1(t) \\ x_2(t) \end{pmatrix} + (u_1(t), u_2(t)) \begin{pmatrix} r_1 & 0 \\ 0 & r_2 \end{pmatrix} \begin{pmatrix} u_1(t) \\ u_2(t) \end{pmatrix} \right\} dt$$

subject to

$$\begin{aligned} dx_1(t) &= (ax_1(t) + bx_2(t))dt + eu_1(t)dt + dw_1(t), \\ dx_2(t) &= (cx_1(t) + dx_2(t))dt + fu_2(t)dt + dw_2(t), \end{aligned}$$

where w_1 and w_2 are standard one-dimensional Brownian motions.

In this case "partial time discretization" means time discretization with respect to the second state component $x_2(t)$. The partially time-discretized problem is

Minimize

$$\overline{\lim_{T\to\infty}}\, T^{-1}\int_0^T \left(q_1 x_{1,\epsilon}^2(t) + r_1 u_1(t)^2\right) dt + \epsilon^{-1}\,\overline{\lim_{N\to\infty}}\, N^{-1}\sum_{n=1}^{N}\left(\epsilon q_2 x_{2,\epsilon}^2(n) + \epsilon r_2 u_{2,\epsilon}^2(n)\right)$$

subject to

$$\begin{aligned} dx_{1,\epsilon}(t) &= (ax_{1,\epsilon}(t) + bx_{2,\epsilon}(n))dt + eu_1(t)dt + dw_1(t),\\ &\quad t \in [\epsilon n, \epsilon(n+1)),\\ x_{2,\epsilon}(n+1) &= \epsilon c x_{1,\epsilon}(\epsilon n) + (\epsilon+1)dx_{2,\epsilon}(n) + \epsilon u_{2,\epsilon}(n) + (w_2(\epsilon(n+1)) - w_2(\epsilon n))\\ &\quad n = 0, 1, 2, \ldots . \end{aligned}$$

Here, the limiting equation (6.2) coincides with the algebraic Riccati equation corresponding to the original problem (6.3).

We believe that our methodology will allow for time discretization of continuous-time control problems using various time steps for various components of state vector, if necessary.

Case ii. Assume A4 and A5. Then

$$\lim_{k_3\to 0}(R(\epsilon,k_1,k_3), \mathcal{P}(\epsilon,k_1,k_3)) = (P(\epsilon,k_1,0), \mathcal{P}(\epsilon,k_1,0)) \,, \tag{6.4}$$

where $\mathcal{P}(\epsilon,k_1,0) = \{P_t = P(\epsilon,k_1,0), t\in[0,\epsilon]\}$ and $P(\epsilon,k_1,0)$ is the solution of

$$0 = Q_2 + A^T P + PA - PER^{-1}E^T P \,. \tag{6.5}$$

Case iii. Assume A4 and A5. Then

$$\lim_{k_1\to 0}(R(\epsilon,k_1,k_3), \mathcal{P}(\epsilon,k_1,k_3)) = (P(\epsilon,0,k_3), \mathcal{P}(\epsilon,0,k_3)) \,, \tag{6.6}$$

where $\mathcal{P}(\epsilon,0,k_3) = \{P_t = P(\epsilon,0,k_3), t\in[0,\epsilon]\}$ and $P(\epsilon,0,k_3)$ is the solution to

$$P = B^T[P - PF(F^T PF + R_2)^{-1}F^T P]B + Q_2 \,. \tag{6.7}$$

7. A simple hybrid control problem.

Consider the following special form of the control problem considered in §4.

System dynamics

$$\begin{aligned} dx_t &= y_n dt + dw_t,\ t\in[n,n+1),\\ y_{n+1} &= y_n + u_n + e_n,\ n = 0,1,2,\ldots\\ x_0 &= x,\ y_0 = y, \end{aligned}$$

where $x_t, y_n \in R^1$, $(w_t)_{t\geq 0}$ is a standard Brownian motion in R^1, and $(e_n)_{n=0}^{\infty}$ is an independently and identically distributed (i.i.d.) sequence of Gaussian random variables with mean zero and variance one.

Cost functional

$$\overline{C}(\overline{u}_\cdot,(x,y)) = \overline{\lim_{T\to\infty}}\, T^{-1}\int_0^T (x_t^2 + \overline{u}_t^2)\, dt \,,$$

where $\overline{u}_t = u_n$, $t\in[n,n+1)$.

The point here is that a continuous-time subsystem corresponding to x_t is controlled via a discrete-time subsystem corresponding to y_n. Using results of §4 we compute optimal controls

$$u_n^o = -\frac{1+\sqrt{13}}{2+\sqrt{13}} y_n, \; n = 0, 1, 2, \ldots,$$

and the optimal cost

$$\overline{C}(\overline{u}^o, (x, y)) = \frac{29 + 3\sqrt{13}}{18} \; .$$

8. Concluding remarks. We refer to the control problem considered in §4 as to the "backward problem." The "forward problem" for which the cost functional is given in terms of

$$\left\{ \int_0^t [x_s^t \widetilde{Q}_1 x_s + v_s^t \widetilde{R}_1 v_s] d\langle M \rangle_s + \int_0^t [x_s^t \widetilde{Q}_s x_s + u_s^t \widetilde{R}_2 u_s] d\langle N \rangle_s \right\}$$

can be studied in the similar way as the "backward problem."

Our formulation of the linear-quadratic stochastic control problem does not allow for a direct consideration of a deterministic linear-quadratic control problem, one of the reasons being that the time scales in (4.1) would vanish for $k_1 = 0$ and/or $k_3 = 0$. An obvious reparametrization will allow for including a deterministic situation in the model (4.1) as well. We have not done that in order to keep the calculations easy. Note that equations (3.1) are serving both deterministic and stochastic situations, as in the "classical" case.

It is still an open question under what nontrivial conditions on the parameters there exists a stationary distribution for $(x_t^0)_{t \geq 0}$. We have some preliminary results for the noncontrolled case corresponding to the one considered by Zabczyk (1983).

In a subsequent paper we shall consider implications of the approach taken here for control and identification of general (multiple time scales) ARMA models represented via a certain integral transform that is given in terms of the predictable quadratic variation process of the driving semimartingale noise.

Acknowledgments. I would like to thank the referees for their valuable remarks, which helped me improve the first version of the manuscript.

Appendix 1. In this appendix we prove Theorem 3.1. We will need the following three technical results, which are counterparts of Theorem 3.6 ii) and Lemmas 12.1 and 12.2 of Wonham (1979).

LEMMA A.1.1. *If $Q \geq 0$ and B is d-stable then the equation*

$$B^T R B + Q = R$$

has a unique solution R and $R \geq 0$.

Proof. $R = \sum_{k=0}^{\infty} (B^T)^k Q \, B^k$. □

LEMMA A.1.2 (d-Liapunov criterion). *Suppose $R \geq 0$, $Q \geq 0$, $(B, \sqrt{Q})$ is d^T-stabilizable and $B^T R B + Q = R$. Then B is d-stable.*

Proof. We have

$$R = (B^T)^k R B^k + \sum_{i=0}^{k-1} (B^T)^i Q B^i, \quad k \geq 0.$$

Assume B is not d-stable and let λ be an eigenvalue of B with $|\lambda| \geq 1$, and X the corresponding eigenvector. We have $X^T RX = |\lambda|^{2k} X^T RX + \sum_{i=0}^{k-1} |\lambda|^{2i} \|\sqrt{Q}\, X\|^2$. This means that $|\lambda| = 1$ and $\sqrt{Q}X = 0$. Let $\widetilde{K}$ be a matrix such that $B + \widetilde{K}\sqrt{Q}$ is d-stable. We see that λ and X are respectively an eigenvalue and corresponding eigenvectors of $B + \widetilde{K}\sqrt{Q}$. This is a contradiction. □

LEMMA A.1.3. *Assume that the four-tuple (A, Q_1, B, Q_2) is cd-detectable. Let $G : [0,1] \to L(R^n, R^n)$ be continuous. Let $G := \int_0^1 G_s ds$ and $M > 0$, $N > 0$, $\Phi \geq 0$, L be arbitrary matrices of appropriate dimensions. Then the pair*

$$\Bigg((B+L)e^{(A+G)},$$
$$\sqrt{Q_2 + L^T NL + \Phi + (B+L)^T \left[\int_0^1 e^{\int_t^1 (A+G_{1-s})^T ds}(Q_1 + G_{1-t}^T M G_{1-t}) e^{\int_0^1 (A+G_{1-s})ds} dt\right]}$$
$$\sqrt{\cdot (B+L)}\Bigg)$$

is d^T-stabilizable.

Proof. It will be shown in Lemma A.2.1 of Appendix 2 that

$$\begin{aligned} \mathrm{Ker} \int_0^1 & e^{\int_0^t (A+G_s)^T ds}[Q_1 + G_t^T M G_t] e^{\int_0^t (A+G_s) ds} dt \\ & \subset \mathrm{Ker}\, e^{A^T} \int_0^1 (Q_1 + G_t^T M G_t) dt e^A. \end{aligned}$$

Therefore we have the following chain of inclusions,

$$\begin{aligned} &\mathrm{Ker}\sqrt{Q_2 + L^T NL + \Phi} \\ &\sqrt{+(B+L)^T \left[\int_0^1 e^{\int_t^1 (A+G_{1-s})^T ds}(Q_1 + G_{1-t}^T M G_{1-t}) e^{\int_t^1 (A+G_{1-s})ds} dt\right](B+L)} \\ &\subset \ \mathrm{Ker}\sqrt{Q_2 + L^T NL + B^T e^{A^T} Q_1 e^A B + (B+L)^T e^{A^T} \int_0^1 G_t^T M G_t dt e^A (B+L)} \\ &\subset \ \mathrm{Ker}\sqrt{Q_2 + B^T e^{A^T} Q_1 e^A B} \cap \ \mathrm{Ker}(-L) \cap \ \mathrm{Ker}(e^A B - e^{A+G} B) \\ &\subset \ \mathrm{Ker}(\sqrt{Q_2 + B^T e^{A^T} Q_1 e^A B} - e^{A+G} L + e^A B - e^{A+G} B). \end{aligned}$$

Let K be such that $e^A B + K\sqrt{Q_2 + B^T e^{A^T} Q_1 e^A B}$ is d-stable. In view of the above inclusions we conclude that there exists matrix $\widetilde{K}$ such that

$$\begin{aligned} &e^{A+G}(B+L) \\ &+ \widetilde{K}\sqrt{Q_2 + L^T NL + \Phi} \\ &\sqrt{+(B+L)^T \left[\int_0^1 e^{\int_t^1 (A+G_{1-s})^T ds}(Q_1 + G_{1-t}^T M G_{1-t}) e^{\int_t^1 (A+G_{1-s} ds} dt\right](B+L)} \\ &= e^A B + K\sqrt{Q_2 + B^T e^{A^T} Q_1 e^A B}. \qquad \square \end{aligned}$$

Proof of Theorem 3.1.

Step 1. Let $R \geq 0$. Consider the control problem

$$J(x_0, R) = \min_{u,v.} J(x_0, u, v., R)$$

where

$$J(x_0, u, v., R) := x_0^T Q_2 x_0 + u^T R_2 u + y_1^T R y_1 + \int_0^1 (y_s^T Q_1 y_s + v_s^T R_1 v_s) ds$$

subject to

$$\begin{cases} x_1 &= Bx_0 + Fu, \\ \dot{y}_t &= Ay_t + Ev_t, \\ y_0 &= x_1, \ t \in [0,1]. \end{cases}$$

It can be easily verified that

$$J(x_0, R) = x_0^T [B^T P_1 B + Q_2 - B^T P_1 F (F^T P_1 F + R_2)^{-1} F^T P_1 B] x_0,$$

and the optimal controls are

$$\begin{aligned} v_t^* &:= L_t(\mathcal{P}) y_t, \ t \in [0,1], \\ u^* &:= L_2(\mathcal{P}) x_0, \end{aligned}$$

where $\mathcal{P}$ corresponds to R in the sense that $\mathcal{P} = P_t, t \in [0,1]$ solves the differential equation in (3.1) with $P_0 = R$.

Step 2. (a) Choose $L_0^1 := \{\widetilde{L}_t^1, \ t \in [0,1]\}$ and L_2^1 so that $\mathcal{A}(L_1^1, L_2^1)$ is d-stable. Here $L_1^1 := \int_0^1 \widetilde{L}_t^1 dt$.

(b) Having chosen $(L_0^1, L_2^1), \dots, (L_0^k, L_2^k)$, obtain $R^k \geq 0$ from (use Lemma A.1.1)

$$\mathcal{A}^T(L_1^k, L_2^k) R^k \mathcal{A}(L_1^k, L_2^k) + \int_0^1 e^{\int_s^1 (A + E\widetilde{L}_{1-t}^k)^T dt} \cdot [Q_1 + (\widetilde{L}_{1-s}^k)^T R_1 \widetilde{L}_{1-s}^k] e^{\int_s^1 (A + E\widetilde{L}_{1-t}^k) dt} ds + Q_2 + (L_2^k)^T R_2 L_2^k = R^k.$$

In the above $L_1^k := \int_0^1 \widetilde{L}_t^k dt$. Note that with regard to the control problem of Step 1 we have $x_0^T R^k x_0 = J(x_0, u^k, v^k., R^k)$, where

$$u^k := L_2^k x_0, \ v_t^k := \widetilde{L}_t^k y_t, \ t \in [0,1].$$

(c) Obtain $\mathcal{P}^{k+1} := \{P_t^{k+1}, t \in [0,1]\}$ from

$$\text{(A.1.1)} \qquad \begin{cases} \dot{P}_1^{k+1} &= Q_1 + A^T P_t^{k+1} + P_t^{k+1} A - P_t^{k+1} E R_1^{-1} E^T P_t^{k+1}, \\ P_0^{k+1} &= R^k, \quad t \in [0,1] \end{cases}$$

and define

$$\begin{aligned} \widetilde{L}_t^{k+1} &:= -R_1^{-1} E^T P_{t-1}^{k+1}, \ t \in [0,1], \\ L_2^{k+1} &:= -(F^T P_1^{k+1} F + R_2)^{-1} F^T P_1^{k+1} B. \end{aligned}$$

Remark A.1.1. In case $B = I$, $Q_2 = 0$, $F = 0$, and $P_t =$ const, $t \in [0,1]$, consider (A.1.1) as

$$0 = Q_1 + (A + EL_1^k)^T R^k + R^k (A + EL_1^k) + (L_1^k)^T R_1 L_1^k$$

and $\widetilde{L}_s^k = L_1, \ s \in [0,1]$.

Note that with regard to the control problem of Step 1 we have

$$x_0^T(B^TP_1^{k+1}B+Q_2-B^TP_1^{k+1}F(F^TP_1^{k+1}F+R_2)^{-1}F^TP_1^{k+1}B)x_0 = J(x_0,R^k) \leq x_0^TR^kx_0.$$

After letting $\mathcal{K}^i := B^TP_1^iB + Q_2 - B^TP_1^iF(F^TP_1^iF + R_2)^{-1}F^TP_1^iB$ we then have

$$\mathcal{K}^{k+1} \leq R^k.$$

Now note that

$$\mathcal{A}_{\mathcal{P}^{k+1}}(R^k) + \mathcal{B}_{\mathcal{P}^{k+1}} = \mathcal{K}^{k+1} - R^k + R^k.$$

Therefore, in view of Lemmas A.1.2 and A.1.3 we conclude that $\mathcal{A}(L_1^{k+1}, L_2^{k+1})$ is d-stable. Obtain R^{k+1} from

$$\mathcal{A}_{\mathcal{P}^{k+1}}(R^{k+1}) + \mathcal{B}_{\mathcal{P}^{k+1}} = R^{k+1}$$

and note that

$$\mathcal{A}^T(L_1^{k+1}, L_2^{k+1})(R^{k+1} - R^k)\mathcal{A}(L_1^{k+1}, L_2^{k+1}) + \mathcal{K}^{k+1} - R^k = R^{k+1} - R^k.$$

Henceforth we have

$$0 \leq R^{k+1} \leq R^k.$$

Thus there exist limits

$$0 \leq \bar{R} = \lim_{k\to\infty} R^k,$$
$$0 \leq \bar{P}_t = \lim_{k\to\infty} P_t^k, \ t \in [0,1],$$

and the pair $(\bar{R}, \bar{\mathcal{P}})$ satisfies (3.1), where $\bar{\mathcal{P}} := \{\bar{P}_t,\ t \in [0,1]\}$. Again by Lemmas A.1.2 and A.1.3, we conclude that $\mathcal{A}(\bar{L}_1, \bar{L}_2)$ is d-stable.

Uniqueness of $(\bar{R}, \bar{\mathcal{P}})$ follows from the following argument. Let $(\widetilde{R}, \widetilde{\mathcal{P}})$ be another solution to (3.1) such that $\widetilde{R} \geq 0$ and $\widetilde{\mathcal{P}}_t \geq 0$, $t \in [0,1]$. In view of the control problem analogous to the one considered in Step 1 we have

$$\mathcal{A}_{\widetilde{\mathcal{P}}}(\bar{R} + \mathcal{B}_{\widetilde{\mathcal{P}}}) \leq \bar{R}.$$

Therefore it holds that

$$\mathcal{A}_{\widetilde{\mathcal{P}}}(\bar{R} - \widetilde{R}) \leq \bar{R} - \widetilde{R},$$

and since $\mathcal{A}(\widetilde{L}_1, \widetilde{L}_2)$ is d-stable (Lemmas A.1.2 and A.1.3 again) we obtain that $\bar{R} - \widetilde{R} \geq 0$. Similarly we get that $\mathcal{A}_{\bar{\mathcal{P}}}(\widetilde{R} - \bar{R}) \leq \widetilde{R} - \bar{R}$ and therefore $\widetilde{R} - \bar{R} \geq 0$. □

Appendix 2.

LEMMA A.2.1. *In the notation of Lemma* A.1.3 *it holds that*

$$\operatorname{Ker} \int_0^1 e^{\int_0^t (A+G_s)^T ds}[Q_1 + G_t^T M G_t] e^{\int_0^t (A+G_s)^T ds} dt$$
$$\subset \operatorname{Ker} e^{A^T} \int_0^1 (Q_1 + G_t^T M G_t) dt \ e^A.$$

Proof. Consider the dynamic system

$$\dot{x}_t = (A + G_t)x_t,$$
$$x_0 = 0, \ t \in [0,1],$$

and the functional

$$I = \int_0^1 x_s^T(Q_1 + G_s^T M G_s)x_s ds.$$

Note that $I = 0$ implies $G_s x_s = 0$ for almost all $s \in [0,1]$ and therefore

$$0 = x_0^T \int_0^1 e^{tA^T}(Q_1 + G_t^T M G_t)e^{tA}dt\ x_0.$$

This implies that

$$x_0^T e^{tA^T} Q_1(t^k A^k)x_0 = x_0^T e^{tA^T} G_t M G_t(t^k A^k)x_0 = 0$$

for $k \geq 0$ and almost all $t \in [0,1]$. Thus we obtain

$$0 = x_0^T e^{A^T} \int_0^1 (Q_1 + G_t^T M G_t)dte^A x_0. \qquad \square$$

Appendix 3.

LEMMA A.3.1. *Under the assumptions of Theorem* 4.1 *the pair of controls* $(v^0., u^0.)$ *defined in* (4.2) *is admissible.*

Proof. Let $(x_t^0)_{t\geq 0}$ be the unique, strong, semimartingale solution to (4.1), under $(v^0., u^0.)$, that exists according to Theorem 4.1(a). It remains to show

$$\text{(A.3.1)} \qquad \overline{\lim_{t\to\infty}} \frac{1}{t}\int_0^t \|x_s^0\|^2 ds < +\infty, \text{ a.s.}$$

and

$$\text{(A.3.2)} \qquad \lim_{t\to\infty} \frac{1}{t}\|x_t^0\|^2 = 0, \text{ a.s.}$$

It is enough to consider the stochastic sequence $\{y_n\}_{n\geq 1}$ where $y_n := x_{n-}^0$, $n \geq 1$. Note that

$$\begin{aligned} y_{n+1} &= \mathcal{A}(\Lambda_1, \Lambda_2)y_n + e_n, \\ y_1 &= x_{1-}^0,\ n \geq 1, \end{aligned}$$

where $\Lambda_1 := \int^1 \bar{\Lambda}_t dt$ and

$$e_n := \int_n^{n+1} e^{\int_s^{n+1}(A+E\bar{\Lambda}_t)dt} dM_s + e^{A+E\Lambda_1}\Delta N_n,\ n \geq 1.$$

Since $\mathcal{A}(\Lambda_1, \Lambda_2)$ is d-stable (Theorem 3.1) we conclude, upon applying the strong law of large numbers for martingales (Lipster and Shiryayev (1989), Thm. 2.6.1), that

$$\lim_{n\to\infty} \frac{\|y_n\|^2}{n} = 0, \text{ a.s.},$$

which in turn implies (A.3.2).

Since $\mathcal{A}(\Lambda_1, \Lambda_2)$ is d-stable then there exists a positive definite matrix G such that

$$\mathcal{A}^T(\Lambda_1, \Lambda_2)G\mathcal{A}(\Lambda_1, \Lambda_2) + 2I = G$$

(compare Lemma A.1.1). Next note that, for $n \geq 1$,

$$\begin{aligned} y_{n+1}^T G y_{n+1} &= y_n^T \mathcal{A}^T(\Lambda_1, \Lambda_2) G \mathcal{A}(\Lambda_1, \Lambda_2) y_n \\ &\quad + 2 y_n^T \mathcal{A}^T(\Lambda_1, \Lambda_2) G e_n + e_n^T G e_n \\ &\leq y_n^T G y_n - \|y_n\|^2 + 2 y_n^T \mathcal{A}^T(\Lambda_1, \Lambda_2) G e_n \\ &\quad + e_n^T G e_n, \quad \text{a.s.} \end{aligned}$$

Therefore we have

$$\begin{aligned} y_{n+1}^T G y_{n+1} + \sum_{k=1}^n \|y_k\|^2 &\leq y_1^T G y_1 \\ &\quad + 2 \sum_{k=1}^n y_k^T \mathcal{A}(\Lambda_1, \Lambda_2) G e_k \\ &\quad + \sum_{k=1}^n e_n^T G e_n, \quad \text{a.s.} \end{aligned}$$

Invoking the law of large numbers for martingales again, we finally obtain

$$\overline{\lim_{n \to \infty}} \frac{1}{n} \sum_{k=1}^n \|y_k\|^2 < +\infty, \quad \text{a.s.},$$

from which (A.3.1) follows. □

TOOLS FOR SEMIGLOBAL STABILIZATION BY PARTIAL STATE AND OUTPUT FEEDBACK*

ANDREW TEEL† AND LAURENT PRALY‡

Abstract. We develop tools for uniform semiglobal stabilization by partial state and output feedback. We show, by means of examples, that these tools are useful for solving a variety of problems. One application is a general result on semiglobal output feedback stabilizability when global state feedback stabilizability is achievable by a control function that is uniformly completely observable. We provide more general results on semiglobal output feedback stabilization as well. Globally minimum phase input–output linearizable systems are considered as a special case. Throughout our discussion we demonstrate the usefulness of considering local convergence separate from boundedness of solutions. For the former we employ a sufficient small gain condition guaranteeing convergence. For the latter we rely on Lyapunov techniques.

Key words. semiglobal (practical) stabilizability, uniform complete observability, dynamic output feedback, high gain control, nonlinear small gain

AMS subject classifications. 93D15, 93D09

Notation.

- A function is said to be smooth if it is in C^r, i.e., r times continuously differentiable, for some integer $r \geq 1$.
- $d(t)$ is a time-varying signal contained in a compact set $D \subset \mathbb{R}^d$. It will be appropriate to denote $d(t)$ and its time derivatives $\dot{d}(t)$, $\ddot{d}(t), \ldots$ by the same symbol d, i.e., $d = (d, \dot{d}, \ddot{d}, \ldots)$. Since this aggregated d is still assumed to lie in a compact set, in some cases we shall implicitly introduce the strong requirement that the external disturbance is smooth.
- $\dot{V}_{(0)}$ denotes the function $\frac{\partial V}{\partial x}(x) f(x,d) : \mathbb{R}^l \times D \to \mathbb{R}$ and the subscript (0) refers to equation number (0) of the differential equation

$$\dot{x} = f(x, d(t)). \tag{0}$$

- $|\cdot|$ denotes the Euclidean norm.
- $||\cdot||_{t_0}$ denotes ess–$\sup_{t_0 \leq t \leq \infty} |\cdot|$.
- A function $\gamma : \mathbb{R}_{\geq 0} \to \mathbb{R}_{\geq 0}$ is said to be *of class-K* if it is continuous, strictly increasing, and satisfies $\gamma(0) = 0$. It is *of class-K_∞* if in addition $\gamma(s) \to \infty$ as $s \to \infty$.
- A function $\beta : \mathbb{R}_{\geq 0} \times \mathbb{R}_{\geq 0} \to \mathbb{R}_{\geq 0}$ is said to be of *class-KL* if, for each fixed $t \in \mathbb{R}_{\geq 0}$, the function $\beta(\cdot, t)$ is of class-K and for each fixed $s \in \mathbb{R}_{\geq 0}$ the function $\beta(s, \cdot)$ is decreasing and

$$\lim_{t \to \infty} \beta(s, t) = 0. \tag{1}$$

- A function $f : \mho \to \mathbb{R}_{\geq 0}$, where $\mho$ is an open set of $\mathbb{R}^p$, is said to be *proper on* $\mho$ if the preimage of a compact subset of $\mathbb{R}_{\geq 0}$ is a compact subset of $\mho$.
- A function $f : \mho \to \mathbb{R}_{\geq 0}$ is said to be *positive* (*negative*) *definite on* $\mho'$, a subset of $\mho$, if $f(x)$ is strictly positive (negative) for all x in $\mho'$.

- A solution $x(t)$ of an ordinary differential equation is said to be *captured by a set* Γ if $x(t)$ is defined on $[0,+\infty)$ and there exists t_o such that $x(t) \in \Gamma$ for all t in $[t_o, +\infty)$.

1. **A motivating problem and some results.** We are interested in the semiglobal stabilization[1] problem, as it is stated in [3], for example. In subsequent sections, the following four tools for solving semiglobal stabilization problems will be presented: two "backstepping" tools, a robust observer, and a local nonlinear small gain theorem. The usefulness of these tools will be illustrated by examples throughout the paper. Initially, to give the reader a sense for what can be proved with these tools, we will state some general nonlinear output feedback stabilization results which will be proved in a stronger form and with full details in later sections.

We start by considering the output feedback stabilization problem for nonlinear systems in the general form

$$\left\{ \begin{array}{rcl} \dot{z} &=& A(z,u), \\ y &=& C(z) . \end{array} \right. \tag{2}$$

We will make use of the following properties.

DEFINITION 1 (stabilizability). *An equilibrium point $z = 0$ of a dynamical system*

$$\dot{z} = A(z,u) \tag{3}$$

with A a smooth function, z in $\mathbb{R}^n$, and u in $\mathbb{R}$ is said to be globally (respectively, locally exponentially and globally) stabilizable if there exists a smooth function $\bar{u}$ such that $z = 0$ is a globally asymptotically (respectively, locally exponentially and globally asymptotically) stable equilibrium of

$$\dot{z} = A(z, \bar{u}(z)) . \tag{4}$$

DEFINITION 2 (uniform complete observability). *A function $\bar{u}(z)$ is said to be uniformly completely observable (UCO) with respect to the dynamical system (2) if there exist two integers n_y and n_u and a C^1 function Ψ such that, for each solution of*

$$\left\{ \begin{array}{rcl} \dot{z} &=& A(z,u_0), \\ \dot{u}_0 &=& u_1, \\ &\vdots& \\ \dot{u}_{n_u} &=& v, \end{array} \right. \tag{5}$$

we have, for all t where the solution makes sense,

$$\bar{u}(z(t)) = \Psi(y(t), \dots, y^{(n_y)}(t), u_0(t), \dots, u_{n_u}(t)), \tag{6}$$

where $y^{(i)}(t)$ denotes the ith time derivative of y at time t.[2]

Achieving global stabilization by output feedback can be impossible for very simple systems that are globally stabilizable by state feedback even when each component

[1] See Definition 3. Depending on the authors, this type of stabilization is also called "potentially global", "on compacta," or "widely local."

[2] If u is not present in (6) we let $n_u = -1$.

of the state is uniformly completely observable. For example, it was shown in [28] that there is no continuous, finite-dimensional dynamic output feedback to globally stabilize the equilibrium point $z = 0$ of the system

$$(7) \qquad \begin{cases} \dot{z}_1 &= z_2, \\ \dot{z}_2 &= z_2^n + u, \\ y &= z_1, \end{cases}$$

with $n \geq 3$. This is true even though the system is globally feedback linearizable and the state is related to the output by $z_1 = y$, $z_2 = \dot{y}$. For this reason we restrict our attention to the semiglobal stabilization problem.

DEFINITION 3 (semiglobal stabilizability). [3] *The equilibrium $z = 0$ of the system* (2) *is said to be semiglobally stabilizable by dynamic state* (*respectively, output*) *feedback if, for each compact set $\mathcal{K}_l$, a neighborhood of* 0, *there exists a locally Lipschitz dynamic state* (*respectively, output*) *feedback $u = \bar{u}(z, \zeta)$, $\dot{\zeta} = \theta(z, \zeta)$* (*respectively, $u = \bar{u}(y, \zeta)$, $\dot{\zeta} = \theta(y, \zeta)$*) *and a compact set $\mathcal{K}_{\zeta l}$ such that the equilibrium $(z, \zeta) = (0, 0)$ is asymptotically stable, with basin of attraction containing $\mathcal{K}_l \times \mathcal{K}_{\zeta l}$.*

It was shown in [40] that, when each component of the state vector z is UCO, global stabilizability by state feedback implies semiglobal stabilizability by output feedback. An implication of the state being UCO is that any globally stabilizing function $\bar{u}(z)$ is UCO. One might hope that this weaker assumption, existence of a UCO globally stabilizing state feedback, would yield semiglobal stabilizability by output feedback as well. Unfortunately, some difficulties appear in this case when attempting to establish local asymptotic stability. To guarantee this local property, we will impose extra local requirements on the system (4). A sufficient condition, generalizations of which are discussed in §5, is local exponential stability.

THEOREM 1.1. *If the equilibrium point $z = 0$ of the system* (2) *is locally exponentially and globally stabilizable by a UCO and C^2 state feedback, then it is semiglobally stabilizable by dynamic output feedback.*

Otherwise, since the only obstruction is local, we can still achieve semiglobal practical stabilization as summarized in the next definition and theorem.

DEFINITION 4 (semiglobal practical stabilizability). *A point $z = 0$* (*not necessarily an equilibrium*) *is said to be semiglobally practically stabilizable by dynamic state* (*respectively, output*) *feedback if, for each pair of compact sets $(\mathcal{K}_s, \mathcal{K}_l)$, neighborhoods of* $(0, 0)$ *with $\mathcal{K}_s \subset \mathcal{K}_l$, there exists a locally Lipschitz dynamic state* (*respectively, output*) *feedback $u = \bar{u}(z, \zeta)$, $\dot{\zeta} = \theta(z, \zeta)$* (*respectively, $u = \bar{u}(y, \zeta)$, $\dot{\zeta} = \theta(y, \zeta)$*) *and a pair of compact sets $(\mathcal{K}_{\zeta s}, \mathcal{K}_{\zeta l})$ such that all the solutions of the closed-loop system, with initial condition in $\mathcal{K}_l \times \mathcal{K}_{\zeta l}$, are captured by the set $\mathcal{K}_s \times \mathcal{K}_{\zeta s}$.*

THEOREM 1.2. *If the equilibrium point $z = 0$ of the system* (2) *is globally stabilizable by a UCO and C^2 state feedback, then it is semiglobally practically stabilizable by dynamic output feedback.*

The technique for proving these theorems is to exhibit a feedback controller based on the given state feedback controller $\bar{u}$, implemented dynamically using estimates of a sufficient number of derivatives of y provided by an observer and a sufficient number of derivatives of u provided by a suitable dynamic extension. The idea of implementing $\bar{u}$ through dynamic extension comes from the work of Tornambè [43]. That such a dynamically extended state feedback controller can be constructed while retaining semiglobal (practical) stabilizability will be shown using the iterating tool of Lemma

[3] It follows from this definition that a family of feedback laws is involved. This family is indexed by $\mathcal{K}_l$.

2.3. Further, we will show that combining the dynamically extended controller and an appropriate observer still yields semiglobal (practical) stability. Our robust observer tool, Lemma 2.4, will provide the technical result for showing this can be done.

Although different from the technicalities of the proof, the intuition behind our analysis follows from considering the closed-loop behavior as having two phases. During the first phase while we are trying to find, in finite time, an exact estimate of the derivatives of y, we acknowledge that this dynamically extended, estimated state feedback makes no sense. Still we must make sure that there is no finite escape time. To solve this problem, we use the a priori information that the actual control $\bar{u}(z)$ is in a known compact set to disregard any estimation $\widehat{\bar{u}(z)}$ which would lie outside this set. Mathematically there are many ways to reject these bad estimates but a very simple and efficient way is to saturate the estimated control as proposed in [11]. Then, using the worst saturated control, we can estimate the smallest time period T which will be needed by the system to go from its initial compact set to some larger compact set on which our estimated state semiglobally stabilizing feedback is valid. This time period is the period within which we should get our exact estimate of the derivatives of y. (See [18, Rem. 5].)

In phase two, if the estimates of the derivatives of y were correct, we could apply our dynamically extended state feedback. Unfortunately we are not always able to get an exact estimate of the derivatives of y. This is due to the possible presence of unobserved states and possible uncertainty in A. However, we can obtain an arbitrarily good approximate estimate. If we have designed our (dynamic) state feedback control using Lyapunov methods we have a measure of the stability robustness achieved by our feedback controller via the derivative of the Lyapunov function. We consequently build our approximate observer to account for this robustness margin. This strategy in fact has been exactly applied in [13] but in discrete time. There, no finite escape time is possible and exact estimation in finite time is assumed.

Finally note that Theorems 1.1 and 1.2 as well as the other results on semiglobal stabilization to come are presented here only as existence results. Nevertheless, the practical significance of the dynamic output feedback we shall exhibit has been investigated in the context of robotics applications in [1] and [2].

The remainder of the paper is organized as follows. In §2 we present tools for semiglobal practical stabilization by state and output feedback. Several applications of these tools are presented including, in §3, the proof of Theorem 1.2 and generalizations. In §4 we present a small gain theorem for local asymptotic stability analysis. This tool along with the tools of §2 are used, in §5, to prove Theorem 1.1 and generalizations. In §6 several corollaries for minimum phase input–output linearizable nonlinear systems are presented. A nonminimum phase example is also discussed.

2. Tools for semiglobal practical stabilization.

As exhibited by the statement of our two theorems, we have found it is very useful to decouple the local convergence analysis in robust semiglobal stabilization problems from the analysis regarding the boundedness of solutions. In this section we are concerned only with the problem of uniform semiglobal practical stabilization by partial state and output feedback. We defer study of local convergence until §4. We will present tools that will be used to construct an output feedback for proving Theorem 1.2. However, these tools have their own interest. As illustrated by examples throughout this section, they can be used to address a wide variety of control problems.

These tools provide conditions under which solutions starting in some compact set are captured by a "smaller" one. They consider systems with an interconnection structure and a state decomposed, accordingly, into two parts, say (z, x), where the $\dot{x}$ equation contains a large gain, say K. The effect of this large gain K is to introduce an exponential dichotomy between the x component and the z component. This implies the existence of a center-stable manifold which can be described by $x = H(z, K)$. It follows that the motion of the solutions can be decomposed into two stages: *convergence* to this manifold and *sliding* along this manifold. This decomposition has been a standard tool used to prove early semiglobal stabilization results (see [36] and [7] for example). Here instead, like in [4], we completely ignore this decomposition and use a Lyapunov argument showing the decrease of an energy function outside a neighborhood of the origin. More precisely what is implicitly used here is the fact that as $K \to \infty$, the manifold tends to the set $\{(z, x) : x = 0\}$. So a Lyapunov function, which is simply the sum of the energy functions of x and z separately, should be sufficient and indeed it is. The availability of a Lyapunov function is extremely useful. It makes explicit the ultimate bound on trajectories as well as the domain of attraction without the formalism of invariant manifolds. It will also allow us to use our tools consecutively.

We will present two closely related "backstepping" tools, to borrow the terminology of [17]. This will be followed by an observer tool useful for analysis when the parameter K comes from a high gain observer. These tools are based on the following technical lemma, inspired by a similar result in [4].

LEMMA 2.1. *Let S be a compact set in a product space $\mathbb{R}^m \times \mathbb{R}^n$, and denote by S_z and S_x its respective projections (i.e., $S \subset S_z \times S_x$). Let $\chi(z)$ be a continuous real function on S_z which is positive definite on the projection of the set $\{(z, x) : x = 0\} \cap S$. Let $\psi(x)$ be a continuous real function on S_x which is positive definite on $S_x \backslash \{0\}$. Let $\varphi(z, x, d)$ be a continuous real function on $S \times D$ which satisfies*

$$\varphi(z, x, d) = 0 \qquad \forall (z, x, d) \in (\{(z, x) : x = 0\} \cap S) \times D. \tag{8}$$

Let κ be a function of class-K_∞. Under these conditions, there exists a positive real number K_* such that, for all $K \geq K_*$,

$$-\chi(z) - \kappa(K)\psi(x) + \varphi(z, x, d) < 0 \qquad \forall (z, x, d) \in S \times D. \tag{9}$$

Proof. For purposes of contradiction, assume the result is false. This implies that, for each n, there exists a point (z_n, x_n, d_n) in $S \times D$ such that

$$-\chi(z_n) - \kappa(n)\psi(x_n) + \varphi(z_n, x_n, d_n) \geq 0. \tag{10}$$

Consequently, since κ is class-K_∞ and $\psi \geq 0$ we have, for each $m \geq 1$ and for all $n \geq m$,

$$-\chi(z_n) - \kappa(m)\psi(x_n) + \varphi(z_n, x_n, d_n) \geq 0. \tag{11}$$

Now, since $S \times D$ is compact, the (sub)sequence (z_n, x_n, d_n) converges to a point (z_*, x_*, d_*) in $S \times D$. By continuity, this point satisfies

$$-\chi(z_*) - \kappa(m)\psi(x_*) + \varphi(z_*, x_*, d_*) \geq 0 \tag{12}$$

for all $m \geq 1$. Then, if $x_* = 0$, (8), (12), and the properties of ψ imply $-\chi(z_*) \geq 0$ which is not possible since χ is strictly positive on the projection of the set $\{(z, x) :$

$x = 0\} \cap S$. On the other hand, if $|x_*| \neq 0$ then $\psi(x_*) > 0$ and there exists an $m_* \geq 1$ such that, for all $m \geq m_*$,

$$-\chi(z_*) - \kappa(m)\psi(x_*) + \varphi(z_*, x_*, d_*) < 0 \tag{13}$$

since $\kappa(\cdot)$ is of class-K_∞. This contradicts (12), however, and completes the proof. □

Throughout the remainder of this section we use the following assumption.

Assumption ULP (*uniform Lyapunov property*)[4]. For the system

$$\dot{z} = h(z, 0, d(t)), \tag{14}$$

there exists an open set $\mho_1$ in $\mathbb{R}^m$, a nonnegative real number $\vartheta < 1$, a real number $c \geq 1$, and a C^1 function $V : \mho_1 \to \mathbb{R}_{\geq 0}$ such that the set $\{z : V(z) \leq c + 1\}$ is a compact subset of $\mho_1$, and we have

$$\dot{V}_{(14)} \leq -\Phi_1(z), \tag{15}$$

where $\Phi_1(z)$ is continuous on $\mho_1$ and positive definite on the set $\{z : \vartheta < V(z) \leq c+1\}$.

Remark 2.1. In the absence of $d(t)$, if the equilibrium $z = 0$ of the system

$$\dot{z} = h(z, 0) \tag{16}$$

is locally asymptotically stable with domain of attraction $\mho_1$, the converse Lyapunov theorem [22, Thm. 7] provides a smooth Lyapunov function satisfying Assumption ULP. Further, ϑ can be chosen to be equal to zero and c can be chosen to be arbitrarily large.

We now present our backstepping tools. The first lemma shows how one can semiglobally practically stabilize from a disturbed first derivative of the control instead of the control itself. The second lemma allows, in one step, the designer to semiglobally practically stabilize from a jth disturbed derivative of the control when the perturbations have a special form.

LEMMA 2.2 (semiglobal backstepping I). *Consider the C^1 nonlinear control system*

$$\left\{ \begin{array}{rcl} \dot{z} &=& h(z, x, d(t)), \\ \dot{x} &=& f(z, x, d(t)) + g(z, x, d(t))u, \end{array} \right. \tag{17}$$

where $x \in \mathbb{R}$, $z \in \mathbb{R}^m$, the sign of $g(z, x, d)$ is constant, and the magnitude of g is bounded away from zero by a strictly positive real number b

$$|g(z, x, d)| \geq b \qquad \forall (z, x, d) \in \mathbb{R}^m \times \mathbb{R} \times D. \tag{18}$$

Suppose Assumption ULP is satisfied. Given $\mu \geq 1$, we define the function

$$W(z, x) = c\frac{V(z)}{c + 1 - V(z)} + \mu\frac{x^2}{\mu + 1 - x^2} \tag{19}$$

and the set

$$\mho_2 = \{z : V(z) < c + 1\} \times \{x : x^2 < \mu + 1\}. \tag{20}$$

[4] The number "1," here and in the following, is arbitrary and could be replaced by any strictly positive real number.

Under these conditions, $W(z,x) : \mho_2 \to \mathbb{R}_{\geq 0}$ is proper on $\mho_2$. Further, if

$$u = -K\mathrm{sgn}(g)x \tag{21}$$

then, for each strictly positive real number ρ, there exists a positive real number K_*, such that, for each $K \geq K_*$, W satisfies

$$\dot{W}_{(17)} \leq -\Phi_2(z,x), \tag{22}$$

where $\Phi_2(z,x)$ is continuous on $\mho_2$ and positive definite on the set $\{(z,x) : \vartheta + \rho \leq W(z,x) \leq c^2 + \mu^2 + 1\}$.

Proof of Lemma 2.2. With $u = -K\mathrm{sgn}(g)x$ the closed loop system is

$$\left\{ \begin{array}{rcl} \dot{z} & = & h(z,x,d(t)), \\ \dot{x} & = & f(z,x,d(t)) - K\mathrm{sgn}(g)g(z,x,d(t))x. \end{array} \right. \tag{23}$$

For sake of generality we replace x^2 in (19) by $U(x)$. Now assume $W(z,x) \leq c^2+\mu^2+1$. This implies

$$V(z) \leq (c+1)\frac{c^2+\mu^2+1}{c^2+\mu^2+1+c}, \qquad U(x) \leq (\mu+1)\frac{c^2+\mu^2+1}{c^2+\mu^2+1+\mu} . \tag{24}$$

Now, we have

$$\dot{W}_{(23)} = \frac{c(c+1)}{(c+1-V)^2}\dot{V}_{(23)} + \frac{\mu(\mu+1)}{(\mu+1-U)^2}\dot{U}_{(23)}. \tag{25}$$

From (24), we get, when $W(z,x) \leq c^2 + \mu^2 + 1$,

$$\begin{array}{c} \frac{c}{c+1} \leq \frac{c(c+1)}{(c+1-V)^2} \leq \frac{(c^2+\mu^2+1+c)^2}{c(c+1)}, \\ \frac{\mu}{\mu+1} \leq \frac{\mu(\mu+1)}{(\mu+1-U)^2} \leq \frac{(c^2+\mu^2+1+\mu)^2}{\mu(\mu+1)}. \end{array} \tag{26}$$

Then, let us define

$$\left\{ \begin{array}{rcl} \chi(z) & = & \frac{c(c+1)}{2(c+1-V(z))^2}\Phi_1(z), \\ \psi(x) & = & \frac{\mu}{\mu+1}bx^2, \\ \varphi(z,x,d) & = & \frac{(c^2+\mu^2+1+c)^2}{c(c+1)} \left|\frac{\partial V}{\partial z}(z)[h(z,x,d) - h(z,0,d)]\right| \\ & & + \frac{(c^2+\mu^2+1+\mu)^2}{\mu(\mu+1)} 2\left|xf(z,x,d)\right|, \\ \kappa(K) & = & K, \end{array} \right. \tag{27}$$

and consider the left-hand side of (9) in Lemma 2.1. We pick an arbitrarily small but strictly positive real number ρ and define a set S by

$$S = \{(z,x) : \vartheta + \rho \leq W(z,x) \leq c^2 + \mu^2 + 1\}. \tag{28}$$

The set S is compact from (24) and Assumption ULP. Also, from (24) the projections of S satisfy

$$S_z \subset \{z : V(z) < c+1\}, \qquad S_x \subset \{x : x^2 < \mu + 1\}. \tag{29}$$

Consequently $\chi(z)$ is continuous on S_z and $\psi(x)$ is continuous on S_x and positive definite on $S_x \backslash \{0\}$. Further, (24) also implies that $\varphi(z,x,d)$ is continuous on $S \times D$. From (27), it follows that

$$\varphi(z,x,d) = 0 \qquad \forall (z,x,d) \in (\{(z,x) : x = 0\} \cap S) \times D. \tag{30}$$

Finally, to see that $\chi(z)$ is positive definite on the projection of the set $\{(z,x) : x = 0\} \cap S$, we note

$$\{x = 0\ ,\ \vartheta + \rho \le W(z,x)\} \quad \Longrightarrow \quad \vartheta + \rho \le c\frac{V(z)}{c+1-V(z)}. \tag{31}$$

Further, for $0 \le \vartheta \le 1$,

$$\vartheta + \rho \le c\frac{V(z)}{c+1-V(z)} \quad \Longrightarrow \quad \vartheta < V(z) \qquad \forall \rho > 0. \tag{32}$$

Then, from Assumption ULP, $\chi(z)$ is positive definite on the projection of the set $\{(z,x) : x = 0\} \cap S$. This demonstrates that the conditions of Lemma 2.1 are satisfied. It follows that there exists a positive real number K_* such that, for all $K \ge K_*$, (22) is satisfied with

$$\Phi_2(z,x) = \frac{c(c+1)}{2(c+1-V)^2}\Phi_1(z) + \frac{\mu}{\mu+1}Kbx^2. \tag{33}$$

Also, since φ is positive, it follows, from (27) and (9), that this function Φ_2 is positive definite on $\{(z,x) : \vartheta + \rho \le W(z,x) \le c^2 + \mu^2 + 1\}$ for all $K \ge K_*$. □

Example 2.1. The first application of Lemma 2.2 is a result for the C^1 control system:

$$\left\{ \begin{array}{rcl} \dot z &=& A(z,\zeta), \\ \dot \zeta &=& F(z,\zeta,d(t)) + G(z,\zeta,d(t))u, \end{array} \right. \tag{34}$$

$z \in \mathbb{R}^m$, $\zeta \in \mathbb{R}$, where the sign of $G(z,\zeta,d(t))$ is constant and the magnitude of G is bounded away from zero. Specifically, *if the equilibrium point $z = 0$ is semiglobally stabilizable by C^ℓ ($\ell \ge 2$) state feedback, with ζ as control, then $(z,\zeta) = (0,0)$ is semiglobally practically stabilizable by C^ℓ state feedback.*

This statement is to be added to the many results known on the stabilization via a disturbed derivative of the input ([6], [9], [12], [44]). Its proof follows.

Let $\bar u(z)$ represent the control law we get once the compact set $\mathcal{K}_{zl}$ of the semiglobal stabilizability property for the z subsystem is chosen. Define $x = \zeta - \bar u(z)$. Then we have

$$\left\{ \begin{array}{rcl} \dot z &=& A(z,\bar u(z) + x) \\ &\doteq& h(z,x) \\ \dot x &=& F(z,x+\bar u(z),d(t)) + G(z,x+\bar u(z),d(t))u - \frac{\partial \bar u}{\partial z}(z)A(z,\bar u(z)+x) \\ &\doteq& f(z,x,d(t)) + g(z,x,d(t))u. \end{array} \right. \tag{35}$$

From [22, Thm. 7], Assumption ULP is satisfied with $\vartheta = 0$ and a positive definite function V such that $\mathcal{K}_{zl}$ is contained in the set $\{z : V(z) \le c\}$ for some real number $c \ge 1$.

With $\mathcal{K}_{\zeta l} \subset \mathbb{R}$, a chosen compact set, we choose μ to satisfy

$$\mu \ge \max\left\{1\ ,\ \max_{\{z\in\mathcal{K}_{zl},\zeta\in\mathcal{K}_{\zeta l}\}}\{\zeta - \bar u(z)\}\right\}\ . \tag{36}$$

Similarly, let $\mathcal{K}_s$, a neighborhood of $(0,0)$, be the compact set we want the solutions of the closed-loop system to be captured by. We choose ρ to satisfy

$$0 < \rho \le \min\left\{1\,,\,\frac{1}{2}\inf_{(z,\zeta)\notin\mathcal{K}_s}\left\{\max\{V(z),(\zeta-\bar{u}(z))^2\}\right\}\right\}\ . \tag{37}$$

With these choices, the function $W(z,x)$ defined in (19) satisfies

$$W(z,\zeta-\bar{u}(z)) \le \rho \implies V(z) < 2\rho\ ,\ (\zeta-\bar{u}(z))^2 < 2\rho\ , \tag{38}$$

$$\implies (z,\zeta)\in\mathcal{K}_s\ . \tag{39}$$

Now, from Lemma 2.2, if u is chosen to be of the form

$$u = -K\mathrm{sgn}(g)x = -K\mathrm{sgn}(G)[\zeta-\bar{u}(z)], \tag{40}$$

then there exists a positive real number K_* such that, for each $K \ge K_*$, (22) holds with $\Phi_2(z,x)$ positive definite on the set $\{(z,x) : \rho \le W(z,x) \le c^2+\mu^2+1\}$. We conclude that, for each initial condition $(z(0),\zeta(0))$ in $\mathcal{K}_{zl}\times\mathcal{K}_{\zeta l}$, the corresponding solution of (34), (40) is captured by the set $\{(z,\zeta) : W(z,\zeta-\bar{u}(z)) \le \rho\}$ and therefore by $\mathcal{K}_s$. Since this holds for any compact sets $\mathcal{K}_{zl}$, $\mathcal{K}_{\zeta l}$, and $\mathcal{K}_s$, the semiglobal practical stabilizability result follows.

Now, if $y = C(z)$ is an output function, the discussion above and the very special structure of (40) yields the following result.

If the equilibrium point $z = 0$ is semiglobally stabilizable by C^ℓ ($\ell \ge 2$) and UCO state feedback, with ζ as control, and ζ is UCO, then the point $(z,\zeta) = (0,0)$ is semiglobally practically stabilizable by C^ℓ and UCO state feedback.

Example 2.2 (almost disturbance decoupling). A solution to the almost disturbance decoupling problem as described in [25] can be obtained by repeated application of Lemma 2.2 for systems that can be put in the following form:

$$\left\{\begin{array}{rcl} \dot{z} & = & h(z,x_1),\\ \dot{x}_1 & = & x_2+f_1(z,x_1,d(t)),\\ \dot{x}_2 & = & x_3+f_2(z,x_1,x_2,d(t)),\\ & \vdots & \\ \dot{x}_{r-1} & = & x_r+f_{r-1}(z,x_1,\dots,x_{r-1},d(t)),\\ \dot{x}_r & = & f_r(z,x_1,\dots,x_r,d(t))+g(z,x_1,\dots,x_r,d(t))u, \end{array}\right. \tag{41}$$

where the equilibrium point $z = 0$ of $\dot{z} = h(z,0)$ is globally asymptotically stable and where the sign of g is constant and the magnitude of g is bounded away from zero. This is illustrated by the following example (compare with (7)):

$$\left\{\begin{array}{rcl} \dot{x}_1 & = & x_2+d_1(t),\\ \dot{x}_2 & = & x_2^3d_2(t)+d_3(t)+u,\\ y & = & x_1, \end{array}\right. \tag{42}$$

where $d_1(t), d_2(t), d_3(t)$ are unknown bounded disturbances. The problem is to achieve $|x_1(t)| \le \wp \le 1$ asymptotically from arbitrarily large domains of attraction. Without loss of generality we assume $|d_i(t)| \le 1$.

Assume the initial conditions satisfy $|x_i(0)|^2 \le c$. We first consider the intermediate subsystem

$$\dot{x}_1 = u_1 + d_1(t). \tag{43}$$

If we choose the control $u_1 = -K_1 x_1$, and the Lyapunov function candidate $W_1(x_1) = x_1^2$, then for the intermediate closed-loop system

$$\dot{x}_1 = -K_1 x_1 + d_1(t) \tag{44}$$

we have

$$\dot{W}_{1_{(44)}} \leq -2x_1[K_1 x_1 - d], \tag{45}$$

which is negative definite on the set $\{x : \frac{1}{(K_1-1)^2} \leq W_1(x_1)\} \times \{|d| \leq 1\}$. We then choose

$$K_1 = 1 + \frac{2}{\wp} \tag{46}$$

so that $\dot{W}_{1_{(44)}}$ is negative definite on the set $\{x : \frac{\wp^2}{4} \leq W_1(x_1)\} \times \{|d| \leq 1\}$. We now make the coordinate change $\zeta = x_2 + K_1 x_1$ to get the system

$$\left\{ \begin{array}{rcl} \dot{x}_1 & = & -K_1 x_1 + \zeta + d_1(t), \\ \dot{\zeta} & = & u + (\zeta - K_1 x_1)^3 d_2(t) + K_1(\zeta - K_1 x_1 + d_1(t)) + d_3(t). \end{array} \right. \tag{47}$$

By applying Lemma 2.2 with $\vartheta = \rho = \frac{\wp^2}{4}$, we get the final control

$$u = -K_2 \zeta = -K_2 x_2 - K_2 K_1 x_1 \tag{48}$$

and a Lyapunov function candidate

$$W_2(x_1, \zeta) = \frac{\mu_1 W_1(x_1)}{\mu_1 + 1 - W_1(x_1)} + \frac{\mu_2 \zeta^2}{\mu_2 + 1 - \zeta^2}, \tag{49}$$

where $\mu_1 = c$ and μ_2 is so that the initial value of ζ satisfies $\zeta^2 \leq \mu_2$, i.e., $\mu_2 = (1 + K_1)^2 c$. We then have that the initial condition satisfies $W_2(x_1, \zeta) \leq \mu_1^2 + \mu_2^2$. Also, we know that, for K_2 large enough (see [41] for an explicit expression), the time derivative of W_2 is negative definite on the compact set

$$\Gamma_2 = \left\{ (x_1, \zeta) : \frac{\wp^2}{2} \leq W_2(x_1, \zeta) \leq \mu_1^2 + \mu_2^2 + 1 \right\}. \tag{50}$$

Therefore, the solutions, with $|x_i(0)|^2 \leq c$, are captured by the set $\{(x_1, \zeta) : W_2(x_1, \zeta) \leq \frac{\wp^2}{2}\}$, contained in the set $\{(x_1, \zeta) : |x_1| \leq \wp\}$.

It is important to note that, with our controller (48), we do not have the vanishing regions of attraction phenomenon as described in [21] and [25]. Indeed, in these papers, the same type of high gain controller is proposed but with the implicit constraint that $K_2 = K_1$. Here, instead, our iterative design leads to gains such that the ratio K_2/K_1 tends to infinity as K_1 tends to $+\infty$. However, although x_1 and ζ can be made ultimately arbitrarily small, x_2, called the peaking component, remains of unity magnitude as long as d_1 is present. For a discussion of the peaking phenomenon in feedback systems, see [36] and the references therein.

Finally, we remark that, if $\dot{d}_1(t)$ has a known bound (see our notation section), by applying our forthcoming robust observer tool, Lemma 2.4, the almost disturbance decoupling problem for the system (42) can be solved semiglobally by output feedback. (See [41].)

It is possible to handle a block of integrators in one step, instead of iterating the application of Lemma 2.2, when the system has the structure described in the following lemma.

LEMMA 2.3 (semiglobal backstepping II). *Consider the C^1 nonlinear control system*

$$(51)\qquad \left\{\begin{array}{rcl} \dot z &=& h(z,x_1,d(t)),\\ \dot x_1 &=& x_2+f_1(z,x_1,d(t)),\\ \dot x_2 &=& x_3+f_2(z,x_1,d(t)),\\ &\vdots& \\ \dot x_{j-1} &=& x_j+f_{j-1}(z,x_1,d(t)),\\ \dot x_j &=& u+f_j(z,x_1,d(t)), \end{array}\right.$$

where $x=(x_1,\dots,x_j)^T\in\mathbb{R}^j$, $z\in\mathbb{R}^m$. Suppose Assumption ULP is satisfied. Let the polynomial

$$(52)\qquad p(s)=s^j+a_js^{j-1}+\cdots+a_1$$

be Hurwitz and let A_c be the companion form matrix corresponding to $p(s)$. Also let P_c solve the matrix equation $A_c^TP_c+P_cA_c=-I$. For $K\geq 1$ to be specified, define the variables

$$(53)\qquad \xi_i=\frac{x_i}{K^{i-1}},\qquad i=1,\dots,j.$$

Then given $\mu\geq 1$, define the function

$$(54)\qquad W(z,\xi)=c\frac{V}{c+1-V}+\mu\frac{\xi^TP_c\xi}{\mu+1-\xi^TP_c\xi}$$

and the set

$$(55)\qquad \mho_2=\{z:V(z)<c+1\}\times\{\xi:\xi^TP_c\xi<\mu+1\}.$$

Under these conditions, $W(z,\xi):\mho_2\to\mathbb{R}_{\geq 0}$ is proper on $\mho_2$. Also, if

$$(56)\qquad u=-K^j(a_1\xi_1+\cdots+a_j\xi_j)\ ,$$

then, for each strictly positive real number ρ, there exists a positive real number $K_*\geq 1$ such that, for all $K\geq K_*$, W satisfies

$$(57)\qquad \dot W_{(17)}\leq-\Phi_2(z,\xi),$$

where $\Phi_2(z,\xi)$ is continuous on $\mho_2$ and positive definite on the set $\{(z,\xi):\vartheta+\rho\leq W(z,\xi)\leq c^2+\mu^2+1\}$.

Proof of Lemma 2.3. With the control (56) and the coordinates ξ defined in (53), the closed-loop system becomes

$$(58)\qquad \left\{\begin{array}{rcl} \dot z &=& h(z,\xi_1,d(t)),\\ \dot\xi &=& KA_c\xi+F_K(z,\xi_1,d(t)), \end{array}\right.$$

where

$$(59)\qquad F_K(z,\xi_1,d)=\begin{pmatrix} f_1(z,\xi_1,d)\\ \frac{1}{K}f_2(z,\xi_1,d)\\ \vdots\\ \frac{1}{K^{j-1}}f_j(z,\xi_1,d) \end{pmatrix}.$$

From here, if we replace $\xi^T P_c \xi$ in (54) by $U(\xi)$, then we can follow the proof of Lemma 2.2 with the only modifications being that, in (27) and (33), x^2 is replaced by $\frac{1}{2}\xi^T\xi$, xf by $\xi^T P_c F_K$, and $b = 1$. The fact that $F_K(z, \xi_1, d)$ depends on K is immaterial because, for $K \geq 1$, $\xi^T P_c F_K$ can be bounded by a continuous function which is independent of K. □

Remark 2.2. Lemma 2.3 is used in the same manner as Lemma 2.2 in Example 2.1. One difference is that the free parameter μ is chosen so that the initial conditions of x satisfy $\xi^T P_c \xi \leq \mu$ with ξ defined as in (53). The parameter μ thus appears to depend on K. However, for $K \geq 1$, we have

$$x^T P_c x \leq \mu \qquad \Longrightarrow \qquad \xi^T P_c \xi \leq \mu \frac{\lambda_{\max}\{P_c\}}{\lambda_{\min}\{P_c\}}, \tag{60}$$

where the left-hand side can be achieved independent of K. Nevertheless, the inequality (57) will not guarantee that x ultimately becomes small but only that (z, ξ) ultimately becomes small. As mentioned in Example 2.2, the coordinates x are called peaking coordinates.

Example 2.3 (observer canonical form). We have used Lemma 2.3 as a tool in [42] to design a semiglobally stabilizing output feedback for the following class of systems:

$$\left\{\begin{array}{rcl} \dot{z} & = & h(z, x_1), \\ \dot{x}_1 & = & x_2 + f_1(z, x_1), \\ & \vdots & \\ \dot{x}_r & = & u + f_r(z, x_1), \\ y & = & x_1 \end{array}\right. \tag{61}$$

under a global minimum phase assumption (the point $z = 0$ of the system $\dot{z} = h(z, 0)$ is globally asymptotically stable) and a small gain-based assumption which guarantees local convergence. Here, h and f_i are C^1 and u in $\mathbb{R}$. The special form of (61) permits a technique for output feedback stabilization different from the one mentioned at the end of §1 and used in the proof of Theorem 1.2. Here, on the contrary, we design the observer first, then we define the controller in such a way that the stability it provides is robust to the estimation errors. Our algorithm is inspired by the global results in [17], [26], [27], and [29]. We begin by building the dynamic compensator

$$\left\{\begin{array}{rcl} \dot{\hat{x}}_1 & = & \hat{x}_2 + \ell_1(x_1 - \hat{x}_1), \\ & \vdots & \\ \dot{\hat{x}}_r & = & u + \ell_r(x_1 - \hat{x}_1), \end{array}\right. \tag{62}$$

where the coefficients ℓ_i are the coefficients of a Hurwitz polynomial. If we define $e_i = x_i - \hat{x}_i$ we get the error dynamics

$$\dot{e} = A_o e + F(z, x_1). \tag{63}$$

We choose to consider the dynamics

$$\dot{e} = A_o e + F(z, 0) \tag{64}$$

as an augmentation of the zero dynamics $\dot{z} = h(z, 0)$ so that the equilibrium point $(z, e) = (0, 0)$ of the augmented system

$$\left\{\begin{array}{rcl} \dot{z} & = & h(z, 0), \\ \dot{e} & = & A_o e + F(z, 0) \end{array}\right. \tag{65}$$

is globally asymptotically stable. This follows from the cascade structure and that the state e is input-to-state stable with respect to the input z. (See [35] or Lemma 4.1.) Now we consider the complete system

$$(66)\qquad \left\{\begin{array}{rcl} \dot{z} &=& h(z,x_1), \\ \dot{e} &=& A_o e + F(z,x_1), \\ \hline \dot{x}_1 &=& \hat{x}_2 + e_2 + f_1(z,x_1), \\ \dot{\hat{x}}_2 &=& \hat{x}_3 + \ell_2 e_1, \\ &\vdots& \\ \dot{\hat{x}}_r &=& u + \ell_r e_1. \end{array}\right.$$

It is in the form (51), and we can apply Lemma 2.3 to construct a controller depending only on $x_1, \hat{x}_2, \ldots, \hat{x}_r$ and achieving bounded trajectories from a given compact set of initial conditions. Local exponential stability of the point $z = 0$ of the system $\dot{z} = h(z,0)$ is a sufficient condition to guarantee convergence to the equilibrium $(z, e, x_1, \hat{x}_2, \ldots, \hat{x}_r) = (0, \ldots, 0)$. This condition can be relaxed by using the tools of §4.

When the output feedback stabilization problem is approached from the point of view discussed in §1, a linear high gain observer is introduced to get approximations of the derivatives of the output. The high gain parameter is tuned according to size of the compact set of initial conditions and the stability robustness that would be achieved by the state feedback controller. However, the linear high gain observer introduces possibly very large values of the state estimate over a short period of time. As already noted, this means that during this short period of time, the state estimate makes no sense and should be disregarded. This was achieved in [11] by saturating the control when the estimates had a value which was known a priori to be unreachable within this period of time by the actual state. The success of this modification was demonstrated by using a singular perturbation approach. However, the result seemed to require a form of nonlocal exponential stability [11, Assump. 2]. Even the more general interconnection conditions of [30] on which this assumption is based are too restrictive for the problem of boundedness (only) of solutions from compact sets. These assumptions mix the local and nonlocal analysis while weaker assumptions can be imposed if these aspects are handled separately. The next lemma demonstrates this.

LEMMA 2.4 (robust observer [11]). *Consider the C^1 nonlinear system*

$$(67)\qquad \left\{\begin{array}{rcl} \dot{z} &=& h(z,e,d(t)), \\ \dot{e} &=& LA_o e + p(z,e,d(t)), \end{array}\right.$$

where $z \in \mathbb{R}^m$, $e \in \mathbb{R}^n$, and L is a strictly positive real number. Suppose Assumption ULP is satisfied and let

$$(68)\qquad \Gamma = \{z : V(z) \leq c+1\} \ .$$

Also assume the matrix A_o is Hurwitz and there exist positive real numbers ν_1 and ν_2 and a bounded continuous function γ with $\gamma(0) = 0$ satisfying

$$(69)\qquad \left.\begin{array}{rcl} |h(z,e,d) - h(z,0,d)| &\leq& \gamma(|e|) \\ |p(z,e,d)| &\leq& \nu_1 + \nu_2|e| \end{array}\right\} \quad \forall (z,e,d) \in \Gamma \times \mathbb{R}^n \times D.$$

Let $\mu(L)$ be a class-K_∞ function satisfying

$$\liminf_{L\to\infty} \frac{L}{\mu^4(L)} \to \infty \ . \tag{70}$$

Let P_o solve the matrix equation $A_o^T P_o + P_o A_o = -I$ and, finally, define the function

$$W(z,e) = c\frac{V(z)}{c+1-V(z)} + \mu(L)\frac{\ln(1+e^T P_o e)}{\mu(L)+1-\ln(1+e^T P_o e)} \tag{71}$$

and the set

$$\mho_2 = \{z : V(z) < c+1\} \times \{e : \ln(1+e^T P_o e) < \mu(L)+1\} \ . \tag{72}$$

Under these conditions, for each strictly positive real number L, the function $W(z,e) : \mho_2 \to \mathbb{R}_{\geq 0}$ is proper on $\mho_2$. Also, for each strictly positive real number ρ, there exists a positive real number L_* such that, for all $L \geq L_*$, W satisfies

$$\dot{W}_{(67)} \leq -\Phi_2(z,e), \tag{73}$$

where $\Phi_2(z,e)$ is continuous on $\mho_2$ and positive definite on the set $\{(z,e) : \vartheta + \rho \leq W(z,e) \leq c^2 + \mu^2(L) + 1\}$.

Remark 2.3. The motivation for allowing μ to depend on L, in contrast to the previous two lemmas, is to allow the initial conditions of e to possibly depend on L. If the initial conditions of e can be bounded independent of L, then

1. the bounds in (69) are not needed,
2. μ can be chosen independent of L and the function $\ln(1+e^T P_o e)$ in (71) can be replaced by $e^T P_o e$.

Examples 2.4 and 2.5 demonstrate situations where the initial condition of the observation error can be bounded independent of L.

The motivation for the choice of the function ln is that for our problem, as will be seen later in the proof of Theorem 1.2, we wish to allow initial conditions of e to be of order L^{n_y}. This requires that we choose a Lyapunov function $U(e)$ and a function $\mu(L)$ satisfying the limit (70) and such that, given a strictly positive real number λ_1, we have

$$|e| \leq \lambda_1 L^{n_y} \quad \Longrightarrow \quad U(e) \leq \mu(L) \ . \tag{74}$$

For instance, if we choose $\mu(L) = \ln(1 + \lambda_2 L^{2(n_y)})$, with λ_2 any strictly positive real number, then the limit (70) is satisfied since we have

$$\lim_{s\to\infty} \frac{s}{\ln(1+\lambda_2 s^{\alpha_1})^{\alpha_2}} = \infty \qquad \forall \lambda_2, \alpha_1, \alpha_2 > 0 \ . \tag{75}$$

Then, with the appropriate choice of λ_2, (74) is satisfied if we choose $U(e) = \ln(1 + e^T P_o e)$. The choice of ln in turn requires the special form of the bounds imposed in (69).

With this remark, we see that if we disregard the issue of ultimate convergence, we recover the result of [11, Thm. 2].

Proof of Lemma 2.4. We follow the lines of the proof of Lemma 2.2. We begin by replacing $\ln(1+e^T P_o e)$ in (71) by $U(e)$. Assume that $W(z,e) \leq c^2 + \mu^2(L) + 1$. From

(24) and the definition of Γ in (68), this implies, for any L, that z is in Γ. Hence from Assumption ULP and the bounds in (69) we can write

(76)

$$\left.\begin{array}{lcl} \dot{V}_{(67)} & \leq & -\Phi_1(z) + \nu_3\gamma(|e|) \\ \dot{U}_{(67)} & \leq & \frac{1}{1+e^T P_o e}\left[-L|e|^2 + 2\lambda_{\max}\{P_o\}|e|\,(\nu_2|e| + \nu_1)\right] \end{array}\right\} \forall (z,e,d) \in \Gamma \times \mathbb{R}^n \times D,$$

where ν_3 is a positive real number which bounds $\frac{\partial V}{\partial z}$ on the set Γ. Such a bound exists because V is C^1 and Γ is compact. Then, from (71), (25), and (76) we can write

$$\begin{aligned} \dot{W}_{(67)} \leq & \tfrac{c(c+1)}{(c+1-V)^2}\left\{-\Phi_1(z) + \nu_3\gamma(|e|)\right\} \\ & + \tfrac{\mu(\mu+1)}{(\mu+1-U)^2}\tfrac{1}{1+e^T P_o e}\left[-L|e|^2 + 2\lambda_{\max}\{P_o\}|e|\,(\nu_2|e| + \nu_1)\right]. \end{aligned} \tag{77}$$

Now fix L_{*_1} so that $\mu^2(L_{*_1}) = c^2 + c + 1$. Such an L_{*_1} exists because $\mu(L)$ is of class-K_∞. Then, using the bounds from (24) and (26), using $c \geq 1$ from Assumption ULP, and choosing $L \geq L_{*_1}$ we have

$$\frac{1}{2} \leq \frac{c(c+1)}{(c+1-V)^2} \leq 2\mu^4. \tag{78}$$

Thus we can rewrite (77) as

$$\begin{aligned} \dot{W}_{(67)} \leq & \tfrac{c(c+1)}{(c+1-V)^2}\Big\{-\Phi_1(z) + \nu_3\gamma(|e|) \\ & + \frac{\mu(\mu+1)}{(\mu+1-U)^2}\frac{1}{1+e^T P_o e}\left[-\frac{L}{2\mu^4}|e|^2 + 4\lambda_{\max}\{P_o\}|e|(\nu_2|e| + \nu_1)\right]\Big\} \end{aligned} \tag{79}$$

Since $(c(c+1))/((c+1-V)^2)$ is positive and bounded away from zero on Γ, it suffices to consider the expression

(80)

$$-\Phi_1(z) + \nu_3\gamma(|e|) + \tfrac{\mu(L)(\mu(L)+1)}{(\mu(L)+1-U(e))^2}\tfrac{1}{1+e^T P_o e}\left[-\tfrac{L}{2\mu(L)^4}|e|^2 + 4\lambda_{\max}\{P_o\}|e|\,(\nu_2|e| + \nu_1)\right].$$

We are interested in evaluating this expression on the set

$$\Lambda_L \doteq \{(z,e) : \vartheta + \rho \leq W(z,e) \leq c^2 + \mu^2(L) + 1\}. \tag{81}$$

We do so by considering the two sets

$$\Lambda_1 \doteq \{(z,e) : V(z) \leq c+1\,,\ 1 < U(e) < \mu(L) + 1\}, \tag{82}$$

$$\begin{aligned} \Lambda_0 \doteq & \{(z,e) : V(z) \leq c+1\,,\ U(e) \leq 1\} \\ & \cap \left\{(z,e) : \vartheta + \rho \leq \frac{cV(z)}{c+1-V(z)} + U(e)\right\} \end{aligned} \tag{83}$$

and by observing that Λ_L is contained in $\Lambda_1 \cup \Lambda_0$, since we have

$$\{U(e) \leq 1\,,\ \vartheta + \rho \leq W(z,e)\} \implies \vartheta + \rho \leq \frac{cV(z)}{c+1-V(z)} + U(e)\,. \tag{84}$$

In the set Λ_1, observe that the limit (70) holds, z is contained in a compact set independent of L, the function $\gamma(|e|)$ is bounded, and $\frac{\mu(\mu+1)}{(\mu+1-U(e))^2}$ is bounded away from zero from (26). We do not use the upper bound on $\frac{\mu(\mu+1)}{(\mu+1-U(e))^2}$ from (26) which depends on L. Finally note that the function $\frac{|e|^2}{1+e^TP_oe}$ is positive and bounded away from 0 on Λ_1. Thus, by examination of expression (80), it follows that there exists a positive real number L_{*_2} such that, for each $L \geq L_{*_2}$, the function $\dot{W}_{(67)}$ can be upper bounded by a function of (z, e) which is negative definite on Λ_1.

In the set Λ_0, to check that $\dot{W}_{(67)}$ is negative for all $(z, e, d) \in \Lambda_0 \times D$, we apply Lemma 2.1 to the expression (80). We remark that, for $L \geq L_{*_1}$, we have

$$(85) \qquad \min_{0\leq U\leq 1}\left\{\frac{\mu(\mu+1)}{(\mu+1-U)^2}\right\} = \frac{\mu}{\mu+1}, \qquad \max_{0\leq U\leq 1}\left\{\frac{\mu(\mu+1)}{(\mu+1-U)^2}\right\} \leq 2.$$

It follows that to know the sign of the expression (80), we can look at (9) by taking

$$(86) \qquad \left\{\begin{array}{rcl} x &=& e\,, \\ K &=& L\,, \\ \chi(z) &=& \frac{1}{2}\Phi_1(z)\,, \\ \psi(e) &=& \frac{1}{2}\frac{e^Te}{1+e^TP_oe}\,, \\ \varphi(z,e) &=& \nu_3\gamma(|e|) + 8\lambda_{\max}\{P_o\}|e|\,(\nu_2|e|+\nu_1) \end{array}\right.$$

and $\kappa(\cdot)$ any class-K_∞ function satisfying

$$(87) \qquad \kappa(L) \leq \frac{L}{2\mu^3(L)(\mu(L)+1)}\,.$$

Such a function exists because $L/(2\mu^3(L)(\mu(L)+1)) > 0$ for $L > 0$ and (70) holds. The set S in Lemma 2.1 is given by Λ_0. It is independent of L and compact. The respective projections satisfy

$$(88) \qquad S_z \subset \{z : V(z) \leq c+1\} = \Gamma, \qquad S_e \subset \{e : U(e) \leq 1\}\,.$$

Then, from (86) and the properties of Φ_1, $\chi(z)$ is continuous on S_z and $\psi(e)$ is continuous on S_e. Clearly, $\psi(e)$ is positive definite on $S_e\backslash\{0\}$. Also, from the continuity of γ and the fact that $\gamma(0) = 0$, $\varphi(z, e)$ is continuous on S and

$$(89) \qquad \varphi(z,e) = 0 \qquad \forall (z,e) \in \{(z,e) : e = 0\} \cap S.$$

To see that $\chi(z)$ is positive definite on the projection of the set $\{(z, e) : e = 0\} \cap S$, we have, with $0 \leq \vartheta \leq 1$ and $\rho > 0$,

$$(90) \qquad \left\{e = 0\,,\ \vartheta + \rho \leq \frac{cV}{c+1-V} + U(e)\right\} \quad \Longrightarrow \quad \vartheta < V(z).$$

So from Assumption ULP, $\chi(z)$ is positive definite on the projection of the set $\{(z, e) : e = 0\} \cap S$. It follows that there exists a positive real number L_{*_3} such that, for each $L \geq L_{*_3}$, the expression (80) can be upper bounded on S by the function

$$-\tfrac{1}{2}\Phi_1(z) - \tfrac{1}{2}\kappa(L)\frac{e^Te}{1+e^TP_oe},$$

which is negative definite on Λ_0 since φ is positive. We then take $L_* = \max\{L_{*_1}, L_{*_2}, L_{*_3}\}$. □

Example 2.4 (mechanical systems). We consider the multi-input nonlinear system

$$\left\{\begin{array}{lcl} \dot{q} & = & r \\ \dot{r} & = & f(q,r) + g(q,r)u, \end{array}\right. \tag{91}$$

where $q \in \mathbb{R}^n$, $r \in \mathbb{R}^n$, $u \in \mathbb{R}^m$ is the input and f and g are C^1. This system could represent a robot model, for example. We assume the existence of a (dynamic) compensator

$$\left\{\begin{array}{lcl} \dot{v} & = & C(q,r,u), \\ u & = & \bar{u}(q,r,v), \end{array}\right. \tag{92}$$

with $v \in \mathbb{R}^l$ such that the closed-loop system

$$\left\{\begin{array}{lcl} \dot{q} & = & r, \\ \dot{r} & = & f(q,r) + g(q,r)\bar{u}(q,r,v), \\ \dot{v} & = & C(q,r,\bar{u}(q,r,v)), \end{array}\right. \tag{93}$$

which we rewrite, with $z = (q^T, r^T, v^T)^T$, as

$$\dot{z} = h(z,0) \ , \tag{94}$$

satisfies Assumption ULP for some neighborhood $\mathcal{U}_1$ and some function V, proper on $\mathcal{U}_1$, with $\vartheta = 0$ and c arbitrarily large. Assumption ULP is satisfied if, for example, the equilibrium $(q,r,v) = (0,0,0)$ is made (locally) asymptotically stable by the compensator (92). To implement the compensator (92) without measurement of r we build the observer

$$\left\{\begin{array}{lcl} \dot{\hat{q}} & = & \hat{r} + L\ell_1(q - \hat{q}), \\ \dot{\hat{r}} & = & L^2\ell_2(q - \hat{q}), \end{array}\right. \tag{95}$$

where L is an adjustable parameter and ℓ_1, ℓ_2 are coefficients of a Hurwitz polynomial. We implement the compensator

$$\left\{\begin{array}{lcl} \dot{v} & = & C(q,\Delta(\hat{r}),v,u), \\ u & = & \bar{u}(q,\Delta(\hat{r}),v), \end{array}\right. \tag{96}$$

where

$$\Delta(\hat{r}) = \hat{r}\min\left\{1, \frac{r_{\max}}{|\hat{r}|}\right\} \tag{97}$$

and $r_{\max}$ is the maximum value of $|r|$ on the set $\Gamma = \{(q,r,v) = z : V(z) \leq c+1\}$, where $V(z)$ and c come from Assumption ULP. This idea for the modification of the compensator is based on the idea in [11]. We choose to saturate the state $\hat{r}$ rather than the entire control u and compensator C because the state r has physical significance and thus determining $r_{\max}$ in the region of interest should be quite natural. Compare with equations (116) and (139) in the proof of Theorem 1.2. If we define the error state

$$e_q \doteq L(q - \hat{q}) \ , \quad e_r \doteq r - \hat{r}, \tag{98}$$

we have the error dynamics

$$\left\{\begin{array}{lcl} \dot{e}_q & = & Le_r - L\ell_1 e_q, \\ \dot{e}_r & = & -L\ell_2 e_q + f(q,r) + g(q,r)\bar{u}(q,\Delta(r - e_r),v) \end{array}\right. \tag{99}$$

and we can apply Lemma 2.4. The bounds in (69) can be readily checked and follow from the introduction of Δ in the compensator (96). Consequently, by choosing c large enough, the modified compensator (96) together with the observer (95) can be used to yield bounded trajectories from the compact set of initial conditions $\mathcal{K}_l \times \mathcal{K}_{(\hat{q},\hat{r})\,l} \subset \mathbb{R}^{2n+l} \times \mathbb{R}^{2n}$, where $\mathcal{K}_l$ is any compact subset of $\mathcal{U}_1$.

As pointed out in Remark 2.3, the bounds in (69) are required because the initial conditions of e grow with L. Specifically, $e_q = L(q-\hat{q})$. However, observe that it may be reasonable to initialize the value of $\hat{q}$ such that $\hat{q}(0) = q(0)$ since q is measured. In this case, the initial condition of e is $(e_q(0) = 0, e_r(0) = r(0) - \hat{r}(0))$ which is independent of L. As mentioned in Remark 2.3, in this case the bounds in (69), and hence the function Δ in (96), are not needed. Nevertheless, if this initialization cannot be done exactly, then the function Δ should be retained.

It would also be possible to build a reduced-order observer for this system. Consider the state $s = r - Lq$. We have

$$\dot{s} = f(q,r) + g(q,r)u - Lr \tag{100}$$

$$= f(q,r) + g(q,r)u - Ls - L^2 q. \tag{101}$$

If we build the observer

$$\left\{ \begin{array}{rcl} \dot{\hat{s}} & = & -L\hat{s} - L^2 q, \\ \hat{r} & = & \hat{s} + Lq, \end{array} \right. \tag{102}$$

then for the error $e_r = r - \hat{r}$, we have

$$\dot{e}_r = f(q,r) + g(q,r)u - Le_r. \tag{103}$$

If we don't specify the initial value of $\hat{s}$, then we choose the modified compensator in (96). If $\hat{s}(0)$ is chosen so that $\hat{s}(0) = -Lq(0)$ then $e_r(0) = r(0)$ and the function Δ is not needed. Let us also remark that the linear operator $q \mapsto \hat{r}$ defined by (102) is output strictly passive. This important property has been exploited in [5].

In all cases, if the original compensator (92) is locally exponentially stabilizing then the conditions of Lemma 4.1 will be satisfied and asymptotic stability is also achieved.

As mentioned earlier, the ideas presented here have been investigated further in [1] and [2].

Example 2.5 (the ball and beam). This example summarizes the result of [37]. Consider the ball-and-beam system

$$\left\{ \begin{array}{rcl} \dot{x}_1 & = & x_2, \\ \dot{x}_2 & = & -G\sin(x_3) + x_1 x_4^2, \\ \dot{x}_3 & = & x_4, \\ \dot{x}_4 & = & \frac{1}{Mx_1^2+J}[\tau - 2Mx_1x_2x_4 - MGx_1\cos(x_3)], \end{array} \right. \tag{104}$$

with three strictly positive real numbers G, M, and J, four state variables x_1 to x_4, and one control τ. See [14] for an interpretation of the state variables and a derivation of the dynamics. We wish to stabilize the system using measurement of x_1 and x_3 only. It can be shown that there exists a semiglobally stabilizing, and locally exponentially stabilizing, control $\bar{u}(x_1, x_2, x_3, x_4)$. See [39] for the case when M, J are known. For the case where M, J are unknown but have known bounds, the procedure is to use the results of [39] to get a result for the (x_1, x_2, x_3) subsystem and then apply Lemma 2.2

and Lemma 4.1 to get a result for the full system. See [37] for a complete discussion. From the results of [22, Thm. 7], Assumption ULP is satisfied with $\vartheta = 0$ for the closed-loop system with $\bar{u}(x_1, x_2, x_3, x_4)$ as the control. To implement this control, we build the observer

$$\left\{\begin{array}{lcl} \dot{\hat{x}}_1 & = & \hat{x}_2 + L\ell_1(x_1 - \hat{x}_1), \\ \dot{\hat{x}}_2 & = & -G\sin(x_3) + L^2\ell_2(x_1 - \hat{x}_1), \\ \dot{\hat{x}}_3 & = & \hat{x}_4 + L\ell_1(x_3 - \hat{x}_3), \\ \dot{\hat{x}}_4 & = & L^2\ell_2(x_3 - \hat{x}_3), \end{array}\right. \tag{105}$$

and we let

$$\tau = \bar{u}(x_1, \hat{x}_2, x_3, \Delta(\hat{x}_4)) \tag{106}$$

where Δ is defined as in Example 2.4. Note that Δ does not need to act on $\hat{x}_2$ because, coincidentally, $\bar{u}$ can be chosen so that the x_2 dependence is already bounded. Again we choose to saturate the state $\hat{x}_4$ instead of the entire control τ because the state x_4 has physical significance. If we define the observer error

$$e_1 = L(x_1 - \hat{x}_1)\ , \quad e_2 = x_2 - \hat{x}_2\ , \quad e_3 = L(x_3 - \hat{x}_3)\ , \quad e_4 = x_4 - \hat{x}_4\ , \tag{107}$$

we have the error dynamics

$$\left\{\begin{array}{lcl} \dot{e}_1 & = & Le_2 - L\ell_1 e_1, \\ \dot{e}_2 & = & -L\ell_2 e_1 + x_1 x_4^2, \\ \dot{e}_3 & = & Le_4 - L\ell_1 e_3, \\ \dot{e}_4 & = & -L\ell_2 e_3 + \frac{1}{Mx_1^2+J}[\tau - 2Mx_1x_2x_4 - MGx_1\cos(x_3)]. \end{array}\right. \tag{108}$$

The bounds in (69) are satisfied and we can achieve bounded solutions from any compact set of initial conditions $(x, \hat{x})$. Furthermore, since $\bar{u}$ is locally exponentially stabilizing, asymptotic stability is also achieved.

Note that, as for the system in Example 2.4, we could choose the initial conditions of $\hat{x}_1$ and $\hat{x}_3$ so that $e_1(0) = 0$ and $e_3(0) = 0$. This is possible because x_1 and x_3 are measured. This, in turn, would remove the need for introducing the function Δ in the control $\bar{u}$. Building a reduced-order observer is also possible.

3. A generalized version of Theorem 1.2.

3.1. Assumptions and results. The proof of Theorem 1.2 follows from an appropriate application of Lemmas 2.3 and 2.4. An even more general case can be considered. Indeed, let the control system be[5]

$$\left\{\begin{array}{lcl} \dot{z} & = & A(z, u, d(t)), \\ y & = & C(z, d(t)). \end{array}\right. \tag{109}$$

We assume only that the point $z = 0$ is semiglobally practically stabilizable by UCO static state feedback, as in the following assumption.

Assumption S-GPS. There exist two integers N_y and N_u so that, for each pair of compact sets $(\mathcal{K}_{zs}, \mathcal{K}_{zl})$, neighborhoods of 0 and with $\mathcal{K}_{zs} \subset \mathcal{K}_{zl}$, we can find

[5] May be augmented with the dynamics of a controller in the case of a dynamically stabilizable system.

1. a positive C^1 function V, zero at 0, which is defined on $\mho$, an open set containing $\mathcal{K}_{zl}$, and such that there exist three positive real numbers ϑ_l, c_s, and c_l satisfying

$$c_s < c_l, \qquad \{z : V(z) \leq \vartheta_l\} \subset \mathcal{K}_{zs}, \qquad \mathcal{K}_{zl} \subset \{z : V(z) \leq c_s\} \tag{110}$$

and so that the set $\{z : V(z) \leq c_l\}$ is compact and contained in $\mho$.

2. a C^2 function $\bar{u}(z)$ which is zero at 0, is defined on $\mho$, and is UCO (i.e. (115) holds) with $n_y \leq N_y$, $n_u \leq N_u$, such that, for the system

$$\dot{z} = A(z, \bar{u}(z), d(t)), \tag{111}$$

we have

$$\dot{V}_{(111)} \leq -\Phi(z), \tag{112}$$

where $\Phi(z)$ is continuous on $\mho$ and positive definite on $\{z : \vartheta_s \leq V(z) \leq c_l\}$ for some real number ϑ_s satisfying

$$0 < \vartheta_s < \vartheta_l. \tag{113}$$

The meaning of this assumption, as we shall make precise later, is that, once a pair of compact sets $(\mathcal{K}_{zs}, \mathcal{K}_{zl})$ is chosen, we know the existence of a UCO control law $\bar{u}$ so that Assumption ULP holds for the system (14). We shall prove the following proposition.

PROPOSITION 3.1. *If Assumption S-GPS holds then the point $z = 0$ of the system (109) is semiglobally practically stabilizable by dynamic output feedback.*

Proof of Theorem 1.2. If the equilibrium $z = 0$ of the system (2) is globally stabilizable by a C^2 state feedback $\bar{u}(z)$, i.e., $z = 0$ is a globally asymptotically stable equilibrium of

$$\dot{z} = A(z, \bar{u}(z)), \tag{114}$$

then, according to the converse Lyapunov theorem [22, Thm. 7], there exists a C^1 function V defined on R^n which is positive definite on $\mathbb{R}^n \backslash \{0\}$ and proper on $\mathbb{R}^n$ so that $\dot{V}_{(114)}$ is negative definite on $\mathbb{R}^n \backslash \{0\}$. It follows that point 1, (112), and (113) in Assumption S-GPS hold for any pair of compact sets $(\mathcal{K}_{zs}, \mathcal{K}_{zl})$. Therefore, if $\bar{u}(z)$ is also UCO, Assumption S-GPS holds. Thus Theorem 1.2 follows from Proposition 3.1. □

3.2. Proof of Proposition 3.1.

Our idea for proving Proposition 3.1 is, instead of using $\bar{u}(z)$ which cannot be "measured", to use an approximation $\widehat{\bar{u}}$. To get this approximation, we use the fact that $\bar{u}$ is UCO, i.e.,[6]

$$\bar{u}(z) = \Psi\left(y, y^{(1)}, \ldots, y^{(n_y)}, u, u^{(1)}, \ldots, u^{(n_u)}\right) . \tag{115}$$

Following [43], the control u and its n_u derivatives can be obtained if we augment the dynamics of the controller. But for y and its n_y derivatives, we shall need an observer. Our proof is made in three steps. The first two steps—dirty derivatives of y and dynamic extension—concern the dynamic output feedback design. In the third step, we shall establish practical stability.

[6] Note the strong requirement that Φ is independent of d.

For the first two steps of this proof, the compact sets $\mathcal{K}_{zs}$ and $\mathcal{K}_{zl}$ are arbitrary but fixed. So from Assumption S-GPS, $\bar{u}$, V, and $\mho$ are given. Then, the following real number is well defined:

$$\bar{u}_{\max} = \max_{\{z : V(z) \leq c_l\}} \{|\bar{u}(z)|\} \ . \tag{116}$$

And, by picking ϑ_1 as an arbitrary real number in $(0, 1/8)$, let κ be a C^1 class-K_∞ function satisfying

$$\kappa(\vartheta_s) = \vartheta_1 \ , \quad \kappa(\vartheta_l) \geq 8\vartheta_1 \ , \quad \kappa(c_s) \geq 1 \ , \quad \kappa(c_l) > 1 + \kappa(c_s). \tag{117}$$

This function exists since our assumption gives

$$0 < \vartheta_s < \vartheta_l \leq c_s < c_l. \tag{118}$$

Then we let

$$V_1(z) = \kappa(V(z)), \qquad c_1 = \kappa(c_s). \tag{119}$$

So Assumption ULP is satisfied and we have

$$\{z : V_1(z) \leq 8\vartheta_1\} \subset \mathcal{K}_{zs}, \qquad \mathcal{K}_{zl} \subset \{z : V_1(z) \leq c_1\} \, . \tag{120}$$

Let us also pick ρ as

$$\rho = \frac{\vartheta_1}{2}. \tag{121}$$

3.2.1. Dirty derivatives of the measurement. With n_y the number of derivatives of y needed in (115) to reconstruct $\bar{u}$, we see, by induction on the order of derivation (see also the notation section), that there exist $n_y + 1$ smooth functions C_i and an integer $m_u \leq n_y$ such that, for each solution of

$$\left\{ \begin{array}{lcl} \dot{z} & = & A(z, u_0, d(t)), \\ \dot{u}_0 & = & u_1, \\ & \vdots & \\ \dot{u}_{m_u - 1} & = & u_{m_u}, \end{array} \right. \tag{122}$$

we have, for all t where the solution makes sense,

$$y^{(i)} = C_i\left(z(t), u_0(t), \ldots, u_{m_u}(t), d(t)\right), \qquad i = 1, \ldots, n_y + 1. \tag{123}$$

Then, for the system

$$\left\{ \begin{array}{lcl} \dot{y} & = & y^{(1)}, \\ & \vdots & \\ \dot{\overbrace{y^{(n_y)}}} & = & C_{n_y+1}\left(z(t), u_0(t), \ldots, u_{m_u}(t), d(t)\right), \end{array} \right. \tag{124}$$

we can propose the following approximate observer:

$$\left\{ \begin{array}{lclcl} \dot{\widehat{y}}_0 & = & \widehat{y}_1 & + & L\ell_0 \left(y - \widehat{y}_0\right), \\ & \vdots & & & \\ \dot{\widehat{y}}_{n_y - 1} & = & \widehat{y}_{n_y} & + & L^{n_y}\ell_{n_y - 1}\left(y - \widehat{y}_0\right), \\ \dot{\widehat{y}}_{n_y} & = & & & L^{n_y+1}\ell_{n_y}\left(y - \widehat{y}_0\right) \ + \ C_{n_y+1}\left(0, u_0, \ldots, u_{m_u}, 0\right), \end{array} \right. \tag{125}$$

with the ℓ_i's chosen as the coefficients of a Hurwitz polynomial associated with a matrix A_o and the real number L to be specified later. It is important to note that (125) is not a true observer since $(y, y^{(1)}, \ldots, y^{(n_y)})$ is not a solution of (125).

3.2.2. Dynamic extension. To reconstruct $\bar{u}$, we need to know n_u derivatives of u. Similarly, to implement the above observer, we need m_u derivatives of u. So, by letting[7]

$$l_u = \max\{n_u, m_u\} + 1 \ , \tag{126}$$

we see that, by adding l_u integrators to the system (109) to be controlled, we shall have u and its required derivatives as measured state components of the system

$$\left\{ \begin{array}{lcl} \dot{z} & = & A(z, u_0, d(t)), \\ \dot{u}_0 & = & u_1, \\ & \vdots & \\ \dot{u}_{l_v - 1} & = & v. \end{array} \right. \tag{127}$$

To design the control v for this augmented system we can use Lemma 2.3. By letting

$$\xi_1 = u_0 - \bar{u}(z) \ , \quad \xi_i = \frac{u_{i-1}}{K^{i-1}} \qquad i = 1, \ldots, l_u \ , \tag{128}$$

with K a positive real number to be specified later, we get the system

$$\left\{ \begin{array}{lcl} \dot{z} & = & A(z, \bar{u}(z) + \xi_1, d(t)) \ \doteq \ h(z, \xi_1, d(t)), \\ \dot{\xi}_1 & = & K\,\xi_2 - \frac{\partial \bar{u}}{\partial z}(z) A(z, \bar{u}(z) + \xi_1, d(t)), \\ \dot{\xi}_2 & = & K\,\xi_3, \\ & \vdots & \\ \dot{\xi}_{l_u} & = & K^{1-l_u}\, v, \end{array} \right. \tag{129}$$

which is in the form of the system (51) written in the ξ_i's coordinates. As we mentioned earlier, Assumption ULP is satisfied by the system

$$\dot{z} = h(z, 0, d(t)) \ . \tag{130}$$

Then we choose coefficients, a_i's, of a Hurwitz polynomial associated with a matrix A_c. Let P_c be the solution of

$$A_c^T P_c + P_c A_c = -I \ . \tag{131}$$

Let $\mathcal{K}_{\xi l}$ be an arbitrary compact set where we choose to initialize ξ. We let

$$\mu_1 = \max\left\{1, \max_{\xi \in \mathcal{K}_{\xi l}} \{\xi^T P_c \xi\}\right\} \ . \tag{132}$$

Then Lemma 2.3 gives the bound K_*, the intermediate control

$$\begin{aligned} v &= -K^{l_u}(a_1 \xi_1 + \ldots + a_{l_u} \xi_{l_u}) \\ &= -K^{l_u}\left(a_1 \left[u_0 - \bar{u}(z)\right] + a_2 \xi_2 + \ldots + a_{l_u} \xi_{l_u}\right) \end{aligned} \tag{133}$$

and the intermediate Lyapunov function

$$W_1(z, \xi) = \frac{c_1 V_1(z)}{c_1 + 1 - V_1(z)} + \frac{\mu_1 \xi^T P_c \xi}{\mu_1 + 1 - \xi^T P_c \xi} \ . \tag{134}$$

[7] In fact the result holds with $l_u = \max\{n_u, m_u\}$ but such a choice leads to more complicated notation.

We have

$$W_1(z,\xi) \le c_1^2 + \mu_1^2 \qquad \forall\,(z,\xi)\, \in\, \mathcal{K}_{zl} \times \mathcal{K}_{\xi l} \tag{135}$$

and, for $K \ge K_*$,

$$\dot{W}_{1\,(127,133)} \le -\Phi_1(z,\xi), \tag{136}$$

where $\Phi_1(z,\xi)$ is positive definite on $\{(z,\xi) : \vartheta_1 + \rho \le W_1(z,\xi) \le c_1^2 + \mu_1^2 + 1\}$.

For future use we define the set

$$\Gamma = \{(z,\xi) : W_1(z,\xi) \le c_1^2 + \mu_1^2 + 1\}\ . \tag{137}$$

This set is compact. (See (24).) We also define the real number $c_2 = c_1^2 + \mu_1^2$. To summarize, by denoting by Z the state vector $(z^T, \xi^T)^T$, we can write the system (127), (133) as

$$\dot{Z} = H_0(Z, d(t)) \tag{138}$$

and we have that Assumption ULP is satisfied for this system with $V = W_1$, $\vartheta = \vartheta_1 + \rho$, and $c = c_2$.

3.2.3. A dynamic output feedback. To summarize our design, we can propose the following dynamic output feedback for the system (109):

(139)

$$\left\{\begin{array}{ll}
\dot{\widehat{y}}_0 & = \widehat{y}_1 + L\ell_0\,(y - \widehat{y}_0)\,, \\
 & \vdots \\
\dot{\widehat{y}}_{n_y-1} & = \widehat{y}_{n_y} + L^{n_y}\ell_{n_y-1}\,(y - \widehat{y}_0)\,, \\
\dot{\widehat{y}}_{n_y} & = \qquad L^{n_y+1}\ell_{n_y}\,(y - \widehat{y}_0) + C_{n_y+1}\,(0, u, K\xi_2, \ldots, K^{m_u}\xi_{m_u+1}, 0)\,, \\
\hline
\dot{u} & = K\,\xi_2, \\
 & \vdots \\
\dot{\xi}_{l_u-1} & = K\,\xi_{l_u}, \\
\dot{\xi}_{l_u} & = K^{1-l_u}\,v, \\
\hline
v & = -K^{l_u}\left(a_1[u - \Delta(\widehat{\overline{u}})] + a_2\xi_2 + \ldots + a_{l_u}\xi_{l_u}\right),
\end{array}\right.$$

where

$$\widehat{\overline{u}} = \Psi\left(y, \widehat{y}_1, \ldots, \widehat{y}_{n_y}, u, K\xi_2, \ldots, K^{n_u}\xi_{n_u+1}\right), \tag{140}$$

and

$$\Delta(s) = s\ \min\left\{1, \frac{\bar{u}_{\max}}{|s|}\right\} \tag{141}$$

with $\bar{u}_{\max}$ given in (116). This function Δ, already encountered in Examples 2.4 and 2.5, is one of the many possible ways of disregarding estimates when they are not in a given compact set and therefore make no sense. More specifically, this function guarantees that the assumption of Lemma 2.4 holds. And, in particular, we have

$$|\Delta(s_1) - \Delta(s_2)| \le \min\{|s_1 - s_2|\,, 2\bar{u}_{\max}\}\ . \tag{142}$$

It would also be possible to saturate each component $\widehat{y}_i$ independently. See Examples 2.4 and 2.5.

For the controller (139), we have chosen the $\widehat{y}_i$s and ξ_is as coordinates for its realization. Indeed, it is for this state that we shall be able to prove the practical stability.

Finally, note that we cannot implement the controller with ξ_1 as one of its state components since $\dot{\xi}_1$ involves unknown quantities.

3.2.4. Practical stability. To study the closed-loop system (109), (139), we use the coordinates $Z = (z^T, \xi^T)^T$ and e where

$$e_i = L^{n_y - i} \left(y^{(i)} - \widehat{y}_i \right) . \tag{143}$$

The closed-loop dynamics can be written

$$\left\{ \begin{array}{rcl} \dot{Z} & = & H(Z, e, d(t)), \\ \dot{e} & = & L A_o \, e + \Xi_e(z, \xi, d(t)), \end{array} \right. \tag{144}$$

where $\Xi_e(z, \xi, d)$ is a vector whose components are zero except the last one which is

$$\begin{aligned} \Xi_e(z, \xi, d)_{n_y} = {} & C_{n_y+1} \left(z, \xi_1 + \bar{u}(z), K\xi_2, \ldots, K^{m_u} \xi_{m_u+1}, d \right) \\ & - C_{n_y+1} \left(0, \xi_1 + \bar{u}(z), K\xi_2, \ldots, K^{m_u} \xi_{m_u+1}, 0 \right) . \end{aligned} \tag{145}$$

This system is in the form (67) considered in Lemma 2.4 with the Z dynamics playing the role of the z dynamics in that lemma.

From the conclusion of the dynamic extension stage and the facts

$$e = 0 \implies \widehat{\bar{u}} = \bar{u}(z), \qquad Z \in \Gamma \implies H(Z, 0, d(t)) = H_0(Z, d(t)), \tag{146}$$

which follow from

$$Z \in \Gamma \implies V(z) \leq c_l, \tag{147}$$

$$\implies \Delta(\bar{u}(z)) = \bar{u}(z), \tag{148}$$

Assumption ULP is satisfied. We also have

$$H(Z, e, d) - H(Z, 0, d) = \left[\begin{array}{c} 0 \\ \vdots \\ 0 \\ K \, a_1 \left[\Delta(\widehat{\bar{u}}) - \Delta(\bar{u}(z)) \right] \end{array} \right] . \tag{149}$$

But, with (123), (128), and the compactness of Γ and D, the following function $\overline{\Psi}$ on $\mathbb{R}^2_{\geq 0}$ is well defined:

$$\begin{aligned} \overline{\Psi}(K, E) = \sup_{(z,e,d,\theta,i,L) \in \mathcal{S}} \Bigg\{ \Bigg| & \tfrac{\partial \Psi}{\partial y^{(i)}} \Big(y, y^{(1)} - \tfrac{\theta}{L^{n_y - 1}} e_1, \ldots, y^{(n_y)} \\ & - \theta e_{n_y}, \xi_1 + \bar{u}(z), K\xi_2, \ldots, K^{n_u} \xi_{n_u+1} \Big) \Bigg| \Bigg\} \end{aligned} \tag{150}$$

where

$$\mathcal{S} = \Gamma \times \{ e : |e| \leq E \} \times D \times [0, 1] \times \{1, \ldots, n_y\} \times [1, \infty) . \tag{151}$$

Then, from (115), (140), and (142), we have, for $L \geq 1$ and all (Z, e, d) in $\Gamma \times \mathbb{R}^{(n_y+1)} \times D$,

$$|H(Z,e,d) - H(Z,0,d)| \leq K\,|a_1|\, \min\left\{|\widehat{u} - \bar{u}(z)|\,,\, 2\bar{u}_{\max}\right\}\ , \tag{152}$$

$$\leq K\,|a_1|\, \min\left\{\overline{\Psi}(K,|e|)|e|\,,\, 2\bar{u}_{\max}\right\}\ , \tag{153}$$

$$\leq \gamma(|e|), \tag{154}$$

for some bounded and continuous function $\gamma : \mathbb{R}_{\geq 0} \to \mathbb{R}_{\geq 0}$ satisfying $\gamma(0) = 0$. Note that γ depends on K which is fixed at this stage. Also $\Xi_e(z, \xi, d)$, given in (145), is bounded on the compact set $\Gamma \times D$ by a positive real number ν_1, independent of L but dependent on K. Now, let P_o satisfy the matrix equation

$$A_o^T P_o + P_o A_o = -I. \tag{155}$$

Also let $\mathcal{K}_{yl}$ be a compact set where we choose to initialize the estimated derivatives of y. Since, from (123), the $y^{(i)}$s are bounded on $\mathcal{K}_{zl} \times \mathcal{K}_{\xi l} \times D$, the following positive real number is well defined and depends on K but not on L:

$$k = \sup_{(z,\xi,(\widehat{y}_i),d) \in \mathcal{K}_{zl} \times \mathcal{K}_{\xi l} \times \mathcal{K}_{yl} \times D} \left\{|y^{(i)} - \widehat{y}_i|\right\}\ . \tag{156}$$

If we then choose

$$\mu_2(L) = \ln(1 + k\lambda_{\max}\{P_o\}L^{2n_y}) \tag{157}$$

we have, for the initial condition $e(0)$,

$$\ln(1 + e^T(0)P_o e(0)) \leq \mu_2(L) \tag{158}$$

and the limit (70) is satisfied. So Lemma 2.4 gives us a bound L_*, depending on K, and the final Lyapunov function

$$W_2(Z,e) = \frac{c_2 W_1(Z)}{c_2 + 1 - W_1(Z)} + \frac{\mu_2(L)\ln(1 + e^T P_o e)}{\mu_2(L) + 1 - \ln(1 + e^T P_o e)} \tag{159}$$

so that for $L \geq L_*$, we have

$$\mu_2(L) \geq 1 \tag{160}$$

and

$$\dot{W}_{2\,(144)} \leq -\Phi_2(Z,e), \tag{161}$$

where $\Phi_2(Z,e)$ is positive definite on $\{(Z,e) : \vartheta_1 + 2\rho \leq W_2 \leq c_2^2 + \mu_2(L)^2 + 1\}$. Since the set $\mathcal{K}_{zl} \times \mathcal{K}_{\xi l} \times \mathcal{K}_{yl}$ is contained in $\{(Z,e) : W_2 \leq c_2^2 + \mu_2(L)^2\}$ and $\rho = \frac{\vartheta_1}{2}$, we conclude that the solutions initialized in $\mathcal{K}_{zl} \times \mathcal{K}_{\xi l} \times \mathcal{K}_{yl}$ remain forever in the set $\{(Z,e) : W_2(Z,e) \leq c_2^2 + \mu_2(L)^2\}$ and are captured by the set $\{(Z,e) : W_2(Z,e) \leq 2\vartheta_1\}$. Then we remark that, c_1, μ_1, μ_2 being larger than 1, we have

$$(W_2(Z,e) \leq 2\vartheta_1) \Longrightarrow \left(e^T P_o e \leq \exp(4\vartheta_1) - 1,\ \xi^T P_c \xi \leq 8\vartheta_1,\ V_1(z) \leq 8\vartheta_1\right). \tag{162}$$

Since the real number ϑ_1 can be chosen arbitrarily small and (120) holds, we have proved the following.

For any pair of compact sets $(\mathcal{K}_{zs}, \mathcal{K}_{zl})$, neighborhoods of 0, with $\mathcal{K}_{zs} \subset \mathcal{K}_{zl}$, we can find compact sets $(\mathcal{K}_{ys}, \mathcal{K}_{\xi s})$ and $(\mathcal{K}_{yl}, \mathcal{K}_{\xi l})$; gains ℓ_is; a_is; a bound K_*; a bounding function $L_*(K)$; integers l_u, n_y; and functions $\bar{u}$, Δ, Ψ so that, for each $K \geq K_*$, $L \geq L_*(K)$, the dynamic output feedback (139) *in closed loop with the system* (109) *makes all the solutions, with initial condition in $\mathcal{K}_{zl} \times \mathcal{K}_{yl} \times \mathcal{K}_{\xi l}$, be captured by the set $\mathcal{K}_{zs} \times \mathcal{K}_{ys} \times \mathcal{K}_{\xi s}$.*

4. The small gain theorem for asymptotic stability. Up to this point we have focused on boundedness of solutions only . However, we have constructed Lyapunov functions to guarantee that, in appropriate coordinates, the states become ultimately arbitrarily small. Now, if the linear approximation in these coordinates is exponentially stable we are effectively done. If the linear approximation is not exponentially stable, then the problem reduces to studying the local stability on the center manifold. See [8]. Because the center manifold analysis can be quite involved, we choose to develop a sufficient condition, other than exponential stability, that can be checked a priori.

Our approach will be to appeal to the notion of "small gain." We will state here a version of the small nonlinear gain theorem, expressed in terms closely related to the nonlinear L_∞-gain from input to state. This is inspired by Sontag's input-to-state (ISS) stability definition [33]. We start with the following definition and give an illustrative fact.

DEFINITION 5. *The system*

$$\dot{x} = h(x, u, t) \tag{163}$$

with $x \in \mathbb{R}^n$, $u \in \mathbb{R}^m$, *and* $t \in \mathbb{R}_{\geq 0}$ *is said to be* uniformly (ϵ, δ) input-to-state stable (*uniformly* (ϵ, δ) *ISS*) *if there exist a class-KL function* β, *a class-K function* γ, *called the gain, and strictly positive real numbers* δ, ϵ *such that, for each* $t_\circ \geq 0$, *for each initial state* $x(t_\circ) = x_\circ$ *satisfying* $|x_\circ| \leq \delta$ *and for each measurable control* $u(\cdot)$ *satisfying* $||u||_{t_\circ} \leq \epsilon$, *the solution of* (163) *exists for each* $t \geq t_\circ$ *and satisfies*

$$|x(t)| \leq \beta(|x_\circ|, t - t_\circ) + \gamma(||u||_{t_\circ}). \tag{164}$$

FACT 4.1 ([35],[20],[45]). *For the system* (163),

1. *if* h *does not depend explicitly on time and the equilibrium point* $x = 0$ *of the system*

$$\dot{x} = h(x, 0) \tag{165}$$

is locally asymptotically stable, then the system is (uniformly) (ϵ, δ) *ISS.*

2. *if* $\frac{\partial h}{\partial x}(x, 0, t)$ *is bounded for sufficiently small* x *uniformly in* t, $h(x, u, t)$ *is locally Lipschitz in* (x, u) *uniformly in* t, *and the equilibrium point* $x = 0$ *of the system*

$$\dot{x} = h(x, 0, t) \tag{166}$$

is uniformly locally asymptotically stable, then the system (163) *is uniformly* (ϵ, δ) *ISS. Moreover, if* $x = 0$ *of* (166) *is locally exponentially stable then* γ *can be taken to be of the form* $\gamma(s) = ks$, *for some positive real number* k, *and* β *can be taken to be of the form* $\beta(s, t) = bse^{-at}$, *for some strictly positive real numbers* b *and* a.

Proof. See the appendix. □

Remark 4.1. For the local exponential stability case, this result was presented in [45]. For the time invariant case, the result is essentially contained in [35, Thm. 2]. For the case where h is differentiable, the proof of this fact can be constructed from theorems in [20, §4.5.2].

The local asymptotic stability of the equilibrium point of interconnected uniformly (ϵ, δ) ISS subsystems can then be analyzed using the following result.

LEMMA 4.1 (small gain). *Consider the feedback interconnection*

$$\left\{\begin{array}{rclrcl}\dot{x}_1 & = & h_1(x_1,u_1,v,t), & u_1 & = & x_2,\\ \dot{x}_2 & = & h_2(x_2,u_2,v,t), & u_2 & = & x_1,\end{array}\right. \tag{167}$$

with $x_i \in \mathbb{R}^{n_i}$ for $i = 1, 2$ and $v \in \mathbb{R}^m$. Define $x = (x_1^T, x_2^T)^T$. Assume h_i is locally Lipschitz in (x_i, u_i, v) and piecewise continuous in t. Assume the ith subsystem is uniformly (ϵ_i, δ_i) ISS with respect to both u_i and v (characterized by δ_i, ϵ_i^u, ϵ_i^v, β_i, γ_i^u and γ_i^v).[8]

Suppose there exist strictly positive real numbers ω and λ such that[9]

$$\left.\begin{array}{r}(1+\lambda)\gamma_1^u \circ (1+\lambda)\gamma_2^u(s) \le s\\ (1+\lambda)\gamma_2^u \circ (1+\lambda)\gamma_1^u(s) \le s\end{array}\right\} \quad \forall s \in [0,\omega] . \tag{168}$$

Under these conditions, the feedback interconnection is uniformly (ϵ, δ) ISS.

More specifically, define

$$\left\{\begin{array}{rcl}\phi_1(s) & = & (1+\lambda^{-1})\left(\beta_1(s,0)+\gamma_1^u\left((1+\lambda^{-1})(1+\lambda^{-1})(\beta_2(s,0))\right)\right),\\ \phi_2(s) & = & (1+\lambda^{-1})\left(\beta_2(s,0)+\gamma_2^u\left((1+\lambda^{-1})(1+\lambda^{-1})(\beta_1(s,0))\right)\right),\\ \phi(s) & = & \phi_1(s)+\phi_2(s)\end{array}\right. \tag{169}$$

and

$$\left\{\begin{array}{rcl}r_1(s) & = & (1+\lambda^{-1})(\gamma_1^v+\gamma_1^u \circ (1+\lambda^{-1})(1+\lambda)(\gamma_2^v))(s),\\ r_2(s) & = & (1+\lambda^{-1})(\gamma_2^v+\gamma_2^u \circ (1+\lambda^{-1})(1+\lambda)(\gamma_1^v))(s),\\ r(s) & = & r_1(s)+r_2(s).\end{array}\right. \tag{170}$$

Then, for any pair (ϵ, δ) satisfying

$$\epsilon \le \min\{\epsilon_1^v, \epsilon_2^v\} \quad , \qquad \phi(\delta)+r(\epsilon) < \min\{\delta_1, \delta_2, \epsilon_1^u, \epsilon_2^u, \omega\} \tag{171}$$

and for each class-K_∞ function α there exists a class-KL function β such that, for each $t_\circ \ge 0$, for each initial state satisfying $|x(t_\circ)| \le \delta$, and for each measurable input $v(\cdot)$ satisfying $||v||_{t_\circ} \le \epsilon$, the solution of (167) *exists for each $t \ge t_\circ$ and satisfies*

$$|x(t)| \le \beta(|x(t_\circ)|, t-t_\circ) + (r+\alpha)(||v||_{t_\circ}). \tag{172}$$

If each subsystem is uniformly globally *ISS and inequality* (168) *holds for all $s \in [0, \infty)$, then inequality* (172) *holds for all initial conditions and all measurable inputs $v(\cdot)$.*

Proof. See the appendix. □

Remark 4.2. 1. Notice that when $||v||_{t_\circ} = 0$, the lemma provides an asymptotic stability result. For the local case, this lemma can be seen as a generalization of [7, Lem. 4.13] where, there, $\gamma_2 \equiv 0$. In the global case, this lemma is a generalization of the result that the cascade of an ISS system and a globally asymptotically stable (GAS) system is GAS.

2. This lemma is a form of the small nonlinear gain theorem (see [10]) which includes explicitly the effects of initial conditions. Its condition (168) was introduced in [24]. For other purely input–output results see [24] and [32] and the references

[8] For example, $|x_1(t)| \le \beta_1(|x_1(t_\circ)|, t-t_\circ) + \gamma_1^u(||u_1||_{t_\circ}) + \gamma_1^v(||v||_{t_\circ})$.

[9] See Fact A.2

therein. In [16], a generalization of this lemma is presented dealing, in particular, with practical stability and the input–output case.

To make this small gain result more efficient we remark that [20, Thm. 4.10], reproduced here, gives us a way to compute effectively the gain function γ.

LEMMA 4.2. *Let B_r^n be the set $\{x \in \mathbb{R}^n : |x| \leq r\}$, $V : \mathbb{R}_{\geq 0} \times B_r^n \to \mathbb{R}$ be a C^1 function, α_1, α_2, α_3, and α_5^{-1} be class-K functions defined on $[0, r]$, and $h : B_r^n \times B_\epsilon^m \times \mathbb{R}_{\geq 0} \to \mathbb{R}^n$ be piecewise continuous in t and locally Lipschitz in (x, u). Assume ϵ satisfies*

$$\epsilon \leq \alpha_5^{-1}(\alpha_2^{-1}(\alpha_1(r))) \tag{173}$$

and, for all $t \geq 0$, for all (x, u) in $B_r^n \times B_\epsilon^m$, we have

$$\alpha_1(|x|) \leq V(t, x) \leq \alpha_2(|x|) \tag{174}$$

and

$$|x| \geq \alpha_5(|u|) \quad \Longrightarrow \quad \frac{\partial V}{\partial t} + \frac{\partial V}{\partial x} h(x, u, t) \leq -\alpha_3(|x|) \ . \tag{175}$$

Under these conditions, the system

$$\dot{x} = h(x, u, t) \tag{176}$$

is uniformly (ϵ, δ) ISS with

$$\delta = \alpha_2^{-1}(\alpha_1(r)) \ , \quad \gamma(s) = \alpha_1^{-1}(\alpha_2(\alpha_5(s))). \tag{177}$$

Furthermore, if $\alpha_i(s) = k_i s^2$, for $i = 1, \ldots, 3$ and some $k_i > 0$ then

$$\beta(s, t) = \sqrt{\frac{k_2}{k_1}}\, s \exp\left(-\frac{k_3}{2k_2}\, t\right) . \tag{178}$$

Example 4.1. Let us consider the system

$$\left\{ \begin{array}{rcl} \dot{z} & = & -z^3 + y, \\ \dot{y} & = & u - z|z|^j, \end{array} \right. \tag{179}$$

where j is some nonnegative real number. We can apply Lemma 2.2 to deduce that the point $(0, 0)$ is semiglobally practically stabilizable by the output feedback

$$u = -Ky \tag{180}$$

with K large enough. To study whether we have asymptotic stability, we check to see if Lemma 4.1 applies.

First we consider the system

$$\dot{x}_1 = -x_1^3 + u_1. \tag{181}$$

To get an expression for γ_1, we apply Lemma 4.2. We have

$$\overset{\cdot}{\widehat{\tfrac{1}{2} x_1^2}}_{(181)} = -x_1^4 + x_1\, u_1, \tag{182}$$

$$\leq -\tfrac{7}{8} x_1^4 - \tfrac{1}{8} |x_1| \left(|x_1|^3 - 8|u_1|\right) . \tag{183}$$

It follows that

$$\gamma_1(s) = 2s^{\frac{1}{3}}, \qquad \epsilon_1 = \delta_1 = +\infty \ . \tag{184}$$

Similarly, for the system

$$\dot{x}_2 = -Kx_2 + u_2|u_2|^j \ , \tag{185}$$

we get

$$\gamma_2(s) = \frac{1}{K-1}|s|^{j+1}, \qquad \epsilon_2 = \delta_2 = +\infty \ . \tag{186}$$

Therefore by choosing K large enough, we can meet the constraint (168) for some λ strictly positive and $\omega = 1$ if

$$j \geq 2 \ . \tag{187}$$

In this condition, we know that the equilibrium $(0,0)$ of (179) and (180) is locally asymptotically stable.

In fact the condition (187) given by Lemma 4.1 is not necessary. Indeed, we have

$$\overset{\cdot}{\overbrace{\frac{|z|^{j+2}}{j+2} + \frac{y^2}{2}}}\Bigg|_{(179)-(180)} = -Ky^2 - |z|^{j+4} \ . \tag{188}$$

This implies global asymptotic stability for all nonnegative j.

Example 4.2 (A continuation of Example 2.1). Consider again the system (34) of Example 2.1. We have seen that the semiglobal stabilizability of the z subsystem, the definite sign of G, as well as the existence of a lower bound for G, are sufficient conditions for the existence of semiglobally practically stabilizing feedback.

We study now whether we have not only practical stability but also asymptotic stability when

$$A(0,0) = 0 \ , \quad \bar{u}(0) = 0 \ , \quad F(0,0,d) = 0 \qquad \forall d \in D \ . \tag{189}$$

For this study and with the notation of Example 2.1, consider the system

$$\dot{x} = f(z,x,d(t)) + g(z,x,d(t))(-K\text{sgn}(g)x) \tag{190}$$

with input z and a disturbance d. We consider the analysis on the set

$$B(\delta) \doteq \{(z,x) : \ \max\{|z|,|x|\} \leq \delta\} \ , \tag{191}$$

where δ is some strictly positive real number. Because of smoothness, compactness of D, and the definition of f, we can write

$$|f| \leq \gamma_f(|z|) + k_1|x| \qquad \forall((z,x),d) \in B(\delta) \times D, \tag{192}$$

where γ_f is any class-K function satisfying

$$\gamma_f(s) \geq \max_{|z| \leq s,\, d \in D} \{|f(z,0,d)|\} \tag{193}$$

and k_1 is some positive real number independent of K. Recall also that $b \leq |g| = |G|$.

We show now that the system (190) is locally asymptotically stable when $z = 0$ and that it has the uniform (ϵ, δ) ISS property with respect to z. Indeed we have, for $((z, x), d) \in B(\delta) \times D$,

$$\frac{1}{2}\overset{\cdot}{\widehat{x^2}}_{(190)} \le -Kbx^2 + |x|[k_1|x| + \gamma_f(|z|)], \tag{194}$$

$$\le -x^2 - |x|\left[(Kb - k_1 - 1)|x| - \gamma_f(|z|)\right]. \tag{195}$$

So, from Lemma 4.2, we have established that, for $K > \frac{k_1+2}{b}$, the system (190) is uniformly (ϵ_x, δ_x) with

$$\left\{ \begin{array}{rcl} \delta_x & = & \delta\ , \\ \gamma_f(\epsilon_x) & < & \delta\ , \\ \gamma_x(s) & = & \frac{1}{Kb-k_1-1}\gamma_f(s)\ , \\ \beta_x(s,t) & = & s\exp(-t)\ . \end{array} \right. \tag{196}$$

On the other hand, we notice with Fact 4.1 that the asymptotic stability assumption for the z subsystem implies the existence of a class-K function γ_z and two strictly positive real numbers δ_z and ϵ_z such that the system (see (35))

$$\dot{z} = A(z, \bar{u}(z) + x) \tag{197}$$

with x as input is (ϵ_z, δ_z) ISS with gain function γ_z and class-KL function β_z.

So let us assume the existence of strictly positive real numbers λ, M, ϖ such that

$$(1 + \lambda)\gamma_z \circ \frac{1}{M}\gamma_f(s) \le s \quad \forall s \in [0, \varpi]\ . \tag{198}$$

Then by imposing the constraint:

$$K \ge \max\left\{\frac{(1 + \lambda)M + 1 + k_1}{b}\ , \ \frac{k_1 + 2}{b}\right\}\ , \tag{199}$$

the conditions of Lemma 4.1 are satisfied with

$$\omega = \min\{\varpi\ , \ (1 + \lambda)\gamma_z(\varpi)\}\ . \tag{200}$$

This result gives that the system

$$\left\{ \begin{array}{rcl} \dot{z} & = & A(z, \bar{u}(z) + x), \\ \dot{x} & = & f(z, x, d(t)) + g(z, x, d(t))(-K\mathrm{sgn}(g)x) \end{array} \right. \tag{201}$$

has a basin of attraction for local asymptotic stability. Precisely, as shown with full details in §5.2.3, there exists a strictly positive number ϑ_0 independent of K, such that the basin of attraction contains the set

$$\mathcal{A} = \{(z, x) : \ |(z, x)| < \vartheta_0\}\ . \tag{202}$$

To complete our proof of semiglobal stabilizability under the condition in (198), it remains to establish that the solutions of the closed-loop system are captured by $\mathcal{A}$. But this follows easily by choosing, in the design, the compact set $\mathcal{K}_s$ so that $\mathcal{K}_s \subset \mathcal{A}$ and picking K large enough.

5. A generalized version of Theorem 1.1.

5.1. Assumptions and results. As was done for Theorem 1.2, we prove here a proposition from which Theorem 1.1 follows directly. We consider again the system (109) under the following assumptions (see (145)).

$$\Xi_e(0,0,d) = 0 \quad A(0,0,d) = 0 \quad \forall d \in D \tag{203}$$

and

Assumption S. We can find

1. a strictly positive real number c_l and a positive C^1 function V which is zero at 0, defined on $\mho$, an open neighborhood of 0, so that the set $\{z : V(z) \leq c_l\}$ is a neighborhood of 0, compact and contained in $\mho$,

2. a C^2 function $\bar{u}(z)$ which is zero at 0, is defined on $\mho$, and is UCO (i.e., (6) holds), such that

$$\dot{V}_{(111)} \leq -\Phi(z) \tag{204}$$

where $\Phi(z)$ is continuous on $\mho$ and positive definite on $\{z : V(z) \leq c_l\} \setminus \{0\}$.

PROPOSITION 5.1. *Suppose the system* (109) *is so that Assumption S and* (203) *hold and there exist strictly positive real numbers* λ, M, ϖ *such that*

$$(1+\lambda)\gamma_z \circ \frac{1}{M}\gamma_{0,(\xi,e)}(s) \leq s \qquad \forall s \; \in [0,\varpi], \tag{205}$$

where $\gamma_{0,(\xi,e)}$ *is a class-*K *function satisfying* (*see* (145))

$$\gamma_{0,(\xi,e)}(s) \geq \max_{(z,d):\,|z|\leq s,\, d\in D} \left\{ \left| \frac{\partial \bar{u}}{\partial z}(z) A(z,\bar{u}(z),d) \right| \,,\, |\Xi_e(z,0,d)| \right\} \tag{206}$$

and γ_z *is the* (ϵ,δ) *gain, with respect to* u *and uniform in* d, *of the system*

$$\dot{z} = A(z,\bar{u}(z)+u,d(t)) \; . \tag{207}$$

Under these conditions, there exists a dynamic output feedback making the origin of the closed-loop system uniformly asymptotically stable with a basin of attraction such that its projection contains any strict compact subset of $\{z : V(z) \leq c_l\}$.

Proof of Theorem 1.1. As already mentioned in the proof of Theorem 1.2, there exists a C^1 function V defined and proper on $\mathbb{R}^n$ and positive definite on $\mathbb{R}^n \setminus \{0\}$ and a C^2 UCO control law so that Assumption S holds for any strictly positive real number c_l. Also, this control being locally exponentially stabilizing, it follows from Fact 4.1 that $\gamma_z(s)$ in (205) is linearly bounded on a neighborhood of 0. On the other hand, with the functions involved in (206) being at least C^1, the function $\gamma_{0,(\xi,e)}(s)$ can be chosen linear on a neighborhood of 0. Inequality (205) follows readily. The conclusion of Theorem 1.1 then follows from Proposition 5.1. □

5.2. Proof of Proposition 5.1.

5.2.1. Practical stabilization. Let us first notice that Assumption S implies the existence of a class-K function α_1 so that

$$V(z) \leq c_l \quad \Longrightarrow \quad \alpha_1(|z|) \leq V(z). \tag{208}$$

Then, let us pick three strictly positive real numbers ϑ_s, ϑ_l, and c_s so that

$$\vartheta_s < \vartheta_l \leq c_s < c_l \tag{209}$$

and define the following compact sets:

$$\mathcal{K}_{zs} = \{z : V(z) \le \vartheta_l\}\,, \qquad \mathcal{K}_{zl} = \{z : V(z) \le c_s\}\,. \tag{210}$$

We are in the condition where the controller design in the proof of Theorem 1.2 applies. So, for any strictly positive real number ϑ_1, and any compact sets $(\mathcal{K}_{yl}, \mathcal{K}_{\xi l})$, we can find, in particular, a real number K_{*1}, a compact set

$$\Gamma \supset \mathcal{K}_{zl} \times \left\{ \xi : \xi^T P_c \xi \le \sup_{\xi \in \mathcal{K}_{\xi l}} \{\xi^T P_c \xi\} \right\}, \tag{211}$$

and positive functions $L_{*1}(K)$, $\mu_2(K)$, so that, for each $K \ge K_{*1}$, $L \ge L_{*1}(K)$, the dynamic output feedback (139) in closed-loop with the system (109) makes all the solutions, with initial condition in $\mathcal{K}_{zl} \times \mathcal{K}_{yl} \times \mathcal{K}_{\xi l}$, remain in the set $\{(z, \widehat{y}, \xi) : (z, \xi) \in \Gamma,\ e^T P_o\, e \le \exp(\mu_2(L) + 1) - 1\}$ and be captured by

$$\mathcal{R} = \left\{(z, \widehat{y}, \xi) \ : \ |z| \le \alpha_1^{-1}(\vartheta_l)\,,\ e^T P_o\, e \le \exp(4\vartheta_1) - 1\,,\ \xi^T P_c \xi \le 8\vartheta_1 \right\}, \tag{212}$$

where P_o is given by (155) and P_c is given by (131).

To study under which condition we have attractivity of a single point, we remark that the closed-loop system is made of the interconnection of

$$\dot{z} = A(z, \bar{u}(z) + \xi_1, d(t)) \tag{213}$$

with:

$$\left\{ \begin{array}{rcl} \dot{\xi} & = & K\, A_c\, \xi + \Xi_\xi(z, \xi, e, d(t)), \\ \dot{e} & = & L\, A_o\, e + \Xi_e(z, \xi, d(t)), \end{array} \right. \tag{214}$$

where Ξ_e is defined in (145) and

$$\Xi_\xi(z, \xi, e, d) = \begin{pmatrix} -\frac{\partial \bar{u}}{\partial z}(z) A(z, \bar{u}(z) + \xi_1, d) \\ 0 \\ \vdots \\ 0 \\ K a_1 \left[\Delta(\widehat{u}) - \bar{u}(z)\right] \end{pmatrix}. \tag{215}$$

From Assumption S, Fact 4.1 applies. So there exist a class-K function γ_z and two strictly positive real numbers δ_z and ϵ_z such that the system

$$\dot{z} = A(z, \bar{u}(z) + u, d(t)) \tag{216}$$

is uniformly (ϵ_z, δ_z) ISS stable with gain function γ_z. It follows then from Lemma 4.1 that local asymptotic stability can be proved if the (ξ, e)-subsystem is also uniformly $(\epsilon_{(\xi,e)}, \delta_{(\xi,e)})$ ISS for some strictly positive real numbers $\epsilon_{(\xi,e)}, \delta_{(\xi,e)}$, and gain $\gamma_{(\xi,e)}$ satisfying a small gain condition like (168).

5.2.2. Input-to-state stability of the $(\boldsymbol{\xi}, \boldsymbol{e})$-subsystem. With (115), (140) and the function $\overline{\Psi}$ defined in (150), we have, for all e, $K \ge 0$, and $L \ge 1$,

$$|\widehat{u} - \bar{u}(z)| \le \overline{\Psi}(K, |e|)\, |e| \qquad \forall ((z, \xi), d) \in \Gamma \times D\,. \tag{217}$$

Also there exists a positive real number ν_4 satisfying, for all $((z,\xi),d)$ in the compact set $\Gamma \times D$,

$$\left|\frac{\partial \bar{u}}{\partial z}(z)A(z,\bar{u}(z)+\xi_1,d) - \frac{\partial \bar{u}}{\partial z}(z)A(z,\bar{u}(z),d)\right| \le \nu_4\,|\xi|. \tag{218}$$

So, with (142), (148), for all $((z,\xi),d)$ in $\Gamma \times D$ and all e, we have

$$|\Xi_\xi(z,\xi,e,d) - \Xi_\xi(z,0,0,d)| \le \nu_4\,|\xi| + \overline{\Psi}(K,|e|)\,K\,|a_1|\,|e|\ . \tag{219}$$

Similarly, from (145), we see that there exists a positive function $\overline{C}$ satisfying, for $K \ge 1$,

$$|\Xi_e(z,\xi,d) - \Xi_e(z,0,d)| \le \overline{C}(K)\,K^{m_u}\,|\xi| \qquad \forall((z,\xi),d) \in \Gamma \times D\ . \tag{220}$$

With (203), let $\gamma_{0,(\xi,e)}$ be any class-K function satisfying

$$\gamma_{0,(\xi,e)}(s) \ge \max_{(z,d):\,|z|\le s,\,d\in D}\left\{\left|\frac{\partial \bar{u}}{\partial z}(z)A(z,\bar{u}(z),d)\right|\ ,\ |\Xi_e(z,0,d)|\right\}. \tag{221}$$

We have, for all $((z,\xi),d)$ in $\Gamma \times D$ and all e,

$$\left\{\begin{array}{lcl}\dot{\overbrace{\xi^T P_c\,\xi}} & \le & -K\xi^T\xi + 2\lambda_{\max}\{P_c\}|\xi|\left[\nu_4\,|\xi| + \gamma_{0,(\xi,e)}(|z|) + \overline{\Psi}(K,|e|)\,K\,|a_1|\,|e|\right],\\ \dot{\overbrace{e^T P_o\,e}} & \le & -Le^Te + 2\lambda_{\max}\{P_o\}|e|\left[\overline{C}(K)\,K^{m_u}\,|\xi| + \gamma_{0,(\xi,e)}(|z|)\right].\end{array}\right. \tag{222}$$

Then, from the properties of V, there exists a strictly positive real number $\epsilon_{(\xi,e)}$ satisfying

$$|z| \le \epsilon_{(\xi,e)} \qquad \Longrightarrow \qquad z \in \mathcal{K}_{zl}. \tag{223}$$

Let also

$$r = \sqrt{\frac{\sup_{\xi\in\mathcal{K}_{\xi l}}\{\xi^T P_c \xi\}}{\lambda_{\max}\{P_c\}}}\,. \tag{224}$$

Then, with (211), we have

$$\left(|z| \le \epsilon_{(\xi,e)}\ ,\ \left|\begin{pmatrix}\xi\\ e\end{pmatrix}\right| \le r\right) \qquad \Longrightarrow \qquad ((z,\xi) \in \Gamma\ ,\ |e| \le r)\,. \tag{225}$$

Finally, define[10]

$$\begin{aligned} K_{*2} &= 2\max\left\{\lambda_{\max}\{P_c\}\,(3+4\nu_4)\,,\right.\\ &\qquad \left. 1 + \tfrac{\max\{\lambda_{\max}\{P_c\},\lambda_{\max}\{P_o\}\}\,(\lambda_{\max}\{P_c\}+\lambda_{\max}\{P_o\})}{r^2\min\{\lambda_{\min}\{P_c\},\lambda_{\min}\{P_o\}\}}\,\gamma_{0,(\xi,e)}\big(\epsilon_{(\xi,e)}\big)^2\right\},\\ L_{*2}(K) &= 2\lambda_{\max}\{P_o\} + K + 2\tfrac{\left(\lambda_{\max}\{P_c\}K|a_1|\overline{\Psi}(K,r)\right)^2+\left(\lambda_{\max}\{P_o\}K^{m_u}\,\overline{C}(K)\right)^2}{\lambda_{\max}\{P_c\}}\,. \end{aligned} \tag{226}$$

[10] The second argument in the max guarantees the condition (173) of Lemma 4.2 holds.

We have established that the condition

$$d \in D \ , \quad |z| \leq \epsilon_{(\xi,e)} \text{ and } \left| \begin{pmatrix} \xi \\ e \end{pmatrix} \right| \leq r$$

implies, for all $K \geq K_{*2}$ and $L \geq L_{*2}(K)$,

$$\overbrace{\xi^T P_c \xi + e^T P_o e}^{\cdot} \leq -\frac{K}{2} \left(\xi^T \xi + e^T e\right) + \left(\lambda_{\max}\{P_c\} + \lambda_{\max}\{P_o\}\right) \gamma_{0,(\xi,e)}(|z|)^2. \tag{227}$$

Then by applying Lemma 4.2, we see that, for $K \geq K_{*2}$ and $L \geq L_{*2}(K)$, the (ξ, e)-subsystem is uniformly $(\epsilon_{(\xi,e)}, \delta_{(\xi,e)})$ ISS with

(228)

$$\left\{ \begin{array}{rcl} \gamma_{(\xi,e)}(s) & = & \sqrt{\frac{2}{K-2}} \sqrt{\frac{\max\{\lambda_{\max}\{P_c\},\lambda_{\max}\{P_o\}\} \left(\lambda_{\max}\{P_c\}+\lambda_{\max}\{P_o\}\right)}{\min\{\lambda_{\min}\{P_c\},\lambda_{\min}\{P_o\}\}}} \gamma_{0,(\xi,e)}(|z|) \ , \\ \delta_{(\xi,e)} & = & \sqrt{\frac{\min\{\lambda_{\min}\{P_o\} \ , \lambda_{\min}\{P_c\}\}}{\max\{\lambda_{\max}\{P_o\}, \ \lambda_{\max}\{P_c\}\}}} \, r, \\ \beta_{(\xi,e)}(s,t) & = & \sqrt{\frac{\max\{\lambda_{\max}\{P_o\} \ , \lambda_{\max}\{P_c\}\}}{\min\{\lambda_{\min}\{P_o\} \ , \lambda_{\min}\{P_c\}\}}} \, s \exp\left(-\frac{1}{\max\{\lambda_{\max}\{P_o\} \ , \lambda_{\max}\{P_c\}\}} t \right) . \end{array} \right.$$

5.2.3. Uniform asymptotic stability.

With Lemma 4.1, we can now conclude that the origin is a uniformly asymptotically stable equilibrium point of the closed-loop system under consideration with domain of attraction containing

$$\mathcal{P} = \left\{ (z, \xi, e) : \phi(|(z, \xi, e)|, K) < \min\{\delta_{(\xi,e)}, \delta_z, \epsilon_{(\xi,e)}, \epsilon_z, \varpi, (1+\lambda)\gamma_z(\varpi)\} \right\} \tag{229}$$

if

1. there exist strictly positive real numbers λ, M, ϖ such that

$$(1+\lambda)\gamma_z \circ \frac{1}{M} \gamma_{0,(\xi,e)}(s) \leq s \qquad \forall s \ \in [0, \varpi] \tag{230}$$

2. K and L are chosen to satisfy

(231)

$$K \geq \max\left\{ K_{*1} \ , \ K_{*2} \ , \ 2 + 2 \frac{\max\{\lambda_{\max}\{P_c\},\lambda_{\max}\{P_o\}\} \left(\lambda_{\max}\{P_c\}+\lambda_{\max}\{P_o\}\right)}{\min\{\lambda_{\min}\{P_c\},\lambda_{\min}\{P_o\}\}} M^2 \left(1+\lambda\right)^2 \right\} ,$$
$$L \geq \max\left\{ L_{*1}(K), L_{*2}(K) \right\} .$$

In (229), the function $\phi(s, K)$ is obtained from (169) as

$$\left\{ \begin{array}{ll} \phi_1(s) & = \left(1+\lambda^{-1}\right) \left(\beta_z(s,0) + \gamma_z\left((1+\lambda^{-1})(1+\lambda^{-1})(\beta_{(\xi,e)}(s,0))\right)\right) , \\ \phi_2(s,K) & = \left(1+\lambda^{-1}\right) \left(\beta_x(s,0) + \gamma_{(\xi,e)}\left((1+\lambda^{-1})(1+\lambda^{-1})(\beta_z(s,0))\right)\right) , \\ \phi(s,K) & = \phi_1(s) + \phi_2(s,K), \end{array} \right. \tag{232}$$

where $\gamma_{(\xi,e)}$, dependent on K but not on L, and $\beta_{(\xi,e)}$ are given by (228). From (228), we see that there exists a class-K function ϱ independent of K and L satisfying

$$\phi(s, K) \leq \varrho(s) \tag{233}$$

for all $s \geq 0$ and K, L satisfying (231). It follows from (229) and (233) that there exists a strictly positive number ϑ_0, independent of K and L, such that the set

$$\mathcal{A} = \left\{ (z, \xi, e) : \ \max\left\{ |z|, \xi^T P_c \xi, e^T P_o e \right\} < \vartheta_0 \right\} \tag{234}$$

is contained in $\mathcal{P}$ and therefore in the domain of attraction for all K and L satisfying (231). Then since, in the controller (139), the gains ℓ_i and a_i and the bound $u_{\max}$ are chosen independent of ϑ_1 and ϑ_l, ϑ_0 does not depend on ϑ_1 and ϑ_l. Therefore, we can choose ϑ_1 and ϑ_l strictly positive and such that

$$\vartheta_1 < \min\left\{\frac{1}{4}\ln(1+\vartheta_0)\,,\ \frac{\vartheta_0}{8}\right\}, \qquad \vartheta_l < \alpha_1(\vartheta_0). \tag{235}$$

With such a choice, we are guaranteed that $\mathcal{A}$ contains $\mathcal{R}$ defined in (212). This implies that the solutions are captured by the set $\mathcal{A}$.

6. Other examples.

6.1. Minimum phase i/o linearizable systems.

Many results in the spirit of Theorems 1.1 and 1.2 can be formulated for minimum phase i/o linearizable systems using the tools developed in this paper. Consider the C^1 system

$$\left\{\begin{array}{rcl} \dot{z} & = & h(z,x,\zeta), \\ \dot{x}_1 & = & x_2, \\ & \vdots & \\ \dot{x}_r & = & \zeta, \\ \dot{\zeta} & = & f(z,x,\zeta,d(t)) + g(z,x,\zeta,d(t))u, \\ y & = & x_1, \end{array}\right. \tag{236}$$

$y \in \mathbb{R}$, $u \in \mathbb{R}$, $z \in \mathbb{R}^m$ and $x = (x_1,\dots,x_r)^T \in \mathbb{R}^r$ and $\zeta \in \mathbb{R}$. We assume a well-defined relative degree and the global minimum phase property as follows.

Assumption HFG. The sign of g is constant and the magnitude of g is bounded away from zero.

Assumption MP. $z = 0$ is a globally asymptotically stable equilibrium for the system

$$\dot{z} = h(z,0,0). \tag{237}$$

We will also assume semiglobal stabilizability for the origin of the (z,x) subsystem:

Assumption RSE. The equilibrium point (0,0) of the (z,x) subsystem, with ζ as input, is semiglobally stabilizable by C^ℓ ($\ell \geq 2$) partial state feedback depending only x. Furthermore, this feedback locally exponentially stabilizes the origin of the x subsystem.

Note that, with Assumption MP, Assumption RSE holds in the following cases:

1. [34], [31] the state z remains bounded for all "disturbances" x and ζ which converge to zero. A special case is when the z subsystem is globally ISS with respect to x and ζ.
2. [36, Thm. 6.2] h is globally Lipschitz.
3. [7], [36] h depends only on z and x_1.
4. [38] h depends on only one component of the vector $(x_1,\dots,x_r,\zeta)^T$.

Then, using Example 2.1 and Proposition 3.1, respectively, we have the following results.

COROLLARY 6.1. *If Assumptions HFG, MP, and RSE hold, then the origin of the system* (236) *is semiglobally practically stabilizable by C^ℓ ($\ell \geq 2$) and UCO state feedback.*

COROLLARY 6.2. *If Assumptions HFG, MP, and RSE hold, then then the origin of* (236) *is semiglobally practically stabilizable by dynamic output feedback.*

The feedback used to prove Corollary 6.1 is of the form $u = -\mathrm{sgn}(g)K(\zeta - \bar{u}(x))$, where $\bar{u}$ is the feedback given by assumption RSE. See Example 2.1. We then remark that the dynamic extension of §3.2.2 is not needed in Corollary 6.2 because the practically stabilizing feedback of Corollary 6.1 is UCO without using u or its derivatives.

Local exponential stability for the origin of the x subsystem is not used in either of these results. It will be used, together with the next assumption, to guarantee asymptotic stabilizability.

Assumption LSG. With γ_z the local gain function of the z subsystem with (x, ζ) as input, there exist a class-K function γ_f and positive real numbers λ, M, and ϖ such that

$$(1+\lambda)\gamma_z \circ \frac{1}{M}\gamma_f(s) \le s \qquad \forall s \in [0, \varpi], \tag{238}$$

$$\gamma_f(s) \ge \sup_{|z|\le s, d\in D} \{|f(z,0,0,d)|\}. \tag{239}$$

We remark that local exponential stability of the origin of the system (237) and $f(0,0,0,d) = 0$ for all $d \in D$ are sufficient to guarantee that Assumption LSG holds.

COROLLARY 6.3. *If Assumptions HFG, MP, RSE, and LSG hold, then the origin of the system* (236) *is semiglobally stabilizable by* C^ℓ ($\ell \ge 2$) *and UCO state feedback.*

Proof. Define $\xi = \zeta - \bar{u}(x)$. With the feedback law mentioned above, the (x, ξ) subsystem has the form

(240)

$$\begin{aligned} \dot{x} &= E(x, \bar{u}(x) + \xi), \\ \dot{\xi} &= f(z, x, \bar{u}(x) + \xi, d(t)) - |g(z, x, \bar{u}(x) + \xi, d(t))|K\xi - \tfrac{\partial \bar{u}}{\partial x}(x)E(x, \bar{u}(x) + \xi), \end{aligned}$$

where

$$|E(x, \bar{u}(x) + \xi) - E(x, \bar{u}(x))| \le |\xi| \ . \tag{241}$$

We will show that, for K sufficiently large, the (x, ξ) subsystem with z as input is uniformly (ϵ, δ) ISS with

$$\beta(s,t) = k_1 s \exp(-k_2 t), \qquad \gamma(s) = \frac{k_3}{\sqrt{K}}\gamma_f(s) \tag{242}$$

for some positive real numbers ϵ, δ, k_1, k_2, k_3, which can all be taken independent of K. The equilibrium point $x = 0$ of

$$\dot{x} = E(x, \bar{u}(x)) \tag{243}$$

is locally exponentially stable. This guarantees the existence of a function $V(x)$ and strictly positive real numbers c_1, c_2, c_3, and r such that, for all $|x| \le r$,

$$\begin{aligned} c_1|x|^2 &\le V(x) \le c_2|x|^2, \\ \dot{V}_{(243)} &\le -|x|^2, \\ |\tfrac{\partial V}{\partial x}| &\le c_3|x| \ . \end{aligned} \tag{244}$$

We restrict our analysis to the set

$$B(\bar{\delta}) \doteq \{(z, x, \xi) : \max\{|z|, |x|, |\xi|\} \le \bar{\delta}\}, \tag{245}$$

where $\bar{\delta} \leq r$ is some strictly positive real number. Because of smoothness and compactness of D we can write

$$\left| f(z,x,\bar{u}(x)+\xi,d) - \frac{\partial \bar{u}}{\partial x}(x) E(x,\bar{u}(x)+\xi) \right| \leq \gamma_f(|z|) + c_4|x| + c_5|\xi| \qquad \forall ((z,x,\xi),d) \in B(\bar{\delta}) \times D, \tag{246}$$

where γ_f is defined in (239) and c_4 and c_5 are some positive real numbers independent of K. With assumption HFG, let $0 < b \leq |g|$. Then, for all $((z,x,\xi),d) \in B(\bar{\delta}) \times D$,

$$\dot{\overbrace{V(x)+\xi^2}}_{(240)} \leq -|x|^2 + c_3|x||\xi| - 2Kb|\xi|^2 + 2|\xi|[\gamma_f(|z|) + c_4|x| + c_5|\xi|], \tag{247}$$

$$\leq -\tfrac{1}{2}|x|^2 - (Kb - 4c_4^2 - c_3^2 - 2c_5)|\xi|^2 + \tfrac{1}{Kb}\gamma_f^2(|z|). \tag{248}$$

For K sufficiently large, the uniform (ϵ, δ) ISS property, with β and γ of the form (242), follows by applying Lemma 4.2. Compare with (227), (228).

From Assumption MP and Fact 4.1, the z subsystem is (ϵ_z, δ_z) ISS with respect to (x, ζ) with gain function γ_z. To identify the gain function with respect to (x, ξ) observe that, $\bar{u}$ being at least C^1, there exists a positive real number k_4 such that

$$|x| \leq \epsilon_z \quad \Longrightarrow \quad \bar{u}(x) \leq k_4|x|. \tag{249}$$

Then, we can take

$$\gamma_z^{(x,\xi)}(s) = \gamma_z((1+k_4)s). \tag{250}$$

Finally, applying Lemma 4.1 to the interconnection of the z and (x, ξ) subsystems, one finds that condition (238) of Assumption LSG is sufficient to guarantee local asymptotic stability for K sufficiently large. Moreover, as in Example 4.2, Lemma 4.1 demonstrates that a neighborhood $\mathcal{A}$ can be described, independent of K, which is contained in the basin of attraction for all K sufficiently large. Then, semiglobal stabilizability follows from Corollary 6.1. □

COROLLARY 6.4. *If Assumptions HFG, MP, RSE, and LSG hold, then the origin of the system* (236) *is semiglobally stabilizable by dynamic output feedback.*

Sketch of proof. The proof is the same as that of the previous corollary. In this instance, the closed-loop system has the state (z, x, ξ, e) and the (x, ξ, e) subsystem is uniformly (ϵ, δ) ISS with β and γ again of the form (242). The conclusion follows from the small gain theorem and Corollary 6.2 with K chosen large enough.

Weaker versions of this last corollary have been published. In [15, §4.7] a similar local result is established for systems with locally exponentially stable zero dynamics. In [19], a similar global result is established for globally Lipschitz nonlinearities. More recently, for the case where the $\dot{z}$ equation in (236) is linear in z, it has been shown in [11] that the equilibrium point $(z, x) = (0, 0)$ is locally stabilizable by output feedback. This result provided estimates for the region of attraction but did not guarantee arbitrarily large domains of attraction. In all of these cases, Assumption LSG is automatically satisfied. When the system does not have zero dynamics it was shown in [18] that the equilibrium point $x = 0$ is semiglobally stabilizable by output feedback. For these results, high gain observers are used. In the special case where only x_1 appears in h, f is generated by differentiation of nonlinearities that depend only on x_1 and z, and $g(x_1)$ is known (see (61)), it has been shown in [42] that the system (236) is semiglobally stabilizable by output feedback, under an assumption similar to Assumption LSG, but without requiring high gain observers. See Example 2.3. If, in addition, the inverse dynamics satisfy an input-to-state stability property with respect to x_1 then, as was shown in [29], the system (236) is *globally* stabilizable by output feedback. This generalized the results of [17] and [26], [27] where it was required that the system be linear up to output injection.

6.2. A nonminimum phase i/o linearizable system. Consider the nonminimum phase system on $\mathbb{R}^3$ with y as the output

$$\left\{\begin{array}{rcl} \dot{z}_1 &=& -z_1 + z_2 - z_1 y^2, \\ \dot{z}_2 &=& z_2^2 + y + z_2 z_1^2, \\ \dot{y} &=& u + z_2. \end{array}\right. \tag{251}$$

The origin of the zero dynamics

$$\left\{\begin{array}{rcl} \dot{z}_1 &=& -z_1 + z_2, \\ \dot{z}_2 &=& z_2^2 + z_2 z_1^2 \end{array}\right. \tag{252}$$

is unstable. Indeed, any solution with initial condition satisfying $z_2(0) > 0$ exhibits finite escape time. Instead of a decomposition into z and y subsystems, we view the system (251) as in Lemma 2.3 with z_1 playing the role of z and (z_2, y) as the block of integrators. Although the assumptions of Lemma 2.3 cannot be satisfied because of the presence of y in the $\dot{z}_1$ equation, the result is still valid. Namely, for K_1 large enough, the control

$$u = -K_1^2 \left(z_2 + \frac{y}{K_1} \right) \tag{253}$$

is semiglobally stabilizing. This can be checked by looking at the time derivative of

$$W = c \frac{z_1^2}{c + 1 - z_1^2} + \mu \frac{\frac{3}{2} z_2^2 + z_2 \frac{y}{K_1} + (\frac{y}{K_1})^2}{\mu + 1 - (\frac{3}{2} z_2^2 + z_2 \frac{y}{K_1} + (\frac{y}{K_1})^2)} . \tag{254}$$

Local exponential convergence follows from the exponential stability of the undriven z_1 subsystem as discussed above. To conclude semiglobal output feedback stabilizability from Propositions 3.1 and 5.1, it remains to verify that the control (253) is UCO. This property holds trivially since we have

$$z_2 = \dot{y} - u. \tag{255}$$

7. Conclusion. We have developed tools for semiglobal stabilization by partial state and output feedback with, as a main application, semiglobal output feedback stabilization for nonlinear systems that admit a uniformly completely observable stabilizing function. Our approach for this problem uses the observer idea of [11] and the dynamic extension of [43]. This result can be seen as an extension of the result given in [40].

An important feature in our approach is to consider the issue of bounded solutions separate from convergence to the equilibrium. To guarantee convergence we have imposed a sufficient, but not necessary, small gain condition which generalizes local exponential stability assumptions.

We have given several applications illustrating our tools:

- We have shown that semiglobal stabilizability by uniformly completely observable state feedback is a sufficient condition for semiglobal practical stabilization by output feedback. Stabilization itself is obtained if an extra local small gain property is satisfied. We have applied this result to input–output linearizable systems.
- We have given output feedback solutions for certain robotics problems (Example 2.4), for the ball and beam (Example 2.5), and for a nonminimum phase system (§6.2).
- We have applied our semiglobal stabilization design to the almost disturbance decoupling problem to eliminate the vanishing regions of the attraction problem discussed in [21] and [25]. See Example 2.2.

Appendix A. Appendix.

A.1. Proof of Fact 4.1. For a strictly positive real number r and a positive integer n, define the set B_r^n, a closed subset of $\mathbb{R}^n$, by

$$B_r^n = \{x \in \mathbb{R}^n : |x| \leq r\} \ . \tag{256}$$

Claim. *Under the conditions of Fact* 4.1, *there exist a strictly positive real number* r, *a* C^1 *function* $V : \mathbb{R}_{\geq 0} \times B_r^n \to \mathbb{R}_{\geq 0}$, *class-$K$ functions* α_1, α_2, α_3, *and* α_5^{-1} *defined on* $[0, r]$ *such that, for all* $t \geq 0$ *and all* (x, u) *in* $B_r^n \times B^m_{\alpha_5^{-1}(r)}$, *we have*

$$\alpha_1(|x|) \leq V(t,x) \leq \alpha_2(|x|) \tag{257}$$

and

$$|x| \geq \alpha_5(|u|) \qquad \Longrightarrow \qquad \frac{\partial V}{\partial t} + \frac{\partial V}{\partial x} h(x,u,t) \leq -\alpha_3(|x|) \ . \tag{258}$$

In the time-invariant case, V can be taken independent of t.

Proof. We start this proof by defining a function $d_\circ : [0, r] \to \mathbb{R}_{\geq 0}$ as follows:

1. For the time-invariant case, as in [35, Eqs. (13), (14)] but assuming only LAS of $x = 0$ for $\dot{x} = h(x, 0)$, we know that there exist a strictly positive real number r, a C^1 function $V : B_r^n \to \mathbb{R}_{\geq 0}$, and functions α_1, α_2, α_3 of class-K defined on $[0, r]$ such that

$$\alpha_1(|x|) \leq V(x) \leq \ \alpha_2(|x|) \forall x \in B_r^n, \tag{259}$$

$$\frac{\partial V}{\partial x}(x) h(x,0) + \alpha_3(|x|) < \ 0 \qquad \forall x \in B_r^n \backslash \{0\}. \tag{260}$$

Then following [35, Proofs of Lem. 3.1 and 3.2], there exists a piecewise constant function $d_\circ : [0, r] \to \mathbb{R}_{\geq 0}$ such that

$$\left\{ \begin{array}{lcl} d_\circ(0) & = & 0 \ , \\ d_\circ(s) & > & 0 \qquad \forall s \in (0, r] \ , \\ |u| \leq d_\circ(|x|) & \Rightarrow & \frac{\partial V}{\partial x}(x) h(x,0) < -\alpha_3(|x|). \end{array} \right. \tag{261}$$

2. For the time-variant case, from the assumptions on h, there exist strictly positive real numbers r and L, a C^1 function $V : \mathbb{R}_{\geq 0} \times B_r^n \to \mathbb{R}_{\geq 0}$, and class-$K$ functions α_1, α_2, α_3, and α_4 defined on $[0, r]$ such that, for all (x, t) in $B_r^n \times \mathbb{R}_{\geq 0}$,

$$\left\{ \begin{array}{rcl} \alpha_1(|x|) & \leq & V(t,x) \leq \alpha_2(|x|), \\ \frac{\partial V}{\partial t}(t,x) + \frac{\partial V}{\partial x}(t,x) h(x,0,t) & \leq & -2\alpha_3(|x|), \\ |\frac{\partial V}{\partial x}(t,x)| & \leq & \alpha_4(|x|), \end{array} \right. \tag{262}$$

(see [20, Thm. 4.7] for example) and

$$(263) \qquad |h(x,u,t) - h(x,0,t)| \leq L|u| \qquad \forall (x,u,t) \in B_r^n \times B_r^m \times \mathbb{R}_{\geq 0} \ .$$

From (262) and (263) it follows that

$$(264) \qquad \begin{aligned} &\frac{\partial V}{\partial t}(t,x) + \frac{\partial V}{\partial x}(t,x)h(x,u,t) \\ &\leq -2\alpha_3(|x|) + \alpha_4(|x|)L|u| \qquad \forall (x,u,t) \in B_r^n \times B_r^m \times \mathbb{R}_{\geq 0}. \end{aligned}$$

In this case, we let the function $d_\circ$ be

$$(265) \qquad \left\{ \begin{array}{rcl} d_\circ(0) & = & 0, \\ d_\circ(s) & = & \frac{\alpha_3(s)}{L\alpha_4(s)} \quad \forall s \in (0,r]. \end{array} \right.$$

From our definitions of $d_\circ$, we have

$$(266) \qquad \inf_{\sigma \in [\tau, r]} \{\sigma, d_\circ(\sigma)\} > 0 \qquad \forall \tau \in (0,r].$$

So let θ be the function defined on $\mathbb{R}_{\geq 0}$ by

$$(267) \qquad \left\{ \begin{array}{rcl} \theta(0) & = & 0 \ , \\ \theta(s) & = & \displaystyle\frac{1}{s}\int_0^s \left(\frac{\tau}{1+\tau} \inf_{\sigma \in [\tau,r]} \{\sigma, d_\circ(\sigma)\} \right) d\tau \qquad \forall s \in (0,r] \ , \\ \theta(s) & = & \theta(r)\displaystyle\frac{s}{r} \qquad \forall s \in (r, +\infty) \ . \end{array} \right.$$

This function is of class-K and the definitions of $d_\circ$ imply, for all (x,u) in $B_r^n \times B_r^m$,

$$(268) \qquad |u| \leq \theta(|x|) \quad \Longrightarrow \quad \frac{\partial V}{\partial t}(t,x) + \frac{\partial V}{\partial x}(t,x)h(x,u,t) \leq -\alpha_3(|x|) \ .$$

So, the claim follows by defining $\alpha_5 = \theta^{-1}$.

If the equilibrium point is locally exponentially stable, then from the assumptions on h, it is well known (see [20, Thm. 4.5]) that the functions α_i, for $i = 1,2,3$, can be taken to be of the form $\alpha_i(s) = k_i r^2$ for some $k_i > 0$. Furthermore, α_4 can be taken of the form $\alpha_4(s) = k_4 s$ for some $k_4 > 0$. It follows that α_5 has the form $\alpha_5(s) = \frac{Lk_4}{k_3}s$.

Finally, Fact 4.1 is established using Lemma 4.2 and the fact that, when $\alpha_i(s) = k_i s^2$, for $i = 1, \ldots, 3$, $\alpha_5 = \frac{Lk_4}{k_3}s$ implies

$$(269) \qquad \alpha_1^{-1}(\alpha_2(\alpha_5(s))) = \sqrt{\frac{k_2}{k_1}\frac{Lk_4}{k_3}}s. \qquad \square$$

A.2. Proof of Lemma 4.1. We will make use of the following facts (see [24]).

FACT A.1. *Let γ be a function of class-K and let g be a function of class-K_∞. We have*

$$(270) \qquad \gamma(a+b) \leq \gamma \circ (Id + g)(a) + \gamma \circ (Id + g^{-1})(b) \ .$$

Proof. The proof follows from considering the two cases $b \leq g(a)$ and $b \geq g(a)$. $\square$

FACT A.2. *Let γ_1 and γ_2 be functions of class-K and let λ and ω be positive real numbers. Then*

$$\begin{aligned} &(1+\lambda)\gamma_1 \circ (1+\lambda)\gamma_2(s) \le s \qquad \forall s \in [0,\omega] \\ &\qquad \Longrightarrow (1+\lambda)\gamma_2 \circ (1+\lambda)\gamma_1 \le s \qquad \forall s \in [0,(1+\lambda)\gamma_2(\omega)]. \end{aligned} \tag{271}$$

Proof. We prove Fact A.2 by contradiction. Assume there exists an $s' \in [0,(1+\lambda)\gamma_2(\omega)]$ such that

$$(1+\lambda)\gamma_2 \circ (1+\lambda)\gamma_1(s') > s'. \tag{272}$$

Since $(1+\lambda)\gamma_2$ is of class-K, this inequality implies that $((1+\lambda)\gamma_2)^{-1}(s')$ is well defined and that

$$(1+\lambda)\gamma_1(s') > ((1+\lambda)\gamma_2)^{-1}(s') \doteq t. \tag{273}$$

This further implies

$$(1+\lambda)\gamma_1 \circ (1+\lambda)\gamma_2(t) > t, \tag{274}$$

which is a contradiction since $t \in [0,\omega]$. □

We now prove Lemma 4.1.

CLAIM. *For the class-K functions ϕ and r defined in* (169) *and* (170), *for positive real numbers δ and ϵ satisfying* (171), *and for each $t_\circ \ge 0$, we have*

$$\{|x(t_\circ)| \le \delta\ ,\ ||v||_{t_\circ} \le \epsilon\} \quad \Longrightarrow \quad \{|x(t)| \le \phi(|x(t_\circ)|) + r(||v||_{t_\circ})\ \forall t \ge t_\circ\}\ . \tag{275}$$

Proof. Define

$$\bar{\delta} = \min\{\delta_1, \delta_2, \epsilon_1^u, \epsilon_2^u, \omega\}. \tag{276}$$

The positive real numbers on the right-hand side come from the uniform (ϵ_i, δ_i) ISS assumption on each subsystem and condition (168). Notice, from (164) and (169), that for any pair (δ, ϵ) satisfying (171) we have

$$\delta < \bar{\delta}. \tag{277}$$

Then, from the assumptions on the system (167), for any initial condition $x(t_\circ)$ satisfying $|x(t_\circ)| \le \delta$ and any measurable function $v(\cdot)$ satisfying $||v||_{t_\circ} \le \min\{\epsilon_1^v, \epsilon_2^v\}$, one can find a strictly positive real number T, possibly infinite, corresponding to a maximal interval $[t_\circ, t_\circ + T)$ such that there exists a unique solution to the feedback interconnection satisfying $|x_i(t)| < \bar{\delta}$ for all $t \in [t_\circ, t_\circ + T)$. Define

$$||x_i||_{t_\circ}^T = \sup_{t_\circ \le \tau < t_\circ + T} |x_i(\tau)|. \tag{278}$$

For ease of notation, we take

$$\gamma_i = \gamma_i^u, \qquad d_i = \gamma_i^v(||v||_{t_\circ}^T). \tag{279}$$

From the uniform (ϵ_i, δ_i) ISS assumption and causality of the feedback interconnection, for all $t \in [t_\circ, t_\circ + T)$, we have

$$\left\{ \begin{array}{lcl} |x_1(t)| & \leq & \beta_1(|x_1(t_\circ)|, t - t_\circ) + \gamma_1(||x_2||_{t_\circ}^T) + d_1, \\ |x_2(t)| & \leq & \beta_2(|x_2(t_\circ)|, t - t_\circ) + \gamma_2(||x_1||_{t_\circ}^T) + d_2. \end{array} \right. \tag{280}$$

Now, using Fact A.1 and (168), we get

$$||x_1||_{t_\circ}^T \leq \beta_1(|x(t_\circ)|, 0) + \gamma_1\left(\beta_2(|x(t_\circ)|, 0) + \gamma_2(||x_1||_{t_\circ}^T) + d_2\right) + d_1 \tag{281}$$

$$\begin{aligned} &\leq \beta_1(|x(t_\circ)|, 0) + \gamma_1\left((1 + \lambda^{-1})(\beta_2(|x(t_\circ)|, 0) + d_2)\right) \\ &\qquad + \gamma_1\left((1 + \lambda)\gamma_2(||x_1||_{t_\circ}^T)\right) + d_1 \end{aligned} \tag{282}$$

$$\begin{aligned} &\leq \beta_1(|x(t_\circ)|, 0) + \gamma_1\left((1 + \lambda^{-1})(1 + \lambda^{-1})(\beta_2(|x(t_\circ)|, 0))\right) \\ &\qquad + \gamma_1\left((1 + \lambda^{-1})(1 + \lambda)(d_2)\right) + (1 + \lambda)^{-1}||x_1||_{t_\circ}^T + d_1 \ . \end{aligned} \tag{283}$$

From this we conclude:

$$\begin{aligned} ||x_1||_{t_\circ}^T \leq (1 + \lambda^{-1})&\left[\beta_1(|x(t_\circ)|, 0) + \gamma_1((1 + \lambda^{-1})(1 + \lambda^{-1})(\beta_2(|x(t_\circ)|, 0))\right] \\ &+ (1 + \lambda^{-1})\left(d_1 + \gamma_1\left((1 + \lambda^{-1})(1 + \lambda)(d_2)\right)\right). \end{aligned} \tag{284}$$

Using the definition of ϕ_1 in (169), r_1 in (170), and d_i in (279), we get

$$||x_1||_{t_\circ}^T \leq \phi_1(|x(t_\circ)|) + r_1(||v||_{t_\circ}^T). \tag{285}$$

We can repeat the analysis for x_2 obtaining the class-K functions ϕ_2 and r_2 defined in (169) and (170), respectively. Then choose

$$\phi(s) = \phi_1(s) + \phi_2(s), \qquad r(s) = r_1(s) + r_2(s). \tag{286}$$

Then, since δ and ϵ are strictly positive real numbers satisfying (171), by contradiction it is easy to see that if $|x(t_\circ)| \leq \delta$ and $||v||_{t_\circ} \leq \epsilon$, T must be infinite which establishes the claim. Note for the global case, there are no restrictions on $|x(t_\circ)|$ or $||v||_{t_\circ}$.

CLAIM. *Let (ϵ, δ) be an arbitrary pair satisfying* (171). *For each strictly positive real number σ and each $(x(t_\circ), v)$ satisfying*

$$|x(t_\circ)| \leq \delta \ , \quad ||v||_{t_\circ} \leq \epsilon \ , \tag{287}$$

there exists a time T so that the corresponding solution satisfies

$$|x(t)| \leq \sigma + r(||v||_{t_\circ}) \qquad \forall t \geq t_\circ + T. \tag{288}$$

Moreover

1. T depends only on σ and m defined as

$$m = \phi(|x(t_\circ)|) + r(||v||_{t_\circ}). \tag{289}$$

2. T is zero for any σ if m is zero.

3. For any fixed $\sigma > 0$, T increases with m.

4. For any fixed $m > 0$, T decreases with σ.

Proof. Given a pair (ϵ, δ) satisfying (171), let $x(t_\circ)$ and v satisfy

$$|x(t_\circ)| \leq \delta, \qquad ||v||_{t_\circ} \leq \epsilon. \tag{290}$$

Then, given the strictly positive real number σ, we pick $t_1(\sigma, m)$ to satisfy

$$\beta_1(m, t_1) + \gamma_1\left((1+\lambda^{-1})^2 \beta_2(m, t_1)\right) \leq \frac{\frac{1}{2}\sigma}{(1+\lambda^{-1})} \ . \tag{291}$$

It is possible to pick such a t_1 because β_i is of class-KL and γ_1 is of class-K. We will show that T given as

$$T = 2t_1 \mathcal{I}\left(\frac{\ln\left(\frac{m}{\frac{1}{2}\sigma}\right)}{\ln(1+\lambda)}\right), \tag{292}$$

where $\mathcal{I}(s)$ is the smallest nonnegative integer greater than or equal to s, is sufficient to establish (288). From (291), (292) this choice satisfies points 1–4 of the claim.

From the uniform (ϵ_i, δ_i) ISS property and the previous claim, we have

$$|x_2(t)| \leq \beta_2(m, t_1) + \gamma_2(||x_1||_{t_s}) + d_2 \qquad \forall t \geq t_1 + t_s \tag{293}$$

for each $t_s \geq t_\circ$. Using this information, we can establish that

$$|x_1(t)| \leq \beta_1(m, t_1) + \gamma_1\left(\beta_2(m, t_1) + \gamma_2(||x_1||_{t_s}) + d_2\right) + d_1 \qquad \forall t \geq 2t_1 + t_s \tag{294}$$

for each $t_s \geq t_\circ$. Using the choice of t_1 in (291), the definition of d_i in (279), and Fact A.1 we get

$$|x_1(t)| \leq \frac{\frac{1}{2}\sigma}{(1+\lambda^{-1})} + (1+\lambda)^{-1}||x_1||_{t_s} + (1+\lambda^{-1})^{-1} r(||v||_{t_\circ}) \quad \forall t \geq 2t_1 + t_s \tag{295}$$

for each $t_s \geq t_\circ$. From this we get

$$||x_1||_{2t_1+t_s} \leq \frac{\frac{1}{2}\sigma}{(1+\lambda^{-1})} + (1+\lambda)^{-1}||x_1||_{t_s} + (1+\lambda^{-1})^{-1} r(||v||_{t_\circ}) \quad \forall t_s \geq t_\circ. \tag{296}$$

Since, from the previous claim, we have

$$||x_1||_{t_\circ} \leq m \ , \tag{297}$$

it follows by induction that, for any positive integer j,

$$||x_1||_t \leq (1+\lambda)^{-j} m + \frac{1}{2}\sigma + r(||v||_{t_\circ}) \qquad \forall t \geq j2t_1 + t_\circ. \tag{298}$$

Thus, with T defined in (292), we have obtained

$$||x_1||_t \leq \sigma + r(||v||_{t_\circ}) \qquad \forall t \geq T + t_\circ. \tag{299}$$

The analysis can be repeated for $x_2(t)$ to establish the claim. □

With the previous claim established, by following the same lines as in [23, Lem. 2.1.4], we can construct a family of mappings $\{T_m\}_{m>0}$ with

1. for each fixed $m > 0$, $T_m : \mathbb{R}_{>0} \to \mathbb{R}_{>0}$ is continuous, strictly decreasing, and onto;
2. for each fixed $\sigma > 0$, $T_m(\sigma)$ is increasing as m increases, and $\lim_{m\to\infty} T_m(\sigma) = \infty$;

such that, for each pair (ϵ, δ) satisfying (171), we have

$$\{|x(t_\circ)| \leq \delta,\ ||v||_{t_\circ} \leq \epsilon,\ m > 0\} \Longrightarrow \{|x(t)| \leq \sigma + r(||v||_{t_\circ})\ \forall t \geq T_m(\sigma) + t_\circ\}\,, \tag{300}$$

$$\{|x(t_\circ)| = ||v||_{t_\circ} = 0\} \Longrightarrow \{|x(t)| = 0 \quad \forall t \geq t_\circ\}\,, \tag{301}$$

where m is defined in (289).

The discussion now follows the proof of [23, Prop. 2.1.5] closely. For each $m > 0$, denote $\psi_m \doteq T_m^{-1}$. Then for each $m > 0$, $\psi_m : \mathbb{R}_{>0} \to \mathbb{R}_{>0}$ is continuous, strictly decreasing, and onto. And, for each fixed $t > 0$, $\psi_m(t)$ is nondecreasing as m increases. We also write $\psi_m(0) = \infty$ which is consistent with ψ_m being strictly decreasing and onto. Finally, we extend this family with

$$\psi_0(t) = 0 \quad \forall t \in \mathbb{R}_{\geq 0}. \tag{302}$$

To summarize the situation, we have established the following implications, for each pair (ϵ, δ) satisfying (171):

$$\{|x(t_\circ)| \leq \delta\ ,\ ||v||_{t_\circ} \leq \epsilon\} \Longrightarrow \{|x(t)| \leq \psi_m(t - t_\circ) + r(||v||_{t_\circ})\ \forall t \geq t_\circ\}\,, \tag{303}$$

$$\{|x(t_\circ)| \leq \delta\ ,\ ||v||_{t_\circ} \leq \epsilon\} \Longrightarrow \{|x(t)| \leq m\ \forall t \geq t_\circ\}\,, \tag{304}$$

with m given in (289).

Now, as in the proof of [23, Prop. 2.1.5], for any $s \geq 0$, $d \geq 0$, and $t \geq 0$, let

$$\bar{\psi}(s, d, t) \doteq \min\{\psi_{\phi(s)+r(d)}(t), \phi(s)\}, \tag{305}$$

where ϕ may need to be extended to be defined for all $s \geq 0$. Since ϕ and r are increasing, for any fixed d, t, $\bar{\psi}(\cdot, d, t)$ is a nondecreasing function and, for any fixed s, t, $\bar{\psi}(s, \cdot, t)$ is a nondecreasing function. Similarly, since, for any fixed m, $\psi_m(\cdot)$ decreases to 0 as $t \to \infty$, the same holds, for fixed s, d, for $\bar{\psi}(s, d, \cdot)$. Finally, if the pair (ϵ, δ) satisfies (171), we have

$$\begin{aligned} &\{|x(t_\circ)| \leq \delta\ ,\ ||v||_{t_\circ} \leq \epsilon\} \\ &\quad\Longrightarrow \quad \{|x(t)| \leq \bar{\psi}(|x(t_\circ)|, ||v||_{t_\circ}, t - t_\circ) + r(||v||_{t_\circ})\ \forall t \geq t_\circ\}\,. \end{aligned} \tag{306}$$

Now, for any class-K_∞ function α, we can find a class-K_∞ function α_1 such that

$$\phi \circ \alpha_1 \leq \alpha. \tag{307}$$

Then, for each $t \geq 0$, we have

$$\bar{\psi}(s, d, t) \leq \bar{\psi}(\alpha_1(d), d, t) + \bar{\psi}(s, \alpha_1^{-1}(s), t). \tag{308}$$

This follows from considering the two cases, $s \leq \alpha_1(d)$ and $d \leq \alpha_1^{-1}(s)$, and by using the monotonicity properties of $\bar{\psi}$. But from the definition of $\bar{\psi}$, it is clear that

$$\bar{\psi}(\alpha_1(d), d, t) \leq \phi(\alpha_1(d)) \leq \alpha(d). \tag{309}$$

Finally, the term $\bar{\psi}(s, \alpha_1^{-1}(s), t)$ can be bounded by a class-KL function $\beta(s, t)$ as in the proof of [23, Prop. 2.1.5]. Combining these manipulations, we have (172). □

CONSISTENCY OF PRIMAL-DUAL APPROXIMATIONS FOR CONVEX OPTIMAL CONTROL PROBLEMS*

STEPHEN E. WRIGHT[†]

Abstract. Problems in the optimal control of linear systems with convex costs are recast in a primal-dual (minimax) framework. An approximation scheme which leads to primal and dual optimal control problems in discrete time having similar structure to the original primal-dual pair is introduced. The discretization is shown to be variationally consistent in the sense of epi/hypo-convergence, so that any limit point of solutions for the approximate minimax problems will solve the original primal and dual problems.

Key words. convex optimal control, duality, Lagrangians, discrete approximation, Euler approximation, epi-convergence, epi/hypo-convergence, variational convergence

AMS subject classifications. 49M15, 49M25

1. Introduction.

In this paper we present a new approach for discretizing convex problems in optimal control based on the *direct* use of minimax formulations. We analyze the method through the concept of epi/hypo-convergence [2]–[4]. There are several advantages to be gained from this viewpoint. First, many nonsmooth problems and most exact penalty representations can be written equivalently as minimax problems with smooth data and simple constraints. Second, epi/hypo-convergence involves convergence of both solutions *and* multipliers, affording better sensitivity analysis at approximate solutions. Finally, the perturbational properties of epi/hypo-convergence make it easier to extend convergence results to a broader class of approximations.

A number of authors have studied methods of discretization for constrained optimal control problems. Some have used direct approximations of the primal problem, including Cullum [9], [10] and Daniel [11]. Others have introduced penalties into the primal formulation; see, for instance, the papers of Chen and Mills [7], Cullum [8], and Russell [27]. Also various dual formulations have been considered by Hager [13], Hager and Ianculescu [15], and Pirronneau and Polak [18]. The use of primal-dual representations for approximation in optimal control as in the current paper is new.

We begin in §2 with the formulation of the optimal control problem and a discussion of Rockafellar's primal-dual representation [22]. In §3 we introduce the basic approximation scheme, given by restricting attention to (primal and dual) controls which are piecewise constant. It is demonstrated that this leads to a dual pair of optimal control problems in discrete time. Section 4 is devoted to an exposition of the relevant facts from the theory of closed saddle functions and epi/hypo-convergence that will be needed later. In §5, we state and prove our main result about the consistency of the approximation scheme introduced earlier. It is assumed at this point that the trajectory and cost corresponding to an approximate control can be calculated precisely at the grid points (as could be done in the autonomous case). The final

section extends the consistency theorem to approximation by Euler's finite-difference scheme.

We will deal with consistency of the approximations, obtaining convergence under the general assumption of continuity on the data. Rates of convergence are not discussed in this paper. Such results typically require the data to have Lipschitz-continuous derivatives (perhaps of several orders). Recent attempts to treat fairly general problems in optimal control, removing extraneous differentiability assumptions, have been undertaken by Dontchev and Hager [12], Mordukhovich [16], and Veliov [28], to name a few. Earlier work was restricted to problems of very simple structure—for example, unconstrained problems—or quadratic problems with simple bounds on endpoints; cf. Bosarge and Johnson [6], Chen and Mills [7], Hager [13], [14], and Mathis and Reddien [17]. All of the above papers treat primal or dual formulations of control problems. At this time, nothing is known about rates for primal-dual approximations. The current paper should provide a natural framework for adapting the concepts of "epi-distance" (cf. [5]) to study this issue.

2. Primal-dual representation of optimal control problems.

The problem we shall consider is the following:

($\mathcal{P}^1$) minimize the functional

$$F(u) = \int_{t_0}^{t_1} [p_t \cdot u_t + \varphi_t(u_t) - c_t \cdot x_t + \psi_t^*(q_t - D_t u_t - C_t x_t)]dt$$
$$+ p_e \cdot u_e + \varphi_e(u_e) - c_e \cdot x_{t_1} + \psi_e^*(q_e - D_e u_e - C_e x_{t_1})$$

over the control space $\mathcal{U}^1 = \mathcal{L}_k^1 \times \mathbf{R}^{k_e}$, with the dynamics given by

$$\dot{x}_t = A_t x_t + B_t u_t + b_t \text{ a.e.}, \quad x_{t_0} = B_e u_e + b_e.$$

We shall also work with the problems ($\mathcal{P}^r$) (for $r \in [1, \infty]$) given by replacing the space $\mathcal{U}^1$ by $\mathcal{U}^r = \mathcal{L}_k^r \times \mathbf{R}^{k_e}$.

The functions φ_t, ψ_t^* (for each $t \in [t_0, t_1]$) and φ_e and ψ_e^* are assumed to be proper, lower semicontinuous convex functions. (A function with values in $\overline{\mathbf{R}} = \mathbf{R} \cup \{\pm\infty\}$ is said to be *proper* if it does not take actually the value $-\infty$ and is not identically $+\infty$.) In addition, we require that φ_t and ψ_t vary epi-continuously with t and that the data elements p_t, q_t, A_t, B_t, b_t, C_t, c_t, D_t are all continuous with respect to $t \in [t_0, t_1]$.

This formulation of an optimal control problem was introduced by Rockafellar [22]. Its main advantage is that it leads to a clean duality theory, exposing those aspects of the problem which are important in the study of optimality conditions and sensitivity. It can also serve as a model in its own right; cf. [21], [22]. Since φ_t, φ_e, ψ_t^*, and ψ_e^* may take values in $\overline{\mathbf{R}}$, constraints on the controls and trajectories (as well as endpoint constraints) can be modelled implicitly. In addition, the expression $\psi_t^*(q_t - D_t u_t - C_t x_t)$ can be viewed as a penalty representation for a constraint of the form

$$q_t \leq D_t u_t - C_t x_t.$$

For $r \in [1, \infty]$, we will also consider the dual problems

($\mathcal{D}^r$) maximize the functional

$$G(v) = \int_{t_0}^{t_1} [q_t \cdot v_t - \psi_t(v_t) - b_t \cdot y_t - \varphi_t^*(D_t^* v_t + B_t^* y_t - p_t)]dt$$
$$+ q_e \cdot v_e - \psi_e(v_e) - b_e \cdot y_{t_0} - \varphi_e^*(D_e^* v_e + B_e y_{t_0} - p_e)$$

over the control space $\mathcal{V}^r = \mathcal{L}_l^r \times \mathbf{R}^{l_e}$ with the dynamics given by

$$-\dot{y}_t = A_t^* y_t + C_t^* v_t + c_t \text{ a.e.}, \qquad y_{t_1} = C_e^* v_e + c_e.$$

Here the superscript $*$ denotes the transpose for a matrix and the *convex conjugate* for a function: $h^*(r) = \sup_s\{r \cdot s - h(s)\}$. (If h is proper, lower semicontinuous, and convex, then $h = (h^*)^*$. See [20].)

Instead of approximating the problems $(\mathcal{P}^r)$ and $(\mathcal{D}^r)$ directly, we will work with a corresponding minimax representation for optimality. To this end, we introduce the functional

$$\mathcal{J}(u,v) = \int_{t_0}^{t_1} J_t(u_t, v_t)dt + J_e(u_e, v_e) - \gamma(u,v),$$

where

$$J_t(u_t, v_t) = \begin{cases} \infty & \text{if } \varphi_t(u_t) = \infty, \\ p_t \cdot u_t + \varphi_t(u_t) - v_t \cdot D_t u_t + q_t \cdot v_t - \psi_t(v_t) & \text{otherwise,} \end{cases}$$

$$J_e(u_e, v_e) = \begin{cases} \infty & \text{if } \varphi_e(u_e) = \infty, \\ p_e \cdot u_e + \varphi_e(u_e) - v_e \cdot D_e u_e + q_e \cdot v_e - \psi_e(v_e) & \text{otherwise,} \end{cases}$$

and

$$\begin{aligned}\gamma(u,v) &= \int_{t_0}^{t_1} y_t \cdot (B_t u_t + b_t)dt + y_{t_0} \cdot (B_e u_e + b_e)dt \\ &= \int_{t_0}^{t_1} x_t \cdot (C_t^* v_t + c_t)dt + x_{t_1} \cdot (C_e^* v_e + c_e).\end{aligned}$$

To avoid ambiguity, $\mathcal{J}$ is defined using the convention that $\infty - \infty = \infty$. This is used twice: first in evaluating the integrals and then in adding the integrals to $J_e(u_e, v_e)$. The expression $\int_{t_0}^{t_1} J_t(u_t, v_t)dt$ is taken to be ∞ if and only if $J_t(u_t, v_t)$ is not majorized by any integrable function; it is taken to be $-\infty$ if and only if $J_t(u_t, v_t)$ is majorized by an integrable function but not minorized by an integrable function. Of course, the term $\gamma(u,v)$ is always finite.

A control pair $(\bar{u}, \bar{v})$ is said to be a *saddle point* for $\mathcal{J}$ on $\mathcal{U}^r \times \mathcal{V}^{r'}$ if, for all $(u,v) \in \mathcal{U}^r \times \mathcal{V}^{r'}$, it is true that

$$\mathcal{J}(\bar{u}, v) \le \mathcal{J}(\bar{u}, \bar{v}) \le \mathcal{J}(u, \bar{v}).$$

A theory of duality for problems $(\mathcal{P}^r)$ and $(\mathcal{D}^{r'})$, linking the primal and dual problems to the quest for saddle points of $\mathcal{J}$, was developed recently by Rockafellar [22]. The next two theorems summarize the facts that are most relevant to our purpose here.

THEOREM 1 [22]. *Consider* $r, r' \in [1, \infty]$.

(i) *The functional* F *is lower semicontinuous and convex on* $\mathcal{U}^r$ *and takes values which are finite or* $+\infty$. *If* ψ_t^* *and* ψ_e^* *are finite-valued everywhere, then* F *is* (inf)-*proper.*

(ii) *The functional* G *is upper semicontinuous and concave on* $\mathcal{V}^{r'}$ *and takes values which are finite or* $-\infty$. *If* φ_t^* *and* φ_e^* *are finite-valued everywhere, then* G *is* (sup)-*proper.*

(iii) *The problems* $(\mathcal{P}^r)$ *and* $(\mathcal{D}^{r'})$ *are the primal and dual problems associated with the problem of finding a saddle point of* $\mathcal{J}$ *on* $\mathcal{U}^r \times \mathcal{V}^{r'}$, *i.e.,*

$$F(u) = \sup_{v \in \mathcal{V}^{r'}} \mathcal{J}(u,v) \text{ and } G(v) = \inf_{u \in \mathcal{U}^r} \mathcal{J}(u,v).$$

In particular, the optimal values satisfy $\inf(\mathcal{P}^r) \geq \sup(\mathcal{D}^{r'})$*, and a pair* $(\bar{u}, \bar{v})$ *is a saddle point for* $\mathcal{J}$ *over* $\mathcal{U}^r \times \mathcal{V}^{r'}$ *if and only if* $\bar{u}$ *solves* $(\mathcal{P}^r)$*,* $\bar{v}$ *solves* $(\mathcal{D}^{r'})$*, and* $\inf(\mathcal{P}^r) = \sup(\mathcal{D}^{r'})$.

THEOREM 2 [22]. *Consider* $r, r' \in [1, \infty]$. *Assume that* $\varphi_t^*, \psi_t^*, \varphi_e^*, \psi_e^*$ *are finite everywhere.*

(i) *The problems* $\mathcal{P}^r$ *and* $\mathcal{D}^{r'}$ *both admit optimal solutions, and*

$$\min(\mathcal{P}^r) = \max(\mathcal{D}^{r'}) \quad (\textit{finite}).$$

(ii) *A pair* $(\bar{u}, \bar{v})$ *is a saddle point of* $\mathcal{J}$ *over* $\mathcal{U}^r \times \mathcal{V}^{r'}$ *if and only if* $\bar{u}$ *solves* $(\mathcal{P}^r)$ *and* $\bar{v}$ *solves* $(\mathcal{D}^{r'})$.

(iii) *Any optimal solution of* $(\mathcal{P}^r)$ *is actually in* $\mathcal{U}^\infty$*, and any optimal solution of* $(\mathcal{D}^{r'})$ *is actually in* $\mathcal{V}^\infty$.

The arguments given by Rockafellar in deriving this duality result (as well as the properness of the functionals F and G) depend heavily on the finiteness assumption made on the conjugate integrands. This assumption is equivalent to requiring the functions $\varphi_t, \psi_t, \varphi_e, \psi_e$ to be coercive. (A function $h : \mathbf{R}^d \mapsto \overline{\mathbf{R}}$ is said to be *coercive* if $\lim_{|w| \to \infty} h(w)/|w| = \infty$. For example, h is coercive if the effective domain of h is bounded. Also, strong convexity implies coercivity.)

Statement (iii) of Theorem 2 tells us that in the search for solutions to problems $(\mathcal{P}^r)$ and $(\mathcal{D}^{r'})$, we need only consider the problem of finding a saddle point of $\mathcal{J}$ over $\mathcal{U}^\infty \times \mathcal{V}^\infty$. Indeed, in applications it is often more natural to restrict attention to essentially bounded controls anyway.

Even so, we still need to work with the larger spaces $\mathcal{U}^r$ and $\mathcal{V}^{r'}$ in our discussion of approximations. The results we give are of the epi/hypo-convergence variety. Thus, any cluster point of a sequence of solutions to the approximate problems will solve the original problem. The difficulty in applying such a result is establishing whether the approximate solutions actually cluster at all. Of course, clustering is more likely in a weaker topology than in a stronger one. Thus the sharpest result is that which guarantees epi/hypo-convergence relative to the weakest topology available. On the other hand, many applications require that the trajectories corresponding to approximate controls converge uniformly (or cluster in the uniform norm) to an optimal trajectory. This requires working with the weak topologies for $\mathcal{L}^r$ on the controls.

3. Approximation by step functions. We now introduce an approximation scheme for finding a saddle point of $\mathcal{J}$ on $\mathcal{U}^r \times \mathcal{V}^{r'}$. The idea is to approximate the controls by feasible *step functions* on $[t_0, t_1]$. Of course, there might not be any feasible step functions, so our hypotheses will eventually require the effective domains $\operatorname{dom} \varphi_t$ and $\operatorname{dom} \psi_t$ to be constant with respect to t. Note, however, that this does not necessarily restrict φ_t and ψ_t from varying with t. More generally, one can obtain similar results when $\operatorname{dom} \varphi_t = W_t \bar{U} + w_t$ and $\operatorname{dom} \psi_t = Z_t \bar{V} + z_t$, where W_t, w_t, Z_t, z_t are continuous with respect to t, and the sets $\bar{U}$ and $\bar{V}$ are fixed convex polyhedrons. It can also be shown that a related procedure can be applied if the graphs of $\operatorname{dom} \varphi_t$ and $\operatorname{dom} \psi_t$ are convex in $\mathbf{R}^k \times \mathbf{R}$ and $\mathbf{R}^l \times \mathbf{R}$.

Let $\pi = (t_0 = a_0 < a_1 < \cdots < a_T = t_1)$ be a partition of the interval $[t_0, t_1]$. Consider the following subsets of $\mathcal{U}^\infty$ and $\mathcal{V}^\infty$:

$$\mathcal{U}_\pi = \{u \in \mathcal{U}^\infty | u_t \text{ is constant a.e. on } [a_{\tau-1}, a_\tau] \text{ for } \tau = 0, \ldots, T\},$$
$$\mathcal{V}_\pi = \{v \in \mathcal{V}^\infty | v_t \text{ is constant a.e. on } [a_{\tau-1}, a_\tau] \text{ for } \tau = 0, \ldots, T\}.$$

The approximate problem is

$(\mathcal{S}_\pi)$ find a saddle point of $\mathcal{J}$ relative to $\mathcal{U}_\pi \times \mathcal{V}_\pi$.

This is a finite-dimensional problem, and we shall show in §5 that it represents a variational approximation to the problem of finding a saddle point of $\mathcal{J}$ relative to $\mathcal{U}^r \times \mathcal{V}^{r'}$. The remainder of this section is devoted to describing how the approximate problem $(\mathcal{S}_\pi)$ leads to a pair of optimal control problems in *discrete time* which are dual to each other. To simplify the discussion, we shall assume that $t_0 = 0$, $t_1 = 1$, and $D_e = 0$. Furthermore, we will work only with the special case where the given partition is $\pi = (0, 1/T, 2/T, \ldots, (T-1)/T, 1)$. It will be clear how to extend the process to the general case.

Let $\mathcal{A}$ be the fundamental matrix for the homogeneous differential equation

$$\dot{x}_t = A_t x_t,$$

i.e., the $\mathbf{R}^{n\times n}$-valued function on $[0,1]$ which satisfies

$$\dot{\mathcal{A}}_t = A_t \mathcal{A}_t, \quad \mathcal{A}_0 = I.$$

Then the unique solution to the initial-value problem

$$\dot{x}_t = A_t x_t + B_t u_t + b_t \text{ a.e.}, \quad x_0 = B_e u_e + b_e$$

is given by

$$x_t = \mathcal{A}_t \left[B_e u_e + b_e + \int_0^t \mathcal{A}_s^{-1} (B_s u_s + b_s) ds \right]. \tag{1}$$

Now suppose that u_t is constant on $[(\tau-1)/T, \tau/T)$ for each $\tau = 0, \ldots, T$. Using (1) we write

$$x_{(\tau-1)/T} = \mathcal{A}_{(\tau-1)/T} \left[x_0 + \int_0^{(\tau-1)/T} \mathcal{A}_s^{-1}(B_s u_s + b_s) ds \right],$$

$$x_{\tau/T} = \mathcal{A}_{\tau/T} \left[x_0 + \int_0^{\tau/T} \mathcal{A}_s^{-1}(B_s u_s + b_s) ds \right].$$

We combine these two equations to get the following representation for $x_{\tau/T}$:

$$x_{\tau/T} = \left[\mathcal{A}_{\tau/T} \mathcal{A}_{(\tau-1)/T}^{-1} \right] x_{(\tau-1)/T} + \left[\int_{(\tau-1)/T}^{\tau/T} \mathcal{A}_{\tau/T} \mathcal{A}_s^{-1} B_s ds \right] u_{\tau/T} + \left[\int_{(\tau-1)/T}^{\tau/T} \mathcal{A}_{\tau/T} \mathcal{A}_s^{-1} b_s \right].$$

This formula leads us to introduce a discrete-time control system with time periods $\tau = 0, \ldots, T$, controls $\tilde{u}_\tau = u_{\tau/T}$, and states $\tilde{x}_\tau = x_{\tau/T}$. The evolution of this system is described by

$$\begin{aligned} \tilde{x}_\tau &= \tilde{A}_\tau \tilde{x}_{\tau-1} + \tilde{B}_\tau \tilde{u}_\tau + \tilde{b}_\tau, \ \tau = 1, \ldots, T \\ \tilde{x}_0 &= \tilde{B}_0 \tilde{u}_0 + \tilde{b}_0, \end{aligned} \tag{2}$$

where we define

$$\begin{aligned} \tilde{A}_\tau &= \mathcal{A}_{\tau/T} \mathcal{A}_{(\tau-1)/T}^{-1}, \\ \tilde{B}_\tau &= \int_{(\tau-1)/T}^{\tau/T} \mathcal{A}_{\tau/T} \mathcal{A}_s^{-1} B_s ds, \text{ for } \tau = 1, \ldots, T, \\ \tilde{B}_0 &= B_e, \\ \tilde{b}_\tau &= \int_{(\tau-1)/T}^{\tau/T} \mathcal{A}_{\tau/T} \mathcal{A}_s^{-1} b_s ds, \text{ for } \tau = 1, \ldots, T, \\ \tilde{b}_0 &= b_e. \end{aligned}$$

In a similar fashion, corresponding to having v_t constant on each $[(\tau-1)/T, \tau/T)$, we can introduce a dual control system:

$$\begin{aligned} \tilde{y}_\tau &= \tilde{A}_\tau^* \tilde{y}_{\tau+1} + \tilde{C}_\tau^* \tilde{v}_\tau + \tilde{c}_\tau, \quad \tau = T, \dots, 1 \\ \tilde{y}_{T+1} &= \tilde{C}_{T+1}^* \tilde{v}_{T+1} + \tilde{c}_{T+1}, \end{aligned} \tag{3}$$

where we define

$$\begin{aligned} \tilde{C}_\tau &= \int_{(\tau-1)/T}^{\tau/T} C_s \mathcal{A}_s \mathcal{A}_{(\tau-1)/T}^{-1} ds \text{ for } \tau = 1, \dots, T, \\ \tilde{C}_{T+1} &= C_e, \\ \tilde{c}_\tau &= \int_{(\tau-1)/T}^{\tau/T} \left(\mathcal{A}_{(\tau-1)/T}^{-1}\right)^* \mathcal{A}_s^* c_s ds \text{ for } \tau = 1, \dots, T, \\ \tilde{c}_{T+1} &= c_e. \end{aligned}$$

Now, for $(u, v) \in \mathcal{U}_\pi \times \mathcal{V}_\pi$, we can reexpress the value of $\mathcal{J}(u, v)$ in terms of the corresponding $(\tilde{u}, \tilde{v})$ as

$$\begin{aligned} \mathcal{J}(u, v) &= \tilde{\mathcal{J}}(\tilde{u}, \tilde{v}) \\ &:= \sum_{\tau=1}^{T} [\tilde{p}_\tau \cdot \tilde{u}_\tau + \tilde{\varphi}_\tau(\tilde{u}_\tau) - \tilde{v}_\tau \cdot \tilde{D}_\tau \tilde{u}_\tau - \tilde{\psi}_\tau(\tilde{v}_\tau) + \tilde{q}_\tau \cdot \tilde{v}_\tau - \tilde{d}_\tau] \\ &\qquad + \tilde{p}_0 \cdot \tilde{u}_0 + \tilde{\varphi}_0(\tilde{u}_0) + \tilde{q}_{T+1} \cdot \tilde{v}_{T+1} - \tilde{\psi}_{T+1}(\tilde{v}_{T+1}) - \tilde{\gamma}(\tilde{u}, \tilde{v}), \end{aligned}$$

where

$$\tilde{\gamma}(\tilde{u}, \tilde{v}) = \sum_{\tau=1}^{T+1} x_{\tau-1}(\tilde{C}_\tau^* \tilde{v}_\tau + \tilde{c}_\tau) = \sum_{\tau=0}^{T} y_{\tau+1}(\tilde{B}_\tau \tilde{u}_\tau + \tilde{b}_\tau),$$

where the "trajectories" $\tilde{x}$ and $\tilde{y}$ are the solutions of the difference equations (2) and (3). The functions $\tilde{\varphi}_\tau$ and $\tilde{\psi}_\tau$ are given by

$$\begin{aligned} \tilde{\varphi}_0(\tilde{u}_0) &= \varphi_e(\tilde{u}_0), \\ \tilde{\varphi}_\tau(\tilde{u}_\tau) &= \int_{(\tau-1)/T}^{\tau/T} \varphi_t(\tilde{u}_\tau) dt \text{ for } \tau = 1, \dots, T, \\ \tilde{\psi}_\tau(\tilde{v}_\tau) &= \int_{(\tau-1)/T}^{\tau/T} \psi_t(\tilde{v}_\tau) dt \text{ for } \tau = 1, \dots, T, \\ \tilde{\psi}_{T+1}(\tilde{v}_{T+1}) &= \psi_e(\tilde{v}_{T+1}). \end{aligned}$$

The coefficients $\tilde{p}_\tau$, $\tilde{q}_\tau$, $\tilde{D}_\tau$, and $\tilde{d}_\tau$ are given by

$$\begin{aligned} \tilde{p}_\tau &= \int_{(\tau-1)/T}^{\tau/T} \left[p_t - \left(\int_{(\tau-1)/T}^{t} \mathcal{A}_s^{-1} B_s ds \right)^* \mathcal{A}_t^* c_t \right] dt \text{ for } \tau = 1, \dots, T, \\ \tilde{p}_0 &= p_e, \\ \tilde{q}_{T+1} &= q_e, \\ \tilde{q}_\tau &= \int_{(\tau-1)/T}^{\tau/T} \left[q_t - C_t \mathcal{A}_t \left(\int_{(\tau-1)/T}^{t} \mathcal{A}_s^{-1} b_s ds \right) \right] dt \text{ for } \tau = 1, \dots, T, \end{aligned}$$

$$\begin{aligned}\tilde{D}_\tau &= \int_{(\tau-1)/T}^{\tau/T}\left[D_t + C_t\mathcal{A}_t\left(\int_{(\tau-1)/T}^{t}\mathcal{A}_s^{-1}B_s ds\right)\right]dt\\ &= \int_{(\tau-1)/T}^{\tau/T}\left[D_t + \left(\int_{t}^{\tau/T}C_s\mathcal{A}_s ds\right)\mathcal{A}_t^{-1}B_t\right]dt,\\ \tilde{d}_\tau &= \int_{(\tau-1)/T}^{\tau/T}(\mathcal{A}_t^*c_t)\cdot\left(\int_{(\tau-1)/T}^{t}\mathcal{A}_s^{-1}b_s ds\right)dt\\ &= \int_{(\tau-1)/T}^{\tau/T}\left(\int_{t}^{\tau/T}\mathcal{A}_s^*c_s ds\right)\cdot\mathcal{A}_t^{-1}b_t dt.\end{aligned}$$

Clearly $\tilde{\mathcal{J}}$ is a saddle function on $(\mathbf{R}^{k_e}\times\mathbf{R}^{k\cdot T})\times(\mathbf{R}^{l\cdot T}\times\mathbf{R}^{l_e})$. Thus the approximate problem of finding a saddle point of $\mathcal{J}$ over $\mathcal{U}_\pi\times\mathcal{V}_\pi$ leads to the following pair of optimal control problems in *discrete time* which are dual to each other:

$$(\tilde{\mathcal{P}}) \qquad \text{minimize } \tilde{F}(\tilde{u}) = \sup_{\tilde{v}}\tilde{\mathcal{J}}(\tilde{u},\tilde{v}) \text{ over all } \tilde{u}\in\mathbf{R}^{k_e}\times\left(\mathop{\times}_{\tau=1}^{T}\mathbf{R}^k\right)$$

and

$$(\tilde{\mathcal{D}}) \qquad \text{maximize } \tilde{G}(\tilde{v}) = \inf_{\tilde{u}}\tilde{\mathcal{J}}(\tilde{u},\tilde{v}) \text{ over all } \tilde{v}\in\left(\mathop{\times}_{\tau=1}^{T}\mathbf{R}^l\right)\times\mathbf{R}^{l_e}.$$

The functions $\tilde{F}$ and $\tilde{G}$ are defined by

$$\begin{aligned}\tilde{F}(\tilde{u}) = \sum_{\tau=1}^{T}&[\tilde{p}_\tau\cdot\tilde{u}_\tau + \tilde{\varphi}_\tau(\tilde{u}_\tau) - \tilde{c}_\tau\cdot\tilde{x}_{\tau-1} + (\tilde{\psi}_\tau)^*(\tilde{q}_\tau - \tilde{D}_\tau\tilde{u}_\tau - \tilde{C}_\tau\tilde{x}_{\tau-1}) - \tilde{d}_\tau]\\ &+\tilde{p}_0\cdot\tilde{u}_0 + \tilde{\varphi}_0(\tilde{u}_0) - \tilde{c}_{T+1}\cdot\tilde{x}_T + (\tilde{\psi}_{T+1})^*(\tilde{q}_{T+1} - \tilde{C}_{T+1}\tilde{x}_T),\\ \tilde{G}(\tilde{v}) = \sum_{\tau=1}^{T}&[\tilde{q}_\tau\cdot\tilde{v}_\tau - \tilde{\psi}_\tau(\tilde{v}_\tau) - \tilde{b}_\tau\cdot\tilde{y}_{\tau+1} - (\tilde{\varphi}_\tau)^*(\tilde{D}_\tau^*\tilde{v}_\tau + \tilde{B}_\tau^*\tilde{y}_{\tau+1} - \tilde{p}_\tau) - \tilde{d}_\tau]\\ &+\tilde{q}_{T+1}\cdot\tilde{v}_{T+1} - \tilde{\psi}_{T+1}(\tilde{v}_{T+1}) - \tilde{b}_0\cdot\tilde{y}_1 + (\tilde{\varphi}_0)^*(\tilde{B}_0\tilde{y}_1 - \tilde{p}_0).\end{aligned}$$

We see that $\tilde{F}$ is convex, while $\tilde{G}$ is concave. The problems $(\tilde{\mathcal{P}})$ and $(\tilde{\mathcal{D}})$ belong to the realm of convex programming. These problems have a very special structure which allows the application of various "decomposition" techniques, such as the *finite envelope method*, which has been studied by Rockafellar and Wets [24]–[26]. A computer implementation for solving problems $(\tilde{\mathcal{P}})$ and $(\tilde{\mathcal{D}})$ (in the extended linear-quadratic case) via this method has been developed by the author [29]; the code was used by Zhu and Rockafellar [31] as the basis for their numerical experiments in solving large-scale optimization problems. In [30], the finite envelope method is shown to converge for a class of saddle point problems more general than the class of extended linear-quadratic problems.

A drawback to using the discretization described in this section is the computational (and numerical) burden of calculating the integrals defining the coefficients for the discrete-time problem, in addition to the calculation of the fundamental matrix $\mathcal{A}$. A computationally simpler scheme using finite differences will be examined in §6, where we explore (from a variational point of view) its relationship to the discretization used here. Of course, in the autonomous case (where the coefficients are constant) the integrals can be calculated explicitly.

4. Epi/hypo-convergence of closed saddle functions.

In this section we set up a basic framework in which to study variational approximations for saddle point problems, which will then be used in §§5 and 6 to analyze the consistency of our approximation scheme for optimal control problems.

First we review the concept of *closed saddle functions*, which play a role in minimax theory similar to that played by closed convex functions in minimization theory. For a more detailed presentation of this topic, we refer the reader to the paper by Rockafellar [19]; see also [20]. Let X and Y be Banach spaces. A bivariate function $K : X \times Y \to \overline{\mathbf{R}}$ is called a *saddle function* if $x \mapsto K(x, y)$ is a convex function for each $y \in Y$ and $y \mapsto K(x, y)$ is a concave function for each $x \in X$. We shall think of such functions as representing a "minimax" problem, where we minimize with respect to $x \in X$ and maximize with respect to $y \in Y$. Note that the inequality

$$\inf_{x \in X} \sup_{y \in Y} K(x, y) \geq \sup_{y \in Y} \inf_{x \in X} K(x, y)$$

is always valid. In the case that

$$\inf_{x \in X} \sup_{y \in Y} K(x, y) = \sup_{y \in Y} \inf_{x \in X} K(x, y)$$

the common value is called the *saddle value* for K. A pair $(\bar{x}, \bar{y})$ is said to be a *saddle point* for K if, for all $(x, y) \in X \times Y$, it is true that

$$K(\bar{x}, y) \leq K(\bar{x}, \bar{y}) \leq K(x, \bar{y}).$$

The *minimax* problem associated with K is that of finding the saddle value and saddle points for K whenever either of these exist.

We define the *effective domain* of K as

$$\operatorname{dom} K := \operatorname{dom}_1 K \times \operatorname{dom}_2 K := \{x | K(x, \cdot) < \infty\} \times \{y | K(\cdot, y) > -\infty\}.$$

K is said to be *proper* if $\operatorname{dom} K \neq \emptyset$. As with minimization problems, where we interpret the effective domain of an $\overline{\mathbf{R}}$-valued objective function as specifying the "constraint" set, the effective domain of a bivariate function is the set to which we are necessarily restricted in the search for saddle points.

To make full use of the usual theory of minimization (or maximization), we need to impose some sort of regularity hypotheses on K. Ideally, we would like to assume that $K(x, y)$ is lower semicontinuous in x and upper semicontinuous in y. It turns out that this requirement is too restrictive: it strictly prohibits the use of saddle functions which take both of the values ∞ and $-\infty$, thus excluding the possibility of modeling constraints on both x and y through the use of infinite penalties. To deal with this difficulty, Rockafellar [19] introduced an equivalence relation for saddle functions. Within this framework, the natural regularity condition to impose is that a saddle function be equivalent to certain upper and lower regularizations of itself. Functions satisfying this condition, which we describe below, will be called *closed.*

By $\operatorname{cl}_1 K$ we denote the lower semicontinuous regularization of K in x, that is,

$$\operatorname{cl}_1 K(x, y) = \liminf_{x' \to x} K(x', y).$$

The *lower closure* $\underline{\operatorname{cl}}_1 K$ is then defined as the function which satisfies, for each $y \in Y$,

$$\underline{\operatorname{cl}}_1 K(\cdot, y) = \begin{cases} \operatorname{cl}_1 K(\cdot, y) & \text{if } \operatorname{cl}_1 K(\cdot, y) > -\infty, \\ -\infty & \text{otherwise.} \end{cases}$$

In other words, $\underline{\mathrm{cl}}_1\, K(\cdot, y)$ is the pointwise supremum of all continuous linear functionals on X which are majorized by $K(\cdot, y)$. Similarly, we define the *upper closure* of K by

$$\overline{\mathrm{cl}}_2\, K(x, \cdot) = \begin{cases} \mathrm{cl}_2\, K(x, \cdot) & \text{if } \mathrm{cl}_2\, K(x, \cdot) < +\infty, \\ +\infty & \text{otherwise,} \end{cases}$$

where $\mathrm{cl}_2\, K$ is the upper semicontinuous regularization of K in y. Note that if L is another saddle function on $X \times Y$ for which $K \le L$, then $\underline{\mathrm{cl}}_1\, K \le \underline{\mathrm{cl}}_1\, L$ and $\overline{\mathrm{cl}}_2\, K \le \overline{\mathrm{cl}}_2\, L$. We say that two saddle functions K and L are *equivalent* if they have the same upper and lower closures, i.e., if

$$\underline{\mathrm{cl}}_1\, K = \underline{\mathrm{cl}}_1\, L \text{ and } \overline{\mathrm{cl}}_2\, K = \overline{\mathrm{cl}}_2\, L.$$

The function K is said to be *closed* if it is equivalent to both $\underline{\mathrm{cl}}_1\, K$ and $\overline{\mathrm{cl}}_2\, K$, in which case we write $\overline{K} = \overline{\mathrm{cl}}_2\, K$ and $\underline{K} = \underline{\mathrm{cl}}_1\, K$. If K is closed and $\underline{K} \le L \le \overline{K}$, then we write $L \in [\underline{K}, \overline{K}]$. The next two propositions are immediate consequences of the definitions.

PROPOSITION 1. *Suppose K is a closed saddle function.*

(i) $L \in [\underline{K}, \overline{K}]$ *if and only if K and L are equivalent.*

(ii) *If L is also closed, then L is equivalent to K if and only if $\underline{K} \le \overline{L}$ and $\underline{L} \le \overline{K}$.*

PROPOSITION 2. *The following are true for any saddle function K:*

(i) *If* $\mathrm{dom}_1\, K = \emptyset$, *then* $\overline{\mathrm{cl}}_2\, K \equiv \infty$.

(ii) *If* $\mathrm{dom}_2\, K = \emptyset$, *then* $\underline{\mathrm{cl}}_1\, K \equiv -\infty$.

In particular, the only closed improper saddle functions are $K \equiv \infty$ and $K \equiv -\infty$.

The following shows why the term *equivalent* is justified as applied to saddle functions.

PROPOSITION 3. *Suppose that K is closed and equivalent to L.*

(i) $\mathrm{cl}(\mathrm{dom}\, L) = \mathrm{cl}(\mathrm{dom}\, K)$.

(ii) $L(x, y) = \begin{cases} -\infty & \textit{if } x \in \mathrm{dom}_1\, K,\ y \in Y \backslash \mathrm{cl}(\mathrm{dom}_2\, K), \\ \infty & \textit{if } x \in X \backslash \mathrm{cl}(\mathrm{dom}_1\, K),\ y \in \mathrm{dom}_2\, K. \end{cases}$

(iii) *If a saddle value exists for K, then it is also the saddle value for L.*

(iv) *If $(\bar{x}, \bar{y})$ is a saddle point for K, then it is also a saddle point for L.*

(v) *L is finite on* $\mathrm{dom}_1\, \overline{K} \times \mathrm{dom}_2\, \underline{K}$.

We now discuss the notion of epi/hypo-convergence, which is a generalization of epi-convergence. There are actually several distinct concepts of epi/hypo-convergence which are useful in different settings; see [3], [4], [23]. In this paper, we shall use a variant of the definitions used in [4] and [23]. In what follows, we denote by s and w the strong (norm) and weak topologies (respectively) on a Banach space.

Consider a sequence $\{K_n\}$ of closed saddle functions on $X \times Y$. We define the *epi/hypo-limits superior* and *inferior* of $\{K_n\}$ to be

$$(\text{seq-e}_\text{s}/\text{h}_\text{w}\text{-ls}\, K_n)(x, y) = \sup_{y_n \xrightarrow[w]{} y} \inf_{x_n \xrightarrow[s]{} x} \limsup_{n \to \infty} K_n(x_n, y_n),$$

$$(\text{seq-h}_\text{s}/\text{e}_\text{w}\text{-li}\, K_n)(x, y) = \inf_{x_n \xrightarrow[w]{} x} \sup_{y_n \xrightarrow[s]{} y} \liminf_{n \to \infty} K_n(x_n, y_n).$$

We say that K_n *epi/hypo-converges* to K if

$$\text{seq-e}_\text{s}/\text{h}_\text{w}\text{-ls}\, \overline{K}_n \le \overline{K} \text{ and } \text{seq-h}_\text{s}/\text{e}_\text{w}\text{-li}\, \underline{K}_n \ge \underline{K}.$$

In this case, we write $K = \text{e/h-lim}\, K_n$. Note that this is actually a convergence of equivalence classes. It is clear from the definitions that if $\{K_{n_k}\}$ is any subsequence of $\{K_n\}$, then $K = \text{e/h-lim}\, K_{n_k}$.

The next theorem demonstrates the variational aspect of epi/hypo-convergence. It is analogous to a similar result given by Attouch, Azé, and Wets [4] and can be proven by the same argument used there. The pair $(\bar{x}, \bar{y})$ is said to be an *ε-saddle point* (for $\varepsilon \geq 0$) for K if

$$\sup_y K(\bar{x}, y) - \varepsilon \leq K(\bar{x}, \bar{y}) \leq \inf_x K(x, \bar{y}) + \varepsilon.$$

THEOREM 3. *Consider a sequence $\{K_n\}$ of closed saddle functions which epi/hypo-converges to the closed saddle function K. Suppose that $(\bar{x}_k, \bar{y}_k)$ is an ε-saddle point for K_{n_k} for some subsequence of $\{K_n\}$. If $\bar{x}_k \xrightarrow[w]{} \bar{x}$, $\bar{y}_k \xrightarrow[w]{} \bar{y}$, and $\varepsilon_k \longrightarrow \varepsilon$, then $(\bar{x}, \bar{y})$ is a 2ε-saddle point for $[\underline{K}, \overline{K}]$ and*

$$K(\bar{x}, \bar{y}) \in [\limsup_{n \to \infty} K_n(\bar{x}_n, \bar{y}_n) - \varepsilon, \liminf_{n \to \infty} K_n(\bar{x}_n, \bar{y}_n) + \varepsilon].$$

In the next two sections we will deal with saddle functions of the form

$$(x, y) \mapsto \Phi(x) - \Psi(y) - \Gamma(x, y).$$

The following result will play a key role in the analysis. Recall that a sequence $\{f_n\}$ of convex functions *Mosco epi-converges* to a function f if

$$\inf_{x_n \xrightarrow[s]{} x} \limsup_{n \to \infty} f(x_n) \leq f(x) \leq \inf_{x_n \xrightarrow[w]{} x} \liminf_{n \to \infty} f(x_n) \text{ for all } x,$$

in which case we write $f = \text{M-e-lim}\, f_n$. We refer the reader to the book by Attouch [1] for an exposition of epi-convergence.

THEOREM 4. *Let $\Gamma : X \times Y \longrightarrow \mathbf{R}$ be a continuous biaffine map. Suppose $\Phi, \Phi_n : X \longrightarrow \overline{\mathbf{R}}$ and $\Psi, \Psi_n : Y \longrightarrow \overline{\mathbf{R}}$ are proper, lower semicontinuous convex functions such that $\Phi = \text{M-e-lim}\, \Phi_n$ and $\Psi = \text{M-e-lim}\, \Psi_n$. Let K_n and K be any saddle functions on $X \times Y$ for which*

$$K_n(x, y) = \Phi_n(x) - \Psi_n(y) - \Gamma(x, y) \textit{ whenever } \infty - \infty \textit{ does not occur, and}$$
$$K(x, y) = \Phi(x) - \Psi(y) - \Gamma(x, y) \textit{ whenever } \infty - \infty \textit{ does not occur.}$$

Then K_n and K are equivalent to closed, proper saddle functions, and K_n epi/hypo-converges to K.

Proof. It is easy to see that $\overline{\mathrm{cl}}_2\, K$ and $\underline{\mathrm{cl}}_1\, K$ are given by

$$\overline{\mathrm{cl}}_2\, K(x, y) = \begin{cases} \infty & \text{if } \Phi(x) = \infty, \\ \Phi(x) - \Psi(y) - \Gamma(x, y) & \text{otherwise,} \end{cases}$$
$$\underline{\mathrm{cl}}_1\, K(x, y) = \begin{cases} -\infty & \text{if } \Psi(y) = \infty, \\ \Phi(x) - \Psi(y) - \Gamma(x, y) & \text{otherwise.} \end{cases}$$

It is clear from these descriptions that $\overline{\mathrm{cl}}_2\, K$ and $\underline{\mathrm{cl}}_1\, K$ are both saddle functions and that $\underline{\mathrm{cl}}_1(\overline{\mathrm{cl}}_2\, K) = \underline{\mathrm{cl}}_1\, K$ and $\overline{\mathrm{cl}}_2(\underline{\mathrm{cl}}_1\, K) = \overline{\mathrm{cl}}_2\, K$. The properness of K follows from that of Φ and Ψ. By the same argument, each K_n is equivalent to a proper, closed saddle function.

Now fix $(\bar{x}, \bar{y}) \in X \times Y$. We will show that $(\text{seq-e}_{\text{s}}/\text{h}_{\text{w}}\text{-ls}\, \overline{K}_n)(\bar{x}, \bar{y}) \leq \overline{K}(\bar{x}, \bar{y})$; the proof that $(\text{seq-h}_{\text{s}}/\text{e}_{\text{w}}\text{-li}\, \underline{K}_n)(\bar{x}, \bar{y}) \geq \underline{K}(\bar{x}, \bar{y})$ is similar. If $\overline{K}(\bar{x}, \bar{y}) = \infty$, we're finished. Assume then that $\overline{K}(\bar{x}, \bar{y}) < \infty$ so that $\Phi(\bar{x}) < \infty$. Suppose $\{y_n\}$ converges weakly to $\bar{y}$, and fix $\alpha > \overline{K}(\bar{x}, \bar{y})$. We need to find a sequence $\{x_n\}$, converging in norm to $\bar{x}$, such that $\limsup \overline{K}_n(x_n, y_n) \leq \alpha$. Choose $\alpha_1 \in (\overline{K}(\bar{x}, \bar{y}), \alpha)$. Since $\Phi = \text{M-e-lim}\, \Phi_n$, there is a sequence $\{x_n\}$ converging to $\bar{x}$ such that

$$\limsup \Phi_n(x_n) \leq \Phi(\bar{x}) + \frac{\alpha - \alpha_1}{2}.$$

Also, $\Psi = \text{M-e-lim}\, \Psi_n$ implies that

$$\liminf \Psi_n(y_n) \geq \Psi(\bar{y}) > -[\alpha_1 - \Phi(\bar{x}) + \Gamma(\bar{x}, \bar{y})].$$

Combining these with the sequential $s \times w$-continuity of Γ allows us to find a positive integer N so that the following three inequalities hold whenever $n \geq N$:

$$\begin{aligned} -\Psi_n(y_n) &< \alpha_1 - \Phi(\bar{x}) + \Gamma(\bar{x}, \bar{y}), \\ -\Gamma(x_n, y_n) &< -\Gamma(\bar{x}, \bar{y}) + \frac{\alpha - \alpha_1}{2}, \\ \Phi_n(x_n) &\leq \Phi(\bar{x}) + \frac{\alpha - \alpha_1}{2}. \end{aligned}$$

Thus, for all $n \geq N$, we have

$$\begin{aligned} K(x_n, y_n) &= \Phi_n(x_n) - \Psi_n(y_n) - \Gamma(x_n, y_n) \\ &\leq \Phi(x_n) - \Psi(y_n) - \Gamma(x_n, y_n) \\ &< \left[\Phi(\bar{x}) + \frac{\alpha - \alpha_1}{2}\right] + [\alpha_1 - \Phi(\bar{x}) + \Gamma(\bar{x}, \bar{y})] + \left[\frac{\alpha - \alpha_1}{2} - \Gamma(\bar{x}, \bar{y})\right] \\ &= \alpha \end{aligned}$$

as desired. □

5. Consistency of internal approximations. We now give our main consistency result for the approximation scheme described in §3. Let $\{\pi^\nu : \nu \in \mathbf{N}\}$ be an increasing sequence of partitions of $[t_0, t_1]$ such that $|a_i^\nu - a_{i+1}^\nu| \longrightarrow 0$ uniformly in i as $\nu \longrightarrow 0$. Define

$$\mathcal{J}_\nu(u, v) = \begin{cases} \mathcal{J}(u, v) & \text{if } u \in \mathcal{U}_{\pi^\nu}, v \in \mathcal{V}_{\pi^\nu}, \\ -\infty & \text{if } u \in \mathcal{U}_{\pi^\nu}, v \notin \mathcal{V}_{\pi^\nu}, \\ \infty & \text{if } u \notin \mathcal{U}_{\pi^\nu}. \end{cases}$$

The following theorem will be concerned with this sequence of problems. In addition, we will make use of the following condition on $r, r' \in [1, \infty)$:

(4) the map $(u, v) \mapsto \int_{t_0}^{t_1} v_t \cdot D_t u_t dt$ defines a continuous functional on $\mathcal{U}^r \times \mathcal{V}^{r'}$.

This condition is satisfied if $r \geq r'/(r'-1)$ (or equivalently, if $r' \geq r/(r-1)$), in which case $\mathcal{L}^r \subset (\mathcal{L}^{r'})^*$ and $\mathcal{L}^{r'} \subset (\mathcal{L}^r)^*$. If $D \equiv 0$, then the condition is satisfied for any choice of $r, r' \in [1, \infty)$.

THEOREM 5. *Consider $r, r' \in [1, \infty)$ satisfying condition* (4). *Assume there exist intervals $I_1, \ldots, I_M$ with $[0, 1] = \cup_{i=1}^M I_i$ such that, for each i, one has either*

(a) *$\varphi_t = \bar{\varphi}_t^i + \delta_{U^i}$ for $t \in I_i$, where U^i is a closed, convex set and $\bar{\varphi}_t^i(\cdot)$ is a proper, lower semicontinous convex function with $u \mapsto \int_{I_i} \bar{\varphi}_t^i(u_t)\, dt$ continuous on $\mathcal{U}^r$, or*

(b) *$\varphi_t = \bar{\varphi}^i$ for $t \in I_i$, where $\bar{\varphi}^i$ is a proper,* inf*-compact convex function.*

Similarly, assume there exist intervals $I'_1, \dots, I'_{M'}$ *with* $[0,1] = \cup_{i=1}^{M'} I'_i$ *such that, for each* i*, one has either*

(a′) $\psi_t = \bar{\psi}^i_t + \delta_{V^i}$ *for* $t \in I'_i$*, where* V^i *is a closed, convex set and* $\bar{\psi}^i_t(\cdot)$ *is a proper, lower semicontinous convex function with* $v \mapsto \int_{I'_i} \bar{\psi}^i_t(v_t)\,dt$ *continuous on* $\mathcal{V}^r$*; or*

(b′) $\psi_t = \bar{\psi}^i$ *for* $t \in I'_i$*, where* $\bar{\psi}^i$ *is a proper, inf-compact convex function.*

Then $\mathcal{J}$ *and* $\mathcal{J}_\nu$ *are equivalent to closed saddle functions on* $\mathcal{U}^r \times \mathcal{V}^{r'}$*, and* $\mathcal{J}_\nu$ *epi/hypo-converges to* $\mathcal{J}$*.*

An immediate consequence of Theorem 5 is the following.

COROLLARY. *Assume the hypotheses for Theorem* 5 *are satisfied, and suppose* $(\bar{u}^\nu, \bar{v}^\nu)$ *is a saddle point for* $\mathcal{J}^\nu$*. If, for some* $s \in [\max\{r, r'\}, \infty)$*, one can guarantee that* $(\bar{u}^\nu, \bar{v}^\nu)$ *converges in the weak topology on* $\mathcal{U}^s \times \mathcal{V}^s$*, then the limit point is a saddle point for* $\mathcal{J}$ *relative to* $\mathcal{U}^s \times \mathcal{V}^s$*.*

Note that for $(\bar{u}, \bar{v})$ to be a saddle point for $\mathcal{J}$, it is sufficient to show that the sequence of approximates merely clusters (weakly) at $(\bar{u}, \bar{v})$. This clustering is guaranteed, for example, when the effective domains $\operatorname{dom} \varphi_t$ and $\operatorname{dom} \psi_t$ are bounded for all t (and therefore uniformly bounded, by continuity) or more generally if $\operatorname{dom} \varphi_t \in \alpha_t \mathbf{B}_k$ and $\operatorname{dom} \psi_t \in \beta_t \mathbf{B}_l$ for some $\mathcal{L}^s$ functions α and β (with $s > 1$).

To show the validity of Theorem 5, we use some basic facts about constrained approximation of measurable functions by simple and step functions. We state these explicitly as lemmas but omit the proofs since they are merely variants of well-known arguments in elementary measure theory.

LEMMA 1. *Let* $(\Omega, \mathcal{F}, \mu)$ *be a finite-measure space, and suppose* $1 \leq p \leq \infty$*. Consider* $f \in \mathcal{L}^p_d(\Omega, \mathcal{F}, \mu)$ *and an inf-compact convex function* h *on* $\mathbf{R}^d$*. If* $f(\omega) \in \operatorname{dom} h$ *almost everywhere (a.e.)* $[\mu]$*, then there is a sequence* $\{f_\nu\}$ *of simple functions satisfying*

(i) $h(f_\nu(\omega)) \leq h(f_{\nu+1}(\omega)) \leq h(f(\omega))$ *a.e.* $[\mu]$*.*

(ii) $f_\nu \to f$ *a.e.* $[\mu]$*.*

(iii) $f_\nu \to f$ *in* $\mathcal{L}^p_d(\Omega, \mathcal{F}, \mu)$*.*

LEMMA 2. *Let* $(\Omega, \mathcal{F}, \mu)$ *be a finite-measure space with* $\mathcal{F} = \sigma(\mathcal{F}_0)$*, where* $\mathcal{F}_0$ *is a field on* Ω*. Let* $p \in [1, \infty)$*. Suppose that* $h : \mathbf{R}^d \to \overline{\mathbf{R}}$*. If* $f : \Omega \to \mathbf{R}^d$ *is an* $\mathcal{F}$*-simple function, then, for any* $\varepsilon > 0$*, there exists an* $\mathcal{F}_0$*-simple function* $\tilde{f}$ *with the same range as* f *for which* $\|\tilde{f} - f\|_p < \varepsilon$ *and*

$$\mu\{\omega \in \Omega | h(\tilde{f}(\omega)) > h(f(\omega))\} < \varepsilon.$$

Proof of Theorem 5. We shall prove the theorem for the special case $k_e = l_e = 0$, $b_e = c_e = 0$. In addition, we will assume that $I_i \cap I_j = \emptyset$ whenever $i \neq j$ and that each endpoint of each I_i coincides with the endpoint of some cell for some π^ν. The proof of the general case is similar.

For $u \in \mathcal{L}^r_k$ and $v \in \mathcal{L}^{r'}_l$, define

$$\Phi(u) = \int_{t_0}^{t_1} \varphi_t(u_t)dt, \quad \Psi(v) = \int_{t_0}^{t_1} \psi_t(v_t)dt,$$

and

$$\Gamma(u, v) = \int_{t_0}^{t_1} [v_t \cdot D_t u_t - p_t \cdot u_t - q_t \cdot v_t]dt + \gamma(u, v).$$

Then, for all $(u, v) \in \mathcal{L}^r_k \times \mathcal{L}^{r'}_l$, we have

$$\mathcal{J}(u, v) = \begin{cases} \infty & \text{if } \Phi(u) = \infty, \\ \Phi(u) - \Psi(v) - \Gamma(u, v) & \text{otherwise.} \end{cases}$$

Also define $\Phi_\nu = \Phi + \delta(\cdot|\mathcal{U}_{\pi^\nu})$ and $\Psi_\nu = \Psi + \delta(\cdot|\mathcal{V}_{\pi^\nu})$. We need to show that Φ, Ψ, Γ, Φ_ν, and Ψ_ν satisfy the hypotheses for Theorem 4, thereby obtaining the stated epi/hypo-convergence. It is easy to see that Φ, Ψ, Φ_ν, and Ψ_ν are proper, lower semicontinuous, convex functions and that Γ is a (norm) continuous biaffine functional. Furthermore, $\mathcal{J}_\nu(u,v)$ agrees with $\Phi_\nu(u) - \Psi_\nu(v) - \Gamma(u,v)$ whenever $\infty - \infty$ does not occur. We must therefore show that $\Phi = \text{M-e-lim}\,\Phi_\nu$ and $\Psi = \text{M-e-lim}\,\Psi_\nu$. Since $\Phi_\nu(u)$ is decreasing in ν for all u, it suffices to show

$$(5) \qquad \forall \bar{u} \in \mathcal{U}^r,\ \exists \bar{u}^\nu \underset{s}{\rightarrow} \bar{u} \text{ such that } \bar{u}^\nu \in \mathcal{U}_{\pi^\nu} \text{ and } \limsup \Phi_\nu(\bar{u}^\nu) \le \Phi(\bar{u}).$$

Fix $\bar{u} \in \mathcal{L}^r_k$. Suppose $\Phi(\bar{u}) = \infty$. Then $\limsup \Phi(u^\nu) \le \Phi(\bar{u})$ for any sequence converging (in norm) to $\bar{u}$; there exists such a sequence with $u^\nu \in \mathcal{U}_{\pi^\nu}$ since $\cup \mathcal{U}_{\pi^\nu}$ is dense in $\mathcal{L}^r_k$.

Assume then that $\Phi(\bar{u}) < \infty$. Then $\bar{u}_t \in \operatorname{dom} \varphi_t$ for almost every t. We shall construct an approximating sequence $\{\bar{u}^\nu\}$ on I_i for each i. First consider I_i satisfying hypothesis (a). Then $\bar{u}_t \in U^i$ for almost every $t \in I_i$. By Lemma 1 (taking $h(\xi) = |\xi| + \delta(\xi|U^i)$), there exists a sequence $\tilde{u}^m$ of simple functions, with $\tilde{u}^m_t \in U^i$ for all $t \in I_i$, such that $\|\tilde{u}^m - \bar{u}\|_r \to 0$ as $m \to 0$. For each $m \in \mathbf{N}$, by Lemma 2, there exists u^m which is measurable with respect to one of the partitions π^ν, has the same range as $\tilde{u}^m$, and has $\|\tilde{u}^m - u^m\|_r < 1/m$. Thus, u^m converges to $\bar{u}$ in $\mathcal{L}^r(I_i)$. Since $u^m_t \in U^i$, we have $\int_{I_i} \varphi_t(u^m_t)dt \to \int_{I_i} \varphi_t(\bar{u}_t)dt$, because the map $u \mapsto \int_{I_i} \bar{\varphi}^i_t(u_t)dt$ is continuous on $\mathcal{L}^r_k$.

Now consider I_i satisfying hypothesis (b). Then $\bar{u}_t \in \operatorname{dom} \bar{\varphi}^i$ for almost every $t \in I_i$. By Lemma 1 (with $h = \bar{\varphi}^i$), there exists a sequence $\{\tilde{u}^m\}$ of simple functions such that $\|\tilde{u}^m - \bar{u}\|_r \to 0$ as $m \to \infty$ and $\bar{\varphi}^i(\tilde{u}^m_t) \le \bar{\varphi}^i(\bar{u}_t)$ almost everwhere. In particular we have $\int_{I_i} \varphi_t(\tilde{u}^m_t)dt \le \int_{I_i} \varphi_t(\bar{u}_t)dt$ for all m. For each $m \in \mathbf{N}$ there exists, by Lemma 2, u^m, which is measurable with respect to one of the partitions π^ν and has $\|\tilde{u}^m - u^m\|_r < 1/m$. Moreover, u^m may be chosen to have the same range as $\tilde{u}^m$ and to satisfy

$$\mu\{t \in I_i | \bar{\varphi}^i(u^m_t) > \bar{\varphi}^i(\tilde{u}^m_t)\} < \frac{1}{m \cdot \max\{1, \bar{\alpha}\}},$$

where $\bar{\alpha} = \max\{\bar{\varphi}^i(\tilde{u}^m_t) - \bar{\varphi}^i(\tilde{u}^m_{t'}) | t, t' \in I_i\}$. Hence u^m may be chosen so that

$$\int_{I_i} \varphi_t(u^m_t)dt < \int_{I_i} \varphi_t(\tilde{u}^m_t)dt + (1/m).$$

Thus, the sequence $\{u^m\}$ converges to $\bar{u}$ in $\mathcal{L}^r(I_i)$, and

$$\limsup_{m\to\infty} \int_{I_i} \varphi_t(u^m_t)dt \le \int_{I_i} \varphi_t(\bar{u}_t)dt.$$

So we now have a sequence $\{u^m\}$ of $\cup_\nu \pi^\nu$-step functions which converges (in norm) to $\bar{u}$ with $\limsup_{m\to\infty} \Phi(u^m) \le \Phi(\bar{u})$. Choose $\{\nu_m\}$ with $\nu_m < \nu_{m+1}$ so that $u^m \in \mathcal{U}_{\pi^\nu}$ for $\nu = \nu_m$. We now define a sequence $\{\bar{u}^\nu\}$ satisfying (5). If $\nu_1 = 1$, set $\bar{u}^1 = u^1$; otherwise, choose $\bar{u}^1$ to be an arbitrary element of $\mathcal{U}_{\pi^1}$, and set $\bar{u}^\nu = \bar{u}^1$ for $\nu = 2, \ldots, \nu_1 - 1$. For $\nu = \nu_m, \ldots, \nu_{m-1}$ set $\bar{u}^\nu = u^m$. Thus the requirement of Mosco epi-convergence for Φ_ν is satisfied. A similar argument yields $\Psi = \text{M-e-lim}\,\Psi^\nu$. The conclusion then follows from Theorem 4. □

6. Approximation by finite differences. In the preceding sections, we introduced a model in optimal control and demonstrated that, under certain assumptions, discretization by partitioning of the time interval can be considered as a form of variational approximation (Theorem 5). Such a discretization leads to a problem in *discrete-time* optimal control. The coefficients for the discretized problem are given by integral formulas involving the fundamental matrix associated with the linear dynamics. These integrals could be evaluated numerically by various methods. In this section, however, we will take an alternative route and discretize the original problem directly using finite differences. It will be shown that this also leads to a consistent variational approximation. To simplify the presentation only the Euler forward-difference scheme is considered.

As before, we shall actually approximate the following saddle point problem which is associated with the original optimal control problem:

$$(\mathcal{S}) \qquad \text{find a saddle point } (u,v) \text{ of } \mathcal{J} \text{ relative to } \mathcal{U}^2 \times \mathcal{V}^2.$$

Here we have

$$\mathcal{J}(u,v) = \int_0^1 [p_t \cdot u_t + \varphi_t(u_t) + q_t \cdot v_t - \psi_t(v_t) - v_t \cdot D_t u_t]dt \\ + p_e \cdot u_e + \varphi_e(u_e) + q_e \cdot v_e - \psi_e(v_e) - \gamma(u,v),$$

where

$$\begin{aligned}\gamma(u,v) &= \int_0^1 x_t \cdot (C^* v_t + c)dt + x_1 \cdot (C_e^* v_e + c_e) \\ &= \int_0^1 y_t \cdot (Bu_t + b)dt + y_0 \cdot (B_e u_e + b_e)\end{aligned}$$

and the dynamics are given by

$$\begin{aligned}\dot{x}_t &= A_t x_t + B_t u_t + b_t \text{ a.e.}, & x_0 &= B_e u_e + b_e, \\ -\dot{y}_t &= A_t^* y_t + C_t^* v_t + c_t \text{ a.e.}, & y_1 &= C_e^* v_e + c_e.\end{aligned}$$

We assume that the functions φ_t and ψ_t satisfy suitable conditions for $\mathcal{J}$ to be a closed saddle function (see §§4 and 5).

We partition the unit interval with a uniform step size $h = 1/T$, where T is a positive integer. Associated with this step size will be two approximate saddle point problems. The first is the discrete-time problem given in §3, which consists of using the original saddle function and dynamics but restricting the controls to be constant on each interval $[\tau h, (\tau+1)h)$:

$$(\tilde{\mathcal{S}}_h) \qquad \begin{array}{l}\text{find a saddle point } (u_0^h, \ldots, u_T^h; v_1^h, \ldots, v_{T+1}^h) \text{ of } \tilde{\mathcal{J}}_h \\ \text{relative to } (\mathbf{R}^{k_e} \times \mathbf{R}^{kT}) \times (\mathbf{R}^{lT} \times \mathbf{R}^{l_e}).\end{array}$$

Here we define

$$\begin{aligned}&\tilde{\mathcal{J}}_h(u_0^h, \ldots, u_T^h; v_1^h, \ldots, v_{T+1}^h) \\ &\quad = \sum_{\tau=1}^{T} [\tilde{p}_\tau^h \cdot u_\tau^h + \tilde{\varphi}_\tau^h(u_\tau^h) + \tilde{q}_\tau^h \cdot v_\tau^h - \tilde{\psi}_\tau^h(v_\tau^h) - v_\tau^h \tilde{D}_\tau^h u_\tau^h - d_\tau^h] \\ &\qquad\qquad + p_e \cdot u_0^h + \varphi_e(u_0^h) + q_e \cdot v_{T+1}^h - \psi_e(v_{T+1}^h) - \tilde{\gamma}_h(u_0^h, \ldots, u_T^h; v_1^h, \ldots, v_{T+1}^h),\end{aligned}$$

where

$$\begin{aligned}\tilde\gamma_h(u_0^h,\dots,u_T^h;v_1^h,\dots,v_{T+1}^h) &= \sum_{\tau=1}^{T} \tilde x^h_{\tau-1}\cdot((\tilde C^h_\tau)^* v^h_\tau + \tilde c^h_\tau) + \tilde x^h_T\cdot(C_e^* v^h_{T+1}+c_e)\\ &= \sum_{\tau=1}^{T} \tilde y^h_{\tau+1}\cdot(\tilde B^h_\tau u^h_\tau + \tilde b^h_\tau) + \tilde y^h_1\cdot(B_e u^h_0 + b_e)\end{aligned}$$

and

$$\begin{aligned}\tilde x^h_\tau &= \tilde A^h_\tau \tilde x^h_{\tau-1} + \tilde B^h_\tau u^h_\tau + \tilde b^h_\tau, \text{ for } \tau = 1,\dots,T\\ \tilde x^h_0 &= B_e u^h_0 + b_e,\\ \tilde y^h_\tau &= (\tilde A^h_\tau)^* \tilde y^h_{\tau+1} + (\tilde C^h_\tau)^* v^h_\tau + \tilde c^h_\tau, \text{ for } \tau = T,\dots,1\\ \tilde y^h_{T+1} &= C_e^* v^h_{T+1} + c_e.\end{aligned}$$

The functions $\tilde\varphi^h$, $\tilde\psi^h$ and the coefficients $\tilde A^h_\tau$, $\tilde B^h_\tau$, $\tilde b^h_\tau$, $\tilde C^h_\tau$, $\tilde c^h_\tau$, $\tilde D^h_\tau$, $\tilde d^h_\tau$, $\tilde p^h_\tau$, $\tilde q^h_\tau$ are defined as in §3.

The following approximate problem is given using forward finite differences:

$(\hat{\mathcal{S}}_h)$ find a saddle point $(u_0^h,\dots,u_T^h;v_1^h,\dots,v_{T+1}^h)$ of $\hat{\mathcal{J}}_h$ relative to $(\mathbf{R}^{k_e}\times\mathbf{R}^{kT})\times(\mathbf{R}^{lT}\times\mathbf{R}^{l_e})$.

This problem has the same form as $(\tilde{\mathcal{S}}_h)$, but we replace $\tilde A^h_\tau$, $\tilde B^h_\tau$, $\tilde b^h_\tau$, $\tilde C^h_\tau$, $\tilde c^h_\tau$, $\tilde D^h_\tau$, $\tilde d^h_\tau$, $\tilde p^h_\tau$, and $\tilde q^h_\tau$ with coefficients $\hat A^h_\tau$, $\hat B^h_\tau$, $\hat b^h_\tau$, $\hat C^h_\tau$, $\hat c^h_\tau$, $\hat D^h_\tau$, $\hat d^h_\tau$ $\hat p^h_\tau$, and $\hat q^h_\tau$ defined by

$$\begin{aligned}&\hat A^h_\tau = I + hA_{(\tau-1)h},\\ &\hat B^h_\tau = hB_{(\tau-1)h}, \qquad \hat b^h_\tau = hb_{(\tau-1)h},\\ &\hat C^h_\tau = hC_{(\tau-1)h}, \qquad \hat c^h_\tau = hc_{(\tau-1)h},\\ &\hat D^h_\tau = hD_{(\tau-1)h}, \qquad \hat d^h_\tau = 0,\\ &\hat p^h_\tau = hp_{(\tau-1)h}, \qquad \hat q^h_\tau = hq_{(\tau-1)h}.\end{aligned}$$

We also define $\hat\varphi^h_\tau(u^h_\tau) = \varphi_{(\tau-1)h}(u^h_\tau)$ and $\hat\psi^h_\tau(v^h_\tau) = \psi_{(\tau-1)h}(v^h_\tau)$. The dynamics in this problem are given by

$$\begin{aligned}\hat x^h_\tau &= \hat A^h_\tau \hat x^h_{\tau-1} + \hat B^h_\tau u^h_\tau + \hat b^h_\tau \text{ for } \tau = 1,\dots,T,\\ \hat x^h_0 &= B_e u^h_0 + b_e,\\ \hat y^h_\tau &= (\hat A^h_\tau)^* \hat y^h_{\tau+1} + (\hat C^h_\tau)^* v^h_\tau + \hat c^h_\tau \text{ for } \tau = T,\dots,1,\\ \hat y^h_{T+1} &= C_e^* v^h_{T+1} + c_e.\end{aligned}$$

Note that the trajectories associated with problem $(\hat{\mathcal{S}}_h)$ are denoted by $(\hat x^h_0,\dots,\hat x^h_T)$ and $(\hat y^h_1,\dots,\hat y^h_{T+1})$, whereas the trajectories for $(\tilde{\mathcal{S}}_h)$ are indicated by tildes.

We shall also think of $(\tilde{\mathcal{S}}_h)$ and $(\hat{\mathcal{S}}_h)$ as problems on $\mathcal{U}^2\times\mathcal{V}^2$ by identifying $\mathbf{R}^{k_e}\times\mathbf{R}^{kT}$ and $(\mathbf{R}^{lT}\times\mathbf{R}^{l_e})$ with the subspaces $\mathcal{U}_h$ and $\mathcal{V}_h$ given by

$$\begin{aligned}\mathcal{U}_h &= \{u\in\mathcal{U}^2 \mid u_t \text{ is constant a.e. on } [(\tau-1)h,\tau h) \text{ for } \tau = 1,\dots,T\},\\ \mathcal{V}_h &= \{v\in\mathcal{V}^2 \mid v_t \text{ is constant a.e. on } [(\tau-1)h,\tau h) \text{ for } \tau = 1,\dots,T\}.\end{aligned}$$

Thus the point $(u_0^h, u_1^h, \dots, u_T^h)$ is identified with the point u, where $u_e = u_0^h$ and $u_t = u_\tau^h$ for almost every $t \in [(\tau-1)h, \tau h)$ for $\tau = 1, \dots, T$. The norm on $\mathbf{R}^{k_e} \times \mathbf{R}^{kT}$ is also given through the identification with $\mathcal{U}_h$:

$$\|(u_0^h, \dots, u_T^h)\|_h = \left(h \sum_{\tau=1}^{T} |u_\tau^h|^2 + |u_0^h|^2 \right)^{1/2}.$$

Here $|\cdot|$ denotes the Euclidean norm on $\mathbf{R}^k$ (or $\mathbf{R}^{k_e}$). A similar formula gives the norm on $\mathbf{R}^{lT} \times \mathbf{R}^{l_e}$. The functionals $\tilde{\mathcal{J}}_h$ are extended to $\mathcal{U}^2 \times \mathcal{V}^2$ by taking $\tilde{\mathcal{J}}_h(u,v)$ to be $-\infty$ if $u \in \mathcal{U}_h$ but $v \notin \mathcal{V}_h$, and to be ∞ if $u \notin \mathcal{U}_h$. We extend $\hat{\mathcal{J}}_h$ in the same manner.

As one may expect, the saddle functions $\tilde{\mathcal{J}}_h$ and $\hat{\mathcal{J}}_h$ are closely related. An important aspect of this relationship is given by the following proposition, which follows essentially from the fact that the Euler forward-difference scheme is a first-order method, combined with the continuity of the affine mapping of controls to trajectories given by the dynamics.

PROPOSITION 4. *Suppose that the coefficients $A_t, B_t, b_t, C_t, c_t, D_t, p_t, q_t$ are Lipschitzian in t. Assume there is a nonnegative constant α so that, for all $u \in \mathbf{R}^k$ and $v \in \mathbf{R}^l$, one has*

$$\varphi_s(u) \geq \varphi_t(u) - \alpha|u||s-t| \text{ and } \psi_s(v) \geq \psi_t(v) - \alpha|v||s-t| \text{ for all } s,t \in [0,1].$$

Then there exists an $r \geq 0$ such that

$$(6) \quad \tilde{\mathcal{J}}_h(u,v) - rh(\|u\|+1)(\|v\|+1) \leq \hat{\mathcal{J}}_h(u,v) \leq \tilde{\mathcal{J}}_h(u,v) + rh(\|u\|+1)(\|v\|+1)$$

for all $(u,v) \in \mathcal{U}^2 \times \mathcal{V}^2$ and all $h = 1/T$ with $T \in \mathbf{N}$.

Remarks. (i) The hypotheses on φ_t are equivalent to saying that its effective domain is a fixed set U which does not vary with t and that for a fixed $u \in U$, the function $t \mapsto \varphi_t(u)$ is Lipschitz continous on $[0,1]$ with modulus $\alpha|u|$. The analogous statement for ψ_t is also valid.

(ii) We are tacitly assuming here that the values of $\tilde{\mathcal{J}}_h$ are defined using the same conventions regarding $\infty - \infty$ that are used in defining $\hat{\mathcal{J}}_h$. If this were not the case, then we could simply replace (6) by similar inequalities involving $\overline{\mathrm{cl}}_2\, \tilde{\mathcal{J}}_h$ and $\overline{\mathrm{cl}}_2\, \hat{\mathcal{J}}_h$ (or, equivalently, $\underline{\mathrm{cl}}_1\, \tilde{\mathcal{J}}_h$ and $\underline{\mathrm{cl}}_1\, \hat{\mathcal{J}}_h$).

(iii) Note that (6) is equivalent to the inequalities given by reversing the rôles of $\tilde{\mathcal{J}}_h$ and $\hat{\mathcal{J}}_h$.

Proof of Proposition 4. It is clear that $\tilde{\mathcal{J}}_h(u,v)$ and $\hat{\mathcal{J}}_h(u,v)$ agree whenever $u \notin \mathcal{U}_h$ or $v \notin \mathcal{V}_h$. Similarly, if $(u,v) \in \mathcal{U}_h \times \mathcal{V}_h$ is identified with $(u_0^h, \dots, u_T^h; v_1^h, \dots, v_{T+1}^h)$, then $\tilde{\mathcal{J}}_h(u,v) = \hat{\mathcal{J}}_h(u,v)$ whenever one of

$$\hat{\varphi}_\tau^h(u_\tau^h),\ \hat{\psi}_\tau^h(v_\tau^h),\ \tilde{\varphi}_\tau^h(u_\tau^h), \text{ and } \tilde{\psi}_\tau^h(v_\tau^h)$$

equals $+\infty$ for some τ or when either $\varphi_e(u_0^h)$ or $\psi_e(v_{T+1}^h)$ is $+\infty$. In these cases, (6) is therefore satisfied trivially, regardless of h or r.

Now suppose that $\tilde{\varphi}_\tau(u_\tau^h)$, $\hat{\varphi}_\tau(u_\tau^h)$, $\tilde{\psi}_\tau(v_\tau^h)$, and $\hat{\psi}_\tau(v_\tau^h)$ are finite for each $\tau = 1, \dots, T$ and that $\varphi_e(u_0^h)$ and $\psi_e(v_{T+1}^h)$ are also finite. In this case we may rewrite (6) as

$$|\hat{\mathcal{J}}_h(u_0^h, \dots, u_T^h; v_1^h, \dots, v_{T+1}^h) - \tilde{\mathcal{J}}_h(u_0^h, \dots, u_T^h; v_1^h, \dots, v_{T+1}^h)| \leq rh(\|u\|+1)(\|v\|+1)$$

since both $\hat{\mathcal{J}}_h(u_0^h,\dots,u_T^h;v_1^h,\dots,v_{T+1}^h)$ and $\tilde{\mathcal{J}}_h(u_0^h,\dots,u_T^h;v_1^h,\dots,v_{T+1}^h)$ are finite. We then have

$$\begin{aligned}
&|\hat{\mathcal{J}}_h(u_0^h,\dots,u_T^h;v_1^h,\dots,v_{T+1}^h) - \tilde{\mathcal{J}}_h(u_0^h,\dots,u_T^h;v_1^h,\dots,v_{T+1}^h)| \\
&\quad\le \left|\sum_{\tau=1}^{T}\left[\hat{\varphi}_\tau^h(u_\tau^h) - \tilde{\varphi}_\tau^h(u_\tau^h) + \tilde{\psi}_\tau^h(v_\tau^h) - \hat{\psi}_\tau^h(v_\tau^h)\right]\right| \\
&\qquad\qquad + \left|\sum_{\tau=1}^{T}\left[(\hat{p}_\tau^h - \tilde{p}_\tau^h)\cdot u_\tau^h + (\hat{q}_\tau^h - \tilde{q}_\tau^h)\cdot v_\tau^h + v_\tau^h\cdot(\tilde{D}_\tau^h u_\tau^h - \hat{D}_\tau^h)u_\tau^h + \tilde{d}_\tau^h\right]\right| \\
&\qquad\qquad\quad + |\tilde{\gamma}_h(u_0^h,\dots,u_T^h;v_1^h,\dots,v_{T+1}^h) - \hat{\gamma}_h(u_0^h,\dots,u_T^h;v_1^h,\dots,v_{T+1}^h)|.
\end{aligned}$$

Thus, to prove (6) it suffices to find r_1, r_2, and r_3 so that the following three inequalities are satisfied:

$$\left|\sum_{\tau=1}^{T}\left[\hat{\varphi}_\tau^h(u_\tau^h) - \tilde{\varphi}_\tau^h(u_\tau^h)\right]\right| + \left|\sum_{\tau=1}^{T}\left[\tilde{\psi}_\tau^h(v_\tau^h) - \hat{\psi}_\tau^h(v_\tau^h)\right]\right| \le r_1 h(\|u\| + \|v\|),$$

$$\begin{aligned}
&\left|\sum_{\tau=1}^{T}\left[(\hat{p}_\tau^h - \tilde{p}_\tau^h)\cdot u_\tau^h + (\hat{q}_\tau^h - \tilde{q}_\tau^h)\cdot v_\tau^h + v_\tau^h\cdot(\tilde{D}_\tau^h u_\tau^h - \hat{D}_\tau^h)u_\tau^h + \tilde{d}_\tau^h\right]\right| \\
&\qquad\qquad\qquad\qquad\le r_2 h(\|u\| + 1)(\|v\| + 1),
\end{aligned}$$

$$|\tilde{\gamma}_h(u_0^h,\dots,u_T^h;v_1^h,\dots,v_{T+1}^h) - \hat{\gamma}_h(u_0^h,\dots,u_T^h;v_1^h,\dots,v_{T+1}^h)| \le r_3 h(\|u\| + 1)(\|v\| + 1).$$

In what follows we sketch how to obtain values for these r_i. For a Lipschitz-continuous matrix-valued function ξ on $[0,1]$, let $\mathrm{Lip}(\xi)$ denote the Lipschitz constant for ξ and define $\|\xi\|_\infty = \sup_{t\in[0,1]}|\xi_t|$. It is easily verified that there exists a constant $\beta > 0$ (which depends only on the function A_t) such that the following estimates hold for all $\tau = 1,\dots,T$:

$$\left|\int_{(\tau-1)h}^{\tau h}\xi_t\,dt - h\xi_{(\tau-1)h}\right| \le \frac{h^2}{2}\mathrm{Lip}(\xi), \tag{7}$$

$$\left|\int_{(\tau-1)h}^{\tau h}\left(\xi_t\mathcal{A}_t\int_{(\tau-1)h}^{t}\mathcal{A}_s^{-1}\eta_s\,ds\right)\,dt\right| \le h^2\beta\|\xi\|_\infty\|\eta\|_\infty, \tag{8}$$

$$\left|\int_{(\tau-1)h}^{\tau h}\mathcal{A}_{\tau h}\mathcal{A}_t^{-1}\xi_t\,dt - h\xi_{(\tau-1)h}\right| \le h^2\beta\cdot[\|\xi\|_\infty + \mathrm{Lip}(\xi)], \tag{9}$$

$$\left|\int_{(\tau-1)h}^{\tau h}\xi_t\mathcal{A}_t\mathcal{A}_{(\tau-1)h}^{-1}\,dt - h\xi_{(\tau-1)h}\right| \le h^2\beta\cdot[\|\xi\|_\infty + \mathrm{Lip}(\xi)]. \tag{10}$$

Now, to find r_1 we use the hypotheses on φ_t and ψ_t (via Remark (i) above) and apply inequality (7) with $\xi_t = \varphi_t(u_\tau^h)$ and $\xi_t = \psi_t(v_\tau^h)$. This yields $r_1 = \alpha/2$.

Next we deal with r_2. Note that we have

$$\left|\sum_{\tau=1}^{T}(\hat{p}_\tau^h - \tilde{p}_\tau^h)\cdot u_\tau^h\right| \le \left(\max_\tau|\hat{p}_\tau^h - \tilde{p}_\tau^h|\right)\left(\sum_{\tau=1}^{T}|u_\tau^h|\right) \le \frac{1}{h}\left(\max_\tau|\hat{p}_\tau^h - \tilde{p}_\tau^h|\right)\|u^h\|_h.$$

By applying inequality (7) with $\xi_t = p_t$ and then inequality (8) with $\xi_t = c_t$ and $\eta_s = B_s$ we see that, for each τ,

$$|\hat{p}_\tau^h - \tilde{p}_\tau^h| \le \frac{h^2}{2}\mathrm{Lip}(p) + h^2\beta\|c\|_\infty\|B\|_\infty.$$

Thus we obtain the bound

$$\left|\sum_{\tau=1}^{T}(\hat{p}_\tau^h - \tilde{p}_\tau^h)\cdot u_\tau^h\right| \le h\left[\frac{1}{2}\mathrm{Lip}(p) + \beta\|c\|_\infty\|B\|_\infty\right]\|u^h\|_h.$$

By similar arguments, we find that

$$\left|\sum_{\tau=1}^{T}(\hat{q}_\tau^h - \tilde{q}_\tau^h)\cdot v_\tau^h\right| \le h\left[\frac{1}{2}\mathrm{Lip}(q) + \beta\|b\|_\infty\|C\|_\infty\right]\|v^h\|_h,$$

$$\left|\sum_{\tau=1}^{T}\tilde{d}_\tau^h\right| \le h\beta\|b\|_\infty\|c\|_\infty,$$

$$\left|\sum_{\tau=1}^{T}v_\tau^h\cdot(\hat{D}_\tau^h - \tilde{D}_\tau^h)u_\tau^h\right| \le h\left[\frac{1}{2}\mathrm{Lip}(D) + \beta\|B\|_\infty\|C\|_\infty\right]\|u^h\|_h\|v^h\|_h.$$

Therefore we can take r_2 to be given by

$$r_2 = \max\{\mathrm{Lip}(p), \mathrm{Lip}(q), \mathrm{Lip}(D)\} + \beta\cdot\max\{\|b\|_\infty, \|B\|_\infty, \|c\|_\infty, \|C\|_\infty\}^2.$$

Finally we turn to finding the coefficient r_3. First we see that

$$\begin{aligned}
&|\tilde{\gamma}_h(u_0^h,\dots,u_T^h;v_1^h,\dots,v_{T+1}^h) - \hat{\gamma}_h(u_0^h,\dots,u_T^h;v_1^h,\dots,v_{T+1}^h)| \\
&\qquad\le \left|\sum_{\tau=1}^{T}v_\tau^h\cdot(\tilde{C}_\tau^h\tilde{x}_{\tau-1}^h - \hat{C}_\tau^h\hat{x}_{\tau-1}^h)\right| + \left|v_{T+1}^h\cdot C_e(\tilde{x}_T^h - \hat{x}_T^h)\right| \\
&\qquad\quad + \left|\sum_{\tau=1}^{T}\tilde{c}_\tau^h\cdot\tilde{x}_{\tau-1}^h - \hat{c}_\tau^h\cdot\hat{x}_{\tau-1}^h\right| + \left|c_e\cdot(\tilde{x}_T^h - \hat{x}_T^h)\right| \\
&\qquad\le \frac{1}{h}\|v^h\|_h\cdot\max_\tau\left|\tilde{C}_\tau^h\tilde{x}_{\tau-1}^h - \hat{C}_\tau^h\hat{x}_{\tau-1}^h\right| + \|v^h\|_h\cdot\left|C_e(\tilde{x}_T^h - \hat{x}_T^h)\right| \\
&\qquad\quad + \frac{1}{h}\|v^h\|_h\cdot\max_\tau\left|\tilde{c}_\tau^h\cdot\tilde{x}_{\tau-1}^h - \hat{c}_\tau^h\cdot\hat{x}_{\tau-1}^h\right| + \|v^h\|_h\cdot\left|c_e\cdot(\tilde{x}_T^h - \hat{x}_T^h)\right|.
\end{aligned}\tag{11}$$

Observing that

$$\left|\tilde{C}_\tau^h\tilde{x}_{\tau-1}^h - \hat{C}_\tau^h\hat{x}_{\tau-1}^h\right| \le \left|\tilde{C}_\tau^h - \hat{C}_\tau^h\right|\left|\tilde{x}_{\tau-1}^h\right| + \left|\tilde{x}_{\tau-1}^h - \hat{x}_{\tau-1}^h\right|\left|\hat{C}_\tau^h\right| \tag{12}$$

and

$$\left|\tilde{c}_\tau^h\cdot\tilde{x}_{\tau-1}^h - \hat{c}_\tau^h\cdot\hat{x}_{\tau-1}^h\right| \le \left|\tilde{c}_\tau^h - \hat{c}_\tau^h\right|\left|\tilde{x}_{\tau-1}^h\right| + \left|\tilde{x}_{\tau-1}^h - \hat{x}_{\tau-1}^h\right|\left|\hat{c}_\tau^h\right|, \tag{13}$$

we see that we need upper bounds, in terms of h and $\|u^h\|_h$, for the quantities

$$\left|\tilde{C}_\tau^h - \hat{C}_\tau^h\right|,\ \left|\tilde{x}_\tau^h\right|,\ \left|\tilde{x}_\tau^h - \hat{x}_\tau^h\right|,\ \left|\hat{C}_\tau^h\right|,\ \left|\tilde{c}_\tau^h - \hat{c}_\tau^h\right|,\ \text{and}\ \left|\hat{c}_\tau^h\right|$$

for each τ. By using the expansions

$$\hat{x}_\tau^h = \left[(\hat{A}_\tau^h\cdots\hat{A}_1^h)(B_e u_0^h + b_e)\right] + \sum_{\tau'=1}^{\tau}\left[(\hat{A}_\tau^h\cdots\hat{A}_{\tau'+1}^h)(\hat{B}_{\tau'}^h u_{\tau'}^h + \hat{b}_{\tau'}^h)\right],$$

$$\tilde{x}_\tau^h = \left[(\tilde{A}_\tau^h\cdots\tilde{A}_1^h)(B_e u_0^h + b_e)\right] + \sum_{\tau'=1}^{\tau}\left[(\tilde{A}_\tau^h\cdots\tilde{A}_{\tau'+1}^h)(\tilde{B}_{\tau'}^h u_{\tau'}^h + \tilde{b}_{\tau'}^h)\right]$$

and continuing with repeated use of inequalities (8)–(10) we can obtain

$$\left|\hat{C}_T^h\right| \le h\|C\|_\infty, \qquad \left|\hat{c}_T^h\right| \le h\|c\|_\infty,$$
$$\left|\tilde{C}_T^h - \hat{C}_T^h\right| \le h^2\beta[\|C\|_\infty + \mathrm{Lip}(C)], \qquad \left|\tilde{c}_T^h - \hat{c}_T^h\right| \le h^2\beta[\|c\|_\infty + \mathrm{Lip}(c)],$$
$$\left|\tilde{x}_T^h\right| \le e^{2\|A\|_\infty} \cdot \left[(\|B\|_\infty + |B_e|)\|u^h\|_h + (\|b\|_\infty + |b_e|)\right],$$
$$\left|\tilde{x}_T^h - \hat{x}_T^h\right| \le h\beta e^{2\|A\|_\infty} \cdot \left[\rho(A, B, B_e)\|u^h\|_h + \rho(A, b, b_e)\right],$$

where

$$\rho(A, B, B_e) = \Big(\|B\|_\infty + |B_e|\Big)\Big(\|A\|_\infty + \mathrm{Lip}(A)\Big) + \Big(\|B\|_\infty + \mathrm{Lip}(B)\Big)$$
$$\rho(A, b, b_e) = \Big(\|b\|_\infty + |b_e|\Big)\Big(\|A\|_\infty + \mathrm{Lip}(A)\Big) + \Big(\|b\|_\infty + \mathrm{Lip}(b)\Big).$$

These inequalities supply us with an upper bound for (11) via (12) and (13), yielding a value for r_3. □

The proposition just proved tells us, in particular, that the nets $\{\tilde{\mathcal{J}}_h\}$ and $\{\hat{\mathcal{J}}_h\}$ are "uniformly cofinal" on bounded sets: for a fixed $\rho > 0$ and $r_\rho = r(\rho + 1)^2$, we have

$$\tilde{\mathcal{J}}_h(u, v) - r_\rho h \le \hat{\mathcal{J}}_h(u, v) \le \tilde{\mathcal{J}}_h(u, v) + r_\rho h$$

whenever $\|u\| \le \rho$ and $\|v\| \le \rho$. The uniformity in (6) actually guarantees that the problems $(\tilde{\mathcal{S}}_h)$ and $(\hat{\mathcal{S}}_h)$ are close from a variational standpoint. This is illustrated by the next theorem.

THEOREM 6. *Suppose $\{T_m\}$ is an increasing sequence of positive integers and let $h_m = 1/T_m$. Consider a proper closed saddle function $\mathcal{K}$ defined on $\mathcal{U}^2 \times \mathcal{V}^2$. Under the hypotheses of Proposition 4, the sequence $\{\hat{\mathcal{J}}_{h_m}\}$ epi/hypo-converges to $\mathcal{K}$ if and only if $\{\tilde{\mathcal{J}}_{h_m}\}$ epi/hypo-converges to $\mathcal{K}$.*

Proof. This follows from the definition of epi/hypo-convergence by combining inequality (6) with the fact that weakly convergent sequences are norm-bounded. □

Combined with Theorem 5, the above result gives us sufficient conditions for the problems $\{(\hat{\mathcal{S}}_h)\}$ to be variational approximations to $(\mathcal{S})$.

We close with a few remarks concerning the advantages and disadvantages of the two discretization schemes considered in this paper. The main consistency result (Theorem 5) applies to the basic discretization scheme given by restricting the controls to belong to the class of step functions over a predetermined partition of the time interval. Since the hypotheses for Theorem 5 are very mild, it is applicable to a wide class of problems. The dicretization entails the calculation of various integrals involving the fundamental matrix solution of the linear dynamics. In the autonomous case, where the data are constant with respect to time, these integrals can be expressed in terms of the power series representation of the matrix exponential. In practice, an adequate approximation for the series requires a study of the eigensystems of the matrix A. For general nonautonomous systems, the fundamental matrix solution is unlikely to be available in closed form, so further approximation is needed. The integrals defining the data of problem $(\tilde{\mathcal{P}})$ of §3 must then be calculated with the approximate matrix solution. It considerably simplifies the computations if instead we use the finite-difference scheme given in the current section. The primary drawback is that this is only a first-order scheme. If the data is sufficiently smooth, then computationally efficient higher-order methods should be employed. (Analogously, in the basic discretization scheme we could replace step functions by higher-order piecewise polynomial functions.) We are led then to questions concerning the *rate of convergence* for various discretization schemes and their efficient implementation. These issues will need to be addressed in future work.

ERROR BOUNDS FOR PIECEWISE CONVEX QUADRATIC PROGRAMS AND APPLICATIONS*

WU LI[†]

Abstract. In this paper, we establish a local error estimate for feasible solutions of a piecewise convex quadratic program and a global error estimate for feasible solutions of a convex piecewise quadratic program. These error estimates provide a unified approach for deriving many old and new error estimates for linear programs, linear complementarity problems, convex quadratic programs, and affine variational inequality problems. The approach reveals the fact that each error estimate is a consequence of some reformulation of the original problem as a piecewise convex quadratic program or a convex piecewise quadratic program. In a sense, even Robinson's result on the upper Lipschitz continuity of a polyhedral mapping can be considered as a special case of error estimates for approximate solutions of a piecewise convex quadratic program. As an application, we derive new (global) error estimates for iterates of the proximal point algorithm for solving a convex piecewise quadratic program.

Key words. local error bound, global error bound, piecewise convex quadratic program, convex quadratic program, monotone linear complementarity problem, affine variational inequality problem, proximal point algorithm, rate of convergence

AMS subject classifications. Primary, 90C31; Secondary, 90C20, 90C33

1. Introduction.

In a series of papers by Luo and Tseng [18]–[22], local error estimates for approximate solutions of a constrained convex minimization problem were proven to be crucial in convergence analysis of descent (or dual ascent) methods for solving constrained convex minimization problems (cf. also [26], [12], [14]). Meanwhile, Ferris [4] showed that the weak sharp minimum property of the solution set of a constrained convex minimization problem is sufficient for the finite convergence of the proximal point algorithm for solving the constrained convex minimization problem. As a consequence, Ferris established the finite convergence of the proximal point algorithm for solving a linear program, since the solution set of a linear program has the weak sharp minimum property [27]. The common feature of an error estimate for approximate solutions and the weak sharp minimum property is the estimation of the distance from an approximate solution to the solution set of the constrained convex minimization problem. In this paper, we give error estimates for feasible solutions of a piecewise convex quadratic program and show some applications of such estimates. In particular, this paper provides a unique perspective to the relationship between Mangasarian and Meyer's weak sharp minimum property of the solution(s) of a linear program [27] and Luo and Tseng's local error estimate for approximate solutions of an affine variational inequality problem [21]. As applications of error estimates for feasible solutions of a convex piecewise quadratic program, we obtain a new global error estimate for approximate solutions of a monotone linear complementarity problem and a new global error estimate for iterates generated by the proximal point algorithm for solving a convex piecewise quadratic program.

Our research on piecewise convex quadratic programs is motivated by a reformulation of certain convex quadratic programs as the problem of minimizing a convex

*Received by the editors January 19, 1993; accepted for publication (in revised form) May 3, 1994.

[†]Department of Mathematics and Statistics, Old Dominion University, Norfolk, Virginia 23529 (wuli@math.odu.edu).

quadratic spline without any constraint [15], [16]. A Newton method with exact line minimization seems very effective for finding the minimizer of a strictly convex quadratic spline [15]. Therefore, it is natural to consider the proximal point algorithm for finding a minimizer of a convex quadratic spline, since one only needs to find the minimizer of a strictly convex quadratic spline in each iteration. Also it is possible to design new iterative algorithms for finding a minimizer of a convex quadratic spline [16]. The error estimates are useful for studying the convergence behavior of new iterative algorithms for solving the unconstrained minimization of a convex quadratic spline (cf. [16]). Moreover, convex piecewise quadratic programs are related to a linear-quadratic minimax problem studied by Rockafellar and Wets in their research on stochastic programming and optimal control problems [34]–[36] (also cf. [37] and some references there).

In §2, we establish local error estimates for feasible solutions of piecewise convex quadratic programs and global error estimates of convex piecewise quadratic programs. In §3, we shows that most existing error estimates for linear programs, linear complementarity problems, and affine variational inequality problems can be recovered easily as consequences of error estimates given in §2. A new global error estimate for monotone linear complementarity problems is derived by using error estimates for convex piecewise quadratic programs. Section 4 is devoted to new error estimates of iterates of the proximal point algorithm, which reveals a new perspective on the relationship between the convergence rate of the proximal point algorithm and the error estimate for feasible solutions. In §5 we mention a few possible extensions of the results to general mathematical programming problems and show how one can view Robinson's result on the upper Lipschitz continuity of a polyhedral mapping as a special case of an error estimate for approximate solutions of a piecewise convex quadratic program.

Now let us give some common assumptions and notations used in the paper. Consider the following minimization problem:

$$f_{\min} := \min_{x \in X} f(x), \tag{1.1}$$

where X is a closed convex polyhedral subset of the n-dimensional Euclidean space $\mathbb{R}^n$. We assume that $f_{\min} > -\infty$ and the solution set of (1.1) is not empty; i.e.,

$$X^* := \{x \in X : f(x) = f_{\min}\} \neq \emptyset.$$

The 2-norm on $\mathbb{R}^n$ is denoted by $\|x\| := \left(\sum_{i=1}^n x_i^2\right)^{1/2}$. The distance from a vector x to the solution set X^* of (1.1) is defined as

$$\operatorname{dist}(x, X^*) := \min\{\|x - x^*\| : x^* \in X^*\}.$$

The transpose of a vector x (or a matrix M) is denoted by x^T (or M^T). For two vectors $x, y \in \mathbb{R}^n$, we write $x \leq y$ if $x_i \leq y_i$ for $1 \leq i \leq n$. A continuous function f on $\mathbb{R}^n$ is called a piecewise (convex) quadratic function if there are finitely many convex polyhedral subsets $\{C_i\}_{i=1}^m$ of $\mathbb{R}^n$ such that $\mathbb{R}^n = \bigcup_{i=1}^m C_i$ and f is a (convex) quadratic function on each C_i. A piecewise convex quadratic function f is called a convex piecewise quadratic function if f is also a convex function. A quadratic spline is a differentiable piecewise quadratic function and a convex quadratic spline is a differentiable convex piecewise quadratic function. We use $f'(x)$ to denote the gradient of $f(x)$ as a column vector.

2. Error bounds for piecewise convex quadratic programs. In this section we give local and global error estimates of $\operatorname{dist}(x, X^*)$ in terms of $(f(x) - f_{\min})$. We first establish error estimates for convex quadratic programs and then extend the results for piecewise convex quadratic programs by using Frank–Wolfe's theorem on solvability of a quadratic program. The main results are Theorems 2.5, 2.6, and 2.7. However, Lemma 2.3, based on the following geometric feature of a polyhedral set and Mangasarian's characterization of the solutions of a convex quadratic program, is crucial for establishing all error estimates in this section.

LEMMA 2.1. *Suppose that $x^k, y^k \in X$ with $x^k \neq y^k$ and*

$$\lim_{k\to\infty} \frac{x^k - y^k}{\|x^k - y^k\|} = z.$$

Then there exist positive constants α_k such that $z^k := y^k + \alpha_k z \in X$ and

$$\lim_{k\to\infty} \frac{\|x^k - z^k\|}{\|x^k - y^k\|} = 0.$$

Proof. Suppose that $X := \{x \in \mathbb{R}^n : Ax \geq b\}$. Let $0 < \lambda < 1$ and $w^k := y^k + \lambda\|x^k - y^k\|z$. Obviously, $(Aw^k)_i \geq (Ay^k)_i \geq b_i$ for $(Az)_i \geq 0$. If $(Az)_i < 0$, then, for k large enough,

$$(Aw^k)_i = (Ax^k)_i + \|x^k - y^k\| \left(A\left(\lambda z - \frac{x^k - y^k}{\|x^k - y^k\|}\right)\right)_i \geq b_i, \tag{2.1}$$

since

$$\lim_{k\to\infty} \left(A\left(\lambda z - \frac{x^k - y^k}{\|x^k - y^k\|}\right)\right)_i = (\lambda - 1)(Az)_i > 0.$$

Since there are only finitely many indices, there exists $k_{\lambda,1} \geq 1$ such that (2.1) holds whenever $(Az)_i < 0$ and $k \geq k_{\lambda,1}$. That is, $w^k \in X$ if $k \geq k_{\lambda,1}$.

On the other hand, since

$$\lim_{k\to\infty} \left\| \frac{x^k - y^k}{\|x^k - y^k\|} - \lambda z \right\| = (1 - \lambda)\|z\| = 1 - \lambda,$$

we obtain that there exists $k_{\lambda,2} \geq 1$ such that, for $k \geq k_{\lambda,2}$,

$$\|x^k - w^k\| = \|x^k - y^k\| \cdot \left\| \frac{x^k - y^k}{\|x^k - y^k\|} - \lambda z \right\| \leq 2(1 - \lambda)\|x^k - y^k\|. \tag{2.2}$$

Set $k_\lambda := \max\{k_{\lambda,1}, k_{\lambda,2}\}$. Then (2.1) and (2.2) hold when $k \geq k_\lambda$.

Let $\lambda_s = 1 - \frac{1}{s}$ for $s = 1, 2\ldots$. Then there exist k_{λ_s} such that (2.1) and (2.2) hold with $\lambda = \lambda_s$ when $k \geq k_{\lambda_s}$. We may assume $k_{\lambda_{s+1}} > k_{\lambda_s}$ for $s = 1, 2, \ldots$. Define $\alpha_k = \lambda_s\|x^k - y^k\|$ and $z^k = y^k + \alpha_k z$ for $k_{\lambda_s} \leq k < k_{\lambda_{s+1}}$ and $s = 1, 2, \ldots$. Then $z^k \in X$ and

$$\frac{\|x^k - z^k\|}{\|x^k - y^k\|} \leq 2(1 - \lambda_s) = \frac{2}{s} \quad \text{for } k \geq k_{\lambda_s}, \;\; s = 1, 2, \ldots. \qquad \square$$

To prove the most important lemma in this section, we need the following characterization of the solutions of a convex quadratic program by Mangasarian [25].

LEMMA 2.2. *Suppose that $f(x) := \frac{1}{2}x^TBx + c^Tx$ is a convex quadratic function, x^* in X^*, and $\bar{x} \in X$. Then the following statements are equivalent:*

(1) $\bar{x} \in X^*$;

(2) $f'(x^*)^T(\bar{x} - x^*) \le 0$ *and* $(\bar{x} - x^*)^TB(\bar{x} - x^*) \le 0$;

(3) $f'(\bar{x}) = f'(x^*)$ *and* $B(\bar{x} - x^*) = 0$;

(4) $f'(\bar{x})^T(x - \bar{x}) \ge 0$ *for any* $x \in X$.

LEMMA 2.3. *Suppose that $f(x)$ is a convex quadratic function. Then, for any constant $\delta > 0$, there exists a positive constant γ such that*

$$\operatorname{dist}(x, X^*) \le \gamma\sqrt{f(x) - f_{\min}} \quad \textit{for } x \in X \text{ with } f(x) - f_{\min} \le \delta. \tag{2.3}$$

Proof. Let $x \in X$ and $\bar{x}, x^* \in X^*$. Then

$$\begin{aligned} f(x) - f(\bar{x}) &= f'(\bar{x})^T(x - \bar{x}) + \frac{1}{2}(x - \bar{x})^TB(x - \bar{x}) \\ &\ge \max\left\{f'(\bar{x})^T(x - \bar{x}), \frac{1}{2}(x - \bar{x})^TB(x - \bar{x})\right\} \\ &= \max\left\{f'(x^*)^T(x - \bar{x}), \frac{1}{2}(x - \bar{x})^TB(x - \bar{x})\right\}, \end{aligned} \tag{2.4}$$

where the first equality is the Taylor expansion of f at $\bar{x}$, the inequality derived from $f'(\bar{x})^T(x - \bar{x}) \ge 0$ (cf. Lemma 2.2 (4)) and $(x - \bar{x})^TB(x - \bar{x}) \ge 0$, and the second equality follows from Lemma 2.2 (3).

Assume the contrary, that there exists a sequence $\{x^k\} \subset X$ such that $f(x) - f_{\min} \le \delta$ and

$$\lim_{k\to\infty} \frac{\sqrt{f(x^k) - f_{\min}}}{\operatorname{dist}(x^k, X^*)} = 0. \tag{2.5}$$

Let $\bar{x}^k \in X^*$ be such that $\|x^k - \bar{x}^k\| = \operatorname{dist}(x^k, X^*)$ and set $z^k := \frac{x^k - \bar{x}^k}{\|x^k - \bar{x}^k\|}$. Then, by (2.4),

$$\frac{f(x^k) - f(\bar{x}^k)}{\|x^k - \bar{x}^k\|^2} \ge \frac{1}{2}(z^k)^TBz^k. \tag{2.6}$$

Without loss of generality, we may assume that $z^k \to z$ as $k \to \infty$. Then it follows from (2.5) and (2.6) that $z^TBz \le 0$. If $\operatorname{dist}(x^k, X^*) \le \delta$ for infinitely many k's, then, by selecting a subsequence, we may assume that $\operatorname{dist}(x^k, X^*) \le \delta$ for all k. In this case, by (2.4),

$$\frac{f(x^k) - f(\bar{x}^k)}{\|x^k - \bar{x}^k\|^2} \ge \frac{1}{\|x^k - \bar{x}^k\|}f'(x^*)^Tz^k \ge \frac{1}{\delta}f'(x^*)^Tz^k. \tag{2.7}$$

By (2.5) and (2.7), we obtain that $f'(x^*)^Tz \le 0$. If $\operatorname{dist}(x^k, X^*) \le \delta$ for finitely many k's, then, by selecting a subsequence, we may assume that $\operatorname{dist}(x^k, X^*) > \delta > 0$ for all k. In this case, since $f(x) - f_{\min} \le \delta$, (2.5) is equivalent to

$$\lim_{k\to\infty} \frac{f(x^k) - f(\bar{x}^k)}{\|x^k - \bar{x}^k\|} = 0. \tag{2.8}$$

By (2.4),

$$\frac{f(x^k)-f(\bar{x}^k)}{\|x^k-\bar{x}^k\|} \geq f'(x^*)^T z^k. \tag{2.9}$$

Again, we get $f'(x^*)^T z \leq 0$ from (2.8) and (2.9).

On the other hand, by Lemma 2.1, there exist positive constants α_k such that $y^k := x^k + \alpha_k z \in X$ and

$$\lim_{k\to\infty} \frac{\|x^k-y^k\|}{\|x^k-\bar{x}^k\|} = 0. \tag{2.10}$$

Since $\|x^k-\bar{x}^k\| = \operatorname{dist}(x^k, X^*)$, (2.10) implies $y^k \notin X^*$ when k is large enough. It follows from Lemma 2.2 (2) and (3) that either

$$f'(x^*)^T z = \frac{1}{\alpha_k} f'(\bar{x}^k)^T (y^k - \bar{x}^k) > 0$$

or

$$z^T B z = \frac{1}{\alpha_k^2}(y^k-\bar{x}^k)^T B (y^k - \bar{x}^k) > 0,$$

a contradiction to $f'(x^*)^T z \leq 0$ and $z^T B z \leq 0$. □

Remark. In contrast to (2.3), Ferris and Mangasarian [5] performed a detailed analysis on characterization conditions which guarantee the global error estimate $\operatorname{dist}(x, X^*) \leq \gamma(f(x) - f_{\min})$ for $x \in X$.

Now, to extend the above estimate for piecewise convex quadratic programs, we need the following theorem by Frank and Wolfe about the solvability of a quadratic program [6].

LEMMA 2.4. *Suppose that f is a quadratic function. If $f_{\min} > -\infty$, then $X^* \neq \emptyset$.*

Using Lemma 2.4 we can easily show (2.3) still holds if f is a piecewise convex quadratic function.

THEOREM 2.5. *If f is a piecewise convex quadratic function, then there exist positive constants δ and γ such that*

$$\operatorname{dist}(x, X^*) \leq \gamma\sqrt{f(x) - f_{\min}} \quad \text{for } x \in X \text{ with } f(x) - f_{\min} \leq \delta. \tag{2.11}$$

Proof. Let $X = \bigcup_{i=1}^{s} X_i$, where X_i's are closed convex polyhedral subsets of X such that f is a convex quadratic function on every X_i. Define $\delta := \min\left\{\frac{\delta_i}{2} : \delta_i > 0, 1 \leq i \leq s\right\} > 0$, where $\delta_i := \min_{x\in X_i} f(x) - f_{\min}$. If $X_i \cap X^* \neq \emptyset$, by Lemma 2.3, there exists $\gamma_i > 0$ such that

$$\operatorname{dist}(x, X^*) \leq \operatorname{dist}(x, X^* \cap X_i) \leq \gamma_i \sqrt{f(x) - f_{\min}} \quad \text{for } x \in X_i \text{ with } f(x) - f_{\min} \leq \delta. \tag{2.12}$$

Let $\gamma := \max\{\gamma_i : X_i \cap X^* \neq \emptyset\}$. By the definition of δ, if $x \in X$ with $f(x) - f_{\min} \leq \delta$, then $x \in X_i$ with $\min_{x\in X_i} f(x) = f_{\min}$. By Lemma 2.4, $X^* \cap X_i \neq \emptyset$. Therefore, (2.12) holds, which implies (2.11). □

The estimate (2.11) is called a local error estimate in the sense that the estimate (2.11) only holds for x near the solution set X^* (cf. Corollary 2.9). Next we give an error estimate for feasible solutions away from the solution set X^* (cf. Corollary 2.10).

THEOREM 2.6. *Suppose that f is a convex piecewise quadratic function. Then, for any constant $\delta > 0$, there exists a positive constant γ such that*

$$\operatorname{dist}(x, X^*) \le \gamma\,(f(x) - f_{\min}) \quad \textit{for } x \in X \textit{ with } f(x) - f_{\min} \ge \delta. \tag{2.13}$$

Proof. Assume the contrary, that there exists a sequence $\{x^k\} \subset X$ such that $f(x) - f_{\min} \ge \delta$ and

$$\lim_{k\to\infty} \frac{f(x^k) - f(\bar{x}^k)}{\|x^k - \bar{x}^k\|} = 0, \tag{2.14}$$

where $\bar{x}^k \in X^*$ with $\|x^k - \bar{x}^k\| = \operatorname{dist}(x^k, X^*)$. We may assume $\|x^k - \bar{x}^k\| > \delta$ for all $k \ge 1$. Then $y^k := \bar{x}^k + \lambda_k(x^k - \bar{x}^k) \in X$ with $\lambda_k := \frac{\delta}{\|x^k - \bar{x}^k\|}$. For any $\bar{x} \in X^*$,

$$\|x^k - \bar{x}^k\| \le \|x^k - \bar{x}\| \le \|x^k - y^k\| + \|y^k - \bar{x}\| = (1 - \lambda_k)\|x^k - \bar{x}^k\| + \|y^k - \bar{x}\|,$$

which implies $\|y^k - \bar{x}\| \ge \delta = \|y^k - \bar{x}^k\|$ for $\bar{x} \in X^*$. Therefore, $\operatorname{dist}(y^k, X^*) = \|y^k - \bar{x}^k\| = \delta$. On the other hand, by the convexity of f,

$$f(y^k) \le (1 - \lambda_k) f(\bar{x}^k) + \lambda_k f(x^k) = f_{\min} + \delta \cdot \frac{f(x^k) - f(\bar{x}^k)}{\|x^k - \bar{x}^k\|} \to f_{\min}.$$

By Theorem 2.5, $\operatorname{dist}(y^k, X^*) \to 0$ as $k \to \infty$. The contradiction proves (2.13). □

If f is only a piecewise convex quadratic function, then Theorem 2.6 is not true. In general, (2.11) does not hold for any $\delta \ge 0$ (cf. Mangasarian and Shiau's example [29]). However, for a convex piecewise quadratic function, the restriction on δ can be removed.

THEOREM 2.7. *Suppose that f is a convex piecewise quadratic function. Then, for any constant $\delta \ge 0$, there exists a positive constant γ such that*

$$\operatorname{dist}(x, X^*) \le \gamma\sqrt{f(x) - f_{\min}} \quad \textit{for } x \in X \textit{ with } f(x) - f_{\min} \le \delta. \tag{2.15}$$

Proof. By Theorem 2.5, there exist positive constants δ_0 and γ_1 such that

$$\operatorname{dist}(x, X^*) \le \gamma_1\sqrt{f(x) - f_{\min}} \quad \text{for } x \in X \text{ with } f(x) - f_{\min} \le \delta_0. \tag{2.16}$$

By Theorem 2.6, there exists a constant $\gamma_2 > 0$ such that

$$\operatorname{dist}(x, X^*) \le \gamma_2(f(x) - f_{\min}) \quad \text{for } x \in X \text{ with } f(x) - f_{\min} \ge \delta_0. \tag{2.17}$$

If $\delta_0 \le f(x) - f_{\min} \le \delta$, then $f(x) - f_{\min} \le \delta \le \frac{\delta}{\sqrt{\delta_0}}\sqrt{f(x) - f_{\min}}$. Therefore, it follows from (2.16) and (2.17) that (2.15) holds with $\gamma := \max\{\gamma_1, \frac{\gamma_2\delta}{\sqrt{\delta_0}}\}$. □

An easy consequence of Theorems 2.5 and 2.6 is the following global error estimate for feasible approximate solutions to a convex piecewise quadratic program.

COROLLARY 2.8. *Suppose that f is a convex piecewise quadratic function. Then there exists a positive constant γ such that*

$$\operatorname{dist}(x, X^*) \le \gamma\left(f(x) - f_{\min} + \sqrt{f(x) - f_{\min}}\right) \quad \textit{for } x \in X. \tag{2.18}$$

Remark. Recently, Luo and Pang [17] studied error estimates for approximate solutions of nonlinear feasibility problems:

$$\begin{aligned} &f_i(x) = 0, \qquad 1 \le i \le m, \\ &Ax \ge b. \end{aligned} \tag{2.19}$$

Let X^* denote the solution set of (2.19). Then they established various bounds for $\operatorname{dist}(x, X^*)$. In particular, they proved [17] that

$$\begin{aligned} \operatorname{dist}(x, X^*) \le& \gamma \left(\sqrt{\|(Ax-b)_+\|} + \|(Ax-b)_+\| + \sum_{i=1}^{m} (\sqrt{|f_i(x)|} + |f_i(x)|) \right) \\ &\text{for } x \in \mathbb{R}^n, \end{aligned} \tag{2.20}$$

if $f_i(x)$ are nonnegative on the polyhedral set $\{x : Ax \ge b\}$ and $f_i(x)$ are convex quadratic functions. If $f(x)$ is a convex quadratic function, then, with $m = 1$ and $f_1(x) = f(x) - f_{\min}$, (2.18) follows from Luo and Pang's global estimate (2.20). It is unclear whether (2.20) can be used to derive the following estimate for any approximate solution (not necessarily feasible) of (1.1):

$$\begin{aligned} \operatorname{dist}(x, X^*) \le& \gamma \left(\sqrt{\|(Ax-b)_+\|} + \|(Ax-b)_+\| + \sqrt{(f(x)-f_{\min})_+} + (f(x)-f_{\min})_+ \right) \\ &\text{for } x \in \mathbb{R}^n, \end{aligned} \tag{2.21}$$

where $f(x)$ is a convex piecewise quadratic function.

The following corollary shows directly why the estimate (2.11) is an error estimate for approximate feasible solutions near the solution set X^*.

COROLLARY 2.9. *Suppose that there exist positive constants δ and γ such that*

$$\operatorname{dist}(x, X^*) \le \gamma \sqrt{f(x) - f_{\min}} \quad \textit{for } x \in X \textit{ with } f(x) - f_{\min} \le \delta. \tag{2.22}$$

Then, for any $\beta > 0$, there exists a positive constant α such that

$$\operatorname{dist}(x, X^*) \le \alpha \sqrt{f(x) - f_{\min}} \quad \textit{for } x \in X \textit{ with } \operatorname{dist}(x, X^*) \le \beta. \tag{2.23}$$

Proof. Let $\alpha := \max\left\{\gamma, \frac{\beta}{\sqrt{\delta}}\right\}$. Let $x \in X$ with $\operatorname{dist}(x, X^*) \le \beta$. If $f(x) - f_{\min} \le \delta$, then (2.23) follows from (2.22); otherwise, $\sqrt{f(x) - f_{\min}} \ge \sqrt{\delta} \ge \frac{\sqrt{\delta}}{\beta} \operatorname{dist}(x, X^*)$. □

Similarly, we can recast Theorem 2.6 as the error estimate for approximate feasible solutions away from the solution set X^*.

COROLLARY 2.10. *Suppose that f is a convex piecewise quadratic function. Then, for any constant $\delta > 0$, there exists a positive constant γ such that*

$$\operatorname{dist}(x, X^*) \le \gamma \sqrt{f(x) - f_{\min}} \quad \textit{for } x \in X \textit{ with } \operatorname{dist}(x, X^*) \le \delta, \tag{2.24}$$

$$\operatorname{dist}(x, X^*) \le \gamma\,(f(x) - f_{\min}) \quad \textit{for } x \in X \textit{ with } \operatorname{dist}(x, X^*) \ge \delta. \tag{2.25}$$

Proof. By Theorem 2.7, there exists a positive constant γ_1 such that

$$\operatorname{dist}(x, X^*) \le \gamma_1 \sqrt{f(x) - f_{\min}} \quad \text{for } x \in X \text{ with } f(x) - f_{\min} \le \delta. \tag{2.26}$$

By Theorem 2.6, there exists a positive constant γ_2 such that

$$\operatorname{dist}(x, X^*) \leq \gamma_2 \left(f(x) - f_{\min}\right) \quad \text{for } x \in X \text{ with } f(x) - f_{\min} \geq \min\left\{\delta, \left(\frac{\delta}{\gamma_1}\right)^2\right\}. \tag{2.27}$$

Let $\gamma := \max\left\{\gamma_1, \gamma_2, 1, \sqrt{\delta}\right\}$. Assume $x \in X$ with $\operatorname{dist}(x, X^*) \leq \delta$. If $f(x) - f_{\min} \leq \delta$, then, by (2.26), $\operatorname{dist}(x, X^*) \leq \gamma\sqrt{f(x) - f_{\min}}$; otherwise,

$$\operatorname{dist}(x, X^*) \leq \delta \leq \sqrt{\delta}\sqrt{f(x) - f_{\min}} \leq \gamma\sqrt{f(x) - f_{\min}}.$$

Hence, (2.24) holds. Now let $x \in X$ with $\operatorname{dist}(x, X^*) \geq \delta$. If $f(x) - f_{\min} \geq \delta$, then, by (2.27), $\operatorname{dist}(x, X^*) \leq \gamma\left(f(x) - f_{\min}\right)$; otherwise, by (2.26), $f(x) - f_{\min} \geq \left(\frac{\delta}{\gamma_1}\right)^2$. In the latter case, by (2.27), we also have $\operatorname{dist}(x, X^*) \leq \gamma\left(f(x) - f_{\min}\right)$. Therefore, (2.25) also holds. □

Remark. In general, we cannot have the estimate $\operatorname{dist}(x, X^*) \leq \gamma(f(x) - f_{\min})$ for $x \in X$ (cf. [5]). It would be interesting to know what additional conditions are needed to guarantee such an estimate.

3. Error bounds for linear programs, linear complementarity problems, convex quadratic programs, and affine variational inequality problems.

Using the local and global error estimates given in the previous section, we can recover the weak sharp minimum property of a linear program by Mangasarian and Meyer [27] and the local error estimate for approximate solutions of an affine variational inequality problem by Luo and Tseng [21]. The unified approach shows that the estimates depend on how the original problem can be reformulated as a piecewise convex quadratic program. Therefore, it becomes clear that different reformulations of a given problem as piecewise convex quadratic programs yield different error estimates for approximate solutions of the given problem. This idea leads to a new global error estimate (cf. Theorem 3.1) for monotone linear complementarity problems which is better than the one given by Mangasarian and Shiau [29]. Moreover, using different reformulations of a convex quadratic program, we have new local and global error estimates for approximate solutions of a convex quadratic program (cf. Theorems 3.2, 3.3, and 3.4).

Consider the linear programming problem

$$c_{\min} := \min_{x \in X} c^T x. \tag{3.1}$$

Let X^* be the solution set of (3.1). Then X^* is also a solution of the following convex quadratic programming problem:

$$\min_{x \in X} (c^T x - c_{\min})^2. \tag{3.2}$$

Applying Theorem 2.7 to (3.2), we obtain that there exists a positive constant γ_1 such that

$$\operatorname{dist}(x, X^*) \leq \gamma_1\sqrt{(c^T x - c_{\min})^2} = \gamma_1(c^T x - c_{\min}) \quad \text{for } x \in X, (c^T x - c_{\min})^2 \leq 1. \tag{3.3}$$

However, (3.1) is also a degenerate convex quadratic programming problem. By Theorem 2.6, there exists a positive constant γ_2 such that

$$\operatorname{dist}(x, X^*) \leq \gamma_2(c^T x - c_{\min}) \quad \text{for } x \in X, (c^T x - c_{\min})^2 \geq 1. \tag{3.4}$$

From (3.3) and (3.4) we can recover the following weak sharp minimum property of the solutions of a linear program, which was proved by Mangasarian and Meyer [27]:

$$\mathrm{dist}(x, X^*) \leq \gamma(c^T x - c_{\min}) \quad \text{for } x \in X,$$

where $\gamma = \max\{\gamma_1, \gamma_2\}$.

An affine variational inequality problem, associated with X, an $n \times n$ matrix M, and a vector $q \in \mathbb{R}^n$, is to find a vector $x \in X$ such that

$$(3.5) \qquad (y - x)^T(q + Mx) \geq 0 \quad \text{for } y \in X.$$

The affine variational inequality problem (3.5) is equivalent to the following system of piecewise linear equations:

$$(3.6) \qquad x - \Pi_X(x - (q + Mx)) = 0,$$

where $\Pi_X(z)$ denotes the orthogonal projection of z onto X. It is known that $\Pi_X(z)$ is a piecewise linear mapping of z if X is a convex polyhedral set. Let $f(x) := \|x - \Pi_X(x - (q + MX))\|^2$. Then $f(x)$ is a piecewise convex quadratic function and (3.6) is equivalent to the following piecewise convex quadratic program:

$$(3.7) \qquad \min_{x \in \mathbb{R}^n} f(x).$$

It follows from Theorem 2.5 and $f_{\min} = 0$ that there exist positive constants γ and δ such that

$$(3.8) \quad \mathrm{dist}(x, X^*) \leq \gamma\|x - \Pi_X(x - (q + Mx))\| \quad \text{for } \|x - \Pi_X(x - (q + Mx))\| \leq \delta,$$

which is the local error estimate derived by Luo and Tseng [21].

Next, consider a special case of the affine variational inequality problem—the monotone linear complementarity problem

$$(3.9) \qquad x^T(q + Mx) = 0, \ x \geq 0, \ q + Mx \geq 0,$$

where M is positive semidefinite. Similarly, the solution set X^* of the monotone linear complementarity problem is the solution set of (3.7) with $f(x) := \|x - (x - (q + Mx))_+\|^2$, where z_+ denotes the vector whose ith component is $\max\{z_i, 0\}$. In order to obtain a global error estimate for approximate solutions to (3.9), we need to use Corollaries 2.9 and 2.10. Since $f_{\min} = 0$ in this case, by Corollary 2.9, there exist positive constants δ_1 and γ_1 such that

$$(3.10) \qquad \mathrm{dist}(x, X^*) \leq \gamma_1\|x - (x - (q + Mx))_+\| \quad \text{for } \mathrm{dist}(x, X^*) \leq \delta_1.$$

On the other hand, by the proof of Lemma 2.5 in [29], there exists a positive constant σ such that

$$(3.11) \qquad x^T(Mx + q) + \frac{\sigma}{2}(\|(-q - Mx)_+\|_1 + \|(-x)_+\|_1) \geq 0 \quad \text{for } x \in \mathbb{R}^n,$$

where $\|z\|_1 := \sum_{i=1}^n |z_i|$. Let $g(x) := x^T(Mx + q) + \sigma(\|(-q - Mx)_+\|_1 + \|(-x)_+\|_1)$. Then it is easy to verify that $g(x)$ is a convex piecewise quadratic function, since M is positive semidefinite. By (3.11), $g(x) \geq 0$ and $g(x) = 0$ if and only if $\|(-q - Mx)_+\|_1 +$

$\|(-x)_+\|_1 = 0$ and $x^T(Mx+q) = 0$. Therefore, the solution set X^* of the monotone linear complementarity problem is the solution set of the following convex piecewise quadratic program:

$$\min_{x \in \mathbb{R}^n} g(x). \tag{3.12}$$

By Corollary 2.10, for the constant $\delta_1 > 0$, there exists a positive constant γ_2 such that, for $\operatorname{dist}(x, X^*) \geq \delta_1$,

$$\begin{aligned} \operatorname{dist}(x, X^*) &\leq \gamma_2(g(x) - g_{\min}) \\ &= \gamma_2(x^T(Mx+q) + \sigma(\|(-q-Mx)_+\|_1 + \|(-x)_+\|_1)) \\ &\leq \gamma_2(\sigma+1)((x^T(Mx+q))_+ + \|(-q-Mx)_+\|_1 + \|(-x)_+\|_1). \end{aligned} \tag{3.13}$$

It is easy to verify (cf. [29]) that there exists a positive constant γ_3 such that

$$\|(-q-Mx)_+\|_1 + \|(-x)_+\|_1 \leq \gamma_3\|x - (x-(Mx+q))_+\| \quad \text{for } x \in \mathbb{R}^n. \tag{3.14}$$

From (3.10), (3.13), and (3.14) we get the following global error estimate for approximate solutions of a monotone linear complementarity problem.

THEOREM 3.1. *Suppose that M is positive semidefinite and X^* is the solution set of the monotone linear complementarity problem* (3.9). *Then there exists a positive constant γ such that*

$$\operatorname{dist}(x, X^*) \leq \gamma((x^T(Mx+q))_+ + \|x - (x-(Mx+q))_+\|) \quad \textit{for } x \in \mathbb{R}^n. \tag{3.15}$$

Remark. Recently, Mangasarian and Ren [28] also obtained an estimate similar to (3.15).

Now, let us compare the error estimate (3.15) with Mangasarian and Shiau's global error estimate for approximate solutions of a monotone linear complementarity problem.

Applying Corollary 2.8 to the convex piecewise quadratic program (3.12), we obtain that there exists a constant γ_0 such that

$$\operatorname{dist}(x, X^*) \leq \gamma_0(g(x) + \sqrt{g(x)}) \quad \text{for } x \in \mathbb{R}^n. \tag{3.16}$$

Since $g(x) \leq (\sigma+1)((x^T(Mx+q))_+ + \|(-q-Mx)_+\|_1 + \|(-x)_+\|_1)$, using Mangasarian and Shiau's notation $\|(x^T(Mx+q), -q-Mx, -x)_+\|^2 := (x^T(Mx+q))_+^2 + \|(-q-Mx)_+\|^2 + \|(-x)_+\|^2$ and the fact that any two norms in $\mathbb{R}^n$ are equivalent, we can derive from (3.16) the following error estimate:

$$\begin{aligned} \operatorname{dist}(x, X^*) \leq \gamma\Big(&\|(x^T(Mx+q), -q-Mx, -x)_+\| \\ &+ \sqrt{\|(x^T(Mx+q), -q-Mx, -x)_+\|}\Big) \quad \text{for } x \in \mathbb{R}^n, \end{aligned} \tag{3.17}$$

which is an equivalent form of Mangasarian and Shiau's estimate (2.6) in [29]. Note that they also have an explicit expression for γ with appropriate norms. However, it is interesting to see that, theoretically, their estimate can be derived as a special case of Corollary 2.8.

In the following analysis, we show that there exists a positive constant κ such that, for $x \in \mathbb{R}^n$,

$$(3.18)\quad \begin{aligned}&(x^T(Mx+q))_+ + \|x-(x-(Mx+q))_+\| \\ &\quad \le \kappa\left(\|(x^T(Mx+q), -q-Mx, -x)_+\| + \sqrt{\|(x^T(Mx+q), -q-Mx, -x)_+\|}\right),\end{aligned}$$

provided (3.17) holds.

Since $\|x-(x-(Mx+q))_+\|_1$ is a piecewise linear function, there exists a positive constant β such that

$$\big|\|x-(x-(Mx+q))_+\|_1 - \|y-(y-(My+q))_+\|_1\big| \le \beta\|x-y\|.$$

For any x, let $y \in X^*$ be such that $\mathrm{dist}(x, X^*) = \|x-y\|$. Then

$$\begin{aligned}\|x-(x-(Mx+q))_+\|_1 &= \|x-(x-(Mx+q))_+\|_1 - \|y-(y-(My+q))_+\|_1 \\ &\le \beta\cdot\|x-y\| = \beta\cdot\mathrm{dist}(x, X^*).\end{aligned}$$

Since any two norms in $\mathbb{R}^n$ are equivalent, there exists a positive constant η such that

$$(3.19)\qquad \|x-(x-(Mx+q))_+\| \le \eta\cdot\mathrm{dist}(x, X^*).$$

By (3.17) and (3.19), we get (3.18) with $\kappa := \gamma\eta + 1$. The inequality (3.18) and the following example show that (3.15) is a better global error estimate than (3.17).

Example. Let $M = \left(\begin{smallmatrix}1 & 1\\ 0 & 0\end{smallmatrix}\right)$ and $q = \left(\begin{smallmatrix}0\\ 0\end{smallmatrix}\right)$. Then it is easy to verify that

$$X^* = \left\{x \equiv \begin{pmatrix}x_1\\ x_2\end{pmatrix} : x_1 = 0, x_2 \ge 0\right\}.$$

Hence, $\mathrm{dist}(x, X^*)^2 = x_1^2 + (-x_2)_+^2$. Next we prove that (3.17) holds and then compare (3.17) with (3.15).

For any $x \in \mathbb{R}^n$,

$$s(x)^2 := \|(x^T(Mx+q), -x, -Mx-q)_+\|^2 = (-x_1)_+^2 + (-x_2)_+^2 + (-x_1-x_2)_+^2 + (x_1^2+x_1x_2)_+^2.$$

For $x_1 \le 0$,

$$s(x)^2 \ge (-x_1)_+^2 + (-x_2)_+^2 = x_1^2 + (-x_2)_+^2 = \mathrm{dist}(x, X^*)^2.$$

If $x_1 > 0$ and $x_2 \ge 0$, then

$$s(x)^2 + s(x) \ge (-x_2)_+^2 + (x_1^2 + x_1x_2)_+ \ge x_1^2 + (-x_2)_+^2 = \mathrm{dist}(x, X^*)^2.$$

When $x_1 > 0$ and $-\frac{x_1}{2} \le x_2 \le 0$,

$$s(x)^2 + s(x) \ge (-x_2)_+^2 + (x_1^2 + x_1x_2)_+ \ge \frac{x_1^2}{2} + (-x_2)_+^2 \ge \frac{1}{2}\mathrm{dist}(x, X^*)^2.$$

When $x_1 > 0$ and $-\frac{x_1}{2} \ge x_2$,

$$s(x)^2 \ge (-x_2)_+^2 \ge \frac{1}{2}(-x_2)_+^2 + \frac{1}{8}x_1^2 \ge \frac{1}{8}\mathrm{dist}(x, X^*)^2.$$

Therefore,

$$\operatorname{dist}(x, X^*) \leq 3(s(x) + \sqrt{s(x)}) \qquad \text{for } x \in \mathbb{R}^n.$$

By (3.18), (3.15) also holds. Actually, we have the following better estimate:

$$\begin{aligned} \|x - (x - (Mx+q))_+\|^2 &= (x_1 - (-x_2)_+)^2 + (-x_2)_+^2 \\ &= x_1^2 - 2x_1(-x_2)_+ + 2(-x_2)_+^2 \\ &= x_1^2 - 2\left(\sqrt{\frac{2}{3}}x_1\right)\left(\sqrt{\frac{3}{2}}(-x_2)_+\right) + 2(-x_2)_+^2 \\ &\geq x_1^2 - \left(\frac{2}{3}x_1^2\frac{3}{2}(-x_2)_+^2\right) + 2(-x_2)_+^2 \\ &\geq \frac{1}{3}(x_1^2 + (-x_2)_+^2). \end{aligned}$$

Thus, for $\lambda = \sqrt{3}$,

$$\operatorname{dist}(x, X^*) \leq \lambda \|x - (x - (Mx+q))_+\| \qquad \text{for } x \in \mathbb{R}^n. \tag{3.20}$$

In the following analysis, we show that (3.20) is better than (3.15), which is better than (3.17).

Let

$$x_\theta = \begin{pmatrix} \theta^2 \\ \theta^{-1} \end{pmatrix}$$

with $0 < \theta < 1$. Then

$$\operatorname{dist}(x_\theta, X^*) = \theta^2, \quad \|x_\theta - (x_\theta - (Mx_\theta + q))_+\| = \theta^2, \quad (x_\theta^T(Mx_\theta + q))_+ = \theta^4 + \theta.$$

Therefore,

$$\lim_{\theta \to 0+} \frac{(x_\theta^T(Mx_\theta + q))_+ + \|x_\theta - (x_\theta - (Mx_\theta + q))_+\|}{\sqrt{\|(x_\theta^T(Mx_\theta + q), -q - Mx_\theta, -x_\theta)_+\|}} = 0, \tag{3.21}$$

$$\lim_{\theta \to 0+} \frac{\|x_\theta - (x_\theta - (Mx_\theta + q))_+\|}{(x_\theta^T(Mx_\theta + q))_+} = 0. \tag{3.22}$$

Remark. An analysis given by Mangasarian and Ren [28] also shows that (3.15) holds whenever (3.17) holds. They give a counterexample showing that (3.15) does not imply (3.17). As a consequence, (3.15) holds for a wider class of linear complementarity problems than (3.17). The above analysis shows that, in the case where $s(x) + \sqrt{s(x)}$ can be used as a global error estimate, one should still use $\|x - (x - (Mx + q))_+\| + (x^T(Mx + q))_+$ as a global error estimate due to (3.18).

Finally, we use the error bounds derived in §2 to establish new error estimates for approximate solutions of a quadratic program.

If f is a convex quadratic function, the estimates given in §2 are only for feasible solutions of (1.1). However, in some cases, we can have global error estimates for any approximate solution of a convex quadratic program. The new global error estimates are based on the unconstrained reformulation of a convex quadratic program and the estimates given in §2. Consider the following convex quadratic program:

$$\min_{l\leq Ax\leq u} \frac{1}{2}x^T Mx - b^T x, \tag{3.23}$$

where M is an $n \times n$ symmetric positive semidefinite matrix, $b \in \mathbb{R}^n$, A is an $m \times n$ matrix, and $l, u \in \mathbb{R}^m$. When M is also nonsingular, x^* is a solution to (3.23) if and only if $x = M^{-1}(A^T w + b)$, where w is a solution of the following piecewise linear equation [15], [16]:

$$\varphi(w) := (\alpha I - B)w + AM^{-1}b - (AM^{-1}b - Bw)_l^u = 0. \tag{3.24}$$

Here α is any positive constant, I is the identity matrix, $B = \alpha I - AM^{-1}A^T$, and $(z)_l^u$ denotes the vector whose ith component is $\min\{u_i, \max\{z_i, l_i\}\}$. When $\alpha > \|AM^{-1}A^T\|$, the piecewise linear equation is equivalent to the following unconstrained minimization problem [15], [16]:

$$\Phi_{\text{min}} := \min_{w\in\mathbb{R}^m} \Phi(w), \tag{3.25}$$

where

$$\Phi(w) := \frac{\alpha}{2}w^T Bw - \frac{1}{2}\|(Bw + l - AM^{-1}b)_+\|^2 - \frac{1}{2}\|(AM^{-1}b - u - Bw)_+\|^2 \tag{3.26}$$

is a convex quadratic spline. That is, w^* is a solution of $\varphi(w) = 0$ (or $\|\varphi(w)\|^2 = 0$) if and only if w^* is a minimizer of $\Phi(w)$. Let W^* be the solution set of (3.24) (or (3.25)). Then W^* is the set of the Lagrange multipliers of the solution to (3.23). By Corollaries 2.9 and 2.10, we can use $\|\varphi(w)\|$ or $\sqrt{\Phi(w) - \Phi_{\text{min}}}$ as an error estimate for w near the solution set W^* and use $\Phi(w) - \Phi_{\text{min}}$ as an error estimate for w away from the solution set W^*. Moreover, if x^* is the solution to (3.23), then $x^* \equiv M^{-1}(A^T w^* + b)$ for all $w^* \in W^*$, which implies $\|M^{-1}(A^T w + b) - x^*\| = \|M^{-1}A^T(w - w^*)\|$ for all $w^* \in W^*$. Thus,

$$\|M^{-1}(A^T w + b) - x^*\| \leq \|M^{-1}A^T\| \cdot \text{dist}(w, W^*),$$

where $\|M^{-1}A^T\|$ denotes the 2-norm of the matrix $M^{-1}A^T$. Therefore, we have the following global estimate for Lagrange multipliers and approximate solution of (3.23).

THEOREM 3.2. *If M is symmetric positive definite and $\alpha > \|AM^{-1}A^T\|$, then there exists a positive constant γ such that, for any w and $x := M^{-1}(A^T w + b)$,*

$$\|x - x^*\| + \text{dist}(w, W^*) \leq \gamma(\min\{\|\varphi(w)\|, \sqrt{\Phi(w) - \Phi_{\text{min}}}\} + (\Phi(w) - \Phi_{\text{min}})). \tag{3.27}$$

If M is singular but A is nonsingular, then we can still have a global error estimate for approximate solutions of (3.23). Let $E := I - \alpha(A^{-1})^T MA^{-1}$ and $\bar{b} = \alpha(A^T)^{-1}b$. Define

$$\psi(x) := Ax - (EAx + \bar{b})_l^u. \tag{3.28}$$

Then, for any $\alpha > 0$, x is a solution to (3.23) if and only if $\psi(x) = 0$ (or $\|\psi(x)\|^2 = 0$). Since $\|\psi(x)\|^2$ is a piecewise convex quadratic function, by Theorem 2.5, we have the following local error estimate for approximate solutions of (3.23).

THEOREM 3.3. *Suppose that A is nonsingular and X^* is the solution set of* (3.23). *Then there exist positive constants γ and δ such that*

$$\text{dist}(x, X^*) \le \gamma \|Ax - (EAx + \bar{b})_l^u\| \quad \textit{for } \|Ax - (EAx + \bar{b})_l^u\| \le \delta. \tag{3.29}$$

When $0 < \alpha < \|(A^{-1})^T M A^{-1}\|^{-1}$, $x \in X^*$ if and only if x is a solution to the following unconstrained minimization problem:

$$\min_{x \in \mathbb{R}^n} \Psi(x), \tag{3.30}$$

where

$$\Psi(x) := \frac{1}{2} x^T A^T (E - E^2) A x + \frac{1}{2} \|(l - (EAx + \bar{b}))_+\|^2 + \frac{1}{2} \|((EAx + \bar{b}) - u)_+\|^2$$

is a convex quadratic spline [15], [16]. We have the following global error estimate for approximate solutions of (3.23).

THEOREM 3.4. *Let X^* be the solution set of* (3.30). *If A is nonsingular and $0 < \alpha < \|(A^{-1})^T M A^{-1}\|^{-1}$, then there exists a positive constant γ such that*

$$\text{dist}(x, X^*) \le \gamma(\min\{\|\psi(x)\|, \sqrt{\Psi(x) - \Psi_{\min}}\} + (\Psi(x) - \Psi_{\min})) \quad \text{for } x \in \mathbb{R}^n. \tag{3.31}$$

Remark. The most interesting case of nonsingular A's is $A = I$. Then (3.23) becomes the convex quadratic program with simple bound constraints. The estimate (3.27) (or (3.31)) involve the unknown value $\Phi_{\min}$ (or $\Psi_{\min}$), which is not desirable as a general error estimate for approximate solutions of (3.23). However, such estimates are useful in convergence analysis of descent methods for solving (3.25) or (3.30) (cf. [13], [16]). Moreover, it is interesting to know when $\|\varphi(w)\|$ (or $\|\psi(x)\|$) can be used as a global error estimate for $\text{dist}(w, W^*)$ (or $\text{dist}(x, X^*)$). Some related global error estimates can be found in [23] and [31].

4. Error estimates for iterates of the proximal point algorithm. Consider the following proximal point algorithm for solving (1.1):

$$x^{k+1} := \arg\min_{x \in X} f(x) + \frac{1}{2\epsilon_k} \|x - x^k\|_D^2 \quad k = 0, 1, \ldots, \tag{4.1}$$

where $\|x\|_D := (x^T D x)^{1/2}$ denotes the norm induced by a positive definite matrix D, f is a convex function, x^0 is any given vector, and $\epsilon_k > 0$ for all k.

The proximal point algorithm was first applied to solving convex programs by Martinet [30]. It is well known that $\{x^k\}$ converges to a solution to (1.1) if $\lim_{k \to \infty} \inf \epsilon_k = \epsilon > 0$. The convergence rate of iterates were studied by Rockafellar [33] and Luque [24], and sufficient conditions for the finite convergence of the proximal point algorithm were given by Rockafellar [33], Ferris [4], and Lefebvre and C. Michelot [9]. See [10] for a survey on the proximal point algorithm and see [7], [1]–[3], [8], [39] for the recent development on the proximal point algorithm.

Using the error bound for feasible approximate solutions to a convex piecewise quadratic program, we can derive new estimates for the distance from x^k to the solution set X^*.

The following result is a special case of Güler's key inequality in convergence analysis of the proximal point algorithm in a Hilbert space setting [7].

LEMMA 4.1. *For any $x \in X$,*

$$f(x^{k+1}) - f(x) \leq \frac{1}{2\epsilon_k}\left(\|x - x^k\|_D^2 - \|x - x^{k+1}\|_D^2 - \|x^{k+1} - x^k\|_D^2\right). \tag{4.2}$$

THEOREM 4.2. *Suppose that there exist positive constants δ, γ such that*

$$\operatorname{dist}(x, X^*) \leq \gamma\sqrt{f(x) - f_{\min}} \quad \textit{for } x \in X \textit{ with } f(x) - f_{\min} \leq \delta. \tag{4.3}$$

Then there exists a positive constant η (depending only on f, X, D, and $\operatorname{dist}(x^0, X^*)_D$*) such that*

$$\|x^{k+1} - x^k\|_D \leq \operatorname{dist}(x^k, X^*)_D \leq \sqrt{\frac{1}{1 + \eta\epsilon_{k-1}}} \cdot \operatorname{dist}(x^{k-1}, X^*)_D \quad \textit{for } k \geq 1, \tag{4.4}$$

where $\operatorname{dist}(x, X^*)_D := \min_{\bar{x} \in X^*} \|x - \bar{x}\|_D$.

Proof. Since D is positive definite, there exists a positive constant β such that

$$\|x\|_D \leq \beta\|x\| \quad \text{for } x, y \in \mathbb{R}^n,$$

which implies $\operatorname{dist}(x, X^*)_D \leq \beta \cdot \operatorname{dist}(x, X^*)$. Therefore, by (4.3) and Corollary 2.9, there exists a positive constant η (depending only on f, X, D, and $\operatorname{dist}(x^0, X^*)_D$) such that

$$\operatorname{dist}(x, X^*)_D \leq \sqrt{\frac{2}{\eta}}\sqrt{f(x) - f_{\min}} \quad \text{for } x \in X \text{ with } \operatorname{dist}(x, X^*)_D \leq \operatorname{dist}(x^0, X^*)_D. \tag{4.5}$$

Let $\bar{x}^k \in X^*$ be such that $\operatorname{dist}(x^k, X^*)_D = \|x^k - \bar{x}^k\|_D$. By (4.5),

$$f(x^{k+1}) - f(\bar{x}^{k+1}) \geq \frac{\eta}{2}\|x^{k+1} - \bar{x}^{k+1}\|_D^2. \tag{4.6}$$

Substituting x by $\bar{x}^k$ in (4.2), we obtain

$$\begin{aligned} f(x^{k+1}) - f(\bar{x}^{k+1}) &= f(x^{k+1}) - f(\bar{x}^k) \\ &\leq \frac{1}{2\epsilon_k}\left(\|x^k - \bar{x}^k\|_D^2 - \|x^{k+1} - \bar{x}^k\|_D^2 - \|x^{k+1} - x^k\|_D^2\right) \\ &\leq \frac{1}{2\epsilon_k}\left(\|x^k - \bar{x}^k\|_D^2 - \|x^{k+1} - \bar{x}^k\|_D^2\right) \\ &\leq \frac{1}{2\epsilon_k}\left(\|x^k - \bar{x}^k\|_D^2 - \|x^{k+1} - \bar{x}^{k+1}\|_D^2\right). \end{aligned} \tag{4.7}$$

It follows from (4.6) and (4.7) that

$$\|x^{k+1} - \bar{x}^{k+1}\|_D^2 \leq \frac{1}{1 + \eta\epsilon_k}\|x^k - \bar{x}^k\|_D^2 \quad \text{for } k = 0, 1, \ldots. \tag{4.8}$$

Substituting x by $\bar{x}^k$ in (4.2), we get

$$\|x^k - x^{k+1}\|_D^2 \leq \|x^k - \bar{x}^k\|_D^2 - \|x^{k+1} - \bar{x}^k\|_D^2 - 2\epsilon_k(f(x^{k+1}) - f(\bar{x}^k)) \leq \|x^k - \bar{x}^k\|_D^2.$$

□

Remark. It follows from (4.4) that

$$\|x^k - x^{k+1}\|_D \le \operatorname{dist}(x^k, X^*)_D \le \operatorname{dist}(x^0, X^*)_D \left(\prod_{i=0}^{k-1} \frac{1}{1+\eta\epsilon_i}\right)^{\frac{1}{2}} \quad \text{for } k \ge 1. \tag{4.9}$$

Note that $\prod_{i=0}^{\infty} \frac{1}{1+\eta\epsilon_i} = 0$ if and only if $\prod_{i=0}^{\infty}(1+\eta\epsilon_i) = \infty$, which is equivalent to

$$\sum_{i=0}^{\infty} \eta\epsilon_i = \sum_{i=1}^{\infty} ((1+\eta\epsilon_i) - 1) = \infty. \tag{4.10}$$

Therefore, by (4.9), any accumulation point of $\{x^k\}$ is a solution of (1.1) whenever $\sum_{i=0}^{\infty} \epsilon_i = \infty$. As a consequence, for any sequence of positive constants $\{\epsilon_k\}$ with $\sum_{i=0}^{\infty} \epsilon_i = \infty$, the iterates $\{x^k\}$ generated by (4.1) converge to a solution to (1.1). This recovers Güler's convergence result for the proximal point algorithm [7] under the assumption (4.3). Moreover, the error estimate (4.9) is interesting in its own right. If $\epsilon_k \ge c > 0$, by (4.9), the iterates $\{x^k\}$ generated by (4.1) converge linearly (in the root sense) to a solution to (1.1). When $\lim_{k\to\infty} \epsilon_k = \infty$, by (4.9), $\{x^k\}$ converges superlinearly (in the root sense) to a solution to (1.1).

By Theorem 2.5, (4.4) and (4.9) hold if f is a convex piecewise quadratic function. However, in this case, the subdifferential mapping ∂f of f is polyhedral [38] and is upper Lipschitz continuous [32]. Thus, if f is a convex piecewise quadratic function, (4.4) also follows from the proof of Theorem 2.1 in [24], which is an extension of Rockafellar's linear convergence result of the proximal point algorithm [33]. Of course, one can also discuss the linear convergence of inexact proximal point algorithms under the assumption (4.3) (cf. [33], [24]).

Somehow, (4.9) provides a link between Rockafellar and Luque's linear convergence results and Güler's convergence result and shows how $\{\epsilon_k\}$ affect the convergence rate of iterates $\{x^k\}$.

The proximal point algorithm can also be formulated as an algorithm for solving the equivalent generalized equation of (1.1). In this case, Luque studied the relationship between convergence rates of iterates and error estimates of approximate solutions in terms of the normal equation. Similar results can be established for the relationship between convergence rates of iterates and error estimates of feasible solutions in terms of the objective function.

Since η in Theorem 4.2 depends on $\operatorname{dist}(x^0, X^*)_D$, (4.9) might not be considered as a "global" error estimate for x^k, even though it holds for all k. However, as an application of global error estimates for feasible solutions of convex piecewise quadratic programs, we can have a "global" error estimate for x^k when f is a convex piecewise quadratic function.

PROPOSITION 4.3. *Suppose that f is a convex piecewise quadratic function. Then there exists a positive constant β (depending only on f, X, and D) such that*

$$\operatorname{dist}(x^{k+1}, X^*) \le \sqrt{\frac{1}{1+\beta\epsilon_k}} \cdot \operatorname{dist}(x^k, X^*)_D \quad \textit{for } \operatorname{dist}(x^{k+1}, X^*)_D \le 1,$$

$$\operatorname{dist}(x^{k+1}, X^*) \le \frac{\operatorname{dist}(x^0, X^*)_D}{\operatorname{dist}(x^0, X^*)_D + \beta\epsilon_k} \cdot \operatorname{dist}(x^k, X^*)_D \quad \textit{for } \operatorname{dist}(x^{k+1}, X^*)_D \ge 1.$$

Proof. Due to the equivalence of any two norms on $\mathbb{R}^n$, by Theorems 2.6 and 2.7, there exists a positive constant β (depending only on f, X, and D) such that

$$\min\{\operatorname{dist}(x, X^*)_D^2, \operatorname{dist}(x, X^*)_D\} \le \frac{1}{\beta}(f(x) - f_{\min}) \quad \text{for } x \in X. \tag{4.11}$$

Let $\bar{x}^k \in X^*$ be such that $\operatorname{dist}(x^k, X^*)_D = \|x^k - \bar{x}^k\|_D$. If $\|x^{k+1} - \bar{x}^{k+1}\|_D \le 1$, then $\|x^{k+1} - \bar{x}^{k+1}\|_D^2 \le \frac{1}{\beta}(f(x^{k+1}) - f(\bar{x}^{k+1}))$ and it follows from the proof of (4.4) that

$$\operatorname{dist}(x^{k+1}, X^*)_D^2 \le \frac{1}{1+2\beta\epsilon_k}\operatorname{dist}(x^k, X^*)_D^2 \le \frac{1}{1+\beta\epsilon_k}\operatorname{dist}(x^k, X^*)_D^2. \tag{4.12}$$

Otherwise,

$$\|x^{k+1} - \bar{x}^{k+1}\|_D \le \frac{1}{\beta}(f(x^{k+1}) - f(\bar{x}^{k+1})). \tag{4.13}$$

By (4.7) and (4.13), we get

$$\|x^{k+1} - \bar{x}^{k+1}\|_D^2 + 2\beta\epsilon_k\|x^{k+1} - \bar{x}^{k+1}\|_D \le \|x^k - \bar{x}^k\|_D^2.$$

Solving the above inequality for $\|x^{k+1} - \bar{x}^{k+1}\|_D$, we obtain

$$\begin{aligned} \|x^{k+1} - \bar{x}^{k+1}\|_D &\le \frac{1}{2}(\sqrt{(2\beta\epsilon_k)^2 + 4\|x^k - \bar{x}^k\|_D^2} - 2\beta\epsilon_k) \\ &= (\sqrt{(\beta\epsilon_k)^2 + \|x^k - \bar{x}^k\|_D^2} - \beta\epsilon_k) \\ &= \frac{\|x^k - \bar{x}^k\|_D^2}{\sqrt{(\beta\epsilon_k)^2 + \|x^k - \bar{x}^k\|_D^2} + \beta\epsilon_k} \\ &\le \frac{\|x^k - \bar{x}^k\|_D^2}{\|x^k - \bar{x}^k\|_D + \beta\epsilon_k}. \end{aligned} \tag{4.14}$$

Since $\frac{t}{t+\beta\epsilon_k}$ is a monotone increasing function for $t \ge 0$ and $\|x^k - \bar{x}^k\|_D \le \operatorname{dist}(x^0, X^*)_D$, it follows from (4.14) that

$$\operatorname{dist}(x^{k+1}, X^*)_D \le \frac{\operatorname{dist}(x^0, X^*)_D}{\operatorname{dist}(x^0, X^*)_D + \beta\epsilon_k} \cdot \operatorname{dist}(x^k, X^*)_D. \tag{4.15}$$

The proposition follows from (4.14) and (4.15). □

Remark. The above estimate suggests that, initially, the convergence rate of the proximal point algorithm might be affected not only by the error bound constant $\frac{1}{\beta}$ for f but also by the distance of x^0 to the solution set X^*.

5. Comments. In this paper, we have established a local error estimate for feasible solutions of a piecewise convex quadratic program and a global error estimate for feasible solutions of a convex piecewise quadratic program. These error estimates provide a unified approach for deriving many old and new error estimates for linear programs, linear complementarity problems, convex quadratic programs, and affine variational inequality problems. The approach reveals the fact that each error estimate is a consequence of some reformulation of the original problem as a piecewise convex quadratic program or a convex piecewise quadratic program.

As an application, we give new (global) error estimates for iterates of the proximal point algorithm for solving a convex piecewise quadratic program, which provide additional insight on the convergence behavior of the iterates.

For those who are interested in general convex programming problems, similar results might be possible when the objective function is a composition of a strongly convex smooth function and a piecewise linear mapping. That is, if $h'(y)$ is Lipschitz continuous and strongly monotone, $g(x)$ is a piecewise linear mapping, and $f(x) := h(g(x))$, then the main results given in §2 might still be true. See [20], [19], [11] for related results. Also it seems natural to conjecture that Theorem 2.5 is still true if f is only a piecewise quadratic function.

As the conclusion of this paper, we want to show that the estimate (2.11) is actually a generalization of Robinson's result on the upper Lipschitz continuity of a polyhedral mapping [32]. Recall that a set-valued mapping $\Gamma(y)$ from $\mathbb{R}^n$ to subsets of $\mathbb{R}^n$ is said to be a polyhedral mapping if its graph $\{(x,y) : x \in \Gamma(y)\}$ is a union of finitely many closed convex polyhedral sets. Therefore, for a given polyhedral mapping $\Gamma(y)$, there exist matrices $\{A_i, B_i\}_{i=1}^r$ and vectors $\{c_i\}_{i=1}^r$ such that

$$\{(x,y) : x \in \Gamma(y)\} = \bigcup_{i=1}^{r} \{(x,y) : A_i x + B_i y \geq c_i\}.$$

Robinson proved that, if $\Gamma(z)$ is not empty, then there exist positive constants δ and γ such that

$$\text{dist}(x, \Gamma(z)) \leq \gamma \|y - z\| \quad \text{for } x \in \Gamma(y) \text{ with } \|z - y\| \leq \delta. \tag{5.1}$$

Define

$$f_z(x) := \left(\min_{1 \leq i \leq r} \|(A_i x + B_i z - c_i)_+\|_1 \right)^2 .$$

Since $\min\{t, s\} = t - (t - s)_+$, one can easily verify that $\sqrt{f_z(x)}$ is a piecewise linear function of both x and z; hence, for a fixed z, $f_z(x)$ is a piecewise convex quadratic function of x. Obviously, $\Gamma(z)$ is the solution set of $(0 =) \min_{x \in \mathbb{R}^n} f_z(x)$. By Theorem 2.5, there exist positive constants β and γ such that

$$\text{dist}(x, \Gamma(z)) \leq \gamma \sqrt{f_z(x)} \quad \text{for } x \in \mathbb{R}^n \text{ with } f_z(x) \leq \beta. \tag{5.2}$$

For $x \in \Gamma(y)$, we have $f_y(x) = 0$. By the piecewise linearity of $\sqrt{f_z(x)}$, there exists a positive constant α such that

$$\sqrt{f_z(x)} = \sqrt{f_z(x)} - \sqrt{f_y(x)} \leq \alpha \cdot \|z - y\|. \tag{5.3}$$

Let $\delta := \frac{\alpha}{\sqrt{\beta}}$ Then (5.1) follows from (5.2) and (5.3). The above discussion shows that (5.1) can be considered as a consequence of the error estimate (5.2) for approximate solutions of the piecewise convex quadratic function $f_z(x)$.

A PERSPECTIVE THEORY FOR MOTION AND SHAPE ESTIMATION IN MACHINE VISION[*]

B. K. GHOSH[†] AND E. P. LOUCKS[†]

Abstract. In this paper, we consider the problem of motion and shape estimation of a moving body with the aid of a monocular camera. We show that the estimation problem reduces to a specific parameter estimation of a perspective dynamical system. Surprisingly, the above reduction is independent of whether the data measured is the brightness pattern which the object produces on the image plane or whether the data observed are points, lines, or curves on the image plane produced as a result of discontinuities in the brightness pattern. Many cases of the perspective parameter estimation problem have been analyzed in this paper. These cases include a fairly complete analysis of a planar textured surface undergoing a rigid flow and an affine flow. These two cases have been analyzed for orthographic, pseudo-orthographic, and image-centered projections. The basic procedure introduced for parameter estimation is to subdivide the problem into two modules, one for "spatial averaging" and the other for "time averaging." The estimation procedure is carried out with the aid of a new "realization theory for perspective systems" introduced for systems described in discrete time and in continuous time. Finally, much of our analysis has been substantiated by computer simulation of specific algorithms developed in order to explicitly compute the parameters. Detailed simulation that would answer the perspective realizability question is a subject of future research.

1. Introduction.

The problem that we consider in this paper is described as follows.

PROBLEM 1. *We have a textured surface which is moving in continuous time following a certain vector field where we assume that both the shape of the surface and the vector field are unknown. Assume that a camera produces a perfect image of the textured surface in continuous time. The problem of interest is to estimate the shape and motion parameters of the surface from the observed time-varying image produced by the camera.*

Two important assumptions regarding the surface being observed, the camera, and its imaging mechanism need to be emphasized. First, we assume that the surface is constantly under focus, i.e., there is no blurring of the image as a result of imperfect focusing. Second, we assume that the photometric effects on the image due to the light source and the physical properties of the surface are negligible and can be ignored. Thus, the process of image formation is such that the intensity corresponding to each pixel on the surface is transferred to the image plane unattenuated via the projection process.

The existing approaches to the estimation problem in the literature can be divided broadly into two categories depending upon what is assumed to be measured from the scene. If the data observed is assumed to be the brightness pattern which the object produces on the image plane, a well-known approach in the literature is based on analyzing the optical flow field (see [1], [32], [33]). For a system theoretic treatment [2] of the subject we refer the reader to [47]. On the other hand, if the data observed are assumed to be the discontinuity curves in the brightness pattern on the image

[*] Received by the editors April 2, 1993; accepted for publication (in revised form) May 6, 1994. This research was supported in part by the Department of Energy under grant DE-FG02-90ER14140.

plane, a well-known feature-based approach is to identify the correspondence of various features such as points, lines, and curves between one frame and the next (see [3]–[6], [8], [10], [12], [13], [40]). The former approach assumes that the image intensity is a smooth function and restricts attention to the smooth part of the image plane only. The latter approach assumes that the image intensity is a piecewise smooth function and restricts attention to the region of the image plane wherein the image intensity is separated by a discontinuity curve. Of course for each of the two approaches, there are various projection models that one might want to consider. The two projection models well known in the literature are called "orthographic" and "perspective."

There are also other projection models (see [11]) that generalize orthographic and perspective projections. They are described as "image centered projection" and "viewer-centered projection." There are still other projection models in the literature [48] not considered in this paper. In this paper, we consider a model of projection (see equation (3.1)) that generalizes the various projection models considered in the literature. The generalized projection degenerates to orthographic, pseudo-orthographic, and perspective projection under various limiting cases. The corresponding estimates of the parameters also degenerate and these have been studied in detail in this paper. Before we describe the main contribution of this paper, we survey some of the important contributions in the field of motion parameter estimation.

The problem of estimating the motion parameters in computer vision has a long history, initiated by the early works of Ullman [9]. The problem was tested subsequently with real images by Roach and Aggarwal [16]. Finally Nagel [17] reduced the problem to solving a single nonlinear equation. A fairly complete analytical solution for eight feature points was given independently by Longuet-Higgins [18] and Tsai and Huang [21]. Zhuang [23], [24] proposed a simplified eight-point algorithm and discussed the uniqueness issue. On the question of uniqueness, Netravali et. al. [25] introduced a numerical technique called the homotopy method and showed the existence of 10 solutions. Using projective geometry, Faugeras and Maybank [7] showed that at most 10 solutions can be obtained from 5 feature points. Using the quaternion representation of three-dimesnional (3-D) rotation, Jerian and Jain [26] reduced the problem to solving the resultant of degree 16 of a pair of polynomials of degree 4 in 2 variables. Jerian and Jain [27] also compared known algorithms exhaustively and compared their performances with noisy data.

Many algorithms in the literature are known to perform poorly under noisy data. A robust algorithm was introduced by Weng, Huang, and Ahuja [28] and by Spetsakis and Aloimonos [14], [15]. They used optimization-based methods to compute "epipolar equations." Grzywacz and Hildreth [29] have also indicated that the effects of image noise on reconstruction from image velocities are severe in some cases. Jerian and Jain [26] and Murray and Buxton [30] proposed various schemes toward a stable reconstruction algorithm. The particular estimation problem has been summarized in two books by Maybank [31] and by Kanatani [11]. In fact, one of the reconstruction algorithms described in this paper has been initiated by Kanatani [11]. For some other related books and references we refer the reader to [39], [41], [45], [42], [43].

In this paper, we consider in detail the problem of estimating motion and shape parameters of a planar surface undergoing an affine motion. The proposed affine motion generalizes the rigid motion already considered in the literature (see [3], [17], [19]–[22]). While preserving the shape of the surface being observed, an affine motion adequately models many other nonrigid deformations. We also consider a generalized projection which includes as a special case both "image-centered projection"

IDM: Intensity Dynamic Module
SDM: Shape Dynamic Module

FIG. 1.1. *A two-module approach to parameter identification.*

and "viewer-centered projection," together with orthographic and perspective projections. Finally, we consider both the "optical flow analysis" (see [6], [32], [33]) and the "feature-based analysis" (see [35], [34], [44], [46], [40]) and show as the main contribution of this paper that irrespective of what is assumed to be the nature of the data observed (within the class of data considered), and regardless of what is assumed to be the projection model (within the chosen class of models), the problem of motion and shape estimation for a moving textured surface can always be analyzed as a specific parameter estimation problem of a perspective system. The specific form of the perspective system depends on how the surface and the motion field have been parameterized. It may be recalled that perspective systems have already been introduced in [36] in order to study feature-based estimation of motion parameters. Roughly speaking, a perspective system is a linear system with a homogeneous observation function (see [36]).

The details about the estimation scheme proposed in this paper are explained as follows. As shown in Fig. 1.1, the estimation problem is broken up into two modules, known as the Intensity Dynamic Module (IDM) and the Shape Dynamic Module (SDM). Data from the observed surface are first processed in the IDM in order to estimate a set of "essential parameters." Effectively, IDM performs a "spatial averaging" throughout the entire image plane from either the observed sequence of features or the optical flow data.

The essential parameters are functions of motion and shape parameters. The shape-dynamic module views them as an observation function corresponding to the "shape dynamics" introduced in this paper. The shape-dynamical system together with the essential parameters (viewed as an output) can be regarded as an example of a perspective system introduced in [36]. By observing the essential parameters over time, the SDM obtains an estimate of the motion and shape parameters.

Thus, via a dynamical systems approach, we characterize a complete set of identifiable parameters or functions of parameters for a planar surface undergoing an affine motion. Such a characterization is done both for a generalized projection (3.1) and for an orthographic projection (3.2). As a special case we consider the case when the motion is restricted to a rigid flow and recover many known results in the literature.

In summary, this paper introduces a new unified treatment of the estimation problem.

2. Shape dynamics of a surface patch. We assume throughout this paper that we have a textured surface patch which faces a camera without any occlusion. Futhermore, we assume that every point on the surface moves according to a certain differential equation. As a result of the motion of the individual points, the shape of the surface undergoes deformation while the surface moves in time. In this section, we write down a differential equation that describes the motion of the surface. We also specialize the equation to a planar surface patch undergoing affine motion and subsequently to a planar surface patch undergoing rigid motion.

Let us assume that (X, Y, Z) is the world coordinate frame wherein we have a surface defined by the equation

$$Z = S(X, Y, t). \tag{2.1}$$

We assume that S is smooth enough so that its derivatives with respect to each of the variables are defined everywhere. We now assume that the motion field is given by the equation

$$\dot{X} = f(X, Y, Z), \quad \dot{Y} = g(X, Y, Z), \quad \dot{Z} = h(X, Y, Z). \tag{2.2}$$

We now describe how the surface (2.1) moves as points on the surface move following the motion field (2.2). This is given by

$$\frac{\partial S}{\partial t} + f(X, Y, S)\frac{\partial S}{\partial X} + g(X, Y, S)\frac{\partial S}{\partial Y} = h(X, Y, S). \tag{2.3}$$

The equation (2.3) is a quasilinear partial differential equation and is called the "shape dynamics." We consider the initial condition

$$S(X, Y, 0) = \phi(X, Y). \tag{2.4}$$

The pair (2.3), (2.4) constitutes an example of a Riccati partial differential equation introduced in [38]. In this paper, we shall assume that the surface (2.1) is a plane described as

$$Z = pX + qY + r, \tag{2.5}$$

where p, q, r are shape parameters that are changing in time as a result of the motion field (2.2). Furthermore we shall also assume that the motion field (2.2) is affine and is given by

$$\dot{\mathcal{X}} = A\mathcal{X} + b, \tag{2.6}$$

where

$$A = [a_{ij}], b = \mathrm{col}[b_1, b_2, b_3] \tag{2.7}$$

are respectively a 3×3 matrix and a 3×1 vector and where $\mathcal{X} = \mathrm{col}\,[X, Y, Z]$. Thus in this paper, we do not assume that the shape undergoes any deformation as a result of the motion field. We now construct a differential equation that describes the motion of the shape parameters p, q, r. This is done as follows. Let us homogenize the vector (X, Y, Z) as $X = \bar{X}/\bar{W}$, $Y = \bar{Y}/\bar{W}$, $Z = \bar{Z}/\bar{W}$ and the vector (p, q, r) as

$$p = \bar{p}/\bar{s}, \quad q = \bar{q}/\bar{s}, \quad r = \bar{r}/\bar{s}. \tag{2.8}$$

We rewrite (2.5) as $\begin{pmatrix} \bar{p}, & \bar{q}, & -\bar{s}, & \bar{r} \end{pmatrix} \bar{\mathcal{X}} = 0$ and (2.6) as $\dot{\bar{\mathcal{X}}} = -\mathcal{A}^T \bar{\mathcal{X}}$ where $\bar{\mathcal{X}} = \begin{pmatrix} \bar{X}, & \bar{Y}, & \bar{Z}, & \bar{W} \end{pmatrix}^T$ and

$$-\mathcal{A}^T = \begin{pmatrix} A & b \\ 0 & 0 \end{pmatrix}. \tag{2.9}$$

It follows that

$$\frac{d}{dt}\left(\ \bar{p},\ \ \bar{q},\ \ -\bar{s},\ \ \bar{r}\ \right)^T = \mathcal{A}\left(\ \bar{p},\ \ \bar{q},\ \ -\bar{s},\ \ \bar{r}\ \right)^T, \tag{2.10}$$

where $\mathcal{A}$ is the 4×4 matrix in (2.9) and is defined up to addition by a scalar multiple of the identity matrix. If we assume initial condition to be $\bar{s}(0) = 1$, $\bar{p}(0) = p(0)$, $\bar{q}(0) = q(0)$, $\bar{r}(0) = r(0)$, it may be concluded that the dynamical system (2.10) describes the motion of the shape parameters p, q, r. In fact, from (2.8) and (2.10) the dynamics of p, q, r can be written as the following Riccati equation:

$$\begin{aligned} \dot{p} &= (a_{33} - a_{11})p - a_{21}q + a_{31} - a_{13}p^2 - a_{23}pq, \\ \dot{q} &= (a_{33} - a_{22})q - a_{12}p + a_{32} - a_{13}pq - a_{23}q^2, \\ \dot{r} &= -(a_{33} + a_{23}q + a_{13}p)r + (b_3 - b_2q - b_1p). \end{aligned} \tag{2.11}$$

In general, Riccati equation (2.3) or (2.11) propagates in time the relationship between coordinates X, Y, and Z expressed via the surface (2.1) or the plane (2.5). Note that the equation (2.11) is parameterized by 12 motion parameters and 3 initial conditions on shape parameters. Thus there is a total of 15 parameters describing the shape dynamics (2.10) for the affine motion.

An important special case of the affine motion (2.6) is the case when A is a skew symmetric matrix given by

$$\begin{pmatrix} 0 & \omega_1 & \omega_2 \\ -\omega_1 & 0 & \omega_3 \\ -\omega_2 & -\omega_3 & 0 \end{pmatrix} \triangleq \Omega. \tag{2.12}$$

Under this assumption, the motion field (2.6) describes a rigid motion. The shape dynamics (2.10) can be written as

$$\frac{d}{dt}\begin{pmatrix} \bar{p} \\ \bar{q} \\ -\bar{s} \\ \bar{r} \end{pmatrix} = \begin{pmatrix} \Omega & 0 \\ -b^T & 0 \end{pmatrix}\begin{pmatrix} \bar{p} \\ \bar{q} \\ -\bar{s} \\ \bar{r} \end{pmatrix}. \tag{2.13}$$

Note that the shape dynamics (2.11) reduces to $\dot{p} = -\omega_2(1 + p^2) + \omega_1 q - \omega_3 pq$, $\dot{q} = -\omega_3(1 + q^2) - \omega_1 p - \omega_2 pq$, and $\dot{r} = b_3 - b_1 p - b_2 q - r(\omega_3 q + \omega_2 p)$ which is parameterized by a total of six motion parameters and three initial conditions on shape parameters. Thus there is a total of nine parameters describing the shape dynamics (2.13) for the rigid motion.

3. Intensity dynamics of a moving textured surface. Assume that the surface described by (2.1) is textured, i.e., the intensity $E(X, Y, Z, t)$ of a point (X, Y, Z) on the surface at time t does not change along the integral curves of (2.2). We also assume that the camera is perfectly focused on the object surface, i.e., intensity from a surface on the object to the image plane is transferred unattenuated under the camera correspondence. The above two assumptions together imply that the intensity on the image plane does not change along the projection of the integral curves of (2.2). In this paper we consider the projection to be described as follows.

Let (x, y) be the coordinates of the image plane obtained under the projection of a point (X, Y, Z) on the surface of the object. We define

$$x = \frac{fX}{Z + \delta}, \quad y = \frac{fY}{Z + \delta}, \tag{3.1}$$

where $\delta \in [0, f]$ and f is the focal length of the camera. Note that if $\delta = 0$ we obtain a viewer-centered projection. If $\delta = f$ we obtain an image-centered projection. These two projections have been described in [11]. Finally note that if $\delta = f$ and $f \rightarrow \infty$ we obtain

$$x = X, \quad y = Y \tag{3.2}$$

which is known in the literature [11] as the "orthographic projection."

In an orthographic projection, a point (X, Y, Z) is projected by dropping the Z coordinate information. In order to motivate the image-centered and viewer-centered projections, assume that the image plane is perpendicular to the Z axis and passes through the point $Z = a$. Assume that the optical axis is the Z axis and a point (X, Y, Z) is projected onto the image plane via the center of the camera located at $Z = -Z_0$. In order to derive the projected point, one computes the line l passing through the points (X, Y, Z) and $(0, 0, -Z_0)$ and computes the intersection of l with the image plane. The projection of the point (X, Y, Z) is this intersection. If the center of the camera is the origin of the coordinate axis, i.e., if $Z_0 = 0$, we obtain a viewer-centered projection. On the other hand, if we assume that the image plane passes through the origin of the coordinate axis, i.e., if $a = 0$, we obtain an image-centered projection.

For a given fixed value of f, δ we have a new set of coordinates (x, y, Z). We now rewrite the shape equation (2.1) and the restriction of the motion field (2.2) on the image plane in the new set of coordinates as

$$Z = \tilde{S}(x, y, t) \tag{3.3}$$

and

$$\dot{x} = \tilde{f}(x, y, \tilde{S}(x, y, t)), \quad \dot{y} = \tilde{g}(x, y, \tilde{S}(x, y, t)) \tag{3.4}$$

for some suitable functions $\tilde{S}$, $\tilde{f}$, $\tilde{g}$.

The integral curves of (3.4) are exactly the projection of the integral curves of the motion field under the generalized projection (3.1). The vector field described by (3.4) has been described in the literature (see Horn [1]) as "optical flow." Note in particular that the optical flow is in general a time-varying dynamical system described via the coordinates of the image plane. The time variation of the optical flow is a result of the motion of the surface (2.1), or equivalently (3.3).

Let $e(x, y, t)$ be the intensity of a point (x, y) on the image plane at time instant t. Since $e(x, y, t)$ does not change along the integral curves of (3.4), it follows that $e(x, y, t)$ satisfies the partial differential equation given by

$$\frac{\partial e}{\partial t} + \tilde{f}(x, y, \tilde{S}(x, y, t))\frac{\partial e}{\partial x} + \tilde{g}(x, y, \tilde{S}(x, y, t))\frac{\partial e}{\partial y} = 0. \tag{3.5}$$

We shall call the dynamical system (3.5) as "intensity dynamics." Let us now assume that the initial condition is given by

$$e(x, y, 0) = \Psi(x, y). \tag{3.6}$$

We shall call the function $\Psi(x, y)$ the "texture function." The above pair (3.5), (3.6) is a linear partial differential equation, which describes the dynamics of the intensity function on the image plane.

Let us now restrict our attention to a planar surface (2.5) with affine motion (2.6) and assume a generalized projection (3.1). The "optical flow" equation for this special case can be written as follows:

$$\begin{aligned} \dot{x} &= d_1 + d_3x + d_4y + \frac{1}{f}\left(d_7x^2 + d_8xy\right), \\ \dot{y} &= d_2 + d_6y + d_5x + \frac{1}{f}\left(d_8y^2 + d_7xy\right), \end{aligned} \tag{3.7}$$

where

$$\begin{aligned} &d_1 = f(a_{13} + c_1), d_2 = f(a_{23} + c_2), d_3 = (a_{11} - a_{33}) - (c_3 + pc_1), \\ &d_4 = a_{12} - qc_1, d_5 = a_{21} - pc_2, \\ &d_6 = (a_{22} - a_{33}) - (c_3 + qc_2), d_7 = pc_3 - a_{31}, d_8 = qc_3 - a_{32} \end{aligned} \tag{3.8}$$

and where

$$c_i = (b_i - a_{i3}\delta)/(r + \delta), i = 1, 2, 3. \tag{3.9}$$

Various limits of the optical flow equation have been considered in the literature. They all pertain to analyzing what happens when f tends to ∞, assuming $f = \delta$. In the process of taking the limit, one would approximate the coefficients of the optical flow equation (3.7) up to order $\frac{1}{f}$, while neglecting the higher-order terms. If we define

$$h_j = \lim_{f\to\infty} d_j; \quad j = 1, 2, \ldots, 8 \tag{3.10}$$

we obtain the following:

$$\begin{aligned} &h_1 = a_{13}r + b_1, h_2 = a_{23}r + b_2, \\ &h_3 = a_{11} + a_{13}p, h_4 = a_{12} + a_{13}q, \\ &h_5 = a_{21} + a_{23}p, h_6 = a_{22} + a_{23}q, \\ &h_7 = -a_{31} - a_{33}p, h_8 = -a_{32} - a_{33}q. \end{aligned} \tag{3.11}$$

Thus when $f \to \infty$ and $f = \delta$, the optical flow equation can be approximated up to order $\frac{1}{f}$ by

$$\begin{aligned} \dot{x} &= h_1 + h_3x + h_4y + \frac{1}{f}(h_7x^2 + h_8xy), \\ \dot{y} &= h_2 + h_5x + h_6y + \frac{1}{f}(h_8y^2 + h_7xy). \end{aligned} \tag{3.12}$$

Of course if the focal length of the camera is fixed at ∞, one observes the optical flow equation as

$$\dot{x} = h_1 + h_3x + h_4y, \dot{y} = h_2 + h_5x + h_6y. \tag{3.13}$$

The projection which produces the optical flow given by (3.13) is known as "orthographic projection." Such a projection described by (3.2) does not give any information about the quadratic component d_7 and d_8 of the optical flow (3.7) in general. The optical flow equation (3.12), on the other hand, is an approximation of (3.7) up to order $\frac{1}{f}$ assuming f is approaching ∞. Thus if the focal length of a camera can be varied, one can obtain the asymptotic values of d_7 and d_8 for large f and use this information to compute h_7 and h_8. We shall call (3.12) the optical flow under "orthographic approximation," as opposed to (3.13), which is the optical flow under "orthographic projection."

We also introduce a "pseudo-orthographic approximation" of (3.7) originally introduced by Kanatani [11]. This is described as follows:

$$\begin{aligned} \dot{x} &= d_1 + d_3 x + d_4 y + \frac{1}{f}\left(h_7 x^2 + h_8 xy\right), \\ \dot{y} &= d_2 + d_6 y + d_5 x + \frac{1}{f}\left(h_8 y^2 + h_7 xy\right). \end{aligned} \tag{3.14}$$

"Orthographic approximation" and "pseudo-orthographic approximation" to the optical flow equation (3.7) is useful in the process of reconstructing the motion and shape parameters from the coefficients of the optical flow equation. The reconstruction algorithm has been described in §5 using an approach described by Kanatani [11].

4. Estimation of essential parameters based on intensity and feature measurements. Assume as in §3 that we have a moving textured plane which produces a time-varying intensity profile on the image plane. In this section we consider the intensity dynamic module problem described as follows.

PROBLEM 2 (intensity dynamic module problem). *Assume that the intensity function $e(x, y, t)$ is measured in a given region of the image plane over a given interval of time. The problem is to estimate the vector $(d_1, \ldots, d_8)$ from this data.*

In subsequent sections, we shall see that the vector $(d_1, \ldots, d_8)$ is of paramount importance in estimating the motion and shape parameters. For this reason we shall call the vector $(d_1, \ldots, d_8)$ the "vector of essential parameters."

4.1. Estimation based on intensity measurements. Assume that the intensity function is smooth so that all its partial derivatives exist and can be computed. If the motion field is affine given by (2.6), it follows from (3.5), (3.7) that the intensity dynamics is given by

$$\frac{\partial e}{\partial t} + F(x, y)\frac{\partial e}{\partial x} + G(x, y)\frac{\partial e}{\partial y} = 0, \tag{4.1}$$

where $e(x, y, t)$ is the observed intensity function on the image plane and

$$\begin{aligned} F(x, y) &= d_1 + d_3 x + d_4 y + \frac{1}{f}\left(d_7 x^2 + d_8 xy\right), \\ G(x, y) &= d_2 + d_6 y + d_5 x + \frac{1}{f}\left(d_8 y^2 + d_7 xy\right). \end{aligned} \tag{4.2}$$

The parameters $d_1, \ldots, d_8$ can be defined from (3.8). Combining (4.1) and (4.2), we now write

$$v^T d = -\frac{\partial e}{\partial t}, \tag{4.3}$$

where

$$v^T = \left(e_x, e_y, xe_x, ye_x, xe_y, ye_y, \frac{1}{f}\left(x^2 e_x + xye_y\right), \frac{1}{f}\left(xye_x + y^2 e_y\right)\right) \tag{4.4}$$

and

$$d = (d_1, \dots, d_8)^T . \tag{4.5}$$

In order to compute an estimate of the coefficient vector d, we proceed as follows. Choose $n \geq 8$ points on the image plane denoted by $(x_i, y_i), i = 1, \dots, n$. From the observed data $e(x, y, t)$ we now form the matrices

$$V = \begin{pmatrix} v(x_1, y_1) & v(x_2, y_2) & . & . & . & v(x_n, y_n) \end{pmatrix} \tag{4.6}$$

and

$$u = \begin{pmatrix} -e_t(x_1, y_1) & -e_t(x_2, y_2) & . & . & . & -e_t(x_n, y_n) \end{pmatrix}^T \tag{4.7}$$

From (4.3) it follows that $V^T d = u$. If the points (x_i, y_i) are chosen in such a way that rank $V = 8$, we compute

$$\hat{d} = (VV^T)^{-1} V u \tag{4.8}$$

as an estimate of d. We therefore have the following theorem.

THEOREM 4.1. *Assume that the function* $e(x, y, t)$ *is such that all its partial derivatives are available and can be measured. Assume furthermore that the points* $(x_i, y_i), i = 1, \dots, n$ *are such that rank* $V = 8$, *where* V *is given by* (4.6). *It is possible to obtain a unique estimate of* d.

4.2. Estimation based on feature measurements: Curve correspondence. By the word "feature" we shall mean points or curves of discontinuity for the intensity function $e(x, y, t)$. We shall assume that, via edge detection, these features can be observed in real time. We shall assume that the moving textured surface produces a time-varying intensity function on the screen. The moving intensity function in turn would make the features move on the screen. The dynamical system which describes such a motion is called "feature dynamics." The main result of this section is to see that the coefficients of the feature dynamics are exactly the essential parameters introduced in (3.8). Thus under an appropriate technical condition, the essential parameters can be estimated from the feature dynamics as well, as was the case for intensity dynamics. In order to describe the feature dynamics we proceed as follows.

Let

$$y = \mathcal{I}(x, t) \tag{4.9}$$

be the curve along which the function $e(x, y, t)$ is discontinuous. We want to study how the feature curve (4.9) changes in time. Differentiating (4.9) with respect to time, we obtain

$$\dot{y} = \frac{\partial \mathcal{I}}{\partial x} \dot{x} + \frac{\partial \mathcal{I}}{\partial t}. \tag{4.10}$$

Recall that

$$\begin{aligned} \dot{x} &= F(x, y), \\ \dot{y} &= G(x, y), \end{aligned} \tag{4.11}$$

where $F(x,y), G(x,y)$ are given in (4.2). It follows that

$$\begin{aligned}\frac{\partial \mathcal{I}}{\partial t} + \frac{\partial \mathcal{I}}{\partial x}\left[d_1 + d_3x + d_4\mathcal{I}(x,t) + \frac{1}{f}(d_7x^2 + d_8x\mathcal{I}(x,t))\right] \\ = d_2 + d_6\mathcal{I}(x,t) + d_5x + \frac{1}{f}\left(d_8\mathcal{I}(x,t)^2 + d_7x\mathcal{I}(x,t)\right. .\end{aligned} \tag{4.12}$$

The above equation (4.12) is referred to as the feature dynamics, which can be rewritten as

$$v^Td = -\frac{\partial \mathcal{I}}{\partial t}, \tag{4.13}$$

where d is defined as in (4.5) to be the vector of essential parameters. The vector v^T is given by

$$v^T = \left(\mathcal{I}_x, -1, x\mathcal{I}_x, \mathcal{I}\mathcal{I}_x, -x, -\mathcal{I}, \frac{1}{f}\left(x^2\mathcal{I}_x - x\mathcal{I}\right), \frac{1}{f}\left(-\mathcal{I}^2 + x\mathcal{I}\mathcal{I}_x\right)\right). \tag{4.14}$$

We now choose $n \geq 8$ points on the curve (4.9) denoted by $(x_i, y_i), i = 1, \ldots, 8$. As in (4.6), (4.7) we construct the matrix V and vector u and obtain an estimate $\hat{d}$ of d given by (4.8), provided of course rank $V = 8$.

In order for the matrix V to have rank 8, the curve (4.9) has to be of sufficiently high order. In fact, if (4.9) is a polynomial, it cannot be of degree < 4. On the other hand, if

$$\mathcal{I}(x,t) = a_0 + a_1x + a_2x^2 + a_3x^3 + a_4x^4, a_4 \neq 0 \tag{4.15}$$

in order for rank $V = 8$, one must have

$$a_3^2 \neq \frac{8}{3}a_2a_4. \tag{4.16}$$

Thus we have essentially proved the following theorem.

THEOREM 4.2. *Assume that the observed feature is a polynomial discontinuity curve* (4.9) *of degree* 4 *given by* (4.15). *It is possible to estimate* $\hat{d}$ *given by* (4.8) *iff* (4.16) *is satisfied.*

If the observed discontinuity curve is of degree < 4, we shall see that one needs to observe a larger number of features in order for rank $V = 8$. Two cases of interest are when the observed feature is a line and when it is a point. These two subcases are now considered.

4.3. Estimation based on line correspondence.

Let

$$y = ax + b \tag{4.17}$$

be the line along which the function $e(x,y,t)$ is discontinuous. Assume furthermore that the line (4.17) is generated as a result of a discontinuity in the texture of the surface (2.5). We also assume that changes in x, y are given by (3.7). Thus, the feature dynamics is given by (4.12) or (4.13) where

$$\frac{\partial \mathcal{I}}{\partial t} = \dot{a}x + \dot{b} \tag{4.18}$$

and

$$v^T = \left(a, -1, ax, a(ax+b), -x, -(ax+b), -\frac{b}{f}x, -\frac{b}{f}(ax+b)\right). \tag{4.19}$$

The vector d of essential parameters (see (4.5)) satisfies the ordinary differential equation

$$\begin{pmatrix} -a & 1 & 0 & -ab & 0 & b & 0 & \frac{b^2}{f} \\ 0 & 0 & -a & -a^2 & 1 & a & \frac{b}{f} & \frac{ab}{f} \end{pmatrix} d = \begin{pmatrix} \dot{a} \\ \dot{b} \end{pmatrix}. \tag{4.20}$$

If we assume that the motion of the line (4.17) is observed, we might infer that in (4.20), a, b, $\dot{a}$, $\dot{b}$ is observed. Thus (4.20) represents a pair of equations in eight variables, the variables being the eight-parameter d vector. Choosing a set of four lines on the surface being observed and assuming that these four lines define a set of eight independent conditions on the d vector, one can obtain an unique estimate of the d vector. The procedure is similar to that outlined in §4.1 and described by (4.8). We now state the following theorem.

THEOREM 4.3. *Assume that the observed feature is a set of four lines on the image plane given by the equation*

$$y = a_i x + b_i, \quad i = 1, \ldots, 4, \tag{4.21}$$

where the lines (4.21) *are generated as a result of discontinuity in the texture of the surface* (2.5). *Define*

$$\phi_i = \begin{pmatrix} -a_i & 1 & 0 & -a_i b_i & 0 & b_i & 0 & \frac{b_i^2}{f} \\ 0 & 0 & -a_i & -a_i^2 & 1 & a_i & \frac{b_i}{f} & \frac{a_i b_i}{f} \end{pmatrix} \tag{4.22}$$

$i = 1, \ldots, 4$ *and the* 8×8 *matrix* $\phi = \left(\phi_1^T \; \phi_2^T \; \phi_3^T \; \phi_4^T\right)^T$. *It is possible to estimate the vector* d *uniquely given by*

$$\hat{d} = \left(\phi^T \phi\right)^{-1} \phi^T \left(\dot{a}_1 \quad \dot{b}_1 \quad \dot{a}_2 \quad \dot{b}_2 \quad \dot{a}_3 \quad \dot{b}_3 \quad \dot{a}_4 \quad \dot{b}_4 \right)^T \tag{4.23}$$

iff rank $\phi = 8$.

4.4. Estimation based on point correspondence. If we assume that the texture function is discontinuous at a single point, one would observe this point as a discontinuity in the function $e(x, y, t)$. Tracking the discontinuity in real time would amount to tracking the projection of the feature point on the image plane. Thus we rewrite the optical flow (3.7) as

$$\begin{pmatrix} 1 & 0 & x & y & 0 & 0 & \frac{x^2}{f} & \frac{xy}{f} \\ 0 & 1 & 0 & 0 & x & y & \frac{xy}{f} & \frac{y^2}{f} \end{pmatrix} d = \begin{pmatrix} \dot{x} \\ \dot{y} \end{pmatrix}, \tag{4.24}$$

where d is once again the vector of essential parameters given by (4.5). The point (x, y) is the projection of the feature point on the image plane. Assuming that we are able to observe $x, y, \dot{x}, \dot{y}$ in real time, it follows that equation (4.24) represents a pair of equations in eight variables, the variables being the eight-parameter d vector of essential parameters. As in §4.3, if we choose a set of four feature points on the image plane that are projections of points of discontinuity in the texture of the surface (2.5), and assume that they define a set of eight independent conditions on the vector d, it follows that one can uniquely obtain an estimate of the vector d. Thus we have the following theorem.

THEOREM 4.4. *Assume that the observed feature is a set of four points on the image plane given by* (x_i, y_i), $i = 1, \ldots, 4$, *where we assume that the points are generated as a result of discontinuity in the texture of the surface* (2.5). *Assume furthermore that the* 8×8 *matrix*

$$\psi = \left(\psi_1^T \ \psi_2^T \ \psi_3^T \psi_4^T\right)^T \tag{4.25}$$

is nonsingular, where

$$\psi_i = \begin{pmatrix} 1 & 0 & x_i & y_i & 0 & 0 & \frac{x_i^2}{f} & \frac{x_i y_i}{f} \\ 0 & 1 & 0 & 0 & x_i & y_i & \frac{x_i y_i}{f} & \frac{y_i^2}{f} \end{pmatrix}, \tag{4.26}$$

$i = 1, 2, 3, 4$. *It is possible to estimate the vector* d *uniquely given by*

$$\hat{d} = \left(\psi^T \psi\right)^{-1} \psi^T \begin{pmatrix} \dot{x}_1 & \dot{y}_1 & \dot{x}_2 & \dot{y}_2 & \dot{x}_3 & \dot{y}_3 & \dot{x}_4 & \dot{y}_4 \end{pmatrix}^T. \tag{4.27}$$

To summarize the main results of this section, we show that the vector d of essential parameters can be estimated from intensity and feature measurements. The task of the IDM is to estimate the vector d. It may be noted that the IDM requires information only at a given instant of time and performs "spatial averaging."

5. Estimating motion and shape parameters from the recovery equation. In this section we shall assume that the essential parameter vector d has already been estimated by the intensity dynamic module. The problem that we would like to consider is to solve (3.8) for the motion and shape parameters. We would also like to study how the solution degenerates for $f = \delta$ as $f \to \infty$, i.e., when the projection model degenerates to that produced by orthographic projection. Some portion of our analysis in this section is an adaptation of earlier work due to Kanatani [11].

5.1. Estimation under general projection. We assume that we have a planar surface (2.5) undergoing a rigid motion (2.13). The essential parameter vector d given by (3.8) for this case is given as follows:

$$\begin{aligned} &d_1 = f(\omega_2 + c_1), \quad d_2 = f(\omega_3 + c_2), \quad d_3 = -(c_3 + pc_1), \quad d_4 = \omega_1 - qc_1, \\ &d_5 = -\omega_1 - pc_2, \quad d_6 = -(c_3 + qc_2), \quad d_7 = (\omega_2 + pc_3), \quad d_8 = (\omega_3 + qc_3), \end{aligned} \tag{5.1}$$

where

$$c_1 = (b_1 - \omega_2 \delta)/(r + \delta), \quad c_2 = (b_2 - \omega_3 \delta)/(r + \delta), \quad c_3 = b_3/(r + \delta). \tag{5.2}$$

The problem that we consider is described as follows.

PROBLEM 3. *Assume that we are given* $(d_1, \ldots, d_8)$. *Using the algebraic equation* (5.1), (5.2), *solve for the parameters* $c_1, c_2, c_3, \omega_1, \omega_2, \omega_3, p, q$.

It may be noted that (5.1) describes exactly a set of eight nonlinear equations in eight parameters. This particular set of equations is known as the "recovery equation." The following result is quite surprising, however.

THEOREM 5.1. *Assume* $c_3 \neq 0$; *then* (5.1) *can be solved for exactly two real solutions. If*

$$(c_1, c_2, c_3, \omega_1, \omega_2, \omega_3, p, q) \tag{5.3}$$

is one solution, then the other solution is given by

$$(-c_3p,\ -c_3q,\ c_3,\ \omega_1 - c_1q + c_2p,\ \omega_2 + c_1 + c_3p,\ \omega_3 + c_2 + c_3q,\ -c_1/c_3,\ -c_2/c_3)\,. \tag{5.4}$$

It may be remarked that the existence of two solutions to the recovery equation (5.1) and described by Theorem 5.1 has been reported earlier in the literature by Waxman and Ullman [8] and by Kanatani [11]. In [8] the analytical steps leading up to the two solutions have not been documented. In [11] the analytical formula (5.4) of the two solutions has not been presented. The purpose of stating and proving Theorem 5.1 is therefore tutorial.

Before we prove Theorem 5.1, we proceed to solve the set of equations (5.1). Let us define

$$\begin{aligned} &T = d_3 + d_6, && R = d_5 - d_4, && U_0 = d_1 + id_2,\\ &K = \frac{1}{f}(d_7 + id_8), && S = d_3 - d_6 + i(d_4 + d_5), && \end{aligned} \tag{5.5}$$

and

$$P = p + iq, \quad V = c_1 + ic_2, \quad W = \omega_3 - i\omega_2, \quad L = fK - \frac{1}{f}U_0. \tag{5.6}$$

The equations (5.1) can be written as

$$\begin{aligned} U_0 &= f(V + iW),\\ S &= -PV, L = c_3P - V,\\ -iPV^* &= R + 2\omega_1 + i(T + 2c_3). \end{aligned} \tag{5.7}$$

Note that (5.7) is a set of four equations in complex variables that needs to be solved. From (5.7) we have

$$V^2 + LV + c_3S = 0. \tag{5.8}$$

Solving (5.8) for V and then using (5.7) for P we have

$$V = \frac{-L \pm \sqrt{L^2 - 4c_3S}}{2}, \tag{5.9}$$

$$P = \frac{L \pm \sqrt{L^2 - 4c_3S}}{2c_3}. \tag{5.10}$$

From (5.7) we have

$$\omega_1 = [Im(PV^*) - R]/2, \tag{5.11}$$

$$T + 2c_3 = -Re(PV^*). \tag{5.12}$$

From (5.9) and (5.10) we have

$$Re(PV^*) = \frac{-|L|^2 + \sqrt{(L^2 - 4c_3S)(L^2 - 4c_3S)^*}}{4c_3}. \tag{5.13}$$

Combining (5.12) and (5.13) we have

$$|L|^2 - 4Tc_3 - 8c_3^2 = \sqrt{|L|^4 + 16c_3^2|S|^2 - 8c_3Re(L^2S^*)}. \tag{5.14}$$

Note that (5.14) as an equation in c_3 has two solutions. One solution is at $c_3 = 0$ and the other solution is at $c_3 = c_3^*$. Squaring (5.14) on both sides, we conclude that c_3^* is the middle root of the cubic equation

$$c_3^3 + Tc_3^2 + \frac{1}{4}(T^2 - |L|^2 - |S|^2)c_3 + \frac{1}{8}(Re(L^2S^*) - T|L|^2) = 0 \tag{5.15}$$

Using c_3, one can solve for a pair of solutions for P and V from (5.9) and (5.10). Finally, from (5.7) we have

$$W = i\left(V - \frac{1}{f}U_0\right) \tag{5.16}$$

and from (5.11) one can solve for ω_1. Thus the set of equations (5.7) can be solved for exactly two distinct solutions if $c_3 \neq 0$. If (5.1) is solved, these are exactly the two solutions that one would obtain.

Proof of Theorem 5.1. It can be easily checked that if (5.3) is one solution of (5.1), then the other solution is given by (5.4). However, since (5.1) has exactly two solutions, these are the only solutions. Moreover the solutions are obtained by solving the cubic polynomial equation (5.15) outlined as above.

From the two solutions to the recovery equation (5.7), it is easy to see what happens when $f \to \infty$. Note that

$$\lim_{f\to\infty} c_1 = -\omega_2, \quad \lim_{f\to\infty} c_2 = -\omega_3, \quad \lim_{f\to\infty} c_3 = 0. \tag{5.17}$$

It follows that one of the two solutions $(c_1, c_2, c_3, \omega_1, \omega_2, \omega_3, p, q)$ approaches the vector

$$(-\omega_2,\ -\omega_3,\ 0,\ \omega_1,\ \omega_2,\ \omega_3,\ p,\ q), \tag{5.18}$$

the first six components of the other solution approach the vector

$$(0,\ 0,\ 0,\ \omega_1 + \omega_2 q - \omega_3 p,\ 0,\ 0) \tag{5.19}$$

and the last two components of the other solution approach ∞ asymptotically along the line

$$p/q = \omega_2/\omega_3. \tag{5.20}$$

The parameters b_1, b_2, b_3, r are never recovered exactly. In fact, from the definition of d_1, d_2, c_3 we have, for a given f, the straight line

$$\omega_2 r + b_1 = \left(1 + \tfrac{r}{f}\right) d_1, \quad \omega_3 r + b_2 = \left(1 + \tfrac{r}{f}\right) d_2, \quad b_3 = c_3(r + f) \tag{5.21}$$

described in the (b_1, b_2, b_3, r) space corresponding to the solution $(c_1, c_2, c_3, \omega_1, \omega_2, \omega_3, p, q)$. On the other hand, corresponding to the other solution we have the straight line

$$\begin{aligned}(\omega_2 + c_1 + c_3 p)r + b_1 &= \left(1 + \frac{r}{f}\right) d_1,\\ (\omega_3 + c_2 + c_3 q)r + b_2 &= \left(1 + \frac{r}{f}\right) d_2,\\ b_3 &= c_3(r + f).\end{aligned} \tag{5.22}$$

As $f \to \infty$, the straight line (5.21) tends to the straight line

$$\omega_2 r + b_1 = h_1, \omega_3 r + b_2 = h_2, b_3 = b_3^*, \tag{5.23}$$

where b_3^* is an arbitrary constant. To see (5.23) we need the following lemma.

LEMMA 5.2. *In the (b_3, r) space the straight line $b_3 = c_3(r+f)$ converges to the line $b_3 = b_3^*$ as $f \to \infty$, where b_3^* is an arbitrary constant.*

Proof. Recall that $d_3 = -c_3 - pc_1$, i.e.,

$$(d_3 + pc_1)r + b_3 = -(d_3 + pc_1)f. \tag{5.24}$$

As $f \to \infty$, we have $(d_3 + pc_1) \to 0$ and $(b_3 + (d_3 + pc_1)f) \to 0$. At a given f, the line (5.24) passes through the point $(0, -f)$ and $(-(d_3 + pc_1)f, 0)$. For large f, the line passes closely through the points $(0, -f)$ and $(b_3^*, 0)$ where b_3^* is a fixed constant, which is also the true value of b_3. Thus as $f \to \infty$ the line (5.24) approaches the line $b_3 = b_3^*$. □

The above calculation can be summarized via the following theorem.

THEOREM 5.3. *Consider the solution vector $(\omega_1, \omega_2, \omega_3, p, q)$ for the recovery equation* (5.7). *For a given fixed f there are exactly two solutions, one of which remains unchanged as $f \to \infty$ and the other of which goes off to infinity as described by* (5.19), (5.20). *For the parameter vector (b_1, b_2, b_3, r), the recovery equation specifies these parameters up to a choice of two straight lines* (5.21) *and* (5.22). *The line* (5.21) *corresponds to the parameter vector $(\omega_1, \omega_2, \omega_3, p, q)$, which does not change with f. Moreover as $f \to \infty$, the line* (5.21) *changes with f and approaches the limit* (5.23).

Remark. It follows from Theorem 5.3 that for large f one recovers (b_1, b_2, r) up to a line given by (5.23) and b_3 exactly.

5.2. Estimation under pseudo-orthographic approximation. Under the pseudo-orthographic approximation, the equation we need to solve for instead of (5.1) is given by

$$\begin{array}{llll} d_1 = f(\omega_2 + c_1), & d_2 = f(\omega_3 + c_2), & d_3 = -(c_3 + pc_1), & d_4 = \omega_1 - qc_1, \\ d_5 = -\omega_1 - pc_2, & d_6 = -(c_3 + qc_2), & h_7 = \omega_2, & h_8 = \omega_3. \end{array} \tag{5.25}$$

Let us define T, R, U_0, S as in (5.5) and replace K by K_1 given by $K_1 = \frac{1}{f}(h_7 + ih_8)$. Furthermore let us define P, V, W as in (5.6) and replace L by L_1 given by $L_1 = fK_1 - \frac{1}{f}U_0$. The recovery equation (5.25) can be written as $U_0 = f(V + iW)$, $S = -PV$, $L_1 = -V$, and $-iPV^* = (R + 2\omega_1) + i(T + 2c_3)$, which can be easily solved (see [11]) and the solution is given by

$$\begin{array}{rl} V = & -L_1, \\ P = & S/L_1, \\ \omega_1 = & -[Im(SL_1^*/L_1) + R]/2, \\ W = & i\left(V - \dfrac{1}{f}U_0\right). \end{array} \tag{5.26}$$

The following theorem describes an important property of the pseudo-orthographic approximation.

THEOREM 5.4. *The solution* (5.26) *of the pseudo-orthographic approximation, converges as $f \to \infty$ to one of the solution of the recovery equation* (5.7), *described by* (5.9), (5.10), (5.11), *and* (5.16). *The solution to which* (5.26) *converges to is exactly the one which does not change with f.*

Proof of Theorem 5.4. It is easy to see from (5.9), (5.10) that

$$\lim_{c_3 \to 0} \frac{-L - \sqrt{L^2 - 4c_3 S}}{2} = -L,$$

$$\lim_{c_3 \to 0} \frac{L - \sqrt{L^2 - 4c_3 S}}{2c_3} = S/L.$$

If $f \to \infty$ it follows that $c_3 \to 0$. Thus it may be concluded that if $f \to \infty$, the solution (5.26) approaches one of the two solutions of the recovery equation (5.7). Finally note that as $f \to \infty$, (5.26) remains finite. To see this we compute

$$\tag{5.27} \begin{aligned} &\bar{V} = -\lim_{f\to\infty} L_1 = -(h_7 + ih_8), \\ &\bar{P} = \lim_{f\to\infty} S/L_1 = \frac{(h_3 - h_6) + i(h_4 + h_5)}{h_7 + ih_8} \\ &\bar{\omega}_1 = [Im(\bar{P}\bar{V}^*) - (h_5 - h_4)]/2, \\ &\bar{W} = i\bar{V}. \end{aligned}$$

Thus the solution (5.26) to the pseudo-orthographic approximation remains finite and approaches one of the two solutions to the recovery equation (5.7). It follows that it must approach the one which does not change with f because the other solution does not remain finite. □

Remark. The limiting solution (5.27) is exactly the solution to the recovery equation under orthographic approximation. Such an equation will be given by $h_1 = \omega_2 r + b_1$, $h_2 = \omega_3 r + b_2$, $h_3 = \omega_2 p$, $h_4 = \omega_1 + \omega_2 q$, $h_5 = -\omega_1 + \omega_3 p$, $h_6 = \omega_3 q$, $h_7 = \omega_2$, and $h_8 = \omega_3$. Verification of this fact is straightforward.

Remark. The advantage of using pseudo-orthographic approximation as opposed to solving the recovery equation (5.7) is that one needs to solve only linear equations in the former whereas one needs to solve a cubic equation in the latter.

6. Identifiability condition of a planar surface undergoing affine motion. We consider a planar surface undergoing an affine motion and note that the motion of the shape parameters is given by (2.10). In this section we shall consider identifying parameters of (2.10) by considering an output equation given by (3.8). However, since (3.8) is nonlinear in the parameters, we would like to homogenize the vector $(d_1, \ldots, d_8)^T$ as follows. Let us define

$$\tag{6.1} d_j = \frac{y_j}{y_9}, \quad j = 1, \ldots, 8$$

so that the vector

$$\tag{6.2} (y_1, \ldots, y_9)$$

is a homogenization of the essential parameters. Equation (3.8) can be written as

$$\tag{6.3} \begin{pmatrix} y_1 \\ y_2 \\ y_3 \\ y_4 \\ y_5 \\ y_6 \\ y_7 \\ y_8 \\ y_9 \end{pmatrix} = \begin{pmatrix} 0 & 0 & -fb_1 & fa_{13} \\ 0 & 0 & -fb_2 & fa_{23} \\ -b_1' & 0 & b_3 - \delta a_{11} & a_{11} - a_{33} \\ 0 & -b_1' & -\delta a_{12} & a_{12} \\ -b_2' & 0 & -\delta a_{21} & a_{21} \\ 0 & -b_2' & b_3 - \delta a_{22} & a_{22} - a_{33} \\ -b_3' & 0 & -\delta a_{31} & a_{31} \\ 0 & -b_3' & -\delta a_{32} & a_{32} \\ 0 & 0 & -\delta & 1 \end{pmatrix} \begin{pmatrix} \bar{p} \\ \bar{q} \\ -\bar{s} \\ \bar{r} \end{pmatrix},$$

where $\bar{p}$, $\bar{q}$, $\bar{s}$, and $\bar{r}$ have been defined as given by (2.8) and

$$b' = (b_1 - a_{13}\delta \; b_2 - a_{23}\delta \; b_3 - a_{33}\delta) \overset{\Delta}{=} (b'_1 \; b'_2 \; b'_3). \tag{6.4}$$

We now consider the shape dynamic module problem described as follows.

Shape dynamic module problem. Consider a dynamical system (2.10) together with the output function (6.3). The problem is to identify the parameters A, b given by (2.7) and the initial conditions $\bar{p}(0), \bar{q}(0), \bar{s}(0), \bar{r}(0)$ to the extent possible.

The main result of this section is to derive a complete answer to the shape dynamic module problem. Note in particular that the perspective system (2.10), (6.3) is parameterized by a set of 12 motion parameters A, b and a set of 3 shape parameters p, q, r. We shall show that not all 15 parameters are identifiable, i.e., there is a nonunique choice of parameters for which the observation described by (6.3) is the same. The main result of this section is described as follows.

THEOREM 6.1. *Under a suitable generic condition on the set of* 15 *parameters of the perspective system* (2.10), (6.3), *the following parameters or functions of parameters are identifiable. They are*

$$(A, p, q, c_1, c_2, c_3)\,, \tag{6.5}$$

where c_1, c_2, c_3 *is defined in* (3.9).

Thus 14 parameters or functions of the parameters out of a total 15 free parameters are identifiable. The method of solving a set of recovery equations presented in §5 cannot be used to identify these 14 parameters. This is because the output equation (6.3) describes only 8 equations in 15 unknowns. In order to identify 14 parameters, one needs to use the dynamical system (2.10) together with the output equation (6.3). The parameter identification has been carried out via a new "realization theory for perspective systems" described in this section (see also [37]). An important corollary of Theorem 6.1 is now described.

COROLLARY 6.2. *Consider the perspective system* (2.13) (6.3) *parameterized by a set of nine parameters.* (*Here we assume that in* (6.3) *the parameters* a_{ij} *have been replaced by* ω_{ij} *as given by* (2.12)). *Under a suitable generic condition on the set of nine parameters, the following parameters or functions of parameters are identifiable. They are*

$$(\omega_1, \omega_2, \omega_3, p, q, c_1, c_2, c_3)\,, \tag{6.6}$$

where c_1, c_2, c_3 *is defined in* (5.2).

Thus for the perspective system (2.13), (6.3), eight functions of the nine parameters are identifiable. In §5, we have shown that the eight functions (6.6) can be identified, up to a choice of two alternative solutions, by solving the output equation (6.3) alone. Thus use of the dynamical system (2.13) results only in recovering the correct alternative.

In order to prove Theorem 6.1 we need the following notation. Define

$$\mathcal{P} = (\bar{p}\;\bar{q}\; -\bar{s}\;\bar{r})^T\,, \tag{6.7}$$

$$\mathcal{Y} = (y_1\; y_2 \cdots y_9)^T\,, \tag{6.8}$$

$$\mathcal{A} = \begin{pmatrix} -A^T & 0 \\ -b^T & 0 \end{pmatrix}, \tag{6.9}$$

$$\Delta = (\text{the } 9 \times 4 \text{ matrix in } (4.12))\,. \tag{6.10}$$

From (2.10), (6.3) it follows that

$$\mathcal{Y} = \Delta e^{\mathcal{A}t}\mathcal{P}(0), \tag{6.11}$$

where the vector $\mathcal{Y}$ is observed up to a homogeneous line. We shall denote this line by $[\mathcal{Y}]$. As has been described in Ghosh, Jankovic, and Wu [36], the nonuniqueness in $\Delta, \mathcal{A}, \mathcal{P}(0)$, which produces the same $[\mathcal{Y}]$, is given by the orbits of the following group action. They are described as follows:

1. $P \in GL(4)$ acting on $(\Delta, \mathcal{A}, \mathcal{P}(0))$ as follows:

$$(\Delta, \mathcal{A}, \mathcal{P}(0)) \mapsto \left(\Delta P, P^{-1}\mathcal{A}P, P^{-1}\mathcal{P}(0)\right). \tag{6.12}$$

2. $\mu \in \mathbb{R}$ acting on $(\Delta, \mathcal{A}, \mathcal{P}(0))$ as follows:

$$(\Delta, \mathcal{A}, \mathcal{P}(0)) \mapsto (\Delta, \mu I + \mathcal{A}, \mathcal{P}(0)). \tag{6.13}$$

3. $\lambda_1, \lambda_2 \in \mathbb{R} - \{0\}$ acting on $(\Delta, \mathcal{A}, \mathcal{P}(0))$ as follows:

$$(\Delta, \mathcal{A}, \mathcal{P}(0)) \mapsto (\lambda_1\Delta, \mathcal{A}, \lambda_2\mathcal{P}(0)). \tag{6.14}$$

The collective actions (6.12), (6.13), (6.14) will be referred to as the action due to the perspective group $\mathcal{G}$. It is easy to see that the parameters in the orbit of the group $\mathcal{G}$ produce the same output $[\mathcal{Y}]$ and hence cannot be identified. The following proposition shows that under an appropriate generic condition on the parameters of the perspective system (2.13), (6.3), two orbits of the group $\mathcal{G}$ indeed produce a different output $[\mathcal{Y}]$. Hence the orbits of the group $\mathcal{G}$ can indeed be identified.

PROPOSITION 6.3. *Consider a perspective system in continuous time given by*

$$\begin{aligned} \dot{x} &= Ax, \\ z &= [Cx], \end{aligned} \tag{6.15}$$

where we assume that the triplet (C, A, x_0) is minimal. The set of all minimal triplets which produce the same output z is given precisely by the orbits of the $\mathcal{G}$ action.

Proof of Proposition 6.3. Note that the vector function $y(t) = Ce^{At}x_0$ is observed for each t up to a homogeneous line. Assume that there is a scaling function $r(t)$ such that $r(t)y(t)$ is the output of a linear system of degree n, where we assume that $r(0) = 1$. Discretizing the system (6.15) at discrete interval $T, 2T, \ldots$, where T has been chosen to be sufficiently small, it follows from [37] that $r(jT) = r(T)^j$. Since T is arbitrary, it follows that the function $r(t)$ is such that $r(jTt) = r(Tt)^j$, for all $t \in \mathbb{R}, \mathrm{j} = 0, 1, \ldots$. If $r(t)$ is a differentiable function at $t = 0$, it follows that

$$\frac{r(t+\Delta t)}{r(t)} = r(\Delta t) = r(0) + r'(0)\Delta t.$$

One therefore concludes that

$$r'(t) = r'(0)r(t).$$

Thus the scaling function $r(t)$ is an exponential function given by

$$r(t) = e^{r'(0)t}.$$

Thus the scaling of C, A, x_0 is such that C, x_0 is scaled by a scalar multiple. The matrix A is scaled as

$$A \mapsto r'(0)I + A. \qquad \square$$

In general the $GL(4)$ action on the triplet $(\Delta, \mathcal{A}, \mathcal{P}(0))$ changes the structure of the matrix Δ and $\mathcal{A}$. The subgroup of $GL(4)$ which preserves the structure is now described.

THEOREM 6.4. *Define*

$$b_1' = b_1 - a_{13}\delta, \quad b_2' = b_2 - a_{23}\delta, \quad b_3' = b_3 - a_{33}\delta. \tag{6.16}$$

Assume that

$$b_1' a_{23} - b_2' a_{13} \neq 0, \quad b_2' a_{31} - b_3' a_{21} \neq 0, \quad b_1' a_{32} - b_3' a_{12} \neq 0, \tag{6.17}$$

$$(b_1' \; b_2' \; b_3') \neq 0, \tag{6.18}$$

$$\begin{pmatrix} A \\ b'^T \end{pmatrix} \text{ has rank } 3, \tag{6.19}$$

where $b'^T = (b_1' \; b_2' \; b_3')$. *Under the generic assumption* (6.17), (6.18), (6.19), *the only subgroup of* $GL(4)$ *which preserves the structure of* $(\Delta, \mathcal{A})$ *under the action* (6.12) *is given by*

$$\bar{P} = \begin{pmatrix} \alpha_{11} & 0 & 0 & 0 \\ 0 & \alpha_{11} & 0 & 0 \\ 0 & 0 & \alpha_{11} & 0 \\ 0 & 0 & \delta\alpha_{11} & \alpha_{44} \end{pmatrix}, \tag{6.20}$$

where $\alpha_{11} \neq 0$, $\alpha_{44} \neq 0$.

Proof of Theorem 6.4. Let

$$Q = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & \delta & 1 \end{pmatrix}. \tag{6.21}$$

It is easy to see that

$$\mathcal{A}_1 \triangleq Q^{-1}\mathcal{A}Q = \begin{pmatrix} -A^T & 0 \\ -b'^T & 0 \end{pmatrix}, \tag{6.22}$$

$$\Delta_1 \triangleq \Delta Q = \begin{pmatrix} 0 & 0 & -fb_1' & fa_{13} \\ 0 & 0 & -fb_2' & fa_{23} \\ -b_1' & 0 & b_3' & a_{11} - a_{33} \\ 0 & -b_1' & 0 & a_{12} \\ -b_2' & 0 & 0 & a_{21} \\ 0 & -b_2' & b_3' & a_{22} - a_{33} \\ -b_3' & 0 & 0 & a_{31} \\ 0 & -b_3' & 0 & a_{32} \\ 0 & 0 & 0 & 1 \end{pmatrix}. \tag{6.23}$$

Let $Q_1 = (\alpha_{ij})$ be a nonsingular 4×4 matrix. Under the generic condition (6.17), (6.18) it may be concluded that $\Delta_1 Q_1$ has the same structure as Δ_1 if Q_1 has the form

$$Q_1 = \begin{pmatrix} \alpha_{11} & 0 & 0 & \alpha_{14} \\ 0 & \alpha_{11} & 0 & \alpha_{24} \\ 0 & 0 & \alpha_{11} & \alpha_{34} \\ 0 & 0 & 0 & \alpha_{44} \end{pmatrix} \triangleq \begin{pmatrix} \alpha_{11} I & \Theta \\ 0 & \alpha_{44} \end{pmatrix}. \tag{6.24}$$

Computing $Q_1^{-1}\mathcal{A}_1 Q_1$ we have

$$Q_1^{-1}\mathcal{A}_1 Q_1 = \begin{pmatrix} -A^T + \frac{1}{\alpha_{44}}\Theta b'^T & -\frac{1}{\alpha_{11}}A^T\Theta + \frac{1}{\alpha_{11}\alpha_{44}}\Theta b'^T\Theta \\ -\frac{\alpha_{11}}{\alpha_{44}}b'^T & -\frac{1}{\alpha_{44}}b'^T\Theta \end{pmatrix}. \tag{6.25}$$

In order for $Q_1^{-1}\mathcal{A}_1 Q_1$ to have the same structure as $\mathcal{A}_1$ we must have

$$b'^T\Theta = 0 \quad \text{and} \quad A^T\Theta = 0.$$

Under the generic condition (6.19), it follows that $\Theta = 0$. Thus Q_1 is of the form

$$Q_1 = \begin{pmatrix} \alpha_{11} & 0 & 0 & 0 \\ 0 & \alpha_{11} & 0 & 0 \\ 0 & 0 & \alpha_{11} & 0 \\ 0 & 0 & 0 & \alpha_{44} \end{pmatrix}. \tag{6.26}$$

The structure (6.20) of the $\bar{P}$ matrix is obtained by defining $\bar{P} = QQ_1$, where Q, Q_1 are given by (6.21), (6.26), respectively. □

Note that $\bar{P}^{-1}\mathcal{A}\bar{P}$ takes up the form

$$\begin{pmatrix} -A^T & 0 \\ -\frac{\alpha_{11}}{\alpha_{44}}b'^T & 0 \end{pmatrix}. \tag{6.27}$$

On the other hand, $\bar{P}^{-1}\mathcal{P}$ is given by

$$\begin{pmatrix} \frac{\bar{p}}{\alpha_{11}} & \frac{\bar{q}}{\alpha_{11}} & -\frac{\bar{s}}{\alpha_{11}} & \frac{\bar{r}+\delta\bar{s}}{\alpha_{44}} \end{pmatrix}^T \tag{6.28}$$

and $\Delta\bar{P}$ is given by

$$\begin{pmatrix} 0 & 0 & -\alpha_{11}fb'_1 & \alpha_{44}fa_{13} \\ 0 & 0 & -\alpha_{11}fb'_2 & \alpha_{44}fa_{23} \\ -\alpha_{11}b'_1 & 0 & \alpha_{11}b'_3 & \alpha_{44}(a_{11}-a_{33}) \\ 0 & -\alpha_{11}b'_1 & 0 & \alpha_{44}a_{12} \\ -\alpha_{11}b'_2 & 0 & 0 & \alpha_{44}a_{21} \\ 0 & \alpha_{11}b'_2 & \alpha_{11}b'_3 & \alpha_{44}(a_{22}-a_{33}) \\ -\alpha_{11}b'_3 & 0 & 0 & \alpha_{44}a_{31} \\ 0 & -\alpha_{11}b'_3 & 0 & \alpha_{44}a_{32} \\ 0 & 0 & 0 & \alpha_{44} \end{pmatrix}. \tag{6.29}$$

In order to get the last row of $\Delta\bar{P}$ to be a unit vector we apply the group in (6.14) to (6.29) with $\lambda_1 = \frac{1}{\alpha_{44}}$. From (6.27), (6.28), (6.29) it can be concluded that the subgroup (6.20) essentially scales the vector b' by the scalar $\frac{\alpha_{11}}{\alpha_{44}}$. Likewise it scales

$r+\delta$ by $\frac{\alpha_{11}}{\alpha_{44}}$. Hence the function $\frac{b'}{(r+\delta)}$ remains invariant in the orbit of the subgroup (6.20) action.

The subgroup (6.13) essentially changes the diagonal of the matrix $\mathcal{A}$. Since the diagonal of the matrix $\mathcal{A}$ is given by $(-a_{11} \;\; -a_{22} \;\; -a_{33} \;\; 0)$ it follows that the subgroup which preserves the structure is given by $\mu = 0$ and the parameters a_{11}, a_{22}, a_{33} remain invariant in the orbit of this subgroup action.

Proof of Theorem 6.1. Note that under the generic conditions (6.17), (6.18), (6.19) the functions (6.5) remain invariant under the action of the perspective group $\mathcal{G}$, i.e., they remain constant in the orbits of the $\mathcal{G}$ action. In Proposition 6.3 we show that additionally if $(\Delta, \mathcal{A}, \mathcal{P}(0))$ is a minimal triplet then no two orbits of the $\mathcal{G}$ action produce the same output $[\mathcal{Y}]$. □

7. Identification of parameters based on the orthographic projection.

The orthographic projection occurs as a special case of the generalized projection (3.1) when we assume $\delta = f$ and let $f \to \infty$. In this case, the parameters d_7, d_8 of the output equation (6.3) or (3.9) are forced to zero or equivalently, the quadratic term in (3.7) or (3.12) drops out. Thus, the optical flow equation is given by (3.13) and the recovery equation is given by the first six components $h_1, \ldots, h_6$ of (3.11).

7.1. Solution to the recovery equation for the rigid motion.

We begin this section by considering a plane undergoing a rigid motion given by (2.13). The corresponding recovery equation is given by

$$\begin{aligned} d_1 &= \omega_2 r + b_1, & d_2 &= \omega_3 r + b_2, & d_3 &= \omega_2 p, \\ d_4 &= \omega_1 + \omega_2 q, & d_5 &= -\omega_1 + \omega_3 p, & d_6 &= \omega_3 q, \end{aligned} \tag{7.1}$$

where we shall assume that the vector $(d_1, \ldots, d_6)$ is estimated by the IDM. Kanatani [11] has considered the problem of solving (7.1) for the parameters $\omega_1, \omega_2, \omega_3, p, q, r, b_1, b_2$. The parameter b_3 does not enter (7.1) and is therefore not recoverable from the equation (7.1). Moreover since we have six equations in eight unknowns we do not expect to recover the parameters even up to finitely many alternatives. In fact, it is already known (see Kanatani [11]) that the recovery equation (7.1) can be solved in the following way.

Let us define

$$\begin{aligned} V &= d_1 + i d_2, & T &= d_3 + d_6, & R &= d_5 - d_4, \\ S &= d_3 - d_6 + i(d_4 + d_5), & P &= p + iq, & W &= -\omega_3 + i\omega_2. \end{aligned} \tag{7.2}$$

From (7.1) we obtain the following:

$$\begin{aligned} PW &= iS, \\ PW^* &= -(2\omega_1 + R) - iT. \end{aligned} \tag{7.3}$$

The equation (7.3) can be solved as follows.

$$\begin{aligned} &\omega_1 = -\tfrac{1}{2}\left(R \pm \sqrt{SS^* - T^2}\right), \\ &W = k \exp\left[i\left\{\tfrac{\pi}{4} + \tfrac{1}{2}\arg S - \tfrac{1}{2}\arg(-2\omega_1 - R - iT)\right\}\right], \\ &P = i\frac{S}{W}, \end{aligned} \tag{7.4}$$

where k is an arbitrary constant. The parameters b_1, b_2 and r are given as $B - iWr = V$ where $B = b_1 + ib_2$. Thus we have the following theorem essentially described by Kanatani [11].

THEOREM 7.1. *The recovery equation* (7.1) *can be solved up to two parameters* k_1, k_2 *and up to a choice of sign as follows:*

$$\begin{aligned}
&\omega_1 = -\tfrac{1}{2}\left(R \pm \sqrt{SS^* - T^2}\right),\\
&W = k_1 \exp\left[i\left\{\tfrac{\pi}{4} + \tfrac{1}{2}\arg S - \tfrac{1}{2}\arg\left(-2\omega_1 - R - iT\right)\right\}\right],\\
&P = i\tfrac{S}{W},\\
&B = V + ik_2W,\\
&r = k_2.
\end{aligned} \tag{7.5}$$

The proof of Theorem 7.1 is clear from the above discussion. Note that the solution to the recovery equation (7.2) is ambiguous up to a sign and is obtained up to a pair of parameters k_1 and k_2, out of a total of eight parameters, which excludes the parameter b_3.

7.2. Identification of a planar surface undergoing affine motion. Let us now homogenize the output equation (7.1) described as follows:

$$\begin{pmatrix} y_1 \\ y_2 \\ y_3 \\ y_4 \\ y_5 \\ y_6 \\ y_9 \end{pmatrix} = \begin{pmatrix} 0 & 0 & -b_1 & a_{13} \\ 0 & 0 & -b_2 & a_{23} \\ a_{13} & 0 & -a_{11} & 0 \\ 0 & a_{13} & -a_{12} & 0 \\ a_{23} & 0 & -a_{21} & 0 \\ 0 & a_{23} & -a_{22} & 0 \\ 0 & 0 & -1 & 0 \end{pmatrix} \begin{pmatrix} \bar{p} \\ \bar{q} \\ -\bar{s} \\ \bar{r} \end{pmatrix}. \tag{7.6}$$

We now proceed to consider the technique described in §7 for the perspective system (2.10), (7.6). Note that (7.6) is the homogeneous version of the recovery equation (3.8). Denote the 7 × 4 matrix in (7.6) by π. The main result of this section is described as follows.

THEOREM 7.2. *Consider the perspective system* (2.10), (7.6) *parameterized by a set of* 15 *parameters. Assume furthermore that the parameters satisfy the generic condition*

$$a_{13} \neq 0, \quad b_1a_{23} - b_2a_{13} \neq 0, \quad a_{12}a_{23} - a_{13}a_{22} \neq 0, \quad a_{11}a_{23} - a_{13}a_{21} \neq 0 \tag{7.7}$$

and the triplet $(\pi, \mathcal{A}, \mathcal{P}(0))$ *is a minimal triplet. The functions of the parameters that can be identified are given by*

$$\begin{gathered}
\tfrac{a_{23}}{a_{13}}, \quad b_2 - b_1\tfrac{a_{23}}{a_{13}}, \quad a_{21} - a_{11}\tfrac{a_{23}}{a_{13}}, \quad a_{22} - a_{12}\tfrac{a_{23}}{a_{13}}, \quad -a_{13}p - a_{11}, \quad -a_{13}q - a_{12},\\
-a_{13}r - b_1, \xi, \quad \left(a_{11}^2 + a_{12}a_{21} + a_{13}a_{31}\right) - a_{11}\xi,\\
\left(a_{11}a_{12} + a_{12}a_{22} + a_{13}a_{32}\right) - a_{12}\xi, \left(a_{11}b_1 + a_{12}b_2 + a_{13}b_3\right) - b_1\xi,
\end{gathered} \tag{7.8}$$

where ξ *is defined to be*

$$\xi = \tfrac{1}{a_{13}}\left(a_{11}a_{13} + a_{12}a_{23} + a_{13}a_{33}\right).$$

Remark. Thus there is a total of 11 functions of motion and shape parameters that can be identified.

Proof of Theorem 7.2. Let P be a nonsingular 4 × 4 matrix. Under the generic condition (7.7) it can be shown that πP has the same structure as that of π provided P is of the form

$$P = \begin{pmatrix} \alpha_{11} & 0 & \alpha_{13} & 0 \\ 0 & \alpha_{11} & \alpha_{23} & 0 \\ 0 & 0 & \alpha_{33} & 0 \\ 0 & 0 & \alpha_{43} & \alpha_{11} \end{pmatrix} \tag{7.9}$$

and $\frac{1}{\alpha_{33}}\pi P$ is of the form

$$\begin{pmatrix} 0 & 0 & -b_1 + \frac{\alpha_{43}}{\alpha_{33}}a_{13} & \frac{\alpha_{11}}{\alpha_{33}}a_{13} \\ 0 & 0 & -b_2 + \frac{\alpha_{43}}{\alpha_{23}}a_{23} & \frac{\alpha_{11}}{\alpha_{33}}a_{23} \\ \frac{\alpha_{11}}{\alpha_{33}}a_{13} & 0 & -a_{11} + \frac{\alpha_{13}}{\alpha_{33}}a_{13} & 0 \\ 0 & \frac{\alpha_{11}}{\alpha_{33}}a_{13} & -a_{12} + \frac{\alpha_{23}}{\alpha_{33}}a_{13} & 0 \\ \frac{\alpha_{11}}{\alpha_{33}}a_{23} & 0 & -a_{21} + \frac{\alpha_{13}}{\alpha_{33}}a_{23} & 0 \\ 0 & \frac{\alpha_{11}}{\alpha_{33}}a_{23} & -a_{22} + \frac{\alpha_{23}}{\alpha_{33}}a_{23} & 0 \\ 0 & 0 & -1 & 0 \end{pmatrix}. \tag{7.10}$$

Likewise $P^{-1}\mathcal{A}P$ is of the form.

$$\begin{pmatrix} -a_{11} + \frac{\alpha_{13}}{\alpha_{33}}a_{13} & -a_{21} + \frac{\alpha_{13}}{\alpha_{33}}a_{23} & \Theta_1 & 0 \\ -a_{12} + \frac{\alpha_{23}}{\alpha_{33}}a_{13} & -a_{22} + \frac{\alpha_{23}}{\alpha_{33}}a_{23} & \Theta_2 & 0 \\ -\frac{\alpha_{11}}{\alpha_{33}}a_{13} & -\frac{\alpha_{11}}{\alpha_{33}}a_{23} & \Theta_3 & 0 \\ -b_1 + \frac{\alpha_{43}}{\alpha_{33}}a_{13} & -b_2 + \frac{\alpha_{43}}{\alpha_{33}}a_{23} & \Theta_4 & 0 \end{pmatrix}, \tag{7.11}$$

where

$$\Theta_1 = -\frac{1}{\alpha_{11}}\left(\alpha_{13}a_{11} + \alpha_{23}a_{21} + \alpha_{33}a_{31}\right) + \frac{\alpha_{13}}{\alpha_{11}\alpha_{33}}\left(\alpha_{13}a_{13} + \alpha_{23}a_{23} + \alpha_{33}a_{33}\right),$$

$$\Theta_2 = -\frac{1}{\alpha_{11}}\left(\alpha_{13}a_{12} + \alpha_{23}a_{22} + \alpha_{33}a_{32}\right) + \frac{\alpha_{23}}{\alpha_{11}\alpha_{33}}\left(\alpha_{13}a_{13} + \alpha_{23}a_{23} + \alpha_{33}a_{33}\right),$$

$$\Theta_3 = -\frac{1}{\alpha_{33}}\left(\alpha_{13}a_{13} + \alpha_{23}a_{23} + \alpha_{33}a_{33}\right),$$

$$\Theta_4 = -\frac{1}{\alpha_{11}}\left(\alpha_{13}b_1 + \alpha_{23}b_2 + \alpha_{33}b_3\right) + \frac{\alpha_{43}}{\alpha_{11}\alpha_{33}}\left(\alpha_{13}a_{13} + \alpha_{23}a_{23} + \alpha_{33}a_{33}\right).$$

Of course the matrices (7.10), (7.11) are the new structures of the matrix π and $\mathcal{A}$ respectively after transformation.

It follows that the set of parameters that would produce the same output (7.6) is given by

$$\begin{aligned}
&a_{11} \mapsto a_{11} - \pi_2 a_{13}, \\
&a_{21} \mapsto a_{21} - \pi_2 a_{23}, \\
&a_{12} \mapsto a_{12} - \pi_3 a_{13}, \\
&a_{22} \mapsto a_{22} - \pi_3 a_{23}, \\
&a_{13} \mapsto \pi_1 a_{13}, \\
&a_{23} \mapsto \pi_1 a_{23}, \\
&b_1 \mapsto b_1 - \pi_4 a_{13}, \\
&b_2 \mapsto b_2 - \pi_4 a_{23}, \\
&a_{31} \mapsto \frac{1}{\pi_1}\left(\pi_2 a_{11} + \pi_3 a_{21} + a_{31}\right) - \frac{\pi_2}{\pi_1}\left(\pi_2 a_{13} + \pi_3 a_{23} + a_{33}\right), \\
&a_{32} \mapsto \frac{1}{\pi_1}\left(\pi_2 a_{12} + \pi_3 a_{22} + a_{32}\right) - \frac{\pi_3}{\pi_1}\left(\pi_2 a_{13} + \pi_3 a_{23} + a_{33}\right), \\
&b_3 \mapsto \frac{1}{\pi_1}\left(\pi_2 b_1 + \pi_3 b_2 + b_3\right) - \frac{\pi_4}{\pi_1}\left(\pi_2 a_{13} + \pi_3 a_{23} + a_{33}\right), \\
&a_{33} \mapsto \pi_2 a_{13} + \pi_3 a_{23} + a_{33}, \\
&p \mapsto \frac{1}{\pi_1}(p + \pi_2), \\
&q \mapsto \frac{1}{\pi_1}(q + \pi_3), \\
&r \mapsto \frac{1}{\pi_1}(r + \pi_4),
\end{aligned} \tag{7.12}$$

where

$$\pi_1 = \frac{\alpha_{11}}{\alpha_{33}}, \quad \pi_2 = \frac{\alpha_{13}}{\alpha_{33}}, \quad \pi_3 = \frac{\alpha_{23}}{\alpha_{33}}, \quad \pi_4 = \frac{\alpha_{43}}{\alpha_{33}}.$$

In fact (7.12) describes the orbit in the parameter space corresponding to the subgroup (7.9). The orbit is parameterized by 4 parameters $\pi_1, \pi_2, \pi_3, \pi_4$.

From the results in Proposition 6.3 it can be inferred that parameters can be identified up to the orbit described in (7.12). Finally the functions (7.8) are derived by choosing $\pi_1, \pi_2, \pi_3, \pi_4$ by restricting $a_{11} - \pi_2 a_{13} = 0$, $b_1 - \pi_4 a_{13} = 0$, $\pi_1 a_{13} = 1$, and $a_{12} - \pi_3 a_{13} = 0$. □

7.3. Identification of a planar surface undergoing rigid motion. If we assume that the matrix A is skew symmetric, one needs to restrict the following in (7.12):

$$a_{11} = a_{22} = a_{33} = 0, \quad a_{12} = -a_{21},\ a_{13} = -a_{31},\ a_{23} = -a_{32}. \tag{7.13}$$

It follows that $\pi_2 = 0$, $\pi_3 = 0$, implying that $\alpha_{13} = 0$, $\alpha_{23} = 0$. Furthermore $\pi_1 a_{13} = -\frac{1}{\pi_1} a_{31}$, i.e., $\pi_1 = \pm 1$ or $\alpha_{11} = \pm\alpha_{33}$. Thus the subgroup P described by (7.9) is further restricted to

$$P_1 = \begin{pmatrix} \alpha_{11} & 0 & 0 & 0 \\ 0 & \alpha_{11} & 0 & 0 \\ 0 & 0 & \pm\alpha_{11} & 0 \\ 0 & 0 & \alpha_{43} & \alpha_{11} \end{pmatrix}. \tag{7.14}$$

The orbit (7.12) under the new subgroup action (7.14) is given by $a_{12} \mapsto a_{12}$, $a_{13} \mapsto \pm a_{13}$, $a_{23} \mapsto \pm a_{23}$, $b_1 \mapsto b_1 \mp \frac{\alpha_{43}}{\alpha_{11}} a_{13}$, $b_2 \mapsto b_2 \mp \frac{\alpha_{43}}{\alpha_{11}} a_{23}$, $b_3 \mapsto \pm b_3$, $p \mapsto \pm p$, $q \mapsto \pm q$, and $r \mapsto \pm(r + \frac{\alpha_{43}}{\alpha_{11}})$.

Thus we have the following theorem regarding the condition of identifiability for a perspective system (2.13), (7.6), parameterized by a set of nine parameters.

THEOREM 7.3. *Consider the perspective system* (2.13), (7.6), *parameterized by* $\omega_1, \omega_2, \omega_3$, b_1, b_2, b_3, p, q, r. *Assume that the parameters satisfy the generic condition* $\omega_2 \neq 0$, $\omega_3 \neq 0$, $\omega_1 \neq 0$, $b_1\omega_3 - b_2\omega_2 \neq 0$. *Assume furthermore that the triplet*

$$\begin{pmatrix} 0 & 0 & -b_1 & \omega_2 \\ 0 & 0 & -b_2 & \omega_3 \\ \omega_2 & 0 & 0 & 0 \\ 0 & \omega_2 & -\omega_1 & 0 \\ \omega_3 & 0 & \omega_1 & 0 \\ 0 & \omega_3 & 0 & 0 \\ 0 & 0 & -1 & 0 \end{pmatrix}, \begin{pmatrix} 0 & \omega_1 & \omega_2 & 0 \\ -\omega_1 & 0 & \omega_3 & 0 \\ -\omega_2 & -\omega_3 & 0 & 0 \\ -b_1 & -b_2 & -b_3 & 0 \end{pmatrix}, \begin{pmatrix} \bar{p} \\ \bar{q} \\ -\bar{s} \\ \bar{r} \end{pmatrix}$$

is minimal. The functions of the parameters that can be identified are given by ω_1, $\pm\omega_2$, $\pm\omega_3$, $b_1 \mp \frac{\alpha_{43}}{\alpha_{11}}\omega_2$, $b_2 \mp \frac{\alpha_{43}}{\alpha_{11}}\omega_3$, $\pm b_3$, $\pm p$, $\pm q$, $\pm(r + \frac{\alpha_{43}}{\alpha_{11}})$. *The ratio* $\frac{\alpha_{43}}{\alpha_{11}}$ *is to be thought of as a single parameter.*

Remark. In Theorem 7.3 the parameters that can be identified are ambiguous up to a sign and up to one parameter. It may be verified that the functions $b_1 + \omega_2 r$ and $b_2 + \omega_3 r$ remain constant regardless of the choice of the sign. Thus one concludes that the parameters b_1, b_2, r can be recovered up to a line in the space (b_1, b_2, r)

THEOREM 7.4. *Let us consider the perspective system* (2.13), (6.3). *Under generic condition, the set of parameters or function of parameters that can be identified in the set* $\omega_1, \omega_2, \omega_3, b_1, b_2, b_3, p, q, r$ *approaches the set of parameters or function of parameters* (*up to possibly a sign ambiguity*) *that can be identified for the perspective system* (2.13), (7.6) *as* $f \to \infty$. *The parameters that can be identified as* $f \to \infty$ *are given precisely by* $\omega_1, \omega_2, \omega_3, p, q, b_3, b_1 + \omega_2 r, b_2 + \omega_3 r$.

Remark. The result of Theorem 7.4 is actually quite surprising. It says that for the projection (3.1), if $f = \delta$ and $f \to \infty$, as the generalized projection (3.1) approaches orthographic projection, the line in the parameter space (b_1, b_2, b_3, r) that can be identified at any given f indeed approaches (modulo sign) the corresponding line in the parameter space (b_1, b_2, b_3, r) that can be identified under orthographic projection. This continuity continues to hold even though under orthographic projection one measures only the vector $(d_1, \ldots, d_6)$, i.e., the measurements d_7 and d_8 are completely lost.

The following theorem generalizes the result stated in the Theorem 7.4.

THEOREM 7.5. *Let us consider the perspective system* (2.10), (6.3). *Under generic condition, the functions of parameters that can be identified as $f \to \infty$ are given precisely by A, p, q, $b_1 + a_{13}r$, $b_2 + a_{23}r$, and $b_3 + a_{33}r$. Thus parameters are recovered up to a one-parameter ambiguity even when $f \to \infty$. Moreover this one-parameter ambiguity curve is a subset of the four-parameter orbit described by* (7.12).

Proof of Theorems 7.4 *and* 7.5. At a given value of f, the parameters that can be identified have been already described by Theorem 6.1 and Corollary 6.2. As $f \to \infty$, the essential parameter d_1 approaches h_1 and d_2 approaches h_2. Hence in the limit one observes $b_1 + a_{13}r$ and $b_2 + a_{23}r$. At a given value of f, the parameters b_3 and r are known only up to the line given by

$$(d_3 + pc_1)r - (a_{11} - a_{33})r + b_3 = (a_{11} - (d_3 + pc_1))f.$$

As $f \to \infty$ the above line converges to the line $b_3 + a_{33}r =$ constant. Hence in the limit one also observes the function $b_3 + a_{33}r$. Finally note that in the orbit described by (7.12), if we assume that $\pi_2 = 0$, $\pi_3 = 0$ and $\pi_1 = 1$, we obtain a one-parameter orbit in which A, p, q, $b_1 + a_{13}r$, $b_2 + a_{23}r$, and $b_3 + a_{33}r$ are all invariants. This completes the proof. □

Remark. The proof of Theorems 7.4 essentially follows from Theorem 5.3.

8. Simulation results. Extensive simulations have been carried out for the methods outlined in §§4 and 5 of this paper. Simulations were performed only for the case of rigid body motion of a planar surface. First, the "intensity-dynamics" based approach was implemented to estimate the essential parameter vector d following equations (4.3)–(4.8). Simulations were performed for this approach using three different texture functions while the effect of varying the spatial and temporal sampling rates (step size) were examined. Additional algorithms were implemented to estimate the vector d using "feature-dynamics" based approaches for points (4.24)–(4.27), lines (4.17)–(4.23), and curves (4.13)–(4.15). Simulations for each of these approaches were performed to examine the effect of varying the number of points sampled and the step size. Motion parameters were estimated following equations (5.9)–(5.11) and (5.15)–(5.16). We draw the following conclusions from the results of the simulations:

1. Under the assumptions of a textured surface, perfect focus, and no noise, the methods outlined in this paper are effective for the estimation of shape and motion parameters.

2. The choice of the initial intensity function does not significantly affect the accuracy of the "intensity-dynamics" based approach. To illustrate, given the initial intensity function $e(x, y, 0) = \sin^2 x + \cos^2 y$ with a step size of $\Delta x = \Delta y = \Delta t = 10^{-8}$, we were able to estimate with a root mean square (rms) error of approximately

TABLE 8.1
Observation at multiple times removes the ambiguity of dual solutions.

	Motion and shape parameters		
	ω	c	$[p, q]^T$
Actual values (at $t = 0.0, f = 1.0$)	-4.000 5.000 1.000	3.500 1.500 1.500	0.500 -1.500
Solution no. 1 for $t = 0.0$	-4.750 0.750 7.000	-0.750 2.250 1.500	-2.333 -1.000
Solution no. 2 for $t = 0.0$	-4.000 5.000 1.000	3.500 1.500 1.500	0.500 -1.500
Solution no. 1 for $t = 0.1$	-3.932 0.083 5.758	-1.244 1.506 1.574	-2.333 -1.000
Solution no. 2 for $t = 0.1$	-4.000 5.000 1.000	3.673 1.574 1.574	0.790 -0.957

2.9×10^{-5}. The rms error for the initial intensity function $e(x, y, 0) = 1/x + 1/y$ was approximately 1.2×10^{-5} for the same step size.

3. Increasing the number of points sampled does not, in general, significantly increase accuracy. For example, in the case of the "feature-point" based approach, observation of the minimum four points yielded an rms error of 1.8×10^{-6} whereas observation of 32 points yielded an rms error of 8.6×10^{-7}. In both cases the step size was as noted before.

4. Decreasing the spatial or temporal sampling rates has a significant adverse affect on accuracy. For example, if the step size is increased to $\Delta x = \Delta y = \Delta t = 10^{-5}$, the rms increases by roughly the same factor, 10^3. This effect cannot be compensated for by increasing the number of points sampled.

Further simulations were performed to demonstrate how the ambiguity of the two solutions described in Theorem 5.1 can be resolved by sampling at either multiple times or multiple focal lengths. The use of multiple times to resolve this ambiguity has previously been suggested by Waxman and Ullman [7] and Tsai and Huang [21].

In Table 8.1 we note that the estimated values for ω do not change with time in solution no. 2 but do change with time in solution no. 1. Thus, since the ω values are constant, solution no. 2 is chosen as the correct solution. The values of c, p, and q change with time in both solutions. This is to be expected since c depends on r and p, q, and r all vary with time. Table 8.2 illustrates corresponding results for multiple focal lengths. For the correct solution in this case, the values of ω, p, and q remain constant while the values of c vary with focal length.

9. Summary and conclusions.

This paper introduces a two-module approach to motion and shape estimation either by observing dynamically moving intensity or shading or by observing dynamically moving feature points, lines, or curves. When restricted to a planar surface undergoing affine motion, the problem can be tackled by estimating an intermediate set of parameters known as essential parameters. We show that the essential parameter vector can be estimated, under a suitable generic condition, independent of whether the observation is the moving intensity function or the moving features on the image plane.

We introduce a new "dynamical systems" viewpoint on the motion and shape

TABLE 8.2
Observation at different focal lengths also removes the ambiguity of dual solutions.

p: position of the actual parameter.

s: 4 dimensional surface passing through p which characterizes the parameters that can be identified under orthographic projection.

f_j: 1 dimensional curve passing through p which characterizes the parameters that can be identified under generalized projection (2.12) when f = δ = j .

$f_{\%}$: limit of f_j when j ‘ %. Note that $f_{\%}$ I S.

FIG. 9.1. *Identifiable parameters for a planar surface undergoing an affine flow.*

estimation problem and show that the dynamics of the plane, known as the shape dynamics, together with the essential parameters viewed as an output equation are an example of a perspective system. Introducing a new realization theory for perspective systems, we show that the parameters of the system can be identified up to orbits of a suitable "perspective group" action, provided of course the parameters satisfy a suitable generic condition.

Using this approach, we analyze a planar surface undergoing a rigid motion and show that the solution to the parameter estimation problem under a general projection and a pseudo-orthographic projection indeed converges to that obtained (up to choice of a sign) under orthographic projection as the general projection model converges in the limit to the orthographic projection. This conclusion is in sharp contrast to that reported by Kanatani [11], wherein only the recovery equation has been used. We also analyze a planar surface undergoing an affine motion and show that under general projection, parameters are recovered up to a one-parameter ambiguity whereas under orthographic projection parameters are recovered up to four-parameter ambiguity. In the limit when the general projection model converges to the orthographic projection, the above family of one-parameter orbits converge to a one-parameter subset of the four-parameter class.

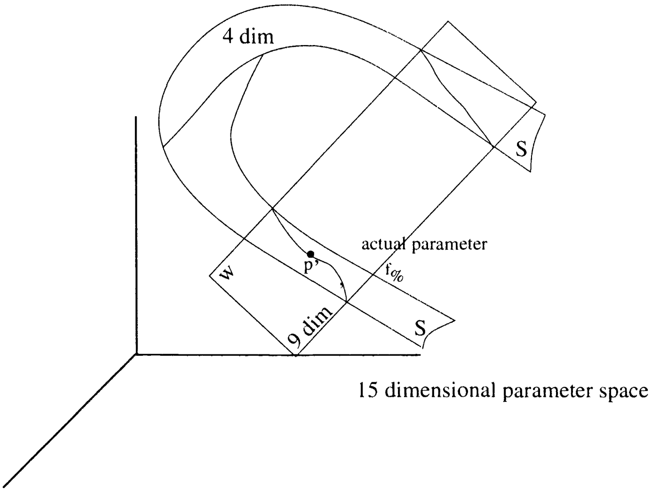

FIG. 9.2. *Identifiable parameters for a planar surface undergoing a rigid motion.*

This indicates that "one can see a nonrigid affine flow better" using a visual system with the capability of varying the focal length f all the way to infinity, as compared to a visual system with focal length f fixed at infinity. However, for a rigid flow, there is no distinction.

The above conclusion has been summarized in Figs. 9.1 and 9.2. In Fig. 9.1 we show that if p is the position of the actual parameters in $\mathbb{R}^{15}$, where $\mathbb{R}^{15}$ is the parameter space for A, b, p, q, r, under projection (3.1), if $f = \delta = j$, the curve f_j, $j = 1, 2, 3, \ldots$ indicates the set of parameters that can be identified for various values of f. In fact when $f \longrightarrow \infty$, , f_∞ denotes the limiting curve that describes the set of parameters that can be asymptotically identified. The four-dimensional surface S characterizes the parameters that can be identified under orthographic projection. In this paper we show that $f_\infty \subset S$. Thus we conclude that for an affine flow it helps to consider a visual system with a capability to vary f. For f permanently with focus at ∞, parameters are recovered up to a four-parameter ambiguity as opposed to one-parameter ambiguity in all the other cases.

In Fig. 9.2 we show a nine-dimensional subspace W of parameters describing the parameters of a planar surface undergoing a rigid flow. The subspace W intersects S in exactly two one-dimensional curves. In this paper we show that one of the two one-dimensional curves is f_∞. Thus for a planar surface undergoing a rigid flow, orthographic projection identifies parameters up to a one-parameter curve and up to a sign ambiguity. Via the process of choosing a projection (3.1) and letting $f \to \infty$, one can determine the sign. The one-parameter ambiguity remains.

Acknowledgment. We would like to acknowledge the comments of a reviewer, which improved the presentation of this paper.

UNIQUENESS FOR VISCOSITY SOLUTIONS OF NONSTATIONARY HAMILTON–JACOBI–BELLMAN EQUATIONS UNDER SOME A PRIORI CONDITIONS (WITH APPLICATIONS)*

WILLIAM M. McENEANEY†

Abstract. This paper extends the uniqueness results for viscosity solutions of nonstationary Hamilton–Jacobi–Bellman equations. The conditions for uniqueness which are obtained can involve a trade-off between the growth of the solution and the growth of the Hamiltonian. In particular, the result is valid for solutions which grow quadratically in the space variable and are associated with Hamiltonians which also grow quadratically. This particular class arises in the robust control limit of risk-sensitive stochastic control problems.

Key words. viscosity solutions, uniqueness, Hamilton–Jacobi–Bellman equations, risk-sensitive control, robust control

AMS subject classifications. 49L25, 35B37, 93E20, 90D25, 60F10

1. Introduction.

The question of uniqueness for viscosity solutions of Hamilton–Jacobi–Bellman (HJB) equations has been considered in great detail in a number of papers, particularly by Ishii [14], Crandall and Lions [6], Ishii [15], and Crandall, Ishii, and Lions [4]. This latter paper [4] summarizes and generalizes much of the work of the other papers. In it both the stationary problem and the Cauchy problem are considered. The chief assumption on each solution is that it be continuous or even, as noted in a remark, only semicontinuous. (Then, however, some additional assumptions, such as the boundedness of the difference between the solutions being compared, may be required.) Some assumptions on the Hamiltonian are then employed to obtain a comparison principle.

More recently, some problems have arisen in risk-sensitive limits and H^∞ control for which the previous assumptions on the Hamiltonian are too strict to yield a comparison result. However, in these cases, the applications were such that one could obtain a priori bounds on the behavior of the solutions. In particular, growth conditions and Lipschitz conditions could be obtained. Once the set of functions being compared is reduced in this manner, the assumptions on the Hamiltonian can be considerably weakened. Since the solutions are then continuous, one obtains a uniqueness result. The approach used here is specific to nonstationary problems. That is, we consider HJB equations of the form

$$0 = U_t + H(t, x, U, \nabla U) \tag{1}$$

on $[0, T] \times E$, where $T < \infty$ and $E \subseteq \Re^n$ has nonempty interior. A remark at the end of §3 extends the result to problems on $[0, \infty) \times E$, although we do not concentrate on that here.

A common approach has been to consider first the related stationary problem, i.e.,

$$0 = U + H(x, U, \nabla U), \tag{2}$$

*Received by the editors February 4, 1994; accepted for publication May 8, 1994.

†Department of Mathematics, Carnegie Mellon University, Pittsburgh, Pennsylvania 15213.

and to apply a maximum principle type of argument to obtain a comparison principle for the stationary problem. A modification of that approach is then applied to the nonstationary problem (1). Thus the required conditions on the Hamiltonian for problem (1) are similar to those for (2). Here a cone of dependence argument is applied to the nonstationary problem directly. This type of approach was first used in the seminal paper of Crandall and Lions [5], although with the earlier definition of a viscosity solution. In the following, this approach is used to prove uniqueness for nonstationary problems in which one does not have uniqueness for the corresponding stationary problem. This will be discussed below.

2. Assumptions. Let $Q_T = [0,T] \times \Re^n$, $Q_T^R = [0,T] \times \{x \in \Re^n : |x| \leq R\}$, and $Q_T^E = [0,T] \times E$. We restrict our attention throughout to solutions (subsolutions and supersolutions) U that are continuous and uniformly locally Lipschitz in x. That is, given $R < \infty$, there exists $K_R < \infty$ such that

$$|U(t,x) - U(t,y)| \leq K_R|x-y|$$

for all $(t,x),(t,y) \in Q_T^R$. Denote this class by C_L. By Rademacher's theorem, $U \in C_L$ implies

$$\|\nabla U(t,\cdot)\|_{L^\infty(\{|x|\leq R\})} \leq K_R \qquad \forall t \in [0,T]. \tag{3}$$

Denote the K_R corresponding to a function U by $K_R(U)$. Let W be a viscosity subsolution to (1), and let V be a viscosity supersolution to (1). Assume that $V, W \in C_L$.

The weakest assumptions under which the results will be obtained here are as follows.

$$H(\cdot,\cdot,\cdot,\cdot) \text{ is continuous.} \tag{A}$$

(B)
$$\begin{aligned}
&\exists a < \infty \text{ such that } \forall R < \infty,\ \exists k_R < \infty \text{ such that if } \exists\ (t,x) \in Q_T^R \cap Q_T^E\\
&\text{such that } W(t,x) > V(t,x), \text{ then}\\
&H(t,x,V(t,x),p) - H(t,x,W(t,x),q) \leq k_R[W(t,x) - V(t,x)] + a(1+R)|p-q|\\
&\forall p,q \in \Re^n \text{ such that } |p|,|q| \leq \max\{K_R(V),K_R(W)\}.
\end{aligned}$$

There may be weaker assumptions obtainable by this method, but they will not be attempted here.

In order to clarify the class of problems satisfying assumption (B), we consider some stronger assumptions. For any $U \in C_L$ let $M_R(U) = \max_{Q_T^R}|U(t,x)|$. We replace assumption (B) by the following stronger pair of assumptions.

$$\begin{aligned}
&\text{Given } R < \infty,\ \exists k_R < \infty \text{ such that } H(t,x,r,p) - H(t,x,s,p) \geq -k_R|r-s|\\
&\forall\ (t,x) \in Q_T^R,\ \forall\,|p| \leq \max\{K_R(V),K_R(W)\},\\
&\forall\, r,s \in \Re \text{ such that } r > s \text{ and } |r|,|s| \leq \max\{M_R(V),M_R(W)\}.
\end{aligned} \tag{C1}$$

$$\begin{aligned}
&\exists a < \infty \text{ such that } \forall R < \infty \quad |H(t,x,r,p) - H(t,x,r,q)| \leq a(1+R)|p-q|\\
&\forall\ (t,x) \in Q_T^R,\ \forall\,|r| \leq \max\{M_R(V),M_R(W)\},\\
&\forall\,|p|,|q| \leq \max\{K_R(V),K_R(W)\}.
\end{aligned} \tag{C2}$$

To obtain (B) from (C1) and (C2), consider the following. By (C2) there exists $a < \infty$ such that for all $R < \infty$

$$|H(t,x,r,p) - H(t,x,r,q)| \leq a(1+R)|p-q|$$

for all t, x, r, p, q as specified in (C2). In particular, this holds if $(t,x) \in Q_T^R$ is such that $W(t,x) > V(t,x)$ and $r = V(t,x)$. In this case we have

$$H(t,x,V(t,x),p) - H(t,x,V(t,x),q) \leq a(1+R)|p-q|. \tag{4}$$

Now, by (C1), there exists $k_R < \infty$ such that

$$H(t,x,W(t,x),q) - H(t,x,V(t,x),q) \geq -k_R|W(t,x) - V(t,x)|. \tag{5}$$

Subtracting (5) from (4), we have (B).

Note that (C2) is essentially a Lipschitz bound on H with respect to its last argument, where the Lipschitz constant may not grow faster than linearly in x. As we discuss below, this involves a trade-off between the growth of H and the growth of the solutions via the dependence of H on the solutions.

The assumptions could be made even stronger by retaining (A) and (C2) and replacing (C1) by

(D1) $\qquad H(t,x,\cdot,p)$ is nondecreasing $\forall\,(t,x,p) \in Q_T \times \Re^n$.

To obtain (C1) from (D1), simply note that (D1) implies that if $r > s$, then

$$H(t,x,r,p) - H(t,x,s,p) \geq 0 \geq -k_R|r-s|.$$

In particular, (C1) states that $H(t,x,\cdot,p)$ may not decrease faster than linearly on compact sets. However, it may still increase as fast as it likes.

We now consider some examples fitting the above assumptions.

Consider the case where

$$H(t,x,r,p) = -|p|^2$$

and $V, W \in C_L$ are such that

$$K_R(V) \leq \hat{a}(1+R),$$
$$K_R(W) \leq \hat{a}(1+R)$$

for all $R < \infty$ (i.e., V, W grow at most quadratically). Then for any $R < \infty$

$$\begin{aligned}|H(t,x,r,p) - H(t,x,r,q)| &\leq (|p| + |q|)|p-q| \\ &\leq 2\hat{a}(1+R)|p-q|\end{aligned}$$

for all $|p|, |q| \leq \max\{K_R(V), K_R(W)\}$. Thus assumption (C2) is satisfied. Assumptions (A) and (D1) are also clearly satisfied.

More generally, consider the case where for some $\gamma \in (1,\infty)$

$$H(t,x,r,p) = -|p|^\gamma \tag{6}$$

and

$$K_R(V) \leq \hat{a}(1+R)^{\frac{1}{\gamma-1}}, \tag{7}$$
$$K_R(W) \leq \hat{a}(1+R)^{\frac{1}{\gamma-1}}$$

for all $R < \infty$. Then, again, assumptions (A), (D1), and (C2) would be satisfied, and the uniqueness result below would follow. Interestingly, however, one does not have a comparison/uniqueness result for the corresponding stationary problem in this case. This was noted in Ishii [14], and the counterexample provided there is as follows. Consider the one-dimensional case $n = 1$, and let $E = \Re$. Then (2) with Hamiltonian (6) has two solutions:

$$U^1 = 0$$

and

$$U^2 = (\gamma^*)^{\gamma^*} |x|^{\gamma^*},$$

where $\gamma^* = \frac{\gamma}{\gamma-1}$. Both solutions satisfy (7). Thus one would not expect the method used to obtain a comparison principle for the stationary problem to yield the result below.

Also consider

$$H(t,x,r,p) = x^T p$$

so that for any $R < \infty$

$$|H(t,x,r,p) - H(t,x,r,q)| \leq R|p-q|$$

for all $(t,x) \in Q_T^R$. Thus (A), (D1), and (C2) would hold without a growth restriction on V or W (other than $V, W \in C_L$).

In §4, we will consider an application to the case where

$$H(t,x,p) = -\frac{1}{4\gamma^2}|p|^2 - \min_{v\in U}\left[f(t,x,v)\cdot p + L(t,x,v)\right], \tag{8}$$

where f grows at most linearly in x, L grows at most quadratically in x, and U is compact. This is related to risk-sensitive control and the robust limit. We will also consider an application to the case where

$$H(x,r,p) = -\max_{v\in U}\left[-\frac{B^2(v)}{2r}x^2p^2 + A(v)xp\right], \tag{9}$$

where A and B are continuous and U is compact. This is related to a risk-sensitive limit in a Merton porfolio problem. Neither of these applications appears to fit within the framework of existing results.

Finally, note that these extensions of the comparison/uniqueness results do not come entirely for free. It is now required that the solutions (subsolutions and supersolutions) be in C_L. This implies that one could not trivially apply these results in cases where the solutions are obtained via the Barles and Perthame procedure (see Barles and Perthame [2] and Fleming and Soner [13]), where one has only semicontinuity of the solutions. In particular, although the comparison/uniqueness results are extended to problems with more rapidly growing solutions and Hamiltonians, the price to be paid is that one must obtain the local Lipschitz bounds on the solutions. Of course, whereas the growth rates for certain problems of interest are not within our control, one may with sufficient effort be able to obtain the required local Lipschitz conditions.

3. Comparison/uniqueness result. In this section we derive the main comparison result which, under the assumptions here, directly yields a uniqueness result. Reiterating from above, we suppose that $V, W \in C_L$ are a viscosity supersolution and a viscosity subsolution, respectively, of (1) on Q_T^E. Further, we assume that

$$W \leq V \qquad \text{on} \quad (\{t=0\} \times E) \cup ([0,T] \times \partial E)\,. \tag{10}$$

(As mentioned above, E may be all of $\Re^n$, in which case ∂E is empty.)

The following two lemmas lead to the result. The statements are similar in form to the corresponding lemmas in Crandall and Lions [5].

LEMMA 1. *Let W, V be as above, and assume* (A) *and* (B). *Let $R < \infty$. Let $\Lambda \in C^1(Q_T)$, $\Lambda \geq 0$, $\Lambda(t,x) = 0$ if $|x| \geq R$, and*

$$-\Lambda_t > a(1+R)|\Lambda_x| + k_R\Lambda \qquad on \quad (\text{supp}\Lambda)^\circ \cap (Q_T^E)^\circ. \tag{11}$$

Then $W \leq V$ on $(\text{supp}\Lambda) \cap Q_T^E$.

Proof. Let $\phi \in C^\infty(\Re^n)$, $\text{supp}(\phi) \subset B(0,1)$, $\phi(0) = 1$, and $0 \leq \phi \leq 1$. Let $\eta \in C^\infty(\Re)$, $\text{supp}(\eta) \subset B(0,1)$, $\phi(0) = 1$, and $0 \leq \phi \leq 1$. Define $\phi_\alpha(x) = \phi(x/\alpha)$ and $\eta_\alpha(t) = \eta(t/\alpha)$.

Assume that

$$M_0 \equiv \max_{Q_T^E} \Lambda(t,x)[W(t,x) - V(t,x)] > 0. \tag{12}$$

(Otherwise there is nothing to prove.) Let $C > C_0$, where

$$C_0 \equiv \max_{Q_T^E \times Q_T^E} \Lambda(s,y)|W(t,x)| + \Lambda(t,x)|V(s,y)|. \tag{13}$$

Consider

$$M_\alpha \equiv \max_{Q_T^E \times Q_T^E} [\Lambda(s,y)W(t,x) - \Lambda(t,x)V(s,y) + C\eta_\alpha(t-s)\phi_\alpha(x-y)]\,, \tag{14}$$

and let the maximum occur at $(t_\alpha, x_\alpha), (s_\alpha, x_\alpha)$. By the definition of C, η_α, and ϕ_α we have

$$|t_\alpha - s_\alpha| \leq \alpha, \quad |x_\alpha - y_\alpha| \leq \alpha, \tag{15}$$

and by (13), (14)

$$\eta_\alpha(t_\alpha - s_\alpha) \geq \min\left\{1, \frac{C - C_0}{C}\right\}, \quad \phi_\alpha(x_\alpha - y_\alpha) \geq \min\left\{1, \frac{C-C_0}{C}\right\}. \tag{16}$$

By the compactness of Q_T^E, there exists a sequence $\alpha_n \downarrow 0$ such that $(t_{\alpha_n}, x_{\alpha_n})$ converges to some $(t_0, x_0) \in Q_T^E$. By (15), we also have $(s_{\alpha_n}, y_{\alpha_n}) \to (t_0, x_0)$.

It is easily shown that

$$\Lambda(t_0,x_0)[W(t_0,x_0) - V(t_0,x_0)] = M_0 > 0.$$

Therefore $(t_0, x_0) \in (\mathrm{supp}\Lambda)^\circ \cap (Q_T^E)^\circ$, where the superscript $\circ$ indicates interior. This implies that for n sufficiently large,

$$(t_{\alpha_n}, x_{\alpha_n}) \in (\mathrm{supp}\Lambda)^\circ \cap (Q_T^E)^\circ,$$
$$(s_{\alpha_n}, y_{\alpha_n}) \in (\mathrm{supp}\Lambda)^\circ \cap (Q_T^E)^\circ.$$

Therefore, for n sufficiently large,

$$(t_{\alpha_n}, x_{\alpha_n}), (s_{\alpha_n}, y_{\alpha_n})$$

is a local, unconstrained maximizer of (14).

Consider

$$(17)\quad W(t,x) - \frac{1}{\Lambda(s_{\alpha_n}, y_{\alpha_n})}[\Lambda(t,x)V(s_{\alpha_n}, y_{\alpha_n}) - C\eta_{\alpha_n}(t - s_{\alpha_n})\phi_{\alpha_n}(x - y_{\alpha_n}) - M_{\alpha_n}],$$

which has a local maximum of zero at $(t_{\alpha_n}, x_{\alpha_n})$. Since W is a subsolution of (1), we have

$$(18)\quad \begin{aligned} &\frac{\Lambda_t(t_{\alpha_n}, x_{\alpha_n})V(s_{\alpha_n}, y_{\alpha_n}) - C\eta'_{\alpha_n}(t_{\alpha_n} - s_{\alpha_n})\phi_{\alpha_n}(x_{\alpha_n} - y_{\alpha_n})}{\Lambda(s_{\alpha_n}, y_{\alpha_n})} \\ &+ H\Bigg(t_{\alpha_n}, x_{\alpha_n}, W(t_{\alpha_n}, x_{\alpha_n}), \\ &\qquad \frac{\Lambda_x(t_{\alpha_n}, x_{\alpha_n})V(s_{\alpha_n}, y_{\alpha_n}) - C\eta_{\alpha_n}(t_{\alpha_n} - s_{\alpha_n})\phi'_{\alpha_n}(x_{\alpha_n} - y_{\alpha_n})}{\Lambda(s_{\alpha_n}, y_{\alpha_n})}\Bigg) \le 0 \end{aligned}$$

where the superscript $'$ indicates differentiation.

Similarly (noting that V is a supersolution), we obtain

$$(19)\quad \begin{aligned} &\frac{\Lambda_s(s_{\alpha_n}, y_{\alpha_n})W(t_{\alpha_n}, x_{\alpha_n}) - C\eta'_{\alpha_n}(t_{\alpha_n} - s_{\alpha_n})\phi_{\alpha_n}(x_{\alpha_n} - y_{\alpha_n})}{\Lambda(t_{\alpha_n}, x_{\alpha_n})} \\ &+ H\Bigg(s_{\alpha_n}, y_{\alpha_n}, V(s_{\alpha_n}, y_{\alpha_n}), \\ &\qquad \frac{\Lambda_y(s_{\alpha_n}, y_{\alpha_n})W(t_{\alpha_n}, x_{\alpha_n}) - C\eta_{\alpha_n}(t_{\alpha_n} - s_{\alpha_n})\phi'_{\alpha_n}(x_{\alpha_n} - y_{\alpha_n})}{\Lambda(t_{\alpha_n}, x_{\alpha_n})}\Bigg) \ge 0. \end{aligned}$$

We would like to take limits as $\alpha_n \downarrow 0$; however, we must ensure that the limits exist for all terms in (18) and (19). Specifically, we will show that there exist subsequential limits for $\eta'_{\alpha_n}(t_{\alpha_n} - s_{\alpha_n})$ and $\phi'_{\alpha_n}(x_{\alpha_n} - y_{\alpha_n})$.

Consider the last term in (18), i.e.,

$$\frac{\Lambda_x(t_{\alpha_n}, x_{\alpha_n})V(s_{\alpha_n}, y_{\alpha_n}) - C\eta_{\alpha_n}(t_{\alpha_n} - s_{\alpha_n})\phi'_{\alpha_n}(x_{\alpha_n} - y_{\alpha_n})}{\Lambda(s_{\alpha_n}, y_{\alpha_n})}.$$

Since this is being evaluated at a maximum of (14), we have

$$(20)\quad \left|\frac{\Lambda_x(t_{\alpha_n}, x_{\alpha_n})V(s_{\alpha_n}, y_{\alpha_n}) - C\eta_{\alpha_n}(t_{\alpha_n} - s_{\alpha_n})\phi'_{\alpha_n}(x_{\alpha_n} - y_{\alpha_n})}{\Lambda(s_{\alpha_n}, y_{\alpha_n})}\right| \le K_R(W).$$

Then, since Λ, Λ_x, and V are bounded on $Q_T^R \times Q_T^R$ and (16) implies that η_{α_n} is bounded away from zero, we have some $B_1 < \infty$ such that

$$|\phi'_{\alpha_n}(x_{\alpha_n} - y_{\alpha_n})| \leq B_1$$

for all n sufficiently large. Therefore, there exists $l_1 \in \Re^n$ such that $|l_1| \leq B_1$ and

$$\phi'_{\alpha_n}(x_{\alpha_n} - y_{\alpha_n}) \to l_1$$

along some subsequence (also denoted by α_n).

Thus, using assumption (A) (continuity of H), we see that all terms in (18) are bounded, with the possible exception of

$$\frac{C\eta'_{\alpha_n}\phi_{\alpha_n}}{\Lambda(s_{\alpha_n}, y_{\alpha_n})}.$$

This implies that there exists some $B_2 > -\infty$ such that

$$\frac{C\eta'_{\alpha_n}\phi_{\alpha_n}}{\Lambda(s_{\alpha_n}, y_{\alpha_n})} \geq B_2$$

for all n sufficiently large, which upon noting (16) implies

$$\eta'_{\alpha_n} \geq \hat{B}_2 > -\infty \tag{21a}$$

for all n sufficiently large. Proceeding similarly with (19), we have

$$\eta'_{\alpha_n} \leq \hat{B}_3 < \infty \tag{21b}$$

for all n sufficiently large. By inequalities (21), there exists $l_2 \in \Re$ such that $\hat{B}_2 \leq l_2 \leq \hat{B}_3$ and

$$\eta'_{\alpha_n}(t_{\alpha_n} - s_{\alpha_n}) \to l_2$$

along some further subsequence (also denoted by α_n).

We may now take the limit in (18) and (19) as $n \to \infty$ and employ (A1) again to obtain

$$\frac{\Lambda_t V - Cl_2}{\Lambda} + H\left(t_0, x_0, W, \frac{\Lambda_x V - Cl_1}{\Lambda}\right) \leq 0, \tag{22}$$

$$\frac{\Lambda_s W - Cl_2}{\Lambda} + H\left(t_0, x_0, V, \frac{\Lambda_y W - Cl_1}{\Lambda}\right) \geq 0, \tag{23}$$

where all terms are evaluated at (t_0, x_0).

Subtracting (23) from (22), we have

$$\begin{aligned} &\frac{\Lambda_t}{\Lambda}(V - W) + H\left(t_0, x_0, W, \frac{\Lambda_x V - Cl_1}{\Lambda}\right) \\ &\qquad - H\left(t_0, x_0, V, \frac{\Lambda_x W - Cl_1}{\Lambda}\right) \leq 0. \end{aligned} \tag{24}$$

By assumption (B), (12), and (20) (and its counterpart for V), this yields

$$\frac{\Lambda_t}{\Lambda}(V - W) \leq a(1 + R)\left|\frac{\Lambda_x}{\Lambda}(V - W)\right| + k_R(W - V)$$

at (t_0, x_0), or equivalently,

$$\frac{\Lambda_t}{\Lambda}(V - W) \leq a(1+R)\frac{|\Lambda_x|}{\Lambda}|V - W| + k_R(W - V),$$

which, by (12), implies

$$-\Lambda_t \leq a(1+R)|\Lambda_x| + k_R\Lambda$$

at (t_0, x_0). But this contradicts the assumption of the lemma. Therefore

$$\max_{Q_T^E \times Q_T^E} \Lambda(t,x)[W(t,x) - V(t,x)] \leq 0,$$

which is the desired result. □

LEMMA 2. *Let V and W be as above, and let assumptions* (A) *and* (B) *be satisfied. Let $R < \infty$. Then*

$$W \leq V \tag{25}$$

on

$$Q_T^E \cap \{(t,x) : |x| \leq R - a(1+R)t,\ t \in [0, \min(T, \tau_R)]\},$$

where $\tau_R = \frac{R}{a(1+R)}$.

Proof. Let $g_\gamma \in C^1(\Re)$ for γ sufficiently small. For $D > 0$, let

$$g_\gamma(r) = 0 \qquad \text{if } r \leq 0$$

and

$$\gamma g'_\gamma(r) \geq g_\gamma(r) > 0 \qquad \text{if } r \in (0, D].$$

To see that such g_γ exist, take for example

$$g_\gamma(x) = \begin{cases} \gamma\left(e^{x/\gamma} - 1\right) - x & \text{if } x \in (0, D], \\ 0 & \text{if } x \leq 0. \end{cases} \tag{26}$$

Choose $D \geq R_0 > 0$, and let

$$\Lambda(t,x) = g_\gamma\left(R_0 - a(1+R)t - \lambda|x|^{1+\beta}\right), \tag{27}$$

where $\beta > 0$ and λ is yet to be specified, so that

$$\begin{aligned} -\Lambda_t &= a(1+R)g'_\gamma\left(R_0 - a(1+R)t - \lambda|x|^{1+\beta}\right), \\ a(1+R)|\Lambda_x| &= a(1+R)\lambda(1+\beta)|x|^\beta g'_\gamma\left(R_0 - a(1+R)t - \lambda|x|^{1+\beta}\right), \\ k_R\Lambda &= k_R g_\gamma \leq \gamma k_R g'_\gamma\left(R_0 - a(1+R)t - \lambda|x|^{1+\beta}\right). \end{aligned} \tag{28}$$

We would like the conditions of Lemma 1 to be satisfied by this choice of Λ. In order that Λ be zero if $|x| \geq R$, we require $R_0 - \lambda R^{1+\beta} \leq 0$, or equivalently,

$$(\lambda^{-1}R_0)^{\frac{1}{1+\beta}} \leq R. \tag{29}$$

In order that $-\Lambda_t > a(1+R)|\Lambda_x| + k_R\Lambda$, by (27), (28), and the properties of g_γ, we require

$$1 > \lambda(1+\beta)\left(\lambda^{-1}R_0\right)^{\frac{1}{1+\beta}} + \gamma\frac{k_R}{a(1+R)}. \tag{30}$$

Let

$$(1+2\beta)R_0^{1+\beta} = R^{1+\beta}. \tag{31}$$

Then conditions (29) and (30) become

$$\lambda \geq \frac{1}{R^{\beta}(1+2\beta)^{\frac{1}{1+\beta}}} \tag{32}$$

and

$$1 > \lambda^{\frac{1}{1+\beta}}(1+\beta)R^{\frac{\beta}{1+\beta}}(1+2\beta)^{\frac{-\beta}{(1+\beta)^2}} + \gamma\frac{k}{a(1+R)}, \tag{33}$$

respectively. We take

$$\lambda = \frac{1}{R^{\beta}(1+2\beta)^{\frac{1}{1+\beta}}} \tag{34}$$

so that (32) is satisfied. Substituting (34) into (33), the last requirement becomes

$$1 > \frac{1+\beta}{(1+2\beta)^{\frac{1}{1+\beta}}} + \gamma\frac{k_R}{a(1+R)}. \tag{35}$$

The first term on the right-hand side of (35) is less than one and converges to one as $\beta \downarrow 0$. This implies that if we take

$$\gamma = \frac{1}{2}\frac{a(1+R)}{k_R}\left[1 - \frac{1+\beta}{(1+2\beta)^{\frac{1}{1+\beta}}}\right], \tag{36}$$

(35) will be satisfied.

Now note that as $\beta \downarrow 0$, we have $\lambda \to 1$, $R_0 \to R$, and $\gamma \to 0$. This implies that any $(t,x) \in \{(t,x) : |x| \leq R - a(1+R)t,\ t \in [0,\tau_R]\}$ is in $\operatorname{supp}(\Lambda)$ for sufficiently small β. Therefore, by Lemma 1, we have the desired result. □

THEOREM 3. *Let V and W be as above, and let assumptions* (A) *and* (B) *be satisfied. Then $W \leq V$ on Q_T^E.*

Proof. By Lemma 2, $W \leq V$ on $Q_T^E \cap \{(t,x) : |x| \leq R - a(1+R)t,\ t \in [0,\tau_R]\}$.

Letting $R \to \infty$, we see that

$$\tau_R \uparrow \tau_\infty = \frac{1}{a}.$$

This implies that as $R \to \infty$, the cones cover $[0,\tau_\infty) \times \Re^n$. Therefore, given any $\delta > 0$, $W \leq V$ on $[0, \min\{T, \tau_\infty - \delta\}] \times E$.

If $\tau_\infty - \delta \geq T$, we are finished. If not, we simply repeat the procedure, with the new initial time being $\tau_\infty - \delta$. This yields $W \leq V$ on $[0, \min\{T, 2(\tau_\infty - \delta)\}] \times E$. Iterating, we obtain the desired result. □

Under our assumptions, the uniqueness result is a trivial corollary to the comparison result.

COROLLARY 4. *Let $U_1, U_2 \in C_L$ be two viscosity solutions of* (1) *with some initial condition $U = g(t,x)$ on $(\{0\} \times E) \cup ([0,T] \times \partial E)$, where $g \in C_L$. Let assumptions* (A) *and* (B) *be satisfied. Then $U_1 = U_2$ on $[0,T] \times E$.*

Remark 5. By noting that $\tau_\infty = \frac{1}{a}$, the comparison and uniqueness results can clearly be extended to $[0,\infty) \times E$ if, for each $T < \infty$, there exists $a < \infty$ such that (B) is satisfied. This yields uniqueness for the Cauchy problem.

Remark 6. An extension in the spirit of the semicontinuity results is possible. In particular, one can weaken the assumption that W, V are in C_L to a one-sided Lipschitz assumption on each. That is, we may assume that $W \in USL$ and $V \in LSL$, which we define as follows. We say that $U \in USC$ is in USL if, given $R < \infty$, there exists $L_R < \infty$ such that, for any $(t_0, x_0) \in Q_T^R$, there exists $\delta > 0$ (depending on (t_0, x_0)) such that

$$U(t,x) \leq U(t_0, x_0) + L_R(|t-t_0| + \|x - x_0\|) \tag{37}$$

for all (t,x) in a ball of radius δ around (t_0, x_0). $LSL \subset LSC$ is defined analogously by changing the direction of the inequality and the sign preceding L_R in (37). The proof of Lemma 2 is unchanged by these assumptions. The proof of Lemma 1 requires some minor modifications. The only nontrivial modification in the proof is in obtaining the bound on $\phi'_{\alpha_n}(x_{\alpha_n} - y_{\alpha_n})$. If we take $\phi(x) = \exp(\frac{-|x|^2}{1-|x|^2})$ and use the one-sided Lipschitz condition, a bound is obtained. However, at present it is not clear that this extension leads to a measurable change in where or how the result may be applied.

4. Two applications. In this section, the two applications mentioned at the end of §2 are discussed.

4.1. Risk-sensitive control and the robust limit. Consider the following finite time-horizon, risk-sensitive stochastic control problem as discussed in Fleming and McEneaney [10], McEneaney [19], and James [18]. Let the dynamics be given by

$$\begin{aligned} dX_t^\epsilon &= f(t, X_t^\epsilon, u_t)\, dt + \sqrt{\frac{\epsilon}{2\gamma^2}}\, dB_t, \\ X_s^\epsilon &= x, \end{aligned}$$

where X_t^ϵ taking values in $\Re^n$ is the state, $u.$ is the control, and $B.$ is an n-dimensional Brownian motion with respect to some reference probability system $(\Omega, \{\mathcal{F}_t\}, P, B.)$. Let ϵ and γ be parameters.

The cost criterion is

$$J^\epsilon(s,x,u) = \epsilon \log \mathrm{E}_{s,x} \exp\left\{ \frac{1}{\epsilon} \left[\int_s^T L(t, X_t^\epsilon, u_t)\, dt + \Psi(X_T^\epsilon) \right] \right\}.$$

The value function is given by

$$V^\epsilon(s,x) = \inf_{u \in \mathcal{U}} J^\epsilon(s,x,u).$$

Here $\mathcal{U}$ is the set of F_t-progressively measurable controls (see [13]) taking values in some compact set U, L is the running cost, and Ψ is the terminal cost.

Make the following assumptions on f, L, and Ψ.

$$\text{(AF1)} \quad \begin{aligned} &f \in C([0,T] \times \Re^n \times U), \\ &|f(t,x,v) - f(t,y,v)| \leq K|x-y| \qquad \forall t \in [0,T],\ \forall x,y \in \Re^n,\ \forall v \in U; \end{aligned}$$

(AF2)
$L \in C([0,T] \times \Re^n \times U)$,
$L(t,x,v) \geq 0 \qquad \forall t \in [0,T],\ \forall x \in \Re^n,\ \forall v \in U$,
$|L(t,x,v) - L(t,y,v)| \leq C(1+|x|+|y|)|x-y| \quad \forall t \in [0,T],\ \forall x,y \in \Re^n,\ \forall v \in U$;

$$\begin{aligned} &\Psi \in C(\Re^n),\\ &\Psi(x) \geq 0 \qquad \forall x \in \Re^n,\\ &|\Psi(x) - \Psi(y)| \leq C(1+|x|+|y|)|x-y| \qquad \forall x,y \in \Re^n, \end{aligned} \tag{AF3}$$

where K and C are generic constants.

It can then be shown (see [19]) that V^ϵ is the solution of

$$\begin{aligned} 0 &= V_s^\epsilon + \frac{\epsilon}{4\gamma^2}\Delta V^\epsilon + \frac{1}{4\gamma^2}|\nabla V^\epsilon|^2 + \min_{v\in U}[f(s,x,v)\cdot\nabla V^\epsilon + L(s,x,v)],\\ V^\epsilon(T,x) &= \Psi(x). \end{aligned}$$

Furthermore,

$$\begin{aligned} &0 \leq V^\epsilon(s,x) \leq C_1 + C_2|x|^2,\\ &|V^\epsilon(s,x) - V^\epsilon(s,y)| \leq [C_3 + C_4 R]|x-y| \ \ \forall |x|,|y| \leq R,\ \forall R < \infty,\\ &|V^\epsilon(s,x) - V^\epsilon(t,x)| \leq g_R(|s-t|) \ \ \forall |x|,|y| \leq R,\ \forall R < \infty, \end{aligned} \tag{38}$$

where $g_R(\rho) \downarrow 0$ as $\rho \downarrow 0$. Here, the C_i represent generic constants.

By the Ascoli–Arzela theorem and the stability property of viscosity solutions [13], there exists a sequence $\{\epsilon_n\}$ such that $\epsilon \downarrow 0$ and $V^{\epsilon_n} \to V^0$ (uniformly on compact sets) where V^0 is a viscosity solution to the limit partial differential equation (PDE)

$$\begin{aligned} 0 &= V_s + H(s,x,\nabla V),\\ V(T,x) &= \Psi(x), \end{aligned} \tag{39}$$

where

$$H(s,x,p) = \frac{1}{4\gamma^2}|p|^2 + \min_{v\in U}[f(s,x,v)\cdot p + L(s,x,v)].$$

Clearly V^0 satisfies (38) as well.

Note that the PDE in (39) is equivalent to (8) with the exception of a time reversal due to the presence of a terminal condition rather than an initial condition.

Also consider the following finite time-horizon deterministic differential game. Let the dynamics be

$$\begin{aligned} \frac{dX}{dt} &= f(t,X_t,u_t) + w_t,\\ X_s &= x, \end{aligned}$$

and let the payoff be

$$P(s,x,u,w) = \int_s^T [L(t,X_t,u_t) - \gamma^2|w_t|^2]\, dt + \Psi(X_T).$$

The minimizing player's control is $u.$, and the maximizing player's control is $w.$. We require that $u.$ be measurable (with respect to t) and take values in U. Let this control set be denoted by $\mathcal{U}^0$. For the maximizing player, we let the control set be $\mathcal{W}^0 = L^2([s,T];\Re^n)$. The Elliott–Kalton definition of value [7] is used. In this context, we define the set of strategies for the minimizing player to be

$$\Theta(s) = \{\theta : \mathcal{W}^0 \to \mathcal{U}^0 \text{ such that given any } \tau \in [s,T],\ w_t = \hat{w}_t\ \forall t \in [s,\tau] \\ \text{implies } \theta[w]_t = \theta[\hat{w}]_t\ \forall t \in [s,\tau]\}$$

and the set of strategies for the maximizing player to be

$$\Lambda(s) = \{\lambda : \mathcal{U}^0 \to \mathcal{W}^0 \text{ such that given any } \tau \in [s,T],\ u_t = \hat{u}_t\ \forall t \in [s,\tau] \\ \text{implies } \lambda[u]_t = \lambda[\hat{u}]_t\ \forall t \in [s,\tau]\}.$$

The lower and upper values are defined to be

$$W(s,x) = \inf_{\theta \in \Theta(s)} \sup_{w \in \mathcal{W}^0} P(s,x,\theta[w],w)$$

and

$$U(s,x) = \sup_{\lambda \in \Lambda(s)} \inf_{u \in \mathcal{U}^0} P(s,x,u,\lambda[u]),$$

respectively. The game has value if $W = U$.

Generalizing a result in Evans and Souganidis [8], it is shown in McEneaney [19] that this game has value in the Elliott–Kalton sense and that this value is a viscosity solution of (39). Furthermore, $W = U$ satisfies conditions (38) (with proper choice of the constants).

Now, suppose that we have a unique solution, V^0, of (39). Then it is easy to show that $V^\epsilon \to V^0$ (not just along a sequence) and that $V^0 = W = U$. That is, the value of the risk-sensitive stochastic control problem converges to the value of the deterministic game. Note (see [19], James [17]) that this game is related to robust control.

All that remains is to verify that (39) satisfies the assumptions of §2 which were shown to be sufficient to yield uniqueness.

Assumptions (A) and (D1) obviously hold. All that remains is to show that (C2) holds. Let $r = T - s$ so that the problem becomes an initial value problem rather than a terminal value problem. Then

$$H(r,x,p) - H(r,x,q) = \frac{1}{4\gamma^2}\left[|q|^2 - |p|^2\right] + \min_{v \in U}[f(T-r,x,v)\cdot q + L(T-r,x,v)] \\ - \min_{v \in U}[f(T-r,x,v)\cdot p + L(T-r,x,v)].$$

Let $v_0 \in \operatorname{argmin}_{v \in U}[f(T-r,x,v)\cdot p + L(T-r,x,v)]$. Then

$$H(r,x,p) - H(r,x,q) \leq \frac{1}{4\gamma^2}\left[|q| + |p|\right]\left[|q| - |p|\right] + f(T-r,x,v_0)\cdot(q-p),$$

which by (AF1)

$$\leq \frac{1}{4\gamma^2}\left[|q| + |p|\right]\left[|q| - |p|\right] + C_1(1+R)|q-p| \tag{40}$$

for all $|x| \leq R$ where C_1 is a generic constant. By the second inequality of (38), there exists $a < \infty$ such that $K_R(V^0) \leq a(1+R)$ and $K_R(W) \leq a(1+R)$ so that (40) implies

$$H(r,x,p) - H(r,x,q) \leq \left(\frac{a}{2\gamma^2} + C_1\right)(1+R)|p-q|$$

for all $|p|, |q| \leq \max\{K_R(V^0), K_R(W)\}$. Switching the order of p and q, one obtains the analogous bound from below. Therefore, assumption (C2) is satisfied, and the uniqueness result can be applied.

The uniqueness result also has an application to the infinite time-horizon risk-sensitive limit analogous to the finite time-horizon limit discussed above. In particular, it can be shown that the value function of the infinite time-horizon risk-sensitive control problem, under sufficiently stringent conditions, converges to a viscosity solution $V^0(x)$ of

$$0 = H^0(x, \nabla V),$$

where

$$H^0(x,p) = \frac{1}{4\gamma^2}|p|^2 + \min_{v\in U}[f(x,v)\cdot p + L(x,v)].$$

See Fleming and McEneaney [11], [12]. (In [12], this is proved for globally Lipschitz L; however, it is anticipated that the result also holds for L exhibiting quadratic growth as in (AF2).)

Then V^0 is a (steady-state) solution to the finite time-horizon PDE

$$\begin{aligned} 0 &= V_s + H^0(x, \nabla V), \\ V(T,x) &= V^0(x) \end{aligned}$$

for any $T < \infty$. Again V^0 satisfies a growth condition analogous to the middle inequality of (38). Then, by the same uniqueness result as used above, one sees that V^0 is also the value of the corresponding finite time-horizon deterministic differential game, that is,

$$V^0(x) = \inf_{\theta\in\Theta(0)} \sup_{w\in\mathcal{W}^0} \left\{ \int_0^T [L(X_t,u_t) - \gamma^2|w_t|^2]\, dt + V^0(X_T) \right\}$$

for any $T < \infty$. This is the dissipation relation used to define nonlinear H^∞ control (see van der Schaft [20], James [17], Ball and Helton [1], and Isidori [16]).

4.2. Risk-sensitive limit in an optimal investment model. In this section, we consider an application leading to a Hamiltonian of the form (9). The following optimal investment problem is discussed in Fleming [9]. The dynamics are of the form

$$\begin{aligned} dX_t &= A(u_t)X_t\, dt + |\gamma|^{-1/2}B(u_t)X_t\, dB_t, \\ X_0 &= x. \end{aligned} \tag{41}$$

Here X_t is the wealth at time t, $u.$ is the control, and $B.$ is Brownian motion with respect to some reference probability system $(\Omega, \{\mathcal{F}_t\}, P, B.)$. Assume that $u. \in \mathcal{U}$, where $\mathcal{U}$ is the set of $\mathcal{F}_t$-progressively measurable controls taking values in some compact set U. Assume that A and B are continuous functions. γ will be a parameter measuring risk sensitivity. The risk-sensitive value at time T is given by

$$V^\gamma(T,x) = \sup_{u\in\mathcal{U}} F_\gamma^{-1}\left[E_{0,x}F_\gamma\left(h_\gamma(x)\right)\right], \tag{42}$$

where F_γ has hyperbolic absolute risk aversion, that is,

$$F_\gamma(r) = \frac{1}{\gamma}r^\gamma, \quad \gamma < 1, \quad \gamma \neq 0, \tag{43}$$

and h_γ will be a perturbation of a linear function (to be discussed below). This type of risk-sensitive utility function is also described in Barron and Jensen [3]. We are interested in the limit as $\gamma \to -\infty$. The dynamic programming equation corresponding to (41)–(43) is

(44)

$$0 = V_T^\gamma - \max_{v\in U}\left[\frac{B^2(v)}{2|\gamma|}x^2V_{xx}^\gamma + A(v)xV_x^\gamma - \left|\frac{\gamma-1}{\gamma}\right|\frac{B^2(v)}{2V^\gamma}x^2(V_x^\gamma)^2\right], \quad (T,x)\in G,$$

$$V^\gamma(T,x) = h_\gamma(x), \qquad (T,x)\in\partial G,$$

where $G = (0,\infty)\times(0,\infty)$. Taking the limit as $\gamma\to-\infty$, one obtains

$$\begin{aligned} 0 &= V_T^0 + H(x,V^0,V_x^0), && (T,x)\in G,\\ V^0(T,x) &= h_0(x), && (T,x)\in\partial G, \end{aligned} \tag{45}$$

where

$$H(x,r,p) = -\max_{v\in U}\left[A(v)xp - \frac{B^2(v)}{2}\frac{x^2p^2}{r}\right].$$

This is equation (4.2) in Fleming [9]; see [9] for further details.

Now suppose that $V,W\in C([0,\infty)\times[0,\infty))$ are both subsequential limits of solutions of (44) and thus viscosity solutions of (45). Some assumptions on A and h_γ will be made, and then the results of §3 will be used to show that $V=W$. (Alternatively, one can transform this problem into one of the form given in §4.1 and then apply the methods used there. This approach is discussed more fully in [9]. In either case, one utilizes the structure of the problem to show that the assumptions in §2 are satisfied.)

Assume that there exists $v_0\in U$ such that

$$A(v_0) > 0. \tag{46}$$

For simplicity, let the form of the h_γ be specified by assuming that $h_\gamma(x) = xk_\gamma(x)$, where

$$k_\gamma(1)\to c_1 > 0 \qquad \text{as } \gamma\to-\infty, \tag{47a}$$

and that there exist $\eta<0$ such that, for all $\alpha\ge 1$ and $x>0$,

$$\alpha^{-\eta/\gamma}k_\gamma(x) \le k_\gamma(\alpha x) \le \alpha^{\eta/\gamma}k_\gamma(x) \tag{47b}$$

and $\eta/\gamma\downarrow 0$ as $\gamma\to-\infty$. In this way, $h_\gamma(x)\to h_0(x) = kx$ for some $k>0$.

A simple computation using (46) and (47) yields

$$V(T,x), W(T,x) \ge C_1xe^{C_2T} \tag{48}$$

for appropriate $C_1, C_2 > 0$. Also there exists $C_3<\infty$ such that, for all $R<\infty$,

$$K_R(V), K_R(W) \le C_3, \tag{49}$$

where we are now considering (45) for some finite time-horizon $T\le T_0$. (Remark 5 can be used to extend the result for all $T<\infty$.)

One way to obtain (49) is as follows. Consider $Z_\cdot = \log X_\cdot$, where $X_\cdot$ is given by (41). In particular, let $Z_\cdot^1 = \log X_\cdot^1$, where $X_0^1 = x_1 = e^{z_1}$, and $Z_\cdot^2 = \log X_\cdot^2$, where $X_0^2 = x_2 = e^{z_2}$. Then one can see that

$$Z_t^1 - Z_t^2 = z_1 - z_2 \qquad \text{a.s.}$$

Also let

$$U^\gamma(T,z) = \log[V^\gamma(T,e^z)].$$

Then one may easily show that

$$U^\gamma(T,z_1) - U^\gamma(T,z_2) \le \frac{\gamma+\eta}{\gamma}(z_1 - z_2)$$

for all $z_1 \ge z_2$. (Note that V^γ and U^γ are monotonically increasing.) After a few calculations, this yields

$$V^\gamma(T,x_1+\delta) - V^\gamma(T,x_1) \le C_4 e^{C_5 T}\left[x_1^{-\eta/\gamma} + x_1^{\eta/\gamma}\right]\delta,$$

which by (47b) yields (49). (Note that the above argument can be used to obtain equicontinuity of the V^γ as well.)

To prove that $V = W$, (48) and (49) will be used to show that the Hamiltonian in (45) satisfies assumptions (A) and (B). Since assumption (A) is clearly satisfied, we need only show that (B) is satisfied.

Note that

$$H(x,r,p) = \min_{v\in U} F(x,r,p,v),$$

where

$$F(x,r,p,v) = -A(v)xp + \frac{B^2(v)}{2}\frac{x^2p^2}{r}.$$

Since U is compact and A and B are continuous, we need only prove that F satisfies (B).

Let $R < \infty$, $x \le R$, $T \le T_0$, and suppose $W(T,x) > V(T,x)$. Then

$$\begin{aligned} &F(x,V(T,x),p,v) - F(x,W(T,x),q,v)\\ &\quad= F(x,V,p,v) - F(x,W,p,v) + F(x,W,p,v) - F(x,W,q,v)\\ &\quad= \frac{B^2(v)}{2}x^2p^2\left(\frac{1}{V} - \frac{1}{W}\right) + A(v)x(q-p) + \frac{B^2(v)}{2}\frac{x^2}{W(T,x)}(p^2-q^2), \end{aligned} \tag{50}$$

where we drop the arguments of V and W where unnecessary.

Now, by the mean value theorem, there exists $\xi \in [V(T,x),W(T,x)]$ such that

$$\frac{B^2(v)}{2}x^2p^2\left(\frac{1}{V} - \frac{1}{W}\right) = \frac{B^2(v)}{2}x^2p^2\frac{1}{\xi^2}(W-V),$$

which by (48)

$$\le \frac{B^2(v)}{2}\frac{p^2}{C_1^2e^{2C_2T}}(W-V),$$

which for $|p| \le \max\{K_R(V),K_R(W)\}$ and using (49)

$$\le C_4(W-V) \tag{51}$$

for appropriate C_4.

Note also that

$$A(v)x(q-p) + \frac{B^2(v)}{2}\frac{x^2}{W(T,x)}(p^2-q^2) \le |A(v)|R|p-q| + \frac{B^2(v)}{2}\frac{x^2}{W(T,x)}|p+q||p-q|,$$

which by (48)

$$\le |A(v)|R|p-q| + \frac{B^2(v)}{2}\frac{R}{C_1 e^{C_2 T}}|p+q||p-q|,$$

which by (49)

$$\le C_5 R|p-q| \tag{52}$$

for appropriate C_5.

Combining (50), (51), and (52), we see

$$F(x,V(T,x),p,v) - F(x,W(T,x),q,v) \le C_4[W(T,x)-V(T,x)] + C_5R|p-q|.$$

Therefore, (B) is satisfied, and consequently, $V = W$. Of course, in this simple example with $h_0(x) = x$, it is trivial to show then that one must have

$$V = W = xe^{CT},$$

where

$$C = \max_{v\in U}\left[A(v) - \frac{B^2(v)}{2}\right].$$

CONTROL TIME FOR GRAVITY-CAPILLARY WAVES ON WATER*

RUSSELL M. REID†

Abstract. This paper considers distributed open-loop control of small-amplitude linear waves on a fluid in which both surface tension and gravity are significant. It formulates the control system as a first-order evolution equation, reducing the null controllability problem to a moment problem involving frequency exponentials. For simple geometries in which eigenvalues can be calculated explicitly, controllability in arbitrary finite time is established, and a relationship between mode frequencies and controller norm is noted.

Key words. water waves, distributed control, moment problem

AMS subject classifications. 93B05, 93B60, 93C15

1. Introduction.

In 1967 D. L. Russell [11] showed that a vibrating string with distributed control could be steered to rest in a time given by

$$2\int_0^1 \sqrt{\frac{\rho(x)}{p(x)}}\, dx. \tag{1}$$

Open-loop control time for the string thus depends only on physical parameters (mass density, modulus of elasticity, and length) and not on the initial state or controller. Russell's result is sharp in that he shows that the string cannot be controlled in shorter time.

For a uniform string, (1) is the period of the fundamental mode, but mass density and elasticity can be chosen to alter the period of any mode but leave the asymptotic behavior of eigenvalues and control time unchanged, showing that control time is in general not the period of any mode. One might also view (1) as a signal time, the round-trip transit time for a wave on a string of length 1, because the integrand is the reciprocal of phase velocity at any point x. The string is nondispersive: all wavelengths propagate at the same speed.

Studies [9], [7] of gravity waves on fluids showed infinite control time, perhaps because wave velocity approaches zero as wavelength decreases, so that transit time for high-frequency modes is arbitrarily large. However, a general relationship between wave propagation speed and control time has not been established.

The primary aim of this paper is to investigate control time in a simple system with dispersive traveling waves, making note of the effect of wave velocity on control time and controller norm. Gravity-capillary waves are a physical system in which wave velocity varies with wavelength (as opposed to the vibrating string) and is bounded away from zero (as opposed to pure gravity waves). Mode shapes for simple geometries are identical to those for the vibrating string, but mode frequencies are different. If wave propagation velocity determines control time, one would expect finite control time for gravity-capillary waves, and this paper proves controllability in arbitrary finite time.

Using the same approach as [9] and [7] and some results found there, this paper writes the equations for gravity-capillary waves in first-order form in an energy space

* Received by the editors February 19, 1992; accepted for publication (in revised form) May 18, 1994.

and argues that the evolution operator has a complete orthonormal set of eigenfunctions. It is then possible to study a distributed control system by reducing it to a moment problem along the classical lines of [1] and [11], considering state spaces of finite energy with L_2 controls. The wavemaker problem is complex, especially at the intersection of the controlling wall with the free surface (see, for example, recent work by Joo, Schultz, and Messiter [3]), where an infinite-dimensional controller has in effect a continuous range of Froude numbers, which can be arbitrarily small. This work adopts a small-amplitude linearization and simplifying assumptions on the geometry and the behavior of solutions at corners of the domain, in pursuit of a tractable model exhibiting the wave behavior of gravity-capillary waves. It is noted that boundary control applied to a section of the containing wall is equivalent to a distributed control at the surface, albeit one whose control distribution coefficients are not easy to estimate. For simple geometry, the eigenvalues of a gravity-capillary fluid system are calculated explicitly.

For the gravity-capillary system, the spectrum of the uncontrolled evolution operator has neither finite density nor asymptotic gap, and in studying the moment problem one cannot appeal to the celebrated results of Paley and Wiener [6], Levinson [4], and others.

This work shows controllability by applying the result [8] showing that moment problems are solvable on an arbitrarily short interval when eigenvalue spacing becomes uniformly large, as is the case for fluids in simple geometries.

The essential difference between distributed control of a fluid and a string lies in the frequencies of eigenmodes; this work shows how those frequencies influence the controller norm.

2. Governing equations.

Consider a two-dimensional region Ω, with fixed boundary Γ (assumed smooth) and no beaches, i.e., with nonzero vertical walls at each end (see Fig. 1).

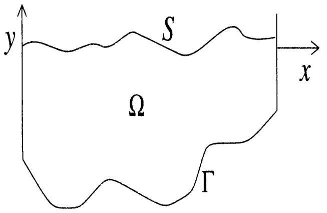

FIG. 1. *Domain and boundary.*

Let the free surface be denoted by S, in a coordinate system in which the undisturbed surface is at $y = 0$ and the vertical segments of the containing walls are at $x = 0$ and $x = \pi$.

Suppose that the fluid is irrotational and incompressible and has uniform density and no viscosity. Then the fluid velocity $u(x, y, t)$ can be expressed in terms of a harmonic potential by $u = -\nabla\Phi$, where Φ has zero normal derivative on the fixed boundary Γ. A small-amplitude linearization of the equations for surface waves, with the surface contour written as $y = \zeta(x, t)$ and $\Phi_y(x, y, t)$ and $\Phi_t(x, y, t)$ evaluated at $y = 0$, takes the form

$$\zeta_t = -\Phi_y, \tag{2}$$

$$\Phi_t = \zeta - T\zeta_{xx}, \tag{3}$$

where T is the surface tension and gravitational and density units have been chosen so that the gravitational constant is 1. Conservation of volume implies

$$\int_0^{\pi} \zeta(x)dx = 0. \tag{4}$$

Equations (2) and (3) can be put in first-order form by letting $\eta = \zeta_t$ and constructing the harmonic function Φ_t whose y-derivative at the surface gives ζ_{tt}. More specifically,

$$\frac{\partial}{\partial t}\begin{bmatrix} \zeta \\ \eta \end{bmatrix} = \begin{bmatrix} 0 & 1 \\ -(A+F) & 0 \end{bmatrix}\begin{bmatrix} \zeta \\ \eta \end{bmatrix}, \tag{5}$$

where A is the evolution operator for pure gravity waves and $F = AL$, with L the Sturm–Liouville operator $Lu = -Tu''$. It is desirable to embed (5) in an energy space where it is skew-symmetric with compact normal resolvent; to do so it is necessary to suppose energy-conserving boundary conditions on L, which we take to be $\zeta'(0) = \zeta'(\pi) = 0$, corresponding physically to an assumption of no friction with the containing walls. Let $L_0^2[0,\pi]$ denote those square integrable functions satisfying equation (4), with the usual L^2 inner product, and let Ψ_ζ be a function harmonic in Ω, with zero normal derivative on the fixed boundary Γ and value $\zeta(x)$ on the free surface. (Ψ_ζ would be Φ_t in (3) if T were 0.) It is shown in [9] and [7] that A defined by

$$A\zeta = \left.\frac{\partial \Psi_\zeta}{\partial y}\right|_{y=0} \tag{6}$$

is the evolution operator for pure gravity waves and is a positive self-adjoint operator with compact resolvent on $L_0^2[0,\pi]$, with domain $\mathcal{D}(A) = H^1 \cap L_0^2$.

The operator $F = AL$ can be seen to be positive and self-adjoint with compact resolvent on $L_0^2[0,\pi]$, with domain $\mathcal{D}(A) = H^3 \cap L_0^2 \cap BC$, where BC represents the Sturm–Liouville boundary conditions $\zeta'(0) = \zeta'(\pi) = 0$. When brackets are used to represent the L^2 inner product, note that for u and v in $\mathcal{D}(F)$,

$$\langle ALu, v\rangle = \langle Lu, Av\rangle = \langle u, LAv\rangle\,. \tag{7}$$

The first equality uses self-adjointness of A and the fact that $\mathcal{D}(A)$ is contained in $\mathcal{D}(F)$, whereas the second uses self-adjointness of L and requires that Av be in $\mathcal{D}(L)$, which comes from noticing that

$$Av = \left.\frac{\partial \Psi_v}{\partial y}\right|_{y=0} \tag{8}$$

so that

$$\frac{d}{dx}(Av) = \left.\frac{\partial^2 \Psi_v}{\partial y \partial x}\right|_{y=0}, \tag{9}$$

which is zero at $x = 0$ and $x = \pi$ because Ψ_v has zero normal (x) derivative there. (This is really a continuity assumption at the corners, the "no beaches" assumption.) One can conclude self-adjointness of F from the further observation that A^{-1} and

L^{-1} are compact operators on $L_0^2[0,\pi]$ (see, for example, [10, p. 353]). One can then embed (5) in a Hilbert space H, defining an inner product

$$\left\langle \begin{bmatrix} \zeta \\ \eta \end{bmatrix}, \begin{bmatrix} z \\ h \end{bmatrix} \right\rangle_H = \langle \zeta, (A+F)z \rangle + \langle \eta, h \rangle . \tag{10}$$

The space H of functions of finite norm is a Hilbert space, and the operator A_0 defined by

$$A_0 = \begin{bmatrix} 0 & 1 \\ -(A+F) & 0 \end{bmatrix}, \tag{11}$$

with domain

$$\mathcal{D}(A_0) = \left\{ \begin{bmatrix} \zeta \\ \eta \end{bmatrix} : \zeta \in H^3 \cap L_0^2 \cap BC \,, \eta \in H^{3/2} \cap L_0^2 \right\}, \tag{12}$$

is skew-symmetric with compact resolvent in this space.

Although the Hilbert space above is convenient for calculation, its norm does not give the actual physical energy; rather that is given by

$$\left\langle \begin{bmatrix} \zeta \\ \eta \end{bmatrix}, \begin{bmatrix} z \\ h \end{bmatrix} \right\rangle_E = \langle \zeta, z \rangle + \langle \eta, A^{-1}h \rangle + \langle \zeta, Lz \rangle , \tag{13}$$

where the first term can be shown to give gravitational potential energy, the second, kinetic energy, and the third, elastic potential energy. It turns out that eigenfunctions are orthogonal in the actual energy inner product also, but for now we use H.

One may summarize these observations in a theorem.

THEOREM 2.1. *The system* (2), (3) *describing gravity-capillary waves on a fluid surface can be written in the form*

$$X_t = A_0 X, \tag{14}$$

where X is in a Hilbert space H and A_0 is skew-symmetric with compact resolvent on H. There is an orthonormal basis for H consisting of eigenfunctions of A_0. The eigenvalues of A_0 are $\omega_k = i\sqrt{\lambda_k}$, $k = 1, 2, 3, \ldots$, with $\omega_{-k} = -\omega_k$, where λ_k denotes the kth eigenvalue of $A + F$. Solutions of (14) *form a group of bounded operators on H, denoted by $X(t) = e^{A_0 t} X_0$.*

3. Moment problem for a null control. Consider a distributed open-loop control applied at the surface, with spatial distribution of control fixed, which can be expressed in the form

$$X_t = A_0 X + Bu, \tag{15}$$

where B is in H and u is the control. An initial state X_0 can be steered to zero in time L (we used T for surface tension), provided that

$$\left\| e^{A_0 L} X_0 + \int_0^L e^{A_0(L-s)} Bu(s)\, ds \right\|_H = 0. \tag{16}$$

In terms of the basis of H consisting of eigenfunctions ϕ_n of A_0, denoting the corresponding eigenvalue of A_0 by ω_n, this becomes

$$\left\| \sum_{-\infty}^{\infty} \left(e^{\omega_n L} a_n \phi_n + \int_0^L e^{\omega_n (L-s)} b_n \phi_n u(s)\, ds \right) \right\|_H = 0, \tag{17}$$

where $X_0 = \sum a_n\phi_n$ and $B = \sum b_n\phi_n$. A necessary and sufficient condition for this to be true is, provided that no b_n is zero,

$$\int_0^L e^{-s\omega_n} u(s)ds = \frac{-a_n}{b_n} = c_n, \tag{18}$$

a standard moment problem for null control of an evolution equation.

One drawback to a moment approach to distributed control is the difficulty in characterizing the controllability space in terms of the coefficients b_n, which themselves may be difficult to calculate. Capillary waves differ little from other distributed linear systems in this regard, however; this work seeks primarily to consider the effect of mode frequencies on the controller norm for a given set of ratios c_n. Before doing so, we note that control applied to a boundary wall can take the form of a distributed control at the surface.

Consider control applied by small-amplitude vibration of the boundary wall at $x = 0$. The argument that such a control takes the form (14) is identical to that for gravity waves in [9], because the influence of the boundary control separates cleanly from the surface dynamics. To briefly review that calculation, let C denote some part of the wall at $x = 0$, controlled so that the harmonic function Φ_t in (3) has normal derivative on C given by

$$\frac{\partial \Phi_t}{\partial n} = h(y)u(t) \tag{19}$$

and normal derivative zero on the rest of Γ. It is required that $h(y) \in H^1$ and that its integral along C be zero to ensure conservation of volume. Let Ψ denote the harmonic function Φ_t that corresponds to a given surface configuration in an uncontrolled system, and let Θ be a harmonic function which is zero on the surface S and has normal derivative $h(y)u(t)$ on C and zero normal derivative elsewhere on Γ. Then it is easy to see that $\Psi + u(t)\Theta$ satisfies the boundary conditions required of Φ_t in the controlled system. It follows that

$$\zeta_{tt} = -\frac{\partial}{\partial y}(\Psi + u(t)\Theta)\bigg|_{y=0} = -(A+F)\zeta - u(t)\frac{\partial \Theta}{\partial y}\bigg|_{y=0} \tag{20}$$

so that (15) holds with

$$B = \begin{bmatrix} 0 \\ g(x) \end{bmatrix} = \begin{bmatrix} 0 \\ -\left.\frac{\partial\Theta}{\partial y}\right|_{y=0} \end{bmatrix}. \tag{21}$$

The control coefficients b_n that result from controlling part of a containing wall instead of applying control directly to the surface can be complicated for even the simplest controllers, however, as the following example, chosen because it can be computed exactly, shows. Suppose Ω is an infinite-depth domain, with controlled wall C the entire vertical wall at $x = 0$, and control function $h(y) = \sin(y)$ in equation (19). The y-derivative of the harmonic function Θ which defines the control element B in equation (21) can be constructed as an integral by using ideas from electrostatic potential theory. Specifying normal derivative on a surface is equivalent to specifying surface charge density on the wall at $x = 0$, and symmetry can be used to ensure zero normal derivative (electric field) at $x = \pi$ by placing the same charge density at $x = 2\pi$. Reflecting both charge distributions above the x-axis with the opposite sign ensures that the value of Θ (the potential) at $y = 0$ be zero. Then $g(x)$ in equation (21), temporarily thought of as the vertical component of an electric field at $y = 0$, can be constructed as an integral (recalling that in two dimensions electric field falls off as $1/r$). The y-component of electric field at location x due to charge $\sin(y)$ at depth y (doubled because of an antisymmetric charge above the x-axis), integrated over y to give the vertical component of electric field at the surface due to the charges at $x = 0$, gives

$$2\int_0^\infty \frac{\sin(y)}{\sqrt{x^2+y^2}}\frac{y}{\sqrt{x^2+y^2}}\,dy. \tag{22}$$

This integral can be calculated explicitly, giving πe^{-x}, and then added to the result for the charges at $x = 2\pi$, which is $\pi e^{-(2\pi - x)}$, to give $g(x) = \pi e^{-x} + \pi e^{-(2\pi-x)}$. The energy inner product of the control element B defined by this $g(x)$ with the nth eigenfunction of ϕ_n of A_0 (ϕ_n not normalized, because c_n is a ratio) can be calculated exactly, giving

$$b_n = \frac{\pi\sinh(\pi) + \pi\sqrt{Tn^3+n}\,\sin(\pi\sqrt{Tn^3+n})}{e^\pi(Tn^3+n+1)}. \tag{23}$$

It is not obvious whether any integer value of n gives exactly zero for b_n, but certainly one gets arbitrarily close to zero, and a plot shows a complicated dependence on n.

4. Eigenvalues for simple geometries. It is well known that existence of a solution $u(t)$ to a moment problem such as (18) depends on the interval L, the eigenvalues $\omega_n = \pm i\sqrt{\lambda_n}$, and the sequence $\{c_n\}$. This work now restricts its attention to a geometry in which the eigenvalues of $A + F$ can be computed explicitly.

Suppose that the region Ω has a flat bottom at $y = -H$. Then any $\zeta(x)$ in $L_0^2[0, \pi]$ satisfying $\zeta'(0) = \zeta'(\pi) = 0$ must be

$$\zeta = \sum_{n=1}^{\infty} a_n \cos(nx). \tag{24}$$

The harmonic function Ψ_ζ meeting boundary conditions and matching ζ at $y = 0$ is

$$\Psi(x,y) = \sum_{n=1}^{\infty} na_n \cos(nx)\frac{\cosh n(y+H)}{\cosh(nH)}, \tag{25}$$

giving

$$A\zeta = \sum_{n=1}^{\infty} na_n \cos(nx)\tanh(nH) \tag{26}$$

and

$$F\zeta = A(-T\zeta_{xx}) = \sum_{n=1}^{\infty} Tn^3 a_n \cos(nx)\tanh(nH). \tag{27}$$

The eigenfunctions of A and F are the same so that

$$(A+F)\cos(nx) = (Tn^3+n)\tanh(nH)\cos(nx). \tag{28}$$

Thus the eigenvalues of $A+F$ in this geometry are $\lambda_n = (Tn^3+n)\tanh(nH)$, so that the eigenvalues of A_0 are $\omega_n = i\sqrt{(Tn^3+n)\tanh(nH)}$, with $\omega_{-n} = -\omega_n$. A similar calculation for an infinite-depth domain leads to $\omega_n = i\sqrt{(Tn^3+n)}$. In particular, eigenvalues ω_n are $\mathcal{O}(n^{3/2})$, so that adjacent differences become arbitrarily large.

It is helpful to compare the infinite-depth example to the simplest vibrating string of length π, taking the string's density and elasticity to be 1. If both are put in skew-adjoint first-order form, the eigenvalues of the first-order evolution operator A_0 are $\omega_n = \pm in$ for the string and $\omega_n = \pm i\sqrt{Tn^3+n}$ for the fluid.

Allowing the ends of the string to slide freely rather than be fixed (to make the comparison to the fluid more obvious) and normalizing in the energy norm, eigenfunctions for the string are

$$\phi_n = \begin{bmatrix} n^{-1}\cos(nx) \\ i\cos(nx) \end{bmatrix}. \tag{29}$$

Similarly, eigenfunctions for the fluid, normalized in the norm of the Hilbert space H, are

$$\phi_n = \begin{bmatrix} (Tn^3+n)^{-1/2}\cos(nx) \\ i\cos(nx) \end{bmatrix}. \tag{30}$$

The same eigenfunctions are orthogonal in the actual energy inner product (13); normalized in that norm they are

$$\phi_n = \begin{bmatrix} (Tn^2+1)^{-1/2}\cos(nx) \\ i\sqrt{n}\cos(nx) \end{bmatrix}. \tag{31}$$

If control is applied as a distributed force, B has the first-order form

$$B = \begin{bmatrix} 0 \\ f(x) \end{bmatrix}. \tag{32}$$

Suppose one makes the assumption, used by Russell for the vibrating string [11, (2.17)], that the ordinary Fourier coefficients γ_n of $f(x)$ decay slowly enough that

$$\liminf_{n\to\infty} n|\gamma_n| > 0. \tag{33}$$

A simple $f(x)$ for which this is true is the piecewise linear function

$$f(x) = \begin{cases} x, & 0 \le x \le \pi/2, \\ (\pi/2 - x), & \pi/2 < x \le \pi. \end{cases}$$

Then for the string, and also for the fluid using the H-norm,

$$|b_n| = |\gamma_n|, \tag{34}$$

so that, under the assumption (33), $a_n/b_n = \mathcal{O}(na_n)$, which is square summable if the initial state is in $\mathcal{D}(A_0)$.

For the fluid, if we use the actual energy norm,

$$|b_n|\sqrt{n} = |\gamma_n|, \tag{35}$$

so that for large n, again under the assumption (33), $a_n/b_n = \mathcal{O}(n^{3/2}a_n)$, which is square summable for initial states in $\mathcal{D}(A_0)$.

However, in this work we are primarily interested in the effect of wave frequencies on control time and controller norm; henceforth we consider only the sequence of ratios c_n under the supposition that it is square summable.

5. Controllability and solutions to the moment problem.

A moment problem such as (18) is

$$(36) \qquad \langle f_n, u \rangle = c_n \, .$$

If the sequence $\{f_n\}$ has the property that the equations (36) have a solution $u \in H$ for every ℓ^2 sequence $\{c_n\}$ so that its moment space contains ℓ^2, it is a *Riesz-Fischer* sequence; if its moment space is contained in ℓ^2, it is a *Bessel* sequence. A sequence which is both a Bessel sequence and a Riesz–Fisher sequence is *strongly independent* and a Riesz basis for its closed linear span. The basic criterion is due to Boas: a sequence $\{f_n\}$ is a Riesz–Fischer sequence if there is an m and a Bessel sequence if there is an M such that, for every sequence of scalars $\{c_n\}$,

$$(37) \qquad m \sum |c_n|^2 \leq \left\| \sum c_n f_n \right\| 2 \leq M \sum |c_n|^2 \, .$$

The sequences $\{f_n\}$ which arise in the control of evolution equations are sequences of complex exponentials $\{e^{\pm i\lambda_n x}\}$; they are Bessel sequences in $L^2[-L, L]$ for every positive L provided only that the λ_n are real and separated [12]. Ingham showed in [2] that a sequence of exponentials $\{e^{\pm i\lambda_n x}\}$ is a Riesz–Fischer sequence in $L^2[-L, L]$, provided that every $|\lambda_{n+1} - \lambda_n|$ exceeds π/L. It can be shown that if a sequence of exponentials is incomplete and satisfies Ingham's condition for all but finitely many n, then it is a Riesz–Fischer sequence. (See, for example, [8] where it is shown that strong independence is unaffected by replacing finitely many λ_n, allowing rearrangement until Ingham's condition is met for all n.) For capillary waves the eigenvalues $|\lambda_n|$ are $\mathcal{O}(n^{3/2})$, so that the sequence $\{f_n\} = \{e^{\pm i\lambda_n x}\}$ is strongly independent in $L^2[-L, L]$ for every positive L.

If a solution u to (36) exists, there is a unique least-norm solution in the closed linear span of the $\{f_n\}$. If the sequence $\{f_n\}$ is strongly independent, every element in its closed linear span can be expressed as a series ([5, p. 317]). If we let $u = \sum a_n f_n$ and denote the sequences of coefficients (finite or infinite) by $a = \{a_1, a_2, a_3, \ldots\}$, $c = \{c_1, c_2, c_3, \ldots\}$, then the requirement (36) is

$$(38) \qquad \left\langle f_n, \sum a_j f_j \right\rangle = \sum a_j \langle f_n, f_j \rangle = c_n \, .$$

If G is the Gram matrix whose entries are $g_{nj} = \langle f_n, f_j \rangle$, this is simply

$$(39) \qquad Ga = c.$$

For the control moment problem (18), the entries of G are inner products of frequency exponentials independent of the initial state or controller; in $L_2[-L, L]$, a simple calculation gives

$$g_{ij} = \frac{\sin L|\omega_i - \omega_j|}{L\,|\omega_i - \omega_j|} \, .$$

The coefficients of the least-norm controller are determined by solving the system $Ga = c$, and the norm of the controller itself is

$$(40) \qquad \|u\|^2 = \left\langle \sum a_n f_n, \sum a_n f_n \right\rangle = a^T G a.$$

The moment problem has a solution for every $c \in \ell^2$ when G is invertible; the Gram matrix of a finite set of modes is always invertible. In either case, since G is symmetric,

$$\|u\|^2 = a^T G a = a^T c = \left(G^{-1}c\right)^T c = c^T G^{-1} c, \tag{41}$$

so that the relationship between controller norm and initial state depends fundamentally on the eigenstructure of the Gram matrix of inner products of mode frequencies.

If G_n denotes the Gram matrix of the first n modes (or rather, to preserve complex conjugates $\pm n$), then D. L. Russell's result can be viewed as showing that, for fixed $L \geq 2\pi$,

$$\lim_{n\to\infty} \left\|G_n^{-1}(L)\right\| < \infty,$$

whereas for any $L < 2\pi$,

$$\lim_{n\to\infty} \left\|G_n^{-1}(L)\right\| = \infty.$$

For capillary waves, for fixed $L > 0$,

$$\lim_{n\to\infty} \left\|G_n^{-1}(L)\right\| = K(L) < \infty,$$

because a Riesz–Fischer sequence is one for which eigenvalues of finite subsections of the Gram matrix are bounded away from zero; equivalently the ℓ^2 operator G is boundedly invertible with norm $\|G^{-1}\| \leq 1/m$ in equation (37).

The remarks above allow a final theorem.

THEOREM 5.1. *In terms of the orthonormal basis for H provided by the eigenfunctions ϕ_n of A_0, let $B = \sum b_n\phi_n$. Let $X_0 = \sum a_n\phi_n$ be an initial state in $\mathcal{D}(A_0)$ for which the sequence of ratios $c_n = a_n/b_n$ is square summable*; *in particular this is true of any initial state in $\mathcal{D}(A_0)$ under the assumption* $\inf|n^{3/2}b_n| > 0$, *or of any finite sequence $\{a_n\}$, provided only that no b_n is zero. Then for any time $L > 0$ there is a control u which steers X_0 to zero in time L and a constant $K(L)$ such that* $\|u\|_{L^2[0,L]} < K(L)\,\|\{c_n\}\|_{\ell^2}$.

It is worth remarking that for a capillary wave system, $K(L)$ is $\mathcal{O}(1)$ as long as L exceeds the natural control time $2\pi/(\omega_{n+1} - \omega_n)$ for every mode pair; it grows extremely rapidly with shorter control times.

Acknowledgments. The author wishes to thank the referees for significant contributions to this work.

AN EMBEDDING OF DOMAINS APPROACH IN FREE BOUNDARY PROBLEMS AND OPTIMAL DESIGN*

P. NEITTAANMÄKI[†] AND D. TIBA[‡]

Abstract. Both free boundary problems and optimal design problems involve unknown or variable domains. We describe a direct approach extending the formulation of the problem to a larger fixed domain without modifying the differential operator. This argument is based on an approximate controllability-type property.

Key words. variable domains, controllability, optimal control, fictitious domain

AMS subject classifications. 49D37, 49D05, 49E05

1. Introduction.

For the solution of partial differential equations defined in exterior domains or in domains with a complicated geometry, one procedure consists of extending the given problem to the whole space or to a convenient simple region, where an associated control problem has to be solved; see the paper by C. Atamian and P. Joly [1].

This idea is very useful in problems involving unknown or variable domains, and we mention the works of J. Blum [3], [4] related to free boundary problems in the physics of plasma and the papers of K. H. Hoffmann, J. Haslinger, and M. Kocvara [8]; D. Tiba [12], [13]; and R. Mäkinen, P. Neittaanmäki, and D. Tiba [14] devoted to applications in optimal shape design.

It turns out that a main ingredient in the argument is given by certain geometric controllability properties of elliptic systems, with or without constraints. From this point of view, the literature is not very rich, and we quote a first result from the classic book by Lions [9, p. 85] and the recent works by V. Barbu and D. Tiba [2] and by D. Tiba [12].

In §2 we analyse from this point of view the rapid method of identification of the plasma boundary in a tokamak used by J. Blum [4, Chap. V], and in §3, we study a typical optimal shape design problem (see Pironneau [11, Chap. VI]). We use a boundary control approximation, which is efficient since it involves convex optimization problems even when the original problem is nonconvex. In §4 we describe a distributed control approach in the case of the optimal packaging problem [16]. This is again based on a controllability-type result, and it may be viewed as a general fixed domain method in optimal shape design. The last section is devoted to numerical experiments which investigate the accuracy of the proposed methods.

Let us underline that one of the main aims of this paper is to present a unitary treatment of the various problems mentioned above and studied previously by other methods. We emphasize the use of fixed domains (containing the original ones), which is advantageous from a numerical point of view. Moreover, the partial differential operator describing the system remains unchanged in this approach and we avoid the

control in the coefficients techniques specific to optimal design problems (see Murat and Simon [10]).

2. Free boundary problems in plasma physics. In a tokamak, it is essential to know the shape and the position of the plasma boundary in the void chamber. In cross section, this gives a regular domain $\Omega \subset \mathbb{R}^2$ and the plasma covers a subdomain $D \subset \mathbb{R}^2$, confined by certain limitators F, which may have various shapes. (See Fig. 2.1, which is a schematic representation of the physics of the problem.)

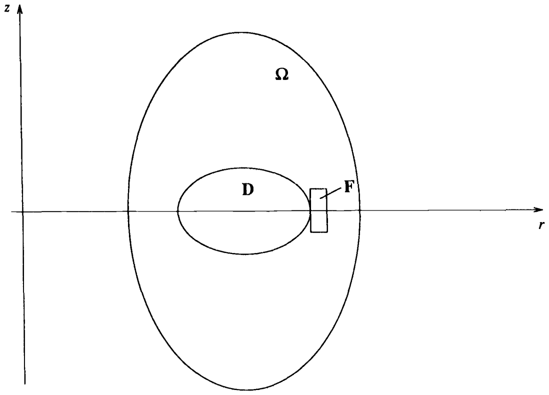

FIG. 2.1.

In void region $\Omega \setminus \overline{D}$ (unknown a priori), the poloidal flux ψ satisfies the linear elliptic equation

$$L\psi = -\frac{\partial}{\partial r}\left(\frac{1}{r}\frac{\partial \psi}{\partial r}\right) - \frac{\partial}{\partial z}\left(\frac{1}{r}\frac{\partial \psi}{\partial z}\right) = 0, \tag{2.1}$$

which is nonsingular since $r > c > 0$ in Ω under the natural choice of axes indicated in Fig. 2.1, which observes the symmetry of the torus representing the void chamber.

On the exterior boundary $\partial\Omega$, it is possible to measure

$$\psi = f \quad \text{on } \partial\Omega, \tag{2.2}$$

$$\frac{1}{r}\frac{\partial \psi}{\partial n} = g \quad \text{on } \partial\Omega, \tag{2.3}$$

thus obtaining a Cauchy problem for the elliptic operator (2.1) in $\Omega \setminus \overline{D}$. Assuming that ψ may be computed, the free boundary ∂D is characterized as a level set by the relation $M \in \partial D$ iff

$$\psi(M) = \sup_{x \in F} \psi(x). \tag{2.4}$$

The idea is to find ∂D using (2.4) and the overdetermined data on $\partial\Omega$. For arbitrary f and g, the obtained geometry of D may be very general, but for real data the method proposed by Blum [4, Chap. V] gives very accurate results, according to his numerical experiments. We follow the same procedure here, but our theoretical justification is different and avoids any extension assumptions, which are equivalent with exact boundary controllability properties and may be not true in general.

Let Γ be a closed regular curve in D, which is not in a neighbourhood of ∂D. (From the point of view of applications it is even preferable that Γ is "far" from ∂D

in order to allow more liberty for the searched position of the free boundary of the plasma.) We denote as Ω_0 the domain between $\partial\Omega$ and Γ, $\Omega_0 \supset \Omega \setminus D$.

We replace the ill-posed Cauchy problem (2.1)–(2.3) by the following noncoercive boundary control problem:

$$\underset{u\in L^2(\Gamma)}{\text{minimize}}\left\{ J(u) = \frac{1}{2}\left|\frac{1}{r}\frac{\partial\psi}{\partial n} - g\right|^2_{L^2(\partial\Omega)}\right\} \tag{2.5}$$

subject to

$$L\psi = 0 \quad \text{in } \Omega_0, \tag{2.6}$$

$$\psi = f \quad \text{on } \partial\Omega, \tag{2.7}$$

$$\psi = u \quad \text{on } \Gamma. \tag{2.8}$$

Here, we notice that if $f \in H^{3/2}(\partial\Omega)$, then $\psi \in H^2(\vartheta)$, where ϑ is a neighbourhood of $\partial\Omega$ in Ω_0 and the cost functional is well defined.

We use the approximate boundary controllability result of Lions [9, p. 85] and we see that

$$\inf_{u\in L^2(\Gamma)} J(u) = 0. \tag{2.9}$$

Therefore, a minimizing sequence of pairs $[u_n, \psi_n]$ will provide a good approximation of the Cauchy data (2.2), (2.3). Due to the absence of coercivity properties in (2.5)–(2.8), we haven't ensured the existence of optimal pairs.

We approximate the problem by the usual Tikhonov regularization technique, and we shall use an argument based on the uniqueness of the Cauchy problem for the adjoint system of the control problem

$$\text{minimize}\left\{ J_\varepsilon(u) = \frac{1}{2}\left|\frac{1}{r}\frac{\partial\psi}{\partial n} - g\right|^2_{L^2(\partial\Omega)} + \frac{\varepsilon}{2}\int_\Gamma u^2\, d\tau\right\} \tag{2.10}$$

subject to (2.6)–(2.8), $\varepsilon > 0$.

Let $[u_\varepsilon, \psi_\varepsilon]$ be the unique optimal pair for the problem (2.10).

THEOREM 2.1. *Assume that $f \in H^{3/2}(\partial\Omega)$, $g \in L^2(\partial\Omega)$. Then, for $\varepsilon \to 0$, we have*

$$\frac{1}{r}\frac{\partial\psi_\varepsilon}{\partial n} \to g \tag{2.11}$$

strongly in $L^2(\partial\Omega)$.

Proof. By taking $u = 0$ in (2.8), we infer that $\{\frac{1}{r}\frac{\partial\psi_\varepsilon}{\partial n}\}$ and $\{\varepsilon^{1/2}u_\varepsilon\}$ are bounded in $L^2(\partial\Omega)$, $L^2(\Gamma)$. We define the adjoint system by

$$Lp_\varepsilon = 0 \quad \text{in } \Omega_0, \tag{2.12}$$

$$p_\varepsilon = 0 \quad \text{on } \Gamma, \tag{2.13}$$

$$p_\varepsilon = \frac{1}{r}\frac{\partial\psi_\varepsilon}{\partial n} - g \quad \text{on } \partial\Omega, \tag{2.14}$$

which has a unique solution $p_\varepsilon \in H^{1/2}(\Omega_0)$, which is regular around Γ.

Standard calculus shows that the maximum principle (Pontryagin) takes the form

$$\frac{1}{r}\frac{\partial p_\varepsilon}{\partial n} = \varepsilon u_\varepsilon \quad \text{on } \Gamma. \tag{2.15}$$

Let $\ell = \lim \left(\frac{1}{r}\frac{\partial \psi_\varepsilon}{\partial n} - g\right)$ in the weak topology of $L^2(\partial\Omega)$ on a subsequence ε_n. The adjoint equation (2.12)–(2.14) defines a bounded linear operator from $L^2(\partial\Omega)$ to $H^{1/2}(\Omega_0)$, so we can pass to the limit $p_\varepsilon \to p$, which satisfies in a weak sense

$$Lp = 0 \quad \text{in } \Omega_0, \tag{2.16}$$

$$p = 0 \quad \text{on } \Gamma, \tag{2.17}$$

$$p = \ell \quad \text{on } \partial\Omega. \tag{2.18}$$

Passing to the limit in (2.15) too, we see that

$$\frac{1}{r}\frac{\partial p}{\partial n} = 0 \quad \text{on } \Gamma. \tag{2.19}$$

Then the uniqueness for the Cauchy problem (2.16), (2.17), (2.19) gives $p = 0$—that is, $\ell = 0$—by (2.18). Therefore, we get (2.11) with weak convergence instead of strong convergence.

Let $\{\tilde{\psi}_{\varepsilon_n}\}$ be a sequence of convex combinations of $\{\psi_{\varepsilon_n}\}$ corresponding to the sequence $\{\tilde{u}_{\varepsilon_n}\}$ of controls given by the Mazur theorem, i.e., $\frac{1}{r}\frac{\partial \tilde{\psi}_{\varepsilon_n}}{\partial n} \to g$ strongly in $L^2(\partial\Omega)$.

Let the fixed control $\tilde{u}_{\varepsilon_n}$ be a convex combination of controls $\{u_{\varepsilon_k}\}_{k=m,\dots,n}$. Then $\{\varepsilon_n^{1/2}\tilde{u}_{\varepsilon_n}\}$ is bounded in $L^2(\Gamma)$. We put the control $\tilde{u}_{\varepsilon_n}$ in the problem corresponding to ε_n^2 and we obtain

$$\begin{aligned}&\frac{1}{2}\left|\frac{1}{r}\frac{\partial \psi_{\varepsilon_n^2}}{\partial n} - g\right|^2_{L^2(\partial\Omega)} + \frac{\varepsilon_n^2}{2}\int_\Gamma u^2_{\varepsilon_n^2}\,d\tau \\ &\le \frac{1}{2}\left|\frac{1}{r}\frac{\partial \tilde{\psi}_{\varepsilon_n}}{\partial n} - g\right|^2_{L^2(\partial\Omega)} + \frac{\varepsilon_n^2}{2}\int_\Gamma \tilde{u}^2_{\varepsilon_n}\,d\tau.\end{aligned} \tag{2.20}$$

By the above argument, we notice that the right-hand side in (2.20) converges to 0; therefore $\frac{1}{r}\frac{\partial \psi_{\varepsilon_n^2}}{\partial n} - g \to 0$ strongly in $L^2(\partial\Omega)$. Finally, (2.11) is valid without taking subsequences. □

3. Boundary control and optimal shape design. We analyse the following standard design problem (see Pironneau [11, Chaps. III and VI]):

$$\underset{D}{\text{minimize}}\left\{V(D) = \int_E |\nabla y - y_d|^2\,dx\right\} \tag{P}$$

subject to

$$-\Delta y = f \quad \text{in } D, \tag{3.1}$$

$$y = 0 \quad \text{on } \partial D. \tag{3.2}$$

Here $y_d \in L^2(\Omega)^N$, $f \in L^2(\Omega)$, $E \subset D \subset \Omega \subset \mathbb{R}^2$ (compare with Fig. 2.1) are bounded domains, $\overline{E} \subset \Omega$ are fixed, D is variable (the minimization parameter), and y is a weak solution of the Dirichlet problem (3.1), (3.2) in D.

In the absence of regularity assumptions on ∂D, we haven't ensured the existence of an optimal subdomain for (P), and we shall study the minimizing sequences.

We associate with (P) the following constrained control problem:

$$\text{(Q)} \qquad \underset{u}{\text{minimize}} \left\{ W(u) = \int_E |\nabla y - y_d|^2 \, dx \right\},$$

$$\text{(3.3)} \qquad -\Delta y = f \quad \text{in } \Omega,$$

$$\text{(3.4)} \qquad y = u \quad \text{on } \partial\Omega,$$

$$\text{(3.5)} \qquad u \leq 0 \quad \text{on } \partial\Omega,$$

$$\text{(3.6)} \qquad y \geq 0 \quad \text{in } \overline{E}.$$

We assume that $\partial\Omega$ is regular, $u \in H^{3/2}(\partial\Omega)$, so $y \in H^2(\Omega)$ and it is continuous by the Sobolev embedding theorem. Then (3.5) and (3.6) have a clear meaning. We show that there is a strong relationship between the design problem (P) and the control problem (Q) defined in a fixed domain. Any admissible control for (Q) generates uniquely a subdomain of Ω with the same associated cost, and we may write the following theorem.

THEOREM 3.1. *The problem* (Q) *is a subproblem of* (P) *if* $f \geq 0$.

Proof. For every $u \in H^{3/2}(\partial\Omega)$ admissible for (Q), we define

$$\widetilde{D}_u = \text{int}\{x \in \Omega, \ \ y_u(x) \geq 0\},$$

which is an open set such that $E \subset \widetilde{D}_u \subset \Omega$, by (3.6). We have denoted by y_u the solution of (3.3), (3.4) corresponding to u. We define $D_u \subset \Omega$ to be the connected component of $\widetilde{D}_u$ which contains E, and we remark that $y_u|_{D_u}$ is the solution of the Dirichlet problem (3.1), (3.2) in D_u.

Therefore, by this correspondence $u \rightarrow D_u$, we associate, with each control $u \in H^{3/2}(\partial\Omega)$ and satisfying (3.5), (3.6), a domain $D_u \subset \Omega$ which gives the same cost $V(D_u) = W(u)$. No smoothness is valid in general for ∂D_u, but the existence of the weak solution of the Dirichlet problem in D_u is ensured. Since this is given by $y_u|_{D_u}$, it is in fact a strong solution. This correspondence is not void since we may take $u \equiv 0$ and $D_u = \Omega$ as an example by the weak maximum principle. It is also injective since otherwise, if u_1 and u_2 produce the same subdomain $\widetilde{D}$ by the above construction, then $y_1 - y_2 \equiv 0$ in $\widetilde{D}$ and, by analyticity, $y_1 - y_2 \equiv 0$ in Ω; that is, $u_1 \equiv u_2$. ▯

For the converse statement, we shall show that it is possible to construct a minimizing sequence for (P) with domains of the type $\{D_{u_k}\}$, where $\{u_k\}$ is an admissible sequence of controls for (Q), generally unbounded. Then, by Theorem 3.1, $\{u_k\}$ is a minimizing sequence for (Q) too, and we have

$$\text{(3.7)} \qquad \inf (\text{P}) = \inf (\text{Q}).$$

Finally, every minimizing sequence $\{w_n\}$ for (Q) will produce a minimizing sequence $\{D_{w_n}\}$ for (P) by (3.7), and this shows that the solution of the design problem (P) is reduced to the solution of the control problem (Q).

Remark. The advantage of this approach is that the control problem (Q) is defined in a fixed domain, which avoids the redefinition of new finite element mesh in each iteration of the algorithm, as in the boundary variation technique. Moreover, the problem (Q) is convex; therefore, the global minimum for (P) may be obtained, which is not ensured by the other methods which generally produce only a local minimizer.

We shall need the following approximate constrained controllability-type hypothesis:

(H) Let Ω be a regular domain and $f \geq 0$ in Ω. For any subdomain $D \subset \Omega$ there is a sequence $u_n \in H^{3/2}(\partial\Omega)$, $u_n \leq 0$ in $\partial\Omega$, such that the solution y_n of (3.3), (3.4) satisfies

$$y_n\Big|_D \to y_D \quad \text{strongly in } L^2(D), \tag{3.8}$$

where y_D is the weak solution of (3.1), (3.2).

Remark. If no control constraints are imposed, the statement is valid. In [12] and [14], it is proved that it remains valid if the control constraint acts up to an open part of $\partial\Omega$ of arbitrarily small measure. Moreover, Example 3.1 below shows that (H) is satisfied in dimension one and Example 3.2 gives a hint in the same sense in dimension two. So, we conjecture that (H) is true in any dimension.

Example 3.1. If $\Omega \subset \mathbb{R}$, we take $\Omega = (0,1)$ to fix the ideas. Let $a, b \in (0,1)$, $a < b$, be arbitrary. Let f be negative in $(0,1)$ and y be the solution of

$$\begin{aligned} y''(x) &= f(x) \quad \text{in } (a,b), \\ y(a) &= y(b) = 0; \end{aligned}$$

that is,

$$y(x) = \int_a^x (x-t)f(t)\,dt + \frac{x-a}{x-b}\int_a^b (b-t)f(t)\,dt.$$

Then y may be viewed as defined over the whole (0,1) and satisfying the same equation. Moreover, we have

$$\begin{aligned} y(0) &= \int_0^a tf(t)\,dt + \frac{a}{b-a}\int_a^b (b-t)f(t)\,dt \leq 0, \\ y(1) &= (1-b)\int_a^b f(t)\left(1 - \frac{b-t}{b-a}\right)dt + \int_b^1 (1-t)f(t)\,dt \leq 0, \end{aligned}$$

so (H) is satisfied as an exact controllability property with constraints. This is also related to the convexity of the mapping $-y$.

Example 3.2. In higher dimension, the situation is by far more complicated. Let $\Omega = D(1, \frac{3}{2}) \subset \mathbb{R}^2$ be the disc centered in the point $A(1,0)$ and with radius $r = \frac{3}{2}$ (see Fig. 5.1) and let

$$y(x_1,x_2) = \begin{cases} \frac{1}{4}x_1^2 - x_2^2, & x_1 \leq 1, \\ \frac{1}{4}x_1^2 - x_2^2 - (x_1-1)^4, & x_1 \geq 1, \end{cases}$$

$$f(x_1,x_2) = \begin{cases} \frac{3}{2}, & x_1 \leq 1, \\ \frac{3}{2} + 12(x_1-1)^2, & x_1 \geq 1, \end{cases}$$

for $(x_1, x_2) \in \Omega$.

We notice that $f \geq 0$ in Ω and y is the solution of (3.3). Moreover, if $D \subset \Omega$ is defined by $D = \{(x_1,x_2) \mid x_1 \geq 0,\ y(x_1,x_2) \geq 0\}$, we obtain, obviously, $y = 0$ on ∂D. As $u = y\big|_{\partial\Omega}$ satisfies $u > 0$ between lines $x_2 = \pm\frac{1}{2}x_1$ for $x_1 < 0$ one may conclude, apparently, that (H) is not valid. This is due to the fact that in higher dimensions the positivity of Δy does not ensure the convexity of y. In our case, y is a saddle function for $x_1 \leq 1$.

However, a standard numerical treatment of the constrained control problem

$$\text{minimize } \frac{1}{2}\int_{\partial D} y^2\, d\tau$$

subject to (3.3)–(3.5) (see Example 5.1) will produce a negative boundary control $\bar{u}$ and its associated state $\bar{y}$, whose level lines are shown in Fig. 5.3, as well as Ω and D (see also Fig. 5.1).

This shows that (H) also remains valid in this setting as an approximate controllability property, but the exact controllability-type property (with constraints) will no longer be true.

Remark. In the parabolic case, distributed controllability properties with constraints are proved in the thesis of J. Henry [7], and constrained approximate boundary controllability properties have been recently announced by J. I. Diaz [5] without complete proofs.

THEOREM 3.2. *Assume* (H) *is valid. Let $E \subset D \subset \Omega$ be any fixed subdomains and $\varepsilon > 0$ be an arbitrary positive parameter. There exists a control $u_{\varepsilon,D} \in H^{3/2}(\partial\Omega)$ admissible for* (Q) *such that*

$$|V(D) - V(D_{u_{\varepsilon,D}})| < \varepsilon. \tag{3.9}$$

Proof. By a variant of a result of Pironneau [11, p. 32] we may limit the analysis to the case $\overline{E} \subset D$.

We may also assume that f is regular enough such that the weak solution of the Poisson equation in various subdomains has C^2 interior regularity. This may be obtained by a regularization of f and doesn't affect (3.9). That is, if f_λ is a regularization of f, $\lambda > 0$, the $H^1(D)$ estimate for the weak solutions associated to f, f_λ shows that the difference between the corresponding costs in (P) is "small." Moreover, this estimate is independent of D.

Let $y \in C^2(D)$ be the weak solution of the Poisson equation

$$-\Delta y = f \quad \text{in } D, \tag{3.10}$$

$$y = 0 \quad \text{on } \partial D. \tag{3.11}$$

The strong maximum principle, since $f \geq 0$, gives $y(x) > 0$ in D; therefore, $y(x) \geq C > 0$ in $\overline{E}$ by the compactness of $\overline{E} \subset D$.

By the (H) condition, there is $u_n \in H^{3/2}(\partial\Omega)$, $u_n \leq 0$ in $\partial\Omega$ such that the corresponding solution of (3.3), (3.4) satisfies (3.8). We show that, for n sufficiently large, the pair $[y_n, u_n]$ will be admissible for (Q); that is, (3.6) is also satisfied.

Let $\bar{y}$ be given by

$$\begin{aligned} -\Delta\bar{y} &= f \quad \text{in } \Omega,\\ \bar{y} &= 0 \quad \text{on } \partial\Omega; \end{aligned}$$

then $y_n \leq \bar{y}$ in Ω by comparison. The harmonic mappings $y_n - y \leq \bar{y} - y$ in D and $y_n - y \to 0$ almost everywhere D by (H). Then, it is well known that

$$y_n - y \to 0$$

in $\mathcal{H}(D)$, the space of harmonic mappings on D; that is, $y_n - y \to 0$ uniformly in compact subsets of D.

In particular, this is valid in $\overline{E}$, and taking into account that $y(x) \geq C > 0$ in $\overline{E}$, we get (3.6) for n big enough. Moreover, we have $W(u_n) = V(D_{u_n}) \to V(D)$.

Choosing n big enough such that (3.9) is fulfilled, we obtain the desired $u_{\varepsilon,D}$. The subdomain $D_{u_{\varepsilon,D}} \subset \Omega$ is associated to it by the technique of Theorem 3.1. $\Box$

Remark. Under this approach, it is not necessary to study geometric convergence properties for minimizing sequences of subdomains as is usual in optimal shape design. We show directly that the control $u_{\varepsilon,n}$ will generate a subdomain which gives a cost close to the optimal value.

Remark. We also underline the simplicity of the method in applications, by comparison with other fixed domain methods. In the mapping method of Murat and Simon [10] the variable domain is mapped on a fixed one and the control appears in the coefficients of the differential operator, while in the above technique we preserve the differential operator unchanged.

4. A distributed control approach in the optimal packaging problem. It is our aim to give a fixed-domain approach to the optimal packaging problem introduced by Zolésio, Sokolowski, and Benedict [16] and discussed by other methods in books by Haslinger and Neittaanmäki [6, Chap. X] and Tiba [15, Chap. III, §5].

The distributed control approach we are proposing here has the advantage of a large range of applications with respect to the equation, the boundary conditions, and the assumptions on the data.

Let $E \subset \Omega \subset \mathbb{R}^2$ be fixed domains with regular boundary and $\varphi\colon \overline{\Omega} \mapsto \mathbb{R}$ be a $C^2(\overline{\Omega})$ mapping with $\varphi|_{\partial\Omega} < 0$. Let D be a variable domain such that $E_\varphi \subseteq D \subseteq \Omega$, where $E \subset E_\varphi = \{x \in \Omega\ ;\ \varphi(x) > 0\}$. In D, we consider the variational inequality

$$-\Delta y + \beta(y - \varphi) \ni f \quad \text{in } D, \tag{4.1}$$

$$y = 0 \quad \text{on } \partial D, \tag{4.2}$$

with $f \in L^2(\Omega)$ and $\beta \subset \mathbb{R} \times \mathbb{R}$, the maximal monotone graph defined by

$$\beta(r) = \begin{cases} 0, & r > 0, \\ ]-\infty, 0], & r = 0, \\ \emptyset, & r < 0. \end{cases} \tag{4.3}$$

The optimal packaging problem, denoted (PA), consists of finding the subdomain $D \supset E_\varphi$ with minimal area such that the coincidence set given by

$$Z_y = \{x \in D\ ;\ y(x) = \varphi(x)\} \tag{4.4}$$

contains (or equals) E, $Z_y \supseteq E$. We note that the whole ∂D may be variable, and no global analytic description is assumed for it.

This problem contains several difficulties: it is governed by variational inequalities, and it involves variable domains and nonstandard state constraints given by (4.4).

We suppose the existence of at least one admissible domain $\check{D}$ such that the associated solution $\check{y}$ satisfies (4.4). In order to get an existence result, one has to impose some uniform regularity assumptions on ∂D (see Pironneau [11, Chap. 3]).

We associate the control system in Ω

$$-\Delta y_u + \beta(y_u - \varphi) \ni u \quad \text{in } \Omega, \tag{4.5}$$

$$y_u = 0 \quad \text{on } \partial\Omega \tag{4.6}$$

and, for a fixed Lipschitzian subdomain $D \supset E_\varphi$, the variational inequalities

$$-\Delta \tilde{y} + \beta(\tilde{y} - \varphi) \ni f \quad \text{in } D, \tag{4.7}$$

$$\tilde{y} = 0 \quad \text{on } \partial D, \tag{4.8}$$

$$-\Delta y_v + \beta(y_v - \varphi) \ni v \quad \text{in } \Omega \setminus \overline{D}, \tag{4.9}$$

$$y_v = 0 \quad \text{on } \partial D \cup \partial\Omega \tag{4.10}$$

with $v \in L^2(\Omega \setminus D)$.

The following exact controllability-type result is true.

THEOREM 4.1. *There is $v \in L^2(\Omega \setminus D)$ such that y_v given by* (4.9), (4.10) *satisfies*

$$\frac{\partial y_v}{\partial n} = -\frac{\partial \tilde{y}}{\partial \nu} \quad \textit{on } \partial D. \tag{4.11}$$

Here n and ν are the normals to ∂D inside and outside D.

Proof. We give a direct argument.

By the trace theorem, there is $\hat{y} \in H^2(\Omega \setminus \overline{D}) \cap H_0^1(\Omega \setminus \overline{D})$ such that it satisfies (4.11). We define $\bar{y} \in H_0^1(\Omega \setminus \overline{D})$ by

$$\bar{y}(x) = \max(\hat{y}(x), \varphi(x)), \tag{4.12}$$

where we have used the fact that $\varphi(x) < 0$ in $\Omega \setminus \overline{D}$ by hypothesis and $\hat{y} \in H_0^1(\Omega \setminus \overline{D})$. We notice that for any $x \in \partial D$, $\hat{y}(x) > \varphi(x)$, which is preserved by continuity in a neighbourhood $\vartheta(x)$; therefore, $\bar{y}(x) = \hat{y}(x)$ in $\vartheta(x)$—that is, $\bar{y}(x)$ satisfies (4.11) too. Moreover, we have $\bar{y}(x) \geq \varphi(x)$ in $\overline{\Omega \setminus D}$. In order to get more smoothness, one may regularize locally $\bar{y}$, which is piecewise smooth. We denote y_ε the regularized function corresponding to the regularization parameter $\varepsilon > 0$. It turns out that y_ε does not necessarily satisfy $y_\varepsilon \geq \varphi$ in $\overline{\Omega \setminus D}$.

To overcome this difficulty, we remark that the set where jumps in the derivatives of $\bar{y}$ may occur is contained in the set $\{\hat{y}(x) = \varphi(x)\} \subset \Omega \setminus \overline{D}$, compact and at positive distance $2c > 0$ from the boundaries $\partial\Omega$ and ∂D where $\hat{y}(x) > \varphi(x)$. Some local regularization y_ε is different from $\bar{y}$ on a compact neighbourhood of this set at positive distance $c > 0$ from $\partial\Omega$ and ∂D. Then, adding to y_ε a regular mapping of the type

$$K \operatorname{dist}(x, \partial\Omega)^2 \cdot \operatorname{dist}(x, \partial D)^2 \tag{4.13}$$

with a sufficiently large $K > 0$, we obtain the function y_K, which satisfies

$$\begin{aligned}
&y_K > \varphi,\\
&\text{it is in } H^2(\Omega \setminus \overline{D}) \cap H_0^1(\Omega \setminus \overline{D}),\\
&\frac{\partial y_K}{\partial n} = \frac{\partial y_\varepsilon}{\partial n} = \frac{\partial \bar{y}}{\partial n} = \frac{\partial \hat{y}}{\partial n} = -\frac{\partial \tilde{y}}{\partial \nu} \quad \text{in } \partial D,
\end{aligned}$$

due to the properties of (4.13) and the definition of y_ε.

Finally, $v = -\Delta y_K \in L^2(\Omega \setminus D)$ is the desired control since $\beta(y_K - \varphi) \equiv 0$ by $y_K(x) > \varphi(x)$ in $\Omega \setminus \overline{D}$. ||

We define the distributed control problem

$$(\mathbb{P}_n) \qquad \min_{u \in L^2(\Omega)} \int_{E_{y_u}} (1 + n(u - f)^2)\, dx \tag{4.14}$$

subject to (4.5), (4.6), (4.4), and $n \in \mathbb{N}$. Here E_{y_u} is the smallest subdomain of Ω containing E_φ and such that $y_u = 0$ on ∂E_{y_u}. The existence of E_{y_u} is trivial due to (4.6). One may ask for ∂E_{y_u} to be Lipschitzian since we have this for $\partial\Omega$ and the intersection of two Lipschitzian domains remains Lipschitzian.

It is to be underlined that, generally, (4.14) has no optimal pair since there is no coercivity ensured for u.

We show that there is a strong approximation relationship between (4.14) and (PA) for $n \to \infty$, without any reference to convergence properties of sequences of subdomains of Ω, as it is a standard argument in optimal design.

THEOREM 4.2. *For any $n \in \mathbb{N}$ and any admissible domain for the problem* (PA) *there is $u \in L^2(\Omega)$ admissible for $(\mathbb{P}_n)$ with an associated lower cost. Then*

$$\inf(\text{PA}) \geq \inf(\mathbb{P}_n). \tag{4.15}$$

Conversely, if $\delta_n > 0$ is small and $[y_n, u_n]$ is a δ_n optimal pair for $(\mathbb{P}_n)$, then E_{y_n} is an ε_n optimal subdomain for (PA) *(in a sense to be specified) with a small $\varepsilon_n > 0$ depending on δ_n.*

Proof. For any Lipschitzian $D \supset E_\varphi$, Theorem 4.1 gives $v \in L^2(\Omega \setminus D)$ such that y_v defined by (4.9) and (4.10) satisfies (4.11), with $\tilde{y}$ given by (4.7), (4.8). Then, we have that

$$y_u(x) = \begin{cases} \tilde{y}(x) & \text{in } \overline{D}, \\ y_v(x) & \text{in } \Omega \setminus D \end{cases} \tag{4.16}$$

satisfies (4.5), (4.6), $y_u \in H^2(\Omega) \cap H_0^1(\Omega)$, and $u \in L^2(\Omega)$ is given by

$$u(x) = \begin{cases} f(x) & \text{in } D, \\ v(x) & \text{in } \Omega \setminus D. \end{cases} \tag{4.17}$$

Furthermore, $y_u|_{\partial D} = 0$, so $E_{y_u} \subset D$ by definition, and $u|_{E_{y_u}} = f|_{E_{y_u}}$. Consequently, the cost in (4.14) is less or equal to meas(D), the cost associated with (PA). It is in this sense that we may speak about embedding of (PA) in (4.14) for any $n \in \mathbb{N}$, which yields (4.15).

Conversely, by (4.15), we have

$$\int_{E_{y_n}} (1 + n(u_n - f)^2)\, dx \leq \inf(\text{PA}) + \delta_n = d + \delta_n. \tag{4.18}$$

That is, $|u_n - f|_{L^2(E_{y_n})} \leq \sqrt{\frac{d+\delta_n}{n}}$. Since $y_n|_{E_{y_n}}$ satisfies the variational inequality

$$\begin{aligned} -\Delta y_n + \beta(y_n - \varphi) \ni u_n \quad & \text{in } E_{y_n}, \\ y_n = 0 \quad & \text{on } \partial E_{y_n}, \end{aligned}$$

then it is close to $\tilde{y}_n$ such that

$$\begin{aligned} -\Delta \tilde{y}_n + \beta(\tilde{y}_n - \varphi) \ni f \quad & \text{in } E_{y_n}, \\ \tilde{y}_n = 0 \quad & \text{on } \partial E_{y_n}; \end{aligned}$$

that is, $|y_n - \tilde{y}_n|_{H_0^1(E_{y_n})} \leq \varepsilon_n$. Therefore E_{y_n} is an ε_n-suboptimal pair for (4.1) in the sense that

$$\begin{aligned} &\text{meas}(E_{y_n}) \leq \inf(4.1) + \delta_n, \\ &|\tilde{y}_n - \varphi|_{H^1(E)} \leq \varepsilon_n, \end{aligned}$$

since $y_n\big|_E \equiv \varphi$ by the definition of $(\mathbb{P}_n)$.

Remark. In practical solving of $(\mathbb{P}_n)$, one also penalizes the state constraint (4.4), which gives a weaker evaluation of the same type of its violation in the above argument.

Remark. It is the controllability property from Theorem 4.1 which, in fact, guarantees that the subdomains D may be automatically generated by the control system (4.5), (4.6), thus allowing us to renounce the geometric parameters. Moreover, another specific feature of the methods developed in §§3 and 4 is that the governing equations remain unchanged when we transfer the problem on the fixed domain.

5. Numerical examples. In this section we note three relevant numerical examples. We begin with the numerical treatment of Example 3.2. The other two examples concern optimal design problems (boundary control and distributed control approaches). A complete computational analysis of the plasma problem may be found in the book by Blum [4], whose "rapid method" is theoretically investigated in §2 in a general setting. Moreover, other approximation procedures and other plasma models are also discussed in [4].

Example 5.1. Let $\Omega = \{(x_1, x_2) \in \mathbb{R}^2 \ ; \ (x_1 - 1)^2 + x_2^2 < 1.5\}$ and $\Gamma = \{(x_1, x_2) \in \mathbb{R}^2; \ \frac{1}{2}x_1^2 - x_2^2 = 0$ for $0 < x_1 < 1$ and $\frac{1}{4}x_1^2 - x_2^2 - (x_1 - 1)^4 = 0$ for $x_1 > 1\}$; see Fig. 5.1.

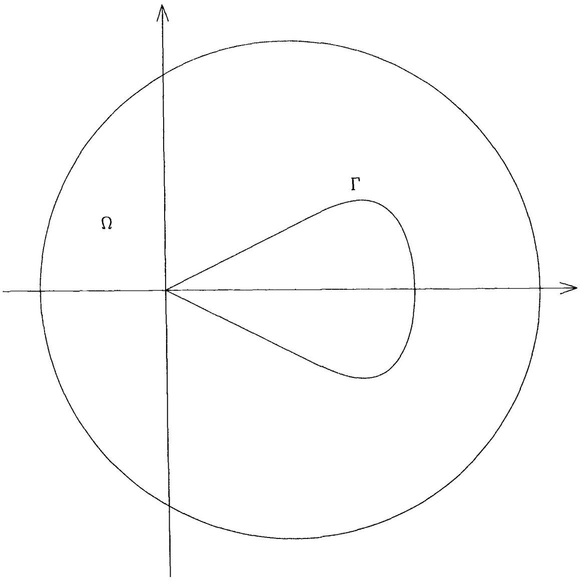

FIG. 5.1.

Consider the minimization problem

$$\text{(5.1)} \qquad \underset{u}{\text{minimize}} \left\{ J(u) = \frac{1}{2} \int_\Gamma y^2 \, d\Gamma \right\}$$

subject to

$$\text{(5.2)} \qquad \begin{cases} -\Delta y = f & \text{in } \Omega, \\ y = u & \text{on } \partial\Omega, \end{cases}$$

$$\text{(5.3)} \qquad u \le 0 \quad \text{on } \partial\Omega,$$

where f is indicated in Example 3.2.

We have discretized the state problem (5.2) using the finite element method with triangular elements consisting of 661 interior nodes and 120 boundary nodes (control variables) and piecewise linear approximation. We formulate the minimization problem (5.1)–(5.3) as a mathematical programming problem and use the sequential quadratic programming method (subroutine E04VDF of the Numerical Algorithms Group library). The state problem was solved by the Cholesky method. As usual, the adjoint state technique was applied to compute the gradient of the cost function $J(\mathbf{u})$ (see J. Haslinger and P. Neittaanmäki [6]).

We have chosen the initial guess as follows: $u_i^0 = -10.0$, $i = 1, \dots, 120$. This gives the value 187.77 for $J(\mathbf{u})$.

After 17 iterations the value of $J(\mathbf{u})$ was reduced to $4.23 \cdot 10^{-4}$. Figure 5.2 shows the value of $\mathbf{u}$ on $\partial\Omega$ (as a function of angle parameter). The expected symmetry of $\mathbf{u}$ with respect to 3.1416 is slightly perturbed due to the round-off errors which accumulate in the way that we solve the algebraic system and due to the chosen triangulation of the disc Ω.

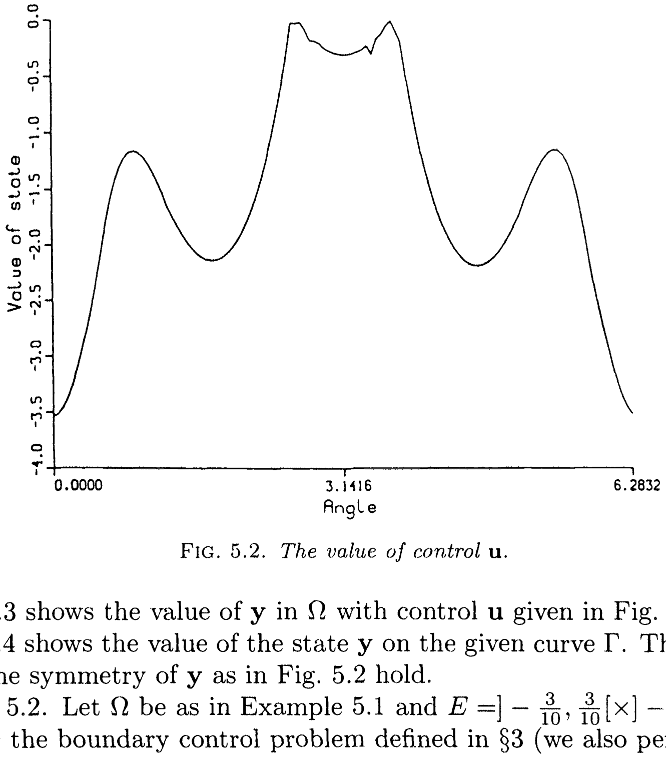

FIG. 5.2. *The value of control* $\mathbf{u}$.

Figure 5.3 shows the value of $\mathbf{y}$ in Ω with control $\mathbf{u}$ given in Fig. 5.2.

Figure 5.4 shows the value of the state $\mathbf{y}$ on the given curve Γ. The same considerations on the symmetry of $\mathbf{y}$ as in Fig. 5.2 hold.

Example 5.2. Let Ω be as in Example 5.1 and $E =]-\frac{3}{10}, \frac{3}{10}[\times]-\frac{7}{10}, \frac{7}{10}[$.

Consider the boundary control problem defined in §3 (we also penalize the state constraint):

$$\text{(5.4)} \qquad \underset{u}{\text{minimize}} \left\{ J(y(u)) = \frac{1}{2}\|y - y_d\|^2_{H^1(E)} + \frac{1}{2\lambda}\int_E y_-^2 \, dx \right\}$$

subject to

$$\text{(5.5)} \qquad \begin{cases} -\Delta y = f & \text{in } \Omega, \\ y = u & \text{on } \partial\Omega, \end{cases}$$

$$\text{(5.6)} \qquad u \leq 0 \quad \text{on } \partial\Omega.$$

Here $y_d = \frac{3}{2} - 4x_1^2 - x_2^2$ and $f = 10$.

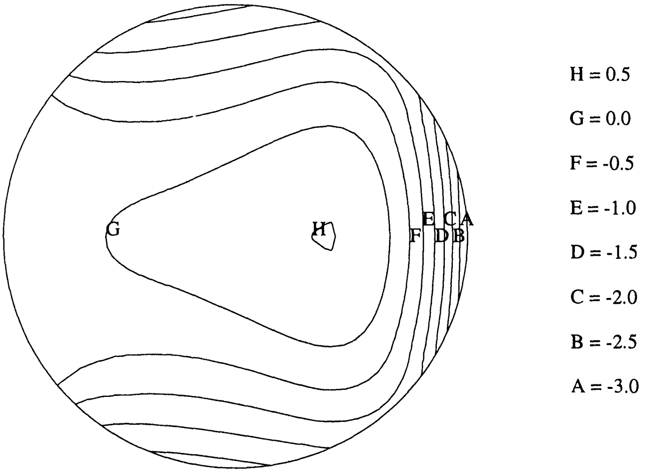

FIG. 5.3. *The value of* $\mathbf{y}$ *in* Ω *with control* $\mathbf{u}$.

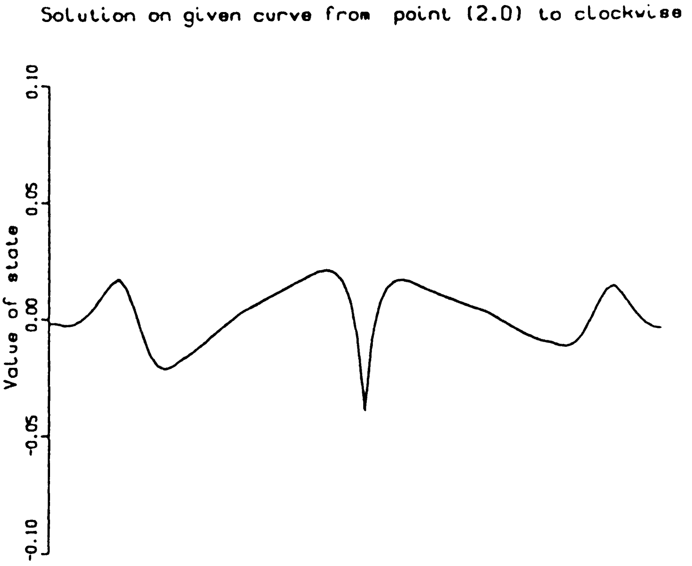

FIG. 5.4. *The value of the state* $\mathbf{y}$ *on the given curve* Γ.

We have applied a finite-element grid and elements similar to those in Example 5.1. The initial guess for the control was $u_i^0 = -4.5$, $i = 1, \dots, 120$, giving the value 3.35 for the cost functional J with the penalty parameter $\lambda = 10^{-3}$. After 12 iterations the value of the cost functional was reduced to $2 \cdot 10^{-4}$. The obtained control and the corresponding state can be seen in Figs. 5.5 and 5.6.

The same problem was solved in [14] with the conventional moving mesh technique, and the radial coordinates of the boundary nodes were chosen as the control variables. The initial guess chosen was a unit disc. The moving mesh approach gives essentially the same design with fewer sequential quadratic programming iterations than the proposed boundary control approach, but the total computational burden is much heavier, as the finite element mesh has to be updated at the beginning of each iteration. As the coefficient matrix in the moving grid method depends on control variables, one cannot utilize the same factorization of the coefficient matrix as in the case of the boundary control approach.

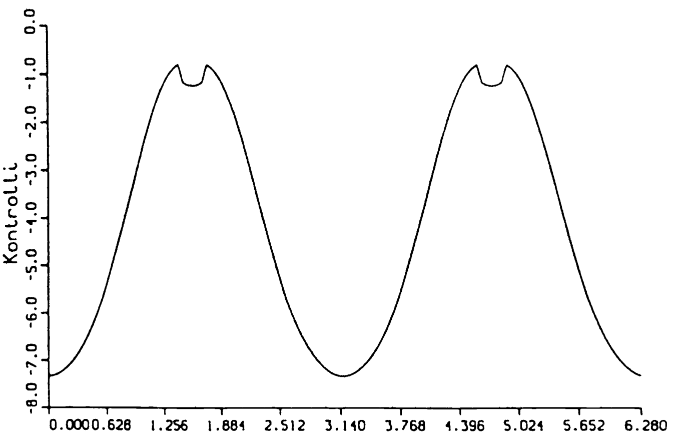

FIG. 5.5. *Obtained control in Ex. 5.2.*

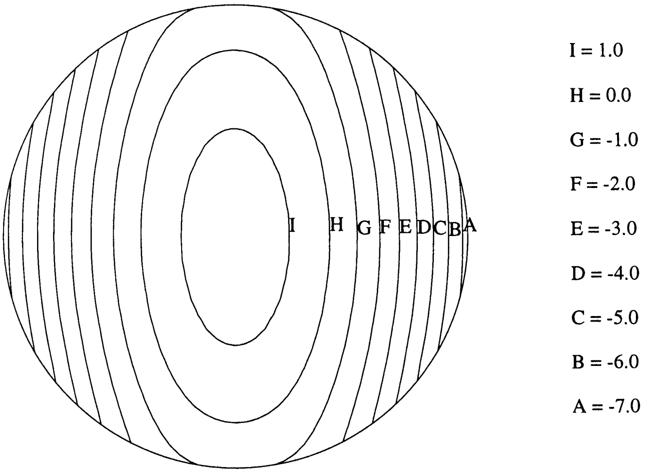

FIG. 5.6. *State corresponding to the control given in Ex. 5.2.*

Example 5.3. In connection with §4, we choose $\Omega = \{(x_1, x_2) \in \mathbb{R}^2\ ;\ x_1^2 + x_2^2 < 1\}$, the obstacle

$$\varphi(x_1, x_2) = \begin{cases} \frac{1}{7} - 2\left(x_1 + \frac{1}{2}\right) - \frac{1}{2}x_2^2, & x_1 < 0, \\ \frac{1}{7} - 2\left(x_1 - \frac{1}{2}\right) - \frac{1}{2}x_2^2, & x_1 \geq 0, \end{cases} \tag{5.7}$$

and $E = E_1 \cup E_2 = [-\frac{5}{8}, -\frac{3}{8}] \times [-\frac{3}{8}, \frac{3}{8}] \cup [\frac{3}{8}, \frac{5}{8}] \times [-\frac{3}{8}, \frac{3}{8}]$, $f \equiv -3$ in Ω. In (4.14), we also penalize the state constraint (4.4) and solve the control problem

$$\underset{u \in L^2(\Omega)}{\text{minimize}} \left\{ J = \int_{E_{y_u}} \left[1 + \frac{1}{2\varepsilon_1}(u - f)^2 \right] dx + \frac{1}{2\varepsilon_2} \int_E (y - \varphi)^2\, dx \right\} \tag{5.8}$$

subject to (4.5), (4.6). Here φ is given by (5.7).

If we take $\varepsilon_1 = 10^{-3}$, $\varepsilon_2 = 10^{-5}$, and initial iteration $u_0 = 2$, which gives $E_{y_{u_0}} = \Omega$, then the initial cost is about $3.569 \cdot 10^4$. After five iterations the cost was reduced to 0.9571 and the value of the penalization terms was about $3 \cdot 10^{-9}$, which shows that the error in the state constraints or in the solution is very small.

In Fig. 5.7, the final solution of the optimal shape problem is shown. One should

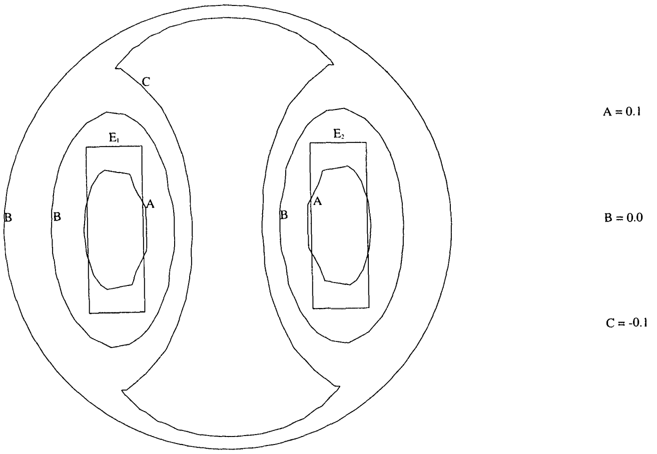

FIG. 5.7.

note that the solution consists of two disjoint open sets. Therefore the topology of the solution set may change during the computation. (Initially it was connected.) This is another advantage over the standard boundary variation technique.

Acknowledgments. The authors are indebted to R. Mäkinen and T. Räisänen for their help with the numerical tests.

SECOND-ORDER OPTIMALITY CONDITIONS IN SETS OF L^∞ FUNCTIONS WITH RANGE IN A POLYHEDRON*

JOSEPH C. DUNN†

Abstract. Formal extensions of the general second-order necessary conditions and sufficient conditions for local optimality in a polyhedral convex set $U \subset \mathbb{R}^m$ are established for L^∞-local optimality and L^2-local optimality in the infinite-dimensional nonpolyhedral convex set Ω of L^∞ functions $u(\cdot) : [0,1] \to U$. A more refined analysis for nonconvex cost functions with specially structured differentials yields optimality conditions that apply to an important class of constrained input Bolza optimal control problems. The gap between the necessary conditions and sufficient conditions in this setting is uncharacteristically small for infinite-dimensional problems. In the control problem context, the L^∞-local optimality conditions and L^2-local optimality conditions entail a mild strengthening of a pointwise strict complementarity condition and variants of the Legendre–Clebsch condition and the Pontryagin minimum principle. In related recent studies, similar second-order sufficient conditions for the special case $U = [0,\infty)$ are the key hypotheses in corresponding local convergence theories for iterative constrained minimization algorithms.

Key words. constrained minimization, function spaces, necessary conditions, sufficient conditions, optimal control, Legendre–Clebsch condition, Pontryagin minimum principle

1. Introduction.

Many problems in the calculus of variations and optimal control theory belong to the class of infinite-dimensional nonlinear programs

$$\min_{u \in \Omega \cap \mathcal{D}} J(u), \tag{1a}$$

$$\Omega = \{u \in \mathsf{L}_m^\infty\,[0,1] : u(t) \overset{\text{a.e.}}{\in} U\}, \tag{1b}$$

where $\mathsf{L}_m^\infty\,[0,1]$ is the vector space of Lebesgue-measurable essentially bounded functions $u : [0,1] \to \mathbb{R}^m$, J is a real-valued function that is differentiable in some sense on a domain $\mathcal{D}$ in $\mathsf{L}_m^\infty\,[0,1]$, and U is a nonempty polyhedral convex set in $\mathbb{R}^m$, i.e., an intersection of finitely many closed half-spaces in $\mathbb{R}^m$. Although Ω is *not* a polyhedral set, its special Cartesian product structure suggests that the well-known second-order necessary conditions and sufficient conditions for local optimality in U may have valid formal extensions in Ω. This question is explored here for two distinct species of local optimality corresponding to the nonequivalent norms $\|\cdot\|_\infty$ and $\|\cdot\|_2$ on $\mathsf{L}_m^\infty[0,1]$ and for nonconvex objective functions J with differentials satisfying structure and continuity hypotheses that are met by a large class of Bolza optimal control problems, and in other contexts as well.

The theorems in §§5 and 6 greatly extend the L^∞-local optimality and L^2-local optimality necessary conditions and sufficient conditions established in [1] for the special case $U = [0,\infty)$. These theorems are proved with geometric techniques that directly exploit the properties of polyhedra and the product structure in Ω, and thereby dispense with the constraint qualifications and multiplier functionals invoked in Lagrangian second-order necessary conditions for general infinite-dimensional nonlinear programs (cf. [3]–[11]). Smoothness hypotheses imposed in the L^∞-local optimality

sufficient conditions of Theorem 6.4 are also substantially weaker than the corresponding hypotheses in [1] and are now comparable to analogous assumptions in the L^∞ sufficiency analysis of [9]. Under stronger smoothness requirements like those in [1], Theorem 6.6 ensures that L^2-local optimality is implied by L^∞-local optimality sufficient conditions and a strengthened form of the L^2-local optimality necessary condition. The latter condition is closely related to the Pontryagin minimum principle in the context of ordinary differential equation (ODE) optimal control problems.

Reference [2] develops another far-reaching extension of the L^∞-local optimality sufficiency theorem in [1] for ODE optimal control problems with terminal state equality constraints and nonpolyhedral time-dependent admissible control input sets $U(t)$ prescribed by finitely many smooth nonlinear inequalities; however, the Lagrangian formulation in [2] imposes constraint qualifications on the inequalities that define U and differs in other important respects from the representation-free geometric approach pursued here. Lemma 6.5, Note 6.3, and the related discussion in §6 interpret the principal algebraic hypotheses of [2] in the geometric framework of Theorems 6.4 and 6.6.

The gaps between the main necessary conditions and sufficient conditions proved here are uncharacteristically small for infinite-dimensional nonlinear programs in general, and optimal control problems in particular [3], [9]. As noted in [10], the sufficiency gap has some computational significance since standard iterative constrained optimization algorithms tend to exhibit their best local convergence behavior near stationary points that satisfy known second-order sufficient conditions. The sufficient conditions in [1] and [2] have already produced new local convergence theorems for gradient projection methods [12], [13] and sequential quadratic programming algorithms [2] in infinite-dimensional settings. While the convergence rate estimates in these theorems are similar to their finite-dimensional counterparts, the developments in [12], [13], and [19] indicate potentially interesting differences in the computational implications of L^∞-local and L^2-local convergence theorems for approximate finite-dimensional implementations of the subject algorithms. The sufficient conditions proved in the present paper support similar local convergence theorems for gradient projection iterations and continuous-time optimal control problems with vector-valued control functions satisfying affine inequality constraints pointwise in bounded time intervals; these theorems will be stated and proved in a later paper.

2. Preliminary considerations.

The following brief review is meant to serve as a bridge between familiar terminology and theorems in $\mathbb{R}^n$ and analogous formulations for Ω in the infinite-dimensional space $\mathsf{L}^\infty_m[0,1]$.

Let J be a real valued function on a domain $\mathcal{D}$ in a vector space V. Then:

(i) J is *twice directionally differentiable* iff each point of $\mathcal{D}$ is an *internal point* of $\mathcal{D}$ [14] and the following limits exist for all u in $\mathcal{D}$ and v, w in V:

$$d^1J(u\ ;\ v) = \lim_{s\to 0} \frac{J(u+sv)-J(u)}{s},$$

$$d^2J(u\ ;\ v,w) = \lim_{s\to 0} \frac{d^1J(u+sv\ ;\ w)-d^1J(u\ ;\ w)}{s}.$$

(ii) J is *twice Gâteaux differentiable relative to a norm* $\|\cdot\|$ *on* V iff J is twice directionally differentiable and, for each u in $\mathcal{D}$, the differentials $d^1J(u\ ;\ \cdot)$ and

$d^2\ J(u\ ;\ \cdot,\cdot)$ are linear and bilinear, respectively, and continuous relative to $\|\cdot\|$.[1]

(iii) J is twice *Fréchet differentiable relative to a norm* $\|\cdot\|$ *on* V iff J is twice Gâteaux differentiable relative to $\|\cdot\|$, $\mathcal{D}$ is open relative to $\|\cdot\|$, and, for all u in $\mathcal{D}$,

$$|J(u+v) - J(u) - d^1J(u\ ;\ v)| = o(\|v\|),$$

$$\sup_{\|w\|=1} |d^1J(u+v\ ;\ w) - d^1J(u\ ;\ w) - d^2J(u\ ;\ v,w)| = o(\|v\|).$$

(iv) J is twice *continuously* Fréchet differentiable relative to a norm $\|\cdot\|$ on V iff J is twice Fréchet differentiable relative to $\|\cdot\|$ and, for all u in $\mathcal{D}$,

$$\lim_{\|\Delta u\|\to 0}\ \sup_{\|v\|=1} |d^1J(u+\Delta u\ ;\ v) - d^1J(u\ ;\ v)| = 0,$$

$$\lim_{\|\Delta u\|\to 0}\ \sup_{\|w\|=1}\ \sup_{\|v\|=1} |d^2J(u+\Delta u\ ;\ v,w) - d^2J(u\ ;\ v,w)| = 0.$$

The uniform approximation property imposed in the definition of Fréchet differentiabilty is closely related to the continuity properties of the directional derivative maps $d^1J(\cdot\ ;\ v)$ and $d^2J(\cdot\ ;\ v,w)$. More precisely, if J is twice Gâteaux differentiable relative to a norm $\|\cdot\|$ on V, if $\mathcal{D}$ is open relative to $\|\cdot\|$, and if the real functions $d^1J(\cdot\ ;\ v)$ and $d^2J(\cdot\ ;\ v,w)$ are continuous at each u in $\mathcal{D}$ relative to $\|\cdot\|$, *uniformly in v and w on the unit sphere* $S(0,1) = \{v \in \mathsf{V} : \|v\| = 1\}$, then J is twice continuously Fréchet differentiable relative to $\|\cdot\|$. When J is twice continuously Fréchet differentiable, the second differential is *symmetric*, i.e.,

$$d^2J(u\ ;\ v,w) = d^2J(u\ ;\ w,v),$$

and Taylor's formula yields the important estimate

$$J(u+v) = J(u) + d^1J(u\ ;\ v) + \tfrac{1}{2}\ d^2J(u\ ;\ v,v) + o(\|v\|^2).$$

Note that in $\mathbb{R}^n$, all norms are equivalent, linearity implies continuity in any norm, continuity and Gâteaux differentiability and Fréchet differentiability are norm-invariant properties, and the directional derivative uniform continuity requirements are met iff all first and second order partial derivatives of J are continuous. On the other hand, in infinite-dimensional vector spaces, two norms are not necessarily equivalent; linearity does not imply continuity; and continuity, Gâteaux differentiability and Fréchet differentiability are norm-dependent properties.

Let J be a twice Gâteaux differentiable real-valued function on a domain $\mathcal{D}$ in a vector space V with inner product $\langle\cdot,\cdot\rangle$ and induced norm $\|u\| = \sqrt{\langle u,u\rangle}$. At each u in $\mathcal{D}$, there is at most one vector $\nabla J(u)$ in V and one continuous linear map $\nabla^2J(u) : \mathsf{V} \to \mathsf{V}$ such that

$$d^1J(u\ ;\ v) = \langle \nabla J(u), v\rangle \quad \text{and} \quad d^2J(u\ ;\ v,w) = \langle v, \nabla^2J(u)w\rangle.$$

The vector $\nabla J(u)$ and operator $\nabla^2J(u)$ are called the *gradient* and *Hessian* of J at u, *corresponding to the inner product* $\langle\cdot,\cdot\rangle$. When $\nabla J(u)$ and $\nabla^2J(u)$ exist at every

[1] This definition of Gâteaux differentiability conforms to [18]. In some references, the terms directional differentiability and Gâteaux differentiability are used interchangeably [23].

u in $\mathcal{D}$ for the given inner product, the function J is then twice continuously Fréchet differentiable (relative to the induced norm) iff $\mathcal{D}$ is open and the maps $\nabla J(\cdot)$ and $\nabla^2 J(\cdot)$ are continuous (relative to the induced norm and the corresponding operator norm). If V is a *Hilbert space*, then the Riesz representation theorem ensures that the gradient and Hessian do exist at each point in the domain of J. In particular, in $\mathbb{R}^n$, every twice Gâteaux differentiable J has gradients and Hessians for the standard inner product, with the familiar matrix representations in the standard basis, i.e.,

$$(\nabla J(u))_i = \frac{\partial J}{\partial u_i}(u) \quad \text{and} \quad (\nabla^2 J(u)v)_i = \sum_{j=1}^{m} \frac{\partial^2 J}{\partial u_i \partial u_j}(u) v_j.$$

Suppose that C is a *convex* set in a vector space V with inner product $\langle \cdot, \cdot \rangle$ and induced norm $\|u\| = \sqrt{\langle u, u \rangle}$. At each u in C, let $\mathcal{N}_C(u)$, $\mathcal{T}_C(u)$, $\mathsf{N}_C(u)$, $\mathsf{T}_C(u)$, and $\operatorname{ri} \mathcal{N}_C(u)$ denote *the cone of outer normals, the polar cone of tangents, and the closed linear hull, orthogonal complement, and relative interior of* $\mathcal{N}_C(u)$ *in* V, respectively; i.e.,

$$\mathcal{N}_C(u) = \{w \in \mathsf{V} : \forall v \in C \quad \langle w, v - u \rangle \leq 0\},$$

$$\mathcal{T}_C(u) = \{v \in \mathsf{V} : \forall w \in \mathcal{N}_C(u) \quad \langle v, w \rangle \leq 0\},$$

$$\mathsf{N}_C(u) = \text{cl span } [\mathcal{N}_C(u)],$$

$$\mathsf{T}_C(u) = \mathcal{N}_C(u)^{\perp} = \mathsf{N}_C(u)^{\perp},$$

and

$$\operatorname{ri} \mathcal{N}_C(u) = \{w \in \mathcal{N}_C(u) : \exists \delta > 0 \; \forall x \in \mathsf{N}_C(u) \quad \|x\| \leq \delta \Rightarrow w + x \in \mathcal{N}_C(u)\}.$$

The closed subspace $\mathsf{T}_C(u)$ is the largest subspace contained in $\mathcal{T}_C(u)$ and is sometimes called the *lineality* in the tangent cone. In a *Hilbert space* V, $\mathcal{N}_C(u)$ is the polar cone for $\mathcal{T}_C(u)$, $\mathsf{N}_C(u)$ is the orthogonal complement of $\mathsf{T}_C(u)$, and for all v in V, the usual orthogonal projection decompositions hold with respect to the pairs $(\mathcal{N}_C(u), \mathcal{T}_C(u))$ and $(\mathsf{N}_C(u), \mathsf{T}_C(u))$; i.e., for all v in V,

$$v = P_{\mathcal{N}_C(u)}\, v + P_{\mathcal{T}_C(u)}\, v, \qquad v = P_{\mathsf{N}_C(u)}\, v + P_{\mathsf{T}_C(u)}\, v,$$

where P_X denotes orthogonal projection into the set $X \subset \mathsf{V}$.

3. Structure and smoothness assumptions. Much of the analysis in §§5 and 6 applies to objective functions J that satisfy the following conditions:

(i) J is twice directionally differentiable on its domain $\mathcal{D}$ in $\mathsf{L}_m^\infty[0,1]$.

(ii) For each u in $\mathcal{D}$ there is a vector $\nabla J(u) \in \mathsf{L}_m^\infty[0,1]$, an essentially bounded $m \times m$ matrix-valued function $S(\cdot) \in \mathsf{L}_{m \times m}^\infty[0,1]$, and a square-integrable $m \times m$ matrix-valued function $K(\cdot) \in \mathsf{L}_{m \times m}^2([0,1] \times [0,1])$ such that

$$d^1 J(u\,;\, v) = \langle \nabla J(u), v \rangle_2 \tag{2a}$$

and

$$d^2 J(u\,;\, v, w) = \langle v, \nabla^2 J(u) w \rangle_2 \tag{2b}$$

with

$$(2c)\qquad \left(\nabla^2 J(u)w\right)(t) = S(u)(t)w(t) + \int_o^1 K(u)(t,s)w(s)ds, \quad t \in [0,1],$$

where $\langle v, w\rangle_2 = \int_0^1 \langle v(t), w(t)\rangle dt$, $\|u\|_2 = \sqrt{\langle u, u\rangle_2}$, and $\langle \xi, \eta\rangle = \sum_{i=1}^m \xi_i\eta_i$ for ξ, η in $\mathbb{R}^m$.

(iii) For $\nu = 2$ or ∞, the domain $\mathcal{D}$ is open relative to $\|\cdot\|_\nu$, and the associated mappings $S(\cdot)$ and $K(\cdot)$ are continuous in the sense that for all u in $\mathcal{D}$

$$(3a)\qquad \lim_{\|v-u\|_\nu \to 0} \|S(v) - S(u)\|_\infty = 0$$

and

$$(3b)\qquad \lim_{\|v-u\|_\nu \to 0} \|K(v) - K(u)\|_2 = 0,$$

where $\|v\|_\infty = \operatorname{ess\,sup}_{t\in[0,1]} \|v(t)\|$, $\|\xi\| = \sqrt{\langle \xi, \xi\rangle}$ and

$$\|S(u)\|_\infty = \operatorname*{ess\ sup}_{t\in[0,1]} \|S(u)(t)\|,$$

$$\|K\|_2 = \left(\int_0^1 \int_0^1 \|K(u)(t,s)\|^2 ds dt\right)^{\frac{1}{2}},$$

$$\|S(u)(t)\| = \sup_{\|\xi\|=1} \|S(u)(t)\xi\|,$$

$$\|K(u)(t,s)\| = \sup_{\|\xi\|=1} \|K(u)(t,s)\xi\|.$$

Assumptions (i) and (ii) imply that J is Gâteaux differentiable relative to *either* of the norms $\|\cdot\|_\infty$ or $\|\cdot\|_2$, with gradients $\nabla J(u)$ and Hessians $\nabla^2 J(u)$ in the incomplete inner product space $\{\mathsf{L}_m^\infty[0,1], \langle\cdot,\cdot\rangle_2, \|\cdot\|_2\}$. In $\mathbb{R}^n$, the analogue of the structure condition (2c) in (ii) can always be met by writing $\nabla^2 J(u)$ as the sum of its diagonal and off-diagonal parts; however, (2c) is a *nontrivial* hypothesis in the vector space $\mathsf{L}_m^\infty[0,1]$. In this infinite-dimensional setting, condition (2c) ensures that the Hessian operator $\nabla^2 J(u)$ acts essentially like the simple multiplication operator $S(u)$ on vectors v that vanish outside a set with small Lebesgue measure in $[0,1]$. This "local diagonal dominance" property is essential for the proofs of the L^∞-local optimality and L^2-local optimality sufficient conditions in Theorems 6.4 and 6.6 and the matching necessary conditions in Theorems 5.3 and 5.4.

If assumption (iii) holds along with (i) and (ii), then J is *twice continuously Fréchet differentiable* relative to $\|\cdot\|_\nu$ on $\mathsf{L}_m^\infty[0,1]$ and, in addition,

$$(4a)\qquad J(v) - J(u) = \langle \nabla J(u), v-u\rangle_2 + \tfrac{1}{2}\langle v-u, \nabla^2 J(u)\,(v-u)\rangle_2 + r(u;v)$$

with

$$(4b)\qquad \lim_{\|v-u\|_\nu \to 0} \frac{|r(u;v)|}{\|v-u\|_2^2} = 0.$$

For $\nu = 2$, (4b) asserts that $r(u;v) = o(\|v-u\|_2^2)$, as in formula 4 of [1]; this standard L^2 version of Taylor's remainder estimate is invoked in the L^2-local optimality *and* L^∞-local optimality analyses in [1]. For $\nu = \infty$, (4) reduces to the weaker condition in the L^∞ analyses of [9] and [2]; this form of (4) is imposed here in §6 (and will also support the L^∞ sufficient conditions in [1]). Note that the continuity hypotheses in (iii) are roughly analogous to partial derivative continuity conditions in $\mathbb{R}^n$; however, the norms $\|\cdot\|_\infty$ and $\|\cdot\|_2$ are not equivalent on the infinite-dimensional space $\mathsf{L}_m^\infty[0,1]$, and conditions (3) with $\nu = 2$ are *stronger* than (3) with $\nu = \infty$. Note also that for $\nu = \infty$, (4b) is stronger than the standard Taylor remainder estimate for objective functions J that are twice continuously Fréchet differentiable relative to $\|\cdot\|_\infty$; thus, conditions (3) with $\nu = \infty$ imply *more* than twice continuous Fréchet differentiability in the L^∞ norm but *less* than twice continuous Fréchet differentiability in the L^2 norm.

Note 3.1. In an optimal control setting, the structure/continuity conditions (2) and (3) are satisfied with $\nu = \infty$ by a large class of Bolza objective functions,

$$J(u) = P(x(1)) + \int_0^1 f^0(t, x(t), u(t))dt, \tag{5a}$$

where $x(\cdot) : [0,1] \to \mathbb{R}^n$ is the solution of an initial value problem

$$x(0) = x_0, \tag{5b}$$

$$\frac{dx}{dt} = f(t, x(t), u(t)), \quad t \in [0,1], \tag{5c}$$

and P, f^0, and f satisfy relatively weak smoothness and growth restrictions. Conditions (2) and (3) are also satisfied with $\nu = 2$ by a smaller but still important class of *quasi-quadratic* Bolza objective functions with associated system Hamiltonians $H(t,\psi,x,u) = \langle \psi, f(t,x,u)\rangle + f^0(t,x,u)$ that are quadratic in $u \in \mathbb{R}^m$. (See [13] for a discussion of the case $m = 1$.)

4. Formal extensions of the optimality conditions in polyhedra.

If C is a *polyhedral* convex set in $\mathbb{R}^n$, then the tangent cone $\mathcal{T}_C(u)$ coincides with the *cone of feasible direction vectors at* u, every vector in the subspace $\mathsf{T}_C(u)$ is a feasible direction vector, and $u + \mathsf{T}_C(u)$ is the affine hull of the unique polyhedral face of C containing u in its relative interior. These observations and an application of elementary calculus immediately produce the following geometric expression of the basic necessary conditions for optimality in polyhedral convex subsets of $\mathbb{R}^n$.

THEOREM 4.1. *Suppose that C is a polyhedral convex set in $\mathbb{R}^n$, u is a local minimizer for the restriction of $J : \mathcal{D} \to \mathbb{R}^1$ to any line in C, and J is twice directionally differentiable at u. Then*

$$\forall v \in C \quad d^1J(u\,;\, v-u) \geq 0$$

and

$$\forall v \in \mathsf{T}_C(u) \quad d^1J(u\,;\, v) = 0 \quad \textit{and} \quad d^2J(u\,;\, v,v) \geq 0.$$

Note that if J is Gâteaux differentiable, then the first-order necessary condition in Theorem 4.1 says that $-\nabla J(u) \in \mathcal{N}_C(u)$.

The corresponding second-order *sufficient* conditions for local optimality in polyhedra also have a representation-free geometric expression. In this theorem, the directional differentiability hypothesis is superceded by a stronger continuous Fréchet differentiability assumption, and the first- and second-order necessary conditions are replaced by a *strict* complementarity condition on $\nabla J(u)$ and a *coercivity* condition on the quadratic form $\langle v, \nabla^2 J(u) v\rangle$ in the subspace $\mathsf{T}_C(u)$. Under these circumstances, Taylor's formula can be used to establish explicit quadratic growth rate estimates for J near u in C.

THEOREM 4.2. *Suppose that C is a polyhedral convex set in $\mathbb{R}^n$ and that $J : \mathcal{D} \to \mathbb{R}^1$ is twice continuously Fréchet differentiable. In addition, suppose that the following conditions hold at a point $u \in C \cap \mathcal{D}$:*

$$-\nabla J(u) \in \operatorname{ri} \mathcal{N}_C(u)$$

and

$$\exists \hat{\mu} > 0 \ \forall v \in \mathsf{T}_C(u) \quad \langle v, \nabla^2 J(u) v\rangle \geq \hat{\mu}\, \|v\|^2.$$

Then u is a strict local minimizer for J in C, and for each $\mu \in (0, \hat{\mu})$, there is a corresponding $\delta > 0$ such that

$$\forall v \in C \quad \|v-u\| \leq \delta \Rightarrow J(v) - J(u) \geq \tfrac{1}{2}\mu\, \|v-u\|^2.$$

Theorem 4.2 can be proved by using the coercivity condition to estimate $J(v) - J(u)$ for increments $v - u$ in a cone of vectors *nearly orthogonal* to the subspace $\mathsf{N}_C(u)$, and the strict complementarity condition to make a similar estimate for $v - u$ in the complement of this cone and v in C. In contrast to the standard indirect proof of the second-order sufficient conditions for nonlinear programs in $\mathbb{R}^n$ [22], this proof technique is not tied to compactness of the unit sphere and can therefore be applied in infinite-dimensional settings as well as $\mathbb{R}^n$; moreover, it establishes explicit quadratic growth estimates for J that are needed in convergence theories for iterative constrained minimization algorithms [17], [20], [21]. Variants of this proof strategy are implicit in the treatment of infinite-dimensional nonlinear programs with finitely many scalar-valued nonlinear inequality constraints in [18], and similar techniques are used in [1] and [2] and here in the proof of Theorem 6.1.

When U is a polyhedral convex set in $\mathbb{R}^m$, the k-fold Cartesian product $\Omega_k = U \times \cdots \times U$ is a polyhedral convex set in $\mathbb{R}^{km} = \mathbb{R}^m \times \cdots \times \mathbb{R}^m$, and for each $u = (u_1 \cdots u_k)$ in $\mathbb{R}^{km}$,

$$\mathcal{N}_{\Omega_k}(u) = \{w \in \mathbb{R}^{km} : w_i \in \mathcal{N}_U(u_i) \quad i = 1, \cdots, k\}, \tag{6a}$$

$$\mathcal{T}_{\Omega_k}(u) = \{w \in \mathbb{R}^{km} : w_i \in \mathcal{T}_U(u_i) \quad i = 1, \cdots, k\}, \tag{6b}$$

$$\mathsf{N}_{\Omega_k}(u) = \{w \in \mathbb{R}^{km} : w_i \in \mathsf{N}_U(u_i) \quad i = 1, \cdots, k\}, \tag{6c}$$

$$\mathsf{T}_{\Omega_k}(u) = \{w \in \mathbb{R}^{km} : w_i \in \mathsf{T}_U(u_i) \quad i = 1, \cdots, k\}. \tag{6d}$$

These cones and subspaces have the following formal counterparts in the nonpolyhedral set Ω:

$$\mathcal{N}_\Omega(u) = \{w \in \mathsf{L}^\infty_m[0,1] : w(t) \overset{\text{a.e.}}{\in} \mathcal{N}_U(u(t))\}, \tag{7a}$$

$$\text{(7b)} \qquad \mathcal{T}_\Omega(u) = \{w \in \mathsf{L}^\infty_m[0,1] : w(t) \overset{\text{a.e.}}{\in} \mathcal{T}_U(u(t))\},$$

$$\text{(7c)} \qquad \mathsf{N}_\Omega(u) = \{w \in \mathsf{L}^\infty_m[0,1] : w(t) \overset{\text{a.e.}}{\in} \mathsf{N}_U(u(t))\},$$

$$\text{(7d)} \qquad \mathsf{T}_\Omega(u) = \{w \in \mathsf{L}^\infty_m[0,1] : w(t) \overset{\text{a.e.}}{\in} \mathsf{T}_U(u(t))\}.$$

It can be seen that $\mathcal{N}_\Omega(u)$ actually *is* the cone of exterior normals at u in Ω in the incomplete inner product space $\mathsf{V} = \{\mathsf{L}^\infty_m[0,1], \langle\cdot,\cdot\rangle_2, \|\cdot\|_2\}$. Similarly, $\mathcal{T}_\Omega(u)$ is the polar of $\mathcal{N}_\Omega(u)$ in this space, and $\mathsf{N}_\Omega(u)$ and $\mathsf{T}_\Omega(u)$ are, respectively, the closed linear hull and orthogonal complement of $\mathcal{N}_\Omega(u)$. Moreover, the cones $\mathcal{N}_\Omega(u)$ and $\mathcal{T}_\Omega(u)$ and subspaces $\mathsf{N}_\Omega(u)$ and $\mathsf{T}_\Omega(u)$ are *pointwise* polar and orthogonal, respectively; i.e., for all v and w,

$$v \in \mathcal{N}_\Omega(u) \quad \text{and} \quad w \in \mathcal{T}_\Omega(u) \Rightarrow \langle v(t), w(t)\rangle \overset{\text{a.e.}}{\leq} 0$$

and

$$v \in \mathsf{N}_\Omega(u) \quad \text{and} \quad w \in \mathsf{T}_\Omega(u) \Rightarrow \langle v(t), w(t)\rangle \overset{\text{a.e.}}{=} 0.$$

Although $\{\mathsf{L}^\infty_m[0,1], \langle\cdot,\cdot\rangle_2, \|\cdot\|_2\}$ is incomplete, it can also be seen that $\mathcal{N}_\Omega(u)$ is the polar cone for $\mathcal{T}_\Omega(u)$, $\mathsf{N}_\Omega(u)$ is the orthogonal complement of $\mathsf{T}_\Omega(u)$, and every vector v in $\mathsf{L}^\infty_m[0,1]$ has a unique orthogonal projection into each of these objects, with

$$v = P_{\mathcal{N}_\Omega(u)}\, v + P_{\mathcal{T}_\Omega(u)}\, v, \qquad v = P_{\mathsf{N}_\Omega(u)}\, v + P_{\mathsf{T}_\Omega(u)}\, v,$$

$$\left(P_{\mathcal{N}_\Omega(u)}\, v\right)(t) \overset{\text{a.e.}}{=} P_{\mathcal{N}_U(u(t))}\, v(t), \qquad \left(P_{\mathcal{T}_\Omega(u)}\, v\right)(t) \overset{\text{a.e.}}{=} P_{\mathcal{T}_U(u(t))}\, v(t),$$

and

$$\left(P_{\mathsf{N}_\Omega(u)}\, v\right)(t) \overset{\text{a.e.}}{=} P_{\mathsf{N}_U(u(t))}\, v(t), \qquad \left(P_{\mathsf{T}_\Omega(u)}\, v\right)(t) \overset{\text{a.e.}}{=} P_{\mathsf{T}_U(u(t))}\, v(t).$$

The necessary conditions in Theorem 4.1 make no reference to a norm on $\mathbb{R}^n$, and formal extensions of these conditions for the nonpolyhedral set Ω are now obtained by simply replacing $\mathsf{T}_C(u)$ with $\mathsf{T}_\Omega(u)$. The formal first-order necessary condition is well known and follows at once from the convexity of Ω and the definition of the directional derivative; however, the formal second-order necessary condition is a nontrivial assertion, since the subspace $\mathsf{T}_\Omega(u)$ is not contained in the cone of feasible directions at u (Example 5.1). When the degree-2 homogeneous function $w \to d^2J(u\ ;\ w,w)$ is L^2 continuous, the second-order necessary condition can be proved by demonstrating that $\mathsf{T}_\Omega(u)$ is the L^2 closure of the union of an increasing sequence of subspaces that *are* contained in the cone of feasible directions (Lemma 5.1 and Theorem 5.2). On the other hand, when $w \to d^2J(u\ ;\ w,w)$ is merely L^∞ continuous, the analogous proof construction fails since $\mathsf{T}_\Omega(u)$ contains vectors w that *cannot* be approximated by feasible direction vectors with arbitrarily small error in the norm $\|\cdot\|_\infty$ (Note 5.2). Thus, the norm-free second-order necessary condition for polyhedra in Theorem 4.1 does have a valid formal extension for Ω, but the extension is evidently norm-dependent and tied to $\|\cdot\|_2$ or other similar integral norms. Note that $w \to d^2J(u\ ;\ w,w)$ is automatically L^2 continuous when J satisfies the structure conditions (2).

Note 4.1. The existence of nontrivial subspaces in the cone of feasible directions at u in the nonpolyhedral set Ω is a special consequence of Ω's product structure. For nonpolyhedral closed convex sets prescribed by finitely many smooth nonlinear inequalities or an infinitely indexed family of affine inequalities, the cone of feasible directions at a boundary point u typically contains *no* subspace other than $\{0\}$; moreover, for nonconvex J, the directional derivative $d^2J(u\ ;\ v,v)$ is typically *negative* for some v in the orthogonal complement of the normal cone at a local minimizer u. For example, in any Hilbert space V, the closed unit ball has the affine inequality constraint representation

$$\overline{B(0,1)} = \{u \in \mathsf{V} : \forall i \in S(0,1) \quad \langle i, u\rangle \leq 1\},$$

where $S(0,1)$ is the unit *sphere* in V. If $\|u\| = 1$, then the normal cone at u consists of all nonnegative multiples of u and there are no nonzero feasible direction vectors v orthogonal to u. Furthermore, if J is twice directionally differentiable and *strictly concave*, then $d^2J(u\ ;\ v,v)$ is negative for all $v \neq 0$ orthogonal to u.

The sufficient conditions in Theorem 4.2 are directly tied to the norm on $\mathbb{R}^n$ in three ways, through the differentiability, strict complementarity, and coercivity hypotheses. Since norm equivalence is lost in the infinite-dimensional vector space $\mathsf{L}^\infty_m[0,1]$, it can be seen that nonequivalent formal extensions of the sufficient conditions in Ω may arise from the assignment of different combinations of norms in these hypotheses. Some of these extensions are essentially vacuous and can be ruled out at once. In particular, any formal extension that invokes an L^2 strict complementarity condition or an L^∞ coercivity condition is uninteresting for present purposes, since the L^2 relative interior of the normal cone $\mathcal{N}_\Omega(u)$ is typically *empty*, and the L^∞ coercivity condition can't hold on nontrivial subspaces $\mathsf{T}_\Omega(u)$ if $w \longrightarrow d^2J(u\ ;\ w,w)$ is continuous in the L^2 norm. Nonvacuous sufficient conditions for L^∞-local optimality in Ω *are* obtained by combining an L^∞ strict complementarity condition with an L^2 coercivity condition and any smoothness conditions that imply the two-norm Taylor formula (4) with $\nu = \infty$ (Theorem 6.1); however, the gap between these sufficient conditions and the corresponding necessary conditions in Theorem 5.2 is far wider than the sufficiency gap in polyhedral subsets of $\mathbb{R}^n$. This is true partly because coercivity is stronger than positive-definiteness in infinite-dimensional spaces, but mainly because L^∞ strict complementarity requires that the distance from $-\nabla J(u)(t)$ to the relative boundary of $\mathcal{N}_U(u(t))$ in the subspace $\mathsf{N}_U(u(t))$ is *bounded away from* 0 *almost everywhere on the interval* $[0,1]$, and this condition typically can't be met if $u(\cdot)$ and $\nabla J(u)(\cdot)$ are continuous at some point τ in $[0,1]$ where $u(t)$ passes from the relative interior of one face of the polyhedron U to the relative interior of a contiguous face. Thus, L^∞ strict complementarity is a nonvacuous but very stringent hypothesis, and the aim of the sufficiency analysis in §6 is to weaken this condition *with no compensatory reinforcement of the* L^2 *coercivity condition on* $\mathsf{T}_\Omega(u)$. Theorems 6.4 and 6.6 achieve this goal with a mild strengthening of the *pointwise strict complementarity condition*

$$-\nabla J(u)(t) \overset{\text{a.e.}}{\in} \operatorname{ri} \mathcal{N}_U(u(t)), \tag{8}$$

which may be viewed as a formal extension of the component-wise expression of strict complementarity in k-fold Cartesian products $\Omega_k = U \times \cdots \times U$ in $\mathbb{R}^{km}$, i.e.,

$$-\left(\nabla J(u)\right)_i \in \operatorname{ri} \mathcal{N}_U(u_i), \quad i = 1, \ldots, k$$

(cf. equations (6)). Reference [1] supplies the prototype for this analysis in the special case $U = [0, \infty)$.

5. Necessary conditions. The special product structure in Ω ensures that subspaces $\mathsf{T}_\Omega(u)$ (analogues of the lineality) can be approximated from below by an increasing sequence of subspaces $T_{(1/n)}$, each of which is contained in the cone of feasible directions, even though $\mathsf{T}_\Omega(u)$ itself is *not* contained in this cone. It follows that each vector w in $\mathsf{T}_\Omega(u)$ is the L^2 limit of a sequence of feasible direction vectors w^n for which $d^1 f(u; w^n) = 0$ and $d^2 f(u; w^n, w^n) \geq 0$. Hence, *for this specially structured nonpolyhedral set* Ω, it *is* possible to extend the inequality $d^2 f(u; w, w) \geq 0$ from the subspaces $T_{(1/n)}$ to $\mathsf{T}_\Omega(u)$ when the directional derivative map $w \to d^2 J(u\ ;\ w, w)$ is L^2 continuous. These points are developed in the following example, lemma, and theorem.

Example 5.1. For $m = 1$ and $U = [0, \infty)$, Ω is the set of real-valued essentially bounded and nonnegative measurable functions on $[0, 1]$. Consider the function u in Ω defined by the rule

$$u(t) = \begin{cases} 0, & t \in [0, \frac{1}{2}], \\ t - \frac{1}{2}, & t \in (\frac{1}{2}, 1]. \end{cases}$$

Note that

$$\mathcal{N}_U(\xi) = \begin{cases} (-\infty, 0], & \xi = 0, \\ \{0\}, & \xi > 0, \end{cases}$$

$$[\text{span}\,\mathcal{N}_U(\xi)]^\perp = \begin{cases} \{0\}, & \xi = 0, \\ \mathbb{R}^1, & \xi > 0, \end{cases}$$

and therefore

$$\mathcal{N}_\Omega(u) = \left\{w \in \mathsf{L}^\infty(0,1) : w(t) \leq 0 \text{ a.e. in } [0, \tfrac{1}{2}] \text{ and } w(t) = 0 \text{ a.e. in } (\tfrac{1}{2}, 1]\right\},$$

$$\mathsf{T}_\Omega(u) = \{w \in \mathsf{L}^\infty(0,1) : w(t) = 0 \text{ a.e. in } [0, \tfrac{1}{2}]\}.$$

Fix $h > 0$ and put

$$w_h(t) = \begin{cases} 0, & t \in [0, \frac{1}{2}], \\ -h, & t \in (\frac{1}{2}, 1]. \end{cases}$$

The function w_h lies in $\mathsf{T}_\Omega(u)$ but is not a feasible direction vector, since $u + s w_h$ has negative values on the interval $[\frac{1}{2}, \frac{1}{2} + sh)$. Thus $\mathsf{T}_\Omega(u)$ is not contained in the cone of feasible directions at u. On the other hand, the subspaces

$$\mathsf{T}_{(1/n)}(u) = \{w \in \mathsf{L}^\infty(0,1) : w(t) = 0 \text{ a.e. in } [0, \tfrac{1}{2} + \tfrac{1}{n}]\}$$

are contained in $\mathsf{T}_\Omega(u)$ and the cone of feasible directions at u, and converge to $\mathsf{T}_\Omega(u)$ in the sense that their union is dense in $\mathsf{T}_\Omega(u)$, relative to the L^2 norm.

The construction in Example 5.1 will now be generalized to show that the subspaces $\mathsf{T}_\Omega(u)$ are approximated from below in the L^2 norm by subspaces of $\mathsf{T}_\Omega(u)$ lying in the cone of feasible directions at $u \in \Omega$. With reference to [15], the polyhedral convex set U has d distinct (polyhedral) *faces* $\mathcal{F}_i$, the *relative interiors* of these faces do not meet, and

$$U = \bigcup_{i=1}^{d} \text{ri}\mathcal{F}_i. \tag{9}$$

Moreover, if $\mathcal{F}(\xi)$ denotes the unique face in $\{\mathcal{F}_1, \ldots, \mathcal{F}_d\}$ containing ξ in its relative interior, then the cones $\mathcal{N}_U(\eta)$ and the subspaces $\mathsf{N}_U(\eta)$ and $\mathsf{T}_U(\eta)$ are invariant for $\eta \in \mathrm{ri}\mathcal{F}(\xi)$, and $\xi + \mathsf{T}_U(\xi)$ is the *affine hull* of $\mathcal{F}(\xi)$; i.e., for some $\{\mathcal{N}_i\}_{i=1}^d$, $\{\mathsf{N}_i\}_{i=1}^d$, and $\{\mathsf{T}_i\}_{i=1}^d$ and for all $\xi \in U$ and $i = 1, \ldots, d$,

(10)

$$(\mathcal{F}(\xi) = \mathcal{F}_i) \Rightarrow (\mathcal{N}_U(\xi) = \mathcal{N}_i,\ \mathsf{N}_U(\xi) = \mathsf{N}_i,\ \mathsf{T}_U(\xi) = \mathsf{T}_i, \text{ and } \mathrm{aff}\, \mathcal{F}(\xi) = \xi + \mathsf{T}_i\ ).$$

(These assertions are deduced in [15] from affine inequality representations for the polyhedral set U and derived representations for the polyhedral cones $\mathcal{N}_U(\xi)$; for further details, see the proof of Lemma 6.5.) For ξ in U, define

$$\rho(\xi) = \sup\{\rho \in (0,1] : B(\xi, \rho) \cap \mathrm{aff}\, \mathcal{F}(\xi) \subset \mathcal{F}(\xi)\}, \tag{11a}$$

where

$$B(\xi, \rho) = \{\eta \in \mathbb{R}^m : \|\xi - \eta\| < \rho\}. \tag{11b}$$

Note that $\rho(\xi)$ is the distance from ξ to the relative boundary of the face $\mathcal{F}(\xi)$ when $\rho(\xi) < 1$. For ξ in U, u in Ω, and $\sigma > 0$, define the corresponding subspaces $\mathsf{T}_{(\sigma)}(u) \subset \mathsf{T}_\Omega(u)$ by the rule

$$\mathsf{T}_{(\sigma)}(u) = \{w \in \mathsf{L}_m^\infty(0,1) : w(t) \overset{\text{a.e.}}{\in} \mathsf{T}_{(\sigma)}(u)(t)\}, \tag{11c}$$

$$\mathsf{T}_{(\sigma)}(u)(t) = \begin{cases} \mathsf{T}_U(u(t)), & \rho\,(u(t)) > \sigma, \\ \{0\}, & \rho\,(u(t)) \le \sigma. \end{cases} \tag{11d}$$

It can be seen that $\rho(\xi)$ is *positive* and the associated restrictions $\rho(\cdot)|_{\mathrm{ri}\mathcal{F}_i}$ are *continuous* for $i = 1, \ldots, d$. Moreover, $\mathrm{ri}\mathcal{F}_i$ is a Borel set for $i = 1, \ldots, d$, and thus for each u in Ω, the partition (9) induces a corresponding family of d pairwise disjoint Lebesgue measurable sets

$$\alpha_i(u) = \{t \in [0,1] : u(t) \in \mathrm{ri}\mathcal{F}_i\} \tag{12a}$$

with

$$\mu\left[[0,1] \setminus \bigcup_{i=1}^d \alpha_i(u)\right] = 0. \tag{12b}$$

The continuity properties of $\rho(\cdot)$ therefore imply that for each u in Ω, the composite function $\rho\,(u(\cdot))$ is *Lebesgue measurable and positive almost everywhere in* $[0,1]$.

LEMMA 5.1. *For all u in Ω and $\sigma > 0$, the subspace $\mathsf{T}_{(\sigma)}(u)$ lies in the cone of feasible directions at u, and the subspace $\bigcup_{n=1}^\infty \mathsf{T}_{(1/n)}(u)$ is dense in $\mathsf{T}_\Omega(u)$ relative to the L^2 norm.*

Proof. Fix u in Ω and $\sigma > 0$. Suppose that $w \in \mathsf{T}_{(\sigma)}(u)$. If $w = 0$, then w is trivially a feasible direction vector at u. Suppose that $w \neq 0$ and $s \in [0, \frac{\sigma}{\|w\|_\infty}]$. By construction,

$$u(t) + sw(t) \overset{\text{a.e.}}{\in} \mathcal{F}\,(u(t)) \subset U.$$

Thus, for all s,

$$s \in [0, \frac{\sigma}{\|w\|_\infty}] \Rightarrow u + sw \in \Omega,$$

and therefore w is a feasible direction vector at u.

Fix u in Ω and w in $\mathsf{T}_\Omega(u)$. For $n = 1, 2, \ldots$, let

$$\theta_n = \{t \in [0,1] : \rho(u(t)) \leq \tfrac{1}{n}\},$$

and construct

$$w_n(t) = \begin{cases} w(t), & t \in [0,1] \setminus \theta_n, \\ 0, & t \in \theta_n. \end{cases}$$

Since $\rho(u(\cdot))$ is measurable and positive almost everywhere, it follows that θ_n is measurable with $\theta_n \supset \theta_{n+1}$ for all n, and

$$\lim_{n\to\infty} \mu[\theta_n] = \mu\left[\bigcap_{n=1}^{\infty} \theta_n\right] = 0.$$

Hence, $w_n \in \mathsf{T}_{(1/n)}(u)$ and

$$\lim_{n\to\infty} \|w_n - w\|_2 = \lim_{n\to\infty} \left(\int_{\theta_n} \|w\|^2 dt\right)^{\frac{1}{2}} = 0. \qquad \square$$

Note 5.2. If u and w_h are defined as in Example 5.1, then w_h *cannot* be approximated by feasible direction vectors with arbitrarily small error in the norm $\|\cdot\|_\infty$. Hence, there is no L^∞ counterpart of Lemma 5.1.

Lemma 5.1 and elementary calculus now produce a basic representation-free second-order necessary condition in the inner product space $\{\mathsf{L}^\infty_m[0,1], \langle\cdot,\cdot\rangle_2, \|\cdot\|_2\}$. Note that the structure/continuity conditions (2)–(3) are not invoked in this theorem.

THEOREM 5.2. *Let u be a local minimizer for the restriction of $J : \mathcal{D} \to \mathbb{R}^1$ to any line in Ω. In addition, suppose that J is twice directionally differentiable and that the associated maps $w \to d^1J(u;w)$ and $w \to d^2J(u;w,w)$ are continuous with respect to the L^2 norm on $\mathsf{L}^\infty_m(0,1)$. Then*

$$\forall v \in \Omega \quad d^1J(u; v-u) \geq 0, \tag{13a}$$

$$\forall w \in \mathsf{T}_\Omega(u) \quad d^1J(u;w) = 0 \quad \text{and} \quad d^2J(u;w,w) \geq 0. \tag{13b}$$

Proof. Fix v in Ω. Since Ω is convex and u is an internal point of $\mathcal{D}$ and a local minimizer on lines, it follows that for all sufficiently small ϵ, the vectors $u + \epsilon(v-u)$ fall in $\Omega \cap \mathcal{D}$ and therefore

$$0 \leq J(u + \epsilon(v-u)) - J(u) = \epsilon d^1J(u; v-u) + o(\epsilon).$$

In the limit as $\epsilon \to 0$, this proves the well-known first-order necessary condition (13a). Suppose that w lies in one of the subspaces $\mathsf{T}_{(1/n)}(u)$ of Lemma 5.1. Then w and $-w$ are feasible direction vectors at u and hence $d^1J(u;w) = 0$ and $d^2J(u;w,w) \geq 0$, since u is a local minimizer on lines. Conditions (13b) now follow from the second part of Lemma 5.1 and the L^2 continuity of $w \to d^1J(u;w)$ and $w \to d^2J(u;w,w)$. $\square$

The next two theorems establish refinements of the second-order necessary conditions for twice Gâteaux differentiable functions that satisfy some or all of the structure/continuity hypotheses (2)–(3) for $\nu = 1$ or 2. The proofs for these results are closely modelled on the proofs for Theorems 2 and 3 in [1] and convert integral conditions to pointwise conditions by arguments that are well established in optimal control theory [18].

THEOREM 5.3. *Let u be a local minimizer for the restriction of $J : \mathcal{D} \to \mathbb{R}^1$ to any line in Ω, and suppose that J has first and second differentials satisfying* (2). *Then conditions* (13) *hold at u, and in addition,*

$$-\nabla J(u)(t) \in \mathcal{N}_U(u(t)) \quad a.e.\ in\ [0,1] \tag{14a}$$

and

$$(\forall \xi \in \mathsf{T}_U(u(t)), \quad \langle \xi, S(u)(t)\xi\rangle \geq 0)) \quad a.e.\ in\ [0,1]. \tag{14b}$$

Proof. Conditions (2) imply that $d^1J(u;w)$ and $d^2J(u;w,w)$ are L^2-continuous in w on $\mathsf{L}^\infty_m(0,1)$. By Theorem 5.2, conditions (13) then hold at u, and (13a) asserts that

$$\forall u \in \Omega \quad \int_0^1 \langle \nabla J(u)(t), v(t) - u(t)\rangle dt \geq 0$$

and hence

$$(\forall \xi \in U \quad \langle \nabla J(u)(t), \xi - u(t)\rangle \geq 0) \quad \text{a.e. in } [0,1].$$

This proves (14a). Now let $\{\alpha_i(u)\}_{i=1}^d$ be the subsets of $[0,1]$ in (12), and for t in $[0,1]$ and $\epsilon > 0$ define a corresponding family of sets $\phi(t,\epsilon) \subset [0,1]$ by the rule

$$t \in \alpha_i(u) \Rightarrow \phi(t,\epsilon) = \alpha_i(u) \cap (t-\epsilon, t+\epsilon). \tag{15}$$

Evidently, $\mu[\phi(t,\epsilon)] \leq 2\epsilon$, and therefore

$$\mu[\phi(t,\epsilon)] \cdot \int\int_{\phi(t,\epsilon)\times\phi(t,\epsilon)} \|K(u)(\tau,s)\|^2 d\tau ds = o(\epsilon). \tag{16a}$$

Moreover, since almost every t in $\alpha_i(u)$ is a point of density for $\alpha_i(u)$ [24], it follows that

$$\int_{\phi(t,\epsilon)} S(u)(\tau)d\tau = 2\epsilon S(u)(t) + o(\epsilon) \quad \text{a.e. in } [0,1]. \tag{16b}$$

Choose any t where the estimates in (16) hold. Suppose that $t \in \alpha_i(u)$. Fix ξ in $\mathsf{T}_i = \mathsf{T}_U(u(t))$, and for $\epsilon > 0$ construct $w_\epsilon \in \mathsf{T}_\Omega(u)$ by the rule

$$w_\epsilon(\tau) = \begin{cases} \xi, & \tau \in \phi(t,\epsilon), \\ 0, & \tau \in [0,1] \setminus \phi(t,\epsilon). \end{cases}$$

Theorem 5.2, conditions (2), and the estimates (16) then yield

$$0 \leq d^2J(u; w_\epsilon, w_\epsilon) = 2\epsilon\langle \xi, S(u)(t)\xi\rangle + o(\epsilon)$$

and hence

$$\langle \xi, S(u)(t)\xi\rangle \geq 0$$

in the limit as $\epsilon \to 0$. Since ξ can be any vector in $\mathsf{T}_i = \mathsf{T}_U(u(t))$, this proves (14b).
□

THEOREM 5.4. *Let u be an L^2-local minimizer of $J : \mathcal{D} \to \mathbb{R}^1$ in $\Omega \cap \mathcal{D}$, and suppose that J has first and second Gâteaux differentials satisfying* (2)–(3) *with $\nu = 2$. Then conditions* (13) *and* (14) *hold at u, and in addition,*

$$(17)\quad \inf_{\xi \in U} \left(\langle \nabla J(u)(t), \xi - u(t) \rangle + \tfrac{1}{2} \langle \xi - u(t), S(u)(t)\,(\xi - u(t)) \rangle \right) = 0 \quad \textit{a.e. in } [0,1].$$

Proof. Conditions (13) and (14) follow at once from Theorems 5.2 and 5.3, since every L^2-local minimizer is also a local minimizer on lines. To prove (17), fix t in $[0,1]$ and ξ in U, and for $\epsilon > 0$ construct $v_{t,\xi,\epsilon} \in \Omega$ by the rule

$$(18)\qquad v_{t,\xi,\epsilon}(\tau) = \begin{cases} \xi, & \tau \in [0,1] \cap (t-\epsilon, t+\epsilon), \\ u(\tau), & \tau \in [0,1] \setminus (t-\epsilon, t+\epsilon). \end{cases}$$

As in the proof of Theorem 5.3, it can be seen that for almost all t in $[0,1]$,

$$\forall \xi \in U \quad \|v_{t,\xi,\epsilon} - u\|_2^2 = 2\epsilon \|\xi - u(t)\|^2 + o(\epsilon),$$

and therefore

$$\forall \xi \in U \quad \|v_{t,\xi,\epsilon} - u\|_2 = O(\epsilon^{\frac{1}{2}}).$$

In the present instance, conditions (2)–(3) imply (4) with $\nu = 2$; hence for almost all t in $[0,1]$, all ξ in U, and sufficiently small $\epsilon > 0$,

$$\begin{aligned} 0 &\le J(v_{t,\xi,\epsilon}) - J(u) \\ &= \langle \nabla J(u), v_{t,\xi,\epsilon} - u \rangle_2 + \tfrac{1}{2} \langle v_{t,\xi,\epsilon} - u, \nabla^2 J(u)\,(v_{t,\xi,\epsilon} - u) \rangle_2 + o(\epsilon) \end{aligned}$$

since u is an L^2-local minimizer. Moreover, for almost all t in $[0,1]$,

$$\forall \xi \in U \quad \langle \nabla J(u), v_{t,\xi,\epsilon} - u \rangle_2 = 2\epsilon \langle \nabla J(u)(t), \xi - u(t) \rangle + o(\epsilon)$$

and

$$\forall \xi \in U \quad \langle v_{t,\xi,\epsilon} - u, \nabla^2 J(u)\,(v_{t,\xi,\epsilon} - u) \rangle_2 = 2\epsilon \langle \xi - u(t), S(u)(t)\,(\xi - u(t)) \rangle + o(\epsilon).$$

Condition (17) now follows in the limit as $\epsilon \to 0$. □

Note 5.3. Assertion (17) in Theorem 5.4 remains true if the range set U in (1b) is an *arbitrary* subset of $\mathbb{R}^m$. Condition (14a) in Theorem 5.3 is implied by (17) if U is a convex set in $\mathbb{R}^m$. Condition (14b) is implied by (17) if U is a polyhedral convex set in $\mathbb{R}^m$.

Note 5.4. For Bolza objective functions (5), the values of the quantities $\nabla J(u)$ and $S(u)$ are given almost everywhere in $[0,1]$ by

$$(19a)\qquad \nabla J(u)(t) = \nabla_u H\,(t, \psi(t), x(t), u(t))$$

and

$$(19b)\qquad S(u)(t) = \nabla^2_{uu} H\,(t, \psi(t), x(t), u(t)),$$

where H is the associated Hamiltonian

$$(20a)\qquad H(t, \psi, x, u) = \langle \psi, f(t,x,u) \rangle + f^0(t,x,u)$$

and $\psi(\cdot)$ solves the adjoint final value problem

$$\frac{d\psi}{dt} = -\nabla_x H\left(t, \psi, x(t), u(t)\right), \tag{20b}$$

$$\psi(1) = \nabla P(x(1)). \tag{20c}$$

(See [13] for a discussion of the case m=1.) If u is an L^2-local minimizer of (5) in the set (1b), then admissible perturbations of the form (18) cannot decrease J when ϵ is sufficiently small, and the Pontryagin minimum principle asserts that

$$H\left(t, \psi(t), x(t), u(t)\right) = \inf_{\xi \in U} H\left(t, \psi(t), x(t), \xi\right). \tag{21}$$

In this setting, conditions (14) in Theorem 5.3 are now seen as first- and second-order necessary conditions for the finite-dimensional constrained minimization problems (21); moreover, if (2) and (3) are to hold with $\nu = 2$ for control problems, then H must be quadratic in u for each fixed (t, ψ, x) (Note 3.1), and condition (17) in Theorem 5.4 is *equivalent* to (21). On the other hand, the Pontryagin minimum principle need not hold at a local minimizer on lines, where (14a) and (14b) may be viewed as extensions of the Euler and Legendre necessary conditions for weak local minimizers in the calculus of variations.

Note 5.5. Theorems 5.2 and 5.3 contain their counterparts in [1]; in particular, for $m = 1$ and $U = [0, \infty)$, condition (17) implies that $S(u)(t) \geq 0$ almost everywhere in $[0, 1]$.

6. Sufficient conditions. A nonvacuous but stringent formal extension of the sufficient conditions in polyhedra is obtained by replacing $\mathcal{N}_C(u)$ and $\mathsf{T}_C(u)$ in Theorem 4.2 with $\mathcal{N}_\Omega(u)$ and $\mathsf{T}_\Omega(u)$ and requiring that Taylor's formula (4) hold with $\nu = \infty$ at the point u in $\Omega \cap \mathcal{D}$, that $-\nabla J(u)$ lie in the L^∞ relative interior of $\mathcal{N}_\Omega(u)$, and that $\nabla^2 J(u)$ be L^2-*coercive* on $\mathsf{T}_\Omega(u)$. As noted in §4, the scope of this theorem is severely limited by its L^∞ strict complementarity condition; however, the proof technique employed here also establishes the more flexible analytical tool in Lemma 6.2. Lemma 6.2 is the key to the proof of the L^∞-local optimality sufficient conditions in Theorem 6.4 for objective functions J that satisfy the structure/continuity conditions (2)–(3) with $\nu = \infty$. Theorem 6.4 postulates the natural L^2 coercivity condition on $\mathsf{T}_\Omega(u)$, but its strict complementarity condition derives from the pointwise condition (8) and is much weaker than L^∞ strict complementarity.

THEOREM 6.1. *Let J be a real-valued function on a domain $\mathcal{D} \subset \mathsf{L}^\infty_m[0,1]$ that is open relative to the norm $\|\cdot\|_\infty$. Suppose that at some point u in $\Omega \cap \mathcal{D}$ there is a vector $\nabla J(u)$ in $\mathsf{L}^\infty_m(0,1)$ and an L^2 continuous linear operator $\nabla^2 J(u)$ on $\mathsf{L}^\infty_m(0,1)$ such that*

$$d^1 J(u; v) = \langle \nabla J(u), v \rangle_2, \tag{22a}$$

$$d^2 J(u; v, w) = \langle v, \nabla^2 J(u) w \rangle_2 \tag{22b}$$

for all v and w in $\mathsf{L}^\infty_m[0,1]$, and

$$J(v) - J(u) = \langle \nabla J(u), v - u \rangle_2 + \tfrac{1}{2}\langle v - u, \nabla^2 J(u)\,(v - u) \rangle_2 + r(u; v), \tag{23a}$$

$$\lim_{\|v-u\|_\infty \to 0} \frac{|r(u;v)|}{\|v-u\|_2^2} = 0 \tag{23b}$$

for all v in $\mathcal{D}$ near u. Suppose that the following L^∞ strict complementarity and L^2 coercivity conditions also hold at u:

$$\exists c_N > 0 \,\forall w \quad (w \in \mathsf{N}_\Omega(u) \textit{ and } \|w\|_\infty \le c_N \Rightarrow -\nabla J(u) + w \in \mathcal{N}_\Omega(u)) \tag{24a}$$

and

$$\exists c_T > 0 \,\forall w \quad \left(w \in \mathsf{T}_\Omega(u) \Rightarrow \langle w, \nabla^2 J(u) w\rangle_2 \ge c_T \|w\|_2^2\right). \tag{24b}$$

Then for each number $c_\infty \in (0, c_T)$, there is a corresponding $\delta_\infty > 0$ such that for all v,

$$v \in \Omega \textit{ and } \|v-u\|_\infty < \delta_\infty \Rightarrow J(v) - J(u) \ge \tfrac{1}{2} c_\infty \|v-u\|_2^2. \tag{25}$$

Proof. Recall first that the subspaces $\mathsf{N}_\Omega(u)$ and $\mathsf{T}_\Omega(u)$ are pointwise orthogonal and that $\mathsf{L}_m^\infty(0,1)$ is the *direct sum* of $\mathsf{N}_\Omega(u)$ and $\mathsf{T}_\Omega(u)$. To prove the latter assertion, fix w in $\mathsf{L}_m^\infty(0,1)$, and for t in $[0,1]$ put

$$w_N(t) = P_{\mathsf{N}_U(u(t))} w(t)$$

and

$$w_T(t) = P_{\mathsf{T}_U(u(t))} w(t).$$

Since the projection operators are nonexpansive and $\mathsf{N}_U(u(t))$ and $\mathsf{T}_U(u)(t))$ are constant almost everywhere on each of the measurable sets $\alpha_i(u)$ in (12), it follows that w_N and w_T are measurable essentially bounded functions in $\mathsf{N}_\Omega(u)$ and $\mathsf{T}_\Omega(u)$, with

$$w = w_N + w_T \tag{26a}$$

and

$$\|w(t)\|^2 = \|w_N(t)\|^2 + \|w_T(t)\|^2 \quad \text{a.e. in } [0,1]. \tag{26b}$$

Moreover, if $w = v_N + v_T$ for some $v_N \in \mathsf{N}_\Omega(u)$ and $v_T \in \mathsf{T}_\Omega(u)$, then the orthogonality of $\mathsf{N}_\Omega(u)$ and $\mathsf{T}_\Omega(u)$ ensures that $v_N = w_N$ and $v_T = w_T$.

Now fix c_∞ in $(0, c_T)$ and v in $\Omega \setminus \{u\}$, and let

$$w = c_N \frac{(v-u)_N}{\|v-u\|_\infty}.$$

With reference to (26), it can be seen that

$$\|w\|_\infty = \frac{c_N}{\|v-u\|_\infty} \|(v-u)_N\|_\infty \le c_N.$$

Hence (24a) implies that

$$\begin{aligned} 0 &\ge \langle -\nabla J(u) + w, v-u\rangle_2 \\ &= -\langle \nabla J(u), v-u\rangle_2 + \frac{c_N}{\|v-u\|_\infty} \langle (v-u)_N, v-u\rangle_2, \end{aligned}$$

and therefore

$$\forall v \in \Omega \quad \langle \nabla J(u), v-u\rangle_2 \geq \frac{c_N}{\|v-u\|_\infty}\|(v-u)_N\|_2^2. \tag{27}$$

Furthermore, conditions (23) and (24b) yield

(28a)

$$\langle v-u, \nabla^2 J(u)\,(v-u)\rangle_2 \geq c_T\|(v-u)_T\|_2^2 - M\|(v-u)_N\|_2\,(\|(v-u)_N\|_2 + 2\|(v-u)_T\|_2)$$

where

$$M = \|\nabla^2 J(u)\| \overset{\text{def}}{=} \sup_{\|v\|_2=1} \|\nabla^2 J(u)v\|_2 < \infty. \tag{28b}$$

The estimates (23), (27), and (28) and a completion of the square in (28) show that for all v in $\Omega \cap \mathcal{D}$,

(29)

$$J(v) - J(u)$$
$$\geq \left(\frac{c_N}{\|v-u\|_\infty} - \frac{M}{2} - \frac{M^2}{(c_T - c_\infty)}\right)\|(v-u)_N\|_2^2 + \frac{(c_T + c_\infty)}{4}\|(v-u)_T\|_2^2 + r(u;v)$$

(cf. the proof of Lemma 1 in [1]). Then assertion (25) holds if δ_∞ is chosen so small that

$$c_N\delta_\infty^{-1} - \frac{M}{2} - \frac{M^2}{(c_T - c_\infty)} \geq \tfrac{1}{4}(c_T + c_\infty)$$

and

$$0 < \|v-u\|_\infty < \delta_\infty \Rightarrow v \in \mathcal{D} \text{ and } \frac{|r(u;v)|}{\|v-u\|_2^2} \leq \tfrac{1}{4}(c_T - c_\infty). \qquad \square$$

The foregoing proof works equally well if the subspaces $\mathsf{N}_\Omega(u)$ and $\mathsf{T}_\Omega(u)$ in Theorem 6.1 are replaced by *any* complementary pointwise orthogonal subspaces $\hat{\mathsf{N}}(u)$ and $\hat{\mathsf{T}}(u)$ in $\mathsf{L}_m^\infty[0,1]$, with $\hat{\mathsf{N}}(u) \subset \mathsf{N}_\Omega(u)$ and $\hat{\mathsf{T}}(u) \supset \mathsf{T}_\Omega(u)$. This observation immediately produces the following extension of Theorem 6.1.

LEMMA 6.2. *Let J be a real-valued function on a domain $\mathcal{D} \subset \mathsf{L}_m^\infty[0,1]$ that is open relative to the norm $\|\cdot\|_\infty$, and suppose that hypotheses* (22) *and* (23) *in Theorem* 6.1 *are satisfied. Let $\hat{\mathsf{N}}(u)$ and $\hat{\mathsf{T}}(u)$ be pointwise orthogonal subspaces in $\mathsf{L}_m^\infty(0,1)$ such that $\hat{\mathsf{N}}(u) \subset \mathsf{N}_\Omega(u)$, $\hat{\mathsf{T}}(u) \supset \mathsf{T}_\Omega(u)$, and $\mathsf{L}_m^\infty(0,1)$ is the direct sum of $\hat{\mathsf{N}}(u)$ and $\hat{\mathsf{T}}(u)$. Assume that*

$$\exists c_{\hat{N}} > 0\; \forall w \quad \left(w \in \hat{\mathsf{N}}(u) \text{ and } \|w\|_\infty \leq c_{\hat{N}} \Rightarrow -\nabla J(u) + w \in \mathcal{N}_\Omega(u)\right) \tag{30a}$$

and

$$\exists c_{\hat{T}} > 0\; \forall w \quad \left(w \in \hat{\mathsf{T}}(u) \Rightarrow \langle w, \nabla^2 J(u)w\rangle_2 \geq c_{\hat{T}}\|w\|_2^2\right). \tag{30b}$$

Then for each number $c_\infty \in (0, c_{\hat{T}})$, there is a corresponding $\delta_\infty > 0$ such that for all v,

$$v \in \Omega \text{ and } \|v-u\|_\infty < \delta_\infty \Rightarrow J(v) - J(u) \geq \frac{1}{2}c_\infty\|v-u\|_2^2. \tag{31}$$

In general, if $\hat{\mathsf{N}}(u)$ is a proper subspace of $\mathsf{N}_\Omega(u)$, then the strict complementarity condition (30a) is *weaker* than (24a), and the L^2 coercivity condition (30b) is correspondingly *stronger* than (24b). However, when J satisfies the structure/continuity conditions (2)–(3) and u meets certain additional regularity conditions, it is possible to construct $\hat{\mathsf{N}}(u)$ and $\hat{\mathsf{T}}(u)$ so that (30a) is implied by a variant of the pointwise strict complementarity condition (8), while (30b) is obtained at no cost by a continuous extension of (24b); in other words, the L^∞ strict complementarity condition can be weakened substantially *with no corresponding reinforcement of the* L^2 *coercivity condition*. The relevant formal strict complementarity and coercivity conditions are collected in the following equations:

$$-\nabla J(u)(t) \in \mathcal{N}_U\,(u(t)) \quad \text{a.e. in } [0,1], \tag{32a}$$

$$\forall \beta \subset \cup_{i=1}^{d} \operatorname{int} \alpha_i(u) \quad (\beta \text{ compact} \Rightarrow \exists c_\beta > 0\ \Delta(u)(t) \geq c_\beta \text{ a.e. in } \beta)\,, \tag{32b}$$

$$\exists c_T > 0\ \forall w \quad \left(w \in \mathsf{T}_\Omega(u) \Rightarrow \langle w, \nabla^2 J(u) w\rangle_2 \geq c_T \|w\|_2^2\right), \tag{32c}$$

where $\Delta(u)(t)$ is the distance from $-\nabla J(u)(t)$ to the relative boundary of $\mathcal{N}_U\,(u(t))$ in the subspace $\mathsf{N}_U(u(t))$ or, equivalently,

$$\Delta(u)(t) = \sup\{\Delta \geq 0 : \forall \xi \in \mathsf{N}_U(u(t)),\ \|\xi\| \leq \Delta \Rightarrow -\nabla J(u)(t) + \xi \in \mathcal{N}_U\,(u(t))\}. \tag{32d}$$

While the strict complementarity conditions (30a)–(30b) are stronger than the pointwise strict complementarity condition (8), they still permit

$$\lim_{t \to \tau} \operatorname{ess\,inf}\ \Delta(u)(t) = 0 \tag{33}$$

at τ in the frontier of $\alpha_i(u)$ and are therefore substantially weaker than (24a). When (33) happens at frontier points of $\alpha_i(u)$, example 1 of [1] shows that (32) alone is in fact not sufficient for L^∞-local optimality in Ω, even for functionals J with differentials satisfying (2)–(3). On the other hand, theorem 4 in [1] shows that (32) may *become* sufficient for L^∞-local optimality when certain mild restrictions are imposed on the sets $\alpha_i(u)$ and the behavior of the function $S(u)(\cdot)$ near the frontiers of $\alpha_i(u)$. The proof construction in [1] applies a restricted version of Lemma 6.2 for $U = [0,1]$ to pointwise orthogonal subspaces

$$\hat{\mathsf{N}}(u) = \{w \in \mathsf{L}_m^\infty[0,1] : w(t) \overset{\text{a.e.}}{\in} \hat{\mathsf{N}}(u)(t)\}, \tag{34a}$$

$$\hat{\mathsf{T}}(u) = \{w \in \mathsf{L}_m^\infty[0,1] : w(t) \overset{\text{a.e.}}{\in} \hat{\mathsf{T}}(u)(t)\}, \tag{34b}$$

where $\hat{\mathsf{N}}(u)(t) \subset \mathsf{N}_U(u(t))$, $\hat{\mathsf{T}}(u)(t) \supset \mathsf{T}_U(u(t))$, and $\hat{\mathsf{N}}(u)(t)$ and $\hat{\mathsf{T}}(u)(t)$ are essentially constant on small neighborhoods of the frontier points of $\alpha_i(u)$, with range in the collection of subspaces $\{\mathsf{N}_i\}_{i=1}^d$ and $\{\mathsf{T}_i\}_{i=1}^d$ in (10). The same basic proof strategy used in [1] also works in the present wider context; however, certain new complications arise from the vector-valuedness of u. More specifically, let

$$\pi(u)(t) = \{i : t \in \partial\alpha_i(u)\} \tag{35a}$$

and

$$\gamma(u) = \{t \in [0,1] : \pi(u)(t) \neq \emptyset\}. \tag{35b}$$

If condition (34) is to hold with $\hat{\mathsf{N}}(u) \subset \mathsf{N}_\Omega(u)$ and $\hat{\mathsf{N}}_U(u)(t)$ essentially constant near $\tau \in \gamma(u)$, the collection of normal spaces N_i corresponding to sets $\alpha_i(u)$ for which τ is a frontier point must have a *minimal element*, i.e., for all τ in $\gamma(u)$, there is an integer ν_τ in $\pi(u)(\tau)$ such that

$$\forall i \in \pi(u)(\tau) \quad \mathsf{N}_{\nu_\tau} \subset \mathsf{N}_i \text{ (and therefore } \mathsf{T}_{\nu_\tau} \supset \mathsf{T}_i\text{)}. \tag{36}$$

This requirement is trivially met for $U \subset \mathbb{R}^1$, since N_i is then always either $\{0\}$ or $\mathbb{R}^1$; however, (36) may not hold for vector-valued u, even in the typical case where $\pi(u)(\tau)$ contains just two elements at each τ in $\gamma(u)$. The following development of an example of Tian [16] demonstrates what can happen when (36) is not satisfied.

Example 6.1. Let $U = \{\xi \in \mathbb{R}^2 : \xi_1 \geq 0 \text{ and } \xi_2 \geq 0\}$. For v in $\mathsf{L}_2^\infty(0,1)$, put

$$J(v) = \int_0^1 (\langle r(t), v(t)\rangle + \tfrac{1}{2}\langle v(t), S(u)(t)v(t)\rangle)dt$$

with

$$r(t) = \begin{cases} \left(3(\tfrac{1}{2} - t), -(\tfrac{1}{2} - t)\right), & t \in [0, \tfrac{1}{2}], \\ \left((\tfrac{1}{2} - t), -3(\tfrac{1}{2} - t)\right), & t \in (\tfrac{1}{2}, 1], \end{cases}$$

and

$$[S(u)(t)\eta]_i = \sum_{j=1}^{2} S_{ij}n_j \quad i = 1, 2,$$

where

$$S = \begin{bmatrix} 1 & -2 \\ -2 & 1 \end{bmatrix}.$$

Note that

$$U = \operatorname{ri} \mathcal{F}_1 \cup \operatorname{ri} \mathcal{F}_2 \cup \operatorname{ri} \mathcal{F}_3 \cup \operatorname{ri} \mathcal{F}_4$$

with

$$\begin{aligned} &\operatorname{ri} \mathcal{F}_1 = \{(0,\xi_2) : \xi_2 > 0\}, && \mathcal{N}_1 = \{(\xi_1, 0) : \xi_1 \leq 0\}, \\ &\operatorname{ri} \mathcal{F}_2 = \{(0,0)\}, && \mathcal{N}_2 = \{(\xi_1,\xi_2) : \xi_1 \leq 0, \xi_2 \leq 0\}, \\ &\operatorname{ri} \mathcal{F}_3 = \{(\xi_1,0) : \xi_1 > 0\}, && \mathcal{N}_3 = \{(0,\xi_2) : \xi_2 \leq 0\}, \\ &\operatorname{ri} \mathcal{F}_4 = \{(\xi_1,\xi_2) : \xi_1 > 0, \xi_2 > 0\}, && \mathcal{N}_4 = \{(0,0)\}, \end{aligned}$$

and therefore

$$\begin{aligned} &\mathsf{N}_1 = \operatorname{span}\{(1,0)\}, && \mathsf{T}_1 = \operatorname{span}\{(0,1)\}, \\ &\mathsf{N}_2 = \mathbb{R}^2, && \mathsf{T}_2 = \{(0,0)\}, \\ &\mathsf{N}_3 = \operatorname{span}\{(0,1)\} && \mathsf{T}_3 = \operatorname{span}\{(1,0)\}, \\ &\mathsf{N}_4 = \{(0,0)\}, && \mathsf{T}_1 = \mathbb{R}^2. \end{aligned}$$

Now let

$$u(t) = \begin{cases} (0, -r_2(t)), & t \in [0, \tfrac{1}{2}], \\ (-r_1(t), 0), & t \in (\tfrac{1}{2}, 1]. \end{cases}$$

By construction, u lies in Ω, with

$$\alpha_1(u) = [0, \tfrac{1}{2}), \quad \alpha_2(u) = \{\tfrac{1}{2}\}, \quad \alpha_3(u) = (\tfrac{1}{2}, 1], \quad \alpha_4(u) = \emptyset,$$

$$\gamma(u) = \{\tfrac{1}{2}\},$$

$$\nabla J(u)(t) = \begin{cases} \left((\tfrac{1}{2} - t), 0\right), & t \in [0, \tfrac{1}{2}], \\ \left(0, -(\tfrac{1}{2} - t)\right), & t \in (\tfrac{1}{2}, 1], \end{cases}$$

$$\langle w, \nabla^2 J(u) w\rangle_2 = \int_0^1 \langle w(t), S(u)(t) w(t)\rangle dt,$$

$$\mathcal{N}_U(u(t)) = \begin{cases} \mathcal{N}_1, & t \in [0, \tfrac{1}{2}), \\ \mathcal{N}_2, & t = \tfrac{1}{2}, \\ \mathcal{N}_3, & t \in (\tfrac{1}{2}, 1], \end{cases}$$

$$\mathsf{T}_U(u(t)) = \begin{cases} \mathsf{T}_1, & t \in [0, \tfrac{1}{2}), \\ \mathsf{T}_2, & t = \tfrac{1}{2}, \\ \mathsf{T}_3, & t \in (\tfrac{1}{2}, 1], \end{cases}$$

and

$$\Delta(u)(t) = \begin{cases} (\tfrac{1}{2} - t), & t \in [0, \tfrac{1}{2}), \\ 0, & t = \tfrac{1}{2}, \\ (t - \tfrac{1}{2}), & t \in (\tfrac{1}{2}, 1]. \end{cases}$$

Conditions (32) are seen to hold at u, and $S(u)(\cdot)$ is constant and therefore continuous everywhere in $[0,1]$; nevertheless, u is not an L^∞-local minimizer of J in Ω. To prove this, construct $v_\epsilon \in \Omega$ by the rule

$$v_\epsilon(t) = \begin{cases} (\epsilon, \epsilon) + u(t), & t \in (\tfrac{1}{2} - \epsilon, \tfrac{1}{2} + \epsilon), \\ u(t), & t \in [0,1] \setminus (\tfrac{1}{2} - \epsilon, \tfrac{1}{2} + \epsilon), \end{cases}$$

for $\epsilon \in (0, \tfrac{1}{2})$, and observe that $\|v_\epsilon - u\|_\infty = \sqrt{2}\epsilon$ and $J(v_\epsilon) - J(u) = -\epsilon^3$.

In Example 6.1, the sole frontier point for the sets α_1, α_2, and α_3 is $\tau = \tfrac{1}{2}$, and every other $t \in [0,1]$ lies in the interior of one of these sets in $[0,1]$. As t approaches $\tfrac{1}{2}$ from the right or the left, $\Delta(u)(t)$ converges to 0 and hence the first-order term in Taylor's formula at u does not satisfy (27). Moreover, the second-order term in Taylor's formula cannot carry the resulting additional burden, since it is not possible to extend coercivity of $S(u)(t)$ on T_1 forward beyond $[0, \tfrac{1}{2})$ (where $\mathsf{N}_U(u(t)) = \mathsf{N}_2 = \mathsf{T}_1$) or to extend coercivity of $S(u)(t)$ on T_2 backward beyond $(\tfrac{1}{2}, 1]$ (where $\mathsf{N}_U(u(t)) = \mathsf{N}_1 = \mathsf{T}_2$), even though $S(u)(\cdot)$ is *constant* and therefore continuous. Circumstances of this kind are ruled out in the present analysis when we enforce the "minimal normal subspace" hypothesis (36) and require that

$$\text{(37)} \qquad \forall \tau \in \gamma(u) \quad \text{cl int } \alpha_{\nu_\tau}(u) \supset \alpha_{\nu_\tau}(u) \supset \text{int } \alpha_{\nu_\tau}(u) \neq \emptyset.$$

The following lemma establishes key features of the set $\gamma(u)$ under the aforementioned conditions.

LEMMA 6.3. *For all u in Ω the set $\gamma(u)$ is closed. In addition, if conditions* (36) *and* (37) *hold at u, then*

$$\mu[\gamma(u)] = 0 \tag{38}$$

and

$$\forall \tau \in \gamma(u)\ \forall \epsilon > 0 \quad \mu[\alpha_{\nu_\tau} \cap (\tau - \epsilon, \tau + \epsilon)] > 0. \tag{39}$$

Proof. The set $\pi(u)(\tau)$ is empty iff for some i, τ lies in the interior of $\alpha_i(u)$ in $[0,1]$. Consequently, $\gamma(u)^c$ is open in $[0,1]$, and hence $\gamma(u)$ is closed. If conditions (36) and (37) hold, then

$$\forall \tau \in \gamma(u) \quad \tau \in (\text{cl int } \alpha_{\nu_\tau}(u)) \setminus \text{int } \alpha_{\nu_\tau}(u).$$

Therefore,

$$\begin{aligned} 0 &\leq \mu[\gamma(u)] \\ &\leq \mu[\cup_{i=1}^{d} \ (\text{cl int } \alpha_i(u)) \setminus \text{int } \alpha_i(u)] \\ &\leq \sum_{i=1}^{d} \mu[(\text{cl int } \alpha_i(u)) \setminus \text{int } \alpha_i(u)] \\ &= 0. \end{aligned}$$

Moreover, for all τ in $\gamma(u)$ and $\epsilon > 0$, the interval $(\tau - \epsilon, \tau + \epsilon)$ contains a nonempty open interval in the interior of $\alpha_{\nu_\tau}(u)$. □

Since the set $\gamma(u)$ is closed and therefore compact, it follows that if

$$\lim_{t \to \tau} \text{ess inf } \Delta(u)(t) > 0 \tag{40}$$

at each τ in $\gamma(u)$, then $\Delta(u)(t)$ is essentially bounded away from 0 on some open neighborhood of $\gamma(u)$ in $[0,1]$, and thus on *all* of $[0,1]$ when (32b) holds. Under these circumstances, u satisfies the L^∞ strict complementarity condition (24a) in Theorem 6.1. Our concern now is with the less tractible but frequently encountered cases in which (32), (33), (36), and (37) hold at $\tau \in \gamma(u)$, but

$$\lim_{t \to \tau} \text{ess inf } \Delta_\tau(u)(t) > 0, \tag{41a}$$

where

$$\Delta_\tau(u)(t) = \sup\{\Delta \geq 0 : \forall \xi \in \mathsf{N}_{\nu_\tau},\ \|\xi\| \leq \Delta \Rightarrow -\nabla J(u)(t) + \xi \in \mathcal{N}_U\,(u(t))\}. \tag{41b}$$

Near τ in $[0,1]$, condition (36) implies that $\mathsf{N}_{\nu_\tau} \subset \mathsf{N}_U(u(t))$ and therefore $\Delta_\tau(u)(t) \geq \Delta(u)(t)$; thus (41) is always consistent with (33). Moreover, the next example demonstrates why (41) is often satisfied when τ is a point of continuity for $u(\cdot)$ and $\nabla J(u)(\cdot)$, whereas (40) cannot hold at such points. (Also see the discussion following Theorem 6.4.)

Example 6.2. Let U, $\mathcal{F}_i$, $\mathcal{N}_i$, N_i, and T_i be defined as in Example 6.1, and let

$$J(v) = \int_0^1 \left(v_1(t) + (2t-1)v_2(t) + v_2(t)^2\right) dt$$

for v in L_2^∞. The functional J has a global minimizer in Ω at

$$u(t) = \begin{cases} (0, \frac{1}{2} - t), & t \in [0, \frac{1}{2}), \\ (0,0), & t \in [\frac{1}{2}, 1], \end{cases}$$

with

$$\alpha_1(u) = [0, \tfrac{1}{2}), \quad \alpha_2(u) = [\tfrac{1}{2}, 1], \quad \alpha_3(u) = \emptyset, \quad \alpha_4(u) = \emptyset,$$

$$\gamma(u) = \{\tfrac{1}{2}\},$$

$$\nu_{1/2} = 1, \quad \mathsf{N}_{\nu_{1/2}} = \mathsf{N}_1 = \text{span}\,\{(1,0)\},$$

$$\mathcal{N}_U\,(u(t)) = \begin{cases} \mathcal{N}_1, & t \in [0, \frac{1}{2}), \\ \mathcal{N}_2, & t \in [\frac{1}{2}, 1], \end{cases}$$

$$\nabla J(u)(t) = \begin{cases} (1,0), & t \in [0, \frac{1}{2}), \\ (1, 2t-1), & t \in [\frac{1}{2}, 1], \end{cases}$$

and therefore

$$\Delta(u)(t) = \begin{cases} 1, & t \in [0, \frac{1}{2}), \\ 2t-1, & t \in [\frac{1}{2}, 1], \end{cases}$$

and

$$\lim_{t \to \frac{1}{2}^+} \Delta(u)(t) = 0,$$

whereas

$$\Delta_{1/2}(u)(t) = 1, \quad t \in [0,1].$$

It is now possible to state and prove the following sufficient conditions for L^∞-local optimality in Ω.

THEOREM 6.4. *Let J be a twice directionally differentiable real-valued function on a domain $\mathcal{D} \subset \mathsf{L}_m^\infty[0,1]$ that is open relative to the norm $\|\cdot\|_\infty$, and assume that the structure/continuity conditions* (2)–(3) *hold with $\nu = \infty$. Suppose that the formal sufficient conditions* (32) *are satisfied at some point u in $\Omega \cap \mathcal{D}$, along with* (36), (37), *and* (41) *at each τ in $\gamma(u)$. In addition, assume that $S(u)(\cdot)$ is continuous on the set $\gamma(u)$ in* (35). *Then for each number $c_\infty \in (0, c_T)$ there is a corresponding δ_∞ such that for all v,*

$$(42) \qquad v \in \Omega \text{ and } \|v - u\|_\infty < \delta_\infty \Rightarrow J(v) - J(u) \geq \tfrac{1}{2} c_\infty \|v - u\|_2^2.$$

Proof. Conditions (22) and (23) follow at once from the hypotheses. Suppose $\gamma(u) = \emptyset$. Then for some i, $[0,1] = \alpha_i(u) = \text{int}\,\alpha_i(u)$, in which case $[0,1]$ is a compact set in int $\alpha_i(u)$, conditions (32a)–(32b) imply the L^∞ strict complementarity condition (24a), and assertion (42) is established by Theorem 6.1. Suppose $\gamma(u) \neq \emptyset$. Then (42) will follow from Lemma 6.2 if it can be shown that for each $c_{\hat{T}} \in (0, c_T)$ the coercivity condition (32c) lifts to (30b) on a larger subspace $\hat{\mathsf{T}}(u) \supset \mathsf{T}_\Omega(u)$, while (32a)–(32b) and (41) imply the strict complementarity condition (30a) on the corresponding pointwise orthogonal complement $\hat{\mathsf{N}}(u) \subset \mathsf{N}_\Omega(u)$.

Fix $c_{\hat{T}}$ in $(0, c_T)$, and note first that by (38) in Lemma 6.3 there is an open set $\mathcal{O}$ in $[0,1]$, with $\mathcal{O} \supset \gamma(u)$ and $\mu[\mathcal{O}]$ so small that

$$\left(\int\int_{(\mathcal{O}^c\times\mathcal{O}^c)^c} \|K(u)(t,s)\|^2 dtds\right)^{\frac{1}{2}} \leq \frac{1}{2}(c_T - c_{\hat{T}}), \tag{43}$$

where $\mathcal{O}^c = [0,1]\setminus\mathcal{O}$, $(\mathcal{O}^c\times\mathcal{O}^c)^c = [0,1]\times[0,1]\setminus(\mathcal{O}^c\times\mathcal{O}^c)$. Moreover, (32c) implies that for all $i = 1,\ldots,d$ and all ξ,

$$\xi \in \mathsf{T}_i \Rightarrow \langle\xi, S(u)(t)\xi\rangle \geq c_T\|\xi\|^2 \quad \text{a.e. in } \alpha_i(u).$$

This can be proved in the same way that (14b) is established in the proof of Theorem 5.3. Since $S(u)(\cdot)$ is continuous on $\gamma(u)$, it now follows from (39) in Lemma 6.3 that for all τ and ξ,

$$\tau \in \gamma(u) \text{ and } \xi \in \mathsf{T}_{\nu_\tau} \Rightarrow \langle\xi, S(u)(\tau)\xi\rangle \geq c_T\|\xi\|^2. \tag{44}$$

By continuous extension, this implies that for each $\tau \in \gamma(u)$ there is a δ_τ such that

$$(\tau - \delta_\tau, \tau + \delta_\tau) \cap [0,1] \subset \mathcal{O}, \tag{45a}$$

and for all t in $[0,1]$ and all ξ,

$$t \in (\tau - \delta_\tau, \tau + \delta_\tau) \cap [0,1] \text{ and } \xi \in \mathsf{T}_{\nu_\tau} \Rightarrow \langle\xi, S(u)(t)\xi\rangle \geq \tfrac{1}{2}(c_T + c_{\hat{T}})\|\xi\|^2. \tag{45b}$$

On the other hand, condition (41) implies that for each τ in $\gamma(u)$, there are positive numbers c_τ and $\delta'_\tau \in (0, \delta_\tau]$ such that

$$\Delta_\tau(u)(t) \geq c_\tau$$

and

$$\mathsf{N}_{\nu_\tau} \subset \mathsf{N}_U(u(t)) \text{ and } \mathsf{T}_{\nu_\tau} \supset \mathsf{T}_U(u(t))$$

for almost all t in $(\tau - \delta'_\tau, \tau + \delta'_\tau) \cap [0,1] \subset \mathcal{O}$. Since $\gamma(u)$ is compact, this ensures the existence of a finite set $\{\tau_1, \ldots, \tau_k\} \subset \gamma(u)$, a corresponding system of intervals $\{\mathcal{I}_1, \cdots, \mathcal{I}_k\}$ in $[0,1]$, and a positive number c_γ such that the set

$$\mathcal{I} = \bigcup_{l=1}^{k} \mathcal{I}_l \tag{46a}$$

is open in $[0,1]$, and for all i and j and almost all t in $\mathcal{I}_i$,

$$i \neq j \Rightarrow \mathcal{I}_i \cap \mathcal{I}_j = \emptyset, \tag{46b}$$

$$\mathcal{I}_i \subset (\tau - \delta'_\tau, \tau + \delta'_\tau) \cap [0,1] \subset \mathcal{O}, \tag{46c}$$

$$\Delta_{\tau_i}(u)(t) \geq c_\gamma, \tag{46d}$$

$$\mathsf{N}_{\nu_{\tau_i}} \subset \mathsf{N}_U(u(t)) \text{ and } \mathsf{T}_{\nu_{\tau_i}} \supset \mathsf{T}_U(u(t)), \tag{46e}$$

and finally

$$\gamma(u) \subset \mathcal{I} \subset \mathcal{O}. \tag{46f}$$

The requisite subspaces $\hat{\mathsf{N}}(u)$ and $\hat{\mathsf{T}}(u)$ are now defined by (34) and the following rule: for all i and t

$$t \in \mathcal{I}_i \Rightarrow \hat{\mathsf{N}}(u)(t) = \mathsf{N}_{\nu_{\tau_i}} \text{ and } \hat{\mathsf{T}}(u)(t) = \mathsf{T}_{\nu_{\tau_i}}, \tag{47a}$$

$$t \in \mathcal{I}^c \Rightarrow \hat{\mathsf{N}}(u)(t) = \mathsf{N}_U(u(t)) \text{ and } \hat{\mathsf{T}}(u)(t) = \mathsf{T}_U(u(t)). \tag{47b}$$

By construction, $\hat{\mathsf{N}}(u) \subset \mathsf{N}_\Omega(u)$, $\hat{\mathsf{T}}(u) \supset \mathsf{T}_\Omega(u)$, $\hat{\mathsf{N}}(u)$ and $\hat{\mathsf{T}}(u)$ are pointwise orthogonal, and the same argument used in the proof of Theorem 6.1 shows that $\mathsf{L}_m^\infty(0,1)$ is the direct sum of $\hat{\mathsf{N}}(u)$ and $\hat{\mathsf{T}}(u)$. Furthermore, since $\mathcal{I}^c$ is compact and $\mathcal{I}^c \subset \gamma(u)^c = \cup_{i=1}^d \operatorname{int} \alpha_i(u)$, conditions (32a)–(32b) and (46d) imply (30a) with $c_{\hat{N}} = \min\{c_\beta, c_\gamma\}$ and $\beta = \mathcal{I}^c$. To prove (30b), note that for all w in $\mathsf{L}_m^\infty(0,1)$,

$$\begin{aligned}\langle w, \nabla^2 J(u) w\rangle_2 &= \int_{[0,1]} \langle w(t), S(u)(t)w(t)\rangle dt + \int\int_{[0,1]\times[0,1]} \langle w(t), K(u)(t,s)w(s)\rangle dtds \\ &= \int_{\mathcal{I}^c} \langle w(t), S(u)(t)w(t)\rangle dt + \int\int_{\mathcal{I}^c\times\mathcal{I}^c} \langle w(t), K(u)(t,s)w(s)\rangle dtds \\ &\quad + \int_{\mathcal{I}} \langle w(t), S(u)(t)w(t)\rangle dt + \int\int_{(\mathcal{I}^c\times\mathcal{I}^c)^c} \langle w(t), K(u)(t,s)w(s)\rangle dtds.\end{aligned}$$

Hence, for all w in $\hat{\mathsf{T}}(u)$, conditions (32c) and (43)–(46) imply that

$$\begin{aligned}\langle w, \nabla^2 J(u) w\rangle_2 &\geq c_T \int_{\mathcal{I}^c} \|w(t)\|^2 dt + \tfrac{1}{2}(c_T + c_{\hat{T}}) \textstyle\int_{\mathcal{I}} \|w(t)\|^2 dt \\ &\quad - \left(\int\int_{(\mathcal{O}^c\times\mathcal{O}^c)^c} \|K(u)(t,s)\|^2 dtds\right)^{\frac{1}{2}} \|w\|_2^2 \\ &\geq \tfrac{1}{2}(c_T + c_{\hat{T}})\|w\|_2^2 - \tfrac{1}{2}(c_T - c_{\hat{T}})\|w\|_2^2 \\ &= c_{\hat{T}}\|w\|_2^2. \qquad \square\end{aligned}$$

Theorem 6.4 has an immediate corollary for optimal control problems with Bolza objective functions (5) and admissible control input sets

$$U = \{\xi \in \mathbb{R}^m; g_j(\xi) \leq 0, \quad j = 1, \ldots, l\}, \tag{48a}$$

where each g_j is an affine real function with values

$$g_j(\xi) = \langle a^j, \xi\rangle - b_j. \tag{48b}$$

Theorem 3 and lemmas 3–5 in [2] produce similar L^∞ sufficient conditions for a large class of Bolza optimal control problems with $\mathcal{C}^2$ equality constraints on the terminal state $x(1)$ and admissible control input sets $U \subset \mathbb{R}^m$ prescribed by l $\mathcal{C}^2$ inequality constraints. Although the analysis in §4 of [2] is also rooted in the proof strategy of [1], it proceeds from different assumptions and does not subsume Theorem 6.4 for the class of fixed-time free-endpoint Bolza problems with polyhedral control input sets U. When U is given by (48), the Farkas lemma implies that at each ξ in U, the normal cone $\mathcal{N}_U(\xi)$ consists of all nonnegative linear combinations of the active constraint gradients

$$\nabla g_j(\xi) = a^j, \quad j \in A_0(\xi), \tag{49a}$$

where

$$A_0(\xi) = \{j : g_j(\xi) = 0\}. \tag{49b}$$

Under these circumstances, the pointwise stationarity condition (14a) holds everywhere in $[0,1]$ iff there are Lagrange multipliers $\lambda(t)$ in $\mathbb{R}^l$ such that

$$\forall t \in [0,1] \quad -\nabla J(u)(t) = \sum_{j=1}^{l} \lambda_j(t) \nabla g_j\left(u(t)\right) \tag{50a}$$

with

$$\lambda_j(t) \geq 0, \quad j \in A_0\left(u(t)\right), \tag{50b}$$

$$\lambda_j(t) = 0, \quad j \notin A_0\left(u(t)\right). \tag{50c}$$

In §4 of [2], the active constraint gradients in (49) are assumed to be linearly independent at $\xi = u(t)$ for $t \in [0,1]$, and the complementarity condition (50b) is strengthened by requiring that

$$\forall i \, \forall \beta_i \subset \text{int } A_0^i \quad \left(\beta_i \text{ compact } \Rightarrow \inf_{t \in \beta_i} \lambda_i(t) > 0\right), \tag{51a}$$

where

$$A_0^i = \{t \in [0,1] : g_i\left(u(t)\right) = 0\}. \tag{51b}$$

It is further assumed in [2] that for all τ,

$$\tau \in \bigcup_{j=1}^{l} \partial A_0^j \Rightarrow \exists c_\tau > 0 \, \forall \xi \in \overline{T}_0(\tau), \quad \langle \xi, S(\tau)\xi \rangle \geq c_\tau \|\xi\|^2, \tag{52a}$$

where

$$\overline{T}_0(\tau) = \left[\{\nabla g_j\left(u(\tau)\right)\}_{j \in \overline{A}_0(\tau)}\right]^\perp, \tag{52b}$$

$$\overline{A}_0(\tau) = \bigcup_{\sigma > 0} \bigcap_{s \in (\tau - \sigma, \tau + \sigma) \cap [0,1]} A_0\left(u(s)\right), \tag{52c}$$

and

$$S(\tau) = \nabla^2_{uu} H\left(\tau, \psi(\tau), x(\tau), u(\tau)\right). \tag{52d}$$

(See Note 5.4.) The following lemma and note explain how the strengthened complementarity condition (51) and the pointwise coercivity condition (52) are related to the hypotheses in Theorem 6.4.

LEMMA 6.5. *Let U be a polyhedral convex set with representation* (48) *in* $\mathbb{R}^m$. *Then for each face $\mathcal{F}_i$ in U, there is a unique subset $\mathcal{A}_i$ of $\{1,\ldots,l\}$ such that*

$$\text{ri } \mathcal{F}_i = \{\xi \in U : A_0(\xi) = \mathcal{A}_i\}. \tag{53}$$

Suppose that

$$u \in \mathsf{L}_m^\infty(0,1) \textit{ and } (\forall t \in [0,1] \quad u(t) \in U). \tag{54}$$

Then

$$\forall i \quad \text{int } \alpha_i(u) \subset \bigcap_{j \in \mathcal{A}_i} \text{int } A_0^j, \tag{55}$$

$$\gamma(u) = \bigcup_{j=1}^{l} \partial A_0^j, \tag{56}$$

and

$$\forall \tau \in \gamma(u) \quad \overline{A}_0(\tau) = \bigcap_{j \in \pi(u)(\tau)} \mathcal{A}_j. \tag{57}$$

Furthermore, assume that (54) *holds at u and, for each τ in $\gamma(u)$, the collection of index sets $\{\mathcal{A}_j\}_{j\in\pi(u)(\tau)}$ has a minimal element, i.e.,*

$$\exists \nu_\tau \in \pi(u)(\tau)\ \forall j \in \pi(u)(\tau) \quad \mathcal{A}_{\nu_\tau} \subset \mathcal{A}_j. \tag{58}$$

Then for all τ in $\gamma(u)$,

$$\overline{A}_0(\tau) = \mathcal{A}_{\nu_\tau}, \tag{59a}$$

$$\forall j \in \pi(u)(\tau) \quad \mathsf{N}_{\nu_\tau} \subset \mathsf{N}_j, \tag{59b}$$

and

$$\mathsf{T}_{\nu_\tau} = \overline{\mathsf{T}}_0(\tau). \tag{59c}$$

Finally, assume that (50), (54), *and* (58) *hold at u and that the active constraint gradients in* (49) *are also linearly independent at $\xi = u(t)$ for all t in $[0,1]$. Then the algebraic strict complementarity condition* (51) *is equivalent to the geometric strict complementarity conditions*

$$\forall \beta \subset \bigcup_{i=1}^{d} \text{int } \alpha_i(u) \quad \left(\beta \text{ compact } \Rightarrow \inf_{t\in\beta} \Delta(u)(t) > 0\right), \tag{60a}$$

$$\forall \tau \in \gamma(u) \quad \lim_{t\to\tau} \inf \Delta_\tau(u)(t) > 0. \tag{60b}$$

Proof. For each $\xi \in U$,

$$\mathcal{N}_U(\xi) = \{\zeta \in \mathbb{R}^m : \exists \lambda \in \mathbb{R}^l_+ \quad \zeta = \sum_{j \in A_0(\xi)} \lambda_j a^j\}, \tag{61a}$$

where

$$\mathbb{R}^l_+ = \{\lambda \in \mathbb{R}^l : \forall j \quad \lambda_j \geq 0\}. \tag{61b}$$

It follows from (48) and (61) that for all $\xi \in U$ the set

$$\mathcal{F}(\xi) = \left[\xi + \mathcal{N}_U(\xi)^\perp\right] \cap U$$

is a polyhedral face in U, with

$$\operatorname{aff} \mathcal{F}(\xi) = \xi + \mathcal{N}_U(\xi)^\perp,$$

$$\operatorname{ri} \mathcal{F}(\xi) = \{\eta \in U : A_0(\eta) = A_0(\xi)\},$$

and

$$\eta \notin \operatorname{ri} \mathcal{F}(\xi) \Rightarrow \operatorname{ri} \mathcal{F}(\eta) \cap \operatorname{ri} \mathcal{F}(\xi) = \emptyset$$

for all $\eta \in U$ [15]. Since $A_0(\cdot)$ has range in the subsets of $\{1, \ldots, l\}$, there are d distinct index sets $\mathcal{A}_i \subset \{1, \ldots, l\}$ and d corresponding polyhedral faces $\mathcal{F}_i \subset U$ such that (53) holds, with

$$\eta \in \operatorname{ri} \mathcal{F}_i \Rightarrow \mathcal{N}_U(\eta) = \mathcal{N}_i = \left\{\zeta \in \mathbb{R}^m : \exists \lambda \in \mathbb{R}^l_+ \quad \zeta = \sum_{j \in \mathcal{A}_i} \lambda_j a^j\right\}, \tag{62a}$$

$$\eta \in \operatorname{ri} \mathcal{F}_i \Rightarrow \operatorname{span} \mathcal{N}_U(\eta) = \mathsf{N}_i = \operatorname{span} \{a^j\}_{j \in \mathcal{A}_i}, \tag{62b}$$

$$\operatorname{ri} \mathcal{F}_i \cap \operatorname{ri} \mathcal{F}_j = \emptyset, \tag{62c}$$

and

$$\cup_{i=1}^d \operatorname{ri} \mathcal{F}_i = U \tag{62d}$$

for all $\eta \in U$ and all $i, j \in \{1, \ldots, l\}$.

Suppose that (54) holds. By (12a) and (53),

$$\alpha_i(u) = \{t \in [0,1] : A_0\left(u(t)\right) = \mathcal{A}_i\} \tag{63a}$$

and

$$\bigcup_{i=1}^d \alpha_i(u) = [0,1]. \tag{63b}$$

If int $\alpha_i(u) = \emptyset$, then (55) holds trivially. Suppose that $\tau \in$ int $\alpha_i(u)$. Then for some $\delta > 0$ and all t,

$$\begin{aligned} t \in (\tau - \delta, \tau + \delta) \cap [0,1] &\Rightarrow A_0\left(u(t)\right) = \mathcal{A}_i \\ &\Rightarrow \forall j \in \mathcal{A}_i \quad g_j\left(u(t)\right) = 0 \\ &\Rightarrow \forall j \in \mathcal{A}_i \quad t \in A_0^j, \end{aligned}$$

and therefore $\tau \in \text{ int } A_0^j$ for all $j \in \mathcal{A}_i$. This proves (55).

Suppose that $\tau \in \partial A_0^i$ for some i. Then every neighborhood of τ in $[0,1]$ contains points t and s where $g_i(u(t)) = 0$ and $g_i(u(s)) \neq 0$, and hence $A_0(u(t)) \neq A_0(u(s))$. By (35), it follows that $\tau \in \left[\cup_{i=1}^d \text{int } \alpha_i(u)\right]^c = \gamma(u)$. Conversely, suppose that $\tau \notin \cup_{i=1}^l \partial A_0^i$ or, equivalently,

$$\forall i \quad \tau \in \text{ int } A_0^i \cup \text{int } (A_0^i)^c.$$

Then

$$\exists \delta > 0 \, \forall t \in (\tau - \delta, \tau + \delta) \cap [0,1] \quad A_0(u(t)) = A_0(u(\tau)),$$

in which case $\tau \in \text{ int } \alpha_i(u)$ for some i and therefore $\tau \in \gamma(u)^c$. This proves (56).

Since $A_0(\cdot)$ has finitely many values $\mathcal{A}_i$, it follows that for all $t \in [0,1]$ there is a $\sigma_t > 0$ such that

$$\forall \sigma \in (0, \sigma_t] \quad \overline{A}_0(t) = \bigcap_{s \in (t-\sigma, t+\sigma) \cap [0,1]} A_0(u(s)).$$

Moreover, if $\tau \in \gamma(u)$, then by (35) it is also true that

$$\forall \sigma \in (0, \sigma_\tau] \quad A_0[(\tau - \sigma, \tau + \sigma) \cap [0,1]] = \{\mathcal{A}_j\}_{j \in \pi(u)(\tau)}.$$

Assertion (57) is now proved, and (59) is an immediate consequence of (35), (52), (57), (62b), and the hypothesis (58).

Suppose that (50), (58), and (60) hold at u and that the active constraint gradients in (49) are linearly independent at $\xi = u(t)$ for $t \in [0,1]$. Let β_q be a compact set in $\text{int} A_0^q$ for some q. Suppose that $\beta_q \cap \gamma(u) \neq \emptyset$. By Lemma 6.3, the set $\beta_q \cap \gamma(u)$ is compact. Hence there is a $\delta > 0$, a finite set $\{\tau_1, \ldots, \tau_k\} \subset \beta_q \cap \gamma(u)$, and a corresponding family of open intervals $\{\mathcal{I}_1, \ldots, \mathcal{I}_k\}$ in $[0,1]$ such that

$$\text{(64a)} \qquad \mathcal{I} \overset{\text{def}}{=} \bigcup_{i=1}^k \mathcal{I}_i \supset \beta_q \cap \gamma(u),$$

$$\text{(64b)} \qquad \inf_{t \in \mathcal{I}_i} \Delta_{\tau_i}(u)(t) \geq \delta,$$

$$\text{(64c)} \qquad \forall i \quad \tau_i \in \mathcal{I}_i \subset \text{int } A_0^q,$$

$$\text{(64d)} \qquad \forall i \quad A_0[\mathcal{I}_i] = \{\mathcal{A}_j\}_{j \in \pi(u)(\tau)},$$

and thus

$$\text{(64e)} \qquad \forall t \in \mathcal{I}_i \quad q \in \mathcal{A}_{\nu_{\tau_i}} \subset A_0(u(t))$$

in view of (58). Now note that

$$\text{(65a)} \qquad \forall \lambda \in \mathbb{R}^l \quad \left\| \sum_{j=1}^l \lambda_j a^j \right\| \leq M_a \max_{1 \leq j \leq l} |\lambda_j|$$

with

$$\text{(65b)} \qquad M_a = \sum_{j=1}^{l} \|a^j\| > 0.$$

Since active constraint gradients are linearly independent, conditions (41b), (50), (58), (62), (64), and (65) imply that

$$\forall i \quad \inf_{t \in \mathcal{I}_i} \lambda_q(t) \geq \frac{\delta}{M_a}$$

and hence

$$\inf_{t \in \beta_q \cap \mathcal{I}} \lambda_q(t) \geq \frac{\delta}{M_a}.$$

Suppose that $\beta_q \cap \mathcal{I}^c \neq \emptyset$. By (64a), $\beta_q \cap \mathcal{I}^c$ is a compact set in $\gamma(u)^c = \cup_{i=1}^d \operatorname{int} \alpha_i(u)$, condition (60a) yields

$$\inf_{t \in \beta_q \cap \mathcal{I}^c} \Delta(u)(t) \overset{\text{def}}{=} \delta_c > 0,$$

and therefore (32d), (50), (62), and (65) give

$$\inf_{t \in \beta_q \cap \mathcal{I}^c} \lambda_q(t) \geq \frac{\delta_c}{M_a} > 0$$

since active constraint gradients are linearly independent and $q \in A_0(u(t))$ for all $t \in A_0^q \supset \beta$. Finally, if $\beta_q \cap \gamma(u) = \emptyset$, then β_q is a compact set in $\gamma(u)^c = \cup_{i=1}^d \operatorname{int} \alpha_i(u)$, and a repetition of the preceding argument shows that $\lambda_q(t)$ is again bounded away from 0 on β_q. This proves that (51) is implied by (60).

Conversely, suppose that (50), (51), and (60) hold at u and that the active constraint gradients in (49) are linearly independent at $\xi = u(t)$ for $t \in [0,1]$. The latter condition ensures that

$$\text{(66)} \qquad \exists m_a > 0 \; \forall t \in [0,1] \; \forall \lambda \in \mathbb{R}^l \quad \left\| \sum_{j \in A_0(u(t))} \lambda_j a^j \right\| \geq m_a \max_{j \in A_0(u(t))} |\lambda_j|.$$

Let β be a compact set in $\cup_{i=1}^d \operatorname{int} \alpha_i(u)$. Since the sets $\operatorname{int} \alpha_i(u)$ are open in $[0,1]$ and pairwise disjoint, the corresponding sets $\beta_i = \beta \cap \operatorname{int} \alpha_i(u)$ are compact sets in $\operatorname{int} \alpha_i(u)$, with $\beta = \cup_{i=1}^d \beta_i$. Therefore, by (55) and (51),

$$\forall i \; \forall j \in \mathcal{A}_i \quad \beta_i \text{ compact and } \beta_i \subset \operatorname{int} A_0^j,$$

and therefore

$$\exists \delta > 0 \; \forall i \quad \inf_{t \in \beta_i} \min_{j \in A_0(u(t))} \lambda_j(t) \geq \delta > 0.$$

It now follows from (12), (32d), (61), (62), and (66) that

$$\forall i \quad \inf_{t \in \beta_i} \Delta(u)(t) \geq \delta m_a > 0,$$

and therefore

$$\inf_{t\in\beta} \Delta(u)(t) \geq \delta m_a > 0.$$

This proves (60a). Furthermore, suppose that (58) also holds at u. Then for each $\tau \in \gamma(u)$ there is a $\delta_\tau > 0$ such that for all t

$$\begin{aligned} t \in (\tau - \delta_\tau, \tau + \delta_\tau) \cap [0,1] \quad &\Rightarrow \mathcal{A}_{\nu_\tau} \subset A_0\left(u(t)\right) \\ &\Rightarrow \forall j \in \mathcal{A}_{\nu_\tau} \quad g_j\left(u(t)\right) = 0. \end{aligned}$$

Thus $\tau \in \operatorname{int} A_0^j$ for all $j \in \mathcal{A}_{\nu_\tau}$, and condition (51) ensures that

$$\forall j \in \mathcal{A}_{\nu_\tau} \quad \lim_{t\longrightarrow\tau} \inf \lambda_j(t) > 0.$$

Assertion (60b) now follows from (41b), (50), (58), (62), and (66). □

Note 6.3. According to (56) and (59c), the pointwise coercivity condition (52) reduces to

$$\text{(67a)} \qquad \forall \tau \in \gamma(u)\, \exists c_\tau > 0\, \forall \xi \in \mathsf{T}_{\nu_\tau} \quad \langle \xi, S(\tau)\xi\rangle \geq c_\tau \left\|\xi\right\|^2,$$

$$\text{(67b)} \qquad S(\tau) = \nabla^2_{uu} H\left(\tau, \psi(\tau), x(\tau), u(\tau)\right)$$

when the minimal index set restriction (58) is satisfied. In [2], condition (52) is taken as a *hypothesis*. In the present analysis, the pointwise coercivity condition (67a) is *deduced* from (36), (37), and the coercivity condition (32c), and the relationship between (32c) and second-order *necessary* conditions for L^∞-local optimality is established in Theorems 5.2 and 5.3. On the other hand, the sufficient conditions in §4 of [2] impose the linear independence qualification on active constraint gradients but do not assume the existence of a minimal element in the family of index sets $\{\mathcal{A}_i\}_{i\in\pi(u)(\tau)}$ for τ in $\gamma(u)$; however, if the active constraint gradient sets in (49) *are* linearly independent at $\xi = u(t)$ for $t \in [0,1]$ and (58) is *not* satisfied, then (52b), (57), and (62) imply that $\overline{\mathsf{T}}_0(\tau)$ contains each subspace in the family $\{\mathsf{T}_i\}_{i\in\pi(u)(\tau)}$ as a *proper subset*, and the pointwise coercivity condition (52) cannot be inferred from the counterpart of (32c) in [2]. To put this another way, when (58) does not hold in the setting of [2], the gap between sufficient conditions and necessary conditions widens substantially.

In this connection, an extreme case of some interest occurs when u is a step function with range in the vertex set of the polyhedron U (e.g., a *bang-bang* control). Under these circumstances, it can be seen that for almost all t in $[0,1]$ and τ in $\gamma(u)$: $\mathsf{N}_U(u(t)) = \mathbb{R}^m$ and $\mathsf{T}_U(u(t)) = \{0\}$; $\{\mathsf{N}_i\}_{i\in\pi(u)} = \mathbb{R}^m$; $\mathsf{N}_{\nu_\tau} = \mathbb{R}^m$; $\Delta_\tau(u)(t) = \Delta(u)(t)$; *card* $A_0\left(u(t)\right) = m$; $\{\mathcal{A}_i\}_{i\in\pi(u)(\tau)}$ has no minimal element; $\overline{A}_0(\tau)$ is a proper subset of $\mathcal{A}_j$ for all $j \in \pi(u)(\tau)$; $1 \leq$ *dim* $\overline{\mathsf{T}}_0(\tau) \leq m$; condition (32c) is satisfied trivially; conditions (51) can hold when conditions (60) do not, but condition (52) is unrelated to the necessary condition (14b) and is not likely to hold for nonconvex objective functions.

The stationary control u in example 2 of [1] satisfies the L^∞ sufficient conditions in Theorem 6.4 with $\nu = 2$ but does not obey the necessary condition (17) for L^2-local optimality in Theorem 5.4. Hence, the L^∞ sufficient conditions do not imply L^2-local optimality, even if (2) and (3) hold with $\nu = 2$. On the other hand, it will now be shown that L^2-local optimality *is* implied by (42) and a strengthened variant of (17) when (2) and (3) hold with $\nu = 2$; this result and *any* sufficient conditions for (42) immediately yield sufficient conditions for L^2-local optimality.

THEOREM 6.6. *Let J be a twice directionally differentiable real-valued function on a domain $\mathcal{D} \subset \mathsf{L}^\infty_m[0,1]$ that is open relative to the norm $\|\cdot\|_2$, and suppose that the structure/continuity conditions* (2)–(3) *hold with $\nu = 2$. Assume that u is a proper L^∞-local minimizer of J in $\Omega \cap \mathcal{D}$ satisfying* (42). *In addition, suppose that for some $c_P > 0$, the condition*

$$(68)\ \forall \xi \in U \quad \langle \nabla J(u)(t), \xi - u(t)\rangle + \tfrac{1}{2}\langle \xi - u(t), S(u)(t)\,(\xi - u(t))\rangle \geq \tfrac{1}{2}c_P\|\xi - u(t)\|^2$$

holds for almost all t in $[0,1]$. Then u is a proper L^2-local minimizer of J in $\Omega \cap \mathcal{D}$, and for each c_2 in the interval $0 < c_2 < \min\{c_T, c_P\}$ there is a corresponding $\delta_2 > 0$ such that for all v

$$(69) \qquad v \in \Omega \text{ and } \|v - u\|_2 < \delta_2 \Rightarrow J(v) - J(u) \geq c_2\|v - u\|_2^2.$$

Proof. Fix c_2 in the interval $0 < c_2 < \min\{c_T, c_P\}$, fix c_∞ in the interval $\frac{1}{2}(\min\{c_T, c_P\} + c_2) < c_\infty < \min\{c_T, c_P\}$, and choose $\delta_\infty > 0$ so that (42) is satisfied. Note that if (2) and (3) are satisfied with $\nu = 2$, then Taylor's formula (4) holds with $\nu = 2$ *and* $\nu = \infty$. Consequently, there is a $\rho \in (0, \delta_\infty]$ such that for all v in Ω,

$$(70\text{a}) \qquad \|v - u\|_2 \leq \rho \Rightarrow v \in \mathcal{D} \cap \Omega \text{ and } |r(u; v)| \leq \tfrac{1}{8}\left(\min\{c_T, c_P\} - c_2\right)\|v - u\|_2^2$$

and

(70b)

$$\|v - u\|_\infty \leq \rho \Rightarrow \langle \nabla J(u), v - u\rangle_2 + \tfrac{1}{2}\langle v - u, \nabla^2 J(u)(v - u)\rangle_2 \geq \tfrac{1}{4}\left(\min\{c_T, c_P\} + c_2\right)\|v - u\|_2^2.$$

Furthermore, there is an $\epsilon \in (0,1]$ such that for all measurable sets $\theta \subset [0,1]$

$$(71) \qquad \mu[\theta] < \epsilon \Rightarrow \int\int_{(\theta^c \times \theta^c)^c} \|K(u)(t,s)\|^2 dtds \leq \tfrac{1}{8}\left(\min\{c_T, c_P\} - c_2\right).$$

For each $v \in \Omega$, let

$$(72\text{a}) \qquad \theta_v = \{t \in [0,1] : \|v(t) - u(t)\| > \rho\},$$

and define $w_v \in \Omega$ by the rule

$$(72\text{b}) \qquad w_v(t) = \begin{cases} v(t), & t \in \theta_v^c, \\ u(t), & t \in \theta_v. \end{cases}$$

By construction, θ_v is measurable, and for all v,

$$(73) \qquad v \in \Omega \text{ and } \|v - u\|_2 \leq \rho\epsilon^{\frac{1}{2}} \Rightarrow v \in \Omega \cap \mathcal{D},\ \mu[\theta_v] < \epsilon \text{ and } \|w_v - u\|_\infty \leq \rho.$$

Put $\delta_2 = \rho\epsilon^{\frac{1}{2}}$. Then, in view of (70)–(73) and Taylor's formula (4) with $\nu = 2$, it now follows that for all $v \in \Omega$ such that $\|v - u\|_2 \leq \delta_2$,

$$\begin{aligned} J(v) - J(u) = {} & \langle \nabla J(u), w_v - u\rangle_2 + \tfrac{1}{2}\langle w_v - u, \nabla^2 J(u)(w_v - u)\rangle_2 \\ & + \int_{\theta_v} \left[\langle \nabla J(u)(t), v(t) - u(t)\rangle + \tfrac{1}{2}\langle v(t) - u(t), S(u)(t)\,(v(t) - u(t))\rangle\right] dt \end{aligned}$$

$$
\begin{aligned}
&+ \int\int_{(\theta_v^c\times\theta_v^c)^c} \langle v(t)-u(t), K(u)(t,s)\,(v(t)-u(t))\rangle dtds + r(u;v)\\
&\geq \tfrac{1}{4}\left(\min\{c_T,c_P\}+c_2\right)\|w_v-u\|_2^2+\tfrac{1}{2}c_P\int_{\theta_v}\|v(t)-u(t)\|^2dt\\
&\quad -\tfrac{1}{4}\left(\min\{c_T,c_P\}-c_2\right)\|v-u\|_2^2\\
&\geq \tfrac{1}{4}\left(\min\{c_T,c_P\}+c_2\right)\|v-u\|_2^2-\tfrac{1}{4}\left(\min\{c_T,c_P\}-c_2\right)\|v-u\|_2^2\\
&= \tfrac{1}{2}c_2\|v-u\|_2^2. \qquad \square
\end{aligned}
$$

Note 6.4. Theorem 6.6 remains valid if the range set U in (1b) is an arbitrary subset of $\mathbb{R}^m$ (cf. Note 5.3).

Note 6.5. Theorem 4 in [1] gives sufficient conditions for L^∞-local optimality and L^2-local optimality in the set of L^p functions with range in $U=[0,\infty)\subset\mathbb{R}^1$. For $p=\infty$, these results are contained in Theorems 6.4 and 6.6, since (36), (37), and (41) hold trivially when $U=[0,\infty)$ and the set $\alpha(u)=\{t\in[0,1]:u(t)=0\}$ is closed, condition (68) is easily verified when $U=[0,\infty)$ and $S(u)(t)$ is essentially bounded away from 0 on $[0,1]$, and the condition $\|K(u)\|_\infty<\infty$ implies the weaker requirement $\|K(u)\|_2<\infty$ imposed here.

Note 6.6. If (2) and (3) hold with $\nu=2$ for Bolza objective functions (5), then the Hamiltonian H is quadratic in u (see Note 5.4), and hypothesis (68) is equivalent to the following strengthened version of the Pontryagin minimum principle: for some $c_P>0$ and almost all t in $[0,1]$,

$$\forall\xi\in U\quad H\left(t,\psi(t),x(t),\xi\right)-H\left(t,\psi(t),x(t),u(t)\right)\geq\tfrac{1}{2}c_P\|\xi-u(t)\|^2.$$

Note 6.7. For optimal control problems, coercivity conditions like (32c) can be derived from disconjugacy conditions of the Jacobi type [9]; however, the latter conditions are more stringent than the former and are further removed from the second-order necessary conditions for optimality (cf. remarks preceding Theorem 5.2 in [9]).

RENDEZVOUS SEARCH ON THE LINE WITH INDISTINGUISHABLE PLAYERS*

EDWARD J. ANDERSON† AND SKANDER ESSEGAIER‡

Abstract. Alpern introduced a problem in which two players are placed on the real line at a distance drawn from a bounded distribution F known to both. They can move at maximum velocity one and wish to meet as soon as possible. Neither knows the direction of the other, nor do they have a common notion of a positive direction on the line. It is required to find the *symmetric rendezvous value* $R^s(F)$, which is the minimum expected meeting time achievable by players using the same mixed strategy. This corresponds to the case where the players are indistinguishable; they both take directions from a controller who does not know their names. In this paper we give a mixed strategy which has an expected meeting time of $1.78D + \mu/2$, where D is the maximum of F and μ its mean. This leads to an upper bound $R^s(F) \leq 1.78D + \mu/2$ on the symmetric rendezvous value, which is better than the upper bound $R^s(F) \leq 2D + \mu/2$ obtained by Alpern.

Key words. search games, rendezvous search

AMS subject classifications. 90B40, 90D26

1. Introduction.

The work on rendezvous problems in unbounded domains was initiated by Alpern [Alp], who introduced the following problem. Two players are placed on the real line. They can move at maximum velocity one and wish to meet as soon as possible. We assume that the players know only the probability distribution F of the distance between them at time 0 but not the direction of the other. This problem is related to the linear search problem; see Gal [Gal80] and Beck and Beck [BB92].

The strategy space for both players is the set of paths with maximum speed one:

$$P = \{f : R^+ \to R,\ f(0) = 0,\ |f(s) - f(t)| \leq |s - t|\}.$$

A player placed at point a who chooses strategy f will follow the trajectories $a + f(t)$ and $a - f(t)$ equiprobably.

Since the problem is translation invariant, we may assume that player I starts at point 0 and player II starts equiprobably at $+x$ or $-x$, the initial distance x between the players being drawn from the known cumulative probability distribution F. If player I chooses $f \in P$ and player II chooses $g \in P$, then the expected meeting time $\hat{T}(f, g)$ is given by

$$\hat{T}(f,g) = \int_0^\infty \frac{1}{4} \sum_{i,j=\pm 1} \min\{t : f(t) = ix + jg(t)\}\, dF(x).$$

The ambiguity of the i indicates the equiprobable placement of player II at $+x$ or $-x$, and the ambiguity of the j reflects the assumption that the players cannot tell left from right.

A mixed strategy f^* is a regular Borel probability measure on P. The set of mixed strategies will be denoted by P^*. The payoff $T^*(f^*, g^*)$ is the expected value of $\hat{T}$ in the cross product measure $f^* \times g^*$. The symmetric rendezvous value $R^s(F)$ is then defined as the minimum expected meeting time achievable by players using the same mixed strategies:

$$R^s(F) = \min_{f^* \in P^*} T^*(f^*, f^*).$$

Alpern and Gal [AG] considered the asymmetric case, where the players are distinguishable. This is to say that they have previously agreed which of the roles each will take, and

* Received by the editors December 29, 1993; accepted for publication (in revised form) June 27, 1994.

† Department of Engineering, Cambridge University, Cambridge CB2 1RX, United Kingdom.

‡ London School of Economics, Houghton Street, London WC2A 2AE, United Kingdom.

they are therefore allowed to use different strategies. The asymmetric case has some connection with Beck's work on the linear search problem (see [AG]). We are interested here in the symmetric version, where players are indistinguishable. There is no prior agreement on which of the roles each will take, and we therefore constrain the players to using the same search strategy. This is essentially a one-person decision problem. However, randomization over the set of available pure strategies is necessary in order to have a finite expected meeting time, since there is a probability of at least $1/2$ that players don't meet if they use the same pure strategy. A related problem in which rendezvous takes place on discrete locations is considered by Anderson and Weber [AW90] and in [Tho92].

In the following, we consider the case where the probability distribution F is bounded; i.e., there is a maximal initial distance between the players. Let $D = D_F = \min\{x : F(x) = 1\}$, and let $\mu = \mu_F$, the mean initial distance. Alpern [Alp] obtained an upper bound $R^s(F) \leq 2D + \mu/2$ in terms of D and μ.

In this paper, we describe how results for the symmetric case can be derived from those of the asymmetric one [AG]. We then show how the method can be generalized to obtain upper bounds significantly better than Alpern's $R^s(F) \leq 2D + \mu/2$. We actually give a strategy which has an expected meeting time of $1.78D + \mu/2$ and obtain the upper bound $R^s(F) \leq 1.78D + \mu/2$.

2. Relation with the asymmetric case. The asymmetric case, where the players are distinguishable, has been analyzed by Alpern and Gal [AG]. In this case, the players have previously agreed which of the two roles each will take, and they are therefore allowed to use different strategies. The asymmetric rendezvous value $R^a(F)$ is given by

$$R^a(F) = \min_{f,g \in P} \hat{T}(f, g).$$

In their analysis, Alpern and Gal [AG] showed that if F has a point distribution, then an optimal strategy pair (f_1, f_2) is defined by the following formulae:

$$f_1(t) = \begin{cases} t & \text{if } 0 \leq t \leq D, \\ 2D - t & \text{if } D \leq t \leq 3D, \end{cases} \qquad f_2(t) = \begin{cases} t & \text{if } 0 \leq t \leq D/2, \\ D - t & \text{if } D/2 \leq t \leq 2D, \\ t - 3D & \text{if } 2D \leq t \leq 3D. \end{cases}$$

Furthermore, they showed that this strategy pair guarantees meeting by time $3D$ and that the expected meeting time it achieves is $\hat{T}(f_1, f_2) = (4\mu + 9D)/8$. This provides us with an upper bound on the asymmetric rendezvous value $R^a(F)$. In the case where F is a point distribution ($\mu = D = d$), this upper bound is exactly the asymmetric rendezvous value $R^a = 13d/8$. It is therefore a good upper bound of the form $\alpha D + \beta\mu$.

In the symmetric case, although players use the same *mixed* strategy, there is a positive probability that they actually follow a different *pure* strategy. Suppose, for example, that the players have two pure strategies, s_1 and s_2, and that they choose one or the other equiprobably. Then there is a probability of $1/2$ that one player is using s_1 while the other is using s_2; in other words, there is one chance in two that players end up playing the asymmetric game with the strategy pair (s_1, s_2).

Therefore, one approach to the symmetric problem would be to have the players randomizing over a set of pure strategies carefully chosen to ensure that in the event where they are actually using different *pure* strategies, their expected meeting time is the least possible. We don't expect to solve the symmetric problem in this way, but this approach enables us to make good use of any result in the asymmetric case and to derive some general upper bounds on the symmetric rendezvous value.

Motivated by these remarks, we consider a mixed strategy where, for every period of $3D$ units of time, the players randomize between the strategies f_1 and f_2. More precisely, the strategy proceeds as follows: once and for all, pick a number p in [0, 1]; then, independently every $3D$ cycle, pick either direction to call forward equiprobably, and over the $3D$ units of time period of the cycle move forward by either using f_1 with probability p or using f_2 with probability $1 - p$. So p is picked once, and the forward direction is picked independently every $3D$ cycle.

Suppose that player II is placed at a distance x from player I, where x is drawn from the bounded distribution F. Let T^* be the expected meeting time achieved by this strategy. Because of the symmetry of the situation, we can carry out the calculations by assuming that player II is initially placed at $-x$.

Let A_{kl} represent the expected meeting time if players move in the same direction, with player I using f_l and player II using f_k. Because of the symmetry of the situation, we can carry out the calculations by assuming that player I begins by moving to the left. We have that

$$A = \begin{bmatrix} T^* + 3D & D/2 + x/2 \\ 5D/2 + x/2 & T^* + 3D \end{bmatrix}.$$

Similarly, let B_{kl} be the expected meeting time if the players move away from each other:

$$B = \begin{bmatrix} 2D + x/2 & 3D/2 + x/2 \\ 3D/2 + x/2 & D + x/2 \end{bmatrix}.$$

Finally, it is clear that if players move toward each other, they meet in time $x/2$, and therefore

$$\hat{T}(f_k, f_l) = \int_0^\infty \frac{1}{4}(x/2 + 2A_{kl} + B_{kl})\, dF(x).$$

Writing $p_1 = p$ and $p_2 = 1 - p$, T^* satisfies the equation

$$T^* = \sum_{1 \le k,l \le 2} p_k p_l \hat{T}(f_k, f_l).$$

Solving for T^* we obtain

$$T^*(p) = \frac{6p^2 - 5p + 7}{-4p^2 + 4p + 2} D + \mu/2 \quad \forall p \in [0, 1].$$

This provides us with a general upper bound on the symmetric rendezvous value of the form $\alpha(p)D + \mu/2$. It is easy to see that for $p \in (1/2, 3/7)$, $\alpha(p)$ is strictly less than 2, and therefore one can find a general upper bound of the form $\alpha D + \beta\mu$ better than $2D + \mu/2$.

The attractiveness of this approach lies in that it establishes a relation between the symmetric and the asymmetric case. If we actually minimize $\alpha(p)$ over p, we find that $T^*_{\text{opt}} \approx 1.99404D + \mu/2$. Therefore, the improvement achieved here is not really substantial. We leave for the next section the task of significantly improving Alpern's general upper bound.

3. A better estimate.

PROPOSITION 1. *For any bounded distribution F,*

$$R^s(F) \le 1.78388D + \mu/2.$$

Proof. The two trajectories considered in the previous section have the feature that if the players don't meet by time $3D$, then their distance at time $3D$ is the same as the initial distance.

Suppose that we restrict ourselves to a set of strategies which have this feature, and let the players randomize over this carefully chosen subset. The calculations can then be carried out in the same way as in the above section.

We introduce the following trajectories, defined on $[0, 3D]$:

$$\begin{cases} f_1 = 2F4B, \\ f_2 = 1F3B2F, \\ f_3 = 1F2B1F2B, \\ f_4 = 1F1B1F3B. \end{cases}$$

For example, $1F2B1F2B$ stands for *one step forward, two steps backward, one step forward, two steps backward*: pick either direction to call forward equiprobably; go a distance $D/2$ forward at unit speed; then go a distance $2D/2$ backward at unit speed; then go a distance $D/2$ forward at unit speed; then go a distance $2D/2$ backward at unit speed. More formally we have, for example,

$$1F2B1F2B(t) = \begin{cases} t & \text{if } 0 \le t \le D/2, \\ D - t & \text{if } D/2 \le t \le 3D/2, \\ t - 2D & \text{if } 3D/2 \le t \le 2D, \\ 2D - t & \text{if } 2D \le t \le 3D. \end{cases}$$

Figure 1 shows how the four trajectories appear when position as a function of time is plotted. (Note that a change in the direction labelled forward corresponds to reflection with respect to the horizontal axis.)

The set $\{f_1, f_2, f_3, f_4\}$ has the feature stated above, and we have that

$$A = \begin{bmatrix} T^* + 3D & D/2 + x/2 & D/2 + x/2 & D/2 + x/2 \\ 5D/2 + x/2 & T^* + 3D & 5D/2 + x/2 & 5D/2 + x/2 \\ T^* + 3D & 3D/2 + x/2 & T^* + 3D & T^* + 3D \\ T^* + 3D & D + x/2 & D + x/2 & T^* + 3D \end{bmatrix}$$

and

$$B = \begin{bmatrix} 2D + x/2 & 3D + x/2 & 2D + x/2 & 2D + x/2 \\ 3D/2 + x/2 & D + x/2 & D + x/2 & 3D2 + x/2 \\ 2D + x/2 & D + x/2 & D + x/2 & 2D + x/2 \\ 2D + x/2 & 3D/2 + x/2 & 2D + x/2 & 2D + x/2 \end{bmatrix},$$

and therefore

$$\hat{T}(f_k, f_l) = \int_0^\infty \frac{1}{4}(x/2 + 2A_{kl} + B_{kl})\, dF(x).$$

Suppose that players choose a probability distribution (p_1, p_2, p_3, p_4), and for each $3D$ units of time, follow f_i with probability p_i. T^* is then the solution of the equation

$$T^* = \sum_{1 \le k, l \le 4} p_k p_l \hat{T}(f_k, f_l).$$

Solving for T^* we obtain, for a given set of probabilities $(p_1, p_2, p_3, 1 - \sum_{1 \le k \le 3} p_k)$,

$$T^*(p_1, p_2, p_3) = \alpha(p_1, p_2, p_3)D + \mu/2,$$

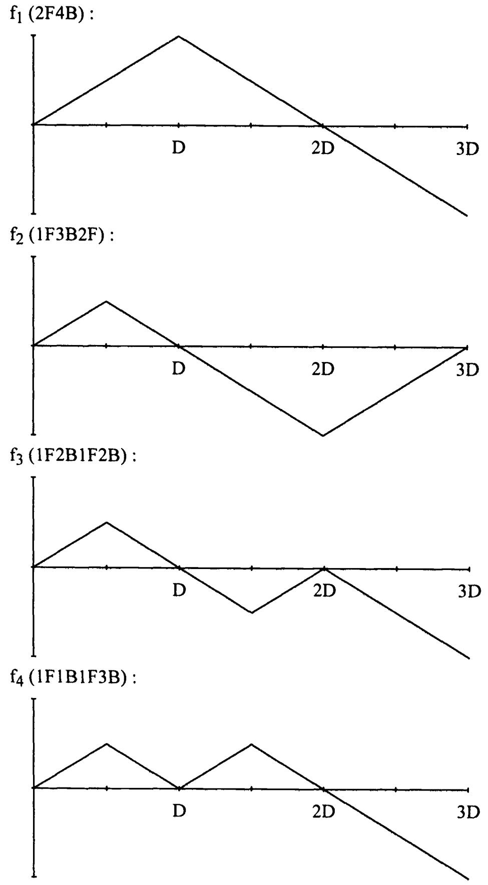

FIG. 1. *Four trajectories for the rendezvous search.*

where

$$(1)\quad \alpha(p_1,p_2,p_3)=\frac{-8+4p_1-3p_1^2+6p_2-4p_1p_2-5p_2^2+5p_3-4p_1p_3-4p_2p_3-5p_3^2}{2(-1-p_1+p_1^2-2p_2+p_1p_2+2p_2^2-p_3+p_1p_3+p_2p_3+p_3^2)}.$$

Taking $p_1 = 0.227917$, $p_2 = 0.404018$, and $p_3 = 0.212053$ and substituting these values in (1), we find that $\alpha(p_1,p_2,p_3) \approx 1.78388$, and this proves the result. We actually used Mathematica to minimize $\alpha(p_1,p_2,p_3)$ subject to the constraints $0 \le p_i \le 1$. The values of the p_i determine a (local) minimum. □

A particular simple version of the rendezvous linear search problem is when the two players know the initial distance (say, 1) between them but neither knows the direction of the other. In this case F is a point distribution and $D_F = \mu_F = 1$, so the above estimate gives $R^s \le 2.28388$. This refutes a conjecture by Alpern [Alp] that the rendezvous value for this problem is $5/2$.

OPTIMAL PROGRAMS ON INFINITE HORIZON 1*

A. J. ZASLAVSKI†

Abstract. We consider the limit behavior, as $N \to \infty$, of the expression $\sum_{i=0}^{N-1} v(x_i, x_{i+1})$ for programs $\{x_i\}_{i=0}^{\infty}$ in a compact metric space K where v is a real-valued function defined on $K \times K$. We study the structure of (v)-good programs and establish the existence of a G_δ set F in $\mathbf{C}(K \times K)$ such that, for each $u \in F$, all (u)-good programs have the same limit points set and also, for every $x \in K$, there exists a (u)-optimal program $\{x_i\}_{i=0}^{\infty}$ satisfying $x_0 = x$.

Key words. good program, minimal-energy configuration, overtaking optimality, (v)-weakly optimal program

AMS subject classification. 49J99

Introduction. In this paper we consider the infinite-horizon problem of minimizing the expression $\sum_{i=0}^{N-1} v(x_i, x_{i+1})$ as N grows to infinity, where $\{x_i\}_{i=0}^{\infty}$ is a sequence in a compact metric space K and v is a continuous function defined on $K \times K$. This provides a convenient setting for the study of various optimization problems, e.g., continuous-time control systems which are represented by ordinary differential equations whose cost integrand contains a discounting factor [1], the infinite-horizon deterministic control problem of minimizing $\int_0^T L(z, \dot{z})\,dt$ as $T \to \infty$ [2], the analysis of a long slender bar of a polymeric material under tension [3], and the analysis of an infinite discrete model for crystals which undergo phase transitions [4], [5].

The continuous-time case can be reduced to this framework in the following manner. A control system is operating on an infinite-time interval $[0, \infty)$. We choose a sampling time interval, say, $[0, T]$. For any action that steers the state $x \in K$ at time $t = 0$ to state $y \in K$ at time $t = T$, there is an associated cost. The value $v(x, y)$ is the minimal cost possible. Any choice of a control generates a trajectory, say, $x(t)$, and we will refer to $z_k = x(kT)$ as a program. If the control action is chosen in an optimal way on finite intervals, the cost of the program $\{z_k\}$ at time $t = NT$ is $\sum_{i=0}^{N-1} v(z_i, z_{i+1})$.

A hidden assumption is that $v(x, y)$ is finitely defined on $K \times K$, namely, a controllability-type assumption. Another assumption is that v is time invariant; therefore, the original control problem is, in general, either stationary or T-periodic. The continuity of v holds for many problems. The same is true for the compactness assumption; namely, in many examples one can show that all the reasonable solutions occur in a prescribed compact set.

Let K be a compact metric space, $\mathbf{R}^n$ be the Euclidean n-dimensional space, $\mathbf{C}(K \times K)$ be the space of all continuous functions $v : K \times K \to \mathbf{R}^1$ with the topology of the uniform convergence ($\|v\| = \sup\{|v(x, y)| : x, y \in K\}$). Let $\mathbf{C}(K)$ be the space of all continuous functions $v : K \to \mathbf{R}^1$ with the topology of the uniform convergence ($\|v\| = \sup\{|v(x)| : x \in K\}$) and $B(K \times K)$ be the set of all bounded and lower semicontinuous functions $v : K \times K \to \mathbf{R}^1$ (i.e., $v(\lim(x_k, y_k)) \le \liminf v(x_k, y_k)$).

Consider any $v \in B(K \times K)$. We are interested in the limit behavior as $N \to \infty$ of the expression $\sum_{i=0}^{N-1} v(x_i, x_{i+1})$, where $\{x_i\}_{i=0}^{\infty}$ is an infinite sequence in K which we call a *program* (or a *configuration*) (see [1], [4], [5]) and which occasionally will be denoted by a boldface $\mathbf{x}$. (Similarly $\{y_i\}_{i=0}^{\infty}$ will be denoted by $\mathbf{y}$, etc.) A finite sequence $\{x_i\}_{i=0}^{N} \subset K$ $(N = 0, 1, \ldots)$ will be also called a program. We shall define three concepts of optimality.

A program $\{x_i\}_{i=0}^{\infty}$ is a (v)-*overtaking optimal program* if for every program $\{z_i\}_{i=0}^{\infty}$ satisfying $z_0 = x_0$ the following inequality holds:

$$\limsup_{N\to\infty} \sum_{i=0}^{N-1} [v(x_i, x_{i+1}) - v(z_i, z_{i+1})] \leq 0.$$

This notion, known as the *overtaking optimality criterion*, was introduced in the economic literature by Gale [6] and von Weizsäcker [7] and was employed to study the infinite-horizon control problems [1], [8]–[10].

A program $\{x_i\}_{i=0}^{\infty}$ is (v)-*weakly optimal* [1], [6], [7] if for every program $\{z_i\}_{i=0}^{\infty}$ satisfying $z_0 = x_0$ the following inequality holds:

$$\liminf_{N\to\infty} \sum_{i=0}^{N-1} [v(x_i, x_{i+1}) - v(z_i, z_{i+1})] \leq 0.$$

A sequence $\{x_i\}_{i=-\infty}^{\infty} \subset K$ is called a (v)-*minimal energy configuration* (*program*) if for each N, $M > 0$ the inequality

$$\sum_{i=-N}^{M-1} v(x_i, x_{i+1}) \leq \sum_{i=-N}^{M-1} v(z_i, z_{i+1})$$

holds for every sequence $\{z_i\}_{i=-N}^{M} \subset K$ satisfying $x_{-N} = z_{-N}$, $x_M = z_M$ [3]–[5].

Of special interest is the *minimal long-run average cost growth rate*,

$$\mu(v) = \inf \left\{ \liminf_{N\to\infty} N^{-1} \sum_{i=0}^{N-1} v(z_i, z_{i+1}) : \{z_i\}_{i=0}^{\infty} \text{is a program} \right\}.$$

A program $\{z_i\}_{i=0}^{\infty}$ is called a (v)-*good program* [1] if the sequence $\{\sum_{i=0}^{N-1} [v(z_i, z_{i+1}) - \mu(v)]\}_{N=1}^{\infty}$ is bounded. It was proved in [1] that for every program $\{z_i\}_{i=0}^{\infty}$ the sequence $\{\sum_{i=0}^{N-1} [v(z_i, z_{i+1}) - \mu(v)]\}_{N=1}^{\infty}$ either is bounded or diverges to infinity and that for every initial value z there is a (v)-good program $\{z_i\}_{i=0}^{\infty}$ satisfying $z_0 = z$. In [1] the following representation formula valid for every $v \in \mathbf{C}(K \times K)$ was also established:

$$v(x,y) = \theta^v(x,y) + \mu(v) - \pi^v(y) + \pi^v(x) \quad (x, y \in K),$$

where π^v, θ^v are continuous functions, θ^v is nonnegative, and $E(x) = \{y \in K : \theta^v(x,y) = 0\}$ is nonempty for every $x \in K$. (π^v, θ^v are calculated directly through v and $\mu(v)$.)

In this paper we study the structure of (v)-good programs and establish for a generic $v \in \mathbf{C}(K \times K)$, for every given $x \in K$, the existence of (v)-optimal program $\{x_i\}_{i=0}^{\infty}$ satisfying $x_0 = x$. For the latter subject we should choose a proper optimality criterion. In spite of the example $v \in C([-1,1] \times [-1,1])$ given in [1] which demonstrates the nonexistence of (v)-weakly optimal programs, the notion of (v)-weak optimality is the most suitable one to meet our goal when we consider generic functions $v \in \mathbf{C}(K \times K)$.

We establish the existence of a set $F \subset \mathbf{C}(K \times K)$ which is a countable intersection of open everywhere dense sets in $\mathbf{C}(K \times K)$ such that for every $u \in F$ the following propositions hold:

a) There exist closed sets $H(u) \subset K \times K$, $H_0(u) \subset K$ such that for every (u)-good program $\{x_i\}_{i=0}^{\infty}$ the limit points set of $\{x_i\}_{i=0}^{\infty}$ is $H_0(u)$ and the limit points set of $\{(x_i, x_{i+1})\}_{i=0}^{\infty}$ is $H(u)$.

b) The set $H(u)$ is approximated by finite periodic programs.

c) For every initial point $x \in K$ there exists a (u)-weakly optimal program $\{x_i\}_{i=0}^{\infty}$ satisfying $x_0 = x$, $\theta^u(x_i, x_{i+1}) = 0$ $(i = 0, 1, \ldots)$.

The paper is organized as follows. In §1 we give the necessary definitions and state precisely our results. In §2 we prove the preliminary lemmas and develop the suitable technique which is used in §3 to prove the theorems. Two examples are given in §4: one concerning the nonexistence of a (v)-overtaking optimal program for each v belonging to some open set $D \subset C([0,1] \times [0,1])$ and the other showing the existence of a (v)-weakly optimal program $\{x_i\}_{i=0}^{\infty}$ for which the relation $\theta^v(x_i, x_{i+1}) = 0$ $(i = 0, 1, \ldots)$ does not hold.

1. Definitions and theorems. Let K be a compact metric space, $v \in B(K \times K)$. We define

$$(1.1)\qquad a(v) = \sup\{v(x,y) : x, y \in K\}, \qquad b(v) = \inf\{v(x,y) : x, y \in K\},$$

$$(1.2)\qquad \mu(v) = \inf\left\{\liminf N^{-1} \sum_{i=0}^{N-1} v(z_i, z_{i+1}) : \{z_i\}_{i=0}^{\infty} \text{ is a program}\right\},$$

(1.3)

$$\lambda(N, v) = \min\left\{N^{-1} \sum_{i=0}^{N-1} v(z_i, z_{i+1}) : \{z_i\}_{i=0}^{N} \subset K,\ z_0 = z_N\right\} \qquad (N = 1, 2, \ldots),$$

$$(1.4)\quad \rho(N, v) = \min\left\{N^{-1} \sum_{i=0}^{N-1} v(z_i, z_{i+1}) : \{z_i\}_{i=0}^{N} \subset K\right\} \qquad (N = 1, 2, \ldots).$$

The following two results established in [1] are very useful in the study of infinite-horizon control problems. They were mentioned and explained in the introduction, but we need their exact formulations.

THEOREM 1 [1]. 1. $\rho(N, v) \le \mu(v) \le \lambda(N, v)$, $N(\lambda(N, v) - \rho(N, v)) \le a(v) - b(v)$ $(N = 1, 2, \ldots)$.

2. *For every program* $\{z_i\}_{i=0}^{\infty}$

$$\sum_{i=0}^{N-1} [v(z_i, z_{i+1}) - \mu(v)] \ge b(v) - a(v) \qquad (N = 1, 2, \ldots).$$

3. *For every program* $\{z_i\}_{i=0}^{\infty}$ *the sequence* $\{\sum_{i=0}^{N-1} [v(z_i, z_{i+1}) - \mu(v)]\}_{N=1}^{\infty}$ *either is bounded or diverges to infinity.*

4. *For every initial value* z_0 *there is a program* $\{z_i\}_{i=0}^{\infty}$ *which satisfies*

$$\left|\sum_{i=0}^{N} [v(z_i, z_{i+1}) - \mu(v)]\right| \le 4|a(v) - b(v)| \qquad (N = 1, 2, \ldots).$$

THEOREM 2 [1]. *Let* $v \in \mathbf{C}(K \times K)$, *and define*

$$(1.5)\qquad \pi^v(x) = \inf\left\{\liminf \sum_{i=0}^{N-1} [v(z_i, z_{i+1}) - \mu(v)] : z \subset K,\ z_0 = x\right\},$$

$$\theta^v(x,y) = v(x,y) - \mu(v) + \pi^v(y) - \pi^v(x) \tag{1.6}$$

for x, $y \in K$. Then π^v, θ^v are continuous functions, θ^v is nonnegative, and

$$E(x) = \{y \in K : \theta^v(x,y) = 0\}$$

is nonempty for every $x \in K$.

In [1] these theorems were established when K was a compact in $\mathbf{R}^n$, but their proofs remain in force also when K is a compact metric space.

For a program $\mathbf{x}$ we denote by $\omega(\mathbf{x})$ the set of all points $z \in K$ such that some subsequence $\{x_{i_k}\}_{k=1}^{\infty}$ converges to z and by $\Omega(\mathbf{x})$ the set of all points $(z_1, z_2) \in K \times K$ such that some subsequence $\{(x_{i_k}, x_{i_k+1})\}_{k=1}^{\infty}$ converges to (z_1, z_2). Denote by $d(x,y)$ $(x, y \in K)$ the metric in K, and define the metric d_1 on $K \times K$ by

$$d_1((x_1,x_2),\ (y_1,y_2)) = d(x_1,y_1) + d(x_2,y_2)\ (x_1,x_2,y_1,y_2 \in K).$$

We denote $d(x,B) = \inf\{d(x,y) : y \in B\}$ for $x \in K$, $B \subset K$ and

$$d_1((x_1,x_2),A) = \inf\{d_1((x_1,x_2),\ (y_1,y_2)) : (y_1,y_2) \in A\}$$

for $(x_1,x_2) \in K \times K$ and $A \subset K \times K$.

Denote the Hausdorff metric for two sets $A \subset K$ and $B \subset K$ by $\operatorname{dist}(A,B)$ and the cardinality of a set A by $\operatorname{Card}(A)$.

A sequence $\{x_i\}_{i=-\infty}^{\infty} \subset K$ is called *almost periodic* if for every $\varepsilon > 0$ there exists an integer $m \geq 1$ such that the relation $d(x_i, x_{i+pm}) \leq \varepsilon$ holds for any i and any p.

A program $\{x_i\}_{i=0}^{\infty}$ is called *asymptotic almost periodic* if for every $\varepsilon > 0$ there exist integers $k \geq 1$, $m \geq 1$ such that $d(x_i, x_{i+mj}) \leq \varepsilon$ for any $i \geq k$ and any $j \geq 1$.

In this paper we prove the existence of a set $F \subset \mathbf{C}(K \times K)$ which is a countable intersection of open everywhere dense sets in $\mathbf{C}(K \times K)$ and for which the following theorems are valid.

THEOREM 3. 1. *For every $u \in F$ there are closed sets $H(u) \subset K \times K$, $H_0(u) \subset K$ such that for every (u)-good program $\mathbf{x}$ we have*

$$H(u) = \Omega(\mathbf{x}), \qquad H_0(u) = \omega(\mathbf{x}).$$

2. *Let $u \in F$. Then every (u)-good program $\mathbf{x}$ is asymptotic almost periodic.*

3. *Let $u \in F$ and δ be a positive number. Then there is a neighborhood $W(u)$ of u in $\mathbf{C}(K \times K)$ such that for every $w \in W(u)$ for every (w)-good program $\mathbf{x}$ we have* $\operatorname{dist}(H(u), \Omega(\mathbf{x})) \leq \delta$.

Assertion 1 of Theorem 3 establishes that for $u \in F$ all the sequences $\{(x_i, x_{i+1})\}_{i=0}^{\infty}$, where $\{x_i\}_{i=0}^{\infty}$ is a (u)-good program, have the same limit points set denoted by $H(u)$. Assertion 2 means that for $u \in F$ every (u)-good program is asymptotic almost periodic, and assertion 3 of Theorem 3 shows that for every w belonging to a small neighborhood of u, for every (w)-good program $\mathbf{x}$ the set $\Omega(\mathbf{x})$ is close enough to $H(u)$ in the Hausdorff metric (here $u \in F$). If we think of $H(u)$ as an analogue of a turnpike set (see [11], [12]), assertion 3 means stability of the turnpike phenomena.

THEOREM 4. *Let $u \in F$, $\{x_i\}_{i=0}^{\infty}$ be a program such that $\theta^u(x_i, x_{i+1}) = 0$ $(i = 0, 1, \ldots)$. Then $\{x_i\}_{i=0}^{\infty}$ is a (u)-weakly optimal program. Moreover, there exists a subsequence $\{x_{i_k}\}_{k=1}^{\infty}$ such that for every program $\{y_i\}_{i=0}^{\infty}$ satisfying $y_0 = x_0$ the inequality*

$$\liminf_{k \to \infty} \sum_{j=0}^{i_k - 1} [u(y_j, y_{j+1}) - u(x_j, x_{j+1})] \geq 0$$

holds, and if for some program $\{y_i\}_{i=0}^{\infty}$ *satisfying* $y_0 = x_0$,

$$\liminf_{k\to\infty} \sum_{j=0}^{i_k-1} [u(y_j, y_{j+1}) - u(x_j, x_{j+1})] = 0,$$

then $\theta^u(y_j, y_{j+1}) = 0\,(j = 0, 1, \ldots)$.

Theorem 4 establishes that for every $u \in F$, for every initial value $x \in K$, there exists a (u)-weakly optimal program $\{x_i\}_{i=0}^{\infty}$ satisfying $x_0 = x$, $\theta^u(x_i, x_{i+1}) = 0\,(i = 0, 1, \ldots)$. This theorem also implies that if $u \in F$ and $\{y_i\}_{i=0}^{\infty}$ is a (u)-overtaking optimal program, then $\theta^u(y_i, y_{i+1}) = 0\,(i = 0, 1, \ldots)$.

In [1] an example of $v \in C([-1, 1] \times [-1, 1])$ which demonstrates the nonexistence of (v)-weakly optimal programs was given. Here we will give an example of an open set $D \subset C([0, 1] \times [0, 1])$ such that for every $v \in D$ there is not any (v)-overtaking optimal program. We will also give an example of $v \in C([0, 1] \times [0, 1])$ for which there exist a (v)-weakly optimal program $\{x_i\}_{i=0}^{\infty}$ and a (v)-minimal energy configuration $\{y_i\}_{i=-\infty}^{\infty}$ such that

$$\sup\{\theta^v(x_i, x_{i+1}) : i = 0, 1, \ldots\} > 0, \qquad \theta^v(y_0, y_1) > 0.$$

2. Preliminary lemmas.

LEMMA 1. *Let* $u \in \mathbf{C}(K \times K)$, $r > 0$. *Then there exist a nonnegative function* $\theta \in \mathbf{C}(K \times K)$, *an integer* $m \geq 1$, *and a sequence* $\{x_i\}_{i=0}^{m} \subset K$ *such that* $x_0 = x_m$, $\theta(x_i, x_{i+1}) = 0\,(i = 0, \ldots, m-1)$, $\|v - u\| \leq r$, *where* $v(x, y) = \mu(u) + \pi^u(x) - \pi^u(y) + \theta(x, y)(x, y \in K)$.

Proof. The uniform continuity of θ^u on $K \times K$ implies the existence of a number $\delta > 0$ such that $|\theta^u(x_1, x_2) - \theta^u(y_1, y_2)| \leq 2^{-1}r$ for each (x_1, x_2) and $(y_1, y_2) \in K \times K$ satisfying $d_1((x_1, x_2), (y_1, y_2)) \leq 2\delta$. We consider a program $\{y_i\}_{i=0}^{\infty}$ such that $\theta^u(y_i, y_{i+1}) = 0\,(i = 0, 1, \ldots)$. It is easy to see that there exist $i \in \{0, 1, \ldots\}$ and $m \in \{1, 2, \ldots\}$ for which $d(y_i, y_{i+m}) < 2^{-1}\delta$. Without loss of generality, suppose that $i = 0$. There exists a continuous function $F : K \times K \to [0, 1]$ such that $F(y_{m-1}, y_0) = 0$, $F(y, z) = 1$ for y, $z \in K$, satisfying $d_1((y, z), (y_{m-1}, y_0)) \geq 3 \cdot 4^{-1}\delta$. We define $\theta(x, y) = \theta^u(x, y)F(x, y)\,(x, y \in K)$, $x_i = y_i\,(i = 0, \ldots, m-1)$, $x_m = y_0$. To complete the proof we should note only that $\|\theta - \theta^u\| \leq r$.

LEMMA 2. *Let* $u \in \mathbf{C}(K \times K)$, $r > 0$. *Then there are an integer* $m \geq 1$, *a sequence* $\{x_i\}_{i=0}^{m} \subset K$, *and a nonnegative function* $\theta \in \mathbf{C}(K \times K)$ *such that*

1. *for integers* i, j *satisfying* $0 \leq i < j \leq m$ *the equality* $x_i = x_j$ *holds if and only if* $i = 0$, $j = m$;
2. *for* x, $y \in K$ *the equality* $\theta(x, y) = 0$ *holds if and only if*

$$(x, y) \in \{(x_i, x_{i+1}) : i = 0, \ldots, m-1\};$$

3. $\|v - u\| \leq r$, *where*

$$v(x, y) = \mu(u) + \pi^u(x) - \pi^u(y) + \theta(x, y) \qquad (x, y \in K).$$

Proof. By Lemma 1, there exist a nonnegative function $\theta_1 \in \mathbf{C}(K \times K)$, an integer $m \geq 1$, and a sequence $\{x_i\}_{i=0}^{m} \subset K$ such that $x_0 = x_m$, $\theta_1(x_i, x_{i+1}) = 0\,(i = 0, \ldots, m-1)$, $\|\theta^u - \theta_1\| \leq 2^{-1}r$. Without loss of generality, we suppose that for integers i, j satisfying $0 \leq i < j \leq m$ the equality $x_i = x_j$ holds if and only if $i = 0$, $j = m$. Define

$$\phi(x, y) = \prod_{i=0}^{m-1} d_1((x, y), (x_i, x_{i+1})) \qquad (x, y \in K).$$

Choose $\gamma > 0$ for which $\gamma\|\phi\| \leq 4^{-1}r$, and set $\theta = \theta_1 + \gamma\phi$, $v(x,y) = \mu(u) + \pi^u(x) - \pi^u(y) + \theta(x,y)$ $(x, y \in K)$. The lemma is proved.

For a number $r > 0$ and a point x of some metric space we denote the open (closed) ball in this space which has the center x and the radius r by $B(x,r)(\bar{B}(x,r))$.

From now on in this section we consider a fixed function $v \in \mathbf{C}(K \times K)$ for which there exist an integer $m \geq 1$, a sequence $\{x_i^*\}_{i=0}^m \subset K$, a number μ, and functions $\pi \in \mathbf{C}(K)$, $\theta \in \mathbf{C}(K \times K)$ such that

1. for integers i, j satisfying $0 \leq i < j \leq m$, the equality $x_i^* = x_j^*$ holds if and only if $i = 0$, $j = m$;

2. $\|\theta\| > 0$, θ is nonnegative, and for each x and $y \in K$ the equality $\theta(x,y) = 0$ holds if and only if $(x,y) \in \{(x_i^*, x_{i+1}^*) : i = 0, \ldots, m-1\}$;

3. $v(x,y) = \mu + \pi(x) - \pi(y) + \theta(x,y)$ $(x, y \in K)$.

We denote by E the set of all such functions v. Lemma 2 implies that the set E is dense everywhere in $\mathbf{C}(K \times K)$. We define $x_i^* \in K$ for $i \in \{0, \pm 1, \ldots\} \setminus \{0, \ldots, m\}$ such that $x_{m+i}^* = x_i^*$ $(i = 0, \pm 1, \ldots)$. For every number $\delta > 0$ we define

$$C_1(\delta) = \sup\left\{\theta(x,y) : (x,y) \in \bigcup_{i=0}^{m-1} \bar{B}((x_i^*, x_{i+1}^*), \delta)\right\}, \tag{2.1}$$

$$C_2(\delta) = \inf\left\{\theta(x,y) : (x,y) \in (K \times K) \setminus \bigcup_{i=0}^{m-1} B((x_i^*, x_{i+1}^*), \delta)\right\}, \tag{2.2}$$

$$C_3(\delta) = \sup\{|\pi(x) - \pi(y)| : x, y \in K,\ d(x,y) \leq \delta\}. \tag{2.3}$$

We define

$$D_0 = 8^{-1} \inf\{d(x_i^*, x_j^*) : i, j \in \{0, \ldots, m-1\},\ i < j\} \tag{2.4}$$

(if $m = 1$, then $D_0 = +\infty$).

LEMMA 3. *Let* $\delta \in (0, D_0)$, $r \in (0, (48m)^{-1}C_2(\delta))$, $\phi \in \mathbf{C}(K \times K)$, $\|\phi\| \leq r$, $u = v + \phi$, $N \in \{1, 2, \ldots\}$, *and* $\{z_i\}_{i=0}^N$ *be a program such that for every program* $\{y_i\}_{i=0}^N$ *satisfying* $y_0 = z_0$, $y_N = z_N$ *the following relation holds*:

$$\sum_{i=0}^{N-1} u(z_i, z_{i+1}) \leq 2\|\theta\| + \sum_{i=0}^{N-1} u(y_i, y_{i+1}).$$

Let $i_0, j_0 \in \{1, 2, \ldots\}$, $0 < i_0 < j_0 < N$, $j_0 - i_0 \geq 240\|\theta\|C_2(\delta)^{-1}m$. *Then there exists an integer* $k \in \{i_0, \ldots, j_0 - 6m\}$ *for which* $d(z_{k+i}, x_i^*) \leq \delta$ $(i = 0, \ldots, 3m)$.

Proof. Assume that there exists an integer $k \in \{i_0, \ldots, j_0 - 6m\}$ for which

$$(z_j, z_{j+1}) \in \bigcup_{p=0}^{m-1} B((x_p^*, x_{p+1}^*), \delta) \qquad (j = k, \ldots, k + 4m - 1).$$

Then for every integer $j \in \{k, \ldots, k + 4m - 1\}$ there exists an integer $p(j) \in \{0, \ldots, m-1\}$ such that

$$(z_j, z_{j+1}) \in B((x_{p(j)}^*, x_{p(j)+1}^*), \delta).$$

Let $j \in \{k, \dots, k+4m-2\}$. It is easy to see that

$$d(z_{j+1}, x^*_{p(j)+1}) \le d_1((z_j, z_{j+1}), (x^*_{p(j)}, x^*_{p(j)+1})) \le \delta,$$
$$d(z_{j+1}, x^*_{p(j+1)}) \le d_1((z_{j+1}, z_{j+2}), (x^*_{p(j+1)}, x^*_{p(j+1)+1})) \le \delta,$$
$$d(x^*_{p(j)+1}, x^*_{p(j+1)}) \le 2\delta.$$

It follows from the definition of δ and D_0 (see (2.4) and the conditions of Lemma 3) that

$$x^*_{p(j)+1} = x^*_{p(j+1)} \quad \text{for all } j \in \{k, \dots, k+4m-2\}.$$

It follows from the definition of v (see condition 1) that for every integer $j \in \{k, \dots, k+4m-2\}$

$$p(j+1) = p(j) + 1 \quad \text{if } p(j) < m-1$$

and

$$p(j+1) = 0 \quad \text{if } p(j) = m-1.$$

Together with the definition of $\{x^*_i\}_{i=-\infty}^{\infty}$ and $\{p(j)\}_{j=k}^{k+4m-1}$ this implies that for every $i \in \{0, \dots, 4m-1\}$ the number $m^{-1}[p(k+i) - p(k) - i]$ is an integer and

$$(z_{k+i}, z_{k+i+1}) \in B((x^*_{p(k)+i}, x^*_{p(k)+i+1}), \delta).$$

To prove the lemma it remains now to show that there is an integer $k \in \{i_0, \dots, j_0 - 6m\}$ for which

$$(z_j, z_{j+1}) \in \bigcup_{p=0}^{m-1} B((x^*_p, x^*_{p+1}), \delta) \qquad (j = k, \dots, k+4m-1).$$

Let us assume the opposite. Then for every $k \in \{i_0, \dots, j_0 - 6m\}$ there is $j(k) \in \{k, \dots, k+4m\}$ such that

$$(z_{j(k)}, z_{j(k)+1}) \notin \bigcup_{i=0}^{m-1} B((x^*_i, x^*_{i+1}), \delta),$$

and by (2.2)

$$\theta(z_{j(k)}, z_{j(k)+1}) \ge C_2(\delta) \qquad (k \in \{i_0, \dots, j_0 - 6m\}). \tag{2.5}$$

Consider a program $\{y_i\}_{i=0}^N$ such that $y_i = z_i$ $(i \in \{0, \dots, i_0 - 1\} \cup \{j_0 + 1, \dots, N\})$, $y_i = x^*_i (i \in [i_0, j_0])$. It follows from the conditions of Lemma 3, the definition of v and $\{y_i\}_{i=0}^N$, and (2.2), (2.5) that

$$-2\|\theta\| \le \sum_{i=0}^{N-1} [u(y_i, y_{i+1}) - u(z_i, z_{i+1})] = \sum_{i=0}^{N-1} [(v+\phi)(y_i, y_{i+1}) - (v+\phi)(z_i, z_{i+1})]$$
$$= \sum_{i=0}^{N-1} [(\theta+\phi)(y_i, y_{i+1}) - (\theta+\phi)(z_i, z_{i+1})]$$
$$\le \sum_{i=i_0}^{j_0-1} [(\theta+\phi)(y_i, y_{i+1}) - (\theta+\phi)(z_i, z_{i+1})] + 2\|\theta\| + 4\|\phi\|$$

$$\begin{aligned}
&\le 2\|\theta\| + 4\|\phi\| + 2\|\phi\|(j_0 - i_0) - \sum_{i=i_0}^{j_0-1} \theta(z_i, z_{i+1}) \\
&\le 2\|\theta\| + 2\|\phi\|(2 + j_0 - i_0) - C_2(\delta)(j_0 - i_0 - 12m)(6m)^{-1} \\
&\le 3\|\theta\| + (2\|\phi\| - C_2(\delta)(12m)^{-1})(j_0 - i_0) \\
&\le 3\|\theta\| - (j_0 - i_0)C_2(\delta)(24m)^{-1} \le -7\|\theta\|.
\end{aligned}$$

The contradiction obtained proves the lemma.

For an integer $N \ge 1$, $\phi \in \mathbf{C}(K \times K)$ we define

$$\ell(\phi, N) = \inf\left\{\sum_{i=0}^{N-1} (\phi + \theta)(y_i, y_{i+1}) : \{y_i\}_{i=0}^{N} \subset K\right\}. \tag{2.6}$$

LEMMA 4. *Let $\delta \in (0, D_0)$. Then there exists a number $r > 0$ such that for every $\phi \in \mathbf{C}(K \times K)$, every integer $N \ge 1$ and every program $\{y_i\}_{i=0}^{N}$ satisfying $\|\phi\| \le r$, $\sum_{i=0}^{N-1} (\phi + \theta)(y_i, y_{i+1}) \le \ell(\phi, N) + r$, there are integers $k(1)$, $k(2)$ for which the following relations hold*:

$$d_1((y_i, y_{i+1}), (x^*_{i-N+k(1)}, x^*_{i-N+k(1)+1})) \le \delta \qquad (i \in [N - 3m, N - 1] \cap \{0, 1, \dots\}), \tag{2.7}$$

$$d_1((y_i, y_{i+1}), (x^*_{i+k(2)}, x^*_{i+k(2)+1})) \le \delta \qquad (i \in [0, \min\{3m, N - 1\}]). \tag{2.8}$$

Proof. We choose numbers $\delta_0 \in (0, \delta)$, $r > 0$ such that

$$8^{-1}C_2(\delta) \ge C_1(\delta_0), \qquad r < (4 \cdot 10^3 m\|\theta\|)^{-1} C_2(2^{-1}\delta_0) C_2(\delta_0).$$

Let $\theta \in \mathbf{C}(K \times K)$, $\|\phi\| \le r$, $N \ge 1$, $\{y_i\}_{i=0}^{N} \subset K$, and

$$\sum_{i=0}^{N-1} (\phi + \theta)(y_i, y_{i+1}) \le \ell(\phi, N) + r. \tag{2.9}$$

There are two cases:

1. $N \le 500m\|\theta\|C_2(2^{-1}\delta_0)^{-1}$;
2. $N > 500m\|\theta\|C_2(2^{-1}\delta_0)^{-1}$.

Consider the first case. Our choice of r and (2.9) imply

$$\begin{aligned}
\sum_{i=0}^{N-1} \theta(y_i, y_{i+1}) &\le \sum_{i=0}^{N-1} (\phi + \theta)(y_i, y_{i+1}) + Nr \le \ell(\phi, N) + (N + 1)r \\
&\le (N + 1)r + \sum_{i=0}^{N-1} (\phi + \theta)(x^*_i, x^*_{i+1}) \le (2N + 1)r \le 2^{-1}C_2(\delta_0),
\end{aligned}$$

$$(y_i, y_{i+1}) \in \bigcup_{j=0}^{m-1} B((x^*_j, x^*_{j+1}), \delta_0) \qquad (i = 0, \dots, N - 1).$$

Now it is easy to see that in the first case the lemma is valid.

Consider the second case. Applying Lemma 3 with $\delta = 2^{-1}\delta_0$ and r to the program $\{y_i\}_{i=0}^N$ we can easily see that there exist integers $i(1)$, $i(2) \in [0, N]$, $q(1)$, and $q(2)$ such that

(2.10)
$$3m < i(1) \le 300m\|\theta\|C_2(2^{-1}\delta_0)^{-1}, \quad d(y_{i(1)-p}, x^*_{q(1)-p}) \le 2^{-1}\delta_0 \quad (p = 0, \dots, 3m),$$

$$\begin{aligned} &N - 3m > i(2) \ge N - 300m\|\theta\|C_2(2^{-1}\delta_0)^{-1}, \\ &d(y_{i(2)+p}, x^*_{q(2)+p}) \le 2^{-1}\delta_0 \quad (p = 0, \dots, 3m). \end{aligned} \tag{2.11}$$

Consider programs $\{\bar{y}_i\}_{i=0}^N$, $\{\bar{\bar{y}}_i\}_{i=0}^N$, where

$$\begin{aligned} &\bar{y}_i = y_i \quad (i = 0, \dots, i(2) + 3m), \quad \bar{y}_i = x^*_{i-i(2)+q(2)} \quad (i = i(2) + 3m + 1, \dots, N), \\ &\bar{\bar{y}}_i = y_i \quad (i = i(1) - 3m, \dots, N), \quad \bar{\bar{y}}_i = x^*_{i-i(1)+q(1)} \quad (i = 0, \dots, i(1) - 3m - 1). \end{aligned}$$

(2.9) implies

$$\begin{aligned} -r &\le \sum_{i=0}^{N-1} [(\phi + \theta)(\bar{y}_i, \bar{y}_{i+1}) - (\phi + \theta)(y_i, y_{i+1})] \\ &\le - \sum_{i=i(2)+3m}^{N-1} \theta(y_i, y_{i+1}) + 2r(N - i(2)) + C_1(\delta_0), \end{aligned}$$

$$\sum_{i=i(2)+3m}^{N-1} \theta(y_i, y_{i+1}) \le C_1(\delta_0) + 601m\|\theta\|C_2(2^{-1}\delta_0)^{-1}r,$$

$$\begin{aligned} -r &\le \sum_{i=0}^{N-1} [(\phi + \theta)(\bar{\bar{y}}_i, \bar{\bar{y}}_{i+1}) - (\phi + \theta)(y_i, y_{i+1})] \\ &\le - \sum_{i=0}^{i(1)-3m-1} \theta(y_i, y_{i+1}) + 2ri(1) + C_1(\delta_0), \end{aligned}$$

$$\sum_{i=0}^{i(1)-3m-1} \theta(y_i, y_{i+1}) \le C_1(\delta_0) + 601m\|\theta\|C_2(2^{-1}\delta_0)^{-1}r.$$

By the choice of δ_0, r

$$\begin{aligned} &\theta(y_i, y_{i+1}) \le 3 \cdot 8^{-1}C_2(\delta), \qquad (y_i, y_{i+1}) \in \bigcup_{j=0}^{m-1} \bar{B}((x^*_j, x^*_{j+1}), \delta) \\ &(i \in \{i(2) + 3m, \dots, N - 1\} \cup \{0, \dots, i(1) - 3m - 1\}). \end{aligned}$$

The last relation and (2.10) and (2.11) imply the validity of the lemma.

LEMMA 5. *Let $\delta \in (0, D_0)$. Then there exists a number $r > 0$ such that for every $\phi \in \mathbf{C}(K \times K)$ satisfying $\|\phi\| \le r$, every integer $N \ge 1$, and every integer k there are programs $\{z_i\}_{i=0}^N$, $\{t_i\}_{i=0}^N$ for which $z_0 = x^*_k$,*

$$d_1((z_i, z_{i+1}), (x^*_{k+i}, x^*_{k+i+1})) \le \delta \qquad (i = 0, \dots, \min\{N - 1, 3m - 1\}),$$

$$(z_{N-1}, z_N) \in \bigcup_{j=0}^{m-1} \bar{B}((x_j^*, x_{j+1}^*), \delta),$$

$$t_N = x_k^*, d_1((t_{N-i-1}, t_{N-i}), \qquad (x_{k-i-1}^*, x_{k-i}^*)) \le \delta$$

$$(i = 0, \ldots, \min\{3m-1, N-1\}), \qquad (t_0, t_1) \in \bigcup_{j=0}^{m-1} \bar{B}((x_j^*, x_{j+1}^*), \delta),$$

$$\text{(2.12)} \quad \sup\left\{\sum_{i=0}^{N-1} (\phi+\theta)(z_i, z_{i+1}), \sum_{i=0}^{N-1} (\phi+\theta)(t_i, t_{i+1})\right\} \le \ell(\phi, N) + 2C_1(\delta).$$

Proof. We choose a number $r \in (0, (16m)^{-1}C_1(\delta))$ such that Lemma 4 is valid for δ, r. Let $\phi \in \mathbf{C}(K \times K)$, $\|\phi\| \le r$, N be a natural number, and k be an integer. There are two cases: 1. $N \le 4m$; 2. $N > 4m$.

Consider the first case. Let q be an integer. We define $y_i^q = x_{q+i}^*$ $(i = 0, \ldots, N)$. It is easy to see that

$$\sum_{i=0}^{N-1} (\phi+\theta)(y_i^q, y_{i+1}^q) \le \ell(\phi, N) + 2rN \le \ell(\phi, N) + C_1(\delta).$$

Set $z_i = y_i^k$, $t_i = y_i^{k-N} (i = 0, \ldots, N)$. For the first case the lemma is proved. Consider the second case. There is a program $\{y_0, \ldots, y_N\}$ such that $\sum_{i=0}^{N-1} (\phi+\theta)(y_i, y_{i+1}) = \ell(\phi, N)$. By Lemma 4 there are integers $k(1)$ and $k(2)$ such that relations (2.7) and (2.8) hold.

Define $y_i = x_{k(2)+i}^*$ $(i = -1, -2, \ldots)$, $y_{i+N} = x_{k(1)+i}^*$ $(i = 1, 2, \ldots)$. There exist $g, q \in \{1, \ldots, m\}$ such that $y_{-g} = x_k^* = y_{N+q}$. We set $z_i = y_{i-g} (i = 0, \ldots, N)$, $t_i = y_{i+q}$ $(i = 0, \ldots, N)$. To complete the proof we should only verify the validity of (2.12). By our choice of r we have

$$\sum_{i=0}^{N-1} [(\phi+\theta)(z_i, z_{i+1}) - (\phi+\theta)(y_i, y_{i+1})]$$
$$= \sum_{i=0}^{g-1} (\phi+\theta)(y_{-g+i}, y_{-g+i+1}) - \sum_{i=N-g}^{N-1} (\theta+\phi)(y_i, y_{i+1}) \le 2gr + C_1(\delta),$$

$$\sum_{i=0}^{N-1} (\theta+\phi)(z_i, z_{i+1}) \le \ell(\phi, N) + 2C_1(\delta).$$

Similarly

$$\sum_{i=0}^{N-1} [(\theta+\phi)(t_i, t_{i+1}) - (\theta+\phi)(y_i, y_{i+1})]$$
$$= \sum_{i=N}^{q+N-1} (\theta+\phi)(y_i, y_{i+1}) - \sum_{i=0}^{q-1} (\theta+\phi)(y_i, y_{i+1}) \le 2qr + C_1(\delta),$$

$$\sum_{i=0}^{N-1} (\theta+\phi)(t_i, t_{i+1}) \le \ell(\phi, N) + 2C_1(\delta).$$

The validity of relation (2.12) is proved. This completes the proof of the lemma.

LEMMA 6. *Let $\varepsilon \in (0, D_0)$. Then there exists $R > 0$ such that for every $\phi \in \mathbf{C}(K \times K)$ satisfying $\|\phi\| \le R$, every integer $N \ge 1$, and every program $\{y_i\}_{i=0}^{N}$ satisfying $\sum_{i=0}^{N-1}(\theta + \phi)(y_i, y_{i+1}) \le \ell(\phi, N) + R$ there is an integer k such that $d_1((y_i, y_{i+1}), (x^*_{k+i}, x^*_{k+i+1})) \le \varepsilon$ $(i = 0, \dots, N-1)$.*

Proof. Choose $r_0 > 0$ such that Lemma 4 holds with $\delta = \varepsilon$, $r = r_0$, and choose $\delta_0 \in (0, \varepsilon)$ such that $8C_1(\delta_0) < r_0$. We choose $R \in (0, r_0)$ such that $16mR \le C_1(\delta_0)$ and Lemma 5 holds with $\delta = \delta_0$, $r = R$. Let $\phi \in \mathbf{C}(K \times K)$, $\|\phi\| \le R$, N be a natural number, and $\{y_i\}_{i=0}^{N}$ be a program satisfying $\sum_{i=0}^{N-1}(\theta + \phi)(y_i, y_{i+1}) \le \ell(\phi, N) + R$.

We suppose that for ϕ, N, $\{y_i\}_{i=0}^{N}$ the lemma does not hold. Then there exists $q \in \{0, \dots, N-1\}$ such that $(y_q, y_{q+1}) \notin \cup_{j=0}^{m-1} \bar{B}((x^*_j, x^*_{j+1}), \varepsilon)$. Lemma 4 implies that $N - 3m > q > 3m$,

$$\sum_{i=0}^{q}(\theta + \phi)(y_i, y_{i+1}) > \ell(\phi, q+1) + r_0. \tag{2.13}$$

Lemma 5 implies the existence of programs $\{z_i\}_{i=0}^{q+1}$, $\{h_i\}_{i=0}^{N-q-1}$ such that

$$z_{q+1} = x^*_0 = h_0, \tag{2.14}$$

$$\sum_{i=0}^{q}(\theta + \phi)(z_i, z_{i+1}) \le \ell(\phi, q+1) + 2C_1(\delta_0), \tag{2.15}$$

$$\sum_{i=0}^{N-q-2}(\theta + \phi)(h_i, h_{i+1}) \le \ell(\phi, N-q-1) + 2C_1(\delta_0). \tag{2.16}$$

Consider a program $\{t_i\}_{i=0}^{N}$, where $t_i = z_i$ $(i = 0, \dots, q+1)$, $t_i = h_{i-q-1}$ $(i = q+2, \dots, N)$. Then using (2.13) and (2.15), (2.16) we have

$$\begin{aligned}
-R &\le \sum_{i=0}^{N-1}[(\theta + \phi)(t_i, t_{i+1}) - (\theta + \phi)(y_i, y_{i+1})] \\
&= \sum_{i=0}^{q}[(\theta + \phi)(z_i, z_{i+1}) - (\theta + \phi)(y_i, y_{i+1})] \\
&\quad + \sum_{i=0}^{N-q-2}(\theta + \phi)(h_i, h_{i+1}) - \sum_{i=q+1}^{N-1}(\phi + \theta)(y_i, y_{i+1}) < \ell(\phi, q+1) \\
&\quad + 2C_1(\delta_0) - (\ell(\phi, q+1) + r_0) + (\ell(\phi, N-q-1) + 2C_1(\delta_0)) \\
&\quad - \ell(\phi, N-q-1) \le 4C_1(\delta_0) - r_0, \qquad r_0 \le R + 4C_1(\delta_0) \le 5C_1(\delta_0) < r_0.
\end{aligned}$$

The obtained contradiction proves the lemma.

LEMMA 7. *Let $\varepsilon \in (0, D_0)$. Then there exists a number $r > 0$ such that for every integer $N \ge 1$, every integer k, and every $\phi \in \mathbf{C}(K \times K)$, satisfying $\|\phi\| \le r$ there is a program $\{z_i\}_{i=0}^{N}$ such that $z_0 = x^*_k$, $z_N = x^*_{k+N}$,*

$$d_1((z_i, z_{i+1}), (x^*_{k+i}, x^*_{k+i+1})) \le \varepsilon \qquad (i = 0, \dots, N-1), \tag{2.17}$$

$$\sum_{i=0}^{N-1}(\phi + \theta)(z_i, z_{i+1}) \le \ell(\phi, N) + 6C_1(\varepsilon). \tag{2.18}$$

Proof. We choose a number $r_0 > 0$ such that Lemma 6 holds for $R = r_0$ and ε. We choose numbers $\delta \in (0, \varepsilon)$, $r \in (0, r_0)$ such that $8C_1(\delta) \le r_0$, $16mr \le C_1(\delta)$, and Lemma 5 holds for r, δ. Let N be a natural number, k be an integer, $\phi \in \mathbf{C}(K \times K)$, and $\|\phi\| \le r$. The validity of Lemma 5 for r, δ implies the existence of a program $\{y_i\}_{i=0}^N$ such that $y_0 = x_k^*$,

$$d_1((y_i, y_{i+1}), (x_{k+i}^*, x_{k+i+1}^*)) \le \delta \qquad (i = 0, \dots, \min\{N-1, 3m-1\}),$$

$$(y_{N-1}, y_N) \in \bigcup_{j=0}^{m-1} \bar{B}((x_j^*, x_{j+1}^*), \delta),$$

$$\sum_{i=0}^{N-1} (\phi + \theta)(y_i, y_{i+1}) \le \ell(\phi, N) + 2C_1(\delta) \le \ell(\phi, N) + r_0. \tag{2.19}$$

The validity of Lemma 6 for $R = r_0$ and ε implies that

$$d_1((y_i, y_{i+1}), (x_{k+i}^*, x_{k+i+1}^*)) \le \varepsilon \quad \text{for}\, i = 0, \dots, N-1.$$

Now to complete the proof of the lemma we should only set $z_i = y_i$ $(i = 0, \dots, N-1)$, $z_N = x_{N+k}^*$ and note (see (2.19)) that

$$\sum_{i=0}^{N-1} (\phi + \theta)(z_i, z_{i+1}) \le \sum_{i=0}^{N-1} (\phi + \theta)(y_i, y_{i+1}) + 2r + C_1(\varepsilon)$$
$$\le \ell(\phi, N) + 2C_1(\delta) + 2r + C_1(\varepsilon) \le \ell(\phi, N) + 6C_1(\varepsilon).$$

LEMMA 8. *Let $\varepsilon_0 \in (0, D_0)$. Then there exists a number $r > 0$ such that for every $u \in \mathbf{C}(K \times K)$ satisfying $\|u - v\| \le r$ and every (u)-good program $\{z_i\}_{i=0}^\infty$ there are an integer $N > 1$ and an integer k such that*

$$d_1((z_{N+i}, z_{N+i+1}), \quad (x_{k+i}^*, x_{k+i+1}^*)) \le \varepsilon_0 \quad (i = 0, 1, \dots).$$

Proof. Choose a number $r_0 > 0$ such that Lemma 6 holds with $\varepsilon = \varepsilon_0$ and $R = r_0$, and choose $\delta \in (0, \varepsilon_0)$ and $r \in (0, r_0)$ such that $8C_1(\delta) \le r_0$, $16mr \le C_1(\delta)$, and Lemma 7 holds with $\varepsilon = \delta$ and r. Let $u \in \mathbf{C}(K \times K)$, $\|u - v\| \le r$, and $\{z_i\}_{i=0}^\infty$ be a (u)-good program. We define $\phi = u - v$. Suppose that the lemma doesn't hold for u, $\{z_i\}_{i=0}^\infty$. Then there exists a sequence of integers $\{i_k\}_{k=1}^\infty$ such that $i_1 \ge 8m$, $i_{k+1} - i_k \ge 8m$:

$$(z_{i_k}, z_{i_k+1}) \notin \bigcup_{j=0}^{m-1} \bar{B}((x_j^*, x_{j+1}^*), \varepsilon_0) \qquad (k = 1, 2, \dots). \tag{2.20}$$

Set $i_0 = -1$. Let $k \in \{0, 1, \dots\}$. Consider a program $\{z_i : i = i_k + 1, \dots, i_{k+1} + 1\}$. By (2.20) and Lemma 6, which holds for $\varepsilon = \varepsilon_0$ and $R = r_0$, we have

$$\sum_{i=i_k+1}^{i_{k+1}} (\phi + \theta)(z_i, z_{i+1}) > \ell(\phi, i_{k+1} - i_k) + r_0. \tag{2.21}$$

Using Lemma 7 with r and $\varepsilon = \delta$ we obtain a program $\{y_i\}_{i=0}^\infty$ such that $y_{i_k+1} \in \{x_j^* : j = 0, \dots, m-1\}$ $(k = 0, 1, \dots)$,

$$\sum_{i=i_k+1}^{i_{k+1}} (\theta + \phi)(y_i, y_{i+1}) \le \ell(\phi, i_{k+1} - i_k) + 6C_1(\delta) \qquad (k = 0, 1, \dots). \tag{2.22}$$

Relations (2.21) and (2.22) and Theorem 1 imply

$$\begin{aligned}
&\sum_{i=0}^{i_N} [u(z_i, z_{i+1}) - u(y_i, y_{i+1})] \\
&\quad \geq -4\|\pi\| + \sum_{i=0}^{i_N} [(\phi + \theta)(z_i, z_{i+1}) - (\theta + \phi)(y_i, y_{i+1})] \\
&\quad \geq -4\|\pi\| + \sum_{k=0}^{N-1} \sum_{i=i_k+1}^{i_{k+1}} [(\phi + \theta)(z_i, z_{i+1}) - (\theta + \phi)(y_i, y_{i+1})] \\
&\quad \geq -4\|\pi\| + N(r_0 - 6C_1(\delta)) \to \infty, \qquad N \to \infty, \\
&\sum_{i=0}^{i_N} [u(z_i, z_{i+1}) - \mu(u)] \\
&\quad = \sum_{i=0}^{i_N} [u(z_i, z_{i+1}) - u(y_i, y_{i+1})] + \sum_{i=0}^{i_N} [u(y_i, y_{i+1}) - \mu(u)] \\
&\quad \geq -4\|\pi\| + N(r_0 - 6C_1(\delta)) + b(u) - a(u) \to \infty, \qquad N \to \infty
\end{aligned}$$

But $\{z_i\}_{i=0}^{\infty}$ is a (u)-good program. The obtained contradiction proves the lemma.

3. Proof of Theorems 3 and 4. We consider the set E of all functions $v \in \mathbf{C}(K \times K)$ for which there exist an integer $m(v) \geq 1$; a sequence $\{x_i^*(v)\}_{i=0}^{m(v)} \subset K$; continuous functions $\pi_v : K \to \mathbf{R}^1$, $\theta_v : K \times K \to \mathbf{R}^1$; and a number μ_v such that the following conditions hold.

1. for i, $j \in \{0, \ldots, m(v)\}$ satisfying $i < j$ the equality $x_i^*(v) = x_j^*(v)$ holds if and only if $i = 0$, $j = m(v)$;

2. $v(x, y) = \mu_v + \pi_v(x) - \pi_v(y) + \theta_v(x, y)(x, y \in K)$;

3. $\|\theta_v\| > 0$, the function θ_v is nonnegative, and $\theta_v(x, y) = 0$ if and only if

$$(x, y) \in \{(x_i^*(v), x_{i+1}^*(v)) : i = 0, \ldots, m(v) - 1\}.$$

At the beginning of §2 we already noted that E is everywhere dense in $\mathbf{C}(K \times K)$ by Lemma 2. It is easy to see that $\mu(v) = \mu_v(v \in E)$, and for every $v \in E$ we can apply Lemmas 3–8. For every $v \in E$ and every $i \in \{0, \pm 1, \ldots\} \backslash \{0, \ldots, m(v)\}$ define $x_i^*(v) \in K$ such that $x_{i+m(v)}^*(v) = x_i^*(v)$ $(i = 0, \pm 1, \ldots)$. Let $v \in E$. We set

$$D(v) = 8^{-1} \inf \{d(x_i^*(v), x_j^*(v)) : i, j \in \{0, \ldots, m(v) - 1\},\ i \neq j\}. \tag{3.1}$$

If $m(v) = 1$, then $D(v) = +\infty$.

Let $p \in \{1, 2, \ldots\}$. We define

$$\delta(v, p) = \inf \{2^{-1} D(v), p^{-1}\}. \tag{3.2}$$

It is easy to see that there exist numbers $\Gamma(v, p) \in (0, \delta(v, p))$, $d(v, p) \in (0, \Gamma(v, p))$ such that Lemma 8 holds for

$$\varepsilon_0 = \Gamma(v, p), \quad r = d(v, p), \quad x_i^* = x_i^*(v) \quad (i = 0, \pm 1, \ldots).$$

Now we define $F = \bigcap_{p=1}^{\infty} \bigcup_{v \in E} B(v, d(v, p))$. For this set F we will prove the theorems.

Proof of Theorem 3. First we will prove that assertion 1 of Theorem 3 holds. Let $u \in F$, $\mathbf{x}, \mathbf{y}$ be (u)-good programs, $p \in \{1, 2, \ldots\}$. There is $v \in E$ such that $u \in B(v, d(v, p))$. It follows from the definition of $d(v, p)$ and $\Gamma(v, p)$ and Lemma 8 that

$$\begin{aligned} \operatorname{dist}(\Omega(\mathbf{x}), \{(x_i^*(v), x_{i+1}^*(v)) : i = 0, \ldots, m(v) - 1\}) &\le \Gamma(v, p), \\ \operatorname{dist}(\Omega(\mathbf{y}), \{(x_i^*(v), x_{i+1}^*(v)) : i = 0, \ldots, m(v) - 1\}) &\le \Gamma(v, p), \\ \operatorname{dist}(\omega(\mathbf{x}), \{x_i^*(v) : i = 0, \ldots, m(v) - 1\}) &\le \Gamma(v, p), \\ \operatorname{dist}(\omega(\mathbf{y}), \{x_i^*(v) : i = 0, \ldots, m(v) - 1\}) &\le \Gamma(v, p), \\ \operatorname{dist}(\Omega(\mathbf{x}), \Omega(\mathbf{y})) \le 2p^{-1}, \ \operatorname{dist}(\omega(\mathbf{x}), \omega(\mathbf{y})) &\le 2p^{-1}. \end{aligned}$$

This completes the proof of assertion 1.

Let us prove assertion 2. Let $u \in F$, $\varepsilon > 0$, and $\{x_i\}_{i=0}^\infty$ be a (u)-good program. Choose an integer $p \ge 1$, $v \in E$ such that $4p^{-1} < \varepsilon$, $u \in B(v, d(v, p))$. Now the validity of assertion 2 follows from the definition of $d(v, p)$, $\Gamma(v, p)$ and Lemma 8.

Now we will prove assertion 3. Let $u \in F$, $\delta > 0$. There is an integer $p \ge 1$, $v \in E$ such that $4p^{-1} < \delta$, $u \in B(v, d(v, p))$. Set $W(u) = B(v, d(v, p))$. The validity of assertion 3 follows from the definition of $d(v, p)$, $\Gamma(v, p)$ and Lemma 8.

We have the following result.

PROPOSITION 1. 1. $\sup\{\pi^u(x) : x \in H_0(u)\} = 0 \ (u \in F)$.

2. *Let $u \in F$, δ be a positive number. Then there are an integer $m \ge 1$ and a sequence $\{x_i^*\}_{i=0}^m$ such that*

$$x_0^* = x_m^*;$$

$$\textit{if } 0 \le i < j \le m, \ x_i^* = x_j^*, \ \textit{then } i = 0, \ j = m;$$

$$\operatorname{dist}(H(u), \{(x_i^*, x_{i+1}^*) : i = 0, \ldots, m - 1\}) \le \min\{\delta, 8^{-1} d(x_i, x_j) \ (0 \le i < j \le m - 1)\}.$$

Proof. It is easy to see that assertion 1 of Proposition 1 follows from Assertion 1 of Theorem 3. Let us prove Assertion 2. Let $\delta > 0$, $u \in F$. Choose an integer $p \ge 1$ satisfying $8p^{-1} < \delta$. There is $v \in E$ such that $u \in B(v, d(v, p))$. By Lemma 8, assertion 1 of Theorem 3, and our choice of $\delta(v, p)$, $\Gamma(v, p)$ we have

$$\Gamma(v, p) < \delta(v, p) \le 16^{-1} \inf\{d(x_i^*(v), x_j^*(v)) : i, j \in \{0, \ldots, m(v) - 1\}, \ i \ne j\},$$

$$\operatorname{dist}(H(u), \{(x_i^*(v), x_{i+1}^*(v)) : i = 0, \ldots, m(v) - 1\}) \le \Gamma(v, p).$$

The validity of assertion 2 follows easily from these relations.

Assertion 2 of Proposition 1 establishes that for $u \in F$ the set $H(u)$ is approximated by finite periodic programs.

Proof of Theorem 4. We will prove the following lemma first.

LEMMA 9. *Assume that $u \in \mathbf{C}(K \times K)$ and there is a closed set $H_0(u) \subset K$ such that for every (u)-good program $\{x_i\}_{i=0}^\infty$ we have $\omega(\{x_i\}_{i=0}^\infty) = H_0(u)$. Then the following assertions hold*:

1. *Let $\{x_i\}_{i=0}^\infty$ be a program satisfying $\theta^u(x_i, x_{i+1}) = 0 \ (i = 0, 1, \ldots)$. Then $\{x_i\}_{i=0}^\infty$ is a (u)-weakly optimal program and there is a subsequence $\{x_{i_k}\}_{k=1}^\infty$ such that for every program $\{y_i\}_{i=0}^\infty$ satisfying $y_0 = x_0$, the relation*

$$\liminf_{k \to \infty} \sum_{j=0}^{i_k - 1} [u(y_j, y_{j+1}) - u(x_j, x_{j+1})] \ge 0$$

holds, and moreover, if we have an equality

$$\liminf_{k\to\infty} \sum_{j=0}^{i_k-1} [u(y_j, y_{j+1}) - u(x_j, x_{j+1})] = 0,$$

then $\theta^u(y_i, y_{i+1}) = 0$ $(i = 0, 1, \ldots)$.

2. *Let* $\{x_i\}_{i=0}^{\infty}$ *be a program. Then the relation*

$$\pi^u(x_0) = \liminf \sum_{i=0}^{N-1} [u(x_i, x_{i+1}) - \mu(u)]$$

holds if and only if $\theta^u(x_i, x_{i+1}) = 0$ $(i = 0, 1, \ldots)$.

Proof. First let us prove assertion 1. There is $x^* \in H_0(u)$ satisfying $\pi^u(x^*) = \sup\{\pi^u(y)\colon y \in H_0(u)\}$. To prove the assertion we should only note that there exists a subsequence $\{x_{i_k}\}_{k=1}^{\infty}$ satisfying $x_{i_k} \xrightarrow[k\to\infty]{} x^*$.

Next we will prove assertion 2. There is $x^* \in H_0(u)$ satisfying $\pi^u(x^*) = \sup\{\pi^u(y)\colon y \in H_0(u)\}$. To prove assertion 2 we should only note that for every (u)-good program $\{x_i\}_{i=0}^{\infty}$ the following relation holds:

$$\liminf \sum_{i=0}^{N-1} [u(x_i, x_{i+1}) - \mu(u)] = \sum_{i=0}^{\infty} \theta^u(x_i, x_{i+1}) + \pi^u(x_0) - \pi^u(x^*). \tag{3.3}$$

Theorem 3 and Lemma 9 imply the validity of Theorem 4.

4. Examples. We will give an example of an open set $D \subset C([0,1] \times [0,1])$ such that for every $v \in D$ there is not any (v)-overtaking optimal program.

Example 1. Let $K = [0,1]$, $0 < x_0^* < x_1^* < 1$, $\pi\colon [0,1] \to \mathbf{R}^1$, and $\theta\colon [0,1] \times [0,1] \to \mathbf{R}^1$ be continuous functions such that θ is nonnegative, $\theta(x,y) = 0$ if and only if $(x,y) \in \{(x_0^*, x_1^*), (x_1^*, x_0^*)\}$, $\pi(x_0^*) - \pi(x_1^*) - \theta(x_0^*, x_0^*) > 0$. Set $v(x,y) = \pi(x) - \pi(y) + \theta(x,y) (x, y \in [0,1])$.

Choose numbers

$$\varepsilon \in (0, 14^{-1}[\pi(x_0^*) - \pi(x_1^*) - \theta(x_0^*, x_0^*)]), \tag{4.1}$$

$\delta \in (0, 8^{-1}|x_0^* - x_1^*|)$ such that

$$\begin{aligned} \sup\{\, &|\pi(z_1) - \pi(z_2)|, |\theta(y_1, y_2) - \theta(y_3, y_4)|\colon z_1, z_2, y_1, y_2, y_3, y_4 \\ &\in [0,1], |z_1 - z_2| \le \delta, |y_1 - y_3| \le \delta, |y_2 - y_4| \le \delta\} \le \varepsilon, \end{aligned} \tag{4.2}$$

and choose $r \in (0, \varepsilon)$ such that Lemma 8 holds for $\varepsilon_0 = \delta$, r, and v.

Let $u \in C([0,1] \times [0,1])$, $\|u - v\| \le r$, and $\phi = u - v$. We prove that there is no (u)-overtaking optimal program.

Suppose that $\{x_i\}_{i=0}^{\infty}$ is a (u)-overtaking optimal program. By Lemma 8 there exists an integer $N \ge 1$ such that

$$|x_{N+2i} - x_0^*| \le \delta, \quad |x_{N+2i+1} - x_1^*| \le \delta \quad (i = 0, 1, \ldots). \tag{4.3}$$

Consider a program $\{y_i\}_{i=0}^{\infty}$, where $y_i = x_i$ $(i = 0, \ldots, N)$, $y_{i+1} = x_i$ $(i = N, N+1, \ldots)$. For every integer $k \ge 1$ by (4.1)–(4.3) we have

$$\begin{aligned}
&\sum_{i=0}^{N+2k} [u(x_i, x_{i+1}) - u(y_i, y_{i+1})] \\
&\quad = \sum_{i=0}^{N+2k} u(x_i, x_{i+1}) \\
&\qquad - \left[\sum_{i=0}^{N-1} u(x_i, x_{i+1}) + u(x_N, x_N) + \sum_{i=N}^{N+2k-1} u(x_i, x_{i+1})\right] \\
&\quad = u(x_{N+2k}, x_{N+2k+1}) - u(x_N, x_N) \\
&\quad \geq \pi(x_{N+2k}) - \pi(x_{N+2k+1}) + \theta(x_{N+2k}, x_{N+2k+1}) - \theta(x_N, x_N) - 2r \\
&\quad \geq -2r + (\pi(x_0^*) - \varepsilon) - (\pi(x_1^*) + \varepsilon) - \theta(x_0^*, x_0^*) - \varepsilon \\
&\quad \geq \pi(x_0^*) - \pi(x_1^*) - \theta(x_0^*, x_0^*) - 3\varepsilon - 2r \\
&\quad \geq \pi(x_0^*) - \pi(x_1^*) - \theta(x_0^*, x_0^*) - 5\varepsilon \geq 6\varepsilon, \\
&\sum_{i=0}^{N+2k} [u(x_i, x_{i+1}) - u(y_i, y_{i+1})] \geq 6\varepsilon \qquad (k = 1, 2 \ldots).
\end{aligned}$$

We thus arrive at a contradiction. Hence, there is no (u)-overtaking optimal program for $u \in \bar{B}(v, r)$.

Next we will give an example of $v \in C([0,1] \times [0,1])$ for which there exist a (v)-weakly optimal program $\{x_i\}_{i=0}^{\infty}$ and a (v)-minimal energy configuration $\{y_i\}_{i=-\infty}^{\infty}$ such that $\sup\{\theta^v(x_i, x_{i+1}) : i = 0, 1, \ldots\} > 0$, $\sup\{\theta^v(y_i, y_{i+1}) : i = 0, \pm 1, \ldots\} > 0$.

Example 2. Let $K = [0,1]$, $0 < x_0^* < x_1^* < 1$, $0 < \varepsilon < 8^{-1}|x_0^* - x_1^*|$, and

$$\theta(x, y) = \min\{1, 64\varepsilon^{-4}[(x - x_0^*)^2 + (y - x_1^*)^2][(x - x_1^*)^2 + (y - x_0^*)^2]\} \\ (x, y \in [0,1]).$$

Let π: $[0,1] \to \mathbf{R}^1$ be a continuous function such that

$$\begin{aligned} &\pi(x_0^*) - \pi(x_1^*) > 1, \\ &v(x, y) = \pi(x) - \pi(y) + \theta(x, y) \qquad (x, y \in [0,1]). \end{aligned} \tag{4.4}$$

We define x_i^* for all integers $i \notin \{0, 1\}$ so that $x_{i+2}^* = x_i^*$ $(i = 0, \pm 1, \ldots)$. It is easy to see that $\mu(v) = 0$. By Lemma 8 $\omega(\mathbf{x}) = \{x_0^*, x_1^*\}$ for every (v)-good configuration $\mathbf{x}$. It is easy to verify that

$$\pi^v(x_0^*) = 0, \quad \pi^v(x_1^*) = \pi(x_1^*) - \pi(x_0^*), \quad \theta^v(x, y) = \theta(x, y)(x, y \in \{x_0^*, x_1^*\}).$$

Fix an integer $k \geq 0$ and consider a program $\mathbf{Y}^k = \{y_i^k\}_{i=0}^{\infty}$, where

$$y_i^k = x_0^* \; (i = 0, \ldots, k), \quad y_i^k = x_{i-1}^* \quad (i \text{ is an integer}, \; i \geq k + 1). \tag{4.5}$$

We shall show that $\{y_i^k\}_{i=0}^{\infty}$ is a (v)-weakly overtaking program.

Let $\mathbf{z}$ be a (v)-good program, $z_0 = x_0^*$. It is easy to see that $\Omega(\mathbf{z}) = \{(x_0^*, x_1^*), (x_1^*, x_0^*)\}$. Hence, there exists an integer $Q \geq 1$ such that

$$|z_{Q+i} - x_i^*| \leq 4^{-1}\varepsilon \qquad (i = 0, 1, \ldots). \tag{4.6}$$

There are two cases: 1. $Q = 2i + 1$ for some integer i; 2. $Q = 2i$ for some integer i. Clearly,

$$\sum_{i=0}^{2N} v(y_i^k, y_{i+1}^k) = \theta(x_k^*, x_k^*) = 1 \qquad (N > k + 1). \tag{4.7}$$

Consider case 1. There exists an integer $q \geq 0$ such that $Q = 2q + 1$. By (4.6)

$$|z_{2q+1} - x_0^*| \leq 4^{-1}\varepsilon. \tag{4.8}$$

Suppose that

$$(z_i, z_{i+1}) \in \bigcup_{j=0}^{1} \bar{B}((x_j^*, x_{j+1}^*), \varepsilon) \qquad (i = 0, \dots, 2q).$$

This relation implies that $|z_i - x_i^*| \leq \varepsilon \, (i = 0, \dots, 2q + 1)$ and we obtained a contradiction (see (4.8)). Hence, there exists $p \in \{0, \dots, 2q\}$ such that

$$(z_p, z_{p+1}) \notin \bigcup_{j=0}^{1} \bar{B}((x_j^*, x_{j+1}^*), \varepsilon).$$

It follows from the definition of θ that $\theta(z_p, z_{p+1}) = 1$. Together with (4.7) the relation $\Omega(\mathbf{z}) = \{(x_0^*, x_1^*), (x_1^*, x_0^*)\}$ implies that

$$\begin{aligned}\liminf_{N\to\infty} \sum_{i=0}^{2N} [v(z_i, z_{i+1}) - v(y_i^k, y_{i+1}^k)] &\geq \sum_{i=0}^{\infty} \theta(z_i, z_{i+1}) - 1\\ &\geq \theta(z_p, z_{p+1}) - 1 = 0,\\ \liminf_{N\to\infty} \sum_{i=0}^{2N} [v(z_i, z_{i+1}) - v(y_i^k, y_{i+1}^k)] &\geq 0.\end{aligned} \tag{4.9}$$

Consider case 2. Relation (4.6) implies that $z_{2i} \to x_0^*$, $z_{2i+1} \to x_1^*$ as $i \to \infty$,

$$\begin{aligned}&\liminf_{N\to\infty} \sum_{i=0}^{2N} [v(z_i, z_{i+1}) - v(y_i^k, y_{i+1}^k)]\\ &\geq \liminf_{N\to\infty} [\pi(x_0^*) - \pi(z_{2N+1}) - 1] = \pi(x_0^*) - \pi(x_1^*) - 1,\end{aligned}$$

and by (4.4) relation (4.9) holds also for case 2. We have proved that $\{y_i^k\}_{i=0}^{\infty}$ is a (v)-weakly overtaking program. For an integer $i < 0$ we set $y_i^k = x_i$. It is easy to see that $\{y_i^k\}_{i=-\infty}^{\infty}$ is a (v)-minimal energy configuration.

Acknowledgments. The author thanks Dr. Arie Leizarowitz for fruitful discussions.

OPTIMAL PROGRAMS ON INFINITE HORIZON 2*

A. J. ZASLAVSKI†

Abstract. We consider the limit behavior, as $N \to \infty$, of the expression $\sum_{i=0}^{N-1} v(x_i, x_{i+1})$ for programs $\{x_i\}_{i=0}^{\infty}$ in a compact metric space K, where v is a real-valued function defined on $K \times K$. We study the structure of (v)-weakly optimal programs and establish a turnpike theorem for a generic continuous function v. We also prove the existence of an almost periodic (v)-optimal program for a generic continuous function v.

Key words. good program, minimal-energy configuration, overtaking optimality, (v)-weakly optimal program

AMS subject classification. 49J99

Introduction. The study of optimization problems defined on infinite intervals has recently been a rapidly growing area of research. In this paper we are concerned with the infinite-horizon problem of minimizing the expression $\sum_{i=0}^{N-1} v(x_i, x_{i+1})$ as N grows to infinity, where $\{x_i\}_{i=0}^{\infty}$ is a sequence in a compact metric space K and v is a continuous function defined on $K \times K$. The interest in this discrete-time infinite-horizon problem stems from the recent study of various optimization problems which can be reduced to this framework, e.g., continuous-time control systems which are represented by ordinary differential equations whose cost integrand contains a discounting factor [1], the infinite-horizon deterministic control problem of minimizing $\int_0^T L(z, \dot{z})\, dt$ as $T \to \infty$ [2], and the analysis of a long slender bar of a polymeric material under tension [3].

Let K be a compact metric space, $\mathbf{R}^n$ be the Euclidean n-dimensional space, $\mathbf{C}(K \times K)$ be the space of all continuous functions $v : K \times K \to \mathbf{R}^1$ with the topology of the uniform convergence ($\|v\| = \sup\{|v(x, y)| : x, y \in K\}$). Let $\mathbf{C}(K)$ be the space of all continuous functions $v : K \to \mathbf{R}^1$ with the topology of the uniform convergence ($\|v\| = \sup\{|v(x)| : x \in K\}$) and $B(K \times K)$ be the set of all bounded and lower semicontinuous functions $v : K \times K \to \mathbf{R}^1$ (i.e., $v(\lim(x_k, y_k)) \leq \liminf v(x_k, y_k)$).

Consider any $v \in B(K \times K)$. We are interested in the limit behavior as $N \to \infty$ of the expression $\sum_{i=0}^{N-1} v(x_i, x_{i+1})$, where $\{x_i\}_{i=0}^{\infty}$ is an infinite sequence in K which we call a *program* (or a *configuration*) (see [1], [4], [5]) and which occasionally will be denoted by a boldface $\mathbf{x}$. (Similarly $\{y_i\}_{i=0}^{\infty}$ will be denoted by $\mathbf{y}$, etc.) A finite sequence $\{x_i\}_{i=0}^{N} \subset K$ $(N = 0, 1, \ldots)$ will be also called a program. We shall define three concepts of optimality.

A program $\{x_i\}_{i=0}^{\infty}$ is a (v)-*overtaking optimal program* if for every program $\{z_i\}_{i=0}^{\infty}$ satisfying $z_0 = x_0$ the following inequality holds:

$$\limsup_{N \to \infty} \sum_{i=0}^{N-1} [v(x_i, x_{i+1}) - v(z_i, z_{i+1})] \leq 0.$$

This notion known as the *overtaking optimality criterion* was introduced in the economic literature by Gale [6] and von Weizsäcker [7] and was employed to study infinite-horizon control problems [1], [8]–[10].

A program $\{x_i\}_{i=0}^{\infty}$ is (v)-weakly optimal [1], [6], [7] if for every program $\{z_i\}_{i=0}^{\infty}$

* Received by the editors October 7, 1993; accepted for publication July 8, 1994. This research was supported in part by a grant from the Israeli Ministry of Science and the MA-AGARA (a special project for the absorption of new immigrants) in the Department of Mathematics, Technion.

satisfying $z_0 = x_0$ the following inequality holds:

$$\liminf_{N\to\infty} \sum_{i=0}^{N-1} [v(x_i, x_{i+1}) - v(z_i, z_{i+1})] \le 0.$$

A sequence $\{x_i\}_{i=0}^{\infty} \subset K$ is called a (v)-*minimal energy configuration* (*program*) if for each N, $M > 0$ the inequality

$$\sum_{i=-N}^{M-1} v(x_i, x_{i+1}) \le \sum_{i=-N}^{M-1} v(z_i, z_{i+1})$$

holds for every sequence $\{z_i\}_{i=-N}^{M} \subset K$ satisfying $x_{-N} = z_{-N}$, $x_M = z_M$ [3]–[5].

Of special interest is the *minimal long-run average cost growth rate*,

$$\mu(v) = \inf\left\{\liminf_{N\to\infty} N^{-1} \sum_{i=0}^{N-1} v(z_i, z_{i+1}) : \{z_i\}_{i=0}^{\infty} \text{is a program}\right\}.$$

A program $\{z_i\}_{i=0}^{\infty}$ is called a (v)-*good program* [1] if the sequence $\{\sum_{i=0}^{N-1} [v(z_i, z_{i+1}) - \mu(v)]\}_{N=1}^{\infty}$ is bounded. It was proved in [1] that for every program $\{z_i\}_{i=0}^{\infty}$ the sequence $\{\sum_{i=0}^{N-1} [v(z_i, z_{i+1}) - \mu(v)]\}_{N=1}^{\infty}$ either is bounded or diverges to infinity and that for every initial value z there is a (v)-good program $\{z_i\}_{i=0}^{\infty}$ satisfying $z_0 = z$. In [1] the following representation formula valid for every $v \in \mathbf{C}(K \times K)$ was also established:

$$v(x, y) = \theta^v(x, y) + \mu(v) - \pi^v(y) + \pi^v(x) \qquad (x, y \in K),$$

where π^v and θ^v are continuous functions,

$$\pi^v(x) = \inf\left\{\liminf \sum_{i=0}^{N-1} [v(z_i, z_{i+1}) - \mu(v)] : \mathbf{z} \subset K,\ z_0 = x\right\},$$

θ^v is nonnegative, and $E(x) = \{y \in K : \theta^v(x, y) = 0\}$ is nonempty for every $x \in K$.

In [13] we studied the structure of (v)-good programs and proved for a generic $v \in \mathbf{C}(K \times K)$, for every given $x \in K$, the existence of a (v)-weakly optimal program $\{x_i\}_{i=0}^{\infty}$ satisfying $x_0 = x$. We established the existence of a set $F_0 \subset \mathbf{C}(K \times K)$ which is a countable intersection of open and everywhere dense sets in $\mathbf{C}(K \times K)$ such that for every $u \in F_0$ the following propositions hold:

a) there are closed sets $H(u) \subset K \times K$, $H_0(u) \subset K$ such that for every (u)-good program $\{x_i\}_{i=0}^{\infty}$ the limit points set of $\{x_i\}_{i=0}^{\infty}$ is $H_0(u)$ and the limit points set of $\{(x_i, x_{i+1})\}_{i=0}^{\infty}$ is $H(u)$;

b) the set $H(u)$ is approximated by finite periodic programs;

c) for every initial point $x \in K$ there is a (u)-weakly optimal program $\{x_i\}_{i=0}^{\infty}$ satisfying $x_0 = x$, $\theta^u(x_i, x_{i+1}) = 0 (i = 0, 1, \ldots)$.

By proposition c), programs $\{x_i\}_{i=0}^{\infty}$ satisfying $\theta^u(x_i, x_{i+1}) = 0$ $(i = 0, 1, \ldots)$ are of great interest. The existence of such a program for any initial value x_0 follows from the properties of θ^u. In this paper we will establish the existence of a set $F \subset F_0$ which is a countable intersection of sets dense open and everywhere in $\mathbf{C}(K \times K)$ such that for every $u \in F$ the following propositions hold:

d) u is a continuity point of the mapping $v \to (\mu(v), \pi^v) \in \mathbf{R}^1 \times \mathbf{C}(K)$;

e) given any $\varepsilon > 0$, there exists $\delta > 0$ such that for every program $\{x_i\}_{i=0}^{\infty}$ satisfying $\theta^u(x_i, x_{i+1}) = 0 (i = 0, 1 \ldots)$ the sequence $\{(x_i, x_{i+1})\}_{i=0}^{\infty}$ is contained in an ε-neighborhood of $H(u)$ if x_0 belongs to a δ-neighborhood of $H_0(u)$ (stability condition);

f) all the sequences $\{(x_i, x_{i+1})\}_{i=0}^{\infty} \subset K \times K$ satisfying $\theta^u(x_i, x_{i+1}) = 0\,(i = 0, 1, \ldots)$ converge uniformity to $H(u)$;

g) every sequence $\{x_i\}_{i=-\infty}^{\infty} \subset K$ satisfying $\theta^u(x_i, x_{i+1}) = 0\,(i = 0, \pm 1, \ldots)$ is almost periodic.

One can see that the set $H(u)$ $(u \in F)$ is an analogue of a turnpike set [11], [12], and we prove for it a weak turnpike theorem.

The paper is organized as follows. In §1 we give the necessary definitions and state precisely our main results. Necessary auxiliary results obtained in [13] are stated in §2. In §§3 and 4 we prove the preliminary lemmas and develop the suitable technique which is used in §5 to prove the theorems.

1. Definitions and theorems. Let K be a compact metric space, $v \in \mathbf{C}(K \times K)$. We define

$$\mu(v) = \inf\left\{\liminf N^{-1} \sum_{i=0}^{N-1} v(z_i, z_{i+1}) : \{z_i\}_{i=0}^{\infty} \text{ is a program}\right\}, \tag{1.1}$$

$$\pi^v(x) = \inf\left\{\liminf \sum_{i=0}^{N-1} [v(z_i, z_{i+1}) - \mu(v)] : \mathbf{z} \subset K,\ z_0 = x\right\}, \tag{1.2}$$

$$\theta^v(x, y) = v(x, y) - \mu(v) + \pi^v(y) - \pi^v(x) \tag{1.3}$$

for x, $y \in K$. It was proved in [1] that π^v and θ^v are continuous functions, θ^v is nonnegative, and $E(x) = \{y \in K : \theta^v(x, y) = 0\}$ is nonempty for every $x \in K$.

In [1] this result was established when K was a compact in $\mathbf{R}^n$, but its proof also remains in force when K is a compact metric space.

For a program $\mathbf{x}$ we denote by $\omega(\mathbf{x})$ the set of all points $z \in K$ such that some subsequence $\{x_{i_k}\}_{k=1}^{\infty}$ converges to z and by $\Omega(\mathbf{x})$ the set of all points $(z_1, z_2) \in K \times K$ such that some subsequence $\{(x_{i_k}, x_{i_k+1})\}_{k=1}^{\infty}$ converges to (z_1, z_2). Denote the metric in K by $d(x, y)$ $(x, y \in K)$, and define the metric d_1 on $K \times K$ by

$$d_1((x_1, x_2), (y_1, y_2)) = d(x_1, y_1) + d(x_2, y_2) \qquad (x_1, x_2, y_1, y_2 \in K).$$

We denote $d(x, B) = \inf\{d(x, y) : y \in B\}$ for $x \in K$, $B \subset K$, and

$$d_1((x_1, x_2), A) = \inf\{d_1((x_1, x_2), (y_1, y_2)) : (y_1, y_2) \in A\}$$

for $(x_1, x_2) \in K \times K$ and $A \subset K \times K$.

Denote the Hausdorff metric for two sets $A \subset K$ and $B \subset K$ by $\operatorname{dist}(A, B)$ and the cardinality of a set A by $\operatorname{Card}(A)$.

A sequence $\{x_i\}_{i=-\infty}^{\infty} \subset K$ is called *almost periodic* if for every $\varepsilon > 0$ there exists an integer $m \geq 1$ such that the relation $d(x_i, x_{i+pm}) \leq \varepsilon$ holds for any i and any p.

A program $\{x_i\}_{i=0}^{\infty}$ is called *asymptotic almost periodic* if for every $\varepsilon > 0$ there exist integers $k \geq 1$, $m \geq 1$, such that $d(x_i, x_{i+mj}) \leq \varepsilon$ for any $i \geq k$ and any $j \geq 1$.

For every $u \in \mathbf{C}(K \times K)$, every number $\Delta > 0$, and every integer $N \geq 1$ we define

$$A(u,N,\Delta) = \left\{ \{y_i\}_{i=0}^{N} \subset K : \text{for every sequence } \{z_i\}_{i=0}^{N} \subset K \text{ satisfying } z_0 = y_0,\ z_N = y_N \text{ the following inequality holds: } \sum_{i=0}^{N-1} [u(y_i, y_{i+1}) - u(z_i, z_{i+1})] \leq \Delta \right\}.$$

In [13] we proved the existence of a set $F_0 \subset \mathbf{C}(K \times K)$, which is a countable intersection of open everywhere dense sets in $\mathbf{C}(K \times K)$ and such that every $u \in F_0$ satisfies assertions a), b), and c) stated in the introduction. In this paper we will establish the existence of a set $F \subset F_0$ which is a countable intersection of open everywhere dense sets in $\mathbf{C}(K \times K)$ and for which the following theorems are valid.

THEOREM 1. *We define* $L : \mathbf{C}(K \times K) \to \mathbf{R}^1 \times \mathbf{C}(K) \times \mathbf{C}(K \times K)$ *by*

$$L(v) = (\mu(v), \pi^v, \theta^v)(v \in \mathbf{C}(K \times K)).$$

Then the set of continuity points of the operator L contains F.

By assertion a), for every $u \in F_0$ there exist compact sets $H(u) \subset K \times K$ and $H_0(u) \subset K$ such that $\Omega(\mathbf{x}) = H(u)$, $\omega(\mathbf{x}) = H_0(u)$ for every (u)-good program $\mathbf{x}$. Theorem 2 is an analogue of the weak turnpike theorem [9], [11], [12], showing that for $u \in F$, for every "nice" finite program $\{z_i\}_{i=0}^{N}$, the number of integers $i \in \{0, \dots N-1\}$ such that (x_i, x_{i+1}) does not belong to a fixed neighborhood of $H(u)$ is bounded by some constant which depends on the neighborhood and does not depend on N.

THEOREM 2. *Let* $u \in F$ *and* δ *be a positive number. Then there are a neighborhood* $W(u)$ *of* u *in* $\mathbf{C}(K \times K)$ *and positive numbers* Q_1, Q_2 *such that for every* $w \in W(u)$, *for every integer* $N \geq 1$, *for every number* $M > 0$ *and every program* $\{y_i\}_{i=0}^{N} \in A(w, N, M)$ *the following relation holds*:

$$\text{Card}\{i \in \{0, \dots, N-1\} : d_1((y_i, y_{i+1}), H(u)) > \delta\} \leq Q_1 + MQ_2.$$

Let $u \in F$. Theorem 3 establishes that for every w belonging to some small neighborhood of u in $\mathbf{C}(K \times K)$, for every program $\{x_i\}_{i=0}^{\infty}$ satisfying $\theta^w(x_i, x_{i+1}) = 0\,(i = 0, 1, \dots)$, the elements of the sequence $\{(x_i, x_{i+1})\}_{i=0}^{\infty}$ belong to a small neighborhood of $H(u)$ for all integers $i \geq N$, where N is a constant which depends on the neighborhoods and does not depend either on w or on x_0. In addition, for every w belonging to some small neighborhood of u in $\mathbf{C}(K \times K)$, for every program $\{x_i\}_{i=0}^{\infty}$ satisfying $\theta^w(x_i, x_{i+1}) = 0$, $(i = 0, 1, \dots)$ whose initial value belongs to some small neighborhood of $H_0(u)$, the sequence $\{(x_i, x_{i+1})\}_{i=0}^{\infty}$ is contained in a small neighborhood of $H(u)$.

Theorem 4 implies that for $w \in F$ every sequence $\{y_i\}_{i=-\infty}^{\infty}$ satisfying $\theta^w(y_i, y_{i+1}) = 0\,(i = 0, \pm 1, \dots)$ is almost periodic and shows that having any ε we can choose m (see the definition of an almost periodic program) uniformly for all w belonging to some small neighborhood of $u \in F$.

THEOREM 3. 1. *Let* $u \in F$ *and* ε *be a positive number. Then there exist a neighborhood* $W(u)$ *of* u *in* $\mathbf{C}(K \times K)$ *and* $\delta > 0$ *such that for every* $w \in W(u)$, *for every program* $\{x_i\}_{i=0}^{\infty}$ *satisfying* $\theta^w(x_i, x_{i+1}) = 0\,(i = 0, 1, \dots)$, $d(x_0, H_0(u)) \leq \delta$, *the relation* $d_1((x_i, x_{i+1}), H(u)) \leq \varepsilon$ *holds for* $i = 0, 1, \dots$.

2. *Let* $u \in F$, ε *be a positive number. Then there exist a neighborhood* $W(u)$ *of* u *in* $\mathbf{C}(K \times K)$ *and an integer* $N \geq 1$ *such that for every* $w \in W(u)$, *for every program* $\{x_i\}_{i=0}^{\infty}$ *satisfying* $\theta^w(x_i, x_{i+1}) = 0\,(i = 0, 1, \dots)$, *the following relation holds*: $d_1((x_i, x_{i+1}), H(u)) \leq \varepsilon$ (i *is an integer*, $i \geq N$).

COROLLARY 1. *Let $u \in F$, $\{x_i\}_{i=-\infty}^{\infty}$ be a program such that $\theta^u(x_i, x_{i+1}) = 0$ $(i = 0, \pm 1, \ldots)$. Then $(x_i, x_{i+1}) \in H(u)$ $(i = 0, \pm 1, \ldots)$.*

COROLLARY 2. *Let $u \in F$, $\varepsilon > 0$. Then there exists a neighborhood $W(u)$ of u in $\mathbf{C}(K \times K)$ such that for every $w \in W(u)$, for every program $\{x_i\}_{i=-\infty}^{\infty}$ satisfying $\theta^w(x_i, x_{i+1}) = 0$ $(i = 0, \pm 1, \ldots)$, the following relation holds: $d_1((x_i, x_{i+1}), H(u)) \leq \varepsilon$ $(i = 0, \pm 1, \ldots)$.*

THEOREM 4. *Let $u \in F$. Then every sequence $\{y_i\}_{i=-\infty}^{\infty}$ satisfying $\theta^u(y_i, y_{i+1}) = 0$ $(i = 0, \pm 1 \ldots)$ is almost periodic. Moreover, for every $\varepsilon > 0$ there exist a neighborhood $W(u)$ of u in $\mathbf{C}(K \times K)$ and an integer $m \geq 1$ such that for every $w \in W(u)$, for every program $\{y_i\}_{i=-\infty}^{\infty}$ satisfying $\theta^w(y_i, y_{i+1}) = 0$ $(i = 0, \pm 1, \ldots)$, the relation $d(y_i, y_{i+pm}) \leq \varepsilon$ holds for any integers i and p.*

2. Auxiliary results. We have the following result.

PROPOSITION 1 [1]. *Let $v \in \mathbf{C}(K \times K)$,*

$$\lambda(N, v) = \min \left\{ N^{-1} \sum_{i=0}^{N-1} v(z_i, z_{i+1}) : \{z_i\}_{i=0}^{N} \subset K,\ z_0 = z_N \right\},$$

$$\rho(N, v) = \min \left\{ N^{-1} \sum_{i=0}^{N-1} v(z_i, z_{i+1}) : \{z_i\}_{i=0}^{N} \subset K \right\} \qquad (N = 1, 2, \ldots).$$

Then $\rho(N, v) \leq \mu(v) \leq \lambda(N, v)$, $N(\lambda(N, v) - \rho(N, v)) \leq 2\|v\|$ $(N = 1, 2, \ldots)$, and for every program $\{z_i\}_{i=0}^{\infty}$ the sequence $\{\sum_{i=0}^{N-1} [v(z_i, z_{i+1}) - \mu(v)]\}_{N=1}^{\infty}$ either is bounded or diverges to infinity.

For a number $r > 0$ and a point x of some metric space we denote by $B(x, r)$ $(\bar{B}(x, r))$ the open (closed) ball in this space which has the center x and the radius r.

From here on in §§2–4 we consider a fixed function $v \in \mathbf{C}(K \times K)$ for which there exist an integer $m \geq 1$, a sequence $\{x_i^*\}_{i=0}^{m} \subset K$, a number μ, and functions $\pi \in \mathbf{C}(K)$, $\theta \in \mathbf{C}(K \times K)$ such that

1. for integers i, j satisfying $0 \leq i < j \leq m$ the equality $x_i^* = x_j^*$ holds if and only if $i = 0$, $j = m$;
2. $\|\theta\| > 0$, θ is nonnegative and for each x and $y \in K$ the equality $\theta(x, y) = 0$ holds if and only if $(x, y) \in \{(x_i^*, x_{i+1}^*) : i = 0, \ldots, m-1\}$;
3. $v(x, y) = \mu + \pi(x) - \pi(y) + \theta(x, y)(x, y \in K)$.

We denote by E the set of all such functions v. Lemma 2 in [13] implies that the set E is dense everywhere in $\mathbf{C}(K \times K)$. We define $x_i^* \in K$ for $i \in \{0, \pm 1, \ldots\} \backslash \{0, \ldots m\}$ such that $x_{m+i}^* = x_i^*$ $(i = 0, \pm 1, \ldots)$. For every number $\delta > 0$ we define

$$C_1(\delta) = \sup \left\{ \theta(x, y) : (x, y) \in \bigcup_{i=0}^{m-1} \bar{B}((x_i^*, x_{i+1}^*), \delta) \right\}, \tag{2.1}$$

$$C_2(\delta) = \inf \left\{ \theta(x, y) : (x, y) \in (K \times K) \backslash \bigcup_{i=0}^{m-1} B((x_i^*, x_{i+1}^*), \delta) \right\}, \tag{2.2}$$

$$C_3(\delta) = \sup \{ |\pi(x) - \pi(y)| : x, y \in K,\ d(x, y) \leq \delta \}. \tag{2.3}$$

We define

$$D_0 = 8^{-1} \inf\{d(x_i^*, x_j^*) : i, j \in \{0, \ldots, m-1\},\ i < j\} \qquad (\text{if } m = 1, \text{ then } D_0 = +\infty). \tag{2.4}$$

In order to establish Theorems 1 – 4 we need the following results, which were proved in [13].

LEMMA 1 [13, Lem. 3]. *Let $\delta \in (0, D_0)$, $r \in (0,(48m)^{-1}C_2(\delta))$, $\phi \in \mathbf{C}(K \times K)$, $\|\phi\| \le r$, $u = v + \phi$, $N \in \{1,2,\dots\}$, and $\{z_i\}_{i=0}^N$ be a program such that for every program $\{y_i\}_{i=0}^N$ satisfying $y_0 = z_0$, $y_N = z_N$, the relation $\sum_{i=0}^{N-1} u(z_i, z_{i+1}) \le 2\|\theta\| + \sum_{i=0}^{N-1} u(y_i, y_{i+1})$ holds. Let i_0, $j_0 \in \{1,2,\dots\}$, $0 < i_0 < j_0 < N$, $j_0 - i_0 \ge 240\|\theta\|C_2(\delta)^{-1}m$. Then there exists an integer $k \in \{i_0, \dots, j_0 - 6m\}$ for which $d(z_{k+i}, x_i^*) \le \delta\,(i = 0, \dots, 3m)$.*

For an integer $N \ge 1$, $\phi \in \mathbf{C}(K \times K)$ we define

$$\ell(\phi, N) = \inf\left\{ \sum_{i=0}^{N-1} (\phi + \theta)(y_i, y_{i+1}) : \{y_i\}_{i=0}^N \subset K \right\}. \tag{2.5}$$

LEMMA 2 [13, Lem. 6]. *Let $\varepsilon \in (0, D_0)$. Then there exists $R > 0$ such that for each $\phi \in \mathbf{C}(K \times K)$ satisfying $\|\phi\| \le R$, each integer $N \ge 1$, and each program $\{y_i\}_{i=0}^N$ satisfying $\sum_{i=0}^{N-1} (\theta + \phi)(y_i, y_{i+1}) \le \ell(\phi, N) + R$ there is an integer k such that $d_1((y_i, y_{i+1}), (x_{k+i}^*, x_{k+i+1}^*)) \le \varepsilon(i = 0, \dots, N-1)$.*

LEMMA 3 [13, Lem. 7]. *Let $\varepsilon \in (0, D_0)$. Then there is a number $r > 0$ such that for each integer $N \ge 1$, each integer k, and each $\phi \in \mathbf{C}(K \times K)$ satisfying $\|\phi\| \le r$ there is a program $\{z_i\}_{i=0}^N$ such that $z_0 = x_k^*$, $z_N = x_{k+N}^*$,*

$$d_1((z_i, z_{i+1}), (x_{k+i}^*, x_{k+i+1}^*)) \le \varepsilon(i = 0, \dots, N-1),$$
$$\sum_{i=0}^{N-1} (\phi + \theta)(z_i, z_{i+1}) \le \ell(\phi, N) + 6C_1(\varepsilon).$$

LEMMA 4 [13, Lem. 8]. *Let $\varepsilon_0 \in (0, D_0)$. Then there exists a number $r > 0$ such that for every $u \in \mathbf{C}(K \times K)$ satisfying $\|u - v\| \le r$, for every (u)-good program $\{z_i\}_{i=0}^\infty$, there are an integer $N > 1$ and an integer k such that*

$$d_1((z_{N+i}, z_{N+i+1}), \quad (x_{k+i}^*, x_{k+i+1}^*)) \le \varepsilon_0 \quad (i = 0, 1, \dots).$$

3. Preliminary lemmas for Theorem 2.

LEMMA 5. *Let $\Delta \in (0, D_0)$. Then there exist a number $r(\Delta) > 0$ and a integer $Q(\Delta) \ge 1$ such that for every $u \in \mathbf{C}(K \times K)$ satisfying $\|u - v\| \le r(\Delta)$, for every integer $N \ge 1$, and every program $\{y_i\}_{i=0}^N \in A(u, N, 2\|\theta\|)$ the following relation holds*:

$$\mathrm{Card}\left\{ i \in \{0, \dots, N-1\} : (y_i, y_{i+1}) \notin \bigcup_{j=0}^{m-1} \bar{B}((x_j^*, x_{j+1}^*), \Delta) \right\} \le Q(\Delta).$$

Proof. We choose positive numbers r_0, δ_1, and $r(\Delta)$ such that $r_0 < 1$, Lemma 2 holds with $\varepsilon = \Delta$ and $R = r_0$, $16\delta_1 \in (0, \Delta)$, $32C_1(2\delta_1) \le r_0$, $8r(\Delta) \in (0, \min\{\|\theta\|, r_0\})$; Lemma 1 holds with $\delta = \delta_1$ and $r = r(\Delta)\,(r(\Delta) < (48m)^{-1}C_2(\delta_1))$; and Lemma 3 holds with $\varepsilon = \delta_1$, $r = r(\Delta)$. Set

$$Q(\Delta) = \inf\{i \in \{1,2,\dots\} : i > (1 + \|\theta\|)m\|\theta\|(C_2(\delta_1)r_0)^{-1}14 \cdot 10^3\}.$$

Let $u \in \mathbf{C}(K \times K)$, $\|u - v\| \le r(\Delta)$, N be an integer, $N \ge 1$, $X = \{x_i\}_{i=0}^N \in A(u, N, 2\|\theta\|)$, and $\phi = u - v$. By Lemma 1, for each integers i_0 and j_0 such that $0 < i_0 < j_0 < N$, $j_0 - i_0 \ge 240\|\theta\|C_2(\delta_1)^{-1}m$, there exists $k \in \{i_0, \dots, j_0 - 6m\}$ such that $d(x_{k+i}, x_i^*) \le \delta_1\,(i = 0, \dots, 3m)$.

For $Y = \{y_i\}_{i=0}^{k} \subset K$ define $G(Y) = k$,

$$P(Y) = \mathrm{Card}\left\{ i \in \{0, \dots, k-1\} : (y_i, y_{i+1}) \notin \bigcup_{j=0}^{m-1} \bar{B}((x_j^*, x_{j+1}^*), \Delta) \right\}.$$

We shall say that a program $Y = \{y_i\}_{i=0}^{G(Y)}$ has a property (A) if for each integers i_0 and j_0 such that $0 < i_0 < j_0 < G(Y)$, $j_0 - i_0 \geq 240\|\theta\|C_2(\delta_1)^{-1}m$, there exists an integer $k \in \{i_0, \dots, j_0 - 3m\}$ for which $d(y_{k+i}, x_i^*) \leq \delta_1$ $(i = 0, \dots, 3m)$.

Consider a program $Y = \{y_i\}_{i=0}^{G(Y)}$ which has the property (A) and for which there is an integer $p \geq 1$ such that

$$\begin{aligned} &800m\|\theta\|C_2(\delta_1)^{-1} < p < G(Y) - 800m\|\theta\|C_2(\delta_1)^{-1}, \\ &(y_p, y_{p+1}) \notin \bigcup_{j=0}^{m-1} \bar{B}((x_j^*, x_{j+1}^*), \Delta). \end{aligned} \tag{3.1}$$

The property (A) which holds for Y implies the existence of integers g and q such that

$$\begin{aligned} &[g, g+3m] \subset [p+1, p+250m\|\theta\|C_2(\delta_1)^{-1}], \\ &[q, q+3m] \subset [p - 250m\|\theta\|C_2(\delta_1)^{-1}, p-1], \\ &d(y_{g+i}, x_i^*) \leq \delta_1, \quad d(y_{q+i}, x_i^*) \leq \delta_1 \qquad (i = 0, \dots, 3m). \end{aligned}$$

Consider a program $\Gamma(Y) = \{t_i\}_{i=0}^{G(\Gamma(Y))}$, where $G(\Gamma(Y)) = G(Y) - g + q + 3m$, $t_i = y_i$ $(i = 0, \dots, q+3m)$, $t_i = y_{i+g-q-3m}$ $(i = q+3m+1, \dots, G(\Gamma(Y)))$. Then

$$G(Y) > G(\Gamma(Y)) \geq G(Y) - 500m\|\theta\|C_2(\delta_1)^{-1}, \; P(\Gamma(Y)) < P(Y), \tag{3.2}$$

and the program $\Gamma(Y)$ has the property (A). We have

$$\begin{aligned} \sum_{i=0}^{G(\Gamma(Y))-1} [u(t_i, t_{i+1}) - \mu(u)] \leq &\sum_{i=0}^{G(Y)-1} [u(y_i, y_{i+1}) - \mu(u)] \\ &- \sum_{i=q+3m}^{g-1} (\theta + \phi)(y_i, y_{i+1}) + 2r(\Delta) + C_1(2\delta_1). \end{aligned} \tag{3.3}$$

By (3.1) and Lemma 2, which holds with $\varepsilon = \Delta$ and $R = r_0$, we have

$$\begin{aligned} \sum_{i=q+3m}^{g-1} (\theta + \phi)(y_i, y_{i+1}) &\geq \ell(\phi, g - q - 3m) + r_0 \\ &= \ell(\phi, G(Y) - G(\Gamma(Y))) + r_0, \end{aligned}$$

and by (3.3)

$$\begin{aligned} \sum_{i=0}^{G(\Gamma(Y))-1} [u(t_i, t_{i+1}) - \mu(u)] \leq &\sum_{i=0}^{G(Y)-1} [u(y_i, y_{i+1}) - \mu(u)] \\ &- \ell(\phi, G(Y) - G(\Gamma(Y))) - r_0 + 2r(\Delta) + C_1(2\delta_1). \end{aligned} \tag{3.4}$$

Consider again the program $X = \{x_i\}_{i=0}^{N}$. If there is no integer $p \geq 1$ satisfying (3.1) with $Y = X$, then $P(X) \leq 2 \cdot 10^3 m \|\theta\| C_2(\delta_1)^{-1}$ and for X the lemma holds. Assume that there is an integer $p \geq 1$ satisfying (3.1) with $Y = X$. We set $X^0 = X$. The program X^0 has the property (A), and we define $X^1 = \Gamma(X^0)$. Clearly, X^1 has the property (A). By induction we define a sequence of programs $\{X^i\}$. Suppose that we have already defined $X^i (i = 0, \dots, k)$ such that for $i = 0, \dots, k-1$ the following conditions hold:

1. X^i has the property (A);
2. there exists an integer $p \geq 1$ such that relation (3.1) holds with $Y = X^i$;
3. $X^{i+1} = \Gamma(X^i)$.

If there is no integer $p \geq 1$ such that for $Y = X^k$ relation (3.1) holds, then X^k is the last element of the sequence and its construction is completed. Otherwise, we define $X^{k+1} = \Gamma(X^k)$. By (3.2), the construction of the sequence will be completed in a finite number of steps. Let X^q be the last element of the sequence. It is easy to see that

$$G(X^q) \geq 10^3 m \|\theta\| C_2(\delta_1)^{-1}, \qquad P(x^q) \leq 2 \cdot 10^3 m \|\theta\| C_2(\delta_1)^{-1}. \tag{3.5}$$

We define $g_i = G(X^0) - G(X^i)\,(i = 0, \dots, q), X^q = \{x_{iq}\}_{i=0}^{G(X^q)}$. Lemma 3, which holds for $\varepsilon = \delta_1$ and $r = \delta_1$, implies the existence of a program $\{z_i : i = 0, \dots, g_q\}$ such that

$$\begin{aligned}\sum_{i=g_s}^{g_{s+1}-1} (\theta + \phi)(z_i, z_{i+1}) &\leq \ell(\phi, g_{s+1} - g_s) + 6C_1(\delta_1) \\ &\leq \ell(\phi, G(X^s) - G(X^{s+1})) + 6C_1(\delta_1) \qquad (s = 0, \dots, q-1).\end{aligned}$$

By this inequality, relation (3.4), and the choice of r_0, $r(\Delta)$, and δ_1,

$$\begin{aligned}
&\sum_{i=0}^{G(X^q)-1} [u(x_{iq}, x_{(i+1)q}) - \mu(u)] \\
&\quad \leq \sum_{i=0}^{G(X)-1} [u(x_i, x_{i+1}) - \mu(u)] \\
&\quad\quad - \sum_{s=0}^{q-1} [\ell(\phi, G(X^s) - G(X^{s+1})) + r_0 - 2r(\Delta) - C_1(2\delta_1)] \\
&\quad \leq \sum_{i=0}^{G(X)-1} [u(x_i, x_{i+1}) - \mu(u)] - q(r_0 - 2r(\Delta) - C_1(2\delta_1)) \qquad (3.6)\\
&\quad\quad - \sum_{s=0}^{q-1} \left[-6C_1(\delta_1) + \sum_{i=g_s}^{g_{s+1}-1} (\phi + \theta)(z_i, z_{i+1}) \right] \\
&\quad \leq \sum_{i=0}^{G(X)-1} [u(x_i, x_{i+1}) - \mu(u)] - q(r_0 - 2r(\Delta) - 8C_1(2\delta_1)) \\
&\quad\quad - \sum_{i=0}^{G(X)-G(X^q)-1} (\phi + \theta)(z_i, z_{i+1}) \\
&\quad \leq \sum_{i=0}^{G(X)-1} [u(x_i, x_{i+1}) - \mu(u)] - \sum_{i=0}^{G(X)-G(X^q)-1} (\phi + \theta)(z_i, z_{i+1}) - 2^{-1} q r_0.
\end{aligned}$$

Consider a program $(f_0, \ldots, f_{G(X)})$, where $f_i = x_{iq}$ $(i = 0, \ldots, G(X^q) - 1)$, $f_{G(X^q)+i} = z_{i+1}$ $(i = 0, \ldots, G(X) - G(X^q) - 1)$, $f_{G(X)} = x_{G(X)}$. Evidently, $f_0 = x_0$, $x_{G(X^q),q} = x_{G(X)}$. Relation (3.6) implies that

$$\begin{aligned}
\sum_{i=0}^{G(X)-1} [u(x_i, x_{i+1}) - \mu(u)] - 2\|\theta\| \leq \sum_{i=0}^{G(X)-1} [u(f_i, f_{i+1}) - \mu(u)]& \\
= \sum_{i=0}^{G(X^q)-2} [u(x_{iq}, x_{(i+1)q}) - \mu(u)]& \\
+ u(x_{(G(X^q)-1)q}, z_1) - \mu(u)& \\
+ \sum_{i=1}^{G(X)-G(X^q)-1} [u(z_i, z_{i+1}) - \mu(u)]& \\
+ u(z_{G(X)-G(X^q)}, x_{G(X)}) - \mu(u)& \\
= \sum_{i=0}^{G(X^q)-1} [u(x_{iq}, x_{(i+1)q}) - \mu(u)]& \\
+ \sum_{i=0}^{G(X)-G(X^q)-1} (\phi + \theta)(z_i, z_{i+1})& \\
+ [u(x_{(G(X^q)-1)q}, z_1) - u(x_{(G(X^q)-1)q}, x_{G(X^q)q})]& \\
- (\phi + \theta)(z_0, z_1) + \pi(z_1) - \pi(z_{G(X)-G(X^q)})& \\
+ (\theta + \phi)(z_{G(X)-G(X^q)}, x_{G(X)})& \\
+ \pi(z_{G(X)-G(X^q)}) - \pi(x_{G(X)})& \\
\leq \sum_{i=0}^{G(X^q)-1} [u(x_{iq}, x_{(i+1)q}) - \mu(u)]& \\
+ \sum_{i=0}^{G(X)-G(X^q)-1} (\phi + \theta)(z_i, z_{i+1}) + 8\|\theta\| + 8r(\Delta)& \\
\leq \sum_{i=0}^{G(X)-1} [u(x_i, x_{i+1}) - \mu(u)] - qr_0 2^{-1} + 8\|\theta\| + 8r(\Delta),&
\end{aligned}$$

$$2^{-1}qr_0 \leq 10\|\theta\| + 8r(\Delta), \qquad q \leq (24\|\theta\|)r_0^{-1}.$$

Relations (3.2) and (3.5) imply that

$$\begin{aligned}
P(X) &\leq P(X^q) + G(X) - G(X^q) + 1 \\
&\leq q500m\|\theta\|C_2(\delta_1)^{-1} + 2 \cdot 10^3 m\|\theta\|C_2(\delta_1)^{-1} + 1 \\
&\leq m\|\theta\|C_2(\delta_1)^{-1}(2 \cdot 10^3 + 12 \cdot 10^3\|\theta\|r_0^{-1}) + 1 \leq Q(\Delta).
\end{aligned}$$

The lemma is proved.

LEMMA 6. *Let $\Delta \in (0, D_0)$. Then there exist positive numbers $r(\Delta)$, $Q_1(\Delta)$, and $Q_2(\Delta)$ such that for every natural number N, for every positive number M, for every $u \in \mathbf{C}(K \times K)$ satisfying $\|u - v\| \leq r(\Delta)$, and for every program $\{y_i\}_{i=0}^N \in A(u, N, M)$, the following relation holds*:

$$\operatorname{Card}\left\{ i \in \{0, \dots, N-1\} : (y_i, y_{i+1}) \notin \bigcup_{j=0}^{m-1} \bar{B}((x_j^*, x_{j+1}^*), \Delta) \right\} \leq Q_1(\Delta) + Q_2(\Delta)M.$$

Proof. We choose an integer $Q(\Delta) \geq 1$ and a positive number $r(\Delta)$ such that for Δ, $Q(\Delta)$, and $r(\Delta)$ Lemma 5 holds, and define $Q_1(\Delta) = 1 + Q(\Delta)$, $Q_2(\Delta) = (1 + Q(\Delta))(2\|\theta\|)^{-1}$. Let N be an integer, $N \geq 1$, $M > 0$, $u \in \mathbf{C}(K \times K)$, $\|u - v\| \leq r(\Delta)$, $\{y_i\}_{i=0}^N \in A(u, N, M)$. If $M \leq 2\|\theta\|$, then Lemma 6 follows from Lemma 5. Consider the case $M > 2\|\theta\|$. By induction we obtain a sequence of integers $\{i_p\}_{p=0}^k$ such that $i_0 = 0 < \cdots < i_p < \cdots < i_k = N$; for every $p \in \{0, \dots, k-1\}$ the relation

$$\{y_j\}_{j=i_p}^q \in A(u, q - i_p, 2\|\theta\|) \qquad (i_p < q < i_{p+1}) \tag{3.7}$$

holds; and for every integer p satisfying $0 \leq p \leq k-2$ the relation

$$\{y_j\}_{j=i_p}^{i_{p+1}} \notin A(u, i_{p+1} - i_p, 2\|\theta\|)$$

holds. This relation implies that $(k-1)2\|\theta\| \leq M$. It is easy to see that $i_{p+1} - i_p \geq 2$ for every integer p satisfying $0 \leq p \leq k-2$. Relation (3.7) and Lemma 5, which holds for Δ, $Q(\Delta)$, and $r(\Delta)$, imply that

$$\begin{aligned}&\operatorname{Card}\left\{ i \in \{0, \dots, N-1\} : (y_i, y_{i+1}) \notin \bigcup_{j=0}^{m-1} \bar{B}((x_j^*, x_{j+1}^*), \Delta) \right\} \\ &\quad \leq k(1 + Q(\Delta)) \leq (1 + M(2\|\theta\|)^{-1})(1 + Q(\Delta)) \leq Q_1(\Delta) + MQ_2(\Delta).\end{aligned}$$

The lemma is proved.

4. Preliminary lemmas for proof of Theorems 1, 3, and 4.

LEMMA 7. *Let $\varepsilon \in (0, D_0)$. Then there exists a number $r > 0$ such that for every $\phi \in \mathbf{C}(K \times K)$ satisfying $\|\phi\| \leq r$ and for every integer k there is a program $\{z_i\}_{i=0}^\infty$ for which the following relations hold*:

$$z_0 = x_k^*,\ d_1((z_i, z_{i+1}), (x_{k+i}^*, x_{k+i+1}^*)) \leq \varepsilon \qquad (i = 0, 1, \dots),$$

$$\sum_{i=p}^{q-1} (\theta + \phi)(z_i, z_{i+1}) \leq \ell(\phi, q - p) + 18C_1(2\varepsilon) \qquad (p,\ q \textit{ are integers}, 0 \leq p < q).$$

Proof. Choose $r \in (0, C_1(\varepsilon))$ such that Lemma 3 holds for ε, r. Let k be an integer, $\phi \in \mathbf{C}(K \times K)$, $\|\phi\| \leq r$. By Lemma 3, for any integer $N \geq 1$ there exists a program $\{z_i(N)\}_{i=0}^N$ such that $z_0(N) = x_k^*$, $z_N(N) = x_{k+N}^*$,

$$\begin{aligned}&d_1((z_i(N), z_{i+1}(N)), (x_{k+i}^*, x_{k+i+1}^*)) \leq \varepsilon \qquad (i = 0, \dots, N-1), \\ &\sum_{i=0}^{N-1} (\phi + \theta)(z_i(N), z_{i+1}(N)) \leq \ell(\phi, N) + 6C_1(\varepsilon).\end{aligned} \tag{4.1}$$

We fix an integer $N \geq 1$, and let p and q be integers satisfying $0 \leq p < q < N$. We will show that

$$\sum_{i=p}^{q-1} (\phi + \theta)(z_i(N), z_{i+1}(N)) \leq \ell(\phi, q-p) + 18C_1(2\varepsilon). \tag{4.2}$$

By Lemma 3 there is a program $\{y_i\}_{i=0}^{q-p}$ such that $y_0 = x^*_{k+p}$, $y_{q-p} = x^*_{k+q}$,

$$\begin{gathered}\sum_{i=0}^{q-p-1} (\phi + \theta)(y_i, y_{i+1}) \leq \ell(\phi, q-p) + 6C_1(\varepsilon), \\ d_1((y_i, y_{i+1}), (x^*_{i+k+p}, x^*_{i+k+p+1})) \leq \varepsilon \qquad (i = 0, \dots, q-p-1).\end{gathered} \tag{4.3}$$

Consider a program $\{t_i\}_{i=0}^{N}$, where $t_i = z_i(N)$ $(i \in \{0, \dots, p\} \cup \{q, \dots, N\})$, $t_i = y_{i-p}$ $(p < i < q)$. By (4.1) and (4.3)

$$\begin{aligned} 6C_1(\varepsilon) &\geq \sum_{i=0}^{N-1} [(\phi + \theta)(z_i(N), z_{i+1}(N)) - (\phi + \theta)(t_i, t_{i+1})] \\ &= \sum_{i=p}^{q-1} [(\phi + \theta)(z_i(N), z_{i+1}(N)) - (\phi + \theta)(t_i, t_{i+1})], \end{aligned}$$

$$\begin{aligned} \sum_{i=p}^{q-1} (\phi + \theta)(t_i, t_{i+1}) &\leq \sum_{i=0}^{q-p-1} (\phi + \theta)(y_i, y_{i+1}) + 4r + 2C_1(2\varepsilon) \\ &\leq \ell(\phi, q-p) + 12C_1(2\varepsilon), \end{aligned}$$

$$\begin{aligned} \sum_{i=p}^{q-1} [(\phi + \theta)(z_i(N), z_{i+1}(N))] &\leq 6C_1(\varepsilon) + \sum_{i=p}^{q-1} (\phi + \theta)(t_i, t_{i+1}) \\ &\leq \ell(\phi, q-p) + 18C_1(2\varepsilon). \end{aligned}$$

Relation (4.2) is proved. It is easy to see that there is a sequence of integers $\{N_j\}_{j=1}^{\infty}$ such that $1 \leq N_1 < \cdots < N_j < N_{j+1} < \cdots$, and for every integer $i \geq 0$ the sequence $z_i(N_j) \to z_i \in K$ as $j \to \infty$. By (4.1) and (4.2) the program $\{z_i\}_{i=0}^{\infty}$ satisfies the lemma conditions. The lemma is proved.

From now on we assume that

$$\pi(x^*_0) = \sup\{\pi(x^*_i) : i = 0, \dots, m\}. \tag{4.4}$$

Let $x \in K$, $u \in \mathbf{C}(K \times K)$, $\varepsilon > 0$, $Q \in \{1, 2, \dots\}$. Set

$$\begin{aligned} H_0(x) &= \{\{z_i\}_{i=0}^{\infty} \subset K : z_0 = x\}, \\ H_1(x, u, Q) &= \{\{z_i\}_{i=0}^{\infty} \in H_0(x) : \{z_i\}_{i=0}^{Q} \in A(u, Q, 2\|\theta\|)\}, \\ H_2(x, Q, \varepsilon) &= \{\{z_i\}_{i=0}^{\infty} \in H_0(x) : \text{there exists an integer } g \in \{0, \dots, Q\} \\ &\qquad \text{such that } d(z_g, x^*_{m-1}) \leq \varepsilon\}, \\ H_3(x, u, Q, \varepsilon) &= \{\{z_i\}_{i=0}^{\infty} \in H_2(x, Q, \varepsilon) : \{z_i\}_{i=0}^{\infty} \text{is a } (u)\text{-good program}\}. \end{aligned}$$

LEMMA 8. *Let $\delta \in (0, D_0)$, $r \in (0, (48m)^{-1}C_2(\delta))$, Q be an integer, and $Q \geq 400m\|\theta\|C_2(\delta)^{-1}$. Then for every $u \in \mathbf{C}(K \times K)$ satisfying $\|u - v\| \leq r$, for every $x \in K$, the following relation holds*:

$$\pi^u(x) = \inf\left\{\liminf \sum_{i=0}^{N-1} [u(z_i, z_{i+1}) - \mu(u)] : \{z_i\}_{i=0}^{\infty} \in H_3(x, u, Q, \delta)\right\}.$$

Proof. Let $u \in \mathbf{C}(K \times K)$, $\|u - v\| \le r$, $x \in K$, $\phi = u - v$. Then

$$\pi^u(x) = \inf \left\{ \liminf \sum_{i=0}^{N-1} [u(z_i, z_{i+1}) - \mu(u)] : \{z_i\}_{i=0}^{\infty} \in H_1(x, u, Q) \right\}.$$

By Lemma 1, $H_1(x, u, Q) \subset H_2(x, Q, \delta) \subset H_0(x)$. This relation implies that

$$\pi^u(x) = \inf \left\{ \liminf \sum_{i=0}^{N-1} [u(z_i, z_{i+1}) - \mu(u)] : \{z_i\}_{i=0}^{\infty} \in H_2(x, Q, \delta) \right\}.$$

The lemma now follows from Proposition 1 and the definition of a (u)-good program.

LEMMA 9. *Let $\varepsilon \in (0, D_0)$. Then there exists a number $r > 0$ such that for every $\phi \in \mathbf{C}(K \times K)$ satisfying $\|\phi\| \le r$ the following conditions hold*:

$$\mu(\phi + v) = \mu + \mu(\phi + \theta);$$

there is a $(\phi + v)$-good program $\{z_i^\phi\}_{i=0}^{\infty}$ such that

$$z_0^\phi = x_0^*, \quad d_1((z_i^\phi, z_{i+1}^\phi), (x_i^*, x_{i+1}^*)) \le \varepsilon \quad (i = 0, 1, \ldots), \tag{4.5}$$

$$\sum_{i=p}^{q-1} (\phi + \theta)(z_i^\phi, z_{i+1}^\phi) \le \ell(\phi, q - p) + 18C_1(2\varepsilon) \tag{4.6}$$
$$(p \textit{ and } q \textit{ are integers}, 0 \le p < q),$$

$$\left| N\mu(\phi + \theta) - \sum_{i=0}^{N-1} (\phi + \theta)(z_i^\phi, z_{i+1}^\phi) \right| \le 30C_1(2\varepsilon) \qquad (N = 1, 2, \ldots), \tag{4.7}$$

$$\left| \liminf \sum_{i=0}^{N-1} [(\phi + v)(z_i^\phi, z_{i+1}^\phi) - \mu(\phi + v)] \right| \le C_3(\varepsilon) + 30C_1(2\varepsilon). \tag{4.8}$$

Proof. We choose a number $r \in (0, (2m)^{-1}C_1(\varepsilon))$ such that Lemma 7 holds for ε, r. Let $\phi \in \mathbf{C}(K \times K)$, $\|\phi\| \le r$. By Lemma 7 there is a program $\{z_i^\phi\}_{i=0}^{\infty}$ for which $z_0^\phi = x_0^*$ and relations (4.5) and (4.6) hold. It is easy to see that $\ell(\phi, N) = N\rho(N, \phi + \theta)$ $(N = 1, 2, \ldots)$ (see Proposition 1 and (2.5)). Let q be an integer, $q \ge 1$, and $\{y_i\}_{i=0}^{qm}$ be a program such that $y_i = z_i^\phi$ $(i = 0, \ldots, qm - 1)$, $y_{qm} = x_0^*$. It is easy to see that

$$\begin{aligned}
qm\lambda(qm, \phi + \theta) &\le \sum_{i=0}^{qm-1} (\phi + \theta)(y_i, y_{i+1}) \\
&\le \sum_{i=0}^{qm-1} (\phi + \theta)(z_i^\phi, z_{i+1}^\phi) + 2r + C_1(2\varepsilon) \\
&\le 2r + C_1(2\varepsilon) + \ell(\phi, qm) + 18C_1(2\varepsilon) \qquad (4.9)\\
&= 2r + 19C_1(2\varepsilon) + qm\rho(qm, \phi + \theta),
\end{aligned}$$

$$\begin{aligned}
qm\lambda(qm, \phi + \theta) - 3C_1(2\varepsilon) &\le \sum_{i=0}^{qm-1} (\phi + \theta)(z_i^\phi, z_{i+1}^\phi) \\
&\le 18C_1(2\varepsilon) + qm\rho(qm, \phi + \theta).
\end{aligned}$$

Let N be an integer, $N > m$. There is an integer $p \geq 1$ such that $pm \leq N < pm + m$. We have by (4.6), Proposition 1, and (4.9)

$$\sum_{i=0}^{N-1} (\phi + \theta)(z_i^\phi, z_{i+1}^\phi) \leq 18C_1(2\varepsilon) + \ell(\phi, N) \leq 18C_1(2\varepsilon) + N\mu(\phi + \theta),$$

$$\begin{aligned}(p+1)m\mu(\phi+\theta) &\leq (p+1)m\lambda((p+1)m,\ \phi+\theta)\\ &\leq \sum_{i=0}^{(p+1)m-1} (\phi+\theta)(z_i^\phi, z_{i+1}^\phi) + 3C_1(2\varepsilon)\\ &\leq \sum_{i=0}^{N-1} (\phi+\theta)(z_i^\phi, z_{i+1}^\phi) + 3C_1(2\varepsilon) + \ell(\phi, (p+1)m - N) + 18C_1(2\varepsilon),\end{aligned}$$

$$\begin{aligned}&\sum_{i=0}^{N-1} (\phi+\theta)(z_i^\phi, z_{i+1}^\phi)\\ &\qquad \geq (p+1)m\mu(\phi+\theta) - 21C_1(2\varepsilon) - \ell(\phi, (p+1)m - N)\\ &\qquad \geq -21C_1(2\varepsilon) + N\mu(\phi+\theta).\end{aligned}$$

Now it is easy to see that (4.7) holds for every $N > m$.

Consider the case with $N \leq m$. We have

$$|\rho(\phi+\theta, N)| = |\rho(\phi+\theta, N) - \rho(\theta, N)| \leq \|\phi\| \leq r, \qquad |\ell(\phi, N)| \leq mr,$$

$$|\mu(\phi+\theta)| = |\mu(\phi+\theta) - \mu(\theta)| \leq \|\phi\| \leq r,$$

and thus the validity of (4.7) for N follows from these relations, from relation (4.6), and from the inequality $2mr < C_1(\varepsilon)$. Thus, we have proved that (4.7) holds for every integer $N \geq 1$.

We will show that $\{z_i^\phi\}_{i=0}^\infty$ is a $(\phi + v)$-good program. Assume the contrary. Then by Proposition 1

$$\sum_{i=0}^{N-1} [(\phi+v)(z_i^\phi, z_{i+1}^\phi) - \mu(\phi+v)] \to +\infty \quad \text{as } N \to \infty.$$

Let $\{y_i\}_{i=0}^\infty$ be a $(\phi + v)$-good program. Then

$$\sum_{i=0}^{N-1} [(\phi+v)(z_i^\phi, z_{i+1}^\phi) - (\phi+v)(y_i, y_{i+1})] \to +\infty \quad \text{as } N \to \infty.$$

On the other hand, relation (4.6) implies that

$$\begin{aligned}&\sum_{i=0}^{N-1} [(\phi+v)(z_i^\phi, z_{i+1}^\phi) - (\phi+v)(y_i, y_{i+1})]\\ &\qquad \leq \sum_{i=0}^{N-1} [(\phi+\theta)(z_i^\phi, z_{i+1}^\phi) - (\phi+\theta)(y_i, y_{i+1})] + 4\|\pi\|\\ &\qquad \leq 18C_1(2\varepsilon) + 4\|\pi\| \qquad (N = 1, 2, \ldots).\end{aligned}$$

The contradiction obtained proves that $\{z_i^\phi\}_{i=0}^\infty$ is a $(\phi+v)$-good program. Then relation (4.7) implies that

$$\begin{aligned}\mu(\phi+v) &= \lim_{N\to\infty} N^{-1}\sum_{i=0}^{N-1}(\phi+v)(z_i^\phi,z_{i+1}^\phi)\\ &= \mu + \lim_{N\to\infty} N^{-1}\sum_{i=0}^{N-1}(\phi+\theta)(z_i^\phi,z_{i+1}^\phi) = \mu+\mu(\phi+\theta).\end{aligned}$$

Now, to complete the proof, we should only prove (4.8). We have for $N=1,2,\dots$ using (4.5), (4.7), and (2.3),

$$\begin{aligned}&\sum_{i=0}^{N-1}[(\phi+v)(z_i^\phi,z_{i+1}^\phi)-\mu(\phi+v)]\\ &\quad = \pi(x_0^*)-\pi(z_N^\phi)+\sum_{i=0}^{N-1}[(\phi+\theta)(z_i^\phi,z_{i+1}^\phi)-\mu(\phi+\theta)],\end{aligned}$$

$$\begin{aligned}&\left|\sum_{i=0}^{N-1}[(\phi+v)(z_i^\phi,z_{i+1}^\phi)-\mu(\phi+v)]-\pi(x_0^*)+\pi(x_N^*)\right|\\ &\quad\le C_3(\varepsilon)+30C_1(2\varepsilon).\end{aligned}$$

This relation and (4.4) imply that (4.8) holds. The lemma is proved.

LEMMA 10. *Let $\Delta\in(0,D_0)$. Then there is $h>0$ such that for every $u\in\mathbf{C}(K\times K)$ satisfying $\|u-v\|\le h$ the relation $\|\pi^u-\pi^v\|\le\Delta$ holds.*

Proof. Choose $\delta_0\in(0,\Delta)$ satisfying $4(220C_1(2\delta_0)+4C_3(2\delta_0))\le\Delta$, an integer $Q\ge 400m\|\theta\|C_2(\delta_0)^{-1}$, and $h\in(0,(48m)^{-1}C_2(\delta_0))$ such that $(Q+4)8h\le\Delta$, Lemma 9 holds for $\varepsilon=\delta_0$, $r=h$, Lemma 4 holds for $\varepsilon_0=\delta_0$, and $r=h$. Let $\phi\in\mathbf{C}(K\times K)$, $\|\phi\|\le h$, $u=v+\phi$, and $x\in K$. Lemma 8 implies that

$$\pi^u(x)=\inf\left\{\liminf\sum_{i=0}^{N-1}[u(z_i,z_{i+1})-\mu(u)] : \{z_i\}_{i=0}^\infty\in H_3(x,u,Q,\delta_0)\right\}.$$

Lemma 9, which holds for $\varepsilon=\delta_0$, $r=h$, implies the existence of a $(\phi+v)$-good program $\{z_i^\phi\}_{i=0}^\infty$ such that $z_0^\phi=x_0^*$ and relations (4.5)-(4.8) hold for $\varepsilon=\delta_0$. By H_4 denote the set of all programs $\{z_i\}_{i=0}^\infty$ such that $z_0=x$, $d(z_g,x_{m-1}^*)\le\delta_0$, $z_{g+i}=z_{i-1}^\phi$ $(i=1,2,\dots)$ for some $g\in\{0,\dots,Q\}$. It is easy to see that $H_4\subset H_3(x,u,Q,\delta_0)$. Let $\{y_i\}_{i=0}^\infty\in H_3(x,u,Q,\delta_0)$. It is a (u)-good program, and there is $q\in\{0,\dots,Q\}$ satisfying $d(y_q,x_{m-1}^*)\le\delta_0$.. Consider a program $\{a_i\}_{i=0}^\infty$, where $a_i=y_i(i=0,\dots,q)$, $a_i=z_{i-q-1}^\phi(i\ge q+1)$. It is easy to see that $\{a_i\}_{i=0}^\infty\in H_4$. So $\{y_i\}_{i=0}^\infty$ is a (u)-good program. By Lemma 4, which is valid for $\varepsilon_0=\delta_0$, $r=h$, there exists an integer $N\ge1$ such that

$$(4.10)\qquad d_1((y_{N+i},y_{N+i+1}),(x_i^*,x_{i+1}^*))\le\delta_0\qquad(i=0,1\dots).$$

We suppose, without loss of generality, that $N\ge 4q+4$. There is an integer $p\ge0$ such that $q+1+pm\le N<q+1+(p+1)m$. For $g=0,1,\dots$ define $s(g)=(p+1)m+g$. Fix integer $g\ge0$. Lemma 9, which holds for $\varepsilon=\delta_0$, $r=h$, implies that $\mu(u)=\mu(\phi+\theta)+\mu$,

$$\begin{aligned}
&\sum_{i=0}^{N+g-1}[u(y_i,y_{i+1})-\mu(u)]-\sum_{i=0}^{q+s(g)}[u(a_i,a_{i+1})-\mu(u)]\\
&\quad=\sum_{i=q}^{N+g-1}[u(y_i,y_{i+1})-\mu(u)]-\sum_{i=q}^{q+s(g)}[u(a_i,a_{i+1})-\mu(u)]\\
&\quad=\sum_{i=q}^{N+g-1}[(\phi+\theta)(y_i,y_{i+1})-\mu(\phi+\theta)]-\sum_{i=q}^{q+s(g)}[(\phi+\theta)(a_i,a_{i+1})-\mu(\phi+\theta)]\\
&\qquad+\pi(z^{\phi}_{s(g)})-\pi(y_{N+g})\\
&\quad=\sum_{i=q}^{N+g-1}[(\phi+\theta)(y_i,y_{i+1})-(\phi+\theta)(a_i,a_{i+1})]\\
&\qquad-\sum_{i=N+g}^{q+s(g)}[(\phi+\theta)(a_i,a_{i+1})-\mu(\phi+\theta)]+\pi(z^{\phi}_{s(g)})-\pi(y_{N+g}).
\end{aligned}\tag{4.11}$$

We will estimate the last expression and each of its terms. By (4.5), which holds for $\varepsilon=\delta_0$, and (4.10) we have

$$d(z^{\phi}_{s(g)},x^*_g)\le\delta_0,\qquad d(y_{N+g},x^*_g)\le\delta_0,\qquad |\pi(z^{\phi}_{s(g)})-\pi(y_{N+g})\,|\le C_3(2\delta_0).\tag{4.12}$$

It follows from the definition of $\{a_i\}_{i=0}^{\infty}$ and (4.7) which holds for $\varepsilon=\delta_0$, that

$$\begin{aligned}
&\left|\sum_{i=N+g}^{q+s(g)}[(\phi+\theta)(a_i,a_{i+1})-\mu(\phi+\theta)]\right|\\
&\quad=\left|\sum_{i=N+g-q-1}^{s(g)-1}[(\phi+\theta)(z^{\phi}_i,z^{\phi}_{i+1})-\mu(\phi+\theta)]\right|\\
&\quad\le\left|\sum_{i=0}^{s(g)-1}[(\phi+\theta)(z^{\phi}_i,z^{\phi}_{i+1})-\mu(\phi+\theta)]\right|\\
&\qquad+\left|\sum_{i=0}^{N+g-q-2}[(\phi+\theta)(z^{\phi}_i,z^{\phi}_{i+1})-\mu(\phi+\theta)]\right|\le 60C_1(2\delta_0).
\end{aligned}\tag{4.13}$$

It follows from the definition of $\{a_i\}_{i=0}^{\infty}$ and $\{z^{\phi}_i\}_{i=0}^{\infty}$ and relation (4.6), which holds for $\varepsilon=\delta_0$, that

$$\begin{aligned}
&\sum_{i=q}^{N+g-1} [(\phi+\theta)(y_i, y_{i+1}) - (\phi+\theta)(a_i, a_{i+1})] \\
&\quad \geq \sum_{i=q+1}^{N+g-1} [(\phi+\theta)(y_i, y_{i+1}) - (\phi+\theta)(a_i, a_{i+1})] - 2h - C_1(\delta_0) \\
&\quad \geq -2h - C_1(\delta_0) + \ell(\phi, N+g-q-1) - \sum_{i=0}^{N+g-q-2} (\phi+\theta)(z_i^\phi, z_{i+1}^\phi) \\
&\quad \geq -2h - 19C_1(2\delta_0).
\end{aligned} \tag{4.14}$$

Relations (4.11)–(4.14) imply that

$$\begin{aligned}
&\sum_{i=0}^{N+g-1} [u(y_i, y_{i+1}) - \mu(u)] - \sum_{i=0}^{q+s(g)} [u(a_i, a_{i+1}) - \mu(u)] \\
&\quad \geq -2h - 19C_1(2\delta_0) - 60C_1(2\delta_0) - C_3(2\delta_0) \qquad (g = 0, 1, \ldots).
\end{aligned}$$

This relation implies

$$\begin{aligned}
\liminf_{S\to\infty} \sum_{i=0}^{S-1} [u(a_i, a_{i+1}) - \mu(u)] &\leq \liminf_{S\to\infty} \sum_{i=0}^{S-1} [u(y_i, y_{i+1}) - \mu(u)] \\
&\quad + 2h + 80C_1(2\delta_0) + C_3(2\delta_0).
\end{aligned}$$

Since $\{a_i\}_{i=0}^\infty \in H_4 \subset H_3(x, u, Q, \delta_0)$ and $\{y_i\}_{i=0}^\infty$ is an arbitrary element of $H_3(x, u, Q, \delta_0)$

$$\begin{aligned}
\pi^u(x) &\leq \inf\left\{\liminf_{S\to\infty} \sum_{i=0}^{S-1} [u(z_i, z_{i+1}) - \mu(u)] : \{z_i\}_{i=0}^\infty \in H_4\right\} \\
&\leq \pi^u(x) + 2h + 80C_1(2\delta_0) + C_3(2\delta_0).
\end{aligned} \tag{4.15}$$

Denote by $H_5(x)$ the set of all programs $\{z_i\}_{i=0}^q (q \in \{0, \ldots, Q\})$ such that $z_0 = x$, $d(z_q, x_{m-1}^*) \leq \delta_0$. There exists a mapping $P : H_5(x) \to H_4$, where

$$\begin{aligned}
&P(\{z_i\}_{i=0}^q) = \{a_i\}_{i=0}^\infty, \quad a_i = z_i \quad (i = 0, \ldots, q), \quad a_i = z_{i-q-1}^\phi \quad (i \geq q+1) \\
&\text{for } q \in \{0, \ldots, Q\}, \ \{z_i\}_{i=0}^q \in H_5(x).
\end{aligned}$$

It is easy to see that $P(H_5(x)) = H_4$. Let $q \in \{0, \ldots, Q\}$, $\{z_i\}_{i=0}^q \in H_5(x)$, $\{a_i\}_{i=0}^\infty = P(\{z_i\}_{i=0}^q)$. Relation (4.8), which holds for $\varepsilon = \delta_0$, implies

$$\begin{aligned}
&\left| u(z_q, x_0^*) - \mu(u) + \sum_{i=0}^{q-1} [u(z_i, z_{i+1}) - \mu(u)] - \liminf_{N\to\infty} \sum_{i=0}^{N-1} [u(a_i, a_{i+1}) - \mu(u)] \right| \\
&\quad = \left| \liminf_{N\to\infty} \sum_{i=q+1}^{N-1} [u(a_i, a_{i+1}) - \mu(u)] \right| \\
&\quad \leq \left| \liminf_{N\to\infty} \sum_{i=0}^{N-1} [u(z_i^\phi, z_{i+1}^\phi) - \mu(u)] \right| \leq C_3(\delta_0) + 30C_1(2\delta_0).
\end{aligned}$$

This relation implies that

$$\left| \inf\left\{ \liminf \sum_{i=0}^{N-1} [u(z_i, z_{i+1}) - \mu(u)] : \{z_i\}_{i=0}^{\infty} \in H_4 \right\} \right.$$
$$\left. - \inf\left\{ \sum_{i=0}^{q-1} [u(z_i, z_{i+1}) - \mu(u)] + u(z_q, x_0^*) - \mu(u) : \{z_i\}_{i=0}^{q} \in H_5(x),\ 0 \le q \le Q \right\} \right|$$
$$\le C_3(\delta_0) + 30C_1(2\delta_0).$$

This relation and (4.15) imply that

(4.16)
$$\left| \pi^u(x) - \inf\left\{ \sum_{i=0}^{q-1} [u(z_i, z_{i+1}) - \mu(u)] + u(z_q, x_0^*) - \mu(u) : \{z_i\}_{i=0}^{q} \in H_5(x) \right\} \right|$$
$$\le 2h + 110C_1(2\delta_0) + 2C_3(2\delta_0).$$

(4.16) holds for every $x \in K$ and for every $u \in \mathbf{C}(K \times K)$ satisfying $\|u - v\| \le h$. Let $x \in K$, $w \in \mathbf{C}(K \times K)$, and $\|w - v\| \le h$. By Proposition 1 $|\mu(w) - \mu(v)| \le h$. It is easy to see that $\mu(v) = \mu$. It follows from the choice of δ_0 and h and relation (4.16), which holds for $u = w$ and for $u = v$, that

$$|\pi^w(x) - \pi^v(x)| \le 4h + 220C_1(2\delta_0) + 4C_3(2\delta_0)$$
$$+ \left| \inf\left\{ \sum_{i=0}^{q-1} [w(z_i, z_{i+1}) - \mu(w)] \right.\right.$$
$$\left. + w(z_q, x_0^*) - \mu(w) : \{z_i\}_{i=0}^{q} \in H_5(x),\ 0 \le q \le Q \right\}$$
$$- \inf\left\{ \sum_{i=0}^{q-1} [v(z_i, z_{i+1}) - \mu(v)] \right.$$
$$\left.\left. + v(z_q, x_0^*) - \mu(v) : \{z_i\}_{i=0}^{q} \in H_5(x),\ 0 \le q \le Q \right\} \right|$$
$$\le 4h + 220C_1(2\delta_0) + 4C_3(2\delta_0) + 2h(Q + 1) \le \Delta.$$

This completes the proof of the lemma.

LEMMA 11. $\mu(v) = \mu$, $\pi^v(x_g^*) = \pi(x_g^*) - \pi(x_0^*)(g = 0, \dots, m - 1)$.

Proof. The equality $\mu(v) = \mu$ follows from the definition of $\mu(v)$ (see (1.1)). Let $g \in \{0, \dots, m - 1\}$ and $y_i = x_{g+i}^*$ $(i = 0, 1, \dots)$. Then

$$\liminf \sum_{i=0}^{N-1} [v(y_i, y_{i+1}) - \mu] = \pi(x_g^*) - \pi(x_0^*), \tag{4.17}$$
$$\pi^v(x_g^*) \le \pi(x_g^*) - \pi(x_0^*),$$

(4.18)
$$\pi^v(x_g^*) = \inf\left\{ \liminf_{N\to\infty} \sum_{i=0}^{N} [v(y_i, y_{i+1}) - \mu] : \{y_i\}_{i=0}^{\infty} \text{ is a } (v)\text{-good program}, y_0 = x_g^* \right\}.$$

Let $\{y_i\}_{i=0}^{\infty}$ be a (v)-good program, $y_0 = x_g^*$, and $\varepsilon \in (0, D_0)$. Lemma 4 implies the existence of an integer $Q \geq 1$ such that

$$d_1((y_{Q+i}, y_{Q+i+1}),\ (x_i^*, x_{i+1}^*)) \leq \varepsilon \quad (i = 0, 1, \ldots). \tag{4.19}$$

Relation (4.19) implies that for every integer $j \geq 0$

$$\begin{aligned}\sum_{i=0}^{Q+j-1} [v(y_i, y_{i+1}) - \mu] &\geq \pi(x_g^*) - \pi(y_{Q+j}) \geq \pi(x_g^*) - \pi(x_j^*) - C_3(\varepsilon)\\ &\geq \pi(x_g^*) - \pi(x_0^*) - C_3(\varepsilon).\end{aligned}$$

This relation and (4.18) imply that $\pi^v(x_g^*) \geq \pi(x_g^*) - \pi(x_0^*)$. The lemma then follows from this inequality and (4.17).

For every number $\varepsilon > 0$ we set

$$C_4(\varepsilon) = \sup\{|\pi^v(z_1) - \pi^v(z_2)| : z_1, z_2 \in K,\ d(z_1, z_2) \leq \varepsilon\}. \tag{4.20}$$

LEMMA 12. *Let $\Delta \in (0, D_0)$. Then there exists a number $R(\Delta) \in (0, \Delta)$ such that for every $u \in \mathbf{C}(K \times K)$ satisfying $\|u - v\| \leq R(\Delta)$, for every integer $g \in \{0, \ldots, m-1\}$, and for every program $\{y_i\}_{i=0}^{\infty}$ satisfying $d(y_0, x_g^*) \leq R(\Delta)$, $\theta^u(y_i, y_{i+1}) = 0\,(i = 0, 1, \ldots)$, the following relation holds: $d_1((y_i, y_{i+1}),\ (x_{g+i}^*, x_{g+i+1}^*)) \leq \Delta\,(i = 0, 1, \ldots)$.*

Proof. We choose $r_0 \in (0, \Delta)$ such that Lemma 2 holds for $R = r_0$, $\varepsilon = \Delta$. We choose $\delta_0 \in (0, r_0)$ satisfying

$$50C_1(2\delta_0) + 2C_4(\delta_0) + 2C_3(\delta_0) \leq 4^{-1}r_0$$

and choose $R(\Delta) \in (0, \delta_0)$ such that Lemma 4 holds for $\varepsilon_0 = \delta_0$, $r = R(\Delta)$, Lemma 9 holds for $\varepsilon = \delta_0$, $r = R(\Delta)$, and the following relation is fulfilled:

$$\|\pi^v - \pi^u\| \leq 4^{-1}r_0 \qquad (u \in \mathbf{C}(K \times K),\ \|u - v\| \leq R(\Delta))$$

(see Lemma 10). Let $u \in \mathbf{C}(K \times K)$, $\|u - v\| \leq R(\Delta)$, $g \in \{0, \ldots, m-1\}$, $\{y_i\}_{i=0}^{\infty}$ be a program satisfying $d(y_0, x_g^*) \leq R(\Delta)$, and $\theta^u(y_i, y_{i+1}) = 0\,(i = 0, 1, \ldots)$. By Lemma 4, which holds for $\varepsilon_0 = \delta_0$, $r = R(\Delta)$, there is an integer $Q \geq 1$ such that

$$d_1((y_{Q+i}, y_{Q+i+1}),\ (x_i^*, x_{i+1}^*)) \leq \delta_0 \qquad (i = 0, 1, \ldots). \tag{4.21}$$

Set $\phi = u - v$. For every integer $j \geq 0$

$$\sum_{i=0}^{Q+j-1} [u(y_i, y_{i+1}) - \mu(u)] = \pi^u(y_0) - \pi^u(y_{Q+j}).$$

Lemma 11 and relation (4.21) imply

$$\begin{aligned}&\left|\sum_{i=0}^{Q+j-1} [u(y_i, y_{i+1}) - \mu(u)] - (\pi(x_g^*) - \pi(x_j^*))\right|\\ &= \left|\sum_{i=0}^{Q+j-1} [u(y_i, y_{i+1}) - \mu(u)] - (\pi^v(x_g^*) - \pi^v(x_j^*))\right|\\ &\leq |\pi^u(y_0) - \pi^u(y_{Q+j}) - (\pi^v(x_g^*) - \pi^v(x_j^*))|\\ &\leq 2\|\pi^v - \pi^u\| + |\pi^v(y_0) - \pi^v(y_{Q+j}) - (\pi^v(x_g^*) - \pi^v(x_j^*))|\\ &\leq 2\|\pi^v - \pi^u\| + 2C_4(\delta_0) \qquad (j = 0, 1, \ldots).\end{aligned} \tag{4.22}$$

It follows from Lemma 9 and the choice of δ_0, $R(\Delta)$ that

$$\mu(\phi+v)=\mu+\mu(\phi+\theta), \tag{4.23}$$

$$\ell(\phi,N)\le N\mu(\phi+\theta)\le \ell(\phi,N)+50C_1(2\delta_0) \qquad (N=1,2,\dots). \tag{4.24}$$

For every integer $j\ge 0$ using (4.21) – (4.23) we have

$$\sum_{i=0}^{Q+j-1}[u(y_i,y_{i+1})-\mu(u)]$$
$$=\pi(y_0)-\pi(y_{Q+j})+\sum_{i=0}^{Q+j-1}[(\theta+\phi)(y_i,y_{i+1})-\mu(\phi+\theta)];$$

$$\left|\sum_{i=0}^{Q+j-1}[(\theta+\phi)(y_i,y_{i+1})-\mu(\phi+\theta)]\right|$$
$$=\left|\sum_{i=0}^{Q+j-1}[u(y_i,y_{i+1})-\mu(u)]-(\pi(y_0)-\pi(y_{Q+j}))\right|$$
$$\le|\pi(x_g^*)-\pi(x_j^*)-(\pi(y_0)-\pi(y_{Q+j}))|+2\|\pi^v-\pi^u\|+2C_4(\delta_0)$$
$$\le 2\|\pi^v-\pi^u\|+2C_4(\delta_0)+2C_3(\delta_0) \qquad (j=0,1,\dots),$$

$$\left|\sum_{i=0}^{N-1}[(\theta+\phi)(y_i,y_{i+1})-\mu(\phi+\theta)]\right|$$
$$\le 2\|\pi^v-\pi^u\|+2C_4(\delta_0)+2C_3(\delta_0) \qquad (N=Q,Q+1,\dots).$$

The last relation, relation (4.24), and our choice of $R(\Delta)$ and δ_0 imply that

$$\sum_{i=0}^{N-1}(\theta+\phi)(y_i,y_{i+1})\le 2\|\pi^v-\pi^u\|+2C_4(\delta_0)+2C_3(\delta_0)+\ell(\phi,N)$$
$$+50C_1(2\delta_0)\le \ell(\phi,N)+r_0 \qquad (N=Q,Q+1,\dots).$$

The validity of the lemma follows from Lemma 2, which holds for $\varepsilon=\Delta$, $R=r_0$.

LEMMA 13. *Let $\Delta\in(0,D_0)$. Then there exist $R\in(0,\Delta)$, an integer $Q\ge 1$ such that for every $u\in \mathbf{C}(K\times K)$ satisfying $\|u-v\|\le R$, for every program $\{y_i\}_{i=0}^{\infty}$ satisfying $\theta^u(y_i,y_{i+1})=0\,(i=0,1,\dots)$, there is $q\in\{1,\dots,Q\}$ such that $d_1((y_{q+i},y_{q+i+1}),(x_i^*,x_{i+1}^*))\le\Delta\,(i=0,1,\dots)$.*

Proof. There exists $R(\Delta)\in(0,\Delta)$ such that Lemma 12 holds for Δ, $R(\Delta)$. We choose $R\in(0,R(\Delta))$ satisfying $R\le(48m)^{-1}C_2(R(\Delta))$ and an integer $Q\ge 400\|\theta\|C_2(R(\Delta))^{-1}m$. Let $u\in\mathbf{C}(K\times K)$, $\|u-v\|\le R$ and $\{y_i\}_{i=0}^{\infty}$ be a program satisfying $\theta^u(y_i,y_{i+1})=0\,(i=0,1,\dots)$. By Lemma 1, which holds for $\delta=R(\Delta)$, there is $q\in\{1,\dots,Q\}$ satisfying $d(y_q,x_0^*)\le R(\Delta)$. The lemma now follows from Lemma 12 and the definition of $R(\Delta)$.

LEMMA 14. *Let $m=1$, $\delta>0$. Then there exist $R_0\in(0,\delta)$ and an integer $Q\ge 1$ such that for every $u\in\mathbf{C}(K\times K)$ satisfying $\|u-v\|\le R_0$, for every integer $N\ge 2Q$, and for every program $\{y_i\}_{i=0}^{N}\in A(u,N,R_0)$ the relation $d(y_i,x_0^*)\le\delta$ holds for $i=Q,\dots,N-Q$. Moreover, if $d(y_0,x_0^*)\le R_0$, then $d(y_i,x_0^*)\le\delta$ for $i=0,\dots,N-Q$.*

Proof. We choose $R\in(0,\min\{\delta,\|\theta\|\})$ such that Lemma 2 holds for $\varepsilon=\delta$ and R. We choose $\delta_0\in(0,8^{-1}R)$ satisfying $64C_1(4\delta_0)\le R$ and choose $R_0\in(0,\delta_0)$ such that $R_0\le(48m)^{-1}C_2(\delta_0)$ and Lemma 3 holds for $\varepsilon=\delta_0$, $r=R_0$. We set $Q=400\|\theta\|C_2(\delta_0)^{-1}m$.

Let $u \in \mathbf{C}(K \times K)$, $\|u - v\| \leq R_0$, integer $N \geq 2Q$, and $\{y_i\}_{i=0}^N \in A(u, N, R_0)$. Lemma 1, which holds for $\delta = \delta_0$, $\phi = u - v$, and $\{y_i\}_{i=0}^N$ by the choice of R_0, implies the existence of integers p and q such that $0 < p < q < N$, $Q \geq p$, $N - q \leq Q$, $d(y_{p-1}, x_0^*) \leq \delta_0$, and $d(y_{q+1}, x_0^*) \leq \delta_0$. If $d(x_0^*, y_0) \leq R_0$, then we assume that $p = 1$. By Lemma 3, which holds for $\varepsilon = \delta_0$, $r = R_0$, there exists a program $\{a_i\}_{i=0}^{q-p}$ such that $a_0 = a_{q-p} = x_0^*$,

$$\sum_{i=0}^{q-p-1} (\phi + \theta)(a_i, a_{i+1}) \leq \ell(\phi, q - p) + 6C_1(\delta_0). \tag{4.25}$$

Consider a program $\{z_i\}_{i=0}^N$, where $z_i = y_i \, (i \in \{0, \ldots, p-1\} \cup \{q+1, \ldots, N\})$, $z_i = a_{i-p} \, (i = p, \ldots, q)$. The relation $\{y_i\}_{i=0}^N \in A(u, N, R_0)$ and our choice of p and q imply that

$$\begin{aligned} R_0 &\geq \sum_{i=0}^{N-1} u(y_i, y_{i+1}) - \sum_{i=0}^{N-1} u(z_i, z_{i+1}) \\ &= \sum_{i=p-1}^{q} [(\theta + \phi)(y_i, y_{i+1}) - (\theta + \phi)(z_i, z_{i+1})] \\ &\geq \sum_{i=p}^{q-1} (\theta + \phi)(y_i, y_{i+1}) - \sum_{i=0}^{q-p-1} (\theta + \phi)(a_i, a_{i+1}) - 4R_0 - 2C_1(\delta_0). \end{aligned}$$

It follows from this relation, relation (4.25), and the choice of R_0 and δ_0 that

$$\sum_{i=p}^{q-1} (\theta + \phi)(y_i, y_{i+1}) \leq \ell(\phi, q - p) + 5R_0 + 8C_1(\delta_0) \leq R + \ell(\phi, q - p).$$

By Lemma 2, which holds for $\varepsilon = \delta$ and R, we have $d(y_{p+i}, x_0^*) \leq \delta_0 \, (i = 0, \ldots, q - p)$. The lemma is proved.

5. Proof of theorems. We consider the set E of all functions $v \in \mathbf{C}(K \times K)$ for which there exist an integer $m(v) \geq 1$, a sequence $\{x_i^*(v)\}_{i=0}^{m(v)} \subset K$, continuous functions $\pi_v : K \to \mathbf{R}^1$, $\theta_v : K \times K \to \mathbf{R}^1$, and a number μ_v such that the following conditions hold:

1. For $i, j \in \{0, \ldots, m(v)\}$ satisfying $i < j$ the equality $x_i^*(v) = x_j^*(v)$ holds if and only if $i = 0$, $j = m(v)$;
2. $v(x, y) = \mu_v + \pi_v(x) - \pi_v(y) + \theta_v(x, y)(x, y \in K)$;
3. $\|\theta_v\| > 0$, the function θ_v is nonnegative, $\theta_v(x, y) = 0$ if and only if

$$(x, y) \in \{(x_i^*(v), x_{i+1}^*(v)) : i = 0, \ldots, m(v) - 1\}.$$

At the beginning of §2 we already noted that E is dense everywhere in $\mathbf{C}(K \times K)$. It is easy to see that $\mu(v) = \mu_v (v \in E)$, and for every $v \in E$ we can apply Lemmas 1–14. For every $v \in E$ and every $i \in \{0, \pm 1, \ldots\} \backslash \{0, \ldots, m(v)\}$ define $x_i^*(v) \in K$ such that $x_{i+m(v)}^*(v) = x_i^*(v) \, (i = 0, \pm 1, \ldots)$. Let $v \in E$. We set

$$D(v) = 8^{-1} \inf\{d(x_i^*(v), x_j^*(v)) : i, j \in \{0, \ldots, m(v) - 1\}, \, i \neq j\}. \tag{5.1}$$

If $m(v) = 1$, then $D(v) = +\infty$.

Let $p \in \{1, 2, \ldots\}$. We define

$$\delta(v, p) = \inf\{2^{-1} D(v), p^{-1}\}. \tag{5.2}$$

It is easy to see that there exist numbers $\Gamma(v,p) \in (0,\delta(v,p))$, $d(v,p) \in (0,\Gamma(v,p))$, positive numbers $Q_1(v,p)$, $Q_2(v,p)$, and an integer $Q_3(v,p) \geq 1$ such that the following conditions hold:

a) If $m(v) = 1$, then Lemma 14 holds for $\delta = \delta(v,p)$, $R_0 = 4\Gamma(v,p)$, $Q = Q_3(v,p)$, $x_0^* = x_0^*(v)$;

b) Lemma 12 holds for $\Delta = \delta(v,p)$, $R(\Delta) = 4\Gamma(v,p)$, $m = m(v)$, $x_i^* = x_i^*(v)$ $(i = 0, \pm 1, \ldots)$;

c) Lemma 13 holds for $\Delta = \delta(v,p)$, $R = 4\Gamma(v,p)$, $Q = Q_3(v,p)$, $x_i^* = x_i^*(v)$ $(i = 0, \pm 1, \ldots)$;

d) Lemma 4 holds for $\varepsilon_0 = \Gamma(v,p)$, $r = d(v,p)$, $x_i^* = x_i^*(v)$ $(i = 0, \pm 1, \ldots)$;

e) Lemma 6 holds for $\Delta = \Gamma(v,p)$, $r(\Delta) = d(v,p)$, $Q_1(\Delta) = Q_1(v,p)$, $Q_2(\Delta) = Q_2(v,p)$, $m = m(v)$, $x_i^* = x_i^*(v)$ $(i = 0, \pm 1, \ldots)$;

f) Lemma 10 holds for $\Delta = \Gamma(vp)$, $h = d(vp)$.

Now, we define $F = \cap_{p=1}^{\infty} \cup_{v \in E} B(v, d(v,p))$. It follows from the construction of F that Theorems 3 and 4 of [13] are valid for F. For the set F we will prove Theorems 1 – 4 of this paper.

It is easy to see that Theorem 1 follows from Lemma 10 and the definition of F (see condition f).

Proof of Theorem 2. Let $u \in F$, $\delta > 0$. Choose an integer $p \geq 1$ satisfying $4p^{-1} < \delta$. There exists $v \in E$ for which $u \in B(v, d(v,p))$. We define

$$W(u) = B(v, d(v,p)), \quad Q_1 = Q_1(v,p), \quad Q_2 = Q_2(v,p). \tag{5.3}$$

By condition d) we have

$$\operatorname{dist}(H(u), \{(x_i^*(v), x_{i+1}^*(v)) : i = 0, \ldots, m(v) - 1\}) \leq \Gamma(v,p). \tag{5.4}$$

By condition e) Lemma 6 holds for $\Delta = \Gamma(v,p)$, $r(\Delta) = d(v,p)$, $Q_i(\Delta) = Q_i$ $(i = 1,2), m = m(v), x_i^* = x_i^*(v) (i = 0, \pm 1, \ldots)$.

Let $w \in W(u)$, N be an integer, $N \geq 1$, $M > 0$, and $\{y_i\}_{i=0}^N \in A(w, N, M)$. Then, by Lemma 6

(5.5)
$$\operatorname{Card}\left\{ i \in \{0, \ldots, N-1\} : (y_i, y_{i+1}) \notin \bigcup_{j=0}^{m(v)-1} \bar{B}((x_j^*(v), x_{j+1}^*(v)), \Gamma(v,p)) \right\} \leq Q_1 + MQ_2.$$

This relation and relation (5.4) imply

$$\operatorname{Card}\{i \in \{0, \ldots, N-1\} : d_1((y_i, y_{i+1}), H(u)) > 4\Gamma(v,p)\} \leq Q_1 + MQ_2.$$

This completes the proof of the theorem.

We have the following result.

PROPOSITION 2. *Let $u \in F$, $(x_0, x_1) \in H(u)$. Then there exists a sequence $\{x_i\}_{i=-\infty}^{\infty} \subset K$ such that $(x_i, x_{i+1}) \in H(u)$, $\theta^u(x_i, x_{i+1}) = 0$ $(i = 0, \pm 1, \ldots)$.*

Proof. Let $\{z_i\}_{i=0}^{\infty}$ be a (u)-good program. For an integer $p \geq 0$ denote by Z^p a sequence $\{z_i^p\}_{i=-p}^{\infty}$, where $z_i^p = z_{i+p}$ $(i = -p, -p+1, \ldots)$. It is easy to see that there exists a subsequence $\{Z^{p_k}\}_{k=1}^{\infty}$ such that

$$z_i^{p_k} \xrightarrow[k \to \infty]{} x_i \in K \qquad (i = 0, \pm 1, \ldots).$$

Clearly, $\{x_i\}_{i=-\infty}^{\infty}$ is the required sequence.

Proof of Theorem 3. Let $u \in F$, $\varepsilon > 0$. We choose an integer $p \geq 1$ satisfying $4p^{-1} < \varepsilon$. There exists $v \in E$ such that $u \in B(v, d(v,p))$. By condition d) and Lemma 4 we have

$$\operatorname{dist}(H_0(u), \{x_i^*(v) : i = 0, \ldots, m(v) - 1\}) \leq \Gamma(v,p), \tag{5.6}$$

$$\operatorname{dist}(H(u), \{(x_i^*(v), x_{i+1}^*(v)) : i = 0, \ldots, m(v) - 1\}) \leq \Gamma(v,p). \tag{5.7}$$

We define

$$W(u) = B(v, d(v,p)), \qquad \delta = \Gamma(v,p). \tag{5.8}$$

Let $w \in W(u)$ and $\{x_i\}_{i=0}^{\infty}$ be a program such that $\theta^w(x_i, x_{i+1}) = 0\ (i = 0, 1, \ldots)$, $d(x_0, H_0(u)) \leq \delta$. Then, by (5.6), (5.8)

$$d(x_0, \{x_i^*(v) : i = 0, \ldots, m(v) - 1\}) \leq 2\Gamma(v,p),$$

and by condition b) and Lemma 12

$$d_1((x_i, x_{i+1}), \{(x_i^*(v), x_{i+1}^*(v)) : i = 0, \ldots, m(v) - 1\}) \leq \delta(v,p)$$

for $i = 0, 1, \ldots$. By (5.7) and by our choice of p

$$d_1((x_i, x_{i+1}), H(u)) \leq 2\delta(v,p) \leq 2p^{-1} < \varepsilon \qquad (i = 0, 1, \ldots).$$

Assertion 1 is proved.

Let us prove assertion 2. Let $u \in F$, $\varepsilon > 0$. We choose an integer $p \geq 1$ satisfying $4 < p\varepsilon$. There exists $v \in E$ such that $u \in B(v, d(v,p))$. By condition d) and Lemma 4 we have

$$\operatorname{dist}(H(u), \{(x_i^*(v), x_{i+1}^*(v)) : i = 0, \ldots, m(v) - 1\}) \leq \Gamma(v,p). \tag{5.9}$$

We define

$$W(u) = B(v, d(v,p)), \qquad N = Q_3(v,p). \tag{5.10}$$

Let $w \in W(u)$ and $\{y_i\}_{i=0}^{\infty}$ be a program satisfying $\theta^w(y_i, y_{i+1}) = 0\,(i = 0, 1, \ldots)$. Then, by condition c), Lemma 13, and relation (5.9)

$$d_1((y_{i+N}, y_{i+N+1}), \{(x_i^*(v), x_{i+1}^*(v)) : i = 0, \ldots, m(v) - 1\}) \leq \delta(v,p)\,(i = 0, 1, \ldots),$$
$$d_1((y_i, y_{i+1}), H(u)) \leq 2\delta(v,p) < \varepsilon \qquad (i \geq N).$$

Hence, Assertion 2 is proved.

Proof of Theorem 4. Let $u \in F$, $\varepsilon > 0$. We choose an integer $p \geq 1$ satisfying $4p^{-1} < \varepsilon$ There exists $v \in E$ such that $u \in B(v, d(v,p))$. By condition d) and Lemma 4 we have

$$\operatorname{dist}(H(u), \{(x_i^*(v), x_{i+1}^*(v)) : i = 0, \ldots, m(v) - 1\}) \leq \Gamma(v,p). \tag{5.11}$$

By corollary 2 of Theorem 3 there exists a neighborhood $W(u)$ of u in $\mathbf{C}(K \times K)$ such that $W(u) \subset B(v, d(v,p))$, and for every $w \in W(u)$, for every program $\{x_i\}_{i=-\infty}^{\infty}$ satisfying $\theta^w(x_i, x_{i+1}) = 0\,(i = 0, \pm 1, \ldots)$ the relation $d_1((x_i, x_{i+1}), H(u)) \leq \Gamma(v,p)\,(i = 0, \pm 1, \ldots)$ holds.

Let $w \in W(u)$ and $\{y_i\}_{i=-\infty}^{\infty}$ be a program satisfying $\theta^w(y_i, y_{i+1}) = 0$ $(i = 0, \pm 1, \ldots)$. By (5.11)

$$(y_i, y_{i+1}) \in \bigcup_{j=0}^{m(v)-1} \bar{B}((x_j^*(v), x_{j+1}^*(v)), 2\Gamma(v,p)) \qquad (i = 0, \pm 1, \ldots),$$

and there is an integer k such that

$$d_1((y_i, y_{i+1}), (x_{i+k}^*(v), x_{i+k+1}^*(v))) \leq 2\Gamma(v,p) \qquad (i = 0, \pm 1, \ldots).$$

Now it is easy to see that for all integers i, j the relation $d(y_i, y_{i+jm(v)}) \leq 4\Gamma(v,p) \leq \varepsilon$ holds. Theorem 4 is proved.

We will prove the following result.

THEOREM 5. 1. *Let $u \in F$, $\{x_i\}_{i=0}^{\infty}$ be a (u)-good program. Then there exists a program $\{y_i\}_{i=-\infty}^{\infty}$ such that*

$$\theta^u(y_i, y_{i+1}) = 0 \quad (i = 0, \pm 1, \ldots), \quad \lim_{i\to\infty} d(x_i, y_i) = 0.$$

2. *Let $u \in F$, $\{x_i\}_{i=-\infty}^{\infty}$ be a (u)- minimal energy configuration. Then there exist programs $\{y_i\}_{i=-\infty}^{\infty}$, $\{z_i\}_{i=-\infty}^{\infty}$ such that*

$$\theta^u(y_i, y_{i+1}) = 0, \quad \theta^u(z_i, z_{i+1}) = 0 \quad (i = 0, \pm 1, \ldots),$$
$$\lim_{i\to+\infty} d(x_i, y_i) = 0, \quad \lim_{i\to-\infty} d(x_i, z_i) = 0.$$

Proof. First we will prove assertion 1. Let $u \in F$, $\{x_i\}_{i=0}^{\infty}$ be a (u)-good program. By [13, Thm. 3] the program $\boldsymbol{x}$ is asymptotic almost periodic. Therefore for every integer $p \geq 1$ there exist integers $k(p) \geq 2$, $m(p) \geq 2$ such that

$$d(x_i, x_{i+m(p)j}) \leq p^{-1} \quad (i \geq k(p),\ j \geq 1). \tag{5.12}$$

For every integer $p \geq 0$ let us denote by X^p a sequence $\{x_i^p\}_{i=-p}^{\infty}$, where $x_i^p = x_{i+p}$ $(i = -p, -p+1, \ldots)$. We define

$$M(p) = \prod_{i=1}^{p} m(i) \qquad (p = 1, 2, \ldots).$$

Let Q be an integer, $Q \geq 1$, and let us consider a program $X^{M(Q)} = \{x_i^{M(Q)}\}_{i=-M(Q)}^{\infty}$. Let $p \in \{1, \ldots, Q\}$ and i be an integer satisfying $i \geq k(p)$. By (5.12) and the definition of $M(Q)$ we have $d(x_i, x_i^{M(Q)}) = d(x_i, x_{i+M(Q)}) \leq p^{-1}$. We have proved that for every integer $Q \geq 1$ the following relation holds:

$$d(x_i, x_i^{M(Q)}) \leq p^{-1} \qquad (i \text{ is an integer}, i \geq k(p)),\ (p \in \{1, \ldots, Q\}). \tag{5.13}$$

There exists a subsequence $\{X^{M(Q_j)}\}_{j=1}^{\infty}$ such that

$$x_i^{M(Q_j)} \xrightarrow[j\to\infty]{} y_i \in K \quad \text{for every integer } i.$$

Assertion 1 now follows from (5.13).

Now we will prove assertion 2. Let $u \in F$ and $\{x_i\}_{i=-\infty}^{\infty}$ be a (u)-minimal energy configuration. The existence of configuration $\{y_i\}_{i=-\infty}^{\infty}$ follows from Assertion 1, which holds for the (u)-good program $\{x_i\}_{i=0}^{\infty}$. Let us prove the existence of the program $\{z_i\}_{i=-\infty}^{\infty}$. Fix an integer $p \geq 1$. There exists $v \in E$ for which $u \in B(v, d(v,p))$. By condition d) and Lemma 4 we have

$$\text{dist}(H(u), \{(x_i^*(v), x_{i+1}^*(v)) : i = 0, \dots, m(v)-1\}) \leq \Gamma(v,p). \tag{5.14}$$

By Theorem 2 there exists an integer $Q(p) \geq 1$ such that for all integers N_1 and N_2 satisfying $N_1 < N_2$ the following relation holds:

$$\text{Card}\{i \in \{N_1, \dots, N_2 - 1\} : d_1((x_i, x_{i+1}), H(u)) > 2^{-1}(\delta(v,p) - \Gamma(v,p))\} \leq Q(p).$$

By this relation and by (5.14) there exists an integer $k(p) \geq 1$ such that

$$\begin{aligned} &d_1((x_i, x_{i+1}), H(u)) \leq 2^{-1}(\delta(v,p) - \Gamma(v,p)) \qquad (i \leq -k(p)),\\ &d_1((x_i, x_{i+1}), \{(x_i^*(v), x_{i+1}^*(v)) : i = 0, \dots, m(v)-1\})\\ &\quad \leq 2^{-1}(\delta(v,p) + \Gamma(v,p)) \qquad (i \leq -k(p)). \end{aligned} \tag{5.15}$$

We have $\delta(v,p) \leq 16^{-1} \inf\{d(x_i^*(v), (x_j^*(v)) : i, j \in \{0, \dots, m(v)-1, i < j\}$; hence, there exists an integer G such that

$$\begin{aligned} &d_1((x_{-k(p)+i}, x_{-k(p)+i+1}), (x_{G+i}^*(v), x_{G+i+1}^*(v))) \leq 2^{-1}(\delta(v,p) + \Gamma(v,p))\\ &(i = 0, -1, -2, \dots). \end{aligned} \tag{5.16}$$

Set $N(p) = m(v)$. Relation (5.16) implies

$$d(x_i, x_{i+jN(p)}) \leq 2p^{-1} \qquad (i \leq -k(p), j \leq -1). \tag{5.17}$$

For an integer $p \geq 1$ we define $M(p) = 2^p \prod_{i=1}^{p} N(i)$ and denote by X^p a sequence $\{x_i^p\}_{i=-\infty}^{\infty}$, where $x_i^p = x_{i-p} (i = 0, \pm 1, \dots)$.

Let $Q \geq 1$ be an integer, $p \in \{1, \dots Q\}$, and i be an integer satisfying $i \leq -k(p)$. It follows from (5.17) and the definition of $M(Q)$ that

$$d(x_i, x_i^{M(Q)}) = d(x_i, x_{i-M(Q)}) \leq 2p^{-1} \qquad (i \leq -k(p)).$$

We have proved that for every integer $Q \geq 1$ the following relation holds:

$$d(x_i, x_i^{M(Q)}) \leq 2p^{-1} \qquad (i \leq -k(p)), (p \in \{1, \dots Q\}). \tag{5.18}$$

There exists a subsequence $\{X^{M(Q_j)}\}_{j=1}^{\infty}$ such that

$$x_i^{M(Q_j)} \xrightarrow[j \to \infty]{} z_i \in K \text{ for every integer } i.$$

Assertion 2 then follows from (5.15) and (5.18). Theorem 5 is proved.

We define $\tilde{\mathbf{C}}(K \times K) = \{v \in \mathbf{C}(K \times K) : \mu(v) = \max\{v(x,x) : x \in K\}\}$. It is easy to see that $\tilde{\mathbf{C}}(K \times K)$ is a closed subspace of $\mathbf{C}(K \times K)$. The space $\tilde{\mathbf{C}}(K \times K)$ has also the topology of the uniform convergence. We reenforce the previous theorems for $u \in \tilde{\mathbf{C}}(K \times K)$ and prove the existence of a set $F_0 \subset F \cap \tilde{\mathbf{C}}(K \times K)$ which is a countable intersection of subsets of $\tilde{\mathbf{C}}(K \times K)$ open everywhere dense in $\tilde{\mathbf{C}}(K \times K)$ and for which Theorem 6 holds. This theorem shows that for every $u \in F_0$ and every $x \in K$ there is a (u)-overtaking optimal program $\{x_i\}_{i=0}^{\infty}$ satisfying $x_0 = x$ and establishes an analogue of the strong turnpike theorem for $u \in F_0$.

THEOREM 6. 1. Card $(H_0(u)) = 1(u \in F_0)$.

2. *Let $u \in F_0$ and δ be a positive number. Then there exists a neighborhood $W(u)$ of u in $\mathbf{C}(K \times K)$ such that for every $w \in W(u)$, for every (w)-good program $\boldsymbol{x}$ the following relation holds*: dist $(\Omega(\mathbf{x}), (H_0(u) \times H_0(u))) \leq \delta$.

3. *Let $u \in F_0$ and $\{x_i\}_{i=0}^{\infty}$ be a program for which $\theta^u(x_i, x_{i+1}) = 0\,(i = 0, 1, \dots)$. Then $\{x_i\}_{i=0}^{\infty}$ is a (u)-overtaking optimal program, and moreover, if $\{y_i\}_{i=0}^{\infty}$ is a program such that $y_0 = x_0$,*

$$\liminf \sum_{i=0}^{N-1} [u(y_i, y_{i+1}) - u(x_i, x_{i+1})] = 0$$

then $\theta^u(y_i, y_{i+1}) = 0(i = 0, 1, \dots)$.

4. *Let $u \in F_0$, $\varepsilon > 0$. Then there exist a neighborhood $W(u)$ of u in $\mathbf{C}(K \times K)$, an integer $Q \geq 1$, and $\varepsilon_0 \in (0, \varepsilon)$ such that for every $w \in W(u)$, every integer $N \geq 2Q$, and every program $\{y_i\}_{i=0}^{N} \in A(w, N, \varepsilon_0)$ the following relation holds*: $d(y_i, H_0(u)) \leq \varepsilon(i = Q, \dots, N-Q)$ *and if $d(y_0, H_0(u)) \leq \varepsilon_0$, then $d(y_i, H_0(u)) \leq \varepsilon(i \in \{0, \dots, N-Q\})$.*

Proof. We define

$$E_0 = \{v \in E : m(v) = 1\}, \qquad F_0 = \bigcap_{p=1}^{\infty} \bigcup_{v \in E_0} B(v, d(v, p)).$$

It is easy to see that E_0 is dense everywhere in $\tilde{\mathbf{C}}(K \times K)$, $F_0 \subset F \cap \tilde{\mathbf{C}}(K \times K)$. Condition d) and Lemma 4 imply the validity of assertion 1. Assertion 2 follows from Assertion 3 of [13, Thm. 3] and the relation Card $\{H_0(u)\} = 1(u \in F_0)$. This relation also implies assertion 3.

Let us prove assertion 4. Let $u \in F_0$, $\varepsilon > 0$. Choose an integer $p \geq 1$ such that $4p^{-1} < \varepsilon$. There is $v \in E_0$ for which $u \in B(v, d(v, p))$. We define $W(u) = B(v, d(v, p))$, $Q = Q_3(v, p)$, $\varepsilon_0 = \Gamma(v, p)$. By condition d) and Lemma 4

$$d(H_0(u), x_0^*(v)) \leq \Gamma(v, p). \tag{5.19}$$

Let $w \in W(u)$, $N \geq 2Q$, and $\{y_i\}_{i=0}^{N} \in A(w, N, \varepsilon_0)$. Then, by condition a) and by Lemma 14 the following conditions hold:

$$d(y_i, x_0^*(v)) \leq \delta(v, p) \qquad (i \in \{Q, \dots, N-Q\});$$

if $d(y_0, x_0^*(v)) \leq 4\Gamma(v, p)$, then $d(y_i, x_0^*(v)) \leq \delta(v, p)(i \in \{0, \dots, N-Q\})$. By these conditions and (5.19) we have

$$d(y_i, H_0(u)) \leq 2\delta(v, p) \leq 2p^{-1} \leq \varepsilon \qquad (i \in \{Q, \dots, N-Q\}),$$

and if $d(y_0, H_0(u)) \leq \varepsilon_0 = \Gamma(v, p)$, then $d(y_0, x_0^*(v)) \leq 2\Gamma(v, p)$,

$$d(y_i, x_0^*(v)) \leq \delta(v, p) \qquad (i \in \{0, \dots, N-Q\}),$$
$$d(y_i, H_0(u)) \leq 2\delta(v, p) \leq 2p^{-1} \leq \varepsilon \qquad (i = 0, \dots, N-Q).$$

Theorem 6 is proved.

Acknowledgments. The author thanks Dr. Arie Leizarowitz for fruitful discussions.

COCOLOG: A CONDITIONAL OBSERVER AND CONTROLLER LOGIC FOR FINITE MACHINES*

PETER E. CAINES[†] AND SUNING WANG[‡]

Abstract. The problem of observation and control for partially observed input–state–output machines is formulated in terms of a tree of first-order logical theories. A set of first-order languages for the description of the controlled evolution and state estimation of any given machine $\mathcal{M}$ is specified; further, extralogical conditional control rules are formulated so that closed loop control actions occur when extralogically specified past observation dependent conditions are fulfilled. In particular, conditional control rules may include commands that steer the system state from a current partially observed state (estimate) to a target state if such a sequence of controls can be proven to exist. Starting from a general theory of $\mathcal{M}$ at the initial instant, observations on the input–output behaviour of the system at each later instant are accepted by the system as new axioms; these are then used together with the previously generated theory to generate the current theory. The acronym COCOLOG is used to denote the family of first-order *conditional observer and controller logics* for any given input–state–output system. A semantics is supplied for each COCOLOG system in terms of interpretations of controlled transitions on a tree indexed by the possible sequences of input–output observations. Extralogical rules, including the conditional control rules, relating members of the family of theories of a COCOLOG system are presented in the form of a set of metalevel rules. Following the complete definition of a COCOLOG system, the consistency and completeness of the first-order theories in a COCOLOG system are established, decidability is obtained using a unique model property, and examples of the operation of a COCOLOG logic control system are given.

AMS subject classifications. 93, 68, 03

1. Introduction. In this paper we introduce certain partially ordered sets of first-order logical theories which we call *conditional observer and controller logics*, or COCOLOG systems for short. A COCOLOG system provides a logical system for (i) describing and reasoning about the state estimation and control of a given finite input–state–output machine $\mathcal{M}$ and (ii) acting upon $\mathcal{M}$ via a closed-loop logic regulator $\mathcal{R}$ carrying the corresponding COCOLOG system.

A particular subset of the formulas in each of the constituent logical languages of a COCOLOG system is called the set of *conditional control rules* (CCRs); these are formulated so that a certain control action is specified at an instant k when a certain set of past measurable (i.e., past observations-dependent) conditions C_k are fulfilled. In COCOLOG this translates precisely into the existence of a proof, in the corresponding first-order logical theory, of a formula describing the conditions C_k. Conditional control statements may include, for example, control commands that will steer the current system state or its estimate to a given target state $\mathbf{x}^{\mathbf{T}}$; such commands would be implemented whenever a sequence of controls achieving this objective can be proven to exist, with the uniqueness of the selected control ensured via a prescribed arrangement of the CCRs.

The conceptualization of a feedback regulator system adopted in this paper is qualitatively different from the usual notion of a feedback system. In the customary formulation, a feedback regulator, which shall be denoted by $\mathcal{R}$, is an input–output dynamical system whose inputs are typically the measured outputs of the controlled system $\mathcal{M}$ and whose outputs are the controlled inputs to $\mathcal{M}$. Hence the system and the regulator are objects of the same type, namely input(–state)–output dynamical systems. However, in our formulation, when $\mathcal{M}$ is in

a feedback loop with a logic regulator $\mathcal{R}$, the situation is quite different and we now give a sketch of the operation of the system $(\mathcal{M}, \mathcal{R})$.

At each discrete time instant k, the previous input $\mathbf{u}_{k-1}$ and output $\mathbf{y}_k$ of the system $\mathcal{M}$, taking the values $\mathbf{u}^{\mathbf{i}}$ and $\mathbf{y}^{\mathbf{j}}$ in the finite sets $\mathbf{U}$ and $\mathbf{Y}$, are mapped extralogically into formulas called *observation axioms*, which are accepted by the regulator $\mathcal{R}$. In the present case, $\mathcal{R}$ is conceived of as a *dynamical logical system* mapping theories to theories (see the papers of Caines, Greiner, and Wang [1988], [1991]) and emitting outputs via a second extralogical map. Let the theory carried by $\mathcal{R}$ at the instant $k-1$ be denoted $Th(o_1^{k-1})$, where o_1^{k-1} denotes the sequence of observations over $[1, k-1]$. At the instant k the equality predicates relating the constant symbols $U(k-1)$ and $Y(k)$ at k to the observed quantities $\mathbf{u}^{\mathbf{i}}$ and $\mathbf{y}^{\mathbf{j}}$ are accepted as new information into the theory $Th(o_1^{k-1})$. By this we mean that these equality predicates are taken as new axioms to be added to $Th(o_1^{k-1})$. In addition, the state estimation axioms indexed by k are also accepted as new axioms. The theory carried by $\mathcal{R}$ is then transformed into the deductive closure of (i) $Th(o_1^{k-1})$, (ii) the observation axioms, and (iii) the state estimation axioms, and this is relabeled as $Th(o_1^k)$. By their design, the conditional control rules yield a unique, deducible, constant symbol for the input, $U(k)$, to $\mathcal{M}$ at k. The predicate defining this value is then mapped by the second extralogical transformation referred to above into the quantity which forms the input, lying in the finite set $\mathbf{U}$, to $\mathcal{M}$ at the instant k, and this predicate is also handed on to the subsequent axiom set as an observation axiom. The system $\mathcal{M}$ now performs another dynamical evolution step to generate the observed output $\mathbf{y}_{k+1} \epsilon \mathbf{Y}$ at the instant $k+1$, and this completes the dynamics-to-logical theory cycle $\mathcal{M} \rightarrow \mathcal{R} \rightarrow \mathcal{M}$.

The process above is initiated with the system $\mathcal{M}$ in its initial state $\mathbf{x}_0$ and the regulator $\mathcal{R}$ carrying only $Th_o \underline{\Delta} Th(o_1^o)$ (where $\underline{\Delta}$ denotes "denotes"), where $Th(o_1^o)$ consists of the deductive closure of the dynamical axioms of $\mathcal{M}$ (i.e., those describing the state transition and output maps) together with the logical axioms, the axioms for equality, the axioms for the reachability predicates, and the axioms for a simple arithmetic.

(It is evident that the $\mathcal{M} \rightarrow \mathcal{R} \rightarrow \mathcal{M}$ feedback loop may be generalized to a loop $\mathcal{L} \rightarrow \mathcal{R} \rightarrow \mathcal{L}$, where $\mathcal{L}$ is itself a dynamical logical system, but the investigation of this is left for future work.)

The exposition in this paper is in terms of finite state machines solely to establish the theory of COCOLOG systems in its simplest context. There is no obstruction, in principle, to extending the theory to machines in continuous time, extended state machines (Ostroff [1989]), and the automata of Ramadge–Wonham discrete events systems theory (Ramadge and Wonham [1987], [1989]).

The development of COCOLOG for dynamical control systems has a twofold motivation: first, the hierarchical nature of contemporary computer controlled systems may be better understood and enhanced by a study of regulator systems conceptualized at the logico-linguistic level. A notable example in this context is the capacity of reasoning systems to accept and operate on existential assertions, something a classical dynamical regulator is incapable of doing. Second, a control objective in COCOLOG, such as steering the system state to some state $\mathbf{x}^{\mathbf{T}}$, may be modified at any instant in the controlled machine's operation by conditions which are expressed via conjunctions and disjunctions of predicates; such conditions will be accepted by a COCOLOG regulator as new CCRs on the basis of which new control laws will be deduced. By their nature, conventional dynamical regulators cannot easily accept significantly modified objectives but must be redesigned to fit a new task. (We note that this is in contradistinction to the ability of conventional regulators with fixed control objectives to adapt to changing system dynamics.) It would also appear that information concerning system dynamics and objectives involving combinations of rules, necessary conditions, and sets of alternatives is best expressed logically, and hence a logic-based controller is most suitable for operating in this domain. (See Dyck and Caines [1995].)

Previous work on the formulation of the theory presented here and its ramifications has appeared in papers by Caines, Greiner, and Wang, [1991]; Caines, Wang, and Greiner [1988]; Caines and Wang [1989a], [1989b]; Wang and Caines [1991]; and, in particular, by Caines and Wang [1990] and in the thesis by Wang [1991], on which the exposition in this paper is based in part.

Other works which are analogous to, but different from, that presented here are the situated automaton work of Rosenschein and Kaebling [1987] and the situation calculus work of Reiter [1991]; these fall within the long-standing program of research in artificial intelligence to create logical decision-making systems which can predict and analyse the properties of formally specified systems (see, e.g., McCarthy and Hayes [1969] and Green [1969]) and which could, in principle, interact with them as they evolve in time.

Further, there is the line of research of Thistle and Wonham [1986], Ostroff [1987], [1989], and Ostroff and Wonham [1985]. In this work a fully elaborated temporal logic framework is presented to verify the correctness of feedback control algorithms for extended state machines. More recently, Kohn [1988], [1991] has devised a formulation of the logic control problem in which equational axiom systems describe the dynamical properties of continuous time systems and the declarative language of the system expresses optimization goals and constraints. Automatic automata-based procedures then create what is called a declarative control architecture. A more distantly related line of work is the use of temporal logic to study the evolution of programmed computational processes (see Harrel [1979] and Goldblatt [1987]).

We conclude this introduction with a brief remark about computational implementation. In its most direct implementation, a COCOLOG controller requires the real-time implementation of automatic theorem-proving (ATP) programs. The status of automatic theorem proving might be thought to indicate that this would be a formidable task. However, the restrictive nature of the system dynamical axioms and the option of defining restricted but nontrivial sets of control rules suggest the possibility of an efficient implementation via some type of ATP program. Current ATP software development in the context of COCOLOG applications (see, e.g., Wang and Caines [1991], [1992]; Dyck and Caines [1995]; and Caines, Mackling, and Wei [1992]) appears to confirm this conjecture.

2. Finite state machines. In this section we formally introduce our finite machine setup and define the notions of observation and control which will be required in subsequent sections of this paper.

DEFINITION 2.1. *A* (partially observed) finite (input–state–output) machine *is a quintuple* $\mathcal{M} = (\mathbf{U},\mathbf{X},\mathbf{Y},\mathbf{\Phi},\boldsymbol{\eta})$, *where* $\mathbf{U}$ *is a (finite) set of* inputs, $\mathbf{X}$ *is a (finite) set of* states, $\mathbf{Y}$ *is a (finite) set of* outputs, $\mathbf{\Phi} : \mathbf{X} \times \mathbf{U} \rightarrow \mathbf{X}$ *is a total* transition function, *and* $\boldsymbol{\eta} : \mathbf{X} \rightarrow \mathbf{Y}$ *is a total* output function.

Concerning notation, we shall sometimes write $\mathbf{u}_i^n$ for the $(n-i+1)$–element sequence $[\mathbf{u}_i, \mathbf{u}_{i+1}, \mathbf{u}_{i+2}, \ldots, \mathbf{u}_n]$, where $\mathbf{u}_j \epsilon \mathbf{U}$ denotes the input at the time instance $j \epsilon \mathbb{N}_+$ (where $\mathbf{u}_j$ is identified with $[\mathbf{u}_j]$) and ϵ will denote the empty input string. We shall use the notion that for all sequences $\mathbf{u}_i^n = \epsilon$ whenever $i > n$.

The dynamical evolution of a finite machine $\mathcal{M} = (\mathbf{U},\mathbf{X},\mathbf{Y},\mathbf{\Phi},\boldsymbol{\eta})$ can be displayed by taking $\mathbf{U}^*$ to be the set of all finite sequence of inputs and by extending $\mathbf{\Phi} : \mathbf{X} \times \mathbf{U} \rightarrow \mathbf{X}$ to $\mathbf{\Phi} : \mathbf{X} \times \mathbf{U}^* \rightarrow \mathbf{X}$, where for all i, $n \epsilon \mathbb{N}_+$, for all $\mathbf{u}_i^n \epsilon \mathbf{U}^*$, and for all $\mathbf{x} \epsilon \mathbf{X}$, $\mathbf{\Phi}$ is recursively defined by

$$\begin{aligned} &\mathbf{\Phi}(\mathbf{x}, \epsilon) = \mathbf{x}, \\ &\mathbf{\Phi}(\mathbf{x}, \mathbf{u}_i^n) = \mathbf{\Phi}(\mathbf{\Phi}(\mathbf{x}, \mathbf{u}_i), \mathbf{u}_{i+1}^n). \end{aligned} \tag{2.1}$$

The *initial* (respectively, *current*) *state dynamical observer problem* for a finite machine $\mathcal{M}$ is to estimate $\mathcal{M}$'s *initial* (respectively, *current*) state from observations on its inputs and outputs over a finite time period. An *initial* (respectively, *current*) *state dynamical observer* takes as input the observed behaviour of a system, i.e., a sequence of input–output pairs, and generates as output a sequence of estimates of the initial (respectively, *current*) state of the system. The notion of estimate is made precise in set theoretic terms in the following definitions.

DEFINITION 2.2. *The N-element state sequence $\mathbf{x}_1^N \in \mathbf{X}^N$ is an N*-consistent state sequence with respect to the input–output sequence $\mathbf{o}_1^N = [\langle \mathbf{y}_1 \rangle, \langle \mathbf{u}_1, \mathbf{y}_2 \rangle, \dots, \langle \mathbf{u}_{N-1}, \mathbf{y}_N \rangle] \in \mathbf{O}_1^N \underline{\Delta} \mathbf{Y} \times (\mathbf{U} \times \mathbf{Y})^{N-1}$ *if $\mathbf{x}_1^N$ satisfies*

$$\mathbf{x}_k = \mathbf{\Phi}(\mathbf{x}_1, \mathbf{u}_1^{k-1}) \quad \textit{and} \quad \mathbf{y}_k = \boldsymbol{\eta}(\mathbf{x}_k) \quad \textit{for all } k \in [1, \dots, N]. \tag{2.2}$$

The set of all N-element state sequences with respect to $\mathbf{o}_1^N$ is denoted $CSS(\mathbf{o}_1^N)$.

We shall denote the projection operator from $\mathbf{o}_1^N$ onto the mth u-coordinate, $1 \le m \le N-1$, by $\mathbf{u}_m(\cdot)$ and that which projects onto the nth y-coordinate, $1 \le n \le N$, by $\mathbf{y}_n(\cdot)$. (Note that $\mathbf{u}_m(\mathbf{o}_1^N) = \mathbf{u}_m(\mathbf{o}_1^{N'})$ for $1 \le m \le N-1 \le N'-1$ and $\mathbf{y}_n(\mathbf{o}_1^N) = \mathbf{y}_n(\mathbf{o}_1^{N'})$ for $1 \le n \le N \le N'$.)

DEFINITION 2.3. *An* initial state estimate *set, with respect to the N-element observation sequence, $\mathbf{o}_1^N$, written $\{\widehat{\mathbf{x}}_1\}(\mathbf{o}_1^N)$, is the set of initial elements of consistent state sequences corresponding to $\mathbf{o}_1^N$, i.e.,*

$$\{\widehat{\mathbf{x}}_1\}(\mathbf{o}_1^N) = \{\mathbf{x} \in \mathbf{X};\ \mathbf{x} = P_1(\mathbf{x}_1^N) \textit{for some} \, \mathbf{x}_1^N \in CSS(\mathbf{o}_1^N)\}, \tag{2.3}$$

where $P_1(\cdot)$ denotes projection on the first component of the argument. Analogously, a current state estimate set, *with respect to the N-element observation sequence $\mathbf{o}_1^N$, written $\{\widehat{\mathbf{x}}_N\}(\mathbf{o}_1^N)$, is the set of final elements of consistent state sequences with respect to $\mathbf{o}_1^N$, i.e.,*

$$\{\widehat{\mathbf{x}}_N\}(\mathbf{o}_1^N) = \{\mathbf{x} \in \mathbf{X};\ \mathbf{x} = P_N(\mathbf{x}_1^N) \textit{for some} \, \mathbf{x}_1^N \in CSS(\mathbf{o}_1^N)\}, \tag{2.4}$$

where $P_N(\cdot)$ denotes projection on the Nth component of the argument.

DEFINITION 2.4. *A finite machine $\mathcal{M} = (\mathbf{U}, \mathbf{X}, \mathbf{Y}, \mathbf{\Phi}, \boldsymbol{\eta})$ is said to be* initial *(respectively,* current) state observable *if there exists a $K \in \mathrm{N}_+$ such that for all $N \ge K$ and all $\mathbf{u}_1^N \in \mathbf{U}^N$, the initial (respectively, current) state estimate $\{\widehat{\mathbf{x}}_1\}(\mathbf{o}_1^N)$ (respectively, $\{\widehat{\mathbf{x}}_N\}(\mathbf{o}_1^N)$) is a singleton.*

Consider any finite machine $\mathcal{M} = (\mathbf{U}, \mathbf{X}, \mathbf{Y}, \mathbf{\Phi}, \boldsymbol{\eta})$. Then for any observation sequence, $\mathbf{o}_1^N \in \mathbf{O}^N$, the following equations hold:

$$\begin{aligned} \{\widehat{\mathbf{x}}_1\}\,(\mathbf{o}_1^{N+1}) &= \{\widehat{\mathbf{x}}_1\}(\mathbf{o}_1^N) \cap \mathbf{\Phi}^{-1}(\boldsymbol{\eta}^{-1}(\mathbf{y}_{N+1}), \mathbf{u}_1^N) \\ &= \bigcap_{k=1}^{N+1} \mathbf{\Phi}^{-1}(\boldsymbol{\eta}^{-1}(\mathbf{y}_k), \mathbf{u}_1^{k-1}), \end{aligned} \tag{2.5}$$

$$\begin{aligned} \{\widehat{\mathbf{x}}_{N+1}\}(\mathbf{o}_1^{N+1}) &= \mathbf{\Phi}(\{\widehat{\mathbf{x}}_N\}(\mathbf{o}_1^N), \mathbf{u}_N) \cap \boldsymbol{\eta}^{-1}(\mathbf{y}_{N+1}) \\ &\subseteq \bigcap_{k=1}^{N} \mathbf{\Phi}(\boldsymbol{\eta}^{-1}(\mathbf{y}_k), \mathbf{u}_k^N) \cap \boldsymbol{\eta}^{-1}(\mathbf{y}_{N+1}), \end{aligned} \tag{2.6}$$

with equality in (2.6) if $\mathbf{\Phi}(\cdot, \mathbf{u})$ is one to one for each $\mathbf{u} \in \mathbf{U}$. In (2.5) and (2.6), $\mathbf{\Phi}$ has been extended to take sets of states in its first argument: $\mathbf{\Phi} : \mathcal{P}(\mathbf{X}) \times \mathbf{U}^* \mapsto \mathcal{P}(\mathbf{X})$, where $\mathcal{P}(\mathbf{S})$ denotes the power set of the set $\mathbf{S}$; this is done by setting $\mathbf{\Phi}(\mathbf{A}, \mathbf{u}_1^*) = \{\mathbf{x} \in \mathbf{X}; \mathbf{x} = \mathbf{\Phi}(\mathbf{x}', \mathbf{u}_1^*)$

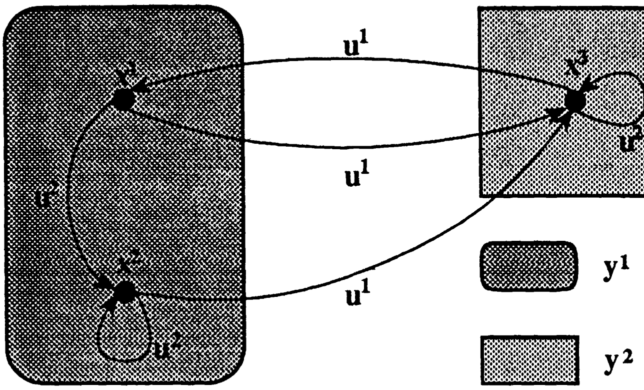

FIG. 1. *A three-state machine.*

for some $\mathbf{x}'\epsilon\mathbf{A}\}$. $\mathbf{\Phi}^{-1}$ denotes the inverse $\mathbf{\Phi}^{-1} : \mathcal{P}(\mathbf{X}) \times \mathbf{U}^* \mapsto \mathcal{P}(\mathbf{X})$, given by $\mathbf{\Phi}^{-1}(\mathbf{A},\mathbf{u}_1^*) = \{\mathbf{x}\epsilon\mathbf{X}; \mathbf{\Phi}(\mathbf{x},\mathbf{u}_1^*)\epsilon\mathbf{A}\}$ and similarly for η^{-1}. Finally, $\{\widehat{\mathbf{x}}_0\}(\mathbf{o}_1^0)$ is defined to be $\mathbf{X}$. (See the papers by Caines, Greiner, and Wang [1988], [1991].) We note that these equations possess the *predictor–corrector* form of many recursive algorithms in systems and control theory.

The corresponding partially ordered sets of initial and current state estimate sets will be referred to as the *initial* and *current observer trees*, respectively (for the given machine). Observe that although the state estimate sets may be identical for distinct input–output sequences, such distinct sequences uniquely define a directed acyclic graph with no confluences of edges. So at the cost of some redundancy, we shall label current state observation processes by the branches of the tree of input–output sequences and shall do the same for a COCOLOG family of theories.

Example 2.1. The following is an elementary example illustrating the notions introduced above. The finite machine $\mathcal{M}^3 = (\mathbf{U},\mathbf{X},\mathbf{Y},\mathbf{\Phi},\eta)$ is given in Fig. 1, where the input, state, and output sets are, respectively, $\mathbf{U} = \{\mathbf{u}^1, \mathbf{u}^2\}, \mathbf{X} = \{\mathbf{x}^1, \mathbf{x}^2, \mathbf{x}^3\}$, and $\mathbf{Y} = \{\mathbf{y}^1, \mathbf{y}^2\}$; the output function is given by $\eta(\mathbf{x}^1) = \eta(\mathbf{x}^2) = \mathbf{y}^1, \eta(\mathbf{x}^3) = \mathbf{y}^2$, and $\mathbf{\Phi}$ is given explicitly by the graph in the figure.

The notion of an N-consistent state sequence with respect to an input–output sequence is illustrated by the sequence of observations

$$\langle \mathbf{y}^1 \rangle, \langle \mathbf{u}^2, \mathbf{y}^1 \rangle, \langle \mathbf{u}^1, \mathbf{y}^2 \rangle,$$

which gives the corresponding 1-, 2-, and 3-consistent state sequences

$$\{\langle \mathbf{x}^1 \rangle, \langle \mathbf{x}^2 \rangle\}, \{\langle \mathbf{x}^1, \mathbf{x}^2 \rangle, \langle \mathbf{x}^2, \mathbf{x}^2 \rangle\}, \{\langle \mathbf{x}^1, \mathbf{x}^2, \mathbf{x}^3 \rangle, \langle \mathbf{x}^2, \mathbf{x}^2, \mathbf{x}^3 \rangle\}$$

and hence the sequence of initial state estimate sets

$$\{\mathbf{x}^1, \mathbf{x}^2\}, \{\mathbf{x}^1, \mathbf{x}^2\}, \{\mathbf{x}^1, \mathbf{x}^2\}$$

and the sequence of current state estimate sets

$$\{\mathbf{x}^1, \mathbf{x}^2\}, \{\mathbf{x}^2\}, \{\mathbf{x}^3\}.$$

We denote that the machine $\mathcal{M}^3$ is current state observable but not initial state observable.

DEFINITION 2.5. *A finite machine $\mathcal{M}$ is said to be* controllable *if for all* $\mathbf{x},\mathbf{x}'\epsilon\mathbf{X}$ *there exists a sequence* $\mathbf{u}_1^{n(\mathbf{x},\mathbf{x}')}$ *such that* $\mathbf{\Phi}(\mathbf{x}, \mathbf{u}_1^{n(\mathbf{x},\mathbf{x}')}) = \mathbf{x}'$ *or, equivalently, if for all* $\mathbf{x},\mathbf{x}'\epsilon\mathbf{X}$ *there exists* $n(\mathbf{x},\mathbf{x}')$ *such that* $\mathbf{x}'$ *is reachable from* $\mathbf{x}$ *in* $n(\mathbf{x},\mathbf{x}')$ *steps.*

By inspection, the machine in Example 2.1 is controllable.

The papers by Caines and Wang [1989] and Caines, Greiner, and Wang [1988], [1991] contain results concerning the combinatoric properties of initial and current state observer trees and give the following elementary dynamic programming theorem for the partially observed control problem: consider the problem of steering any unknown initial condition to an arbitrary target state x^T; then for current state observable and controllable finite state machines there exists a controller whose feedback control law is a function only of x^T and the sequence of current state estimate sets and which steers any initial unknown state to x^T.

3. COCOLOG: Syntax and semantics.

3.1. Syntax of COCOLOG L. The COCOLOG language consists of a set of symbols $S(L)$ and specified formation rules (or syntax). The subject of a COCOLOG language L is some given finite machine $\mathcal{M} = (\mathbf{U},\mathbf{X},\mathbf{Y},\mathbf{\Phi},\boldsymbol{\eta})$, where $\mathbf{U}$ is the set of inputs, $\mathbf{X}$ is the set of states, $\mathbf{Y}$ is the set of outputs, $\mathbf{\Phi}$ is a state transition function $\mathbf{\Phi} : \mathbf{X} \times \mathbf{U} \to \mathbf{X}$, and $\boldsymbol{\eta}$ is a state output function $\boldsymbol{\eta} : \mathbf{X} \to \mathbf{Y}$. It will be evident that we could construct a language L without reference to a finite machine, but this case will not be of interest to us in this paper.

We first define $S(L)$ *for the machine* $\mathcal{M}$ as

$$S(L) = \mathrm{Cons}_L \cup \mathrm{Var}_L \cup \mathrm{Fun}_L \cup \mathrm{Apr}_L \cup \mathrm{Qua}_L \cup \mathrm{Lco}_L \cup \{\perp\}.$$

The component sets of $S(L)$ are defined as follows.

Constant symbols. The constant symbols fall into the following typed subsets:

$$\mathrm{Cons}_L = \{u^1,\dots,u^m\} \cup \{x^1,\dots,x^N\} \cup \{y^1,\dots,y^p\} \cup \{0,1,\dots,k(N),k(N)+1\},$$

where $k(N)$ is an integer symbol and where the symbols $u^1,\dots,u^m; x^1,\dots,x^N$; and $y^1,\dots,y^p$ denote the individual elements of the input set $\mathbf{U}$, the state set $\mathbf{X}$, and the output set $\mathbf{Y}$, respectively.

Variable symbols. The variable symbols fall into the following typed subsets:

$$\mathrm{Var}_L = \{u,u',u'',\dots\} \cup \{x,x',x'',\dots\} \cup \{y,y',y'',\dots\} \cup \{l,l',l'',\dots\},$$

where the variables will be taken to be varying over different domains. $u,u',u'',\dots$ will be interpreted to represent elements in the set of inputs $\mathbf{U}$; the variables $x,x',x'',\dots,$ elements in the set of states $\mathbf{X}$; the variables $y,y',y'',\dots,$ elements in the set of outputs $\mathbf{Y}$; and the variables $l,l',l'',\dots,$ elements in the set of numbers $I_{k(N)}$; see §3.2 below.

Function symbols.

$$\mathrm{Fun}_L = \{\bar{\Phi}(\cdot,\cdot),\bar{\eta}(\cdot),+_L(\cdot,\cdot),-_L(\cdot,\cdot)\}.$$

Terms. The elements of the set Term_L are defined by the following:

(i) Each constant and variable symbol is a term; i.e., $\mathrm{Cons}_L \cup$ $\mathrm{Var}_L \subseteq \mathrm{Term}_L$.

(ii) If $t_1,\dots,t_n$ are terms and f is a function symbol of arity n, then $f(t_1,\dots,t_n)$ is a term.

(iii) The elements of Term_L are constructed only by steps (i) and (ii) above.

Atomic predicate symbols. $\mathrm{Apr}_L = \{\mathrm{E}q(\cdot,\cdot), Rbl(\cdot,\cdot,\cdot)\}$.

Sorting constraints. The predicate and function symbols are taken to satisfy the following sorting constraints on their arguments, where all admissible symbol strings are of finite length:

$\mathrm{E}q(\alpha,\beta)$: α and β are terms of the same type.

$\mathrm{E}q(\bar{\Phi}(a,b),c)$: a and c are symbols in $\{x^1,\dots,x^N\}$ or in $\{x,x',\dots\}$ or are symbols of the form $\bar{\Phi}(a,b)$, and b is a symbol in $\{u^1,\dots,u^m\}$ or in $\{u,u',\dots\}$.

$Eq(\bar{\eta}(a), d)$: a is a symbol as described above, and d is a symbol in $\{y^1, y^2, \ldots, y^p\}$ or in $\{y, y', y'', \ldots\}$ or is a symbol of the form $\bar{\eta}(a)$.

$Eq(+_L(i,j),k)$ and $Eq(-_L(i,j),k)$: i, j, and k are symbols in $\{0, 1, 2, \ldots, k(N), k(N)+1\}$ or in $\{l, l', \ldots\}$ or are of the form $+_L(i,j)$ or $-_L(i,j)$, where j is of the same type as i.

$Rbl(a, a', i)$: a and a' are symbols of the same type as the symbol a described above, and i is a symbol as described above.

Quantifiers. $\mathrm{Qua}_L = \{\forall\}$.

Logical connectives. $\mathrm{Lco}_L = \{\rightarrow\}$.

Logical constants. $\{\perp\}$.

Any *well-formed formula* of L is given by the *Backus–Naur* syntactic rule (see Goldblatt [1987]):

$$A ::= \varphi(t_1, \ldots, t_n) \mid A_1 \rightarrow A_2 \mid \perp \mid \forall v A_1,$$

where $\varphi(\cdot, \cdot, \ldots, \cdot) \in \mathrm{Apr}_L$; A_1 and A_2 are well-formed formulas; and $t_1, \ldots, t_n \in \mathrm{Term}_L$, in the sense that a well-formed formula is an expression that parses according to these rules until after a finite sequence of steps one halts at a set consisting only of elements of $S(L)$. The set of such formulas will be denoted Fma_L or L.

The other logical connectives $\neg$, $\vee$, $\wedge$, and $\longleftrightarrow$ and the quantifier $\exists$ are defined as follows, where the parentheses (and) are used whenever they clarify the meaning of a formula:

$$\begin{aligned}
\neg A &\triangleq A \rightarrow \perp, \\
A_1 \wedge A_2 &\triangleq \neg(A_1 \rightarrow \neg A_2), \\
A_1 \longleftrightarrow A_2 &\triangleq (A_1 \rightarrow A_2) \wedge (A_2 \rightarrow A_1), \\
A_1 \vee A_2 &\triangleq \neg A_1 \rightarrow A_2, \\
\exists v A &\triangleq \neg(\forall v \neg A).
\end{aligned}$$

3.2. Semantics of COCOLOG L. In the following discussion we shall distinguish symbols used in the specification of a (set-theoretic) finite machine $\mathcal{M}$ and those used in a COCOLOG language L; this is achieved by the convention that COCOLOG symbols will be the lightface versions of the boldface symbols denoting the constants, variables, and functions (in this case also with an overbar) of the machine $\mathcal{M}$. Following standard terminology (see, e.g., Goldblatt [1987]), an *L-structure $\mathcal{U}_L = (\mathbf{D}, I)$*, or an *interpretation I* (with *domain* $\mathbf{D}$), is a pair where, first, $\mathbf{D} = \mathbf{U} \cup \mathbf{X} \cup \mathbf{Y} \cup \mathbf{I}_{\mathbf{k(N)}}$, where $\mathbf{U}$, $\mathbf{X}$, and $\mathbf{Y}$ are the sets appearing in the specification of some *arbitrary* finite machine $\mathcal{M}$ as specified in §2 (which is not necessarily the machine which defined the language L) and $\mathbf{I}_{\mathbf{k(N)}} = \{\mathbf{0}, \mathbf{1}, \mathbf{2}, \ldots, \mathbf{k(N)}, \mathbf{k(N)}+\mathbf{1}\}$ is the set of integers between 0 and $k(N)+1$, inclusive, and, second, I is an interpretation function which respects the typing of L and which in COCOLOG is defined as follows:

$$\begin{aligned}
I(\bar{\Phi}) &: \mathbf{X} \times \mathbf{U} \rightarrow \mathbf{X}, \\
I(\bar{\eta}) &: \mathbf{X} \rightarrow \mathbf{Y}, \\
I(+_L) &= +_{\mathbf{k(N)}} : \mathbf{I}_{\mathbf{k(N)}} \times \mathbf{I}_{\mathbf{k(N)}} \rightarrow \mathbf{I}_{\mathbf{k(N)}}, \\
I(-_L) &= -_{\mathbf{k(N)}} : \mathbf{I}_{\mathbf{k(N)}} \times \mathbf{I}_{\mathbf{k(N)}} \rightarrow \mathbf{I}_{\mathbf{k(N)}}, \\
I(c) &\in \mathbf{D}, \quad \text{where } c \in \mathrm{Cons}_L, \\
I(Eq) &= \{(\mathbf{t}, \mathbf{t}'); \mathbf{t}, \mathbf{t}' \in \mathbf{D}, \mathbf{t} = \mathbf{t}'\} \subseteq \mathbf{D}^2, \\
I(Rbl) &\subseteq \mathbf{X}^2 \times \mathbf{I}_{\mathbf{k(N)}}.
\end{aligned}$$

Note that without further conditions being imposed, $I(\cdot)$ may be a many-to-one function on Cons_L.

Here $\mathbf{k(N)}$ is taken to be an arbitrary number greater than $|\mathbf{X}|^2$; this is motivated by the fact that (see Caines, Greiner, and Wang [1991]), counting from the root, a current state observer tree can have at most $|\mathbf{X}|^2$ layers at which there is a reduction in size of some nonsingleton node.

Addition $+_{\mathbf{k(N)}}$ and subtraction $-_{\mathbf{k(N)}}$ in the arithmetic $\mathbf{A_{k(N)}}$ over the finite set of integers $\{\mathbf{0,1,2,\ldots,k(N),k(N)+1}\}$, where $\mathbf{k(N)+1}$ plays the role of infinity, are defined by the following expressions, where we follow the convention that $+_{\mathbf{k(N)}}$ and $-_{\mathbf{k(N)}}$ denote the addition and subtraction in the L-structure $\mathcal{U}_L$ and $+$ and $-$ denote the standard integer arithmetical operations:

$$\mathbf{a} +_{\mathbf{k(N)}} \mathbf{b} = \begin{cases} \mathbf{a+b} & \text{if}\, \mathbf{a+b} \leq \mathbf{k(N)}, \\ \mathbf{k(N)+1} & \text{if}\, \mathbf{a+b} > \mathbf{k(N)}, \end{cases}$$

$$\mathbf{a} -_{\mathbf{k(N)}} \mathbf{b} = \begin{cases} \mathbf{a-b} & \text{if}\, \mathbf{a-b} \geq \mathbf{0}\, \text{and}\, \mathbf{a} \neq \mathbf{k(N)+1}\, \text{and}\, \mathbf{b} \neq \mathbf{k(N)+1}, \\ \mathbf{k(N)+1} & \text{if}\, \mathbf{a-b} < \mathbf{0}\, \text{or if}\, \mathbf{a} = \mathbf{k(N)+1}. \end{cases}$$

These finite-integer arithmetical operations are chosen to express the dynamical properties of $\mathcal{M}$ over a bounded integral number of steps or discrete time instants.

In COCOLOG, a $\mathcal{U}_L$*-valuation* (i.e., I*-valuation*) is a function V :$\text{Var}_L \longrightarrow \mathbf{D}$ satisfying

$$V(v) \,\epsilon \begin{cases} \mathbf{X} & \text{if}\, v \,\epsilon \{x, x', x'', \ldots\}, \\ \mathbf{Y} & \text{if}\, v \,\epsilon \{y, y', y'', \ldots\}, \\ \mathbf{U} & \text{if}\, v \,\epsilon \{u, u', u'', \ldots\}, \\ \mathbf{I_{k(N)}} & \text{if}\, v \,\epsilon \{l, l', l'', \ldots\}, \end{cases}$$

which can be extended to V : $\text{Term}_L \longrightarrow \mathbf{D}$ by

$$V(t) = \begin{cases} V(t) & \text{if}\, t \,\epsilon\, \text{Var}_L, \\ I(t) & \text{if}\, t \,\epsilon\, \text{Cons}_L, \\ I(f)(V(t_1), V(t_2), \ldots, V(t_n)) & \text{if}\, t = f(t_1, t_2, \ldots, t_n)\, \text{and}\, f \,\epsilon\, \text{Fun}_L \text{ is a} \\ & \qquad \text{function of arity}\, n. \end{cases}$$

We take $V \sim_v V'$ to mean that V and V' are identical except in the value they assign to v and

$$V(v/\mathbf{d}) = V' \quad \text{iff}\; V \sim_v V' \,\text{and}\, V'(v) = \mathbf{d}.$$

$\mathcal{U}_L \models A[V]$ stands for the property that a structure $\mathcal{U}_L$ (or interpretation I) satisfies a formula A under the valuation V; this is defined recursively by

$$\begin{aligned} &\mathcal{U}_L \models \text{E}q(t,t')[V] \quad \text{iff}\; V(t) = V(t'), \\ &\mathcal{U}_L \models Rbl(x,x',k)[V] \quad \text{iff}\, (V(x), V(x'), V(k)) \,\epsilon\, I(Rbl), \\ &\mathcal{U}_L \models (A_1 \rightarrow A_2)[V] \quad \text{iff}\, \mathcal{U}_L \models A_1[V]\, \text{implies}\, \mathcal{U}_L \models A_2[V], \\ &\mathcal{U}_L \models \perp [V] \quad \text{iff not}\, \mathcal{U}_L \models \perp [V], \\ &\mathcal{U}_L \models \forall v A[V] \quad \text{iff for all}\, \mathbf{d} \,\epsilon\, \mathbf{D},\, \text{it is the case that}\, \mathcal{U}_L \models A[V(v/\mathbf{d})]. \end{aligned}$$

The property that the formula A is *true* in the structure $\mathcal{U}_L$, written $\mathcal{U}_L \models A$, or equivalently that I (on the domain $\mathbf{D}$) is a *model* for A, is defined by

$$\mathcal{U}_L \models A \quad \text{iff for all}\; V \;\text{it is the case that}\; \mathcal{U}_L \models A[V];$$

and A is *false* in $\mathcal{U}_L$, written $\mathcal{U}_L \not\models A$, or I (on the domain $\mathbf{D}$) is *not a model* for A, is defined by

$$\mathcal{U}_L \not\models A \quad \text{iff for some}\; V \;\text{it is the case that}\; \mathcal{U}_L \not\models A[V],\; \text{i.e.,}\, \mathcal{U}_L \models \neg A[V].$$

In standard terminology, a formula A is called *valid* if it is true in all structures $\mathcal{U}_L$ (i.e., all interpretations I), which is the case if and only if for all $\mathcal{U}_L$, $\mathcal{U}_L \models A$. A formula A is *satisfiable* if there exists some structure $\mathcal{U}_L$ and some valuation V such that the satisfaction relation $\mathcal{U}_L \models A[V]$ holds. Obviously a formula A is valid if and only if $\neg A$ is unsatisfiable. Unless we relativize to a set of interpretations, the only valid formulas in a theory are those given by the logical axiom schemata given below. This is because these must hold for any set theoretic interpretation. Other formulas, in particular the special axioms of a particular theory, may not be true under some interpretation.

The constant symbols, variable symbols, and function symbols, and hence the terms of a COCOLOG language, are typed because the constant and variable symbols are sorted as indicated in §3.1; furthermore, all interpretation functions I together with their associated valuations respect this sorting as specified above. As a result, the term model used in this paper is the same as that used in conventional typed logic (see, e.g., Goldblatt [1987]).

3.3. Axiomatic theory of Th_0. The formal logical theory Th_0 of the language L for $\mathcal{M}$ consists of a set of axioms, that is to say, a set of formulas from Fma_L which shall be required to hold in the intended models (in particular for $\mathcal{M}$), and the set of inference rules operating on Fma_L; these are taken together with the concepts of proof and theoremhood.

In this subsection we first present the axiomatic COCOLOG theory Th_0 corresponding to the information at the root node of the observer tree for a given finite machine $\mathcal{M}$. Further specializations of this theory to $Th(o_1^k)$ are obtained as observations are collected (as time proceeds) on the input–output behaviour of $\mathcal{M}$. This development is presented in the next subsection. Note that since the dynamics of $\mathcal{M}$ are known, the incomplete information aspect of $Th(o_1^k)$ is due solely to the partial observation nature of the problem.

Th_0 has a set of *logical axioms*, a set of *equality axioms*, a set of *arithmetic axioms*, and a set of *special axioms* which specify facts concerning the subject that the logic describes (in at least one of its interpretations). Correspondingly, $Th(o_1^k)$ is a logical theory that has the *observation axioms* and the *state estimation axioms* (all defined below) added to the logical theory Th_0.

The first two sets of axiom schemata below are relatively standard (see, e.g., Mendelson [1964]).

Logical axiom schemata. For all $A, B, C \in Fma_L$, $t \in \mathrm{Term}_L$, and $v \in \mathrm{Var}_L$,

$$(\mathrm{AXM}^{\mathrm{log}})\qquad \begin{array}{rl} \text{(i)} & A \rightarrow (B \rightarrow A) \\ \text{(ii)} & (A \rightarrow (B \rightarrow C)) \rightarrow ((A \rightarrow B) \rightarrow (A \rightarrow C)); \\ \text{(iii)} & (\neg B \rightarrow \neg A) \rightarrow ((\neg B \rightarrow A) \rightarrow B); \\ \text{(iv)} & \forall v\, A(v) \rightarrow A(t); \\ \text{(v)} & \forall v (A \rightarrow B) \rightarrow (A \rightarrow \forall v B), \quad v \text{ not free in } A. \end{array}$$

Any formula having the same form as one of these logical axiom schemata shall be called a logical axiom.

Equality axiom schemata. In the following equality axiom schemata, $t, t', t'' \in \mathrm{Term}_L$, $f \in \mathrm{Fun}_L$, and $P \in \mathrm{Apr}_L$:

$$(\mathrm{AXM}^{\mathrm{eq}}(L))\qquad \begin{array}{rl} \text{(i)} & \mathrm{E}q(t,t); \\ \text{(ii)} & \mathrm{E}q(t,t') \rightarrow \mathrm{E}q(t',t); \\ \text{(iii)} & \mathrm{E}q(t,t'') \wedge \mathrm{E}q(t',t'') \rightarrow \mathrm{E}q(t,t'); \\ \text{(iv)} & \mathrm{E}q(t,t') \rightarrow \mathrm{E}q(f(t),f(t')); \\ \text{(v)} & \mathrm{E}q(t,t') \rightarrow (P(t) \rightarrow P(t')). \end{array}$$

Arithmetic axiom schemata. For any constant symbols l, l', l'' with corresponding elements $\mathbf{l}, \mathbf{l}', \mathbf{l}'' \in \mathbf{I}_{\mathbf{k}(\mathbf{N})}$, if $\mathbf{l} +_{\mathbf{k}(\mathbf{N})} \mathbf{l}' = \mathbf{l}''$, or $\mathbf{l} -_{\mathbf{k}(\mathbf{N})} \mathbf{l}' = \mathbf{l}''$, respectively, then the following axioms for the arithmetic $A_{k(N)}$ hold respectively:

$$(\mathrm{AXM}^{\mathrm{arith}}(L)) \qquad \mathrm{E}q(l +_L l', l''), \qquad \mathrm{E}q(l -_L l', l'').$$

Finite machine axiom schemata. The special axioms for a given finite machine $\mathcal{M}$ are as follows: for any pair of constant symbols x^i, x^j and constant symbol u^l, if $\mathbf{x}^\mathbf{j} = \mathbf{\Phi}(\mathbf{x}^\mathbf{i}, \mathbf{u}^\mathbf{l})$ holds for $\mathcal{M}$, then the following *dynamic axiom* holds:

$$(\mathrm{AXM}^{\mathrm{dyn}}(L)) \qquad \mathrm{E}q(\bar{\Phi}(x^i, u^l), x^j).$$

Further, for any pair of constant symbols x^i, y^j such that $\boldsymbol{\eta}(\mathbf{x}^\mathbf{i}) = \mathbf{y}^\mathbf{j}$ holds for $\mathcal{M}$, the following *output axiom* holds:

$$(\mathrm{AXM}^{\mathrm{out}}(L)) \qquad \mathrm{E}q(\bar{\eta}(x^i), y^i).$$

Reachability axioms. We recursively define the *reachability predicate* $Rbl(\cdot, \cdot, \cdot)$ by the following axioms:

$$(\mathrm{AXM}^{Rbl}(L)) \quad \begin{array}{l} 0.\ \forall x \forall x', \mathrm{E}q(x, x') \longleftrightarrow Rbl(x, x', 0), \\ 1.\ \forall x \forall x', (\exists u, \mathrm{E}q(\bar{\Phi}(x, u), x')) \longleftrightarrow Rbl(x, x', 1), \\ 2.\ \forall x \forall x'' \forall l, \mathrm{E}q(l, k(N) + 1) \vee [\{\exists x' \exists u, Rbl(x', x'', l) \\ \quad \wedge \mathrm{E}q(\bar{\Phi}(x, u) x')\} \longleftrightarrow Rbl(x, x'', l +_L 1)]. \end{array}$$

The reachability axioms specify the l-step reachability relation $Rbl(x, x', l)$ between any pair of states x, x', with axioms 0 and 1 having obvious interpretations. Axiom 2 first excludes consideration of the infinity case and then characterizes reachability on the finite numbers in the arithmetic; specifically it states that either l equals $k(N) + 1$ or x'' is reachable from x in $l + 1$ steps if and only if there is an intermediate state x' such that state x'' is reachable in l steps and x' is reachable from x in one step. We note that if $l = k(N)$, i.e., the predecessor of $k(N) + 1$, then x'' is reachable from x in $k(N) + 1$ steps if and only if x'' is reachable from some x' in $k(N)$ steps, where x' is reachable from x in one step. We further note this does not necessarily make all states mutually reachable in $k(N) + 1$ steps.

Rules of inference. R1. Modus ponens (MP):

$$\frac{A, A \rightarrow B}{B} \quad \text{where } A, B \in Fma_L.$$

R2. Generalization:

$$\frac{A}{\forall v A} \quad \text{where } v \in Var_L, A \in Fma_L.$$

DEFINITION 3.1. *Let Σ denote the set of special axioms of $\mathcal{M}$ expressed in L, i.e., $\Sigma = \{\mathrm{AXM}^{\mathrm{arith}}(L), \mathrm{AXM}^{\mathrm{dyn}}(L), \mathrm{AXM}^{\mathrm{out}}(L), \mathrm{AXM}^{Rbl}(L)\}$. Then Σ is said to be the* axiom set for the finite machine $\mathcal{M}$.

A *proof* in L is a sequence of formulas $A_1, \ldots, A_k$ in Fma_L where A_i, $1 \leq i \leq k$, is either an axiom or a direct consequence of previous formulas via R1 or R2. The last formula A_k in the sequence is called a *theorem*, and $A_1, \ldots, A_{k-1}$ is a proof of the theorem A_k. A formula A is a theorem of a first-order theory with equality, written $\vdash A$, if, in a proof of A, only logical axioms and equality axioms have been involved; A is called a *consequence* (or *theorem*) of Σ, written $\Sigma \vdash A$, if, in a proof of A, only logical axioms, equality axioms, and axioms in Σ are involved. For brevity we write $Th_0 \equiv Th_0(L)$ for the set of theorems of Σ; hence we have $Th_0 = \{A : \Sigma \vdash A\}$ and we use the standard notation $Th_0 \vdash A$, which is customarily read as A is a *theorem* of, or is *provable* (*derivable*) in, the theory Th_0.

A structure $\mathcal{U}_L$ (i.e., an interpretation I on a domain $\mathbf{D}$) is called a *model* of the theory Th_0 if and only if all the axioms Σ of Th_0 are interpreted *true* in $\mathcal{U}_L$, i.e., if and only if I is a model for each axiom of Th_0.

Example 3.1. An illustration of the construction of a model of the COCOLOG theory Th_0 may be given in terms of the simple machine $\mathcal{M}^3$.

Let L_3 denote the first-order COCOLOG language whose constant symbols are taken to be

$$\mathrm{Cons}_{L_3} = \{u^1, u^2\} \cup \{x^1, x^2, x^3\} \cup \{y^1, y^2\} \cup \{0, 1, \ldots, 9, 9+1\}.$$

For L_3 let the variable symbols, function symbols, atomic predicate symbols, sorting constraints, quantifiers, logical connectives, and logical constants be taken to be exactly as specified in §3.1 above. The first-order COCOLOG theory Th_0 of the first-order language L_3 is taken to consist of the general logical axioms, the equality axioms, the axioms of reachability, and the rules of inference as given in §3.3 above. The special machine axioms are taken to be as follows:

$$(\mathrm{AXM}^{\mathrm{dyn}}(L_3)) \quad \begin{matrix} \mathrm{E}q(\bar{\Phi}(x^1, u^1), x^3) & \mathrm{E}q(\bar{\Phi}(x^2, u^2), x^3) & \mathrm{E}q(\bar{\Phi}(x^3, u^1), x^1), \\ \mathrm{E}q(\bar{\Phi}(x^1, u^2), x^2) & \mathrm{E}q(\bar{\Phi}(x^2, u^2), x^2) & \mathrm{E}q(\bar{\Phi}(x^3, u^2), x^3), \end{matrix}$$

$$(\mathrm{AXM}^{\mathrm{out}}(L_3)) \quad \mathrm{E}q(\bar{\eta}(x^1), y^1) \qquad \mathrm{E}q(\bar{\eta}(x^2), y^1) \qquad \mathrm{E}q(\bar{\eta}(x^3), y^2).$$

The axioms $\mathrm{AXM}^{\mathrm{arith}}(L_3)$ of the finite arithmetic A_9 of the theory Th_0 shall be taken to be those satisfied by the following finite arithmetic model $\mathbf{A_9}$, where here $\mathbf{k(N)} = 9$. Let $\mathbf{I_9} = \{\mathbf{0}, \mathbf{1}, \mathbf{2}, \ldots, \mathbf{9} + \mathbf{1}\}$; then $\mathbf{A_9} = (\mathbf{I_9}, +_\mathbf{9}, -_\mathbf{9})$ is given by the following addition and subtraction operations:

$$\mathbf{a} +_\mathbf{9} \mathbf{b} = \begin{cases} \mathbf{a}+\mathbf{b} & \text{if}\, \mathbf{a}+\mathbf{b} \le \mathbf{9}, \\ \mathbf{9}+\mathbf{1} & \text{if}\, \mathbf{a}+\mathbf{b} > \mathbf{9}, \end{cases}$$

$$\mathbf{a} -_\mathbf{9} \mathbf{b} = \begin{cases} \mathbf{a}-\mathbf{b} & \text{if}\, \mathbf{a}-\mathbf{b} \ge \mathbf{0} \,\text{and}\, \mathbf{a} \ne \mathbf{9}+\mathbf{1} \,\text{and}\, \mathbf{b} \ne \mathbf{9}+\mathbf{1}, \\ \mathbf{9}+\mathbf{1} & \text{if}\, \mathbf{a}-\mathbf{b} < \mathbf{0} \,\text{or if}\, \mathbf{a} = \mathbf{9}+\mathbf{1}. \end{cases}$$

We denote the special axioms $\mathrm{AXM}^{\mathrm{arith}}(L_3)$, $\mathrm{AXM}^{\mathrm{dyn}}(L_3)$, $\mathrm{AXM}^{\mathrm{out}}(L_3)$, and $\mathrm{AXM}^{Rbl}(L_3)$ collectively by $\Sigma(L_3)$.

Next consider the input–state–output machine $\mathcal{M}^3$, with (two-element) input set $\mathbf{U} = \{\mathbf{u}^1, \mathbf{u}^2\}$; (three-element) state set $\mathbf{X} = \{\mathbf{x}^1, \mathbf{x}^2, \mathbf{x}^3\}$; (two-element) output set $\mathbf{Y} = \{\mathbf{y}^1, \mathbf{y}^2\}$; state transition function $\boldsymbol{\Phi} : \mathbf{X} \times \mathbf{U} \to \mathbf{X}$ given by

$$\begin{matrix} \boldsymbol{\Phi}(\mathbf{x}^1, \mathbf{u}^1) = \mathbf{x}^3, & \boldsymbol{\Phi}(\mathbf{x}^2, \mathbf{u}^1) = \mathbf{x}^3, & \boldsymbol{\Phi}(\mathbf{x}^3, \mathbf{u}^1) = \mathbf{x}^1, \\ \boldsymbol{\Phi}(\mathbf{x}^1, \mathbf{u}^2) = \mathbf{x}^2, & \boldsymbol{\Phi}(\mathbf{x}^2, \mathbf{u}^2) = \mathbf{x}^2, & \boldsymbol{\Phi}(\mathbf{x}^3, \mathbf{u}^2) = \mathbf{x}^3; \end{matrix}$$

and state output function $\boldsymbol{\eta} : \mathbf{X} \to \mathbf{Y}$ given by

$$\boldsymbol{\eta}(\mathbf{x}^1) = \mathbf{y}^1, \quad \boldsymbol{\eta}(\mathbf{x}^2) = \mathbf{y}^1, \quad \boldsymbol{\eta}(\mathbf{y}^3) = \mathbf{x}^2.$$

We claim that a model (in the sense of §3.2) for Th_0 is given by $(\mathbf{D}, I)$, where $\mathbf{D} \,\underline{\triangle}\, \mathbf{U} \cup \mathbf{X} \cup \mathbf{Y} \cup \mathbf{I_9}$ and where I, the interpretation function defined in §3.2, is specified as follows: I maps from the language symbols $c \,\epsilon\, \mathrm{Cons}_L$ in L_3 to the corresponding elements of $\mathbf{D}$. The function symbols $\bar{\Phi}(\cdot, \cdot)$ and $\bar{\eta}(\cdot)$ map, respectively, to $I(\bar{\Phi}) = \boldsymbol{\Phi}$, the function from $\mathbf{X} \times \mathbf{U}$ to $\mathbf{X}$ denoted by the equations above, and $I(\bar{\eta}) = \boldsymbol{\eta}$, the function from $\mathbf{X}$ to $\mathbf{Y}$ denoted by the equations above. The binary arithmetic function symbols $+_L$ and $-_L$ map to $I(+_L) = +_{\mathbf{9}}$ and $I(-_L) = -_{\mathbf{9}}$, whose values on $I_9 \times I_9$ are given above.

Depending upon the I-valuation $V(\cdot)$ given by the particular interpretation I, $v \,\epsilon\, \{u, u', u'', \ldots\}$ maps to some $V(v) \,\epsilon\, \mathbf{U} \subset \mathbf{D}$, a variable $v \,\epsilon \{x, x', x'', \ldots\}$ maps to some $V(v) \,\epsilon\, \mathbf{X} \subset \mathbf{D}$, and, similarly, $v \,\epsilon \{y, y', y'', \ldots\}$ to some $V(v) \,\epsilon\, \mathbf{Y} \subset \mathbf{D}$, and $v \,\epsilon \{l, l', l'', \ldots\}$ to some $V(v) \in \mathbf{I}_9 \epsilon \mathbf{D}$.

The predicate symbols $\mathrm{E}q(\cdot\,, \cdot)$ and $Rbl(\cdot\,, \cdot\,, \cdot)$ are mapped to the relations on $\mathbf{D} \times \mathbf{D}$ and on $\mathbf{X} \times \mathbf{X} \times \mathbf{I}_9 \subset \mathbf{D} \times \mathbf{D} \times \mathbf{D}$ as specified in §3.2.

The claim that this definition of $(\mathbf{D}, I)$ provides a model for $\mathrm{AXM}^{\mathrm{log}} \cup \mathrm{AXM}^{\mathrm{eq}}(L_3) \cup \Sigma(L_3)$ is established by inspection, namely by the explicit verification that the function relations above for $\mathbf{\Phi}$ and $\boldsymbol{\eta}$ satisfy the machine axioms and that the interpretation of the equality and reachability predicates satisfy the axioms given in $\Sigma(L_3)$. The corresponding verification of $\mathrm{AXM}^{\mathrm{arith}}(L_3)$ for A_9 is immediate by virtue of its construction in terms of $\mathbf{A_9}$.

The set of theorems of $Th_0(L_3)$ is exactly the set of formulas which are true in all models satisfying the axioms $\Sigma(L_3)$; this is guaranteed by the completeness result proved below in §4.

To illustrate logical deduction in COCOLOG we shall give a proof of the theorem $Rbl(x^1, x^3, 2)$ in theory Th_0; this theorem asserts that the state x^1 is controllable to the state x^3 in two steps. The logical truth of (i.e., satisfaction of) $Rbl(x^1, x^3, 2)$ in the model $\mathcal{U}_{L_3} \triangleq (\mathbf{D}, I)$ of the axioms $\Sigma(L_3)$ can be verified from the model in Fig. 1. In standard notation we have $\mathcal{U}_{L_3} \models Rbl(x^1, x^3, 2)$, which reads that the relation corresponding to the formula $Rbl(x^1, x^3, 2)$ holds in the model $\mathcal{U}_{L_3}$.

Proof of $Rbl(x^1, x^3, 2)$. 1. $\mathrm{E}q(\bar{\Phi}(x^2, u^1), x^3)$: $\mathrm{AXM}^{\mathrm{dyn}}(L_3)$.

2. $\exists u, \mathrm{E}q(\bar{\Phi}(x^2, u), x^3)$: 1, $\mathrm{AXM}^{\mathrm{log}}$(iv), and definition of $\exists$.

3. $Rbl(x^2, x^3, 1)$: 2, $\mathrm{AXM}^{\mathrm{log}}$(iv), $\mathrm{AXM}^{Rbl}(L_3)(1)$, and MP.

4. $\mathrm{E}q(\bar{\Phi}(x^1, u^2), x^2)$: $\mathrm{AXM}^{\mathrm{dyn}}(L_3)$.

5. $\exists u, \mathrm{E}q(\bar{\Phi}(x^1, u), x^2)$: 4, $\mathrm{AXM}^{\mathrm{log}}$(iv), and definition of $\exists$.

6. $\neg \mathrm{E}q(1, 9 + 1)$: $\mathrm{AXM}^{\mathrm{arith}}(L_3)$.

7. $\exists x' \exists u, Rbl(x, x^3, 1) \wedge \mathrm{E}q(\bar{\Phi}(x^1, u), x)$: $\Leftrightarrow Rbl(x^1, x^3, 1 +_L 1)$, 6, MP, and instantiation of $\mathrm{AXM}^{Rbl}(2)$.

8. $Rbl(x^2, x^3, 1) \wedge \exists u, \mathrm{E}q(\bar{\Phi}(x^1, u), x^2)$: 3 and 5.

9. $\exists x' \exists u, Rbl(x', x^3, 1) \wedge \ \mathrm{E}q(\bar{\Phi}(x^1, u), x')$: 8 and definition of $\exists$.

10. $Rbl(x^1, x^3, 1 +_L 1)$: 7, 9, and MP.

11. $\mathrm{E}q(2, 1 +_L 1)$: Arithmetic axiom.

12. $Rbl(x^1, x^3, 2)$: 10, 11, and $\mathrm{AXM}^{\mathrm{eq}}(L_3)$(v).

3.4. The COCOLOG language $L(o_1^k)$: Syntax and semantics. The language $L^k \triangleq L(o_1^k)$ is an extension of the language L obtained by adding new constant symbols and atomic predicates in the following way:

$$S(L^k) = S(L) \bigcup_{j=1}^{k} \mathrm{Cons}_{L^j} \bigcup_{j=1}^{k} \mathrm{Apr}_{L^j},$$

where $\mathrm{Apr}_j = \{CSE_j(\cdot)\}$, $j \geq 1$; $\mathrm{Cons}_{L^1} = \{Y(1)\}$; and $\mathrm{Cons}_{L_j} = \{U(j-1), Y(j)\}, j \geq 2$, where $U(j-1), 2 \leq j \leq k, Y(j), 1 \leq j \leq k$, are constant names equal, respectively, to a sequence of names of input set elements $\mathbf{u}_1^{k-1}$ and output set elements $\mathbf{y}_1^k$ in $\mathbf{o}_1^k$; this sequence names the set $\mathbf{o}_1^k = (\mathbf{y}_1, \langle \mathbf{u}_1, \mathbf{y}_2 \rangle, \ldots, \langle \mathbf{u}_{k-1}, \mathbf{y}_k \rangle)$ indexing the language $L^k = L(o_1^k)$. Here we maintain the convention that lightface subscripts and superscripts on boldface symbols denote time indices. The sort of each new constant symbol in L^k is given by

$U(j)$ is a symbol of type $\{u^1, \ldots, u^m\}$ and $Y(j)$ is a symbol of type $\{y^1, \ldots, y^p\}$.

Set $L \equiv Fma_{L^0} \equiv Fma_L$; then the set of well-formed formulas $L^j \equiv Fma_{L^j}$, $j \geq 1$, is defined as the set formulas which parse according to

$$A ::= \varphi(t_1, \ldots, t_n) | CSE_k(x) | B | A' \rightarrow A'' | \forall v A',$$

where $\varphi \in \mathrm{Apr}_{L^j}, t_1, \ldots, t_n \in \mathrm{Term}_{L^j}$, $x \in \mathrm{Term}_j$ is of state type, $B \in Fma_{L^{j-1}}$, and A', $A'' \in Fma_{L^j}$.

Let I be the mapping associated with the L-structure $\mathcal{U}_L = (\mathbf{D}, I)$. An L^k-structure $\mathcal{U}_{L^k} = (\mathbf{D}, I_k)$ is a pair where the interpretation function I_k is an extension of the mapping I into an *arbitrary* machine $\mathcal{M}$ as given by

$I_k(U(j-1)) \in \mathbf{U}$, where the image is the input string element $\mathbf{u}_{j-1}(\mathbf{o}_1^j)$, $1 \leq j \leq k$, lying in $\mathbf{U}$;

$I_k(Y(j)) \in \mathbf{Y}$, where the image is the output string element $\mathbf{y}_j(\mathbf{o}_1^j)$, $1 \leq j \leq k$, lying in $\mathbf{Y}$;

$I_k(CSE_j) \subseteq \mathbf{X}$, $1 \leq j \leq k$.

The satisfaction relation $\mathcal{U}_{L^k} \models A[V]$ is the extension of $\mathcal{U}_L \models A[V]$ obtained by adding the following definitions:

$\mathcal{U}_{L^k} \models CSE_k(x)[V]$ iff $V(x) \in I_k(CSE_k)$,

$\mathcal{U}_{L^k} \models B[V]$ iff $\mathcal{U}_{L^{k-1}} \models B[V]$ for any $B \in Fma_{L^{k-1}}$,

$\mathcal{U}_{L^k} \models \forall v A[V]$ iff for all $\mathbf{x} \in \mathbf{D}$, it is the case that $\mathcal{U}_{L^k} \models A[V](v/\mathbf{x})$ for any $A \in Fma_{L^k}$,

$\mathcal{U}_{L^k} \models (A_1 \rightarrow A_2)[V]$ iff $\mathcal{U}_{L^k} \models A_1[V]$ implies $\mathcal{U}_{L^k} \models A_2[V]$.

The properties *true* and *false* for a formula A in a structure $\mathcal{U}_{L^k}$, or, equivalently, the existence of a *model* for a formula A, are defined as for a structure $\mathcal{U}_L$ in §3.2.

3.5. Axiomatic theory of $Th(o_1^k)$. We shall refer to a sequence $\mathbf{o}_1^k$, $k \geq 1$, which satisfies the input–output relation of a machine $\mathcal{M}$ for some initial condition, as *a sequence generated by the machine* $\mathcal{M}$, without reference to any initial condition for the machine $\mathcal{M}$.

At the instant $k = 1$, the system generates some observed system output $\mathbf{y}_1$ and this is recorded in theory $Th(o_1^1)$ via the axiom $\mathrm{E}q(Y(1), *)$, where $* = y_1(o_1^1)$, the constant symbol in the language L denoting $\mathbf{y}_1$. Similarly, at each successive instant $k \geq 2$, the axiom set of the theory $Th(o_1^k)$ is augmented with the axioms $\mathrm{E}q(U(k-1), *)$, where $* = u_{k-1}(o_1^k)$, and $\mathrm{E}q(Y(k), *)$, where $* = y_k(o_1^k)$, to record the fact that the input $\mathbf{u}_{k-1}$ and output $\mathbf{y}_k$ generated by the system $\mathcal{M}$ have been received as observations. We express this formally by the following set of axioms, which we shall term the observation axioms corresponding to $\mathbf{o}_1^k$.

Observation axiom schemata $(\mathbf{o}_1^k)$.

$$(\mathrm{AXM}^{\mathrm{obs}}(L^k)) \quad \begin{array}{lll} 1.\ \mathrm{E}q(Y(1), *), & \text{where } * = y_1(o_1^k) \in \mathrm{Cons}_L, & k = 1, \\ 2.\ \mathrm{E}q(U(k -_L 1), *), & \text{where } * = u_{k-1}(o_1^k) \in \mathrm{Cons}_L, & k \geq 2, \\ 3.\ \mathrm{E}q(Y(k), *), & \text{where } * = y_k(o_1^k) \in \mathrm{Cons}_L, & k \geq 2. \end{array}$$

State estimation axioms. The following axioms express the recursive formulas (2.6) for the current state estimate sets.

In case $k = 1$:

$$(\mathrm{AXM}^{\mathrm{est}}(L^1)) \quad \begin{array}{c} \mathrm{E}q(\bar{\eta}(x^1), Y(1)) \longleftrightarrow CSE_1(x^1), \\ \vdots \qquad \vdots \qquad \vdots \\ \mathrm{E}q(\bar{\eta}(x^N), Y(1)) \longleftrightarrow CSE_1(x^N). \end{array}$$

In case $k \geq 2$:

$(\mathrm{AXM}^{\mathrm{est}}(L^k))$

$$\begin{array}{c}
\exists x, CSE_{k-1}(x) \wedge \mathrm{E}q(\bar{\Phi}(x, U(k -_L 1)), x^1) \wedge \mathrm{E}q(\bar{\eta}(x^1), Y(k)) \longleftrightarrow CSE_k(x^1), \\
\vdots \\
\exists x, CSE_{k-1}(x) \wedge \mathrm{E}q(\bar{\Phi}(x, U(k -_L 1)), x^N) \wedge \mathrm{E}q(\bar{\eta}(x^N), Y(k)) \longleftrightarrow CSE_k(x^N).
\end{array}$$

We extend Definition 3.1 in the following way.

DEFINITION 3.2. *The* axiom set $\Sigma_k, k \geq 0$, for the finite machine $\mathcal{M}$ and the (input–output) sequence $\mathbf{o}_1^k, k \geq 0$, *is defined as the union of the axiom set* Σ *for the machine* $\mathcal{M}$, *the observation axiom sets indexed by* j, $1 \leq j \leq k$, *corresponding to the sequence* $\mathbf{o}_1^k$, *and the estimation axioms, i.e.,*

$$\Sigma_k = \Sigma \cup \bigcup_{j=1}^{k} \{\mathrm{AMX}^{\mathrm{obs}}(L^j), \mathrm{AMX}^{\mathrm{est}}(L^j)\}, \qquad k \geq 1. \tag{3.1}$$

A structure $\mathcal{U}_{L^k} = (\mathbf{D}, I_k)$ is called a *model* of the theory Th_k if and only if all the axioms Σ_k of Th_k are interpreted true in $\mathcal{U}_{L^k}$, i.e., if and only if I_k is a model for each axiom of Th_k.

We observe that if a language L and a set of axioms Σ_L are given a priori, one may obviously construct a set theoretic machine $\mathcal{M}$ which satisfies Σ_L and for which $|\mathbf{U}| = m, |\mathbf{X}| = N$, and $|\mathbf{Y}| = p$. However, in general, given a priori some axiom system Σ_k corresponding to a symbol sequence $o_1^k, k \geq 1$, it is not the case that such a set theoretic machine $\mathcal{M}$ will form part of a model $\mathcal{U}_{L^k}$ for Σ_k. In fact, it may happen that the only machine in a model $\mathcal{U}_{L^k}$ is the trivial machine with singleton sets of inputs, states, and outputs, respectively.

3.6. Extralogical conditional control rules and theory transitions.

Conditional Control Rules. The following is the general form of a set of CCRs at the instant $k \geq 1$, where C_j is a *conditional control formula* expressed in Fma_{L^k}, which we note contains no appearance of $U(k)$:

$$(\mathrm{CCR}(L^k)) \qquad \begin{array}{lll}
\mathbf{IF}\; C_1 & \mathbf{THEN} & \mathrm{E}q(U(k), u^1), \\
\mathbf{IF}\; \neg C_1 \wedge C_2 & \mathbf{THEN} & \mathrm{E}q(U(k), u^2), \\
\vdots & \vdots & \\
\mathbf{IF}\; \bigwedge_{j=1}^{m-1} \neg C_j \wedge C_m & \mathbf{THEN} & \mathrm{E}q(U(k), u^m), \\
\mathbf{IF}\; \bigwedge_{j=1}^{m} \neg C_j & \mathbf{THEN} & \mathrm{E}q(U(k), u_k^*),
\end{array}$$

where u_k^* is an arbitrary element of $\{u^1, u^2, \ldots, u^p\}$.

The sets of rules $\mathrm{CCR}(L^k), k \geq 1$, are central to the construction of COCOLOG. The function of any given set $\mathrm{CCR}(L^k)$ in the feedback control of $\mathcal{M}$ has the following specification: if the condition C_1 is true (and hence provable) in the decidable theory $Th(o_1^k)$ generated by the axiom set $\Sigma_{k,\mathcal{M}}$ specified in §4, then, invoking the first rule, we obtain the defined constant value u^1 as the value of the control constant $U(k)$; if not, but if C_2 is true (and hence can be proved), then the second axiom gives the defined value u^2 to the control constant $U(k)$; and so on. If none of the conditions $C_1, C_2, \ldots, C_m$ hold at the instant k, then the last rule sets the control constant $U(k)$ equal to the arbitrary constant $u_k^* \in \{u^1, \ldots, u^p\}$.

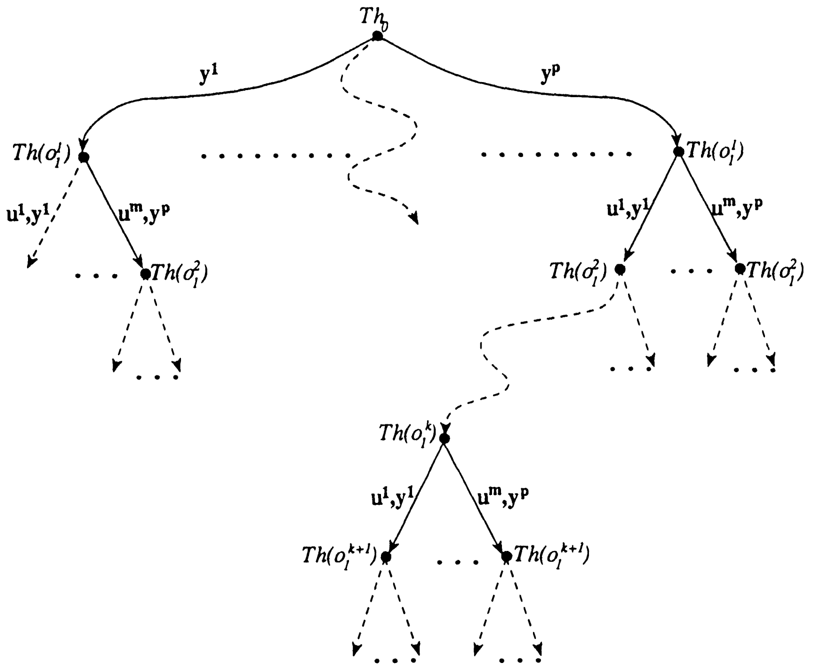

FIG. 2. *A COCOLOG tree of logical theories.*

This procedure uniquely determines the value of $U(k)$. It is proven in §4 that each theory $Th(o_1^k), k \geq 1$, is decidable. Hence an effective procedure to establish the value of $U(k)$ is to run in parallel a set of procedures each of which will effectively decide the truth of a distinct conjunction of control formulas associated with a distinct **IF** statement.

Extralogical theory transitions. When $k \rightarrow k+1$, we make the extralogical step of passing to the theory $Th(o_1^{k+1})$, carrying along all the previous axioms and adding axioms recording the observation of the input $\mathbf{u}_k = \mathbf{u}^\mathbf{i}$ and the resulting output $\mathbf{y}_{k+1} = \mathbf{y}^\mathbf{j}$ for some $\mathbf{u}^\mathbf{i} \in \mathbf{U}, \mathbf{y}^\mathbf{j} \in \mathbf{Y}$ (see Fig. 2). This is formally enforced by the definition of the axiom set Σ_{k+1} generating $Th(o_1^{k+1})$. Hence, in the new theory $Th(o_1^{k+1})$, the observed control action symbol $U(k)$ and the constant symbol u^i determined via $Th(o_1^k)$ satisfy an equality predicate.

Example 3.2. Consider a machine $\mathcal{M} = (\mathbf{U},\mathbf{X},\mathbf{Y},\mathbf{\Phi},\boldsymbol{\eta})$ for which $\mathbf{Y} = \mathbf{X}$ and $\boldsymbol{\eta}$ is the identity map, together with the control objective: if $\mathbf{x}^T$ is reachable from all the current state estimates (i.e., all states satisfying the $CSE_k(\cdot)$ predicate at the current instant k) starting with the application of some common control, then steer towards $\mathbf{x}^T$ and apply some specified control when the current state estimate equals $\mathbf{x}^T$, or else apply $\mathbf{u}^*$.

An example of the operation of the state estimation axioms, $\mathrm{AXM}^{\mathrm{est}}(L^k)$, in this case is the following:

$k = 1$: Let the initial state of the system $\mathcal{M}$ be $\mathbf{x}^\mathbf{j}$; then $\mathbf{y}_1 = \mathbf{y}^\mathbf{j} = \mathbf{x}^\mathbf{j}$. Hence $\mathrm{E}q(Y(1), y^j)$ and it must be the case that $\mathrm{E}q(\bar{\eta}(x^j), y^j)$, hence, by use of $\mathrm{AXM}^{\mathrm{est}}(L^1)$, $CSE_1(x^j)$ is derivable in Th_1.

$k = 2$: Let $\mathbf{u}_1 = \mathbf{u}^\mathbf{s}$ and assume $\mathbf{\Phi}(\mathbf{x}^\mathbf{j}, \mathbf{u}^\mathbf{s}) = \mathbf{x}^l$. Then $\mathbf{y}_2 = \mathbf{y}^l = \mathbf{x}^l$. Hence, $\mathrm{E}q(\bar{\Phi}(x^j, u^s), x^l)$ and $\mathrm{E}q(\bar{\eta}(x^l), y^l)$ are formulas in Th_o. But the axiom set of Th_2 includes the observation axioms

$$\mathrm{E}q(U(1), u^s) \quad \text{and} \quad \mathrm{E}q(Y(2), y^l)$$

in $\mathrm{AXM}^{\mathrm{obs}}(L^2)$. So taking u as u^s, y as y^l, and x as x^j, it follows that the following formula is deducible in Th_2:

$$CSE_1(x^j) \wedge \mathrm{E}q(\bar{\Phi}(x^j, u^s), x^l) \wedge \mathrm{E}q(U(1), u^s) \wedge \mathrm{E}q(\bar{\eta}(x^l), y^l) \wedge \mathrm{E}q(Y(2), y^l),$$

and hence, by use of $\mathrm{AXM}^{\mathrm{eq}}(L^1)(v)$,

$$\exists x \; CSE_1(x) \wedge \mathrm{E}q(\bar{\Phi}(x, U(1)), x^l) \wedge \mathrm{E}q(\bar{\eta}(x^l), Y(2))$$

is derivable in Th_2. So by $\mathrm{AXM}^{\mathrm{est}}(L^1)$

$$CSE_2(x^l) \quad \text{and} \quad \neg CSE_2(x^m), \qquad m \neq l,\ 1 \leq m \leq N,$$

are derivable in Th_2, where the negated predicates are obtained by deducing a negation of a disjunction of the negations of the literals on the left-hand sides of the corresponding lines of $\mathrm{AXM}^{\mathrm{est}}(L^1)$.

For the control problem in this example we may set

$$\begin{aligned}
C_1 &= \forall\, x(\neg CSE_k(x) \vee \mathrm{E}q(x, x^T) \vee [\exists x' \exists l \mathrm{E}q(\bar{\Phi}(x, u^1), x') \wedge \mathit{Rbl}(x', x^T, l)]),\\
C_2 &= \forall\, x(\neg CSE_k(x) \vee \mathrm{E}q(x, x^T) \vee [\exists x' \exists l \mathrm{E}q(\bar{\Phi}(x, u^2), x') \wedge \mathit{Rbl}(x', x^T, l)]),\\
&\vdots\\
C_m &= \forall\, x(\neg CSE_k(x) \vee \mathrm{E}q(x, x^T) \vee [\exists x' \exists l \mathrm{E}q(\bar{\Phi}(x, u^m), x') \wedge \mathit{Rbl}(x' x^T, l)])
\end{aligned}$$

and arrange these conditional control rules into the schemata $\mathrm{CCR}(L^k)$.

If the jth condition C_j is derivable in Th_k, then for any instantiation x^+ of the variable x, either

first, the current state estimate predicate CSE_k does not hold at x^+, or,

second, x^+ is equal to the target state x^T, or,

third, there exists a path of length $l^* + 1$ (where l^* instantiates l, and is greater than or equal to zero) from the current state x^+, via the intermediate state x^* (where x^* instantiates x'), to the target state x^T (since the reachability predicate $\mathit{Rbl}(x^+, x^T, l^*)$ holds), and the control u^j either steers the state x^+ to x^T in one step or is an initial control of a sequence (of length greater than one) which steers the state x^+ to x^T. (Note that the case of a path of length one corresponds to x^* equal to x^T and l equal to 0.)

The corresponding CCR states that C_k holds for no control index k strictly less than j but C_j itself holds. We observe that if the $m + 1$–th control option is used at the instant k by this COCOLOG controller, this indicates that for every control u there is some x^+ that satisfies $CSE_k(\cdot)$ and which is such that, first, x^+ is not equal to x^T and, second, x^T is not reachable from x^+ by the application of a sequence of controls starting with u.

Further inspection of the CCRs shows that they allow the possibility, for certain machines, that the system would maintain itself in a sequence of states from which x^T was reachable in a fixed number of steps l (l greater than or equal to 1) without ever actually converging to x^T. Such apparently perverse behaviour may be prevented by the following elaboration of C_j^* for $1 \leq j \leq m$:

$$\begin{aligned}
C_j^* = \forall\, x\{&\neg CSE_k(x) \vee \mathrm{E}q(x, x^T) \vee [\exists x' \exists\, l \,\forall\, s, \mathrm{E}q(\bar{\Phi}(x, u^j), x') \wedge \mathit{Rbl}(x', x^T, l)\\
&\wedge \{\mathrm{E}q(s, k(N) + 1) \vee \neg \mathrm{E}q(s -_L (l +_L 1), k(N) + 1) \vee \neg \mathit{Rbl}(x, x^T, s)\}]\}.
\end{aligned}$$

This conditional control formula C_j^* states that for all instantiations of the variable x, the conditions stated in C_j above hold and, in addition, x^T is not reachable from each such instantiation of x in strictly less than $l + 1$ steps, where l depends upon x.

4. Consistency, completeness, and decidability of COCOLOG theories. The consistency and completeness of the axiomatic theories presented in §3 can be established by a simple application of classical results on the consistency and completeness of first-order theories with equality; these results depend upon demonstrations of the existence of a model for any given theory.

THEOREM 4.1 (model existence and soundness for Σ). *Consider a finite machine $\mathcal{M}$; then there exists a model $\mathcal{U}_L$ for the axiom set Σ for $\mathcal{M}$, and for any model $\mathcal{U}_L$ of Σ and for any formula $A \epsilon Fma_L$ it is the case that*

$$\Sigma \vdash A \Rightarrow \mathcal{U}_L \models A.$$

Proof. By definition, the axioms in Σ are true formulas in any model $\mathcal{U}_L$ of Σ. It is immediate from the definition of a valuation V of a model $\mathcal{U}_L$ that the rules of inference preserve satisfaction under V and hence truthfulness. It follows that all theorems deducible from the axioms will be true in any model of the axioms.

To establish the theorem it remains to show that there exists at least one model $\mathcal{U}_L$ for the axiom set Σ. We do this by the completely natural choice of the machine $\mathcal{M}$ for $\mathcal{U}_L$ that defined $S(L)$ and the axioms Σ. That is to say, we now choose the particular domain and interpretation function I (and hence structure $\mathcal{U}_L$) given by $\mathbf{D}, I(\bar{\Phi}) = \mathbf{\Phi}, I(\bar{\eta}) = \boldsymbol{\eta}$, where $\mathbf{D}$,$\mathbf{\Phi}$, and $\boldsymbol{\eta}$ are defined in the specification of $\mathcal{M}$. I shall be chosen to map constant names to the constants themselves in $\mathbf{D}$ and to map the reachability predicate to the reachability set relation.

We observe that any structure $\mathcal{U}_L$ of the form specified in §3.2 is a structure for L subject to the restriction that it is *typed*. Hence, if it is verified that $\mathcal{U}_L \models \Sigma$, then a model of Σ has been shown to exist. This is the case for each of the axioms as is shown in the following way:

$\mathrm{AXM}^{\mathrm{dyn}}(L)$: Each of the axioms has the form $\mathrm{E}q(\bar{\Phi}(x^i, u^l), x^j)$, where x^i and x^j lie in $\{x^1, \ldots, x^N\}$ and u^l lies in $\{u^1, \ldots, u^m\}$ and where any such axiom falls in this set if and only if it is the case for the machine $\mathcal{M}$ that $\mathbf{\Phi}(\mathbf{x^i}, \mathbf{u}^l) = \mathbf{x^j}$.

$\mathrm{AXM}^{\mathrm{out}}(L)$: The second subset has the form $\mathrm{E}q(\bar{\eta}(x^i), y^l)$, where x^i lies in $\{x^1, \ldots, x^n\}$ and y^l lies in $\{y^1, \ldots, y^p\}$ and where any such axiom falls in this set if and only if it is the case for $\mathcal{M}$ that $\boldsymbol{\eta}(\mathbf{x^i}) = \mathbf{y}^l$.

Now $\mathcal{U}_L \models \mathrm{E}q(\bar{\Phi}(x^i, u^l), x^j)$ if and only if the equality relation $I(\bar{\Phi}(x^i, u^l)) = I(x^j)$ holds, i.e., if and only if $I(\bar{\Phi})(I(x^i), I(u^l)) = I(x^j)$, i.e., if and only if $\mathbf{\Phi}(\mathbf{x^i}, \mathbf{u}^l) = \mathbf{x^j}$, which is the case since this equality holds for $\mathcal{M}$.

A similar evaluation of $I(\mathrm{E}q(\bar{\eta}(x^i), y^l))$ as the equality relation $I(\bar{\eta}(x^i)) = y^l)$ shows that $\mathcal{U}_L \models \mathrm{E}q(\bar{\eta}(x^i), y^l)$ if and only if $I(\bar{\eta}((x^i)) = I(y^l)$, i.e., if and only if $\boldsymbol{\eta}(\mathbf{x^i}) = \mathbf{y}^l$, which is the case since this equality holds for $\mathcal{M}$. The verification that $\mathcal{U}_L$ is a model for Σ is straightforward for $\mathrm{AXM}^{\mathrm{arith}}(L)$; here we shall only carry out the verification of $\mathcal{U}_L \models \Sigma$ for the reachability axioms.

$\mathrm{AXM}^{Rbl}(L)$: Let us denote the three lines of the reachability axioms by $\mathrm{AXM}^{Rbl}(L)(0)$, $\mathrm{AXM}^{Rbl}(L)(1)$, and $\mathrm{AXM}^{Rbl}(L)(2)$. Then we may proceed case by case.

(i) $\mathcal{U}_L \models \mathrm{AXM}^{Rbl}(L)(0)$.

This holds if and only if for each V

$$\mathcal{U}_L \models \mathrm{E}q(x, x')[V] \text{ implies and is implied by (denoted } \Longleftrightarrow) \\ \mathcal{U}_L \models Rbl(x, x', 0)[V],$$

i.e., if and only if

$$V(x) = V(x') \Longleftrightarrow \mathbf{\Phi}(V(x), \mathbf{u}_1^0) = V(x'), \tag{4.1}$$

but by definition, $\mathbf{\Phi}(\mathbf{x},\mathbf{u}_1^0) = \mathbf{\Phi}(\mathbf{x},\epsilon) = \mathbf{x}$, and so the right-hand equality is true if and only if $V(x) = V(x')$. Consequently the left-hand side of equation implies and is implied by the right-hand side, demonstrating that $\mathrm{AXM}^{Rbl}(L)(0)$ is satisfied by $\mathcal{U}_L$.

(ii) $\mathcal{U}_L \models \mathrm{AXM}^{Rbl}(L)(1)$.

This holds if and only if for each V

$$\mathcal{U}_L \models \exists u, \mathrm{E}q(\bar{\Phi}(x,u),x'))[V] \Longleftrightarrow \mathcal{U}_L \models Rbl(x,x',1)[V],$$

i.e., if and only if

$$\mathcal{U}_L \not\models \forall u \neg \mathrm{E}q(\bar{\Phi}(x,u)x')[V] \Longleftrightarrow (V(x),V(x'),V(1)) \in I(Rbl),$$

i.e., if and only if

$$\begin{aligned}&\{\text{it does not hold that for all } \mathbf{u}' \in \{\mathbf{u}^1,\dots,\mathbf{u}^m\}\\ &\ \mathcal{U}_L \models \neg\mathrm{E}q(\bar{\Phi}(x,u),x')[V(u/\mathbf{u}')]\}\\ &\qquad \Longleftrightarrow \exists \mathbf{u} \in \{\mathbf{u}^1,\dots,\mathbf{u}^m\} \text{ such that } \mathbf{\Phi}(V(x),\mathbf{u}) = V(x').\end{aligned}$$

i.e., if and only if

$$\begin{aligned}&\{\text{it does not hold that for all } \mathbf{u} \in \{\mathbf{u}^1,\dots,\mathbf{u}^m\}\\ &\ \text{it is not the case that } \mathbf{\Phi}(V(x),\mathbf{u}) = V(x')\}\\ &\qquad \Longleftrightarrow \exists \mathbf{u} \in \{\mathbf{u}^1,\dots,\mathbf{u}^m\} \text{ such that } \mathbf{\Phi}(V(x),\mathbf{u}) = V(x'),\end{aligned}$$

i.e., if and only if

$$\begin{aligned}&\{\text{it is the case that for some } \mathbf{u} \in \{\mathbf{u}^1,\dots,\mathbf{u}^m\}\\ &\ \mathbf{\Phi}(V(x),\mathbf{u}) = V(x')\}\\ &\qquad \Longleftrightarrow \exists \mathbf{u} \in \{\mathbf{u}^1,\dots,\mathbf{u}^m\} \text{ such that } \mathbf{\Phi}(V(x),\mathbf{u}) = V(x').\end{aligned}$$

But this is the case, demonstrating that $\mathcal{U}_L \models \mathrm{AXM}^{Rbl}(L)(1)$.

(iii) $\mathcal{U}_L \models \mathrm{AXM}^{Rbl}(L)(2)$.

This holds if and only if $\mathcal{U}_L \models \neg\mathrm{E}q(l, k(N)+1)$ implies

$$\begin{aligned}&\mathcal{U}_L \models \exists x', \exists u, Rbl(x',x'',l) \wedge \mathrm{E}q(\bar{\Phi}(x,u),x')\\ &\qquad \Longleftrightarrow \mathcal{U}_L \models Rbl(x,x'',l +_L 1) \qquad (\text{rule for } \mathcal{U}_L \models A \vee B)\end{aligned}$$

i.e., if and only if for each V, if $V(l) \neq V(k(N)+1)$, then

$$\begin{aligned}&\{\text{for some } \mathbf{d} \in \mathbf{D}, \text{ it is the case that } \mathcal{U}_L \models Rbl(x',x'',l)[V(x'/\mathbf{d})]\\ &\ \text{and for some } \mathbf{c} \in \mathbf{D}, \text{ it is the case that } \mathcal{U}_L \models \mathrm{E}q(\bar{\Phi}(x,u),x')[V(u/\mathbf{c},x'/\mathbf{d})]\}\\ &\qquad \Longleftrightarrow (V(x),V(x''),V(l +_L 1)) \in I(Rbl),\end{aligned}$$

i.e., if and only if for each V, if $\mathbf{l} \neq \mathbf{k}(\mathbf{N}) + \mathbf{1}$, then

$$\begin{aligned}&\{\text{for some } \mathbf{d} \in \mathbf{D},\ (\mathbf{d}, V(x''), V(l)) \in I(Rbl) \text{ and for some } \mathbf{c} \in \mathbf{D},\ \Phi(V(x),\mathbf{c}) = \mathbf{d}\}\\ &\qquad \Longleftrightarrow \{\exists \mathbf{u}_1^{l+1} \in \mathbf{D}^{l+1} \text{ for } 1 \le l \le k(N) \text{ such that } \mathbf{\Phi}(V(x),\mathbf{u}_1^{l+1}) = V(x'')\},\end{aligned}$$

i.e., if and only if for each V, if $\mathbf{l} \neq \mathbf{k}(\mathbf{N}) + \mathbf{1}$, then

$$\begin{aligned}&\{\text{for some } \mathbf{d} \in \mathbf{D}, \exists \mathbf{u}_1^l \in \mathbf{D}^l,\ 1 \le l \le k(N), \text{ such that } \mathbf{\Phi}(\mathbf{d},\mathbf{u}_1^l) = V(x'')\\ &\ \text{and for some } \mathbf{c} \in \mathbf{D},\ \mathbf{\Phi}(V(x),\mathbf{c}) = \mathbf{d}\}\\ &\qquad \Longleftrightarrow \{\exists \mathbf{u}_1^{l+1} \in \mathbf{D}^{l+1} \text{ for } 1 \le l \le k(N) \text{ such that } \mathbf{\Phi}(V(x),\mathbf{u}_1^{l+1}) = V(x'')\}.\end{aligned}$$

But this is the case, demonstrating that $\mathcal{U}_L \models \mathrm{AXM}^{Rbl}(2)$. This completes all three cases for AXM^{Rbl} and hence completes the proof of the theorem. □

THEOREM 4.2 (model existence and soundness for Σ_k). *Consider any input–output sequence $\mathbf{o}_1^k, k \geq 1$, generated by a finite machine $\mathcal{M}$; then there exists a model $\mathcal{U}_{L^k}$ for the axiom set $\Sigma_k, k \geq 1$, for $\mathcal{M}$ and the sequence $\mathbf{o}_1^k$, and for any model $\mathcal{U}_{L^k}$ for Σ_k and any formula $A \,\epsilon Fma_{L^k}$ it is the case that*

$$\Sigma_k \vdash A \Rightarrow \mathcal{U}_{L^k} \models A.$$

Proof. A structure $\mathcal{U}_{L^k}$, defined as an extension of a structure $\mathcal{U}_L$ in §3.4, is specified by the interpretation function I_k mapping (1) the constant symbols $U(j-1), 2 \leq j \leq k$, and $Y(j), 1 \leq j \leq k$, into elements of $\mathbf{U}$ and $\mathbf{Y}$ so as to satisfy the observation axioms (3.5.1); and (2) the consistent state estimate predicates $CSE_j(\cdot), 1 \leq j \leq k$, into subsets of $\mathbf{X}$ so as to satisfy the state estimation axioms (3.5.2) and (3.5.3). The elements of $\mathbf{U}$ and $\mathbf{Y}$ we select so as to satisfy the first condition are those given by the sequence $\mathbf{o}_1^k$, and the subsets of $\mathbf{X}$ we select to satisfy the second condition are those generated by the formula (2.6).

In order to establish the soundness of the first-order rules of inference in $Th(o_1^k)$ we must verify that they preserve satisfaction under any valuation V of any model $\mathcal{U}_{L^k}$ of Σ_k. Since it is evident that satisfaction is preserved by MP and generalization for any given V for any model $\mathcal{U}_{L^k}$, it is sufficient to demonstrate that there exists at least one model $\mathcal{U}_{L^k}$ for the axiom set Σ_k.

Because we have verified the existence of a model for the axioms $\Sigma \subset \Sigma_k$, and because the structure $\mathcal{U}_{L^k}$ contains $\mathcal{U}_L$ as a subset, it is sufficient to verify that a model $\mathcal{U}_{L^k}$ satisfies the axioms $\mathrm{AMX}^{\mathrm{obs}}(L^j), 1 \leq j \leq k$, and $\mathrm{AMX}^{\mathrm{est}}(L^j), 1 \leq j \leq k$. As in Theorem 4.1, we do this by using the natural and obvious choice of the machine $\mathcal{M}$ that defined the axioms Σ and generated the input–output sequence $\mathbf{o}_1^k$.

We begin with the observation axiom schemata for the observation sequences $\mathbf{o}_1^1, \mathbf{o}_1^2, \ldots, \mathbf{o}_1^k$.

$\mathrm{AXM}^{\mathrm{obs}}(L^1)(1)$: For $k = 1, \mathcal{U}_{L^1} \models \mathrm{E}q(Y(1), \star)$, where $\star = y_1(o_1^1)$, if and only if the equality $I_1(Y(1)) = I_1(\star)$ holds, where $\star = y_1(o_1^1)$. But this is the case since $I_1(Y(1)) = \mathbf{y}_1 = I_1(*)$ by the definition of I_1 in §3.4 and the definition of the observation axiom in the axiom set Σ_1 in §3.5.

$\mathrm{AXM}^{\mathrm{obs}}(L^k)(2)$: For $k \geq 2$ we need to verify that, for $2 \leq j \leq k, \mathcal{U}_{L^k} \models \mathrm{E}q(U(j -_L 1), \star)$, where $\star = u_{j-1}(o_1^j)$, if and only if $I_k(U(j -_L 1)) = I_k(\star)$, where $\star = u_{j-1}(o_1^j)$. But this is the case since $I_k(U(j -_L 1)) = I_k(\star)$ by the definition of I_k in §3.4 and the definition of the observation axiom schemata in the axiom system $\Sigma_j, 2 \leq j \leq k$, in §3.5.

$\mathrm{AXM}^{\mathrm{obs}}(L^k)(3)$: Similarly for $2 \leq j \leq k$, we may verify $\mathcal{U}_{L^k} \models \mathrm{E}q(Y(j), \star)$, where $\star = y_j(o_1^j)$, and this shows that the third set of observation axiom schemata are satisfied by $\mathcal{U}_{L^k}$.

Next, we consider the state estimation axioms.

$\mathrm{AXM}^{\mathrm{est}}(L^1)$: Taking $k = 1$ first, we have $\mathcal{U}_{L^1} \models \mathrm{AXM}^{\mathrm{est}}(L^1)(1)$ if and only if, for each valuation

$$\begin{array}{ccc}
\mathcal{U}_{L^1} \models \mathrm{E}q(\bar{\eta}(x^1),\ Y(1)) & \Longleftrightarrow & \mathcal{U}_{L^1} \models CSE_1(x^1), \\
\vdots & \vdots & \vdots \\
\mathcal{U}_{L^1} \models \mathrm{E}q(\bar{\eta}(x^N), Y(1)) & \Longleftrightarrow & \mathcal{U}_{L^1} \models CSE_1(x^N),
\end{array}$$

i.e., if and only if

$$\begin{aligned} I_1(\bar{\eta}(x^1)) &= I_1(Y(1)) \\ &\Longleftrightarrow \mathcal{U}_{L^1} \models CSE_1(x^1), \\ \vdots \qquad & \vdots \qquad \vdots \\ I_1(\bar{\eta}(x^N)) &= I_1(Y(1)) \Longleftrightarrow \\ \mathcal{U}_{L^1} &\models CSE_1(x^N), \end{aligned}$$

i.e., if and only if

$$\begin{aligned} \{\boldsymbol{\eta}(\mathbf{x}^1) = \mathbf{y}_1(\mathbf{o}_1^1)\} &\Longleftrightarrow \mathbf{x}^1 \in \{\mathbf{x}; \mathbf{x} \in \boldsymbol{\eta}^{-1}(\mathbf{y}_1(\mathbf{o}_1^1))\}, \\ \vdots \qquad \vdots \qquad & \qquad\qquad\qquad \vdots \\ \{\boldsymbol{\eta}(\mathbf{x}^{\mathrm{N}}) = \mathbf{y}_1(\mathbf{o}_1^1)\} &\Longleftrightarrow \mathbf{x}^N \in \{\mathbf{x}; \mathbf{x} \in \boldsymbol{\eta}^{-1}(\mathbf{y}_1(\mathbf{o}_1^1))\}, \end{aligned}$$

which is the case.

AXM$^{\mathrm{est}}(L^2)$: We now verify that the model $\mathcal{U}_{L^k}$ satisfies the estimation axioms in the case $k \geq 2$. For $k = 2$, we have $\mathcal{U}_{L^2} \models$ AXM$^{\mathrm{est}}(L^2)$ if and only if for each $\mathcal{U}_{L^2}$ valuation V

$$\begin{aligned} \mathcal{U}_{L^2} &\models (\exists x, CSE_1(x) \wedge \mathrm{E}q(\bar{\Phi}(x, U(1)), x^1) \wedge \mathrm{E}q(\bar{\eta}(x^1), Y(2)))[V] \\ &\Longleftrightarrow \mathcal{U}_{L^2} \models CSE_2(x^1)[V], \\ &\vdots \qquad \vdots \\ \mathcal{U}_{L^2} &\models (\exists x, CSE_1(x) \wedge \mathrm{E}q(\bar{\Phi}(x, U(1)), x^N) \wedge \mathrm{E}q(\bar{\eta}(x^N), Y(2)))[V] \\ &\Longleftrightarrow \mathcal{U}_{L^2} \models CSE_2(x^N)[V], \end{aligned}$$

i.e., if and only if for each V

$$\begin{aligned} \mathcal{U}_{L^2} &\models (\exists x, CSE_1(x) \wedge \mathrm{E}q(\bar{\Phi}(x, U(1)), x^1))[V] \\ &\quad \text{and } \mathcal{U}_{L^2} \models \mathrm{E}q(\bar{\eta}(x^1), Y(2))[V] \\ &\quad \Longleftrightarrow \mathcal{U}_{L^2} \models CSE_2(x^1)[V], \\ &\quad \vdots \quad \vdots \qquad \vdots \quad \vdots \\ \mathcal{U}_{L^2} &\models (\exists x CSE_1(x) \wedge \mathrm{E}q(\bar{\Phi}(x, U(1)), x^N))[V] \\ &\text{and } \mathcal{U}_{L^2} \models \mathrm{E}q(\bar{\eta}(x^N), Y(2))[V] \\ &\Longleftrightarrow \mathcal{U}_{L^2} \models CSE_2(x^N)[V], \end{aligned}$$

i.e., if and only if for each V

$$\begin{aligned} \text{for some } \mathbf{d} \in \mathbf{D},\ \mathcal{U}_{L^2} &\models CSE_1(x) \wedge \mathrm{E}q(\bar{\Phi}(x, U(1)), x^1)[V(x/\mathbf{d})] \\ &\text{and } \mathcal{U}_{L^2} \models \mathrm{E}q(\bar{\eta}(x^1), Y(2))[V] \\ &\Longleftrightarrow \mathcal{U}_{L^2} \models CSE_2(x^1)[V] \\ &\vdots \quad \vdots \quad \vdots \quad \vdots \\ \text{for some } \mathbf{d} \in \mathbf{D},\ \mathcal{U}_{L^2} &\models CSE_1(x) \wedge \mathrm{E}q(\bar{\Phi}(x, U(1)), x^N)[V(x/\mathbf{d})] \\ &\text{and } \mathcal{U}_{L^2} \models \mathrm{E}q(\bar{\eta}(x^N), Y(2))[V] \\ &\Longleftrightarrow \mathcal{U}_{L^2} \models CSE_2(x^N)[V] \end{aligned}$$

if and only if for each V

$$\begin{aligned}
&\text{for some } \mathbf{d} \in \mathbf{D},\ \mathbf{d} \in I_2(CSE_1) \text{ and } \boldsymbol{\Phi}(\mathbf{d},\mathbf{u}_1) = \mathbf{x}^1\\
&\qquad \text{and } \boldsymbol{\eta}(\mathbf{d}) = \mathbf{y}_1\\
&\qquad \Longleftrightarrow \mathbf{x}^1 \in I_2(CSE_2)\\
&\qquad \vdots \quad \vdots \quad \vdots \quad \vdots\\
&\text{for some } \mathbf{d} \in \mathbf{D},\ \mathbf{d} \in I_2(CSE_1) \text{ and } \boldsymbol{\Phi}(\mathbf{d},\mathbf{u}_1) = \mathbf{x}^N\\
&\qquad \text{and } \boldsymbol{\eta}(\mathbf{d}) = \mathbf{y}_1\\
&\qquad \Longleftrightarrow \mathbf{x}^N \in I_2(CSE_2),
\end{aligned}$$

i.e., if and only if

$$\begin{aligned}
&\text{for some } \mathbf{d} \in \mathbf{D}, \boldsymbol{\eta}(\mathbf{d}) = \mathbf{y}_1\\
&\text{and } \boldsymbol{\Phi}(\mathbf{d},\mathbf{u}_1) = \mathbf{x}^1\\
&\text{and } \boldsymbol{\eta}(\mathbf{x}^1) = \mathbf{y}_2\\
&\Longleftrightarrow \mathbf{x}^1 \in \{\hat{\mathbf{x}}_2\}(\mathbf{o}_1^2)\\
&\vdots \quad \vdots \quad \vdots \quad \vdots\\
&\text{for some } \mathbf{d} \in \mathbf{D},\ \boldsymbol{\eta}(\mathbf{d}) = \mathbf{y}_1\\
&\text{and } \boldsymbol{\Phi}(\mathbf{d},\mathbf{u}_1) = \mathbf{x}^N\\
&\text{and } \boldsymbol{\eta}(\mathbf{x}^N) = \mathbf{y}_2\\
&\Longleftrightarrow \mathbf{x}^N \in \{\hat{\mathbf{x}}_2\}(\mathbf{o}_1^2),
\end{aligned}$$

i.e., if and only if

$$\begin{aligned}
&\text{for some } \mathbf{d} \in \mathbf{D},\\
&\boldsymbol{\eta}(\mathbf{d}) = \mathbf{y}_1 \text{ and } \boldsymbol{\Phi}(\mathbf{d},\mathbf{u}_1) = \mathbf{x}^1 \text{ and } \boldsymbol{\eta}(\mathbf{x}^1) = \mathbf{y}_2\\
&\Longleftrightarrow \mathbf{x}^1 \in \{\mathbf{x} \in \mathbf{X}; \boldsymbol{\eta}(\mathbf{x}) = \mathbf{y}_2 \text{ and there exists}\\
&\qquad\qquad \mathbf{x}' \in \mathbf{X} \text{ such that } \mathbf{x} = \boldsymbol{\Phi}(\mathbf{x}', \mathbf{u}_1) \text{ and } \boldsymbol{\eta}(\mathbf{x}') = \mathbf{y}_1\},\\
&\quad \vdots \quad \vdots \quad \vdots \quad \vdots\\
&\text{for some } \mathbf{d} \in \mathbf{D},\\
&\boldsymbol{\eta}(\mathbf{d}) = \mathbf{y}_1 \text{ and } \boldsymbol{\Phi}(\mathbf{d},\mathbf{u}_1) = \mathbf{x}^N \text{ and } \boldsymbol{\eta}(\mathbf{x}^N) = \mathbf{y}_2\\
&\Longleftrightarrow \mathbf{x}^N \in \{\mathbf{x} \in \mathbf{X}; \boldsymbol{\eta}(\mathbf{x}) = \mathbf{y}_2 \text{ and there exists}\\
&\qquad\qquad \mathbf{x}' \in \mathbf{X} \text{ such that } \mathbf{x} = \boldsymbol{\Phi}(\mathbf{x}', \mathbf{u}_1) \text{ and } \boldsymbol{\eta}(\mathbf{x}') = \mathbf{y}_1\},
\end{aligned}$$

which is evidently the case.

To verify that $\mathcal{U}_{L^k} \models \mathrm{AXM}^{\mathrm{est}}(L^k)$ for any $k > 2$ we need to establish that for any $\mathcal{U}_{L^k}$ and valuation V

$$\begin{aligned}
&\mathcal{U}_{L^k} \models (\exists x, CSE_{k-1}(x) \wedge \mathrm{E}q(\bar{\Phi}(x, U(k-1)), x^1) \wedge \mathrm{E}q(\bar{\eta}(x^1), Y(k)))[V]\\
&\qquad \Longleftrightarrow \mathcal{U}_{L^k} \models CSE_k(x^1)[V],\\
&\quad \vdots \quad \vdots \quad \vdots \quad \vdots\\
&\mathcal{U}_{L^k} \models (\exists x, CSE_{k-1}(x) \wedge \mathrm{E}q(\bar{\Phi}(x, U(k-1)), x^N) \wedge \mathrm{E}q(\bar{\eta}(x^N), Y(k)))[V]\\
&\qquad \Longleftrightarrow \mathcal{U}_{L^k} \models CSE_k(x^N)[V].
\end{aligned}$$

Arguing in a parallel manner to the case $k = 2$, the implications above will hold if and only if

$$\begin{aligned}
\{\text{for some } \mathbf{d} \epsilon \mathbf{D} \text{ and some } \mathbf{x}_1^{k-2} &= (\mathbf{x}_1, \dots, \mathbf{x}_{k-2}) \, \epsilon \, \mathbf{D}^{k-2}, \\
\mathbf{u}_1^{k-2} &= (\mathbf{u}_1, \dots, \mathbf{u}_{k-2}) \, \epsilon \, \mathbf{D}^{k-2}, \\
\text{it is the case that} & \\
\mathbf{x}_j &= \mathbf{\Phi}(\mathbf{x}_1, \mathbf{u}_1^{j-1}), j \, \epsilon \, [1, \dots, k-2] \\
\mathbf{y}_j &= \boldsymbol{\eta}(\mathbf{x}_j), j \, \epsilon \, [1, \dots, k-2], \\
\mathbf{d} &= \mathbf{\Phi}(\mathbf{x}_{k-2}, \mathbf{u}_{k-2}), \\
\text{and} & \\
\mathbf{x}^{\mathbf{1}} &= \mathbf{\Phi}(\mathbf{d}, \mathbf{u}_{k-1}) \text{ with } \mathbf{y}_k = \boldsymbol{\eta}(\mathbf{x}^{\mathbf{1}})\} \\
\Longleftrightarrow \mathbf{x}^{\mathbf{1}} &\; \epsilon \; \{\widehat{\mathbf{x}}_k\}(\mathbf{o}_1^k), \\
\vdots \quad \vdots \qquad \vdots &\qquad \vdots \quad \vdots \quad \vdots \\
\{\text{for some } \mathbf{d} \epsilon \mathbf{D} \text{ and some } \mathbf{x}_1^{k-2} &= (\mathbf{x}_1, \dots, \mathbf{x}_{k-2}) \, \epsilon \, \mathbf{D}^{k-2}, \\
\mathbf{u}_1^{k-2} &= (\mathbf{u}_1, \dots, \mathbf{u}_{k-2}) \epsilon \, \mathbf{D}^{k-2}, \\
\text{it is the case that} & \\
\mathbf{x}_j &= \mathbf{\Phi}(\mathbf{x}_1, \mathbf{u}_1^{j-1}), j \, \epsilon \, [1, \dots, k-2], \\
\mathbf{y}_j &= \boldsymbol{\eta}(\mathbf{x}_j), j \, \epsilon \, [1, \dots, k-2], \\
\mathbf{d} &= \mathbf{\Phi}(\mathbf{x}_{k-2}, \mathbf{u}_{k-2}) \\
\text{and} & \\
\mathbf{x}^N &= \mathbf{\Phi}(\mathbf{d}, \mathbf{u}_{k-1}) \text{ with } \mathbf{y}_k = \boldsymbol{\eta}(\mathbf{x}^{\mathbf{N}})\} \\
\Longleftrightarrow \mathbf{x}^{\mathbf{N}} &\; \epsilon \; \{\widehat{\mathbf{x}}_k\}(\mathbf{o}_1^k),
\end{aligned}$$

which is the case. This completes the proof of the theorem. □

THEOREM 4.3 (consistency). *Σ_k is consistent with respect to the first-order theory with equality, i.e., $\Sigma_k \nvdash \bot$ for all $k \geq 0$.*

Proof. This follows in the standard way from the existence of the model $\mathcal{U}_{L^k}$ for the set of axioms Σ_k. Take any formula $A \, \epsilon \, \Sigma_k$. Then we have $\mathcal{U}_{L^k} \not\models \neg A$. By Theorems 4.1 and 4.2, this implies $\Sigma_k \nvdash \neg A$. But by $\mathrm{AXM}^{\log}(1), \vdash \bot \rightarrow (A \rightarrow \bot)$, that is to say $\vdash \bot \rightarrow \neg A$, for any formula A; consequently $\Sigma_k \nvdash \bot$, and hence Σ_k is consistent. □

THEOREM 4.4 (completeness). *Let $\mathbf{o}_1^k, k \geq 0$, be any input–output sequence generated by a finite machine $\mathcal{M}$. Then any formula $A \, \epsilon \, Fma_{L^k}$ is true in every model $\mathcal{V}_{L^k}$ of the axiom set $\Sigma_k, k \geq 0$, for $\mathcal{M}$ and the input–output sequence $\mathbf{o}_1^k$, if and only if A is a consequence of Σ_k, i.e.,*

$$\textit{for all } \mathcal{V}_{L^k}, \; \mathcal{V}_{L^k} \models A \Longleftrightarrow \Sigma_k \vdash A.$$

Proof. We prove only the completeness part here, as soundness follows from Theorems 4.1 and 4.2.

Suppose $\Sigma_k \nvdash A$; then it is sufficient to show there exists a model $\mathcal{V}_{L^k}$ such that $\mathcal{V}_{L^k} \not\models A$. $\Sigma_k \cup \{\neg A\}$ is consistent since Σ_k is consistent and the assumption is that $\Sigma_k \nvdash A$. Now Henkin's theorem (see, e.g., Mendelson [1964]) states that every consistent set of first-order formulas has a model. The standard proof of this theorem applied to the present case gives a model $\mathcal{V}_{L^k}$ for $\Sigma_k \cup \{\neg A\}$. But the model $\mathcal{V}_{L^k}$ is also a model for Σ_k, and clearly $\mathcal{V}_{L^k} \not\models A$, as required. □

We note that in the case above the domain produced by the proof method in the general uninterpreted symbol case is collapsed by the replacements of the classes of cosets of interpretations of the equality and binary arithmetic symbols.

Next, we establish the unique model property for Σ_k, $k \geq 0$, and from this we shall obtain the decidability of COCOLOG theories.

As previously stated, we can get a unique model for a theory Th_o by adding additional axioms to specify the sizes of $\mathbf{U}, \mathbf{X}$, and $\mathbf{Y}$. Otherwise, there can be infinitely many different models. For example, any finite machine $\mathcal{M}' = (\mathbf{U}', \mathbf{X}', \mathbf{Y}', \mathbf{\Phi}', \boldsymbol{\eta}')$ satisfying $\mathbf{U} \subseteq \mathbf{U}'$, $\mathbf{X} \subseteq \mathbf{X}'$, and $\mathbf{Y} \subseteq \mathbf{Y}'$ and such that $\mathbf{\Phi}'$ and $\boldsymbol{\eta}'$ are compatible with $\mathbf{\Phi}$ and $\boldsymbol{\eta}$ on $\mathbf{U}, \mathbf{X}$, and $\mathbf{Y}$ can be used to construct a model of the given machine axioms. This property is analogous to that displayed by nonminimal realizations of input–state–output systems. We conclude that the machine axioms alone cannot uniquely characterize a given finite machine. In fact, even with the addition of further axioms, the most one can achieve by axiomatization is a set of equivalent models up to isomorphism, and consequently uniqueness is used only in this sense.

Suppose $|\mathbf{X}| = N$, $|\mathbf{U}| = m$, and $|Y| = p$. We first consider the state space *size axioms* for $\mathcal{M}$.

Size axioms $\mathbf{X}^{\mathcal{M}}$.

$$
\begin{aligned}
&(1)\quad X_N^{\mathcal{M}} : \neg\mathrm{E}q(x^1, x^2) \wedge \neg\mathrm{E}q(x^1, x^3) \wedge \neg\mathrm{E}q(x^1, x^4) \wedge \cdots \wedge \neg\mathrm{E}q(x^1, x^N) \\
&\qquad\qquad \wedge \neg\mathrm{E}q(x^2, x^3) \wedge \neg\mathrm{E}q(x^2, x^4) \wedge \cdots \wedge \neg\mathrm{E}q(x^2, x^N) \\
&\qquad\qquad \wedge \neg\mathrm{E}q(x^3, x^4) \wedge \cdots \wedge \neg\mathrm{E}q(x^3, x^N), \\
&(\mathrm{AXM}^{\mathrm{size}}(L)) \qquad\qquad \vdots \\
&\qquad\qquad \wedge \neg\mathrm{E}q(x^{N-1}, x^N), \\
&(2)\quad \neg X_{N+1}^{\mathcal{M}} : \forall x \left(\bigvee_{i=1}^{N} \mathrm{E}q(x, x^i) \right).
\end{aligned}
$$

The formula $X_N^{\mathcal{M}}$ expresses the statement that there are at least N distinct constant elements in the state space $\mathbf{X}$ of the finite machine $\mathcal{M}$, i.e., $|\mathbf{X}| \geq N$, and the statement that there are at most N elements in $\mathbf{X}$, i.e., $|\mathbf{X}| \leq N$, is expressed by the formula $\neg X_{N+1}^{\mathcal{M}}$.

Adding $X_N^{\mathcal{M}}$ and $\neg X_{N+1}^{\mathcal{M}}$ to the originally proposed machine axioms ensures that all models of the axioms will have exactly N distinct states.

Size axioms $\mathbf{U}^{\mathcal{M}}$. These are analogous to the size axioms $\mathbf{X}^{\mathcal{M}}$ and specify $|\mathbf{U}| = m$.

Size axioms $\mathbf{Y}^{\mathcal{M}}$. These are analogous to the size axioms $\mathbf{X}^{\mathcal{M}}$ and specify $|\mathbf{Y}| = p$.

In the following we let $\mathcal{M}$ and $\mathcal{M}'$ denote finite machines and $\mathbf{D}$ and $\mathbf{D}'$ denote the sets $\mathbf{D} = \mathbf{U} \cup \mathbf{X} \cup \mathbf{Y}$ and $\mathbf{D}' = \mathbf{U}' \cup \mathbf{X}' \cup \mathbf{Y}'$.

DEFINITION 4.1. *Let $\mathcal{M}$ and $\mathcal{M}'$ be two finite machines in the models $\mathcal{U}_L$ and $\mathcal{U}_L'$, respectively; then a map h from $\mathcal{M}, \mathbf{I}_{\mathbf{k(N)}}$ to $\mathcal{M}', \mathbf{I}'_{\mathbf{k(N)}}$ is a* homomorphism *if for all $\mathbf{u} \in \mathbf{U}, \mathbf{x} \in \mathbf{X}, \mathbf{l}, \mathbf{l}' \in \mathbf{I}_{k(\mathbf{N})}$, it is the case that*

$$
\begin{aligned}
h(\mathbf{\Phi}(\mathbf{x}, \mathbf{u})) &= h(\mathbf{\Phi})(h(\mathbf{x}), h(\mathbf{u})), \\
h(\boldsymbol{\eta}(\mathbf{x})) &= h(\boldsymbol{\eta})(h(\mathbf{x})), \\
h(+_{\mathbf{k(N)}}(\mathbf{l}, \mathbf{l}')) &= h(+_{\mathbf{k(N)}})(h(\mathbf{l}), h(\mathbf{l}')), \\
h(-_{\mathbf{k(N)}}(\mathbf{l}, \mathbf{l}')) &= h(-_{\mathbf{k(N)}})(h(\mathbf{l}), h(\mathbf{l}')).
\end{aligned}
$$

h is an isomorphism *if there exists a homomorphism h' from $\mathbf{D}'$ to $\mathbf{D}$ such that the composition $h' \circ h$ of h' and h is the identity on $\mathbf{D}$.*

If two L-structures $\mathcal{U}_L, \mathcal{U}_L'$ for Th_0 are such that $\mathcal{M}, \mathbf{I}_{\mathbf{k(N)}}$ and $\mathcal{M}', \mathbf{I}'_{\mathbf{k(N)}}$ are isomorphic, we say $\mathcal{U}_L, \mathcal{U}_L'$ have *isomorphic preinterpretations*. If the sets in the products of the domains corresponding respectively to (i) the predicates $Rbl(\cdot, \cdot, \cdot)$ and (ii) the predicates expressing the axiom schemata $\mathrm{AXM}^{\mathrm{obs}}(L^k)$ and $\mathrm{AXM}^{\mathrm{est}}(L^k)$ are also isomorphic, we say the *interpretations*, or *models*, are *isomorphic*. (We note that the standard interpretation for the equality predicate has been taken as a fixed interpretation in all models $\mathcal{U}_L$.) Define

$$\Sigma_{k,\mathcal{M}} = \Sigma_k \cup X_N^{\mathcal{M}} \cup \neg X_{N+1}^{\mathcal{M}} \cup U_m^{\mathcal{M}} \cup \neg U_{m+1}^{\mathcal{M}} \cup Y_p^{\mathcal{M}} \cup \neg Y_{p+1}^{\mathcal{M}}$$

as the set of axioms for the given finite machine $\mathcal{M}$, at the instant $k \geq 0$.

THEOREM 4.5 (unique model property). *The logical theory generated by the axiom set* $\Sigma_{k,\mathcal{M}}, k \geq 0$, *for the finite machine* $\mathcal{M}$ *and the input–output sequence* $\mathbf{o}_1^k, k \geq 1$, *generated by* $\mathcal{M}$ *has a unique model up to isomorphism.*

Remark. In the proof of the following theorem it should be noted that there is an a priori restriction on any model $\mathcal{U}'_{L^k}$ of Σ_k. Recall from §§3.2 and 3.4 that the constant symbol sets

$$\text{Cons}_{L^o} \text{ and } \text{Cons}_{L^k} \triangleq \{u^1, \dots u^m, U(1), U(2), \dots, U(k-1); x^1, \dots, x^N; y^1, \dots, y^p, \\ Y(1), Y(2), \dots, Y(k)\}, \qquad k \geq 1,$$

in the languages $L^k, k \geq 0$, map under any interpretation $I'_k, k \geq 0$, to the corresponding constants in a the set theoretic model domain $\mathbf{D}'$ for some machine. All the axiom systems $\Sigma_0, \Sigma_1, \Sigma_2, \dots$ are axiomatizations of the behaviour (at successive time instants along a system trajectory) of the given set theoretic machine $\mathcal{M}$ defining the language L and the axioms Σ; by definition, this machine $\mathcal{M}$ has the input, state, and output elements $\{\mathbf{u^1}, \dots, \mathbf{u^m}\} = \mathbf{U}$, $\{\mathbf{x^1}, \dots, \mathbf{x^N}\} = \mathbf{X}$, and $\{\mathbf{y^1}, \dots, \mathbf{y^p}\} = \mathbf{Y}$. Consequently, whether or not the size axioms are in force, the images of the elements of Cons_{L^k} under the mapping I'_k of a structure $\mathcal{U}'_{L^k}, k \geq 0$, must be isomorphic to a subset of the union of the sets **U**,**X**, and **Y** appearing in the definition of $\mathcal{M}$. In particular, we shall see that when the size axioms are in force, then under any I'_k the images of $U(1), U(2), \dots; Y(1), Y(2), \dots$ must be in one-to-one correspondence with the occurrences of the inputs and outputs $\mathbf{u}_k, \mathbf{y}_k, k \geq 1$, along the given trajectory of the original machine $\mathcal{M}$ generating these observations; this is the case since the constant names $U(1), U(2), \dots; Y(1), Y(2), \dots$ appear in the observation axiom schemata $\text{AXM}^{\text{obs}}(L^k)$, $k \geq 1$, as the left arguments of equality predicates whose corresponding right arguments have as images under I'_k the elements of the trajectory of the model $\mathcal{U}'_{L^k}, k \geq 1$.

Proof. First we establish that all preinterpretations are isomorphic by showing the existence of a homomorphic mapping between any given pair of models of $\Sigma_0 = \Sigma$.

Now consider the model $\mathcal{U}_L$ constructed in Theorems 4.1 and 4.2 and any other model $\mathcal{U}'_L$. By the size axioms we have $|\mathbf{X}| = |\mathbf{X}'| = N$, $|\mathbf{Y}| = |\mathbf{Y}'| = p$, and $|\mathbf{U}| = |\mathbf{U}'| = m$, and by the machine axioms we have $\mathbf{\Phi} : \mathbf{X} \times \mathbf{U} \to \mathbf{X}$ and $\mathbf{\Phi}' : \mathbf{X}' \times \mathbf{U}' \to \mathbf{X}'$; $\boldsymbol{\eta} : \mathbf{X} \to \mathbf{Y}$ and $\boldsymbol{\eta}' : \mathbf{X}' \to \mathbf{Y}'$.

Let L denote the set of symbols of the theory for the machine $\mathcal{M}$ generated by the axioms $\Sigma_{k,\mathcal{M}}$, and let $I : L \to \mathbf{D}$ and $I' : L \to \mathbf{D}'$ be the interpretation functions corresponding to the domains $\mathbf{D}$ and $\mathbf{D}'$, respectively. Each of the maps may be seen to be bijective by invoking the size axioms and the definition of an interpretation function. Define $h : D \to D'$ such that the following relation is satisfied:

$$h(\mathbf{m}) = I'(I^{-1}(\mathbf{m})) \quad \text{for any } \mathbf{m} \in \mathbf{D}.$$

The relations among L, **D**,**D**$'$ and the mappings of I, I', and h are shown as follows:

$$\begin{tikzcd} & L \arrow[dl, "I"'] \arrow[dr, "I'"] & \\ \mathbf{D} \arrow[rr, "h"] & & \mathbf{D}' \end{tikzcd}$$

It is straightforward to show that h is a bijective mapping: first, to establish h is onto, take any $\mathbf{m}' \epsilon \mathbf{D}'$, then we have $I'^{-1}(\mathbf{m}') = l$ for some $l \epsilon L$ and $I(l) = \mathbf{m}$ for some $\mathbf{m} \epsilon \mathbf{D}$. This $\mathbf{m}$ is obviously the preimage of $\mathbf{m}'$ under h because

$$h(\mathbf{m}) = I'(I^{-1}(\mathbf{m})) = I'(l) = I'(I'^{-1}(\mathbf{m}')) = \mathbf{m}'.$$

Similarly, the one-to-one property is immediately obtained from

$$h(\mathbf{m}_1) = h(\mathbf{m}_2) \quad \text{iff}\, I'(I^{-1}(\mathbf{m}_1)) = I'(I^{-1}(\mathbf{m}_2)) \quad \text{iff}\, \mathbf{m}_1 = \mathbf{m}_2.$$

Now let us write $h(\mathbf{m}) = \mathbf{m}'$ for any $\mathbf{m} \epsilon \mathbf{D}$ and corresponding $\mathbf{m}' \epsilon \mathbf{D}'$ and take some dynamical axiom formula $\mathrm{E}q(\bar{\Phi}(x^i, u^l), x^j)$ from the language L. Since $\mathcal{U}_L$ is a model, the interpretation I will map this formula to $I(\Phi)(I(x^i), I(u^l)) = I(x^j)$, which is the equality $\mathbf{\Phi}(\mathbf{x^i}, \mathbf{u}^l) = \mathbf{x^j}$, and the interpretation I' will map the formula to $I'(\Phi)(I'(x^i), I'(u^l)) = I'(x^j)$, which is $\mathbf{\Phi}'(\mathbf{x}'^{\mathbf{i}}, \mathbf{u}'^l) = \mathbf{x}'^{\mathbf{j}}$. Then since $h(\mathbf{m}) = I'(I^{-1}(\mathbf{m}))$ we have the following relationship between the two models:

$$\mathbf{\Phi}(\mathbf{x^i}, \mathbf{u}^l) = \mathbf{x}^j \quad \text{iff}\, \mathbf{\Phi}'(\mathbf{x}'^{\mathbf{i}}, \mathbf{u}'^l) = \mathbf{x}'^{\mathbf{j}}.$$

Similarly, reference to the output axioms $\mathrm{AXM}^{\mathrm{out}}(L)$ yields

$$\boldsymbol{\eta}(\mathbf{x^i}) = \mathbf{y^m} \quad \text{iff}\, \boldsymbol{\eta}'(\mathbf{x}'^{\mathbf{i}}) = \mathbf{y}'^{\mathbf{m}}.$$

For the finite arithmetic of Th_0 things are yet simpler since the properties of $+_L, -_L$ were defined in terms of the fixed interpretation of $+_{\mathbf{k(N)}}, -_{\mathbf{k(N)}}$ on the fixed interpretation of a fragment $\mathbf{I}_{\mathbf{k(N)}}$ of the integers. Hence

$$+_{\mathbf{k(N)}}(\mathbf{l},\mathbf{l}') = \mathbf{l}'' \quad \text{iff } +'_{\mathbf{k(N)}}(\mathbf{l},\mathbf{l}') = \mathbf{l}'',$$
$$-_{\mathbf{k(N)}}(\mathbf{l},\mathbf{l}') = \mathbf{l}'' \quad \text{iff } -'_{\mathbf{k(N)}}(\mathbf{l},\mathbf{l}') = \mathbf{l}''.$$

Consequently, defining $h(\Phi)$ to be the functional relation from $\mathbf{X}' \times \mathbf{U}'$ to $\mathbf{X}'$ given by $\mathbf{\Phi}'$ and $h(\eta)$ to be that from $\mathbf{X}'$ to $\mathbf{Y}'$ given by $\boldsymbol{\eta}'$, it follows that $\Sigma_{k,\mathcal{M}}$ has a unique preinterpretation up to isomorphism.

For the interpretations of the predicate $Rbl(x, x', k)$, the interpretation functions I and I' give, respectively, the relational sets $\{(\mathbf{x}, \mathbf{x}', \mathbf{k}); \mathbf{x}, \mathbf{x}' \epsilon, \mathbf{X}, \mathbf{k} \epsilon \mathbf{I}_{\mathbf{k(N)}}$, such that there exists $\mathbf{u}_1^k \epsilon \mathbf{U}^k$ and $k \epsilon \mathbf{I}_{\mathbf{k(N)}}$ such that $\mathbf{\Phi}(\mathbf{x}, \mathbf{u}_1^k) = \mathbf{x}'\}$, and the same expression with the substitutions $\mathbf{X}'$ for $\mathbf{X}, \mathbf{U}'$ for $\mathbf{U}$, and $\mathbf{I}'_{\mathbf{k(N)}}$ for $\mathbf{I}_{\mathbf{k(N)}}$, etc. But it follows from the isomorphism of the preinterpretations that the corresponding relational sets are isomorphic, as required.

To establish the isomorphic nature of the interpretations of the observation and estimation axioms we proceed as follows.

For the first observation axiom schemata, in the case $k = 1$, we have $\mathrm{E}q(Y(1), \star)$, where $\star = y_1(o_1^k) \epsilon \mathrm{Cons}_{L^k}$.

Let us consider the particular case where $\mathbf{y}_1(\mathbf{o}_1^1) = \mathbf{y}^1 \epsilon \mathbf{Y}$. In that case we must treat the particular axiom for Th_1 given by $\mathrm{E}q(Y(1), y^1)$.

Under I and I', respectively, this formula maps to the relations

$$I(\mathrm{E}q(Y(1), y^1)), \quad \text{i.e., } \{I(Y(1)) = \mathbf{y}^1\}$$

and

$$I'(\mathrm{E}q(Y(1), y^1)), \quad \text{i.e., } \{I'(Y(1)) = \mathbf{y}'^1\}$$

for some $\mathbf{y}'^1 \epsilon \mathbf{Y}'$. But then the isomorphism $h = I' \circ I^{-1}$ gives the isomorphism of the relational sets in $\mathcal{U}_{L^1}$ and $\mathcal{U}'_{L^1}$ corresponding to the single observation axiom schemata in this case.

Moreover, the same assertion holds in each of the alternative cases

$$\mathbf{y}_1(\mathbf{o}_1^1) = \mathbf{y}^{\mathbf{j}} \epsilon \mathbf{Y}, \qquad \mathbf{2} \leq \mathbf{j} \leq \mathbf{p}.$$

Similar arguments hold for the observation axiom schemata (2) and (3) in the case $k \geq 2$.

It follows that the isomorphism $I'(I^{-1}(\cdot))$ maps the images of the constant names $\{Y(1), Y(2), \ldots, Y(k); U(1), U(2), \ldots, U(k-1)\}$ in the model $\mathcal{U}_{L^k}$ bijectively to the images of these constant names in $\mathcal{U}'_{L^k}$ and that the relational sets corresponding to the observation axiom schemata are also isomorphic.

Finally, we see that the relations given by the images of the state estimation axioms $\mathrm{AXM}^{\mathrm{est}}(L^k), k \geq 1$, under an interpretation I are isomorphic to their images under I' by the isomorphism $I' \circ I^{-1}$. This is the case since all of the set elements, function mappings, and set relations given by the interpretation of these axioms have been shown to be isomorphic to the image of these axioms under I' via the isomorphism $I' \circ I^{-1}$. □

DEFINITION 4.2 (proper formula). *A closed formula P is a* proper formula *with respect to a set of formulas Γ if P contains neither any constant, variable, predicate symbols nor function symbols which do not appear in any formulas in Γ.*

DEFINITION 4.3 (complete axiomatization). *A* set of formulas Γ *is said to be* complete *if either P or $\neg P$ is a consequence of Γ for any proper formula P with respect to Γ, and an* axiomatization Γ *is said to be* complete *if the set of formulas Γ is complete. A* theory *Th is said to be* complete *if it is consistent and for every closed formula A either $Th \vdash A$ or $Th \vdash \neg A$.*

THEOREM 4.6. *The axiomatization defined by $\Sigma_{k,\mathcal{M}}, k \geq 0$, for the finite machine $\mathcal{M}$ and the input–output sequence $\mathbf{o}_1^k, k \geq 0$, generated by $\mathcal{M}$, is a complete axiomatization.*

Proof. To prove that $\Sigma_{k,\mathcal{M}}$ is a complete axiomatization, we need to show that for any formula $A \epsilon L^k$ either $\Sigma_{k,\mathcal{M}} \vdash A$ or $\Sigma_{k,\mathcal{M}} \vdash \neg A$. We know $\Sigma_{k,\mathcal{M}}$ is consistent by the existence of a model for $\Sigma_{k,\mathcal{M}}$. By Lindenbaum's lemma (see Mendelson [1964]) if $\Sigma_{k,\mathcal{M}}$ is a consistent first-order theory, then there is a consistent complete extension of $\Sigma_{k,\mathcal{M}}$. But since $\Sigma_{k,\mathcal{M}}$ has a unique model, the complete extension of $\Sigma_{k,\mathcal{M}}$ is $\Sigma_{k,\mathcal{M}}$. Hence $\Sigma_{k,\mathcal{M}}$ is complete. □

THEOREM 4.7 (decidable theoremhood). *The logical theory Th_k generated by $\Sigma_{k,\mathcal{M}}$ for the finite machine $\mathcal{M}$ and the input–output sequence $\mathbf{o}_1^k, k \geq 0$, generated by $\mathcal{M}$, is recursively decidable.*

Proof. It is known that any axiomatizable complete theory is recursively decidable (Bell and Machover [1977, Thm. 11.5, p. 355]). Now the theory Th_k generated by $\Sigma_{k,\mathcal{M}}$ is (finitely) axiomatizable since it is generated by the set of postulates $\Sigma_{k,\mathcal{M}}$. Furthermore, Theorem 4.6 gives the completeness of the theory Th_k generated by $\Sigma_{k,\mathcal{M}}$; hence the result follows. □

5. Extralogical transitions between logical theories. We recall that a COCOLOG control system operates via a cyclical interaction between a controlled dynamical system, represented by the mathematical system $\mathcal{M}$, and a logic controller carrying the sequence of COCOLOG theories $\{Th(o_1^k), k \geq 0\}$.

At any instant $k \geq 0$, $\Sigma_{k,\mathcal{M}}$ contains axioms specifying the observed system input $\mathbf{u}_{k-1}$ and output $\mathbf{y}_k$. The deductive closure $Th(o_1^k)$ of $\Sigma_{k,\mathcal{M}}$ is then generated and the controller selects the control input $\mathbf{u}_k$ by the metalogical step of finding the unique **IF**. . .**THEN**. . . element of the list CCR_k for which the antecedent formula lies in $Th(o_1^k)$.

The equality predicate specifying (in the precise sense given in §3.5) the input $\mathbf{u}_k$ to $\mathcal{M}$ and the equality predicate specifying the resulting observed output $\mathbf{y}_{k+1}$ of $\mathcal{M}$ are then adjoined as new axioms to $\Sigma_{k,\mathcal{M}}$, along with the estimation axioms corresponding to the instant $k+1$, to form the axiom set $\Sigma_{k+1,\mathcal{M}}$ in the extended language $L_{k+1,\mathcal{M}}$.

FIG. 3. *A closed-loop logic control system.*

With respect to the modelling of the relation between the evolution of the sequence of COCOLOG theories and the controlled system $\mathcal{M}$, it has been assumed that there are no errors in the observations or in the communication of control inputs and that the control inputs generated by the logic controller are implemented instantaneously with respect to the discrete time indices of the system $\mathcal{M}$. Hence there is no inconsistency between the values of system inputs and outputs as given by the axiom sets $\Sigma_{k,\mathcal{M}}$ and the evolution of the model $\mathcal{M}$. Furthermore, it has been assumed that the entire deductive closure $Th(o_1^k)$ of the axioms $\Sigma_{k,\mathcal{M}}$ is instantaneously generated in the logic regulator $\mathcal{R}$ at each discrete time instant k, thus permitting the instantaneous selection of the appropriate conditional control rule determining the subsequent control input.

These requirements constitute restrictions on the transitions between logical theories which cannot be represented within these theories themselves and which have consequently been expressed in the description of the overall system.

In this setting we evidently obtain the following statement concerning the evolution of a sequence of COCOLOG theories.

THEOREM 5.1 (nesting of theories). *Let* $\mathcal{M} = (\mathbf{U}, \mathbf{X}, \mathbf{Y}, \mathbf{\Phi}, \eta)$ *be a finite machine in an initial state* $\mathbf{x}_0$, *and let* $\{\mathrm{CCR}_k, k \geq 1\}$ *be a sequence of* CCRs *formulated in the sequence of languages* $\{L^k, k \geq 1\}$. *Assume that the input sequence to the machine* $\mathcal{M}$ *is such that at the instant k the input* $\mathbf{u}_k \in \mathbf{U}$ *is that determined by the associated* CCR_k. *Then* (*up to isomorphism*) *the observation axioms* $\{\mathrm{AXM}^{\mathrm{obs}}(L^k), k \geq 1\}$ *of the COCOLOG theories* $\{Th(o_1^k), k \geq 1\}$ *generated by* $\{\Sigma_{k,\mathcal{M}}, k \geq 1\}$ *satisfy the interpretation constraint expressed by*

$$I_k(U(k-1)) = \mathbf{u}_{k-1}(\mathbf{o}_1^k), \qquad I_k(Y(k)) = \mathbf{y}_k(\mathbf{o}_1^k),$$

and the sequence of COCOLOG theories $\{Th(o_1^k), k \geq 0\}$ *generated by* $\{\Sigma_{k,\mathcal{M}}, k \geq 0\}$ *satisfies*

$$Th_0 \subseteq Th(o_1^1) \subseteq \cdots \subseteq Th(o_1^k) \subseteq Th(o_1^{k+1}) \subseteq \cdots, \qquad k \geq 0.$$

A representation of a COCOLOG closed-loop control system is displayed in Fig. 3.

6. Conclusion. Several problems concerning COCOLOG systems may be posed at this point.

(i) There is the problem of the definition of a tractable, analysable fragment of COCOLOG obtained by suitably restricting the COCOLOG languages $\{L_k; k \geq 0\}$, the associated axioms, or the class of CCRs. This has been undertaken in Wei and Caines [1992], where the notion of the Markovian fragments of a COCOLOG system is defined and analysed.

(ii) The issue of implementability of COCOLOG for real-time systems leads to the question of automatic theorem proving in COCOLOG. As remarked in the introduction, current experiments using the FE-resolution extension of the GTP automatic theorem-proving software of Newborn [1987] (proposed by the authors and developed by Q.-X. Yu) are encouraging (see Wang and Caines [1991], [1992]), as are the results in Caines, Mackling, and Wei [1992], which employs the Blitzensturm theorem-proving software of Mackling [1993]. A complexity analysis of such algorithms would be of great value.

(iii) A realization of a COCOLOG system is a sequence of first-order theories generated by a given sequence of input–output observations corresponding to a path in a COCOLOG tree structure (see Fig. 2). The true formulas at the nodes of this tree can be captured by a possible-worlds interpretation of a model logic (see Goldblatt [1987]), and a study of the mathematical properties of such an overall modal logic formulation of COCOLOG merits attention.

Acknowledgments. The authors gratefully acknowledge conversations concerning this paper with Tom Mackling, Michael Makkai, and Yuan-Jun Wei and the valuable comments of anonymous referees; they also wish to thank David Delchamps for suggesting the name COCOLOG.

REMARKS ON NONLINEAR STOCHASTIC PARTIAL DIFFERENTIAL EQUATIONS: AN APPLICATION OF THE SPLITTING-UP METHOD*

NORIAKI NAGASE†

Abstract. The objective of this article is to apply the splitting-up method to the existence theorem for nonlinear stochastic partial differential equations. With use of this method an approximating sequence is constructed. By the compactness argument a convergent subsequence can be extracted, and this fact provides the solution.

Key words. splitting-up method, stochastic partial differential equation

AMS subject classifications. 60H15, 35R60

1. Introduction.

We consider in this article the existence of solutions for the following nonlinear stochastic partial differential equation derived by white noise:

$$dy(t) + A(t)y(t)\,dt = f(t, y(t))\,dt + g(t, y(t))\,dW(t), \tag{1.1}$$

where $A(t)$ is a second-order elliptic differential operator, $f(t,\cdot)$ and $g(t,\cdot)$ are continuous operators from $L^2(\mathbb{R}^d)$ to itself, and $W(t)$ is an m-dimensional Brownian motion. A solution $y(t)$ of the problem is sought in the space of Sobolev type $H^1(\mathbb{R}^d)$. (For the precise definition, see Definition 2.1.)

When $f(t,\cdot)$ and $g(t,\cdot)$ satisfy the Lipschitz condition, Pardoux [4] and Walsh [5] proved the existence and uniqueness of the solutions for (1.1) by Picard's method of successive approximation. But if $f(t,\cdot)$ and $g(t,\cdot)$ are merely continuous, Picard's method is not effective.

Recently Bensoussan [1] has given a new result for stochastic partial differential equations for Leray–Lions operators on a compact subset of $\mathbb{R}^d$. The main idea is to use the splitting-up method, considering $A(t)y(t)\,dt - f(t, y(t))\,dt - g(t, y(t))\,dW(t)$ as the sum of two operators. According to Bensoussan's idea, we shall show the existence of solutions for the nonlinear stochastic partial differential equation (1.1) on whole space $\mathbb{R}^d$. (See also [2].)

This paper is formulated as follows. In §2 we state our problem, and in §3 we state the main theorem. In §4 we construct an approximating sequence of the equation (1.1) by the splitting-up method and show some estimates for this sequence. In §5 we show the fundamental lemma which is the whole-space $\mathbb{R}^d$ version of Bensoussan's compactness results. By this lemma, we can apply an argument similar to that of Bensoussan [1]. Section 6 is devoted to the proof of the main theorem.

2. Setting of the problem.

2.1. Notations and assumptions.

We denote by L^2_γ, $\gamma \geq 0$, the space of real-valued Borel functions on $\mathbb{R}^d$ with the norm defined by

$$|u|_\gamma = \left(\int_{\mathbb{R}^d} |(1 + |x|^2)^{\gamma/2} u(x)|^2\,dx \right)^{1/2}.$$

Clearly L^2_γ becomes a Hilbert space with the inner product

$$(u, v)_\gamma = \int_{\mathbb{R}^d} (1 + |x|^2)^\gamma u(x)v(x)\,dx.$$

* Received by the editors March 26, 1993; accepted for publication (in revised form) July 14, 1994.

† Department of Mathematics, Faculty of Science, Hirosaki University, 3 Bunkyo-cho, Hirosaki, Aomori-ken 036, Japan.

Let us set $L^2_0 = L^2$, $|\cdot|_0 = |\cdot|$, $(\cdot\,,\cdot)_0 = (\cdot\,,\cdot)$ ($\gamma = 0$), for simplicity, if no confusion occurs. $H^1 = H^1(\mathbb{R}^d)$ denotes the Sobolev space $W^{1,2}(\mathbb{R}^d)$ with its norm $\|\cdot\|$.

We shall consider second-order uniformly elliptic operators of the form

$$\begin{aligned} A(t)u(x) = &-\sum_{i,j=1}^{d} \frac{\partial}{\partial x_i}\left(a_{ij}(t,x)\frac{\partial}{\partial x_j}u(x)\right) \\ &+\sum_{i=1}^{d} b_i(t,x)\frac{\partial}{\partial x_i}u(x) + c(t,x)u(x), \end{aligned} \tag{2.1}$$

where a_{ij}, $b_i (i,j = 1,\dots,d)$, and c are bounded Borel functions on $(0,T)\times\mathbb{R}^d$ satisfying the conditions

$$\begin{aligned} &\text{i)}\ \ a_{ij}(t,x) = a_{ji}(t,x), \qquad i,j = 1,\dots,d, \\ &\text{ii)}\ \ \sum_{i,j=1}^{d} a_{ij}(t,x)\xi_i\xi_j \ge \alpha|\xi|^2 \quad \forall\xi = (\xi_1,\dots,\xi_d)\in\mathbb{R}^d, \end{aligned} \tag{A.1}$$

where $\alpha > 0$.

It is easy to check that the operator $A(t)$ satisfies the property

$$2\langle A(t)u,u\rangle + \lambda|u|^2 \ge \alpha\|u\|^2 \quad \forall u\in H^1 \tag{2.2}$$

for some $\lambda\in\mathbb{R}$, where $\langle\cdot\,,\cdot\rangle$ denotes the duality pairing between H^{-1} (the dual space of H^1 under identifying L^2 with its dual) and H^1.

Next we shall consider maps $f(t,u)$, $g(t,u) = (g_1(t,u),\dots,g_m(t,u))$ such that

$$\begin{aligned} &\text{i)}\ \ f:(0,T)\times L^2\to L^2 \text{ measurable,} \\ &\text{ii)}\ \ \text{a.e. } t,\ f(t,\cdot): L^2\to L^2 \text{ continuous,} \\ &\text{iii)}\ \ |f(t,u)|^2 \le K(1+|u|^2); \end{aligned} \tag{A.2}$$

$$\begin{aligned} &\text{i)}\ \ g_j:(0,T)\times L^2\to L^2 \text{ continuous,} \\ &\text{ii)}\ \ |g(t,u)|^2 = \sum_{j=1}^{m}|g_j(t,u)|^2 \le K(1+|u|^2), \\ &\text{iii)}\ \ |g_j(t,u)-g_j(s,u)|^2 \le o(|t-s|)(1+|u|^2). \end{aligned} \tag{A.3}$$

With $o(h)$ monotonic increasing, $o(h)\to 0$ as $h\to 0$.

2.2. The problem. We consider the following equation:

$$\begin{cases} dy(t) + A(t)y(t)\,dt = f(t,y(t))\,dt + \displaystyle\sum_{j=1}^{m} g_j(t,y(t))\,dW_j(t), \\ y(0) = y_0, \end{cases} \tag{2.3}$$

where $W(t) = (W_1(t),\dots,W_m(t))$ is an m-dimensional Brownian motion.

DEFINITION 2.1. *By a solution of the equation* (2.3), *we mean an H^1-valued process $y = (y(t))$ defined on a probability space $(\Omega,\mathcal{F},P)$ with a reference family $(\mathcal{F}_t)$ such that*

(I) *there exists an m-dimensional $(\mathcal{F}_t)$-Brownian motion $W(t) = (W_1(t),\dots,W_m(t))$ with $W(0) = 0$;*

(II) $y = (y(t))$ *is adapted to* $(\mathcal{F}_t)$ *and*

$$E\left[\int_0^T \|y(t)\|^2 \, dt\right] < \infty;$$

(III) *for any* $\varphi \in C_0^\infty(\mathbb{R}^d)$ (C^∞*-function on* $\mathbb{R}^d$ *with compact support*) *and almost all* $t \in [0,T]$

$$\begin{aligned}(y(t),\varphi) &+ \int_0^t \langle A(s)y(s),\varphi\rangle \, ds \\ &= (y_0,\varphi) + \int_0^t (f(s,y(s)),\varphi)\, ds + \sum_{j=1}^m \int_0^t (g_j(s,y(s)),\varphi)\, dW_j(s)\end{aligned} \tag{2.4}$$

holds.

To emphasize the particular role of $(\mathcal{F}_t)$-Brownian motion $W(t)$, sometimes we call the pair (W,y) itself a solution of (2.3).

3. Existence of the solution. Besides (A.1)–(A.3), we assume the following conditions.

(A.4) For some $\gamma > 0$, the restrictions of $f(t,\cdot)$ and $g_j(t,\cdot)$ on L^2_γ operate to itself and satisfy the linear growth condition. Namely, there exists a constant K such that

$$|h(t,u)|^2_\gamma \le K(1+|u|^2_\gamma) \quad \forall u \in L^2_\gamma, \tag{3.1}$$

where $h = f$, g_j $(j = 1,\dots,m)$.

(A.5) $y_0 \in L^2_\gamma$, where γ is the same number as in (A.4).

THEOREM 3.1. *Under the assumptions* (A.1)–(A.5), *the equation* (2.3) *has a solution in the sense of Definition* 2.1.

4. The splitting-up approximation scheme.

4.1. The algorithm. Let k be a positive integer which will tend to $+\infty$, and set $\delta = \frac{T}{k+1}$.

For each $w(\cdot) = (w_1(\cdot),\dots,w_m(\cdot)) \in C(0,T;\mathbb{R}^m)$, we shall define a process $z_k(t)$ depending on k and $w(\cdot)$. Consider an interval $[r\delta,(r+1)\delta)$, $r = 0,1,\dots,k$; then z_k is defined on this interval by the relation

$$\begin{cases} \dfrac{dz_k(t)}{dt} + A(t)z_k(t) = 0, \\ z_k(r\delta) = z_k^r, \end{cases} \tag{4.1}$$

where

$$\begin{aligned} z_k^{r+1} &= z_k((r+1)\delta - 0) + \int_{r\delta}^{(r+1)\delta} f(t,z_k(t))\, dt \\ &\quad + g(r\delta,\bar{z}_k^r)\cdot(w((r+1)\delta) - w(r\delta)), \\ z_k^0 &= y_0, \end{aligned}$$

and

$$\bar{z}_k^r = \frac{1}{\delta}\int_{r\delta}^{(r+1)\delta} z_k(t)\, dt.$$

By (2.2), (4.1) has a unique solution in $L^2(r\delta,(r+1)\delta;H^1)\cap C(r\delta,(r+1)\delta;L^2)$ once $z_k^r(\in L^2)$ is given. So (4.1) completely defines z_k on $[0,T)$. We set for completeness $z_k(T)=z_k^{k+1}$ and note that z_k is discontinuous at points $r\delta$ $(r=1,\dots,k+1)$ and has left-hand-side limits.

Hence we can define a map $\Psi_k : C(0,T;\mathbb{R}^m)\to L^2(0,T;H^1)$ by

$$\Psi_k(w)=z_k=\text{the solution of (4.1) corresponding to } w\in C(0,T;\mathbb{R}^m).$$

It is easy to see that Ψ_k is a continuous map from $C(0,T;\mathbb{R}^m)$ to $L^2(0,T;H^1)$, where $C(0,T;\mathbb{R}^m)$ is equipped with the uniform topology and $L^2(0,T;H^1)$ with the strong topology.

Let $B=(B_1,\dots,B_m)$ be an m-dimensional standard Brownian motion defined on a probability space $(\Omega,\mathcal{F},P)$, and put $z_k=\Psi_k(B)$.

4.2. Estimations. According to Bensoussan [1], we shall prove the following a priori estimates.

LEMMA 4.1. *There is a constant $C>0$ such that*

$$E\left[\int_0^T \|z_k(t)\|^2\,dt\right]\le C, \tag{4.2}$$

$$\sup_{0\le t\le T} E[|z_k(t)|^2]\le C, \tag{4.3}$$

$$\sup_{0\le t\le T} E[|z_k(t)|^4]\le C \tag{4.4}$$

for any $k=1,2,\dots$.

Remark 4.1. Hereafter we denote by C a constant independent of $k=1,2,\dots$ and $r=0,1,\dots,k+1$.

Proof. From the energy equality related to (4.1), we get

$$|z_k(t)|^2+2\int_{r\delta}^t\langle A(s)z_k(s),z_k(s)\rangle\,ds=|z_k^r|^2,\qquad t\in[r\delta,(r+1)\delta). \tag{4.5}$$

Using (2.2), we have

$$|z_k(t)|^2+\alpha\int_{r\delta}^t\|z_k(s)\|^2\,ds\le|z_k^r|^2+|\lambda|\int_{r\delta}^t|z_k(s)|^2\,ds. \tag{4.6}$$

Gronwall's inequality derives

$$|z_k(t)|^2\le e^{|\lambda|(t-r\delta)}\,|z_k^r|^2,\qquad t\in[r\delta,(r+1)\delta). \tag{4.7}$$

It follows that

$$\alpha\int_{r\delta}^{(r+1)\delta}\|z_k(t)\|^2\,dt\le e^{|\lambda|\delta}\,|z_k^r|^2 \tag{4.8}$$

and

$$|\bar{z}_k^r|^2\le\frac{e^{|\lambda|\delta}-1}{|\lambda|\delta}\,|z_k^r|^2. \tag{4.9}$$

Define the process $\tilde{z}_k$ by

$$\begin{aligned}\tilde{z}_k(t) = z_k((r+1)\delta - 0) &+ \int_{r\delta}^{t} f(s, z_k(s))\,ds \\ &+ g(r\delta, \bar{z}_k^r)\cdot(B(t) - B(r\delta))\end{aligned} \tag{4.10}$$

for $t \in [r\delta, (r+1)\delta)$, $r = 0, 1, \dots, k$.

It follows from Itô's formula that

$$\begin{aligned}d|\tilde{z}_k(t)|^2 &= 2(f(t, z_k(t)), \tilde{z}_k(t))\,dt \\ &\quad + 2(g(r\delta, \bar{z}_k^r), \tilde{z}_k(t))\,dB(t) + |g(r\delta, \bar{z}_k^r)|^2\,dt\end{aligned} \tag{4.11}$$

for $t \in [r\delta,\ (r+1)\delta)$, $r = 0, 1, \dots, k$.

Using (A.2), (A.3), (4.7), and (4.9), we get

$$\begin{aligned}E|\tilde{z}_k(t)|^2 &= E|z_k((r+1)\delta - 0)|^2 \\ &\quad + 2E\left[\int_{r\delta}^{t} (f(s, z_k(s)), \tilde{z}_k(s))\,ds\right] + E\left[\int_{r\delta}^{t} |g(r\delta, \bar{z}_k^r)|^2\,dt\right] \\ &\le e^{|\lambda|\delta} E|z_k^r|^2 + C\{1 + E|z_k^r|^2\}(t - r\delta) + E\left[\int_{r\delta}^{t} |\tilde{z}_k(s)|^2\,ds\right].\end{aligned} \tag{4.12}$$

So Gronwall's inequality derives

$$\begin{aligned}E|z_k^{r+1}|^2 &= E|\tilde{z}_k((r+1)\delta - 0)|^2 \\ &\le e^{(|\lambda|+1)\delta} E|z_k^r|^2 + C\{1 + E|z_k^r|^2\}(e^{\delta} - 1) \\ &\le (C\delta + 1)E|z_k^r|^2 + C\delta,\end{aligned} \tag{4.13}$$

which yields

$$\begin{aligned}E|z_k^r|^2 &\le (1 + C\delta)^r\{|y_0|^2 + 1\} \\ &\le \left(1 + \frac{CT}{k+1}\right)^{k+1}\{|y_0|^2 + 1\}\end{aligned} \tag{4.14}$$

for any $r = 0, 1, \dots, k+1$. Hence we obtain

$$E|z_k^r|^2 \le C \tag{4.15}$$

for any $k = 1, 2, \dots$ and $r = 0, 1, \dots, k+1$.

Combining (4.15) with (4.7) and (4.8), we get (4.2) and (4.3). For the proof (4.4), we note that from (4.7)

$$|z_k(t)|^4 \le e^{2|\lambda|(t - r\delta)}\,|z_k^r|^4, \qquad t \in [r\delta, (r+1)\delta). \tag{4.16}$$

Applying Itô's formula to (4.11), we get

$$\begin{aligned}&d|\tilde{z}_k(t)|^4 \\ &\quad = 2|\tilde{z}_k(t)|^2\{2(f(t, z_k(t)), \tilde{z}_k(t)) + |g(r\delta, \bar{z}_k^r)|^2\}\,dt \\ &\quad\quad + 4|\tilde{z}_k(t)|^2(g(r\delta, \bar{z}_k^r), \tilde{z}_k(t))\,dB(t) \\ &\quad\quad + 4|(g(r\delta, \bar{z}_k^r), \tilde{z}_k(t))|^2\,dt\end{aligned} \tag{4.17}$$

for $t \in [r\delta, (r+1)\delta)$, $r = 0, 1, \dots, k$.

By the same argument as above, we get

$$E|z_k^{r+1}|^4 = E|\tilde{z}_k((r+1)\delta - 0)|^4 \le (C\delta + 1)E|z_k^r|^4 + C\delta, \tag{4.18}$$

which yields

$$E|z_k^r|^4 \le C \tag{4.19}$$

for any $k = 1, 2, \dots$ and $r = 0, 1, \dots, k+1$.

This implies (4.4).

Remark 4.2. Combining (4.12) and (4.15), we can easily see that

$$\sup_{0 \le t \le T} E|\tilde{z}_k(t)|^2 \le C \quad \forall\, k = 1, 2, \dots. \tag{4.20}$$

Similarly it follows from (4.17) and (4.19) that

$$\sup_{0 \le t \le T} E|\tilde{z}_k(t)|^4 \le C \quad \forall\, k = 1, 2, \dots. \tag{4.21}$$

LEMMA 4.2. *There is a constant $C > 0$ such that*

$$E\left[\sup_{0 \le t \le T} |z_k(t)|^2\right] \le C \tag{4.22}$$

for any $k = 1, 2, \dots$.

Proof. Using (4.7), we have

$$\begin{aligned}\sup_{0 \le t \le T} |z_k(t)|^2 &\le e^{|\lambda|\delta} \max_{0 \le r \le k+1} |z_k^r|^2 \\ &\le e^{|\lambda|T} \max_{0 \le r \le k+1} |z_k^r|^2.\end{aligned} \tag{4.23}$$

Consider next the process $\tilde{z}_k$ defined in the proof of Lemma 4.1. Combining (4.6) with (4.11), we get

$$\begin{aligned}|z_k^{r+1}|^2 \le |z_k^r|^2 &+ |\lambda| \int_{r\delta}^{(r+1)\delta} |z_k(t)|^2\, dt \\ &+ 2\int_{r\delta}^{(r+1)\delta} (f(t, z_k(t)), \tilde{z}_k(t))\, dt \\ &+ 2\int_{r\delta}^{(r+1)\delta} (g(r\delta, \bar{z}_k^r), \tilde{z}_k(t))\, dB(t) \\ &+ \int_{r\delta}^{(r+1)\delta} |g(r\delta, \bar{z}_k^r)|^2\, dt.\end{aligned} \tag{4.24}$$

Adding these relations, we deduce

$$\begin{aligned}|z_k^r|^2 &\le |y_0|^2 + |\lambda| \int_0^{r\delta} |z_k(t)|^2\, dt + 2\int_0^{r\delta} (f(t, z_k(t)), \tilde{z}_k(t))\, dt \\ &\quad + 2\int_0^{r\delta} (\bar{g}(t), \tilde{z}_k(t))\, dB(t) + \int_0^{r\delta} |\bar{g}(t)|^2\, dt \\ &\le |y_0|^2 + |\lambda| \int_0^T |z_k(t)|^2\, dt + \int_0^T |f(t, z_k(t))|^2\, dt + \int_0^T |\tilde{z}_k(t)|^2\, dt \\ &\quad + \int_0^T |\bar{g}(t)|^2\, dt + 2\int_0^{r\delta} (\bar{g}(t), \tilde{z}_k(t))\, dB(t),\end{aligned} \tag{4.25}$$

where $\bar{g}(t) = g(r\delta, \bar{z}_k^r)$, $t \in [r\delta, (r+1)\delta)$, $r = 0, 1, \ldots, k$.

From (4.3) and (4.20), we deduce

$$\begin{aligned} E\left[\max_{0\le r\le k+1} |z_k^r|^2\right] \\ \le C + 2E\left[\sup_{0\le t\le T}\left|\int_0^t (\bar{g}(s), \tilde{z}_k(s))\, dB(s)\right|\right]. \end{aligned} \tag{4.26}$$

Using the Burkholder–Gundy inequality, we have

$$\begin{aligned} &E\left[\sup_{0\le t\le T}\left|\int_0^t (\bar{g}(s), \tilde{z}_k(s))\, dB(s)\right|\right] \\ &\le CE\left[\left\{\int_0^T (\bar{g}(s), \tilde{z}_k(s))^2\, ds\right\}^{1/2}\right] \\ &\le C\left\{E\left[\int_0^T |\tilde{z}_k(t)|^2\, dt\right] + E\left[\sum_{r=0}^k |\bar{z}_k^r|^2 \int_{r\delta}^{(r+1)\delta} |\tilde{z}_k(t)|^2\, dt\right]\right\}^{1/2} \\ &\le C\left\{E\left[\int_0^T |\tilde{z}_k(t)|^2\, dt\right]\right. \\ &\quad \left. + E\left[\sum_{r=0}^k \frac{1}{\delta}\int_{r\delta}^{(r+1)\delta} |z_k(t)|^2\, dt \int_{r\delta}^{(r+1)\delta} |\tilde{z}_k(t)|^2\, dt\right]\right\}^{1/2} \\ &\le C\left\{E\left[\int_0^T |\tilde{z}_k(t)|^2\, dt\right] + E\left[\int_0^T |z_k(t)|^4\, dt\right] + E\left[\int_0^T |\tilde{z}_k(t)|^4\, dt\right]\right\}^{1/2} \\ &\le C \quad \text{by (4.4), (4.20), and (4.21).} \end{aligned} \tag{4.27}$$

From (4.23), the desired result (4.22) follows.

LEMMA 4.3. *There is a constant $C > 0$ such that*

$$E\left[\sup_{|\theta|\le\eta}\int_0^T \|z_k(t+\theta) - z_k(t)\|_*^2\, dt\right] \le C\eta \tag{4.28}$$

for any $0 < \eta \le 1$, $k = 1, 2, \ldots$, where z_k is extended by 0 outside of $[0, T]$ and $\|\cdot\|_*$ is the norm of the dual space $H^{-1} = (H^1)^*$.

Proof. Assume $\theta > 0$. A similar calculation is done whenever $\theta < 0$. We write

$$I = E\left[\sup_{0\le\theta\le\eta}\int_0^T \|z_k(t+\theta) - z_k(t)\|_*^2\, dt\right] \le I_1 + I_2, \tag{4.29}$$

where

$$I_1 = E\left[\sup_{0\le\theta\le\eta}\int_0^{T-\eta} \|z_k(t+\theta) - z_k(t)\|_*^2\, dt\right]$$

and

$$I_2 = E\left[\sup_{0\le\theta\le\eta}\int_{T-\eta}^T \|z_k(t+\theta) - z_k(t)\|_*^2\, dt\right].$$

From (4.22), we can see

$$I_2 \le C\eta. \tag{4.30}$$

Now we deal with I_1. Using (4.1) and (4.10), we have

$$\begin{aligned} &z_k(t+\theta) - z_k(t) + \int_t^{t+\theta} A(s) z_k(s) ds \\ &\quad = \int_{[t/\delta]\delta}^{[(t+\theta)/\delta]\delta} f(s, z_k(s))\, ds + \int_{[t/\delta]\delta}^{[(t+\theta)/\delta]\delta} \bar{g}(s)\, dB(s) \end{aligned} \tag{4.31}$$

for $t \in [0, T-\eta]$ and $0 \le \theta \le \eta$, where $\bar{g}$ is the process defined in (4.25) and $[t]$ denotes the integral part of t.

Next we have

$$\begin{aligned} \left\| \int_t^{t+\theta} A(s) z_k(s)\, ds \right\|_* &\le \int_t^{t+\theta} \|A(s) z_k(s)\|_*\, ds \\ &\le \theta^{1/2} \left\{ \int_t^{t+\theta} \|A(s) z_k(s)\|_*^2\, ds \right\}^{1/2}. \end{aligned} \tag{4.32}$$

Using (4.2), we get

$$\begin{aligned} &E\left[\sup_{0 \le \theta \le \eta} \int_0^{T-\eta} \left\| \int_t^{t+\theta} A(s) z_k(s)\, ds \right\|_*^2 dt \right] \\ &\quad \le \eta E\left[\int_0^{T-\eta} \int_0^T \left\| A(s) z_k(s) \right\|_*^2 ds\, dt \right] \\ &\quad \le C\eta. \end{aligned} \tag{4.33}$$

For the first term of the right-hand side of (4.31), we have

$$\begin{aligned} &\sup_{0 \le \theta \le \eta} \left\| \int_{[t/\delta]\delta}^{[(t+\theta)/\delta]\delta} f(s, z_k(s))\, ds \right\|_*^2 . \\ &\quad \le C \left\{ \int_{[t/\delta]\delta}^{[(t+\eta)/\delta]\delta} (1 + |z_k(s)|)\, ds \right\}^2 . \end{aligned} \tag{4.34}$$

Using (4.22), we get

$$\begin{aligned} &E\left[\sup_{0 \le \theta \le \eta} \int_0^{T-\eta} \left\| \int_{[t/\delta]\delta}^{[(t+\theta)/\delta]\delta} f(s, z_k(s))\, ds \right\|_*^2 dt \right] \\ &\quad \le CE\left[\sup_{0 \le s \le T} (1 + |z_k(s)|)^2 \int_0^{T-\eta} \left(\left[\frac{t+\eta}{\delta}\right] \delta - \left[\frac{t}{\delta}\right] \delta \right)^2 dt \right] \\ &\quad \le C \int_0^{T-\eta} \left(\left[\frac{t+\eta}{\delta}\right] \delta - \left[\frac{t}{\delta}\right] \delta \right)^2 dt \\ &\quad \le C\eta. \end{aligned} \tag{4.35}$$

Finally, using the Burkholder–Gundy inequality and (4.3), we have

$$
\begin{aligned}
&E\left[\sup_{0\le\theta\le\eta}\int_0^{T-\eta}\left\|\int_{[t/\delta]\delta}^{[(t+\theta)/\delta]\delta}\bar{g}(s)\,dB(s)\right\|_*^2\,dt\right]\\
&\le\int_0^{T-\eta}E\left[\sup_{0\le\theta\le\eta}\left|\int_{[t/\delta]\delta}^{[(t+\theta)/\delta]\delta}\bar{g}(s)\,dB(s)\right|^2\right]dt\\
&\le C\int_0^{T-\eta}E\left[\int_{[t/\delta]\delta}^{[(t+\eta)/\delta]\delta}|\bar{g}(s)|^2\,ds\right]dt\\
&\le C\int_0^{T-\eta}\left(\left[\frac{t+\eta}{\delta}\right]\delta-\left[\frac{t}{\delta}\right]\delta\right)dt\\
&\le C\eta.
\end{aligned}\tag{4.36}
$$

Combining (4.33), (4.35), and (4.36) with (4.31), we obtain $I_1 \le C\eta$, and this completes the proof.

LEMMA 4.4. *There is a constant $C > 0$ such that*

$$\sup_{0\le t\le T} E|z_k(t)|_\gamma^2 \le C \tag{4.37}$$

for any $k = 1, 2, \dots$, where γ is the same number as in (A.4).

Proof. We define the operator $\bar{A}(t)$ by

$$
\begin{aligned}
\bar{A}(t)u(x) = &-\sum_{i,j=1}^d \frac{\partial}{\partial x_i}\left(a_{ij}(t,x)\frac{\partial}{\partial x_j}u(x)\right)\\
&+\sum_{j=1}^d \bar{b}_{0j}(t,x)\frac{\partial}{\partial x_j}u(x)+\sum_{i=1}^d\frac{\partial}{\partial x_i}(\bar{b}_{i0}(t,x)u(x))\\
&+\bar{c}(t,x)u(x),
\end{aligned}\tag{4.38}
$$

where

$$
\begin{aligned}
\bar{b}_{0j}(t,x) &= b_j(t,x)+\sum_{i=1}^d a_{ij}(t,x)R_i(x),\\
\bar{b}_{i0}(t,x) &= \sum_{j=1}^d a_{ij}(t,x)R_j(x),\\
\bar{c}(t,x) &= c(t,x)-\sum_{i,j=1}^d a_{ij}(t,x)R_i(x)R_j(x)\\
&\quad-\sum_{i=1}^d b_i(t,x)R_i(x),
\end{aligned}
$$

and

$$R_i(x)=\frac{\gamma x_i}{1+|x|^2}\qquad (i=1,\dots,d).$$

Then $\langle\bar{A}(t)(Ru),\varphi\rangle = \langle A(t)u, R\varphi\rangle$ for any $u \in H^1$ and $\varphi \in C_0^\infty(\mathbb{R}^d)$ where $R(x) = (1+|x|^2)^{\gamma/2}$. Hence $q_k(t) = Rz_k(t)$ satisfies the following equation:

$$
\begin{cases}
\dfrac{dq_k(t)}{dt}+\bar{A}(t)q_k(t)=0,\\
q_k(r\delta)=q_k^r, \qquad t\in[r\delta,(r+1)\delta),
\end{cases}\tag{4.39}
$$

where

$$q_k^{r+1} = q_k((r+1)\delta - 0) + \int_{r\delta}^{(r+1)\delta} Rf(t, z_k(t))\,dt$$
$$+Rg(r\delta, \bar{z}_k^r) \cdot (B((r+1)\delta) - B(r\delta))$$

and

$$q_k^0 = Ry_0.$$

By virtue of assumptions (A.4) and (A.5), we can repeat an argument similar to (4.5) – (4.15) and obtain

$$\sup_{0 \le t \le T} E|q_k(t)|^2 \le C. \tag{4.40}$$

This yields (4.37) and completes the proof.

5. Tightness property. Now we introduce the fundamental lemma which is the whole-space $\mathbb{R}^d$ version of Bensoussan's compactness result (see Bensoussan [1, Prop. 3.1]). We consider a subset Z of $L^2(0,T;H^1(\mathbb{R}^d))$ depending on three constants, K, L, and M, and two sequences, μ_n and ν_n, with μ_n, $\nu_n > 0$ and μ_n, $\nu_n \to 0$ as $n \to 0$. The set Z is defined as follows:

$$Z = \left\{ u \in L^2(0,T;H^1(\mathbb{R}^d));\ \int_0^T \|u(t)\|^2\,dt \le K,\ \int_0^T |u(t)|_\gamma^2\,dt \le L, \right.$$
$$\left. \text{and} \sup_{|\theta| \le \mu_n} \int_0^T \|u(t+\theta) - u(t)\|_*^2\,dt \le \nu_n M \quad \forall n \ge 1 \right\}, \tag{5.1}$$

where u is extended by 0 outside of $[0,T]$.

LEMMA 5.1. *The set Z is a compact subset of $L^2(0,T;L^2(\mathbb{R}^d))$.*

Proof. Let $\{u_k\}$ be a sequence in Z. By the first condition of Z, we can extract a subsequence, still denoted by $\{u_k\}$, such that

$$u_k \to u \quad \text{in } L^2(0,T;H^1) \text{ weakly.} \tag{5.2}$$

Clearly the limit u satisfies the first and third conditions of Z. Put

$$D_p = \{x \in \mathbb{R}^d;\ |x| < p\}, \qquad p = 1, 2, \ldots.$$

First we shall prove that

$$u_k \to u \quad \text{in } L^2((0,T) \times D_p) \text{ strongly.} \tag{5.3}$$

Since the injection $H^1(D_p) (= W^{1,2}(D_p))$ into $L^2(D_p)$ is compact, for any $\varepsilon > 0$ there is a constant $C(\varepsilon)$ such that

$$|\varphi|_{D_p}^2 \le \varepsilon \|\varphi\|_{D_p}^2 + C(\varepsilon)\|\varphi\|_*^2 \quad \forall \varphi \in H^1(D_p), \tag{5.4}$$

where $|\cdot|_{D_p}$ and $\|\cdot\|_{D_p}$ are the norm of $L^2(D_p)$ and $H^1(D_p)$, respectively. (Apply Proposition 4.1 of Lions [3, p. 59] to the triplet $(H^1(D_p), L^2(D_p), (H^1(\mathbb{R}^d))^*)$.)

Hence

$$\begin{aligned}\int_0^T &|u_k(t)-u(t)|_{D_p}^2\,dt\\ &\le \varepsilon\int_0^T \|u_k(t)-u(t)\|_{D_p}^2\,dt + C(\varepsilon)\int_0^T \|u_k(t)-u(t)\|_*^2\,dt\\ &\le 2K\varepsilon + C(\varepsilon)\int_0^T \|u_k(t)-u(t)\|_*^2\,dt.\end{aligned}\tag{5.5}$$

Therefore, to prove (5.3), it is sufficient to prove that

$$\int_0^T \|u_k(t)-u(t)\|_*^2\,dt \to 0.\tag{5.6}$$

Consider a function $\psi \in C_0^\infty(\mathrm{R})$ with $\psi \ge 0$, $\int_{-\infty}^{\infty}\psi(t)\,dt = 1$, $\mathrm{supp}(\psi) = [-1,1]$, and the mollifier

$$\begin{aligned}\psi_\varepsilon * u(t) &= \frac{1}{\varepsilon}\int_{-\infty}^{\infty}\psi\left(\frac{t-s}{\varepsilon}\right)u(s)ds\\ &= \int_{-1}^{1} u(t-\varepsilon s)\psi(s)\,ds.\end{aligned}$$

Put $\tilde{u}_k = u_k - u$. Since u_k and u satisfy the third condition of Z, we see

$$\begin{aligned}\int_0^T &\|\psi_{\mu_n} * \tilde{u}_k(t) - \tilde{u}_k(t)\|_*^2\,dt\\ &\le \int_{-1}^{1}\left\{\int_0^T \|\tilde{u}_k(t-\mu_n s) - \tilde{u}_k(t)\|_*^2\,dt\right\}\psi(s)\,ds\\ &\le 4\nu_n M.\end{aligned}\tag{5.7}$$

Now, from (5.2), we have

$$\psi_{\mu_n} * \tilde{u}_k(t) = \frac{1}{\mu_n}\int_0^T \psi\left(\frac{t-s}{\mu_n}\right)\tilde{u}_k(s)\,ds \to 0 \quad \text{as}\, k\to\infty\tag{5.8}$$

in $H^1(D_p)$ weakly for any $n \ge 1$, $t \in [0,T]$.

Recalling that for the triplet $(H^1(D_p), L^2(D_p), (H^1(\mathrm{R}^d))^*)$ the injection $H^1(D_p)$ into $L^2(D_p)$ is compact, we have

$$\psi_{\mu_n} * \tilde{u}_k(t) \to 0 \quad \text{as}\, k\to\infty \quad \text{in}\,(H^1(\mathrm{R}^d))^* \quad \text{strongly.}\tag{5.9}$$

Since

$$\|\psi_{\mu_n} * \tilde{u}_k(t)\|_*^2 \le C(n)\int_0^T \|\tilde{u}_k(t)\|^2\,dt \le 4C(n)K,$$

we get

$$\psi_{\mu_n} * \tilde{u}_k \to 0 \quad \text{as}\, k\to\infty \quad \text{in}\, L^2(0,T;(H^1(\mathrm{R}^d))^*) \quad \text{strongly.}\tag{5.10}$$

(5.7) and (5.10) imply (5.6). Hence we obtain (5.3). From (5.3), it is easy to see that u satisfies the second condition of Z and thus $u \in Z$.

Finally

$$\begin{aligned}
&\int_0^T |u_k(t) - u(t)|^2\,dt \\
&\quad \le \int_0^T |u_k(t) - u(t)|^2_{D_p}\,dt + \frac{1}{(1+p^2)^\gamma}\int_0^T |u_k(t) - u(t)|^2_\gamma\,dt \\
&\quad \le \int_0^T |u_k(t) - u(t)|^2_{D_p}\,dt + \frac{4L}{(1+p^2)^\gamma}.
\end{aligned} \tag{5.11}$$

Therefore we deduce from (5.3) that

$$u_k \to u \quad \text{in } L^2(0,T;L^2(\mathbb{R}^d)) \quad \text{strongly,} \tag{5.12}$$

and this completes the proof.

Put $S = C(0,T;\mathbb{R}^m) \times L^2(0,T;L^2(\mathbb{R}^d))$. We denote by π_k the image measure of $(B, z_k) = (B, \Psi_k(B))$ on S. By virtue of the above compactness result, we can prove the following tightness property.

LEMMA 5.2. *The family* $\{\pi_k\}_{k\ge 1}$ *is uniformly tight.*

Proof. Put

$$W_\varepsilon = \left\{ w \in C(0,T;\mathbb{R}^m);\ \sup_{0\le t\le T} |w(t)| \le q_\varepsilon \ \text{ and } \sup_{|t-s|\le T/n^6} |w(t) - w(s)| \le \frac{r_\varepsilon}{n}\,\forall n \ge 1 \right\}$$

and $Z_\varepsilon =$ the set defined by (5.1) for constants K_ε, L_ε, and M_ε, and sequences $\nu_n = \frac{1}{n}$, $\mu_n = \frac{1}{n^3}$, where q_ε, r_ε, K_ε, L_ε, and M_ε are constants to be chosen later, depending on a given $\varepsilon > 0$. From Ascoli–Arzelà's theorem and Lemma 5.1, $W_\varepsilon \times Z_\varepsilon$ is a compact subset of S.

Then

$$\begin{aligned}
&\pi_k((W_\varepsilon \times Z_\varepsilon)^c) \\
&\quad \le P\left(\sup_{0\le t\le T} |B(t)| > q_\varepsilon\right) + \sum_{n=1}^\infty P\left(\sup_{|t-s|\le T/n^6} |B(t) - B(s)| > \frac{r_\varepsilon}{n}\right) \\
&\qquad + P\left(\int_0^T \|z_k(t)\|^2\,dt > K_\varepsilon\right) + P\left(\int_0^T |z_k(t)|^2_\gamma\,dt > L_\varepsilon\right) \\
&\qquad + \sum_{n=1}^\infty P\left(\sup_{|\theta|\le\mu_n} \int_0^T \|z_k(t+\theta) - z_k(t)\|^2_*\,dt > \nu_n M_\varepsilon\right) \\
&\quad \le \frac{1}{q_\varepsilon} E[\sup_{0\le t\le T} |B(t)|] \\
&\qquad + \sum_{n=1}^\infty \sum_{i=0}^{n^6-1} \left(\frac{3n}{r_\varepsilon}\right)^4 E\left[\sup_{iT/n^6\le t\le (i+1)T/n^6} |B(t) - B(iT/n^6)|^4\right] \\
&\qquad + \frac{1}{K_\varepsilon} E\left[\int_0^T \|z_k(t)\|^2\,dt\right] + \frac{1}{L_\varepsilon} E\left[\int_0^T |z_k(t)|^2_\gamma\,dt\right] \\
&\qquad + \sum_{n=1}^\infty \frac{1}{\nu_n M_\varepsilon} E\left[\sup_{|\theta|\le\mu_n} \int_0^T \|z_k(t+\theta) - z_k(t)\|^2_*\,dt\right].
\end{aligned} \tag{5.13}$$

By Lemmas 4.1, 4.3, and 4.4, we have

$$\begin{aligned}&\pi_k((W_\varepsilon \times Z_\varepsilon)^c)\\ &\le C\left\{\frac{1}{q_\varepsilon}+\frac{1}{r_\varepsilon^4}\sum_{n=1}^{\infty}\frac{1}{n^2}+\frac{1}{K_\varepsilon}+\frac{1}{L_\varepsilon}+\frac{1}{M_\varepsilon}\sum_{n=1}^{\infty}\frac{1}{n^2}\right\}\\ &\le C\left\{\frac{1}{q_\varepsilon}+\frac{1}{r_\varepsilon^4}+\frac{1}{K_\varepsilon}+\frac{1}{L_\varepsilon}+\frac{1}{M_\varepsilon}\right\}<\varepsilon\end{aligned} \tag{5.14}$$

for a convenient choice of q_ε, r_ε, K_ε, L_ε, and M_ε.

This completes the proof.

6. Proof of Theorem 3.1. By Prokhorov's theorem, $\{\pi_k\}_{k\ge 1}$ is relatively compact. Hence there is a subsequence, still denoted by $\{\pi_k\}_{k\ge 1}$, and a probability measure π on S such that $\{\pi_k\}_{k\ge 1}$ converges to π weakly. Moreover, by Skorokhod's theorem, there exist S-valued random variables (W_k, y_k) and (W, y) on a suitable probability space $(\tilde{\Omega}, \tilde{\mathcal{F}}, \tilde{P})$ such that

$$\text{the probability law of } (W_k, y_k) = \pi_k, \tag{6.1}$$

$$\text{the probability law of } (W, y) = \pi, \tag{6.2}$$

and with probability 1,

$$W_k \longrightarrow W \quad \text{uniformly on } [0,T], \tag{6.3}$$

$$y_k \longrightarrow y \quad \text{in } L^2(0,T;L^2(\mathbb{R}^d)) \quad \text{strongly.} \tag{6.4}$$

By the same argument as in the proof of Theorem 1.1 in Bensoussan [1], we can see that

$$y_k = \Psi_k(W_k) \quad \text{a.s.} \tag{6.5}$$

and

$$W(t) \text{ is an } \mathcal{F}_t = \sigma\{(W(s), y(s));\ s \le t\}\text{-Brownian motion.} \tag{6.6}$$

From (6.5), Lemmas 4.1 and 4.2 hold for y_k. Therefore, by extracting a new subsequence, still denoted by y_k, we have

$$\begin{aligned} y_k \longrightarrow y \ &\text{in } L^2(\tilde{\Omega}; L^2(0,T;H^1)) \text{ weakly,}\\ &\text{in } L^2(\tilde{\Omega}; L^\infty(0,T;L^2(\mathbb{R}^d))) \text{ weak star,}\\ &\text{in } L^\infty(0,T;L^4(\tilde{\Omega};L^2(\mathbb{R}^d))) \text{ weak star.}\end{aligned} \tag{6.7}$$

From this and Lemmas 4.1 and 4.2, we see that

$$\tilde{E}\left[\int_0^T \|y(t)\|^2\,dt\right] \le C, \tag{6.8}$$

$$\sup_{0\le t\le T} \tilde{E}|y(t)|^4 \le C, \tag{6.9}$$

$$\tilde{E}\left[\sup_{0\le t\le T} |y(t)|^2\right] \le C. \tag{6.10}$$

Combining (6.4) with (4.4) and (6.9), we have

$$y_k \to y \quad \text{in } L^2(\tilde{\Omega} \times (0,T); L^2(\mathbb{R}^d)), \tag{6.11}$$

and thus by extracting a new subsequence, we obtain

$$y_k(t) \to y(t) \quad \text{in } L^2(\mathbb{R}^d) \quad \text{for almost all } (\tilde{\omega}, t). \tag{6.12}$$

By the assumption (A.2) and estimates (4.4) and (6.9), we have

$$f(\cdot\,, y_k(\cdot)) \to f(\cdot\,, y(\cdot)) \quad \text{in } L^2(\tilde{\Omega} \times (0,T); L^2(\mathbb{R}^d)). \tag{6.13}$$

Put

$$\bar{y}_k(t) = \frac{1}{\delta}\int_{r\delta}^{(r+1)\delta} y_k(s)\,ds, \quad t \in [r\delta, (r+1)\delta), \quad r = 0, 1, \dots, k,$$

and

$$\bar{y}^{(k)}(t) = \frac{1}{\delta}\int_{r\delta}^{(r+1)\delta} y(s)\,ds, \quad t \in [r\delta, (r+1)\delta), \quad r = 0, 1, \dots, k.$$

Then, by (6.11) we have

$$\begin{aligned} &\tilde{E}\left[\int_0^T |\bar{y}_k(t) - \bar{y}^{(k)}(t)|^2\,dt\right] \\ &\quad\le \tilde{E}\left[\int_0^T |y_k(t) - y(t)|^2\,dt\right] \to 0 \quad \text{as } k \to \infty. \end{aligned} \tag{6.14}$$

On the other hand, by Lebesgue's theorem

$$\bar{y}^{(k)}(t) \to y(t) \quad \text{in } L^2(\tilde{\Omega} \times \mathbb{R}^d) \quad \text{for almost all } t. \tag{6.15}$$

From this and (6.9), it follows that

$$\bar{y}^{(k)} \to y \quad \text{in } L^2(\tilde{\Omega} \times (0,T); L^2(\mathbb{R}^d)), \tag{6.16}$$

which yields

$$\bar{y}_k \to y \quad \text{in } L^2(\tilde{\Omega} \times (0,T); L^2(\mathbb{R}^d)). \tag{6.17}$$

Moreover, by extracting a new subsequence, we obtain

$$\bar{y}_k(t) \to y(t) \quad \text{in } L^2(\mathbb{R}^d) \quad \text{for almost all } (\tilde{\omega}, t). \tag{6.18}$$

By assumption (A.3) and estimates (4.4) and (6.9), we have

$$g\left(\left[\frac{t}{\delta}\right]\delta, \bar{y}_k(t)\right) \to g(t, y(t)) \quad \text{in } L^2(\tilde{\Omega} \times (0,T); L^2(\mathbb{R}^d)). \tag{6.19}$$

By the same argument as in Bensoussan [1], we can deduce from (6.3) and (6.19) that

$$\int_0^{[t/\delta]\delta} g\left(\left[\frac{s}{\delta}\right]\delta, \bar{y}_k(s)\right) dW_k(s) \to \int_0^t g(s, y(s))\, dW(s) \tag{6.20}$$

$$\text{in } L^2(\tilde{\Omega}; L^2(\mathbb{R}^d)) \text{ weakly.}$$

Since y_k satisfies (4.1), we have

$$\begin{aligned} y_k(t) + \int_0^t A(s) y_k(s)\, ds = y_0 &+ \int_0^{[t/\delta]\delta} f(s, y_k(s))\, ds \\ &+ \int_0^{[t/\delta]\delta} g\left(\left[\frac{s}{\delta}\right]\delta, \bar{y}_k(s)\right) dW_k(s). \end{aligned} \tag{6.21}$$

Using (6.7), (6.13), and (6.20), we can pass to the limit and obtain

$$\begin{aligned} y(t) + \int_0^t A(s) y(s)\, ds = y_0 &+ \int_0^t f(s, y(s))\, ds \\ &+ \int_0^t g(s, y(s))\, dW(s). \end{aligned} \tag{6.22}$$

Hence (W, y) is a solution of (2.3). This completes the proof of Theorem 3.1.

Acknowledgments. The author would like to thank the referees, who read the manuscript carefully and gave him helpful comments.

SOLUTION OF OPTIMAL CONTROL PROBLEMS BY A POINTWISE PROJECTED NEWTON METHOD*

C. T. KELLEY† AND E. W. SACHS‡

Abstract. In the context of optimal control of ordinary differential equations, we prove local superlinear convergence and constraint identification results for an extension of the projected Newton method of Bertsekas. The estimates are also valid for discretized versions of the method-problem pair.

Key words. projected Newton iteration, optimal control

AMS subject classifications. 47H17, 49K15, 49M15, 65J15, 65K10

1. Introduction.

In many areas of optimal control the problems are formulated with simple constraints on the control. For these problems, the gradient projection type algorithms have proven to be quite successful, because they are able to take into account the structure of the underlying optimization problem. Another interesting feature of these methods is that they often can be formulated in infinite-dimensional spaces, which is important for the application to optimal control problems.

In general, let H denote a Hilbert space and for some closed convex subset $U \in H$ consider the optimization problem

$$\text{Minimize} \quad \phi(u) \quad \text{subject to} \quad u \in U. \tag{1.1}$$

If $\mathcal{P} : H \longrightarrow U$ denotes the projection onto the feasible set, then the gradient projection method iterates are given by

$$u_+ = \mathcal{P}(u_c - \alpha_c \nabla\phi(u_c)), \tag{1.2}$$

where $\alpha > 0$ is determined by a step-size rule. In Hilbert space, this algorithm has been formulated and investigated by Goldstein [10] and Levitin and Polyak [13]. The books [4] and [3] discussed the convergence properties of gradient projection methods. In [7] a thorough convergence analysis of the gradient projection method was presented which yields various convergence rates of the algorithm under various assumptions.

Since the gradient projection method as presented in (1.2) is based on and identical for $U = H$ with the steepest descent method, its convergence properties exhibit locally a rather slow rate. This was the motivation to extend Newton's method to a projection method. There are basically two routes by which this goal can be achieved.

If one considers in the unconstrained case a Newton step as the solution of the minimization of a quadratic approximation of ϕ at the current iterates u_c, then for a problem of the type (1.1) one would have to solve

$$\text{Minimize} \ (\nabla\phi(u_c), u - u_c) + \frac{1}{2}(u - u_c, \nabla^2\phi(u_c)(u - u_c)) \ \text{subject to} \ u \in U. \tag{1.3}$$

This algorithm has been analyzed in [13] and [6]. The disadvantage of the method (1.3) is that at each step a quadratic problem with constraints needs to be solved. The simplicity of the constraints cannot be used in a direct way through the projection $\mathcal{P}$ except in solving the quadratic problem.

The other route to extend Newton's method to the constrained case is as follows. Instead of projecting the steepest descent direction onto the feasible set, one projects the Newton direction onto the feasible set:

$$u_+ = \mathcal{P}(u_c - \alpha_c(\nabla^2\phi(u_c))^{-1}\nabla\phi(u_c)). \tag{1.4}$$

This method utilizes again the simple projection but has the drawback that it does not always produce a descent in the objective function. Bertsekas [1] and [2] introduced for the finite-dimensional case with simple constraints, such as upper and lower bounds on the variables, a projected Newton method which alleviated this problem. For $H = R^n$ let

$$u_+ = \mathcal{P}(u_c - \alpha_c D_c^{-1}\nabla\phi(u_c)), \tag{1.5}$$

where D_c is a properly chosen matrix such that descent in the objective function is ensured. Let C_J denote the map that sets the components which lie in J of a vector $u \in R^n$ to zero. Then Bertsekas suggested that

$$D_c = C_J^T \nabla^2\phi(u_c) C_J + C_{J^c}^T I C_{J^c},$$

where J contains the components of u_c which are active and the corresponding components of $\nabla\phi(u_c)$ point outside the feasible set. J^c denotes the complement of J in the index set. This algorithm combined with a proper step-size rule can be shown to converge locally at a quadratic rate since it identifies all active constraints after finitely many steps and becomes Newton's method for an unconstrained problem. The assumptions required for superlinear convergence of the method proposed in this paper include assumptions of the type of second-order sufficiency (2.4) and of nondegeneracy (2.3). The latter assumption might not be needed in an approach similar to (1.3), but a larger problem has to be solved at each step.

Since optimal control problems are problems formulated in function space, an analysis of the projected Newton method in this framework would give some insight for the case of fine discretizations. As shown in [16], this issue is important because the identification of finite indices is only mesh independent if proper measures are taken. The goal of this paper is to extend the algorithm to the infinite-dimensional setting of optimal control problems.

The class of problems we seek to solve is

$$\text{minimize} \int_0^T L(x(t),\, u(t),\, t)\, dt$$

over $u \in U$ such that $x \in W_N^{1,\infty}[0,T]$ solves

$$\dot{x}(t) = f(x(t), u(t), t), \quad x(0) = x_0, \quad t \in (0,T).$$

Here $f : R^N \times R \times [0,T] \to R^N$ and $L : R^N \times R \times [0,T] \to R$ and for $t \in [0,T]$ we let U be given by

$$U(t) = \{u \in L^\infty[0,T] \,|\, u_{\min}(t) \le u(t) \le u_{\max}(t)\}$$

with $u_{\min}$ and $u_{\max}$ in $L^\infty[0,T]$.

The projection $\mathcal{P}$ is the map on $L^\infty[0,T]$ given by

$$\mathcal{P}(u)(t) = \begin{cases} u_{\min}(t), & \text{if } u(t) \leq u_{\min}(t), \\ u(t), & \text{if } u_{\min}(t) \leq u(t) \leq u_{\max}(t), \\ u_{\max}(t), & \text{if } u(t) \geq u_{\max}(t). \end{cases} \tag{1.6}$$

We use the notation

$$L_N^\infty[0,T] = L^\infty([0,T];R^N), \quad W_N^{1,\infty}[0,T] = W^{1,\infty}([0,T];R^N)$$

for the spaces of R^N valued functions on $[0,T]$ having components in $L^\infty[0,T]$ and $W^{1,\infty}[0,T]$, respectively. If $w : [0,T] \to R^N$ has components w_i, the norms on $L_N^\infty[0,T]$ and $W_N^{1,\infty}[0,T]$ are given by

$$\|w\|_{L_N^\infty[0,T]} = \sum_{i=1}^N \|w_i\|_{L^\infty[0,T]} \text{ and } \|w\|_{W_N^{1,\infty}[0,T]} = \sum_{i=1}^N \|w_i\|_{W^{1,\infty}[0,T]}.$$

The L^∞ and $W^{1,\infty}$ are defined by

$$\|u\|_{L^\infty[0,T]} = \text{ess-sup}_{t\in[0,T]}|u(t)| \text{ and } \|u\|_{W^{1,\infty}[0,T]} = \|u\|_{L^\infty[0,T]} + \|du/dt\|_{L^\infty[0,T]}.$$

We will work in the spaces

$$X = W_N^{1,\infty}[0,T] \oplus W_N^{1,\infty}[0,T] \oplus L^\infty[0,T] \text{ and } Y = L_N^\infty[0,T] \oplus L_N^\infty[0,T] \oplus L^\infty[0,T].$$

For the unconstrained case, the first-order necessary conditions for optimality can be defined in terms of the Hamiltonian function $H : R^N \times R^N \times R \times R \to R$

$$H(p,x,u,t) = f^T(x,u,t)\,p + L(x,u,t), \quad (p,x,u,t) \in R^{2N+2}.$$

Usually, $p \in W_N^{1,\infty}[0,T]$ denotes the solution of the adjoint equation

$$-\dot{p} = f_x^T p + L_x^T, \quad p(T) = 0.$$

For simplicity we will also use the notation for the Hamiltonian

$$H(p,x,u)(t) := H(p(t),x(t),u(t),t), \quad t \in [0,T]$$

and likewise for the partial derivatives of H.

The first-order necessary conditions for the unconstrained case can be expressed as the system of nonlinear equations

$$F(z) = F(p,x,u) = \begin{pmatrix} \dot{x} - f(x,u,\cdot) \\ \dot{p} + H_x(p,x,u) \\ H_u(p,x,u) \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \\ 0 \end{pmatrix} \tag{1.7}$$

for $z = (p,x,u)^T \in X$ and $F : X \to Y$. The advantage of solving the system (1.7) over applying a Newton-like method directly to $\nabla f = H_u = 0$ is that the linear equations for the Newton steps in (1.7) can be expressed as linear equations for the new iterates, without solving a nonlinear differential equation.

For the constrained case, the third equation in (1.7) must be modified to take the constraints into account. The system of nonlinear equations we consider here is

$$\mathcal{F}(z) = \mathcal{F}(p,x,u) = \begin{pmatrix} \dot{x} - f(x,u,\cdot) \\ \dot{p} + H_x(p,x,u) \\ u - \mathcal{P}(u - H_u(p,x,u)) \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \\ 0 \end{pmatrix}. \tag{1.8}$$

To formulate the algorithm we introduce some more notation: For $I \subset [0,T]$, $A = [0,T] \setminus I$, and $z \in X$ define

$$Q_I z = (p, x, \chi_I u)^T,$$

$$\mathcal{F}_I(z) = Q_I F(p, x, \chi_I u + \chi_A u^*).$$

Note that in the definition of $\mathcal{F}_I$, $Q_I F$ and not $Q_I \mathcal{F}$ is used. This is important not only to make $\mathcal{F}_I'$ well defined but also for the success of the algorithm described in §4.

$\mathcal{F}_I$ can be regarded as a map from

$$X_I = W_N^{1,\infty}[0,T] \oplus W_N^{1,\infty}[0,T] \oplus L^\infty[I]$$

to

$$Y_I = L_N^\infty[0,T] \oplus L_N^\infty[0,T] \oplus L^\infty[I].$$

If the third component of $\mathcal{F}_I$ is understood to be identically zero on A, we may also regard $\mathcal{F}_I$ as a map from X to Y. We will use $\mathcal{F}_I$ as both a theoretical and computational tool. When used in computation we must have knowledge of u^* on A. This is analogous to identification of the active set in finite-dimensional problems [1], [2]. In the infinite-dimensional setting considered in this paper, complete identification of A^* is not possible. However, as we will show in §4, a useful subset of A^* can be identified.

The authors extended in [12] Bertsekas' gradient projection method to constrained compact fixed-point problems. It was combined with a multilevel algorithm of Atkinson and Brakhage and applied to a parabolic boundary control problem with simple bound constraints on the control. In this paper, we do not assume any compactness of the nonlinear map and analyze the resulting algorithm in infinite dimensions. As we will see in §4, relaxing the assumptions with regard to the compactness gives rise to an additional smoothing step in the algorithm so that a proper identification of the active set can be done at the subsequent iteration.

Section 3 contains a series of lemmas that are rather technical but lead to an important estimate in Theorem 3.5 in which the norm of the residual $\mathcal{F}$ can be used in an upper bound on the distance of the current iterate to the solution in the strong X-norm. The transfer from a projection-based method, which has its natural formulation in a Hilbert space like L^2, to an L^∞-type norm in X poses in the analysis of the convergence various difficulties. In another context this aspect has been the focus of other research activities, see, e.g., [9], [8]. The estimate in Theorem 3.5 enables us to show a result on the identification of the set of active indices. It estimates the measure of the set on which the active set at the current iterate differs from the active set of the solution by the distance of the iterate from the solution in the X-norm. This result is the key for the convergence analysis of the algorithm.

In the following algorithm we set $u_c = u^*$ on $\bar{A}$, which is a well-defined step by Lemma 3.7, and then apply a projected Newton iteration with $\bar{A}(z_c)$ as the active set. This yields an intermediate iterate $(x_{1/2}, p_{1/2})$ for the state and costate. Then a smoothing step for x and p is added which properly determines the set $\bar{A}(z_+)$ at the next iterate. The iteration is formally given by the following algorithm.

ALGORITHM proj_newt($\mathcal{F}, z_c, z_+$). Choose $\bar{p} \in (1/2, 1)$

1. Compute

$$\bar{A}(z_c) = \{t \,|\, |H_u(z_c)(t)| \geq \|\mathcal{F}(z_c)\|_Y^{\bar{p}}\}.$$

2. Set $u_c = u^*$ on $\bar{A}(z_c)$.
3. Compute the projected Newton step

$$s = -Q_{\bar{I}} \mathcal{F}_{\bar{I}}'(z_c)^{-1} Q_{\bar{I}} F(z_c).$$

4. Set $z_{1/2} = \bar{P}(z_c + s)$ and $u_+ = u_{1/2}$, where

$$\bar{P} = \begin{pmatrix} I & 0 & 0 \\ 0 & I & 0 \\ 0 & 0 & \mathcal{P} \end{pmatrix}.$$

5. Compute

$$x_+(t) = \int_0^t f(x_{1/2}(s), u_+(s), s)\, ds + x_0,$$
$$p_+(t) = \int_t^T H_x(p_{1/2}(s), x_{1/2}(s), u_+(s))\, ds.$$

Apart from the smoothing step, this algorithm differs from the gradient projection method given by Bertsekas even in the finite-dimensional case. To clarify this point consider a optimal control problem where in step (1.5) the new state x_+ in Bertsekas' algorithm has to be computed by solving the nonlinear system equation. In Algorithm proj_newt the correction for the new state is computed from a linearized version of the system equation, see, e.g., (6.6).

In §4 we prove the local convergence of the iterates of the algorithm to the solution which is superlinear. The order of the rate of convergence is dependent on how stringently the identification of the active set is carried out. The convergence is of q-order $2\bar{p}$ depending on the choice of $\bar{p} > 1/2$ in $\bar{A}(z)$ in the algorithm. The norm which we use in the convergence statement is the X-norm which is stronger than the Y-norm.

The contents of §5 relate the assumptions of the lemmas and theorems to other assumptions which have been used in the literature. In particular, the relation to second-order sufficiency conditions is clarified. Also, the role of the growth conditions in [6] is indicated in our context.

Section 6 contains comments on the implementation of the algorithm. Furthermore, we present for an example numbers illustrating the convergence rate estimates of the convergence theorem. In particular, the dependence on $\bar{p}$ can be observed.

2. Notation. In this section we introduce some more notation, assumptions, and immediate consequences of these.

Since U is given by

$$U(t) = \{u \in L^\infty[0,T] \,|\, u_{\min}(t) \leq u(t) \leq u_{\max}(t)\}$$

we define the 2-point set

$$\partial U(t) = \{u_{\min}(t), u_{\max}(t)\}.$$

We assume the existence of a solution to the first-order necessary conditions.

ASSUMPTION 2.1. *There exists $z^* = (p^*, x^*, u^*)$ such that $\mathcal{F}(z^*) = 0$.*

Since $z^* \in X$, its range is contained in the bounded set

$$\mathcal{R} = \{\xi \in R^N \times R^N \times R \,|\, \|\xi\|_\infty \leq \|z^*\|_X\}.$$

Also $(x, u) \in \mathcal{R}_1 \subset R^N \times R$ where

$$\mathcal{R}_1 = \{\zeta \in R^N \times R \,|\, \|\zeta\|_\infty \leq \|z^*\|_X\}.$$

ASSUMPTION 2.2. *There is an open set $\mathcal{R}_0 \supset \mathcal{R}_1$ such that f, L and their first and second partial derivatives with respect to x and u are uniformly Lipschitz continuous on $\mathcal{R}_0 \times [0, T]$.*

Lemma 2.1 is an immediate consequence of Assumption 2.2 and the fact that for $z, w \in X$, $F'(z) - F'(w)$ is a multiplication operator and not a differential operator.

In the rest of the paper we denote function space norms by $\|\cdot\|$ and norms in R^k by

$$|x| = \max\{|x_j| \mid j = 1, ..., k\}.$$

LEMMA 2.1. *There are $\sigma^*, L_F, M_F > 0$ such that for all $z, w \in \mathcal{N} = \{v \in X \,|\, \|v - z^*\|_X < \sigma^*\}$ and $t \in [0, T]$,*

$$|F(z)(t) - F(w)(t)| \leq M_F |z(t) - w(t)|, \tag{2.1}$$

$$\begin{aligned} &\|F'(z) - F'(w)\|_{\mathcal{L}(X,Y)} \leq L_F \|z - w\|_Y \text{ and} \\ &\|F'(z) - F'(w)\|_{\mathcal{L}(Y,Y)} \leq L_F \|z - w\|_Y. \end{aligned} \tag{2.2}$$

We define active and inactive sets for u by

$$A(u) = \{t \,|\, u(t) \in \partial U(t)\} \text{ and } I(u) = [0, T] \setminus A(u) = \{t \,|\, u(t) \in \text{int}(U)(t)\}. \tag{2.3}$$

In (2.3) $\text{int}(U)(t)$ is defined to be the interval

$$\text{int}(U)(t) = (u_{\min}(t), u_{\max}(t)).$$

We let

$$A^* = A(u^*) \text{ and } I^* = I(u^*).$$

If $S \subset R^k$ for some k and $t \in R^k$ we denote the distance from t to S by

$$\text{dist}(t, S) = \inf\{s \in S \,|\, |t - s|\}.$$

As in [12] we make structural assumptions on the active set at the solution.

ASSUMPTION 2.3. *There is $\nu \in (0, 1)$ such that $u_{\max}(t) \geq u_{\min}(t) + \nu$ for all $t \in [0, T]$. A^* is the closure of a finite union of open sets. On each component of A^* either $u = u_{\max}$ or $u = u_{\min}$.*

Moreover, there is c_1 such that

$$\begin{aligned} &|H_u(p^*, x^*, u^*)(t)| \geq c_1 \mathrm{dist}(t, \partial A^*) \textit{ for all } t \in A^* \textit{ and} \\ &\mathrm{dist}(t, A^*) \leq c_1^{-1} \mathrm{dist}(u^*(t), \partial U(t)) \textit{ for all } t \in I^*. \end{aligned} \tag{2.4}$$

This assumption is a condition on the slope of the function H_u, which is also called switching function in the control context. In §5 we relate Assumption 2.3 to the growth condition in [7]. We also give a connection to a similar condition in [16] which has been used for the finite identification of active indices in the gradient projection method.

The fact that we consider problems of dimension 1 with regard to the control together with the assumption on the structure of A^* yields the following lemma, which we give without proof.

LEMMA 2.2. *There is $c_0 > 0$ such that for all $\delta > 0$ the sets*

$$E_\delta = \{t \in R \,|\, \mathrm{dist}(t, \partial A^*) < \delta\}$$

are uniformly bounded in measure by

$$\mu(E_\delta) \leq c_0 \delta. \tag{2.5}$$

We define projections P_1 and P_2 for $z = (p, x, u)^T \in Y$ by

$$P_1 z = (p, x, 0)^T, \qquad P_2 z = (0, 0, u)^T.$$

The observations that $P_1 F = P_1 \mathcal{F}$ and $Q_J P_1 = P_1 Q_J = P_1$ for any $J \subset [0, T]$ lead to the following result.

PROPOSITION 2.3. *Let Assumptions 2.1 and 2.2 hold. If $I \subset I^*$ then $\mathcal{F}_I(z^*) = 0$ and for all $t \in [0, T]$*

$$|P_1 \mathcal{F}_I(z)(t)| \leq \|P_1 \mathcal{F}(z)\|_Y + M_F |(I - Q_I)(z - z^*)(t)|.$$

Proof. Since

$$P_1 \mathcal{F}_I(z) = P_1 Q_I F(Q_I z + (I - Q_I) z^*)$$

and

$$P_1 Q_I \mathcal{F}(z) = P_1 Q_I F(z)$$

we have the result by Lemma 2.1. □

Nonsingularity assumptions are also complicated by the constraints.

ASSUMPTION 2.4. *There are K_η and $\tilde{\eta} > 0$ such that if*

$$I \subset \{t \,|\, |H_u(p^*, x^*, u^*)(t)| \leq \tilde{\eta}\} \tag{2.6}$$

then $\mathcal{F}_I'(z^*)$ is a nonsingular map from X_I to Y_I. Moreover,

$$\|\mathcal{F}_I'(z^*)^{-1}\|_{\mathcal{L}(Y_I, X_I)} \leq K_\eta \tag{2.7}$$

and for any measurable set $S \subset [0, T]$

$$\|P_1 \mathcal{F}_I'(z^*)^{-1}(I - Q_S)\|_{\mathcal{L}(Y_I, Y_I)} \leq K_\eta \mu(S). \tag{2.8}$$

There is $\tilde{\alpha}$ such that

$$H_{uu}(p^*, x^*, u^*)(t) \geq \tilde{\alpha}$$

for all $t \in I$.

This assumption is related to second-order sufficiency conditions for optimal control problems. Details are discussed in §5.

3. Identification of the active set.

We begin by summarizing the definitions of the many projections that will be used in the following sections. Beginning with the definition of $\mathcal{P}$ in (1.6) as the projection of u onto the feasible set, we define $\bar{P}$ $z = (p, x, u)^T \in Y$ by

$$\bar{P}(z) = (p, x, \mathcal{P}(u))^T.$$

For a measurable set $I \in [0, T]$ we define

$$Q_I(z) = (p, x, \chi_I u)^T,$$

where χ_I is the characteristic function of the set I. Finally we define P_1 and P_2, which decompose z into the state-costate and control parts by

$$P_1(z) = (p, x, 0)^T, \qquad P_2 z = (0, 0, u)^T.$$

For $z \in X$ we let

$$e = (e_p, e_x, e_u)^T = z - z^*.$$

We want to show that provided $\|e\|_X$ is sufficiently small, it can be estimated by a constant multiple of $\|\mathcal{F}\|_Y$. This estimate is important in that it allows us to identify a subset of A^*. We will require a sequence of lemmas.

LEMMA 3.1. *Assume that Assumptions 2.1–2.4 hold. Then there are B_0, c_2, and $\tau_0 > 0$ such that if $z = \bar{P}(z) \in X$ is such that $\|e\|_X \leq \tau_0$, then for $S(z) = \{t \,|\, u(t) - H_u(p, x, u)(t) \notin U(t)\} \cap I^* \cap I(u)$,*

$$|P_2 \mathcal{F}_{I(u) \cap I^*}(z)(t)| \leq B_0(\|\mathcal{F}(z)\|_Y + \chi_{S(z)}(t)\|e\|_Y),$$

where

$$\mu(S(z)) \leq c_2 \|e\|_Y.$$

Proof. We assume that $\tau_0 < \min(\sigma^*, \nu)$, where σ^* is the diameter of the set $\mathcal{N}$ in Lemma 2.1. We set $J = I^* \cap I(u)$ in this proof and set $\|e\|_Y = \sigma \leq \|e\|_X$.

Observe that

$$P_2 \mathcal{F}_J(z) = (0, 0, \chi_J H_u(p, x, \chi_J u + \chi_{J^c} u^*))^T = (0, 0, \chi_J H_u(p, x, u))^T$$

and therefore

$$P_2 \mathcal{F}_J(z) = (0, 0, (1 - \chi_{S(z)})\chi_J H_u(p, x, u) + \chi_{S(z)} H_u(p, x, u)(t))^T. \tag{3.1}$$

On $S(z)$ we have $H_u(p^*, x^*, u^*) = 0$, since $S(z) \subset J \subset I^*$. Hence for $t \in S(z)$

$$\begin{aligned} |\chi_{S(z)} H_u(p, x, u)(t)| &= |\chi_{S(z)}(H_u(p, x, u) - H_u(p^*, x^*, u^*))(t)| \\ &\leq \chi_{S(z)} M_F \|e\|_Y. \end{aligned} \tag{3.2}$$

For $t \in S(z)^c$ we have $u - H_u(p,x,u) \in U$ and

$$(1 - \chi_{S(z)})(0, 0, H_u(p,x,u))^T = (1 - \chi_{S(z)}) P_2 \mathcal{F}(z);$$

hence

$$|(1 - \chi_{S(z)}) H_u(p,x,u)| \leq \|\mathcal{F}\|_Y.$$

This proves the first part of the assertion with $B_0 = \max\{1, M_F\}$.

We now complete the proof with an estimate of the measure of $S(z)$. Let $t \in S(z)$. The estimate (3.2) and $H_u(p^*, x^*, u^*)(t) = 0$ yield

$$\|\chi_{S(z)}(u^* - H_u(p^*, x^*, u^*) - (u - H_u(p,x,u)))\|_\infty \leq (1 + M_F)\sigma.$$

Since $u - H_u(p,x,u) \notin U(t)$ we must have

$$\mathrm{dist}(u^*(t), \partial U(t)) \leq (1 + M_F)\sigma.$$

Hence, by Assumption 2.3,

$$\mathrm{dist}(t, A^*) \leq c_1^{-1}(1 + M_F)\sigma$$

for any $t \in S(z)$. Therefore

$$S(z) \subset \{t \,|\, \mathrm{dist}(t, \partial A^*) \leq c_1^{-1}(1 + M_F)\sigma\},$$

and, further, by Lemma 2.2,

$$\mu(S(z)) \leq c_0 c_1^{-1}(1 + M_F)\sigma.$$

This completes the proof with $c_2 = c_0 c_1^{-1}(1 + M_F)$. □

COROLLARY 3.2. *Assume that Assumptions* 2.1–2.4 *hold. Then if* $\|e\|_X \leq \tau_0$

$$\|P_1 \mathcal{F}'_{I(u)\cap I^*}(z^*)^{-1} P_2 \mathcal{F}_{I(u)\cap I^*}(z)\|_Y \leq B_1(\|\mathcal{F}(z)\|_Y + \|e\|_Y^2). \tag{3.3}$$

Proof. The result follows directly from Assumption 2.4 and Lemma 3.1 with $B_1 = K_\eta B_0(1 + c_2)$. □

LEMMA 3.3. *Assume that Assumptions* 2.1–2.4 *hold. Then there are* B_5 *and* $\tau_1 > 0$ *such that if* $z = \bar{P}(z) \in X$ *is such that* $\|e\|_X \leq \tau_1$, *then*

$$\|P_1 \mathcal{F}'_{I(u)\cap I^*}(z^*)^{-1} P_1 \mathcal{F}_{I(u)\cap I^*}(z)\|_Y \leq B_5(\|\mathcal{F}(z)\|_Y + \|e\|_Y^2). \tag{3.4}$$

Proof. We assume that $\tau_1 \leq \tau_0$ with τ_0 chosen as in Lemma 3.1. We set $I = I(u)$ and $A = A(u)$ in this proof. We let $\|e\|_Y = \sigma \leq \|e\|_X \leq \tau_1$ and $\|\mathcal{F}(z)\|_Y = \delta$. We let $J = I^* \cap I$.

By Proposition 2.3

$$|P_1 \mathcal{F}_J(z)| \leq \delta + M_F(1 - \chi_J)|e_u| = \delta + M_F \chi_{S_U}|e_u|,$$

for all $t \in [0,T]$, where S_U is the support of $(1 - \chi_J)e_u$. Our next task is to study S_U.

Assumption 2.3 implies that if we choose $\tau_1 < \nu$ then $u = u^*$ on $E = A(u) \cap A^*$. Hence $(1 - \chi_J)e_u$ is nonzero only in the set

$$E_1 = ([0,T] \setminus (E \cup J)) = (I^* \cap A) \cup (I \cap A^*)$$

and hence $S_U \subset E_1$. We consider three cases. First, if $t \in (I^* \cap A)$ then $H_u(p^*, x^*, u^*) = 0$. If $t \in (I \cap A^*)$ and $u - H_u(p, x, u) \in \operatorname{int}(U)$, then $|H_u(p, x, u)(t)| = |P_2 \mathcal{F}(z)(t)| \leq \delta$ and therefore

$$|H_u(p^*, x^*, u^*)(t)| \leq \delta + M_F \sigma.$$

If we now let

$$E_2 = \{t \in E_1 \,|\, u - H_u(p, x, u) \in \operatorname{int}(U)\} \cup (I^* \cap A)$$

then for all $t \in E_2$ and $B_2 = 1 + M_F$

$$|H_u(p^*, x^*, u^*)(t)| \leq B_2(\delta + \sigma). \tag{3.5}$$

We must consider a third case:

$$t \in E_3 = \{t \in I \cap A^* \,|\, u - H_u(p, x, u) \notin \operatorname{int}(U)\}.$$

Since

$$\begin{aligned} |\mathcal{P}(u - H_u(p, x, u)) - u^*| &= |\mathcal{P}(u - H_u(p, x, u)) - \mathcal{P}(u^* - H_u(p^*, x^*, u^*))| \\ &\leq (1 + M_F)\sigma \end{aligned} \tag{3.6}$$

for all $t \in [0, T]$, we may reduce τ_1 if needed so that $(1 + M_F)\tau_1 < \nu$ to conclude that if $\sigma < \tau_1$ and if $t \in E_3$ then

$$u^* = \mathcal{P}(u - H_u(p, x, u));$$

hence

$$P_2 \mathcal{F}(z) = (0, 0, u - \mathcal{P}(u - H_u(p, x, u)))^T = (0, 0, e_u)^T. \tag{3.7}$$

This implies that

$$|\chi_{E_3} e_u| \leq \|\mathcal{F}(z)\|_Y = \delta.$$

At this point we have

$$\begin{aligned} |P_1 \mathcal{F}_J(z)| \leq \delta + M_F(1 - \chi_J)|e_u| &= \delta + M_F \chi_{E_2}|e_u| + M_F \chi_{E_3}|e_u| \\ &\leq (1 + M_F)\delta + M_F \chi_{E_2}|e_u|. \end{aligned} \tag{3.8}$$

The Banach lemma, Assumption 2.4, and Lemma 2.1 imply that if $\sigma < \sigma^*$ then

$$\|\mathcal{F}_J'^{\,-1}\|_{\mathcal{L}(Y_I, X_I)} \leq K_\eta / (1 - \sigma M_F).$$

Hence, reducing τ_1 if needed so that $\tau_1 M_F < 1/2$, we have

$$\|(\mathcal{F}_J')^{-1} P_1 \mathcal{F}_J(z)\|_Y \leq 2K_\eta((1 + M_F)\delta + M_F \sigma \mu(E_2)). \tag{3.9}$$

We now estimate the measure of E_2. Using (2.4) we see that if $t \in E_2$ then either $t \in I \cap A^*$ and from (3.5)

$$\operatorname{dist}(t, \partial A^*) \leq c_1^{-1} B_2(\sigma + \delta)$$

or $t \in I^* \cap A$ and

$$\operatorname{dist}(t, \partial A^*) \le c_1^{-1} \operatorname{dist}(u^*(t), \partial U(t)) \le c_1^{-1}|u(t) - u^*(t)| \le c_1^{-1}\sigma.$$

Hence, setting $B_3 = c_1^{-1}\max(B_2, 1)$

$$\operatorname{dist}(t, \partial A^*) \le c_1^{-1} B_3(\sigma + \delta) \text{ for all } t \in E_2.$$

Then Lemma 2.2 implies that

$$\mu(E_2) \le B_4(\sigma + \delta), \tag{3.10}$$

where $B_4 = B_3 c_0 c_1^{-1}$. If we reduce τ_1 if needed so that $M_F B_4 \tau_1 \le 1$ and set $B_5 = 2K_\eta(2 + M_F + M_F B_4)$, then the proof is complete. □

LEMMA 3.4. *Assume that Assumptions* 2.1–2.4 *hold. Then there are* B_9 *and* $\tau_2 > 0$ *such that if* $z = \bar{P}(z) \in X$ *is such that* $\|e\|_X \le \tau_2$, *then*

$$\|P_2 e\|_Y \le B_9(\|\mathcal{F}(z)\|_Y + \|P_2 e\|_Y^2 + \|P_1 e\|_Y). \tag{3.11}$$

Proof. We assume that $\tau_2 \le \tau_1$ with τ_1 from Lemma 3.3. Let $e_p = p - p^*$, $e_x = x - x^*$, and $e_u = u - u^*$. We set $I = I(u)$ and $A = A(u)$ in this proof. We let $\|e\|_Y = \sigma \le \|e\|_X \le \tau_1$, $\|P_1 e\|_Y = \beta$, and $\|\mathcal{F}(z)\|_Y = \delta$. We let $J = I^* \cap I$.

We define a set $\mathcal{S}$ by

$$\mathcal{S} = \{t \,|\, u - H_u(p, x, u) \in U(t)\}.$$

Note that if $t \in \mathcal{S}$ then the third component of $\mathcal{F}(z)$ is H_u. Therefore $|H_u(p, x, u)| \le \delta$ for all $t \in \mathcal{S}$. Therefore, since $H_u(p^*, x^*, u^*) = 0$ on I^*, both $H_u(p^*, x^*, u^*) = 0$ and $H_u(p, x, u) = O(\delta)$ on the set $\mathcal{S} \cap I^*$. Hence, for all $t \in \mathcal{S} \cap I^*$ we have

$$\begin{aligned} 0 = H_u(p^*, x^*, u^*) &= H_u(p, x, u^*) + O(\beta) \\ &= H_u(p, x, u) - H_{uu}(p^*, x^*, u^*)e_u + O(\sigma^2 + \beta). \end{aligned}$$

The bound away from 0 of H_{uu} implies that there is B_6 such that

$$\|\chi_{\mathcal{S} \cap I^*} e_u\|_\infty \le B_6(\delta + \sigma^2 + \beta).$$

On $\mathcal{S} \cap A^*$, $|H_u(p, x, u)| \le \delta$ and hence

$$H_u(p^*, x^*, u^*) + H_{uu}(p^*, x^*, u^*)e_u = O(\delta + \sigma^2 + \beta).$$

As for $H_u(p^*, x^*, u^*)$ we know that

$$H_u(p^*, x^*, u^*)(u - u^*) \ge 0.$$

If $u^* = u_{\max}$, say, then $e_u \le 0$ and therefore $H_u(p^*, x^*, u^*) \le 0$. Hence

$$0 \le -H_u(p^*, x^*, u^*) = H_{uu}(p^*, x^*, u^*)e_u + O(\delta + \sigma^2 + \beta).$$

Since $e_u \le 0$ we must have $|e_u| = O(\delta + \sigma^2 + \beta)$. Applying a similar argument to the case where $u = u_{\min}$ implies that

$$\|\chi_{\mathcal{S} \cap A^*} e_u\|_\infty \le B_7(\delta + \sigma^2 + \beta).$$

We must now estimate $|e_u|$ on $\mathcal{S}^c = [0,T] \setminus \mathcal{S}$. If $t \in \mathcal{S}^c$ we have $u - H_u(p,x,u) \notin U(t)$ and therefore $\mathcal{P}(u - H_u(p,x,u)) \in \partial U(t)$. On $A^* \cap \mathcal{S}^c$, $u^* = \mathcal{P}(u - H_u(p,x,u))$ if σ_0 is sufficiently small by (3.6). Therefore (3.7) holds and so

$$\|\chi_{A^* \cap \mathcal{S}^c} e_u\|_\infty \leq \delta.$$

On $I^* \cap \mathcal{S}^c$, $0 = H_u(p^*, x^*, u^*)$. Since $\mathcal{P}(u - H_u(p,x,u)) \in \partial U(t)$, either $\mathcal{P}(u - H_u(p,x,u)) = u_{\max}$ or $\mathcal{P}(u - H_u(p,x,u)) = u_{\min}$. If $\mathcal{P}(u - H_u(p,x,u)) = u_{\max}$, say, then

$$|u - \mathcal{P}(u - H_u(p,x,u))| = |u - u_{\max}| \leq \delta. \tag{3.12}$$

Hence

$$u_{\max} + \delta - H_u(p,x,u) \geq u - H_u(p,x,u) \geq u_{\max}$$

and therefore $H_u(p,x,u) \leq \delta$. Similarly if $\mathcal{P}(u - H_u(p,x,u)) = u_{\min}$, $H_u(p,x,u) \geq -\delta$. Now, if $\mathcal{P}(u - H_u(p,x,u)) = u_{\max}$ then $H_u(p,x,u) \leq \delta$ and therefore

$$-\delta \leq u - \mathcal{P}(u - H_u(p,x,u)) = u - u_{\max} \leq u - u^*. \tag{3.13}$$

Hence $e_u \geq -\delta$. Also,

$$\begin{aligned} 0 = H_u(p^*, x^*, u^*) &= H_u(p,x,u) - H_{uu}(p^*, x^*, u^*)e_u + O(\delta + \sigma^2 + \beta) \\ &\leq -H_{uu}(p^*, x^*, u^*)e_u + \delta + O(\delta + \sigma^2 + \beta) \\ &= -H_{uu}(p^*, x^*, u^*)e_u + O(\delta + \sigma^2 + \beta). \end{aligned} \tag{3.14}$$

Since $H^*_{uu} \geq \tilde{\alpha}$ on I^* by Assumption 2.4, (3.14) implies

$$e_u \leq \tilde{\alpha}^{-1} O(\delta + \sigma^2 + \beta) = O(\delta + \sigma^2 + \beta). \tag{3.15}$$

We may use (3.13) and (3.15) to conclude that

$$-\delta \leq e_u \leq O(\delta + \sigma^2 + \beta)$$

and therefore $e_u = O(\delta + \sigma^2 + \beta)$. The estimate is exactly the same if $u = u_{\min}$. Hence there is B_8 such that

$$\|\chi_{I^* \cap \mathcal{S}^c} e_u\|_\infty \leq B_8(\delta + \sigma^2 + \beta).$$

This completes the proof with $B_9 = \max\{B_6, B_7, B_8\}$. □

THEOREM 3.5. *Assume that Assumptions* 2.1–2.4 *hold. Then there are* $K_X, \sigma_0 > 0$ *such that if* $z = \bar{P}(z) \in X$ *satisfies* $\|z - z^*\|_X \leq \sigma_0$ *then*

$$\|z - z^*\|_X \leq K_X \|\mathcal{F}(z)\|_Y. \tag{3.16}$$

Proof. We assume that $\sigma_0 < \tau_1$ with τ_1 by Lemma 3.3. We let $\|e\|_Y = \sigma \leq \|e\|_X \leq \sigma_0$ and $\|\mathcal{F}(z)\|_Y = \delta$. We let $J = I^* \cap I(u)$. By Proposition 2.3, $\mathcal{F}_J(z^*) = 0$.

$$\begin{aligned} \mathcal{F}_J(z) &= \mathcal{F}_J(z^*) + \int_0^1 \mathcal{F}'_J(z^* + tQ_J e)Q_J e\, dt \\ &= \mathcal{F}'_J(z^*)Q_J e + \int_0^1 (\mathcal{F}'_J(z^* + tQ_J e) - \mathcal{F}'_J(z^*))Q_J e\, dt. \end{aligned} \tag{3.17}$$

We now have, using (3.17),

$$Q_J e = \mathcal{F}_J'(z^*)^{-1}\left(\mathcal{F}_J(z) - \int_0^1 (\mathcal{F}_J'(z^* + tQ_J e) - \mathcal{F}_J'(z^*))Q_J e\, dt\right). \tag{3.18}$$

By Lemma 2.1 the integral term satisfies

$$\left\|\int_0^1 (\mathcal{F}_J'(z^* + tQ_J e) - \mathcal{F}_J'(z^*))Q_J e\, dt\right\|_Y \leq L_F\sigma^2/2, \tag{3.19}$$

where L_F is the bound in Lemma 2.1 and hence with (2.7)

$$\left\|\mathcal{F}_J'(z^*)^{-1}\int_0^1 (\mathcal{F}_J'(z^* + tQ_J e) - \mathcal{F}_J'(z^*))Q_J e\, dt\right\|_X \leq K_\eta L_F\sigma^2. \tag{3.20}$$

It remains to estimate $\mathcal{F}_J'(z^*)^{-1}\mathcal{F}_J(z)$.

By Lemma 3.3 and Corollary 3.2 we have

$$\|P_1\mathcal{F}_J'(z^*)^{-1}\mathcal{F}_J(z)\|_Y \leq B_{10}(\delta + \sigma^2), \tag{3.21}$$

where $B_{10} = B_1 + B_5$. At this point we can estimate (3.18) using (3.20), (3.21), and $\|x\|_Y \leq \|x\|_X$ for $x \in X$ as follows:

$$\|P_1 e\|_Y = \|P_1 Q_J e\|_Y \leq B_{11}(\delta + \sigma^2), \tag{3.22}$$

where $B_{11} = B_{10} + K_\eta L_F$.

By the definition of P_2, Lemma 3.4, and Assumption 2.4 we have

$$\|P_2 e\|_X = \|P_2 e\|_Y \leq B_9(1 + B_{11})(\delta + \sigma^2). \tag{3.23}$$

From this we conclude with (3.22) that

$$\sigma = \|e\|_Y \leq B_{12}(\delta + \sigma^2),$$

where $B_{12} = B_{11} + B_9(1 + B_{11})$. Hence, reducing σ_0 if necessary so that $B_{12}\sigma \leq B_{12}\sigma_0 \leq 1/2$,

$$\|e\|_Y = \sigma \leq 2B_{12}\delta \text{ and } \sigma^2 \leq \sigma 2B_{12}\delta \leq \delta. \tag{3.24}$$

To obtain an estimate for $\|e\|_X$, not $\|e\|_Y$, we use (3.23) and the second two parts of (3.24):

$$\|e\|_X \leq \|P_1 e\|_X + \|P_2 e\|_X \leq \|P_1 Q_J e\|_X + 2B_9(1 + B_{11})\delta. \tag{3.25}$$

We estimate $\|P_1 Q_J e\|_X$ in two parts based on (3.18). Lemma 3.1 and Proposition 2.3 together with (3.24) imply that

$$\begin{aligned}\|\mathcal{F}_J(z)\|_Y &\leq \|P_1\mathcal{F}(z)\|_Y + M_F\|(I - Q_J)e\|_Y + B_0(\|\mathcal{F}(z)\|_Y + \|e\|_Y)\\ &\leq (1 + B_0)\delta + (M_F + B_0)\|e\|_Y \leq B_{13}\delta,\end{aligned}$$

where

$$B_{13} = (1 + 2M_F B_{12}) + B_0(1 + 2B_{12}).$$

Therefore by Assumption 2.4

$$\|\mathcal{F}_J'(z^*)^{-1}\mathcal{F}_J(z)\|_X \leq K_\eta\|\mathcal{F}_J(z)\|_Y \leq K_\eta B_{13}\delta. \tag{3.26}$$

Hence we can conclude the proof by estimating (3.25) further with (3.18), (3.26), (3.20), and (3.24) to obtain (3.16) with $K_X = K_\eta(B_{13} + L_F) + 2B_9(1 + B_{11})$. □

As a consequence we have a result on identification of the active set A^*.

THEOREM 3.6. *Assume that Assumptions* 2.1–2.4 *hold. For all* $\bar{p} \in (0,1)$ *there is* σ_1 *such that if* $\|z - z^*\|_X < \sigma_1, z \neq z^*$ *and*

$$\bar{A}(z) = \{t \,|\, |H_u(z)(t)| \geq \|\mathcal{F}(z)\|_Y^{\bar{p}}\}, \tag{3.27}$$

then $\bar{A}(z) \subset A^*$ *and there is* c_μ *such that*

$$\mu(A^* \setminus \bar{A}(z)) \leq c_\mu\|z - z^*\|_X^{\bar{p}}. \tag{3.28}$$

Proof. Let $\sigma_1 < \sigma_0$ as in Theorem 3.5, so that the consequences of Theorem 3.5 hold. Let $\|\mathcal{F}(z)\|_Y = \delta$ and $\|z - z^*\|_X = \sigma$. Let L_H denote the Lipschitz constant of H_u. For $t \in \bar{A}(z)$ we have

$$|H_u(z^*)(t)| \geq |H_u(z)(t)| - L_H\sigma \geq \delta^{\bar{p}} - L_H\sigma \geq (K_X^{-1}\sigma)^{\bar{p}} - L_H\sigma > 0$$

if

$$\sigma^{1-\bar{p}} \leq K_X^{-\bar{p}}/L_H.$$

Hence if

$$\sigma_1 \leq (K_X^{-\bar{p}}/L_H)^{1/(1-\bar{p})},$$

then $t \in \bar{A}(z)$ implies that $H_u(z^*)(t) > 0$ and therefore that $t \in A^*$. We now set

$$\sigma_1 = \min(\sigma_0, (K_X^{-\bar{p}}/L_H)^{1/(1-\bar{p})}).$$

If $t \in A^* \setminus \bar{A}$ then, using (2.4) from Assumption 2.3,

$$\begin{aligned} c_1\text{dist}(t, \partial A^*) \leq |H_u(z^*)(t)| &\leq |H_u(z^*)(t) - H_u(z)| + |H_u(z)| < L_H\sigma + \delta^{\bar{p}} \\ &\leq L_H\sigma + M_F^{\bar{p}}\sigma^{\bar{p}}. \end{aligned} \tag{3.29}$$

This implies that $t \in E_\zeta$ where

$$\zeta = (L_H\sigma + M_F^{\bar{p}}\sigma^{\bar{p}})/c_1.$$

Hence

$$\mu(A^* \setminus \bar{A}(z)) \leq \mu(E_\zeta) \leq c_0\zeta.$$

If we set

$$c_\mu = c_0(L_H\sigma_1^{1-\bar{p}} + M_F^{\bar{p}})/c_1$$

the proof is complete. □

The final result in this section is that if z is sufficiently near z^* then u can be set to u^* on $\bar{A}(z)$ in a well-defined way.

LEMMA 3.7. *Assume that Assumptions* 2.1–2.4 *hold. Then for all* $\bar{p} \in (0,1)$ *there is* σ_2 *such that if* $\|z - z^*\|_X < \sigma_2, z \neq z^*$ *and* $t \in \bar{A}(z)$ *then*

$$|u(t) - u^*(t)| < |u(t) - w(t)|$$

for all $w \neq u^*$, $w(t) \in \partial U(t)$. *Therefore the assignment of* u *to* $u_{\min}$ *or* $u_{\max}$, *whichever is closer to* u, *on* $\bar{A}$ *is well defined and decreases the* X*-norm of* $z - z^*$.

Proof. Let $\sigma_2 \leq \sigma_1$ so that the conclusions of Theorem 3.6 hold. If $t \in \bar{A}(z) \subset A^*$ then either $u^*(t) = u_{\max}(t)$ or $u^*(t) = u_{\min}(t)$. Without loss of generality we assume that $u^*(t) = u_{\max}(t)$. Letting $\|z - z^*\|_X = \sigma$ we have $|u(t) - u_{\max}(t)| \leq \sigma$ and

$$|u(t) - u_{\min}(t)| \geq |u^*(t) - u_{\min}(t)| - |u(t) - u^*(t)| \geq \nu - \sigma,$$

where ν is from Assumption 2.3. This completes the proof if $\sigma_2 < \nu/2$. □

4. The algorithm.

Let z be such that the conclusions of Theorem 3.5 hold and let $\|\mathcal{F}(z)\|_Y = \delta$. Let $\bar{p} \in (0,1)$ and let $\bar{A}(z)$ be given by (3.27). Let $\bar{I} = \bar{A}^c = [0,T]\backslash\bar{A}$.

Note that if $v = Q_{\bar{I}}z + (I - Q_{\bar{I}})(z - \mathcal{F}(z))$ then $v_u = u^*$ on $\bar{A}(z)$ and hence $\mathcal{F}_I$ can be computed since the value of z^* on $\bar{A}$ is known.

The variant of the projected Newton algorithm that we propose here makes the transition from a current iterate z_c to a new point z_+ by setting $u_c = u^*$ on $\bar{A}$, which is a well-defined step by Lemma 3.7, and then applying a projected Newton iteration with $\bar{A}(z_c)$ as the active set. The iteration is formally given by the following algorithm.

ALGORITHM 4.1. Algorithm proj_newt($\mathcal{F}, z_c, z_+$)

1. Compute

$$\bar{A}(z_c) = \{t \,|\, |H_u(z_c)(t)| \geq \|\mathcal{F}(z_c)\|_Y^{\bar{p}}\}.$$

2. Set $u_c = u^*$ on $\bar{A}(z_c)$.
3. Compute the projected Newton step

$$\begin{aligned} s &= -(I - Q_{\bar{I}})\mathcal{F}(z_c) - Q_{\bar{I}}\mathcal{F}'_{\bar{I}}(z_c)^{-1}Q_{\bar{I}}\mathcal{F}_{\bar{I}}(z_c) \\ &= -Q_{\bar{I}}\mathcal{F}'_{\bar{I}}(z_c)^{-1}Q_{\bar{I}}F(z_c) \\ &= -(Q_{\bar{I}}F'(z_c)Q_{\bar{I}})^{-1}Q_{\bar{I}}F(z_c). \end{aligned} \tag{4.1}$$

4. Set $z_{1/2} = \bar{P}(z_c + s)$ and $u_+ = u_{1/2}$, where

$$\bar{P} = \begin{pmatrix} I & 0 & 0 \\ 0 & I & 0 \\ 0 & 0 & \mathcal{P} \end{pmatrix}.$$

5. Compute

$$\begin{aligned} x_+(t) &= \int_0^t f(x_{1/2}(s), u_+(s), s)\, ds + x_0, \\ p_+(t) &= \int_t^T H_x(p_{1/2}(s), x_{1/2}(s), u_+(s))\, ds. \end{aligned}$$

Remark. The term $(I - Q_{\bar{I}})\mathcal{F}(z_c)$ in the right side of (4.1) in step 3 of Algorithm 4.1 vanishes because of the change in u_c on $\bar{A}$ in step 2 in the algorithm. We include it in the first line of (4.1) to emphasize the similarity of the algorithm we propose with the projected Newton algorithm in [2]. Hence after the overwriting of u_c with u^* on $\bar{A}$ in step 2 we need only compute the step on $\bar{I}$. Another effect of step 2 is the relation

$$Q_{\bar{I}}\mathcal{F}_{\bar{I}}(z_c) = Q_{\bar{I}}F(z_c),$$

which follows from $u = u^*$ on $\bar{A}$.

The convergence behavior of the iteration is given by the following theorem.

THEOREM 4.1. *Let the assumptions of Theorem* 3.5 *hold. There are* $K_N > 0$ *and* $\sigma_3 > 0$ *such that if* $\|e_c\|_X < \sigma_3$ *and* z_+ *is given by Algorithm* 4.1 *then*

$$\|e_+\|_X \leq K_N \|e_c\|_X^{2\bar{p}}. \tag{4.2}$$

Proof. First let $\sigma_3 \leq \sigma_2$ so that the conclusions of our previous results are valid. The proof begins by estimating $\|P_1 e_+\|_X$ in terms of $\|e_c\|_X$ and $\|P_2 e_+\|$. This first step reduces the proof to an estimate of $\|P_2 e_+\|_X$ in terms of $\|e_c\|$, which only involves the u-component of the error.

Step 5 of Algorithm 4.1 serves as a smoothing step. By definition we have $\|e_+\|_X = \|e_+\|_Y + \|\frac{d}{dt} P_1 e_+\|_Y$. Assumption 2.2 yields with a constant $B_{14} > 0$

$$\begin{aligned}\left\|\frac{d}{dt}P_1 e_+\right\|_Y &= \|f(x_{1/2}, u_+) - f(x^*, u^*)\|_{L^\infty} + \|H_x(p_{1/2}, x_{1/2}, u_+) - H_x(p^*, x^*, u^*)\|_{L^\infty} \\ &\leq B_{14}\|e_{1/2}\|_Y.\end{aligned}$$

Similarly,

$$\begin{aligned} e_{x+}(t) &= \int_0^t (f(x_{1/2}(s), u_+(s)) - f(x^*(s), u^*(s)))ds \quad \text{and} \\ e_{p+}(t) &= \int_t^T H_x(p_{1/2}(s), x_{1/2}(s), u_+(s)) - H_x(p^*(s), x^*(s), u^*(s)))ds. \end{aligned} \tag{4.3}$$

Hence there is B_{15} such that

$$\|P_1 e_+\|_Y \leq B_{15}\|e_{1/2}\|_Y.$$

Therefore

$$\|e_+\|_X \leq (B_{14} + B_{15})\|e_{1/2}\|_Y.$$

Step 2 of Algorithm 4.1 forces $u_c = u^*$ on $\bar{A} \subset A^*$ by Theorem 3.6. $Q_{\bar{I}}s$ can be viewed as a perturbation of the Newton step $\bar{s}$ for the map $Q_{\bar{I}}(\mathcal{F}_{\bar{I}}(z) - \mathcal{F}_{\bar{I}}(z^*))$ from the point z_c. We have

$$\bar{s} = -Q_{\bar{I}}\mathcal{F}'_{\bar{I}}(z_c)^{-1}Q_{\bar{I}}(\mathcal{F}_{\bar{I}}(z_c) - \mathcal{F}_{\bar{I}}(z^*))$$

and $\bar{z}_{1/2} = z_c + \bar{s}$ satisfies

$$\|Q_{\bar{I}}\bar{e}_{1/2}\|_X \leq B_{16}\|Q_{\bar{I}}e_c\|_X^2. \tag{4.4}$$

Here, for this proof,

$$B_{16} = K_\eta L_F/2$$

as is standard for Newton's method.

Now,

$$Q_{\bar I} e_{1/2} = Q_{\bar I} \bar e_{1/2} + \mathcal{F}'_{\bar I}(z_c)^{-1} \mathcal{F}_{\bar I}(z^*). \tag{4.5}$$

To estimate $\mathcal{F}'_{\bar I}(z_c)^{-1}\mathcal{F}_{\bar I}(z^*)$ we note that because $\bar A \subset A^*$, $I^* \subset \bar I$, $\mathcal{F}_{\bar I}(z^*)$ vanishes on I^*. $\mathcal{F}_{\bar I}(z^*)$ also vanishes on $\bar A \subset A^*$ by definition. Therefore

$$\mathcal{F}_{\bar I}(z^*) = P_2 \mathcal{F}_{\bar I}(z^*) = \begin{pmatrix} 0 \\ 0 \\ \chi_{\bar I \setminus I^*} H_u(p^*, x^*, u^*) \end{pmatrix}.$$

Hence, as in (3.9), we may require σ_3 to be small enough so that

$$\|P_1 \mathcal{F}'_{\bar I}(z_c)^{-1} \mathcal{F}_{\bar I}(z^*)\|_Y \le 2K_\eta \|\mathcal{F}_{\bar I}(z^*)\|_Y \mu(\bar I \setminus I^*). \tag{4.6}$$

We may estimate $\|\mathcal{F}_{\bar I}(z^*)\|_Y$ by using the fact that

$$\mathcal{F}_{\bar I}(z^*) = P_2 \mathcal{F}_{\bar I}(z^*)$$

and the definition of $\bar A$ to find

$$\begin{aligned} \|\mathcal{F}_{\bar I}(z^*)\|_Y &\le \|\mathcal{F}_{\bar I}(z^*) - \mathcal{F}_{\bar I}(z_c)\|_Y \|\mathcal{F}_{\bar I}(z_c)\|_Y \\ &\le M_F \|e_c\|_X + M_F^{\bar p} \|e_c\|_Y^{\bar p} \\ &\le (M_F \sigma_2^{1-\bar p} + M_F^{\bar p}) \|e_c\|_X^{\bar p}. \end{aligned}$$

The fact that $\bar I \setminus I^* = A^* \setminus \bar A$ and Theorem 3.6 imply

$$\mu(\bar I \setminus I^*) \le c_\mu \|e_c\|_X^{\bar p}. \tag{4.7}$$

From (4.5), (4.6), (4.7) we obtain

$$\begin{aligned} \|P_1 e_{1/2}\|_Y = \|P_1 Q_{\bar I} e_{1/2}\|_Y &\le \|P_1 Q_{\bar I} \bar e_{1/2}\|_Y + \|P_1 \mathcal{F}'_{\bar I}(z_c)^{-1} \mathcal{F}_{\bar I}(z^*)\|_Y \\ &\le B_{16} \|e_c\|_X^2 + K_\eta c_\mu (M_F \sigma_2^{1-\bar p} + M_F^{\bar p}) \|e_c\|_X^{2\bar p} \le B_{17} \|e_c\|_X^{2\bar p}, \end{aligned} \tag{4.8}$$

where

$$B_{17} = B_{16} \sigma_2^{2-2\bar p} + c_\mu K_\eta (M_F \sigma_2^{1-\bar p} + M_F^{\bar p}).$$

This gives

$$\|P_1 e_+\|_X \le B_{15} B_{17} \|e_c\|_X^{2\bar p} + \|P_2 e_+\|_X. \tag{4.9}$$

We must now consider the equation for the third component $P_2 z_+$ of the projected Newton iterate. If $t \in \bar A \subset A^*$ then $u_+ = u_c = u^*$ and the third components of the step, the current error, and the new error vanish.

By (4.1), on $\bar I$ we have

$$f_u(x_c, p_c, u_c) s_p + H_{ux}(x_c, p_c, u_c) s_x + H_{uu}(p_c, x_c, u_c) s_u = -H_u(p_c, x_c, u_c).$$

By Taylor's theorem and the fact that $f_u = H_{up}$ we have

$$\begin{aligned} H_{uu}(p_c, x_c, u_c) s_u &= -(H_u(p_c, x_c, u_c) + H_{up}(p_c, x_c, u_c) s_p + H_{ux}(p_c, x_c, u_c) s_x) \\ &= -H_u(p_{1/2}, x_{1/2}, u_c) - \Delta_1, \end{aligned}$$

where

$$\Delta_1 = \int_0^1 (H_{up}(p_c + ts_p, x_c + ts_x, u_c) - H_{up}(p_c, x_c, u_c))s_p \\ +(H_{ux}(p_c + ts_p, x_c + ts_x, u_c) - H_{ux}(p_c, x_c, u_c))s_x \, dt.$$

By Assumption 2.2

$$\|\Delta_1\|_\infty \leq 2M_H \|P_1 s\|_X^2,$$

where M_H is an upper bound for the Lipschitz constants of $f_u = H_{up}$, H_{ux}, and H_{uu}.

Now,

$$H_{uu}(p_c, x_c, u_c)s_u = -H_u(p^*, x^*, u_c) + \Delta_2,$$

where

$$\Delta_2 = H_u(p^*, x^*, u) - H_u(p_{1/2}, x_{1/2}, u) - \Delta_1.$$

Since

$$\|P_1 s\|_X \leq K_\eta \delta \leq K_\eta L_F \|e_c\|_X$$

and (4.8) implies

$$\|H_u(p_{1/2}, x_{1/2}, u) - H_u(p^*, x^*, u)\|_\infty \leq L_H \|P_1 e_{1/2}\|_Y \leq L_H B_{17} \|e_c\|_X^{2\bar{p}},$$

we have that Δ_2 can be bounded by

$$\|\Delta_2\|_\infty \leq B_{18} \|e_c\|_X^{2\bar{p}},$$

where

$$B_{18} = 2M_H K_\eta^2 L_F^2 \sigma_0^{2-2\bar{p}} + L_H B_{17}.$$

We expand $H_u(p^*, x^*, u_c)$ about u^* and apply Taylor's theorem again to obtain

$$H_u(p^*, x^*, u) = H_u(p^*, x^*, u^*) + H_{uu}(p^*, x^*, u^*)e_u + O(\|e_c\|_Y^2)$$

and hence

$$H_{uu}(p_c, x_c, u_c)s_u = -H_u(p^*, x^*, u^*) - H_{uu}(p^*, x^*, u^*)e_u + \Delta_3, \tag{4.10}$$

where

$$\|\Delta_3\|_\infty \leq B_{19} \|e_c\|_X^{2\bar{p}},$$

for some $B_{19} > 0$.

Let $\tilde{u}_+ = u_c + s_u$. Equation (4.10) may be rewritten as

$$\tilde{u}_+ = u^* - (H_{uu}(p_c, x_c, u_c))^{-1} H_u(p^*, x^*, u^*) \\ -[1 - (H_{uu}(p_c, x_c, u_c))^{-1} H_{uu}(p^*, x^*, u^*)]e_u + \Delta_3. \tag{4.11}$$

Since

$$(1 - H_{uu}(p_c, x_c, u_c))^{-1} H_{uu}(p^*, x^*, u^*))e_u = O(\|e_c\|_Y^2)$$

we have, for all $t \in \bar{I}$,

$$\tilde{u}_+ = u^* - (H_{uu}(p_c, x_c, u_c))^{-1} H_u(p^*, x^*, u^*) + \Delta_4, \tag{4.12}$$

where

$$\|\Delta_4\|_\infty \leq B_{20} \|e_c\|_X^{2\bar{p}}$$

for some $B_{20} > 0$.

Since $H_{uu}(p_c, x_c, u_c) > \tilde{\alpha}$ for all $t \in \bar{I}$ we have that

$$u^* = \mathcal{P}(u^* - (H_{uu}(p_c, x_c, u_c))^{-1} H_u(p^*, x^*, u^*)),$$

for all $t \in \bar{I}$. Therefore

$$\begin{aligned} u_+ = \mathcal{P}(\tilde{u}_+) &= \mathcal{P}(u^* - (H_{uu}(p_c, x_c, u_c))^{-1} H_u(p^*, x^*, u^*) + \Delta_4) \\ &= u^* + \Delta_5, \end{aligned}$$

where

$$\Delta_5 = \mathcal{P}(u^* - (H_{uu}(p_c, x_c, u_c))^{-1} H_u(p^*, x^*, u^*) + \Delta_4) - u^*$$

satisfies

$$\|\Delta_5\|_\infty \leq \|\Delta_4\|_\infty \leq B_{20} \|e_c\|_X^{2\bar{p}}.$$

Hence

$$\|P_2 e_+\|_X \leq B_{20} \|e_c\|_X^{2\bar{p}}. \tag{4.13}$$

We combine this with (4.9) to obtain

$$\begin{aligned} \|e_+\|_X &\leq \|P_1 e_+\|_X + \|P_2 e_+\|_X \\ &\leq B_{15} B_{17} \|e_c\|_X^{2\bar{p}} + 2\|P_2 e_+\|_X \\ &\leq (B_{15} B_{17} + 2B_{20}) \|e_c\|_X^{2\bar{p}}. \end{aligned}$$

Setting $K_N = B_{15} B_{17} + 2B_{20}$ completes the proof. □

5. Assumptions. In this section we review the assumptions posed in §2 and relate them to other conditions used in the context of optimal control problems with ordinary differential equations.

Since the theory developed uses an L^∞-framework in contrast to L^2, there is no problem in establishing the proper differentiability assumptions of the mappings. Recall that $\mathcal{F}_I : X_I \to Y_I$ for some measurable set $I \subset [0, T]$ with $A = [0, T] \setminus I$ is defined by

$$\mathcal{F}_I(z) = Q_I F \begin{pmatrix} p \\ x \\ \chi_I u + \chi_A u^* \end{pmatrix} = \begin{pmatrix} \dot{x} - f(x, \chi_I u + \chi_A u^*, t) \\ \dot{p} + H_x(x, \chi_I u + \chi_A u^*, t) \\ \chi_I(H_u(x, \chi_I u + \chi_A u^*, t)) \end{pmatrix} \tag{5.1}$$

for $z \in X_I$. Therefore the derivative is given by

$$\mathcal{F}_I'(z)(\zeta) = Q_I F' \begin{pmatrix} p \\ x \\ \chi_I u + \chi_A u^* \end{pmatrix} \begin{pmatrix} \pi \\ \xi \\ \chi_I \nu \end{pmatrix} = \begin{pmatrix} \dot{\xi} - f_x \xi - f_u \chi_I \nu \\ \dot{\pi} + f_x^T \pi + H_{xx} \xi + H_{xu} \chi_I \nu \\ \chi_I (f_u^T \pi + H_{ux} \xi + H_{uu} \chi_I \nu) \end{pmatrix}, \tag{5.2}$$

where $\zeta = (\pi, \xi, \nu) \in X$. In (5.2) we have omitted the arguments for the derivatives of the functions.

The regularity assumptions in Assumption 2.4 are related to second-order sufficiency conditions in optimal control. In the papers [15] and [14] second-order sufficiency conditions of the following type are used. A strengthened Legendre–Clebsch condition is posed with the existence of a solution to a Riccati equation, both appropriately altered to the case of control constraints. We assume the existence of a solution $Z(t) \in R^{n \times n}$ on [0,T] of the Riccati equation

$$-\dot{Z} = Z f_x + f_x^T Z + H_{xx} - (H_{xu} + Z f_u) H_{uu}^+ (H_{ux} + f_u^T Z), \quad Z(T) = 0, \tag{5.3}$$

where H_{uu}^+ is defined as

$$H_{uu}^+ = \chi_I H_{uu}^{-1} \chi_I.$$

LEMMA 5.1. *Let $z^* = (p^*, x^*, u^*) \in X$ be given. Assume that for I given by* (2.6) *there exists a solution $Z \in W_{n\times n}^{1,\infty}[0,T]$ of* (5.3) *and for some $\delta > 0$*

$$H_{uu}(t) \geq \delta \quad a.e. \text{ on } I. \tag{5.4}$$

Then (2.7) *and* (2.8) *of Assumption* 2.4 *hold.*

Proof. For given $(a,b,c)^T \in Y^\infty$ let γ be the solution of the initial value problem

$$\dot{\gamma} - (-f_x^T + H_{xu} H_{uu}^+ f_u^T)\gamma = b - H_{xu} H_{uu}^+ c - Z(a + f_u H_{uu}^+ c), \quad \gamma(T) = 0. \tag{5.5}$$

With γ known, denote by ξ the solution of

$$\dot{\xi} + (f_u H_{uu}^+ f_u^T Z - f_x + f_u H_{uu}^+ f_u^T)\xi = a + f_u H_{uu}^+ c - f_u H_{uu}^+ f_u^T \gamma, \quad \xi(0) = 0. \tag{5.6}$$

Define π by

$$\pi = Z\xi + \gamma \tag{5.7}$$

and ν on I by

$$\nu = H_{uu}^+ (c - f_u^T \pi - H_{ux} \xi), \tag{5.8}$$

which can be defined also as a function on $[0,T]$ by extension with 0.

Then one can verify that $(\pi, \xi, \nu)^T \in X_I$ solve the system

$$\mathcal{F}_I'(z^*)(\pi, \xi, \nu)^T = (a, b, c)^T, \tag{5.9}$$

which proves the surjectivity of $\mathcal{F}_I'(z^*)$. The continuous dependence of solutions of initial value problems on the right-hand side of the differential equation allows us to deduce from (5.5) with (5.4) that $\|\gamma\|_{W^{1,\infty}}$ depends continuously on $\|(a,b,c)\|_{Y_I}$. Using this fact one obtains the same statement from (5.6) for ξ. Finally, one estimates the L^∞-norm of ν by (5.8) and this altogether yields the estimate

$$\|\mathcal{F}_I'(z^*)^{-1}(a,b,c)\|_{X_I} = \|(\pi, \xi, \nu)\|_{X_I} \leq B_{21} \|(a,b,c)\|_{Y_I} \tag{5.10}$$

for some positive number B_{21}. This proves (2.7).

To show (2.8), let S be a measurable subset of $[0,T]$ and let $(a,b,c)^T \in Y^\infty$. Then

$$(I - Q_{S^c})(a,b,c)^T = (0,0,\chi_S c)$$

and let $(\pi,\xi,\nu)^T \in X_I$ be the solution of

$$\mathcal{F}_I'(z^*)(\pi,\xi,\nu)^T = (0,0,\chi_S c)^T = (I - Q_{S^c})(a,b,c)^T. \tag{5.11}$$

We define γ and ξ as solutions of (5.5) and (5.6), respectively, with (a,b,c) replaced by $(0,0,\chi_S c)$. Then we obtain from the modified (5.5) that for some constant B_{22} we have

$$\|\gamma\|_\infty \le B_{22}\|\chi_S \nu\|_1 \le B_{22} T \mu(S)\|\nu\|_\infty$$

and a similar estimate follows from modified (5.6) for $\|\xi\|_\infty$. Hence we obtain with (5.11)

$$\|P_1 \mathcal{F}_I'(z^*)^{-1}(I - Q_{S^c})(a,b,c)\|_{Y_I} = \|P_1(\pi,\xi,\nu)\|_{Y_I} = \|(\pi,\xi,0)\|_{Y_I} \le B_{23}\mu(S)\|\nu\|_\infty$$

which implies (2.8). □

The last condition in Assumption 2.4 is a trivial consequence of the assumption on the strengthened Legendre–Clebsch condition (5.4) in Lemma 5.1 if we choose I properly. We can relax the second-order sufficiency conditions to hold only on I^* under a proper smoothness assumption on the control.

LEMMA 5.2. *Let $z^* = (p^*, x^*, u^*) \in X$ be given such that $u^* \in C[0,T]$ and let Assumption 2.3 hold. Assume that for I^* we have for some $\delta > 0$*

$$H_{uu}(t) \ge \delta \quad a.e. \ on\ I^* \tag{5.12}$$

and that there exists a solution $Z \in W^{1,\infty}_{n\times n}[0,T]$ of (5.3) with $H^+_{uu} = \chi_{I^*} H^{-1}_{uu} \chi_{I^*}$. Then (2.7) and (2.8) of Assumption 2.4 hold.

Proof. Note that p^*, x^* are continuous as solutions of differential equations. With the assumption on u^* we have $H_{uu} \in C[0,T]$. Furthermore, Assumption 2.3 yields that for small ρ

$$I_\rho = \{t \in [0,T] \mid |H_u(p^*, x^*, u^*)| \le \rho\}$$

and we have that

$$\lim_{\rho \to 0} \mu(I_\rho \setminus I^*) = 0.$$

Since by (5.12) the continuous function H_{uu} is greater or equal to $\delta > 0$ on I^*, we can choose $\rho = \tilde{\sigma} > 0$ small enough so that for an appropriately small $\tilde{\alpha}$

$$H_{uu}(t) \ge \tilde{\alpha} > 0 \text{ on } I_{\tilde{\sigma}}.$$

We have assumed the existence of a solution of the Riccati equation where H^+_{uu} has support only on I^*. If $\tilde{\sigma}$ is small enough then the Riccati equation with H^+_{uu} and support on $I_{\tilde{\sigma}}$ also has a bounded solution on $[0,T]$. This completes the proof. □

Next we discuss the statements in Assumption 2.3. For the finite-dimensional case, a typical nondegeneracy condition would require that each component of $H_u(p^*, x^*, u^*)_i$

is nonzero if the corresponding component u_i^* of the optimal control lies in the active set A^*. The additional difficulty occurring for the infinite-dimensional problem is that H_u can approach zero in different ways. Here we had to impose a requirement that $|H_u|$ grows at a similar rate as the distance from the boundary of the active set when moving away from the boundary. Obviously, this condition reduces to the previously mentioned nondegeneracy condition in finite dimensions.

We can relate (2.4) to a condition on the zeroes of the switching function H_u. A similar condition was used in [5, Thm. 6.2] and also in [16, (2.14)]. To state this more precisely we prove the following lemma.

LEMMA 5.3. *Assume that for* $0 \le t_1 \le \cdots \le t_{2r+1} \le T$

$$\{t \in [0,T] \mid H_u(x^*,p^*,u^*)(t) = 0\} = \bigcup_{i=0}^{r} [t_{2i}, t_{2i+1}] \tag{5.13}$$

and that the function $g(t) := |H_u(x^*,p^*,u^*)(t)|$ *is continuous and has one-sided derivatives with*

$$g'_-(t_{2i}), g'_+(t_{2i+1}) > 0 \quad \text{for } i = 1,\dots,r. \tag{5.14}$$

Then the first line of (2.4) *in Assumption* 2.3 *holds.*

Proof. The assumption (5.13) yields that A^* consists of finitely many subintervals. Let $A_i^* = [t_{2i-1}, t_{2i}]$ denote such an interval. Then (5.14) implies that there are $\epsilon, m > 0$ such that

$$g(t) \ge m|t - t_{2i-1}| \text{ on } [t_{2i-1}, t_{2i-1} + \epsilon] \quad \text{and} \quad g(t) \ge m|t - t_{2i}| \text{ on } [t_{2i} - \epsilon, t_{2i}].$$

By definition g is positive on (t_{2i-1}, t_{2i}). Therefore, we can choose $\epsilon > 0$ so small that

$$g(t) \ge m\epsilon \text{ on } [t_{2i-1} + \epsilon, t_{2i} - \epsilon].$$

With $m^* = \min\{m, 2\epsilon/(t_{2i} - t_{2i-1})\}$ we obtain

$$g(t) \ge m|t - t_{2i-1}| \text{ on } [t_{2i-1}, (t_{2i-1}+t_{2i})/2] \text{ and } g(t) \ge m|t - t_{2i}| \text{ on } [(t_{2i-1}+t_{2i})/2, t_{2i}],$$

i.e., $g(t) \ge m \operatorname{dist}(t, \partial A^*)$ on A_i^*. □

To reconsider the second line of (2.4), we need more information about H_u which vanishes identically on I^*. The following lemma addresses a class of problems where the objective function contains a quadratic control term as is the case in many applications.

LEMMA 5.4. *Suppose that the objective function contains a quadratic control term*

$$L(x,u) = \bar{L}(x,u) + \frac{\alpha}{2}u^2,$$

with some $\alpha > 0$. *If the function* $f_u(x^*,u^*)^T p^* + \bar{L}_u(x^*,u^*)$ *has a nonzero slope when entering and leaving the active set, then the second line of* (2.4) *is also true.*

The form of L implies $H_u = f_u^T p + \bar{L}_u + \alpha u^*$ and

$$u^* = -\frac{1}{\alpha}(f_u(x^*,u^*)^T p^* + \bar{L}_u(x^*,u^*)) \text{ on } I^*.$$

The proof of this lemma is similar to the one given for Lemma 5.3.

6. Implementation. In this section we want to touch upon some of the details of the implementation of the algorithm. The unconstrained version of the algorithm presented in the previous sections can be given as the following system of nonlinear equations:

$$F(z) = F(p,x,u) = \begin{pmatrix} \dot{x} - f(x,u,t) \\ \dot{p} + H_x(p,x,u) \\ H_u(p,x,u) \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \\ 0 \end{pmatrix} \tag{6.1}$$

for $z = (p,x,u)^T$ which satisfy the boundary conditions $x(0) = x_0$ and $p(T) = 0$.

The Fréchet derivative of F is given by

$$F'(p,x,u) \begin{pmatrix} \pi \\ \xi \\ \nu \end{pmatrix} = \begin{pmatrix} 0 & D - f_x & -f_u \\ D + f_x^T & H_{xx} & H_{xu} \\ f_u^T & H_{ux} & H_{uu} \end{pmatrix} \begin{pmatrix} \pi \\ \xi \\ \nu \end{pmatrix} \tag{6.2}$$

with $D = \frac{d}{dt}$ and all other components as multiplication operators.

If one considers the constrained optimal control problem with the corresponding system of nonlinear equations $\mathcal{F}(z) = 0$, then the projected Newton step requires a decision on the set of active indices. In the implementation we used the rule

$$\bar{A}(z) = \{t \in [0,T] : |H_u(z)(t)| \geq \|.5\mathcal{F}(z)\|_Y^{\bar{p}}\}.$$

Then the projected Newton step is computed by solving for (π,ξ,ν) with $\pi(T) = \xi(0) = 0$

$$\begin{aligned} Q_I F'(p,x,u) Q_I \begin{pmatrix} \pi \\ \xi \\ \nu \end{pmatrix} &= \begin{pmatrix} 0 & D - f_x & -f_u \chi_I \\ D + f_x^T & H_{xx} & H_{xu}\chi_I \\ \chi_I f_u^T & \chi_I H_{ux} & \chi_I H_{uu} \chi_I \end{pmatrix} \begin{pmatrix} \pi \\ \xi \\ \nu \end{pmatrix} \\ = -Q_I F(p,x,u) &= \begin{pmatrix} -\dot{x} + f(x,u,t) \\ -\dot{p} - f_x^T p - L_x \\ -\chi_I (f_u^T p + L_u) \end{pmatrix}, \end{aligned} \tag{6.3}$$

where

$$I = \{t \in [0,T] : |H_u(t)| < \|\mathcal{F}(z)\|_Y^{\bar{p}}\}.$$

The new control is then computed as

$$u_+ = \mathcal{P}(u + \chi_I \nu - \chi_A H_u).$$

The intermediate new state and adjoint variable are given by

$$(p_{1/2},\ x_{1/2}) = (p,\ x) + (\pi,\ \xi).$$

If one observes that in (6.3) π and ξ appear with derivatives, we can derive a differential equation for the sum $x_{1/2} = x + \xi$ and likewise for $p_{1/2}$. Hence, a more efficient way to compute $(p_{1/2}, x_{1/2})$ is to solve the following differential equations (all unsubscripted quantities are evaluated along the current values (p_c, x_c, u_c)):

$$\begin{aligned} \dot{x}_{1/2} - f_x x_{1/2} &= -f_x x + f + f_u \chi_I \nu, \\ \dot{p}_{1/2} + f_x^T p_{1/2} + H_{xx} x_{1/2} &= H_{xx} x - L_x - H_{xu} \chi_I \nu \end{aligned} \tag{6.4}$$

with boundary conditions $x_{1/2}(0) = x_0, p_{1/2}(T) = 0$. In addition, if we use the invertibility of $\chi_I H_{uu} \chi_I$ for all $t \in I$, then ν can be expressed in terms of $x_{1/2}, p_{1/2}, x, p$ as follows:

$$\chi_I \nu = -(H_{uu}^I)^+ (f_u^T p_{1/2} + H_{ux}(x_{1/2} - x) + L_u),$$

where we substitute

$$(H_{uu}^I)^+ = \begin{cases} (\chi_I H_{uu} \chi_I)^{-1}(t) & \text{if} \quad (\chi_I H_{uu} \chi_I)(t) \neq 0, \\ 0 & \text{if} \quad (\chi_I H_{uu} \chi_I)(t) = 0. \end{cases} \tag{6.5}$$

Hence a linear 2-point boundary value problem needs to be solved at each iteration. Solve for $p_{1/2}, x_{1/2}$ with $p_{1/2}(T) = 0, x_{1/2}(0) = 0$

$$\begin{aligned} &\dot{x}_{1/2} + (-f_x + f_u (H_{uu}^I)^+ H_{ux}) x_{1/2} + f_u (H_{uu}^I)^+ f_u^T p_{1/2} \\ &\quad = (-f_x + f_u (H_{uu}^I)^+ H_{ux}) x + f - f_u (H_{uu}^I)^+ L_u, \\ &\dot{p}_{1/2} + (f_x^T - H_{xu} (H_{uu}^I)^+ f_u^T) p_{1/2} + (H_{xx} - H_{xu} (H_{uu}^I)^+ H_{ux}) x_{1/2} \\ &\quad = (H_{xx} - H_{xu} (H_{uu}^I)^+ H_{ux}) x - L_x + H_{xu} (H_{uu}^I)^+ L_u. \end{aligned} \tag{6.6}$$

At the end of each iteration a smoothing step has to be carried out as follows:

$$\begin{aligned} x_+(t) &= \textstyle\int_0^t f(x_{1/2}(s), u_+(s), s)\, ds + x_0, \\ p_+(t) &= \textstyle\int_t^T H_x(p_{1/2}(s), x_{1/2}(s), u_+(s))\, ds. \end{aligned} \tag{6.7}$$

Termination and the identification of the active set is based on the size of the residual which can be computed as follows:

$$\begin{aligned} F(z_+) &= \begin{pmatrix} \dot{x}_+ - f(x_+, u_+, t) \\ \dot{p}_+ + H_x(p_+, x_+, u_+) \\ u_+ - \mathcal{P}(u_+ - H_u(p_+, x_+, u_+)) \end{pmatrix} \\ &= \begin{pmatrix} f(x_{1/2}, u_+, t) - f(x_+, u_+, t) \\ H_x(p_+, x_+, u_+) - H_x(p_{1/2}, x_{1/2}, u_+) \\ u_+ - \mathcal{P}(u_+ - H_u(p_+, x_+, u_+)) \end{pmatrix} \end{aligned} \tag{6.8}$$

We also list the size of the step $\|z_+ - z_c\|_X$ which we calculate by (the intermediate iterate $x_{1/2}$ has a corresponding iterate in the previous step denoted by $x_{-1/2}$)

TABLE 6.1

&\qquad \|p_+ - p_c\|_\infty + \|H_x(p_{1/2}, x_{1/2}, u_+) - H_x(p_{-1/2}, x_{-1/2}, u_c)\|_\infty, \|u_+ - u_c\|_\infty\}.
\end{aligned}
$$

We use the next example to illustrate the results. Let

$$
\begin{pmatrix} \dot{x}_1 \\ \dot{x}_2 \end{pmatrix} = \begin{pmatrix} (1 - x_2^2)x_1 - x_2 + u \\ x_1 \end{pmatrix}, \quad L(x, u) = \frac{1}{2}(x_1^2 + x_2^2 + u^2),
$$

and $T = 3, x(0) = (0, 1)^T$. Furthermore let

$$
0 \leq u(t) \leq 0.8,
$$

and starting data $x_0 \equiv (0, 1)^T, p_0 \equiv (0, 0)^T, u_0 \equiv 0$.

In Tables 6.1, 6.2, and 6.3 we tabulate, for different values of $\bar{p}$, the progress of the iteration for the example above. The 2-point boundary value problem (6.4) was solved with the trapezoid rule extrapolation approach used in [11] and the integration in (4.3) was done with the trapezoid rule. A uniform mesh of 1400 points was used.

For each iterate k we tabulate the norm of the nonlinear residual

$$
\rho = \|(\dot{x} - f, \dot{p} + H_x, u - \mathcal{P}(u - H_u))\|_\infty,
$$

the ratio $\rho_{k+1}/\rho_k^{\bar{p}}$, and the norm of the step $\sigma = \|(p_{k+1} - p_k, x_{k+1} - x_k, u_{k+1} - u_k)\|_\infty$.

We see from the tables that the convergence follows the predictions of Theorem 4.1 until the residual can be reduced no further as a result of truncation error effects. In several numerical experiments with different numbers of mesh points, a sharp increase in $\rho_{k+1}/\rho_k^{\bar{p}}$ seemed to be an indicator that truncation error effects were dominating the computation.

With Table 6.4 we want to illustrate the effect of Assumption 2.3 on the rate of convergence. If this assumption does not hold we are no longer guaranteed a local

superlinear rate of convergence as in Theorem 4.1. In Lemma 5.4 we give a sufficient condition for Assumption 2.3 to be true. For the example under consideration we have

$$f_u(x^*, u^*)^T p^* + \bar{L}_u(x^*, u^*) = p_1^*,$$

which looks like a parabola $-(t-2)^2 + 1$ with negative curvature. Here we impose only upper bounds on the controls. If the upper bound is relatively high, like 0.95, the slope of p_1^* at the boundary of the active set is small. The assumption in Lemma 5.4 is still satisfied but we can see a slower rate of convergence locally compared to an example where the upper bound on the control is set to 0.8, yielding a steeper slope of p_1^* at the boundary of the active set.

We have 1400 discretization points and select $\bar{p} = 0.6$.

Acknowledgments. The authors appreciate the work of the two very careful referees.

ON THE ADAPTIVE CONTROL OF JUMP PARAMETER SYSTEMS VIA NONLINEAR FILTERING*

PETER E. CAINES† AND JI-FENG ZHANG‡

Abstract. In this paper we first present an error analysis for the process of estimates generated by the Wonham filter when it is used for the estimation of the (finite set-valued) jump-Markov parameters of a random parameter linear stochastic system and further give bounds on certain functions of these estimates. We then consider a certainty equivalence adaptive linear-quadratic Gaussian feedback control law using the estimates generated by the nonlinear filter and demonstrate the global existence of solutions to the resulting closed-loop system. A stochastic Lyapunov analysis establishes that the certainty equivalence law stabilizes the Markov jump parameter linear system in the mean square average sense. The conditions for this result are that certain products of (i) the parameter process jump rate and (ii) the solution of the control Riccati equation and its second derivatives should be less than certain given bounds. An example is given where the controlled linear system has state dimension 2. Finally, the stabilizing properties of certainty equivalence laws which depend on (i) the maximum likelihood estimate of the parameter value and (ii) a modified version of this estimate are established under certain conditions.

AMS subject classifications. 93E11, 93E15, 93E35

1. Introduction.

The hybrid system considered in this work is taken to have the following form:

$$dx_t = [A(\theta_t)x_t + B(\theta_t)u_t]dt + dw_t, \tag{1.1}$$

where $x_t \in I\!R^n$ and $u_t \in I\!R^m$ are the state and input of the system, $\{w_t, \mathcal{F}_t\}$ is a standard Wiener process in $I\!R^n$ with respect to a probability space $(\Omega, P, \mathcal{F})$, and $\theta_t \in \{1, 2, \dots, N\}$ is the N-state jump-Markov parameter process subject to

$$\Phi_t = \Phi_0 + \Pi \int_0^t \Phi_s ds + m_t. \tag{1.2}$$

Here, $\Phi_t = [1\!\!1_{\{\theta_t=1\}}, 1\!\!1_{\{\theta_t=2\}}, \dots, 1\!\!1_{\{\theta_t=N\}}]^\tau$ is the indicator process for θ_t, Π is the transition probability rate matrix, m_t is a zero-mean L^2 martingale, measurable with respect to an increasing σ-field $\mathcal{F}_t$. Φ_0 is $\mathcal{F}_0$-measurable and $E\Phi_0 = p_0$.

For $\theta = i$, $A(\theta) = A_i$, and $B(\theta) = B_i$, where the A_i's and B_i's are, respectively, $I\!R^{n\times n}$ and $I\!R^{n\times m}$ matrices such that $\|A_i - A_j\| + \|B_i - B_j\| \neq 0$ for $i \neq j$. Here and hereafter, $\|X\| \triangleq [\lambda_{\max}(X^\tau X)]^{1/2}$, where $\lambda_{\max}(A)$ denotes the largest eigenvalue of a matrix A.

The model (1.1), (1.2) is particularly appropriate for the analysis of the control of time varying systems, since (1.1) has a variable structure. As indicated by the dependence of all matrix parameters on the indicator process Φ_t, it can be used as

a model for systems subject to random failures and structural changes. Moreover, (1.2) is a general model for jump-Markov parameter processes (see, e.g., Liptser and Shiryaev (1977)).

Control problems for such systems in a nonadaptive setting have been the subject of considerable theoretical research for the past two decades and Sworder and Chou (1985) and Ezzine and Haddad (1989) have given surveys of previous work on this topic.

Generally speaking, the previous works can be classified into three groups: one group (see, e.g., Sworder and Chou (1985); Ezzine and Haddad (1989); Mariton and Bertrand (1985); Mariton (1986); Ji and Chizeck (1990); Feng, Loparo, Ji, and Chizeck (1992)) deals with the case where the system state process x and the jump parameter process Φ can be observed completely at any time instant. The second group (see, e.g., Wonham (1965), Rishel (1981), Caines and Chen (1985), Chen and Caines (1989), Helmes and Rishel (1990), Caines and Nassiri-Toussi (1991)) is concerned with the adaptive case where the system state process x can be observed, but the jump parameter process Φ cannot be directly observed and is consequently estimated. This may, for instance, be carried out by an application of the Wonham filter (see, e.g., Caines and Chen (1985), Chen and Caines (1989), Caines and Nassiri-Toussi (1991)). The third group (see, e.g., Sworder (1991)) discusses the adaptive case where neither the system state process x nor the jump parameter process Φ can be observed.

Among the first group, it is worth mentioning that Ji and Chizeck (1990) and Feng, Loparo, Ji, and Chizeck (1992) examine the relationship between appropriately defined controllability and stabilizability properties, and establish necessary and sufficient conditions for (i) system stabilization and (ii) infinite time jump linear quadratic (JLQ) optimal controls to exist. However, in most situations, direct observation of system parameters is impossible and this leads to the use of adaptive control. Caines and Chen (1985) used the Wonham filter and a dynamic programming approach to obtain a finite-horizon adaptive optimal control law for a general jump-Markov system. In a continuation of this work, Caines and Nassiri-Toussi (1991) and Nassiri-Toussi and Caines (1991) carried out a stochastic Lyapunov analysis of a certainty equivalence stabilizing control law and gave an analysis of the resulting ergodic behavior of the system. It is shown that, under rather strong conditions on the magnitude of the jumps of the parameters and the rate of the jump parameter process, a certainty equivalence linear feedback regulator (using the parameter estimates generated by the Wonham filter) gives rise to stable ergodic behavior of the system (1.1), (1.2). In some special cases, where the system is deterministic or where indirect observations of the parameter are available, special solutions to this problem have also been given in Sworder and Chou (1985), while the general adaptive control problem for stochastic jump-Markov parameter systems is addressed in Rishel (1981), Caines and Chen (1985), Chen and Caines (1989), Helmes and Rishel (1990), Sworder (1991), Caines and Nassiri-Toussi (1991), Nassiri-Toussi and Caines (1991), and Dufour and Bertrand (1993). It should be remarked that Rishel (1981) was the first to use the Wonham filter to find the equations of the optimal linear quadratic Gaussian (LQG) controller for a system depending upon a (constant in time) unobserved finite set-valued random variable. More recently, Helmes and Rishel (1990) have given an explicit solution to this problem for the case of minimizing the expectation of the quadratic state deviation at a final time plus the integrated square of the control action. Sworder (1991) presents an approximation to the quadratic-optimal regulator problem for a situation in which there is an unconventional measurement architecture; the solution is in a form quite similar to that obtained in the complete observation case, but the gain equation is made more complicated by the presence of noise. Finally, in a recent paper, Dufour and Bertrand (1993) responded to an announcement (Caines and Zhang (1992)) of the results of the present paper by giving a form of averaged control law (with respect to the conditional densities) that adaptively stabilizes the jump parameter system in question whenever it satisfies a simple set of algebraic sufficient conditions.

The object of this paper is to establish the existence of stabilizing adaptive feedback controllers for jump parameter systems under relatively weak conditions.

In §2 of this paper, the Wonham filter for estimating the indicator process Φ from observations on x and u is presented, and the error behavior of the filter is analyzed. Theorem 2.1 gives a formula for the mean square estimation error of Φ and Corollaries 2.1 and 2.2 give bounds for the expectation of certain weighted integrals of the estimates; these are required in the subsequent stability analysis. Section 3 contains the principal adaptive control result of the paper. By use of a stochastic Lyapunov technique it is shown that an adaptive LQG certainty equivalence feedback control law, which employs parameter estimates generated by the nonlinear filter, stabilizes the system in an average mean square sense. This result is subject to the condition that (i) the rate of the jump process of the system and (ii) the magnitude of the solution to the control Riccati equation and its second derivative are such that two products of these quantities fall below specified bounds (see (3.8)). It is to be noted that there is no condition on the size of the jumps of the parameters. In §4, a nontrivial example of this theory is given concerning the adaptive control of a two-dimensional linear system with jump-Markov system matrices $\{A_i,\ 1 \leq i \leq N\}$. Finally, in §5, the stabilizing properties of certainty equivalence laws which depend on (i) the maximum likelihood estimate of the parameter value and (ii) a modified version of this estimate are established under certain conditions.

2. The nonlinear filter and preliminary results.

Suppose that (i) A_i and B_i are known for $i = 1, \dots, N$, (ii) $E\|x_0\|^2 < \infty$, (iii) the cross quadratic variation of m and w, i.e., $d\langle m, w\rangle_t/dt \equiv 0$, and (iv) u_t is an m-dimensional $\mathcal{F}_t^x \triangleq \sigma\{x_s,\ s \leq t\}$-measurable control process. Set

$$\widehat{\Phi}_t = [\widehat{\Phi}_t(1), \dots, \widehat{\Phi}_t(N)]^\tau \triangleq E(\Phi_t|\mathcal{F}_t^x), \quad \forall t \geq 0, \tag{2.1}$$

$$H_t = [A_1 x_t + B_1 u_t, \dots, A_N x_t + B_N u_t], \tag{2.2}$$

and

$$\mathrm{Diag}\widehat{\Phi}_t = \begin{bmatrix} \widehat{\Phi}_t(1) & & 0 \\ & \ddots & \\ 0 & & \widehat{\Phi}_t(N) \end{bmatrix}. \tag{2.3}$$

Then the nonlinear Wonham filter for the values of the parameter indicator process Φ_t is given by (see, e.g., Chen and Caines (1989))

$$d\widehat{\Phi}_t = \Pi \widehat{\Phi}_t dt + (\mathrm{Diag}\widehat{\Phi}_t - \widehat{\Phi}_t \widehat{\Phi}_t^\tau) H_t^\tau d\overline{w}_t, \tag{2.4}$$

where $\{\overline{w}_t,\ \mathcal{F}_t^x\}$ is the Wiener process of innovations defined by the innovation representation of x_t:

$$d\overline{w}_t = dx_t - H_t \widehat{\Phi}_t dt. \tag{2.5}$$

THEOREM 2.1. *The conditional mean square estimation error of the filter* (2.4) *for the system* (1.1) *satisfies*

$$
\begin{aligned}
E\|\widetilde{\Phi}_t\|^2 = E\|\widetilde{\Phi}_0\|^2 &+ 2E\int_0^t \widetilde{\Phi}_s^\tau \Pi \widetilde{\Phi}_s ds - 2E\int_0^t \Phi_s^\tau \Pi \Phi_s ds \\
&-E\int_0^t \mathrm{Tr}\left([\widehat{\Phi}_s\widehat{\Phi}_s^\tau - \mathrm{Diag}\widehat{\Phi}_s](H_s^\tau H_s)[\widehat{\Phi}_s\widehat{\Phi}_s^\tau - \mathrm{Diag}\widehat{\Phi}_s]\right) ds, \qquad (2.6)
\end{aligned}
$$

where $\widetilde{\Phi}_t \overset{\triangle}{=} \Phi_t - \widehat{\Phi}_t$, *and* $\mathrm{Tr}(X)$ *denotes the trace of matrix* X.

Proof. By (2.2), (1.1) can be rewritten as

$$dx_t = H_t\Phi_t dt + dw_t,$$

which together with (2.5) results in

$$d\overline{w}_t = H_t\widetilde{\Phi}_t dt + dw_t.$$

Therefore, by (1.2) and (2.4), we have

$$
\begin{aligned}
d\widetilde{\Phi}_t &= \Pi\widetilde{\Phi}_t dt + [\widehat{\Phi}_t\widehat{\Phi}_t^\tau - \mathrm{Diag}\widehat{\Phi}_t]H_t^\tau d\overline{w}_t + dm_t \\
&= \Pi\widetilde{\Phi}_t dt + [\widehat{\Phi}_t\widehat{\Phi}_t^\tau - \mathrm{Diag}\widehat{\Phi}_t]H_t^\tau H_t\widetilde{\Phi}_t dt \\
&\quad +[\widehat{\Phi}_t\widehat{\Phi}_t^\tau - \mathrm{Diag}\widehat{\Phi}_t]H_t^\tau dw_t + dm_t,
\end{aligned}
$$

which combined with Ito's formula (see, e.g., Schwartz (1984)) leads to

$$
\begin{aligned}
\widetilde{\Phi}_t^\tau\widetilde{\Phi}_t = \widetilde{\Phi}_0^\tau\widetilde{\Phi}_0 &+ 2\int_0^t \widetilde{\Phi}_s^\tau\Pi\widetilde{\Phi}_s ds \\
&+2\int_0^t \widetilde{\Phi}_s^\tau(\widehat{\Phi}_s\widehat{\Phi}_s^\tau - \mathrm{Diag}\widehat{\Phi}_s)H_s^\tau H_s\widetilde{\Phi}_s ds \\
&+2\int_0^t \widetilde{\Phi}_s^\tau[\widehat{\Phi}_s\widehat{\Phi}_s^\tau - \mathrm{Diag}\widehat{\Phi}_s]H_s^\tau dw_s + 2\int_0^t \widetilde{\Phi}_s^\tau dm_s \\
&+\int_0^t \mathrm{Tr}\left([\widehat{\Phi}_s\widehat{\Phi}_s^\tau - \mathrm{Diag}\widehat{\Phi}_s](H_s^\tau H_s)[\widehat{\Phi}_s\widehat{\Phi}_s^\tau - \mathrm{Diag}\widehat{\Phi}_s]\right) ds \\
&+\sum_{0<s\leq t}(\widetilde{\Phi}_s - \widetilde{\Phi}_{s-})^\tau(\widetilde{\Phi}_s - \widetilde{\Phi}_{s-}). \qquad (2.7)
\end{aligned}
$$

Since $\widehat{\Phi}_t$, as a solution of (2.4), is continuous, $(\widetilde{\Phi}_s - \widetilde{\Phi}_{s-}) = \Phi_s - \Phi_{s-}$. From this we see that

$$\sum_{0<s\leq t}(\widetilde{\Phi}_s - \widetilde{\Phi}_{s-})^\tau(\widetilde{\Phi}_s - \widetilde{\Phi}_{s-}) = \sum_{0<s\leq t}(\Phi_s - \Phi_{s-})^\tau(\Phi_s - \Phi_{s-}) = 2J_t, \qquad (2.8)$$

where J_t is the number of the jump points of Φ_s in $[0, t]$.

Substituting (2.8) into (2.7) and taking expectations on both sides, we see that

$$
\begin{aligned}
E\widetilde{\Phi}_t^\tau\widetilde{\Phi}_t = E\widetilde{\Phi}_0^\tau\widetilde{\Phi}_0 &+ 2E\int_0^t \widetilde{\Phi}_s^\tau\Pi\widetilde{\Phi}_s ds + 2EJ_t \\
&+2E\int_0^t \widetilde{\Phi}_s^\tau(\widehat{\Phi}_s\widehat{\Phi}_s^\tau - \mathrm{Diag}\widehat{\Phi}_s)H_s^\tau H_s\widetilde{\Phi}_s ds \\
&+E\int_0^t \mathrm{Tr}\left([\widehat{\Phi}_s\widehat{\Phi}_s^\tau - \mathrm{Diag}\widehat{\Phi}_s](H_s^\tau H_s)[\widehat{\Phi}_s\widehat{\Phi}_s^\tau - \mathrm{Diag}\widehat{\Phi}_s]\right) ds. \qquad (2.9)
\end{aligned}
$$

From (1.2) and Ito's formula it follows that

$$\Phi_t^\tau \Phi_t = \Phi_0^\tau \Phi_0 + 2\int_0^t \Phi_s^\tau \Pi \Phi_s ds + 2\int_0^t \Phi_s^\tau dm_s + 2J_t,$$

which, together with $\Phi_t^\tau \Phi_t = \Phi_0^\tau \Phi_0 = 1$, implies

$$EJ_t = -E\int_0^t \Phi_s^\tau \Pi \Phi_s ds. \tag{2.10}$$

Notice that

$$E(\widetilde{\Phi}_t \widetilde{\Phi}_t^\tau | \mathcal{F}_t^x) = E(\Phi_t \Phi_t^\tau | \mathcal{F}_t^x) - \widehat{\Phi}_t \widehat{\Phi}_t^\tau = \mathrm{Diag}\widehat{\Phi}_t - \widehat{\Phi}_t \widehat{\Phi}_t^\tau.$$

Then, by (2.9) and (2.10), we can conclude that

$$\begin{aligned} E\widetilde{\Phi}_t^\tau \widetilde{\Phi}_t &= E\widetilde{\Phi}_0^\tau \widetilde{\Phi}_0 + 2E\int_0^t \widetilde{\Phi}_s^\tau \Pi \widetilde{\Phi}_s ds - 2E\int_0^t \Phi_s^\tau \Pi \Phi_s ds \\ &\quad -E\int_0^t \mathrm{Tr}\left([\widehat{\Phi}_s \widehat{\Phi}_s^\tau - \mathrm{Diag}\widehat{\Phi}_s](H_s^\tau H_s)[\widehat{\Phi}_s \widehat{\Phi}_s^\tau - \mathrm{Diag}\widehat{\Phi}_s]\right) ds, \end{aligned}$$

i.e., (2.6) holds. □

COROLLARY 2.1. (2.6) implies that

$$E\int_0^t \sum_{i=1}^N [\widehat{\Phi}_s(i)]^2 \| A_{\widehat{\Phi}_s} x_s + B_{\widehat{\Phi}_s} u_s - A_i x_s - B_i u_s \|^2 ds \le 1 + 4\|\Pi\| t, \tag{2.11}$$

where $\widehat{\Phi}_t$ and $\widehat{\Phi}_t(i)$ are defined in (2.1), and

$$A_{\widehat{\Phi}_s} = \sum_{i=1}^N \widehat{\Phi}_s(i) A_i, \qquad B_{\widehat{\Phi}_s} = \sum_{i=1}^N \widehat{\Phi}_s(i) B_i. \tag{2.12}$$

Proof. Let

$$H_{t,i} = A_i x_t + B_i u_t \quad \text{and} \quad H_{t,\widehat{\Phi}_t} = A_{\widehat{\Phi}_t} x_t + B_{\widehat{\Phi}_t} u_t. \tag{2.13}$$

Then, by (2.1)–(2.3), we have

$$\begin{aligned} H_t[\widehat{\Phi}_t \widehat{\Phi}_t^\tau - \mathrm{Diag}\widehat{\Phi}_t] &= [H_{t,\widehat{\Phi}_t} \widehat{\Phi}_t(1), \ldots, H_{t,\widehat{\Phi}_t} \widehat{\Phi}_t(N)] - H_t \mathrm{Diag}\widehat{\Phi}_t \\ &= [(H_{t,\widehat{\Phi}_t} - H_{t,1})\widehat{\Phi}_t(1), \ldots, (H_{t,\widehat{\Phi}_t} - H_{t,N})\widehat{\Phi}_t(N)]. \end{aligned}$$

Thus, by (2.13) and (2.6) we get

$$\begin{aligned} & E\int_0^t \sum_{i=1}^N [\widehat{\Phi}_s(i)]^2 \| A_{\widehat{\Phi}_s} x_s + B_{\widehat{\Phi}_s} u_s - A_i x_s - B_i u_s \|^2 ds \\ & = E\int_0^t \sum_{i=1}^N [\widehat{\Phi}_s(i)]^2 \| H_{s,\widehat{\Phi}_s} - H_{s,i} \|^2 ds \\ & = E\int_0^t \mathrm{Tr}\left([\widehat{\Phi}_s \widehat{\Phi}_s^\tau - \mathrm{Diag}\widehat{\Phi}_s](H_s^\tau H_s)[\widehat{\Phi}_s \widehat{\Phi}_s^\tau - \mathrm{Diag}\widehat{\Phi}_s]\right) ds \\ & \le E\widetilde{\Phi}_0^\tau \widetilde{\Phi}_0 + 2E\int_0^t \widetilde{\Phi}_s^\tau \Pi \widetilde{\Phi}_s ds - 2E\int_0^t \Phi_s^\tau \Pi \Phi_s ds \\ & \le 1 + 4\|\Pi\| t, \end{aligned} \tag{2.14}$$

where we have used the fact that $E\|\widetilde{\Phi}_t\|^2 = 1 - E\|\widehat{\Phi}_t\|^2 \le 1$ and $\|\Phi_t\|^2 = 1$ for $t \ge 0$ in order to get the last inequality.

This completes the proof of Corollary 2.1. □

COROLLARY 2.2. *For any constant $\eta > 0$, we have*

$$\begin{aligned} &E\int_0^T \|x_t\|^2 \sum_{i=1}^N [\widehat{\Phi}_t(i)]^2 \|A_{\widehat{\Phi}_t} x_s + B_{\widehat{\Phi}_t} u_s - A_i x_t - B_i u_t\|^2 dt \\ &\quad \le E\|x_0\|^2 + (\eta + 2\|\Pi\|)E\int_0^T \|x_t\|^2 dt + 2E\int_0^T |x_t^\tau H_t \widehat{\Phi}_t| dt \\ &\qquad +4\eta^{-1}(1 + 4\|\Pi\|T) + NT. \end{aligned} \tag{2.15}$$

Proof. From Ito's formula and (2.4) it follows that

$$\begin{aligned} d(\widehat{\Phi}_t^\tau \widehat{\Phi}_t) &= 2\widehat{\Phi}_t^\tau \Pi \widehat{\Phi}_t dt + 2\widehat{\Phi}_t^\tau \left(\mathrm{Diag}\widehat{\Phi}_t - \widehat{\Phi}_t \widehat{\Phi}_t^\tau\right) H_t^\tau d\overline{w}_t \\ &\quad + \mathrm{Tr}\left[\left(\mathrm{Diag}\widehat{\Phi}_t - \widehat{\Phi}_t\widehat{\Phi}_t^\tau\right) H_t^\tau H_t \left(\mathrm{Diag}\widehat{\Phi}_t - \widehat{\Phi}_t\widehat{\Phi}_t^\tau\right)\right] dt, \end{aligned}$$

and from (2.5),

$$d(x_t^\tau x_t) = 2x_t^\tau H_t \widehat{\Phi}_t dt + 2x_t^\tau d\overline{w}_t + N dt.$$

Therefore, by Ito's formula we have

$$\begin{aligned} &d[(1 - \widehat{\Phi}_t^\tau \widehat{\Phi}_t) x_t^\tau x_t] \\ &\quad = -x_t^\tau x_t \mathrm{Tr}\left[\left(\mathrm{Diag}\widehat{\Phi}_t - \widehat{\Phi}_t\widehat{\Phi}_t^\tau\right) H_t^\tau H_t \left(\mathrm{Diag}\widehat{\Phi}_t - \widehat{\Phi}_t\widehat{\Phi}_t^\tau\right)\right] dt \\ &\qquad -2x_t^\tau x_t \widehat{\Phi}_t^\tau \Pi \widehat{\Phi}_t dt + 2(1 - \widehat{\Phi}_t^\tau \widehat{\Phi}_t) x_t^\tau H_t \widehat{\Phi}_t dt + N(1 - \widehat{\Phi}_t^\tau \widehat{\Phi}_t) dt \\ &\qquad -4\widehat{\Phi}_t^\tau \left(\mathrm{Diag}\widehat{\Phi}_t - \widehat{\Phi}_t\widehat{\Phi}_t^\tau\right) H_t^\tau x_t dt + 2(1 - \widehat{\Phi}_t^\tau \widehat{\Phi}_t) x_t^\tau d\overline{w}_t \\ &\qquad -2x_t^\tau x_t \widehat{\Phi}_t^\tau \left(\mathrm{Diag}\widehat{\Phi}_t - \widehat{\Phi}_t\widehat{\Phi}_t^\tau\right) H_t^\tau d\overline{w}_t. \end{aligned}$$

Taking expectations of both sides, and noticing $0 < \|\widehat{\Phi}_t\| \le 1$, $(1 - \widehat{\Phi}_t^\tau \widehat{\Phi}_t) x_t^\tau x_t \ge 0$, and $4ab \le 4\eta^{-1}a^2 + \eta b^2$ (for all $a, b \ge 0, \eta > 0$) we get that for any fixed constant $\eta > 0$

$$\begin{aligned} &E\int_0^T \|x_t\|^2 \mathrm{Tr}\left[\left(\mathrm{Diag}\widehat{\Phi}_t - \widehat{\Phi}_t\widehat{\Phi}_t^\tau\right) H_t^\tau H_t \left(\mathrm{Diag}\widehat{\Phi}_t - \widehat{\Phi}_t\widehat{\Phi}_t^\tau\right)\right] dt \\ &\quad \le E\|x_0\|^2 + 2\|\Pi\| E\int_0^T \|x_t\|^2 dt + 2E\int_0^T |x_t^\tau H_t \widehat{\Phi}_t| dt + NT \\ &\qquad +4E\int_0^T \left\|\left(\mathrm{Diag}\widehat{\Phi}_t - \widehat{\Phi}_t\widehat{\Phi}_t^\tau\right) H_t^\tau x_t\right\| dt \\ &\quad \le E\|x_0\|^2 + (\eta + 2\|\Pi\|)E\int_0^T \|x_t\|^2 dt \\ &\qquad +2E\int_0^T |x_t^\tau H_t \widehat{\Phi}_t| dt + NT \\ &\qquad +4\eta^{-1} E\int_0^T \mathrm{Tr}\left[\left(\mathrm{Diag}\widehat{\Phi}_t - \widehat{\Phi}_t\widehat{\Phi}_t^\tau\right) H_t^\tau H_t \left(\mathrm{Diag}\widehat{\Phi}_t - \widehat{\Phi}_t\widehat{\Phi}_t^\tau\right)\right] dt, \end{aligned}$$

which, together with (2.14), leads to

$$E\int_0^T \|x_t\|^2 \mathrm{Tr}\left[\left(\mathrm{Diag}\widehat{\Phi}_t - \widehat{\Phi}_t\widehat{\Phi}_t^\tau\right) H_t^\tau H_t \left(\mathrm{Diag}\widehat{\Phi}_t - \widehat{\Phi}_t\widehat{\Phi}_t^\tau\right)\right] dt$$
$$\leq E\|x_0\|^2 + (\eta + 2\|\Pi\|)E\int_0^T \|x_t\|^2 dt + 2E\int_0^T |x_t^\tau H_t \widehat{\Phi}_t| dt$$
$$+4\eta^{-1}(1 + 4\|\Pi\|T) + NT, \quad \forall\eta > 0,$$

i.e., (2.15) holds. □

3. Quadratic index-based adaptive control. The following lemma is to be found in Caines and Nassiri-Toussi (1991).

LEMMA 3.1. *Let the Markov process X_t satisfy the following regular Ito stochastic differential equation:*

$$dX_t = b_t(X_t)dt + G_t(X_t)dw_t. \tag{3.1}$$

Furthermore, assume that there exist a $C^1(\mathbb{R}^+) \times C^2(\mathbb{R}^n)$ nonnegative function $V_{\cdot}(\cdot)$, a positive real number α_0, and a nonnegative function k_t, such that

$$\frac{\partial V_t(x)}{\partial t} + \mathcal{A}V_t(x) \leq -\alpha_0\|x\|^2 + k_t, \quad \forall x \in \mathbb{R}^n, \quad \forall t \geq 0,$$

where $\mathcal{A}$ is the infinitesimal generator of (3.1).

Then, if

$$\lim\ \mathrm{sup}_{t\to\infty}\frac{1}{t}E\int_0^t k_s ds < \infty \quad \text{and} \quad E[V_0(X_0)] < \infty,$$

$$\limsup_{t\to\infty}\frac{1}{t}E\int_0^t \|X_s\|^2 ds \leq \limsup_{t\to\infty}\frac{1}{\alpha_0 t}E\int_0^t k_s ds < \infty. \tag{3.2}$$

Proof. By (3.1) and Ito's formula, we know that $dV_t(X_t)$ satisfies the following equality:

$$dV_t(X_t) = \ \frac{\partial V_t(x)}{\partial t} + \mathcal{A}V_t(x)\Big) dt + \frac{\partial V_t(x)}{\partial x}G_t(X_t)dw_t.$$

With the assumptions on $V_t(X_t)$, this results in

$$V_t(X_t) \leq V_0(X_0) - \alpha_0\int_0^t \|X_s\|^2 ds + \int_0^t k_s ds + \int_0^t \frac{\partial V_s(x)}{\partial x}G_s(X_s)dw_s.$$

Taking the expectation of both sides of this inequality we get

$$E[V_t(X_t)] - E[V_0(X_0)] \leq -\alpha_0 E\int_0^t \|X_s\|^2 ds + E\int_0^t k_s ds.$$

This, combined with the positiveness of V_t, gives the desired result (3.2). □

It is well known that if (A_α, B_α) is controllable and (A_α, C) is observable (with $C^\tau C = Q$), then for all $S > 0$ the following Riccati equation has a unique, positive definite solution P_α:

$$P_\alpha A_\alpha + A_\alpha^\tau P_\alpha - P_\alpha B_\alpha S^{-1} B_\alpha^\tau P_\alpha + Q = 0. \tag{3.3}$$

LEMMA 3.2. *Suppose that (A_α, B_α) is controllable and (A_α, C) is observable (with $C^\tau C = Q$). If A_α and B_α are continuous or i-times differentiable with respect to α in an interval $[\alpha_*, \alpha^*]$, then so is the solution P_α.*

Proof. From Martensson (1971) we see that the solution P_α can actually be expressed in the following form:

$$P_\alpha = Y_\alpha X_\alpha^{-1}, \quad \text{for all } \ \alpha \in [\alpha_*, \alpha^*]$$

where the columns of the composed matrix $[\begin{smallmatrix} X_\alpha \\ Y_\alpha \end{smallmatrix}]$ are eigenvectors or generalized eigenvectors of matrix

$$\Gamma_\alpha \triangleq \begin{bmatrix} A_\alpha & -B_\alpha S^{-1} B_\alpha^\tau \\ -Q & -A_\alpha^\tau \end{bmatrix}.$$

Now, the eigenvectors (respectively, generalized eigenvectors) of a matrix are (respectively, may be chosen to be) continuous functions of its elements. Thus, if A_α and B_α are continuous with respect to α, then Y_α, X_α, and hence P_α are continuous with respect to α.

Similarly, if A_α and B_α are i-times differentiable with respect to α, then P_α is i-times differentiable with respect to α. □

We define the adaptive control law via the certainty equivalence principle and the following quadratic index:

$$\lim_{t \to \infty} \frac{1}{t} \int_0^t (x_s^\tau Q x_s + u_s^\tau S u_s) ds.$$

Hence, we will use the following adaptive control law:

$$u_t = -S^{-1} B_{\widehat{\Phi}_t}^\tau P_{\widehat{\Phi}_t} x_t, \tag{3.4}$$

where $\widehat{\Phi}_t$ is a solution of (2.4), and $P_{\widehat{\Phi}_t}$ is a solution of (3.3) with A_α and B_α replaced by $A_{\widehat{\Phi}_t}$ and $B_{\widehat{\Phi}_t}$, respectively.

Let $\Pi(i)$ denote the ith row of matrix Π and

$$\varepsilon = \sup_{\widehat{\Phi}_t \in \mathcal{D}} \max_{i,j=1,\ldots,N} \left\{ \left\| \frac{\partial^2 \left(P_{\widehat{\Phi}_t}\right)}{\partial \widehat{\Phi}_t(i) \partial \widehat{\Phi}_t(j)} \right\| \right\}, \tag{3.5}$$

$$c_1 = \sup_{\widehat{\Phi}_t \in \mathcal{D}} \left\{ \|A_{\widehat{\Phi}_t} - B_{\widehat{\Phi}_t} S^{-1} B_{\widehat{\Phi}_t}^\tau P_{\widehat{\Phi}_t}\| \right\}, \tag{3.6}$$

$$c_2 = \sup_{\widehat{\Phi}_t \in \mathcal{D}} \max_{i=1,\ldots,N} \left\{ \left\| \frac{\partial \left(P_{\widehat{\Phi}_t}\right)}{\partial \widehat{\Phi}_t(i)} \right\| \right\}, \tag{3.7}$$

where

$$\mathcal{D} \triangleq \left\{ \widehat{\Phi}_t : \ 0 \le \widehat{\Phi}_t(i) \le 1, \ \ i = 1, \ldots, N \ \text{ with } \ \sum_{i=1}^N \widehat{\Phi}_t(i) = 1 \right\}.$$

In other words, $\widehat{\Phi}_t$ ranges over the closed unit simplex $\mathcal{D}$ in $\mathbb{R}^N$.

The closed-loop system referred to in the statement of the main result below is given by the system and parameter process equations (1.1), (1.2), the filter equations (2.4), (2.5), and the Riccati and feedback equations (3.3), (3.4).

THEOREM 3.1. *Suppose that* $(A_{\widehat{\Phi}_t}, B_{\widehat{\Phi}_t})$ *is controllable for all* $\widehat{\Phi}_t$ *in the closed unit simplex* $\mathcal{D}$ *and that for some appropriate positive matrix* S*, the unique solution* $P_{\widehat{\Phi}_t}$ *to* (3.3) *combined with the matrix* Π *in* (1.2) *satisfies*

$$\|\Pi\|\varepsilon + \varepsilon c_1 < \frac{1}{4N}, \qquad c_2 \sum_{i=1}^{N} \|\Pi(i)\| < \frac{1}{2}. \tag{3.8}$$

Then, under the adaptive control law (3.4) *with* $\widehat{\Phi}_t$ *a solution of* (2.4)*, the closed-loop system has a unique strong solution* $\{x_t,\ \widehat{\Phi}_t,\ t \geq 0\}$*, and is stabilized in the following average sense:*

$$\limsup_{T\to\infty} \frac{1}{T} E \int_0^T (\|x_t\|^2 + \|u_t\|^2)dt < \infty.$$

To prove Theorem 3.1, we introduce some notation following Guo (1993). For any fixed positive number K, denote by $\mathcal{C}_K^{n+N}$ the space of $\mathbb{R}^{n+N}$-valued continuous functions on the interval $[0, K]$. When $g = \{g_t\}_{0\leq t\leq K}$ is a $\mathcal{C}_K^{n+N}$ process, we set $\|g\|_{[0,K]} = \max_{0\leq t\leq K} \|g_t\|$.

Proof. First of all, we show that the closed-loop system has a solution $\{x_t,\ \widehat{\Phi}_t,\ t \geq 0\}$. Let

(3.9)

$$z_t = \begin{bmatrix} x_t \\ \widehat{\Phi}_t \end{bmatrix},$$

(3.10)

$$a(z_t) = \begin{bmatrix} (A(\theta_t) - B(\theta_t)S^{-1}B^\tau_{\widehat{\Phi}_t} P_{\widehat{\Phi}_t})x_t \\ \Pi\widehat{\Phi}_t + \left(\mathrm{Diag}\widehat{\Phi}_t - \widehat{\Phi}_t\widehat{\Phi}_t^\tau\right) H_t^\tau \left[(A(\theta_t) - B(\theta_t)S^{-1}B^\tau_{\widehat{\Phi}_t} P_{\widehat{\Phi}_t})x_t - H_t\widehat{\Phi}_t\right] \end{bmatrix},$$

(3.11)

$$b(z_t) = \begin{bmatrix} 1 \\ \left(\mathrm{Diag}\widehat{\Phi}_t - \widehat{\Phi}_t\widehat{\Phi}_t^\tau\right) H_t^\tau \end{bmatrix}.$$

Then from (1.1), (2.4), and (3.4) the closed-loop system can be rewritten in the following form:

$$dz_t = a(z_t)dt + b(z_t)dw_t. \tag{3.12}$$

Obviously, it follows from (2.12) that $A_{\widehat{\Phi}_t}$ and $B_{\widehat{\Phi}_t}$ are differentiable with respect to each component of $\widehat{\Phi}_t$. This combined with Lemma 3.2 implies that $P_{\widehat{\Phi}_t}$ is continuous and bounded on $\mathcal{D}$, since $\mathcal{D}$ is a compact set. Thus, by (3.9)–(3.11), we can conclude that for any fixed $\Delta > 0$, there exists a constant $L^{(\Delta)}$ such that

$$\left[\|a(g_t) - a(h_t)\|^2 + \|b(g_t) - b(h_t)\|^2\right] \mathbb{1}_{\{\|g\|_{[0,K]}\leq\Delta,\ \|h\|_{[0,K]}\leq\Delta\}} \leq L^{(\Delta)}\|g_t - h_t\|^2$$

and

$$\left[\|a(g_t)\|^2 + \|b(g_t)\|^2\right] \mathbb{1}_{\{\|g\|_{[0,K]}\leq\Delta\}} \leq L^{(\Delta)}(1 + \|g_t\|^2),$$

where $\mathbb{1}_{\{\cdot\}}$ is the indicator function of the set $\{\cdot\}$.

Therefore, by Lemma 2.2 of Guo (1993) we know that there is an $\mathcal{F}_t$-time $\sigma_K > 0$ such that (3.12) has a unique strong solution $z_t(\omega)$ on $\{\omega,\ t:\ t < \sigma_K(\omega)\}$, and

$$\sup_{t<\sigma_K(\omega)} \|z_t(\omega)\| = \infty \quad \text{a.s. on } \mathcal{G} \overset{\triangle}{=} \{\omega:\ \sigma_K(\omega) < K\}. \tag{3.13}$$

We now prove $\sigma_K(\omega) = K$ a.s., i.e., $P(\mathcal{G}) = 0$.

Substituting (3.4) into (1.1) results in

$$dx_t = [A(\theta_t) - B(\theta_t)S^{-1}B^\tau_{\widehat{\Phi}_t} P_{\widehat{\Phi}_t}]x_t dt + dw_t,$$

which together with Ito's formula leads to

$$\begin{aligned}\|x_t\|^2 = &\int_0^t x_s^\tau \left([A(\theta_s) - B(\theta_s)S^{-1}B^\tau_{\widehat{\Phi}_s} P_{\widehat{\Phi}_s}]^\tau + [A(\theta_s) - B(\theta_s)S^{-1}B^\tau_{\widehat{\Phi}_s} P_{\widehat{\Phi}_s}]\right) x_s ds\\ &+\|x_0\|^2 + 2\int_0^t x_s^\tau dw_s + nt.\end{aligned} \tag{3.14}$$

Notice that, by Lemma 3.2, $\alpha_1 \overset{\triangle}{=} 2\sup_{s\geq 0,\widehat{\Phi}_s\in\mathcal{D}} \|A(\theta_s) - B(\theta_s)S^{-1}B^\tau_{\widehat{\Phi}_s} P_{\widehat{\Phi}_s}\| < \infty$ a.s., and that by Lemma 4 of Christopeit (1986) there is a random constant $0 < \alpha_2(\omega) < \infty$ a.s. such that

$$2\left|\int_0^t x_s^\tau dw_s\right| \leq \alpha_2(\omega)\int_0^t \|x_s\|^2 ds + \alpha_2(\omega), \quad \forall t \geq 0.$$

By (3.14) we get

$$\|x_t\|^2 \leq (\|x_0\|^2 + nt + \alpha_2(\omega)) + (\alpha_1 + \alpha_2(\omega))\int_0^t \|x_s\|^2 ds.$$

Thus, by the Bellman–Grownwall lemma (see e.g., Desoer and Vidyasagar (1975)) we have

(3.15)

$$\begin{aligned}\|x_t\|^2 &\leq \|x_0\|^2 + nt + \alpha_2(\omega) + (\alpha_1 + \alpha_2(\omega))\int_0^t (\|x_0\|^2 + \lambda + \alpha_2(\omega))e^{(\alpha_1+\alpha_2(\omega))(t-\lambda)}d\lambda\\ &\leq (\|x_0\|^2 + nt + \alpha_2(\omega))e^{(\alpha_1+\alpha_2(\omega))t}, \quad \forall t \geq 0.\end{aligned}$$

If $P(\mathcal{G}) > 0$, then by (3.15) and the fact that $\|\widehat{\Phi}_t\| \leq 1$ we see that

$$\begin{aligned}\sup_{0\leq t<\sigma_K(\omega)} \|z_t(\omega)\|^2 &\leq 2 + 2\sup_{0\leq t<\sigma_K(\omega)} \|x_t(\omega)\|^2\\ &\leq (\|x_0\|^2 + n\sigma_K(\omega) + \alpha_2(\omega))e^{(\alpha_1+\alpha_2(\omega))\sigma_K(\omega)} < \infty \quad \text{a.s. on } \mathcal{G},\end{aligned}$$

contradicting (3.13) and $P(\mathcal{G}) > 0$.

Noting that K can be any positive number, we see that the closed-loop system (3.12) has a unique strong solution $z_t(\omega)$ on any finite time interval.

We now prove the stability of the closed-loop system.

Let $\overline{A}_{\widehat{\Phi}_t} = A_{\widehat{\Phi}_t} - B_{\widehat{\Phi}_t} S^{-1} B^\tau_{\widehat{\Phi}_t} P_{\widehat{\Phi}_t}$ and $\overline{A}_{\widehat{\Phi}_t}(i) = A_i - B_i S^{-1} B^\tau_{\widehat{\Phi}_t} P_{\widehat{\Phi}_t}$. Then from (2.5) and (2.12) it follows that

$$dx_t = H_t \widehat{\Phi}_t dt + d\overline{w}_t = \overline{A}_{\widehat{\Phi}_t} x_t dt + d\overline{w}_t. \tag{3.16}$$

Applying the general Ito formula to $V(x_t) = x_t^\tau P_{\widehat{\Phi}_t} x_t$, and employing (3.3), (2.4), and (2.5), we have the following inequalities (see, e.g., Caines and Nassiri-Toussi (1991)):

$$\begin{aligned}
\mathcal{A}V(x_t) = & -x_t^\tau x_t - x_t^\tau P_{\widehat{\Phi}_t} B_{\widehat{\Phi}_t} S^{-1} B^\tau_{\widehat{\Phi}_t} P_{\widehat{\Phi}_t} x_t \\
& + x_t^\tau \sum_{i=1}^{N} \Pi(i) \widehat{\Phi}_t \frac{\partial \left(P_{\widehat{\Phi}_t}\right)}{\partial \widehat{\Phi}_t(i)} x_t + \mathrm{Tr} P_{\widehat{\Phi}_t} \\
& + x_t^\tau \sum_{i=1}^{N} \widehat{\Phi}_t(i) \frac{\partial \left(P_{\widehat{\Phi}_t}\right)}{\partial \widehat{\Phi}_t(i)} (\overline{A}_{\widehat{\Phi}_t} - \overline{A}_{\widehat{\Phi}_t}(i)) x_t \\
& + x_t^\tau \sum_{i=1}^{N} \widehat{\Phi}_t(i) (\overline{A}_{\widehat{\Phi}_t} - \overline{A}_{\widehat{\Phi}_t}(i))^\tau \frac{\partial \left(P_{\widehat{\Phi}_t}\right)}{\partial \widehat{\Phi}_t(i)} x_t \\
& + \frac{1}{2} \sum_{i=1}^{N} \sum_{j=1}^{N} \widehat{\Phi}_t(i) \widehat{\Phi}_t(j) x_t^\tau \frac{\partial^2 \left(P_{\widehat{\Phi}_t}\right)}{\partial \widehat{\Phi}_t(i) \partial \widehat{\Phi}_t(j)} x_t \\
& \cdot x_t^\tau (\overline{A}_{\widehat{\Phi}_t} - \overline{A}_{\widehat{\Phi}_t}(i))^\tau (\overline{A}_{\widehat{\Phi}_t} - \overline{A}_{\widehat{\Phi}_t}(i)) x_t \\
\leq & -x_t^\tau x_t + c_2 \sum_{i=1}^{N} \|\Pi(i)\| \|x_t\|^2 + \mathrm{Tr} P_{\widehat{\Phi}_t} \\
& + 2c_2 \|x_t\| \sum_{i=1}^{N} \widehat{\Phi}_t(i) \|(\overline{A}_{\widehat{\Phi}_t} - \overline{A}_{\widehat{\Phi}_t}(i)) x_t\| \\
& + \frac{\varepsilon}{2} \|x_t\|^2 \left[\sum_{i=1}^{N} \widehat{\Phi}_t(i) \|(\overline{A}_{\widehat{\Phi}_t} - \overline{A}_{\widehat{\Phi}_t}(i)) x_t\| \right]^2 \\
\leq & -\left(\frac{3}{4} - c_2 \sum_{i=1}^{N} \|\Pi(i)\| \right) \|x_t\|^2 + \mathrm{Tr} P_{\widehat{\Phi}_t} \\
& + 4Nc_2^2 \sum_{i=1}^{N} [\widehat{\Phi}_t(i)]^2 \|(\overline{A}_{\widehat{\Phi}_t} - \overline{A}_{\widehat{\Phi}_t}(i)) x_t\|^2 \\
& + \frac{N\varepsilon}{2} \|x_t\|^2 \sum_{i=1}^{N} [\widehat{\Phi}_t(i)]^2 \|(\overline{A}_{\widehat{\Phi}_t} - \overline{A}_{\widehat{\Phi}_t}(i)) x_t\|^2,
\end{aligned}$$

where we have used the sum of squares bound $2ab \leq 1/4a^2 + 4b^2$ and a standard sum of squares bound to obtain the last inequality above and where ε and c_2 are given by (3.5) and (3.7), respectively.

By the second inequality of condition (3.8), we see

$$\beta \triangleq \frac{3}{4} - c_2 \sum_{i=1}^{N} \|\Pi(i)\| > \frac{1}{4} > 0,$$

and hence, by Lemma 3.1, we get

$$\begin{aligned}
&\limsup_{T\to\infty}\frac{1}{T}E\int_0^T \|x_t\|^2 dt\\
&\le \limsup_{T\to\infty}\frac{1}{\beta T}E\int_0^T \mathrm{Tr}P_{\widehat{\Phi}_t}dt\\
&+\limsup_{T\to\infty}\frac{4Nc_2^2}{\beta T}E\int_0^T\sum_{i=1}^N[\widehat{\Phi}_t(i)]^2\|(\overline{A}_{\widehat{\Phi}_t}-\overline{A}_{\widehat{\Phi}_t}(i))x_t\|^2dt\\
&+\limsup_{T\to\infty}\frac{N\varepsilon}{2\beta T}E\int_0^T\|x_t\|^2\sum_{i=1}^N[\widehat{\Phi}_t(i)]^2\|(\overline{A}_{\widehat{\Phi}_t}-\overline{A}_{\widehat{\Phi}_t}(i))x_t\|^2dt.
\end{aligned}\tag{3.17}$$

By (3.4), i.e., $u_t = -S^{-1}B^\tau_{\widehat{\Phi}_t}P_{\widehat{\Phi}_t}x_t$, we have

$$[\overline{A}_{\widehat{\Phi}_t}-\overline{A}_{\widehat{\Phi}_t}(i)]x_t = A_{\widehat{\Phi}_t}x_t + B_{\widehat{\Phi}_t}u_t - A_ix_t - B_iu_t.$$

Thus, from (3.17) and Corollaries 2.1 and 2.2 it follows that for any fixed $\eta > 0$,

$$\begin{aligned}
&\limsup_{T\to\infty}\frac{1}{T}E\int_0^T \|x_t\|^2 dt\\
&\le \limsup_{T\to\infty}\frac{1}{\beta T}E\int_0^T \mathrm{Tr}P_{\widehat{\Phi}_t}dt\\
&+\left\{16N\|\Pi\|\beta^{-1}c_2^2+N\varepsilon(16\|\Pi\|\eta^{-1}+N)(2\beta)^{-1}\right\}\\
&+\limsup_{T\to\infty}\frac{N(\eta+2\|\Pi\|)\varepsilon}{2\beta T}E\int_0^T\|x_t\|^2dt\\
&+\limsup_{T\to\infty}\frac{N\varepsilon}{\beta T}E\int_0^T|x_t^\tau H_t\widehat{\Phi}_t|dt.
\end{aligned}\tag{3.18}$$

It is easy to see that

$$|x_t^\tau H_t\widehat{\Phi}_t| = |x_t^\tau\overline{A}_{\widehat{\Phi}_t}x_t| \le c_1\|x_t\|^2,\tag{3.19}$$

where c_1 is defined in (3.6).

Substituting (3.19) into (3.18) we get that for all $\eta > 0$,

$$\begin{aligned}
&\limsup_{T\to\infty}\frac{1}{T}E\int_0^T \|x_t\|^2 dt\\
&\le \limsup_{T\to\infty}\frac{1}{\beta T}E\int_0^T \mathrm{Tr}P_{\widehat{\Phi}_t}dt\\
&+\left\{16N\|\Pi\|\beta^{-1}c_2^2+N\varepsilon(16\|\Pi\|\eta^{-1}+N)(2\beta)^{-1}\right\}\\
&+\limsup_{T\to\infty}\frac{N(\eta+2\|\Pi\|)\varepsilon+2N\varepsilon c_1}{2\beta T}E\int_0^T\|x_t\|^2dt.
\end{aligned}\tag{3.20}$$

Notice that (3.8) implies

$$N\beta^{-1}(\|\Pi\|\varepsilon+\varepsilon c_1) < 1.$$

So we can fix a constant $\eta > 0$ at such a value that

$$\frac{N(\eta + 2\|\Pi\|)\varepsilon + 2N\varepsilon c_1}{2\beta} < 1. \tag{3.21}$$

Recalling that $P_{\widehat{\Phi}_t}$ is bounded on $\mathcal{D}$, we get

$$\limsup_{T\to\infty} \frac{1}{T} E \int_0^T \operatorname{Tr} P_{\widehat{\Phi}_t}\, dt < \infty,$$

and hence, by (3.21) and (3.20) we have

$$\limsup_{T\to\infty} \frac{1}{T} E \int_0^T \|x_t\|^2 dt < \infty,$$

which together with (3.4) results in

$$\limsup_{T\to\infty} \frac{1}{T} E \int_0^T \|u_t\|^2 dt < \infty.$$

Therefore, Theorem 3.1 is true. □

4. An example. In this section, we present an example to demonstrate that the conditions of Theorem 3.1 are verifiable in certain nontrivial cases.

EXAMPLE 4.1. If system (1.1) is such that $n = 2$, $m = 1$, $B_1 = B_2 = \cdots = B_N = \left[\begin{smallmatrix} 0 \\ b \end{smallmatrix}\right]$ with

$$b \neq 0 \quad \text{and} \quad A_i = \begin{bmatrix} 0 & 1 \\ 0 & -a_i \end{bmatrix}$$

for a_i distinct, $i = 1, \ldots, N$, then (i) $(A_{\widehat{\Phi}_t}, B_{\widehat{\Phi}_t})$ is controllable for all $\widehat{\Phi}_t$ in the closed unit simplex, and (ii) condition (3.8) and the conclusion of Theorem 3.1 are true when the parameter S in the control Riccati equation (4.2) for $P_{\widehat{\Phi}_t}$ is sufficiently small.

Proof. The truth of (i) is evident. Concerning (ii) set

$$a_{\widehat{\Phi}_t} = \sum_{i=0}^{N} \widehat{\Phi}_t(i) a_i \quad \text{and} \quad P_{\widehat{\Phi}_t} = \begin{bmatrix} P_{\widehat{\Phi}_t}(1,1) & P_{\widehat{\Phi}_t}(1,2) \\ P_{\widehat{\Phi}_t}(1,2) & P_{\widehat{\Phi}_t}(2,2) \end{bmatrix}. \tag{4.1}$$

Then the algebraic Riccati equation (3.3) becomes

$$\begin{bmatrix} P_{\widehat{\Phi}_t}(1,1) & P_{\widehat{\Phi}_t}(1,2) \\ P_{\widehat{\Phi}_t}(1,2) & P_{\widehat{\Phi}_t}(2,2) \end{bmatrix} \begin{bmatrix} 0 & 1 \\ 0 & -a_{\widehat{\Phi}_t} \end{bmatrix} + \begin{bmatrix} 0 & 0 \\ 1 & -a_{\widehat{\Phi}_t} \end{bmatrix} \begin{bmatrix} P_{\widehat{\Phi}_t}(1,1) & P_{\widehat{\Phi}_t}(1,2) \\ P_{\widehat{\Phi}_t}(1,2) & P_{\widehat{\Phi}_t}(2,2) \end{bmatrix}$$
$$- \begin{bmatrix} P_{\widehat{\Phi}_t}(1,1) & P_{\widehat{\Phi}_t}(1,2) \\ P_{\widehat{\Phi}_t}(1,2) & P_{\widehat{\Phi}_t}(2,2) \end{bmatrix} \begin{bmatrix} 0 & 0 \\ 0 & S^{-1}b^2 \end{bmatrix} \begin{bmatrix} P_{\widehat{\Phi}_t}(1,1) & P_{\widehat{\Phi}_t}(1,2) \\ P_{\widehat{\Phi}_t}(1,2) & P_{\widehat{\Phi}_t}(2,2) \end{bmatrix} + I = 0, \tag{4.2}$$

which is equivalent to

$$\begin{aligned}
0 &= 1 - S^{-1}b^2 P^2_{\widehat{\Phi}_t}(1,2), \\
0 &= P_{\widehat{\Phi}_t}(1,1) - S^{-1}b^2 P_{\widehat{\Phi}_t}(1,2) P_{\widehat{\Phi}_t}(2,2) - a_{\widehat{\Phi}_t} P_{\widehat{\Phi}_t}(1,2), \\
0 &= P^2_{\widehat{\Phi}_t}(2,2) + 2Sb^{-2} a_{\widehat{\Phi}_t} P_{\widehat{\Phi}_t}(2,2) - Sb^{-2}(1 + 2|b|^{-1}\sqrt{S}).
\end{aligned}$$

Solving this set of equations we get

$$P_{\hat{\Phi}_t}(1,1) = |b|^{-1}\sqrt{S}\left[a^2_{\hat{\Phi}_t} + S^{-1}b^2 + 2|b|S^{-1/2}\right]^{1/2}, \tag{4.3}$$

$$P_{\hat{\Phi}_t}(1,2) = |b|^{-1}\sqrt{S}, \tag{4.4}$$

$$P_{\hat{\Phi}_t}(2,2) = Sb^{-2}\left[a^2_{\hat{\Phi}_t} + S^{-1}b^2 + 2|b|S^{-1/2}\right]^{1/2} - Sb^{-2}a_{\hat{\Phi}_t}. \tag{4.5}$$

Hence, when S is small enough,

$$\begin{aligned}\mathrm{Tr}P_{\hat{\Phi}_t} &= P_{\hat{\Phi}_t}(1,1) + P_{\hat{\Phi}_t}(2,2)\\ &= -Sb^{-2}a_{\hat{\Phi}_t} + (|b|^{-1}\sqrt{S} + Sb^{-2})\left[a^2_{\hat{\Phi}_t} + S^{-1}b^2 + 2|b|S^{-1/2}\right]^{1/2}\\ &= O(S),\end{aligned}$$

where $O(S)$ denotes a function of S satisfying $\limsup_{S\to 0}\frac{|O(S)|}{S} < \infty$.

From this it follows that

$$\limsup_{T\to\infty}\frac{1}{T}E\int_0^T \mathrm{Tr}P_{\hat{\Phi}_t}\,dt < \infty.$$

Let $\mu = S^{-1}b^2 + 2|b|S^{-1/2}$ and $\gamma_{\hat{\Phi}_t} = \left[a^2_{\hat{\Phi}_t} + \mu\right]^{1/2}$. Then it is easy to see that

$$\frac{\partial\left(\gamma_{\hat{\Phi}_t}\right)}{\partial\hat{\Phi}_t(i)} = \left[a^2_{\hat{\Phi}_t} + \mu\right]^{-1/2} a_{\hat{\Phi}_t}\frac{\partial\left(a_{\hat{\Phi}_t}\right)}{\partial\hat{\Phi}_t(i)} = \left[a^2_{\hat{\Phi}_t} + \mu\right]^{-1/2} a_{\hat{\Phi}_t}a_i, \tag{4.6}$$

where $i = 1,\dots,N$.

Furthermore,

$$\begin{aligned}\frac{\partial^2\left(\gamma_{\hat{\Phi}_t}\right)}{\partial\hat{\Phi}_t(i)\partial\hat{\Phi}_t(j)} &= \left[a^2_{\hat{\Phi}_t} + \mu\right]^{-1/2} a_ia_j - a^2_{\hat{\Phi}_t}\left[a^2_{\hat{\Phi}_t} + \mu\right]^{-3/2} a_ia_j\\ &= \mu\left[a^2_{\hat{\Phi}_t} + \mu\right]^{-3/2} a_ia_j, \quad i,\, j = 1,\dots,N.\end{aligned} \tag{4.7}$$

From (4.3)–(4.6) it follows that for $i = 1,\dots,$ or N,

$$\frac{\partial\left(P_{\hat{\Phi}_t}\right)}{\partial\hat{\Phi}_t(i)} = \begin{bmatrix}\dfrac{a_ia_{\hat{\Phi}_t}|b|^{-1}S^{1/2}}{\left[a^2_{\hat{\Phi}_t} + S^{-1}b^2 + 2|b|S^{-1/2}\right]^{1/2}} & 0\\ 0 & \dfrac{a_ia_{\hat{\Phi}_t}Sb^{-2}}{\left[a^2_{\hat{\Phi}_t} + S^{-1}b^2 + 2|b|S^{-1/2}\right]^{1/2}} - Sb^{-2}a_i\end{bmatrix},$$

which implies that for S sufficiently small

$$c_2 \equiv c_2(S) \leq c_3S, \tag{4.8}$$

where c_3 is a constant depending on a_i and b only.

Since

$$\frac{\partial^2\left(a_{\widehat{\Phi}_t}\right)}{\partial\widehat{\Phi}_t(i)\partial\widehat{\Phi}_t(j)}=0,$$

(4.3)–(4.5) and (4.7) yield

$$\frac{\partial^2\left(P_{\widehat{\Phi}_t}\right)}{\partial\widehat{\Phi}_t(i)\partial\widehat{\Phi}_t(j)}=\begin{bmatrix}\dfrac{a_ia_j(2+|b|S^{-1/2})}{\left[a^2_{\widehat{\Phi}_t}+S^{-1}b^2+2|b|S^{-1/2}\right]^{3/2}} & 0\\ 0 & \dfrac{a_ia_j(1+2|b|^{-1}S^{1/2})}{\left[a^2_{\widehat{\Phi}_t}+S^{-1}b^2+2|b|S^{-1/2}\right]^{3/2}}\end{bmatrix}.$$

From this we obtain that as $S\to 0$,

$$\left\|\frac{\partial^2\left(P_{\widehat{\Phi}_t}\right)}{\partial\widehat{\Phi}_t(i)\partial\widehat{\Phi}_t(j)}\right\|=|a_ia_j|Sb^{-2}\left(1+O(S^{1/2})\right),$$

which implies that as $S\to 0$,

$$\varepsilon=S\max_{i,j=1,\dots,N}|a_ia_j|b^{-2}\left(1+O(S^{1/2})\right). \tag{4.9}$$

From (4.3)–(4.5) it follows that

$$\begin{bmatrix}0 & 1\\ 0 & a_{\widehat{\Phi}_t}\end{bmatrix}-S^{-1}\begin{bmatrix}0\\ b\end{bmatrix}\begin{bmatrix}0 & b\end{bmatrix}\begin{bmatrix}P_{\widehat{\Phi}_t}(1,1) & P_{\widehat{\Phi}_t}(1,2)\\ P_{\widehat{\Phi}_t}(1,2) & P_{\widehat{\Phi}_t}(2,2)\end{bmatrix}$$

$$=\begin{bmatrix}0 & 1\\ -|b|S^{-1/2} & 2a_{\widehat{\Phi}_t}-\left[a^2_{\widehat{\Phi}_t}+S^{-1}b^2+2|b|S^{-1/2}\right]^{1/2}\end{bmatrix}.$$

Then we get

$$\|A_{\widehat{\Phi}_t}-S^{-1}B_{\widehat{\Phi}_t}B^{\tau}_{\widehat{\Phi}_t}P_{\widehat{\Phi}_t}\|\le 2S^{-1/2}|b|\left(1+O(S^{1/2})\right),$$

which implies that

$$c_1\le 2S^{-1/2}|b|\left(1+O(S^{1/2})\right).$$

From this and (4.8), (4.9) we see that for some sufficiently small S, condition (3.8), and hence the results of Theorem 3.1, are true. □

5. Maximum likelihood-based adaptive control. Intuitively, if $\widehat{\Phi}_t$ is a good estimate of Φ_t, in some sense, then $A_{\widehat{\Phi}_t}$ and $B_{\widehat{\Phi}_t}$ are good estimates of $A(\theta_t)$ and $B(\theta_t)$. Therefore, in the last two sections, we discuss the stabilization problem of the filtered system (2.5):

$$dx_t=A_{\widehat{\Phi}_t}x_tdt+B_{\widehat{\Phi}_t}u_tdt+d\overline{w}_t\quad\text{by (2.1), (2.2), and (2.12),}$$

rather than that of system (1.1).

Let i_t be defined by

$$i_t = \arg \max_{i=1,\ldots,N} \{\widehat{\Phi}_t(i)\}, \quad t \geq 0. \tag{5.1}$$

Again, if $\widehat{\Phi}_t$ is a good estimate of Φ_t, in some sense, then $A(i_t)$ and $B(i_t)$ should also be good estimates of $A(\theta_t)$ and $B(\theta_t)$. In this case, it is natural to ask whether we could find an adaptive stabilization control law for system (1.1) by only discussing the following system:

$$dx_t = A(i_t)x_t dt + B(i_t)u_t dt + d\overline{w}_t\,.$$

This section, as an application of Corollary 2.1, will answer this problem. By using the notion of a maximum likelihood estimate, we present some sufficient conditions for stabilization control of the system (1.1)–(1.2). These sufficient conditions are different from those used in §3, but similar to those introduced in Ezzine and Haddad (1989).

For simplicity of notation, for a matrix A, let

$$\mu(A) = \lambda_{\max}\left(\frac{A + A^\tau}{2}\right).$$

THEOREM 5.1. *Suppose there is a matrix $K(i)$ $(i = 1, \ldots, N)$ such that*

$$\nu \triangleq -\max_{i=1,\ldots,N} \mu\left(A(i) - B(i)K(i)\right) > 0. \tag{5.2}$$

Then, under the adaptive control law $u_t = -K(i_t)x_t$, the closed-loop system has a solution $\{x_t,\, u_t,\, t \geq 0\}$, and the input and output of the closed-loop system are bounded in the following average sense:

$$\sup_{t\geq 0} \frac{1}{t+1} E \int_0^t (\|x_s\|^2 + \|u_s\|^2) ds < \infty. \tag{5.3}$$

Proof. Similar to the argument of Theorem 3.1, we see that the closed-loop system has a solution $\{x_t,\, \widehat{\Phi}_t,\, t \geq 0\}$. So, here we only need prove (5.3).

From (2.5) and (2.12) it follows that

$$\begin{aligned} dx_t &= H_t\widehat{\Phi}_t dt + d\overline{w}_t = A_{\widehat{\Phi}_t} x_t dt + B_{\widehat{\Phi}_t} u_t dt + d\overline{w}_t \\ &= A(i_t)x_t dt + B(i_t)u_t dt \\ &\quad + [A_{\widehat{\Phi}_t} x_t + B_{\widehat{\Phi}_t} u_t - A(i_t)x_t - B(i_t)u_t]dt + d\overline{w}_t, \end{aligned} \tag{5.4}$$

where i_t is given in (5.1)

Substituting $u_t = -K(i_t)x_t$ into (5.4) we get

$$\begin{aligned} dx_t &= [A(i_t) - B(i_t)K(i_t)]x_t dt \\ &\quad + [A_{\widehat{\Phi}_t} x_t + B_{\widehat{\Phi}_t} u_t - A(i_t)x_t - B(i_t)u_t]dt + d\overline{w}_t, \end{aligned} \tag{5.5}$$

which together with Ito's formula and (5.2) implies that for the ν given by (5.2)

$$\|x_t\|^2 = \|x_0\|^2 + \int_0^t x_s^\tau \left([A(i_s) - B(i_s)K(i_s)]^\tau + [A(i_s) - B(i_s)K(i_s)]\right) x_s ds$$

$$
\begin{aligned}
&+t+2\int_0^t x_s^\tau d\overline{w}_s + 2\int_0^t x_s^\tau[A_{\widehat{\Phi}_s}x_s + B_{\widehat{\Phi}_s}u_s - A(i_s)x_s - B(i_s)u_s]ds \\
&\le \|x_0\|^2 - 2\nu\int_0^t \|x_s\|^2 ds + 2\int_0^t x_s^\tau d\overline{w}_s + t \\
&+2\int_0^t x_s^\tau[A_{\widehat{\Phi}_s}x_s + B_{\widehat{\Phi}_s}u_s - A(i_s)x_s - B(i_s)u_s]ds. \qquad (5.6)
\end{aligned}
$$

Notice that

$$
\begin{aligned}
&2\int_0^t x_s^\tau[A_{\widehat{\Phi}_s}x_s + B_{\widehat{\Phi}_s}u_s - A(i_s)x_s - B(i_s)u_s]ds \\
&\quad\le \nu\int_0^t \|x_s\|^2 ds + \nu^{-1}\int_0^t \|A_{\widehat{\Phi}_s}x_s + B_{\widehat{\Phi}_s}u_s - A(i_s)x_s - B(i_s)u_s\|^2 ds;
\end{aligned}
$$

by (5.6) we get

$$
\begin{aligned}
\|x_t\|^2 \le \|x_0\|^2 - \nu\int_0^t \|x_s\|^2 ds + 2\int_0^t x_s^\tau d\overline{w}_s + t \\
+\nu^{-1}\int_0^t \|A_{\widehat{\Phi}_s}x_s + B_{\widehat{\Phi}_s}u_s - A(i_s)x_s - B(i_s)u_s\|^2 ds,
\end{aligned}
$$

which implies

$$
\begin{aligned}
E\int_0^t \|x_s\|^2 ds \le \nu^{-2}E\int_0^t \|A_{\widehat{\Phi}_s}x_s + B_{\widehat{\Phi}_s}u_s - A(i_s)x_s - B(i_s)u_s\|^2 ds \\
+\nu^{-1}E\|x_0\|^2 + \nu^{-1}t. \qquad (5.7)
\end{aligned}
$$

By (2.1) we see that $\widehat{\Phi}_t(i) \ge 0$ for $i = 1, \dots, N$ and $t \ge 0$; further, since

$$\sum_{i=1}^N \widehat{\Phi}_t(i) = 1,$$

we have $\widehat{\Phi}_t(i_t) \ge \frac{1}{N}$. Thus, by Corollary 2.1 we get

(5.8)

$$
\begin{aligned}
&E\int_0^t \|A_{\widehat{\Phi}_s}x_s + B_{\widehat{\Phi}_s}u_s - A(i_s)x_s - B(i_s)u_s\|^2 ds \\
&\le N^2E\int_0^t \|\widehat{\Phi}_s(i_s)]^2[A_{\widehat{\Phi}_s}x_s + B_{\widehat{\Phi}_s}u_s - A(i_s)x_s - B(i_s)u_s\|^2 ds \\
&\le N^2E\int_0^t \sum_{i=1}^N [\widehat{\Phi}_s(i)]^2\|A_{\widehat{\Phi}_s}x_s + B_{\widehat{\Phi}_s}u_s - A(i)x_s - B(i)u_s\|^2 ds \quad (\text{since } i_s \in \{1, \dots, N\}) \\
&\le N^2(2 + 6\|\Pi\|t).
\end{aligned}
$$

Substituting this into (5.7) leads to the desired result, (5.3). □

From the definition (5.1) of i_t and $u_t = -K(i_t)x_t$ it follows that u_t may jump at any time instant t. In order to get a piecewise continuous control u_t, that is, one that has with probability 1 no accumulation points of switching times on the time axis, one can modify the definition (5.1) of i_t as follows:

$$i_t = i'_{\tau_{k-1}}, \quad \forall t \in [\tau_{k-1},\ \tau_k), \quad \forall k = 1,\ 2, \dots, \qquad (5.9)$$

where

$$i'_t = \arg \max_{i=1,\dots,N} \{\widehat{\Phi}_t(i)\}, \quad \forall t \geq 0, \tag{5.10}$$

$$\tau_k = \inf \left\{ t > \tau_{k-1} : \quad \widehat{\Phi}_t(i_{\tau_{k-1}}) \leq (\gamma N)^{-1} \right\} \tag{5.11}$$

with $\tau_0 = 0$, $\gamma > 1$, and $k = 1, 2, \dots$ being positive integers.

Since the trajectories of $\widehat{\Phi}$ are continuous and $\gamma > 1$ it is evident that $K(\cdot)$ and hence u has the required piecewise continuous property.

THEOREM 5.2. *If $\{i_t;\ t \geq 0\}$ and $\{\tau_k;\ k = 1, 2, \dots\}$ are generated from* (5.9)–(5.11) *and $u_t \in \mathcal{F}_t^x$, then $\lim_{k\to\infty} \tau_k = \infty$ a.s. and i_t is piecewise constant a.s. Furthermore, if condition* (5.2) *of Theorem* 5.1 *is true and the adaptive control law is chosen to be $u_t = -K(i_t)x_t$, then u_t is piecewise continuous and the input and output of the closed-loop system are bounded in the average sense* (5.3).

Proof. First, we show $\lim_{k\to\infty} \tau_k = \infty$ a.s. Noticing that

$$\max_{i=1,\dots,N} \{\widehat{\Phi}_t(i)\} \geq N^{-1}$$

and every component of $\widehat{\Phi}_t$ is a continuous function of t, by $\gamma > 1$ we see that $\tau_k > \tau_{k-1}$. Thus, $\lim_{k\to\infty} \tau_k$ exists a.s.

If the sample set $\mathcal{S} \triangleq \{\omega : \lim_{k\to\infty} \tau_k < \infty\}$ had positive probability, i.e., $P(\mathcal{S}) > 0$, then there would exist a deterministic constant $T < \infty$ such that $\mathcal{S}_1 \triangleq \{\omega : \lim_{k\to\infty} \tau_k \leq T\}$ with positive probability, i.e., $P(\mathcal{S}_1) > 0$.

Notice that for any constant $t \geq 0$,

$$\{\omega :\ 0 < \tau_k I_{\mathcal{S}_1} \leq t\} = \{\omega :\ 0 < \tau_k \leq t\} \cap \{\omega :\ I_{\mathcal{S}_1} = 1\} \in \mathcal{F}_t^x,$$

where

$$I_{\mathcal{S}_1} = \begin{cases} 1, & \text{if } \omega \in \mathcal{S}_1, \\ 0, & \text{if } \omega \notin \mathcal{S}_1. \end{cases}$$

By $\|\widehat{\Phi}_{\tau_{k+1}} - \widehat{\Phi}_{\tau_k}\|^2 \geq N^{-2}(1-\gamma^{-1})^2 > 0$, (2.4), and (2.14) we have

$$\begin{aligned}
\infty = \sum_{k=0}^{\infty} N^{-2}(1-\gamma^{-1})^2 P(\mathcal{S}_1) &\leq E I_{\mathcal{S}_1} \sum_{k=0}^{\infty} \|\widehat{\Phi}_{\tau_{k+1}} - \widehat{\Phi}_{\tau_k}\|^2 \\
&\leq 2\|\Pi\|^2 E I_{\mathcal{S}_1} \sum_{k=0}^{\infty} (\tau_{k+1} - \tau_k)^2 + 2 E I_{\mathcal{S}_1} \sum_{k=0}^{\infty} \left(\int_{\tau_k}^{\tau_{k+1}} (\mathrm{Diag}\widehat{\Phi}_s - \widehat{\Phi}_s \widehat{\Phi}_s^\tau) H_s^\tau d\overline{w}_s \right)^2 \\
&\leq 2\|\Pi\|^2 T E I_{\mathcal{S}_1} \sum_{k=0}^{\infty} (\tau_{k+1} - \tau_k) + 2E \sum_{k=0}^{\infty} \int_{\tau_k I_{\mathcal{S}_1}}^{\tau_{k+1} I_{\mathcal{S}_1}} \left\| (\mathrm{Diag}\widehat{\Phi}_s - \widehat{\Phi}_s \widehat{\Phi}_s^\tau) H_s^\tau \right\|^2 ds \\
&\leq 2\|\Pi\|^2 T^2 P(\mathcal{S}_1) + 2E \int_0^T \left\| (\mathrm{Diag}\widehat{\Phi}_s - \widehat{\Phi}_s \widehat{\Phi}_s^\tau) H_s^\tau \right\|^2 ds \\
&\leq 2\|\Pi\|^2 T^2 P(\mathcal{S}_1) + 2(2 + 6\|\Pi\| T) < \infty.
\end{aligned}$$

This contradiction means that $\lim_{k\to\infty} \tau_k = \infty$ a.s. Thus, from $\tau_k > \tau_{k-1}$ and (5.9) it follows that i_t is piecewise constant a.s.

As in Theorem 5.1, with condition (5.2) we can prove that the under-control law $u_t = -K(i_t)x_t$, with i_t given by (5.9)–(5.11), the closed-loop system has a solution

$\{x_t,\ t \geq 0\}$ a.s. and is stabilized in the average sense of (5.3); this is because the only difference between the proofs is due to (5.8), which now becomes

$$E\int_0^t \|A_{\widehat{\Phi}_s} x_s + B_{\widehat{\Phi}_s} u_s - A(i_s)x_s - B(i_s)u_s\|^2 ds \leq (\gamma N)^2(2 + 6\|\Pi\|t),$$

since, in this case, $\widehat{\Phi}_t(i_t) \geq (\gamma N)^{-1}$ for all $t \geq 0$.

Noticing that $\lim_{k\to\infty} \tau_k = \infty$ a.s. and that i_t is piecewise constant a.s., we see that the control $u_t = -K(i_t)x_t$ is almost surely defined for all $t \geq 0$ and is a piecewise continuous function of t. □

Remark 5.1. Although it is hard to say whether or not condition (5.2) is true in general cases, there exist specific situations where it is readily verified; for instance, (i) the case where $A(i)$ and $B(i)$ are scalar and $(A(i), B(i))$ is stabilizable for every $i = 1, \ldots, N$, and (ii) that where $B(i)$ is invertible for $i = 1, \ldots, N$, and there exists $K(i)$ such that (5.2) holds.

In fact, for case (i), $K(i)$ can be chosen as

$$K(i) = \begin{cases} [B(i)]^{-1}[1 + A(i)], & \text{if } B(i) \neq 0, \\ 0, & \text{if } B(i) = 0, \end{cases}$$

and the constant ν in (5.2) may be taken equal to the following positive quantity:

$$-\max\{\nu_i, \quad i = 1, \ldots, N\},$$

where

$$\nu_i = \begin{cases} -1, & \text{if } B(i) \neq 0, \\ A(i), & \text{if } B(i) = 0. \end{cases}$$

For case (ii), $K(i)$ can be chosen as $K(i) = [B(i)]^{-1}[I + A(i)]$, which results in $\nu = 1$.

Remark 5.2. We now revisit the example given by Dufour and Bertrand (1993). In (1.1), they set $n = 2$, $m = 1$,

$$B_1 = \begin{bmatrix} 0 \\ 1 \end{bmatrix}, B_2 = \begin{bmatrix} 0 \\ -1 \end{bmatrix}, A_1 = \begin{bmatrix} -1 & -1 \\ 0 & 2 \end{bmatrix} \quad \text{and} \quad A_2 = \begin{bmatrix} -1 & 1 \\ 0 & -1 \end{bmatrix}.$$

In this case the conditions of Theorem 3.1 above do not hold, but the conditions of the theorem of Dufour and Bertrand are valid.

However, for this example, the adaptive control law described in Theorem 5.1 or 5.2 is applicable, and can stabilize the closed-loop system. This is because for $K(1) = [0,\ 4]$ and $K(2) = [0,\ -1]$, we get $\nu = \frac{3-\sqrt{2}}{2} > 0$ by a straightforward manipulation. This implies that condition (5.2), and hence the conclusion of Theorems 5.1 and 5.2, are true.

PERIODIC STABILITY OF NONLINEAR FLEXIBLE SYSTEMS WITH DAMPING*

KOICHIRO NAITO†

Abstract. We study periodic stability of solutions of nonlinear elastic systems with damping under periodic perturbations. Investigating the sufficient conditions for the stability, we find some inequality relations between the system parameters of its linear term and those of its nonlinear term.

Key words. stability, periodic perturbation, nonlinear beam equation, damping

AMS subject classifications. 35B10, 73D35, 73K05

1. Introduction.

Let Ω be a bounded domain in a finite-dimensional Euclidean space. We consider the class of flexible systems that can be described by the following second-order damped evolution equation in $X := L^2(\Omega)$ with a nonlinear forcing term under a periodic perturbation:

$$\frac{d^2u(t)}{dt^2} + 2\alpha A\frac{du(t)}{dt} + Au(t) = F(u(t)) + w(t), \quad t > 0, \tag{1.1}$$

$$u(0) = u_0, \quad u_t(0) = u_1, \quad w(t+T) = w(t). \tag{1.2}$$

We assume that A is a self-adjoint positive definite operator with dense domain $D(A)$ in $L^2(\Omega)$, and that A^{-1} exists and is compact. It is well known that there exist eigenvalues λ_i and corresponding eigenfunctions $\varphi_{i,j}(x)$ of the operator A satisfying the following conditions:

$$\begin{aligned}&0 < \lambda_1 < \lambda_2 < \cdots < \lambda_i < \cdots, \quad \lim_{i\to\infty} \lambda_i = \infty,\\ &A\varphi_{ij} = \lambda_i\varphi_{ij}, \quad j = 1, \ldots, m_i, \quad i = 1, 2, \ldots,\\ &\{\varphi_{ij}(\cdot)\} \text{ forms a complete orthonormal system in } L^2(\Omega).\end{aligned}$$

For each constant $0 \le \sigma \le 1$, the domain $D(A^\sigma)$ of the fractional power A^σ, denoted by X_σ, is topologized by the norm

$$|x|_\sigma^2 := |A^\sigma x|_0^2 = \sum_{i=1}^{\infty}\sum_{j=1}^{m_i} \lambda_i^{2\sigma}|(x, \varphi_{ij})|^2, \quad x \in X_\sigma, \tag{1.3}$$

where $|\cdot|_0$ denotes the norm of X. We also assume that the perturbation function $w(t) : R^+ \to X$ is locally Hölder continuous and uniformly bounded and we denote its usual supremum norm by

$$|w|_\infty := \sup\{|w(t)|_X : t \in R^+\}.$$

We consider the following conditions on the nonlinear function F for a given fixed constant $\beta : 0 < \beta < 1$. F is locally Lipschitz continuous from X_β to X and there exists a constant $k(c) > 0$ such that

$$|Fx - Fy|_0 \le k(c)|x - y|_\beta \quad \text{for } |x|_\beta, |y|_\beta \le c. \tag{1.4}$$

† Department of Mathematics, Faculty of Engineering, Kumamoto University, Kurokami 2-39-1, Kumamoto, 860 Japan (knaito@gpo.kumamoto-u.ac.jp).

There exists a positive constant K_0 such that

$$|F(x)|_0 \le K_0(1+|x|_\beta), \quad x \in X_\beta. \tag{1.5}$$

The formulation (1.1) includes vibrations in mechanically flexible systems, e.g., flexible arms of industrial robots or flexible structures such as antennas of spacecrafts (cf. [1], [10]–[12] in linear systems: $F \equiv 0$). In this paper we treat the case with nonlinear forcing, which is determined not only by the displacement $u(t,x)$, but also by the bending force $u_{xx}(t,x)$. Our main objective is to show sufficient conditions for periodicity and stability of solutions under periodic perturbations $w(t)$. We introduce some inequality relations between system parameters, the eigenvalues of the linear term, and the growth rate or the (locally) Lipschitz constant of the nonlinear term. While it should be considered that the first eigenvalue of the linear operator A essentially determines these relations, we find that the eigenvalues λ_h, λ_{h+1} which satisfy

$$0 < \lambda_1 < \cdots < \lambda_h < \frac{1}{\alpha^2} < \lambda_{h+1} < \cdots$$

have some significant properties for the stability of this system. If the values λ_1, $\lambda_{k+1} - (1/\alpha^2), (1/\alpha^2) - \lambda_h$ are sufficiently large, we can show the asymptotic behavior of solutions, the existence of a global attractor, and periodicity or asymptotic periodicity of solutions under periodic perturbations. Also, we estimate some essential relations among the system parameters $\lambda_1, \lambda_h, \lambda_{h+1}, \alpha$, and $K_0, k(\cdot)$, considering the equation of motion of a one-dimensional nonlinear flexible beam.

Our formulation depends on the method by Sakawa [10] in linear flexible systems and we use spectral properties of analytic semigroups. To analyze nonlinear systems we apply a variation of the Gronwall inequality, which was introduced in [5] (see also [8]). As for the other methods to show periodic stability of nonlinear systems, we can refer to [4], [6], and [7], which mainly depend on the monotone operator theory.

In §2 we give the formulation and state the main theorems: stability, periodicity, and asymptotic periodicity of solutions. We prepare some lemmas on analytic semigroups in §3 and prove the main results in §4. In §5 we investigate a one-dimensional nonlinear flexible beam system to derive sufficient conditions, described by its system parameters, for stability and periodic stability.

2. Formulation and main theorems.

Following the formulation by Sakawa [10] in the linear part, we assume that

$$\alpha^2\lambda_i^2 - \lambda_i \neq 0, \quad i = 1, 2, \ldots$$

and that $\alpha > 0$ is so small that

$$\alpha\lambda_1 < \frac{1}{2\alpha}. \tag{2.1}$$

Define a complex-valued function g by

$$g(\lambda) = \sqrt{\alpha^2\lambda^2 - \lambda}.$$

Then, since A is self-adjoint, we can define an operator $g(A)$ by

$$g(A)u = \sum_{i=1}^{\infty}\sum_{j=1}^{m_i} g(\lambda_i)(u, \varphi_{ij})\varphi_{ij},$$

$$D(g(A)) = \left\{ u \in L^2(\Omega) : \sum_{i=1}^{\infty} \sum_{j=1}^{m_i} |g(\lambda_i)(u, \varphi_{ij})|^2 < \infty \right\}.$$

Note that $D(g(A)) = D(A)$ and define the following two operators by

$$A^+ := \alpha A - g(A), \quad A^- := \alpha A + g(A).$$

Then for each $u \in D(A)$,

$$A^{\pm} u = \sum_{i=1}^{\infty} \sum_{j=1}^{m_i} (\alpha \lambda_i \mp g(\lambda_i))(u, \varphi_{ij})\varphi_{ij}$$

and the eigenvalues and the eigenfunctions of $A^{\pm}$ are given by

$$\begin{aligned} &\nu_i = \alpha\lambda_i - g(\lambda_i), \quad \mu_i = \alpha\lambda_i + g(\lambda_i), \\ &A^+ u = \nu_i \varphi_{ij}, \quad A^- u = \mu_i \varphi_{ij}, \quad j = 1, \dots, m_i, \quad i = 1, 2, \dots. \end{aligned}$$

It follows from (2.1) that there is an integer $h \geq 1$ such that

$$\alpha^2 \lambda_h^2 - \lambda_h < 0, \quad \alpha^2 \lambda_{h+1}^2 - \lambda_{h+1} > 0.$$

In this paper we can show that the three eigenvalues $\lambda_1, \lambda_h, \lambda_{h+1}$ are the most essential parameters in the sufficient conditions for periodic stability.

Since the operators $-A^+, -A^-$ generate analytic semigroups $S_1(t), S_2(t)$, respectively (cf. Lemma 3.1 in [10]), and especially since A^+ is a bounded operator, we can consider the following system of the semilinear equations:

$$\dot{\xi}(t) + A^+ \xi(t) = g^{-1}(A) \left[F\left(\frac{\xi + \eta}{2}\right) + w(t) \right], \tag{2.2}$$

$$\dot{\eta}(t) + A^- \eta(t) = -g^{-1}(A) \left[F\left(\frac{\xi + \eta}{2}\right) + w(t) \right], \tag{2.3}$$

which can be described by

$$\dot{\zeta}(t) + \mathcal{A}\zeta(t) = \mathcal{F}(\zeta(t)) + \mathbf{w}(t), \tag{2.4}$$

where

$$\zeta(t) = \begin{bmatrix} \xi(t) \\ \eta(t) \end{bmatrix}, \quad \mathcal{A} = \begin{bmatrix} A^+ & 0 \\ 0 & A^- \end{bmatrix},$$

$$\mathcal{F}(\zeta(t)) = \begin{bmatrix} g^{-1}(A) F\left(\dfrac{\xi+\eta}{2}\right) \\ -g^{-1}(A) F\left(\dfrac{\xi+\eta}{2}\right) \end{bmatrix}, \quad \mathbf{w}(t) = \begin{bmatrix} g^{-1}(A) w(t) \\ -g^{-1}(A) w(t) \end{bmatrix},$$

and $g^{-1}(A)$ is the inverse operator of $g(A)$, that is,

$$g^{-1}(A) u = \sum_{i=1}^{\infty} \sum_{j=1}^{m_i} (g(\lambda_i))^{-1} (u, \varphi_{ij}) \varphi_{ij}.$$

Also, their mild forms are described as follows:

$$\xi(t) = S_1(t)\xi_0 + \int_0^t S_1(t-s)g^{-1}(A)\left[F\left(\frac{\xi+\eta}{2}(s)\right) + w(s)\right] ds, \tag{2.5}$$

$$\eta(t) = S_2(t)\eta_0 - \int_0^t S_2(t-s)g^{-1}(A)\left[F\left(\frac{\xi+\eta}{2}(s)\right) + w(s)\right] ds. \tag{2.6}$$

Under the conditions (1.4), (1.5) for a fixed constant $0 < \beta < 1$, we can admit the (classical) solution (cf. Appendix 2)

$$[\xi(t), \eta(t)] \in C(0,T : D(A^\beta) \times D(A^\beta)) \cap C^1(0,T : L^2(\Omega) \times L^2(\Omega)) \tag{2.7}$$

for each initial condition $[\xi_0, \eta_0] \in D(A^\beta) \times D(A^\beta)$ and for an arbitrarily fixed constant $T > 0$.

Furthermore, we can estimate the regularity of the solutions as follows: if $[\xi_0, \eta_0] \in D(A) \times D(A^{1+\sigma})$ for some constant $\sigma : 0 < \beta \le \sigma < 1$, then by multiplying λ_i^2 and $\lambda_i^{2(1+\sigma)}$ to the spectral expansions of (2.5) and (2.6), respectively, and applying the direct estimation, such as (1.3), we have

$$\xi \in C(0,T : D(A)), \quad \eta \in C(0,T : D(A^{1+\sigma})). \tag{2.8}$$

Then it follows from (2.2) and (2.3) that

$$\dot{\xi} \in C(0,T : D(A)), \quad \dot{\eta} \in C(0,T : D(A^\sigma)). \tag{2.9}$$

Now, define the functions u, v by

$$u := \frac{\xi+\eta}{2}, \quad v := \frac{\xi-\eta}{2}. \tag{2.10}$$

Then from (2.8) and (2.9) it follows that

$$u, v \in C(0,T : D(A)) \cap C^1(0,T : D(A^\sigma)). \tag{2.11}$$

Hereafter, we consider the case $\sigma = \beta$. From (2.2) and (2.3) we have

$$\dot{u} + \dot{v} + (\alpha A - g(A))(u+v) = g^{-1}(A)(F(u) + w),$$
$$\dot{u} - \dot{v} + (\alpha A + g(A))(u-v) = -g^{-1}(A)(F(u) + w),$$

and then the difference and the sum of the above equations give

$$\dot{u} = -\alpha A u + g(A)v, \tag{2.12}$$
$$\dot{v} - g(A)u + \alpha A v = g^{-1}(A)(F(u) + w). \tag{2.13}$$

By modifying the argument in [10] without the assumption $\dot{u} \in D(A)$, we have

$$\begin{aligned} \dot{v} &= g(A)u - \alpha A v + g^{-1}(A)(F(u) + w) \\ &= g^2(A)g(A)^{-1}u - \alpha A g^{-1}(A)g(A)v + g^{-1}(A)(F(u) + w) \\ &= (\alpha^2 A^2 - A)g^{-1}(A)u - \alpha A g^{-1}(A)g(A)v + g^{-1}(A)(F(u) + w) \\ &= \alpha A(g^{-1}(A)\alpha A u - g^{-1}(A)g(A)v) - A g^{-1}(A)u + g^{-1}(A)(F(u) + w). \end{aligned} \tag{2.14}$$

Thus, using (2.12), we have

$$\dot{v} = -\alpha A g^{-1}(A)\dot{u} - A g^{-1}(A)u + g^{-1}(A)(F(u) + w). \tag{2.15}$$

Also, we note that (2.13) and (2.15) give

$$\alpha A v - g(A)u = \alpha A g^{-1}(A)\dot{u} + A g^{-1}(A)u. \tag{2.16}$$

Obviously, by differentiating (2.12) under the assumption that $\dot{u} \in D(A)$ and using (2.15), we can obtain the evolution equation (1.1). On the other hand, without the assumption $\dot{u} \in D(A)$, consider an initial condition

$$[u(0), \dot{u}(0)] = [u_0, u_1] \in D(A) \times D(A^{\beta}).$$

Then, since (2.12) yields

$$v(0) = g^{-1}(A)(u_1 + \alpha A u_0) \in D(A),$$

we have

$$\xi(0) = u(0) + v(0) \in D(A). \tag{2.17}$$

And also, since (2.12) yields

$$\begin{aligned} g(A)u - g(A)v &= -\dot{u} - (\alpha A u - g(A)u) \\ &= -\dot{u} - A^{+}u, \end{aligned}$$

we have

$$\begin{aligned} \eta(0) &= u(0) - v(0) \\ &= g^{-1}(A)(-u_1 - A^{+}u_0) \in D(A^{1+\beta}). \end{aligned} \tag{2.18}$$

Thus, by applying the previous argument with (2.17) and (2.18), we can admit the solution $u = (\xi + \eta)/2$ in the mild sense such that

$$[u, \dot{u}] \in C(0, T : D(A)) \times C(0, T : D(A^{\beta})).$$

Before stating the stability of solutions, we introduce some notations. Define

$$\begin{aligned} \lambda(\beta) &= \min\{\sqrt{\lambda_1}, \lambda_1^{1-\beta}\}, \\ M_h &= \max\left\{\frac{1}{\sqrt{1-\alpha^2\lambda_h}}, \sqrt{\frac{\alpha^2\lambda_{h+1}}{\alpha^2\lambda_{h+1}-1}+1}\right\}, \\ C_h &= \max\left\{\sqrt{\frac{\lambda_h}{1-\alpha^2\lambda_h}}, \sqrt{\frac{\lambda_{h+1}}{\alpha^2\lambda_{h+1}-1}}\right\}. \end{aligned} \tag{2.19}$$

Furthermore, for a given constant $\delta : 0 < \delta < \alpha\lambda_1$, define

$$M_\beta = M_h\left(\lambda_1^{\beta} + \frac{1}{\alpha}\right)\left(\frac{\beta}{\alpha\lambda_1 - \delta}\right)^{\beta} e^{-\beta}. \tag{2.20}$$

THEOREM 2.1. *Under hypotheses* (1.4), (1.5), *let* $[\xi_0, \eta_0] \in D(A) \times D(A^{1+\beta})$ *and assume that system parameters,* $\delta, \alpha, \beta, \lambda_1, \lambda_h, \lambda_{h+1}, K_0$, *satisfy the following inequality conditions*: $0 < \delta < \alpha\lambda_1$, $0 < \beta \le 1/2$, *and*

$$\delta > \vartheta := \left(\frac{M_\beta K_0 \Gamma(\bar{\beta})}{2\lambda(\beta)}\right)^{1/\bar{\beta}}, \tag{2.21}$$

where $\bar{\beta} = 1 - \beta$. Then the estimate

$$|A\xi(t)|_0 + |A^-\eta(t)|_\beta \le K_1(t)(|A\xi_0|_0 + |A^-\eta_0|_\beta) + K_2|w|_\infty + K_3 \tag{2.22}$$

holds for some positive constants K_2, K_3, and

$$K_1(t) = \frac{e^{-(\delta-\vartheta)t}}{\bar{\beta}} + e^{-\alpha\lambda_1 t}\Gamma(\bar{\beta}). \tag{2.23}$$

Consequently, the solution $[u(t), \dot{u}(t)]$, given by $u = (\xi + \eta)/2$, has a global attractor in $X_1 \times X_\beta$: $\{[x, y] \in X_1 \times X_\beta : |x|_1 + |y|_\beta \le K_p(K_2|w|_\infty + K_3)\}$ for some $K_p > 0$.

Remark 2.1. In case $1/2 < \beta < 1$ the assertion of Theorem 2.1 holds if one substitutes the constant $\Gamma(\bar{\beta})$ by $\Gamma'(\bar{\beta}) := \Gamma(\bar{\beta})/(\sin\bar{\beta}\pi)^{\bar{\beta}}$ (cf. Appendix 1).

Remark 2.2. Obviously, if the constant K_0 is sufficiently small, then (2.21) must be satisfied. In §5, investigating a flexible beam model, we will derive an essential relation, described by its system parameters, from (2.21).

For convenience we give the following estimation of the constants:

$$\begin{aligned} K_p &= \frac{1}{2}\left(1 + \max\left\{\frac{1}{\alpha\lambda_1^\beta}, \frac{1}{\alpha\lambda_1^{1-\beta}}\right\}\right), \\ K_2 &= M_\beta \times \left[\delta\Gamma_1\left\{\frac{1}{\bar{\beta}(\delta-\vartheta)} + \frac{\Gamma(\bar{\beta})}{\delta}\right\} + (\delta e)^{-(1-\beta)}(1-\beta)^{-\beta}\Gamma(\bar{\beta}) + \frac{\Gamma_2}{\bar{\beta}}\right], \\ K_3 &= K_2K_0, \end{aligned} \tag{2.24}$$

where

$$\Gamma_1 = \int_0^\infty s^{-\beta}e^{-\delta s}ds, \quad \Gamma_2 = \int_0^\infty s^{-\beta}e^{-\vartheta s}ds. \tag{2.25}$$

Next, let $w(t)$ be a periodic function. Then we consider periodicity of solution $[u(t), \dot{u}(t)]$. As in Theorem 2.1, we also use the pair of functions $[\xi(t), \eta(t)] \in X_1 \times X_{1+\beta}$. Define the norm $|||[x, y]|||_{1,\beta}$ by

$$|||[x, y]|||_{1,\beta} := |Ax|_0 + |A^-y|_\beta,$$

which is equivalent to the $X_1 \times X_{1+\beta}$-norm. Then we can show the periodicity or the asymptotic periodicity of $[u(t), \dot{u}(t)]$ in $X_1 \times X_\beta$ by estimating $|||[\xi(t), \eta(t)]|||_{1,\beta}$.

THEOREM 2.2. *Let $w(t)$ be periodic: $w(t) = w(t+T)$ and assume the same hypotheses as Theorem 2.1. For a given constant $d > 0$ which satisfies*

$$d > K_2 r + K_3, \tag{2.26}$$

where $r := |w|_\infty$ and K_2, K_3 are the constants in (2.24), assume that

$$\delta > \vartheta' := \left(\frac{M_\beta k(d)\Gamma(\bar{\beta})}{2\lambda(\beta)}\right)^{1/\bar{\beta}}, \tag{2.27}$$

where $k(\cdot)$ is the locally Lipschitz coefficient in (1.4). Then there exists a unique T-periodic solution $[\xi_\infty(t), \eta_\infty(t)]$ such that

$$|||[\xi_\infty(t), \eta_\infty(t)]|||_{1,\beta} \le d, \quad t \ge 0, \tag{2.28}$$

and consequently, there exists a unique T-periodic solution $[u_\infty, \dot{u}_\infty]$:

$$|u_\infty(t)|_1 + |\dot{u}_\infty(t)|_\beta \le K_p d, \quad t \ge 0.$$

THEOREM 2.3. *Assume the same hypotheses as Theorem 2.2 and let $w(t)$ be asymptotically periodic:*

$$|w(t) - w_\infty(t)|_0 \to 0 \quad \textit{as } t \to \infty$$

for some T-periodic function $w_\infty : |w_\infty|_\infty \le r$. Then the solution $[u(t:w), \dot{u}(t:w)]$, starting with any initial state $[u_0, u_1] \in X_1 \times X_\beta$, converges to the T-periodic solution $[u_\infty(t:w_\infty), \dot{u}_\infty(t:w_\infty)]$ under the periodic perturbation w_∞:

$$(2.29) \quad |u(t:w) - u_\infty(t:w_\infty)|_1 + |\dot{u}(t:w) - \dot{u}_\infty(t:w_\infty)|_\beta \to 0 \quad \textit{as } t \to \infty.$$

3. Fundamental lemmas. In order to prove the main results we need the estimate of the norm of $[u(t), \dot{u}(t)]$ using the norm of $[\xi(t), \eta(t)]$. First, we show the equivalence of the norms $|u(t)|_\beta + |\dot{u}(t)|_\beta$ and $|A^+\xi|_\beta + |A^-\eta|_\beta$.

LEMMA 3.1. *For the solutions of* (2.5)–(2.6),

$$\xi \in C^1(0,T : D(A)) \cap C(0,T : D(A)),$$
$$\eta \in C^1(0,T : D(A^\beta)) \cap C(0,T : D(A^{1+\beta})),$$

and $u = (\xi + \eta)/2$, there exist constants $N_1, N_h > 0$ such that

$$(3.1) \quad N_1(|u(t)|_\beta + |\dot{u}(t)|_\beta) \le |A^+\xi(t)|_\beta + |A^-\eta(t)|_\beta \le N_h(|u(t)|_\beta + |\dot{u}(t)|_\beta).$$

Proof. From the definition of the operators A^+, A^- and (2.12), we have

$$(3.2) \quad \begin{aligned} |A^+\xi|_\beta + |A^-\eta|_\beta &\ge |(\alpha A - g(A))(u+v) + (\alpha A + g(A))(u-v)|_\beta \\ &= 2|\alpha A u - g(A)v|_\beta = 2|\dot{u}(t)|_\beta. \end{aligned}$$

Also, (2.16) yields

$$(3.3) \quad \begin{aligned} |A^+\xi|_\beta + |A^-\eta|_\beta &\ge |(\alpha A - g(A))(u+v) - (\alpha A + g(A))(u-v)|_\beta \\ &= 2|\alpha A v - g(A)u|_\beta \\ &= 2|\alpha A g^{-1}(A)\dot{u} + A g^{-1}(A) u|_\beta. \end{aligned}$$

Now we estimate the operator norm of $Ag^{-1}(A)$ by using the eigenvalues.
If $i \le h$, we have

$$|g^{-1}(\lambda_i)|\lambda_i = \sqrt{\frac{\lambda_i}{1-\alpha^2\lambda_i}} \ge \sqrt{\frac{\lambda_1}{1-\alpha^2\lambda_1}},$$

and if $i \ge h+1$, we have

$$|g^{-1}(\lambda_i)|\lambda_i = \sqrt{\frac{\lambda_i}{\alpha^2\lambda_i - 1}} \ge \frac{1}{\alpha}.$$

Put

$$N(\alpha, \lambda_1) := \min\left\{ \sqrt{\frac{\lambda_1}{1-\alpha^2\lambda_1}}, \frac{1}{\alpha} \right\}.$$

Then we can estimate

$$\begin{aligned}(3.4)\qquad |Ag^{-1}(A)(a\dot{u}+u)|_\beta^2 &= \sum_{i=1}^{\infty}\sum_{j=1}^{m_i}\lambda_i^{2\beta}\lambda_i^2|g^{-1}(\lambda_i)|^2|(\alpha\dot{u}+u,\varphi_{ij})|^2\\ &\geq N(\alpha,\lambda_1)^2|a\dot{u}+u|_\beta^2.\end{aligned}$$

On the other hand, it follows from (3.2) that

$$(3.5)\qquad |A^+\xi|_\beta+|A^-\eta|_\beta \geq \frac{2}{\alpha}|\alpha\dot{u}|_\beta \geq 2N(\alpha,\lambda_1)|\alpha\dot{u}|_\beta.$$

Combining (3.3), (3.4), and (3.5), and taking the sum with (3.2), we have

$$(3.6)\qquad |A^+\xi|_\beta+|A^-\eta|_\beta \geq \min\left\{1,\frac{N(\alpha,\lambda_1)}{2}\right\}(|u(t)|_\beta+|\dot{u}(t)|_\beta).$$

Since it follows from (2.1) that

$$N(\alpha,\lambda_1)\geq\sqrt{\lambda_1},$$

we obtain the left-hand side estimate in (3.1) by putting

$$N_1 := \min\left\{1,\frac{\sqrt{\lambda_1}}{2}\right\}.$$

To show the converse relation we also need to estimate $\|Ag^{-1}(A)\|$. If $i\leq h$,

$$\lambda_i^2|g^{-1}(\lambda_i)|^2=\frac{\lambda_i^2}{\lambda_i-\alpha^2\lambda_i^2}\leq\frac{1}{\frac{1}{\lambda_h}-\alpha^2},$$

and if $i\geq h+1$,

$$\lambda_i^2|g^{-1}(\lambda_i)|^2=\frac{\lambda_i^2}{\alpha^2\lambda_i^2-\lambda_i}\leq\frac{1}{\alpha^2-\frac{1}{\lambda_{h+1}}}.$$

Thus we have

$$(3.7)\qquad \lambda_i|g^{-1}(\lambda_i)|\leq\max\left\{\sqrt{\frac{\lambda_h}{1-\alpha^2\lambda_h}},\sqrt{\frac{\lambda_{h+1}}{\alpha^2\lambda_h-1}}\right\}=C_h.$$

Since the relations (2.12) and (2.16) yield

$$\begin{aligned}&|A^+\xi|_\beta+|A^-\eta|_\beta\\ &\quad\leq|(\alpha Au-g(A)v)+(\alpha Av-g(A)u)|_\beta+|(\alpha Au-g(A)v)+(-\alpha Av+g(A)u)|_\beta\\ &\quad=|-\dot{u}+(\alpha Ag^{-1}(A)\dot{u}+Ag^{-1}(A)u)|_\beta+|-\dot{u}-(\alpha Ag^{-1}(A)\dot{u}+Ag^{-1}(A)u)|_\beta,\end{aligned}$$

we can estimate

$$|A^+\xi|_\beta+|A^-\eta|_\beta\leq2|\dot{u}|_\beta+2C_h|\alpha\dot{u}+u|_\beta.$$

Thus we can complete the proof by putting

$$(3.8)\qquad N_h:=2\max\{1+\alpha C_h,C_h\}.\qquad\square$$

We prepare some inequality relations.

LEMMA 3.2. *For the operators A, A^+, A^-, the following inequalities hold:*

$$|Ax|_0 \geq \lambda_1^{1-\beta}|x|_\beta, \quad x \in X_1, \tag{3.9}$$

$$|A^+y|_\beta \geq \sqrt{\lambda_1}|y|_\beta, \quad y \in X_\beta, \tag{3.10}$$

$$|A^-z|_\beta \geq \sqrt{\lambda_1}|z|_\beta, \quad z \in X_{1+\beta}, \tag{3.11}$$

$$|A^-w|_\beta \geq \alpha\lambda_1^\beta|w|_1, \quad w \in X_{1+\beta}, \tag{3.12}$$

$$|A\xi|_0 \geq \alpha\lambda_1^{1-\beta}|A^+\xi|_\beta, \quad \xi \in X_1. \tag{3.13}$$

Proof. By the following spectral expansions:

$$|Ax|_0^2 = \sum_{i=1}^\infty \sum_{j=1}^{m_i} \lambda_i^2 |(x, \varphi_{ij})|^2,$$

$$|A^+y|_\beta^2 = \sum_{i=1}^\infty \sum_{j=1}^{m_i} |\nu_i|^2 \lambda_i^{2\beta} |(y, \varphi_{ij})|^2,$$

$$|A^-z|_\beta^2 = \sum_{i=1}^\infty \sum_{j=1}^{m_i} |\mu_i|^2 \lambda_i^{2\beta} |(z, \varphi_{ij})|^2,$$

we have (3.9), since

$$|Ax|_0^2 = \sum_{i=1}^\infty \sum_{j=1}^{m_i} \lambda_i^{2(1-\beta)} \lambda_i^\beta |(x, \varphi_{ij})|^2$$
$$\geq \lambda_1^{2(1-\beta)} \sum_{i=1}^\infty \sum_{j=1}^{m_i} \lambda_i^\beta |(x, \varphi_{ij})|^2,$$

and, for (3.10), (3.11), it is sufficient to estimate the eigenvalues ν_i, μ_i as follows. For ν_i, if $i \leq h$,

$$|\nu_i|^2 = |\alpha\lambda_i - g(\lambda_i)|^2 = \alpha^2\lambda_i^2 + (\lambda_i - \alpha^2\lambda_i^2)$$
$$= \lambda_i \geq \lambda_1,$$

and, if $i \geq h+1$,

$$|\nu_i|^2 = \left(\alpha\lambda_i - \sqrt{\alpha^2\lambda_i^2 - \lambda_i}\right)^2 = \left(\frac{\lambda_i}{\alpha\lambda_i + \sqrt{\alpha^2\lambda_i^2 - \lambda_i}}\right)^2$$
$$\geq \left(\frac{1}{2\alpha}\right)^2.$$

It follows from (2.1) that

$$|\nu_i| \geq \min\left\{\sqrt{\lambda_1}, \frac{1}{2\alpha}\right\} \geq \sqrt{\lambda_1}. \tag{3.14}$$

On the other hand, if $i \leq h$, we have

$$|\mu_i|^2 = |\alpha\lambda_i + g(\lambda_i)|^2 = \lambda_i \geq \lambda_1,$$

and, if $i \geq h+1$,

$$\begin{aligned}|\mu_i|^2 &= |\alpha\lambda_i + \sqrt{\alpha^2\lambda_i^2 - \lambda_i}|^2 \\ &= \left(\frac{\lambda_i}{\alpha\lambda_i - \sqrt{\alpha^2\lambda_i^2 - \lambda_i}}\right)^2 \\ &\geq \left(\frac{\lambda_i}{\alpha\lambda_i + \alpha\lambda_i}\right)^2 = \left(\frac{1}{2\alpha}\right)^2.\end{aligned}$$

For (3.12), consider the estimate

$$|\mu_i|^2 = \left|\alpha\lambda_i + \sqrt{\alpha^2\lambda_i^2 - \lambda_i}\right|^2 \geq \alpha^2\lambda_i^2.$$

Then (3.13) is an easy consequence of the estimate $|\nu_i|^2 \leq (1/\alpha)^2$. □

Given Lemma 3.1 and Lemma 3.2, we can estimate $|u(t)|_1 + |\dot{u}(t)|_\beta$ by the norm $|A\xi(t)|_0 + |A^-\eta(t)|_\beta$.

LEMMA 3.3. *There exists a constant $K_p > 0$ such that*

$$|u(t)|_1 + |\dot{u}(t)|_\beta \leq K_p(|A\xi(t)|_0 + |A^-\eta(t)|_\beta), \tag{3.15}$$

where K_p is given in (2.24).

Proof. From Lemma 3.2 we have

$$\begin{aligned}|u(t)|_1 &\leq \frac{1}{2}(|\xi(t)|_1 + |\eta(t)|_1) \\ &\leq \frac{1}{2}|A\xi(t)|_0 + \frac{1}{2\alpha\lambda_1^\beta}|A^-\eta(t)|_\beta, \\ |A^+\xi(t)|_\beta &\leq \frac{1}{\alpha\lambda_1^{1-\beta}}|A\xi(t)|_0.\end{aligned}$$

The estimate (3.2) and the above inequality relations yield (3.15). □

Since the definitions (2.19) and (2.20) imply that $\alpha C_h \leq M_h$, the estimate

$$(M_h\lambda_1^\beta + C_h)\left(\frac{\beta}{\alpha\lambda_1 - \delta}\right)^\beta e^{-\beta} \leq M_\beta \tag{3.16}$$

holds. Now we prepare the estimate, which corresponds to the well-known estimate of the operator norm of an analytic semigroup and its generator.

LEMMA 3.4. *For a given constant δ : $0 < \delta < \alpha\lambda_1$, we have the following estimate*:

$$|AS_1(t)g^{-1}(A)y|_0 + |A^-A^\beta S_2(t)g^{-1}(A)y|_0 \leq M_\beta e^{-\delta t}t^{-\beta}|y|_0, \quad y \in L^2(\Omega). \tag{3.17}$$

Proof. By using spectral expansion we have

$$\begin{aligned}|A^-A^\beta S_2(t)g^{-1}(A)y|_0^2 = &\left(\sum_{i=1}^{\infty}\sum_{j=1}^{m_i}\lambda_i^{2\beta}|\mu_i|^2|g^{-1}(\lambda_i)|^2 e^{-2(\mathrm{Re}[\mu_i]-\delta)t}t^{2\beta}|(y,\varphi_{ij})|^2\right) \\ &\times e^{-2\delta t}t^{-2\beta}.\end{aligned}$$

If $i \le h$,

$$|(\alpha\lambda_i + g(\lambda_i))g^{-1}(\lambda_i)|^2 = \left(\frac{\alpha^2\lambda_i^2}{\lambda_i - \alpha^2\lambda_i^2} + 1\right) \le \frac{1}{1-\alpha^2\lambda_h},$$

and, if $i \ge h+1$,

$$|(\alpha\lambda_i + g(\lambda_i))g^{-1}(\lambda_i)|^2 = \left(\frac{\alpha\lambda_i}{\sqrt{\alpha^2\lambda_i^2 - \lambda_i}} + 1\right)^2 \le \left(\frac{\alpha\lambda_{h+1}}{\sqrt{\alpha^2\lambda_{h+1}^2 - \lambda_{h+1}}} + 1\right)^2 .$$

Furthermore, since we can easily see from elementary calculations that each term $\lambda_i^{2\beta} e^{-2(\mathrm{Re}[\mu_i]-\delta)t} t^{2\beta}$ takes its maximal value at $t = \beta/(\mathrm{Re}[\mu_i] - \delta)$, we have

$$|A^- A^\beta S_2(t) g^{-1}(A) y|_0^2 \le M_h^2 \left(\sum_{i=1}^{\infty}\sum_{j=1}^{m_i} e^{-2\beta}\left(\frac{\lambda_i\beta}{\mathrm{Re}[\mu_i]-\delta}\right)^{2\beta} |(y,\varphi_{ij})|^2\right) e^{-2\delta t} t^{-2\beta}.$$

Since

$$\begin{aligned}\frac{\lambda_i\beta}{\mathrm{Re}[\mu_i]-\delta} &= \begin{cases} \lambda_i\beta/(\alpha\lambda_i - \delta), & \text{if } i \le h, \\ \lambda_i\beta/(\alpha\lambda_i + g(\lambda_i) - \delta), & \text{if } i \ge h+1 \end{cases} \\ &\le \frac{\lambda_1\beta}{\alpha\lambda_1 - \delta},\end{aligned}$$

we obtain

$$\begin{aligned}(3.18)\qquad &|A^- A^\beta S_2(t) g^{-1}(A) y|_0^2 \\ &\le M_h^2 e^{-2\beta}\left(\frac{\lambda_1\beta}{\alpha\lambda_1-\delta}\right)^{2\beta}\left(\sum_{i=1}^{\infty}\sum_{j=1}^{m_i} |(y,\varphi_{ij})|^2\right) e^{-2\delta t} t^{-2\beta}.\end{aligned}$$

On the other hand, applying the same argument as above, we have

$$\begin{aligned}(3.19)\ &|AS_1(t) g^{-1}(A) y|_0^2 \\ &= \left(\sum_{i=1}^{\infty}\sum_{j=1}^{m_i} \lambda_i^2 |g^{-1}(\lambda_i)|^2 e^{-2(\mathrm{Re}[\nu_i]-\delta)t} t^{2\beta} |(y,\varphi_{ij})|^2\right) e^{-2\delta t} t^{-2\beta} \\ &\le \left(\sum_{i=1}^{\infty}\sum_{j=1}^{m_i} \lambda_i^2 e^{-2\beta} |g^{-1}(\lambda_i)|^2 \left(\frac{\beta}{\mathrm{Re}[\nu_i]-\delta}\right)^{2\beta} |(y,\varphi_{ij})|^2\right) e^{-2\delta t} t^{-2\beta}.\end{aligned}$$

Since, if $i \ge h+1$,

$$\begin{aligned}\mathrm{Re}[\nu_i] = \alpha\lambda_i - g(\lambda_i) &= \frac{\lambda_i}{\alpha\lambda_i + \sqrt{\alpha^2\lambda_i^2 - \lambda_i}} \\ &\ge \frac{1}{2\alpha} \ge \alpha\lambda_1,\end{aligned}$$

we have

$$\frac{\beta}{\mathrm{Re}[\nu_i]-\delta} \le \frac{\beta}{\alpha\lambda_1 - \delta}$$

for every i. It follows from (3.7) that

$$(3.20)\quad |AS_1(t)g^{-1}(A)y|^2 \le C_h^2 e^{-2\beta}\left(\frac{\beta}{\alpha\lambda_1 - \delta}\right)^{2\beta}\left(\sum_{i=1}^{\infty}\sum_{j=1}^{m_i}|(y,\varphi_{ij})|^2\right)e^{-2\delta t}t^{-2\beta}.$$

Thus, combining (3.18) with (3.20) and using (3.16), we obtain the conclusion. □

4. Proofs of main theorems. In this section we give the proofs of our main theorems.

Proof of Theorem 2.1. From (2.5) and (2.6) we have

$$|A\xi(t)|_0 \le |S_1(t)A\xi_0|_0 + \int_0^t \left|AS_1(t-s)g^{-1}(A)\left\{F\left(\frac{\xi+\eta}{2}\right) + w(s)\right|_0\right\}ds,$$
$$|A^-\eta(t)|_\beta \le |S_2(t)A^-\eta_0|_\beta + \int_0^t \left|A^-A^\beta S_2(t-s)g^{-1}(A)\left\{F\left(\frac{\xi+\eta}{2}\right) + w(s)\right\}\right|_0 ds.$$

Summing up and using Lemma 3.2, Lemma 3.4, and (1.5), we obtain

$$\begin{aligned}
&|A\xi(t)|_0 + |A^-\eta(t)|_\beta \\
&\quad\le e^{-\alpha\lambda_1 t}(|A\xi_0|_0 + |A^-\eta_0|_\beta) + \int_0^t M_\beta e^{-\delta(t-s)}(t-s)^{-\beta}(K_0 + |w(s)|_0)ds \\
&\qquad + \int_0^t M_\beta e^{-\delta(t-s)}(t-s)^{-\beta}\frac{K_0}{2\lambda(\beta)}(|A\xi(s)|_0 + |A^-\eta(s)|_\beta)ds.
\end{aligned}$$

Multiplying each term by $e^{\delta t}$ and putting

$$\begin{aligned}
a(t) &:= e^{-(\alpha\lambda_1-\delta)t}(|A\xi_0|_0 + |A^-\eta_0|_\beta) + M_\beta(K_0 + |w|_\infty)\int_0^t e^{\delta\sigma}(t-\sigma)^{-\beta}d\sigma, \\
y(t) &:= e^{\delta t}(|A\xi(t)|_0 + |A^-\eta(t)|_\beta), \\
b &:= \frac{M_\beta K_0}{2\lambda(\beta)}
\end{aligned}$$

in the Gronwall inequality, introduced in Appendix 1, we obtain the following estimate:

$$\begin{aligned}
&|A\xi(t)|_0 + |A^-\eta(t)|_\beta \\
&\quad\le E(\vartheta t)e^{-\delta t}(|A\xi_0|_0 + |A^-\eta_0|_\beta) \\
&\qquad + \int_0^t E(\vartheta(t-s))\left\{M_\beta(K_0 + |w|_\infty)e^{-\delta t}\left[\delta e^{\delta s}\int_0^s \sigma^{-\beta}e^{-\delta\sigma}d\sigma + s^{-\beta}\right]\right. \\
&\qquad\qquad\left. - e^{-\delta t}(\alpha\lambda_1 - \delta)(|A\xi_0|_0 + |A^-\eta_0|_\beta)e^{-(\alpha\lambda_1-\delta)s}\right\}ds
\end{aligned}$$

where, as we can see in Appendix 1 also

$$\vartheta = [b\Gamma(\bar\beta)]^{1/\bar\beta}, \quad E(z) := \sum_{n=0}^{\infty}\frac{z^{n\bar\beta}}{\Gamma(n\bar\beta+1)}, \quad E(z) \le \frac{e^z}{\bar\beta} + \Gamma(\bar\beta), \quad z \ge 0.$$

Thus, we have the following sequence of estimation:

$$\begin{aligned}
&|A\xi(t)|_0 + |A^- \eta(t)|_\beta \\
&\quad \le (|A\xi_0|_0 + |A^-\eta_0|_\beta) e^{-\delta t} \left\{ \frac{e^{\vartheta t}}{\bar{\beta}} + \Gamma(\bar{\beta}) \right\} \\
&\quad\quad + M_\beta (K_0 + |w|_\infty) e^{-\delta t} \int_0^t \left(\frac{e^{\vartheta(t-s)}}{\bar{\beta}} + \Gamma(\bar{\beta}) \right) (\delta e^{\delta s}\Gamma_1 + s^{-\beta}) ds \\
&\quad\quad - e^{-\delta t}(\alpha\lambda_1 - \delta)(|A\xi_0|_0 + |A^-\eta_0|_\beta) \int_0^t \left(\frac{e^{\vartheta(t-s)}}{\bar{\beta}} + \Gamma(\bar{\beta}) \right) e^{-(\alpha\lambda_1-\delta)s} ds \\
&\quad \le M_\beta(K_0 + |w|_\infty) \\
&\quad\quad \times \left[\delta\Gamma_1 \left\{ \frac{1 - e^{-(\delta-\vartheta)t}}{\bar{\beta}(\delta-\vartheta)} + \frac{\Gamma(\bar{\beta})(1-e^{-\delta t})}{\delta} \right\} + e^{-\delta t} \frac{t^{1-\beta}}{1-\beta}\Gamma(\bar{\beta}) + e^{-(\delta-\vartheta)t}\frac{\Gamma_2}{\bar{\beta}} \right] \\
&\quad\quad + (|A\xi_0|_0 + |A^-\eta_0|_\beta) e^{-\delta t} \left\{ \frac{e^{\vartheta t}}{\bar{\beta}} + \Gamma(\bar{\beta}) \right\} - (\alpha\lambda_1 - \delta)(|A\xi_0|_0 + |A^-\eta_0|_\beta) \\
&\quad\quad \times \left[\frac{e^{-(\delta-\vartheta)t}}{\bar{\beta}} \int_0^t e^{-(\vartheta+\alpha\lambda_1-\delta)s} ds + e^{-\delta t}\Gamma(\bar{\beta}) \int_0^t e^{-(\alpha\lambda_1-\delta)s} ds \right] \\
&\quad \le M_\beta(K_0 + |w|_\infty) \\
&\quad\quad \times \left[\delta\Gamma_1 \left\{ \frac{1 - e^{-(\delta-\vartheta)t}}{\bar{\beta}(\delta-\vartheta)} + \frac{\Gamma(\bar{\beta})(1-e^{-\delta t})}{\delta} \right\} + e^{-\delta t} \frac{t^{1-\beta}}{1-\beta}\Gamma(\bar{\beta}) + e^{-(\delta-\vartheta)t}\frac{\Gamma_2}{\bar{\beta}} \right] \\
&\quad\quad + (|A\xi_0|_0 + |A^-\eta_0|_\beta) \left\{ \frac{e^{-(\delta-\vartheta)t}}{\bar{\beta}} \left(\frac{\vartheta + (\alpha\lambda_1 - \delta)e^{-(\vartheta+\alpha\lambda_1-\delta)t}}{\vartheta + \alpha\lambda_1 - \delta} \right) + \Gamma(\bar{\beta})e^{-\alpha\lambda_1 t} \right\},
\end{aligned}$$

where Γ_1, Γ_2 are the constants, given in (2.25). Hence, we can estimate

$$|A\xi(t)| + |A^-\eta(t)|_\beta \le K_1(t)(|A\xi_0|_0 + |A^-\eta_0|_\beta) + K_2|w|_\infty + K_3 \tag{4.1}$$

using the constants K_2, K_3, defined in (2.24). Thus we can complete the proof by using Lemma 3.3. □

Proof of Theorem 2.2. From Theorem 2.1 we can assume that there exists a solution $[\xi, \eta]$ with an initial condition $[\xi_0, \eta_0]$ in $X_1 \times X_{1+\beta}$:

$$\|[\xi(t), \eta(t)]\|_{1,\beta} \le d, \quad t \ge 0.$$

Then we show that $[\xi_n(t), \eta_n(t)] := [\xi(t+nT), \eta(t+nT)]$ converges to a T-periodic solution $[\xi_\infty(t), \eta_\infty(t)]$ as $n \to \infty$.

By using (2.5) and (2.6), we have

$$\begin{aligned}
&|A(\xi_n - \xi_{n+m})(t)|_0 \\
&\quad \le |S_1(nT)A(\xi - \xi_m)(t)|_0 \\
&\quad\quad + \int_0^{nT} \left| AS_1(nT-s)g^{-1}(A) \left[F\left(\frac{\xi+\eta}{2}(s+t) \right) - F\left(\frac{\xi_m + \eta_m}{2}(s+t) \right) \right] \right|_0 ds, \\
&|A^-(\eta_n - \eta_{n+m})(t)|_\beta \\
&\quad \le |S_2(nT)A^-(\eta - \eta_m)(t)|_\beta \\
&\quad\quad + \int_0^{nT} \left| A^- A^\beta S_2(nT-s)g^{-1}(A) \left[F\left(\frac{\xi+\eta}{2}(s+t) \right) - F\left(\frac{\xi_m + \eta_m}{2}(s+t) \right) \right] \right|_0 ds.
\end{aligned}$$

It follows from Lemma 3.4, (1.4), and Lemma 3.2 that

$$\begin{aligned}&|A(\xi_n-\xi_{n+m})(t)|_0+|A^-(\eta_n-\eta_{n+m})(t)|_\beta\\&\quad\le e^{-\alpha\lambda_1 nT}(|A(\xi-\xi_m)(t)|_0+|A^-(\eta-\eta_m)(t)|_\beta)\\&\quad+\int_0^{nT}M_\beta\frac{k(d)}{2\lambda(\beta)}e^{-\delta(nT-s)}(nT-s)^{-\beta}\\&\quad\times\{|A(\xi-\xi_m)(s+t)|_0+|A^-(\eta-\eta_m)(s+t)|_\beta\}ds.\end{aligned}$$

Thus the Gronwall inequality and the same argument as in Theorem 2.1 give

$$\begin{aligned}&|A(\xi_n-\xi_{n+m})(t)|_0+|A^-(\eta_n-\eta_{n+m})(t)|_\beta\\&\le\left[\frac{e^{-(\delta-\vartheta')nT}}{\bar\beta}+\Gamma(\bar\beta)e^{-\alpha\lambda_1 nT}\right](|A(\xi-\xi_m)(t)|_0+|A^-(\eta-\eta_m)(t)|_\beta)\\&\le 2d\left[\frac{e^{-(\delta-\vartheta')nT}}{\bar\beta}+\Gamma(\bar\beta)e^{-\alpha\lambda_1 nT}\right].\end{aligned}$$

Hence the sequence $[\xi_n(t),\eta_n(t)]$ is a Cauchy sequence in $BC(R^+:X_1\times X_{1+\beta})$, the space of uniformly bounded, continuous, and $X_1\times X_{1+\beta}$-valued functions. So there exists $[\xi_\infty(t),\eta_\infty(t)]$ such that

$$[\xi_n(t),\eta_n(t)]\to[\xi_\infty,\eta_\infty]\ \text{ in }\ BC(R^+:X_1\times X_{1+\beta}).$$

By taking the limit $n\to\infty$ of the mild formulas:

$$\begin{aligned}\xi(t+nT)&=S_1(t)\xi(nT)+\int_0^t S_1(t-s)g^{-1}(A)\left[F\left(\frac{\xi+\eta}{2}(s+nT)\right)+w(s)\right]ds,\\\eta(t+nT)&=S_2(t)\eta(nT)-\int_0^t S_2(t-s)g^{-1}(A)\left[F\left(\frac{\xi+\eta}{2}(s+nT)\right)+w(s)\right]ds,\end{aligned}$$

we can show that $[\xi_\infty(t),\eta_\infty(t)]$ satisfies the mild formulas (2.5), (2.6) with the initial state $[\xi_\infty(0),\eta_\infty(0)]$.

Furthermore, T-periodicity of $[\xi_\infty(t),\eta_\infty(t)]$ holds, since

$$\begin{aligned}[\xi_\infty(t+T),\eta_\infty(t+T)]&=\lim_{n\to\infty}[\xi_\infty(t+T+nT),\eta_\infty(t+T+nT)]\\&=\lim_{n\to\infty}[\xi_\infty(t+(n+1)T),\eta_\infty(t+(n+1)T)]\\&=[\xi_\infty(t),\eta_\infty(t)].\end{aligned}$$

As for the uniqueness of the T-periodic solution, since we have the following estimate for a sufficiently large N:

$$\begin{aligned}&\|[\xi_\infty(t+NT),\eta_\infty(t+NT)]-[\xi'_\infty(t+NT),\eta'_\infty(t+NT)]\|_{1,\beta}\\&=\|[\xi_\infty(t),\eta_\infty(t)]-[\xi'_\infty(t),\eta'_\infty(t)]\|_{1,\beta}\\&\le\left[\frac{e^{-(\delta-\vartheta')NT}}{\bar\beta}+\Gamma(\bar\beta)e^{-\alpha\lambda_1 NT}]\|[\xi_\infty(t),\eta_\infty(t)\right]-[\xi'_\infty(t),\eta'_\infty(t)]\|_{1,\beta},\end{aligned}$$

we can complete the proof. □

Proof of Theorem 2.3. Instead of estimating the solution $u(\cdot : w)$, it is sufficient to show the convergence of the pair of functions $[\xi(t), \eta(t)]$ to a pair of T-periodic functions $[\xi_\infty, \eta_\infty]$ in $X_1 \times X_{1+\beta}$-norm. Here we can also assume that

$$\| [\xi(t), \eta(t)] \|_{1,\beta} \le d, \quad t \ge 0.$$

Let N be a large integer which satisfies

$$\frac{e^{-(\delta-\vartheta')NT}}{\bar{\beta}} + \Gamma(\bar{\beta}) e^{-\alpha\lambda_1 NT} < 1$$

and define the following sequences:

$$\begin{aligned} w_m(t) &= w(t + mNT), \\ \xi_m(t) &= \xi(t + mNT), \\ \eta_m(t) &= \eta(t + mNT), \quad m = 0, 1, 2, \ldots. \end{aligned}$$

Then, applying the same argument as that in the proof of Theorem 2.2 to the difference of the solutions

$$[\xi(t + (m+1)NT), \eta(t + (m+1)NT)] - [\xi_\infty(t + (m+1)NT), \eta_\infty(t + (m+1)NT)],$$

which start with the initial values

$$[\xi(t + mNT), \eta(t + mNT)], \quad [\xi_\infty(t + mNT), \eta_\infty(t + mNT)],$$

respectively, we have

$$\begin{aligned} &\| [(\xi_{m+1} - \xi_\infty)(t), (\eta_{m+1} - \eta_\infty)(t)] \|_{1,\beta} \\ &\quad = \| [(\xi - \xi_\infty)(t + (m+1)NT), (\eta - \eta_\infty)(t + (m+1)NT)] \|_{1,\beta} \\ &\quad \le \left\{ \frac{e^{-(\delta-\vartheta)NT}}{\bar{\beta}} + \Gamma(\bar{\beta}) e^{-\alpha\lambda_1 NT} \right\} \| [(\xi - \xi_\infty)(t + mNT), (\eta - \eta_\infty)(t + mNT)] \|_{1,\beta} \\ &\qquad + \left[\delta\Gamma_1 \left\{ \frac{1}{\bar{\beta}(\delta - \vartheta)} + \frac{\Gamma(\bar{\beta})}{\delta} \right\} + (\delta e)^{-(1-\beta)} (1-\beta)^{-\beta} \Gamma(\bar{\beta}) + \frac{\Gamma_2}{\bar{\beta}} \right] \\ &\qquad \times M_\beta \sup\{ |w(s) - w_\infty(s)|_0 : t + mNT \le s \le t + (m+1)NT \}. \end{aligned}$$

Put

$$\begin{aligned} \varphi_m &= \| [(\xi_m - \xi_\infty)(t), (\eta_m - \eta_\infty)(t)] \|_{1,\beta}, \\ K &= \left[\frac{e^{-(\delta-\vartheta)NT}}{\bar{\beta}} + \Gamma(\bar{\beta}) e^{-\alpha\lambda_1 NT} \right] < 1 \end{aligned}$$

and for a small constant $\varepsilon > 0$, take a large number $m_0 : m \ge m_0 \Longrightarrow$

$$\begin{aligned} &\left[\delta\Gamma_1 \left\{ \frac{1}{\bar{\beta}(\delta - \vartheta)} + \frac{\Gamma(\bar{\beta})}{\delta} \right\} + (\delta e)^{-(1-\beta)} (1-\beta)^{-\beta} \Gamma(\bar{\beta}) + \frac{\Gamma_2}{\bar{\beta}} \right] \\ &\qquad \times M_\beta \sup\{ |w(s) - w_\infty(s)| : t + mNT \le s \le t + (m+1)NT \} < \varepsilon. \end{aligned}$$

Then we have

$$\varphi_m \le K\varphi_{m-1} + \varepsilon \le \cdots \le K^m \varphi_0 + \varepsilon \frac{1 - K^m}{1 - K}.$$

Since $\varphi_0 = |||[(\xi - \xi_\infty)(t), (\eta - \eta_\infty)(t)]|||_{1,\beta} \leq 2d$, we can show that for every small $\varepsilon > 0$, there exists a large number $m_1 : m \geq m_1 \Longrightarrow$

$$|||[\xi(t + mNT), \eta(t + mNT)] - [\xi_\infty(t + mNT), \eta_\infty(t + mNT)]|||_{1,\beta} < \varepsilon$$

for every $t \in [0, NT]$, that is,

$$|||[\xi(t), \eta(t)] - [\xi_\infty(t), \eta_\infty(t)]|||_{1,\beta} < \varepsilon$$

for every $t \geq m_1 NT$. Estimating $|u(t) - u_\infty(t)|_1$ and $|\dot{u}(t) - \dot{u}_\infty(t)|_\beta$ according to the argument in (3.2) and Lemma 3.3, we have

$$|u(t) - u_\infty(t)|_1 + |\dot{u}(t) - \dot{u}_\infty(t)|_\beta \leq K_p |||[\xi(t), \eta(t)] - [\xi_\infty(t), \eta_\infty(t)]|||_{1,\beta},$$

which completes the proof. □

5. Flexible beam. We consider the equation of motion of slender and flexible structures with internal viscous damping and nonlinear forcing, determined by displacement $u(t,x)$ and bending force $u_{xx}(t,x)$, under a periodic perturbation:

$$\text{(5.1)} \quad \frac{\partial^2 u(t,x)}{\partial t^2} + 2\alpha \frac{\partial^5 u(t,x)}{\partial t \partial x^4} + \frac{\partial^4 u(t,x)}{\partial x^4} = f\left(x, u(t,x), \frac{\partial^2 u(t,x)}{\partial x^2}\right) + w(t,x),$$

where $0 < x < L$. The beam is clamped at one end, $x = 0$, and at the free end, $x = L$, the bending moment and the shearing force vanish. Then the boundary conditions and the initial conditions are given by

$$\text{(5.2)} \quad \begin{aligned} &u(t,0) = \frac{\partial u(t,0)}{\partial x} = 0, \\ &\frac{\partial^2 u(t,L)}{\partial x^2} + 2\alpha \frac{\partial^3 u(t,L)}{\partial x^2 \partial t} = 0, \\ &\frac{\partial^3 u(t,L)}{\partial x^3} + 2\alpha \frac{\partial^4 u(t,L)}{\partial x^3 \partial t} = 0, \end{aligned}$$

$$\text{(5.3)} \quad u(0,x) = u_0(x), \quad \frac{\partial u(0,x)}{\partial t} = u_1(x),$$

and the periodic perturbation satisfies $w(t+T) = w(t)$. We define an operator A in $L^2(0,L)$ by

$$\begin{aligned} &D(A) = \{u \in H^4(0,L) : u(0) = u_x(0) = 0, \quad u_{xx}(L) = u_{xxx}(L) = 0\}, \\ &Au = \frac{\partial^4 u}{\partial x^4}. \end{aligned}$$

Let γ_i be the solutions of

$$\cosh \gamma \cos \gamma + 1 = 0$$

such that $0 < \gamma_1 < \gamma_2 < \ldots$. Then the eigenvalues of A are given by

$$\lambda_i = \left(\frac{\gamma_i}{L}\right)^4, \quad i = 1, 2, \ldots$$

(cf. [10]).

We assume that the nonlinear function $f(x,u,v) : R \times R \times R \to R$ satisfies the growth condition

$$|f(x,u,v)| \leq k_0(|u|+|v|) \quad \text{for some } k_0 > 0$$

and the following Lipschitz and locally Lipschitz continuity: there exists positive constants $k_0(c), k$ such that

$$|f(x,u,v) - f(x,u',v')| \leq k_0(c)|u-u'| + k|v-v'| \quad \text{for } |u|,|u'| \leq c, \quad v,v' \in R.$$

Define a nonlinear mapping $F : D(A^{\frac{1}{2}}) \to L^2(0,L)$ by

$$F(u)(x) = f(x, u(x), u_{xx}(x)).$$

Then, since the injections

$$D(A^{\frac{1}{2}}) \hookrightarrow H^2(0,L) \hookrightarrow C(0,L)$$

are continuous, the conditions (1.4) and (1.5) hold for the constant $\beta = 1/2$ and some constants $K_0, k(c)$.

Now we investigate the inequality conditions in the case where $\beta = 1/2$. Our purpose is to find some relations among the constants $\lambda_1, \lambda_h, \lambda_{h+1}, \alpha, K_0, k(d)$, where $d > K_2 r + K_3$ and K_2, K_3 are given in (2.24). Let $\delta := \alpha\lambda_1/2$. Then we can describe (2.19) by

$$M_{\frac{1}{2}} = M_h \left(\sqrt{\lambda_1} + \frac{1}{\alpha}\right)\left(\frac{1}{\alpha\lambda_1}\right)^{\frac{1}{2}} e^{-\frac{1}{2}} \tag{5.4}$$

and it follows that

$$\begin{aligned} \vartheta &= \left(M_{\frac{1}{2}} K_0 \frac{\sqrt{\pi}}{2\sqrt{\lambda_1}}\right)^2 \\ &= M_h^2 \left(\sqrt{\lambda_1} + \frac{1}{\alpha}\right)^2 \frac{1}{\alpha\lambda_1^2} \frac{K_0^2\pi}{4e}. \end{aligned}$$

Thus the condition $\alpha\lambda_1/2 > \vartheta$ can be described by

$$\alpha^2\lambda_1^2 > 2M_h^2 \left(1 + \frac{1}{\alpha\sqrt{\lambda_1}}\right)^2 \frac{K_0^2\pi}{4e}.$$

Taking the square root yields

$$\alpha(\sqrt{\lambda_1})^3 - K_0\sqrt{\frac{\pi}{2e}} M_h \sqrt{\lambda_1} - K_0\sqrt{\frac{\pi}{2e}} M_h \frac{1}{\alpha} > 0. \tag{5.5}$$

Hence we can admit the first eigenvalue $\lambda_1 : 0 < \lambda_1 < 1/(2\alpha^2)$, which satisfies the condition $\delta > \vartheta$, if

$$\alpha\left(\frac{1}{\sqrt{2}\alpha}\right)^3 - K_0\sqrt{\frac{\pi}{2e}} M_h \frac{1}{\sqrt{2}\alpha} - K_0\sqrt{\frac{\pi}{2e}} M_h \frac{1}{\alpha} > 0. \tag{5.6}$$

It follows that

$$\alpha M_h < \frac{1}{(\sqrt{2}+1)K_0\sqrt{\frac{2\pi}{e}}}. \tag{5.7}$$

Hereafter, we use the notations

$$\kappa = (\sqrt{2}+1)K_0\sqrt{\frac{2\pi}{e}},$$
$$\kappa' = (\sqrt{2}+1)k(d)\sqrt{\frac{2\pi}{e}}.$$

Considering the definition of M_h and (5.7), we have

$$\frac{\alpha}{\sqrt{1-\alpha^2\lambda_h}} < \frac{1}{\kappa}, \tag{5.8}$$

$$\alpha\left(\sqrt{\frac{\alpha^2\lambda_{h+1}}{\alpha^2\lambda_{h+1}-1}}+1\right) < \frac{1}{\kappa}. \tag{5.9}$$

By (5.8) we can derive the conditions on $\lambda_h, \alpha, \kappa$:

$$\lambda_h < \frac{1}{\alpha^2} - \kappa^2, \quad \alpha\kappa < 1 \tag{5.10}$$

and, assuming $\alpha\kappa < 1/2$, from (5.9) we obtain

$$\lambda_{h+1} > \frac{1}{\alpha^2} + \frac{\kappa^2}{1-2\alpha\kappa}. \tag{5.11}$$

We note that as the values

$$\frac{1}{\alpha^2} - \lambda_h, \;\; \lambda_{h+1} - \frac{1}{\alpha^2}$$

become sufficiently large, $M_h \downarrow 2$.

When (5.10) and (5.11) are satisfied, the first eigenvalue λ_1 can be estimated as follows. The third-order algebraic inequality

$$ax^3 - bx - \frac{b}{a} > 0, \;\; a, b > 0 \tag{5.12}$$

admits a solution

$$x > \frac{b}{3a\left(\frac{b}{2a^2}+\sqrt{-\frac{b^3}{27a^3}+\frac{b^2}{4a^4}}\right)^{\frac{1}{3}}} + \left(\frac{b}{2a^2}+\sqrt{-\frac{b^3}{27a^3}+\frac{b^2}{4a^4}}\right)^{\frac{1}{3}}$$

in the positive real $x > 0$. For sufficiently small $a > 0$, a rough estimation,

$$\begin{aligned}\sqrt{-\frac{b^3}{27a^3}+\frac{b^2}{4a^4}} &= \frac{b}{2a^2}\sqrt{1-\frac{4ab}{27}} \\ &\simeq \frac{b}{2a^2},\end{aligned}$$

gives a sufficient condition for (5.12)

$$x > \frac{b^{\frac{2}{3}}}{3a^{\frac{1}{3}}} + \frac{b^{\frac{1}{3}}}{a^{\frac{2}{3}}},$$

where we take a positive real value of each fractional power 1/3. Considering the case

$$a = \alpha, \quad b = \sqrt{\frac{\pi}{2e}} K_0 M_h$$

with α sufficiently small, we can then estimate λ_1, which satisfies our inequality conditions, as follows:

$$\left(1 + \frac{1}{3}(K_0 M_h \alpha)^{\frac{1}{3}} \left(\frac{\pi}{2e}\right)^{\frac{1}{6}}\right)^2 (K_0 M_h)^{\frac{2}{3}} \left(\frac{\pi}{2e}\right)^{\frac{1}{3}} \left(\frac{1}{\alpha}\right)^{\frac{4}{3}} < \lambda_1 < \frac{1}{2\alpha^2}. \tag{5.13}$$

For sufficiently small $\alpha > 0$, it follows that

$$C_1 \left(\frac{K_0 M_h}{\alpha^2}\right)^{\frac{2}{3}} < \lambda_1 < \frac{1}{2\alpha^2}$$

for some constant $C_1 > 0$. Furthermore, if the values $1/\alpha^2 - \lambda_h$ and $\lambda_{h+1} - 1/\alpha^2$ are sufficiently large, for instance,

$$\frac{1}{\alpha^2} - \lambda_h \simeq \frac{K}{\alpha^2},$$
$$\lambda_{h+1} - \frac{1}{\alpha^2} \simeq \frac{K}{\alpha^2},$$

for some large $K > 0$, we have

$$M_h \simeq 1 + \sqrt{1 + \frac{1}{K}}.$$

Then we can estimate the stability condition for the first eigenvalue:

$$C_2 \left(\frac{K_0}{\alpha^2}\right)^{\frac{2}{3}} < \lambda_1 < \frac{1}{2\alpha^2} \tag{5.14}$$

for some constant $C_2 > 0$.

For the condition $\delta > \vartheta'$, we can derive a similar estimate as (5.14), substituting K_0 with $k(d)$ and κ with κ'. Using a sufficiently small constant α, we can roughly estimate the first eigenvalue λ_1 as follows. Assume that $\delta - \vartheta \simeq \delta \simeq \alpha\lambda_1$. Then it follows from (2.24) that we can estimate the order of the constants $K_2, K_3 \simeq M_{\frac{1}{2}} \delta^{-1/2}$. Thus, when the perturbation of w is comparatively small, $r << \alpha^{-1}$, we may assume that $d \simeq M_{\frac{1}{2}} \delta^{-1/2}$. Since we can roughly estimate $M_{\frac{1}{2}} \simeq \alpha^{-3/2} \lambda_1^{-1/2}$ from (5.4), it follows that $d \simeq \alpha^{-2} \lambda_1^{-1}$. For instance, assume that $k(d) = kd$. Then from (5.14), substituting K_0 with $k(d)$, we have

$$\lambda_1 > C_3 \alpha^{-\frac{4}{3}} [\alpha^{-2} \lambda_1^{-1}]^{\frac{2}{3}}, \quad C_3 > 0.$$

It follows that the periodic stability condition is possibly satisfied if the value λ_1 has the order between $\alpha^{-\frac{8}{5}}$ and α^{-2}.

Remark 5.1. As another main example for (1.1) we can consider the following a strongly damped wave equation:

$$u_{tt} - 2\alpha \Delta u_t - \Delta u = f(x, u, \text{grad} u) + w(t), \tag{5.15}$$

where Δ denotes the Laplacian on a bounded domain Ω in a finite-dimensional Euclidean space with a sufficiently smooth boundary Γ. For a homogeneous Dirichlet boundary condition we can define a operator A

$$\begin{aligned} &D(A) = H^2(\Omega) \cap H_0^1(\Omega), \\ &Au = -\Delta u, \end{aligned}$$

which has the positive discrete eigenvalues:

$$0 < \lambda_1 < \lambda_2 < \cdots < \cdots \to \infty.$$

Under suitable conditions on the nonlinear function f we can treat the case as $\beta = 1/2$, using the well-known fact

$$D(A^{\frac{1}{2}}) = H_0^1(\Omega)$$

(cf. [3]), and then we can follow the same estimate as above.

Remark 5.2. In Theorem 2.2 and Theorem 2.3, instead of hypothesis (1.5) it is sufficient to assume the uniform boundedness of solutions

$$[u(t), \dot{u}(t)] \in X_{1+\beta} \times X_\beta, \quad t > 0,$$

since this boundedness assumption yields the uniform boundedness $[\xi(t), \eta(t)]$ in $X_{1+\beta} \times X_{1+\beta}$ (cf. (2.10) and (2.12)) and, consequently, in $X_1 \times X_{1+\beta}$.

6. Appendix 1. In [5] the following Gronwall's inequality was proved: Suppose $b \geq 0, \bar{\beta} > 0$ and $a(t)$ is a nonnegative function locally integrable on $0 \leq t < +\infty$, and suppose that $y(t)$ is nonnegative and locally integrable on $0 \leq t < +\infty$ with

$$y(t) \leq a(t) + b\int_0^t (t-s)^{\bar{\beta}-1} y(s)ds$$

on this interval. Then

$$y(t) \leq a(t) + \vartheta \int_0^t E'(\vartheta(t-s))a(s)ds,$$

where

$$\vartheta = [b\Gamma(\bar{\beta})]^{1/\bar{\beta}}, \quad E(z) = \sum_{n=0}^{\infty} \frac{z^{n\bar{\beta}}}{\Gamma(n\bar{\beta}+1)}, \quad E'(z) = \frac{dE(z)}{dz}.$$

If $a(t)$ is differentiable, we note that, since

$$\frac{dE(\vartheta(t-s))}{ds} = E'(\vartheta(t-s)) \cdot (-\vartheta),$$

integration by parts gives

$$\begin{aligned} y(t) &\leq a(t) - \int_0^t \frac{dE(\vartheta(t-s))}{ds} a(s)ds \\ &= a(t) - [E(\vartheta(t-s))a(s)]_0^t + \int_0^t E(\vartheta(t-s))a'(s)ds \\ &= E(\vartheta t)a(0) + \int_0^t E(\vartheta(t-s))a'(s)ds. \end{aligned} \tag{6.1}$$

Here we consider the estimate of the entire function $E(z)$. If $0 < z < 1$, we can estimate

$$E(z) \le 1 + \frac{z^{\bar\beta}}{\Gamma_0(1 - z^{\bar\beta})}, \tag{6.2}$$

where $\Gamma_0 := \inf_{1<x<2} \Gamma(x) \approx 0.8$.

On the other hand, for a constant $\alpha : 0 < \alpha < 1$, it is known [2] that, if $z \ge \alpha$,

$$E(z) \le \frac{e^z}{\bar\beta} + \left| \frac{1}{2\pi i} \int_l \frac{u^{\bar\beta - 1} e^u}{u^{\bar\beta} - z^{\bar\beta}} du \right|,$$

where the contour $l : (-\infty - 0i, 0, -\infty + 0i)$ is the negative real axis described twice. Since elementary calculations give

$$\inf\{|u^{\bar\beta} - z^{\bar\beta}| : \; u \in (-\infty, 0), \; z > \alpha\} \ge \begin{cases} \alpha^{\bar\beta} & \text{if } \frac{1}{2} \le \bar\beta < 1, \\ (\alpha \sin \bar\beta\pi)^{\bar\beta} & \text{if } 0 < \bar\beta < \frac{1}{2}, \end{cases}$$

we have

$$E(z) \le \frac{e^z}{\bar\beta} + \frac{\Gamma(\bar\beta)}{\pi\alpha^{\bar\beta}}$$

if $1/2 \le \bar\beta < 1$ and

$$E(z) \le \frac{e^z}{\bar\beta} + \frac{\Gamma(\bar\beta)}{\pi(\alpha \sin \bar\beta\pi)^{\bar\beta}}$$

if $0 < \bar\beta < 1/2$. It follows from (6.2) that for every constant $\alpha_0 : 0 < \alpha_0 < 1$, which satisfies

$$1 + \frac{\alpha_0^{\bar\beta}}{\Gamma_0(1 - \alpha_0^{\bar\beta})} \le \frac{e^{\alpha_0}}{\bar\beta} + \frac{\Gamma(\bar\beta)}{\pi\alpha_0^{\bar\beta}} \quad \left[1 + \frac{\alpha_0^{\bar\beta}}{\Gamma_0(1 - \alpha_0^{\bar\beta})} \le \frac{e^{\alpha_0}}{\bar\beta} + \frac{\Gamma(\bar\beta)}{\pi(\alpha_0 \sin \bar\beta\pi)^{\bar\beta}} \right],$$

the following estimate holds:

$$E(z) \le \frac{e^z}{\bar\beta} + \frac{\Gamma(\bar\beta)}{\pi\alpha_0^{\bar\beta}} \quad \left[E(z) \le \frac{e^z}{\bar\beta} + \frac{\Gamma(\bar\beta)}{\pi(\alpha_0 \sin \bar\beta\pi)^{\bar\beta}} \right]$$

for every $z \ge 0$ if $\frac{1}{2} \le \bar\beta < 1$ $[0 < \bar\beta < \frac{1}{2}]$. For instance, taking $\alpha_0 = \pi^{-1/\bar\beta}$, we have

$$E(z) \le \frac{e^z}{\bar\beta} + \Gamma(\bar\beta) \quad \left[E(z) \le \frac{e^z}{\bar\beta} + \frac{\Gamma(\bar\beta)}{(\sin \bar\beta\pi)^{\bar\beta}} \right]$$

for every $z \ge 0$ if $\frac{1}{2} \le \bar\beta < 1$ $[0 < \bar\beta < \frac{1}{2}]$, since

$$1 + \frac{\alpha_0^{\bar\beta}}{\Gamma_0(1 - \alpha_0^{\bar\beta})} \approx 1.58,$$
$$\frac{e^{\alpha_0}}{\bar\beta} + \frac{\Gamma(\bar\beta)}{(\sin \bar\beta\pi)^{\bar\beta}} \ge \frac{e^{\alpha_0}}{\bar\beta} + \frac{\Gamma(\bar\beta)}{\pi\alpha_0^{\bar\beta}} > 1.8.$$

7. Appendix 2. Following a routine argument (for instance, see Theorems 3.1 and 3.3 in §6 of [9]), we can show the existence of the (classical) solution of (2.4). In fact, note that

$$D(\mathcal{A}^\beta) = L^2(\Omega) \times D(A^\beta)$$

and put

$$\begin{aligned} Y_\beta &:= D(A^\beta) \times D(A^\beta), \\ Y &:= D(A^\beta) \times L^2(\Omega). \end{aligned}$$

Then it follows from (1.4) that the nonlinear function $\mathcal{F}(t,\zeta) := \mathcal{F}(\zeta) + \mathbf{w}(t)$ is locally Hölder continuous and locally Lipschitz continuous from $R^+ \times Y_\beta$ to Y such that there exist constants $L(c), 0 < \gamma \leq 1$:

$$\|\mathcal{F}(t_1,\zeta_1) - \mathcal{F}(t_2,\zeta_2)\|_Y \leq L(c)(\|\zeta_1 - \zeta_2\|_{Y_\beta} + |t_1 - t_2|^\gamma)$$

for $(t_i,\zeta_i) \in R^+ \times Y_\beta : |t_i| + \|\zeta_i\|_{Y_\beta} \leq c,\ i = 1,2$. Since the function $w(t)$ is uniformly bounded, from (1.5) we can show that $\mathcal{F}$ satisfies the linear growth condition: there exists a constant K_0' such that

$$\|\mathcal{F}(t,\zeta)\|_Y \leq K_0'(1 + \|\zeta\|_{Y_\beta}), \quad \zeta \in Y_\beta. \tag{7.1}$$

On the other hand, denote the analytic semigroup, generated by $\mathcal{A}$, by $T(t) := [S_1(t), S_2(t)]$. Then, since the operator A^+ is bounded, we can easily show that $T(t) : Y \to Y, \quad t \geq 0$. Thus, to apply the contraction principle as in the proof of Theorems 3.1 and 3.3 in [9], it is sufficient to define the mapping $\mathcal{G}$ on the space $\mathcal{Y} := C(0,t_0 : Y)$ by

$$\mathcal{G}y(t) = T(t)\mathcal{A}^\beta y_0 + \int_0^t \mathcal{A}^\beta T(t-s)\mathcal{F}(s, \mathcal{A}^{-\beta}y(s))ds,$$

where $y_0 \in Y_\beta$ and t_0 are given by a routine estimate, which yields the contraction property of $\mathcal{G}$, to obtain a local solution. Furthermore, following the conventional argument with (7.1), we obtain the global solution $\zeta(t) = \mathcal{A}^{-\beta}y(t)$ in $C(0,T : Y_\beta) \cap C^1(0,T : L^2(\Omega) \times L^2(\Omega))$ for every $T > 0$.

Acknowledgments. The author would like to thank the referees for many suggestions that improved the presentation of this paper.

IDENTIFICATION FOR PARABOLIC DISTRIBUTED PARAMETER SYSTEMS WITH CONSTRAINTS ON THE PARAMETERS AND THE STATE*

WENHUAN YU†

Abstract. We consider the problems for identifying the parameters $a_{11}(x,t),\ldots, a_{mm}(x,t)$ and $c(x,t)$ involved in a second-order, linear, uniformly parabolic equation

$$\begin{cases} \partial_t u - \partial_i(a_{ij}(x,t)\partial_j u) + b_i(x,t)\partial_i u + c(x,t)u = f(x,t) & \text{in } \Omega \times (0,T), \\ u \mid_{\partial\Omega} = g, \quad u \mid_{t=0} = u_0(x), \quad x \in \Omega \end{cases}$$

on the basis of noisy measurement data

$$z(x) = u(x,T) + w(x), \quad x \in \Omega$$

with equality and inequality constraints on the parameters and the state variable. The cost functionals are (one-sided) Gâteaux-differentiable with respect to the state variables and the parameters. Using the Duboviskii–Miljutin lemma we get the two maximum principles for the two identification problems, respectively, i.e., the necessary conditions for the existence of optimal parameters.

Key words. system identification, constraints on the parameters and state, Gâteaux-differentiable functional, distributed parameter systems, maximum principle

1. Introduction.

In this paper we use a general optimization theory, the Duboviskii–Miljutin theory, to study identification problems for a parabolic distributed parameter system with constraints on the parameters and the state variable.

These problems are motivated by a number of practical, industrial applications. For example, one hopes to identify the parameter $q(x)$ in the parabolic differential equation:

$$\frac{\partial p}{\partial t} = \nabla \cdot (q(x)\nabla p) + f(x,t), \tag{1}$$

based on noisy measurements of $p(x,t)$, $p^{\text{obs}}(x_i,t)$, at a set of discrete spatial locations, $i = 1,\ldots,m$.

It is well known that the equation (1) can be used to describe the motion of a fluid flow in the so-called reservoir region, where the dependent variable $p(x,t)$ represents the pressure distribution, $f(x,t)$ accounts for the withdrawal or injection of the fluid, and $q(x)$ is the transmissibility in the reservoir. In this instance one can get not only the observation of $p(x)$, $p^{\text{obs}}(x_i,t)$, but also the observations of $q(x)$, $q(x_i)$, at the measurement locations, $x_1,\ldots,x_m$. Furthermore, the pressure $p(x,t)$ is always nonnegative. So, this is a typical identification problem for a parabolic distributed parameter system with constraints on the parameter and the state variable.

There are many papers dealing with various identification problems. We only list a few references [1]–[18] for the reader's convenience. Most of the research workers only considered that the parameters submit certain limits, such as smoothness properties or upper and lower bounds. But only a few papers are concerned with equality constraints on parameters and/or inequality constraints on state variables;

for example, cf. the references [19]–[22], some of which discuss optimal control problems with constraints on the controls and the state variables. In many cases one can get the direct measurement on a subset S of the parameters to be determined and the properties of the state variables. Of course, this kind of information is very helpful to estimate the parameters. Therefore, it is natural for us to present identification problems with inequality and/or equality constraints on the parameters. For these problems we could not directly use any method that needs the computation of Fréchet derivatives with respect to (w.r.t.) unknown parameter functions because the admissible parameter sets in these cases, perhaps, are those with empty interior.

Next, the outline of this paper is given as follows. In §2 we present a description of the identification problem we discuss and of the main results of the paper. That is, we consider identification problems for the distributed parameter system governed by a uniformly parabolic partial differential equation (PDE) of order two, of which we want to determine the coefficients of the lowest-order derivative and the highest-order derivatives, which satisfy certain inequality constraints and have given values at a set, by means of measurement data of the state variable on the final time.

In §3 we state the above-mentioned identification problems as optimization problems in appropriate function spaces and then state the Duboviskii–Miljutin lemma for general optimization problems. In §4 we, first, calculate a descent direction cone, cones of admissible directions, a tangent direction cone, and their dual cones according to the requirement of the Duboviskii–Miljutin lemma. Next, from the dual cones we get functionals that satisfy the Euler–Lagrange equation. Finally, from the Euler–Lagrange equation we derive the useful necessary conditions that are satisfied by the optimal parameters minimizing the cost functionals, which may be only one-sided Gâteaux differentiable.

By the way, it should be pointed out that the study of uniqueness of the solution to an inverse problem remains a great challenge for applied mathematics, so there are only a few papers concerning this topic; see, e.g., [9]–[14], [16], and [18]. But it is a most important topic for practical researchers. We do not discuss this problem in the paper.

Finally, we also mention the relationship between identification of distributed parameter systems governed by PDEs or inverse problems in PDEs and the optimal control theory or optimization theory. Usually, one recognizes an identification problem as a special optimal control problem and the parameter as a special control. Therefore, the optimization theory offers a research approach for the study of identification. On the other hand, because of the specific characteristics of identification problems, they provide new research topics for optimization theory.

2. Description of the problem.

Consider the problem of identifying the unknown coefficient functions $a_{11}(x,t), \ldots, a_{mm}(x,t)$ and $c(x,t)$, which are regarded as a parameter vector $q \equiv (a_{11}, \ldots, a_{mm}, c)$, involved in the following second-order, linear, uniformly parabolic system:

$$\begin{aligned} &Lu \equiv \partial_t u - \partial_i(a_{ij}(x,t)\partial_j u) + b_i(x,t)\partial_i u + c(x,t)u = f(x,t), \quad (x,t) \in D, \\ &u\mid_{\partial\Omega} = g(s,t), \quad (s,t) \in \partial\Omega \times [0,T], \quad u\mid_{t=0} = u^0(x), x \in \bar{\Omega}, \end{aligned} \tag{2}$$

on the basis of the measurement

$$u\mid_{t=T} = z(x) + w(x), \quad x \in \Omega, \tag{3}$$

where $D \equiv \Omega \times (0, T)$, z is a given function defined on Ω, w is a white measurement noise with zero mean, and

$$\begin{array}{ll} x \equiv (x_1, \ldots, x_m), & a_i b_i \equiv \sum_i a_i b_i, \\ \partial_t \equiv \partial / \partial t, & \partial_i \equiv \partial / \partial x_i. \end{array}$$

In addition, some value of q is given:

$$q \mid_S = q_o, \tag{4}$$

where S is a subset of $\bar{\Omega}$ and q_o is an $(m^2 + 1)$-valued given function defined on S.

Furthermore, the solution of (2) is subject to a constraint:

$$\beta(x, t, u(x, t)) \leq 0, \qquad \forall (x, t) \in D. \tag{5}$$

Remark. If we take $\beta(x, t, u) = -u$, then (5) means that the solution of (2) is nonnegative on D.

In order to let the problem (2) be well posed we always suppose in the paper that the following assumptions are true.

- H1. $\Omega \subset \mathbb{R}^m$ is a bounded open set and its boundary $\partial\Omega \in C^{2+\alpha}$.
- H2. $b_i \in \bar{C}^{1+\alpha}(D)$, $f \in \bar{C}^{\alpha}(D)$, $u^0 \in C^{2+\alpha}$, and $g \in \bar{C}^{2+\alpha}$ are given.
- H3. u^0 and g satisfy the compatibility conditions, i.e., $\zeta \in C^{2+\alpha}$, where

$$\zeta(x, t) = \begin{cases} g(x, t), & (x, t) \in \partial\Omega \times [0, T], \\ u^0(x), & (x, t) \in \bar{\Omega} \times \{0\}. \end{cases}$$

Then by [24] for any q in

$$Q_{\mathrm{ad},1} \equiv \{q \in Q; \quad \nu|\xi|^2 \leq a_{ij}(x, t)\xi_i\xi_j \leq \mu|\xi|^2, \ \forall \xi \in \mathbb{R}^m, \ \forall (x, t) \in D\}, \tag{6}$$

there exists a unique solution $u \in V \equiv \bar{C}^{2+\alpha}(D)$ to the problem (2), which is denoted by $u = u(q) = u(x, t; q)$ to show the dependence of u on q, where $Q \equiv [\bar{C}^{1+\alpha}(D)]^{m^2} \times \bar{C}^{\alpha}(D)$, and the definitions of $\bar{C}^{\alpha}(D)$, $\bar{C}^{1+\alpha}(D)$, and $\bar{C}^{2+\alpha}(D)$ can be found in [24].

One can recognize the above-mentioned parameter identification problem as a minimum problem exactly as most researchers have done. That is, seek a minimal parameter $\hat{q} \in Q_{\mathrm{ad}}$ such that the cost functional

$$F_o(q) \equiv f_o(u(q), q; z) \tag{7}$$

reaches its minimum over the admissible parameter set Q_{ad} at $\hat{q}$, i.e.,

$$F_o(\hat{q}) = \min_{q \in Q_{\mathrm{ad}}} F_o(q), \tag{8}$$

where the admissible set Q_{ad} is defined by

$$Q_{\mathrm{ad}} \equiv Q_{\mathrm{ad},1} \cap Q_{\mathrm{ad},2}, \tag{9}$$

$$Q_{\mathrm{ad},2} \equiv \{q \in Q; \ q \mid_S = q_o\}, \tag{10}$$

and f_o is a (one-sided) Gâteaux-differentiable functional.

Under the same constraint conditions (2), (6), and (10), depending upon the choice of f_o, one can consider the following extremum problems.

PROBLEM A. The cost functional is

$$F_a(q) \equiv \int_\Omega \phi(x, u(x,T;q), q(x,T); z(x))\, dx. \tag{11}$$

PROBLEM B. The cost functional is

$$F_b(q) \equiv \max_\Omega |u(x,T;q) - z(x)|. \tag{12}$$

Adding to the assumptions H1–H3, we also suppose that the function ϕ satisfies the following assumption, H4.

$$H4 \left\{ \begin{array}{l} \phi \text{ is continuous w.r.t. all their arguments. Moreover, } \phi(x,\cdot,\cdot;z) \text{ satisfies} \\ \text{the Lipschitz condition} \\ \qquad |\phi(x,u_1,q_1;z) - \phi(x,u_2,q_2;z)| \le L\{|u_1 - u_2| + |q_1 - q_2|\} \\ \text{for any } \ x \in \Omega \text{ and for any bounded } u \text{ and } q, \text{ and is differentiable w.r.t.} \\ u \text{ and } q \text{ in the directions } \dot{u} \text{ and } \dot{q}. \text{ That is, there exist the following limits :} \end{array} \right.$$

$$\begin{array}{l} \lim_{t\to+0}[\phi(x,u+t\dot{u},q;z) - \phi(x,u,q;z)]/t \equiv \phi_u(x,u,q;z)\dot{u}, \\ \lim_{t\to+0}[\phi(x,u,q+t\dot{q};z) - \phi(x,u,q;z)]/t \equiv \langle\phi_q(x,u,q;z),\dot{q}\rangle. \end{array} \tag{13}$$

Now, we state the main results as follows.

THEOREM 2.1. *Suppose that the hypotheses* H1–H4 *are valid and that there exists a solution* $q^o \in Q_{\text{ad}} \equiv Q_{\text{ad},1} \cap Q_{\text{ad},2}$ *to Problem A, where* $q^o \equiv (a^o_{11}, \ldots, a^o_{mm}, c^o)$, *and* $Q_{\text{ad},1}$ *and* $Q_{\text{ad},2}$ *are defined by* (6) *and* (10), *respectively, such that* (u^o, q^o) *with* $u^o = u(q^o)$ *minimizes the functional* (11).

Then there is a nonnegative measure $\nu \in rca(D)$ *with compact support contained in the set*

$$\mathfrak{N} \equiv \{(x,t) \in D; \quad \beta(x,t,u^o(x,t)) = 0\}, \tag{14}$$

such that the following maximum principle,

$$\begin{array}{l} \sup_{q\in Q_{\text{ad}}}\{\int_D[a_{ij}\partial_j u^o\partial_i v + cu^o v] - \int_\Omega\langle\phi_q(x,u^o(x,T),q^o(x,T);z(x)),q\rangle\} \\ \quad = \int_\Omega[a^o_{ij}\partial_j u^o\partial_i v + c^o u^o v] - \int_\Omega\langle\phi_q(x,u^o(x,T),q^o(x,T);z(x)),q^o(x,T)\rangle, \end{array} \tag{15}$$

holds, where v is the generalized solution in Ladyzhenskaya's sense to the adjoint equation of (2), *i.e., v is the solution of the following variation equation:*

$$\begin{array}{l} \int_D[(\partial_t w + b_i\partial_i w + c^o w)v + a^o_{ji}\partial_i w\partial_j v] \\ \quad = \int_\Omega \phi_u(x,u^o(x,T),q^o(x,T);z(x))w(x,T)dx \\ \quad + \int_D \chi_{\mathfrak{N}}\beta_u(x,t,u^o;z)w\,\nu(dxdt), \qquad \forall w \in \mathfrak{H}, \end{array} \tag{16}$$

where $\beta_u \equiv \partial\beta/\partial u$, $\chi_{\mathfrak{N}} = 0$ *if* $\mathfrak{N} = \emptyset$; *otherwise* $\chi_{\mathfrak{N}}$ *is the characteristic function of* $\mathfrak{N}$,

$$\mathfrak{H} \equiv \{w \in H^1(0,T;H^1_0(\Omega)); \quad w\,|_{t=0} = 0\},$$

and $rca(\mathfrak{S})$ *is the space of all regular countably additive scalar-valued functions on the* σ*-field of all Borel sets in* $\mathfrak{S}$ *and the norm in* $rca(\mathfrak{S})$, $|\mu|$, *is the total variation* $v(\mu,\mathfrak{S})$.

Similarly, for Problem B, we have the following results.

THEOREM 2.2. *Suppose that the hypotheses* H1–H3 *are valid and that there exists an optimal solution* $q^o \in Q_{\text{ad}}$ *to Problem B, such that* $u^o = u(q^o)$ *minimizes the functional* (12).

Then there is a nonnegative measure $\mu \in rca(\Omega)$, *of which support is contained in the set*

$$\mathfrak{C} \equiv \left\{ x \in \Omega; \quad |u^o(x,T) - z(x)| = \max_{y \in \bar{\Omega}} |u^o(y,T) - z(y)| \right\}, \tag{17}$$

and a nonnegative measure $\nu \in rca(D)$ *with compact support contained in the set* $\mathfrak{N}$ *such that the following maximum principle,*

$$\sup_{q \in Q_{ad}} \int_D [a_{ij}\partial_j u^o \partial_i v + cu^o v]\, dxdt = \int_D [a^o_{ij}\partial_j u^o \partial_i v + c^o u^o v]\, dxdt, \tag{18}$$

holds, where v *is defined by the following variation equation:*

$$\begin{aligned} &\textstyle\int_D [(\partial_t w + b_i \partial_i w + c^o w)v + a^o_{ij}\partial_j w \partial_i v]\, dxdt \\ &= \textstyle\int_\Omega \chi_{\mathfrak{C}} \operatorname{sign}[u^o(s,T) - z(s)] w(s,T)\, \mu(ds) + \int_D \chi_{\mathfrak{N}} \beta_u(x,t,u^o;z) w\, \nu(dxdt), \\ &\qquad \forall w \in \mathfrak{H}, \end{aligned} \tag{19}$$

and the definitions of Q_{ad}, $rca(D)$, $rca(\Omega)$, $\mathfrak{N}$, $\chi_{\mathfrak{N}}$, β_u, *and* $\mathfrak{H}$ *are the same as those in Theorem* 2.1, *and* $\chi_{\mathfrak{C}} = 0$ *if* $u^o(\cdot,T) = z(\cdot)$, *otherwise* $\chi_{\mathfrak{C}}$ *is the characteristic function of* $\mathfrak{C}$.

3. Preliminary.

In order to solve the minimum problems we use the Duboviskii–Miljutin lemma [25]. Therefore, we consider a general extremum problem in a locally convex topological space E, i.e., minimize a cost functional

$$F_o(Y) \tag{20}$$

with inequality constraints

$$Y \in E_j \quad (j = 1, \ldots, n) \tag{21}$$

and an equality constraint

$$Y \in E_{n+1}, \tag{22}$$

where E_j $(j = 1, \ldots, n)$ are sets with a nonempty interior in E.

From [25] or [28] we get the following lemma.

LEMMA 3.1 (Duboviskii–Miljutin). *Assume that the following hypotheses hold.*

- $F_o(Y)$ *is a regular decrease functional at* $Y_o \in \cap_{j=1}^{n+1} E_j$, *and its decrease direction cone at* Y_o *is* K_0.
- *The inequality constraints* E_j $(j = 1, \ldots, n)$ *are regular at* Y_o *and their admissible direction cones at* Y_o *are* K_j.
- *The equality constraint* E_{n+1} *is regular at* Y_o *and its tangential direction cone at* Y_o *is* K_{n+1}.
- *The functional* $F_o(Y)$ *reaches its minimum at* Y_o *on* $\cap_{j=1}^{n+1} E_j$.

Then $\psi_i \in K_i^+$, K_i^+ *are the dual cones of* K_i, $i = 0, \ldots, n+1$, *such that* $\psi_0, \ldots, \psi_{n+1}$, *which are not all simultaneously equal to zero, satisfy the Euler–Lagrange equation*

$$\sum_{i=0}^{n+1} \psi_i = 0. \tag{23}$$

From now on we suppose

$$Y \equiv (u, q), \quad E \equiv V \times Q, \tag{24}$$

where $V = \bar{C}^{2+\alpha}(D)$ and $Q = [\bar{C}^{1+\alpha}(D)]^{m^2} \times \bar{C}^{\alpha}(D)$. Moreover, it is obvious that

$$E^* = \{f = (f_1, f_2); \quad f_1 \in V^*, \quad f_2 \in Q^*\},$$

i.e., $E^* = V^* \otimes Q^*$, where E^*, V^*, and Q^* are the adjoint spaces of E, V, and Q, respectively.

Moreover, suppose

$$E_1 \equiv \{Y = (u, q); \quad u \in V, \ q \in Q_{\mathrm{ad},1}\} = V \times Q_{\mathrm{ad},1}, \tag{25}$$

$$E_2 \equiv \{Y = (u, q) \in E; \quad P(Y) = 0\}, \tag{26}$$

$$E_3 \equiv \{Y \in E; \quad \beta(x, t, u(x, t)) \leq 0, \quad \forall\, (x, t) \in D\}, \tag{27}$$

where $Q_{\mathrm{ad},1}$ is defined by (6) and $P : E \longrightarrow F$ is defined by

$$P(Y) \equiv \{L(q)u - f, L_b(q)u - g, L_s q - q_o\}, \tag{28}$$

$$L(q)u \equiv \partial_t u - \partial_i(a_{ij}\partial_j u) + b_i \partial_i u + cu, \tag{29}$$

$$L_b(q)u \equiv u \mid_{\partial\Omega}, \tag{30}$$

$$L_s q \equiv q \mid_S, \tag{31}$$

where

$$F \equiv \bar{C}^{\alpha}(D) \times \bar{C}^{2+\alpha}(\partial\Omega \times [0, T]) \times \Psi, \tag{32}$$

$$\Psi \equiv \{p(x, \cdot) \in (\bar{C}^{1+\alpha}([0, T]))^{m^2} \times \bar{C}^{\alpha}([0, T]); \quad x \in S, \quad p \text{ is continuous on } S \times [0, T]\};$$

moreover, if we set $\|w\|_F \equiv \|w_1\|_\alpha + \|w_2\|_{2+\alpha} + \|w_3\|_\Psi$ and $\|w_3\|_\Psi \equiv \max_{x \in S} \|w_3(x, \cdot)\|$, then F is a Banach space.

Furthermore, set

$$Z = E_1 \cap E_2 \cap E_3, \tag{33}$$

$$J_a(Y) \equiv \int_\Omega \phi(x, u(x; T), q(x); z(x))\, dx, \tag{34}$$

$$J_b(Y) \equiv \max_{\bar{\Omega}} |u(x, T) - z(x)|. \tag{35}$$

Therefore, the parameter estimation problems A and B will be deduced to special extremum problems.

PROBLEM A′. Minimize $J_a(Y)$ on the same constraints (33) with (25)–(27).

PROBLEM B′. Minimize $J_b(Y)$ on the same constraints (33) with (25)–(27).

4. Proof of the main results.

In order to use the Duboviskii–Miljutin lemma to prove Theorems 2.1 and 2.2 we need several lemmas.

From [25] one can get the following.

LEMMA 4.1. *Let $f \in E^*$ and*

$$I_1 \equiv \{x \in E; \quad f(x) = 0\}, \qquad I_2 \equiv \{x \in E; \quad f(x) \geq 0\},$$
$$I_3 \equiv \{x \in E; \quad f(x) > 0\}.$$

Then

$$I_1^+ = \{\lambda f;\ \lambda \in \mathbf{R}^1\}, \quad I_2^+ = \{\lambda f;\ \lambda \in \mathbf{R}_+^1\},$$

and $I_3^+ = E^*$ *if* $f = 0$; *otherwise* $I_3^+ = I_2^+$.

From [25] one also gets the following.

LEMMA 4.2. *Suppose that* $F(Y)$ *satisfies the Lipschitz condition in a neighborhood of* $Y_0 \in E$ *and is (one-sided) Gâteaux differentiable at* Y_0 *in any direction* $\dot{Y}$, *and that the Gâteaux variation,* $F'(Y_0, \dot{Y})$, *of* $F(Y)$ *at* Y_0 *is convex w.r.t.* $\dot{Y}$. *Then* $F(Y)$ *regularly descends at* Y_0 *and the descent direction cone,* K, *of* F *at* Y_0 *is*

$$K = \{\dot{Y};\quad F'(Y_0, \dot{Y}) < 0\}.$$

LEMMA 4.3. *The functional* $J_a(Y)$ *is one-sided Gâteaux differentiable, and its Gâteaux differential is determined by*

$$\begin{aligned} J_a'(Y)\dot{Y} = {} & \textstyle\int_\Omega [\phi_u(s, u(s,T), q(s,T); z(s))\dot{u}(s,T) \\ & + \langle \phi_q(s, u(s,T), q(s,T); z(s)), \dot{q}(s,T)\rangle]\, ds, \qquad \forall \dot{Y} = (\dot{u}, \dot{q}) \in E, \end{aligned} \tag{36}$$

where ϕ_u *and* ϕ_q *are defined by* (13). *Moreover,* $J_a(Y)$ *is a regular descent functional at* $Y = (u, q)$, *and its descent direction cone,* K_0, *at* Y *is*

$$K_0 = \{\dot{Y} \in E;\ \ J_a'(Y)\dot{Y} < 0\}, \tag{37}$$

and the dual cone of K_0 *is*

$$K_0^+ = \{-\lambda_0 J_a'(Y);\quad 0 < \lambda_0 < +\infty\}. \tag{38}$$

Proof. By the assumption H4 one immediately gets

$$\begin{aligned} \lim\nolimits_{t\to+0} [J_a(Y + t\dot{Y}) - J_a(Y)]/t = {} & \lim\nolimits_{t\to+0} \textstyle\int_\Omega \{[\phi(s, u + t\dot{u}, q + t\dot{q}; z) \\ & -\phi(s, u, q + t\dot{q}; z)]/t + [\phi(s, u, q + t\dot{q}; z) - \phi(s, u, q; z)]/t\}\, ds \\ = {} & \textstyle\int_\Omega [\phi_u(s, u, q; z)\dot{u} + \langle \phi_q(s, u, q; z), \dot{q}\rangle]\, ds, \end{aligned}$$

and then (36) is true.

It is obvious that $J_a'(Y)\dot{Y} < 0$ if $\dot{Y} \in K_0$.

On the other hand, if $\dot{Y}$ satisfies $J_a'(Y)\dot{Y} = -\delta < 0$, then there exists $\epsilon_1 > 0$ such that $J_a(Y + \epsilon\dot{Y}) \leq J_a(Y) - \epsilon\delta/2$, $\forall \epsilon \in (0, \epsilon_1)$, by the definition of Gâteaux differential. Let $h \in B_1(\dot{Y}) \equiv \{h \in E;\ \|h - \dot{Y}\| < \delta/(4L)\}$. Then, by the assumption H4,

$$\begin{aligned} J_a(Y + \epsilon h) = {} & J_a(Y + \epsilon\dot{Y}) + [J_a(Y + \epsilon h) - J_a(Y + \epsilon\dot{Y})] \leq J_a(Y + \epsilon\dot{Y}) \\ & +\epsilon\delta/4 \leq J_a(Y) - \epsilon\delta/2 + \epsilon\delta/4 = J_a(Y) - \epsilon\delta/4. \end{aligned}$$

So, if we take $\alpha = -\delta/4$, then $\dot{Y} \in K_0$. Therefore, (37) is true. In addition, it follows by (36) that the set K_0 is convex. Hence, $J_a(Y)$ is a regular descent functional at Y.

Finally, (38) can be deduced by Lemma 4.1. □

Furthermore, we also have the following lemma.

LEMMA 4.4. *The functional* $J_b(Y)$ *is one-sided Gâteaux differentiable, and its Gâteaux variation is determined by*

$$J_b'(Y, \dot{Y}) = \max_{s \in \mathfrak{C}} \{\dot{u}(s,T)\, \mathrm{sign}[u(s,T) - z(s)]\}, \quad \forall \dot{Y} = (\dot{u}, \dot{q}) \in E, \quad u\,|_{t=T} \neq z, \tag{39}$$

$$\textit{or} \quad J_b'(\tilde{Y}, \dot{Y}) = \max_{s \in \Omega} |\dot{u}(s,T)|, \quad \forall q \in Q, \tilde{Y} = (\tilde{u}, q) \in E \ \ \textit{with}\ \ \tilde{u}\,|_{t=T} = z. \tag{40}$$

Moreover, $J_b(Y)$ is a regular descent functional at $Y = (u,q)$; its descent direction cone at Y, K_0, and the dual cone of K_0, K_0^+, are

(i) *if $Y = (u,q)$ with $u \,|_{t=T} \neq z$,*

$$K_0 = \{\dot{Y} \in E;\quad \dot{u}(x,T)\operatorname{sign}[u(x,T) - z(x)] < 0,\ \ x \in \mathfrak{C}\}, \tag{41}$$

$$K_0^+ = \left\{\mu \in \Phi;\quad -\int_{\mathfrak{C}} \dot{u}(x,T)\operatorname{sign}[u(x,T) - z(x)]\,\mu(dx) > 0,\ \ \forall \dot{Y} \in K_0\right\}, \tag{42}$$

(ii) *or if $\tilde{Y} = (\tilde{u},q)$ with $\tilde{u} \,|_{t=T} = z$,*

$$K_0 = \emptyset, \qquad\qquad K_0^+ = 0, \tag{43}$$

where

$$\Phi \equiv \{\mu \in rca(\mathfrak{C});\quad \operatorname{supp}(\mu) \subseteq \mathfrak{C},\ \ \mu(dx) \geq 0\}. \tag{44}$$

Proof. For all $u \,|_{t=T} \neq z$ we have

$$\begin{aligned} J_b'(Y,\dot{Y}) &= \lim\nolimits_{t\to+0}\{\max|u(x,T) + t\dot{u}(x,T) - z(x)| - \max|u(x,T) - z(x)|\}/t \\ &= \lim\{\max|\,|u(x_o,T) - z(x_o)| \\ &\qquad + t\dot{u}(x,T)\operatorname{sign}[u(x,T) - z(x)]| - \max|u(x,T) - z(x)|\}/t. \end{aligned}$$

Obviously, for t small enough we have

$$\begin{aligned} &\max\nolimits_{x\in\bar{\Omega}}|\,|u(x,T) - z(x)| + t\dot{u}(x,T)\operatorname{sign}[u(x,T) - z(x)]| \\ &\quad = \max\nolimits_{x\in\mathfrak{C}}|u(x,T) - z(x)| + t\max\nolimits_{x\in\mathfrak{C}}\dot{u}(x,T)\operatorname{sign}[u(x,T) - z(x)] + o(t). \end{aligned}$$

Thus,

$$J_b'(Y,\dot{Y}) = \max_{x\in\mathfrak{C}}\{\dot{u}(x,T)\operatorname{sign}[u(x,T) - z(x)]\}.$$

Obviously, (40) and (43) are true.

Next, one easily obtains that the Gâteaux variation, $J_b'(Y,\dot{Y})$, defined by (39) or (40) is convex and that the functional $J_b(Y)$ satisfies the Lipschitz condition and is one-sided differentiable in any direction $\dot{Y}$. So, by Lemma 4.2 $J_b(Y)$ is a regular descent functional. Moreover, (41) is true.

From the definition of a dual cone and the Riesz representation theorem, (e.g., cf. [23, p. 265]), it immediately follows that the equality (42) is also true. □

Regarding the set E_1 we have the following lemma.

LEMMA 4.5. *Suppose $Y_o = (u^o, q^o) \in E_1 = V \times Q_{\text{ad},1}$, where $Q_{\text{ad},1}$ is defined by (6). Then E_1 is regular at Y_o and the dual cone of E_1 at Y_o is*

$$K_1^+ = \{(0,f_2) \in E^*;\ \ f_2(q - q^o) \geq 0,\ \forall q \in Q^o_{\text{ad},1}\}, \tag{45}$$

where $Q^o_{\text{ad},1}$ is the interior of $Q_{\text{ad},1}$, i.e., f_2 is a support functional of $Q_{\text{ad},1}$ at q^o.

Proof. It is obvious that the cone of admissible directions of E_1 at $Y_o = (u^o, q^o)$ is

$$K_1 = V \times \{k \in Q;\ \ k = \lambda(q - q^o),\ q \in Q^o_{\text{ad},1},\ \lambda \geq 0\}. \tag{46}$$

Thus, K_1 is convex and E_1 is regular at Y_o.

Next, by $E^* = V^* \otimes Q^*$ and (46) we have

$$K_1^+ = \{(f_1, f_2);\ f_1(u) \geq 0,\ \forall u \in V,\ f_2(k) \geq 0,\ k = \lambda(q - q^o),\ \lambda \geq 0\}. \tag{47}$$

Considering that V is the whole space, we have $f_1 = 0$. Owing to $\lambda \geq 0$, we get $f_2(q - q^o) \geq 0$, $\forall q \in Q^o_{\text{ad},1}$. □

From [27] we can get the following.

LEMMA 4.6 (Lusternik). *Let $W(Y)$ be an operator mapping E into F, differentiable in a neighborhood of a point Y_o with $W(Y_o) = 0$. Let $W'(Y)$ be continuous in a neighborhood of Y_o, and suppose $W'(Y_o)$ maps E onto F (i.e., the linear equation $W'(Y_o)\dot{Y} = h$ has a solution $\dot{Y} \in E$ for any $h \in F$).*

Then the set of tangential directions to the set

$$\tilde{E}_2 \equiv \{Y \in E;\quad W(Y) = 0\}$$

at the point Y_o is the subspace

$$\tilde{K}_2 \equiv \{\dot{Y} \in E;\quad W'(Y_o)\dot{Y} = 0\}.$$

LEMMA 4.7. *The operator $P(Y)$, which is defined by (28), is Fréchet differentiable with respect to $Y = (u, q)$ and $\forall \dot{Y} = (\dot{u}, \dot{q}) \in E$ the Fréchet differential of $P(Y)$ at $Y \in E_1$ is determined by*

$$P'(Y)\dot{Y} = \{L(q)\dot{u} - \partial_i(\dot{a}_{ij}\partial_j u) + \dot{c}u, L_b(q)\dot{u}, L_s\dot{q}\}, \tag{48}$$

where $\dot{q} \equiv (\dot{a}_{11}, \ldots, \dot{a}_{mm}, \dot{c})$, i.e.,

$$P'(Y) \in \mathcal{L}(E; F), \tag{49}$$

and F is defined by (32).

In addition, the tangential direction cone K_2 to E_2, where E_2 is defined by (26), at $Y \in E_1$, is

$$K_2 = \{\dot{Y} \in E;\ P'(Y)\dot{Y} = 0\}; \tag{50}$$

i.e., $\forall \dot{q} \in Q$ satisfying the condition

$$L_s\dot{q} = 0, \tag{51}$$

$\dot{u}$ is the solution to the problem

$$\left\{ \begin{array}{ll} \partial_t\dot{u} - \partial_i(a_{ij}\partial_j\dot{u}) + b_i\partial_i\dot{u} + c\dot{u} = \partial_i(\dot{a}_{ij}\partial_j u) - \dot{c}u, & (x, t) \in D, \\ \dot{u}\,|_{\partial\Omega} = 0, \qquad \dot{u}\,|_{t=0} = 0, & \end{array} \right. \tag{52}$$

where $(u, q) \equiv (u, a_{11}, \ldots, a_{mm}, c) \in E_1$ also locates on the manifold E_2, or $u = u(q)$ is the solution to the problem (2) with the constraints on q.

Proof. The results (48) and (49) are evident. So, we only need to prove (50) using Lemma 4.6.

By [26] we know that the mapping is surjective, in fact, $\forall (f, g, q_o) \in F$, the operator equation

$$P'(Y_o)\dot{Y} = \{f, g, q_o\} \tag{53}$$

has a unique solution $\dot{Y} = (\dot{u}, \dot{q}) \in E$. And then it follows from Lemma 4.6 that (50), and therefore (51) and (52), is true. □

LEMMA 4.8. *The dual cone of* K_2, *which is defined by* (50), *is determined by*

$$\begin{aligned} K_2^+ \equiv &\{f = (f_1, f_2) \in E^*;\ f_1 \in V^*,\ f_2 = -[u'(q)]^* f_1\} \\ &+ \cup_{x \in S} \{(0, \lambda_x) L_x;\ \lambda_x \in \mathbb{R}^1\}, \\ L_x q \equiv &\, q(x), \quad \forall x \in S, \end{aligned} \tag{54}$$

where $[u'(q)]^*$ *is the adjoint operator of* $u'(q)$ *and* $u'(q)\dot{q} = \dot{u}$ *is determined by* (52).

Proof. We first denote the cone of tangent directions K_2 as

$$K_2 = L_1 \cap L_2, \tag{55}$$

where

$$L_1 \equiv \{(\dot{u}, \dot{q}) \in E;\ L(q)\dot{u} - \partial_i(\dot{a}_{ij}\partial_j u) + \dot{c}u = 0,\ L_b(q)\dot{u} = 0\} \tag{56}$$

and

$$L_2 \equiv \{(\dot{u}, \dot{q}) \in E;\ L_s \dot{q} = 0\}. \tag{57}$$

Obviously, we have

$$K_2^+ = L_1^* + L_2^*, \tag{58}$$

where L_1^* and L_2^* are dual spaces of L_1 and L_2, respectively, which are subspaces of E^*.

For any $(\dot{u}, \dot{q}) \in L_1$ we have

$$\left\{ \begin{array}{ll} L(q)\dot{u} = \partial_i(\dot{a}_{ij}\partial_j u) - \dot{c}u, & (x,t) \in D, \\ \dot{u}\,|_{\partial\Omega} = 0, & \dot{u}\,|_{t=0} = 0. \end{array} \right. \tag{59}$$

It is easy to see $\dot{u} = u'(q)\dot{q}$, where $\dot{q} = (\dot{a}_{11}, \ldots, \dot{a}_{mm}, \dot{c})$, i.e., $\dot{u}$ is the Fréchet differential of u at q. Therefore,

$$L_1 = \{(\dot{u}, \dot{q}) \in E;\ \dot{u} = u'(q)\dot{q}\}.$$

Moreover, L_1 is a subspace of E, so

$$L_1^* = \{f = (f_1, f_2) \in E^*;\ 0 = f_1(\dot{u}) + f_2(\dot{q}),\ \forall(\dot{u}, \dot{q}) \in L_1\}.$$

Considering $\dot{u} = u'(q)\dot{q}$ on L_1 we have

$$\begin{aligned} 0 &= f_1(\dot{u}) + f_2(\dot{q}) = \langle f_1, u'(q)\dot{q}\rangle + \langle f_2, \dot{q}\rangle \\ &= \langle [u'(q)]^* f_1 + f_2, \dot{q}\rangle, \quad \forall \dot{q} \in Q. \end{aligned}$$

Thus, $[u'(q)]^* f_1 + f_2 = 0$, i.e.,

$$f_2 = -[u'(q)]^* f_1.$$

Next, $L_2 = \cap_{x \in S} A_x$, where $A_x \equiv \{(\dot{u}, \dot{q}) \in E;\ L_x \dot{q} = 0\}$.

Obviously, $L_2^* = \cup_{x \in S} A_x^*$ and by Lemma 4.1 we have $f_1 = 0$ and $f_2 = \lambda_x L_x$, hence

$$A_x^* = \{(0, \lambda_x) L_x;\quad \lambda_x \in \mathbb{R}^1\}.$$

So, we get (54). □

LEMMA 4.9. *The inequality constraint, E_3, which is defined by (27), is regular at $Y_o = (u^o, q^o) \in E_3$, and its admissible direction cone, K_3, at Y_o is determined by*

$$K_3 = E, \qquad \textit{if} \quad \mathfrak{N} = \emptyset; \tag{60}$$

otherwise

$$K_3 = \{\dot{Y} = (\dot{u}, \dot{q}) \in E; \quad \beta_u(x,t,u(x,t)) < 0, \ \forall\,(x,t) \in \mathfrak{N}\}. \tag{61}$$

Furthermore, the dual cone of K_3 is

$$K_3^+ = \{0\}, \qquad \textit{if}\, \mathfrak{N} = \emptyset, \tag{62}$$

or, $\forall\, w \in K_3^+$ there is $\tilde{\nu} \in rca(\bar{D})$ with supp$\tilde{\nu}$ $\subseteq \mathfrak{N}$ *and $\tilde{\nu}(dxdt) \geq 0$ such that*

$$\begin{aligned} & w = (\tilde{w}, 0) \in E^*, \\ & w(Y) = \tilde{w}(\dot{u}) = -\int_{\mathfrak{N}} \beta_u(x,t,u^o(x,t))\dot{u}(x,t)\tilde{\nu}(dxdt), \quad \forall\, \dot{Y} \in E. \end{aligned} \tag{63}$$

Proof. Obviously, (60) and (62) are valid.

Next, consider the following nonlinear functional

$$G(u) = \max_{(x,t)\in\bar{D}} \beta(x,t,u(x,t)). \tag{64}$$

Then $G(u^o) = 0$ if $\mathfrak{N} \neq \emptyset$. Moreover, following [25], we can prove that the mapping $G : \ C(\bar{D}) \to \mathbb{R}^1$ is Gâteaux differentiable and its Gâteaux differential at u^o in direction h is

$$G'(u^o)h = \max_{(x,t)\in\mathfrak{N}} [\beta_u(x,t,u^o(x,t))h(x,t)]. \tag{65}$$

By the definition of admissible direction cone, $\dot{Y} = (\dot{u}, \dot{q}) \in K_3$ means that there exist an $\epsilon_0 > 0$ and a neighborhood of zero, $U(0)$, such that

$$Y_o + \epsilon(\dot{Y} + Y) \in E_3, \quad \forall\,\epsilon \in [0, \epsilon_0], \quad \forall\, Y = (u,q) \in U(0).$$

So, by the definition of E_3

$$G(u^o + \epsilon(\dot{u} + u)) \leq 0,$$

and owing to $G(u^o) = 0$,

$$\epsilon G'(u^o)(\dot{u} + u) + o(\epsilon) \leq 0.$$

Consider $(u,q) \in U(0)$; therefore,

$$G'(u^o)\dot{u} < 0. \tag{66}$$

Hence, $\forall\, \dot{Y} \in K_3$, we have

$$\beta_u(x,t,u^o(x,t))\dot{u}(x,t) < 0, \qquad \forall\,(x,t) \in \mathfrak{N}. \tag{67}$$

On the contrary, if $\dot{Y} = (\dot{u}, \dot{q})$ satisfies (67), then (66) is true, and it is easy to prove $\dot{Y} \in K_3$.

Therefore, (61) is valid.

Because the space V is a dense subset of $C(\bar{D})$, $\forall w = (\tilde{w}, 0) \in K_3^+$ there is $\tilde{\nu} \in rca(\bar{D})$ by the Riesz representation theorem [23] and the Minkowskii–Farkas theorem [25] such that (62) is valid. □

Now, we return to the proof of Theorem 2.1.

Proof of Theorem 2.1. If (u^o, q^o) $[u^o = u(q^o)]$ is the solution to Problem A′ (i.e., Problem A), then the cost functional $J_a(Y)$ defined by (11) attains the minimum at $Y_o = (u^o, q^o)$.

By (Duboviskii–Miljutin) Lemma 3.1 there exist $\psi_i \in K_i^+$ $(i = 0, 1, \dots, 3)$, which are not all simultaneously equal to zero and satisfy the Euler–Lagrange equation

$$\sum_{i=0}^{3} \psi_i(\dot{Y}) = 0, \quad \forall \dot{Y} \in \bigcap_{i=0}^{3} K_i \equiv \tilde{Z}. \tag{68}$$

By Lemma 4.3 there is a $\lambda_0 \geq 0$ such that

$$\psi_0(\dot{Y}) = -\lambda_0 J_a'(Y_o)(\dot{Y}), \tag{69}$$

and by Lemma 4.5 we have

$$\begin{aligned} &\psi_1(\dot{Y}) = (0, f_2)(\dot{Y}) = f_2(\dot{q}), \\ &f_2 \text{ is a support functional of } Q_{\text{ad},1} \text{ at } q^o, \end{aligned} \tag{70}$$

and by Lemma 4.8 we have

$$\psi_2(\dot{Y}) = \psi_{2,1}(\dot{Y}) + \psi_{2,2}(\dot{Y}), \tag{71}$$

where

$$\psi_{2,1} = (f_1, f_2) \in E^*, \quad f_1 \in V^*, \quad f_2 = -[u'(q^o)]^* f_1.$$

Therefore, we get

$$\psi_{2,1}(\dot{Y}) = f_1(\dot{u}) + f_2(\dot{q}) = f_1(\dot{u}) - [u'(q^o)]^* f_1(\dot{q}) \tag{72}$$

and

$$\psi_{2,2}(\dot{Y}) = \sum_{x \in S} \lambda_x \dot{q}(x). \tag{73}$$

Considering $\dot{Y} = (\dot{u}, \dot{q}) \in \tilde{Z}$ we have

$$\dot{q}(x) = 0, \quad x \in S, \tag{74}$$

and by Lemma 4.7, $\dot{u} = u'(q^o)\dot{q}$, so it follows from (72) and (73) that

$$\psi_{2,1}(\dot{Y}) = 0, \quad \forall \dot{Y} \in \tilde{Z}, \tag{75}$$

$$\psi_{2,2}(\dot{Y}) = 0, \quad \forall \dot{Y} \in \tilde{Z}. \tag{76}$$

If we take $\dot{q} \equiv (q - q^o) \in Q$ and $q \in Q_{\text{ad},1}^o$, then by (70)

$$\psi_1(\dot{Y}) = f_2(\dot{q}) = f_2(q - q^o) \geq 0, \quad \forall q \in Q_{\text{ad},1}^o.$$

And then by the continuity of f_2 and the convexity of $Q_{\mathrm{ad},1}$ we have

$$f_2(q - q^o) \geq 0, \quad \forall q \in Q_{\mathrm{ad},1}. \tag{77}$$

Finally, by Lemma 4.9,

$$\begin{aligned}\psi_3(\dot{Y}) = \lambda_0 J'_a(Y_o)(\dot{Y}) + \textstyle\int_D \chi_{\mathfrak{N}}(x,t)\beta_u(x,t,u^o(x,t))\dot{u}(x,t)\,\tilde{\nu}(dxdt),\\ \forall \dot{Y} \in \tilde{Z}.\end{aligned} \tag{78}$$

Substituting (69), (70), (71), and (78) into (68) and considering (75)–(77) one gets

$$\begin{aligned}0 \leq f_2(\dot{q}) = \psi_1(\dot{Y}) = \lambda_0 J'_a(Y_o)(\dot{Y})\\ + \textstyle\int_D \chi_{\mathfrak{N}}(x,t)\beta_u(x,t,u^o(x,t))\dot{u}(x,t)\,\tilde{\nu}(dxdt), \quad \forall \dot{Y} \in \tilde{Z}.\end{aligned} \tag{79}$$

Obviously, $\lambda_0 \neq 0$, otherwise by (69) and (79) one can get $\psi_0 = \psi_1 = \psi_3 = 0$; besides, by (75) and (76), $\psi_2 = 0$, but by Lemma 3.1 this is impossible.

Therefore,

$$J'_a(Y_o)(\dot{Y}) + \int_D \chi_{\mathfrak{N}}(x,t)\beta_u(x,t,u^o(x,t))\dot{u}(x,t)\,\nu(dxdt) \geq 0, \quad \forall \dot{Y} \in \tilde{Z}, \tag{80}$$

where $\nu = \tilde{\nu}/\lambda_0$. Furthermore, by Lemma 4.3 and (16)

$$\begin{aligned}0 \leq &\textstyle\int_\Omega [\phi_u(s,u^o(s,T),q^o(s,T);z(s))\dot{u}(s,T) + \langle \phi_q(s,u^o(s,T),q^o(s,T);z),\dot{q}(s,T)\rangle]\,ds\\ &+ \textstyle\int_D \chi_{\mathfrak{N}}(x,t)\beta_u(x,t,u^o(x,t))\dot{u}(x,t)\,\nu(dxdt)\\ = &\textstyle\int_D [\partial_t \dot{u} - \partial_i(a^o_{ij}\partial_j \dot{u}) + b_i\partial_i\dot{u} + c^o\dot{u}]v\,dxdt\\ &+ \textstyle\int_\Omega \langle \phi_q(s,u^o(s,T),q^o(s,T);z(s)),\dot{q}(s,T)\rangle\,ds.\end{aligned} \tag{81}$$

Because $(\dot{u},\dot{q}) \in \tilde{Z} \subset K_2$, by (52) in Lemma 4.7

$$\begin{aligned}0 \leq &\textstyle\int_\Omega \langle \phi_q(x,u^o(x,T),q^o(x,T);z(x)),\dot{q}(x,T)\rangle\,dx + \int_D [\partial_i(\dot{a}_{ij}\partial_j u^o) - \dot{c}u^o]v\,dxdt\\ = &\textstyle\int_\Omega \langle \phi_q(s,u^o(x,T),q^o(x,T);z(x)),\dot{q}(x,T)\rangle\,dx\\ &- \textstyle\int_D [\dot{a}_{ij}\partial_j u^o\partial_i v + \dot{c}u^o v]\,dxdt.\end{aligned}$$

Taking $\dot{q} = q - q^o$ we immediately have

$$\begin{aligned}&\textstyle\int_D [a_{ij}\partial_j u^o \partial_i v + cu^o v]\,dxdt - \int_\Omega \langle \phi_q(x,u^o,q^o;z),q\rangle\,dx\\ &\quad \leq \textstyle\int_D [a^o_{ij}\partial_j u^o\partial_i v + c^o u^o v]\,dxdt - \int_\Omega \langle \phi_q(x,u^o,q^o;z),q^o\rangle\,dx\\ &\qquad \forall q = (a_{11},\dots,a_{mm},c) \in Q_{\mathrm{ad}},\end{aligned}$$

which is just (15). □

Proof of Theorem 2.2. Obviously, most of the proof is the same as that in Theorem 2.1 except the proof of the inequalities (18) with (19). We have, especially,

$$\psi_0(\dot{Y}) + \psi_3(\dot{Y}) = -\psi_1(\dot{Y}) = -f_2(\dot{q}) \leq 0.$$

By Lemma 4.4 there exists $\mu \in \Phi$ such that

$$\psi_0(\dot{Y}) = -\int_\Omega \chi_{\mathfrak{C}}(x)\dot{u}(x,T)\mathrm{sign}[u^o(x,T) - z(x)]\,\mu(dx),$$

and by Lemma 4.9 there exists $\nu \in rca(D)$ with supp$\nu \subseteq \mathfrak{N}$ and $\nu(dxdt) \geq 0$ such that

$$\psi_3(\dot{Y}) = -\int_D \chi_{\mathfrak{N}}(x,t)\beta_u(x,t,u^o(x,t))\dot{u}(x,t)\,\nu(dxdt).$$

From the above two equalities and the inequality one can get

$$\begin{aligned} &\textstyle\int_D \chi_{\mathfrak{N}}(x,t)\beta_u(x,t,u^o(x,t))\dot{u}(x,t)\,\nu(dxdt) \\ &\quad + \textstyle\int_\Omega \chi_{\mathfrak{C}}(x)\dot{u}(x,T)\,\mathrm{sign}[u^o(x,T) - z(x)]\,\mu(dx) \geq 0. \end{aligned} \tag{82}$$

Owing to (19), one has

$$\int_D [(\partial_t \dot{u} + b_i\partial_i\dot{u} + c^o\dot{u})v + a^o_{ij}\partial_i v\partial_j\dot{u}]\,dxdt \geq 0. \tag{83}$$

Considering $\dot{Y} \in \tilde{Z} \subset K_2$, it follows by (52) in Lemma 4.7 that

$$0 \leq \int_D [\partial_i(\dot{a}_{ij}\partial_j u^o) - \dot{c}u^o]v\,dxdt = -\int_D (\dot{a}_{ij}\partial_j u^o\partial_i v + \dot{c}u^o v)\,dxdt. \tag{84}$$

In particular, take $\dot{q} = q - q^o$ with $q = (a_{11}, \ldots, a_{mm}, c)$ and $q^o = (a^o_{11}, \ldots, a^o_{mm}, c^o)$, and then we can immediately get (18). □

A CONVEX APPROACH TO THE MIXED $\mathcal{H}_2/\mathcal{H}_\infty$ CONTROL PROBLEM FOR DISCRETE-TIME UNCERTAIN SYSTEMS*

J. C. GEROMEL†, P. L. D. PERES†, AND S. R. SOUZA‡

Abstract. This paper considers $\mathcal{H}_2/\mathcal{H}_\infty$ control problems involving discrete-time uncertain linear systems. The uncertain domain is supposed to be convex bounded, which naturally covers, as a particular case, the important class of interval matrices. The $\mathcal{H}_\infty$ guaranteed-cost control problem, solved for this class of uncertain systems, under no matching conditions, can be stated as follows: determine a state feedback gain (if one exists) such that the $\mathcal{H}_\infty$ norm of a given transfer function remains bounded by a prespecified level for all possible models. In the same context, problems on the determination of the smallest $\mathcal{H}_\infty$ upper bound and the minimization of an $\mathcal{H}_2$ cost upper bound subject to $\mathcal{H}_\infty$ constraints are also addressed. The results follow from the fact that those problems are convex in the particular parametric space under consideration. Some examples illustrate the theory.

Key words. discrete-time system, uncertain systems, mixed $\mathcal{H}_2/\mathcal{H}_\infty$ control, convex analysis

AMS subject classifications. 93C15

1. Introduction.

In the last decade, $\mathcal{H}_\infty$ control theory has been largely developed in both frequency and state-space approaches. Concerning continuous-time systems, [4] states elegantly the optimal solutions of $\mathcal{H}_\infty$ and $\mathcal{H}_2$ control problems in terms of algebraic Riccati equations where both state feedback and observer-based output feedback are considered (see [4] and [21] and the references therein). However, few papers have proposed methods that take into account uncertain models. In [13], $\mathcal{H}_\infty$ control by state feedback is related to quadratic stabilizability in norm-bounded uncertain domains, but no control synthesis is proposed. On the other hand, methods such as the one introduced in [23] do not consider any uncertainty acting on the input matrix or assume some kind of matching conditions. This obviously restricts the class of uncertain systems to be dealt with. Quadratic stabilizability of continuous-time systems under convex-bounded uncertainties, by means of a state feedback control and with prescribed $\mathcal{H}_\infty$ norm upper bound, is addressed in [7].

The development is not quite the same when one regards discrete-time systems. Necessary and sufficient conditions have appeared in [5], [12], [17], and [24] for known models (i.e., all parameters are precisely known), relating discrete-time Riccati-like equations and $\mathcal{H}_\infty$ norm bounds. An interesting work [15], dealing with mixed $\mathcal{H}_2/\mathcal{H}_\infty$ control via convex optimization, focuses on precisely known systems. Using an appropriate matrix transformation, the state feedback control problem with mixed $\mathcal{H}_2/\mathcal{H}_\infty$ performance measure, the same used in [11], can be reduced to the minimization of a nonlinear—but convex—function over a bounded convex set of real matrices.

However, the extension of the above necessary and sufficient conditions to uncertain systems is not straightforward and, if possible, may lead to highly nonlinear problems to be solved. In [22], discrete-time norm-bounded uncertain systems are

investigated under $\mathcal{H}_\infty$ constraints. Sufficient conditions for quadratic stability with disturbance attenuation are provided, which circumvents the above-cited difficulty. The results presented in the control synthesis problem suppose the existence of a dynamic output controller, which remains to be determined.

This paper is devoted to analyze the convexity and solve several problems involving discrete-time uncertain systems. First we consider the $\mathcal{H}_\infty$ guaranteed cost control problem, for which preliminary results have already been presented in [19]. It consists of the determination of a constant state feedback control gain such that a certain closed-loop transfer function remains bounded by a prespecified $\mathcal{H}_\infty$ level for all uncertainties varying in a convex-bounded domain. Further, related control problems are also analyzed and solved. For instance, the above $\mathcal{H}_\infty$ norm bound may be included in the optimization procedure in order to determine the smallest feasible one [1], [14]. Moreover, an approximate version of the the mixed $\mathcal{H}_2/\mathcal{H}_\infty$ control problem is considered. It is important to emphasize that all results provided here follow from the definition of a special parameter space [6] on which the above problems are shown to be convex.

This paper is organized as follows. The next section introduces the system to be dealt with and basic assumptions needed throughout. Section 3 is devoted to the parametrization of $\mathcal{H}_2$ and $\mathcal{H}_\infty$ norms in terms of algebraic Riccati inequalities. In §4, the $\mathcal{H}_\infty$ guaranteed-cost control problem is solved, including the determination of the smallest $\mathcal{H}_\infty$ norm bound. The approximate mixed $\mathcal{H}_2/\mathcal{H}_\infty$ control problem is addressed in §5, where, in addition, decentralized control structures are considered and compared with [10]. Section 6 particularizes the results to the case of precisely known discrete-time systems and compares them with the ones provided in [24]. The examples included in §7 illustrate the theory, and in §8 the conclusion follows.

The notation used throughout is standard. The set of real numbers is denoted by $\Re$, Tr $(\cdot)$ means the trace of $(\cdot)$, $(')$ stands for transpose of matrices and vectors, and $\langle A, B\rangle = \mathrm{Tr}\,(A'B)$ denotes the inner product of matrices with appropriate dimensions. Singular values and eigenvalues are denoted by $\sigma(\cdot)$ and $\lambda(\cdot)$, respectively. Finally, $\mathcal{H}_\infty$ and $\mathcal{H}_2$ norms are defined as follows:

$$\| H\|_\infty \triangleq \max_{\omega\in[-\pi,\pi]} \sigma_{\max}\left[H(e^{j\omega})\right],$$

$$\| H\|_2^2 \triangleq \frac{1}{2\pi}\int_{-\pi}^{\pi} \mathrm{Tr}\left\{H(e^{-j\omega})'H(e^{j\omega})\right\} d\omega.$$

2. Preliminaries. Let us consider the following LTI discrete-time system:

$$(1)\qquad \left\{\begin{array}{rcl} x(k+1) & = & Ax(k) + B_1w(k) + B_2u(k), \\ u(k) & = & -Kx(k), \\ z(k) & = & C_1x(k) + D_1u(k), \end{array}\right.$$

where $x(k) \in \Re^n$ is the state, $u(k) \in \Re^m$ is the control, $z(k) \in \Re^q$ is the controlled output, and $w(k) \in \Re^l$ is the external disturbance. It is assumed that all matrices are of appropriate and known dimensions and, as usual, $C_1'D_1 = 0$ and $D_1'D_1 > 0$. In fact, the above orthogonality hypothesis could be weakened with minor changes in the results that follow. Associated with (1), we define the following extended matrices

$(p = n + m)$:

$$F = \begin{bmatrix} A & -B_2 \\ \mathbf{0} & \mathbf{0} \end{bmatrix} \in \Re^{p\times p}, \quad G = \begin{bmatrix} \mathbf{0} \\ \mathbf{I} \end{bmatrix} \in \Re^{p\times m} \tag{2}$$

and

$$Q = \begin{bmatrix} B_1B_1' & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix} \in \Re^{p\times p}, \quad R = \begin{bmatrix} C_1{}'C_1 & \mathbf{0} \\ \mathbf{0} & D_1'D_1 \end{bmatrix} \in \Re^{p\times p}. \tag{3}$$

It is further assumed that matrices Q and R are precisely known. On the contrary, matrix F, which defines the open-loop model, belongs to a convex-bounded uncertain polyhedral domain $\mathcal{D}$, defined as [6]

$$\mathcal{D} \overset{\triangle}{=} \left\{ F \ : \ F = \sum_{i=1}^{N} \xi_i F_i \ , \ \xi_i \geq 0 \ , \ \sum_{i=1}^{N} \xi_i = 1 \right\}. \tag{4}$$

That is, any feasible F can be expressed as an unknown convex combination of the "extreme matrices" $F_i \sim (A, B_2)_i$, $i = 1, \ldots, N$. At this point, it is important to stress that any polyhedral convex and bounded domain can be expressed as (4) by a suitable choice of F_i, $i = 1, \ldots, N$ and N. It is clear that $\mathcal{D}$ generalizes the well known and important case of interval matrices uncertainties.

For each feasible model $F \in \mathcal{D}$ and $K \in \Re^{m\times n}$, the closed-loop transfer function from $w(k)$ to $z(k)$ is given by

$$H_F(\zeta) \overset{\triangle}{=} C_{\text{cl}} \left[\zeta \mathbf{I} - A_{\text{cl}} \right]^{-1} B_1, \tag{5}$$

where $C_{\text{cl}} = C_1 - D_1K$ and $A_{\text{cl}} = A - B_2K$. Now, restricting our attention to those gains such that $K \in \mathcal{K}_F$, with $\mathcal{K}_F$ being the set of all stabilizing state feedback gains for the model defined by $F \in \mathcal{D}$,

$$\mathcal{K}_F \overset{\triangle}{=} \left\{ \ K \in \Re^{m\times n} \ : \ A_{\text{cl}} \text{ asympt. stable} \ \right\}, \tag{6}$$

the norms $\|H_F\|_2$ and $\|H_F\|_\infty$ are easily calculated [12]. Indeed, the $\mathcal{H}_2$ norm is given by

$$\|H_F\|_2^2 = \text{Tr}\left(C_{\text{cl}} L_c C_{\text{cl}}' \right) = \text{Tr}\left(B_1' L_o B_1 \right), \tag{7}$$

where L_o and L_c are the observability and controllability Gramians, respectively. That is, L_o and L_c are the solutions to the linear equations

$$\begin{aligned} A_{\text{cl}} L_c A_{\text{cl}}' - L_c + B_1B_1' &= 0, \\ A_{\text{cl}}' L_o A_{\text{cl}} - L_o + C_{\text{cl}}' C_{\text{cl}} &= 0. \end{aligned} \tag{8}$$

The determination of the $\mathcal{H}_\infty$ norm is numerically more involved. The results presented in [12] can be used to define a unidimensional search procedure for its calculation. As will be clear later, neither $\mathcal{H}_2$ nor $\mathcal{H}_\infty$ norms have to be calculated explicitly. From the above discussion, it is clear that the real-valued functions $g_F(K) = \|H_F\|_2$ and $h_F(K) = \|H_F\|_\infty$ are well defined for all elements of the set $\mathcal{K}_F$.

Let us state the problems to be dealt with in the rest of the paper. The reader is referred to the appendix A for the definition of the epigraph of real-valued functions.

$\mathcal{H}_\infty$ guaranteed-cost control (P1). Given a prespecified $\mathcal{H}_\infty$ norm level γ, find a constant state feedback gain K such that $K \in \mathcal{K}_F$ and $\|H_F\|_\infty \leq \gamma \; \forall F \in \mathcal{D}$. This is equivalent to the determination of K such that $(K, \gamma) \in \text{epi } h_F \; \forall \; F \in \mathcal{D}$. Note that in the case of precisely known systems ($N = 1$), the above problem reduces to the one considered in [12], [24].

Optimal $\mathcal{H}_\infty$ guaranteed-cost control (P2). It is a natural generalization of the previous one, where γ itself is involved in the optimization process, that is,

$$\min \left\{ \gamma \; : \; (K, \gamma) \in \text{epi } h_F \quad \forall \; F \in \mathcal{D} \right\}. \tag{9}$$

Obviously, in the case $N = 1$, (9) reduces to the classical $\mathcal{H}_\infty$ optimal control problem $\min\{\|H_F\|_\infty \; : \; K \in \mathcal{K}_F\}$.

Mixed $\mathcal{H}_2/\mathcal{H}_\infty$ guaranteed-cost control (P3). Given a prespecified $\mathcal{H}_\infty$ norm level γ, find a constant state feedback gain K and the smallest $\mathcal{H}_2$ norm level β such that $K \in \mathcal{K}_F$, $\|H_F\|_\infty \leq \gamma$, and $\|H_F\|_2 \leq \beta \; \forall \; F \in \mathcal{D}$. Equivalently, it can be restated as

$$\min \left\{ \beta \; : \; (K, \beta) \in \text{epi } g_F \; , \; (K, \gamma) \in \text{epi } h_F \quad \forall \; F \in \mathcal{D} \right\}. \tag{10}$$

Once again, in the case ($N = 1$), the above problem amounts to the determination of a constant state feedback gain K such that

$$\min \left\{ \|H_F\|_2 \; : \; \|H_F\|_\infty \leq \gamma \; , \; K \in \mathcal{K}_F \right\}, \tag{11}$$

which, after some approximations, has already been solved in [1] and [14] for continuous-time linear systems.

To the authors' knowledge, there are no available results for the above problems for discrete-time uncertain systems in convex-bounded domains. Even then, the motivation for introducing them is quite clear in the sense that they generalize the most important and well-known $\mathcal{H}_\infty$ control design results available for precisely known models to uncertain systems.

Note that (P1) is a generalization of the state-space $\mathcal{H}_\infty$ control approach proposed in [12] and [24]. The same is true for (P2), on which γ is included as an additional decision variable in the optimization process. In principle, results available to solve (P1) can also be used for solving (P2) iteratively. For instance, consider the following procedure: set γ^k sufficiently large, solve (P1), redefine $\gamma^{k+1} = \max_{F \in \mathcal{D}} \; \|H_F\|_\infty$, and iterate until convergence. Since the sequence $\{\gamma^k\}$ is bounded below and $\gamma^{k+1} \leq \gamma^k$, it converges but not necessarily to the optimal solution of (P2). Furthermore, it may be time consuming due to the fact that its rate of convergence is normally poor and γ^{k+1} is hard to obtain. For this reason, we propose here a new method which solves (P2) directly and provides both the stabilizing state feedback gain and the optimal $\mathcal{H}_\infty$-norm level. Finally, it is important to add that (P3) is a generalization to discrete-time uncertain systems of the mixed $\mathcal{H}_2/\mathcal{H}_\infty$ control problem solved in [1] and [14].

As stated, problems (P1)–(P3) are difficult to solve. The main difficulty stems from the nonconvexity of the set $\mathcal{K}_F$ and functions $g_F(\cdot)$ and $h_F(\cdot)$ in the parameter space generated by the elements of K, for each $F \in \mathcal{D}$. The obvious conclusion is that some kind of approximation or majorization should be adopted in order to render them more tractable. In this way we consider the following:

(i) Instead of $\mathcal{K} = \bigcap_{F\in\mathcal{D}} \mathcal{K}_F$, the set of all state feedback gains which stabilize simultaneously all models $F \in \mathcal{D}$, we restrict our attention to the subset $\mathcal{K}_Q \subseteq \mathcal{K}$ composed by all state feedback gains which stabilize quadratically the uncertain system (1) and impose on it a certain disturbance attenuation level γ (see Definition 4.1).

(ii) The $\mathcal{H}_2$ norm is replaced by a suitable and convex upper bound. On the other hand, the inequality $\|H_F\|_\infty \leq \gamma$ is tested by means of a simple sufficient condition yielding only convex problems to be solved.

Throughout the paper, we assume that matrix $\mathcal{W} \in \Re^{p\times p}$, partitioned as

$$\mathcal{W} = \begin{bmatrix} W_1 & W_2 \\ W_2' & W_3 \end{bmatrix} \geq 0, \tag{12}$$

is symmetric with $W_1 > 0 \in \Re^{n\times n}$, $W_2 \in \Re^{n\times m}$, and $W_3 \in \Re^{m\times m}$. The null space of G' is denoted by $\mathcal{N}$. From (2), it is clear that all $v \in \mathcal{N}$ have the particular structure $v' = [x' \ \ 0]$ with $x \in \Re^n$. In addition, we define the matrix functions $\Theta_{\infty F}(\mathcal{W}, \mu) = F\mathcal{W}F' - \mathcal{W} + \mathcal{W}R\mathcal{W} + \mu Q$ and $\Theta_{\infty i}(\cdot)$, which is the same as $\Theta_{\infty F}(\cdot)$, but with F replaced by the extreme matrix F_i, $i = 1, \ldots, N$. Furthermore, we suppose that $\forall\ F \in \mathcal{D}$, the pair (A, B_1) is controllable and range $(B_2) \subseteq$ range (B_1). This condition implies that (A_{cl}, B_1) is controllable $\forall\ K \in \Re^{m\times n}$ and $\forall\ F \in \mathcal{D}$. It is simple to verify that this assumption can be dropped if the inequalities, given in what follows, involving functions $\Theta_{\infty F}(\cdot)$ and $\Theta_{\infty i}(\cdot)$, $i = 1, \ldots, N$ are strict.

3. $\mathcal{H}_2$ and $\mathcal{H}_\infty$ norm bounds. In this section, we consider $F \in \mathcal{D}$ fixed but arbitrary. Our aim is to establish bounds to $\mathcal{H}_2$ and $\mathcal{H}_\infty$ norms in terms of an algebraic Riccati inequality.

LEMMA 3.1. *Given $(K, \gamma > 0)$, if the matrix inequality*

$$A_{\text{cl}}PA_{\text{cl}}' - P + PC_{\text{cl}}'C_{\text{cl}}P + \gamma^{-2}B_1B_1' \leq 0 \tag{13}$$

admits a symmetric positive definite solution, then $K \in \mathcal{K}_F$ and

$$H_F(\zeta)H_F(\zeta^{-1})' \leq \gamma^2(\mathbf{I} - C_{\text{cl}}PC_{\text{cl}}'), \qquad \zeta = e^{j\omega} \quad \forall\, \omega \in [-\pi, \pi]. \tag{14}$$

Proof. For the proof of this lemma, see appendix A. □

This result is a generalization of the one presented in [10]. Indeed, it provides a sufficient condition under which upper bounds to the closed-loop transfer function $\mathcal{H}_2$ and $\mathcal{H}_\infty$ norms can be determined. In addition, it enables the definition of an estimate of the difference between the actual $\|H_F\|_\infty$ and the prescribed value γ.

LEMMA 3.2. *Given $(K, \gamma > 0)$, suppose that* (13) *holds for some positive definite matrix $P \in \Re^{n\times n}$. The following hold:*

(a) *There exists* $0 \leq \theta^2 \leq \text{Tr}\ (C_{\text{cl}}PC_{\text{cl}}')$ *such that* $\|H_F\|_\infty^2 \leq \gamma^2(1 - \theta^2) \leq \gamma^2$;

(b) $\|H_F\|_2^2 \leq \gamma^2\text{Tr}\ (C_{\text{cl}}PC_{\text{cl}}')$.

Proof. For the proof of this lemma, see appendix A. □

To provide an interpretation of the above results, it is important to keep in mind that, for a given pair (K, γ), the solution of (13) is not necessarily unique and that the exact value of θ^2 cannot be determined a priori since (see appendix A) it depends on $\|H_F\|_\infty$ itself. As a result, the only information we get from part (a) of Lemma 3.2 is $\|H_F\|_\infty \leq \gamma$ or equivalently that $(K, \gamma) \in$ epi h_F whenever (13) admits a positive definite solution. However, from the part (b) of Lemma 3.2 we notice that for (K, γ) fixed, the best upper bound to the $\|H_F\|_2$ is determined by choosing P which minimizes Tr $(C_{\text{cl}}PC_{\text{cl}}')$ among all positive definite solutions of (13). By doing this, θ^2

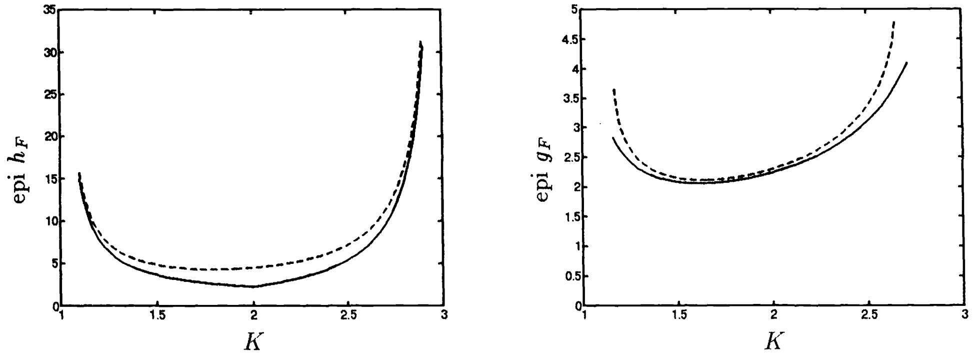

FIG. 1. epi h_F *(—), epi* g_F *(—), and approximations (– –).*

is constrained to be small, which implies that the inequality $\|H_F\|_\infty \le \gamma$ becomes tighter.

The above discussion will be important in the sequel. For the moment, let us compare numerically the results provided by Lemma 3.2 and the exact ones. Consider a linear time-invariant system such that

$$F = \begin{bmatrix} 2 & -1 \\ 0 & 0 \end{bmatrix}; \; R = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}; \; Q = \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix}. \tag{15}$$

In this case, it is obvious that $\mathcal{K}_F = \{K \in \Re \;:\; 1 < K < 3\}$. Figure 1 shows the epi h_F and its approximation given by all pairs (K, γ) such that (13) holds for some $P > 0$. Figure 1 also shows the epi g_F constrained to those $K \in \mathcal{K}_F$ such that $\|H_F\|_\infty \le \gamma = 10$ and its approximation provided by part (b) of Lemma 3.2. The solution of (P2) is calculated as $K = 2$ (exact) and $K \cong 1.8$ (approximate). For (P3), both (exact and approximate) coincide at $K \cong 1.6$. This fact (see also the numerical examples in §7) gives a measure of the "quality" of approximations introduced.

In addition, note that, in the general case, all shapes in Fig. 1 are nonconvex. Fortunately, those defined by the approximations can be generated from a nonlinear mapping acting on the elements of a convex set. This key property is proved below. Before that, let us introduce the following definition.

DEFINITION 3.3. *The pair* (A, B_2) *is said to be stabilizable with* γ *disturbance attenuation if there exist* $K \in \mathcal{K}_F$ *and* $P > 0$ *such that* (13) *holds.*

THEOREM 3.4. *Define the set* $\mathcal{C}_{\infty F}$ *as*

$$\mathcal{C}_{\infty F} \overset{\triangle}{=} \left\{ (\mathcal{W}, \mu) \;:\; \mathcal{W} \ge 0, \mu \ge 0 \quad , v'\Theta_{\infty F}(\mathcal{W}, \mu)v \le 0 \;\; \forall \, v \in \mathcal{N} \right\}. \tag{16}$$

Then $\mathcal{C}_{\infty F}$ *is convex and* $\{(W_2'W_1^{-1}, 1/\sqrt{\mu}) \;:\; (\mathcal{W}, \mu) \in \mathcal{C}_{\infty F}\} \subseteq$ epi h_F. *Furthermore, the pair* (A, B_2) *is stabilizable with* γ *disturbance attenuation if and only if, for some* $\mathcal{W}$, $(\mathcal{W}, \gamma^{-2}) \in \mathcal{C}_{\infty F}$.

Proof. Let us first prove that $\mathcal{C}_{\infty F}$ is convex. Indeed, since the set of nonnegative definite matrix is convex, it remains to show that for an arbitrary $v \in \mathcal{N}$, the function $v'\Theta_{\infty F}(\mathcal{W}, \mu)v$ is convex. To this end, note that

$$\nabla^2_\alpha \; v'\Theta_{\infty F}(\mathcal{W} + \alpha\Delta\mathcal{W}, \mu + \alpha\Delta\mu)v = 2v'\Delta\mathcal{W}R\Delta\mathcal{W}v \ge 0 \tag{17}$$

holds for all $\Delta\mathcal{W} = \Delta\mathcal{W}' \in \Re^{p\times p}$ and $\Delta\mu \in \Re$, then the convexity of $\mathcal{C}_{\infty F}$ follows. Now suppose that $(\mathcal{W}, \mu) \in \mathcal{C}_{\infty F}$. From (16), for all $v \in \mathcal{N}$,

$$0 \ge v'\Theta_{\infty F}(\mathcal{W}, \mu)v$$

$$\geq x'\Big[(A - B_2W_2'W_1^{-1})W_1(A - B_2W_2'W_1^{-1})' - W_1$$

$$+W_1(C_1 - D_1W_2'W_1^{-1})'(C_1 - D_1W_2'W_1^{-1})W_1$$

$$+ \mu B_1B_1' + B_2(W_3 - W_2'W_1^{-1}W_2)B_2'\Big]x. \tag{18}$$

Since $\mathcal{W} \geq 0$ implies $W_3 - W_2'W_1^{-1}W_2 \geq 0$, the conclusion is that (13) holds for $K = W_2'W_1^{-1}$, $\gamma = 1/\sqrt{\mu}$, and $P = W_1 > 0$. Consequently, from Lemma 3.2, $(K, \gamma) \in$ epi h_F. On the other hand, suppose the pair (A, B_2) is stabilizable with γ disturbance attenuation. From Definition 3.3, we know that there exist K and $P > 0$ such that (13) holds. Consequently, for all $x \in \Re^n$ we have

$$0 \geq x'\Big[(A - B_2K)P(A - B_2K)' - P$$

$$+ P(C_1 - D_1K)'(C_1 - D_1K)P + \gamma^{-2}B_1B_1'\Big]x$$

$$\geq v'\Theta_{\infty F}(\mathcal{W}, \gamma^{-2})v, \tag{19}$$

where the last inequality holds for

$$\mathcal{W} = \begin{bmatrix} P & PK' \\ KP & KPK' \end{bmatrix} \geq 0, \tag{20}$$

implying that $(\mathcal{W}, \gamma^{-2}) \in \mathcal{C}_{\infty F}$, and the proof is concluded. □

THEOREM 3.5. *Consider the convex set $\mathcal{C}_{\infty F}$ defined in Theorem* 3.4 *and assume that $\gamma > 0$ is given. Then $\{(W_2'W_1^{-1}, \beta) \ : \ (\mathcal{W}, \gamma^{-2}) \in \mathcal{C}_{\infty F}\} \subseteq$* epi g_F *for $\beta^2 = \gamma^2$*Tr $(R\mathcal{W})$.

Proof. Consider any $\mathcal{W}$ such that $(\mathcal{W}, \gamma^{-2}) \in \mathcal{C}_{\infty F}$. From (18) we note that (13) holds with $K = W_2'W_1^{-1}$ and $P = W_1 > 0$. We use part (b) of Lemma 3.2 to get

$$\|H_F\|_2^2 \leq \gamma^2 \mathrm{Tr}\,\Big((C_1 - D_1W_2'W_1^{-1})W_1(C_1 - D_1W_2'W_1^{-1})'\Big)$$

$$\leq \gamma^2 \mathrm{Tr}\,\Big(C_1W_1C_1' + D_1W_2'W_1^{-1}W_2D_1'\Big)$$

$$\leq \gamma^2 \mathrm{Tr}\,\Big(C_1W_1C_1' + D_1W_3D_1'\Big)$$

$$\leq \gamma^2 \mathrm{Tr}\,\Big(R\mathcal{W}\Big) \ = \ \beta^2, \tag{21}$$

which implies that $(W_2'W_1^{-1}, \beta) \in$ epi g_F. The proof is complete. □

As noticed before, both Theorem 3.4 and Theorem 3.5 provide convex approximations to epi h_F and epi g_F, respectively. Each of them is generated by a nonlinear mapping with the same convex domain $\mathcal{C}_{\infty F}$. As a result, the main difficulty to solve (P1)–(P3) directly in terms of the state feedback gain matrix K is circumvented by simply reformulating them as convex programming problems over $\mathcal{C}_{\infty F}$. Only after their solutions have been calculated, the corresponding feedback gain K is determined by $K = W_2'W_1^{-1}$ for the optimal $\mathcal{W} \in \mathcal{C}_{\infty F}$. Furthermore, the same reasoning can be easily generalized to deal with uncertain systems in convex-bounded domains.

4. The $\mathcal{H}_\infty$ guaranteed-cost control problem. This section is completely devoted to solve (P1) and (P2). For that, the key observation (see [6]) is that for any $\mathcal{W} = \mathcal{W}' \geq 0$ and $\mu \geq 0$, the function $\Theta_{\infty F}(\mathcal{W}, \mu)$ is convex with respect to $F \in \mathcal{D}$. Using the notation introduced before, this means that

$$\Theta_{\infty F}(\mathcal{W}, \mu) \leq \sum_{i=1}^{N} \xi_i \Theta_{\infty i}(\mathcal{W}, \mu) \tag{22}$$

holds for $\xi_i \geq 0$, $\sum_{i=1}^{N} \xi_i = 1$. Before proceeding, we need the following definition.

DEFINITION 4.1. *System* (1) *is said to be quadratically stabilizable with γ disturbance attenuation if there exist $K \in \mathcal{K}_F$ and $P > 0$ such that* (13) *holds for all $F \in \mathcal{D}$.*

The set of all state feedback matrix gain K satisfying the above definition is denoted by $\mathcal{K}_Q$. It is important to keep in mind that the concept of quadratic stabilizability with γ disturbance attenuation implies that for $K \in \mathcal{K}_Q$, the same matrix $P > 0$ should satisfy (13) for all $F \in \mathcal{D}$.

THEOREM 4.2. *Define the convex set $\mathcal{C}_{\infty i}$ as $\mathcal{C}_{\infty F}$ for all extreme matrices $F = F_i$, $i = 1, \ldots, N$. The following hold:*

(a) $\mathcal{C}_\infty \overset{\triangle}{=} \bigcap_{i=1}^{N} \mathcal{C}_{\infty i} \equiv \bigcap_{F \in \mathcal{D}} \mathcal{C}_{\infty F}$,

(b) $\{(W_2' W_1^{-1}, 1/\sqrt{\mu}) \ : \ (\mathcal{W}, \mu) \in \mathcal{C}_\infty\} \subseteq \bigcap_{F \in \mathcal{D}} \text{epi } h_F$.

Furthermore, the system (1) *is quadratically stabilizable with γ disturbance attenuation if and only if for some $\mathcal{W}$, $(\mathcal{W}, \gamma^{-2}) \in \mathcal{C}_\infty$.*

Proof. Only part (a) will be proved. The other statement follows immediately from part (a) and Theorem 3.4. First suppose that $(\mathcal{W}, \mu) \in \mathcal{C}_{\infty i}$, $i = 1, \ldots, N$. In this case, $v' \Theta_{\infty i}(\mathcal{W}, \mu) v \leq 0$, $i = 1, \ldots, N \ \forall \ v \in \mathcal{N}$. However, each $F \in \mathcal{D}$ can be expressed as a convex combination of the extreme matrices F_i, $i = 1, \ldots, N$. Consequently, with (22) we have

$$\begin{aligned} v' \Theta_{\infty F}(\mathcal{W}, \mu) v &\leq \sum_{i=1}^{N} \xi_i v' \Theta_{\infty i}(\mathcal{W}, \mu) v \\ &\leq 0 \quad \forall \, v \in \mathcal{N}, \quad \forall \, F \in \mathcal{D}, \end{aligned} \tag{23}$$

meaning that $(\mathcal{W}, \mu) \in \mathcal{C}_{\infty F}$, $\forall \ F \in \mathcal{D}$. The converse is straightforward because $F_i \in \mathcal{D}$, $i = 1, \ldots, N$. This concludes the proof of the theorem. □

This results furnishes the theoretical basis to the solution of both problems (P1) and (P2). Indeed, as a consequence of the convexity of the uncertain domain $\mathcal{D}$, a convex subset of epi h_F $\forall \ F \in \mathcal{D}$ can be easily generated only from the N extreme matrices that define $\mathcal{D}$. In addition, using the last part of Theorem 4.2 we conclude immediately that

$$\mathcal{K}_Q = \left\{ W_2' W_1^{-1} \ : \ (\mathcal{W}, \gamma^{-2}) \in \mathcal{C}_\infty \right\}. \tag{24}$$

Viewed the intricate dependence of (13) on K, it is somewhat surprising that $\mathcal{K}_Q$ could be generate from the elements of the convex set $\mathcal{C}_\infty$. Furthermore, given $\gamma > 0$, any $K \in \mathcal{K}_Q$ solves (P1) and the global solution of the convex programming problem

$$\max \ \left\{ \ \mu \ : \ (\mathcal{W}, \mu) \in \mathcal{C}_\infty \ \right\} \tag{25}$$

provides $K = W_2' W_1^{-1}$ and $\gamma = 1/\sqrt{\mu}$ such that the pair (K, γ) is suboptimal to (P2).

It is obvious that $\gamma = 1/\sqrt{\mu}$ is the minimum value of γ as far as the approximation introduced in part (b) of Theorem 4.2 is adopted. As noticed before, we claim that this approximation is good enough (see the numerical examples included in §7) to produce near-optimal solutions to (P2).

Being convex, the global optimal solution of (25) can be found by many powerful convex programming methods available in the literature (for details, see [2], [3], [8], and [9]). However, from the numerical point of view, the difficulty in solving (25) may be increased due to the fact that μ is not explicitly bounded. For this reason, we now determine an upper bound to μ such that the optimal solution of (25) does not change.

THEOREM 4.3. *Consider F fixed but arbitrary. Assume that matrix $V_F \in \Re^{l \times p}$ given by*

$$V_F \triangleq (B_1' B_1)^{-1} B_1' \begin{bmatrix} A - \mathbf{I} & -B_2 \end{bmatrix} \tag{26}$$

is of full rank and the perturbations $w(k)$ are "rich" in the sense that $\dim(w(k)) > n -$ rank (C_1)*. Then $(\mathcal{W}, \mu) \notin \mathcal{C}_{\infty F}$ $\forall$ $\mu > \overline{\mu}(F)$, where*

$$\overline{\mu}(F) = \min \left\{ \mu > 0 \ : \ \det(V_F' V_F - \mu R) = 0 \right\}. \tag{27}$$

Proof. Define $R_\epsilon = R + \epsilon \mathbf{I}$ for $\epsilon > 0$ sufficiently small and $\tilde{F} = F - \mathbf{I}$. After simple but tedious algebraic manipulations, we can show that the following factorization holds:

$$\begin{aligned} F\mathcal{W}F' - \mathcal{W} + \mathcal{W}R_\epsilon \mathcal{W} + \mu Q = {} & (\tilde{F} R_\epsilon^{-1} + \mathcal{W}) R_\epsilon (\tilde{F} R_\epsilon^{-1} + \mathcal{W})' \\ & + \tilde{F} \mathcal{W} \tilde{F}' - \tilde{F} R_\epsilon^{-1} \tilde{F}' + \mu Q. \end{aligned} \tag{28}$$

Since the left-hand side of (28) goes to $\Theta_{\infty F}(\mathcal{W}, \mu)$ as $\epsilon \to 0^+$ then, $\forall$ $v \in \mathcal{N}$,

$$v' \Theta_{\infty F}(\mathcal{W}, \mu) v \geq - \lim_{\epsilon \to 0^+} \ v' \left(\tilde{F} R_\epsilon^{-1} \tilde{F}' - \mu Q \right) v. \tag{29}$$

We conclude that $(\mathcal{W}, \mu) \notin \mathcal{C}_{\infty F}$ provided that μ is chosen sufficiently large in order that the right-hand side of (29) becomes positive for some $v \in \mathcal{N}$. An immediate consequence of this fact is that $(\mathcal{W}, \mu) \notin \mathcal{C}_{\infty F}$ for all $\mu > \overline{\mu}(F)$, where

$$\begin{aligned} \overline{\mu}(F) &= \lim_{\epsilon \to 0^+} \ \min \left\{ w' V_F R_\epsilon^{-1} V_F' w \ : \ w'w = 1 \right\} \\ &\geq \lim_{\epsilon \to 0^+} \ \sup \left\{ \mu \ : \ v' \left(\tilde{F} R_\epsilon^{-1} \tilde{F}' - \mu Q \right) v \geq 0 \ \forall \ v \in \mathcal{N} \right\}. \end{aligned} \tag{30}$$

Calling the full rank matrix $E = \begin{bmatrix} C_1 & D_1 \end{bmatrix}$ and $E^{\#} = E'(EE')^{-1}$ its pseudoinverse, it is a simple task to verify that

$$R_\epsilon^{-1} \longrightarrow E^{\#} E^{\#'} + \epsilon^{-1} \left(\mathbf{I} - E^{\#} E \right) \tag{31}$$

as $\epsilon \to 0^+$. Using this fact and (30) we get

$$\begin{aligned} \overline{\mu}(F) &= \min \left\{ w' V_F E^{\#} E^{\#'} V_F' w \ : \ (\mathbf{I} - E^{\#} E) V_F' w = 0 \ , \ w'w = 1 \right\} \\ &= \min \left\{ z'z \ : \ V_F' w - E'z = 0 \ , \ w'w = 1 \right\}, \end{aligned} \tag{32}$$

where the last inequality follows from the definition of the new variable z such that $E'z = V_F' w$. It is important to observe that (32) always provides $0 < \overline{\mu}(F) < +\infty$. Indeed, $w(k)$ being "rich," a $w \neq 0$ always exists such that $(\mathbf{I} - E^{\#}E)V_F' w = 0$, and on the other hand, with V_F of full rank, $V_F' w = 0$ implies $w = 0$ which is not feasible. Now, writing the optimality conditions to (32) we immediately conclude that $\mu(F)$ is given by (27), which proves the theorem. □

Defining the upper bound $\overline{\mu} = \min \{ \overline{\mu}(F_i) \ : \ i = 1, \ldots, N \}$, the convex programming problem

$$\max \left\{ \mu \ : \ (\mathcal{W}, \mu) \in \mathcal{C}_\infty, \ 0 \leq \mu \leq \overline{\mu} \right\} \tag{33}$$

is equivalent to (25) in the sense that they have the same global optimal solution. In fact, for $\mu > \overline{\mu}$, there exists an extreme matrix $F = F_i \in \mathcal{D}$ such that $\mu > \overline{\mu}(F)$. From Theorem 4.3, any pair $(\mathcal{W}, \mu) \notin \mathcal{C}_\infty$ whenever $\mu > \overline{\mu}$.

The above result is very useful for numerical computation. Actually the search interval on μ is reduced to the closed line segment $[0, \overline{\mu}]$. The upper bound $\overline{\mu}$ can be easily computed since no operations involving $\mathcal{H}_\infty$ norms calculation is needed. As a matter of fact, in many cases, $\overline{\mu}(F)$ can also be obtained directly from (30) without using equation (27), i.e.,

$$\begin{aligned} \overline{\mu}(F) &= \lim_{\epsilon \to 0^+} \min \left\{ w' V_F R_\epsilon^{-1} V_F' w \ : \ w'w = 1 \right\} \\ &= \lim_{\epsilon \to 0^+} \lambda_{\min} \left\{ V_F \left(R + \epsilon \mathbf{I} \right)^{-1} V_F' \right\}, \end{aligned} \tag{34}$$

overcoming the hypothesis concerning the richness of $w(k)$ introduced in Theorem 4.3. Note, however, that under the sufficient conditions in Theorem 4.3, the limit (34) always exists and is finite.

As a final remark concerning (P1) and (P2), we want to add that majorizations/approximations as introduced here have also been adopted in several papers [1], [14]. The main advantage of our approach is that we always obtain convex problems to be solved. As a consequence, the convergence of any applicable method is sure toward their global optimal solutions. For instance, this is not the case of the interesting procedure given in [1], for which, however, no proof of convergence is known.

5. The $\mathcal{H}_2/\mathcal{H}_\infty$ guaranteed-cost control problem.

In this section, we analyze the solution of problem (P3). The results are based on the convex combination (22) and on Theorem 3.5. Once again, it will be possible to approximate (P3) by a convex programming problem.

THEOREM 5.1. *Consider the convex set $\mathcal{C}_\infty$ as defined in Theorem 4.2 and assume that $\gamma > 0$ is given. Then*

$$\left\{ (W_2' W_1^{-1}, \beta) \ : \ (\mathcal{W}, \gamma^{-2}) \in \mathcal{C}_\infty \right\} \subseteq \bigcap_{F \in \mathcal{D}} \operatorname{epi} g_F, \tag{35}$$

where $\beta^2 = \gamma^2 \mathrm{Tr}\ (R\mathcal{W})$.

Proof. From Theorem 4.2 we note that $(\mathcal{W}, \gamma^{-2}) \in \mathcal{C}_\infty$ implies $(\mathcal{W}, \gamma^{-2}) \in \mathcal{C}_{\infty F}$ $\forall\ F \in \mathcal{D}$. Using Theorem 3.5 we have $\|H_F\|_2^2 \leq \gamma^2 \mathrm{Tr}\ (R\mathcal{W}) = \beta^2\ \forall\ F \in \mathcal{D}$. Consequently (35) holds. □

With Theorem 5.1, we are able to rewrite problem (P3) as a convex problem, that is,

$$\min \left\{ \gamma^2 \mathrm{Tr}\ (R\mathcal{W}) \ : \ (\mathcal{W}, \gamma^{-2}) \in \mathcal{C}_\infty \right\}. \tag{36}$$

For γ fixed, its objective function is linear. Furthermore, its global optimal solution provides $K = W_2'W_1^{-1}$, which is feasible to (P3) being consequently a suboptimal solution. Indeed, with $(\mathcal{W}, \gamma^{-2}) \in \mathcal{C}_\infty$, the associated state feedback gain given above is such that $(K, \gamma) \in \text{epi } h_F \; \forall \; F \in \mathcal{D}$ and $(K, \beta) \in \text{epi } g_F \; \forall \; F \in \mathcal{D}$. Clearly, the objective function of (36) is the available upper bound to $\|H_F\|_2^2$ for all $F \in \mathcal{D}$, which is reduced to its minimum level. An observation that has perhaps occurred to the reader is that the above conclusions hold only because the same nonlinear mapping $(W_2'W_1^{-1})$ generates elements on both epi g_F and epi h_F.

Finally, we have to notice that problems (33) and (36) are of the same kind. Actually, both are convex with linear objectives. The main difference between them is that the former presents one more variable than (36).

We are now in position to generalize our results along the lines of [14]. Suppose that to the basic model (1), we add a new output variable $y(k) = C_2x(k) + D_2u(k)$, where $C_2'D_2 = 0$ and $D_2'D_2 > 0$ and whose closed-loop transfer function from $w(k)$ to $y(k)$ is denoted by $T_F(\zeta)$. Our goal is to solve the $\mathcal{H}_2/\mathcal{H}_\infty$ guaranteed-cost control problem considering $\|T_F\|_2 \leq \beta$ subject to $\|H_F\|_\infty \leq \gamma \; \forall \; F \in \mathcal{D}$. To this end, defining the matrix

$$R_2 = \begin{bmatrix} C_2'C_2 & \mathbf{0} \\ \mathbf{0} & D_2'D_2 \end{bmatrix} \in \Re^{p\times p},$$

the functions $g_F(K) = \|T_F\|_2$ and $h_F(K) = \|H_F\|_\infty$, and using the same reasoning adopted before, we get

$$\min \left\{ \gamma^2 \text{Tr } (R_2\mathcal{W}) \; : \; (\mathcal{W}, \gamma^{-2}) \in \mathcal{C}_\infty \right\}. \tag{37}$$

This shows that the above generalization is easily incorporated in problem (P3) without loss of any of its geometric properties.

Another important generalization of the above problem was first proposed in [10] in the case of precisely known systems. In our context, it consists of the solution of (P3) with a decentralized control structure. Under the approximation and majorizations introduced before, it can be solved by simply noticing that if $\mathcal{W}$ is constrained as (see (12))

$$\mathcal{W} = \mathcal{W}_D = \begin{bmatrix} W_{1D} & W_{2D} \\ W_{2D}' & W_3 \end{bmatrix} \geq 0, \tag{38}$$

where the subscript D imposes a prespecified decentralized structure on each matrix, then the mapping which defines the control gain turns out to be

$$K = W_{2D}'W_{1D}^{-1} = K_D, \tag{39}$$

meaning that $K = K_D$ presents the same decentralized structure imposed on $\mathcal{W}$ in (38). Consequently, (P3) can be rewritten as

$$\min \left\{ \gamma^2 \text{Tr } (R_2\mathcal{W}_D) \; : \; (\mathcal{W}_D, \gamma^{-2}) \in \mathcal{C}_\infty \right\}. \tag{40}$$

Problem (40) is once again convex and easier to solve than (37). In fact, $\mathcal{W} = \mathcal{W}_D$ imposes a priori the zero value on many elements of $\mathcal{W}$ which clearly can be simply eliminate in the optimization process, reducing consequently the number of free variables to be determined. As before, the solution of (40) (if any) provides $\mathcal{W}_D$ which is used with (39) to get the decentralized control gain.

Before concluding this section, a final remark. In many practical applications, the "inverse" $\mathcal{H}_2/\mathcal{H}_\infty$ guaranteed-cost control problem may be more attractive. It consists of the determination of the smaller $\mathcal{H}_\infty$ norm level $\gamma > 0$ such that $\|H_F\|_\infty \leq \gamma$ subject to the $\mathcal{H}_2$ norm constraint $\|T_F\|_2 \leq \beta$, for some $\beta > 0$ fixed. Even in the case $F \in \mathcal{D}$ fixed, this problem cannot be solved by the procedures introduced in [1], [14]. On the contrary, in our context, it can be approximated by a convex programming problem. To show this, note that from Theorem 5.1 we have

$$\|T_F\|_2^2 \leq \mu^{-1}\text{Tr }(R_2\mathcal{W}) \quad \forall\ (\mathcal{W}, \mu) \in \mathcal{C}_\infty, \tag{41}$$

which implies that for $\beta > 0$ fixed, Tr $(R_2\mathcal{W}) - \beta^2\mu \leq 0$ imposes $\|T_F\|_2 \leq \beta$. Consequently, the problem stated before can be written as

$$\max \left\{\mu \ : \ \text{Tr }(R_2\mathcal{W}) - \beta^2\mu \leq 0 \ , \ (\mathcal{W}, \mu) \in \mathcal{C}_\infty \right\}, \tag{42}$$

which exhibits the same number of variables as and only one additional linear constraint than (P2). Once (42) is solved, the corresponding state feedback gain is given by $K = W_2'W_1^{-1}$, and as expected, (42) reduces to (25) whenever β is chosen sufficiently large.

6. Comparisons. We are able to compare our results with those of [24], where the necessary and sufficient counterpart of Lemma 3.2, part (a) has been proposed. For that we have to restrict our analysis only to the case of precisely known systems $(N = 1)$.

We immediately observe that (13) is a good approximation to the necessary and sufficient condition of [24] if its solution is such that

$$(\mathbf{I} + C_{\text{cl}}PC_{\text{cl}}')^{-1} \simeq \mathbf{I}. \tag{43}$$

For $\mathcal{W} \geq 0$ being the optimal solution of (25) or (36), condition (43) must be verified for $P = W_1$ and $C_{\text{cl}} = C_1 - D_1W_2'W_1^{-1}$. Using the fact that $W_3 \geq W_2'W_1^{-1}W_2$, (43) holds whenever

$$\lambda_{\max}\left(\left[\begin{array}{cc} C_1 & -D_1 \end{array}\right]\mathcal{W}\left[\begin{array}{c} C_1' \\ -D_1' \end{array}\right]\right) \ll 1, \tag{44}$$

which shows that the quality of our results can be verified by a simple postoptimization test. Furthermore, it is interesting to note (see the discussion after Lemma 3.2) that the trace of the matrix indicated in (44) equals Tr $(R\mathcal{W})$, yielding the conclusion that for (P3) the condition (44) generally holds because an upper bound of its left-hand side is minimized. To show that this fact actually occurs, we have calculated, for the simple example included in §3, the maximum eigenvalue indicated in (44). For the optimal solution of (25) it is equal to $\simeq 0.47$, while for the one of (36) it is equal to $\simeq 0.04$.

As a final and important remark we note that problems (25) and (36) always provide feasible solutions to (P2) and (P3), respectively, even when (44) is not verified. The suboptimality of their solutions is the price to be paid for the approximation of both (P2) and (P3) by convex programming problems. Unfortunately, if we replace (13) by the necessary and sufficient condition of [24], the same reasoning as used before does not lead to convex problems being thus an open problem for future research.

We now turn our attention to problem (36). The goal is to analyze its optimal solution as $\gamma \to +\infty$ in the particular case of precisely known systems. We observe that since $N = 1$, then $\mathcal{C}_\infty \equiv \mathcal{C}_{\infty F}$, and with $\mu = 1/\gamma^2$ and $\mathcal{W} \geq 0$ fixed we get

$$\lim_{\mu \to 0^+} \mu^{-1}\Theta_{\infty F}(\mu\mathcal{W}, \mu) = F\mathcal{W}F' - \mathcal{W} + Q$$

$$\triangleq \Theta_{2F}(\mathcal{W}). \tag{45}$$

On the other hand, calling $J(\mathcal{W}) = \mu^{-1}\mathrm{Tr}\ (R\mathcal{W})$ the objective function of (36), it is obvious that $J(\mu\mathcal{W}) = \mathrm{Tr}\ (R\mathcal{W})$. This fact together with (45) allows us to conclude that as $\gamma \to +\infty$, problem (36) degenerates to the convex problem

$$\min \left\{ \mathrm{Tr}\ (R\mathcal{W}) \ : \ \mathcal{W} \in \mathcal{C}_2 \right\}, \tag{46}$$

where $\mathcal{C}_2 = \{\mathcal{W} = \mathcal{W}' \geq 0 \ : \ v'\Theta_2(\mathcal{W})v \leq 0 \ \forall \ v \in \mathcal{N}\}$. It is possible to prove that the optimal solution of (46) coincides with the optimal solution of the linear quadratic regulator problem (see [18]). In other words, as $\gamma \to +\infty$, the optimal solution of the approximate problem (36) coincides with the optimal solution of (P3), which in this case is nothing more than the classical linear quadratic problem.

7. Numerical examples. In this section we consider a numerical example first proposed in [16] and also analyzed in a preliminary version of [24]. Using the notation introduced before, the data are as follows:

$$F = F_1 = \begin{bmatrix} 0.9974 & 0.0539 & -0.0013 \\ -0.1078 & 1.1591 & -0.0539 \\ 0 & 0 & 0 \end{bmatrix},$$

$$Q = \begin{bmatrix} 1 & 1 & 0 \\ 1 & 1 & 0 \\ 0 & 0 & 0 \end{bmatrix}, \quad R = \begin{bmatrix} 1 & -1 & 0 \\ -1 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}. \tag{47}$$

By reducing successively the γ parameter and testing for the existence of a positive definite solution to the necessary and sufficient conditions provided in [24], we get a near-optimum solution to the $\mathcal{H}_\infty$ optimal control problem as being $K^* \cong \left[\ 37.1242 \quad 22.4845\ \right]$, $\|H_F\|_\infty \cong \gamma^* \cong 36.44$ **dB**. The numerical difficulty involved increases as $\gamma \to \gamma^*$ because the condition to be tested becomes ill conditioned.

Considering $N = 1$ and $\bar{\mu} = 4.0 \times 10^{-4}$, problem (33) has been solved, yielding

$$\gamma = 1/\sqrt{\bar{\mu}} \cong 38.65 \ \mathbf{dB},$$

$$\mathcal{W} \cong \begin{bmatrix} 0.1375 & -0.1641 & -0.4410 \\ -0.1641 & 0.3954 & 2.5492 \\ -0.4410 & 2.5492 & 21.8803 \end{bmatrix} \times 10^{-2}. \tag{48}$$

The quality of this suboptimal solution (against the optimal one) can be measured a priori by simply verifying that the left-hand side of (44) gives $\simeq 0.2230$. Indeed (48) provides

$$K \cong \left[\ 8.8829 \quad 10.1327\ \right],$$

$$\|H_F\|_\infty \cong 37.63 \ \mathbf{dB}, \tag{49}$$

which corresponds to a loss of optimality of about 3.2%. It is important to remark that in solving problem (33) we did not observe the ill-conditioning of its solution as pointed out before.

We turn now our attention to the case of uncertain systems. Our goal is to obtain an approximate solution to (P2) for $N = 2$ and $\mathcal{D}$ given by (4), where F_1 is as before and

$$F_2 = \begin{bmatrix} 0.9974 & 0.0539 & -0.0013 \\ -0.1078 & 1.1591 & -0.1078 \\ 0 & 0 & 0 \end{bmatrix}, \tag{50}$$

which has been calculated assuming that the $(2,1)$ element of the input matrix B_2 may increase 100%. Once again, problem (33) has been solved with the same algorithm and the same upper bound $\overline{\mu}$ as before, yielding

$$\gamma = 1/\sqrt{\overline{\mu}} \cong 38.82 \text{ dB},$$

$$\mathcal{W} \cong \begin{bmatrix} 0.1231 & 0.1478 & 0.2768 \\ 0.1478 & 0.4608 & 3.0178 \\ 0.2768 & 3.0178 & 26.0642 \end{bmatrix} \times 10^{-2}, \tag{51}$$

$$K \cong \begin{bmatrix} 9.1290 & 9.4792 \end{bmatrix}.$$

Since every $F \in \mathcal{D}$ can be expressed as $F = F_1 + \xi(F_2 - F_1)$ for $\xi \in [0,1]$, Fig. 2 shows the "shadow" singular value diagram corresponding to the closed-loop uncertain system under consideration, that is, $\sigma_{\max}[H_F(e^{j\omega})]$ versus ω, parametrized on $\xi \in [0,1]$. Figure 2 also shows the closed-loop system $\mathcal{H}_\infty$ norm versus ξ with both the guaranteed $\mathcal{H}_\infty$ cost control gain (51) (—) and the optimal $\mathcal{H}_\infty$ state feedback gain K^* (– –) (which is optimal for $F = F_1$ or equivalently for $\xi = 0$). The following conclusions can be drawn.

(i) Although both feedback gains are quite different, comparing (51) with the optimal solution for $F = F_1$, we note that the guaranteed cost is very close to the optimal one. This occurs mainly because for each $\xi \in [0,1]$, the associate singular value diagram is kept near enough to the optimal one.

(ii) Figure 2 makes evident the importance of the suboptimal solution to the $\mathcal{H}_\infty$ guaranteed-cost control problem proposed here. The state feedback gain K is stabilizing and $\|H_F\|_\infty \leq \gamma \; \forall \; \xi \in [0,1]$. The same conclusion does not hold if instead of K we use the state feedback gain K^* which is $\mathcal{H}_\infty$-optimal for the "nominal" model F_1 (or equivalently $\xi = 0$). Indeed, with K^*, the closed-loop system becomes unstable for $\xi > 0.8$ and, worse, the $\mathcal{H}_\infty$ norm of the closed-loop transfer function becomes greater than the one with K for $\xi > 0.05$. This shows that for very small parameter variations (about 5%) the solution of (33) is already better than K^*.

8. Conclusions. In this paper, we have investigated three important problems arising in $\mathcal{H}_\infty$ and mixed $\mathcal{H}_2/\mathcal{H}_\infty$ control design. The results follow from two basic facts. The first one concerns the proposition of a simple sufficient condition for testing whenever the $\mathcal{H}_\infty$ norm of a certain closed-loop transfer function is smaller than a prespecified level γ. The second one consists of the definition of a suitable majorization to the $\mathcal{H}_2$ norm of the same closed-loop transfer function. Based only on that, the three problems considered are approximated by convex problems all with linear objective functions. Obviously an immediate consequence is that all machinery of convex programming can be used to solve them in order to find directly the

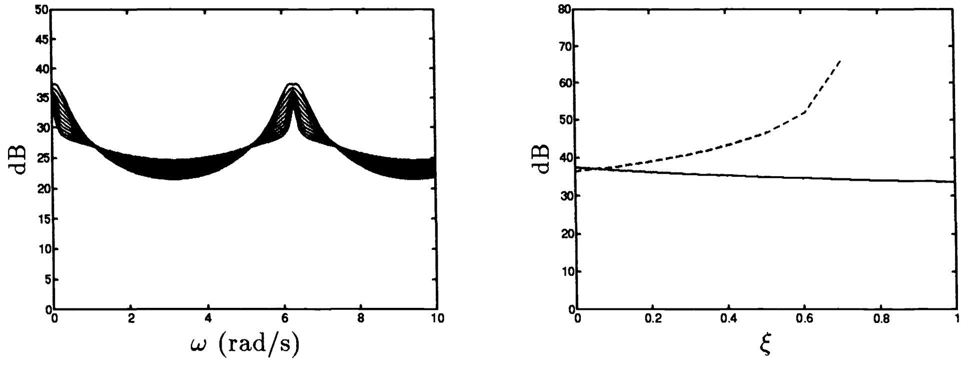

FIG. 2. *Singular value diagram and $\mathcal{H}_\infty$-norm level.*

corresponding optimal state feedback gain matrix. Furthermore, it is important to emphasize that the convex problems are defined in a special augmented parameter space whose elements generate through a nonlinear mapping the set of all stabilizing state feedback gains of a given linear discrete-time system.

In the real world all systems are subject to parameter uncertainties. Then the results presented here are important because, for the first time, they generalize to actual systems many basic and well-known control design tools available in the literature to date.

In this sense, based on the numerical solution of some examples we claim that our suboptimal and easy-to-determine solution to the three problems proposed before may constitute a useful and valid tool design when convex-bounded uncertainties have to be considered. The suboptimality is largely compensated by taking into account the uncertainties, and in many cases, the results presented here can be even better than the ones obtained by using an optimal policy calculated for the "nominal" model.

Appendix A. Consider $f(\cdot) \; : \; S \longrightarrow \Re$ a real-valued function defined for all $x \in S \subset \Re^n$. Following [20] we define the epigraph of $f(\cdot)$ as

$$\text{epi}\, f \triangleq \Big\{(x,\gamma) \; : \; x \in S \; , \; f(x) \leq \gamma\Big\} \subseteq \Re^{n+1}. \tag{52}$$

An important property relating a function and its epigraph is that $f(\cdot)$ is convex if and only if epi f is convex. In our context, the function $h_F(K) \; : \; \mathcal{K}_F \longrightarrow \Re$ given by

$$h_F(K) = \|(C_1 - D_1 K)\left(\zeta \mathbf{I} - (A - B_2 K)\right)^{-1} B_1\|_\infty \tag{53}$$

is well defined for all $K \in \mathcal{K}_F$ since as required in (53) any element of $\mathcal{K}_F$ stabilizes the closed-loop system. Consequently

$$\text{epi}\, h_F \triangleq \Big\{(K,\gamma) \; : \; K \in \mathcal{K}_F \; , \; \|H_F\|_\infty \leq \gamma\Big\}. \tag{54}$$

Unfortunately epi h_F is not a convex set because generally the set $\mathcal{K}_F$ is not convex. The set epi g_F is similarly defined.

Proof of Lemma 3.1. Given (K,γ), assume that $P = P' > 0$ satisfies the matrix inequality (13). In this case it follows that

$$A_{\text{cl}} P A_{\text{cl}}' - P \;\leq\; -\gamma^{-2} B_1 B_1' \;\leq\; 0. \tag{55}$$

However, we also assume that the pair (A, B_1) is controllable and range $(B_2) \subseteq$ range (B_1). This implies that $(A_{\rm cl}, B_1)$ is also controllable, which together with (55) enables us to say that $A_{\rm cl}$ is asymptotically stable. Consequently $K \in \mathcal{K}_F$. To prove the inequality (14) we first note that for $\zeta = e^{j\omega}$, $\omega \in [-\pi, \pi]$, we have

$$(\zeta\mathbf{I} - A_{\rm cl})P(\zeta^{-1}\mathbf{I} - A'_{\rm cl}) + A_{\rm cl}P(\zeta^{-1}\mathbf{I} - A'_{\rm cl}) + (\zeta\mathbf{I} - A_{\rm cl})PA'_{\rm cl} = P - A_{\rm cl}PA'_{\rm cl}. \tag{56}$$

So inequality (13) can be rewritten as

$$\begin{aligned} &-(\zeta\mathbf{I} - A_{\rm cl})P(\zeta^{-1}\mathbf{I} - A'_{\rm cl}) - A_{\rm cl}P(\zeta^{-1}\mathbf{I} - A'_{\rm cl}) - (\zeta\mathbf{I} - A_{\rm cl})PA'_{\rm cl} \\ &+ PC'_{\rm cl}C_{\rm cl}P + \gamma^{-2}B_1B_1' \leq 0, \end{aligned} \tag{57}$$

which after some algebraic manipulations gives

$$\begin{aligned} &C_{\rm cl}PC'_{\rm cl} - \zeta C_{\rm cl}(\zeta\mathbf{I} - A_{\rm cl})^{-1}PC'_{\rm cl} - \zeta^{-1}C_{\rm cl}P(\zeta^{-1}\mathbf{I} - A'_{\rm cl})^{-1}C'_{\rm cl} \\ &+ C_{\rm cl}(\zeta\mathbf{I} - A_{\rm cl})^{-1}PC'_{\rm cl}C_{\rm cl}P(\zeta^{-1}\mathbf{I} - A'_{\rm cl})^{-1}C'_{\rm cl} \\ &+ \gamma^{-2}C_{\rm cl}(\zeta\mathbf{I} - A_{\rm cl})^{-1}B_1B_1'(\zeta^{-1}\mathbf{I} - A'_{\rm cl})^{-1}C'_{\rm cl} \leq 0. \end{aligned} \tag{58}$$

Keeping in mind the definition of $H_F(\zeta)$ (see (5)) and defining the auxiliary transfer function $L_F(\zeta) = \zeta C_{\rm cl}(\zeta\mathbf{I} - A_{\rm cl})^{-1}PC'_{\rm cl}$, from (58) we have

$$C_{\rm cl}PC'_{\rm cl} - L_F(\zeta) - L_F(\zeta^{-1})' + L_F(\zeta)L_F(\zeta^{-1})' + \gamma^{-2}H_F(\zeta)H_F(\zeta^{-1})' \leq 0, \tag{59}$$

which after completing squares becomes

$$\begin{aligned} H_F(\zeta)H_F(\zeta^{-1})' &\leq \gamma^2\mathbf{I} - \gamma^2C_{\rm cl}PC'_{\rm cl} - \gamma^2[\mathbf{I} - L_F(\zeta)][\mathbf{I} - L_F(\zeta^{-1})]' \\ &\leq \gamma^2(\mathbf{I} - C_{\rm cl}PC'_{\rm cl}). \end{aligned} \tag{60}$$

Since (60) holds for all $\zeta = e^{j\omega}$, $\omega \in [-\pi, \pi]$ the lemma is proved. □

Proof of Lemma 3.2. From the definition of the $\mathcal{H}_\infty$ norm, there exist $\omega \in [-\pi, \pi]$ and a vector z ($z^\sim$ denotes its complex conjugate) such that

$$\begin{aligned} \|H_F\|_\infty^2 &= \frac{z^\sim H_F(e^{j\omega})H_F(e^{-j\omega})'z}{z^\sim z} \\ &\leq \gamma^2 - \gamma^2\frac{z^\sim C_{\rm cl}PC'_{\rm cl}z}{z^\sim z} \\ &\leq \gamma^2(1 - \theta^2), \end{aligned} \tag{61}$$

where the second inequality follows from Lemma 3.1 and

$$\begin{aligned} \theta^2 &= \frac{z^\sim C_{\rm cl}PC'_{\rm cl}z}{z^\sim z} \\ &\leq \lambda_{\max}(C_{\rm cl}PC'_{\rm cl}) \ \leq \ \mathrm{Tr}\ (C_{\rm cl}PC'_{\rm cl}). \end{aligned} \tag{62}$$

It is clear that the exact value of θ^2 cannot be calculated only in terms of the inequality (13) because it depends on the value of $\|H_F\|_\infty$. The above inequality provides an upper bound for it, thus proving part (a).

For part (b) we note once again that if $P = P' > 0$ satisfies (13), then it also satisfies (55). As a result, L_c being the controllability Gramian defined in (8) we get

$$\begin{aligned} P &\geq \gamma^{-2} \sum_{k=0}^{\infty} A_{\mathrm{cl}}^k B_1 B_1' {A_{\mathrm{cl}}'}^k \\ &\geq \gamma^{-2} L_c. \end{aligned} \tag{63}$$

This inequality together with (7) yields

$$\begin{aligned} \|H_F\|_2^2 &= \mathrm{Tr}\ (C_{\mathrm{cl}} L_c C_{\mathrm{cl}}') \\ &\leq \gamma^2 \mathrm{Tr}\ (C_{\mathrm{cl}} P C_{\mathrm{cl}}'), \end{aligned} \tag{64}$$

which concludes the proof of Lemma 3.2. □

A FINITE-DIMENSIONAL RISK-SENSITIVE CONTROL PROBLEM*

ALAIN BENSOUSSAN† AND ROBERT J. ELLIOTT‡

Abstract. A partially observed stochastic control problem with exponential running cost is considered. The dynamics are linear and the running cost is quadratic, although the control may enter nonlinearly. Explicit solutions are found to a modified Zakai equation and a backward adjoint equation. This enables the problem to be expressed in terms of observable finite-dimensional dynamics and a separation principle to be applied.

Key words. risk-sensitive partially observed stochastic control

AMS subject classifications. 93E20, 93E03, 93E11

1. Introduction.

There are few partially observed stochastic control problems for which the optimal control can be given in terms of finite-dimensional sufficient statistics. The linear quadratic Gaussian case is one. In [12] Wonham extended this result to a nonquadratic cost function. In recent years there has been interest in the case of linear dynamics for the state and observation and a cost which is the exponential of a standard quadratic cost. This model can be used to study risk aversion, or preference, in terms of a real parameter θ, and it was first discussed by Jacobson [6]. Whittle solved the linear discrete time partially observed problem in [11]. In continuous time the existence of finite-dimensional sufficient statistics was studied in particular cases by Jacobson [6], Speyer [10], and Kumar and van Schuppen [8] and was finally solved by Bensoussan and van Schuppen [2]. A detailed treatment can be found in Bensoussan [1].

In this paper, motivated by Wonham's contributions, we consider dynamics and running cost which are, respectively, linear and exponential quadratic in the state variables but which may be nonlinear functionals of the control. The terminal cost is also a general measurable function. An explicit solution of a modified Zakai equation is found, and the problem can then be described in terms of an information state defined by finite-dimensional fully observed dynamics. The value function, in turn, is a function of these finite-dimensional parameters and so is not a finite-dimensional quantity.

In §1 a general partially observed stochastic control problem with an exponential running cost is discussed. A modified Zakai equation is introduced whose solution is a measure related not only to the state of the process but also to the exponential running cost. A robust form of this equation is defined, and an adjoint measure valued process introduced. Section 3 discusses a verification result for a fully observed stochastic control problem. The case when the dynamics are linear and the exponential running cost is quadratic is considered in §4, although the control parameter may enter both dynamics and cost nonlinearly. It is shown that in this situation there is

‡ Department of Mathematical Sciences, University of Alberta, Edmonton, Alberta T6G 2G1, Canada.

an explicit solution of the modified Zakai equation in terms of a modified mean r and variance Π of the state process and also an explicit solution for the backward, adjoint process. Results of §4 extend those in [1] and [2] and permit the partially observed stochastic control problem, with exponential cost, to be written as a completely observed stochastic control problem with finite-dimensional state variables r and Π. If the verification theorem of §3 can be applied, we can conclude the separation principle holds.

2. Dynamics. Suppose $(\Omega, \mathcal{A}, P)$ is a probability space with a complete filtration $\{\mathcal{F}_t\}$, $t \geq 0$, on which are given two independent $\mathcal{F}_t$-Wiener processes $w(t)$ and $z(t)$. We assume that

- $w(\cdot)$ takes values in R^n and has covariance matrix $Q(\cdot)$;
- $z(\cdot)$ takes values in R^m and has covariance matrix $R(\cdot)$;
- $R(\cdot)$ is uniformly positive definite.

ξ is an R^n-valued random variable which is $\mathcal{F}_0$ measurable and independent of $w(\cdot)$ and $z(\cdot)$. The distribution of ξ is the measure $\Pi_0(\cdot)$.

U is a nonempty subset of R^k. Consider the Borel functions

$$g : R^n \times U \times [0, \infty) \to R^n,$$
$$\sigma : R^n \times [0, \infty) \to L(R^n, R^n),$$

where

$$|g(x_1, v, t) - g(x_2, v, t)| \leq k|x_1 - x_2|$$

and

$$\|\sigma(x_1, t) - \sigma(x_2, t)\| \leq k|x_1 - x_2|.$$

$Z_t = \sigma\{z_s : s \leq t\}$ is the complete filtration generated by z and an admissible control is a Z_t-adapted process which takes values in U. For any admissible control v_t there is a strong solution $x^v_\cdot = x_\cdot$ of the stochastic differential equation

$$\begin{aligned} dx_t &= g(x_t, v_t)dt + \sigma(x_t)dw_t, \\ x_0 &= \xi. \end{aligned} \tag{2.1}$$

Equation (2.1) describes the dynamics of the state process. Note that here, and in what follows, to simplify notation we omit t when writing g, σ, etc.

Consider the Borel function $h : R^n \times [0, \infty) \to R^m$, where we suppose

$$|h(x, t)| \leq k(1 + |x|).$$

For any admissible control v, with $x_\cdot$ the corresponding solution of (2.1), we suppose

$$E\Big[\exp\Big(\frac{1}{2}\int_0^t h^*(x_s, s)R_s^{-1}h(x_s, s)ds\Big)\Big] < \infty.$$

Define

$$\Lambda_{0,t} = \exp\Big(\int_0^t h^*(x_s, s)R_s^{-1}dz_s - \frac{1}{2}\int_0^t h^*(x_s, s)R_s^{-1}h(x_s, s)ds\Big).$$

Then from Novikov's result, (see Thm. 13.27 of [3]), Λ is an $\mathcal{F}_t$ martingale and

$$E[\Lambda_{0,t}] = 1.$$

A new probability measure $\widehat{P} = \widehat{P}(v)$ can be defined if we put

$$\frac{d\widehat{P}}{dP}\Big|_{\mathcal{F}_t} = \Lambda_{0,t}.$$

Define the process $b_t = b_t^v$ by the formula $b_t = z_t - \int_0^t h(x_s, s)ds$. Then $b.$ is a Wiener process under $\widehat{P}$ with covariance matrix $R(\cdot)$. Therefore, under $\widehat{P}$

$$z_t = \int_0^t h(x_s, s)ds + b_t. \tag{2.2}$$

Note it is under measure $\widehat{P}$ that z, satisfying (2.2), describes the noisy observations of the state process. Note also that $\Lambda_{0,t}$ is given by

$$\begin{aligned} d\Lambda_{0,t} &= \Lambda_{0,t}h^*(x_t, t)R_t^{-1}dz_t, \\ \Lambda_{0,0} &= 1. \end{aligned} \tag{2.3}$$

Consider Borel functions

$$\begin{aligned} L &: R^n \times U \times [0, \infty) \to R, \\ \Phi &: R^n \to R. \end{aligned}$$

For any admissible control v and real number θ we consider the expected exponential risk-sensitive cost

$$\begin{aligned} J(v) &= \theta \widehat{E}\Big[\exp \theta \Big(\int_0^T L(x_s, v_s)ds + \Phi(x_T)\Big)\Big] \\ &= \theta E\Big[\Lambda_{0,T} \exp \theta \Big(\int_0^T L(x_s, v_s)ds + \Phi(x_T)\Big)\Big]. \end{aligned}$$

Write

$$D_{0,t} = D_t = \exp\Big(\theta \int_0^t L(x_s, v_s)ds\Big)$$

so

$$dD_t = \theta L(x_t, v_t)D_t dt, \tag{2.4}$$

with $D_0 = 1$.

Following [7] we now define an information state σ.

Notation 2.1. For any function $\phi : R^n \to R$ for which the expectation is defined, write

$$\sigma(\phi)_t = E[\Lambda_{0,t}D_t\phi(x_t)|Z_t].$$

In case the measure defined by $\sigma(\cdot)_t$ has a density $q(x, t)$ we have

$$\sigma(\phi)_t = \int_{R^n} \phi(x)q(x, t)dx.$$

Write

$$A = \sum_i g_i(x_t, v_t)\frac{\partial}{\partial x_i} + \sum_{i,j} a_{ij}(x_t)\frac{\partial^2}{\partial x_i \partial x_j},$$

where $a(x_t) = \frac{1}{2}\sigma(x_t)Q_t\sigma^*(x_t)$. We now obtain a modified Zakai equation for $\sigma(\phi)_t$.

PROPOSITION 2.2. *Suppose $\phi : R^n \to R$ is a C^2 function with compact support. Then*

$$\sigma(\phi)_t = \sigma(\phi_0) + \theta \int_0^t \sigma(L\phi)_r dr + \int_0^t \sigma(\phi h^*(x_r, r) R_r^{-1}) dz_r + \int_0^t \sigma(A\phi)_r dr,$$

where $\sigma(\phi)_0 = E[\phi(x_0)] = \int \phi(\xi)\Pi_0(d\xi)$.

Proof. The Itô rule implies

$$\phi(x_t) = \phi(x_0) + \int_0^t (A\phi)(x_r)dr + \int_0^t D\phi \cdot \sigma(x_r)dw_r, \tag{2.5}$$

where $D = \left(\frac{\partial}{\partial x_1}, \ldots, \frac{\partial}{\partial x_n}\right)$. From (2.3), (2.4), and (2.5) we have

(2.6)

$$\Lambda_{0,t}D_t\phi(x_t) = \phi(x_0) + \int_0^t \Lambda_{0,r}D_r\phi(x_r)h^*(x_r, r)R_r^{-1}dz_r + \theta \int_0^t \Lambda_{0,r}D_rL_r\phi(x_r)dr$$
$$+ \int_0^t \Lambda_{0,r}D_r(A\phi)(x_r)dr + \int_0^t \Lambda_{0,r}D_r(D\phi) \cdot \sigma(x_r)dw_r.$$

We now condition each side of (2.6) on Z_t and use the facts that $w(\cdot)$ and $z(\cdot)$ are independent and that $z(\cdot)$ has independent increments under P (it is Wiener). (See Lemma 3.2 of Chapter 7 of Hajek and Wong [5].) We thus obtain

$$\sigma(\phi)_t = \sigma(\phi)_0 + \int_0^t \sigma(L\phi)_r dr + \int_0^t \sigma(\phi h^*(x_r, r)R_r^{-1})dz_r + \int_0^t \sigma(A\phi)_r dr. \tag{2.7}$$

COROLLARY 2.3. *If $\sigma(\cdot)_t$ has a density $q(x,t)$, integrating each term of (2.7) by parts implies that q satisfies*

(2.8)

$$q(x,t) = q_0(x) + \int_0^t q(x,r)h^*(x,r)R_r^{-1}dz_r + \theta \int_0^t L(x,r)q(x,r)dr + \int_0^t (A^*q)(x,r)dr.$$

Here A^* is the adjoint of A, and $q_0(x)$ is the density such that

$$\Pi_0(dx) = q_0(x)dx.$$

Remark 2.4. Analogs of (2.8) appear in [2] and [7]. For any admissible control v we have defined

$$\begin{aligned} J(v) &= \theta E[\Lambda_{0,T}D_T \exp(\theta\Phi(x_T))] \\ &= \theta E\big[E[\Lambda_{0,T}D_T \exp(\theta\Phi(x_T)) \mid Z_T]\big] \\ &= \theta E\Big[\int_{R^n} \exp(\theta\Phi(x)) \cdot q(x,T)dx\Big]. \end{aligned}$$

With $\Lambda_{t,T}$ and $D_{t,T}$ defined in the obvious way and with $\mathcal{X}_t = \sigma\{x_s : s \le t\}$ the filtration generated by $x(\cdot)$,

$$\begin{aligned} E[\Lambda_{0,T}D_T \exp(\theta\Phi(x_T)) \mid Z_T] &= E\big[E[\Lambda_{0,t}\Lambda_{t,T}D_{0,t}D_{t,T} \exp(\theta\Phi(x_T)) \mid Z_T, \mathcal{X}_t]Z_T\big] \\ &= E\big[\Lambda_{0,t}D_{0,t}E[\Lambda_{t,T}D_{t,T} \exp(\theta\Phi(x_T)) \mid Z_T, x_t]Z_T\big], \end{aligned}$$

using the Markov property. Write

$$p(x,t) = E[\Lambda_{t,T}D_{t,T} \exp(\theta\Phi(x_T)) \mid Z_T, x_t = x].$$

Then

$$\begin{aligned}E[\Lambda_{0,T}D_T\exp(\theta\Phi(x_T)) \mid Z_T] &= E[\Lambda_{0,t}D_tp(x_t,t) \mid Z_T]\\ &= \int_{R^n} q(x,t)p(x,t)dx.\end{aligned}$$

Clearly this quantity is independent of t. The expression is similar to results of Pardoux [9] on filtering and smoothing. Pardoux obtains the forward Zakai equation for q and an adjoint backward stochastic partial differential equation for the analog of p. However, in the control case which we are considering, we cannot immediately find the backward stochastic partial differential equation for p because, although the Wiener process $z(\cdot)$ could be reversed, the coefficients and running cost $L(x_r, v_r)$ involve the control $v(\cdot)$ which is adapted to the forward filtration. Consequently, we consider the robust form of the equation for q.

That is, we introduce the factor

$$\Psi_t(x) := \exp(-h^*(x,t)R_t^{-1}z_t).$$

We suppose the derivative

$$\frac{d}{dt}(h^*(x,t)R_t^{-1}) = (h^*(x,t)R_t^{-1})'$$

exists so that

$$d\Psi = \Psi_t(-h^*(x,t)R_t^{-1}dz_t - (h^*(x,t)R_t^{-1})'z_tdt + \frac{1}{2}(h^*(x,t)R_t^{-1}h(x,t))dt). \tag{2.9}$$

Define $\hat{q}(x,t) := q(x,t)\Psi_t(x)$. Then $d\hat{q} = dq\cdot\Psi + q\cdot d\Psi + \langle dq, d\Psi\rangle$, and from (2.8) this is

$$= \theta q\Psi.Ldt + \Psi.(A^*q)dt - q\Psi.(h^*R^{-1})'z_tdt - \frac{1}{2}q\Psi.(h^*R^{-1}h)dt. \tag{2.10}$$

Note here that the stochastic integral, dz-term has cancelled. The $\Psi.(A^*q)$ coefficient on the right side can be written as $\Psi.(A^*(\Psi^{-1}\hat{q}))$ so that $\hat{q}(x,t)$ is defined by a forward parabolic partial differential equation in which the observation process z appears as a parameter. That is,

$$\begin{aligned}\frac{\partial\hat{q}}{\partial t} &= \theta\hat{q}Ldt + \Psi.(A^*(\Psi^{-1}\hat{q}))dt - \hat{q}.(h^*R^{-1})'z_tdt - \frac{1}{2}\hat{q}.(h^*R^{-1}h)dt\\ &= B(\hat{q}),\ \text{say}, \qquad \hat{q}_0(x) = q_0(x),\end{aligned}$$

where B is a second-order operator. We can then consider a backward adjoint equation for a function $\hat{p}(x,t)$:

$$-\frac{\partial\hat{p}}{\partial t} = B^*(\hat{p}), \qquad \hat{p}(x,T) = \exp(\Phi(x) + h^*(x,T)R_T^{-1}z_T).$$

Defining $p(x,t) = \hat{p}(x,t)\Psi_t^{-1}$ we have

$$\int_{R^n} p(x,t)q(x,t)dx = \int_{R^n} \hat{p}(x,t)\hat{q}(x,t)dx,$$

a quantity independent of t.

We can, therefore, write

$$\begin{aligned} J(v) &= E\Big[\int_{R^n} p(x,t)q(x,t)dx\Big] = E\Big[\int_{R^n} \hat{p}(x,t)\hat{q}(x,t)dx\Big] \\ &= E\Big[\int_{R^n} \exp(\theta\Phi(x))\cdot q(x,T)dx\Big] = E\Big[\int_{R^n} p(x,0)q_0(x)dx\Big]. \end{aligned}$$

For any times $0 \leq s < t \leq T$ write $\mathcal{U}_{s,t}$ for the admissible controls on the interval $[s,t]$, that is, the functions $v : [s,t] \times \Omega \to U$ which are adapted to $\{Z_r\}$. The minimum cost from time 0 is of course

$$V(q_0,0) = \inf_{v\in\mathcal{U}_{0,T}} J(v).$$

The density $q(x,t)$, or alternatively $\hat{q}(x,t)$, can be taken as the observable state of the system at any time $t \in [0,T]$. In general, therefore, this state is infinite dimensional. Consider an intermediate time t and suppose the system is in state $q = q(x,t)$ at time t. For $s > t$ and any $v \in \mathcal{U}_{t,T}$, using (2.8), write $q_q^v(x,s) = q_q^v$ for the solution of

$$\text{(2.11)}\quad q_q^v := q + \int_t^s q(x,r)h^*(x,r)R_r^{-1}dz_r + \theta\int_t^s L(x,v_r)q(x,r)dr + \int_t^s (A^*q)(x,r)dr.$$

Then the cost for this process, using control v and starting in state q at time t, is

$$\begin{aligned} J(v,q,t) &= E\Big[\int_{R^n} \exp(\theta\Phi(x))q_q^v(x,T)dx\Big] \\ &= E\Big[\int_{R_n} p^v(x,t)q(x,t)dx\Big]. \end{aligned}$$

The minimum cost starting from state q at time t is, therefore,

$$V(q,t) = \inf_{v\in\mathcal{U}_{t,T}} J(v,q,t).$$

Consider $h > 0$ such that $0 \leq t < t+h \leq T$. We have the following dynamic programming result.

THEOREM 2.5.

$$\text{(2.12)}\qquad V(q,t) = \inf_{u\in\mathcal{U}_{t,t+h}} E\big[V(q_q^u(\cdot,t+h),t+h) \mid q(\cdot,t) = q\big].$$

Proof.

$$\begin{aligned} V(q,t) &= \inf_{v\in\mathcal{U}_{t,T}} J(v,q,t) = \inf_{v\in\mathcal{U}_{t,T}} E\Big[\int_{R^n} p^v(x,t)q(x,t)dx \mid q(\cdot,t) = q\Big] \\ &= \inf_{u\in\mathcal{U}_{t,t+h}} \inf_{v\in\mathcal{U}_{t+h,T}} E\Big[\int_{R^n} p^v(x,t+h)q_q^u(x,t+h)dx \mid q(\cdot,t) = q\Big] \\ &= \inf_{u\in\mathcal{U}_{t,t+h}} \inf_{v\in\mathcal{U}_{t+h,T}} E\Big[E\Big[\int_{R^n} p^v(x,t+h)q_q^u(x,t+h)dx \mid Z_{t+h}, q(\cdot,t)\Big]q(\cdot,t) = q\Big] \\ &= \inf_{u\in\mathcal{U}_{t,t+h}} E\Big[\inf_{v\in\mathcal{U}_{t+h,T}} E\Big[\int_{R^n} p^v(x,t+h)q_q^u(x,t+h)dx \mid q_q^u(\cdot,t+h)\Big]q(\cdot,t) = q\Big] \\ &= \inf_{u\in\mathcal{U}_{t,t+h}} E[V(q_q^u(x,t+h),t+h) \mid q(\cdot,t) = q]. \end{aligned}$$

The interchange of minimization and conditional expectation is justified because of the lattice property of the set of controls. See Elliott [3, Chap. 16].

Remark 2.6. There is a similar result in terms of the robust state $\hat{q}(\cdot, t)$:

$$V(\hat{q}, t) = \inf_{u \in \mathcal{U}_{t,t+h}} E[V(\hat{q}^u_{\hat{q}}(\cdot, t+h), t+h) \mid \hat{q}(\cdot, t) = \hat{q}].$$

Here $\hat{q}$ evolves according to (2.10). We have noted that the state q, a density, is in general infinite-dimensional. Consequently, it is difficult to differentiate (2.12) and obtain a minimum principle. In §4, however, we consider a situation where $q(\cdot, t)$ (and $\hat{q}$, $\hat{p}$) are defined in terms of finite-dimensional parameters.

3. A verification theorem.

The notation is that of §2. In this section we consider a fully observed risk-sensitive control problem with dynamics

$$dx_t = g(x_t, v_t)dt + \sigma(x_t)dw_t, \qquad x_0 = \xi \in R^n, \qquad 0 \le t \le T, \tag{3.1}$$

and cost

$$J(v) = \theta E\Big[\exp \theta\Big(\int_0^T L(x_s, v_s)ds + \Phi(x_T)\Big)\Big]. \tag{3.2}$$

The admissible controls are those functions on $U \times [0, \infty)$ with values in U which are adapted to the filtration generated by x and for which the expectation (3.2) is finite. Sufficient conditions for the latter result to hold are given in [2].

Recall $a = (a_{ij}(x)) = \frac{1}{2}\sigma Q \sigma^*$. Suppose there is a solution $\mathcal{X}(x, t)$ of the nonlinear parabolic equation

$$\frac{\partial \mathcal{X}}{\partial t} + \min_v [D\mathcal{X}.g(x, v) + L(x, v)] + TrD^2\mathcal{X}.a + \theta D\mathcal{X}^*_. a.D\mathcal{X} = 0, \tag{3.3}$$

with $\mathcal{X}(x, T) = \Phi(x)$. Write

$$h_t := \int_0^t L(x_s, v_s)ds + \mathcal{X}(x_t, t).$$

Then $J(v) = \theta E[\exp \theta h_T]$. Suppose $u^* : R^n \to U$ is the function such that for each $x \in R^n$

$$D\mathcal{X}.g(x, u^*(x)) + L(x, u^*(x)) = \min_{v \in U}[D\mathcal{X}.g(x, v) + L(x, v)]. \tag{3.4}$$

We can then establish the following verification theorem. A similar proof is given in the paper by Fleming and McEneaney [4].

THEOREM 3.1. *Suppose there is a function $\mathcal{X} \in C^{2,1}$ which is a solution of* (3.3). *With $u^*(\cdot)$ defined by* (3.4) *the feedback control $u^*(x_t)$ is optimal for the fully observed, risk-sensitive control problem* (3.1), (3.2).

Proof. Using Itô's rule

$$\mathcal{X}(x_t, t) = \mathcal{X}(x_0, 0) + \int_0^t \Big(\frac{\partial \mathcal{X}}{\partial s} + D\mathcal{X}.g(x_s, v_s) + TrD^2\mathcal{X}.a)ds + \int_0^t D\mathcal{X}.\sigma dw_s.$$

Therefore,

$$\begin{aligned}
J(v) &= \theta E\Big[\exp\theta\Big(\int_0^T L(x_s,v_s)ds + \mathcal{X}(x,T)\Big)\Big]\\
&= \theta E\Big[\exp\theta\Big(\mathcal{X}(x_0,0) + \int_0^T \Big(\frac{\partial\mathcal{X}}{\partial s} + D\mathcal{X}.g(x_s,v_s) + L(x_s,v_s) + TrD^2\mathcal{X}.a\Big)ds\\
&\qquad + \int_0^T D\mathcal{X}.\sigma dw_s\Big)\Big]\\
&= \theta\exp\theta\mathcal{X}(x_0,0).E\Big[\exp\theta\Big(\int_0^T \Big(\frac{\partial\mathcal{X}}{\partial s} + D\mathcal{X}.g(x_s,v_s) + L(x_s,v_s)\\
&\qquad\qquad + TrD^2\mathcal{X}.a + \theta D\mathcal{X}^*.a.D\mathcal{X}\Big)ds.\Big)\\
&\qquad\qquad \times\exp\Big(\theta\int_0^T D\mathcal{X}.\sigma dw_s - \theta^2\int_0^T D\mathcal{X}^*.a.D\mathcal{X}ds\Big)\Big].
\end{aligned} \tag{3.5}$$

From (3.3), therefore,

$$\begin{aligned}
J(u^*) &= \theta\exp\theta\mathcal{X}(x_0,0).E\Big[\exp\Big(\theta\int_0^T D\mathcal{X}.\sigma dw - \theta^2\int_0^T D\mathcal{X}^*.a.D\mathcal{X}ds\Big)\Big]\\
&= \theta\exp\theta\mathcal{X}(x_0,0)
\end{aligned}$$

because the term in the expectation is a martingale. For any other control v

$$\begin{aligned}
&\frac{\partial\mathcal{X}}{\partial s} + D\mathcal{X}.g(x_s,v_s) + L(x_s,v_s) + TrD^2\mathcal{X}.a + \theta D\mathcal{X}^*.a.D\mathcal{X}\\
&\quad\geq \frac{\partial\mathcal{X}}{\partial s} + D\mathcal{X}.g(x_s,u^*(x_s)) + L(x_s,u^*(x_s)) + TrD^2\mathcal{X}.a + \theta D\mathcal{X}^*.a.D\mathcal{X} = 0.
\end{aligned}$$

Consequently, from (3.5)

$$\begin{aligned}
J(v) &\geq \theta\exp(\theta\mathcal{X}(x_0,0))E\Big[\exp\Big(\theta\int_0^T D\mathcal{X}.\sigma dw_s - \theta^2\int_0^T D\mathcal{X}^*.a.D\mathcal{X}ds\Big)\Big]\\
&= \theta\exp(\theta\mathcal{X}(x_0,0)) = J(u^*).
\end{aligned}$$

Therefore, u^* is an optimal control.

4. Linear dynamics. The results of §2 are now specialized to the situation where

$$\begin{aligned}
g(x,v) &= F(v).x + G(v),\\
\sigma &= I, \quad \text{the } n\times n \text{ identity matrix},\\
a &= \frac{1}{2}Q(t), \quad \text{a time-varying } n\times n \text{ matrix},\\
h(x,t) &= H_t x + h_t,\\
L(x,v) &= \frac{1}{2}M(v)x\cdot x + m(v)\cdot x + N(v),\\
\Phi(x) &= \Phi(x).
\end{aligned}$$

Here $F(\cdot)$ and $M(\cdot)$ are maps from U into the space of $n\times n$ matrices $L(R^n,R^n)$, $G(\cdot)$ and $m(\cdot)$ are maps from U into R^n, $H_t\in L(R^n,R^m)$, $h_t\in R^m$, and N is a real function defined on U. We suppose ξ is described by a normal density

$$p_0(x) = \exp\frac{\left(-\frac{1}{2}P_0^{-1}(x-x_0)\cdot(x-x_0)\right)}{(2\Pi)^{n/2}|P_0|^{1/2}}.$$

The mean of ξ is, therefore, x_0. We shall often write H for H_t, Q for Q_t, etc.

LEMMA 4.1. *In this case the equation* (2.8) *for* $q(x,t)$ *is*

$$\begin{aligned}(4.1)\quad dq = \Big[&- Dq.(F(v)x + G(v)) - qTr.F(v) \\ &+ \theta q\Big(\frac{1}{2}M(v)x\cdot x + m(v)\cdot x + N(v)\Big) + \frac{1}{2}TrQD^2q\Big]dt \\ &+ q(Hx+h)^* R_t^{-1} dz_t,\end{aligned}$$

with $q(x,0) = p_0(x)$.

THEOREM 4.2. *The solution of* (4.1) *is*

$$(4.2)\qquad q(x,t) = \frac{\nu_t \cdot \exp\left(-\frac{1}{2}\Pi_t^{-1}(x-r_t)\cdot(x-r_t)\right)}{(2\Pi)^{n/2}|\Pi_t|^{1/2}}.$$

Here $r_t = r_t^v$ *is given by*

$$\begin{aligned}(4.3)\quad dr_t = \big(F(v)\cdot r_t + G(v) + \theta\Pi_t(M(v)\cdot r_t + m(v))\big)dt \\ + \Pi_t H^* R_r^{-1}(dz_t - (Hr_t + h)dt),\end{aligned}$$

with $r(0) = x_0$; $\Pi_t = \Pi_t^v$ *is given by the Riccati equation*

$$(4.4)\qquad \dot{\Pi}_t = F(v)\Pi_t + \Pi_t F^*(v) + Q + \Pi_t(\theta M(v) - H^* R_t^{-1} H)\Pi_t,$$

with $\Pi_0 = P_0$; *and*

$$\begin{aligned}(4.5)\quad \nu_t = \exp\Big[&\int_0^t (Hr_s + L)^* R_s^{-1} dz_s - \frac{1}{2}\int_0^t (Hr_s+h)^* R_s^{-1}(Hr_s+h)ds \\ &+ \theta\int_0^t \Big(\frac{1}{2}M(v)r_s\cdot r_s + m(v)\cdot r_s + N(v) + \frac{1}{2}Tr.\Pi_s M(v)\Big)ds\Big].\end{aligned}$$

Note that we are making the following assumption: we suppose (4.4) has a bounded, symmetric solution $\Pi^v_\cdot$.

Proof. Differentiating $q(x,t)$ defined by (4.2), (4.3), (4.4), and (4.5) and substituting in (4.1) verify the result.

Remark 4.3. Recall that under measure $\widehat{P}$ $b^v_\cdot = b$ is a Wiener process where

$$b_t = z_t - \int_0^t (Hr_s + h)ds;$$

consequently equation (4.3) for r can be written

$$(4.6)\qquad dr_t = \big(F(v)r_t + G(v) + \theta\Pi_t(M(v)r_t + m(v))\big)dt + \Pi_t H^* R_t^{-1} db_t.$$

PROPOSITION 4.4. *Suppose the derivative* $\frac{d}{dt}((Hx+h)R_t^{-1}) = ((Hx+h)R_t^{-1})'$ *exists. If we write* $\Psi_t(x) = \exp(-(Hx+h)^* R_t^{-1} z_t)$, *the robust process* $\hat{q}(x,t) =$

$q(x,t)\Psi_t(x)$ is the solution of the parabolic partial differential equation

$$\begin{aligned} d\hat{q} = \Big[&- (\hat{q}H^* R_t^{-1} z_t + D\hat{q})(F(v)x + G(v)) \\ &- \hat{q} Tr F(v) + \theta \hat{q}\Big(\frac{1}{2} M(v)x \cdot x + m(v) \cdot x + N(v)\Big) \\ &- \hat{q}((Hx+h)^* R_t^{-1})' z_t - \frac{\hat{q}}{2}(Hx+h)^* R_t^{-1}(Hx+h) \\ &+ \frac{1}{2} Tr Q_t \cdot D^2 \hat{q} + \frac{1}{2} \hat{q} z_t^* R_t^{-1} H Q_t H^* R_t^{-1} z_t + z_t^* H^* R_t^{-1} Q_t \cdot D\hat{q}\Big] dt, \end{aligned} \tag{4.7}$$

$$\hat{q}(x,0) = p_0(x).$$

Proof. From (2.10) and (4.1) we have

$$\begin{aligned} d\hat{q} = \Big[&- \Psi \cdot Dq(F(v)x + G(v)) - \Psi q \cdot Tr F(v) \\ &+ \theta \Psi q \cdot \Big(\frac{1}{2} M(v)x \cdot x + m(v) \cdot x + N(v)\Big) + \frac{1}{2}\Psi . Tr Q D^2 q \\ &- \Psi q.((Hx+h)R_t^{-1})' z_t - \frac{1}{2}\Psi q.(Hx+h)^* R_t^{-1}(Hx+h)\Big] dt. \end{aligned} \tag{4.8}$$

We wish to write the right-hand side in terms of $\hat{q} = \Psi q$. Now

$$\begin{aligned} D\Psi_t &= -\Psi_t \cdot H^* R_t^{-1} z_t, \\ D^2 \Psi_t &= \Psi_t H^* R_t^{-1} z_t \otimes H^* R_t^{-1} z_t. \end{aligned}$$

Also, $D(\Psi q) = D\Psi \cdot q + \Psi \cdot Dq$ and

$$D^2(\Psi q) = D^2 \Psi \cdot q + 2(D\Psi) \otimes (Dq) + \Psi \cdot D^2 q,$$

so

$$-\Psi \cdot Dq = -(\Psi q) H^* R_t^{-1} z_t dt - D(\Psi q)$$

and

$$\Psi \cdot D^2 q = D^2(\Psi q) - (\Psi q) H^* R_t^{-1} z_t \otimes H^* R_t^{-1} z_t + 2H^* R_t^{-1} z_t \otimes (D(\Psi q) - (D\Psi) \cdot q).$$

Substituting in (4.8) we obtain (4.7).

Remark 4.5. The adjoint backward parabolic equation for $\hat{p}(x,t)$ is, therefore,

$$\begin{aligned} -\frac{\partial \hat{p}}{\partial t} = \Big[&(D\hat{p} - \hat{p} H^* R_t^{-1} z_t)(F(v)x + G(v)) \\ &+ \theta \hat{p}\Big(\frac{1}{2} M(v)x \cdot x + m(v) \cdot x + N(v)\Big) - \hat{p}((Hx+h)^* R_t^{-1})' z_t \\ &- \frac{\hat{p}}{2}(Hx+h)^* R_t^{-1}(Hx+h) + \frac{1}{2} Tr Q_t \cdot D^2 \hat{p} + \frac{1}{2}\hat{p} z_t^* R_t^{-1} H Q_t H^* R_t^{-1} z_t \\ &+ z_t^* H^* R_t^{-1} Q_t \cdot D\hat{p}\Big] dt, \end{aligned} \tag{4.9}$$

$$\hat{p}(x,T) = \exp(\Phi(x) + (Hx+h)^* R_T^{-1} z_T).$$

It is of interest that we can give a finite-dimensional solution of (4.9).

THEOREM 4.6. *The solution of* (4.9) *is*

$$\hat{p}(x,t) = \mu_t \cdot \int_{R^n} \frac{\exp\big(-\frac{1}{2}S_t^{-1}(x-\gamma_t(y))\cdot(x-\gamma_t(y))\big)}{(2\Pi)^{n/2}|S_t|^{1/2}} \cdot \exp(\Phi(y) + z_T^* R_T^{-1} H_T y)dy. \tag{4.10}$$

Here $S_t = S_t^v$ *is given by*

$$\dot{S}_t = F(v)S_t + S_t F^*(v) - Q + S_t(H^*R^{-1}H - \theta M(v))S_t, \tag{4.11}$$

with $S_T = 0$; $\gamma_t = \gamma_t(y) = \gamma_t^v(y)$ *is given by*

$$\begin{aligned}\dot{\gamma}_t = {} & S_t(H^*R^{-1}H - \theta M(v))\gamma_t + F(v)\gamma_t + S_t(H^*R^{-1})'z_t \\ & + S_t F^*(v)H^*R^{-1}z_t + S_t H^*R^{-1}h - \theta S_t m(v) + G(v) - QH^*R^{-1}z_t,\end{aligned} \tag{4.12}$$

with $\gamma_T = y \in R^n$, *and*

$$\begin{aligned}\mu_t = \exp\Big(-\frac{1}{2}\int_t^T & \Big[2Tr.F(v) + Tr.(S_s H^*R^{-1}H) - \theta Tr.(S_s M(v)) \\ & + \gamma_s^* H^*R^{-1}H\gamma_s - \gamma_s^* M(v)\gamma_s + 2\gamma_s^* F^*(v)H^*R^{-1}z_s - \gamma_s^*(H^*R^{-1})'z_s \\ & - 2\gamma_s^* m(v) - 2\theta N(v) + 2\gamma_s^* H^*R^{-1}h - z_s^* R^{-1}HQH^*R^{-1}z_s \\ & + 2(h^*R^{-1})'z_s + h^*R^{-1}h + 2z_s^*R^{-1}HG(v)\Big]ds - h_T^* R_T^{-1} z_T\Big).\end{aligned} \tag{4.13}$$

Proof. Differentiating $\hat{p}(x,t)$ defined by (4.10), (4.11), (4.12), and (4.13) and substituting in (4.9) verify the result.

5. A separation principle. With the linear dynamics and cost of §4, for any admissible, Z_t-adapted control v

$$\begin{aligned}J(v) &= \theta\hat{E}\Big[\exp\Big(\theta\int_0^T L(x_s,v_s)ds\Big)\cdot\exp\theta\Phi(x_T)\Big] \\ &= \theta E\Big[\int_{R^n}\exp(\theta\Phi(x))\cdot q(x,T)dx\Big].\end{aligned}$$

Using the explicit form of equation (4.2) for q, this is

$$\begin{aligned}= \theta E\Big[\int_{R^n} & \exp(\theta\Phi(x)).\exp\Big[\int_0^T (Hr_s+h)^*R_s^{-1}dz_s - \frac{1}{2}\int_0^T (Hr_s+h)^*R_s^{-1}(Hr_s+h)ds\Big] \\ & \times\exp\Big[\theta\int_0^T\Big(\frac{1}{2}M(v)r_s\cdot r_s + m(v)\cdot r_s + N(v) + \frac{1}{2}Tr\Pi_s\cdot M(v)\Big)ds\Big] \\ & \times\exp\frac{\big(-\frac{1}{2}\Pi_T^{-1}(x-r_T)\cdot(x-s_T)\big)}{(2\Pi)^{n/2}|\Pi_T|^{1/2}}\cdot dx\Big],\end{aligned}$$

and, in terms of the measure $\hat{P}$, this is

$$\begin{aligned}= \theta\hat{E}\Big[\int_{R^n} & \exp(\theta\Phi(x))\cdot\frac{\exp\big(-\frac{1}{2}\Pi_T^{-1}(x-r_T)\cdot(x-r_T)\big)}{(2\Pi)^{n/2}|\Pi_T|^{1/2}}\cdot dx \\ & \times\exp\Big[\theta\int_0^T\Big(\frac{1}{2}M(v)r_s\cdot r_s + m(v)\cdot r_s + N(v) + \frac{1}{2}Tr\Pi_s\cdot M(v)\Big)ds\Big]\Big].\end{aligned}$$

Write $x = r_T^v + (\Pi_T^v)^{1/2}$, $\xi = r_T + \Pi_T^{1/2}\xi$, and

$$\tilde{\phi}(x, \Pi_T) = (2\Pi)^{-n/2} \int_{R^n} \exp(\theta\Phi(x + \Pi_T^{1/2}\xi)) \exp\Big(- \frac{1}{2}|\xi|^2\Big) d\xi.$$

Then

$$J(v) = \theta\widehat{E}\Big[\exp\theta\Big(\hat{\phi}(r_T, \Pi_T) + \int_0^T \Big(\frac{1}{2}M(v)r_s \cdot r_s + m(v)\cdot r_s + N(v) + \frac{1}{2}Tr\Pi_s \cdot M(v)\Big)ds\Big)\Big], \tag{5.1}$$

where $\hat{\phi}(x, \Pi) = \theta^{-1}\log\tilde{\phi}(x, \Pi)$.

The partially observed, stochastic control problem of §4 is now expressed as a fully observed stochastic control problem with finite-dimensional state (r, Π) defined by (4.6) and (4.4). Consequently, if there is a function $\mathcal{X}$ which is the solution of the analog of equation (3.3) for these dynamics and cost (5.1), we can conclude that the optimal control u^* is the feedback control determined by the function which minimizes the Hamiltonian (3.4). Therefore, in this situation the separation principle holds.

Alternatively, we note that the observed state q is determined by the parameters ν, r, and Π:

$$q(x,t) = q(x,t,\nu,r,\Pi) = \nu \cdot \frac{\exp\big(- \frac{1}{2}\Pi^{-1}(x-r)\cdot(x-r)\big)}{(2\Pi)^{n/2}|\Pi|^{1/2}}.$$

Consequently, the cost process $V(q,t)$ defined in §4 can be considered as a function of ν, r, Π: $V(\nu, r, \Pi, t)$.

If there is an optimal control u^*, consider the $\hat{p}(x,t) = \hat{p}(x,t,\mu_t^{u^*}, S_t^{u^*}, \gamma_t^{u^*})$ defined by (4.10). Write

$$p^*(x,t) = \hat{p}(x,t,\mu_t^{u^*}, S_t^{u^*}, \gamma_t^{u^*})\exp((Hx+h)^*R_t^{-1}z_t).$$

Then

$$V(q,t) = V(\nu, r, \Pi, t) = E\Big[\int_{R^n} p^*(x,t)q(x,t,\nu,r,\Pi)dx\Big].$$

The dynamic programming result, Theorem 2.5, becomes

$$V(\nu, r, \Pi, t) = \inf_{u\in\mathcal{U}_{t,t+h}} E[V(\nu_{t+h}^u, r_{t+h}^u, \Pi_{t+h}^u, t+h) \mid \nu_t = \nu, r_t = r, \Pi_t = \Pi]. \tag{5.2}$$

Suppose V is twice diffentiable in ν and r and differentiable in Π and t so that

$$\begin{aligned} V(\nu_{t+h}^u, r_{t+h}^u, \Pi_{t+h}^u, t+h) &= V(\nu, r, \Pi, t) + \int_t^{t+h} \frac{\partial V}{\partial t}\cdot ds + \int_t^{t+h}\frac{\partial V}{\partial \nu}\cdot d\nu_s \\ &+ \int_t^{t+h}\frac{\partial V}{\partial r}\cdot dr_s + \int_t^{t+h}\frac{\partial V}{\partial \Pi}\cdot d\Pi_s + \frac{1}{2}\int_t^{t+h}\frac{\partial^2 V}{\partial \nu^2}\Pi H^* R^{-1}H\Pi ds \\ &+ \frac{1}{2}\int_t^{t+h}\frac{\partial^2 V}{\partial r^2}\nu(Hr+h)^*R^{-1}(Hr+h)ds. \end{aligned}$$

Substituting in (5.2), dividing by $h > 0$, and letting h go to 0 we obtain the separated minimum principle which states that, for almost all t, the optimal control

$u^*(\nu, r, \Pi)$ is the value which minimizes the Hamiltonian

$$\frac{\partial V}{\partial r} \cdot \big(F(v)r + G(v) + \theta\Pi(M(v)r + m(v))\big) + \frac{\partial V}{\partial \Pi} \cdot (F(v)\Pi + \Pi F^*(v) + \theta\Pi M(v)\Pi) + \frac{\partial V}{\partial v} \cdot v\theta\Big(\frac{1}{2}M(v)r \cdot r + m(v) \cdot r + N(v) + \frac{1}{2}Tr.\Pi M(v)\Big).$$

6. Conclusion. In a partially observed stochastic control problem with an exponential running cost of modified Zakai equation was introduced whose solution is a measure which is related not only to the state of the process but also to the cost. The situation when the dynamics are linear and the exponential running cost is quadratic is discussed, although the control parameter may enter both dynamics and cost nonlinearly. In this case the solution of the modified Zakai equation can be found explicitly. An explicit solution was also found for the backward adjoint process. This permits the partially observed stochastic control problem to be written as a fully observed problem in terms of an information state with finite-dimensional dynamics so that the separation principle holds.

ON THE TOPOLOGY OF THE KARUSH–KUHN–TUCKER SET UNDER MANGASARIAN–FROMOVITZ CONSTRAINT QUALIFICATION*

HARALD GÜNZEL†

Abstract. This paper deals with smooth optimization problems $\mathcal{P}$ in $I\!R^n$ depending on parameter $y \in I\!R^p$. The problem $\mathcal{P}(y)$ is defined by means of a finite number of equality and inequality constraints. We study the set $\mathbf{\Sigma}_{KKT}$ of pairs (x,y) such that x is a Karush–Kuhn–Tucker point of the problem $\mathcal{P}(y)$. Let $\mathbf{\Sigma}$ denote the subset of $\mathbf{\Sigma}_{KKT}$ at which the Mangasarian–Fromovitz constraint qualification is fulfilled. For problem data in general position we prove that $\mathbf{\Sigma}$ is a topological manifold of dimension p.

Key words. parametric optimization, Karush–Kuhn–Tucker set, Mangasarian–Fromovitz constraint qualification, topological manifold

AMS subject classification. 90C31

1. Introduction. Consider the optimization problem $\mathcal{P}(y)$, where $y \in I\!R^p$ is a parameter:

$$\mathcal{P}(y) \quad : \quad \max\{\, f(x,y) \mid x \in M(y) \,\}, \qquad \text{where}$$

$$M(y) \;=\; \{\, x \in I\!R^n \mid h_i(x,y) = 0,\; i \in \mathcal{H}\;;\; g_j(x,y) \le 0,\; j \in \mathcal{G} \,\}.$$

The sets $\mathcal{H} = \{1,\ldots,\mathrm{h}\}$ and $\mathcal{G} = \{1,\ldots,\mathrm{g}\}$ are finite index sets. If not explicitly stated otherwise, all appearing mappings and manifolds are assumed to be smooth, i.e., of class C^∞. Let $\mathbf{\Sigma}_{KKT} \subset I\!R^n \times I\!R^p$ denote the set of Karush–Kuhn–Tucker (KKT) points of $\mathcal{P}$; a pair $(x,y) \in I\!R^n \times I\!R^p$ is called a KKT-point if the following conditions hold with some $\lambda \in I\!R^{\mathrm{h}}$ and $\mu \in I\!R^{\mathrm{g}}$:

(KKT1) $x \in M(y)$,
(KKT2) $\mu_j \ge 0\;,\quad j \in \mathcal{G}_0(x,y)$,
(KKT3) $\mu_j = 0\;,\quad j \notin \mathcal{G}_0(x,y)$,
(KKT4) $D_x f \;=\; \sum_i \lambda_i\, D_x h_i \;+\; \sum_j \mu_j\, D_x g_j\;\Big|_{(x,y)}$.

Here, $\mathcal{G}_0(x,y) := \{\, j \in \mathcal{G} \mid g_j(x,y) = 0 \,\}$ denotes the set of active inequality constraints. A pair (λ,μ) satisfying conditions (KKT1)–(KKT4) is called a Lagrange multiplier associated with (x,y). Note that the set of Lagrange multipliers associated with (x,y) is a convex polyhedron.

The Mangasarian–Fromovitz constraint qualification (MFCQ) is said to hold at (x,y) if (KKT1)–(KKT3), together with the relation $\sum_i \lambda_i\; D_x h_i(x,y) + \sum_j \mu_j\; D_x g_j(x,y) \;=\; 0$, imply that (λ,μ) vanishes. In that case, the set of Lagrange multipliers for (x,y) is compact (cf. [3]) and will be referred to as a Lagrange polytope. Let $\mathbf{\Sigma} \subset \mathbf{\Sigma}_{KKT}$ denote the subset of those KKT-points at which the MFCQ is satisfied. The set $\mathbf{\Sigma}$ is called the KKT-set.

MAIN THEOREM. *There exists a C^2-open and C^∞-dense subset $\mathcal{F}$ of $C^\infty(I\!R^{n+p}, I\!R^{1+\mathrm{h}+\mathrm{g}})$ with the following property: If $(f,H,G) \in \mathcal{F}$, then the corresponding KKT-set $\mathbf{\Sigma}$ is a topological manifold of dimension p.*

† Department of Mathematics (C), Aachen University of Technology, D-52056 Aachen, Germany (guenzel@RWTH-Aachen.de).

Here, $H = (h_1, \dots, h_{\mathrm{h}})$. The topology used above is defined as follows. First, let $s \in I\!N$. For $\bar{F} \in C^\infty(I\!R^n, I\!R^m)$ and $\varepsilon \in C^0(I\!R^n, I\!R_+)$, we define an ε-neighborhood of $\bar{F}$:

$$U_\varepsilon(\bar{F}) := \left\{ F \in C^\infty(I\!R^n, I\!R^m) \;\middle|\; \| \partial_\alpha F(x) - \partial_\alpha \bar{F}(x) \| < \varepsilon(x) \ \ \forall x \in I\!R^n \ , \ |\alpha| \le s \right\}.$$

Here, α stands for the multiindex of a partial derivative, $I\!R_+ := (0, \infty)$. The sets $U_\varepsilon(\bar{F})$ form a basis of the C^s-topology. The C^∞-topology is defined to be the union of all C^s-topologies. Let $\mathcal{X}$ be the KKT-set blown up by means of the associated Lagrange polytope, i.e.,

$$\mathcal{X} = \{(x, y, \lambda, \mu) \in I\!R^n \times I\!R^p \times I\!R^{\mathrm{h}} \times I\!R^{\mathrm{g}} \mid \text{(KKT1)–(KKT4) and MFCQ hold at } (x, y)\}.$$

We call $\mathcal{X}$ the extended KKT-set. We actually will prove the following theorem, which implies our main theorem.

THEOREM 1.1. *There exists a C^2-open and C^∞-dense subset $\mathcal{F}$ of $C^\infty(I\!R^{n+p}, I\!R^{1+\mathrm{h}+\mathrm{g}})$ with the following property: If $(f, H, G) \in \mathcal{F}$, then the extended KKT-set $\mathcal{X}$ is a topological manifold of dimension p. Moreover, there exists a homeomorphism $\varphi : \mathcal{X} \to \mathbf{\Sigma}$, arbitrarily C^0-close to the natural projection $\mathcal{X} \to \mathbf{\Sigma}$.*

The main point in Theorem 1.1 is the existence of the homeomorphism φ. The fact that the extended KKT-set $\mathcal{X}$ is a topological manifold was already known (cf. [12]). For a nice outline of the latter idea see [9]. The one-parametric case (including the KKT-set $\mathbf{\Sigma}$) was treated by Kojima and Hirabayashi (cf. [10]).

The reason for the homeomorphy between $\mathcal{X}$ and $\mathbf{\Sigma}$ can be illustrated as follows. There is a natural equivalence relation on $\mathcal{X}$, namely, to belong to the same Lagrange polytope. The set $\mathbf{\Sigma}$ then becomes the quotient space. The family of Lagrange polytopes is upper semicontinuous; i.e., each Lagrange polytope has an arbitrarily small open neighborhood which itself is union of Lagrange polytopes (cf. [11]). There are general techniques dealing with topological spaces (like $\mathbf{\Sigma}$) obtained by simultaneous identification of an upper semicontinuous family of closed discs in a manifold (like $\mathcal{X}$) (cf. [2]). However, it seems hard to verify the assumptions made there, in particular the so-called disjoint disk property of the target space. Nevertheless, in our case we can exploit the special structure.

There are only a few partial results about the (local) homeomorphy of $\mathcal{X}$ and $\mathbf{\Sigma}$. In fact, the two-parameter case is treated by Hirabayashi, Shida, and Shindoh (cf. [7]). Under additional assumptions, the multiparametric case is studied by Schecter [12], where our main theorem was conjectured. In particular, Schecter assumes a certain rank condition as well as a condition on the "nondegeneracy" of the Lagrange polytopes. Both conditions, however, are not generic.

Roughly speaking, our homeomorphy proof is based on induction. Suppose we have established a homeomorphism sending the subset of $\mathcal{X}$ formed by all Lagrange polytopes with dimension less than d to its projection in $\mathbf{\Sigma}$. The induction step consists of perturbing the latter homeomorphism in order to make an extension to the critical set, which is the union of Lagrange polytopes of dimension equal to d. To this end, one considers certain fibres in $\mathcal{X}$ which properly contain exactly one Lagrange polytope of dimension d. These fibres are pairwise disjoint and form a partition for a neighborhood of the critical set. For a specific fibre we make a special construction, and then we extend this construction over the bundle of all fibres. For the latter extension we apply Thom's isotopy lemma.

The rest of this paper is organized as follows. In §2 we cover the background material needed for the application of Thom's isotopy lemma in a nonproper setting.

Section 3 is devoted to the special construction on a specific fibre. Finally, in §4 all information is put together in order to prove Theorem 1.1.

2. The characteristic set. Our situation modelled in terms of jet extensions. First applications of this technique to mathematical programming are due to Jongen, Jonker, and Twilt (cf. [8]). We define characteristic sets $\mathbf{S} \subset \mathrm{Jet}_{\mathbf{\Sigma}}$ and $\mathbf{K} \subset \mathrm{Jet}_{\mathcal{X}} \equiv \mathrm{Jet}_{\mathbf{\Sigma}} \times I\!R^{\mathrm{h}} \times I\!R^{\mathrm{g}}$ in jet spaces and a characteristic mapping $j^1 : I\!R^{n+p} \longrightarrow \mathrm{Jet}_{\mathbf{\Sigma}}$ such that we have the fundamental relations

$$z \in \mathbf{\Sigma} \iff j^1(z) \in \mathbf{S} \qquad \text{and} \qquad (z, \lambda, \mu) \in \mathcal{X} \iff (j^1(z), \lambda, \mu) \in \mathbf{K}.$$

The characteristic mapping j^1 will in fact be a (reduced) 1-jet extension of (f, H, G). In this section we show that $\mathbf{S}$ admits a Whitney regular disc stratification. Here, we use tools from real algebraic geometry (cf. [1]). Finally, we introduce a nonproper version of the well-known first isotopy lemma by R. Thom.

Put $\mathrm{Jet}_{\mathbf{\Sigma}} := I\!R^{\mathrm{h}} \times I\!R^{\mathrm{g}} \times \mathcal{M}_{n,\mathrm{h}} \times \mathcal{M}_{n,\mathrm{g}} \times \mathcal{M}_{n,1}$, where $\mathcal{M}_{n,k}$ stands for the space of real (n, k)-matrices. For problem data (f, H, G), define the following reduced 1-jet extension:

$$\begin{aligned} j^1_{(f,H,G)} &: I\!R^{n+p} \longrightarrow \mathrm{Jet}_{\mathbf{\Sigma}}, \\ j^1_{(f,H,G)} &:= (H, G, D_x^{\top} H, D_x^{\top} G, D_x^{\top} f). \end{aligned}$$

Here, $D_x f$ stands for $(\partial_{x_1} f, \ldots, \partial_{x_n} f)$ and $D_x^{\top}$ for the transposed matrix of D_x. When there is no ambiguity, we omit the index (f, H, G). We define the following conditions for a point $(a, b, V, W, v, \lambda, \mu) \in \mathrm{Jet}_{\mathcal{X}}$:

(K1) $a = 0,\ b \leq 0,\ \mu \geq 0,$ *and* $b^{\top}\mu = 0$;
(K2) $v = V\lambda + W\mu$;
(MF) (K1) and (K2) imply $(\lambda', \mu') = (0, 0)$ for any $(a, b, V, W, 0, \lambda', \mu') \in \mathrm{Jet}_{\mathcal{X}}$.

Using the above abbreviations, we define the characteristic set $\mathbf{K}$:

$$\mathbf{K} = \{\ (a, b, V, W, v, \lambda, \mu) \in \mathrm{Jet}_{\mathcal{X}} \ \big|\ (K1), (K2), \text{ and } (MF)\ \}.$$

Denote the restriction of the natural projection by $\Pi : \mathbf{K} \longrightarrow \mathrm{Jet}_{\mathbf{\Sigma}}$; we then have the relation $\mathbf{S} = \Pi(\mathbf{K})$.

2.1. Whitney regular disc stratifications. We prove the existence of a Whitney regular disc stratification of $\mathbf{S}$ which extends as such to its closure $\overline{\mathbf{S}}$. By virtue of [6], both $\mathbf{S}$ and its closure are semialgebraic sets. For details on semialgebraic sets see, e.g., [1].

DEFINITION 2.1. *Let A be a subset of $I\!R^m$ with a locally finite partition $\mathcal{A}$. If the elements of $\mathcal{A}$ are smooth manifolds, then $\mathcal{A}$ is called a stratification of A and the pair $(A, \mathcal{A})$ a stratified set. In the latter case, the elements of $\mathcal{A}$ are also called strata. The stratification $\mathcal{A}$ is called a disc stratification if its strata are open discs, i.e., diffeomorphic to open real unit balls.*

DEFINITION 2.2. *Let $(A, \mathcal{A})$ be a stratified subset of $I\!R^m$. Let $X, Y \in \mathcal{A}$ be distinct strata and $\bar{x} \in X$. Then Y is called Whitney regular over X at point $\bar{x}$ if for any pair of sequences $x^k \longrightarrow \bar{x}$ and $y^k \longrightarrow \bar{x}$ with the following properties*

1. $x^k \in X$, $y^k \in Y$;
2. $T_{y^k}Y \longrightarrow T$ *in* $G(m, \mathrm{dim}Y)$;
3. $\mathcal{L}(y^k - x^k) \longrightarrow L$ *in* $G(m, 1)$

the inclusion $L \subset T$ holds. Y is called Whitney regular over X if this holds at any point $\bar{x}$ of X. The stratification $\mathcal{A}$ is called Whitney regular if any stratum is over any other stratum.

Here $G(m,k)$ denotes the Grassmann manifold of k-dimensional linear subspaces of $\mathbb{R}^m$, whereas $\mathcal{L}$ stands for the linear hull and T_y for the tangent space considered as a subspace of the embedding space. Note that Whitney regularity is well defined on manifolds as well, since it is invariant with respect to diffeomorphisms.

DEFINITION 2.3. *Let $\mathcal{A}$ and $\mathcal{B}$ be families of subsets of a given set M. Then $\mathcal{A}$ is called a refinement of $\mathcal{B}$ if each $X \in \mathcal{A}$ is contained in some $Y \in \mathcal{B}$.*

LEMMA 2.4 (cf. [1]). *Let A be a semialgebraic subset of $\mathbb{R}^m$ and assume a finite family $\mathcal{B}$ of subsets of A, all semialgebraic. Then there exists a finite refinement $\mathcal{A}$ of $\mathcal{B}$ into semialgebraic manifolds constituting a Whitney regular stratification of A.*

LEMMA 2.5 (cf. [1]). *Let A be a semialgebraic subset of $\mathbb{R}^m$. Then there exists a finite disc stratification of A with semialgebraic strata.*

In the present paper we need the following corollary of Lemmas 2.4 and 2.5.

COROLLARY 2.6. *Let A be a semialgebraic subset of $\mathbb{R}^m$ and $\mathcal{B}$ a finite family of semialgebraic subsets of A. Then A admits a (finite) Whitney regular disc stratification refining $\mathcal{B}$.*

Proof. For arbitrary $d \in \mathbb{N}$ we prove the following claim.

CLAIM (d). *There exists a finite Whitney regular stratification $\mathcal{A}$ of A refining $\mathcal{B}$ with semialgebraic strata such that any stratum is a disc or has dimension less than d.*

Claim (0) yields the desired result. Claim (m+1) follows from Lemma 2.4. It remains to show that claim (d+1) implies claim (d).

Put $\mathcal{A}_d := \{ X \in \mathcal{A} \mid \dim(X) = d \}$ and $\mathcal{A}_{>d} := \{ X \in \mathcal{A} \mid \dim(X) > d \}$, where $\mathcal{A}$ has been chosen according to claim (d+1). By virtue of Lemma 2.5, for any $X \in \mathcal{A}_d$ there exists a finite semialgebraic disc stratification $\mathcal{C}_X$ of X. Let $\mathcal{C}_d$ denote the set of all d-dimensional strata in the union of all $\mathcal{C}_X$, $X \in \mathcal{A}_d$. Then, the semialgebraic set $C := A \setminus \bigcup \mathcal{A}_{>d} \setminus \bigcup \mathcal{C}_d$ has dimension less than d; i.e., each stratum of any stratification of C is of dimension less than D. Moreover, $\mathcal{A}_{>(d-1)} := \mathcal{A}_{>d} \cup \mathcal{C}_d$ is a finite Whitney regular disc stratification refining $\mathcal{B}$ (since $\mathcal{C}_d$ refines $\mathcal{A}_d$). Let $\mathcal{D}$ be a refinement of the family $\mathcal{A}_{>(d-1)} \cup \mathcal{B}$ as stated in Lemma 2.4. We replace the subset of $\mathcal{D}$ refining $\mathcal{A}_{>(d-1)}$ by $\mathcal{A}_{>(d-1)}$ itself. In such a way we again obtain a Whitney regular stratification. Now, the stratification $\mathcal{D}$ satisfies the assertion of claim (d). □

COROLLARY 2.7. *There exist Whitney regular disc stratifications $\mathcal{A}$ of $\mathbf{S}$ and $\bar{\mathcal{A}}$ of $\overline{\mathbf{S}}$, respectively, such that $\mathcal{A} \subset \bar{\mathcal{A}}$.*

2.2. Thom's isotopy lemma. We need a slight extension of Thom's first isotopy lemma; see Proposition 2.9 below.

Notation. Let $(A, \mathcal{A})$ be a stratified set in a manifold N, and let N' be an open subset of N. Define $(A, \mathcal{A})|_{N'} := (A \cap N', \mathcal{A}|_{N'})$, where $\mathcal{A}_{N'} := \{X \cap N' | X \in \mathcal{A}\}$.

Note that the restriction $(A, \mathcal{A})|_{N'}$ again is a stratified set. Whitney regularity is carried over as well.

DEFINITION 2.8. *Let $f : N \to M$ be a mapping between manifolds and $(A, \mathcal{A})$ be a stratified subset of N. Then $(A, \mathcal{A})$ is said to be topologically trivial over M (with respect to f) if there exist a stratified set $(B, \mathcal{B})$ and a homeomorphism $h : M \times B \to A$ such that*

1. *$f \circ h = \Pi_M$, Π_M denoting the natural projection;*
2. *for each $X \in \mathcal{B}$ there exists some $Y \in \mathcal{A}$ such that $h : M \times X \to Y$.*

For later use, we emphasize that in the following proposition the set B in Definition 2.8 can be chosen as $A \cap f^{-1}(y)$, and $\mathcal{B}$ can be chosen as $\{ X \cap f^{-1}(y) \mid X \in \mathcal{A} \}$ for some $y \in M$.

PROPOSITION 2.9. *Let $f : N \to I\!R^m$ be a mapping between manifolds and $(A, \mathcal{A})$ be a locally closed Whitney regularly stratified subset of N. Let $\tilde{\mathcal{A}} \subset \mathcal{A}$ be such that $\tilde{A} := \bigcup \tilde{\mathcal{A}}$ is locally closed and such that the following conditions hold for any $X \in \tilde{\mathcal{A}}$:*

1. *$f|_X$ is a submersion,*
2. *$f|_{\overline{X} \cap \tilde{A}}$ is proper.*

Then there exists an open set $N' \subset N$ containing $\tilde{A}$ such that $(A, \mathcal{A})|_{N'}$ is trivial over $I\!R^m$ (with respect to f).

Sketch of Proof. We use the proof (cf. [4]) of the proper version of the isotopy lemma (i.e., Proposition 2.9 for the case $A = \tilde{A}$). In order to keep the exposition short, we focus on merely pointing out the modifications to be made. For missing details we refer to [4]. Starting from the fibre $\{0\}$ in $I\!R^m$, we can fill out the space $I\!R^m$ by successive integration of the constant coordinate vector fields ∂_{x_i}. The main idea of the proof is to perform the same construction on A, starting from the fibre $A \cap f^{-1}(0)$ and integrating controlled lifts of the coordinate vector fields. Any vector field ξ on $I\!R^m$ admits a controlled lift ξ^A onto A, at least in a neighborhood of $\tilde{A}$; i.e., we have $Df\ \xi^A = \xi \circ f$, and certain control relations hold with respect to a tube system. We essentially use the fact that ξ^A is globally integrable if ξ is. Beyond [4], it remains to show that ξ^A (and not just $\xi^A|_{\tilde{A}}$) is globally integrable. In order to see this, recognize that the vector field ξ^A lifts $(\xi^A|_X, 0)$ from $X \times I\!R$ with respect to the mapping (π_X, ρ_X), where $X \in \tilde{\mathcal{A}}$. This is due to the control relations with respect to the tube system; π_X is standing for the tubular projection mapping and ρ_X for the distance function of the tube at X. Since (π_X, ρ_X) is proper, an analogous argument as above yields that ξ^A is globally integrable on a tubular neighborhood of X. Finally, N' can be chosen as a union of tubular neighborhoods of the strata in $\tilde{\mathcal{A}}$. □

3. Controlled explosions in special fibres.

For an arbitrary stratification $\mathcal{A}$ of $\mathbf{S}$ and $X \in \mathcal{A}$, $\bar{x} \in X$, we construct a special projection mapping π onto X such that the fibre $\Pi^{-1}\pi^{-1}(\bar{x}) \subset \mathbf{K}$ can be handled as well as a differentiable manifold. To this end we use a topological transformation of $\mathbf{K}$ which removes the natural creases. This is done in §3.2. Then we can obtain a controlled explosion of the Lagrange polytope $\Pi^{-1}(\bar{x})$ within this fibre by virtue of the construction made in §3.1.

3.1. Controlled explosions.

DEFINITION 3.1. *Let P be a compact subset of a metric space M and $\bar{y} \in P$. A continuous mapping $\psi : (0,1) \times (M \setminus \{\bar{y}\}) \to M \setminus P$ is called a controlled explosion of P (in M) if the following conditions hold for any $\varepsilon \in (0,1)$:*

1. *$\psi_\varepsilon : M \setminus \{\bar{y}\} \to M \setminus P$ is a homeomorphism,*
2. *$\psi_\varepsilon : P \ \setminus \{\bar{y}\} \to U_\varepsilon(P) \setminus P$,*
3. *$\psi_\varepsilon|_{M \setminus U_{3\varepsilon}(P)} = \mathrm{id}_{M \setminus U_{3\varepsilon}(P)}$,*
4. *$\psi_\varepsilon^{(-1)} : M \setminus P \to M \setminus \{\bar{y}\}$ extends continuously by $P \to \{\bar{y}\}$.*

Here define $\psi_\varepsilon(y) := \psi(\varepsilon, y)$ and $\psi_\varepsilon^{(-1)} := {\psi_\varepsilon}^{-1}$. $U_\varepsilon(P)$ stands for the union of the ε-neighborhoods $U_\varepsilon(y)$, $y \in P$. Point $\bar{y}$ is called the centre of explosion.

PROPOSITION 3.2. *Let $M \subset I\!R^n$ be a smooth manifold and $P \subset M$ be a compact convex subset of $I\!R^n$. Then P admits a controlled explosion in M.*

The following technical lemma is essential for the proof of Proposition 3.2.

LEMMA 3.3. *There exists a continuous mapping $\eta : (0,1) \times [0,1] \times I\!R_+ \to I\!R_+$ such that the following conditions hold for any $\varepsilon \in (0,1)$ and $\delta \in [0,1]$:*

1. $\eta_{\varepsilon,\delta} : \mathbb{R}_+ \to \mathbb{R}_+$ *is a homeomorphism if* $\delta > 0$;
2. $\eta_{\varepsilon,0} : \mathbb{R}_+ \to (1,\infty)$ *is a homeomorphism*;
3. $\eta_{\varepsilon,\delta} : (0,1) \to (0, 1+\varepsilon)$;
4. $\eta_{\varepsilon,1} = \mathrm{id}_{\mathbb{R}_+}$;
5. $\eta_{\varepsilon,\delta}\big|_{(1+2\varepsilon,\infty)} = \mathrm{id}_{(1+2\varepsilon,\infty)}$;
6. *by* $(0,1) \times \{0\} \times (0,1] \to \{0\}$, $\eta^{(-1)}$ *extends to a continuous mapping* $(0,1) \times [0,1] \times \mathbb{R}_+ \to \overline{\mathbb{R}_+}$.

Here define $\eta_{\varepsilon,\delta}(x) := \eta(\varepsilon,\delta,x)$ *and* $\eta^{(-1)}(\varepsilon,\delta,x) := {\eta_{\varepsilon,\delta}}^{-1}(x)$.

Proof. Put, for instance,

$$\eta_{\varepsilon,\delta}(x) := \begin{cases} x/\delta, & x \in (0,\delta], \\ 1 \;+\; \varepsilon(x-\delta), & x \in (\delta,1], \\ x \;+\; (1+2\varepsilon-x)(1-\delta)/2, & x \in (1,1+2\varepsilon], \\ x, & x > 1+2\varepsilon. \end{cases} \qquad \square$$

Proof of Proposition 3.2. Reduction Step. Let d be the dimension of P. Assume the nontrivial case $d > 0$. In a neighborhood of M there is defined a projection mapping $\pi : \mathbb{R}^n \to M$; i.e., we have $\pi|_M = \mathrm{id}_M$. Consider the affine hull $\mathrm{aff}(P) \subset \mathbb{R}^n$, which is a submanifold of $\mathbb{R}^n$. Note that $\pi|_P = \mathrm{id}_P$. Hence $\pi|_{\mathrm{aff}(P)}$ is a diffeomorphism in an open neighborhood of P. Consequently, $\tilde{M} := \pi(\mathrm{aff}(P))$ is a d-dimensional submanifold of M containing P. Finally, near P the manifold M is diffeomorphic $\tilde{M} \times \mathbb{R}^{\dim M - d}$. Hence we have without loss of generality $M = \mathbb{R}^n$ and $P \subset \mathbb{R}^d \subset \mathbb{R}^n$. Using a standard coordinate transformation in $\mathbb{R}^d$, we also can assume that $P = D^d \times \{0\}$, where D^d stands for the d-dimensional closed unit ball in $\mathbb{R}^d$.

Application of Lemma 3.3. We may assume that $M = \mathbb{R}^n \equiv \mathbb{R}^d \times \mathbb{R}^{n-d}$ and $P = D^d \times \{0\}$. Now we define $\psi_\varepsilon : \mathbb{R}^n \setminus \{0\} \to \mathbb{R}^n \setminus D^d$ as follows:

$$\psi_\varepsilon(x,y) := \begin{cases} \Big(\frac{x}{\|x\|}\eta_{\varepsilon,\min\{1,\|y\|/\varepsilon\}}(\| x \|),\ y \Big), & x \neq 0, \\ \Big(0 \ , \ y \Big), & x = 0. \end{cases}$$

Here η has been chosen according to Lemma 3.3. A moment of reflection shows that ψ is a controlled explosion of P in M with centre in 0. $\square$

3.2. The special fibre. Consider the following topological embedding:

$$\begin{array}{lccl} \phi & : & \mathcal{M}_{n,k} \times \mathcal{M}_{n,g} \times \mathbb{R}^{\mathrm{h}} \times \mathbb{R}^{\mathrm{g}} & \hookrightarrow & \mathrm{Jet}_{\mathcal{X}}, \\ \phi & : & (V, W, \lambda, \mu) & \mapsto & (0, \mu_-, V, W, V\lambda + W\mu_+, \lambda, \mu_+). \end{array}$$

Here let $\mu_+ := \max\{0,\mu\}$ and $\mu_+ + \mu_- = \mu$. Put $\mathcal{K} := \phi^{-1}(\mathbf{K})$; note that $\mathcal{K}$ is open in its embedding space (hence a manifold) and that $\phi : \mathcal{K} \to \mathbf{K}$ is a homeomorphism. Hence the set $\mathbf{K}$ constitutes a topological manifold which has codimension $n + \mathrm{h} + \mathrm{g}$ in $\mathrm{Jet}_{\mathcal{X}}$.

Let be $I \subset \{1,\dots,\mathrm{g}\}$. For any $b \in \mathbb{R}^{\mathrm{g}}$ let $b^I \in \mathbb{R}^{\mathrm{g}}$ be defined by means of the following relations: $b^I_i = b_i$ if $i \in I$, and $b^I_i = 0$ otherwise. Note that $(b^I)_+ = (b_+)^I$. Define $\mathbb{R}^I := \{b^I \mid b \in \mathbb{R}^{\mathrm{g}}\}$. Put $CI := \{1,\dots,g\} \setminus I$. Let $\mathbf{S}^I$ denote the subset of $\mathbf{S}$ with active index set I, i.e.,

$$\mathbf{S}^I = \{\ (a,b,V,W,v) \in \mathbf{S} \mid b_i = 0 \iff i \in I\ \}.$$

PROPOSITION 3.4. *Let X be a smooth submanifold of* $\mathrm{Jet}_{\boldsymbol{\Sigma}}$ *such that* $X \subset \mathbf{S}^I$ *for some* $I \subset \{1,\dots,\mathrm{g}\}$, *and let* $\bar{x} \in X$. *Then there exists a projection mapping*

$\pi : \mathrm{Jet}_{\mathbf{\Sigma}} \to X$ *(defined in a neighborhood of* $\bar{x}$*) such that* $\phi^{-1}\Pi^{-1}\pi^{-1}(\bar{x})$ *is a smooth manifold.*

Proof. Consider the following linear subspaces of the Euclidean space $\mathrm{Jet}_{\mathbf{\Sigma}} \equiv \mathbb{R}^{\mathrm{h}} \times \mathbb{R}^{\mathrm{g}} \times \mathbb{R}^{\mathrm{h}n} \times \mathbb{R}^{\mathrm{g}n} \times \mathbb{R}^{n}$. $L_1 := \{0\} \times \mathbb{R}^n$ and $L_2 := {L_1}^{\perp}$, the orthogonal complement. Let $\Pi_{L_2} : \mathrm{Jet}_{\mathbf{\Sigma}} \to L_2$ denote the orthogonal projection and $T_{\bar{x}}X$ the tangent space considered a subspace of $\mathrm{Jet}_{\mathbf{\Sigma}}$. Let us consider the subspaces $T_1 := T_{\bar{x}}X \cap L_1$ and $T_2 := \Pi_{L_2} T_{\bar{x}}X$. Put $\Pi_i := \Pi_{T_i}$ and note that $(\Pi_1, \Pi_2)|_X$ is a diffeomorphism at $\bar{x}$. We define the following mapping:

$$\begin{array}{rccc} \alpha & : & \mathrm{Jet}_{\mathbf{\Sigma}} & \to & \mathrm{Jet}_{\mathbf{\Sigma}}, \\ \alpha & : & (a, b, V, W, v) & \mapsto & (a, b^{CI}, V, W, v + Wb^I). \end{array}$$

Since $X \subset \mathbf{S}^I$, we have $\alpha|_X = \mathrm{id}_X$. Hence there is defined a projection mapping $\pi : \mathrm{Jet}_{\mathbf{\Sigma}} \to X$ (defined on a neighborhood of $\bar{x}$) by the relation $(\Pi_1, \Pi_2) \circ \pi = (\Pi_1, \Pi_2) \circ \alpha$. It suffices to show that $\psi^{-1}(\bar{y})$ is a manifold, where $\psi : \mathcal{K} \to T_1 \times T_2$ is defined by $\psi := (\Pi_1, \Pi_2) \circ \alpha \circ \Pi \circ \phi$ and $\bar{y}$ by $\bar{y} := (\Pi_1, \Pi_2)(\bar{x})$. Now

$$(V, W, \lambda, \mu) \overset{\Pi\circ\phi}{\mapsto} (0, \mu_-^I + \mu_-^{CI}, V, W, V\lambda + W\mu_+).$$

In a neighborhood of $\phi^{-1}\Pi^{-1}(\bar{x})$ we have $\mu_+ = \mu_+^I$ and $\mu_-^{CI} = \mu^{CI}$. Hence

$$(V, W, \lambda, \mu) \overset{\alpha\circ\Pi\circ\phi}{\mapsto} (0, \mu^{CI}, V, W, V\lambda + W\mu^I).$$

The latter mapping is smooth and thus ψ is as well. Note that at point $\bar{x}$ the Jacobian $D_{(V,W,\mu^{CI})}\psi$ maps surjectively onto T_2 and $D_{(\lambda,\mu^I)}\psi$ onto T_1. An application of the theorem on implicit functions yields the desired result. □

Remark. The problem in the latter construction was to find a differentiable mapping defined on $\mathrm{Jet}_{\mathbf{\Sigma}}$ such the fibre induced to $\mathcal{K}$ became a differentiable manifold, although this induction was due to a mapping which not had been differentiable at all.

4. Proof of the theorem. The concepts of active index set and Lagrange polytope are extended to $\mathbf{S}$ in a natural way. For $x \in \mathbf{S}$ we put $\mathcal{G}_0(x) = I$ iff $x \in \mathbf{S}^I$. Using the abbreviation $x = (a, b, V, W, v)$ for elements of $\mathrm{Jet}_{\mathbf{\Sigma}}$, we define the Lagrange polytope $P(x)$ for $x \in \mathbf{S}$:

$$P(x) := (V|W)^{-1}(v) \cap (\mathbb{R}^{\mathrm{h}} \times \overline{\mathbb{R}_+}^{\mathcal{G}_0(x)}).$$

Here $\overline{\mathbb{R}_+} = [0, \infty)$. Note that $\Pi^{-1}(x) = \{x\} \times P(x)$. It is useful to consider the faces of the Lagrange polytope $P(x)$ by means of its generating index sets:

$$\mathcal{J}(x) := \{J \subset \mathcal{G}_0(x) \mid P(x) \cap (\mathbb{R}^{\mathrm{h}} \times {\mathbb{R}_+}^J) \neq \emptyset\}.$$

We have an estimation result for the fineness of disc stratifications of $\mathbf{S}$.

PROPOSITION 4.1 (cf. [5]). *Let* $\mathcal{A}$ *be a Whitney regular disc stratification for* $\mathbf{S}$ *and* $X \in \mathcal{A}$. *Then both set-valued mappings* $\mathcal{G}_0 : X \to 2^{\mathcal{G}}$ *and* $\mathcal{J} : X \to 2^{2^{\mathcal{G}}}$ *are constant.*

From now on, let us use the following notation. If X is a set, then $\widehat{X} := \mathbb{R}^{n+p} \times X$, and if $f : X \to Y$ is a mapping between sets, then $\widehat{f} : \widehat{X} \to \widehat{Y}$ denotes the mapping $\widehat{f} := \mathrm{id}_{\mathbb{R}^{n+p}} \times f$.

Note that the mappings $(\mathrm{id}_{\mathbb{R}^{n+p}}, j^1) : \mathbb{R}^{n+p} \to \widehat{\mathrm{Jet}_{\mathbf{\Sigma}}}$ and $(\mathrm{id}_{\mathbb{R}^{n+p}}, j^1) \times \mathrm{id}_{\mathbb{R}^{\mathrm{h}+\mathrm{g}}}$ are embeddings of $\mathbf{\Sigma}$ into $\widehat{\mathbf{S}}$ and of $\mathcal{X}$ into $\widehat{\mathbf{K}}$, respectively. In this setting, the mapping

$\widehat{\Pi} : \widehat{\mathbf{K}} \to \widehat{\mathbf{S}}$ coincides on $\mathcal{X} \subset \widehat{\mathbf{K}}$ with the natural projection onto $\mathbf{\Sigma} \subset \widehat{\mathbf{S}}$. We have a mapping $\xi : \widehat{\mathrm{Jet}_{\mathbf{\Sigma}}} \to \mathrm{Jet}_{\mathbf{\Sigma}}$ defining $\mathbf{\Sigma}$ as a subset of $\widehat{\mathbf{S}}$, i.e., $\mathbf{\Sigma} = \widehat{\mathbf{S}} \cap \xi^{-1}(0)$. This mapping is given by $\xi := j^1 \circ \Pi_{\mathbb{R}^{n+p}} - \Pi_{\mathrm{Jet}_{\mathbf{\Sigma}}}$, where $\Pi_{\mathbb{R}^{n+p}}$ and $\Pi_{\mathrm{Jet}_{\mathbf{\Sigma}}}$ denote the natural projections. Note that $\xi = \xi_{(f,H,G)}$ depends on the problem data (f, H, G) which have been used.

For $J \subset I \subset \mathcal{G}$, we define the following subset of $\mathbf{K}$:

$$K_J^I := \big\{(a, b, V, W, v, \lambda, \mu) \in \mathbf{K} \ \big| \ b_i = 0 \iff i \in I \text{ and } \mu_j > 0 \iff j \in J\big\}.$$

In view of Corollary 2.7, there exist Whitney regular disc stratifications $\mathcal{A} \subset \bar{\mathcal{A}}$ of $\mathbf{S}$ and $\overline{\mathbf{S}}$, respectively. With $\widehat{\mathcal{A}} := \{\widehat{X} \mid X \in \mathcal{A}\}$ we have a disc stratification of $\widehat{\mathbf{S}}$. Applying the jet transversality theorem as described in [6], we see the existence of a C^2-open and C^∞-dense subset $\mathcal{F} \subset C^\infty(\mathbb{R}^{n+p}, \mathbb{R}^{1+\mathrm{h}+\mathrm{g}})$ such that $\xi|_{\widehat{X}}$ is submersive on $\xi^{-1}(0)$ for any $X \in \mathcal{A}$. Here we assume $\xi = \xi_{(f,H,G)}$ with $(f, H, G) \in \mathcal{F}$.

For $d \in \mathbb{N}$, let $\mathbf{S}_d$ be the union of all strata $X \in \mathcal{A}$ with dimension $\dim X \geq d$. Put $\mathbf{K}_d := \Pi^{-1}\mathbf{S}_d$. Let $\widehat{\mathbf{S}}_d := \widehat{\mathbf{S}_d}$. Now let $\bar{d}$ denote the dimension of $\mathbf{S}$; i.e., we have $\mathbf{S}_{\bar{d}} \neq \emptyset$ and $\mathbf{S}_{\bar{d}+1} = \emptyset$. For $d = 0, 1, \ldots, \bar{d}$ we are going to prove the following assertion.

Assertion (d). There exists a continuous mapping $\varphi_d : \widehat{\mathbf{K}} \to \widehat{\mathbf{S}}$, arbitrarily C^0-close to $\widehat{\Pi}$, such that the following conditions are satisfied:

1. φ_d maps $\mathcal{X}$ onto $\mathbf{\Sigma}$;
2. φ_d maps $\widehat{\mathbf{K}}_d$ homeomorphically onto $\widehat{\mathbf{S}}_d$;
3. outside $\widehat{\mathbf{K}}$, φ_d and $\widehat{\Pi}$ coincide.

Besides showing that $\mathcal{X}$ is a topological manifold, it suffices to verify Assertion (0) in order to prove the theorem.

Let $X \in \mathcal{A}$ be of dimension $\bar{d}$. Whitney regularity of $\mathcal{A}$ guarantees that X is open in $\mathbf{S}$; hence $\Pi^{-1}(X)$ is open in $\mathbf{K}$. A moment of reflection shows that the dimensions of the topological manifolds X and $\Pi^{-1}(X)$ coincide. According to Proposition 4.1, the Lagrange polytope has a constant dimension on X; hence this dimension is zero. Consequently, again in view of Proposition 4.1, we have $\Pi^{-1}(X) \subset \mathbf{K}^{\mathcal{G}_0}_{\mathcal{G}_0}$. That implies $\widehat{\Pi} : \widehat{\Pi}^{-1}(\widehat{X}) \to \widehat{X}$ to be a homeomorphism. Altogether, Assertion $(\bar{d})$ holds with $\varphi_{\bar{d}} = \widehat{\Pi}$.

Now assume Assertion (d) for some $d \in \{1, \ldots, \bar{d}\}$ and $X \in \mathcal{A}$ with $\dim X = d-1$. Since $\mathcal{A}$ is locally finite, it suffices to verify the following assertion in order to prove Assertion $(d-1)$.

Assertion (X). There exists a continuous mapping $\varphi : \widehat{\mathbf{K}} \to \widehat{\mathbf{S}}$ such that the following conditions are satisfied:

1. outside an arbitrarily small neighborhood of $\widehat{\Pi}^{-1}(\widehat{X})$, φ coincides with φ_d;
2. φ maps $\mathcal{X}$ onto $\mathbf{\Sigma}$;
3. φ maps $\widehat{\mathbf{K}}_X$ homeomorphically onto $\widehat{\mathbf{S}}_X$, where $\widehat{\mathbf{S}}_X := \widehat{\mathbf{S}}_d \cup \widehat{X}$ and $\widehat{\mathbf{K}}_X := \widehat{\Pi}^{-1}(\widehat{\mathbf{S}}_X)$;
4. outside $\widehat{\mathbf{K}}_X$, φ coincides with $\widehat{\Pi}$.

If the Lagrange polytopes have dimension zero on X, then we have finished by taking $\varphi = \varphi_d$. In the remainder of this paper we exclude this trivial case.

Step 1 (*fitting together special fibre and problem data*). The first step combines two projection mappings onto $\widehat{X}$. The first one, $\pi_1 : \widehat{\mathrm{Jet}_{\mathbf{\Sigma}}} \to \widehat{X}$, is defined in a neighborhood of $\widehat{X} \cap \xi^{-1}(0)$ and compatible with ξ; i.e., we have $\xi \circ \pi_1 = \xi$. This will prove that the approximation φ to be constructed maps $\mathcal{X}$ onto $\mathbf{\Sigma}$. The existence of π_1 follows from that of a tube at X which is compatible with ξ (cf. [4]).

The codimension of $\{0\}$ in $\mathrm{Jet}_{\mathbf{\Sigma}}$ is greater than zero; hence that of $\xi^{-1}(0)$ in $\widehat{X}$ is as well. Thus, we can assume a certain point $(\bar{z}, \bar{x}) \in \widehat{X}$ ($\bar{z} \in \mathbb{R}^{n+p}$, $\bar{x} \in X$) outside the open set on which π_1 is defined. X is stratum in a Whitney regular disk stratification. According to Proposition 4.1, it holds $X \subset \mathbf{S}^{\mathcal{G}_0}$ and the application of Proposition 3.4 yields a projection mapping $\pi_2 : \mathrm{Jet}_{\mathbf{\Sigma}} \to X$ (near $\bar{x}$) such that $\phi^{-1}\Pi^{-1}\pi_2^{-1}(\bar{x})$ is a smooth manifold. The second projection mapping onto $\widehat{X}$ is just $\widehat{\pi}_2$. It will provide the special fibre. In order to combine π_1 and $\widehat{\pi}_2$ we use a third projection mapping, π_3, defined in a neighborhood of the whole set $\widehat{X}$. By means of an appropriate partition of the unity we obtain a convex combination $\check{\pi} : \mathrm{Jet}_{\mathbf{\Sigma}} \to \widehat{X}$, which coincides with π_1 near $\xi^{-1}(0)$ and with $\widehat{\pi}_2$ near $(\bar{z}, \bar{x})$. Obviously, $\check{\pi}$ constitutes a projection mapping.

Step 2 (*application of the isotopy lemma*). Identify $\mathcal{G}_0$ and $\mathcal{J}$ with their (constant) images on X (in view of Proposition 4.1). The dimension of the affine space $\mathcal{A}\!f\!f_J(x) := (V|W)^{-1}(v) \cap (\mathbb{R}^{\mathrm{h}} \times \mathbb{R}^J)$ does not depend on the particular choice of $x \equiv (a, b, V, W, v)$ in X, provided that $J \in \mathcal{J}$. Hence $A_J := \{(x, \lambda, \mu) \mid x \in X, (\lambda, \mu) \in \mathcal{A}\!f\!f_J(x)\}$ is a manifold which contains $X_J := \Pi^{-1}(X) \cap \mathbf{K}_J^{\mathcal{G}_0}$ as an open subset. Finally, we have $A_{J'} \subset A_J$ for $J', J \in \mathcal{J}$ with $J' \subset J$. Altogether, $\{X_J \mid J \in \mathcal{J}\}$ gives a Whitney regular stratification of $\Pi^{-1}(X)$ refining $\{\mathbf{K}_J^I \mid J \subset I \subset \mathcal{G}\}$, which is a Whitney regular stratification of $\mathbf{K}$. Let $\mathcal{U}$ be an open set in $\widehat{\mathrm{Jet}_{\mathcal{X}}}$ containing $\widehat{\Pi}^{-1}(\widehat{X})$ as a closed subset. Then the following is a Whitney regular stratification of $\widehat{\mathrm{Jet}_{\mathcal{X}}} \cap \mathcal{U}$:

$$\begin{aligned} \mathcal{B} &:= \widetilde{\mathcal{B}} \cup \{\widehat{\mathbf{K}}_J^I \setminus \widehat{\Pi}^{-1}(\widehat{X}) \mid J \subset I \subset \mathcal{G}\}\Big|_{\mathcal{U}}, \text{ where} \\ \widetilde{\mathcal{B}} &:= \{\widehat{X}_J \mid J \in \mathcal{J}\}. \end{aligned}$$

$\widehat{\mathbf{K}} \cap \mathcal{U}$ and $\widehat{\Pi}^{-1}(\widehat{X}) = \bigcup \widetilde{\mathcal{B}}$ are closed subsets of $\mathcal{U}$. Restricting the mapping $\check{\pi} \circ \widehat{\Pi} : \mathcal{U} \to \widehat{X}$ to $\widehat{\Pi}^{-1}(\widehat{X})$ one obtains a proper mapping and, restricting it to the strata from $\widetilde{\mathcal{B}}$, a submersion. Since $\mathcal{A}$ is a disk stratification, it holds $\widehat{X} \equiv \mathbb{R}^m$ for some m. We define the special fibre $\bar{F} := \widehat{\Pi}^{-1}\check{\pi}^{-1}(\bar{z}, \bar{x})$. This fibre contains the polytope $\bar{P} := \widehat{\Pi}^{-1}(\bar{z}, \bar{x})$. After we shrink the open set $\mathcal{U}$ if necessary, an application of Proposition 2.9 yields a homeomorphism $h : \widehat{X} \times \bar{F} \to \widehat{\mathbf{K}} \cap \mathcal{U}$ with the following properties:

1. $\check{\pi} \circ \widehat{\Pi} \circ h = \Pi_{\widehat{X}}$, the natural projection;
2. $h : \widehat{X} \times (\bar{F} \cap Y) \to Y$ for any $Y \in \mathcal{B}$.

Since h preserves strata, it maps $\widehat{X} \times \bar{P}$ onto $\widehat{\Pi}^{-1}(\widehat{X})$. In order to see that $\mathcal{X}$ is a topological manifold, recall that $\mathcal{X} = \widehat{\mathbf{K}} \cap \widehat{\Pi}^{-1}\xi^{-1}(0)$ and that $\xi \circ \widehat{\Pi} \circ h$ coincides with $\xi \circ \Pi_{\widehat{X}}$ (where defined). (The latter relation is in view of 1. above and Step 1.) Hence $h^{-1}(\mathcal{X}) = \big(\widehat{X} \cap \xi^{-1}(0)\big) \times \bar{F}$. For problem data from $\mathcal{F}$, $\widehat{X} \cap \xi^{-1}(0)$ is a manifold. We will see that $\widehat{\phi}(\bar{F})$ is a topological manifold and thus $\mathcal{X}$ is as well.

Step 3 (*tame explosion*). Recall the construction of $\check{\pi}$ near the point $(\bar{z}, \bar{x})$ made in Step 1. We have $\check{\pi}^{-1}(\bar{z}, \bar{x}) = \{\bar{z}\} \times {\pi_2}^{-1}(\bar{x})$. Thus, $\widehat{\phi}^{-1}(\bar{F})$ is a smooth manifold which contains the polytope $\widehat{\phi}^{-1}(\bar{P})$. Using the homeomorphism $\widehat{\phi}$, Proposition 3.2 yields a controlled explosion ψ of $\bar{P}$ in $\bar{F}$. Let $\bar{y}$ denote the centre of explosion and T the trace of $\bar{y}$ under application of h, defined by $T := h(\widehat{X}, \{\bar{y}\})$. Also, put $\partial\widehat{X} := \overline{\widehat{X}} \setminus \widehat{X}$.

Let $\varepsilon : \widehat{X} \to (0,1)$ be a continuous mapping such that $\varepsilon(x_i)$ tends to zero for any sequence $\{x_i\} \subset \widehat{X}$ converging to some point in $\partial\widehat{X}$. There exists a continuous mapping $\delta : \widehat{X} \to (0,1)$ such that h maps $\{x\} \times U_{4\delta(x)}(\bar{P})$ into $U_{\varepsilon(x)}\widehat{\Pi}^{-1}(x)$. The fact that ε can be chosen arbitrarily small proves the approximation property claimed in Assertion (X). Let denote $U := \bigcup_{x \in \widehat{X}} h\big[\, \{x\} \times U_\varepsilon(\bar{P}) \,\big]$ and $U' := \bigcup_{x \in \widehat{X}} h\big[\, \{x\} \times$

$U_{3\delta(x)}(\bar{P})\,]$. The sets U and U' are open subsets of $\widehat{\mathbf{K}}$, and it holds $\overline{U}'\setminus U \subset \widehat{\Pi}^{-1}(\partial\widehat{X})$. Define an explosion $\Psi : U \setminus T \to U \setminus \widehat{\Pi}^{-1}(\widehat{X})$ by $\Psi := h \circ (\mathrm{id}_{\widehat{X}} \times \psi_\delta) \circ h^{-1}$. Then

(T1) $\Psi|_{\widehat{\mathbf{K}}_X}$ is a homeomorphism;

(T2) outside U', Ψ and $\mathrm{id}_{\widehat{\mathbf{K}}}$ coincide;

(T3) $\widehat{\Pi} \circ \Psi$ extends continuously onto $T \cup \widehat{\Pi}^{-1}(\partial\widehat{X})$ by $\widehat{\Pi}$;

(T4) $\xi \circ \widehat{\Pi} \circ \Psi = \xi \circ \widehat{\Pi}$, where defined.

In fact, Ψ operates within the fibres $h(x, \bar{F}) = \widehat{\Pi}^{-1}\check{\pi}^{-1}(x)$, and we also have $\|\, \widehat{\Pi} \circ \Psi - \widehat{\Pi}\, \| < \varepsilon \circ \check{\pi} \circ \widehat{\Pi}$. If we use $\mathrm{id}_{\widehat{\mathbf{K}}}$, Ψ extends continuously to $\Psi : \widehat{\mathbf{K}} \setminus (T \cup \widehat{\Pi}^{-1}(\partial\widehat{X})) \to \widehat{\mathbf{K}}\setminus\widehat{\Pi}^{-1}(\widehat{\widehat{X}})$, being globally defined and satisfying (T1), (T3), and (T4).

Step 4 (*perturbed extension of the homeomorphism*). Define

$$\varphi := \begin{cases} \varphi_d & \text{on } T \cup \widehat{\Pi}^{-1}(\partial\widehat{X}), \\ \varphi_d \circ \Psi & \text{elsewhere.} \end{cases}$$

By the very construction it suffices to check that φ is continuous at $\tilde{y} \in \widehat{\Pi}^{-1}(\partial\widehat{X})$. To this end assume a sequence $y^k \in \widehat{\mathbf{K}}$ converging to $\tilde{y}$. Assume the nontrivial case that $y^k \notin T \cup \widehat{\Pi}^{-1}(\partial\widehat{X})$. By (T3), $\widehat{\Pi} \circ \Psi(y^k)$ tends to $\widehat{\Pi}(\tilde{y})$. Since the family of Lagrange polytopes is upper semicontinuous, $\Psi(y^k)$ is arbitrarily close to the polytope $\widehat{\Pi}^{-1}(\widehat{\Pi}(\tilde{y}))$, provided that k is sufficiently large. Hence, $\varphi_d \circ \Psi(y^k)$ converges to $\widehat{\Pi}(\tilde{y}) = \varphi_d(\tilde{y})$. This completes the proof of the theorem. □

PONTRYAGIN MAXIMUM PRINCIPLE FOR SEMILINEAR AND QUASILINEAR PARABOLIC EQUATIONS WITH POINTWISE STATE CONSTRAINTS*

BEI HU† AND JIONGMIN YONG‡

Abstract. This paper studies the first-order necessary conditions for the optimal controls of semilinear and quasilinear parabolic partial differential equations with pointwise state constraints. A Pontryagin-type maximum principle is obtained.

Key words. parabolic equations, pointwise state constraints, optimal control, Pontryagin maximum principle, Ekeland variational principle

AMS subject classifications. 49K20, 35K10, 35K20

1. Introduction.

In this paper, we are concerned with the following parabolic equation:

$$\left\{\begin{array}{ll} y_t - \sum_{i,j=1}^{n} (a_{ij}(x,t)y_{x_i})_{x_j} = f(x,t,y,u(t,x)), & \text{in } \Omega_T, \\ y\,\big|_{\partial\Omega} = 0, & \\ y\,\big|_{t=0} = y_0(x), \qquad x \in \Omega, & \end{array}\right. \tag{1.1}$$

where a_{ij} and f are some given functions, $\Omega_T = \Omega \times (0,T)$, with $\Omega \subset \mathbb{R}^n$ being a bounded domain and $T > 0$ being a given time duration. The function $u(x,t)$ is called the control, which takes value in some separable metric space U. The solution $y(x,t)$ to (1.1) (for given $y_0(x)$ and $u(x,t)$) is called the state of the system, and $y_0(x)$ is referred to as the initial state. We set $\mathcal{U} = \{u : \Omega_T \to U \mid u \text{ is measurable }\}$. Under proper conditions (see §2), we have that for any $y_0 \in C_0^\alpha(\bar\Omega)$ and $u \in \mathcal{U}$, (1.1) admits a unique solution $y(x,t)$ which is in $C(\bar\Omega_T)$ (actually, it is even better; see §2). Then, we may talk about the state constraint of form,

$$G(y) \in Q, \tag{1.2}$$

for some continuously Fréchet differentiable map $G : C_0(\bar\Omega_T) \to Z$, where $C_0(\bar\Omega_T) = \{\eta \in C(\bar\Omega_T) \mid \eta\big|_{\partial\Omega\times[0,T]} = 0\}$, Z is some Banach space, and $Q \subset Z$. Let us take a look at two important examples of the above type of constraint. First, let $Z = C_0(\bar\Omega_T)$,

$$Q = \{\eta \in Z \mid \eta(x,t) \le 0, \;\; (x,t) \in \bar\Omega_T \}, \tag{1.3}$$

and $G(y)(x,t) = g(x,t,y(x,t))$ for some function $g : \bar\Omega_T \times \mathbb{R} \to \mathbb{R}$. Then, (1.2) reads

$$g(x,t,y(x,t)) \le 0, \qquad (x,t) \in \bar\Omega_T. \tag{1.4}$$

Part of this research was performed while this author was visiting the Institute for Mathematics and its Applications, University of Minnesota.

Our second example is as follows: We again let $Z = C_0(\bar{\Omega}_T)$, and define

$$Q = \{\eta \in Z \mid \eta(x_i, t_i) = b_i, \quad 1 \leq i \leq m\} \tag{1.5}$$

for some given (different) points $(x_i, t_i) \in \Omega_T \bigcup(\Omega \times \{T\})$ and numbers b_i, and $G = I$, the identity operator on Z. Then, (1.2) reads

$$y(x_i, t_i) = b_i, \qquad 1 \leq i \leq m. \tag{1.6}$$

For elliptic equations, similar constraints like (1.4) and (1.6) were considered in [4], [5], and [19]. The above two examples all require pointwise behavior of the state $y(x, t)$. There are many other examples covered by (1.2) (see §5). It is seen that our state constraint (1.2) is very general.

Now, we introduce the following functional:

$$J(u) = \int_{\Omega_T} f^0(x, t, y(x, t), u(x, t))dxdt, \tag{1.7}$$

for some function f^0, where $y(x, t)$ is the solution of (1.1) corresponding to u. This is called the cost functional. Next, we set

$$\mathcal{U}_{\text{ad}} \equiv \{u \in \mathcal{U} \mid \text{the corresponding } y \text{ satisfies (1.2)}\}. \tag{1.8}$$

Any element $u \in \mathcal{U}_{\text{ad}}$ is called an admissible control. In what follows, we assume that $\mathcal{U}_{\text{ad}} \neq \emptyset$. Then, we may state our optimal control problem as follows.

PROBLEM C. Find $\bar{u} \in \mathcal{U}_{\text{ad}}$, such that

$$J(\bar{u}) = \inf_{\mathcal{U}_{\text{ad}}} J(u). \tag{1.9}$$

Whenever such a $\bar{u} \in \mathcal{U}_{\text{ad}}$ exists, we call it an optimal control; the corresponding state $\bar{y}$ is called an optimal state and $(\bar{y}, \bar{u})$ is called an optimal pair.

Our goal is to obtain a set of first-order necessary conditions for the optimal pairs. This set of conditions is called the Pontryagin maximum principle.

In recent papers [3]–[5], [20], the Pontryagin maximum principle was derived for semilinear and quasilinear elliptic partial differential equations with pointwise state constraints (see [2] also). For parabolic equations, an abstract evolution equation setting was used a little earlier to obtain similar results [9], [10], [14], [15], [18]. We note that by using the abstract framework for parabolic equations, people treat the time variable t and the spatial variable x unequally, in the sense that the variable x is "averaged" and actually does not appear explicitly in the whole process. Consequently, some pointwise information on the state $y(x, t)$, like Hölder continuity, and values at some particular points $(x_0, t_0) \in \Omega_T$ are lost. In particular, the problem with the state constraint (1.6) cannot be covered by abstract framework. In this paper, we use the idea of [5] (see [13] and [20] also) to discuss the optimal control problem for parabolic equations without using the abstract evolution equations. By this approach, we retain some pointwise behavior of the state $y(x, t)$. Consequently, we can treat general (pointwise) state constraint (1.2), which contains (1.6) as a special case.

Due to the fact that U is just a separable metric space, only the spike perturbation of the control is allowed when we derive the necessary conditions. On the other hand, the pointwise state constraint is presented. These two together cause the main difficulty in our procedure. The key which overcomes this main difficulty is to find the

"Taylor expansion" of the state with respect to the spike variation of the control, in a strong enough topology that is sufficient for us to treat the pointwise constraint. We achieve this by improving a technical lemma found in [5] and using proper estimates for parabolic equations. Once this is obtained, we then use the usual procedure of applying Ekeland's variational principle to derive the desired conclusion.

We refer readers to [17] and [19] for some classical relevant results.

The rest of the paper is organized as follows. In §2, we give some preliminary results and state the main result. Section 3 is devoted to proving some technical lemmas. The proof of the Pontryagin maximum principle is carried out in §4. Some applications are given in §5. The result corresponding to quasilinear parabolic equations is briefly discussed in §6.

2. Preliminary results and the main result. Let us first give some assumptions and preliminary results. We let $\Omega \subset \mathbb{R}^n$ be a bounded domain with $\partial\Omega \in C^2$, $\Omega_T = \Omega \times (0,T)$, $\partial_p\Omega_T = (\bar{\Omega} \times \{0\}) \bigcup (\partial\Omega \times [0,T])$ be the parabolic boundary of Ω_T, and U be a separable metric space. We use $|\cdot|$ or $\|\cdot\|$ (sometimes with a subscript) as the norm in various spaces, which can be identified from the context. For any measurable set $S \subset \mathbb{R}^n$, we use $|S|$ to denote the Lebesgue measure of the set S. In what follows, we will denote by $C_0(\bar{\Omega}_T) \subset C(\bar{\Omega}_T)$ the set of all continuous functions on $\bar{\Omega}_T$ which vanish on $\partial\Omega \times [0,T]$, by $C^{\beta,\beta/2}(\bar{\Omega}_T)$ the set of all continuous functions on $\bar{\Omega}_T$ which are Hölder continuous in (x,t) with the exponent β in x and $\beta/2$ in t ($\beta \in (0,1)$), and by $C_0(\bar{\Omega})$ the set of all continuous functions on $\bar{\Omega}$ which vanish on $\partial\Omega$.

The following assumptions will be assumed throughout the paper.

(A1) The function $a_{ij} : \Omega_T \to \mathbb{R}$ is measurable, $a_{ij} = a_{ji}$, and there exist constants $\Lambda > \lambda > 0$, such that

$$\lambda|\xi|^2 \leq \sum_{i,j=1}^{n} a_{ij}(x,t)\xi_i\xi_j \leq \Lambda|\xi|^2, \qquad \text{for a.e. } (x,t) \in \bar{\Omega}_T, \quad \xi \in \mathbb{R}^n. \tag{2.1}$$

(A2) The function $f : \bar{\Omega} \times [0,T] \times \mathbb{R} \times U \to \mathbb{R}$ has the following properties: $f(\cdot,\cdot\ ,y,u)$ is measurable on $\Omega \times [0,T]$, $f(x,t,\cdot,u)$ is in $C^1(\mathbb{R})$ with $f(x,t,\cdot,\cdot)$ and $f_y(x,t,\cdot,\cdot)$ being continuous on $\mathbb{R} \times U$. There exists a constant $C > 0$, such that

$$f(x,t,y,u)y \leq C(|y|^2 + 1), \qquad \forall (x,t,y,u) \in \bar{\Omega} \times [0,T] \times \mathbb{R} \times U. \tag{2.2}$$

Moreover, for any $R > 0$, there exists an $M_R > 0$, such that

$$|f(x,t,y,u)| + |f_y(x,t,y,u)| \leq M_R, \qquad \forall (x,t,u) \in \bar{\Omega} \times [0,T] \times U, |y| \leq R. \tag{2.3}$$

The same conditions, except (2.2), hold for the function $f^0 : \bar{\Omega} \times [0,T] \times \mathbb{R} \times U \to \mathbb{R}$.

(A3) Z is a Banach space with the dual Z^* being strictly convex. $Q \subset Z$ is convex and closed, and is of finite codimension in Z (see below or [15, Def. 2.2]). The map $G : C_0(\bar{\Omega}_T) \to Z$ is continuously Fréchet differentiable.

Let us make some remarks on (A3). First, a set $Q \subset Z$ is said to be finite codimensional in Z if for some $z_0 \in Q$, the space Z_0 spanned by $Q - z_0 \equiv \{z - z_0 \mid z \in Q\}$ is a finite codimensional subspace of Z and the convex hull $\overline{\text{co}}(Q - z_0)$ of $Q - z_0$ has a nonempty relative interior in Z_0. It is not hard to see that the set Q defined by (1.3) has a nonempty interior in Z and hence is of codimension 0 in Z; the set Q defined by (1.5) is of codimension m in Z.

Next, we consider the case $Z = C_0(\bar{\Omega}_T)$. Then, by the Hahn–Banach Theorem, for any $\mu \in Z^* \equiv C_0(\bar{\Omega}_T)^*$, there exists a $\widetilde{\mu} \in C(\bar{\Omega}_T)^* = \mathcal{M}(\bar{\Omega}_T)$ (the set of all Radon measures on $\bar{\Omega}_T$), such that $\mu = \widetilde{\mu}\big|_{C_0(\bar{\Omega}_T)}$ and

$$(2.4) \qquad \langle\, \widetilde{\mu}, \eta\, \rangle = \int_{\bar{\Omega}_T} \eta d\widetilde{\mu}, \qquad \forall \eta \in C(\bar{\Omega}_T).$$

Then, for any $\eta \in C_0(\bar{\Omega}_T)$ (note $\eta\big|_{\partial\Omega} = 0$)

$$(2.5) \qquad \langle\, \mu, \eta\, \rangle = \int_{\bar{\Omega}_T} \eta d\mu = \int_{\Omega_T \bigcup (\Omega \times \{0,T\})} \eta d\mu.$$

In what follows, we let $\mathcal{M}_0(\bar{\Omega}_T)$ be the set of all Radon measures on $\bar{\Omega}_T$ with the support contained in $\Omega_T \bigcup (\Omega \times \{0,T\})$. Clearly, $\mathcal{M}_0(\bar{\Omega}_T) = C_0(\bar{\Omega}_T)^*$, with the identification being (2.5). It is known that if we use the usual norm in $C_0(\bar{\Omega}_T)$, the dual $C_0(\bar{\Omega}_T)^*$ of it is not strictly convex. However, since the space $C_0(\bar{\Omega}_T)$ is a separable Banach space, by [7, p. 167], there exists a norm, denoted by $|\cdot|_0$, which is equivalent to the norm $\|\cdot\|_{C_0(\bar{\Omega}_T)}$, such that the dual of $(C_0(\bar{\Omega}_T), |\cdot|_0)$ is strictly convex. It is clear that any element $\mu \in (C_0(\bar{\Omega}_T), |\cdot|_0)^*$ can still be identified with an element of $\mathcal{M}_0(\bar{\Omega}_T)$, such that (2.5) holds. This will be useful when we discuss the case with $Z = C(\bar{\Omega}_T)$ (see §5).

Next, we define

$$(2.6) \qquad d_Q(\eta) = \inf_{\eta \in Q} |z - \eta|, \qquad \forall \eta \in Z.$$

Then, $d_Q : Z \to \mathbb{R}$ is convex and Lipschitz continuous (with the Lipschitz constant being 1). From [6], we know that the Clarke's generalized gradient, denoted by ∂d_Q, which coincides with the subdifferential in the sense of the convex analysis in this case [6, Prop. 2.2.7], is convex and weak*-compact. Therefore, given $\xi \in \partial d_Q(\eta)$, we have that

$$(2.7) \qquad \langle\, \xi, z - \eta\, \rangle + d_Q(\eta) \le d_Q(z), \qquad \forall z \in Z.$$

This implies that $|\langle\, \xi, z - \eta\, \rangle| \le |z - \eta|$, for all $z \in Z$, since $d_Q(\cdot)$ is Lipschitz continuous with Lipschitz constant 1. Thus, $\|\xi\|_{Z^*} \le 1$. The identity $\|\xi\|_{Z^*} = 1$ is true whenever $\eta \notin Q$; see [15, Lem. 3.4]. Since Z^* is strictly convex, $\partial d_Q(\eta)$ is a singleton for every $\eta \notin Q$ [15, Cor. 3.5]. Furthermore, $d_Q : Z \to \mathbb{R}$ is Gâteaux differentiable at every point $\eta \notin Q$ and $\{\nabla d_Q(\eta)\} = \partial d_Q(\eta)$ [6, Prop. 2.2.4], where $\nabla d_Q(\eta)$ is the Gâteaux derivative of $d_Q(\eta)$ at η. Hence

$$(2.8) \qquad \|\nabla d_Q(\eta)\|_{Z^*} = 1, \qquad \forall \eta \notin Q.$$

The following result is basic.

PROPOSITION 2.1. *Let* (A1)–(A2) *hold. Then, for any* $u \in \mathcal{U}$ *and* $y_0 \in C^\alpha(\bar{\Omega}) \bigcap C_0(\bar{\Omega})$ $(0 < \alpha < 1)$*, there exists a* $\beta \in (0,1)$*, such that* (1.1) *has a unique solution* $y \equiv y(\cdot,\cdot\,;u) \in C^{\beta,\beta/2}(\bar{\Omega}_T) \bigcap L^2(0,T;H_0^1(\Omega))$*. Furthermore, there exists a constant* $C > 0$*, independent of* $u \in \mathcal{U}$*, such that*

$$(2.9) \qquad \|y(\cdot,\cdot\,;u)\|_{C^{\beta,\beta/2}(\bar{\Omega}_T)} \le C, \qquad \forall u \in \mathcal{U}.$$

Sketch of the proof. Uniqueness follows immediately from the energy estimates. For the existence, it suffices to establish the a priori estimates for the solution. The assumption (2.2) immediately gives us the $L^\infty(\Omega_T)$ estimates. Then the standard energy inequality gives $L^2(0,T;H^1(\Omega))$ estimates, and the existence of the solution follows. The estimates (2.9) is standard and can be found in [12, Chap. III, §10]. □

In what follows, any pair $(y,u) \in \big(C^{\beta,\beta/2}(\bar{\Omega}_T)\bigcap C_0(\bar{\Omega}_T)\big) \times \mathcal{U}$ satisfying (1.1) is called a feasible pair and we refer to the corresponding y and u as feasible state and control, respectively. Clearly, under (A1)–(A2), $\mathcal{U}$ coincides with the set of all feasible controls and for each feasible control $u \in \mathcal{U}$ there corresponds a unique feasible state. Also, we see that the cost functional $J(u)$ is well defined for each $u \in \mathcal{U}$ and the state constraint (1.2) clearly makes sense.

Now, we assume that the set $\mathcal{U}_{\text{ad}}$ defined in (1.8) is nonempty and there exists an optimal pair $(\bar{y},\bar{u})$ to Problem C. Our main result then can be stated as follows.

THEOREM 2.2 (Maximum Principle). *Let (A1)– (A3) hold and let the following compatibility condition, for the set Q, the map G, and the initial state y_0, hold:*

$$\begin{aligned}&\operatorname{supp} G'(\eta)^*\partial d_Q(G(\eta)) \subset \Omega_T \bigcup(\Omega \times \{T\}),\\ &\qquad\qquad \forall \eta \in C_0(\bar{\Omega}_T) \textit{ with } G(\eta) \in Q, \quad \eta\big|_{t=0} = y_0(x).\end{aligned} \tag{2.10}$$

Let $(\bar{y},\bar{u})$ be an optimal pair of Problem C. Then, there exists a constant $\psi^0 \le 0$, a function $\psi \in L^q(0,T;W_0^{1,q}(\Omega))$ $(1 < q < \frac{n+2}{n+1})$, and a $\varphi \in \partial d_Q(G(\bar{y})) \subset Z^*$, such that

$$|\psi^0| + \|\varphi\|_{Z^*} > 0, \tag{2.11}$$

$$\begin{cases} \psi_t + \sum\limits_{i,j=1}^n (a_{ij}(x,t)\psi_{x_j})_{x_i} = -f_y(x,t,\bar{y}(x,t),\bar{u}(x,t))\psi \\ \qquad\qquad - \psi^0 f_y^0(x,t,\bar{y}(x,t),\bar{u}(x,t)) + (G'(\bar{y})^*\varphi)\big|_{\Omega_T}, \qquad \textit{in } \Omega_T, \\ \psi\ \big|_{\partial\Omega} = 0, \\ \psi\ \big|_{t=T} = (G'(\bar{y})^*\varphi)\big|_{\Omega\times\{T\}}, \end{cases} \tag{2.12}$$

$$\langle\, z - G(\bar{y}), \varphi\,\rangle \le 0, \qquad \forall z \in Q. \tag{2.13}$$

$$\begin{aligned}&H(x,t,\bar{y}(x,t),\bar{u}(x,t),\psi^0,\psi(x,t)) = \max_{v\in U} H(x,t,\bar{y}(x,t),v,\psi^0,\psi(x,t)),\\ &\qquad\qquad a.e.(x,t) \in \Omega \times [0,T],\end{aligned} \tag{2.14}$$

where

$$\begin{aligned}&H(x,t,y,u,\psi^0,\psi) =\psi^0 f^0(x,t,y,u) + \psi f(x,t,y,u),\\ &\qquad\qquad \forall (x,t,y,u,\psi^0,\psi) \in \Omega \times [0,T] \times \mathbb{R} \times U \times \mathbb{R} \times \mathbb{R}.\end{aligned} \tag{2.15}$$

In the above, (2.12) is called the adjoint equation, (2.13) is called the transversality condition, and (2.14) is called the maximum condition. It will be seen that in the proof, we only need (2.10) to hold for $\eta = \bar{y}$. Also, in §5, we will give some examples for which such a compatible condition holds.

3. Some technical lemmas. In order to derive the first-order necessary conditions for optimal pairs, we need some sort of "directional derivatives" of the state y and the cost functional $J(u)$ in the control variable u. However, since the control domain U is just a metric space and there is no convexity in general, the perturbation of the control variable is restricted to be of "spike" type. Thus, to find the "directional derivative" is not obvious. In this section, we will present some technical lemmas which will give us exactly the "directional derivatives" we need in the proof of the maximum principle in §4. The results of this section are comparable with those in [5] for elliptic equations (see [13]–[15] and [20] also).

LEMMA 3.1. *Let $h^0 \in L^1(\Omega)$ and $h \in L^p(\Omega)$, $1 < p < \infty$. For any $\rho \in (0,1)$, we define*

$$\mathcal{E}_\rho = \{E \subset \Omega \mid E \text{ measurable and } |E| = \rho|\Omega|\}. \tag{3.1}$$

Let $\mathcal{Y}$ be a Banach space with the embedding $\mathcal{Y} \hookrightarrow L^{p'}(\Omega)$ being compact ($p' = \frac{p}{p-1}$). Then,

$$\inf_{E \in \mathcal{E}_\rho} \left\{ \left| \int_\Omega \left(1 - \frac{1}{\rho}\chi_{E_\rho}(x)\right) h^0(x)dx \right| + \left\| \left(1 - \frac{1}{\rho}\chi_{E_\rho}\right) h \right\|_{\mathcal{Y}^*} \right\} = 0. \tag{3.2}$$

Proof. Let $\rho \in (0,1)$ be given and let $\delta > 0$ be arbitrary. We let B be the closed unit ball in $\mathcal{Y}$. This set is compact in $L^{p'}(\Omega)$ by our assumption. Thus, we can find a set of finitely many step functions $\Theta \equiv \{\theta_i, 1 \le i \le r\}$, such that for any $y \in B$, there exists a $\theta_i \in \Theta$ satisfying

$$\|y - \theta_i\|_{L^{p'}(\Omega)} < \delta. \tag{3.3}$$

Since Θ is a finite set, we may let $\{K_j\}_{j=1}^m$ be a partition of Ω with $|K_j| > 0$ for each $1 \le j \le m$, such that

$$\theta_i(x) = \sum_{j=1}^m c_{ij}\chi_{K_j}(x), \qquad x \in \Omega, \quad 1 \le i \le r. \tag{3.4}$$

Then, for any $y \in B$, by choosing $\theta_i \in \Theta$ with the property (3.3), we have

$$\begin{aligned}
&\sum_{j=1}^m \int_{K_j} \left| y(x) - \frac{1}{|K_j|}\int_{K_j} y(\xi)d\xi \right|^{p'} dx \\
&\le 3^{p'-1} \sum_{j=1}^m \left\{ \int_{K_j} |y(x) - \theta_i(x)|^{p'}dx + \int_{K_j} \left| \theta_i(x) - \frac{1}{|K_j|}\int_{K_j} \theta_i(\xi)d\xi \right|^{p'} dx \right. \\
&\qquad \left. + \int_{K_j} \left| \frac{1}{|K_j|}\int_{K_j} (y(\xi) - \theta_i(\xi))d\xi \right|^{p'} dx \right\} \\
&\le 3^{p'-1} \left\{ \int_\Omega |y(x) - \theta_i(x)|^{p'}dx \right. \\
&\qquad \left. + \sum_{j=1}^m \frac{1}{|K_j|^{p'}} \int_{K_j} |K_j|^{p'/p} \int_{K_j} |y(\xi) - \theta_i(\xi)|^{p'}d\xi dx \right\} \\
&\le 3^{p'-1} \left\{ \delta^{p'} + \int_\Omega |y(\xi) - \theta_i(\xi)|^{p'}d\xi \right\} \le 2 \cdot 3^{p'-1}\delta^{p'}.
\end{aligned} \tag{3.5}$$

Here, we have used the fact that $\theta_i(x)$ is a constant on each set K_j. We have seen that the above estimate is uniform for $y \in B$.

Now, for any $y \in B$, let us define $\widetilde{y} : \Omega \to \mathbb{R}$ to be the following:

$$\widetilde{y}(x) = \frac{1}{|K_j|}\int_{K_j} y(\xi)d\xi, \qquad x \in K_j, \qquad 1 \le j \le m. \tag{3.6}$$

Then, (3.5) can be written as (by setting $\varepsilon^{p'} = 2 \cdot 3^{p'-1}\delta^{p'}$, which is still arbitrary)

$$\|y - \widetilde{y}\|_{L^{p'}(\Omega)} < \varepsilon, \qquad y \in B. \tag{3.7}$$

Next, on each K_j, we approximate the functions h^0 and h by step functions:

$$h_j^0(x) = \sum_{i=1}^{r_j} \alpha_{ij}\chi_{F_{ij}}(x), \quad h_j(x) = \sum_{i=1}^{r_j} \beta_{ij}\chi_{F_{ij}}(x), \qquad x \in \Omega, \tag{3.8}$$

with $\alpha_{ij}, \beta_{ij} \in \mathbb{R}$, $\{F_{ij}\}_{i=1}^{r_j}$ being a partition of K_j, $|F_{ij}| > 0$, and such that

$$\int_{K_j} |h^0(x) - h_j^0(x)|dx + \int_{K_j} |h(x) - h_j(x)|dx < \varepsilon|K_j|, \qquad 1 \le j \le m. \tag{3.9}$$

Let us take $E_\rho^{ij} \subset F_{ij}$, such that $|E_\rho^{ij}| = \rho|F_{ij}|$. Set $E_\rho^j = \bigcup_{i=1}^{r_j} E_\rho^{ij}$. Since $h_j^0(x)$ and $h_j(x)$ are simple functions, we have

$$\left\{\begin{aligned} &\int_{K_j} h_j^0(x)dx = \int_{K_j} \frac{1}{\rho}\chi_{E_\rho^j}(x)h_j^0(x)dx,\\ &\int_{K_j} h_j(x)dx = \int_{K_j} \frac{1}{\rho}\chi_{E_\rho^j}(x)h_j(x)dx, \end{aligned}\right. \qquad 1 \le j \le m. \tag{3.10}$$

Finally, we take $E_\rho = \bigcup_{j=1}^m E_\rho^j$. Then, $E_\rho \in \mathcal{E}_\rho$, and for any $y \in B$,

$$\begin{aligned} \left|\int_\Omega \left(1 - \frac{1}{\rho}\chi_{E_\rho}\right) h(x)y(x)dx\right| &\le \left|\int_\Omega \left(1 - \frac{1}{\rho}\chi_{E_\rho}\right) h(x)\widetilde{y}(x)dx\right| \\ &\quad + \int_\Omega \left(1 + \frac{1}{\rho}\chi_{E_\rho}\right) |h(x)|\,|y(x) - \widetilde{y}(x)|dx \\ &\le \left|\sum_{j=1}^m \int_{K_j} \left(1 - \frac{1}{\rho}\chi_{E_\rho^j}(x)\right) h(x)\widetilde{y}(x)dx\right| + \left(1 + \frac{1}{\rho}\right) \|h\|_{L^p(\Omega)}\|y - \widetilde{y}\|_{L^{p'}(\Omega)}. \end{aligned} \tag{3.11}$$

From (3.7) we see that

$$\left(1 + \frac{1}{\rho}\right) \|h\|_{L^p(\Omega)}\|y - \widetilde{y}\|_{L^{p'}(\Omega)} \le \varepsilon\left(1 + \frac{1}{\rho}\right) \|h\|_{L^p(\Omega)}. \tag{3.12}$$

On the other hand, we notice that $\widetilde{y}(x)$ is a constant on each set K_j (we denote this constant by $\widetilde{y}(K_j)$). Thus, by (3.9)–(3.10) and (3.6), we have

$$
\begin{aligned}
&\left|\sum_{j=1}^{m}\int_{K_j}\left(1-\frac{1}{\rho}\chi_{E_\rho^j}(x)\right)h(x)\widetilde{y}(x)dx\right| \\
&\le \sum_{j=1}^{m}|\widetilde{y}(K_j)|\int_{K_j}\left(1+\frac{1}{\rho}\chi_{E_\rho^j}(x)\right)|h(x)-h_j(x)|dx \\
&\quad+\left|\sum_{j=1}^{m}\widetilde{y}(K_j)\int_{K_j}\left(1-\frac{1}{\rho}\chi_{E_\rho^j}\right)h_j(x)dx\right| \\
&\le\left(1+\frac{1}{\rho}\right)\sum_{j=1}^{m}\varepsilon|K_j|\,|\widetilde{y}(K_j)|\le\varepsilon\left(1+\frac{1}{\rho}\right)\|y\|_{L^1(\Omega)}\le\varepsilon\left(1+\frac{1}{\rho}\right)C.
\end{aligned}
\tag{3.13}
$$

Here, $\|y\|_{L^1(\Omega)}\le C\|y\|_{\mathcal{Y}}\le C$, since $y\in B$. Thus, (3.11)–(3.13) imply that

$$
\left\|\left(1-\frac{1}{\rho}\chi_{E_\rho}\right)h\right\|_{\mathcal{Y}^*}\le\varepsilon\left(1+\frac{1}{\rho}\right)(C+\|h\|_{L^p(\Omega)}).
\tag{3.14}
$$

On the other hand by (3.9)–(3.10) again, we have

$$
\begin{aligned}
&\left|\int_{\Omega}\left(1-\frac{1}{\rho}\chi_{E_\rho}(x)\right)h^0(x)dx\right|\le\sum_{j=1}^{m}\left|\int_{K_j}\left(1-\frac{1}{\rho}\chi_{E_\rho^j}(x)\right)h^0(x)dx\right| \\
&\le\sum_{j=1}^{m}\left(1+\frac{1}{\rho}\right)\int_{K_j}|h^0(x)-h_j^0(x)|dx+\sum_{j=1}^{m}\left|\int_{K_j}\left(1-\frac{1}{\rho}\chi_{E_\rho^j}\right)h_j^0(x)dx\right| \\
&<\varepsilon\left(1+\frac{1}{\rho}\right).
\end{aligned}
\tag{3.15}
$$

Therefore, our conclusion follows. □

The above result was proved for $\mathcal{Y}=W_0^{1,p}(\Omega)$ in [5] using different methods. The proof given here is inspired by a personal communication of the second author with E. Casas.

Now we consider the equation

$$
\begin{cases}
\zeta_t-(a_{ij}(x,t)\zeta_{x_i})_{x_j}+c_\rho(x,t)\zeta(x,t)=\left(1-\frac{1}{\rho}\chi_{E_\rho}(x,t)\right)h(x,t), \text{ in } \Omega_T, \\
\zeta\big|_{\partial_p\Omega_T}=0,
\end{cases}
\tag{3.16}
$$

where a_{ij} satisfies (A1) and $\partial_p\Omega_T=(\partial\Omega\times[0,T])\bigcup(\bar{\Omega}\times\{0\})$ is the parabolic boundary of Ω_T. It is clear that the solution $\zeta=\zeta_{E_\rho}(x,t)$ is uniquely determined by the choice of the coefficient c_ρ and the set E_ρ.

LEMMA 3.2. *Suppose that $\frac{n+2}{2}<p<\infty$. Then, there exists a $\theta\in(0,1)$ such that for each $h^0\in L^1(\Omega_T)$, $h\in L^p(\Omega_T)$, $\mathcal{K}=\{c(x,t);\|c\|_{L^\infty(\Omega_T)}\le K\}$ $(K>0)$, and any $\rho\in(0,1)$,*

$$
\inf_{E_\rho\in\mathcal{E}_\rho}\sup_{c_\rho\in\mathcal{K}}\left\{\left|\int_{\Omega_T}\left(1-\frac{1}{\rho}\chi_{E_\rho}(x,t)\right)h^0(x,t)dxdt\right|+\|\zeta_{E_\rho}\|_{C^{\theta,\theta/2}(\bar{\Omega}_T)}\right\}=0.
\tag{3.17}
$$

Proof. By the assumption, $h \in L^p(\Omega_T)$, $p > \frac{n+2}{2}$. Therefore, the right-hand side of the equation (3.16) is in $L^p(\Omega_T)$ (although the $L^p(\Omega_T)$ norm may blow up as $\rho \to 0$). It follows from the parabolic estimates [12, Chap. III, §10] that there exists $\beta \in (0,1)$, such that

$$\sup_{E_\rho \in \mathcal{E}_\rho} \sup_{c_\rho \in \mathcal{K}} \|\zeta_{E_\rho}\|_{C^{\beta,\beta/2}(\Omega_T)} \le C_\rho. \tag{3.18}$$

We claim that, for any $0 < \theta < \beta$, (3.17) holds. In fact, we first note that the identity mapping $C^{\beta,\beta/2}(\bar{\Omega}_T) \hookrightarrow L^{p'}(\Omega_T)$ is compact. Therefore, if we take $\mathcal{Y} = C^{\beta,\beta/2}(\bar{\Omega}_T)$ in Lemma 3.1, then

$$\begin{aligned} &\inf_{E_\rho \in \mathcal{E}_\rho} \sup_{c_\rho \in \mathcal{K}} \left\{ \left| \int_{\Omega_T} \left(1 - \frac{1}{\rho}\chi_{E_\rho}\right) h^0 dxdt \right| + \left| \int_{\Omega_T} \left(1 - \frac{1}{\rho}\chi_{E_\rho}\right) h \cdot \zeta_{E_\rho} dxdt \right| \right\} \\ &\le \inf_{E_\rho \in \mathcal{E}_\rho} \left\{ \left| \int_{\Omega_T} \left(1 - \frac{1}{\rho}\chi_{E_\rho}\right) h^0 dxdt \right| + C_\rho \left\| \left(1 - \frac{1}{\rho}\chi_{E_\rho}\right) h \right\|_{\mathcal{Y}^*} \right\} = 0. \end{aligned} \tag{3.19}$$

Using a change of variable $\zeta(x,t) = \phi(x,t)e^{Kt}$ if necessary, we may assume without loss of generality that $c_\rho(x,t) \ge 0$. Multiplying equation (3.16) with ζ_{E_ρ} and integrating over Ω_T, we immediately obtain

$$\begin{aligned} &\int_\Omega (\zeta_{E_\rho})^2(x,T)dx + \int_{\Omega_T} |\nabla \zeta_{E_\rho}(x,\tau)|^2 dxd\tau \\ &\qquad \le C \left| \int_0^T \int_\Omega \left(1 - \frac{1}{\rho}\chi_{E_\rho}\right) h \cdot \zeta_{E_\rho} dxdt \right|. \end{aligned} \tag{3.20}$$

Notice that $\zeta_{E_\rho} = 0$ on $\partial\Omega \times \{t\}$, for each $t \in (0,T)$. Therefore, $\int_\Omega (\zeta_{E_\rho})^2(x,t)dx \le C \int_\Omega |\nabla \zeta_{E_\rho}|^2(x,t)dx$, by Poincaré's inequality. Integrating over $t \in [0,T]$, and taking (3.20) into account, yields

$$\int_{\Omega_T} (\zeta_{E_\rho})^2(x,t)dxdt \le C \left| \int_{\Omega_T} \left(1 - \frac{1}{\rho}\chi_{E_\rho}(x,t)\right) h(x,t)\zeta_{E_\rho}(x,t)dxdt \right|. \tag{3.21}$$

By the interpolation theorem (see Lemma 3.4 below), for any $\varepsilon > 0$, there exists $C_\varepsilon > 0$, such that

$$\|\zeta\|_{C^{\theta,\theta/2}(\bar{\Omega}_T)} \le \varepsilon \|\zeta\|_{C^{\beta,\beta/2}(\bar{\Omega}_T)} + C_\varepsilon \|\zeta\|_{L^2(\Omega_T)}, \quad \forall \zeta \in C^{\beta,\beta/2}(\bar{\Omega}_T). \tag{3.22}$$

Using (3.19), (3.21) and (3.22), we obtain

$$\inf_{E \in \mathcal{E}_\rho} \sup_{c_\rho \in \mathcal{K}} \left\{ \left| \int_{\Omega_T} \left(1 - \frac{1}{\rho}\chi_{E_\rho}(x,t)\right) h^0(x,t)dxdt \right| + \|\zeta_{E_\rho}\|_{C^{\theta,\theta/2}(\bar{\Omega}_T)} \right\} \le \varepsilon C_\rho.$$

Since ε can be arbitrarily small, the lemma follows. □

Now, for any feasible pair (y,u), we define

$$\begin{cases} c(x,t) = -f_y(x,t,y(x,t),u(x,t)), \\ c^0(x,t) = f_y^0(x,t,y(x,t),u(x,t)), \end{cases} \tag{3.23}$$

and for given $v \in \mathcal{U}$,

$$
\left\{\begin{array}{l}
h(x,t)=f(x,t,y(x,t),v(x,t))-f(x,t,y(x,t),u(x,t)),\\
h^0(x,t)=f^0(x,t,y(x,t),v(x,t))-f^0(x,t,y(x,t),u(x,t)).
\end{array}\right. \tag{3.24}
$$

Consider the following problem:

$$
\left\{\begin{array}{ll}
z_t-\sum\limits_{i,j=1}^{n}(a_{ij}(x,t)z_{x_i})_{x_j}+c(x,t)z=h(x,t), & \text{in } \Omega_T,\\
z\,\big|_{\partial_p\Omega_T}=0.
\end{array}\right. \tag{3.25}
$$

Clearly, since $h \in L^\infty(\Omega_T)$, this problem admits a unique solution $z \in C^{\beta,\beta/2}(\bar{\Omega}_T)\bigcap L^2(0,T;H_0^1(\Omega))$, as in Proposition 2.1.

Our main result of this section is the following.

THEOREM 3.3. *Let (y,u) be a given feasible pair and $v \in \mathcal{U}$ be fixed. Then, for any $\rho \in (0,1)$, there exists a measurable set $E_\rho \subset \Omega_T$, with property $|E_\rho| = \rho|\Omega_T|$, such that if we define u_ρ by*

$$
u_\rho(x,t)=\left\{\begin{array}{ll}
u(x,t), & \text{if } (x,t)\in\Omega_T\setminus E_\rho,\\
v(x,t), & \text{if } (x,t)\in E_\rho,
\end{array}\right. \tag{3.26}
$$

and let y_ρ be the state corresponding to u_ρ, then the following hold:

$$
\left\{\begin{array}{l}
y_\rho=y+\rho z+r_\rho,\\
\lim\limits_{\rho\to0}\dfrac{1}{\rho}\|r_\rho\|_{C^{\theta,\theta/2}(\bar{\Omega}_T)}=0,
\end{array}\right. \tag{3.27}
$$

for some $\theta \in (0,1)$, and

$$
\left\{\begin{array}{l}
J(u_\rho)=J(u)+\rho z^0+r_\rho^0,\\
\lim\limits_{\rho\to0}\dfrac{1}{\rho}|r_\rho^0|=0,
\end{array}\right. \tag{3.28}
$$

where z is the solution of (3.25) *and z^0 is given by*

$$
z^0=\int_\Omega[c^0(x,t)z(x,t)+h^0(x,t)]dx. \tag{3.29}
$$

Proof. First, we recall the so-called Ekeland distance. For any $u, v \in \mathcal{U}$, we let

$$
\bar{d}(u,v)=|\{(x,t)\in\Omega \mid u(x,t)\neq v(x,t)\}|. \tag{3.30}
$$

It is standard that $(\mathcal{U},\bar{d}(\cdot,\cdot))$ is a complete metric space (see [8]). Clearly, $\bar{d}(u,u_\rho)\le |E_\rho|$.

Now, we set

$$
z_\rho(x,t)=\frac{y_\rho(x,t)-y(x,t)}{\rho}, \qquad x\in\Omega. \tag{3.31}
$$

Then, z_ρ satisfies the following:

$$\tag{3.32}\begin{cases}(z_\rho)_t - \sum_{i,j=1}^n (a_{ij}(x,t)(z_\rho)_{x_i})_{x_j} + c_\rho(x,t)z_\rho = \frac{1}{\rho}\chi_{E_\rho}(x,t)h(x,t),\\ z_\rho \,\big|_{\partial_p\Omega_T} = 0,\end{cases}$$

where

$$\tag{3.33} c_\rho(x,t) = -\int_0^1 f_y(x,t,y(x,t)+\tau(y_\rho(x,t)-y(x,t)),u_\rho(x,t))d\tau.$$

We see that (note (2.9) and (2.3)) $c_\rho(x,t)$ and $h(x,t)$ are uniformly bounded (with the bounds independent of E_ρ, the controls u and v). The function $h(x,t)$ is actually independent of the set E_ρ; we shall use this fact when we apply Lemma 3.2. Since $h \in L^\infty(\Omega_T) \subset L^p(\Omega_T)$ for any $p > 1$, the parabolic Hölder's estimate implies that $y_\rho - y = \rho z_\rho$ satisfies, for fixed $p > \frac{n+2}{2}$,

$$\tag{3.34} \|y_\rho - y\|_{C^{\beta,\beta/2}(\bar\Omega_T)} \le C\|\chi_{E_\rho}\|_{L^p(\Omega_T)} \equiv \omega(C\rho) \to 0, \qquad \text{as } \rho \to 0,$$

where the constant C is independent of E_ρ, and ω is a modulus of continuity. It follows that

$$\tag{3.35} c_\rho(x,t) \to c(x,t) \equiv -f_y(x,t,y(x,t),u(x,t)), \qquad \text{in } L^p(\Omega_T),\ 1 \le p < \infty.$$

By recalling z, the solution of (3.25), we have the following:

$$\tag{3.36}\begin{cases}(z_\rho - z)_t - \sum_{i,j=1}^n \left(a_{ij}(x,t)(z_\rho - z)_{x_i}\right)_{x_j} + c_\rho(x,t)(z_\rho - z)\\ \qquad = -(c_\rho(x,t) - c(x,t))z - \left(1 - \frac{1}{\rho}\chi_{E_\rho}(x,t)\right)h(x,t),\\ (z_\rho - z)\big|_{\partial_p\Omega_T} = 0,\end{cases}$$

We note that the above equation is linear in $(z_\rho - z)$. Thus, we may write $z_\rho - z = \bar\zeta_\rho + \zeta_\rho$ with $\bar\zeta_\rho$ and ζ_ρ satisfying the following:

$$\tag{3.37}\begin{cases}(\bar\zeta_\rho)_t - \sum_{i,j=1}^n \left(a_{ij}(x,t)(\bar\zeta_\rho)_{x_i}\right)_{x_j} + c_\rho(x,t)\bar\zeta_\rho = -(c_\rho(x,t) - c(x,t))z\\ \bar\zeta_\rho \,\big|_{\partial_p\Omega_T} = 0,\end{cases}$$

and

$$\tag{3.38}\begin{cases}(\zeta_\rho)_t - \sum_{i,j=1}^n (a_{ij}(x,t)(\zeta_\rho)_{x_i})_{x_j} + c_\rho(x,t)\zeta_\rho = -\left(1 - \frac{1}{\rho}\chi_{E_\rho}(x,t)\right)h(x,t),\\ \zeta_\rho \,\big|_{\partial_p\Omega_T} = 0.\end{cases}$$

By Hölder estimates, again (notice that $z \in C^{\beta,\beta/2}(\bar\Omega_T) \subset L^\infty(\Omega_T)$, and p is fixed with $p > \frac{n+2}{2}$), we have

$$\tag{3.39} \|\bar\zeta_\rho\|_{C^{\beta,\beta/2}(\bar\Omega_T)} \le C\|(c_\rho - c)z\|_{L^p(\Omega_T)} = o(1) \quad \text{as } \rho \to 0;$$

all the constants involved in the above are independent of the choices of E_ρ.

Now we fix $\theta \in (0, \beta)$ as in Lemma 3.2. Then we can choose $E_\rho \subset \Omega_T$ with the property $|E_\rho| = \rho|\Omega_T|$, such that the solution ζ_ρ of (3.38) satisfies

$$\left|\int_{\Omega_T}\left(1-\frac{1}{\rho}\chi_{E_\rho}(x,t)\right)h^0(x,t)dxdt\right| + \|\zeta_\rho\|_{C^{\theta,\theta/2}(\bar\Omega_T)} \le \rho. \tag{3.40}$$

This proves (3.27). The proof of (3.28) is similar but simpler. □

The above result will play a very important role in the proof of our main result (Theorem 2.2). Conclusion (3.27) gives a "Taylor expansion" (of first order) in the space $C^{\theta,\theta/2}(\bar\Omega_T) \subset C(\bar\Omega_T)$. This will be sufficient for us to deal with the pointwise state constraint. It is not hard for us to see that the stronger the topology under which (3.27) holds, the harder for us to prove it. Thus, for example, if in (3.27), $C^{\theta,\theta/2}(\bar\Omega_T)$ is replaced by $L^p(\Omega_T)$, then it will be much easier to prove it. In another word, an $L^p(\Omega_T)$ constraint of the state is much easier to treat than a $C(\bar\Omega_T)$ constraint.

We now give a proof for the interpolation theorem used in the proof of Lemma 3.2. The identity mappings $C^{\beta,\beta/2}(\bar\Omega_T) \hookrightarrow C^{\theta,\theta/2}(\bar\Omega_T) \hookrightarrow L^2(\Omega_T)$ are continuous and compact. Therefore, the interpolation follows from a compactness argument. However, the compactness argument does not give us the exact form of the constants C_ε. Lemma 3.4 below is a stronger statement.

The interpolation involves *different types* of spaces. Nonetheless, the proof is similar to that in, for example, [11].

LEMMA 3.4. *Suppose that $\partial\Omega$ is Lipschitz continuous, $0 \le \theta < \beta < 1$ and $0 < p \le \infty$. Then there exists a constant C, depending only on Ω and T, such that*

$$\begin{gathered}\|\zeta\|_{C^{\theta,\theta/2}(\bar\Omega_T)} \le 4\varepsilon[\zeta]_{C^{\beta,\beta/2}(\bar\Omega_T)} + \frac{3C^{1/p}}{\varepsilon^\mu}\|\zeta\|_{L^p(\Omega_T)},\\ \forall\zeta \in C^{\beta,\beta/2}(\bar\Omega_T), \quad \forall 0<\varepsilon\le 1,\end{gathered} \tag{3.41}$$

where $\mu = \frac{\theta}{(\beta-\theta)} + \frac{n+2}{(\beta-\theta)p}$, *and*

$$\begin{cases} [\zeta]_{C^{\theta,\theta/2}(\bar\Omega_T)} = \sup\left\{\dfrac{|\zeta(x,t)-\zeta(\bar x,\bar t)|}{(\sqrt{|x-\bar x|^2+|t-\bar t|}\,)^\theta}; \quad (x,t) \ne (\bar x,\bar t) \in \bar\Omega_T\right\},\\ \|\zeta\|_{C^{\theta,\theta/2}(\bar\Omega_T)} = \|\zeta\|_{C(\bar\Omega_T)} + [\zeta]_{C^{\theta,\theta/2}(\bar\Omega_T)} \qquad \textit{when } 0<\theta<1,\\ \|\zeta\|_{C^{\theta,\theta/2}(\bar\Omega_T)} = \|\zeta\|_{C(\bar\Omega_T)} \qquad \textit{when } \theta = 0.\end{cases} \tag{3.42}$$

(*The* $\|\cdot\|_{L^p(\Omega_T)}$ *should be understood in the usual sense*; *it should be noted that it is not a norm when* $0<p<1$.)

Proof. We let $\delta = \varepsilon^{1/(\beta-\theta)}$; then $0 < \delta \le 1$. Splitting the *sup* in (3.42) into two sets $\{\sqrt{|x-\bar x|^2+|t-\bar t|} \le \delta\}$ and $\{\sqrt{|x-\bar x|^2+|t-\bar t|} > \delta\}$ immediately gives us

$$\|\zeta\|_{C^{\theta,\theta/2}(\bar\Omega_T)} \le \delta^{\beta-\theta}[\zeta]_{C^{\beta,\beta/2}(\bar\Omega_T)} + \left(1+\frac{2}{\delta^\theta}\right)\|\zeta\|_{C(\bar\Omega_T)}, \tag{3.43}$$

from which the case $p=\infty$ follows.

Now consider the case $0<p<\infty$. Since ζ is continuous on $\bar\Omega_T$, $\|\zeta\|_{C(\bar\Omega_T)} = |\zeta(\tilde x,\tilde t)|$, for some $(\tilde x,\tilde t) \in \bar\Omega_T$. Now let $B_\delta = \{(x,t) \in \bar\Omega_T;\ \sqrt{|x-\tilde x|^2+|t-\tilde t|} \le \delta\}$; then by the mean value theorem,

$$\left(\frac{1}{|B_\delta\bigcap\bar\Omega_T|}\int_{B_\delta\bigcap\bar\Omega_T}|\zeta(x,t)|^p dxdt\right)^{1/p} = |\zeta(x^*,t^*)|$$

for some $(x^*,t^*) \in B_\delta \bigcap \bar{\Omega}_T$. Since $\partial\Omega$ is Lipschitz continuous, $|B_\delta \bigcap \bar{\Omega}_T| \geq \delta^{n+2}/C$ for some generic constant $C > 0$. It follows that

$$\begin{aligned} \|\zeta\|_{C(\bar{\Omega}_T)} &= |\zeta(\widetilde{x},\widetilde{t})| \leq |\zeta(\widetilde{x},\widetilde{t}) - \zeta(x^*,t^*)| + |\zeta(x^*,t^*)| \\ &\leq \delta^\beta[\zeta]_{C^{\beta,\beta/2}(\bar{\Omega}_T)} + \left(\frac{C}{\delta^{n+2}}\right)^{1/p} \|\zeta\|_{L^p(\Omega_T)}; \end{aligned} \tag{3.44}$$

the case $\theta = 0$ follows immediately. Now substituting (3.45) into (3.44), we obtain

$$\|\zeta\|_{C^{\theta,\theta/2}(\bar{\Omega}_T)} \leq 4\delta^{\beta-\theta}[\zeta]_{C^{\beta,\beta/2}(\bar{\Omega}_T)} + \frac{3}{\delta^\theta}\left(\frac{C}{\delta^{n+2}}\right)^{1/p} \|\zeta\|_{L^p(\Omega_T)},$$

and the general case $0 < \theta < \beta < 1$, $0 < p < \infty$ follows. □

4. Proof of Theorem 2.2. In this section, we are going to prove the main theorem of this paper.

Proof of Theorem 2.2. Let $(\bar{y},\bar{u})$ be an optimal pair. For any $u \in \mathcal{U}$, let $y(\cdot,\cdot\,;\,u)$ be the corresponding state, emphasizing the dependence of it on the control. For any $\varepsilon > 0$, we define

$$J_\varepsilon(u) = \{[(J(u) - J(\bar{u}) + \varepsilon)^+]^2 + d_Q(G(y(\cdot,\cdot\,;\,u)))^2\}^{1/2}. \tag{4.1}$$

Clearly, this functional is continuous on the (complete) metric space $(\mathcal{U},\bar{d})$ (recall that $\bar{d}$ is the Ekeland distance; see (3.30)). Also, we have

$$J_\varepsilon(u) > 0, \qquad \forall u \in \mathcal{U}, \tag{4.2}$$

$$J_\varepsilon(\bar{u}) = \varepsilon \leq \inf_{\mathcal{U}} J_\varepsilon(u) + \varepsilon. \tag{4.3}$$

Hence, by Ekeland's variational principle [6], we can find a $u^\varepsilon \in \mathcal{U}$, such that

$$\bar{d}(\bar{u},u^\varepsilon) \leq \sqrt{\varepsilon}, \tag{4.4}$$

$$J_\varepsilon(u^\varepsilon) \leq J_\varepsilon(\bar{u}), \tag{4.5}$$

$$J_\varepsilon(\widehat{u}) - J_\varepsilon(u^\varepsilon) \geq -\sqrt{\varepsilon}\,d(\widehat{u},u^\varepsilon), \qquad \forall \widehat{u} \in \mathcal{U}. \tag{4.6}$$

We let $v \in \mathcal{U}$ and $\varepsilon > 0$ be fixed and let $y^\varepsilon = y(\cdot,\cdot\,;u^\varepsilon)$. By Theorem 3.3, we know that for any $\rho \in (0,1)$, there exists a measurable set $E^\varepsilon_\rho \subset \Omega_T$ with the property $|E^\varepsilon_\rho| = \rho|\Omega_T|$, such that if we define

$$u^\varepsilon_\rho(x,t) = \begin{cases} u^\varepsilon(x,t), & \text{if } (x,t) \in \Omega_T \setminus E^\varepsilon_\rho, \\ v(x,t), & \text{if } (x,t) \in E^\varepsilon_\rho, \end{cases} \tag{4.7}$$

and let $y^\varepsilon_\rho = y(\cdot,\cdot\,;\,u^\varepsilon_\rho)$ be the corresponding state, then

$$\begin{cases} y^\varepsilon_\rho = y^\varepsilon + \rho z^\varepsilon + r^\varepsilon_\rho, \\ J(u^\varepsilon_\rho) = J(u^\varepsilon) + \rho z^{0,\varepsilon} + r^{0,\varepsilon}_\rho, \end{cases} \tag{4.8}$$

where z^ε and $z^{0,\varepsilon}$ satisfy the following:

$$\begin{cases} z^\varepsilon_t - \displaystyle\sum_{i,j}^{n} (a_{ij}(x,t) z^\varepsilon_{x_i})_{x_j} - f_y(x,t,y^\varepsilon(x,t),u^\varepsilon(x,t)) z^\varepsilon = h^\varepsilon(x,t), & \text{in } \Omega_T, \\ z^\varepsilon \,\big|_{\partial_p \Omega_T} = 0. \end{cases} \tag{4.9}$$

$$z^{0,\varepsilon} = \int_{\Omega_T} [f^0_y(x,t,y^\varepsilon(x,t),u^\varepsilon(x,t)) z^\varepsilon(x,t) + h^{0,\varepsilon}(x,t)]dx, \tag{4.10}$$

with

$$\begin{cases} h^\varepsilon(x,t) = f(x,t,y^\varepsilon(x,t),v(x,t)) - f(x,t,y^\varepsilon(x,t),u^\varepsilon(x,t)), \\ h^{0,\varepsilon}(x,t) = f^0(x,t,y^\varepsilon(x,t),v(x,t)) - f^0(x,t,y^\varepsilon(x,t),u^\varepsilon(x,t)). \end{cases} \tag{4.11}$$

and for some $\theta \in (0,1)$,

$$\lim_{\rho\to0} \frac{1}{\rho} \|r^\varepsilon_\rho\|_{C^{\theta,\theta/2}(\bar\Omega_T)} = \lim_{\rho\to0} \frac{1}{\rho} |r^{0,\varepsilon}_\rho| = 0. \tag{4.12}$$

Now, we take $\widehat{u} = u^\varepsilon_\rho$ in (4.6). Then, it follows that

$$\begin{aligned} -\sqrt{\varepsilon}|\Omega_T| &\le \frac{J_\varepsilon(u^\varepsilon_\rho) - J_\varepsilon(u^\varepsilon)}{\rho} \\ &= \frac{1}{J_\varepsilon(u^\varepsilon_\rho) + J_\varepsilon(u^\varepsilon)} \left\{ \frac{[(J(u^\varepsilon_\rho) - J(\bar u) + \varepsilon)^+]^2 - [(J(u^\varepsilon) - J(\bar u) + \varepsilon)^+]^2}{\rho} \right. \\ &\qquad \left. + \frac{d_Q(G(y^\varepsilon_\rho))^2 - d_Q(G(y^\varepsilon))^2}{\rho} \right\} \\ &\to \frac{(J(u^\varepsilon) - J(\bar u) + \varepsilon)^+}{J_\varepsilon(u^\varepsilon)} z^{0,\varepsilon} + \left\langle \frac{d_Q(G(y^\varepsilon))\xi_\varepsilon}{J_\varepsilon(u^\varepsilon)}, G'(y^\varepsilon) z^\varepsilon \right\rangle, \qquad (\rho \to 0), \end{aligned} \tag{4.13}$$

where

$$\xi_\varepsilon = \begin{cases} \nabla d_Q(G(y^\varepsilon)), & \text{if } G(y^\varepsilon) \notin Q, \\ 0, & \text{if } G(y^\varepsilon) \in Q. \end{cases} \tag{4.14}$$

We note that since $G : C_0(\bar\Omega_T) \to Z$, to obtain the convergence in (4.13), the expansion (4.8) *in the space* $C_0(\bar\Omega_T)$ is necessary.

Next, we define $(\varphi^{0,\varepsilon}, \varphi^\varepsilon) \in [0,1] \times \mathcal{M}(\bar\Omega_T)$ as follows:

$$\begin{cases} \varphi^{0,\varepsilon} = \dfrac{(J(u^\varepsilon) - J(\bar u) + \varepsilon)^+}{J_\varepsilon(u^\varepsilon)}, \\ \varphi^\varepsilon = \dfrac{d_Q(G(y^\varepsilon))\xi_\varepsilon}{J_\varepsilon(u^\varepsilon)}. \end{cases} \tag{4.15}$$

Then we see that (4.13) becomes

$$-\sqrt{\varepsilon}|\Omega_T| \le \varphi^{0,\varepsilon} z^{0,\varepsilon} + \langle \varphi^\varepsilon, G'(y^\varepsilon) z^\varepsilon \rangle. \tag{4.16}$$

By (2.8) and (4.1), we have

$$|\varphi^{0,\varepsilon}|^2 + \|\varphi^\varepsilon\|^2_{Z^*} = 1. \tag{4.17}$$

On the other hand, by the definition of subdifferential, we have

$$\langle \varphi^\varepsilon, \eta - G(y^\varepsilon) \rangle \le 0, \qquad \forall \eta \in Q. \tag{4.18}$$

Next, by (4.4), we have

$$\|y^\varepsilon - \bar{y}\|_{C^{\beta,\beta/2}(\bar{\Omega}_T)} \to 0, \qquad (\varepsilon \to 0). \tag{4.19}$$

Thus, (4.18) implies

$$\langle \varphi^\varepsilon, \eta - G(\bar{y}) \rangle \le \langle \varphi^\varepsilon, G(y^\varepsilon) - G(\bar{y}) \rangle \le \|G(y^\varepsilon) - G(\bar{y})\|_Z \to 0, \qquad \forall \eta \in Q. \tag{4.20}$$

Since Q is finite codimensional in Z, from [15, Lem. 3.2], we know that by extracting some subsequence, still denoted by itself, one has

$$(\varphi^{0,\varepsilon}, \varphi^\varepsilon) \overset{*}{\rightharpoonup} (\varphi^0, \varphi) \ne 0. \tag{4.21}$$

On the other hand, from (4.19) and the equations (4.9), (4.10), we have

$$\begin{cases} z^\varepsilon \longrightarrow z, & \text{in } C^{\beta,\beta/2}(\bar{\Omega}_T), \\ z^{0,\varepsilon} \longrightarrow z^0, & \end{cases} \qquad (\varepsilon \to 0), \tag{4.22}$$

where z is the solution of the following variational system:

$$\begin{cases} z_t - \displaystyle\sum_{i,j=1}^n (a_{ij}(x,t) z_{x_i})_{x_j} = f_y(x,t,\bar{y}(x,t),\bar{u}(x,t)) z \\ \qquad\qquad + f(x,t,\bar{y}(x,t),v(x,t)) - f(x,t,\bar{y}(x,t),\bar{u}(x,t)), \qquad \text{in } \Omega_T, \\ z \,\big|_{\partial_p \Omega_T} = 0 \end{cases} \tag{4.23}$$

and

$$\begin{aligned} z^0 = & \int_{\Omega_T} f^0_y(x,t,\bar{y}(x,t),\bar{u}(x,t)) z(x,t)\,dxdt \\ & + \int_{\Omega_T} [f^0(x,t,\bar{y}(x,t),v(x,t)) - f^0(x,t,\bar{y}(x,t),\bar{u}(x,t))]\,dxdt. \end{aligned} \tag{4.24}$$

We note that the solution z of (4.23) and the quantity z^0 defined by (4.24) depend on the choice of $v \in \mathcal{U}$. Thus, we denote them by $z(\cdot,\cdot\,;\, v)$ and $z^0(v)$, respectively. Then, taking limits in (4.16), we obtain

$$\varphi^0 z^0(v) + \langle \varphi, G'(\bar{y}) z(\cdot,\cdot\,; v) \rangle \ge 0, \qquad \forall v \in \mathcal{U}. \tag{4.25}$$

Now, we let

$$\psi^0 = -\varphi^0 \in [-1, 0]. \tag{4.26}$$

Then, (2.11) follows from (4.21). Also, we obtain (2.13) by taking limits in (4.20) (along the above-mentioned subsequence). Furthermore, (4.25) can be written as

$$\psi^0 z^0(v) - \langle G'(\bar y)^*\varphi, z(\cdot,\cdot\,;v)\rangle \le 0, \qquad \forall v \in \mathcal{U}. \tag{4.27}$$

We note that $G'(\bar y)^*\varphi \in \mathcal{M}(\bar\Omega_T)$, and by our compatible condition (2.10), we see that

$$\begin{aligned}\langle G'(\bar y)^*\varphi, z\rangle &= \langle (G'(\bar y)^*\varphi)\big|_{\Omega_T}, z\rangle_{\mathcal{M}(\Omega_T),C(\bar\Omega_T)}\\ &\quad + \langle (G'(\bar y)^*\varphi)\big|_{\Omega\times\{T\}}, z\big|_{t=T}\rangle_{\mathcal{M}(\Omega),C(\bar\Omega)}.\end{aligned} \tag{4.28}$$

By [1], we know that (2.12) admits a solution in $L^q(0,T,W_0^{1,q}(\Omega))$ for any $1 < q < \frac{n+2}{n+1}$. However, unlike the elliptic equations, the function $z(x,t;v)$ is not smooth enough (in the t direction) to be a test function for the equation (2.12). We shall get around this problem by approximating the equations for z and the equations (2.12).

We consider the following approximation for $z(x,t;v)$:

$$\begin{cases} z_t^\delta - \displaystyle\sum_{i,j=1}^n (a_{ij}^\delta(x,t) z_{x_i}^\delta)_{x_j} = f_y(x,t,\bar y(x,t),\bar u(x,t)) z^\delta \\ \qquad\qquad + f(x,t,\bar y(x,t),v(x,t)) - f(x,t,\bar y(x,t),\bar u(x,t)), \qquad \text{in } \Omega_T, \\ z^\delta\,\big|_{\partial_p\Omega_T} = 0, \end{cases} \tag{4.29}$$

where $a_{ij}^\delta \in C^{2,1}(\bar\Omega_T)$, a_{ij}^δ satisfies (A1), and

$$a_{ij}^\delta \to a_{ij} \qquad \text{in } L^p(\Omega_T), \text{ as } \delta \to 0, \tag{4.30}$$

for any $1 < p < \infty$. By L^p estimates for the parabolic equations, $z^\delta = z^\delta(\cdot,\cdot\,;v) \in W_p^{2,1}(\Omega_T)$ for any $1 < p < \infty$. As before, we have the estimates

$$\|z^\delta\|_{C^{\beta,\beta/2}(\bar\Omega_T)} + \|\nabla_x z^\delta\|_{L^2(\Omega_T)} \le C, \tag{4.31}$$

where the constants C and β are independent of δ and $v \in \mathcal{U}$. Thus, by compactness and the uniqueness of the equation (4.23), one can easily derive that

$$\|z^\delta - z\|_{C(\bar\Omega_T)} \to 0, \qquad \text{as } \delta \to 0. \tag{4.32}$$

Clearly, (4.27) and (4.32) imply that

$$\lim_{\delta\to 0} \{\psi^0 z^0(v) - \langle G'(\bar y)^*\varphi, z^\delta(\cdot,\cdot\,;v)\rangle\} \le 0, \qquad \forall v \in \mathcal{U}. \tag{4.33}$$

By [1], if we replace a_{ij} with a_{ij}^δ, then (2.12) has a solution $\psi^\delta \in L^q(0,T,W_0^{1,q}(\Omega))$, where $1 < q < \frac{n+2}{n+1}$. (ψ^δ is actually unique.) Furthermore,

$$\|\psi^\delta\|_{L^q(0,T,W_0^{1,q}(\Omega))} \le C, \tag{4.34}$$

where the constant C is independent of δ. Clearly, v is not involved in the definition of ψ^δ. By passing to a subsequence if necessary, we have, as $\delta \to 0$,

$$\psi^\delta \overset{w}{\rightharpoonup} \psi \quad \text{in } L^q(\Omega_T), \qquad \psi_{x_j}^\delta \overset{w}{\rightharpoonup} \psi_{x_j} \quad \text{in } L^q(\Omega_T), \tag{4.35}$$

for some function ψ. It follows that ψ is a solution of (2.12).

Since $z^\delta \in W_p^{2,1}(\Omega_T)$ for $p > q/(q-1)$, we can use z^δ as a test function in the equation for ψ^δ.

Then, by some direct computation, we can reduce (4.33) to the following:

$$\begin{aligned}\int_{\Omega_T} &\{\psi^0[f^0(x,t,\bar{y}(x,t),\bar{u}(x,t)) - f^0(x,t,\bar{y}(x,t),v(x,t))] \\ &+ \psi^\delta(x,t)[f(x,t,\bar{y}(x,t),\bar{u}(x,t)) - f(x,t,\bar{y}(x,t),v(x,t))]\}dx \\ \geq\ & o(1), \qquad \text{as } \delta \to 0.\end{aligned} \tag{4.36}$$

Now letting $\delta \to 0$ and recalling (4.35), we obtain

$$\begin{aligned}&\int_{\Omega_T} \{\psi^0[f^0(x,t,\bar{y}(x,t),\bar{u}(x,t)) - f^0(x,t,\bar{y}(x,t),v(x,t))] \\ &\qquad + \psi(x,t)[f(x,t,\bar{y}(x,t),\bar{u}(x,t)) - f(x,t,\bar{y}(x,t),v(x,t))]\}dx \\ &\equiv \int_\Omega [H(x,t,\bar{y}(x,t),\bar{u}(x,t),\psi^0,\psi(x,t)) - H(x,t,\bar{y}(x,t),v(x,t),\psi^0,\psi(x,t))]dx, \\ &\geq 0, \qquad\qquad \forall v \in \mathcal{U}.\end{aligned} \tag{4.37}$$

Then, by the separability of U and the continuity of the Hamiltonian H in the variable v, noticing also that $v \in \mathcal{U}$ is arbitrary, we obtain the maximum condition (2.14) (see [5]). □

5. Applications. In this section, we would like to discuss some special cases which are covered by our main result.

We first consider the following case. Let $Z = C_0(\bar{\Omega}_T)$ with some norm $|\cdot|_0$ which is equivalent to $\|\cdot\|_{C(\bar{\Omega}_T)}$ and whose dual, still denoted by $\mathcal{M}_0(\bar{\Omega}_T)$, is strictly convex. We let $Q \subset Z$ be defined as in (1.3) and $g : \bar{\Omega}_T \times \mathbb{R} \to \mathbb{R}$ be continuous, with $g_y(x,t,y)$ also being continuous. Moreover,

$$\begin{cases} g(x,t,0) < 0, & \forall (x,t) \in \partial\Omega \times [0,T], \\ g(x,0,y_0(x)) < 0, & \forall x \in \bar{\Omega}, \end{cases} \tag{5.1}$$

where $y_0 \in C_0(\bar{\Omega})$. We let $G(\eta)(x,t) = g(x,t,\eta(x,t))$, for any $\eta \in C_0(\bar{\Omega}_T)$. Then, the following result holds.

PROPOSITION 5.1. *For the above Q, G, and y_0, condition* (2.10) *holds.*

Proof. By (5.1), we see that for any $\varepsilon > 0$, there exists a $\delta > 0$, such that

$$\begin{aligned} g(x,t,y) \leq -\varepsilon, \quad & \text{if } t \in [\delta,T], |y| < \delta, d(x,\partial\Omega) < \delta, \\ & \text{or } t \in [0,\delta], x \in \Omega, |y - y_0(x)| < \delta. \end{aligned} \tag{5.2}$$

Thus, for any $\eta \in C_0(\bar{\Omega}_T)$ with $G(\eta) \in Q$ and $\eta\big|_{t=0} = y_0(x)$, we have the following: For any $\varepsilon > 0$, there exists a $\delta > 0$, such that

$$g(x,t,\eta(x,t)) \leq -\varepsilon, \qquad \text{if } d((x,t),\partial_p\Omega_T) < \delta. \tag{5.3}$$

Now, for any $\varphi \in C(\bar{\Omega}_T)$, if for some $\delta > 0$, it holds that

$$\operatorname{supp}\varphi \subset \{(x,t) \in \bar{\Omega}_T \bigm| d((x,t),\partial_p\Omega_T) \leq \delta\}; \tag{5.4}$$

then, for all small enough $\sigma > 0$, we have

$$g(x,t,\eta(x,t)) + \sigma\varphi(x,t) \le 0, \qquad (x,t) \in \bar{\Omega}_T. \tag{5.5}$$

This means $G(\eta) + \sigma\varphi \in Q$ for all small $\sigma > 0$. Hence, by the definition of the generalized gradient, we obtain

$$\langle \zeta, \varphi \rangle = 0, \qquad \forall \zeta \in \partial d_Q(G(\eta)) \subset \mathcal{M}(\bar{\Omega}_T). \tag{5.6}$$

In other words, we have (for the above η)

$$\operatorname{supp}\zeta \subset \{(x,t) \in \bar{\Omega}_T \mid d((x,t), \partial_p\Omega_T) \ge \delta\}. \tag{5.7}$$

Since $G'(\eta) = g_y(x,t,\eta(x,t))I$, with I being the identity on Z, we see that (2.10) holds. □

We already know that Q has a nonempty interior in Z, hence it is of codimension 0 in Z. Then, our main result is applicable to this case. Let us state the corresponding result.

THEOREM 5.2. *Let $(\bar{y}, \bar{u})$ be an optimal pair. Then, there exists a constant $\psi^0 \le 0$, a function $\psi \in L^q(0,T; W_0^{1,q}(\Omega))$ $(q < \frac{n+2}{n+1})$, and a $\varphi \in \mathcal{M}_0(\bar{\Omega}_T)$, such that*

$$|\psi^0| + \|\varphi\|_{\mathcal{M}_0(\bar{\Omega}_T)} > 0, \tag{5.8}$$

$$\begin{cases} \psi_t + \displaystyle\sum_{i,j=1}^n (a_{ij}(x,t)\psi_{x_j})_{x_i} = -f_y(x,t,\bar{y}(x,t),\bar{u}(x,t))\psi \\ \qquad\qquad - \psi^0 f_y^0(x,t,\bar{y}(x,t),\bar{u}(x,t)) + g_y(x,t,\bar{y}(x,t))^*\varphi\big|_{\Omega_T}, \qquad \text{in } \Omega_T, \\ \psi \big|_{\partial\Omega} = 0, \\ \psi \big|_{t=T} = g_y(x,T,\bar{y}(x,T))\varphi\big|_{\Omega\times\{T\}}, \end{cases} \tag{5.9}$$

$$\int_{\bar{\Omega}_T} \Big[z(x,t) - g(x,t,\bar{y}(x,t))\Big] d\varphi(x,t) \le 0, \qquad \forall z \in Q. \tag{5.10}$$

$$\begin{aligned} H(x,t,\bar{y}(x,t),&\bar{u}(x,t),\psi^0,\psi(x,t)) = \max_{v\in U} H(x,t,\bar{y}(x,t),v,\psi^0,\psi(x,t)), \\ &a.e.(x,t) \in \Omega \times [0,T], \end{aligned} \tag{5.11}$$

where H is the Hamiltonian defined by (2.15).

Let us make some further remark on the above result. We set

$$\Omega_T^0 = \{(x,t) \in \bar{\Omega}_T \mid g(x,t,\bar{y}(x,t)) = 0\}. \tag{5.12}$$

Then, by our condition (5.1), we see that

$$\Omega_T^0 \subset \Omega_T \bigcup (\Omega \times \{T\}). \tag{5.13}$$

The set Ω_T^0 is called the active set for the optimal state $\bar{y}$. We have that

$$\operatorname{supp}\varphi \subset \Omega_T^0. \tag{5.14}$$

In fact, for any $\eta \in C(\bar{\Omega}_T)$ with $\operatorname{supp}\eta \subset \bar{\Omega}_T \setminus \Omega_T^0$, $g(\cdot,\cdot,\bar{y}(\cdot,\cdot)) \pm \varepsilon\eta \in Q$ if ε is small enough. By the transversality condition (5.10), we see immediately that

$$\int_{\bar{\Omega}_T} \eta(x,t)d\varphi(x,t) = 0. \tag{5.15}$$

This gives (5.14).

The above situation is comparable with the case discussed in [5] for quasilinear elliptic equations.

Next, let us look at another important case. Let $Z = C_0(\bar{\Omega}_T)$ as before and let $(x_i,t_i) \in \Omega_T \bigcup(\Omega \times \{T\})$ $(1 \le i \le m)$ be given m (different) points and also let $b_i \in \mathbb{R}, 1 \le i \le m$. We define Q as in (1.5). Then, we see that Q is a finite codimensional convex and closed subset of Z. Also, it is not hard to see that for any $\eta \in Q$ and any $\zeta \in \partial d_Q(\eta)$, we have

$$\zeta = \sum_{i=1}^{m} \lambda_i \delta_{(x_i t_i)}, \tag{5.16}$$

where $\lambda_i \in \mathbb{R}$ and $\delta_{(x_i,t_i)}$ is the Dirac measure concentrated at point (x_i,t_i) with mass 1. Thus, we see that condition (2.10) holds (in the present case, $G = I$, the identity). Hence, our result applies to this situation. Let us state the corresponding result below.

THEOREM 5.3. *Let $(\bar{y},\bar{u})$ be an optimal pair. Then, there exists a constant $\psi^0 \le 0$, a function $\psi \in L^q(0,T;W_0^{1,q}(\Omega))$ $(q < \frac{n+2}{n+1})$, and real numbers $\lambda_i, 1 \le i \le m$, such that*

$$|\psi^0| + \sum_{i=1}^{m} |\lambda_i| > 0, \tag{5.17}$$

$$\begin{cases} \psi_t + \displaystyle\sum_{i,j=1}^{n} (a_{ij}(x,t)\psi_{x_j})_{x_i} = -f_y(x,t,\bar{y}(x,t),\bar{u}(x,t))\psi \\ \qquad - \psi^0 f_y^0(x,t,\bar{y}(x,t),\bar{u}(x,t)) + \displaystyle\sum_{t_i<T} \lambda_i\delta_{(x_i,t_i)}, \qquad \textit{in } \Omega_T, \\ \psi \mid_{\partial\Omega} = 0, \\ \psi \mid_{t=T} = \displaystyle\sum_{t_i=T} \lambda_i\delta_{(x_i,t_i)}, \end{cases} \tag{5.18}$$

$$\begin{aligned} H(x,t,\bar{y}(x,t),\bar{u}(x,t),\psi^0,\psi(x,t)) &= \max_{v\in U} H(x,t,\bar{y}(x,t),v,\psi^0,\psi(x,t)), \\ &\qquad a.e.(x,t) \in \Omega \times [0,T]. \end{aligned} \tag{5.19}$$

Next, let us point out some other state constraints, which are covered by our general result.

1°. Let $Z = L^p(\Omega_T)$, $1 < p < \infty$. $F : \Omega_T \times \mathbb{R} \to \mathbb{R}$ and

$$\begin{cases} Q = \left\{ z \in L^p(\Omega_T) \mid \displaystyle\int_{\Omega_T} z(x,t)dxdt \le 0 \right\}, \\ G(\eta)(x,t) = F(x,t,\eta(x,t)), \qquad \forall \eta \in C_0(\bar{\Omega}_T). \end{cases} \tag{5.20}$$

Then, the corresponding state constraint is

$$\int_{\Omega_T} F(x,t,\eta(x,t))dxdt \le 0. \tag{5.21}$$

2°. Let $Z = L^p(\Omega_T)^m$, $1 < p < \infty$, $F_i : \Omega_T \times \mathbb{R} \to \mathbb{R}$, $1 \le i \le m$,

$$\begin{cases} Q = \left\{ z \in L^p(\Omega_T)^m \mid \int_{\Omega_T} z(x,t)dxdt = 0 \right\}, \\ G(\eta)(x,t) = (F_1(x,t,\eta(x,t)), \dots, F_m(x,t,\eta(x,t))), \qquad \forall \eta \in C_0(\bar{\Omega}_T). \end{cases} \tag{5.22}$$

Then, the state constraint is

$$\int_{\Omega_T} F_i(x,t,y(x,t))dxdt = 0, \qquad 1 \le i \le m. \tag{5.23}$$

3°. Let $Z = C_0(\bar{\Omega}_T)$, $F : \bar{\Omega}_T \times \mathbb{R} \to \mathbb{R}$ such that

$$F(x_i,t_i,y) = g_i(y), \qquad 1 \le i \le m, \tag{5.24}$$

where $(x_i,t_i) \in \Omega_T \bigcup (\Omega \times \{T\})$ are given different points. Let

$$\begin{cases} Q = \{ z \in C_0(\bar{\Omega}_T) \mid z(x_i,t_i) = b_i, \ 1 \le i \le m \}, \\ G(\eta)(x,t) = F(x,t,\eta(x,t)), \qquad \forall \eta \in C_0(\bar{\Omega}_T). \end{cases} \tag{5.25}$$

Then, the state constraint is

$$g_i(y(x_i,t_i)) = b_i, \qquad 1 \le i \le m. \tag{5.26}$$

This is a generalization of (1.6).

4°. Let $Z = C_0(\bar{\Omega}_T)$, $F : \bar{\Omega}_T \times \mathbb{R} \to \mathbb{R}$ such that (5.24) holds. Let

$$\begin{cases} Q = \{ z \in C_0(\bar{\Omega}_T) \mid z(x_i,t_i) = z(x_j,t_i), \ 1 \le i,j \le m \}, \\ G(\eta)(x,t) = F(x,t,\eta(x,t)), \qquad \forall \eta \in C_0(\bar{\Omega}_T). \end{cases} \tag{5.27}$$

Then, the state constraint is

$$g_i(y(x_i,t_i)) = g_j(y(x_j,t_j)), \qquad 1 \le i,j \le m. \tag{5.28}$$

In particular, if we take $F(x,t,y) = y$, then (5.29) means

$$y(x_i,t_i) = y(x_j,t_j), \qquad 1 \le i,j \le m. \tag{5.29}$$

Physically, this means that we want the temperatures, say, at points (x_i,t_i) to be the same.

There are many other examples, but we prefer to omit them here. We should point out that the pointwise constraint, like (1.6), is actually an approximation of the constraint, like

$$|y(x_i,t_i) - b_i| \le \varepsilon, \qquad 1 \le i \le m, \tag{5.30}$$

with $\varepsilon > 0$ being very small. Physically, this means, for example, that the temperature at point (x_i, t_i) has to be controlled near b_i with an accuracy ε.

6. Quasilinear parabolic equations. Finally, let us remark that the result extends to the quasilinear parabolic equations as those considered in [5] for elliptic cases. The Hölder estimates for the gradient (in the x direction) of the solution are required. These are available [16] when the leading coefficients are assumed to be Hölder continuous in the x direction. After a careful examination of the proof of Lemma 3.2, we conclude that a_{ij} can actually be allowed to depend on ρ.

We consider the equations

$$\begin{cases} \zeta_t - \sum\limits_{i,j=1}^{n} \left(a_{ij}^{\rho}(x,t)\zeta_{x_i}\right)_{x_j} + c_\rho(x,t)\zeta(x,t) = \left(1 - \frac{1}{\rho}\chi_{E_\rho}(x,t)\right) h(x,t), \\ \zeta = 0, \qquad (x,t) \in \partial_p \Omega_T. \end{cases} \tag{6.1}$$

It is clear that the solution $\zeta = \zeta_{E_\rho}(x,t)$ is uniquely determined by the choice of the coefficients a_{ij}^{ρ}, c_ρ and the set E_ρ. Let $K > 0$, $0 < \lambda < \Lambda$, and

$$\begin{aligned} \mathcal{K} = \Bigg\{ &(a_{ij}(x,t), c(x,t)); \ \ \|c\|_{L^\infty(\Omega_T)} \le K, \\ &\lambda|\xi|^2 \le \sum_{i,j=1}^{n} a_{ij}(x,t)\xi_i\xi_j \le \Lambda|\xi|^2, \ \forall (x,t) \in \bar{\Omega}_T, \xi \in \mathbb{R}^n \Bigg\}. \end{aligned} \tag{6.2}$$

LEMMA 6.1. *Suppose that $\frac{n+2}{2} < p < \infty$. Then, there exists $\theta \in (0,1)$ such that for each $h^0 \in L^1(\Omega_T)$, $h \in L^p(\Omega_T)$, $K > 0$, and any $\rho \in (0,1)$*

$$\begin{aligned} \inf_{E_\rho \in \mathcal{E}_\rho} \sup_{(a_{ij}^\rho, c_\rho) \in \mathcal{K}} \Bigg\{ &\left| \int_0^T \int_\Omega \left(1 - \frac{1}{\rho}\chi_{E_\rho}(x,t)\right) h^0(x,t)\,dx\,dt \right| \\ &+ \|\zeta_{E_\rho}\|_{C^{\theta,\theta/2}(\bar{\Omega}\times[0,T])} \Bigg\} = 0. \end{aligned} \tag{6.3}$$

We now consider the following parabolic equation:

$$\begin{cases} y_t - \nabla_x \left(a(x,t,\nabla_x y)\right) = f(x,t,y,u(t,x)), & \text{in } \Omega_T, \\ y \,\big|_{\partial\Omega} = 0, \\ y \,\big|_{t=0} = y_0(x), & x \in \Omega, \end{cases} \tag{6.4}$$

where a satisfies the follwoing assumption.

($\overline{\text{A1}}$) The functions $a : \bar{\Omega}_T \times \mathbb{R}^n \to \mathbb{R}^n$ and $\frac{\partial a_i}{\partial p_j} : \bar{\Omega}_T \times \mathbb{R}^n \to \mathbb{R}$ are continuous. There exist $\Lambda > \lambda > 0$, $\Lambda_1 > 0$, $\alpha \in (0,1)$, and $m > 1$ such that

$$\begin{cases} \dfrac{\partial a_i}{\partial p_j}(x,t,p)\xi_i\xi_j \ge \lambda(1+|p|)^{m-2}|\xi|^2, & \forall (x,t,p) \in \bar{\Omega} \times [0,T] \times \mathbb{R}^n, \\ \left|\dfrac{\partial a_i}{\partial p_j}(x,t,p)\right| \le \Lambda(1+|p|)^{m-2}, & \forall (x,t,p) \in \bar{\Omega} \times [0,T] \times \mathbb{R}^n, \end{cases} \tag{6.5}$$

and

$$
\begin{aligned}
(6.6)\qquad & |a(x,t,p)-a(\widetilde{x},t,p)| \le \Lambda_1(1+|p|)^{m-1}|x-\widetilde{x}|^{\alpha}, \\
& \qquad\qquad \forall (x,t),\ (\widetilde{x},t) \in \bar{\Omega}\times[0,T],\ p\in \mathbb{R}^n.
\end{aligned}
$$

Under the assumptions $(\overline{\text{A1}})$ and (A2), (6.4) has a unique solution $y(x,t)$ such that $y, y_{x_j} \in C^{\beta,\beta/m}(\bar{\Omega}_T)$ for any $y_0 \in C^{1+\alpha}(\bar{\Omega})\bigcap C_0(\bar{\Omega})$ (see [16]). The a priori estimates for y and y_{x_j} in the space $C^{\beta,\beta/m}(\bar{\Omega}_T)$ are valid uniformly for $u \in \mathcal{U}$. If $u, \widehat{u} \in \mathcal{U}$ and $y, \widehat{y}$ are the corresponding states, then by using an interpolation theorem of the $C^{k+\alpha}$ spaces, we have, for any $0<\theta<\beta$,

$$
(6.7)\qquad \|y-\widehat{y}\|_{C(\bar{\Omega}_T)} + \|\nabla_x(y-\widehat{y})\|_{C^{\theta,\theta/m}(\bar{\Omega}_T)} \to 0, \qquad \text{uniformly as } \bar{d}(u,\widehat{u}) \to 0.
$$

Lemma 6.1 and (6.7) are the essential estimates needed to establish the variation theorem similar to Theorem 3.3. We have the following lemma.

LEMMA 6.2. *The same statement of Theorem* 3.3 *is still valid for the quasilinear case, with the $a_{ij}(x,t)$ in* (3.25) *being replaced by $\bar{a}_{ij}(x,t) \equiv \frac{\partial a_i}{\partial p_j}(x,t,\nabla_x y(x,t))$.*

Sketch of Proof. The proof of Theorem 3.3 also goes through, where we shall replace $a_{ij}(x,t)$ in (3.32) with

$$
a^{\rho}_{ij}(x,t) \equiv \int_0^1 \frac{\partial a_i}{\partial p_j}(x,t,\nabla_x y(x,t) + \tau\nabla_x(y_\rho(x,t)-y(x,t))d\tau.
$$

Using (6.7), we can easily obtain

$$
(6.8)\qquad a^{\rho}_{ij} \to \bar{a}_{ij}, \qquad \text{in } C(\bar{\Omega}_T).
$$

Write $z_\rho - z \equiv (z_\rho - \widehat{z}_\rho) + (\widehat{z}_\rho - z)$, where $\widehat{z}_\rho$ satisfies the equation

$$
(6.9)\qquad \begin{cases} (\widehat{z}_\rho)_t - \displaystyle\sum_{i,j=1}^n (a^{\rho}_{ij}(x,t)(\widehat{z}_\rho)_{x_i})_{x_j} + c(x,t)\widehat{z}_\rho = h(x,t), & \text{in } \Omega_T, \\ \widehat{z}_\rho \,\big|_{\partial_p\Omega_T} = 0. \end{cases}
$$

We can treat $z_\rho - \widehat{z}_\rho$ the same way as before, apply Lemma 6.1 instead of Lemma 3.2, and then obtain

$$
(6.10)\qquad \|z_\rho - \widehat{z}_\rho\|_{C^{\theta,\theta/2}(\bar{\Omega}_T)} \to 0 \qquad \text{as } \rho \to 0,
$$

for a special choice of E_ρ with $|E_\rho| = \rho|\Omega_T|$. Clearly, by Hölder's estimates [12, Chap. III, §10], for $\widehat{\zeta}_\rho = \widehat{z}_\rho - z$,

$$
(6.11)\qquad \|\widehat{\zeta}_\rho\|_{C^{\beta,\beta/2}(\bar{\Omega}_T)} \le \|\widehat{z}_\rho\|_{C^{\beta,\beta/2}(\bar{\Omega}_T)} + \|z\|_{C^{\beta,\beta/2}(\bar{\Omega}_T)} \le C,
$$

and $\widehat{\zeta}_\rho$ satisfies the equation

$$
(6.12)\qquad \begin{cases} (\widehat{\zeta}_\rho)_t - \displaystyle\sum_{i,j=1}^n \Big(a^{\rho}_{ij}(x,t)(\widehat{\zeta}_\rho)_{x_i}\Big)_{x_j} + c(x,t)\widehat{\zeta}_\rho \\ \qquad = \Big([a^{\rho}_{ij}(x,t) - \bar{a}_{ij}(x,t)]z_{x_i}(x,t)\Big)_{x_j}, \\ \widehat{\zeta}_\rho \,\big|_{\partial_p\Omega_T} = 0. \end{cases}
$$

Multiplying the above equation with $\widehat{\zeta}_\rho$ and integrating over Ω_T give us the usual energy estimates:

$$\begin{aligned}\|\widehat{\zeta}_\rho\|_{L^2(\Omega_T)} &\le \|\nabla_x\widehat{\zeta}_\rho\|_{L^2(\Omega_T)}\\ &\le C\|a^\rho_{ij}-\bar{a}_{ij}\|_{C(\bar{\Omega}_T)}\|\nabla_x z\|_{L^2(\Omega_T)} \to 0, \qquad \text{as } \rho\to 0,\end{aligned} \tag{6.13}$$

where we have used the fact that $\|\nabla_x z\|_{L^2(\Omega_T)} \le C$, which is an easy consequence of the energy estimates for the solution $z(x,t)$.

Using the interpolation (Lemma 3.4) and the estimates (6.11) and (6.13), we immediately obtain, for any $0<\theta<\beta$,

$$\|\widehat{z}_\rho - z\|_{C^{\theta,\theta/2}(\bar{\Omega}_T)} = \|\widehat{\zeta}_\rho\|_{C^{\theta,\theta/2}(\bar{\Omega}_T)} \to 0, \qquad \text{as } \rho\to 0. \tag{6.14}$$

Combining (6.10) and (6.14), we get a variation theorem like Theorem 3.3. □

Therefore, with the same argument as in §4 (where we used (6.7) for the convergence of the leading coefficients), we have the following maximum principle.

THEOREM 6.3. *Consider the same problem except that the governing equation* (1.1) *is replaced by* (6.4). *Let* $(\overline{A1})$, $(A2)$, *and* $(A3)$ *be in force. Suppose that* $y_0 \in C^{1+\alpha}(\bar{\Omega})\bigcap C_0(\bar{\Omega})$ *and that* (2.10) *holds. Let* $(\bar{y},\bar{u})$ *be an optimal pair of Problem C corresponding to the state equation* (6.4). *Then, there exists a constant* $\psi^0 \le 0$, *a function* $\psi \in L^q(0,T;W^{1,q}_0(\Omega))$ $(1<q<\frac{n+2}{n+1})$, *and a* $\varphi \in \partial d_Q(G(\bar{y})) \subset Z^*$, *such that*

$$|\psi^0| + \|\varphi\|_{Z^*} > 0, \tag{6.15}$$

$$\begin{cases}\psi_t + \displaystyle\sum_{i,j=1}^n \left(\frac{\partial a_i}{\partial p_j}(x,t,\nabla_x\bar{y}(x,t))\psi_{x_j}\right)_{x_i} = -f_y(x,t,\bar{y}(x,t),\bar{u}(x,t))\psi \\ \qquad - \psi^0 f^0_y(x,t,\bar{y}(x,t),\bar{u}(x,t)) + (G'(\bar{y})^*\varphi)\big|_{\Omega_T}, \qquad \text{in } \Omega_T,\\ \psi\,\big|_{\partial\Omega} = 0,\\ \psi\,\big|_{t=T} = (G'(\bar{y})^*\varphi)\big|_{\Omega\times\{T\}},\end{cases} \tag{6.16}$$

$$\langle z - G(\bar{y}), \varphi\rangle \le 0, \qquad \forall z \in Q. \tag{6.17}$$

$$\begin{aligned}H(x,t,\bar{y}(x,t),\bar{u}(x,t),\psi^0,\psi(x,t)) &= \max_{v\in U} H(x,t,\bar{y}(x,t),v,\psi^0,\psi(x,t)),\\ &\qquad a.e.\ (x,t)\in\Omega\times[0,T],\end{aligned} \tag{6.18}$$

where

$$\begin{aligned}H(x,t,y,u,\psi^0,\psi) &= \psi^0 f^0(x,t,y,u) + \psi f(x,t,y,u),\\ &\qquad \forall (x,t,y,u,\psi^0,\psi)\in\Omega\times[0,T]\times\mathbb{R}\times U\times\mathbb{R}\times\mathbb{R}.\end{aligned} \tag{6.19}$$

Remark 6.4. The semilinear case is not a special case of the quasilinear case, since the Hölder continuity of a_{ij} (in the x direction) is not assumed in the semilinear case.

Acknowledgment. The authors thank Dr. Hong-Ming Yin for a stimulating discussion on this problem.

RISK-SENSITIVE CONTROL ON AN INFINITE TIME HORIZON*

WENDELL H. FLEMING† AND WILLIAM M. McENEANEY‡

Abstract. Stochastic control problems on an infinite time horizon with exponential cost criteria are considered. The Donsker–Varadhan large deviation rate is used as a criterion to be optimized. The optimum rate is characterized as the value of an associated stochastic differential game, with an ergodic (expected average cost per unit time) cost criterion. If we take a small-noise limit, a deterministic differential game with average cost per unit time cost criterion is obtained. This differential game is related to robust control of nonlinear systems.

Key words. risk-sensitive control, H^∞ control, differential games, viscosity solutions, Hamilton–Jacobi equations, Isaacs equations

1. Introduction.

There are various approaches to treating disturbances in control systems. In stochastic control, disturbances are modelled as stochastic processes (random noise). On the other hand, in robust control theory, disturbances are modelled deterministically. The theory of risk-sensitive optimal control provides a link between stochastic and deterministic approaches.

For linear systems with quadratic cost criteria, H^∞-optimization provides a method for robust control design. The disturbance attenuation problem is one of those considered in robust H^∞-control theory. If a state space formulation is used, an associated "soft constrained" differential game arises naturally; see Basar and Bernhard [2]. The stochastic control counterpart is a linear exponential quadratic regulator (LEQR) problem, introduced by Jacobson [24]. This analysis of the LEQR problem leads to the same differential game. Glover and Doyle [20] gave a further connection between the LEQR problem and H^∞-control via a minimum entropy principle.

An interesting question is to find, for nonlinear systems or nonquadratic cost criteria, similar connections between stochastic and robust control approaches to disturbance attenuation problems. Whittle [40], [41] introduced an interesting approach to this question, using large-deviations ideas. Whittle considered problems on a finite-time horizon $0 \leq t \leq T$ and used Freidlin–Wentzell-type "small-noise" asymptotics. In [11] and [25] Whittle's formula for the optimal large-deviations rate was obtained using partial differential equation (PDE)–viscosity solution methods in a special case when the process being controlled is governed by a stochastic differential equation (SDE).

In this paper we are concerned with infinite-horizon risk-sensitive control problems with state-feedback control laws (the "complete state information case.") For these problems a different kind of large-deviations principle, of Donsker–Varadhan type, is needed. Runolfsson [32], [33] used Donsker–Varadhan-type large-deviations ideas to obtain a corresponding stochastic differential game for which the game payoff is an ergodic (expected average cost per unit time) criterion.

‡ Department of Mathematics, Carnegie Mellon University, Pittsburgh, Pennsylvania 15213.

As outlined in [12], we approach these problems with different methods. To illustrate the ideas we will consider the following "model problem." Let x_t and u_t denote respectively the state and control at time $t \geq 0$, with $x_t \in I\!R^n, u_t \in U$. ($U$ is the control space.) The state dynamics are

$$dx_t = f(x_t, u_t)dt + \left(\frac{\epsilon}{2\gamma^2}\right)^{\frac{1}{2}} db_t, \tag{1.1}$$

with initial state $x_0 = x$, where $b_.$ is an n-dimensional Brownian motion. Here γ is a given constant and ϵ is a parameter related to the noise intensity. As a criterion to be minimized we take a long run expected rate of exponential growth criterion:

$$\lambda^\epsilon = \epsilon \lim_{T\to\infty} \frac{1}{T} \log E_x \exp\left[\epsilon^{-1}\int_0^T L(x_t, u_t)dt\right], \tag{1.2}$$

where $L \geq 0$. Further assumptions on f, L, and U will be stated later (see (7.1), (7.2)). The risk-sensitive stochastic control problem is to minimize λ^ϵ among all U-valued progressively measurable control processes $u_.$.

To postpone discussions involving stochastic differential games, we begin in §§2–5 with the conceptually simpler situation when the control u_t is absent. For the model corresponding to (1.1)–(1.2), x_t is then a Markov diffusion process satisfying an SDE

$$dx_t = g(x_t)dt + \left(\frac{\epsilon}{2\gamma^2}\right)^{\frac{1}{2}} db_t, \tag{1.3}$$

and the long run expected rate of growth is

$$\lambda^\epsilon = \epsilon \lim_{T\to\infty} \frac{1}{T} \log E_x \exp\left[\epsilon^{-1}\int_0^T \ell(x_t)dt\right]. \tag{1.4}$$

The functions g and ℓ are assumed to satisfy assumptions (3.1). For given $\epsilon > 0$, formula (1.4) is just a particular case of a Donsker–Varadhan large-deviations formula. We wish to give a stochastic control interpretation of λ^ϵ and afterward (§5) take a deterministic limit as $\epsilon \longrightarrow 0$.

If the expectation in (1.4) is denoted by $\phi^\epsilon(T, x)$, then ϕ^ϵ satisfies a PDE of parabolic type related to this expectation via the Feynman–Kac formula. If one formally writes for large T that $\phi^\epsilon \sim \exp[\epsilon^{-1}(\lambda^\epsilon T + W^\epsilon(x))]$, then $\lambda^\epsilon, W^\epsilon(x)$ satisfy formally the dynamic programming equation for a stochastic control problem with expected average cost per unit time criterion. This formalism is explained in §2. Then the model (1.3)–(1.4) is treated rigorously in §§3 and 4. A stochastic control interpretation of λ^ϵ was first given by Holland [21] in a slightly different formulation. The assumptions (3.1) on g and ℓ are stronger than necessary in order to obtain the Donsker–Varadhan formula (1.4). However, they are used to obtain the "cost potential" function $W^\epsilon(x)$ and also in passing to the deterministic limit in §5. Bounds are obtained for λ^ϵ and $|\nabla W^\epsilon|$ which do not depend on ϵ. In the limit, λ^0 and $W^0(x)$ are obtained, with W^0 a viscosity solution of the first-order PDE (5.3) which is the dynamic programming equation for a deterministic average cost per unit time control problem. For applications to robust nonlinear control, a key question is whether $\lambda^0 = 0$ or $\lambda^0 > 0$. If $\lambda_0 = 0$, then a dissipation inequality which is familiar in robust control holds. See (5.15).

In §§6 and 7 we return to considering risk-sensitive stochastic control problems, with the goal of finding a control which minimizes the long-term growth rate λ^ϵ in (1.2). If the control enters (1.1) via a stationary Markov control policy $\underline{u}(x)$, namely, $u_t = \underline{u}(x_t)$, then (1.1)–(1.2) correspond to (1.3)–(1.4) with

$$g(x) = f(x, \underline{u}(x)),\ \ell(x) = L(x, \underline{u}(x)).$$

The corresponding growth rate $\lambda^\epsilon = \lambda^\epsilon(\underline{u})$ depends on the control policy $\underline{u}$. One would like to find a policy $\underline{u}^*$ which minimizes $\lambda^\epsilon(\underline{u})$. In §6 we describe a formalism by which dynamic programming leads to a kind of nonlinear eigenvalue problem for a pair Λ^ϵ, Ψ^ϵ. See (6.3). By making a logarithmic transformation of the positive eigenfunction Ψ^ϵ, equation (6.3) becomes the Isaacs equation (6.10) for a stochastic differential game with an expected average cost per unit time payoff criterion. The number Λ^ϵ has two interpretations: first as the optimal growth rate and second as the value of the stochastic differential game. These results are treated rigorously in §7, for the model problem (1.1)–(1.2). In §8, we consider the deterministic limit $\epsilon \to 0$. As $\epsilon \to 0$, Λ^ϵ tends to a limit Λ^0, which is the value of the corresponding deterministic differential game. Connections with nonlinear robust control are also discussed in §§5 and 8.

Recently Dupuis and Ellis [7] introduced a different technique, based on stochastic control ideas, which is applicable to a wide variety of large-deviations problems.

We consider only risk-sensitive control problems with complete state information in which the current state of the process being controlled is known. For problems with partial state information see [26], [33], [39], [41] and references cited there.

2. Logarithmic transformations and exponential growth. In this section we recall a large-deviations formula (2.1) of Donsker and Varadhan [6] and reformulate it in terms of a stochastic control interpretation. The discussion in the present section is formal, without proofs. In §§3 and 4 we will put things on a rigorous basis in a particular case of interest for disturbance attenuation control problems.

Let x_t be a time-homogeneous Markov process with state space Σ. Thus $x_t \in \Sigma$ for $t \geq 0$. Let ℓ be a bounded, continuous function on Σ, and $\epsilon > 0$ a parameter. Under suitable assumptions on x_t, the following limit exists:

$$\lambda = \epsilon \lim_{T\to\infty} \frac{1}{T} \log E_x \exp\left[\epsilon^{-1} \int_0^T \ell(x_t)dt\right], \tag{2.1}$$

where the subscript x indicates the initial state $x_0 = x$. Among the assumptions a sufficiently strong kind of ergodicity is needed. Moreover, one anticipates that $\epsilon^{-1}\lambda$ can be interpreted as the dominant eigenvalue of the linear operator $G + \epsilon^{-1}\ell$, where G is the generator of the Markov process x_t. See [6, part I] in case Σ is compact and [6, part III] for noncompact Σ. Moreover, considered as a function of ℓ, $\epsilon^{-1}\lambda(\ell)$ is dual (in the sense of convex duality) to the Donsker–Varadhan entropy function $I(\mu)$. This viewpoint is well developed in Stroock [36].

Let

$$\phi(T, x) = E_x \exp\left[\epsilon^{-1} \int_0^T \ell(x_t)dt\right]. \tag{2.2}$$

Then (2.1) implies that $\phi(T, x)$ grows exponentially at rate $\epsilon^{-1}\lambda$ as $T \to \infty$. To obtain heuristically the eigenvalue interpretation of $\epsilon^{-1}\lambda$, we proceed formally as follows. Under suitable assumptions, ϕ satisfies the linear evolution equation

$$\frac{\partial \phi}{\partial T} = G_x \phi + \epsilon^{-1} \ell(x) \phi, \tag{2.3}$$

where $G_x \phi = G\phi(T, \cdot)$. If we formally separate variables, namely,

$$\phi \sim \exp(\epsilon^{-1} \lambda T) \psi(x),$$

then ψ should be a positive eigenfunction corresponding to the dominant eigenvalue $\epsilon^{-1}\lambda$:

$$\epsilon^{-1} \lambda \psi = G\psi + \epsilon^{-1} \ell \psi. \tag{2.4}$$

The Donsker–Varadhan formula (2.1) involves λ but not the eigenfunction ψ. Extra assumptions are generally needed to ensure that ψ exists. However, for compact state space Σ, the eigenfunction ψ exists under the original assumptions in [6, part I]. See Fleming, Sheu, and Soner [14, §4]. The eigenfunction ψ, or more precisely its log transform $W = \epsilon \log \psi$, plays an essential role for the stochastic control interpretation which we use.

In §5, we will let x_t depend on the parameter ϵ in such a way that x_t is nearly deterministic for small ϵ. Thus $G = G^\epsilon, \lambda = \lambda^\epsilon$. The scaling is such that λ^ϵ tends to a limit λ^0 as $\epsilon \to 0$.

Logarithmic transformations. Let $W = \epsilon \log \psi$. Then (2.4) is changed into a nonlinear equation

$$\lambda = \mathcal{H}(W) + \ell, \quad \text{where} \tag{2.5}$$

$$\mathcal{H}(W) = \epsilon \exp(-\epsilon^{-1} W) G[\exp(\epsilon^{-1} W)].$$

For a broad class of generators G, (2.5) has an interpretation as the dynamic programming equation for a stochastic control problem with average cost per unit time cost criterion. Then λ is the optimal expected average cost per unit time, and $W(x)$ is an associated cost potential function. Heuristically, $\epsilon \log \phi(x,T) \approx \lambda T + W(x)$ for large T.

In the stochastic control problem arising from the logarithmic transformation, we will denote by ξ_t the state of the process being controlled and by v_t the control acting at time t. The goal is to find a control process $v_{\cdot}$ which maximizes an average cost per unit time criterion

$$J = \limsup_{T \to \infty} \frac{1}{T} E_x \int_0^T k(\xi_t, v_t) dt, \tag{2.6}$$

where k is a suitably chosen "running cost" function. We will describe the choice of k and the state dynamics for ξ_t only for nondegenerate diffusions in $\mathbb{R}^n$. For other classes of processes (for example, Markov chains or jump Markov processes) see [15, Chaps. 3 and 6] and Sheu [34].

Consider a Markov diffusion x_t with generator G of the following form. Sufficiently strong ergodicity properties will be needed in order for the results outlined formally above to hold.

For $\psi \in C^2(I\!R^n), x = (x_1, \dots, x_n)$, let

$$G\psi(x) = \frac{\epsilon}{2} \sum_{i,j=1}^{n} a_{ij}(x)\psi_{x_i x_j}(x) + g(x) \cdot \nabla\psi(x).$$

In this case

$$\mathcal{H}(W) = GW + \frac{1}{2}a(x)\nabla W \cdot \nabla W,$$

where for any vector $p = (p_1, \dots, p_n)$

$$ap \cdot p = \sum_{i,j=1}^{n} a_{ij} p_i p_j.$$

If the symmetric matrices $a(x) = (a_{ij}(x))$ are positive definite, then

$$\frac{1}{2}ap \cdot p = \max_{v} \left[-\frac{a^{-1}v \cdot v}{2} + v \cdot p \right], \tag{2.7}$$

where the maximum is taken over $\mathcal{V} = I\!R^n$. In this case, (2.5) takes the form

$$\begin{aligned} \lambda &= \frac{\epsilon}{2} \sum_{i,j=1}^{n} a_{ij}(x) W_{x_i x_j} \\ &+ \max_{v}[(g(x) + v) \cdot \nabla W + k(x, v)], \end{aligned} \tag{2.8}$$

where the running cost function is

$$k(x, v) = \ell(x) - \frac{1}{2}a^{-1}(x)v \cdot v. \tag{2.9}$$

If $a(x) = \sigma(x)\sigma^{'}(x)$, then the dynamics of the controlled Markov process ξ_t are governed by the Ito-sense SDE

$$d\xi_t = [g(\xi_t) + v_t]dt + \epsilon^{\frac{1}{2}}\sigma(\xi_t)dw_t, \tag{2.10}$$

with w_t a Brownian motion. We admit any bounded, progressively measurable control process $v_.$, associated with some reference probability system [15, p. 160]. If the control is feedback via a Markov control policy $\underline{v}$ ($v_t = \underline{v}(\xi_t)$), then under suitable technical assumptions on $\underline{v}$ the process ξ_t is Markov. We anticipate that an optimal Markov control policy $\underline{v}^*$ can be found by taking arg max in (2.8), namely, $\underline{v}^* = a\nabla W$.

For the class of problems to be considered in §§3–5, we take $a = (2\gamma^2)^{-1}I$, with $\gamma > 0$ a constant and I the identity matrix. The "drift" coefficient $g(x)$ satisfies assumption (3.1) which ensures a sufficiently strong form of ergodicity of the Markov diffusion x_t needed for the analysis.

3. Ergodic stochastic control problem. In this section and §4 we will put the formalism in §2 on a rigorous basis in the following special case. In (2.8) we take the matrix $a = (a_{ij})$ to be constant and positive definite. By a linear change of coordinates in $I\!R^n$, we may then assume that $a = (2\gamma^2)^{-1}I$, where I is the identity matrix and $\gamma > 0$ is a constant which has a prominent role in robust, deterministic control theory (§5). Assume that $\ell \in C^1(I\!\!R^n), g \in C^1(I\!\!R^n)$. Let g_x denote the matrix of partial derivatives of g. Additionally we assume the following.

$$\text{(3.1)}\qquad \begin{array}{ll} \text{(a)} & \ell,\ \nabla\ell \text{ are bounded and } \ell \geq 0; \\ \text{(b)} & g_x \text{ is bounded;} \\ \text{(c)} & \text{there exists } c > 0 \text{ such that, for all } x, y \in I\!\!R^n, \\ & (x-y)\cdot[g(x)-g(y)] \leq -c|x-y|^2. \end{array}$$

These assumptions are considerably stronger than what is needed to prove the results that follow. However, these strong assumptions will make the proofs much less technical. Proofs of similar results under weaker assumptions can be found in McEneaney [30]. In (3.1a), the assumption that ℓ is bounded can be omitted. See Remark 4.4 below. The assumption that $\nabla\ell$ is bounded allows linear growth of $\ell(x)$ as $|x| \to \infty$ but not quadratic growth. Some issues concerning quadratically growing $\ell(x)$ are discussed at the end of §5. Assumption (3.1b) can be replaced by a weaker assumption, involving one-sided bounds [30]. However, assumption (3.1c) plays a crucial role in the proof of Theorem 3.3 and in passage to a deterministic limit in §5. By the mean value theorem, (3.1c) has the equivalent form

$$\text{(3.2)}\qquad z \cdot g_x(x) z \leq -c|z|^2 \text{ for all } x, z \in I\!\!R^n.$$

For the results of the present section to hold, it may suffice to require (3.2) only for x outside some bounded set. See Remark 4.5. However, to obtain the dissipation inequality (5.15) of deterministic robust control theory, we need (3.2) for all $x \in I\!\!R^n$.

We consider the Markov diffusion process x_t governed by the SDE

$$\text{(3.3)}\qquad dx_t = g(x_t)dt + \left(\frac{\epsilon}{2\gamma^2}\right)^{\frac{1}{2}} db_t, \qquad t \geq 0,$$

with the initial data

$$\text{(3.4)}\qquad x_0 = x.$$

This SDE has a strong (pathwise) solution for any reference probability system [28] $\nu = (\Omega, \{\mathcal{F}_t\}, P, b_.)$, where Ω is a sample space, $\{\mathcal{F}_t\}$ a filtration, P a probability measure, and $b_.$ a P-Brownian motion adapted to $\{\mathcal{F}_t\}$. The generator G of x_t is

$$\text{(3.5)}\qquad G\psi = \frac{\epsilon}{4\gamma^2}\Delta\psi + g \cdot \nabla\psi.$$

Assumptions (3.1b) and (3.1c) imply that x_t is ergodic. More than that, we will show that they insure that the Donsker–Varadhan large-deviations formula (2.1) holds and that the positive eigenfunction ψ in (2.4) exists.

Let us now introduce controlled processes ξ_t, already discussed in an imprecise way in §2. Let $\mu = (\Omega, \{\mathcal{F}_t\}, P, w_.)$ be some reference probability system, which may or may not be the same as the reference probability system ν for (3.3). We admit as control processes all $I\!\!R^n$-valued $\mathcal{F}_t$-progressively measurable processes $v_.$ such that v_t is bounded. Let $\mathcal{W}_M$ denote the set of all such $v_.$ for which $|v_t| \leq M$ for all $t \geq 0$. Of course, $\mathcal{W}_M$ depends on μ but our notation does not make this explicit. Then

$$\mathcal{W} = \bigcup_{M>0} \mathcal{W}_M$$

is the set of all admissible control processes. Given $v_{.}$, let ξ_t be the solution to

$$d\xi_t = [g(\xi_t) + v_t]dt + \left(\frac{\epsilon}{2\gamma^2}\right)^{\frac{1}{2}} dw_t \tag{3.6}$$

with $\xi_0 = x$. The goal is to choose $v_{.} \in \mathcal{W}$ to maximize the criterion J in (2.6).

LEMMA 3.1. *Let $F(x) = \exp[K\sqrt{1+|x|^2}]$, where $K > 0$ is any constant. Then there exists C_1 (depending on x and previously introduced constants) such that*

$$E_x F(\xi_t) \le C_1 \text{ for all } t < \infty.$$

The proof is rather standard and is postponed to Appendix A.

Remark 3.2. Comparing (3.3) and (3.6), we see that we also have $E_x F(x_t) \le C_1$ for all $t < \infty$. Furthermore, this bound implies a bound for all moments of ξ_t and x_t for all $t < \infty$.

We proceed to state the main results of this section. The dynamic programming equation (2.5) now takes the form

$$\lambda = \frac{\epsilon}{4\gamma^2}\Delta W + g(x)\cdot\nabla W + \frac{1}{4\gamma^2}|\nabla W|^2 + \ell(x), \tag{3.7}$$

or equivalently (see (2.8)–(2.9))

$$\lambda = \frac{\epsilon}{4\gamma^2}\Delta W + \max_{v\in I\!R^n}[(g(x)+v)\cdot\nabla W + k(x,v)], \tag{3.7$'$}$$

where

$$k(x,v) = \ell(x) - \gamma^2|v|^2. \tag{3.8}$$

Let $\|\cdot\|$ denote the sup norm.

THEOREM 3.3. *There exist $\lambda \in I\!R$, $W \in C^2(I\!R^n)$ such that (3.7) holds. Moreover, there exists B (not depending on ϵ) such that $|\nabla W| \le B$ and $0 \le \lambda \le \|\ell\|$.*

This theorem is similar to one by Bensoussan [3, Thm. 7.1]. Unfortunately, the presence of the (maximizing) controller taking values in all of $\mathcal{R}^n$ and the unbounded cost (at least in the control but also possibly in the state as in Remark 4.4) prevents a direct application of the Bensoussan result. The addition of a second (minimizing) controller in §§6–8 will further complicate matters.

The proof will give $B = c^{-1}\|\nabla\ell\|$, with c the constant in assumption (3.1c). We postpone the proof of Theorem 3.3 to §4. In (2.6) let us write $J = J(x, v_{.})$ to indicate dependence on the initial state x and the control process $v_{.}$. The maximum in (3.7$'$) is attained at $\underline{v}^*(x) = (2\gamma^2)^{-1}\nabla W(x)$. This gives an optimal Markov control policy for the control problem with the average cost per unit time criterion J, as is seen by the following corollary to Theorem 3.3. Define ξ_t^* as the solution to

$$d\xi_t^* = [g(\xi_t^*) + \underline{v}^*(\xi_t^*)]dt + \left(\frac{\epsilon}{2\gamma^2}\right)^{\frac{1}{2}} dw_t$$

with $\xi_0^* = x$. The control process $v_{.}^*$ defined by

$$v_t^* = \underline{v}^*(\xi_t^*) = (2\gamma^2)^{-1}\nabla W(\xi_t^*)$$

belongs to $\mathcal{W}$ since ∇W is bounded.

COROLLARY 3.4 (a) $J(x, v_.) \le \lambda$ *for all* $x \in I\!\!R^n$, $v_. \in \mathcal{W}$.

(b) $J(x, v_.^*) = \lambda$ *for all* $x \in I\!\!R^n$.

Proof of (a). We apply Ito's rule to obtain

$$E_x W(\xi_T) = W(x) + E_x \int_0^T \left\{ [g(\xi_t) + v_t] \cdot \nabla W(\xi_t) + \frac{\epsilon}{4\gamma^2} \Delta W(\xi_t) \right\} dt.$$

Note that since $\ell(x)$ and $\nabla W(x)$ are bounded, $|\Delta W(x)|$ grows at most linearly with $|x|$ as $|x| \to \infty$, by (3.1b) and (3.7). Therefore, by (3.7′)

$$E_x W(\xi_T) \le W(x) - E_x \int_0^T k(\xi_t, v_t) dt + \lambda T, \tag{3.9}$$

which yields

$$\lambda \ge J(x, v_.) + \limsup_{T \to \infty} \left[\frac{E_x W(\xi_T) - W(x)}{T} \right]. \tag{3.10}$$

Since ∇W is bounded,

$$|W(\xi_T)| \le k_1 |\xi_T| + k_2$$

for suitable k_1, k_2. Since $E_x |\xi_T|$ is bounded, by Remark 3.2, the last term on the right side of (3.10) is 0. This proves (a).

Proof of (b). In (3.9) equality now holds when $v_. = v_.^*$, $\xi_. = \xi_.^*$. We repeat the argument for part (a). □

Without referring to the controlled process ξ_t, we also obtain from Theorem 3.3 that λ is the Donsker–Varadhan large-deviations rate in formula (2.1). Also note that the function $\psi = \exp(\epsilon^{-1} W)$ satisfies the eigenfunction equation (2.4), with generator G as in (3.5).

THEOREM 3.5. *If* λ, W *are as in Theorem* 3.3, *then*

$$\lambda = \lim_{T \to \infty} \frac{\epsilon}{T} \log E_x \exp \left[\frac{1}{\epsilon} \int_0^T \ell(x_t) dt \right].$$

Proof. Let $\nu = (\Omega, \{\mathcal{F}_t\}, P, b_.)$ be a reference probability system, and let $x_.$ be the corresponding solution to (3.3)–(3.4). Let $v_t = (2\gamma^2)^{-1} \nabla W(x_t)$, which is $\mathcal{F}_t$-progressively measurable and bounded since ∇W is bounded. From (3.3)–(3.4)

$$\begin{aligned} x_t &= x + \int_0^t [g(x_r) + v_r] dr + \left(\frac{\epsilon}{2\gamma^2} \right)^{\frac{1}{2}} b_t - \int_0^t v_r dr \\ &= x + \int_0^t [g(x_r) + v_r] dr + \left(\frac{\epsilon}{2\gamma^2} \right)^{\frac{1}{2}} b_t^0, \end{aligned} \tag{3.11}$$

which defines b^0.

Since $v_\cdot$ is bounded, we may use Girsanov's theorem [27] to obtain a probability measure P^0 under which $b^0_\cdot$ is a Brownian motion. In fact,

$$\begin{aligned} P^0(d\omega) &= \exp\left[\sqrt{\frac{2\gamma^2}{\epsilon}}\int_0^t v_r \cdot db_r - \frac{\gamma^2}{\epsilon}\int_0^t |v_r|^2 dr\right] P(d\omega) \\ &= \exp\left[\sqrt{\frac{2\gamma^2}{\epsilon}}\int_0^t v_r \cdot db^0_r + \frac{\gamma^2}{\epsilon}\int_0^t |v_r|^2 dr\right] P(d\omega). \end{aligned}$$

Under this change of measure

$$\begin{aligned} E_x \exp\left[\frac{1}{\epsilon}\int_0^T \ell(x_t)dt\right] = E^0_x \exp\Biggl\{\frac{1}{\epsilon}\biggl[\int_0^T (\ell(x_t) - \gamma^2|v_t|^2)dt \\ - \sqrt{2\gamma^2\epsilon}\int_0^T v_t \cdot db^0_t\biggr]\Biggr\}, \end{aligned} \tag{3.12}$$

where E^0_x indicates expectation with respect to P^0.

On the other hand, by (3.7), (3.11), the definition of v_t, and Ito's rule

$$\begin{aligned} W(x_T) - W(x) = \int_0^T [\lambda - \ell(x_t) + \gamma^2|v_t|^2]dt \\ + \sqrt{2\gamma^2\epsilon}\int_0^T v_t \cdot db^0_t. \end{aligned} \tag{3.13}$$

Combining (3.12) and (3.13) yields

$$E_x \exp\left[\frac{1}{\epsilon}\int_0^T \ell(x_t)dt\right] = \exp\left[\frac{\lambda T + W(x)}{\epsilon}\right] E^0_x \exp\left[\frac{-W(x_T)}{\epsilon}\right],$$

which implies

$$\lim_{T\to\infty} \frac{\epsilon}{T}\log E_x \exp\left[\frac{1}{\epsilon}\int_0^T \ell(x_t)dt\right] = \lambda + \lim_{T\to\infty}\frac{\epsilon}{T}\log E^0_x \exp\left[\frac{-W(x_T)}{\epsilon}\right] \tag{3.14}$$

(where we anticipate the existence of the limit which follows below).

Now note that by assumption, there exists $K < \infty$ such that

$$-K\sqrt{1+|z|^2} \le \frac{-W(z)}{\epsilon} \le K\sqrt{1+|z|^2} \quad \forall z \in I\!R^n.$$

(The constant K depends on ϵ, which is fixed throughout this section.)

By Lemma 3.1 and Jensen's inequality $(E^0(Z^{-1}) \ge (E^0 Z)^{-1})$ this implies that there exists $C_1 < \infty$ such that

$$\frac{1}{C_1} \le E^0_x \exp\left[\frac{-W(x_T)}{\epsilon}\right] \le C_1 \quad \text{for all } T < \infty.$$

Employing this in (3.15) yields the result. □

4. Proof of Theorem 3.3. In this section we prove existence of $\lambda, W(x)$ satisfying the dynamic programming PDE for the average cost per unit time control problem governed by (3.6) with running cost function (3.8). This is done by a rather standard technique. We consider the corresponding infinite-horizon discounted-cost problem, with small discount factor $\rho > 0$. Let $W_\rho(x)$ be the value function for this problem. Once an a priori bound for $\nabla W_\rho(x)$ is found, Theorem 3.3 is obtained by letting $\rho \to 0$ and using standard estimates for elliptic PDEs.

We begin by considering finite-horizon discounted-cost problems. Let

$$J_\rho(T,x;v_.) = E_x \int_0^T e^{-\rho t} k(\xi_t, v_t)dt, \tag{4.1}$$

where ξ_t is the solution to (3.6) with $\xi_0 = x$.

LEMMA 4.1. *For every $T > 0, x, y \in I\!R^n$, and $v_. \in \mathcal{W}$*

(a) $\rho J_\rho(T,x;v_.) \leq \|\ell\|$,

(b) $|J_\rho(T,x;v_.) - J_\rho(T,y;v_.)| \leq \frac{\|\nabla \ell\|}{\rho + c}$.

Proof. Part (a) is immediate from (4.1). To prove (b), let $\xi^x_.$ and $\xi^y_.$ denote the solutions to (3.6) with initial data $\xi^x_0 = x$, $\xi^y_0 = y$. By applying Ito's rule to $|\xi^x_t - \xi^y_t|^2$, one easily obtains, using (3.1c),

$$|\xi^x_t - \xi^y_t|^2 \leq |x-y|^2 - 2c\int_0^t |\xi^x_s - \xi^y_s|^2 ds.$$

Gronwall's inequality gives

$$|\xi^x_t - \xi^y_t|^2 \leq e^{-2ct}|x-y|^2.$$

Since

$$|J_\rho(T,x;v_.) - J_\rho(T,y;v_.)| \leq \|\nabla \ell\| E_x \int_0^T e^{-\rho t}|\xi^x_t - \xi^y_t|dt,$$

we get part (b). □

LEMMA 4.2. *For $T^{'} > T$,*

$$|J_\rho(T^{'},x;v_.) - J_\rho(T,x;v_.)| \leq \rho^{-1}(\|\ell\| + \gamma^2\|v_.\|^2)(e^{-\rho T} - e^{-\rho T^{'}}).$$

Lemma 4.2 is immediate from (4.1). Let us fix a bound $|v_t| \leq M$ for the controls, and denote by $\mathcal{W}_M$ the corresponding class of admissible control processes. Later we will show that the choice of M is arbitrary if M is large enough (in fact, if $M \geq (2\gamma^2)^{-1}B$ with B the bound for ∇W in Theorem 3.3). Consider the value function

$$V_\rho(T,x) = \sup_{\mathcal{W}_M} J_\rho(T,x;v_.). \tag{4.2}$$

By results about parabolic PDEs and a verification theorem, V_ρ is a solution to the dynamic programming equation

$$\begin{aligned} &\frac{\partial V_\rho}{\partial T} + \rho V_\rho = \frac{\epsilon}{4\gamma^2}\Delta_x V_\rho + \max_{|v|\leq M}[(g(x)+v)\cdot \nabla_x V_\rho + k(x,v)], \\ &V_\rho(0,x) = 0. \end{aligned} \tag{4.3}$$

Moreover, V_ρ and the partial deviatives $V_{\rho T}, V_{\rho x_i}$, $V_{\rho x_i x_j}$, $i, j = 1, \ldots, n$, are continuous. See Appendix B. Since $\ell \geq 0, J_\rho(T, x; 0) \geq 0$. Hence, $V_\rho \geq 0$. Lemma 4.1 implies the estimates

$$\text{(4.4)} \qquad \begin{aligned} &\text{(a)} \quad 0 \leq \rho V_\rho \leq \|\ell\|, \\ &\text{(b)} \quad |\nabla_x V_\rho| \leq \frac{\|\nabla \ell\|}{\rho + c}. \end{aligned}$$

Lemma 4.2 implies that

$$\text{(4.5)} \qquad |V_\rho(T', x) - V_\rho(T, x)| \leq \rho^{-1}(\|\ell\| + \gamma^2 M^2)(e^{-\rho T} - e^{-\rho T'}).$$

By (4.5) the limit

$$\text{(4.6)} \qquad W_\rho(x) = \lim_{T \to \infty} V_\rho(T, x)$$

exists. Moreover, $W_\rho(x)$ is the value function for the corresponding infinite-horizon discounted control problem. From (4.4), for each $x, y \in I\!R^n$

$$\text{(4.7)} \qquad \begin{aligned} &\text{(a)} \quad 0 \leq \rho W_\rho(x) \leq \|\ell\|, \\ &\text{(b)} \quad |W_\rho(x) - W_\rho(y)| \leq \frac{\|\nabla \ell\|}{\rho + c}|x - y|. \end{aligned}$$

Since the right side of (4.7b) is less than $c^{-1}\|\nabla \ell\||x - y|$, the bounds in (4.7) do not depend on ρ. (They also do not depend on ϵ.) If in (4.5) we set $T' = T + h$ and let $h \to 0$, we obtain

$$\text{(4.8)} \qquad |(V_\rho)_T| \leq \rho^{-1}(\|\ell\| + \gamma^2 M^2)e^{-\rho T}.$$

Thus $(V_\rho)_T$ tends uniformly to 0 as $T \to \infty$. Since V_ρ satisfies the PDE (4.3), $\Delta_x V_\rho$ is also bounded uniformly on compact sets. (This bound may depend on ϵ but not on ρ.) From (4.6)–(4.8) and standard estimates for semilinear parabolic PDEs (see Appendix B) $W_\rho \in C^2(I\!R^n)$ and satisfies the steady-state form of (4.3):

$$\text{(4.9)} \qquad \begin{aligned} \rho W_\rho = &\frac{\epsilon}{4\gamma^2}\Delta W_\rho \\ &+ \max_{|v| \leq M}[(g(x) + v) \cdot \nabla W_\rho + k(x, v)]. \end{aligned}$$

Let $B = c^{-1}\|\nabla \ell\|$. By (4.7b), $|\nabla W_\rho(x)| \leq B$ for each $x \in I\!R^n$. We take $M \geq (2\gamma^2)^{-1}B$. Then the maximum in (4.9) is an interior max, achieved at $\underline{v}_\rho^*(x) = (2\gamma^2)^{-1}|\nabla W_\rho(x)|$. Thus, W_ρ satisfies the same equation as (4.9), with max over $|v| \leq M$ replaced by max over $I\!R^n$.

Proof of Theorem 3.3. Fix any "reference point" $x_0 \in I\!R^n$. By (4.7), $\rho W_\rho(x_0)$ is uniformly bounded and the functions $W_\rho(x) - W_\rho(x_0)$ are equicontinuous. If we use Ascoli's theorem there is a sequence ρ_m tending to 0 as $m \to \infty$ such $\rho_m W_{\rho_m}(x_0)$ tends to a limit λ and $W_{\rho_m}(x) - W_{\rho_m}(x_0)$ tends to a limit $W(x)$ uniformly on compact sets. We have

$$\text{(4.10)} \qquad \begin{aligned} &\text{(a)} \quad 0 \leq \lambda \leq \|\ell\|, \\ &\text{(b)} \quad |W(x) - W(y)| \leq \tfrac{\|\nabla \ell\|}{c}|x - y| \end{aligned}$$

for all $x, y \in I\!R^n$. Since $\rho_m W_{\rho_m}$ and ∇W_{ρ_m} are bounded independent of m, ΔW_{ρ_m} is also bounded on compact sets independent of m. This implies a Hölder estimate for ∇W_{ρ_m} which is uniform on compact sets. Standard arguments for elliptic PDEs [19] then give that $W \in C^2(I\!R^n)$ and that λ, W satisfy (3.7). This proves Theorem 3.3. □

Remark 4.3. According to Corollary 3.4 (or Theorem 3.5), the number λ in Theorem 3.3 is unique. We anticipate that $W(x)$ is unique up to an additive constant, i.e. that the corresponding solution $\psi = \exp(\epsilon^{-1} W)$ to equation (2.4) is unique up to a positive multiplicative constant. (This has since been proved. See [42, Thm. 3.1].)

Remark 4.4. In all of the results of §3, the assumption that $\ell(x)$ is bounded in (3.1a) can actually be omitted. The remaining assumptions in (3.1a) imply that, for suitable C,

$$0 \le \ell(x) \le C(1 + |x|).$$

The fact that there exists $K(x)$ such that $E_x|\xi_t| \le K(x)$ for any solution ξ_t of (3.6) corresponding to $v_. \in \mathcal{W}_M$ depends on assumptions (3.1b) and (3.1c). In the definition (4.1) of J_ρ let us replace ℓ by ℓ_ρ, where $\ell_\rho(x)$ is bounded:

$$\|\nabla \ell_\rho\| \le \|\nabla \ell\|,$$

$$0 \le \ell_\rho(x) \le C(1 + |x|),$$

$$\ell_\rho(x) = \ell(x) \text{ if } |x| \le \rho^{-1}.$$

In Lemma 4.1, inequality (a) is replaced by

$$\rho J_\rho(T, x; v_.) \le C(1 + K(x)),$$

and inequality (b) is unchanged. In (4.7), inequality now becomes

$$0 \le \rho W_\rho(x) \le C(1 + K(x)),$$

and inequality (b) is unchanged. The proof of Theorem 3.3 proceeds as before, with (4.10a) replaced by

$$0 \le \lambda \le C(1 + K(x_0)).$$

The proofs of Corollary 3.4 and Theorem 3.5 relied on boundedness of ∇W, which still is true without boundedness of $\ell(x)$.

Remark 4.5. The crucial step in the proof of Theorem 3.3 was to get a priori bounds for ρW_ρ and ∇W_ρ (see (4.7)). The bound $0 \le \rho W_\rho \le \|\ell\|$ was immediate. We conjecture that it suffices to assume (3.2) only outside some bounded set in order for a bound $|\nabla W_\rho| \le B$ to hold. This is seen to be correct in dimension $n = 1$ by the following argument. Assume that $g_x(x) \le -c < 0$ if $|x| \ge r$. Since $W_\rho(x)$ is bounded on $I\!R^1$ there exist sequences tending to $\pm\infty$ for which $(W_\rho)_x(x)$ tends to 0. To obtain an a priori bound for $(W_\rho)_x$ it suffices to do so at inflection points (local maxima and minima of $(W_\rho)_x$.) At an inflection point x_0 with $|x_0| \le r$, we have $(W_\rho)_{xx}(x_0) = 0$. Since

$$\rho W_\rho = \frac{\epsilon}{4\gamma^2}(W_\rho)_{xx} + g(x)(W_\rho)_x + \frac{1}{4\gamma^2}(W_\rho)_x^2 + \ell(x) \tag{4.11}$$

and ρW_ρ is bounded, the quadratic formula gives a bound $|(W_\rho)_x(x_0)| \leq B_1$. If $|x_0| > r$, we differentiate (4.11). Then $Z = (W_\rho)_x$ satisfies

$$\rho Z = \frac{\epsilon}{4\gamma^2} Z_{xx} + g_x Z + g Z_x + \frac{1}{2\gamma^2} Z Z_x + \ell_x. \tag{4.12}$$

If Z has a positive local maximum at x_0, then $Z_x(x_0) = 0$, $Z_{xx}(x_0) \leq 0$. Hence $(\rho+c)Z(x_0) \leq (\rho - g_x(x_0))Z(x_0) \leq \|\ell_x\|$. A similar estimate holds if Z has a negative local minimum at x_0. Thus

$$|(W_\rho)_x| \leq \frac{\|\ell_x\|}{\rho + c} \quad \text{if } |x| \geq r. \tag{4.13}$$

This is the same bound obtained in (4.7b). When combined with the bound above for $|x| \leq r$, we obtain $|(W_\rho)_x| \leq B$ for some B which does not depend on ρ.

5. Limiting deterministic control problem. We now let the noise intensity in (3.6) tend to 0. Thus, in (3.6) we consider $\epsilon \to 0$ with $\gamma > 0$ fixed. The formal limit of the stochastic control problem in §3 is then a deterministic problem with average cost per unit time criterion. The deterministic analogue of (3.7) is the first-order PDE (5.3), and the cost potential function $W^0(x)$ turns out to be a solution of (5.3) in the viscosity sense [4], [15].

Let us indicate the dependence of $\lambda, W(x)$ on ϵ in §§3 and 4 by relabelling them as $\lambda^\epsilon, W^\epsilon(x)$. According to (4.10)

$$0 \leq \lambda^\epsilon \leq \|\ell\|, \ |\nabla W^\epsilon(x)| \leq \frac{\|\nabla \ell\|}{c}. \tag{5.1}$$

By Ascoli's theorem, there is a sequence $\epsilon_m \to 0$ such that as $m \to \infty$

$$\lambda^{\epsilon_m} \to \lambda^0, \ W^{\epsilon_m}(x) \to W^0(x). \tag{5.2}$$

The convergence of W^{ϵ_m} is uniform on compact subsets of $I\!R^n$. It is easy to show that $W^0(x)$ is a viscosity solution to the corresponding first-order PDE

$$\lambda^0 = \max_{v \in I\!R^n} [(g(x) + v) \cdot \nabla W^0(x) + k(x,v)]. \tag{5.3}$$

See [15, Chap. 2]. Thus we have the following theorem.

THEOREM 5.1. *There exist $\lambda^0 \geq 0$ and Lipschitz continuous W^0 such that W^0 is a viscosity solution of* (5.3).

By (3.8) the PDE (5.3) can be rewritten in the form

$$\lambda^0 = g(x) \cdot \nabla W^0(x) + \frac{1}{4\gamma^2} |\nabla W^0(x)|^2 + \ell(x). \tag{5.4}$$

If B is a Lipschitz constant for W^0, then in (5.3) the max over $v \in I\!R^n$ can be replaced by the max over $|v| \leq M$, if $M \geq (2\gamma^2)^{-1}B$. For W^0 obtained as the limit of W^{ϵ_m} as above, we can take $B = c^{-1}\|\nabla \ell\|$ according to (5.1). Since W^0 is a Lipschitz continuous viscosity solution, the gradient $\nabla W^0(x)$ exists and (5.3) holds for almost all $x \in I\!R^n$ However, W^0 may not have continuous first-order partial derivatives, and thus W^0 need not be a solution to (5.3) in the classical sense. By Corollary 5.3 below, λ^0 is unique.

Let us now consider the deterministic control problem which is the formal limit of the stochastic control problem in §3 as $\epsilon \to 0$. The state dynamics are

$$\frac{d\xi_t^0}{dt} = g(\xi_t^0) + v_t \tag{5.5}$$

with $\xi_0^0 = x$. The control $v_.$ is a bounded Lebesgue-measurable function of $[0, \infty)$, such that $|v_t| \leq M$ for some fixed (sufficiently large) M. As in the discussion above, we require that $M \geq (2\gamma^2)^{-1}B$, with B a Lipschitz constant for W^0. Let $\mathcal{W}_M^0$ denote the set of all such admissible deterministic control functions $v_.$. The running cost function is $k(x, v)$ given by (3.8).

THEOREM 5.2. *If W^0 is a Lipschitz continuous solution to* (5.3), *then for every* $T < \infty$

$$W^0(x) = \sup_{v_. \in \mathcal{W}_M^0} \left[\int_0^T k(\xi_t^0, v_t)dt + W^0(\xi_T^0) \right] - \lambda^0 T. \tag{5.6}$$

Proof. Denote the right side by $\tilde{W}(T, x)$. Then $\tilde{W}$ is the value function of the finite-time-horizon control problem on $0 \leq t \leq T$, with running cost function $k - \lambda^0$ and terminal cost function W^0. Moreover, $\tilde{W}$ is Lipschitz continuous on $[0, T_0] \times \mathbb{R}^n$ for any $T_0 < \infty$. See [15, §4.8]. Therefore, by standard results [15, Chap. 2], $\tilde{W}$ is a viscosity solution of the time-dependent PDE

$$\tilde{W}_T = \max_{|v| \leq M} [(g(x) + v) \cdot \nabla_x \tilde{W} + k(x, v) - \lambda^0] \tag{5.7}$$

with initial data

$$\tilde{W}(0, x) = W^0(x), \; x \in \mathbb{R}^n. \tag{5.8}$$

However, W^0 is also a (stationary) Lipschitz continuous viscosity solution to (5.7)–(5.8). By a uniqueness theorem for viscosity solutions, (see [5, Thm. 7.2] among others) $\tilde{W} = W^0$. □

Since M is arbitrary, subject only to $M \geq (2\gamma^2 c)^{-1} \|\nabla \ell\|$, in (5.6) we can replace $\mathcal{W}_M^0$ by the class $\mathcal{W}^0$ of all bounded measurable $v_.$. Let us consider the finite-time control problem, with running cost $k(x, v)$ and zero terminal cost. Let $V^0(T, x)$ be the value function

$$V^0(T, x) = \sup_{v_. \in \mathcal{W}_M^0} \int_0^T k(\xi_t^0, v_t)dt. \tag{5.9}$$

COROLLARY 5.3.

$$\lambda^0 = \lim_{T \to \infty} \frac{1}{T} V^0(T, x) \tag{5.10}$$

uniformly for x in any compact set.

Proof. Let $|x| \leq R$ and $v_. \in \mathcal{W}_M^0$. By assumption (3.1c) there exists $R_1 \geq R$ such that $|\xi_t^0| \leq R_1$ for all $T \geq 0$. In (5.6) we divide by T and let $T \to \infty$. Then $T^{-1}W^0(x)$ tends to 0, and $T^{-1}W^0(\xi_t^0)$ tends to 0 uniformly with respect to $v_. \in \mathcal{W}_M^0$ and $x = \xi_0$ in the ball $\{|x| \leq R\}$. □

Let us next show that λ^0 is the maximum of the infinite-horizon average cost per unit time criterion $J^0(x; v_.)$, which is the deterministic version of (2.6). Let

$$J^0(x; v_.) = \limsup_{T \to \infty} \frac{1}{T} \int_0^T k(\xi^0, v_t)dt. \tag{5.11}$$

We have the following theorem.

THEOREM 5.4. *For any $x \in I\!\!R^n$*

$$\lambda^0 = \sup_{v_. \in \mathcal{W}^0_M} J^0(x; v_.). \tag{5.12.}$$

Proof. For any $v_. \in \mathcal{W}^0_M$ and $T < \infty$ (5.6) implies that

$$W^0(\xi^0_T) - W^0(x) \leq - \int_0^T k(\xi^0_t, v_t)dt + \lambda^0 T. \tag{5.13}$$

By dividing by T and letting $T \to \infty$, we obtain as in the proof of Corollary 5.3 that λ^0 is no less than the right side of (5.12). It remains to show that $v_.$ can be chosen so that $J^0(x, v_.)$ is arbitrarily close to λ^0. Fix x, with $|x| \leq R$. As in the proof of Corollary 5.3, $|\xi^0_t| \leq R_1$ for some $R_1 \geq R$. Given $\delta > 0$, by Corollary 5.3 there exists T_0 such that

$$|V^0(T_0, y) - \lambda^0 T_0| < \frac{\delta T_0}{2} \text{ for } |y| \leq R_1. \tag{5.14}$$

On $[0, T_0)$ we choose v_t such that

$$\int_0^T k(\xi^0_t, v_t)dt > V^0(T_0, x) - \frac{\delta T_0}{2},$$

which by (5.14) exceeds $\lambda^0 T_0 - \delta T_0$. Proceeding by induction on $N = 1, 2, \ldots$, we choose v_t on $[NT_0, (N+1)T_0)$ such that

$$\int_{NT_0}^{(N+1)T_0} k(\xi^0_t, v_t)dt > V^0(T_0, \xi^0_{NT_0}) - \frac{\delta T_0}{2} > \lambda^0 T_0 - \delta T_0.$$

By summing from 0 to $N - 1$,

$$\frac{1}{NT_0} \int_0^{NT_0} k(\xi^0_t, v_t)dt > \lambda^0 - \delta.$$

Since $k(x, v)$ is bounded, this implies that

$$J^0(x; v_.) \geq \lambda^0 - \delta$$

as required. □

Robust regulation of nonlinear systems. Let us now relate these results to recent work on robust control approaches to the disturbance attenuation problem for nonlinear systems. See [22], [23], [37], for example. As mentioned earlier, we consider in this paper only the complete state observation case. We claim that, from the viewpoint of robust regulation, a key question is whether $\lambda^0 = 0$ or $\lambda^0 > 0$. Since we have assumed that the running cost function $\ell(x)$ is bounded, our results are not immediately comparable with those in robust control in which $\ell(x)$ is quadratic. In order to make this comparison, some "cut-off" argument is needed. See the comments at the end of the section. By (3.8), when $\lambda^0 = 0$ the inequality (5.13) becomes

$$\int_0^T [\ell(\xi_t^0) - \gamma^2|v_t|^2]dt + W^0(\xi_T^0) \leq W^0(x) \tag{5.15}$$

for every deterministic control function $v_.$ and $T < \infty$. Inequality (5.15) is called a *dissipation inequality* in robust control theory. Whether $\lambda^0 = 0$ or $\lambda^0 > 0$ depends on the parameter γ. We note that if $W^0(x)$ has a minimum at some point x^*, then for the initial data $\xi_0^0 = x^*$ the dissipation inequality (5.15) implies that for each $v_.$ and T

$$\int_0^T \ell(\xi_t^0)dt \leq \int_0^T \gamma^2|v_t|^2dt. \tag{5.16}$$

For quadratic $\ell(x)$, (5.16) is a similar condition in robust control theory corresponding to bounding an L^2-operator norm by γ. See [2]. Typically, in robust control theory x^* is a point about which the system $dx_t^0 = g(x_t^0)dt$ without disturbances is globally asymptotically stable. Let us assume that $x^* = 0$ and that $\ell(0) = 0$, $\ell(x) > 0$ for $x \neq 0$. We recall that the PDE (5.3) can be rewritten as

$$\lambda^0 = g(x) \cdot \nabla W^0 + \frac{1}{4\gamma^2}|\nabla W^0|^2 + \ell(x). \tag{5.4}$$

Since W^0 is a Lipschitz continuous viscosity solution to (5.4), it satisfies (5.4) in the usual sense for almost all x (in fact, at each x where W^0 is differentiable). This implies the following necessary condition for $\lambda^0 = 0$:

$$\ell(x) \leq \gamma^2|g(x)|^2 \text{ for all } x \in I\!R^n. \tag{5.17}$$

If (5.4) holds in the usual sense at x, then (5.17) is immediate from the inequality

$$\left|\gamma g(x) + \frac{1}{2\gamma}\nabla W^0(x)\right|^2 \geq 0.$$

By continuity of g and ℓ, (5.17) then holds for all x.

In dimension $n = 1$, (5.17) implies that (5.4) has a classical solution $W^0 \in C^1(I\!R^1)$ with $\lambda^0 = 0$. In fact,

$$W_x^0(x) = -2\gamma^2 g(x) - 2\ (\operatorname{sgn} x)(\gamma^4 g^2(x) - \gamma^2\ell(x))^{\frac{1}{2}}. \tag{5.18}$$

Since $g(0) = \ell(0) = 0$, we have $W_x^0(0) = 0$. By (3.1), $\ell(x) << g^2(x)$ as $|x| \to \infty$ and hence $W_x^0(x)$ is bounded. In fact, $W_x^0(x) \to 0$ as $|x| \to \infty$. For $x > 0$

$$W_x^0(x) = 2\gamma^2|g(x)|\left[1 - \left(1 - \frac{\ell(x)}{\gamma^2 g^2(x)}\right)^{\frac{1}{2}}\right]$$

$$\sim \frac{\ell(x)}{|g(x)|} \quad \text{as} \quad |x| \to \infty.$$

Since $\ell(x)$ is bounded and $|g(x)|x^{-1}$ is bounded below, the last term tends to 0. Similarly, $W_x(x) \to 0$ as $x \to -\infty$.

If $\lambda^0 = 0$, then (5.4) is just the steady-state form of the time-dependent PDE (5.7) satisfied by the value function $V^0(T,x)$. Corollary 5.2 says in case $\lambda^0 = 0$ that $T^{-1}V^0(T,x)$ tends to 0 uniformly on compact sets as $T \to \infty$. Under suitable further assumptions it should be true that $V^0(T,x)$ tends to a Lipschitz continuous viscosity solution $W^0(x)$ as $T \to \infty$. However, we have not proved any result of that kind.

If $\lambda^0 > 0$, then according to Theorem 5.3 there is a control $v_.$ for which average cost per unit time accumulates at a rate arbitrarily close to λ^0. The dissipation property is violated by the appearance of the term $\lambda^0 T$ on the right side of (5.13). If $W^0(x)$ has a minimum at the reference point $x^* = 0$ and $\lambda^0 > 0$, then W^0 cannot be differentiable at 0. Indeed, if W^0 is differentiable at 0, then $\nabla W^0(0) = 0$. Since $\ell(0) = 0$, this implies $\lambda^0 = 0$ by (5.4).

Example 5.5. Let $n = 1, g(-x) = -g(x), \ell(-x) = \ell(x)$ with $\ell(0) = 0$, $\ell(x) > 0$ for $x \neq 0$. Suppose that, for $x > 0$, $\ell(x) - \gamma^2 g^2(x)$ has a positive maximum at a unique point x_1. Let

$$\lambda^0 = \max_x[\ell(x) - \gamma^2 g^2(x)] = \ell(x_1) - \gamma^2 g^2(x_1). \tag{5.19}$$

We define $W^0(x)$ by

$$W^0(0) = 0, \qquad W^0(-x) = W^0(x),$$

and for $x > 0$

$$\begin{aligned} W^0_x(x) &= -2\gamma^2 g(x) + 2\alpha(x)(\gamma^4 g^2(x) - \gamma^2\tilde{\ell}(x))^{\frac{1}{2}}, \\ \alpha(x) &= \begin{cases} 1 & \text{if } 0 < x \le x_1 \\ -1 & \text{if } x > x_1, \end{cases} \\ \tilde{\ell}(x) &= \ell(x) - \lambda^0. \end{aligned} \tag{5.20}$$

Then W^0_x is continuous except at $x = 0$ and satisfies (5.4). At $x = 0, W^0_x$ jumps, with

$$W^0_x(0^-) = -2\gamma(\lambda^0)^{\frac{1}{2}}, \qquad W^0_x(0^+) = 2\gamma(\lambda^0)^{\frac{1}{2}}.$$

Let us rewrite (5.4) as

$$\lambda^0 + H(x, \nabla W^0) = 0,$$

$$H(x,p) = -g(x)\cdot p - \frac{1}{4\gamma^2}|p|^2 - \ell(x).$$

Since $H(x,p)$ is concave in p, in dimension 1 the derivative W^0_x of a viscosity solution $W^0(x)$ can have positive jumps but not negative jumps. See [15, §2.8]. Thus, $W^0(x)$ defined above is a viscosity solution. As in the discussion following (5.18), $W^0_x(x)$ is bounded. In fact, since $\alpha(x) = -\text{sgn } x$ for $|x| > x_1$, $W^0_x(x) \to 0$ as $|x| \to \infty$.

Remark 5.6. As already noted in Remark 4.4, the assumption that $\ell(x)$ is bounded in (3.1a) can be omitted. In dimension $n = 1$, if $\ell_x(x)$ is bounded but not $\ell(x)$, then in (5.18) one cannot expect that $W^0_x(x) \to 0$ as $|x| \to \infty$. If $|g(x)|^{-1}\ell(x)$ tends to limits as $x \to \pm\infty$, then the elementary argument below (5.18) shows that $W^0_x(x)$ tends to the same limits.

In robust control theory, typically $\ell(x)$ is taken to be quadratic. Of course, a quadratic ℓ does not have $\nabla\ell(x)$ bounded; hence a different result must be expected. This is seen from the following simple example.

Example 5.7. Let $n = 1$, $g(x) = -cx, \ell(x) = Kx^2$. The value function $V^0(T,x)$ for the finite-time-horizon problem (with $\mathcal{W}_M^0$ replaced by $\mathcal{W}^0$ in (5.9)) is quadratic in x. If $c^2\gamma^2 > K$, then $V^0(T,x)$ tends to a limit $W^0(x) = kx^2$ as $T \to \infty$. Moreover, $W^0(x)$ satisfies (5.4) with $\lambda^0 = 0$. On the other hand, if $c^2\gamma^2 < K$, then $V^0(T,x)$ explodes at some time $T^* < \infty$, and there is no infinite-horizon, average cost per unit time control problem.

One can reintroduce average cost per unit time control problems by a "cutoff" procedure, in which quadratic $\ell(x)$ is replaced by bounded functions which agree with $\ell(x)$ on large bounded sets. Of course, the optimal average cost per unit time must tend to infinity as the cutoff is relaxed. We illustrate this idea in Example 5.7. For $R > 0$ let

$$\ell_R(x) = \begin{cases} Kx^2 & \text{if } |x| \le R, \\ KR^2 & \text{if } |x| > R. \end{cases}$$

When $g(x) = -cx$,

$$\ell_R(x) - \gamma^2 g^2(x) = \begin{cases} (K - c^2\gamma^2)x^2 & \text{if } |x| \le R, \\ KR^2 - c^2\gamma^2 x^2 & \text{if } |x| > R. \end{cases}$$

When $c^2\gamma^2 < K$, this is maximum when $|x| = R$. By (5.19), $\lambda^0 = \lambda_R^0 = (K - c^2\gamma^2)R^2$, which tends to infinity as $R \to \infty$. On the other hand, if $c^2\gamma^2 > K$ then $\lambda_R^0 = 0$ for every $R > 0$.

This example suggests the following kind of result. If $\ell(x)$ is unbounded, with $\ell(x)$ growing quadratically as $|x| \to \infty$, then one should look for a critical value γ_1 of the parameter γ with the following properties. If $\gamma > \gamma_1$, then a dissipation inequality like (5.15) should hold with $W^0(x)$ a quadratically growing viscosity solution to (5.15) for $\lambda^0 = 0$. On the other hand, if $\gamma < \gamma_1$ then the optimal average cost per unit time λ_R^0 for cutoff problems should tend to infinity as $R \to \infty$.

6. Infinite-horizon risk-sensitive control. In the remainder of the paper, we return to consider risk-sensitive control problems of the kind mentioned in the introduction. The format will be similar to that of §§3–5. The present section is concerned with a rather general problem formulation, without proofs. The method of dynamic programming leads, in a formal way, to a nonlinear analogue of the eigenvalue problem in §2. By making a logarithmic transformation we arrive (again formally) at an Isaacs equation for a stochastic differential game, with average cost per unit time payoff criterion. In §7, we put these ideas on a rigorous basis for a particular class of risk-sensitive control problems governed by SDEs. Then in §8 we consider deterministic limits.

We now consider controlled Markov processes x_t with state space Σ, with the dynamics of x_t affected by a control process u_t. We require that $u_t \in U$, where U is a given "control space." Proceeding formally, for each constant control $u \in U$, the process x_t should be Markov with generator G^u. More generally, given a stationary Markov control policy $\underline{u}(x)$ belonging to some admissible class, x_t is a Markov process with generator $G^{\underline{u}}$. For further discussion of controlled Markov processes in this general setting, see [15, Chap. 3].

Let $L(x,u)$ be a running cost criterion, and $\epsilon > 0$ a parameter (in this section and §7, ϵ is fixed.) Given a stationary Markov control policy $\underline{u}$, we may refer to the formal results in §2 with $G = G^{\underline{u}}$ and

$$\ell^{\underline{u}}(x) = L(x, \underline{u}(x)).$$

From (2.1) we anticipate that (under suitable hypotheses) the limit

$$\lambda^{\underline{u}} = \epsilon \lim_{T\to\infty} \frac{1}{T} \log E_x \exp\left[\epsilon^{-1} \int_0^T \ell^{\underline{u}}(x_t)dt\right] \tag{6.1}$$

exists and that $\epsilon^{-1}\lambda^{\underline{u}}$ can be interpreted as the dominant eigenvalue of the linear operator $G^{\underline{u}} + \epsilon^{-1}\ell^{\underline{u}}$.

The goal is to find a stationary Markov control policy $\underline{u}^*$ which minimizes $\lambda^{\underline{u}^*}$. Again proceeding formally, we let

$$\Lambda = \inf_{\underline{u}} \lambda^{\underline{u}}. \tag{6.2}$$

Then dynamic programming and the separation of variables technique in §2 lead formally to a nonlinear eigenvalue problem for Λ and a positive eigenfunction $\Psi(x)$:

$$\epsilon^{-1}\Lambda\Psi(x) = \min_{u\in U}[G^u\Psi(x) + \epsilon^{-1}L(x,u)\Psi(x)]. \tag{6.3}$$

This is done via the heuristic $\Phi(T,x) \sim \exp(\epsilon^{-1}\Lambda T)\Psi(x)$, where $\Phi(T,x)$ is the value function for a finite-time-horizon control problem of minimizing the exponential cost criterion

$$E_x \exp\left[\epsilon^{-1} \int_0^T L(x_t, u_t,)dt\right].$$

The dynamic programming equation for the finite-time problem is

$$\Phi_T = \min_{u\in U}[G^u\Phi + \epsilon^{-1}L\Phi]. \tag{6.4}$$

As in §2, we make the logarithmic transformation $W = \epsilon \log \Psi$, and let

$$\mathcal{H}^u(W) = \epsilon \exp(-\epsilon^{-1}W)G^u[\exp(\epsilon^{-1}W)]. \tag{6.5}$$

Then (6.3) becomes

$$\Lambda = \min_{u\in U}[\mathcal{H}^u(W) + \ell]. \tag{6.6}$$

By introducing another (maximizing) control v in the same way as in §2, (6.6) becomes the Isaacs equation for a stochastic differential game. The game payoff has the average cost per unit time form

$$J = \limsup_{T\to\infty} \frac{1}{T} E_x \int_0^T K(\xi_t, u_t, v_t)dt, \tag{6.7}$$

with suitably defined running cost function $K(x,u,v)$. Here ξ_t denotes the state of the game at time t.

Let us describe explicitly the game and the form of the Isaacs equation (6.6) only for controlled nondegenerate Markov diffusions in $\mathbb{R}^n$. Proceeding in a way similar to §2, we suppose that x_t is governed by an SDE

$$dx_t = f(x_t, u_t)dt + \epsilon^{\frac{1}{2}}\sigma(x_t, u_t)db_t, \tag{6.8}$$

with initial data $x_0 = x$. Here $b_.$ is an n-dimensional Brownian motion, and the matrix $a = \sigma\sigma^{'}$ is positive definite for all $x \in I\!R^n$, $u \in U$. (In the rigorous treatment in §7 we will take U compact, $a = (2\gamma^2)^{-1}I$ with assumptions on $f(x,u), L(x,u)$ corresponding to those made for $g(x), \ell(x)$ in §3.)

For the dynamics (6.8), the family G^u of generators becomes (see [15, p. 173]) for $\psi \in C^2(I\!R^n)$

$$G^u\psi(x) = \frac{\epsilon}{2}\sum_{i,j=1}^{n} a_{ij}(x,u)\psi_{x_ix_j} + f(x,u)\cdot\nabla\psi(x). \tag{6.9}$$

By arguing as in §2 (see (2.7)–(2.9)) we obtain for $W = \epsilon \log \psi$ the PDE

$$\Lambda = \min_{u\in U}\max_{v\in I\!R^n}\left[\frac{\epsilon}{2}\sum_{i,j=1}^{n} a_{ij}(x,u)W_{x_ix_j}(x) \right. \tag{6.10}$$
$$\left. +(f(x,u)+v)\cdot\nabla W(x) + K(x,u,v)\right],$$

$$K(x,u,v) = L(x,u) - \frac{a^{-1}(x,u)}{2}v\cdot v. \tag{6.11}$$

Equation (6.10) is the Isaacs equation for a stochastic differential game with state ξ_t governed by the dynamics

$$d\xi_t = [f(\xi_t,u_t)+v_t]dt + \epsilon^{\frac{1}{2}}\sigma(\xi_t,u_t)dw_t, \tag{6.12}$$

with w_t some Brownian motion and with payoff J as in (6.7). Note that (6.12) is just a "controlled" version of (2.10). Formally, Λ corresponds to the upper game value, since min max and max min cannot in general be exchanged in (6.10). However, if $a = a(x)$, then the minimizing control u and the maximizing control v appear separately in (6.10). In that case, the Isaacs condition min max = max min holds. In particular, this is true when a is constant, as in §7.

7. Ergodic stochastic differential game. In this section we will put the formalism in §6 on a rigorous basis, in a special case in which the matrix σ in (6.10) is constant. In fact, we assume as in §3 that $a = \sigma\sigma^{'} = (2\gamma^2)^{-1}I$, with assumptions on $f(x,u), L(x,u)$ similar to the assumptions (3.1) made earlier. Then in §8 we will consider the deterministic differential game obtained in the limit $\epsilon \to 0$ and its relation to some questions in robust nonlinear control theory. The results of these two sections are analogous to those of §§3–5, and we will simply adapt those proofs whenever possible.

We make the following assumptions.

(7.1) The control space U is compact.

The functions L, f are continuous on $I\!R^n \times U$. Moreover, $L(\cdot,u), f(\cdot,u)$ are of class $C^1(I\!R^n)$ for all $u \in U$, and

(7.2)
(a) $L, \nabla_x L$ are bounded and $L \geq 0$;

(b) f_x is bounded;

(c) There exists $c > 0$ such that for all $x, y \in I\!R^n, u \in U$, $(x-y)\cdot[f(x,u)-f(y,u)] \leq -c|x-y|^2$.

As in the discussion following (3.1) these assumptions are considerably stronger than needed to prove the results that follow. However, they make the proofs much less technical. In particular, the assumption that L is bounded can be omitted, using arguments similar to Remark 4.4. The assumption that f, L are of class $C^1(\mathbb{R}^n)$ can be weakened to assume Lipschitz conditions for $f(x,\cdot), L(x,\cdot)$ which are uniform in u.

Equation (6.3) for Λ and $\Psi(x)$ now has the form

$$\begin{aligned}\epsilon^{-1}\Lambda\Psi(x) &= \frac{\epsilon}{4\gamma^2}\Delta\Psi(x) \\ &+ \min_{u\in U}[f(x,u)\cdot\nabla\Psi(x) + \epsilon^{-1}L(x,u)\Psi(x)].\end{aligned} \tag{7.3}$$

Equivalently, equation (6.6) for Λ and $W(x)$ now takes the form

$$\begin{aligned}\Lambda &= \frac{\epsilon}{4\gamma^2}\Delta W + \frac{1}{4\gamma^2}|\nabla W(x)|^2 \\ &+ \min_{u\in U}[f(x,u)\cdot\nabla W(x) + L(x,u)].\end{aligned} \tag{7.4}$$

This is the same as (6.10) with $a = (2\gamma^2)^{-1}I$ and

$$K(x,u,v) = L(x,u) - \gamma^2|v|^2. \tag{7.5}$$

THEOREM 7.1. *There exist $\Lambda \in \mathbb{R}$, $W \in C^2(\mathbb{R}^n)$ such that* (7.4) *holds. Moreover, there exists B (not depending on ϵ) such that $|\nabla W| \le B$ and $0 \le \Lambda \le B$.*

We defer the proof of Theorem 7.1 to later in this section. The proof will give $B = c^{-1}\|\nabla_x L\|$, with constant c as in assumption (7.2c). Instead, we will first demonstrate that Λ has an interpretation as the minimum cost for the risk-sensitive control problem introduced in §6. We recall from §3 the definition of reference probability system. Given any reference probability system $\nu = (\Omega, \{\mathcal{F}_t\}, P, b_\cdot)$, let $\mathcal{U}_\nu$ be the set of $\mathcal{F}_t$-progressively measurable processes with values in U.

We consider the dynamics given by (1.1):

$$\begin{aligned} dx_t &= f(x_t,u_t)dt + \left(\frac{\epsilon}{2\gamma^2}\right)^{\frac{1}{2}} db_t, \\ x_0 &= x, \end{aligned} \tag{7.6}$$

where b_t is the Brownian motion of the reference probability system ν and $u_\cdot \in \mathcal{U}_\nu$. This system has a strong solution [28].

A candidate for an optimal control policy is defined as follows. By a measurable selection theorem [11, Appendix B], there exists a Borel measurable U-valued function $\underline{u}^*$ on $\mathbb{R}^n$ such that

$$\underline{u}^*(x) \in \arg\min_{u\in U}[f(x,u)\cdot\nabla W(x) + L(x,u)] \tag{7.7}$$

for almost all $x \in \mathbb{R}^n$. By a result of Veretennikov [38] as extended in [30], the SDE

$$\begin{aligned} dx_t^* &= f(x_t^*, \underline{u}^*(x_t^*))dt + \left(\frac{\epsilon}{2\gamma^2}\right)^{\frac{1}{2}} db_t, \\ x_0^* &= x \end{aligned} \tag{7.8}$$

has a strong solution x_t^*.

THEOREM 7.2. *Let Λ, W be as in Theorem 7.1, and let ν be any reference probability system. Then*

(a) *For every $u_. \in \mathcal{U}_\nu$,*

$$\Lambda \leq \epsilon \liminf_{T\to\infty} \frac{1}{T} \log E_x \exp\left[\epsilon^{-1}\int_0^T L(x_t,u_t)dt\right].$$

(b) *Let $u_t^* = \underline{u}^*(x_t^*)$, with $\underline{u}^*, x_t^*$ as in (7.7), (7.8). Then*

$$\Lambda = \epsilon \lim_{T\to\infty} \frac{1}{T} \log E_x \exp\left[\epsilon^{-1}\int_0^T L(x_t^*,u_t^*)dt\right].$$

Proof. The proof of (a) is nearly identical to the proof of Theorem 3.5. However, in place of (3.13) we have

$$\begin{aligned} W(x_T) - W(x) \geq & \int_0^T [\Lambda - L(x_t,u_t) + \gamma^2|v_t|^2]dt \\ & + \sqrt{2\gamma^2\epsilon}\int_0^T v_t \cdot db_t^0. \end{aligned} \tag{7.9}$$

Thus, we have inequality rather than equality due to the minimization in (7.4). The inequality passes transparently through the remainder of the proof.

For part (b), equality holds in (7.9) with probability 1, and this gives the desired equality exactly as in the proof of Theorem 3.5. □

Remark 7.3. Given any Borel measurable, U-valued Markov contol policy $\underline{u}$, let $u_t = \underline{u}(x_t)$ where x_t is the solution to the SDE (7.8) with $\underline{u}^*$ replaced by $\underline{u}$ and with initial data $x_0 = x$. If the limit $\lambda^{\underline{u}}$ in (6.1) exists, then by Theorem 7.2(a), $\Lambda \leq \lambda^{\underline{u}}$. Without knowing that the limit exists in (6.1) Theorem 7.2(a) provides a slightly weaker result in which limit is replaced by lim inf. Theorem 7.2(b) asserts that $\lambda^{\underline{u}^*}$ exists and that $\lambda^{\underline{u}^*} = \Lambda$. This justifies calling $\underline{u}^*$ an optimal Markov control policy.

We now turn to the proof of Theorem 7.1. The proof will be structurally similar to the proof of Theorem 3.3 given in §4. However, the addition of the minimizing controller $u_.$ implies that we must now work with differential games which have two controllers (or players), $u_.$ and $v_.$. In contrast, in §4 we had a control problem with one (maximizing) controller.

In parallel with §4, we start with the finite-time-horizon, discounted-cost differential game with dynamics

$$\begin{aligned} & d\xi_t = [f(\xi_t,u_t) + v_t]dt + \left(\frac{\epsilon}{2\gamma^2}\right)^{\frac{1}{2}} dw_t, \\ & \xi_0 = x \end{aligned} \tag{7.10}$$

and payoff

$$J_\rho(T,x;u_.,v_.) = E_x\int_0^T e^{-\rho t}K(\xi_t,u_t,v_t)dt \tag{7.11}$$

where K is given by (7.5). We use the Elliott–Kalton definition of value of a differential game [8] as extended to stochastic differential games by Fleming and Souganidis [16]. We summarize this definition. Given a reference probability system $\mu = (\Omega, \{\mathcal{F}_t\}, P, w_.)$ let $\mathcal{U}$ denote the set of all U-valued, $\mathcal{F}_t$-progressively measurable processes $u_.$. As in §4, let $\mathcal{W}_M$ denote the set of all $I\!R^n$-valued $\mathcal{F}_t$-progressively measurable process $v_.$ such that $|v_t| \leq M$. The processes u_t, v_t are defined for all $t \geq 0$, although in the present discussion only $0 \leq t \leq T$ is relevant. Of course, $\mathcal{U} = \mathcal{U}^\mu$ and $\mathcal{W}_M = \mathcal{W}_M^\mu$ depend on μ. A strategy for the minimizing controller is a mapping $\beta : \mathcal{W}_M \to \mathcal{U}$ with the following property. For each $t > 0, v_r = \hat{v}_r$ for almost all $r \in [0,t]$ almost surely implies $\beta[v_.]_r = \beta[\hat{v}_.]_r$ for almost all $r \in [0,t]$ almost surely. This set of strategies is denoted by Δ_M. Similarly, a strategy for the maximizing controller is a mapping $\alpha : \mathcal{U} \to \mathcal{W}_M$ with the corresponding property. This set of strategies is denoted by Θ_M. The lower value is defined to be

$$V_\rho^\ell(T,x) = \inf_{\Delta_M} \sup_{\mathcal{W}_M} J_\rho(T,x;\beta[v_.],u_.), \tag{7.12}$$

and the upper value is

$$V_\rho^u(T,x) = \sup_{\Theta_M} \inf_{\mathcal{U}} J_\rho(T,x;u_.,\alpha[u_.]). \tag{7.13}$$

The Isaacs PDE for this differential game is

$$\begin{aligned} \rho V + V_T = {} & \frac{\epsilon}{4\gamma^2}\Delta_x V + \min_{u\in U}[f(x,u)\cdot\nabla_x V + L(x,u)] \\ & + \max_{|v|\leq M}[v\cdot\nabla_x V - \gamma^2|v|^2] \end{aligned} \tag{7.14}$$

with the initial data

$$V(0,x) = 0. \tag{7.15}$$

Results about semilinear parabolic PDEs (see Appendix B) imply that (7.14)–(7.15) has a classical solution $\bar{V}(T,x)$, with all partial derivatives $\bar{V}_T, \bar{V}_{x_i}, \bar{V}_{x_i x_j}$, $i,j = 1,\ldots,n$, continuous. Moreover, $\nabla_x \bar{V}$ is bounded. In order to obtain a priori estimates which do not depend on ϵ, ρ, or T for small ρ and large T, similar to (4.4) and (4.5), we first show that $\bar{V}(T,x)$ equals the upper value $V_\rho^u(T,x)$.

LEMMA 7.4. $\bar{V} = V_\rho^u$.

Proof. We show first that $\bar{V} \leq V_\rho^u$ and then the opposite inequality. We consider the control policy $h(t,x)$ defined by

$$h(t,x) = \arg\max_{|v|\leq M}[v\cdot\nabla_x\bar{V}(T-t,x) - \gamma^2|v|^2]. \tag{7.16}$$

Then h is continuous on $[0,T]\times I\!R^n$, and $h(t,\cdot)$ satisfies a local Lipschitz condition uniformly for $0 \leq t \leq T$. See [13, p. 170]. For each $u_. \in U$ define $\alpha^*[u_.]$ by

$$\begin{aligned} d\xi_t^* &= [f(\xi_t^*,u_t) + h(t,\xi_t^*)]dt + \left(\frac{\epsilon}{2\gamma^2}\right)^{\frac{1}{2}} dw_t, \\ \xi_0^* &= x, \end{aligned} \tag{7.17}$$

$$\alpha^*[u_.]_t = h(t,\xi_t^*). \tag{7.18}$$

Since h is continuous, bounded, and locally Lipschitz in x, the strong solution to (7.17) exists. Then (7.14) and (7.16) imply, for any $u_. \in \mathcal{U}$,

$$0 \le -\bar{V}_T(T-t,\xi_t^*) - \rho\bar{V}(T-t,\xi_t^*) + \frac{\epsilon}{4\gamma^2}\Delta_x\bar{V}(T-t,\xi_t^*)$$

$$+f(\xi_t^*,u_t)\cdot\nabla_x\bar{V}(T-t,\xi_t^*) + L(\xi_t^*,u_t)$$

$$+h(t,\xi_t^*)\cdot\nabla_x\bar{V}(T-t,\xi_t^*) - \gamma^2|h(t,\xi_t^*)|^2.$$

Since $\nabla_x\bar{V}$ is bounded, $\bar{V}(T,x)$ grows at most linearly as $|x|\to\infty$. By using the Feynman–Kac formula and the fact that $\bar{V}(0,x)=0$, we conclude that

$$\bar{V}(T,x) \le \inf_{\mathcal{U}} J_\rho(T,x;u_.,\alpha^*[u_.]).$$

Therefore, $\bar{V}(T,x) \le V_\rho^u(T,x)$.

In order to prove the opposite inequality $\bar{V}(T,x) \ge V_\rho^u(T,x)$ it suffices to show that, given any strategy $\alpha \in \Theta_M$ and $\delta > 0$, there exists $u_. \in \mathcal{U}$ such that

$$J_\rho(T,x;u_.,\alpha[u_.]) \le \bar{V}(T,x) + \delta. \tag{7.19}$$

We will define u_t to be piecewise constant in time, via a discrete time Markov control policy $\vec{u}$ in a way similar to [15, p 183]. Let π be a partition of [0,T] into intervals $[t_{j-1},t_j], j = 1,\dots,j_0$ with $0 = t_0 < t_1 < \cdots < t_{j_0} = T$. A discrete-time Markov control policy is

$$\vec{u} = (\underline{u}_1,\dots,\underline{u}_{j_0}),$$

where $\underline{u}_j$ is a Borel measurable function from $\mathbb{R}^n$ into U. Given initial data $\xi_0 = x$, a strategy α and a discrete time Markov control policy $\vec{u}$, we define u_t inductively as follows. For $0 \le t < t_1$, $u_t = \underline{u}_1(x)$. Then (7.10) is solved on $[0,t_1]$ with $v_t = \alpha[u_.]_t$ to obtain ξ_t. Proceeding by induction, if u_t and the corresponding solution ξ_t have been defined on $[0,t_j]$ we let

$$u_t = \underline{u}_{j+1}(\xi_{t_j}) \text{ for } t_j \le t < t_{j+1}.$$

We then extend ξ_t to $[t_j,t_{j+1}]$ as the solution to (7.10) on $[0,t_{j+1}]$ with the initial data $\xi_0 = x$. By uniqueness of strong solutions to (7.10), this is consistent with the definition of ξ_t on $[0,t_j]$. We will choose $\vec{u}$ in the following way. In addition to a partition π of $[0,T]$ we will partition $\mathbb{R}^n$ into disjoint Borel sets $A_0,A_1,\dots,A_{k_0}$. We will also choose $u_{jk} \in U$ and let

$$u_j(y) = u_{jk} \text{ if } y \in A_k.$$

These partitions are chosen as follows. Since $\bar{V}(T,x)$ is a solution to (7.14),

$$-\rho\bar{V} - \bar{V}_T + \frac{\epsilon}{4\gamma^2}\nabla_x\bar{V} + \min_{u\in U}[f(x,u)\cdot\nabla_x\bar{V} + L(x,u)] \tag{7.20}$$

$$+v\cdot\nabla_x\bar{V} - \gamma^2|v|^2 \le 0$$

for all v such that $|v| \leq M$. As in the proof of [15, Lem. 4.7.1], we choose R sufficiently large and $A_1, \ldots, A_{k_0}$ a partition of the ball $\{|y| \leq R\}$ into disjoint Borel sets of sufficiently small diameter. Let $A_0 = \{|y| > R\}$. The points $u_{jk} \in U, j = 1, \ldots, j_0, k = 1, \ldots, k_0$ are chosen such that

$$f(y, u_{jk}) \cdot \nabla_x \bar{V}(T-t, y) + L(y, u_{jk}) \tag{7.21}$$

$$< \min_{u \in U}[f(y,u) \cdot \nabla_x \bar{V}(T-t,y) + L(y,u)] + \eta$$

for all $t \in [t_{j-1}, t_j], y \in A_k$, where $\eta > 0$. We choose $u_{j0} \in U$ arbitrarily. By (7.20) and (7.21)

$$-\rho \bar{V}(T-t, \xi_{t_j}) - \bar{V}_T(T-t, \xi_{t_j}) + \frac{\epsilon}{4\gamma^2} \Delta_x \bar{V}(T-t, \xi_{t_j})$$

$$+(f(\xi_{tj}, u_t) + v_t) \cdot \nabla \bar{V}(T-t, \xi_{t_j}) + K(\xi_{t_j}, u_t, v_t) < \eta,$$

where $v_t = \alpha[u_.]_t$ if $t_j \leq t \leq t_{j+1}$ and $|\xi_{t_j}| \leq R$. By an argument in [15, p. 184], if η and the lengths of the intervals $[t_j, t_{j+1}]$ are chosen small enough,

$$\bar{V}(T,x) \geq E_x \int_0^{\tau_R} e^{-\rho t} K(\xi_t, u_t, \alpha[u_.]_t) dt \tag{7.22}$$

$$+E_x e^{-\rho \tau_R} \bar{V}(T - \tau_R, \xi_{\tau_R}) - \frac{\delta}{2},$$

where τ_R is the smaller of T and the exit time of ξ_t from the ball $\{|y| \leq R\}$. Since U is compact and $|v_t| \leq M$, we have from Cauchy–Schwartz, together with

$$|\bar{V}(s,y)| \leq C(1 + |y|), \; V(0,y) = 0,$$

that for suitable C,

$$J_\rho(T, x; u_., \alpha[u_.]) \leq \bar{V}(T,x) + \frac{\delta}{2}$$

$$+T(\|L\| + \gamma^2 M^2) P_x(\tau_R < T) \tag{7.23}$$

$$+C[E_x(1 + |\xi_{\tau_R}|)^2]^{\frac{1}{2}} [P_x(\tau_R < T)]^{\frac{1}{2}}.$$

Now $\tau_R < T$ if and only if $\|\xi_.\| \geq R$, where $\| \; \|$ is the sup norm on $[0,T]$, Moreover, $|\xi_{\tau_R}| \leq \|\xi_.\|$. By standard estimates for SDEs (see, for example, [28, §1.5] or [15, Appendix D]), the sum of the last two terms in (7.23) is less than $\delta/2$, if R is large enough. (The choice of R does not depend on $u_.$ or α.) Then (7.19) holds, which completes the proof. □

The assumptions (7.2) are essentially the same as assumptions (3.1), with the exception that the bounds are now uniform in the new control variable $u_.$. Thus by the same methods as employed in §4 we obtain the same bounds on J_ρ and V_ρ^u. In particular, we have the following lemma.

LEMMA 7.5. *For every $T > 0, x, y \in I\!R^n, u_. \in \mathcal{U},\ v_. \in \mathcal{W}_M$ we have*

$$\begin{aligned}
&\text{(a)}\quad \rho J_\rho(T,x;u_.,v_.) \le \|L\|;\\
&\text{(b)}\quad |J_\rho(T,x;u_.v_.) - J_\rho(T,y;u_.,v_.)| \le \frac{\|\nabla_x L\|}{\rho+c};\\
&\text{(c)}\quad 0 \le \rho V_\rho^u(T,x) \le \|L\|;\\
&\text{(d)}\quad |\nabla_x V_\rho^u| \le \frac{\|\nabla_x L\|}{\rho+c};\\
&\text{(e)}\quad |(V_\rho^u)_T| \le \rho^{-1}e^{-\rho T}(\|L\| + \gamma^2 M^2).
\end{aligned} \tag{7.24}$$

Let $M^* = (2\gamma^2 c)^{-1}\|\nabla_x L\|$, and note that by (7.14) and (7.24d)

$$\max_{v\in I\!R^n}[v\cdot\nabla V_\rho^u - \gamma^2|v|^2] = \max_{|v|\le M}[v\cdot\nabla V_\rho^u - \gamma^2|v|^2].$$

Therefore, the solution $\bar{V} = V_\rho^u$ of (7.14)–(7.15) does not depend on M, if $M \ge M^*$. Moreover, in the definition (7.13) of upper value, Θ_M can be replaced by the set Θ of all bounded strategies α.

Since V_ρ^u is a classical solution to (7.14), its first-order partial derivative in T and first- and second-order partial derivatives in x are continuous. By (7.24e) the limit

$$W_\rho(x) = \lim_{T\to\infty} V_\rho^u(T,x)$$

exists. Furthermore, the same argument used for (4.9) shows that $W_\rho \in C^2(I\!R^n)$ satisfies

$$\begin{aligned}
\rho W_\rho\ (x) = {}& \frac{\epsilon}{4\gamma^2}\Delta W_\rho(x)\\
&+\min_{u\in U}[f(x,u)\cdot\nabla W_\rho(x) + L(x,u)]\\
&+\max_{v\in I\!R^n}[v\cdot\nabla W_\rho(x) - \gamma^2|v|^2].
\end{aligned} \tag{7.25}$$

In fact, $W_\rho(x)$ is the upper value of the infinite-horizon, discounted-cost game (with $T=\infty$ on the right side of (7.11)). Moreover, by (7.24c) and (7.24d)

$$\begin{aligned}
&\text{(a)}\quad 0 \le \rho W_\rho \le \|L\|,\\
&\text{(b)}\quad |\nabla W_\rho| \le \frac{\|\nabla_x L\|}{\rho+c}.
\end{aligned} \tag{7.26}$$

To complete the proof of Theorem 7.1, we proceed just as in §4. By Ascoli's theorem, there is a sequence $\rho_m \to 0$ as $m\to\infty$ such that $\rho_m W_{\rho_m}(x)$ tends to some number Λ and, for fixed x_0, $W_{\rho_m}(x) - W_{\rho_m}(x_0)$ tends to a limit $W(x)$ uniformly on compact sets. Moreover, $W \in C^2(I\!R^n)$ and Λ, W satisfy (7.4). Finally, (7.26) implies that $|\nabla W| \le B$ and $0 \le \Lambda \le B$ if

$$B = \max\{\|L\|, c^{-1}\|\nabla_x L\|\}. \qquad \square \tag{7.27}$$

8. Limiting deterministic differential game. Following the same procedure as in §5, we take deterministic limits as $\epsilon \to 0$. We indicate the dependence on ϵ of $\Lambda, W(x)$ in §7 by writing $\Lambda = \Lambda^\epsilon, W = W^\epsilon$. According to (7.26), the following inequalities corresponding to (5.1) hold:

$$0 \le \Lambda^\epsilon \le \|L\|, \qquad |\nabla W^\epsilon(x)| \le \frac{\|\nabla_x L\|}{c}. \tag{8.1}$$

We again use Ascoli's theorem to find a sequence $\epsilon_m \to 0$ such that as $m \to \infty$

$$\Lambda^{\epsilon_m} \to \Lambda^0, \qquad W^{\epsilon_m}(x) \to W^0(x) \tag{8.2}$$

uniformly on compact subsets of $I\!R^n$. Moreover, W^0 is a viscosity solution to the first-order PDE

$$\begin{aligned}\Lambda^0 &= \min_{u\in U}[f(x,u)\cdot\nabla W^0(x) + L(x,u)]\\ &\quad+\max_{v\in I\!R^n}[v\cdot\nabla W^0(x) - \gamma^2|v|^2].\end{aligned} \tag{8.3}$$

The analogue of Theorem 5.1 is therefore the following theorem.

THEOREM 8.1. *There exist $\Lambda^0 \ge 0$ and Lipschitz continuous W^0 such that W^0 is a viscosity solution of* (8.3).

The PDE (8.3) can alternatively be written as

$$\begin{aligned}\Lambda^0 &= \min_{u\in U}[f(x,u)\cdot\nabla W^0(x) + L(x,u)]\\ &\quad+\frac{1}{4\gamma^2}|\nabla W^0(x)|^2.\end{aligned} \tag{8.3$'$}$$

As noted in §5, the maximum over $v \in I\!R^n$ in (8.3) can be replaced by the maximum over $|v| \le M$, provided $M \ge (2\gamma^2)^{-1}B$ with B a Lipschitz constant for W^0.

Equation (8.3) is the Isaacs equation for a (deterministic) differential game, with average cost per unit time payoff. Before considering this game, let us first consider some corresponding finite-time-horizon games. There are two controllers (or players). The minimizing controller chooses a Lebesgue-measurable function $u_.$, with values in U. Let $\mathcal{U}^0$ denote the set of such $u_.$. The maximizing controller chooses $v_. \in \mathcal{W}_M^0$, with $\mathcal{W}_M^0$ the set of Lebesgue-measurable $v_.$ such that $|v_t| \le M$ as in §5. The state of the game at time t is ξ_t^0, and the state dynamics are

$$\frac{d\xi_t^0}{dt} = f(\xi_t^0, u_t) + v_t, \tag{8.4}$$

with $\xi_0^0 = x$. The running cost function is $K(x,u,v)$ (see (7.5)). The payoff for the finite-time-horizon game is

$$P = \int_0^T K(\xi_t^0, u_t, v_t)dt + Z(\xi_T^0), \tag{8.5}$$

where Z is a Lipschitz continuous terminal cost function. Later in the section we will consider two choices for Z, namely, $Z = W^0$ and $Z = 0$.

This differential game has a value in the Elliott–Kalton sense. The Elliott–Kalton value is defined in terms of strategies, as follows [8]. A strategy for the maximizing controller is a map α from $\mathcal{U}^0$ into $\mathcal{W}_M^0$ which is "progressive" in the following sense. For each $t > 0$ and $u_., \tilde{u}_. \in \mathcal{U}^0$, $u_r = \tilde{u}_r$ for almost all $r \in [0,t]$ implies that $\alpha[u_.]_r = \alpha[\tilde{u}_.]_r$ for almost all $r \in [0,t]$. This set of strategies is denoted by Δ_M^0. Similarly, a strategy for the minimizing controller is a progressive map $\beta : \mathcal{W}_M^0 \to \mathcal{U}^0$. Let Θ_M^0 denote this set of strategies. For a game with payoff P, let us denote the upper and lower values by $u -$ val P and $\ell -$ val P. Thus

$$(8.6)\qquad \begin{aligned} u - \text{ val } P &= \sup_{\Delta_M^0} \inf_{\mathcal{U}^0} P, \\ \ell - \text{ val } P &= \inf_{\Theta_M^0} \sup_{\mathcal{W}_M} P. \end{aligned}$$

If $u -$ val $P = \ell -$ val P, this is called the Elliott–Kalton value and will be denoted by val P. For the finite-time game (8.4)–(8.5) we also denote upper and lower values by W^u and W^ℓ.

The Isaacs PDE for the finite-time game formulated above is

$$(8.7)\qquad \begin{aligned} W_T = &\min_{u\in U}[f(x,u)\cdot \nabla_x W + L(x,u)) \\ &+ \max_{|v|\le M}[v\cdot \nabla_x W - \gamma^2|v|^2] \end{aligned}$$

with initial data $W(0,x) = Z(x)$. Considered as functions of (T,x), the upper and lower values W^u, W^ℓ are both Lipschitz continuous viscosity solutions to (8.7) with the initial data. This follows from a dynamic programming principle, as was proved by Evans and Souganidis [9]. Uniqueness of viscosity solutions (see [30]) then implies that the finite-time-horizon game has a value $W(T,x)$, where $W = W^\ell = W^u$ is the unique Lipschitz continuous viscosity solution to (8.7) with $W(0,x) = Z(x)$.

Several other definitions of value have been given for differential games; see, for example, [10], [18]. All "reasonable" definitions of value lead to the same (unique) viscosity solution of (8.7) with the initial data. Such results can be proved by a method of Souganidis [35].

THEOREM 8.2. *If W^0 is any Lipschitz continuous viscosity solution of* (8.3), *then for every $T < \infty$*

$$(8.8)\qquad W^0(x) = \text{ val } \left[\int_0^T K(\xi_t^0, u_t, v_t)dt + W^0(\xi_T^0)\right] - \Lambda^0 T.$$

Proof. We replace the running cost function K by $K - \Lambda^0$ and proceed as in the proof of Theorem 5.2. □

We next consider zero terminal cost, and let

$$(8.9)\qquad V^0(T,x) = \text{ val } \int_0^T K(\xi_t^0, u_t, v_t)dt.$$

By the same proof as for Corollary 5.3, we get Corollary 8.3.

COROLLARY 8.3.

$$(8.10)\qquad \Lambda^0 = \lim_{T\to\infty} \frac{1}{T} V^0(T,x)$$

uniformly for x in any compact set.

Let us next show that Λ^0 is the value of the infinite-time-horizon differential game with payoff

$$J^0 = \limsup_{T\to\infty} \frac{1}{T} \int_0^T K(\xi_t^0, u_t, v_t)dt. \tag{8.11}$$

THEOREM 8.4 *For every initial state $x \in I\!R^n, \Lambda^0 =$ val J^0.*

Proof. Let us show that the lower value $\ell -$ val J^0 equals Λ^0. The same technique shows that $u -$ val $J^0 = \Lambda^0$. Given a strategy β for the minimizing controller and an initial state $x = \xi_0^0$, we write in (8.11) $J^0 = J^0(x; \beta, v_.)$, where the control $u_.$ is chosen by $u_t = \beta[v_.]_t$ for all $t \geq 0$. We begin by showing that, given any initial state x, strategy β, and $\delta > 0$, there exists $v_. \in \mathcal{W}_M^0$ such that

$$J^0(x; \beta, v_.) \geq \Lambda^0 - \delta. \tag{8.12}$$

To do this, we proceed in a way similar to the proof of Theorem 5.4. We choose R_1 and T_0 such that (5.14) holds for $|y| \leq R_1$ (where λ^0 is replaced by Λ^0 and V^0 is given by (8.9)). Since $V^0(T, y)$ is the value of the finite-time game with initial state y, given a strategy $\bar\beta$ we have

$$\sup_{v_.} \int_0^{T_0} K(\eta_t^0, \bar\beta[v_.]_t, v_t)dt \geq V^0(T_0, y), \tag{8.13}$$

where η_t^0 is the solution to (8.4) with $\eta_0^0 = y$ and $u_t = \bar\beta[v_.]_t$. We first take $y = x, \bar\beta = \beta$, and choose v_t on $[0, T_0)$ such that

$$\int_0^{T_0} K(\xi_t^0, \beta[v_.]_t, v_t)dt > V^0(T_0, x) - \frac{\delta T_0}{2}.$$

Then we proceed inductively to define v_t on $[NT_0, (N+1)T_0)$ as follows. Suppose that v_t has already been defined for $0 \leq t < NT_0$. Define the strategy β_N as follows. For each $z_. \in \mathcal{W}_M$,

$$\beta_N[z_.] = \beta[z_.^N], \text{ where}$$

$$z_t^N = \begin{cases} v_t & \text{if } 0 \leq t < NT_0, \\ z_{t-NT_0} & \text{if } NT_0 \leq t. \end{cases}$$

In (8.13) we take $y = \xi_{NT_0}^0, \bar\beta = \beta_N$, and $v_.^N$ such that

$$\int_0^{T_0} K(\eta_t^0, \beta_N[v_.^N]_t, v_t^N)dt > V^0(T_0, \xi_{NT_0}^0) - \frac{\delta T_0}{2}.$$

Let $v_t = v_{t+NT_0}^N$ for $NT_0 \leq t < (N+1)T_0$. Then

$$\int_{NT_0}^{(N+1)T_0} K(\xi_t^0, \beta[v_.]_t, v_t)dt > V^0(T_0, \xi_{NT_0}^0) - \frac{\delta T_0}{2}.$$

As in the proof of Theorem 5.5, we obtain (8.12). Thus

$$\ell - \text{ val } J^0 = \inf_\beta \sup_v J^0 \geq \Lambda^0. \tag{8.14}$$

It remains to prove the opposite inequality. Given an initial state x and $\delta > 0$, we again consider R_1, T_0 such that (5.14) holds for $|y| \leq R_1$. For each y with $|y| \leq R_1$ there exists a strategy β^y such that

$$\sup_{v.} \int_0^{T_0} K(\eta_t^0, \beta^y[v.]_t, v_t)dt \leq V^0(T, y) + \frac{\delta T_0}{2}, \tag{8.15}$$

where η_t^0 is the solution of (8.4) with $\eta_0^0 = y$ and $u_t = \beta^y[v.]_t$. We define a strategy β as follows. For $0 \leq t < T_0$, $\beta[v.]_t = \beta^x[v.]_t$. Proceeding inductively, suppose that $\beta[v.]_t$ is defined for $0 \leq t < NT_0$. In (8.14) let $y = y_N = \xi_{NT_0}^0$ and for $NT_0 \leq t < (N+1)T_0$ let

$$\beta[v.]_t = \beta^{y_N}[v_{N}.]_t,$$

$$v_{Nt} = v_t - NT_0, t \geq NT_0.$$

Then

$$\sup_{v.} \int_{NT_0}^{(N+1)T_0} K(\xi_t^0, \beta[v.]_t, v_t)dt \leq V^0(T_0, \xi_{NT_0}^0) + \frac{\delta T_0}{2}.$$

As before we obtain

$$\ell - \text{ val } J^0 = \inf_{\beta} \sup_{v.} J^0 \leq \Lambda^0. \qquad \square \tag{8.16}$$

Robust regulation of nonlinear systems (continued). At the end of §5, we related our results on risk-sensitive control to robust control approaches to disturbance attenuation. The results in §5 apply if a control policy $\underline{u}$ for the minimizing controller is given, and we take $g = g^{\underline{u}}, \ell = \ell^{\underline{u}}$ with

$$g^{\underline{u}}(x) = f(x, \underline{u}(x)), \ \ell^{\underline{u}}(x) = L(x, \underline{u}(x)).$$

If $g^{\underline{u}}$ and $\ell^{\underline{u}}$ satisfy (3.1), then according to Theorem 5.1 there is a pair $\lambda^{0,\underline{u}}$, $W^{0,\underline{u}}$ satisfying the PDE (5.3). Moreover, $\lambda^{0,\underline{u}}$ is the limit of the corresponding long-term growth rate $\lambda^{\epsilon,\underline{u}}$ in (2.1) as $\epsilon \to 0$. From Theorem 7.2(a), $\lambda^{\epsilon,\underline{u}} \geq \Lambda^\epsilon$ and hence $\lambda^{0,\underline{u}} \geq \Lambda^0$. If $\lambda^{0,\underline{u}} = \Lambda^0$ for $\underline{u} = \underline{u}^*$, then we call $\underline{u}^*$ an optimal Markov control policy.

A formal application of dynamic programming suggests that one should take

$$\underline{u}^*(x) \in \arg\min_{u \in U}[f(x,u) \cdot \nabla W^0(x) + L(x,u)]. \tag{8.17}$$

However, this formalism encounters evident, well-known difficulties. For example, the gradient $\nabla W^0(x)$ of the viscosity solution W^0 to (8.3) may not exist for all x.

In view of these difficulties, let us merely state and prove some results which hold in a "classical" setting. Suppose that $W^0 \in C^2(\mathbb{R}^n)$ is a solution to (8.3), with ∇W^0 bounded. Moreover, suppose that $\underline{u}^*$ is Lipschitz continuous on each compact subset of $\mathbb{R}^n$ and satisfies (8.17) for all $x \in \mathbb{R}^n$. Let

$$g^*(x) = g(x, \underline{u}^*(x)), \qquad \ell^*(x) = L(x, \underline{u}^*(x)), k^*(x,v) = \ell^*(x) - \gamma^2|v|^2.$$

By (8.3) and (8.17),

$$\Lambda^0 = g^*(x) \cdot \nabla W^0(x) + \max_{v \in \mathbb{R}^n}[v \cdot \nabla W^0(x) + k^*(x,v)],$$

which is just equation (5.3) with $g = g^*, k = k^*$. Let ξ_t^0 satisfy (5.5) with $g = g^*$. Formula (5.6) with $k = k^*, \lambda^0 = \Lambda^0$ is now elementary, since W^0 is a classical solution. An optimal $v^*_\cdot$ in (5.6) is given via the Markov control policy $\underline{v}^*(x) = (2\gamma^2)^{-1}\nabla W^0(x)$, namely, $v_t^* = \underline{v}^*(\xi_t^*)$, where ξ_t^* is the corresponding solution to (5.5) with $\xi_0^* = x$. We have not assumed that g^* satisfies (3.1c). However, the corresponding assumption (7.2) implies that given $R > 0$ there exists R_1 such that $|\xi_t^0| \le R_1$ whenever $|\xi_0^0| \le R$. As in the proof of Corollary 5.3,

$$\Lambda_0 = \lim_{T\to\infty} \frac{1}{T} V^{0*}(T, x),$$

where $V^{0*} = V^0$ for the above choices g^*, k^*. We then define, as in (5.11),

$$J^{0*}(x; v_\cdot) = \limsup_{T\to\infty} \frac{1}{T} \int_0^T k^*(\xi_t^0, v_t)dt.$$

The proof of Theorem 5.5 is unchanged. Thus

$$\Lambda^0 = \sup_{v_\cdot \in \mathcal{W}_M} J^{0*}(x; v_\cdot).$$

Moreover, (5.13) holds: for every T and $v_\cdot \in \mathcal{W}_M$

$$W^0(\xi_T^*) - W^0(x) \le -\int_0^T [\ell^*(\xi_t^0) - \gamma^2|v_t|^2]dt + \Lambda^0 T.$$

In particular, if $\Lambda^0 = 0$ this is the dissipation inequality (5.15).

Appendix A. *Proof of Lemma* 3.1. Let $\xi_\cdot$ be a solution to (3.6), and let $k \ge |x|$. We define the stopped process $\xi_\cdot^k$ by

$$\tau_k = \inf\{t : |\xi_t| \ge k\},$$

$$\xi_t^k = \begin{cases} \xi_t & \text{if } t \le \tau_k, \\ \xi_{\tau_k} & \text{if } t > \tau_k. \end{cases}$$

By the continuity of ∇F and the boundedness of $\xi_\cdot^k$, we see that

$$\int_0^t \nabla F(\xi_r^k) \cdot dw_r$$

is a square-integrable martingale. Therefore, by Ito's rule

$$E_x F(\xi_t^k) = F(x) + E_x \left[\int_0^{t\wedge\tau_k} \hat{G}F(\xi_r^k)dr\right], \tag{A.1}$$

where

$$\hat{G}\psi = \frac{\epsilon}{4\gamma^2}\Delta\psi + (g + v)\cdot\nabla\psi.$$

Note that, when $|v| \le M$,

$$\begin{aligned}\hat{G}F(\xi_t^k) \le \frac{KF(\xi_t^k)}{\sqrt{1+|\xi_t^k|^2}} \Bigg\{ & 2KM|\xi_t^k| - 2cK|\xi_t^k|^2 \\ & + \frac{\epsilon}{4\gamma^2}(n+K)(1+|\xi_t^k|)\Bigg\} \\ \equiv h(\xi_t^k).\end{aligned}$$

There exists $R_0 < \infty$ such that $h(x) \le 0$ if $|x| \ge R_0$. Thus, letting $C_2 = \max_{|x| \le R_0} h(x)$, we have by (A.1)

$$E_x F(\xi_t^k) \le F(x) + C_2 t \text{ for all } t < \infty. \tag{A.2}$$

Since C_2 is independent of k, applying Fatou's lemma to (A.2) yields

$$E_x F(\xi_t) \le F(x) + C_2 t. \tag{A.3}$$

Applying Ito's rule to the original system, (3.6), one has

$$\begin{aligned} F(\xi_t) = F(x) &+ \int_0^t \hat{G}F(\xi_r)dr \\ &+ \sqrt{\frac{\epsilon}{2\gamma^2}}K \int_0^t \frac{F(\xi_r)}{\sqrt{1+|\xi_r|^2}}\xi_r \cdot dw_r. \end{aligned} \tag{A.4}$$

But since (A.3) holds for arbitrary K, the last term in (A.4) is a square-integrable martingale. Therefore, taking expectations, one obtains

$$E_x F(\xi_t) = F(x) + E_x \int_0^t \hat{G}F(\xi_r)dr. \tag{A.5}$$

Note that (3.1c) implies that there exists $m < \infty$ such that $x \cdot g(x) \le -c|x|^2 + m|x|$ for all x. This yields a $C_3 < \infty$ such that

$$\hat{G}F \le [C_3 - c \log F]F.$$

Employing this inequality, Tonelli's theorem, and (A.5) yields

$$E_x F(\xi_t) \le F(x) + \int_0^t E_x\{[C_3 - c\log G(\xi_r)]G(\xi_r)\}ds.$$

Then, by Jensen's inequality, we have

$$E_x F(\xi_t) \le F(x) + \int_0^t \{C_3 - c \log E_x F(\xi_r)\} E_x F(\xi_r) dr.$$

A simple Lyapunov argument then yields the result. □

Appendix B. In this appendix we review, without proofs, some results about semilinear parabolic PDEs which were used in §§4 and 7. Consider an initial value problem for a PDE of the form

$$\frac{\partial V}{\partial T} + \rho V = D\Delta_x V + H(x, \nabla_x V), \qquad \rho > 0, D > 0 \tag{B.1}$$

with the initial data

$$V(0, x) = 0. \tag{B.2}$$

In (4.3), we have $D = \epsilon(4\gamma^2)^{-1}$ and

$$H(x,p) = \max_{|v| \le M} [(g(x) + v) \cdot p + k(x, v)], \tag{B.3}$$

with $k(x,v) = \ell(x) - \gamma^2|v|^2$, while in (7.14) we have the same D and

$$H(x,p) = \min_{u \in V}[f(x,u) \cdot p + L(x,u)] \tag{B.4}$$
$$+ \max_{|v| \leq M}[v \cdot p - \gamma^2 |v|^2].$$

Assumptions (3.1a) and (3.1b), (7.1)–(7.2) in both cases lead to

$$\text{(B.5)}\qquad \begin{aligned} &\text{(a)} \quad |H(x,p) - H(x',p)| \leq C_1(1+|p|)|x - x'|, \\ &\text{(b)} \quad |H(x,p) - H(x,p')| \leq C_2(1+|x|)|p - p'| \end{aligned}$$

for suitable constant C_1, C_2. If H is as in either (B.3) or (B.4), then there exists a "classical" solution $V(T,x)$ to (B.1)–(B.2) with all partial derivatives $V_T, V_{x_i}, V_{x_i x_j}$, $i,j = 1,\ldots,n$, continuous and $|\nabla_x V|$ bounded. In fact, these partial derivatives are Hölder continuous on every compact set. (In §§3 and 4 this solution is denoted by $V_\rho(T,x)$, and in §7 by $\bar{V}(T,x)\cdot$.) This existence theorem can be obtained from standard existence theorems for parabolic PDEs (see [17], [29], or [31]) by making some approximations. This procedure is described in detail in [30], and hence we merely sketch it here. If in addition to (3.1a) and (3.1b), the function g is bounded, then on the right side of (B.5b) one can replace $C_2(1+|x|)$ by some constant C_3. Existence of a classical solution then follows from [31, Thm. 14] or corresponding results in [17], [29]. One then approximates g by a sequence of bounded functions g_k, with $(g_k)_x$ bounded independent of $k = 1, 2, \ldots$. If we use the control interpretation (4.2) for the correponding solution $V_k(T,x)$, a uniform bound for $|\nabla_x V_k|$ is obtained. (Unlike the bound (4.4b) the bound may depend on T.) Once a uniform bound for $|\nabla_x V_k|$ is obtained, estimates for solutions of linear parabolic PDEs imply Hölder estimates for all partial derivatives $(V_k)_T, (V_k)_{x_i x_j}, i,j = 1,\ldots,n$, which are uniform on every compact set. Finally, the uniform bound $0 \leq V_k \leq \rho^{-1}\|\ell\|$ holds. We obtain V as the limit of V_k as $k \to \infty$ through some sequence.

The Hölder estimates for $V_{x_i}, V_{x_i x_j}$ are also uniform with respect to ρ and T, since the bound $|\nabla_x V| \leq \|\nabla \ell\| c^{-1}$ holds independent of ρ and T according to (4.4b). (Here $V = V_\rho$ in the notation of §4.) Therefore, the limit $W = W_\rho$ as $T \to \infty$ is a classical solution to the semilinear elliptic PDE (4.9).

For §7, with H as in (B.4), one proceeds similarly by making bounded approximations f_k to f, with $(f_k)_x$ uniformly bounded. A uniform bound for $|\nabla_x V_k|$ can be obtained by using the interpretation of $V_k(T,x)$ as the upper value of a stochastic differential game (with f replaced by f_k in (7.10).)

PARALLEL GRADIENT DISTRIBUTION IN UNCONSTRAINED OPTIMIZATION*

O. L. MANGASARIAN†

Abstract. A parallel version is proposed for a fundamental theorem of serial unconstrained optimization. The parallel theorem allows each of k parallel processors to use simultaneously a different algorithm, such as a descent, Newton, quasi-Newton, or conjugate gradient algorithm. Each processor can perform one or many steps of a serial algorithm on a portion of the gradient of the objective function assigned to it, independently of the other processors. Eventually a synchronization step is performed which, for differentiable convex functions, consists of taking a strong convex combination of the k points found by the k processors. A more general synchronization step, applicable to convex as well as nonconvex functions, consists of taking the best point found by the k processors or any point that is better. The fundamental result that we establish is that any accumulation point of the parallel algorithm is stationary for the nonconvex case and is a global solution for the convex case. Computational testing on the Thinking Machines CM-5 multiprocessor indicates a speedup of the order of the number of processors employed.

Key words. parallel optimization, gradient methods, unconstrained optimization

AMS subject classification. 90C30

1. Introduction.

In this work we are interested in parallel algorithms for solving the unconstrained minimization problem

$$\min_{x \in R^n} f(x), \tag{1}$$

where f is a differentiable function from the n-dimensional real space R^n into R. The basic idea behind our approach is to assign a portion of the gradient ∇f of f to one of k processors, let each processor perform one or more steps of a serial algorithm on its portion of the gradient, and then synchronize the processors eventually. The synchronization consists of taking a strong convex combination of the k points found by the k processors when f is convex. For nonconvex f, the best point found by the k processors can be taken, or any other point with a lower value of f will work.

The fundamental theorem we intend to parallelize is related to some classical forcing function theorems given in [7], [4], [11] that establish convergence for a wide class of algorithms. Such algorithms typically consist of a direction choice followed by a stepsize choice. The combined direction–stepsize choice generates a decrease in the objective function that forces the eventual satisfaction of an optimality condition, namely, the vanishing of the gradient. Direction choices include descent directions, Newton, quasi-Newton, and conjugate directions. Stepsize choices along the chosen direction include minimization, finding the first stationary point, interval stepsize, the Armijo stepsize, and others. Related algorithms, wherein the objective function is sequentially minimized with respect to certain variables, include the serial algorithm proposed by Warga [16] for a strictly convex function in each block of variables and in which the function is sequentially minimized for each block of variables, and the coordinate descent methods of Tseng [15] and Luo and Tseng [8]. Other parallelization schemes are discussed extensively in [2].

This research was supported by Air Force Office of Scientific Research grants AFOSR-89-0410 and F49620-94-1-0036 and National Science Foundation grants CCR-9101801, CCR-9322479, and CDA-9024618.

We note that our parallelization proofs are direct extensions of those for general serial algorithms. However the resulting parallel algorithms are quite general and have significant theoretical and computational implications. For example, the parallelization proposed here played an important role in establishing the convergence and computational results of the parallel back-propagation algorithm of neural networks [9], the parallel variable distribution algorithm for unconstrained and constrained optimization [6], and the parallel multicategory discrimination problem [1].

We give now an outline of the paper. In §2 we establish two serial convergent algorithm theorems, 2.1 and 2.2 (SCAT1 and SCAT2), which cover many unconstrained direction–stepsize algorithms that are suitable for parallelization. We also give a number of specific instances of well-known algorithms satisfying conditions of these theorems. In §3 we establish a number of parallel convergent algorithm theorems that utilize the serial algorithms. In Theorem 3.1 (convex PCAT1), which covers the convex case, each processor takes one step of any serial algorithm covered by SCAT1 or SCAT2, and then a strong convex combination (positively weighted average) of all the points is taken as the next iterate. Corollary 3.1 (nonconvex PCAT1) differs from convex PCAT1 in that the synchronization step consists of taking the best point found by the k processors or searching for a better point. By better we mean, of course, lower f value. Corollary 3.2 (partially asynchronous nonconvex PCAT1) allows partial asynchronization among the k processors in the sense that each processor is free to perform any number of steps of the serial algorithm that is desirable (say, until further improvement in each processor is very small), followed by a synchronization step that consists of taking the best point or searching for a better one. Theorem 3.2 (partially asynchronous nonconvex PCAT2) combines, in a manner similar to SCAT2 for the serial case, the direction and stepsize choices of Corollary 3.2 into a simpler and more general forcing function condition (20). However, this theorem is not as suggestive of an explicit computational scheme as the partially asynchronous nonconvex PCAT1 of Corollary 3.2. In the concluding section we report briefly on computational experience with parallel gradient distribution algorithms on multicategory discrimination problems [1] and on publicly available test problems [6] from the constrained and unconstrained testing environment CUTE [3]. Computations were carried out on the Thinking Machines CM-5 multiprocessor. Speedup efficiency depended on problem size and number of processors employed (2 to 32) and averaged between 129% and 20%.

We now briefly describe our notation. The sequence $\{x_i\}$, $i = 0, 1, \ldots,$ will represent iterates in the n-dimensional real space R^n generated by some algorithm. For $\ell = 1, \ldots, k$, $x_i^\ell \in R^{n^\ell}$ will represent an n^ℓ-dimensional subset of components of x_i, where $\sum_{\ell=1}^k n^\ell = n$. The complement of ℓ in $\{1, \ldots, k\}$ will be denoted by $\bar{\ell}$, and we write $x_i = (x_i^\ell, x_i^{\bar{\ell}})$, $\ell = 1, \ldots, k$. For a differentiable function $f\colon R^n \to R$, ∇f will denote the n-dimensional vector of partial derivatives with respect to x, and $\nabla_\ell f$ will denote the n^ℓ-dimensional vector of partial derivatives with respect to $x^\ell \in R^{n^\ell}$, $\ell = 1, \ldots, k$. For k points y in R^n, $\sum_{j=1}^k \lambda_j y_j$, such that $\lambda_j \geq \delta > 0$ and $\sum_{j=1}^k \lambda_j = 1$, is said to be a strong convex combination of the points y_j, $j = 1, \ldots, k$. If f has continuous first partial derivatives on R^n, we say $f \in C^1(R^n)$. If f has Lipschitz continuous first partial derivatives on R^n with constant $K > 0$, that is,

$$\|\nabla f(y) - \nabla f(x)\| \leq K\|y - x\| \qquad \forall x,\ y \in R^n,$$

we write $f \in LC_K^1(R^n)$. Here and throughout, $\|\cdot\|$ denotes the two norm, that is, $\|z\| = (z^T z)^{\frac{1}{2}}$ for z in a finite-dimensional real space of unspecified dimension.

2. Serial convergent algorithm theorems. We begin first with a simple serial convergent algorithm theorem (SCAT1) for the solution of the unconstrained minimization problem (1). The theorem is related to some classical forcing function theorems given in [7] and [4] that establish convergence for a wide class of algorithms that consist of a direction choice followed by a stepsize choice. The decrease in the objective function forces the satisfaction of an optimality condition, namely, the vanishing of the gradient. Before stating and proving SCAT1 we adapt the definition of a forcing function [10, p. 479] for our purposes.

DEFINITION 2.1 (forcing function). *A continuous function σ from the nonnegative real line R_+ into itself such that $\sigma(0) = 0$, $\sigma(\zeta) > 0$ for $\zeta > 0$, and for the sequence of nonnegative real numbers $\{\zeta_i\}$*

$$\{\sigma(\zeta_i)\} \rightarrow 0 \text{ implies } \{\zeta_i\} \rightarrow 0$$

is said to be a forcing function on the sequence $\{\zeta_i\}$.

Some simple typical examples of forcing functions are

$$\alpha\zeta,\ \alpha\zeta^2,\ \max\{\sigma_1(\zeta),\ \sigma_2(\zeta)\},\ \min\{\sigma_1(\zeta),\ \sigma_2(\zeta)\} \text{ and } \sigma_2(\sigma_1(\zeta)),$$

where α is a positive number and $\sigma_1(\zeta)$ and $\sigma_2(\zeta)$ are forcing functions. We now state and prove SCAT1.

THEOREM 2.1 (serial convergent algorithm theorem 1 (SCAT1)). *Let $f \in C^1(R^n)$. Start with any $x_0 \in R^n$. Given x_i, stop if $\nabla f(x_i) = 0$, else compute x_{i+1} from a direction d_i and stepsize λ_i as follows. Choose direction d_i such that*

$$-\nabla f(x_i)^T d_i \geq \sigma_1(\|\nabla f(x_i)\|), \tag{2}$$

where σ_1 is a forcing function on $\{\|\nabla f(x_i)\|\}$. Choose stepsize λ_i such that

$$x_{i+1} = x_i + \lambda_i d_i \tag{3}$$

and

$$f(x_i) - f(x_{i+1}) \geq \sigma_2(-\nabla f(x_i)^T d_i) \geq 0, \tag{4}$$

where σ_2 is a forcing function on the sequence of nonnegative real numbers $\{-\nabla f(x_i)^T d_i\}$ for bounded $\{d_i\}$. Then either $\{x_i\}$ terminates at a stationary point $x_{\bar{i}}$, that is, $\nabla f(x_{\bar{i}}) = 0$, or $\nabla f(\bar{x}) = 0$ for each accumulation point $(\bar{x}, \bar{d})$ of the sequence $\{x_i, d_i\}$.

Proof. The algorithm terminates at an $x_{\bar{i}}$ only if $\nabla f(x_{\bar{i}}) = 0$. Suppose now it does not terminate and that $\{(x_{i_j},\ d_{i_j})\} \rightarrow (\bar{x},\ \bar{d})$. Since f is continuous, $\lim_{j\rightarrow\infty} f(x_{i_j}) = f(\bar{x})$. By the stepsize condition (4), the sequence $\{f(x_i)\}$ is nonincreasing and has an accumulation point $f(\bar{x})$, and hence converges to $f(\bar{x})$. By (4) and the continuity of $\sigma_2(\zeta)$

$$0 = \lim_{j\rightarrow\infty} f(x_{i_j}) - f(x_{i_j+1}) \geq \lim_{j\rightarrow\infty} \sigma_2(-\nabla f(x_{i_j})^T d_{i_j}) = \sigma_2(-\nabla f(\bar{x})^T \bar{d}) \geq 0.$$

Hence $\nabla f(\bar{x})^T \bar{d} = 0$. But by the direction condition (2)

$$0 = -\nabla f(\bar{x})^T \bar{d} = -\lim_{j\rightarrow\infty} \nabla f(x_{i_j})^T d_{i_j} \geq \lim_{j\rightarrow\infty} \sigma_1(\|\nabla f(x_{i_j})\|) = \sigma_1(\|\nabla f(\bar{x})\|) \geq 0.$$

Hence $\nabla f(\bar{x}) = 0$. □

We note that the boundedness condition on $\{d_i\}$, which does not restrict Theorem 2.1, was not explicitly used in the proof. However, this condition simplifies the application of the theorem to specific stepsize choices, such as the first stationary point and Armijo stepsize choices given below.

We give now examples of direction and stepsize choices that satisfy the assumptions of Theorem 2.1.

Example 2.1 (serial direction choices). For $f \in C^1(R^n)$ and σ a forcing function, a direction $d_i \in R^n$ satisfying any of the following conditions will satisfy condition (2):

(i) descent direction:

$$-d_i^T \nabla f(x_i) \geq \alpha \|\nabla f(x_i)\|^\beta \text{ for some } \alpha > 0,\ \beta > 0.$$

(ii) quasi-Newton direction:

$$d_i = -H_i \nabla f(x_i),\ H_i \in R^{n \times n},\ z^T H_i z \geq \alpha \|z\|^2 \qquad \forall z \in R^n, \text{ for some } \alpha > 0.$$

(iii) conjugate direction:

$$d_i = -\nabla f(x_i) + \alpha_i d_{i-1},$$

$$\frac{\|\nabla f(x_i)\|^2}{\|\nabla f(x_i)\| + |\alpha_i| \|d_{i-1}\|} \geq \sigma(\|\nabla f(x_i)\|), \tag{5}$$

where σ is a forcing function on $\{\|\nabla f(x_i)\|\}$.

We note that the conjugate direction conditions of (iii) are satisfied by the Polyak–Polak–Ribière [11]–[14] coefficient

$$\alpha_i := \frac{(\nabla f(x_i) - \nabla f(x_{i-1}))^T \nabla f(x_i)}{\|\nabla f(x_{i-1})\|^2} \tag{6}$$

for $f \in C^2(R^n)$ and such that

$$\beta \|z\|^2 \geq z^T \nabla^2 f(x) z \geq \alpha \|z\|^2 \qquad \forall z \in R^n \text{ for some } \beta \geq \alpha > 0. \tag{7}$$

We also note that the Newton direction $d_i = -\nabla^2 f(x_i)^{-1} \nabla f(x_i)$ satisfies (ii) above under the same condition (7).

We give now stepsize choices that satisfy conditions (3) and (4) of Theorem 2.1.

Example 2.2 (serial stepsize choices). For $d_i \in R^n$ and $f \in C^1(R^n)$, a $\lambda_i \geq 0$ satisfying any one of the following conditions will satisfy conditions (3) and (4) of Theorem 2.1:

(i) minimum along d_i:

$$\lambda_i \in \arg\min_{\lambda \geq} f(x_i + \lambda d_i),\ f \in LC_K^1(R^n);$$

(ii) first stationary point:

$$\lambda_i \in \arg\min_{\lambda \geq} \{\lambda | \nabla f(x_i + \lambda d_i)^T d_i = 0\},\ f \in LC_K^1(R^n);$$

(iii) interval stepsize:

$$0 < \varepsilon_1 \leq \lambda_i \leq \frac{2}{\rho K} - \varepsilon_2,\ \|d_i\|^2 \leq -\rho \nabla f(x_i)^T d_i,\ f \in LC^1_K(R^n)$$

for some $\varepsilon_1 > 0$, $\varepsilon_2 > 0$ and $\rho > 0$;

(iv) Armijo [5, pp. 118–119]:

$$\lambda_i = \max\left\{\bar{\lambda}_i,\ \frac{\bar{\lambda}_i}{2}, \ldots\right\} \text{ such that}$$

$$f(x_i) - f(x_i + \lambda_i d_i) \geq -\delta \lambda_i \nabla f(x_i)^T d_i \quad \text{for some } \delta \in (0,1),$$

and $\bar{\lambda}_i \geq (\sigma(-\nabla f(x_i)^T d_i))/(-\nabla f(x_i)^T d_i)$, where σ is a forcing function and $f \in LC^1_K(R^n)$.

It takes a bit of algebra to show that each of the four stepsizes (i) to (iv) above satisfy conditions (3) and (4) of Theorem 2.1. We omit the details here.

We note that Theorem 2.1 can be written in a more general and simpler but algorithmically less suggestive form by combining conditions (2) and (4) into the single condition (8) below. This results in the following theorem, the proof of which either follows from that of Theorem 2.1 or can be given in a few lines as is done below.

THEOREM 2.2 (serial convergent algorithm theorem 2 (SCAT2)). *Let $f \in C^1(R^n)$. Start with any $x_0 \in R^n$. Given x_i, stop if $\nabla f(x_i) = 0$, else determine x_{i+1} such that*

$$f(x_i) - f(x_{i+1}) \geq \sigma(\|\nabla f(x_i\|), \tag{8}$$

where σ is a forcing function on $\{\|\nabla f(x_i)\|\}$. Then either $\{x_i\}$ terminates at a stationary point $x_{\bar{i}}$ or each accumulation point $\bar{x}$ of $\{x_i\}$ is stationary.

Proof. Suppose $\nabla f(x_i) \neq 0$ for all i and that $\{x_{i_j}\}$ converges to $\bar{x}$. Since the nonincreasing sequence $\{f(x_i)\}$ has an accumulation $f(\bar{x})$, it converges to $f(\bar{x})$. By (8) we have that

$$0 = \lim_{j\to\infty} (f(x_{i_j}) - f(x_{i_j+1})) \geq \lim_{j\to\infty} \sigma(\|\nabla f(x_{i_j})\|) \geq 0.$$

Hence $\lim_{j\to\infty} \|\nabla f(x_{i_j})\| = 0$ and $\nabla f(\bar{x}) = 0$. □

We note that the full sequences $\{f(x_i)\}$ and $\{\|\nabla f(x_i)\|\}$ converge if f is bounded below. We state this as the following corollary.

COROLLARY 2.1 (function and gradient convergence). *Let f be bounded below on the level set $S(x_0) = \{x | f(x) \leq f(x_0)\}$. Then the sequence $\{f(x_i)\}$ of Theorems* 2.1 *and* 2.2 *converges, and* $\lim_{i\to\infty} \|\nabla f(x_i)\| = 0$.

Proof. From (8) the sequence $\{f(x_i)\}$ is nonincreasing, and since $\{x_i\}$ remains in $S(x_0)$, $\{f(x_i)\}$ is bounded below and hence converges. From (8), we have that $\lim_{i\to\infty} \sigma(\|\nabla f(x_i)\|) = 0$, and hence $\lim_{i\to\infty} \|\nabla f(x_i)\| = 0$. □

We now proceed to establish parallel versions of Theorems 2.1 and 2.2 and other parallel results.

3. Parallel convergent algorithm theorems.

We shall establish in this section parallel versions of Theorems 2.1 and 2.2. The importance of these theorems, PCAT1 and PCAT2, is that they enable each of k processors to perform, on a portion of the gradient that is assigned to it, one or more iterations of the serial algorithms independently of the other processors. The processor picks a direction and stepsize based on the partial gradient assigned to it. A simple synchronization step follows in which a new point is generated by a strong convex combination of the k points obtained by the k processors for the convex case and by using the best, or better, point obtained by the k processors for the nonconvex case. We first state and prove Theorem 3.1, our parallel theorem for the convex case. Corollary 3.1 extends Theorem 3.1 to the nonconvex case. Corollary 3.2 further extends Corollary 3.1 by allowing partial asynchronization by letting each processor take as many steps as desirable. Finally Theorem 3.2 gives a more general version of Theorem 3.1 for the nonconvex case. We note here that a referee pointed out that the distribution of the gradient can also be made with respect to subspaces induced by other decompositions of R^n. For example, the iterate x_i can be decomposed into $x_i^\ell = P_\ell x_i$, $\ell = 1, \ldots, k$, instead of into subvectors x_i^ℓ of x_i. Here $P_1, \ldots, P_k$ are projection matrices (that is $P_i^2 = P_i$, $P_i^T = P_i$, $i = 1, \ldots, k$) such that $\sum_{i=1}^k P_i = I$.

THEOREM 3.1 (convex parallel convergent algorithm theorem 1 (convex PCAT1)). *Let $f \in C^1(R^n)$ be convex on R^n. Start with any $x_0 \in R^n$. Given x_i, stop if $\nabla f(x_i) = 0$, else compute x_{i+1} from directions $d_i^\ell \in R^{n^\ell}$ and stepsizes $\lambda_i^\ell \in R$, $\ell = 1, \ldots, k$, $\sum_{\ell=1}^k n^\ell = n$. Choose directions d_i^ℓ such that*

$$-\nabla_\ell f(x_i)^T d_i^\ell \geq \tau_\ell(\|\nabla_\ell f(x_i)\|),\ \ell = 1, \ldots k, \tag{9}$$

where τ_ℓ is a forcing function on $\{\|\nabla_\ell f(x_i)\|\}$, $\ell = 1, \ldots, k$. Choose stepsizes λ_i^ℓ, choose λ_i^ℓ, $\ell = 1, \ldots, k$ such that for $\bar{\ell}$, the complement of ℓ in $\{1, \ldots, k\}$,

$$f(x_i) - f(x_i^\ell + \lambda_i^\ell d_i^\ell,\ x_i^{\bar{\ell}}) \geq \mu_\ell(-\nabla_\ell f(x_i)^T d_i^\ell) \geq 0, \qquad \ell = 1, \ldots, k, \tag{10}$$

where μ_ℓ is a forcing function on the sequence of nonnegative real numbers $\{-\nabla_\ell f(x_i)^T d_i^\ell\}$ for bounded $\{d_i^\ell\}$, $\ell = 1, \ldots, k$. For synchronization, let

$$x_{i+1}^\ell = x_i^\ell + \nu_i^\ell \lambda_i^\ell d_i^\ell, \qquad \ell = 1, \ldots, k, \tag{11}$$

$$\sum_{\ell=1}^k \nu_i^\ell = 1, \qquad \nu_i^\ell \geq \delta > 0,\ \ell = 1, \ldots, k. \tag{12}$$

Then either $\{x_i\}$ terminates at a solution $x_{\bar{i}}$ of (1) or, for each accumulation point $(\bar{x}, \bar{d})$ of $\{x_i, d_i\}$, $\bar{x}$ is a solution of (1).

Proof. First we show that the sequence $\{f(x_i)\}$ is nonincreasing.

$$\begin{aligned}
&f(x_i) - f(x_{i+1}) \\
&\quad = f(x_i^1, \ldots, x_i^k) - f(x_i^1 + \nu_i^1 \lambda_i^1 d_i^1, \ldots, x_i^k + \nu_i^k \lambda_i^k d_i^k) \\
&\quad = f(x_i^1, \ldots, x_i^k) \\
&\qquad -f\left(\nu_i^1(x_i^1 + \lambda_i^1 d_i^1) + \left(\sum_{\ell=2}^k \nu_i^\ell\right) x_i^1, \ldots, \nu_i^k(x_i^k + \lambda_i^k d_i^k) + \left(\sum_{\ell=1}^{k-1} \nu_i^\ell\right) x_i^k\right) \\
&\quad \geq \nu_i^1[f(x_i^1, \ldots, x_i^k) - f(x_i^1 + \lambda_i^1 d_i^1,\ x_i^2, \ldots\ x_i^k)] \\
&\qquad + \cdots + \nu_i^k[f(x_i^1, \ldots,\ x_i^k) - f(x_i^1, \ldots,\ x_i^{k-1},\ x_i^k + \lambda_i^k d_i^k)] \quad \text{(by convexity of } f) \\
&\quad \geq \delta \sum_{\ell=1}^k \mu_\ell(-\nabla_\ell f(x_i)^T d_i^\ell) \qquad \text{(by (12) and (10))}. \qquad (13)
\end{aligned}$$

Hence

$$f(x_i) - f(x_{i+1}) \geq \delta \sum_{\ell=1}^{k} \mu_\ell(-\nabla_\ell f(x_i)^T d_i^\ell) \geq 0, \tag{14}$$

and the sequence $\{f(x_i)\}$ is nonincreasing.

Now the sequence $\{x_i\}$ of the PCAT1 algorithm terminates only if $\nabla f(x_{\bar{i}}) = 0$, in which case $x_{\bar{i}}$ solves (1). Now suppose that it does not terminate and that $\{(x_{i_j}, d_{i_j})\} \to (\bar{x}, \bar{d})$. Since f is continuous, $\lim_{j\to\infty} f(x_{i_j}) = f(\bar{x})$. Hence the nonincreasing sequence $\{f(x_i)\}$ has an accumulation point $f(\bar{x})$, and consequently the sequence converges to $f(\bar{x})$. By (14) and the continuity of μ_ℓ, $\ell = 1, \ldots, k$, we have that

$$\begin{aligned} 0 &= \lim_{j\to\infty} (f(x_{i_j}) - f(x_{i_j+1})) \\ &\geq \delta \lim_{j\to\infty} \sum_{\ell=1}^{k} \mu_\ell(-\nabla_\ell f(x_{i_j})^T d_{i_j}^\ell) = \delta \sum_{\ell=1}^{k} \mu_\ell(-\nabla_\ell f(\bar{x})^T \bar{d}^\ell) \geq 0. \end{aligned}$$

Hence $\nabla f(\bar{x})^T \bar{d} = 0$. But by the direction condition (9)

$$\begin{aligned} 0 = \nabla f(\bar{x})^T \bar{d} &= -\lim_{j\to\infty} \nabla f(x_{i_j})^T d_{i_j} \\ &\geq \lim_{j\to\infty} \sum_{\ell=1}^{k} \tau_\ell(\|\nabla f_\ell(x_{i_j})\|) = \sum_{\ell=1}^{k} \tau_\ell(\|\nabla f_\ell(\bar{x})\|) \geq 0. \end{aligned}$$

Hence $\nabla_\ell f(\bar{x}) = 0$, $\ell = 1, \ldots, k$, and consequently $\nabla f(\bar{x}) = 0$ and $\bar{x}$ solves (1). □

We note that the convexity of f was needed in (13) in the proof above, as well as to show that the stationary point generated by PCAT1 is a global solution of $\min_{x\in R^n} f(x)$. However, it is easy to extend Theorem 3.1 to nonconvex f by changing the synchronization procedure (11)–(12) to one that takes the best of the points found by the k processors or a better point. We state this as the following corollary.

COROLLARY 3.1 (nonconvex parallel convergence algorithm theorem 1 (nonconvex PCAT1)). *Theorem* 3.1 *holds for nonconvex f, with a resulting stationary point, if the synchronization procedure* (11)–(12) *is replaced by the following:*

For synchronization, find x_{i+1} such that

$$f(x_{i+1}) \leq \min_{1\leq\ell\leq k} f(x_i^\ell + \lambda_i^\ell d_i^\ell, x_i^{\bar{\ell}}). \tag{15}$$

Proof. The only changes needed in the proof of Theorem 3.1 in order to apply it here are the following. Replace δ with $\frac{1}{k}$ in (14) and the string of inequalities of (13), which establish the monotonicity of $\{f(x_i)\}$ through the convexity of f, with the following:

$$\begin{aligned} f(x_i) - f(x_{i+1}) &\geq \frac{1}{k}\left[f(x_i) - f(x_i^1 + \lambda_i^1 d_i^1, x_1^2, \ldots, x_i^k)\right] \\ &\quad + \cdots + \frac{1}{k}\left[f(x_i) - f(x_i^1, \ldots, x_i^{k-1}, x_i^k + \lambda_i^k d_i^k)\right] \quad \text{(by (15))} \\ &\geq \frac{1}{k} \sum_{\ell=1}^{k} \mu_\ell(-\nabla_\ell f(x_i)^T d_i^\ell). \qquad \square \end{aligned}$$

We note now that partial asynchronization of the k processors for the nonconvex PCAT1 is possible if we allow each of the k processors to take as many steps as desired until, say, they encounter slow convergence, provided we terminate each processor ℓ, $\ell = 1, \dots, k$, at a point $(y_i^\ell, x_i^{\bar{\ell}})$ such that

$$f(y_i^\ell, x_i^{\bar{\ell}}) \leq f(x_i^\ell + \lambda_i^\ell d_i, x_i^{\bar{\ell}}), \qquad \ell = 1, \dots k, \tag{16}$$

where λ_i^ℓ, $\ell = 1, \dots, k$, satisfy (10). Such an inequality is easily satisfied, for example, when each processor takes a desired number of steps in R^{n^ℓ} determined by any of the standard serial algorithms described in §2 on the function $f(x_i^\ell, x_i^{\bar{\ell}})$ starting at $(x_i^\ell + \lambda_i^\ell d_i^\ell, x_i^{\bar{\ell}})$. After these parallel steps are performed by each processor, then an eventual synchronization step is needed that consists of determining x_{i+1} such that

$$f(x_{i+1}) \leq \min_{1 \leq \ell \leq k} f(y_i^\ell, x_i^{\bar{\ell}}). \tag{17}$$

We summarize these procedures as the following partially asynchronous algorithm.

COROLLARY 3.2 (partially asynchronous nonconvex PCAT1). *Theorem* 3.1 *holds for nonconvex f, with a resulting stationary point, if the stepsize choices* (10) *and synchronization procedure* (11)–(12) *are changed to the following.*

Partially asynchronous stepsize: Choose y_i^ℓ, $\ell = 1, \dots, k$, such that for $\bar{\ell}$, the complement of ℓ in $\{1, \dots, k, \}$,

$$f(x_i) - f(y_i^\ell, x_i^{\bar{\ell}}) \geq \mu_\ell(-\nabla_\ell f(x_i)^T d_i^\ell) \geq 0, \qquad \ell = 1, \dots, k, \tag{18}$$

where μ_ℓ is a forcing function on the sequence of nonnegative real numbers $\{-\nabla_\ell f(x_i)^T d_i^\ell\}$ for bounded $\{d_i^\ell\}$, $\ell = 1, \dots, k$.

Comment: Inequality (18) *is easily implemented by satisfying* (16) *and* (10).

Synchronization: Find x_{i+1} such that

$$f(x_{i+1}) \leq \min_{1 \leq \ell \leq k} f(y_i^\ell, x_i^{\bar{\ell}}). \tag{19}$$

Proof. The only changes needed in the proof of Theorem 3.1 in order to apply it here are to replace δ with $\frac{1}{k}$ in (14) and the string of inequalities of (13) that establish the monotonicity of $\{f(x_i)\}$ by using (18)and (19) as follows:

$$\begin{aligned} f(x_i) - f(x_{i+1}) &\geq \frac{1}{k}\left[f(x_i) - f(y_i^1, x_i^2, \dots, x_i^k)\right] \\ &\quad + \cdots + \frac{1}{k}\left[f(x_i) - f(x_i^1, \dots, x_i^{k-1}, y_i^k)\right] \quad \text{(by (19))} \\ &\geq \frac{1}{k} \sum_{\ell=1}^{k} \mu_\ell(-\nabla_\ell f(x_i)^T d_i^\ell). \qquad \square \end{aligned}$$

By combining the direction (9) and stepsize (18) choices of the partially asynchronous nonconvex PCAT1 of Corollary 3.2 into a single forcing function condition (20) below, we obtain Theorem 3.2, which is a simpler and more general theorem than PCAT1 of Corollary 3.2. We omit the proof, which is similar to that of Theorem 2.2.

THEOREM 3.2 (partially asynchronous nonconvex PCAT2). *Let $f \in C^1(R^n)$ on R^n. Start with any $x_0 \in R^n$. Given x_i, stop if $\nabla f(x_i) = 0$, else determine x_{i+1} in the following manner.*

Parallel steps: Determine y^ℓ, $\ell = 1, \ldots, k$, *such that for* $\bar{\ell}$, *the complement of* ℓ *in* $\{i, \ldots, k\}$,

$$f(x_i) - f(y_i^\ell, x_i^{\bar{\ell}}) \geq \sigma_\ell(\|\nabla_\ell f(x_i)\|), \qquad \ell = 1, \ldots, k, \tag{20}$$

where σ_ℓ *is a forcing function on* $\{\|\nabla_\ell f(x_i)\|\}$ *for* $\ell = 1, \ldots, k$.

Synchronization step: Choose x_{i+1} *such that*

$$f(x_{i+1}) \leq \min_{1 \leq \ell \leq k} f(y_i^\ell, x_i^{\bar{\ell}}). \tag{21}$$

Either $\{x_i\}$ *terminates at a stationary point* $x_{\bar{i}}$ *or each accumulation point* $\bar{x}$ *of* $\{x_i\}$ *is stationary.*

We conclude this section with the remark that the synchronization step in all the proposed methods in this section can be further modified if desired. In particular, we can search along the direction $x^i + \lambda(x^{i+1} - x^i)$, $\lambda \in R$, for a better point than x^{i+1} as the next iterate and replace x^{i+1} by this better point. All the convergence results remain valid because of the forcing function arguments used to establish them.

4. Conclusion and numerical results. We have given a number of parallel versions of fundamental convergence theorems for unconstrained minimization. These basic results enable k possible massively large, parallel processors to perform on portions of the gradient what one processor performs on the entire gradient in a serial algorithm. The direction choices in these theorems include many of the popular directions (gradient, quasi-Newton, Newton, conjugate gradient) and stepsizes (minimization, first stationary point, interval, Armijo). Note that each processor can apply direction and stepsize choices different from those of the other processors. A synchronization step is then used to obtain a strongly convex combination of the k points obtained by the k processors for the convex case, or alternatively the best of the k points or a better point can be taken as the next iterate for the convex as well as the nonconvex case.

Numerical implementations of parallel gradient distribution algorithms have been carried out in [1] and [6] on the Thinking Machines CM-5 multiprocessor. In these implementations, inexact quasi-Newton minimization was used in each parallel processor so as to satisfy (16). Each processor was allowed to take a number of steps before synchronization. The synchronization consisted of searching the affine hull of the points generated by the parallel processors as well as the current point. The problems solved in [1] consisted of real-world multicategory discrimination problems, formulated as unconstrained minimization of piecewise convex quadratic functions with Lipschitz continuous gradients. Problem size varied between 70 and 140 variables. For these multicategory discrimination problems, it is most efficient to use as many parallel processors as there are categories. This happened to be 7 for the problems tested. A standard measure of efficiency for parallel algorithms is the speedup efficiency, defined as

$$\text{speedup efficiency} = \frac{\text{time on 1 processor}}{(\text{time on } k \text{ processors}) * k}.$$

Thus, a speedup efficiency of 100% means that the time taken by one processor is cut exactly by a factor of k when k processors are employed. An efficiency of over 100% indicates that some of the parallel processors that are solving smaller subproblems have obtained very good points or that the affine hull generated by these points spans some very good points. For the multicategory discrimination problems, speedup efficiency was between 50% and 91%. For more details see [1].

In [6], 30 unconstrained problems from the publicly available CUTE [3] were tested. Among others, the parallel variable distribution algorithm version PVD0 was tested, which is equivalent to a parallel gradient distribution algorithm. Problems solved were between 100 and 1024 variables in size. These problems were solved on 2, 4, 8, 16, and 32 processors, with respective average speedup efficiencies of 129%, 122%, 77%, 44%, and 20%. These figures indicate that for problems of the size attempted, parallel gradient distribution is capable of producing a speedup equal to or better than 44% of the number of processors used for 16 or less processors. In order to exploit more fully a larger number of processors, larger problems need to be solved. We believe, however, that we have demonstrated that parallel gradient distribution can achieve speedups of the order of the processors employed and hence warrant further study and testing.

THE CONTINUUM-ARMED BANDIT PROBLEM*

RAJEEV AGRAWAL[†]

Abstract. In this paper we consider the multiarmed bandit problem where the arms are chosen from a subset of the real line and the mean rewards are assumed to be a continuous function of the arms. The problem with an infinite number of arms is much more difficult than the usual one with a finite number of arms because the built-in learning task is now infinite dimensional. We devise a kernel estimator-based learning scheme for the mean reward as a function of the arms. Using this learning scheme, we construct a class of certainty equivalence control with forcing schemes and derive asymptotic upper bounds on their learning loss. To the best of our knowledge, these bounds are the strongest rates yet available. Moreover, they are stronger than the $o(n)$ required for optimality with respect to the average-cost-per-unit-time criterion.

Key words. bandit problems, controlled i.i.d. process, stochastic adaptive control, certainty equivalence with forcing, learning loss, continuous arms

AMS subject classifications. Primary, 93E35, 62G20, 62L05; Secondary, 60F15, 60F25.

1. Introduction.

In this paper we consider the multiarmed bandit problem where the arms are chosen from a subset of the real line and the mean rewards are assumed to be a continuous function of the arms. Prior work on the multiarmed bandit problem has dealt almost exclusively with only a finite number of independent arms. One of the early papers on this topic was by Robbins [26] who constructs a *consistent* (or optimal average-reward-per-unit-time) policy. More recently, the seminal work of Lai and Robbins [23], [22] addressed this problem with the stronger *learning loss* criterion (defined in (5)). They obtained asymptotic lower bounds on the learning loss and constructed *asymptotically efficient* schemes that achieved those bounds. Various extensions of the basic Lai and Robbins formulation have been obtained by Anantharam, Varaiya, and Walrand [6], [7]; by Agrawal, Hegde, and Teneketzis [2], [3]; and by Agrawal, Teneketzis, and Anantharam [5], [4]. In [5] the arms are allowed to be dependent, and the dependence is explicitly exploited to improve the performance. One of the few papers that does deal with an infinite set of arms is by Yakowitz and Lowe [28]. They consider only the *ϵ-learning loss* criterion (defined in (6)), and for this criterion they get a weaker rate than the one obtained in this paper (Corollary 5.4). However, unlike us, they do not make any continuity assumptions.

Note that the case of an infinite number of arms is much more difficult than the usual one of a finite number of arms because the built-in learning task is now infinite dimensional whereas previously it was only finite dimensional. In this paper we exploit the continuity of the mean reward as a function of the arms to devise a class of learning schemes based on kernel estimators. We obtain an upper bound on the almost sure and L^p uniform consistency rates for these estimators. These bounds strengthen the ones available in the nonparametric regression literature as detailed in §3, and may thus be of independent interest.

Subsequently, using the approach taken in [4], we construct a class of adaptive control schemes based on certainty equivalence control with forcing and derive asymptotic upper bounds on their learning loss. These bounds are not only much stronger

than the $o(n)$ required for optimality with respect to the average-cost-per-unit-time criterion, but are also, to the best of our knowledge, the best rates available to date.

The rest of the paper is organized as follows: In §2 we give the precise problem formulation. In §3 we concentrate solely on the learning aspect of the problem. We construct a class of learning schemes and derive an upper bound on its rate of convergence (Corollary 3.4). In §4 we derive various limit laws for "moving averages" that are needed to obtain the rates of convergence in §3. Finally, in §5 we construct a class of adaptive control schemes based on the learning schemes of §3, and obtain upper bounds on their learning loss (Corollaries 5.2 and 5.4).

2. The problem. Consider a (memoryless) discrete-time stochastic system modeled by a controlled i.i.d. process, i.e.,

$$\begin{aligned} P(X_n \in B | U_1, X_1, \ldots, U_{n-1}, X_{n-1}, U_n = u) &= P(X_n \in B | U_n = u) \\ &= P(X_1 \in B | U_1 = u) \end{aligned} \tag{1}$$

where $\{U_n, X_n\}_{n=1}^{\infty}$ is the chronological sequence of controls and states. The states X_n take values in some arbitrary set $\mathcal{X}$, and the controls U_n are chosen from a bounded set $\mathcal{U} \subset \mathbb{R}$. In particular, we will assume that $\mathcal{U} = [\Delta, 1 - \Delta]$ for some $0 < \Delta < 1/2$; any arbitrary bounded subset of $\mathbb{R}$ can be handled easily by a slight modification. There is a one-step reward, $r(U_n, X_n)$, associated with each pair $(U_n, X_n), n \geq 1$, where $r : \mathcal{U} \times \mathcal{X} \to \mathbb{R}$. Let $m : \mathcal{U} \to \mathbb{R}$ be defined by

$$m(u) := E[r(U_n, X_n) | U_n = u] = E[r(u, X_1) | U_1 = u],$$

and let $W_n := r(U_n, X_n) - m(U_n)$. Then we can write

$$r(U_n, X_n) = m(U_n) + W_n,$$

where $E[W_n | U_n = u] = 0$ and

$$\begin{aligned} P(W_n \in B | U_1, W_1, \ldots, U_{n-1}, W_{n-1}, U_n = u) &= P(W_n \in B | U_n = u) \\ &= P(W_1 \in B | U_1 = u). \end{aligned} \tag{2}$$

Throughout the rest of the paper we shall assume that $\{U_n, W_n\}$ satisfy the following condition. There exist $\varsigma, s_0 > 0$ such that

$$E[\exp(sW_n) | U_n = u] \leq \exp(\varsigma^2 s^2 / 2) \quad \forall |s| \leq s_0, u \in \mathcal{U}. \tag{3}$$

In that case define

$$\sigma := \inf\{\varsigma > 0 : \text{ there exists } s_0 > 0 \text{ such that (3) holds}\}. \tag{4}$$

Then $E[|W_n|^2 | U_n = u] \leq \sigma^2$ for all $u \in \mathcal{U}$.

The problem is to design an adaptive control scheme $\gamma = \{\gamma_n\}_{n=1}^{\infty}$, i.e., $U_n = \gamma_n(U_1, X_1, \ldots, U_{n-1}, X_{n-1})$, so as to "maximize" the total reward

$$J_n^{\gamma} := \sum_{i=1}^{n} r(U_i, X_i) = \sum_{i=1}^{n} m(U_i) + \sum_{i=1}^{n} W_i\ ,$$

as $n \to \infty$. First note that

$$J_n^{\gamma} \leq nm^* + \sum_{i=1}^{n} W_i,$$

where $m^* := \sup_{u \in \mathcal{U}} m(u)$. Now if $m : \mathcal{U} \to \mathbb{R}$ were known, then for any constant $M > 0$, we could construct a scheme γ^M such that

$$J_n^{\gamma^M} \geq nm^* + \sum_{i=1}^{n} W_i - M.$$

In the absence of knowledge of m it is desirable to approach this performance as closely as possible. For this purpose define the *learning loss*

$$L_n := \sum_{i=1}^{n} m^* - m(U_i)\ . \tag{5}$$

Also define the *ϵ-learning loss*

$$L_n^{\epsilon} := \sum_{i=1}^{n} I\{m^* - m(U_i) > \epsilon\}\ . \tag{6}$$

Therefore, more precisely, the problem is to design adaptive control schemes for which the learning loss (or ϵ-learning loss) increases slowly regardless of the actual m. In this paper we will investigate almost sure and L^p $(p \geq 1)$ rates for the learning loss and L^1 rate for the ϵ-learning loss.

Throughout the rest of the paper we shall assume that $m : \mathcal{U} \to \mathbb{R}$ is uniformly locally Lipschitz with constant L $(0 \leq L < \infty)$, exponent α $(0 < \alpha \leq 1)$, and restriction δ $(\delta > 0)$, i.e.,

$$u, u' \in \mathcal{U}, |u' - u| \leq \delta \quad \Rightarrow \quad |m(u') - m(u)| \leq L|u' - u|^{\alpha}.$$

Let $ulL(\alpha, L, \delta)$ denote the class of all such functions.

3. The learning scheme. In this section we concentrate solely on the learning aspect of the problem as a first step toward the construction of adaptive control schemes. More precisely, we are interested in choosing the controls $\{U_n\}$ and in constructing the estimates $\{U_n^*\}$ based on the observations $\{m(U_n) + W_n\}$ made at those points, so that $m^* - m(U_n^*)$ converges to 0 as rapidly as possible. Note that the estimates U_n^* need not be the same as the control values U_n. In this section we construct a class of learning schemes and obtain bounds on their rates of convergence. These bounds are important because they determine precisely how the learning schemes can be used to design good adaptive control schemes.

First note that the only assumption we have made on the function m is that it is uniformly locally Lipschitz. Since we do not make any unimodality assumptions we will need a "global search" strategy. Moreover, since the function m may not be differentiable, we cannot use algorithms that rely on the estimation of the gradient. For both these reasons, the Kiefer–Wolfowitz-type (K–W-type) stochastic approximation algorithm is not appropriate for the problem at hand. Even with the unimodality assumption, we would require additional differentiability conditions (existence, boundedness, continuity of the second derivative) in order to get any rate of convergence results for the K–W-type algorithms (see Fabian [12], Nevel'son and Has'minskii [25], Kushner and Clark [21]). Furthermore, the rates of convergence obtained for these algorithms are slower than the ones obtained for the algorithm used in this paper. This is possibly due to the fact that we are interested in constructing the estimates U_n^* so as to minimize the difference from the maximum, $m^* - m(U_n^*)$, rather than to minimize the actual distance $|u^* - U_n^*|$ from the point of maximum u^*. In fact, a point of maximum need not even exist for the problem considered in this paper.

Recently, several researchers have studied a variant of the K–W-type gradient algorithm, which incorporates the global search aspects of simulated annealing algorithms by adding a slowly decreasing noise term. For this algorithm, convergence to the set of global maxima can be established without any unimodality assumption, but with suitable differentiability conditions (see [15], [20], [8], [14]). However, to the best of our knowledge, no results are available on the rate of convergence of these algorithms.

The learning schemes constructed in this section are based on the approach used by Devroye [11]. We first obtain a "uniformly good" estimate $\hat{m}_n$ of the function m, and then use the point of maximum of $\hat{m}_n$ as the estimate U_n^*. We use a nearly equispaced control (*design*) sequence $\{u_n\}$ defined below in (7)–(8). This is a natural choice that corresponds to a progressively finer sampling of $[0, 1]$ along the dyadic rationals. Note that the equispaced design scheme itself is not a *progressive* design scheme, i.e., the set of design points at stage n is not a subset of the design points at stage $n + 1$. The nearly equispaced design scheme described below is the best progressive approximation to the equispaced design scheme in the sense that it visits the equispaced design at stages $n = 2^m, m = 0, 1, \ldots,$ which occur earlier than the successive visits of any other progressive design scheme.[1] Based on the observations obtained at these points, we estimate the function m by means of a kernel estimator defined below in (9)–(11). In Theorem 3.1 we obtain an upper bound (with an explicit constant) on the almost sure and L^p $(p \geq 1)$ uniform consistency rates of this estimation scheme. In Theorem 3.2 we show that the above upper bound is also a lower bound on the in-probability uniform consistency rates of this estimation scheme for the i.i.d. noise case. This shows us that the rate and associated constant obtained in Theorem 3.1 cannot be improved in general.

The problem of estimating the function $m : \mathcal{U} \to \mathbb{R}$ on the basis of "noisy" measurements $\{m(U_n) + W_n\}_{n=1}^{\infty}$ taken at a sequence of points $\{U_n\}_{n=1}^{\infty} \in \mathcal{U}$ has been extensively investigated in the nonparametric regression literature in statistics. While the almost sure rate itself is well known in the nonparametric regression literature, the associated constant is not (see Stone [27]; Mack and Silverman [24]; Härdle and Luckhaus [18]; Härdle, Janssen and Serfling [17]). Also see Härdle [16, Chap. 4, pp. 89–98] for excellent coverage of results available to date on this nonparametric regression problem. The identification of a sharp constant associated with this rate is an important and challenging problem, as evidenced by the work of Fabian [13], who obtains a constant associated with the in-probability rate for a nonprogressive design scheme with a piecewise polynomial estimator. In fact, Fabian comments that specifying the constants in the order of convergence seems difficult for the estimates considered up to now. One of the key contributions of this section is to provide precisely such a constant for a kernel estimator, which is one of the popular estimators considered in the nonparametric regression literature. As explained in §4, we crucially exploit the structure of the progressive nearly equispaced scheme to obtain the sharp constant associated with the almost sure rate. The constant corresponding to the design/estimation scheme considered in this paper is better than the constant obtained

[1] There are other progressive design schemes which visit the equispaced design scheme at stages $n = 2^m, m = 0, 1, \ldots.$ The design scheme described in this paper is the "best" progressive approximation to the equispaced design scheme in possibly a much stronger sense.

by Fabian [13] for his design/estimation scheme (see the second remark following Corollary 3.3). Another contribution of the results obtained in this section is to establish that the same rates also hold both almost surely and in L^p, whereas all of the papers cited above obtain the rates only in probability or almost surely.

Note that the uniform error between the estimate and the true function m can easily be decomposed into the sum of a bias term and a variance term (see (14) below). The bias term is controlled by the continuity of the function m, while the variance term is controlled by the "noise" in the measurements and by the choice of the design scheme. The variance term is essentially a "moving average." Our main result in Theorem 3.1 on the rate of convergence makes use of some fundamental limit theorems on these moving averages that are developed in §4.

We use the nearly equispaced design sequence $\{u_n\}_{n=1}^{\infty} \in \mathcal{U} \not\subset [0,1]$ described below. For $n = 1, 2, \ldots$, consider the binary representation of $n-1$:

$$n - 1 = \ldots b_3 b_2 b_1. \tag{7}$$

First, choose the points $\tilde{u}_n \in [0,1]$ to be dyadic rationals with the binary representation:

$$\tilde{u}_n = 0.b_1 b_2 b_3 \ldots. \tag{8}$$

Note that this is the best progressive approximation to the equispaced design scheme on $[0,1]$. The actual design points, $u_n \in \mathcal{U} = [\Delta, 1-\Delta] \subset [0,1]$, are obtained by projecting $\tilde{u}_n$ onto the control set $\mathcal{U}$. Thus

$$u_n := (\tilde{u}_n \wedge (1-\Delta)) \vee \Delta.$$

The reason for choosing the actual design points in this manner is to ensure that asymptotically we get enough observations close to the two boundaries. If we had chosen $\mathcal{U} = [0,1]$ and $u_n = \tilde{u}_n$, then we would have gotten only half as many observations in a window centered at one of the boundary points as we would in the interior. Note that under any deterministic design scheme (such as the one above), $\{W_n\}$ are independent by (2).

We use a window estimator which is a special case of the more general class of Nadaraya–Watson kernel estimators to estimate m. Thus,

$$\hat{m}_n(u) = \frac{\sum_{i=1}^{n} K_{h_n}(u - \tilde{u}_i)(m(u_i) + W_i)}{\sum_{i=1}^{n} K_{h_n}(u - \tilde{u}_i)}, \tag{9}$$

where

$$K_{h_n}(u) = h_n^{-1} K(u/h_n), \tag{10}$$

$$K(u) = I\{|u| \le 1/2\} \tag{11}$$

is the window kernel, and $\{h_n\}$ is a sequence of bandwidths to be specified later. Finally, we choose the estimate U_n^* by

$$U_n^* := \operatorname*{argmax}_{u \in \mathcal{U}} \hat{m}_n(u).$$

Note that $\hat{m}_n$ is a piecewise constant function with at most a finite number of discontinuities. Hence, there exists at least one such argmax. Ties may be resolved in some fixed but arbitrary measurable manner. This completes the description of our class of learning schemes.

In the remaining part of this section we obtain bounds on the rate of convergence of the above scheme: in Theorem 3.1 and Corollary 3.3 for the estimates $\hat{m}_n$, and in Corollary 3.4 for U_n^*. Let

$$d_\infty(\hat{m}, m) = \sup_{u \in \mathcal{U}} |\hat{m}(u) - m(u)|$$

be the uniform metric. The following theorem obtains (1) almost sure and L^p rates of convergence for $\sup_{m \in ulL(\alpha,L,\delta)} d_\infty(\hat{m}_n, m)$, along with a sharp constant, and (2) a large deviations-type result for $P(\sup_{m \in ulL(\alpha,L,\delta)} d_\infty(\hat{m}_n, m) > \epsilon)$ for any $\epsilon > 0$.

THEOREM 3.1. *For the above window estimator with any bandwidth sequence, h_n, such that* (i) *h_n is nonincreasing,* (ii) *nh_n is nondecreasing, and* (iii) *$A'n^{a'} \le nh_n \le An^a$ for some $0 < a' \le a < 1$, $A', A > 0$, we have*

$$\overline{\lim_{n\to\infty}} \frac{\sup_{m \in ulL(\alpha,L,\delta)} d_\infty(\hat{m}_n, m)}{\frac{L}{\alpha+1}\left(\frac{h_n}{2}\right)^\alpha + \left(\frac{2\log(1/h_n)}{nh_n}\right)^{1/2}\sigma} \le 1 \quad \textit{a.s. and in } L^p, p \ge 1. \tag{12}$$

Also, for the above window estimator with any bandwidth sequence, h_n, such that (i) *$h_n \to 0$ as $n \to \infty$, and* (ii) *$nh_n \ge A'n^{a'}$ for some $0 < a' < 1$, $A' > 0$, we have*

$$\overline{\lim_{\epsilon\searrow 0}} \frac{1}{\epsilon^2} \overline{\lim_{n\to\infty}} \frac{1}{nh_n} \log P\left(\sup_{m \in ulL(\alpha,L,\delta)} d_\infty(\hat{m}_n, m) > \epsilon\right) \le -\frac{1}{8\sigma^2}. \tag{13}$$

Remark. The above theorem can easily be adapted to handle $\mathcal{U} = [a,b]$ for any $-\infty < a < b < \infty$. For each $m : [a,b] \to \mathbb{R}$, $m \in ulL(\alpha, L, \delta)$, simply consider the shifted and rescaled function $\tilde{m} : [\Delta, 1-\Delta] \to \mathbb{R}$ defined by $\tilde{m}(u) = m(a + (u - \Delta)(b-a)(1-2\Delta)^{-1})$. Note that

$$m \in ulL(\alpha, L, \delta) \Leftrightarrow \tilde{m} \in ulL\left(\alpha, L\left(\frac{b-a}{1-2\Delta}\right)^\alpha, \delta\left(\frac{1-2\Delta}{b-a}\right)\right).$$

Next observe that (12) holds for any $\delta > 0$ and $0 < \Delta < 1/2$; however, it does explicitly depend on α and L. Hence, in light of the above discussion, it would be desirable to choose Δ arbitrarily small.

Proof. Since $nh_n \ge A'n^{a'}$ for some $0 < a' < 1$, $A' > 0$, we can pick n_0 such that for all $n \ge n_0$, $\sum_{i=1}^n I\{|u - \tilde{u}_i| \le h_n/2\} > 0 \quad \forall u \in \mathcal{U}$. Then, for all $n \ge n_0$,

$$\begin{aligned}\hat{m}_n(u) &= \frac{\sum_{i=1}^n K_{h_n}(u-\tilde{u}_i)(m(u_i)+W_i)}{\sum_{i=1}^n K_{h_n}(u-\tilde{u}_i)} \\ &= \frac{\sum_{i=1}^n h_n^{-1} I\{|u-\tilde{u}_i| \le h_n/2\}(m(u_i)+W_i)}{\sum_{i=1}^n h_n^{-1} I\{|u-\tilde{u}_i| \le h_n/2\}} \\ &= \frac{\sum_{i=1}^n I\{|u-\tilde{u}_i| \le h_n/2\}(m(u_i)+W_i)}{\sum_{i=1}^n I\{|u-\tilde{u}_i| \le h_n/2\}}.\end{aligned}$$

Thus,

$$\begin{aligned}|\hat{m}_n(u) - m(u)| \le \frac{\sum_{i=1}^n I\{|u-\tilde{u}_i| \le h_n/2\}|m(u_i) - m(u)|}{\sum_{i=1}^n I\{|u-\tilde{u}_i| \le h_n/2\}} \\ + \frac{|\sum_{i=1}^n I\{|u-\tilde{u}_i| \le h_n/2\}W_i|}{\sum_{i=1}^n I\{|u-\tilde{u}_i| \le h_n/2\}}.\end{aligned} \tag{14}$$

Since $h_n \to 0$ as $n \to \infty$, we can pick $n_1 \geq n_0$ so that $h_n/2 \leq \min\{\delta, \Delta\}$ for all $n \geq n_1$. Then, for any $u \in \mathcal{U} = [\Delta, 1-\Delta]$ and $n \geq n_1$, we have

$$b_n := nh_n - \lfloor \log_2 n \rfloor - 1 \leq \sum_{i=1}^{n} I\{|u - \tilde{u}_i| \leq h_n/2\} \leq nh_n + \lfloor \log_2 n \rfloor + 1 =: a_n. \tag{15}$$

Thus, by the condition $nh_n \geq A'n^{a'}$ for some $0 < a' < 1$, $A' > 0$, it follows that $\sum_{i=1}^{n} I\{|u - \tilde{u}_i| \leq h_n/2\} \approx a_n \approx b_n \approx nh_n$, where by $x_n \approx y_n$ we mean that $x_n/y_n \to 1$ as $n \to \infty$.

Also, for any $m \in ulL(\alpha, L, \delta)$ and $n \geq n_1$, we have

$$\begin{aligned} &\sum_{i=1}^{n} I\{|u - \tilde{u}_i| \leq h_n/2\}|m(u_i) - m(u)| \\ &\qquad \leq \sum_{i=1}^{n} I\{|u - \tilde{u}_i| \leq h_n/2\} L|\tilde{u}_i - u|^{\alpha} \\ &\qquad \leq \frac{L}{\alpha+1}\left(\frac{h_n}{2}\right)^{\alpha} [nh_n + 2(\alpha+1)(\lfloor \log_2 n \rfloor + 1)], \end{aligned} \tag{16}$$

where the second inequality is established in the appendix. Combining this with (15), we get for any $m \in ulL(\alpha, L, \delta)$ and $n \geq n_1$,

$$\begin{aligned} \frac{\sum_{i=1}^{n} I\{|u - \tilde{u}_i| \leq h_n/2\}|m(u_i) - m(u)|}{\sum_{i=1}^{n} I\{|u - \tilde{u}_i| \leq h_n/2\}} &\leq \frac{L}{\alpha+1}\left(\frac{h_n}{2}\right)^{\alpha} \frac{1 + 2(\alpha+1)\frac{\lfloor \log_2 n \rfloor + 1}{nh_n}}{1 - \frac{\lfloor \log_2 n \rfloor + 1}{nh_n}} \\ &= \frac{L}{\alpha+1}\left(\frac{h_n}{2}\right)^{\alpha} (1 + \gamma_n) \quad \text{(say)} \\ &\approx \frac{L}{\alpha+1}\left(\frac{h_n}{2}\right)^{\alpha}. \end{aligned} \tag{17}$$

Let $\{\tilde{W}_i^n\}_{i=1}^n$ be a permutation of $\{W_i\}_{i=1}^n$ arranged in order of $\{\tilde{u}_i\}_{i=1}^n$. Define the partial sums of $\{\tilde{W}_i^n\}_{i=1}^n$ as follows:

$$\tilde{S}_{j,k}^n := \sum_{i=j+1}^{k} \tilde{W}_i^n. \tag{18}$$

Also let

$$\tilde{B}_{n,a_n} := \max_{\substack{0 \leq j \leq k \leq n \\ k-j \leq a_n}} |\tilde{S}_{j,k}^n|. \tag{19}$$

Then

$$\left|\sum_{i=1}^{n} I\{|u - \tilde{u}_i| \leq h_n/2\} W_i\right| \leq \tilde{B}_{n,a_n}. \tag{20}$$

Putting together (14)–(20) we get that for all $n \geq n_1$,

$$\begin{aligned} \sup_{m \in ulL(\alpha,L,\delta)} d_{\infty}(\hat{m}_n, m) &= \sup_{m \in ulL(\alpha,L,\delta)} \sup_{u \in \mathcal{U}} |\hat{m}_n(u) - m(u)| \\ &\leq \frac{L}{\alpha+1}\left(\frac{h_n}{2}\right)^{\alpha} (1 + \gamma_n) + \frac{\tilde{B}_{n,a_n}}{b_n}. \end{aligned} \tag{21}$$

Asymptotic bounds on the "moving average" $\tilde{B}_{n,a_n}$ are obtained in §4. In particular, by Theorems 4.5 and 4.7 we know that $\overline{\lim}_n \tilde{B}_{n,a_n}/\beta_n \leq \sigma$ a.s. and in L^p, $p \geq 1$, respectively, where $\beta_n = (2a_n(\log(n/a_n) + \log\log n))^{1/2}$, provided a_n satisfies some conditions. It is straightforward to check that $a_n = nh_n + \lfloor \log_2 n \rfloor + 1$ satisfies the conditions of Theorems 4.5 and 4.7 whenever h_n satisfies the conditions of this theorem. Finally, we have

$$\begin{aligned}\beta_n/b_n &= \frac{(2a_n(\log(n/a_n) + \log\log n))^{1/2}}{nh_n - \lfloor \log_2 n \rfloor - 1}\\ &\approx \frac{(2nh_n(\log(n/nh_n) + \log\log n))^{1/2}}{nh_n}\\ &\approx \left(\frac{2\log(1/h_n)}{nh_n}\right)^{1/2}. \qquad (22)\end{aligned}$$

Combining all of the above, we get (12).

We will now prove the remaining part of the theorem. Let $0 < \eta < \epsilon$ be fixed but arbitrary. Since the bandwidth sequence $h_n \to 0$ and $\gamma_n \to 0$ as $n \to 0$, we can pick $n_2 \geq n_1$ so that $h_n/2 \leq \min\{\delta, \Delta, (\eta(\alpha+1)/2L(1+\gamma_n))^{1/\alpha}\}$, for all $n \geq n_2$. Also, by the condition that $nh_n \geq A'n^{a'}$ for some $0 < a' < 1$, $A' > 0$, it follows that $b_n/a_n \to 1$ as $n \to \infty$. Thus, we can pick $n_3 \geq n_2$ so that we have $(\epsilon - \eta/2)b_n \geq (\epsilon - \eta)a_n$ for all $n \geq n_3$. Then, from (21), we have for all $n \geq n_3$

$$\begin{aligned}P\left(\sup_{m \in ulL(\alpha,L,\delta)} d_\infty(\hat{m}_n, m) > \epsilon\right) &\leq P\left(\frac{L}{\alpha+1}(h_n/2)^\alpha + \tilde{B}_{n,a_n}/b_n > \epsilon\right)\\ &\leq P(\tilde{B}_{n,a_n}/b_n > \epsilon - \eta/2)\\ &\leq P(\tilde{B}_{n,a_n}/a_n > \epsilon - \eta). \qquad (23)\end{aligned}$$

Substituting n, m, p, t, s, a in Lemma 4.1 by $n, a_n, \lfloor nd/a_n \rfloor + 1, (\epsilon - 2\eta), \eta, (\epsilon - 2\eta - 2\rho)/(\epsilon - 2\eta)$, respectively, we have

$$\begin{aligned}P(\tilde{B}_{n,a_n}/a_n > \epsilon - \eta) \leq \frac{1}{1-c}\left(\frac{nd}{a_n} + 1\right)\Big[&\max_{0 \leq j \leq n} P(|\tilde{S}^n_{j,j+a_n}|/a_n > (\epsilon - 2\eta - 2\rho))\\ &+ \max_{0 \leq j \leq n} P(|\tilde{S}^n_{j,j+\lfloor a_n/d \rfloor + 1}|/a_n > \rho)\Big] \qquad (24)\end{aligned}$$

where c is such that

$$\max_{0 \leq j \leq n} \max_{1 \leq k \leq a_n + 1} P(|\tilde{S}^n_{j,j+k}|/a_n > \eta/4) \leq c < 1. \qquad (25)$$

By Chebyshev's inequality we have

$$\max_{0 \leq j \leq n} \max_{1 \leq k \leq a_n + 1} P(|\tilde{S}^n_{j,j+k}|/a_n > \eta/4) \leq \frac{\sigma^2(a_n+1)}{(a_n\eta/4)^2}.$$

By the assumptions on h_n, $a_n = nh_n + \lfloor \log_2 n \rfloor + 1 \to \infty$ as $n \to \infty$. Therefore, given any $0 < c < 1$, there exists $n_4 \geq n_3$ such that (25) holds for all $n \geq n_4$. We now apply Lemma 4.2 to upper bound the right-hand side (RHS) of (24). Given any $\varsigma > \sigma$, let s_0 be such that (30) holds. Let $\epsilon \leq \varsigma^2 s_0$. Then by Lemma 4.2 we have

$$P(|\tilde{S}^n_{j,j+a_n}|/a_n > (\epsilon - 2\eta - 2\rho)) \leq 2\exp\left(-\frac{(\epsilon - 2\eta - 2\rho)^2 a_n^2}{2a_n\varsigma^2}\right).$$

Similarly, if $d\rho \le \varsigma^2 s_0$, then by Lemma 4.2 we have

$$P(|\tilde{S}^n_{j,j+\lfloor a_n/d\rfloor+1}|/a_n > \rho) \le 2\exp\left(-\frac{d\rho^2 a_n^2}{2a_n\varsigma^2}\right).$$

Thus, by choosing $d = 4$ and $\rho = \epsilon/4$, we get that for all $\epsilon \le \varsigma^2 s_0$, $\eta < \epsilon/4$, and $n \ge n_4$,

$$P(\tilde{B}_{n,a_n}/a_n > \epsilon - \eta) \le \frac{1}{1-c}\left(\frac{nd}{a_n}+1\right)4\exp\left(-\frac{((\epsilon/2)-2\eta)^2 a_n}{2\varsigma^2}\right).$$

Thus, by (23) and the above, it follows that

$$\begin{aligned}\overline{\lim_{n\to\infty}}\frac{1}{a_n}\log P\left(\sup_{m\in ulL(\alpha,L,\delta)} d_\infty(\hat{m}_n,m) > \epsilon\right) &\le \overline{\lim_{n\to\infty}}\frac{\log(1/h_n)}{nh_n+\lfloor\log_2 n\rfloor+1} - \frac{((\epsilon/2)-2\eta)^2}{2\varsigma^2}\\ &= -\frac{((\epsilon/2)-2\eta)^2}{2\varsigma^2}.\end{aligned}$$

Note that the last equality follows from the assumptions on h_n. The left-hand side (LHS) above does not depend on η. By letting $\eta \to 0$, we get for all $\epsilon \le \varsigma^2 s_0$,

$$\overline{\lim_{n\to\infty}}\frac{1}{a_n}\log P\left(\sup_{m\in ulL(\alpha,L,\delta)} d_\infty(\hat{m}_n,m) > \epsilon\right) \le -\frac{\epsilon^2}{8\varsigma^2}.$$

Now dividing by ϵ^2, taking limits as $\epsilon \to 0$, and finally letting $\varsigma \to \sigma$, we obtain (13). □

Below, we show that the rate and the associated constant identified in (12) in the previous theorem are the best possible ones.

THEOREM 3.2. *If, in addition to the conditions already imposed on* $\{W_n\}$, *we assume that*

$$P(W_n \in B|U_n = u') = P(W_1 \in B|U_1 = u), \quad \forall B,\ u', u,\ n,$$

then we can also show that (12) *holds with equality in probability, i.e.,*

$$\lim_{n\to\infty} P\left(\frac{\sup_{m\in ulL(\alpha,L,\delta)} d_\infty(\hat{m}_n,m)}{\frac{L}{\alpha+1}(\frac{h_n}{2})^\alpha + (\frac{2\log(1/h_n)}{nh_n})^{1/2}\sigma} < 1-\epsilon\right) = 0 \quad \forall\epsilon > 0.$$

Proof. This follows because by choosing $m \in ulL(\alpha,L,\delta)$ to be given by $m(u) = \pm|u-c|^\alpha$ for $c \in [\Delta', 1-\Delta']$ with $\Delta < \Delta' < 1/2$, one can show that there exists an n_0' such that for all $n \ge n_0'$,

$$\begin{aligned}\sup_{m\in ulL(\alpha,L,\delta)} d_\infty(\hat{m}_n,m) \ge \sup_{c\in[\Delta',1-\Delta']}&\left[\frac{\sum_{i=1}^n I\{|c-\tilde{u}_i| \le h_n/2\}L|\tilde{u}_i - c|^\alpha}{\sum_{i=1}^n I\{|c-\tilde{u}_i| \le h_n/2\}}\right.\\ &\left.+\frac{|\sum_{i=1}^n I\{|c-\tilde{u}_i| \le h_n/2\}W_i|}{\sum_{i=1}^n I\{|c-\tilde{u}_i| \le h_n/2\}}\right].\end{aligned}\tag{26}$$

Corresponding to the upper bound on the first term on the RHS used earlier in (16), we have the following lower bound which is also established in the appendix. For all $n \ge 1$ and $u \in \mathcal{U}$,

$$\sum_{i=1}^n I\{|u-\tilde{u}_i| \le h_n/2\}L|\tilde{u}_i - u|^\alpha \ge \frac{L}{\alpha+1}\left(\frac{h_n}{2}\right)^\alpha [nh_n - 2(\alpha+1)(\lfloor\log_2 n\rfloor+1)].\tag{27}$$

Using (27) and (15) in (26) we get for all $n \geq n_0'$,

$$\begin{aligned}\sup_{m\in ulL(\alpha,L,\delta)} d_\infty(\hat{m}_n, m) \geq \frac{L}{\alpha+1}\left(\frac{h_n}{2}\right)^\alpha \frac{1-2(\alpha+1)\frac{\lfloor \log_2 n\rfloor+1}{nh_n}}{1+\frac{\lfloor \log_2 n\rfloor+1}{nh_n}} \\ + \max_{\Delta' n\leq j\leq(1-\Delta')n} \frac{|\tilde{S}^n_{j,j+a_{n,j}}|}{\beta_n}\frac{\beta_n}{a_n} \\ =: r_n + s_n t_n,\end{aligned}$$

where $b_n \leq a_{n,j} \leq a_n$ for all $1 \leq j \leq n$, $n = 1, 2, \ldots$. As shown earlier in (17) and (22), for any $\epsilon > 0$ there exists an $n_1' \geq n_0'$ such that for all $n \geq n_1'$,

$$r_n \geq (1-\epsilon)\frac{L}{\alpha+1}\left(\frac{h_n}{2}\right)^\alpha$$

and

$$t_n \geq (1-\epsilon)^{1/2}\left(\frac{2\log(1/h_n)}{nh_n}\right)^{1/2}.$$

Thus, for all $n \geq n_1'$ we get

$$\begin{aligned}&P\left(\frac{\sup_{m\in ulL(\alpha,L,\delta)} d_\infty(\hat{m}_n, m)}{\frac{L}{\alpha+1}(\frac{h_n}{2})^\alpha + (\frac{2\log(1/h_n)}{nh_n})^{1/2}\sigma} < 1-\epsilon\right) \\ &\leq P\left(r_n + s_n t_n < (1-\epsilon)\left(\frac{L}{\alpha+1}\left(\frac{h_n}{2}\right)^\alpha + \left(\frac{2\log(1/h_n)}{nh_n}\right)^{1/2}\sigma\right)\right) \\ &\leq P(s_n < (1-\epsilon)^{1/2}\sigma)\end{aligned}$$

which goes to 0 as $n \to \infty$ by Theorem 4.3. Note that the collection of random variables $\{V_i^n\}$ obtained by setting $\{V_i^n\}_{i=1}^n = \{\tilde{W}_i^n\}_{i=1}^n$ for $n = 1, 2, \ldots$ satisfies conditions (C1)–(C4), but not (C5) (see §4). However, since the RHS above does not depend on (C5), we can still apply Theorem 4.3, whereas we would need condition (C5) to obtain the corresponding almost sure result from Theorem 4.3. □

COROLLARY 3.3. *For the above window estimator with the bandwidth sequence* $h_n = h(\log n/n)^{1/(2\alpha+1)}$, $h > 0$, *we have*

$$\overline{\lim_{n\to\infty}} \frac{\sup_{m\in ulL(\alpha,L,\delta)} d_\infty(\hat{m}_n, m)}{(\frac{\log n}{n})^{\alpha/(2\alpha+1)}} \leq c(\alpha, L, \sigma, h) \quad \textit{a.s. and in } L^p, p \geq 1, \tag{28}$$

where

$$c(\alpha, L, \sigma, h) := \frac{L}{\alpha+1}\left(\frac{h}{2}\right)^\alpha + \left(\frac{2}{h(2\alpha+1)}\right)^{1/2}\sigma. \tag{29}$$

Proof. First note that the above choice of h_n satisfies the conditions of Theorem 3.1. Moreover,

$$\frac{L}{\alpha+1}\left(\frac{h_n}{2}\right)^\alpha + \left(\frac{2\log(1/h_n)}{nh_n}\right)^{1/2}\sigma$$

$$
\begin{aligned}
&= \frac{L}{\alpha+1}\left(\frac{h}{2}\right)^{\alpha}\left(\frac{\log n}{n}\right)^{\alpha/(2\alpha+1)} \\
&\quad + \left[\frac{-2\log h + \frac{2}{(2\alpha+1)}(\log n - \log\log n)}{hn^{2\alpha/(2\alpha+1)}(\log n)^{1/(2\alpha+1)}}\right]^{1/2}\sigma \\
&\approx \left[\frac{L}{\alpha+1}\left(\frac{h}{2}\right)^{\alpha} + \sigma\left(\frac{2}{h(2\alpha+1)}\right)^{1/2}\right]\left(\frac{\log n}{n}\right)^{\alpha/(2\alpha+1)}. \qquad \square
\end{aligned}
$$

Remark. Note that the bandwidth sequence $\{h_n\}$ chosen above minimizes the rate of convergence given by (12). This is so because if $h_n/(\log n/n)^{1/(2\alpha+1)} \to 0$ or ∞, then

$$
\left[\frac{L}{\alpha+1}\left(\frac{h_n}{2}\right)^{\alpha} + \left(\frac{2\log(1/h_n)}{nh_n}\right)^{1/2}\sigma\right]\left(\frac{\log n}{n}\right)^{\alpha/(2\alpha+1)} \to \infty.
$$

Moreover, the constant $c(\alpha, L, \sigma, h)$ associated with the above rate is minimized by choosing

$$
h^* = 2(\sigma(\alpha+1)/2\alpha L(2\alpha+1)^{1/2})^{2/(2\alpha+1)}.
$$

The minimum value of the above constant, say $c^*(\alpha, L, \sigma)$, is given by

$$
c^*(\alpha, L, \sigma) = \left[\frac{L}{\alpha+1}\sigma^{2\alpha}(2\alpha+1)^{-\alpha}\right]^{1/(2\alpha+1)} [(2\alpha)^{-2\alpha/(2\alpha+1)} + (2\alpha)^{1/(2\alpha+1)}].
$$

Remark. The above constant can be compared with the one obtained by Fabian [13]. Note that while we consider uniformly locally Lipschitz functions with exponent $0 < \alpha \leq 1$, [13] considers functions with bounded rth derivative, $r \geq 1$. Thus $\alpha = r = 1$ is the only case in common between the two papers. In particular, for $\alpha = 1$ and $\sigma = 1$, our constant reduces to

$$
c^*(1, L, 1) = L^{1/3}\frac{(1/4)^{1/3} + 2^{1/3}}{6^{1/3}}.
$$

In comparison, the optimal constant in [13, Thm. 5.4, p. 1359] for the above case ($r = 1, s = 2$) is greater by a factor of $\pi^{1/3}$. Also note that while our results hold both almost surely and in $L^p, p \geq 1$, those of [13] hold only in probability.

The following corollary establishes the same rates for the sequence U_n^*.

COROLLARY 3.4. *For the learning scheme constructed above with the bandwidth sequence $h_n = h(\log n/n)^{1/(2\alpha+1)}$, $h > 0$, we have*

$$
\overline{\lim_{n\to\infty}} \frac{\sup_{m\in ulL(\alpha,L,\delta)}(m^* - m(U_n^*))}{(\frac{\log n}{n})^{\alpha/(2\alpha+1)}} \leq 2c(\alpha, L, \sigma, h) \quad \textit{a.s. and in } L^p, p \geq 1,
$$

where $c(\alpha, L, \sigma, h)$ is given by (29). *Also, for the the same learning scheme with any bandwidth sequence, h_n, such that* (i) *$h_n \to 0$ as $n \to \infty$, and* (ii) *$nh_n \geq A'n^{a'}$ for some $0 < a' < 1$, $A' > 0$, we have*

$$
\overline{\lim_{n\to\infty}} \frac{1}{nh_n}\log P\left(\sup_{m\in ulL(\alpha,L,\delta)}(m^* - m(U_n^*)) > \epsilon\right) \leq -\Gamma(\epsilon/2)
$$

for all $\epsilon > 0$, for some $\Gamma(\epsilon) > 0$.

Proof. Both parts of the corollary follow immediately from Theorem 3.1, Corollary 3.3, and the following observation. Since, $\hat{m}_n(U_n^*) = \max_{u \in \mathcal{U}} \hat{m}_n(u)$,

$$m(u) - m(U_n^*) \leq \hat{m}_n(u) + d_\infty(\hat{m}_n, m) - \hat{m}_n(U_n^*) + d_\infty(\hat{m}_n, m) \leq 2d_\infty(\hat{m}_n, m).$$

Taking $\sup_{u \in \mathcal{U}}$ on both sides we get $m^* - m(U_n^*) \leq 2d_\infty(\hat{m}_n, m)$. □

4. Limit laws for moving averages. In this section we obtain almost sure and L^p limit theorems for the moving averages that comprise the variance term in the analysis of the kernel estimator considered in §3. If the noise were i.i.d. and the design scheme were equispaced (see conditions (C4) and (C5) below), then exact almost sure limit theorems are available in the literature for these moving averages (see Theorem 4.3). These results can be viewed as generalizations of the law of iterated logarithm. In light of the paragraph following Theorem 4.3, the weaker in-probability result also holds for the the i.i.d. noise case with the progressive nearly equispaced design scheme employed in this paper. This identifies the desired rate and constant. However, in order to get the stronger almost sure results for the progressive nearly equispaced design scheme, we have to work considerably harder. We first obtain a coarser constant in Theorem 4.4 and then recover the desired constant in Theorem 4.5, by applying that result on an appropriately chosen subsequence. This subsequence argument relies heavily on the exact structure of the nearly equispaced design scheme. Thus, the specific design scheme plays a crucial role in the analysis, if we desire to get a sharp constant.

It is also worth noting that the techniques used here to obtain the abovementioned limit theorems parallel those of de Acosta and Kuelbs [10], by relying on classical probability inequalities rather than on the strong approximations approach of Csörgő and Révész [9]. This allows us to obtain results for $\{W_i\}$ which are independent but not necessarily identically distributed. Also, it gives us a way of extending these results to higher dimensions (obtained in a forthcoming paper [1]), for which the strong approximation results are not yet available, to the best of our knowledge (see Mack and Silverman [24]).

In Theorem 4.7 we establish the same rates (with the same constant) in L^p. This is done by means of a device due to Hoffman-Jørgensen [19]. The proof of Theorem 4.7 can be used more generally for establishing L^p counterparts of in-probability rates.

Throughout this section we will consider a collection of random variables $\{V_i^n : n = 1, 2, \ldots; i = 1, 2, \ldots, n\}$ satisfying some of the following conditions.

(C1) $E[V_i^n] = 0$ for all $n = 1, 2, \ldots; i = 1, 2, \ldots, n$.

(C2) $\{V_i^n\}_{i=1}^n$ is an independent collection for each $n = 1, 2, \ldots$.

(C3) There exist $\varsigma, s_0 > 0$ such that

$$E[\exp(sV_i^n)] \leq \exp(\varsigma^2 s^2/2) \quad \forall |s| \leq s_0,\ n = 1, 2, \ldots; i = 1, 2, \ldots, n. \tag{30}$$

In that case define

$$\sigma := \inf\{\varsigma > 0 : \text{ there exists } s_0 > 0 \text{ such that (30) holds}\}. \tag{31}$$

(C4) $\{V_i^n : n = 1, 2, \ldots; i = 1, 2, \ldots, n\}$ are identically distributed.

(C5) $V_i^n = V_i^i$ for all $n = 1, 2, \ldots; i = 1, 2, \ldots, n$.

Note that under (C1) and (C3), it follows that $E[|V_i^n|^2] \leq \sigma^2$, and under (C1), (C3), and (C4), $E[|V_i^n|^2] = \sigma^2$. Also, note that the collection of random variables $\{\tilde{W}_i^n : n = 1, 2, \ldots; i = 1, 2, \ldots, n\}$ obtained in the previous section with $\{\tilde{W}_i^n\}_{i=1}^n$

being a permutation of $\{W_i\}_{i=1}^n$ arranged in order of $\{\tilde{u}_i\}_{i=1}^n$, $n = 1, 2, \ldots$, satisfies conditions (C1), (C2), and (C3).

For each $n = 1, 2, \ldots$, define the partial sums of the random variables $\{V_i^n\}_{i=1}^n$ by

$$S_{j,k}^n := \sum_{i=j+1}^{k} V_i^n. \tag{32}$$

For $m \leq n$, define

$$B_{n,m} := \max_{0 \leq j \leq n} \max_{1 \leq k \leq (m \wedge n-j)} |S_{j,j+k}^n|. \tag{33}$$

Note that by setting $V_i^n = \tilde{W}_i^n$ of the previous section, we get $S_{j,k}^n = \tilde{S}_{j,k}^n$ and $B_{n,m} = \tilde{B}_{n,m}$ defined in (18) and (19), respectively.

Let $\{a_n\}$ be a sequence of positive integers satisfying some of the following conditions:

(A1) $1 \leq a_n \leq n$,
(A2) a_n is nondecreasing,
(A3) n/a_n is nondecreasing,
(A4) $a_n/\log n \to \infty$ as $n \to \infty$.
(A5) For some $a > 0$, $n^{a-1}a_n = o(n^{\varepsilon})$
(A6) For some $a', A' > 0$, $a_n \geq A'n^{a'}$. for every $\varepsilon > 0$.

Finally, let

$$\beta_n = (2a_n(\log(n/a_n) + \log\log n))^{1/2}.$$

In this section we determine the limiting behavior of $\{B_{n,a_n}/\beta_n\}$.

Below we give two lemmas that will be used to establish the limit theorems. The first is a minor modification of a maximal inequality due to de Acosta and Kuelbs [10, Lem. 3.1].

LEMMA 4.1. *Let $\{V_i\}$ be a sequence of independent random variables and let $S_{j,k} := \sum_{i=j+1}^{k} V_i$. Then for every integer $n \geq 0$, $m \geq 0$, $p \geq 0$, $p < n$, $m \leq n$, and $t > 0$, $s > 0$, $0 < a < 1$,*

$$P(B_{n,m} > t+s) \leq \frac{p}{1-c}\left[\max_{0 \leq j \leq n} P(|S_{j,j+m}| > at) + \max_{0 \leq j \leq n} P\left(|S_{j,j+\lfloor \frac{n}{p} \rfloor+1}| > \frac{(1-a)}{2}t\right)\right],$$

provided

$$\max_{0 \leq j \leq n} \max_{1 \leq k \leq m \vee \lfloor \frac{n}{p} \rfloor+1} P(|S_{j,j+k}| \geq s/4) \leq c < 1.$$

LEMMA 4.2. *Let $\{V_i^n\}$ be a collection of random variables satisfying conditions (C2) and (C3) with σ as defined in (31). Given any $\varsigma > \sigma$, let $s_0 > 0$ be such that (30) holds. Then for all $j \geq 0$, $k \geq 1$, and $0 < a \leq k\varsigma^2 s_0$,*

$$P(|S_{j,j+k}^n| \geq a) \leq 2\exp\left(-\frac{a^2}{2k\varsigma^2}\right).$$

Proof. For any $0 < s \leq s_0$,

$$\begin{aligned} P(S_{j,j+k}^n \geq a) &\leq \exp(-sa)E[\exp(sS_{j,j+k}^n)] \\ &= \exp(-sa)E[\exp(sV_{j+1}^n)] \cdots E[\exp(sV_{j+k}^n)] \\ &\leq \exp\left(\frac{k\varsigma^2 s^2}{2} - sa\right). \end{aligned}$$

The same upper bound also holds for $P(-S^n_{j,j+k} \geq a)$. Optimizing the upper bound over $0 \leq s \leq s_0$, we get the desired result. □

The first theorem from [9] gives almost sure rates for the process $\{B_{n,a_n}\}_{n=1}^{\infty}$ under conditions (C1)–(C5).

THEOREM 4.3 (Csörgő and Révész [9, Thm. 3.1.1]). *Let $\{V_i^n\}$ be a be a collection of random variables satisfying conditions* (C1)–(C5) *with variance σ^2. Let $\{a_n\}$ satisfy conditions* (A1)–(A4). *Then*

$$\overline{\lim_{n\to\infty}} \frac{B_{n,a_n}}{\beta_n} = \sigma \ a.s.$$

If in addition $\{a_n\}$ satisfies (A5), *then*

$$\lim_{n\to\infty} \frac{\max_{\Delta n \leq j \leq (1-\Delta)n} |S^n_{j,j+a_{n,j}}|}{\beta_n} = \sigma \ a.s.$$

for all $0 \leq \Delta < 1/2$, $0 < \rho \leq 1$, and $a_{n,j}$ satisfying $\rho a_n \leq a_{n,j} \leq a_n, \forall 1 \leq j \leq n$, $n = 1, 2, \ldots$.

From the above theorem we immediately have the same rate in probability for any collection $\{V_i^n\}$ satisfying conditions (C1)–(C4) (but not necessarily (C5)), i.e.,

$$\lim_n P(B_{n,a_n}/\beta_n > (\sigma + \epsilon)) = 0, \quad \forall \epsilon > 0, \tag{34}$$

and σ is the smallest constant for which (34) holds. In the next theorem we obtain upper bounds on the in-probability rate (with the above constant) and on the almost sure rate (with a larger constant) for $\{V_i^n\}$ that do not necessarily satisfy conditions (C4) or (C5).

THEOREM 4.4. *Let $\{V_i^n\}$ be a collection of random variables satisfying conditions* (C1)–(C3) *with σ as defined in* (31). *Let $\{a_n\}$ satisfy conditions* (A1)–(A4). *Then* (34) *holds. If in addition $\{a_n\}$ satisfies* (A5) *for some $a > 0$, then*

$$\overline{\lim_{n\to\infty}} \frac{B_{n,a_n}}{\beta_n} \leq \left(1 + \frac{1}{a}\right)^{1/2} \sigma \ a.s.$$

Proof. The theorem will follow from the Borel–Cantelli lemma if we can show that for all $\varsigma > \sigma$ and $\epsilon > 0$,

$$\sum_n P(B_{n,a_n}/\beta_n > (\rho\varsigma + 4\epsilon)) < \infty, \tag{35}$$

where $\rho = (1 + a^{-1})^{1/2}$. Substituting n, m, p, t, s in Lemma 4.1 by $n, a_n, \lfloor nd/a_n \rfloor + 1, (\rho\varsigma + 3\epsilon)\beta_n, \epsilon\beta_n$, respectively, we have

$$\begin{aligned} P(B_{n,a_n}/\beta_n > (\rho\varsigma + 4\epsilon)) &\leq 2\left(\frac{nd}{a_n} + 1\right) \max_{0\leq j\leq n} P(|S^n_{j,j+a_n}|/\beta_n > (\rho\varsigma + \epsilon)) \\ &\quad + 2\left(\frac{nd}{a_n} + 1\right) \max_{0\leq j\leq n} P(|S^n_{j,j+\lfloor a_n/d \rfloor + 1}|/\beta_n > \epsilon) \end{aligned} \tag{36}$$

provided

$$\max_{0\leq j\leq n} \max_{1\leq k\leq a_n+1} P(|S^n_{j,j+k}|/\beta_n \geq \epsilon/4) \leq 1/2. \tag{37}$$

By Chebyshev's inequality we have

$$\max_{0\le j\le n}\max_{1\le k\le a_n+1} P(|S^n_{j,j+k}|/\beta_n \ge \epsilon/4) \le \frac{\sigma^2(a_n+1)}{(\beta_n\epsilon/4)^2}.$$

By the definition of β_n and the assumptions on a_n, $a_n/\beta_n^2 \to 0$ as $n\to\infty$. So there exists an n_0 such that (37) holds for all $n \ge n_0$. We now apply Lemma 4.2 to upper bound the RHS of (36). Let s_0 be such that (30) holds. Note that by condition (A4) on $\{a_n\}$ it follows that $\beta_n/a_n \to 0$ as $n\to\infty$. Hence, there exists an $n_1 \ge n_0$ such that for all $n \ge n_1$, $(\rho\varsigma+\epsilon)\beta_n \le a_n\varsigma^2 s_0$, and consequently for all $n \ge n_1$,

$$\begin{aligned} P(|S^n_{j,j+a_n}|/\beta_n > (\rho\varsigma+\epsilon)) &\le 2\exp\left(-\frac{(\rho\varsigma+\epsilon)^2\beta_n^2}{2\varsigma^2 a_n}\right)\\ &= 2\exp\left(-\frac{(\rho\varsigma+\epsilon)^2 2a_n(\log(n/a_n)+\log\log n)}{2\varsigma^2 a_n}\right)\\ &= 2\exp(-(\rho')^2(\log(n/a_n)+\log\log n))\\ &= 2\left(\frac{a_n}{n\log n}\right)^{(\rho')^2}, \end{aligned}$$

where $\rho' = \rho + \epsilon/\varsigma$. Thus, for all $n \ge n_1$, the first term on the RHS of (36) is bounded above by

$$(38)\ 2\left(\frac{nd}{a_n}+1\right)\max_{0\le j\le n} P(|S^n_{j,j+a_n}|/\beta_n > (\rho\varsigma+\epsilon)) \le 8d\left(\frac{a_n}{n}\right)^{(\rho')^2-1}(\log n)^{-(\rho')^2}.$$

In view of the additional condition on a_n it is easy to check that

$$\left(\frac{a_n}{n}\right)^{(\rho')^2-1}(\log n)^{-(\rho')^2} \le \left(\frac{a_n}{n}\right)^{(\rho')^2-1} = o(1/n^\gamma),$$

where $\gamma = a((\rho+\epsilon/2\varsigma)^2-1) > 1$. By choosing the constant $d > ((\rho\varsigma+\epsilon)/\epsilon)^2$, the same asymptotic upper bound can be obtained for the second term on the RHS of (36). This establishes (35).

Finally, by setting $\rho = 1$ in (36) through (38), it can easily be seen that (34) holds. □

In the next theorem we obtain the same upper bound as in Theorem 4.3 for the sequence $\{\tilde B_{n,a_n}\}$ that was defined in the previous section.

THEOREM 4.5. *Let $\{\tilde W_i^n\}$ be the collection of random variables defined in the previous section with σ as defined in* (31). *Let $\{\tilde B_{n,a_n}\}$ be as defined in* (19). *Let $\{a_n\}$ satisfy conditions* (A1)–(A5) *with $a > 0$ as in* (A5). *Then*

$$\overline{\lim_{n\to\infty}}\frac{\tilde B_{n,a_n}}{\beta_n} \le \sigma \ a.s.$$

Proof. Let $\{\tilde W_i^{m,n}\}_{i=m}^n$ be a permutation of $\{W_i\}_{i=m}^n$ arranged in order of $\{\tilde u_i\}_{i=m}^n$. Define their partial sums

$$(39)\qquad \tilde S^{m,n}_{j,k} := \sum_{i=j+1}^{k}\tilde W_i^{m,n},\qquad m-1\le j\le k\le n.$$

Define

$$\tilde{B}^m_{n,a_n} := \max_{m-1\le j\le n}\ \max_{1\le k\le(a_n\wedge n-j)} |\tilde{S}^{m,n}_{j,j+k}|. \tag{40}$$

Then, in terms of our prior notation, $\tilde{B}_{n,a_n} = \tilde{B}^1_{n,a_n}$. The proof of this theorem depends crucially on the following simple observation:

$$\tilde{B}_{n,a_n} \le \tilde{B}_{m,a_n} + \tilde{B}^m_{n,2\frac{n-m}{n}a_n+1} \qquad \forall m \le n.$$

This fact is a consequence of the nearly uniformly spaced design sequence $\{u_n\}$. Now let $n_k = \lfloor \theta^k \rfloor$, $k = 1, 2, \dots$ for some $\theta > 1$. Given any n, let k be such that $n_k \le n < n_{k+1}$. Then by substituting $m = n_k$ above and using the fact that a_n is increasing, we get

$$\tilde{B}_{n,a_n} \le \tilde{B}_{n_k,a_{n_{k+1}}} + \tilde{B}^{n_k}_{n,2\frac{n-n_k}{n}a_n+1}.$$

Now, since $\beta_{n_k} \le \beta_n \le \beta_{n_{k+1}}$, we get

$$\frac{\tilde{B}_{n,a_n}}{\beta_n} \le \frac{\beta_{n_{k+1}}}{\beta_{n_k}} \frac{\tilde{B}_{n_k,a_{n_{k+1}}}}{\beta_{n_{k+1}}} + \frac{\tilde{B}^{n_k}_{n,2\frac{n-n_k}{n}a_n+1}}{\beta_n}.$$

Let $\rho = (1 + a^{-1})^{1/2}$. The theorem will follow if for all $\varsigma > \sigma$ and $0 < \eta < 2\varsigma\rho^2$, we can find a $\theta > 1$ such that

$$\overline{\lim_{k\to\infty}} \frac{\beta_{n_{k+1}}}{\beta_{n_k}} \frac{\tilde{B}_{n_k,a_{n_{k+1}}}}{\beta_{n_{k+1}}} \le \varsigma + \eta \text{ a.s.}, \tag{41}$$

and

$$\overline{\lim_{n\to\infty}} \frac{\tilde{B}^{n_k}_{n,2\frac{n-n_k}{n}a_n+1}}{\beta_n} \le \eta \text{ a.s.} \tag{42}$$

Choose $\theta = 1 + (\eta/\sqrt{2}\rho\varsigma)^2$. It is easy to check that

$$\overline{\lim_{k\to\infty}} \frac{\beta_{n_{k+1}}}{\beta_{n_k}} \le \theta.$$

Hence, (41) will follow by Borel–Cantelli if we establish that for all $\epsilon > 0$,

$$\sum_k P\left(\frac{\tilde{B}_{n_{k-1},a_{n_k}}}{\beta_{n_k}} > \varsigma + 4\epsilon\right) < \infty. \tag{43}$$

Using Lemmas 4.1 and 4.2, as was done in the proof of Theorem 4.4 (cf. (36), (38)), we get

$$P\left(\frac{\tilde{B}_{n_{k-1},a_{n_k}}}{\beta_{n_k}} > \varsigma + 4\epsilon\right) \le O((\log n_k)^{-(1+\epsilon/\varsigma)}) \le O(k^{-(1+\epsilon/\varsigma)})$$

and (43) holds. Similarly, (42) will follow by Borel–Cantelli if we establish that for all $\epsilon > 0$,

$$\sum_n P\left(\frac{\tilde{B}^{n_k}_{n,2\frac{n-n_k}{n}a_n+1}}{\beta_n} > \eta + 4\epsilon\right) < \infty.$$

Since $\tilde{B}^{n_k}_{n,2\frac{n-n_k}{n}a_n+1} \leq \tilde{B}^{n_k}_{n,2\frac{\theta-1}{\theta}a_n+1}$, the above will follow from

$$\sum_n P\left(\frac{\tilde{B}^{n_k}_{n,2\frac{\theta-1}{\theta}a_n+1}}{\beta_n} > \eta + 4\epsilon\right) < \infty. \tag{44}$$

Again, using Lemmas 4.1 and 4.2, as was done in the proof of Theorem 4.4 (cf. (36), (38)), we get

$$P\left(\frac{\tilde{B}^{n_k}_{n,2\frac{\theta-1}{\theta}a_n+1}}{\beta_n} > \eta + 4\epsilon\right) \leq O\left(\left(\frac{a_n}{n}\right)^{(1+a^{-1})(1+\epsilon/\eta)-1}\right) \leq o(n^{-\gamma})$$

for some $\gamma > 1$. Hence (44) holds. □

We now proceed to obtain the same upper bound as in Theorem 4.3 but in L^p instead of almost surely. We first establish the following lemma which is needed to obtain the L^p upper bound.

LEMMA 4.6. *Let $\{V_i^n\}$ be a collection of random variables satisfying condition* (C2). *If $\{B_{n,a_n}/\beta_n\}_{n=1}^{\infty}$ is stochastically bounded and* $\sup_n E[\sup_{1\leq i\leq n}(|V_i^n|/\beta_n)^{p'}] < \infty$, *then* $\sup_n E[(B_{n,a_n}/\beta_n)^{p'}] < \infty$ *and consequently, $\{(B_{n,a_n}/\beta_n)^p\}_{n=1}^{\infty}$ is uniformly integrable for all $1 \leq p < p'$.*

Proof. The proof of this lemma is based on a technique borrowed from [19]. We first prove the following claim:

$$P(B_{n,a_n} \geq 2t + s) \leq P(B_{n,a_n} \geq t)^2 + P(N_n \geq s),$$

where $N_n := \sup_{1\leq i\leq n} |V_i^n|$. Let

$$B^{l,m}_{n,a_n} := \max_{\substack{l-1\leq j\leq k\leq m\\ k-j\leq a_n}} |S^n_{j,k}|, \qquad 1 \leq l \leq m \leq n.$$

Thus,

$$B_{n,a_n} = B^{1,n}_{n,a_n} \leq B^{1,m-1}_{n,a_n} + |V^n_m| + B^{m+1,n}_{n,a_n} \quad \text{for any } 1 \leq m \leq n. \tag{45}$$

Let T be the stopping time defined by

$$T := \inf\{1 \leq m \leq n : B^{1,m}_{n,a_n} \geq t\},$$

where $\inf\emptyset = \infty$. Then $B^{1,n}_{n,a_n} \geq 2t + s$ implies that $T \leq n$, and so we have

$$\begin{aligned} P(B_{n,a_n} \geq 2t + s) &= \sum_{m=1}^{n} P(B_{n,a_n} \geq 2t + s, T = m) \\ &\leq \sum_{m=1}^{n} P(B^{1,m-1}_{n,a_n} + |V^n_m| + B^{m+1,n}_{n,a_n} \geq 2t + s, T = m) \\ &\leq \sum_{m=1}^{n} P(B^{m+1,n}_{n,a_n} \geq t + s - N_n, T = m) \\ &\leq \sum_{m=1}^{n} P(B^{m+1,n}_{n,a_n} \geq t, T = m) + P(N_n \geq s) \end{aligned}$$

$$
\begin{aligned}
&= \sum_{m=1}^{n} P(B_{n,a_n}^{m+1,n} \geq t) P(T = m) + P(N_n \geq s) \\
&\leq P(B_{n,a_n}^{1,n} \geq t) \sum_{m=1}^{n} P(T = m) + P(N_n \geq s) \\
&= P(B_{n,a_n} \geq t)^2 + P(N_n \geq s).
\end{aligned}
$$

The first inequality follows from (45), the second from the fact that $T = m$ implies that $B_{n,a_n}^{1,m-1} < t$, and the third by the definition of N_n. The next equality follows from the fact that $\{B_{n,a_n}^{m+1,n} \geq t\}$ and $\{T = m\}$ are independent events.

Pick A so that $P(B_{n,a_n}/\beta_n \geq A) \leq 1/(2.3^{p'})$. Note that this is possible by the assumption that $\{B_{n,a_n}/\beta_n\}_{n=1}^{\infty}$ is stochastically bounded. Now we have

$$
\begin{aligned}
E[(B_{n,a_n}/\beta_n)^{p'}] &= \int_0^\infty p' x^{p'-1} P(B_{n,a_n}/\beta_n \geq x)\, dx \\
&\leq (3A)^{p'} + \int_{3A}^\infty p' x^{p'-1} P(B_{n,a_n}/\beta_n \geq x)\, dx \\
&\leq (3A)^{p'} + \int_{3A}^\infty p' x^{p'-1} P(N_n/\beta_n \geq x/3)\, dx \\
&\qquad + \int_{3A}^\infty p' x^{p'-1} P(B_{n,a_n}/\beta_n \geq x/3)^2\, dx \\
&= (3A)^{p'} + 3^{p'} \int_A^\infty p' x^{p'-1} P(N_n/\beta_n \geq x)\, dx \\
&\qquad + 3^{p'} \int_A^\infty p' x^{p'-1} P(B_{n,a_n}/\beta_n \geq x)^2\, dx \\
&\leq (3A)^{p'} + 3^{p'} \int_A^\infty p' x^{p'-1} P(N_n/\beta_n \geq x)\, dx \\
&\qquad + \frac{1}{2} \int_A^\infty p' x^{p'-1} P(B_{n,a_n}/\beta_n \geq x)\, dx \\
&\leq (3A)^{p'} + 3^{p'} E[(N_n/\beta_n)^{p'}] + \frac{1}{2} E[(B_{n,a_n}/\beta_n)^{p'}].
\end{aligned}
$$

Thus

$$
E[(B_{n,a_n}/\beta_n)^{p'}] \leq 2(3A)^{p'} + 2.3^{p'} E[(N_n/\beta_n)^{p'}] < \infty.
$$

The uniform integrability of $\{(B_{n,a_n}/\beta_n)^p\}_{n=1}^{\infty}$ for all $1 \leq p < p'$ is an immediate consequence. This completes the proof of Lemma 4.6. □

The L^p upper bound is now established in the following theorem.

THEOREM 4.7. *Let* $\{V_i^n\}$ *be a collection of random variables satisfying conditions* (C1)–(C3) *with* σ *as defined in* (31). *Let* $\{a_n\}$ *satisfy conditions* (A1)–(A4) *and* (A6). *Then*

$$
\varlimsup_{n \to \infty} E[(B_{n,a_n}/\beta_n)^p]^{1/p} \leq \sigma \quad \forall p \geq 1.
$$

Proof. The theorem will follow from the in-probability bound (34) obtained in Theorem 4.4, if we establish uniform integrability of $\{(B_{n,a_n}/\beta_n)^p\}_{n=1}^{\infty}$. In view of Lemma 4.6, it suffices to establish that $\{B_{n,a_n}/\beta_n\}_{n=1}^{\infty}$ is stochastically bounded and that $\sup_n E[\sup_{1\le i\le n}(|V_i^n|/\beta_n)^{p'}] < \infty$ for some $p' > p$. That $\{B_{n,a_n}/\beta_n\}_{n=1}^{\infty}$ is stochastically bounded also follows from the in-probability bound (34) obtained in Theorem 4.4. Finally, using the fact that $E[|X|] \le E[|X|^r]^{1/r}$ for any $r \ge 1$, we get

$$\begin{aligned}\sup_n E\left[\sup_{1\le i\le n}(|V_i^n|/\beta_n)^{p'}\right] &= \sup_n (1/\beta_n)^{p'} E\left[\sup_{1\le i\le n}|V_i^n|^{p'}\right]\\ &\le \sup_n (1/\beta_n)^{p'} E\left[\sup_{1\le i\le n}|V_i^n|^{p'r}\right]^{1/r}\\ &\le \sup_n (1/\beta_n)^{p'} E\left[\sum_{i=1}^n |V_i^n|^{p'r}\right]^{1/r}\\ &\le \sup_n (1/\beta_n)^{p'}\left(\sum_{i=1}^n E[|V_i^n|^{p'r}]\right)^{1/r}\\ &\le \sup_n (n/(\beta_n)^{p'r})^{1/r}\sup_{\substack{1\le i\le n\\ 1\le n<\infty}} E[|V_i^n|^{p'r}]^{1/r}\\ &\le \sup_n (n/((2A')^{1/2}n^{a'/2})^{p'r})^{1/r}\sup_{\substack{1\le i\le n\\ 1\le n<\infty}} E[|V_i^n|^{p'r}]^{1/r}\\ &\le (2A')^{-p'/2}(1\vee n^{1/r-a'p'/2})\sup_{\substack{1\le i\le n\\ 1\le n<\infty}} E[|V_i^n|^{p'r}]^{1/r}\\ &= (2A')^{-p'/2}\sup_{\substack{1\le i\le n\\ 1\le n<\infty}} E[|V_i^n|^{p'r}]^{1/r}\\ &< \infty\end{aligned}$$

if we choose $r = 1 \vee 2/a'p'$. Note that we have used the condition that $a_n \ge A'n^{a'}$ to obtain a corresponding bound on β_n in one of the above steps. Also, we have used condition (C3) on the moment-generating function of $\{V_i^n\}$ to deduce the last inequality. This completes the proof of the theorem. □

5. The adaptive control scheme. In this section we construct a class of certainty equivalence control with forcing-type adaptive control schemes based on the learning schemes constructed in §3. Let $\{\tau_i\}_{i=1}^{\infty}$ be a positive integer-valued sequence to be specified later. Define the related sequence $\{t_i\}_{i=1}^{\infty}$ as follows:

$$t_i := 1 + \sum_{k=1}^{i-1}(\tau_k+1) = \sum_{k=1}^{i-1}\tau_k + i, \quad i \ge 1.$$

At times t_i, $i \ge 1$ use (force) the ith control u_i from the design sequence of the learning scheme such as the one described in the previous section. Let U_i^* be the estimate based on the corresponding observations at times t_k, $1 \le k \le i$, with the design sequence u_k, $1 \le k \le i$. Use the control U_i^* from time t_i+1 to time $t_{i+1}-1$, i.e., τ_i times. Thus,

$$U_{t_i} = u_i, \quad U_n = U_i^* \text{ for } t_i+1 \le n \le t_{i+1}-1, \quad i \ge 1.$$

This completes the description of the adaptive control scheme.

Let

$$\kappa(n) := \min\{i : t_i > n\} - 1 = \max\{i : t_i \le n\} = \max\left\{i : \sum_{k=1}^{i-1}\tau_k + i \le n\right\}.$$

The following theorems and their corollaries provide upper bounds on the learning loss associated with the class of schemes constructed above in terms of $\kappa(n)$.

THEOREM 5.1. *Assume that for a certain learning scheme $m^* - m(U_i^*) = O(r_i)$ a.s. (resp., in L^p with $p \geq 1$) for some known sequence r_i. Then for the certainty equivalence control with forcing-type scheme constructed above with the sequence $\tau_i = \lfloor br_i^{-1} \rfloor$ for some $b > 0$, we have $L_n = O(\kappa(n))$ a.s. (resp., in L^p with $p \geq 1$).*

Proof. Since, $m : \mathcal{U} = [\Delta, 1 - \Delta] \to \mathbb{R}$ is uniformly locally Lipschitz, it follows that $K := \sup_{u \in \mathcal{U}} m(u) - \inf_{u \in \mathcal{U}} m(u) < \infty$. Thus,

$$\begin{aligned} L_n &= \sum_{l=1}^{n} m^* - m(U_l) \\ &\leq K\kappa(n) + \sum_{i=1}^{\kappa(n)} \sum_{l=t_i+1}^{t_{i+1}-1} m^* - m(U_l) \\ &= K\kappa(n) + \sum_{i=1}^{\kappa(n)} (m^* - m(U_i^*))\tau_i \\ &\leq K\kappa(n) + \sum_{i=1}^{\kappa(n)} (m^* - m(U_i^*))br_i^{-1}. \end{aligned}$$

Now, for the first part we are given that $m^* - m(U_i^*) = O(r_i)$ a.s. Thus, $\overline{\lim}_i (m^* - m(U_i^*))r_i^{-1} \leq C$ a.s. for some $C \geq 0$ that could depend on ω. That is, for all $\epsilon > 0$, there exists an $i_0 \geq 1$, such that for all $i \geq i_0$, $m^* - m(U_i^*) \leq (C + \epsilon)r_i$ a.s. Then, clearly,

$$\begin{aligned} L_n &\leq K\kappa(n) + \sum_{i=1}^{i_0 - 1} (m^* - m(U_i^*))br_i^{-1} + \sum_{i=i_0}^{\kappa(n)} (m^* - m(U_i^*))br_i^{-1} \\ &\leq K\kappa(n) + M(\epsilon) + (C + \epsilon)b\kappa(n) \qquad \text{a.s.}, \end{aligned}$$

where $M(\epsilon) = \sum_{i=1}^{i_0 - 1} (m^* - m(U_i^*))br_i^{-1}$ depends on ϵ but not on n. Dividing by $\kappa(n)$ and taking the limit as $n \to \infty$ we get

$$\overline{\lim_n} \frac{L_n}{\kappa(n)} \leq K + (C + \epsilon)b \qquad \text{a.s.}$$

Now, by letting $\epsilon \to 0$ we get

$$\overline{\lim_n} \frac{L_n}{\kappa(n)} \leq K + Cb \qquad \text{a.s.}$$

For the second part we are given that $m^* - m(U_i^*) = O(r_i)$ in L^p with $p \geq 1$. Thus, $\overline{\lim}_i E[|m^* - m(U_i^*)|^p]r_i^{-p} \leq C^p$ for some $C \geq 0$. That is, for all $\epsilon > 0$ there exists an $i_0 \geq 1$, such that for all $i \geq i_0$, $E[|m^* - m(U_i^*)|^p]r_i^{-p} \leq C^p + \epsilon$. Also by the well-known inequality $|x_1 + \cdots + x_k|^p \leq k^{p-1}(|x_1|^p + \cdots + |x_k|^p)$ we get

$$|L_n|^p \leq 2^{p-1} \left(K^p(\kappa(n))^p + (\kappa(n))^{p-1} \sum_{i=1}^{\kappa(n)} |m^* - m(U_i^*)|^p b^p r_i^{-p} \right).$$

Therefore,

$$\begin{aligned} E[|L_n|^p] &\le 2^{p-1}\left(K^p(\kappa(n))^p + (\kappa(n))^{p-1}\sum_{i=1}^{\kappa(n)} E[|m^* - m(U_i^*)|^p]b^p r_i^{-p}\right) \\ &\le 2^{p-1}\Bigg(K^p(\kappa(n))^p + (\kappa(n))^{p-1}\sum_{i=1}^{i_0-1} E[|m^* - m(U_i^*)|^p]b^p r_i^{-p} \\ &\qquad + (\kappa(n))^{p-1}\sum_{i=i_0}^{\kappa(n)} E[|m^* - m(U_i^*)|^p]b^p r_i^{-p}\Bigg) \\ &\le 2^{p-1}(K^p(\kappa(n))^p + (\kappa(n))^{p-1}M(\epsilon) + (C^p+\epsilon)b^p(\kappa(n))^p), \end{aligned}$$

where $M(\epsilon) = \sum_{i=1}^{i_0-1} E[|m^* - m(U_i^*)|^p]b^p r_i^{-p}$ depends on ϵ but not on n. Dividing by $(\kappa(n))^p$ and taking the limit as $n \to \infty$ we get

$$\varlimsup_n \frac{E[|L_n|^p]}{(\kappa(n))^p} \le 2^{p-1}(K^p + (C^p+\epsilon)b^p).$$

Now, by letting $\epsilon \to 0$ we get

$$\varlimsup_n \frac{E[|L_n|^p]}{(\kappa(n))^p} \le 2^{p-1}(K^p + C^p b^p). \qquad \square$$

Note that we can also obtain a constant (in terms of K, C, b) associated with the rate of increase of the learning loss, $\kappa(n)$. Moreover, $\kappa(n)$ itself depends on b. In fact, if $\tau_i \to \infty$ as $i \to \infty$, then asymptotically $\kappa_b(n) \approx \kappa_1(n/b)$, where the subscript on $\kappa(n)$ denotes the dependence on b. We may therefore want to choose b to minimize the rate along with the constant.

COROLLARY 5.2. *For the certainty equivalence control with forcing-type scheme constructed above, with the learning scheme of* §3 *with the bandwidth sequence* $h_i = h(\log i/i)^{1/(2\alpha+1)}$, *and with the sequence* $\tau_i = \lfloor b(i/\log i)^{\alpha/(2\alpha+1)}\rfloor$ *for some* $b > 0$, *we have* $L_n = O(\tilde{B}^{-1}(n))$ *a.s. and in* $L^p, p \ge 1$, *where* $\tilde{B}^{-1} : [0,\infty) \to [e,\infty)$ *is the inverse of the function* $\tilde{B} : [e,\infty) \to [0,\infty)$ *defined by*

$$\tilde{B}(t) := \int_e^t b\left(\frac{s}{\log s}\right)^{\alpha/(2\alpha+1)} ds.$$

Moreover, $\tilde{B}^{-1}(n) = o(n^{\frac{2\alpha+1}{3\alpha+1}+\eta})$ *for all* $\eta > 0$.

Proof. This corollary will follow immediately from Theorems 5.1 and 3.1, if we can show that $\kappa(n) = O(\tilde{B}^{-1}(n))$, and that $\tilde{B}^{-1}(n) = o(n^{\frac{2\alpha+1}{3\alpha+1}+\eta})$ for all $\eta > 0$, when $\tau_i = \lfloor b(i/\log i)^{\alpha/(2\alpha+1)}\rfloor$. To this end, define the functions $v, B : \mathbb{R}^+ \to \mathbb{R}^+$ based on the sequence $\{\tau_i\}$ as follows:

$$\begin{aligned} v(s) &:= \tau_{\lceil s\rceil} + 1, \\ B(t) &:= \int_0^t v(s)\, ds. \end{aligned}$$

Then

$$B(i) = \sum_{k=1}^{i} \tau_k + i, \quad i = 0, 1, \ldots.$$

Also, observe that (1) $B(t)$ is continuous in $t > 0$, (2) $B(0) = 0$, (3) $B(t)$ is strictly increasing in $t > 0$ (since $v(s) > 0$), and (4) $B(t) \geq t$ (since $v(s) \geq 1$). Hence, given any n, there exists a unique $0 \leq t \leq n$ such that $B(t) = n$. Denote this solution by $B^{-1}(n)$. Then

$$\begin{aligned} \sum_{k=1}^{\lceil B^{-1}(n)\rceil+1-1} \tau_k + \lceil B^{-1}(n)\rceil + 1 &= B(\lceil B^{-1}(n)\rceil) + 1 \\ &\geq B(B^{-1}(n)) + 1 \\ &= n + 1 > n. \end{aligned}$$

Therefore, by the definition of $\kappa(n)$ it follows that $\kappa(n) \leq \lceil B^{-1}(n)\rceil \leq B^{-1}(n)+1$. It is also easy to see that if we have a function $\tilde{v} : \mathbb{R}^+ \to \mathbb{R}^+$ such that $v(s) \geq \tilde{v}(s)$, $s > 0$, then $B(t) \geq \tilde{B}(t)$, $t > 0$, and hence $B^{-1}(n) \leq \tilde{B}^{-1}(n)$, $n \geq 1$. For the sequence $\tau_i = \lfloor b(i/\log i)^{\alpha/(2\alpha+1)} \rfloor$ under consideration, note that $v(s) = \lfloor b(\lceil s\rceil/\log\lceil s\rceil)^{\alpha/(2\alpha+1)} \rfloor + 1 \geq b(s/\log s)^{\alpha/(2\alpha+1)} I\{s \geq e\} =: \tilde{v}(s)$. Thus $\kappa(n) = O(\tilde{B}^{-1}(n))$. It is easy to verify that $\tilde{B}^{-1}(n) = o(n^{\frac{2\alpha+1}{3\alpha+1}+\eta})$ for any $\eta > 0$. □

THEOREM 5.3. *Assume that for a certain learning scheme $P(m^* - m(U_i^*) > \epsilon) = O(r_i)$ for some known sequence r_i. Then for the certainty equivalence control with forcing-type scheme constructed above with the sequence $\tau_i = \lfloor br_i^{-1} \rfloor$ for some $b > 0$, we have $E[L_n^\epsilon] = O(\kappa(n))$ for all $\epsilon > 0$.*

Proof.

$$\begin{aligned} E[L_n^\epsilon] &= \sum_{l=1}^{n} P(m^* - m(U_l) > \epsilon) \\ &\leq \kappa(n) + \sum_{i=1}^{\kappa(n)} \sum_{l=t_i+1}^{t_{i+1}-1} P(m^* - m(U_l) > \epsilon) \\ &= \kappa(n) + \sum_{i=1}^{\kappa(n)} P(m^* - m(U_i^*) > \epsilon)\tau_i \\ &\leq \kappa(n) + \sum_{i=1}^{\kappa(n)} P(m^* - m(U_i^*) > \epsilon) b r_i^{-1}. \end{aligned}$$

Now, we are given that $P(m^* - m(U_i^*) > \epsilon) = O(r_i)$. Thus, $\overline{\lim}_i P(m^* - m(U_i^*) > \epsilon) r_i^{-1} \leq C$ for some $C \geq 0$. That is, for all $\eta > 0$ there exists an $i_0 \geq 1$, such that for all $i \geq i_0$, $P(m^* - m(U_i^*) > \epsilon) \leq (C + \eta) r_i$. Then, clearly

$$\begin{aligned} E[L_n^\epsilon] &\leq \kappa(n) + \sum_{i=1}^{i_0-1} P(m^* - m(U_i^*) > \epsilon) b r_i^{-1} + \sum_{i=i_0}^{\kappa(n)} P(m^* - m(U_i^*) > \epsilon) b r_i^{-1} \\ &\leq \kappa(n) + M(\eta) + (C + \eta) b \kappa(n), \end{aligned}$$

where $M(\eta) = \sum_{i=1}^{i_0-1} P(m^* - m(U_i^*) > \epsilon) b r_i^{-1}$ depends on η but not on n. Dividing by $\kappa(n)$ and taking the limit as $n \to \infty$ we get

$$\overline{\lim_{n}} \frac{E[L_n^\epsilon]}{\kappa(n)} \leq 1 + (C + \eta) b.$$

Now, by letting $\eta \to 0$ we get

$$\overline{\lim_n} \frac{E[L_n^\epsilon]}{\kappa(n)} \leq 1 + Cb. \qquad \square$$

COROLLARY 5.4. *For the certainty equivalence control with forcing-type scheme constructed above, with the learning scheme of* §3 *with any bandwidth sequence* h_i *such that* (i) $h_i \to 0$ *as* $i \to \infty$ *and* (ii) $ih_i \geq A'i^{a'}$ *for some* $0 < a' < 1$, $A' > 0$, *and with the sequence* $\tau_i = \lfloor be^{i(h_i)^2} \rfloor$ *for some* $b > 0$, *we have*

$$E[L_n^\epsilon] = O((h_n)^{-2} \log n), \tag{46}$$

for all $\epsilon > 0$.

Proof. This corollary will follow immediately from Theorems 5.3 and 3.1, if we can show that

$$\kappa(n) = O((h_n)^{-2} \log n) \tag{47}$$

when $\tau_i = \lfloor be^{i(h_i)^2} \rfloor$. Now by the definition of $\kappa(n)$, it follows that

$$\sum_{k=1}^{\kappa(n)-1} \tau_k + \kappa(n) \leq n.$$

Taking only the last term in the above sum we get

$$(\kappa(n) - 1) \leq h_{\kappa(n)-1}^{-2} (\log n - \log b) \leq h_n^{-2} (\log n - \log b).$$

This establishes (47). $\square$

Remark. In light of (46) above, we can choose $h_n \to 0$ arbitrarily slowly, thereby making $E[L_n^\epsilon]$ arbitrarily close to $O(\log n)$.

6. Concluding remarks. The ϵ-learning loss of the class of adaptive control schemes constructed in this paper for the case of an infinite number of arms is of the same order as those obtained previously for the finite case. For the finite case it is easy to see that the learning loss is within a constant factor of the ϵ-learning loss. The infinite case is fundamentally different in this respect. Thus, the learning loss that we obtain for the infinite case is considerably worse than those available for the finite case. Since we do not have any tighter lower bounds on the learning loss other than those available for the finite case, there may be room for improvement. However, to the best of our knowledge, these are the best rates available to date. Moreover, the rates obtained by us are still stronger than the $o(n)$ required for optimality with respect to the average-cost-per-unit-time criterion.

In a forthcoming paper [1] we extend the results of this paper to the multiarmed bandit problem as well as to the adaptive control of Markov chains, both with a control set $\mathcal{U}$ which is a bounded subset of $\mathbb{R}^d$, $d > 1$. The principal difficulty with this extension is that strong limit laws for moving averages in higher dimensions are not available in the literature, and are also much more difficult to obtain for the kind of sampling/design scheme that we employ.

Appendix: Proof of (15), (16), (27). First let $l(n) := \lfloor \log_2 n \rfloor + 1$, and consider the representation of n in base 2:

$$n = n_{l(n)} \dots n_2 n_1.$$

Note that we can partition $\{1 \dots n\}$ as

$$\{1 \dots n\} = \bigcup_{\substack{i=1,\dots,l(n):\\ n_i=1}} E_i^n,$$

where for $i = 1, \dots, l(n)$ such that $n_i = 1$, E_i^n are defined by

$$\begin{aligned} E_i^n &= \sum_{l=i+1}^{l(n)} n_l 2^{l-1} + \{1, \dots, 2^{i-1}\} \\ &= \{(n_{l(n)} \dots n_{i+1} 00 \dots 01), \dots, \\ &\qquad (n_{l(n)} \dots n_{i+1} 01 \dots 11), (n_{l(n)} \dots n_{i+1} 10 \dots 00)\} \\ &=: \{\underline{e}_i^n, \dots, \overline{e}_i^n\}. \end{aligned}$$

We can now partition $\{\tilde{u}_i\}_{i=1}^n$ correspondingly as

$$\{\tilde{u}_i\}_{i=1}^n = \bigcup_{\substack{i=1,\dots,l(n):\\ n_i=1}} \{\tilde{u}_k, k \in E_i^n\}.$$

It is easy to see that $\{\tilde{u}_k, k \in E_i^n\}$ is a uniform lattice of 2^{i-1} points in $[0, 1]$. More precisely,

$$\tilde{u}_k = \tilde{u}_{\underline{e}_i^n} + \tilde{u}_{k+1-\underline{e}_i^n}$$

for $k \in E_i^n$. As k ranges over the set E_i^n, the first term on the RHS stays fixed, and the second term gives us precisely the set of all dyadic rationals in $[0, 1]$ with denominators dividing 2^{i-1}. There are a total of 2^{i-1} such points. Thus we can think of $\{\tilde{u}_i\}_{i=1}^n$ as an overlay of these lattices of various levels of coarseness.

Then, we get for all $n \geq 1$ and $u \in \mathcal{U}$,

$$\begin{aligned} \sum_{i=1}^n I\{|u - \tilde{u}_i| \leq h_n/2\} &= \sum_{\substack{i=1,\dots,l(n):\\ n_i=1}} \sum_{k \in E_i^n} I\{|u - \tilde{u}_k| \leq h_n/2\} \\ &\leq \sum_{\substack{i=1,\dots,l(n):\\ n_i=1}} (2^{i-1} h_n + 1) \\ &= n h_n + l(n). \end{aligned}$$

Similarly, for all $n \geq n_1$ and $u \in \mathcal{U}$,

$$\begin{aligned} \sum_{i=1}^n I\{|u - \tilde{u}_i| \leq h_n/2\} &= \sum_{\substack{i=1,\dots,l(n):\\ n_i=1}} \sum_{k \in E_i^n} I\{|u - \tilde{u}_k| \leq h_n/2\} \\ &\geq \sum_{\substack{i=1,\dots,l(n):\\ n_i=1}} (2^{i-1} h_n - 1) \\ &= n h_n - l(n). \end{aligned}$$

This establishes (15).

Also, all $n \geq 1$ and $u \in \mathcal{U}$,

$$
\begin{aligned}
&\sum_{i=1}^{n} I\{|u-\tilde{u}_i| \leq h_n/2\}|\tilde{u}_i - u|^\alpha \\
&= \sum_{\substack{i=1,\ldots,l(n):\\ n_i=1}} \sum_{k\in E_i^n} I\{|u-\tilde{u}_k| \leq h_n/2\}|\tilde{u}_k - u|^\alpha \\
&= \sum_{\substack{i=1,\ldots,l(n):\\ n_i=1}} \sum_{k\geq 0} [(s(u,n,i)+k2^{1-i})^\alpha I\{(s(u,n,i)+k2^{1-i}) \leq h_n/2\} \\
&\qquad\qquad +(2^{1-i}-s(u,n,i)+k2^{1-i})^\alpha I\{(2^{1-i}-s(u,n,i)+k2^{1-i}) \leq h_n/2\}],
\end{aligned}
$$

where $0 \leq s(u,n,i) < 2^{1-i}$ is the distance from u to the closest point in $E_i^n \cap [u,1]$. Next, note that

$$
\begin{aligned}
&\sum_{\substack{i=1,\ldots,l(n):\\ n_i=1}} \sum_{k\geq 0} [(s(u,n,i)+k2^{1-i})^\alpha I\{(s(u,n,i)+k2^{1-i}) \leq h_n/2\} \\
&\qquad\qquad +(2^{1-i}-s(u,n,i)+k2^{1-i})^\alpha I\{(2^{1-i}-s(u,n,i)+k2^{1-i}) \leq h_n/2\}] \\
&\leq \sum_{\substack{i=1,\ldots,l(n):\\ n_i=1}} \sum_{k\geq 0} 2\left[2^{i-1}\int_0^{h_n/2} x^\alpha dx + \left(\frac{h_n}{2}\right)^\alpha\right] \\
&= 2 \sum_{\substack{i=1,\ldots,l(n):\\ n_i=1}} \sum_{k\geq 0} \left[2^{i-1}\frac{1}{\alpha+1}\left(\frac{h_n}{2}\right)^{\alpha+1} + \left(\frac{h_n}{2}\right)^\alpha\right] \\
&= 2\left[\frac{1}{\alpha+1}\left(\frac{h_n}{2}\right)^{\alpha+1} n + \left(\frac{h_n}{2}\right)^\alpha l(n)\right] \\
&= \frac{1}{\alpha+1}\left(\frac{h_n}{2}\right)^\alpha [nh_n + 2(\alpha+1)l(n)],
\end{aligned}
$$

which establishes (16). Similarly,

$$
\begin{aligned}
&\sum_{\substack{i=1,\ldots,l(n):\\ n_i=1}} \sum_{k\geq 0} [(s(u,n,i)+k2^{1-i})^\alpha I\{(s(u,n,i)+k2^{1-i}) \leq h_n/2\} \\
&\qquad\qquad +(2^{1-i}-s(u,n,i)+k2^{1-i})^\alpha I\{(2^{1-i}-s(u,n,i)+k2^{1-i}) \leq h_n/2\}] \\
&\geq \sum_{\substack{i=1,\ldots,l(n):\\ n_i=1}} \sum_{k\geq 0} 2\left[2^{i-1}\int_0^{h_n/2} x^\alpha dx - \left(\frac{h_n}{2}\right)^\alpha\right] \\
&= \frac{1}{\alpha+1}\left(\frac{h_n}{2}\right)^\alpha [nh_n - 2(\alpha+1)l(n)],
\end{aligned}
$$

which establishes (27).

Acknowledgments. The author would like to thank Professor J. Kuelbs for some very helpful discussions, and also two anonymous referees for comments that helped improve the exposition.

FORMS OF OPTIMAL SOLUTIONS FOR SEPARATED CONTINUOUS LINEAR PROGRAMS*

MALCOLM C. PULLAN†

Abstract. This paper discusses the nature of optimal solutions for a class of continuous linear programs called separated continuous linear programs. It is shown that under various different assumptions on the problem data there exist optimal solutions that are piecewise constant, piecewise polynomial, or, more generally, piecewise analytic. These results are reminiscent of bang-bang results in linear optimal control.

Key words. continuous linear programming, linear optimal control, bang-bang solutions

AMS subject classifications. 49J30, 49N05, 90C45

1. Introduction. In 1953, Bellman [6] introduced a class of optimization problems which he called *bottleneck problems.* These problems have now become known as *continuous linear programs* because they can be formulated as linear programs having variables that are functions of time as follows:

$$\begin{aligned} \text{CLP:}\quad & \text{maximize} && \int_0^T c(t)^T x(t)\,dt \\ & \text{subject to} && B(t)x(t) + \int_0^t K(s,t)x(s)\,ds \le b(t), \\ & && x(t) \ge 0, \qquad t \in [0,T], \end{aligned}$$

with $x(t)$, $c(t)$, and the elements of $B(t)$ and $K(s,t)$ bounded measurable functions.

The usual way to solve these problems is by discretization (see, for example, Buie and Abrham [7]); however, a number of authors have tried to solve this problem by extending the simplex method for finite linear programming. This was first attempted by Lehman [15] and extended by Drews [8], Hartberger [9], and Segers [22]. The most comprehensive, but still incomplete, solution method based on the simplex method is that by Perold [17], later followed up by Anstreicher [4].

In this paper we will be considering the following subclass of CLP called *separated continuous linear programs*, first introduced by Anderson [1] in an attempt to model job-shop scheduling problems:

$$\begin{aligned} \text{SCLP:}\quad & \text{minimize} && \int_0^T c(t)^T x(t)\,dt \\ (1)\qquad & \text{subject to} && \int_0^t Gx(s)\,ds + y(t) = a(t), \\ (2)\qquad & && Hx(t) + z(t) = b(t), \\ & && x(t), y(t), z(t) \ge 0, \qquad t \in [0,T]. \end{aligned}$$

Here $x(t)$, $z(t)$, $b(t)$, and $c(t)$ are bounded measurable functions and $y(t)$ and $a(t)$ are absolutely continuous functions. The dimensions of $x(t)$, $y(t)$, and $z(t)$ are n_1, n_2, and n_3, respectively. We let $\omega(t)$ denote a complete set of variables for SCLP, i.e.,

* Received by the editors April 23, 1993; accepted for publication (in revised form) July 14, 1994.

† Judge Institute of Management Studies, Mill Lane, Cambridge CB2 1RX, United Kingdom.

$\omega(t)^T = (x(t)^T, y(t)^T, z(t)^T)$. SCLP has an alternative formulation as a linear optimal control problem with state positivity constraints but without feedback as follows:

$$\begin{array}{lll} & \text{minimize} & \int_0^T [p(t)^T x(t) + q(t)^T y(t)]\, dt \\ (3) & \text{subject to} & \dot{y}(t) = Bx(t) + v(t), \\ & & H(t)x(t) \leq b(t), \\ & & x(t), y(t) \geq 0, \qquad t \in [0,T], \end{array}$$

where $v(t) = -\dot{a}(t)$ and $B = -G$. The objective functions can be seen to be equivalent by integrating by parts and substituting in (3).

The main existing theoretical results relating to SCLP may be found in Anderson et al. [2]. These consist of three key results, which we now summarise.

THEOREM 1.1. *If the feasible region for SCLP is nonempty and bounded, then there exists an optimal solution for SCLP at an extreme point of the set of feasible solutions (or simply, at an* extreme point solution).

THEOREM 1.2. *A feasible solution, $\omega(t)$, for SCLP is an extreme point solution if and only if the columns of the matrix*

$$K = \begin{bmatrix} G & I & 0 \\ H & 0 & I \end{bmatrix}$$

corresponding to the support of $\omega(t)$ (that is, i such that $\omega_i(t) > 0$) are linearly independent for almost all $t \in [0,T]$.

THEOREM 1.3. *Suppose that $a(t)$ and $c(t)$ are piecewise linear (but with $a(t)$ continuous) and that $b(t)$ is piecewise constant on $[0,T]$. Suppose also that the feasible region for SCLP is nonempty and bounded, then there exists an optimal solution for SCLP with $x(t)$ piecewise constant on $[0,T]$.*

The statements of these results make use of the following standard definitions which will also be used throughout this paper.

DEFINITION 1.

1. *A set $P = \{t_0, \ldots, t_m\}$ is said to be a* partition *of $[a,b]$ if*

$$a = t_0 < t_1 < \ldots < t_m = b.$$

2. *We say that $f : [a,b] \to \mathbb{R}^n$ is* analytic on a neighbourhood of $[a,b]$ *(or $[a,b)$) if there exists $\varepsilon > 0$ and an analytic function $g : (a-\varepsilon, b+\varepsilon) \to \mathbb{R}^n$ such that $f(t) = g(t)$ for all $t \in [a,b]$ (respectively, $[a,b)$).*
3. *We say that $f : [a,b] \to \mathbb{R}^n$ is* piecewise analytic *on $[a,b]$ if there exists a partition $P = \{t_0, \ldots, t_m\}$ of $[a,b]$ such that $f(t)$ is analytic on a neighbourhood of $[t_{i-1}, t_i)$ for $i = 1, \ldots, m$. The elements of the smallest such partition P (excluding a and, if f is continuous at b, b) are called the* breakpoints.

We use similar definitions for piecewise constant, linear, polynomial, and continuous.

In a recent paper by Anderson and Philpott [3] the following result was also proved.

THEOREM 1.4. *Suppose that $a(t)$ and $b(t)$ are piecewise analytic (but with $a(t)$ continuous) and that $c(t)$ is piecewise constant on $[0,T]$. Suppose also that the set $\{\, \xi : H\xi \leq b(t),\ \xi \geq 0 \,\}$ is bounded for each $t \in [0,T]$ and that the feasible region for SCLP is nonempty; then there exists an optimal solution for SCLP with $x(t)$ piecewise analytic on $[0,T]$.*

Results similar to Theorems 1.3 and 1.4 are well known in the context of linear optimal control and are often termed *bang-bang* results. Bang-bang results are results that give conditions under which an optimal solution can be found that is "bang-bang," that is, where the solution is always on the boundary of the feasible region and, moreover, the number of breakpoints is finite. For instance, many bang-bang results exist for the linear optimal control version of SCLP with feedback, i.e., with (3) replaced by

$$\dot{y}(t) = A(t)y(t) + B(t)x(t) + v(t)$$

but without state-positivity constraints, i.e., without $y(t) \geq 0$ (see, for example, Lee and Markus [14] for a sample of such results).

When state positivity is imposed, the results seem much harder to establish (and, in fact, may not even be true), although many have conjectured that such results are true for various instances of CLP (e.g., Perold [17] and Tyndall [23]). This is now known not to be true for all instances of CLP (see, for example, Ilyotovich [10]). In fact we present simple counterexamples in §5 to show that this is not true for SCLP without sufficiently well behaved problem data (Examples 5.1 and 5.2). However, some authors have attempted to give conditions on CLP that guarantee an optimal solution with a finite number of breakpoints, with limited success, and these include Ilyotovich [10], Jasiulek [11], and Jóhannesson and Hanson [12] (and of course Anderson et al. [2] and Anderson and Philpott [3] for SCLP).

There are many reasons why results that guarantee optimal solutions with a finite number of breakpoints for either CLP, SCLP, or linear optimal control problems are important. First, from the point of view of practical problems, it is useful to have such results, as a practical problem with an optimal solution having an infinite number of breakpoints would not be very worthwhile. Second, such results may enable useful duality results to be established. For instance, Theorem 1.3 was used in Pullan [19] to establish a strong duality result for SCLP under the conditions of Theorem 1.3. Also in the context of linear optimal control, some authors, such as Köhler [13] and Maurer [16], have developed maximum principles given that an optimal solution exists that is piecewise continuous. However, these authors did not establish conditions for the existence of such optimal solutions and thus it is not known under what conditions their results apply.

For the problem SCLP there is a third reason why results guaranteeing an optimal solution with a finite number of breakpoints are important. This reason is from an algorithmic point of view. If it is known that an optimal solution exists with a finite number of breakpoints and, moreover, that this solution is an extreme point solution and also that the maximum number of breakpoints is bounded, then the problem of solving SCLP becomes a finite one. The reason for this is as follows. By Theorem 1.2, the value of an extreme point solution for SCLP at any time (or, at least, at almost all times) is uniquely determined by the choice of nonzero variables at that time (see the proof of Lemma 2.1). Therefore, there are two main unknowns one wishes to determine in finding an optimal extreme point solution for SCLP. The first of these is the set of variables that are positive at any particular time, and the second, the set of breakpoints. Thus, if one can show that there is an upper bound on the number of breakpoints of an optimal extreme point solution for a given SCLP problem, then the problem of finding the optimal solution, given that the feasible region of SCLP is nonempty and bounded, becomes a finite one. Hence, in theory, one may construct an algorithm that terminates in a finite number of steps. This was part of the motivation in Pullan [19] for developing an algorithm for solving SCLP under the assumption of piecewise linear and continuous $a(t)$, piecewise constant $b(t)$, and piecewise linear $c(t)$.

In this paper we consider the form of optimal solutions under different conditions to either Theorems 1.3 or 1.4. In particular, in §3 we consider the case of SCLP with piecewise linear and continuous $a(t)$, piecewise constant $b(t)$, and piecewise analytic $c(t)$. In this case, given that the feasible region for SCLP is also nonempty and bounded, we prove that an optimal extreme point solution for SCLP exists with $x(t)$ piecewise constant (Theorem 3.3). This result also gives an upper bound on the number of breakpoints for an optimal solution for a given SCLP problem. In §4 we then consider SCLP with piecewise analytic $a(t)$, $b(t)$, and $c(t)$. The result in this case is that SCLP has an optimal extreme point solution that is piecewise analytic, given again that the feasible region for SCLP is both nonempty and bounded (Theorem 4.3). The proof uses Theorem 3.3 as a starting point and considers a problem with analytic right-hand sides as a limit of a sequence of problems where $a(t)$ is piecewise linear and continuous and $b(t)$ is piecewise constant. The proof also uses ideas from the proof of Theorem 1.4 in Anderson and Philpott [3]. Using a simple observation, however, we are able to weaken the assumption used in [3] that the set $\{\, \xi : H\xi \leq b(t),\ \xi \geq 0 \,\}$ is bounded for each $t \in [0, T]$ to the assumption that just the feasible region for SCLP itself is bounded. As a conclusion to the section we give a simple breakpoint condition, namely that $\dot{c}(t)^T x(t)$ must not increase at a breakpoint (Theorem 4.4). As with Theorem 3.3, Theorem 4.3 also gives an upper bound on the number of breakpoints in an optimal extreme point solution for a given SCLP problem. However, as this bound is slightly cumbersome to state, it is only given implicitly in the proof. Although the results of §3 are just special cases of those in §4, it is convenient to consider these as separate cases in order to bring greater clarity and understanding to the proofs.

It is worth noting that neither Theorem 1.3 nor Theorem 1.4 guarantees an optimal solution of the appropriate form that is also an extreme point. However, the results in this paper do guarantee such a solution.

As a conclusion to this paper we then postulate more general results in §5. First, however, we present simple counterexamples to show that the assumption of analyticity of the problem data cannot be weakened, e.g., to continuous or n-times differentiable for some n, to ensure that an optimal solution exists with only a finite number of breakpoints (Examples 5.1 and 5.2). These examples, however, suggest possible extensions to the results in previous sections. Finally in §5, we comment on what happens if $a(t)$ and $b(t)$ are chosen from a more restrictive class of functions than that of piecewise analytic functions, e.g., piecewise polynomial (Theorem 5.1).

Before beginning the discussion we introduce some more standard definitions and notations that will be used throughout this paper.

DEFINITION 2. 1. *For any set S, we use the notation $|S|$ to denote its cardinality.*

2. *We use the notation a.e. to mean almost everywhere with respect to the standard Lebesgue measure on $\mathbb{R}$.*
3. *Let f be any real-valued function. We use the notations $f(t-)$ to denote $\lim_{s\uparrow t} f(s)$ and $f(t+)$ to denote $\lim_{s\downarrow t} f(s)$ when these limits exist.*
4. *For any $\zeta \in \mathbb{R}^n$ we define $\operatorname{sgn}(\zeta) \in \mathbb{R}^n$ by*

$$(\operatorname{sgn}(\zeta))_i = \begin{cases} -1, & \zeta_i < 0, \\ 0, & \zeta_i = 0, \\ 1, & \zeta_i > 0. \end{cases}$$

5. *For any $\zeta \in \mathbb{R}^n$, $\zeta \geq 0$, we use the notation*

$$\operatorname{supp}(\zeta) = \{\, i : \zeta_i > 0 \,\}$$

to denote the support of ζ.

We now begin the discussion by establishing some preliminary results that will be used throughout the main body of this paper.

2. Preliminary results.

Before we begin the development of the main results in this paper, it is useful to establish some preliminary notation and results that can be frequently referred to. We begin by the introduction of some notation relating to the matrix K used to describe extreme point solutions in Theorem 1.2.

DEFINITION 3. *We define*

$$K = \begin{bmatrix} G & I & 0 \\ H & 0 & I \end{bmatrix}.$$

Let B be a basis matrix for K.

1. *Let $\omega(t)^T = (x(t)^T, y(t)^T, z(t)^T)$ be a set of variables for SCLP. We let $x_B(t)$ denote the elements of $x(t)$ corresponding to those of the first n_1 columns of K that are also in B, arranged in the same order as the columns of B.*
2. *Let $\rho(t)$ be a solution to $B\rho(t) = d(t)$ for some $d(t)$ (that is, $\rho(t) = B^{-1}d(t)$). We use the notation $\rho_x(t)$ to denote the elements of $\rho(t)$ corresponding to those of the first n_1 columns of K that are also in B, arranged in the same order as the columns of B.*

Using this notation we now present a simple lemma that is essentially contained in Anderson et al. [2]. The result shows that if $\omega(t)$ is an extreme point solution for SCLP, then $x(t)$ can only take the values of a finite number of functions, these functions being linear combinations of $\dot{a}(t)$ and $b(t)$. It is this finite nature of any extreme point solution which allows us to show that an optimal extreme point exists with only a finite number of breakpoints, given that the problem data are piecewise analytic.

LEMMA 2.1. *Let $a(t)$ be any absolutely continuous function and $b(t)$ be any bounded measurable function on $[0, T]$. Let $B^{(1)}, \ldots, B^{(L)}$ be the basis matrices for K, and let*

$$\rho^{(i)}(t) = B^{(i)^{-1}} \begin{bmatrix} \dot{a}(t) \\ b(t) \end{bmatrix}.$$

Define $x^{(i)}(t)$ by $x^{(i)}_{B^{(i)}}(t) = \rho^{(i)}_x(t)$ with the other components of $x^{(i)}(t)$ set to zero. Let $\omega(t)$ be any extreme point solution for SCLP; then for almost all $t \in [0, T]$, $x(t) = x^{(i_t)}(t)$ for some i_t.

Proof. The constraints of SCLP, (1) and (2), are equivalent to

$$K \begin{bmatrix} x(t) \\ \dot{y}(t) \\ z(t) \end{bmatrix} = \begin{bmatrix} \dot{a}(t) \\ b(t) \end{bmatrix},$$
$$y(0) = a(0),$$

a.e. on $[0, T]$. However, by Theorem 1.2, we know that the columns of K corresponding to the nonzero variables of $\omega(t)$ are linearly independent for almost all $t \in [0, T]$. Thus for almost all $t \in [0, T]$, the nonzero variables (and possibly some zero variables) of $(x(t)^T, \dot{y}(t)^T, z(t)^T)^T$ are given by $\rho^{(i_t)}$ for some i_t. This establishes the result. □

Throughout the course of the proofs in the following sections, we will frequently derive our results for SCLP with problem data of a particular form and then establish the result in the general case by considering SCLP with the general problem data as a limit of a sequence of SCLP problems with the less general problem data. In such cases it is useful to know that the limit of optimal extreme point solutions for the simpler problems will be an optimal extreme point solution for the general problem. This is the content of the next result. We note that the result we present is by no means the most general result available. We only give the result for the circumstances required in this paper.

LEMMA 2.2. *Let $a^{(n)}$ be absolutely continuous and $b^{(n)}$ and $c^{(n)}$ be piecewise continuous on $[0,T]$ with $a^{(n)}(t) \geq a(t)$ and $b^{(n)}(t) \geq b(t)$ on $[0,T]$ for each $n \in \mathbb{N}$ and $a^{(n)} \to a$, $b^{(n)} \to b$ and $c^{(n)} \to c$ uniformly on $[0,T]$. Let SCLP$_n$ be the problem SCLP with a, b, and c replaced by $a^{(n)}$, $b^{(n)}$, and $c^{(n)}$, respectively. Suppose that $\omega_n(t)$ is an optimal extreme point solution for SCLP$_n$ for $n \in \mathbb{N}$ and that $x_n(t) \to x(t)$ a.e. on $[0,T]$. Suppose also that $x(t)$ and $x_n(t)$ for each n are piecewise continuous. Define $\omega(t)$ from the constraints of SCLP, i.e., from* (1) *and* (2). *Then $\omega(t)$ is an optimal extreme point solution for SCLP.*

Proof. By Lebesgue's dominated convergence theorem (see, for example, Rudin [21]) we have $y_n(t) \to y(t)$ for all $t \in [0,T]$. Let s be such that $x_n(s) \to x(s)$ and such that s is not a point of discontinuity for x or x_n for any n. Then $\omega_n(s) \to \omega(s)$ and thus $\omega(s) \geq 0$. Hence $\omega(t) \geq 0$ a.e. on $[0,T]$ and so $\omega(t)$ is feasible for SCLP.

Now suppose that $\omega(t)$ is not an extreme point solution for SCLP. Then by Theorem 1.2 there exists a set S of nonzero measure such that the columns of K corresponding to $\operatorname{supp}(\omega(t))$ for $t \in S$ are linearly dependent. Choose $s \in S$ such that $x_n(s) \to x(s)$ and such that s is not a point of discontinuity of x or x_n for any n. Now, as noted above, we have $\omega_n(s) \to \omega(s)$. Hence there exists n such that

$$\operatorname{supp}(\omega(s)) \subseteq \operatorname{supp}(\omega_n(s)).$$

Now ω_n is continuous at s and so there exists (α, β) such that $s \in (\alpha, \beta)$ and

$$\operatorname{supp}(\omega_n(s)) \subseteq \operatorname{supp}(\omega_n(t)),$$

for all $t \in (\alpha, \beta)$. Thus $\operatorname{supp}(\omega(s)) \subseteq \operatorname{supp}(\omega_n(t))$ for all $t \in (\alpha, \beta)$, and so by Theorem 1.2, $\omega_n(t)$ is not an extreme point solution for SCLP$_n$. This contradiction establishes that $\omega(t)$ is an extreme point solution for SCLP.

Finally, suppose that $\omega(t)$ is not optimal for SCLP. Then there exists $\bar{\omega}(t)$ feasible for SCLP satisfying

$$\int_0^T c(t)^T \bar{x}(t)\, dt < \int_0^T c(t)^T x(t)\, dt.$$

Now $a^{(n)}(t) \geq a(t)$ and $b^{(n)}(t) \geq b(t)$ on $[0,T]$, and so $\bar{\omega}(t)^T + (0^T, (a^{(n)}(t) - a(t))^T, (b^{(n)}(t) - b(t))^T)$ forms a feasible solution for SCLP$_n$ for each n. But by Lebesgue's dominated convergence theorem again we then have

$$\int_0^T c(t)^T \bar{x}(t)\, dt < \int_0^T c(t)^T x^{(n)}(t)\, dt,$$

for some n, contradicting the optimality of $\omega^{(n)}(t)$ in SCLP$_n$. Thus $\omega(t)$ must be optimal for SCLP. □

Our final result in this section is quite unrelated to the previous ones and concerns the zeros of a linear combination of a finite set of analytic functions on a compact interval $[a,b]$. While it is well known that such a linear combination will only have a finite number of zeros (see, for example, Apostol [5, Thm. 16.25]), we show that the number of zeros in this linear combination is dependent only on the functions involved and not the particular scalars chosen. This result will be useful in establishing that a sequence of SCLP problems with problem data all of some similar general form will have optimal solutions with a uniform upper bound on the number of breakpoints.

LEMMA 2.3. *Let $f : [a,b] \to \mathbb{R}^n$ be a function analytic on a neighbourhood of $[a,b]$. Then there exists $M(f)$ $(< \infty)$ such that for all $\lambda \in \mathbb{R}^n$, if*

$$S(\lambda, f) = \{\, t \in [a,b] : \lambda^T f(t) = 0 \,\},$$

then either $S(\lambda,f) = [a,b]$ or $|S(\lambda,f)| \le M(f)$.

Proof. We prove the result by induction. For $n = 1$ the result is well known (see, for example, Apostol [5, Thm. 16.25]).

Let n be given. Suppose that for all $m < n$ and for all $f : [a,b] \to \mathbb{R}^m$ analytic on a neighbourhood of $[a,b]$ there exists $M(f) < \infty$ such that for all $\lambda \in \mathbb{R}^m$ we have either $S(\lambda,f) = [a,b]$ or $|S(\lambda,f)| \le M(f)$, where $S(\lambda,f)$ is as given in the statement of the theorem. Let $f : [a,b] \to \mathbb{R}^n$ be a given function analytic on a neighbourhood of $[a,b]$. Define $g, h : [a,b] \to \mathbb{R}^{n-1}$ by $g_i = \dot{f}_n f_i - f_n \dot{f}_i$ and $h_i = f_i$ for $i = 1, \ldots, n-1$. We now define

$$M = \max\{(M(h)+1)(M(g)+2)+1, M(f_n)\},$$

where $M(g)$ and $M(h)$ are the required bounds for g and h given by the inductive assumption. We claim that $M(f) = M$ satisfies the requirements of the lemma.

Let $\lambda \in \mathbb{R}^n$. Suppose that $\lambda^T f \not\equiv 0$ (i.e., $\lambda^T f(t) \neq 0$ for some $t \in [a,b]$). Let μ denote the first $n-1$ components of λ. Suppose that $\mu^T h \equiv 0$. Then $\lambda^T f(t) = 0$ if and only if $\lambda_n f_n(t) = 0$. Hence either $S(\lambda,f) = [a,b]$ or $|S(\lambda,f)| \le M(f_n) \le M$.

Similarly, if $\lambda_n f_n \equiv 0$, then either $S(\lambda,f) = [a,b]$ or $|S(\lambda,f)| \le M(h) \le M$.

Now suppose that $\mu^T h \not\equiv 0$ and $\lambda_n f_n \not\equiv 0$. Let $P = \{t_0, \ldots, t_m\}$ be the partition of $[a,b]$ consisting of all the zeros of the analytic function $\mu^T h$ and the points a and b. Then $m \le M(h)+1$ (a and b may not be zeros of $\mu^T h$). Consider the interval (t_{i-1}, t_i). Let $t \in (t_{i-1}, t_i)$, then

$$\lambda^T f(t) = 0 \iff \frac{f_n(t)}{\mu^T h(t)} = -\frac{1}{\lambda_n}. \tag{4}$$

Now either (4) has at most one solution in (t_{i-1}, t_i) or it has more than one solution in (t_{i-1}, t_i). Assume the latter. As $\lambda^T f \not\equiv 0$ there can only be a finite number of solutions to (4). Let s_1 and s_2 be two consecutive solutions to (4) in (t_{i-1}, t_i). By Rolle's theorem there exists $t \in (s_1, s_2)$ such that

$$\mu^T g(t) = \dot{f}_n(t)\mu^T h(t) - f_n(t)\mu^T \dot{h}(t) = 0. \tag{5}$$

Clearly (5) cannot be true for all $t \in [a,b]$; otherwise we would have $\lambda^T f \equiv 0$ on (t_{i-1}, t_i). Hence (5) only has a finite number of solutions. Thus by the inductive assumption,

$$|\{\, t \in (t_{i-1}, t_i) : (5) \text{ holds} \,\}| \le M(g).$$

Thus (and this includes the case where (4) has at most one solution in (t_{i-1}, t_i)),

$$|\{\, t \in (t_{i-1}, t_i) : (4) \text{ holds} \,\}| \leq M(g) + 1.$$

Now $m \leq M(h) + 1$, and so $|S(\lambda, f) - P| \leq (M(h) + 1)(M(g) + 1)$. As P contains $m+1 \leq M(h)+2$ points, we have $|S(\lambda, f)| \leq M$. This proves the result by induction. □

We may now begin the development of the main results of this paper.

3. SCLP with analytic costs. In this section we consider the case of SCLP with $a(t)$ piecewise linear (and continuous), $b(t)$ piecewise constant, and $c(t)$ piecewise analytic on $[0, T]$. Under the assumption that the feasible region for SCLP is nonempty and bounded, we show that there exists an optimal extreme point solution with $x(t)$ piecewise constant (Theorem 3.3). Our proof is based on the proof of Theorem 1.3 contained in Anderson et al. [2]. As with [2], we begin by concentrating on the case where the problem data contain no discontinuities and present the proof in stages.

We outline the stages of the proof as follows. We begin with the assumption that the components of the costs and their derivatives are concave, i.e., that the components of $c(t)$ have nonpositive second and third derivatives. Under this assumption we derive a certain convexity property of all optimal solutions (Lemma 3.1). This is a simple extension of a similar result in [2] (namely, Theorem 3). We now recall Lemma 2.1, which states that in the case of constant $\dot{a}(t)$ and $b(t)$, there are only a finite number of possible values, $x^{(1)}, \ldots, x^{(L)}$, for an extreme point. Now as $c(t)$ is analytic, we either have for some k and j that $\dot{c}(t)^T x^{(k)} = \dot{c}(t)^T x^{(j)}$ for all $t \in [0, T]$, or there is a partition $P = \{t_0, \ldots, t_n\}$ of $[0, T]$ such that for all $k \neq j$ we have $\dot{c}(t)^T x^{(k)} \neq \dot{c}(t)^T x^{(j)}$ for all $t \in [0, T] - P$. In the latter case we consider a typical subinterval (t_{i-1}, t_i) of the partition P. Using the convexity property established in Lemma 3.1 it is then shown in Lemma 3.2 that $\dot{c}(t)^T x(t)$ is decreasing at a breakpoint. Hence there can be at most L breakpoints in $[t_{i-1}, t_i)$ and hence nL overall.

In the case where for some $k \neq j$ we have $\dot{c}(t)^T x^{(k)} = \dot{c}(t)^T x^{(j)}$ for all $t \in [0, T]$, we then construct a sequence of piecewise constant solutions for SCLP whose costs approach the optimal value of SCLP. This then completes the proof of Lemma 3.2, which guarantees an optimal solution with $x(t)$ piecewise constant in the case of costs whose second and third derivatives are nonpositive.

To complete the proof of the result for general analytic costs it is required only to transform a general problem into an equivalent one with costs that have nonpositive second and third derivatives. This simple transformation is contained in Theorem 3.3.

We now begin by establishing the convexity property of all optimal solutions under the restricted assumption of costs with nonpositive second and third derivatives.

LEMMA 3.1. *Suppose that $a(t)$ is linear and $b(t)$ is constant on $[0, T]$. Suppose also that $c(t)$ is analytic on a neighbourhood of $[0, T]$ and has nonpositive second and third derivatives. Let $\omega(t)$ be optimal for SCLP; then*

$$q(t) = -\dot{c}(t)^T \int_0^t x(s)\, ds$$

is convex on $[0, T]$.

Proof. Suppose that $\omega(t)$ is optimal for SCLP. Suppose the result is false; then as q is continuous there is some interval $[t_1, t_2] \subseteq [0, T]$ such that

$$q(t) > r(t), \quad t \in (t_1, t_2),$$

where

$$r(t) = q(t_1) + \left(\frac{t-t_1}{t_2-t_1}\right)(q(t_2) - q(t_1)), \quad t \in [t_1, t_2].$$

Define

$$\bar{q}(t) = \int_0^t x(s)\,ds, \quad t \in [t_1, t_2],$$

and

$$\bar{r}(t) = \bar{q}(t_1) + \left(\frac{t-t_1}{t_2-t_1}\right)(\bar{q}(t_2) - \bar{q}(t_1)), \quad t \in [t_1, t_2];$$

then $q(t) = -\dot{c}(t)^T\bar{q}(t)$ for $t \in [t_1, t_2]$. We now claim that

$$r(t) \geq -\dot{c}(t)^T\bar{r}(t), \quad t \in [t_1, t_2]. \tag{6}$$

Let $t \in (t_1, t_2)$; then

$$\frac{d^2}{dt^2}(-\dot{c}(t)^T\bar{r}(t)) = -\dddot{c}(t)^T\bar{r}(t) - 2\ddot{c}(t)^T\dot{\bar{r}}(t).$$

But

$$\dot{\bar{r}}(t) = \frac{1}{t_2-t_1}\int_{t_1}^{t_2} x(s)\,ds \geq 0,$$

and so $\ddot{c}(t)^T\dot{\bar{r}}(t) \leq 0$ as $\ddot{c}(t)$ is nonpositive on $[0,T]$. Similarly, $\dddot{c}(t)^T\bar{r}(t) \leq 0$ and hence $-\dot{c}(t)^T\bar{r}(t)$ is convex on (t_1, t_2). Thus $r(t) \geq -\dot{c}(t)^T\bar{r}(t)$ on $[t_1, t_2]$, as claimed, as $r(t)$ is linear on $[t_1, t_2]$ and $r(t) = -\dot{c}(t)^T\bar{r}(t)$ for $t = t_1$ and $t = t_2$.

We now define $\bar{x}(t)$ by

$$\bar{x}(t) = \begin{cases} \dfrac{1}{t_2-t_1}\displaystyle\int_{t_1}^{t_2} x(s)\,ds, & t \in [t_1, t_2), \\ x(t), & \text{otherwise.} \end{cases}$$

Define $\bar{\omega}(t)$ from $\bar{x}(t)$ by the constraints of SCLP, i.e., so that $\bar{x}(t)$, $\bar{y}(t)$, and $\bar{z}(t)$ satisfy (1) and (2) in place of $x(t)$, $y(t)$, and $z(t)$, respectively. Then $\bar{\omega}(t)$ is feasible for SCLP. Comparing objective function values for $\omega(t)$ and $\bar{\omega}(t)$ gives

$$\begin{aligned}
&\int_0^T c(t)^T\bar{x}(t)\,dt - \int_0^T c(t)^T x(t)\,dt \\
&= \int_{t_1}^{t_2} c(t)^T(\bar{x}(t) - x(t))\,dt \\
&= \int_{t_1}^{t_2} c(t)^T\frac{d}{dt}(\bar{r}(t) - \bar{q}(t))\,dt \\
&= -\int_{t_1}^{t_2} \dot{c}(t)^T(\bar{r}(t) - \bar{q}(t))\,dt + c(t_2)^T(\bar{r}(t_2) - \bar{q}(t_2)) - c(t_1)^T(\bar{r}(t_1) - \bar{q}(t_1))
\end{aligned}$$

by integrating by parts. But $\bar{r}(t_1) = \bar{q}(t_1)$ and $\bar{r}(t_2) = \bar{q}(t_2)$ and so

$$\begin{aligned}\int_0^T c(t)^T \bar{x}(t)\, dt - \int_0^T c(t)^T x(t)\, dt &= -\int_{t_1}^{t_2} \dot{c}(t)^T (\bar{r}(t) - \bar{q}(t))\, dt \\ &\leq \int_{t_1}^{t_2} (r(t) - q(t))\, dt\end{aligned}$$

by (6). Hence

$$\int_0^T c(t)^T \bar{x}(t)\, dt - \int_0^T c(t)^T x(t)\, dt < 0,$$

since $r(t) < q(t)$ on (t_1, t_2). This contradicts the assumed optimality of $\omega(t)$. Hence $q(t)$ is convex, and this establishes the result. □

We now use this result, as outlined at the beginning of this section, to establish that SCLP has a piecewise constant optimal solution in the case of costs with nonpositive second and third derivatives. We also explicitly state the upper bound on the number of breakpoints derived for such an optimal solution as this bound will be useful in the next section.

LEMMA 3.2. *Suppose that $a(t)$ is linear and $b(t)$ is constant on $[0, T]$. Suppose also that $c(t)$ is analytic on a neighbourhood of $[0, T]$ and has nonpositive second and third derivatives. If, furthermore, the feasible region for SCLP is nonempty and bounded, then there exists an optimal extreme point solution for SCLP with $x(t)$ piecewise constant on $[0, T]$. Moreover, let $x^{(1)}, \dots, x^{(L)}$ be given by Lemma 2.1, where L is the number of basis matrices for K, and $P = \{t_0, t_1, \dots, t_n\}$ be any partition of $[0, T]$ with $\dot{c}(t)^T x^{(i)} = \dot{c}(t)^T x^{(j)}$ for all $t \in (t_{m-1}, t_m)$ or $\dot{c}(t)^T x^{(i)} \neq \dot{c}(t)^T x^{(j)}$ for all $t \in (t_{m-1}, t_m)$, for each $i \neq j$ and each m. Then such $x(t)$ may be chosen so that for all m, the maximum number of breakpoints of $x(t)$ in $[t_{m-1}, t_m)$ is L.*

Proof. Let $\omega(t)$ be an optimal extreme point solution, which exists by Theorem 1.1 as the feasible region is nonempty and bounded. By Lemma 2.1 there exist constants $x^{(1)}, \dots, x^{(L)}$ such that for almost all $t \in [0, T]$, $x(t) = x^{(i_t)}$ for some i_t. Assume, without loss of generality, that this is true for all $t \in [0, T]$.

Now by Lemma 3.1

$$q(t) = -\dot{c}(t)^T \int_0^t x(s)\, ds$$

is convex on $[0, T]$. Hence (see, for example, Rockafellar [20]), $\dot{q}(t)$ is monotonic increasing a.e. on $[0, T]$; i.e., there exists a set $S_1 \subseteq [0, T]$ of measure T such that $\dot{q}(t)$ is monotonic increasing on S_1. But $\dot{q}(t) = -f(t)$ a.e., where

$$f(t) = \dot{c}(t)^T x(t) + \ddot{c}(t)^T \int_0^t x(s)\, ds.$$

Let

$$S = S_1 \cap \{\, t \in [0, T] : \dot{q}(t) = -f(t) \,\};$$

then f is monotonic decreasing on S. We now show that there is no loss of generality by assuming that f is monotonic decreasing on $[0, T]$ by redefining $x(t)$ on $[0, T] - S$, which has measure zero.

Let $s \in [0,T] - S$. Define

$$\gamma = \sup\{ f(t) : t > s,\ t \in S \}.$$

As f is decreasing on S and S is dense in $[0,T]$, we have a sequence $\{t_k\}_{k=1}^{\infty}$ such that $t_k \downarrow t$, $t_k \in S$ and $\lim_{k\to\infty} f(t_k) = \gamma$. As $x(t)$ takes only a finite number of values on S, there is an l and a subsequence $\{t_{i_k}\}_{k=1}^{\infty}$ such that $x(t_{i_k}) = x^{(l)}$ and $\lim_{k\to\infty} f(t_{i_k}) = \gamma$. Redefine $x(s) = x^{(l)}$; then $f(t) \le f(s)$ for all $t > s$, $t \in S$. If this is done for each $s \in [0,T] - S$, then it is clear that f is monotonic decreasing on $[0,T]$.

We now assume that f is monotonic decreasing on $[0,T]$ and that $x(t)$ takes only the values $x^{(1)}, \ldots, x^{(L)}$. We have two cases to consider. Either for each $k \neq j$ we have

$$\dot{c}(t)^T x^{(k)} \neq \dot{c}(t)^T x^{(j)} \quad \text{for some } t \in [0,T], \tag{7}$$

or there exists $k \neq j$ such that $\dot{c}(t)^T x^{(k)} = \dot{c}(t)^T x^{(j)}$ for all $t \in [0,T]$. We consider the former case first; i.e., (7) holds for all $k \neq j$. Now as $\dot{c}(t)^T x^{(i)}$ is analytic on a neighbourhood of $[0,T]$ for each i, there are only a finite number of $t \in [0,T]$ such that $\dot{c}(t)^T x^{(k)} = \dot{c}(t)^T x^{(j)}$ for some $k \neq j$. Label these t as $t_1, \ldots, t_{n-1}$, and set $t_0 = 0$ and $t_n = T$. Then $\dot{c}(t)^T x^{(k)} \neq \dot{c}(t)^T x^{(j)}$ for all $t \in (t_{i-1}, t_i)$ and for all $k \neq j$ and $i = 1, \ldots, n$.

Consider the interval (t_{i-1}, t_i). Assume without loss of generality that

$$\dot{c}(t)^T x^{(1)} > \dot{c}(t)^T x^{(2)} > \cdots > \dot{c}(t)^T x^{(L)}$$

for $t \in (t_{i-1}, t_i)$. We will show that $x(t)$ takes the values $x^{(j)}$ in this interval with j increasing; i.e., that if $x(s_1) = x^{(k)}$ and $x(s_2) = x^{(j)}$ with $s_1 < s_2$, then $k \le j$. Suppose otherwise, then there is some $s_1 < s_2$ with $x(s_1) = x^{(k)}$ and $x(s_2) = x^{(j)}$ but $k > j$. Let

$$\sigma = \sup\left\{ s : x(t) = x^{(l)} \text{ for some } l > j, \text{ for all } t \in [s_1, s] \right\}.$$

Then $s_1 \le \sigma < s_2$. Define

$$\varepsilon = \frac{1}{2} \min\left\{ \left| \dot{c}(\sigma)^T x^{(l)} - \dot{c}(\sigma)^T x^{(j)} \right| : l \neq j \right\};$$

then since $\dot{c}(t)$ is continuous, we can choose $\delta_1 > 0$ with

$$\left| \dot{c}(\tau_2)^T x^{(l)} - \dot{c}(\tau_1)^T x^{(j)} \right| > \varepsilon$$

for all $l \neq j$ and τ_1, $\tau_2 \in (\sigma - \delta_1, \sigma + \delta_1)$. If we now define

$$d(t) = \ddot{c}(t)^T \int_0^t x(s)\, ds,$$

then $d(t)$ is continuous on $[0,T]$ and $f(t) = \dot{c}(t)^T x(t) + d(t)$. We now choose δ_2 so that

$$|d(\tau_2) - d(\tau_1)| < \frac{\varepsilon}{2},$$

for all τ_1, $\tau_2 \in (\sigma - \delta_2, \sigma + \delta_2)$. Set $\delta = \min\{\delta_1, \delta_2\}$. Now from the definition of σ we can choose $\sigma_1 \in (\sigma - \delta, \sigma]$ with $x(\sigma_1) = x^{(l)}$ for some $l > j$ and $\sigma_2 \in [\sigma, \sigma + \delta)$ with $x(\sigma_2) = x^{(m)}$ for some $m \leq j$. Then

$$f(\sigma_2) - f(\sigma_1) > \varepsilon - |d(\sigma_1) - d(\sigma_2)| > 0,$$

which contradicts the assumption that f is monotonic decreasing.

Hence if $x(s_2) = x^{(j)}$ and $x(s_1) = x^{(k)}$ with $s_2 > s_1$ then $k \leq j$. So if we define

$$U_k = \{\, t \in (t_{i-1}, t_i) : x(t) = x^{(k)} \,\}$$

for any k, and if $U_k \neq \emptyset$ we also define

$$\begin{aligned} u_k &= \inf\{\, t : t \in U_k \,\}, \\ v_k &= \sup\{\, t : t \in U_k \,\}, \end{aligned}$$

then $x(t) = x^{(k)}$ for all $t \in (u_k, v_k)$. Hence, by redefining $x(t)$ at u_k and v_k if necessary, we can see that $x(t)$ is piecewise constant on $[t_{i-1}, t_i)$ and hence, as i was arbitrary, on $[0, T]$. Moreover, $x(t)$ has the maximum number of breakpoints as specified in the statement of the lemma.

Now suppose that (7) does not hold for some $k \neq j$, i.e., that

$$\dot{c}(t)^T x^{(k)} = \dot{c}(t)^T x^{(j)} \quad \text{for all } t \in [0, T].$$

Suppose there exists i and l such that

$$\dot{c}(t)^T x^{(i)} \neq \dot{c}(t)^T x^{(l)} \tag{8}$$

for some $t \in [0, T]$. In this case, let $P = \{t_0, \ldots, t_n\}$ be any partition of $[0, T]$ so that (8) holds for all $t \in [0, T] - P$ and for all such i and l. If, on the other hand, no such i and l exist then let $P = \{0, T\}$.

Let $\{\varepsilon_m(t)\}_{m=1}^{\infty}$ be any sequence of vector-valued functions analytic on a neighbourhood of $[0, T]$ satisfying the following properties:

1. $\varepsilon_m(t) \to 0$ uniformly on $[0, T]$ as $m \to \infty$.
2. $\varepsilon_m(t_i) = 0$ for $i = 0, \ldots, n$.
3. $[\dot{c}(t) + \varepsilon_m(t)]^T x^{(\eta)} \neq [\dot{c}(t) + \varepsilon_m(t)]^T x^{(\zeta)}$ for $t \in [0, T] - P$ and η, $\zeta = 1, \ldots, L$ $(\eta \neq \zeta)$.
4. $[\dot{c}(t) + \varepsilon_m(t)]^T x^{(\eta)} < [\dot{c}(t) + \varepsilon_m(t)]^T x^{(\zeta)}$ for some $t \in (t_{i-1}, t_i)$ if and only if the same is true for all $t \in (t_{i-1}, t_i)$.

It is clear that such functions exist as a suitable sequence of polynomials will do.

Let $\omega_m(t)$ be an optimal extreme point solution for the SCLP problem with $\dot{c}(t)$ replaced by $\dot{c}(t) + \varepsilon_m(t)$. From the above we can choose $\omega_m(t)$ so that $x_m(t)$ is piecewise constant on $[0, T]$. Assume now without loss of generality that

$$[\dot{c}(t) + \varepsilon_m(t)]^T x^{(1)} > [\dot{c}(t) + \varepsilon_m(t)]^T x^{(2)} > \cdots > [\dot{c}(t) + \varepsilon_m(t)]^T x^{(L)}$$

for $t \in (t_0, t_1)$ and $m \in \mathbb{N}$. Then by the above, we can find $p_{m,j} \geq 0$ with $\sum_{j=0}^{L} p_{m,j} = t_1 - t_0$ and

$$x_m(t) = x^{(i)} \quad \text{a.e. on} \quad \left[t_0 + \sum_{j=0}^{i-1} p_{m,j}, t_0 + \sum_{j=0}^{i} p_{m,j} \right).$$

As $p_{m,j}$ is bounded for all m and j (by $t_1 - t_0$), we may choose a subsequence, $\{p_{m_k,j}\}_{k=1}^{\infty}$, of $\{p_{m,j}\}_{m=1}^{\infty}$ for each j, converging to p_j, say. Define $\bar{x}(t)$ on $[t_0, t_1)$ by

$$\bar{x}(t) = x^{(i)}, \quad t \in \left[t_0 + \sum_{j=0}^{i-1} p_j, t_0 + \sum_{j=0}^{i} p_j \right).$$

We now repeat the above process for the subsequence $\{x_{m_k}\}_{k=1}^{\infty}$ of $\{x_m\}_{m=1}^{\infty}$ for the next interval $[t_1, t_2)$. Continuing in this manner will produce $\bar{x}(t)$ that is piecewise constant on $[0, T]$ and also the limit of some subsequence of $\{x_m\}_{m=1}^{\infty}$. Hence by Lemma 2.2, $\bar{\omega}(t)$, defined from $\bar{x}(t)$ by the constraints of SCLP, is an optimal extreme point solution for SCLP. Moreover, $x(t)$ has the maximum number of breakpoints as specified in the statement of the lemma. This establishes the result. $\square$

By transforming a general problem into one where the costs have nonpositive second and third derivatives, we may now establish the main result of this section.

THEOREM 3.3. *Suppose that $a(t)$ is piecewise linear and continuous, $b(t)$ is piecewise constant, and $c(t)$ is piecewise analytic on $[0, T]$. Suppose also that the feasible region for SCLP is nonempty and bounded; then there exists an optimal extreme point solution for SCLP with $x(t)$ piecewise constant on $[0, T]$. Moreover, let $x^{(1)}, \ldots, x^{(L)}$ be given by Lemma 2.1, where L is the number of basis matrices for K, and $P = \{t_0, t_1, \ldots, t_n\}$ be any partition of $[0, T]$ containing the breakpoints of $a(t)$, $b(t)$, and $c(t)$ and with $\dot{c}(t)^T x^{(i)} = \dot{c}(t)^T x^{(j)}$ for all $t \in (t_{m-1}, t_m)$ or $\dot{c}(t)^T x^{(i)} \neq \dot{c}(t)^T x^{(j)}$ for all $t \in (t_{m-1}, t_m)$ for each $i \neq j$ and each m. Then such $x(t)$ may be chosen so that for all m, the maximum number of breakpoints of $x(t)$ in $[t_{m-1}, t_m)$ is L.*

Proof. We begin by considering the case where the problem data contain no breakpoints, i.e., that $a(t)$ is linear, $b(t)$ is constant, and $c(t)$ is analytic on a neighbourhood of $[0, T]$. We transform the problem into one where the costs have nonpositive second and third derivatives. Let

$$N = \max\{\|\ddot{c}\|_{\infty}, \|\dddot{c}\|_{\infty}\},$$

and $d(t) = -Nt^2(t + 1)$. Let e denote the n_1-dimensional vector of all ones. We now define

$$\tilde{c}(t) = c(t) + d(t)e,$$

for $t \in [0, T]$. Now by the definition of N, $\tilde{c}$ has nonpositive second and third derivatives. Finally, let M be such that $\|e^T x\|_{\infty} \leq M$ for all feasible solutions $\omega^T = (x^T, y^T, z^T)$ for SCLP. Consider now the following separated continuous linear program:

$$\begin{aligned}
&\text{SCLP}(M, N)\text{:} && \text{minimize} && \int_0^T \left[\tilde{c}(t)^T x(t) + d(t) x_{n_1+1}(t)\right] dt \\
& && \text{subject to} && \int_0^t G x(s)\, ds + y(t) = a(t), \\
& && && H x(t) + z(t) = b(t), \\
&(9) && && e^T x(t) + x_{n_1+1}(t) = M, \\
& && && x(t), y(t), z(t), w(t) \geq 0, \qquad t \in [0, T].
\end{aligned}$$

Strictly speaking, this is not in the form of a separated continuous linear program as (9) is an equality. However, this problem can be removed by replacing (9) by two inequalities.

Now by the definition of M, $\omega(t)^T = (x(t)^T, y(t)^T, z(t)^T)$ is feasible for SCLP if and only if $\tilde{\omega}(t)^T = (x(t)^T, M - e^T x(t), y(t)^T, z(t)^T)$ is feasible for SCLP(M,N). But

$$\int_0^T \left[\tilde{c}(t)^T x(t) + d(t)(M - e^T x(t))\right] dt = M \int_0^T d(t)\, dt + \int_0^T c(t)^T x(t)\, dt,$$

and so $\omega(t)$ is optimal for SCLP if and only if $\tilde{\omega}(t)$ is optimal for SCLP(M,N). But by Lemma 3.2, SCLP(M,N) has a piecewise constant optimal extreme point solution and hence so does SCLP. It is also clear that Lemma 3.2 gives the required bound on the number of breakpoints of $x(t)$ on $[0,T]$.

If we repeat the above argument a finite number of times, it is now not difficult to extend the result to the case of problem data with breakpoints. We omit the details as there is little to be gained from their inclusion. □

4. SCLP with analytic right-hand sides.

In this section we consider the case of SCLP with $a(t)$, $b(t)$, and $c(t)$ piecewise analytic (with of course $a(t)$ continuous). Under the assumption that the feasible region for SCLP is nonempty and bounded, we show that there exists an optimal extreme point solution with $x(t)$ piecewise analytic (Theorem 4.3). Although the result in the previous section, Theorem 3.3, is just a special case of Theorem 4.3, it is convenient to separate the two and use Theorem 3.3 as a starting point. In particular, we approximate $a(t)$ and $b(t)$ by sequences of piecewise linear and piecewise constant functions, respectively, and use Theorem 3.3 on these approximating problems to construct an optimal solution for the original problem. The difficulty is in constructing appropriate approximations to $a(t)$ and $b(t)$.

To perform this construction we need to introduce a definition that allows us to distinguish between two types of breakpoints in an extreme point solution for SCLP when the problem data have breakpoints. We recall that an extreme point solution for SCLP can only take the values of a finite number of functions $x^{(1)}(t), \dots, x^{(L)}(t)$ (Lemma 2.1). Moreover each $x^{(1)}(t), \dots, x^{(L)}(t)$ is given by a linear combination of the problem data and their derivatives. Thus $x^{(1)}(t), \dots, x^{(L)}(t)$ will have breakpoints when the problem data have breakpoints. Hence an extreme point solution will, in general, have breakpoints that arise from these breakpoints and also from switching from $x^{(i)}(t)$ to $x^{(j)}(t)$ for some $i \neq j$. It is this second type of breakpoint which is of importance and that we now define formally.

DEFINITION 4. *Let $\omega(t)$ be a piecewise analytic extreme point solution for* SCLP *and $x^{(1)}(t), \dots, x^{(L)}(t)$ be given by Lemma* 2.1. *By a* change of basis *we mean a time $s \in (0,T)$ such that for some $\varepsilon > 0$, $x(t) = x^{(i)}(t)$ for $t \in (s-\varepsilon, s)$ and $x(t) = x^{(j)}(t)$ for $t \in (s, s+\varepsilon)$ for some i and j such that $x^{(i)}(t) \not\equiv x^{(j)}(t)$ on $(s-\varepsilon, s+\varepsilon)$.*

We note that if a and b are analytic on a neighbourhood of $[0,T]$, then a change of basis is identical to a breakpoint. However, if a and b are piecewise analytic on $[0,T]$, then, in general, the set of changes of basis for an extreme point solution will be a subset of the set of breakpoints for that solution.

Using the above definition we may now give more details about the development of Theorem 4.3. We begin by taking sequences $\{a^{(n)}\}_{n=1}^{\infty}$ and $\{b^{(n)}\}_{n=1}^{\infty}$ of piecewise linear (and continuous) and piecewise constant functions, respectively, so that $a^{(n)}(t) \geq a(t)$ and $b^{(n)}(t) \geq b(t)$ on $[0,T]$ and $a^{(n)} \to a$ and $b^{(n)} \to b$ uniformly on $[0,T]$. This ensures that if SCLP$_n$ is the problem SCLP with a and b replaced by $a^{(n)}$ and $b^{(n)}$, respectively, then feasibility of SCLP implies feasibility of SCLP$_n$. Moreover, we also choose $a^{(n)}$ and $b^{(n)}$ so that SCLP$_n$ has an optimal extreme point solution with a bounded number of changes of basis independent of n. This is the difficult part of the result. It is then relatively easy to construct a piecewise analytic optimal solution for the original SCLP, in a similar way to the proof of the second half of Lemma 3.2.

To establish that the problem SCLP$_n$ mentioned above will have an optimal extreme point solution with a uniform bound on the number of changes of basis, we will need to use ideas from Anderson and Philpott [3]. To use these ideas it is necessary to have the set $\{\, \xi : H\xi \leq b(t),\ \xi \geq 0 \,\}$ bounded for each $t \in [0,T]$. To guarantee this, we begin by considering the case where there are upper bounds on $x(t)$. This extra assumption is removed later. As with the previous section, it is also convenient to begin by considering the case where the problem data contain no breakpoints. We therefore introduce the following assumption that we will use throughout this section.

Assumption 4.1. The costs, $c(t)$, the right-hand sides, $a(t)$ and $b(t)$, are analytic on a neighbourhood of $[0,T]$; H is of the form

$$H = \begin{bmatrix} \bar{H} \\ I \end{bmatrix};$$

and the feasible region for SCLP is nonempty.

We now develop some ideas and notation similar to those Anderson and Philpott [3]. Let

$$\bar{K} = \begin{bmatrix} G & I & -I & 0 \\ H & 0 & 0 & I \end{bmatrix}.$$

We note that $\bar{K}$ has full rank, and so any $n_2 + n_3$ linearly independent columns of $\bar{K}$ form a basis matrix.

Now suppose that $a(t)$ is piecewise analytic and continuous and that $b(t)$ is piecewise analytic on $[0,T]$. Let $S = [\alpha,\beta] \subseteq [0,T]$ satisfy the following: if B is any basis matrix for $\bar{K}$ and

$$\rho(t) = B^{-1} \begin{bmatrix} \dot{a}(t) \\ b(t) \end{bmatrix},$$

then for each i, either $\rho_i(t) > 0$ for all $t \in S$, $\rho_i(t) < 0$ for all $t \in S$, or $\rho_i(t) = 0$ for all $t \in S$. We now define

$$\hat{a}_S = \frac{1}{\beta - \alpha}(a(\beta) - a(\alpha)),$$
$$\hat{b}_S = \frac{1}{\beta - \alpha}\int_\alpha^\beta b(t)\,dt.$$

Now given any $\pi \in \{-1,0,1\}^{n_2}$ we define

$$\hat{E}_S = \{\, \hat{\psi} : H\hat{\psi} \leq \hat{b}_S,\ \hat{\psi} \geq 0,\ \operatorname{sgn}(\hat{a}_S - G\hat{\psi}) = \pi \,\},$$
$$E_S(t) = \{\, \psi : H\psi \leq b(t),\ \psi \geq 0,\ \operatorname{sgn}(\dot{a}(t) - G\psi) = \pi \,\}, \quad t \in S.$$

Strictly speaking, $\hat{E}_S$ and $E_S(t)$ depend on π; however, we choose to omit this dependence in the notation for simplicity. The following straightforward lemma is a simple extension of results in Anderson and Philpott [3, Lems. 2.3–2.5]. As K is a submatrix of $\bar{K}$, we extend the notations Definition 3 (i.e., of x_B and ρ_x) in a natural way to include basis matrices of $\bar{K}$.

LEMMA 4.1. *Let S be as above and $\hat{\psi}$ be any extreme point of $\hat{E}_S$. Then there exists a basis matrix B of $\bar{K}$ such that the nonzero components of $\hat{\psi}$ are contained in $\hat{\psi}_B$ and $\hat{\psi}_B = \hat{\rho}_x$, where*

$$\hat{\rho} = B^{-1} \left[\begin{array}{c} \hat{a}_S \\ \hat{b}_S \end{array} \right].$$

Moreover, let

$$\rho(t) = B^{-1} \left[\begin{array}{c} \dot{a}(t) \\ b(t) \end{array} \right]$$

and define $\psi(t)$ by $\psi_B(t) = \rho_x(t)$ with the other components of $\psi(t)$ set to zero for $t \in S$. Then

$$\int_\alpha^\beta \psi(t)\, dt = \int_\alpha^\beta \hat{\psi}\, dt$$

and $\psi(t)$ is an extreme point for $E_S(t)$ for $t \in S$.

For any piecewise analytic and continuous $a(t)$ and piecewise analytic $b(t)$ it is easy to construct a partition P of $[0,T]$ so that each subinterval satisfies the requirements for an interval S in the above lemma. Indeed, let

$$Q = \left\{ B^{-1} \left[\begin{array}{c} \dot{a}(t) \\ b(t) \end{array} \right] : B \text{ is a basis matrix of } \bar{K} \right\},$$
$$R = \{ \rho_j(t) : \rho \in Q,\ 1 \le j \le n_2 + n_3 \}.$$

Now since each component of $\dot{a}(t)$ and $b(t)$ is piecewise analytic on $[0,T]$, R consists of a finite set of piecewise analytic functions. Thus if $a(t)$ and $b(t)$ are analytic on a neighbourhood of some interval I, then each function in R is either identically zero or contains a finite number of zeros on I. We can now let P be the (finite) partition of $[0,T]$ that contains all the zeros of each function in R that is not identically zero on some interval, along with the breakpoints of $a(t)$ and $b(t)$. We call this the *canonical partition* of $[0,T]$. It was for the subintervals of this partition that the above lemma was proved in [3].

We may now begin the development of Theorem 4.3 by constructing appropriate functions $a^{(n)}$ and $b^{(n)}$ to approximate a and b. This construction is rather complicated although it is based on a relatively simple idea.

LEMMA 4.2. *Suppose that Assumption* 4.1 *holds. Then there exists $M \in \mathbb{N}$, a sequence $\{a^{(n)}\}_{n=1}^{\infty}$ of piecewise linear and continuous functions and a sequence $\{b^{(n)}\}_{n=1}^{\infty}$ of piecewise constant functions with $a^{(n)}(t) \ge a(t)$ and $b^{(n)}(t) \ge b(t)$ on $[0,T]$ for each n, $a^{(n)} \to a$ and $b^{(n)} \to b$ uniformly on $[0,T]$, and such that SCLP$_n$ has a piecewise constant optimal extreme point solution with at most M changes of basis, where SCLP$_n$ is the problem SCLP with right-hand sides $a^{(n)}$ and $b^{(n)}$.*

Proof. Let $B^{(1)}, \ldots, B^{(L)}$ be the possible basis matrices for $\bar{K}$. The construction of the $a^{(n)}$ and $b^{(n)}$ is done in two stages. Let

$$d(t) = \left[\begin{array}{c} \dot{a}(t) \\ b(t) \end{array} \right].$$

First we consider approximating $d(t)$ by $d(t) + 1/n\,e$, where e is the vector of all ones. We now define

$$\rho^{(n_j)}(t) = B^{(j)^{-1}} d(t) + \frac{1}{n} B^{(j)^{-1}} e.$$

Note that $\rho^{(n_j)}$ is analytic on a neighbourhood of $[0, T]$. This completes the first stage of the construction.

Second, we approximate $d(t) + 1/n\,e$ by a piecewise constant function

$$d^{(n)}(t) = \begin{bmatrix} \dot{a}^{(n)}(t) \\ b^{(n)}(t) \end{bmatrix},$$

with the approximation being done so that $a^{(n)}(t) \geq a(t)$ and $b^{(n)}(t) \geq b(t)$ on $[0, T]$ for each n and $a^{(n)} \to a$ and $b^{(n)} \to b$ uniformly on $[0, T]$, where $a^{(n)}$ is the integral of $\dot{a}^{(n)}$ taking the value $a(0) + 1/n\,e$ at zero. This second approximation is achieved by taking a sufficiently fine partition, $P_n = \{t_0^{(n)}, t_1^{(n)}, \ldots, t_{m_n}^{(n)}\}$, and setting $d^{(n)}(t) = d(t_{i-1}^{(n)}) + 1/n\,e$ for $t \in [t_{i-1}^{(n)}, t_i^{(n)})$, $i = 1, \ldots, m_n$.

Now by Lemma 2.3 there exists M_1, independent of n, so that if

$$\mathcal{F}_n = \left\{ t \in [0, T] : \rho_i^{(n_j)}(t) = 0 \text{ for some } i \text{ and } j \text{ but } \rho_i^{(n_j)} \not\equiv 0 \right\},$$

then $|\mathcal{F}_n| \leq M_1$. Again by Lemma 2.3 we may choose M_2 so that if

$$\mathcal{G}_n = \Big\{ t \in [0, T] : \dot{c}_{B^{(j)}}(t)^T \rho_x^{(n_j)}(t) = \dot{c}_{B^{(k)}}(t)^T \rho_x^{(n_k)}(t) \text{ for some } k \text{ and } j \text{ but}$$
$$\dot{c}_{B^{(j)}}^T \rho_x^{(n_j)} \not\equiv \dot{c}_{B^{(k)}}^T \rho_x^{(n_k)} \Big\},$$

then $|\mathcal{G}_n| \leq M_2$. Define

$$N = M_1 + M_2 + 1.$$

Choose n. Let $R_n = \{r_0^{(n)}, r_1^{(n)}, \ldots, r_{N_n}^{(n)}\}$ be the partition of $[0, T]$ that contains all the points in $\mathcal{F}_n$ and $\mathcal{G}_n$. By the definition of N, we have $N_n \leq N$. Such a partition R_n has been chosen for two reasons. First any subinterval $[r_{h-1}^{(n)}, r_h^{(n)}]$ of R_n satisfies the conditions required by an interval $[\alpha, \beta]$ in Lemma 4.1. Second any subinterval $[r_{h-1}^{(n)}, r_h^{(n)}]$ also satisfies the conditions of the form required by an interval $[\alpha, \beta]$ in Theorem 3.3 to bound the number of breakpoints in an optimal solution for SCLP if $\dot{a}$ and b are piecewise constant with no breakpoints in $(r_{h-1}^{(n)}, r_h^{(n)})$.

Having constructed a partition fine enough so that Theorem 3.3 and Lemma 4.1 can be applied when necessary on the subintervals, we now proceed to subdivide it further so that approximations can be made to $d + 1/n\,e$ so that $a^{(n)}(t) \geq a(t)$ and $b^{(n)}(t) \geq b(t)$ on $[0, T]$ for each n. Now by the uniform continuity of $d(t)$ on $[0, T]$, there exists δ_n so that $0 < 2\delta_n < \|R_n\|$ (where $\|R_n\|$, the norm of R_n, is the maximum distance between consecutive points of R_n) and such that

$$(10) \qquad |t - s| \leq \delta_n \Rightarrow \|d(t) - d(s)\|_\infty < \min\left\{ \frac{1}{nT}, \frac{1}{n} \right\}.$$

This δ_n gives the required upper bound on the norm of the partition P_n needed to form $a^{(n)}(t) \geq a(t)$ and $b^{(n)}(t) \geq b(t)$ on $[0, T]$.

We now require one last bound on the size of the partition P_n. This bound will ensure that an optimal solution for the problem SCLP$_n$ has a uniform bound on the number of changes of basis. Define

$$\varepsilon_n = \min\left\{ \left|\dot{c}_{B(j)}(t)^T \rho_x^{(n_j)}(t) - \dot{c}_{B(k)}(t)^T \rho_x^{(n_k)}(t)\right| : t \in [r_{h-1}^{(n)} + \delta_n, r_h^{(n)} - \delta_n] \text{ for } \right.$$
$$\left. \text{some } h \text{ and } \dot{c}_{B(j)}^T \rho_x^{(n_j)} \not\equiv \dot{c}_{B(k)}^T \rho_x^{(n_k)} \right\}.$$

Note that by the construction of R_n we have $\varepsilon_n > 0$. Again by the uniform continuity of $\rho^{(n_j)}$ and $\dot{c}$ there exists $\zeta_n > 0$ such that

$$\left|\dot{c}_{B(j)}(\tau_1)^T \rho_x^{(n_j)}(\tau_2) - \dot{c}_{B(k)}(\tau_1)^T \rho_x^{(n_k)}(\tau_3)\right| > \frac{\varepsilon_n}{2} \tag{11}$$

and

$$\left|\dot{c}_{B(k)}(\tau_1)^T \rho_x^{(n_k)}(\tau_2) - \dot{c}_{B(k)}(\tau_1)^T \rho_x^{(n_k)}(\tau_3)\right| < \frac{\varepsilon_n}{2} \tag{12}$$

for all $\tau_1, \tau_2, \tau_3 \in [r_{h-1}^{(n)} + \delta_n, r_h^{(n)} - \delta_n]$ for some h such that $|\tau_1 - \tau_2| \leq \zeta_n$ and $|\tau_1 - \tau_3| \leq \zeta_n$ and for all n_j and n_k such that $\dot{c}_{B(j)}^T \rho_x^{(n_j)} \not\equiv \dot{c}_{B(k)}^T \rho_x^{(n_k)}$.

We now define a partition P_n of $[0, T]$ with the following properties.

1. $P_n \cap [r_{h-1}^{(n)}, r_{h-1}^{(n)} + \delta_n) = \{r_{h-1}^{(n)}\}$ and $P_n \cap [r_h^{(n)} - \delta_n, r_h^{(n)}) = \{r_h^{(n)} - \delta_n\}$ for $h = 1, \ldots, N_n$.
2. $P_n \cap [r_{h-1}^{(n)} + \delta_n, r_h^{(n)} - \delta_n]$ is a partition of $[r_{h-1}^{(n)} + \delta_n, r_h^{(n)} - \delta_n]$ with norm no greater than $\min\{\delta_n, \zeta_n\}$ for $h = 1, \ldots, N_n$.

We are now ready to define $a^{(n)}$ and $b^{(n)}$. Suppose that $P_n = \{t_0^{(n)}, t_1^{(n)}, \ldots, t_{m_n}^{(n)}\}$. Define $a^{(n)}(0) = a(0) + 1/n\, e$ for $j = 1, \ldots, n_2$ and then define $d^{(n)}(t)$ by

$$d^{(n)}(t) \equiv \begin{bmatrix} \dot{a}^{(n)}(t) \\ b^{(n)}(t) \end{bmatrix} = \begin{bmatrix} \dot{a}(t_{i-1}^{(n)}) \\ b(t_{i-1}^{(n)}) \end{bmatrix} + \frac{1}{n} e \equiv d(t_{i-1}^{(n)}) + \frac{1}{n} e$$

for $t \in [t_{i-1}^{(n)}, t_i^{(n)})$. Thus

$$a^{(n)}(t) = a(0) + \frac{1}{n} e + \int_0^t \dot{a}^{(n)}(s)\, ds$$

for $j = 1, \ldots, n_2$. This defines a piecewise linear and continuous function $a^{(n)}$ and a piecewise constant function $b^{(n)}$ for each n. Moreover, by the construction of $a^{(n)}$ and $b^{(n)}$, in particular by (10), we have $a^{(n)}(t) \geq a(t)$ and $b^{(n)}(t) \geq b(t)$ on $[0, T]$ for each n with $a^{(n)} \to a$ and $b^{(n)} \to b$ uniformly on $[0, T]$, and hence the problem SCLP$_n$ with right-hand sides of $a^{(n)}$ and $b^{(n)}$ is feasible. We finally note that due to the structure of the matrix H, the feasible region for SCLP$_n$ is bounded.

We now claim that a piecewise constant optimal extreme point solution for SCLP$_n$ exists with at most $3N_n L$ changes of basis, where L is the number of basis matrices for K (as opposed to $\bar{L}$ for $\bar{K}$). As $N_n \leq N$ for each n, we can then set $M = 3NL$, and this will then establish the result.

Fix n and let $x^{(1)}(t), \ldots, x^{(L)}(t)$ be the possible values of an extreme point solution for SCLP$_n$ as given by Lemma 2.1. Strictly speaking, $x^{(1)}(t), \ldots, x^{(L)}(t)$ depend on n, but as we will now only be considering the one problem, SCLP$_n$, we choose to omit this dependence in the notation for simplicity. Now for each j there exists i such that the nonzero components of $x^{(j)}(t)$ are contained in $x^{(j)}_{B^{(i)}}(t)$ and $x^{(j)}_{B^{(i)}}(t) = \rho_x^{(n_i)}(t^{(n)}_{l-1})$ for $t \in [t^{(n)}_{l-1}, t^{(n)}_l)$, $l = 1, \ldots, m_n$. Hence $x^{(j)}(t)$ is piecewise constant with breakpoints in P_n for each j.

Consider the intervals $[r^{(n)}_{h-1} - \delta_n, r^{(n)}_{h-1})$ and $[r^{(n)}_h, r^{(n)}_h + \delta_n)$ for some h. Now $\dot{a}^{(n)}$ and $b^{(n)}$ are constant on these intervals, and so by Theorem 3.3 an optimal solution can be chosen for SCLP$_n$ such that the number of breakpoints, and hence the number of changes of basis, in each of $[r^{(n)}_{h-1} - \delta_n, r^{(n)}_{h-1})$ and $[r^{(n)}_h, r^{(n)}_h + \delta_n)$ is at most L. We now establish that such an optimal solution can be chosen so that for each h, the number of changes of basis in $[r^{(n)}_{h-1} + \delta_n, r^{(n)}_h - \delta_n)$ is at most L. This will establish the result. Note that we cannot expect $\omega(t)$ to have only L breakpoints on $[r^{(n)}_{h-1} + \delta_n, r^{(n)}_h - \delta_n)$ as the problem data $a^{(n)}$ and $b^{(n)}$ themselves may have more than L breakpoints on this interval.

Now by the assumption on the partition R_n, for each k and j we have either $\dot{c}(t)^T x^{(k)}(t) \neq \dot{c}(t)^T x^{(j)}(t)$ for all $t \in (r^{(n)}_{h-1}, r^{(n)}_h)$ or $\dot{c}(t)^T x^{(k)}(t) = \dot{c}(t)^T x^{(j)}(t)$ for all $t \in (r^{(n)}_{h-1}, r^{(n)}_h)$. We assume that $\dot{c}(t)^T x^{(k)}(t) \neq \dot{c}(t)^T x^{(j)}(t)$ for all $t \in (r^{(n)}_{h-1}, r^{(n)}_h)$ and for all $k \neq j$. The case when $\dot{c}(t)^T x^{(k)}(t) = \dot{c}(t)^T x^{(j)}(t)$ for all $t \in (r^{(n)}_{h-1}, r^{(n)}_h)$ for some $k \neq j$ can be treated in a way identical to Lemma 3.2 by taking a sequence $c^{(m)} \to c$ uniformly so that $\dot{c}^{(m)}(t)^T x^{(k)}(t) \neq \dot{c}^{(m)}(t)^T x^{(j)}(t)$ for all $t \in (r^{(n)}_{h-1}, r^{(n)}_h)$ for all $k \neq j$ and for all m. Having made this assumption we now note that from (11) and the definition of P_n we have

$$\left|\dot{c}(s)^T (x^{(k)}(s-) - x^{(j)}(s+))\right| > \frac{\varepsilon_n}{2}$$

for all $k \neq j$ and $s \in (r^{(n)}_{h-1} + \delta_n, r^{(n)}_h - \delta_n)$.

Suppose that $P_n \cap [r^{(n)}_{h-1} + \delta_n, r^{(n)}_h - \delta_n] = \{s_0, s_1, \ldots, s_\tau\}$. Again by Theorem 3.3 we know that an optimal solution, $\omega(t)$, for SCLP$_n$ can be chosen such that the number of breakpoints in $[s_{i-1}, s_i)$ is at most L (and with the conditions on the number of breakpoints in $[r^{(n)}_h - \delta_n, r^{(n)}_h + \delta_n)$ specified above). This is not sufficient for our purposes since bounding the number of breakpoints in $[s_{i-1}, s_i)$ will not give a bound independent of n. For such a bound we prove the following claim. If $[u, v] \subseteq [r^{(n)}_{h-1} + \delta_n, r^{(n)}_h - \delta_n]$ and

$$x(t) = \begin{cases} x^{(k)}(t), & t \in [u, s), \\ x^{(j)}(t), & t \in [s, v), \end{cases}$$

then $\dot{c}(s)^T x^{(k)}(s-) > \dot{c}(s)^T x^{(j)}(s+)$. This will show that $\omega(t)$ must have at most L changes of basis in $[r^{(n)}_{h-1} + \delta_n, r^{(n)}_h - \delta_n)$ (note that $x(t)$ will still have breakpoints at each s_i).

Suppose that the result is not true; i.e., for some $u, v, s \in [r^{(n)}_{h-1} + \delta_n, r^{(n)}_h - \delta_n]$ we have x defined as above but $\dot{c}(s)^T x^{(k)}(s-) < \dot{c}(s)^T x^{(j)}(s+)$. By the above, we now have

$$\dot{c}(s)^T (x^{(k)}(s-) - x^{(j)}(s+)) < -\frac{\varepsilon_n}{2}. \tag{13}$$

We will construct a new feasible solution with strictly improved objective function, thus contradicting the optimality of $\omega(t)$. We assume without loss of generality that $[u, v]$ is chosen small enough so that either $s = s_i$ for some i or $P_n \cap [u, v] = \emptyset$.

Let γ be such that $0 < \gamma \leq \min\{s-u, v-s\}$. Define

$$\hat{x}_\gamma = \frac{x^{(k)}(\tau_1) + x^{(j)}(\tau_2)}{2}$$

for $\tau_1 \in [s-\gamma, s)$, $\tau_2 \in [s, s+\gamma]$. Note that $\hat{x}_\gamma$ does not depend on τ_1 or τ_2. Let $S = [s-\gamma, s+\gamma]$ and let $\hat{a}_S$ and $\hat{b}_S$ be given by

$$\hat{a}_S = \frac{1}{2\gamma}(a^{(n)}(s+\gamma) - a^{(n)}(s-\gamma)),$$
$$\hat{b}_S = \frac{1}{2\gamma}\int_{s-\gamma}^{s+\gamma} b^{(n)}(t)\,dt.$$

Let $\pi = \operatorname{sgn}(\hat{a}_S - G\hat{x}_\gamma)$ and define $\hat{E}_S$ and $E_S(t)$ for $t \in S$ by

$$\hat{E}_S = \{\,\hat{\psi} : H\hat{\psi} \leq \hat{b}_S,\ \hat{\psi} \geq 0,\ \operatorname{sgn}(\hat{a}_S - G\hat{\psi}) = \pi\,\},$$
$$E_S(t) = \{\,\psi : H\psi \leq b^{(n)}(t),\ \psi \geq 0,\ \operatorname{sgn}(\dot{a}^{(n)}(t) - G\psi) = \pi\,\}.$$

Note that $\hat{E}_S$ is a convex set and, due to the structure of the matrix H, also a compact set. Let $\{\,\hat{\psi}^{(j)} : j = 1, \ldots, \bar{L}\,\}$ be the extreme points of $\hat{E}_S$; then by Minkowski's theorem (see, for example, Rockafellar [20]), there exists $\mu_j \geq 0$, $j = 1, \ldots, \bar{L}$ with

$$\sum_{j=1}^{\bar{L}} \mu_j = 1$$

and

$$\hat{x}_\gamma = \sum_{j=1}^{\bar{L}} \mu_j \hat{\psi}^{(j)}.$$

Now $S \subseteq [r_{h-1}^{(n)}, r_h^{(n)}]$, and so by a remark above, S satisfies the requirements for an interval in Lemma 4.1. Hence by this lemma, there exists $\psi^{(j)}(t)$, extreme points for $E_S(t)$, $t \in S$, that are piecewise constant (with a possible breakpoint at s only) such that

$$\int_{s-\gamma}^{s+\gamma} \psi^{(j)}(t)\,dt = \int_{s-\gamma}^{s+\gamma} \hat{\psi}^{(j)}\,dt,$$

or in this case,

$$\gamma(\psi^{(j)}(s-) + \psi^{(j)}(s+)) = 2\gamma\hat{\psi}^{(j)}. \tag{14}$$

Moreover, there exists k such that the nonzero components of $\psi^{(j)}(t)$ are contained in $\psi_{B(k)}^{(j)}(t)$ and either $\psi_{B(k)}^{(j)}(t) = \rho_x^{(n_k)}(s_{i-1})$ for $t \in [s-\gamma, s)$ and $\psi_{B(k)}^{(j)}(t) = \rho_x^{(n_k)}(s)$ for $t \in [s, s+\gamma]$ if $s = s_i$ for some i, or $\psi_{B(k)}^{(j)}(t) = \rho_x^{(n_k)}(s_i)$ for $t \in [s-\gamma, s+\gamma]$ for some i, if $P_n \cap [u,v] = \emptyset$. Define

$$\bar{x}_\gamma(t) = \begin{cases} \displaystyle\sum_{j=1}^{\bar{L}} \mu_j \psi^{(j)}(t), & t \in [s-\gamma, s+\gamma), \\ x(t) & \text{otherwise.} \end{cases}$$

Note that $\bar{x}_\gamma(t)$ is no more than a vector of components of a convex combination of $\rho^{(n_j)}(t)$ for $j = 1, \ldots, \bar{L}$. Hence $\bar{x}_\gamma(t)$ is piecewise constant on $[s-\gamma, s+\gamma)$, with a possible breakpoint at s only. Also from (12) and the definition of P_n we have

$$\dot{c}(s)^T(\bar{x}_\gamma(s+) - \bar{x}_\gamma(s-)) < \frac{\varepsilon_n}{2}. \tag{15}$$

Define $\bar{\omega}_\gamma(t)$ from the constraints of SCLP$_n$, i.e., so that $\bar{x}_\gamma(t)$, $\bar{y}_\gamma(t)$, and $\bar{z}_\gamma(t)$ satisfy (1) and (2) for SCLP$_n$ in place of $x(t)$, $y(t)$, and $z(t)$, respectively. Then $\bar{\omega}_\gamma(t)$ is feasible for SCLP$_n$. The proof of this argument is given in Anderson and Philpott [3], of which we present a brief description. Clearly we have $\bar{x}_\gamma(t), \bar{z}_\gamma(t) \geq 0$. By the construction of $\bar{x}_\gamma(t)$ we have $\bar{y}_\gamma(t) = y(t) \geq 0$ for $t \in [0, s-\gamma] \cup [s+\gamma, T]$. However, by the construction of $E_S(t)$, $\operatorname{sgn}(\dot{a}(t) - G\bar{x}_\gamma(t))$ is constant for $t \in (u, v)$. Hence each component of $\bar{y}_\gamma(t)$ is monotonic on $[s-\gamma, s+\gamma]$ and thus we have $(\bar{y}_\gamma)_i(t)$ between $(\bar{y}_\gamma)_i(s-\gamma)$ and $(\bar{y}_\gamma)_i(s+\gamma)$ for each i and $t \in (s-\gamma, s+\gamma)$. Thus $\bar{y}_\gamma(t) \geq 0$ for $t \in (s-\gamma, s+\gamma)$ as well and so $\bar{\omega}_\gamma(t)$ is feasible for SCLP.

We now claim that for some $\gamma > 0$ an improvement in the objective function can be made. For this purpose we use the standard notation $o(h^n)$ for $n \in \mathbb{N}$ to mean a function defined on an interval containing zero such that $\lim_{h \downarrow 0} o(h^n)/h^n = 0$. Now

$$\begin{aligned}
&\int_{s-\gamma}^{s} c(t)^T(\psi^{(j)}(t) - \hat{\psi}^{(j)})\,dt \\
&= \int_{s-\gamma}^{s} c(s)^T(\psi^{(j)}(s-) - \hat{\psi}^{(j)})\,dt + \int_{s-\gamma}^{s} (t-s)\dot{c}(s)^T(\psi^{(j)}(s-) - \hat{\psi}^{(j)})\,dt \\
&\quad + \int_{s-\gamma}^{s} o((t-s))\,dt \\
&= \gamma c(s)^T(\psi^{(j)}(s-) - \hat{\psi}^{(j)}) - \frac{\gamma^2}{2}\dot{c}(s)^T(\psi^{(j)}(s-) - \hat{\psi}^{(j)}) + o(\gamma^2).
\end{aligned}$$

Similarly,

$$\begin{aligned}
\int_{s}^{s+\gamma} c(t)^T(\psi^{(j)}(t) - \hat{\psi})\,dt = \gamma c(s)^T(\psi^{(j)}(s+) - \hat{\psi}^{(j)}) + \frac{\gamma^2}{2}\dot{c}(s)^T(\psi^{(j)}(s+) - \hat{\psi}^{(j)}) \\
+ o(\gamma^2).
\end{aligned}$$

Hence by (14) we obtain

$$\int_{s-\gamma}^{s+\gamma} c(t)^T(\psi^{(j)}(t) - \hat{\psi})\,dt = \frac{\gamma^2}{2}\dot{c}(s)^T(\psi^{(j)}(s+) - \psi^{(j)}(s-)) + o(\gamma^2),$$

thus giving

$$\int_0^T c(t)^T(\bar{x}_\gamma(t) - \hat{x}_\gamma)\,dt = \frac{\gamma^2}{2}\dot{c}(s)^T(\bar{x}_\gamma(s+) - \bar{x}_\gamma(s-)) + o(\gamma^2).$$

By a similar argument we now obtain

$$\begin{aligned}
&\int_0^T c(t)^T(\bar{x}_\gamma(t) - x(t))\,dt \\
&= \int_0^T c(t)^T(\bar{x}_\gamma(t) - \hat{x}_\gamma)\,dt + \int_0^T c(t)^T(\hat{x}_\gamma - x(t))\,dt \\
&= \frac{\gamma^2}{2}\dot{c}(s)^T\left(\bar{x}_\gamma(s+) - \bar{x}_\gamma(s-) + x^{(k)}(s-) - x^{(j)}(s+)\right) + o(\gamma^2).
\end{aligned}$$

Hence

$$\begin{aligned}
&\lim_{\gamma\downarrow 0}\frac{1}{\gamma^2}\int_0^T c(t)^T(\bar{x}_\gamma(t)-x(t))\,dt\\
&=\frac{1}{2}\dot{c}(s)^T\left(\bar{x}_\gamma(s+)-\bar{x}_\gamma(s-)+x^{(k)}(s-)-x^{(j)}(s+)\right)\\
&<\frac{\varepsilon_n}{4}-\frac{\varepsilon_n}{4}\\
&=0
\end{aligned}$$

by (13) and (15). Hence for some $0<\gamma\le\min\{s-u,v-s\}$ we have

$$\int_0^T c(t)^T\bar{x}_\gamma(t)\,dt<\int_0^T c(t)^T x(t)\,dt,$$

contradicting the optimality of $\omega(t)$. □

It is now a simple matter to construct a piecewise analytic optimal solution for SCLP under Assumption 4.1. Again if we repeat the above argument a finite number of times, it is now possible to extend this result to the case where the problem data are piecewise analytic. We may also weaken the assumption that there are upper bounds on $x(t)$ to the assumption that just the feasible region for SCLP is bounded to arrive at the main result of this paper.

THEOREM 4.3. *Suppose that the costs, $c(t)$, right-hand sides, $a(t)$ and $b(t)$, are piecewise analytic on $[0,T]$ (but with $a(t)$ continuous) and that the feasible region for SCLP is nonempty and bounded; then there exists an optimal extreme point solution for SCLP with $x(t)$ piecewise analytic on $[0,T]$.*

Proof. We first prove the result under Assumption 4.1. Let $\{a^{(n)}\}_{n=1}^{\infty}$ and $\{b^{(n)}\}_{n=1}^{\infty}$ be sequences of functions given by Lemma 4.2. Let SCLP$_n$ be the problem SCLP with right-hand sides $a^{(n)}$ and $b^{(n)}$, M be the uniform bound on the number of changes of basis in optimal solutions for SCLP$_n$, and $\omega^{(n)}$ be the optimal solution for SCLP$_n$ with no more than M changes of basis. Finally, let $P_n=\{t_0^{(n)},t_1^{(n)},\dots,t_{m_n}^{(n)}\}$ be the partition of $[0,T]$ containing the changes of basis for $\omega^{(n)}$ and $B(t_i^{(n)})$ be a basis matrix for K corresponding to the support of $\omega^{(n)}$ on $[t_{i-1}^{(n)},t_i^{(n)})$.

Now by introducing artificial changes of basis, if necessary, we can assume that $m_n=M$, i.e., that each $\omega^{(n)}$ has exactly M changes of basis. Now as $[0,T]$ is a bounded interval, there exists a subsequence $\{n_k\}_{k=1}^{\infty}$ and $t_0,t_1,\dots,t_M$ such that $t_i^{(n_k)}\to t_i$. Moreover, as there are only a finite number of choices for basis matrices for K, we may also assume that the subsequence $\{n_k\}_{k=1}^{\infty}$ is chosen so that for each i, $B(t_i^{(n)})=B^{(i)}$ for some basis matrix $B^{(i)}$ of K for $t\in[t_{i-1}^{(n_k)},t_i^{(n_k)})$. We now define the nonzero components of $x(t)$ by

$$x_{B^{(i)}}(t)=\rho_x^{(i)}(t),\quad t\in[t_{i-1},t_i),$$

for $i=1,\dots,M$, where

$$\rho^{(i)}(t)=B^{(i)^{-1}}\begin{bmatrix}\dot{a}(t)\\ b(t)\end{bmatrix}.$$

We now have $x^{(n_k)}(t)\to x(t)$ a.e. on $[0,T]$. Hence by Lemma 2.2, $\omega(t)$, defined from $x(t)$ by the constraints of SCLP, is an optimal extreme point for SCLP.

As mentioned above, we may now repeat the above argument a finite number of times to extend the result to the case where the problem data are piecewise analytic. It is therefore now only required to prove the result when the feasible region for SCLP bounded, given that it is true for SCLP with upper bounds on $x(t)$. Suppose then that the feasible region is bounded. Let N be such that $\|x\|_\infty \leq N$ for all feasible solutions for SCLP. Let SCLP(N) be the problem SCLP with the extra constraints

$$\begin{aligned} x(t) + v(t) &= Ne, \\ v(t) &\geq 0, \end{aligned}$$

where e is the vector of all ones. Now SCLP(N) has an optimal extreme point solution, $\omega(t)^T = (x(t)^T, y(t)^T, z(t)^T, v(t)^T)$ that is piecewise analytic on $[0, T]$. Clearly $(x(t)^T, y(t)^T, z(t)^T)$ forms a piecewise analytic optimal extreme point solution for the original SCLP. □

As a closing remark we state a simple condition that must hold at a breakpoint. As its proof is essentially contained in Lemma 4.2, we omit the details.

THEOREM 4.4. *Suppose that the costs, $c(t)$, right-hand sides, $a(t)$ and $b(t)$, are piecewise analytic on $[0, T]$ (but with $a(t)$ continuous) and that the feasible region for SCLP is nonempty and bounded. Let $\omega(t)$ be a piecewise analytic optimal solution for SCLP. Let $[\alpha, \beta]$ be a subinterval of the canonical partition. Suppose that $\omega(t)$ has a breakpoint at $s \in [\alpha, \beta]$; i.e., for some functions $x^{(k)}(t)$ and $x^{(j)}(t)$ analytic on neighbourhoods of $[\alpha, \beta]$ we have*

$$x(t) = \begin{cases} x^{(k)}(t) & a.e. \text{ on } [u, s), \\ x^{(j)}(t) & a.e. \text{ on } [s, v) \end{cases}$$

for some u and v. Then $\dot{c}(s)^T x^{(k)}(s) \geq \dot{c}(s)^T x^{(j)}(s)$.

Note that under the restrictions of piecewise linear $a(t)$ and piecewise constant $b(t)$ of the previous section, the canonical partition is just the set of breakpoints of $a(t)$ and $b(t)$ and the points 0 and Tn.

5. Extensions and remarks. It is interesting to speculate on possible extensions to the results contained in the previous sections. One possible extension could be that the costs need not be analytic but only n-times differentiable for some n, or even just continuous. However, as the counterexample below shows, the result given in Theorem 3.3 cannot be extended beyond analytic costs.

Example 5.1. Let $c(t)$ be any continuous real-valued function defined on $[0, 1]$ such that if

$$S = \{ t \in [0, 1] : c(t) < 0 \},$$

then S is an open disconnected set containing an infinite number of components. For example we could take

$$c(t) = \begin{cases} t^{n+1} \sin 1/t, & t \in (0, 1], \\ 0, & t = 0, \end{cases}$$

for some n. Consider the following SCLP problem:

$$\text{minimize} \quad \int_0^1 c(t)x(t)\, dt$$

$$\begin{aligned} \text{subject to} \quad & \int_0^t x(s)\,ds + y(t) = 1, \\ & x(t) + z(t) = 1, \\ & x(t), y(t), z(t) \geq 0, \qquad t \in [0,1]. \end{aligned}$$

Clearly this has the following optimal solution:

$$x(t) = \begin{cases} 1 & \text{a.e. on } S, \\ 0 & \text{a.e. on } [0,1] - S. \end{cases}$$

By the definition of $c(t)$, $x(t)$ has an infinite number of breakpoints.

In a similar way we may not extend Theorem 4.3 to allow $a(t)$ or $b(t)$ chosen from classes of more general functions, provided that a breakpoint is understood to be a point where the optimal solution is not as well behaved as the problem data rather than just a discontinuity (i.e., if the problem data are n-times differentiable, then a breakpoint is a point where the solution is not n-times differentiable).

Example 5.2. Define $b_1(t)$ and $b_2(t)$ on $[0,1]$ as follows.

$$b_1(t) = \begin{cases} t^{n+1}\sin 1/t + 1, & t \in (0,1], \\ 1, & t = 0, \end{cases} \qquad b_2(t) = \begin{cases} t^{n+1}\cos 1/t + 1, & t \in (0,1], \\ 1, & t = 0, \end{cases}$$

for some n. Consider the following SCLP problem:

$$\begin{aligned} \text{minimize} \quad & -\int_0^1 x(t)\,dt \\ \text{subject to} \quad & \int_0^t x(s)\,ds + y(t) = 2, \\ & x(t) + z_1(t) = b_1(t), \\ & x(t) + z_2(t) = b_2(t), \\ & x(t), y(t), z_1(t), z_2(t) \geq 0, \qquad t \in [0,1]. \end{aligned}$$

Let $S = \{t \in [0,1] : t^{n+1}\cos 1/t > t^{n+1}\sin 1/t\}$. Clearly the given problem has the following optimal solution:

$$x(t) = \begin{cases} b_1(t) & \text{a.e. on } S, \\ b_2(t) & \text{a.e. on } [0,1] - S. \end{cases}$$

Using the definition of breakpoints above, $x(t)$ has an infinite number of breakpoints.

Note, however, that the optimal solution for the above problem is continuous. It is an open question whether continuously differentiable $a(t)$ and continuous $b(t)$ (and sufficiently well behaved costs) give rise to an optimal solution that is piecewise continuous.

It is also worth noting that the optimal solutions to the above two problems both have a *countable* number of breakpoints. It is possible that extensions to Theorem 4.3 (and Theorem 3.3) could be made if we allow an optimal solution to have a countable number instead of just a finite number of breakpoints.

A simple extension to the results in this paper comes from recalling that each of the functions $x^{(1)}(t), \ldots, x^{(L)}(t)$ in Lemma 2.1 lie in the linear space spanned by the components of $\dot{a}(t)$ and $b(t)$. However, for $\omega(t)$ to be a piecewise analytic extreme point solution for SCLP with piecewise analytic problem data, on each interval where $x(t)$

is analytic we must have $x(t) \equiv x^{(i)}(t)$ for some i. (This was seen in the construction of the optimal solution in Theorem 4.3.) Thus, if $\dot{a}(t)$ and $b(t)$ are in some linear subspace S of the vector space of functions piecewise analytic on $[0, T]$, then under the remaining conditions of Theorem 4.3, we obtain an optimal extreme point solution for SCLP that is piecewise analytic, and on intervals where $x(t)$ is analytic, $x(t)$ is in the linear subspace S. In particular the following result holds.

THEOREM 5.1. *Suppose that $c(t)$ is piecewise analytic on $[0, T]$ and that $a(t)$ and $b(t)$ are piecewise polynomials of degrees $n+1$ and n, respectively (with $a(t)$ continuous). Suppose furthermore that the feasible region for SCLP is nonempty and bounded, then there exists an optimal extreme point solution for SCLP with $x(t)$ piecewise polynomial of degree n on $[0, T]$.*

Acknowledgments. The author wishes to thank Eddie Anderson for his help in correcting an error in an earlier version of this paper. In particular, the general nature of the method used in Theorem 3.3 to transform a problem with general costs into one where the costs have nonpositive second and third derivatives was his idea.
